A GENERAL INTEGRAL REPRESENTATION RESULT FOR CONTINUUM LIMITS OF DISCRETE ENERGIES WITH SUPERLINEAR GROWTH*

ROBERTO ALICANDRO† AND MARCO CICALESE‡

Abstract. We study the asymptotic behavior, as the mesh size ε tends to zero, of a general class of discrete energies defined on functions $u : \alpha \in \varepsilon\mathbb{Z}^N \cap \Omega \mapsto u(\alpha) \in \mathbb{R}^d$ of the form

$$F_\varepsilon(u) = \sum_{\substack{\alpha,\beta\in\varepsilon\mathbb{Z}^N \\ [\alpha,\beta]\subset\Omega}} g_\varepsilon(\alpha,\beta,u(\alpha)-u(\beta))$$

and satisfying superlinear growth conditions. We show that all the possible variational limits are defined on $W^{1,p}(\Omega;\mathbb{R}^d)$ of the local type

$$\int_\Omega f(x,\nabla u)\,dx.$$

We show that, in general, f may be a quasi-convex nonconvex function even if very simple interactions are considered. We also treat the case of homogenization, giving a general asymptotic formula that can be simplified in many situations (e.g., in the case of nearest neighbor interactions or under convexity hypotheses).

Key words. discrete systems, homogenization, Γ-convergence

1. Introduction.

The energetic description of the asymptotic behavior of lattice systems when the mesh size tends to zero turns out to be useful both as a microscopical theoretical justification of theories in continuum mechanics and as a powerful means, thanks to which a great number of microscopical phenomena can be read in the macroscopical setting. In this paper we describe variational limits of discrete lattice systems in a vectorial and nonconvex setting when general "atomic" interaction energies are taken into account that lead to continuum "elastic" theories described by bulk integral energies. We will limit our analysis to square lattices, but more general geometries, e.g., hexagonal lattices, can be easily included in this framework by a change of variables (see, for instance, [10, Examples 5.1 and 5.2], for details). In mathematical terms, given a fixed open set $\Omega \subset \mathbb{R}^N$ and $\varepsilon > 0$, we consider energies defined on functions $u : \alpha \in \varepsilon\mathbb{Z}^N \cap \Omega \mapsto u(\alpha) \in \mathbb{R}^d$ of the general form

$$F_\varepsilon(u) = \sum_{\substack{\alpha,\beta\in\varepsilon\mathbb{Z}^N \\ [\alpha,\beta]\subset\Omega}} g_\varepsilon(\alpha,\beta,u(\alpha)-u(\beta)).$$

In the case $N = d = 3$ we can picture the lattice $\varepsilon\mathbb{Z}^N \cap \Omega$ as the reference configuration

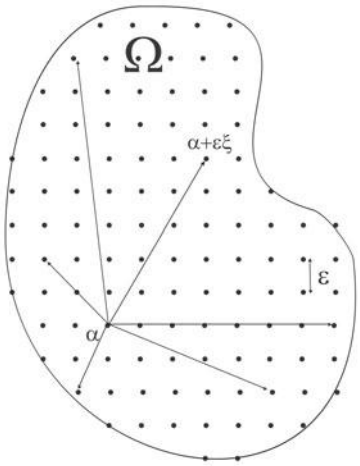

FIG. 1. *Interactions on the lattice* $\varepsilon\mathbb{Z}^N$.

of a set of interacting material points (see Figure 1). Here u is the field mapping the reference configuration into the deformed one; thus the total stored energy $F_\varepsilon(u)$ is obtained, according to the classical theory of crystalline structures in "hyperelastic" regime, by the superposition of the energy densities $g_\varepsilon(\alpha, \beta, u(\alpha) - u(\beta))$ weighing the pairwise interaction between points in positions α and β in the reference configuration lattice. Note that the only assumption we make is that g_ε depends on the displacement field in α and β through the differences $u(\alpha) - u(\beta)$. This condition, expressing the invariance under translation of our energies, arises naturally in many situations, as, for example, in frame indifferent models.

It is usually more convenient to group the energy densities as

$$F_\varepsilon(u) = \sum_{\xi\in\mathbb{Z}^N} \sum_{\alpha\in R_\varepsilon^\xi(\Omega)} g_\varepsilon(\alpha, \alpha+\varepsilon\xi, u(\alpha+\varepsilon\xi) - u(\alpha)),$$

where $R_\varepsilon^\xi(\Omega) := \{\alpha \in \varepsilon\mathbb{Z}^N : \ [\alpha, \alpha+\varepsilon\xi] \subset \Omega\}$. Setting

$$f_\varepsilon^\xi(\alpha, \zeta) = \varepsilon^{-N} g_\varepsilon(\alpha, \alpha+\varepsilon\xi, \varepsilon|\xi|\zeta)$$

we can rewrite

$$F_\varepsilon(u) = \sum_{\xi\in\mathbb{Z}^N} \sum_{\alpha\in R_\varepsilon^\xi(\Omega)} \varepsilon^N f_\varepsilon^\xi\left(\alpha, \frac{u(\alpha+\varepsilon\xi) - u(\alpha)}{\varepsilon|\xi|}\right), \tag{1.1}$$

thus highlighting the dependence of the energy on discrete difference quotients in the direction ξ.

The aim of this paper is to provide a characterization of all the possible variational limits, as the mesh size ε tends to zero, of a very general class of energies of the form (1.1). Upon identifying u with a function constant on each cell of the lattice $\varepsilon\mathbb{Z}^N$, we can make the asymptotic analysis precise, thanks to the notions and the methods of De Giorgi's Γ-convergence (see [16], [4], [15]). On the functions $f_\varepsilon^\xi(\alpha, \cdot)$ we make assumptions of two types: a growth hypothesis of superlinear type on nearest

neighbors (see 3.2) that ensures that the limit is finite only on $W^{1,p}(\Omega;\mathbb{R}^d)$ and a decay assumption as $\xi \to +\infty$ (see (3.3), (H1), (H2)) that allows us to neglect very long-range interactions. Under these conditions, a compactness theorem holds asserting that, up to passing to a subsequence, the energies F_ε have a Γ-limit energy F defined on the Sobolev space $W^{1,p}(\Omega;\mathbb{R}^d)$ and taking the form

$$F(u) = \int_\Omega f(x, Du)\, dx$$

(see Theorem 3.1). A similar compactness result for quadratic interactions in planar networks has been observed by Vogelius [23] (see also Piatnitski and Remy [20]).

Note that the decay assumption on the density energies f_ε^ξ as $|\xi| \to +\infty$ guarantees that the nonlocality of our discrete functionals disappears in the limit. If this hypothesis is lifted, then we may have nonlocal Γ-limits (see [3]). On the other hand, if growth conditions are removed, the limit may be defined on sets of functions with bounded variation where a different analytical approach is needed (see [22], [5], [14], [1], [3], [8], [10]).

To perform our analysis, we develop the discrete analogue of a localization argument used, for example, in the context of homogenization theory for multiple integrals which allows us to regard our energies and their Γ-limits as functionals defined on pairs function-set and then to prove that all the hypotheses of an integral representation theorem are fulfilled. In order to treat minimum problems with boundary data, we also derive a compactness theorem in case that our functionals are subject to Dirichlet boundary conditions (see (3.30) and Theorem 3.10).

An interesting special case is when the arrangement of the "material points" presents a periodic feature; i.e., in terms of f_ε, we have

$$f_\varepsilon^\xi(\cdot, z) = f^\xi\left(\frac{\cdot}{\varepsilon}, z\right) \qquad f^\xi(\cdot, z), \quad Q_k\text{-periodic},$$

where $Q_k = (0,k)^N$. By adapting the integral homogenization arguments to our discrete setting, we prove that the whole family F_ε Γ-converges to a limit energy of the form

$$F(u) = \int_\Omega f_{hom}(Du)\, dx.$$

Note that in this setting we also include, when $k = 1$, the situation when $f^\xi(\alpha, z)$ is independent of α. If not only nearest neighbor interactions are present, the formula for f_{hom} highlights a multiple-scale effect also in this case (see [4]). An interesting example showing the effect of nonlinearities of "geometrical" origin is contained in a work by Friesecke and Theil [18], where an interpretation in terms of the Cauchy–Born rule is given.

Here f_{hom} is given by the following homogenization formula:

$$f_{hom}(M) = \lim_{h\to+\infty} \frac{1}{h^N} \min\left\{\mathcal{F}_h(u),\ u|_{\partial Q_h} = M\alpha\right\}, \tag{1.2}$$

where

$$\mathcal{F}_h(u) = \sum_{\xi\in\mathbb{Z}^N} \sum_{\alpha\in R^\xi(Q_h)} f^\xi\left(\alpha, \frac{u(\alpha+\xi) - u(\alpha)}{|\xi|}\right),$$

and $u|_{\partial Q_h} = M\alpha$ means that "near" the boundary of Q_h the function u is the discrete interpolation of the affine function Mx (for more precise definitions see (3.29) and Theorem 4.1). This formula generalizes that obtained in [11] in a one-dimensional scalar setting.

In general, (1.2) cannot be simplified to a cell problem formula and gives rise to a quasi-convex nonconvex function even for simple interactions. Indeed, in section 7 we provide an example of quasi-convex nonconvex f_{hom} drawing inspiration from Šverák's construction of a quasi-convex function which is not polyconvex (see [21]).

In sections 5 and 6 we study some important cases when the formula for f_{hom} can be simplified. For convex interactions a periodicity cell problem formula holds: if f^ξ is a convex function in the second variable for all $\xi \in \mathbb{Z}^N$, then (1.2) can be written as

$$f_{hom}(M) = \frac{1}{k^N} \min \left\{ \mathcal{F}(u),\ u\, Q_k\text{-periodic} \right\},$$

where

$$\mathcal{F}(u) = \sum_{\xi\in\mathbb{Z}^N} \sum_{\alpha\in\{0,1,\dots,k-1\}^N} f^\xi \left(\alpha, \frac{u(\alpha+\xi)-u(\alpha)}{|\xi|} + M\cdot\frac{\xi}{|\xi|} \right)$$

(see Theorem 5.1). An analogous result for discrete quadratic forms has been obtained by Piatnitski and Remy [20]. Our result has been used by Braides and Francfort [7] as a step for the derivation of optimal bounds for composite conducting networks in the particular case of quadratic interactions (see Remarks 3.2 and 5.2).

If we consider only interactions along independent directions a reduction to the one-dimensional case occurs: if $k = 1$, that is, f^ξ does not depend on α, and

$$f^\xi \equiv 0 \quad \forall \xi \in \mathbb{Z}^N :\ \xi \neq j e_i, \quad i \in \{1,2,\dots,N\}, \quad j \in \mathbb{N}, \tag{1.3}$$

where $\{e_1, e_2, \dots, e_N\}$ is the standard orthonormal base in $\mathbb{R}^N$, then

$$f_{hom}(M) = \sum_{i=1}^{N} (\tilde{f}_i)(M^i),$$

$(\tilde{f}_i)$ being convex functions defined by a one-dimensional homogenization formula and M^i the ith column of M (see Theorem 6.3). Note that here a superposition principle holds, in the sense that the limit energy is obtained by relaxing the energies due to the interactions in every coordinate direction independently and then summing over them.

From the results obtained in the one-dimensional setting in [11] (see Theorems 6.1 and 6.2), we deduce that the limit energy density f_{hom} can be rewritten by a nonasymptotic formula only if nearest and next-to-nearest neighbor interactions along the coordinate directions are considered (see Remark 6.5). In particular, in the case of only nearest neighbor interactions, the only effect of the passage from the discrete setting to the continuum is a separate convexification process in the coordinate directions.

2. Notation and preliminaries. We denote by $\{e_1, e_2, \dots, e_N\}$ the standard basis in $\mathbb{R}^N$, by $|\cdot|$ the usual euclidean norm, and by $\langle\cdot,\cdot\rangle$ the scalar product in $\mathbb{R}^N$. We denote by $\mathcal{M}^{d\times N}$ and $\mathcal{M}^{d\times d}_{sym}$ the space of $d\times N$ matrices and symmetric $d\times d$

matrices, respectively. For $P \in \mathcal{M}^{d\times N}$, $Q \in \mathcal{M}^{N\times l}$, $P \cdot Q$ denotes the standard row by column product. For $x,\ y \in \mathbb{R}^N$, $[x, y]$ denotes the segment between x and y. If Ω is a bounded open subset of $\mathbb{R}^N$, $\mathcal{A}(\Omega)$ is the family of all open subsets of Ω, while $\mathcal{A}_0(\Omega)$ denotes the family of all open subsets of Ω whose closure is a compact subset of Ω. If $B \subset \mathbb{R}^N$ is a Borel set, we will denote by $|B|$ its Lebesgue measure. We use standard notation for L^p and Sobolev spaces.

We also recall the standard notation for slicing arguments (see [4]). Let $\xi \in S^{N-1}$, and let $\Pi_\xi = \{y \in \mathbb{R}^N : \langle y, \xi\rangle = 0\}$ be the linear hyperplane orthogonal to ξ. If $y \in \Pi_\xi$ and $E \subset \mathbb{R}^N$ we define $E^\xi = \{y \text{ s.t. } \exists t \in \mathbb{R} : y + t\xi \in E\}$ and $E^\xi_y = \{t \in \mathbb{R} : y + t\xi \in E\}$. Moreover, if $u : E \to \mathbb{R}$ we set $u_{\xi,y} : E^\xi_y \to \mathbb{R}$ by $u_{\xi,y}(t) = u(y + t\xi)$.

We also introduce a useful notation for difference quotient along any direction. Fix $\xi \in \mathbb{R}^N$; for $\varepsilon > 0$ and for every $u : \mathbb{R}^N \to \mathbb{R}^d$ we define

$$D^\xi_\varepsilon u(x) := \frac{u(x + \varepsilon\xi) - u(x)}{\varepsilon|\xi|}.$$

2.1. Γ-convergence. We recall the notion of Γ-convergence in $L^p(\Omega;\mathbb{R}^d)$ (see [16], [15], [4]). A sequence of functionals $F_j : L^p(\Omega;\mathbb{R}^d) \to [0, +\infty]$ is said to Γ-converge to a functional $F : L^p(\Omega;\mathbb{R}^d) \to [0, +\infty]$ at $u \in L^p(\Omega;\mathbb{R}^d)$ as $j \to +\infty$, and we write $F(u) = \Gamma\text{-}\lim_j F_j(u)$ if the following two conditions hold:

(i) (lower semicontinuity inequality) for all sequences (u_j) converging to u in $L^p(\Omega;\mathbb{R}^d)$ we have that $F(u) \le \liminf_j F_j(u_j)$;

(ii) (existence of a recovery sequence) there exists a sequence (u_j) converging to u in $L^p(\Omega;\mathbb{R}^d)$ such that $F(u) = \lim_j F_j(u_j)$.

We say that F_j Γ-converges to F if $F(u) = \Gamma\text{-}\lim_j F_j(u)$ at all points $u \in L^p(\Omega;\mathbb{R}^d)$ and that F is the Γ-limit of F_j. The main reason for the introduction of this convergence is the following fundamental theorem.

THEOREM 2.1. *Let $F = \Gamma\text{-}\lim_j F_j$, and let a compact set $K \subset L^p(\Omega;\mathbb{R}^d)$ exist such that $\inf_{L^p(\Omega;\mathbb{R}^d)} F_j = \inf_K F_j$ for all j. Then*

$$\exists \min_{L^p(\Omega;\mathbb{R}^d)} F = \lim_j \inf_{L^p(\Omega;\mathbb{R}^d)} F_j.$$

Moreover, if (u_j) is a converging sequence such that $\lim_j F_j(u_j) = \lim_j \inf_{L^p(\Omega;\mathbb{R}^d)} F_j$, then its limit is a minimum point for F. If (F_ε) is a family of functionals indexed by $\varepsilon > 0$, then we say that F_ε Γ-converges to F as $\varepsilon \to 0^+$ if $F = \Gamma\text{-}\lim_j F_{\varepsilon_j}$ for all (ε_j) converging to 0. If we define the *lower and upper Γ-limits* by

$$F'(u) = \Gamma\text{-}\liminf_{\varepsilon\to0^+} F_\varepsilon(u) = \inf\left\{\liminf_{\varepsilon\to0^+} F_\varepsilon(u_\varepsilon) :\ u_\varepsilon \to u\right\},$$

$$F''(u) = \Gamma\text{-}\limsup_{\varepsilon\to0^+} F_\varepsilon(u) = \inf\left\{\limsup_{\varepsilon\to0^+} F_\varepsilon(u_\varepsilon) :\ u_\varepsilon \to u\right\},$$

respectively, then F_ε Γ-converges to F as $\varepsilon \to 0^+$ if and only if $F'(u) = F''(u) = F(u)$. Note that the functions F' and F'' are lower semicontinuous (see [15, Proposition 6.8]).

2.2. Integral representation on Sobolev spaces. In this section we recall an integral representation result on Sobolev spaces for functionals defined on pairs function-sets (see [13]).

THEOREM 2.2. *Let $1 \le p < \infty$, and let $F : W^{1,p}(\Omega;\mathbb{R}^d) \times \mathcal{A}(\Omega) \to [0, +\infty]$ be a functional satisfying the following conditions:*

(i) (locality) *F is local, i.e., $F(u,A)=F(v,A)$, if $u=v$ a.e. on $A\in\mathcal{A}(\Omega)$;*
(ii) (measure property) *for all $u\in W^{1,p}(\Omega;\mathbb{R}^d)$ the set function $F(u,\cdot)$ is the restriction of a Borel measure to $\mathcal{A}(\Omega)$;*
(iii) (growth condition) *there exists $c>0$ and $a\in L^1(\Omega)$ such that*

$$F(u,A)\le c\int_A (a(x)+|Du|^p)\,dx$$

for all $u\in W^{1,p}(\Omega;\mathbb{R}^d)$ and $A\in\mathcal{A}(\Omega)$;
(iv) (translation invariance in u) *$F(u+z,A)=F(u,A)$ for all $z\in\mathbb{R}^d$, $u\in W^{1,p}(\Omega;\mathbb{R}^d)$, and $A\in\mathcal{A}(\Omega)$;*
(v) (lower semicontinuity) *for all $A\in\mathcal{A}(\Omega)$, $F(\cdot,A)$ is sequentially lower semicontinuous with respect to the weak convergence in $W^{1,p}(\Omega;\mathbb{R}^d)$.*

Then there exists a Carathéodory function $f:\Omega\times\mathbb{M}^{d\times N}\to[0,+\infty)$ satisfying the growth condition

$$0\le f(x,M)\le c(a(x)+|M|^p)$$

for all $x\in\Omega$ and $M\in M^{d\times N}$ such that

$$F(u,A)=\int_A f(x,Du(x))\,dx$$

for all $u\in W^{1,p}(\Omega;\mathbb{R}^d)$ and $A\in\mathcal{A}(\Omega)$.
If, in addition, it holds that
(vi) (translation invariance in x)

$$F(Mx,B(y,\varrho))=F(Mx,B(z,\varrho))$$

for all $M\in M^{d\times N}$, $y,z\in\Omega$, and $\varrho>0$ such that $B(y,\varrho)\cup B(z,\varrho)\subset\Omega$, then f does not depend on x.

3. Compactness and integral representation. In this section we define the class of discrete energies we are going to consider in the rest of the paper, and we prove a general compactness theorem, asserting that any sequence of energies in this class has a subsequence whose Γ-limit F is an integral functional.

In what follows, Ω will denote a bounded open set of $\mathbb{R}^N$ with Lipschitz boundary. We consider the family of functionals $F_\varepsilon: L^p(\Omega;\mathbb{R}^d)\to[0,+\infty]$ defined as

$$F_\varepsilon(u)=\begin{cases}\displaystyle\sum_{\xi\in\mathbb{Z}^N}\sum_{\alpha\in R_\varepsilon^\xi(\Omega)}\varepsilon^N f_\varepsilon^\xi\left(\alpha,D_\varepsilon^\xi u(\alpha)\right) & \text{if } u\in\mathcal{A}_\varepsilon(\Omega),\\ +\infty & \text{otherwise,}\end{cases}\tag{3.1}$$

where for any $\xi\in\mathbb{Z}^N$ and $\varepsilon>0$

$$R_\varepsilon^\xi(\Omega):=\{\alpha\in\varepsilon\mathbb{Z}^N:\ [\alpha,\alpha+\varepsilon\xi]\subset\Omega\},$$

$$\mathcal{A}_\varepsilon(\Omega):=\{u:\mathbb{R}^N\to\mathbb{R}^d\ :\ u\text{ constant on }\alpha+[0,\varepsilon)^N\text{ for any }\alpha\in\varepsilon\mathbb{Z}^N\cap\Omega\},$$

and $f_\varepsilon^\xi:(\varepsilon\mathbb{Z}^N\cap\Omega)\times\mathbb{R}^d\to[0,+\infty)$ is a given function. On f_ε^ξ we make the following assumptions:

$$f_\varepsilon^{e_i}(\alpha,z)\ge c_1(|z|^p-1)\quad\forall(\alpha,z)\in(\varepsilon\mathbb{Z}^N\cap\Omega)\times\mathbb{R}^d,\quad i\in\{1,\dots,N\},\tag{3.2}$$

$$f_\varepsilon^\xi(\alpha,z)\le C_\varepsilon^\xi(|z|^p+1)\quad\forall(\alpha,z)\in(\varepsilon\mathbb{Z}^N\cap\Omega)\times\mathbb{R}^d,\quad\xi\in\mathbb{Z}^N, \tag{3.3}$$

where $c_1>0$, and $\{C_\varepsilon^\xi\}_{\varepsilon,\xi}$ satisfies

$$\limsup_{\varepsilon\to0^+}\sum_{\xi\in\mathbb{Z}^N}C_\varepsilon^\xi<+\infty; \tag{H1}$$

$$\forall\delta>0\quad\exists\,M_\delta>0:\quad\limsup_{\varepsilon\to0^+}\sum_{|\xi|>M_\delta}C_\varepsilon^\xi<\delta. \tag{H2}$$

The main result of this section is stated in the following theorem.

THEOREM 3.1 (compactness). *Let $\{f_\varepsilon^\xi\}_{\varepsilon,\xi}$ satisfy* (3.2), (3.3), *and let* (H1)–(H2) *hold. Then for every sequence (ε_j) of positive real numbers converging to* 0, *there exists a subsequence (ε_{j_k}) and a Carathéodory function quasi-convex in the second variable $f:\Omega\times\mathbb{R}^{d\times N}$ satisfying*

$$c(|M|^p-1)\le f(x,M)\le C(|M|^p+1),$$

with $0<c<C$, such that $(F_{\varepsilon_{j_k}}(\cdot))$ Γ-converges with respect to the $L^p(\Omega;\mathbb{R}^d)$-topology to the functional $F:L^p(\Omega;\mathbb{R}^d)\to[0,+\infty]$ defined as

$$F(u)=\begin{cases}\displaystyle\int_\Omega f(x,\nabla u)\,dx & \text{if } u\in W^{1,p}(\Omega;\mathbb{R}^d),\\ +\infty & \text{otherwise.}\end{cases} \tag{3.4}$$

Remark 3.2 (quadratic forms). Under the hypotheses of Theorem 3.1, if, in addition, for any $\xi\in\mathbb{Z}^N$ and $\varepsilon>0$ $f_\varepsilon^\xi(\alpha,\cdot)$ is a positive quadratic form on $\mathbb{R}^d$, that is,

$$f_\varepsilon^\xi(\alpha,z)=\ \langle A_\varepsilon^\xi(\alpha)z,z\rangle,\quad A_\varepsilon^\xi(\alpha)\in\mathcal{M}^{d\times d}_{sym},$$

then, by the properties of Γ-convergence (see [15]), the limit energy density $f(x,\cdot)$ is a quadratic form on $\mathcal{M}^{d\times N}$, that is,

$$f(x,M)=A(x)\,(M,M)\,,\quad A(x)\in T_2\mathcal{M}^{d\times N}, \tag{3.5}$$

where $T_2\mathcal{M}^{d\times N}$ is the vectorial space of all two times covariant tensors on $\mathcal{M}^{d\times N}$.

To prove Theorem 3.1 we use a localization technique, which is a standard argument dealing with limits of integral functionals (see, for example, [6] in the context of homogenization theory). We stress the fact that here this analysis becomes more difficult to perform because of the nonlocality of our discrete energies.

The first step is to define a "localized" version of our energies: given an open set A we isolate the contributions due to interactions within A as follows. For $u\in\mathcal{A}_\varepsilon(\Omega)$, $A\in\mathcal{A}(\Omega)$, and $\xi\in\mathbb{Z}^N$, set

$$\mathcal{F}_\varepsilon^\xi(u,A):=\sum_{\alpha\in R_\varepsilon^\xi(A)}\varepsilon^N f_\varepsilon^\xi\left(\alpha,D_\varepsilon^\xi u(\alpha)\right), \tag{3.6}$$

where

$$R_\varepsilon^\xi(A):=\{\alpha\in\varepsilon\mathbb{Z}^N:\ [\alpha,\alpha+\varepsilon\xi]\subset A\}.$$

The function $\mathcal{F}_\varepsilon^\xi$ represents the energy due to the interactions within A along the direction ξ. Then the local version of the functional in (3.1) is given by

$$F_\varepsilon(u,A)=\begin{cases}\displaystyle\sum_{\xi\in\mathbb{Z}^N}\mathcal{F}_\varepsilon^\xi(u,A) & \text{if } u\in\mathcal{A}_\varepsilon(\Omega),\\ +\infty & \text{otherwise.}\end{cases} \tag{3.7}$$

We will prove also the following result.

THEOREM 3.3 (local compactness). *Let $\{f_\varepsilon^\xi\}_{\varepsilon,\xi}$ satisfy* (3.2), (3.3), *and let* (H1)–(H2) *hold. Given (ε_j), a sequence of positive real numbers converging to* 0, *let (ε_{j_k}) and f be as in Theorem* 3.1. *Then for any $u\in W^{1,p}(\Omega;\mathbb{R}^d)$ and $A\in\mathcal{A}(\Omega)$ there holds*

$$\Gamma\text{-}\lim_k F_{\varepsilon_{j_k}}(u,A)=\int_A f(x,\nabla u)\,dx.$$

We will derive the proof of Theorems 3.1 and 3.3 as a direct consequence of some propositions and lemmas which are fundamental steps to show that our limit functionals satisfy all the hypotheses of the representation theorem, Theorem 2.2.

In the next two propositions we show that, thanks to hypotheses (3.2) and (3.3), the Γ-lim inf and the Γ-lim sup of F_ε are finite only on $W^{1,p}(\Omega;\mathbb{R}^d)$ and satisfy standard p-growth conditions.

PROPOSITION 3.4. *Let $\{f_\varepsilon^{e_i}\}_{\varepsilon,i}$ satisfy* (3.2). *If $u\in L^p(\Omega;\mathbb{R}^d)$ is such that $F'(u,A)<+\infty$, then $u\in W^{1,p}(A;\mathbb{R}^d)$, and*

$$F'(u,A)\geq c\ \left(\|\nabla u\|^p_{L^p(A;\mathbb{R}^{d\times N})}-|A|\right) \tag{3.8}$$

for some positive constant c independent of u and A.

Proof. Let $\varepsilon_n\to 0^+$, and let u_n converge to u in $L^p(\Omega;\mathbb{R}^d)$ and be such that $\liminf_n F_{\varepsilon_n}(u_n,A)<+\infty$. By the growth condition (3.2) we get

$$F_{\varepsilon_n}(u_n,A)\geq c_1\sum_{i=1}^N\sum_{\alpha\in R^{e_i}_{\varepsilon_n}(A)}\varepsilon_n^N|D^{e_i}_{\varepsilon_n}u_n(\alpha)|^p-c_1N|A|.$$

For any $i\in\{1,\dots,N\}$, consider the sequence of piecewise-affine functions (v_n^i) defined as follows:

$$v_n^i(x):=u_n(\alpha)+D^{e_i}_{\varepsilon_n}u_n(\alpha)(x_i-\alpha_i),\quad x\in\left(\alpha+[0,\varepsilon_n)^N\right)\cap\Omega,\quad \alpha\in R^{e_i}_{\varepsilon_n}(A).$$

Note that v_n^i is a function of bounded variation, and we will denote by $\frac{\partial v_n^i}{\partial x_i}$ the density of the absolutely continuous part of $D_{x_i}v_n^i$ with respect to the Lebesgue measure. Moreover, for $\mathcal{H}^{N-1}$-a.e. $y\in(A)^{e_i}$ the slices $(v_n^i)_{e_i,y}\in W^{1,p}\left((A)^{e_i}_y;\mathbb{R}^d\right)$. For any $\eta>0$, set

$$A_\eta:=\{x\in A:\ \text{dist }(x,A^c)>\eta\}.$$

Then, with fixed $\eta>0$, it is easy to check that $v_n^i\to u$ in $L^p(A_\eta;\mathbb{R}^d)$ for every $i\in\{1,\dots,N\}$; moreover, since $\frac{\partial v_n^i}{\partial x_i}(x)=D^{e_i}_{\varepsilon_n}u_n(\alpha)$ for $x\in\alpha+[0,\varepsilon_n)^N$, we get

$$F_{\varepsilon_n}(u_n,A)\geq c_1\sum_{i=1}^N\int_{A_\eta}\left|\frac{\partial v_n^i}{\partial x_i}(x)\right|^p\,dx-c_1N|A|. \tag{3.9}$$

We apply now a standard slicing argument. By Fubini's theorem and Fatou's lemma for any i we get

$$\liminf_n \int_{(A_\eta)} \left|\frac{\partial v_n^i}{\partial x_i}(x)\right|^p \geq \int_{(A_\eta)^{e_i}} \liminf_n \int_{(A_\eta)_y^{e_i}} \left|(v_n^i)'_{e_i,y}(t)\right|^p \, dt \, d\mathcal{H}^{N-1}(y).$$

Since, up to passing to a subsequence, we may assume that, for $\mathcal{H}^{N-1}$-a.e. $y \in (A_\eta)^{e_i}$ $(v_n^i)_{e_i,y} \to u_{e_i,y}$ in $L^p\left((A_\eta)_y^{e_i};\mathbb{R}^d\right)$, we deduce that $u_{e_i,y} \in W^{1,p}\left((A_\eta)_y^{e_i};\mathbb{R}^d\right)$ for $\mathcal{H}^{N-1}$-a.e. $y \in (A_\eta)^{e_i}$, and

$$\liminf_n \int_{(A_\eta)} \left|\frac{\partial v_n^i}{\partial x_i}(x)\right|^p \geq \int_{(A_\eta)^{e_i}} \int_{(A_\eta)_y^{e_i}} \left|u'_{e_i,y}(t)\right|^p \, dt \, d\mathcal{H}^{N-1}(y).$$

Then, by (3.9), we have

$$\liminf_n F_{\varepsilon_n}(u_n, A) \geq c_1 \sum_{i=1}^N \int_{(A_\eta)^{e_i}} \int_{(A_\eta)_y^{e_i}} \left|u'_{e_i,y}(t)\right|^p \, dt \, d\mathcal{H}^{N-1}(y) - c_1 N|A|.$$

Since, in particular, the previous inequality implies that

$$\sum_{i=1}^N \int_{(A_\eta)^{e_i}} \int_{(A_\eta)_y^{e_i}} \left|u'_{e_i,y}(t)\right|^p \, dt \, d\mathcal{H}^{N-1}(y) < +\infty,$$

thanks to the characterization of $W^{1,p}$ by slicing, we obtain that $u \in W^{1,p}\left(A_\eta;\mathbb{R}^d\right)$, and

$$\begin{aligned}\liminf_n F_{\varepsilon_n}(u_n, A) &\geq c_1 \sum_{i=1}^N \int_{A_\eta} \left|\frac{\partial u}{\partial x_i}(x)\right|^p \, dx - c_1 N|A| \\ &\geq c\left(\int_{A_\eta} \|\nabla u(x)\|^p \, dx - |A|\right).\end{aligned}$$

Letting $\eta \to 0^+$, we get the conclusion. □

PROPOSITION 3.5. *Let $\{f_\varepsilon^\xi\}_{\varepsilon,\xi}$ satisfy* (3.3)*, and let* (H1) *hold. Then for every $u \in W^{1,p}(\Omega;\mathbb{R}^d)$ there holds*

$$F''(u, A) \leq C \, \left(\|\nabla u\|^p_{L^p(A;\mathbb{R}^{d\times N})} + |A|\right) \tag{3.10}$$

for some positive constant C independent of u and A.

Proof. We first show that inequality (3.5) holds for u smooth and then recover the proof for any $u \in W^{1,p}(\Omega;\mathbb{R}^d)$ by using a density argument.

Let $u \in C_c^\infty(\mathbb{R}^N;\mathbb{R}^d)$, and consider the family $(u_\varepsilon) \subset \mathcal{A}_\varepsilon(\Omega)$ defined as

$$u_\varepsilon(\alpha) := u(\alpha), \quad \alpha \in \varepsilon\mathbb{Z}^N.$$

Then $u_\varepsilon \to u$ in $L^p(\Omega;\mathbb{R}^d)$ as $\varepsilon \to 0^+$. Moreover, for any $\alpha \in \varepsilon\mathbb{Z}^N$, we have

$$D_\varepsilon^\xi u_\varepsilon(\alpha) = \frac{1}{|\xi|}\int_0^1 \nabla u(\alpha + \varepsilon\xi s)\xi \, ds$$

so that, by Jensen's inequality, we get

$$|D_\varepsilon^\xi u_\varepsilon(\alpha)|^p = \frac{1}{|\xi|^p}\left|\int_0^1 \nabla u(\alpha+\varepsilon\xi s)\xi\, ds\right|^p \\ \leq \frac{1}{|\xi|^p}\int_0^1 |\nabla u(\alpha+\varepsilon\xi s)\xi|^p\, ds \leq \int_0^1 |\nabla u(\alpha+\varepsilon\xi s)|^p\, ds.$$

By the regularity hypothesis on u and by Fubini's theorem, we easily obtain the following inequalities:

$$\varepsilon^N\int_0^1 |\nabla u(\alpha+\varepsilon\xi s)|^p\, ds = \int_{\alpha+[0,\varepsilon)^N}\int_0^1 |\nabla u(\alpha+\varepsilon\xi s)|^p\, ds\, dx \\ \leq \int_{\alpha+[0,\varepsilon)^N}\int_0^1 |\nabla u(x+\varepsilon\xi s)|^p\, ds\, dx + c(u)\int_{\alpha+[0,\varepsilon)^N}\int_0^1 |x-\alpha|^p\, ds\, dx \\ \leq \int_0^1\int_{\alpha+s\varepsilon\xi+[0,\varepsilon)^N} |\nabla u(x)|^p\, dx\, ds + c(u)\varepsilon^p\varepsilon^N,$$

where by $c(u)$ we denote a constant depending only on u. By (3.3) and the last inequality, we then have

$$F_\varepsilon(u_\varepsilon, A) \leq \sum_{\xi\in\mathbb{Z}^N} C_\varepsilon^\xi \sum_{\alpha\in R_\varepsilon^\xi(A)}\int_0^1\int_{\alpha+s\varepsilon\xi+[0,\varepsilon)^N} |\nabla u(x)|^p\, dx\, ds \\ + (1+c(u)\varepsilon^p)\sum_{\xi\in\mathbb{Z}^N} C_\varepsilon^\xi \sum_{\alpha\in R_\varepsilon^\xi(A)} \varepsilon^N \\ \leq \sum_{\xi\in\mathbb{Z}^N} C_\varepsilon^\xi\left(\int_{A^\varepsilon} |\nabla u(x)|^p\, dx + (1+c(u)\varepsilon^p)\,|A^\varepsilon|\right),$$

where

$$A^\varepsilon := A + [0,\varepsilon)^N.$$

Eventually, letting $\varepsilon\to 0^+$, by (H1) we get

$$\limsup_{\varepsilon\to 0^+} F_\varepsilon(u_\varepsilon, A) \leq C\left(\int_A |\nabla u(x)|^p\, dx + |A|\right),$$

and the conclusion follows by the definition of F''. Now let $u\in W^{1,p}(\Omega;\mathbb{R}^d)$, and let $(u_n)\subset C_c^\infty(\mathbb{R}^N;\mathbb{R}^d)$ converge to u in the $W^{1,p}(\Omega;\mathbb{R}^d)$-topology. Then, by the lower semicontinuity of F'', we obtain

$$F''(u,A) \leq \liminf_n F''(u_n,A) \leq \lim_n C\left(\|\nabla u_n\|^p_{L^p(A;\mathbb{R}^{d\times N})} + |A|\right) \\ = C\left(\|\nabla u\|^p_{L^p(A;\mathbb{R}^{d\times N})} + |A|\right). \qquad \square$$

The next technical lemma asserts that finite difference quotients along any direction can be controlled by finite difference quotients along the coordinate directions.

LEMMA 3.6. *Let $A\in\mathcal{A}(\Omega)$, and set $A_\varepsilon := \{x\in A : \operatorname{dist}(x,\partial A) > 2\sqrt{N}\varepsilon\}$. Then for any $\xi\in\mathbb{Z}^N$ and $u\in\mathcal{A}_\varepsilon(\Omega)$ there holds*

$$\sum_{\alpha\in R_\varepsilon^\xi(A_\varepsilon)} |D_\varepsilon^\xi u(\alpha)|^p \leq C\sum_{i=1}^N \sum_{\alpha\in R_\varepsilon^{e_i}(A)} |D_\varepsilon^{e_i} u(\alpha)|^p. \tag{3.11}$$

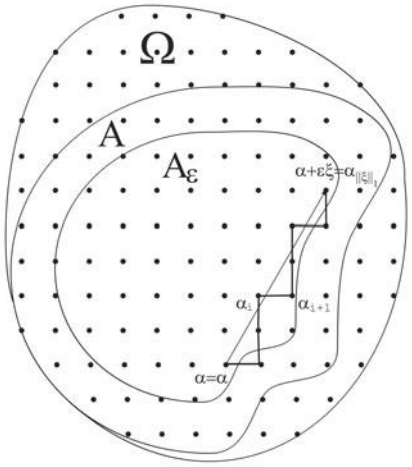

FIG. 2.

Proof. Let us fix some notations: for $\xi \in \mathbb{Z}^N$ and $\alpha \in \varepsilon\mathbb{Z}^N$, set

$$I_\varepsilon^\xi(\alpha) := \left\{\beta \in \varepsilon\mathbb{Z}^N : \ \left(\beta + [-\varepsilon,\varepsilon]^N\right) \cap [\alpha, \alpha + \varepsilon\xi] \neq \emptyset\right\};$$

moreover, we will denote by $\|\cdot\|_1$ the norm on $\mathbb{R}^N$ defined as

$$\|\xi\|_1 := \sum_{i=1}^N |\xi_i|, \quad \xi = (\xi_1, \dots, \xi_N) \in \mathbb{R}^N.$$

Let $\alpha \in R_\varepsilon^\xi(A_\varepsilon)$, and consider $\{\alpha_h\}_{h=1}^{\|\xi\|_1} \subset I_\varepsilon^\xi(\alpha)$ such that

$$\alpha_{\|\xi\|_1} = \alpha + \varepsilon\xi, \quad \alpha_1 = \alpha, \quad \alpha_h = \alpha_{h-1} + \varepsilon e_{i(h)}$$

for some $i(h) \in \{1, \dots, N\}$ (see Figure 2). Then, since

$$D_\varepsilon^\xi u(\alpha) = \frac{1}{|\xi|} \sum_{h=1}^{\|\xi\|_1} D_\varepsilon^{e_{i(h)}} u(\alpha_h)$$

by Jensen's inequality, we get

$$\begin{aligned} |D_\varepsilon^\xi u(\alpha)|^p &= \left(\frac{\|\xi\|_1}{|\xi|}\right)^p \left| \frac{1}{\|\xi\|_1} \sum_{h=1}^{\|\xi\|_1} D_\varepsilon^{e_{i(h)}} u(\alpha_h) \right|^p \\ &\le \left(\frac{\|\xi\|_1}{|\xi|}\right)^p \frac{1}{\|\xi\|_1} \sum_{h=1}^{\|\xi\|_1} |D_\varepsilon^{e_{i(h)}} u(\alpha_h)|^p. \end{aligned}$$

Since for any $h = 1, \dots, N$, $\alpha_h \in R_\varepsilon^{e_{i(h)}}(A)$ and all the norms are equivalent in a finite-dimensional space, we infer that

$$\sum_{\alpha \in R_\varepsilon^\xi(A_\varepsilon)} |D_\varepsilon^\xi u(\alpha)|^p \le C \sum_{i=1}^N \sum_{\beta \in R_\varepsilon^{e_i}(A)} \frac{\gamma_\varepsilon^\xi(\beta)}{\|\xi\|_1} |D_\varepsilon^{e_i} u(\beta)|^p,$$

where

$$\gamma_\varepsilon^\xi(\beta) := \#\{\alpha \in R_\varepsilon^\xi(A_\varepsilon) :\ \beta \in I_\varepsilon^\xi(\alpha)\}.$$

Hence, the proof is complete if we show that $\gamma_\varepsilon^\xi(\beta) \le C|\xi|$. To this aim, notice that

$$\{\alpha \in R_\varepsilon^\xi(A_\varepsilon) :\ \beta \in I_\varepsilon^\xi(\alpha)\} \subseteq \varepsilon\mathbb{Z}^N \cap Q_\varepsilon^\xi(\beta),$$

where

$$Q_\varepsilon^\xi(\beta) := \{x \in \mathbb{R}^N : x = y + t\xi,\ y \in \beta + [-\varepsilon,\varepsilon]^n,\ t \in [-\varepsilon,\varepsilon]^N\}.$$

Thus, we infer that

$$\gamma_\varepsilon^\xi(\beta) \le C\frac{\left|Q_\varepsilon^\xi(\beta)\right|}{\varepsilon^N}.$$

Now we use a slicing argument to provide an estimate of $\left|Q_\varepsilon^\xi(\beta)\right|$. By Fubini's theorem, we get

$$\begin{aligned}|Q_\varepsilon^\xi(\beta)| &= \int_{\left(Q_\varepsilon^\xi(\beta)\right)^\xi} \mathcal{H}^1\left(Q_\varepsilon^\xi(\beta)\right)_y^\xi \, d\mathcal{H}^{N-1}(y)\\ &\le \mathcal{H}^{N-1}\left((Q_\varepsilon^\xi(\beta))^\xi\right) 2(\sqrt{N}+|\xi|)\varepsilon \le c(N)|\xi|\varepsilon^N,\end{aligned}$$

where the last inequality holds, since for any $\xi \in \mathbb{Z}^N$

$$\mathcal{H}^{N-1}\left((Q_\varepsilon^\xi(\beta))^\xi\right) \le c(N)\varepsilon^{N-1}. \qquad \square$$

In the next two propositions we establish the subadditivity and the inner regularity of the set function $F''(u,\cdot)$. To this end we use a careful modification of De Giorgi's cut-off functions argument, which appears frequently in the proof of the integral representation of Γ-limits of integral functionals (see [6], [15]). We underline that the nonlocality of our energies requires a deeper analysis in which a key role is played by hypothesis (H2), which allows us to show that very long-range interactions do not lead to nonlocal terms in the limit.

PROPOSITION 3.7. *Let $\{f_\varepsilon^\xi\}_{\varepsilon,\xi}$ satisfy* (3.2),(3.3)*, and let* (H1)–(H2) *hold. Let $A, B \in \mathcal{A}(\Omega)$, and let $A', B' \in \mathcal{A}(\Omega)$ be such that $A' \subset\subset A$ and $B' \subset\subset B$. Then, for any $u \in W^{1,p}(\Omega;\mathbb{R}^d)$,*

$$F''(u, A' \cup B') \le F''(u, A) + F''(u, B).$$

Proof. Without loss of generality, we may suppose that $F''(u,A)$ and $F''(u,B)$ are finite. Let $u_\varepsilon, v_\varepsilon \in \mathcal{A}_\varepsilon(\Omega)$ both converge to u in $L^p(\Omega;\mathbb{R}^d)$ and be such that

$$\limsup_{\varepsilon\to 0^+} F_\varepsilon(u_\varepsilon, A) = F''(u,A), \quad \limsup_{\varepsilon\to 0^+} F_\varepsilon(v_\varepsilon, B) = F''(u,B).$$

By (3.2) and Lemma 3.6, we infer that

$$\sup_{\xi\in\mathbb{Z}^N}\sup_{\varepsilon>0} \sum_{\alpha\in R_\varepsilon^\xi(A_\varepsilon)} \varepsilon^N |D_\varepsilon^\xi u_\varepsilon(\alpha)|^p < +\infty, \tag{3.12}$$

$$\sup_{\xi\in\mathbb{Z}^N}\sup_{\varepsilon>0} \sum_{\alpha\in R_\varepsilon^\xi(B_\varepsilon)} \varepsilon^N |D_\varepsilon^\xi v_\varepsilon(\alpha)|^p < +\infty, \tag{3.13}$$

where A_ε and B_ε are defined as in Lemma 3.6. Moreover, since (u_ε) and (v_ε) converge to u in the $L^p(\Omega;\mathbb{R}^d)$-topology, we have

$$\sum_{\alpha\in\varepsilon\mathbb{Z}^N\cap\Omega'} \varepsilon^N \left(|u_\varepsilon(\alpha)|^p + |v_\varepsilon(\alpha)|^p\right) \le \|u_\varepsilon\|^p_{L^p(\Omega;\mathbb{R}^d)} + \|v_\varepsilon\|^p_{L^p(\Omega;\mathbb{R}^d)} \le C < +\infty, \tag{3.14}$$

$$\sum_{\alpha\in\varepsilon\mathbb{Z}^N\cap\Omega'} \varepsilon^N \left(|u_\varepsilon(\alpha) - v_\varepsilon(\alpha)|^p\right) \le \|u_\varepsilon - v_\varepsilon\|^p_{L^p(\Omega;\mathbb{R}^d)} \to 0^+ \tag{3.15}$$

for any $\Omega' \subset\subset \Omega$. Set

$$d := \operatorname{dist}(A', A^c),$$

and for any $i \in \{1,\dots,N\}$ define

$$A_i := \left\{ x \in A :\ \operatorname{dist}(x, A') < i\frac{d}{N} \right\}.$$

Let φ_i be a cut-off function between A_i and A_{i+1}, with $\|\nabla\varphi_i\|_\infty \le 2\frac{N}{d}$. Then for any $i \in \{1,\dots,N\}$ consider the family of functions $w^i_\varepsilon \in \mathcal{A}_\varepsilon(\Omega)$ still converging to u in $L^p(\Omega;\mathbb{R}^d)$ defined as

$$w^i_\varepsilon(\alpha) := \varphi_i(\alpha)u_\varepsilon(\alpha) + (1-\varphi_i(\alpha))\, v_\varepsilon(\alpha).$$

Note that, for any $\xi \in \mathbb{Z}^N$, we have

$$\begin{aligned} D^\xi_\varepsilon w^i_\varepsilon(\alpha) = \varphi_i(\alpha+\varepsilon\xi) D^\xi_\varepsilon u_\varepsilon(\alpha) + (1-\varphi_i(\alpha+\varepsilon\xi))\, D^\xi_\varepsilon v_\varepsilon(\alpha) \\ + (u_\varepsilon(\alpha) - v_\varepsilon(\alpha))\, D^\xi_\varepsilon\varphi(\alpha). \end{aligned} \tag{3.16}$$

Fix $i \in \{1,2,\dots,N-3\}$. Given $\xi \in \mathbb{Z}^N$ and $\alpha \in R^\xi_\varepsilon(A'\cup B')$, then either $\alpha \in R^\xi_\varepsilon(A_i)$ or $\alpha \in R^\xi_\varepsilon(\overline{A}^c_{i+1} \cap B')$, or

$$[\alpha, \alpha+\varepsilon\xi] \cap \left(\overline{A}_{i+1} \setminus A_i\right) \cap B' \neq \emptyset.$$

Then, if we set

$$\left(\overline{A}_{i+1} \setminus A_i\right)^{\varepsilon,\xi} := \{x = y + t\xi,\ |t| \le \varepsilon,\ y \in \overline{A}_{i+1} \setminus A_i\},$$

$$S^{\varepsilon,\xi}_i := \left(\overline{A}_{i+1} \setminus A_i\right)^{\varepsilon,\xi} \cap (A'\cup B'),$$

we get

$$R^\xi_\varepsilon(A'\cup B') \subseteq R^\xi_\varepsilon(A_i) \cup R^\xi_\varepsilon(B' \setminus \overline{A}_{i+1}) \cup R^\xi_\varepsilon\left(S^{\varepsilon,\xi}_i\right)$$

(see Figure 3). Thus, since $D^\xi_\varepsilon w^i_\varepsilon(\alpha) = D^\xi_\varepsilon u_\varepsilon(\alpha)$ if $\alpha \in R^\xi_\varepsilon(A_i)$ and $D^\xi_\varepsilon w^i_\varepsilon(\alpha) = D^\xi_\varepsilon v_\varepsilon(\alpha)$ if $\alpha \in R^\xi_\varepsilon(\overline{A}^c_{i+1} \cap B')$, we get by (3.3) and (3.16)

$$\begin{aligned} \mathcal{F}^\xi_\varepsilon\ (w^i_\varepsilon, A'\cup B') &\le \mathcal{F}^\xi_\varepsilon(u_\varepsilon, A) + \mathcal{F}^\xi_\varepsilon(v_\varepsilon, B) \\ &+ C\ C^\xi_\varepsilon \sum_{\alpha\in R^\xi_\varepsilon(S^{\varepsilon,\xi}_i)} \varepsilon^N \left(|D^\xi_\varepsilon u_\varepsilon(\alpha)|^p + |D^\xi_\varepsilon v_\varepsilon(\alpha)|^p + N^p\,|u_\varepsilon(\alpha) - v_\varepsilon(\alpha)|^p + 1\right). \end{aligned} \tag{3.17}$$

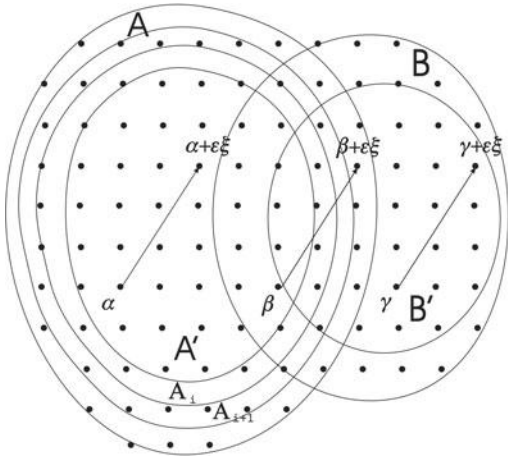

FIG. 3. $\alpha \in R^\xi_\varepsilon(A_i), \beta \in R^\xi_\varepsilon(S_i^{\varepsilon,\xi}), \gamma \in R^\xi_\varepsilon(B' \setminus A^c_{i+1})$.

If $\varepsilon|\xi| \le \frac{d}{2N}$, then

$$S_i^{\varepsilon,\xi} \subseteq \left(A_{N-1} \setminus \overline{A'}\right) \cap B' =: S_N \subset\subset A \cap B. \tag{3.18}$$

If $\varepsilon|\xi| \ge \frac{d}{2N}$, then

$$\frac{1}{\varepsilon^p|\xi|^p} \le \frac{2^p N^p}{d^p},$$

and so

$$|D^\xi_\varepsilon u_\varepsilon(\alpha)|^p \le CN^p \left(|u_\varepsilon(\alpha)|^p + |u_\varepsilon(\alpha+\varepsilon\xi)|^p\right),$$

and the same inequality holds for v_ε. Thus, in this case we get by (3.17)

$$\begin{aligned}\mathcal{F}^\xi_\varepsilon(w^i_\varepsilon, A' \cup B') &\le \mathcal{F}^\xi_\varepsilon(u_\varepsilon, A) + \mathcal{F}^\xi_\varepsilon(v_\varepsilon, B)\\ &+ CN^p\, C^\xi_\varepsilon \sum_{\alpha \in R^\xi_\varepsilon(A' \cup B')} \varepsilon^N \left(|u_\varepsilon(\alpha)|^p + |u_\varepsilon(\alpha+\varepsilon\xi)|^p + |v_\varepsilon(\alpha)|^p + |v_\varepsilon(\alpha+\varepsilon\xi)|^p + 1\right).\end{aligned} \tag{3.19}$$

Let $M_\delta > 0$ be such that $\limsup_{\varepsilon\to 0^+} \sum_{|\xi|>M_\delta} C^\xi_\varepsilon < \delta$. Then, by (3.17), (3.18), and (3.19), summing over $\xi \in \mathbb{Z}^N$, for ε small enough we get

$$\begin{aligned}F_\varepsilon(w^i_\varepsilon, A' \cup B') &\le F_\varepsilon(u_\varepsilon, A) + F_\varepsilon(v_\varepsilon, B)\\
&+ C \sum_{|\xi| \le M_\delta} C^\xi_\varepsilon \sum_{\alpha \in R^\xi_\varepsilon(S_i^{\varepsilon,\xi})} \varepsilon^N \left(|D^\xi_\varepsilon u_\varepsilon(\alpha)|^p + |D^\xi_\varepsilon v_\varepsilon(\alpha)|^p + N^p\,|u_\varepsilon(\alpha) - v_\varepsilon(\alpha)|^p + 1\right)\\
&+ C \sum_{M_\delta < |\xi| \le \frac{d}{2N\varepsilon}} C^\xi_\varepsilon \sum_{\alpha \in R^\xi_\varepsilon(S_N)} \varepsilon^N \left(|D^\xi_\varepsilon u_\varepsilon(\alpha)|^p + |D^\xi_\varepsilon v_\varepsilon(\alpha)|^p + N^p\,|u_\varepsilon(\alpha) - v_\varepsilon(\alpha)|^p + 1\right)\\
&+ CN^p \sum_{|\xi| > \frac{d}{2N\varepsilon}} C^\xi_\varepsilon \sum_{\alpha \in \varepsilon\mathbb{Z}^N \cap A' \cup B'} \varepsilon^N \left(|u_\varepsilon(\alpha)|^p + |v_\varepsilon(\alpha)|^p + 1\right).\end{aligned}$$

Note that, for ε small enough and $|\xi| \le M_\delta$, we have that $R^\xi_\varepsilon(S_i^{\varepsilon,\xi}) \cap R^\xi_\varepsilon(S_j^{\varepsilon,\xi}) \ne \emptyset$ if and only if $|i-j| = 1$, and $\bigcup_{i=1}^{N-3} R^\xi_\varepsilon(S_i^{\varepsilon,\xi}) \subseteq R^\xi_\varepsilon(A_\varepsilon \cap B_\varepsilon)$. Thus, summing over

$i \in \{1, 2, \dots, N-3\}$, averaging, and taking into account (3.12), (3.13), (3.14), and (3.15), we get

$$\begin{aligned}(3.20)\quad \frac{1}{N-3}\sum_{i=1}^{N-3} F_\varepsilon(w_\varepsilon^i, A' \cup B') \le F_\varepsilon(u_\varepsilon, A) + F_\varepsilon(v_\varepsilon, B) \\ + \frac{C}{N-3}(1 + N^p O(\varepsilon)) + C(\delta + O(\varepsilon))(1 + N^p O(\varepsilon)) \\ + C\,(\delta + O(\varepsilon))(N^p)\,.\end{aligned}$$

For any $\varepsilon > 0$ there exists $i(\varepsilon) \in \{1, \dots, N-3\}$ such that

$$(3.21)\qquad F_\varepsilon(w_\varepsilon^{i(\varepsilon)}, A' \cup B') \le \frac{1}{N-3}\sum_{i=1}^{N-3} F_\varepsilon(w_\varepsilon^i, A' \cup B').$$

Then, since $w_\varepsilon^{i(\varepsilon)}$ still converges to u in $L^p(\Omega; \mathbb{R}^d)$, by (3.20) and (3.21), letting $\varepsilon \to 0^+$, we get

$$F''(u, A' \cup B') \le F''(u, A) + F''(u, B) + \frac{C}{N-3} + C\delta\,(1 + N^p)\,.$$

Eventually, letting first $\delta \to 0^+$ and then $N \to +\infty$, we obtain the thesis. □

PROPOSITION 3.8. *Let $\{f_\varepsilon^\xi\}_{\varepsilon,\xi}$ satisfy* (3.2), (3.3)*, and let* (H1)–(H2) *hold. Then, for any $u \in W^{1,p}(\Omega; \mathbb{R}^d)$ and for any $A \in \mathcal{A}(\Omega)$, there holds*

$$\sup_{A' \subset\subset A} F''(u, A') = F''(u, A).$$

Proof. Since $F''(u, \cdot)$ is an increasing set function, it suffices to prove that

$$\sup_{A' \subset\subset A} F''(u, A') \ge F''(u, A).$$

To do this, we apply the same argument of the proof of Proposition 3.7. Given $\delta > 0$, there exists $A'' \subset\subset A$ such that

$$|A \setminus \overline{A''}| + \|\nabla u\|^p_{L^p(A \setminus \overline{A''})} \le \delta.$$

Let $\tilde\Omega \supset\supset \Omega$, and let $\tilde u \in W^{1,p}(\tilde\Omega; \mathbb{R}^d)$ be an extension of u. By reasoning as in the proof of Proposition 3.5, we may find $v_\varepsilon \in \mathcal{A}_\varepsilon(\tilde\Omega)$ such that v_ε converges to $\tilde u$ in $L^p(\tilde\Omega; \mathbb{R}^d)$ and

$$(3.22)\qquad \limsup_{\varepsilon \to 0^+} F_\varepsilon(v_\varepsilon, A \setminus \overline{A''}) \le C\left(|A \setminus \overline{A''}| + \|\nabla u\|^p_{L^p(A \setminus \overline{A''})}\right) \le C\delta.$$

We remark that this extension on $\tilde\Omega$ is just a technical tool to exploit an analogue of inequality (3.14) and obtain a control of the interactions near the boundary of Ω. Let $A' \in \mathcal{A}(\Omega)$ be such that $A'' \subset\subset A' \subset\subset A$, and let $u_\varepsilon \in \mathcal{A}_\varepsilon(\Omega)$ converge to u in $L^p(\Omega; \mathbb{R}^d)$, with

$$\limsup_{\varepsilon \to 0^+} F_\varepsilon(u_\varepsilon, A') = F''(u, A').$$

Set

$$d := \operatorname{dist}(A'', A'^c),$$

and for any $i \in \{1,\dots,N\}$ define

$$A_i := \left\{ x \in A : \ \operatorname{dist}(x, A') < i\frac{d}{N} \right\}.$$

Let φ_i be a cut-off function between A_i and A_{i+1}, with $\|\nabla\varphi_i\|_\infty \le 2\frac{N}{d}$. Then for any $i \in \{1,\dots,N\}$ consider the family of functions $w_\varepsilon^i \in \mathcal{A}_\varepsilon(\Omega)$ still converging to u in $L^p(\Omega;\mathbb{R}^d)$ defined as

$$w_\varepsilon^i(\alpha) := \varphi_i(\alpha)u_\varepsilon(\alpha) + (1-\varphi_i(\alpha))\, v_\varepsilon(\alpha).$$

Now we can set

$$S_i^{\varepsilon,\xi} := \left(\overline{A}_{i+1} \setminus A_i\right)^{\varepsilon,\xi} \cap A$$

so that

$$R_\varepsilon^\xi(A) \subseteq R_\varepsilon^\xi(A_i) \cup R_\varepsilon^\xi(A \setminus \overline{A}_{i+1}) \cup R_\varepsilon^\xi\left(S_i^{\varepsilon,\xi}\right).$$

Let $\delta > 0$, and let $M_\delta > 0$ be such that $\limsup_{\varepsilon\to 0^+} \sum_{|\xi|>M_\delta} C_\varepsilon^\xi < \delta$. Then, by reasoning as in the proof of Proposition 3.7, for ε small enough, we get

$$\begin{aligned}
&F_\varepsilon(w_\varepsilon^i, A) \le F_\varepsilon(u_\varepsilon, A') + F_\varepsilon(v_\varepsilon, A \setminus \overline{A''}) \\
&+\ C \sum_{|\xi|\le M_\delta} C_\varepsilon^\xi \sum_{\alpha\in R_\varepsilon^\xi(S_i^{\varepsilon,\xi})} \varepsilon^N \left(|D_\varepsilon^\xi u_\varepsilon(\alpha)|^p + |D_\varepsilon^\xi v_\varepsilon(\alpha)|^p + N^p\,|u_\varepsilon(\alpha) - v_\varepsilon(\alpha)|^p + 1\right) \\
&+\ C \sum_{M_\delta<|\xi|\le \frac{d}{2N\varepsilon}} C_\varepsilon^\xi \sum_{\alpha\in R_\varepsilon^\xi(S_N)} \varepsilon^N \left(|D_\varepsilon^\xi u_\varepsilon(\alpha)|^p + |D_\varepsilon^\xi v_\varepsilon(\alpha)|^p + N^p\,|u_\varepsilon(\alpha) - v_\varepsilon(\alpha)|^p + 1\right) \\
&+\ CN^p \sum_{|\xi|>\frac{d}{2N\varepsilon}} C_\varepsilon^\xi \left(\|u_\varepsilon\|^p_{L^p(\Omega;\mathbb{R}^d)} + \|v_\varepsilon\|^p_{L^p(\tilde\Omega;\mathbb{R}^d)} + 1\right).
\end{aligned}$$

Since u_ε and v_ε satisfy (3.12), (3.13), (3.14), and (3.15) with A_ε replaced by A'_ε and B_ε by $(A \setminus \overline{A''_\varepsilon})$, then we can choose $i(\varepsilon) \in \{1,\dots,N-3\}$ such that

$$\begin{aligned}
F_\varepsilon(w_\varepsilon^{i(\varepsilon)}, A) &\le \frac{1}{N-3}\sum_{i=1}^{N-3} F_\varepsilon(w_\varepsilon^i, A) \\
&\le F_\varepsilon(u_\varepsilon, A') + C\delta + \frac{C}{N-3}\left(1 + N^p O(\varepsilon)\right) \\
&+C(\delta + O(\varepsilon))\left(1 + N^p O(\varepsilon)\right) + CN^p(\delta + O(\varepsilon)).
\end{aligned} \tag{3.23}$$

Then, since $w_\varepsilon^{i(\varepsilon)}$ still converges to u in $L^p(\Omega;\mathbb{R}^d)$, by (3.23), letting $\varepsilon \to 0^+$, we get

$$F''(u, A) \le \sup_{A'\subset\subset A} F''(u, A') + C\left(\frac{1}{N-3} + \delta + \delta N^p\right).$$

Eventually, letting first $\delta \to 0^+$ and then $N \to +\infty$, we obtain the thesis. □

The following proposition asserts that $F''(\cdot,\cdot)$ satisfies hypothesis (i) of Theorem 2.2. The argument we use for the proof is still the same one exploited in the last two propositions.

PROPOSITION 3.9. *Let* $\{f_\varepsilon^\xi\}_{\varepsilon,\xi}$ *satisfy* (3.2), (3.3), *and let* (H1)–(H2) *hold. Then for any* $A \in \mathcal{A}(\Omega)$ *and for any* $u,\ v \in W^{1,p}(\Omega;\mathbb{R}^d)$ *such that* $u = v$ *a.e. there holds*

$$F''(u,A) = F''(v,A).$$

Proof. Thanks to Proposition 3.8, we may assume that $A \in \mathcal{A}_0(\Omega)$. We first prove

$$F''(u,A) \geq F''(v,A). \tag{3.24}$$

Once more we apply the argument used in the previous proposition. Given $\delta > 0$, there exists $A_\delta \subset\subset A$ such that

$$|A \setminus \overline{A_\delta}| + \|\nabla u\|^p_{L^p(A\setminus\overline{A_\delta})} \leq \delta.$$

Let $v_\varepsilon \in \mathcal{A}_\varepsilon(\Omega)$ and $u_\varepsilon \in \mathcal{A}_\varepsilon(\Omega)$ be such that

$$v_\varepsilon \to v \text{ in } L^p(\Omega;\mathbb{R}^d), \tag{3.25}$$

$$u_\varepsilon \to u \text{ in } L^p(\Omega;\mathbb{R}^d), \tag{3.26}$$

and

$$\limsup_{\varepsilon\to 0^+} F_\varepsilon(u_\varepsilon, A) = F''(u,A),$$

$$\limsup_{\varepsilon\to 0^+} F_\varepsilon(v_\varepsilon, A\setminus\overline{A_\delta}) = F''(v, A\setminus\overline{A_\delta}) \leq C\left(|A\setminus\overline{A_\delta}| + \|\nabla u\|^p_{L^p(A\setminus\overline{A_\delta})}\right) \leq C\delta. \tag{3.27}$$

Set

$$d := \operatorname{dist}(A_\delta, A^c),$$

and for any $i \in \{1,\dots,N\}$ define

$$A_i := \left\{x \in A :\ \operatorname{dist}(x,A_\delta) < i\frac{d}{N}\right\}.$$

Let φ_i be a cut-off function between A_i and A_{i+1}, with $\|\nabla\varphi_i\|_\infty \leq 2\frac{N}{d}$. Then for any $i \in \{1,\dots,N\}$ consider the family of functions $w_\varepsilon^i \in \mathcal{A}_\varepsilon(\Omega)$ converging to v in $L^p(\Omega;\mathbb{R}^d)$ defined as

$$w_\varepsilon^i(\alpha) := \varphi_i(\alpha)u_\varepsilon(\alpha) + (1-\varphi_i(\alpha))\,v_\varepsilon(\alpha).$$

Then, following the same steps as in the proofs of Propositions 3.7 and 3.8, we can choose $i(\varepsilon) \in \{1,\dots,N-3\}$ such that

$$\begin{aligned} F_\varepsilon(w_\varepsilon^{i(\varepsilon)}, A) &\leq \frac{1}{N-3}\sum_{i=1}^{N-3} F_\varepsilon(w_\varepsilon^i, A) \\ &\leq F_\varepsilon(u_\varepsilon, A) + C\delta + \frac{C}{N-3}\left(1 + N^p O(\varepsilon)\right) \\ &\quad + C(\delta + O(\varepsilon))\left(1 + N^p O(\varepsilon)\right) + C(\delta + O(\varepsilon))N^p. \end{aligned} \tag{3.28}$$

Then, since $w_\varepsilon^{i(\varepsilon)}$ still converges to v in $L^p(\Omega;\mathbb{R}^d)$, by (3.28), letting $\varepsilon \to 0^+$, we get

$$F''(v,A) \le F''(u,A) + C\left(\frac{1}{N-3} + \delta + \delta N^p\right).$$

Eventually, letting first $\delta \to 0^+$ and then $N \to +\infty$, we obtain (3.24). Reversing the roles of u and v we obtain the thesis. □

Proof of Theorems 3.1 *and* 3.3. By the compactness property of the Γ-convergence and by Proposition 3.8, there exists a subsequence (ε_{j_k}) such that, for any $(u,A) \in W^{1,p}(\Omega;\mathbb{R}^d) \times \mathcal{A}(\Omega)$, there holds

$$\Gamma(L^p)\text{-}\lim_k F_{\varepsilon_{j_k}}(u,A) := F(u,A)$$

(see [6, Theorem 10.3]). Moreover, by Proposition 3.4,

$$\Gamma(L^p)\text{-}\lim_k F_{\varepsilon_{j_k}}(u) = +\infty$$

for $u \in L^p(\Omega;\mathbb{R}^d) \setminus W^{1,p}(\Omega;\mathbb{R}^d)$. So far, it suffices to check that, for every $(u,A) \in W^{1,p}(\Omega;\mathbb{R}^d) \times \mathcal{A}(\Omega)$, $F(u,A)$ satisfies all the hypotheses of Theorem 2.2. In fact, it can be easily seen that the superadditivity property of $F_\varepsilon(u,\cdot)$ is conserved in the limit. Thus, as an easy consequence of Propositions 3.5, 3.7, 3.8, and 3.9 and thanks to the De Giorgi–Letta criterion (see [17], [6]), hypotheses (i), (ii), and (iii) hold true. Moreover, as $F_\varepsilon(u,A)$ depends on u only through its difference quotients, hypothesis (iv) is satisfied, and, finally, by the lower semicontinuity property of the Γ-limit, also hypothesis (v) is fulfilled. □

3.1. Convergence of minimum problems. In order to treat minimum problems with boundary data, we also derive a compactness theorem in case that our functionals are subject to Dirichlet boundary conditions.

Given $\varphi \in Lip\,(\mathbb{R}^N)$ and $l \in \mathbb{N}$, set, for any $\varepsilon > 0$ and $A \in \mathcal{A}(\Omega)$,

$$\mathcal{A}^l_{\varepsilon,\varphi}(A) := \{u \in \mathcal{A}_\varepsilon(\mathbb{R}^N) : u(\alpha) = \varphi(\alpha) \text{ if } \big(\alpha + [-l\varepsilon, l\varepsilon]^N\big) \cap A^c \neq \emptyset\big)\}. \tag{3.29}$$

Then define $F^{\varphi,l}_\varepsilon : L^p(\Omega;\mathbb{R}^d) \times \mathcal{A}(\Omega) \to [0,+\infty]$ as

$$F^{\varphi,l}_\varepsilon(u,A) = \begin{cases} F_\varepsilon(u,A) & \text{if } u \in \mathcal{A}^l_{\varepsilon,\varphi}(A), \\ +\infty & \text{otherwise.} \end{cases} \tag{3.30}$$

By simplicity of notation we set $\mathcal{A}_{\varepsilon,\varphi}(A) := \mathcal{A}^1_{\varepsilon,\varphi}(A)$ and $F^\varphi_\varepsilon := F^{\varphi,1}_\varepsilon$.

THEOREM 3.10. *Let* $\{f^\xi_\varepsilon\}_{\varepsilon,\xi}$ *satisfy* (3.2), (3.3), *and let* (H1)–(H2) *hold. Given* (ε_j), *a sequence of positive real numbers converging to* 0, *let* (ε_{j_k}) *and* f *be as in Theorem* 3.1. *For any* $\varphi \in Lip\,(\mathbb{R}^N)$, *let* $F^\varphi : L^p(\Omega;\mathbb{R}^d) \times \mathcal{A}(\Omega) \to [0,+\infty]$ *be defined as*

$$F^\varphi(u,A) = \begin{cases} \displaystyle\int_A f(x,\nabla u)\,dx & \text{if } u - \varphi \in W^{1,p}_0(A;\mathbb{R}^d), \\ +\infty & \text{otherwise.} \end{cases}$$

Then, for any $A \in \mathcal{A}(\Omega)$ *with Lipschitz boundary and* $l \in \mathbb{N}$, $(F^{\varphi,l}_{\varepsilon_{j_k}}(\cdot,A))$ Γ-*converges with respect to the* $L^p(\Omega;\mathbb{R}^d)$-*topology to the functional* $F^\varphi(\cdot,A)$.

Proof. For the sake of simplicity we prove the theorem with $l = 1$, the proof being the same in the other cases. Let us first prove the Γ-liminf inequality. Let (u_k) be a sequence of functions belonging to $\mathcal{A}_{\varepsilon_{j_k},\varphi}(A)$ converging to u in the L^p-topology such that

$$\liminf_k F^{\varphi}_{\varepsilon_{j_k}}(u_k, A) = \lim_k F^{\varphi}_{\varepsilon_{j_k}}(u_k, A) < +\infty.$$

Then, from (3.2), we get in particular that

$$\sup_k \sum_{i=1}^{N} \sum_{\alpha \in R^{e_i}_{\varepsilon_{j_k}}(A)} \varepsilon_{j_k}^N |D^{e_i}_{\varepsilon_{j_k}} u_n(\alpha)|^p < +\infty. \tag{3.31}$$

Thanks to the boundary conditions on u_k it is easy to deduce that

$$\sup_k \sum_{i=1}^{N} \sum_{\alpha \in R^{e_i}_{\varepsilon_{j_k}}(\Omega)} \varepsilon^N |D^{e_i}_{\varepsilon_{j_k}} u_n(\alpha)|^p < +\infty.$$

Then, by reasoning as in the proof of Proposition 3.4, we can prove that $u \in W^{1,p}(\Omega; \mathbb{R}^d)$, and, since (u_k) converge to φ in $L^p(\Omega \setminus A; \mathbb{R}^d)$, we get that $u - \varphi \in W^{1,p}_0(A; \mathbb{R}^d)$. By Theorem 3.3 one has

$$\liminf_k F^{\varphi}_{\varepsilon_{j_k}}(u_k, A) = \liminf_k F_{\varepsilon_{j_k}}(u_k, A) \geq F^{\varphi}(u, A).$$

To prove the Γ-limsup inequality, let us first consider $u \in W^{1,p}(\Omega; \mathbb{R}^d)$ such that supp $(u - \varphi) \subset\subset A$. Let $u_k \in \mathcal{A}_{\varepsilon_{j_k}}(\Omega)$ be such that (u_k) converges to u in $L^p(\Omega; \mathbb{R}^d)$, and

$$\limsup_k F_{\varepsilon_{j_k}}(u_k, A) = F^{\varphi}(u, A).$$

Then, by reasoning as in the proof of Proposition 3.8, given $\delta > 0$, we can find suitable cut-off functions ϕ_k with supp $(u - \varphi) \subset\subset$ supp $\phi_k \subset\subset A$ such that if we set

$$v_k(\alpha) := \phi_k(\alpha) u_k(\alpha) + (1 - \phi_k(\alpha))\varphi(\alpha),$$

then (v_k) still converges to u in $L^p(\Omega; \mathbb{R}^d)$, $v_k \in \mathcal{A}_{\varepsilon_{j_k},\varphi}(\Omega)$ for k large enough, and

$$\limsup_k F_{\varepsilon_{j_k}}(v_k, A) \leq \limsup F_{\varepsilon_{j_k}}(u_k, A) + \delta.$$

Thus, thanks to the definition of Γ-limsup, we have

$$\Gamma\text{-limsup} F^{\varphi}_{\varepsilon_{j_k}}(u, A) \leq F^{\varphi}(u, A) + \delta.$$

By the arbitrariness of δ, we obtain the required inequality. In the general case the thesis follows by a density argument, thanks to the lower semicontinuity of Γ-limsup and to the continuity of F with respect to the strong convergence in $W^{1,p}(\Omega; \mathbb{R}^d)$. □

As a consequence of the previous theorem we derive the following result about the convergence of minimum problems with boundary data.

COROLLARY 3.11. *Under the hypotheses of Theorem* 3.10 *we get that, for any* $\varphi \in Lip\ (\mathbb{R}^N)$, $l \in \mathbb{N}$ *and* $A \in \mathcal{A}(\Omega)$ *with Lipschitz boundary,*

$$\liminf_k \{F_{\varepsilon_{j_k}}(u,A):\ u \in \mathcal{A}^l_{\varepsilon_{j_k},\varphi}\} = \min\{F(u,A):\ u-\varphi \in W^{1,p}_0(A;\mathbb{R}^d)\}.$$

Moreover, if (u_k) *is a converging sequence such that*

$$\lim_k F_{\varepsilon_{j_k}}(u_k,A) = \liminf_k \{F_{\varepsilon_{j_k}}(u,A):\ u \in \mathcal{A}^l_{\varepsilon_{j_k},\varphi}\},$$

then its limit is a minimizer for $\min\{F(u,A):\ u-\varphi \in W^{1,p}_0(A;\mathbb{R}^d)\}$.

Proof. Let (u_k) be a sequence such that $F_{\varepsilon_{j_k}}(u_k,A) < +\infty$. Then, by (3.2) and by the boundary conditions on u_k, it is easy to show that

$$\sup_n \sum_{i=1}^N \sum_{\alpha \in \varepsilon_n \mathbb{Z}^N \cap K} \varepsilon^N |D^{e_i}_{\varepsilon_{j_k}} u_k(\alpha)|^p < +\infty$$

for any compact set K of $\mathbb{R}^N$. By virtue of this property, up to passing to a continuous extension of u_k vanishing outside a bounded open set containing Ω, we get

$$\lim_{|h|\to 0} \sup_k \|\tau_h u_k - u_k\|_{L^p(\mathbb{R}^N;\mathbb{R}^d)} = 0,$$

where we have set

$$(\tau_h u)(x) := u(x+h), \quad x \in \mathbb{R}^N, \quad h \in \mathbb{R}^N.$$

Then, by the Frechét–Kolmogorov theorem, there exists a subsequence (u_{k_n}) converging in $L^p(\Omega;\mathbb{R}^d)$ to a function $u \in L^p(\Omega;\mathbb{R}^d)$. Arguing as in the previous proof it is easy to show that $u-\varphi \in W^{1,p}_0(\Omega)$. The thesis follows, thanks to Theorem 3.10 and Theorem 2.1. □

We can also derive the analogue of Theorem 3.10 and Corollary 3.11 about the convergence of minimum problems with periodic conditions.

Let $\mathcal{Q}(\Omega)$ be the family of all open N-cubes contained in Ω. For any $\varepsilon > 0$, $r > 0$, $Q = (x_0, x_0+r)^N \in \mathcal{Q}(\Omega)$, and $\varphi \in Lip\ (\mathbb{R}^N)$, set

$$r_\varepsilon = \varepsilon\left(\left[\frac{r}{\varepsilon}\right] - 2\right),$$

$$\mathcal{A}^{\#}_{\varepsilon,\varphi}(Q) = \left\{u \in \mathcal{A}_\varepsilon(\mathbb{R}^N):\ u-\hat{\varphi}\ \ r_\varepsilon - \text{periodic}\right\},$$

where $\hat{\varphi} \in \mathcal{A}_\varepsilon(\mathbb{R}^N)$, $\hat{\varphi}(\alpha) = \varphi(\alpha)$ for any $\alpha \in \varepsilon\mathbb{Z}^N$. Then define $F^{\varphi,\#}_\varepsilon : L^p(\Omega;\mathbb{R}^d) \times \mathcal{Q}(\Omega) \to [0,+\infty]$ as

$$F^{\varphi,\#}_\varepsilon(u,Q) = \begin{cases} F_\varepsilon(u,Q) & \text{if } u \in \mathcal{A}^{\#}_{\varepsilon,\varphi}(Q), \\ +\infty & \text{otherwise.} \end{cases} \tag{3.32}$$

THEOREM 3.12. *Let* $\{f^\xi_\varepsilon\}_{\varepsilon,\xi}$ *satisfy* (3.2), (3.3), *and let* (H1)–(H2) *hold. Given* (ε_j), *a sequence of positive real numbers converging to* 0, *let* (ε_{j_k}) *and* f *be as in*

Theorem 3.1. *Then, for any* $\varphi \in Lip\ (\mathbb{R}^N)$, *let* $F^{\#} : L^p(\Omega;\mathbb{R}^d) \times \mathcal{Q}(\Omega) \to [0,+\infty]$ *be defined as*

$$F^{\varphi,\#}(u,Q) = \begin{cases} \displaystyle\int_Q f(x,\nabla u)\,dx & \text{if } u \in W^{1,p}_{\#}(Q;\mathbb{R}^d), \\ +\infty & \text{otherwise.} \end{cases}$$

Then, for any $Q \in \mathcal{Q}(\Omega)$, $(F^{\varphi,\#}_{\varepsilon_{j_k}}(\cdot,Q))$ Γ-*converges with respect to the* $L^p(\Omega;\mathbb{R}^d)$-*topology to the functional* $F^{\varphi,\#}(u,Q)$.

Proof. To prove the Γ-liminf inequality, let (u_k) be a sequence of functions belonging to $\mathcal{A}^{\#}_{\varepsilon_{j_k},\varphi}(Q)$ converging to u in the L^p-topology such that

$$\liminf_k F^{\varphi,\#}_{\varepsilon_{j_k}}(u_k,Q) = \lim_k F^{\varphi,\#}_{\varepsilon_{j_k}}(u_k,Q) < +\infty.$$

Then, arguing as in the proof of Theorem 3.10 and observing that $r_\varepsilon \to r$, we can conclude that $u-\varphi \in W^{1,p}_{\#}(Q;\mathbb{R}^d)$, and

$$\liminf_k F^{\varphi,\#}_{\varepsilon_{j_k}}(u_k,Q) \geq F^{\varphi,\#}(u,Q).$$

By a density argument it suffices to prove the Γ-limsup inequality for u such that $u-\varphi \in W^{1,\infty}_{\#}(Q';\mathbb{R}^d)$ for any open N-cube Q' such that $(x_0+\delta, x_0+r-\delta) \subseteq Q' \subseteq Q$ for some $\delta > 0$. Note that, for such a u, $\mathcal{A}_{\varepsilon_{j_k},u} \subseteq \mathcal{A}^{\#}_{\varepsilon_{j_k},\varphi}$ for k large enough. Then the existence of a recovery sequence is ensured by Theorem 3.10. □

As a consequence of the previous theorem, by reasoning as in the proof of Corollary 3.11 one can prove the following result.

Corollary 3.13. *Under the hypotheses of Theorem* 3.12 *we get that, for any* $\varphi \in Lip\ (\mathbb{R}^N)$ *and* $Q \in \mathcal{Q}(\Omega)$,

$$\liminf_k \{F_{\varepsilon_{j_k}}(u,Q) :\ u \in \mathcal{A}^{\#}_{\varepsilon_{j_k},\varphi}(Q)\} = \min\{F(u,Q) :\ u-\varphi \in W^{1,p}_{\#}(Q;\mathbb{R}^d)\}.$$

Moreover, if (u_k) *is a converging sequence such that*

$$\lim_k F_{\varepsilon_{j_k}}(u_k,Q) = \liminf_k \{F_{\varepsilon_{j_k}}(u,Q) :\ u \in \mathcal{A}^{\#}_{\varepsilon_{j_k},\varphi}\},$$

then its limit is a minimizer for $\min\{F(u,Q) :\ u-\varphi \in W^{1,p}_{\#}(Q;\mathbb{R}^d)\}$.

4. Homogenization. In this section we will show that if the functions f^ξ_ε are obtained by rescaling by ε functions f^ξ periodic in the space variable, then a Γ-convergence result holds true. This models the case when the arrangement of the "material points" presents a periodic feature (see Figure 4).

Let $\mathbf{k} = (k_1,\dots,k_N) \in \mathbf{Z}^N$ be given, and set

$$\mathcal{R}_{\mathbf{k}} := (0,k_1) \times \cdots \times (0,k_N).$$

For any $\xi \in \mathbf{Z}^N$, let $f^\xi : \mathbf{Z}^N \times \mathbf{R}^d \to [0,+\infty)$ be such that $f^\xi(\cdot,z)$ is $\mathcal{R}_{\mathbf{k}}$-periodic for any $z \in \mathbf{R}^d$. Then we consider f^ξ_ε of the following form:

$$f^\xi_\varepsilon(\alpha,z) := f^\xi\left(\frac{\alpha}{\varepsilon},z\right). \tag{4.1}$$

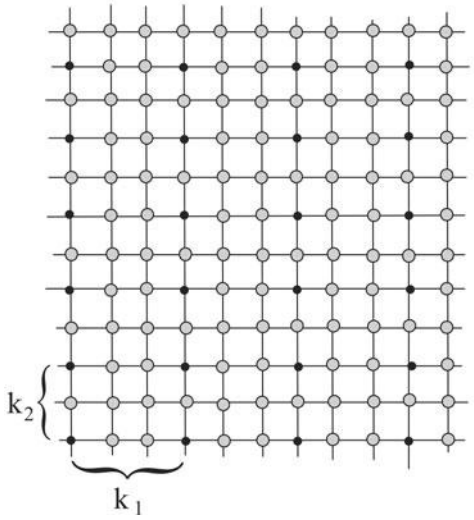

FIG. 4. *Example of periodic structure.*

In this case, the growth conditions (3.2) and (3.3) and hypotheses (H1) and (H2) can be rewritten as follows:

$$f^{e_i}(\alpha, z) \geq c_1(|z|^p - 1) \quad \forall i \in \{1, \dots, N\}, \tag{4.2}$$

$$f^{\xi}(\alpha, z) \leq C^{\xi}(|z|^p + 1), \tag{4.3}$$

where

$$\sum_{\xi \in \mathbf{Z}^N} C^{\xi} < +\infty. \tag{H3}$$

In what follows we will use the following notation: for any $x = (x_1, \dots, x_N) \in \mathbf{R}^N$ define

$$[x]_{\mathbf{k}} := \left(\left[\frac{x_1}{k_1} \right] k_1, \dots, \left[\frac{x_N}{k_N} \right] k_N \right).$$

Moreover, for any $A \in \mathcal{A}(\Omega)$, $\varepsilon > 0$, $l \in \mathbf{N}$, and $M \in \mathcal{M}^{d \times N}$ we denote by $\mathcal{A}^l_{\varepsilon,M}(A)$ the set defined in formula (3.29) with $\varphi(x) = Mx$. By simplicity of notation, we set $\mathcal{A}^1_{\varepsilon,M}(A) := \mathcal{A}_{\varepsilon,M}(A)$. Finally, for every $r > 0$ we set $Q_r := (0, r)^N$.

The following theorem is the main result of this section, and its proof is obtained by adapting a homogenization argument to the discrete setting. We remark that a central role is played by Theorems 3.1 and 3.3 and by the convergence of minimum problems with boundary data stated in Corollary 3.11. Moreover, we recall that the following result has been already proven in [11] in the one-dimensional case, where a more straightforward proof is possible.

THEOREM 4.1. *Let* $\{f^{\xi}_{\varepsilon}\}_{\varepsilon,\xi}$ *satisfy* (4.1)–(4.3)*, and let* (H3) *hold. Then* (F_ε) Γ*-converges with respect to the* $L^p(\Omega; \mathbf{R}^d)$*-topology to the functional* $F : L^p(\Omega; \mathbf{R}^d) \to [0, +\infty]$ *defined as*

$$F(u) = \begin{cases} \displaystyle\int_\Omega f_{hom}(\nabla u)\, dx & \text{if } u \in W^{1,p}(\Omega; \mathbf{R}^d), \\ +\infty & \text{otherwise,} \end{cases} \tag{4.4}$$

where $f_{hom} : \mathcal{M}^{d\times N} \to [0,+\infty)$ is given by the following homogenization formula:

$$(4.5)\quad f_{hom}(M) := \lim_{h\to+\infty} \frac{1}{h^N} \min\left\{ \sum_{\xi\in\mathbf{Z}^N} \sum_{\beta\in R_1^\xi(Q_h)} f^\xi(\beta, D_1^\xi v(\beta)),\quad v \in \mathcal{A}_{1,M}(Q_h) \right\}.$$

Proof. Let (ε_n) be a sequence of positive numbers converging to 0. Then, by Theorems 3.1 and 3.3, we can extract a subsequence (not relabelled) such that (F_{ε_n}) Γ-converges to a functional F defined as in (3.4) and such that, for any $u \in W^{1,p}(\Omega;\mathbf{R}^d)$, $A \in \mathcal{A}(\Omega)$,

$$\Gamma\text{-}\lim_n F_{\varepsilon_n}(u,A) = \int_A f(x,\nabla u)\,dx.$$

The theorem is proved if we show that f does not depend on the space variable x and $f \equiv f_{hom}$. To prove the first claim, by Theorem 2.2, it suffices to show that if we set

$$F(u,A) = \int_A f(x,\nabla u)\,dx,$$

then

$$F(Mx, B(y,\rho)) = F(Mx, B(z,\rho))$$

for all $M \in \mathcal{M}^{d\times N}$, $y,z \in \Omega$ and $\rho > 0$ such that $B(y,\rho)\cup B(z,\rho) \subset \Omega$. We will prove that

$$F(Mx, B(y,\rho)) \le F(Mx, B(z,\rho)),$$

the proof of the opposite inequality being analogous. By the inner regularity of $F(Mx,\cdot)$, given by Proposition 3.8, it suffices to show that for any $\rho' < \rho$ we get

$$F(Mx, B(y,\rho')) \le F(Mx, B(z,\rho)). \tag{4.6}$$

Then let $v_n \in \mathcal{A}_{\varepsilon_n}(\Omega)$ be such that (v_n) converges to Mx in $L^p(\Omega;\mathbf{R}^d)$, and

$$\lim_n F_{\varepsilon_n}(v_n, B(z,\rho)) = F(Mx, B(z,\rho)). \tag{4.7}$$

For $n \in \mathbf{N}$, define $u_n \in \mathcal{A}_{\varepsilon_n}(\Omega)$ as

$$u_n(\alpha) := \begin{cases} v_n\left(\alpha - \varepsilon_n\left[\frac{y-z}{\varepsilon_n}\right]_{\mathbf{k}}\right) + \varepsilon_n M\left[\frac{y-z}{\varepsilon_n}\right]_{\mathbf{k}} & \text{if } \alpha \in \varepsilon_n\mathbf{Z}^N \cap B(y,\rho'),\\ M\alpha & \text{otherwise.}\end{cases}$$

Then it is easy to verify that (u_n) converges to Mx in $L^p(\Omega;\mathbf{R}^d)$. Moreover, for n large enough

$$R^\xi_{\varepsilon_n}(B(y,\rho')) - \varepsilon_n\left[\frac{y-z}{\varepsilon_n}\right]_{\mathbf{k}} \subseteq R^\xi_{\varepsilon_n}(B(z,\rho)).$$

Thus, since, by the periodicity hypothesis, $f^\xi(\alpha - \varepsilon_n[\frac{y-z}{\varepsilon_n}]_{\mathbf{k}}, z) = f^\xi(\alpha,z)$ and $D^\xi_\varepsilon u_n(\alpha)$ $= D^\xi_\varepsilon v_n(\alpha - \varepsilon_n[\frac{y-z}{\varepsilon_n}]_{\mathbf{k}})$, we get for n large enough

$$F_{\varepsilon_n}(u_n, B(y,\rho')) \le F_{\varepsilon_n}(v_n, B(z,\rho)).$$

Eventually, by (4.7), we obtain

$$\begin{aligned} F(Mx, B(y,\rho')) &\le \liminf_{n\to+\infty} F_{\varepsilon_n}(u_n, B(y,\rho')) \\ &\le \lim_{n\to+\infty} F_{\varepsilon_n}(v_n, B(z,\rho)) = F(Mx, B(z,\rho)). \end{aligned}$$

In order to prove that $f \equiv f_{hom}$, first note that, by the lower semicontinuity of F in $W^{1,p}(\Omega;\mathbf{R}^d)$, f is quasi-convex so that, by the p-growth properties of f, for any $A \in \mathcal{A}(\Omega)$ with Lipschitz boundary and for any $M \in \mathcal{M}^{d\times N}$ there holds

$$\begin{aligned} f(M) &= \frac{1}{|A|}\min\left\{\int_A f(\nabla u)\,dx : \quad u - Mx \in W_0^{1,p}(A;\mathbf{R}^d)\right\} \\ &= \frac{1}{|A|}\min\left\{F(u,A) : \quad u - Mx \in W_0^{1,p}(A;\mathbf{R}^d)\right\} \\ &= \frac{1}{|A|}\liminf_n \left\{F_{\varepsilon_n}(u,A) : \quad u \in \mathcal{A}_{\varepsilon_n,M}(A)\right\}, \end{aligned}$$

where the last equality follows by Corollary 3.11. In particular, if $x_0 \in \Omega$ and $r > 0$ are such that $Q_r(x_0) := (x_0, x_0 + r)^N \subseteq \Omega$, then

$$f(M) = \lim_n \frac{1}{r^N}\inf\{F_{\varepsilon_n}(u, Q_r(x_0)) :\ u \in \mathcal{A}_{\varepsilon_n,M}(Q_r(x_0))\}.$$

Without loss of generality, we may suppose $x_0 = 0$. If we set

$$T_n := \left[\frac{r}{\varepsilon_n}\right] + 1,$$

then it is easy to show that $\mathcal{A}_{\varepsilon_n,M}(Q_r) = \mathcal{A}_{\varepsilon_n,M}(Q_{\varepsilon_n T_n})$ and that for $\xi \in \mathbf{Z}^N$ $R^\xi_{\varepsilon_n}(Q_r) = R^\xi_{\varepsilon_n}(Q_{\varepsilon_n T_n})$. Thus

$$f(M) = \lim_n \frac{1}{r^N}\inf\{F_{\varepsilon_n}(u, Q(0,\varepsilon_n T_n)) :\ u \in \mathcal{A}_{\varepsilon_n,M}(Q_{\varepsilon_n T_n})\}.$$

Eventually, through the change of variable

$$\beta = \frac{\alpha}{\varepsilon}, \quad v(\beta) = \frac{1}{\varepsilon}u(\varepsilon\beta), \tag{4.8}$$

we get

$$\begin{aligned} f(M) &= \lim_n \left(\frac{\varepsilon_n}{r}\right)^N \inf\left\{\sum_{\xi\in\mathbf{Z}^N}\sum_{\beta\in R_1^\xi(Q_{T_n})} f^\xi(\beta, D_1^\xi v(\beta)), \quad v \in \mathcal{A}_{1,M}(Q_{T_n})\right\} \\ &= \lim_n \frac{1}{T_n^N}\inf\left\{\sum_{\xi\in\mathbf{Z}^N}\sum_{\beta\in R_1^\xi(Q_{T_n})} f^\xi(\beta, D_1^\xi v(\beta)), \quad v \in \mathcal{A}_{1,M}(Q_{T_n})\right\}, \end{aligned}$$

where the last equality holds since

$$\lim_n T_n \frac{\varepsilon_n}{r} = 1.$$

Then the thesis will follow by the next proposition.

PROPOSITION 4.2. *Let f^ξ satisfy* (4.2), (4.3), *and* (H3) *for any $\xi \in \mathbf{Z}^N$. Then the limit*

$$\lim_{h\to+\infty} \frac{1}{h^N} \inf \left\{ \sum_{\xi\in\mathbf{Z}^N} \sum_{\beta\in R_1^\xi(Q_h)} f^\xi(\beta, D_1^\xi v(\beta)), \quad v \in \mathcal{A}_{1,M}(Q_h) \right\}$$

exists for all $M \in \mathcal{M}^{d\times N}$.

Proof. Let $M \in \mathcal{M}^{d\times N}$ be fixed, and set

$$F_1(v, A) := \sum_{\xi\in\mathbf{Z}^N} \sum_{\beta\in R_1^\xi(A)} f^\xi(\beta, D_1^\xi v(\beta)),$$

$$f_h(M) := \frac{1}{h^N} \inf \{F_1(v, Q_h), \quad v \in \mathcal{A}_{1,M}(Q_h)\}.$$

Moreover, for any $R > 0$, set

$$F_1^R(v, A) := \sum_{|\xi|\le R} \sum_{\beta\in R_1^\xi(A)} f^\xi(\beta, D_1^\xi v(\beta)),$$

$$f_h^R(M) := \frac{1}{h^N} \inf \left\{F_1^R(v, Q_h), \quad v \in \mathcal{A}_{1,M}(Q_h)\right\}.$$

We prove that

$$\lim_{R\to+\infty} \sup_h |f_h^R(M) - f_h(M)| = 0. \tag{4.9}$$

To this end, since $f_h^R(M) \le f_h(M)$ for any $h \in \mathbf{N}$ and $R > 0$, it suffices to prove that for any $\delta > 0$, there exist $R_\delta > 0$ such that

$$f_h(M) \le f_h^R(M) + \delta \quad \forall R > R_\delta, \quad h \in \mathbf{N}.$$

Fix $\delta > 0$, and let $v_h^R \in \mathcal{A}_{1,M}(Q_h)$ be such that

$$\frac{1}{h^N} F_h^R(v_h^R, Q_h) \le f_h^R(M) + \frac{1}{R}. \tag{4.10}$$

By testing the minimum problem defining $f_h^R(M)$ with $v(\alpha) = M\alpha$, we get, by (4.3) and (H3), that

$$f_h^R(M) \le \frac{1}{h^N} F_h^R(M\alpha, Q_h) \le C|M|^p.$$

Thus, by (4.10) and (4.2), we obtain that

$$\sup_{h,R} \frac{1}{h^N} \sum_{i=1}^N \sum_{\beta\in R_1^{e_i}(Q_h)} |D_1^{e_i} v_h^R(\beta)|^p < +\infty.$$

Then, by arguing as in the proof of Lemma 3.6 and thanks to the particular geometry of the sets Q_h, we deduce that

$$\sup_{h,R} \frac{1}{h^N} \sup_{\xi\in\mathbf{Z}^N} \sum_{\beta\in R_1^\xi(Q_h)} |D_1^\xi v_h^R(\beta)|^p < +\infty.$$

Eventually, we have

$$f_h(M) \le \frac{1}{h^N} F_h(v_h^R, Q_h) \le \frac{1}{h^N} F_h^R(v_h^R, Q_h) + \frac{1}{h^N} \sum_{|\xi|>R} C^\xi \sum_{\beta \in R_1^\xi(Q_h)} |D_1^\xi v_h^R(\beta)|^p$$
$$\le f_h^R(M) + \frac{1}{R} + C \sum_{|\xi|>R} C^\xi.$$

Thus, it suffices to choose $R_\delta > 0$ such that for $R > R_\delta$

$$\frac{1}{R} + C \sum_{|\xi|>R} C^\xi \le \delta.$$

So far, in order to prove the thesis, it suffices to show that for any $R > 0$ there exists the limit

$$\lim_h f_h^R(M).$$

Set

$$f_h^{R,R}(M) := \frac{1}{h^N} \inf \left\{ F_1^R(v, Q_h), \quad v \in \mathcal{A}_{1,M}^{[R]}(Q_h) \right\}.$$

Using backward the scaling argument exploited in the proof of the previous proposition and thanks to Theorem 3.10 and Corollary 3.11, one can show that, for any subsequence $(h_n) \subset \mathbf{N}$, it is possible to extract a further subsequence (not relabelled) such that

$$\lim_n f_{h_n}^R(M) = \lim_n f_{h_n}^{R,R}(M). \tag{4.11}$$

Thus, to complete the proof, it is sufficient to prove that there exists the limit

$$\lim_h f_h^{R,R}(M).$$

Let $h \in \mathbf{N}$, and let $v_h \in \mathcal{A}_{1,M}^{[R]}(Q_h)$ be such that

$$\frac{1}{h^N} F_1^R(v_h, Q_h) \le f_h^{R,R}(M) + \frac{1}{h}.$$

For any $k > h$ define a function $u_k \in \mathcal{A}_{1,M}^{[R]}(Q_k)$ as follows:

$$u_k(\alpha) = \begin{cases} v_h(\alpha - h\mathbf{i}) + hM\mathbf{i} & \text{if } \alpha \in h\mathbf{i} + Q_h,\ \mathbf{i} \in \left\{0, \dots, \left[\frac{k}{h}\right] - 1\right\}^N, \\ M\alpha & \text{otherwise.} \end{cases}$$

Note that for any $\xi \in \mathbf{Z}^N$, $|\xi| \le R$ we have

$$R_1^\xi(Q_k) \subseteq \left(\bigcup_{\mathbf{i} \in \left\{0, \dots, \left[\frac{k}{h}\right]-1\right\}^N} R_1^\xi(h\mathbf{i} + Q_h) \right) \cup R_1^\xi \left(Q_k \setminus \bigcup_{\mathbf{i} \in \left\{0, \dots, \left[\frac{k}{h}\right]-1\right\}^N} (h\mathbf{i} + Q_h) \right)$$
$$\cup \left(\bigcup_{\mathbf{i} \in \left\{0, \dots, \left[\frac{k}{h}\right]-1\right\}^N} \left(h\mathbf{i} + \left(\{0, \dots, h+R\}^N \setminus \{0, \dots, h-R\}^N \right) \right) \right).$$

Moreover, $D_1^\xi u_k(\alpha) = M\frac{\xi}{|\xi|}$ if $\alpha \in R_1^\xi(Q_k \setminus \bigcup_{\mathbf{i}\in\{0,\dots,[\frac{k}{h}]-1\}^N}(h\mathbf{i}+Q_h))$ or $\alpha \in \bigcup_{\mathbf{i}\in\{0,\dots,[\frac{k}{h}]-1\}^N}\left(h\mathbf{i}+\left(\{0,\dots,h+R\}^N \setminus \{0,\dots,h-R\}^N\right)\right)$, and

$$\#\left(R_1^\xi\left(Q_k \setminus \bigcup_{\mathbf{i}\in\{0,\dots,[\frac{k}{h}]-1\}^N}(h\mathbf{i}+Q_h)\right)\right) \le k^N - \left[\frac{k}{h}\right]^N h^N,$$

$$\#\left(\{0,\dots,h+R\}^N \setminus \{0,\dots,h-R\}^N\right) \le (h+R)^N - (h-R)^N.$$

Then, by (4.3) and (H3), we get

$$\begin{aligned} f_k^{R,R}(M) &\le \frac{1}{k^N}F_1^R(u_k,Q_k) \le \left[\frac{k}{h}\right]^N \frac{1}{k^N}F_1^R(v_h,Q_h) \\ &+ C|M|^P\frac{1}{k^N}\left(k^N - \left[\frac{k}{h}\right]^N h^N + \left[\frac{k}{h}\right]^N\left((h+R)^N-(h-R)^N\right)\right) \\ &\le \left[\frac{k}{h}\right]^N \frac{h^N}{k^N}\left(f_h^{R,R}(M)+\frac{1}{h}\right) \\ &+ C|M|^P\frac{1}{k^N}\left(k^N - \left[\frac{k}{h}\right]^N h^N + \left[\frac{k}{h}\right]^N\left((h+R)^N-(h-R)^N\right)\right). \end{aligned}$$

By letting k tend to $+\infty$, we then get

$$\limsup_k f_k^{R,R}(M) \le f_h^{R,R}(M) + \frac{1}{h} + C|M|^P\frac{1}{h^N}\left((h+R)^N-(h-R)^N\right).$$

Eventually, letting h tend to $+\infty$, we obtain

$$\limsup_k f_k^{R,R}(M) \le \liminf_h f_h^{R,R}(M),$$

that is, the conclusion. □

Remark 4.3. In formula (4.5) we can replace $\mathcal{A}_{1,M}(Q_h)$ by $\mathcal{A}^l_{1,M}(Q_h)$ for any fixed $l \in \mathbf{N}$, the proof being exactly the same.

Remark 4.4. The function f_{hom} in Theorem 4.1 also satisfies

$$\begin{aligned} f_{hom}(M) = \lim_{h\to+\infty}\frac{1}{h^N}\inf\Bigg\{ &\sum_{\xi\in\mathbf{Z}^N}\sum_{\beta\in R_1^\xi(Q_h)} f^\xi\left(\beta, M\frac{\xi}{|\xi|}+D_1^\xi v(\beta)\right), \\ &v \in \mathcal{A}_{1,\#}(Q_{h-2})\Bigg\}, \end{aligned} \tag{4.12}$$

where, for every $k \in \mathbf{R}$,

$$\mathcal{A}_{1,\#}(Q_k) := \{v \in \mathcal{A}_1(\mathbf{R}^N) : \ v \ k\text{-periodic}\}.$$

This characterization can be proved by arguing as in the proof of Theorem 4.1 and Proposition 4.2, taking into account Corollary 3.13 and recalling that, since f_{hom} is

quasi-convex, there holds

$$f_{hom}(M) = \frac{1}{r^N}\min\left\{\int_{Q_r} f_{hom}(M+\nabla\psi)\,dx : \psi \in W^{1,p}_{\#}(Q_r;\mathbf{R}^d)\right\}$$
$$= \frac{1}{r^N}\min\left\{F(M\alpha+\psi,Q_r) : \psi \in W^{1,p}_{\#}(Q_r;\mathbf{R}^d)\right\}.$$

As a consequence of Theorem 3.10, Corollary 3.11, and Theorem 4.1 we immediately derive the following result about Γ-convergence and convergence of minimum problems for homogeneous functionals subject to Dirichlet boundary conditions.

THEOREM 4.5. *For any $\varphi \in Lip\,(\mathbf{R}^N)$ and $l \in \mathbf{N}$ let $F^{\varphi,l}_\varepsilon$ be defined by* (3.30)*, and let $F^\varphi : L^p(\Omega;\mathbf{R}^d)\times\mathcal{A}(\Omega)\to[0,+\infty]$ be defined as*

$$F^\varphi(u,A) = \begin{cases} \displaystyle\int_A f_{hom}(\nabla u)\,dx & \text{if } u-\varphi \in W^{1,p}_0(A;\mathbf{R}^d),\\ +\infty & \text{otherwise.}\end{cases} \tag{4.13}$$

Under the hypotheses of Theorem 4.1*, $F^\varphi_\varepsilon(\cdot,A)$ Γ-converges with respect to the $L^p(\Omega;\mathbf{R}^d)$-topology to $F^\varphi(\cdot,A)$ for any $A\in\mathcal{A}$.*

COROLLARY 4.6. *Under the hypotheses of Theorem* 4.5*, for any $\varphi \in Lip\,(\mathbf{R}^N)$, $l\in\mathbf{N}$, and $A\in\mathcal{A}(\Omega)$,*

$$\liminf_{\varepsilon\to0}\{F_\varepsilon(u,A) :\ u\in\mathcal{A}^l_{\varepsilon,\varphi}\} = \min\{F(u,A) :\ u-\varphi\in W^{1,p}_0(A;\mathbf{R}^d)\}.$$

Moreover, for any (ε_j) converging to zero as j tends to infinity, if (u_j) is a converging sequence such that

$$\lim_j F_{\varepsilon_j}(u_j,A) = \liminf_j\{F_{\varepsilon_j}(u,A) :\ u\in\mathcal{A}^l_{\varepsilon_j,\varphi}\},$$

then its limit is a minimizer for $\min\{F(u,A) :\ u-\varphi\in W^{1,p}_0(A;\mathbf{R}^d)\}$.

An analogous result about the convergence of minimum problems with periodic conditions follows by Theorem 3.12 and Corollary 3.13.

5. The convex case: A cell problem formula. In this section we will see that in the convex case the function f_{hom} can be rewritten by a single periodic minimization problem on the periodic cell $\mathcal{R}_{\mathbf{k}}$. Set

$$\hat{k} := \prod_{i=1}^N k_i,$$

$$I_{\mathbf{k}} := \prod_{i=1}^N\{0,\dots,k_i-1\},$$

and

$$\mathcal{A}_{1,\#}(\mathcal{R}_{\mathbf{k}}) := \{u\in\mathcal{A}_1(\mathbf{R}^N)\ :\ u \text{ is } \mathcal{R}_{\mathbf{k}}\text{-periodic}\}.$$

THEOREM 5.1. *Let $(f^\xi_\varepsilon)_{\varepsilon,\xi}$ satisfy all the assumptions of Theorem* 4.1*, and in, addition, let $f^\xi_\varepsilon(\alpha,\cdot)$ be convex for all $\alpha\in\varepsilon\mathbf{Z}^N$, $\varepsilon>0$, and $\xi\in\mathbf{Z}^N$. Then the conclusion of Theorem* 4.1 *holds with f_{hom} satisfying*

$$f_{hom}(M) = \frac{1}{\hat{k}}\inf\left\{\sum_{\xi\in\mathbf{Z}^N}\sum_{\beta\in I_{\mathbf{k}}} f^\xi\left(\beta, M\frac{\xi}{|\xi|}+D^\xi_1 v(\beta)\right),\quad v\in\mathcal{A}_{1,\#}\left(\mathcal{R}_{\mathbf{k}}\right)\right\}$$

for all $M \in \mathcal{M}^{d\times N}$.

Proof. Set

$$\overline{f}(M) := \frac{1}{\hat{k}} \inf \left\{ \sum_{\xi\in\mathbf{Z}^N} \sum_{\beta\in I_{\mathbf{k}}} f^{\xi}\left(\beta, M\frac{\xi}{|\xi|} + D_1^{\xi} v(\beta)\right), \quad v \in \mathcal{A}_{1,\#}\left(\mathcal{R}_{\mathbf{k}}\right) \right\}.$$

We first prove that

$$f_{hom}(M) \le \overline{f}(M). \tag{5.1}$$

With fixed $\delta > 0$, let $v \in \mathcal{A}_{1,\#}\left(\mathcal{R}_k\right)$ be such that

$$\frac{1}{\hat{k}} \sum_{\xi\in\mathbf{Z}^N} \sum_{\beta\in I_{\mathbf{k}}} f^{\xi}\left(\beta, M\frac{\xi}{|\xi|} + D_1^{\xi} v(\beta)\right) \le \overline{f}(M) + \delta.$$

$$f_h^{\#}(M) := \inf \left\{ \sum_{xi\in\mathbf{Z}^N} \sum_{\beta\in R_1^{\xi}(Q_h)} f^{\xi}\left(\beta, M\frac{\xi}{|\xi|} + D_1^{\xi} v(\beta)\right), \quad v \in \mathcal{A}_{1,\#}(Q_{h-2}) \right\}.$$

For $n \in \mathbf{N}$, since in particular $v \in \mathcal{A}_{1,\#}(Q_{n\hat{k}})$, we get

$$\begin{aligned} f_{n\hat{k}+2}^{\#}(M) &\le \sum_{\xi\in\mathbf{Z}^N} \sum_{\beta\in R_1^{\xi}(Q_{n\hat{k}})} f^{\xi}\left(\beta, M\frac{\xi}{|\xi|} + D_1^{\xi} v(\beta)\right) \\ &\le n^N \hat{k}^{N-1} \sum_{\xi\in\mathbf{Z}^N} \sum_{\beta\in I_{\mathbf{k}}} f^{\xi}\left(\beta, M\frac{\xi}{|\xi|} + D_1^{\xi} v(\beta)\right), \end{aligned}$$

where the last inequality follows by the periodicity of v, $(f(\cdot, z))$ and by the fact that $Q_{n\hat{k}}$ is the union of $n^N \hat{k}^{N-1}$ periodicity cells. Eventually, by Remark 4.4, we get

$$\begin{aligned} f_{hom}(M) &\le \limsup_n \frac{1}{(n\hat{k}+2)^N} f_{n\hat{k}+2}^{\#}(M) \\ &\le \frac{1}{\hat{k}} \sum_{\xi\in\mathbf{Z}^N} \sum_{\beta\in I_{\mathbf{k}}} f^{\xi}\left(\beta, M\frac{\xi}{|\xi|} + D_1^{\xi} v(\beta)\right) \le \overline{f}(M) + \delta, \end{aligned}$$

and inequality (5.1) follows by letting δ tend to 0. Let us prove that

$$f_{hom}(M) \ge \overline{f}(M).$$

For any $R > 0$, set

$$f_{hom}^R(M) := \lim_{h\to+\infty} \frac{1}{h^N} \inf \left\{ \sum_{|\xi|\le R} \sum_{\beta\in R_1^{\xi}(Q_h)} f^{\xi}(\beta, D_1^{\xi} v(\beta)), \quad v \in \mathcal{A}_{1,M}^{[R]}\left(Q_h\right) \right\},$$

$$\overline{f}^R(M) := \frac{1}{\hat{k}} \inf \left\{ \sum_{|\xi|\le R} \sum_{\beta\in I_{\mathbf{k}}} f^{\xi}\left(\beta, M\frac{\xi}{|\xi|} + D_1^{\xi} v(\beta)\right), \quad v \in \mathcal{A}_{1,\#}\left(\mathcal{R}_{\mathbf{k}}\right) \right\}.$$

By (4.9) and (4.11)we easily derive that

$$\lim_{R\to+\infty} f^R_{hom}(M) = f_{hom}(M).$$

Analogously one can prove that

$$\lim_{R\to+\infty} \overline{f}^R(M) = \overline{f}(M).$$

Thus it suffices to prove that for any $R>0$

$$f^R_{hom}(M) \geq \overline{f}^R(M). \tag{5.2}$$

For $n\in\mathbf{N}$, let $u\in\mathcal{A}^{[R]}_{1,M}(Q_{n\hat{k}})$, and let $v\in\mathcal{A}_{1,\#}(Q_{n\hat{k}})$ be such that

$$v(\alpha) = u(\alpha) - M\alpha \quad \forall \alpha\in Q_{n\hat{k}}.$$

Moreover, set

$$I^n_{\mathbf{k}} := \prod_{i=1}^N \left\{0,\dots,n\prod_{j\neq i}k_j - 1\right\}.$$

Then we get

$$\begin{aligned}
&\frac{1}{(n\hat{k})^N}\sum_{|\xi|\leq R}\sum_{\beta\in R^\xi_1(Q_{n\hat{k}})} f^\xi\left(\beta, M\frac{\xi}{|\xi|}+D^\xi_1 v(\beta)\right)\\
&= \frac{1}{(n\hat{k})^N}\sum_{|\xi|\leq R}\sum_{\beta\in\{0,\dots,n\hat{k}\}^N} f^\xi\left(\beta, M\frac{\xi}{|\xi|}+D^\xi_1 v(\beta)\right) - O\left(\frac{1}{n}\right)\\
&= \frac{1}{\hat{k}}\sum_{|\xi|\leq R}\sum_{\beta\in I_k}\frac{1}{\hat{k}^{N-1}n^N}\sum_{\gamma\in I^n_{\mathbf{k}}} f^\xi\left(\beta, M\frac{\xi}{|\xi|}+D^\xi_1 v\left(\beta+\sum_{i=1}^N\gamma_i k_i e_i\right)\right) - O\left(\frac{1}{n}\right)\\
&\geq \frac{1}{\hat{k}}\sum_{|\xi|\leq R}\sum_{\beta\in I_k} f^\xi\left(\beta, M\frac{\xi}{|\xi|}+\frac{1}{\hat{k}^{N-1}n^N}\sum_{\gamma\in I^n_{\mathbf{k}}} D^\xi_1 v\left(\beta+\sum_{i=1}^N\gamma_i k_i e_i\right)\right) - O\left(\frac{1}{n}\right),
\end{aligned}$$

where in the last inequality we have used the convexity hypothesis on f^ξ. Eventually, set

$$v_n(\beta) := \frac{1}{\hat{k}^{N-1}n^N}\sum_{\gamma\in I^n_{\mathbf{k}}} v\left(\beta+\sum_{i=1}^N\gamma_i k_i e_i\right).$$

It is easy to show that $v_n\in\mathcal{A}_{1,\#}(\mathcal{R}_k)$, and so, by the previous inequality, we get

$$\begin{aligned}
&\frac{1}{(n\hat{k})^N}\sum_{|\xi|\leq R}\sum_{\beta\in R^\xi_1(Q_{n\hat{k}})} f^\xi\left(\beta, M\frac{\xi}{|\xi|}+D^\xi_1 v(\beta)\right)\\
&\quad\geq \frac{1}{\hat{k}}\sum_{|\xi|\leq R}\sum_{\beta\in I_k} f^\xi\left(\beta, M\frac{\xi}{|\xi|}+D^\xi_1 v_n(\beta)\right) - O\left(\frac{1}{n}\right)\\
&\quad\geq \overline{f}^R(M) - O\left(\frac{1}{n}\right).
\end{aligned}$$

Passing to the inf with respect to $u \in \mathcal{A}^R_{1,\#}(Q_{n\hat{k}})$, we get

$$f^{R,R}_{n\hat{k}+2}(M) \geq \overline{f}^R(M) - O\left(\frac{1}{n}\right),$$

and then, letting n tend to $+\infty$, we obtain (5.2). □

Remark 5.2 (quadratic forms). Under the hypotheses of Theorem 5.1, if, in addition, for any $\xi \in \mathbf{Z}^N$ $f^\xi(\alpha, \cdot)$ is a positive quadratic form on $\mathbf{R}^d$, that is,

$$f^\xi(\alpha, z) = \langle A^\xi(\alpha)z, z\rangle, \quad A^\xi(\alpha) \in \mathcal{M}^{d\times d}_{sym},$$

then, thanks to Remark 3.2, the limit energy density $f_{hom}(\cdot)$ is a homogeneous quadratic form on $\mathcal{M}^{d\times N}$, and formula (3.5) becomes

$$\begin{aligned} f_{hom}(M) &= A_{hom}(M, M) \\ &= \frac{1}{\hat{k}} \inf \left\{ \sum_{\xi\in\mathbf{Z}^N} \sum_{\beta\in I_{\mathbf{k}}} \left\langle A^\xi(\beta) \cdot \left(M\frac{\xi}{|\xi|} + D^\xi_1 v(\beta)\right), \left(M\frac{\xi}{|\xi|} + D^\xi_1 v(\beta)\right)\right\rangle, \right. \\ &\qquad \left. v \in \mathcal{A}_{1,\#}(\mathcal{R}_{\mathbf{k}}) \right\} \end{aligned}$$

with $A_{hom} \in T_2(\mathcal{M}^{d\times N})$.

If $N = d = 1$ and only nearest-neighbor interactions are taken into account, that is,

$$f^\xi \equiv 0 \text{ if } \xi \neq e_1, \qquad f^{e_1}(\alpha, z) = a(\alpha)z^2,$$

with $a : \mathbf{Z}^N \to (0, +\infty)$ k-periodic, the previous minimum problem can be easily solved (see [9]), giving the analogue in the discrete setting of a well-known homogenization result for integral functionals (see [6]). In fact, in this case

$$A_{hom} = \frac{1}{k}\left(\sum_{\beta=0}^{k-1} \frac{1}{a(\beta)}\right)^{-1}$$

is the harmonic mean of $a(\cdot)$.

Remark 5.3. Note that if $\mathcal{R}_{\mathbf{k}} = (0, 1)^N$, that is, f^ξ does not depend on the space variable α, in Theorem 5.1 we obtain

$$f_{hom}(M) = \sum_{\xi\in\mathbf{Z}^N} f^\xi\left(M\frac{\xi}{|\xi|}\right).$$

6. Interactions along independent directions and reduction to the one-dimensional case. In this section we first recall some results proven in the one-dimensional setting in [11], where a nonasymptotic formula defining the limit energy density f_{hom} is provided when only nearest and next-to-nearest neighbor interactions are considered.

Then in Theorem 6.3 we will show that if only interactions along the coordinate directions are taken into account, the N-dimensional problem can be reduced to a one-dimensional one.

The following two theorems have been proven in [11] in the case $d = 1$. Their proof in the case $d > 1$ is the same.

THEOREM 6.1 (nearest-neighbor interactions). *Let $\Omega = (0, l) \subset \mathbf{R}$, and let $F_\varepsilon : L^p(\Omega; \mathbf{R}^d) \to [0, +\infty)$ be defined as*

$$F_\varepsilon(u) := \begin{cases} \displaystyle\sum_{i=1}^{l-2} \varepsilon f\left(\frac{u(\varepsilon(i+1)) - u(\varepsilon i)}{\varepsilon}\right) & \text{if } u \in \mathcal{A}_\varepsilon(\Omega), \\ +\infty & \text{otherwise,} \end{cases}$$

with $f : \mathbf{R}^d \to [0, +\infty)$ satisfying $f(z) \geq C(|z|^p - 1)$. Then the conclusions of Theorem 4.1 hold with

$$f_{hom}(z) = f^{**}(z).$$

THEOREM 6.2 (next-to-nearest neighbor interactions). *Let $\Omega = (0, l) \subset \mathbf{R}$, and let $F_\varepsilon : L^p(\Omega; \mathbf{R}^d) \to [0, +\infty)$ be defined as*

$$F_\varepsilon(u) := \begin{cases} \displaystyle\sum_{i=1}^{l-2} \varepsilon f^1\left(\frac{u(\varepsilon(i+1)) - u(\varepsilon i)}{\varepsilon}\right) + \sum_{i=1}^{l-3} \varepsilon f^2\left(\frac{u(\varepsilon(i+2)) - u(\varepsilon i)}{2\varepsilon}\right) & \\ \qquad\qquad \text{if } u \in \mathcal{A}_\varepsilon(\Omega), & \\ +\infty \qquad\qquad \text{otherwise,} & \end{cases}$$

with $f^1, f^2 : \mathbf{R}^d \to [0, +\infty)$ satisfying $f^1(z) \geq C(|z|^p - 1)$. Then the conclusions of Theorem 4.1 hold with

$$f_{hom}(z) = \tilde{f}^{**}(z),$$

where $\tilde{f}(z) = f^2(z) + \frac{1}{2} \inf\{f^1(z_1) + f^1(z_2),\ z_1 + z_2 = 2z\}$. Back to the general N-dimensional setting, we consider now energies of the form

$$F_\varepsilon(u) = \begin{cases} \displaystyle\sum_{i=1}^{N} \mathcal{F}_\varepsilon^i(u, \Omega) & \text{if } u \in \mathcal{A}_\varepsilon(\Omega), \\ +\infty & \text{otherwise,} \end{cases} \tag{6.1}$$

where, for any $i \in \{1, \dots, N\}$, $\mathcal{F}_\varepsilon^i : \mathcal{A}_\varepsilon(\Omega) \times \mathcal{A}(\Omega) \to [0, +\infty]$ is defined as

$$\mathcal{F}_\varepsilon^i(u, A) := \sum_{k=1}^{+\infty} \sum_{\alpha \in R_\varepsilon^{ke_i}(A)} \varepsilon^N f_i^k(D_\varepsilon^{ke_i} u(\alpha)), \tag{6.2}$$

with $f_i^k : \mathbf{R}^d \to [0, +\infty)$ satisfying

$$f_i^1(z) \geq c(|z|^p - 1), \qquad f_i^k(z) \leq C_i^k(|z|^p + 1),$$

and

$$\sum_{i=1}^{N} \sum_{k=1}^{+\infty} C_i^k < +\infty.$$

This is a particular case of the model considered in section 4, with $f^\xi \equiv 0$ if $\xi \neq ke_i$, $f^{ke_i}(0,z) = f_i^k(z)$, $i \in \{1,\dots,N\}$, $k \in \mathbf{N}$, and $\mathcal{R}_{\mathbf{k}} = (0,1)^N$.

The following theorem shows that, in this case, the homogenization formula defining f_{hom} can be rewritten as a sum of N one-dimensional homogenization formulas.

THEOREM 6.3. *Let F_ε be defined by* (6.2). *Then the Γ-convergence result stated in Theorem* 4.1 *holds with f_{hom} satisfying*

$$f_{hom}(M) = \sum_{i=1}^{N} \tilde{f}_i(M^i) \tag{6.3}$$

for any $M = (M^1,\dots,M^N) \in \mathcal{M}^{d\times N}$, where $\tilde{f}_i : \mathbf{R}^d \to \mathbf{R}$, $i \in \{1,\dots,N\}$, is defined by the following one-dimensional homogenization formula:

$$\tilde{f}_i(z) := \lim_{h\to+\infty} \frac{1}{h} \inf \left\{ \sum_{k=1}^{+\infty} \sum_{j=1}^{h-k-1} f_i^k\left(\frac{v(j+k)-v(j)}{k}\right),\ v \in \mathcal{A}_{1,z}((0,h)) \right\}.$$

Proof. We first prove that

$$f_{hom}(M) \geq \sum_{i=1}^{N} \tilde{f}_i(M^i).$$

To do this, by the definition of $f_{hom}(M)$, it suffices to show that for any $i \in \{1,\dots,N\}$, $u \in \mathcal{A}_{1,M}(Q_h)$ we have

$$\frac{1}{h^N} \mathcal{F}_1^i(u,Q_h) \geq \tilde{f}_i(M^i) + O(h). \tag{6.4}$$

We use a slicing argument. For $i \in \{1,\dots,N\}$, set

$$m_h^i(z) := \frac{1}{h} \inf \left\{ \sum_{k=1}^{+\infty} \sum_{j=1}^{h-k-1} f_i^k\left(\frac{v(j+k)-v(j)}{k}\right),\ v \in \mathcal{A}_{1,z}((0,h)) \right\}.$$

By simplicity of notation, we prove (6.4) for $i = 1$. Given $u \in \mathcal{A}_{1,M}(Q_h)$, we may write

$$\mathcal{F}_1^1(u,Q_h) = \sum_{\beta\in\{1,\dots,h-1\}^{N-1}} \sum_{k=1}^{+\infty} \sum_{j=1}^{h-k-1} f_1^k\left(\frac{u(j+k,\beta)-u(j,\beta)}{k}\right). \tag{6.5}$$

Since for any $\beta \in \{1,\dots,h-1\}^{N-1}$ the function $v(j) := u(j,\beta) - \tilde{M}\beta$ belongs to $\mathcal{A}_{1,M^1}(0,h)$, where $\tilde{M} := \left(M^2,\dots,M^N\right)$, from (6.5) we get

$$\frac{1}{h^N} \mathcal{F}_1^1(u,Q_h) \geq \frac{1}{h^{N-1}} \#\left(\{1,\dots,h-1\}^{N-1}\right) m_h^1(M^1) \geq m_h^1(M^1).$$

We then easily infer inequality (6.4).

We now prove that

$$f_{hom}(M) \leq \sum_{i=1}^{N} \tilde{f}_i(M^i). \tag{6.6}$$

With fixed $\eta > 0$, for any $i \in \{1, \dots N\}$ let $v_h^i \in \mathcal{A}^2_{1,M^i}(0,h)$ be such that

$$\frac{1}{h}\sum_{k=1}^{+\infty}\sum_{j=1}^{h-k-1} f_i^k\left(\frac{v_h^i(j+k)-v_h^i(j)}{k}\right) \le m_h^i(M^i)+\eta, \tag{6.7}$$

and set

$$u_h(\alpha) := \sum_{i=1}^N v_h^i(\alpha_i), \quad \alpha = (\alpha_1, \dots, \alpha_N).$$

Note that $u_h \in M\alpha + \mathcal{A}_{1,\#}(Q_{h-2})$. Moreover, by the analogue of (6.5) applied to $\mathcal{F}_1^i(u,Q_h)$ for any $i \in \{1,\dots,N\}$ and by (6.7), we easily deduce that

$$\frac{1}{h^N}\sum_{i=1}^N \mathcal{F}_1(u_h, Q_h) \le \sum_{i=1}^N m_h^i(M^i) + N\eta.$$

Eventually, by the characterization of f_{hom} given by formula (4.12), letting first h tend to $+\infty$ and then η tend to 0, we get (6.6). □

Remark 6.4. Note that formula (6.3) highlights that a superposition principle holds, in the sense that the limit energy is obtained by relaxing the energies due to the interactions in every coordinate direction independently and then summing over them.

Remark 6.5. (a) (nearest-neighbors) by Theorem 6.1, if $f_i^k = 0$ for all $k \neq 1$, then formula (6.3) can be rewritten as

$$f_{hom}(M) = \sum_{i=1}^N (f_i^1)^{**}(M^i);$$

(b) (next-to-nearest neighbors) by Theorem 6.2, if $f_i^k = 0$ for all $k \neq 1, 2$, then formula (6.3) can be rewritten as

$$f_{hom}(M) = \sum_{i=1}^N (\tilde{f}_i)^{**}(M^i),$$

with

$$\tilde{f}_i(z) = f_i^2(z) + \frac{1}{2}\inf\{f_i^1(z_1) + f_i^1(z_2),\ z_1 + z_2 = 2z\}.$$

7. An example of quasi-convex nonconvex limit energy density. In the following we provide an example of vector-valued discrete interaction energies defined in the plane whose continuous counterpart has an energy density which is a quasi-convex (nonpolyconvex) function. Our example draws inspiration from Šverák's construction of a quasi-convex function which is not polyconvex (see [21]). Let $N = d = 2$, $p > 1$, and define $f_i : \mathbf{R}^2 \to [0, +\infty)$, $i = 1, 2, 3$, as

$$f_i(z) = \begin{cases} 1 + |z|^p & \text{if } z \neq \pm\frac{\xi_i}{|\xi_i|}, \\ \\ 0 & \text{otherwise,} \end{cases}$$

where $\xi_1 = e_1$, $\xi_2 = e_2$, $\xi_3 = e_1 + e_2$. Let F_ε be defined as

$$F_\varepsilon(u) = \sum_{i=1}^{3} \sum_{\alpha \in R_\varepsilon^{\xi_i}} \varepsilon^2 f_i\left(D_\varepsilon^{\xi_i} u(\alpha)\right);$$

then the conclusions of Theorems 4.1 and 4.5 and Corollary 4.6 hold with f_{hom} given by

$$f_{hom}(M) = \lim_{h \to +\infty} \frac{1}{h^N} \min \left\{ \sum_{i=1}^{3} \sum_{\beta \in R_1^{\xi_i}(Q_h)} f_i(D_1^{\xi_i} v(\beta)), \quad v \in \mathcal{A}_{1,M}\left(Q_h\right) \right\}.$$

THEOREM 7.1. *f_{hom} is not convex.*

Proof. By testing the minimum problem defining f_{hom} with the identity function and its opposite, we immediately obtain that

$$f_{hom}(I) = f_{hom}(-I) = 0,$$

where I is the identity matrix in $M^{2\times 2}$. The claim is proven if we show that $f_{hom}(0) > 0$. We argue by contradiction. Without loss of generality we may assume that Theorem 4.5 holds with $A = Q_1$. If $f_{hom}(0)$ were zero, there should exist a sequence $u_n \in \mathcal{A}_{\varepsilon_n,0}(Q_1)$ such that $u_n \to 0$ in $L^p(Q_1; \mathbf{R}^2)$ and

$$\lim_n F_{\varepsilon_n}(u_n) = 0. \tag{7.1}$$

Set

$$\begin{aligned} T^+ &:= \{(x_1, x_2) \in \mathbf{R}^2 : \ 0 \le x_1 \le 1, \quad x_1 \le x_2 \le 1\}, \\ T^- &:= \{(x_1, x_2) \in \mathbf{R}^2 : \ 0 \le x_1 \le 1, \quad 0 \le x_2 \le x_1\}, \end{aligned}$$

and consider the family of piecewise affine functions $v_n : Q_1 \to \mathbf{R}^2$ defined as follows:

$$v_n(x) = \begin{cases} u_n(\alpha) + D_{\varepsilon_n}^{e_1} u_n(\alpha)(x_1 - \alpha_1) \\ +D_{\varepsilon_n}^{e_2} u_n(\alpha + \varepsilon_n e_1)(x_2 - \alpha_2) & \text{if } x \in \alpha + \varepsilon_n T^-, \\ \\ u_n(\alpha) + D_{\varepsilon_n}^{e_1} u_n(\alpha + \varepsilon_n e_2)(x_1 - \alpha_1) \\ +D_{\varepsilon_n}^{e_2} u_n(\alpha)(x_2 - \alpha_2) & \text{if } x \in \alpha + \varepsilon_n T^+. \end{cases}$$

Note that $v_n|_{\partial Q_1} = 0$. Moreover, it is easy to check that

$$F_{\varepsilon_n}(u_n) = \int_{Q_1} \tilde{f}(\nabla v_n)\, dx, \tag{7.2}$$

where $\tilde{f} : M^{2\times 2} \to [0, +\infty)$ is defined as

$$\tilde{f}(\zeta) := f_1(\zeta_1) + f_2(\zeta_2) + f_3\left(\frac{\zeta_1 + \zeta_2}{\sqrt{2}}\right), \quad \zeta = (\zeta_1, \zeta_2) \in M^{2\times 2}.$$

In particular, by (7.1)

$$\lim_n \int_{Q_1} \tilde{f}(\nabla v_n)\, dx = 0. \tag{7.3}$$

Since we have

$$\tilde{f}(\zeta) \geq c(|\zeta_{11} - \zeta_{22}|^p + |\zeta_{12} + \zeta_{21}|^p),$$

by (7.1) and (7.2) we obtain

$$\lim_n \int_{Q_1} (|\nabla_1 v_n^1 - \nabla_2 v_n^2|^p + |\nabla_1 v_n^2 + \nabla_2 v_n^1|^p)\ dx = 0. \tag{7.4}$$

Since

$$\Delta v_n^1 = \operatorname{div}(\nabla_1 v_n^1 - \nabla_2 v_n^2, \nabla_1 v_n^2 + \nabla_2 v_n^1),$$

$$\Delta v_n^2 = \operatorname{div}(\nabla_1 v_n^2 + \nabla_2 v_n^1, -\nabla_1 v_n^1 + \nabla_2 v_n^2),$$

using the L^p estimates for the Laplace operator (see [19]) we obtain that

$$\begin{aligned}\|\nabla v_n^i\|^p_{L^p(Q_1;\mathbf{R}^2)} &\leq \|\Delta v_n^i\|^p_{W^{-1,p}(Q_1;\mathbf{R}^2)} \\ &\leq \int_{Q_1} (|\nabla_1 v_n^1 - \nabla_2 v_n^2|^p + |\nabla_1 v_n^2 + \nabla_2 v_n^1|^p)\ dx\end{aligned}$$

for $i = 1, 2$. Then, by (7.4) and the previous estimates, ∇v_n converges to 0 strongly in $L^p(Q_1; M^{2\times 2})$, so that

$$\lim_n \int_{Q_1} \tilde{f}(\nabla v_n)\ dx = \tilde{f}(0)\ |Q_1| > 0.$$

Hence we reach a contradiction. □

Remark 7.2. In the particular case $1 < p < 2$, thanks to the growth hypotheses on f_i, f_{hom} is a quasi-convex nonpolyconvex function (see [6, Remark 6.9]).

Acknowledgment. Our attention to this problem was drawn by Andrea Braides. We thank him for fruitful discussions and useful remarks.

TRAVELING WAVE SOLUTIONS OF FOURTH ORDER PDEs FOR IMAGE PROCESSING*

J. B. GREER† AND A. L. BERTOZZI‡

Abstract. The authors introduce two nonlinear advection-diffusion equations, each of which combines Burgers's convection with a fourth order nonlinear diffusion previously designed for image denoising. One equation uses the L^2-curvature diminishing diffusion of You and Kaveh [*IEEE Trans. Image Process.*, 9 (2000), pp. 1723–1730], and the other uses the "low curvature image simplifiers" diffusion of Tumblin and Turk [*Proceedings of the* 26*th Annual Conference on Computer Graphics*, ACM Press/Addison-Wesley, New York, 1999, pp. 83–90]. The new PDEs are compared with a third advection-diffusion equation that combines Burgers's convection with a second order diffusion recommended by Perona and Malik for denoising and edge detection [*IEEE Trans. Pattern Anal. Machine Intell.*, 12 (1990), pp. 629–639]. We prove results regarding the existence and nonexistence of traveling wave solutions of each PDE. Visualizations of each ODE's phase space show qualitative differences between the two fourth order problems. The combined work gives insight into the existence of finite time singularities in solutions of the diffusion equations.

Key words. fourth order diffusion, image denoising, traveling waves, edge detection, Conley index, advection diffusion, dynamical systems, nonlinear partial differential equations

1. Introduction.

We introduce two nonlinear advection-diffusion equations that each combine Burgers's convection with a fourth order nonlinear diffusion intended for image processing:

$$u_t + \left(\frac{1}{2}u^2\right)_x = -(g(u_{xx})u_{xx})_{xx} \tag{YK}$$

and

$$u_t + \left(\frac{1}{2}u^2\right)_x = -(g(u_{xx})u_{xxx})_x, \tag{TT}$$

with $g(s) = \frac{1}{1+s^2}$. Very little is known about the fourth order diffusions, despite recent demonstrations of their effectiveness for image denoising [43, 51]. The combined advection-diffusion equations have the possibility of smooth traveling wave solutions approximating Burgers's shocks. We prove rigorously that such smooth traveling wave solutions of (YK) do not exist for sufficiently large jumps, whereas smooth traveling wave solutions of (TT) exist for all jump values. These results suggest very different behavior of the fourth order nonlinear imaging equations introduced by You and Kaveh [51] and Tumblin and Turk [43].

1.1. Nonlinear PDEs for image denoising. Nonlinear PDEs are now commonly used in image processing for issues ranging from edge detection, denoising, and image inpainting to texture decomposition. Before the development of nonlinear PDE-based methods, the problem of noise reduction in images was treated through linear filtering, in which the image intensity function is convolved with a Gaussian. The method of linear filtering was introduced by Marr and Hildreth [34] and then further developed by Witkin [50], Koenderink [28], and Canny [15]. It is equivalent to solving the heat equation with initial data given by the noisy image intensity function. Although this technique quickly damps out any noise in the image, it also badly blurs edges, often leaving objects in the image unrecognizable.

Nonlinear second order PDEs were introduced with the intention of smoothing while preserving edges. Examples of second order nonlinear PDEs for image processing date back to the seminal works of Perona and Malik [36] and Rudin, Osher, and Fatemi [38]. Their methods are based on a nonlinear version of the heat equation,

$$u_t = \nabla \cdot ((g(|\nabla u|)\nabla u), \tag{1.1}$$

in which the "thresholding function" g is small in regions of sharp gradients. A number of mathematical issues arise with these equations and their use. For example, Perona and Malik suggest using a smooth, positive, and even function g that decays fast enough for large ∇u so that significant diffusion takes place only in regions away from image edges. Specifically, Perona and Malik required the existence of some $K > 0$ such that

$$\frac{d}{ds}\left(g(s)s\right) > 0 \text{ for } 0 < s < K \tag{1.2}$$

and

$$\frac{d}{ds}\left(g(s)s\right) < 0 \text{ for } s > K. \tag{1.3}$$

However, the nonmonotonicity of $g(s)s$ causes (1.1) to be ill-posed in regions of high gradients, and the ensuing dynamics result in a characteristic "staircase" instability. Following [1] and [26], the cause of this ill-posedness can be seen by rewriting the Laplacian locally in terms of $\nu = \frac{\nabla u}{|\nabla u|}$ and a direction η perpendicular to ν. Letting $F(s) = g(s)s$, (1.1) can be rewritten as

$$u_t = F'(|\nabla u|)u_{\nu\nu} + g(|\nabla u|)u_{\eta\eta}. \tag{1.4}$$

Requirement (1.3) then implies that in regions where $|\nabla u| > K$, (1.4) (and therefore (1.1)) is backwards parabolic in the direction of the gradient.

A typical thresholding function g is

$$g(s) = \frac{1}{1 + \left(\frac{s}{k}\right)^2}, \tag{1.5}$$

where k is a parameter used to establish a standard edge size for the image [21, 27, 45, 46]. Figure 1 shows (1.5) for $k = 1$. We note that degenerate parabolic equations which have structure similar to those of Perona and Malik, and which exhibit the same "staircasing" effect, arise in simplified models for the velocity field of a sheared granular medium [49].

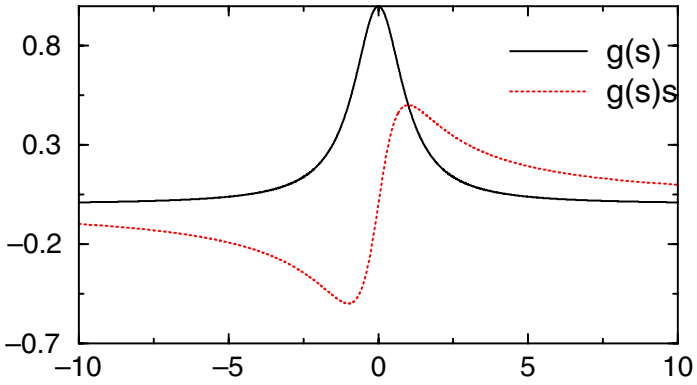

FIG. 1. *An example thresholding function.* $g(s)$ *and* $g(s)s$ *are shown for* $g(s) = \frac{1}{1+s^2}$.

In the past few years, a number of authors have proposed analogous fourth order PDEs for edge detection and image denoising with the hope that these methods would perform better than their second order analogues [17, 18, 32, 33, 43, 44, 51]. Indeed there are good reasons to consider fourth order equations. First, fourth order linear diffusion damps oscillations at high frequencies (i.e., noise) much faster than second order diffusion. Second, there is the possibility of having schemes that include effects of curvature (i.e., the second derivatives of the image) in the dynamics, thus creating a richer set of functional behaviors. On the other hand, the theory of fourth order nonlinear PDEs is far less developed than that of their second order analogues. Also, such equations often do not possess a maximum principle or comparison principle, and implementation of the equations could thus introduce artificial singularities or other undesirable behavior.

Some examples of fourth order equations include the L^2-*curvature* gradient flow method of You and Kaveh [51],

$$u_t = -\Delta(g(\Delta u)\Delta u), \tag{1.6}$$

the Perona–Malik analogue by Wei [44],

$$u_t = -\nabla \cdot (g(|\nabla u|)\nabla \Delta u), \tag{1.7}$$

and Tumblin and Turk's "low curvature image simplifiers" [43],

$$u_t + \nabla \cdot (g(D_{ij}u)\nabla \Delta u) = 0. \tag{1.8}$$

In (1.8), g is a function of the second derivatives of the image intensity function u. Although application of these PDEs to images as demonstrated in [43], [44], and [51] give similar results, it is unclear how the dynamics of the equations compare to each other and to the more established second order methods. Rigorous analysis is thus needed to better understand the new PDEs. One immediate observation is that (1.6) is linearly ill-posed in regions of high curvature, while (1.8) is not. Further insight into the two equations is gained by again defining $F(s) = g(s)s$ and noticing that (1.6) can be rewritten as

$$u_t = -F'(\Delta u)\,\Delta^2 u - F''(\Delta u)\,|\nabla \Delta u|^2, \tag{1.9}$$

while picking $D_{ij}u = \Delta u$ allows us to rewrite (1.8) as

$$u_t = -g\left(\Delta u\right)\Delta^2 u - g'\left(\Delta u\right)\left|\nabla\Delta u\right|^2. \tag{1.10}$$

We see that (1.9), like (1.1), is ill-posed in regions where $F'(s)$ is negative. On the other hand, (1.10) is always linearly well-posed. Also note that (1.9) becomes unstable in all directions when $F'(s)$ changes sign, whereas (1.4) has the instability only in the direction of ∇u.

A class of equations including (1.7) and (1.8) was studied in [24] by the authors, who proved global existence of H^1 solutions when the argument of g, in the form of derivatives of the intensity u, is convolved with a standard mollifier kernel. However, as is well known for some second order equations, as in (1.1), such mollification can turn an ill-posed problem into a well-posed problem [16]. The resulting numerical methods for the equations with mollification appear to smooth out, but not remove, undesirable artifacts of the method without mollification, such as the staircase instability of the Perona–Malik method.

1.2. The model equations. We introduce two model problems designed for studying the dynamics of these new image processing equations without mollification. Both are convection-diffusion equations which can be studied by a combination of analytical and computational methods. We introduce a Burgers convection into the dynamics of the fourth order diffusions (1.6) and (1.8) in order to instigate shock or jump-type behavior typical of edges in images. Such convective motion has real application in image processing. One area in particular is *image inpainting* [2, 3], for which image information is convectively flowed into a region where the image content is unknown. Thus our study gives insight into the behavior of hybrid imaging methods that combine diffusion and convection.

The two fourth order equations are compared with a second order convection diffusion equation that was introduced in [23] and [29]. This equation combines a Burgers convection term with the second order diffusion of (1.1). The authors of [23] and [29] share our motivation of using these equations as tools for understanding the diffusion dynamics.

The three model equations that we consider are

$$u_t + \left(\frac{1}{2}u^2\right)_x = (g(u_x)u_x)_x, \tag{PM}$$

$$u_t + \left(\frac{1}{2}u^2\right)_x = -(g(u_{xx})u_{xx})_{xx}, \tag{YK}$$

and

$$u_t + \left(\frac{1}{2}u^2\right)_x = -(g(u_{xx})u_{xxx})_x. \tag{TT}$$

In each equation, we use the thresholding function

$$g(s) = \frac{1}{1+s^2}, \tag{1.11}$$

as in [36]. Many of our results can be easily generalized to thresholding functions g which satisfy the properties stated in [36]. Remarks are made regarding possible generalizations of our results.

The idea of creating a simplified model PDE in order to understand more complex dynamics is an approach in applied analysis that has met with tremendous success in recent decades. A few examples include applications in combustion [12], singularities [25], aggregation in bacterial colonies [13], surface tension driven interfaces [4, 6, 11], shockwaves [19], vortex dynamics [20], and solidification [39]. In imaging, a very relevant problem is the interaction of higher order diffusion with jump discontinuities. Thus it is very natural to consider a model problem combining Burgers's equation, which produces shocks, with higher order diffusion.

We are interested in one overarching question for all three problems: When do the equations have smooth solutions, and when do they develop singularities (jumps in u or its derivatives)? This fundamental question arises when using such methods for image processing. Moreover, if a singularity forms, it is unclear whether a solution to the equation will continue to exist, perhaps as a weak or distribution solution, as is the case with shock dynamics.

We focus on a special class of similarity solutions—*traveling waves* of the form $u(x-ct)$. This traveling wave ansatz reduces the fourth order PDEs (YK) and (TT) to third order ODEs, to which we apply phase plane analysis from dynamical systems theory, as well as rigorous analysis using Conley index theory and estimates involving Lyapunov functions. Analyzing the simpler Perona–Malik equation (PM) is much more straightforward; however, it gives some insight and provides a standard for comparison with the more complicated fourth order equations.

Our approach in this paper has been successfully used for other fourth order nonlinear equations that model physical systems. A mathematically similar family of PDEs are the lubrication equations used to model thin liquid films under the influence of surface tension. These equations take the form

$$u_t + \nabla \cdot (m(u)\nabla\Delta u) = 0,$$

where $m(u)$ is typically degenerate (i.e., f vanishes when u vanishes). Convection in thin films can arise due to body forces such as gravity or surface stresses involving gradients of surface tension. Recent analysis of traveling waves for the PDE

$$u_t + (f(u))_x = -(u^3 u_{xxx})_x$$

has led to an understanding of compressive and undercompressive shock dynamics in driven films [8, 10, 9, 14]. Similar work has also been done to study the convective Cahn–Hilliard equation [47, 48]. We consider some of the analytical methods for these problems in our study of traveling waves for image processing.

1.3. Organization. We derive traveling wave ODEs for all three PDEs in section 2. By restricting ourselves to traveling wave solutions, the problems simplify to nonlinear ODEs. Sections 3–5 each contain an analysis of one of the three traveling wave ODEs. We first consider the simpler problem (PMODE) in section 3 and use it as a standard for comparing (YKODE), discussed in section 4, and (TTODE), considered in section 5. The three sections share the same outline. We first prove analytic results for the considered ODE. These results are then illustrated with phase plane visualizations which also provide strong evidence for ODE properties that are not proved here. We close each section with a numerical demonstration of the PDE's behavior and its relationship with the corresponding ODE.

2. Traveling wave solutions to PDEs. Traveling waves are similarity solutions of the form

$$u(x,t) = \phi(x - ct), \tag{2.1}$$

where $c \in \mathbb{R}$ is the wave speed. By substituting (2.1) into the PDE, we reduce the problem to an ODE in the variable $\xi = x - ct$. ODEs are typically easier to study, as there are many well-understood analytical and numerical methods for examining their qualitative behavior.

In this paper we consider traveling wave solutions that satisfy

$$\lim_{\xi \to -\infty} \phi(\xi) = u_L \quad \text{and} \quad \lim_{\xi \to +\infty} \phi(\xi) = u_R. \tag{2.2}$$

Such solutions correspond to trajectories connecting $\phi = u_L$ to $\phi = u_R$ in the phase space of the traveling wave ODE. They give diffusive shocks, similar to those for the viscous Burgers equation [31]. The values of u_L and u_R determine the viscous shock's wave speed, c.

2.1. ODEs resulting from (PM), (YK), and (TT). Assume

$$u(x,t) = \phi(x - ct) = \phi(\xi) \tag{2.3}$$

for some real number c to be determined. Using the notation $\phi' := \frac{d}{d\xi}\phi$ and substituting (2.3) into (PM), (YK), and (TT), we derive the ODEs

$$\phi'(\phi - c) = (g(\phi')\phi')', \tag{2.4}$$

$$\phi'(\phi - c) = -(g(\phi'')\phi'')'', \tag{2.5}$$

and

$$\phi'(\phi - c) = -(g(\phi'')\phi''')', \tag{2.6}$$

respectively. Assuming (2.2) and that all of the derivatives of ϕ decay at infinity, integrating each ODE yields

$$r(\phi) = g(\phi')\phi', \tag{PMODE}$$

$$r(\phi) = -(g(\phi'')\phi'')', \tag{YKODE}$$

and

$$r(\phi) = -g(\phi'')\phi''', \tag{TTODE}$$

where

$$r(\phi) := \frac{1}{2}\phi^2 - c\phi + \frac{1}{2}u_L u_R, \tag{2.7}$$

with wave speed

$$c = \frac{1}{2}(u_L + u_R). \tag{2.8}$$

For reference, we call (PMODE) the Perona–Malik ODE, (YKODE) the You–Kaveh ODE, and (TTODE) the Tumblin–Turk ODE. Each ODE has two equilibrium points: L, where $\phi = u_L$, and R, where $\phi = u_R$. A trajectory of one of the given ODEs is a traveling wave solution of the respective PDE if and only if that trajectory is a heteroclinic orbit connecting L and R. Each equation also has an entropy condition (which we derive) requiring $u_L > u_R$ for such an orbit to exist. This entropy condition is analogous to that of the viscous Burgers equation [31].

2.2. Reducing the number of parameters. Consider (PMODE), for a given pair u_L and u_R, and corresponding wave speed, $c = \frac{1}{2}(u_L + u_R)$. Letting $\Phi = \phi - c$, (PMODE) becomes

$$\frac{1}{2}\left(\Phi^2 - \frac{1}{4}(u_R - u_L)^2\right) = g(\Phi')\Phi'. \tag{2.9}$$

The dynamics of (PMODE) and (2.9) are affected solely by the difference between u_L and u_R. Changing their average, which gives the wave speed c, alters ϕ by only an added constant. The same holds true for (YKODE) and (TTODE).

For simplicity, we consider only the case $c = 0$, and we do so without loss of generality. All of our computational examples are done with $\phi(0) = c = 0$. These ODE solutions correspond to PDE solutions that travel with zero speed. We study the full range of behavior of the traveling wave ODEs by adjusting only one parameter, $\gamma := u_L > 0$. Insisting $c = 0$ forces $u_R = -\gamma$. With these conditions $r(\phi) = \frac{1}{2}\left(\phi^2 - \gamma^2\right)$. For both fourth order equations, $L = (0, 0, \gamma)$ and $R = (0, 0, -\gamma)$. For (PMODE), L corresponds to $\phi = \gamma$, and R corresponds to $\phi = -\gamma$.

2.3. Comparing the traveling wave ODEs. In [29], Kurganov, Levy, and Rosenau proved the existence of traveling wave solutions of (PM) for the case $g(s) = \frac{1}{1+s^2}$. Traveling wave solutions exist for only a small range of left and right states. In particular, if u_L is much larger than u_R, the ODE will not have a solution connecting L to R. We generalize the results of [23] and [30] in section 3, which contains a proof of the existence of solutions of (PMODE) for the general class of functions g satisfying the properties listed by Perona and Malik. By studying (PM) and (PMODE), we develop a framework for analyzing the higher order equations. In section 3.4, we compare solutions of (PMODE) with the PDE (PM). Numerical experiments show a one-to-one correspondence between heteroclinic orbits of the ODE and attracting steady state solutions of the PDE. When there is no trajectory connecting L to R in the ODE, a jump discontinuity forms in the PDE. We show that this restriction of left and right states stems from a singularity in the ODE which is caused by the lack of monotonicity of $g(s)s$. The same dilemma also occurs in (YKODE), and we establish results in section 3 that parallel the higher order problem.

The higher order diffusion makes analytical results more difficult to obtain for (YKODE) and (TTODE). However, in section 4 we prove that (YKODE) does not have a smooth solution connecting L and R for large γ. By studying the ODE phase plane with the method introduced by [8], we discover that the unstable manifold of the left state intersects the stable manifold of the right state only when γ is small enough—just as in the second order case. We conclude the section by comparing the ODE solutions with the PDE (YK).

The Tumblin–Turk ODE is remarkably different from the other two ODEs. In section 5, we use a topological argument to prove that (TTODE) has smooth solutions connecting L and R for all $\gamma > 0$. Cross-sections of its phase plane illustrate the key differences between the phase plane geometries of (YKODE) and (TTODE). Once again, we follow the discussion with numerical computations of the PDE.

3. Perona–Malik with advection. Equation (PM) is carefully studied in [23] and [29]. We review and expand upon those results here, as they provide an excellent foundation for our analysis of (YK) and (TT). We first prove that (PMODE) has an orbit corresponding to a traveling wave solution of (PM) only when $\gamma > 0$ is smaller than a critical value, γ_c. This result is followed with a numerical and asymptotic description of solutions of (PMODE) for $\gamma > \gamma_c$.

3.1. The traveling wave ODE. We consider a general thresholding function g, as described in the introduction. Define

$$F(s) = g(s)s \tag{3.1}$$

so that (PMODE) can be written as

$$r(\phi) = F(\phi').$$

Since $g(s)s$ is bounded, we can only define F^{-1} on a subset of $\mathbb{R}$. F^{-1} has three branches that depend on the unique K satisfying

$$g'(K)K + g(K) = 0. \tag{3.2}$$

Two of these branches correspond to the regions $|s| > K$, where $\frac{d}{ds}(g(s)s) < 0$. The third is an interior branch with its range centered around zero and corresponds to the interval $|s| < K$, where $\frac{d}{ds}(g(s)s) > 0$. We define F^{-1} on the interior branch, since our traveling waves have $\phi' \to 0$ as $\xi \to \pm\infty$. With this definition, we rewrite (PMODE) as

$$\phi' = F^{-1}(r(\phi)),$$

with the requirement

$$|r(\phi)| \le F(K) = g(K)K. \tag{3.3}$$

This condition is satisfied if and only if

$$0 \le \gamma \le \sqrt{2g(K)K} \tag{3.4}$$

and is essential to proving the following theorem, which is proved in [29] for the specific case $g(s) = \frac{1}{1+s^2}$.

THEOREM 3.1. *Let g be a smooth, positive, and nonincreasing function of $|s|$, with some $K > 0$ satisfying*

$$\frac{d}{ds}(g(s)s) > 0 \text{ for } |s| < K \quad \text{and} \quad \frac{d}{ds}(g(s)s) < 0 \text{ for } |s| > K.$$

Then the ODE (PMODE) has a continuous solution $\phi(\xi)$ satisfying

$$\lim_{x\to-\infty} \phi(\xi) = \gamma \quad \text{and} \quad \lim_{x\to+\infty} \phi(\xi) = -\gamma \tag{3.5}$$

if and only if

$$0 \le \gamma \le \sqrt{2g(K)K}. \tag{3.6}$$

Proof. Any traveling wave solution of (PM) satisfying (2.2) corresponds to a trajectory of (PMODE) connecting L, the point $\phi = \gamma$, to R, the point $\phi = -\gamma$. Such a trajectory can only exist when $\gamma > 0$, since $F^{-1}(r(\phi)) < 0$ for $|\phi| < |\gamma|$. This is analogous to the Lax–Oleinik entropy condition for Burgers's equation [31]. If $\gamma \le 1$, $r(\phi) \le \sqrt{2g(K)K}$ for all $\phi \in (-\gamma, \gamma)$, so the existence of an orbit connecting L to R is obvious.

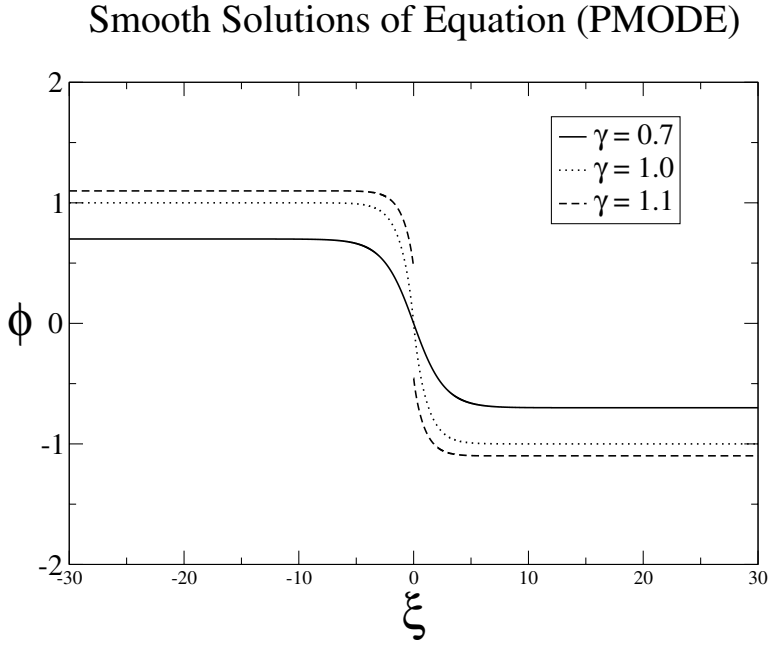

FIG. 2. *Heteroclinic orbits of* (PMODE) *for different values of* γ. *Solutions connecting* L *to* R *exist only for* $\gamma \leq 1$. *For* $\gamma = 1.1$, *we show two trajectories—one starting near* L *and one approaching* R.

Suppose $\gamma > \sqrt{2g(K)K}$. Any continuous heteroclinic orbit, ϕ, connecting L to R must have $\phi(\xi_0) = 0$ for some ξ_0. We calculate $|r(0)| = \frac{1}{2}\gamma^2 > g(K)K$ and remember that $g(s)s \leq g(K)K$ for all s, implying that ϕ cannot possibly satisfy (PMODE). ∎

Remark. For the remainder of the paper, we restrict the main part of our discussion to $g(s) = \frac{1}{1+s^2}$, for which $K = 1$, and $|g(s)s| \leq \frac{1}{2}$. Comments regarding generalizing our results to other thresholding functions will be made throughout the paper.

Figure 2 shows solutions of (PMODE) for $g(s) = \frac{1}{1+s^2}$ and various values of γ. Equation (PMODE) has a trajectory connecting L to R only when $\gamma \leq 1$. When $\gamma > 1$, (PMODE) has only a solution near the equilibrium points. Starting with ϕ slightly smaller than γ, we integrate forward in time until $|r(\phi)| = \frac{1}{2} = \max\{g(s)s\}$. We then start with ϕ slightly larger than $-\gamma$ and integrate backward in time until $|r(\phi)| = \frac{1}{2}$. Figure 2 shows $\phi(\xi)$ for $\gamma = 1.1$ in the regions of ξ, where $F^{-1}(r(\phi(\xi)))$ is defined.

3.2. Second order version of (PMODE). Expanding the right side of (2.4) yields a second order form of the traveling wave ODE for (PM):

$$\phi' = (g'(\phi')\phi' + g(\phi'))\,\phi''. \tag{3.7}$$

Unlike (PMODE), (3.7) does not depend on the choice of γ. Due to the properties of g, (3.7) becomes singular as $|\phi'| \to 1$. We rewrite (3.7) as a system of two ODEs:

$$\phi' = v, \quad v' = \frac{\phi v}{g'(v)v + g(v)}. \tag{3.8}$$

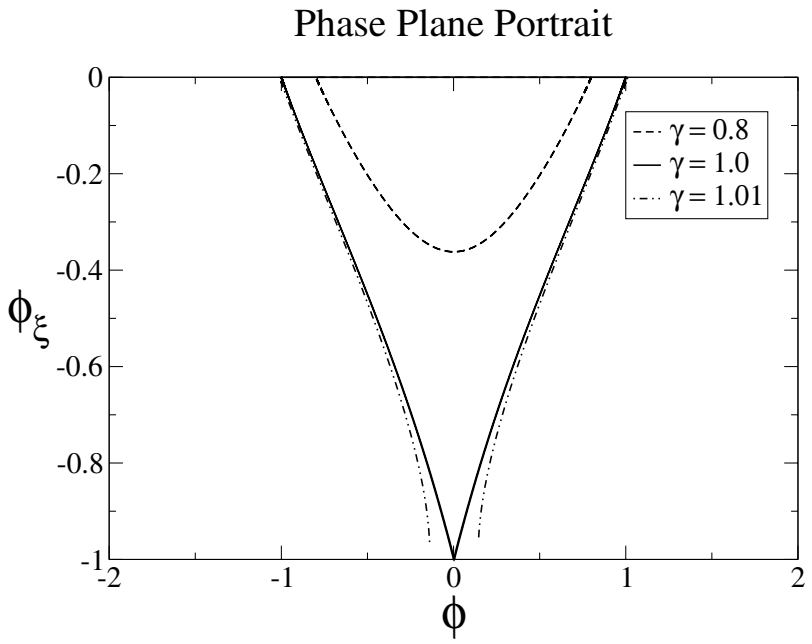

FIG. 3. *Phase plane of ODE system* (3.8). *A series of trajectories are plotted for different values of* γ. *If* $\gamma > 1$, *any connection from* $(\gamma, 0)$ *to* $(-\gamma, 0)$ *would need to pass through the line of singularity,* $\phi' = -1$.

System (3.8) has a line of equilibrium points at $v = 0$. Figure 3 shows integral curves where $\phi \to -\gamma$ as $\xi \to \infty$ and $\phi \to \gamma$ as $\xi \to -\infty$. Each integral curve coincides with a particular value of γ. As γ increases, the integral curves move toward the singular line $v = -1$, clearly illustrating the results of section 3 and showing why heteroclinic orbits of (PMODE) do not exist for large γ. Such traveling waves would require ϕ' to pass through the singular value $\phi' = -1$.

3.3. Singularities in solutions of (PMODE). We now consider the behavior of singular solutions of (PMODE). We examine two cases: $\gamma > 1$ and $\gamma = 1$. When $\gamma > 1$, there is no traveling wave solution. We consider a trajectory $\phi(\xi)$ starting near L and moving toward R and examine ξ_0 satisfying

$$\lim_{\xi \to \xi_0^-} \phi'(\xi) = -1 \text{ and } \lim_{\xi \to \xi_0^-} \phi(\xi) = \phi^*$$

for some $\phi^* > 0$. We have $\phi'\phi \to -\phi^*$ as $\xi \to \xi_0$. Near $\phi' = -1$,

$$g'(\phi')\phi' + g(\phi') \sim \frac{1}{2}(\phi' + 1),$$

so

$$\int_\xi^{\xi_0} -\phi^* \sim \int_\xi^{\xi_0} (\phi' + 1)\phi'',$$

and

$$\phi'(\xi) \sim \sqrt{4\phi^*(\xi_0 - \xi)} - 1. \tag{3.9}$$

When $\gamma = 1$, there is a nonsmooth traveling wave solution. In this case, $\phi^* = 0$ and $\phi(\xi) \sim -(\xi_0 - \xi)$ near $\xi = \xi_0$, so

$$\phi'(\xi) \sim \sqrt{2}|\xi - \xi_0| - 1. \tag{3.10}$$

This singular behavior is demonstrated by the solid line trajectory in Figure 3.

3.4. Second order PDE computations. We test the stability of each traveling wave solution found from (PMODE) by choosing an initial condition near the traveling wave and numerically integrating the PDE (PM). We use centered differences in space and backward Euler in time with an adaptive time step. The Burgers term is computed with a centered difference in flux form. We use Newton's method to approximate solutions of the nonlinear system, and the time step is adjusted to expedite convergence of Newton's method. If convergence requires more than three iterations, the time step is decreased by 10%.

Figure 4 shows computations for $\gamma = 1$ and $\gamma = 1.1$. When $0 \le \gamma \le 1$ (PMODE) has a heteroclinic orbit between L and R. The case $\gamma = 1$ is discussed in section 3.3. This traveling wave, ϕ, is continuous but nonsmooth. ϕ' behaves like (3.10) near $\phi = 0$. Given an initial condition near this traveling wave, the PDE solution converges to the traveling wave solution, as long as the gradient of the initial condition is not too large (for large gradients, (PM) becomes ill-posed, and a jump discontinuity occurs). There is no traveling wave solution for $\gamma > 1$, as seen in the computations for $\gamma = 1.1$; although the initial condition is smooth with small gradient, a discontinuity develops in finite time, and the long time solution has a jump discontinuity.

4. You–Kaveh with advection. Equation (YK) shares many of the properties of (PM). We prove that orbits of (YKODE) corresponding to traveling wave solutions of (YK) do not exist when γ is too large. This nonexistence follows from a singularity in (YKODE) that is analogous to that of (PMODE). We study the phase space of (YKODE) for evidence of the existence of traveling wave solutions when γ is small. For simplicity, we assume $g(s) = \frac{1}{1+s^2}$, which is the thresholding function chosen by You and Kaveh in [51]. However, our results generalize to other thresholding functions as described in section 1.1.

4.1. The traveling wave ODE. Equation (YKODE) can be expanded to

$$r(\phi) = -\left(g'(\phi'')\phi'' + g(\phi'')\right)\phi'''. \tag{4.1}$$

Since $g'(s)s + g(s) = 0$ for $s = \pm 1$, we immediately see a similarity to (PMODE): a solution ϕ of (YKODE) becomes singular in ϕ''' when $|\phi''| \to \pm 1$, just as a solution ϕ of (PMODE) becomes singular in ϕ'' when $|\phi'| \to \pm 1$.

Remark. For general functions g as described in [36], there exists a $K > 0$ satisfying (3.2), so (4.1) is singular at $\phi'' = \pm K$. A solution ϕ of (PMODE) becomes singular in ϕ'' when $|\phi'| \to K$, and a solution ϕ of (YKODE) becomes singular in ϕ''' when $|\phi''| \to K$.

4.2. Lyapunov function for the You–Kaveh ODE. Equation (YKODE) has a Lyapunov function. Multiplying (YKODE) by ϕ' and integrating, we have

$$\int_{-\infty}^{\xi} r(\phi(y))\phi'(y)dy + g(\phi''(\xi))\phi'(\xi)\phi''(\xi) = \int_{-\infty}^{\xi} g(\phi''(y))(\phi''(y))^2 dy. \tag{4.2}$$

Define

$$\mathcal{R}(s) = \int^{s} r(\alpha)d\alpha.$$

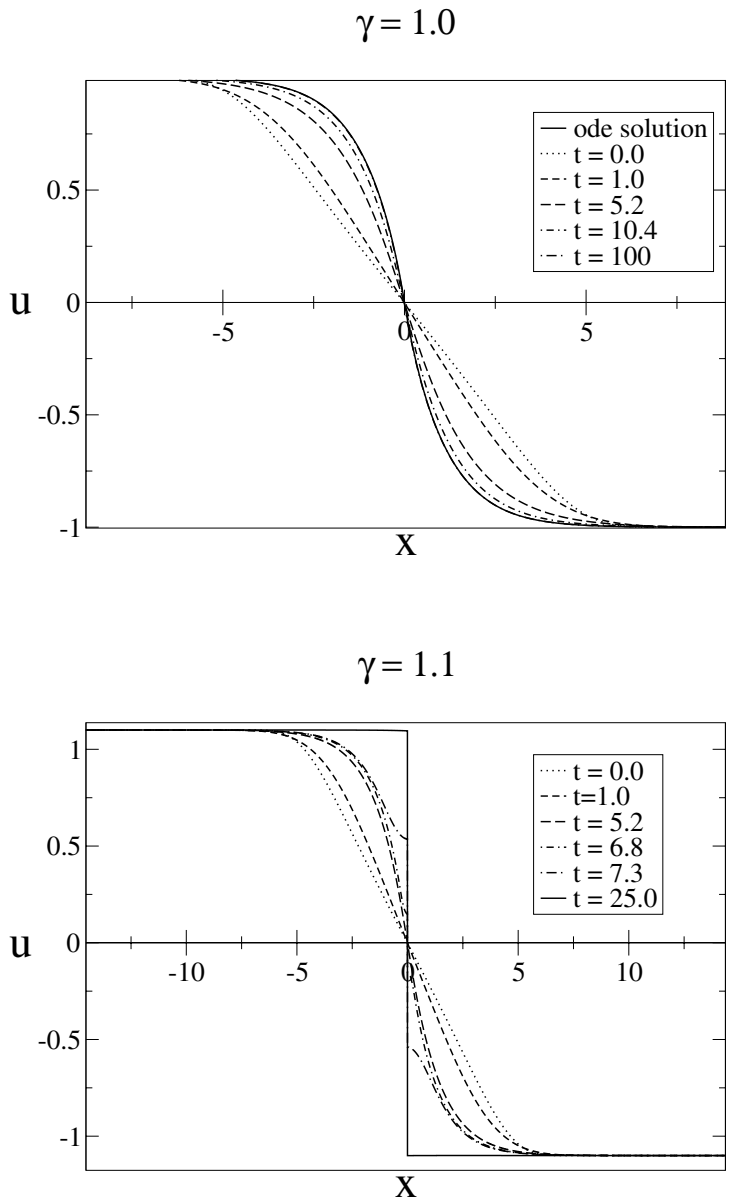

FIG. 4. *PDE* (PM) *solution,* u*, for* $\gamma = 1.0$ *and* $\gamma = 1.1$*. When* $\gamma = 1.0$*,* u *approaches the corresponding traveling wave ODE solution as* t *increases.* $\gamma = 1.0$ *is the maximum value for which the PDE has a traveling wave connecting* γ *to* $-\gamma$*. When* $\gamma = 1.1$*,* u *forms a jump discontinuity in finite time.*

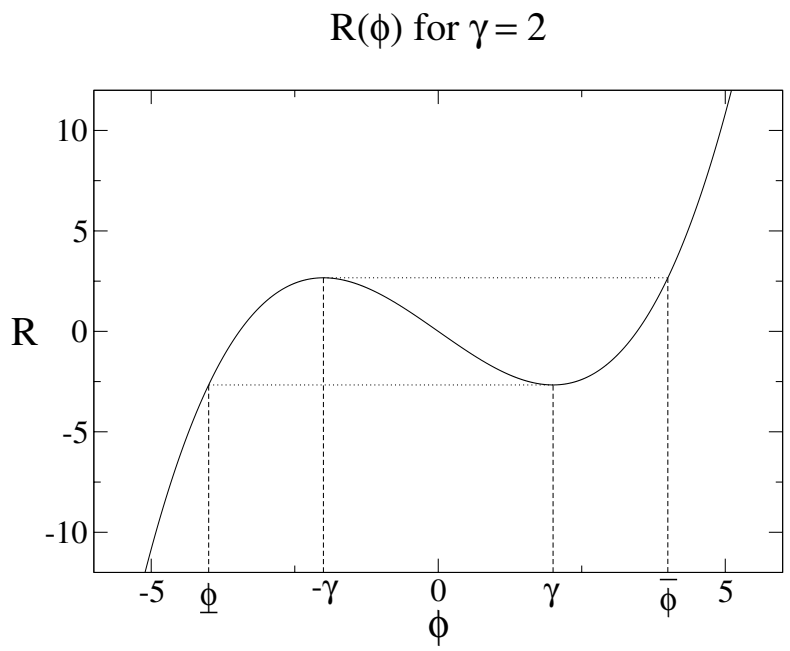

FIG. 5. $\mathcal{R}(\phi)$ *for* $\gamma = 2$. *We mark the maximum and minimum values,* $\overline{\phi}$ *and* $\underline{\phi}$, *for a bounded solution of* (YKODE).

We see that

$$\mathcal{L}_1(\xi) = \mathcal{R}(\phi(\xi)) + g(\phi''(\xi))\phi'(\xi)\phi''(\xi) \tag{4.3}$$

is nondecreasing, since

$$\frac{d}{d\xi}\mathcal{L}_1(\xi) = g(\phi''(\xi))(\phi''(\xi))^2 \geq 0. \tag{4.4}$$

Since $\mathcal{L}_1(\xi) = \mathcal{R}(\phi(\xi))$ at extrema of ϕ, the structure of $\mathcal{R}(\phi) = \frac{1}{6}\phi^3 - \frac{1}{2}\gamma^2\phi$ has a tremendous effect on solutions of (YKODE). Figure 5 shows $\mathcal{R}$ for a particular γ. The structure of $\mathcal{R}$ implies the entropy condition $\gamma > 0$. If $\gamma < 0$, then $\mathcal{R}(\gamma) > \mathcal{R}(-\gamma)$, so there could not be a heteroclinic orbit traveling from $L = (0, 0, \gamma)$ to $R = (0, 0, -\gamma)$. $\mathcal{R}$'s essential behavior remains the same for different values of γ. Assuming $\gamma > 0$, $\mathcal{R}$ is a cubic polynomial with a local maximum at $-\gamma$ and a local minimum at γ. $\mathcal{R}(\phi)$ strictly increases for $\phi < -\gamma$ and for $\phi > \gamma$, while it strictly decreases for $-\gamma < \phi < \gamma$.

Let

$$\overline{\phi} = 2\gamma \quad \text{and} \quad \underline{\phi} = -2\gamma. \tag{4.5}$$

A simple calculation shows

$$\mathcal{R}(\overline{\phi}) = \mathcal{R}(-\gamma) \quad \text{and} \quad \mathcal{R}(\underline{\phi}) = \mathcal{R}(\gamma). \tag{4.6}$$

The following lemmas are essential for proving that (YKODE) does not have a smooth heteroclinic orbit connecting L and R when γ is large. Lemma 4.1 is merely a tool for proving Lemma 4.2.

LEMMA 4.1. *Let $\overline{\phi}$ and $\underline{\phi}$ be defined by* (4.5). *Let $\xi_* \in \mathbb{R}$ be given. Suppose $\phi(\xi)$ is a bounded solution of* (YKODE) *that is defined for all $\xi \in \mathbb{R}$. Then there exists a $\xi+ > \xi_*$ satisfying*

$$\underline{\phi} \ < \ \phi(\xi_+) \ < \ \overline{\phi}.$$

Similarly, there is a $\xi_- < \xi_*$ satisfying the same

$$\underline{\phi} \ < \ \phi(\xi_-) \ < \ \overline{\phi}.$$

Proof. Consider any bounded solution ϕ of (YKODE). We first show that given any $\xi_* \in \mathbb{R}$, there exists a $\xi_+ > \xi_*$ such that $\underline{\phi} < \phi(\xi_+) < \overline{\phi}$. If this were not the case, $|r(\phi(\xi))| \geq |r\left(\overline{\phi}\right)| = |r\left(2\gamma\right)| > 0$ for all $\xi > \xi_*$, thus implying $\left|(g(\phi'')\phi'')'\right| \geq |r(2\gamma)| > 0$ for all $\xi > \xi*$, contradicting the fact that $g(s)s$ is bounded. Similarly, given $\xi_* \in \mathbb{R}$, there exists a $\xi_- < \xi_*$ with $\underline{\phi} < \phi(\xi_-) < \overline{\phi}$. ∎

LEMMA 4.2. *Let $\overline{\phi}$ and $\underline{\phi}$ be defined by* (4.5). *Any bounded solution $\phi(\xi)$ of* (YKODE) *that is defined for all $\xi \in \mathbb{R}$ must satisfy*

$$\underline{\phi} \ \leq \ \phi(\xi) \ \leq \ \overline{\phi} \tag{4.7}$$

for all $\xi \in \mathbb{R}$.

Proof. For the sake of contradiction, suppose there exists a ξ_1 with $\phi(\xi_1) > \overline{\phi}$. With the knowledge of Lemma 4.1, we choose some $\xi_0 < \xi_1$ with $\underline{\phi} < \phi(\xi_0) < \overline{\phi}$. By the same lemma, there also exists a $\xi_2 > \xi_1$ with $\phi(\xi_1) < \overline{\phi}$, so ϕ has a local maximum, $\phi(\xi_M) = \phi_M > \overline{\phi}$ with $\xi_0 < \xi_M < \xi_2$. Since $\phi' = 0$ at extrema,

$$\mathcal{L}_1(\xi_M) \ = \ \mathcal{R}(\phi(\xi_M)) \ > \ \mathcal{R}(-\gamma) \ > \ \mathcal{R}(\gamma).$$

Since ϕ is smooth, there exists some $\overline{\xi}$ with $\xi_M < \overline{\xi} < \xi_2$ satisfying $\phi(\overline{\xi}) = \overline{\phi}$ and $\phi(\xi) < \overline{\phi}$ for all $\xi \in (\overline{\xi}, \xi_1]$. There are two possible behaviors of $\phi(\xi)$ for $\xi > \overline{\xi}$. Either ϕ has an extrema $\phi(\xi_*) < \overline{\phi}$ or ϕ is monotonically decreasing for $\xi > \overline{\xi}$. Consider the first case. Since $\phi(\xi_*)$ is an extrema,

$$\mathcal{L}_1(\xi_*) \ = \ \mathcal{R}(\phi(\xi_*)) < \ \mathcal{R}(\phi(\xi_M)) \ = \ \mathcal{L}_1(\xi_M).$$

This contradicts the fact that $\mathcal{L}_1$ is strictly increasing, since $\xi_M < \xi_*$. Now suppose $\phi(\xi)$ decreases monotonically for $\xi > \overline{\xi}$. Since ϕ is bounded, it approaches a limit as $\xi \to \infty$. This limit must be either γ or $-\gamma$, or $g(\phi'')\phi''$ would blow up as argued in the proof of Lemma 4.1. For each limit,

$$\lim_{\xi \to \infty} \mathcal{L}_1(\xi) < \mathcal{L}_1(\xi_M),$$

contradicting the fact that $\mathcal{L}_1$ increases. It follows that $\phi(\xi) < \overline{\phi}$ for all ξ. A similar argument shows that ϕ is bounded below by $\underline{\phi}$. ∎

As already noted, $|\phi''| = 1$ is a singular value for (YKODE). We use the Lyapunov function to prove the following lemma, which shows that smooth heteroclinic orbits are forbidden from crossing this value. Lemma 4.3 is essential for showing that (YKODE) does not have a smooth heteroclinic orbit connecting L to R when γ is too large.

LEMMA 4.3. *Let $\phi(\xi)$ be a smooth heteroclinic orbit connecting L to R. Then for all ξ, $|\phi''(\xi)| \leq 1$.*

Proof. We show $\phi''(\xi) \leq 1$. Proving $\phi''(\xi) \geq -1$ follows the same line of argument. Suppose that ϕ is a smooth trajectory for which there exists a ξ_* such that $\phi''(\xi_*) > 1$.

We show that ϕ cannot connect L to R. Our argument follows directly from the ODE and its Lyapunov function. Since ϕ is a smooth heteroclinic orbit,

$$\lim_{\xi\to-\infty}\phi''(\xi)=0,$$

so we can find some ξ_c so that $\phi''(\xi_c)=1$ and $\phi''(\xi)>1$ for $\xi\in(\xi_c,\xi_*]$. Since ϕ is smooth, and $g'(\phi'')\phi''+g(\phi'')=0$ for $\phi''=1$, we must have $r(\phi(\xi_c))=0$, and therefore $\phi(\xi_c)=\pm\gamma$. Suppose $\phi(\xi_c)=\gamma$. Then the Lyapunov function implies $\phi'(\xi_c)>0$, so there is some $\epsilon>0$ so that $\phi(\xi)>\gamma$ for $\xi\in(\xi_c,\xi_c+\epsilon)$. The ODE then implies $\phi'''(\xi)>0$ for $\xi\in(\xi_c,\xi_c+\epsilon)$, and since both $\phi'(\xi)$ and $\phi''(\xi)$ are positive on the same interval, ϕ will continue to grow without bound, prohibiting it from being a heteroclinic orbit.

Now suppose $\phi(\xi_c)=-\gamma$. Then the Lyapunov function implies $\phi'(\xi_c)<0$. We can pick a new $\epsilon>0$ such that $\phi(\xi)<-\gamma$ and $\phi''(\xi)>1$ for $\xi\in(\xi_c,\xi_c+\epsilon)$. The ODE then implies $\phi'''(\xi)>0$ on the same interval. In fact, the ODE ensures that this interval can be extended and ϕ'' will continue to increase until ϕ' becomes positive and ϕ once again intersects $-\gamma$. So there is some $\xi'>\xi_c$ with $\phi(\xi')=-\gamma$, $\phi'(\xi')>0$, and $\phi''(\xi')>1$. So $\mathcal{L}_1(\xi')>\mathcal{R}(-\gamma)$, and ϕ cannot be a heteroclinic orbit connecting L to R. ∎

4.3. Nonexistence of traveling waves for (YKODE). Integrating (YKODE) on an arbitrary interval $[\xi_1,\xi_2]$, we see

$$g(\phi''(\xi_2))\phi''(\xi_2)-g(\phi''(\xi_1))\phi''(\xi_1)=\int_{\xi_1}^{\xi_2}r(\phi(y))dy. \tag{4.8}$$

Since $|g(s)s|\le\frac{1}{2}$, smooth solutions of (YKODE) are restricted by

$$\left|\int_{\xi_1}^{\xi_2}r(\phi(y))dy\right|\le 1 \tag{4.9}$$

on any interval $[\xi_1,\xi_2]$. We now use (4.9) to show that when γ is too large, the You–Kaveh ODE does not have a smooth heteroclinic orbit between L and R.

THEOREM 4.4. *There exists a finite $C>0$ such that* (YKODE) *has no smooth solution satisfying*

$$\lim_{\xi\to-\infty}\phi(\xi)=\gamma \quad \textit{and} \quad \lim_{\xi\to+\infty}\phi(\xi)=-\gamma \tag{4.10}$$

when $\gamma>C$.

Proof. Suppose ϕ is a smooth solution of (YKODE) that satisfies (4.10). Then ϕ must be a heteroclinic orbit connecting L to R, and there exists at least one ξ with $\phi(\xi)=0$. Let ξ_0 be the minimum of all points ξ satisfying $\phi(\xi)=0$. Let ξ_- be the largest number satisfying both $\xi_-<\xi_0$ and $\phi(\xi_-)=\gamma$. Since $\phi'''>0$ when $-\gamma<\phi<\gamma$, $\phi'(\xi)\le 0$ for all $\xi\in[\xi_-,\xi_0]$. Otherwise both ϕ' and ϕ'' would become positive in (ξ_-,ξ_0). ϕ' would have to become negative again so that $\phi(\xi_0)=0$, but this would require that ϕ become larger than γ, contradicting the assumptions on ξ_-.

Let μ denote the minimum of ϕ' on $[\xi_-,\xi_c]$. Then restriction (4.9) implies

$$\begin{aligned}1\ge\int_{\xi_-}^{\xi_c}-r(\phi(s))ds&=\int_{\xi_-}^{\xi_c}-r(\phi(s))\frac{\phi'(s)}{\phi'(s)}ds\ge\frac{1}{\mu}\int_{\xi_-}^{\xi_c}-r(\phi(s))\phi'(s)ds\\&=\frac{1}{\mu}(\mathcal{R}(\gamma)-\mathcal{R}(0)).\end{aligned}$$

Since $\mu < 0$ and $\mathcal{R}(\gamma) < \mathcal{R}(0)$, the above gives

$$\mathcal{R}(0) - \mathcal{R}(\gamma) \leq |\mu| \,. \tag{4.11}$$

From the bounds on ϕ and ϕ'' given by Lemmas 4.2 and 4.3, we see that

$$|\mu| \leq 2\sqrt{2\gamma} \tag{4.12}$$

as a result of the following interpolation lemma.

LEMMA 4.5. *Suppose $f \in C^2(\mathbb{R})$ satisfies $|f| \leq M$ and $|f''| \leq C$. Then*

$$|f'| \leq 2\sqrt{CM}.$$

Proof. Given $x \in \mathbb{R}$, Taylor's theorem shows

$$f'(x) = \frac{f(x+2h) - f(x)}{2h} - f''(\xi)h \tag{4.13}$$

for all $h > 0$ and some $\xi \in [-h, h]$. The bounds on f and f'' give us

$$|f'(x)| \leq \frac{M}{h} + Ch.$$

Choosing $h = \sqrt{\frac{M}{C}}$ gives

$$|f'(x)|^2 \leq \left(\frac{M}{h} + Ch\right)^2 = 4MC. \qquad \square$$

Calculating

$$\mathcal{R}(0) - \mathcal{R}(\gamma) = \frac{1}{3}(\gamma)^3$$

and combining (4.11) with (4.12) proves Theorem 4.4. $\square$

Remark. Theorem 4.4 does not depend on the choice $g = \frac{1}{1+s^2}$. It relies only on the properties of thresholding functions as explained in [36] and in section 1.1. In particular, the nonexistence follows mainly from the nonmonotonicity of $g(s)s$.

4.4. The (YKODE) phase space. We rewrite (4.1) as a system of first order ODEs:

$$\phi' = v, \quad v' = w, \quad w' = -\frac{r(\phi)}{g'(w)w + g(w)}. \tag{4.14}$$

System (4.14) has two equilibrium points, $L = (\gamma, 0, 0)$ and $R = (-\gamma, 0, 0)$. A traveling wave solution of (YK) satisfying (2.2) corresponds to a heteroclinic orbit connecting L to R. Let $W^s(L)$ and $W^u(L)$ denote, respectively, the stable and unstable manifolds of L, and define $W^s(R)$ and $W^u(R)$ in the same way.

Since $\gamma > 0$, $W^u(L)$ and $W^s(R)$ are both two-dimensional with complex eigenvalues, while $W^u(R)$ and $W^s(L)$ are one-dimensional manifolds. We follow the method used in [8] and [14]. We illustrate the unstable manifold of L by considering a set of initial values near L and integrating (4.14) forward in time. Each trajectory will approach $W^u(L)$. To visualize the manifold, we mark the intersections of each computed trajectory with a two-dimensional plane (a Poincaré section) in the phase space.

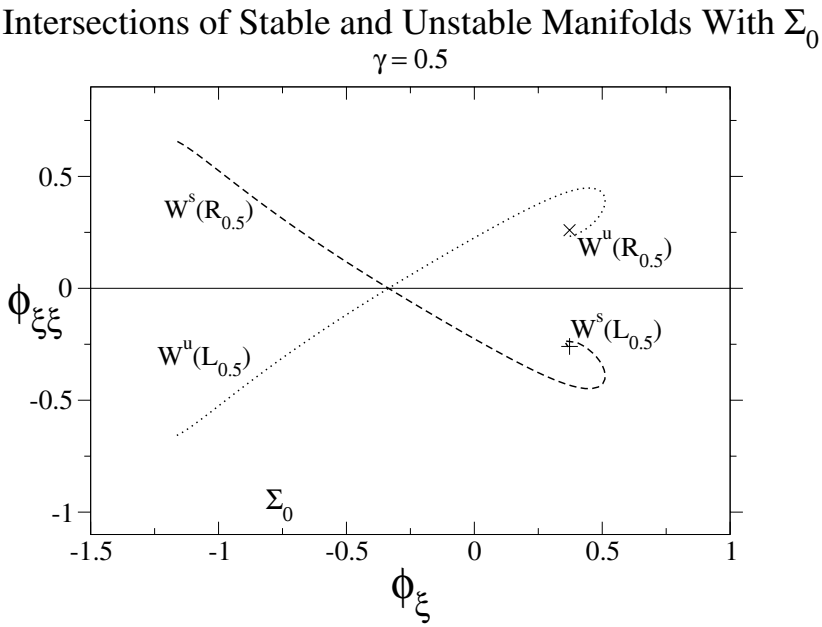

FIG. 6. *Cross-section of the phase plane of* (YKODE) *with* $\gamma = 0.5$. *We show the intersections of the stable and unstable manifolds of both equilibrium points with the plane* $\phi = 0$ *(denoted* Σ_0*).*

This plane is chosen so that all trajectories intersect the plane transversely. Any two-dimensional manifold intersects the plane on a curve, and any one-dimensional manifold intersects at a point. Picking initial points near R and integrating the ODE backward in time produces trajectories approaching $W^s(R)$. Traveling wave solutions of (4.14) correspond to intersections of $W^u(L)$ with $W^s(R)$.

In each figure, initial values are taken at a distance of 10^{-7} to 10^{-5} from the corresponding equilibrium point. We consider the plane $\phi = 0$, denoted by Σ_0. Any intersection of $W^u(L)$ with $W^s(R)$ must appear on Σ_0. The symmetry of (4.14) implies that the restriction of $W^u(L) \bigcap W^s(R)$ to Σ_0 occurs on the line $w = 0$.

Figure 6 shows the intersection of stable and unstable manifolds of u_L and u_R with Σ_0 for $\gamma = 0.5$. Since $W^u(L)$ and $W^s(R)$ intersect each other, there is a heteroclinic orbit connecting L to R. One end of $W^u(L)$ spirals around the one-dimensional manifold, $W^u(R)$. Symmetry gives the same relationship between $W^s(R)$ and $W^s(L)$. As γ is increased, the spiral structure of $W^u(L)$ shifts toward the line $w = 1$, while $W^s(R)$ shifts toward $w = -1$. Figure 7 demonstrates that the manifolds do not have this spiral structure on Σ_0 when γ is too large. The one-dimensional manifolds $W^s(L)$ and $W^s(R)$ no longer intersect Σ_0 when these spiral structures disappear. Further increasing γ moves $W^u(L)$ and $W^s(R)$ away from each other. For large enough γ, $W^u(L)$ and $W^s(R)$ do not intersect each other, as seen in Figure 7, where $\gamma = 1.3$.

In Figure 8, we draw $W^u(L)$ for a sequence of γ values. $W^s(R)$ is not shown, since it can be deduced by reflecting $W^u(L)$ across the line $w = 0$. The two manifolds intersect only when the restriction of $W^u(L)$ to Σ_0 intersects the line $w = 0$. $W^u(L)$ (and consequently $W^s(R)$) shifts away from the line $w = 0$ as γ increases. For large enough γ, $W^u(L)$ does not intersect the line $w = 0$ at Σ_0. As proved in Theorem 4.4, there is a value γ_c such that $W^u(L)$ and $W^s(L)$ do not intersect when $\gamma > \gamma_c$. Our numerical experiments suggest that $1.16 < \gamma_c < 1.17$.

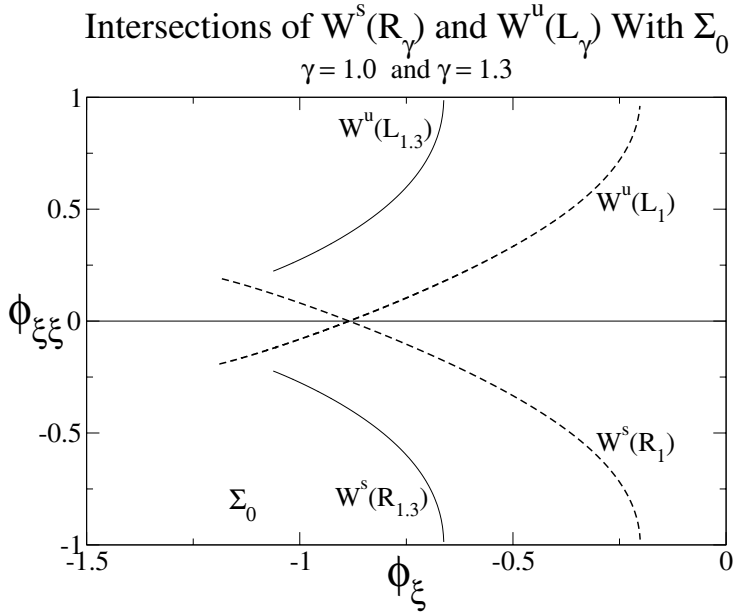

FIG. 7. *Changing manifolds of* (YKODE) *with increasing* γ. *The intersections of* $W^u(L)$ *and* $W^s(R)$ *with* Σ_0 *are shown for* $\gamma = 1.0$ *and* $\gamma = 1.3$. *In both cases,* $W^s(L)$ *and* $W^u(R)$ *do not intersect* Σ_0. *When* $\gamma = 1.3$, $W^u(L)$ *does not intersect* $W^s(R)$, *so there can be no traveling wave solution of the PDE.*

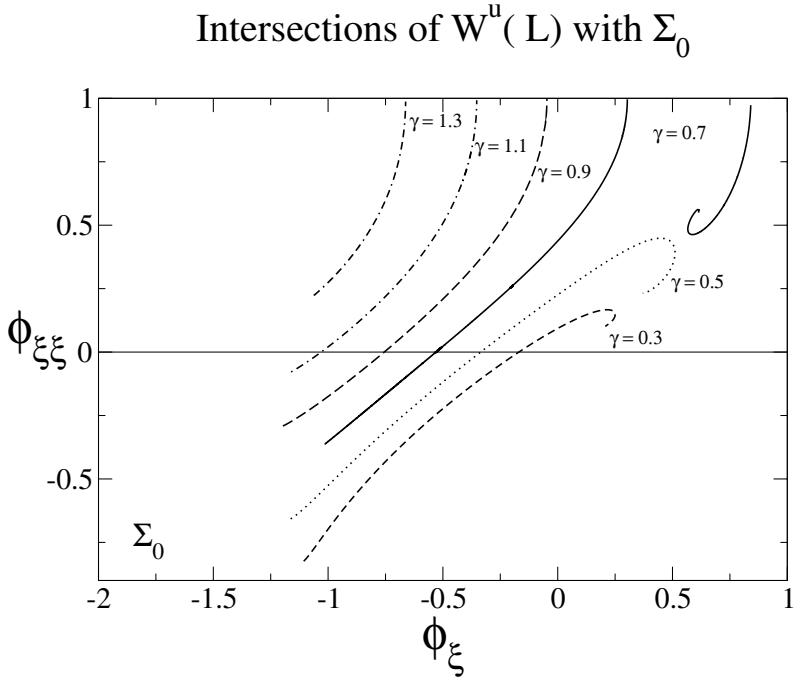

FIG. 8. $W^u(L) \bigcap \Sigma_0$ *for* (YKODE) *with different values of* γ. *A traveling wave solution exists when* $W^u(L) \bigcap \Sigma_0$ *intersects the line* $\phi'' = 0$. *We see that no such intersection exists for large enough* γ.

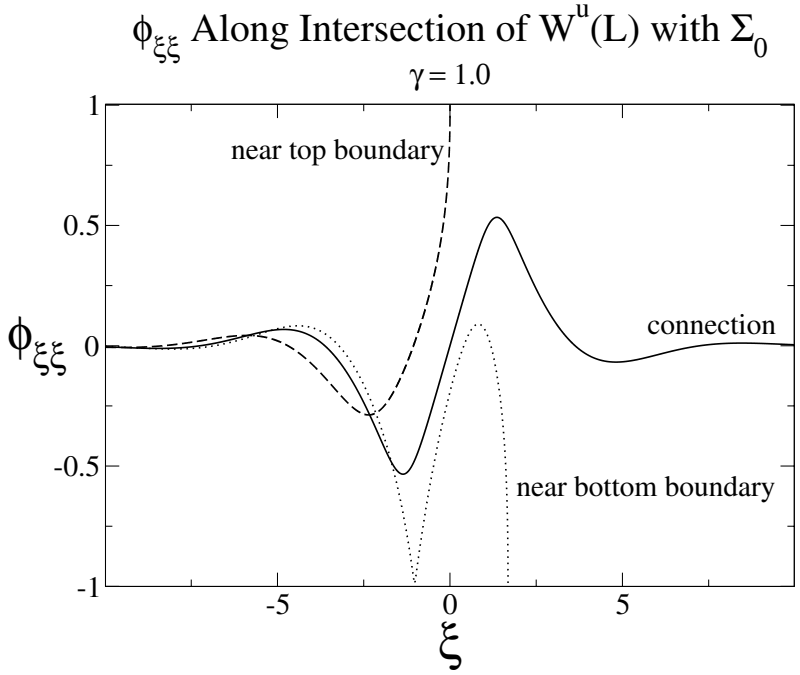

FIG. 9. *Trajectories of* (YKODE) *near the boundaries of* $W^u(L)$ *for* $\gamma = 1.0$. *We show the second derivatives of trajectories that pass near the top and bottom boundaries of* $W^u(L) \bigcap \Sigma_0$. *Trajectories near the top boundary have second derivatives approaching the singular value* $w = 1$ *as* ϕ *approaches* 0, *as can be seen from Figure* 7. *Trajectories near the bottom boundary have a second derivative near* $\phi'' = -1$ *but not where* $\phi = 0$. *The traveling wave solution's second derivative is shown for comparison.*

4.5. Manifold boundaries caused by singularities in solutions of (YKODE). $W^u(L)$ and $W^s(R)$ have boundaries caused by the ODE's singularity. Consider $\gamma = 1.0$, for which $W^u(L) \bigcap \Sigma_0$ is bounded above by $w = 1$. Certainly the manifold cannot extend past $w = 1$, since (4.14) is singular there, but there is also a boundary on the opposite end of $W^u(L) \bigcap \Sigma_0$. This boundary is far from either line of singularity, $w = \pm 1$. Figure 9 shows the second derivative of trajectories near these top and bottom boundaries of $W^u(L) \bigcap \Sigma_0$. Let ξ_0 denote the value of ξ for which a given trajectory $\phi(\xi)$ intersects Σ_0 (ξ_0 could be different for each trajectory). Near the top boundary, $\phi''(\xi_0)$ gets arbitrarily close to $\phi''(\xi_0) = 1$. Trajectories near the bottom boundary approach $\phi''(\xi_c) = -1$ for some $\xi_c < \xi_0$.

The singularities of solutions to (YKODE) are similar to those of (PMODE), but they occur in higher derivatives. Consider a trajectory ϕ with second derivative approaching -1 (the case $\phi'' \to 1$ is very similar). Assume there is some ξ_* with

$$\lim_{\xi \to \xi_*} \phi''(\xi) = -1 \text{ and } \lim_{\xi \to \xi_*} \phi(\xi) = \phi^*.$$

Again we have multiple cases, but this time they depend on the zeros of $r(\phi)$.

Case 1. $r(\phi^*) \neq 0$. This corresponds to the case $\gamma > 1$ for (PMODE). But now the singularity occurs in ϕ''' as $\xi \to \xi_*$:

$$\phi''(\xi) \sim 2\sqrt{r(\phi^*)(\xi_* - \xi)} - 1. \tag{4.15}$$

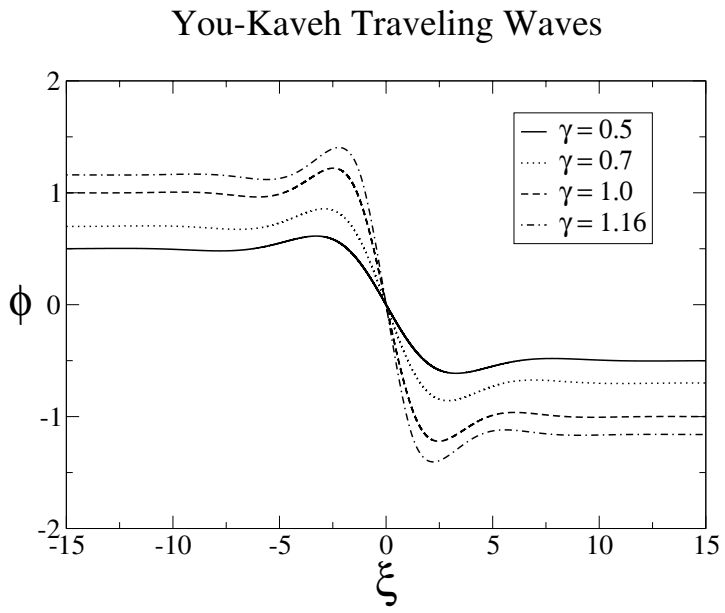

FIG. 10. *Traveling wave solutions of* (YK). *We show them for different values of* γ.

This singularity is demonstrated by trajectory near the top boundary of $W^u(L)$, drawn in Figure 9.

Case 2. $r(\phi^*) = 0$. Either $\phi^* = \gamma$ or $\phi^* = -\gamma$. It is easy to check that

$$\phi''(\xi) \sim \sqrt{2}|\xi - \xi_*| - 1. \tag{4.16}$$

Case 2 is demonstrated by the trajectory near the bottom boundary of $W^u(L)$, as seen in Figure 9. It also corresponds to a critical case for traveling wave solutions of (YKODE). We expect that there is some γ_c for which (YKODE) has a nonsmooth traveling wave solution analogous to the solution of (PMODE) for $\gamma = 1$.

4.6. Traveling wave solutions of (YK). Solutions of ODE (4.1) that correspond to traveling waves connecting L to R are given by the intersection of $W^u(L)$ with $W^s(R)$. Our study of the phase space suggests that there is at most one such intersection for any given γ. The traveling waves shown in Figure 10 were produced by finding this intersection.

In Figure 11, we provide graphs of the second derivative of traveling wave solutions. In each case, $|\phi''|$ is bounded by 1 as expected. The local extrema of ϕ'' are achieved at $\phi = \pm\gamma$, where $\phi''' = 0$. As γ increases, these extreme values approach the singular values $\phi'' = \pm 1$. Because of the ODE's symmetry, ϕ'' approaches a singular value in two places. ϕ'' approaches -1 when $\phi = \gamma$, and it approaches $+1$ when $\phi = -\gamma$.

To illustrate that the traveling waves are stable for the PDE dynamics, we implement (YK) with a fully implicit scheme. We use centered differences for all spatial derivatives, including the Burgers term, which is approximated by centered differences in flux form. We use a Newton solver and an adaptive time step. The time step was adjusted to expedite convergence of the Newton method, as was done for (PM) in

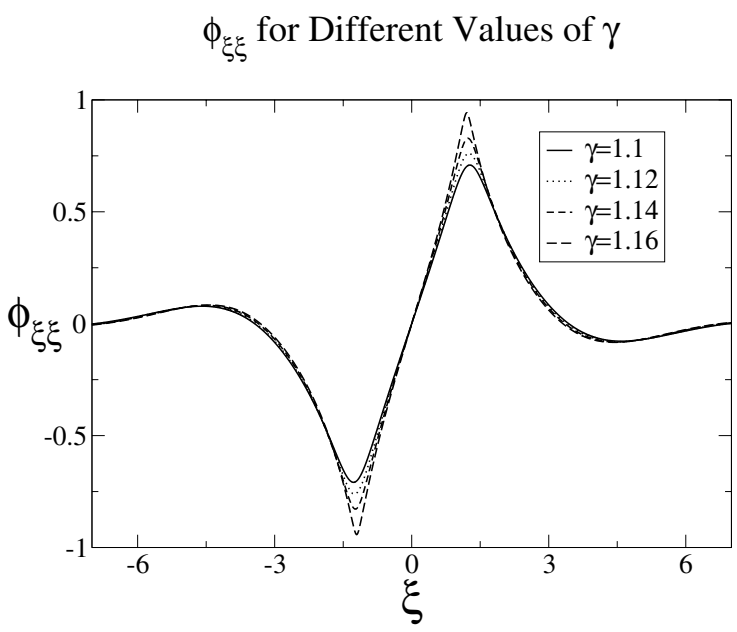

FIG. 11. *The second derivatives of traveling wave solutions of* (YK). *Traveling waves for* γ *near* 1.16 *have second derivatives near the singular value* $w = -1$.

section 3.4. The correspondence between (YK) and (YKODE) is not as clear as it is for (PM) and (PMODE). The numerics become very difficult for γ near the range of nonexistence of traveling waves. In this parameter range, the PDE numerics do not converge nicely to a traveling wave solution, even when our ODE numerics suggest one exists. It is not clear whether this difficulty results from the numerics or from the PDE. We show an example with a smaller γ in Figure 12. In this case, the PDE solution clearly converges to the solution of (YKODE).

5. Tumblin–Turk with advection. We show that (TT) is qualitatively different from both (PM) and (YK). We first use a topological argument to prove that for all $\gamma > 0$, (TTODE) has an orbit corresponding to a traveling wave solution of (TT). Our primary tool is the Conley index, as discussed in [40]. We use standard methods [8, 37], but the particular nonlinear structure of (TTODE) requires new a priori bounds and estimates. We rely on the observation that (TTODE) can be rewritten as

$$r(\phi) = -(\arctan(\phi''))' \tag{5.1}$$

when $g(s) = \frac{1}{1+s^2}$. The analysis consequently depends very much on this particular choice of g.

In section 5.3, we present phase plane illustrations that contrast solutions of (TTODE) to those of (YKODE) and (PMODE). We conclude our discussion of the Tumblin–Turk equations with numerical simulations of (TT).

5.1. Lyapunov function for (TTODE). We seek a Lyapunov function, $\mathcal{L}_2(\xi)$, for (TTODE). Let $\mathcal{R}(s)$ denote a primitive of $r(s)$. Multiplying (5.1) by ϕ' and integrating produces

$$\mathcal{R}(\phi) = -\arctan(\phi'')\phi' + \int^{\xi} \arctan(\phi''(s))\phi''(s)ds.$$

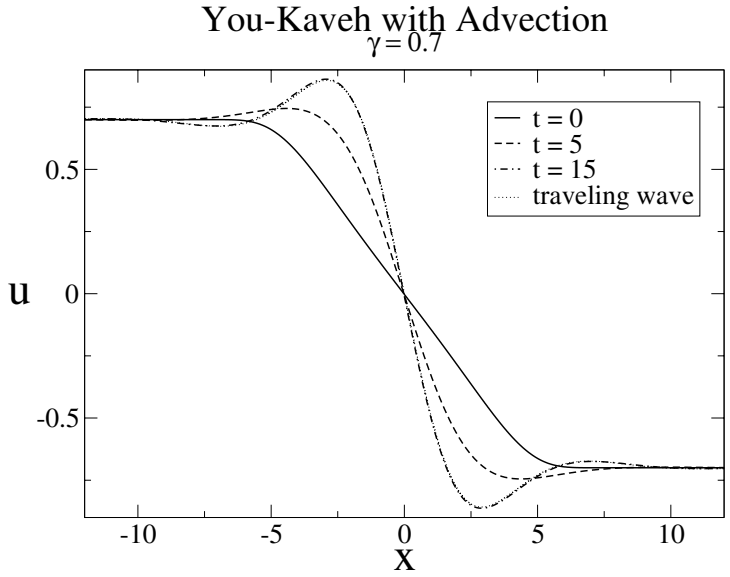

FIG. 12. *Approximate solution of* (YK). *When* $\gamma = 0.7$, u *approaches the traveling wave solution given by* (YKODE).

Since $\arctan(s)s \geq 0$ for all s, we easily check that

$$\mathcal{L}_2(\xi) = \mathcal{R}(\phi(\xi)) + \arctan(\phi''(\xi))\phi'(\xi) \tag{5.2}$$

satisfies

$$\frac{d}{d\xi}\mathcal{L}_2(\xi) = \arctan(\phi''(\xi))\phi''(\xi) \geq 0. \tag{5.3}$$

As was the case for $\mathcal{L}_1$, $\mathcal{L}_2(\xi) = \mathcal{R}(\phi(\xi))$ at zeros of ϕ' and ϕ''. This establishes the entropy condition $\gamma > 0$ and the following lemma.

LEMMA 5.1. *Let* $\overline{\phi}$ *and* $\underline{\phi}$ *be defined by* (4.5). *Any bounded smooth solution* ϕ *of* (TTODE) *that is defined on the real line must satisfy*

$$\underline{\phi} \;\leq\; \phi(\xi) \;\leq\; \overline{\phi} \tag{5.4}$$

for all $\xi \in \mathbb{R}$.

Proof. The proof follows the same argument as that of Lemma 4.2. ∎

5.2. System of ODEs for (TTODE). We rewrite (TTODE) as a system of three ODEs:

$$\phi' = v, \quad v' = \tan(w), \quad w' = -r(\phi). \tag{5.5}$$

System (5.5) has two equilibrium points, $L = (\gamma, 0, 0)$ and $R = (-\gamma, 0, 0)$. We use Conley index theory to prove the existence of a heteroclinic orbit connecting L to R. To do this, we first find uniform bounds for all bounded solutions (ϕ, v, w) of (5.5). Lemma 5.1 provides such a bound for ϕ. It is particularly important to find a bound C such that $|w| \leq C < \frac{\pi}{2}$. To do so, we first examine $v' = \phi''$.

LEMMA 5.2. *Any bounded smooth solution ϕ of* (TTODE) *satisfies*

$$\int_{-\infty}^{\infty} \arctan(\phi''(s))\phi''(s)ds \;\leq\; \mathcal{R}(-\gamma) - \mathcal{R}(\gamma) \;=\; \frac{2}{3}\gamma^3. \tag{5.6}$$

Proof. We follow an argument used in the proof of Theorem 4.8 in [10]. Let ϕ be a bounded solution of (TTODE). Bound (5.6) is obvious if either $\phi(\xi) = \gamma$ or $\phi(\xi) = -\gamma$ for all ξ. Since $L = (\gamma, 0, 0)$ and $R = (-\gamma, 0, 0)$ are the only equilibrium points of (TTODE), we now assume that ϕ is nonconstant. We first examine the behavior of $\phi(\xi)$ as $\xi \to \infty$. There are two cases to consider, depending on the set of extrema of ϕ.

Case 1. Suppose there exists a ξ_M such that ϕ has no extrema for $\xi > \xi_M$. Then ϕ approaches an equilibrium point as $\xi \to \infty$. Since L is increasing, $\phi \to -\gamma$ as $\xi \to \infty$; otherwise all extrema of ϕ would be less than $\underline{\phi}$, and ϕ would grow without bound as $\xi \to -\infty$. We therefore have

$$\int_{0}^{\infty} \arctan(\phi''(s))\phi''(s)ds \;=\; \mathcal{R}(-\gamma) - \mathcal{R}(\phi(0)).$$

Case 2. Now assume that there is no such ξ_M. Since ϕ solves (TTODE), it is analytic (see, e.g., [41]) and must have a countable set of extrema with no limit point. Suppose the extrema occur at ξ_i with $\xi_i > 0$ and $\xi_i < \xi_{i+1}$. The Lyapunov function implies that $\mathcal{R}(\xi_i)$ is a bounded increasing sequence, and we therefore have $\mathcal{R}(\xi) \to \mathcal{R}_+$ for some $\mathcal{R}_+ \leq \mathcal{R}(-\gamma)$. For each ξ_i,

$$\int_{0}^{\xi_i} \arctan\left(\phi''(s)\right)\phi''(s)ds \;=\; \mathcal{R}\left(\phi(\xi_i) - \mathcal{R}\left(\phi(0)\right) \;\leq\; \mathcal{R}(-\gamma) - \mathcal{R}(\phi(0)).\right.$$

The monotone convergence theorem gives us

$$\int_{0}^{\infty} \arctan(\phi''(s))\phi''(s)ds = \mathcal{R}_+ - \mathcal{R}(\phi(0)) \leq \mathcal{R}(-\gamma) - \mathcal{R}(\phi(0)). \tag{5.7}$$

Similar arguments show

$$\int_{-\infty}^{0} \arctan(\phi''(s))\phi''(s)ds \leq \mathcal{R}(\phi(0)) - \mathcal{R}(\gamma). \tag{5.8}$$

Combining (5.7) and (5.8) completes the proof. ∎

We interpret Lemma 5.2 to mean that $\phi'' = v'$ is *almost* L^1, since $\arctan(s)s$ is linear in s for large s. Specifically, for any $\epsilon > 0$, we define $S = \{s : |\phi''(s)| > \epsilon\}$ and discover

$$\begin{aligned} \int_S |\phi''(s)|ds &\leq \frac{1}{\arctan\epsilon} \int_S |\arctan(\phi''(s))\phi''(s)|ds \\ &\leq \frac{1}{\arctan\epsilon} \int_{-\infty}^{\infty} \arctan(\phi''(s))\phi''(s)ds \leq \frac{2}{3\arctan\epsilon}\gamma^3. \end{aligned} \tag{5.9}$$

We now show that w is bounded away from $\pm\frac{\pi}{2}$, the asymptotes of $\tan w$.

LEMMA 5.3. *There exists a positive $C_1 < \frac{\pi}{2}$ such that for any bounded solution (ϕ, v, w) of system* (5.5)*, $|w| \leq C_1$ for all $\xi \in \mathbb{R}$.*

Proof. Since $\underline{\phi} \leq \phi(\xi) \leq \overline{\phi}$ for all ξ, $|-r(\phi)| \leq \gamma^2$, which by (5.5) implies a uniform Lipschitz bound for w,

$$w(\xi_0 - h) \geq w(\xi_0) - \gamma^2 h \text{ for all } \xi_0 \text{ and all } h > 0. \tag{5.10}$$

We use (5.9) with the uniform Lipschitz continuity of w to derive a pointwise bound on w. We focus on bounding w away from $w = +\frac{\pi}{2}$. To make use of (5.9), we must find an interval on which w is bounded away from zero. Pick ξ_0 with $\frac{\pi}{4} < w(\xi_0) < \frac{\pi}{2}$. If no such ξ_0 exists, then $w(\xi) \leq \frac{\pi}{4}$. Choose $\delta > 0$ so

$$\frac{\pi}{4} > w(\xi_0) - \gamma^2\delta \geq \frac{\pi}{6}, \tag{5.11}$$

also implying by (5.10) that $w(\xi) \geq \frac{\pi}{6}$ for all $\xi \in [\xi_0 - \delta, \delta]$. Let

$$S = \left\{ \xi : \phi''(\xi) \geq \frac{\sqrt{3}}{3} = \tan\frac{\pi}{6} \right\}.$$

Then Lemma 5.2 ensures

$$\int_S |v'| = \int_S |\phi''| \leq \frac{6}{\pi}\left(\mathcal{R}(-\gamma) - \mathcal{R}(\gamma)\right) = \frac{4}{\pi}\gamma^3. \tag{5.12}$$

Now using (5.10) and (5.11), we calculate

$$\begin{aligned}
\int_S |v'(s)|ds &\geq \int_{\xi_0-\delta}^{\xi_0} |v'(s)|ds \\
&= \int_{\xi_0-\delta}^{\xi_0} |\tan(w(s))|ds \\
&\geq \int_{\xi_0-\delta}^{\xi_0} \tan(w(\xi_0) - \gamma^2(\xi_0 - s))ds \\
&= \frac{1}{\gamma^2}\log\left|\frac{\cos(w(\xi_0) - \gamma^2\delta)}{\cos(w(\xi_0))}\right| \\
&\geq \frac{1}{\gamma^2}\log\left|\frac{\cos\frac{\pi}{4}}{\cos(w(\xi_0))}\right|.
\end{aligned}$$

Combining this with (5.12), we see

$$\frac{1}{\gamma^2}\log\left|\frac{\sqrt{2}}{2\cos(w(\xi_0))}\right| \leq \frac{4}{\pi}\gamma^3, \tag{5.13}$$

so

$$\cos(w(\xi_0)) \geq \frac{\sqrt{2}}{2}e^{-\gamma^2(\frac{4}{\pi}\gamma^3)} > 0, \tag{5.14}$$

and

$$w(\xi_0) \leq C_1 := \arccos\left(\frac{\sqrt{2}}{2}e^{-\frac{4}{\pi}\gamma^5}\right) < \frac{\pi}{2}. \tag{5.15}$$

The same argument with slight adjustments shows that

$$w(\xi_0) \geq -C_1 = -\arccos\left(\frac{\sqrt{2}}{2}e^{-\frac{4}{\pi}\gamma^5}\right) > -\frac{\pi}{2}. \qquad \square$$

COROLLARY 5.4. *There exists a $C_2 > 0$ satisfying $|v| \leq C_2$.*

Proof. Since w is bounded in an interval strictly contained within $(-\frac{\pi}{2}, \frac{\pi}{2})$, we have a bound on $\phi'' = \tan w$. We use Lemma 4.5 to bound $v = \phi'$. $\square$

THEOREM 5.5. *Given any $\gamma > 0$, there exists a solution ϕ of* (TTODE) *such that $\phi(\xi) \to \gamma$ as $\xi \to -\infty$, and $\phi(\xi) \to -\gamma$ as $\xi \to \infty$.*

Proof. Our proof centers on the Conley index. We refer the reader to [40], which contains an excellent description of Conley index theory. Let C_1 and C_2 be given by Lemma 5.3 and Corollary 5.4. Define the set

$$N = \left\{ (\phi, v, w) : \begin{array}{r} \underline{\phi} \leq \phi \leq \overline{\phi} \\ |v| \leq C_2 \\ |w| \leq C_1 \end{array} \right\}. \tag{5.16}$$

N is an isolating neighborhood, as all bounded trajectories are strictly contained within the interior of N. As explained in Theorem 22.18 of [40], N contains an isolating block, B. Isolating blocks of (TTODE) are special isolating sets whose boundary points immediately leave the set in positive or negative time under the flow defined by (TTODE). The Conley index is the homotopic equivalence class of the quotient space B/b^+, where b^+ is the set of all points on ∂B that leave B in positive time.

Let $\beta \in \mathbb{R}$, and define the continuous deformation of (TTODE),

$$r(\phi) + \beta = -g(\phi'')\phi'''. \tag{5.17}$$

Let $\beta_0 = \frac{\gamma^2}{2}$. Consider $\beta \in [0, \beta_0)$. The new system has a new function

$$\mathcal{R}_\beta(\phi) = \frac{1}{6}\phi^3 + \left(\beta - \frac{1}{2}\gamma^2\right)\phi.$$

The new Lyapunov function is found by replacing $\mathcal{R}$ with $\mathcal{R}_\beta$. The system has two equilibrium points: $L_\beta = (0, 0, \sqrt{\gamma^2 - 2\beta})$ and $R_\beta = (0, 0, -\sqrt{\gamma^2 - 2\beta})$. The system has new upper and lower bounds for all bounded solutions:

$$\overline{\phi}_\beta = 2\sqrt{\gamma^2 - 2\beta} \leq \overline{\phi}$$

and

$$\underline{\phi}_\beta = -2\sqrt{\gamma^2 - 2\beta} \geq \underline{\phi}.$$

It is easy to check that B is an isolating block for the adjusted system with $0 \leq \beta \leq \beta_0$.

When $\beta = \beta_0$, the only bounded trajectory of (5.17) is the constant function $\phi = 0$, so B remains an isolating block. Choosing $\beta > \beta_0$ produces a differential equation with no equilibrium points. B remains an isolating block of the flow and contains no isolated invariant set (other than the null set). It follows that the homotopic equivalence class of $B/b+$ is that of the null set, implying the existence of an orbit of (TTODE) connecting L and R (see Theorem 22.33 in [40]). The Lyapunov function ensures that the trajectory flows from L to R. $\square$

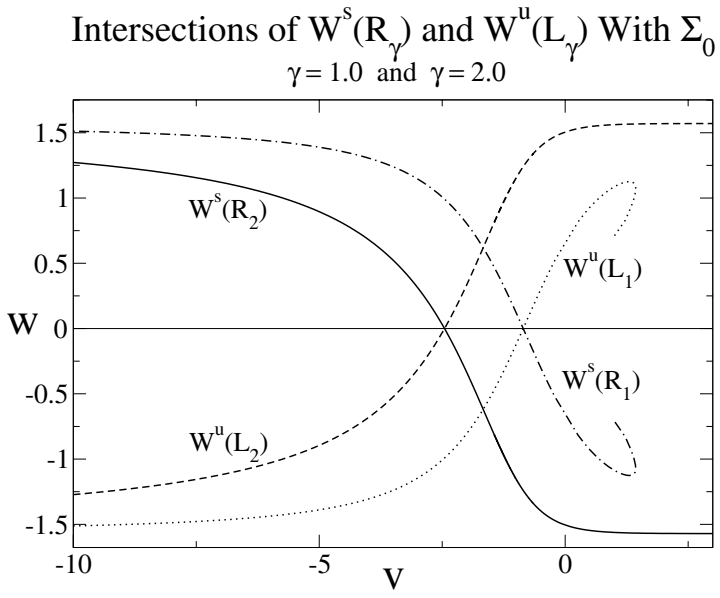

FIG. 13. *Changes of the manifolds for* (TTODE) *with increasing* γ. *The intersections of* $W^u(L)$ *and* $W^s(R)$ *with* Σ_0 *are shown for* $\gamma = 1.0$ *and* $\gamma = 2.0$.

5.3. The (TTODE) phase space. As suggested by our analysis of both equations, the phase plane geometry of (TTODE) is remarkably different from that of (YKODE). Using the method discussed in section 4.4, we visualize the phase space by considering the cross-section $u = 0$, denoted by Σ_0. Any intersection of $W^u(L)$ with $W^s(R)$ is visible on Σ_0, where it must occur on the line $w = 0$. We draw $W^u(L)$ by computing trajectories with initial conditions near L and marking their intersections with Σ_0. $W^s(R)$ is drawn similarly but by numerically integrating (TTODE) backward in time.

Smooth curves in the phase space must lie between the two planes $w = \pm\frac{\pi}{2}$, since $v = \tan w$. Figures 13 and 14 show the intersections of $W^s(R)$ and $W^u(L)$ with Σ_0 for various values of γ. Since $W^s(R)$ and $W^u(L)$ do not have boundaries caused by singularities of (TTODE), both manifolds stretch from $w = -\frac{\pi}{2}$ to $w = \frac{\pi}{2}$, even for large γ. This allows an intersection at $w = 0$ for all $\gamma > 0$; increasing γ shifts only the manifolds in the $-v = -\phi'$ direction. This is remarkably different from the You–Kaveh ODE (YKODE), for which $W^s(R)$ and $W^u(L)$ have boundaries that allow the manifolds to shift away from each other when γ is increased.

5.4. Traveling wave solutions of (TT). Figure 15 shows traveling wave solutions of (TT) for a series of γ-values. Each traveling wave was produced by finding the intersection of $W^u(L)$ with $W^s(R)$ in the phase space of (TTODE). As the jump height from u_L to u_R increases, so does the traveling wave's slope near the jump. Although the ODE solutions are smooth, the jump transition can be so severe that when viewed at large length scales the solution appears to have a shock. This is demonstrated when $\gamma = 7$, as shown in Figure 15.

Numerical examples suggest that the heteroclinic orbits of (TTODE) are stable traveling wave solutions of (TT). To numerically integrate (TT), we use the change

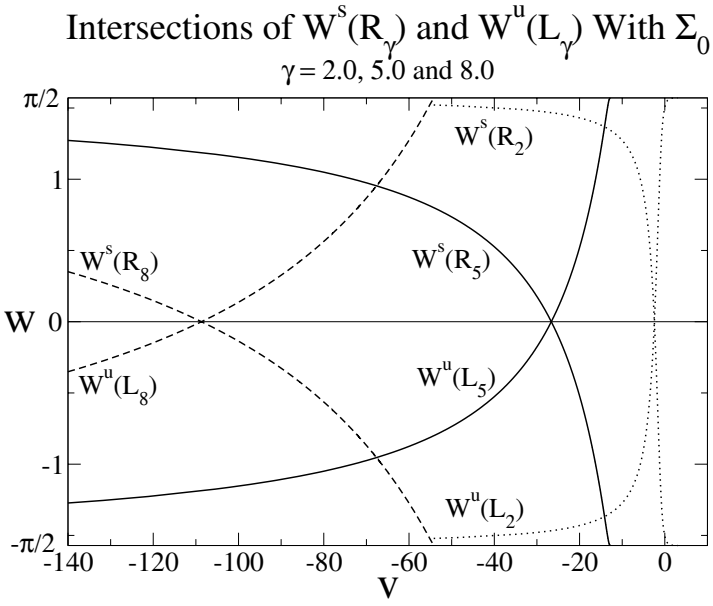

FIG. 14. *Changes of the manifolds for* (TTODE) *with increasing* γ. *The intersections of* $W^u(L)$ *and* $W^s(R)$ *with* Σ_0 *are shown for* $\gamma = 2.0, 5.0,$ *and* 8.0. *Each manifold's structure persists while increasing* γ.

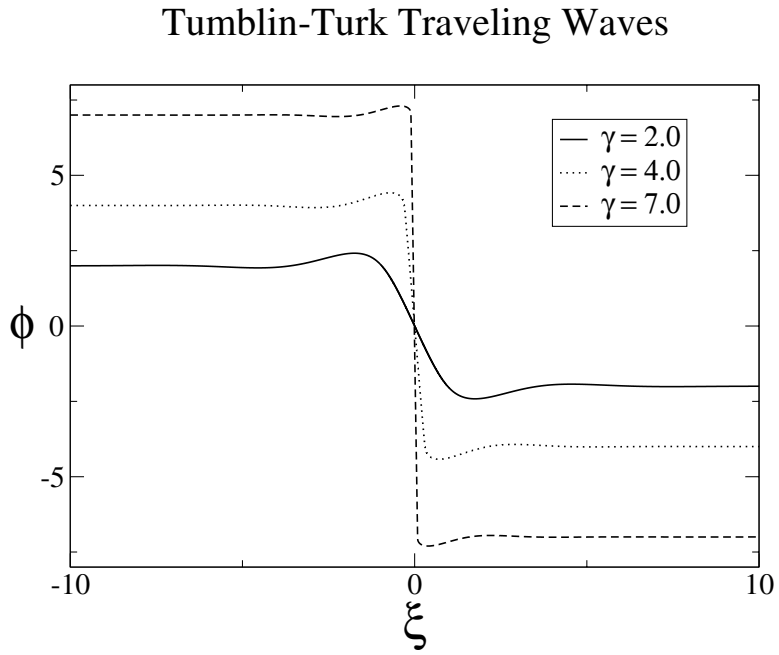

FIG. 15. *Heteroclinic orbits of* (TTODE). *At this length scale, the traveling wave solution for* $\gamma = 7$ *appears to have a shock.*

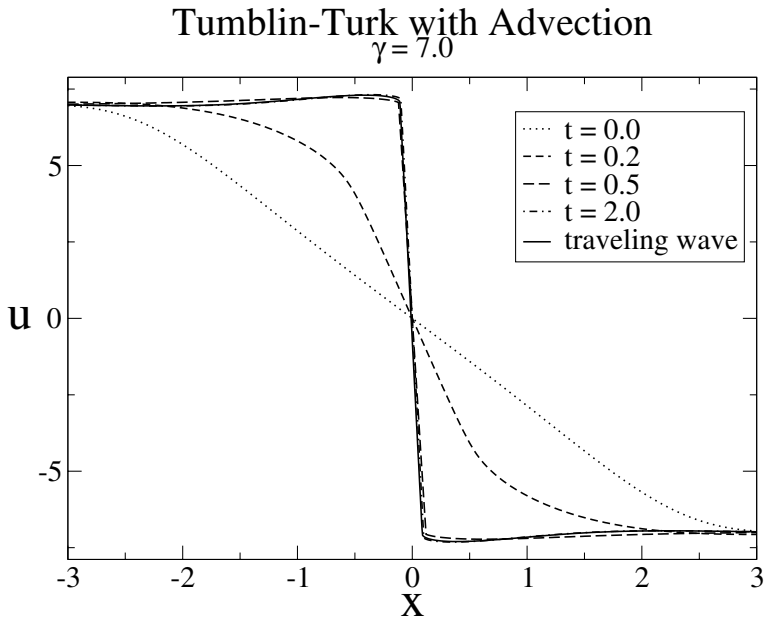

FIG. 16. *Numerically integrated solution of* (TT) *for* $\gamma = 7.0$.

of variables $w = \arctan u_{xx}$ and solve the nonlinear system

$$u_t + uu_x = w_{xx}, \qquad \tan w = -u_{xx} \tag{5.18}$$

using a fully implicit scheme with centered differences in space. We use Newton's method and an adaptive time step, as we did for (PM) in section 3.4. The change of variables $w = \arctan u_{xx}$ is used to ensure that u_{xx} remains bounded. See [7] for a discussion on numerically implementing the fourth order diffusion.

Figure 16 shows the behavior of u, given an initial condition near the traveling wave profile. The computations suggest that the traveling wave is a stable solution of the PDE.

6. Conclusions. We have considered traveling wave solutions of the advection-diffusion equations

$$u_t + \left(\frac{1}{2}u^2\right)_x = -(g(u_{xx})u_{xx})_{xx} \tag{YK}$$

and

$$u_t + \left(\frac{1}{2}u^2\right)_x = -(g(u_{xx})u_{xxx})_x, \tag{TT}$$

with $g(s) = \frac{1}{1+s^2}$, in order to clearly illustrate the features of higher order nonlinear diffusion equations recently proposed for use in image processing.

The advection term $(\frac{1}{2}u^2)_x$ in (YK) and (TT) serves two roles. First, it allows for traveling wave solutions that approximate shocks, which in images correspond to edges. By converting the problem to one of traveling waves, we reduce a fourth order PDE to a third order ODE for which we are able to prove rigorous results and perform clear phase space computations. Second, advective PDEs combining similar diffusion terms are being used for such processes as image inpainting [2, 3]. Thus these kinds of equations are interesting for image processing in their own right.

We discover a fundamental difference between solutions of (YK) and (TT). Smooth traveling waves solutions of (YK) do not exist for sufficiently large jump height, whereas solutions of (TT) exist for all jumps. This suggests that the dynamics of the full PDE (YK) is quite different from that of (TT). In a separate paper, we prove that in one dimension the PDE (TT) without advection has globally smooth solutions, given smooth initial data. The study in this paper would lead us to conjecture that (YK) without advection does have finite time singularities in u_{xx}, just as the classical Perona–Malik equation has finite time singularities in the slope.

Although the PDE numerics suggest that the smooth traveling waves are stable, a rigorous proof of this is still forthcoming. Rigorous stability results for traveling wave solutions of second order convection-diffusion equations include Goodman's proof of multidimensional stability of viscous scalar shock fronts [22] and Osher and Ralston's proof of stability of traveling wave solutions of the convective porous media equation [35]. Fourth order traveling waves are more difficult to analyze due to the lack of a maximum principle and the fact that the traveling waves themselves often do not have a closed form expression. In [9], Evans function techniques are used to prove instability of fourth order thin film traveling waves, although they establish only a consistent condition for stability.

Our work is done entirely in one dimension, but there is at least one obvious extension to two dimensions. Traveling wave solutions of the model equations correspond to plane wave solutions of the equations with diffusions in two dimensions, while the advection term remains only in the x-direction. These plane waves move in the x-direction and do not depend on y. In physical applications, the existence and stability of plane waves is relevant for pattern formation [5, 22, 42]. Analagous questions in imaging are interesting and have not been explored to our knowledge.

THE SUBCRITICAL MOTION OF A SEMISUBMERGED BODY: SOLVABILITY OF THE FREE BOUNDARY PROBLEM*

CARLO D. PAGANI† AND DARIO PIEROTTI†

Abstract. We discuss existence and regularity of the solutions of the wave-resistance problem for a thin semisubmerged body moving at uniform subcritical velocity in a heavy fluid (e.g., water) of constant depth. The main assumption (on the geometry of the body) is that the flow is two-dimensional; i.e., it can be completely described in the vertical plane containing the direction of the motion. Then the problem can be formulated in terms of a boundary value problem for a holomorphic function (the complex velocity field) satisfying a nonlinear condition (the Bernoulli condition) on a free boundary (the free surface of the fluid). By a hodograph transformation and choosing an appropriate functional setting, we first reduce the problem to the resolution of a nonlinear functional equation depending on two unknown parameters, which are related to the positions in the hodograph plane of the points of contact between the free surface and the body. The main result of this paper is the proof of the existence, under mild assumptions on the body's profile, of an exact solution of the nonlinear problem: the resulting free surface is asymptotically flat at infinity upstream and is oscillating downstream; moreover, it is tangent to the body's profile at the contact points.

Key words. free boundary, nonlinear boundary condition, hodograph transformation

1. Introduction and statement of the problem.

Let us consider an infinitely long, semisubmerged horizontal cylinder, moving at a uniform speed on the free surface of a heavy fluid, in the direction orthogonal to its generators. The unperturbed fluid, which is at rest, has finite constant depth H. Compressibility and viscosity are neglected as well as surface tension; moreover, the fluid motion is assumed to be irrotational.

We want to find the steady flow generated by the cylinder's motion. Because of the geometry of the problem, the flow can be completely described in the vertical plane containing the direction of the motion. Then the problem can be formulated in terms of a boundary value problem for a holomorphic function (the complex velocity field) satisfying a nonlinear condition (the Bernoulli condition) on a free boundary (the free surface of the fluid); moreover, the free boundary is the union of two disconnected curves ending on the cylinder's profile at unknown points (see Figure 1).

The solvability of this problem was established in [1] (for a cylinder with symmetric cross section) and in [2] (for a generic cylinder) in the case of *supercritical velocity* (see below). The proof relies on the assumption that the piercing part of the cylinder is small compared to its length (and to the fluid's depth) and essentially consists in the application of the implicit function theorem to a functional equation in the hodograph plane. In this approach, a crucial step is the proof of the unique solvability of a *linear problem*, which is obtained by considering the limit when the cylinder's section becomes a beam and the flow (in a reference system connected with the cylinder) approaches the constant, parallel flow [3].

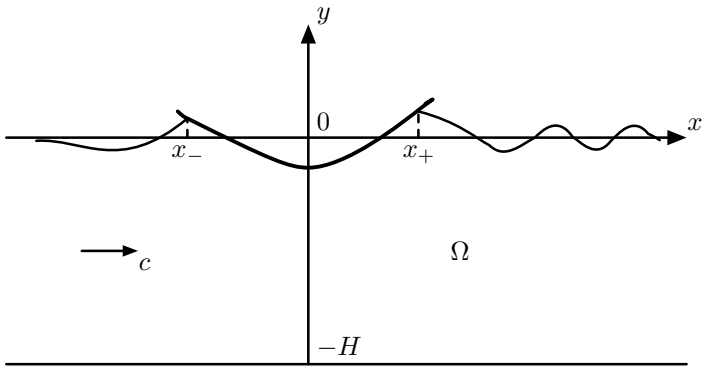

FIG. 1.

In the present work, we prove the solvability of the free boundary problem in the case of *subcritical velocities*. As it is already clear at the level of the linearized problem [4] and from numerical experiments [5], the properties of the solutions are quite different for subcritical and supercritical flows. For example, in the former case the flow may have nontrivial oscillations at infinity downstream, while in the latter case it is asymptotically parallel. This behavior is of course related to the situation that arises in the free-surface water waves: there, a supercritical flow is associated with solitary waves (that exponentially decay at infinity in both directions; see, e.g., [6], [7]), while subcritical flows develop a periodic wave train [7], [8, Chap. 71]. As a consequence, the former proof of the solvability will not extend in a trivial way to the subcritical flow. Nevertheless, we can still formulate the problem in terms of a functional equation in the hodograph plane with the same assumptions on the geometry of the cylinder. As in the case of supercritical velocities, we seek a "local" result of existence for a solution which, for some small parameter ϵ tending to zero, approaches the constant parallel flow. To reach this goal, in contrast with the supercritical case, *we will not fix a priori the asymptotic velocity of the perturbed field at infinity upstream*; the solution that we obtain will be a perturbation of the constant flow with prescribed subcritical velocity

$$c_0 < \sqrt{gH} \tag{1.1}$$

(here g is the acceleration of gravity); the perturbed flow will be parallel at upstream infinity, but its velocity c will depend on the parameter ϵ and will approach the unperturbed velocity c_0 as $\epsilon \to 0$. Similarly, the origin in the hodograph plane will not be completely fixed a priori, but we let it depend on a parameter changing with ϵ; we prescribe only its value in the limit $\epsilon = 0$ when the hodograph map is linear (see section 2). Both these quantities will be determined, as functions of ϵ, from the resolution of the problem, together with the free surface and the velocity field. The necessity of considering additional unknowns comes from the requirement to satisfy two *nonresonance conditions* at infinity downstream, where the velocity field is oscillating. More precisely, one finds that in the linearized problem (see below) the *wave number* and the *phase* of the oscillating far field are directly related to the above parameters; hence, by suitably setting their values, we can search the perturbed solutions in a common space of functions oscillating with the same wave number at downstream infinity.

In order to state the various equations of the problem, we choose a coordinate system connected with the cylinder and such that the xy-plane is orthogonal to the

horizontal generators of the cylinder; the x-axis is directed as the unperturbed flow, the undisturbed free surface is at $y = 0$, and the bottom of the region occupied by the fluid is at $y = -H$. The cross section of the "hull" is described by the equation

$$y = \epsilon f(x), \tag{1.2}$$

where $\epsilon > 0$ is a small parameter and f is a $\mathcal{C}^1$ function defined in some neighborhood of the origin, say J, and such that, for some other neighborhood of the origin $J' = (a, b) \subset J$, we have

$$\begin{aligned} &f(x) < 0 \qquad \text{for} \quad x \in J', \\ &f(x) = 0 \qquad \text{for} \quad x = a \quad \text{and} \quad x = b, \\ &f(x) > 0 \qquad \text{for} \quad x \in J \backslash \bar{J}', \\ &xf'(x) > 0 \qquad \text{for} \quad x \in J \backslash \{0\}, \\ &f'(0) = 0. \end{aligned} \tag{1.3}$$

The fluid surface is described by the equation $y = h(x)$, where h is an unknown smooth function defined in $\mathbf{R}\backslash[x_-, x_+]$, with $x_\pm \in J$. The two numbers $x_\pm$ are the abscissae of the points where the free surface meets the hull so that $h(x_\pm) = \epsilon f(x_\pm)$. Note that the values $x_\pm$ are unknown, and their determination is part of the problem. It is natural to assume that x_- and x_+ lie in small neighborhoods of the points a and b, respectively, which are bounded away from the origin.

We set

$$h^*(x) = \begin{cases} h(x) & \text{for } x \le x_-,\ x \ge x_+ \\ \epsilon f(x) & \text{for } x_- \le x \le x_+. \end{cases} \tag{1.4}$$

Then

$$S^* = \{(x, y) \in \mathbf{R}^2 \,:\, -H < y < h^*(x)\} \tag{1.5}$$

will denote the region filled with the fluid. We assume (as usual) that the curve $y = h^*(x)$ is a streamline; i.e., the free surface and the wetted part of the cylinder form a single streamline; the bottom $\{y = -H\}$ is also assumed to be a streamline. Let us introduce the complex variable $z = x + iy$ and the complex velocity function $\omega(z) = u(x, y) - iv(x, y)$, holomorphic in S^*, with u and v components of the velocity vector. We can now state our problem in the following form: find three scalars, the asymptotic velocity c, the abscissae $x_+ > 0$ and $x_- < 0$, and a real function $h \in \mathcal{C}^1(\mathbf{R}\backslash[x_-, x_+])$ and a complex function $\omega = u - iv$ holomorphic in S^* and bounded in $\overline{S^*}$, such that the following boundary conditions hold:

$$\frac{1}{2}|\omega(x, h(x))|^2 + gh(x) = \text{constant}, \qquad x < x_- \text{ or } x > x_+, \tag{1.6}$$

$$v(x, h(x)) = h'(x)u(x, h(x)), \qquad x < x_- \text{ or } x > x_+, \tag{1.7}$$

$$v(x, \epsilon f(x)) = \epsilon f'(x)u(x, \epsilon f(x)), \qquad x_- \le x \le x_+, \tag{1.8}$$

$$v(x, -H) = 0, \qquad x \in \mathbf{R}, \tag{1.9}$$

$$\lim_{x \to -\infty} \omega(z) = c, \tag{1.10}$$

$$\lim_{x \to -\infty} h(x) = 0. \tag{1.11}$$

Equations (1.7), (1.8) indicate that the free surface and the wetted hull are arcs of a streamline; (1.9) expresses the same property for the bottom, while (1.6) is the

Bernoulli condition on the free surface. The asymptotic conditions (1.10), (1.11) state that at infinity upstream the flow approaches a constant parallel flow, and the free boundary approaches the straight line $h(x) = 0$. We stress that the asymptotic velocity c is an unknown function of ϵ which tends to c_0 as $\epsilon \to 0$. As discussed above, the perturbation due to the presence of the cylinder does not in general vanish (in two dimensions) at infinity downstream if (1.1) holds. The statement of the problem is completed by the *continuity conditions*

$$h(x_\pm) = \epsilon f(x_\pm). \tag{1.12}$$

Rigorous mathematical results about nonlinear ship waves are quite rare in the literature; the problem appears in a linearized version (the Neumann–Kelvin problem; see, e.g., [4, Part 2] and references cited therein), or it has been treated by numerical methods [5]. Some authors [9], [10] (see also [7]) consider the water waves problem by assuming a variable pressure of the form: p_0 (atmospheric pressure) $+\epsilon p(x)$ acting on the free surface; if $p(x)$ is compactly supported, this extra pressure may simulate the action of a ship.

The aim of this paper is to prove the existence, for small values of the parameter ϵ, of an exact solution of the nonlinear problem, which, for $\epsilon \to 0$, reduces to the trivial parallel flow $\omega = c_0$, $h = 0$. The main steps in implementing this program are the following: in the next section, we use a hodograph transformation which (partially) overcomes the difficulties due to the free boundary; the transformed problem proves to be convenient for a functional reformulation. The proof of solvability is achieved in two steps: see sections 3 and 4; in particular, in section 3 we exploit the results obtained in [3] for the linearized problem. Some technical results and side properties of the solution are described in the appendix.

The main result of the paper (the precise statement is Theorem 5.6) is that, for a given profile $\epsilon f(x)$ with $\epsilon > 0$ small, f satisfying (1.3), and some additional technical conditions (also involving the data c_0 and H) there is a solution of the system (1.6)–(1.12). More specifically, there is a flow $\omega_\epsilon(z)$ which is asymptotically parallel when $x \to -\infty$; the asymptotic velocity c is a known quantity depending on ϵ and tending to c_0 as $\epsilon \to 0$. The free surface and the cylinder profile form a single $\mathcal{C}^1$ streamline: they match at known points x_- and x_+ (depending on ϵ). Moreover, the free surface is exponentially vanishing for $x \to -\infty$ and is bounded and asymptotically periodic when $x \to +\infty$; the period is also a known function of ϵ. This result qualitatively agrees with the numerical experiments presented in [5, Par. 3] for Froude numbers approximately ranging from 0.35 to 0.6 and for a parabolic profile. Also, the analysis developed in [9] (where we still have a localized obstacle on the bottom and a localized extra pressure on the free surface) shows that, for Froude numbers strictly less than 1, all bounded solutions are asymptotically periodic at infinity downstream.

2. The hodograph transformation. By means of the hodograph transformation (see [2] for details) we can reformulate the problem by taking the complex potential

$$w = \varphi + i\psi \tag{2.1}$$

(where $\varphi(x, y)$ is the velocity potential and $\psi(x, y)$ the stream function) as the independent variable and the reciprocal of the velocity field

$$\frac{1}{\omega(z)} = \Omega(w), \qquad \Omega = U - iV, \tag{2.2}$$

as the unknown. Given the function Ω, the (inverse) hodograph map $w \mapsto z = x + iy$ is defined by the relation $dz/dw = \Omega$ modulo an additive complex constant; the imaginary part of this constant can be fixed in such a way that the streamline consisting of the free surface and the wetted hull corresponds to $\psi = 0$ (see (2.5)). Then the domain S^* of the physical plane is mapped onto the strip

$$A_H \equiv \{(\varphi, \psi) \in \mathbf{R}^2 : \quad -cH < \psi < 0\}. \tag{2.3}$$

The real part of the additive constant is left undetermined for the moment and is assumed to change with ϵ. For $\epsilon = 0$ we assume that the image of the point $w = 0$ coincides with the origin in the physical plane, which can be placed at a minimum point of the function f on the x-axis; for $\epsilon > 0$, the origin of the hodograph plane will be mapped (for small enough ϵ) to an unknown point $(\bar{x}, \epsilon f(\bar{x}))$ on the cylinder's profile according to the discussion of the introduction. Taking account of the above conditions, the relation between the physical plane variables and the hodograph plane ones can be written

$$x(\varphi, \psi) = \bar{x} + \int_0^{\varphi} U(s, \psi) ds + \int_0^{\psi} V(0, t) dt, \tag{2.4}$$

$$y(\varphi, \psi) = \int_{-cH}^{\psi} U(\varphi, t) dt - H = \frac{1}{c}\psi - \int_{-\infty}^{\varphi} V(s, \psi) ds. \tag{2.5}$$

We stress that the functions U, V and the parameters $\bar{x}$, c in (2.4), (2.5) depend on ϵ; for $\epsilon = 0$, we have $U = 1/c_0$, $V = 0$, $\bar{x} = 0$, and $c = c_0$, and the map is simply the multiplication by $1/c_0$.

We call φ_- and φ_+ the values of φ at the separating points $P_- = (x_-, \epsilon f(x_-))$ and $P_+ = (x_+, \epsilon f(x_+))$, respectively. Then the upper boundary of the strip consists of the segment

$$I = \{(\varphi, \psi) : \quad \psi = 0, \quad \varphi_- < \varphi < \varphi_+\}, \tag{2.6}$$

which is the image of the cylinder's hull, and the two half-lines

$$F = \{(\varphi, \psi) : \quad \psi = 0, \quad \varphi < \varphi_-\} \cup \{(\varphi, \psi) : \quad \psi = 0, \quad \varphi > \varphi_+\}, \tag{2.7}$$

which are the image of the free surface; we stress that the separating abscissae $\varphi_- < 0$ and $\varphi_+ > 0$ are also unknown. The bottom is mapped onto the line

$$B = \{(\varphi, \psi) : \quad \psi = -cH, \quad \varphi \in \mathbf{R}\}. \tag{2.8}$$

Then the function Ω must be holomorphic in A_H and satisfy the boundary conditions

$$-\frac{1}{2}\frac{\partial |\Omega|^{-2}}{\partial \varphi} + gV = 0 \qquad \text{on } F, \tag{2.9}$$

$$V + \epsilon f'(x) U = 0 \qquad \text{on } I, \tag{2.10}$$

$$V = 0 \qquad \text{on } B. \tag{2.11}$$

Moreover, we require the condition at infinity upstream

$$\lim_{\varphi \to -\infty} \Omega = \frac{1}{c}. \tag{2.12}$$

The continuity conditions (1.12) are written

$$-\int_{-\infty}^{\varphi_\pm} V(s,0)ds = \epsilon f\left(\bar{x} + \int_0^{\varphi_\pm} U(s,0)ds\right). \tag{2.13}$$

As already noticed in [2] these two conditions, now written in the hodograph plane, are *not* independent if (2.10) holds. We now show, however, that there is another independent condition at the point $(\varphi_+, 0)$, related to the Bernoulli equation (1.6). In fact, for physical reasons and recalling the asymptotic conditions (1.10), (1.11), the constant appearing on the right-hand side of (1.6) must have the same value $c^2/2$ on both components of the free surface; this holds in particular at the two points $P_\pm$. In terms of the hodograph variables, we get by (2.5), (2.9), and the limit condition (2.12)

$$\frac{1}{2}\,|\,\Omega(\varphi,0)\,|^{-2} + g\,y(\varphi,0) = \frac{c^2}{2}$$

for $\varphi \le \varphi_-$ (and $\psi = 0$); by (2.2), this is equivalent to (1.6). On the other hand, there is no prescribed limit at infinity downstream (only boundedness of the flow field is required). This means that we have the *additional condition*

$$|c\,\Omega(\varphi_+,0)|^{-2} + \frac{2g}{c^2}y(\varphi_+,0) = 1,$$

which, taking account of (2.13), becomes

$$|c\,\Omega(\varphi_+,0)|^{-2} + \frac{2g}{c^2}\epsilon f\left(\bar{x} + \int_0^{\varphi_+} U(s,0)ds\right) = 1. \tag{2.13$'$}$$

Equations (2.9)–(2.13$'$) formulate the problem in the hodograph plane; by the previous discussion, we could replace (2.13) with the analogous of (2.13$'$) at φ_-.

We stress that in the above problem the size and the position of the segment I defined by (2.6) are unknown (the same is true for the depth of the bottom B of the strip in the hodograph plane; see (2.8)). Therefore, a further change of the independent variables and unknowns will prove convenient in the following. Let us first introduce the new parameters

$$\varphi^* = \frac{\varphi_+ - \varphi_-}{2c}, \qquad \varphi^m = \frac{\varphi_+ + \varphi_-}{2c}. \tag{2.14}$$

Then, by setting

$$\rho = \frac{\varphi - c\varphi^m}{c\varphi^*}, \qquad \sigma = \frac{\psi}{c\varphi^*}, \tag{2.15}$$

the beam I is mapped onto the interval $(-1,1)$ of the ρ-axis, and the strip A_H becomes

$$A^* = \{(\rho,\sigma) \in \mathbf{R}^2 \,:\quad -H^* < \sigma < 0\}, \tag{2.16}$$

where

$$H^* = \frac{H}{\varphi^*}. \tag{2.17}$$

Then we define the new unknown

$$\chi = \xi - i\eta$$

(as a function of the new variables (2.15)) by subtracting the asymptotic field $1/c$ from Ω and dividing by ϵ; namely, we set

$$U(\varphi,\psi) = \frac{1}{c}\Big(1+\epsilon\xi(\rho,\sigma)\Big), \qquad V(\varphi,\psi) = \frac{\epsilon}{c}\eta(\rho,\sigma). \tag{2.18}$$

We now want to write the nonlinear boundary conditions (2.9), (2.10) as formal operator equations in the new variables. We first note that on the line $\sigma = 0$ (that is, $\psi = 0$) the right-hand side of (2.4) takes the form

$$\bar{x} + \varphi^* \int_{\rho^m}^{\rho} (1+\epsilon\xi(s,0))ds \equiv x(\rho), \tag{2.19}$$

where we set $\rho^m = -\varphi^m/\varphi^*$; note that (2.19) is independent of c.

We now define the functions

$$G(\rho) = f'(x(\rho)) \tag{2.20}$$

and

$$B^I(\chi,\bar{x};\varphi^m,\varphi^*,\epsilon) = \Big\{\eta + G(\,\cdot\,)(1+\epsilon\xi)\Big\}\Big|_{|\rho|<1,\,\sigma=0}. \tag{2.21}$$

Furthermore, by introducing the parameter

$$\nu^* = \varphi^*\nu = \varphi^*\frac{g}{c^2}, \tag{2.22}$$

we define

$$B^F(\chi,\nu^*;\epsilon) = \Big\{ -\frac{1}{2\epsilon}\frac{\partial}{\partial\rho}|1+\epsilon\chi|^{-2} + \nu^*\eta\Big\}\Big|_{|\rho|>1,\,\sigma=0} \tag{2.23}$$

and

$$\mathbf{B}(\chi,\bar{x},\nu^*;\varphi^m,\varphi^*,\epsilon) = (B^I(\chi,\bar{x};\varphi^m,\varphi^*,\epsilon), B^F(\chi,\nu^*;\epsilon)). \tag{2.24}$$

Then, for every $\epsilon > 0$, the equation

$$\mathbf{B}(\chi,\bar{x},\nu^*;\varphi^m,\varphi^*,\epsilon) = 0 \tag{2.25}$$

is equivalent to the conditions (2.9), (2.10). Moreover, the function χ must be holomorphic in A^*, vanishing for $\rho \to -\infty$, and satisfying the *linear* condition $\eta(\rho,-H^*) = 0$. The notation used stresses the dependence of the differential system on the various parameters of the problem: $\bar{x}$, ν^* (and then c), φ^m, φ^*; such quantities are unknown functions of ϵ as well as the field χ. Our strategy for solving the problem in the hodograph plane will consists of two steps: first, *we fix φ^* and φ^m independent of* ϵ and solve (via the implicit function theorem) (2.25) with respect to χ, ν^*, and $\bar{x}$ for small ϵ, starting with the solution of a linear problem at $\epsilon = 0$ (see section 3.1 below). The values of ν^* and $\bar{x}$ for $\epsilon > 0$ will be determined by requiring the solution χ to belong to an appropriate Banach space (see section 3.2). Thus, in this way, we determine a family of hodograph maps depending on the parameters φ^*, φ^m, and ϵ

(note that also the strip A^* where the function χ is defined depends on φ^*; see (2.16), (2.17)). Then, in the second step, we select a pair $\varphi^* = \varphi^*(\epsilon)$, $\varphi^m = \varphi^m(\epsilon)$ by solving (2.13), (2.13′): the selected map, corresponding to those values of the parameters, will finally determine the solution of the problem in the physical plane. The reason for this two-step procedure is that we do not know a priori the limit positions for $\epsilon \to 0$ of the points $P_\pm$ so that we cannot linearize the whole problem around a known solution at $\epsilon = 0$.

In the next section, we will formulate (2.25) as an operator equation between suitable Banach spaces; this equation will be solved, for fixed φ^m, φ^*, in section 4, while in section 5 we discuss (2.13), (2.13′) determining φ^m, φ^*.

3. The functional setting of the problem.

3.1. The problem at $\epsilon = 0$ in the hodograph plane. According to the previous discussion, we fix the two parameters $\varphi^* > 0$ and φ^m and discuss the linear problem obtained from (2.25) by letting $\epsilon \to 0$ (formally) in the expressions (2.21), (2.23); the results obtained will suggest the correct functional setting of the nonlinear problem.

We first recall that $c \to c_0$ and $\bar{x} \to 0$ as $\epsilon \to 0$; hence, by recalling (2.22) we also have $\nu^* \to \nu_0^*$, where

$$\nu_0^* = \varphi^* g / c_0^2. \tag{3.1}$$

Then, for $\epsilon \to 0$ the system (2.25), together with the condition on the bottom and the asymptotic condition, leads to the following problem for a holomorphic function $\chi_0 = \xi_0 - i\eta_0$ in the domain A^* (see [2]):

$$\partial_\rho \xi_0 + \nu_0^* \eta_0 = 0 \qquad \text{for} \quad \sigma = 0, \ \ |\rho| > 1,$$

$$\eta_0(\rho, 0) = -f'(\varphi^* \rho + \varphi^m) \qquad \text{for} \quad |\rho| < 1,$$

$$\eta_0 = 0 \qquad \text{for} \quad \sigma = -H^*, \ \ \rho \in \mathbf{R},$$

$$\lim_{\rho \to -\infty} \chi_0 = 0.$$

By substituting, in the first equation, $\partial_\rho \xi_0$ with $-\partial_\sigma \eta_0$, we obtain a boundary value problem for the harmonic function η_0 (the harmonic conjugate ξ_0 is then determined by the requirement of vanishing at infinity upstream).

Problem $\mathbf{L_0}$. Find η_0 harmonic in A^* such that

$$\partial_\sigma \eta_0(\rho, 0) - \nu_0^* \, \eta_0(\rho, 0) = 0 \qquad \text{for} \quad |\rho| > 1, \tag{3.2}$$

$$\eta_0(\rho, 0) = -f'(\varphi^* \rho + \varphi^m) \qquad \text{for} \quad |\rho| < 1, \tag{3.3}$$

$$\eta_0(\rho, -H^*) = 0 \qquad \text{for} \quad \rho \in \mathbf{R}, \tag{3.4}$$

$$\lim_{\rho \to -\infty} \eta_0(\rho, \cdot) = 0. \tag{3.5}$$

By adding to (3.2)–(3.5) the natural requirement that the solution is H^1_{loc} and bounded (more generally, polynomially bounded) in the strip outside any neighborhood of the interval $[-1, 1] \times \{0\}$, Problem $\mathbf{L_0}$ coincides with the problem obtained by formal linearization of the original nonlinear problem in the physical plane; see [3]. Then, by the results of [3], we have the following.

THEOREM 3.1. *Given $f' \in H^{1/2}(I)$ (with I defined by (2.6)), Problem* $\mathbf{L_0}$ *is uniquely solvable for $\nu_0^* H^* = gH/c_0^2 > 1$, provided the positive solution μ of*

$$\tanh(\mu H^*) = \frac{\mu}{\nu_0^*} \tag{3.6}$$

is different from $n\pi/2$, $n = 1, 2, \ldots$. Furthermore, if $f' \in H^{3/2}(I)$, the solution is continuous and bounded in the closed strip $\overline{A^*}$, and there are real constants A_0, B_0 such that

$$\sup_{(\rho,\sigma)\in A^*} e^{\lambda_0|\rho|}\Big|\eta_0(\rho,\sigma) - \theta(\rho)[A_0\sin(\mu\rho) + B_0\cos(\mu\rho)]\sinh(\mu(\sigma + H^*))\Big| < \infty, \tag{3.7}$$

where λ_0 is the first positive solution of the equation

$$\tan(\lambda H^*) = \frac{\lambda}{\nu_0^*} \tag{3.8}$$

and θ is the characteristic function of the interval $(0, +\infty)$.

From Theorem 3.1 we get no information on the solvability of Problem $\mathbf{L_0}$ at the "singular values" $\mu = n\pi/2$, $n = 1, 2, \ldots$. However, by a careful reconsideration of some arguments of [3], it can be shown that the solutions defined by Theorem 3.1 have well defined limits for $\mu \to n\pi/2$ and that these limits are still solutions to Problem $\mathbf{L_0}$ with the same regularity and asymptotic properties (3.7). In fact, we can now state the following.

THEOREM 3.2. *Let f be given as in Theorem* 3.1*, and suppose that the positive solution of* (3.6) *satisfies $\mu = n\pi/2$, $n = 1, 2, \ldots$. Then there is a unique solution η_0 of Problem* $\mathbf{L_0}$*, which is defined as the limit for $\mu \to n\pi/2$ of the solutions given by Theorem* 3.1*.*

The proof is given in the appendix.

Remark 3.3. It is worthwhile to point out further properties of the solution of Problem $\mathbf{L_0}$ which will be useful for the definition of an appropriate functional setting for (2.25). We stress that these properties, as well as the asymptotic representation (3.7), *hold for every positive value of μ.*

(i) It can be shown (see also [1]) that if the datum in (3.2) belongs to the Sobolev space $W_p^{2-\frac{1}{p}}(-1, 1)$, with $p \in (1, 4/3)$, then η_0 belongs to $W_p^2(B)$ for every bounded, measurable $B \subset A^*$. We recall the inclusion $W_p^2(B) \subset \mathcal{C}^{0,\alpha}(\bar{B})$, with $\alpha = 2 - 2/p$; also notice that the space W_p^2 is *an algebra* for $p > 1$ and that the product between functions of W_p^2 is continuous. Moreover, since the gradient of η_0 is locally integrable along any curve contained in the closed strip $\overline{A^*}$, the harmonic conjugate ξ_0 is continuous on $\overline{A^*}$ (and also in W_p^2 of any bounded subset).

(ii) The holomorphic function $\chi_0 = \xi_0 - \eta_0$ is everywhere bounded in $\overline{A^*}$ and smooth up to the boundary outside any neighborhood of the interval $[-1, 1] \times \{0\}$. Moreover, a bound similar to (3.7) also holds for the function $\partial_\rho \xi_0$.

(iii) For coefficients A_0 and B_0, in the representation (3.7), the following formulas hold (see Proposition A.4 of the appendix):

$$A_0 = \int_{-1}^{1} f'(\varphi^*\rho + \varphi^m)\alpha(\rho)d\rho, \tag{3.9}$$

$$B_0 = \int_{-1}^{1} f'(\varphi^*\rho + \varphi^m)\beta(\rho)d\rho, \tag{3.10}$$

where α, β are real continuous functions on $[-1,1]$ depending only on ν_0^* and H^*.

Remark 3.4. By Theorems 3.1 and 3.2, we have that *the linearized problem of the flow past a surface-piercing obstacle is uniquely solvable for every subcritical value of the velocity* c_0. This property was never proved before in the linear theory of wave-body interaction, [4] and will be discussed in a more general framework in a forthcoming paper.

Let us now go back to the representation (3.7); we note that the parameter ν_0^* determines the wave number of the perturbed flow at downstream infinity. Moreover, the choice $\bar{x} = 0$ at $\epsilon = 0$ affects the asymptotic phase of η_0. Actually, for $\rho \to +\infty$ we can write

$$\eta_0(\rho,\sigma) \approx C_0 \sin(\mu\rho + \delta_0)\sinh(\mu(\sigma + H^*)), \tag{3.11}$$

where $\delta_0 = \arctan(B_0/A_0)$; since A_0 and B_0 are linear functionals of the boundary datum of Problem $\mathbf{L_0}$, i.e., of $-f'(\varphi^*\rho + \varphi^m)$ for $|\rho| < 1$, a different choice of the limit value of $\bar{x}$ corresponds to a shift of the argument of f' and therefore to a change of δ_0. Now, it is clear that, given φ^*, φ^m, ν_0^*, and H^*, the constant δ_0 in (3.11) is fixed by the integrals on the right-hand sides of (3.9), (3.10) (we suppose that at least one of these integrals is not vanishing; if $A_0 = 0$ we take $\delta_0 = \pi/2$). In the following, for the sake of simplicity, we shall assume that the function $\rho \mapsto f'(\varphi^*\rho + \varphi^m)$ is orthogonal to β so that $B_0 = 0$ and $\delta_0 = 0$. In this case, the solution η_0 is *asymptotically odd* with respect to ρ for $\rho \to +\infty$. Then we will look for solutions of the nonlinear problem (2.25) with the same symmetry at infinity. We point out that the restriction to invariant subspaces of functions with definite symmetry is also a crucial step in the proof of the existence of periodic water waves by bifurcation methods [8], [11]. Later, we will show how to get rid of the previous orthogonality assumption; we remark only here that, in the general case, the function $\rho \mapsto \eta_0(\rho - \delta_0^*, \sigma)$ is asymptotically odd, where

$$\delta_0^* = \delta_0/\mu. \tag{3.12}$$

Remark 3.5. When A_0, B_0 are both vanishing, we get $C_0 = 0$ in (3.11), and the phase δ_0 is undetermined. In this case, we have a waveless solution of the linear Problem $\mathbf{L_0}$ (see [4], [14]), which is also uniquely determined.

3.2. The functional equation. It is now convenient to outline our strategy for solving (2.25); we want to solve such an equation for every pair φ^*, φ^m in a neighborhood of the previously discussed solution at $\epsilon = 0$. We remark that this solution is a function $\chi_0 = \xi_0 - i\eta_0$ holomorphic in the strip (2.16); moreover, χ_0 vanishes for $\rho \to -\infty$ and approaches, for $\rho \to +\infty$, a holomorphic function $\chi_0^\#$ which is $2\pi/\mu$ periodic with respect to ρ, where μ is the positive solution of (3.6). Finally, by the discussion at the end of the previous section, $\chi_0^\#$ satisfies the *symmetry condition* $\chi_0^\#(-\rho,\sigma) = \overline{\chi_0^\#(\rho,\sigma)}$.

Thus, it is natural to solve the functional equation (2.25) in a space of functions defined in the *fixed* strip A^* and with the above asymptotic properties. We note in particular that we look for solutions having *the same wave number and symmetry*, in the limit $\rho \to +\infty$, for every positive (small enough) ϵ; as we will see, this can be accomplished by letting the parameters ν^*, $\bar{x}$ vary from the initial values ν_0^*, 0. This means that we will solve the functional equation with respect to the unknowns $(\chi, \bar{x}, \nu^*)$ in a neighborhood of the solution $(\chi_0, 0, \nu_0^*)$. We first define suitable Banach spaces for

the discussion of the functional equation (2.25); then we will show that the operator $\mathbf{B}$ is a continuously differentiable map between these spaces. In the next section, we will prove the invertibility of the Frechet derivative $\mathbf{B}'$ at $\epsilon = 0$ and solve (2.25) by the implicit function theorem. Taking account of Theorem 3.1 and Remark 3.3, we now introduce a Banach space X of holomorphic functions defined in A^* and continuous up to the boundary. Let us fix $\rho_0 > 1$ and set $Q_{\rho_0} = [-H^*, 0] \times \mathbf{R}\backslash(-\rho_0, \rho_0)$; moreover, given $\bar\rho > \rho_0$, let $B_{\bar\rho} \subset A^*$ be the bounded rectangle $(-H^*, 0) \times (-\bar\rho, \bar\rho)$. Finally, take $1 < p < 4/3$, $\alpha = 2 - 2/p$, and define

$$X = \Big\{\chi = \xi - i\eta \in \mathrm{Hol}(A^*), \quad \chi|_{B_{\bar\rho}} \in W^2_p(B_{\bar\rho}),\ \chi|_{Q_{\rho_0}} \in \mathcal{C}^{1,\alpha}(Q_{\rho_0}),$$
$$\eta(\cdot, -H^*) = 0, \quad \lim_{\rho\to-\infty} \chi = 0, \quad \lim_{\rho\to+\infty} |\chi - \chi^\#| = 0, \Big\}, \tag{3.13}$$

where $\chi^\# = \xi^\# - i\eta^\#$ is holomorphic in the strip and $2\pi/\mu$-periodic with respect to ρ and such that $\chi^\#(-\rho, \sigma) = \overline{\chi^\#(\rho, \sigma)}$. The limits in (3.13) are uniform with respect to σ. The space X is endowed with the following norm:

$$||\chi||_X = ||\chi||_{\mathcal{C}^{1,\alpha}(Q_{\rho_0})} + ||\chi||_{W^2_p(B_{\bar\rho})}$$
$$+ \sup_{Q_{\rho_0}} e^{\lambda^*|\rho|}\{|\eta(\rho,\sigma) - \theta(\rho)\eta^\#(\rho,\sigma)| + |\partial_\rho\xi(\rho,\sigma) - \theta(\rho)\partial_\rho\xi^\#(\rho,\sigma)|\}, \tag{3.14}$$

where $0 < \lambda^* < \lambda_0$ and λ_0 is the lowest positive solution of (3.8). We note that X is a linear space of bounded, continuous functions up to the boundary of A^*; furthermore, X is complete with respect to the norm (3.14). In fact, if χ_n is a Cauchy sequence in X, we have in particular that χ_n converges uniformly on the closure of the strip A^* to a continuous function χ which is holomorphic in A^*; moreover, it can be shown that χ is the limit in X of the sequence. For, by (3.14), if $\chi_n \in X$ is a Cauchy sequence of functions asymptotic to the periodic functions $\chi^\#_n$, then the $\chi^\#_n$ form is also a Cauchy sequence in $\mathcal{C}^0([\varrho, \varrho + 2\pi/\mu] \times [-H^*, 0])$, with $\varrho \geq \rho_0$; hence, $\chi^\#_n \to \chi^\#$ uniformly, with $\chi^\#$ holomorphic and satisfying the properties described below (3.13). Now, by writing explicitly the Cauchy condition for $\chi_n - \chi_m$ and taking the limit for $m \to \infty$ at every point of the closed strip, we find that $\chi \in X$ with the above limit $\chi^\#$ in the definition (3.13); moreover, $\lim_{n\to\infty} \chi_n = \chi$ in X. Let us now define the space

$$Y = W_p^{2-\frac{1}{p}}(-1, 1) \times Y_{\rho_0,\bar\rho}\,, \tag{3.15}$$

where $Y_{\rho_0,\bar\rho}$ is the set of the real functions l defined (a.e.) in $\mathbf{R}\backslash[-1, 1]$ and with the following properties:

$$l|_{(-\bar\rho,-1)\cup(1,\bar\rho)} \in W_p^{1-\frac{1}{p}}((-\bar\rho, -1) \cup (1, \bar\rho)),$$
$$l|_{\mathbf{R}\backslash(-\rho_0,\rho_0)} \in \mathcal{C}^{0,\alpha}(\mathbf{R}\backslash(-\rho_0, \rho_0)),$$
$$\sup_{|\rho|\geq\rho_0} e^{\lambda^*|\rho|}|l(\rho) - \theta(\rho)l_\#(\rho)| < \infty, \tag{3.16}$$

where $l_\#$ is continuous, $2\pi/\mu$-periodic, and odd. The linear space $Y_{\rho_0,\bar\rho}$, equipped with the norm

$$||l||_Y = ||l||_{W_p^{1-\frac{1}{p}}((-\bar\rho,-1)\cup(1,\bar\rho))} + ||l||_{\mathcal{C}^{0,\alpha}(\mathbf{R}\backslash(-\rho_0,\rho_0))}$$
$$+ \sup_{|\rho|\geq\rho_0} e^{\lambda^*|\rho|}|l(\rho) - \theta(\rho)l_\#(\rho)|, \tag{3.17}$$

is a Banach space. The crucial result of this section is the following.

THEOREM 3.6. *Let f be a $\mathcal{C}^{3,1}$ function defined in an interval J containing the interval* (2.6)*. Then, for every bounded domain $\Phi \subset \mathbf{R}^2$ of the form $\varphi^* \in [a,b] \subset \mathbf{R}_+$, $\varphi^m \in [-\varphi^*, \varphi^*]$, there exists $\epsilon_0 > 0$ and a bounded open set $\mathcal{U} \subset X \times \mathbf{R}^2$ such that the operator*

$$\mathbf{B} : \mathcal{U} \times \Phi \times [0, \epsilon_0) \to Y,$$

defined by (2.24)*, is continuously differentiable with respect to $(\chi, \bar{x}, \nu^*)$; furthermore, the solution $(\chi_0, 0, \nu_0^*)$ of the linear problem*

$$\mathbf{B}(\chi, \bar{x}, \nu^*; \varphi^m, \varphi^*, 0) = 0$$

belongs to $\mathcal{U}$.

Proof. This proof follows along the same lines as the proof of Theorem 3.5 in [1] and of Theorem 3.2 in [2] and is only sketched here. We recall that $\mathbf{B}$ is a *family of operators*, acting on the variables $(\chi, \bar{x}, \nu^*) \in X \times \mathbf{R}^2$, depending on three parameters: φ^*, φ^m, and ϵ. We assume that ϵ belongs to some interval $[0, \epsilon_0)$ and the pair φ^*, φ^m to some bounded domain Φ as defined above. We prove the assertions of the theorem separately for the two components of the operator $\mathbf{B}$. We stress that the assumption $f \in \mathcal{C}^{3,1}(J)$ guarantees the continuity of the Nemitski operator associated with f'' from $W_p^{3-\frac{1}{p}}(-1,1)$ to $W_p^{2-\frac{1}{p}}(-1,1)$; furthermore, by Remark 3.3(i) it follows that $W_p^{2-\frac{1}{p}}(-1,1)$ is an algebra and that the product between functions in this space is continuous (see also [12, Theorem 1.4.4.2]). These properties allow us to conclude that, for suitably chosen $\mathcal{U}_I \subset X \times \mathbf{R}$ (containing the point $(\chi_0, 0)$) and $\epsilon_0 > 0$, the operator $\mathbf{B}^I$ given by (2.21) is continuous from $\mathcal{U}_I \times \Phi \times [0, \epsilon_0)$ into $W_p^{2-\frac{1}{p}}(-1,1)$ and continuously differentiable with respect to $(\chi, \bar{x})$; its G-differential at the point $(\chi_0, 0) \in \mathcal{U}_I$ is given by

$$\begin{aligned} &d_G\mathbf{B}^I(\chi_0, 0; \epsilon)[\chi, \bar{x}] \\ &= \eta(\rho, 0) + \epsilon f' \left(\varphi^* \int_{\rho^m}^{\rho} \big(1 + \epsilon\xi_0(s,0)\big) ds \right) \xi(\rho, 0) \\ &+ f'' \left(\varphi^* \int_{\rho^m}^{\rho} \big(1 + \epsilon\xi_0(s,0)\big) ds \right) \big(1 + \epsilon\xi_0(\rho, 0)\big) \left(\bar{x} + \epsilon\varphi^* \int_{\rho^m}^{\rho} \xi(s,0) ds \right) \\ &= \eta(\rho, 0) + \bar{x} f''(\varphi^* \rho + \varphi^m) + \mathcal{O}(\epsilon), \qquad |\rho| < 1. \end{aligned} \tag{3.18}$$

It is easy to check that the map $(\chi, \bar{x}; \varphi^m, \varphi^*, \epsilon) \mapsto d_G\mathbf{B}^I(\chi, \bar{x}; \varphi^m, \varphi^*, \epsilon)$ is continuous; then $\mathbf{B}^I$ is Frechet differentiable with the continuous derivative in $\mathcal{U}_I \times \Phi \times [0, \epsilon_0)$. Similarly, we can check differentiability of $\mathbf{B}^I$ with respect to the parameters φ^m, φ^*, and ϵ.

In order to exploit similar arguments for the second component of $\mathbf{B}$, i.e., $\mathbf{B}^F$ given by (2.23), it is convenient to write it in the form

$$\mathbf{B}^F(\chi, \nu^*; \epsilon) = \left\{ \nu^* \eta + \xi_\rho + \epsilon \frac{\partial}{\partial \rho} \frac{\frac{1}{2}(\eta^2 - 3\xi^2) - \epsilon\xi(\xi^2 + \eta^2)}{(1 + \epsilon\xi)^2 + \epsilon^2\eta^2} \right\} \Big|_{|\rho|>1,\, \sigma=0}. \tag{3.19}$$

Again by the properties of the spaces $W_p^{2-\frac{1}{p}}$ with $p > 1$ and recalling the definitions (3.16), (3.17), one can verify that, for suitably chosen $\mathcal{U}_F \subset X \times \mathbf{R}_+$ (containing the

point (χ_0, ν_0^*)) and $\epsilon_0 > 0$, the operator $\mathbf{B}^F$ acts continuously from $\mathcal{U}_F \times [0, \epsilon_0)$ into $Y_{\rho_0,\bar\rho}$; we particularly emphasize that if χ satisfies the asymptotic symmetry condition specified in the definition of the space X, then the right-hand side of (3.19) satisfies the analogous condition for the space $Y_{\rho_0,\bar\rho}$ (see (3.16)). The operator $\mathbf{B}^F$ is also differentiable with respect to (χ, ν^*), and its G-differential at the point (χ_0, ν_0^*) can be written

$$d_G\mathbf{B}^F(\chi_0, \nu_0^*; \epsilon)[\chi, \nu^*] = \nu^*\eta_0(\rho, 0) + \nu_0^*\eta(\rho, 0) + \xi_\rho(\rho, 0) + \mathcal{O}(\epsilon), \qquad |\rho| > 1. \tag{3.20}$$

The map $(\chi, \nu^*; \epsilon) \mapsto d_G\mathbf{B}^F(\chi, \nu^*; \epsilon)$ is continuous; then $\mathbf{B}^F$ is Frechet differentiable with the continuous derivative in $\mathcal{U}_F \times [0, \epsilon_0)$. We can also readily check the differentiability of $\mathbf{B}^F$ with respect to ϵ. By collecting all these facts, we get the proof of the theorem.

4. Solvability of the functional equation. In this section we solve (2.25) in a neighborhood of the solution at $\epsilon = 0$. To this aim, we prove the invertibility of the Frechet derivative $\mathbf{B}'(\chi_0, 0, \nu_0^*; \varphi^m, \varphi^*, 0)$; by Theorem 3.6 and evaluating (3.18), (3.20) at $\epsilon = 0$, we are led to consider the following boundary value problem.

Problem **L**. Find $\chi = \xi - i\eta \in X$ such that

$$\eta_\sigma(\rho, 0) - \nu_0^*\,\eta - \nu^*\,\eta_0(\rho, 0) = l(\rho) \qquad \text{for} \quad |\rho| > 1, \tag{4.1}$$

$$\eta(\rho, 0) + \bar x f''(\varphi^*\rho + \varphi^m) = k(\rho) \qquad \text{for} \quad |\rho| < 1, \tag{4.2}$$

$$\eta(\rho, -H^*) = 0, \tag{4.3}$$

where the pair (k, l) belongs to the space Y defined by (3.15), (3.16). We will show that problem (4.1)–(4.3) is uniquely solvable in the space X (see (3.13)) for a unique choice of the pair $(\bar x, \nu^*)$ in a neighborhood of $(0, \nu_0^*)$. We search a solution of the problem in the form

$$\eta = \eta_1 + \eta_2,$$

where η_1, η_2 are harmonic in the strip and satisfy, respectively, the conditions

$$\partial_\sigma\eta_1(\rho, 0) - \nu_0^*\eta_1 = 0 \qquad \text{for} \quad |\rho| > 1, \tag{4.4}$$

$$\eta_1(\rho, 0) = k(\rho) - \bar x f''(\varphi^*\rho + \varphi^m) - \eta_2(\rho, 0) \qquad \text{for} \quad |\rho| < 1, \tag{4.5}$$

$$\eta_1(\rho, -H^*) = 0 \qquad \text{for} \quad \rho \in \mathbf{R}, \tag{4.6}$$

$$\partial_\sigma\eta_2(\rho, 0) - \nu_0^*\,\eta_2 = l(\rho) + \nu^*\,\eta_0(\rho, 0) \qquad \text{for} \quad |\rho| > 1, \tag{4.7}$$

$$\eta_2(\rho, -H^*) = 0 \qquad \text{for} \quad \rho \in \mathbf{R}. \tag{4.8}$$

It is readily verified that if η_1, η_2 solve the system (4.4)–(4.8), their sum η solves Problem **L**; on the other hand, we know that (4.4)–(4.6) is solvable by Theorem 3.1. Now we will consider problem (4.7)–(4.8). By the definition of the space $Y_{\rho_0,\bar\rho}$ and by the continuation properties of Sobolev space functions [12, Par. 1.4.3], we can assume that the datum l on the right-hand side of (4.7) is defined on $\mathbf{R}$ and satisfies $l|_{(-\bar\rho,\bar\rho)} \in W_p^{1-\frac{1}{p}}(-\bar\rho, \bar\rho)$. Furthermore, let us define

$$l^*(\rho) = l(\rho) + \nu^*\,\eta_0(\rho, 0), \quad \rho \in \mathbf{R}. \tag{4.9}$$

We denote by Z the set of functions l^* defined in $\mathbf{R}$ such that

$$l^*|_{(-\bar\rho,\bar\rho)} \in W_p^{1-\frac{1}{p}}(-\bar\rho,\bar\rho) \quad \text{and have property (3.16) in } \mathbf{R}\backslash(-1,1).$$

We stress that a function $l^* \in Z$ may be decomposed as

$$l^*(\rho) = l_0^*(\rho) + \theta(\rho) l^\#(\rho), \tag{4.10}$$

where l_0^* is integrable and exponentially decaying for $|\rho| \to \infty$, while $l^\#$ is $2\pi/\mu$-periodic, continuously differentiable, and odd. We now discuss an auxiliary problem in the strip whose solution proves the existence of the required function η_2.

4.1. An auxiliary problem. Let us consider the following problem:

$$\Delta\Psi = 0 \qquad \text{in} \quad A^*, \tag{4.11}$$

$$\partial_\sigma \Psi(\rho,0) - \nu_0^*\, \Psi(\rho,0) = l^*(\rho) \qquad \text{for} \quad \rho \in \mathbf{R}, \tag{4.12}$$

$$\Psi(\rho,-H^*) = 0 \qquad \text{for} \quad \rho \in \mathbf{R}. \tag{4.13}$$

Moreover, we require that Ψ vanishes for $\rho \to -\infty$. Then, we have the following.

PROPOSITION 4.1. *For every $l^* \in Z$ there exists a function Ψ satisfying* (4.11)–(4.13) *and vanishing exponentially for $\rho \to -\infty$. Moreover, if l^* satisfies the linear condition*

$$\int_{-\pi/\mu}^{\pi/\mu} \sin(\mu\rho) l^\#(\rho) = 0, \tag{4.14}$$

then Ψ is bounded and asymptotically $2\pi/\mu$-periodic (with respect to ρ) for $\rho \to +\infty$.

Proof. Let us consider the convolution

$$(K \star l^*)(\rho,\sigma) = \int_{\mathbf{R}} K(\rho-\rho',\sigma) l^*(\rho')\, d\rho', \tag{4.15}$$

where

$$K(\rho,\sigma) = \frac{1}{2\pi} \int_{\mathbf{R}} e^{ip\rho} \frac{\sinh[p(\sigma+H^*)]}{p\cosh(pH^*) - \nu_0^* \sinh(pH^*)} dp. \tag{4.16}$$

We stress that the integrand in (4.16) has two simple poles at $p = \pm\mu$ on the real axis; therefore, the integral is understood as the Fourier transform of a tempered distribution, which can be evaluated by integrating along the path in the complex plane consisting of the intervals $(-\infty, -\mu-\epsilon)$, $(-\mu+\epsilon, \mu-\epsilon)$, $(\mu+\epsilon, +\infty)$ of the real axis and two semicircles of radius ϵ and center at $(\pm\mu, 0)$ surrounding the poles in the lower half plane. As a result, we obtain

$$K(\rho,\sigma) = \kappa(\rho,\sigma) + C\,\theta(\rho)\sin(\mu\rho)\sinh[\mu(\sigma+H^*)], \tag{4.17}$$

where C is a constant, θ is the characteristic function of the interval $(0,+\infty)$, and

$$\kappa(\rho,\sigma) = \sum_{n=0}^{\infty} c_n \sin[\lambda_n(\sigma+H^*)] e^{-\lambda_n|\rho|}.$$

The coefficients c_n are given by

$$c_n = [(1 - \nu_0^* H^*)\cos(\lambda_n H^*) - \lambda_n H^* \sin(\lambda_n H^*)]^{-1}, \quad n = 0, 1, 2 \ldots,$$

where λ_n are the positive solutions of the equation

$$\tan(\lambda H^*) = \frac{\lambda}{\nu_0^*}.$$

Note that $\lambda_n H^* \approx (n + 3/2)\pi$ for large n so that $|c_n| = \mathcal{O}(1/n)$. It follows in particular that $|\kappa(\rho, \sigma)| \leq C \log(|\rho|)$ for ρ in a neighborhood of the origin so that, for every $\sigma \in [-H^*, 0]$ and $p \geq 1$, the function $\rho \mapsto \kappa(\rho, \sigma)$ belongs to $L^p(\mathbf{R})$. Moreover, we have from (4.16) that $\Delta K = 0$ in A^* and that $K_\sigma(\rho, \sigma) - \nu_0^* K(\rho, \sigma) \to \delta(\rho)$ in $\mathcal{S}'(\mathbf{R})$ for $\sigma \to 0$; then (4.15) solves (4.11)–(4.13) at least for $l^* \in \mathcal{S}(\mathbf{R})$. We will now show that (4.15) is well defined also for $l^* \in Z$ and that the proposition holds with $\Psi = (K \star l^*)$.

Let us first consider the function $\kappa \star l^*$; by (4.10), we can write

$$(\kappa \star l^*)(\rho, \sigma) = (\kappa \star l_0^*)(\rho, \sigma) + \int_0^{+\infty} \kappa(\rho - \rho', \sigma) l^\#(\rho') d\rho'.$$

By explicit bounds using the integrability and the decay properties of the factors we get $|(\kappa \star l_0^*)(\rho, \sigma)| \leq Ce^{-\lambda^* |\rho|}$, where C depends on the norms of κ and l_0^* in $L^1(\mathbf{R})$. The second term is a bounded function defined in $\mathbf{R}$ and decreasing like $Ce^{\lambda_0 \rho}$ for large negative values of ρ (recall that $\lambda_0 > \lambda^*$); moreover, we have the identity

$$\int_0^{+\infty} \kappa(\rho - \rho', \sigma) l^\#(\rho') d\rho' = \int_{\mathbf{R}} \kappa(\rho', \sigma) l^\#(\rho - \rho') d\rho' - \int_\rho^{+\infty} \kappa(\rho', \sigma) l^\#(\rho - \rho') d\rho'. \tag{4.18}$$

Recalling that $l^\#$ is periodic and odd and observing that $\kappa(-\rho, \sigma) = \kappa(\rho, \sigma)$, we have that the first term on the right-hand side is periodic and odd with respect to ρ. The second term is also vanishing as $Ce^{-\lambda_0 \rho}$ for $\rho \to +\infty$. Let us now consider the convolution between l^* and the last term of (4.17); it is proportional to the function

$$\sinh[\mu(\sigma + H^*)] \int_{-\infty}^{\rho} \sin[\mu(\rho - \rho')] l^*(\rho') d\rho', \tag{4.19}$$

which is bounded by $Ce^{\lambda^* \rho}$ for $\rho \to -\infty$. To study the other limit, we write

$$\int_{-\infty}^{\rho} \sin[\mu(\rho - \rho')] l^*(\rho') d\rho' = [A(\rho) + P_c(\rho)] \sin(\mu\rho) + [B(\rho) + P_s(\rho)] \cos(\mu\rho), \tag{4.20}$$

where

$$A(\rho) = \int_{-\infty}^{\rho} l_0^*(\rho') \cos(\mu\rho') d\rho', \quad B(\rho) = -\int_{-\infty}^{\rho} l_0^*(\rho') \sin(\mu\rho') d\rho', \tag{4.21}$$

$$P_c(\rho) = \int_0^{\rho} \cos(\mu\rho') l^\#(\rho') d\rho', \quad P_s(\rho) = -\int_0^{\rho} \sin(\mu\rho') l^\#(\rho') d\rho'. \tag{4.22}$$

By expanding $l^\#$ in Fourier sine series and integrating term by term in (4.22), we find that the function P_s is bounded (and periodic) only if condition (4.14) holds. We point out that a second "nonresonance" condition for P_c is ruled out by the choice of

an odd $l^{\#}$. Then the right-hand side of (4.20) approaches a $2\pi/\mu$-periodic function for $\rho \to +\infty$; note that such a function is *not* odd, unless $\lim_{\rho\to+\infty} B(\rho) = 0$.

It remains to prove that (4.15) actually solves the problem. We point out that, by (4.10), the Fourier transform in $\mathcal{S}'$ of a function $l^* \in Z$ has the form

$$\hat{l}^*(p) = \hat{l}_0^*(p) - \sum_{n=1}^{\infty} b_n \hat{l}_n^*(p), \tag{4.23}$$

where $\hat{l}_0^*(p)$ is a smooth function, b_n are the coefficients of the Fourier series of $l^{\#}$, and $\hat{l}_n^*(p) = \lim_{\epsilon\to 0} n\mu/[(p-i\epsilon)^2 - (n\mu)^2]$ (the limit being in $\mathcal{S}'(\mathbf{R})$). Then we can define the one-parameter family of tempered distributions

$$\hat{\Psi}(p,\sigma) = \frac{\sinh[p(\sigma+H^*)]}{p\cosh(pH^*) - \nu_0^* \sinh(pH^*)} \hat{l}^*(p), \quad \sigma \in [-H, 0],$$

where the first factor on the right-hand side is regularized as in the discussion following (4.16). It is readily checked that

$$\lim_{\sigma\to 0} [\partial_\sigma \hat{\Psi}(p,\sigma) - \nu_0^* \hat{\Psi}(p,\sigma)] = \hat{l}^*(p)$$

in the distributional sense. Thus, by the properties of the Fourier transform $\mathcal{F}$ in $\mathcal{S}'$ (see [13], Thm. 7.15) we have that the inverse transform $\mathcal{F}^{-1}\hat{\Psi}$ solves (4.11)–(4.13) and is equal (a.e.) to the convolution (4.15). □

Remark 4.2. We remark that if (4.14) holds, the coefficient b_1 of the series on the right-hand side of (4.23) vanishes. As a consequence, in evaluating the inverse Fourier transform of $\hat{\Psi}$ by complex plane integration, we have only contributions of *simple poles*, which produce the oscillating terms of the solution at $+\infty$. If $b_1 \neq 0$, there are poles of order two at $p = \pm\mu$, generating a "resonance" term in Ψ, whose amplitude grows linearly for $\rho \to +\infty$, in agreement with the previous calculations (see (4.20) and (4.22)).

By taking l^* as in (4.9) we can now choose $\eta_2 = \Psi$ as the harmonic function satisfying (4.7) and (4.8). We now show that there is a unique value of ν^* such that (4.14) holds. For, by (4.9) and by the asymptotic properties of η_0, we have

$$l^{\#}(\rho) = l_{\#}(\rho) + \nu^* A_0 \sinh(\mu H^*) \sin(\mu\rho);$$

inserting in (4.14) we find

$$\nu^* = -\frac{1}{\pi A_0 \sinh(\mu H^*)} \int_{-\pi/\mu}^{\pi/\mu} l_{\#}(\rho) \sin(\mu\rho) d\rho. \tag{4.24}$$

4.2. Invertibility of the Frechet derivative. We can now state the main result of this section.

THEOREM 4.3. *Let $\nu_0^* > 1/H^*$, and assume that*

$$F(\varphi^m, \varphi^*) \equiv \int_{-1}^{1} f''(\varphi^*\rho + \varphi^m)\beta(\rho) d\rho \neq 0. \tag{4.25}$$

Then, for every pair $(k,l) \in Y$, there is a unique pair $(\bar{x}, \nu^*) \in \mathbf{R}^2$ such that Problem **L** *is uniquely solvable in X.*

Proof. We first note that, by Theorems 3.1 and 3.2, there is a unique harmonic function η_1 which satisfies (4.4)–(4.6) and the asymptotic condition (3.7). Then the function $\eta = \eta_1 + \eta_2$, with η_2 defined in section 4.1, satisfies (4.1)–(4.3) and vanishes (exponentially) at $-\infty$. Moreover, by choosing ν^* as in (4.24), we have that η is bounded and asymptotically $2\pi/\mu$-periodic for $\rho \to +\infty$. It remains to satisfy the symmetry condition. To this aim, we recall that by (4.18)–(4.22) the function η_2 approaches, for $\rho \to +\infty$, the sum of an odd (periodic) function with the function

$$B_+ \cos(\mu\rho) \sinh[\mu(\sigma + H^*)], \tag{4.26}$$

where B_+ is proportional to the limit for $\rho \to +\infty$ of the function $B(\rho)$ defined in (4.21). On the other hand, by denoting with k^* the right-hand side of (4.5), we have for large positive values of ρ

$$\eta_1 \approx [A_1 \sin(\mu\rho) + B_1 \cos(\mu\rho)] \sinh[\mu(\sigma + H^*)], \tag{4.27}$$

where, by recalling (3.10), $B_1 = \int_{-1}^{1} k^*(\rho)\beta(\rho)d\rho$.

Then η is asymptotically odd if

$$B_1 + B_+ = 0.$$

By the definition of k^* and by (4.25) the above equation is satisfied by choosing

$$\bar{x} = \frac{1}{F(\varphi^*, \varphi^m)} \left\{ B_+ + \int_{-1}^{1} [k(\rho) - \eta_2(\rho, 0)]\beta(\rho)d\rho \right\}. \tag{4.28}$$

It remains to prove uniqueness. Assume that the real numbers $\tilde{x}$ and $\tilde{\nu}^*$ and the function $\tilde{\eta}$ solve the *homogeneous* Problem **L**. By Proposition 4.1, there is a harmonic function $\tilde{\eta}_2$, vanishing for $\rho \to -\infty$, bounded by a linear function for $\rho \to +\infty$ (see Remark 4.2), and satisfying conditions (4.7), (4.8) with $l = 0$ and $\nu^* = \tilde{\nu}^*$. As a consequence, $\tilde{\eta}_1 = \tilde{\eta} - \tilde{\eta}_2$ solves (4.4)–(4.6) with $k = 0$ and with $\bar{x} = \tilde{x}$ and satisfies the same conditions at infinity. Then, by Theorems 3.1 and 3.2, such an $\tilde{\eta}_1$ is uniquely determined and satisfies (3.7); it follows that $\tilde{\eta}$ is bounded and asymptotically periodic only if $\tilde{\eta}_2$ has the same properties. By (4.24), this implies $\tilde{\nu}^* = 0$ so that $\tilde{\eta}_2 = 0$. In this case, condition (4.5) becomes $\tilde{\eta}_1(\rho, 0) = -\tilde{x} f''(\varphi^*\rho + \varphi^m)$, for $|\rho| < 1$. However, by condition (4.25), $\tilde{\eta} = \tilde{\eta}_1$ cannot approach an odd (periodic) function for $\rho \to +\infty$, unless $\tilde{x} = 0$. Then we also get $\tilde{\eta} = 0$.

We could now deduce local solvability of (2.25) by the implicit function theorem. We recall, however, that Theorem 4.3 has been proved by assuming a specific symmetry of the solutions at downstream infinity, starting from the additional condition that the right-hand side of (3.10) vanishes. We now show that the theorem holds without this extra assumption if one suitably modifies the definitions of the function spaces X, Y and the condition (4.25); at the end of the section, we will discuss the restrictions on the form of the cylinder's profile f for the validity of the latter condition.

Recalling the discussion at the end of section 3.1, if $\delta_0^* \neq 0$ in (3.12), we change the definition (3.13) of the space X by requiring that the limit function $\chi^\#$ satisfies the condition $\chi^\#(-\rho - \delta_0^*, \sigma) = \overline{\chi^\#(\rho - \delta_0^*, \sigma)}$. Similarly, in the definition (3.16) of the space $Y_{\rho_0,\bar{\rho}}$ we assume $l_\#(-\rho - \delta_0^*) = -l_\#(\rho - \delta_0^*)$; then we can formulate Problem **L** as before, referring to the new spaces X, Y. We can also modify in the obvious way the definition of the space Z below (4.9) and the properties of the function $l^\#$ in the decomposition (4.10). The first crucial remark is that a solution of the auxiliary

problem (see section 4.1) with datum l^* in the new space Z is simply a translation (with respect to ρ) of the solution Ψ given by Proposition 4.1, corresponding to the asymptotically odd datum $\rho \mapsto l^*(\rho - \delta_0^*)$. More precisely, Proposition 4.1 is now satisfied by the function $(\rho, \sigma) \mapsto \Psi(\rho + \delta_0^*, \sigma)$, provided the following condition holds:

$$\int_{-\pi/\mu}^{\pi/\mu} \sin[\mu(\rho + \delta_0^*)] l^{\#}(\rho) = 0. \tag{4.29}$$

We can now proceed as in section 4.1 and choose $\eta_2(\rho, \sigma) = \Psi(\rho + \delta_0^*, \sigma)$ to satisfy conditions (4.7), (4.8); by (4.9) and recalling (3.11), we easily check that there is again a unique value of ν^* such that (4.29) holds. Let us now turn to Theorem 4.3; we define as before $\eta = \eta_1 + \eta_2$, with η_1 solving (4.4)–(4.6) and satisfying the asymptotic condition (4.27); then, by a suitable translation of (4.26) we find that η belongs to the (new) space X if

$$(A_1 - B_+ \sin\delta_0)\sin(\mu\rho) + (B_1 + B_+ \cos\delta_0)\cos(\mu\rho) = C\sin(\mu\rho + \delta_0),$$

that is,

$$A_1 \sin\delta_0 - B_1 \cos\delta_0 = B_+. \tag{4.30}$$

Note that, for $\delta_0 = 0$, (4.30) reduces to the previous condition $B_1 + B_+ = 0$. Recalling (3.9), (3.10), if the assumption (4.25) is replaced by

$$F_0(\varphi^m, \varphi^*) \equiv \int_{-1}^{1} f''(\varphi^*\rho + \varphi^m)[\cos\delta_0\, \beta(\rho) - \sin\delta_0\, \alpha(\rho)]d\rho \neq 0, \tag{4.31}$$

we can solve (4.30) by choosing

$$\bar{x} = \frac{1}{F_0(\varphi^*, \varphi^m)} \left\{ B_+ + \int_{-1}^{1} [k(\rho) - \eta_2(\rho, 0)][\cos\delta_0\, \beta(\rho) - \sin\delta_0\, \alpha(\rho)]d\rho \right\}. \tag{4.32}$$

The rest of the proof of Theorem 4.3 now follows with obvious modifications. Now, with the new definitions of the space X (and Y) and by the implicit function theorem, we can state the following.

THEOREM 4.4. *Let $f \in \mathcal{C}^{3,1}$, $(\varphi^m, \varphi^*) \in \Phi \subset \mathbf{R}^2$, and $\mathcal{U} \subset X \times \mathbf{R}^2$ be given as in Theorem* 3.6*; moreover, assume that condition* (4.31) *holds, with δ_0 defined by the asymptotic condition* (3.11)*. Then there exists $\epsilon_0 > 0$ such that, for every $\epsilon \in [0, \epsilon_0)$, the equation $\mathbf{B}(\chi, \bar{x}, \nu^*, \varphi^m, \varphi^*, \epsilon) = 0$ has a unique solution*

$$(\chi(\varphi^m, \varphi^*, \epsilon), \nu(\varphi^m, \varphi^*, \epsilon), \bar{x}(\varphi^m, \varphi^*, \epsilon)) \in \mathcal{U}.$$

Moreover, the map $\epsilon \mapsto (\chi(\varphi^m, \varphi^*, \epsilon), \nu(\varphi^m, \varphi^*, \epsilon), \bar{x}(\varphi^m, \varphi^*, \epsilon))$ is differentiable.

In view of the discussion of the last conditions (2.13), (2.13′), it will be important to investigate the properties the function F_0 defined in (4.31) (see section 5 and the appendix). We remark here that the form of this function also depends on the data c_0, H, f'. □

5. Solution of the additional conditions. Theorem 4.4 provides, for a given pair of parameters φ^m, φ^*, a function χ holomorphic in A^*, satisfying the requested conditions on the boundary of A^* and the prescribed asymptotic behavior. We still

have to satisfy the continuity condition (2.13) and the additional condition (2.13′). These two conditions, when $\epsilon \to 0$, reduce to

$$\begin{cases} -\varphi^* \displaystyle\int_{-\infty}^{-1} \eta_0(s,0)ds = f(\varphi^m - \varphi^*), \\ \frac{c_0^2}{g}\xi_0(1,0) = f(\varphi^m + \varphi^*). \end{cases} \tag{5.1}$$

Here η_0 is the solution to Problem $\mathbf{L_0}$, and ξ_0 is its harmonic conjugate vanishing at infinity upstream. We shall prove that there exists a pair of numbers (φ^m, φ^*) satisfying system (5.1); then, by a continuity argument, we will deduce the existence, for small enough values of ϵ, of a pair solving (2.13) and (2.13′). Notice that, by integrating from $-\infty$ to -1 the boundary condition following (3.1), we get

$$-\varphi^* \int_{-\infty}^{-1} \eta_0(s,0)ds = \frac{c_0^2}{g}\xi_0(-1,0).$$

Then, by returning to the parameters $\varphi_\pm$ (see (2.14)), we can write system (5.1) in the form

$$\begin{cases} f(\varphi_-/c_0) = \frac{c_0^2}{g}\xi_0(-1,0;\varphi_-,\varphi_+), \\ f(\varphi_+/c_0) = \frac{c_0^2}{g}\xi_0(1,0;\varphi_-,\varphi_+). \end{cases} \tag{5.2}$$

Here we have stressed the dependence of ξ_0 on the unknowns $\varphi_\pm$. By arguments similar to those used in the proof of Proposition 4.1 in [2], one finds that the maps $(\varphi_-,\varphi_+) \mapsto \xi_0(\pm 1,0;\varphi_-,\varphi_+)$ are continuous on the second quadrant of the plane (φ_-,φ_+). We first show that system (5.2) has a solution. Let us fix $R>0$ and define $\mathcal{Q}_R = (-c_0R, 0)\times(0, c_0R)$; consider now the function

$$\mathbf{G} : \mathcal{Q}_R \to \mathbf{R}^2,$$

$$G_1(\varphi_-,\varphi_+) = f(\varphi_-/c_0) - \frac{c_0^2}{g}\xi_0(-1,0;\varphi_-,\varphi_+), \tag{5.3}$$

$$G_2(\varphi_-,\varphi_+) = f(\varphi_+/c_0) - \frac{c_0^2}{g}\xi_0(1,0;\varphi_-,\varphi_+). \tag{5.4}$$

Then we have the following.

LEMMA 5.1. *Let f be a function satisfying* (1.3) *and such that $f' \in W_p^{2-\frac{1}{p}}$ on any interval including the origin; assume further that f satisfies the growth condition $f(x) \approx C_0|x|^\alpha$ (C_0, α positive constants) for large $|x|$ and that this relation can be differentiated. Then there exists $R>0$ such that $G_1(-c_0R,\varphi_+) > 0$ for $0<\varphi_+<c_0R$ and $G_2(\varphi_-, c_0R) > 0$ for $-c_0R < \varphi_- < 0$.*

Proof. By recalling Remark 3.3, the quantities $|\xi_0(\pm 1,0;\varphi_-,\varphi_+)|$ can be bounded by a (local) Sobolev norm of the solution of Problem $\mathbf{L_0}$; then, mapping the problem in the plane of the scaled hodograph variables $(\varphi/c_0, \psi/c_0)$ (which equal the physical space variables at $\epsilon = 0$; see the discussion following (2.4), (2.5)) and using estimates on the solution (see, e.g., [1, equation (4.9)]), it can be proved that the absolute values of the right-hand sides of (5.2) are bounded by the Sobolev norm of f' in the interval $(\varphi_-/c_0, \varphi_+/c_0)$. Then the proposition follows by the assumptions on the growth of f and its derivatives. ∎

Remark 5.2. We note that the quantities $|\xi_0(\pm 1, 0; \varphi_-, \varphi_+)|$ decrease to zero for $\varphi_+ - \varphi_- \to 0$; this means that, in this limit, both components of $\mathbf{G}$ are strictly negative.

PROPOSITION 5.3. *Let f satisfy the assumptions of Lemma* 5.1*; suppose further that for every point in $\mathcal{Q}_R$ with $\varphi_- = 0$ or $\varphi_+ = 0$ we have*

$$f(0) < \frac{c_0^2}{g}\xi_0(1, 0; 0, \varphi_-), \quad f(0) < \frac{c_0^2}{g}\xi_0(-1, 0; \varphi_+, 0). \tag{5.5}$$

Then system (5.2) *has a solution.*

Proof. By Lemma 5.1, conditions (5.5) and definitions (5.3), (5.4) we have

$$G_1(-c_0 R, \varphi_+) > 0, \qquad G_1(0, \varphi_+) < 0$$

for $0 < \varphi_+ < c_0 R$ and

$$G_2(\varphi_-, c_0 R) > 0, \qquad G_2(\varphi_-, 0) < 0$$

for $0 < \varphi_- < c_0 R$. Now the statement that the map $\mathbf{G}$ has a zero in $\mathcal{Q}_R$ is equivalent to the Brouwer fixed point theorem. ∎

Remark 5.4. Regarding condition (5.5), we notice that, in the linear problem, the two quantities $\frac{c_0^2}{g}\xi_0(\pm 1, 0)$ represent the height of the free boundary at the contact points with the cylinder. Then, roughly speaking, the two inequalities in (5.5) state the (quite natural) requirement that the free surface reaches the cylinder's hull at least at the minimum of its profile (placed at $x = 0$). It can be shown that, for fixed $(\varphi_-/c_0, \varphi_+/c_0)$, the quantities $\frac{c_0^2}{g}\xi_0(\pm 1, 0)$ are vanishing for $c_0 \to 0$; hence, the assumptions of Proposition 5.3 hold (for a given f) if the velocity c_0 is small enough. This is in agreement with the physical intuition, since for small values of the velocity the perturbation of the free boundary from the line $y = 0$ should be small, even if compared to the width of a thin obstacle. It is also clear that, for $c_0 \ll 1$, the solutions of (5.2) are such that $\varphi_-/c_0 \approx a$ and $\varphi_+/c_0 \approx b$, where a, b are, respectively, the negative and positive solutions of $f = 0$ (see (1.3)).

Now, assuming that condition (4.31) holds for every pair (φ^*, φ_m) corresponding (through (2.14)) to a point of $\mathcal{Q}_R$, we get the solvability of the system (2.13), (2.13′) for small ϵ. In fact, by Theorem 4.4, we can define a map $\epsilon \mapsto \Omega(\varphi, 0; \varphi_+, \varphi_-, \epsilon)$ such that the composite maps appearing in (2.13), (2.13′) are continuous on $\mathcal{Q}_R$; moreover, (2.13), (2.13′) reduce to (5.1) (that is, (5.2)) when $\epsilon \to 0$.

Thus, as remarked at the end of the previous section, we should study the domain of validity of condition (4.31) for a given profile f and positive c_0, H satisfying (1.1); we note, however, that it is not strictly necessary to satisfy such a condition at every point of $\mathcal{Q}_R$. In fact, by homotopy with the linear map $(\varphi_-, \varphi_+) \mapsto (-\frac{2}{c_0 R}\varphi_- - 1, \frac{2}{c_0 R}\varphi_+ - 1)$, it follows that the topological degree $\deg(\mathcal{Q}_R, \mathbf{G}, \mathbf{0})$ is equal to 1; then, if the solutions of (5.2) are isolated points in $\mathcal{Q}_R$, there is at least one solution $\Phi^* = (\varphi_-^*, \varphi_+^*)$ with local mapping degree (or index $i(\mathbf{G}, \Phi^*, \mathbf{0})$) different from zero by the index sum theorem [15]. Now, assuming only that (4.31) holds at Φ^* and observing that the function F_0 appearing in this condition is continuous, we can still define a map $\epsilon \mapsto \Omega(\varphi, 0; \varphi_+, \varphi_-, \epsilon)$ in a suitable neighborhood of this point and write (2.13), (2.13′) as small perturbations of (5.1) in the same neighborhood; by the continuity property, the local mapping degree does not change for small enough ϵ so that (2.13), (2.13′) have a solution near Φ^*. Then we introduce the following definition:

DEFINITION 5.5. *We say that a pair of positive real numbers c_0, H satisfying* (1.1) *and a real function f (satisfying* (1.3)*) are* admissible data *for the nonlinear problem if the following conditions hold:*

(i) *f satisfies the assumptions of Theorem* 4.4 *and has polynomial growth;*
(ii) *relations* (5.5) *hold;*
(iii) *condition* (4.31) *is satisfied at least for one solution $\Phi^* = (\varphi_-^*, \varphi_+^*)$ of system* (5.2) *with index $i(\mathbf{G}, \Phi^*, \mathbf{0}) \neq 0$.*

In the appendix, by exploiting some qualitative properties of the function F_0, we will show, as an example, that all the conditions of the above definition are satisfied for hulls with parabolic profiles and for every subcritical value of the Froude number $c_0/\sqrt{gH}$.

Summing up the previous results, we can finally state our main result.

THEOREM 5.6. *Let f, c_0, H be admissible data as in Definition* 5.5. *Then one can find $\epsilon_0 > 0$ such that, for every $\epsilon \in [0, \epsilon_0)$, there exist a positive constant c ($c = c_0$ at $\epsilon = 0$), two real numbers $x_- < 0$, $x_+ > 0$, a real function $h(x)$ on $(-\infty, x_-) \cup (x_+, +\infty)$, and a complex function ω holomorphic in the domain S^* defined by* (1.5) *such that conditions* (1.6)–(1.12) *hold. Moreover, the free surface and the cylinder profile form a single $\mathcal{C}^1$ streamline, given in parametric form by*

$$\begin{cases} x(\rho) = \bar{x} + \varphi^* \displaystyle\int_{\rho^m}^{\rho} (1 + \epsilon\xi(s,0))ds, \\ y(\rho) = -\epsilon\varphi^* \displaystyle\int_{-\infty}^{\rho} \eta(s,0)ds, \end{cases} \qquad \rho \in \mathbf{R},$$

where $\varphi^* > 0$, ρ^m, and $\bar{x} \in (x_-, x_+)$ are known quantities (depending on ϵ) and the functions $\xi(\rho, 0)$, $\eta(\rho, 0)$ are now determined from Theorem 4.4. *By the properties of ξ and η, the free surface is exponentially vanishing for $x \to -\infty$ and is bounded and asymptotic to a $\frac{2\pi}{\mu_0}$-periodic function when $x \to +\infty$; here μ_0 is the positive solution of the equation*

$$\tanh(\mu_0 H) = \mu_0 \frac{c_0^2}{g}.$$

As a concluding remark, we observe that, in contrast with the situation encountered in the supercritical case, we are not able to give more detailed information on the location of the contact points $x_\pm$.

Appendix. In part I we prove Theorem 3.2 and property (iii) of Remark 3.3. Moreover, by exploiting some technical results obtained in the course of the proof (see Proposition A.4 below) in part II we write a more explicit form of the function F_0 defined in (4.31) and provide simple examples of data satisfying Definition 5.5.

I. To begin with, we need the following result, which is proved in [3, section 4].

PROPOSITION A.1. *For every $\nu_0^* > 1/H^*$ such that $\mu \neq n\pi/2$ (with μ the solution of* (3.6) *there are nontrivial harmonic functions ζ^s, ζ^c satisfying* (3.2), (3.4) *and the homogeneous condition* (3.3) *(i.e., with $f' = 0$) and with the following properties:*

$$\zeta^s(-\rho, \sigma) = -\zeta^s(\rho, \sigma), \qquad \zeta^c(-\rho, \sigma) = \zeta^c(\rho, \sigma), \tag{A.1}$$

$$\zeta^s(\rho, \sigma) = [\mathcal{A}_s \sin(\mu\rho) + \operatorname{sgn}(\rho)\mathcal{B}_s \cos(\mu\rho)] \sinh[\mu(\sigma + H^*)] + \zeta_0^s(\rho, \sigma), \tag{A.2}$$

$$\zeta^c(\rho, \sigma) = [\operatorname{sgn}(\rho)\mathcal{A}_c \sin(\mu\rho) + \mathcal{B}_c \cos(\mu\rho)] \sinh[\mu(\sigma + H^*)] + \zeta_0^c(\rho, \sigma)), \tag{A.3}$$

where the functions ζ_0^s, ζ_0^c are exponentially decreasing as $\rho \to \infty$ and the coefficients $\mathcal{A}_s$, $\mathcal{A}_c$, $\mathcal{B}_s$, $\mathcal{B}_c$ depend analytically on μ and are such that

$$\mathcal{A}_s\mathcal{B}_c - \mathcal{B}_s\mathcal{A}_c = \Lambda(\mu)\sin\mu\cos\mu, \tag{A.4}$$

with $\Lambda(\mu) > 0$. We stress that the functions ζ^s, ζ^c do not satisfy the asymptotic condition (3.5) and therefore are *not* solutions of the homogeneous Problem $\mathbf{L_0}$. However, they play a crucial role in the proof of unique solvability in Theorem 3.1; in fact, it is proved in [3, Theorem 4.7] that if $\mu \neq n\pi/2$ the solution of Problem $\mathbf{L_0}$ is uniquely determined and has the form

$$\eta_0 = \tilde{\eta}_0 + \alpha_0\zeta^s + \beta_0\zeta^c, \tag{A.5}$$

where $\tilde{\eta}_0$ is a suitably defined harmonic function satisfying the conditions of Problem $\mathbf{L_0}$ *except for the asymptotic condition* (it is in general oscillating at both limits $x \to \pm\infty$; see [3, Proposition 4.3]) and the coefficients α_0, β_0 are uniquely determined by imposing condition (3.5).

Now there are further properties of the functions ζ^s, ζ^c and of the coefficients α_0, β_0 which allow us to prove solvability when the relation $\mu = n\pi/2$ holds. Actually, we have the following.

PROPOSITION A.2. *Let η_0 be the solution of Problem $\mathbf{L_0}$ given by Theorem* 3.1. *Then there exists the limit of η_0 for $\mu \to n\pi/2$ and is still a solution of Problem $\mathbf{L_0}$ with the same regularity and asymptotic properties.*

Proof. Let η_0 be given by (A.5). By Proposition 4.3 of [3], the function $\tilde{\eta}_0$ on the right-hand side is defined for every positive value of μ and satisfies the regularity properties discussed in Remark 3.3; further results in [3] (see section 4 and the appendix) show that the coefficients $\mathcal{A}_s$, $\mathcal{B}_s$ and the function ζ_0^s in (A.2) are proportional to $\sin\mu$, while the coefficients $\mathcal{A}_c$, $\mathcal{B}_c$ and the function ζ_0^c in (A.3) are proportional to $\cos\mu$. Then the functions $\frac{1}{\sin\mu}\zeta^s$, $\frac{1}{\cos\mu}\zeta^c$ have well-defined *uniform limits* in the strip A^* for $\mu \to n\pi/2$, $n = 1, 2, \ldots$; such limits define nontrivial harmonic functions in the strip satisfying the same homogeneous boundary conditions. On the other hand, it follows by explicit calculation (see [3, equation (4.21)]) that for $\mu \neq n\pi/2$ the coefficients of ζ^s, ζ^c in (A.5) have the form

$$\alpha_0 = \frac{\Lambda_{f'}(\mu)}{\sin\mu}, \qquad \beta_0 = \frac{\Lambda_{f'}(\mu)}{\cos\mu},$$

where, for every positive μ, $\Lambda_{f'}(\mu)$ is a linear functional proportional to

$$\int_{-1}^{1} f'(\varphi^*\rho + \varphi^m)\Big[\frac{1}{\cos\mu}\zeta_\sigma^c(\rho,0) - \frac{1}{\sin\mu}\zeta_\sigma^s(\rho,0)\Big]d\rho. \tag{A.6}$$

(The traces of the derivatives ζ_σ^s, ζ_σ^c are continuous functions on $[-1,1]$ by the regularity results of [3]). From the previous discussion, we have that the uniform limits for $\mu \to n\pi/2$, $n = 1, 2, \ldots$, of the functions η_0 given by Theorem 3.1 exist and are solutions to Problem $\mathbf{L_0}$ corresponding to the values $n\pi/2$ of the solution of (3.6). ∎

In order to prove the uniqueness statement of Theorem 3.2, we investigate the relation between the coefficients A_0, B_0 in the asymptotic representation (3.7) and the functions ζ^s, ζ^c.

LEMMA A.3. *Let η_0 be a solution of Problem $\mathbf{L_0}$ with $\mu \neq n\pi/2$, and let ζ^s, ζ^c be defined by Proposition* A.1. *Then the following formulas hold:*

$$A_0 = \frac{K^*}{\mu\Lambda\sin\mu\cos\mu}\int_{-1}^{1} f'(\varphi^*\rho + \varphi^m)[\mathcal{A}_c\zeta_\sigma^s(\rho,0) - \mathcal{A}_s\zeta_\sigma^c(\rho,0)]d\rho, \tag{A.7}$$

$$B_0 = \frac{K^*}{\mu\Lambda \sin\mu\cos\mu}\int_{-1}^{1} f'(\varphi^*\rho+\varphi^m)[\mathcal{B}_c\zeta^s_\sigma(\rho,0)-\mathcal{B}_s\zeta^c_\sigma(\rho,0)]d\rho, \tag{A.8}$$

where Λ *is defined by* (A.4) *and*

$$K^* = \frac{2}{H^*}\Big(\frac{\sinh(2\mu H^*)}{2\mu H^*}-1\Big)^{-1}. \qquad \square$$

Proof. Apply Green's formula to η_0 and to each of the harmonic functions ζ^s, ζ^c in the bounded rectangle $(-R,R)\times(-H^*,0)$, with $R>1$; then, letting $R\to\infty$ and taking account of (3.7), (A.2), and (A.3) (which can be differentiated with respect to ρ) we get

$$\begin{aligned}
0 &= \int_{-1}^{1} f'(\varphi^*\rho+\varphi^m)\zeta^s_\sigma(\rho,0)d\rho \\
&+ \lim_{R\to+\infty}\int_{-H^*}^{0}\Big[\zeta^s(R,\sigma)\partial_\rho\eta_0(R,\sigma)-\eta_0(R,\sigma)\zeta^s_\rho(R,\sigma)\Big]d\sigma \\
&= \int_{-1}^{1} f'(\varphi^*\rho+\varphi^m)\zeta^s_\sigma(\rho,0)d\rho \\
&+ \mu(A_0\mathcal{B}_s - B_0\mathcal{A}_s)\int_{-H^*}^{0}\sinh^2[\mu^*(\sigma+H^*)]d\sigma,
\end{aligned}$$

$$\begin{aligned}
0 &= \int_{-1}^{1} f'(\varphi^*\rho+\varphi^m)\zeta^c_\sigma(\rho,0)d\rho \\
&+ \lim_{R\to+\infty}\int_{-H^*}^{0}\Big[\zeta^c(R,\sigma)\partial_\rho\eta_0(R,\sigma)-\eta_0(R,\sigma)\zeta^c_\rho(R,\sigma)\Big]d\sigma \\
&= \int_{-1}^{1} f'(\varphi^*\rho+\varphi^m)\zeta^c_\sigma(\rho,0)d\rho \\
&+ \mu(A_0\mathcal{B}_c - B_0\mathcal{A}_c)\int_{-H^*}^{0}\sinh^2[\mu^*(\sigma+H^*)]d\sigma.
\end{aligned}$$

Then, (A.7) and (A.8) follow by elementary calculations. $\square$

PROPOSITION A.4. *Let* $\mu\neq n\pi/2$*; then the relations* (3.9), (3.10) *are satisfied by choosing*

$$\alpha(\rho) = \frac{K^*}{\mu\Lambda\sin\mu\cos\mu}[\mathcal{A}_c\zeta^s_\sigma(\rho,0)-\mathcal{A}_s\zeta^c_\sigma(\rho,0)], \tag{A.9}$$

$$\beta(\rho) = \frac{K^*}{\mu\Lambda\sin\mu\cos\mu}[\mathcal{B}_c\zeta^s_\sigma(\rho,0)-\mathcal{B}_s\zeta^c_\sigma(\rho,0)]. \tag{A.10}$$

Moreover, the right-hand sides of (A.9), (A.10) *have limits for* $\mu\to n\pi/2$*, which verify* (3.9), (3.10) *for* $\mu = n\pi/2$.

Proof. From (A.7), (A.8), the above defined α, β verify relations (3.9), (3.10) for $\mu\neq n\pi/2$. On the other hand, recalling the proof of Proposition A.2, the proof of Lemma A.3 is also valid for $\mu = n\pi/2$ by replacing ζ^s, ζ^c with the limits for

$\mu \to n\pi/2$ of $\frac{1}{\sin\mu}\zeta^s$, $\frac{1}{\cos\mu}\zeta^c$, respectively. Furthermore, it is easily checked that also the right-hand sides of (A.9), (A.10) have finite uniform limits for $\mu \to n\pi/2$. Hence, the proposition follows. □

Proof of Theorem 3.2. Existence of a solution η_0 for the "singular values" of μ follows from Proposition A.2. Suppose that $\hat{\eta}_0$ is another solution corresponding to $\mu = n\pi/2$ and with the same boundary data; then by (3.9), (3.10) we have that $\hat{\eta}_0$ satisfies (3.7) with the same coefficients A_0, B_0 as η_0. Then $\eta_0 - \tilde{\eta}_0$ is a waveless solution of the *homogeneous* Problem $\mathbf{L_0}$; in particular, $\eta_0 - \hat{\eta}_0$ belongs to $H^1(A^*)$. By the uniqueness of a variational solution (see [14, Theorem 4.7]) we get $\eta_0 = \tilde{\eta}_0$.

II. *Discussion of condition* (4.31) *and an example of data satisfying Definition* 5.5. From (A.9), (A.10), the function F_0 in condition (4.31) can be written

$$F_0(\varphi^*, \varphi^m) = \int_{-1}^{1} f''(\varphi^*\rho + \varphi^m)\gamma_0(\rho)d\rho,$$

where $\gamma_0(\rho)$ is proportional to the function

$$\frac{1}{\sin\mu\cos\mu}\Big[(\cos\delta_0\,\mathcal{B}_c - \sin\delta_0\,\mathcal{A}_c)\zeta^s_\sigma(\rho,0) - (\cos\delta_0\mathcal{B}_s - \sin\delta_0\,\mathcal{A}_s)\zeta^c_\sigma(\rho,0)\Big].$$

We note that, by the proof of Lemma A.3 and by the definition of δ_0 in (3.11), the coefficients of ζ^s_σ, ζ^c_σ in the above expression are proportional to the scalar products

$$(f', \zeta^c_\sigma) = \int_{-1}^{1} f'(\varphi^*\rho + \varphi^m)\zeta^c_\sigma(\rho,0)d\rho,$$

$$(f', \zeta^s_\sigma) = \int_{-1}^{1} f'(\varphi^*\rho + \varphi^m)\zeta^s_\sigma(\rho,0)d\rho,$$

respectively; hence, we can write (4.31) in the form

$$\frac{1}{\sin\mu\cos\mu}\Big[(f', \zeta^c_\sigma)(f'', \zeta^s_\sigma) - (f'', \zeta^c_\sigma)(f', \zeta^s_\sigma)\Big] \neq 0, \tag{A.11}$$

where the scalar products involving f'' are defined in the same way. It can be shown that the above scalar products are analytic functions of the parameters ν_0^*, H^* of Problem $\mathbf{L_0}$; recalling (2.17) and (3.1), we conclude that the left-hand side of (A.11) is an analytic function of φ^* and φ^m if also f is analytic. We now show that this function does not vanish identically in the simple case of the parabolic profile $f(x) = x^2/2 - \gamma$ ($\gamma > 0$). Then we have $f'(\varphi^*\rho + \varphi^m) = \varphi^*\rho + \varphi^m$ and $f''(\varphi^*\rho + \varphi^m) = 1$, with $\rho \in [-1, 1]$; by the symmetry relations (A.1) we get from (A.11)

$$\frac{\varphi^*}{\sin\mu\cos\mu}\left(\int_{-1}^{1}\zeta^c_\sigma(\rho,0)d\rho\right)\left(\int_{-1}^{1}\rho\zeta^s_\sigma(\rho,0)d\rho\right) \neq 0. \tag{A.12}$$

We note that the left-hand side of (A.12) is independent of φ^m. By estimates of the above integrals which follow from the definitions of ζ^s, ζ^c (see [3, equations (4.13), (4.14)]) and by scaling $\rho \to \varphi^*\rho$, $\sigma \to \varphi^*\sigma$, one can show that (A.12) holds for $\varphi^* > 0$ small enough. Then (A.12) is satisfied for every positive value of φ^*, except possibly for a discrete set. We further remark that the integrals in the above condition depend on φ^* only through the parameters ν_0^*, H^*; therefore, *for a given Froude number*

$\frac{c_0}{\sqrt{gH}} = \frac{1}{\sqrt{\nu_0^* H^*}}$ we can say that (A.12) holds for any *fixed* value of the ratio ν_0^*/H^* outside a discrete set. Let us now discuss system (5.2) for the parabolic profile; we denote by $a_\pm$ and $b_\pm$ the values of $\xi_0(\pm 1, 0)$ corresponding to a solution of Problem $\mathbf{L_0}$, respectively, with the functions ρ and 1 on the right-hand side of (3.3). We stress that, for a given Froude number, the quantities $a_\pm$, $b_\pm$ depend only on the ratio ν_0^*/H^*; by linearity and the relation $\frac{c_0^2}{g} = \varphi^*/\nu_0^*$, system (5.2) takes the form (in terms of the variables φ^*, φ^m)

$$\text{(A.13)} \qquad \begin{cases} \frac{1}{2}(\varphi^m - \varphi^*)^2 - \gamma = \frac{a_-}{\nu_0^*}\varphi^{*2} + \frac{b_-}{\nu_0^*}\varphi^*\varphi^m, \\ \frac{1}{2}(\varphi^m + \varphi^*)^2 - \gamma = \frac{a_+}{\nu_0^*}\varphi^{*2} + \frac{b_+}{\nu_0^*}\varphi^*\varphi^m. \end{cases}$$

We will solve this system with respect to φ^*, φ^m for *given values* of ν_0^*, H^*; in terms of the physical parameters, this means that we do not fix c_0 and H but only the Froude number $\frac{c_0}{\sqrt{gH}}$. Now, again by scaling arguments, one can show that the four quantities $\frac{a_\pm}{\nu_0^*}$, $\frac{b_\pm}{\nu_0^*}$ are vanishing for $\nu_0^*/H^* \to \infty$ (at a fixed Froude number). Then, by elementary calculations, we find that (A.13) has a unique solution (with $\varphi^* > 0$) for any large enough values of ν_0^*/H^*; by the previous discussion, these values, except possibly for a discrete subset, also satisfy (A.12). ∎

SUPREMAL MULTISCALE SIGNAL ANALYSIS*

ULISSES BRAGA-NETO† AND JOHN GOUTSIAS‡

Abstract. We introduce a novel approach to nonlinear signal analysis, which is referred to as *supremal multiscale analysis*. The proposed approach provides a rigorous mathematical foundation for a class of nonlinear multiscale signal analysis schemes and leads to a decomposition that can effectively be used in signal processing and analysis. Moreover, it is related to the supremal scale-spaces proposed by Heijmans and van den Boomgaard and is similar in flavor to the well-known linear multiresolution theory of Mallat and Meyer. In this framework, linear concepts such as vector spaces, projections, and linear operators are replaced by conceptually analogous nonlinear notions.

We use supremal multiscale analysis to construct a multiscale image decomposition scheme based on two mathematical concepts that play a key role in the analysis and interpretation of images by vision systems, namely, regional maxima and connectivity. The resulting scheme is referred to as *skyline supremal multiscale analysis* and satisfies several useful properties desired by any multiscale image analysis tool. It is grayscale invariant, as well as translation and scale invariant. Moreover, it progressively removes connected components from the level sets of an image without introducing new ones. But, most importantly, it decomposes the regional maxima of an image in a natural causal hierarchy by gradually removing these maxima without introducing new ones.

Image decomposition by skyline supremal multiscale analysis can be used to construct nonlinear tools for image processing and analysis that provide solutions to problems where traditional linear techniques are ineffective. We discuss one such tool and illustrate its use in object-based extraction and denoising.

1. Introduction.

An important methodology for signal processing and analysis represents a signal at multiple scales. This methodology is based on the fundamental observation that information pertaining to features of interest in a signal is not confined to a particular scale, but it may span several scales. In order to effectively characterize such information, it is necessary to gradually simplify the signal, by means of a scale-dependent operator, which monotonically removes features of interest as the scale increases. The resulting evolution of a signal from fine to coarse scales is known as a *scale-space* (e.g., see [1, 2, 18, 21, 22, 42]).

Although early scale-space techniques were based on linear operators, it has been increasingly recognized that these techniques severely limit the capability of scale-spaces to accurately represent features of interest at coarser scales. For this reason, scale-space techniques based on nonlinear operators (or nonlinear partial differential equations) have appeared in the literature (e.g., see [1, 2, 32, 38, 41]). It is noticeable

that several of these techniques are based on *morphological operators* [1, 2, 3, 8, 9, 10, 15, 17, 28, 29, 37, 38].

On the other hand, a popular approach for multiscale signal processing and analysis is based on the multiresolution theory of Mallat [23, 24, 25] and Meyer [30]. According to this approach, approximations of a given signal at various scales (or resolutions) can be computed by means of orthogonal projections of the signal on a sequence of approximation spaces. The signal is then represented by means of a coarse approximation plus added details. The details are computed by means of orthogonal projections of the given signal on a sequence of detail spaces, with the detail spaces being orthogonal complements to the corresponding approximation spaces. At finer scales, the approximation error tends to zero, and a signal is spanned by spaces of successive details at all resolutions. This approach has naturally led to popular techniques for signal processing and analysis based on wavelet decompositions and filter banks (e.g., see [25, 39]).

The basic assumption behind the multiresolution theory of Mallat and Meyer is that signals reside in a vector space (namely, the space $L^2(\mathbb{R})$ of finite energy functions), with the approximation and detail spaces being subspaces of this vector space. Therefore, the theory is applied to linear multiscale tools for signal analysis. An attempt to conceptualize this approach in a nonlinear setting has appeared in [13, 14]. However, the discussion in [13, 14] on this issue is only preliminary.

To accomplish this goal, it is necessary (among other things) to extend linear concepts such as vector spaces, orthogonal projections, orthogonal spaces, and linear operators to a nonlinear setting. One way to do this is to assume that the signal space is a *complete lattice* (i.e., a nonempty collection of partially ordered elements such that any subcollection has a supremum and an infimum [4]). Complete lattices form the algebraic foundation of *mathematical morphology* [16], which assumes that signals are not combined by means of numerical addition and subtraction but by means of supremum and infimum. In mathematical morphology, an operator is "linear" if it commutes over suprema or infima. In the former case, the operator is called a *dilation*, whereas, in the latter case, it is called an *erosion*. Many linear concepts, such as convolution, can be recast in terms of suprema and infima (e.g., see [12, 26, 27]).

In this paper, we introduce a novel approach to nonlinear signal analysis that provides a rigorous mathematical foundation for a class of nonlinear multiscale signal analysis schemes and leads to a decomposition that can effectively be used for signal processing and analysis. The proposed approach, which we refer to as *supremal multiscale analysis*, is related to the supremal scale-spaces proposed by Heijmans and van den Boomgaard in [15] and is similar in flavor to the well-known linear multiresolution theory of Mallat and Meyer. In this framework, vector spaces are replaced by sup-closed spaces, projections are replaced by idempotent operators, orthogonal projections are replaced by sup-projections, orthogonal spaces are replaced by sup-orthogonal spaces, and linear operators are replaced by morphological operators.

We use supremal multiscale analysis to construct a multiscale image decomposition scheme, based on morphological reconstruction operators, which selectively removes regional maxima from a signal. Perhaps the most important feature of the proposed scheme, which is referred to as *skyline supremal multiscale analysis*, is its construction by means of two mathematical concepts that play a key role in the analysis and interpretation of images by vision systems, namely, regional maxima and connectivity (e.g., see [17, 20, 34]). This scheme represents a signal as the supremum of a coarse approximation and details. The coarse approximation preserves regional

maxima that are at some level σ or above, while it flattens the rest. In addition, the details preserve regional maxima with values in nonoverlapping subintervals of $(0, \sigma)$ and flatten the rest. The skyline supremal multiscale analysis is shown to satisfy a number of useful properties desired by any multiscale signal analysis tool. It is grayscale, translation, and scale invariant. Moreover, it progressively removes connected components from the level sets of a signal without introducing new ones. But, most importantly, it decomposes the regional maxima of a signal in a natural causal hierarchy by gradually removing these maxima without introducing new ones.

Image decomposition by skyline supremal multiscale analysis can be used to construct nonlinear tools for image processing and analysis that can provide solutions to some problems where traditional linear techniques are ineffective. We discuss one such tool and illustrate its effectiveness in object-based extraction and denoising.

This paper is structured as follows. In section 2, we provide a brief overview of basic mathematical concepts used throughout the paper and introduce our notation. In section 3, we introduce our framework for nonlinear multiscale analysis, which leads to the concepts of supremal multiscale approximation and supremal multiscale analysis. We also establish a relationship between the supremal multiscale approximation and scale-spaces and present two binary examples that illustrate these concepts. In section 4, we present the skyline supremal multiscale analysis scheme, constructed by means of morphological reconstruction operators, which decomposes the regional maxima of a signal in a natural causal hierarchy by selectively removing these maxima without introducing new ones. We show that the proposed scheme is indeed a supremal multiscale analysis, and we study its main properties. In section 5, we present examples that illustrate the use of the proposed multiscale approach in two image processing and analysis problems: object-based extraction and denoising. In the first case, the skyline supremal multiscale decomposition scheme is used to extract objects of interest, by placing them on individual frames, and enhance their presence by suppressing (flattening) surrounding details. In the second case, the scheme is used to restore an image corrupted by structured (more than a pixel thick) "pepper" noise. Finally, we summarize our conclusions in section 6.

2. Mathematical preliminaries. In this section, we review basic mathematical concepts and introduce our notation. For a more detailed exposition, the reader is referred to [4, 5, 6, 7, 16, 35, 36].

A *partially ordered set* or, briefly, a *poset*, is a nonempty set furnished with a binary *partial order relation* $\leq$ (i.e., a binary order relation that is reflexive, antisymmetric, and transitive). A *complete lattice* $(\mathcal{L}, \leq)$ is a poset such that every family $\mathcal{M} \subseteq \mathcal{L}$ has an infimum $\bigwedge \mathcal{M}$ and a supremum $\bigvee \mathcal{M}$ in $\mathcal{L}$. Every complete lattice $(\mathcal{L}, \leq)$ has a *least element* O and a *greatest element* I, given by $O = \bigwedge \mathcal{L}$ and $I = \bigvee \mathcal{L}$, respectively. In this paper, whenever we use the term "lattice" we mean "complete lattice." In addition, we often refer to "lattice $\mathcal{L}$" when there is no confusion as to the underlying partial order.

The following are some examples of lattices.

Example 1.

(a) The collection $\mathcal{P}(E)$ of all subsets of a set E, with set inclusion as the partial order. The infimum and supremum are set intersection and set union, respectively. This lattice is used as a mathematical model for binary images defined on E.

(b) The collection $\mathcal{G}(\mathbb{R}^d)$ of all open subsets of the Euclidean space $\mathbb{R}^d$, with set inclusion as the partial order. The infimum is the topological interior of set

intersection, whereas the supremum is set union. This lattice can also be used as a mathematical model for binary images on E. In this case, it is assumed that images do not include their boundary.

(c) The set $\overline{\mathbb{R}} = \mathbb{R} \cup \{-\infty, \infty\}$ of extended real numbers and the set $\overline{\mathbb{Z}} = \mathbb{Z} \cup \{-\infty, \infty\}$ of extended integers, as well as any closed subinterval of those, with the usual numerical ordering as the partial order. The infimum and supremum are given by the usual numerical infimum and supremum. These are *chains* (i.e., totally ordered lattices), which are used for modeling image values.

(d) The collection $\mathrm{Fun}(E, \mathcal{T})$ of all functions from a set E into a lattice $\mathcal{T}$, with the partial order $f \leq g$ if $f(v) \leq_{\mathcal{T}} g(v)$, for all $v \in E$, where "$\leq_{\mathcal{T}}$" is the partial order relation on $\mathcal{T}$. The infimum and supremum are the pointwise infimum and supremum, given, respectively, by $(\bigwedge f_\alpha)(v) = \bigwedge f_\alpha(v)$ and $(\bigvee f_\alpha)(v) = \bigvee f_\alpha(v)$, for all $v \in E$, where the infimum and supremum on the right-hand side are in $\mathcal{T}$. When $\mathcal{T}$ is a chain, this lattice is used as a mathematical model for grayscale images defined on E.

(e) The collection $\mathrm{Fun}_u(E, \mathcal{T})$ of all *upper semicontinuous* (u.s.c.) functions [19] from a topological space E into a lattice $\mathcal{T}$, with the partial order $f \leq g$ if $f(v) \leq_{\mathcal{T}} g(v)$, for $v \in E$. The infimum is the usual pointwise infimum, given by $(\bigwedge_u f_\alpha)(v) = \bigwedge f_\alpha(v)$, for $v \in E$. However, the supremum is given by $(\bigvee_u f_\alpha)(v) = \bigvee\{t \in \mathcal{T} \mid v \in \overline{\bigcup X_t(f_\alpha)}\}$, for $v \in E$, where $X_t(f) = \{v \in E \mid f(v) \geq t\}$ is the *level set* of f at level t, and $\overline{A}$ denotes the *closure* of a set A [7, Prop. 4.2.6]. Nevertheless, it can be shown that the supremum of any finite family of u.s.c. functions corresponds to the usual pointwise supremum. In general, whenever $\bigvee f_\alpha$ is u.s.c., then $\bigvee_u f_\alpha = \bigvee f_\alpha$ so that the supremum in lattice $\mathrm{Fun}_u(E, \overline{\mathbb{R}})$ can, and often does, reduce to the usual pointwise supremum. When $\mathcal{T}$ is a chain, this lattice is also used as a mathematical model for grayscale images defined on E. In this case, however, images are assumed to satisfy the property of upper semicontinuity.

The level sets of a function $f \in \mathrm{Fun}(E, \mathcal{T})$ satisfy the following properties: (a) $X_t(f) \subseteq X_s(f)$ if $t \geq s$; (b) $f \leq g$ if and only if $X_t(f) \subseteq X_t(g)$ for all $t \in \mathcal{T}$ (in particular, $f = g$ if and only if $X_t(f) = X_t(g)$ for all $t \in \mathcal{T}$); (c) for $t \in \mathcal{T}$, we have that $X_t(\bigwedge f_\alpha) = \bigcap X_t(f_\alpha)$, whereas $X_t(\bigvee f_\alpha) = \bigcup X_t(f_\alpha)$ if $\{f_\alpha\}$ is a finite family or if $\mathcal{T}$ is finite; (d) $f \in \mathrm{Fun}_u(E, \mathcal{T})$ if and only if the sets $X_t(f)$ are closed in E for all $t \in \mathcal{T}$.

Given a family $\mathcal{M} \subseteq \mathcal{L}$, we denote by $\langle\, \mathcal{M} \mid \vee \,\rangle$ the family sup-generated by $\mathcal{M}$, i.e., the family consisting of all elements of $\mathcal{L}$ that are obtained by taking suprema of elements of $\mathcal{M}$. The family $\mathcal{M}$ is said to be *sup-closed* if $\mathcal{M} = \langle\, \mathcal{M} \mid \vee \,\rangle$ (in particular, $\mathcal{M}$ must be nonempty, since $O = \bigvee \emptyset \in \mathcal{M}$).

A subset $\mathcal{S}$ of a lattice $\mathcal{L}$ is called a *sup-generating family* for $\mathcal{L}$ if every element of $\mathcal{L}$ can be written as the supremum of elements in $\mathcal{S}$; i.e., $\mathcal{L} = \langle\, \mathcal{S} \mid \vee \,\rangle$. An element of the sup-generating family $\mathcal{S}$ is called a *sup-generator*. It is assumed here that O is not a sup-generator; i.e., $O \notin \mathcal{S}$. For example, the lattice $\mathcal{P}(E)$ of binary images is sup-generated by the points in E. We define the family $\mathcal{S}(A) = \{x \in \mathcal{S} \mid x \leq A\}$ for $A \in \mathcal{L}$. Clearly, A is sup-generated by $\mathcal{S}(A)$.

An *operator* ψ on a lattice $\mathcal{L}$ is a mapping $\psi\colon \mathcal{L} \to \mathcal{L}$. The *invariance domain* of ψ is defined as $\mathrm{Inv}(\psi) = \{A \in \mathcal{L} \mid \psi(A) = A\}$. An operator ψ is said to be *increasing*, if $A \leq B \Rightarrow \psi(A) \leq \psi(B)$, for all $A, B \in \mathcal{L}$; *antiextensive*, if $\psi(A) \leq A$, for all $A \in \mathcal{L}$; *idempotent*, if $\psi\psi(A) = \psi(A)$, for all $A \in \mathcal{L}$. If ψ distributes over infima,

it is called an *erosion*, whereas, if it distributes over suprema, it is called a *dilation*. If ψ is increasing, antiextensive, and idempotent, it is called an *opening*. It can be shown (e.g., see [33]) that if $\{\gamma_\alpha\}$ is a family of openings, then $\bigvee \gamma_\alpha$ is an opening as well, with $\mathrm{Inv}(\bigvee \gamma_\alpha) = \langle \bigcup \mathrm{Inv}(\gamma_\alpha) \mid \vee \rangle$. Given a poset $\mathcal{K}$, the family of openings $\{\gamma_\alpha \mid \alpha \in \mathcal{K}\}$ is a *granulometry* if $\gamma_{\alpha_1} \leq \gamma_{\alpha_2}$ for $\alpha_1 \geq \alpha_2$.

The translation A_h of a set $A \in \mathcal{P}(E)$ is another set in $\mathcal{P}(E)$, given by $A_h = \{v + h \mid v \in A\}$. The *translation-invariant erosion* of $A \in \mathcal{P}(E)$ by a *structuring element* $B \in \mathcal{P}(E)$ is defined as $\epsilon_B(A) = A \ominus B = \{h \in E \mid B_h \subseteq A\}$. Similarly, the *translation-invariant dilation* of A by B is defined as $\delta_B(A) = A \oplus B = \bigcup\{B_h \mid h \in A\}$. It can be shown that the operator $\theta_B(A) = A \bigcirc B = (A \ominus B) \oplus B = \bigcup_{h \in E}\{B_h \mid B_h \subseteq A\}$ is an opening. This operator is referred to as a *structural opening*. If $A \in \mathrm{Inv}(\theta_B)$, we say that A is *B-open*.

An increasing operator ψ on $\mathcal{L}$ is said to be *$\downarrow$-continuous* if, for every totally ordered subset $\mathcal{K}$ of $\mathcal{L}$ that contains at most a countable number of elements, we have that

$$\psi\left(\bigwedge \mathcal{K}\right) = \bigwedge_{A \in \mathcal{K}} \psi(A).$$

If ψ is an $\downarrow$-continuous operator on a lattice $\mathcal{L}$ and if $\{A(s) \mid s \in \overline{\mathbb{R}}\}$ is a decreasing family of elements in $\mathcal{L}$, then [7, Prop. 2.2.10]

$$\psi\left(\bigwedge_{s<t} A(s)\right) = \bigwedge_{s<t} \psi(A(s)) \quad \forall\, t \in \overline{\mathbb{R}}. \tag{2.1}$$

Consider now a lattice $\mathcal{L}$, with a sup-generating family $\mathcal{S}$. A family $\mathcal{C} \subseteq \mathcal{L}$ is called a *connectivity class* in $\mathcal{L}$ if the following conditions are satisfied:

(i) $O \in \mathcal{C}$;
(ii) $\mathcal{S} \subseteq \mathcal{C}$;
(iii) for a family $\{C_\alpha\}$ in $\mathcal{C}$ such that $\bigwedge C_\alpha \neq O$, we have that $\bigvee C_\alpha \in \mathcal{C}$.

The family $\mathcal{C}$ generates a *connectivity* in $\mathcal{L}$, and the elements in $\mathcal{C}$ are said to be *connected*.

Classical topological and graph-theoretic connectivities correspond to connectivity classes, and so do several examples of fuzzy connectivity [5, 7]. Moreover, based on the notion of connectivity class, many new interesting examples of connectivity can be defined [5, 6, 7, 35, 36].

We say that C is a *connected component* of $A \in \mathcal{L}$ if $C \in \mathcal{C}$, $C \leq A$, and there is no $C' \in \mathcal{C}$ different from C such that $C \leq C' \leq A$. In other words, a connected component of an object is a maximal connected part of the object. The set of connected components of A is denoted by $\mathcal{C}(A)$.

We can define an operator $\gamma_x(A)$ that extracts connected components from elements $A \in \mathcal{L}$ by

$$\gamma_x(A) = \bigvee\{C \in \mathcal{C} \mid x \leq C \leq A\}, \quad A \in \mathcal{L}, \quad x \in \mathcal{S}.$$

It can be seen that this operator is an opening; it is called the *connectivity opening* associated with $\mathcal{C}$. It can also be checked that $\gamma_x(A) \in \mathcal{C}$. As a matter of fact, $\gamma_x(A)$ is the connected component C of A *marked* by x (i.e., such that $x \leq C$).

It is natural to extend connectivity openings to operators that extract connected components marked by arbitrary markers, not just sup-generators. This gives rise

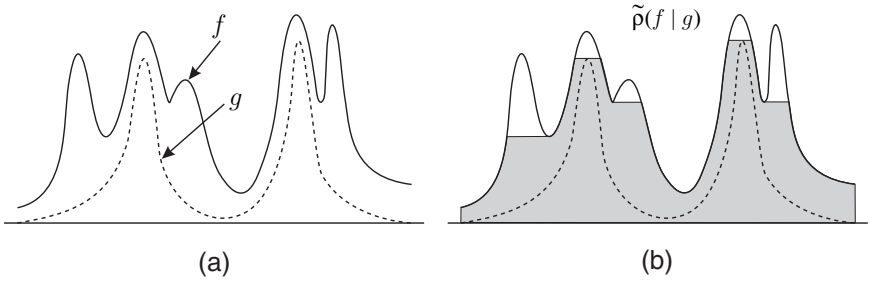

FIG. 1. (a) *Original image f and a marker g.* (b) *The grayscale reconstruction $\widetilde{\rho}(f \mid g)$, according to the usual topological connectivity of the Euclidean real line.*

to the *reconstruction operator* associated with a connectivity class $\mathcal{C}$. For a marker $M \in \mathcal{L}$, the *reconstruction* $\rho(A \mid M)$ of a given $A \in \mathcal{L}$ from M is defined by

$$\rho(A \mid M) = \bigvee_{x \in \mathcal{S}(M)} \gamma_x(A) = \bigvee \{C \in \mathcal{C}(A) \mid C \wedge M \neq O\}.$$

The second equality above can be easily verified [6, 7]. Hence, the reconstruction operator $\rho(A \mid M)$ extracts the connected components of A that "intersect" marker M. Being a supremum of openings, the operator $\rho(\cdot \mid M)$ is an opening on $\mathcal{L}$ for a fixed marker $M \in \mathcal{L}$. When M reduces to a sup-generator x, the reconstruction $\rho(A \mid x)$ reduces to the connectivity opening $\gamma_x(A)$, provided that $x \leq A$.

Given a connectivity class $\mathcal{C}$ in the binary lattice $\mathcal{P}(E)$ and the associated reconstruction operator ρ: $\mathcal{P}(E) \times \mathcal{P}(E) \to \mathcal{P}(E)$, we can define an operator $\widetilde{\rho}$: $\mathrm{Fun}(E, \mathcal{T}) \times \mathrm{Fun}(E, \mathcal{T}) \to \mathrm{Fun}(E, \mathcal{T})$ by

$$\widetilde{\rho}(f \mid g)(v) = \bigvee \{t \in \mathcal{T} \mid v \in \rho(X_t(f) \mid X_t(g))\}, \quad v \in E. \tag{2.2}$$

It can be shown that $\widetilde{\rho}(\cdot \mid g)$ is an opening on $\mathrm{Fun}(E, \mathcal{T})$ for a fixed marker $g \in \mathrm{Fun}(E, \mathcal{T})$. If we assume that $\mathcal{T}$ is a chain, then the operator $\widetilde{\rho}(f \mid g)$ in (2.2) is known as the *grayscale reconstruction* of f from marker g associated with the connectivity class $\mathcal{C}$. The grayscale reconstruction is a very useful operator in applications [40]. Figure 1 illustrates the grayscale reconstruction operator in the one-dimensional case.

3. Supremal scale-spaces and multiscale analysis. In this section, we introduce a framework for nonlinear multiscale signal analysis, which is related to the supremal scale-spaces introduced by Heijmans and van den Boomgaard [15]. The proposed framework is referred to as *supremal multiscale analysis* and leads to a nonlinear multiscale signal representation scheme that decomposes a signal into the supremum of a coarse approximation and details. We show that supremal multiscale analysis satisfies a number of properties, which are similar in flavor to properties satisfied by the well-known linear multiresolution signal analysis scheme of Mallat [23, 24, 25] and Meyer [30]. As a matter of fact, we derive the supremal multiscale analysis scheme by using nonlinear analogues of certain linear concepts (e.g., vector spaces, orthogonal projections, and orthogonal complements).

We assume that signals of interest reside in a complete lattice $(\mathcal{V}, \leq)$. An operator ϕ on $\mathcal{V}$ is said to be a *projection* if it is idempotent [14, 31]. Furthermore, we say that ϕ is a projection on $\mathcal{U} \subseteq \mathcal{V}$ if $\mathrm{Ran}(\phi) = \mathcal{U}$ and ϕ is idempotent on $\mathcal{U}$ (in which case $\mathrm{Inv}(\phi) = \mathrm{Ran}(\phi) = \mathcal{U}$), where $\mathrm{Ran}(\phi)$ denotes the *range* of operator ϕ. In the linear

multiresolution framework proposed in [23, 24, 25, 30], approximations of signals at various scales are computed by means of orthogonal projections on a sequence of approximation spaces. An orthogonal projection of a signal $f \in \mathcal{V}$ on a vector subspace $\mathcal{U} \subseteq \mathcal{V}$ is defined as the signal $\phi(f) \in \mathcal{U}$ that minimizes the norm $\|f - g\|$ over all signals $g \in \mathcal{U}$. Note that the range of this operator is $\mathcal{U}$ and that the operator is idempotent; therefore, it is a projection on $\mathcal{U}$. In the nonlinear framework proposed here, $\mathcal{V}$ is not a vector space in general. Therefore, we introduce the alternative notion of sup-projection, which is conceptually analogous to an orthogonal projection.

DEFINITION 3.1. *Let $\mathcal{U} \subseteq \mathcal{V}$ such that $\mathcal{U}$ is sup-closed in $\mathcal{V}$. The operator*

$$\phi(f) = \bigvee \{g \in \mathcal{U} \mid g \leq f\}, \quad f \in \mathcal{V}, \tag{3.1}$$

defines the sup-projection *of f on $\mathcal{U}$.*

The sup-closure requirement and (3.1) imply that $\mathrm{Ran}(\phi) = \mathcal{U}$ and that ϕ is idempotent on $\mathcal{U}$; therefore, ϕ is a projection on $\mathcal{U}$. The requirement that $\mathcal{U}$ must be sup-closed is analogous to the linear requirement that $\mathcal{U}$ must be a vector space (i.e., closed under linear combinations). Note that (3.1) implies that $\phi(f)$ is the "closest" element to f in $\mathcal{U}$, in the sense of the underlying partial order. Hence, a sup-projection is a nonlinear analogue of an orthogonal projection.

A fundamental aspect of (linear) multiresolution analysis is that distinct signal approximations can be obtained from each other by means of scaling (this is known as the "dilation" property). In order to formulate this idea in a nonlinear setting, we use a general definition of scaling, proposed in [15]. In what follows, id denotes the identity operator.

DEFINITION 3.2. *A family $S = \{s_t \mid t \in (0, \infty)\}$ of operators on a lattice $\mathcal{V}$ is a* scaling *if*

(i) $s_1 = \mathsf{id}$,
(ii) $s_r s_t = s_{rt}$ *for* $r, t \in (0, \infty)$.

This definition implies that S is a commutative group, where the inverse s_t^{-1} of s_t is given by $s_t^{-1} = s_{1/t}$ for $t \in (0, \infty)$. Moreover, if $S = \{s_t \mid t \in (0, \infty)\}$ is a scaling on $\mathcal{V}$, then so is $S^p = \{s_{t^p} \mid t \in (0, \infty)\}$, $p \in \mathbb{R}$ [15].

Example 2.

(a) For $\mathcal{V} = \mathcal{P}(\mathbb{R}^d)$, the scaling $\{tA \mid t \in (0, \infty)\}$, where $tA = \{tv \mid v \in A\}$, for $A \in \mathcal{V}$, is known as the *spatial scaling*.
(b) For $\mathcal{V} = \mathrm{Fun}(E, \overline{\mathbb{R}})$, the scalings $\{tf(\cdot) \mid t \in (0, \infty)\}$, $\{f(\cdot/t) \mid t \in (0, \infty)\}$, and $\{tf(\cdot/t) \mid t \in (0, \infty)\}$ are known as the *gray-level*, *spatial*, and *umbral scalings*, respectively.

In practice, useful scalings consist of increasing operators. We refer to these as *increasing scalings*. For example, all scalings considered in Example 2 are increasing. The following result shows that scalings are increasing if and only if they consist of dilations.

PROPOSITION 3.3. *A scaling $S = \{s_t \mid t \in (0, \infty)\}$ on a lattice $\mathcal{V}$ is increasing if and only if s_t is a dilation for every $t \in (0, \infty)$.*

Proof. The reverse implication follows trivially from the fact that every dilation is an increasing operator [16]. We show the direct implication. Given $t \in (0, \infty)$ and $\{f_\alpha\} \subseteq \mathcal{V}$, we have that $s_t(\bigvee f_\alpha) \geq \bigvee s_t(f_\alpha)$, since s_t is increasing. To show the reverse inequality, note that $s_t^{-1}(\bigvee s_t(f_\alpha)) \geq \bigvee s_t^{-1} s_t(f_\alpha) = \bigvee f_\alpha$, since $s_t^{-1} = s_{1/t}$ is increasing. Applying s_t on both sides of this inequality gives $s_t s_t^{-1}(\bigvee s_t(f_\alpha)) = \bigvee s_t(f_\alpha) \geq s_t(\bigvee f_\alpha)$. Therefore, $s_t(\bigvee f_\alpha) = \bigvee s_t(f_\alpha)$, and s_t is a dilation on $\mathcal{V}$. ∎

We now introduce an axiomatic formulation for supremal multiscale approximations, which compute approximations of signals at various scales by means of sup-projections on a sequence of approximation spaces.

DEFINITION 3.4. *Let S be a scaling on a lattice $\mathcal{V}$. A family $\{\mathcal{V}_\sigma \mid \sigma \in (0,\infty)\}$ of sup-closed subsets of $\mathcal{V}$ is said to be a* supremal multiscale S-approximation *of $\mathcal{V}$ if the following properties are satisfied:*

1. *The sequence $\{\mathcal{V}_\sigma \mid \sigma \in (0,\infty)\}$ is decreasing; i.e.,*

$$\mathcal{V}_\tau \subseteq \mathcal{V}_\sigma \quad \text{for} \quad \tau \geq \sigma. \tag{3.2}$$

   This implies that an approximation at scale σ contains all necessary information to compute an approximation at a coarser scale $\tau \geq \sigma$.

2. *The sequence $\{\mathcal{V}_\sigma \mid \sigma \in (0,\infty)\}$ "converges" to $\mathcal{V}$, as $\sigma \to 0^+$, in the sense that*

$$\lim_{\sigma \to 0^+} \mathcal{V}_\sigma \triangleq \left\langle \bigcup_{\sigma \in (0,\infty)} \mathcal{V}_\sigma \mid \vee \right\rangle = \mathcal{V}. \tag{3.3}$$

   This implies that any signal can be recovered by the supremum of its approximations at sufficiently small scales.

3. *(S-invariance). We have that*

$$f \in \mathcal{V}_\sigma \quad \Leftrightarrow \quad s_{\tau/\sigma}(f) \in \mathcal{V}_\tau \quad \text{for} \quad \sigma, \tau \in (0,\infty). \tag{3.4}$$

   This means that an approximation space $\mathcal{V}_\sigma$ can be obtained from another approximation space $\mathcal{V}_\tau$, and vice-versa, by means of scaling.

The previous properties are similar in flavor to properties satisfied by the linear multiresolution analysis scheme of Mallat and Meyer. The approximation of a signal $f \in \mathcal{V}$ at scale $\sigma \in (0,\infty)$ is given by the sup-projection of f on the approximation space $\mathcal{V}_\sigma$, which therefore must be sup-closed. This is the nonlinear analogue of the assumption that the approximation spaces are vector subspaces. The inclusion property specified by (3.2) is also true in the linear case. The convergence requirement specified by (3.3) is similar to the one in the linear case, except that linear closure is replaced by sup-closure. Finally, the scaling requirement specified by (3.4) is similar to the one in the linear case. However, a very important property of the linear case is the existence of vector bases for the approximation spaces. This is an inherently linear property and has no counterpart in a nonlinear setting.

Note that the sup-closure assumption implies that, for $\sigma \in (0,\infty)$, $\mathcal{V}_\sigma$ is a complete lattice under the partial order of $\mathcal{V}$ [16, Prop. 2.12]. The proof of the following result is straightforward.

PROPOSITION 3.5. *The family $\{\mathcal{V}_\sigma \mid \sigma \in (0,\infty)\}$ is a supremal multiscale S-approximation of $\mathcal{V}$ if and only if the family $\{\mathcal{V}_{\sigma^p} \mid \sigma \in (0,\infty)\}$, $p \in \mathbb{R}$, is a supremal multiscale S^p-approximation of $\mathcal{V}$.*

For each $\sigma \in (0,\infty)$, let us define the *approximation operator* ϕ_σ on $\mathcal{V}$ as the operator that maps an element $f \in \mathcal{V}$ to its sup-projection on $\mathcal{V}_\sigma$; i.e.,

$$\phi_\sigma(f) = \bigvee \{g \in \mathcal{V}_\sigma \mid g \leq f\}, \quad f \in \mathcal{V}, \quad \sigma \in (0,\infty). \tag{3.5}$$

The operator ϕ_σ provides the approximation of a signal in $\mathcal{V}$ at scale σ. The following fundamental result implies that a supremal multiscale approximation can be specified by its approximation operators.

PROPOSITION 3.6. *Let $\{\mathcal{V}_\sigma \mid \sigma \in (0,\infty)\}$ be a supremal multiscale S-approximation of $\mathcal{V}$, where S is an increasing scaling. The family $\{\phi_\sigma \mid \sigma \in (0,\infty)\}$ of approximation operators is such that $\mathrm{Inv}(\phi_\sigma) = \mathcal{V}_\sigma$, for $\sigma \in (0,\infty)$, and*

(i) *the family $\{\phi_\sigma \mid \sigma \in (0,\infty)\}$ is a granulometry on $\mathcal{V}$,*
(ii) $\bigvee_{\sigma\in(0,\infty)} \phi_\sigma = \mathsf{id}$,
(iii) $\phi_\sigma = s_{\sigma/\tau}\, \phi_\tau\, s^{-1}_{\sigma/\tau}$ *for $\sigma, \tau \in (0,\infty)$.*

Conversely, if $\{\phi_\sigma \mid \sigma \in (0,\infty)\}$ is a family of operators on $\mathcal{V}$ that satisfies the previous properties (i)–(iii)*, then $\{\mathcal{V}_\sigma = \mathrm{Inv}(\phi_\sigma) \mid \sigma \in (0,\infty)\}$ is a supremal multiscale S-approximation of $\mathcal{V}$, with approximation operators that coincide with $\{\phi_\sigma \mid \sigma \in (0,\infty)\}$.*

Proof. For $f \in \mathrm{Inv}(\phi_\sigma)$, we have that $f = \phi_\sigma(f) = \bigvee\{g \in \mathcal{V}_\sigma \mid g \le f\} \Rightarrow f \in \langle \mathcal{V}_\sigma \mid \vee \rangle = \mathcal{V}_\sigma$, since $\mathcal{V}_\sigma$ is sup-closed, so that $\mathrm{Inv}(\phi_\sigma) \subseteq \mathcal{V}_\sigma$. The reverse inclusion follows easily from (3.5); hence, $\mathrm{Inv}(\phi_\sigma) = \mathcal{V}_\sigma$. We now show (i). From (3.5), it is clear that ϕ_σ is increasing and antiextensive. This implies that $\phi_\sigma\phi_\sigma \le \phi_\sigma$. On the other hand, (3.5) implies that $g \in \mathcal{V}_\sigma$, $g \le f \Rightarrow g \le \phi_\sigma(f)$ so that $\phi_\sigma(f) = \bigvee\{g \in \mathcal{V}_\sigma \mid g \le f\} \le \bigvee\{g \in \mathcal{V}_\sigma \mid g \le \phi_\sigma(f)\} = \phi_\sigma\phi_\sigma(f)$ for $f \in \mathcal{V}$. Therefore, ϕ_σ is idempotent, and hence it is an opening. For $\tau \ge \sigma$, we have that $\mathrm{Inv}(\phi_\tau) = \mathcal{V}_\tau \subseteq \mathcal{V}_\sigma = \mathrm{Inv}(\phi_\sigma)$, which implies that $\phi_\tau \le \phi_\sigma$ [16, Thm. 3.24]. Therefore, $\{\phi_\sigma \mid \sigma \in (0,\infty)\}$ is a granulometry on $\mathcal{V}$. To show (ii), we use the fact that the supremum $\bigvee \theta_\alpha$ of openings is an opening, with $\mathrm{Inv}(\bigvee \theta_\alpha) = \langle \bigcup \mathrm{Inv}(\theta_\alpha) \mid \vee \rangle$. Hence, $\mathrm{Inv}(\bigvee_{\sigma\in(0,\infty)} \phi_\sigma) = \langle \bigcup_{\sigma\in(0,\infty)} \mathrm{Inv}(\phi_\sigma) \mid \vee \rangle = \langle \bigcup_{\sigma\in(0,\infty)} \mathcal{V}_\sigma \mid \vee \rangle = \mathcal{V} = \mathrm{Inv}(\mathsf{id})$. But, since id is an opening and two openings are equal if and only if their domains of invariance are equal [16, Thm. 3.24], we get that $\bigvee_{\sigma\in(0,\infty)} \phi_\sigma = \mathsf{id}$. We now show (iii). For $f \in \mathcal{V}$, we have that $\phi_\sigma(f) = \bigvee\{g \in \mathcal{V}_\sigma \mid g \le f\} = \bigvee\{s_{\sigma/\tau}(h) \mid h \in \mathcal{V}_\tau,\ s_{\sigma/\tau}(h) \le f\} = s_{\sigma/\tau}(\bigvee\{h \mid h \in \mathcal{V}_\tau,\ h \le s^{-1}_{\sigma/\tau}(f)\}) = s_{\sigma/\tau}\, \phi_\tau\, s^{-1}_{\sigma/\tau}(f)$, since $s_{\sigma/\tau}$ is a dilation (see Proposition 3.3). Therefore, $\phi_\sigma = s_{\sigma/\tau}\, \phi_\tau\, s^{-1}_{\sigma/\tau}$ for $\sigma, \tau \in (0,\infty)$.

We now show the converse implication. Note that, for each $\sigma \in (0,\infty)$, $\mathcal{V}_\sigma = \mathrm{Inv}(\phi_\sigma)$ is sup-closed, since ϕ_σ is an opening. Equation (3.2) follows from the fact that $\phi_\sigma \le \phi_\tau$ for $\sigma \ge \tau$ [16, Thm. 3.24]. Equation (3.3) follows from $\mathcal{V} = \mathrm{Inv}(\mathsf{id}) = \mathrm{Inv}(\bigvee_{\sigma\in(0,\infty)} \phi_\sigma) = \langle \bigcup_{\sigma\in(0,\infty)} \mathcal{V}_\sigma \mid \vee \rangle$. To verify (3.4), note that $f \in \mathcal{V}_\sigma \Leftrightarrow f = \phi_\sigma(f) = s_{\sigma/\tau}\, \phi_\tau\, s^{-1}_{\sigma/\tau}(f) \Leftrightarrow s_{\tau/\sigma}(f) = \phi_\tau s_{\tau/\sigma}(f) \Leftrightarrow s_{\tau/\sigma}(f) \in \mathcal{V}_\tau$ for $\sigma, \tau \in (0,\infty)$. Finally, if $\{\phi'_\sigma \mid \sigma \in (0,\infty)\}$ are the approximation operators associated with $\{\mathcal{V}_\sigma \mid \sigma \in (0,\infty)\}$, then $\mathrm{Inv}(\phi'_\sigma) = \mathcal{V}_\sigma = \mathrm{Inv}(\phi_\sigma) \Leftrightarrow \phi'_\sigma = \phi_\sigma$ for $\sigma \in (0,\infty)$ (see [16, Thm. 3.24]). ∎

The following proposition shows that we can build supremal multiscale approximations by using unions of existing ones.

PROPOSITION 3.7. *Let S be an increasing scaling. If, for each α, $\{\mathcal{V}^\alpha_\sigma \mid \sigma \in (0,\infty)\}$ is a supremal multiscale S-approximation of $\mathcal{V}$, with approximation operators $\{\phi^\alpha_\sigma \mid \sigma \in (0,\infty)\}$, then $\{\langle \bigcup_\alpha \mathcal{V}^\alpha_\sigma \mid \vee \rangle \mid \sigma \in (0,\infty)\}$ is a supremal multiscale S-approximation of $\mathcal{V}$ as well, with approximation operators $\{\bigvee_\alpha \phi^\alpha_\sigma \mid \sigma \in (0,\infty)\}$.*

Proof. Equations (3.2) and (3.3) are easy to show; therefore, we show only (3.4). Let $\mathcal{V}_\sigma = \langle \bigcup_\alpha \mathcal{V}^\alpha_\sigma \mid \vee \rangle$ for $\sigma \in (0,\infty)$. For $f \in \mathcal{V}_\sigma$, we have that $f = \bigvee f_\beta$, where each f_β belongs to some $\mathcal{V}^\alpha_\sigma$. Therefore, $s_{\tau/\sigma}(f_\beta) \in \mathcal{V}_\tau$, for each β and $\tau \in (0,\infty)$. Since $\mathcal{V}_\tau$ is sup-closed and since $s_{\tau/\sigma}$ is a dilation (see Proposition 3.3), we have that $s_{\tau/\sigma}(f) = s_{\tau/\sigma}(\bigvee f_\beta) = \bigvee s_{\tau/\sigma}(f_\beta) \in \mathcal{V}_\tau$, as required. Now let ϕ_σ be the approximation operator associated with $\mathcal{V}_\sigma$. Since $\mathrm{Inv}(\phi^\alpha_\sigma) = \mathcal{V}^\alpha_\sigma$, we have that $\mathrm{Inv}(\phi_\sigma) = \mathcal{V}_\sigma = \langle \bigcup_\alpha \mathcal{V}^\alpha_\sigma \mid \vee \rangle = \mathrm{Inv}(\bigvee_\alpha \phi^\alpha_\sigma)$. Since two openings are equal if and only if their domains of invariance are equal [16, Thm. 3.24] and since $\bigvee_\alpha \phi^\alpha_\sigma$ is an opening, we conclude that $\phi_\sigma = \bigvee_\alpha \phi^\alpha_\sigma$, as required. ∎

To illustrate the concept of supremal multiscale approximation, we now provide two binary examples. A grayscale supremal multiscale approximation scheme will be discussed in the next section.

Example 3.

(a) Let $\mathcal{V} = \mathcal{G}(\mathbb{R}^d)$ be the lattice of open subsets of the Euclidean space, and consider the spaces

$$\mathcal{V}_\sigma = \{A \in \mathcal{V} \mid A \text{ is } \sigma B\text{-open}\}, \quad \sigma \in (0, \infty), \tag{3.6}$$

where $B \in \mathcal{V}$ is a bounded convex structuring element (e.g., an open ball of unit radius). In (3.6), $\sigma B = \{\sigma b \mid b \in B\}$. The family $\{\mathcal{V}_\sigma \mid \sigma \in (0, \infty)\}$ is a supremal multiscale S-approximation of $\mathcal{V}$, where S is the spatial scaling: $\mathcal{V}_\sigma$ is sup-closed, for $\sigma \in (0, \infty)$, and (3.2) and (3.4) are clearly satisfied, whereas (3.3) follows from the facts that $\mathcal{B} = \{(\sigma B)_v \mid v \in \mathbb{R}^d, \sigma \in (0, \infty)\} \subset \bigcup_{\sigma \in (0,\infty)} \mathcal{V}_\sigma$ and $\mathcal{B}$ is a basis for the Euclidean topology. In this case, the approximation operators are the structural openings

$$\phi_\sigma(A) = A \bigcirc \sigma B, \quad A \in \mathcal{V}, \quad \sigma \in (0, \infty).$$

(b) Let $\mathcal{V} = \mathcal{G}(\mathbb{R}^d)$, furnished with a connectivity class $\mathcal{C}$, and consider the *opening by reconstruction operators*:

$$\phi_\sigma(A) = \rho(A \mid A \bigcirc \sigma B), \quad A \in \mathcal{V}, \quad \sigma \in (0, \infty), \tag{3.7}$$

where $B \in \mathcal{V}$ is a bounded structuring element. It can be shown that the invariance domain of ϕ_σ is given by

$$\mathcal{V}_\sigma(A) = \{A \in \mathcal{V} \mid C \bigcirc \sigma B \neq \emptyset \ \forall\, C \in \mathcal{C}(A)\}, \quad \sigma \in (0, \infty). \tag{3.8}$$

The family $\{\mathcal{V}_\sigma \mid \sigma \in (0, \infty)\}$ is a supremal multiscale S-approximation of $\mathcal{V}$, where S is the spatial scaling. Properties (i) and (iii) of Proposition 3.6 are clearly satisfied. Now we have that $\phi_\sigma(A) = \bigcup\{C \in \mathcal{C}(A) \mid C \cap (A \ominus \sigma B) \neq \emptyset\} = \bigcup\{C \in \mathcal{C}(A) \mid \exists\, v \in C \text{ such that } (\sigma B)_v \subseteq A\}$. Since A is open, for any $C \in \mathcal{C}(A)$ and $v \in C$, we can find a σ such that $(\sigma B)_v \subseteq A$ so that $C \subseteq \phi_\sigma(A)$. It then follows that $A = \bigcup_{\sigma \in (0,\infty)} \phi_\sigma(A)$, which shows property (ii). The approximation operators $\{\phi_\sigma \mid \sigma \in (0, \infty)\}$ are, of course, given by (3.7).

We now show that supremal multiscale approximations and scale-spaces are related. The following definition introduces the notion of supremal scale-space in the terminology of [15].

DEFINITION 3.8. *Let $\mathcal{V}$ be a lattice, and let S be a scaling on $\mathcal{V}$. A family $\{\phi_\sigma \mid \sigma \in (0, \infty)\}$ of operators on $\mathcal{V}$ is said to be a* supremal S-scale-space *if*

(i) $\phi_\sigma \phi_\tau = \phi_{\sigma \vee \tau}$ *for* $\sigma, \tau \in (0, \infty)$,

(ii) $\phi_\sigma s_\sigma = s_\sigma \phi_1$ *for* $\sigma \in (0, \infty)$.

We have the following result.

PROPOSITION 3.9. *Let $\{\mathcal{V}_\sigma \mid \sigma \in (0, \infty)\}$ be a supremal multiscale S-approximation of $\mathcal{V}$, where S is an increasing scaling. The family $\{\phi_\sigma \mid \sigma \in (0, \infty)\}$ of approximation operators, given by* (3.5)*, is a supremal S-scale-space.*

Proof. Properties (i) and (ii) of a supremal scale-space follow directly from properties (i) and (iii) in Proposition 3.6. □

Therefore, given a signal $f \in \mathcal{V}$, its approximations $\{\phi_\sigma(f) \mid \sigma \in (0, \infty)\}$ form a scale-space, where increasing scale corresponds to an "evolution" of f towards decreasing levels of "detail." Several scale-spaces that coincide with or are similar to the

two binary supremal multiscale approximation schemes of Example 3 have appeared in [3, 8, 9, 10, 15, 17, 28, 29, 37].

We now proceed to derive a nonlinear multiscale signal analysis scheme based on supremal multiscale approximations.

In linear orthogonal wavelet decomposition schemes, given two approximation spaces $\mathcal{V}_{\sigma+1} \subseteq \mathcal{V}_\sigma$, one defines a *detail space* $\mathcal{W}_{\sigma+1}$ (also called a *wavelet space*) as the orthogonal complement of $\mathcal{V}_{\sigma+1}$ in $\mathcal{V}_\sigma$, given by

$$\mathcal{W}_{\sigma+1} = \{f \in \mathcal{V}_\sigma \mid f \perp \mathcal{V}_{\sigma+1}\}. \tag{3.9}$$

From the fact that $\mathcal{V}_\sigma$ and $\mathcal{V}_{\sigma+1}$ are vector spaces, it follows that $\mathcal{W}_{\sigma+1}$ is a vector space as well. Moreover, $\mathcal{W}_{\sigma+1} \subseteq \mathcal{V}_\sigma$ and $\mathcal{W}_{\sigma+1} \perp \mathcal{V}_{\sigma+1}$.

In vector analysis, a space $\mathcal{V}$ is said to be the *direct sum* of two subspaces $\mathcal{V}_1$ and $\mathcal{V}_2$, which is denoted by $\mathcal{V} = \mathcal{V}_1 \oplus \mathcal{V}_2$, if

$$\mathcal{V} = \{f + g \mid f \in \mathcal{V}_1 \text{ and } g \in \mathcal{V}_2\} \quad \text{and} \quad \mathcal{V}_1 \cap \mathcal{V}_2 = \{O\}. \tag{3.10}$$

A fundamental property of linear wavelet analysis is that $\mathcal{V}_\sigma = \mathcal{V}_{\sigma+1} \oplus \mathcal{W}_{\sigma+1}$; i.e., the approximation space at scale σ is the direct sum of the approximation and detail spaces at scale $\sigma + 1$ (which, in this case, is also an orthogonal sum, since $\mathcal{W}_{\sigma+1} \perp \mathcal{V}_{\sigma+1}$).

In order to formulate similar ideas in a nonlinear setting, we need to define nonlinear analogues of the notions of "orthogonal complement" and "direct sum." A signal f is said to be *sup-orthogonal* to a sup-closed space $\mathcal{V}$ if its sup-projection on $\mathcal{V}$ is O. Therefore, a signal f is sup-orthogonal to an approximation space $\mathcal{V}_\sigma$ if and only if $\phi_\sigma(f) = O$. A space $\mathcal{W}$ is said to be sup-orthogonal to $\mathcal{V}$ if every signal in $\mathcal{W}$ is sup-orthogonal to $\mathcal{V}$. Note that this implies that $\mathcal{W}$ and $\mathcal{V}$ cannot have any common elements other than $\{O\}$. Given two approximation spaces $\mathcal{V}_\sigma$ and $\mathcal{V}_\tau$, with $\tau > \sigma$, we define a detail space $\mathcal{W}_{\sigma,\tau}$ as the *sup-orthogonal complement* of $\mathcal{V}_\tau$ in $\mathcal{V}_\sigma$, given by

$$\mathcal{W}_{\sigma,\tau} = \{f \in \mathcal{V}_\sigma \mid \phi_\tau(f) = O\}, \quad \tau > \sigma. \tag{3.11}$$

Note that this is the nonlinear analogue of (3.9). Moreover, we say that a space $\mathcal{V}$ is the *direct sup-sum* of two subspaces $\mathcal{V}_1$ and $\mathcal{V}_2$, which we denote by $\mathcal{V} = \mathcal{V}_1 \bigvee \mathcal{V}_2$, if

$$\mathcal{V} = \langle\, \mathcal{V}_1 \cup \mathcal{V}_2 \mid \vee \,\rangle \quad \text{and} \quad \mathcal{V}_1 \cap \mathcal{V}_2 = \{O\}.$$

This is the analogue of (3.10), where vector summation is replaced by supremum.

We now have the following definition.

DEFINITION 3.10. *Let $\{\mathcal{V}_\sigma \mid \sigma \in (0,\infty)\}$ be a supremal multiscale S-approximation of $\mathcal{V}$. If the detail spaces $\mathcal{W}_{\sigma,\tau}$, given by* (3.11)*, satisfy the property*

$$\mathcal{V}_\sigma = \mathcal{V}_\tau \bigvee \mathcal{W}_{\sigma,\tau} \quad \textit{for} \quad \sigma \in (0,\infty),\ \tau \in (\sigma,\infty), \tag{3.12}$$

then $\{\mathcal{V}_\sigma,\ \mathcal{W}_{\sigma,\tau} \mid \sigma \in (0,\infty),\ \tau \in (\sigma,\infty)\}$ is said to be a supremal multiscale S-analysis *of $\mathcal{V}$.*

It follows that, in a supremal multiscale analysis, for every $\sigma \in (0,\infty)$, $\tau \in (\sigma,\infty)$, we have that

(a) $\mathcal{V}_\tau, \mathcal{W}_{\sigma,\tau} \subseteq \mathcal{V}_\sigma$,
(b) $\mathcal{W}_{\sigma,\tau}$ is sup-orthogonal to $\mathcal{V}_\tau$,
(c) $\mathcal{V}_\sigma$ is the direct sup-sum of $\mathcal{V}_\tau$ and $\mathcal{W}_{\sigma,\tau}$.

These properties are the nonlinear analogues of similar properties satisfied by the approximation and detail spaces in linear orthogonal wavelet analysis.

Next, we define the notion of detail operator.

DEFINITION 3.11. *Let* $\{\mathcal{V}_\sigma, \mathcal{W}_{\sigma,\tau} \mid \sigma \in (0,\infty), \tau \in (\sigma,\infty)\}$ *be a supremal multiscale S-analysis of* $\mathcal{V}$. *If* $\psi_{\sigma,\tau}$ *is a projection on* $\mathcal{W}_{\sigma,\tau}$ *and*

$$\phi_\sigma = \phi_\tau \vee \psi_{\sigma,\tau} \quad \textit{for} \quad \sigma \in (0,\infty),\ \tau \in (\sigma,\infty), \tag{3.13}$$

then $\{\psi_{\sigma,\tau} \mid \sigma \in (0,\infty), \tau \in (\sigma,\infty)\}$ *is a family of* detail operators *of the supremal multiscale S-analysis.*

From (3.13), it follows that an approximation $\phi_\sigma(f)$ of a signal $f \in \mathcal{V}$ can be decomposed, in a unique way, as the supremum of a sup-projection $\phi_\tau(f)$ on $\mathcal{V}_\tau$ and a projection $\psi_{\sigma,\tau}(f)$ on $\mathcal{W}_{\sigma,\tau}$. Furthermore, $\psi_{\sigma,\tau}(f)$ is sup-orthogonal to $\mathcal{V}_\tau$; i.e., $\phi_\tau\psi_{\sigma,\tau}(f) = O$. Therefore, the approximation of f at scale σ has a unique decomposition as the supremum of the approximation signal at scale τ and a sup-orthogonal detail signal, which contains information about f that is present at scale σ but is removed at the coarser scale τ. Finally, by applying the supremum $\bigvee_{\sigma\in(0,\tau)}$ on both sides of (3.13) and by using properties (i) and (ii) of Proposition 3.6, we get

$$f = \phi_\tau(f) \vee \bigvee_{\sigma\in(0,\tau)} \psi_{\sigma,\tau}(f) \quad \text{for} \quad \tau \in (0,\infty). \tag{3.14}$$

This shows that a signal $f \in \mathcal{V}$ can be uniquely decomposed in terms of a scaled signal $\phi_\tau(f)$ at scale $\tau \in (0,\infty)$ and detail signals $\psi_{\sigma,\tau}(f)$, $\sigma \in (0,\tau)$. It is worthwhile noticing that the decomposition suggested by (3.14) is conceptually analogous to the well-known wavelet decomposition.

Note that, for $\tau' \geq \tau$, we have $\phi_{\tau'}\psi_{\sigma,\tau}(f) \leq \phi_\tau\psi_{\sigma,\tau}(f) = O \Rightarrow \phi_{\tau'}\psi_{\sigma,\tau}(f) = O$. Therefore, a detail signal $\psi_{\sigma,\tau}(f)$ is sup-orthogonal to all approximation spaces $\mathcal{V}_{\tau'}$, $\tau' \geq \tau$.

In practice, a multiscale signal decomposition scheme can be constructed by selecting initial and final approximation scales σ and τ and a set of intermediary scales $\sigma_0 = \sigma, \sigma_1, \ldots, \sigma_{N-1}, \sigma_N = \tau$ such that $\sigma_k < \sigma_{k+1}$ for $k = 0, 1, \ldots, N-1$. Then, by repeatedly applying (3.13), we get

$$\phi_\sigma(f) \;=\; \phi_\tau(f) \;\vee \bigvee_{0\leq k\leq N-1} \psi_{\sigma_k,\sigma_{k+1}}(f), \quad \tau > \sigma, \tag{3.15}$$

which provides a decomposition of the approximation $\phi_\sigma(f)$ of a signal f into the sequence $\{\phi_\tau(f), \psi_{\sigma,\sigma_1}(f), \psi_{\sigma_1,\sigma_2}(f), \ldots, \psi_{\sigma_{N-1},\tau}(f)\}$. Clearly, all detail signals are sup-orthogonal to the final approximation space $\mathcal{V}_\tau$; i.e., $\phi_\tau\psi_{\sigma_k,\sigma_{k+1}}(f) = O$ for $k = 0, 1, \ldots, N-1$.

Example 4.

(a) Let $\mathcal{V} = \mathcal{G}(\mathbb{R}^d)$, and consider the supremal multiscale approximation of $\mathcal{V}$ given in Example 3(a). Using (3.6) and (3.11), we get

$$\mathcal{W}_{\sigma,\tau} = \{A \in \mathcal{V} \mid A \bigcirc \sigma B = A \ \text{ and } \ A \bigcirc \tau B = \emptyset\}, \quad \tau > \sigma.$$

Clearly, $\mathcal{V}_\sigma = \langle\, \mathcal{V}_\tau \cup \mathcal{W}_{\sigma,\tau} \mid \vee \,\rangle$ and $\mathcal{V}_\sigma \cap \mathcal{W}_{\sigma,\tau} = \{\emptyset\}$. Therefore, (3.12) is satisfied so that $\{\mathcal{V}_\sigma, \mathcal{W}_{\sigma,\tau} \mid \sigma \in (0,\infty), \tau \in (\sigma,\infty)\}$ is a supremal multiscale S-analysis of $\mathcal{V}$, where S is the spatial scaling. If B is a structuring element that contains the origin, then the operators

$$\psi_{\sigma,\tau}(A) = A \bigcirc \sigma B \smallsetminus A \ominus \tau B, \quad \tau > \sigma,$$

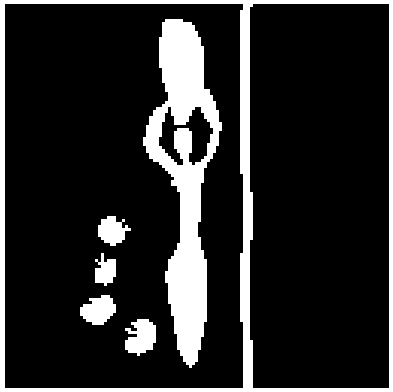

FIG. 2. *A binary "Matisse" image.*

are projections on $\mathcal{W}_{\sigma,\tau}$ that satisfy (3.13). Therefore, $\{\psi_{\sigma,\tau} \mid \sigma \in (0,\infty),\ \tau \in (\sigma,\infty)\}$ is a family of detail operators associated with the supremal multiscale analysis. As an illustration, this scheme is applied on the binary "Matisse" image[1] depicted in Figure 2. The result is depicted in Figure 3. Note that

$$\psi_{\sigma,\tau}(A) = (A \ominus \sigma B) \oplus \sigma B \smallsetminus (A \ominus \sigma B) \ominus (\tau - \sigma)B, \quad \tau > \sigma.$$

This shows that the detail signal $\psi_{\sigma,\tau}(A)$ is obtained by applying a *morphological gradient* on the erosion $A \ominus \sigma B$ (a morphological gradient is an operator of the form $A \oplus tB \smallsetminus A \ominus sB$, where B is a structuring element that contains the origin—see [12, 16]).

(b) Let $\mathcal{V} = \mathcal{G}(\mathbb{R}^d)$, and consider the supremal multiscale approximation of $\mathcal{V}$ given in Example 3(b). Using (3.8) and (3.11), we get

$$\mathcal{W}_{\sigma,\tau} = \{A \in \mathcal{V} \mid C \bigcirc \sigma B \neq \emptyset \ \text{ and } \ C \bigcirc \tau B = \emptyset \ \forall\, C \in \mathcal{C}(A)\}, \quad \tau > \sigma,$$

for $\sigma \in (0,\infty)$ and $\tau \in (\sigma,\infty)$. Again, $\mathcal{V}_\sigma = \langle\, \mathcal{V}_\tau \cup \mathcal{W}_{\sigma,\tau} \mid \vee \,\rangle$ and $\mathcal{V}_\sigma \cap \mathcal{W}_{\sigma,\tau} = \{\emptyset\}$. Therefore, (3.12) is satisfied so that $\{\mathcal{V}_\sigma,\ \mathcal{W}_{\sigma,\tau} \mid \sigma \in (0,\infty),\ \tau \in (\sigma,\infty)\}$ is a supremal multiscale S-analysis of $\mathcal{V}$, where S is the spatial scaling. The operators

$$\psi_{\sigma,\tau}(A) = \rho(A \mid A \bigcirc \sigma B) \smallsetminus \rho(A \mid A \bigcirc \tau B), \quad \tau > \sigma,$$

are projections on $\mathcal{W}_{\sigma,\tau}$ that satisfy (3.13). Therefore, $\{\psi_{\sigma,\tau} \mid \sigma \in (0,\infty),\ \tau \in (\sigma,\infty)\}$ is a family of detail operators associated with the supremal multiscale analysis. The detail signal $\psi_{\sigma,\tau}(A)$ contains the connected components of A whose "size" is between σ and τ. The resulting supremal multiscale S-analysis scheme is a *discrete size transform* based on openings by reconstruction (see [12, 16] for the notion of the discrete size transform and [10] for such a decomposition). This scheme is illustrated in Figure 4.

The previous examples are binary. In the following, we present an important example of supremal multiscale analysis based on a reconstructive scheme that selectively removes regional maxima from a grayscale signal.

[1] Henri Matisse: *Woman with Amphora and Pomegranates*, 1952—Paper on canvas.

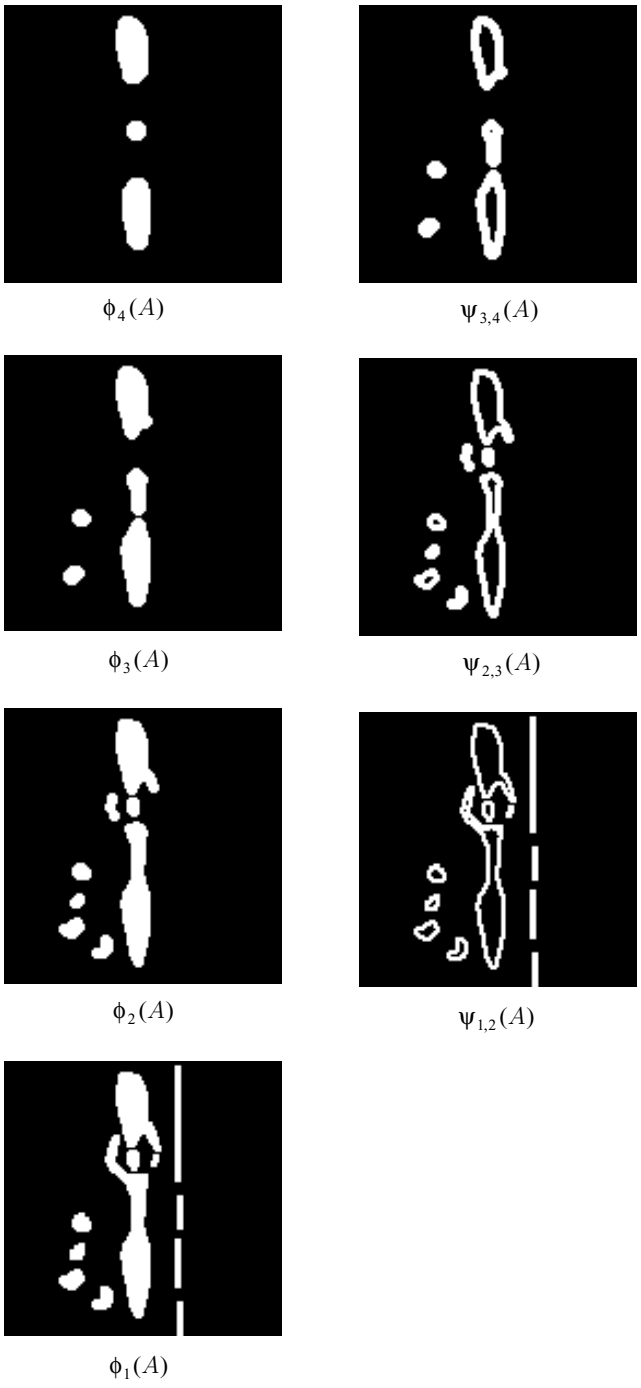

FIG. 3. *An illustration of supremal multiscale analysis of a binary "Matisse" image A depicted in Figure* 2 *based on structural openings. Note that* $\phi_k(A) = \phi_{k+1}(A) \cup \psi_{k,k+1}(A)$*, for* $k = 1, 2, 3$*, and* $\phi_1(A) = \phi_4(A) \cup \psi_{1,2}(A) \cup \psi_{2,3}(A) \cup \psi_{3,4}(A)$*, in accordance with* (3.13) *and* (3.15)*. In this example, B is a disk structuring element of unit radius.*

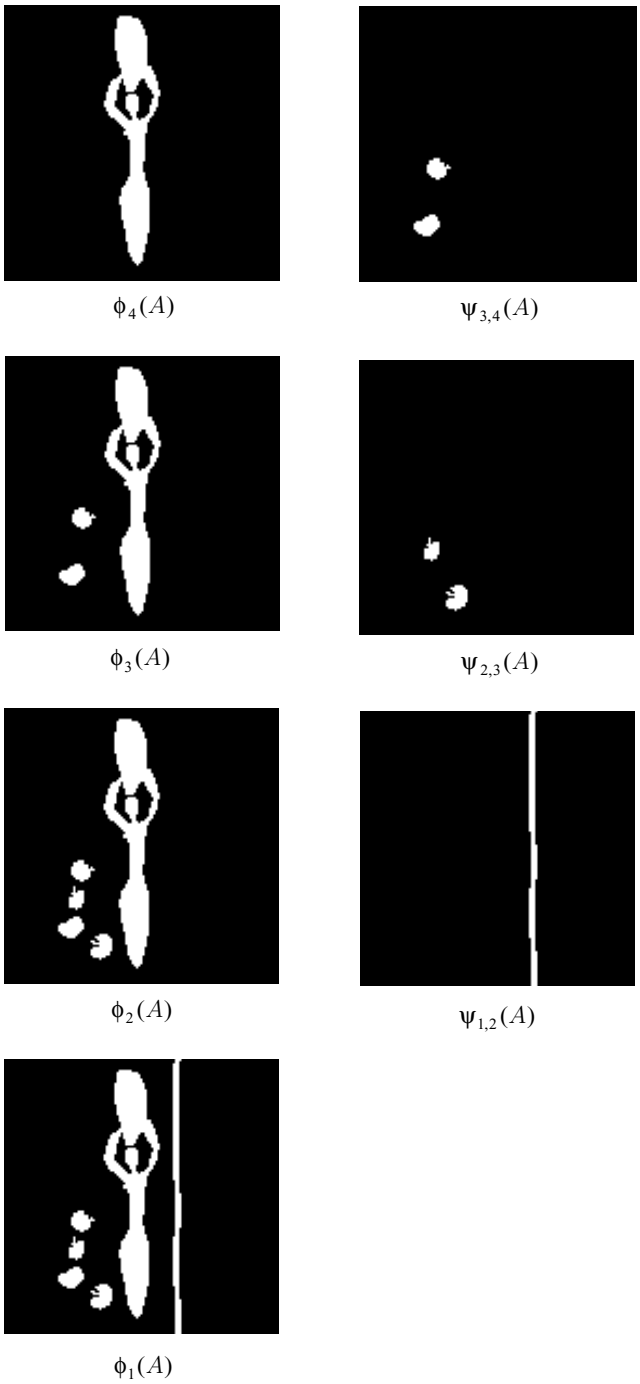

FIG. 4. *An illustration of supremal multiscale analysis of the binary "Matisse" image A depicted in Figure* 2 *based on openings by reconstruction. Note that* $\phi_k(A) = \phi_{k+1}(A) \cup \psi_{k,k+1}(A)$*, for* $k = 1, 2, 3$*, and* $\phi_1(A) = \phi_4(A) \cup \psi_{1,2}(A) \cup \psi_{2,3}(A) \cup \psi_{3,4}(A)$*, in accordance with* (3.13) *and* (3.15)*. In this example, B is a disk structuring element of unit radius.*

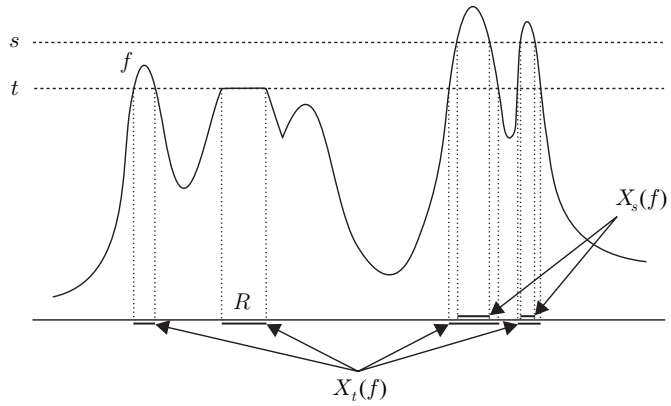

FIG. 5. *A signal f with a regional maximum R at level t. Note that R is a connected component of $X_t(f)$, that $R \cap X_s(f) = \emptyset$, for $s > t$, and that f is constant over R. The usual topological connectivity of the Euclidean real line is assumed.*

4. Skyline supremal multiscale analysis. Recall the lattice $\mathrm{Fun}_u(E, \mathcal{T})$ of u.s.c. functions, discussed in Example 1(e). Here we adopt as the lattice $\mathcal{V}$ of signals of interest the lattice $\mathcal{V} = \mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$ of nonnegative u.s.c. real-valued functions defined on a topological space E. We are making the following basic assumption.

Assumption 1. We assume that E is a compact Hausdorff space with a countable basis. Moreover, we assume that E is furnished with a connectivity class $\mathcal{C} \subseteq \mathcal{P}(E)$ such that we have the following:

(a) $A \in \mathcal{C}$ implies that $\overline{A} \in \mathcal{C}$ (in this case, the connectivity class $\mathcal{C}$ is said to be *compatible* with the topology of E [6]).
(b) The connectivity openings $\{\gamma_x \mid x \in E\}$, associated with $\mathcal{C}$, are $\downarrow$-continuous operators on $\mathcal{F}(E)$ (i.e., on the collection of all closed subsets of E).
(c) For each $A \in \mathcal{F}(E)$, $\gamma_x(A)$ is an u.s.c. function from A into $\mathcal{F}(E)$.

For example, one may assume E to be a connected, closed, and bounded subset of $\mathbb{R}^d$, with the Euclidean topology, and take $\mathcal{C}$ to be the connectivity class consisting of the usual Euclidean connected subsets of E. It has been shown in [6] that this choice satisfies all conditions stated in Assumption 1.

Next, we give a precise definition of a regional maximum of a signal in $\mathcal{V}$.

DEFINITION 4.1. *A set $R \subseteq E$ is a* regional maximum of $f \in \mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$ at level $t \in \overline{\mathbb{R}}_+$ *if R is a connected component of $X_t(f)$ and $R \cap X_s(f) = \emptyset$ for all $s > t$.*

Therefore, regional maxima depend on the underlying connectivity assumed. See Figure 5 for an illustration. A regional maximum is always a closed set, since $X_t(f)$ is closed and $\mathcal{C}$ is compatible [7]. It is easy to see that a signal $f \in \mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$ is constant over a regional maximum R; we denote this constant value by $f(R)$. In addition, we denote by $\mathcal{R}(f)$ the set of all regional maxima of a signal f and by $\mathcal{R}_t(f)$ the set of all regional maxima of f at level t or above; i.e., $\mathcal{R}_t(f) = \{R \in \mathcal{R}(f) \mid f(R) \geq t\}$ for $t \in \overline{\mathbb{R}}_+$.

We have the following result regarding regional maxima.

PROPOSITION 4.2.

(a) *Any function $f \in \mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$ has at least one regional maximum.*
(b) *A function $f \in \mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$ has exactly one regional maximum if and only if $X_t(f) \in \mathcal{C}$ for all $t \in \overline{\mathbb{R}}_+$.*

Proof. (a) From Weierstrass's theorem of real analysis [19] and the facts that E is compact and f is an u.s.c. function, f achieves its supremum in E; i.e., there is a

point $x_0 \in E$ such that $f(x_0) = \bigvee\{f(x) \mid x \in E\}$. It is clear that $X_t(f) = \emptyset$ for all $t > f(x_0)$. Hence, $R = \gamma_{x_0}(X_{f(x_0)}(f))$ is a regional maximum of f at level $f(x_0)$.

(b) We show that f has two or more regional maxima if and only if $X_t(f) \notin \mathcal{C}$, for some $t \in \overline{\mathbb{R}}_+$, which is the contrapositive of the assertion. To show the direct implication, assume that R_1 and R_2 are two regional maxima of f. If $f(R_1) = f(R_2) = t$, then $X_t(f) \notin \mathcal{C}$. Otherwise, let $f(R_1) = t_1 > t_2 = f(R_2)$. We have that $R_1 \subseteq X_{t_1}(f) \subseteq X_{t_2}(f)$. But $R_2 \cap X_{t_1}(f) = \emptyset \Rightarrow R_1 \cap R_2 = \emptyset$ so that R_2 must be a strict subset of $X_{t_2}(f)$, which implies that $X_{t_2}(f) \notin \mathcal{C}$. To show the converse implication, assume that $X_t(f) \notin \mathcal{C}$, for some $t \in \overline{\mathbb{R}}_+$, and let C_1 and C_2 be two connected components of $X_t(f)$. Sets C_1 and C_2 are closed subsets of the compact space E; thus C_1 and C_2 are themselves compact [11]. Hence, the restrictions f_1 and f_2 of f to C_1 and C_2, respectively, are u.s.c. functions defined on compact sets so that each achieves its supremum, say, at points $x_1 \in R_1$ and $x_2 \in R_2$. Clearly, the corresponding regional maxima of f_1 and f_2 at $f(x_1)$ and $f(x_2)$, respectively, are distinct regional maxima of f. □

Part (a) of the previous proposition shows that the set $\mathcal{R}(f)$ of regional maxima of f is nonempty, whereas part (b) indicates that the notions of regional maxima and connectivity of level sets are closely related.

Recall from section 2 the grayscale reconstruction operator associated with a connectivity class $\mathcal{C} \subseteq \mathcal{P}(E)$. This operator will be central for our purposes. The next fundamental result shows that a signal $f \in \mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$ can be "reconstructed" from the grayscale reconstructions of f "marked" by each of its regional maxima. Before that, we need the following definition: A *cylinder* $h_{A,t}$ of base $A \subseteq E$ and height $t \in \overline{\mathbb{R}}_+$ is a function in $\mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$ defined by

$$h_{A,t}(x) = \begin{cases} t & \text{if } x \in A, \\ 0 & \text{otherwise} \end{cases} \quad \text{for } x \in E.$$

PROPOSITION 4.3. *Let $f \in \mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$. For each $R \in \mathcal{R}(f)$, we have that $g = \widetilde{\rho}(f \mid h_{R,f(R)}) \in \mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$, and $\mathcal{R}(g) = \{R\}$, with $g(R) = f(R)$. Moreover,*

$$f = \bigvee_u \{\widetilde{\rho}(f \mid h_{R,f(R)}) \mid R \in \mathcal{R}(f)\}. \tag{4.1}$$

Proof. From the definition of $\widetilde{\rho}$ in (2.2), we can write

$$g(v) = \widetilde{\rho}(f \mid h_{R,f(R)})(v) = \bigvee\{t \in \overline{\mathbb{R}}_+ \mid v \in \rho(\, X_t(f) \mid X_t(h_{R,f(R)}))\}, \quad v \in E. \tag{4.2}$$

Note that $X_t(h_{R,f(R)}) = R$, if $t \leq f(R)$, and $X_t(h_{R,f(R)}) = \emptyset$ if $t > f(R)$. Also, $X_t(f) \cap R = \emptyset$ for $t > f(R)$. Hence, $\rho(X_t(f) \mid X_t(h_{R,f(R)})) = \rho(X_t(f) \mid R)$ for all $t \in \overline{\mathbb{R}}_+$. Moreover, R is connected so that it must be contained in one of the connected components of $X_t(f)$, and, therefore, $\rho(X_t(f) \mid R) = \gamma_x(X_t(f))$ for some $x \in R$. Thus, (4.2) becomes $g(v) = \bigvee\{t \in \overline{\mathbb{R}}_+ \mid v \in \gamma_x(X_t(f))\}$ for $v \in E$. Hence, $X_t(g) = \bigcap_{s<t} \gamma_x(X_s(f)) = \gamma_x\left(\bigcap_{s<t} X_s(f)\right) = \gamma_x(X_t(f))$, for all $t \in \overline{\mathbb{R}}_+$, from the $\downarrow$-continuity of γ_x on $\mathcal{F}(E)$ and (2.1). In other words, $X_t(g)$ is a closed (by the compatibility of $\mathcal{C}$) connected set, for all $t \in \overline{\mathbb{R}}_+$, so that, by Proposition 4.2(b), g is u.s.c. and has a single regional maximum. In addition, we have that $X_t(g) = R$, for $t = f(R)$, and $X_t(g) = \emptyset$, for $t > f(R)$, so that R is the only regional maximum of g at level $g(R) = f(R)$. This shows the first part of the result. Note that the right-hand side of (4.1) makes sense, since $\widetilde{\rho}(f \mid h_{R,f(R)})$ is a function in $\mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$ for each $R \in \mathcal{R}(f)$. Let C be a connected component of any nonempty level set $X_t(f)$ of f. It

follows from the fact that any closed subset of a compact space is compact and from the compatibility of $\mathcal{C}$ that C is compact. In addition, the restriction of f to C is an u.s.c. function; hence, C contains some regional maximum $R \in \mathcal{R}_t(f)$. Moreover, the definition of regional maximum implies that each $R \in \mathcal{R}_t(f)$ must be contained in some component C of $X_t(f)$. Since $X_t(f)$ equals the union of its components, we conclude that $X_t(f) = \bigcup_{R\in\mathcal{R}_t(f)} \rho(X_t(f) \,|\, R)$. But, by definition, any $R \in \mathcal{R}(f) \setminus \mathcal{R}_t(f)$ does not intersect $X_t(f)$. Hence, $X_t(f) = \bigcup_{R\in\mathcal{R}(f)} \rho(X_t(f) \,|\, R)$. In addition, from our previous discussion, we have that $X_t(\,\widetilde{\rho}(f \mid h_{R,f(R)})) = \rho(X_t(f) \,|\, R)$ for all $t \in \overline{\mathbb{R}}_+$. It follows from the last two equations and the fact $X_t(f) = \bigcap_{s<t} \overline{\bigcup X_s(f_\alpha)}$ that [7]

$$\begin{aligned} X_t\left(\bigvee_u \{\widetilde{\rho}(f \mid h_{R,f(R)}) \mid R \in \mathcal{R}(f)\}\right) &= \bigcap_{s<t} \overline{\bigcup_{R\in\mathcal{R}(f)} X_t(\,\widetilde{\rho}(f \mid h_{R,f(R)}))} \\ &= \bigcap_{s<t} \overline{\bigcup_{R\in\mathcal{R}(f)} \rho(X_s(f) \,|\, R)} \\ &= \bigcap_{s<t} \overline{X_s(f)} = \bigcap_{s<t} X_s(f) = X_t(f), \end{aligned}$$

for all $t \in \overline{\mathbb{R}}_+$, which implies (4.1). □

Now consider the subsets $\mathcal{V}_\sigma$ of $\mathcal{V}$ given by

$$\mathcal{V}_\sigma = \{O\} \cup \{f \in \mathcal{V} \mid \mathcal{R}(f) = \mathcal{R}_\sigma(f)\}, \quad \sigma \in (0,\infty). \tag{4.3}$$

In other words, $\mathcal{V}_\sigma$ consists of the least signal O and all signals whose regional maxima are at level σ or above. The following is a fundamental result for our purposes.

PROPOSITION 4.4. *The space $\mathcal{V}_\sigma$ is sup-closed in* $\mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$ *for* $\sigma \in (0,\infty)$.

Proof. First, note that $\bigvee \emptyset = O \in \mathcal{V}_\sigma$ for every $\sigma \in (0,\infty)$. For a given $\sigma \in (0,\infty)$, let $\{f_\alpha\}$ be a family of functions in $\mathrm{Fun}_u(E, \overline{\mathbb{R}}_+)$ such that $\{f_\alpha\} \subseteq \mathcal{V}_\sigma$. We can assume, without loss of generality, that $f_\alpha \neq O$ for all α. Hence, $\mathcal{R}_\sigma(f_\alpha) = \mathcal{R}(f_\alpha) \neq \emptyset$, for each f_α, which implies that $X_t(f_\alpha) \neq \emptyset$ for all $t \leq \sigma$. Let $f = \bigvee_u f_\alpha$. We have that $X_t(f) = \bigcap_{s<t} \overline{\bigcup X_s(f_\alpha)} \supseteq \bigcup X_t(f_\alpha)$ [7]. Therefore, $X_t(f) \neq \emptyset$ for all $t \leq \sigma$. Suppose that R is a regional maximum of f at a level $r < \sigma$. By definition, we have that $R \cap X_t(f) = \emptyset$ for all $t > r$. Therefore, the sets R and $T = X_\sigma(f)$ are closed nonempty disjoint sets. Moreover, since E is a compact Hausdorff space, there exist disjoint open sets U and V such that $R \subset U$ and $T \subset V$ [11]. Now, given $x \in R$, we have that $R = \gamma_x(X_r(f)) = \gamma_x(\bigcap_{s<r} \overline{\bigcup X_s(f_\alpha)}) = \bigcap_{s<r} \gamma_x(\overline{\bigcup X_s(f_\alpha)})$ from the $\downarrow$-continuity of γ_x on $\mathcal{F}(E)$ and (2.1). Let $C(s) = \gamma_x(\overline{\bigcup X_s(f_\alpha)})$ for $s < r$. Note that $\{C(s)\}_{s<r}$ is a decreasing family of nonempty closed sets in the compact space E, and $\bigcap_{s<r} C(s) \subset U$. It follows that there is some $p < r$ such that $C(p) \subset U$ [7, Prop. 2.3.7]. Since $\gamma_x(A)$ is an u.s.c. function from A into $\mathcal{F}(E)$, we can apply Proposition 4.1.14 in [7] to conclude that there is some connected component C of $\bigcup X_p(f_\alpha)$ such that $C \subset U$. Clearly, this implies that there is some index α' such that a connected component C' of $X_p(f_{\alpha'})$ is contained in U. This follows from the fact that each component of $\bigcup A_\alpha$ must contain at least one component of some $A_{\alpha'}$. However, note that $T = X_\sigma(f) \supseteq \bigcup X_\sigma(f_\alpha)$ implies that $X_\sigma(f_\alpha) \subset V$ for all α. Hence, $C' \cap X_\sigma(f_{\alpha'}) = \emptyset$ so that function $f_{\alpha'}$ has a regional maximum inside C' at some level below t, which is a contradiction. Therefore, $f = \bigvee_u f_\alpha$ must not have any regional maxima below level σ; i.e., $f \in \mathcal{V}_\sigma$, as required. □

We can now use the previous result to show that the family $\{\mathcal{V}_\sigma \mid \sigma \in (0,\infty)\}$ is a supremal multiscale approximation of $\mathcal{V}$.

PROPOSITION 4.5. *The family* $\{\mathcal{V}_\sigma \mid \sigma \in (0,\infty)\}$*, given by* (4.3)*, is a supremal multiscale* S*-approximation of* $\mathcal{V}$ *for the gray-level scaling* $S = \{tf(\cdot) \mid t \in (0,\infty)\}$.

Proof. From Proposition 4.4, $\mathcal{V}_\sigma$ is sup-closed in $\mathcal{V}$ for each $\sigma \in (0,\infty)$. In addition, (3.2) is clearly satisfied, whereas (3.4) is a direct consequence of the fact that $X_\tau(f) = X_{t\tau}(tf)$, which implies that R is a regional maximum of f at level τ if and only if R is a regional maximum of tf at level $t\tau$. To show (3.3), note that Proposition 4.3 implies that, for a given $f \in \mathcal{V}$, $\widetilde{\rho}(f \mid h_{R,f(R)}) \in \mathcal{V}_{f(R)}$ for each $R \in \mathcal{R}(f)$. Moreover, it implies that $f = \bigvee_u\{\widetilde{\rho}(f \mid h_{R,f(R)}) \mid R \in \mathcal{R}(f)\} \in \langle \bigcup \mathcal{V}_\sigma \mid \vee_u \rangle$, from which we obtain the desired result. ∎

The next result provides an expression for the associated approximation operators.

PROPOSITION 4.6. *Let* $\{\mathcal{V}_\sigma \mid \sigma \in (0,\infty)\}$ *be the supremal multiscale approximation of* $\mathcal{V}$*, given by* (4.3)*. The associated approximation operators are given by*

$$\phi_\sigma(f) = \bigvee_u\{\,\widetilde{\rho}(f \mid h_{R,f(R)}) \mid R \in \mathcal{R}_\sigma(f)\}, \quad f \in \mathcal{V}, \quad \sigma \in \overline{\mathbb{R}}_+. \tag{4.4}$$

Proof. Let $\sigma \in (0,\infty)$, and consider the operator $\theta(f) = \bigvee_u\{\,\widetilde{\rho}(f \mid h_{R,f(R)}) \mid R \in \mathcal{R}_\sigma(f)\}$ for $f \in \mathcal{V}$. Note that Proposition 4.3 guarantees that θ is an operator on $\mathcal{V}$. We show that $\phi_\sigma(f) = \bigvee_u\{g \in \mathcal{V}_\sigma \mid g \leq f\} = \theta(f)$ for $f \in \mathcal{V}$. First, we show that θ is an increasing operator. Let $f, g \in \mathcal{V}$ such that $f \leq g$. Consider a regional maximum $R \in \mathcal{R}_\sigma(f)$ at level $t = f(R)$. Since $R \in \mathcal{C}$ and $R \subseteq X_t(f) \subseteq X_t(g)$, we must have that $R \subseteq C$ for some connected component C of $X_t(g)$. As argued in the proof of Proposition 4.3, there is a regional maximum $R' \in \mathcal{R}_\sigma(g)$ such that $R' \subseteq C$. For any $s \leq t$, it is clear that $\rho(X_s(g) \mid R) = \rho(X_s(g) \mid R')$, since both R and R' are contained in the same connected component of $X_s(g)$ that contains C. This implies that $X_s(\,\widetilde{\rho}(f \mid h_{R,f(R)})) = \rho(X_s(f) \mid R) \subseteq \rho(X_s(g) \mid R) = \rho(X_s(g) \mid R') = X_s(\,\widetilde{\rho}(g \mid h_{R',g(R')}))$, for all $s \leq f(R)$, where we have used the fact that $\rho(\cdot \mid R)$ is an opening and thus is increasing. Since $X_s(\,\widetilde{\rho}(f \mid h_{R,f(R)})) = \emptyset$, for $s > f(R)$, we conclude that $\widetilde{\rho}(f \mid h_{R,f(R)}) \leq \widetilde{\rho}(g \mid h_{R',g(R')})$. This implies that $\theta(f) \leq \theta(g)$ so that θ is increasing. Now let $f \in \mathcal{V}$. If $\mathcal{R}_\sigma(f) = \emptyset$, then clearly $\theta(f) = \phi_\sigma(f) = O$. Hence, we can assume that $\mathcal{R}_\sigma(f) \neq \emptyset$. We have that $\phi_\sigma(f) \in \mathcal{V}_\sigma$; hence $\mathcal{R}_\sigma(\phi_\sigma(f)) = \mathcal{R}(\phi_\sigma(f))$. It follows from Proposition 4.3 that $\phi_\sigma(f) = \theta(\phi_\sigma(f))$. But, since θ is increasing and ϕ_σ is antiextensive, we have that $\theta(\phi_\sigma(f)) \leq \theta(f)$. Therefore, $\phi_\sigma(f) \leq \theta(f)$. To show the converse inequality, note that Proposition 4.3 implies that $\widetilde{\rho}(f \mid h_{R,f(R)}) \in \mathcal{V}_\sigma$ for each $R \in \mathcal{R}_\sigma(f)$. Since $\mathcal{V}_\sigma$ is sup-closed, we must have $\theta(f) \in \mathcal{V}_\sigma$. Combined with the fact that $\theta(f) \leq f$, this implies that $\theta(f) \leq \phi_\sigma(f)$. Hence, $\phi_\sigma(f) = \theta(f)$. ∎

Given a signal $f \in \mathcal{V}$, its approximation $\phi_\sigma(f)$, obtained from f by means of (4.4), preserves the regional maxima of f that are at level σ or above, while it flattens the rest. As the scale σ increases, only the highest peaks in the signal survive. In this scale-space, evolution towards decreasing levels of detail is akin to viewing a city skyline as one moves away from it: near the city, the shorter buildings are visible, but far away only the tallest buildings can be discerned. This is illustrated in Figure 6. For this reason, we refer to this scheme as a *skyline supremal multiscale approximation*, whereas the associated scale-space is referred to as a *skyline supremal scale-space*.

In addition to being grayscale, translation, and scale invariant, the most striking property of the skyline supremal scale-space is that, by construction, it decomposes the regional maxima of a function f in a natural causal hierarchy. As σ increases, the scaling operator ϕ_σ removes regional maxima from f without introducing new ones. Moreover, as σ increases, the scaling operator ϕ_σ progressively removes connected

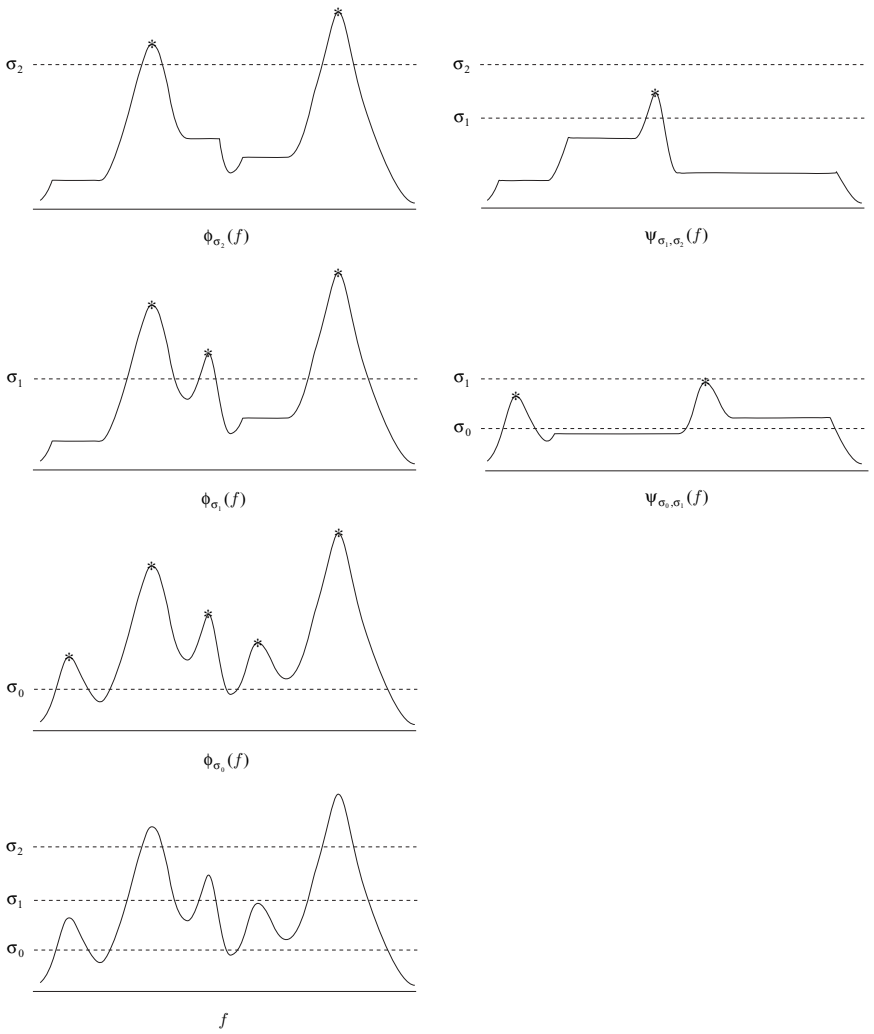

FIG. 6. *Skyline supremal multiscale analysis of a one-dimensional signal f. Note that the scaling $\phi_\sigma(f)$ preserves the regional maxima (depicted by $*$) of f that are at level σ or above, while it flattens the rest. Moreover, the detail signal $\psi_{\sigma,\tau}(f)$ preserves the regional maxima of f with values in $[\sigma,\tau)$ and flattens the rest. Finally, $\phi_{\sigma_k}(f) = \phi_{\sigma_{k+1}}(f) \vee \psi_{\sigma_k,\sigma_{k+1}}(f)$, for $k = 0, 1$, and $\phi_{\sigma_0}(f) = \phi_{\sigma_2}(f) \vee \psi_{\sigma_0,\sigma_1}(f) \vee \psi_{\sigma_1,\sigma_2}(f)$, in accordance with* (3.13) *and* (3.15)*, respectively.*

components from the level sets $X_t(f)$ of f without introducing new ones. These properties are much desired by any useful scale-space scheme [3, 18, 21, 22, 41].

We now derive the corresponding supremal multiscale analysis. From (3.11), (4.3), and (4.4), we have that

$$\mathcal{W}_{\sigma,\tau} = \{O\} \cup \{f \in \mathcal{V} \mid \mathcal{R}(f) = \mathcal{R}_\sigma(f) \smallsetminus \mathcal{R}_\tau(f)\}, \quad \tau > \sigma.$$

It is easy to check that (3.12) is satisfied so that $\{\mathcal{V}_\sigma, \mathcal{W}_{\sigma,\tau} \mid \sigma \in (0,\infty), \tau \in (\sigma,\infty)\}$ is a supremal multiscale S-analysis of $\mathcal{V}$, where S is the gray-level scaling. This is referred to as the *skyline supremal multiscale analysis* of $\mathcal{V}$. The operators

$$\psi_{\sigma,\tau}(f) = \bigvee_u \{\widetilde{\rho}(f \mid h_{R,f(R)}) \mid R \in \mathcal{R}_s(f) \smallsetminus \mathcal{R}_\tau(f)\}, \quad \tau > \sigma,$$

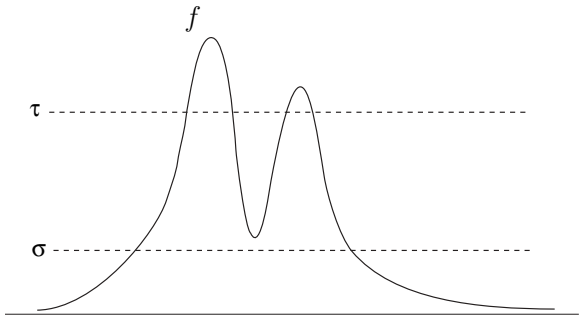

FIG. 7. *The function $f \in \mathcal{V}_\sigma$ is level-σ connected, but it is not level-τ connected. The usual topological connectivity of the Euclidean real line is assumed for the underlying binary connectivity class $\mathcal{C}$.*

are projections on $\mathcal{W}_{\sigma,\tau}$. Therefore, these are detail operators associated with the skyline supremal multiscale analysis scheme. The detail signal $\psi_{\sigma,\tau}(f)$ preserves the regional maxima of f with values in $[\sigma, \tau)$ and flattens the rest. This is illustrated in Figure 6.

From our previous discussion, it is clear that (4.3) satisfies (3.2) and (3.3), regardless of the choice of scaling. Whether or not (3.4) is satisfied depends on the choice of scaling and the choice of the connectivity class $\mathcal{C}$, since the concept of regional maximum depends on the underlying connectivity class. In the case of gray-level scaling, our results hold true for any choice of connectivity class $\mathcal{C}$. However, in the cases of spatial and umbral scalings, the results are valid if $\mathcal{C}$ is invariant to spatial scalings, i.e., if $A \in \mathcal{C} \Leftrightarrow tA \in \mathcal{C}$, for all $A \in \mathcal{F}(E)$ and $t \in (0, \infty)$. Topological connectivity clearly satisfies this property.

Additional insight can be gained by realizing that each approximation space $\mathcal{V}_\sigma$ constitutes a complete lattice, under the partial order of $\mathcal{V}$, with supremum $\bigvee^\sigma$ and infimum $\bigwedge^\sigma$, given by

$$\bigvee\nolimits^\sigma f_\alpha = \bigvee_u f_\alpha,$$

$$\bigwedge\nolimits^\sigma f_\alpha = \phi_\sigma\Big(\bigwedge f_\alpha\Big) = \bigvee_u \Big\{\widetilde{\rho}\Big(\bigwedge f_\alpha \mid h_{R,(\bigwedge f_\alpha)(R)}\Big) \mid R \in \mathcal{R}_\sigma\Big(\bigwedge f_\alpha\Big)\Big\}.$$

In this framework, $\bigwedge^\sigma f_\alpha = O$ if and only if $\bigwedge f_\alpha$ has no regional maxima at level σ or above. Hence, even if the signals $\{f_\alpha\}$ have nonzero pointwise infimum, they can still have zero infimum in $\mathcal{V}_\sigma$.

It has been shown in [7] that the family

$$\mathcal{S}_\sigma = \{\delta_{v,t} \mid t \geq \sigma\} \cup \{f \in \mathcal{V} \mid \mathcal{R}(f) = \{R\},\ f(R) = \sigma\}$$

is sup-generating in $\mathcal{V}_s$. Moreover, assuming this sup-generating family, we can define a connectivity class $\mathcal{C}_\sigma$ on $\mathcal{V}_\sigma$, given by [7]

$$\mathcal{C}_\sigma = \{f \in \mathcal{V}_\sigma \mid X_t(f) \in \mathcal{C}\ \forall\, t \leq \sigma\}.$$

We call this the *level-σ connectivity class*. In this framework, a function $f \in \mathcal{V}_\sigma$ is level-σ connected if all level sets below level σ are connected, according to the connectivity class $\mathcal{C}$. Loosely speaking, this means that f is not allowed to have any "disconnecting dips" below level σ. See Figure 7 for an illustration.

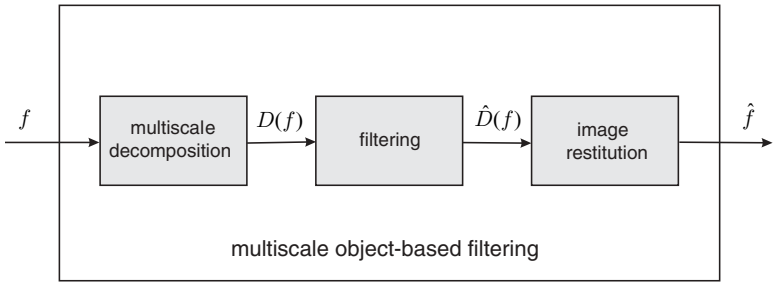

FIG. 8. *Block diagram for multiscale object-based filtering.*

The connected components of a function $f \in \mathcal{V}_\sigma$ are associated with the regional maxima of f contained in the connected components of the level set $X_\sigma(f)$. For each $C \in \mathcal{C}(X_\sigma(f))$, there corresponds a grayscale level-σ connected component f_C of f, given by

$$f_C = \bigvee\nolimits_u \{\widetilde{\rho}(f \mid h_{R,f(R)}) \mid R \in \mathcal{R}_\sigma(f) \text{ and } R \subseteq C\}.$$

Therefore, we can write the approximation signal $\phi_\sigma(f)$ as the supremum of grayscale connected components; i.e.,

$$\phi_\sigma(f) = \bigvee\nolimits_u \{f_C \mid C \in \mathcal{C}(X_\sigma(f))\}, \quad \sigma \in (0, \infty).$$

These grayscale connected components are "mutually disjoint," in the sense that, for $\alpha \neq \beta$, we have that $\phi_\sigma(f_{C_\alpha} \wedge f_{C_\beta}) = O$, which says that the infimum $f_{C_\alpha} \wedge f_{C_\beta}$ has no regional maxima above level σ. This is similar to the linear case, in which the orthogonal projection of a function f over a linear approximation space $\mathcal{V}_\sigma$ is obtained with an expansion in terms of the orthogonal scaling basis [25].

5. Multiscale object-based filtering. Several image processing and analysis tasks are geared towards identifying objects of interest and manipulating those objects to achieve a desired result. For example, if we want to remove certain objects from a scene, we should first identify those objects and then extract them from the scene with operators that do not affect other objects. This task is referred to as *object-based filtering* and can be effectively implemented by the three-step multiscale approach depicted in Figure 8. The first step performs a multiscale decomposition of an image f into a finite collection $D(f) = \{f_1, f_2, \ldots, f_N\}$ of images that contain objects of interest in f at various scales such that f can be uniquely reconstructed from $D(f)$. The images in $D(f)$ are then processed individually by the filtering step. This produces a new multiscale decomposition $\widehat{D}(f)$, which is then used to restitute the filtered image $\hat{f}$. Note that $D(\hat{f}) = \widehat{D}(f)$.

In this paper, we assume that objects of interest are identified by their intensity distribution and, more precisely, by the regional maxima of such intensities. Moreover, we assume that regional maxima associated with similar objects have similar values. In this case, we are interested in a technique that identifies the regional maxima of an image f and decomposes f into a finite collection $D(f) = \{f_1, f_2, \ldots, f_N\}$, with each image f_k containing all regional maxima of f with similar values, such that f can be uniquely reconstructed from $D(f)$. This naturally leads to the previously discussed skyline supremal multiscale analysis scheme.

We specify a finite collection $\{\sigma_k \mid k \in I\}$ of scales, where $I = \{0, 1, \ldots, N\}$, such that $\phi_{\sigma_0}(f) = f$ and $\sigma_k < \sigma_{k+1}$, and decompose the grayscale image f into the

collection $D(f) = \{\psi_{\sigma_k,\sigma_{k+1}}(f) \mid k \in I\}$, where $\psi_{\sigma_N,\sigma_{N+1}}(f) \triangleq \phi_{\sigma_N}(f)$. The image f can be uniquely reconstructed from such decomposition, since (recall (3.15))

$$f = \phi_{\sigma_0}(f) = \bigvee_{k\in I} \psi_{\sigma_k,\sigma_{k+1}}(f).$$

Recall that $\psi_{\sigma_k,\sigma_{k+1}}(f)$ contains the regional maxima of f with values in $[\sigma_k, \sigma_{k+1})$ with all other regional maxima suppressed (flattened), whereas $\phi_{\sigma_N}(f)$ contains the regional maxima of f that are above level σ_N with all other regional maxima suppressed.

During the filtering step, a subset $J \subseteq I$ is determined, and then the images $\{\psi_{\sigma_j,\sigma_{j+1}}(f) \mid j \in J\}$ are processed to produce a new collection $\{\widehat{\psi}_{\sigma_j,\sigma_{j+1}}(f) \mid j \in J\}$. The output of the filtering step depicted in Figure 8 is given by $\widehat{D}(f) = \{\psi_{\sigma_k,\sigma_{k+1}}(f), \widehat{\psi}_{\sigma_j,\sigma_{j+1}}(f) \mid k \in I \smallsetminus J, j \in J\}$, and the new filtered image $\widehat{f}$ is obtained by means of

$$\widehat{f} = \bigvee_{k\in I\smallsetminus J} \psi_{\sigma_k,\sigma_{k+1}}(f) \vee \bigvee_{j\in J} \widehat{\psi}_{\sigma_j,\sigma_{j+1}}(f).$$

We illustrate the previous filtering approach with two examples. Figure 9(a) depicts a grayscale MRI "tumor" image f that contains several objects, including a large tumor on the right-hand side and a small tumor slightly above it.[2] Our objective is to extract the tumors and place them on two different image frames. Moreover, we would like to enhance their presence by flattening surrounding details. We set $\sigma_k = k + 1$, for $k = 0, 1, \ldots, N - 1$, where N is the maximum grayscale value in f (in this case, $N = 255$). The skyline supremal multiscale decomposition of the "tumor" image f reveals that most information related to the small tumor is contained in the detail images $\psi_{k,k+1}(f)$, $153 \leq k \leq 173$, whereas most information related to the large tumor is contained in the detail images $\psi_{k,k+1}(f)$, $206 \leq k \leq 212$. This observation leads to a "filtering" step in Figure 8 that preserves the previous detail images and sets the rest equal to zero. The images $\hat{f}$, obtained by the "restitution" step of Figure 8, are depicted in Figures 9(b) and (c). The results indicate that, as expected, the skyline supremal multiscale decomposition scheme successfully extracts the two tumors and flattens surrounding details.

Figure 10 depicts a grayscale "boat" image f that has been corrupted by "pepper" noise. The noise consists of black spots (that may be more than one pixel thick), which are randomly distributed over the entire image. Our objective is to remove the noise from the image depicted in Figure 10(b) and recover a sufficiently good approximation of the original image depicted in Figure 10(a). This is the classical problem of *image denoising*.

As before, we set $\sigma_k = k + 1$, for $k = 0, 1, \ldots, N - 1$, where $N = 255$. Skyline supremal multiscale analysis of the noisy "boat" image f depicted in Figure 10(b) reveals that most information related to noise is contained in image $\phi_N(N - f)$, since the black spots in f show as narrow bright peaks of amplitude N in the negative image $N - f$. This observation leads to a "filtering" step in Figure 8 that preserves all detail images but replaces $\phi_N(N - f)$ with its grayscale reconstruction $\widetilde{\rho}(\phi_N(N - f) \mid \phi_N(N - f) \bigcirc B)$, where B is a disk structuring element of radius 4. The structural opening $\phi_N(N - f) \bigcirc B$ removes most peaks in $\phi_N(N - f)$ due to noise and provides

[2]The image is courtesy of Christos Davatzikos.

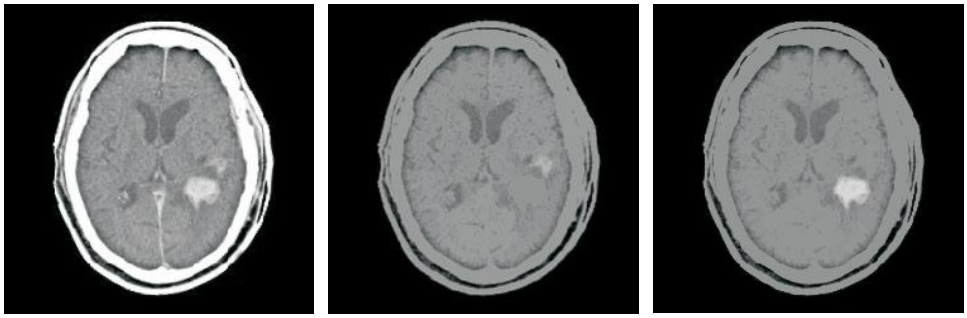

FIG. 9. (a) *A grayscale MRI "tumor" image.* (b) *Extraction of the small tumor and flattening of surrounding details.* (c) *Extraction of the large tumor and flattening of surrounding details.*

a marker for the reconstruction of the "noise-free" part of $\phi_N(N - f)$. The image $\hat{f}$, obtained by subtracting the result of the "restitution" step of Figure 8 from N, is depicted in the first row of Figure 11(a).

On the other hand, the first row of Figure 11(b) depicts the result obtained from a conventional morphological denoising approach that subtracts the grayscale reconstruction $\widetilde{\rho}(N - f \mid (N - f) \bigcirc B)$, applied on the negative noisy image $N - f$, from N. Although, at first glance, the two results seem to be similar, the details depicted in the second row of Figure 11 reveal that they are different in quality. Although noise has been equally suppressed in both cases, the result depicted in Figure 11(b) shows that direct application of grayscale reconstruction on the noisy image may result in excessive smoothing of important features (e.g., the masts and the letters on the stern). Clearly, a denoising approach based on skyline supremal multiscale analysis is more preferable in this case.

6. Conclusion. In this paper, we have presented a new approach to nonlinear multiscale signal analysis. The proposed scheme is related to the concept of supremal scale-spaces, introduced by Heijmans and van den Boomgaard, and is referred to as supremal multiscale analysis. To develop this approach, we have extended (among other things) the concepts of (orthogonal) vector spaces, (orthogonal) projections, and linear operators to a nonlinear setting. We have accomplished this by employing the theory of complete lattices in conjunction with mathematical morphology and by replacing numerical addition with supremum. We have also proposed a particular supremal multiscale analysis scheme that is based on morphological reconstruction operators. This approach, which is referred to as skyline supremal multiscale analysis, decomposes the regional maxima of a signal in a natural causal hierarchy by gradually removing these maxima without introducing new ones. More precisely, the skyline supremal multiscale analysis scheme represents a signal as the supremum of a coarse approximation and details. The coarse approximation preserves the regional maxima above some level σ, while it flattens the rest. On the other hand, the details preserve regional maxima with values in nonoverlapping subintervals of $(0, \sigma)$ and flatten the rest. We show that this scheme is grayscale, translation, and scale invariant, and it progressively removes connected components from the level sets of a signal without introducing new ones. We believe that skyline supremal multiscale analysis can be effectively used for multiscale signal decomposition, representation, and analysis.

REGULARITY FOR THE VLASOV–POISSON SYSTEM IN A CONVEX DOMAIN*

HYUNG JU HWANG†

Abstract. We consider the initial-boundary value problem in a convex domain for the Vlasov–Poisson system. Boundary effects play an important role in such physical problems that are modeled by the Vlasov–Poisson system. We establish the global existence of classical solutions with regular initial boundary data under the absorbing boundary condition. We also prove that regular symmetric initial data lead to unique classical solutions for all time in the specular reflection case.

Key words. regularity, global existence, initial-boundary value problem, convexity, Vlasov–Poisson system

1. Introduction. The behavior of a confined hot plasma is governed by the Vlasov–Maxwell system with boundary conditions. A simpler model is the Vlasov–Poisson system where the speed of light is treated as infinity and the magnetic field is neglected. For the absorbing case, we consider $\Pi = [0,T] \times \Omega \times \mathbb{R}^3$, where Ω is a smooth bounded convex domain in $\mathbb{R}^3$ and $T > 0$ is arbitrary, while we restrict to the unit ball $\Omega = B$ in the case of the specular reflection. We denote by n_x the outward normal vector at a boundary point $x \in \partial\Omega$. The Vlasov–Poisson system describes a collisionless plasma electrostatic:

$$\begin{aligned} &f_t + v \cdot \partial_x f + \nabla\varphi \cdot \partial_v f = 0, \\ &\Delta\varphi = \rho = 4\pi \int_{\mathbb{R}^3} f(t,x,v)\, dv, \\ &f|_{t=0} = f_0, \end{aligned} \tag{1.1}$$

where $f(t,x,v)$ represents the distribution of an electron gas, and φ is the electrostatic potential. The particles have the same sign of charge inside the region Ω, and $\nabla\varphi(t,x)$ is the self-consistent electric field. Boundary effects play an important role in such physical problems as tokamaks, diodes, and electron guns. Particles can be either *absorbed* at the boundary or *reflected* specularly at the boundary. For the absorbing boundary case, at $\{v \cdot n_x < 0\}$, with n_x the outward normal at $x \in \partial\Omega$, we have

$$f(t,x,v) = g(t,x,v), \tag{1.2}$$

where g is a given function. In the case of the specular reflection, at $\{v \cdot n_x < 0\}$, we have

$$f(t,x,v) = f(t,x,v_*), \tag{1.3}$$

where $v_* = v - 2(v \cdot n_x) n_x$.

In this article, we construct classical solutions for the nonlinear Vlasov–Poisson system in a three-dimensional smooth bounded convex domain. We demonstrate our results of regularity as follows.

THEOREM 1.1 (absorbing case). *Assume the absorbing condition* (1.2) *for the Vlasov and the Dirichlet boundary condition for the Poisson. Let* $f_0 \geq 0$, $g \geq 0$ *be smooth with compact supports and* f_0 *be not identically zero. Let* f_0 *and* g *satisfy some compatibility conditions. Moreover, assume some vanishing condition for* g *at* $\{x \cdot n_x = 0\}$. *Then there exists a unique smooth solution* f *and* φ *of* (1.1) *with* (1.2), *where* f *has compact support for* v.

THEOREM 1.2 (specular reflection case). *Assume the specular boundary condition* (1.3) *for the Vlasov and the Dirichlet boundary condition for the Poisson. Assume there is an* $\omega_0 > 0$ *such that* $f_0(x,v)$ *is constant for* $\left(1-|x|^2\right)^2 + (2v \cdot x)^2 \leq \omega_0$.

(a) *Assume* $f_0 \in C^1$. *Let* f_0 *have compact support and satisfy the compatibility conditions. Let* f_0 *be spherically symmetric. Then there exists a unique spherically symmetric solution* (f, φ) *of* (1.1) *with* (1.3) *such that* $f \in W^{1,\infty}$ *with compact support.*

(b) *Assume* $f_0 \in C^{1,\eta}$ *for some* $\eta > 0$. *Let* f_0 *have compact support and satisfy the compatibility conditions. Let* f_0 *be spherically symmetric. Then there exists a unique spherically symmetric solution* (f, φ) *of* (1.1) *with* (1.3) *such that* $f \in C^{1,\mu}$, $\varphi \in C^{3,\mu}$ *for some* $0 < \mu < \eta$, *with compact support.*

Much effort and fruitful achievement have been made for the Cauchy problem for the Vlasov–Poisson system during the last few decades. Many mathematicians have made their contributions to the Vlasov–Poisson system in the whole three space dimensions without boundary conditions. In particular, in [22], [18], [23], and [16], global classical solutions for the Vlasov–Poisson system have been constructed by different methods, provided the initial data is regular.

However, the boundary-value problem is much more complicated since the boundary is always characteristic. In a half space with a flat boundary [7], [8], it is known that singularities of distribution function are expected, forming from the boundaries, *unless* the electric field has the correct sign. The global classical solutions for the full Vlasov–Poisson system have been constructed for a half space with a flat boundary in [7], [8] for one dimension and three dimensions, respectively.

This article extends the work of Guo to a three-dimensional smooth convex domain. We note that convexity plays an important role in obtaining regularity of the solutions of the Vlasov equation with boundary conditions. We refer the reader to [8] for a simple counterexample. We begin by generalizing the linear $C^{1,\alpha}$ and $W^{1,p}$ estimates in [7] and [8] to a general smooth bounded convex domain where a new geometric part comes in. As in the half space case, the main difficulty lies in the estimation of the particles moving slowly in the normal direction near the boundary. This can be overcome via the geometric velocity lemma with an extra factor coming from the geometry of the convexity. We still require the outwardness of the electric field E at the boundary and the flatness of the initial density f_0 to ensure the regularity in the linear problem. In the absorbing case, we adopt the high-moment technique in [18] in order to establish the existence of global classical solutions for the absorbing boundary condition. The key step to get control of large velocities is to represent the macrocharge density in the presence of the boundary condition. We are able to attain a representation for the charge density in spite of the complex particle paths by an *exact cancellation* at the boundary. This cancellation demands a new computation. Unfortunately, neither this high-moment method nor the technique first invented by

Pfaffelmoser worked for the specular reflection case. The central difficulty comes from the fact that we cannot avoid so many repeated bounces of the particles near the boundary with very small tangential angles if the particles are allowed to reflect at the boundary. This accelerates the hindrance to the control on the behavior of the particles near the boundary in addition to the difficulty from large velocities. In fact, the number of bounces of a particle near the boundary with constant velocity v and its tangential angle θ is proportional to $|v|/\theta$. So even if the particle moves slowly near the boundary, we easily lose the control on the number of bounces, because the particle moves almost tangentially with the very small θ. However, the invariance of the angular momentum in the spherically symmetric case enables us to treat the particles with small tangential angles since the angular momentum of the particles near the boundary with small tangential velocity amounts approximately to the full velocity. This leads to a global bound on the increase in velocity, employing the idea in [14].

This article is arranged as follows. From section 2 to section 4, we study the linear problem. In section 2, we establish the velocity lemma for a convex domain, followed by the study of the bouncing trajectories. The absorbing case is discussed in section 3. We deal with the linear estimates for the specular reflection in section 4. In section 5, we treat the fully nonlinear Vlasov–Poisson system with the absorbing boundary condition and get its regularity. Finally, in section 6, the nonlinear Vlasov–Poisson system, endowed with the specular boundary condition, obtains the regularity for the spherically symmetric case.

2. Bouncing trajectories. Let the boundary γ of Π consist of

$$\begin{aligned} \gamma^+ &= \{(t,x,v)\,|0 \le t \le T, x \in \partial\Omega, v \cdot n_x < 0\}, \\ \gamma^- &= \{(t,x,v)\,|0 \le t \le T, x \in \partial\Omega, v \cdot n_x > 0\}, \\ \gamma^0 &= \{(t,x,v)\,|0 \le t \le T, x \in \partial\Omega, v \cdot n_x = 0\}. \end{aligned} \tag{2.1}$$

Let $\Pi_s = \{t = s\} \cap \Pi$, $\gamma_s = \{t = s\} \cap \gamma$, $\gamma_s^+ = \{t = s\} \cap \gamma^+$, and $\gamma_s^- = \{t = s\} \cap \gamma^-$ for $0 \le s \le t$.

Let the unique trajectory of

$$\frac{d}{d\tau}X = V, \quad \frac{d}{d\tau}V = E \tag{2.2}$$

such that $X(t;t,x,v) = x$, $V(t;t,x,v) = v$ be the following:

$$\Gamma(\tau;t,x,v) = (\tau; X(\tau;t,x,v), V(\tau;t,x,v)), \tag{2.3}$$

where $E(t,x) = \nabla\varphi(t,x)$ is the given electric field.

We consider in this section the initial-boundary problem for the linear Vlasov equation

$$\begin{aligned} f_t + v \cdot \partial_x f + E \cdot \partial_v f = 0, \\ f|_{t=0} = f_0, \quad f|_{\gamma^+} = g, \end{aligned} \tag{2.4}$$

where the given electric field $E(t,x)$ satisfies $E(t,x) \cdot n_x \ge \delta > 0$ at the boundary, for a fixed $\delta > 0$.

In the following, we establish a generalized velocity lemma [8] for our convex domain.

Let $x_0 \in \partial\Omega$; there exist a neighborhood V of x_0 and a smooth convex function $\phi(x_1, x_2)$ such that, after proper translation and rotation, $x_0 = (0,0,0)$, $\partial\Omega \cap V = \{x = (x_1, x_2, x_3) \,|x_1 = \phi(x_2, x_3)\}$, and $\Omega \cap V = \{x = (x_1, x_2, x_3) \,|x_1 > \phi(x_2, x_3)\}$. Straightening out the portion of the boundary by the diffeomorphism $\Phi(x_1, x_2, x_3) = (x_1 - \phi(x_2, x_3), x_2, x_3)$ with the inverse $\Psi(x_1, x_2, x_3) = (x_1 + \phi(x_2, x_3), x_2, x_3)$, we may assume that near the point $x_0 = (0,0,0)$, $\partial\Omega = \{x_1 = 0\}$, $\Omega = \{x_1 > 0\}$. Now we consider the Vlasov–Poisson system in the new coordinates

$$\begin{aligned}
\tilde{t} := t, \quad \tilde{x} := \Phi(x), \quad \tilde{v} =: \partial\Phi(x)\, v,\\
\tilde{E}(\tilde{t}, \tilde{x}) := \partial\Phi(x)\, E(t,x) = \partial\Phi(\Psi(\tilde{x}))\, E(\tilde{t}, \Psi(\tilde{x})),\\
\tilde{f}(\tilde{t}, \tilde{x}, \tilde{v}) := f(t,x,v) = f(\tilde{t}, \Psi(\tilde{x}), \partial\Psi(\tilde{x})\,\tilde{v}).
\end{aligned}$$

Then we have

$$\begin{aligned}
0 &= f_t + v \cdot \partial_x f + E \cdot \partial_v f\\
&= \tilde{f}_{\tilde{t}} + \tilde{v} \cdot \partial_{\tilde{x}} \tilde{f} + \left[\tilde{E}(\tilde{t}, \tilde{x}) + v\partial^2\Phi(x)\, v\right] \cdot \partial_{\tilde{v}} \tilde{f}.
\end{aligned}$$

Notice that the outward normal $\tilde{n}_{\tilde{x}} = n_x \partial\Psi(\tilde{x})$, and so the boundary set γ^+ corresponds to $\tilde{\gamma}^+$, γ^0 corresponds to $\tilde{\gamma}^0$, and γ^- corresponds to $\tilde{\gamma}^-$, respectively, under this change of variables since

$$\tilde{n}_{\tilde{x}} \cdot \tilde{v} = [n_x \partial\Psi(\tilde{x})] \cdot [\partial\Phi(x)\, v] = n_x \cdot v.$$

Furthermore, the assumption on the electric field is invariant under the change of variables for the same reason. We shall now look at the sign on $v\partial^2\Phi^1(x)\, v$ as follows:

$$\begin{aligned}
v \cdot \partial^2\Phi^1 \cdot v &= \begin{bmatrix} v_1 & v_2 & v_3 \end{bmatrix} \begin{bmatrix} 0 & 0 & 0\\ 0 & -\partial_{22}\phi & -\partial_{23}\phi\\ 0 & -\partial_{32}\phi & -\partial_{33}\phi \end{bmatrix} \begin{bmatrix} v_1\\ v_2\\ v_3 \end{bmatrix}\\
&= \begin{bmatrix} v_2 & v_3 \end{bmatrix} \begin{bmatrix} -\partial_{22}\phi & -\partial_{23}\phi\\ -\partial_{32}\phi & -\partial_{33}\phi \end{bmatrix} \begin{bmatrix} v_2\\ v_3 \end{bmatrix} \le 0
\end{aligned}$$

since ϕ is a convex function.

We can thus reduce locally our case to the half space case with a different equation. For our convenience, we will use the notation without a tilde, indicating things with a tilde, throughout this section. We now consider locally the following system in the upper half space in the time interval $[\tilde{t}, \tilde{t} + \varepsilon]$:

$$f_t + v \cdot \partial_x f + [E(t,x) + J(x,v)] \cdot \partial_v f = 0,$$

where $E_1(t,x) \le -\delta < 0$, $J_1(x,v) \le 0$ for all v, at $\gamma = \{(t,x,v) \,|x_1 = 0\}$.

LEMMA 2.1 (velocity lemma). *Suppose $E_1(t,0,\bar{x}) \le -\delta$ and $J_1(x,v) \le 0$. Let $E \in C^1$ and $J \in C^1$. Let $(\tau, X(\tau), V(\tau)) \in \bar{\Pi}$ for small time interval $[\tilde{t}, \tilde{t} + \varepsilon]$. Then for $\tilde{t} \le s \le t \le \tilde{t} + \varepsilon$,*

$$e^{-C(t-s)}\alpha(s) \le \alpha(t) \le e^{C(t-s)}\alpha(s), \tag{2.5}$$

where

$$\alpha(t) = X_1^2(t) + V_1^2(t) - 2\left[E_1\left(t; 0, \bar{X}(t)\right) + J_1(X,V)\right] X_1,$$

$(\tau, X(\tau), V(\tau))$ *is a trajectory* (2.2)*, and* C *depends on* Ω, $\|E\|_{C^1}$, δ, *and* $\sup_{s\le\tau\le t}|V(\tau)|$.

Proof. We follow closely the proof of Lemma 1.1 in [7]. Expanding $E_1(t,x)$ around $x_1 = 0$, we get from (2.2)

$$
\begin{aligned}
(2.6)\qquad & X_1^\bullet = V_1,\\
& V_1^\bullet = E_1\left(\tau; 0, \bar{X}(\tau)\right) + \partial_{x_1} E\left(\tau; \zeta, \bar{X}(\tau)\right) X_1(\tau) + J_1\left(X(\tau), V(\tau)\right),
\end{aligned}
$$

where $\bullet$ means the τ derivative, and $0 \le \zeta \le X_1(\tau)$. We multiply the first of (2.6) with $X_1(\tau)$ and the second of (2.6) with $V_1(\tau)$. Then there is a C large, depending on $\|\nabla_x E\|_\infty$, such that, along the trajectory,

$$
\left[e^{C\tau}\left(X_1^2(\tau) + V_1^2(\tau)\right)\right]^\bullet \ge 2\left[E_1\left(\tau; 0, \bar{X}(\tau)\right) + J_1\left(X(\tau), V(\tau)\right)\right] e^{C\tau} V_1(\tau)
$$

for $s \le \tau \le t$. Notice that

$$
\begin{aligned}
(2.7)\qquad & \left[E_1\left(\tau; 0, \bar{X}(\tau)\right) + J_1\left(X(\tau), V(\tau)\right)\right] e^{C\tau} V_1(\tau)\\
&= \left\{\left[E_1\left(\tau; 0, \bar{X}(\tau)\right) + J_1\left(X(\tau), V(\tau)\right)\right] e^{C\tau} X_1(\tau)\right\}^\bullet\\
&\quad - C\left[E_1\left(\tau; 0, \bar{X}(\tau)\right) + J_1\left(X(\tau), V(\tau)\right)\right] e^{C\tau} X_1(\tau)\\
&\quad - \frac{d}{d\tau}\left[E_1\left(\tau; 0, \bar{X}(\tau)\right) + J_1\left(X(\tau), V(\tau)\right)\right] e^{C\tau} X_1(\tau).
\end{aligned}
$$

Integrating (2.7) from s to t, for C large enough, we get the left-hand side (LHS) of (2.5) as

$$
\begin{aligned}
& e^{Ct}\left(X_1^2(\tau) + V_1^2(\tau)\right) - e^{Cs}\left(X_1^2(\tau) + V_1^2(\tau)\right)\\
&\ge 2\left[E_1\left(t; 0, \bar{X}(t)\right) + J_1\left(X(t), V(t)\right)\right] e^{Ct} X_1(t)\\
&\quad - 2\left[E_1\left(s; 0, \bar{X}(s)\right) + J_1\left(X(s), V(s)\right)\right] e^{Cs} X_1(s)\\
&\quad - \int_s^t \frac{d}{d\tau}\left[E_1\left(\tau; 0, \bar{X}(\tau)\right) + J_1\left(X(\tau), V(\tau)\right)\right] e^{C\tau} X_1(\tau)\, d\tau\\
&\quad - \int_s^t C\left[E_1\left(\tau; 0, \bar{X}(\tau)\right) + J_1\left(X(\tau), V(\tau)\right)\right] e^{C\tau} X_1(\tau)\, d\tau\\
&\ge 2\left[E_1\left(t; 0, \bar{X}(t)\right) + J_1\left(X(t), V(t)\right)\right] e^{Ct} X_1(t)\\
&\quad - 2\left[E_1\left(s; 0, \bar{X}(s)\right) + J_1\left(X(s), V(s)\right)\right] e^{Cs} X_1(s).
\end{aligned}
$$

We have used the fact that

$$
\begin{aligned}
& \left|\frac{d}{d\tau}\left[E_1\left(\tau; 0, \bar{X}(\tau)\right) + J_1\left(X(\tau), V(\tau)\right)\right]\right|\\
&\le \left|E_{1t}\left(\tau; 0, \bar{X}(\tau)\right) + \nabla_{\bar{x}} E_1\left(\tau; 0, \bar{X}(\tau)\right)\cdot \bar{V}(\tau) + \nabla_x J\left(X(\tau), V(\tau)\right)\cdot V(\tau)\right.\\
&\qquad \left. + \nabla_v J_1\left(X(\tau), V(\tau)\right)\cdot\left[E\left(\tau; X(\tau)\right) + J\left(X(\tau), V(\tau)\right)\right]\right|\\
&\le C\left(1 + \|E\|_{C^1}\right),
\end{aligned}
$$

and $E_1\left(\tau; 0, \bar{X}(\tau)\right) + J_1\left(X(\tau), V(\tau)\right) \le -\delta < 0$. Similarly, we establish the right-hand side (RHS) of (2.5). □

Corollary 2.2. *Suppose that* $E(t,x)\cdot n_x \ge \delta > 0$ *for all* $x \in \partial\Omega$ *for some fixed constant* $\delta > 0$. *Let* (t,x,v) *with* $x \notin \partial\Omega$ *connect to* (t_0, x_0, v_0) *with* $x \in \partial\Omega$ *through*

a trajectory, where $t_0 < t$ and the trajectory stays in the domain Ω in $(t_0, t]$. Then we have $(t_0, x_0, v_0) \in \gamma^+$.

Proof. We may assume without loss of generality that x is near the boundary so that we can localize near the point x. Then, by Lemma 2.1, we deduce that $(t_0, x_0, v_0) \in \gamma^+$. □

The following corollary gives a better estimate for C in the velocity lemma when $(d/dt) E_1|_\gamma \equiv 0$. We refer the reader to [7], [8] for the proof in the half space case with the flat boundary. It is important for the nonlinear specular case.

COROLLARY 2.3. *If $E \in C^{0,1}_{t,x}$ and $E_1(t, 0, \bar{x}) \equiv E_0(0, \bar{x}) < 0$ for all $0 \le t \le T$, then for $\tilde{t} \le s \le t \le \tilde{t} + \varepsilon$,*

$$e^{-C(t-s)}\beta(s) \le \beta(t) \le e^{C(t-s)}\beta(s),$$

where

$$\beta(t) = V_1^2(t) - 2\left[E_0\left(0, \bar{X}(t)\right) + J_1(X(t), V(t))\right] X_1(t),$$

and C depends only on $\sup_{0\le t\le T} \|E\|_{C^{0,1/2}(\Omega)}(t)$, E_0, and $\sup_{s\le\tau\le t} |V(\tau)|$.

In many physical problems, particles may have the complex behavior of bouncing off the boundary repeatedly. In order to describe such phenomena and to study especially the specular reflection case, we will investigate trajectories which bounce many times at the boundary. We call such a particle path which ends at a given point a "back-time cycle" as in [8]. Notice that the density is constant along these kinds of generalized trajectories.

DEFINITION 2.4. *$v_* = v - 2(v \cdot n_x) n_x$ is said to be the reflected velocity of v.*

DEFINITION 2.5 (back-time cycles). *Given a C^1 field $E(t, x)$, by an l-cycle, we mean the trajectories in $\bar{\Pi}$ which connect $(t, x, v) = \left(t^l, x^l, v^l\right)$ with $\left(t^{l-1}, x^{l-1}, v^{l-1}\right)$, $\left(t^{l-1}, x^{l-1}, v_*^{l-1}\right)$ with $\left(t^{l-2}, x^{l-2}, v^{l-2}\right)$, $\ldots$, $\left(t^i, x^i, v_*^i\right)$ with $\left(t^{i-1}, x^{i-1}, v^{i-1}\right)$, $\ldots$, $\left(t^1, x^1, v_*^1\right)$ with $(0, x_0, v_0)$, where $t^i > t^{i-1}$, $x^i \in \partial\Omega$ for $1 \le i \le l-1$, $v^i \cdot n_x \ge 0$, $1 \le i \le l$.*

We rewrite the velocity lemma, Lemma 2.1, involving our geometry. Let $\xi(x)$ be a smooth function which defines the boundary such that

$$\partial\Omega = \{\xi(x) = 0\}, \quad \Omega = \{\xi(x) > 0\}; \tag{2.8}$$

then $n_x = -\nabla\xi(x) / |\nabla\xi(x)|$ is the outward normal at each point x at the boundary. For instance, $\xi(x) = 1 - |x|^2$ for the unit ball.

LEMMA 2.6 (geometric velocity lemma). *Let $E(t, x) \cdot n_x \ge \delta > 0$ for all $x \in \partial\Omega$ with $E \in C^1$. If the trajectory stays away from the origin, i.e., $|X(\tau)| \ge \sigma$ for $s \le \tau \le t$, for any small fixed $\sigma > 0$, then*

$$e^{-C(t-s)}\alpha(s) \le \alpha(t) \le e^{C(t-s)}\alpha(s), \tag{2.9}$$

where

$$\begin{aligned}\alpha(t) = {} & \xi^2(X(t)) + [V(t) \cdot \nabla\xi(X(t))]^2 \\ & - 2\left[E\left(t, \bar{X}(t)\right) \cdot \nabla\xi\left(\bar{X}(t)\right) + V(t) \cdot \nabla^2\xi(X(t)) \cdot V(t)\right] \xi(X(t))\end{aligned}$$

and where C depends on $\|E\|_{C^1}$, $\sup_{0\le\tau\le t}[|X(\tau)| + |V(\tau)|]$, δ, and σ.

Proof. Let $\bar{X}$ be the point at the boundary which lies on the half-line from the point X in the direction $-\nabla\xi(X)$. Then we expand $E \cdot \nabla\xi(X)$ around $E \cdot \nabla\xi\left(\bar{X}\right)$ to

get

$$\begin{aligned}(E\cdot\nabla\xi)(X) &= (E\cdot\nabla\xi)\left(\bar{X}\right)+\nabla_x(E\cdot\nabla\xi)\cdot\left(X-\bar{X}\right)\\ &= E\left(t,\bar{X}\right)\cdot\nabla\xi\left(\bar{X}\right)+\left[\nabla_x(E\cdot\nabla\xi)\cdot\frac{\left(X-\bar{X}\right)}{\xi(X)}\right]\xi(X).\end{aligned}$$

From the fact that $\xi(X)=\xi\left(\bar{X}\right)+\nabla\xi(\theta)\cdot\left(X-\bar{X}\right)=\nabla\xi(\theta)\cdot\left(X-\bar{X}\right)$ for some point θ on the line segment connecting X and $\bar{X}$, which implies that $\nabla\xi(\theta)\cdot\frac{(X-\bar{X})}{\xi(X)}=1$, we can easily see that $\left|\frac{(X-\bar{X})}{\xi(X)}\right|\le C$. (Near the boundary where $\xi(X)\approx 0$, we have $|\nabla\xi(\theta)|\ge c>0$, and $\nabla\xi(\theta)$ is almost parallel to $X-\bar{X}$.) Along the trajectory, there is a C so large that

$$\begin{aligned}&\left\{e^{C\tau}\left[\xi^2(X)+(V\cdot\nabla\xi)^2\right]\right\}^{\bullet}\\ &= e^{C\tau}\Big[C\xi^2(X)+C(V\cdot\nabla\xi)^2+2\xi(X)(V\cdot\nabla\xi)\\ &\qquad +2(V\cdot\nabla\xi)\left(E\cdot\nabla\xi(X)+V\cdot\nabla^2\xi\cdot V\right)\Big]\\ &= e^{C\tau}\left[C\xi^2(X)+C(V\cdot\nabla\xi)^2+2\left(1+\nabla_x(E\cdot\nabla\xi)\cdot\frac{\left(X-\bar{X}\right)}{\xi(X)}\right)\xi(X)(V\cdot\nabla\xi)\right.\\ &\qquad \left.+2(V\cdot\nabla\xi)\left(E\left(t,\bar{X}\right)\cdot\nabla\xi\left(\bar{X}\right)+V\cdot\nabla^2\xi\cdot V\right)\right]\\ &\ge e^{C\tau}\left[2(V\cdot\nabla\xi)\left(E\left(t,\bar{X}\right)\cdot\nabla\xi\left(\bar{X}\right)+V\cdot\nabla^2\xi\cdot V\right)\right].\end{aligned}$$

Assuming that $E(t,x)\cdot n_x\ge\delta>0$, we notice that for a large C,

$$\begin{aligned}&e^{C\tau}\left[2(V\cdot\nabla\xi)\left(E\left(t,\bar{X}\right)\cdot\nabla\xi\left(\bar{X}\right)+V\cdot\nabla^2\xi\cdot V\right)\right]\\ &= \left\{2e^{C\tau}\xi(X)\left[E\left(t,\bar{X}\right)\cdot\nabla\xi\left(\bar{X}\right)+V\cdot\nabla^2\xi\cdot V\right]\right\}^{\bullet}\\ &\quad -2e^{C\tau}C\left[E\left(t,\bar{X}\right)\cdot\nabla\xi\left(\bar{X}\right)+V\cdot\nabla^2\xi\cdot V\right]\xi(X)\\ &\quad -2e^{C\tau}\left[E_t\left(t,\bar{X}\right)\cdot\nabla\xi\left(\bar{X}\right)+\bar{X}^{\bullet}\cdot\nabla_{\bar{x}}E\left(t,\bar{X}\right)\cdot\nabla\xi\left(\bar{X}\right)\right.\\ &\qquad\qquad +E\left(t,\bar{X}\right)\cdot\nabla^2\xi\left(\bar{X}\right)\cdot\bar{X}^{\bullet}+2E\cdot\nabla^2\xi(X)\cdot V\\ &\qquad\qquad \left.+V\cdot\left(\nabla^3\xi(X)\cdot V\right)\cdot V\right]\xi(X)\\ &\ge \left\{2e^{C\tau}\xi(X)\left[E\left(t,\bar{X}\right)\cdot\nabla\xi\left(\bar{X}\right)+V\cdot\nabla^2\xi\cdot V\right]\right\}^{\bullet},\end{aligned}$$

where $\xi(X)\ge 0$, and $\left|\bar{X}^{\bullet}\right|\le C$ (since $|X(\tau)|\ge\sigma>0$), $|X(\tau)|\le C$, $|V(\tau)|\le C$, and $|E|_{C^1}\le C$. This proves the LHS of (2.9). Similarly, we get the RHS of (2.9) to complete the proof of the lemma. □

The following lemma shows that if a particle initially has a nonzero normal velocity, then its normal velocity of a particle remains bounded away from 0, and the bound is independent of the number of the bounces.

LEMMA 2.7. *Let $E(t,x)\cdot n_x\ge\delta>0$ for all $x\in\partial\Omega$. Consider the back-time cycle of (t,x,v). Then there exist C_1 and C_2 such that*

$$\begin{aligned}C_1\left[\xi(x)+(v\cdot\nabla\xi(x))^2\right] &\le \left(v^i\cdot\nabla\xi\left(x^i\right)\right)^2\le C_2\left[\xi(x_0)+(v_0\cdot\nabla\xi(x_0))^2\right],\\ C_1\left[\xi(x_0)+(v_0\cdot\nabla\xi(x_0))^2\right] &\le \left(v^i\cdot\nabla\xi\left(x^i\right)\right)^2\le C_2\left[\xi(x)+(v\cdot\nabla\xi(x))^2\right],\end{aligned}$$

where $1 \le i \le l$, *and* C_1 *and* C_2 *are independent of* l *and dependent on* $\|E\|_{C^1}$, δ, *and the bound for* $|V(\tau)|$.

Proof. We may assume that Ω contains the origin without loss of generality. We first consider small balls B_σ with radius $\sigma > 0$ small and let (s, y, w) connect with $(\tilde{t}, \tilde{x}, \tilde{v})$ through a trajectory in the ball B_σ. Since $|X(\tau)| \le \sigma$, we have $\xi(X(\tau)) \ge C(\sigma)$. Then there is a constant D such that

$$\begin{aligned}\left\{e^{D\tau}\left[\xi(X) + (V \cdot \nabla\xi(X))^2\right]\right\}^\bullet &= e^{D\tau}\Big[D\xi(X) + D(V \cdot \nabla\xi(X))^2 + V \cdot \nabla\xi(X) \\ &\qquad + 2(V \cdot \nabla\xi(X))\left(E \cdot \nabla\xi(X) + V \cdot \nabla^2\xi \cdot V\right)\Big] \\ &\ge 0,\end{aligned}$$

where D depends on $\|E\|_\infty$, Ω, σ, and the bound for $|V(\tau)|$. Hence we get

$$e^{Ds}\left[\xi(y) + (w \cdot \nabla\xi(y))^2\right] \le e^{D\tilde{t}}\left[\xi(\tilde{x}) + (\tilde{v} \cdot \nabla\xi(\tilde{x}))^2\right]. \tag{2.10}$$

Next, let (s, y, w) connect with $(\tilde{t}, \tilde{x}, \tilde{v})$ through a trajectory which goes through the σ-ball, where both y and $\tilde{x}$ are at the boundary. Let (s', y', w') and $(\tilde{t}', \tilde{x}', \tilde{v}')$ be the two points with $|y'| = |\tilde{x}'| = \sigma$ on the trajectory connecting (s, y, w), $(\tilde{t}, \tilde{x}, \tilde{v})$. Then by the geometric velocity lemma and by (2.10), there exist a C and D such that

$$\begin{aligned}e^{Ds}(w \cdot \nabla\xi(y))^2 &\le e^{Ds'}\Big[\xi^2(y') + \left(w' \cdot \nabla\xi(y')\right)^2 \\ &\qquad - 2\left\{(E \cdot \nabla\xi)(s', \bar{y}') + w' \cdot \nabla^2\xi(y') \cdot w'\right\}\xi(y')\Big] \\ &\le Ce^{Ds'}\left[\xi(y') + \left(w' \cdot \nabla\xi(y')\right)^2\right] \\ &\le Ce^{D\tilde{t}'}\left[\xi(\tilde{x}') + \left(\tilde{v}' \cdot \nabla\xi(\tilde{x}')\right)^2\right] \\ &\le Ce^{D\tilde{t}'}\Big[\xi^2(\tilde{x}') + \left(\tilde{v}' \cdot \nabla\xi(\tilde{x}')\right)^2 \\ &\qquad - 2\left\{(E \cdot \nabla\xi)(\tilde{t}', \tilde{x}') + \tilde{v}' \cdot \nabla^2\xi(\tilde{x}') \cdot \tilde{v}'\right\}\xi(\tilde{x}')\Big] \\ &\le Ce^{D\tilde{t}}(\tilde{v} \cdot \nabla\xi(\tilde{x}))^2,\end{aligned}$$

where C depends on $\|E\|_\infty$, Ω, δ, and the bound for $|V(\tau)|$. Now we observe that the number $\#$ of such happenings of hitting the σ-ball through the whole cycle is uniformly bounded. Along the trajectory, we have

$$C\Delta t \ge \left|\int_{t'}^{t''} V(\tau)\, d\tau\right| = |\Delta x| \ge c_\sigma,$$

which implies that $\Delta t \ge C_\sigma > 0$. Then $C_\sigma \times \# \le \sum \Delta t \le T$ indicates that $\#$ is uniformly bounded. Now pick i and consider $\left|v^i \cdot \nabla\xi(x^i)\right|^2$. For the upper bound,

we have

$$\begin{aligned}
&e^{Dt^i}\left(v^i\cdot\nabla\xi\left(x^i\right)\right)^2\\
&\le C^{\#}e^{Dt}\left[\xi^2(x)+(v\cdot\nabla\xi(x))^2-2\left(E\cdot\nabla\xi(\bar{x})+v\cdot\nabla^2\xi(x)\cdot v\right)\xi(x)\right]\\
&\le C\times C^{\#}e^{Dt}\left[\xi(x)+(v\cdot\nabla\xi(x))^2\right].
\end{aligned}$$

On the other hand, the lower bound is achieved as

$$\begin{aligned}
&c^{\#}\left[2\delta\xi(x_0)+(v_0\cdot\nabla\xi(x_0))^2\right]\\
&\le c^{\#}\left[\xi^2(x_0)+(v_0\cdot\nabla\xi(x_0))^2-2\left(E\cdot\nabla\xi(\bar{x}_0)+v_0\cdot\nabla^2\xi(x_0)\cdot v_0\right)\xi(x_0)\right]\\
&\le e^{Dt^i}\left(v^i\cdot\nabla\xi\left(x^i\right)\right)^2.
\end{aligned}$$

Therefore, we get

$$C_1\left[\xi(x_0)+(v_0\cdot\nabla\xi(x_0))^2\right]\le\left(v^i\cdot\nabla\xi\left(x^i\right)\right)^2\le C_2\left[\xi(x)+(v\cdot\nabla\xi(x))^2\right],$$

where C_1 and C_2 are independent of l and dependent on $\|E\|_{C^1}$, δ, Ω, and the bound for $|V(\tau)|$ on the cycle. Similarly, we can get the second part of the lemma. □

We prove the following corollary by the same method as in [7], [8].

COROLLARY 2.8. *Suppose that $E\in C^{0,1}_{t,x}$ and $[E(t,x)\cdot n_x]|_\gamma\equiv E_0(x)>0$. Consider the back-time cycle of (t,x,v). Then there are C_1 and $C_2>0$ such that*

$$\begin{aligned}
C_1\left[\xi(x)+(v\cdot\nabla\xi(x))^2\right]&\le\left(v^i\cdot\nabla\xi\left(x^i\right)\right)^2\le C_2\left[\xi(x_0)+(v_0\cdot\nabla\xi(x_0))^2\right],\\
C_1\left[\xi(x_0)+(v_0\cdot\nabla\xi(x_0))^2\right]&\le\left(v^i\cdot\nabla\xi\left(x^i\right)\right)^2\le C_2\left[\xi(x)+(v\cdot\nabla\xi(x))^2\right],
\end{aligned}$$

where C_1 and C_2 are independent of the number of the bounces, depend on $\sup_{0\le\tau\le T}\|E\|_{C^{0,1/2}(\Omega)}(\tau)$, $\|E_0\|_{C^1}$, and the bound for $|V(\tau)|$ on the cycle.

We now see that $t_0(t,x,v)$, $x_0(t,x,v)$, $v_0(t,x,v)$ are C^1 functions of (t,x,v) locally when (t_0,x_0,v_0) connects with (t,x,v) through a trajectory:

$$x_0=x+\int_t^{t_0}\left[v+\int_t^s E(\tau)\,d\tau\right]ds.$$

Let ξ be the smooth function which defines the boundary in (2.8). Then we have

$$\begin{aligned}
0&=\xi(x_0)\\
&=\xi\left(x+\int_t^{t_0}\left[v+\int_t^s E(\tau)\,d\tau\right]ds\right):=\bar{\xi}(t_0;t,x,v)
\end{aligned}$$

with C^1 coefficients. By differentiating $\bar{\xi}$ with respect to t_0, we get, by Corollary 2.2,

$$\begin{aligned}
\frac{\partial\bar{\xi}}{\partial t_0}(t_0;t,x,v)&=\nabla\xi(x_0)\cdot\left[v+\int_t^{t_0}E(\tau)\,d\tau\right]\\
&=\nabla\xi(x_0)\cdot v_0=n_{x_0}\cdot v_0<0.
\end{aligned}$$

We thus have $t_0=t_0(t,x,v)\in C^1$ by the implicit function theorem and $v_0=v_0(t,x,v)$, $x_0=x_0(t,x,v)\in C^1$.

Now we consider trajectories without any bounces from a point to a boundary point, which are close to each other, and from any point to an initial point.

LEMMA 2.9. *Let (t,x,v) connect with $(0,x_0,v_0)$ through a trajectory. Then*

$$v_0 = v + \int_t^0 E\left(\tau, X\left(\tau;t,x,v\right)\right) d\tau,$$
$$x_0 = x - vt - \int_0^t \int_t^s E\left(\tau, X\left(\tau;t,x,v\right)\right) d\tau ds.$$

Considering x_0 and v_0 as functions of (t,x,v), we have

$$v_{0t} = -E\left(t,x\right) + \int_t^0 \nabla_x E \cdot X_t d\tau,$$
$$x_{0t} = -v + E\left(t,x\right) t - \int_0^t \int_t^s \nabla_x E \cdot X_t d\tau,$$
$$\nabla_x v_0 = \int_t^0 \nabla_x E \, \nabla_x X d\tau, \qquad \nabla_v v_0 = I + \int_t^0 \nabla_x E \, \nabla_v X d\tau,$$
$$\nabla_x x_0 = I - \int_0^t \int_t^s \nabla_x E \, \nabla_x X d\tau, \ \nabla_v x_0 = -tI - \int_0^t \int_t^s \nabla_x E \, \nabla_v X d\tau.$$

Here all the integrations are taken along the trajectory $\left(\tau, X\left(\tau;t,x,v\right), V\left(\tau;t,x,v\right)\right)$. $\nabla_x E \, \nabla_x X$ and $\nabla E_x \, \nabla_v X$ are matrix multiplications.

LEMMA 2.10. *Let (t,x,v) connect with (t_0,x_0,v_0) through a trajectory, where $x_0 \in \partial\Omega$. Then*

$$v_0 = v + \int_t^{t_0} E\left(\tau\right) d\tau, \quad x_0 = x + \int_t^{t_0} \left[v + \int_t^s E\left(\tau\right) d\tau \right] ds. \tag{2.11}$$

For v_0 with $n_{x_0} \cdot v_0 < 0$,

$$x_{0t} = t_{0t} v - v + t_{0t} \int_t^{t_0} E\left(\tau\right) d\tau - \int_t^{t_0} E\left(t,x\right) ds + \int_t^{t_0} \int_t^s \nabla_x E \cdot X_t d\tau,$$
$$\nabla_x x_0 = I + t_{0x} \otimes \left(v + \int_t^{t_0} E\left(\tau\right) d\tau \right) + \int_t^{t_0} \int_t^s \nabla_x E \, \nabla_x X d\tau ds,$$
$$\nabla_v x_0 = \left(t_0 - t\right) I + t_{0v} \otimes \left(v + \int_t^{t_0} E\left(\tau\right) d\tau \right) + \int_t^{t_0} \int_t^s \nabla_x E \, \nabla_v X d\tau ds,$$
$$v_{0t} = t_{0t} E\left(t_0,x_0\right) - E\left(t,x\right) + \int_t^{t_0} \nabla_x E \cdot X_t d\tau,$$
$$\nabla_x v_0 = E\left(t_0,x_0\right) \otimes t_{0x} + \int_t^{t_0} \nabla_x E \, \nabla_x X d\tau,$$
$$\nabla_v v_0 = I + E\left(t_0,x_0\right) \otimes t_{0v} + \int_t^{t_0} \nabla_x E \, \nabla_v X d\tau,$$
$$t_{0x} = \left(n_{x_0} \cdot v_0\right)^{-1} \left[n_{x_0} + \int_{t_0}^t \int_t^s n_{x_0} \cdot \left(\nabla_x E \, \nabla_x X \right) d\tau ds \right],$$
$$t_{0v} = \left(n_{x_0} \cdot v_0\right)^{-1} \left[\left(t - t_0\right) n_{x_0} + \int_{t_0}^t \int_t^s n_{x_0} \cdot \left(\nabla_x E \, \nabla_v X \right) d\tau ds \right],$$
$$t_{0t} = 1 + \left(n_{x_0} \cdot v_0\right)^{-1} n_{x_0} \cdot \left[\int_{t_0}^t E\left(\tau\right) d\tau + \left(t_0 - t\right) E\left(t,x\right) + \int_t^{t_0} \int_t^s \nabla_x E \cdot X_t d\tau ds \right].$$

Proof. Let ξ be the function defining the boundary as in (2.8); then we have

$$\xi\left(x_0\left(t,x,v\right)\right)=0. \tag{2.12}$$

We differentiate (2.12) with respect to x, v, and t to get

$$n_{x_0}\cdot\nabla_x x_0=0,\quad n_{x_0}\cdot\nabla_v x_0=0,\quad n_{x_0}\cdot x_{0t}=0. \tag{2.13}$$

We now differentiate the second equation of (2.11) to get

$$\nabla_x x_0=I+v_0\otimes t_{0x}+\int_t^{t_0}\int_t^s \nabla_x E\,\nabla_x X\,d\tau ds. \tag{2.14}$$

By multiplying (2.14) with n_{x_0} and by (2.13), we get

$$0=n_{0x}\cdot\nabla_x x_0=\left(n_{0x}\cdot v_0\right)t_{0x}+n_{0x}+\int_t^{t_0}\int_t^s n_{0x}\cdot\left(\nabla_x E\,\nabla_x X\right)d\tau ds.$$

We thus have if $n_{0x}\cdot v_0<0$,

$$t_{0x}=\left(n_{x_0}\cdot v_0\right)^{-1}\left[n_{x_0}+\int_{t_0}^t\int_t^s n_{x_0}\cdot\left(\nabla_x E\,\nabla_x X\right)d\tau ds\right]. \tag{2.15}$$

By differentiating the second equation of (2.11) with respect to v and t, we deduce the formulas for t_{0v} and t_{0t}. We differentiate the first equation of (2.11) and do the same thing to obtain the formulas for $\nabla_x v_0$, $\nabla_v v_0$, and v_{0t}. Thus our lemma follows. ∎

LEMMA 2.11. *Let (t,x,v) connect with (t_0,x_0,v_0) through a trajectory with t close to t_0, where $x_0\in\partial\Omega$. If $E\cdot n\geq\delta>0$ at the boundary for all time, then*

$$\left|t-t_0\right|\leq C\left|v_0\cdot n_{x_0}\right|,$$

where C depends on $\|E\|_{C^1}$ and δ.

Proof. We need only to consider the case when $|v_0\cdot n_{x_0}|$ is small. Notice that

$$x=x_0+v_0\left(t-t_0\right)+\int_{t_0}^t\int_{t_0}^s E\left(\tau\right)d\tau ds.$$

Setting

$$h\left(t\right)=\xi\left(x\right)=\xi\left(x_0+v_0\left(t-t_0\right)+\int_{t_0}^t\int_{t_0}^s E\left(\tau\right)d\tau ds\right),$$

we expand $h\left(t\right)$ around $t=t_0$ to get

$$\begin{aligned}\xi\left(x\right)&=\xi\left(x_0\right)+h^{'}\left(t_0\right)\left(t-t_0\right)+h^{''}\left(t_0\right)\left(t-t_0\right)^2+O\left(t-t_0\right)^3\\&=\left(v_0\cdot\nabla\xi\left(x_0\right)\right)\left(t-t_0\right)\\&\quad+\left[v_0\cdot\nabla^2\xi\left(x_0\right)\cdot v_0+E\left(t_0,x_0\right)\cdot\nabla\xi\left(x_0\right)\right]\left(t-t_0\right)^2+O\left(t-t_0\right)^3.\end{aligned}$$

Thus, we obtain

$$\begin{aligned}&t-t_0\\&=\frac{v_0\cdot\nabla\xi\left(x_0\right)\pm\sqrt{\left(v_0\cdot\nabla\xi\left(x_0\right)\right)^2+4\xi\left(x\right)\left[v_0\cdot\nabla^2\xi\left(x_0\right)\cdot v_0+E\left(t_0,x_0\right)\cdot\nabla\xi\left(x_0\right)\right]}}{-2\left[v_0\cdot\nabla^2\xi\left(x_0\right)\cdot v_0+E\left(t_0,x_0\right)\cdot\nabla\xi\left(x_0\right)\right]}\\&\quad+o\left(t-t_0\right).\end{aligned}$$

Since $-\left[v_0\cdot\nabla^2\xi\left(x_0\right)\cdot v_0+E\left(t_0,x_0\right)\cdot\nabla\xi\left(x_0\right)\right]\geq\delta\left|\nabla\xi\left(x_0\right)\right|>0$, we have

$$\left|t-t_0\right|\leq\frac{1}{2\delta\left|\nabla\xi\left(x_0\right)\right|}2\left|v_0\cdot\nabla\xi\left(x_0\right)\right|=\frac{1}{\delta}\left|v_0\cdot n_{x_0}\right|. \qquad ∎$$

3. Regularity for linear absorbing.

THEOREM 3.1. *Let Ω be a smooth bounded convex domain, $E(t,x) \in C^1\left([0,\infty)\times\bar{\Omega}\right)$, and $E(t,x)\cdot n_x \geq \delta > 0$ for all $x \in \partial\Omega$ for some fixed constant $\delta > 0$. Let an initial datum $f_0 \in C^1\left(\bar{\Pi}_0\right)$ and a boundary datum $g \in C^1\left(\bar{\gamma}^+\right)$ be compactly supported. Assume the following compatibility conditions hold for $x \in \partial\Omega$ and v with $n_x \cdot v < 0$ (2.1):*

$$f_0(x,v) = g(0,x,v), \tag{3.1}$$

$$g_t(0,x,v) + v\cdot\nabla_x f_0(x,v) + E(0,x)\cdot\nabla_v f_0(x,v) = 0. \tag{3.2}$$

(a) *Then there exists a solution $f \in C^1\left(\bar{\Pi}\backslash\gamma^0\right)$ to (2.4).*

(b) *Furthermore, assume the following vanishing conditions hold:*

$$|\nabla g(t,x,v)| \leq C|n_x\cdot v|^{1+\kappa}, \quad |\nabla f_0(x,v)| \leq C(|\xi(x)| + |n_x\cdot v|)^{\kappa}, \tag{3.3}$$

where ξ is the function defining the boundary $\partial\Omega$ in (2.8) and $\kappa > 0$. Then $f(t,x,v) \in C^1\left(\bar{\Pi}\right)$.

Proof. We define $f(t,x,v)$ as follows. For any $(t,x,v) \in [0,T]\times\bar{\Omega}\times\mathbb{R}^3\backslash\gamma^0$, let (t_0,x_0,v_0) be the first point on $\partial\Pi$ which connects with (t,x,v) through a back-time trajectory. By applying the velocity lemma, Lemma 2.1, it follows that $(t_0,x_0,v_0) \notin \gamma^0$; i.e., (t_0,x_0,v_0) is not in the singular set. If $t_0 = 0$, we define

$$f(t,x,v) = f_0(x_0,v_0).$$

The t-derivative of f is given by

$$\begin{aligned} f_t(t,x,v) &= \nabla_x f_0(x_0,v_0)\cdot x_{0t} + \nabla_v f_0(x_0,v_0)\cdot v_{0t} \\ &= \nabla_x f_0(x_0,v_0)\cdot\left[-v + E(t,x)\,t - \int_0^t\int_t^s \nabla_x E\cdot X_t d\tau ds\right] \\ &\quad + \nabla_v f_0(x_0,v_0)\cdot\left[-E(t,x) + \int_t^0 \nabla_x E\cdot X_t d\tau\right]. \end{aligned} \tag{3.4}$$

On the other hand, if $x_0 \in \partial\Omega$, we define

$$f(t,x,v) = g(t_0,x_0,v_0). \tag{3.5}$$

When $n_x\cdot v < 0$, by Lemma 2.10, the t-derivative of f is

$$f_t(t,x,v) = g_t(t_0,x_0,v_0)\,t_{0t} + \nabla_{\bar{x}} g(t_0,x_{0,}v_0)\cdot x_{0t} + \nabla_v g(t_0,x_{0,}v_0)\cdot v_{0t}. \tag{3.6}$$

It is clear to see that f is well defined when $t_0 = 0$ and $x_0 \in \partial\Omega$ by the assumption (3.1). We now show that the two different t-derivatives of f coincide in the case that $t_0 = 0$, $x_0 \in \partial\Omega$, and $n_{x_0}\cdot v_0 < 0$. Using the formulas

$$\begin{aligned} v &= v_0 + \int_0^t E(\tau)\,d\tau, \\ t_{0t} &= 1 + (n_{x_0}\cdot v_0)^{-1} n_{x_0}\cdot\left[\int_{t_0}^t E(\tau)\,d\tau + (t_0 - t)\,E(t,x) + \int_t^{t_0}\int_t^s \nabla_x E\cdot X_t d\tau ds\right] \end{aligned}$$

from Lemma 2.10 and the compatibility conditions (3.1), (3.2) into (3.6) yields

$$\begin{aligned} f_t(t,x,v) &= \left[-v_0\cdot\nabla_x f_0 - E(0,x_0)\cdot\nabla_v f_0\right] t_{0t} \\ &\quad + \nabla_x f_0\cdot\left[t_{0t}v_0 - v - E(t,x)\,t - \int_0^t\int_t^s \nabla_x E\cdot X_t d\tau ds\right] \\ &\quad + \nabla_v f_0\cdot\left[t_{0t}E(0,x_0) - E(t,x) + \int_t^0 \nabla_x E\cdot X_t d\tau\right] \\ &= \nabla_x f_0\cdot\left[-v - E(t,x)\,t - \int_0^t\int_t^s \nabla_x E\cdot X_t d\tau ds\right] \\ &\quad + \nabla_v f_0\cdot\left[-E(t,x) + \int_t^0 \nabla_x E\cdot X_t d\tau\right]. \end{aligned}$$

This is the same as (3.4). By similar computations, we see that f_x and f_v are continuous when $t_0 = 0$ and $x_0 \in \partial\Omega$. Thus part (a) follows.

For (b), we define $f(t,x,v) = 0$ for $(t,x,v) \in \gamma^0$. We show that $|\nabla f(t,x,v)| \to 0$ when (t,x,v) goes to a point in γ^0. If (t,x,v) connects with (t_0,x_0,v_0), then it follows from (3.5), (3.4), and from the velocity lemma, Lemma 2.1, and Lemma 2.10 that

$$\left|\nabla_{(t,x,v)} f(t,x,v)\right| \le C\frac{1}{|n_{x_0}\cdot v_0|}\left|\nabla g(t_0,x_0,v_0)\right| \le C\left|n_{x_0}\cdot v_0\right|^{\kappa}.$$

If (t,x,v) connects with $(0,x_0,v_0)$, then by (3.4)

$$|\nabla f(t,x,v)| \le C\left|\nabla f_0(x_0,v_0)\right| \le C(|\xi(x_0)| + |n_{x_0}\cdot v_0|)^{\kappa}.$$

By the velocity lemma, Lemma 2.1, as $\xi^2(x) + (n_x\cdot v)^2 \to 0$, $n_{x_0}\cdot v_0 \to 0$ and $|\xi(x_0)| + |n_{x_0}\cdot v_0| \to 0$. The theorem thus follows. □

We also deduce the following theorem.

THEOREM 3.2. *Let $E(t,x) \in C^1\left([0,\infty]\times\bar{\Omega}\right)$ with $E(t,x)\cdot n_x \ge \delta > 0$ on $\partial\Omega$. Let $F_0(x,v)$, $H(t,x,v)$, and $G(t,x,v)$ be $(n\times 1)$-vector-valued functions and $A(t,x,v)$ be an $(n\times n)$-matrix function such that $G(t,x,v) \in C^1(\bar{\gamma}^+)$, $F_0 \in C^1\left(\bar{\Pi}_0\right)$, $H(t,x,v)$ and $A(t,x,v) \in C^1\left(\bar{\Pi}\right)$, and H, G, and F_0 have compact support in v. Assume the compatibility conditions hold for $x \in \partial\Omega$, v with $v\cdot n_x < 0$:*

$$\begin{aligned} &F_0(x,v) = G(0,x,v), \\ &G_t(x,v) + v\cdot\nabla_x F_0 + E(0,x)\cdot\nabla_v F_0 = A(0,x,v)\,F_0(x,v) + H(0,x,v). \end{aligned} \tag{3.7}$$

(a) *Then there exists a unique $(n\times 1)$-vector-valued function $F(t,x,v) \in C^1\left(\bar{\Pi}\backslash\gamma_0\right)$ such that $F_t + v\cdot\nabla_x F + E\cdot\nabla_v F = AF + H$, $F|_{\gamma^+} = G$, $F|_{t=0} = F_0$ for $(t,x,v) \in \bar{\Pi}\backslash\gamma_0$.*

(b) *Furthermore, assume that the vanishing conditions hold:*

$$\begin{aligned} &|\nabla G(t,x,v)| \le C\left|v\cdot n_x\right|^{1+\kappa}, \quad |\nabla H(t,x,v)| \le C\left(|\xi(x)| + |v\cdot n_x|\right)^{1+\kappa}, \\ &|\nabla F_0(t,x,v)| \le C\left(|\xi(x)| + |v\cdot n_x|\right)^{\kappa}. \end{aligned}$$

Then $F(t,x,v) \in C^1\left(\bar{\Pi}\right)$.

From now on, ∇_x^T denotes the tangential derivative, $\nabla_x^{\perp}$ denotes the normal derivative, v^T denotes the tangential component of v, and $v^{\perp}$ denotes the normal component of v.

THEOREM 3.3. *Let $1 \le p \le \infty$, and let*

$$f_0 \in W^{1,p}(\Pi_0), \quad g \in W^{1,p}(\gamma^+),$$
$$|\nabla g| \le C\,|n_x \cdot v|. \tag{3.8}$$

Let f_0 and g have compact support and satisfy

$$f_0(x,v) = g(0,x,v) \text{ for all } x \in \partial\Omega \text{ and } v \text{ with } n_x \cdot v < 0.$$

Let $E(t,x) \in W^{1,\infty}\left([0,\infty) \times \bar{\Omega}\right)$ ($E \in W^{1,\infty} \cap C^1$ for $p = \infty$) and $E(t,x) \cdot n_x \ge \delta > 0$. Then there exists an $f(t,x,v) \in W^{1,p}(\Pi_s)$ for $0 \le s \le T$ such that

$$f_t + v \cdot \nabla_x f + E \cdot \nabla_v f = 0, \quad f|_{t=0} = f_0, \quad f|_{\gamma^+} = g \tag{3.9}$$

in the sense of distribution. The following estimates hold:

$$\begin{aligned}
\int_{\Pi_s} |f_t|^p + \int_{\gamma_s^-} (n_x \cdot v)\,|f_t|^p &\le \int_{\Pi_0} |f_{0t}|^p - \int_{\gamma_s^+} (n_x \cdot v)\,|g_t|^p \\
&\quad + C \int_0^s \int_{\Pi_\tau} |\nabla f|^p \, d\tau, \\
\int_{\Pi_s} \left|\nabla_x^T f\right|^p + \int_{\gamma_s^-} (n_x \cdot v)\left|\nabla_x^T f\right|^p &\le \int_{\Pi_0} \left|\nabla_x^T f_0\right|^p - \int_{\gamma_s^+} (n_x \cdot v)\left|\nabla_x^T g\right|^p \\
&\quad + C \int_0^s \int_{\Pi_\tau} |\nabla f|^p \, d\tau, \\
\int_{\Pi_s} \left|\nabla_x^\perp f\right|^p + \int_{\gamma_s^-} (n_x \cdot v)\left|\nabla_x^\perp f\right|^p &\le \int_{\Pi_0} \left|\nabla_x^\perp f_0\right|^p - \int_{\gamma_s^+} (n_x \cdot v)\left|\nabla_x^\perp g\right|^p \\
&\quad + C \int_0^s \int_{\Pi_\tau} |\nabla f|^p \, d\tau, \\
\int_{\Pi_s} |\nabla_v f|^p + \int_{\gamma_s^-} (n_x \cdot v)\,|\nabla_v f|^p &\le \int_{\Pi_0} |\nabla_v f_0|^p - \int_{\gamma_s^+} (n_x \cdot v)\,|\nabla_v g|^p \\
&\quad + C \int_0^s \int_{\Pi_\tau} |\nabla f|^p \, d\tau,
\end{aligned}$$

where

$$\begin{aligned}
\nabla_x^\perp f|_{\gamma^+} &= -(n_x \cdot v)^{-1}\left[g_t + v^T \cdot \nabla_x^T g + E \cdot \nabla_v g\right], \\
\nabla_x^\perp g &= -(n_x \cdot v)^{-1}\left[g_t + v^T \cdot \nabla_x^T g + E \cdot \nabla_v g\right], \\
\nabla_x^\perp f|_{t=0} &= f_{0x}, \qquad 0 \le s \le T.
\end{aligned}$$

Proof. Let N_σ be a σ-neighborhood of $\gamma^0 = \{x \in \partial\Omega,\ n_x \cdot v = 0\}$.
We construct $f_0^n \in C_c^\infty$, which is constant on N_σ, and $E^n \in C^\infty$ such that

$$f_0^n \to f_0 \text{ in } W^{1,p}(\Pi_0 \backslash N_\sigma), \quad E^n \to E \text{ in } W^{1,\infty}, \quad E^n \cdot n_x \ge \delta/2 > 0.$$

After choosing f_0^n and E^n, we construct g^n such that

$$\begin{aligned}
g^n(0,x,v) &= f_0^n(x,v) \text{ on } \gamma^+ \backslash N_\sigma, \\
g_t^n(0,x,v) &= -v \cdot \nabla_x f_0^n - E^n(0,x) \cdot \nabla_v f_0^n \text{ on } \gamma^+ \backslash N_\sigma, \\
g^n &\to g \text{ in } W^{1,p}\left(\gamma^+ \backslash N_\sigma\right).
\end{aligned}$$

We first choose $g^n \to g$ in $W^{1,p}(\gamma^+\backslash N_\sigma)$, where $g^n \in C_c^\infty$. Then modify it as $g^n(t,x,v)+[f_0^n(x,v)-g^n(0,x,v)]+t\chi(t)[-v\cdot\nabla_x f_0^n - E^n(0,x) - g_t^n(0,x,v)]$, where $\chi(t)\in C^\infty$, $\chi(0)=1$, and $\int|\chi(t)|^p\,dt$ is very small. We can see that this sequence satisfies all the above conditions. Clearly, from Theorem 3.1 there exists $f^n \in C^1\left(\bar{\Pi}\backslash\gamma^0\right)$ such that f^n satisfies (3.9) with initial and boundary data f_0^n and g^n, respectively. By applying the Gronwall inequality and since $|n_x\cdot v|\geq\sigma$, we deduce that

$$\|f^n\|_{W^{1,p}(\Pi\backslash N_\sigma)} \leq C_\sigma,$$
$$\|f^n\|_{W^{1,p}(\gamma^-\backslash N_\sigma)} \leq C_\sigma$$

for all $\sigma>0$, uniformly in n. By letting $n\to\infty$, we show that for $1<p<\infty$ there exists an f in $W^{1,p}$ such that

$$f^n \rightharpoonup f \text{ in } W^{1,p}(\Pi\backslash N_\sigma)\cap W^{1,p}(\gamma\backslash N_\sigma)$$

for all $\sigma>0$, and our theorem thus follows. For $p=1$, we show that $\{f^n\}$ is a Cauchy sequence in W^1 by considering f^n-f^m in (3.9). From the equation for f^n-f^m,

$$\partial_t(f^n-f^m)+v\cdot\nabla_x(f^n-f^m)+E^n\cdot\nabla_v(f^n-f^m)=(E^m-E^n)\cdot\nabla_v f^m,$$

we take derivatives (in the sense of distribution) and integrate with respect to x and v and then with respect to time. Using that $\{f_0^n\},\{g^n\}$ are Cauchy in $W^{1,1}$ and f^n and its derivatives are compactly supported uniformly in n (since $\|E^n\|_{W_{1,\infty}}$ are uniformly bounded in n and f_0^n, g^n are compactly supported), we can deduce that $\{f^n\}$ is a Cauchy sequence. For $p=\infty$, we use $E\in C^1$ itself instead of using approximate fields E^n in our construction of f_0^n, g^n to apply Theorem 3.1. Then we have, by taking derivatives,

$$\partial_t\partial(f^n-f^m)+v\cdot\nabla_x(\partial(f^n-f^m))+E\cdot\nabla_v(\partial(f^n-f^m))=\partial E\cdot\nabla_v(f^m-f^n).$$

By integrating along the corresponding trajectory, we get the Gronwall inequality for $\partial(f^n-f^m)$, which implies that $\{f^n\}$ is a Cauchy sequence in $W^{1,\infty}$. Here we note that by the vanishing assumption (3.8),

$$\|f\|_{W^{1,p}(\Pi)}\leq C\left(1+\|f_0\|_{W^{1,p}(\Pi_0)}+\|g\|_{W^{1,p}(\gamma^+)}\right),$$

where C depends on T, the support of f_0 and g, and the constant on the vanishing condition on g, $\|E\|_{W^{1,\infty}}$. Our theorem thus follows. □

We also deduce the following theorem.

THEOREM 3.4. *Let $1\leq p\leq\infty$, and let $F_0(x,v)$, $H(t,x,v)$, and $G(t,x,v)$ be $(n\times 1)$-vector-valued functions and $A(t,x,v)$ be an $(n\times n)$-matrix function such that $G(t,x,v)\in W^{1,p}(\gamma^+)$, $F_0(x,v)\in W^{1,p}(\Pi_0)$, $H(\cdot,x,v)\in W^{1,p}(\Pi_s)\cap W^{1,p}(\gamma^+)$ for $0\leq s\leq T$, and $A\in C^{0,1}(\Pi)$. Let the vanishing condition hold on $\partial\Omega$:*

$$|\nabla G|\leq C|n_x\cdot v|,\quad |\nabla H|\leq C|n_x\cdot v|.$$

Let F_0 and G have compact support in v, and let F_0 and G satisfy

$$F_0(x,v)=G(0,x,v) \text{ for all } x\in\partial\Omega \text{ and } v \text{ with } n_x\cdot v<0.$$

Let $E(t,x)\in W^{1,\infty}\left([0,\infty)\times\bar{\Omega}\right)$ ($E\in W^{1,\infty}\cap C^1$ for $p=\infty$) and $E(t,x)\cdot n_x\geq\delta>0$. Then there exists an $F(t,x,v)\in W^{1,p}(\Pi_s)\cap W^{1,p}(\gamma^+)$ for $0\leq s\leq T$ such that

$$F_t+v\cdot\nabla_x F+E\cdot\nabla_v F=A(F)+H,\quad F|_{t=0}=F_0,\quad F|_{\gamma^+}=G$$

in the sense of distribution. The following estimates hold:

$$\begin{aligned}
\int_{\Pi_s} |F_t|^p + \int_{\gamma_s^-} (n_x \cdot v) |F_t|^p &\le \int_{\Pi_0} |F_{0t}|^p - \int_{\gamma_s^+} (n_x \cdot v) |G_t|^p \\
&\quad + C \int_0^s \int_{\Pi_\tau} (|\nabla F|^p + |\nabla H|^p) \, d\tau, \\
\int_{\Pi_s} \left|\nabla_x^T F\right|^p + \int_{\gamma_s^-} (n_x \cdot v) \left|\nabla_x^T F\right|^p &\le \int_{\Pi_0} \left|\nabla_x^T F_0\right|^p - \int_{\gamma_s^+} (n_x \cdot v) \left|\nabla_x^T G\right|^p \\
&\quad + C \int_0^s \int_{\Pi_\tau} (|\nabla F|^p + |\nabla H|^p) \, d\tau, \\
\int_{\Pi_s} \left|\nabla_x^\perp F\right|^p + \int_{\gamma_s^-} (n_x \cdot v) \left|\nabla_x^\perp F\right|^p &\le \int_{\Pi_0} \left|\nabla_x^\perp F_0\right|^p - \int_{\gamma_s^+} (n_x \cdot v) \left|\nabla_x^\perp G\right|^p \\
&\quad + C \int_0^s \int_{\Pi_\tau} (|\nabla F|^p + |\nabla H|^p) \, d\tau, \\
\int_{\Pi_s} |\nabla_v F|^p + \int_{\gamma_s^-} (n_x \cdot v) |\nabla_v F|^p &\le \int_{\Pi_0} |\nabla_v F_0|^p - \int_{\gamma_s^+} (n_x \cdot v) |\nabla_v G|^p \\
&\quad + C \int_0^s \int_{\Pi_\tau} (|\nabla F|^p + |\nabla H|^p) \, d\tau,
\end{aligned}$$

where $\nabla_x^\perp F|_{\gamma^+} = -(n_x \cdot v)^{-1} \left[G_t + v^T \cdot \nabla_x^T G + E \cdot \nabla_v G\right]$, $\nabla_x^\perp F|_{t=0} = F_{0x}$, *and* $\nabla_x^\perp G = -(n_x \cdot v)^{-1} \left[G_t + v^T \cdot \nabla_x^T G + E \cdot \nabla_v G\right]$, $0 \le s \le T$.

DEFINITION 3.5 (boundary and initial operators). *Suppose that* $f \in C_c^\infty$ *satisfies*

$$f_t + v \cdot \nabla_x f + E \cdot \nabla_v f = 0, \quad f|_{t=0} = f_0, \quad f|_{\gamma^+} = g$$

in the classical sense. The unique boundary operator L_+ *and the unique initial operator* L_0 *are defined by*

$$\partial^\alpha f|_{\gamma^+} = L_+^\alpha \left(\nabla_x^T, \partial_v, \partial_t\right) f|_{\gamma^+}, \quad \partial^\alpha f|_{t=0} = L_0^\alpha \left(\partial_x, \partial_v\right) f|_{t=0},$$

where ∂ *is the usual differential operator of* t, x, v *with multi-index* α; $|\alpha|$ *is the order of* α.

For the higher regularity, we refer the reader to [7], [8].

THEOREM 3.6 (high regularity). *Suppose that* $E(t,x,v) \cdot n_x \ge \delta > 0$ *on* $\partial\Omega$, $E \in W^{k,\infty}$. *Let* $0 \le f_0 \in W^{k,p}(\Pi_0)$, f_0 *have compact support in* v, $0 \le g \in W^{k,p}(\gamma^+)$, *and* g *have compact support in* v. *Let* $\partial^\alpha g(t,x,v) = 0$ *for* $x \in \partial\Omega$, $v \cdot n_x = 0$, $|\alpha| = k$, *and let* $\left|\partial^{(k)} g\right| \le C |v \cdot n_x|^k$. *Assume that the following compatibility conditions are satisfied:*

$$\partial^\alpha f|_{\{t=0\} \cap \gamma^+} = \left\{L_+^\alpha \left(\nabla_x^T, \partial_v, \partial_t\right) g\right\}|_{t=0} = \left\{L_0^\alpha \left(\partial_x, \partial_v\right) f_0\right\}|_{\gamma^+}, \tag{3.10}$$

where $|\alpha| \le k-1$. *Then there is a unique* $W^{k,p}$ *solution* f *such that*

$$\int_{\Pi_s} \left|\partial^\theta f\right|^p + \int_{\gamma_s^-} (v \cdot n_x) \left|\partial^\theta f\right|^p \le C, \quad 0 \le s \le T,$$

where C *depends on* f_0, g, *and* E, $|\theta| \le k$. *For* $|\alpha| \le k$,

$$\partial^\alpha f|_{\gamma^+} = L_+^\alpha \left(\nabla_x^T, \partial_v, \partial_t\right) g, \quad \partial^\alpha f|_{t=0} = L_0^\alpha \left(\partial_x, \partial_v\right) f_0.$$

Sketch of proof. We use an induction on the order k. We omit the detailed proof; instead we shall prove our theorem with $|\alpha| = k = 2$:

$$\begin{aligned}
\partial_t\partial_t f + v\cdot\nabla_x\partial_t f + E\cdot\nabla_v\partial_t f &= -\partial_t E\cdot\nabla_v f,\\
\partial_t\partial_v f + v\cdot\nabla_x\partial_v f + E\cdot\nabla_v\partial_v f &= -\partial_x f,\\
\partial_t\partial_x f + v\cdot\nabla_x\partial_x f + E\cdot\nabla_v\partial_x f &= -\partial_x E\cdot\nabla_v f.
\end{aligned}$$

We think of $F = (\partial_t f, \partial_x f, \partial_v f)$ as an unknown vector-valued function. We already know that $F \in L^p$ by Theorem 3.3, and we want to prove here that F is actually in $W^{1,p}$. Theorem 3.4 applies to this case with $H = \vec{0}$, and

$$A = \begin{pmatrix} 0 & 0 & -\partial_t E \\ 0_3 & -I_3 & 0_3 \\ 0_3 & 0_3 & -\partial_x E \end{pmatrix},$$

which is in $W^{1,\infty}$ by assumption, where $F_0 = (-v\cdot\nabla_x f_0 - E\cdot\nabla_v f_0, \partial_x f_0, \partial_v f_0) \in W^{1,p}(\Pi_0)$, $G = \left(g_t, \partial_x^T g, -(v\cdot n_x)^{-1}\left[g_t + v^T\cdot\nabla_x^T g + E\cdot\nabla_v g\right], \partial_v g\right) \in W^{1,p}(\gamma^+)$. By our assumption that $\left|\partial^2 g\right| \le C\left|v\cdot n_x\right|^2$, $\|E\|_{W^{1,\infty}} \le M$, we have

$$|\nabla G| \le C\left|v\cdot n_x\right|.$$

Moreover, by our compatibility condition, we have

$$F_0(x,v) = G(0,x,v).$$

We then apply Theorem 3.4 to get $F \in W^{1,p}$. The theorem thus follows. ∎

4. Regularity for linear specular reflection. Now we study the purely specular problem:

$$\begin{aligned}
f_t + v\cdot\nabla_x f + E\cdot\nabla_v f = 0, \quad f|_{t=0} = f_0,\\
f(t,x,v) = f(t,x,v_*), \quad x\in\partial\Omega.
\end{aligned} \tag{4.1}$$

We seek the compatibility conditions. After the change of coordinates (flattening out the boundary), we transform the original Vlasov–Poisson system into an equivalent system. Using the same notation (t,x,v) and f, we have

$$f_t + v\cdot\nabla_x f + (E+J)\cdot\nabla_v f = 0,$$

where $J_1(x,v) = (v_2,v_3)\cdot\partial^2\phi(x)\cdot(v_2,v_3)$, $J_i(x,v) = 0$ for $j = 2,3$. From the specular reflection condition on f, we have $f(t,0,\bar{x},v_1,\bar{v}) = f(t,0,\bar{x},-v_1,\bar{v})$ for all $\bar{x}\in\mathbb{R}^2$ and $v\in\mathbb{R}^3$, which also implies that $f_0(0,\bar{x},v_1,\bar{v}) = f_0(0,\bar{x},-v_1,\bar{v})$. By taking the t-derivative and plugging in $t = 0$, we get

$$f_t(0,0,\bar{x},v_1,\bar{v}) = f_t(0,0,\bar{x},-v_1,\bar{v}),$$

where

$$\begin{aligned}
f_t(0,0,\bar{x},v_1,\bar{v}) = &-v_1 f_{0x_1}(0,\bar{x},v_1,\bar{v}) - v_2 f_{0x_2}(0,\bar{x},v_1,\bar{v}) - v_3 f_{0x_3}(0,\bar{x},v_1,\bar{v})\\
&-\sum_{i=1}^{3}(E_i+J_i) f_{0v_i}(0,\bar{x},v_1,\bar{v}),\\
f_t(0,0,\bar{x},-v_1,\bar{v}) = &\,v_1 f_{0x_1}(0,\bar{x},-v_1,\bar{v}) - v_2 f_{0x_2}(0,\bar{x},-v_1,\bar{v}) - v_3 f_{0x_3}(0,\bar{x},-v_1,\bar{v})\\
&-\sum_{i=1}^{3}(E_i+J_i) f_{0v_i}(0,\bar{x},-v_1,\bar{v}).
\end{aligned}$$

Since $f_{0v_1}(0,\bar{x},v_1,\bar{v}) = -f_{0v_1}(0,\bar{x},v_1,\bar{v})$, we get

$$v_1 f_{0x_1}(0,\bar{x},v_1,\bar{v}) + v_1 f_{0x_1}(0,\bar{x},-v_1,\bar{v}) + 2(E_1+J_1)(0,0,\bar{x},v) f_{0v_1}(0,\bar{x},v_1,\bar{v}) = 0. \tag{4.2}$$

Therefore, the corresponding compatibility conditions under the original coordinate system are

$$f_0(x,v) = f_0(x,v_*), \tag{4.3}$$

$$v_*^{\perp}\nabla_x^{\perp} f_0(x,v_*) + v^{\perp}\nabla_x^{\perp} f_0(x,v) + 2E^{\perp}(0,x)\nabla_v^{\perp} f_0(x,v) = 0 \tag{4.4}$$

for all $x \in \partial\Omega$. Assume that $E(t,x) \in C^1$ and $E(t,x)\cdot n_x \geq \delta > 0$ at the boundary. We also assume that $f_0 \in C^1$ and has compact support, and

$$f_0 \equiv \text{constant} \quad \text{when } \xi^2(x) + (v\cdot\nabla\xi(x))^2 \leq \omega_0$$

for some fixed $\omega_0 > 0$. We then define an iterating sequence as a family of the solutions of the following linear problems:

$$\begin{aligned} &f_t^{k+1} + v\cdot\nabla_x f^{k+1} + E\cdot\nabla_v f^{k+1} = 0, \quad f^{k+1}|_{t=0} = f_0, \\ &f^{k+1}(t,x,v) = f^k(t,x,v_*), \quad x\in\partial\Omega, \quad v\cdot n_x \leq 0 \end{aligned} \tag{4.5}$$

for $k = 0,1,2,\ldots$, where f_0 is a smooth extension of Π satisfying the compatibility conditions. Since $\|E\|_{L^\infty} \leq C$, it easily follows that f^k has a uniform bound for its support in x and v. The major result in this section is the following theorem.

THEOREM 4.1. *Let $E(t,x)\cdot n_x = E_0(x) > 0$ for all $x \in \partial\Omega$. Let f_0 have compact support, and assume that when $\xi^2(x) + (v\cdot\nabla\xi(x))^2 \leq \omega_0$ for some fixed $\omega_0 > 0$,*

$$f_0(x,v) \equiv \text{constant}.$$

(a) *Assume $f_0 \in C^1$, $E \in C^0([0,T]\times\Omega)$, and*

$$\sup_{0\leq t\leq T} \|\nabla_x E\|_{C^0(\Omega)}(t) < \infty.$$

Let f_0 satisfy (4.3). Then there exists a unique $W^{1,\infty}$ solution f of (4.1), and $\|f\|_{W^{1,\infty}}$ depends only on ω_0, $\|E\|_{C^0} + \sup_{0\leq t\leq T}\|\nabla_x E\|_{C^0(\Omega)}(t)$, $\|E_0\|_{C^1}$, and $\|f_0\|_{C^1}$.

(b) *Moreover, if $f_0 \in C^{1,\eta}$ for some $\eta > 0$, assume that $E \in C^{0,\eta}([0,T]\times\Omega)$ and*

$$\sup_{0\leq t\leq T} \|\nabla_x E\|_{C^{0,\eta}(\Omega)}(t) < \infty.$$

Let f_0 satisfy both (4.3) and (4.4). Then there exists a unique $C^{1,\mu}$ solution f of (4.1), for some $0 < \mu < \eta$ depending on ω_0, $\|E\|_{C^{0,\eta}} + \sup_{0\leq t\leq T}\|\nabla_x E\|_{C^{0,\eta}(\Omega)}(t)$, $\|E_0\|_{C^{1,\eta}}$, and $\|f_0\|_{C^{1,\eta}}$.

We first show a uniform C^1 bound for the iterating sequence f^k.

LEMMA 4.2 (C^1 bounds). *Suppose that $E(t,x)\cdot n_x = E_0(x) > 0$ for all $x \in \partial\Omega$, $E, E_0 \in C^1$, $f_0 \in C^{1,\beta}$, and*

$$f_0 \equiv \text{constant} \quad \text{when } \xi^2(x) + (v\cdot\nabla\xi(x))^2 \leq \omega_0,\ \omega_0 > 0.$$

Suppose that (4.5) has a solution f^k. Let $(0,x_0,v_0)$ be on the back-time cycle of (t,x,v). Then

$$\left|\nabla_{(t,x,v)} f(t,x,v)\right| \leq C\left|\nabla_{(x,v)} f_0(x_0,v_0)\right|,$$

where C is independent of k, and depends on f_0, ω_0, E_0, and E.

Proof. Let the back-time cycle from (t,x,v) be $\left(t^l,x^l,v^l\right)=(t,x,v)$, $\left(t^{l-1},x^{l-1},v^{l-1}\right),\ldots,\left(t^1,x^1,v^1\right),(0,x_0,v_0)$. We need only to consider when $\xi(x)+\left(v\cdot\nabla\xi(x)\right)^2$ is small. We distinguish, on the back-time cycle from (t,x,v) to (t_0,x_0,v_0), large-time intervals from small-time intervals in the following way. By Lemma 2.7, we may assume that $\left|v^j\cdot n_{x^j}\right|\geq c\,\omega_0^{1/2}$ for all j, since $\nabla f_0=0$ when $\xi^2(x)+|v\cdot\nabla\xi(x)|^2\leq\omega_0$. If $t^j-t^{j-1}\geq c\,\omega_0^{1/2}$, then it is called a large-time interval on the cycle, otherwise a small-time interval with $t^j-t^{j-1}\leq c\,\omega_0^{1/2}\leq\left|v^j\cdot n_{x^j}\right|$. We first treat the portion of our back-time cycle with small-time intervals, which is more complicated but crucial to estimate. Without loss of generality, we use the same back-time cycle as above for our convenience in dealing with small-time intervals. From our construction (4.5), we have

$$\begin{aligned}f^k(t,x,v)&=f^k\left(t^{l-1},x^{l-1},v^{l-1}\right)=f^{k-1}\left(t^{l-1},x^{l-1},v_*^{l-1}\right)\\&=f^{k-1}\left(t^{l-2},x^{l-2},v^{l-2}\right)=\cdots=f_0(x_0,v_0).\end{aligned}$$

From the first relation that $f^k(t,x,v)=f^k\left(t^{l-1},x^{l-1},v^{l-1}\right)$, with $x^{l-1}\in\partial\Omega$, $v^{l-1}\cdot n_{x^{l-1}}<0$, we have

$$\left|\nabla f^k(t,x,v)\right|=\left|I_{l-1}^l\nabla f^k\left(t^{l-1},x^{l-1},v^{l-1}\right)\right|,$$

where

$$I_{l-1}^l=\begin{pmatrix}\frac{\partial t^{l-1}}{\partial t}&\frac{\partial x^{l-1}}{\partial t}&\frac{\partial v^{l-1}}{\partial t}\\\frac{\partial t^{l-1}}{\partial x}&\frac{\partial x^{l-1}}{\partial x}&\frac{\partial v^{l-1}}{\partial x}\\\frac{\partial t^{l-1}}{\partial v}&\frac{\partial x^{l-1}}{\partial v}&\frac{\partial v^{l-1}}{\partial v}\end{pmatrix}.$$

By Lemmas 2.10 and 2.11, I_{l-1}^l takes the form

$$\begin{pmatrix}C&C&C\\C(\omega_0)&C(\omega_0)&C(\omega_0)\\C&C&C\end{pmatrix}.$$

Here we have used Lemma 2.7 and the assumption to get

$$\begin{aligned}\left|\frac{\partial t^{l-1}}{\partial x}\right|&\leq C+\frac{1}{\left|v^{l-1}\cdot n_{x^{l-1}}\right|}\leq C+\frac{1}{C\left[\xi(x_0)+\left(v_0\cdot\nabla\xi(x_0)\right)^2\right]^{1/2}}\\&\leq C+\frac{C}{C\omega_0}=C(\omega_0),\end{aligned}$$

where C depends on $\|E\|_{C^1}$. Next we consider

$$f^k\left(t^{l-1},x^{l-1},v^{l-1}\right)=f^{k-1}\left(t^{l-1},x^{l-1},v_*^{l-1}\right),$$

where $v_*^{l-1}=v^{l-1}-2\left(v^{l-1}\cdot n_{x^{l-1}}\right)n_{x^{l-1}}$. Clearly, we have

$$\left|\nabla f^k\left(t^{l-1},x^{l-1},v^{l-1}\right)\right|=\left|I_*^{l-1}\nabla f^{k-1}\left(t^{l-1},x^{l-1},v_*^{l-1}\right)\right|,$$

where I_*^{l-1} takes the form

$$\begin{pmatrix}1&0&0\\0&Id&C\\0&0&C\end{pmatrix}.$$

Now consider the map $\left(t^{j-1}, x^{j-1}, v^{j-1}\right) \longmapsto \left(t^j, x^j, v_*^j\right)$, where $x^{j-1}, x^j \in \partial\Omega$, $2 \leq j \leq l$. Let J_{j-1}^j be the Jacobian matrix of the map. We now estimate it. Since $\left(t^{j-1}, x^{j-1}, v^{j-1}\right)$ connects with $\left(t^j, x^j, v_*^j\right)$ through a trajectory,

$$\begin{aligned} v_*^j &= v^{j-1} + \int_{t^{j-1}}^{t^j} E(\tau)\, d\tau, \\ x^j &= x^{j-1} + v_*^j \left(t^j - t^{j-1}\right) + \int_{t^{j-1}}^{t^j} \int_{t^j}^{s} E(\tau)\, d\tau ds. \end{aligned}$$

Here we notice that

$$c\left(t^j - t^{j-1}\right) \leq \left|v^{j-1} \cdot n_{x^{j-1}}\right| \leq C\left(t^j - t^{j-1}\right) \tag{4.6}$$

by Lemma 2.11 and by expanding $\xi\left(x^j\right)$ around $\xi\left(x^{j-1}\right)$ as

$$\begin{aligned} 0 = \xi\left(x^j\right) &= \xi\left(x^{j-1} + v_*^{j-1}\left(t^j - t^{j-1}\right) + \int_{t^{j-1}}^{t^j} \int_{t^j}^{s} E(\tau)\, d\tau ds\right) \\ &= \left(v_*^{j-1} \cdot \nabla\xi\left(x^{j-1}\right)\right)\left(t^j - t^{j-1}\right) + O\left(t^j - t^{j-1}\right)^2. \end{aligned}$$

We then get a similar estimate

$$\left|\nabla f^{k-1}\left(t^j, x^j, v_*^j\right)\right| = \left|J_{j-1}^j \nabla f^{k-1}\left(t^{j-1}, x^{j-1}, v^{j-1}\right)\right|,$$

where

$$J_{j-1}^j = \begin{pmatrix} C & C & C \\ C(\omega_0) & C(\omega_0) & C(\omega_0) \\ C & C & C \end{pmatrix},$$

and C depends only on the C^1 norm of E. Since $\left(t^1, x^1, v^1\right)$ connects with $(0, x_0, v_0)$, with $x_1 \in \partial\Omega$, we have

$$\begin{aligned} \left|\nabla f^{k-(l-2)}\left(t^1, x^1, v^1\right)\right| &= \left|I_0^1 \nabla f_0(x_0, v_0)\right| \\ &\leq C\left|\nabla f_0(x_0, v_0)\right|. \end{aligned}$$

By Lemma 2.7 and (4.6), we have $\left|v^i \cdot n_{x^i}\right| \geq c(\omega_0)$ for all i and $l \times c(\omega_0) \leq \sum_i \left|v^i \cdot n_{x^i}\right| \leq \sum\left(t^{i+1} - t^i\right) \leq T$ to see that the number of bounces is uniformly bounded and dependent on ω_0, δ, and $\|E\|_{C^1}$. Therefore,

$$\begin{aligned} \left|\nabla f^k(t, x, v)\right| &= \left|I_{l-1}^l \prod_{j=1}^{l-1} I_*^j \prod_{j=2}^{l-1} J_{j-1}^j I_0^1 \nabla f_0(x_0, v_0)\right| \\ &\leq C(\omega_0)\left|\nabla f_0(x_0, v_0)\right|. \end{aligned}$$

In a similar manner, we can obtain estimates on the portion of the cycle with large-time intervals. Here we have the uniform bound on the number of bounces with large-time intervals in a rather trivial way since the size of each interval was chosen to be $\Delta t \geq c\,\omega_0^{1/2}$ by the construction. We thus deduce our lemma. □

LEMMA 4.3. *Suppose that* $E(t,x)\cdot n_x = E_0(x) > 0$ *at the boundary and that* (4.5) *has the solution* f^k. *Then*

$$\left\|f^k\right\|_{L^\infty(\Pi)} \le \|f_0\|_{L^\infty(\Pi_0)} \quad \textit{for all } k.$$

Proof. Let the cycle from (t,x,v) be $\left(t^i,x^i,v^i\right)$, $1\le i\le l$, and $(0,x_0,v_0)$. Clearly, on each trajectory f^k is a constant. ∎

We establish a uniform $C^{0,\mu}$ estimate for f^k in (4.5) by using Corollaries 2.2 and 2.3.

LEMMA 4.4. (a) *The sequence is well defined, and* $f^k \in C^1$.

(b) *If* $|x-y|$ *is small and the field satisfies*

$$\sup_{0\le t\le T} |E(t,x)-E(t,y)| \le -L|x-y|\log|x-y|,$$

then there is a $\omega>0$, *depending on* L *and* $\|E\|_\infty$, *such that if* $\xi^2(x)+(v\cdot\nabla\xi(x))^2 \le \omega$,

$$f^k(t,x,v) \equiv \text{constant} \quad \textit{for any } k.$$

(c) *Moreover, for constants* C *and* $\mu>0$ *depending on* L, ω, *and* α,

$$\left\|f^k\right\|_{C^{0,\mu}} \le C\|f_0\|_{C^{0,\alpha}}.$$

Proof. For (a), we apply Theorem 3.1. From the velocity lemma, Lemma 2.1, and Lemma 4.2, $\left|\nabla_{(t,x,v)} f^k(t,x,v)\right| \equiv 0$ when $|v\cdot n_x| \le C(\omega_0)$ to satisfy the vanishing condition (3.3). It suffices to check for any k that the compatibility condition in Theorem 3.1 is satisfied. First, it is trivial to see that $f_0(x,v) = f^k(0,x,v_*)$ by (4.2). We use an induction on k. Clearly, it is true for $k=0$ if we choose f_0 properly. Supposing that the condition for $k=n-1$ is true, we deduce from (4.5) and (4.2) that for $x\in\partial\Omega$,

$$\begin{aligned} f_t^n(0,x,v) &= f_t^{n-1}(t,x,v_*)\,|_{t=0} \\ &= -v_*\cdot\nabla_x f^{n-1}(0,x,v_*) - E(0,x)\cdot\nabla_v f^{n-1}(0,x,v_*) \\ &= -v_*\cdot\nabla_x f_0(x,v_*) - E(0,x)\cdot\nabla_v f_0(x,v_*) \\ &= -v\cdot\nabla_x f_0(x,v) - E(0,x)\cdot\nabla_v f_0(x,v). \end{aligned}$$

This is exactly (3.2) in Theorem 3.1.

For part (b), we use Corollary 2.3, since

$$\sup_{0\le t\le T} |E(t,x)-E(t,y)| \le C|x-y|^{1/2}.$$

For any $(t,x,v)\in\bar\Pi$ and for all k, let the back-time cycle of (t,x,v) be $\left(t^{l-1},x^{l-1},v^{l-1}\right)$, $\ldots$, $(0,x_0,v_0)$. From (4.5),

$$\begin{aligned} f^k(t,x,v) &= f^k\left(t^{l-1},x^{l-1},v^{l-1}\right) \\ &= f^{k-1}\left(t^{l-1},x^{l-1},v_*^{l-1}\right) \\ &= f^{k-1}\left(t^{l-2},x^{l-2},v^{l-2}\right) \\ &\vdots \\ &= f_0(x_0,v_0). \end{aligned}$$

By Corollary 2.8, we have

$$\begin{aligned} C_1\left[\xi^2(x)+\left(v\cdot\nabla\xi(x)\right)^2\right] &\le \left(v^i\cdot\nabla\xi\left(x^i\right)\right)^2 \le C_2\left[\xi^2(x_0)+\left(v_0\cdot\nabla\xi(x_0)\right)^2\right], \\ C_1\left[\xi^2(x_0)+\left(v_0\cdot\nabla\xi(x_0)\right)^2\right] &\le \left(v^i\cdot\nabla\xi\left(x^i\right)\right)^2 \le C_2\left[\xi^2(x)+\left(v\cdot\nabla\xi(x)\right)^2\right], \end{aligned}$$

for $1\le i\le l$, and C_1 and C_2 depend only on $L,\|E_0\|_{C^1}$. Let $\omega=C_1\omega_0$. Then we clearly have the conclusion of (b).

We omit the proof of part (c) and refer the reader to [8] for the proof in the case of a half space with a flat boundary. □

Now we are ready to prove Theorem 4.1.

Proof. From Lemma 4.2, $\left\|f^k\right\|_{C^1}$ is bounded uniformly in k, and it suffices to show that the iterated sequence f^k defined in (4.5) is indeed uniformly bounded in $C^{1,\alpha}$. Now we pick two points (t,x,v) and $\left(\tilde{t},\tilde{x},\tilde{v}\right)$. Consider the back-time cycles through the two points. Let $\varepsilon=\left(\left|t-\tilde{t}\right|+|x-\tilde{x}|+|v-\tilde{v}|\right)$. We keep track of the difference of these two points case by case.

Case 1. Both of the trajectories emanate from $\{t=0\}$.

This reduces to the Cauchy problem and the theory of ordinary differential equations.

Case 2. One trajectory emanates from $\{t=0\}$, and the other one emanates from the boundary $\partial\Omega$.

We first note that $\xi^2(x)+(v\cdot\nabla\xi(x))^2\ge\omega>0$ and $\xi^2(\tilde{x})+(\tilde{v}\cdot\nabla\xi(\tilde{x}))^2\ge\omega>0$ from the velocity lemma, Lemma 2.1, since otherwise $f^k\equiv$ constant. In this case, we have

$$\begin{aligned} v_0 &= v+\int_t^0 E(\tau)\,d\tau, \quad x=x_0+vt+\int_0^t\int_t^s E(\tau)\,d\tau ds, \\ \tilde{v}^1 &= \tilde{v}+\int_{\tilde{t}}^{\tilde{t}^1} E(\tau)\,d\tau, \quad \tilde{x}=\int_{\tilde{t}^1}^{\tilde{t}}\left[\tilde{v}+\int_{\tilde{t}}^s E(\tau)\,d\tau\right]ds. \end{aligned}$$

We choose a third point $\left(\hat{t},\hat{x},\hat{v}\right)$ such that $\left(\hat{t},\hat{x},\hat{v}\right)$ connects with $\left(0,\tilde{x}^1,v_0\right)$ through a trajectory and satisfies

$$\begin{aligned} &\left|t-\hat{t}\right|+\left|\hat{t}-\tilde{t}\right|\le 2\left|t-\tilde{t}\right|, \quad |x-\hat{x}|+|\hat{x}-\tilde{x}|\le 2|x-\tilde{x}|, \\ &|v-\hat{v}|+|\hat{v}-\tilde{v}|\le 2|v-\tilde{v}|. \end{aligned}$$

We can apply Lemmas 2.9 and 2.10 and the mean value theorem through the third point $\left(\hat{t},\hat{x},\hat{v}\right)$ to get

$$\left|\tilde{t}^1\right|+\left|x_0-\tilde{x}^1\right|+\left|v_0-\tilde{v}^1\right|\le C\left[\left|t-\tilde{t}\right|+|x-\tilde{x}|+|v-\tilde{v}|\right]=C\varepsilon,$$

where C depends on $\|E\|_{C^1},\delta,\omega$. From the fact that $\left|\nabla\xi\left(\tilde{x}^1\right)\cdot\tilde{v}_*^1\right|\ge\omega>0$ and $\nabla\xi\left(\tilde{x}^1\right)\cdot\tilde{v}_*^1<0$, we know that $\nabla\xi\left(\tilde{x}^1\right)\cdot\tilde{v}_*^1<-\omega<0$. Since

$$\left|\left[\nabla\xi\left(X\left(\tau\right)\right)\cdot V\left(\tau\right)\right]^{\bullet}\right| = \left|V\cdot\nabla^{2}\xi\cdot V+\nabla\xi\cdot E\right| \leq C,$$

we have

$$\begin{aligned}\nabla\xi\left(X\left(\tau\right)\right)\cdot V\left(\tau\right) &= \nabla\xi\left(\tilde{x}^{1}\right)\cdot\tilde{v}_{*}^{1}+\int_{\tilde{t}^{1}}^{\tau}\frac{d}{ds}\left[\nabla\xi\left(X\left(s\right)\right)\cdot V\left(s\right)\right]ds\\ &\leq \nabla\xi\left(\tilde{x}^{1}\right)\cdot\tilde{v}_{*}^{1}+O\left(\tilde{t}^{1}-\tau\right)\\ &\leq -c\left(\omega\right)+O\left(\varepsilon\right)<0\end{aligned}$$

for $0\leq\tau\leq\tilde{t}^{1}$. This means that the trajectory from $\left(\tilde{t}^{1},\tilde{x}^{1},\tilde{v}^{1}\right)$ hits $\{t=0\}$ directly and does not hit γ^{+}. Now we express $\nabla_{(t,x,v)}f^{k}\left(t,x,v\right)$ and $\nabla_{(t,x,v)}f^{k}\left(\tilde{t},\tilde{x},\tilde{v}\right)$ in terms of the initial value $\nabla_{(x,v)}f_{0}$. It will turn out that the compatibility condition (4.2) exactly guarantees our theorem in this case.

For computational simplicity, we flatten out the boundary near $\left(\tilde{t}^{1},\tilde{x}^{1},\tilde{v}^{1}\right)$ and $(0,x_{0},v_{0})$. We choose $\left(t^{'},x^{'},v^{'}\right)$ and $\left(\tilde{t}^{'},\tilde{x}^{'},\tilde{v}^{'}\right)$ near $\partial\Omega$ such that $\left(t^{'},x^{'},v^{'}\right)$ is on the trajectory from (t,x,v) to $(0,x_{0},v_{0})$, between (t,x,v) and $(0,x_{0},v_{0})$, and $\left(\tilde{t}^{'},\tilde{x}^{'},\tilde{v}^{'}\right)$ is on the trajectory from $\left(\tilde{t},\tilde{x},\tilde{v}\right)$ to $\left(\tilde{t}^{1},\tilde{x}^{1},\tilde{v}^{1}\right)$, between $\left(\tilde{t},\tilde{x},\tilde{v}\right)$ and $\left(\tilde{t}^{1},\tilde{x}^{1},\tilde{v}^{1}\right)$, respectively. Hence we have

$$\left|t^{'}-\tilde{t}^{'}\right|+\left|x^{'}-\tilde{x}^{'}\right|+\left|v^{'}-\tilde{v}^{'}\right|\leq C\varepsilon.$$

Since

$$\begin{aligned}\left|t_{t}^{'}-\tilde{t}_{\tilde{t}}^{'}\right|+\left|x_{t}^{'}-\tilde{x}_{\tilde{t}}^{'}\right|+\left|v_{t}^{'}-\tilde{v}_{\tilde{t}}^{'}\right|&\leq C\varepsilon,\\ \left|t_{t}^{'}\right|+\left|\tilde{t}_{\tilde{t}}^{'}\right|+\left|x_{t}^{'}\right|+\left|\tilde{x}_{\tilde{t}}^{'}\right|+\left|v_{t}^{'}\right|+\left|\tilde{v}_{\tilde{t}}^{'}\right|&\leq C,\end{aligned}$$

and $\left|\nabla f^{k}\right|\leq C$, it reduces to the case when (t,x,v) and $\left(\tilde{t},\tilde{x},\tilde{v}\right)$ are all near the boundary. Recall that in the flat coordinates, the Vlasov equation is transformed to $f_{t}^{k}+v\cdot\nabla_{x}f^{k}+(E+J)\cdot\nabla_{v}f^{k}=0$, where $J_{1}=v\cdot\partial^{2}\Phi\cdot v\leq 0$, $J_{2}=J_{3}=0$.

We first consider $f_{t}^{k}\left(t,x,v\right)$. Since the back-time trajectory emanates from $t=0$ directly, we have

$$\begin{aligned}&f_{t}^{k}\left(t,x,v\right)\\ &=\nabla_{x}f_{0}\left(x_{0},v_{0}\right)\cdot\left[-v+t\left(E+J\right)\left(t,x,v\right)-\int_{0}^{t}\int_{t}^{s}\left\{\nabla_{x}\left(E+J\right)\cdot X_{t}+\nabla_{v}J\cdot V_{t}\right\}d\tau ds\right]\\ &\quad+\nabla_{v}f_{0}\left(x_{0},v_{0}\right)\cdot\left[-\left(E+J\right)\left(t,x,v\right)+\int_{t}^{0}\left\{\nabla_{x}\left(E+J\right)\cdot X_{t}+\nabla_{v}J\cdot V_{t}\right\}d\tau\right]\end{aligned}$$

$$
\begin{aligned}
&= \nabla_x f_0\left(\tilde{x}^1, v_0\right)\cdot\left[-\tilde{v}+\left(\tilde{t}-\tilde{t}^1\right)(E+J)\left(\tilde{t},\tilde{x},\tilde{v}\right)\right.\\
&\qquad\left.-\int_{\tilde{t}^1}^{\tilde{t}}\int_{\tilde{t}}^{s}\left\{\nabla_x(E+J)\cdot X_t+\nabla_v J\cdot V_t\right\}d\tau ds\right]\\
&\quad+\nabla_v f_0\left(\tilde{x}^1, v_0\right)\cdot\left[-(E+J)\left(\tilde{t},\tilde{x},\tilde{v}\right)+\int_{\tilde{t}}^{\tilde{t}^1}\left\{\nabla_x(E+J)\cdot X_t+\nabla_v J\cdot V_t\right\}d\tau\right]\\
&\quad+O\left(\varepsilon^{\eta}\right),
\end{aligned}
$$

where we have used $\left(\tilde{t},\tilde{x},\tilde{v}\right)=(t,x,v)+O(\varepsilon)$, $\tilde{x}^1=x_0+O(\varepsilon)$, $E\in C^{1,\eta}$, and $f_0\in C^{1,\eta}$. Notice that

$$
\begin{aligned}
&-\tilde{v}_1+\left(\tilde{t}-\tilde{t}^1\right)(E_1+J_1)-\int_{\tilde{t}^1}^{\tilde{t}}\int_{\tilde{t}}^{s}\left\{\nabla_x(E_1+J_1)\cdot X_t+\nabla_v J_1\cdot V_t\right\}d\tau ds\\
&=-\tilde{t}_{\tilde{t}}^1\tilde{v}_1^1=-\tilde{t}_{\tilde{t}}^1 v_{01},
\end{aligned}
$$

since $\tilde{v}^1=v_0+O(\varepsilon)$. Therefore, we get

(4.7)

$$
\begin{aligned}
&f_t^k(t,x,v)\\
&=\left(-\tilde{t}_{\tilde{t}}^1 v_{01}\right)f_{0x_1}\left(\tilde{x}^1,v_0\right)\\
&\quad+\sum_{j=2}^{3}f_{0x_j}\left(\tilde{x}^1,v_0\right)\left[-\tilde{v}_j+\left(\tilde{t}-\tilde{t}^1\right)E_j\left(\tilde{t},\tilde{x}\right)-\int_{\tilde{t}^1}^{\tilde{t}}\int_{\tilde{t}}^{s}\nabla_x E_j\cdot X_t d\tau ds\right]\\
&\quad+f_{0v_1}\left(\tilde{x}^1,v_0\right)\left[-(E_1+J_1)\left(\tilde{t},\tilde{x},\tilde{v}\right)+\int_{\tilde{t}}^{\tilde{t}^1}\left\{\nabla_x(E_1+J_1)\cdot X_t+\nabla_v J_1\cdot V_t\right\}d\tau\right]\\
&\quad+\sum_{j=2}^{3}f_{0v_j}\left(\tilde{x}^1,v_0\right)\left[-E_j\left(\tilde{t},\tilde{x}\right)+\int_{\tilde{t}}^{\tilde{t}^1}\nabla_x E_j\cdot X_t d\tau\right]+O\left(\varepsilon^{\eta}\right),
\end{aligned}
$$

where we have used that $\tilde{t}_{\tilde{t}}^1\le C(\omega)$ and $\left|\nabla f^k\right|\le C$.

Now we treat $f_t^k\left(\tilde{t},\tilde{x},\tilde{v}\right)$. The trajectory first hits $\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right)$, reflects $\left(\tilde{t}^1,\tilde{x}^1,P\tilde{v}^1\right)$ with $P\tilde{v}^1=\left(-\tilde{v}_1^1,\tilde{v}_2^1,\tilde{v}_3^1\right)$, and then hits $(0,\tilde{x}_0,\tilde{v}_0)$. We have

$$
f_t^k\left(\tilde{t},\tilde{x},\tilde{v}\right)=f_{\tilde{t}^1}^k\left(\tilde{t}_{\tilde{t}}^1\right)+f_{\tilde{x}_2^1}^k\partial_t\tilde{x}_2^1+f_{\tilde{x}_3^1}^k\partial_t\tilde{x}_3^1+\sum_{j=1}^{3}f_{\tilde{v}_j^1}^k\partial_t\tilde{v}_j^1
$$

at $\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right)$. From the specular reflection condition on f, we have

$$
\begin{aligned}
&f_{\tilde{t}^1}^k\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right)=f_{\tilde{t}^1}^{k-1}\left(\tilde{t}^1,\tilde{x}^1,P\tilde{v}^1\right),\quad f_{\tilde{x}_j^1}^k\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right)=f_{\tilde{x}_j^1}^{k-1}\left(\tilde{t}^1,\tilde{x}^1,P\tilde{v}^1\right),\quad j=2,3,\\
&f_{\tilde{v}_1^1}^k\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right)=-f_{\tilde{v}_1^1}^{k-1}\left(\tilde{t}^1,\tilde{x}^1,P\tilde{v}^1\right),\quad f_{\tilde{v}_j^1}^k\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right)=f_{\tilde{v}_j^1}^{k-1}\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right),\quad j=2,3.
\end{aligned}
$$

Since the trajectory finally hits $(0,\tilde{x}_0,\tilde{v}_0)$ directly, we have that

$$
\begin{aligned}
&f_t^k\left(\tilde{t},\tilde{x},\tilde{v}\right)\\
&=\left\{\nabla_x f_0\cdot\left[-P\tilde{v}^1+\tilde{t}^1(E+J)\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right)\right.\right.\\
&\qquad\left.\left.-\int_0^{\tilde{t}^1}\int_{\tilde{t}^1}^{s}\left\{\nabla_x(E+J)\cdot X_t+\nabla_v J\cdot V_t\right\}d\tau ds\right]\right.
\end{aligned}
$$

$$
\begin{aligned}
&+\nabla_v f_0\cdot\left[-\left(E+J\right)\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right)+\int_{\tilde{t}^1}^0\left\{\nabla_x\left(E+J\right)\cdot X_t+\nabla_v J\cdot V_t\right\}d\tau\right]\Bigg\}\tilde{t}_{\tilde{t}}^1\\
&+\Bigg\{\nabla_x f_0\cdot\left[\delta_{ij}+\int_{\tilde{t}^1}^0\int_{\tilde{t}^1}^s\left\{\nabla_x\left(E+J\right)\,\nabla_x X+\nabla_v J\,\nabla_x V\right\}d\tau ds\right]\\
&\quad+\nabla_v f_0\cdot\left[\int_{\tilde{t}^1}^0\left\{\nabla_x\left(E+J\right)\,\nabla_x X+\nabla_v J\,\nabla_x V\right\}d\tau\right]\Bigg\}\cdot\partial_{\tilde{t}}\tilde{x}^1\\
&+\Bigg\{\nabla_x f_0\cdot\left[-\tilde{t}^1\delta_{ij}-\int_0^{\tilde{t}^1}\int_{\tilde{t}^1}^s\left\{\nabla_x\left(E+J\right)\,\nabla_x X+\nabla_v J\,\nabla_x V\right\}d\tau ds\right]\\
&\quad+\nabla_v f_0\cdot\left[\delta_{ij}+\int_{\tilde{t}^1}^0\left\{\nabla_x\left(E+J\right)\,\nabla_x X+\nabla_v J\,\nabla_x V\right\}d\tau\right]\Bigg\}\cdot\partial_{\tilde{t}}P\tilde{v}^1
\end{aligned}
$$

at $(0,\tilde{x}_0,\tilde{v}_0)$. Notice that $\tilde{t}^1=O\left(\varepsilon\right)$ to deduce

$$
\begin{aligned}
&f_t\left(\tilde{t},\tilde{x},\tilde{v}\right)\\
&=\tilde{t}_{\tilde{t}}^1\left[-\nabla_x f_0\cdot P\tilde{v}^1-\nabla_v f_0\cdot\left(E+J\right)\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right)\right]\\
&\quad+\sum_{j=2}^3\partial_{\tilde{t}}\tilde{x}_j^1 f_{0x_j}-f_{0v_1}\partial_{\tilde{t}}\tilde{v}_1^1+\sum_{j=2}^3 f_{0v_j}\partial_{\tilde{t}}\tilde{v}_j^1+O\left(\varepsilon\right),
\end{aligned}
$$

evaluated at $(0,x_0,v_0)$. By using $(0,\tilde{x}_0,\tilde{v}_0)=\left(0,\tilde{x}^1,P\tilde{v}^1\right)+O\left(\varepsilon\right)=\left(0,\tilde{x}^1,Pv_0\right)+O\left(\varepsilon\right)$, we get, at $\left(0,\tilde{x}^1,Pv_0\right)$,

$$
\begin{aligned}
&f_t^k\left(\tilde{t},\tilde{x},\tilde{v}\right)\\
&=\tilde{t}_{\tilde{t}}^1\left[-Pv_0\cdot\nabla_x f_0\left(\tilde{x}^1,Pv_0\right)-\left(E+J\right)\left(0,\tilde{x}^1,v_0\right)\cdot\nabla_v f_0\right]\\
&\quad+\sum_{j=2}^3\partial_{\tilde{t}}\tilde{x}_j^1 f_{0x_j}-\partial_{\tilde{t}}\tilde{v}_1^1 f_{0v_1}+\sum_{j=2}^3\partial_{\tilde{t}}\tilde{v}_j^1 f_{0v_j}+O\left(\varepsilon^\eta\right),
\end{aligned}
$$

where we used $f_0\in C^{1,\eta}$. Hence, we have, by Lemma 2.10,

(4.8)

$$
\begin{aligned}
&f_t^k\left(\tilde{t},\tilde{x},\tilde{v}\right)\\
&=\tilde{t}_{\tilde{t}}^1 v_{01}f_{0x_1}\left(\tilde{x}^1,Pv_0\right)-\sum_{j=2}^3\tilde{t}_{\tilde{t}}^1 v_{0j}f_{0x_j}\left(\tilde{x}^1,v_0\right)+\tilde{t}_{\tilde{t}}^1\left(E_1+J_1\right)\left(0,\tilde{x}^1,v_0\right)f_{0v_1}\left(\tilde{x}^1,v_0\right)\\
&\quad-\sum_{j=2}^3\tilde{t}_{\tilde{t}}^1 E_j\left(0,\tilde{x}^1\right)f_{0v_j}\left(\tilde{x}^1,v_0\right)+\sum_{j=2}^3\tilde{t}_{\tilde{t}}^1 v_{0j}f_{0x_j}\left(\tilde{x}^1,v_0\right)\\
&\quad+\sum_{j=2}^3\left[-\tilde{v}_j+\left(\tilde{t}-\tilde{t}^1\right)E_j\left(\tilde{t},\tilde{x}\right)-\int_{\tilde{t}^1}^{\tilde{t}}\int_{\tilde{t}}^s\nabla_x E_j\cdot X_t d\tau ds\right]f_{0x_j}\left(\tilde{x}^1,v_0\right)\\
&\quad+\tilde{t}_{\tilde{t}}^1\left(E_1+J_1\right)\left(0,\tilde{x}^1,v_0\right)f_{0v_1}\left(\tilde{x}^1,v_0\right)\\
&\quad+\left[-\left(E_1+J_1\right)\left(\tilde{t},\tilde{x}\right)+\int_{\tilde{t}}^{\tilde{t}^1}\left\{\nabla_x\left(E_1+J_1\right)\cdot X_t+\nabla_v J\cdot V_t\right\}d\tau\right]f_{0v_1}\left(\tilde{x}^1,v_0\right)\\
&\quad+\sum_{j=2}^3\tilde{t}_{\tilde{t}}^1 E_j\left(0,\tilde{x}^1\right)f_{0v_j}\left(\tilde{x}^1,v_0\right)+\sum_{j=2}^3\left[-E_j\left(\tilde{t},\tilde{x}\right)+\int_{\tilde{t}}^{\tilde{t}^1}\nabla_x E_j\cdot X_t d\tau\right]f_{0v_j}\left(\tilde{x}^1,v_0\right)\\
&\quad+O\left(\varepsilon^\eta\right).
\end{aligned}
$$

Now we estimate the difference of (4.8) and (4.7) as

$$
\begin{aligned}
(4.9)\qquad & \left|f_t^k(t,x,v)-f_t^k\left(\tilde{t},\tilde{x},\tilde{v}\right)\right| \\
&= \left|\tilde{t}_t^1\left[v_{01}f_{0x_1}\left(\tilde{x}^1,-v_{01},v_{02},v_{03}\right)+v_{01}f_{0x_1}\left(\tilde{x}^1,v_{01},v_{02},v_{03}\right)\right.\right. \\
&\qquad \left.\left.+2\left(E_1+J_1\right)\left(0,\tilde{x}^1,v_0\right)f_{0v_1}\left(\tilde{x}^1,v_0\right)\right]\right|+O\left(\varepsilon^\eta\right).
\end{aligned}
$$

By our compatibility condition (4.2), the first term exactly vanishes. Similar computations hold for x- and v-derivatives. Therefore, in Case 2, we obtain from (4.9) that

$$
\left|\nabla_{(t,x,v)}f^k(t,x,v)-\nabla_{(t,x,v)}f^k\left(\tilde{t},\tilde{x},\tilde{v}\right)\right|\le C\left[\left|t-\tilde{t}\right|+|x-\tilde{x}|+|v-\tilde{v}|\right]^\eta.
$$

Case 3. The trajectories emanate from $\left(t^{l-1},x^{l-1},v^{l-1}\right)$ and $\left(\tilde{t}^{l-1},\tilde{x}^{l-1},\tilde{v}^{l-1}\right)$. In this case, we also have

$$
(4.10)\qquad \left|t^{l-1}-\tilde{t}^{l-1}\right|+\left|x^{l-1}-\tilde{x}^{l-1}\right|+\left|v^{l-1}-\tilde{v}^{l-1}\right|\le C\varepsilon,\quad C=C(\omega).
$$

Consider the back-time trajectories from $\left(t^{l-1},x^{l-1},v^{l-1}\right)$ and $\left(\tilde{t}^{l-1},\tilde{x}^{l-1},\tilde{v}^{l-1}\right)$. Assume that they are $\left(t^{i-1},x^{i-1},v^{i-1}\right)$ and $\left(\tilde{t}^{i-1},\tilde{x}^{i-1},\tilde{v}^{i-1}\right)$. Without loss of generality, we may assume that the first trajectory hits $\{t=0\}$ after l bounces. We have then

$$
\begin{aligned}
\nabla f^{k-j}\left(t^j,x^j,v^j\right)&=J_{j-1}^j\nabla f^{k-j-1}\left(t^{j-1},x^{j-1},v^{j-1}\right),\\
\nabla f^{k-j}\left(\tilde{t}^j,\tilde{x}^j,\tilde{v}^j\right)&=J_{j-1}^j\nabla f^{k-j-1}\left(\tilde{t}^{j-1},\tilde{x}^{j-1},\tilde{v}^{j-1}\right).
\end{aligned}
$$

Taking the difference, we get

$$
\begin{aligned}
&\nabla f^{k-j}\left(t^j,x^j,v^j\right)-\nabla f^{k-j}\left(\tilde{t}^j,\tilde{x}^j,\tilde{v}^j\right)\\
&=J_{j-1}^j\Delta\nabla f^{k-j-1}+\Delta J_{j-1}^j\nabla f^{k-j-1}\left(t^{j-1},x^{j-1},v^{j-1}\right).
\end{aligned}
$$

By induction on j,

$$
\begin{aligned}
&\left|\nabla f^k\left(t^{l-1},x^{l-1},v^{l-1}\right)-\nabla f^k\left(\tilde{t}^{l-1},\tilde{x}^{l-1},\tilde{v}^{l-1}\right)\right|\\
&\le\left|\prod_{j=1}^l J_{j-1}^j\left[\nabla f^{k-l-1}\left(t^1,x^1,v^1\right)-\nabla f^{k-l-1}\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right)\right]\right|\\
&\quad+\sum_{j=1}^l\left|\Delta J_{j-1}^j\left[\nabla f^{k-j-1}\left(t^{l-j+1},x^{l-j+1},v^{l-j+1}\right)\right.\right.\\
&\qquad\qquad\left.\left.-\nabla f^{k-j-1}\left(\tilde{t}^{l-j+1},\tilde{x}^{l-j+1},\tilde{v}^{l-j+1}\right)\right]\right|.
\end{aligned}
$$

Notice that the number of bounces is uniformly bounded as in Lemma 4.2, and thus $\left|\prod_{j=1}^l J_{j-1}^j\right|\le C$. We thus get

$$
\begin{aligned}
(4.11)\qquad &\left|\nabla f^k\left(t^{l-1},x^{l-1},v^{l-1}\right)-\nabla f^k\left(\tilde{t}^{l-1},\tilde{x}^{l-1},\tilde{v}^{l-1}\right)\right|\\
&\le C\left|\nabla f^{k-l-1}\left(t^1,x^1,v^1\right)-\nabla f^{k-l-1}\left(\tilde{t}^1,\tilde{x}^1,\tilde{v}^1\right)\right|+C\sum_{j=1}^l\left|\Delta J_{j-1}^j\right|.
\end{aligned}
$$

Since $E\in C^{1,\eta}$ and by Lemma 2.10, (4.10), and applying the mean value theorem, we obtain

$$
(4.12)\qquad \left|\Delta J_{j-1}^j\right|\le C\varepsilon^\eta.
$$

Similarly, by using $f_0 \in C^{1,\eta}$, we get

$$\left|\nabla f^{k-l-1}\left(t^1, x^1, v^1\right) - \nabla f^{k-l-1}\left(\tilde{t}^1, \tilde{x}^1, \tilde{v}^1\right)\right| \le C\varepsilon^\eta. \tag{4.13}$$

Hence by plugging (4.12), (4.13) into (4.11), we finally obtain

$$\left|\nabla f^{k}\left(t^{l-1}, x^{l-1}, v^{l-1}\right) - \nabla f^{k}\left(\tilde{t}^{l-1}, \tilde{x}^{l-1}, \tilde{v}^{l-1}\right)\right| \le C\varepsilon^\eta.$$

Since $\left|t^1 - \tilde{t}^1\right| + \left|x^1 - \tilde{x}^1\right| + \left|v^1 - \tilde{v}^1\right| \le C\varepsilon$, the second cycle hits $t = 0$ after at most one bounce, as in Case 2. Applying Case 2 yields

$$\left|\nabla_{(t,x,v)} f^k(t,x,v) - \nabla_{(t,x,v)} f^k\left(\tilde{t}, \tilde{x}, \tilde{v}\right)\right| \le C\varepsilon^\eta.$$

This completes part (b) of the theorem.

For part (a), we construct f_0^n smooth such that $f_0^n \to f_0$ a.e., $\|f_0^n\|_{C^1}$ is uniformly bounded (depending on $\|f_0\|_{C^1}$), and f_0^n satisfies (4.3) and (4.4). By the result of part (b), there is a unique solution f^n of (4.1) with data f_0^n such that $\|f^n\|_{C^1} \le C\|f_0^n\|_{C^1} \le C$. Hence part (a) follows by letting $n \to \infty$. For part (c), we refer the reader to [8]. ∎

5. Regularity for the Vlasov–Poisson system with the absorbing boundary condition. In this section, we consider the fully nonlinear Vlasov–Poisson system with the absorbing boundary condition for the Vlasov and the Dirichlet boundary condition for the Poisson equation:

$$\begin{gathered} f_t + v\cdot\nabla_x f + \nabla\varphi\cdot\nabla_v f = 0, \\ f|_{t=0} = f_0, \quad f|_{\gamma^+} = g, \\ \Delta\varphi = \rho = 4\pi\int f dv, \\ \varphi|_{\partial\Omega} = 0. \end{gathered}$$

THEOREM 5.1. *Let $k \ge 1$, $3 < p \le \infty$. Let $f_0 \in W^{k,p}(\Pi_0)$ and $g \in W^{k,p}(\gamma^+)$ have compact support and $f_0 \ge 0$, $g \ge 0$. Assume the compatibility condition* (3.10) *holds for $x \in \partial\Omega$ and v with $n_x \cdot v < 0$ and for $|\alpha| \le k-1$. Moreover, assume the vanishing condition:*

$$\begin{gathered} g(t,x,v) \equiv 0 \ \text{ on } \gamma^0, \\ \left|\partial^\alpha g(t,x,v)\right| \le C\left|n_x\cdot v\right|^{|\alpha|} \ \text{ on } \gamma^+, \quad |\alpha| = k, \end{gathered}$$

where α is a multi-index. Then there exists a unique solution $f \in W^{k,p}(\Pi)$ and $\varphi \in W^{k+2,p}$, where f has compact support in v.

We shall construct approximate solutions by establishing an iterating system. Let f^0 be a suitable smooth extension of f_0 to Π and satisfy the corresponding compatibility condition (3.10). Let the iterating sequence be

$$\begin{gathered} \partial_t f^{n+1} + v\cdot\nabla_x f^{n+1} + \nabla\varphi^n\cdot\nabla_v f^{n+1} = 0, \\ f^{n+1}|_{t=0} = f_0, \quad f^{n+1}|_{\gamma^+} = g, \end{gathered} \tag{5.1}$$

$$\Delta\varphi^n = \rho^n = 4\pi\int f^n dv, \quad \varphi^n|_{\partial\Omega} = 0. \tag{5.2}$$

Since $f_0 \geq 0$, $g \geq 0$, and $\varphi^n|_{\partial\Omega} = 0$, by the Vlasov equation (5.1), we have

$$\Delta\varphi^n = 4\pi\rho^n = 4\pi \int f^n dv \geq 0.$$

By the strong maximal principle and since f_0 is not identically zero,

$$\varphi^n < 0 \text{ on } \Omega.$$

We then apply the Hopf boundary principle to get

$$E^n(t,x) \cdot n_x = \frac{\partial \varphi^n}{\partial n}(t,x) \geq \delta_n > 0$$

on $\partial\Omega \cap \{\text{support of } f^n\}$. From Theorem 3.6, f^{n+1} is well defined in $W^{k,p}$ for every fixed n.

We shall use the idea which was in [18] for the Cauchy problem without boundary. The key step is to represent the macrocharge density ρ^n in the presence of the complex particle path, along the straight-line trajectory

$$\frac{dX}{dt} = V, \quad \frac{dV}{dt} = 0. \tag{5.3}$$

We consider the back-time trajectory of $dX/dt = V$, $dV/dt = 0$ from a generic point (t,x,v). We denote by $B(t,x,v) = (t_0, x_0, v)$ the possible boundary point when the trajectory hits $\partial\Omega$. We first note that for $v \neq 0$, there exists a unique $x_0 = x_0(x,v) \in \partial\Omega$ along the straight-line trajectory from (t,x,v) since Ω is convex. Let t_0 be the time when the trajectory from (t,x,v) hits the boundary. Then $x_0 = x + v(t_0 - t)$ and $t_0 - t = [(x_0 - x) \cdot v] / |v|^2$. We define

$$a(x,v) = -[(x_0 - x) \cdot v] / |v|^2$$

to see that the function $a(x,v)$ is locally differentiable as follows: Let ξ be the function which defines the boundary (2.8). Then we have

$$0 = \xi(x_0) = \xi(x + v(t_0 - t)).$$

Set $s = t_0 - t$ to get that $0 = \xi(x + sv) = \xi(s; x, v)$ and $\partial\xi/\partial s = \nabla\xi(x_0) \cdot v = n_{x_0} \cdot v < 0$ since Ω is convex. By the implicit function theory, $s = t_0 - t = -a(x,v)$ is a locally differentiable function of x and v. Before giving the representation formula for the macrocharge density, we present two preliminary lemmas.

LEMMA 5.2. *$a \cdot \nabla_x a + \nabla_v a = 0$ for $v \neq 0$, $x \in \Omega$.*

Proof. Let ξ be the function which defines the boundary (2.8). Since $x_0 = x - va(x,v)$, we have

$$0 = \xi(x_0) = \xi(x - va(x,v)). \tag{5.4}$$

Differentiate (5.4) with respect to x to get

$$\nabla\xi - (\nabla\xi \cdot v)\nabla_x a = 0. \tag{5.5}$$

We now differentiate (5.4) with respect to v to get

$$-a\nabla\xi - (\nabla\xi \cdot v)\nabla_v a = 0. \tag{5.6}$$

By multiplying (5.5) with a and adding it to (5.6), we get

$$(\nabla\xi(x_0)\cdot v)\left[a\nabla_x a+\nabla_v a\right]=0.$$

Since $\nabla\xi(x_0)\cdot v\neq 0$ from the convexity of Ω, the lemma follows. □

First we note that for fixed x and t, $a(x,v)=t$ defines a smooth surface except for the origin and $a(x,v)<t$ defines the three-dimensional unbounded set outside of the surface while $a(x,v)>t$ defines the object inside of the surface. We shall use the spherical coordinates (r,ϕ,θ) instead of the usual rectangular coordinates (v_1,v_2,v_3) for the moment. We denote by $\nu=\left(\nu^r,\nu^\phi,\nu^\theta\right)$ the outward normal in the spherical coordinates to the surface defined by $a(x,r,\phi,\theta)=t$ for fixed x. We also denote by $dS(r,\phi,\theta)$ the surface infinitesimal increment for the surface $a(x,r,\phi,\theta)=t$.

LEMMA 5.3. *Let $\Gamma(x,v)$ be the C^1-vector-valued function in x,v. Then for fixed t, we have*

$$\begin{aligned}\operatorname{div}_x\int_{a(x,v)\le t}\Gamma(x,v)\,dv&=\int_{a(x,v)\le t}\operatorname{div}_x\Gamma(x,v)\,dv\\&\quad-\int_{a(x,r,\phi,\theta)=t}\Gamma(x,r,\phi,\theta)\,r^2\sin\phi\cdot\nabla_x a\frac{\nu^r}{a_r}dS(r,\phi,\theta),\end{aligned}$$

$$\begin{aligned}\operatorname{div}_x\int_{a(x,v)\ge t}\Gamma(x,v)\,dv&=\int_{a(x,v)\ge t}\operatorname{div}_x\Gamma(x,v)\,dv\\&\quad+\int_{a(x,r,\phi,\theta)=t}\Gamma(x,r,\phi,\theta)\,r^2\sin\phi\cdot\nabla_x a\frac{\nu^r}{a_r}dS(r,\phi,\theta).\end{aligned}$$

Proof. Note, by multiplying (5.6) with v, that $v\cdot\nabla_v a\neq 0$ if $x\notin\partial\Omega$ and $v\neq 0$ since $a=t_0-t\neq 0$, $\nabla\xi\neq 0$, and $\nabla\xi\cdot v\neq 0$. By using the spherical coordinates, we get $r\partial_r a\neq 0$ and so $\partial_r a\neq 0$. We first consider a C^1-scalar function $h(r,\phi,\theta)$ without x-variables. We change variables as follows:

$$(r,\phi,\theta)\longmapsto(\eta_1,\eta_2,\eta_3),$$

where for fixed x,

$$\eta_1=a(x,r,\phi,\theta),\quad \eta_2=\phi,\quad \eta_3=\theta. \tag{5.7}$$

We find the Jacobian of (η_1,η_2,η_3) with respect to (r,ϕ,θ):

$$J\left(\frac{\eta_1,\eta_2,\eta_3}{r\ ,\phi\ ,\theta}\right)=\det\begin{bmatrix}\frac{\partial a}{\partial r}&\frac{\partial a}{\partial\phi}&\frac{\partial a}{\partial\theta}\\0&1&0\\0&0&1\end{bmatrix}=\frac{\partial a}{\partial r}.$$

For fixed η_1, we differentiate with respect to x the equation $\eta_1=a(x,r,\phi,\theta)$ to get

$$0=\nabla_x\eta_1=\nabla_x a+a_r\nabla_x r \tag{5.8}$$

or

$$\nabla_x r = -\frac{\nabla_x a}{a_r}.$$

We now consider, using the change of variables (5.7) back and forth and by changing the orders of the integration,

$$\begin{aligned}
&\frac{\partial}{\partial x_i}\int_{a(x,r,\phi,\theta)\le t} h(r,\phi,\theta)\,dr d\phi d\theta \\
&= \frac{\partial}{\partial x_i}\int_{\eta_1\le t} h(r(\eta_1,\eta_2,\eta_3),\eta_2,\eta_3)\frac{1}{a_r}d\eta_1 d\eta_2 d\eta_3 \\
&= \int_{\eta_1\le t}\frac{\partial h}{\partial r}\frac{\partial r}{\partial x_i}\frac{1}{a_r}d\eta_1 d\eta_2 d\eta_3 - \int_{\eta_1\le t} h\frac{a_{rx_i}+a_{rr}r_{x_i}}{a_r^2}d\eta_1 d\eta_2 d\eta_3 \\
&= \int_{-\infty}^{t}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\left[-\frac{h_r a_{x_i}}{a_r^2} - \frac{h a_{rx_i}}{a_r^2} + \frac{h a_{x_i} a_{rr}}{a_r^3}\right] d\eta_2 d\eta_3 d\eta_1 \qquad (5.9)\\
&= \int_{\eta_1\le t}\left[-\frac{(ha_{x_i})_r}{a_r^2} + \frac{h a_{x_i} a_{rr}}{a_r^3}\right] d\eta \\
&= \int_{a(x,r,\phi,\theta)\le t}\left[-\frac{(ha_{x_i})_r}{a_r^2} + \frac{h a_{x_i} a_{rr}}{a_r^3}\right] a_r dr d\phi d\theta \\
&= \int_{a(x,r,\phi,\theta)\le t}\left[-\frac{(ha_{x_i})_r}{a_r} + \frac{h a_{x_i} a_{rr}}{a_r^2}\right] dr d\phi d\theta \\
&= -\int_{a(x,r,\phi,\theta)\le t}\left(\frac{h a_{x_i}}{a_r}\right)_r dr d\phi d\theta \\
&= -\int_{a(x,r,\phi,\theta)=t}\frac{h a_{x_i}}{a_r}\nu^r dS(r,\phi,\theta), \qquad (5.10)
\end{aligned}$$

where we have used (5.8) in (5.9) and the Gauss theorem in (5.10). We now consider a C^1-scalar function $h(v_1,v_2,v_3)$. We then take the x_i-derivative ($i=1,2,3$) of the integration of h with respect to v over $a(x,v)\le t$ for fixed t. By changing variables from (v_1,v_2,v_3) to (r,ϕ,θ), we have, by (5.10),

$$\begin{aligned}
&\frac{\partial}{\partial x_i}\int_{a(x,v)\le t} h(v_1,v_2,v_3)\,dv_1 dv_2 dv_3 \qquad (5.11)\\
&= \frac{\partial}{\partial x_i}\int_{a(s,r,\phi,\theta)\le t} h(r,\phi,\theta)\,r^2\sin\phi\, dr d\phi d\theta \\
&= -\int_{a(x,r,\phi,\theta)=t}\frac{h r^2\sin\phi a_{x_i}}{a_r}\nu^r dS(r,\phi,\theta).
\end{aligned}$$

Now we consider the integration in our lemma

$$\begin{aligned}
&\mathrm{div}_x\int_{a(x,v)\le t}\Gamma(x,v)\,dv \\
&= \sum_{i=1}^{3}\frac{\partial}{\partial x_i}\int_{a(x,v)\le t}\Gamma^i(x,v)\,dv \\
&= \sum_{i=1}^{3}\left[\int_{a(x,v)\le t}\partial_{x_i}\Gamma^i(x,v)\,dv - \int_{a(x,r,\phi,\theta)=t}\Gamma^i r^2\sin\phi\frac{a_{x_i}}{a_r}\nu^r dS\right],
\end{aligned}$$

where we have used the product rule of the differentiation and (5.11). This leads to the conclusion of the first part of the lemma. Similarly, we get the second part, and the lemma thus follows. ∎

We present the representation formula for the macrocharge density in the following lemma.

LEMMA 5.4 (charge density). *Let f^{n+1} and φ^n be defined in* (5.1) *and* (5.2). *Let*

$$B(t,x,v) = (t - a(x,v), x - a(x,v)\, v, v) \in \gamma.$$

Then

(5.12)

$$\begin{aligned}\rho^{n+1}(t,x) = &\int_{a(x,v)\geq t} f_0(x - tv, v)\, dv + \int_{a(x,v)\leq t} g \circ B(t,x,v)\, dv \\ &- \operatorname{div}_x \int_{a(x,v)\geq t} \int_0^t (t-\tau) \left(\nabla_x \varphi^n f^{n+1}\right)(\tau, x - (t-\tau)\, v, v)\, d\tau dv \\ &- \operatorname{div}_x \int_{a(x,v)\leq t} \int_{t-a(x,v)}^t (t-\tau) \left(\nabla_x \varphi^n f^{n+1}\right)(\tau, x - (t-\tau)\, v, v)\, d\tau dv.\end{aligned}$$

Proof. We fix x and t and consider the back-time straight-line trajectory from a generic point (t,x,v). If $t \leq a(x,v)$, then the back-time trajectory of (5.1) hits $\{t = 0\}$ directly. From the transport equation (5.1), we have

$$\begin{aligned}f^{n+1}(t,x,v) &= f_0(x - tv, v) + \int_0^t \frac{d}{d\tau} f^{n+1}(\tau, x - (t-\tau)\, v, v)\, d\tau \\ &= f_0(x - tv, v) + \int_0^t \big[\partial_t f^{n+1}(\tau, x - (t-\tau)\, v, v) \\ &\qquad + v \cdot \nabla_x f^{n+1}(\tau, x - (t-\tau)\, v, v)\big]\, d\tau \\ &= f_0(x - tv, v) - \int_0^t \left[\operatorname{div}_v \left(\nabla_x \varphi^n f^{n+1}\right)\right](\tau, x - (t-\tau)\, v, v)\, d\tau \\ &= f_0(x - tv, v) - \int_0^t \operatorname{div}_v \left[\left(\nabla_x \varphi^n f^{n+1}\right)(\tau, x - (t-\tau)\, v, v)\right] d\tau \\ &\quad - \int_0^t (t-\tau) \operatorname{div}_x \left(\nabla_x \varphi^n f^{n+1}\right)(\tau, x - (t-\tau)\, v, v)\, d\tau \\ &= f_0(x - tv, v) - \operatorname{div}_v \int_0^t \left(\nabla_x \varphi^n f^{n+1}\right)(\tau, x - (t-\tau)\, v, v)\, d\tau \\ &\quad - \operatorname{div}_x \int_0^t (t-\tau) \left(\nabla_x \varphi^n f^{n+1}\right)(\tau, x - (t-\tau)\, v, v)\, d\tau.\end{aligned} \tag{5.13}$$

On the other hand, if $t \geq a(x,v)$, then the backward trajectory hits the boundary

$\partial\Omega$. Hence we have

(5.14)

$$\begin{aligned}
f^{n+1}(t,x,v) &= g\circ B(t,x,v)+\int_{t-a(x,v)}^{t}\frac{d}{d\tau}f^{n+1}(\tau,x-(t-\tau)v,v)\,d\tau\\
&= g\circ B(t,x,v)+\int_{t-a(x,v)}^{t}\big[\partial_t f^{n+1}(\tau,x-(t-\tau)v,v)\\
&\qquad\qquad +v\cdot\nabla_x f^{n+1}(\tau,x-(t-\tau)v,v)\big]\,d\tau\\
&= g\circ B-\int_{t-a(x,v)}^{t}\left[\operatorname{div}_v\left(\nabla_x\varphi^n f^{n+1}\right)\right](\tau,x-(t-\tau)v,v)\,d\tau\\
&= g\circ B-\int_{t-a(x,v)}^{t}\operatorname{div}_v\left[\left(\nabla_x\varphi^n f^{n+1}\right)(\tau,x-(t-\tau)v,v)\right]d\tau\\
&\quad -\int_{t-a(x,v)}^{t}(t-\tau)\operatorname{div}_x\left(\nabla_x\varphi^n f^{n+1}\right)(\tau,x-(t-\tau)v,v)\,d\tau\\
&= g\circ B-\operatorname{div}_v\int_{t-a(x,v)}^{t}\left(\nabla_x\varphi^n f^{n+1}\right)(\tau,x-(t-\tau)v,v)\,d\tau\\
&\quad -\operatorname{div}_x\int_{t-a(x,v)}^{t}(t-\tau)\left(\nabla_x\varphi^n f^{n+1}\right)(\tau,x-(t-\tau)v,v)\,d\tau\\
&\quad +\left(\nabla_x\varphi^n f^{n+1}\right)(t-a(x,v),x-a(x,v)v,v)\cdot\nabla_v a\\
&\quad +\left(\nabla_x\varphi^n f^{n+1}\right)(t-a(x,v),x-a(x,v)v,v)\cdot a\nabla_x a\\
&= g\circ B-\operatorname{div}_v\int_{t-a(x,v)}^{t}\left(\nabla_x\varphi^n f^{n+1}\right)(\tau,x-(t-\tau)v,v)\,d\tau\\
&\quad -\operatorname{div}_x\int_{t-a(x,v)}^{t}(t-\tau)\left(\nabla_x\varphi^n f^{n+1}\right)(\tau,x-(t-\tau)v,v)\,d\tau,
\end{aligned}$$

since we apply Lemma 5.2 to get, for $v\neq 0$, $x\notin\partial\Omega$,

$$\begin{aligned}
&\left(\nabla_x\varphi^n f^{n+1}\right)(t-a(x,v),x-a(x,v)v,v)\cdot\nabla_v a\\
&\quad+\left(\nabla_x\varphi^n f^{n+1}\right)(t-a(x,v),x-a(x,v)v,v)\cdot a\nabla_x a\\
&=\left(\nabla_x\varphi^n f^{n+1}\right)(t_0,x_0,v)\cdot[\nabla_v a+a\nabla_x a]=0.
\end{aligned}$$

For fixed t and x, we now integrate v over $\mathbb{R}^3$. By dividing v by the region $\{a(x,v)\geq t\}$ and the region $\{a(x,v)\leq t\}$, we get

$$\begin{aligned}
\rho^{n+1}(t,x) &= \int_{a(x,v)\geq t}f^{n+1}(t,x,v)\,dv+\int_{a(x,v)\leq t}f^{n+1}(t,x,v)\,dv\\
&= I_1+I_2.
\end{aligned}$$

For I_1, we use (5.13), Lemma 5.3, and the Gauss theorem to get

$$\begin{aligned}
&\int_{a(x,v)\geq t} f^{n+1}(t,x,v)\,dv \\
&= \int_{a(x,v)\geq t} f_0(x-tv,v)\,dv \\
&\quad + \int_{a(x,v)=t}\int_0^t (\nabla_x\varphi^n\cdot n_v) f^{n+1}(\tau,x-(t-\tau)v,v)\,d\tau dS(v) \\
&\quad - \int_{a(x,v)\geq t} \operatorname{div}_x \int_0^t (t-\tau)\left(\nabla_x\varphi^n f^{n+1}\right)(\tau,x-(t-\tau)v,v)\,d\tau dv \\
&= \int_{a(x,v)\geq t} f_0(x-tv,v)\,dv \\
&\quad + \int_{a(x,v)=t}\int_0^t (\nabla_x\varphi^n\cdot n_v) f^{n+1}(\tau,x-(t-\tau)v,v)\,d\tau dS(v) \\
&\quad - \operatorname{div}_x \int_{a(x,v)\geq t}\int_0^t (t-\tau)\left(\nabla_x\varphi^n f^{n+1}\right)(\tau,x-(t-\tau)v,v)\,d\tau dv \\
&\quad + \int_{a(x,r,\phi,\theta)=t}\int_0^t (t-\tau)\left(\nabla_x\varphi^n f^{n+1}\right) r^2\sin\phi\cdot\nabla_x a\frac{\nu^r}{a_r} dS(r,\phi,\theta),
\end{aligned}$$

where n_v is the outward normal to the surface $\{a(x,v)=t\}$ which contains inside the region $\{a(x,v)\leq t\}$. For I_2, using (5.15), Lemma 5.3, and the Gauss theorem, we have

$$\begin{aligned}
&\int_{a(x,v)\leq t} f^{n+1}(t,x,v)\,dv \\
&= \int_{a(x,v)\leq t} g\circ B(t,x,v)\,dv \\
&\quad - \int_{a(x,v)=t}\int_0^t (\nabla_x\varphi^n\cdot n_v) f^{n+1}(\tau,x-(t-\tau)v,v)\,d\tau dS(v) \\
&\quad - \int_{a(x,v)\leq t} \operatorname{div}_x \int_0^t (t-\tau)\left(\nabla_x\varphi^n f^{n+1}\right)(\tau,x-(t-\tau)v,v)\,d\tau dv \\
&= \int_{a(x,v)\leq t} g\circ B(t,x,v)\,dv \\
&\quad - \int_{a(x,v)=t}\int_0^t (\nabla_x\varphi^n\cdot n_v) f^{n+1}(\tau,x-(t-\tau)v,v)\,d\tau dS(v) \\
&\quad - \operatorname{div}_x \int_{a(x,v)\leq t}\int_0^t (t-\tau)\left(\nabla_x\varphi^n f^{n+1}\right)(\tau,x-(t-\tau)v,v)\,d\tau dv \\
&\quad - \int_{a(x,r,\phi,\theta)=t}\int_0^t (t-\tau)\left(\nabla_x\varphi^n f^{n+1}\right) r^2\sin\phi\cdot\nabla_x a\frac{\nu^r}{a_r} dS(r,\phi,\theta).
\end{aligned}$$

Therefore, by all the cancellations out of I_1 and I_2, we obtain our lemma. □

In the following, we shall give some estimates on the sequences of f^n and φ^n, uniformly in n.

LEMMA 5.5. *We have* $\|f^n t\|_{L^p} \le C$ *for* $1 \le p \le \infty$ *and*

$$\begin{aligned}
&\left\|\nabla_x \varphi^{n+1}\right\|_{L^p(\Omega)}(t) \\
&\le \left\| \int_{\mathbb{R}^3} \int_0^t \mathbf{1}_{\{a(x,v)\ge t\}}(v)(t-\tau)\left|\left(\nabla\varphi^n f^{n+1}\right)(\tau, x-(t-\tau)v, v)\right| d\tau dv \right\|_{L^p(\Omega)} \\
&\quad + \left\| \int_{\mathbb{R}^3} \int_0^t \mathbf{1}_{\{a\le t\}}(v)\mathbf{1}_{(t-a,t)}(\tau)(t-\tau)\left|\left(\nabla\varphi^n f^{n+1}\right)(\tau, x-(t-\tau)v, v)\right| d\tau dv \right\|_{L^p(\Omega)} \\
&\quad + C,
\end{aligned}$$

where $1 \le p < \infty$*, and* C *is a constant independent of* n*, depending only on the data* f_0 *and* g*.*

Proof. The first estimate on f^n easily follows from standard estimates for the transport equation (5.1). For the second estimate, we employ the elliptic equation $\Delta\varphi^{n+1} = \rho^{n+1}$ and the representation formula for φ^{n+1} (5.12). We note that since Ω is bounded and the v-support of f_0 is compact, we get

$$\frac{1}{|x|^2} * \left[\int f_0(x-tv, v)\mathbf{1}_{\{a(x,v)\ge t\}}(v)\, dv\right] \le C. \tag{5.15}$$

Similarly, we have

$$\frac{1}{|x|^2} * \left[\int f(B(t,x,v))\mathbf{1}_{\{a(x,v)\le t\}}(v)\, dv\right] \le C. \tag{5.16}$$

By standard elliptic estimates for a bounded domain [15] and by (5.15), (5.16), our lemma follows. □

Now we give the lemma which is a major step for the global bound on the velocity.

LEMMA 5.6 (high moments bound). *Let* f^n *and* φ^n *be defined in* (5.1), (5.2)*. Then for a fixed* $m > 3$*, we have*

$$\sup_n \int_{\Omega\times\mathbb{R}^3} |v|^m f^n(t,x,v)\, dxdv < \infty$$

for all $0 \le t \le T$*. In particular, there is a uniform bound (independent of* n*) for the support of* f^n*.*

Proof. We shall closely follow the method given in [18]. We first define

$$M_m(f^n)(s) = \sup_{0\le t\le s} \int_{\Omega\times\mathbb{R}^3} |v|^m f^n(t,x,v)\, dxdv.$$

Then note that

$$\begin{aligned}
\frac{d}{dt}\int_{\Omega\times\mathbb{R}^3} |v|^m f^n(t,x,v)\, dxdv &= -\int \nabla_x\cdot\left(|v|^m v f^n\right) dxdv \\
&\quad - \int |v|^m \nabla_v\cdot\left(\nabla_x\varphi^{n-1} f^n\right) dxdv.
\end{aligned} \tag{5.17}$$

By the Gauss theorem, the first integral on the RHS of (5.17) becomes

$$\begin{aligned}
-\int_{\partial\Omega\times\mathbb{R}^3} |v|^m f^n v\cdot n_x dS(x)\, dv &= -\int_{v\cdot n_x\le 0} - \int_{v\cdot n_x\ge 0} \\
&\le -\int_{\gamma_t^+} |v|^m g(t,x,v)\, v\cdot n_x dSdv \\
&\le C
\end{aligned}$$

since g has compact support. For the second integral on the RHS of (5.17), we first use the integration by parts to get

$$\begin{aligned}
&-\int \nabla_v \cdot \left(|v|^m \nabla_x \varphi^{n-1} f^n\right) dxdv + m\int |v|^m f^n \nabla_x \varphi^{n-1} \cdot \nabla_v \left(|v|\right) dxdv \\
&= m\int |v|^m f^n \nabla_x \varphi^{n-1} \cdot \nabla_v \left(|v|\right) dxdv,
\end{aligned}$$

where the first integral vanishes. Now, by using the interpolation method, we get

$$\begin{aligned}
&\left|-\int |v|^m \nabla_v \cdot \left(\nabla_x \varphi^{n-1} f^n\right) dxdv\right| \\
&\le \left|m\int |v|^m f^n \nabla_x \varphi^{n-1} \cdot \nabla_v \left(|v|\right) dxdv\right| \\
&\le C\int_\Omega \left|\nabla_x \varphi^{n-1}(t,x)\right| \left(\int_{|v|\ge R} |v|^{m-1} f^n dv + \int_{|v|\le R} |v|^{m-1} f^n dv\right) dx \\
&\le C\int_\Omega \left|\nabla_x \varphi^{n-1}(t,x)\right| \left(R^{-1}\int |v|^m f^n dv + CR^{m+2}\right) dx \\
&\le C\int_\Omega \left|\nabla_x \varphi^{n-1}(t,x)\right| \left(\int |v|^m f^n dv\right)^{\frac{m+2}{m+3}} dx \\
&\le C\left\|\nabla_x \varphi^{n-1}(t)\right\|_{L^{m+3}(\Omega)} M_m \left(f^n\right)^{\frac{m+2}{m+3}},
\end{aligned}$$

where $R = \left(\int |v|^m f^n dv\right)^{1/(m+3)}$ was used for the optimal inequality, and we used the Hölder inequality. Thus we get

(5.18)
$$\frac{d}{ds} M_m\left(f^n\right)(s) \le C_1 + C\sup_{0\le t\le s} \left\|\nabla_x \varphi^{n-1}(t)\right\|_{L^{m+3}(\Omega)} M_m\left(f^n\right)(s)^{(m+2)/(m+3)},$$

where C_1 depends on f_0 and g. We shall estimate $\left\|\nabla_x \varphi^{n-1}(t)\right\|_{L^{m+3}(\Omega)}$. From Lemma 5.4, we have

(5.19)
$$\begin{aligned}
&\left\|\nabla_x \varphi^{n-1}\right\|_{m+3}(t) \\
&\le \left\|\int_{\mathbb{R}^3}\int_0^t \mathbf{1}_{\{a(x,v)\ge t\}}(v)(t-\tau)\left|\left(\nabla\varphi^{n-2} f^{n-1}\right)(\tau, x-(t-\tau)v, v)\right| d\tau dv\right\|_{m+3} \\
&\quad + \left\|\int_{\mathbb{R}^3}\int_0^t \mathbf{1}_{\{a(x,v)\le t\}}(v)\mathbf{1}_{(t-a,t)}(\tau)(t-\tau) \right. \\
&\qquad\qquad \left. \times \left|\left(\nabla\varphi^{n-2} f^{n-1}\right)(\tau, x-(t-\tau)v, v)\right| d\tau dv\right\|_{m+3} \\
&\quad + C.
\end{aligned}$$

We shall estimate the two terms in the RHS by the sum of the long-time integral and the short-time integral:

$$\left\|\int_{t_0}^t \cdots\right\|_{m+3} + \left\|\int_0^{t_0} \cdots\right\|_{m+3}, \tag{5.20}$$

where t_0 is some small time to be chosen later. We first do the long-time estimate which is the first term in (5.20). Choose $r^{'}=3$, $r=3/2$. By the Hölder inequality,

$$\begin{aligned}\left\|\int_{t_0}^{t}\cdots\right\|_{m+3} &\le C\int_{t_0}^{t}\frac{1}{\tau}d\tau\left[\sup_{\tau\in(0,T)}\left\|E\left(\tau\right)\right\|_{3/2}M_m\left(f^n\right)^{1/(m+3)}\right]\left(\tau\right)\\ &\le C\log t_0\sup_{\tau\in(0,T)}\left\|E\left(\tau\right)\right\|_{3/2}M_m\left(f^n\right)^{1/(m+3)}\left(t\right)\\ &\le C\log t_0 M_m\left(f^n\right)^{1/(m+3)}\left(t\right).\end{aligned}\tag{5.21}$$

For the short-time integral over $(0,t_0)$, we use the standard interpolation estimate for ρ^{n-2},

$$\begin{aligned}\rho^{n-2}=\int_{\mathbb{R}^3}f^{n-2}dv &= \int_{|v|\le R}+\int_{|v|\ge R}\\ &\le CR^3\left\|f^{n-2}\right\|_{\infty}+CR^{-m}\int|v|^m f^{n-2}dv\\ &\le C\left(\int|v|^m f^{n-2}dv\right)^{3/(m+3)}\quad\text{for any } R,\end{aligned}\tag{5.22}$$

where we have chosen R so as to optimize the last inequality. Since $\left|\nabla_x\varphi^{n-2}\right|\le\frac{1}{|x|^2}*\rho^{n-2}\left(x\right)$, we apply the Hardy–Littlewood–Sobolev inequality to get

$$\begin{aligned}\sup_{\tau\in(0,t)}\left\|\nabla_x\varphi^{n-2}\right\|_r &\le C\sup_{\tau\in(0,t)}\left\|\rho^{n-2}\right\|_{\frac{3r}{3+r}}\\ &\le C\sup_{\tau\in(0,t)}\left\|\rho^{n-2}\right\|_{\frac{m+3}{3}}\\ &\le CM_m^{\alpha}\left(f^{n-2}\right)\left(t\right),\end{aligned}\tag{5.23}$$

where $\alpha=3/\left(m+3\right)<1$, and we have used that $\frac{3r}{3+r}<\frac{m+3}{3}$ and Ω is bounded. By the same argument as in (5.22), we have

$$\begin{aligned}&\sup_{\tau\in(0,t)}\left\|\left[\int_{\mathbb{R}^3}\mathbf{1}_{\{a(x,v)\ge t\}}f^{n-1}\left(t-\tau,x-\tau v,v\right)dv\right]^{1/r^{'}}\right\|_{m+3}\\ &=\sup_{\tau\in(0,t)}\left\|\int_{\mathbb{R}^3}\mathbf{1}_{\{a(x,v)\ge t\}}f^{n-1}\left(t-\tau,x-\tau v,v\right)dv\right\|_{\frac{m+3}{r^{'}}}^{\frac{1}{r^{'}}}\\ &\le CM_k^{1/(m+3)}\left(f^{n-1}\right)\left(t\right)\\ &\le C+C\sup_{\tau\in(0,t)}\left\|\nabla_x\varphi^{n-1}\right\|_{k+3}^{(k+3)/(m+3)}\\ &\le C+C\sup_{\tau\in(0,t)}\left\|\nabla_x\varphi^{n-1}\right\|_{q}^{(k+3)/(m+3)}\\ &\le C+C\sup_{\tau\in(0,t)}\left\|\rho^{n-1}\left(\tau\right)\right\|_{(m+3)/3}^{(k+3)/(m+3)}\\ &\le C+CM_m^{\beta}\left(f^{n-1}\right)\left(t\right),\end{aligned}\tag{5.24}$$

where $\frac{m+3}{r^{'}}=\frac{k+3}{3}$, $\beta=\frac{3(k+3)}{(m+3)^2}$, we have chosen q,k such that $\frac{1}{q}=\frac{3}{m+3}-\frac{1}{3}$, $m+3\lesssim k+3\le q$, and we have used $M_k\left(t\right)\le C\left\{M_k\left(0\right)+\sup_{\tau\in(0,t)}\left\|\nabla_x\varphi^{n-1}\left(\tau\right)\right\|_{k+3}^{k+3}\right\}$.

Therefore, by (5.23), (5.24),

(5.25)

$$\begin{aligned}
&\left\|\int_0^{t_0}\cdots\right\|_{m+3}\\
&\le Ct_0^{2-3/r}\sup_{\tau\in(0,t)}\left\|\nabla_x\varphi^{n-2}\right\|_r\\
&\qquad\times\sup_{\tau\in(0,t)}\left\|\left[\int_{\mathbb{R}^3}\mathbf{1}_{\{a(x,v)\ge t\}}f^{n-1}\left(t-\tau,x-\tau v,v\right)dv\right]^{1/r'}\right\|_{m+3}\\
&\quad+Ct_0^{2-3/r}\sup_{\tau\in(0,t)}\left\|\nabla_x\varphi^{n-2}\right\|_r\\
&\qquad\times\sup_{\tau\in(0,t)}\left\|\left[\int_{\mathbb{R}^3}\mathbf{1}_{\{a(x,v)\le t\}}\mathbf{1}_{(t-a(x,v),t)}f^{n-1}\left(t-\tau,x-\tau v,v\right)dv\right]^{1/r'}\right\|_{m+3}\\
&\le Ct_0^{2-3/r}M_m^{\alpha}\left(f^{n-1}\right)(t)\left[C+CM_m^{\beta}\left(f^{n-1}\right)(t)\right]\\
&\le Ct_0^{2-3/r}M_m^{\alpha+\beta}\left(f^{n-1}\right)(t).
\end{aligned}$$

Hence we have from (5.19), (5.21), and (5.25)

$$\sup_{0\le t\le s}\left\|\nabla_x\varphi^{n-1}\right\|_{m+3}(t)\le C+C\log t_0M_m\left(f^n\right)^{1/(m+3)}(t)+Ct_0^{2-3/r}M_m^{\alpha+\beta}\left(f^{n-1}\right)(t).$$

Setting $\bar{M}_{n,m}=\max_{1\le i\le n}M_m\left(f^i\right)$, we get, by (5.18),

$$\frac{d}{dt}\bar{M}_{n,m}(t)\le C+C\log t_0\bar{M}_{n,m}(t)+Ct_0^{2-3/r}\bar{M}_{n,m}^{\alpha+\beta+(m+2)/(m+3)}(t).$$

Choosing $t_0^{2-3/r}=\bar{M}_{n,m}^{1-\alpha-\beta-(m+2)/(m+3)}$, we deduce our lemma. By choosing $m>6$, we have $\|\nabla_x\varphi^n\|_{L^\infty}$ uniformly bounded and get a uniform upper bound for the v-support of f^n. □

Now we shall prove the main theorem of this section, Theorem 5.1.

Proof of Theorem 5.1. We first show that

$$\left\|f^{n+1}\right\|_{W^{1,p}}<\infty,$$

uniformly in n, for fixed $3<p\le\infty$. It suffices to show it in $W^{1,\infty}$. In doing so, we shall prove that $\|\nabla\varphi^n\|_{W^{1,\infty}}$ does not grow faster than $\log\|f^n\|_{W^{1,\infty}}$ in time. Since $\Delta\varphi^n=\rho^n$, $\varphi^n|_{\partial\Omega}=0$, we have

$$\varphi^n(t,x)=\int_\Omega\rho^n(t,y)\,G(x,y)\,dy,$$

where $G(x,y)$ is Green's function for the Laplacian, associated with the domain Ω. Then we find in [6] or [17] that

$$|\nabla_xG(x,y)|\le\frac{C}{|x-y|^2},\quad\left|\nabla_x^2G(x,y)\right|\le\frac{C}{|x-y|^3}.$$

Assuming that the v-support of f^n is uniformly bounded in n, we have

$$\begin{aligned}
&\partial_{x_ix_j}\varphi^n(t,x)\\
&=\partial_{x_ix_j}\int_\Omega G(x,y)\,\rho^n(t,y)\,dy\\
&=\partial_{x_i}\int_\Omega \partial_{x_j}G(x,y)\,\rho^n(t,y)\,dy\\
&=\partial_{x_i}\int_\Omega \partial_{x_j}G(x,y)\,[\rho^n(t,y)-\rho^n(t,x)]\,dy+\partial_{x_i}\int_\Omega \partial_{x_j}G(x,y)\,\rho^n(t,x)\,dy\\
&=\int_\Omega \partial_{x_ix_j}G(x,y)\,[\rho^n(t,y)-\rho^n(t,x)]\,dy-\int_\Omega \partial_{x_j}G(x,y)\,\partial_{x_i}\rho^n(t,x)\,dy\\
&\quad+\partial_{x_i}\rho^n(t,x)\int_\Omega \partial_{x_j}G(x,y)\,dy+\rho^n(t,x)\,\partial_{x_ix_j}\int_\Omega G(x,y)\,dy\\
&=\rho^n(t,x)\,\partial_{x_ix_j}\int_\Omega G(x,y)\,dy+\int_{|x-y|\ge a}\partial_{x_ix_j}G(x,y)\,[\rho^n(t,y)-\rho^n(t,x)]\,dy\\
&\quad+\int_{|x-y|\le a}\partial_{x_ix_j}G(x,y)\,[\rho^n(t,y)-\rho^n(t,x)]\,dy.
\end{aligned}$$

Hence we get

$$\begin{aligned}
&\left|\partial_{x_ix_j}\varphi^n(t,x)\right|\\
&\le C+C\int_{|x-y|\ge a}\frac{1}{|x-y|^3}dy+C\int_{|x-y|\le a}\frac{1}{|x-y|^3}\,\|\rho^n\|_{W^{1,\infty}(\Omega)}\,|x-y|\,dy\\
&\le C+C\,|\log a|+Ca\,\|f^n\|_{W^{1,\infty}(\Omega)}\\
&\le C\left[1+\log\left(1+\|f^n\|_{W^{1,\infty}(\Omega)}\right)\right].
\end{aligned}\tag{5.26}$$

Here we have chosen a with $a=\|f^n\|^{-1}_{W^{1,\infty}(\Omega)}$. For $\partial_t\nabla\varphi^n$, we employ from (5.1)

$$\rho^n_t+\operatorname{div}_x j^n=0,$$

where $j^n(t,x)=\int vf^n(t,x,v)\,dv$, to get

$$\begin{aligned}
&\partial_{tx_i}\varphi^n(t,x)\\
&=\partial_{x_i}\int_\Omega \operatorname{div}_y j^n(t,y)\,G(x,y)\,dy\\
&=\int_{|x-y|\le a}\operatorname{div}_y j^n(t,y)\,\partial_{x_i}G(x,y)\,dy+\int_{|x-y|\ge a}\operatorname{div}_y j^n(t,y)\,\partial_{x_i}G(x,y)\,dy\\
&=\int_{|x-y|\le a}\operatorname{div}_y j^n(t,y)\,\partial_{x_i}G(x,y)\,dy+\int_{|x-y|\ge a}\operatorname{div}_y\left(j^n(t,y)\,\partial_{x_i}G(x,y)\right)dy\\
&\quad-\int_{|x-y|\ge a}j^n(t,y)\,\nabla_y\partial_{x_i}G(x,y)\,dy.
\end{aligned}$$

Therefore, by the same choice of a, we have

$$\begin{aligned}
&|\partial_{tx_i}\varphi^n(t,x)| \\
&\le Ca\|f^n\|_{W^{1,\infty}(\Omega)} + \left|\int_{|x-y|=a} \frac{x-y}{a}\cdot j^n(t,y)\,\partial_{x_i}G(x,y)\,dS_a(y)\right| \\
&\quad + \int_{|x-y|\ge a} \frac{|j^n(t,y)|}{|x-y|^3}dy \\
&\le Ca\|f^n\|_{W^{1,\infty}(\Omega)} + C + C|\log a| \\
&\le C\left[1+\log\left(1+\|f^n\|_{W^{1,\infty}(\Omega)}\right)\right].
\end{aligned}$$

Now we start with the first derivatives of f^n. By taking v-derivatives of (5.1), we get

$$\partial_t(\partial_v f^n) + v\cdot\nabla_x(\partial_v f^n) + \nabla_x\varphi^{n-1}\cdot\nabla_v(\partial_v f^n) = -\partial_x f^n.$$

Along the trajectory given by $\frac{d}{ds}X^{n-1} = V^{n-1}$, $\frac{d}{ds}V^{n-1} = \nabla_x\varphi^{n-1}$, we have

$$\partial_s\left[\partial_v f^n\left(s, X^{n-1}(s), V^{n-1}(s)\right)\right] = -\partial_x f^n,$$

and thus

$$|\partial_v f^n(t,x,v)| \le C + \int_0^t |\partial_x f^n(s)|\,ds.$$

For $\partial_x f^n$, we have

$$\partial_s\left[\partial_x f^n\left(s, X^{n-1}(s), V^{n-1}(s)\right)\right] = -\left(\nabla_x\partial_x\varphi^{n-1}\right)\cdot\nabla_v f^n\left(s, X^{n-1}(s), V^{n-1}(s)\right),$$

which implies, upon integrating over time,

$$\partial_x f^n(t,x,v) = \begin{cases} \partial_x f_0(x_0,v_0) - \int_0^t \left(\partial_x^2\varphi^{n-1}\right)\cdot\left(\nabla_v f^n\right)(s)\,ds, \\ \lim_{s\to t_0(t,x,v)}\partial_x f^n(s) - \int_{t_0}^t \left(\partial_x^2\varphi^{n-1}\right)\cdot\left(\nabla_v f^n\right)(s)\,ds, \end{cases}$$

depending on the back trajectory from (t,x,v) to either $(0,x_0,v_0)$ or (t_0,x_0,v_0) with $x_0\in\partial\Omega$. To compute $\lim_{s\to t_0(t,x,v)}\partial_x f^n(s)$, we look at $\nabla_x f^n(t_0,x_0,v_0) = \nabla^T g(t_0,x_0,v_0) + \lim_{s\to t_0}\nabla^\perp f^n\left(s, X^{n-1}(s), V^{n-1}(s)\right)$. From the transport equation

$$f_t^n + v^T\cdot\nabla^T f^n + (v\cdot n_x)\nabla^\perp f^n + \nabla_x\varphi^{n-1}\cdot\nabla_v f^n = 0,$$

we get, by the assumption $|\nabla g(t_0,x_0,v_0)| \le C|v_0\cdot n_{x_0}|$,

$$\begin{aligned}
\left|\lim_{s\to t_0(t,x,v)}\partial_x f^n(s)\right| &= \left|-(v\cdot n_x)^{-1}\left[g_t + v_0^T\cdot\nabla^T g + \nabla_x\varphi^{n-1}\cdot\nabla_v g\right]|_{(t_0,x_0,v_0)}\right| \\
&\le C,
\end{aligned}$$

since the support of g is bounded and $\left\|\nabla_x\varphi^{n-1}\right\|_\infty$ is uniformly bounded. Therefore, we have, by (5.26),

$$\begin{aligned}
\left\|\partial_{(x,v)}f^n(t)\right\|_\infty &\le C + \int_0^t \left(1+\left\|\nabla_x\varphi^{n-1}(s)\right\|_{W^{1,\infty}}\right)\left\|\partial_{(x,v)}f^n(s)\right\|_\infty ds \\
&\le C + \int_0^t \log\left(1+\left\|f^{n-1}(s)\right\|_{W^{1,\infty}}\right)\left\|\partial_{(x,v)}f^n(s)\right\|_\infty ds,
\end{aligned}$$

where C depends on $\|f_0\|_{W^{1,\infty}}$, $\|g\|_{W^{1,\infty}}$, the support of f_0 and g, $\left\|\nabla\varphi^{n-1}\right\|_\infty$, and the constant C which appears in the vanishing condition on g. We thus get a uniform bound on $\|f^n(t)\|_{W^{1,\infty}}$ by the Gronwall inequality. For the t-derivative, we employ

$$f_t^n + v\cdot\nabla_x f^n + \nabla_x\varphi^{n-1}\cdot\nabla_v f^n = 0$$

to get a uniform bound on $\|\partial_t f^n\|_\infty$. It follows that $\|f^n\|_{W^{1,p}}$ is uniformly bounded in n. For higher derivatives, for general $i \le k$, we can take the derivatives repeatedly in (5.1). The only term involving $\left\|\nabla_x\varphi^{n-1}\right\|_{W^{1,p}}$ is that $\partial^\alpha\nabla\varphi^{n-1}\partial_v f^n$, where $|\alpha| = i$. Since $\|\partial_v f^n\|_\infty \le C$, we then have

$$\left\|\partial^\alpha\nabla\varphi^{n-1}\partial_v f^n\right\|_p \le \left\|\partial^\alpha\nabla\varphi^{n-1}\right\|_p \|\partial_v f^n\|_\infty \le \left\|\partial^\alpha\nabla\varphi^{n-1}\right\|_p.$$

We know, by elliptic theory, that

$$\|\nabla\varphi^n\|_{W^{i,p}} \le C\|f^n\|_{W^{i-1,p}}.$$

Thus, $\left\|f^{n+1}\right\|_{W^{k,p}}$ is unformly bounded in n, and the uniform boundedness of $\|\varphi^n\|_{W^{k+2,p}}$ is also established from elliptic theory again. Once we have shown that $\left\|f^{n+1}\right\|_{W^{k,p}}$ and $\|\varphi^n\|_{W^{k+2,p}}$ are uniformly bounded in n, we obtain their weak limits f and φ, respectively, in $W^{k,p}$ and $W^{k+2,p}$ by a standard compactness argument. Last, since $\nabla\varphi^n$ converges strongly to $\nabla\varphi$ by compact embedding ($p > 3$), we can pass to the limits in (5.1) and (5.2). The uniqueness of solution for (5.1) and (5.2) can be attained by considering the difference between two solutions with the same initial and boundary conditions. It reduces to looking at the solution for the same (Vlasov–Poisson) system (5.1) and (5.2) with vanishing initial and boundary data. Integrating (5.1) over all x, v leads to the decrease of the L^1 norm in time. Together with the positivity of solution, we obtain the uniqueness. Hence, our theorem follows. ∎

6. Regularity for the Vlasov–Poisson system with the purely specular boundary condition. In this section, we assume the purely specular boundary condition for the Vlasov equation with the Dirichlet boundary condition on the electric potential. The Vlasov–Poisson system takes the form

$$\begin{gathered} f_t + v\cdot\nabla_x f + \nabla\varphi\cdot\nabla_v f = 0, \quad f|_{t=0} = f_0(x,v), \\ f(t,x,v) = f(t,x,v_*), \quad x\in\partial\Omega, \\ \Delta\varphi = \rho = 4\pi\int f dv, \\ \varphi|_{\partial\Omega} = 0, \end{gathered} \tag{6.1}$$

where f_0 is a given initial datum. We now restrict ourselves to the case when $\Omega = B$ and f_0 is spherically symmetric, where B is the unit ball in $\mathbb{R}^3$. Then we look for a spherically symmetric solution of (6.1) with datum f_0. Our main result in this section is the following.

THEOREM 6.1. *Assume that there is an $\omega_0 > 0$ such that $f_0(x,v)$ is constant for $\left(1-|x|^2\right)^2 + (2v\cdot x)^2 \le \omega_0$.*

(a) *Assume $f_0 \in C^1$. Let f_0 have compact support and satisfy the compatibility conditions* (4.3)*. Let f_0 be spherically symmetric. Then there exists a unique spherically symmetric solution (f,φ) of* (6.1) *such that $f \in W^{1,\infty}$ with compact support.*

(b) *Assume $f_0 \in C^{1,\eta}$ for some $\eta > 0$. Let f_0 have compact support and satisfy the compatibility conditions* (4.3) *and* (4.4)*. Let f_0 be spherically symmetric. Then*

there exists a unique spherically symmetric solution (f,φ) *of* (6.1) *such that* $f \in C^{1,\mu}$, $\varphi \in C^{3,\mu}$ *for some* $0 < \mu < \eta$, *with compact support.*

We first give a preliminary lemma on some conserved quantities in a bounded domain without the spherically symmetric assumption.

LEMMA 6.2. *Let* f *be a classical solution of* (6.1) *on some time interval* $(0,T]$ *with a nonnegative compactly supported datum* $f_0 \in C^1\left(\Omega \times \mathbb{R}^3\right)$. *Then we have the following:*

(a) *The total mass is conserved, i.e.,*

$$\int_\Omega \int_{\mathbb{R}^3} f dv dx \equiv \text{constant} = M_0.$$

(b) *The total energy is conserved, i.e.,*

$$\int_\Omega \left[\int_{\mathbb{R}^3} |v|^2 f dv + |E|^2 \right] dx \equiv \text{constant} = \epsilon_0.$$

(c) $\|\rho(t)\|_{L^{5/3}} \le C$ *for* $0 \le t \le T$, $C = C\left(\|f_0\|_\infty, \epsilon_0\right)$.

Proof. For (a), notice that from the specular boundary condition $f|_\gamma$ is an even function of the normal component $x \cdot v$ of v. Hence by integrating the Vlasov equation over x and v, we get

$$0 = -\int_{\partial B} \int_{\mathbb{R}^3} x \cdot v f(t,x,v)\, dv dS_x = \int_B \rho(t,x)\, dx - \int \rho_0(x)\, dx.$$

Therefore, the total mass is conserved. For (b), by multiplying the Vlasov equation (6.1) with $|v|^2$ and then integrating over x and v, we get

$$\begin{aligned} 0 &= \partial_t \int_\Omega \int_{\mathbb{R}^3} |v|^2 f dv dx + \int_{\mathbb{R}^3} \int_\Omega \nabla_x \cdot \left(|v|^2 v f \right) dx dv \\ &\quad - 2 \iint v f \cdot E dv dx \\ &= \partial_t \int_\Omega \int_{\mathbb{R}^3} |v|^2 f dv dx + \int_{\mathbb{R}^3} \int_{\partial\Omega} v \cdot n_x |v|^2 f dS_x dv \\ &\quad - 2 \iint v f \cdot E dv dx \\ &= \partial_t \int_\Omega \int_{\mathbb{R}^3} |v|^2 f dv dx - 2 \int_\Omega j \cdot E dx. \end{aligned}$$

Here we have used the specular reflection condition at the boundary. Now we integrate (6.1) over x and v to get

$$\rho_t + \nabla_x \cdot j = 0,$$

where $j(t,x)=\int vfdv$. Next we observe that

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_\Omega |E|^2\,dx &= \int_\Omega E\cdot E_t dx = \int_\Omega \nabla\varphi\cdot\nabla\varphi_t dx\\ &= \int_{\partial\Omega}\varphi n_x\cdot\nabla\varphi_t dS_x - \int_\Omega \varphi\Delta\varphi_t dx\\ &= -\int_\Omega \varphi\rho_t dx\\ &= \int_\Omega \varphi\nabla_x\cdot j dx\\ &= \int_{\partial\Omega}\varphi\left[\int n_x\cdot vfdv\right]dS_x - \int_\Omega\nabla\varphi\cdot j dx\\ &= -\int_\Omega j\cdot E dx,\end{aligned}$$

since $\varphi|_{\partial\Omega}=0$. Hence we obtain part (b). Since $|E(t,x)|\le Cr^{-2}*\rho(t,x)$, we have, by the Hardy–Littlewood–Sobolev lemma,

$$\begin{aligned}\|E(t)\|_{L^2} &\le C\left\|r^{-2}*\rho(t,\cdot)\right\|_{L^2}\le C\|\rho(t)\|_{L^{6/5}}\\ &\le C\|\rho\|_{L^1}^{7/12}\|\rho(t)\|_{L^{5/3}}^{5/12}\le C\|\rho(t)\|_{L^{5/3}}^{5/12}.\end{aligned}$$

By a standard interpolation method, we get

$$\int_\Omega \rho^{5/3}dx\le C\int|v|^2 fdv\le C. \qquad \square$$

Now we construct approximate solutions for (6.1) through an iterating sequence. Let f^0 be a suitable smooth extension of f_0 to Π, which satisfies the compatibility conditions (4.3), (4.4). Consider the following iterating sequences:

$$\begin{aligned}&f_t^{n+1}+v\cdot\nabla_x f^{n+1}+\nabla\varphi^n\cdot\nabla_v f^{n+1}=0,\quad f^{n+1}|_{t=0}=f_0,\\ &f^{n+1}(t,x,v)=f^{n+1}(t,x,v_*),\quad x\in\partial B,\\ &\Delta\varphi^n=\rho^n=4\pi\int f^n dv,\quad \varphi|_{\partial B}=0.\end{aligned}\tag{6.2}$$

In contrast to the absorbing boundary case, we shall adopt the idea in [14] in order to get a global bound for the velocity in the spherically symmetric case. The key point is to employ the invariance of the angular momentum in order to control the particles with small tangential angles near the boundary.

We assume that f_0 is spherically symmetric; i.e., $f_0(\Lambda x,\Lambda v)=f_0(x,v)$ for every proper rotation Λ on $\mathbb{R}^3$. It is known that the solution $f(t,x,v)$ satisfies the same property in x and v, and therefore depends only on $r\equiv|x|$, $u\equiv|v|$, α, and t, where α is the angle between x and v. The density ρ depends then only on r and t and has the following representation:

$$\rho(t,r)=2\pi\int_0^\infty\int_0^\pi f(t,r,u,\alpha)\,u^2\sin\alpha d\alpha du.$$

Thus φ is also radial and has the following relation with ρ:

$$\begin{aligned}\varphi(t,r)&=-\frac{1}{r}\int_0^r\lambda^2\rho(t,\lambda)\,d\lambda-\int_r^1\lambda\rho(t,\lambda)\,d\lambda+M_0/4\pi,\\ &\lim_{r\to0}r^2\varphi_r(t,r)=0.\end{aligned}$$

To see this relation, we use the harmonic operator Δ_x in the spherical coordinates, $\partial_{rr} + \frac{2}{r}\partial_r$. Hence the corresponding Poisson equation in these spherical coordinates is

$$\varphi_{rr} + \frac{2}{r}\varphi_r = \rho. \tag{6.3}$$

By multiplying (6.3) with r and r^2, respectively, we get

$$(r\varphi_r + \varphi)_r = r\rho, \tag{6.4}$$

$$\left(r^2\varphi_r\right)_r = r^2\rho. \tag{6.5}$$

We integrate (6.4) from r to 1 and (6.5) from 0 to r to get

$$\varphi_r(t,1) - r\varphi_r - \varphi = \int_r^1 \lambda\rho(t,\lambda)\,d\lambda, \tag{6.6}$$

$$r\varphi_r = \frac{1}{r}\int_0^r \lambda^2\rho(t,\lambda)\,d\lambda, \tag{6.7}$$

where we used the Dirichlet boundary condition. Plugging (6.7) into (6.6) yields

$$\varphi(t,r) = -\frac{1}{r}\int_0^r \lambda^2\rho(t,\lambda)\,d\lambda - \int_r^1 \lambda\rho(t,\lambda)\,d\lambda + \varphi_r(t,1),$$
$$E(t,x) = \nabla_x\varphi(t,r) = \frac{x}{r^3}\int_0^r \lambda^2\rho(t,\lambda)\,d\lambda = r^{-2}M(t,r)\frac{x}{r},$$

where $M(t,r) = \int_0^r \lambda^2\rho(t,\lambda)\,d\lambda$. Note that $|E| = r^{-2}M(t,r)$ and $M(t,1) = M_0/4\pi$ for all t. Note also that for $x \in \partial B$, $n_x \cdot E(t,x) = x \cdot E(t,x) = M(t,1) = M_0/4\pi \equiv$ constant. Hence, $\varphi_r(t,1) = \frac{x}{r}\cdot\nabla_x\varphi(t,x)|_{r=1} = M(t,1) = M_0/4\pi$. Moreover, the normal component of the electric field at the boundary is unchanged over time. This satisfies the condition for Corollaries 2.3 and 2.8.

Spherical symmetry also leads to a simplification of the trajectory equations:

$$\begin{aligned}
\frac{dR}{d\tau} &= U\cos A,\\
\frac{dU}{d\tau} &= \frac{\cos A}{R^2}M(\tau,R),\\
\frac{dA}{d\tau} &= -\left(\frac{M(\tau,R)}{R^2U} + \frac{U}{R}\right)\sin A,
\end{aligned} \tag{6.8}$$

where $R(t;t,r,u,\alpha) = r$, $U(t;t,r,u,\alpha) = u$, $A(t;t,r,u,\alpha) = \alpha$. Notice from (6.8) that we have the invariance of angular momentum, i.e.,

$$RU\sin A = ru\sin\alpha \text{ for all } \tau. \tag{6.9}$$

This is a crucial fact which will be used to treat such trajectories with small tangential angles near the boundary and lead to the velocity bounds. We now define, for $t \geq 0$,

$$P(t) = \sup\left\{U(s;0,r,u,\alpha)\,\middle|\,0 \leq s \leq t,\ (r,u,\alpha) \in \{\text{support of } f_0\}\right\}$$

and note that P is nondecreasing.

LEMMA 6.3. *There exists a constant C_1 such that for $r \geq 0$ and $0 \leq t \leq T$,*

$$|E(t,x)| = \frac{M(t,r)}{r^2} \leq \min\left(M_0 r^{-2}, C_1 P^{4/3}(t)\right),$$

where C_1 depends only on $\|f_0\|_\infty$ and $\|\rho(t)\|_{L^{5/3}}$ and M_0 is the total mass.

Proof. Clearly $|E(t,x)| \leq M_0 r^{-2}$. We employ the Poisson equation $\Delta\varphi = \rho$ with the Dirichlet boundary condition for φ and $E = \nabla_x \varphi$. Let $0 < R_0 < 2$, and note that

$$\begin{aligned}
|E(t,x)| &\leq \int \frac{\rho(t,y)}{|x-y|^2} dy \\
&= \int_{|x-y|<R_0} \frac{\rho(t,y)}{|x-y|^2} dy + \int_{|x-y|>R_0} \frac{\rho(t,y)}{|x-y|^2} dy \\
&\leq \|\rho(t)\|_\infty \int_{|x-y|<R_0} |x-y|^{-2} dy \\
&\quad + \|\rho(t)\|_{L^{5/3}} \left[\int_{|x-y|>R_0} \left(|x-y|^{-2}\right)^{5/2} dy\right]^{2/5} \\
&= \|\rho(t)\|_\infty 4\pi R_0 + \|\rho(t)\|_{L^{5/3}} \left[2\pi\left(R_0^{-2} - 2^{-2}\right)\right]^{2/5} \\
&\leq \|\rho(t)\|_\infty 4\pi R_0 + \|\rho(t)\|_{L^{5/3}} (2\pi)^{2/5} R_0^{-4/5},
\end{aligned}$$

where we have used that $|\nabla G(x,y)| \leq C/|x-y|^2$ for Green's function $G(x,y)$ for the unit ball. Now we choose $R_0 > 0$ such that $R_0 \|\rho(t)\|_\infty = \|\rho(t)\|_{L^{5/3}} R_0^{-4/5}$ or $R_0 = \left(\|\rho(t)\|_{L^{5/3}} / \|\rho(t)\|_\infty\right)^{5/9}$. Here we may assume that $R_0 < 2$ because otherwise we would have $\|\rho(t)\|_\infty \leq C$, and so $\|E(t,x)\|_\infty \leq 8\pi \|\rho(t)\|_\infty \leq C$. Then we have

$$\begin{aligned}
|E(t,x)| &\leq C \|\rho(t)\|_{L^{5/3}}^{5/9} \|\rho(t)\|_\infty^{4/9} \\
&\leq C \|\rho(t)\|_{L^{5/3}}^{5/9} \|f_0\|_\infty^{4/9} P^{4/3}(t) \\
&\leq C_1 P^{4/3}(t).
\end{aligned}$$

This completes the proof of the lemma. □

Now consider a trajectory through some point (r_0, u_0, α_0) with a positive angular momentum $r_0 u_0 \sin\alpha_0 > 0$. Then $L = R(s) U(s) \sin A(s)$ is a positive invariant along the trajectory. We define

$$K(t,r) = -\int_r^1 \min\left(M_0 \lambda^{-2}, C_1 P^{4/3}(t)\right) d\lambda$$

for $0 \leq r \leq 1$ and $t \geq 0$. Note that K is continuously differentiable in r and increasing in r. We also let $R_0 = M_0^{1/2} \left(C_1 P^{4/3}(t)\right)^{-1/2}$. If $0 \leq \lambda \leq R_0$, then $C_1 P^{4/3}(t) \leq M_0 \lambda^{-2}$, and if $R_0 \leq \lambda \leq 1$, then $M_0 \lambda^{-2} \leq C_1 P^{4/3}(t)$. Here again we may assume without loss of generality that $R_0 < 1$, since otherwise $M_0^{1/2} \left(C_1 P^{4/3}(t)\right)^{-1/2} \geq 1$

would imply the bound for $P(t)$. We compute

$$\begin{aligned}
K(t,0) &= -\int_0^1 \min\left(M_0\lambda^{-2}, C_1P^{4/3}(t)\right)d\lambda \\
&= -\int_0^{R_0} C_1P^{4/3}(t)\,d\lambda - \int_{R_0}^1 M_0\lambda^{-2}d\lambda \\
&= -C_1P^{4/3}(t)\,R_0 + M_0 - M_0^{1/2}\left(C_1P^{4/3}(t)\right)^{1/2} \\
&= -M_0^{1/2}\left(C_1P^{4/3}(t)\right)^{1/2} + M_0 - M_0^{1/2}\left(C_1P^{4/3}(t)\right)^{1/2} \\
&\geq -2M_0^{1/2}\left(C_1P^{4/3}(t)\right)^{1/2}.
\end{aligned}$$

Therefore

$$\begin{aligned}
|K(t,r_1) - K(t,r_2)| &\leq |K(t,0)| \leq 2M_0^{1/2}\left(C_1P^{4/3}(t)\right)^{1/2} \\
&= C_2P^{4/6}(t), \quad C_2 = 2M_0^{1/2}C_1^{1/2}.
\end{aligned}$$

LEMMA 6.4. *Assume that either $\dot{R} \geq 0$ on $[t_1,t_2]$ or $\dot{R} \leq 0$ on $[t_1,t_2]$. Then*

$$\left|\frac{1}{2}U^2(t_2) - \frac{1}{2}U^2(t_1)\right| \leq |K(R(t_2),t_2) - K(R(t_1),t_2)|.$$

Proof. Note that

$$\begin{aligned}
|K(R(t_2),t_2) - K(R(t_1),t_2)| &= \left|\int_{t_1}^{t_2} \frac{\partial K}{\partial r}(R(s),t_2)\,\dot{R}(s)\,ds\right| \\
&= \int_{t_1}^{t_2}\left|\frac{\partial K}{\partial r}(R(s),t_2)\,\dot{R}(s)\right|ds,
\end{aligned}$$

since $\dot{R}$ is of one sign on $[t_1,t_2]$ and $\partial K/\partial r \geq 0$. We also note that for $t_2 \geq s$,

$$\begin{aligned}
\frac{\partial K}{\partial r}(R(s),t_2) &= \min\left(M_0\lambda^{-2}, C_1P^{4/3}(t_2)\right) \\
&\geq \min\left(M_0\lambda^{-2}, C_1P^{4/3}(s)\right) \\
&= \frac{\partial K}{\partial r}(R(s),s).
\end{aligned}$$

Since $|E(t,x)| = r^{-2}M(t,r) \leq \partial K/\partial r\,(t,r)$ and by the trajectory equations (6.8), we have

$$\begin{aligned}
\left|\frac{\partial K}{\partial r}(R(s),t_2)\,\dot{R}(s)\right| &\geq \left|\frac{\partial K}{\partial r}(R(s),s)\,\dot{R}(s)\right| \\
&\geq \left|\frac{M(R(s),s)}{R^2(s)}U(s)\cos A(s)\right| = \left|U(s)\,\dot{U}(s)\right| \\
&= \left|\frac{d}{ds}\frac{1}{2}U^2(s)\right|.
\end{aligned}$$

Therefore

$$\begin{aligned}|K(R(t_2),t_2)-K(R(t_1),t_2)| &\geq \int_{t_1}^{t_2}\left|\frac{d}{ds}\frac{1}{2}U^2(s)\right|ds\\ &\geq \left|\int_{t_1}^{t_2}\frac{d}{ds}\frac{1}{2}U^2(s)\,ds\right|\\ &= \left|\frac{1}{2}U^2(t_2)-\frac{1}{2}U^2(t_1)\right|.\end{aligned}$$

Thus the proof of the lemma is complete. □

LEMMA 6.5. *On each interval where the trajectory is smooth, $\dot{R}$ can be zero at most one value of s. If $\dot{R}(t_1)=0$, then R has an absolute minimum at t_1 on the interval.*

Proof. Recall that $R(s)U(s)\sin A(s) = r_0u_0\sin\alpha_0 \neq 0$ by hypothesis. So $R(s)\neq 0$, $U(s)\neq 0$, and $\sin A(s)\neq 0$ for all s. From (6.8),

$$\dot{R}(s) = U(s)\cos A(s);$$

thus $\dot{R}=0$ only if $A(s)=\pi/2$. However, also from (6.8),

$$\dot{A}(s) = -\left(\frac{M(R(s),s)}{R^2(s)U(s)}+\frac{U(s)}{R(s)}\right)\sin A(s) < 0$$

for all s. $A(s)$ is thus strictly decreasing for s on the interval and hence can attain the value of $\pi/2$ at most once. So $\dot{R}$ can be zero at most once as long as the trajectory is smooth on the interval. Now suppose that $\dot{R}(t_1)=0$; then $A(s)>\pi/2$ for $s<t_1$, $A(t_1)=\pi/2$, and $A(s)<\pi/2$ for $s>t_1$. From (6.8), $\dot{R}<0$ for $s<t_1$, $\dot{R}(t_1)=0$, and $\dot{R}>0$ for $s>t_1$. Therefore R has an absolute minimum at t_1 on the smooth interval. □

Now we consider the trajectory from a generic point (t,x,v), and we compute the lower bound on the time spent travelling from one boundary point to another along the trajectory.

LEMMA 6.6. *Let $\left(t^0,x^0,v^0\right)$ and $\left(t^1,x^1,v^1\right)$ be two points on the trajectory, where $x^0,x^1\in\partial B$, $t^0<t^1$. Suppose that the trajectory stays inside the unit ball B on the interval $\left(t^0,t^1\right)$. Then*

$$t^1-t^0 \geq \min\left(-\frac{\left|v^0\right|\cos\alpha^0}{3\sup_{0\leq s\leq t}\|E(s)\|_\infty}, -\frac{\cos\alpha^0}{3\left|v^0\right|}, \frac{1}{\left[\sup_{0\leq s\leq t}\|E(s)\|_\infty\right]^{1/2}}\right),$$

where α^0 is the angle between x^0 and v^0.

Proof. Since

$$x^1 = x^0+\int_{t^0}^{t^1}V(\tau)\,d\tau, \quad V(\tau) = v^0+\int_{t^0}^{\tau}E(s)\,ds,$$

we have

$$\begin{aligned}1=\left|x^1\right|^2 &= \left(x^0+\int_{t^0}^{t^1}V(\tau)\,d\tau\right)\cdot\left(x^0+\int_{t^0}^{t^1}V(\tau)\,d\tau\right)\\ &= 1+2x^0\cdot\int_{t^0}^{t^1}\left[v^0+\int_{t^0}^{\tau}E(s)\,ds\right]d\tau+\left|\int_{t^0}^{t^1}V(\tau)\,d\tau\right|^2.\end{aligned}$$

So, if $t^1 - t^0 \le \frac{1}{[\sup_{0\le s\le t}\|E(s)\|_\infty]^{1/2}}$, then

$$\begin{aligned}
0 &\le 2x^0 \cdot v^0 \left(t^1 - t^0\right) + 2 \sup_{0\le s\le t} \|E(s)\|_\infty \left(t^1 - t^0\right)^2 \\
&\quad + 2\left|v^0\right|^2 \left(t^1 - t^0\right)^2 + 2\left(\sup_{0\le s\le t} \|E(s)\|_\infty\right)^2 \left(t^1 - t^0\right)^4, \\
0 &\le x^0 \cdot v^0 + \sup_{0\le s\le t} \|E(s)\|_\infty \left(t^1 - t^0\right) + \left|v^0\right|^2 \left(t^1 - t^0\right) \\
&\quad + \sup_{0\le s\le t} \|E(s)\|_\infty \left(t^1 - t^0\right).
\end{aligned}$$

Thus we get

$$t^1 - t^0 \ge \frac{-x^0 \cdot v^0}{\left|v^0\right|^2 + 2\sup_{0\le s\le t}\|E(s)\|_\infty}.$$

Note that $-x^0 \cdot v^0 > 0$. If $\sup_{0\le s\le t}\|E(s)\|_\infty \le \left|v^0\right|^2$,

$$t^1 - t^0 \ge -\frac{\left|v^0\right|\cos\alpha^0}{3\sup_{0\le s\le t}\|E(s)\|_\infty},$$

and if $\sup_{0\le s\le t}\|E(s)\|_\infty \ge \left|v^0\right|^2$,

$$t^1 - t^0 \ge -\frac{\cos\alpha^0}{3\left|v^0\right|}.$$

We thus obtain the lemma. □

In the presence of the boundary, the central obstacle comes from the particles near the boundary with so many bounces or with small tangential angles, in addition to the difficulty of controlling the particles with high velocity. However, the invariance of the angular momentum enables us to overcome this main barrier. The angular momentum of the particles near the boundary with small tangential angle amounts approximately to the full velocity. This observation suggests that the initial control on the invariant angular momentum would reduce to the concern only on the high velocities and thus lead to resolving our difficulty.

Now fix $M_1 > 0$. Suppose that $f_0(x,v) \equiv 0$ when the angular momentum

$$\digamma = ru\sin\alpha = |x|\,|v|\sin\alpha \ge M_1.$$

Note that if (t,x,v) connects with an initial point in the support of f_0, $x \in \partial B$, and $|\alpha - \pi/2| \le \pi/6$, then

$$\frac{1}{2}|v| \le |v|\sin\alpha = \digamma \le M_1,$$

and therefore

$$|v| \le 2M_1. \tag{6.10}$$

Let $\left(t^0, x^0, v^0\right)$ be the first point at the boundary on the back-time cycle from (t,x,v) such that $|v_0| \le 2M_1$, and, if it does not happen through the whole cycle, then let

$t_0 = 0$. Let the back-time cycle from the time t to the time t^0 be $(t, x, v) = (t^n, x^n, v^n)$, $\left(t^{n-1}, x^{n-1}, v^{n-1}\right)$, $\ldots$, $\left(t^0, x^0, v^0\right)$. We compute $\Delta t^i = t^{i+1} - t^i$ for $0 \le i \le n-2$. By the definition of the time t^0, we have, for all i, $\left|\alpha^i - \pi/2\right| > \pi/6$ and $\left|v^i\right| \ge 2M_1$ from (6.10). We then apply Lemma 6.6 to compute the time spent for each bounce, and we have

$$
\begin{aligned}
-\frac{\left|v^i\right| \cos\alpha^i}{3 \sup_{0\le s\le t} \|E(s)\|_\infty} &\ge \frac{2M_1 \frac{\sqrt{3}}{2}}{3C_1 P^{4/3}(t)} = \frac{M_1}{\sqrt{3}C_1} P^{-4/3}(t), \\
-\frac{\cos\alpha^i}{3\left|v^i\right|} &\ge \frac{\sqrt{3}/2}{3P(t)} = \frac{1}{2\sqrt{3}} P^{-1}(t), \\
\frac{1}{\left[\sup_{0\le s\le t} \|E(s)\|_\infty\right]^{1/2}} &\ge C_1^{-1/2} P^{-4/6}(t).
\end{aligned} \tag{6.11}
$$

Since we are concerned only with large $P(t)$, we may assume that the minimum among (6.11) is $\frac{M_1}{\sqrt{3}C_1} P^{-4/3}(t)$, and thus $\Delta t^i \ge \frac{M_1}{\sqrt{3}C_1} P^{-4/3}(t)$. Therefore the number of bounces on the cycle through (t, x, v) until the time t^0 is at most

$$
\frac{\sqrt{3}TC_1}{M_1} P^{4/3}(t) + 2. \tag{6.12}
$$

Now we assert the control on the increase in velocity.

LEMMA 6.7. *Let f be a classical solution of* (6.1) *on $[0,T)$ with a smooth, non-negative, spherically symmetric data f_0 which has compact support and vanishes for $(r,u,\alpha) \notin (0,1] \times (0,\infty) \times (0,\pi)$, $ru\sin\alpha \ge M_1$, where M_1 is a fixed constant such that $M_1 > 8\sqrt{3}M_0^{1/2}C_1^{3/2}T$, M_0 is the total mass, and $C_1 = C\|\rho(t)\|_{L^{5/3}}^{5/9}\|f_0\|_\infty^{4/9}$. Then $P(t)$ is uniformly bounded on $[0,T)$.*

Proof. Let $t \in [0,T)$. Consider the back-time cycle from a generic point (t,x,v) with $0 < ru\sin\alpha \le M_1$. Suppose $0 \le t_1 \le t_2 \le t$ and the trajectory remains smooth on $[t_1,t_2]$, i.e., $[t_1,t_2]$ is between the two jump times, and suppose that $\dot{R} \ge 0$ on $[t_1,t_2]$ or $\dot{R} \le 0$ on $[t_1,t_2]$. Then, by Lemma 6.4,

$$
\begin{aligned}
\frac{1}{2}U^2(t_2) &\le \frac{1}{2}U^2(t_1) + \left|K(R(t_2),t_2) - K(R(t_1),t_2)\right| \\
&\le \frac{1}{2}U^2(t_1) + C_2 P^{4/6}(t_2) \\
&\le \frac{1}{2}U^2(t_1) + C_2 P^{4/6}(t),
\end{aligned} \tag{6.13}
$$

where $C_2 = 2M_0^{1/2}C_1^{1/2}$. Now we consider the back-time cycle from (t,x,v) until the point $\left(t^0,x^0,v^0\right)$ with $\left|v^0\right| \le 2M_1$. Suppose that $\dot{R}$ vanishes somewhere on $\left[t^i, t^{i+1}\right]$. By Lemma 6.5, there is only one such point where $\dot{R}$ vanishes; call it $\hat{t}^i \in \left[t^i, t^{i+1}\right]$. Then $\dot{R}$ cannot change sign on $\left[t^i, \hat{t}^i\right]$ or on $\left[\hat{t}^i, t^{i+1}\right]$. Hence applying (6.13) twice yields

$$
\begin{aligned}
\frac{1}{2}U^2\left(t^{i+1}\right) &\le \frac{1}{2}U^2\left(\hat{t}^i\right) + C_2 P^{4/6}(t) \\
&\le \frac{1}{2}U^2\left(t^i\right) + 2C_2 P^{4/6}(t).
\end{aligned}
$$

Thus by (6.12), we have through the back-time cycle until t^0,

$$\begin{aligned}\frac{1}{2}U^2(t) &\le \frac{1}{2}U^2\left(t^0\right) + 2NC_2P^{4/6}(t)\\ &\le \frac{1}{2}U^2\left(t^0\right) + 2C_2\left(\frac{\sqrt{3}TC_1}{M_1}P^{4/3}(t) + 2\right)P^{4/6}(t)\\ &\le \frac{1}{2}(2M_1)^2 + \frac{2\sqrt{3}C_1C_2T}{M_1}P^2(t) + 4C_2P^{4/6}(t),\end{aligned}$$

where N is the number of bounces through the cycle. Applying this argument to all possible (t,x,v), we deduce

$$P^2(t) \le (2M_1)^2 + 8C_2P^{4/6}(t) + \frac{4\sqrt{3}C_1C_2T}{M_1}P^2(t).$$

Since $4\sqrt{3}C_1C_2T = 8\sqrt{3}M_0^{1/2}C_1^{3/2}T < M_1$, we have

$$P^2(t) \le (2M_1)^2 + 8C_2P^{4/6}(t) + C_3P^2(t),$$

where $C_3 = \frac{4\sqrt{3}C_1C_2T}{M_1} < 1$. This implies that $P(t)$ is bounded by a constant depending on C_1, C_2, T, and M_1 or a constant depending only on the total mass M_0, the total energy ε_0, T, $\|f_0\|_\infty$, and M_1. Thus this completes the proof of the lemma. ∎

We consider our iterated scheme (6.2). Lemma 6.7 yields the uniform and global bound on the support of f^n.

Now we are ready to establish our main theorem in this section, Theorem 6.1.

Proof of Theorem 6.1. Uniqueness can be proven by using a standard Gronwall-type argument, since now the solutions are regular. We consider only the existence. By Lemma 6.7, ρ^n is uniformly bounded in L^∞. Therefore, φ^n is uniformly bounded in $W^{2,p}$ for $1 \le p < \infty$. Hence φ^n is uniformly bounded in $C^{1,\eta}$. We claim that

$$|\nabla\varphi^n(t,x) - \nabla\varphi^n(t,y)| \le -L|x-y|\log|x-y|,$$

where L is independent of n, and $|x-y|$ is small.

Proof of the claim. By the representation formula for the Poisson equation with the Dirichlet boundary condition for φ, we have

$$\nabla\varphi^n(t,x) = \int_B \rho^n(t,z)\left[\frac{x-z}{|x-z|^3} - \frac{x-\bar{z}}{|z|\,|x-\bar{z}|^3}\right]dz,$$

where $|\cdot|$ is the Euclidean distance in $\mathbb{R}^3$ and $\bar{z} = z/|z|^2$. Therefore,

$$\begin{aligned}|\nabla[\varphi^n(t,x) - \varphi^n(t,y)]| \le &\left|\int_B \rho^n(t,z)\left[\frac{x-z}{|x-z|^3} - \frac{y-z}{|y-z|^3}\right]dz\right|\\ &+ \left|\int_B \rho^n(t,z)\left[\frac{x-\bar{z}}{|z|\,|x-\bar{z}|^3} - \frac{y-\bar{z}}{|z|\,|y-\bar{z}|^3}\right]dz\right|.\end{aligned} \tag{6.14}$$

We first estimate the first term of (6.14) by splitting it as

$$\begin{aligned}&\left|\int_B \rho^n(t,z)\left[\frac{x-z}{|x-z|^3}-\frac{y-z}{|y-z|^3}\right]dz\right|\\&=\int_{\{z:\min[|x-z|,|y-z|]\geq|x-y|/2\}}+\int_{\{z:\min[|x-z|,|y-z|]\leq|x-y|/2\}}\\&=I_1+I_2.\end{aligned}$$

For I_1, we apply the mean value theorem to get

$$\left|\frac{x-z}{|x-z|^3}-\frac{y-z}{|y-z|^3}\right|\leq C|x-y|\left[\frac{1}{|x-z|^3}+\frac{1}{|y-z|^3}\right].$$

Thus

$$I_1\leq C|x-y|\int_{|x-y|/2}^{C}\frac{1}{r}dr\leq -L|x-y|\log|x-y|,$$

where L is a constant, independent of n. For I_2, without loss of generality, we may assume that $|x-z|\leq|x-y|/2$ and $|y-z|\geq|x-y|/2$. Then we have

$$\begin{aligned}\left|\frac{x-z}{|x-z|^3}-\frac{y-z}{|y-z|^3}\right|&=\left|\frac{x-z}{|x-z|^3}-\frac{x-z}{|y-z|^3}+\frac{x-z}{|y-z|^3}-\frac{y-z}{|y-z|^3}\right|\\&\leq\frac{2}{|x-z|^2}+\frac{|x-y|}{|y-z|^3}.\end{aligned}$$

Hence,

$$I_2\leq C\int_0^{|x-y|/2}1dr+C|x-y|\int_{|x-y|/2}^{C}\frac{1}{r}dr\leq -L|x-y|\log|x-y|.$$

Now we estimate the second term of (6.14). By the change of coordinates $z\longmapsto\bar{z}=z/|z|^2$,

$$\begin{aligned}\left|\int_B\rho^n(t,z)\left[\frac{x-\bar{z}}{|z||x-\bar{z}|^3}-\frac{y-\bar{z}}{|z||y-\bar{z}|^3}\right]dz\right|&\leq C\int_{|\bar{z}|\geq1}\left|\frac{x-\bar{z}}{|x-\bar{z}|^3}-\frac{y-\bar{z}}{|y-\bar{z}|^3}\right||z|\,d\bar{z}\\&\leq C\int\left|\frac{x-\bar{z}}{|x-\bar{z}|^3}-\frac{y-\bar{z}}{|y-\bar{z}|^3}\right|d\bar{z},\end{aligned}$$

which reduces to the first case. Thus our claim holds.

By Lemma 4.4, f^n is uniformly bounded in $C^{0,\eta}$ for some $\eta>0$. Hence, from the Poisson equation $\Delta\varphi^n=\rho^n$, $\sup_{1\leq\tau\leq t}\|\nabla_x\varphi^n\|_{C^{1,\eta}}$ and $\|\nabla_x\varphi^n\|_{C^{0,\eta}}$ are uniformly bounded. Applying Theorem 4.1 to f^n yields that f^n is uniformly bounded in $C^{1,\mu}$, $\mu>0$. Let f and φ be the limits of f^n and φ^n, respectively, such that

$$\sup_{0\leq\tau\leq t}\|\nabla_x\varphi\|_{C^{1,\mu}}+\|\nabla_x\varphi\|_{C^{0,\mu}}+\|f\|_{C^{1,\mu}}<\infty.$$

Therefore, our theorem follows by letting $n\to\infty$ in (6.2). □

Acknowledgments. The author truly thanks her thesis advisor, Yan Guo, for his encouragement and discussions. She also thanks Walter Strauss, Constantine Defermos, and Gerhard Rein for their constant interest and comments on this work. Finally, she would like to give her thanks to the referees for their helpful comments.

UNIQUENESS OF LIMIT SOLUTIONS TO A FREE BOUNDARY PROBLEM FROM COMBUSTION*

J. FERNÁNDEZ BONDER† AND N. WOLANSKI†

Abstract. We investigate the uniqueness of limit solutions for a free boundary problem in heat propagation that appears as a limit of a parabolic system that arises in flame propagation.

Key words. free boundary problem, combustion, heat equation, uniqueness, classical solution, limit solution

AMS subject classifications. 35K05, 35K60, 80A25

DOI. 10.1137/S0036141002412938

1. Introduction.

In this paper we consider the following problem arising in combustion theory:

$$\begin{cases} \Delta u^\varepsilon - u_t^\varepsilon &= Y^\varepsilon f_\varepsilon(u^\varepsilon) \quad \text{in } \mathcal{D}, \\ \Delta Y^\varepsilon - Y_t^\varepsilon &= Y^\varepsilon f_\varepsilon(u^\varepsilon) \quad \text{in } \mathcal{D}, \end{cases} \tag{1.1}$$

where $\mathcal{D} \subset \mathbb{R}^{N+1}$.

This model appears in combustion theory in the analysis of the propagation of curved flames. It is derived in the framework of the theory of equidiffusional premixed flames analyzed in the relevant limit of high activation energy for Lewis number 1. In this application, Y^ε represents the fraction of some reactant (and hence it is assumed to be nonnegative), and u^ε is minus the temperature (more precisely, $u^\varepsilon = \lambda(T_f - T^\varepsilon)$, where T_f is the flame temperature and λ is a normalization factor). Observe that the term $Y^\varepsilon f_\varepsilon(u^\varepsilon)$ acts as an absorption term in (1.1). Since $T^\varepsilon = T_f - (u^\varepsilon/\lambda)$, it is in fact a reaction term for the temperature. In the flame model, such a term represents the effect of the exothermic chemical reaction and f has, accordingly, a number of properties: it is a nonnegative Lipschitz continuous function which is positive in an interval $(-\infty, \varepsilon)$ and vanishes otherwise (i.e., reaction occurs only when $T > T_f - \frac{\varepsilon}{\lambda}$). The parameter ε is essentially the inverse of the activation energy of the chemical reaction. For the sake of simplicity we will assume that $f_\varepsilon(s) = \frac{1}{\varepsilon^2} f(\frac{s}{\varepsilon})$, where f is a Lipschitz continuous function with $f(s) > 0$ if $s < 1$ and $f(s) = 0$ if $s \geq 1$.

For the derivation of the model, we cite [1].

Here we are interested in high activation energy limits (i.e., $\varepsilon \to 0$). These limits are currently the subject of active investigation, especially in the case $u^\varepsilon = Y^\varepsilon$. This is a natural assumption in the case of traveling waves.

In a previous paper [5] we have studied this problem in the case in which the initial values for u^ε and Y^ε, both converging to the same function u_0, satisfy the

condition

$$\frac{Y_0^\varepsilon(x) - u_0^\varepsilon(x)}{\varepsilon} \to w_0(x) \quad \text{uniformly in } \mathbb{R}^N \tag{1.2}$$

with $w_0 > -1$.

Problem (1.1) reduces to a single equation, namely,

$$\Delta u^\varepsilon - u_t^\varepsilon = (u^\varepsilon + w^\varepsilon) f_\varepsilon(u^\varepsilon), \tag{P_ε}$$

where the function $w^\varepsilon(x,t)$ is the solution of the heat equation with initial datum $Y_0^\varepsilon(x) - u_0^\varepsilon(x)$. Observe that $u^\varepsilon + w^\varepsilon = Y^\varepsilon \geq 0$.

By (1.2) there exists the limit

$$\lim_{\varepsilon \to 0} \frac{w^\varepsilon(x,t)}{\varepsilon} = w_0(x,t), \tag{1.3}$$

and $w_0(x,t)$ is the solution of the heat equation with initial datum $w_0(x)$.

In this way, at least formally, the reaction term converges to a delta function, and a free boundary problem appears. In fact, we have proved in [5] that every sequence of uniformly bounded solutions to (1.1), $\{u^{\varepsilon_n}\}$, with $\varepsilon_n \to 0$ has a subsequence $\{u^{\varepsilon_{n_k}}\}$ converging to a limit function $u \geq 0$ which is a solution of the following free boundary problem:

$$\text{(P)} \qquad \begin{cases} \Delta u - u_t = 0 & \text{in } \{u > 0\}, \\ |\nabla u^+| = \sqrt{2M(x,t)} & \text{on } \partial\{u > 0\}, \end{cases}$$

where $M(x,t) = \int_{-w_0(x,t)}^1 \big(s + w_0(x,t)\big) f(s) ds$.

We see that the free boundary condition strongly depends on the approximation u_0^ε, Y_0^ε of the initial datum u_0. In particular, the limit function u is different for different approximations of the initial datum u_0.

It is therefore natural to wonder whether the only condition that determines the limit function u is condition (1.2).

The purpose of this paper is to prove that this is indeed the case, at least under some monotonicity assumption on the initial value u_0. This monotonicity assumption is similar to that used to prove uniqueness of the limit for the case $u^\varepsilon = Y^\varepsilon$ in [9].

In fact, we follow here some of the ideas of [9] which are based on the fact that any limit function is a supersolution to (P). This is still true in our case. Unfortunately, the simple construction in [9] of supersolutions of (P_ε) that approximate a strict classical supersolution of (P), when $w^\varepsilon = 0$, does not work in the general case unless one asks for a lot of complementary conditions on the reaction function f.

Therefore, we follow here the construction done in [7]. The proof that this construction works is based on blow up of the constructed functions. This technique was already seen to work very well for (P_ε), under condition (1.2), in [5].

Our result can be summarized as saying that *under suitable assumptions on the domain and on the initial datum u_0, there exists at most one limit solution to the free boundary problem* (P) *with nonvanishing gradient near its free boundary, as long as the approximate initial data, converging uniformly to u_0 with supports that converge to the support of u_0, satisfy* (1.2).

Moreover, under the same geometric assumptions, *if there exists a classical solution to* (P)*, this is the only limit of solutions to* (P_ε) *with initial data satisfying the conditions above. In particular, it is the only classical solution to* (P).

As already stated, in the case $u^\varepsilon = Y^\varepsilon$, uniqueness results for limit solutions under geometric hypotheses similar to the ones made here can be found in [9]. Also, in [7] the authors study the uniqueness and agreement between different concepts of solutions of problem (P) (again in the case $u^\varepsilon = Y^\varepsilon$) under the assumption of the existence of a classical solution and under different geometric assumptions. See also [8] for a similar result in the two-phase case.

Notation. Throughout the paper N will denote the spatial dimension. In addition, the following notation will be used:

For any $x_0 \in \mathbb{R}^N$, $t_0 \in \mathbb{R}$, and $\tau > 0$, $B_\tau(x_0) := \{x \in \mathbb{R}^N / |x - x_0| < \tau\}$ and $B_\tau(x_0, t_0) := \{(x,t) \in \mathbb{R}^{N+1} / |x - x_0|^2 + |t - t_0|^2 < \tau^2\}$.

When necessary, we will denote points in $\mathbb{R}^N$ by $x = (x_1, x')$, with $x' \in \mathbb{R}^{N-1}$. Given a function v, we will denote $v^+ = \max(v, 0)$.

The symbols Δ and ∇ will denote the corresponding operators in the space variables; the symbol ∂_p applied to a domain will denote parabolic boundary.

Finally, we will say that u is supercaloric if $\Delta u - u_t \le 0$, and u is subcaloric if $\Delta u - u_t \ge 0$.

Outline of the paper. An outline of the contents is as follows. In section 2 we give precise definitions of classical sub- and supersolutions and prove a comparison result for problem (P) (Lemma 2.1). In section 3 we state some auxiliary results. In section 4 we prove that a strict classical supersolution to problem (P) is the uniform limit of a family of supersolutions to problem (P_ε) (Theorem 4.1), and as a consequence we obtain the boundedness of the support for limit solutions in the geometry under consideration (Proposition 4.1). Finally, in section 5 we prove our main result (Theorem 5.1). We discuss in a final section (section 6) the results proved in the paper as well as other possible geometries that can be considered.

2. Preliminaries. Following [9] we will define what we will understand by a classical supersolution of problem (P). Note that the meaning of *classical* here differs from the usual one since we are not assuming that the function is C^1 up to the free boundary or that the free boundary is C^1.

DEFINITION 2.1. *A continuous nonnegative function u in $\overline{Q}_T = \mathbb{R}^N \times [0,T]$, $T > 0$, is called a classical supersolution of* (P) *if $u \in C^1(\{u > 0\})$ and*

(i) $\Delta u - u_t \le 0$ *in* $\Omega = \{u > 0\}$;

(ii) $\limsup_{\Omega \ni (y,s) \to (x,t)} |\nabla u(y,s)| \le \sqrt{2M(x,t)}$ *for every* $(x,t) \in \partial\Omega \cap Q_T$;

(iii) $u(\cdot, 0) \ge u_0$.

Respectively, u is a classical subsolution of (P) *if conditions* (i), (ii), *and* (iii) *are satisfied with reversed inequalities and* $\liminf$ *instead of* $\limsup$ *in* (ii).

A function u is a classical solution of (P) *if it is both a classical subsolution and a classical supersolution of* (P).

Next, a classical supersolution u of (P) *is a strict classical supersolution of* (P) *if there is a $\delta > 0$ such that the stronger inequalities*

(ii') $\limsup_{\Omega \ni (y,s) \to (x,t)} |\nabla u(y,s)| \le \sqrt{2M(x,t) - \delta}$ *for every* $(x,t) \in \partial\Omega \cap Q_T$,

(iii') $u(\cdot, 0) \ge u_0 + \delta$ *on* $\Omega_0 = \{u_0 > 0\}$

hold. Analogously, a strict classical subsolution is defined.

As a consequence of the results in [5], one can check that every limit solution $u = \lim_{j \to \infty} u^{\varepsilon_j}$ of (P) is a classical supersolution in the sense of Definition 2.1.

PROPOSITION 2.1. *Let u^{ε_j} be solutions to* (P_{ε_j}), *with w^{ε_j} satisfying* (1.3) *and $w_0 > -1$, such that $u^{\varepsilon_j} \to u$ uniformly on compact sets and $\varepsilon_j \to 0$. Assume that the initial datum u_0 is Lipschitz continuous and that the approximations of the initial*

datum verify $|u_0^\varepsilon(x)|, |\nabla u_0^\varepsilon(x)| \le C$, *and* $u_0^\varepsilon \in C^1(\overline{\{u_0^\varepsilon > 0\}})$. *Then* u *is a classical supersolution of* (P).

Proof. We have to verify conditions (i)–(iii) of Definition 2.1.

From our assumptions on the initial datum u_0, by Proposition 5.2.1 of [6], we have that $u^\varepsilon \to u$ uniformly on compact sets of $\overline{Q_T}$ so that u is continuous up to $t = 0$ and (iii) holds.

Now (i) is proved in [5].

Finally, (ii) is a straightforward modification of Theorem 6.1 of [2] using Lemmas 2.1, 2.2, and 2.3 of [5] instead of Lemma 3.2 and Propositions 5.2 and 5.3 of [2], respectively. □

Let us suppose that the initial datum u_0 of problem (P) is starshaped with respect to a point x_0, which we always assume to be 0, in the following sense: For every $\lambda \in (0,1)$ and $x \in \mathbb{R}^N$,

$$u_0(\lambda x) \ge u_0(x), \qquad \lambda\Omega_0 \subset\subset \Omega_0, \tag{2.1}$$

where $\Omega_0 = \{u_0 > 0\}$.

Also, assume that

$$w_0(\lambda x, 0) \le w_0(x, 0) \quad \text{if } x \in \mathbb{R}^N,\ 0 < \lambda < 1. \tag{2.2}$$

Let u be a classical supersolution of (P). Let λ and λ' be two real numbers with $0 < \lambda < \lambda' < 1$. Define

$$u_\lambda(x,t) = \frac{1}{\lambda'} u(\lambda x, \lambda^2 t) \tag{2.3}$$

in Q_{T/λ^2}. The rescaling is taken so that u_λ is a supersolution of the heat equation in

$$\Omega_\lambda = \{(x,t) :\ (\lambda x, \lambda^2 t) \in \Omega\}. \tag{2.4}$$

Moreover, the fact that $0 < \lambda < \lambda' < 1$ makes u_λ a strict classical supersolution of (P).

In fact, let us first see that

$$M(\lambda x, \lambda^2 t) \le M(x,t) \qquad \text{if } 0 < \lambda < 1.$$

This is a consequence of the fact that the function

$$a \longrightarrow \int_{-a}^{1} (s + a) f(s)\, ds$$

is nondecreasing and

$$w_0(\lambda x, \lambda^2 t) \le w_0(x,t) \qquad \text{if } 0 < \lambda < 1. \tag{2.5}$$

In fact, the function $w_\lambda(x,t) = w_0(\lambda x, \lambda^2 t)$ is caloric, and $w_\lambda(x,0) \le w_0(x,0)$ if $0 < \lambda < 1$ by hypothesis. Thus, by the comparison principle, $w_\lambda(x,t) \le w_0(x,t)$ in $\mathbb{R}^N \times (0,T)$.

Now let $(x_0, t_0) \in \partial\{u_\lambda > 0\}$. Then

$$\begin{aligned}\limsup_{\Omega_\lambda \ni (x,t) \to (x_0,t_0)} |\nabla u_\lambda(x,t)| &= \limsup_{\Omega \ni (\lambda x, \lambda^2 t) \to (\lambda x_0, \lambda^2 t_0)} \left| \frac{\lambda}{\lambda'} \nabla u(\lambda x, \lambda^2 t) \right| \\ &\le \frac{\lambda}{\lambda'} \sqrt{2M(\lambda x_0, \lambda^2 t_0)} \le \sqrt{2M(x_0,t_0)} - \left(1 - \frac{\lambda}{\lambda'}\right)\sqrt{2M_0},\end{aligned}$$

where $0 < M_0 < M(x,t)$ in $\mathbb{R}^N \times (0,T)$.

On the other hand, since $\lambda\Omega_0 \subset\subset \Omega_0$, there holds that

$$u_0(\lambda x) \geq \gamma > 0 \qquad \text{if } x \in \Omega_0.$$

Thus, for $x \in \Omega_0$,

$$\begin{aligned} u_\lambda(x,0) = \frac{1}{\lambda'} u_0(\lambda x) &= u_0(\lambda x) + \Big(\frac{1}{\lambda'} - 1\Big) u_0(\lambda x) \\ &\geq u_0(x) + \Big(\frac{1}{\lambda'} - 1\Big)\gamma. \end{aligned}$$

The following comparison lemma for problem (P) can be proved as Lemma 2.4 in [9]. We omit the proof.

LEMMA 2.1. *Let u_0 satisfy* (2.1) *and w_0 satisfy* (2.2). *Then every classical subsolution of* (P) *with bounded support is smaller than every classical supersolution of* (P)*; i.e., if u' is a classical subsolution such that Ω' is bounded and u is a classical supersolution, then*

$$\Omega' \subset \Omega \quad \textit{and} \quad u' \leq u,$$

where $\Omega' = \{u' > 0\}$ and $\Omega = \{u > 0\}$.

3. Auxiliary results. This section contains results on the following problem:

$$\Delta u - u_t = (u + \omega_0) f(u), \tag{P_0}$$

where the function f is as in section 1 and ω_0 is a constant, $\omega_0 > -1$. The results will be used in the next sections where (P_0) appears as a blow-up limit. The proofs are very similar to those of Lemmas 4.1, 4.3, and 4.4 in [7]. We leave the details to the reader.

LEMMA 3.1. *Let $a, b \geq 0$, and let ψ be the classical solution to*

$$\begin{aligned} &\psi_{ss} = (\psi + \omega_0) f(\psi) \quad \textit{for } s > 0, \\ &\psi(0) = a, \quad \psi_s(0) = -\sqrt{2b}. \end{aligned} \tag{3.1}$$

Let $B(\tau) = \int_{-\omega_0}^{\tau} (\rho + \omega_0) f(\rho)\, d\rho$.

(3.2) *If $b = 0$ and $a \in \{-\omega_0\} \cup [1, +\infty)$, then $\psi \equiv a$.*

(3.3) *If $b = 0$ and $a \in (-\omega_0, 1)$, then $\lim_{s\to+\infty} \psi(s) = +\infty$.*

(3.4) *If $b \in \big(0,\, B(a)\big)$, then $\lim_{s\to+\infty} \psi(s) = +\infty$.*

(3.5) *If $0 < b = B(a)$, then $\psi_s < 0$ and $\lim_{s\to+\infty} \psi(s) = -\omega_0$.*

(3.6) *If $b \in \big(B(a),\, +\infty\big)$, then $\psi_s < 0$ and $\lim_{s\to+\infty} \psi(s) = -\infty$.*

LEMMA 3.2. *Let $B(\tau)$ be as in the previous lemma, let $\mathcal{R}_\gamma = \big\{(x,t) \in \mathbb{R}^{N+1} / x_1 > 0\,,\, -\infty < t \leq \gamma\big\}$, $0 \leq \theta < 1 + \omega_0$, and let $U \in C^{2+\alpha, 1+\frac{\alpha}{2}}(\overline{\mathcal{R}_\gamma})$ be such that*

$$\begin{aligned} \Delta U - U_t = (U + \omega_0) f(U) \quad &\textit{in } \mathcal{R}_\gamma, \\ U = 1 - \theta \quad &\textit{on } \{x_1 = 0\}, \\ -\omega_0 \leq U \leq 1 - \theta \quad &\textit{in } \overline{\mathcal{R}_\gamma}. \end{aligned}$$

(1) *If $\theta = 0$, then $|\nabla U| \leq \sqrt{2B(1)}$ on $\{x_1 = 0\}$.*

(2) *If $0 < \theta < 1 + \omega_0$ and $0 < \sigma < B(1)$ are such that $\int_{-\omega_0}^{1-\theta} (\rho + \omega_0) f(\rho)\, d\rho = B(1) - \sigma$, then $|\nabla U| = \sqrt{2(B(1) - \sigma)}$ on $\{x_1 = 0\}$.*

Finally, we state a compactness result.

LEMMA 3.3. *Let ε_j, γ_{ε_j}, and τ_{ε_j} be sequences such that $\varepsilon_j > 0$, $\varepsilon_j \to 0$, $\gamma_{\varepsilon_j} > 0$, $\gamma_{\varepsilon_j} \to \gamma$, with $0 \le \gamma \le +\infty$, $\tau_{\varepsilon_j} > 0$, $\tau_{\varepsilon_j} \to \tau$ with $0 \le \tau \le +\infty$, and such that $\tau < +\infty$ implies that $\gamma = +\infty$. Assume that $w^{\varepsilon_j}/\varepsilon_j$ converge to w_0 uniformly in compact sets of $\mathbb{R}^N \times [0,T]$. Let $\rho > 0$ and*

$$\mathcal{A}_{\varepsilon_j} = \left\{ (x,t) \ / \ |x| < \frac{\rho}{\varepsilon_j} \, , \ -\min\left(\tau_{\varepsilon_j}, \frac{\rho^2}{\varepsilon_j^2}\right) < t < \min\left(\gamma_{\varepsilon_j}, \frac{\rho^2}{\varepsilon_j^2}\right) \right\}.$$

Let $(x_0,t_0) \in \mathbb{R}^N \times [0,T]$. Assume that $0 \le \theta < 1 + w_0(x_0,t_0)$, and let $\bar{u}^{\varepsilon_j}$ be weak solutions to

$$\begin{aligned}
&\Delta \bar{u}^{\varepsilon_j} - \bar{u}_t^{\varepsilon_j} = \left(\bar{u}^{\varepsilon_j} + \frac{w^{\varepsilon_j}(\varepsilon_j x + x_{\varepsilon_j}, \varepsilon_j^2 t + t_{\varepsilon_j})}{\varepsilon_j} \right) f(\bar{u}^{\varepsilon_j}) \text{ in } \{x_1 > \bar{h}_{\varepsilon_j}(x',t)\} \cap \mathcal{A}_{\varepsilon_j}, \\
&\bar{u}^{\varepsilon_j} = 1 - \theta \quad \text{on } \{x_1 = \bar{h}_{\varepsilon_j}(x',t)\} \cap \mathcal{A}_{\varepsilon_j}, \\
&-\frac{w^{\varepsilon_j}(\varepsilon_j x + x_{\varepsilon_j}, \varepsilon_j^2 t + t_{\varepsilon_j})}{\varepsilon_j} \le \bar{u}^{\varepsilon_j} \le 1 - \theta \quad \text{in } \{x_1 \ge \bar{h}_{\varepsilon_j}(x',t)\} \cap \overline{\mathcal{A}_{\varepsilon_j}},
\end{aligned}$$

where $(x_{\varepsilon_j}, t_{\varepsilon_j}) \to (x_0,t_0)$, with $\bar{u}^{\varepsilon_j} \in C(\{x_1 \ge \bar{h}_{\varepsilon_j}(x',t)\} \cap \overline{\mathcal{A}_{\varepsilon_j}})$, and $\nabla \bar{u}^{\varepsilon_j} \in L^2$. Here $\bar{h}_{\varepsilon_j}$ are continuous functions such that $\bar{h}_{\varepsilon_j}(0,0) = 0$ with $\bar{h}_{\varepsilon_j} \to 0$ uniformly on compact subsets of $\mathbb{R}^{N-1} \times (-\tau, \gamma)$. Moreover, we assume that $\|\bar{h}_{\varepsilon_j}\|_{C^1(K)} + \|\nabla_{x'} \bar{h}_{\varepsilon_j}\|_{C^{\alpha, \frac{\alpha}{2}}(K)}$ are uniformly bounded for every compact set $K \subset \mathbb{R}^{N-1} \times (-\tau, \gamma)$.

Then there exists a function $\bar{u}$ such that, for a subsequence,

$$\begin{aligned}
&\bar{u} \in C^{2+\alpha, 1+\frac{\alpha}{2}}\big(\{x_1 \ge 0, \, \gamma > t > -\tau\}\big), \\
&\bar{u}^{\varepsilon_j} \to \bar{u} \quad \text{uniformly on compact subsets of } \{x_1 > 0, \, \gamma > t > -\tau\}, \\
&\begin{aligned}
&\Delta \bar{u} - \bar{u}_t = (\bar{u} + w_0(x_0,t_0)) f(\bar{u}) && \text{in } \{x_1 > 0, \, \gamma > t > -\tau\}, \\
&\bar{u} = 1 - \theta && \text{on } \{x_1 = 0, \, \gamma > t > -\tau\}, \\
&-w_0(x_0,t_0) \le \bar{u} \le 1 - \theta && \text{in } \{x_1 \ge 0, \, \gamma > t > -\tau\}.
\end{aligned}
\end{aligned}$$

If $\gamma < +\infty$, we require, in addition, that

$$\|\bar{h}_{\varepsilon_j}(x', t + \gamma_{\varepsilon_j} - \gamma)\|_{C^1(K)} + \|\nabla_{x'} \bar{h}_{\varepsilon_j}(x', t + \gamma_{\varepsilon_j} - \gamma)\|_{C^{\alpha, \frac{\alpha}{2}}(K)}$$

be uniformly bounded for every compact set $K \subset \mathbb{R}^{N-1} \times (-\infty, \gamma]$. We deduce that

$$\bar{u} \in C^{2+\alpha, 1+\frac{\alpha}{2}}\big(\{x_1 \ge 0, \, t \le \gamma\}\big).$$

If $\tau < +\infty$, we let

$$\mathcal{B}_{\varepsilon_j} = \left\{ x \ / \ |x| < \frac{\rho}{\varepsilon_j} \, , \ x_1 > \bar{h}_{\varepsilon_j}(x', -\tau_{\varepsilon_j}) \right\},$$

and we require, in addition, that for every $R > 0$,

$$\|\bar{u}^{\varepsilon_j}(x, -\tau_{\varepsilon_j})\|_{C^\alpha\left(\overline{\mathcal{B}}_{\varepsilon_j} \cap \overline{B}_R(0)\right)} \le C_R,$$

and that there exists $r > 0$ such that

$$\|\bar{u}^{\varepsilon_j}(x, -\tau_{\varepsilon_j})\|_{C^{1+\alpha}\left(\overline{\mathcal{B}}_{\varepsilon_j} \cap \overline{B}_r(0)\right)} \le C_r.$$

Moreover, we assume that $\|\bar{h}_{\varepsilon_j}(x', t-\tau_{\varepsilon_j}+\tau)\|_{C^1(K)} + \|\nabla_{x'}\bar{h}_{\varepsilon_j}(x', t-\tau_{\varepsilon_j}+\tau)\|_{C^{\alpha,\frac{\alpha}{2}}(K)}$ *are uniformly bounded for every compact set* $K \subset \mathbb{R}^{N-1}\times[-\tau,+\infty)$.

Then there holds that

$$\bar{u} \in C^{\alpha,\frac{\alpha}{2}}\big(\{x_1 \geq 0,\, t \geq -\tau\}\big),\ \nabla\bar{u} \in C\big(\{0 \leq x_1 < r,\, t \geq -\tau\}\big),$$
$$\bar{u}^{\varepsilon_j}(x, -\tau_{\varepsilon_j}) \to \bar{u}(x,-\tau) \quad \textit{uniformly on compact subsets of } \{x_1 > 0\}.$$

In any case (τ, γ *be infinite or finite*)

$$|\nabla\bar{u}^{\varepsilon_j}(0,0)| \to |\nabla\bar{u}(0,0)|.$$

4. Approximation result. In this section we prove that, under certain assumptions, a classical supersolution to problem (P) is the uniform limit of a family of supersolutions to problem (P_ε) (Theorem 4.1), and we prove an analogous result for subsolutions (Theorem 4.2). Also, we prove that for compactly supported initial data, limit solutions have bounded support (Proposition 4.1).

The following construction follows the lines of Theorem 5.2 in [7]. In our case we have to be more careful with the construction of the initial data.

THEOREM 4.1. *Let* $\widetilde{u}$ *be a classical supersolution to* (P) *in* Q_T *with* $\widetilde{u} \in C^1(\overline{\{\widetilde{u}>0\}})$ *and such that* $\{\widetilde{u} > 0\}$ *is bounded. Assume, in addition, that there exist* $\delta_0, s_0 > 0$ *such that*

$$|\nabla\widetilde{u}^+| \leq \sqrt{2M(x,t)-\delta_0} \quad \textit{on } Q \cap \partial\{\widetilde{u}>0\},$$
$$|\nabla\widetilde{u}| > \delta_0 \quad \textit{in } Q \cap \{0 < \widetilde{u} < s_0\}.$$

Let w^ε *be a solution of the heat equation in* $\mathbb{R}^N\times(0,T)$ *such that* $\frac{w^\varepsilon(x,t)}{\varepsilon} \to w_0(x,t)$ *uniformly in* $\mathbb{R}^N\times[0,T]$ *with* $w_0 \in C(\mathbb{R}^N\times[0,T])$ *and* $w_0 \geq -1+\delta_1$ *for a certain positive constant* δ_1.

Then there exists a family $u^\varepsilon \in C(\overline{Q_T})$, *with* $\nabla u^\varepsilon \in L^2_{\mathrm{loc}}(\overline{Q_T})$, *of weak supersolutions to* (P_ε) *in* Q_T *such that, as* $\varepsilon \to 0$, $u^\varepsilon \to \widetilde{u}$ *uniformly in* $\overline{Q_T}$.

Proof.

Step 1. Construction of the family u^ε. Let $0 < \theta < \delta_1$ be such that

$$\int_{1-\theta}^{1}(s+W)f(s)\,ds = \frac{\delta_0}{8},$$

where W is a suitable uniform bound of $\|w^\varepsilon/\varepsilon\|_{L^\infty(\{\widetilde{u}>0\})}$. For every $\varepsilon > 0$ small, we define the domain $D^\varepsilon = \{\widetilde{u} < (1-\theta)\varepsilon\} \subset Q_T$.

Let z^ε be the bounded solution to

$$\Delta z^\varepsilon - z^\varepsilon_t = (z^\varepsilon + w^\varepsilon)f_\varepsilon(z^\varepsilon) \quad \text{in } D^\varepsilon,$$

with boundary data

$$z^\varepsilon(x,t) = \begin{cases} (1-\theta)\varepsilon & \text{on } \partial D^\varepsilon \cap t > 0, \\ z_0^\varepsilon(x) & \text{in } D^\varepsilon \cap \{t=0\}. \end{cases}$$

In order to give the initial data z_0^ε, we let $\psi^\varepsilon(s,x)$ be the solution to (3.1) with

$$a = 1-\theta, \quad b = \int_{-w^\varepsilon(x,0)/\varepsilon}^{1-\theta}\left(s + \frac{w^\varepsilon(x,0)}{\varepsilon}\right)f(s)\,ds, \quad \omega_0 = \frac{w^\varepsilon(x,0)}{\varepsilon}.$$

Assume first that $|\nabla\widetilde{u}|$ is smooth. Then, by extending $|\nabla\tilde{u}(x,0)|$ to the whole $\mathbb{R}^N$ as a positive function, we let

$$\varphi^\varepsilon(\xi,x)=\psi^\varepsilon\left(\frac{1-\theta-\xi}{|\nabla\widetilde{u}(x,0)|},x\right),$$

and we define

$$z_0^\varepsilon(x)=\varepsilon\varphi^\varepsilon\left(\frac{1}{\varepsilon}\widetilde{u}(x,0),x\right).$$

If $\widetilde{u}$ is not regular enough, we can replace $|\nabla\widetilde{u}(x,0)|$ by a smooth approximation $F_\varepsilon(x)$ so that the initial datum z_0^ε is $C^{1+\alpha}$. We leave the details to the reader.

Finally, we define the family u^ε as follows:

$$u^\varepsilon=\begin{cases}\widetilde{u} & \text{in } \{\widetilde{u}\geq(1-\theta)\varepsilon\},\\ z^\varepsilon & \text{in } \overline{D^\varepsilon}.\end{cases}$$

Step 2. Passage to the limit. If $(x,0)\in\overline{D^\varepsilon}$, then we have $0\leq\frac{1}{\varepsilon}\widetilde{u}(x,0)\leq 1-\theta$. Since, from Lemma 3.1, we know that $-w^\varepsilon(x,0)/\varepsilon\leq\psi^\varepsilon(s,x)\leq 1-\theta$ for $s\geq 0$, it follows that $-w^\varepsilon(x,0)\leq z^\varepsilon(x,0)\leq(1-\theta)\varepsilon$. Since $f_\varepsilon(s)\geq 0$, constant functions larger than $-w^\varepsilon(x,t)$ are supersolutions to (P_ε). Therefore, $(1-\theta)\varepsilon$ is a supersolution if $\varepsilon<\varepsilon_1$, for some $\varepsilon_1>0$, and we may apply the comparison principle for bounded super- and subsolutions of (P_ε) to conclude that $-w^\varepsilon\leq z^\varepsilon\leq(1-\theta)\varepsilon$.

Hence,

$$\sup_{\overline{Q_T}}|u^\varepsilon-\widetilde{u}|=\sup_{D^\varepsilon}|z^\varepsilon-\widetilde{u}|\leq C\varepsilon,$$

and therefore the convergence of the family u^ε follows.

Step 3. Let us show that there exists $\varepsilon_0>0$ such that the functions u^ε are supersolutions to (P_ε) for $\varepsilon<\varepsilon_0$.

If $u^\varepsilon>(1-\theta)\varepsilon$, then $u^\varepsilon=\widetilde{u}$, which by hypothesis is supercaloric. Since $f_\varepsilon(s)\geq 0$ and $(1-\theta)\varepsilon\geq-w^\varepsilon$ if $\varepsilon<\varepsilon_1$, it follows that u^ε are supersolutions to (P_ε) here.

If $u^\varepsilon<(1-\theta)\varepsilon$, then we are in D^ε, and therefore, by construction, u^ε are solutions to (P_ε).

That is, the u^ε's are continuous functions, and they are piecewise supersolutions to (P_ε). In order to see that u^ε are globally supersolutions to (P_ε), it suffices to see that the jumps of the gradients (which occur at smooth surfaces) have the right sign.

To this effect, we will show that there exists $\varepsilon_0>0$ such that

$$|\nabla u^\varepsilon|\geq\sqrt{2M(x,t)-\delta_0/2}\quad\text{on }\partial\{\widetilde{u}<(1-\theta)\varepsilon\}\ \text{ for }\varepsilon<\varepsilon_0. \tag{4.1}$$

Assume that (4.1) does not hold. Then, for every $j\in\mathbb{N}$, there exist $\varepsilon_j>0$ and $(x_{\varepsilon_j},t_{\varepsilon_j})\in Q$, with

$$\varepsilon_j\to 0\quad\text{and}\quad(x_{\varepsilon_j},t_{\varepsilon_j})\to(x_0,t_0)\in\partial\{\widetilde{u}>0\},$$

such that

$$u^{\varepsilon_j}(x_{\varepsilon_j},t_{\varepsilon_j})=(1-\theta)\varepsilon_j\quad\text{and}\quad|\nabla u^{\varepsilon_j}(x_{\varepsilon_j},t_{\varepsilon_j})|<\sqrt{2M(x_{\varepsilon_j},t_{\varepsilon_j})-\delta_0/2}. \tag{4.2}$$

From now on we will drop the subscript j when referring to the sequences defined above, and $\varepsilon \to 0$ will mean $j \to \infty$.

We can assume (performing a rotation in the space variables if necessary) that there exists a family g_ε of smooth functions such that, in a neighborhood of $(x_\varepsilon, t_\varepsilon)$,

$$\begin{aligned} &\{u^\varepsilon = (1-\theta)\varepsilon\} = \{(x,t) \,/\, x_1 - x_{\varepsilon 1} = g_\varepsilon(x' - x_\varepsilon{}', t - t_\varepsilon)\}, \\ &\{u^\varepsilon < (1-\theta)\varepsilon\} = \{(x,t) \,/\, x_1 - x_{\varepsilon 1} > g_\varepsilon(x' - x_\varepsilon{}', t - t_\varepsilon)\}, \end{aligned} \tag{4.3}$$

where there holds that

$$g_\varepsilon(0,0) = 0, \quad |\nabla_{x'} g_\varepsilon(0,0)| \to 0, \quad \varepsilon \to 0.$$

We can assume that (4.3) holds in $\big(B_\rho(x_\varepsilon) \times (t_\varepsilon - \rho^2, t_\varepsilon + \rho^2)\big) \cap \{0 \le t \le T\}$ for some $\rho > 0$.

Let us now define

$$\bar{u}^\varepsilon(x,t) = \frac{1}{\varepsilon} u^\varepsilon(x_\varepsilon + \varepsilon x, t_\varepsilon + \varepsilon^2 t), \quad \bar{g}_\varepsilon(x',t) = \frac{1}{\varepsilon} g_\varepsilon(\varepsilon x', \varepsilon^2 t),$$

and let

$$\tau_\varepsilon = \frac{t_\varepsilon}{\varepsilon^2}, \quad \gamma_\varepsilon = \frac{T - t_\varepsilon}{\varepsilon^2}.$$

We have, for a subsequence,

$$\tau_\varepsilon \to \tau, \quad \gamma_\varepsilon \to \gamma,$$

where $0 \le \tau, \gamma \le +\infty$, and τ and γ cannot be both finite.

We now let

$$\mathcal{A}_\varepsilon = \left\{ (x,t) \;/\; |x| < \frac{\rho}{\varepsilon}, \; -\min\left(\tau_\varepsilon, \frac{\rho^2}{\varepsilon^2}\right) < t < \min\left(\gamma_\varepsilon, \frac{\rho^2}{\varepsilon^2}\right) \right\}.$$

Then the functions $\bar{u}^\varepsilon$ are weak solutions to

$$\begin{aligned} &\Delta \bar{u}^\varepsilon - \bar{u}^\varepsilon_t = \left(\bar{u}^\varepsilon + \frac{w^\varepsilon(x_\varepsilon + \varepsilon x, t_\varepsilon + \varepsilon^2 t)}{\varepsilon}\right) f(\bar{u}^\varepsilon) && \text{in } \{x_1 > \bar{g}_\varepsilon(x',t)\} \cap \mathcal{A}_\varepsilon, \\ &\bar{u}^\varepsilon = 1 - \theta && \text{on } \{x_1 = \bar{g}_\varepsilon(x',t)\} \cap \mathcal{A}_\varepsilon, \\ &-\frac{w^\varepsilon(x_\varepsilon + \varepsilon x, t_\varepsilon + \varepsilon^2 t)}{\varepsilon} \le \bar{u}^\varepsilon \le 1 - \theta && \text{in } \{x_1 \ge \bar{g}_\varepsilon(x',t)\} \cap \overline{\mathcal{A}_\varepsilon}. \end{aligned}$$

Note that we are under the hypotheses of Lemma 3.3. Then there exists a function $\bar{u}$ such that, for a subsequence,

$$\begin{aligned} &\bar{u} \in C^{2+\alpha, 1+\frac{\alpha}{2}}\big(\{x_1 \ge 0, \, -\tau < t < \gamma\}\big), \\ &\bar{u}^\varepsilon \to \bar{u} \quad \text{uniformly on compact subsets of } \{x_1 > 0, \, -\tau < t < \gamma\}, \\ &\Delta \bar{u} - \bar{u}_t = (\bar{u} + w_0(x_0,t_0)) f(\bar{u}) && \text{in } \{x_1 > 0, \, -\tau < t < \gamma\}, \\ &\bar{u} = 1 - \theta && \text{on } \{x_1 = 0, \, -\tau < t < \gamma\}, \\ &-w_0(x_0,t_0) \le \bar{u} \le 1 - \theta && \text{in } \{x_1 \ge 0, \, -\tau < t < \gamma\}. \end{aligned}$$

We will divide the remainder of the proof into two cases, depending on whether $\tau = +\infty$ or $\tau < +\infty$.

Case 1. Assume $\tau = +\infty$.

In this case, Lemma 3.3 also gives

$$|\nabla \bar{u}^\varepsilon(0,0)| \to |\nabla \bar{u}(0,0)|.$$

On the other hand, $\bar{u}$ satisfies the hypotheses of Lemma 3.2, and therefore

$$|\nabla \bar{u}| \geq \sqrt{2M(x_0,t_0) - \delta_0/4} \quad \text{on } \{x_1 = 0\},$$

which yields

$$|\nabla \bar{u}^\varepsilon(0,0)| \geq \sqrt{2M(x_0,t_0) - 3\delta_0/8}$$

for ε small. But this gives

$$|\nabla u^\varepsilon(x_\varepsilon,t_\varepsilon)| \geq \sqrt{2M(x_\varepsilon,t_\varepsilon) - \delta_0/2}$$

for ε small. This contradicts (4.2) and completes the proof in case $\tau = +\infty$.

Case 2. Assume $\tau < +\infty$. (In this case $\gamma = +\infty$.)

There holds that $\bar{u}^\varepsilon(x,-\tau_\varepsilon) = \frac{1}{\varepsilon} u^\varepsilon(x_\varepsilon + \varepsilon x, 0)$; then

$$\bar{u}^\varepsilon(x,-\tau_\varepsilon) = \varphi^\varepsilon \left(\frac{1}{\varepsilon} \widetilde{u}(x_\varepsilon + \varepsilon x, 0), x_\varepsilon + \varepsilon x \right). \tag{4.4}$$

Here we want to apply the result of Lemma 3.3 corresponding to $\tau < +\infty$. In fact, we can see that there exist $C, r > 0$ such that $\|\bar{u}^\varepsilon(\cdot,-\tau_\varepsilon)\|_{C^{1+\alpha}(\overline{B}_r(0))} \leq C$.

Now Lemma 3.3 gives, for a subsequence,

$$\bar{u} \in C^{\alpha,\frac{\alpha}{2}}\big(\{x_1 \geq 0,\, t \geq -\tau\}\big),$$
$$\bar{u}^\varepsilon(x,-\tau_\varepsilon) \to \bar{u}(x,-\tau) \quad \text{uniformly on compact subsets of } \{x_1 > 0\}.$$

Therefore, we get that (recall that in the case we are considering $t_0 = 0$)

$$\bar{u}(x,-\tau) = \bar{\varphi}\Big(1 - \theta - |\nabla \widetilde{u}^+(x_0,t_0)|\, x_1, x_0\Big),$$

where $\bar{\varphi}(s,x) = \psi(\frac{1-\theta-s}{|\nabla \widetilde{u}(x,0)|}, x)$ and $\psi(s,x)$ is the solution of (3.1) with

$$a = 1-\theta, \quad b = \int_{-w_0(x,0)}^{1-\theta} (s + w_0(x,0)) f(s)\, ds, \quad \omega_0 = w_0(x,0).$$

Thus,

$$\bar{u}(x,-\tau) = \psi(x_1,x_0).$$

Since the function $\psi(x_1,x_0)$ is a stationary solution to equation (P_0), bounded for $x_1 \geq 0$, and $\bar{u} = \psi$ on the parabolic boundary of the domain $\{x_1 > 0,\, t > -\tau\}$, we conclude that

$$\bar{u}(x,t) = \psi(x_1,x_0) \quad \text{in } \{x_1 \geq 0,\, t \geq -\tau\}.$$

It follows from Lemma 3.1 and the choice of θ that

$$\frac{1}{2}|\nabla \bar{u}(0,0)|^2 = \frac{1}{2}\big(\psi_s(0,x_0)\big)^2 = \int_{-w_0(x_0,t_0)}^{1-\theta} (s + w_0(x_0,t_0)) f(s)\, ds \geq M(x_0,t_0) - \frac{\delta_0}{8}.$$

That is,

$$|\nabla \bar{u}| \geq \sqrt{2M(x_0,t_0) - \delta_0/4} \quad \text{on } \{x_1 = 0, t \geq -\tau\}.$$

But Lemma 3.3 gives

$$|\nabla \bar{u}^\varepsilon(0,0)| \to |\nabla \bar{u}(0,0)|,$$

which yields

$$|\nabla \bar{u}^\varepsilon(0,0)| \geq \sqrt{2M(x_0,t_0) - 3\delta_0/8}$$

for ε small. Then

$$|\nabla u^\varepsilon(x_\varepsilon,t_\varepsilon)| \geq \sqrt{2M(x_\varepsilon,t_\varepsilon) - \delta_0/2}$$

for ε small. This contradicts (4.2) and completes the proof in case $\tau < +\infty$. □

Remark 4.1. Observe that from the construction of u^ε done in the previous proof it follows that

$$u^\varepsilon \equiv \widetilde{u} \qquad \text{in } \{\widetilde{u} > (1-\theta)\varepsilon\}.$$

THEOREM 4.2. *Let $\widetilde{u}$ be a classical subsolution to* (P) *in Q_T with $\widetilde{u} \in C^1(\overline{\{\widetilde{u} > 0\}})$ such that $\{\widetilde{u} > 0\}$ is bounded. Assume, in addition, that there exist $\delta_0 > 0$ such that*

$$|\nabla \widetilde{u}^+| \geq \sqrt{2M(x,t) + \delta_0} \quad \text{on } Q \cap \partial\{\widetilde{u} > 0\}.$$

Let w^ε be a solution of the heat equation in $\mathbb{R}^N \times (0,T)$ such that $\frac{w^\varepsilon(x,t)}{\varepsilon} \to w_0(x,t)$ uniformly in $\mathbb{R}^N \times [0,T]$. Assume, moreover, that $w_0 \in C(\mathbb{R}^N \times [0,T])$ and $w_0(x,t) \geq -1 + \delta_1$ for a certain positive constant δ_1.

Then there exists a family $u^\varepsilon \in C(\overline{Q_T})$, with $\nabla u^\varepsilon \in L^2_{\mathrm{loc}}(\overline{Q_T})$, of weak subsolutions to (P_ε) *in Q_T such that, as $\varepsilon \to 0$, $u^\varepsilon \to \widetilde{u}$ uniformly in $\overline{Q_T}$.*

Proof. The proof is analogous to Theorem 4.1. See [7] for a similar result in the case $w^\varepsilon = 0$. □

Finally, we end this section by showing that, for compactly supported initial data, the support of a limit solution of problem (P) is bounded.

PROPOSITION 4.1. *Let $u_0 \in C(\mathbb{R}^N)$ with compact support. Let u_0^ε converge uniformly to u_0 with supports converging to the support of u_0, and let w^ε be a solution of the heat equation in $\mathbb{R}^N \times (0,T)$ such that $\frac{w^\varepsilon(x,t)}{\varepsilon} \to w_0(x,t)$ uniformly in $\mathbb{R}^N \times [0,T]$. Assume, moreover, that $w_0 \in C(\mathbb{R}^N \times [0,T])$ and $w_0(x,t) \geq -1 + \delta_1$ for a certain positive constant δ_1. Finally, let u^ε be the solution to* (P_ε) *with function w^ε and initial condition u_0^ε.*

Let $u = \lim u^{\varepsilon_j}$. Then $\{u > 0\}$ is bounded. Moreover, u vanishes in finite time.

Proof. Let $-1 < \omega_0 < w^\varepsilon(x,t)/\varepsilon$. Then it is easy to check that

$$M_{\omega_0} = \int_{-\omega_0}^1 (s+\omega_0) f(s)\, ds < M(x,t) = \int_{-w_0(x,t)}^1 (s + w_0(x,t)) f(s)\, ds. \tag{4.5}$$

Let us now consider the following self-similar function:

$$V(x,t;T) = (T-t)^{1/2} h(|x|(T-t)^{-1/2}),$$

where $h = h(r)$ is a solution of

$$
\begin{aligned}
&h'' + \left(\frac{N-1}{r} + \frac{1}{2}r\right)h' + \frac{1}{2}h = 0, \quad 0 < r < R,\\
&h'(0) = 0, \quad h(r) > 0, \quad 0 \le r < R,\\
&h(R) = 0, \quad h'(R) = -\sqrt{2M_{\omega_0}}.
\end{aligned} \tag{4.6}
$$

It is proved in [4, Proposition 1.1] that there exists a unique $R > 0$ and a unique h solution of (4.6).

Moreover, it can be checked that if one picks T sufficiently large, then

$$V(x, 0; T) \ge u_0 + 1 \quad \text{in } \{u_0 > 0\},$$

and so $V(x, t; T)$ is a strict classical supersolution of (P) with bounded support and a positive gradient near its free boundary.

Now let u^{ε_j} be solutions to $(\mathrm{P}_{\varepsilon_j})$, with initial data $u_0^{\varepsilon_j}$ converging uniformly to u_0 such that support $u_0^{\varepsilon_j} \to$ support u_0 such that $u = \lim u^{\varepsilon_j}$.

By Theorem 4.1, there exists a family v^{ε_j} of supersolutions of $(\mathrm{P}_{\varepsilon_j})$ such that $v^{\varepsilon_j} \to V$ uniformly on compact sets, and $v^{\varepsilon_j}(x, 0) \ge u^{\varepsilon_j}(x, 0)$. Therefore, by the comparison principle, we obtain $u^{\varepsilon_j} \le v^{\varepsilon_j}$ and, passing to the limit, $u(x, t) \le V(x, t; T)$; the result follows. □

5. Uniqueness of the limit solution. In this section we arrive at the main point of the article: we prove that, under certain assumptions, there exists at most one limit solution to the initial and boundary value problem associated with (P) as long as condition (1.2) is satisfied.

Let us begin with the following proposition, which is the key ingredient in the proof of our main result.

PROPOSITION 5.1. *Let $\widetilde{u}$ be a strict classical supersolution to* (P) *with bounded support in $\mathbb{R}^N \times (0, T)$ such that there exists $s_0 > 0$ so that $|\nabla \widetilde{u}| > 0$ in $\{0 < \widetilde{u} < s_0\}$, and let $w^\varepsilon/\varepsilon$ be solutions to the heat equation in $\mathbb{R}^N \times (0, T)$ converging to w_0 uniformly with $w_0 \in C(\mathbb{R}^N \times [0, T])$ and $w_0 \ge -1 + \delta_1$ for a certain positive constant δ_1.*

Let u^ε be solutions to (P_ε) *with function w^ε and initial condition u_0^ε, where u_0^ε are uniform approximations of u_0 with* support $u_0^\varepsilon \to$ support u_0. *Then*

$$\limsup_{\varepsilon \to 0+} u^\varepsilon(x, t) \le \widetilde{u}(x, t)$$

for every $(x, t) \in Q_T$.

Proof. Let $\widetilde{u}$ be a strict classical supersolution of (P). Let us first define the following regularization:

$$u(x, t) = (\widetilde{u}(x, t + h) - \eta)^+$$

for $h, \eta > 0$ small so that u is a strict classical supersolution of (P) with C_x^1 free boundary, $C^1(\overline{\{u > 0\}})$, and $|\nabla u| > \delta_0 > 0$ in a neighborhood of its free boundary. So, by Theorem 4.1, there exists a v^ε supersolution of (P_ε) such that $v^\varepsilon \to u$ uniformly in Q_{T-h}.

Now, using the comparison principle, we conclude that $u^\varepsilon \le v^\varepsilon$ in Q_{T-h}, and the proposition now follows letting first $\varepsilon \to 0+$ and then $h, \eta \to 0+$. □

Finally, we arrive at the main point of the paper: the uniqueness of limit solutions of (P).

THEOREM 5.1. *Let the initial datum u_0 be Lipschitz continuous with compact support and satisfy condition* (2.1). *Then there exists at most one limit solution such that its gradient does not vanish near its free boundary as long as the function w^ε in problem* (P_ε) *satisfies condition* (1.3).

More precisely, let $u_0^{\varepsilon_j}, \tilde{u}_0^{\varepsilon_k}$ be uniformly Lipschitz continuous in $\mathbb{R}^N$ with uniformly bounded Lipschitz norms and $\varepsilon_j, \varepsilon_k \to 0$. Assume that $u_0^{\varepsilon_j} \in C^1(\overline{\{u_0^{\varepsilon_j} > 0\}})$, $\tilde{u}_0^{\varepsilon_k} \in C^1(\overline{\{\tilde{u}_0^{\varepsilon_k} > 0\}})$, $u_0^{\varepsilon_j}, \tilde{u}_0^{\varepsilon_k} \to u_0$ uniformly and support $u_0^{\varepsilon_j}$, support $\tilde{u}_0^{\varepsilon_k} \to$ support u_0. *Let $w^{\varepsilon_j}/\varepsilon_j$ and $\tilde{w}^{\varepsilon_k}/\varepsilon_k$ be solutions of the heat equation converging to the same function $w_0 \in C(\overline{Q_T})$, uniformly bounded from below by $-1+\delta_1$ for a certain positive constant δ_1. Also, assume that w_0 satisfies the monotonicity condition* (2.2).

Let u^{ε_j} (resp., $\tilde{u}^{\varepsilon_k}$) be the solution to ($\mathrm{P}_{\varepsilon_j}$) *with function w^{ε_j} and initial datum $u_0^{\varepsilon_j}$ (resp., the solution to* ($\mathrm{P}_{\varepsilon_k}$) *with function $\tilde{w}^{\varepsilon_k}$ and initial datum $\tilde{u}_0^{\varepsilon_k}$). Let $u = \lim u^{\varepsilon_j}$ and $\tilde{u} = \lim \tilde{u}^{\varepsilon_k}$. If there exists $s_0 > 0$ such that $|\nabla \tilde{u}| > 0$ in $\{0 < \tilde{u} < s_0\}$, then $u \le \tilde{u}$.*

Proof. Since $\tilde{u}$ is a classical supersolution of (P), $\tilde{u} \in C^1(\{\tilde{u} > 0\})$, and, by Proposition 4.1, its support is bounded, the function $\tilde{u}_\lambda$ as defined in (2.3) satisfies the hypotheses of Proposition 5.1 in $Q_{T/\lambda^2} \supset Q_T$. So by letting $\lambda \to 1-$ we arrive at

$$u(x,t) \le \tilde{u}(x,t). \tag{5.1}$$

This finishes the proof. ∎

THEOREM 5.2. *Let the initial datum u_0 be as in Theorem* 5.1. *Assume that there exists a classical solution v to* (P) *with initial datum u_0, and let $u_0^{\varepsilon_j}$ be uniformly Lipschitz continuous in $\mathbb{R}^N$ with $\varepsilon_j \to 0$ such that $u_0^{\varepsilon_j} \in C^1(\overline{\{u_0^{\varepsilon_j} > 0\}})$, $u_0^{\varepsilon_j} \to u_0$ uniformly, and* support $u_0^{\varepsilon_j} \to$ support u_0. *Assume $w^{\varepsilon_j}/\varepsilon_j$ is a solution of the heat equation converging to w_0 uniformly with $w_0 \in C(\mathbb{R}^N \times [0,T])$ and $w_0 \ge -1+\delta_1$ in $\mathbb{R}^N \times (0,T)$ for a certain $\delta_1 > 0$. Also, assume that w_0 satisfies the monotonicity condition* (2.2).

Let u^{ε_j} be the solution to ($\mathrm{P}_{\varepsilon_j}$) *with function w^{ε_j} and initial datum $u_0^{\varepsilon_j}$, and let $u = \lim u^{\varepsilon_j}$. Then $u = v$.*

In particular, there exists at most one classical solution to (P).

Proof. Since u is a classical supersolution to (P) and v is a classical subsolution, Lemma 2.1 applies, and we get that $v \le u$.

On the other hand, if we define v_λ as in (2.3), with $0 < \lambda < \lambda' < 1$, we have that v_λ is a strict classical supersolution. Since v_λ has compact support (see Proposition 4.1) it satisfies the hypotheses of Proposition 5.1. Thus,

$$u = \lim u^{\varepsilon_j} \le v_\lambda.$$

Letting $\lambda \to 1^-$ we obtain the desired result. ∎

6. Conclusions. In this paper we have proved that the limits of sequences of solutions to (P_ε) with different constitutive functions w^ε and initial data u_0^ε coincide, as long as certain monotonicity assumptions are made, if the limits of $w^\varepsilon/\varepsilon$ and of u_0^ε are prescribed.

The monotonicity assumptions are necessary to provide strict classical supersolutions as close as we want to any classical supersolution. This kind of condition was also used with the same purpose, in the case in which $w^\varepsilon = 0$, in [9] and [7]. In the latter, a different geometry was considered; namely, the domain was a cylinder, Neumann boundary conditions were given on the boundary of the cylinder, and monotonicity in

the direction of the cylinder axis was assumed. In [7] it was proved that, if a classical solution exists and $w^\varepsilon = 0$, then it is equal to any limit of solutions to (P_ε).

In our case, this is with $w^\varepsilon \neq 0$ satisfying (1.3) and nondecreasing in the direction of the cylinder axis; the uniqueness result in the presence of a classical solution still holds.

The cylindrical geometry has the advantage of giving the condition of nonvanishing gradient in the positivity set of any limit solution. Since in dimension 2 one can prove that limit solutions are classical supersolutions up to the fixed boundary, the uniqueness of limit solutions follows in this case without further assumptions.

SUFFICIENT CONDITIONS FOR THE EXISTENCE OF VISCOSITY SOLUTIONS FOR NONCONVEX HAMILTONIANS*

GIOVANNI PISANTE†

Abstract. We study a sufficient geometric condition for the existence of a $W^{1,\infty}(\Omega)$ *viscosity solution* of the Hamilton–Jacobi equation

$$\begin{cases} F(Du) = 0 & \text{in} \quad \Omega, \\ u = \varphi & \text{on} \quad \partial\Omega, \end{cases}$$

where $\Omega \subset \mathbb{R}^n$ and $F : \mathbb{R}^n \to \mathbb{R}$ are not necessarily convex.

Key words. Hamilton–Jacobi equations, viscosity solutions

AMS subject classifications. 49L25, 70H20

DOI. 10.1137/S0036141003426902

1. Introduction.

In this paper we consider the Dirichlet problem

$$\begin{cases} F(Du) = 0 & \text{in} \quad \Omega, \\ u = \varphi & \text{on} \quad \partial\Omega, \end{cases} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^n$ is a bounded open set, $F : \mathbb{R}^n \to \mathbb{R}$ is continuous, and $\varphi \in Lip(\partial\Omega)$ (by the notation $\varphi \in Lip(\partial\Omega)$ we mean that there exists a constant $C \geq 0$ such that $|\varphi(x) - \varphi(y)| \leq C|x - y|$ for all $x, y \in \partial\Omega$). In particular, we are interested in the existence of viscosity solutions $u \in W^{1,\infty}(\Omega) \cap C(\overline{\Omega})$ of problem (1.1).

The study of Hamilton–Jacobi equations arises from classical problems in calculus of variations, and the notion of viscosity solution has aroused much interest since its introduction by Crandall and Lions in [11]. In particular, the interest of finding viscosity solutions of problem (1.1) is well known and studied in optimal control theory, differential games theory, etc. (see [1, 2, 9, 10, 21] for further details).

We should remark that the notion of viscosity solution is stronger than that of the almost everywhere solution: indeed, the viscosity method, when it establishes the existence of solutions, at the same time, gives a criterion of selection among them. Moreover, under appropriate hypotheses, we have uniqueness, maximality, stability, and explicit formulas (see [9, 10, 21]).

Here we want to investigate some sufficient geometrical conditions for the existence of $W^{1,\infty}(\Omega) \cap C(\overline{\Omega})$ viscosity solutions of (1.1).

This study has been motivated by a recent paper of Cardaliaguet et al. [6], where they gave a necessary and sufficient geometric condition for the problem (1.1) to admit a $W^{1,\infty}(\Omega)$ viscosity solution, under some restrictive hypotheses on Ω and φ. In particular, they showed that if Ω is convex, $\varphi \in C^1(\overline{\Omega})$, and verifies the compatibility condition

$$D\varphi(x) \in E \cup \operatorname{int} \operatorname{co} E \quad \forall\, x \in \Omega, \tag{1.2}$$

†Dipartimento di Matematica e Applicazioni "Renato Caccioppoli":—Universita Degli, Studi di Napoli "Federico II" Via Cintia, Monte S. Angelo I-80126 Napoli, Italy (pisante@unina.it) and Institut de Mathematiques, EPFL, 1015 Lausanne, Switzerland (giovanni.pisante@epfl.ch).

where $E = \{\xi \in \mathbb{R}^n \mid F(\xi) = 0\}$ and $\operatorname{int}\operatorname{co} E$ is the interior of the convex envelope of E, then the condition

- (G1) $\forall\, y \in \partial\Omega$, where the inward normal, $\nu(y)$, is uniquely defined, there exists $\lambda(y) > 0$ such that

$$D\varphi(y) + \lambda(y)\nu(y) \in E$$

is necessary and sufficient for the existence of $W^{1,\infty}(\Omega)$ viscosity solution of (1.1).

We should remark that, as shown in [15], the compatibility condition (1.2) is sufficient for the existence of infinitely many $W^{1,\infty}(\Omega)$ almost everywhere solutions of problem (1.1); in fact, the aim of [6] was to compare the theory for existence of almost everywhere solutions of implicit partial differential equations developed by Dacorogna and Marcellini (see [12, 13, 14, 15]) with the classical method of viscosity and to investigate the existence of $W^{1,\infty}$ viscosity solutions under assumption (1.2) only.

Our aim goes in a different direction: we want to show that the same type of techniques used in [6] can be refined to obtain a more general result in a more general framework. Moreover, we will see that the compatibility condition (1.2) can also be weakened in order to obtain a condition for the existence of viscosity solutions of equation (1.1).

We will prove that if Ω is bounded and connected, not necessarily convex, $\varphi \in Lip(\partial\Omega)$, and verifies a compatibility condition like (1.2) only on the boundary $\partial\Omega$ (the precise meaning of this condition will also be clarified in what follows), then the geometrical condition (G1) can be replaced by

- (G2) $\forall\, y \in \partial\Omega$, where $N^N_{\mathbb{R}^n\setminus\Omega}(y) \neq \emptyset$ there exists $h \in D^+\varphi(y)$ such that $\forall \nu \in N^N_{\mathbb{R}^n\setminus\Omega}(y)$ there exists a unique $\lambda_{\nu,h} > 0$ such that

$$h + \lambda_{\nu,h}\nu \in E,$$

  where $N^N_{\mathbb{R}^n\setminus\Omega}(y)$ is the normal cone to the set $\mathbb{R}^n \setminus \Omega$ and $D^+\varphi(y)$ is the superdifferential of φ in y (see Definitions 2.1 and 2.5).

In particular, we will see that (G2) is a sufficient condition for the existence of $W^{1,\infty}(\Omega)$ viscosity solutions of (1.1).

We should remark that (G2) strictly extends (G1): indeed, if Ω is convex, $\forall\, y \in \partial\Omega$, where the inward normal, $\nu(y)$, is uniquely defined, we have $N^N_{\mathbb{R}^n\setminus\Omega}(y) = \{\nu(y)\}$, and if $\varphi \in C^1$, then $D^+\varphi(y) = \{D\varphi(y)\}$ (see Remark 2.2 and Proposition 2.6).

REMARK 1.1. *If φ is an affine function, then the condition* (G2) *is also necessary for the existence of viscosity solutions, as it can be deduced by the last section of* [6].

To better understand the conditions (G1) and (G2) one should keep in mind the following examples.

EXAMPLE 1.2. *Let*

$$F_1(\xi_1, \xi_2) = -(\xi_1^2 - 1)^2 - (\xi_2^2 - 1)^2\ ;\ \varphi = 0.$$

Clearly,

$$\begin{cases} E_1 = \{\xi \in \mathbb{R}^2\ :\ \xi_1^2 = \xi_2^2 = 1\} = \{\xi \in \mathbb{R}^2\ :\ F_1(\xi) = 0\}, \\ \operatorname{co} E_1 = \{\xi \in \mathbb{R}^2\ :\ |\xi_1| \le 1\,,\ |\xi_2| \le 1\}, \\ E_1 \subset \partial(\operatorname{co} E_1)\ \ \textit{and}\ \ E_1 \neq \partial(\operatorname{co} E_1). \end{cases}$$

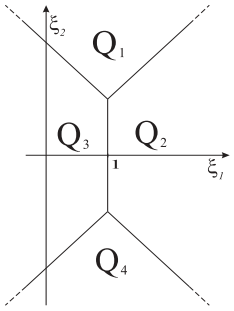

FIG. 1. *Partition of the plane in the definition of f.*

For this classical example the condition (G1) allows us to say that the only convex Ω for which there exists a $W^{1,\infty}(\Omega)$ viscosity solution of

$$\begin{cases} F_1(Du) = 0 & \text{in} \quad \Omega, \\ u = 0 & \text{on} \quad \partial\Omega \end{cases} \tag{1.3}$$

are rectangles whose normals are in E_1. The condition (G2) instead allows us to make this selection among all the sets Ω, convex and not; in particular, there are no $W^{1,\infty}(\Omega)$ viscosity solutions of problem (1.3) if Ω is a nonconvex domain.

EXAMPLE 1.3. *Let $f : \mathbb{R}^2 \to \mathbb{R}$ be a positive continuous function which is zero only on the vertical segment $S = \{(\xi_1, \xi_2) \ : \ \xi_1 = 1, \xi_2 \in [-1, 1]\}$; for instance, we can consider*

$$f(\xi_1, \xi_2) = \begin{cases} \xi_2 - 1 \text{ if } (\xi_1, \xi_2) \in Q_1, \\ \xi_1 - 1 \text{ if } (\xi_1, \xi_2) \in Q_2, \\ -\xi_1 + 1 \text{ if } (\xi_1, \xi_2) \in Q_3, \\ -\xi_2 - 1 \text{ if } (\xi_1, \xi_2) \in Q_4, \end{cases}$$

where Q_i, $i = 1, \dots, 4$, is a partition of the plane as in Figure 1.

Let

$$F_2(\xi_1, \xi_2) = f(\xi_1, \xi_2) F_1(\xi_1, \xi_2) = f(\xi_1, \xi_2)[-(\xi_1^2 - 1)^2 - (\xi_2^2 - 1)^2],$$

where $F_1(\xi_1, \xi_2)$ is the function defined in the previous example and $\varphi = 0$.

Clearly, we have

$$\begin{cases} E_2 = E_1 \cup S = \{\xi \in \mathbb{R}^2 \ : \ F_2(\xi) = 0\}, \\ \operatorname{co} E_2 = \{\xi \in \mathbb{R}^2 \ : \ |\xi_1| \le 1 \, , \, |\xi_2| \le 1\}, \\ E_2 \subset \partial(\operatorname{co} E_2) \ \text{ and } \ E_2 \neq \partial(\operatorname{co} E_2). \end{cases}$$

If we consider the problem

$$\begin{cases} F_2(Du) = 0 & \text{in} \quad \Omega, \\ u = 0 & \text{on} \quad \partial\Omega, \end{cases} \tag{1.4}$$

where Ω is the nonconvex domain as in Figure 2*, we can easily verify the condition* (G2) *that ensures the existence of viscosity solutions. Indeed, since $\varphi = 0$, to verify* (G2) *it is sufficient to show that the sets of directions of the internal normal cone to*

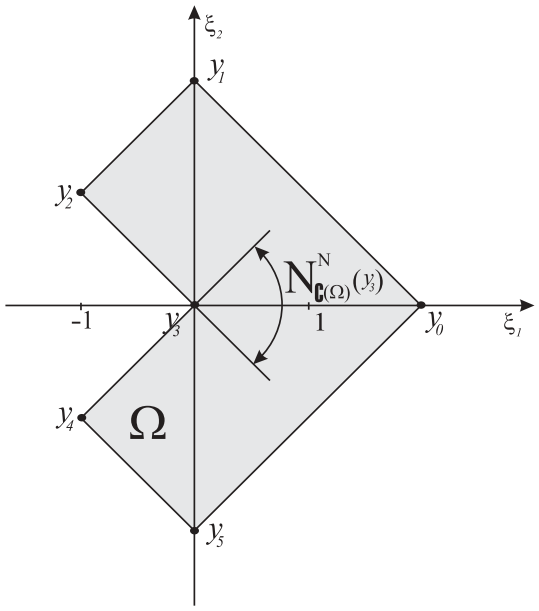

FIG. 2. *Domain of problem* (1.4).

$\partial\Omega$ at y, $N^N_{\mathbb{R}^n\setminus\Omega}(y)$, are contained in E_2 for every $y \in \partial\Omega$. In order to see this, we start by observing that in the points of regularity of $\partial\Omega$ the inward unit normal is in E_1. Then we have to consider $N^N_{\mathbb{R}^n\setminus\Omega}(y_i)$ for $i = 0, \dots, 5$. The only point at which $N^N_{\mathbb{R}^n\setminus\Omega}(y_i) \neq \emptyset$ is y_3, since at the other points Ω is convex and $N^N_{\mathbb{R}^n\setminus\Omega}(y_i)$ is empty; moreover, we can see that

$$N^N_{\mathbb{R}^n\setminus\Omega}(y_3) = S,$$

and this proves (G2).

2. Preliminaries. This section is divided into two parts. In the first part we recall several definitions of normal and tangent cones to a compact set that generalize the notions of normal and tangent vectors in the case where the set is not regular. In the second part, after recalling the definition of a viscosity solution of a Hamilton–Jacobi equation, we state some preliminary results on the existence of viscosity solutions of a Dirichlet problem with a convex Hamiltonian.

2.1. Normal and tangent cones. We start by giving some definitions.

DEFINITION 2.1. *Let K be a locally compact subset of $\mathbb{R}^n$ and $x \in K$. A vector $v \in \mathbb{R}^n$ is a* generalized tangent *to K at x if there are $h_n \to 0^+$, $v_n \to v$ such that $x + h_n v_n \in K \ \forall\, n \in \mathbb{N}$. The set of all generalized tangent vectors to K at x is denoted by $T_K(x)$, that is,*

$$T_K(x) := \left\{ v \in \mathbb{R}^n \,|\, \exists\, h_n \to 0^+ \,,\, v_n \to v \ :\ x + h_n v_n \in K \right\}.$$

A vector $\nu \in \mathbb{R}^n$ is a generalized outward normal *to K at x if, for every generalized tangent v to K at x, $\langle v, \nu \rangle \leq 0$. We denote by $N_K(x)$ the set of generalized normals to K at x. That is,*

$$N_K(x) := \left\{ \nu \in \mathbb{R}^n \,|\, \langle v, \nu \rangle \leq 0 \ \ \forall\, v \in T_K(x) \right\}.$$

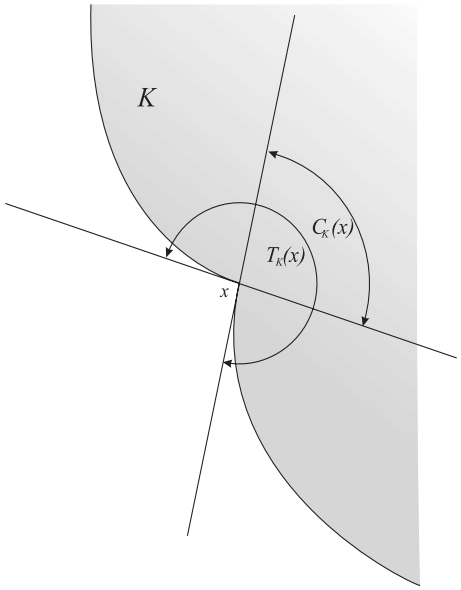

FIG. 3. *Different tangent cones.*

The set $T_K(x)$ is a closed cone containing the origin, and we will refer to it as *tangent cone*[1] to K at x; by duality we will call $N_K(x)$ the *normal cone* to K at x. Moreover, we denote by $N_K^N(x)$ the set of directions of the normal cone to K at x, that is,

$$N_K^N(x) := \left\{ \frac{\nu}{|\nu|}, \nu \in N_K(x) \setminus \{0\} \right\}.$$

REMARK 2.2. *Let K be a locally compact subset of $\mathbb{R}^n$ and $x \in K$.*

(i) *If the boundary of K is piecewise C^1, then $N_K^N(x)$ reduces to a single vector ν_x, where ν_x is the usual outward normal at any $x \in \partial K$, where the normal exists.*

(ii) *If Ω is an open subset of $\mathbb{R}^n$ and $x \in \partial\Omega$, then a generalized normal $\nu \in N_{\mathbb{R}^n \setminus \Omega}(x)$ can be regarded as an interior normal to Ω at x.*

Another useful set that can be defined is *Clarke's tangent cone* to K at x (see [8, 22]). It is defined by[2]

$$C_K(x) := \left\{ v \in \mathbb{R}^n \,|\, \forall x_n \to x\,, \forall t_n \to 0^+\,, \exists\, v_n \to v \;:\; x_n + t_n v_n \in K\,, \forall\, n \in \mathbb{N} \right\}.$$

DEFINITION 2.3. *A set K is said to be* regular *in the sense of Clarke at x, provided $T_K(x) = C_K(x)$.*

To have an idea of the relations between the two definitions of tangent cones $T_K(x)$ and $C_K(x)$ we can take a look at Figure 3.

[1] The set $T_K(x)$ was introduced in 1932 by Bouligand [4] with the name of *contingent cone* and it was studied for the theory of derivations of functions on $\mathbb{R}^2$. Later, in the theory of optimal control it was called simply *tangent cone* (see, for example, [19, 23, 24]).

[2] The original definition of $C_K(x)$ was given by Clarke in a slightly different way, more indirectly, but the two definitions are equivalent (see [7]).

REMARK 2.4. *Let K be a locally compact subset of $\mathbb{R}^n$ and $x \in K$.*

(i) *$C_K(x)$ is always a closed convex cone contained in $T_K(x)$; for this reason some authors prefer $C_K(x)$ instead of $T_K(x)$ as definition of tangent cone in many applications (see, for example,* [22]*).*

(ii) *If $T_K(x)$ is convex, then $N_K(x)$ is, in fact, the polar cone of $T_K(x)$ in the sense of convex analysis. It is the case, for example, of a set K regular in Clarke's sense at x for which we have*

$$N_K(x) = T_K^0(x) = C_K^0(x), \tag{2.1}$$

where $C_K^0(x)$ and $T_K^0(x)$ denote the polar cones of $C_K(x)$ and $T_K(x)$ in the sense of convex analysis.

(iii) *Any convex set is regular in the sense of Clarke.*

2.2. Viscosity solutions and convex Hamiltonians. Let us start by giving the definition of subdifferential and superdifferential of continuous functions defined on an open set $\Omega \subseteq \mathbb{R}^n$ (see [1, 2, 11, 17]).

DEFINITION 2.5. *Let $u \in C(\Omega)$; we define for $x \in \Omega$ the following sets:*

$$D^+u(x) = \left\{ p \in \mathbb{R}^n \ : \ \limsup_{y \to x, y \in \Omega} \frac{u(y) - u(x) - \langle p, y - x \rangle}{|x - y|} \leq 0 \right\},$$

$$D^-u(x) = \left\{ p \in \mathbb{R}^n \ : \ \liminf_{y \to x, y \in \Omega} \frac{u(y) - u(x) - \langle p, y - x \rangle}{|x - y|} \geq 0 \right\}.$$

$D^+u(x)$ ($D^-u(x)$) is called the superdifferential (subdifferential) of u at x.

In the following proposition we recall some useful properties of $D^+u(x)$ and $D^-u(x)$ that we will need in what follows.

PROPOSITION 2.6. *Let $u \in C(\Omega)$ and $x \in \Omega$. Then we have the following.*

(i) *$D^+u(x)$ and $D^-u(x)$ are closed, convex (possibly empty) subsets of $\mathbb{R}^n$.*

(ii) *If u is differentiable at x, then*

$$D^+u(x) = D^-u(x) = \{Du(x)\}. \tag{2.2}$$

(iii) *If for some x both $D^+u(x)$ and $D^-u(x)$ are nonempty, then* (2.2) *holds.*

(iv) *If $u \in W^{1,\infty}(\Omega)$, then*

$$D^+u(x) \cup D^-u(x) \subseteq \operatorname{co} \left\{ p \in \mathbb{R}^n \ \mid \ p = \lim_{n \to \infty} Du(x_n) \, , \, x_n \to x \right\}, \tag{2.3}$$

where the limit is taken over all the sequence $x_n \to x$ such that $Du(x_n)$ exists and the sequence $\{Du(x_n)\}$ converges.

There are many ways to define the $W^{1,\infty}$ viscosity solution of a differential equation (see [1, 11, 17]). Here we give a definition of such a solution in terms of sub- and superdifferential. We use this definition since it is more convenient for our purposes.

DEFINITION 2.7.

(i) *$u \in C(\Omega)$ is a viscosity subsolution of $F(Du(x)) = 0$ in Ω if and only if $F(p) \leq 0$ for every $x \in \Omega$ $\forall p \in D^+u(x)$.*

(ii) *$u \in C(\Omega)$ is a viscosity supersolution of $F(Du(x)) = 0$ in Ω if and only if $F(p) \geq 0$ for every $x \in \Omega$ $\forall p \in D^-u(x)$.*

A function $u \in C(\Omega)$ is a viscosity solution of $F(Du(x)) = 0$ if u is a viscosity subsolution and supersolution.

REMARK 2.8. *The definition of viscosity solution was originally given in terms of test functions (see, for example,* [21]*). The equivalence of the two definitions can be found in* [1] *or* [21].

For stating the main result we need to recall some preliminary results on viscosity solutions of Hamilton–Jacobi equations with convex Hamiltonians (cf. [18, 21] for further details).

We focus our attention on the problem

$$\begin{cases} H(Du) = n(x) & \text{in} \quad \Omega, \\ u(x) = \varphi(x) & \text{on} \quad \partial\Omega, \end{cases} \tag{2.4}$$

where $H : \mathbb{R}^n \to \mathbb{R}$ is convex, continuous, and satisfies

$$H(p) \to \infty \text{ as } |p| \to \infty,$$

and $n \in C(\overline{\Omega})$ is such that $n \geq \inf_{\mathbb{R}^n} H(p)$ in $\overline{\Omega}$.

We first define the function $L(x, y)\ \forall\, (x, y) \in \overline{\Omega} \times \overline{\Omega}$ as

$$L(x,y) := \inf_{\xi \,\in\, S_{x,y}} \left\{ \int_0^1 \max_{p \,\in\, P_{\xi,t}} \left\langle -\frac{d\xi}{dt}, p \right\rangle dt \right\}, \tag{2.5}$$

where

$$P_{\xi,t} := \Big\{ p \in \mathbb{R}^n \mid H(p) = n\big(\xi(t)\big) \Big\},$$

$$S_{x,y} := \left\{ \xi : [0,1] \to \bar{\Omega} \mid \xi(0) = x\,,\, \xi(1) = y\,,\, \frac{d\xi}{dt} \in L^\infty(0,1) \right\}.$$

REMARK 2.9. *We should point out that L can be written also in terms of the Lagrangian (i.e., the dual convex function) of H (see* [21, *section* 5.3]*).*

REMARK 2.10. *Many authors refer to the function L as optical length; let us point out why. For an admissible path ξ (i.e., a function $\xi : [0,1] \to \overline{\Omega}$ such that $\xi(0) = x$ and $\xi(1) = y$) we define the* optical length *of ξ as*

$$L(\xi) = \int_0^1 \max_{p \,\in\, P_{\xi,t}} \left\langle -\frac{d\xi}{dt}, p \right\rangle dt,$$

and this denomination introduced by Kružkov in [20] *is motivated by the fact that in the very special case $H(p) = |p|^2$, $n(x) = \text{const}$, this coincides with the optical length introduced by Born and Wolf in* [5].

Now we can state the classical (cf. [21, Theorem 5.2]).

THEOREM 2.11 (Hopf–Lax formula). *Let Ω be a bounded, connected domain of $\mathbb{R}^n$ with Lipschitz boundary $\partial\Omega$. Let $\varphi \in Lip(\partial\Omega)$. If φ verifies the compatibility condition*

$$\varphi(x) - \varphi(y) \leq L(x,y) \ \ \forall\, x, y \,\in\, \partial\Omega, \tag{2.6}$$

then the function

$$u(x) = \inf_{y \in \partial\Omega} \{\varphi(y) + L(x,y)\}$$

is the unique $W^{1,\infty}(\Omega)$ viscosity solution of the problem (2.4).

In section 3 we will apply Theorem 2.11 in the particular case where the Hamiltonian H is the gauge function of a convex set. For this reason we now want to investigate how L can be rewritten in the special case where $n(x) = 1$ and H is a gauge function; that is, H is convex and

$$\begin{cases} H(\xi) > 0 & \forall\, \xi \neq 0, \\ H(t\xi) = tH(\xi) & \forall\, \xi \in \mathbb{R}^n, \quad \forall\, t > 0. \end{cases}$$

Under these assumptions the function L can be rewritten as

$$L(x,y) := \inf_{S_{x,y}} \left\{ \int_0^1 \max_{H(p)=1} \left\langle -\frac{d\xi}{dt}, p \right\rangle dt \right\}, \tag{2.7}$$

and, by the definition of the polar[3] function of a gauge, (2.7) is equivalent to

$$L(x,y) := \inf_{S_{x,y}} \left\{ \int_0^1 H^0\left(-\frac{d\xi}{dt}\right) dt \right\}, \tag{2.8}$$

where H^0 is the polar function of H.

In the last part of this section we recall a Mac–Shane-type extension lemma which is, in fact, a consequence of the Hopf–Lax formula (for more details see, for example, [15]).

LEMMA 2.12. *Let $\Omega \subset \mathbb{R}^n$ be a bounded closed set. Let $H : \mathbb{R}^n \to \mathbb{R}$ be a gauge function, that is, a positively homogeneous convex function, and let H^0 be its polar. If $\varphi : \partial\Omega \to \mathbb{R}$ satisfies*

$$\varphi(x) - \varphi(y) \leq H^0(x-y) \quad \forall\, x, y \in \partial\Omega, \tag{2.9}$$

then the function

$$\tilde{\varphi}(x) = \inf_{y \in \partial\Omega} \left\{ \varphi(y) + H^0(x-y) \right\}$$

is a Lipschitz extension of φ to the whole $\mathbb{R}^n$, and, moreover, it satisfies

$$\tilde{\varphi}(x) - \tilde{\varphi}(y) \leq H^0(x-y) \quad \forall\, x, y \in \mathbb{R}^n$$

and

$$H^0(D\tilde{\varphi}(x)) \leq 1 \ \text{ a.e. in } \mathbb{R}^n. \tag{2.10}$$

REMARK 2.13. *The condition* (2.9) *is more restrictive than* (2.6) *since using Jensen's inequality we can easily prove that*

$$L(x,y) \geq H^0(x-y).$$

Moreover, we should note that if the segment $[x,y]$ is an admissible path for the definition of L (that is, it is completely contained in $\overline{\Omega}$), then $L(x,y) = H^0(x-y)$; this is the case, for example, when Ω is convex.

---

[3]The polar of a gauge H is defined as

$$H^0(\xi^*) = \inf \{ \lambda \geq 0 \ : \ \langle \xi, \xi^* \rangle \leq \lambda H(\xi) \ \ \forall\, \xi \in \mathbb{R}^n \}$$

and is characterized by

$$H^0(\xi^*) = \sup_{\xi \neq 0} \left\{ \frac{\langle \xi, \xi^* \rangle}{H(\xi)} \right\}.$$

3. Main result. In this section we establish a sufficient condition for the existence of a $W^{1,\infty}(\Omega)$ viscosity solution of the problem (1.1) under the following hypotheses:

- (H1) Let $F : \mathbb{R}^n \longrightarrow \mathbb{R}$ be continuous and such that

$$E = \{\xi \in \mathbb{R}^n \,:\, F(\xi) = 0\} \subset \partial(\operatorname{co} E),$$

with E bounded, $0 \in \operatorname{int}\operatorname{co} E$, and $F(\xi) < 0$ for every $\xi \in \operatorname{int}\operatorname{co} E$.

REMARK 3.1. *If F is convex and coercive, as in the classical literature, then*

$$\operatorname{co} E := \{\xi \in \mathbb{R}^n \,:\, F(\xi) \leq 0\},$$

and (H1) *is satisfied with* $E = \partial(\operatorname{co} E)$.

Following an idea used in [6], we want to compare the solution of (1.1) with the viscosity solution of the equation

$$\begin{cases} \rho(Du) = 1 & \text{in} \quad \Omega, \\ u = \varphi & \text{on} \quad \partial\Omega, \end{cases} \tag{3.1}$$

where ρ is the gauge associated with $\operatorname{co} E$ defined as

$$\rho(\xi) = \inf\{\lambda \geq 0 \mid \xi \in \lambda \operatorname{co} E\}.$$

We start by observing that ρ is well defined since by (H1) $0 \in \operatorname{int}\operatorname{co} E$ and $\operatorname{co} E$ is compact; moreover, ρ is, by definition, convex and positively homogeneous of degree 1. Therefore we have the right hypotheses to apply the preliminary work done in the previous section for the convex Hamiltonian; in particular, we can write the "optical length" $L(x, y)$ related to problem (3.1) as follows:

$$L(x,y) := \inf_{S_{x,y}} \left\{ \int_0^1 \rho^0 \left(-\frac{d\xi}{dt} \right) dt \right\}, \tag{3.2}$$

where ρ^0 is the polar function of ρ in the sense of convex analysis and, therefore, ρ^0 is convex and positively homogeneous.

Before stating the main result, we need to set our hypotheses on φ.

- (H2) Let $\varphi \in Lip(\partial\Omega)$, with

$$\emptyset \neq D^+\varphi(x) \subseteq E \cup \operatorname{int}\operatorname{co} E \;\; \forall\, x \in \partial\Omega \tag{3.3}$$

and satisfying the compatibility condition

$$\varphi(x) - \varphi(y) \leq \rho^0(x,y) \;\; \forall\, x, y \in \partial\Omega. \tag{3.4}$$

REMARK 3.2. *We should note that in condition* (H2) *we refer to $D^+\varphi(x)$ as the superdifferential of the Lipschitz extension of φ given by Lemma* 2.12. *Moreover, we can prove that $D^+\varphi(x) \subseteq \overline{\operatorname{co} E}\; \forall\, x \in \Omega$ (see the proof of Theorem* 3.3*).*

Finally, Theorem 2.11, Remark 2.13, and (H2) allow us to write the $W^{1,\infty}(\Omega)$ viscosity solution of (3.1) as follows:

$$u(x) = \inf_{y \in \partial\Omega} \{\varphi(y) + L(x,y)\}, \quad x \in \overline{\Omega}. \tag{3.5}$$

Now we are in the position to state the main theorem of this section.

THEOREM 3.3. *Let $\Omega \subset \mathbb{R}^n$ be a bounded connected set. Let F and φ satisfy* (H1) *and* (H2). *If $\forall\, y \in \partial\Omega$, where $N^N_{\mathbb{R}^n\setminus\Omega}(y) \neq \emptyset$, there exists $h \in D^+\varphi(y)$ such that $\forall \nu \in N^N_{\mathbb{R}^n\setminus\Omega}(y)$ there exists a unique $\lambda_{\nu,h} > 0$ that verifies*

$$h + \lambda_{\nu,h}\nu \in E,$$

then there exists $u \in W^{1,\infty}(\Omega)$ viscosity solution of (1.1).

REMARK 3.4. *Let $h \in D^+\varphi(y)$ be as in Theorem* 3.3 *and $\nu \in N^N_{\mathbb{R}^n\setminus\Omega}(y)$; then, since $E \subset \partial(\operatorname{co} E)$, the unique $\lambda_{\nu,h} > 0$ such that $h + \lambda_{\nu,h}\nu \in E$ is determined by the equality*

$$\rho(h + \lambda_{\nu,h}\nu) = 1.$$

We will prove that, under the hypotheses of Theorem 3.3, the function $u : \overline{\Omega} \to \mathbb{R}$ defined by (3.5) is actually the viscosity solution of (1.1). Before starting the proof we need to investigate the properties of u. Let us start by proving the following key lemma and making some remarks.

LEMMA 3.5. *Let Ω be a bounded connected open set of $\mathbb{R}^n$ with Lipschitz boundary $\partial\Omega$, and let $\varphi \in Lip(\partial\Omega)$ verify* (H2). *Let u be defined by* (3.5) *and $y(x) \in \partial\Omega$ be such that $u(x) = \varphi(y(x)) + L(x, y(x))$. Then $\forall\, p \in D^-u(x)$ and $\forall\, h \in D^+\varphi(y(x))$,*

$$\langle p - h, q\rangle \leq 0 \quad \forall\, q \in T_{\mathbb{R}^n\setminus\Omega}(y(x)),$$

that is, $p - h \in N_{\mathbb{R}^n\setminus\Omega}(y(x))$.

Proof. Let $x_0 \in \Omega$, $y_0 \in \partial\Omega$ such that $u(x_0) = \varphi(y_0) + L(x_0, y_0)$ and $q \in T_{\mathbb{R}^n\setminus\Omega}(y_0)$. Let $q_k \to q$, as in Definition 2.1, such that $y_0 + \varepsilon_k q_k \notin \Omega$ and $x_0 + \varepsilon_k q_k \in \Omega$. By definition of $L(x_0, y_0)$ for every $\varepsilon > 0$ we can find $\xi_0 \in S_{x_0,y_0}$ (that is, $\xi_0 : [0,1] \to \overline{\Omega} \mid \xi(0) = x_0\,,\ \xi(1) = y_0\,,\ \frac{d\xi_0}{dt} \in L^\infty(0,1)$) such that

$$L(x_0, y_0) + \varepsilon \geq \int_0^1 \rho^0\left(-\frac{d\xi_0}{dt}(t)\right) dt. \tag{3.6}$$

Next we define, for every $k \in \mathbb{N}$, $\xi_k(t) = \xi_0(t) + \varepsilon_k q_k$; clearly, we have $\xi_k(0) = x_0 + \varepsilon_k q_k$, $\xi_k(1) = y_0 + \varepsilon_k q_k$, and $\frac{d\xi_k}{dt} = \frac{d\xi_0}{dt}$.

Since ξ_k and $\partial\Omega$ are continuous, there exist $t_k \in (0,1)$ and $y_k \in \partial\Omega$ such that $\xi_k(t_k) = y_k$ and $\xi_k(t) \in \overline{\Omega} \quad \forall\, t < t_k$ (see Figure 4).

Using (3.6), the properties of ξ_k, and the definition (3.5) of u, we have

$$\begin{aligned}
u(x_0) &= \varphi(y_0) + L(x_0, y_0) \\
&\geq \varphi(y_0) + \int_0^1 \rho^0\left(-\frac{d\xi_0}{dt}(t)\right) dt - \varepsilon \\
&= \varphi(y_0) - \varphi(y_0 + \varepsilon_k q_k) \\
&+ \varphi(y_0 + \varepsilon_k q_k) - \varphi(y_k) + \int_{t_k}^1 \rho^0\left(-\frac{d\xi_0}{dt}(t)\right) dt \\
&+ \varphi(y_k) + \int_0^{t_k} \rho^0\left(-\frac{d\xi_0}{dt}(t)\right) dt - \varepsilon \\
&\geq \varphi(y_0) - \varphi(y_0 + \varepsilon_k q_k) + u(x_0 + \varepsilon_k q_k) \\
&+ \varphi(y_0 + \varepsilon_k q_k) - \varphi(y_k) + \int_{t_k}^1 \rho^0\left(-\frac{d\xi_0}{dt}(t)\right) dt - \varepsilon,
\end{aligned} \tag{3.7}$$

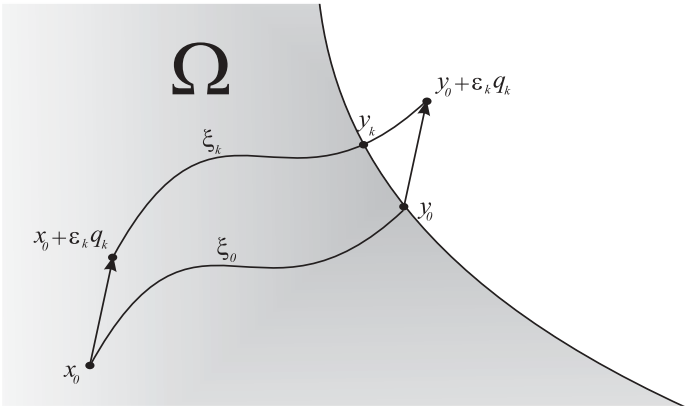

FIG. 4. *Geometrical construction of path* ξ_k.

where we have used the homogeneity of ρ^0 to establish

$$\int_0^{t_k} \rho^0\left(-\frac{d\xi_0}{dt}(t)\right)dt = \int_0^1 \rho^0\left(-\frac{d(\xi_k(t_k s))}{ds}\right)ds \geq L(x_0+\varepsilon_k q_k, y_k).$$

We claim that

$$\varphi(y_0+\varepsilon_k q_k) - \varphi(y_k) + \int_{t_k}^1 \rho^0\left(-\frac{d\xi_0}{dt}(t)\right)dt \geq 0. \tag{3.8}$$

Indeed, Lemma 2.12 ensures us that

$$\varphi(y_0+\varepsilon_k q_k) - \varphi(y_k) \geq -\rho^0(y_k - y_0 - \varepsilon_k q_k); \tag{3.9}$$

moreover, by Jensen's inequality we have

$$\begin{aligned}\int_{t_k}^1 \rho^0\left(-\frac{d\xi_0}{dt}(t)\right)dt &= \int_0^1 \rho^0\left(-\frac{d\xi_k((1-t_k)s+t_k)}{ds}\right)ds \\ &\geq \rho^0(y_k - y_0 - \varepsilon_k q_k).\end{aligned} \tag{3.10}$$

Combining (3.9) and (3.10) we obtain the claim.

Now using (3.7) and (3.8) we can write, letting $\varepsilon \to 0$,

$$u(x_0) \geq u(x_0+\varepsilon_k q_k) - \big(\varphi(y_0+\varepsilon_k q_k) - \varphi(y_0)\big). \tag{3.11}$$

Therefore, taking $h \in D^+\varphi(y_0)$ and $p \in D^- u(x_0)$, we have by definition that

$$\begin{aligned}\varphi(y_0+\varepsilon_k q_k) - \varphi(y_0) &\leq \langle h, \varepsilon_k q_k\rangle + o(\varepsilon_k),\\ u(x_0+\varepsilon_k q_k) - u(x_0) &\geq \langle p, \varepsilon_k q_k\rangle + o(\varepsilon_k),\end{aligned}$$

and in light of (3.11), we can say that

$$\begin{aligned}\langle p, \varepsilon_k q_k\rangle &\leq u(x_0+\varepsilon_k q_k) - u(x_0) + o(\varepsilon_k)\\ &\leq \varphi(y_0+\varepsilon_k q_k) - \varphi(y_0) + o(\varepsilon_k)\\ &\leq \langle p, \varepsilon_k q_k\rangle + o(\varepsilon_k).\end{aligned}$$

Finally, dividing both sides of the last inequality by ε_k and taking the limit for $k \to \infty$, we obtain

$$\langle p - h, q \rangle \leq 0.$$

This proves the lemma. □

REMARK 3.6. *If we fix $p \in D^- u(x)$ and $h \in D^+\varphi(y(x))$ with $h \neq p$, then there exist $\nu_{p,h} \in N^N_{\mathbb{R}^n \setminus \Omega}(y(x))$ and a unique $\lambda_{p,h} > 0$ such that $p = h + \lambda_{p,h}\nu_{p,h}$.*

We now give the proof of the main theorem.

Proof of Theorem 3.3. Let u be defined as in (3.5); by definition, u is a viscosity solution of (3.1). We claim that u is also a viscosity solution of (1.1). We divide the proof into two steps: first, we show that u is in fact a supersolution of (1.1) and then show that u is also a subsolution.

- We start by observing that $\forall\, x \in \Omega$ and $\forall\, p \in D^- u(x)$ we have $\rho(p) = 1$ (see also [3]). Indeed, since u is a supersolution of (3.1), we have that $\forall\, x \in \Omega$ and $\forall\, p \in D^- u(x)$, $\rho(p) \geq 1$. Moreover, since u is also a viscosity subsolution of (3.1), in particular we have $\rho(Du(x)) \leq 1$ (i.e., $Du(x) \in \overline{\operatorname{co} E}$) $\forall\, x \in \Omega$, where $Du(x)$ exists, since in such points $D^+ u(x) = \{Du(x)\}$. The continuity of ρ ensures us that

$$\rho\left(\lim_{n\to\infty} Du(x_n)\right) \leq 1$$

$\forall\, x_n \to x$ such that $Du(x_n)$ is well defined and $Du(x_n)$ converges; that is, the following inclusion holds:

$$\left\{p \in \mathbb{R}^n \mid p = \lim_{n\to\infty} Du(x_n) \ : \ x_n \to x\right\} \subseteq \overline{\operatorname{co} E}. \tag{3.12}$$

Therefore, by Proposition 2.6(iv) and (3.12) we can say that

$$D^- u(x) \subseteq \operatorname{co}\left\{p \in \mathbb{R}^n \mid p = \lim_{n\to\infty} Du(x_n) \ : \ x_n \to x\right\} \subseteq \overline{\operatorname{co} E},$$

that is, $\rho(p) \leq 1\ \forall\, p \in D^- u(x)$, and this proves the claim.
Now let $y(x) \in \partial\Omega$ be such that $u(x) = \varphi(y(x)) + L(x, y(x))$ and $h \in D^+\varphi(y(x))$ as in the hypotheses. We distinguish two cases.

(1) If $h = p$, then $\rho(h) = 1$; since $h \in E \cup \operatorname{int}\operatorname{co} E$, we have $h \in E$, and so $p \in E$, that is, $F(p) = 0$.

(2) If $h \neq p$, by Remark 3.6, there exist $\nu_{p,h} \in N^N_{\mathbb{R}^n \setminus \Omega}(y(x))$ and a unique $\lambda_{p,h} > 0$ such that

$$p = h + \lambda_{p,h}\nu_{p,h}; \tag{3.13}$$

moreover, $\lambda_{p,h}$ is uniquely determined by $\rho(h + \lambda_{p,h}\nu_{p,h}) = 1$. The hypothesis made on h and (3.13) imply $p \in E$; that is, as before, $F(p) = 0$.
In particular, u is a viscosity supersolution of (1.1).

- Since u is also a viscosity subsolution of (3.1), then for every $x \in \Omega$ and $p \in D^+ u(x)$ we have $p \in \overline{\operatorname{co} E}$ (i.e., $\rho(p) \leq 1$). As (H1) is satisfied and F is continuous, it follows that $F(p) \leq 0$. So u is a viscosity subsolution of (1.1).

The two above observations complete the proof. □

4. Corollaries. This section is divided into two parts. In the first part we focus our attention on the differentiability properties of Lipschitz and semiconcave functions with the aim of relating the notions of normal and tangent cones to the sets described by such types of functions (e.g., epigraphs or level-sets) to their generalized gradients. In the second part we state two corollaries of Theorem 3.3 in which the hypotheses on the geometry of the domain Ω can be written in a nicer way in terms of the differential property of the functions that represent the boundary $\partial\Omega$.

4.1. Lipschitz continuity and semiconcavity. Let us recall briefly some definitions and relevant differential properties of locally Lipschitz continuous functions that we will use in what follows. By the Rademacher theorem such functions are almost everywhere differentiable with locally bounded gradients (see [16]). Hence, if $u \in Lip_{\mathrm{loc}}(\Omega)$, we can consider the set

$$D^*u(x) := \Big\{ p \in \mathbb{R}^n \,:\, p = \lim_{n\to\infty} Du(x_n), x_n \to x \Big\},$$

where x_n is a sequence of points of differentiability for u. We note that $D^*u(x)$ is nonempty and closed for any $x \in \Omega$.

Let $u : \Omega \to \mathbb{R}$ be Lipschitz in a neighborhood of a given point x, and let $q \in S^{n-1}$ be a direction in $\mathbb{R}^n$. We define

- the *one-sided directional derivative* of u at x in the direction q as

$$u'(x,q) = \lim_{t\to 0^+} \frac{u(x+tq)-u(x)}{t},$$

- the *generalized directional derivatives* of u at x in the direction q as

$$u^0(x,q) = \limsup_{y\to x, t\to 0^+} \frac{u(y+tq)-u(y)}{t},$$

$$u_0(x,q) = \liminf_{y\to x, t\to 0^+} \frac{u(y+tq)-u(y)}{t},$$

- the *generalized gradient* (or Clarke's gradient) of u at x as

$$\begin{aligned} \partial u(x) &= \{ p \in \mathbb{R}^n \,:\, u^0(x,q) \geq p\cdot q \ \forall q \in \mathbb{R}^n \} \\ &= \{ p \in \mathbb{R}^n \,:\, u_0(x,q) \leq p\cdot q \ \forall q \in \mathbb{R}^n \}. \end{aligned}$$

In the following proposition we collect some well-known properties of Lipschitz functions (see [1, 8]).

PROPOSITION 4.1. *Let $u : \Omega \to \mathbb{R}$ be locally Lipschitz continuous in the open set Ω; then*

(i) $u_0(x,q) = -u^0(x,-q)\ \forall\, x \in \Omega,\ q \in \mathbb{R}^n$;

(ii) $\forall\, x \in \Omega$ *the function $q \mapsto u^0(x,q)$ is finite, positively homogeneous, subadditive, and convex (and locally Lipschitz continuous);*

(iii) *the map $(x,q) \mapsto u^0(x,q)$ is upper semicontinuous;*

(iv) $\forall\, x \in \Omega$ *we have $\operatorname{co} D^*u(x) = \partial u(x)$;*

(v) *$D^+u(x)$ and $D^-u(x)$ are bounded $\forall\, x \in \Omega$ and*

$$D^+u(x) \cup D^-u(x) \subseteq \partial u(x);$$

(vi) $\forall\, q \in S^{n-1}$ *there exists the classical one-sided directional derivative* $u'(x,q)$ *at any* $x \in \Omega$, *where* $D^+u(x) = \partial u(x)$ *and the following equality holds:*

$$u'(x,q) = \min_{p \in D^+u(x)} p \cdot q = u_0(x,q). \tag{4.1}$$

REMARK 4.2. *Looking at the definition of* $D^*u(x)$ *and Proposition* 4.1(iv), *one can observe that Proposition* 4.1(v) *is just a reformulation of Proposition* 2.6(iv).

Now we introduce a definition of regularity of functions that is in some way related to regularity of sets in Clarke's sense (from which the name derives). It will be useful for stating some hypotheses that allow us to write the normal cone of a set in a nicer way.

DEFINITION 4.3. *A function* $u : \Omega \to \mathbb{R}$ *is said to be* regular *at* x *(in the sense of Clarke), provided*

(i) $\forall\, q \in \mathbb{R}^n$ *the one-sided directional derivative* $u'(x,q)$ *exists;*

(ii) $\forall\, q \in \mathbb{R}^n$ *the equality* $u'(x,q) = u^0(x,q)$ *holds.*

The following theorem (a proof of which can be found in [8]) and its corollaries give us a useful characterization of normal cone to the level sets of regular functions.

THEOREM 4.4. *Let* $f : \mathbb{R}^n \to \mathbb{R}$ *be Lipschitz near a given point* x, *and suppose that* $0 \notin \partial f(x)$. *If* K *is defined as*

$$K := \{y \in \mathbb{R}^n \,:\, f(y) \le f(x)\},$$

then

$$C_K^0(x) \subset \bigcup_{\lambda \ge 0} \lambda \partial f(x).$$

If, in addition, f *is regular in the sense of Clarke at* x, *then equality holds, and* K *is Clarke regular at* x, *that is,*

$$N_K(x) = C_K^0(x) = \bigcup_{\lambda \ge 0} \lambda \partial f(x). \tag{4.2}$$

REMARK 4.5. *The first equality in* (4.2) *follows by* (2.1) *of Remark* 2.4(iii), *since* K *is regular.*

REMARK 4.6. *The above proposition holds also in a more general framework, that is, for functions defined in a general Banach space, as stated in* [8].

COROLLARY 4.7. *Let* $\Omega := \{y \in \mathbb{R}^n \,:\, f(y) > 0\}$, *where* f *is a Lipschitz continuous function. Let* $y_0 \in \partial\Omega$, *and suppose that* f *verifies the following properties:*

(i) f *is regular in Clarke's sense at* y_0;

(ii) $0 \notin \partial f(y_0) = D^- f(y_0) \cup D^+ f(y_0)$;

then

$$N^N_{\mathbb{R}^n \setminus \Omega}(y_0) = \left(D^- f(y_0) \cup D^+ f(y_0)\right)^N. \tag{4.3}$$

Proof. We note first that $\partial\Omega \subseteq \{y \in \mathbb{R}^n \,:\, f(y) = 0\}$; then $y_0 \in \partial\Omega$ imply $f(y_0) = 0$. So we can write

$$\mathbb{R}^n \setminus \Omega := \{y \in \mathbb{R}^n \,:\, f(y) \le f(y_0)\}.$$

Hence we can apply Theorem 4.4, and, in particular, since f is Clarke regular, by (4.2) we have

$$N_{\mathbb{R}^n \setminus \Omega}(y_0) = \bigcup_{\lambda \ge 0} \lambda \partial f(y_0).$$

Finally, we can conclude, using hypothesis (ii) of Corollary 4.7, that

$$N^N_{\mathbb{R}^n\setminus\Omega}(y_0) = \left(\bigcup_{\lambda\geq 0}\lambda\partial f(y_0)\right)^N = (\partial f(y_0))^N = \left(D^- f(y_0)\cup D^+ f(y_0)\right)^N. \qquad \square$$

In order to prove a second corollary of Theorem 4.4 that is equally useful, we need to recall the definition and some relevant properties of semiconcave and semiconvex functions (see [1] for further details).

DEFINITION 4.8. *We say that* $u:\Omega\to\mathbb{R}$ *is* semiconcave *on an open convex set* Ω *if there exists a constant* $C>0$ *such that*

$$\lambda u(x)+(1-\lambda)u(y)\leq u\left(\lambda x+(1-\lambda)y\right)+\frac{1}{2}C\lambda(1-\lambda)|x-y|^2 \tag{4.4}$$

or, equivalently, if the application $x\mapsto u(x)-\frac{1}{2}C|x|^2$ *is concave.*

We say that $u:\Omega\to\mathbb{R}$ *is semiconvex if* $-u$ *is semiconcave.*

If u is continuous, an equivalent way to express condition (4.4) is to require that

$$u(x+h)-2u(x)+u(x-h)\leq C|h|^2$$

for any $x\in\Omega$ and $h\in\mathbb{R}^n$ with sufficiently small $|h|$.

REMARK 4.9. *It can be proved (see, for example,* [1]*) that a semiconcave function* u *in* Ω *is in fact locally Lipschitz continuous and* $\forall\, x\in\Omega$ *we have*

$$D^+u(x)=\partial u(x)=co\, D^*u(x),$$

while

$$D^-u(x)\neq 0\ \Rightarrow\ u \text{ is differentiable in } x.$$

Now we can prove the following corollary.

COROLLARY 4.10. *Let* $\Omega:=\{y\in\mathbb{R}^n\,:\,f(y)\leq 0\}$*, where* f *is a semiconcave function, if* $y_0\in\partial\Omega$ *and* $0\notin D^+f(y_0)$*; then*

$$N^N_{\mathbb{R}^n\setminus\Omega}(y_0)=-(D^+f(y_0))^N.$$

Proof. We first note that from Remark 4.9 f is locally Lipschitz continuous and $D^+f(y_0)=\partial f(y_0)$. So we can say, by Proposition 4.1(vi), that

$$f'(y_0,q)=f_0(y_0,q)\quad\forall\, q\in S^{n-1}.$$

Moreover, using the definition of generalized derivatives we have

$$-\left(-f'(y_0,q)\right)=f'(y_0,q)=f_0(y_0,q)=-\left(-f^0(y_0,q)\right)\quad\forall\, q\in S^{n-1};$$

that is, $-f$ is regular at y_0 in the sense of Clarke. We now observe that, since

$$-D^-(-f)(y_0)=D^+f(y_0)=\partial f(y_0)=-\partial(-f)(y_0),$$

f verifies the hypothesis of Corollary 4.7 with $\Omega:=\{y\in\mathbb{R}^n\,:\,-f(y)>0\}$, and so we have

$$N^N_{\mathbb{R}^n\setminus\Omega}(y_0)=\left(D^-(-f)(y_0)\right)^N=-(D^+f(y_0))^N. \qquad \square$$

REMARK 4.11. *The two above corollaries hold also if the hypotheses are verified only locally, that is, if for* $y_0 \in \partial\Omega$ *there exists a ball* $B(y_0, r)$ *centered in* y_0 *such that* $\Omega \cap B(y_0, r)$ *can be represented as the sublevel or superlevel set of a function defined on* $B(y_0, r)$ *satisfying the hypotheses required.*

The last result that we want to recall can be found in [8], and it gives us a useful relation between the generalized gradient of a locally Lipschitz function f and Clarke's normal cone $C^0_{epi\, f}$ to its epigraph.

PROPOSITION 4.12. *Let* $f : \Omega \subseteq \mathbb{R}^n \to \mathbb{R}$ *be Lipschitz continuous near a given point* x*; then* $\xi \in \mathbb{R}^n$ *belongs to* $\partial f(x)$ *if and only if* $(\xi, -1)$ *belongs to* $C^0_{epi\, f}(x, f(x))$.

4.2. Corollaries. In the two following corollaries we consider some hypotheses on the geometry of the domain Ω that allow us to write Theorem 3.3 in a nicer way.

Let Ω be a Lipschitz domain, and we have that Ω can be locally represented as the epigraph of a Lipschitz function; that is, $\forall y \in \partial\Omega$ there exists a direction ν_y and a function ω_y defined on the hyperplane orthogonal to ν_y such that in a neighborhood of y, Ω is the epigraph of ω_y.

DEFINITION 4.13. *We will say that* Ω *is convex (concave) at* $y \in \partial\Omega$ *if there exists a* $\nu_y \in S^{n-1}$ *such that the function* ω_y*, which represents* Ω *in the direction* ν_y*, is convex (concave).*

COROLLARY 4.14. *Let* Ω *be a locally Lipschitz domain, and denote by* J *the set of the points of nondifferentiability of* $\partial\Omega$*. Suppose that* Ω *is convex or concave at* $y\ \forall\, y \in J$*. Let* F *and* φ *satisfy* (H1) *and* (H2).

If $\forall y \in \partial\Omega$*, where* $D^+\omega_y(y) \neq \emptyset$*, there exists* $h \in D^+\varphi(y)$ *such that* $\forall \xi \in D^+(\omega_y)(y)$ *there exists a unique* $\lambda_{h,\xi}$ *that verify*

$$h - \lambda_{h,\xi}(\xi + \nu_y) \in E, \tag{4.5}$$

then there exists a $u \in W^{1,\infty}(\Omega)$ *viscosity solution of* (1.1).

REMARK 4.15. *We have to note that in* (4.5) ξ *has to be considered as a point of* $\mathbb{R}^n$ *using the classical immersion in* $\mathbb{R}^n$ *of the hyperplane orthogonal to* ν_y *to which* ξ *belongs by definitions.*

REMARK 4.16. *In the statement of Corollary* 4.14 *we have used the functions* ω_y*; with this notation it seems that we have to change* $\omega_y\ \forall\, y \in \partial\Omega$*, but we can simply observe that the compactness of* $\partial\Omega$ *ensures us that we need only a finite number of* ω_y*. In fact, we can consider for every* $y \in \partial\Omega$ *a neighborhood* Ω_y *of* y *in which* Ω *is represented by the function* ω_y*. From this cover we can extract a finite one* $\cup_{i=1}^k \Omega_{y_i}$*, where* $\omega_y = \omega_{y_i}$ *for every* $y \in \Omega_{y_i} \cap \partial\Omega$.

REMARK 4.17. *If we consider an orthogonal basis* $\{e_1, \ldots, e_n\}$ *for* $\mathbb{R}^n$*, with* $e_n = \nu_y$*, we note that* ξ *lives in the space spanned by* $\{e_1, \ldots, e_{n-1}\}$*, and* (4.5) *can be rewritten as*

$$h - \lambda_{h,\xi}(\xi, 1) \in E \quad \forall \xi \in D^+(f_y)(y).$$

Proof of Corollary 4.14. Looking at the proof of Theorem 3.3 we need only to work with the points on $\partial\Omega$ that realize the minimum in definition (3.5). Now let $x \in \Omega$ and $y \in \partial\Omega$ be such that $u(x) = \varphi(y) + L(x, y)$. If $D^+\omega_y(y) \neq \emptyset$, then Ω is convex in y, and we can prove, using the same argument of Lemma 2.9 in [6], that y must be a point of differentiability for $\partial\Omega$, and this is a contradiction. Hence we have that all the points that realize the minimum in (3.5) have $D^+\omega_y \neq \emptyset$.

Now we want to identify the set $N_{\mathbb{R}^n \setminus \Omega}(y)$ and write it in terms of the superdifferential of ω_y in order to apply Theorem 3.3.

We first observe that if ω_y is differentiable in y, then $N_{\mathbb{R}^n\setminus\Omega}(y)$ reduces to the classic interior normal to $\partial\Omega$ given by $(D\omega(y)+\nu_y)$, and there is nothing to prove.

The last case that we have to consider is if Ω is concave at y and $D^+\omega_y(y)$ does not reduce to a single vector. In this case we have that $-\omega_y$ is convex near y, and it represents $\mathbb{R}^n\setminus\Omega$ in the direction $-\nu_y$. Hence $\mathbb{R}^n\setminus\Omega$ is convex near y, and so, by Remark 2.4(iii), is Clarke regular, and we have

$$N_{\mathbb{R}^n\setminus\Omega}(y)=C^0_{\mathbb{R}^n\setminus\Omega}(y)=C^0_{epi\,(-\omega_y)}(y). \tag{4.6}$$

Moreover, by Proposition 4.12 we can write

$$C^0_{epi\,(-\omega_y)}(y)=\{(\xi,-1)\,:\,\xi\in\partial(-\omega_{y(y)})(y)\}. \tag{4.7}$$

We now observe that, since $-\omega_y$ is convex, we have

$$\partial(-\omega_{y(y)})(y)=D^-(-\omega_y)(y)=-D^+\omega_y(y), \tag{4.8}$$

and, finally, by (4.6), (4.7), and (4.8) we have

$$N^N_{\mathbb{R}^n\setminus\Omega}(y)=\{(\xi,-1)\,:\,\xi\in-D^+\omega_y(y)\}^N.$$

The conclusion follows by Theorem 3.3. □

Another way to represent a domain is like a sublevel- or superlevel-set of a given function. Also in such a case, we have an appropriate version of Theorem 3.3. It is clear that if $\partial\Omega$ is regular in a neighborhood of a point $y\in\partial\Omega$, we can locally (near y) write Ω as the sublevel-set of a regular function f^Ω_y; suppose, moreover, that Ω verifies the following hypothesis:

- (H3) Let Ω be a locally Lipschitz domain, and denote by J the set of the points of nondifferentiability of $\partial\Omega$. Suppose that if for $y\in J$ there exists an $x\in\Omega$ such that $u(x)=\varphi(y)+L(x,y)$ (that is, y realizes the minimum in definition (3.5)), then Ω can be represented near y as the sublevel-set of a semiconcave function f^Ω_y (see Remark 4.9).

The following corollary is an easy consequence of Theorem 3.3 and Corollary 4.10.

COROLLARY 4.18. *Let Ω, F, and φ satisfy* (H1), (H2), *and* (H3).

If $\forall y\in\partial\Omega$, where $D^+f^\Omega_y(y)\neq\emptyset$, there exists $h\in D^+\varphi(y)$ such that $\forall\xi\in D^+f^\Omega_y(y)$ there exists a unique $\lambda_{h,\xi}$ that verify

$$h-\lambda_{h,\xi}\xi\in E, \tag{4.9}$$

then there exists a $u\in W^{1,\infty}(\Omega)$ viscosity solution of (1.1).

Acknowledgments. The author would like to thank Bernard Dacorogna for stimulating discussions and useful suggestions. He also wants to thank the Institute of Mathematics of the EPFL in Lausanne, Switzerland, where part of this work was done.

ON SQUIRT SINGULARITIES IN HYDRODYNAMICS*

DIEGO CÓRDOBA†, CHARLES FEFFERMAN‡, AND RAFAEL DE LA LLAVE§

Abstract. We consider certain singularities of hydrodynamic equations that have been proposed in the literature. We present a kinematic argument that shows that if a volume preserving field presents these singularities, certain integrals related to the vector field have to diverge. We also show that if the vector fields satisfy certain partial differential equations (Navier–Stokes, Boussinesq), then the integrals have to be finite. As a consequence, these singularities are absent in the solutions of the above equations.

Key words. singularities, Boussinesq equations, Navier–Stokes equations

1. Introduction.

One way to make progress towards settling the question of existence of singularities in incompressible fluid motion is to conjecture plausible scenarios for the formation of singularities supported by numerical evidence. Then, it becomes a natural object to develop mathematically rigorous arguments that derive quantitative consequences of the different scenarios and possibly show that these singularities cannot occur in solutions of hydrodynamic equations.

In this note we introduce some classes of singularities which we call *"squirt"* singularities in which some portion of material is ejected from a set of positive measure. These squirt singularities include as particular cases several other singularities that had been considered in the literature (for example, the *"potato chip"* singularities, the *"saddle collapse,"* and the *"tube collapse"*; see section 2 for precise definitions).

In section 3 we present a very simple argument that shows that if a volume preserving vector field u presents a squirt singularity at time T, then

$$\int_0^T ||u||_{L^\infty}\, dt = \infty. \tag{1.1}$$

In section 4 we show that if the vector field satisfies certain partial differential equations (e.g., Navier–Stokes in two and three dimensions, Boussinesq equations in two and three dimensions with positive viscosity), then

$$\int_0^T ||u||_{L^\infty}\, dt < \infty. \tag{1.2}$$

As a consequence of the results in sections 3 and 4, we conclude that volume preserving vector fields satisfying the partial differential equations considered in section 4 do not experience any of the squirt singularities.

The above results include as a particular case a partial answer to a question proposed by Moffatt in [20]. We show that if a two-dimensional fluid satisfies the Boussinesq equation describing a fluid moving under buoyancy forces with positive fluid viscosity $\nu > 0$, but possibly with zero molecular diffusivity $\kappa = 0$, then it cannot have a saddle collapse.

Even if the arguments presented here exclude that the singularities happen, they give little information on how fast the singular terms may grow. In some of the cases discussed here, these more quantitative arguments are available in the literature (see [8]). They, of course, require using more heavily the details of the equation and the singularity.

2. Squirt singularities. In this section we collect the definitions of the different types of singularities that we will be considering in this paper.

2.1. Notation. We denote the Lebesgue measure of a set A by $|A|$ and the ball centered at $\mathbf{x}^0$ with radius r by $B_r(\mathbf{x}^0)$.

Let $\Omega \subset \mathbb{R}^n$ be an open set. We consider a C^1 time dependent vector field $u : \Omega \times [0, T) \to \mathbb{R}^n$.

This vector field defines an evolution for trajectories $\Phi_t(x)$, where $\Phi_t(x)$ denotes the position at time t of the trajectory with initial condition x at time $t = 0$. More generally, we denote by $\Phi_{t,a}(x)$ the position at time t of the trajectory which at time $t = a$ is in x. Note that, when both sides of the formulas make sense, $\Phi_t(x) = \Phi_{t,0}(x)$, $\Phi_{t,a} = \Phi_t \circ \Phi_a^{-1}(x)$, $\Phi_{t,a} \circ \Phi_{a,b}(x) = \Phi_{t,b}(x)$.

For $\mathcal{S} \subset \Omega$, we denote by

$$\Phi_{t,a}^{\Omega}\mathcal{S} = \{x \in \Omega \mid x = \Phi_t(y),\ y \in \mathcal{S},\ \Phi_s(y) \in \Omega,\ 0 \le s \le t\}.$$

That is, $\Phi_{t,a}^{\Omega}$ is the evolution of the set $\mathcal{S}$, starting at time a, after we eliminate the trajectories which step out of Ω at some time.

We will henceforth assume that u is divergence free. Given the fact that u has zero divergence, we have that $|\Phi_{t,s}\mathcal{S}|$ is independent of t and $|\Phi_{t,a}^{\Omega}\mathcal{S}|$ is nonincreasing in t.

2.2. Definition of singularities.

2.2.1. Squirt singularities. The following definition will be the hypothesis of the main kinematic result of this paper, Theorem 3.1.

DEFINITION 1. *Let Ω_-, Ω_+ be open and bounded sets. $\overline{\Omega_-} \subset \Omega_+$. Therefore,* $\operatorname{dist}(\Omega_-, \mathbb{R}^d - \Omega_+) \ge r > 0$.

We say that u experiences a squirt singularity in Ω_-, at time $T > 0$, when for every $0 \le s < T$, we can find a set $\mathcal{S}_s \subset \Omega_+$ such that

- *$\mathcal{S}_s \cap \Omega_-$ has positive measure, $0 \le s < T$,*
- $\lim_{t \to T} |\Phi_{t,s}^{\Omega_+}\mathcal{S}_s| = 0$.

The physical intuition is that there is a region of positive volume so that all the fluid occupying it gets ejected from a slightly bigger region in a finite time.

As we see in the following subsections, Definition 1 includes as particular cases other singularities that have been considered in the literature. Of course the conclusions of Theorem 3.1, which uses only Definition 1 as hypothesis, are a fortiori valid when we use as hypothesis the existence of the other singularities that we now formulate.

2.2.2. Potato chip singularities.

DEFINITION 2. *We say that u experiences a potato chip singularity when we can find continuous functions*

$$f_\pm : \mathbb{R}^{n-1} \times [0,T) \to \mathbb{R}$$

such that

$$\begin{aligned} &f_+(x_1,\dots,x_{n-1},t) \geq f_-(x_1,\dots,x_{n-1},t), \quad t \in [0,T], x_1,\dots,x_{n-1} \in B_{2r}(\Pi \mathbf{x}^0),\\ &f_+(x_1,\dots,x_{n-1},0) > f_-(x_1,\dots,x_{n-1},0), \quad x_1,\dots,x_{n-1} \in B_r(\Pi \mathbf{x}^0),\\ &\lim_{t\to T^-} (f_+(x_1,\dots,x_{n-1},t) - f_-(x_1,\dots,x_{n-1},t)) = 0 \quad \forall \quad x_1,\dots,x_{n-1} \in B_{2r}(\Pi \mathbf{x}^0) \end{aligned}$$

and such that the surfaces

$$\Sigma_{\pm,t} = \{x_n = f_\pm(x_1,\dots,x_{n-1},t)\} \subset \Omega$$

are transformed into each other by the flow

$$\Phi_t(\Sigma_{\pm,0}) \supset \Sigma_{\pm,t} \ .$$

Note that in Definition 2 we are not requiring that the functions are C^1 as was done in [12]. For us, it suffices that $f_\pm$ are continuous. That is, we allow the singularities to be ruffled potato chips. Since the arguments we will present in section 3 do not depend on calculus identities, there is no need for the boundaries of the sets to be differentiable.

If we denote by $\mathcal{S}_t^{(f)} = \{x \mid f_-(x_1,t) \leq x_n \leq f_+(x_1,t)\}$, we have, by the intermediate value theorem and the continuity of the trajectories

$$\Phi_{t,s}^{B_r(\mathbf{x}^0)}(\mathcal{S}_s^{(f)}) \subset \mathcal{S}_t. \tag{2.1}$$

In particular, if $f_\pm$ verify Definition 2, then $\mathcal{S}_s^{(f)}$ verifies the assumptions of Definition 1.

Hence, if a system satisfies Definition 2, it also satisfies Definition 1.

Potato chip singularities were introduced as a conjectural mechanism (see [17] and [19]) of singularities for a three-dimensional ideal magnetohydrodymamic flow in which two linked flux rings approach each other forming two-dimensional current sheets. In two-dimensional cases, similar singularities were proposed by [21], [22].

The two-dimensional potato chip singularities were considered in [9], where they were called *"sharp fronts."* Using calculus identities and the fact that the fluid admits a stream function representation, it was shown that if a sharp front exits, then (1.1) holds. This result was generalized to three dimensions in [12]. Both of these results follow from Theorem 3.1.

2.2.3. Tube collapse singularities. The following definition appears for the case $n = 3$ in [11]. In the case $d = 2$ the concept was introduced in [9], [10].

Let $I_i \subset \mathbb{R}$, $i = 1,\dots,n$, be bounded intervals. Let $Q = \times_i I_i \subset \mathbb{R}^n$ be a cube.

DEFINITION 3. *A regular tube is a relatively open set $\mathcal{S} \subset Q$, characterized as*

$$\mathcal{S} = \{x \in Q \mid f(x) < 0\}, \tag{2.2}$$

where $f : Q \to \mathbb{R}$ is a C^1 function that satisfies

$$f(x) = 0 \implies \nabla_{x_1,\dots,x_{n-1}} f \neq 0.$$

For every $x_n \in I_n$, the set

$$\mathcal{S}(x_n) = \mathcal{S} \cap I_1 \times \cdots \times I_{n-1} \times \{x_n\}$$

is nonempty, and its closure is contained in the interior of $I_1 \times \cdots \times I_{n-1} \times \{x_n\}$.

We will also consider the situation when f_t is a family of functions indexed by time $t \in [0, T)$.

DEFINITION 4. *We say that the vector field u experiences a tube collapse singularity at time T when the boundaries of the tube evolve with the velocity field u and* $\liminf_{t\to T} |\mathcal{S}_t| = 0$.

An example worth keeping in mind is when $f_t(x) = \operatorname{dist}(x, \gamma) + r(t)$, where γ is a curve, dist denotes the distance, and $r(t) \to 0$ as $t \to 0$. S_t is the set of points which are at a distance less than $r(t)$ from the curve γ. (Of course, we could let the curve γ depend on time, provided that it does not become too pathological.)

Again, we point out that Definition 4 implies Definition 1. We can take $\Omega_- = \times_{i=1,\dots,n-1} I_i \times J$, $\Omega_- = \times_{i=1,\dots,n-1} I_i \times I_d$, where $J \subset I_d$ is an interval contained in the interior of I_d.

2.2.4. Saddle collapse singularity. This singularity is specific for two-dimensional flows. We follow the definition in [8]. We refer to that paper for a comparison with alternative definitions in the literature.

DEFINITION 5. *We consider foliations of a neighborhood of the origin (with coordinates x_1, x_2) whose leaves are given by equations of the form*

$$\rho \equiv (y_1\beta(t) + y_2) \cdot (y_1\delta(t) + y_2) = \text{cte} \tag{2.3}$$

and $(y_1, y_2) = F_t(x_1, x_2)$, where $\beta, \delta : [0, T) \to \mathbb{R}^+$ are C^1 functions, F is a C^2 function of x, t, for a fixed t, and F_t is an orientation preserving diffeomorphism.

We say that the foliation experiences a saddle collapse when

$$\liminf_{t\to T} \beta(t) + \delta(t) = 0.$$

If the leaves of the foliation are transported by a vector field u, we say that the vector field u experiences a saddle collapse.

If we take as $\Omega_\pm$ balls centered at $F(0, 0, T)$ and as the set $\mathcal{S}_s$ a connected component of the set $\rho < 0$, we see that Definition 5 implies Definition 1.

3. Kinematic arguments. The main result of this section follows.

THEOREM 3.1. *If u as before has a squirt singularity, then*

$$\int_s^T \sup_x |u(x, t)|\, dt = \infty \quad \forall s \in (0, T). \tag{3.1}$$

Moreover, if u has a potato chip singularity, then

$$\int_s^T \sup_x |\Pi u(x, t)|\, dt = \infty, \tag{3.2}$$

where Π *is the projection on the first* $n-1$ *coordinates.*

REMARK 1. *We note that in the argument for Theorem* 3.1*, some of the hypotheses can be somewhat weakened.*

For example, using the theory of [13]*, the hypothesis that* $u \in C^1$ *can be weakened to* $u \in H^1$*.*

We also note that strict volume preservation is not needed. It suffices that the volume contraction remains bounded. That is, for some constant $C \geq 1$ *and all* $M \subset \mathbb{R}^n$ *measurable,* $C^{-1}|M| \leq |\Phi_t(M)| \leq C|M|$*.*

REMARK 2. *We note that if* $u(x,t)$ *experiences a squirt singularity at* $t = T$ *and* $\Gamma : [0,T) \hookleftarrow [0,T)$ *is a reparameterization, then*

$$\tilde{u}(x,t) = u(x,\Gamma(t))\Gamma'(t)$$

also has a potato chip singularity.

It is reassuring to note that the conclusions of Theorem 3.1 *remain true for* $\tilde{u}$*. But the observation that the existence of potato chip singularities is invariant under time reparameterizations shows that, with the present assumptions, one cannot obtain more precise rates of the blow-up of* $\sup_x |u(x,t)|$ *than* (3.1)*.*

In case we assume that singularities are somewhat more uniform, it is possible to develop more quantitative information about the rates of collapse.

Roughly speaking, we just need to assume that the exit area of the set $\mathcal{S}_s$ controls the volume of the set.

For example, in potato chip singularities (Definition 2), we say that the collapse is uniform when

$$\max_{x_1,x_2}(f_+(x_1,x_2,t) - f_-(x_1,x_2,t)) \leq M \min_{x_1,x_2}(f_+(x_1,x_2,t) - f_-(x_1,x_2,t)),$$

where M is a constant independent of time.

In tube collapse singularities (Definitions 4 and 3) we say that the collapse is uniform when

$$\max |S(x_n)|_{n-1} \leq M \min |S(x_n)|,$$

where M is a constant independent of time and $|\cdot|_{n-1}$ denotes the $n-1$ dimensional area.

Given a S_t a C^1 set, we denote by $\tilde{\partial} S_t$ the portion of the boundary which is not evolving with the fluid.

We note that by zero divergence of the fluid the change of volume is the integral of u over $\tilde{\partial} S_t$. Hence, we always have

$$\frac{d}{dt}|\mathcal{S}_t| \geq -||u||_{L^\infty} |\tilde{\partial}\mathcal{S}_t|_{n-1}.$$

In the uniform cases, we have

$$\frac{d}{dt}|\mathcal{S}_t| \geq -M||u||_{L^\infty} |\mathcal{S}_t|.$$

Integrating the above equation we have

$$|\mathcal{S}_t| \geq |\mathcal{S}_0| \exp\left(-M \int_0^t ||u(s)||_{L^\infty}\, ds\right)$$

so that uniform collapses cannot happen too fast.

3.1. Proof of Theorem 3.1. From the assumption that $|\Phi_{T,s}^{\Omega_+}\mathcal{S}_s| \to 0$, we conclude that almost all the trajectories starting in $\mathcal{S}_s$ at time s leave the set Ω_+ at a time $\tau \in (s,T)$.

Therefore, we conclude that for any trajectory $x(t)$ starting in $\Omega_- \cap \mathcal{S}_s$ at time s we have

$$\left|\int_s^\tau u(\Phi_t(x),t)\,dt\right| \geq r > 0. \tag{3.3}$$

Therefore,

$$\int_s^T \sup_x |u(x,t)|\,dt \geq r > 0. \tag{3.4}$$

Since (3.4) holds for every $s \in (0,T)$ we conclude that (3.1) holds.

To establish (3.2) we observe that in the classical potato chip singularity, since the escape can happen only by increasing the $n-1$ first components, we can sharpen (3.3) to

$$\left|\int_s^T \Pi u(\Phi_t(x),t)\,dt\right| \geq r/2$$

again for all $s \in [0,T)$.

4. A priori bounds. In this section, we show how if the vector field u satisfies certain partial differential equations, then (1.2) holds. By Theorem 3.1, we conclude immediately that these equations do not exhibit any of the singularities considered in Definition 1.

We consider two- and three-dimensional Boussinesq equations and Navier–Stokes equations in three dimensions.

We note that the results on two-dimensional Boussinesq equations are closely related to the problem proposed by Moffatt [20]:

XXI Century Problem 3: *The problem is to examine the evolution of the θ-field for Boussinesq equations (see* [1]*) in the neighborhood of its saddle points, to determine whether singularities of $\nabla\theta$ can develop, and to examine the influence of weak molecular diffusivity k in controlling the approach to such singularities.*

We show that the saddle collapse singularities and similar ones cannot occur. We do not exclude the possibility that singularities other than squirt singularities could also occur. For example, the argument presented here does not exclude singularities in which the surfaces evolve until they touch at just one point other than the origin.

The proof of (1.2) for the case of Navier–Stokes equations has been in the literature for a long time. See, for example, [16], [23] and the exposition in [14], where it is called the *"second F_N ladder."* Hence, we will present only the proof in the case of the Boussinesq equation in two and three dimensions.

The proofs are based on very elementary arguments, basically, integration by parts without boundary terms, Sobolev inequalities and interpolation inequalities. Hence, they remain valid for all the boundary conditions that allow us to carry out these operations. These include problems defined in the whole space and in a bounded domain with periodic as well as Neumann and Dirichlet conditions with respect to appropriate fields or their gradients. We will henceforth assume that the boundary conditions are such that they allow integration by parts without boundary terms.

4.1. Two-dimensional Boussinesq equations. The Boussinesq equations are

$$\frac{\partial u}{\partial t} + u \cdot \nabla u = -\nabla p + \nu \Delta u + (0, \theta), \tag{4.1}$$

$$\nabla \cdot u = 0, \tag{4.2}$$

$$(\partial_t + u \cdot \nabla)\, \theta = \kappa \Delta \theta, \tag{4.3}$$

with $u = (u_1, u_2)$, $x = (x_1, x_2) \in \mathbb{R}^2$ or $\mathbb{R}^2/\mathbb{Z}^2$, and finite energy at initial time.

The Cauchy problem for the system (4.1), (4.2), and (4.3) has been extensively studied in the literature; see [5], [18], and [24]. In the case $\kappa > 0$ it is known that the equation does not develop singularities in finite time. In order to study the evolution of the level sets of θ it is reasonable to take $\kappa = 0$, where the collapse of the saddle would produce a singularity on $\nabla\theta$. This is a two-dimensional potato chip singularity; for more details, see [9].

In [6], [7], and [15] the two-dimensional Boussinesq convection in the absence of viscous effects was studied numerically and analytically.

THEOREM 4.1. *If u satisfies the two-dimensional Boussinesq equation with $\nu > 0$ and $||\theta(0)||_{L^2} \le A < \infty$, then* (1.2) *holds.*

In particular, using Theorem 3.1*, u does not exhibit any singularity satisfying Definition* 1.

Proof. We denote by C_1, C_2 constants that depend only on ν, A and the initial conditions. In particular, they can change the meaning from line to line.

From (4.3) we obtain that the L^p norms $p \ge 1$ are nonincreasing—they are conserved if $\kappa = 0$:

$$\|\theta(\cdot, t)\|_{L^p} \le \|\theta(\cdot, 0)\|_{L^p} \quad \text{for } 1 \le p \le \infty \quad \forall t \ge 0.$$

Taking the curl of (4.1) of the velocity field we get

$$(\partial_t + u \cdot \nabla)\, \omega = \theta_{x_1} + \nu \Delta \omega, \tag{4.4}$$

where $\omega = \operatorname{curl}(u)$.

We multiply (4.4) by ω and integrate by parts to obtain

$$\frac{1}{2}\frac{d}{dt}\int |\omega|^2\, dx + \nu \int |\nabla \omega|^2 dx = \int \omega \theta_{x_1} dx. \tag{4.5}$$

Integration by parts and the Hölder inequality gives

$$\frac{1}{2}\frac{d}{dt}\int |\omega|^2\, dx + \nu ||\nabla \omega||_{L^2}^2 \le ||\nabla \omega||_{L^2} ||\theta||_{L^2}.$$

This implies that

$$\frac{d}{dt}\int |\omega|^2\, dx \le C_1,$$

and therefore $||\omega||_{L^2} \le C_1 t + C_2$.

Substituting this into (4.5) gives

$$\nu ||\nabla \omega||_{L^2}^2 \le A ||\nabla \omega||_{L^2} - \frac{1}{2}\frac{d}{dt}||\omega||_{L^2}.$$

An integration with respect to time and a Hölder inequality for the integration with respect to time yields

$$\nu \int_0^t ds\, ||\nabla\omega(s)||_{L^2}^2 \le A \int_0^t ds\, ||\nabla\omega(s)||_{L^2} - \frac{1}{2}||\omega(t)||_{L^2}^2 + \frac{1}{2}||\omega(0)||_{L^2}^2$$
$$\le At^{1/2}\left(\int_0^t ds\, ||\nabla\omega(s)||_{L^2}^2\right)^{1/2} + \frac{1}{2}||\omega(0)||_{L^2}^2.$$

This yields

$$\int_0^t ds\, ||\nabla\omega(s)||_{L^2}^2 \le C_1 t + C_2, \tag{4.6}$$

and, using Hölder inequality again,

$$\int_0^t ds\, ||\nabla\omega(s)||_{L^2} \le C_1 t + C_2. \tag{4.7}$$

The well-known Biot–Savart law recovers the velocity field from the vorticity by the integral operator

$$u(x,t) = \frac{1}{2\pi}\int K(x-y)\omega(y,t)dy,$$

with $K(x) = (-\frac{x_2}{x_1^2+x_2^2}, \frac{x_1}{x_1^2+x_2^2})$ for $x \in \mathbb{R}^2$, and a similar formula holds for $\mathbb{R}^2/\mathbb{Z}^2$.

Furthermore, ∇u is a singular integral operator of ω, and Δu is a singular integral operator of $\nabla\omega$ (for details, see [3]). From the classical Calderon–Zygmund theory we have

$$\|\nabla u\|_{L^2} \le C\|\omega\|_{L^2}, \qquad \|\Delta u\|_{L^2} \le C\|\nabla\omega\|_{L^2}. \tag{4.8}$$

Combining estimates (4.6), (4.7), and (4.8) and using Sobolev inequalities we finally get

$$\int_0^t \|u\|_{L^\infty} ds \le C\int_0^t (\|u\|_{L^2} + \|\Delta u\|_{L^2})ds$$
$$\le C_1 t + C_2. \qquad \square$$

REMARK 3. *The argument above works for $\nu > 0$. For $\nu = 0$ we do not have control on any norm of the derivatives of the vorticity.*

4.2. Three-dimensional Boussinesq equations. In this section we adapt Theorem 4.1 to three dimensions.

THEOREM 4.2. *If u satisfies the three-dimensional Boussinesq equation with $\nu > 0$ and $||\theta_0||_{L^2} < \infty$, then* (1.2) *holds.*

In particular, using Theorem 3.1*, u does not exhibit any singularity satisfying Definition* 1.

Compared with the proof of Theorem 4.1, the proof of Theorem 4.2 requires an extra estimate on the nonlinear term that appears on the vorticity equation. Below we give the argument which is based on the argument in [16] for Navier–Stokes.

By the usual integration by parts

$$\frac{1}{2}\frac{d}{dt}\int |u|^2\, dx + \nu\int |\nabla u|^2 dx \le C\int |u\theta| dx.$$

Therefore, proceeding as before,

$$\|u\|_{L^2}^2 \le C_1 t + C_2,$$
$$\int_0^t \|\nabla u\|_{L^2}^2 ds \le \tilde{C}_1 t + \tilde{C}_2. \tag{4.9}$$

The vorticity equation is

$$(\partial_t + u \cdot \nabla)\, \omega = \omega \cdot \nabla u + \theta_{x_1} - \theta_{x_2} + \nu \Delta \omega.$$

Multiply the vorticity equation by ω and integrate by parts

$$\frac{1}{2}\frac{d}{dt}\int |\omega|^2\, dx + \nu \int |\nabla \omega|^2 dx \le \int |(\omega \cdot \nabla u)\omega| dx + \frac{1}{2\nu}\int |\theta|^2\, dx + \frac{\nu}{2}\int |\nabla \omega|^2 dx.$$

The nonlinear term can be bounded by (see [16])

$$\begin{aligned}\int |(\omega \cdot \nabla u)\omega| dx &\le C \|\omega\|_{L^2}^{\frac{3}{2}} \|\nabla \omega\|_{L^2}^{\frac{3}{2}} \\ &\le \tilde{C}\|\omega\|_{L^2}^6 + \frac{\nu}{4}\|\nabla \omega\|_{L^2}^2;\end{aligned}$$

then

$$\frac{1}{2}\frac{d}{dt}\int |\omega|^2\, dx + \frac{\nu}{4}\int |\nabla \omega|^2 dx \le \tilde{C}(1 + \|\omega\|_{L^2}^6)$$

and

$$\frac{\frac{1}{2}\frac{d}{dt}\|\omega\|_{L^2}^2}{(1+\|\omega\|_{L^2}^2)^2} + \nu \frac{\|\nabla \omega\|_{L^2}^2}{(1+\|\omega\|_{L^2}^2)^2} \le \tilde{C}(1 + \|\omega\|_{L^2}^2),$$

and we get

$$\int_0^t \frac{\|\nabla \omega\|_{L^2}^2}{(1+\|\omega\|_{L^2}^2)^2} ds \le \tilde{\tilde{C}}(1+t). \tag{4.10}$$

Finally, we estimate $\int_0^t \|u\|_{L^\infty} ds$ applying Sobolev inequalities, Calderon–Zygmund theory, (4.9), and (4.10):

$$\begin{aligned}\int_0^t \|u\|_{L^\infty} ds &\le C \int_0^t \|\nabla u\|_{L^2}^{\frac{1}{2}} \|\Delta u\|_{L^2}^{\frac{1}{2}} ds \\ &\le C\left(\int_0^t \|\nabla u\|_{L^2}^2 ds + \int_0^t \|\Delta u\|_{L^2}^{\frac{2}{3}} ds\right) \\ &\le C\left[\int_0^t \|\omega\|_{L^2}^2 ds + \left(\int_0^t \frac{\|\nabla \omega\|_{L^2}^2}{(1+\|\omega\|_{L^2}^2)^2} ds\right)^{\frac{1}{3}} \left(\int_0^t (1+\|\omega\|_{L^2}^2) ds\right)^{\frac{2}{3}}\right] \\ &\le C(1+t),\end{aligned}$$

where C depends on the initial data and on the viscosity.

Acknowledgment. We thank W. Strauss for several comments.

A KINETIC FORMULATION FOR MULTIDIMENSIONAL SCALAR CONSERVATION LAWS WITH BOUNDARY CONDITIONS AND APPLICATIONS*

C. IMBERT† AND J. VOVELLE‡

Abstract. We state a kinetic formulation of weak entropy solutions of a general multidimensional scalar conservation law with initial and boundary conditions. We first associate with any weak entropy solution an entropy defect measure; the analysis of this measure at the boundary of the domain relies on the study of weak entropy sub- and supersolutions and implies the introduction of the notion of sided boundary defect measures. As a first application, we prove that any weak entropy subsolution of the initial-boundary value problem is bounded above by any weak entropy supersolution (comparison theorem). We next study a Bhatnagar–Gross–Krook-like kinetic model that approximates the scalar conservation law. We prove that such a model converges by adapting the proof of the comparison theorem.

Key words. conservation law, initial-boundary value problem, boundary defect measures, kinetic traces, weak entropy sub- and supersolutions, comparison theorem, generalized kinetic solutions, Bhatnagar–Gross–Krook-like kinetic model

1. Introduction.

Let Ω be a strong Lipschitz open subset of $\mathbb{R}^d$. Let $\partial\Omega$ denote its boundary, $n(\overline{x})$ denote the outward unit normal to Ω at a point $\overline{x} \in \Omega$, $Q = (0,+\infty) \times \Omega$, and $\Sigma = (0,+\infty) \times \partial\Omega$. We consider the following multidimensional scalar conservation law:

$$\partial_t u + \operatorname{div}_x A(u) = 0 \text{ in } Q, \tag{1.1a}$$

with the initial condition

$$u(0,x) = u_0(x) \quad \forall x \in \Omega \tag{1.1b}$$

and the boundary condition

$$u(s,y) = u_b(s,y) \quad \forall (s,y) \in \Sigma. \tag{1.1c}$$

The first step in the understanding of (1.1c) is the work of Bardos, Le Roux, and Nédélec [1]: they show that if the initial datum u_0 is BV and the boundary datum is C^2-regular, there exists a unique (weak entropy) solution of (1.1). In particular, they show that an inequality must hold at the boundary. This inequality is known as the Bardos–Le Roux–Nédélec (BLN) condition (see (3.19)). Note that the BLN condition makes sense only if the solution u admits a trace on $\partial\Omega$. In the case of the Cauchy problem with merely essentially bounded (L^∞) data, some notions of a generalized solution have been defined. The measure-valued entropy solutions were introduced by DiPerna [9] and the entropy process solutions by Eymard, Gallouët,

and Herbin [11]. These notions of a very weak solution are well adapted to the study of the convergence of numerical schemes, and error estimates are also available. In the case of the Cauchy–Dirichlet problem with L^∞ data, Otto [25] proposed a notion of *weak entropy solution* $u \in \mathsf{L}^\infty(Q)$, relying on the notion of boundary entropy-flux pairs. An equivalent definition can be given by using "Kružkov semientropies" (see [8, 30, 34, 17]). An accurate notion of an entropy process solution can be given in order to prove the convergence of certain numerical methods [34], but it does not seem possible to get an error estimate with respect to the approximation by vanishing viscosity, for example. In order to fill this gap, we follow the ideas developed by Lions, Perthame, and Tadmor [18]. Their heuristic idea, which is, in part, a continuation of the works of Brenier [7] and Di Perna [9], is to take into account the decrease of the entropy by introducing an "entropy defect" measure. More precisely, a kinetic function f is associated with the macroscopic function u by setting

$$f(t,x,\xi) = \begin{cases} 1 & \text{if } 0 < \xi < u(t,x), \\ -1 & \text{if } u(t,x) < \xi < 0, \\ 0 & \text{otherwise.} \end{cases} \tag{1.2}$$

Such a kinetic function is a so-called equilibrium function. The kinetic formulation of Lions, Perthame, and Tadmor states that u is a weak entropy solution of the conservation law if and only if there exists a bounded nonnegative measure m such that

$$(\partial_t + a.\nabla_x) f = \partial_\xi m \text{ in } \mathcal{D}'((0,T) \times \mathbb{R}^d \times \mathbb{R}). \tag{1.3}$$

Next, Perthame [27] showed that these techniques supply a good technical framework to easily prove, for instance, the L^1-contraction property and the error estimate with respect to the parabolic approximation, without relying on the dedoubling variable technique.

We start from [27] and develop analogous techniques for a conservation law with boundary conditions. The main difficulty is to study how the weak entropy solution u and the defect measure m behave at the boundary of the domain. We handle this difficulty by considering the space kinetic trace f^τ of the kinetic function f [32, 33]. As far as the defect measure is concerned, two nonnegative measures $m^b_\pm$ supported by $\Sigma \times \mathbb{R}_\xi$ must therefore be considered. They are characterized by the formula

$$(-a \cdot n) f^\tau = M f^b + (-a \cdot n)\mathrm{sgn}_\mp + \partial_\xi m^b_\pm, \tag{1.4}$$

where the constant M is a Lipschitz constant of the flux A on a compact subset of $\mathbb{R}$ in which the data u_0 and u^b, which are supposed to be measurable essentially bounded functions, take a.e. their values (see section 2). Relation (1.4) can be understood as a kinetic analogue of the BLN condition.[1] Why do we need two nonnegative measures to describe the behavior of the entropy defect measure at the boundary? It is because the notion of weak entropy solution is "sided." Let us be more specific. We define weak entropy sub- and supersolutions for the initial-boundary value problem and give a kinetic formulation of them. Hence two different defect measures $m_\pm$ are a priori associated with each weak entropy solution. But, eventually, we prove they coincide in $Q \times \mathbb{R}_\xi$ and can be different at the boundary. Notions of weak entropy sub- and supersolutions for the Cauchy problem were previously considered [2, 15, 16, 26, 3, 4],

[1] It is a generalization of it in the sense that no strong traces are required; thus merely L^∞ data can be treated.

and comparison principles were established: any weak entropy subsolution of the Cauchy problem is bounded above by any weak entropy supersolution. Such results have also been proved by Terracina [31] for the initial-boundary value problem in the context of BV solutions. We state and prove an analogous result for the initial-boundary value problem in the context of L^∞ solutions. The L^1-contraction property and the maximum principle follow from it.

We then use our results to study an approximation of the conservation law, namely a kinetic model "à la Bhatnagar, Gross, and Krook" (BGK-like kinetic model for short). It was first introduced by Perthame and Tadmor [29] for the Cauchy problem and adapted by Nouri, Omrane, and Vila [22, 23, 24] to the initial-boundary value problem. Nouri, Omrane, and Vila prove the convergence of the BGK-like kinetic model whenever the data are at equilibrium or not. Here, we restrict our study to the case where the data are at equilibrium and show how, in this framework, the concept of a *generalized kinetic solution* can be used to prove the convergence of the BGK-like kinetic model. Such very weak solutions were introduced by Perthame [28] for the Cauchy problem. They can be viewed as the analogue of the measure-valued solutions of DiPerna [9] or the entropy process solutions of Eymard, Gallouët, and Herbin [11]. The definition of a generalized kinetic solution is based on the following kinetic formulation: instead of considering an equilibrium function, a solution can be a general kinetic function (see sections 2 and 5 for precise definitions). The proof of the comparison theorem is slightly modified in order to prove that there is at most one generalized kinetic solution of (1.1) and that it is in fact a weak entropy solution. Hence, it permits us to easily pass to the limit in the kinetic model.

To conclude this introduction, let us mention the recent work of Ben Moussa and Szepessy [6] in which the concept of measure-valued solution to deal with "very weak solutions" is used, and let us state some other occurrences of "kinetic methods" in the study of first-order problems with boundary conditions [5, 20]; see also [21, 13, 14].

The paper is organized as follows. Section 2 is devoted to notations and assumptions. In section 3, kinetic formulations of weak entropy solutions (Theorem 3.1) and entropy semisolutions (Proposition 3.3) are stated and proved. In particular, kinetic traces and boundary defect measures are constructed and characterized (Proposition 3.4). In section 4, the comparison theorem (Theorem 4.1) is proved. Section 5 is devoted to the study of the BGK-like kinetic model.

Finally, let us mention that in a forthcoming paper [10] we study another approximation of the initial-boundary value problem: the parabolic regularization of the conservation law by an artificial viscosity. We get an error estimate between the entropy solution of the conservation law and the regular solution of the parabolic equation. Even if we adapt once again the proof of the comparison theorem, additional difficulties arise, and the proof is rather long and technical.

2. Preliminaries. We give here some notations, assumptions, and basic properties that are used throughout the paper.

The space $\mathbb{R}^d$ is endowed with its usual Euclidean structure. The scalar product is denoted by $x \cdot y$ and the Euclidean norm by $|x|$. For the sake of clarity, $\mathbb{R}_t$ and $\mathbb{R}_\xi$ denote the lines of reals, respectively, related to the t and ξ variables.

Data. We assume u_0 and u_b to be essentially bounded measurable functions. Let $K > 0$ be a positive constant such that

$$-K \le u_0(x) \le K \text{ for a.e. } x \in \Omega \quad \text{and} \quad -K \le u_b(t,x) \le K \text{ for a.e. } (t,x) \in \Sigma\,.$$

The flux function A is assumed to be locally Lipschitz continuous. Let M be the

Lipschitz constant of the function A restricted to $[-K,K]$, and let $a(\xi)=A'(\xi)$.

Remark 1. We could as well consider the equation $\partial_t u+\operatorname{div}_x(A(t,x,u))=0$. All the results presented in this paper remain valid under the assumption that the function A is locally Lipschitz continuous with respect to $(t,x)\in[0,T]\times\overline{\Omega}$ uniformly with respect to the u variable, while for every $u\in\mathbb{R}$, $(t,x)\mapsto A(t,x,u)$ is in $\mathsf{C}^1([0,T]\times\overline{\Omega})$.

Kružkov semientropies. Define

$$\operatorname{sgn}_+(\xi)=\begin{cases}1 & \text{if} \quad \xi>0,\\ 0 & \text{if} \quad \xi\le 0\end{cases} \qquad \text{and} \quad \operatorname{sgn}_-(\xi)=\begin{cases}-1 & \text{if} \quad \xi<0,\\ 0 & \text{if} \quad \xi\ge 0\end{cases}$$

and $\xi^{\pm}=\operatorname{sgn}_{\pm}(\xi)\xi$. Let $a\top b$ denote $\max\{a,b\}$, and let $a\bot b$ denote $\min\{a,b\}$. The Kružkov semientropies are the convex functions $u\mapsto(u-\kappa)^{\pm}$ for $\kappa\in\mathbb{R}$. The corresponding entropy fluxes are given by the formula

$$\mathcal{F}^{\pm}(u,\kappa)=\operatorname{sgn}_{\pm}(u-\kappa)(A(u)-A(\kappa)).$$

Kinetic and equilibrium functions. We previously recalled what an equilibrium function is (see (1.2)). More generally, a kinetic function is a function $f(t,x,\xi)$ such that

$$\begin{aligned}&0\le f(t,x,\xi)\operatorname{sgn}(\xi)\le 1,\\ &\partial_\xi f(t,x,\xi)=\delta(\xi)-\nu_{t,x}(\xi),\end{aligned} \tag{2.1}$$

where ν is a Young measure. For an equilibrium function, $\nu_{t,x}(\xi)=\delta(\xi-u(t,x))$. In the following, we also consider two functions associated with any kinetic one:

$$\begin{aligned}f_+(t,x,\xi)&=f(t,x,\xi)-\operatorname{sgn}_-(\xi),\\ f_-(t,x,\xi)&=f(t,x,\xi)-\operatorname{sgn}_+(\xi).\end{aligned}$$

Notice that $\partial_\xi f_\pm=-\nu_{t,x}(\xi)$ and that these functions no longer have a bounded support with respect to the kinetic variable ξ. Nevertheless, and it is essential, there exists $\kappa\in\mathbb{R}_\xi$ such that $f_+(t,x,\xi)=0$ if $\xi\ge\kappa$, and there exists $\kappa'\in\mathbb{R}_\xi$ such that $f_-(t,x,\xi)=0$ if $\xi\le\kappa'$. We simply say that f_+ vanishes for $\xi\gg 1$ and f_+ vanishes for $\xi\ll -1$. For equilibrium functions, if (t,x) is fixed, then for a.e. $\xi\in\mathbb{R}_\xi$,

$$\begin{aligned}f_+(t,x,\xi)&=\operatorname{sgn}_+(u(t,x)-\xi),\\ f_-(t,x,\xi)&=\operatorname{sgn}_-(u(t,x)-\xi).\end{aligned}$$

Localization. The set Ω is assumed to be a strong Lipschitz open subset of $\mathbb{R}^d$, which means that, locally, Ω can be represented as the epigraph of a Lipschitz continuous function. More precisely, there exists a locally finite open cover $\{B_{\lambda_i}\}_{i\in I}$ of $\overline{\Omega}$ and a partition of unity $\{\lambda_i\}_{i\in I}$ of $\overline{\Omega}$ subordinate to $\{B_{\lambda_i}\}_{i\in I}$ such that for any λ,

$$\begin{aligned}\Omega_\lambda&:=\Omega\cap B_\lambda=\{x\in B_\lambda\ ;\ (A_\lambda\, x)_d>h_\lambda(\overline{A_\lambda\, x})\},\\ \partial\Omega_\lambda&:=\partial\Omega\cap B_\lambda=\{x\in B_\lambda\ ;\ (A_\lambda\, x)_d=h_\lambda(\overline{A_\lambda\, x})\},\end{aligned}$$

where $x\mapsto A_\lambda\, x$ is a change of coordinates of $\mathbb{R}^d$ (i.e., the composition of a translation and a rotation of $\mathbb{R}^d$) and where $\overline{y}$ stands for $(y_1,\dots,y_{d-1})$ if $y\in\mathbb{R}^d$. In the following, we also use the notations $Q_\lambda=(0,+\infty)\times\Omega_\lambda$ and $\Sigma_\lambda=(0,+\infty)\times\partial\Omega_\lambda$. When proving the comparison theorem and the error estimate, the problem is localized with the help of the functions λ_i. For the sake of clarity, we drop the index i and suppose that the change of coordinates is trivial: $A=\mathrm{Id}$. The open set $\Pi_\lambda=\{\overline{x}\,;\ x\in B_\lambda\}\subset\mathbb{R}^{d-1}$ is

used to parametrize $\partial\Omega_\lambda$. As a matter of fact, we even identify $\partial\Omega_\lambda$ with the graph of h restricted to Π_λ and Ω_λ with its epigraph. The outward unit normal to Ω_λ at any point $(\overline{x}, h(\overline{x}))$ of $\partial\Omega_\lambda$ is given by

$$n(\overline{x}) := n(\overline{x}, h(\overline{x})) = \frac{1}{\sqrt{1+|\nabla_{\overline{x}} h(\overline{x})|^2}}(\nabla_{\overline{x}} h(\overline{x}), -1).$$

Eventually, in order to make clearer integrations on $\partial\Omega_\lambda$, we use the notation

$$d\overline{\sigma}(\overline{x}) = \sqrt{1+|\nabla_{\overline{x}} h(\overline{x})|^2}\, d\overline{x}\,.$$

Regularization. Functions that are defined locally, i.e., that are defined on Ω_λ and $\partial\Omega_\lambda$, are regularized in the following way. Fix $\delta \in]0,1[$ and consider a smooth function $\theta : \mathbb{R} \to \mathbb{R}^+$ whose support is a subset of $[\delta, 1]$ and such that $\int \theta = 1$. Then define a (right-decentered) regularizing kernel $\theta_\varepsilon := \frac{1}{\varepsilon}\theta(\frac{\cdot}{\varepsilon})$ and set $\gamma_{\alpha,\varepsilon}(t, \bar{x}, x_d) = \theta_\alpha(t) \times \Pi_{i=1}^{d-1}\theta_{\overline{\varepsilon}}(x_i) \times \theta_{\varepsilon_d}(x_d)$. The space regularizing kernel $\Pi_{i=1}^{d-1}\theta_{\overline{\varepsilon}}(x_i) \times \theta_{\varepsilon_d}(x_d)$ is denoted by γ_ε. Consider now a function H defined on Q_λ and a function $\overline{H}$ defined on Σ_λ. Their (local) regularized functions are (both) defined on Q_λ by the following formulae:

$$\begin{cases} H^{\alpha,\varepsilon}(t,x) := (H \times 1_Q) \star \gamma_{\alpha,\varepsilon}(t,x) = \int_Q H(r,z)\gamma_{\alpha,\varepsilon}(t-r, x-z)\, dr\, dz, \\ \overline{H}^{\alpha,\varepsilon}(t,x) := (\overline{H} \times 1_\Sigma) \star \gamma_{\alpha,\varepsilon}(t,x) = \int_\Sigma \overline{H}(r,z)\gamma_{\alpha,\varepsilon}(t-r, x-z)\, dr\, d\sigma(z). \end{cases}$$

These two functions equal zero out of Q_λ as soon as $\delta\, \varepsilon_d \geq \sqrt{d}\, \mathrm{Lip} h\, \overline{\varepsilon}$, which is always assumed. Of course, if a function ψ is defined both on Q_λ and Σ_λ, then the two means of regularization described above do not lead to the same functions $\psi^{\alpha,\varepsilon}$; nevertheless, there will be no risk of confusion in the forthcoming proofs. Let us also point out the fact that this regularization is local and in fact depends on the map A_λ, even if it is hidden in computations in order to make them more readable.

3. A kinetic formulation of the Cauchy–Dirichlet problem. The main result of the paper is the following kinetic formulation of generalized entropy solutions. For any smooth test function $\phi \in \mathsf{C}_\mathsf{c}^\infty(\mathbb{R}^{d+2})$, $\phi^{(t=0)}$ and $\overline{\phi}$ denote, respectively, the restriction of ϕ to $\{0\} \times \Omega \times \mathbb{R}_\xi$ and to $\Sigma \times \mathbb{R}_\xi$.

THEOREM 3.1. *Consider a bounded function $u \in \mathsf{L}^\infty(Q)$. Let f^0 and f^b be the equilibrium functions associated with u_0 and u_b. Then u is a weak entropy solution of (1.1) if and only if there exists a bounded nonnegative measure $m \in \mathcal{M}^+(Q \times \mathbb{R}_\xi)$ and two nonnegative measurable functions $m_+^b, m_-^b \in \mathsf{L}^\infty_{\mathsf{loc}}(\Sigma \times \mathbb{R}_\xi)$ such that the function m_+^b vanishes for $\xi \gg 1$ (resp., the function m_-^b vanishes for $\xi \ll -1$) and such that the equilibrium function f associated with u satisfies for any $\phi \in \mathsf{C}_\mathsf{c}^\infty(\mathbb{R}^{d+2})$*

$$\begin{aligned} (3.1) \quad \int_{Q\times\mathbb{R}_\xi} f(\partial_t + a\cdot\nabla_x)\phi + \int_{\Omega\times\mathbb{R}_\xi} f^0\phi^{(t=0)} + \int_{\Sigma\times\mathbb{R}_\xi} (Mf_\pm^b + (-a\cdot n)\mathrm{sgn}_\mp)\overline{\phi} \\ = \int_{Q\times\mathbb{R}_\xi} \partial_\xi\phi\, dm + \int_{\Sigma\times\mathbb{R}_\xi} \partial_\xi\phi\, dm_\pm^b, \end{aligned}$$

where M is the Lipschitz constant of the flux function A on $\overline{Q} \times [-K, K]$.

In order to prove and understand this formulation, we define weak entropy sub- and supersolutions of the initial-boundary value problem (1.1) and exhibit a kinetic formulation for these semisolutions.

3.1. Weak entropy sub- and supersolutions. Let us define weak entropy sub- and supersolutions for the initial-boundary value problem (1.1).

DEFINITION 3.2. *Consider a bounded function* $u \in \mathsf{L}^\infty(Q)$.

1. *The function* u *is a* weak entropy subsolution *(resp.,* weak entropy supersolution*) of* (1.1) *if for any* $\kappa \in \mathbb{R}$ *and any* $\phi \in \mathsf{C}_c^\infty(\mathbb{R}_t \times \mathbb{R}^d)$, $\phi \geq 0$,

$$\begin{aligned}(3.2)\quad &\int_Q \left[(u(t,x)-\kappa)^\pm \partial_t \phi(t,x) + \mathcal{F}^\pm(u(t,x),\kappa).\nabla_x \phi(t,x)\right] dt\, dx \\ &+ \int_\Omega (u_0(x)-\kappa)^\pm \phi(0,x)dx + M\int_\Sigma (u_b(s,y)-\kappa)^\pm \phi(s,y)ds\, d\sigma(y) \geq 0.\end{aligned}$$

2. *The function* u *is a* weak entropy solution *of* (1.1) *if it is both a weak entropy subsolution and a supersolution.*

PROPOSITION 3.3. *Let* f^0 *and* f^b *be the equilibrium functions associated with* u_0 *and* u_b. *Consider a bounded function* $u \in \mathsf{L}^\infty(Q)$. *Then* u *is a weak entropy subsolution (resp., weak entropy supersolution) of* (1.1) *if and only if there exists* $m_\pm \in \mathsf{C}(\mathbb{R}_\xi; w - \mathcal{M}^+(\overline{Q}))$ *such that* m_ξ *vanishes for* $\xi \gg 1$ *(resp., for* $\xi \ll -1$*) and such that for any* $\phi \in \mathsf{C}_c^\infty(\mathbb{R}^{d+2})$,

$$\begin{aligned}(3.3)\quad &\int_{Q\times\mathbb{R}_\xi} f(\partial_t + a\cdot\nabla_x)\phi + \int_{\Omega\times\mathbb{R}_\xi} f^0\phi^{(t=0)} + \int_{\Sigma\times\mathbb{R}_\xi} (Mf^b_\pm + (-a\cdot n)\mathrm{sgn}_\mp)\overline{\phi} \\ &\qquad = \int_{\overline{Q}\times\mathbb{R}_\xi} \partial_\xi \phi dm_\pm.\end{aligned}$$

Remark 2. The function f satisfies (3.3) if and only if the function $f_\pm$ satisfies

$$(3.4)\quad \int_{Q\times\mathbb{R}_\xi} f_\pm(\partial_t + a\cdot\nabla_x)\phi + \int_{\Omega\times\mathbb{R}_\xi} f^0_\pm\phi^{(t=0)} + M\int_{\Sigma\times\mathbb{R}_\xi} f^b_\pm\overline{\phi} = \int_{\overline{Q}\times\mathbb{R}_\xi} \partial_\xi\phi dm_\pm.$$

Notice that here the expression of the boundary term is simplified. Moreover, (3.4) is the kinetic equation that appears in the construction $m_\pm$, and it is also the one we consider when proving the comparison theorem.

Proof of Proposition 3.3. Consider a weak entropy subsolution (resp., weak entropy supersolution) u of (1.1). Let us fix $\kappa \in \mathbb{R}$, and define a linear form $m^\kappa_\pm$ on $\mathsf{C}_c^\infty(\bar{Q})$ by

$$(3.5)\quad m^\kappa_\pm(\phi) = \int_Q (u-\kappa)^\pm \partial_t\phi + \mathcal{F}^\pm(u,\kappa)\cdot\nabla_x\phi + \int_\Omega (u_0-\kappa)^\pm\phi^{(t=0)} + M\int_\Sigma (u_b-\kappa)^\pm\overline{\phi}.$$

Since u is a weak entropy subsolution (resp., weak entropy supersolution), we know that $m^\kappa_\pm(\phi)$ is nonnegative for any κ and any ϕ. We conclude that for any κ, $m^\kappa_\pm$ is a nonnegative measure on $\overline{Q}$, and $m_\pm \in \mathsf{C}(\mathbb{R}_\xi, w - \mathcal{M}^+(\overline{Q}))$. Since $m_\pm \geq 0$, we have $||m_\pm|| = m_\pm(1) < +\infty$ by (3.5), and $m_\pm$ is bounded; moreover, $m_\pm$ vanishes for

$\kappa \gg 1$ (resp., $\kappa \ll 1$). Next, we compute

$$\begin{aligned}
&\int_{\bar{Q}\times\mathbb{R}_\xi} \partial_\xi\phi(t,x,\xi)dm_\pm(t,x,\xi)\\
&= \int_{Q\times\mathbb{R}_\xi} (u-\xi)^\pm \partial_t\partial_\xi\phi + \mathcal{F}^\pm(u,\xi)\cdot\nabla_x\partial_\xi\phi + \int_{\Omega\times\mathbb{R}_\xi} (u_0-\xi)^\pm\partial_\xi\phi^{(t=0)} + M\int_\Sigma (u_b-\xi)^\pm\overline{\partial_\xi\phi}\\
&= \int_{Q\times\mathbb{R}_\xi} \mathrm{sgn}_\pm(u-\xi)(\partial_t\phi + a\cdot\nabla_x\phi) + \int_{\Omega\times\mathbb{R}_\xi} \mathrm{sgn}_\pm(u_0-\xi)\phi^{(t=0)} + M\int_\Sigma \mathrm{sgn}_\pm(u_b-\xi)\overline{\phi}\\
&\qquad = \int_{Q\times\mathbb{R}_\xi} f_\pm(\partial_t\phi + a\cdot\nabla_x\phi) + \int_{\Omega\times\mathbb{R}_\xi} f^0_\pm\phi^{(t=0)} + M\int_\Sigma f^b_\pm\overline{\phi}\\
&\qquad = \int_{Q\times\mathbb{R}_\xi} f(\partial_t\phi + a\cdot\nabla_x\phi) + \int_{\Omega\times\mathbb{R}_\xi} f^0\phi^{(t=0)} + \int_\Sigma (Mf^b_\pm + (-a\cdot n)\mathrm{sgn}_\mp)\overline{\phi}.
\end{aligned}$$

Hence (3.3) is proved.

Conversely, consider $u \in \mathsf{L}^\infty(Q)$ and $g \in \mathsf{C}^\infty_{\mathsf{c}}(\mathbb{R}_t\times\mathbb{R}^d)$. Let $\xi \mapsto E_n(\xi)$ be a smooth approximation of $\xi \mapsto (\xi-\kappa)^\pm$ such that $|E_n'(\xi)| \le 1$ for any positive integer n. Let Ψ be a smooth function with support in $[-2,2]$, with values in $[0,1]$, and that equals 1 on $[-1,1]$. Next, define $\Psi_n(\xi) = \Psi(\xi/n)$. Now apply (3.4) to the test function $\phi(t,x,\xi) = g(t,x)\Psi_n(\xi)E_n'(\xi)$:

$$\begin{aligned}
&\int_Q \left[\int_{\mathbb{R}_\xi} \Psi_n E_n' f_\pm\right]\partial_t g + \left[\int_{\mathbb{R}_\xi} a\Psi_n E_n' f_\pm\right].\nabla_x g + \int_\Omega \left[\int_{\mathbb{R}_\xi} \Psi_n E_n' f^0_\pm\right] g^{(t=0)}\\
&\qquad + M\int_\Sigma \left[\int_{\mathbb{R}_\xi} \Psi_n E_n' f^b_\pm\right]\overline{g} = \int_{\bar{Q}\times\mathbb{R}_\xi} g[\Psi_n' E_n' + \Psi_n E_n'']dm_\pm.
\end{aligned}$$

Letting $n \to +\infty$, we get

(3.6)
$$\begin{aligned}
&\int_Q (u(t,x)-\kappa)^\pm\partial_t g(t,x) + \mathcal{F}^\pm(u(t,x),\kappa)\cdot\nabla_x g(t,x)dtdx + \int_\Omega (u_0(x)-\kappa)^\pm g(0,x)dx\\
&\qquad + M\int_\Sigma (u_b(s,y)-\kappa)^\pm g(s,y)ds\, d\sigma(y) = \int_Q g(t,x)dm_\pm(t,x,\kappa).
\end{aligned}$$

If, moreover, g is assumed to be nonnegative, (3.6) yields (3.2). ∎

3.2. Kinetic traces. In this subsection, we prove the following proposition. See [32, 33] and [19, Lemma 7.34, p. 115].

PROPOSITION 3.4. *Consider a function $f \in L^\infty(Q\times\mathbb{R}_\xi)$ satisfying* (3.3).

1. *There exist two kinetic functions $f^{\tau_0} \in \mathsf{L}^\infty(Q\times\mathbb{R}_\xi)$ and $f^\tau \in \mathsf{L}^\infty(\Sigma\times\mathbb{R}_\xi)$ such that*

$$\lim_{\alpha\to 0^+}\int_{\Omega\times\mathbb{R}_\xi}\left[\int_0^{+\infty} f(t)\theta_\alpha(t)dt\right]\phi = \int_{\Omega\times\mathbb{R}_\xi} f^{\tau_0}\phi, \tag{3.7}$$

$$\begin{aligned}
&\lim_{\varepsilon_d\to 0^+}\int_{[0;+\infty)\times\Pi_\lambda\times\mathbb{R}_\xi}(-a\cdot n)\left[\int_0^{+\infty} f(h(\overline{x})+r)\theta_{\varepsilon_d}(r)\,\lambda(h(\overline{x})+r)dr\right]\psi\\
&\qquad = \int_{[0;+\infty)\times\Pi_\lambda\times\mathbb{R}_\xi}(-a\cdot n)\, f^\tau\,\overline{\lambda}\,\psi
\end{aligned} \tag{3.8}$$

for any $\phi \in \mathsf{L}^1(\Omega \times \mathbb{R}_\xi)$ *and any* $\psi \in \mathsf{L}^1(\Sigma \times \mathbb{R}_\xi)$ *and any function* λ*, the element of the partition of unity* $\{\lambda_i\}_{i\in I}$.

2. *The time kinetic trace* f^{τ_0} *is bounded above (resp., bounded below) by* f^0*, and the space kinetic trace* f^τ *satisfies* (1.4)*, where* $m_\pm^b$ *denotes the restriction of* $m_\pm$ *to* $\Sigma \times \mathbb{R}_\xi$.

Proof. The proof of the existence of f^{τ_0} and of f^τ such that (3.7), (3.8) hold true can be found in [32, 33]. Let us prove that for any test function $\phi \in \mathsf{C}_\mathsf{c}^\infty(\mathbb{R}^{d+2})$,

$$\int_{Q\times\mathbb{R}_\xi} f(\partial_t + a\cdot\nabla_x)\phi + \int_{\Omega\times\mathbb{R}_\xi} f^{\tau_0}\phi^{(t=0)} + \int_{\Sigma\times\mathbb{R}_\xi} (-a\cdot n) f^\tau \overline{\phi} = \int_{Q\times\mathbb{R}_\xi} \partial_\xi \phi dm_\pm. \tag{3.9}$$

Let $\phi \in \mathsf{C}_\mathsf{c}^\infty([0;+\infty)\times\Omega\times\mathbb{R}_\xi)$; consider a right-decentered regularizing kernel $\theta_\alpha(r)$; define a cut-off function $w_\alpha(r) = \int_0^r \theta_\alpha(\tau)d\tau$ and apply (3.3) to the test function $w_\alpha(t)\phi(t,x,\xi)$:

$$\int_{Q\times\mathbb{R}_\xi} w_\alpha(t) f(\partial_t + a\cdot\nabla_x)\phi(t,x,\xi)dtdxd\xi + \int_{Q\times\mathbb{R}_\xi} \theta_\alpha(t) f(t,x,\xi)\phi(t,x,\xi)dtdxd\xi$$
$$= \int_{Q\times\mathbb{R}_\xi} w_\alpha(t)\partial_\xi\phi(t,x,\xi)dm(t,x,\xi).$$

Letting $\alpha \to 0+$ and using the Lebesgue dominated convergence theorem and (3.7), we obtain

$$\int_{Q\times\mathbb{R}_\xi} f(\partial_t + a\cdot\nabla_x)\phi + \int_{\Omega\times\mathbb{R}_\xi} f^{\tau_0}\phi^{(t=0)} = \int_{Q\times\mathbb{R}_\xi} \partial_\xi\phi dm. \tag{3.10}$$

Next, ϕ^λ denotes the function $\phi\,\lambda$, and we define a cut-off function

$$W_{\varepsilon_d}(x) = \int_0^{x_d - h(\bar{x})} \theta_{\varepsilon_d}(s)\,ds\,.$$

We apply (3.10) to the test function $\phi^\lambda W_{\varepsilon_d}$:

$$\int_{Q\times\mathbb{R}_\xi} W_{\varepsilon_d}(x) f(\partial_t + a\cdot\nabla_x)\phi^\lambda(t,x,\xi)dtdxd\xi + \int_{Q\times\mathbb{R}_\xi} f\phi^\lambda a\cdot\nabla_x W_{\varepsilon_d}$$
$$+ \int_{\Omega\times\mathbb{R}_\xi} f^{\tau_0}(x,\xi){\phi^\lambda}^{(t=0)} W_{\varepsilon_d}(x)dxd\xi = \int_{Q\times\mathbb{R}_\xi} \partial_\xi\phi^\lambda(t,x,\xi)W_{\varepsilon_d}(x)dm(t,x,\xi). \tag{3.11}$$

In (3.11), we can pass to the limit in each term, except from $\int_{Q\times\mathbb{R}_\xi} f\phi^\lambda a(\xi)\cdot\nabla_x W_{\varepsilon_d}$. Let us study it. Notice that

$$\nabla_x W_{\varepsilon_d}(x) = \theta_{\varepsilon_d}(x_d - h(\overline{x}))(-\nabla_{\overline{x}}h(\overline{x}),1) = -\theta_{\varepsilon_d}(x_d - h(\overline{x}))\sqrt{1+|\nabla_{\overline{x}}h(\overline{x})|^2}\; n(\overline{x}).$$

Hence,

$$\int_{Q\times\mathbb{R}_\xi} \phi^\lambda f a(\xi)\cdot\nabla_x W_{\varepsilon_d} dtdxd\xi$$
$$= \int_{Q\times\mathbb{R}_\xi} \phi^\lambda(t,x,\xi)(-a\cdot n) f(t,x,\xi)\theta_{\varepsilon_d}(x_d - h(\overline{x}))\sqrt{1+|\nabla_{\overline{x}}h(\overline{x})|^2}dtdxd\xi$$
$$= \int_{[0;+\infty)\times\Pi_\lambda\times\mathbb{R}_\xi} (-a\cdot n)\left[\int_{x_d=h(\overline{x})}^{+\infty} f(x_d)\theta_{\varepsilon_d}(x_d - h(\overline{x}))\,\lambda(x_d)dx_d\right]\phi^\lambda\; dtd\overline{\sigma}d\xi.$$

Using (3.8), we get (3.9) with ϕ^λ instead of ϕ as a test function. Recalling that the function λ is an element of the partition of unit $\{\lambda_i\}_{i\in I}$ and summing this previous inequality over $i \in I$ yields (3.9). We then deduce from (3.2) and (3.9) that (1.4) holds true and that $f^{\tau_0} = f^0 + \partial_\xi m^0_\pm$, where $m^0_\pm$ stands for the restriction of $m_\pm$ to $\{0\} \times \Omega \times \mathbb{R}_\xi$. It follows that

$$\int f^{\tau_0}_\pm(x,\xi)\mathrm{sgn}_\pm(\xi-\kappa)d\xi \le (u_0(x)-\kappa)^\pm.$$

Since f^{τ_0} is a kinetic function and $f^{\tau_0}(\xi) = 0$ for $\xi \gg 1$, we conclude that it can be written under the following form:

$$\begin{array}{ll} & f^{\tau_0}(x,\xi) = \nu^{\tau_0}_x(\xi,+\infty) + \mathrm{sgn}_- \\ (\text{resp.} & f^{\tau_0}(x,\xi) = \nu^{\tau_0}_x(-\infty;\xi) + \mathrm{sgn}_+). \end{array} \tag{3.12}$$

Next, replace κ with $u_0(x)$ and conclude that the support of $\nu^{\tau_0}_x$ lies in $(-\infty, u_0(x)]$ (resp., in $[u_0(x),+\infty)$). Finally, f^{τ_0} satisfies

$$f^{\tau_0}_+(x,\xi) = \nu^{\tau_0}_x\ (\xi \perp u_0(x), u_0(x)] \le \mathrm{sgn}_+(u_0(x)-\xi) \tag{3.13}$$

$$(\text{resp. } f^{\tau_0}_-(x,\xi) = -\nu^{\tau_0}_x\ [u_0(x), \xi \top u_0(x)) \ge \mathrm{sgn}_-(u_0(x)-\xi)). \tag{3.14}$$

This achieves the proof. □

Proof of Theorem 3.1. From Proposition 3.3, we get two measures $m_\pm$. If u is a weak entropy solution of the initial-boundary value problem, then m_+ and m_- coincide in $Q \times \mathbb{R}_\xi$. Indeed, from (3.5) we get

$$m_\pm(t,x,\kappa) = -\partial_t(u-\kappa)^\pm - \mathrm{div}_x\ \mathcal{F}^\pm(u,\kappa) \text{ in } \mathcal{D}'(Q\times\mathbb{R}_\xi). \tag{3.15}$$

Choosing κ large enough and $-\kappa$ large enough, respectively, we obtain that u is a weak solution of (1.1); i.e., $\partial_t u + \mathrm{div}_x\ A(u) = 0$ in $\mathcal{D}'(Q)$. Next, we conclude that $m_+ = m_-$ in $Q \times \mathbb{R}_\xi$:

$$m_\pm(t,x,\kappa) = -\frac{1}{2}\partial_t|u-\kappa| - \frac{1}{2}\mathrm{div}_x\ \mathcal{F}(u,\kappa) \text{ in } \mathcal{D}'(Q\times\mathbb{R}_\xi), \tag{3.16}$$

where $\mathcal{F} = \mathcal{F}^+ + \mathcal{F}^-$. Moreover, we proved in Proposition 3.4 that $f^{\tau_0} = f^0 + \partial_\xi m^0_\pm$ and that f^{τ_0} is bounded above and below by f^0. We then conclude that $\partial_\xi m^0_\pm = 0$, and hence that $m^0_\pm$ is constant in ξ. Since it equals 0 for large ξ, we conclude that $m^0_\pm = 0$. Eventually, the two measures $m^b_\pm$ are functions: indeed, since they satisfy (1.4) and vanish for $\xi \gg 1$ and $\xi \ll -1$, respectively, we have

$$m^b_+(s,y,\kappa) := M(u_b(s,y)-\kappa)^+ - \int_\kappa^{+\infty}(-a\cdot n)f^\tau_+(s,y,\xi)d\xi \ge 0, \tag{3.17}$$

$$m^b_-(s,y,\kappa) := M(u_b(s,y)-\kappa)^- + \int_{-\infty}^{\kappa}(-a\cdot n)f^\tau_-(s,y,\xi)d\xi \ge 0\,. \tag{3.18}$$

The proof of Theorem 3.1 is therefore achieved. □

Remark 3. Formula (3.16) appears in [18, p. 173]. Additional properties of m can be derived. See [18].

Link with the BLN condition. We detail here the link between the kinetic formulation of weak entropy solutions given in Theorem 3.1 and the BLN condition. Suppose that the function u is a weak entropy solution of problem (1.1) such that $u \in \mathsf{BV}(Q)$.

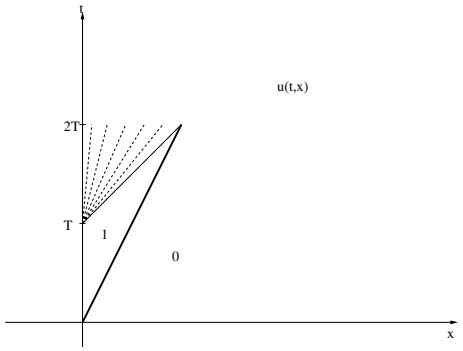

FIG. 3.1. *Weak entropy solution.*

Let u_τ denote the (strong) trace of the function u on Σ. Obviously, the space kinetic trace is the associated equilibrium function: $f^\tau = \chi_{u_\tau}$ (see Proposition 3.4). Next, remark that

$$\int_\kappa^{+\infty} a(\xi)\cdot n(y) f_+^\tau(s,y,\xi)d\xi = \mathcal{F}^+(u_\tau(s,y),\kappa)\cdot n(y)$$

and combine with (3.17) in order to get

$$m_+^b(s,y,\kappa) = M(u_b(s,y)-\kappa)^+ + \mathcal{F}^+(u_\tau(s,y),\kappa)\cdot n(y).$$

The fact that the function m_+^b is nonnegative is equivalent to the following condition:

$$\forall \kappa \in [u_b,u_\tau], \quad \operatorname{sgn}_+(u_\tau-u_b)[A(u_\tau)-A(\kappa)]\cdot n \geq 0.$$

Similarly, $m_-^b \geq 0$ if and only if the previous condition holds true replacing sgn_+ with sgn_-. Summing these two inequalities yields the well-known BLN condition [1]

$$\forall \kappa \in [u_b,u_\tau], \quad \operatorname{sgn}(u_\tau-u_b)[A(u_\tau)-A(\kappa)]\cdot n \geq 0. \tag{3.19}$$

3.3. An example. Let us detail the expressions of the entropy defect measure m and the boundary defect measures $m_\pm^b$ for the Burgers equation $\partial_t u + \partial_x(u^2/2) = 0$ considered on the domain $(0,2T)\times(0,+\infty)$ with data $u_0(x)=0$ and

$$u^b(t) = \begin{cases} 1 & \text{if} \quad 0<t<T, \\ -1 & \text{if} \quad T<t<2T. \end{cases}$$

A shock occurs at the time $t=0$, and a rarefaction wave appears at the time $t=T$. It collides with the shock at time $t=2T$. The corresponding weak entropy solution u is represented in Figure 3.1. Then the entropy defect measure is

$$m = \frac{1}{2}\left(\frac{1}{2}[|u-\xi|]_1^0 - [\operatorname{sgn}(u-\xi)(u^2/2-\xi^2/2)]_1^0\right)\delta_L,$$

where L is the line $t=2x$ in the (x,t)-plane and where $[G(u)]_1^0 := G(0)-G(1)$. In particular, the measure m is concentrated on the line of discontinuity of u, and the entropy criterion ensures that it is nonnegative. On the other hand, the boundary defect measures are given by

$$\begin{aligned} m_+^b(t,\xi) = (M(1-\xi)^+ - \operatorname{sgn}^+(1-\xi)(1/2-\xi^2/2))1_{(0,T)}(t) \\ + (M(1+\xi)^- - \operatorname{sgn}^-(\xi)\xi^2/2)1_{(T,2T)}(t) \end{aligned}$$

and

$$m_-^b(t,\xi) = (M(1-\xi)^- - \mathrm{sgn}^-(1-\xi)(1/2-\xi^2/2))\mathbf{1}_{(0,T)}(t) \\ + (M(1+\xi)^+ - \mathrm{sgn}^+(\xi)\xi^2/2)\mathbf{1}_{(T,2T)}(t),$$

where M is a constant greater than 1. The identity $a^2-b^2=(a+b)(a-b)$ ensures that the two functions are nonnegative. The reader can check that the expressions of m and $m_\pm^b$ are consistent with the formula (3.16) and (3.18)–(3.17), respectively.

4. A comparison theorem.

THEOREM 4.1. *Let $u \in \mathsf{L}^\infty(Q)$ be a weak entropy subsolution of* (1.1) *with data (u_0,u_b), and let $v \in \mathsf{L}^\infty(Q)$ be a weak entropy supersolution of* (1.1) *with data (v_0,v_b). Then*

$$\frac{1}{T}\int_0^T\int_\Omega (u(t,x)-v(t,x))^+dx\,dt \le \int_\Omega (u_0(x)-v_0(x))^+dx \\ + M\int_0^T\int_{\partial\Omega}(u_b(t,x)-v_b(t,x))^+dtd\sigma\,. \tag{4.1}$$

*In particular, $u \le v$ as soon as $u_0 \le v_0$ and $u_b \le v_b$ (*comparison principle*).*

Before proving Theorem 4.1, we state that the L^1-contraction property and the maximum principle follow from it.

COROLLARY 4.2.

1. *Let $u,v \in \mathsf{L}^\infty(Q)$ be two weak entropy solutions of* (1.1)*. Then*

$$\frac{1}{T}\int_0^T\int_\Omega |u(t,x)-v(t,x)|dx\,dt \le \int_\Omega |u_0(x)-v_0(x)|dx \\ + M\int_{(0;T)\times\partial\Omega}|u_b(t,y)-v_b(t,y)|dtd\sigma(y)$$

   (L^1-contraction property*).*

2. *Let u be a weak entropy solution of* (1.1)*, and suppose that there exists two constants $U_m, U_M \in \mathbb{R}$ such that*

$$U_m \le u_0 \le U_M \quad \text{a.e. in } \Omega \quad \text{and} \quad U_m \le u_b \le U_M \quad \text{a.e. in } \Sigma;$$

   *then $U_m \le u \le U_M$ a.e. in Q (*maximum principle*).*

Proof. The L^1-contraction property is obtained by combining the equations as (4.1) obtained successively with u as a weak entropy subsolution and v as a weak entropy supersolution and with v as a weak entropy subsolution and u as a weak entropy supersolution. In order to prove the maximum principle, one may remark that the constant function U_m is a weak entropy subsolution for data u_0,u_b and that the constant function U_M is a weak entropy supersolution for data u_0,u_b. ∎

Proof of Theorem 4.1. In order to prove Theorem 4.1, we show that

$$\int_Q (u-v)^+\partial_t\phi + \mathcal{F}^+(u,v)\cdot\nabla_x\phi + \int_\Omega (u_0-v_0)^+\phi^{(t=0)} + M\int_\Sigma (u_b-v_b)^+\overline{\phi} \ge 0 \tag{4.2}$$

holds true for any test function $\phi \in \mathsf{C}_\mathsf{c}^\infty(\mathbb{R}_t\times\mathbb{R}^d)$. Passing from (4.2) to (4.1) is classical. Let f, f^0, and f^b (resp., g, g^0, and g^b) denote the equilibrium functions

associated with u, u_0, and u_b (resp., with v, v_0, and v_b). The kinetic traces associated with u (resp., with v) are denoted by f^{τ_0} and f^{τ} (resp., g^{τ_0} and g^{τ}). Eventually, let m (resp., q) denote the entropy defect measure associated with u (resp., v) and set, for $(s, y, \xi) \in \Sigma \times \mathbb{R}_\xi$,

$$\overline{F_+}(s,y,\xi) = (-a(\xi)\cdot n(y)) f_+^{\tau}(s,y,\xi) \quad \text{and} \quad \overline{G_-}(s,y,\xi) = (-a(\xi)\cdot n(y)) g_-^{\tau}(s,y,\xi).$$

Since u is a weak entropy subsolution of (1.1), the following kinetic equation holds true:

$$\int_{Q\times\mathbb{R}_\xi} f_+(\partial_t + a\cdot\nabla_x)\phi + \int_{\Omega\times\mathbb{R}_\xi} f_+^{\tau_0}\ \phi^{(t=0)} + \int_{\Sigma\times\mathbb{R}_\xi} \overline{F_+}\phi = \int_{Q\times\mathbb{R}_\xi} \partial_\xi \phi dm \tag{4.3}$$

for any $\phi \in \mathsf{C}_{\mathsf{c}}^\infty(\mathbb{R}^{d+2})$. Let us fix a test function $\phi \in \mathsf{C}_{\mathsf{c}}^\infty(\mathbb{R}^{d+2})$ and apply (4.3) to the test function $\phi^\lambda \star \check{\gamma}_{\alpha,\varepsilon}$, where $\gamma_{\alpha,\varepsilon}$ denotes a right-decentered regularizing kernel and ϕ^λ denotes $\phi\lambda$:

$$\int_{\mathbb{R}^{d+2}} f_+^{\alpha,\varepsilon}(\partial_t + a\cdot\nabla_x)\phi^\lambda + f_+^{\tau_0\,\varepsilon}\theta_\alpha\phi^\lambda + \overline{F_+}^{\alpha,\varepsilon}\phi^\lambda = \int_{\mathbb{R}^{d+2}} \partial_\xi\phi^\lambda\ dm^{\alpha,\varepsilon}, \tag{4.4}$$

where $f_+^{\alpha,\varepsilon} = (f_+ \times 1_Q) \star_{t,x} \gamma_{\alpha,\varepsilon}$, $f_+^{\tau_0\,\varepsilon} = (f_+^{\tau_0} \times 1_{\Omega_\lambda}) \star_x \gamma_\varepsilon$, $m^{\alpha,\varepsilon} = (m \times 1_Q) \star_{t,x} \gamma_{\alpha,\varepsilon}$, and $\overline{F_+}^{\alpha,\varepsilon} = (\overline{F_+} \times 1_{\Sigma_\lambda}) \star_{t,x} \gamma_{\alpha,\varepsilon}$. Now, let us also regularize the kinetic equation satisfied by g but with different parameters:

$$\int_{\mathbb{R}^{d+2}} g_-^{\beta,\nu}(\partial_t + a\cdot\nabla_x)\phi^\lambda + g_-^{\tau_0\,\nu}\theta_\beta\phi^\lambda + \overline{G_-}^{\beta,\nu}\phi^\lambda = \int_{\mathbb{R}^{d+2}} \partial_\xi\phi^\lambda\ dq^{\beta,\nu}. \tag{4.5}$$

Now apply (4.4) to $-g_-^{\beta,\nu}(t,x,\xi)\phi^\lambda(t,x)$ and (4.5) to $-f_+^{\alpha,\varepsilon}(t,x,\xi)\phi^\lambda(t,x)$ and sum the two equations:

$$\begin{aligned}
&\int_{\mathbb{R}^{d+2}} -\phi^\lambda(\partial_t + a\cdot\nabla_x)(f_+^{\alpha,\varepsilon} g_-^{\beta,\nu}) + 2\int_{\mathbb{R}^{d+2}} (-f_+^{\alpha,\varepsilon} g_-^{\beta,\nu})(\partial_t + a\cdot\nabla_x)\phi^\lambda \\
&\quad - \int_{\mathbb{R}^{d+2}} \left[f_+^{\tau_0\,\varepsilon} g_-^{\beta,\nu}\theta_\alpha + g_-^{\tau_0\,\nu} f_+^{\alpha,\varepsilon}\theta_\beta \right] \phi^\lambda - \int_{\mathbb{R}^{d+2}} \left[\overline{F_+}^{\alpha,\varepsilon} g_-^{\beta,\nu} + \overline{G_-}^{\beta,\nu} f_+^{\alpha,\varepsilon} \right] \phi^\lambda \\
&\qquad\qquad = \int_{\mathbb{R}^{d+2}} \phi^\lambda [\delta_v^{\beta,\nu}\ dm^{\alpha,\varepsilon} + \delta_u^{\alpha,\varepsilon}\ dq^{\beta,\nu}],
\end{aligned} \tag{4.6}$$

where $\delta_u^{\alpha,\varepsilon} = (\delta(\xi - u(t,x)) \times 1_Q) \star \gamma_{\alpha,\varepsilon}$ and $\delta_v^{\beta,\nu} = (\delta(\xi - v(t,x)) \times 1_Q) \star \gamma_{\beta,\nu}$. Use the fact that the right-hand side of (4.6) is nonnegative and make an integration by parts in the first line:

$$\begin{aligned}
&\int_{\mathbb{R}^{d+2}} (-f_+^{\alpha,\varepsilon} g_-^{\beta,\nu})(\partial_t + a\cdot\nabla_x)\phi^\lambda \\
&\quad - \int_{\mathbb{R}^{d+2}} \left[f_+^{\tau_0\,\varepsilon} g_-^{\beta,\nu}\theta_\alpha + g_-^{\tau_0\,\nu} f_+^{\alpha,\varepsilon}\theta_\beta \right] \phi^\lambda - \int_{\mathbb{R}^{d+2}} \left[\overline{F_+}^{\alpha,\varepsilon} g_-^{\beta,\nu} + \overline{G_-}^{\beta,\nu} f_+^{\alpha,\varepsilon} \right] \phi^\lambda \geq 0.
\end{aligned}$$

Now let successively $\beta, \bar{\nu}$, and ν_d go to 0^+:

$$\int_{Q_\lambda\times\mathbb{R}_\xi} (-f_+^{\alpha,\varepsilon} g_-)(\partial_t + a\cdot\nabla_x)\phi^\lambda - \int_{Q_\lambda\times\mathbb{R}_\xi} f_+^{\tau_0\,\varepsilon} g_-\theta_\alpha\phi^\lambda - \int_{Q_\lambda\times\mathbb{R}_\xi} \overline{F_+}^{\alpha,\varepsilon} g_-\ \phi^\lambda \geq 0. \tag{4.7}$$

We used the fact that regularized functions equal zero at $t = 0$ and at the boundary. Next, let successively $\alpha, \overline{\varepsilon}$, and ε_d go to 0^+. The first limit is easy to compute:

(4.8)
$$\lim_{\varepsilon_d\to 0^+}\lim_{\overline{\varepsilon}\to 0^+}\lim_{\alpha\to 0^+}\int_{Q_\lambda\times\mathbb{R}_\xi}(-f_+^{\alpha,\varepsilon}g_-)(\partial_t + a\cdot\nabla_x)\phi^\lambda = \int_{Q\times\mathbb{R}_\xi}(-f_+g_-)(\partial_t + a\cdot\nabla_x)\phi^\lambda$$
$$= \int_Q (u-v)^+\partial_t\phi^\lambda + \mathcal{F}^+(u,v)\cdot\nabla\phi^\lambda.$$

Use (3.7) for g, (3.13) for f, and (3.14) for g:

(4.9)
$$\lim_{\varepsilon_d\to 0^+}\lim_{\overline{\varepsilon}\to 0^+}\lim_{\alpha\to 0^+} -\int_{Q_\lambda\times\mathbb{R}_\xi} f_+^{\tau_0\varepsilon}g_-\theta_\alpha\phi^\lambda = \lim_{\varepsilon_d\to 0^+}\lim_{\overline{\varepsilon}\to 0^+} -\int_{\Omega_\lambda\times\mathbb{R}_\xi} f_+^{\tau_0\varepsilon}g_-^{\tau_0}\left(\phi^\lambda\right)^{(t=0)}$$
$$= -\int_{\Omega_\lambda\times\mathbb{R}_\xi} f_+^{\tau_0}g_-^{\tau_0}\left(\phi^\lambda\right)^{(t=0)} \le -\int_{\Omega_\lambda\times\mathbb{R}_\xi} f_+^0 g_-^0\left(\phi^\lambda\right)^{(t=0)} = \int_\Omega (u_0-v_0)^+\left(\phi^\lambda\right)^{(t=0)}.$$

We proceed analogously with the boundary term:

$$\lim_{\varepsilon_d\to 0^+}\lim_{\overline{\varepsilon}\to 0^+}\lim_{\alpha\to 0^+} -\int_{Q_\lambda\times\mathbb{R}_\xi}\overline{F_+}^{\alpha,\varepsilon}g_-\,\phi^\lambda = \int_{\Sigma\times\mathbb{R}_\xi}(-a\cdot n)f_+^\tau\, g_-^\tau\overline{\phi^\lambda}$$
$$\le M\int_\Sigma (u_b-v_b)^+\overline{\phi^\lambda}. \tag{4.10}$$

Let us now justify the inequality in (4.10). In order to do so, we use (1.4) and represent f^τ and g^τ with their Young measures as in (3.12):

$$\int_{\mathbb{R}_\xi}(-a\cdot n)f_+^\tau\, g_-^\tau = -\int_{-\infty}^{v_b}\nu^\tau(\xi;+\infty)\partial_\xi q_-^b$$
$$+\int_{v_b}^{v_b\top u_b}(-a\cdot n)\nu^\tau(\xi;+\infty)\mu^\tau(-\infty;\xi) + \int_{v_b\top u_b}^{+\infty}\mu^\tau(-\infty;\xi)\partial_\xi m_+^b$$
$$\le -\int_{-\infty}^{v_b} q_-^b\, d\nu^\tau - \left[q_-^b\nu^\tau(\xi;+\infty)\right]_{-\infty}^{v_b} + M(u_b-v_b)^+$$
$$-\int_{v_b\top u_b}^{+\infty} m_+^b d\mu^\tau + \left[m_+^b\mu^\tau(-\infty;\xi)\right]_{v_b\top u_b}^{+\infty} \le M(u_b-v_b)^+.$$

Hence, we can pass to the limit in (4.7). By using (4.8), (4.9), and (4.10) and by summing over $i\in I$, (4.1) follows, and the proof of Theorem 4.1 is complete. ∎

5. Convergence of a BGK-like model. In this section, we present the first application of the kinetic formulation we introduced above. Let us consider the following BGK-like model:

$$(\partial_t + a\cdot\nabla_x)f_\varepsilon = \frac{\chi_{u_\varepsilon} - f_\varepsilon}{\varepsilon} \qquad \text{in } Q\times\mathbb{R}_\xi, \tag{5.1a}$$

$$u_\varepsilon(t,x) = \int_{\mathbb{R}} f_\varepsilon(t,x,\xi)d\xi, \quad (t,x)\in Q, \tag{5.1b}$$

$$f_\varepsilon(0,x,\xi) = f^0(x,\xi), \quad (x,\xi) \in \Omega \times \mathbb{R}_\xi, \tag{5.1c}$$

$$f_\varepsilon(t,y,\xi) = f^b(y,\xi), \quad (t,y,\xi) \in \Sigma^+, \tag{5.1d}$$

where f^0 and f^b are the equilibrium functions, respectively, associated with the initial and the boundary data and where $\Sigma^+ = \{(t,y,\xi) \in \Sigma \times \mathbb{R}_\xi : -a(\xi)\cdot n(y) > 0\}$. The approximation (5.1a)–(5.1c) for the Cauchy problem (i.e., when $\Omega = \mathbb{R}^n$) was first considered by Perthame and Tadmor [29]. They proved that the "hydrodynamic limit" as $\varepsilon \to 0$ is precisely the entropy solution of the initial value problem (1.1a)–(1.1b). Their study relies on the fact that the right-hand side of (5.1a) can be written as the derivative of a measure: $\partial_\xi m_\varepsilon$. This is a consequence of the following observation.

LEMMA 5.1 (see [18]). *Let $g \in \mathsf{L}^1(\mathbb{R})$ satisfy $0 \le \operatorname{sgn}(\xi) g(\xi) \le 1$ a.e. Then the function $m_g : \xi \mapsto \int_{-\infty}^{\xi} (\chi_{u_g} - g)(\zeta)\, d\zeta$ is nonnegative.*

As ε goes to 0, the measure m_ε converges to the entropy defect measure m. This kinetic model has been adapted by Nouri, Omrane, and Vila [22, 23] to take into account boundary conditions. In [22, 23], data at equilibrium as well as general kinetic ones are considered. The convergence of the kinetic model is proved and, particularly in the nonequilibrium case, the boundary conditions satisfied by the limit so obtained are discussed and compared to the BLN condition. In the present paper, we restrict ourselves to the case of data at equilibrium and show how the concept of boundary defect measures can help in the understanding of the "hydrodynamic limit"; more precisely, we define approximate boundary defect measures and prove that they converge to $m^b_\pm$ (see subsection 3.2). As in [28], we intend to show how a concept of a generalized kinetic solution can be used to prove the convergence of the kinetic model associated with (1.1) without "strong" (for instance BV) a priori estimates.

5.1. Solution of the kinetic model. We suppose that Ω is convex. The problem (5.1) admits an integral representation and is therefore solved by a fixed point method. The characteristic of the partial differential operator $\partial_t + a(\xi)\partial_x$ arriving at $(t,x) \in Q$ is the line of equation $X(\tau) = a(\xi)(\tau - t) + x$. If $u_\varepsilon \in \mathsf{C}(0,T;\mathsf{L}^1(\Omega))$, the solution f_ε of the linear equation $\partial_t f_\varepsilon + a(\xi)\cdot\nabla f_\varepsilon + \frac{1}{\varepsilon} f_\varepsilon = \frac{1}{\varepsilon}\chi_{u_\varepsilon}$ satisfies

$$f_\varepsilon(t,x,\xi) = f_\varepsilon(\tau, X(\tau), \xi) e^{\frac{\tau - t}{\varepsilon}} + \int_\tau^t \frac{1}{\varepsilon} \chi_{u_\varepsilon(s,X(s))}(\xi) e^{\frac{s-t}{\varepsilon}}\, ds \tag{5.2}$$

for any $\tau < t$ such that $X([\tau,t]) \subset \Omega$. Using the boundary condition (5.1d), we see that the computation of the value $f_\varepsilon(t,x,\xi)$ depends on the point of intersection of the characteristic line with the parabolic boundary:

- if $X([0,t]) \subset \Omega$, the characteristic starts from $\{0\} \times \Omega$ at $\tau = 0$, and we put $f_\varepsilon(\tau, X(\tau), \xi) = f^0(x - ta(\xi), \xi)$ in (5.2);
- if there exists $\tau^* \in [0,t]$ such that $X([\tau^*, t]) \subset \Omega$ and $X(\tau^* - 0) \notin \Omega$, the characteristic starts from the boundary Σ at $\tau = \tau^*$, and we put $f_\varepsilon(\tau, X(\tau), \xi) = f^b(\tau^*, X(\tau^*), \xi)$ in (5.2).

Thanks to the integral representation (5.2), it is therefore possible to build an operator T from $\mathsf{C}(0,T;\mathsf{L}^1(\Omega))$ to itself which maps u on $v : (t,x) \mapsto \int_{\mathbb{R}} f_\varepsilon(t,x,\xi)\, d\xi$. We then show that this operator is a contracting map, and the existence and the uniqueness of the solution f_ε of (5.1) follows [29, 22, 28]. This solution satisfies additional properties.

PROPOSITION 5.2 (see [29, 22, 28]). *Suppose that Ω is convex. Let $\varepsilon > 0$, and let $f_\varepsilon \in \mathsf{C}(0,T;\mathsf{L}^1(\Omega \times \mathbb{R}_\xi))$ be the solution of (5.1). Under the hypotheses of section 2, we have that*

1. f_ε *satisfies*

$$0 \le \operatorname{sgn}(\xi) f_\varepsilon(t,x,\xi) \le 1 \text{ for a.e. } (t,x,\xi) \in Q \times \mathbb{R}_\xi;$$

2. *there exists a nonnegative function* m_ε *such that*

$$\frac{\chi_{u_\varepsilon} - f_\varepsilon}{\varepsilon} = \partial_\xi m_\varepsilon; \tag{5.3}$$

3. *for every convex function* $\eta \in \mathsf{C}^2(\mathbb{R},\mathbb{R})$ *with a bounded derivative* η' *satisfying* $\eta'(0) = 0$,

$$\int_{Q\times\mathbb{R}_\xi} m_\varepsilon(t,x,\xi)\eta''(\xi)d\xi dx dt \le \int_{\Omega\times\mathbb{R}_\xi} f^0(\xi)\eta'(\xi)d\xi dx + \int_{\Sigma\times\mathbb{R}_\xi} (-a\cdot n)^+(s,y,\xi) f^b(\xi)\eta'(\xi)d\xi dt; \tag{5.4}$$

4. *there exists* $\mu \in \mathsf{L}^\infty(\mathbb{R})$ *independent of* ε *and such that* $\mu(\xi) = 0$ *if* $|\xi| \gg 1$ *and*

$$\int_Q m_\varepsilon(t,x,\xi)dx dt \le \mu(\xi); \tag{5.5}$$

5. *for a.e.* $(t,x,\xi) \in Q \times \mathbb{R}_\xi$: $f_\varepsilon(t,x,\xi) = 0$ *as soon as* $|\xi| > K$ *and*

$$\left| \int_{\mathbb{R}_\xi} f_\varepsilon(t,x,\xi)d\xi \right| \le K \text{ for a.e. } (t,x) \in Q. \tag{5.6}$$

Sketch of the proof. The fact that f_ε is a kinetic function follows from (5.2). We previously mentioned that (5.3) is a consequence of Lemma 5.1. A rigorous proof of (5.4) relies on the integral representation (5.2). Here is a formal argument: multiply the equation $\partial_t f_\varepsilon + a(\xi)\partial_x f_\varepsilon = \partial_\xi m_\varepsilon$ by $\eta'(\xi)$, integrate the result with respect to (t,x,ξ), and use the fact that $\eta'(\xi) f_\varepsilon(t,x,\xi) \ge 0$ (for $\operatorname{sgn}(\eta'(\xi)) = \operatorname{sgn}(\xi)$). Estimate (5.5) is a consequence of (5.4) with $\eta(\xi) = (\xi - \xi_0)^+$ if $\xi_0 > 0$ and $\eta(\xi) = (\xi - \xi_0)^-$ if $\xi_0 < 0$. It leads to the expression $\mu = \mu^+ + \mu^-$ with

$$\mu^\pm(\xi) = |\operatorname{sgn}_\pm(\xi)| \ \ (||(u_0 - \xi)^\pm||_{\mathsf{L}^1(\Omega)} + M||(u_b(t,y) - \xi)^\pm||_{\mathsf{L}^1(\Sigma)}).$$

Since f_ε is a kinetic function, (5.6) is a consequence of the fact that $f_\varepsilon(\cdot,\xi)$ vanishes for $|\xi| > K$. This argument also shows that the operator T maps

$$\left\{ u \in \mathsf{C}(0,T;\mathsf{L}^1(\Omega)),\ |u(t,x)| \le K \ \forall (t,x) \right\}$$

into itself: (5.6) follows from the uniqueness of the fixed point. ∎

5.2. Generalized kinetic solutions. In order to prove the convergence of the model, we need to introduce a very weak notion of solution of (1.1).

DEFINITION 5.3. *Consider a kinetic function* $f \in \mathsf{L}^\infty(Q \times \mathbb{R}_\xi)$. *We say that* f *is a* generalized kinetic solution *of* (1.1) *if there exists a bounded nonnegative measure* $m \in \mathcal{M}^+(Q \times \mathbb{R}_\xi)$ *and two nonnegative measurable functions* $m^b_+, m^b_- \in \mathsf{L}^\infty_{\mathsf{loc}}(\Sigma \times \mathbb{R}_\xi)$ *such that the function* m^b_+ *vanishes for* $\xi \gg 1$ *(resp., the function* m^b_- *vanishes for* $\xi \ll -1$*) and such that* (3.1) *holds true.*

The kinetic formulation can therefore be stated in the following terms: a function u is an entropy solution of (1.1) if and only if its associated equilibrium function is a generalized kinetic solution of (1.1).

THEOREM 5.4. *Any generalized kinetic solution of* (1.1) *is in fact an equilibrium function associated with an entropy solution of the initial-boundary value problem.*

Proof. We just adapt the proof of the comparison theorem. Consider a generalized kinetic solution f of the initial-boundary value problem. We can therefore easily prove that for a.e. $t > 0$:

$$\int_{\Omega\times\mathbb{R}_\xi} (-f^+ f^-)(t,x,\xi)dxd\xi \le 0.$$

Now use the fact that f is a kinetic function to get that for a.e. $(t,x) \in Q$:

$$f^-(t,x,\xi) = \nu_{t,x}(-\infty;\xi) \qquad \text{and} \qquad f^+(t,x,\xi) = \nu_{t,x}(\xi;+\infty).$$

Consequently, $\nu_{t,x}(-\infty;\xi) = 0$ or $\nu_{t,x}(\xi;+\infty) = 0$. It follows that $\nu_{t,x}$ is a Dirac mass. The proof is therefore complete. □

5.3. Proof of the convergence. We now state and prove a precise convergence result.

THEOREM 5.5. *Suppose that Ω is convex. Under the hypotheses of section 2, if f_ε denotes the solution of* (5.1)*, then the sequence of function u_ε defined by $u_\varepsilon(t,x) = \int_{\mathbb{R}} f_\varepsilon(t,x,\xi)d\xi$ converges as $\varepsilon \to 0$ to the entropy solution u of* (1.1) *in any $L^p((0,T)\times\Omega)$, $1 \le p < +\infty$.*

Proof. Let $\overline{f}_\varepsilon$ denote the space kinetic trace of f_ε, and consider $\varphi \in \mathsf{C}_c^\infty(\bar{Q}\times\mathbb{R}_\xi)$. By integrating the equation $\partial_t f_\varepsilon + a(\xi)\cdot\partial_x f_\varepsilon = \partial_\xi m_\varepsilon$ against φ we get

$$\int_{Q\times\mathbb{R}_\xi} f_\varepsilon(\partial_t\varphi + a\cdot\nabla_x\varphi) + \int_{\Omega\times\mathbb{R}_\xi} f^0\varphi^{(t=0)} + \int_{\Sigma\times\mathbb{R}_\xi} (-a\cdot n)\overline{f}_\varepsilon\overline{\varphi} = \int_{Q\times\mathbb{R}_\xi} \partial_\xi\varphi dm_\varepsilon. \tag{5.7}$$

By analogy with (3.17), define the function $m_+^{b,\varepsilon}$ by

$$m_+^{b,\varepsilon}(t,y,\xi) := M(u_b(t,y)-\xi)^+ - \int_\xi^{+\infty} (-a\cdot n)(\overline{f}_\varepsilon - \mathrm{sgn}_-)(\kappa)d\kappa$$

and get from (5.7)

$$\int_{Q\times\mathbb{R}_\xi} f_\varepsilon(\partial_t\varphi + a\cdot\nabla_x\varphi) + \int_{\Omega\times\mathbb{R}_\xi} f^0\varphi^{(t=0)} + \int_{\Sigma\times\mathbb{R}_\xi} (Mf_+^b + (-a\cdot n)\mathrm{sgn}_-)\overline{\varphi} = \int_{Q\times\mathbb{R}_\xi} \partial_\xi\varphi dm_\varepsilon + \int_{\Sigma\times\mathbb{R}_\xi} \partial_\xi\overline{\varphi} dm_+^{b,\varepsilon}. \tag{5.8}$$

Let us check that $m_+^{b,\varepsilon}(t,y,\xi)$ is a nonnegative function. Since $\overline{f}_\varepsilon$ is a kinetic function, $\overline{f}_\varepsilon - \mathrm{sgn}_-$ is nonnegative; hence,

$$\begin{aligned} m_+^{b,\varepsilon}(t,y,\xi) &\ge M(u_b(t,y)-\xi)^+ - \int_\xi^{+\infty} (-a\cdot n)^+(\overline{f}_\varepsilon(t,y,\kappa) - \mathrm{sgn}_-(\kappa))d\kappa \\ &= M(u_b(t,y)-\xi)^+ - \int_\xi^{+\infty} (-a\cdot n)^+(f^b(t,y,\kappa) - \mathrm{sgn}_-(\kappa))d\kappa \end{aligned}$$

$$\begin{aligned} &= \int_\xi^{+\infty} (M - (-a\cdot n)^+)(f^b(t,y,\kappa) - \mathrm{sgn}_-(\kappa))d\kappa \\ &\geq 0. \end{aligned}$$

Since f_ε is bounded in the L^∞-norm and m_ε is bounded in mass by (5.5), we have, up to subsequences,

$$\begin{array}{lll} f_\varepsilon \rightharpoonup f & \text{in} & w-*-L^\infty(Q\times\mathbb{R}_\xi), \\ \overline{f}_\varepsilon \rightharpoonup \widetilde{f} & \text{in} & w-*-L^\infty(\Sigma\times\mathbb{R}_\xi), \\ m_\varepsilon \rightharpoonup m & \text{in} & w-*-\mathcal{M}^+(Q\times\mathbb{R}_\xi), \end{array}$$

where f and $\widetilde{f}$ are, respectively, functions of $L^\infty(Q\times\mathbb{R}_\xi)$ and $L^\infty(\Sigma\times\mathbb{R}_\xi)$ such that (this property is preserved at the $w-*-$limit) $0\leq f(\cdot,\xi)\mathrm{sgn}(\xi)\leq 1$ and $0\leq \widetilde{f}(\cdot,\xi)\mathrm{sgn}(\xi)\leq 1$. We first deduce from Proposition 5.2 that

$$\int_\xi^{+\infty} (-a\cdot n)(\overline{f}_\varepsilon(t,y,\kappa) - \mathrm{sgn}_-(\kappa))d\kappa = \int_\xi^{K} (-a\cdot n)(\overline{f}_\varepsilon(t,y,\kappa) - \mathrm{sgn}_-(\kappa))d\kappa.$$

It follows that $m_+^{b,\varepsilon}(t,y,\xi)\rightharpoonup m_+^b$, where

$$m_+^b(t,y,\xi) := M(u_b(t,y)-\xi)^+ - \int_\xi^K (-a\cdot n)(f^\tau - \mathrm{sgn}_-(\kappa))d\kappa \tag{5.9}$$

so that, at the limit $\varepsilon\to 0$ in (5.8), we have

$$\begin{aligned} \int_{Q\times\mathbb{R}_\xi} f(\partial_t\varphi + a\cdot\nabla_x\varphi) + \int_{\Omega\times\mathbb{R}_\xi} f^0\varphi^{(t=0)} + \int_{\Sigma\times\mathbb{R}_\xi} (Mf_+^b + (-a\cdot n)\mathrm{sgn}_-)\overline{\varphi} \\ = \int_{Q\times\mathbb{R}_\xi} \partial_\xi\varphi dm + \int_{\Sigma\times\mathbb{R}_\xi} \partial_\xi\overline{\varphi} dm_+^b\,. \end{aligned} \tag{5.10}$$

Besides, it is clear from (5.9) that $m_+^b(t,y,\xi)$ vanishes for $\xi\gg 1$; moreover, (5.5) remains true at the limit. Derivating (5.1a) with respect to ξ gives

$$\partial_\xi f_\varepsilon = \partial_\xi\chi_{u_\varepsilon} + \alpha_\varepsilon = \delta_0(\xi) - \delta_{u_\varepsilon}(\xi) + \alpha_\varepsilon,$$

where $\alpha_\varepsilon = \varepsilon\,(\partial_{\xi t} f_\varepsilon + a(\xi)\partial_{\xi x} f_\varepsilon)$ tends to zero in $\mathcal{D}'(Q\times\mathbb{R}_\xi)$. We then define a Young measure $\nu_{t,x}(\xi)$ as an adherence value of $\delta(\xi - u_\varepsilon(t,x))$, and we obtain that

$$\partial_\xi f = \delta_0(\xi) - \nu_{t,x}(\xi) \quad \text{ in } \mathcal{D}'(Q\times\mathbb{R}_\xi).$$

Of course, the same arguments remain valid for m_-^b, and, consequently, f is a generalized kinetic solution of (1.1). By virtue of Theorem 5.4, it is therefore the equilibrium function associated with the unique entropy solution of (1.1). Since f is an equilibrium function, the weak-$*$ convergence of f_ε to f in $L^\infty(Q\times\mathbb{R}_\xi)$ implies the strong convergence of u_ε to u in $L^p(Q)$, $1\leq p<+\infty$. The proof is therefore complete. ∎

NORMAL FORM OF REVERSIBLE SYSTEMS AND PERSISTENCE OF LOWER DIMENSIONAL TORI UNDER WEAKER NONRESONANCE CONDITIONS*

JUNXIANG XU†

Abstract. In this paper we give a normal form for reversible systems and then prove the persistence of lower dimensional invariant tori for integrable reversible systems under small perturbations with weaker nonresonance conditions than have previously been imposed. Our nonresonance conditions correspond to the first Melnikov's conditions in the case of Hamiltonian systems.

Key words. reversible systems, Kolmogorov–Arnold–Moser iteration, invariant tori, nonresonance conditions

1. Introduction.

Reversible systems form a class of special conservative systems with an involution structure. In studying persistence of invariant tori for reversible systems, there is a small divisor problem reminiscent of the case of Hamiltonian systems. Since reversible systems have many similar properties to Hamiltonian systems, we can apply some of the technique developed for Hamiltonian systems to them. Recently, there has been progress in the theory of invariant tori for Hamiltonian systems (see [1, 2, 3, 4, 5, 6, 8, 9, 10, 11, 14, 19, 20]). In particular, under weaker and fewer nonresonance conditions, many KAM results have been improved for persistence of invariant tori of integrable Hamiltonian systems [1, 2, 3, 6, 21, 22]. Using the motivation of KAM theorems for Hamiltonian systems, we consider the persistence of invariant tori for reversible systems under weaker and fewer nonresonance conditions.

Consider the following dynamical system:

$$\begin{cases} \dot{x} = \omega + f(x,u,v;\omega), \\ \dot{u} = A(\omega)v + g_1(x,u,v;\omega), \\ \dot{v} = -B(\omega)u + g_2(x,u,v;\omega), \end{cases} \tag{1.1}$$

where the variables $x = (x_1,\dots,x_n)^T$, $u = (u_1,\dots,u_p)^T$, and $v = (v_1,\dots,v_q)^T$ are all column vectors and $(x,u,v) \in T^n \times R^p \times R^q$, $(p \le q)$. Note that here and below the superscript "T" always indicates the transpose of matrix. $\omega = (\omega_1,\dots,\omega_n)^T \in O \subset R^n$ is the frequency parameter. $A(\omega)$ and $B(\omega)$ are $p \times q$ and $q \times p$ matrices depending on ω, respectively. The corresponding involution G which characterizes the class of reversible systems is defined by

$$G : (x,u,v) \to (-x,-u,v).$$

Denote the vector field of the dynamical system (1.1) by

$$F = ((\omega + f)^T, (Av + g_1)^T, (-Bu + g_2)^T)^T.$$

System (1.1) is called reversible if $DG \cdot F = -F \circ G$. System (1.1) is reversible with respect to G when

$$\begin{cases} f(-x,-u,v;\omega) = f(x,u,v;\omega), \\ g_1(-x,-u,v;\omega) = g_1(x,u,v;\omega), \\ g_2(-x,-u,v;\omega) = -g_2(x,u,v;\omega). \end{cases} \tag{1.2}$$

A mapping $\Phi : (x,u,v) \to (x_+,u_+,v_+)$ is called a compatible transformation with respect to the involution G if $\Phi \circ G = G \circ \Phi$. Under compatible transformations, reversible systems are transformed to reversible systems.

For reversible systems, there are already many well-known results on the persistence of invariant tori. In [15, 16, 17, 18], Sevryuk studied the persistence of n-dimensional invariant tori for reversible systems of the form (1.1) under the following assumptions:

(i) $\det(\Omega) \neq 0$.

(ii) Every eigenvalue of the matrix Ω is simple, where

$$\Omega = \begin{pmatrix} 0 & A \\ -B & 0 \end{pmatrix}.$$

The assumption (i) means that the matrix Ω has no zero-eigenvalue and, (ii) implies that the matrix Ω is diagonalizable.

Recently, in [7] Liu weakened Sevryuk's assumptions and allowed Ω to have the eigenvalue zero or multiple eigenvalues. In the proof, he supposed the following nonresonance conditions: for all $k \neq 0$,

$$|\langle \omega, k\rangle| \geq \alpha |k|^{-\tau}, \tag{1.3}$$

$$|\det(i\langle \omega, k\rangle I_{(p+q)} - \Omega)| \geq \alpha |k|^{-\tau}, \tag{1.4}$$

$$|\det(i\langle \omega, k\rangle I_{(p+q)^2} + I_{(p+q)^2} \otimes \Omega - \Omega \otimes I_{(p+q)^2})| \geq \alpha |k|^{-\tau}, \tag{1.5}$$

where $i = \sqrt{-1}$, I_N indicates the Nth-order unit matrix, and $\otimes$ is the notation of tensor product of matrices (see [7]).

In this paper we want to prove that conditions (1.3) and (1.4) alone are sufficient for Liu's result. To state our results, we first give some definitions and assumptions. Denote a complex neighborhood of $T^n \times \{0\} \times \{0\}$ by

$$D(s,r) = \{(x,u,v) \mid |\mathrm{Im}\ x| \leq s, |u| \leq r, |v| \leq r\},$$

where $|\mathrm{Im}\ x| = \max_{1\leq i\leq n} |\mathrm{Im}\ x_i|$, $|u| = \max_{1\leq i\leq p} |u_i|$, and $|v| = \max_{1\leq i\leq q} |v_i|$.

Let O be a bounded closed simply connected domain of R^n with positive Lebesgue measure. Let $C^L(O)$ be the space of the Lth continuously differentiable function on O in Whitney's sense (see [23]). For $f(\omega) \in C^L(O)$, define a norm by $\|f\|^L = \max_{|\alpha|\leq L} \sup_{\omega\in O} |D^\alpha f(\omega)|$.

If f is analytic in $(x,u,v;\omega) \in D(s,r) \times O$, then we can write

$$f = \sum_{k,l,m} f_{k,l,m}(\omega) e^{\mathrm{i}\langle k,x\rangle} u^l v^m.$$

Define

$$\|f\|^L_{D(s,r)} = \sup_{(x,u,v)\in D(s,r)} \left| \sum_{k,l,m} \|f_{k,l,m}(\omega)\|^L e^{s|k|} u^l v^m \right|.$$

It is a stronger norm than the usual supremum-norm. If f depends only on x and ω, we write $\|f\|_s^L := \|f\|_{D(s,r)}^L$.

Assume that $A(\omega)$ and $B(\omega)$ are analytic with respect to ω on O. Also assume that f, g_1, and g_2 are analytic on $D(s,r) \times O$.

THEOREM 1.1. *Assume that*

(A.1) $p = q$ *and* $\operatorname{rank}(A) = p$;

(A.2) *there are* $\lambda_1(\omega), \ldots, \lambda_q(\omega)$, *which are analytic in* ω, *such that* $\lambda_1^2, \ldots, \lambda_q^2$ *are the eigenvalues of the matrix* AB *and the following nonresonance conditions hold:*

$$\langle \omega, k \rangle \neq 0 \quad \forall k \neq 0, \tag{1.6}$$

$$\langle \omega, k \rangle - \lambda_j \neq 0 \quad \forall k \neq 0, \ \ j = 1, \ldots, q. \tag{1.7}$$

Then, for sufficiently small $\alpha > 0$, *there exists an* $\epsilon > 0$ *depending on* $\lambda_1, \ldots, \lambda_q, \alpha, O$, n, m *such that if*

$$\|f\|_{D(s,r)}^L \leq \epsilon, \quad \frac{1}{r}\|g_1\|_{D(s,r)}^L \leq \epsilon, \quad \frac{1}{r}\|g_2\|_{D(s,r)}^L \leq \epsilon \tag{1.8}$$

with $L \geq q^2$, *the following holds true: There exists a nonempty subset* O_α *of* O *such that, for all* $\omega \in O_\alpha$, *there exists an analytic compatible transformation*

$$\Phi_*(\cdot;\omega) : D(s/2, r/2) \to D(s,r)$$

which transforms the reversible system (1.1) *into the form*

$$\dot{x} = \omega_* + f_*, \quad \dot{u} = A_*(\omega)v + g_{*1}, \quad \dot{v} = -B_*(\omega)u + g_{*2}, \tag{1.9}$$

where f_*, g_{*1}, *and* g_{*2} *satisfy*

$$f_*(x,0,0;\omega) = 0, \quad g_{*1}(x,0,0;\omega) = 0, \quad g_{*2}(x,0,0;\omega) = 0.$$

Hence, for $\omega \in O_\alpha$, $\Phi_*(T^n \times \{0\} \times \{0\};\omega)$ *is an invariant torus of the reversible system* (1.1) *with the frequency* ω_* *satisfying* $\|\omega_*(\omega) - \omega\|^L \leq 2\epsilon$. *Moreover, we have* $\operatorname{meas}(O \setminus O_\alpha) \to 0$ *as* $\alpha \to 0$.

THEOREM 1.2. *Assume that*

(A.3) $p < q$ *and* $\operatorname{rank}(A) = p$;

(A.4) *there are* $\lambda_1, \ldots, \lambda_q$, *which are analytic in* ω, *such that* $\lambda_1^2, \ldots, \lambda_q^2$ *are the eigenvalues of the square matrix* $(Q^{-1}BP, 0_1)$ *and conditions* (1.6) *and* (1.7) *hold. Here* P *is a nonsingular* $p \times p$*-matrix and* Q *is a nonsingular* $q \times q$*-matrix such that* $PAQ = (I_p, 0_2)$, *where* 0_1 *and* 0_2 *are* $p \times (q-p)$ *and* $(q-p) \times q$ *zero matrices, respectively. Then, for sufficiently small* $\alpha > 0$, *there exists an* $\epsilon > 0$ *depending on* $\lambda_j (1 \leq j \leq q), \alpha, O, n, m$ *such that if* (1.8) *holds, then there exists a nonempty subset* O_α *of* O *such that for all* $\omega \in O_\alpha$, *the reversible system* (1.1) *has an invariant torus.*

Below we first consider the case $p = q$. As preparation for the proof of these two theorems, we reduce a linear reversible system to a normal form, which is necessary to our KAM steps, and we construct a special compatible transformation, which is used to deal with certain resonant relations. Then we prove Theorem 1.1 by KAM iteration. The case $p < q$ we reduce to the special case $p = q$ in Theorem 1.1 and then prove Theorem 1.2.

2. Normal forms for linear reversible systems. In this section we consider the reversible system of the form

$$\dot{x} = \omega, \quad \dot{u} = Av, \quad \dot{v} = -Bu, \tag{2.1}$$

where $(x, u, v) \in T^n \times R^p \times R^p$, A and B being p-order square matrices. Moreover, we take A to be nonsingular. We want to transform the reversible system (2.1) to a simple, symmetrical form, which we call normal form.

At first we consider a special class of compatible transformations. Let a mapping $\Phi : (x, u, v) \to (x_+, u_+, v_+)$, defined by

$$x_+ = x, \quad u_+ = \phi_{11}(x)u + \phi_{12}(x)v, \quad v_+ = \phi_{21}(x)u + \phi_{22}(x)v, \tag{2.2}$$

where ϕ_{ij} $(i, j = 1, 2)$ are $p \times p$ matrices. By definition, Φ is compatible if and only if

$$\begin{aligned} &\phi_{11}(x) = \phi_{11}(-x), \quad \phi_{12}(x) = -\phi_{12}(-x), \\ &\phi_{22}(x) = \phi_{22}(-x), \quad \phi_{21}(x) = -\phi_{21}(-x) \end{aligned}$$

and the matrix $(\phi_{ij})_{1\le i,j\le 2}$ is nonsingular. In particular, if $\phi_{12} = \phi_{21} = 0$ and ϕ_{11} and ϕ_{22} are nonsingular constant matrices, then Φ is a linear compatible transformation. Under this compatible transformation, the reversible system (2.1) is changed to

$$\dot{x} = \omega, \quad \dot{u} = A_+v, \quad \dot{v} = -B_+u, \tag{2.3}$$

where $A_+ = \phi_{11}A\phi_{22}^{-1}$ and $B_+ = \phi_{22}B\phi_{11}^{-1}$. Note that for simplicity we always use (x, u, v) instead of the new variables (x_+, u_+, v_+) in the transformed equations. Taking $\phi_{11} = I_p$ and $\phi_{22} = A$, we have $A_+ = I_p$, $B_+ = AB$.

From hypothesis (A.2) there exists a nonsingular matrix S such that

$$SB_+S^{-1} = \operatorname{diag}(B_{+1}, \dots, B_{+d}) \ \text{ with } B_{+j} = \lambda_j^2 I_{p_j} + J_j,$$

where λ_j^2 $(j = 1, \dots, d)$ are all different eigenvalues of B_+, and $J_j = \operatorname{diag}(J_{j1}, \dots, J_{jd_j})$ is a p_j-order matrix, where $J_{jj'}$ is a zero-matrix or a Jordan form (b_{lm}) satisfying $b_{lm} = 1$ for $m = l + 1$ and $b_{lm} = 0$ for $m \ne l + 1$.

It is easy to see that for $\lambda_j \ne 0$, $I_{p_j} + \lambda_j^{-2}J_j$ and $(I_{p_j} + J_j)^2$ are similar . Thus, there exists a nonsingular matrix $\tilde{S}_j$ such that $\tilde{S}_j(\lambda_j^2 I_{p_j} + J_j)\tilde{S}_j^{-1} = [\lambda_j(I_{p_j} + J_j)]^2$. Suppose $\lambda_j \ne 0$ for $j = 1, \dots, d-1$ and $\lambda_d = 0$. Let $\tilde{S} = \operatorname{diag}(\tilde{S}_1, \tilde{S}_2, \dots, \tilde{S}_{d-1}, I_{p_d})$. Under a compatible transformation of the form (2.2) with $\phi_{12} = \phi_{21} = 0$ and $\phi_{11} = \phi_{22} = \tilde{S}S$, the reversible system (2.3) becomes

$$\dot{x} = \omega, \quad \dot{u} = I_pv, \quad \dot{v} = -\tilde{B}u, \tag{2.4}$$

where $\tilde{B} = \operatorname{diag}(\tilde{B}^1, \dots, \tilde{B}^d)$ with $\tilde{B}^j = \lambda_j^2(I_{p_j} + J_j)^2$ for $j \le d - 1$ and $\tilde{B}_d = J_d$.

Taking a compatible transformation of the form (2.2) with

$$\phi_{11} = \operatorname{diag}(\lambda_1 E_1, \dots, \lambda_{d-1}E_{d-1}, I_{p_d}), \quad \phi_{22} = I_p, \quad \phi_{12} = \phi_{21} = 0,$$

where $E_j = I_{p_j} + J_j$, system (2.4) is changed to

$$\dot{x} = \omega, \quad \dot{u} = A_*v, \quad \dot{v} = -B_*u, \tag{2.5}$$

where

$$A_* = \operatorname{diag}(\lambda_1 E_1, \dots, \lambda_{d-1}E_{d-1}, I_{p_d}), \ \ B_* = \operatorname{diag}(\lambda_1 E_1, \dots, \lambda_{d-1}E_{d-1}, J_d).$$

We call the form (2.5) a normal form for the reversible system. This result is stated concisely in the following lemma.

LEMMA 2.1. *The reversible system* (2.1) *can always be changed to the normal form* (2.5) *by compatible transformation. Moreover, if all the eigenvalues of* AB *are not zero, we have* $\lambda_j \neq 0$, $j = 1, 2, \ldots, d$, *and* $A_* = B_* = \operatorname{diag}(\lambda_1 E_1, \ldots, \lambda_d E_d)$.

Now we consider a small perturbation of normal form (2.5), namely the following reversible systems:

$$\dot{x} = \omega, \quad \dot{u} = (A + g_1)v, \quad \dot{v} = -(B + g_2)u, \tag{2.6}$$

where $A = A^*, B = B^*$.

LEMMA 2.2. *There exists a compatible transformation* Φ *satisfying* $\|\Phi - Id\|^L \leq c\epsilon$ *by which* (2.6) *is changed to*

$$\dot{x} = \omega, \quad \dot{u} = A_+ v, \quad \dot{v} = -B_+ u, \tag{2.7}$$

where $A_+ = \operatorname{diag}(A_{+1}, \ldots, A_{+d})$ *and* $B_+ = \operatorname{diag}(B_{+1}, \ldots, B_{+d})$, *with* $A_{+j} = A_j + \hat{A}_j, B_{+j} = A_{+j}$ *for* $j = 1, 2, \ldots, d-1$, *and* $A_{+d} = I_{p_d}$, $B_{+d} = J_d + \hat{B}_d$. *Moreover,* $\|A_+ - A\|^L, \|B_+ - B\|^L \leq c\epsilon$.

Proof. Since A has the eigenvalues $\lambda_1, \ldots, \lambda_{d-1}, 1$ satisfying $|\lambda_j| \geq \delta > 0$ for $1 \leq j \leq d-1$, we have

$$A + g_1 = A(I_p + A^{-1} g_1) \quad \text{with} \quad \|A^{-1} g_1\| \leq c\epsilon,$$

where c depends on δ and p. If ϵ is sufficiently small, $I_p + A^{-1} g_1$ is nonsingular, and

$$(I_p + A^{-1} g_1)^{-1} = I_p - A^{-1} g_1 + (A^{-1} g_1)^2 - \ldots = I_p + P.$$

It follows that $\|P\| \leq c\epsilon$. So $A + g_1$ is also nonsingular. With the compatible transformation $\Phi^1 : (x, u, v) \to (x_+, u_+, v_+)$, defined by

$$x_+ = x, \quad u_+ = (A + g_1)^{-1} u, \quad v_+ = I_p v,$$

the reversible system (2.6) is changed to

$$\dot{x} = \omega, \quad \dot{u} = I_p v, \quad \dot{v} = -\tilde{B} u, \tag{2.8}$$

where $\tilde{B} = AB + P'$, with $P' = g_2 A + B g_1 + g_2 g_1$ and $\|P'\| \leq c\epsilon$. Since

$$AB = \operatorname{diag}\big((\lambda_1 E_1)^2, \ldots, (\lambda_{d-1} E_{d-1})^2, J_d\big),$$

by Lemmas 6.2 and 6.3, if ϵ is sufficiently small, we have a nonsingular matrix S satisfying $\|S - I_p\| \leq |P'\| \leq c\epsilon$ such that

$$S\tilde{B}S^{-1} = AB + \operatorname{diag}(P_1, \ldots, P_d),$$

where the P_j are $p_j \times p_j$-matrices with $\|P_j\| \leq c\|P'\| \leq c\epsilon$.

Define a compatible transformation $\Phi^2 : (x, u, v) \to (x_+, u_+, v_+)$ by

$$x_+ = x, \;\; u_+ = Su, \;\; v_+ = Sv.$$

Then the reversible system (2.8) is changed to

$$\dot{x} = \omega, \quad \dot{u} = I_p v, \quad \dot{v} = -(AB + P'')u, \tag{2.9}$$

where $P'' = \operatorname{diag}(P_1, \ldots, P_d)$.

By Lemma 6.4, for sufficiently small ϵ, there exist $\hat{A}_j$ such that

$$(\lambda_j E_j)^2 + P_j = (\lambda_j E_j + \hat{A}_j)^2,\ 1 \le j \le d-1, \text{ and } \|\hat{A}_j\| \le c\epsilon.$$

Let $\hat{A} = \mathrm{diag}(\hat{A}_1, \dots, \hat{A}_{d-1}, 0)$ and $A_+ = A + \hat{A} = \mathrm{diag}(A_{+1}, \dots, A_{+d})$. We have $A_{+j} = \lambda_j E_j + \hat{A}_j$ $(j \le d-1)$ and $A_{+d} = I_{p_d}$. Let $B_{+j} = A_{+j}$ $(j \le d-1)$ and $B_{+d} = J_d + P_d$. Set $B_+ = \mathrm{diag}(B_{+1}, \dots, B_{+d})$.

Define a compatible transformation

$$\Phi^3 : (x, u, v) \to (x_+, u_+, v_+) \text{ by } x_+ = x,\ u_+ = A_+ u,\ v_+ = I_p v.$$

Thus, the reversible system (2.9) is changed to (2.7). By the compatible transformation $\Phi = \Phi^3\Phi^2\Phi^1$, the reversible system (2.6) is changed to the normal form (2.7). Moreover, Φ is given by $x_+ = x$ and $w_+ = \phi w$, where

$$w = (u, v)^T,\ w_+ = (u_+, v_+)^T, \text{ and } \phi = \mathrm{diag}(A_+ S(A + g_1)^{-1}, S).$$

Write the term

$$A_+ S(A + g_1)^{-1} = (A + \hat{A})S(A + g_1)^{-1} = I_p + P'''.$$

It follows easily that $\|P'''\| \le c\epsilon$. Thus we have $\|\phi - I_{2p}\| \le c\epsilon$. Moreover,

$$\|\phi - I_{2p}\|^L \le c\epsilon, \quad \|A_+ - A\|^L \le c\epsilon, \quad \|B_+ - B\|^L \le c\epsilon,$$

where c indicates constants independent of ϵ. Thus, Lemma 2.2 is proved.

3. A compatible transformation. Define a transformation $\Phi : (x, u, v) \to (x_+, u_+, v_+)$ by

$$\begin{cases} x_+ = x, \\ u_+ = (e^{\mathrm{i}\langle k,x\rangle} + e^{-\mathrm{i}\langle k,x\rangle})u - \mathrm{i}(e^{\mathrm{i}\langle k,x\rangle} - e^{-\mathrm{i}\langle k,x\rangle})v, \\ v_+ = \mathrm{i}(e^{\mathrm{i}\langle k,x\rangle} - e^{-\mathrm{i}\langle k,x\rangle})u + (e^{\mathrm{i}\langle k,x\rangle} + e^{-\mathrm{i}\langle k,x\rangle})v, \end{cases} \tag{3.1}$$

where $k \in Z^n$ is fixed. Obviously, this transformation is compatible.

For simplicity, let

$$E = \begin{pmatrix} I_p & -\mathrm{i}I_p \\ \mathrm{i}I_p & I_p \end{pmatrix}, \quad \bar{E} = \begin{pmatrix} I_p & \mathrm{i}I_p \\ -\mathrm{i}I_p & I_p \end{pmatrix},$$

so that (3.1) can be written in the more compact form

$$x_+ = x, \quad w_+ = \phi w, \tag{3.2}$$

where $\phi = e^{\mathrm{i}\langle k,x\rangle}E + e^{-\mathrm{i}\langle k,x\rangle}\bar{E}$. It follows that $E\bar{E} = 0$, $E^2 = 2E$, $E + \bar{E} = 2I_{2p}$, and so ϕ is invertible with

$$\phi^{-1} = \frac{1}{4}(e^{\mathrm{i}\langle k,x\rangle}\bar{E} + e^{-\mathrm{i}\langle k,x\rangle}E). \tag{3.3}$$

By means of this compatible transformation, we have the following result.

LEMMA 3.1. *Consider the reversible system*

$$\dot{x} = \omega, \quad \dot{u} = \lambda(I + J)v, \quad \dot{v} = -\lambda(I + J)u, \tag{3.4}$$

where for simplicity $I = I_{p_j}$ *and* $J = J_j$ *. If* $\lambda \neq 0$ *and* $\lambda + \langle k, \omega \rangle \neq 0$*, then there is a compatible transformation which carries over the system* (3.4) *to the system*

$$\dot{x} = \omega, \quad \dot{u} = (\lambda + \langle k, \omega \rangle)(I + J)v, \quad \dot{v} = -(\lambda + \langle k, \omega \rangle)(I + J)u. \tag{3.5}$$

Proof. Let

$$\Omega = \begin{pmatrix} 0 & A \\ -B & 0 \end{pmatrix}, \quad A = B = \lambda(I + J).$$

Then (3.4) can be written as $\dot{x} = \omega$, $\dot{w} = \Omega w$. Under the transformation (3.2) the reversible system (3.4) is changed to

$$x_+ = \omega, \quad \dot{w}_+ = (\partial_\omega \phi \phi^{-1} + \phi \Omega \phi^{-1}) w_+ = \Omega_+ w_+. \tag{3.6}$$

By direct calculation, we have

$$\Omega_+ = \begin{pmatrix} 0 & A + \langle k, \omega \rangle I \\ -B - \langle k, \omega \rangle I & 0 \end{pmatrix}.$$

Since $\lambda + \langle k, \omega \rangle \neq 0$, in the same way as in section 2, we have a compatible transformation that changes the reversible system (3.6) to (3.5). □

In the normal form (2.5), if λ_i and λ_j satisfy

$$\lambda_j - \lambda_i = \langle k, \omega \rangle, \qquad k \neq 0 \text{ and } \lambda_i \neq \langle k, \omega \rangle,$$

the normal form can be changed by a compatible transformation to another normal form with $\lambda_j = \lambda_i$. This means that the resonant case $\lambda_j - \lambda_i = \langle k, \omega \rangle$ is equivalent to the multiple case $\lambda_j = \lambda_i$ by a compatible transformation. Thus, in the proof of our results, we can always suppose that λ_i and λ_j satisfy $\lambda_j - \lambda_i \neq \langle k, \omega \rangle$ for all $k \in Z^n$.

4. Proof of Theorem 1.1. Below we use the KAM iteration to prove Theorem 1.1. By Lemma 2.1, without loss of generality, we suppose that $\Omega = \Omega^0$ has the form

$$\Omega^0 = \begin{pmatrix} 0 & A_0 \\ -B_0 & 0 \end{pmatrix},$$

where A_0 and B_0 have the same form as A_* and B_* in (2.5). Let $\lambda_d = 0$. By condition (1.7) and Lemma 3.1 we suppose that on the set O the nonresonance conditions hold:

$$\langle \omega, k \rangle \neq 0 \qquad \forall k \in Z^n \setminus \{0\}, \tag{4.1}$$

$$\langle \omega, k \rangle + \lambda_j(\omega) \neq 0 \qquad \forall k \in Z^n, \forall j = 1, \ldots, d-1, \tag{4.2}$$

$$\langle \omega, k \rangle + \lambda_i(\omega) - \lambda_j(\omega) \neq 0 \qquad \forall k \in Z^n, \ \forall i \neq j. \tag{4.3}$$

Moreover, suppose that there exist the following resonant relations:

$$2\lambda_j(\omega) = \langle \omega, k_j \rangle \ \forall \omega \in O, \qquad k_j \neq 0, \ j = 1, \ldots, d-1. \tag{4.4}$$

Remark. The nonresonant condition (4.3) is the second Melnikov's condition. By Lemma 3.1, the second Melnikov's condition can hold automatically by compatible transformation, so we need not give them as an additional condition.

Remark. Because of the resonant relations (4.4), in the KAM steps we have to retain some x-dependent terms from terms which are linear in u and v; this makes the KAM iteration more complicated.

A. *Outline of the iteration.* At each step we consider the reversible system

$$\begin{cases} \dot{x} = \tilde{\omega} + f(x,w;\omega), \\ \dot{w} = \Omega w + G(x)w + g(x,w;\omega), \end{cases} \tag{4.5}$$

where

$$\Omega = \begin{pmatrix} 0 & A \\ -B & 0 \end{pmatrix},$$

$$A = \mathrm{diag}(A_1,\dots,A_d),\ A_j = \lambda_j E_j + \hat{A}_j,\ 1 \le j \le d-1,\ A_d = I_{p_d},$$
$$B = \mathrm{diag}(B_1,\dots,B_d),\ B_j = A_j,\qquad 1 \le j \le d-1,\ B_d = J_d + \hat{B}_d.$$

Moreover, we have $\|\hat{A}_j\|^L \le c\epsilon_0$ for $1 \le j \le d-1$ and $\|\hat{B}_d\|^L \le c\epsilon_0$. The matrix G depends on x and satisfies $\|G\|^L \le c\epsilon_0$. Write as $G = (G_{lm})_{1\le l,m\le 2}$ in block form, where $G_{ij} = \mathrm{diag}(G_{ij}^1,\dots,G_{ij}^d)$ with $G_{ij}^d = 0$ for $i,\ j = 1,2$, and G_{ij}^l being a $p_l \times p_l$-matrix. Let $G^j = (G_{lm}^j)_{1\le l,m\le 2}$ with

$$G_{11}^j = \frac{\mathrm{i}}{2}\left(G_{k_j}^j e^{\mathrm{i}\langle k_j,x\rangle} + G_{-k_j}^j e^{-\mathrm{i}\langle k_j,x\rangle}\right),\quad G_{22}^j = -G_{11}^j,$$
$$G_{12}^j = -\frac{1}{2}\left(G_{k_j}^j e^{\mathrm{i}\langle k_j,x\rangle} - G_{-k_j}^j e^{-\mathrm{i}\langle k_j,x\rangle}\right),\quad G_{21}^j = G_{12}^j.$$

Let

$$S^j = \begin{pmatrix} I_{p_j} & I_{p_j} \\ \mathrm{i}I_{p_j} & -\mathrm{i}I_{p_j} \end{pmatrix} \quad \text{for } 1 \le j \le d-1,\ S^d = I_{p_d}. \tag{4.6}$$

It is easy to verify that

$$(S^j)^{-1} G^j S^j = \mathrm{i}\begin{pmatrix} 0 & G_{k_j}^j e^{\mathrm{i}\langle k_j,x\rangle} \\ G_{-k_j}^j e^{-\mathrm{i}\langle k_j,x\rangle} & 0 \end{pmatrix}$$

and

$$(S^j)^{-1}\begin{pmatrix} 0 & A_j \\ -B_j & 0 \end{pmatrix} S^j = \mathrm{i}\begin{pmatrix} A_j & 0 \\ 0 & -B_j \end{pmatrix}.$$

Remark. Gw consists of some special x-dependent terms which cannot be killed in KAM steps because of the resonant relations (4.4). These terms are retained through the iteration step.

Considering small perturbations, suppose that f and g are analytic on $D(s,r)$ in (x,w) and belong to $C^L(O)$ in ω with

$$\|f\|^L_{D(s,r)} \le \epsilon,\quad \|g\|^L_{D(s,r)} \le r\epsilon. \tag{4.7}$$

The idea of our KAM iteration is to find a compatible transformation such that the system (4.5) can be changed to

$$\begin{cases} \dot{x} = \tilde{\omega}_+ + f_+(x,w;\omega), \\ \dot{w} = \Omega_+ w + G_+(x)w + g_+(x,w;\omega) \end{cases} \tag{4.8}$$

with f_+ and g_+ being a much smaller perturbation and $\tilde{\omega}_+, \Omega_+, G_+(x)$ being the corrections of $\tilde{\omega}, \Omega, G(x)$, respectively. If this correction can be carried out at each step of the iteration, then, after infinitely many steps, the system converges to the form in Theorem 1.1.

B. *Normalization.* We first normalize the first order constant terms of w. Let $f^0 = f(x,w)|_{w=0}$, $[f^0]$ being the average of f^0 with respect to x on T^n, and $\hat{\Omega} = [\mathcal{D}_w g(x,w)\,|_{w=0}]$. Since the system is reversible, we have

$$\hat{\Omega} = \begin{pmatrix} 0 & \mathcal{D}_v g_1(x,u,v)\,|_{u,v=0} \\ \mathcal{D}_u g_2(x,u,v)\,|_{u,v=0} & 0 \end{pmatrix}.$$

By Lemma 2.2, we have a linear compatible transformation Φ^1 defined by $x_+ = x, w_+ = Sw$ satisfying

$$\|S - I_{2p}\|^L \le c\epsilon \tag{4.9}$$

such that the system (4.5) is changed to

$$\begin{cases} \dot{x} = \tilde{\tilde{\omega}} + \big(f(x,S^{-1}w;\omega) - [f^0]\big), \\ \dot{w} = \tilde{\Omega} w + SG(x)S^{-1}w + Sg(x,S^{-1}w;\omega) - S\hat{\Omega}S^{-1}w, \end{cases} \tag{4.10}$$

where $\tilde{\tilde{\omega}} = \tilde{\omega} + [f^0]$ and $\tilde{\Omega} = \left(\begin{smallmatrix} 0 & \tilde{A} \\ -\tilde{B} & 0 \end{smallmatrix}\right)$ with

$$\begin{aligned} &\tilde{A} = \operatorname{diag}(\tilde{A}_1, \dots, A_d), \quad \tilde{A}_j = \lambda_j E_j + \hat{\tilde{A}}_j,\ 1 \le j \le d-1, \quad \tilde{A}_d = I_{p_d}, \\ &\tilde{B} = \operatorname{diag}(\tilde{B}_1, \dots, \tilde{B}_d), \quad \tilde{B}_j = \tilde{A}_j, \qquad\qquad 1 \le j \le d-1, \quad \tilde{B}_d = J_d + \hat{\tilde{B}}_d\,. \end{aligned}$$

Moreover, we have the estimates

$$\|\hat{\tilde{A}}_j - \hat{A}_j\|^L \le c\epsilon \ \text{ for } \ 1 \le j \le d-1, \ \ \|\hat{\tilde{B}}_d - \hat{B}_d\|^L \le c\epsilon. \tag{4.11}$$

Write $SG(x)S^{-1} = G + (S - I_{2p})GS^{-1} + SG(S^{-1} - I_{2p})$. Let

$$\begin{aligned} &\tilde{f} = \big(f(x,S^{-1}w;\omega) - [f^0]\big), \\ &\bar{g} = S\big(g(x,S^{-1}w;\omega) - \hat{\Omega}S^{-1}w\big) + \big[(S - I_{2p})GS^{-1} + SG(S^{-1} - I_{2p})\big]w. \end{aligned}$$

It is easy to see that

$$\|\tilde{f}\|^L_{D(s,r/2)} \le 2\epsilon, \quad \|\bar{g}\|^L_{D(s,r/2)} \le cr\epsilon. \tag{4.12}$$

Note that in the KAM steps we use c to indicate constants which are independent of the iteration process.

Let

$$\bar{g}^1 = \frac{\partial \bar{g}}{\partial w}\bigg|_{w=0} = \begin{pmatrix} \bar{g}_{11} & \bar{g}_{12} \\ \bar{g}_{21} & \bar{g}_{22} \end{pmatrix}.$$

Write $\bar g_{ij}=(\bar g_{ij}^{lm})_{1\le l,m\le d}$, where $\bar g_{ij}^{lm}$ is a $p_l\times p_m$-matrix. Take

$$\begin{aligned}
\hat G_{11}^j =& -\frac14\Big\{-\bar g_{11k_j}^{jj}e^{\mathrm{i}\langle k_j,x\rangle}-\bar g_{11-k_j}^{jj}e^{-\mathrm{i}\langle k_j,x\rangle}+\bar g_{22k_j}^{jj}e^{\mathrm{i}\langle k_j,x\rangle}+\bar g_{22-k_j}^{jj}e^{-\mathrm{i}\langle k_j,x\rangle}\\
&+\mathrm{i}\big[\bar g_{12k_j}^{jj}e^{\mathrm{i}\langle k_j,x\rangle}-\bar g_{12-k_j}^{jj}e^{-\mathrm{i}\langle k_j,x\rangle}+\bar g_{21k_j}^{jj}e^{\mathrm{i}\langle k_j,x\rangle}-\bar g_{21-k_j}^{jj}e^{-\mathrm{i}\langle k_j,x\rangle}\big]\Big\},\\
\hat G_{21}^j =& -\frac14\Big\{-\mathrm{i}\big[\bar g_{11k_j}^{jj}e^{\mathrm{i}\langle k_j,x\rangle}-\bar g_{11-k_j}^{jj}e^{-\mathrm{i}\langle k_j,x\rangle}\big]\\
&+\mathrm{i}\big[\bar g_{22k_j}^{jj}e^{\mathrm{i}\langle k_j,x\rangle}-\bar g_{22-k_j}^{jj}e^{-\mathrm{i}\langle k_j,x\rangle}\big]\\
&-\bar g_{12k_j}^{jj}e^{\mathrm{i}\langle k_j,x\rangle}-\bar g_{12-k_j}^{jj}e^{-\mathrm{i}\langle k_j,x\rangle}-\bar g_{21k_j}^{jj}e^{\mathrm{i}\langle k_j,x\rangle}-\bar g_{21-k_j}^{jj}e^{-\mathrm{i}\langle k_j,x\rangle}\Big\},\\
\hat G_{22}^j =& -\hat G_{11}^j,\ \ \hat G_{12}^j=\hat G_{21}^j \text{ for } j=1,\dots,d-1,\ \ \hat G_{ij}^d=0,\\
\hat G_{ij} =& \operatorname{diag}\big(\hat G_{ij}^1,\dots,\hat G_{ij}^{d-1},0\big),\ \hat G=\big(\hat G_{ij}\big)_{1\le i,j\le 2},\ \hat G^j=\begin{pmatrix}\hat G_{11}^j & \hat G_{12}^j\\ \hat G_{21}^j & \hat G_{22}^j\end{pmatrix}.
\end{aligned}$$

In addition, set

$$\tilde G=G+\hat G,\ \tilde g=\bar g-\hat G w,\ \text{and } \tilde g^1=\frac{\partial\tilde g}{\partial w}\Big|_{w=0}=\bar g^1-\hat G. \tag{4.13}$$

It follows easily that $\|\tilde g\|^L_{D(s,r/2)}\le cr\epsilon$. The system (4.10) becomes

$$\begin{cases}\dot x &= \tilde{\tilde\omega} \qquad\qquad +\tilde f,\\ \dot w &= \tilde\Omega w+\tilde G(x)w+\tilde g.\end{cases} \tag{4.14}$$

By the above discussion, we have $[\tilde f\ |_{w=0}]=0$ and $[\tilde g_w\ |_{w=0}]=0$. In particular, we take the terms $\tilde g_{ij}^{ll}$ from $\tilde g^1$ in the same way as $\bar g_{ij}^{ll}$ from $\bar g^1$ and let

$$(\tilde g_{ij}^l)_{1\le i,j\le 2}=(S^l)^{-1}(\tilde g_{ij}^{ll})_{1\le i,j\le 2}S^l.$$

Then for the Fourier coefficients of $\tilde g_{ij,k}^l$ we have

$$\tilde g_{12,k_l}^l=0\ \text{ and }\ \tilde g_{21,-k_l}^l=0. \tag{4.15}$$

C. *Constructing compatible transformation.* Define $\Phi^2:(x_+,w_+)\to(x,w)$ by

$$x=x_++h(x_+),\quad w=\big(I_{2p}+a(x_+)\big)w_++b(x_+),$$

where $h(x)$, $b(x)$ are vector functions, respectively, and $a(x)$ is a $2p\times 2p$-matrix function. Write a and b in the block form

$$a=\begin{pmatrix}a_{11} & a_{12}\\ a_{21} & a_{22}\end{pmatrix},\quad b=\begin{pmatrix}b_1\\ b_2\end{pmatrix},$$

where a_{ij} are $p\times p$-matrices and b_1,b_2 are p-dimensional vectors. By definition, it is easy to see that Φ^2 is compatible if and only if

$$\begin{cases}h(-x) &= -h(x),\\ b_1(-x) &= -b_1(x), \quad b_2(-x)=b_2(x),\\ a_{11}(-x)=a_{11}(x), &\quad a_{12}(-x)=-a_{12}(x),\\ a_{21}(-x)=-a_{21}(x), &\quad a_{22}(-x)=\ a_{22}(x).\end{cases} \tag{4.16}$$

Before doing the transformation, we first consider the composition function $\tilde{G}(x+h(x))$. Suppose that $\|h(x)\|^L_{D(s-\rho,r/2)} \le 1$. By series expansion, it follows that

$$e^{\mathrm{i}\langle k_j,h(x)\rangle} = 1 + \mathrm{i}\langle k_j, h(x)\rangle + O_j(h^2),$$

where $O_j(h^2)$ satisfies $\|O_j(h^2)\| \le c\|h\|^2$ as $h \to 0$. Let

$$\tilde{G}^j_*(x) = -\mathrm{i}(S^j)^{-1}\tilde{G}^j S^j = \begin{pmatrix} 0 & \tilde{G}^j_{k_j} e^{\mathrm{i}\langle k_j,x\rangle} \\ \tilde{G}^j_{-k_j} e^{-\mathrm{i}\langle k_j,x\rangle} & 0 \end{pmatrix}.$$

Then we have

$$\tilde{G}^j_*(x+h) = \tilde{G}^j_* + \tilde{G}^j_* \operatorname{diag}\big(-\mathrm{i}\langle k_j,h\rangle, \mathrm{i}\langle k_j,h\rangle\big) + \tilde{G}^j_* \operatorname{diag}\big(O_j(-h^2), O_j(h^2)\big)\big).$$

With

$$\begin{aligned} \tilde{G}^j_h(x) &= \mathrm{i}S^j\tilde{G}^j_*(x)\operatorname{diag}\big(-\mathrm{i}\langle k_j,h\rangle, \mathrm{i}\langle k_j,h\rangle\big)(S^j)^{-1}, \\ \tilde{G}^j_{h^2}(x) &= \mathrm{i}S^j\tilde{G}^j_*(x)\operatorname{diag}\big(O_j(-h^2), O_j(h^2)\big)(S^j)^{-1} \end{aligned}$$

we obtain

$$\tilde{G}^j(x+h(x)) = \tilde{G}^j(x) + \tilde{G}^j_h(x) + \tilde{G}^j_{h^2}(x).$$

In the same way as defining G from G^j, we define $\tilde{G}(x+h(x))$, $\tilde{G}(x)$, $\tilde{G}_h(x)$, and $\tilde{G}_{h^2}(x)$. It is easy to see that

$$\tilde{G}(x+h(x)) = \tilde{G}(x) + \tilde{G}_h(x) + \tilde{G}_{h^2}(x).$$

Moreover, we have

$$\|\tilde{G}_h\|^L_{D(s-\rho,r/2)} \le c\|h\|^L_{D(s-\rho,r/2)}, \quad \|\tilde{G}_{h^2}\|^L_{D(s-\rho,r/2)} \le c(\|h\|^L_{D(s-\rho,r/2)})^2.$$

In particular, if $[h(x)] = 0$, $\tilde{G}_h$ has the same property as (4.15) for $\tilde{g}^1$.

Under the transformation Φ_2 the system (4.14) is changed to

$$\begin{cases} \dot{x} = \tilde{\tilde{\omega}} + (I_n + \mathcal{D}_x h)^{-1}(\tilde{f}^0 - \partial_{\tilde{\tilde{\omega}}} h) + R_0 = \tilde{\tilde{\omega}} + f_+, \\ \dot{w} = (\tilde{\Omega} + \tilde{G})w + (I_{2p} + a)^{-1}[(\tilde{\Omega} + \tilde{G})b - \partial_{\tilde{\tilde{\omega}}} b + \tilde{g}^0 \\ \qquad + (\tilde{\Omega} + \tilde{G})aw - a(\tilde{\Omega} + \tilde{G})w - \partial_{\tilde{\tilde{\omega}}} aw + (\tilde{g}^1 + \tilde{G}_h)w] + R \\ \qquad = (\tilde{\Omega} + \tilde{G})w + g_+, \end{cases} \tag{4.17}$$

where

$$\tilde{f}^0 = \tilde{f}(x,0), \;\; \tilde{g}^0 = \tilde{g}(x,0), \;\; \tilde{g}^1 = \tilde{g}_w(x,0), \;\; \partial_{\tilde{\tilde{\omega}}} h = \sum_k \mathrm{i}\langle k, \tilde{\tilde{\omega}}\rangle h_k e^{\mathrm{i}\langle k,x\rangle},$$

$$R_0 = (I_n + \mathcal{D}_x h)^{-1}\left(\tilde{f} - \tilde{f}^0 + \int_0^1 < \nabla_z \tilde{f}(z + t\delta z), \delta z > \, dt\right) \tag{4.18}$$

with $\mathcal{D}_x h$ the Jacobian matrix of h with respect to x, $z = (x, w)$, and $\delta z = (h, aw + b)$,

$$\begin{aligned} R = {} & (I_{2p} + a)^{-1}\big[(\tilde{G}_h + \tilde{G}_{h^2})(aw + b) + G_{h^2} w - (\partial_{f_+} aw + \partial_{f_+} b)\big] \\ & + \; (I_{2p} + a)^{-1}\left[\tilde{g} - \tilde{g}^0 - \tilde{g}^1 w + \int_0^1 < \nabla_z \tilde{g}(z + t\delta z), \delta z > \, dt\right]. \end{aligned} \tag{4.19}$$

Here $\partial_f a = (\partial_f a_{ij})_{ij}$ is also a matrix.

We want to find h, a, b such that

$$-\partial_{\tilde{\omega}} h + \tilde{f}^0 = 0, \tag{4.20}$$

$$(\tilde{\Omega} + \tilde{G})b - \partial_{\tilde{\omega}} b + \tilde{g}^0 = 0, \tag{4.21}$$

$$(\tilde{\Omega} + \tilde{G})a - a(\tilde{\Omega} + \tilde{G}) - \partial_{\tilde{\omega}} a + \tilde{g}^1 + \tilde{G}_h = 0. \tag{4.22}$$

Thus, the system (4.17) becomes

$$\begin{cases} \dot{x} = \tilde{\omega}_+ \qquad\qquad + f_+, \\ \dot{w} = (\Omega_+ + G_+)w + g_+, \end{cases} \tag{4.23}$$

where $\tilde{\omega}_+ = \tilde{\tilde{\omega}},\ \Omega_+ = \tilde{\Omega},\ G_+ = \tilde{G},\ f_+ = R_0,\ g_+ = R.$

D. *Solving linear homological equations.* As usual, the first equation (4.20) is easy to solve. By condition (4.1) and Lemma 6.5, there exists a subset O_+ of O such that for $\omega \in O_+$, we have $|\langle\tilde{\tilde{\omega}}, k\rangle| \geq \alpha/|k|^\tau$ for all $0 \neq k \in Z^n$, and $\tau > n-1$. By $[\tilde{f}^0] = 0$, for $\omega \in O_+$ we obtain $h_k = \tilde{f}^0_k / \mathrm{i}\langle\tilde{\tilde{\omega}}, k\rangle$ for all $k \neq 0$, where h_k and $\tilde{f}^0_k$ are the Fourier coefficients of h and $\tilde{f}^0$. Since $\|\tilde{f}^0\|^L_{D(s,r/2)} \leq \|\tilde{f}\|^L_{D(s,r/2)} \leq \epsilon$, it follows that

$$\|h\|^L_{D(s-\rho,r/2)} \leq c\epsilon\, \alpha^{-L-1}\rho^{-\kappa}, \quad \kappa = 2\tau + n + 1. \tag{4.24}$$

Note that the measure of the set $O \setminus O_+$ will be estimated later.

Remark. In this paper, we can also use Rüssmann's nondegeneracy condition and Bruno's small divisor condition; for this case we refer the reader to [12, 13].

To solve (4.21), let $b = (b_1^T, \ldots, b_d^T, b_{d+1}^T, \ldots, b_{2d}^T)^T$, where b_j and b_{d+j} are p_j-dimensional column vectors. Let $y = \tilde{g}^0 = \tilde{g}(x, 0)$. Similarly, write $y = (y_1^T, \ldots, y_d^T, y_{d+1}^T, \ldots, y_{2d}^T)^T$. It follows easily that

$$\|y\|^L_{D(s,r/2)} \leq \|\tilde{g}\|^L_{D(s,r/2)} \leq cr\epsilon.$$

Let

$$\tilde{\Omega}^j = \begin{pmatrix} 0 & \tilde{A}_j \\ -\tilde{B}_j & 0 \end{pmatrix}.$$

By the special form of $\tilde{\Omega}$ and $\tilde{G}$, (4.21) is equivalent to

$$\begin{pmatrix} \partial_{\tilde{\omega}} b_j \\ \partial_{\tilde{\omega}} b_{d+j} \end{pmatrix} - \left(\tilde{\Omega}^j + \tilde{G}^j\right) \begin{pmatrix} b_j \\ b_{d+j} \end{pmatrix} = \begin{pmatrix} y_j \\ y_{d+j} \end{pmatrix},\ j = 1, 2, \ldots, d.$$

Let

$$(\tilde{b}_j^T, \tilde{b}_{d+j}^T)^T = (S^j)^{-1}(b_j^T, b_{d+j}^T)^T S^j, \quad (\tilde{y}_j^T, \tilde{y}_{d+j}^T)^T = (S^j)^{-1}(y_j^T, y_{d+j}^T)^T S^j,$$

where S^j is defined in (4.6). Set $\tilde{\Omega}^j_* = -\mathrm{i}(\mathrm{S}^\mathrm{j})^{-1}\tilde{\Omega}^\mathrm{j}\mathrm{S}^\mathrm{j}$. Then we have

$$\mathrm{i}\begin{pmatrix} \partial_{\tilde{\tilde{\omega}}} \tilde{b}_j \\ \partial_{\tilde{\tilde{\omega}}} \tilde{b}_{d+j} \end{pmatrix} + \tilde{\Omega}^j_* \begin{pmatrix} \tilde{b}_j \\ \tilde{b}_{d+j} \end{pmatrix} + \tilde{G}^j_* \begin{pmatrix} \tilde{b}_j \\ \tilde{b}_{d+j} \end{pmatrix} = \mathrm{i}\begin{pmatrix} \tilde{y}_j \\ \tilde{y}_{d+j} \end{pmatrix};$$

that is,

$$\begin{aligned} -\mathrm{i}\partial_{\tilde{\tilde{\omega}}} \tilde{b}_j - \tilde{A}_j \tilde{b}_j - \tilde{G}^j_{k_j} e^{\mathrm{i}\langle k_j, x\rangle} \tilde{b}_{d+j} &= -\mathrm{i}\tilde{y}_j, \\ -\mathrm{i}\partial_{\tilde{\tilde{\omega}}} \tilde{b}_{d+j} + \tilde{B}_j \tilde{b}_{d+j} - \tilde{G}^j_{-k_j} e^{-\mathrm{i}\langle k_j, x\rangle} \tilde{b}_j &= -\mathrm{i}\tilde{y}_{d+j}. \end{aligned}$$

Let $\tilde{b}_j = \sum_{k\in Z^n} \tilde{b}_{j,k} e^{\mathrm{i}\langle k,x\rangle}$. Then we obtain the following linear equations for the Fourier coefficients $\{\tilde{b}_{j,k}\}$:

$$[\langle k,\tilde{\tilde{\omega}}\rangle I_{p_j} - \tilde{A}_j]\tilde{b}_{j,k} - \tilde{G}^j_{k_j}\tilde{b}_{d+j,k-k_j} = -\mathrm{i}\tilde{y}_{j,k},$$
$$[\langle k-k_j,\tilde{\tilde{\omega}}\rangle I_{p_j} + \tilde{B}_j]\tilde{b}_{d+j,k-k_j} - \tilde{G}^j_{-k_j}\tilde{b}_{j,k} = -\mathrm{i}\tilde{y}_{d+j,k-k_j}.$$

Using (4.4), the coefficient matrix for $\tilde{b}_{j,k}$, and $\tilde{b}_{d+j,k-k_j}$,

$$\tilde{M} = \langle k,\tilde{\tilde{\omega}}\rangle I_{2p} - \mathrm{diag}(\lambda_j(I_{p_j}+J_j),\lambda_j(I_{p_j}-J_j)) + O(\epsilon_0) = M + O(\epsilon_0).$$

Obviously, M has only the eigenvalue $\langle k,\tilde{\tilde{\omega}}\rangle - \lambda_j$, and $O(\epsilon_0)$ is a small matrix. Suppose that

$$\|\tilde{\tilde{\omega}} - \tilde{\omega}\|^L,\ \|\tilde{A}_j - A_j\|^L,\ \|\tilde{B}_j - B_j\|^L,\ \|\tilde{G}^j_{\pm k_j}\|^L \le c\epsilon_0. \tag{4.25}$$

Then we have $\|O(\epsilon_0)\|^L \le c\epsilon_0$. By condition (4.2) and Lemmas 6.6 and 6.7, there exists a subset O_+ of O such that, for $\omega \in O_+$, $\tilde{M}$ is nonsingular and, for its inverse $\tilde{M}^{-1}$, we have

$$\|\tilde{M}^{-1}\|^L \le c(|k|+1)^\tau \alpha^{-L-1}.$$

Thus, we solve $\tilde{b}_{j,k}$ and $\tilde{b}_{d+j,k-k_j}$ and have the following estimates:

$$\|(\tilde{b}^T_{j,k},\tilde{b}^T_{d+j,k-k_j})^T\|^L \le c(|k|+1)^\tau\alpha^{-L-1}\|(\tilde{y}^T_{j,k},\tilde{y}^T_{d+j,k-k_j})^T\|^L \tag{4.26}$$

for $j = 1,\dots,d-1$ and for all $k \in Z^n$.

For $j = d$, we need to solve the following equations:

$$\begin{cases} \mathrm{i}\langle k,\tilde{\tilde{\omega}}\rangle\tilde{b}_{d,k} - \tilde{b}_{2d,k} = \tilde{y}_{d,k}, \\ \mathrm{i}\langle k,\tilde{\tilde{\omega}}\rangle\tilde{b}_{2d,k} + (J_d + \hat{\tilde{B}}_d)\tilde{b}_{d,k} = \tilde{y}_{2d,k}. \end{cases} \tag{4.27}$$

If $k \neq 0$, similarly to the above, we can find $\tilde{b}_{d,k}$ and $\tilde{b}_{2d,k}$ for $\omega \in O_+$ and have

$$\|(\tilde{b}^T_{d,k},\tilde{b}^T_{2d,k})^T\|^L_{D(s-\rho,r/2)} \le c(1+|k|)^\tau\alpha^{-L-1}\|(\tilde{y}^T_{d,k},\tilde{y}^T_{2d,k})^T\|^L. \tag{4.28}$$

For $k = 0$, (4.27) becomes $\tilde{b}_{2d,0} = -\tilde{y}_{d,0}$ and $(J_d + \hat{J}_d)\tilde{b}_{d,0} = \tilde{y}_{2d,0}$. Since $\tilde{y}_{2d,0} = 0$ by the special structure of reversible systems, we take $\tilde{b}_{d,0} = 0$. Thus, (4.28) still holds for $k = 0$. Combining the above estimates, for all $k \in Z^n$, we have

$$\|b_k\|^L \le c\|\tilde{b}_k\|^L \le c(|k|+1)^\tau\alpha^{-L-1}\|y_k\|^L.$$

Hence,

$$\|b(x)\|^L_{D(s-\rho,r/2)} \le cr\epsilon\alpha^{-L-1}\rho^{-\kappa}. \tag{4.29}$$

Now we consider the last equation, (4.22), which is the most difficult one. Let $a = (a_{ij})_{1\le i,j\le 2}$ and $y = \tilde{g}^1 + \tilde{G}_h = (y_{ij})_{1\le i,j\le 2}$, where a^{ij} and y^{ij} are $p\times p$-matrices. By (4.24), we have

$$\|y(x)\|^L_{D(s-\rho,r/2)} \le c\epsilon\alpha^{-L-1}\rho^{-\kappa}. \tag{4.30}$$

Write the matrices $a_{ij} = (a_{ij}^{lm})_{1\le l,m\le d}$ and $y_{ij} = (y_{ij}^{lm})_{1\le l,m\le d}$ in block form with a_{ij}^{lm} and y_{ij}^{lm} being $p_l \times p_m$-matrices. Define two $2p_l \times 2p_m$-matrices x^{lm} and y^{lm} by $x^{lm} = (a_{ij}^{lm})_{1\le i,j\le 2}$ and $y_{lm} = (y_{ij}^{lm})_{1\le i,j\le 2}$. Let

$$\tilde\Omega^j = \begin{pmatrix} 0 & \tilde A_j \\ -\tilde B_j & 0 \end{pmatrix} \text{ for } 1 \le j \le d-1 \text{ and } \tilde\Omega^d = \begin{pmatrix} 0 & I_{p_d} \\ J_d + \hat{\tilde B}_d & 0 \end{pmatrix}.$$

Then (4.22) becomes

$$\partial_{\tilde\omega} x^{ij} + x^{ij}(\tilde\Omega^j + \tilde G^j) - (\tilde\Omega^i + \tilde G^i)x^{ij} = y^{ij}. \tag{4.31}$$

Let $X = (S^i)^{-1}x^{ij}S^j = (X^{lm})_{1\le l,m\le 2}$, $Y = (S^i)^{-1}y^{ij}S^j = (Y^{lm})_{1\le l,m\le 2}$, with X^{lm}, Y^{lm} being $p_i \times p_j$-matrices. Then (4.31) changes to

$$\partial_{\tilde\omega} X + X(S^j)^{-1}(\tilde\Omega^j + \tilde G^j)S^j - (S^i)^{-1}(\tilde\Omega^i + \tilde G^i)S^i X = Y. \tag{4.32}$$

In the case of $i = j = d$, $\tilde G^d = 0$, so (4.32) becomes

$$\partial_{\tilde\omega} X - \tilde\Omega^d X + X\tilde\Omega^d = Y. \tag{4.33}$$

Hence, using Lemma 6.1, the equation for the Fourier coefficient $\{X_k\}$ is

$$\tilde M\{X_k\} = \big(\langle k, \tilde\omega\rangle I_{2p} + M + O(\epsilon_0)\big)\{X_k\} = -\mathrm{i}\{Y_k\},$$

where M has the only eigenvalue zero and $O(\epsilon_0)$ depends on $\hat{\tilde B}_d$ with the same estimates as before. For the notation $\{X_k\}$, see Lemma 6.1. In the same way as above, by Lemmas 6.6 and 6.7, there exists a subset O_+ of O such that, for $\omega \in O_+$, we can find $\{X_k\}$ for the above equation and obtain $\|X_k\|^L \le c|k|^\tau \alpha^{-L-1}\|Y_k\|^L$ for all $k \ne 0$. If $k = 0$, we take $X_0 = 0$ because of $Y_0 = 0$.

If $i = d$ and $1 \le j < d$, (4.32) becomes

$$\partial_{\tilde\omega} X + X(S^j)^{-1}(\tilde\Omega^j + \tilde G^j)S^j - \tilde\Omega^d X = Y. \tag{4.34}$$

Then

$$\begin{aligned}
&-\mathrm{i}\partial_{\tilde\omega} X^{11} + X^{11}\tilde A_j + e^{-\mathrm{i}\langle k_j,x\rangle}X^{12}\tilde G^j_{-k_j} + \mathrm{i}X^{21} = -\mathrm{i}Y^{11},\\
&-\mathrm{i}\partial_{\tilde\omega} X^{12} - X^{12}\tilde B_j + e^{\mathrm{i}\langle k_j,x\rangle}X^{11}\tilde G^j_{k_j} + \mathrm{i}X^{22} = -\mathrm{i}Y^{12},\\
&-\mathrm{i}\partial_{\tilde\omega} X^{21} + X^{21}\tilde A_j + e^{-\mathrm{i}\langle k_j,x\rangle}X^{22}\tilde G^j_{-k_j} - \mathrm{i}\tilde B_d X^{11} = -\mathrm{i}Y^{21},\\
&-\mathrm{i}\partial_{\tilde\omega} X^{22} - X^{22}\tilde B_j + e^{\mathrm{i}\langle k_j,x\rangle}X^{21}\tilde G^j_{k_j} - \mathrm{i}\tilde B_d X^{12} = -\mathrm{i}Y^{22}.
\end{aligned}$$

Comparing the Fourier coefficients on both sides of these equations and replacing k by $k|_j = k + k_j$ in the second and the fourth equation, we obtain

$$\begin{aligned}
&\langle k,\tilde\omega\rangle X^{11}_k + X^{11}_k\tilde A_j + X^{12}_{k|_j}\tilde G^j_{-k_j} + \mathrm{i}X^{21}_k = -\mathrm{i}Y^{11}_k,\\
&\langle k|_j,\tilde\omega\rangle X^{12}_{k|_j} - X^{12}_{k|_j}\tilde B_j + X^{11}_k\tilde G^j_{k_j} + \mathrm{i}X^{22}_{k_j} = -\mathrm{i}Y^{12}_{k|_j},\\
&\langle k,\tilde\omega\rangle X^{21}_k + X^{21}_k\tilde A_j + X^{22}_{k|_j}\tilde G^j_{-k_j} - \mathrm{i}\tilde B_d X^{11}_k = -\mathrm{i}Y^{21}_k,\\
&\langle k|_j,\tilde\omega\rangle X^{22}_{k|_j} - X^{22}_{k|_j}\tilde B_j + X^{21}_k\tilde G^j_{k_j} - \mathrm{i}\tilde B_d X^{12}_{k|_j} = -\mathrm{i}Y^{22}_{k|_j}.
\end{aligned}$$

Set

$$\tilde{X}_k = \begin{pmatrix} X_k^{11} & X_{k|_j}^{12} \\ X_k^{21} & X_{k|_j}^{22} \end{pmatrix}, \quad \tilde{Y}_k = \begin{pmatrix} Y_k^{11} & Y_{k|_j}^{12} \\ Y_k^{21} & Y_{k|_j}^{22} \end{pmatrix}, \quad \tilde{G}_{**}^j = \begin{pmatrix} 0 & \tilde{G}_{k_j}^j \\ \tilde{G}_{-k_j}^j & 0 \end{pmatrix}.$$

Then we find

$$\langle k, \tilde{\tilde{\omega}}\rangle \tilde{X}_k + \tilde{X}_k \Big[\mathrm{diag}\big(\tilde{A}_j, -\tilde{B}_j + \langle k_j, \tilde{\tilde{\omega}}\rangle I_{p_j}\big) + \tilde{G}_{**}^j \Big] - \mathrm{i}\tilde{\Omega}^{\mathrm{d}}\tilde{\mathrm{X}}_{\mathrm{k}} = -\mathrm{i}\tilde{\mathrm{Y}}_{\mathrm{k}}.$$

By Lemma 6.1, we consider the above matrix equation for $\tilde{X}_k$ as a linear equation for $\{\tilde{X}_k\}$. Denote the coefficient matrix for $\{\tilde{X}_k\}$ by

$$\tilde{M} = \langle k, \tilde{\tilde{\omega}}\rangle I_{4p_j p_d} + M + O(\epsilon_0),$$

where M has the only eigenvalue λ_j and $O(\epsilon_0)$ is a small matrix with the same estimates as before. By Lemma 6.6, there exists a subset O_+ of O such that, for $\omega \in O_+$, we can find $\tilde{X}_k$ with $\|\tilde{X}_k\|^L \le c(|k|+1)^\tau \alpha^{-L-1}\|\tilde{Y}_k\|^L$.

If $1 \le i, j < d$, (4.32) becomes

$$-\mathrm{i}\partial_{\tilde{\tilde{\omega}}}\mathrm{X} - (\tilde{\Omega}_*^{\mathrm{i}} + \tilde{\mathrm{G}}_{**}^{\mathrm{i}})\mathrm{X} + \mathrm{X}(\tilde{\Omega}_*^{\mathrm{j}} + \tilde{\mathrm{G}}_{**}^{\mathrm{j}}) = -\mathrm{i}\mathrm{Y}.$$

Using the abbreviation $\tilde{G}_{k_\alpha}^{x,\alpha} = e^{\mathrm{i}\langle k_\alpha, x\rangle}\tilde{G}_{k_\alpha}^{\alpha}$, we have

$$\begin{aligned}
&-\mathrm{i}\partial_{\tilde{\tilde{\omega}}}X^{11} - \tilde{A}_i X^{11} - \tilde{G}_{k_i}^{x,i} X^{21} + X^{11}\tilde{A}_j + X^{12}\tilde{G}_{-k_j}^{x,j} = -\mathrm{i}Y^{11},\\
&-\mathrm{i}\partial_{\tilde{\tilde{\omega}}}X^{12} - \tilde{A}_i X^{12} - \tilde{G}_{k_i}^{x,i} X^{22} - X^{12}\tilde{B}_j + X^{11}\tilde{G}_{k_j}^{x,j} = -\mathrm{i}Y^{12},\\
&-\mathrm{i}\partial_{\tilde{\tilde{\omega}}}X^{21} + \tilde{B}_i X^{21} - \tilde{G}_{-k_i}^{x,i} X^{11} + X^{21}\tilde{A}_j + X^{22}\tilde{G}_{-k_j}^{x,j} = -\mathrm{i}Y^{21},\\
&-\mathrm{i}\partial_{\tilde{\tilde{\omega}}}X^{22} + \tilde{B}_i X^{22} - \tilde{G}_{-k_i}^{x,i} X^{12} - X^{22}\tilde{B}_j + X^{21}\tilde{G}_{k_j}^{x,j} = -\mathrm{i}Y^{22}.
\end{aligned}$$

Comparing the Fourier coefficients and replacing k by $k|_j = k + k_j$, $k|_i = k - k_i$, and $k|_{ji} = k + k_j - k_i$ in the last three equations of the above system, respectively, we find

$$\begin{aligned}
&\langle k, \tilde{\tilde{\omega}}\rangle X_k^{11} - \tilde{A}_i X_k^{11} - \tilde{G}_{k_i}^i X_{k|_i}^{21} + X_k^{11}\tilde{A}_j + X_{k|_j}^{12}\tilde{G}_{-k_j}^j = -\mathrm{i}Y_k^{11},\\
&\langle k|_j, \tilde{\tilde{\omega}}\rangle X_{k|_j}^{12} - \tilde{A}_i X_{k|_j}^{12} - \tilde{G}_{k_i}^i X_{k|_{ji}}^{22} - X_{k|_j}^{12}\tilde{B}_j + X_k^{11}\tilde{G}_{k_j}^j = -\mathrm{i}Y_{k|_j}^{12},\\
&\langle k|_i, \tilde{\tilde{\omega}}\rangle X_{k|_i}^{21} + \tilde{B}_i X_{k|_i}^{21} - \tilde{G}_{-k_i}^i X_k^{11} + X_{k|_i}^{21}\tilde{A}_j + X_{k|_{ji}}^{22}\tilde{G}_{-k_j}^j = -\mathrm{i}Y_{k|_i}^{21},\\
&\langle k|_{ji}, \tilde{\tilde{\omega}}\rangle X_{k|_{ji}}^{22} + \tilde{B}_i X_{k|_{ji}}^{22} - \tilde{G}_{-k_i}^i X_{k|_j}^{12} - X_{k|_{ji}}^{22}\tilde{B}_j + X_{k|_i}^{21}\tilde{G}_{k_j}^j = -\mathrm{i}Y_{k|_{ji}}^{22}.
\end{aligned}$$

Set

$$\tilde{X}_k = \begin{pmatrix} X_k^{11} & X_{k|_j}^{12} \\ X_{k|_i}^{21} & X_{k|_{ij}}^{22} \end{pmatrix}, \quad \tilde{Y}_k = \begin{pmatrix} Y_k^{11} & Y_{k|_j}^{12} \\ Y_{k|_i}^{21} & Y_{k|_{ij}}^{22} \end{pmatrix}.$$

Then we have

$$\begin{aligned}
\langle k, \tilde{\tilde{\omega}}\rangle \tilde{X}_k + \tilde{X}_k[\mathrm{diag}(\tilde{A}_j, -\tilde{B}_j + \langle k_j, \tilde{\tilde{\omega}}\rangle I_{p_j}) + \tilde{G}_{**}^j]\\
-[\mathrm{diag}(\tilde{A}_i, -\tilde{B}_i + \langle k_i, \tilde{\tilde{\omega}}\rangle I_{p_i}) + \tilde{G}_{**}^i]\tilde{X}_k = -\mathrm{i}\tilde{Y}_k.
\end{aligned}$$

Using the resonant relations (4.4) in the same way as before, the above matrix equation is equivalent to a linear equation for $\{\tilde{X}_k\}$:

$$(\langle k, \tilde{\tilde{\omega}}\rangle I_{4p_i p_j} + M + O(\epsilon_0))\{\tilde{X}_k\} = -\mathrm{i}\{\tilde{Y}_k\},$$

where M has the eigenvalue $\lambda_j - \lambda_i$ and $O(\epsilon_0)$ has the same estimates as stated previously.

If $i \neq j$ or $i = j, k \neq 0$, by Lemmas 6.6 and 6.7, there exists a subset O_+ of O such that, for $\omega \in O_+$, the above linear equation for $\{\tilde{X}_k\}$ is solvable, and we have

$$\|\tilde{X}_k\|^L \leq c(|k|+1)^\tau \alpha^{-L-1} \|\tilde{Y}_k\|^L.$$

If $i = j$ and $k = 0$, by our choice of $\hat{G}$ and (4.15), it follows that $\tilde{Y}_0 = 0$, and, consequently, we have $\tilde{X}_0 = 0$.

Thus, for $\omega \in O_+$ we can find all X_k satisfying

$$\|X_k\|^L \leq c(|k|+1)^\tau \alpha^{-L-1} \|Y_k\|^L.$$

So

$$\|a_k\|^L \leq c(|k|+1)^\tau \alpha^{-L-1} \|y_k\|^L. \tag{4.35}$$

By (4.30) it follows that

$$\|a(x)\|^L_{D(s-2\rho,r/2)} \leq c\epsilon \alpha^{-2L-2} \rho^{-2\kappa}. \tag{4.36}$$

By (4.24), (4.29), and (4.36), there exists a subset O_+ of O such that, for $\omega \in O_+$, we can solve (4.20), (4.21), and (4.22) for h, b, a with the estimates

$$\|h\|^L_{D(s-\rho,r/2)},\ \frac{1}{r}\|b\|^L_{D(s-\rho,r/2)} \leq \frac{c\epsilon}{\alpha^{L+1}\rho^\kappa},\ \ \|a\|^L_{D(s-2\rho,r/2)} \leq \frac{c\epsilon}{\alpha^{2(L+1)}\rho^{2\kappa}}.$$

By Cauchy's estimate it follows that

$$\|\mathcal{D}_x h\|^L_{D(s-2\rho,r/2)},\ \frac{1}{r}\|\mathcal{D}_x b\|^L_{D(s-2\rho,r/2)} \leq \frac{c\epsilon}{\alpha^{L+1}\rho^{\kappa+1}},$$
$$\|\mathcal{D}_x a\|^L_{D(s-3\rho,r/2)} \leq \frac{c\epsilon}{\alpha^{2(L+1)}\rho^{2\kappa+1}}.$$

Now we consider the Lebesgue measure of O_+. For simplicity, denote by $\tilde{M}_k$ the matrices of coefficients for the linear equations in the above discussion. Thus

$$O_+ = \{\omega \in O \mid \forall k, \|\tilde{M}_k^{-1}\| \leq (1+|k|)^\tau/\alpha\},$$

where $\tilde{M}_k^{-1}$ is the inverse of $\tilde{M}_k$. We divide the set O_+ into two parts, O_+^1 and O_+^2, where

$$O_+^1 = \{\omega \in O \mid \forall |k| \leq K, \|\tilde{M}_k^{-1}\| \leq (1+|k|)^\tau/\alpha\}$$

and $O_+^2 = O_+ \setminus O_+^1$. By Lemma 6.6, if $\tau \geq nL+1$ and K is sufficiently large, we have

$$\operatorname{meas}(O - O_+^2) \leq c\alpha^{\frac{1}{L}} \sum_{k\neq 0} (|k|+1)^{\frac{L-\tau}{L}} \leq c\alpha^{\frac{1}{L}}. \tag{4.37}$$

For $|k| \leq K$, by the remark for Lemma 6.6, we need only consider $M_k = \tilde{M}_k|_{\epsilon_0=0}$. By the assumption of analyticity and conditions (4.1), (4.2), and (4.3), the set $\{\omega \,|\, \det(M_k) = 0\}$ has zero-measure. Let

$$O^1 = \{\omega \in O \mid \forall |k| \leq K, \|M_k^{-1}\| \leq (1+|k|)^\tau/(2\alpha_0)\},$$

where α_0 is the α at the first step with $\alpha \le \alpha_0$. We have $\mathrm{meas}(O \setminus O^1)$ tends to zero as $\alpha_0 \to 0$. Since $\tilde{M}_k$ is a small perturbation of M_k with $\|\tilde{M}_k - M_k\| \le c\epsilon_0$, if ϵ_0 is sufficiently small, we always have $O^1 \subseteq O^1_+$. Thus, we can take $O^1_+ = O^1$ and $O_+ = O^1 \cup O^2_+$, where O^1 is independent of the KAM step.

Below we verify the symmetry of (4.16). The symmetry of h holds by its definition. So we need only to consider b and a. Let $Q = \mathrm{diag}(-I_p, I_p)$. Then it follows easily that

$$Q\tilde{g}^0(-x) = -\tilde{g}^0(x),\ Q\tilde{G}(-x)Q = -\tilde{G}(x),\ \text{and}\ \ Q\tilde{g}^1(-x)Q = -\tilde{g}^1(x).$$

By (4.21), we have

$$(\tilde{\Omega} + \tilde{G}(-x))b(-x) + \partial_{\tilde{\omega}} b(-x) + \tilde{g}^0(-x) = 0.$$

Multiplying the above equation by Q from the left and using the properties of $\tilde{g}^0$ and $\tilde{G}$, we have

$$-(\tilde{\Omega} + \tilde{G}(x))Qb(-x) + \partial_{\tilde{\omega}} Qb(-x) + Q\tilde{g}^0(-x) = 0.$$

By (4.21) it follows that

$$(\tilde{\Omega} + \tilde{G}(x))(b(x) - Qb(-x)) - \partial_{\tilde{\omega}}(b(x) - Qb(-x)) = 0.$$

Because the solution of b in the above equation is unique, we have $b(x) = Qb(-x)$, which exhibits the symmetry of b in (4.16). Let $X = Qa(-x)Q - a$. By (4.22) and in the same way, we obtain

$$(\tilde{\Omega} + \tilde{G}(x))X - X(\tilde{\Omega} + \tilde{G}(x)) - \partial_{\tilde{\omega}} X = 0.$$

So $X = 0$ and $a = Qa(-x)Q$, which is equivalent to the symmetry of a.

E. *Estimates for the transformation.* By means of our construction, if

$$\omega \in O_+ \quad \text{and} \quad \frac{c\epsilon}{\alpha^{2(L+1)}\rho^{2\kappa+1}} \le \eta < \rho < \frac{1}{8},$$

we have a compatible transformation

$$\Phi^2 : (x_+, w_+) \in D(s - 3\rho, \eta r) \to (x, w) \in D(s - \rho, 2\eta r) \subset D(s, r/2)$$

such that

$$\|x - x_+\|^L_{D_+}, \qquad \frac{1}{r}\|w - w_+\|^L_{D_+} \le \frac{c\epsilon}{\alpha^{2(L+1)}\rho^{2\kappa}}, \tag{4.38}$$

$$\|\mathcal{D}_{x_+} x - I_n\|^L_{D_+}, \qquad \frac{1}{r}\|\mathcal{D}_{x_+} w\|^L_{D_+} \le \frac{c\epsilon}{\alpha^{2(L+1)}\rho^{2\kappa+1}}, \tag{4.39}$$

$$\|\mathcal{D}_{w_+} w - I_{2p}\|^L_{D_+} \le \frac{c\epsilon}{\alpha^{2(L+1)}\rho^{2\kappa}}, \tag{4.40}$$

where $D_+ = D(s - 3\rho, \eta r)$.

Define the compatible transformation $\Phi = \Phi^2 \circ \Phi^1 : (x_+, w_+) \to (x, w)$. By (4.9) it follows easily that Φ has the same structure and satisfies the same estimates as Φ^2, with possibly different constants. So we may regard Φ^2 as Φ for simplicity.

F. *Estimates of the perturbation after transformation.* Let

$$\eta = \left(\frac{\epsilon}{\alpha^{2(L+1)}\rho^{2\kappa+1}}\right)^{\frac{1}{2}}, \quad r_+ = r\eta, \quad s_+ = s - 3\rho.$$

By (4.18) and (4.19), using the procedure of [7] and [21], it follows that

$$\|f_+\|^L_{D(s_+,r_+)} \le c\epsilon\eta \quad = \epsilon_+, \tag{4.41}$$

$$\|g_+\|^L_{D(s_+,r_+)} \le c\epsilon\eta r_+ = \epsilon_+ r_+ \tag{4.42}$$

with $\epsilon_+ = c\epsilon\eta$. Here we omit the details of estimating, as they are very similar to those of [7] and [21].

G. *Convergence of the iteration.* For given s, ϵ, r in the theorems, we define several sequences, which depend inductively on s, ϵ, r:

$$\epsilon_0 = \epsilon, \quad r_0 = r, \quad s_0 = s, \quad \alpha_0 = \alpha, \quad \rho_0 = \frac{s_0}{12}, \quad \eta_0 = \frac{\epsilon_0^{\frac{1}{2}}}{\alpha_0^{L+1}\rho_0^{\kappa+\frac{1}{2}}},$$

$$A_0 = A, \quad B_0 = B, \quad G^0 = 0, \quad \Omega^0 = \begin{pmatrix} 0 & A_0 \\ -B_0 & 0 \end{pmatrix} = \text{normal form (2.5)},$$

$$\epsilon_{\nu+1} = c\eta_\nu\epsilon_\nu, \quad r_{\nu+1} = \eta_\nu r_\nu, \quad s_{\nu+1} = s_\nu - 3\rho_\nu, \quad \rho_{\nu+1} = \frac{1}{2}\rho_\nu,$$

$$\eta_\nu = \frac{\epsilon_\nu^{\frac{1}{2}}}{\alpha_\nu^{L+1}\rho_\nu^{\kappa+\frac{1}{2}}}, \quad D_\nu = D(s_\nu, r_\nu),\ \alpha_{\nu+1} = \alpha_\nu/2, \quad \nu = 0, 1, \ldots.$$

At the νth step, there exists a subset $O_\nu = O^1 \cap O^2_\nu$ of O. For $\omega \in O_\nu$, there exists a compatible transformation $\Phi_\nu : (x_{\nu+1}, w_{\nu+1}) \to (x_\nu, w_\nu)$ satisfying

$$\|x_{\nu+1} - x_\nu\|^L_{D_\nu} \le c\eta_\nu^2, \quad \|w_{\nu+1} - w_\nu\|^L_{D_\nu} \le cr_\nu\eta_\nu^2. \tag{4.43}$$

Moreover, we have $\text{meas}(O - O^2_\nu) \le c\alpha_\nu^{\frac{1}{L}}$.

Let $\Phi^{\nu+1} = \Phi^\nu \circ \Phi_{\nu+1}$ with $\Phi^0 = Id$ and $f_0 = f,\ g_0 = g,\ \tilde{\omega}^0 = \omega$. By the compatible transformation Φ^ν, system (1.1) is changed to

$$\begin{cases} \dot{x} = \tilde{\omega}^\nu \qquad\qquad + f^\nu(x, w; \omega), \\ \dot{w} = (\Omega^\nu + G^\nu)w + g^\nu(x, u, v; \omega). \end{cases} \tag{4.44}$$

Moreover,

$$\|\tilde{\omega}^{\nu+1} - \tilde{\omega}^\nu\|^L \le \epsilon_\nu, \quad \|\Omega^{\nu+1} - \Omega^\nu\|^L \le c\epsilon_\nu, \tag{4.45}$$

$$\|G^{\nu+1} - G^\nu\|^L \le c\epsilon_\nu, \quad \|f^\nu\|^L_{D_\nu} \le \epsilon_\nu, \quad \|g^\nu\|^L_{D_\nu} \le r_\nu\epsilon_\nu. \tag{4.46}$$

By definition, we have $\eta_{\nu+1} \le c^{\frac{1}{2}}(\eta_\nu)^{\frac{3}{2}}$; hence, $c\eta_{\nu+1} \le (c\eta_\nu)^{\frac{3}{2}}$. If $c\eta_0 = c\epsilon_0{}^{\frac{1}{2}}\alpha_0^{-L-1}\rho_0^{-\kappa-\frac{1}{2}} \le 2^{-1}$, then $\eta_{\nu+1} \le c^{-1}2^{-(\frac{3}{2})^\nu}$. Thus, we have $\epsilon_{\nu+1} \le 2^{-1}\epsilon_\nu$, and so $\epsilon_\nu \le 2^{-\nu}\epsilon_0$. By the above estimates, assumption (4.25) obviously holds.

Let $O_\alpha = \cap_{\nu\ge1}O_\nu$. For $(x, w; \omega) \in D(s/2, r/2) \times O_\alpha$, we can prove that the transformation Φ^ν is convergent to Φ_*. The proof is the same as in the case of Hamiltonian systems (in fact simpler), so we omit the details and refer the reader to [10]. For $\nu \to \infty$ let $\tilde{\omega}^\nu \to \omega_*,\ \Omega^\nu \to \Omega_*,\ G^\nu \to G_*,\ f^\nu \to f_*,\ g^\nu \to g^*$. By (4.45)

and (4.46), it follows that $\|\omega_* - \omega\|^L \le c\epsilon$, $\|\Omega_* - \Omega\|^L \le c\epsilon$, $\|G_*\|^L \le c\epsilon$. Moreover, by (4.46) we have

$$f_*(x,w)\mid_{w=0}= 0, \quad g^*(x,w)\mid_{w=0}= 0, \quad \text{and} \quad g^*_w(x,w)\mid_{w=0}= 0.$$

H. *Measure estimate.* It remains to estimate the measure of O_α. By the previous discussion, $O_\alpha = O^1 \cap O^2$, where $O^2 = \cap_{\nu=1}^{\infty} O^2_\nu$. It follows that

$$\mathrm{meas}(O \setminus O^2) \le \sum_{\nu\ge 1} \mathrm{meas}(O \setminus O^2_\nu) \le c\alpha^{\frac{1}{L}}.$$

Thus,

$$\mathrm{meas}(O \setminus O_\alpha) \le \mathrm{meas}(O \setminus O^1) + \mathrm{meas}(O \setminus O^2) \to 0 \ (\alpha \to 0).$$

For $\omega \in O_\alpha$, by the compatible transformation Φ_*, the reversible system (1.1) is changed to (1.9). Thus, the proof of Theorem 1.1 is complete .

5. Proof of Theorem 1.2. Take the matrices P and Q as in Theorem 1.2. By the compatible map $\Phi : (x,w) \to (x_+, w_+)$ defined by $x_+ = x, w_+ = \mathrm{diag}(P,Q)w$, the reversible system (1.1) is changed to

$$\begin{cases} \dot x = \omega & + f(x,u,v;\omega), \\ \dot u = (I_p, 0_2)v & + g_1(x,u,v;\omega), \\ \dot v = PBQu & + g_2(x,u,v;\omega). \end{cases} \tag{5.1}$$

Note that here f, g_1, g_2 may be different from those in (1.1). Let $\tilde u = (u_1, \dots, u_p, u_{p+1}, \dots, u_q)^T = (u^T, u_*^T)^T$ and $v_* = (v_{p+1}, \dots, v_q)^T$, where $u_* = (u_{p+1}, \dots, u_q)^T$. We consider the reversible system

$$\begin{cases} \dot x = \omega & + f(x,u,v;\omega), \\ \dot u = (I_p, 0_2)v & + g_1(x,u,v;\omega), \\ \dot u_* = I_{q-p} v_*, & \\ \dot v = (PBQ, 0_1)\tilde u & + g_2(x,u,v;\omega), \end{cases} \tag{5.2}$$

where $(PBQ, 0_1)$ is a $q \times q$-matrix. Using Theorem 1.1 we obtain a nonempty subset O_α of O. For $\omega \in O_\alpha$, we have a compatible transformation $\Phi(x, \tilde u, v; \omega)$ such that $\Phi(T^n, 0, 0; \omega)$ is an invariant torus of the reversible system (5.2). Taking projection maps $P_{u_*} : (x,u,u_*,v) \to (x,u,0,v)$ and $P_0 : (x,u,0,v) \to (x,u,v)$, then $P_0 \circ P_{u_*}(\Phi(T^n, 0, 0; \omega))$ is an invariant torus of the reversible system (5.1).

Remark. Here we show that condition (A.1) and (1.3) are necessary for the result. If $\mathrm{rank}(A) = \gamma < p$, there exists a compatible transformation such that the reversible system (1.1) is changed to

$$\begin{cases} \dot x = \omega & + f(x,u,v;\omega), \\ \dot u = \tilde I v & + g_1(x,u,v;\omega), \\ \dot v = PBQu & + g_2(x,u,v;\omega), \end{cases} \qquad \tilde I = \begin{pmatrix} I_\gamma & 0 \\ 0 & 0 \end{pmatrix}. \tag{5.3}$$

Let $g_1 = (0, 0, \dots, \epsilon)$. Then for all $\epsilon > 0$ the reversible system (5.3) has no invariant torus. From section 3, we know that if there are $\lambda_j \ne 0$ and $\lambda_j = \langle \omega, k \rangle$, then, by a compatible transformation, we arrive at the case $\lambda_j = 0$ and $\mathrm{rank}(A) < p$. This means that condition (1.7) is necessary.

6. Appendix.

LEMMA 6.1. *Let A and B be an $m \times m$ and $n \times n$-matrix, respectively, and let C and $X = (x_{ij})$ be $m \times n$-matrices. Then the matrix equation $AX + XB = C$ is equivalent to the following linear equation $D\{X\} = \{C\}$, where*

$$\{X\} = (x_{11}, x_{12}, \dots, x_{1n}, x_{21}, x_{22}, \dots, x_{2n}, \dots, x_{m1}, x_{m2}, \dots, x_{mn})^T,$$
$$\{C\} = (c_{11}, c_{12}, \dots, c_{1n}, c_{21}, c_{22}, \dots, c_{2n}, \dots, c_{m1}, c_{m2}, \dots, c_{mn})^T$$

are mn-columns and the coefficient matrix

$$D = \begin{pmatrix} a_{11}I_n + B^T & a_{12}I_n & \cdots & a_{1m}I_n \\ a_{21}I_n & a_{22}I_n + B^T & \cdots & a_{2m}I_n \\ \vdots & \vdots & \cdots & \vdots \\ a_{m1}I_n & a_{m2}I_n & \cdots & a_{mn}I_n + B^T \end{pmatrix}$$

is an $mn \times mn$-matrix with the eigenvalues $\{\lambda_i + \mu_j \mid i = 1, \dots, m, j = 1, \dots, n\}$, if A has the eigenvalues $\lambda_1, \dots, \lambda_m$ and B has the eigenvalues $\mu_1, \dots, \mu_n$.

This lemma has a straightforward proof, which we will omit.

LEMMA 6.2. *Let A and B be an $m \times m$ and an $n \times n$-matrix, respectively, let $\lambda_1, \dots, \lambda_m$ be the eigenvalues of A and $\mu_1, \dots, \mu_n$ the eigenvalues of B, and let $P = (P_{ij})$ be an $(m+n) \times (m+n)$-matrix. If*

$$|\lambda_i - \mu_j| \geq \alpha > 0 \ \text{ for } \ i = 1, \dots, m, \ \ j = 1, \dots, n,$$

where α is constant, then there exists an $\epsilon > 0$ such that, if $\|P\| \leq \epsilon$, $\operatorname{diag}(A, B) + P$ is similar to a diagonal block form $\operatorname{diag}(A', B')$. Moreover, there is a nonsingular matrix $S = I_{m+n} + \hat{S}$ satisfying $\|\hat{S}\| \leq c\|P\|$ such that

$$S^{-1}\big(\operatorname{diag}(A, B) + P\big)S = \operatorname{diag}(A', B') = \operatorname{diag}(A + \hat{A}, B + \hat{B})$$

with $\|\hat{A}\| \leq c\|P\|$ and $\|\hat{B}\| \leq c\|P\|$.

Proof. Write

$$P = \begin{pmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{pmatrix}, \quad S = \begin{pmatrix} I_m & S_{12} \\ S_{21} & I_n \end{pmatrix}, \quad \operatorname{diag}(A', B') = \begin{pmatrix} A + Q_{11} & 0 \\ 0 & B + Q_{22} \end{pmatrix}.$$

We solve the following equation for S_{12}, S_{21}, Q_{11}, and Q_{22}:

$$\begin{pmatrix} A + P_{11} & P_{12} \\ P_{21} & B + P_{22} \end{pmatrix} \times \begin{pmatrix} I_m & S_{12} \\ S_{21} & I_n \end{pmatrix} = \begin{pmatrix} I_m & S_{12} \\ S_{21} & I_n \end{pmatrix} \times \begin{pmatrix} A + Q_{11} & 0 \\ 0 & B + Q_{22} \end{pmatrix}.$$

This equation is equivalent to

$$\begin{cases} (A + P_{11})S_{12} - S_{12}B - S_{12}Q_{22} = -P_{12}, \\ (B + P_{22})S_{21} - S_{21}A - S_{21}Q_{11} = -P_{21}, \\ Q_{11} - P_{12}S_{21} = \ \ P_{11}, \\ Q_{22} - P_{21}S_{12} = \ \ P_{22}. \end{cases} \tag{6.1}$$

Using the last two equations in (6.1), the first two equations become

$$(A + P_{11})S_{12} - S_{12}(B + P_{22}) + S_{12}P_{21}S_{12} = -P_{12}, \tag{6.2}$$
$$(B + P_{22})S_{21} - S_{21}(A + P_{11}) + S_{21}P_{12}S_{21} = -P_{21}. \tag{6.3}$$

Instead of (6.2) for S_{12}, we now consider the equivalent equation for the column $\{S_{12}\}$; see Lemma 6.1. Let $\lambda'_1, \dots, \lambda'_m$ be the eigenvalues of $A + P_{11}$ and $\mu'_1, \dots, \mu'_n$ be the eigenvalues of $B + P_{22}$. At first, we take ϵ sufficiently small such that

$$|\lambda'_i - \mu'_j| \geq \frac{\alpha}{2} > 0 \text{ for } i = 1, \dots, m, \ \ j = 1, \dots, n.$$

By Lemma 6.1 the coefficient matrix for the linear part of $\{S_{12}\}$ has eigenvalues $\lambda'_i - \mu'_j$ for $i = 1, \dots, m$, $j = 1, \dots, n$. Thus, the coefficient matrix is nonsingular. The equation for $\{S_{12}\}$ is nonlinear. But by the implicit function theorem we can solve this equation near $\{P_{12}\} = 0$. Thus if $\{P_{12}\}$ is sufficiently small, there exists a unique solution $\{S_{12}\}$. Moreover, we have $\|S_{12}\| \leq c\|P\|$. Similarly, we can solve (6.3) with the same estimate $\|S_{21}\| \leq c\|P\|$. From the last two equations in (6.1) we can get Q_{11} and Q_{22} with $\|Q_{11}\| \leq c\|P\|$ and $\|Q_{22}\| \leq c\|P\|$. □

By induction we can easily obtain the following result.

LEMMA 6.3. *Let $\tilde{A}_j$ be an $n_j \times n_j$-matrix and $\lambda^j_1, \dots, \lambda^j_{m_j}$ be the eigenvalues of $\tilde{A}_j$. Let $P = (P_{ij})$ be a $\sum_j n_j \times \sum_j n_j$-matrix. If*

$$|\lambda^l_i - \lambda^m_j| \geq \alpha > 0 \text{ for } i = 1, \dots, n_l, \ \ j = 1, \dots, n_m, \ \ l \neq m,$$

where α is a constant, then there exists an $\epsilon > 0$ such that, if $\|P\| \leq \epsilon$, there is a nonsingular matrix $S = I_{\sum_j n_j} + \hat{S}$, satisfying $\|\hat{S}\| \leq c\|P\|$, with

$$S^{-1}\big(\operatorname{diag}(A_1, \dots, A_d) + P\big)S = \operatorname{diag}(A_1 + \hat{A}_1, \dots, A_d + \hat{A}_d).$$

Moreover, we have $\|\hat{A}_j\| \leq c\|P\|$ for $j = 1, \dots, d$.

LEMMA 6.4. *Let A and P be as in Lemma 6.2. Let $\{\lambda_j\}$ be the eigenvalues of the matrix A. Suppose that $\lambda_j = \lambda + \epsilon_j$, where $\lambda \neq 0$ and $|\epsilon_j| \leq \frac{1}{2}|\lambda|$ for all j. Suppose $\|P\| \leq \epsilon$. If ϵ is sufficiently small, then there exists a matrix X such that $(A + X)^2 = A^2 + P$ with $\|X\| \leq c\epsilon$.*

Proof. We consider the following equivalent equation $AX + XA + X^2 = P$. The coefficient matrix of the linear part $AX + XA$ for $\{X\}$ has all eigenvalues of $\{\lambda_i + \lambda_j = 2\lambda + \epsilon_i + \epsilon_j\}$. Because $|\lambda_i + \lambda_j| \geq 2|\lambda| - |\epsilon_i| - |\epsilon_j| \geq |\lambda|$, it is nonsingular. Using the same method as in the proof of Lemma 6.2 and by the implicit function theorem, we can obtain the solution of the above equation for $\{X\}$ with an estimate for small ϵ. □

LEMMA 6.5. *Let D be an $N \times N$-matrix depending on ω and $\|D\|^L \leq M$. Let P be an $N \times N$-matrix with $\|P\| \leq 1$. Then $\det(D + \epsilon P) = \det(D) + \epsilon F$ with $\|F\|^L \leq cM^{N-1}$, where c is a constant depending on N.*

Proof. Let $f(\epsilon) = \det(D + \epsilon P)$. Then $f(\epsilon) = f_0 + f_1\epsilon + f_2\epsilon^2 + \cdots + f_n\epsilon^N$, where $f_j = \frac{1}{j!}\frac{d^j f}{d\epsilon^j}\,|_{\epsilon=0}$. Obviously, $f_0 = \det(D)$. By the properties of determinants with respect to differentiation, it is easy to obtain $\|f_j\|^L \leq cM^{N-j}$, where c depends only on N.

LEMMA 6.6. *Suppose that $\|\tilde{\omega} - \omega\|^L \leq \epsilon$, where $f_j(\omega)$ is an Lth continuously differentiable function with $\|f_j(\omega)\|^L \leq M$ $(1 \leq j \leq L)$. Let $P(\omega) = (p_{ij}(\omega))$ be an $L \times L$-matrix, Lth continuously differentiable with respect to $\omega \in O$, with $\|P\|^L = \max_{|\beta| \leq L} \max_{1 \leq i,j \leq L} \sup_{\omega \in O} |\frac{\partial^\beta p_{ij}}{\partial \omega^\beta}| \leq \epsilon$. Let $\mathcal{R}_k(\alpha)$ be the subset of O such that $\|D^{-1}\| > \frac{c|k|^\tau}{\alpha}$, where $D = \langle \tilde{\omega}, k\rangle I + \operatorname{diag}(f_1(\omega), f_2(\omega), \dots, f_L(\omega)) + P(\omega)$, $\tau > nL$. Then, if $\epsilon > 0$ is sufficiently small, there is a constant $K > 0$ depending on M such*

that, for $\alpha > 0$ and $|k| > K$,

$$\mathrm{meas}(\mathcal{R}_k(\alpha)) \le \left(\frac{c\alpha}{|k|^{\tau-L}}\right)^{\frac{1}{L}},$$

where c is a constant depending on ϵ, M.

Proof. Since $\|D\| = O(|k|)$, we know that the norm of the inverse of a matrix is controlled by $|k|^L$ times of the lower bound of its determinant. In fact,

$$\mathcal{R}_k(\alpha) \subseteq \left\{\omega \in O \;\middle|\; \det D| < c\frac{\alpha}{|k|^{\tau-L}}\right\}.$$

Note that

$$g(k,\omega) = \det(D) = \prod_{j=1}^{L}(\langle\tilde{\omega}, k\rangle + f_j(\omega)) + \sum_{l=0}^{L-1} a_l \prod_{j=1}^{L}(\langle\tilde{\omega}, k\rangle + f_j(\omega))_j^l,$$

where $\|a_l\|^L \le c\epsilon$ and $l = (l_1, l_2, \ldots, l_L), l_j = 0$ or 1 and $\sum_{j=1}^{L} l_j \le L-1$. Also note that there exists a sufficiently large $K > 0$ such that, if $|k| \ge K$ and ϵ is sufficiently small,

$$\left|\frac{\partial^L}{\partial\nu^L} g(k,\omega)\right| \ge \left|\prod_{j=1}^{L}\left(\left\langle\frac{\partial}{\partial\nu}\tilde{\omega}, k\right\rangle + \frac{\partial}{\partial\nu} f_j(\omega)\right)\right| - c\epsilon|k|^L \ge [(1-c\epsilon)|k| - M]^L - c\epsilon|k|^L,$$

where $\frac{\partial^L}{\partial\nu^L}$ is the Lth direction derivative along the direction $\nu = \frac{k}{|k|}$ at ω. Thus, if ϵ is sufficiently small, it follows that $|\frac{\partial^L g(\omega)}{\partial\nu^L}| \ge \frac{1}{4}|k|^L$, which implies

$$\mathrm{meas}(\mathcal{R}_k(\alpha) \le c\left(\frac{\alpha}{|k|^{\tau-L}}\right)^{\frac{1}{L}} \mathrm{diam}(O)^{n-1},$$

where c is a constant depending only on M, ϵ, n, K, and, in particular, it is independent of α, k. ∎

Remark. If $f_j(\omega)$ is analytic and $\langle\omega, k\rangle + f_j(\omega) \ne 0$, then $\{\omega \mid \langle\omega, k\rangle + f_j(\omega) = 0\} \subset O$ has zero-measure. Let $O^1 = \{\omega \in O \mid |\langle\omega, k\rangle + f_j(\omega)| \ge \alpha \text{ for all } |k| \le K\}$. We have $\mathrm{meas}(\mathrm{O} \setminus \mathrm{O}^1) \to 0$ as $\alpha > 0 \to 0$. Therefore, $|\langle\omega, k\rangle + f_j(\omega)| \ge \alpha > 0$ holds on a nonempty subset O^1 of O. Then, for sufficiently small $\epsilon > 0$ depending on α, if $\|P\| \le \epsilon$, the matrix D is invertible for all $\omega \in O^1 \subset O$ and $|k| \le K$ with $\|D^{-1}\| \le \frac{c}{\alpha}$.

LEMMA 6.7. *Let D be a matrix depending on ω and $\|D\|^L \le M$. If D is invertible with $\|D^{-1}\| \le N$, then $\|D^{-1}\|^L \le cM^L N^{L+1}$, where c is a constant depending on L.*

Proof. By differentiating the two sides of the equation $D^{-1}D = I$, we have $(D^{-1})' = D^{-1}D'D^{-1}$. So

$$\|(D^{-1})'\| \le \|D'\| \cdot \|D^{-1}\|^2 \le MN^2.$$

Inductively it follows that $\|D^{-1}\|^L \le cM^L N^{L+1}$. ∎

Acknowledgments. This paper was finished under the guidance of Professor Helmut Rüssmann when the author was visiting Mainz University in Germany with a scholarship from the People's Republic of China. The author thanks him for many heuristic suggestions for this paper and is also very grateful to him for much help

during the author's stay in Mainz. The author would also like to thank Professor Jiangong You and Mr. Joachim Albrecht for much help. A WELL-POSED FREE BOUNDARY VALUE PROBLEM FOR A HYPERBOLIC EQUATION WITH DIRICHLET BOUNDARY CONDITIONS*

JOHN V. MATTHEWS† AND DAVID G. SCHAEFFER‡

Abstract. We construct solutions of a free boundary value problem for a hyperbolic equation with Dirichlet boundary data. This problem arises from a model of deformation of granular media.

Key words. hyperbolic, PDE, free boundary, Dirichlet

AMS subject classifications. 35L20, 35R35, 76T25

1. Introduction.

In this work we will study the partial differential equation (PDE) for a scalar function $v(x, y)$,

$$\operatorname{div}\left(R_\alpha \frac{\nabla v}{|\nabla v|}\right) = 0\,, \tag{1.1}$$

where R_α is a rotation counterclockwise by an angle $0 < \alpha < \pi/4$,

$$R_\alpha = \begin{bmatrix} \cos\alpha & -\sin\alpha \\ \sin\alpha & \cos\alpha \end{bmatrix}.$$

Throughout the paper we consider only functions v such that $\nabla v \neq 0$, which avoids the singularity of (1.1). As will be discussed more fully in the appendix, this equation represents the steady state of a kind of granular flow problem studied in [12], [11].

The domain Ω on which we consider this equation is approximately rectangular, with one free boundary along the topmost edge (see Figure 1.1(a)). Even though, as we will show below, (1.1) is hyperbolic, we will impose Dirichlet-type boundary conditions: specifically,

$$\begin{aligned} v(0,y) &= \phi_0(y), & 0 < y < L_0, \\ v(1,y) &= \phi_1(y), & 0 < y < L_1, \\ v(x,0) &= 0, & 0 < x < 1, \\ v(x,s(x)) &= V, & 0 < x < 1, \end{aligned} \tag{1.2}$$

where the function $s = s(x)$ defined on $0 < x < 1$ describes the free boundary and V is a constant. Naturally, s must satisfy

$$s(0) = L_0, \quad s(1) = L_1.$$

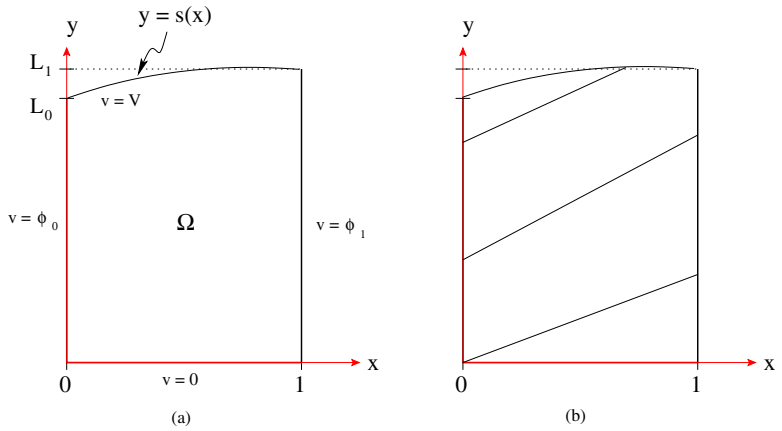

FIG. 1.1. *Two portraits of the domain* Ω, (a) *showing the boundary data and the free boundary and* (b) *illustrating straight-line characteristics along which* v *may have a discontinuity in its third derivative.*

We also impose the obvious compatibility conditions at the corners of the domain,

$$\begin{aligned} \phi_0(0) &= 0, \quad \phi_1(0) = 0, \\ \phi_0(L_0) &= V, \quad \phi_1(L_1) = V. \end{aligned}$$

Finally, to ensure that a solution v is differentiable on Ω, we will need to impose the nonlocal compatibility conditions

$$\phi_0'(0) = \phi_1'(0) \qquad \text{and} \tag{1.3a}$$

$$\phi_0''(0) = \phi_1''(0). \tag{1.3b}$$

Nonlocal compatibility conditions for the boundary data arise in this problem because (1.1) is hyperbolic. Even when (1.3a), (1.3b) are satisfied, a possible discontinuity in third-order derivatives of v propagates along a sequence of straight-line characteristics starting at the lower left corner of Ω (see Figure 1.1(b)). (Note that, even though Dirichlet boundary conditions are imposed, singularity information flows from the fixed boundary to the free boundary.) By imposing additional compatibility conditions like (1.3a), (1.3b), one could increase the order of the derivative of v that may suffer a discontinuity. If one or both conditions (1.3a), (1.3b) were omitted, one could study weak solutions of (1.1), (1.2). We do not pursue this idea here.

In a rectangular domain (as opposed to the quasi-rectangular domain Ω) with boundary data given by $\phi_0 = \phi_1 = y$, the equation (1.1) admits the simple solution $v(x, y) = y$. The problem we consider may be regarded as perturbing the data on the left and right, necessitating the incorporation of the free surface along the top boundary. For the perturbed problem, we will show the following.

THEOREM 1.1. *There exists an* $\epsilon > 0$ *such that if* $\phi_0, \phi_1 \in C^2$ *satisfy* (1.3a), (1.3b), *and* $\|\phi_0 - y\|_2 < \epsilon$, $\|\phi_1 - y\|_2 < \epsilon$, *then there exists a unique* C^2 *solution* v *in* Ω *to* (1.1) *and* (1.2).

Here and throughout, $\|g\|_k$ denotes the C^k-norm of the function g:

$$\|g\|_k = \max_{x \in D(g)} \left\{ |g(x)|, |g'(x)|, \ldots, |g^{(k)}(x)| \right\}.$$

If $0 < \epsilon < 1$, then both of the ϕ_i are monotone. Below we shall in fact assume that

$$\epsilon < \frac{1}{2}. \tag{1.4}$$

Thus, for such ϵ, monotonicity is an implicit assumption. Incidentally, the hypothesis that $\|\phi_i - y\|_2 < \epsilon$ implies that $|L_1 - L_0| = O(\epsilon)$; however, we shall not make explicit use of this fact. The ϵ that we derive below depends on L_0, L_1; indeed, it decreases geometrically as $L_0, L_1 \to \infty$. We are not sure whether this limitation could be avoided through a different argument.

As we shall see below, the free boundary is a characteristic curve. The well-posedness of (1.1), (1.2) depends crucially on this fact: because of it, (1.1), (1.2) resemble a Goursat problem [5].

In section 2 we analyze the characteristics of (1.1) and without loss of generality simplify the boundary data. In section 3, the original BVP for v is reduced to solving a functional equation along the left boundary of the domain; also, limitations on the regularity of the solution are explained. The existence of solutions to the functional equation is proven in section 4, thereby establishing the existence of solutions to the original BVP. Uniqueness is obtained in section 5. Finally, in the appendix we discuss the physical interpretation of (1.1) and describe connections with similar equations from mathematical modeling of granular flow.

2. Preliminaries.

2.1. Analysis by characteristics. We begin our analysis of (1.1) by converting it into an equivalent first-order system. We define

$$\tau = R_\alpha \frac{\nabla v}{|\nabla v|}$$

such that (1.1) becomes

$$\begin{aligned} \operatorname{div} \tau &= 0, \\ |\tau| &= 1, \\ R_\alpha^{-1}\tau \times \nabla v &= 0, \end{aligned} \tag{2.1}$$

where $\times$ denotes the cross product in two dimensions, interpreted as a scalar. This equation implies that $R_\alpha^{-1}\tau$ and ∇v are parallel vectors. Note that the middle equation involves no derivatives; thus (2.1) is a differential-algebraic system. However, (2.1) is easily reduced to a purely differential system. Since τ is a unit vector, we may represent it as

$$\tau = \begin{bmatrix} -\sin(\theta + \alpha) \\ \cos(\theta + \alpha) \end{bmatrix},$$

for some angle $\theta = \theta(x, y)$. This representation of τ, while unusual, simplifies the analysis of characteristics below. Then the three equations in (2.1) are equivalent to the 2×2 quasi-linear system of differential equations,

$$\partial_x \begin{bmatrix} \theta \\ v \end{bmatrix} + \begin{bmatrix} \tan(\theta + \alpha) & 0 \\ 0 & \tan\theta \end{bmatrix} \partial_y \begin{bmatrix} \theta \\ v \end{bmatrix} = 0, \tag{2.2}$$

which is clearly hyperbolic, but not in conservation form.

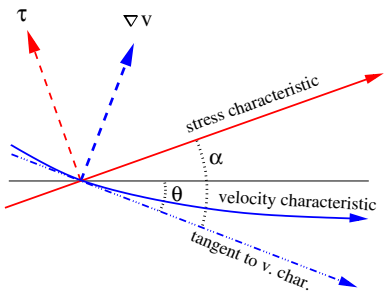

FIG. 2.1. *The orientation of τ, ∇v, and the stress and velocity characteristics. Velocity characteristics are inclined at an angle θ relative to the x-axis, and stress characteristics are inclined at an angle $\theta + \alpha$. (The angle θ in the figure is negative.)*

Observe that the first equation in (2.2) completely decouples from the second. The characteristics of this equation, along which θ is constant, are straight lines of slope

$$\frac{dy}{dx} = \tan(\theta + \alpha). \tag{2.3}$$

Although this equation is decoupled from the other, we cannot solve it separately because no explicit data for θ is given on the boundary of the domain.[1]

The equation for v is not independent of θ, but if we regard θ as known, then the v equation is linear. Characteristics for this equation, along which v is constant, are curves $y = y(x)$ that satisfy the differential equation

$$\frac{dy}{dx} = \tan\theta. \tag{2.4}$$

Boundary data for v—Dirichlet data—is given by (1.2), but we cannot solve the v equation without knowing θ. Based on the interpretation of (2.1) discussed in the appendix, we shall refer to the θ-characteristics and v-characteristics, described by (2.3) and (2.4), as *stress* and *velocity* characteristics, respectively.

Comparing (2.3) and (2.4), we see that the velocity characteristics intersect the stress characteristics at an angle α. To be more precise, the unit tangent along a stress characteristic at a point (x, y) equals the unit tangent at the same point along the velocity characteristic, rotated by an angle α counterclockwise (see Figure 2.1).

Recall our assumption that both ϕ_0, ϕ_1 are strictly monotonic and onto a common range. Therefore, given a point y_r in $[0, L_1]$ along the right boundary of the domain, $\{x = 1\}$, there exists a unique point y_ℓ in $[0, L_0]$ along the left boundary such that

$$\phi_0(y_\ell) = \phi_1(y_r). \tag{2.5}$$

(See Figure 2.2.) Velocity characteristics are level curves for the velocity, and we shall see that y_ℓ and y_r are connected by a velocity characteristic. However, this association of boundary points can be made without knowing the function v on the interior of Ω.

[1] While it is not obvious from the analysis thus far, data for θ actually is determined along the bottom edge of Ω, $\{(x, y) : 0 < x < 1, y = 0\}$. Indeed, it will be shown in the next section that $\theta \equiv 0$ there.

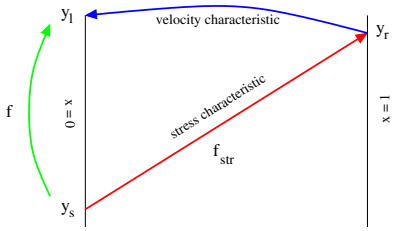

FIG. 2.2. *Connecting boundaries with characteristics: θ is constant along stress characteristics and v is constant along velocity characteristics.*

2.2. Simplification of the boundary data. Suppose that Φ is a C^2 function on the real line such that $\Phi' > 0$. If v satisfies the PDE (1.1) and boundary conditions (1.2) then the function $\Phi(v)$ also satisfies the same PDE,

$$\operatorname{div}\left(R_\alpha \frac{\nabla\Phi(v)}{|\nabla\Phi(v)|}\right) = \operatorname{div}\left(R_\alpha \frac{\Phi'(v)\nabla v}{|\Phi'(v)\nabla v|}\right) = \operatorname{div}\left(R_\alpha \frac{\nabla v}{|\nabla v|}\right) = 0,$$

with the modified boundary data

$$\begin{aligned}\tilde{\phi}_0 &= \Phi \circ \phi_0,\\ \tilde{\phi}_1 &= \Phi \circ \phi_1.\end{aligned}$$

In the following, we use $\Phi = \phi_1^{-1}$ to simplify the boundary data and the subsequent analysis. Because of this transformation, it suffices to solve (1.1) with the boundary data on the sides

$$\begin{aligned}\tilde{\phi}_0(y_\ell) &= \phi_1^{-1} \circ \phi_0(y_\ell), \qquad 0 < y_\ell < L_0,\\ \tilde{\phi}_1(y_r) &= y_r, \qquad 0 < y_r < L_1,\end{aligned} \tag{2.6}$$

provided that $\|\tilde{\phi}_0 - y\|_2$ is sufficiently small. As regards estimates, note that given (1.4) there is a constant C such that

$$\|\tilde{\phi}_0 - y\|_2 \le C \max\left\{\|\phi_0 - y\|_2, \|\phi_1 - y\|_2\right\}.$$

Henceforth, we drop the tilde notation but assume that the boundary data is given as in (2.6). On the left boundary, let us introduce the notation

$$\phi_0(y_\ell) = y_\ell + \beta(y_\ell), \quad 0 < y_\ell < L_0. \tag{2.7}$$

Note that after the reduction in (2.6), equations (1.3a), (1.3b) become

$$\phi_0'(0) = 1, \text{ or equivalently, } \beta'(0) = 0 \text{ and} \tag{2.8a}$$

$$\phi_0''(0) = 0, \text{ or equivalently, } \beta''(0) = 0. \tag{2.8b}$$

For convenient reference below, we list the boundary data on the top and bottom of Ω:

$$\begin{aligned}v(x,0) &= 0, \qquad 0 < x < 1,\\ v(x,s(x)) &= L_1, \qquad 0 < x < 1,\end{aligned} \tag{2.9}$$

where the transformation ϕ_1^{-1} in (2.6) has modified the data on the top of Ω.

3. Reduction of the BVP to a functional equation on the boundary. For a solution v of (1.1), $\theta(x,y)$ represents the angle of inclination of the velocity characteristic at the point (x,y) (see Figure 2.1). The θ equation in (2.2) can be rewritten as

$$\partial_x\theta + \partial_y \ln\left(\frac{1}{\cos(\theta+\alpha)}\right) = 0, \tag{3.1}$$

a scalar hyperbolic equation in conservation form. In the following we will consider x as a time-like variable, as its placement in this equation suggests.

We shall derive an initial condition for (3.1) along $\{(x,y) : x = 0\}$. To do so, however, we will need the following result about certain special solutions of (1.1) and their properties.[2]

LEMMA 3.1. *If $\theta(x,y)$ is a C^1 solution of* (3.1) *such that $|\theta| \le \alpha/2$, then there exists a C^2 function $T(x,y)$ such that*

$$\nabla T = e^{(\cot\alpha)\theta}\begin{bmatrix} -\sin\theta \\ \cos\theta \end{bmatrix}, \tag{3.2}$$

and T is a solution of (1.1). *If θ is derived from a solution v of* (1.1), *then T is a function of v, say $T = \Phi(v)$, and Φ is invertible; in particular, T is constant along velocity characteristics.*

Proof. Given a solution $\theta(x,y)$ of (3.1), define a vector field

$$H = \begin{bmatrix} H_1 \\ H_2 \end{bmatrix} = e^{(\cot\alpha)\theta}\begin{bmatrix} -\sin\theta \\ \cos\theta \end{bmatrix}. \tag{3.3}$$

By (3.1), it is easy to verify that

$$\partial_y H_1 = \partial_x H_2.$$

Since the domain is simply connected, H is conservative. That is, there exists a C^2 function T such that $\nabla T = H$.

Recall that τ is given by

$$\tau = \begin{bmatrix} -\sin(\theta+\alpha) \\ \cos(\theta+\alpha) \end{bmatrix}.$$

Then by (3.1), $\operatorname{div}\tau = 0$, and of course $|\tau| = 1$. Also,

$$R_\alpha^{-1}\tau \times \nabla T = \cos\theta\,\partial_x T + \sin\theta\,\partial_y T = 0.$$

Thus the pair τ, T satisfy (2.1), which means that T satisfies (1.1).

Suppose $\theta(x,y)$ is the angle of inclination of the velocity characteristics of a solution v of (1.1). The directional derivative of T along a velocity characteristic equals $\cos\theta\,\partial_x T + \sin\theta\,\partial_y T$, and by (3.3) this vanishes. Thus, T is constant along velocity characteristics, and it follows that $T = \Phi(v)$. Moreover, since neither ∇T nor ∇v vanishes, Φ is invertible. □

[2]The idea for this step in the proof is due to Robert Bryant. Using Darboux's method [1], [2], he obtained this result as an affirmative answer to the question, Are there coordinates in which the general solution of (1.1) be can represented explicitly in terms of two arbitrary functions (as in d'Alembert's solution of the wave equation)?

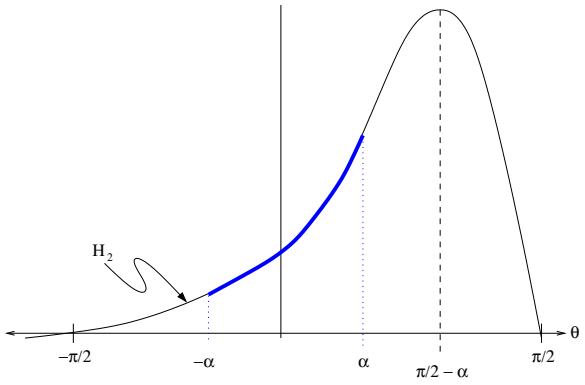

FIG. 3.1. *Graph of the function H_2. This function is invertible on the interval $[-\alpha, \alpha]$, for $0 < \alpha < \pi/4$.*

Only the second component of $\nabla T = H$ will be used below. Slightly changing the notation from (3.3), we shall let H_2 denote the function of one real variable,

$$H_2(\theta) = e^{(\cot \alpha)\theta} \cos \theta. \tag{3.4}$$

The profile of a typical H_2 is shown in Figure 3.1.

Remark 1. We observe that H_2 is strictly positive on $[-\alpha, \alpha]$, a fact which follows from $\alpha < \pi/4$ and the definition of H_2.

Let $v(x, y)$ be a solution of (1.1) with boundary data on the sides of Ω as in (2.6), and let $\theta(x, y)$ be the angle of inclination of the corresponding velocity characteristics. As illustrated in Figure 2.2, given a starting point y_s on the y-axis, define

$$y_r = y_s + \tan\left[\theta(0, y_s) + \alpha\right] \tag{3.5}$$

such that $(1, y_r)$ is connected to $(0, y_s)$ by a stress characteristic, and define

$$y_\ell = \phi_0^{-1}(y_r) \tag{3.6}$$

such that $(0, y_\ell)$ is connected to $(1, y_r)$ by a velocity characteristic. We claim that

$$H_2 \circ \theta(0, y_\ell) = \phi_0'(y_\ell)\, H_2 \circ \theta(0, y_s). \tag{3.7}$$

With this relation we will be able to determine boundary conditions for θ from the given boundary conditions for v.

Proof of (3.7). By the above lemma, the function T is constant along velocity level lines. Therefore,

$$T\left(0, \phi_0^{-1}(y_r)\right) = T\left(1, y_r\right).$$

Temporarily treating y_r as an independent variable, we differentiate T with respect to its second argument on both sides of the above equation to obtain

$$\partial_2 T\left(0, \phi_0^{-1}(y_r)\right)\left(\phi_0^{-1}\right)'(y_r) = \partial_2 T\left(1, y_r\right). \tag{3.8}$$

Recalling (3.2), (3.4), and (3.6), we can rewrite (3.8) as

$$H_2 \circ \theta\left(0, y_\ell\right) \phi_0^{-1}(y_r) = H_2 \circ \theta\left(1, y_r\right). \tag{3.9}$$

As noted above, stress characteristics are straight lines along which θ is constant. Since $(0, y_s)$ and $(1, y_r)$ lie on the same stress characteristic,

$$\theta(0, y_s) = \theta(1, y_r). \tag{3.10}$$

Finally, from (2.5) and (2.6) one can derive

$$\left(\phi_0^{-1}\right)'(y_r) = \frac{1}{\phi_0'\left(\phi_0^{-1}(y_r)\right)} = \frac{1}{\phi_0'(y_\ell)}. \tag{3.11}$$

Then equation (3.7) follows immediately from the substitution of (3.10) and (3.11) into (3.9). □

Below it will be useful to rewrite (3.7) in a more systematic notation. First, we abbreviate $\theta(0, y)$ to $\theta_0(y)$. Let f be the mapping

$$y_s \to y_r \to y_\ell$$

as given by (3.5), (3.6) (see Figure 2.2). In this notation, (3.7) becomes

$$H_2 \circ \theta_0(f(y)) = \phi_0'(f(y))\, H_2 \circ \theta_0(y). \tag{3.12}$$

The above derivation, in which θ is determined from a solution v of (1.1), (2.6), shows that (3.12) holds for all y such that

$$0 \le y < f(y) \le L_0.$$

We now show that if v also satisfies (2.9), then in fact (3.12) holds for a slightly larger range of y.

If follows from (2.9) that the bottom edge of Ω is a velocity characteristic and, since it has zero slope, we conclude that

$$\theta(x, 0) = 0, \quad 0 < x < 1. \tag{3.13}$$

If we regard (3.13) as initial data, then (3.1) has the unique solution $\theta \equiv 0$ in the parallelogram B indicated in Figure 3.2, the parallelogram with vertices $(0, 0)$, $(1, \tan\alpha)$, $(1, 0)$, $(-\tan\alpha, 0)$. This construction shows that if θ is the slope of the velocity characteristics of a solution v of (1.1), (2.6), (2.9), then

(i) $\theta \equiv 0$ on the triangle $B \cap \Omega$, and

(ii) θ has a natural extension from its original domain Ω to $B \cup \Omega$, where $\theta \equiv 0$ on B.

Let v be a solution of (1.1), (2.6), (2.9), and let θ be the angle of inclination of the corresponding velocity characteristics, extended as in (ii). We claim that (3.12) holds for all y such that

$$-\tan\alpha \le y < f(y) \le L_0. \tag{3.14}$$

Indeed, this claim follows from the above proof of (3.7).

With these ideas, we can now explain why θ and v may fail to have higher-order derivatives. Let us consider the continuity of θ_0 at $y = 0$. Of course, for the limit from below, $\lim_{y\to 0^-} \theta_0(y) = 0$. For the limit $y \to 0^+$, we let $y \to -\tan\alpha$ from above in (3.12), observing that $f(-\tan\alpha) = 0$; thus

$$H_2\left(\lim_{y\to 0^+} \theta_0(y)\right) = \phi_0'(0)\, H_2(0).$$

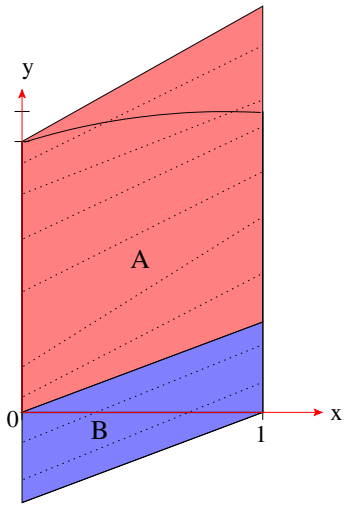

FIG. 3.2. *How θ is determined in Ω from its boundary data θ_0. The region A along with the function θ in A are determined by θ_0 on $\{y \geq 0\}$. Note that the stress characteristics pass out of the top of the domain, through the free boundary. Likewise θ in region B is determined by $\theta \equiv 0$ along $y = 0$.*

Since $H_2(0) = 1$, we conclude that $\lim_{y\to 0^+} \theta_0(y) = 0$ if and only if $\phi_0'(0) = 1$, as required in (2.8a). Thus θ_0 is continuous at $y = 0$ if and only if (2.8a) holds. Similarly, θ' is continuous at $y = 0$ if and only if (2.8b) holds. However, without further restrictions on ϕ_0, second- or higher-order derivatives of θ_0 may jump at $y = 0$.

According to (3.1), a jump in θ_0'' propagates into the interior of Ω along a stress characteristic at the origin. Also, according to (3.12), the jump in θ_0'' at the origin creates other jumps at points $f(0), f \circ f(0), \ldots$ higher on the y-axis, which in turn also propagate into Ω. As in (3.3), jumps in the second-order derivatives of $\theta(x, y)$ lead to jumps in the third derivatives of v. In this way, v may exhibit singularities along a set of straight-line characteristics, as illustrated in Figure 1.1(b).

We derived (3.12) for θ_0 by assuming that a solution v existed in the domain Ω. In the following theorem, we assume that (3.12) has a solution θ_0 along the boundary and construct the related solution v in Ω.

THEOREM 3.2. *Suppose θ_0 is a C^1 function on $[-\tan\alpha, L_0]$ such that*

(i) *$\theta_0 \equiv 0$ on $[-\tan\alpha, 0]$,*

(ii) *θ_0 satisfies* (3.12) *for all y such that* (3.14) *holds, and*

(iii) *$\|\theta_0\|_0 < \frac{\alpha}{2}$ and $\|\theta_0'\|_0 < \frac{1}{2}\cos^2(\frac{3}{2}\alpha)$.*

Then there exists a C^2 solution v to (1.1) *that satisfies the boundary conditions* (2.6), (2.9).

Proof. Consider the IVP for (3.1) with the initial condition θ_0 given in the hypothesis of the theorem: in symbols,

$$\theta(0, y) = \theta_0(y), \quad -\tan\alpha \leq y \leq L_0. \tag{3.15}$$

The theory of scalar conservation laws [4] indicates that this problem has a C^1 solution in a portion of some narrow strip

$$\{(x, y) : 0 < x < \zeta\}$$

that is bounded above and below by characteristics. This solution extends to larger values of x provided the characteristics of (3.1) do not cross. If the initial condition satisfies

$$1 + \sec^2(\theta_0(y) + \alpha)\,\theta_0'(y) > 0 \tag{3.16}$$

for all $y \in [-\tan\alpha, L_0]$, then the characteristics do not cross in the larger strip $\{(x,y) : 0 < x < 1\}$. For convenience below, we have assumed a stronger estimate on θ_0 that bounds the left-hand side of (3.16) from below by $1/2$. Therefore, this initial value problem has a C^1 solution θ in a quadrilateral domain $A \cup B$ as sketched in Figure 3.2. Further, by the theory of hyperbolic conservation laws, that solution on $A \cup B$ satisfies $|\theta| < \alpha/2$ since the boundary data satisfies (iii).

Having constructed $\theta(x,y)$, we now define $T(x,y)$ as in Lemma 3.1. We construct Ω such that its top boundary is a level curve of T:

$$\Omega = \{(x,y) : 0 < x < 1,\ 0 < y,\ T(x,y) < T(0,L_0)\}.$$

Since the stress characteristics arising in the solution of (3.1) are inclined at the positive angle α with respect to level curves of T, we have $\Omega \subset A \cup B$.

To construct v from T, we define

$$\Phi(y) = T(1,y), \quad y > 0. \tag{3.17}$$

We may compute a first derivative of Φ using (3.8), (3.9),

$$\Phi'(y) = H_2 \circ \theta(1,y) \neq 0, \tag{3.18}$$

since $|\theta| < \alpha/2$ on Ω and H_2 is strictly positive for such θ, as we noted in Remark 1; therefore, Φ is invertible. Let us define

$$v = \Phi^{-1} \circ T. \tag{3.19}$$

By the discussion in section 2, we know that v satisfies (1.1). By construction, $v(1,y) = y$ along the right boundary of Ω as required in (2.6). Examining the derivation of (3.7), we see that $v = \phi_0$ along the left boundary. Finally, also by the construction, the remaining boundary conditions (2.9) are satisfied. □

Remark 2. Let f_{str} be the mapping $y_s \to y_r$ as given by (3.5). The derivative of this map is given by the left-hand side of (3.16). Therefore, condition (iii) of the theorem guarantees that

$$f_{str}'(y) \geq \frac{1}{2}; \tag{3.20}$$

in particular f_{str} is one-to-one.

4. Solution of the functional equation. In the next three lemmas, we suppose that θ_0 is a C^1 function defined for y in a subinterval of the y-axis

$$I = [-\tan\alpha, y^*], \tag{4.1}$$

where

$$f(y^*) \leq L_0. \tag{4.2}$$

We assume that $\theta_0 \equiv 0$ for $y \leq 0$ and that θ_0 satisfies the functional equation (3.12) for all y such that both y and $f(y)$ are in I. We propose to use (3.12) to extend θ_0 to the larger interval

$$I_+ = [-\tan\alpha, f(y^*)]\,. \tag{4.3}$$

Formally, we may apply H_2^{-1} to (3.12) and obtain

$$\theta_0\left(f(y)\right) = H_2^{-1}\left[\phi_0'\left(f(y)\right)\, H_2 \circ \theta_0(y)\right], \tag{4.4}$$

a formula which relates θ_0 at $f(y)$ to the boundary data ϕ_0 at $f(y)$ and θ_0 at y. However, care must be taken to ensure that (4.4) represents a meaningful definition. Below, by iterating this basic step, we shall obtain a function θ_0 defined on the entire interval $[-\tan\alpha, L_0]$ as needed in Theorem 3.2.

In these lemmas we explicitly indicate the precise domain over which certain norms are to be evaluated: e.g.,

$$\|\theta_0 : I\|_0 = \max_{x\in I} |\theta_0(x)|.$$

The norms $\|\beta\|_k$ are to be evaluated over $[0, L_0]$; although $I_+ \cap [0, L_0]$ would suffice, enlarging to $[0, L_0]$ simplifies the notation.

LEMMA 4.1. *There exists $\delta > 0$ such that if*

(i) $\|\beta\|_1 < \delta$ *and*

(ii) $\|\theta_0 : I\|_0 < \frac{\alpha}{2}$ *and* $\|\theta_0' : I\|_0 < \frac{1}{2}\cos^2(\frac{3}{2}\alpha)$,

then (4.4) *supplies a well-defined extension of θ_0 from I to I_+ that satisfies the functional equation* (3.12) *for all y such that y and $f(y)$ belong to I_+.*

Proof. For (4.4) to be a valid definition, we need the argument of H_2^{-1} on the right-hand side of (4.4) to belong to the domain of H_2^{-1} and we need f to be one-to-one. Regarding the latter point, we recorded in Remark 2 that if θ_0 satisfies condition (ii), then the map f_{str}, and hence $f = \phi_0^{-1} \circ f_{str}$, is one-to-one. Regarding the former point, observe that by (i), $H_2 \circ \theta_0(y)$ belongs to the set $H_2([-\alpha/2, \alpha/2])$. However, since $\alpha < \pi/4$, the function H_2 is monotone on the larger interval $[-\alpha, \alpha]$. Thus H_2^{-1} is defined and smooth on $H_2([-\alpha, \alpha])$, and $H_2([-\alpha, \alpha])$ contains $H_2([-\alpha/2, \alpha/2])$ in its interior. Provided δ is sufficiently small, if (i) and (ii) hold, then for any $y \in I$

$$\phi_0'(f(y))\, H_2 \circ \theta_0(y) = [1 + \beta'(f(y))]\; H_2 \circ \theta_0(y) \in H_2([-\alpha, \alpha]). \tag{4.5}$$

Then (4.4) gives an unambiguous extension of θ_0 on I_+, and by construction (3.12) is satisfied on the extended interval. □

For subsequent arguments we need to be more quantitative about the monotonicity of H_2 in this proof: let

$$m = \min_{\theta\in[-\alpha,\alpha]} H_2'(\theta) > 0, \tag{4.6}$$

the positivity following from the fact that $[-\alpha, \alpha]$ is compact.

LEMMA 4.2. *If β and θ_0 satisfy conditions* (i) *and* (ii) *of Lemma* 4.1*, then there are positive constants C_1 and C_2 such that*

$$\|\theta_0 : I_+\|_0 \leq \|\theta_0 : I\|_0 + C_1\, \|\beta\|_1 \tag{4.7}$$

and

$$\|\theta_0' : I_+\|_0 \leq C_2\, \|\theta_0' : I\|_0 + C_1\, \|\beta\|_2\,. \tag{4.8}$$

Proof. In proving this result, it is convenient to introduce the inverse function $g = f^{-1}$ and rewrite (4.4) as

$$\theta_0(y) = H_2^{-1}\left[\phi_0'(y)\, H_2 \circ \theta_0\left(g(y)\right)\right]. \tag{4.9}$$

Applying H_2 to both sides of (4.9), subtracting $H_2 \circ \theta_0(g(y))$ from both sides, and recalling the definition (2.7) of β, we see that

$$H_2 \circ \theta_0(y) - H_2 \circ \theta_0(g(y)) = \beta'(y)\, H_2 \circ \theta_0(g(y)). \tag{4.10}$$

Regarding the left-hand side of (4.10), since H_2 is monotone and satisfies (4.6) on $[-\alpha, \alpha]$, we deduce by the mean-value theorem that

$$m\left|\theta_0(y) - \theta_0(g(y))\right| \le \left|H_2 \circ \theta_0(y) - H_2 \circ \theta_0(g(y))\right|. \tag{4.11}$$

Combining (4.10) and (4.11) with the triangle inequality

$$\left|\theta_0\left(y\right)\right| \le \left|\theta_0(g(y))\right| + \left|\theta_0\left(y\right) - \theta_0(g(y))\right|,$$

we obtain (4.7) with

$$C_1 = m^{-1} \max_{\theta \in [-\alpha, \alpha]} |H_2(\theta)|. \tag{4.12}$$

Turning to (4.8), by differentiating (4.9), we obtain

$$\theta_0'(y) = \frac{\left[\phi_0'(y)\right]^2 H_2' \circ \theta_0(g(y))}{H_2' \circ \theta_0(y) f_{str}'(g(y))}\theta_0'(g(y)) + \frac{H_2 \circ \theta_0(g(y))}{H_2' \circ \theta_0(y)}\phi_0''(y). \tag{4.13}$$

The second term in (4.13) is no greater than $C_1\|\beta\|_2$, where C_1 is given by (4.12). The first term is no greater than $C_2\|\theta_0' : I\|_0$, where to obtain C_2 we invoke condition (i) of Lemma 4.1 to estimate ϕ_0', (4.6) to estimate H_2', and (3.20) to estimate f_{str}'. This proves (4.8). □

In the next lemma, we show that a single application of Lemma 4.1 extends the domain of θ_0 by a distance of at least h, where

$$h = \frac{1}{2}\tan\left(\frac{\alpha}{2}\right). \tag{4.14}$$

LEMMA 4.3. *If β and θ_0 satisfy conditions* (i) *and* (ii) *of Lemma* 4.1, *where in condition* (ii) *we have $\delta \le h$, then*

$$f(y^*) > y^* + h.$$

Proof. Recall that $f(y^*) = \phi_0^{-1} \circ f_{str}(y^*)$ and that

$$f_{str}(y^*) = y^* + \tan\left[\theta_0(y^*) + \alpha\right].$$

By condition (ii), $\theta_0(y^*) \ge -\alpha/2$, so

$$f_{str}(y^*) \ge y^* + \tan\left(\frac{\alpha}{2}\right) = y^* + 2h. \tag{4.15}$$

Regarding ϕ_0^{-1}, the other factor in f, first observe that for any y

$$|\phi_0(y) - y| = |\beta(y)| < \delta \le h.$$

Substituting $z = \phi_0(y)$ we deduce

$$\left|\phi_0^{-1}(z) - z\right| < h,$$

from which it follows that

$$\phi_0^{-1}(z) > z - h.$$

Taking $z = f_{str}(y^*)$ and recalling (4.15), we see that

$$f(y^*) > f_{str}(y^*) - h \geq y^* + h,$$

as claimed. □

Given the boundary data (2.6), (2.9) for (1.1), we want to construct a function θ_0 on $[-\tan\alpha, L_0]$ as in Theorem 3.2. Starting from $\theta_0 \equiv 0$ on

$$I_0 = [-\tan\alpha, 0],$$

we propose to apply Lemma 4.1 iteratively on an increasing sequence of intervals

$$I_1 = [-\tan\alpha, y_1],\ I_2 = [-\tan\alpha, y_2], \ldots$$

where $y_0 = 0$ and for $k = 1, 2, \ldots$

$$y_k = f(y_{k-1}).$$

Provided $\|\beta\|_1 < \delta$, it follows from Lemma 4.1 that extension from I_0 to I_1 is possible. By Lemma 4.2, provided

$$C_1\|\beta\|_1 < \frac{\alpha}{2} \qquad \text{and} \qquad C_1\|\beta\|_2 < \frac{1}{2}\cos^2\left(\frac{3}{2}\alpha\right),$$

extension from I_1 to I_2 is also possible. More generally, provided

$$N \cdot C_1\|\beta\|_1 < \frac{\alpha}{2} \qquad \text{and} \qquad \frac{C_2^N - 1}{C_2 - 1}\, C_1\, \|\beta\|_2 < \frac{1}{2}\cos^2\left(\frac{3}{2}\alpha\right),$$

the estimates of Lemma 4.1 will remain valid for N iterations. Thus for any positive integer N, if $\|\beta\|_2$ is sufficiently small, we can extend θ_0 to I_N, provided $y_k \leq L_0$ for $k = 1, 2, \ldots, N$.

According to Lemma 4.3, after some number N iterations, where $N \leq L_0/h$, we shall arrive at a point where

$$y_N \leq L_0 \qquad \text{but} \qquad f_{str}(y_N) > L_1$$

so that $f(y_N)$ is undefined. In this case, there is some $\tilde{y} < y_N$ such that $f(\tilde{y}) = L_0$, and Lemma 4.1 may be applied one more time to extend θ_0 from $[-\tan\alpha, \tilde{y}]$ to the entire interval $[-\tan\alpha, L_0]$. (This modification of the process also handles the "short domain" case in which $f_{str}(0) > L_1$.) In this way, provided $\|\beta\|_2$ is sufficiently small, we may obtain θ_0 as in Theorem 3.2 and then invoke that theorem to solve (1.1), (2.6), and (2.9).

5. Proof of uniqueness. Briefly, the uniqueness proof proceeds by checking that each step of the existence proof, which is constructive, has a unique outcome. Specifically, let v and $\widehat{v}$ be two solutions of (1.1) on domains Ω and $\widehat{\Omega}$ and satisfying the reduced boundary conditions (2.6), (2.9). We assume that (i) neither ∇v nor $\nabla\widehat{v}$ vanishes and (ii) the boundary-data function $\phi_0(y) = y+\beta(y)$ satisfies $\|\beta\|_2 < \epsilon$ where ϵ is the constant of Theorem 1.1: i.e., ϵ is sufficiently small to guarantee existence through the above construction.

- Define $\theta = \arg(\nabla v) - \pi/2$ to be the angle of inclination of the level curves, or characteristics, of this solution, and define $\widehat{\theta}$ likewise. Both θ and $\widehat{\theta}$ satisfy (3.1), vanish identically on the triangle $B \cap \Omega$ of Figure 3.2, and extend as solutions of (3.1) to be identically zero on all of B. In particular for the extended functions, $\theta_0(y) = \widehat{\theta}_0(y) = 0$ for $-\tan\alpha \le y \le 0$.
- Both θ and $\widehat{\theta}$ satisfy the functional equation (3.12). It follows from the estimates in section 3 that f is one-to-one and that $\theta_0(f(y))$ belongs to the domain of H_2^{-1}, and likewise for $\widehat{f}$ and $\widehat{\theta}_0(\widehat{f}(y))$. Therefore, (3.12) may be rewritten in the form (4.9), which shows that $\theta_0(y) = \widehat{\theta}_0(y)$ for the entire interval $-\tan\alpha \le y \le L_0$.
- By solving (3.1) with the initial condition (3.15), we obtain identical extensions of θ and $\widehat{\theta}$ on the quadrilateral domain $A \cup B$ of Figure 3.2 (the same domain for both functions).
- Thus the characteristic equation (2.4) for the two solutions, v and $\widehat{v}$, is the same. Integrating this equation with the initial condition $y(0) = L_0$ to obtain the upper boundary of Ω we conclude that $\Omega = \widehat{\Omega}$. More generally, all the level curves or characteristics of v and $\widehat{v}$ in Ω coincide. Since v and $\widehat{v}$ are equal on the left boundary of Ω, they are equal throughout Ω.

Appendix: Connection to granular flow. Equation (1.1), or the equivalent first-order system (2.1), arises from a model [12] for steady-state antiplane shearing of a granular medium. The term *antiplane shear* refers to a special class of deformation of a three-dimensional solid in which: (i) all motion is in the z-direction,

$$\overrightarrow{v} = (0, 0, v),$$

where v is the scalar velocity in (2.1); (ii) the stress tensor has the reduced form

$$T = \begin{pmatrix} \sigma & 0 & \tau_1 \\ 0 & \sigma & \tau_2 \\ \tau_1 & \tau_2 & \sigma \end{pmatrix},$$

where σ is a uniform confining pressure and τ is the vector in (2.1); and (iii) the velocity and the stress depend on x and y but are independent of z. (The confining pressure σ is independent of all three coordinates.) The three equations in (2.1) represent the following, respectively: (a) Force balance or Newton's second law of motion with inertia neglected (appropriate for slow flow). (b) Coulomb's law of friction—for motion to occur, the shearing stress must equal a threshold. In general, this threshold depends on the confining pressure σ and on the internal friction of the material, but we have nondimensionalized the equations. (c) The nonassociative constitutive law proposed in [12]. More accurately, the constitutive law should read as follows: there exists a nonnegative function $\lambda(x, y)$ such that

$$\nabla v = \lambda R_\alpha^{-1} \tau.$$

In (2.1) the function λ has been eliminated, but the condition $\lambda \geq 0$—that friction acts dissipatively—needs to be checked a posteriori in order to verify that a solution of (2.1) is physical.[3]

Physically, (2.1) may be viewed as describing the continuum limit of a collection of infinitely long, thin rods. These rods are parallel to the z-axis, their cross sections fill the domain Ω, and they slide over one another along their axes, subject to the constitutive law proposed in [12]. On physical grounds, one would expect to be able to control the velocity of all the rods at the boundary of Ω—in mathematical terms Dirichlet boundary conditions are suggested. Similarly, it would seem impossible to control *both* velocity and stress on any portion of $\partial\Omega$—again in mathematical terms, Cauchy data are excluded.

The model (2.1) was proposed as a technically simpler analogue of the equations of slow, two-dimensional flow of an incompressible Coulomb material [3], [8], [7]. The physical unknowns for such flow consist of a 2-component velocity v and a 2×2 stress tensor T (three scalars, since T is symmetric). These unknowns satisfy

$$
\begin{aligned}
\sum_{j=1}^{2} \partial_j T_{ij} &= \rho g_i, && i = 1, 2, \\
\sum_{i,j=1}^{2} \left(T_{ij} - \sigma\delta_{ij}\right)^2 &= k\sigma, && \\
\lambda \left(T_{ij} - \sigma\delta_{ij}\right) &= -\tfrac{1}{2}\left(\partial_i v_j + \partial_j v_i\right), && i, j = 1, 2
\end{aligned}
\tag{5.1}
$$

where ρ is the (constant) density, g is the acceleration of gravity, k is a constant describing internal friction, σ is the mean stress

$$\sigma = \frac{1}{2}\sum_{i=1}^{2} T_{ii},$$

and $\lambda(x_1, x_2) \geq 0$ is an auxiliary function that arises in the mathematical formulation of plasticity.

The close analogy in form between (5.1) and (2.1) is readily apparent, even though the number of equations is different. However, the analogy is far closer than a superficial appearance. Specifically, as with (2.1), we have the following: (i) The algebraic constraint may be eliminated by an appropriate reparameterization of the stress (the Sokolovskii variables [13]). (ii) The two remaining stress variables satisfy a strictly hyperbolic system that is uncoupled from the velocity. (iii) If λ is eliminated from the third equation in (5.1), the two velocity equations—with T regarded as known—are a linear, strictly hyperbolic system in v.

The present work originated from an attempt to use the three-dimensional analogue of (5.1) to model slow, steady flow in a hopper [6], [9]. Although boundary conditions along the walls of the hopper are natural and easy to formulate, the situation at the top and bottom is very unclear: e.g., how many conditions should be imposed at the top and how many at the bottom? Exactly where should they be imposed? Since the equations are hyperbolic, one might seek a Cauchy problem. The stress and velocity equations decouple, and therefore there are various ways of posing

[3] This positivity is readily checked for the problem in the present paper: the coefficient λ is identically $+1$ for the unperturbed solution $v(x, y) = y$, and the perturbation is too small to change the sign of λ.

different Cauchy problems. However, in [9] all ways of prescribing Cauchy data led to unphysical solutions in which the constraint $\lambda \geq 0$ was violated. In such a solution, friction is *adding* energy to the flow.

This paper identifies a well-posed, Dirichlet-type boundary value problem for the analogous, but technically simpler system (2.1). The appearance of a free boundary, which is crucial for the result, was suggested by hopper flow: there is some evidence that exit boundary conditions should be posed along a velocity characteristic, and for a nonlinear equation the location of characteristics is unknown a priori.

While answering one question, this paper raises many others: e.g., finding larger classes of well-posed boundary problems for (1.1) and extending understanding of the model problem to (5.1) and its three-dimensional analogue.

Acknowledgment. We are grateful to Robert Bryant for helpful discussions of the geometry of (1.1) that culminated in the crucial result of Lemma 3.1.

ON THE STRUCTURE OF SOLUTIONS TO THE PERIODIC HUNTER–SAXTON EQUATION*

ZHAOYANG YIN†

Abstract. We prove the local existence of strong solutions of the periodic Hunter–Saxton equation, and we show that all strong solutions except space-independent solutions blow up in finite time.

Key words. local existence of strong solutions, Hunter–Saxton equation, blow-up of strong solutions

AMS subject classifications. 35G25, 35L05

1. Introduction. In this paper, we study the periodic Hunter–Saxton equation [9]

$$\begin{cases} u_{txx} = -2u_x u_{xx} - u u_{xxx}, & t > 0,\ x \in \mathbb{R}, \\ u(0,x) = u_0(x), & x \in \mathbb{R}, \\ u(t,x+1) = u(t,x), & t \geq 0,\ x \in \mathbb{R}, \end{cases} \tag{1.1}$$

which describes the propagation of weakly nonlinear orientation waves in a massive nematic liquid crystal director field. Here, $u(t,x)$ describes the director field of a nematic liquid crystal, x is a space variable in a reference frame moving with the linearized wave velocity, and t is a slow time variable. Nematic liquid crystals are fluids consisting of long rigid molecules. The orientation of the molecules is described by the field of unit vectors

$$(\cos(u(t,x)), \sin(u(t,x))),$$

where $u(t,x)$ is a perturbation about some constant value. Equation (1.1) describes the weakly nonlinear dynamics of the director field of a nematic liquid crystal in the simplest possible setting which includes the effects of the inertia of the director field; cf. [9].

Equation (1.1) also arises in a different physical context as the high-frequency limit [7, 10] of the Camassa–Holm equation—a model equation for shallow water waves [2, 11] and a re-expression of the geodesic flow on the diffeomorphism group of the circle [5] with a bi-Hamiltonian structure [8] which is completely integrable [6]. The Hunter–Saxton equation also has a bi-Hamiltonian structure [9, 16] and is completely integrable [1, 10].

The initial value problem for the Hunter–Saxton equation on the line (nonperiodic case) has been studied by Hunter and Saxton in [9]. Using the method of characteristics, they show that smooth solutions exist locally and break down in finite time;

cf. [9]. The occurrence of blow-up can be interpreted physically as the phenomenon by which waves that propagate away from the perturbation "knock" the director field out of its unperturbed state (see [9]).

However, the Cauchy problem of the periodic Hunter–Saxton seems not yet to have been discussed. The aim of this paper is to prove the local existence of strong solutions to (1.1) for a large class of initial data and to show that all strong solutions except space-independent solutions to (1.1) blow-up in finite time. Our methods are different from the ones used in [9] and the behavior of the solutions exhibits different features, for example regarding uniqueness (see Theorem 2.12).

Our paper is organized as follows. In section 2, we prove the local existence of the initial value problem associated with (1.1). In section 3, we investigate the blow-up phenomenon of strong solutions to (1.1).

Let us conclude the introduction with a short summary of the mathematical methodology that will be used in our approach. The existence of solutions to the nonlinear partial differential equation (1.1) is established by investigating an equivalent problem. We eliminate two spatial derivatives in (1.1) at the cost of obtaining a nonlocal nonlinear partial differential equation of order 1. Methods of functional analysis are then used to show the local existence of solutions and to address regularity issues. Finally, by looking at the time evolution of the minimum of the slope of a solution, we prove that all solutions of (1.1) with initial data that are not constant functions develop singularities in finite time.

2. Local well-posedness. In this section, we will apply Kato's theory to establish local existence for strong solutions to (1.1) in $H^r(\mathbb{S})$, $r > \frac{3}{2}$ with $\mathbb{S} = \mathbb{R}/\mathbb{Z}$ (the circle of unit length).

Let us first introduce some notation. Let A denote an unbounded operator and let $D(A)$ denote the domain of the operator A. $[A, B]$ denotes the commutator of the linear operators A and B. $\|\cdot\|_X$ denotes the norm of the Banach space X. In particular, $\|\cdot\|_r$ and $(\cdot,\cdot)_r$ denote the norm and the inner product of $H^r(\mathbb{S})$, $r \geq 0$, respectively.

For convenience, we state here Kato's theorem in the form suitable for our purpose.

Consider the abstract quasi-linear evolution equation:

$$\frac{dv}{dt} + A(v)v = f(t, v), \quad t \geq 0,\ v(0) = v_0. \tag{2.1}$$

Let X and Y be Hilbert spaces such that Y is continuously and densely embedded in X and let $Q : Y \to X$ be a topological isomorphism. $L(Y, X)$ denotes the space of all bounded linear operators from Y to X ($L(X)$, if $X = Y$). Assume the following.

(i) $A(y) \in L(Y, X)$ for $y \in X$ with

$$\|(A(y) - A(z))w\|_X \leq \mu_1 \|y - z\|_X \|w\|_Y, \quad y, z, w \in Y,$$

and $A(y) \in G(X, 1, \beta)$ (i.e., $A(y)$ is quasi-m-accretive), uniformly on bounded sets in Y.

(ii) $QA(y)Q^{-1} = A(y) + B(y)$, where $B(y) \in L(X)$ is bounded, uniformly on bounded sets in Y. Moreover,

$$\|(B(y) - B(z))w\|_X \leq \mu_2 \|y - z\|_Y \|w\|_X, \quad y, z \in Y,\ w \in X.$$

(iii) For each $y \in Y$, $t \to f(t,y)$ is continuous on $[0,\infty)$ to X. For each $t \in [0,\infty)$, $f(t,y) : Y \to Y$ and extends also to a map from X into X. For all $t \in [0,\infty)$, f is uniformly bounded on bounded sets in Y, and

$$\|f(t,y) - f(t,z)\|_Y \le \mu_3 \|y - z\|_Y, \quad t \in [0,\infty),\ y, z \in Y,$$
$$\|f(t,y) - f(t,z)\|_X \le \mu_4 \|y - z\|_X, \quad t \in [0,\infty),\ y, z \in X.$$

Here μ_1, μ_2, μ_3, and μ_4 depend only on $\max\{\|y\|_Y, \|z\|_Y\}$.

THEOREM 2.1 (Kato [12]). *Assume that* (i), (ii), *and* (iii) *hold. Given $v_0 \in Y$, there is a maximal $T > 0$ depending only on $\|v_0\|_Y$ and a unique solution v to* (2.1) *such that*

$$v = v(\cdot, v_0) \in C([0,T); Y) \bigcap C^1([0,T); X).$$

Moreover, the map $v_0 \mapsto v(\cdot, v_0)$ is continuous from Y to $C([0,T); Y) \bigcap C^1([0,T); X)$.

We provide now the framework in which we shall reformulate problem (1.1). In order to obtain an equation describing the evolution of u rather than that of u_{xx}, we observe that

$$-2u_x u_{xx} - u u_{xxx} = -\left(u u_{xx} + \frac{1}{2} u_x^2\right)_x.$$

Integrating both sides of (1.1) with respect to x, we obtain

$$\begin{cases} u_{tx} = -u u_{xx} - \dfrac{1}{2} u_x^2 + a, & t > 0,\ x \in \mathbb{R}, \\ u(0,x) = u_0(x), & x \in \mathbb{R}, \\ u(t, x+1) = u(t,x), & t \ge 0,\ x \in \mathbb{R}, \end{cases} \tag{2.2}$$

where $a = -\frac{1}{2}\int_{\mathbb{S}} u_x^2\, dx = -\frac{1}{2}\int_{\mathbb{S}} u_{0,x}^2\, dx$ is a constant (see Lemma 3.2 later in the paper). Then integrating both sides of (2.2) with respect to x, we have

$$\begin{cases} u_t + u u_x = \partial_x^{-1}\left(\dfrac{1}{2} u_x^2 + a\right) + h(t), & t > 0,\ x \in \mathbb{R}, \\ u(0,x) = u_0(x), & x \in \mathbb{R}, \\ u(t, x+1) = u(t,x), & t \ge 0,\ x \in \mathbb{R}, \end{cases} \tag{2.3}$$

where $a = -\frac{1}{2}\int_{\mathbb{S}} u_x^2\, dx$, $\partial_x^{-1} f(x) = \int_0^x f(x)\, dx$ and $h(t) : [0, +\infty) \to \mathbb{R}$ is an arbitrary continuous function.

THEOREM 2.2. *Given $h(t) \in C([0,+\infty); \mathbb{R})$ and $u_0 \in H^r(\mathbb{S})$, $r > \frac{3}{2}$. Then there exists a maximal $T = T(a, h(t), u_0) > 0$, and a unique solution u to* (2.3), *such that*

$$u = u(\cdot, u_0) \in C([0,T); H^r(\mathbb{S})) \bigcap C^1([0,T); H^{r-1}(\mathbb{S})).$$

Moreover, the solution depends continuously on the initial data, i.e., the mapping $u_0 \to u(\cdot, u_0) : H^r(\mathbb{S}) \to C([0,T); H^r(\mathbb{S})) \bigcap C^1([0,T); H^{r-1}(\mathbb{S}))$ is continuous.

Set $A(u) = u\partial_x$, $f(t,u) = \partial_x^{-1}(\frac{1}{2}u_x^2 + a) + h(t)$, $Y = H^r(\mathbb{S})$, $X = H^{r-1}(\mathbb{S})$, and $Q = \Lambda = (1 - \partial_x^2)^{\frac{1}{2}}$. Obviously, Q is an isomorphism of $H^r(\mathbb{S})$ onto $H^{r-1}(\mathbb{S})$. In order to prove Theorem 2.2, by applying Theorem 2.1, we only need to verify that $A(u)$ and $f(t,u)$ satisfy the conditions (i)–(iii).

The following three lemmas are useful for our approach.

LEMMA 2.3 (see [12]). *Let s, t be real numbers such that $-s < t \le s$. Then*

$$\|fg\|_t \le c\|f\|_s\|g\|_t \quad \text{if } s > \frac{1}{2},$$
$$\|fg\|_{s+t-\frac{1}{2}} \le c\|f\|_s\|g\|_t \quad \text{if } s < \frac{1}{2},$$

where c is a positive constant depending on s, t.

LEMMA 2.4 (see [13]). *Let $f \in H^r$, $r > \frac{3}{2}$. Then,*

$$\|\Lambda^{-s}[\Lambda^{s+t+1}, M_f]\Lambda^{-t}\|_{L(L^2(\mathbb{S}))} \le c\|f\|_r, \quad |s|, |t| \le r-1,$$

where M_f is the operator of multiplication by f, c is a constant depending only on r, t.

LEMMA 2.5 (see [17]). *Let X and Y be two Banach spaces such that Y is continuously and densely embedded in X. Let $-A$ be the infinitesimal generator of the C_0-semigroup $T(t)$ on X and let S be an isomorphism from Y onto X. Then Y is $-A$-admissible (i.e., $T(t)Y \subset Y$ for all $t \ge 0$, and the restriction of $T(t)$ to Y is a C_0-semigroup on Y) if and only if $-A_1 = -SAS^{-1}$ is the infinitesimal generator of the C_0-semigroup $T_1(t) = ST(t)S^{-1}$ on X. Moreover, if Y is $-A$-admissible, then the part of $-A$ in Y is the infinitesimal generator of the restriction of $T(t)$ to Y.*

The proof of Lemma 2.5 is given in section 4.5 (Theorems 5.5 and 5.8) in [17].

Next, we prove the following lemma.

LEMMA 2.6. *The operator $A(u) = u\partial_x$, with $u \in H^r(\mathbb{S})$, $r > \frac{3}{2}$, belongs to $G(L^2(\mathbb{S}), 1, \beta)$.*

Proof. Due to $L^2(\mathbb{S})$ being a Hilbert space, $A(u) \in G(L^2(\mathbb{S}), 1, \beta)$ [14] if and only if there is a real number β such that

(1) $(A(u)y, y)_0 \ge -\beta\|y\|_0^2$,

(2) the range of $A + \lambda$ is all of X for some (or all) $\lambda > \beta$.

First, let us prove (1). Due to $u \in H^r(\mathbb{S})$, $r > \frac{3}{2}$, it follows that u and u_x belong to $L^\infty(\mathbb{S})$. Note that $\|u_x\|_{L^\infty(\mathbb{S})} \le \|u\|_r$. Then we have

$$\begin{aligned}(A(u)y, y)_0 = (u\partial_x y, y)_0 &= -\frac{1}{2}(u_x y, y)_0 \\ &\le \frac{1}{2}\|u_x\|_{L^\infty(\mathbb{S})}\|y\|_0^2 \le c\|u\|_r\|y\|_0^2.\end{aligned}$$

Setting $\beta = c\|u\|_s$, we have $(A(u)y, y)_0 \ge -\beta\|y\|_0^2$.

Next, we prove (2). Because $A(u)$ is a closed operator and satisfies (1), it follows that $(\lambda I + A)$ has closed range in $L^2(\mathbb{S})$ for all $\lambda > \beta$. Thus, it suffices to prove that $(\lambda I + A)$ has dense range in $L^2(\mathbb{S})$ for all $\lambda > \beta$.

Given $u \in H^r(\mathbb{S})$, $r > \frac{3}{2}$, $y \in L^2(\mathbb{S})$. Then we have the generalized Leibnitz formula,

$$\partial_x(uy) = u_x y + u\partial_x y \quad \text{in } H^{-1}(\mathbb{S}).$$

Due to $u_x \in L^\infty(\mathbb{S})$, we obtain

$$\begin{aligned}D(A) = D(u\partial_x) &= \{y \in L^2(\mathbb{S}),\ u\partial_x y \in L^2(\mathbb{S})\} \\ &= \{z \in L^2(\mathbb{S}),\ -\partial_x(uz) \in L^2(\mathbb{S})\} = D((u\partial_x)^*) = D(A^*).\end{aligned}$$

Assume that the range of $(A+\lambda)$ is not all of $L^2(\mathbb{S})$. Then there exists $z \in L^2(\mathbb{S})$, $z \ne 0$, such that $((\lambda I + A)y, z)_0 = 0$ for all $y \in D(A)$. Since $H^1(\mathbb{S}) \subset D(A)$, we have

that $D(A)$ is dense in $L^2(\mathbb{S})$. So, it follows that $z \in D(A^*)$ and $\lambda z + A^* = 0$ in $L^2(\mathbb{S})$. Note that $D(A) = D(A^*)$. Multiplying by z and then integrating by parts, we obtain

$$0 = ((\lambda I + A^*)z, z)_0 = (\lambda z, z) + (z, Az) \geq (\lambda - \beta)\|z\|_0^2 \quad \forall \lambda > \beta.$$

Thus, we obtain $z = 0$. This contradicts the previous assumption $z \neq 0$ and completes the proof of Lemma 2.6. □

LEMMA 2.7. *The operator $A(u) = u\partial_x$, with $u \in H^r(\mathbb{S})$, $r > \frac{3}{2}$, belongs to $G(H^{r-1}(\mathbb{S}), 1, \beta)$.*

Proof. Due to $H^{r-1}(\mathbb{S})$ being a Hilbert space, $A(u)$ belongs to $G(H^{r-1}(\mathbb{S}), 1, \beta)$ [14] if and only if there is a real number β such that

(1) $(A(u)y, y)_{r-1} \geq -\beta\|y\|_{r-1}^2$,

(2) $-A(u)$ is the infinitesimal generator of a C_0-semigroup on $H^{r-1}(\mathbb{S})$, for some (or all) $\lambda > \beta$.

First, let us prove (1). Due to $u \in H^r(\mathbb{S})$, $r > \frac{3}{2}$, it follows that u and u_x belong to $L^\infty(\mathbb{S})$ and $\|u_x\|_{L^\infty(\mathbb{S})} \leq \|u\|_r$. Note that

$$\Lambda^{r-1}(u\partial_x y) = [\Lambda^{r-1}, u]\partial_x y + u\Lambda^{r-1}(\partial_x y) = [\Lambda^{r-1}, u]\partial_x y + u\partial_x \Lambda^{r-1} y.$$

Then we have

$$\begin{aligned}
(A(u)y, y)_{r-1} &= (\Lambda^{r-1}(u\partial_x y), \Lambda^{r-1} y)_0 \\
&= ([\Lambda^{r-1}, u]\partial_x y, \Lambda^{r-1} y)_0 - \frac{1}{2}(u_x \Lambda^{r-1} y, \Lambda^{r-1} y)_0 \\
&\leq \|[\Lambda^{r-1}, u]\Lambda^{2-r}\|_{L(L^2(\mathbb{S}))}\|\Lambda^{r-1} y\|_0^2 + \|u_x\|_{L^\infty(\mathbb{S})}\|\Lambda^{r-1} y\|_0^2 \\
&\leq c\|u\|_r\|y\|_{r-1}^2,
\end{aligned}$$

where we applied Lemma 2.4 with $s = 0$, $t = r - 2$. Setting $\beta = c\|u\|_r$, we have $(A(u)y, y)_{r-1} \geq -\beta\|y\|_{r-1}^2$.

Next, we prove (2). Let $S = \Lambda^{r-1}$. Note that S is an isomorphism of $H^{r-1}(\mathbb{S})$ onto $L^2(\mathbb{S})$ and that $H^{r-1}(\mathbb{S})$ is continuously and densely embedded in $L^2(\mathbb{S})$ as $r > \frac{3}{2}$. Define

$$A_1(u) := SA(u)S^{-1} = \Lambda^{r-1}A(u)\Lambda^{1-r}, \qquad B_1(u) = A_1(u) - A(u).$$

Let $y \in L^2(\mathbb{S})$ and $u \in H^r(\mathbb{S})$, $r > \frac{3}{2}$. Then we have

$$\begin{aligned}
\|B_1(u)y\|_0 &= \|[\Lambda^{r-1}, u\partial_x]\Lambda^{1-r} y\|_0 \\
&\leq \|[\Lambda^{r-1}, u]\Lambda^{2-r}\|_{L(L^2(\mathbb{S}))}\|\Lambda^{-1}\partial_x y\|_0 \\
&\leq c\|u\|_r\|y\|_0,
\end{aligned}$$

where we applied Lemma 2.4 with $s = 0$, $t = r - 2$. Therefore, we obtain $B_1(u) \in L(L^2(\mathbb{S}))$.

Note that $A_1(u) = A(u) + B_1(u)$ and $A(u) \in G(L^2(\mathbb{S}), 1, \beta)$ in Lemma 2.6. By a perturbation theorem for semigroups (cf. Section 5.2, Theorem 2.3 in [17]), we obtain $A_1(u) \in G(L^2(\mathbb{S}), 1, \beta')$. Applying Lemma 2.5 with $Y = H^{r-1}(\mathbb{S})$, $X = L^2(\mathbb{S})$, and $S = \Lambda^{r-1}$, we conclude that $H^{r-1}(\mathbb{S})$ is A-admissible. Therefore, $-A(u)$ is the infinitesimal generator of a C_0-semigroup on $H^{r-1}(\mathbb{S})$. This completes the proof of Lemma 2.7. □

LEMMA 2.8. *Let the operator $A(u) = u\partial_x$ with $u \in H^r(\mathbb{S})$, $r > \frac{3}{2}$. Then $A(u) \in L(H^r(\mathbb{S}), H^{r-1}(\mathbb{S}))$ for $u \in H^r(\mathbb{S})$. Moreover,*

$$\|(A(u) - A(z))w\|_{r-1} \le \mu_1 \|u - z\|_{r-1} \|w\|_r, \quad u, z, w \in H^r(\mathbb{S}).$$

Proof. Let $u, z, w \in H^r(\mathbb{S})$, $r > \frac{3}{2}$. Note that $H^{r-1}(\mathbb{S})$ is a Banach algebra. Then we have

$$\begin{aligned}\|(A(u) - A(z))w\|_{r-1} &\le c\|u - z\|_{r-1} \|\partial_x w\|_{r-1} \\ &\le \mu_1 \|u - z\|_{r-1} \|w\|_r.\end{aligned}$$

Taking $z = 0$ in the above inequality, we obtain $A(u) \in L(H^r(\mathbb{S}), H^{r-1}(\mathbb{S}))$. This completes the proof of Lemma 2.8. □

LEMMA 2.9. *$B(u) = [\Lambda^1, u\partial_x]\Lambda^{-1} \in L(H^{r-1}(\mathbb{S}))$ for $u \in H^r(\mathbb{S})$. Moreover,*

$$\|(B(u) - B(z))w\|_{r-1} \le \mu_2 \|u - z\|_r \|w\|_{r-1}.$$

Proof. Let $u, z \in H^r(\mathbb{S})$, $r > \frac{3}{2}$, $w \in H^{r-1}(\mathbb{S})$. Then

$$\begin{aligned}\|(B(u) - B(z))w\|_{r-1} &= \|\Lambda^{r-1}[\Lambda^1, (u - v)\partial_x]\Lambda^{-1} w\|_0 \\ &\le \|\Lambda^{r-1}[\Lambda, (u - v)]\Lambda^{1-r}\|_{L(L^2(\mathbb{S}))} \|\Lambda^{r-2}\partial_x w\|_0 \\ &\le \mu_2 \|y - z\|_r \|w\|_{r-1},\end{aligned}$$

where we applied Lemma 2.4 with $s = 1 - r,\ t = r - 1$. Taking $z = 0$ in the above inequality, we obtain $B(u) \in L(H^{r-1}(\mathbb{S}))$. This completes the proof of Lemma 2.9. □

LEMMA 2.10. *Let $f(t, u) = \partial_x^{-1}(\frac{1}{2}u_x^2 + a) + h(t)$, where $a = -\frac{1}{2}\int_{\mathbb{S}} u_x^2\, dx$. Then for each $y \in Y$, $t \to f(t, y)$ is continuous on $[0, \infty)$ to $H^{r-1}(\mathbb{S})$, $f(t, u)$ is uniformly bounded on bounded sets in $H^r(\mathbb{S})$ for all $t \in [0, \infty)$, and satisfies*

(1) $\|f(t, y) - f(t, z)\|_r \le \mu_3 \|y - z\|_s, \quad t \in [0, \infty),\ y, z \in H^r(\mathbb{S}),$

(2) $\|f(t, y) - f(t, z)\|_{r-1} \le \mu_4 \|y - z\|_{r-1}, \quad t \in [0, \infty),\ y, z \in H^r(\mathbb{S}).$

Proof. Due to $h(t) \in C([0, \infty); \mathbb{R})$, it follows that for each $y \in Y$, $t \to f(t, y)$ is continuous on $[0, \infty)$ to $H^{r-1}(\mathbb{S})$. Therefore, we only need to prove $f(t, u)$ satisfies (1) and (2). Let $y, z \in H^r(\mathbb{S})$, $r > \frac{3}{2}$. Note that $H^{r-1}(\mathbb{S})$ is a Banach algebra. Then we have

$$\begin{aligned}\|f(t, y) - f(t, z)\|_r &= \left\| \partial_x^{-1} \left(\frac{1}{2}(y_x^2 - z_x^2) \right) \right\|_r \\ &\le \frac{1}{2} \|(y_x - z_x)(y_x + z_x)\|_{r-1} \\ &\le \frac{1}{2} \|\partial_x (y - z)\|_{r-1} \|y_x + z_x\|_{r-1} \\ &\le \frac{1}{2} (\|y\|_r + \|z\|_r) \|y - z\|_r.\end{aligned}$$

This proves (1). Taking $z = 0$ in the above inequality, we obtain that f is uniformly bounded on bounded set in $H^r(\mathbb{S})$ for all $t \in [0, \infty)$.

Next, we prove (2). Let $y, z \in H^{r-1}(\mathbb{S})$, $r > \frac{3}{2}$. Note that $H^r(\mathbb{S})$ is a Banach algebra. Then we have

$$\begin{aligned}\|f(t,y) - f(t,z)\|_{r-1} &= \left\| \partial_x^{-1}\left(\frac{1}{2}(y_x^2 - z_x^2)\right)\right\|_{r-1} \\ &\le \frac{1}{2}\|(y_x - z_x)(y_x + z_x)\|_{r-2} \\ &\le \frac{1}{2}\|\partial_x(y-z)\|_{r-2}\|y_x + z_x\|_{r-1} \\ &\le \frac{1}{2}(\|y\|_r + \|z\|_r)\|y - z\|_{r-1},\end{aligned}$$

where we applied Lemma 2.3 with $s = r-1$, $t = r-2$. This completes the proof of Lemma 2.10. □

Proof of Theorem 2.2. Combining Theorem 2.1 and Lemmas 2.7–2.10, we can get the statement of Theorem 2.2. □

THEOREM 2.11. *The maximal time T in Theorem* 2.2 *may be chosen independent of r in the following sense. If $u = u(\cdot, u_0) \in C([0,T); H^r(\mathbb{S})) \bigcap C^1([0,T); H^{r-1}(\mathbb{S}))$ to* (2.3)*, and if $u_0 \in H^{r'}(\mathbb{S})$ for some $r' \neq r$, $r' > \frac{3}{2}$, then*

$$u \in C([0,T); H^{r'}(\mathbb{S})) \bigcap C^1([0,T); H^{r'-1}(\mathbb{S}))$$

and with the same T. In particular, $u_0 \in H^\infty(\mathbb{S}) = \bigcap_{r\ge 0} H^r(\mathbb{S})$, then $u \in C([0,T); H^\infty(\mathbb{S}))$.

Proof. It suffices to consider the case $r' > r$, since the case $r' < r$ is obvious from uniqueness which is guaranteed by Theorem 2.2. In order to prove that Theorem 2.11 is true for the case $r' > r$, let us return to (1.1). By setting $y(t) = \partial_x^2 u(t)$, we have

$$\frac{dy}{dt} + A(t)y + B(t)y = 0, \qquad y(0) = \partial_x^2 u(0). \tag{2.4}$$

Here, $A(t)y = \partial_x(u\,y)$ and $B(t)y = u_x y$.

Because $u \in C([0,T); H^r(\mathbb{S}))$ and $u_0 \in H^{r'}(\mathbb{S})$, we have $y \in C([0,T); H^{r-2}(\mathbb{S}))$ and $y(0) = \partial_x^2 u(0) \in C([0,T); H^{r'-2}(\mathbb{S}))$. It is our purpose to deduce $y \in C([0,T); H^{r'-2}(\mathbb{S}))$, which imply $u \in C([0,T); H^{r'}(\mathbb{S}))$, because ∂_x^2 is an isomorphism from $H^{r'}(\mathbb{S})$ to $H^{r'-2}(\mathbb{S})$. This will complete the proof of Theorem 2.11.

Note that $u \in C([0,T); H^r(\mathbb{S}))$, $u_x \in H^{r-1}(\mathbb{S})$, and $H^{r-1}(\mathbb{S})$ is a Banach algebra. Then we obtain $B(t) \in L(H^{r-1}(\mathbb{S}))$.

To this end, (see Lemmas 3.1–3.3 in [13]) we first need to prove that the family $A(t)$ has a unique evolution operator $\{U(t,\tau)\}$ associated with the spaces $X = H^h(\mathbb{S})$ and $Y = H^k(\mathbb{S})$, where $-r \le h \le r-2$, $1-r \le k \le r-1$, and $k \ge h+1$. Therefore, according to the proof of Lemma 3.1 in [13], we need to verify the following three conditions.

(i) $A(t) \in G(H^h(\mathbb{S}), 1, \beta)$ for all $y \in H^r(\mathbb{S})$.

(ii) $\Lambda^h \partial_x [\Lambda^{k-h}, u]\Lambda^{-k}$ is uniformly bounded on $L^2(\mathbb{S})$.

(iii) $A(t) \in L(H^k(\mathbb{S}), H^h(\mathbb{S}))$ is strongly continuous in t.

Let us begin by verifying condition (i). Due to $H^h(\mathbb{S})$ being a Hilbert space, $A(t) \in G(H^h(\mathbb{S}), 1, \beta)$ [14] if and only if there is a real number β such that

(1) $(A(t)y, y)_h \ge -\beta\|y\|_h^2$,

(2) $-A(t)$ is the infinitesimal generator of a C_0-semigroup on $H^h(\mathbb{S})$, for some (or all) $\lambda > \beta$.

First, we prove (1). Take $y \in H^h(\mathbb{S})$. Note that

$$\begin{aligned}\Lambda^h \partial_x(u\,y) &= \Lambda^h \partial_x(-[\Lambda^{-h}, u]\Lambda^h y + \Lambda^{-h}(u\Lambda^h y)) \\ &= -\Lambda^h \partial_x[\Lambda^{-h}, u]\Lambda^h y + \partial_x(u\Lambda^h y).\end{aligned}$$

Then we have

$$\begin{aligned}(A(t)y, y)_h &= (-\Lambda^h \partial_x[\Lambda^{-h}, u]\Lambda^h y + \partial_x(u\Lambda^h y), \Lambda^h y)_0 \\ &= (\Lambda^{h+1}[\Lambda^{-h}, u]\Lambda^h y, \partial_x \Lambda^{h-1} y)_0 + \frac{1}{2}(u_x \Lambda^h y, \Lambda^h y)_0 \\ &\le \|\Lambda^{h+1}[\Lambda^{-h}, u]\|_{L(L^2(\mathbb{S}))}\|\Lambda^h y\|_0^2 + \frac{1}{2}\|u_x\|_{L^\infty(\mathbb{S})}\|\Lambda^h y\|_0^2 \\ &\le c\|u\|_r \|y\|_h^2,\end{aligned}$$

where we applied Lemma 2.4 with $s = -(h+1)$, $t = 0$. Setting $\beta = c\|u\|_r$, we have $(A(t)y, y)_h \ge -\beta\|y\|_h^2$.

Second, we prove (2). Let $S = \Lambda^{r-1-h}$. Note that S is an isomorphism of $H^{r-1}(\mathbb{S})$ onto $H^h(\mathbb{S})$ and that $H^{r-1}(\mathbb{S})$ is continuously and densely embedded in $H^h(\mathbb{S})$ as $-r \le h \le r-2$. Define

$$\begin{aligned}A_1(t) &:= SA(t)S^{-1} = \Lambda^{r-1-h} A(t) \Lambda^{h+1-r}, \\ B_1(t) &:= A_1(t) - A(t) = [S, A(t)]S^{-1}.\end{aligned}$$

Let $y \in H^h(\mathbb{S})$ and $u \in H^r(\mathbb{S})$, $r > \frac{3}{2}$. Then we have

$$\begin{aligned}\|B_1(t)y\|_h &= \|\Lambda^h \partial_x[\Lambda^{r-1-h}, u]\Lambda^{h+1-r} y\|_0 \\ &\le \|\Lambda^h \partial_x[\Lambda^{r-1-h}, u]\Lambda^{1-r}\|_{L(L^2(\mathbb{S}))}\|\Lambda^h y\|_0 \\ &\le c\|u\|_r \|y\|_h,\end{aligned}$$

where we applied Lemma 2.4 with $s = -(h+1)$, $t = r-1$. Therefore, we obtain $B_1(t) \in L(H^h(\mathbb{S}))$. Note that

$$A(t)y = \partial_x(uy) = u_x y + u\partial_x y \quad \text{and} \quad u_x \in L(H^{r-1}(\mathbb{S})).$$

By applying Lemma 2.7 and a perturbation theorem for semigroups, we obtain that $H^{r-1}(\mathbb{S})$ is $A(t)$-admissible. Then, by applying Lemma 2.5 with $Y = H^{r-1}(\mathbb{S})$, $X = H^h(\mathbb{S})$, and $S = \Lambda^{r-1-h}$, we get that $-A_1(t)$ is the infinitesimal generator of a C_0-semigroup on $H^h(\mathbb{S})$. Note that $A_1(t) = A(t) + B_1(t)$ and $B_1(t) \in L(H^h(\mathbb{S}))$. By a perturbation theorem for semigroups, we have that $-A(t)$ is the infinitesimal generator of a C_0-semigroup on $H^h(\mathbb{S})$. This proves (b).

Next, we verify (ii). Take $y \in L^2(\mathbb{S})$. Then

$$\|\Lambda^h \partial_x[\Lambda^{k-h}, u]\Lambda^{-k} y\|_0 \le c\|u\|_s \|y\|_0,$$

where we applied Lemma 2.4 with $s = -(h+1)$, $t = k$.

Finally, we verify (iii). Take $y \in H^k(\mathbb{S})$. Then

$$\begin{aligned}\|(A(t+\tau) - A(t))y\|_h &= \|\partial_x((u(t+\tau) - u(t))y)\|_h \\ &\le \|(u(t+\tau) - u(t))y\|_{h+1} \\ &\le c\|u(t+\tau) - u(t)\|_{s-1}\|y\|_{h+1} \\ &\le c\|u(t+\tau) - u(t)\|_s \|y\|_k,\end{aligned}$$

where we applied Lemma 2.3 with $s = r-1$, $t = h+1$. So, by the continuity of u, we prove (iii). Thus, the above three conditions imply the existence and uniqueness of evolution operator $U(t,\tau)$ for the family $A(t)$. In particular $U(t,\tau)$ maps $H^s(\mathbb{S})$ into itself for $-r \le s \le r-1$.

Next, choosing $Y = H^{r-2}(\mathbb{S})$, $X = H^{r-3}(\mathbb{S})$, note that

$$y \in C([0,T); H^{r-1}(\mathbb{S})) \bigcap C^1([0,T); H^{r-2}(\mathbb{S})),$$

and by the properties of evolution operator $U(t,\tau)$, we can obtain

$$\frac{d}{d\tau}(U(t,\tau)y(\tau)) = -U(t,\tau)B(\tau)y(\tau).$$

An integration in $\tau \in [0,t]$ yields

$$y(t) = U(t,0)y(0) - \int_0^t U(t,\tau)B(\tau)y(\tau)d\tau. \tag{2.5}$$

If $r < r' \le r+1$, then we have that $B(t) = u_x(t) \in L(H^{r'-2}(\mathbb{S}))$ is strongly continuous in $[0,t)$, and

$$H^{r-1}(\mathbb{S})H^{r'-2}(\mathbb{S}) \subset H^{r'-2}(\mathbb{S})$$

by $r-1 > \frac{1}{2}$. Due to $-r < r-2 < r'-2 \le r-1$, the family $\{U(t,\tau)\}$ is strongly continuous on $H^{r'-2}(\mathbb{S})$ to itself. Note that $y(0) \in H^{r'-2}(\mathbb{S})$. Let us regard (2.5) as an integral equation of Volterra type which can be solved for y by successive approximation. Then the result of Theorem 2.11 is obtained.

If $r' > r+1$, then we obtain the result of Theorem 2.11 by repeating the application of the above argument. This completes the proof of Theorem 2.11. □

From (2.3), we see that if $h_1(t) \not\equiv h_2(t)$, then the corresponding solutions to (2.3) with the same initial data satisfy $u_{h_1}(t) \not\equiv u_{h_2}(t)$. Thus, for each initial data $u_0 \in H^r$, $r > \frac{3}{2}$, there exists an entire corresponding family of solutions to (1.1).

As a consequence of Theorems 2.2 and 2.11, we have the following.

THEOREM 2.12. *Given $u_0 \in H^r(\mathbb{S})$, $r > \frac{3}{2}$. Then there exists locally a family of solutions to* (1.1)*. Moreover, the maximal existence time T of each solution in the family can be chosen independent of r.*

Remark 2.13. If $u_0(x)$ is a constant, then the solution to equation (1.1) is of the form $u(t,x) = H(t)$ with $H \in C^1([0,T))$ for some $T > 0$ and $H(0) = u_0$. Because $\int_{\mathbb{S}} u_x^2(t,x)dx = 0$, it follows that $u_x(t,x) \equiv 0$.

3. Blow-up. In this section, we discuss the question of finite time blow-up of solutions to (1.1) with arbitrary initial data.

In our investigation we will use the following result.

LEMMA 3.1 (see [4]). *Let $T > 0$ and $v \in C^1([0,T); H^2(\mathbb{R}))$. Then for every $t \in [0,T)$, there exists at least one point $\xi(t) \in \mathbb{R}$ with*

$$m(t) := \inf_{x \in R}[v_x(t,x)] = v_x(t,\xi(t)).$$

The function $m(t)$ is absolutely continuous on $(0,T)$ with

$$\frac{dm}{dt} = v_{tx}(t,\xi(t)) \quad \textit{a.e. on } (0,T).$$

Let us now prove the following lemma.

LEMMA 3.2. *If $u_0 \in H^r$, $r \geq 3$, then as long as the solution $u(t,x)$ given by Theorem* 2.12 *exists, we have*

$$\int_{\mathbb{S}} u_x^2(t,x)dx = \int_{\mathbb{S}} u_{0,x}^2(x)dx.$$

Proof. Multiplying (1.1) by u and integrating with respect to x, in view of the periodicity of u, we get

$$\begin{aligned} -\frac{1}{2}\frac{d}{dt}\int_{\mathbb{S}} u_x^2 dx &= -\int_{\mathbb{S}} u_{tx}u_x\,dx = \int_{\mathbb{S}} u_{txx}u\,dx \\ &= -\int_{\mathbb{S}} 2u_x u_{xx}u\,dx - \int_{\mathbb{S}} u^2 u_{xxx}dx \\ &= -\int_{\mathbb{S}} 2u_x u_{xx}u\,dx + \int_{\mathbb{S}} 2u_x u_{xx}u\,dx = 0. \end{aligned}$$

Thus, we have

$$\int_{\mathbb{S}} u_x^2(t,x)\,dx = \int_{\mathbb{S}} u_x^2(0,x)\,dx.$$

This completes the proof of Lemma 3.2. □

We now present the following blow-up theorem.

THEOREM 3.3. *Assume that $u_0 \in H^r$, $r \geq 3$, and u_0 is not a constant. Then the corresponding solution to* (2.3) *blows up in finite time.*

Proof. Let $T > 0$ be the maximal existence time of the solution $u(t,\cdot)$ of (2.3) with initial data $u_0 \in H^3(\mathbb{S})$. By (2.2) and Lemma 3.2, we have

$$u_{tx} = -uu_{xx} - \frac{1}{2}u_x^2 - \frac{1}{2}\int_{\mathbb{S}} u_{0,x}^2(x)dx \quad \text{a.e. } t > 0. \tag{3.1}$$

Define $m(t) = u_x(t,\xi(t)) = \inf_{x\in R}\{u_x(t,x)\}$. Since we deal with a minimum, $u_{xx}(t,\xi(t)) = 0$ for all $t \in [0,T)$. We obtain

$$m'(t) = -\frac{1}{2}m^2(t) - \frac{1}{2}\int_{\mathbb{S}} u_{0,x}^2(x)dx \quad \text{a.e. } t > 0. \tag{3.2}$$

By the above equality, we can get

$$m(t) \leq m(0) - t\frac{1}{2}\int_{\mathbb{S}} u_{0,x}^2(x)dx, \quad t \geq 0.$$

Since $u_0(x)$ is not a constant, it follows that $\frac{1}{2}\int_{\mathbb{S}} u_{0,x}^2(x)dx > 0$. Therefore, there is some $t_0 \geq 0$ such that $m(t) < 0$ for $t \geq t_0$. On the other hand, by (3.2) we have

$$m'(t) \leq -\frac{1}{2}m^2(t) \quad \text{a.e. } t \geq t_0.$$

Thus, it follows that

$$0 > \frac{1}{m(t)} \geq \frac{t-t_0}{2} + \frac{1}{m(t_0)}, \quad t \geq t_0.$$

This forces $T < \infty$ and completes the proof of Theorem 3.3. □

To describe the blow-up mechanism, let us observe that the H^1-norm of the solution does not blow up in finite time. Indeed, multiplying (2.3) by $2u$ and integrating over the unit circle, we obtain that for all $t \in (0,T)$, where $T > 0$ is the maximal existence time of a solution to (2.3) with the initial data $u_0 \in H^r$, $r \geq 3$,

$$\begin{aligned}\frac{d}{dt}\int_{\mathbb{S}} u^2\,dx &= 2\int_{\mathbb{S}} u\partial_x^{-1}\left(\frac{1}{2}u_x^2 + a\right)\,dx + 2h(t)\int_{\mathbb{S}} u\,dx\\ &\leq \int_{\mathbb{S}} u^2\,dx + \int_{\mathbb{S}}\left[\partial_x^{-1}\left(\frac{1}{2}u_x^2 + a\right)\right]^2\,dx + |h(t)|\left[1 + \int_{\mathbb{S}} u^2\,dx\right]\\ &\leq |h(t)| + (1 + |h(t)|)\int_{\mathbb{S}} u^2\,dx + \int_0^1\left(\frac{1}{2}u_x^2 + |a|\right)\,dx\\ &= |h(t)| + (1 + |h(t)|)\int_{\mathbb{S}} u^2\,dx + |a| + \frac{1}{2}\int_0^1 u_{0,x}^2\,dx, \quad t \in (0,T),\end{aligned}$$

where we use Lemma 3.2 in the last step. By Gronwall's inequality, we infer that the L^2-norm of the solution does not blow up in finite time. Considering this in combination with Lemma 3.2, we see that the H^1-norm of any solution to (2.3) with initial data $u_0 \in H^r$, $r \geq 3$, does not blow up in finite time. However, if u_0 is not a constant, then the proof of Theorem 3.3 shows that $\inf u_x(t,\cdot) \to -\infty$ in finite time. We have therefore a weak type of singularity, similar to the case of the Camassa–Holm equation (see [3]) of which (1.1) is the high-frequency limit. As pointed out in the introduction, the blow-up can be interpreted as an altering of the director field from its original state.

As a consequence of Theorem 3.3, and in view of the connection between the family of solutions to (1.1) and the solution to (2.3), we have the following result.

THEOREM 3.4. *Assume that $u_0 \in H^r$, $r \geq 3$, and u_0 is not a constant. Then the corresponding solutions to* (1.1) *blow up in finite time.*

Remark 3.5. Although the Hunter–Saxton equation is the high-frequency limit [7, 10] of the Camassa–Holm equation [2], the structure of its solutions is different. While there are global smooth solutions of the periodic Camassa–Holm [3] with a genuine dependence on the spatial variable, Theorem 3.4 and Remark 2.13 show that the only global solutions of (1.1) are those independent of the spatial variable.

Acknowledgments. This work was performed while the author was a Visiting Researcher at the University of Hanover. The author thanks the referees for their valuable comments and helpful suggestions.

SCATTERED-DATA INTERPOLATION ON $\mathbb{R}$: ERROR ESTIMATES FOR RADIAL BASIS AND BAND-LIMITED FUNCTIONS*

FRANCIS J. NARCOWICH† AND JOSEPH D. WARD†

Abstract. Error estimates for scattered-data interpolation via radial basis functions (RBFs) for target functions in the associated reproducing kernel Hilbert space (RKHS) have been known for a long time. However, apart from settings where data is gridded, these estimates do not apply when the target functions generating the data are outside of the associated RKHS, and, in fact, no estimates were known in such situations. In this paper, we deal with these cases, obtaining Sobolev-type error estimates on compact regions of $\mathbb{R}^n$ when the RBFs have Fourier transforms that decay algebraically. In addition, we show that it is possible to construct band-limited interpolants that are also near-best approximants to such functions, with the band size being inversely proportional to the minimal separation of the data sites.

Key words. interpolation, scattered data, radial basis functions, band-limited functions, error estimates

1. Introduction.

The problem of effectively representing an underlying function based on its values sampled at finitely many distinct scattered sites $X = \{x_1, \ldots, x_N\}$ lying in a compact region $\Omega \subset \mathbb{R}^n$ is important and arises in many applications—neural networks, computer aided geometric design, and gridless methods for solving partial differential equations, to name a few. A good example of the type of problem we have in mind is addressed in a recent paper by Carr et al. [6]. There, the authors used radial basis function (RBF) interpolation to reconstruct three-dimensional objects from "clouds" of points. Handling the large numbers of points was aided by new, fast evaluation techniques for RBFs [3].

The problem of representing a multivariate function by interpolating at scattered values is a difficult one. RBFs were introduced as a means to attack this problem. An RBF is a radial function $\Phi(x) = \Phi(|x|)$ that is either positive definite or conditionally positive definite on $\mathbb{R}^n$. Interpolants for multivariate functions sampled at scattered sites are constructed from translates of RBFs, with the possible addition of a polynomial term (see section 4 for details).

It was Duchon [7, 8] who introduced a type of RBF, the thin-plate spline, which he constructed via a variational technique similar to those used to obtain ordinary splines. The error analysis he provided for thin-plate splines involved reproducing kernel Hilbert space (RKHS) methods. Later, there were important contributions by Madych and Nelson [13] and Wu and Schaback [24], who also used RKHS methods to obtain scattered-data interpolation error estimates for a wide class of RBFs, including the Hardy multiquadrics and the Gaussians.

Important as these results are, they do suffer from a common difficulty. In all cases, convergence is proved only for functions in an RKHS that depends on Φ: the smoother the function Φ, the smaller the RKHS for which convergence estimates

apply. This restriction has seemed artificial, especially in light of both the lattice-based least-squares theory, which was completely and satisfactorily solved in [4], and the work of Schaback [19] dealing with pure approximation by RBFs. Indeed, Yoon [25] also noted this problem and introduced scaled RBFs in which a parameter λ is required to depend on the spacing of the data. In effect, the radial function is changing with the data.

In a recent paper [17], we dealt with these issues when the domain of the underlying function is the n-sphere, rather than $\mathbb{R}^n$, and the interpolants were derived from selected "translates" of spherical basis functions (SBFs). In particular, interpolatory error estimates were established for functions lying *outside* the RKHS for a wide variety of SBFs.

In this paper, we turn to the historically more important (and more difficult) $\mathbb{R}^n$ case, with the interpolants being derived from RBFs whose "centers" come from X. We start with samples $f|_X$ of a function $f \in C^k(\mathbb{R}^n) \cap W_2^k(\mathbb{R}^n)$ that decays to 0 at infinity but that may *not* be smooth enough to be in the RKHS associated with the RBF Φ. (If the target function f is defined only on Ω, then it may be necessary to extend it to all of $\mathbb{R}^n$. See the comments at the end of section 4.2.) For algebraic decay, i.e., $\hat{\Phi}(\xi) \sim |\xi|^{-2r}$, the RKHS is essentially $W_2^r(\mathbb{R}^n)$, so we assume that $k \leq r$. Let $I_X f$ be the RBF interpolant for f. We show that

$$\|D^\alpha f - D^\alpha f\|_{L^\infty(\Omega)} \leq C h^{k-|\alpha|-\frac{n}{2}} \|f\|_{C_0^k \cap W_2^k},$$

provided the sites X cover Ω in an approximately uniform manner and the multi-index satisfies $|\alpha| < k - \frac{n}{2}$. (The parameter h is a mesh norm.) The precise results are given in section 4.2. Prior to this, no estimates were known for $k \leq r$. Our results apply to both the thin-plate splines and to Wendland's class of compactly supported RBFs.

The first step to orchestrating this "escape" from the RKHS setting is showing that it is possible to use band-limited functions simultaneously to approximate and to interpolate an unknown, continuous, square-integrable function f that decays to 0 at infinity. This step is in a sense connected with irregular sampling theory [2]; of course, it differs in that samples $f|_X$ of f are taken on a *finite* set rather than an infinite one. In section 3.1, using functional analytic techniques, we show that there *is* a band-limited function f_σ, where $\operatorname{supp} \hat{f}_\sigma$ is contained in a ball of radius σ, that satisfies $f_\sigma|_X = f_X$ and that approximates f nearly optimally. The only requirement is that the size of the band or "Nyquist frequency" be inversely proportional to the minimal separation of points in X. The second step, taken in section 3.2, is obtaining Jackson-type estimates on distances to spaces of band-limited functions for $f \in C_0^k \cap W_2^k$ and then applying them (section 3.3) to bound the difference $f - f_\sigma$ in the appropriate norm. The last step makes use of these facts: both f and f_σ have the same RBF interpolant, because $f|_X = f_\sigma|_X$, and they have a comparable W_2^k norm. This allows us to deal with $\|D^\alpha f_\sigma - D^\alpha I_X f_\sigma\|$ in place of $\|D^\alpha f - D^\alpha I_X f\|$ and thus permits us to employ known RKHS estimates.

The main results of this paper may be viewed in two ways. From the theoretical point of view, they provide a much larger class of functions for which interpolation error estimates apply. From a practical point of view, they allow more flexibility in the choice of RBFs when applied for collocation purposes and faster convergence rates of interpolants away from singularities of the target function. This may even make possible using RBF methods for singularity detection. In addition, with a little more work, our methods should yield error estimates for discrete least-squares approximation by scattered shifts. We remark that in the situation of continuous least

squares over a domain without boundary, the least-squares approximation problem by shifts of Φ can be recast as an interpolation problem involving shifts of $\Phi * \bar{\Phi}$.

The remainder of the paper is organized as follows. In the next section, we provide the notation and set forth conventions we use throughout the paper. In section 3, we construct a band-limited function that both interpolates and is a near-best approximant to a given continuous L^2 function sampled on X. In addition, we use the Calderón formula to obtain Jackson-type estimates for this interpolant/approximant, provided the target function is in $C_0^k \cap W_2^k$. Finally, in the last section, we establish error estimates for interpolation via RBFs whose Fourier transforms decay algebraically.

2. Notation.

The set of centers. Let $X = \{x_j\}_{j=1}^N$ be a finite subset of $\mathbb{R}^n$, with the points all assumed to be distinct. There are two useful lengths associated with X. The first is the diameter of X, $\operatorname{diam}(X) = \max_{j,k} \|x_j - x_k\|_2$, which is the maximum distance between points in X. Throughout the paper, we will assume that $\operatorname{diam}(X) \leq 1$. The other length is the *separation radius*,

$$q = q_X := \frac{1}{2} \min_{j \neq k} \|x_j - x_k\|_2 \,,$$

which is half of the smallest distance between any two distinct points in X. Clearly, $q \leq \frac{1}{2}\operatorname{diam}(X) \leq \frac{1}{2}$. The set X is itself contained in an n-cube with sides of length $\operatorname{diam}(X) \leq 1$. The union of X, together with the closed balls $B(x_j, q)$ having centers $x_j \in X$ and radius q, can be enclosed in an n-cube with sides of length $\operatorname{diam}(X)+2q \leq 2$. The number of points in X, N can be estimated in terms of the volume of this second cube:

$$N \leq \frac{2^n}{\operatorname{vol}(B(0,q))} = \frac{\Gamma(\frac{n+2}{2})2^n}{\pi^{\frac{n}{2}} q^n}. \tag{1}$$

The region Ω. We take Ω to be a compact, connected region in $\mathbb{R}^n$ that satisfies the *uniform interior cone condition* [11]; i.e., there exists a fixed (open) cone $K \subset \mathbb{R}^n$ such that each $x \in \partial\Omega$ is the vertex of a cone $K_x \subset \Omega$ that is congruent to K. The *mesh norm* for X relative to Ω is

$$h = h_{X,\Omega} := \sup_{x \in \Omega} \inf_{x_j \in X} \|x - x_j\|_2 \,;$$

it measures the maximum distance any point in Ω can be from X. It is easy to see that $h_{X,\Omega} \geq q_X$; equality can hold only for a uniform distribution of points on an interval in $\mathbb{R}^1$. The *mesh ratio*

$$\rho = \rho_{X,\Omega} := h/q \geq 1$$

provides a measure of how uniformly points in X are distributed in Ω. When Ω is an interval ($n = 1$), $\rho = 1$ means that the points are uniformly distributed. In all other cases, $\rho > 1$.

Conventions. Our conventions for the Fourier transform and its inverse are

$$\hat{f}(\xi) := \int_{\mathbb{R}^n} f(x) e^{-i\xi\cdot x} d^n x \quad \text{and} \quad \check{f}(x) = \frac{1}{(2\pi)^n} \int_{\mathbb{R}^n} f(\xi) e^{i\xi\cdot x} d^n \xi.$$

We will make use of the Sobolev space $W_2^k = W_2^k(\mathbb{R}^n)$, which is defined to be all $f \in L^2$ having distributional derivatives $D^\alpha f$, $|\alpha| \leq k$, in L^2. The norm that we will

use here is

$$\|f\|_{W_2^k} = \left(\int_{\mathbb{R}^n} (1 + |\xi|^2)^k |\hat{f}(\xi)|^2 d^n\xi \right)^{\frac{1}{2}}.$$

We will denote by $C_0^k = C_0^k(\mathbb{R}^n)$ the set of all functions that are continuously differentiable through order k, that vanish at infinity, and that have all derivatives of order k or less bounded. Of course, $C_0^0 = C_0$ and $C_0^k = C_0(\mathbb{R}^n) \cap C_B^k(\mathbb{R}^n)$. We will use $\mathcal{S}$ to denote Schwartz space and $\mathcal{S}'$ to denote the space of tempered distributions.

Frequently, we will deal with the intersection of two function spaces, for example $C_0 \cap L^2$ or $C_0^k \cap W_2^k$. In these cases, the norm on the intersection will be the maximum of the norm on each space: if $\mathcal{X}$ and $\mathcal{Y}$ are normed spaces of functions, then on the intersection space $\mathcal{X} \cap \mathcal{Y}$ we will always use the norm

$$\|f\|_{\mathcal{X}\cap\mathcal{Y}} := \max\left(\|f\|_{\mathcal{X}}, \|f\|_{\mathcal{Y}}\right).$$

Finally, for an integer $k \geq 0$, we will denote the polynomials of total degree k on $\mathbb{R}^n$ by $\pi_k(\mathbb{R}^n)$. For $k = -1$, we will let $\pi_{-1}(\mathbb{R}^n) = \{0\}$.

3. Band-limited functions. We discuss interpolation and approximation in the Paley–Wiener class of band-limited functions. Since we are dealing with a multi-dimensional space, we will interpret the transform variable ξ as a wavenumber having units of reciprocal length. Let $\sigma > 0$. We then define $\mathcal{B}_\sigma$ to be

$$\mathcal{B}_\sigma := \{f \in L^2(\mathbb{R}^n) \colon \operatorname{supp}(\hat{f}) \subseteq B(0,\sigma)\},$$

where $B(0,\sigma)$ is the (closed) ball in $\mathbb{R}^n$ having center 0 and radius σ. (In optics, σ denotes the spectroscopic wavenumber and is the reciprocal of the wavelength.)

Functions in $\mathcal{B}_\sigma$ are, of course, in L^2 and are continuous. Moreover, they decay to 0 as $|x| \to \infty$. A natural class of functions that includes all $\mathcal{B}_\sigma$ is $C_0 \cap L^2 := C_0(\mathbb{R}^n) \cap L^2(\mathbb{R}^n)$. We can make this a Banach space by employing the norm

$$\|f\|_{C_0\cap L^2} = \max(\|f\|_\infty, \|f\|_2).$$

3.1. Approximation and interpolation from $\mathcal{B}$. The main goal of this section is to show that we can both approximate and interpolate functions in $C_0 \cap L^2$ on X by means of band-limited functions in $\mathcal{B}_\sigma$ if we take $\sigma \sim 1/q$. In finite-dimensional settings, similar problems for interpolation and approximation by polynomials go back to the work of Erdös [9], and problems for trigonometric polynomials on the circle and spherical harmonics on the n-sphere were discussed in [14, 17]. The case of $\mathcal{B}_\sigma$, which is infinite dimensional, is dealt with here.

We begin with the proposition below, which is stated in terms of Banach spaces; in it we show that the problem of finding interpolants that are also near-best approximants can be solved if we can uniformly bound the ratio of the norm of a linear functional to the norm of its restriction to a smaller space.

PROPOSITION 3.1. *Let $\mathcal{Y}$ be a (possibly complex) Banach space, $\mathcal{V}$ be a subspace of $\mathcal{Y}$, and Z^* be a finite-dimensional subspace of $\mathcal{Y}^*$, the dual of $\mathcal{Y}$. If, for every $z^* \in Z^*$ and some $\beta > 1$, β independent of z^*,*

$$\|z^*\|_{\mathcal{Y}^*} \leq \beta \|z^*|_{\mathcal{V}}\|_{\mathcal{V}^*}, \tag{2}$$

then for $y \in \mathcal{Y}$ there exists $v \in \mathcal{V}$ such that v interpolates y on Z^*; that is, $z^*(y) = z^*(v)$ for all $z^* \in Z^*$. In addition, v approximates y in the sense that $\|y - v\|_{\mathcal{Y}} \leq (1 + 2\beta)\operatorname{dist}(y, \mathcal{V})$.

Proof. Given $\varepsilon > 0$, we can find $u \in \mathcal{V}$ for which

$$\|y - u\|_{\mathcal{Y}} = (1+\varepsilon)\text{dist}(y, \mathcal{V}).$$

Set $x := y - u$. Let the restriction map $S\colon\ Z^* \to Z^*|_{\mathcal{V}}$ be given by $S(z^*) = z^*|_{\mathcal{V}}$ for every $z^* \in Z^*$. By (2), S is both one-to-one and onto the image space $S(Z^*) \subset \mathcal{V}^*$. Moreover, $\|S^{-1}\| \le \beta$, where $S^{-1}\colon S(Z^*) \to Z^*$. Viewing x as an element of Z^{**} (i.e., as a functional on Z^*), we have

$$\langle x, z^* \rangle = \langle x, S^{-1}Sz^* \rangle = \langle (S^*)^{-1}x, Sz^* \rangle,$$

where we used the fact that $(S^{-1})^* = (S^*)^{-1}$. Note that $(S^*)^{-1}x$ is in $(S(Z^*))^*$, where $S(Z^*)$ is a finite-dimensional subspace of $\mathcal{V}^*$. By the Hahn–Banach theorem, $(S^*)^{-1}x$ extends in a norm preserving manner to $v_x^{**} \in \mathcal{V}^{**}$. Thus $\langle x, z^* \rangle = \langle y - u, z^* \rangle = \langle v_x^{**}, Sz^* \rangle$ for all $z^* \in Z^*$, and

$$\begin{aligned} \|v_x^{**}\|_{V^{**}} &= \|(S^*)^{-1}x\|_{V^{**}} \le \|S^{-1}\|\,\|x\|_{\mathcal{Y}} \le \beta\|y-u\|_{\mathcal{Y}} \\ &= \beta(1+\epsilon)\,\text{dist}(y, \mathcal{V}). \end{aligned}$$

We would be done if the spaces involved were reflexive, because then we would have v_x^{**} in $\mathcal{V}$, and we could simply set $v = u + v_x^{**}$. Unfortunately, the spaces of interest are *not* reflexive. However, the fact that Z^* is finite dimensional allows us to apply the *principle of local reflexivity* [12, p. 53], which states that for $\delta > 0$ we can find $v_x \in \mathcal{V}$ such that both $\langle v_x^{**}, z^* \rangle = \langle z^*, v_x \rangle$ for all $z^* \in Z^*$ and $\|v_x\| \le (1+\delta)\|v_x^{**}\|$. Setting $v := u + v_x$ gives an element in $\mathcal{V}$ that interpolates y on Z^* and satisfies

$$\begin{aligned} \|y - v\|_{\mathcal{Y}} &\le \|y-u\|_{\mathcal{Y}} + \|v_x\|_{\mathcal{Y}} \le \|y-u\|_{\mathcal{Y}} + (1+\delta)\|v_x^{**}\|_{\mathcal{V}^{**}} \\ &\le (1 + (1+\delta)\beta)\|y-u\|_{\mathcal{Y}} \\ &\le (1 + (1+\delta)\beta)(1+\varepsilon)\text{dist}(y, \mathcal{V}). \end{aligned}$$

To complete the proof, take $\delta < 1/5$ and $\varepsilon < 1/4$ and note that, because $\beta > 1$, we have $(1 + (1+\delta)\beta)(1+\varepsilon) < \frac{5}{4} + \frac{6}{4}\beta < 1 + 2\beta$. ∎

We are interested in the case in which $\mathcal{Y} = C_0 \cap L^2$, $Z^* = \text{span}\{\delta_{x_j}\colon x_j \in X\}$, and $\mathcal{V} = \mathcal{B}_\sigma$. To employ the proposition, the first thing that we need to do is find $\|z^*\|_{C_0 \cap L^{2*}}$ when $z^* := \sum_{x_j \in X} c_j \delta_{x_j} \in Z^*$.

We will use "bump" functions to do this. Let $g_R(x) = (1 - |x|/R)_+$. The support of g_R is the closed ball of radius R and center 0. It is easy to show that $\|g_R\|_2 = C_n R^{n/2}$ and $\|g_R\|_\infty = 1$. Next, we choose $R < \min\{q, (NC_n^2)^{-1/n}\}$, where q is the separation radius of X. Also, take $d_j = \bar{c}_j/|c_j|$ if $c_j \neq 0$ and set $d_j = 1$ if $c_j = 0$. The supports of the $g_R(x - x_j)$'s, $x_j \in X$, are then all disjoint and for $f(x) = \sum_j d_j\, g_R(x - x_j)$ we have

$$\langle z^*, f \rangle = \sum_{j,k} c_k d_j g_R(x_k - x_j) = \sum_j c_j d_j = \sum_j |c_j|.$$

In addition, we have $\|f\|_\infty = 1$ and $\|f\|_2 = N^{1/2}\|g_R\|_2 = C_n R^{n/2} N^{1/2} < 1$. Consequently, $\|f\|_{C_0 \cap L^2} = 1$, and $\langle z^*, f \rangle = \sum_j |c_j| = (\sum_j |c_j|)\|f\|_{C_0 \cap L^2}$. It follows that $\|z^*\|_{C_0 \cap L^{2*}} \ge \sum_j |c_j|$. On other hand, we have that $|\langle z^*, f \rangle| \le (\sum_j |c_j|)\|f\|_\infty \le (\sum_j |c_j|)\|f\|_{C_0 \cap L^2}$. We arrive at the following lemma.

LEMMA 3.2. *If $z^* := \sum_{x_j \in X} c_j \delta_{x_j} \in Z^*$, then*

$$\|z^*\|_{C_0 \cap L^{2*}} = \sum_j |c_j|. \tag{3}$$

The next step in showing that we can both interpolate and approximate with band-limited functions is to estimate $\|z^*|_{\mathcal{B}_\sigma^*}\|_{\mathcal{B}_\sigma^*}$. The approach we take runs parallel to the one above but is technically more difficult because we must work with functions in $\mathcal{B}_\sigma$, all of which are analytic and thus *not* compactly supported. Fortunately, many of the computations required were done in [16, section 3]. Indeed, we summarize what we need below, with appropriate adaptations to our current notation.

We begin by noting that if $\chi_{\frac{\sigma}{2}}(\xi)$ is the characteristic function for the ball $B(0,\sigma/2)$, then its inverse Fourier transform is given by [16, eq. (3.9)]

$$\check{\chi}_{\frac{\sigma}{2}}(x) = \left(\frac{\sigma}{4\pi|x|}\right)^{\frac{n}{2}} J_{\frac{n}{2}}\left(\frac{|x|\sigma}{2}\right),$$

where one also has [16, eq. (3.10)]

$$\check{\chi}_{\frac{\sigma}{2}}(0) = \frac{\left(\frac{\sigma}{(4\sqrt{\pi})}\right)^n}{\Gamma(\frac{n+2}{2})}.$$

We define φ_σ via

$$\varphi_\sigma := \check{\chi}^2_{\frac{\sigma}{2}} = (2\pi)^{-n}(\chi_{\frac{\sigma}{2}} * \chi_{\frac{\sigma}{2}})^{\check{}}, \tag{4}$$

where the second equality follows from the convolution theorem. We also have from the expression for $\check{\chi}(0)$ that

$$\varphi_\sigma(0) = \frac{\left(\frac{\sigma}{(4\sqrt{\pi})}\right)^{2n}}{\Gamma(\frac{n+2}{2})^2}. \tag{5}$$

Because the support of $\chi_{\frac{\sigma}{2}}$ is $B(0,\sigma/2)$, we have $\operatorname{supp}(\chi_{\frac{\sigma}{2}} * \chi_{\frac{\sigma}{2}}) \subset B(0,\sigma)$. This, of course, implies that $\varphi_\sigma \in \mathcal{B}_\sigma$ and that

$$\Upsilon(x) := \sum_{j=1}^{N} \varphi_\sigma(x - x_j) \in \mathcal{B}_\sigma. \tag{6}$$

LEMMA 3.3. *If* $z^* := \sum_{x_j \in X} c_j \delta_{x_j} \in Z^*$, *then*

$$\|z^*|_{\mathcal{B}_\sigma}\|_{\mathcal{B}_\sigma^*} \geq \left(\frac{\varphi_\sigma(0) - \max_k \sum_{j\neq k} \varphi_\sigma(x_j - x_k)}{\|\Upsilon\|_{C_0\cap L^2}}\right)\|z^*\|_{C_0\cap L^{2*}}. \tag{7}$$

Proof. Set $d_j = \bar{c}_j/|c_j|$ if $c_j \neq 0$ and $d_j = 1$ if $c_j = 0$. If we let

$$b_\sigma = \sum_{x_j \in X} d_j \varphi(x - x_j),$$

then we can compute $\langle z^*, b_\sigma\rangle$ using $z^* = \sum_{x_j\in X} c_j\delta_{x_j}$ and the definition of b_σ. What we obtain is $\langle z^*, b_\sigma\rangle = \sum_{j,k} c_j\, d_k \varphi_\sigma(x_j - x_k)$. We can then use this together with

$\sum_j c_j d_j = \sum_j |c_j|$ to obtain the following:

$$\begin{aligned}
|\langle z^*, b_\sigma\rangle| &= \left| \sum_j c_j\, d_j \varphi_\sigma(0) + \sum_{j\neq k} c_j\, d_k \varphi_\sigma(x_j - x_k)\right| \\
&\geq \left(\sum_j |c_j|\right)\varphi_\sigma(0) - \left| \sum_{j\neq k} c_j\, d_k \varphi_\sigma(x_j - x_k)\right| \\
&\geq \left(\sum_j |c_j|\right)\left(\varphi_\sigma(0) - \max_k \sum_{j\neq k} \varphi_\sigma(x_j - x_k)\right) \\
&\geq \|z^*\|_{C_0\cap L^{2*}}\left(\varphi_\sigma(0) - \max_k \sum_{j\neq k} \varphi_\sigma(x_j - x_k)\right), \qquad (8)
\end{aligned}$$

where the last inequality uses Lemma 3.2. Next, since $|d_j| = 1$, we have that b_σ satisfies

$$|b_\sigma(x)| \leq \sum_{x_j\in X} \varphi(x - x_j) = \Upsilon(x).$$

Thus, $\|b_\sigma\|_\infty \leq \|\Upsilon\|_\infty$ and $\|b_\sigma\|_2 \leq \|\Upsilon\|_2$, and, consequently,

$$\|b_\sigma\|_{C_0\cap L^2} \leq \|\Upsilon\|_{C_0\cap L^2}. \qquad (9)$$

Dividing both sides of (8) by $\|b_\sigma\|_{C_0\cap L^2}$ and then using (9) results in

$$\frac{|\langle z^*, b_\sigma\rangle|}{\|b_\sigma\|_{C_0\cap L^2}} \geq \left(\frac{\varphi_\sigma(0) - \max_k \sum_{j\neq k} \varphi_\sigma(x_j - x_k)}{\|\Upsilon\|_{C_0\cap L^2}}\right)\|z^*\|_{C_0\cap L^{2*}}.$$

Since $b_\sigma \in \mathcal{B}_\sigma$, the left-hand side above is bounded by $\|z^*|_{\mathcal{B}_\sigma}\|_{\mathcal{B}_\sigma^*}$. Using this bound in the last inequality results in (7). □

We will need estimates on sums of translates of φ_σ. This is the object of our next result.

PROPOSITION 3.4. *If $X = \{x_1, x_2, \ldots, x_N\} \subset \mathbb{R}^n$ is a set of N distinct points having separation radius q and satisfying* $\operatorname{diam}(X) \leq 1$, *then*

$$\max_k \sum_{j\neq k} \varphi_\sigma(x_j - x_k) \leq \varphi_\sigma(0)\frac{\pi\Gamma^2(\frac{n+2}{2})}{18}\left(\frac{\sigma q}{24}\right)^{-n-1}. \qquad (10)$$

In addition, if $\Upsilon(x) := \sum_{j=1}^N \varphi_\sigma(x - x_j)$, then we have

$$\|\Upsilon\|_{C_0\cap L^2} \leq \varphi_\sigma(0)\max\left(\frac{\Gamma(\frac{n+2}{2})8^{\frac{n}{2}}}{(\sigma q)^{\frac{n}{2}}}, 1\right)\left(1 + \frac{\pi\Gamma^2(\frac{n+2}{2})}{18}\left(\frac{\sigma q}{48}\right)^{-n-1}\right). \qquad (11)$$

Proof. The bound in (10) was actually established in [16, section III] and in [15, section IV] but with different notation. In [16], β corresponds to $\sigma/2$ and $\chi(x)/K$ to φ_σ. From [15, eqs. (4.4) and (4.11)],

$$\max_k \sum_{j\neq k} \varphi_\sigma(x_j - x_k) \leq 3^n \sum_{k=1}^\infty k^{n-1}\kappa_k := 3^n\Sigma.$$

The quantity Σ is estimated on [16, p. 96]. Adjusting the formula there by dividing by K and replacing β by $\sigma/2$, we obtain the bound in (10). To bound $\Upsilon(x)$, we first choose the point in $\{x_1, x_2, \ldots, x_N\}$ nearest to x. After renumbering, we may take this to be x_1, and we may rewrite the sum in Υ as

$$\Upsilon(x) = \varphi_\sigma(x - x_1) + \sum_{j=2}^{N} \varphi_\sigma(x - x_j).$$

The function φ_σ is a positive definite function, because $\chi_{\frac{\sigma}{2}} * \chi_{\frac{\sigma}{2}}$ is nonnegative. Consequently, $\varphi_\sigma(x - x_1) \le \varphi_\sigma(0)$. To bound the remaining terms in Υ, we first note that the separation radius for the set $\{x, x_2, \ldots, x_N\}$ is at least $\frac{1}{2}q$. Applying the bound in (10) to the remaining terms in Υ, while replacing q by $\frac{1}{2}q$, we obtain

$$\|\Upsilon\|_\infty \le \varphi_\sigma(0) \left(1 + \frac{\pi\Gamma^2(\frac{n+2}{2})}{18} \left(\frac{\sigma q}{48}\right)^{-n-1}\right). \tag{12}$$

Given this bound, we can get the bound on $\|\Upsilon\|_2$ this way. Note that $\|\Upsilon\|_1 = \sum_{j=1}^{N} \|\varphi_\sigma(x - x_j)\|_1 = N\|\varphi_\sigma\|_1$. Since $\varphi_\sigma = \check{\chi}^2_{\frac{\sigma}{2}} = (2\pi)^{-n}(\chi_{\frac{\sigma}{2}} * \chi_{\frac{\sigma}{2}})\hat{} \ge 0$, we see that

$$\|\varphi_\sigma\|_1 = \hat{\varphi}_\sigma(0) = (2\pi)^{-n}\chi_{\frac{\sigma}{2}} * \chi_{\frac{\sigma}{2}}(0) = (2\pi)^{-n}\|\chi_{\frac{\sigma}{2}}\|_2^2.$$

Moreover, $\chi_{\frac{\sigma}{2}}$ is a characteristic function; hence, $\chi^2_{\frac{\sigma}{2}} = \chi_{\frac{\sigma}{2}}$ and

$$(2\pi)^{-n}\|\chi_{\frac{\sigma}{2}}\|_2^2 = (2\pi)^{-n}\|\chi_{\frac{\sigma}{2}}\|_1 = \check{\chi}_{\frac{\sigma}{2}}(0) = \varphi_\sigma(0)^{\frac{1}{2}}.$$

Finally, we obtain

$$\|\varphi_\sigma\|_1 = \varphi_\sigma(0)^{\frac{1}{2}} \quad \text{and} \quad \|\Upsilon\|_1 = N\varphi_\sigma(0)^{\frac{1}{2}}. \tag{13}$$

Applying the standard inequality $\|\Upsilon\|_2 \le \left(\|\Upsilon\|_1\|\Upsilon\|_\infty\right)^{\frac{1}{2}}$ in conjunction with (12) and (13), we have that

$$\begin{aligned}\|\Upsilon\|_2 &\le \sqrt{\frac{N}{\varphi_\sigma(0)^{\frac{1}{2}}}}\,\varphi_\sigma(0)\left(1 + \frac{\pi\Gamma^2(\frac{n+2}{2})}{18}\left(\frac{\sigma q}{48}\right)^{-n-1}\right)^{\frac{1}{2}} \\ &\le \frac{\Gamma(\frac{n+2}{2})8^{\frac{n}{2}}}{(\sigma q)^{\frac{n}{2}}}\,\varphi_\sigma(0)\left(1 + \frac{\pi\Gamma^2(\frac{n+2}{2})}{18}\left(\frac{\sigma q}{48}\right)^{-n-1}\right)^{\frac{1}{2}}, \qquad (14)\end{aligned}$$

where in the last step we have used (1) and (5) to bound $\sqrt{N/\varphi_\sigma(0)^{\frac{1}{2}}}$. The final estimate (11) follows from taking the maximum of the right-hand sides of (12) and (14) and then using the fact that $x^{\frac{1}{2}} \le x$ when $x \ge 1$. □

We now come to the main result of this section.

THEOREM 3.5. *Let $X = \{x_1, x_2, \ldots, x_N\} \subset \mathbb{R}^n$ be a set of N distinct points having separation radius q and satisfying* $\operatorname{diam}(X) \le 1$, *and choose σ so that*

$$\sigma \ge \sigma_0 := \frac{24}{q}\left\{\frac{\sqrt{\pi}}{3}\Gamma\left(\frac{n+2}{2}\right)\right\}^{\frac{2}{n+1}}. \tag{15}$$

If $f \in C_0 \cap L^2$, there exists $f_\sigma \in \mathcal{B}_\sigma$ such that

$$f|_X = f_\sigma|_X \quad \textit{and} \quad \|f - f_\sigma\|_{C_0 \cap L^2} \le (5 + 2^{n+3})\operatorname{dist}_{C_0 \cap L^2}(f, \mathcal{B}_\sigma). \tag{16}$$

Proof. We made this choice of σ_0 so that

$$\frac{\pi\Gamma^2(\frac{n+2}{2})}{18}\left(\frac{24}{\sigma q}\right)^{n+1} \leq \frac{\pi\Gamma^2(\frac{n+2}{2})}{18}\left(\frac{24}{\sigma_0 q}\right)^{n+1} = \frac{1}{2}\,. \tag{17}$$

Thus, the inequality in (10) becomes

$$\max_k \sum_{j\neq k} \varphi_\sigma(x_j - x_k) \leq \frac{1}{2}\varphi_\sigma(0).$$

Inserting this on the right-hand side in (7) yields

$$\|z^*|_{\mathcal{B}_\sigma}\|_{\mathcal{B}_\sigma^*} \geq \left(\frac{\varphi_\sigma(0)}{2\|\Upsilon\|_{C_0\cap L^2}}\right)\|z^*\|_{C_0\cap L^{2^*}}\,. \tag{18}$$

We now need to estimate $\|\Upsilon\|_{C_0\cap L^2}$. First note that, since σ_0 satisfies the equation on the right-hand side in (17), we have

$$\frac{\Gamma(\frac{n+2}{2})8^{\frac{n}{2}}}{(\sigma q)^{\frac{n}{2}}} \leq \frac{\Gamma(\frac{n+2}{2})8^{\frac{n}{2}}}{(\sigma_0 q)^{\frac{n}{2}}} = \sqrt{\frac{\sigma_0 q}{8\pi 3^{n-1}}}\,.$$

With this and (17), the inequality in (11) becomes

$$\|\Upsilon\|_{C_0\cap L^2} \leq \varphi_\sigma(0)(1+2^n)\max\left\{\sqrt{\frac{\sigma_0 q}{8\pi 3^{n-1}}},\, 1\right\}\,. \tag{19}$$

Using $n = 1$ in (15), we have $\sigma_0 q = 4\pi$ and $\sigma_0 q/(8\pi 3^{1-1}) = \frac{1}{2} < 1$. To treat $n \geq 2$, consider the expression below for $\Gamma(x)$ [23, p. 253], which holds for $x > 0$:

$$\Gamma(x) = x^{x-\frac{1}{2}}e^{-x}(2\pi)^{\frac{1}{2}}e^{\frac{\theta}{12x}},\ \text{where } 0 < \theta = \theta(x) < 1.$$

Let $x = \frac{n+2}{2}$. Since $n \geq 2$, we have $x \geq 2$ and $\frac{\theta}{12x} < \frac{1}{24} < \frac{1}{2}$. Consequently,

$$\sqrt{\frac{2\pi}{e}}\left(\frac{n+2}{2e}\right)^{\frac{n+1}{2}} < \Gamma\left(\frac{n+2}{2}\right) < \sqrt{2\pi}\left(\frac{n+2}{2e}\right)^{\frac{n+1}{2}}\,.$$

Coupling this with (15) gives us

$$12e^{-1}\left(\frac{\sqrt{2}\pi}{3\sqrt{e}}\right)^{\frac{2}{n+1}}(n+2) < \sigma_0 q < 12e^{-1}\left(\frac{\sqrt{2}\pi}{3}\right)^{\frac{2}{n+1}}(n+2). \tag{20}$$

Using a little calculus along with the upper bound in (20), it is easy to show that $\sigma_0 q/(8\pi 3^{n-1}) < 1$. Thus, we arrive at our final bound on $\|\Upsilon\|_{C_0\cap L^2}$,

$$\|\Upsilon\|_{C_0\cap L^2} \leq \varphi_\sigma(0)(1+2^n). \tag{21}$$

Employing the bound above in (18) yields

$$\|z^*|_{\mathcal{B}_\sigma}\|_{\mathcal{B}_\sigma^*} \geq \left(\frac{1}{2+2^{n+1}}\right)\|z^*\|_{C_0\cap L^{2^*}}\,. \tag{22}$$

Equivalently, $\|z^*\|_{C_0\cap L^{2^*}} \leq (2+2^{n+1})\|z^*|_{\mathcal{B}_\sigma}\|_{\mathcal{B}_\sigma^*}$. Applying Proposition 3.1 then completes the proof. □

Remark. It is interesting to note that the connection between σ_0 and q given in (15) is asymptotically linear in the dimension n. Indeed, from (20), we easily derive this asymptotic formula. As $n \to \infty$, $\sigma_0 \sim 12e^{-1}(n+2)q^{-1}$.

3.2. Jackson-type estimates for $\mathcal{B}$. The purpose of this section is to provide estimates on $\operatorname{dist}_{C_0\cap L^2}(f,\mathcal{B}_\sigma)$ when f has certain smoothness properties. Nikolskii [18, section 5.2] obtains many of the results that we need, albeit implicitly and, unfortunately, less than transparently. For the convenience of the reader, we will obtain the results that we need here, employing methods[1] considerably different from those in [18].

The approach we take is based on the Calderón decomposition formula [5, 10], which essentially states that if $f \in L^2(\mathbb{R}^n)$, then

$$f = \int_0^\infty \bar{\psi}_t * \psi_t * f \,\frac{dt}{t},\ \ \psi_t(x) := t^{-n}\psi\left(\frac{x}{t}\right), \tag{23}$$

where $\psi \in L^1$ is an arbitrary radial function with a (radial) Fourier transform that satisfies $\int_0^\infty |\hat{\psi}(t|\xi|)|^2 \frac{dt}{t} = 1$ if $\xi \in \mathbb{R}^n \setminus \{0\}$. The integral in (23), which is improper, is understood as an L^2 limit of $\int_\epsilon^T \bar{\psi}_t * \psi_t * f \frac{dt}{t}$ as $T \to \infty$ and $\epsilon \to 0^+$ independently [10, Theorem 1.2].

We are interested in approximating f with

$$g_\sigma := \int_{\frac{1}{\sigma}}^\infty \bar{\psi}_t * \psi_t * f \,\frac{dt}{t}, \tag{24}$$

where on ψ we make the additional assumptions that ψ is in $\mathcal{S}$ and that $\operatorname{supp}(\hat{\psi}) \subset B(0,1)$ and that $\int_0^\infty |\hat{\psi}(t|\xi|)|^2 \frac{dt}{t^{1+r}} < \infty$ for all $r \geq 0$ and all $\xi \in \mathbb{R}^n \setminus \{0\}$. The first assumption implies that $\psi \in \mathcal{B}_1$ and the second that all moments of ψ vanish. From

$$\hat{g}_\sigma(\xi) = \hat{f}(\xi)\int_{\frac{1}{\sigma}}^\infty |\hat{\psi}(t|\xi|)|^2 \frac{dt}{t} = \hat{f}(\xi)\begin{cases} 0 & \text{if } |\xi| \geq \sigma, \\ \int_{\frac{|\xi|}{\sigma}}^1 |\hat{\psi}(t)|^2 \frac{dt}{t} & \text{if } |\xi| < \sigma, \end{cases} \tag{25}$$

it follows that $\operatorname{supp}(\hat{g}_\sigma) \subset B(0,\sigma)$, and so $g_\sigma \in \mathcal{B}_\sigma$. Since $\int_0^\infty |\hat{\psi}(t|\xi|)|^2 \frac{dt}{t} = 1$, we also have

$$\hat{f} - \hat{g}_\sigma = \hat{f}(\xi)\begin{cases} 1 & \text{if } |\xi| \geq \sigma, \\ \int_0^{\frac{|\xi|}{\sigma}} |\hat{\psi}(t)|^2 \frac{dt}{t} & \text{if } |\xi| < \sigma. \end{cases} \tag{26}$$

This leads to useful Sobolev norm estimates.

PROPOSITION 3.6. *Let $r \geq 0$ and $s \geq 0$. If $f \in W_2^{s+r}(\mathbb{R}^n)$, then*

$$\|f - g_\sigma\|_{W_2^s} \leq c_r \sigma^{-r} \|f\|_{W_2^{r+s}}, \tag{27}$$

where $c_r := \int_0^1 |\hat{\psi}(t)|^2 \frac{dt}{t^{1+r}}$.

Proof. Note that

$$\int_0^{\frac{|\xi|}{\sigma}} |\hat{\psi}(t)|^2 \frac{dt}{t} = \int_0^{\frac{|\xi|}{\sigma}} t^r |\hat{\psi}(t)|^2 \frac{dt}{t^{1+r}} \leq \left(\frac{|\xi|}{\sigma}\right)^r \int_0^1 |\hat{\psi}(t)|^2 \frac{dt}{t^{1+r}}.$$

Since $c_r \geq c_0 = 1$, from (26) and the previous inequality we have

$$\begin{aligned}(1+|\xi|^2)^{\frac{s}{2}}|\hat{f} - \hat{g}_\sigma| &\leq c_r \sigma^{-r}(1+|\xi|^2)^{\frac{s}{2}}|\xi|^r |\hat{f}(\xi)| \\ &\leq c_r \sigma^{-r}(1+|\xi|^2)^{\frac{s+r}{2}}|\hat{f}(\xi)|.\end{aligned}$$

[1] The authors wish to thank Professor W. R. Madych for pointing these methods out to us.

Taking the L^2 norms of both sides above yields (27). □

We now require L^∞ bounds on derivatives $D^\alpha f - D^\alpha g_\sigma$, where α is a multi-index of nonnegative integers and $D^\alpha = (\frac{\partial}{\partial x_1})^{\alpha_1} \cdots (\frac{\partial}{\partial x_n})^{\alpha_n}$. These we will use in conjunction with our bounds above to estimate $\|f - g_\sigma\|_{C_0 \cap L^2}$ and, eventually, $\|f - f_\sigma\|_{C_0 \cap L^2}$, where f_σ both interpolates and approximates f.

Suppose that f is in $C_0^k(\mathbb{R}^n)$, where $k > 0$ is an integer. For x fixed, we can use Taylor's theorem with remainder to obtain

$$D^\alpha f(x - ty) = \sum_{|\beta| \le k-1-|\alpha|} \frac{(-t)^{|\beta|} y^\beta}{\beta!} D^{\alpha+\beta} f(x) + \sum_{|\beta| = k-|\alpha|} \frac{(-t)^{k-|\alpha|} y^\beta}{\beta!} D^{\alpha+\beta} f(\tilde{x}),$$

where $\tilde{x}$ is on the line between x and $x - ty$. Next, note that

$$\begin{aligned} \psi_t * D^\alpha f(x) &= \int_{\mathbb{R}^n} t^{-n} \psi(y/t) D^\alpha f(x - y) d^n y \\ &= \int_{\mathbb{R}^n} \psi(y) D^\alpha f(x - ty) d^n y. \end{aligned}$$

Inserting the expression for $D^\alpha f(x - ty)$ into the bottom integral and noting that all of the moments of ψ are 0, we see that

$$\psi_t * D^\alpha f(x) = \sum_{|\beta| = k-|\alpha|} \frac{(-t)^{k-|\alpha|}}{\beta!} \int_{\mathbb{R}^n} \psi(y) y^\beta D^{\alpha+\beta} f(\tilde{x}) d^n y.$$

Taking absolute values and using the boundedness of the derivatives, we have

$$\begin{aligned} \|\psi_t * D^\alpha f\|_{L^\infty} &\le t^{k-|\alpha|} \big\| |y|^{k-|\alpha|} \psi \big\|_{L^1} \Big(\sum_{|\beta| = k-|\alpha|} \frac{\|D^{\alpha+\beta} f\|_{L^\infty}}{\beta!} \Big) \\ &\le t^{k-|\alpha|} \big\| |y|^{k-|\alpha|} \psi \big\|_{L^1} \|D^\alpha f\|_{C_0^{k-|\alpha|}} \\ &\le t^{k-|\alpha|} \big\| |y|^{k-|\alpha|} \psi \big\|_{L^1} \|f\|_{C_0^k}. \end{aligned}$$

From this, the fact that $\|\bar{\psi}_t\|_{L^1} = \|\psi\|_{L^1}$, and Young's inequality, we see that

$$\|\bar{\psi}_t * \psi_t * D^\alpha f\|_{L^\infty} \le t^{k-|\alpha|} \|\psi\|_{L^1} \big\| |y|^{k-|\alpha|} \psi \big\|_{L^1} \|f\|_{C_0^k}. \tag{28}$$

Next, recall that from (23) and (24) the difference $D^\alpha f - D^\alpha g_\sigma$ is

$$D^\alpha f - D^\alpha g_\sigma = \int_0^{\frac{1}{\sigma}} \bar{\psi}_t * \psi_t * D^\alpha f \, \frac{dt}{t}. \tag{29}$$

Taking the L^∞ norm of $D^\alpha f - D^\alpha g_\sigma$, using the bound in (28) above, and doing the simple integral involved, we have proven the following result.

PROPOSITION 3.7. *Let $k > 0$ be an integer, and let α be a multi-index satisfying $k > |\alpha|$. If $f \in C_0^k \cap W_2^k$, then*

$$\|D^\alpha f - D^\alpha g_\sigma\|_{L^\infty} \le \sigma^{|\alpha|-k} c'_{k-|\alpha|} \|f\|_{C_0^k},$$

where $c'_{k-|\alpha|} = (k - |\alpha|)^{-1} \big\| |y|^{k-|\alpha|} \psi \big\|_{L^1} \|\psi\|_{L^1}$.

Combining Propositions 3.6 and 3.7 immediately yields these distance estimates.

THEOREM 3.8. *Let $k > 0$ be an integer, and let $\sigma > 0$. If $f \in C_0^k \cap W_2^k$, then there is a constant $C = C(k, n)$ such that*

$$\operatorname{dist}_{C_0 \cap L^2}(f, \mathcal{B}_\sigma) \le C\sigma^{-k} \|f\|_{C_0^k \cap W_2^k}.$$

Proof. From Proposition 3.6, with $s = 0$ and $r = k$, we have $\|f - g_\sigma\|_{L^2} \le c_k \sigma^{-k} \|f\|_{W_2^k}$. In addition, from Proposition 3.7, with $\alpha = 0$, we have that $\|f - g_\sigma\|_{C_0} \le c_k' \sigma^{-k} \|f\|_{C_0^k}$. Consequently, we obtain

$$\begin{aligned} \|f - g_\sigma\|_{C_0 \cap L^2} &\le \max(c_k, c_k') \sigma^{-k} \max\left(\|f\|_{C_0^k}, \|f\|_{W_2^k} \right) \\ &\le C\sigma^{-k} \|f\|_{C_0^k \cap W_2^k}, \end{aligned}$$

where $C = \max(c_k, c_k')$. Since $\operatorname{dist}_{C_0 \cap L^2}(f, \mathcal{B}_\sigma) \le \|f - g_\sigma\|_{C_0 \cap L^2}$, the result follows immediately. ∎

3.3. Error estimates for $\mathcal{B}$ interpolants. We will conclude our discussion of band-limited functions by proving error estimates for the interpolant f_σ for $f \in C_0 \cap L^2$, whose existence was shown in Theorem 3.5. The first is an immediate corollary to Theorems 3.5 and 3.8.

COROLLARY 3.9. *Let $f \in C_0^k \cap W_2^k$, and let f_σ be as in Theorem* 3.5. *Then*

$$\|f - f_\sigma\|_{C_0 \cap L^2} \le C\sigma^{-k} \|f\|_{C_0^k \cap W_2^k},$$

where $C = C(k, n)$.

We turn to obtaining estimates on $\|D^\alpha f - D^\alpha f_\sigma\|_{L^\infty}$. To do this, we will make use of Bernstein's theorem for functions of exponential type [18, section 3.2.2, eq. (8)]: If $h_\sigma \in \mathcal{B}_\sigma$, then

$$\|D^\alpha h_\sigma\|_{L^p} \le \sigma^{|\alpha|} \|h_\sigma\|_{L^p}, \quad 1 \le p \le \infty. \tag{30}$$

Our result is the following theorem.

THEOREM 3.10. *Let $k > 0$ be an integer and α be a multi-index with $|\alpha| < k$, $\sigma > 0$, and $f \in C_0^k \cap W_2^k$. If $f_\sigma \in \mathcal{B}_\sigma$ is the interpolant to f from Theorem* 3.5, *then there is a constant $C = C(|\alpha|, k, n)$ for which*

$$\|D^\alpha f - D^\alpha f_\sigma\|_{L^\infty} \le C\sigma^{|\alpha|-k} \|f\|_{C_0^k \cap W_2^k}. \tag{31}$$

Proof. Let g_σ be defined by (24). Then we have

$$\|D^\alpha f - D^\alpha f_\sigma\|_{L^\infty} \le \|D^\alpha f - D^\alpha g_\sigma\|_{L^\infty} + \|D^\alpha g_\sigma - D^\alpha f_\sigma\|_{L^\infty}.$$

By Proposition 3.7, we can bound the first term on the right-hand side by $\sigma^{|\alpha|-k} C_1 \|f\|_{C_0^k}$. Using Bernstein's inequality (30) for $p = \infty$, with $h_\sigma = g_\sigma - f_\sigma$, we may bound the second term by $\sigma^{|\alpha|} \|g_\sigma - f_\sigma\|_{L^\infty}$. Putting these two together yields

$$\|D^\alpha f - D^\alpha f_\sigma\|_{L^\infty} \le \sigma^{|\alpha|-k} C_1 \|f\|_{C_0^k} + \sigma^{|\alpha|} \|g_\sigma - f_\sigma\|_{L^\infty}.$$

Next, observe that $\|g_\sigma - f_\sigma\|_{L^\infty} \le \|f - f_\sigma\|_{L^\infty} + \|g_\sigma - f\|_{L^\infty}$. By Proposition 3.7 and Corollary 3.9, we have

$$\begin{aligned} \|g_\sigma - f_\sigma\|_{L^\infty} &\le C_2 \sigma^{-k} \|f\|_{C_0^k \cap W_2^k} + C_3 \sigma^{-k} \|f\|_{C_0^k} \\ &\le (C_2 + C_3)\, \sigma^{-k} \|f\|_{C_0^k \cap W_2^k}. \end{aligned}$$

Finally, inserting this bound on the right-hand side in the previous one gives us (31), with $C = C_1 + C_2 + C_3$. ∎

It is easy to obtain bounds in W_2^r similar to the ones above. We do not need them, however, except in the following case.

PROPOSITION 3.11. *Let $f \in C_0^k \cap W_2^k$, and let f_σ be as in Theorem* 3.5. *Assume that $\sigma \geq 1$. Then there is a constant $C' = C'(k,n)$ such that*

$$\|f_\sigma\|_{W_2^k} \leq C' \|f\|_{C_0^k \cap W_2^k} . \tag{32}$$

Proof. To bound $\|f_\sigma\|_{W_2^k}$, we begin with the inequality

$$\|f_\sigma\|_{W_2^k} \leq \|f_\sigma - g_\sigma\|_{W_2^k} + \|f - g_\sigma\|_{W_2^k} + \|f\|_{W_2^k}.$$

Proposition 3.6, with $s = k$ and $r = 0$, gives us $\|f_\sigma - g_\sigma\|_{W_2^k} \leq c_0 \|f\|_{W_2^k}$. In addition, Bernstein's inequality (30) in conjunction with the definition of the Sobolev norm for W_2^k yields

$$\|f_\sigma - g_\sigma\|_{W_2^k} \leq (1 + \sigma^k) \|f_\sigma - g_\sigma\|_{L^2}.$$

Thus, we have that

$$\|f_\sigma\|_{W_2^k} \leq (1 + \sigma^k) \|f_\sigma - g_\sigma\|_{L^2} + (c_0 + 1) \|f\|_{W_2^k} .$$

Next, by Corollary 3.9 and Proposition 3.6, we also have

$$\begin{aligned} \|f_\sigma - g_\sigma\|_{L^2} &\leq \|f_\sigma - f\|_{C_0 \cap L^2} + \|f - g_\sigma\|_{L^2} \\ &\leq C\sigma^{-k} \|f\|_{C_0^k \cap W_2^k} + c_k \sigma^{-k} \|f\|_{W_2^k} \\ &\leq (C + c_k) \sigma^{-k} \|f\|_{C_0^k \cap W_2^k} . \end{aligned}$$

Combining this with the inequality previous to it yields

$$\|f_\sigma\|_{W_2^k} \leq \left((1 + \sigma^{-k})(C + c_k) + (c_0 + 1) \right) \|f\|_{C_0^k \cap W_2^k} \leq C' \|f\|_{C_0^k \cap W_2^k} ,$$

which completes the proof. ∎

4. RBFs. Let m be a nonnegative integer, and let $\Phi(x) = \Phi(|x|)$ be continuous. We say Φ is an order $m \geq 0$ RBF if for every subset $X = \{x_1, \ldots, x_n\}$ comprising distinct points in $\mathbb{R}^n$ and for every $c \in \mathbb{C}^N \setminus \{0\}$ satisfying $\sum_{j=1}^N c_j p(x_j) = 0$ for all $p \in \pi_{m-1}(\mathbb{R}^n)$ we have that

$$c^H A c = \sum_{j,k=1}^N \bar{c}_j c_k \Phi(x_k - x_j) > 0.$$

That is, the function Φ is *strictly* conditionally positive definite of order m. Interpolants are formed from an order m RBF Φ in the following way. When X is a unisolvent set for $\pi_{m-1}(\mathbb{R}^n)$ and data is generated by a continuous function f, then there is a unique $c \in \mathbb{C}^N$ satisfying $\sum_{j=1}^N c_j p(x_j) = 0$ for every $p \in \pi_{m-1}(\mathbb{R}^n)$ and a unique $q \in \pi_{m-1}(\mathbb{R}^n)$ such that

$$I_X f(x) = \sum_{x_j \in X} c_j \Phi(x - x_j) + q(x)$$

satisfies $I_X f|_X = f|_X$. Moreover, if f is a polynomial in $\pi_{m-1}(\mathbb{R}^n)$, then $I_X f = q$. That is, the method reproduces polynomials of degree less than m.

4.1. RKHS and RBFs. An order m RBF Φ has $\mathcal{O}(|x|^{2m})$ growth as $|x| \to \infty$ [13, Corollary 2.3]. Consequently, we may view it as being a tempered distribution. As such, it has a (radial) Fourier transform $\hat{\Phi} \in \mathcal{S}'$. In all cases of practical interest, $\hat{\Phi}(\xi)$ in $\mathbb{R}^n$ is a positive, continuous function for $\xi \in \mathbb{R}^n \setminus \{0\}$ that may have a singularity of the form $|\xi|^{-\tau}$ as $|\xi| \to 0$. With these RBFs, we can associate a RKHS, the native space of Φ,

$$\mathcal{N}_\Phi := \left\{ f \in L^2(\mathbb{R}^n) \colon \|f\|_\Phi^2 := \int_{\mathbb{R}^n} |\hat{f}(\xi)|^2 \widehat{\Phi}(\xi)^{-1} d^n\xi < \infty \right\}. \tag{33}$$

We will mention two important classes of RBFs. Duchon's thin-plate splines

$$\Phi_\nu^{\mathrm{TPS}}(x) = \begin{cases} (-1)^{\lfloor \nu \rfloor + 1} |x|^{2\nu}, & \nu > 0,\ \nu \notin \mathbb{N}, \\ (-1)^{\nu+1} |x|^{2\nu} \log(|x|), & \nu \in \mathbb{N}, \end{cases}$$

are of order $m_\nu = \lfloor \nu \rfloor + 1$ and have distributional Fourier transforms (in $\mathbb{R}^n$) given by [20, Table 1]

$$\widehat{\Phi}_\nu^{\mathrm{TPS}}(\xi) = C_{\nu,n} |\xi|^{-n-2\nu}.$$

Wendland's compactly supported RBFs [21, 22] also display similar behavior in their Fourier transforms. The functions themselves are all (order 0) RBFs but only on $\mathbb{R}^d$, $d \le n$. Each has the form

$$\Phi_{n,k}^{\mathrm{WEN}}(x) = \begin{cases} p_{n,k}(|x|), & 0 \le |x| \le 1, \\ 0, & |x| > 1, \end{cases}$$

where $p_{n,k}$ is a univariate polynomial of degree $\lfloor \frac{n}{2} \rfloor + 3k + 1$; also, $\Phi_{n,k}$ is in $C^{2k}(\mathbb{R}^n)$. Their Fourier transforms satisfy the bounds [22, Theorem 2.1]

$$c_{n,k}(1 + |\xi|^2)^{-\frac{n}{2}-k-\frac{1}{2}} \le \widehat{\Phi}_{n,k}^{\mathrm{WEN}}(\xi) \le C_{n,k}(1 + |\xi|^2)^{-\frac{n}{2}-k-\frac{1}{2}}.$$

Error estimates on $I_X f$ and $D^\alpha I_X f$, where α is a standard multi-index, are known in the case where f belongs to a native space $\mathcal{N}_\Phi$ [13, 24] stemming from an order m RBF.

THEOREM 4.1. *Let α be a multi-index, $r, s \in \mathbb{R}$, with $\frac{n}{2} + |\alpha| < r$ and $s + \frac{n}{2} < m$, and suppose that $\widehat{\Phi}(\xi)$ is positive and continuous on $\xi \in \mathbb{R}^n \setminus \{0\}$ and satisfies*

$$\widehat{\Phi}(\xi)^{-1} = \mathcal{O}(|\xi|^{2s}) \text{ as } |\xi| \to 0 \quad \text{and} \quad \widehat{\Phi}(\xi)^{-1} = \mathcal{O}(|\xi|^{2r}) \text{ as } |\xi| \to \infty. \tag{34}$$

If $\Omega \supset X$ is a compact region satisfying a uniform interior cone condition and if $f \in \mathcal{N}_\Phi$, then

$$\|D^\alpha f - D^\alpha I_X f\|_{L^\infty(\Omega)} \le C h^{r - \frac{n}{2} - |\alpha|} \|f\|_\Phi, \quad C = C(|\alpha|, \Omega, \Phi), \tag{35}$$

where $h = h_{X,\Omega}$ is the mesh norm.

Various versions of these estimates are found in Madych and Nelson [13, Theorem 4.4] and in Wu and Schaback [24, Theorems 4.5 and 5.14]. A cone condition on Ω is alluded to in [13] and explicitly incorporated in the estimates in [19, p. 333].

4.2. Extended error estimates for RBF interpolants. We are now ready to obtain the RBF interpolation error estimates discussed in section 1. Let $f \in C_0^k \cap W_2^k$, σ, and f_σ be as in Theorem 3.5, and let α be a multi-index with $\frac{n}{2} + |\alpha| < k$. We will assume that Ω satisfies a uniform interior cone condition and that $\mathrm{diam}(\Omega) \leq 1$. Of course, $\Omega \supset X$ implies that $\mathrm{diam}(X) \leq 1$. Next, we will take $\sigma = \sigma_0$ in (15). This choice of σ implies two things: first, since $q \leq \mathrm{diam}(X) \leq 1$, $\sigma > 1$; and, second, σh has the form

$$\sigma h = \gamma_n \rho, \text{ where } \rho := \frac{h}{q} \text{ and } \gamma_n := 24 \left\{ \frac{\sqrt{\pi}}{3} \Gamma\left(\frac{n+2}{2}\right) \right\}^{\frac{2}{n+1}}. \tag{36}$$

Since the ratio $\rho = h/q \geq 1$, we also see that the product $\sigma h > 1$ and that $\sigma > 1$.

The idea for obtaining new bounds is to write the difference $D^\alpha f - D^\alpha I_X f$ as the sum of three pieces:

$$D^\alpha f - D^\alpha I_X f = (D^\alpha f - D^\alpha f_\sigma) + (D^\alpha f_\sigma - D^\alpha I_X f_\sigma) + D^\alpha (I_X f_\sigma - I_X f).$$

Now, $(f_\sigma - f)|_X = 0$, and so the uniqueness of the RBF interpolant implies that $I_X f_\sigma - I_X f \equiv 0$. The third term above is thus 0. Our error then becomes

$$\|D^\alpha f - D^\alpha I_X f\|_{L^\infty(\Omega)} \leq \|D^\alpha f - D^\alpha f_\sigma\|_{L^\infty(\Omega)} + \|D^\alpha f_\sigma - D^\alpha I_X f_\sigma\|_{L^\infty(\Omega)}.$$

We can replace the first term on the right-hand side above by its bound from Theorem 3.10 and the second term by its RKHS bound from (35), since Ω satisfies the requisite cone condition. Doing so yields

$$\|D^\alpha f - D^\alpha I_X f\|_{L^\infty(\Omega)} \leq C_1 \sigma^{|\alpha|-k} \|f\|_{C_0^k \cap W_2^k} + C_2 h^{r-\frac{n}{2}-|\alpha|} \|f_\sigma\|_\Phi, \tag{37}$$

provided $\widehat{\Phi}$ satisfies the conditions in Theorem 4.1. The norm $\|\cdot\|_\Phi$ is given in (33). Under these assumptions on Φ, plus the additional assumption that $k \leq r$, the norm $\|f_\sigma\|_\Phi$ can be estimated as follows:

$$\begin{aligned}
\|f_\sigma\|_\Phi^2 &= \int_{|\xi| \leq \sigma} \frac{|\hat{f}_\sigma|^2}{\widehat{\Phi}} d^n\xi \\
&\leq C_3^2 \int_{|\xi| \leq \sigma} (1 + |\xi|^{2r}) |\hat{f}_\sigma|^2 d^n\xi \\
&\leq C_3^2 \int_{|\xi| \leq \sigma} \frac{1 + |\xi|^{2r}}{(1 + |\xi|^2)^k} (1 + |\xi|^2)^k |\hat{f}_\sigma|^2 d^n\xi \\
&\leq C_3^2 \sigma^{2r-2k} \|f_\sigma\|_{W_2^k}^2.
\end{aligned}$$

Taking square roots and employing Proposition 3.11, which holds since $\sigma > 1$, then gives us

$$\|f_\sigma\|_\Phi \leq C_4 \sigma^{r-k} \|f\|_{C_0^k \cap W_2^k}.$$

Inserting this in (37) yields

$$\|D^\alpha f - D^\alpha I_X f\|_{L^\infty(\Omega)} \leq \left(C_1 \sigma^{|\alpha|-k} + C_5 h^{r-\frac{n}{2}-|\alpha|} \sigma^{r-k} \right) \|f\|_{C_0^k \cap W_2^k}.$$

Factoring $h^{k-|\alpha|-\frac{n}{2}}$ from the right-hand side and manipulating the resulting expression, we have

$$\|D^\alpha f - D^\alpha I_X f\|_{L^\infty(\Omega)} \leq h^{k-|\alpha|-\frac{n}{2}} \left(C_1 (\sigma h)^{|\alpha|-k} h^{\frac{n}{2}} + C_5 (\sigma h)^{r-k} \right) \|f\|_{C_0^k \cap W_2^k}.$$

From $|\alpha| + \frac{n}{2} < k \le r$, $h \le 1$, and $\sigma h > 1$, it follows that $(\sigma h)^{|\alpha|-k} h^{\frac{n}{2}} < (\sigma h)^{r-k}$, and so the coefficient on the right-hand side above is less than a multiple of $h^{k-|\alpha|-\frac{n}{2}}(\sigma h)^{r-k}$. From (36), $\sigma h = \gamma_n \rho$, and the final bound is $Ch^{k-|\alpha|-\frac{n}{2}}\rho^{r-k}$. In summary, we have obtained this result.

THEOREM 4.2. *Let the notation and assumptions of Theorem* 4.1 *hold. In addition, suppose that* $\operatorname{diam}(\Omega) \le 1$. *If* k *is an integer satisfying* $|\alpha| + \frac{n}{2} < k \le r$ *and if* $f \in C_0^k \cap W_2^k$, *then there is a constant* $C = C(k, |\alpha|, n, \Omega, \Phi)$ *such that*

$$\|D^\alpha f - D^\alpha I_X f\|_{L^\infty(\Omega)} \le Ch^{k-|\alpha|-\frac{n}{2}}\rho^{r-k}\|f\|_{C_0^k \cap W_2^k}$$

holds. Here, $\rho = \rho_{X,\Omega}$ *is the mesh ratio, and* $h = h_{X,\Omega}$ *is the mesh norm.*

Note that if we require a uniform bound on the mesh ratio, we immediately get uniform bounds on the error.

COROLLARY 4.3. *For any set of centers* $X \subset \Omega$ *for which* $\rho_{X,\Omega} \le R$, *with* R *fixed, we have*

$$\frac{\|D^\alpha f - D^\alpha I_X f\|_{L^\infty(\Omega)}}{\|f\|_{C_0^k \cap W_2^k}} = \mathcal{O}(h^{k-|\alpha|-\frac{n}{2}}).$$

We have assumed throughout the paper that f is in $C_0 \cap L^2$, and so it is defined and, at the very least, continuous on all of $\mathbb{R}^n$. In many applications, for example solving a partial differential equation, this is not the case. The function f is then only defined on Ω. To deal with this situation, one can appeal to one of the many extension theorems available (cf. [1, Chapter IV] or [11, section 6.9]) and again have a function defined on $\mathbb{R}^n$. This will usually require some additional assumptions concerning the smoothness of the boundary.

ANALYSIS OF A MULTIDIMENSIONAL PARABOLIC POPULATION MODEL WITH STRONG CROSS-DIFFUSION*

LI CHEN† AND ANSGAR JÜNGEL‡

Abstract. The global existence of a nonnegative weak solution to a multidimensional parabolic strongly coupled model for two competing species is proved. The main feature of the model is that the diffusion matrix is nonsymmetric and generally not positive definite and that the nondiagonal matrix elements (the cross-diffusion terms) are allowed to be "large." The ideas of the existence proof are a careful approximation of the cross-diffusion terms using finite differences and the use of an entropy inequality yielding a priori estimates.

Key words. cross-diffusion system, entropy functional, existence of weak solutions, Orlicz space

AMS subject classifications. 35K55, 35D05, 92D25

1. Introduction.

For the time evolution of two competing species with homogeneous population density, usually the Lotka–Volterra differential equations are used as an appropriate mathematical model. In the case of nonhomogeneous densities, diffusion effects have to be taken into account leading to reaction-diffusion equations. Shigesada, Kawasaki, and Teramoto proposed in their pioneering work [25] to introduce further so-called cross-diffusion terms modeling segregation phenomena of the competing species. Denoting by $u_i(x,t)$ the population density of the ith species and by $J_i(x,t)$ the corresponding population flows, the time-dependent equations can be written as

$$\partial_t u_i - \mathrm{div} J_i = f_i(u_1,u_2), \quad J_i = \nabla(c_i u_i + a_i u_i^2 + u_1 u_2) + d_i u_i q, \tag{1.1}$$

where $i = 1,2$. The equations are solved in the bounded domain $\Omega \subset \mathbb{R}^N$ $(N \le 3)$ with time $t > 0$. The function q is given by $q = \nabla U$, and $U = U(x,t)$ is a prescribed environmental potential, modeling areas where the environmental conditions are more or less favorable [20, 25]. The diffusion coefficients c_i and a_i are nonnegative, and $d_i \in \mathbb{R}$ $(i = 1,2)$. The source terms are in Lotka–Volterra form:

$$f_i(u_1,u_2) = (R_i - \beta_{i1}u_1 - \beta_{i2}u_2)u_i, \quad i = 1,2, \tag{1.2}$$

where $R_i \ge 0$ is the intrinsic growth rate of the ith species, $\beta_{ii} > 0$ are the coefficients of intraspecific competition, and $\beta_{12} \ge 0$ and $\beta_{21} \ge 0$ are those of interspecific competition. The above system of equations is supplemented with (biologically motivated) homogeneous Neumann boundary conditions and initial conditions:

$$J_i \cdot \gamma = 0 \quad \text{on } \partial\Omega \times (0,\infty), \tag{1.3}$$

$$u_i(\cdot,0) = u_i^0 \quad \text{in } \Omega, \quad i = 1,2, \tag{1.4}$$

and γ denotes the exterior unit normal to $\partial\Omega$, which is assumed to exist almost everywhere.

Notice that the above system is scaled in such a way that the coefficient of the *cross-diffusion term* $\nabla(u_1u_2)$ is equal to one (see [8] for details).

The problem (1.1)–(1.4) is strongly coupled with full diffusion matrix

$$A(u_1,u_2)=\begin{pmatrix} c_1+2a_1u_1+u_2 & u_1 \\ u_2 & c_2+2a_2u_2+u_1 \end{pmatrix}.$$

Nonlinear problems of this kind are quite difficult to deal with since the usual idea of applying maximum principle arguments to get a priori estimates cannot be used here. Furthermore, the diffusion matrix is not symmetric and of degenerate type if $c_1=c_2=0$.

Until now, only partial results were available in the literature concerning the well posedness of the above problem. We summarize some of the available results for the time-dependent equations (see [28] for a review) and refer the reader to [16, 17, 23, 24] for the stationary problem. Global existence of solutions and their qualitative behavior for $a_1=a_2=0$ and no cross-diffusion for the second species have been proved in, e.g., [3, 18, 21, 22, 27]. In this case, (1.1) for $i=2$ is only weakly coupled. The existence of an attractor has been studied in [15, 22]. Notice that in chemotaxis, related models appear [7, 9, 19].

For sufficiently small cross-diffusion terms (or "small" initial data) and vanishing self-diffusion coefficients $a_1=a_2=0$, Deuring proved the global existence of solutions in [6]. For the case $c_1=c_2$, a global existence result in one space dimension has been obtained by Kim [12]. Furthermore, under the condition

$$2a_1>1, \quad 2a_2>1, \tag{1.5}$$

Yagi [29] has shown the global existence of solutions in two space dimensions. A global existence result for weak solutions in any space dimension under assumption (1.5) can be found in [8]. Condition (1.5) can be easily understood by observing that in this case, the diffusion matrix is positive definite:

$$\xi^TA(u_1,u_2)\xi\ge\min\{c_1,c_2\}|\xi|^2 \quad \text{for all } \xi\in\mathbb{R}^2,$$

hence yielding an elliptic operator. If the condition (1.5) does not hold, there are choices of c_i, a_i, $u_i\ge 0$ for which the matrix $A(u_1,u_2)$ is *not* positive definite. Finally, Galiano, Garzòn, and Jüngel [8] proved the existence of global weak solutions for *any* a_1, $a_2>0$. However, the proof uses the embedding $H^1(\Omega)\subset L^\infty(\Omega)$ in a crucial way such that the result is restricted to one space dimension only.

In this paper we solve the problem (1.1)–(1.4) for (up to) *three* space dimensions without any restriction on the diffusion coefficients. More precisely, we prove the following result.

THEOREM 1.1. *Let $T>0$, and assume that*

- *$\Omega\subset\mathbb{R}^N$ $(N\le 3)$ is a bounded domain with boundary $\partial\Omega\in C^{0,1}$;*
- *the parameters satisfy $c_i\ge 0$, $a_i>0$; $R_i\ge 0$, $\beta_{ii}>0$ $(i=1,2)$, $\beta_{12}=\beta_{21}\ge 0$; $q\in(L^2(Q_T))^N$, where $Q_T=\Omega\times(0,T)$;*
- *the initial data satisfy $u_i^0\in L_\Psi(\Omega)$ and $u_i^0\ge 0$ in Q_T $(i=1,2)$.*

Then problem (1.1)–(1.4) has a weak solution (u_1,u_2) satisfying $u_i\ge 0$ in Q_T and

$$u_i\in L^2(0,T;H^1(\Omega))\cap L^\infty(0,T;L_\Psi(\Omega))\cap W^{1,r}(0,T;(W^{1,r'}(\Omega))'), \quad i=1,2,$$

where $r = (2N+2)/(2N+1)$ *and* $r' = r/(r-1) = 2N+2$, *in the sense that for all* $\varphi \in L^{r'}(0,T;W^{1,r'}(\Omega))$, $i = 1,2$,

$$\int_0^T \langle \partial_t u_i, \varphi\rangle\, dt + \int_{Q_T} (c_i\nabla u_i + 2a_i u_i \nabla u_i + \nabla(u_1u_2) + d_i u_i q)\cdot\nabla\varphi dxdt = \int_{Q_T} f_i(u_1,u_2)\varphi dxdt,$$

and $\langle\cdot,\cdot\rangle$ *denotes the dual product between* $W^{1,r'}(\Omega)$ *and its dual* $(W^{1,r'}(\Omega))'$.

Here, $L_\Psi(\Omega)$ denotes the Orlicz space for $\Psi(s) = (1+s)\ln(1+s) - s$, $s \geq 0$. Orlicz space techniques for a related parabolic system have already been employed in [13]. We refer the reader to the appendix for its definition and some properties.

In order to explain the method of our proof it is convenient to recall the ideas of [8]. By using the exponential transformation of variables $u_1 = \exp(w_1)$, $u_2 = \exp(w_2)$, (1.1) transform into

$$\partial_t \begin{pmatrix} e^{w_1} \\ e^{w_2}\end{pmatrix} - \operatorname{div}\left(B(w_1,w_2)\nabla\begin{pmatrix} w_1\\ w_2\end{pmatrix} + \begin{pmatrix} d_1e^{w_1}\\ d_2e^{w_2}\end{pmatrix} q\right) = \begin{pmatrix} f_1\\ f_2\end{pmatrix},$$

and the new diffusion matrix

$$B(w_1,w_2) = \begin{pmatrix} c_1e^{w_1} + 2a_1e^{2w_1} + e^{w_1+w_2} & e^{w_1+w_2} \\ e^{w_1+w_2} & c_2e^{w_2} + 2a_2e^{2w_2} + e^{w_1+w_2}\end{pmatrix}$$

is symmetric and positive definite:

$$\det B(w_1,w_2) \geq (c_1e^{w_1} + 2a_1e^{2w_1})(c_2e^{w_2} + 2a_2e^{2w_2}) > 0.$$

In this formulation the matrix B provides an elliptic operator for all $c_i > 0$, $a_i \geq 0$ or $c_i \geq 0$, $a_i > 0$ $(i = 1,2)$. In this sense, the system (1.1)–(1.2) is called *parabolic*. We remark that exponential transformations of variables have also been used in other applications, such as chemotaxis [19] and semiconductor modeling [10].

The above change of unknowns symmetrizing the problem implies the existence of an *entropy functional*

$$E(t) = \sum_{i=1}^2 \int_\Omega (u_i(\ln u_i - 1) + 1)dx \geq 0,$$

with the corresponding entropy inequality

$$E(t) + 2\int_0^t \int_\Omega \Big(\sum_{i=1}^2 (2c_i|\nabla\sqrt{u_i}|^2 + a_i|\nabla u_i|^2) + 2|\nabla\sqrt{u_1u_2}|^2\Big)dxdt \leq E(0) + C \tag{1.6}$$

for $0 < t < T$ and any $T > 0$, where the constant $C > 0$ depends on T, q, and the source terms. It can be formally derived by using $\ln u_i$ as a test function in the weak formulation of (1.1)–(1.4). This inequality provides an $L^2(0,T;H^1(\Omega))$ estimate for u_1 and u_2 if a_1, $a_2 > 0$. The existence of a symmetric formulation of the problem is even equivalent to the existence of an entropy functional [5, 11]. We notice that the above entropy functional has also been employed in angiogenesis-chemotactic applications as an analytical tool [4].

However, the entropy inequality can be made rigorous only if $u_i \geq 0$, which cannot be easily obtained from the minimum principle. The nonnegativity of the solutions is obtained in [8] by proving that the transformed variable satisfies $w_i \in L^2(0,T;H^1(\Omega))$. As $H^1(\Omega)$ embeds continuously into $L^\infty(\Omega)$ in one space dimension, this implies $w_i(\cdot,t) \in L^\infty(\Omega)$ for almost every $t > 0$, and hence $u_i(\cdot,t) = \exp(w_i(\cdot,t)) > 0$ in Ω. Clearly, this method cannot be used in several space dimensions.

The main idea of our proof is to *discretize* the cross-diffusion term $\nabla(u_1 u_2)$ by *finite differences* and first to prove the existence of solutions to the approximate problem, which is now only weakly coupled. The precise approximation has to be chosen in such a way that the above entropy inequality also holds for the approximate problem. This provides the a priori estimates necessary to perform the limit of vanishing approximation parameters. The idea is inspired from [13], where a different problem is studied.

One possibility is to approximate the cross-diffusion term $\Delta(u_1 u_2) = \operatorname{div}(u_1 u_2 \nabla \ln(u_1 u_2))$ by the finite differences

$$D^{-h}[\chi_h u_1 u_2 D^h(\ln(u_1 u_2))],$$

where D^h is an approximation of the gradient,

$$D^h f = (D_1^h f, \ldots, D_N^h f) \quad \text{and} \quad D_j^h f(x,t) = \frac{f(x+he_j,t) - f(x,t)}{h}, \tag{1.7}$$

D^{-h} is an approximation of the divergence,

$$D^{-h}F(x,t) = \sum_{j=1}^N \frac{F_j(x-he_j,t) - F_j(x,t)}{-h}, \tag{1.8}$$

with the jth unit vector e_j of $\mathbb{R}^N$, $j = 1, \ldots, N$, and χ_h is the characteristic function of $\{x \in \Omega : \operatorname{dist}(x, \partial\Omega) > h\}$. It can be shown formally that the problem with this discrete cross-diffusion term possesses the entropy inequality

$$E(t) + \int_0^t \int_\Omega \Big(\sum_{i=1}^2 (4c_i |\nabla \sqrt{u_i}|^2 + 2a_i |\nabla u_i|^2) + \chi_h u_1 u_2 |D^h \ln(u_1 u_2)|^2 \Big) dt dx \leq E(0) + C$$

for some constant $C > 0$.

However, this estimate is valid only for *positive* population densities u_i. In order to deal with this difficulty, we employ Stampacchia's truncation method; i.e., we replace u_i by $(u_i)_+ + \eta$, where $(u_i)_+ = \max\{0, u_i\}$ and $\eta > 0$. This allows us to define the expression $\ln\big(((u_1)_+ + \eta)((u_2)_+ + \eta)\big)$, for instance.

The above estimate is formally derived by employing $\ln((u_i)_+ + \eta)$ as a test function in the weak formulation. Therefore, we obtain only estimates for $(u_i)_+$. In order to derive estimates also for $(u_i)_- = \min\{0, u_i\}$, we employ $(u_i)_-$ as a test function. This yields, for instance, an estimate of the type $\|(u_i)_-\|_{L^\infty(0,T;L^2(\Omega))} \leq C/|\ln \eta|$ for some constant $C > 0$ which is independent of η. In the limit $\eta \to 0$ this gives $(u_i)_- = 0$ in Q_T, and hence the nonnegativity of the population densities.

We notice that our strategy can also be applied to general systems of the type

$$\partial_t u - \operatorname{div}(A(u)\nabla u) = f(u),$$

where $u = u(x,t) \in \mathbb{R}^n$, $f(u) \in \mathbb{R}^n$ satisfies some growth condition, and $A(u) \in \mathbb{R}^{n\times n}$ is a diffusion matrix, maybe nonsymmetric and not positive definite, provided that

the system is symmetrizable in the sense given above and that the a priori estimates derived from the entropy inequality (which exists due to the symmetrizability) are sufficient to define a weak solution.

Let us summarize the main features of the presented method of proof:

- No restrictions on the diffusion coefficients c_i and a_i are needed.
- The global existence result holds in up to three space dimensions.
- The method provides the nonnegativity of the solutions.
- The degenerate case $c_i = 0$ can also be treated.

The idea of discretizing the cross-diffusion term by finite differences can be used for numerical purposes. We will exploit this idea in [2].

The paper is organized as follows. In section 2 we define and solve an approximate problem yielding an discrete entropy inequality. The key estimates are contained in Lemma 2.5. The limit of vanishing approximation parameters is then performed in section 3. Finally, in the appendix we recall the definition of Orlicz spaces and some of its properties.

2. Existence of solutions to an approximate problem. We use semidiscretization in time to construct the approximate problem. Moreover, as explained in the introduction, we also discretize the cross-diffusion terms by finite differences. For this, we decompose $(0,T] = \cup_{k=1}^K ((k-1)\tau, k\tau]$ for some $\tau > 0$ such that $\tau = T/K$. Furthermore, let $h > 0$, and let χ_h be the characteristic function of $\{x \in \Omega : \mathrm{dist}(x, \partial\Omega) > h\}$. Finally, let $0 < \eta < 1$, and set $\overline{s} = s/(1 + \eta(s)_+)$.

As the proof of Theorem 1.1 is highly technical, it is convenient, for the sake of a smoother presentation, to assume in this section the regularity $u_i^0 \in L^2(\Omega)$ and $q \in (L^\infty(Q_T))^N$ instead of the weaker conditions $u_i^0 \in L_\Psi(\Omega)$ and $q \in (L^2(Q_T))^N$. The general result can be proved by using appropriate smooth approximations and passing to the limit. Details are left to the reader. In fact, we simplify further and assume that $q \in (L^\infty(\Omega))^N$. The time-dependence can be treated as in [5], for instance, by averaging $q(x,t)$ over $((k-1)\tau, k\tau]$. Moreover, we assume that c_1, c_2 are *positive* numbers. We refer the reader to Remark 3.5 for the case $c_1 = 0$ or $c_2 = 0$.

For given u_1^{k-1}, $u_2^{k-1} \in L^2(\Omega)$, we solve recursively the problem

$$\begin{aligned}
&\frac{u_i^k - u_i^{k-1}}{\tau} - \mathrm{div}\big(c_i\nabla u_i^k + 2a_i((u_i^k)_+ + \eta)\nabla u_i^k + d_i(u_i^k)_+ q\big) \\
&= D^{-h}\left[\chi_h \overline{u_1^k}\,\overline{u_2^k} D^h \ln\big(((u_1^k)_+ + \eta)((u_2^k)_+ + \eta)\big)\right] + f_i\big((u_1^k)_+ + \eta, (u_2^k)_+ + \eta\big) \text{ in } \Omega, \\
&\big(c_i\nabla u_i^k + 2a_i((u_i^k)_+ + \eta)\nabla u_i^k + d_i(u_i^k)_+ q\big)\cdot\gamma = 0 \quad \text{on } \partial\Omega,
\end{aligned} \tag{2.1}$$

where $i = 1, 2$. The finite difference operators are defined in (1.7) and (1.8).

The existence of solutions to the approximate system (2.1) is proved in two steps. In order to apply Lax–Milgram's lemma we need bounded diffusion coefficients. Therefore, we approximate the diffusion coefficients $2a_i((u_i^k)_+ + \eta)$ by

$$2a_i \frac{(u_i^k)_+ + \eta}{1 + \nu((u_i^k)_+ + \eta)}$$

for some $\nu > 0$ and prove the existence of solutions to the resulting system. Then we derive uniform bounds with respect to ν which allows us to pass to the limit $\nu \to 0$.

The second approximate system reads as follows:

$$\frac{u_i^k-u_i^{k-1}}{\tau}-\operatorname{div}\Big(c_i\nabla u_i^k+2a_i\frac{(u_i^k)_+ +\eta}{1+\nu((u_i^k)_+ +\eta)}\nabla u_i^k+d_i(u_i^k)_+ q\Big)$$
$$=D^{-h}\Big[\chi_h\overline{u_1^k}\,\overline{u_2^k}D^h\ln\big(((u_1^k)_+ +\eta)((u_2^k)_+ +\eta)\big)\Big]+f_i\big((u_1^k)_+ +\eta,(u_2^k)_+ +\eta\big)\text{ in }\Omega,$$

$$\Big(c_i\nabla u_i^k+2a_i\frac{(u_i^k)_+ +\eta}{1+\nu((u_i^k)_+ +\eta)}\nabla u_i^k+d_i(u_i^k)_+ q\Big)\cdot\gamma=0\quad\text{on }\partial\Omega,\ i=1,2. \tag{2.2}$$

In subsection 2.1 we prove some bounds uniform in ν and the existence of weak solutions to (2.2). Then by letting $\nu\to 0$ in subsection 2.2 we conclude the solvability of (2.1).

In the following, C and $C(\cdots)$ denote positive constants with values varying from occurrence to occurrence and depending on the quantities indicated in the brackets.

2.1. Existence of solutions to the second approximate problem (2.2).

LEMMA 2.1. *Assume that the time discretization parameter $\tau>0$ is so small that*

$$\frac{3}{16\tau}\ge\max_{i=1,2}\Big\{\frac{d_i^2}{2c_i}\|q\|_{L^\infty(\Omega)}^2+2(R_i+\beta_{i1}+\beta_{i2})\Big\}\quad\textit{and}\quad 32\tau\le h^2\eta^2. \tag{2.3}$$

Then there exists a solution $(u_1,u_2)\in(H^1(\Omega))^2$ of problem (2.2) satisfying the following estimate:

$$\int_\Omega\sum_{i=1}^2\left(\frac{c_i}{2}|\nabla u_i|^2+\frac{u_i^2}{4\tau}+2a_i\frac{(u_i)_+ +\eta}{1+\nu((u_i)_+ +\eta)}|\nabla u_i|^2\right)dx\le C(\tau), \tag{2.4}$$

where the constant $C(\tau)>0$ depends on τ but not on ν.

The above estimate is used only to pass to the limit $\nu\to 0$ for *fixed* parameters τ, h, and η. For the limits $\tau,h\to 0$ and $\eta\to 0$ we need other estimates.

Remark 2.2. The second restriction on the time discretization parameter τ in (2.3) is similar to the well-known condition $\tau/h^2\le$ const needed for explicit finite difference approximations of parabolic equations since we treat the discrete cross-diffusion term in an "explicit" way. Clearly, this condition has no importance for the existence result.

Proof. Construct a mapping

$$\mathcal{T}:(\sigma,v_1,v_2)\in[0,1]\times(L^4(\Omega))^2\to(L^4(\Omega))^2$$

by solving the following linear problem:

$$\begin{aligned}-\operatorname{div}(c_i\nabla u_i)+\frac{u_i}{\tau}-\sigma\operatorname{div}\Big(2a_i\frac{(v_i)_+ +\eta}{1+\nu((v_i)_+ +\eta)}\nabla u_i\Big)-\sigma\operatorname{div}(d_i(v_i)_+ q)&\\ =\sigma\frac{u_i^{k-1}}{\tau}+\sigma F_i(v_1,v_2)\quad\text{in }\Omega,&\\ \Big(c_i\nabla u_i+2\sigma a_i\frac{(v_i)_+ +\eta}{1+\nu((v_i)_+ +\eta)}\nabla u_i+\sigma d_i(v_i)_+ q\Big)\cdot\gamma=0\quad\text{on }\partial\Omega,&\end{aligned} \tag{2.5}$$

where

$$F_i(v_1,v_2)=D^{-h}\left[\chi_h\overline{v_1}\,\overline{v_2}D^h\ln\big(((v_1)_+ +\eta)((v_2)_+ +\eta)\big)\right]+f_i((v_1)_+ +\eta,(v_2)_+ +\eta)$$

and v_1, $v_2 \in L^4(\Omega)$, $i = 1, 2$. The functionals F_i satisfy the estimate $\|F_i(v_1, v_2)\|_{L^2(\Omega)} \le C(1 + \|v_1\|^2_{L^4(\Omega)} + \|v_2\|^2_{L^4(\Omega)})$ for $i = 1, 2$. The above problem has a unique solution (by Lax–Milgram's lemma) since the diffusion coefficients are bounded. Thus, the mapping $\mathcal{T}$ is well defined. It is not difficult to prove the continuity of $\mathcal{T}$. Moreover, since the embedding $H^1(\Omega) \hookrightarrow L^4(\Omega)$ is compact, for every $\sigma \in [0, 1]$, the mapping $\mathcal{T}$ is compact. Here, we use the restriction $N \le 3$ of the space dimension (see Remark 2.3). When $\sigma = 0$, the equation $\mathcal{T}(0, u_1, u_2) = (u_1, u_2)$ immediately yields $u_1 = u_2 = 0$ in Ω.

It remains to establish uniform estimates for every fixed point of $\mathcal{T}$. Any fixed point (u_1, u_2) satisfies the equation

$$
\begin{aligned}
&- \operatorname{div}(c_i \nabla u_i) + \frac{u_i}{\tau} - \sigma \operatorname{div}\Big(2a_i \frac{(u_i)_+ + \eta}{1 + \nu((u_i)_+ + \eta)} \nabla u_i\Big) - \sigma \operatorname{div}(d_i (u_i)_+ q) \\
&\qquad = \sigma \frac{u_i^{k-1}}{\tau} + \sigma F_i(u_1, u_2) \quad \text{in } \Omega,\ i = 1, 2,
\end{aligned} \tag{2.6}
$$

together with homogeneous Neumann boundary conditions. We use $u_i \in H^1(\Omega)$ as a test function in the weak formulation of (2.6) for $i = 1, 2$ and add the resulting equations:

$$
\begin{aligned}
&\sum_{i=1}^2 \int_\Omega \Big(c_i |\nabla u_i|^2 + \frac{u_i^2}{\tau} + 2\sigma a_i \frac{(u_i)_+ + \eta}{1 + \nu((u_i)_+ + \eta)} |\nabla u_i|^2 \Big) dx \\
&= - \sum_{i=1}^2 \int_\Omega \sigma d_i (u_i)_+ q \cdot \nabla u_i dx + \frac{\sigma}{\tau} \sum_{i=1}^2 \int_\Omega u_i u_i^{k-1} dx \\
&\quad + \sum_{i=1}^2 \int_\Omega \sigma D^{-h} \left[\chi_h \overline{u_1}\, \overline{u_2} D^h \ln\big(((u_1)_+ + \eta)((u_2)_+ + \eta)\big) \right] u_i dx \\
&\quad + \sum_{i=1}^2 \int_\Omega \sigma \big[R_i - \beta_{i1}((u_1)_+ + \eta) - \beta_{i2}((u_2)_+ + \eta) \big] ((u_i)_+ + \eta) u_i dx.
\end{aligned} \tag{2.7}
$$

The terms on the right-hand side are estimated by Young's inequality. For the third term we also use the elementary inequalities $|\overline{u_i}| \le 1/\eta$ and $|\ln(x + \eta)| \le x + |\ln \eta|$ for all $x \ge 0$ and $0 < \eta < 1$. This yields after some computations

$$
\begin{aligned}
&\sum_{i=1}^2 \int_\Omega \Big(\frac{c_i}{2} |\nabla u_i|^2 + \frac{u_i^2}{4\tau} + 2\sigma a_i \frac{(u_i)_+ + \eta}{1 + \nu((u_i)_+ + \eta)} |\nabla u_i|^2 \Big) dx \\
&\le \frac{1}{\tau} \sum_{i=1}^2 \int_\Omega (u_i^{k-1})^2 dx + 2|\Omega| \sum_{i=1}^2 (R_i + \beta_{i1} + \beta_{i2}) + \frac{128\tau}{h^4 \eta^4} |\ln \eta|^2 |\Omega| \\
&\quad + \sum_{i=1}^2 \int_\Omega u_i^2 \Big(- \frac{1}{4\tau} + \frac{d_i^2}{2c_i} \|q\|^2_{L^\infty} + \frac{64\tau}{h^4 \eta^4} + 2(R_i + \beta_{i1} + \beta_{i2}) \Big) dx,
\end{aligned}
$$

where $|\Omega|$ is the measure of Ω. By choosing τ so small that (2.3) is satisfied, in particular $64\tau/(h^4\eta^4) \le 1/16\tau$, we obtain

$$
\sum_{i=1}^2 \int_\Omega \Big(\frac{c_i}{2} |\nabla u_i|^2 + \frac{u_i^2}{4\tau} + 2\sigma a_i \frac{(u_i)_+ + \eta}{1 + \nu((u_i)_+ + \eta)} |\nabla u_i|^2 \Big) dx
$$

$$\le \frac{1}{\tau}\sum_{i=1}^2\int_\Omega (u_i^{k-1})^2dx + \sum_{i=1}^2\int_\Omega u_i^2\Big(-\frac{3}{16\tau}+\frac{d_i^2}{2c_i}\|q\|_{L^\infty}^2+2(R_i+\beta_{i1}+\beta_{i2})\Big)dx + C(\tau)$$
$$\le \frac{1}{\tau}\sum_{i=1}^2\int_\Omega (u_i^{k-1})^2dx + C(\tau) \le C(\tau).$$

By the Leray–Schauder theorem, $\mathcal{T}(1,\cdot)$ has a fixed point. Thus we conclude the existence of a weak solution of problem (2.2). The inequality (2.4) follows from the above estimate with $\sigma = 1$. □

Remark 2.3. From the proof of the above lemma we see that if $\beta_{ij} = 0$ for all $i,j = 1,2$, then the fixed-point mapping $\mathcal{T}$ can be defined on $[0,1]\times(L^2(\Omega))^2$. This allows us to prove the above result for *any* space dimension N (see Remark 3.6).

2.2. The limit $\nu \to 0$. We show in the following that the limit $\nu\to 0$ can be performed in (2.2).

LEMMA 2.4. *There exists a weak solution $(u_1,u_2)\in(H^1(\Omega))^2$ of problem (2.1) in the sense that for all $\varphi\in W^{1,2\cdot 2^*/(2^*-2)}(\Omega)$,*

$$\begin{aligned}&\int_\Omega \frac{u_i-u_i^{k-1}}{\tau}\varphi dx + \int_\Omega (c_i\nabla u_i + 2a_i((u_i)_+ +\eta)\nabla u_i + d_i(u_i)_+ q)\cdot\nabla\varphi dx\\ &\quad -\int_\Omega D^{-h}\left[\chi_h\overline{u_1}\,\overline{u_2}D^h\ln\big(((u_1)_+ +\eta)((u_2)_+ +\eta)\big)\right]\varphi dx\\ &\quad = \int_\Omega f_i\big((u_1)_+ +\eta,(u_2)_+ +\eta\big)\varphi dx,\end{aligned}\tag{2.8}$$

where $2^*=\infty$ if $N=1$, 2^* can be any real number if $N=2$, and $2^*=2N/(N-2)$ if $N\ge 3$.

Proof. Let $(u_1^\nu,u_2^\nu)\in(H^1(\Omega))^2$ be a weak solution of (2.2). From the uniform estimate (2.4) we conclude the existence of a subsequence of (u_1^ν,u_2^ν) (not relabeled) such that, as $\nu\to 0$,

$$\begin{aligned}\nabla u_i^\nu &\rightharpoonup \nabla u_i \quad \text{weakly in } (L^2(\Omega))^N,\\ u_i^\nu &\to u_i \quad \text{strongly in } L^r(\Omega),\ 1\le r<2^*,\ i=1,2.\end{aligned}\tag{2.9}$$

The last convergence result follows from the compactness of the embedding $H^1(\Omega)\hookrightarrow L^r(\Omega)$ for all $r<2^*$. In particular, we have $(u_i^\nu)_+\to(u_i)_+$ strongly in $L^r(\Omega)$ and

$$((u_i^\nu)_+ +\eta)\nabla u_i^\nu \rightharpoonup ((u_i)_+ +\eta)\nabla u_i \quad \text{weakly in } (L^s(\Omega))^N \text{ for all } 1\le s\le\frac{2r}{r+2}.$$

Here, we used the fact that the product of a strongly convergent and a weakly convergent sequence is weakly convergent (in an appropriate space). Since (u_i^ν) is uniformly bounded in $H^1(\Omega)$, Hölder's inequality implies

$$\|((u_i^\nu)_+ +\eta)\nabla u_i^\nu\|_{L^{2\cdot 2^*/(2+2^*)}(\Omega)} \le \|(u_i^\nu)_+ +\eta\|_{L^{2^*}(\Omega)}\|\nabla u_i^\nu\|_{L^2(\Omega)}\le C,$$

where $C>0$ is independent of ν. Thus, the above weak convergence also holds for $s = 2\cdot 2^*/(2+2^*)$.

Now we use the following result: Let $(v_\nu)\subset L^\infty(\Omega)$ and $(w_\nu)\subset L^s(\Omega)$ with $s\ge 1$ be two sequences such that (v_ν) is bounded in $L^\infty(\Omega)$, $v_\nu\to v$ pointwise

almost everywhere in Ω as $\nu \to 0$, and $w_\nu \rightharpoonup w$ weakly in $L^s(\Omega)$. Then, as $\nu \to 0$, $v_\nu w_\nu \rightharpoonup vw$ weakly in $L^s(\Omega)$. Applying this result to $v_\nu = 1/(1+\nu((u_i^\nu)_+ + \eta))$ and $w_\nu = ((u_i^\nu)_+ + \eta)\nabla u_i^\nu$ with $s = 2\cdot 2^*/(2+2^*)$ yields

$$\frac{(u_i^\nu)_+ + \eta}{1+\nu((u_i^\nu)_+ + \eta)}\nabla u_i^\nu \rightharpoonup ((u_i)_+ + \eta)\nabla u_i \quad \text{weakly in } (L^s(\Omega))^N, \quad s = \frac{2\cdot 2^*}{2+2^*}.$$

Moreover, by similar arguments as above, as $\nu \to 0$,

$$\begin{aligned}
&f_i((u_1^\nu)_+ + \eta, (u_2^\nu)_+ + \eta) = \big(R_i - \beta_{i1}((u_1^\nu)_+ + \eta) - \beta_{i2}((u_2^\nu)_+ + \eta)\big)((u_i^\nu)_+ + \eta) \\
&\rightharpoonup \big(R_i - \beta_{i1}((u_1)_+ + \eta) - \beta_{i2}((u_2)_+ + \eta)\big]((u_i)_+ + \eta) \quad \text{weakly in } L^{2^*/2}(\Omega), \\
&D^{-h}\left[\chi_h \overline{u_1^\nu}\ \overline{u_2^\nu} D^h \ln\left(((u_1^\nu)_+ + \eta)((u_2^\nu)_+ + \eta)\right)\right] \\
&\rightharpoonup D^{-h}\left[\chi_h \overline{u_1}\ \overline{u_2} D^h \ln\left(((u_1)_+ + \eta)((u_2)_+ + \eta)\right)\right] \quad \text{weakly in } L^s(\Omega)
\end{aligned}$$

for all $1 < s < \infty$. These convergence results allow us to pass to the limit $\nu \to 0$ in the weak formulation of (2.2) which yields (2.8), and hence the conclusion. ∎

2.3. Uniform estimates with respect to τ and h. The following entropy inequality is the key estimate of this paper providing uniform bounds in τ, h, and η.

LEMMA 2.5. *Let $(u_1, u_2) \in (H^1(\Omega))^2$ be a solution of (2.1). Then the following estimates hold:*

$$\begin{aligned}
&\int_\Omega \left[\sum_{i=1}^2 \Big(c_i \frac{|\nabla(u_i)_+|^2}{(u_i)_+ + \eta} + a_i |\nabla(u_i)_+|^2\Big)\right. \\
&\left. + \chi_h \overline{u_1}\ \overline{u_2} \left|D^h \ln\left(((u_1)_+ + \eta)((u_2)_+ + \eta)\right)\right|^2\right] dx \\
&+ \frac{1}{\tau}\sum_{i=1}^2 \int_\Omega \left[((u_i)_+ + \eta)\left(\ln((u_i)_+ + \eta) - 1\right) + (u_i)_- \ln \eta\right] dx \\
&\le \frac{1}{\tau}\sum_{i=1}^2 \int_\Omega \left[((u_i^{k-1})_+ + \eta)\left(\ln((u_i^{k-1})_+ + \eta) - 1\right) + (u_i^{k-1})_- \ln \eta\right] dx + C
\end{aligned} \tag{2.10}$$

and

$$\begin{aligned}
&\sum_{i=1}^2 \int_\Omega \Big(\frac{c_i}{2}|\nabla(u_i)_-|^2 + 2a_i\eta|\nabla(u_i)_-|^2\Big)dx + \frac{1}{2\tau}\sum_{i=1}^2 \int_\Omega |(u_i)_-|^2 dx \\
&\le \frac{1}{2\tau}\sum_{i=1}^2 \int_\Omega |(u_i^{k-1})_-|^2 dx + \eta C \int_\Omega \sum_{i=1}^2 (|(u_i)_+|^2 + |(u_i)_-|^2) dx \\
&+ \frac{C(c_1,c_2)}{\eta^2}\int_\Omega \chi_h \overline{u_1}\ \overline{u_2} \left|D^h \ln\left(((u_1)_+ + \eta)((u_2)_+ + \eta)\right)\right|^2 dx + C,
\end{aligned} \tag{2.11}$$

where $C > 0$ depends only on R_i, β_{ij} $(i,j = 1,2)$, and $\|q\|_{L^2(\Omega)}$.

Proof. Let (u_1, u_2) be a solution of (2.1); i.e., $u_i \in H^1(\Omega)$ satisfies (2.8), $i = 1, 2$. As $\ln((u_i)_+ + \eta) \notin W^{1,2\cdot 2^*/(2^*-2)}(\Omega)$ in general, we cannot use this function as a test function in the weak formulation (2.8). Therefore, we choose a sequence (v^ε) of smooth functions satisfying $v^\varepsilon \to (u_i)_+$ in $H^1(\Omega)$ (for some fixed i) and $v^\varepsilon \ge 0$ in Ω

and use $\varphi = \ln(v^\varepsilon + \eta)$ as a test function in (2.8):

$$
\begin{aligned}
&\int_\Omega \frac{u_i - u_i^{k-1}}{\tau} \ln(v^\varepsilon + \eta) dx \\
&+ \int_\Omega \big(c_i \nabla u_i + 2a_i((u_i)_+ + \eta)\nabla u_i + d_i (u_i)_+ q\big) \cdot \nabla \ln(v^\varepsilon + \eta) dx \\
&- \int_\Omega D^{-h}\left[\chi_h \overline{u_1}\,\overline{u_2} D^h \ln\left(((u_1)_+ + \eta)((u_2)_+ + \eta)\right)\right] \ln(v^\varepsilon + \eta) dx \\
&= \int_\Omega \big[R_i - \beta_{i1}((u_1)_+ + \eta) - \beta_{i2}((u_2)_+ + \eta)\big]((u_i)_+ + \eta)\ln(v^\varepsilon + \eta) dx.
\end{aligned} \tag{2.12}
$$

We claim that, as $\varepsilon \to 0$,

$$
\int_\Omega ((u_i)_+ + \eta)\nabla u_i \cdot \nabla \ln(v^\varepsilon + \eta) dx \to \int_\Omega |\nabla (u_i)_+|^2 dx. \tag{2.13}
$$

In order to prove this claim we observe that

$$
((u_i)_+ + \eta)\nabla \ln(v^\varepsilon + \eta) \rightharpoonup ((u_i)_+ + \eta)\nabla \ln((u_i)_+ + \eta) = \nabla (u_i)_+
$$

weakly in $L^{2\cdot 2^*/(2+2^*)}(\Omega)$ and

$$
\|((u_i)_+ + \eta)\nabla \ln(v^\varepsilon + \eta)\|_{L^2(\Omega)} \le \left\| \frac{(u_i)_+ + \eta}{v^\varepsilon + \eta} \right\|_{L^\infty(\Omega)} \|\nabla v^\varepsilon\|_{L^2(\Omega)} \le C,
$$

where $C > 0$ is a constant independent of ε. Therefore, the above weak convergence holds also in $L^2(\Omega)$. Since $\nabla u_i \in L^2(\Omega)$, the claim follows.

As $\ln(v^\varepsilon + \eta) \to \ln((u_i)_+ + \eta)$ in $H^1(\Omega)$, we can pass to the limit $\varepsilon \to 0$ in (2.12). Adding (2.12) for $i = 1$ and $i = 2$ and using (2.13) then gives in the limit $\varepsilon \to 0$

$$
\begin{aligned}
&\int_\Omega \Big[\sum_{i=1}^2 \Big(c_i \frac{|\nabla (u_i)_+|^2}{(u_i)_+ + \eta} + 2a_i |\nabla (u_i)_+|^2 \Big) \\
&+ \chi_h \overline{u_1}\,\overline{u_2} \left| D^h \ln\left(((u_1)_+ + \eta)((u_2)_+ + \eta)\right)\right|^2 \Big] dx \\
&+ \sum_{i=1}^2 \int_\Omega \frac{u_i - u_i^{k-1}}{\tau} \ln((u_i)_+ + \eta) dx - \sum_{i=1}^2 \int_\Omega |d_i q \nabla (u_i)_+| dx \\
&\le \sum_{i=1}^2 \int_\Omega \big[R_i - \beta_{i1}((u_1)_+ + \eta) - \beta_{i2}((u_2)_+ + \eta)\big]((u_i)_+ + \eta)\ln((u_i)_+ + \eta) dx.
\end{aligned} \tag{2.14}
$$

In the following we estimate the terms of the above inequality. With the elementary inequality $x(\ln x - \ln y) \ge x - y$ for all $x, y > 0$ (which is a consequence of the convexity of $x \mapsto \ln x$), we obtain

$$
\begin{aligned}
&\int_\Omega \frac{u_i - u_i^{k-1}}{\tau} \ln((u_i)_+ + \eta) dx \\
&= \frac{1}{\tau} \int_\Omega \big[((u_i)_+ + \eta)\ln((u_i)_+ + \eta) - ((u_i^{k-1})_+ + \eta)\ln((u_i^{k-1})_+ + \eta) \\
&\quad + ((u_i^{k-1})_+ + \eta)(\ln((u_i^{k-1})_+ + \eta) - \ln((u_i)_+ + \eta))\big] dx \\
&\quad + \frac{1}{\tau} \int_\Omega ((u_i)_- - (u_i^{k-1})_-)\ln((u_i)_+ + \eta) dx
\end{aligned} \tag{2.15}
$$

$$\geq \frac{1}{\tau}\int_\Omega [((u_i)_+ + \eta)(\ln((u_i)_+ + \eta) - 1) + (u_i)_- \ln\eta]dx$$
$$- \frac{1}{\tau}\int_\Omega [((u_i^{k-1})_+ + \eta)(\ln((u_i^{k-1})_+ + \eta) - 1) + (u_i^{k-1})_- \ln\eta]dx.$$

The last term on the left-hand side in (2.14) is estimated by employing Young's inequality:

$$\sum_{i=1}^2 \int_\Omega |d_i q \nabla(u_i)_+|dx \leq \sum_{i=1}^2 a_i \int_\Omega |\nabla(u_i)_+|^2 dx + C(a_1, a_2, d_1, d_2, \|q\|_{L^2(\Omega)}). \tag{2.16}$$

Finally, by the assumptions $\beta_{ii} > 0$ and $\beta_{12} = \beta_{21}$, the right-hand side of (2.14) is uniformly bounded. Putting the above estimates (2.15)–(2.16) together, the first inequality (2.10) follows from (2.14).

In order to derive the second inequality (2.11), we take a sequence (v^ε) of smooth functions satisfying $v^\varepsilon \to (u_i)_-$ in $H^1(\Omega)$ and $v^\varepsilon = 0$ in $\{u_i \geq 0\}$, and we choose $\varphi = v^\varepsilon$ as a test function in the weak formulation (2.8):

$$\sum_{i=1}^2 \int_\Omega \Big(c_i \nabla(u_i)_- \cdot \nabla v^\varepsilon + 2a_i\eta\nabla(u_i)_- \cdot \nabla v^\varepsilon\Big)dx + \sum_{i=1}^2 \int_\Omega \frac{u_i - u_i^{k-1}}{\tau} v^\varepsilon dx$$
$$\leq -\sum_{i=1}^2 \int_\Omega \chi_h \overline{u_1}\,\overline{u_2} D^h \ln\big(((u_1)_+ + \eta)((u_2)_+ + \eta)\big) \cdot D^h v^\varepsilon dx$$
$$+ \sum_{i=1}^2 \int_\Omega \big[R_i - \beta_{i1}((u_1)_+ + \eta) - \beta_{i2}((u_2)_+ + \eta)\big]\eta v^\varepsilon dx.$$

As above we can let $\varepsilon \to 0$ to obtain

$$\sum_{i=1}^2 \int_\Omega \Big(c_i|\nabla(u_i)_-|^2 + 2a_i\eta|\nabla(u_i)_-|^2\Big)dx + \sum_{i=1}^2 \int_\Omega \frac{u_i - u_i^{k-1}}{\tau}(u_i)_- dx$$
$$\leq -\sum_{i=1}^2 \int_\Omega \chi_h \overline{u_1}\,\overline{u_2} D^h \ln\big(((u_1)_+ + \eta)((u_2)_+ + \eta)\big) \cdot D^h(u_i)_- dx \tag{2.17}$$
$$+ \sum_{i=1}^2 \int_\Omega \big[R_i - \beta_{i1}((u_1)_+ + \eta) - \beta_{i2}((u_2)_+ + \eta)\big]\eta(u_i)_- dx.$$

The second term on the left-hand side can be estimated as follows:

$$\int_\Omega \frac{u_i - u_i^{k-1}}{\tau}(u_i)_- dx = \frac{1}{\tau}\int_\Omega \big(|(u_i)_-|^2 - (u_i^{k-1})_+(u_i)_- - (u_i^{k-1})_-(u_i)_-\big)\,dx$$
$$\geq \frac{1}{2\tau}\int_\Omega \big(|(u_i)_-|^2 - |(u_i^{k-1})_-|^2\big)\,dx. \tag{2.18}$$

For the first term on the right-hand side of (2.17) we employ Young's inequality:

$$-\int_\Omega \chi_h \overline{u_1}\,\overline{u_2} D^h \ln\big(((u_1)_+ + \eta)((u_2)_+ + \eta)\big) \cdot D^h(u_i)_- dx$$
$$\leq \frac{c_i}{2}\int_\Omega |\nabla(u_i)_-|^2 dx + \frac{C(c_i)}{\eta^2}\int_\Omega \chi_h \overline{u_1}\,\overline{u_2}\,\big|D^h \ln\big(((u_1)_+ + \eta)((u_2)_+ + \eta)\big)\big|^2 dx + C. \tag{2.19}$$

Finally, for the last term on the right-hand side of (2.17) follows

$$\sum_{i=1}^2\int_\Omega \big[R_i-\beta_{i1}((u_1)_+ +\eta)-\beta_{i2}((u_2)_+ +\eta)\big]\eta(u_i)_-dx$$
$$\le \eta C\sum_{i=1}^2\int_\Omega (|(u_i)_+|^2+|(u_i)_-|^2)dx. \tag{2.20}$$

Hence, (2.11) is a consequence of (2.17)–(2.20). □

3. Proof of Theorem 1.1. Let $(u_1^k,u_2^k)\in(H^1(\Omega))^2$ be a solution to (2.1). We set $u_i^{(\tau)}(x,t)=u_i^k(x)$ if $(x,t)\in\Omega\times((k-1)\tau,k\tau]$. With the discrete time derivative

$$D_t^\tau v(x,t):=\frac{v(x,t+\tau)-v(x,t)}{\tau},\quad (x,t)\in\Omega\times[0,\infty),$$

we can rewrite the approximate problem (2.1) as

$$\begin{aligned}
&D_t^\tau u_i^{(\tau)}-\operatorname{div}\Big(c_i\nabla u_i^{(\tau)}+2a_i((u_i^{(\tau)})_+ +\eta)\nabla u_i^{(\tau)}+d_i(u_i^{(\tau)})_+q\Big)\\
&\quad -D^{-h}\Big[\chi_h\overline{u_1^{(\tau)}}\,\overline{u_2^{(\tau)}}D^h\ln\big(((u_1^{(\tau)})_+ +\eta)((u_2^{(\tau)})_+ +\eta)\big)\Big]\\
&=f_i\big((u_1^{(\tau)})_+ +\eta,(u_2^{(\tau)})_+ +\eta\big)\quad\text{in }\Omega,\\
&\Big(c_i\nabla u_i^{(\tau)}+2a_i((u_i^{(\tau)})_+ +\eta)\nabla u_i^{(\tau)}+d_i(u_i^{(\tau)})_+q\Big)\cdot\gamma=0\quad\text{on }\partial\Omega,
\end{aligned}\tag{3.1}$$

together with the initial conditions corresponding to (1.4).

The proof of Theorem 1.1 is divided into two parts. In subsection 3.1, we assume that $\eta>0$ is fixed and perform the limit $\tau,h\to 0$. In subsection 3.2, we prove the limit $\eta\to 0$. At this step we show the nonnegativity of the solution.

3.1. The limit $\tau,h\to 0$. The problem (2.1) has a solution under the condition that the parameters τ and h are related by the inequality $32\tau\le h^2\eta^2$. Therefore we let τ and h tend to zero simultaneously in such a way that the inequality $32\tau\le h^2\eta^2$ is satisfied (for fixed $\eta>0$).

LEMMA 3.1. *Let $T>0$. The following estimates hold for $i=1,2$:*

$$\|\nabla(u_i^{(\tau)})_+\|_{L^2(Q_T)}+\|(u_i^{(\tau)})_+\|_{L^\infty(0,T;L_\Psi(\Omega))}\le C, \tag{3.2}$$

$$\Big\|\chi_h\sqrt{\overline{u_1^{(\tau)}}\,\overline{u_2^{(\tau)}}}D^h\ln\Big((u_1^{(\tau)})_+ +\eta)((u_2^{(\tau)})_+ +\eta)\Big)\Big\|_{L^2(Q_T)}\le C, \tag{3.3}$$

$$\|\nabla(u_i^{(\tau)})_-\|_{L^2(Q_T)}+\|(u_i^{(\tau)})_-\|_{L^\infty(0,T;L^2(\Omega))}\le C/\eta, \tag{3.4}$$

where $C>0$ is independent of c_1, c_2, h, τ, and η. Furthermore,

$$\|u_i^{(\tau)}\|_{L^2(0,T;H^1(\Omega))}+\|u_i^{(\tau)}\|_{L^p(Q_T)}\le C(\eta), \tag{3.5}$$

$$\|D_t^\tau u_i^{(\tau)}\|_{L^r(0,T;(W^{1,r'}(\Omega))')}\le C(\eta), \tag{3.6}$$

where $p=(2N+2)/N$, $r=(2N+2)/(2N+1)$, $r'=r/(r-1)=2N+2$, and $C(\eta)>0$ does not depend on τ or h.

Proof. The estimates (3.2)–(3.5) are consequences of the key inequalities (2.10) and (2.11). First, we prove (3.2) and (3.3). Let $K\in\mathbb{N}$, and set $\tau=T/K$. The

estimate (2.10) can be rewritten at $t_k = k\tau$ as

$$\begin{aligned}
&\int_0^{t_k}\int_\Omega \Big[\sum_{i=1}^2 \Big(4c_i\Big|\nabla\sqrt{(u_i^{(\tau)})_+ + \eta}\Big|^2 + a_i|\nabla(u_i^{(\tau)})_+|^2\Big) \\
&\quad + \chi_h \overline{u_1^{(\tau)}}\,\overline{u_2^{(\tau)}}\Big|D^h \ln\big(((u_1^{(\tau)})_+ + \eta)((u_2^{(\tau)})_+ + \eta)\big)\Big|^2\Big]dxdt \\
&\quad + \sum_{i=1}^2 \int_\Omega \Big(((u_i^{(\tau)})_+ + \eta)(\ln((u_i^{(\tau)})_+ + \eta) - 1) + \ln\eta(u_i^{(\tau)})_-\Big)\Big|_{t=t_k} dx \\
&\le C(T, \|u_i^0\|_{L_\Psi(\Omega)}).
\end{aligned}$$

From the elementary inequalities $x \le x(\ln x - 1) + C$ and $(1+x)\ln(1+x) - x \le x(\ln x - 1) + x + C$ for all $x \ge 0$ for some $C > 0$ and from (4.1) we obtain at $t = t_k$

$$\begin{aligned}
&\int_\Omega (u_i^{(\tau)})_+ dx \le \int_\Omega ((u_i^{(\tau)})_+ + \eta)(\ln((u_i^{(\tau)})_+ + \eta) - 1)dx + C|\Omega| \le C, \\
&\|(u_i^{(\tau)})_+\|_{L_\Psi(\Omega)} \le 1 + \int_\Omega \Psi\big((u_i^{(\tau)})_+\big)dx \le C.
\end{aligned} \tag{3.7}$$

Since the functions $u_i^{(\tau)}$ are piecewise constant with respect to t, we have

$$\begin{aligned}
&\int_0^T\int_\Omega \Big[\sum_{i=1}^2 \Big(4c_i\Big|\nabla\sqrt{(u_i^{(\tau)})_+ + \eta}\Big|^2 + a_i|\nabla(u_i^{(\tau)})_+|^2\Big) \\
&\quad + \chi_h \overline{u_1^{(\tau)}}\,\overline{u_2^{(\tau)}}\Big|D^h(\ln\big(((u_1^{(\tau)})_+ + \eta)((u_2^{(\tau)})_+ + \eta)\big)\Big|^2\Big]dxdt \\
&\quad + \sum_{i=1}^2 \sup_{0<t<T}\Big(\|(u_i^{(\tau)})_+(\cdot,t)\|_{L_\Psi(\Omega)} + \|\ln\eta(u_i^{(\tau)})_-(\cdot,t)\|_{L^1(\Omega)}\Big) \le C.
\end{aligned} \tag{3.8}$$

This gives a uniform bound for $\|\nabla(u_i^{(\tau)})_+\|_{L^2(Q_T)}$ and shows (3.2)–(3.3). An L^2 bound for $(u_i^{(\tau)})_+$ can be derived from this estimate, the Poincaré inequality, and (3.7):

$$\int_0^T \|(u_i^{(\tau)})_+\|^2_{L^2(\Omega)}dt \le C(|\Omega|,T)\int_0^T \|\nabla(u_i^{(\tau)})_+\|^2_{L^2(\Omega)}dt + C(|\Omega|,T). \tag{3.9}$$

For the proof of (3.4) we employ the estimate (2.11), rewritten at $t_k = k\tau$ as

$$\begin{aligned}
&\int_0^{t_k}\int_\Omega \sum_{i=1}^2 \Big(\frac{c_i}{2}|\nabla(u_i^{(\tau)})_-|^2 + 2a_i\eta|\nabla(u_i^{(\tau)})_-|^2\Big)dxdt + \frac{1}{2}\sum_{i=1}^2\int_\Omega |(u_i^{(\tau)})_-(\cdot,t_k)|^2dx \\
&\le C + \eta C\sum_{i=1}^2\int_0^{t_k}\int_\Omega (|(u_i^{(\tau)})_+|^2 + |(u_i^{(\tau)})_-|^2)dxdt \\
&\quad + \frac{C}{\eta^2}\int_0^{t_k}\int_\Omega \chi_h \overline{u_1^{(\tau)}}\,\overline{u_2^{(\tau)}}\Big|D^h\ln\big(((u_1^{(\tau)})_+ + \eta)((u_2^{(\tau)})_+ + \eta)\big)\Big|^2 dxdt.
\end{aligned}$$

Taking into account (3.3) and (3.9) and applying Gronwall's inequality, this proves (3.4).

Next we show the estimate (3.5). As the functions $u_i^{(\tau)}$ are piecewise constant with respect to t, we obtain, with the help of (3.8) and (3.9),

$$\int_0^t\int_\Omega\sum_{i=1}^2\Big(\frac{c_i}{2}|\nabla(u_i^{(\tau)})_-|^2+2a_i\eta|\nabla(u_i^{(\tau)})_-|^2\Big)dxdt+\frac12\sum_{i=1}^2\int_\Omega|(u_i^{(\tau)})_-(\cdot,t)|^2dx$$
$$\le C(|\Omega|,T,\|u_i^0\|_{L_\Psi(\Omega)},\eta)+C\int_0^t\int_\Omega\sum_{i=1}^2|(u_i^{(\tau)})_-|^2dxdt.$$

Thus, by Gronwall's inequality,

$$\sum_{i=1}^2\int_0^T\int_\Omega\Big(\frac{c_i}{2}|\nabla(u_i^{(\tau)})_-|^2+2a_i\eta|\nabla(u_i^{(\tau)})_-|^2\Big)dxdt$$
$$+\frac12\sum_{i=1}^2\sup_{0<t<T}\int_\Omega|(u_i^{(\tau)})_-(\cdot,t)|^2dx\le C(\eta). \tag{3.10}$$

This provides a uniform bound for $(u_i^{(\tau)})_-$ in $L^2(0,T;H^1(\Omega))$, and from (3.2), (3.8), (3.9), and (3.10) we infer

$$\|u_i^{(\tau)}\|_{L^2(0,T;H^1(\Omega))}+\|u_i^{(\tau)}\|_{L^\infty(0,T;L^1(\Omega))}\le C(\eta).$$

Applying the Gagliardo–Nirenberg inequality with $p=(2N+2)/N$ and $\theta=2N(p-1)/(p(N+2))$ (and thus $\theta p=2$) yields

$$\|u_i^{(\tau)}\|_{L^p(Q_T)}\le\left(\int_0^T\|u_i^{(\tau)}\|_{L^1(\Omega)}^{(1-\theta)p}\|u_i^{(\tau)}\|_{H^1(\Omega)}^{\theta p}dt\right)^{1/p}$$
$$\le\|u_i^{(\tau)}\|_{L^\infty(0,T;L^1(\Omega))}^{1-\theta}\left(\int_0^T\|u_i^{(\tau)}\|_{H^1(\Omega)}^{\theta p}dt\right)^{1/p}\le C(\eta).$$

Finally, we derive a bound for the discrete time derivative $D_t^\tau u_i^{(\tau)}$. Using (3.1), we obtain, for $r=(2N+2)/(2N+1)$, since $p>r$,

$$\begin{aligned}
&\|D_t^\tau u_i^{(\tau)}\|_{L^r(0,T;(W^{1,r'}(\Omega))')}\\
&\le\|c_i\nabla u_i^{(\tau)}+2a_i((u_i^{(\tau)})_++\eta)\nabla u_i^{(\tau)}\|_{L^r(Q_T)}\\
&\quad+\Big\|\chi_h\overline{u_1^{(\tau)}}\,\overline{u_2^{(\tau)}}D^h\ln\big(((u_1^{(\tau)})_++\eta)((u_2^{(\tau)})_++\eta)\big)+d_i(u_i^{(\tau)})_+q\Big\|_{L^r(Q_T)}\\
&\quad+\big\|f_i\big((u_1^{(\tau)})_++\eta,(u_2^{(\tau)})_++\eta\big)\big\|_{L^r(Q_T)}\\
&\le C(|\Omega|,T)\|\nabla u_i^{(\tau)}\|_{L^2(Q_T)}+2a_i\|u_i^{(\tau)}+\eta\|_{L^p(Q_T)}\|\nabla u_i^{(\tau)}\|_{L^2(Q_T)}\\
&\quad+\frac12(\|u_1^{(\tau)}\|_{L^p(Q_T)}+\|u_2^{(\tau)}\|_{L^p(Q_T)})\\
&\quad\times\left\|\chi_h\sqrt{\overline{u_1^{(\tau)}}\,\overline{u_2^{(\tau)}}}D^h\ln\big(((u_1^{(\tau)})_++\eta)((u_2^{(\tau)})_++\eta)\big)\right\|_{L^2(Q_T)}\\
&\quad+|d_i|\,\|u_i^{(\tau)}\|_{L^p(Q_T)}\|q\|_{L^2(Q_T)}+C(T,|\Omega|)(\|u_i^{(\tau)}\|_{L^p(Q_T)}+\|u_i^{(\tau)}\|_{L^p(Q_T)}).
\end{aligned}$$

Then (3.6) follows from (3.3) and (3.5). ∎

Now we are able to perform the limit $\tau,\, h \to 0$.

LEMMA 3.2. *As $\tau, h \to 0$ such that $32\tau \le h^2\eta^2$, there exists a pair (u_1^η, u_2^η) satisfying (up to a subsequence which is not relabeled), for $i = 1, 2$,*

$$\nabla u_i^{(\tau)} \rightharpoonup \nabla u_i^\eta \quad \text{weakly in } (L^2(Q_T))^N, \tag{3.11}$$

$$((u_i^{(\tau)})_+ + \eta)\nabla u_i^{(\tau)} \rightharpoonup ((u_i^\eta)_+ + \eta)\nabla u_i^\eta \quad \text{weakly in } (L^r(Q_T))^N, \tag{3.12}$$

$$\chi_h \overline{u_1^{(\tau)}}\,\overline{u_2^{(\tau)}} D^h \ln\big(((u_1^{(\tau)})_+ + \eta)((u_2^{(\tau)})_+ + \eta)\big)$$

$$\rightharpoonup \overline{u_1^\eta}\,\overline{u_2^\eta}\nabla \ln\big(((u_1^\eta)_+ + \eta)((u_2^\eta)_+ + \eta)\big) \quad \text{weakly in } (L^2(Q_T))^N, \tag{3.13}$$

$$d_i(u_i^{(\tau)})_+ q \rightharpoonup d_i(u_i^\eta)_+ q \quad \text{weakly in } (L^r(Q_T))^N, \tag{3.14}$$

$$f_i\big((u_1^{(\tau)})_+ + \eta, (u_2^{(\tau)})_+ + \eta\big)$$

$$\rightharpoonup f_i\big((u_1^\eta)_+ + \eta, (u_2^\eta)_+ + \eta\big) \quad \text{weakly in } L^{p/2}(\Omega), \tag{3.15}$$

$$D_t^\tau u_i^{(\tau)} \rightharpoonup \partial_t u_i^\eta \quad \text{weakly in } L^r(0,T;(W^{1,r'}(\Omega))'),$$

where $p = (2N+2)/N$, $r = (2N+2)/(2N+1)$, and $r' = 2N+2$.

Proof. The first and last convergences are direct consequences of (3.2) and (3.5). In order to treat the nonlinear terms, we need a strong convergence result. Taking into account (3.5) and (3.6), we can apply the version of Aubin's lemma in [26, Thm. 6] to obtain, for a subsequence which is not relabeled, as $\tau, h \to 0$,

$$u_i^{(\tau)} \to u_i^\eta \quad \text{strongly in } L^q(0,T;L^2(\Omega)), \quad 1 < q < 2. \tag{3.16}$$

In particular, (a subsequence of) $(u_i^{(\tau)})$ converges pointwise almost everywhere in Q_T to u_i^η. This, together with the bound $\|u_i^{(\tau)}\|_{L^p(Q_T)} \le C$ (which comes from (3.5)), implies

$$u_i^{(\tau)} \to u_i^\eta \quad \text{strongly in } L^\alpha(Q_T), \quad 2 < \alpha < p, \tag{3.17}$$

and $(u_i^{(\tau)})_+ \to (u_i^\eta)_+$ strongly in $L^\alpha(Q_T)$. By (3.11) we obtain for $s = 2\alpha/(2+\alpha) < r$

$$(u_i^{(\tau)})_+ \nabla u_i^{(\tau)} \rightharpoonup (u_i^\eta)_+ \nabla u_i^\eta \quad \text{weakly in } (L^s(Q_T))^N.$$

Since

$$\|(u_i^{(\tau)})_+ \nabla u_i^{(\tau)}\|_{L^r(Q_T)} \le \|u_i^{(\tau)}\|_{L^p(Q_T)} \|\nabla u_i^{(\tau)}\|_{L^2(Q_T)} \le C,$$

the above weak convergence also holds for $s = r$. In a similar way, since $q \in (L^2(Q_T))^N$, the convergences (3.14) and (3.15) can be proved.

Finally, we show (3.13). Using

$$\|\ln((u_i^{(\tau)})_+ + \eta)\|_{L^2(Q_T)} \le |\ln\eta| + \|(u_i^{(\tau)})_+ + \eta\|_{L^2(Q_T)} \le C(\eta),$$

$$\|D^h \ln((u_i^{(\tau)})_+ + \eta)\|_{L^2(Q_T)} \le \frac{C}{\eta} \|\nabla (u_i^{(\tau)})_+\|_{L^2(Q_T)} \le C(\eta),$$

and $(u_i^{(\tau)})_+ \to (u_i^\eta)_+$ almost everywhere in Q_T, we conclude that

$$D^h \ln((u_i^{(\tau)})_+ + \eta) \rightharpoonup \nabla \ln((u_i^\eta)_+ + \eta) \quad \text{weakly in } (L^2(Q_T))^N.$$

Then (3.13) follows from

$$\left\|\chi_h \overline{u_1^{(\tau)}}\,\overline{u_2^{(\tau)}}\right\|_{L^\infty(Q_T)} \le \frac{1}{\eta^2}.$$

This proves Lemma 3.2. □

Letting $\tau, h \to 0$ in the weak version of (3.1) such that $32\tau \le h^2\eta^2$, we obtain for all $\varphi \in L^{r'}(0,T;W^{1,r'}(\Omega))$

$$\begin{aligned}\int_0^T \langle \partial_t u_i^\eta, \varphi\rangle_{(W^{1,r'}(\Omega))',W^{1,r'}(\Omega)}\,dt + \int_{Q_T} (c_i\nabla u_i^\eta + 2a_i((u_i^\eta)_+ + \eta)\nabla u_i^\eta)\cdot\nabla\varphi dxdt \\ + \int_{Q_T}\Big[\overline{u_1^\eta}\,\overline{u_2^\eta}\nabla\ln\big(((u_1^\eta)_+ + \eta)((u_2^\eta)_+ + \eta)\big) + d_i(u_i)_+ q\Big]\cdot\nabla\varphi dxdt \\ = \int_{Q_T} f_i\big((u_1^\eta)_+ + \eta, (u_2^\eta)_+ + \eta\big)\varphi dxdt.\end{aligned} \tag{3.18}$$

By Lemma 3.2, the functions u_1^η and u_2^η are satisfying the properties

$$\begin{aligned}&u_i^\eta \in L^2(0,T;H^1(\Omega)) \cap L^p(Q_T),\\ &(u_i^\eta)_+ \in L^\infty(0,T;L_\Psi(\Omega)),\quad (u_i^\eta)_- \in L^\infty(0,T;L^2(\Omega)),\quad i=1,2.\end{aligned} \tag{3.19}$$

3.2. The limit $\eta \to 0$. The last step in the proof of Theorem 1.1 is to perform the limit $\eta \to 0$. First, we need some a priori estimates.

LEMMA 3.3. *Let $T > 0$. The following estimates hold for $i = 1, 2$:*

$$\|\nabla(u_i^\eta)_+\|_{L^2(Q_T)} + \|(u_i^\eta)_+\|_{L^\infty(0,T;L_\Psi(\Omega))} \le C, \tag{3.20}$$

$$\|\ln\eta(u_i^\eta)_-\|_{L^\infty(0,T;L^1(\Omega))} \le C, \tag{3.21}$$

$$\left\|\sqrt{\overline{u_1^\eta}\,\overline{u_2^\eta}}\nabla\ln\big(((u_1^\eta)_+ + \eta)((u_2^\eta)_+ + \eta)\big)\right\|_{L^2(Q_T)} \le C, \tag{3.22}$$

$$\|\nabla(u_i^\eta)_-\|_{L^2(Q_T)} + \|(u_i^\eta)_-\|_{L^\infty(0,T;L^2(\Omega))} \le C, \tag{3.23}$$

$$\|u_i^\eta\|_{L^2(0,T;H^1(\Omega))} + \|u_i^\eta\|_{L^p(Q_T)} \le C, \tag{3.24}$$

$$\|\partial_t u_i^\eta\|_{L^r(0,T;(W^{1,r'}(\Omega))')} \le C, \tag{3.25}$$

where $p = (2N+2)/N$, $r = (2N+2)/(2N+1)$, $r' = 2N+2$, and $C > 0$ is a constant independent of c_1, c_2, and η.

Proof. Let $i \in \{1,2\}$. Choose a sequence (v^ε) of smooth functions such that, as $\varepsilon \to 0$,

$$v^\varepsilon \to (u_i^\eta)_+ \quad \text{in } L^2(0,T;H^1(\Omega)) \cap L^\infty(0,T;L_\Psi(\Omega)) \cap L^p(Q_T) \tag{3.26}$$

and $v^\varepsilon = 0$ on $\{u_i \le 0\}$. Such a choice is possible in view of the regularity (3.19). We claim that

$$\begin{aligned}\int_0^t \langle \partial_t u_i^\eta, \ln(v^\varepsilon + \eta)\rangle dt \to \int_\Omega \big((u_i^\eta)_+ + \eta)(\ln(u_i^\eta)_+ + \eta) - 1) + \ln\eta(u_i^\eta)_-\big)dx \\ - \int_\Omega (u_i^0 + \eta)(\ln(u_i^0 + \eta) - 1)dx\end{aligned} \tag{3.27}$$

and

$$\int_{Q_T} a_i((u_i^\eta)_+ + \eta)\nabla u_i^\eta \cdot \nabla\ln(v^\varepsilon + \eta)dxdt \to \int_{Q_T} a_i|\nabla(u_i^\eta)_+|^2 dxdt. \tag{3.28}$$

In fact, in order to show the second claim (3.28), we need only to show

$$((u_i^\eta)_+ + \eta)\nabla \ln(v^\varepsilon + \eta) \rightharpoonup \nabla (u_i^\eta)_+ \quad \text{weakly in } (L^2(Q_T))^N.$$

This convergence follows from $((u_i^\eta)_+ + \eta)/(v^\varepsilon + \eta) \to 1$ almost everywhere in Q_T and $\nabla v^\varepsilon \to \nabla (u_i^\eta)_+$ in $(L_2(Q_T))^N$.

The proof of the first claim (3.27) is more delicate. By integration by parts, we have

(3.29)

$$\begin{aligned}\int_0^t \langle \partial_t u_i^\eta, \ln(v^\varepsilon + \eta)\rangle dt &= \int_0^t \langle \partial_t (u_i^\eta)_+, \ln(v^\varepsilon + \eta)\rangle dt + \int_0^t \langle \partial_t (u_i^\eta)_-, \ln \eta\rangle dt \\ &= \int_\Omega [((u_i^\eta)_+ + \eta)\ln(v^\varepsilon + \eta)]_0^t \, dx - \int_{Q_t} \frac{(u_i^\eta)_+ + \eta}{v^\varepsilon + \eta} \partial_t v^\varepsilon dx dt + \ln \eta \int_\Omega [(u_i^\eta)_-]_0^t \, dx.\end{aligned}$$

We consider the first term on the right-hand side. It holds for all $t \in (0,T)\backslash\mathcal{N}$, where $\mathcal{N}$ is a set of measure zero, that

$$\|\ln(v^\varepsilon(\cdot,t) + \eta) - \ln((u_i^\eta)_+(\cdot,t) + \eta)\|_{L^\infty(\Omega)} = \left\| \ln \frac{v^\varepsilon(\cdot,t) + \eta}{(u_i^\eta)_+(\cdot,t) + \eta} \right\|_{L^\infty(\Omega)} \le C$$

for some $C > 0$ and, as $\varepsilon \to 0$,

$$\ln(v^\varepsilon(\cdot,t) + \eta) - \ln((u_i^\eta)_+(\cdot,t) + \eta) \to 0 \quad \text{strongly in } L^1(\Omega),$$

uniformly in $t \in (0,T)\backslash\mathcal{N}$. In particular, this sequence converges in measure. Now let $\Phi(s) = e^s - s - 1$ be the complementary Young function to Ψ, and define $\Phi_2(s) = \exp(s^2) - 1$, $s \ge 0$. Then Φ_2 is a Young function, and

$$\lim_{t\to\infty} \frac{\Phi(kt)}{\Phi_2(t)} = 0 \quad \text{for all } k > 0.$$

Thus, by Theorem 4.1 of the appendix,

$$\ln(v^\varepsilon(\cdot,t) + \eta) - \ln((u_i^\eta)_+(\cdot,t) + \eta) \to 0 \quad \text{strongly in } L_\Phi(\Omega),$$

uniformly in $t \in (0,T)\backslash\mathcal{N}$. Therefore, as $(u_i^\eta)_+ + \eta \in L^\infty(0,T;L_\Psi(\Omega))$, Young's inequality (4.2) implies, for $t \in (0,T)\backslash\mathcal{N}$,

$$\begin{aligned}&\int_\Omega ((u_i^\eta)_+(\cdot,t) + \eta)\big(\ln(v^\varepsilon(\cdot,t) + \eta) - \ln((u_i^\eta)_+(\cdot,t) + \eta)\big)dx \\ &\le 2\|(u_i^\eta)_+(\cdot,t) + \eta\|_{L_\Psi(\Omega)} \|\ln(v^\varepsilon(\cdot,t) + \eta) - \ln((u_i^\eta)_+(\cdot,t) + \eta)\|_{L_\Phi(\Omega)} \to 0.\end{aligned}$$

We conclude that, for almost every $t \in (0,T)$, as $\varepsilon \to 0$,

$$\int_\Omega [((u_i^\eta)_+ + \eta)\ln(v^\varepsilon + \eta)]_0^t dx \to \int_\Omega [((u_i^\eta)_+ + \eta)\ln((u_i^\eta)_+ + \eta)]_0^t \, dx.$$

It remains to treat the second term in (3.29). Let $(0,t] = \cup_{k=0}^{K-1}(t_k, t_{k+1}]$, where $t_k \in (0,t]\backslash\mathcal{N}$ and $t_K := t$, be a partition of the interval $(0,t]$. Then we can write the term as follows:

$$\begin{aligned}&\lim_{\varepsilon\to 0} \int_{Q_t} \frac{(u_i^\eta)_+ + \eta}{v^\varepsilon + \eta} \partial_t v^\varepsilon dx dt \\ &= \lim_{\varepsilon\to 0} \lim_{K\to\infty} \sum_{k=0}^{K-1} \int_\Omega \frac{(u_i^\eta)_+(x,t_k) + \eta}{v^\varepsilon(x,t_k) + \eta} (v^\varepsilon(x,t_{k+1}) - v^\varepsilon(x,t_k))dx.\end{aligned}$$

The sequence $((u_i^\eta)_+(\cdot,t_k)+\eta)/(v^\varepsilon(\cdot,t_k)+\eta)$ converges to one weakly* in $L^\infty(\Omega)$ as $\varepsilon\to 0$ and $v^\varepsilon(\cdot,t_{k+1})-v^\varepsilon(\cdot,t_k)$ converges to $(u_i^\eta)_+(\cdot,t_{k+1})-{-(u_i^\eta)_+}(\cdot,t_k)$ strongly in $L^1(\Omega)$, uniformly in $t\in(0,T)\backslash\mathcal{N}$. Hence, we can exchange the limits $\varepsilon\to 0$ and $K\to\infty$ to obtain

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\int_{Q_t}\frac{(u_i^\eta)_+ +\eta}{v^\varepsilon+\eta}\partial_t v^\varepsilon dxdt\\
&=\lim_{K\to\infty}\lim_{\varepsilon\to 0}\sum_{k=0}^{K-1}\int_\Omega\frac{(u_i^\eta)_+(x,t_k)+\eta}{v^\varepsilon(x,t_k)+\eta}(v^\varepsilon(x,t_{k+1})-v^\varepsilon(x,t_k))dx\\
&=\lim_{K\to\infty}\sum_{k=0}^{K-1}\int_\Omega((u_i^\eta)_+(x,t_{k+1})-(u_i^\eta)_+(x,t_k))dx\\
&=\int_\Omega((u_i^\eta)_+(x,t)-u_i^0(x))dx.
\end{aligned}$$

This proves (3.27).

Now we use $\varphi=\ln(v^\varepsilon+\eta)$ as a test function in (3.18) and perform the limit $\varepsilon\to 0$ by employing the above claims (3.27) and (3.28). This implies, after addition of the two equations for $i=1,2$ and estimating as above,

$$\begin{aligned}
&\sum_{i=1}^2\int_\Omega\big((u_i^\eta)_+ +\eta)(\ln(u_i^\eta)_+ +\eta)-1)+\ln\eta(u_i^\eta)_-\big)dx\\
&+\int_{Q_T}\sum_{i=1}^2\Big(c_i\frac{|\nabla(u_i^\eta)_+|^2}{(u_i^\eta)_+ +\eta}+a_i|\nabla(u_i^\eta)_+|^2\Big)dxdt\\
&+\int_{Q_T}\overline{u_1^\eta}\,\overline{u_2^\eta}\left|\nabla\ln\big(((u_1^\eta)_+ +\eta)((u_2^\eta)_+ +\eta)\big)\right|^2dxdt\le C,
\end{aligned}\tag{3.30}$$

where $C>0$ depends only on a_1, a_2, $\|q\|_{L^2(Q_T)}$, and $\|u_i^0\|_{L_\Psi(\Omega)}$. This shows (3.20)–(3.22).

In the next step, we choose $\varphi=w^\varepsilon$ as a test function in (3.18), where (w^ε) is a smooth sequence such that, as $\varepsilon\to 0$,

$$w^\varepsilon\to(u_i^\eta)_-\quad\text{in } L^2(0,T;H^1(\Omega))\cap L^\infty(0,T;L^2(\Omega))\tag{3.31}$$

and $w^\varepsilon=0$ in $\{u_i^\eta\ge 0\}$. Then we have

$$\begin{aligned}
&\int_0^t\langle\partial_t(u_i^\eta)_-,w^\varepsilon\rangle dt+\int_{Q_t}(c_i\nabla(u_i^\eta)_-\cdot\nabla w^\varepsilon+2a_i\eta\nabla(u_i^\eta)_-\cdot\nabla w^\varepsilon)dxdt\\
&=\int_{Q_t}\big[R_i-\beta_{i1}((u_1^\eta)_+ +\eta)-\beta_{i2}((u_2^\eta)_+ +\eta)\big]\eta w^\varepsilon dxdt.
\end{aligned}\tag{3.32}$$

We infer from (3.31) that

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\int_0^t\langle\partial_t(u_i^\eta)_-,w^\varepsilon\rangle dt=\lim_{\varepsilon\to 0}\frac12\int_\Omega[|w^\varepsilon|^2]_0^t dx+\lim_{\varepsilon\to 0}\int_0^t\langle\partial_t((u_i^\eta)_- -w^\varepsilon),w^\varepsilon\rangle dt\\
&=\frac12\int_\Omega[|(u_i^\eta)_-|^2]_0^t dx+\lim_{\varepsilon\to 0}\int_\Omega[((u_i^\eta)_- -w^\varepsilon)w^\varepsilon]_0^t dx+\lim_{\varepsilon\to 0}\int_{Q_t}\partial_t w^\varepsilon((u_i^\eta)_- -w^\varepsilon)dxdt\\
&=\frac12\int_\Omega[|(u_i^\eta)_-|^2]_0^t dx
\end{aligned}$$

$$
\begin{aligned}
&+\lim_{\varepsilon\to 0}\lim_{K\to\infty}\sum_{k=0}^{K-1}\int_\Omega (w^\varepsilon(x,t_{k+1})-w^\varepsilon(x,t_k))((u_i^\eta)_-(x,t_k)-w^\varepsilon(x,t_k))dx\\
&=\frac{1}{2}\int_\Omega [|(u_i^\eta)_-|^2]_0^t dx,
\end{aligned}
$$

where similarly as above $(0,t]=\cup_{k=0}^{K-1}(t_k,t_{k+1}]$. The convergence of the other terms in (3.32) as $\varepsilon\to 0$ follows directly from (3.31). This yields

$$
\begin{aligned}
&\frac{1}{2}\sum_{i=1}^2\int_\Omega |(u_i^\eta)_-(\cdot,t)|^2dx+\sum_{i=1}^2\int_{Q_t}(c_i|\nabla(u_i^\eta)_-|^2+2a_i\eta|\nabla(u_i^\eta)_-|^2)dxdt\\
&=\sum_{i=1}^2\int_{Q_t}\big[R_i-\beta_{i1}((u_1^\eta)_+ +\eta)-\beta_{i2}((u_2^\eta)_+ +\eta)\big]\eta(u_i^\eta)_-dxdt\\
&\le C\sum_{i=1}^2\int_{Q_t}(|(u_i^\eta)_+|^2+|(u_i^\eta)_-|^2)+C,
\end{aligned}
\tag{3.33}
$$

where $C>0$ is independent of η. The estimate (3.20) and Gronwall's inequality then imply (3.23). Finally, the inequalities (3.24) and (3.25) can be derived similarly as in the proof of Lemma 3.1. ∎

LEMMA 3.4. *As $\eta\to 0$, there exist functions u_1, $u_2\ge 0$ such that the following convergences hold (up to subsequences which are not relabeled), for $i=1,2$:*

$$
\begin{aligned}
c_i\nabla u_i^\eta &\rightharpoonup c_i\nabla u_i \quad \text{weakly in } (L^2(Q_T))^N,\\
2a_i((u_i^\eta)_+ +\eta)\nabla u_i^\eta &\rightharpoonup 2a_iu_i\nabla u_i \quad \text{weakly in } (L^r(Q_T))^N,\\
\overline{u_1^\eta}\,\overline{u_2^\eta}\nabla\ln((u_1^\eta)_+ +\eta)((u_2^\eta)_+ +\eta) &\rightharpoonup \nabla(u_1u_2) \quad \text{weakly in } (L^r(Q_T))^N,\\
d_i(u_i^\eta)_+ q &\rightharpoonup d_iu_iq \quad \text{weakly in } (L^r(Q_T))^N,\\
f_i\big((u_1^\eta)_+ +\eta,(u_2^\eta)_+ +\eta\big) &\rightharpoonup f_i(u_1,u_2) \quad \text{weakly in } L^{p/2}(Q_T),\\
\partial_t u_i^\eta &\rightharpoonup \partial_t u_i \quad \text{weakly in } L^r(0,T;(W^{1,r'}(\Omega))').
\end{aligned}
$$

Proof. Similar to the discussion in the proof of Lemma 3.2, we conclude that there exist functions u_1 and u_2 such that $u_i^\eta\to u_i$ in $L^\alpha(Q_T)$ for all $2\le\alpha<p$. The estimate (3.21) implies

$$
\|(u_i^\eta)_-\|_{L^\infty(0,T;L^1(\Omega))}\le\frac{C}{|\ln\eta|}\to 0,
$$

from which we obtain $u_i\ge 0$ in Q_T, $i=1,2$.

Except for the third convergence, the discussion of the remaining convergence results are similar to those in the proof of Lemma 3.2. Observe that

$$
\overline{u_1^\eta}\,\overline{u_2^\eta}\nabla\ln((u_1^\eta)_+ +\eta)=\frac{1}{1+\eta(u_2^\eta)_+}\frac{1}{1+\eta(u_1^\eta)_+}\frac{(u_1^\eta)_+}{(u_1^\eta)_+ +\eta}(u_2^\eta)_+\nabla(u_1^\eta)_+.
$$

By similar arguments as above, it holds that

$$(u_2^\eta)_+\nabla(u_1^\eta)_+ \rightharpoonup u_2\nabla u_1 \quad \text{weakly in } (L^r(Q_T))^N.$$

Taking into account

$$\frac{1}{1+\eta(u_2^\eta)_+}\frac{1}{1+\eta(u_1^\eta)_+}\frac{(u_1^\eta)_+}{(u_1^\eta)_+ + \eta} \le 1,$$

we infer the desired convergence. □

Now, Theorem 1.1 is a consequence of the convergence results of Lemma 3.4 applied to (3.18).

Remark 3.5. Since the estimates in Lemma 3.3 are independent of c_1 and c_2, we obtain the existence of a weak solution even in the case $c_1 = 0$ or $c_2 = 0$. Indeed, we first obtain a weak solution for $c_1 > 0$, $c_2 > 0$, respectively. The a priori estimates of Lemma 3.3 allow us to perform the limit $c_1, c_2 \to 0$.

Remark 3.6. All the above estimates are true in *any* space dimension. The restriction $N \le 3$ is used only in the proof of Lemma 2.1. As mentioned in Remark 2.3, Lemma 2.1 holds in any space dimension if $\beta_{ij} = 0$ for all $i, j = 1, 2$. Therefore, Theorem 1.1 is true in *any* space dimension, provided that $\beta_{ij} = 0$ for all $i, j = 1, 2$.

4. Appendix. We recall the definition of an Orlicz space and some of its properties. For details, we refer the reader, e.g., to [1, 14].

A real-valued function $\Psi : [0,\infty) \to \mathbb{R}$ is called a *Young function* if $\Psi(t) = \int_0^t \psi(s)ds$ and $\psi : [0,\infty) \to [0,\infty)$ has the following properties:

- $\psi(0) = 0$, $\psi > 0$ on $(0,\infty)$, $\psi(t) \to \infty$ as $t \to \infty$;
- ψ is nondecreasing and right continuous at any point $s \ge 0$.

The function $\Phi(t) = \int_0^t \phi(s)ds$ with $\phi(s) = \sup_{\psi(t)\le s} t$ is called the *complementary Young function* of Ψ. For instance, $\Psi(s) = (1+s)\ln(1+s) - s$ and $\Phi(s) = e^s - s - 1$ are a pair of complementary Young functions.

Let Ψ be a Young function. The *Orlicz class* $K_\Psi(\Omega)$ is the set of (equivalence classes of) real-valued measurable functions u on Ω satisfying $\int_\Omega \Psi(|u(x)|)dx < \infty$. Then the *Orlicz space* $L_\Psi(\Omega)$ is the linear hull of $K_\Psi(\Omega)$ supplemented with the *Luxemburg norm*

$$\|u\|_{L_\Psi(\Omega)} := \inf\left\{k > 0 : \int_\Omega \Psi\Big(\frac{|u(x)|}{k}\Big) \le 1\right\}.$$

With this norm, the Orlicz space $L_\Psi(\Omega)$ is a Banach space.

We need some properties of Orlicz spaces. The first is the inequality [14, sections 3.6.3 and 3.8.5]

$$\|u\|_{L_\Psi(\Omega)} \le 1 + \int_\Omega \Psi(|u(x)|)dx, \quad u \in L_\Psi. \tag{4.1}$$

The second property is the *Hölder inequality* [14, sections 3.8.5 and 3.8.6]: Let Ψ and Φ be a pair of complementary Young functions and $u \in L_\Psi(\Omega)$, $v \in L_\Phi(\Omega)$. Then

$$\left|\int_\Omega uvdx\right| \le 2\|u\|_{L_\Psi(\Omega)}\|v\|_{L_\Phi(\Omega)}. \tag{4.2}$$

Finally, we need the following theorem [1, Thm. 8.22].

THEOREM 4.1. *Let $\Omega \in \mathbb{R}^N$ be bounded, and let Φ_1 and Φ_2 be two Young functions such that for all $k > 0$,*

$$\lim_{t\to\infty} \frac{\Phi_1(kt)}{\Phi_2(t)} = 0.$$

Then, any (u_n) sequence which is bounded in $L_{\Phi_2}(\Omega)$ and convergent in measure is convergent in $L_{\Phi_1}(\Omega)$.

ASYMPTOTIC NORMALITY OF SCALING FUNCTIONS*

LOUIS H. Y. CHEN†, TIM N. T. GOODMAN‡, AND S. L. LEE†

Abstract. The Gaussian function $G(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$, which has been a classical choice for multiscale representation, is the solution of the scaling equation

$$G(x) = \int_{\mathbb{R}} \alpha G(\alpha x - y) dg(y), \quad x \in \mathbb{R},$$

with scale $\alpha > 1$ and absolutely continuous measure

$$dg(y) = \frac{1}{\sqrt{2\pi}(\alpha^2 - 1)} e^{-y^2/2(\alpha^2-1)} dy.$$

It is known that the sequence of normalized B-splines (B_n), where B_n is the solution of the scaling equation

$$\phi(x) = \sum_{j=0}^{n} \frac{1}{2^{n-1}} \binom{n}{j} \phi(2x - j), \quad x \in \mathbb{R},$$

converges uniformly to G. The classical results on normal approximation of binomial distributions and the uniform B-splines are studied in the broader context of normal approximation of probability measures m_n, $n = 1, 2, \dots$, and the corresponding solutions ϕ_n of the scaling equations

$$\phi_n(x) = \int_{\mathbb{R}} \alpha \phi_n(\alpha x - y) dm_n(y), \quad x \in \mathbb{R}.$$

Various forms of convergence are considered and orders of convergence obtained. A class of probability densities are constructed that converge to the Gaussian function faster than the uniform B-splines.

Key words. normal approximation, probability measures, scaling functions, uniform B-splines, asymptotic normality

1. Introduction.

The Gaussian function, $G(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$, and its derivatives have been widely used in scale-space representation (see [1], [11], [18]). The uniform B-spline, B_n, which is the solution of the scaling equation

$$\phi(x) = \sum_{j=0}^{n} \frac{1}{2^{n-1}} \binom{n}{j} \phi(2x - j), \quad x \in \mathbb{R}, \tag{1.1}$$

associated with the binomial distribution $\frac{1}{2^n}\binom{n}{j}$, $j = 0, 1, \dots, n$, approximates the Gaussian and provides fast computational algorithms for practical implementation of Gaussian scale-space representation (see [15], [16]). The B-spline, B_n, is the probability density function of the sum of n copies of independent identically distributed

uniform random variables on the interval $[0,1)$. It is well known that the binomial distributions converge to the normal distribution in the sense that

$$\lim_{n\to\infty} \sum_{k=0}^{[x_n]} \frac{1}{2^n} \binom{n}{k} = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-t^2/2}\, dt, \tag{1.2}$$

where $x_n = \sqrt{n}x/2 + n/2$, and it is also known that

$$\lim_{n\to\infty} \int_{-\infty}^{x_n'} B_n(t)dt = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-t^2/2}\, dt, \tag{1.3}$$

where $x_n' := \sqrt{n}x/2\sqrt{3} + n/2$. Further, the normalized B-splines converge uniformly on $\mathbb{R}$ to the Gaussian function (see [5] and [13]). In fact, Curry and Schoenberg [5] considered the more general class of Polya frequency functions as limits of nonuniform B-splines with arbitrary knots. The Gaussian function satisfies the integral scaling equation

$$G(x) = \int_{\mathbb{R}} \alpha G(\alpha x - y) dg(y), \quad x \in \mathbb{R},$$

where $\alpha > 1$ is a scaling constant and g is the absolutely continuous measure given by

$$dg(y) = \frac{1}{\sqrt{2\pi}(\alpha^2 - 1)} e^{-y^2/2(\alpha^2-1)} dy.$$

The Gaussian function and its derivatives and the modulated Gaussian have been used extensively in many applications such as scale-space analysis and computer vision (see [1], [11], [18]). The normal approximation of the binomial distributions and the uniform B-splines enables the binomial coefficients and B-splines to replace the Gaussian function in the Gaussian scale-space representation and vice versa (see [11], [15], [16]). The Gaussian function is optimal in time-frequency localization, amenable to statistical analysis, and provides an accurate model of human vision (see [18]). While inheriting approximately many of the rich properties of the Gaussian, the binomial distributions and B-splines have the added advantage of providing fast algorithms for practical computations.

We shall consider a sequence of scaling equations

$$\phi_n(x) = \int_{\mathbb{R}} \alpha \phi_n(\alpha x - y) dm_n(y), \quad x \in \mathbb{R},\ n = 1, 2, \dots, \tag{1.4}$$

where $\alpha > 1$ and (m_n) is a sequence of probability measures with finite first and second moments. It will be shown in the next section that for each n, (1.4) has a unique solution, which is also a probability measure. We shall call ϕ_n the *m_n-scaling function* and m_n its *filter*. If m_n is a discrete measure concentrated on the integers $\mathbb{Z}$ with mass $h_n(j)$ at $j \in \mathbb{Z}$, then (1.4) becomes the discrete scaling equation

$$\phi_n(x) = \sum_{j\in\mathbb{Z}} \alpha h_n(j) \phi_n(\alpha x - j), \quad x \in \mathbb{R}. \tag{1.5}$$

In particular, if m_n is the discrete measure concentrated on the set $\{0, 1, \dots, n\}$ with mass $\frac{1}{2^n}\binom{n}{j}$ at $j = 0, 1, \dots, n$ and scale $\alpha = 2$, then (1.5) reduces to (1.1). The

object of this paper is to investigate the approximation of the Gaussian function by probability measures and the corresponding scaling functions in the same way as the normal approximation by binomial and B-spline distributions and to construct sequences of distributions that converge to the Gaussian faster than the binomial and B-spline distributions.

Suppose that (m_n) is a sequence of probability measures on $\mathbb{R}$ with mean $\mu(m_n) = \mu_n$ and standard deviation $\sigma(m_n) = \sigma_n$, and define

$$\widetilde{m}_n(S) = m_n(\sigma_n S + \mu_n) \quad \text{for measurable } S \subset \mathbb{R},$$

or, equivalently,

$$\widehat{\widetilde{m}}_n(u) = e^{iu\mu_n/\sigma_n}\widehat{m}_n(u/\sigma_n), \quad u \in \mathbb{R}. \tag{1.6}$$

We say that (m_n) is *asymptotically normal* if for all $x \in \mathbb{R}$,

$$\lim_{n\to\infty} \int_{-\infty}^{x} d\widetilde{m}_n(t) = \int_{-\infty}^{x} G(t)dt. \tag{1.7}$$

If m_n is absolutely continuous, then by the Radon–Nikodym theorem, $dm_n(t) = f_n(t)dt$ for a probability density function f_n, and then $d\widetilde{m}_n(t) = \widetilde{f}_n(t)dt$, where

$$\widetilde{f}_n(t) = \sigma_n f_n(\sigma_n t + \mu_n).$$

The central limit theorem tells us that if m_n is the probability distribution for the sum of n independent, identically distributed random variables, then (m_n) is asymptotically normal. In the case that each such random variable is uniformly distributed on the interval $[0, 1)$, m_n has density function B_n, and the asymptotic normality is also implied by the convergence of the normalized B-splines discussed earlier. Now it is well known that asymptotic normality can be stated in terms of convergence of characteristic functions, i.e., Fourier transforms of the probability density functions. To be precise, (1.7) is equivalent to

$$\widehat{\widetilde{m}}_n(u) \to e^{-u^2/2} \text{ locally uniformly on } \mathbb{R}, \tag{1.8}$$

where local uniform convergence means convergence that is uniform on compact subsets. This result is given in [7, p. 249], and more modern expositions are given in [10] and [17].

In section 2, we show that if m is a probability measure on $\mathbb{R}$ with finite first moment, then the solution of the scaling equation

$$\phi(x) = \int_{\mathbb{R}} \alpha\phi(\alpha x - y)dm(y), \quad x \in \mathbb{R}, \tag{1.9}$$

is also a probability measure. In (1.9), and throughout the paper, α is a number larger than 1, which we call the *scale*. We remark that if the solution is absolutely continuous, then its probability density satisfies (1.9). If the solution ϕ is not absolutely continuous, then it satisfies (1.9) in the weak sense, i.e.,

$$\widehat{\phi}(u) = \widehat{m}(u/\alpha)\widehat{\phi}(u/\alpha), \quad u \in \mathbb{R}. \tag{1.10}$$

The following result puts in perspective the asymptotic normality exhibited by the binomial coefficients and the uniform B-splines.

THEOREM 1.1. *Let (m_n) be a sequence of probability measures on $\mathbb{R}$ with finite first and second moments and $(\widehat{\widehat{m}}_n{}')$ be uniformly bounded in a neighborhood of the origin. Then (m_n) is asymptotically normal if and only if the corresponding sequence of m_n-scaling functions is asymptotically normal.*

In order to study the asymptotic normality of scaling functions, we need only to study the asymptotic normality of their filters, because of Theorem 1.1. The binomial coefficients, which are the filters for the uniform B-splines, define a sequence of discrete probability measures that is asymptotically normal. It follows from Theorem 1.1 that the coefficients $b_{n,k}$ in the expansion

$$\left(\frac{1+z+\cdots+z^{\alpha-1}}{\alpha}\right)^n = \sum_{k=0}^{n(\alpha-1)} b_{n,k} z^k, \tag{1.11}$$

where the scale α is here an integer, also define a sequence of probability measures that is asymptotically normal. This is because the uniform B-splines are also the solution of the scaling equations with measures $m_n(k) = b_{n,k}$, $k = 0, 1, \ldots, n(\alpha-1)$, for any integer scale $\alpha > 1$. For such α, the roots of the polynomials on the left of (1.11) that generate $b_{n,k}$ are the complex αth roots of unity that are not equal to 1. The next theorem gives a general result that holds for a large class of polynomials including those with negative roots as well as those in (1.11).

THEOREM 1.2. *Let $\gamma \in [0, \pi/2)$, and define $D_\gamma = \{z \in \mathbb{C} : \text{ satisfies } (1.12)\}$:*

$$\left|\operatorname{Im}\left\{\frac{z}{(1+z)^2}\right\}\right| \le \tan\gamma \operatorname{Re}\left\{\frac{z}{(1+z)^2}\right\}. \tag{1.12}$$

For $n = 1, 2, \ldots$, take $r_{n,1}, \ldots, r_{n,n}$ in D_γ and define

$$\sum_{k=0}^{n} a_{n,k} z^k = \prod_{j=1}^{n} (z + r_{n,j})/(1 + r_{n,j}). \tag{1.13}$$

We also assume that the $r_{n,j}$, $n = 1, 2, \ldots$, $j = 1, \ldots, n$, are bounded away from -1, that the coefficients $a_{n,k}$, $n = 1, 2, \ldots$, $k = 0, \ldots n$, are real, and that

$$\sigma_n^2 = \sum_{j=1}^{n} r_{n,j}/(1 + r_{n,j})^2 \to \infty \text{ as } n \to \infty. \tag{1.14}$$

If m_n, $n = 1, 2, \ldots$, denote the discrete measures defined by $m_n(\{k\}) = a_{n,k}$, $k = 0, 1, \ldots, n$, it follows that $\widehat{\widehat{m}}_n(u) \to e^{-u^2/2}$ locally uniformly as $n \to \infty$. If, in addition, $a_{n,k} \ge 0$, $k = 0, 1, \ldots, n$, for all sufficiently large n, then (m_n) is asymptotically normal.

Remark 1. We remark that the first part of Theorem 1.2 does not require m_n to be a probability measure; i.e., some of the coefficients $a_{n,k}$ could be negative.

After some preliminary results in the next section, we shall prove Theorem 1.1 in section 3. A proof of Theorem 1.2 is given in section 4. We note that a special case of this result, when all $r_{n,j} > 0$, was proved earlier using probabilistic techniques [3]. The completely different analytic techniques, which we employ here, give considerably more general results. These techniques also allow us to analyze, in the remainder of section 4, the order of convergence in the frequency domain for both the measures m_n and the corresponding scaling functions. In particular we shall prove the following theorem.

THEOREM 1.3. *We assume the conditions of Theorem* 1.2 *and that* $a_{n,k} \geq 0$, $k = 0, 1, \ldots, n$.

(a) *Then*

$$\left|\left|\widehat{\widetilde{\phi}}_n - e^{-(\cdot)^2/2}\right|\right|_\infty = O(\sigma_n^{-1}).$$

(b) *If* $\sum_{k=0}^n a_{n,k} z^k$ *is a reciprocal polynomial, i.e.,* $a_{n,0} \neq 0$ *and* $a_{n,k} = a_{n,n-k}$, $k = 0, 1, \ldots, n$, *then*

$$\left|\left|\widehat{\widetilde{\phi}}_n - e^{-(\cdot)^2/2}\right|\right|_\infty = O(\sigma_n^{-2}).$$

(c) *If, in addition to the condition in* (b),

$$\sigma_n^{-1} \sum_{j=1}^n r_{n,j}(r_{n,j}^2 - 4r_{n,j} + 1)/(1 + r_{n,j})^4 \text{ is bounded,} \tag{1.15}$$

then

$$\left|\left|\widehat{\widetilde{\phi}}_n - e^{-(\cdot)^2/2}\right|\right|_\infty = O(\sigma_n^{-3}).$$

Asymptotic normality entails weak convergence in the time domain. We show in section 5 that, under mild conditions on the shape of the filters and the scaling functions, both the measures and the corresponding scaling functions converge uniformly in the time domain. The shape conditions are satisfied if $r_{n,j}$ are restricted to certain sectors of the complex plane, reminiscent of total positivity. It is noted that for a special case of the choice, when all $r_{n,j} > 0$, Chui and Wang [4] consider convergence of the scaling functions. However, their approach is different, and they do not consider the related convergence of the measures m_n. Finally, in the same section, we consider the order of convergence in the time domain and prove the following results.

THEOREM 1.4. *We assume the conditions of Theorem* 1.2 *and that all* $r_{n,j}$ *lie in the sector* $|\arg z| \leq \frac{\pi}{3}$. *Then as* $n \to \infty$,

$$\max_{k=0,\ldots,n} \left|\sigma_n a_{n,k} - G\left(\frac{k - \mu_n}{\sigma_n}\right)\right| = O(\sigma_n^{-\frac{1}{2}}),$$

and if $\sum_{k=0}^n a_{n,k} z^k$ *is reciprocal,*

$$\max_{k=0,\ldots,n} \left|\sigma_n a_{n,k} - G\left(\frac{k - \mu_n}{\sigma_n}\right)\right| = O(\sigma_n^{-\frac{2}{3}}).$$

We remark that in [3], this problem is considered, using probabilistic techniques, for the special case when $a_{n,0}, \ldots, a_{n,n}$ are the Eulerian numbers. In this case $\sigma_n = \sqrt{\pi(n+1)/6}$. Thus our result gives order of convergence $O(\sigma_n^{-\frac{2}{3}}) = O(n^{-\frac{1}{3}})$, while [3] shows only convergence $O(n^{-\frac{1}{4}})$.

THEOREM 1.5. *We assume the conditions of Theorem* 1.2, *that* $r_{n,j}$ *include* 1 *and all* $\mathrm{Re}(r_{n,j}) \geq 0$. *For* $n = 1, 2, \ldots$, *let* ϕ_n *denote the scaling function corresponding to the measure* $m_n(\{k\}) = a_{n,k}$, $k = 0, 1, \ldots, n$, *with scale* 2, *and define*

$$\widetilde{\phi}_n(x) = \sigma(\phi_n)\phi_n(\sigma(\phi_n)x + \mu(\phi_n)), \quad x \in \mathbb{R}.$$

Then

$$\|\widetilde{\phi}_n - G\|_\infty = O(\sigma_n^{-\frac{1}{2}}).$$

If $\sum_{n=0}^{n} a_{n,k} z^k$ *is reciprocal for large enough* n, *then*

$$\|\widetilde{\phi}_n - G\|_\infty = O(\sigma_n^{-1}).$$

If, in addition, (1.15) *is satisfied, then*

$$\|\widetilde{\phi}_n - G\|_\infty = O(\sigma_n^{-\frac{3}{2}}).$$

It is noted that certain sequences of scaling functions give a faster rate of convergence to the Gaussian than the uniform B-splines. Also on considering Theorems 1.3 and 1.5, it might be expected that the second part of Theorem 1.4 should give order of convergence $O(\sigma_n^{-1})$ instead of $O(\sigma_n^{-2/3})$ and that under the additional condition (1.15) we should obtain order $O(\sigma_n^{-3/2})$. We have been unable to prove orders better than $O(\sigma_n^{-2/3})$ due to a technical restriction in Lemma 5.4, and we do not know whether this restriction can be removed.

2. Probability measures and scaling equations. Consider the scaling equation (1.9) where m is a probability measure and, as before, α is a number (not necessarily an integer) satisfying $\alpha > 1$. We shall show that (1.9) has a unique solution, which is a probability measure. Further, if m has finite first and second moments, then the solution of (1.9) also has finite first and second moments. Equation (1.10) suggests that, when $\widehat{\phi}(0) = 1$, $\widehat{\phi}(u)$ is given by the infinite product (2.1) below but with n replaced by ∞. We remark that products of the form (2.1) occur in the study of groups of transformations in Hilbert space (see, for example, [6, section 38]). For the case when ϕ is the B-spline B_n and $\alpha = 2$, this reduces to the classical formula of Viète:

$$\sin x/x = \prod_{j=1}^{\infty} \cos(x/2^j).$$

So as a preliminary result we need to consider the convergence of (2.1) in Lemma 2.1 below.

LEMMA 2.1. *Suppose that* m *is a probability measure with finite first moment. Then the products*

$$\prod_{j=1}^{n} \widehat{m}(u/\alpha^j), \quad u \in \mathbb{R}, \tag{2.1}$$

converge locally uniformly as $n \to \infty$.

Proof. Since m is a probability measure, $|\widehat{m}(u)| \le 1$ for all $u \in \mathbb{R}$. Then for every nonnegative integer n and all u,

$$\left| \prod_{j=1}^{n} \widehat{m}(u/\alpha^j) \right| \le 1 \quad \text{for all } u \in \mathbb{R}.$$

Also, since m has finite first moment, $\widehat{m}'$ is bounded, and so

$$\left|\widehat{m}(u/\alpha^j) - 1\right| \le C|u|/\alpha^j, \quad j = 1, 2, \dots,$$

for a constant $C > 0$. Thus for integers $n > \ell$,

$$\left| \prod_{j=1}^{\ell} \widehat{m}(u/\alpha^j) - \prod_{j=1}^{n} \widehat{m}(u/\alpha^j) \right| \le \sum_{j=1}^{n-\ell} |1 - \widehat{m}(u/\alpha^{\ell+j})| \le C|u|(\alpha^{-\ell} - \alpha^{-n})/(\alpha - 1),$$

which tends to zero uniformly on compact subsets of $\mathbb{R}$ as $\ell, n \to \infty$. Therefore, the product $\prod_{j=1}^{n} \widehat{m}(u/\alpha^j)$ converges uniformly on compact sets as $n \to \infty$. □

PROPOSITION 2.2. *If m is a probability measure with finite first and second moments, then the scaling equation* (1.9) *has a unique solution ϕ, which is also a probability measure with finite first and second moments. Further,*

$$\mu(\phi) = (\alpha - 1)^{-1}\mu(m) \quad \text{and} \quad \sigma(\phi)^2 = (\alpha^2 - 1)^{-1}\sigma(m)^2. \tag{2.2}$$

Proof. Choose a nonnegative initial function $f_0 \in C(\mathbb{R})$ with compact support and $\widehat{f_0}(0) = 1$, and for $n = 1, 2, \ldots$ define

$$f_n(x) = \int_{\mathbb{R}} \alpha f_{n-1}(\alpha x - y) dm(y), \quad x \in \mathbb{R}. \tag{2.3}$$

Then

$$\widehat{f_n}(u) = \widehat{f}_{n-1}(u/\alpha)\widehat{m}(u/\alpha) = \prod_{j=1}^{n} \widehat{m}(u/\alpha^j)\widehat{f_0}(u/\alpha^n), \quad u \in \mathbb{R}. \tag{2.4}$$

Further, f_n is nonnegative, and $\widehat{f_n}(0) = 1$ for $n = 0, 1, \ldots$. Therefore, f_n defines a sequence of probability measures $\mu_n \in C_0(\mathbb{R})^*$, where $d\mu_n(x) = f_n(x)dx$ and $C_0(\mathbb{R})^*$ is the dual of the space $C_0(\mathbb{R})$ of continuous functions that vanish at infinity. Therefore, $\widehat{\mu}_n = \widehat{f_n},\ n = 0, 1, \ldots$. Since the unit ball in $C_0(\mathbb{R})^*$ is weak* compact, there exist a subsequence μ_{n_ℓ} and a probability measure ϕ on $\mathbb{R}$ such that $\mu_{n_\ell} \to \phi$ as $\ell \to \infty$ in the weak* topology. It follows (see [7, p. 249]) that $\widehat{\mu}_{n_\ell}$ converges locally uniformly to $\widehat{\phi}$ as $n \to \infty$. By Lemma 2.1 and (2.4),

$$\widehat{\phi}(u) = \prod_{j=1}^{\infty} \widehat{m}(u/\alpha^j), \quad u \in \mathbb{R},$$

which satisfies (1.10).

Define

$$\Pi_n(u) := \prod_{j=1}^{n} \widehat{m}(u/\alpha^j), \quad u \in \mathbb{R}. \tag{2.5}$$

Then

$$\Pi_n(u) \to \widehat{\phi}(u) \ \text{ locally uniformly on } \mathbb{R}, \tag{2.6}$$

where ϕ is the solution of (1.9). We shall show that ${\Pi_n}'$ converges uniformly in a neighborhood of the origin. Since $\widehat{m}(0) = 1$, there exists a closed disc D centered at the origin such that $\widehat{m}(u) \neq 0$ for all $u \in D$. Differentiating (2.5) gives

$${\Pi_n}'(u) = \prod_{j=1}^{n} \widehat{m}(u/\alpha^j) \sum_{j=1}^{n} \frac{1}{\alpha^j} \frac{\widehat{m}\,'(u/\alpha^j)}{\widehat{m}(u/\alpha^j)}, \tag{2.7}$$

which shows that $\Pi_n{}'$ is uniformly convergent on D. It follows that $\widehat{\phi}\,'$ exists and $\Pi_n{}'$ converges uniformly to $\widehat{\phi}\,'$ on D. Hence $\widehat{\phi}\,'$ is continuous on D, and

$$\widehat{\phi}\,'(0) = (\alpha-1)^{-1}\widehat{m}\,'(0). \tag{2.8}$$

Differentiating (2.7) gives

$$\begin{aligned}\Pi_n{}''(u) = {} & \prod_{j=1}^{n}\widehat{m}(u/\alpha^j)\left(\sum_{j=1}^{n}\frac{1}{\alpha^j}\frac{\widehat{m}\,'(u/\alpha^j)}{\widehat{m}(u/\alpha^j)}\right)^2 \\ & + \prod_{j=1}^{n}\widehat{m}(u/\alpha^j)\sum_{j=1}^{n}\frac{1}{\alpha^{2j}}\frac{\widehat{m}\,''(u/\alpha^j)\widehat{m}(u/\alpha^j)-\widehat{m}\,'(u/\alpha^j)^2}{\widehat{m}(u/\alpha^j)^2},\end{aligned} \tag{2.9}$$

which shows that $\Pi_n{}''$ is uniformly convergent on D. Thus $\widehat{\phi}\,''$ exists and is continuous on D. A straightforward computation using (2.9) leads to

$$\widehat{\phi}\,''(0) = \frac{1}{(\alpha^2-1)}\left\{\widehat{m}\,''(0) + \frac{2\widehat{m}\,'(0)^2}{(\alpha-1)}\right\}. \tag{2.10}$$

It follows that ϕ has finite first and second moments, and the relationships (2.2) follow from (2.8) and (2.10). □

3. Proof of Theorem 1.1. We shall prove a slightly stronger result than that of Theorem 1.1. This result is contained in Theorem 3.1.

THEOREM 3.1. *Let (m_n) be a sequence of probability measures on $\mathbb{R}$ with finite first and second moments, and $(\widehat{\widehat{m}}_n{}')$ is uniformly bounded in a neighborhood of 0. Then the following are equivalent:*

(a) $\widehat{\widehat{m}}_n(u) \to e^{-u^2/2}$ *locally uniformly on* $\mathbb{R}$ *as* $n \to \infty$.
(b) $\widehat{\widehat{\phi}}_n(u) \to e^{-u^2/2}$ *locally uniformly on* $\mathbb{R}$ *as* $n \to \infty$.
(c) (m_n) *is asymptotically normal.*
(d) (ϕ_n) *is asymptotically normal.*

Further, if (a) *holds locally uniformly on* $\mathbb{R}$, *then* (b) *holds uniformly on* $\mathbb{R}$.

Proof. By Proposition 2.2, for each $n = 0, 1, \ldots$, (1.4) has a unique solution ϕ_n, which is also a probability measure with finite first and second order moments, and

$$\mu(m_n) = (\alpha-1)\mu(\phi_n) \quad \text{and} \quad \sigma(m_n)^2 = (\alpha^2-1)\sigma(\phi_n)^2. \tag{3.1}$$

By (1.6), (1.10), and (3.1),

$$\widehat{\widehat{\phi}}_n(u) = \widehat{\widehat{m}}_n(\alpha^{-1}\sqrt{\alpha^2-1}\,u)\widehat{\widehat{\phi}}_n(\alpha^{-1}u), \quad u \in \mathbb{R}. \tag{3.2}$$

Iterating (3.2) leads to

$$\widehat{\widehat{\phi}}_n(u) = \prod_{j=1}^{\infty}\widehat{\widehat{m}}_n(\alpha^{-j}\sqrt{\alpha^2-1}\,u), \quad u \in \mathbb{R}, \tag{3.3}$$

where the infinite product on the right converges locally uniformly on $\mathbb{R}$ and uniformly in n, since $(\widehat{\widehat{m}}_n{}')$ is uniformly bounded in a neighborhood of 0.

If (a) holds, then by (3.3) we have

$$\lim_{n\to\infty} \widehat{\widetilde{\phi}}_n(u) = \lim_{n\to\infty} \prod_{j=1}^{\infty} \widehat{\widetilde{m}}_n(\alpha^{-j}\sqrt{\alpha^2-1}\, u)$$
$$= \prod_{j=1}^{\infty} e^{-(\alpha^2-1)u^2/2\alpha^{2j}} = e^{-u^2/2}, \quad u \in \mathbb{R}.$$

Conversely, if $\lim_{n\to\infty} \widehat{\widetilde{\phi}}_n(u) = e^{-u^2/2}$, then by (3.2)

$$\widehat{\widetilde{m}}_n(u) = \frac{\widehat{\widetilde{\phi}}_n(\alpha\, u/\sqrt{\alpha^2-1})}{\widehat{\widetilde{\phi}}_n(u/\sqrt{\alpha^2-1})}, \quad u \in \mathbb{R},$$

for sufficiently large n. It follows that

$$\lim_{n\to\infty} \widehat{\widetilde{m}}_n(u) = \frac{e^{-\alpha^2 u^2/2(\alpha^2-1)}}{e^{-u^2/2(\alpha^2-1)}} = e^{-u^2/2}, \quad u \in \mathbb{R}.$$

A similar argument shows that (a) holds locally uniformly on $\mathbb{R}$ if and only if (b) holds locally uniformly on $\mathbb{R}$.

Now suppose that (a) holds uniformly on compact subsets of $\mathbb{R}$. Note that for any $u \in \mathbb{R}$ and $n \geq 1$,

$$|\widehat{\widetilde{m}}_n(u)| = \left| \int_{-\infty}^{-\infty} e^{-iux} dm_n(x) \right| \leq \int_{-\infty}^{-\infty} dm_n(x) = 1.$$

So for any $k \geq 1$,

$$\left| \widehat{\widetilde{\phi}}_n(u) \right| = \prod_{j=1}^{\infty} \left| \widehat{\widetilde{m}}_n(\alpha^{-j}\sqrt{\alpha^2-1}\, u) \right|$$
$$\leq \prod_{j=k+1}^{\infty} \left| \widehat{\widetilde{m}}_n(\alpha^{-j}\sqrt{\alpha^2-1}\, u) \right|$$
$$= \left| \widehat{\widetilde{\phi}}_n(\alpha^{-k}\, u) \right|, \quad u \in \mathbb{R}. \tag{3.4}$$

For any $\epsilon > 0$, we choose $A > 0$ and integer N so that $e^{-A^2/2} < \epsilon$ and

$$\left| \widehat{\widetilde{\phi}}_n(u) - e^{-u^2/2} \right| < \epsilon, \quad |u| \leq \alpha A,\ n > N.$$

Take any u with $|u| > A$. Then there is a nonnegative integer k such that $A < \alpha^{-k}|u| \leq \alpha A$, and so

$$e^{-(\alpha^{-k}u)^2/2} < e^{-A^2/2} < \epsilon.$$

Also for $n > N$, $|\widehat{\widetilde{\phi}}_n(\alpha^{-k}u) - e^{-(\alpha^{-k}u)^2/2}| < \epsilon$, and so

$$\left| \widehat{\widetilde{\phi}}_n(u) \right| \leq \left| \widehat{\widetilde{\phi}}_n(\alpha^{-k}\, u) \right| < 2\epsilon.$$

Since $e^{-u^2/2} < e^{-A^2/2} < \epsilon$, it follows that $|\widehat{\widetilde{\phi}}_n(u) - e^{-u^2/2}| < 3\epsilon$. Thus for all $n > N$ and $u \in \mathbb{R}$, $|\widehat{\widetilde{\phi}}_n(u) - e^{-u^2/2}| < 3\epsilon$, and hence (b) holds uniformly on $\mathbb{R}$.

Recall that the asymptotic normality of a sequence of distribution functions is equivalent to the local uniform convergence of their characteristic functions (see, for instance, [7, p. 249]). □

We remark that if (m_n) is a sequence of discrete probability measures on $\mathbb{Z}$ with finite first and second moments, then the condition that $(\widehat{\widetilde{m}}_n{}')$ be uniformly bounded in a neighborhood of 0 is automatically satisfied. The following lemma gives a slightly stronger result.

LEMMA 3.2. *If (m_n) is a sequence of discrete probability measures on $\mathbb{Z}$ with finite first and second moments, then $(\widehat{\widetilde{m}}_n{}')$ is uniformly bounded on any compact subset of $\mathbb{R}$.*

Proof. Let $m_n(\{k\}) = b_{n,k} \geq 0$, $n = 1, 2, \ldots$, $k \in \mathbb{Z}$, where $\sum_{k=-\infty}^{\infty} b_{n,k} = 1$. As before, we write

$$\mu_n := \sum_{k=-\infty}^{\infty} k b_{n,k} \quad \text{and} \quad \sigma_n^2 := \sum_{k=-\infty}^{\infty} (k - \mu_n)^2 b_{n,k}.$$

Then

$$\widehat{\widetilde{m}}_n(u) = \sum_{k=-\infty}^{\infty} b_{n,k} e^{i(\mu_n - k)u/\sigma_n},$$

and so

$$\begin{aligned} \widehat{\widetilde{m}}_n{}'(u) &= \frac{i}{\sigma_n} \sum_{k=-\infty}^{\infty} b_{n,k}(\mu_n - k) e^{i(\mu_n - k)u/\sigma_n} \\ &= \frac{i}{\sigma_n} \sum_{k=-\infty}^{\infty} b_{n,k}(\mu_n - k)(e^{i(\mu_n - k)u/\sigma_n} - 1). \end{aligned}$$

Since $|e^{iu} - 1| \leq 2|u|$ for all $u \in \mathbb{R}$,

$$\left| \widehat{\widetilde{m}}_n{}'(u) \right| \leq \frac{2|u|}{\sigma_n^2} \sum_{k=-\infty}^{\infty} (k - \mu_n)^2 b_{n,k} = 2|u|. \qquad \square$$

COROLLARY 3.3. *Let (m_n) be a sequence of discrete probability measures on $\mathbb{Z}$ with finite first and second moments. Then (m_n) is asymptotically normal if and only if the corresponding sequence of m_n-scaling functions with scale α is asymptotically normal.*

4. Convergence in the frequency domain. In order to apply Theorem 1.1 to study the asymptotic normality of scaling functions, we need first to study the asymptotic normality of their filters. We begin with a proof of Theorem 1.2.

Proof of Theorem 1.2. Let

$$\sum_{k=0}^{n} a_{n,k} z^k = \prod_{j=1}^{n} (p_{n,j} z + q_{n,j}), \tag{4.1}$$

where $q_{n,j} = 1 - p_{n,j}$. Then

$$\widehat{m}_n(u) = \prod_{j=1}^{n} (p_{n,j} e^{-iu} + q_{n,j})$$

and

$$\widehat{\widehat{m}}_n(u) = e^{iu\mu_n/\sigma_n} \prod_{j=1}^{n} (p_{n,j} e^{-iu/\sigma_n} + q_{n,j}),$$

where

$$\mu_n = \mu(m_n) = \sum_{j=1}^{n} p_{n,j}, \tag{4.2}$$

and

$$\sigma_n^2 = \sigma(m_n)^2 = \sum_{j=1}^{n} p_{n,j} q_{n,j}. \tag{4.3}$$

Therefore,

$$\log \widehat{\widehat{m}}_n(u) = \frac{iu\mu_n}{\sigma_n} + \sum_{j=1}^{n} F\left(p_{n,j}, \frac{-iu}{\sigma_n}\right), \tag{4.4}$$

where

$$F(p,t) = \log(pe^t + q), \quad q = 1 - p.$$

By induction, for $n = 2, 3, \ldots$,

$$F^{(n)}(p,t) := \frac{\partial^n}{\partial t^n} F(p,t) = (pe^t + q)^{-n} pq \sum_{j=0}^{n-2} (-1)^j c_n(j) p^j q^{n-2-j} e^{(j+1)t}, \tag{4.5}$$

where $c_2(j) = \delta_0(j)$, $j \in \mathbb{Z}$, and for $n = 2, 3, \ldots$, c_n satisfies the recursive relation

$$c_{n+1}(j) = (j+1)c_n(j) + (n-j)c_n(j-1), \quad j \in \mathbb{Z}. \tag{4.6}$$

From (4.6) we have $\sum_{j=-\infty}^{\infty} c_{n+1}(j) = n \sum_{j=-\infty}^{\infty} c_n(j)$, and since $\sum_{j=-\infty}^{\infty} c_2(j) = 1$, we have

$$\sum_{j=-\infty}^{\infty} c_n(j) = (n-1)!, \quad n = 2, 3. \ldots . \tag{4.7}$$

By (4.5) the Taylor series of $F(p,t)$ is given by

$$F(p,t) = \sum_{\nu=0}^{\infty} a_\nu(p) t^\nu, \tag{4.8}$$

where

$$a_0(p) = 0, \ a_1(p) = p, \ a_2(p) = \frac{1}{2} pq, \tag{4.9}$$

and for $\nu = 3, 4, \ldots$,

$$a_\nu(p) = \frac{pq}{\nu!} \sum_{k=0}^{\nu-2} (-1)^k c_\nu(k) p^k q^{\nu-2-k}. \tag{4.10}$$

By (4.4) and (4.8),

$$\log \widehat{\widetilde{m}}_n(u) = \frac{iu\mu_n}{\sigma_n} + \sum_{j=1}^{n} \sum_{\nu=0}^{\infty} a_\nu(p_{n,j}) \sigma_n^{-\nu} (-iu)^\nu. \tag{4.11}$$

By (4.2), (4.3), and (4.9),

$$\sum_{j=1}^{n} a_1(p_{n,j}) \sigma_n^{-1} (-iu) = -\frac{iu\mu_n}{\sigma_n},$$

$$\sum_{j=1}^{n} a_2(p_{n,j}) \sigma_n^{-2} (-iu)^2 = -\frac{u^2}{2},$$

so that (4.11) becomes

$$\log \widehat{\widetilde{m}}_n(u) = -\frac{u^2}{2} + \sum_{\nu=3}^{\infty} \sigma_n^{-\nu} (-iu)^\nu \sum_{j=1}^{n} a_\nu(p_{n,j}). \tag{4.12}$$

Now $r_{n,j} \in D_\gamma$ if and only if

$$\left| \mathrm{Im} \left\{ \frac{r_{n,j}}{(1+r_{n,j})^2} \right\} \right| \le \tan\gamma \ \mathrm{Re} \left\{ \frac{r_{n,j}}{(1+r_{n,j})^2} \right\}$$

or

$$|\mathrm{Im}\,(p_{n,j}q_{n,j})| \le \tan\gamma \ \mathrm{Re}\,(p_{n,j}q_{n,j})\,.$$

Therefore,

$$|p_{n,j}q_{n,j}| \le \sec\gamma \ \mathrm{Re}\,(p_{n,j}q_{n,j})\,. \tag{4.13}$$

On the other hand, $r_{n,j}$ being bounded away from -1 is equivalent to

$$|p_{n,j}| \le A - 1, \qquad n = 1, 2, \ldots, \quad j = 1, 2, \ldots, n, \tag{4.14}$$

for some constant A. By (4.10), (4.13), and (4.14),

$$\begin{aligned} |a_\nu(p_{n,j})| &\le \frac{|p_{n,j}q_{n,j}|}{\nu!} \sum_{k=0}^{\nu-2} c_\nu(k) |p_{n,j}|^k |q_{n,j}|^{\nu-2-k} \\ &\le \sec\gamma \ \mathrm{Re}(p_{n,j}q_{n,j}) A^{\nu-2}/\nu. \end{aligned} \tag{4.15}$$

By (4.12) and (4.15),

$$\begin{aligned} \left| \log \widehat{\widetilde{m}}_n(u) + \frac{u^2}{2} \right| &\le \sec\gamma \ \sum_{\nu=3}^{\infty} \frac{\sigma_n^{-\nu}|u|^\nu}{\nu} \sum_{j=1}^{n} \mathrm{Re}(p_{n,j}q_{n,j}) A^{\nu-2} \\ &\le \sec\gamma \ \sum_{\nu=3}^{\infty} \frac{|u|^\nu}{\nu} \left(\frac{A}{\sigma_n} \right)^{\nu-2} \\ &\le \sec\gamma \ \frac{A|u|^3}{\sigma_n} \left(1 - \frac{A|u|}{\sigma_n} \right)^{-1} \end{aligned} \tag{4.16}$$

whenever $A|u| < \sigma_n$. Since $\sigma_n \to \infty$ as $n \to \infty$, taking the limits as $n \to \infty$, (4.16) gives $\lim_{n\to\infty} \widehat{\widehat{m}}_n(u) = e^{-u^2/2}$ locally uniformly. □

Recall that the region D_γ in Theorem 1.2 comprises all $z \in \mathbb{C}$ satisfying

$$\left|\operatorname{Im}\left\{\frac{z}{(1+z)^2}\right\}\right| \le \tan\gamma \operatorname{Re}\left\{\frac{z}{(1+z)^2}\right\}.$$

It can be seen that D_γ contains the sector $|\arg z| \le \gamma$, and for $z = \pm re^{i\theta}$, $r > 0$, $\gamma \le \theta \le \pi$, (1.12) is equivalent to

$$\frac{\sin(\frac{\theta-\gamma}{2})}{\sin(\frac{\theta+\gamma}{2})} \le r \le \frac{\sin(\frac{\theta+\gamma}{2})}{\sin(\frac{\theta-\gamma}{2})}.$$

In particular D_γ contains the unit circle $r = 1$.

For the special case of Theorem 1.2, when all $r_{n,j} > 0$, the result was proved using probabilistic methods in [3] and [12]. Our analytic techniques allow us not only to prove asymptotic normality for a much larger class of measures but also, in the next result, to give information on the order of convergence in the frequency domain.

PROPOSITION 4.1. *We assume the conditions of Theorem* 1.2 *(except that we do not require* $a_{n,k} \ge 0$, $k = 0, 1, \dots, n$*). As before,*

$$\sigma_n^2 = \sum_{j=1}^{n} \frac{r_{n,j}}{(1+r_{n,j})^2}.$$

Then there is a constant $K > 0$ *so that for* $S_n := \{u : |u| \le K\sigma_n\}$ *the following hold.*

(a) *There is a constant* B *such that*

$$\left|\widehat{\widehat{m}}_n(u) - e^{-u^2/2}\right| \le B\sigma_n^{-1}, \quad u \in S_n,\ n = 1, 2, \dots . \tag{4.17}$$

(b) *If* $\sum_{k=0}^{n} a_{n,k} z^k$ *is a reciprocal polynomial, then there is a constant* C *such that*

$$\left|\widehat{\widehat{m}}_n(u) - e^{-u^2/2}\right| \le C\sigma_n^{-2}, \quad u \in S_n,\ n = 1, 2, \dots . \tag{4.18}$$

(c) *Finally, if in addition to the condition in* (b), (1.15) *is satisfied, then there is a constant* D *such that*

$$\left|\widehat{\widehat{m}}_n(u) - e^{-u^2/2}\right| \le D\sigma_n^{-3}, \quad u \in S_n,\ n = 1, 2, \dots . \tag{4.19}$$

Proof. (a) From (4.16) we see that for $|u| \le \frac{1}{4}A^{-1}\cos\gamma\ \sigma_n$,

$$\log \widehat{\widehat{m}}_n(u) + \frac{u^2}{2} \le \sec\gamma\ \frac{4A|u|^3}{3\sigma_n} \le \frac{1}{3}u^2,$$

and so $\log \widehat{\widehat{m}}_n(u) \le -\frac{1}{6}u^2$. By the mean value theorem,

$$\begin{aligned}\left|\widehat{\widehat{m}}_n(u) - e^{-u^2/2}\right| &\le e^{-u^2/6}\left|\log \widehat{\widehat{m}}_n(u) + \frac{u^2}{2}\right| \\ &\le \sec\gamma \left(\frac{4A|u|^3}{3\sigma_n}\right) e^{-u^2/6} \\ &\le B\sigma_n^{-1}\end{aligned}$$

for a constant B, which gives (4.17).

(b) We note from (4.6) and (4.10) that

$$a_3(p) = \frac{pq}{3!}(q-p), \tag{4.20}$$

$$a_4(p) = \frac{pq}{4!}(q^2 - 4pq + p^2). \tag{4.21}$$

Suppose that $P_n(z) = \sum_{k=0}^n a_{n,k} z^k$ is a reciprocal polynomial. Then $P_n(z) = 0$ if and only if $P_n(z^{-1}) = 0$. Noting that if $r_{n,j} = r_{n,k}^{-1}$, then $p_{n,j} = q_{n,k}$ and $q_{n,j} = p_{n,k}$, it follows that

$$\sum_{j=1}^n a_3(p_{n,j}) = 0. \tag{4.22}$$

So from (4.12) and (4.15),

$$\left| \log \widehat{\widetilde{m}}_n(u) + \frac{u^2}{2} \right| \le \sec\gamma \ \frac{A^2|u|^4}{\sigma_n^2} \ \left(1 - \frac{A|u|}{\sigma_n}\right)^{-1}$$

whenever $A|u| < \sigma_n$. Then (4.18) follows in a similar manner as before.

(c) Finally, we assume (1.15). Then (4.12), (4.21), (4.22), and (4.15) give (4.19). □

We note that $r^2 - 4r + 1 = 0$ when $r = 2 \pm \sqrt{3}$, and so (1.15) requires that in some sense the roots of $P_n(z) := \sum_{k=0}^n \ a_{n,k} z^k$ are close to $-2 \pm \sqrt{3}$. In particular, (1.15) will be satisfied if

$$P_n(z) = Q_{\ell_n}(z)(z^2 + 4z + 1)^{k_n},$$

where Q_{ℓ_n} is a reciprocal polynomial of degree $\ell_n = n - 2k_n$ and $n^{-1/2}\ell_n$ is bounded over n. In this case (4.19) takes the form

$$\left| \widehat{\widetilde{m}}_n(u) - e^{-u^2/2} \right| \le Cn^{-3/2}, \quad u \in S_n, \ n = 1, 2, \dots \ .$$

We now consider the order of convergence of the normalized m_n-scaling functions $\widetilde{\phi}_n$ as in Theorem 1.1, again in the frequency domain. From (3.3) it follows as in (4.4) that

$$\log \widehat{\widetilde{\phi}}_n(u) = \frac{iu\mu_n}{\sigma_n} + \sum_{j=1}^\infty \sum_{k=1}^n \ F\left(p_{n,k}, -\frac{iu}{\alpha^j \sigma_n}\right)$$

and as in (4.12) that

$$\log \widehat{\widetilde{\phi}}_n(u) = -\frac{u^2}{2} + \sum_{\nu=3}^\infty \ \frac{(-iu)^\nu}{(\alpha^2 - 1)\sigma_n^\nu} \ \sum_{j=1}^n a_\nu(p_{n,j}).$$

So as in (4.16) there is a constant A with

$$\left| \log \widehat{\widetilde{\phi}}_n(u) + \frac{u^2}{2} \right| \le \frac{A|u|^3}{\sigma_n} \left(1 - \frac{A|u|}{\sigma_n}\right)^{-1}$$

whenever $A|u| < \sigma_n$. By the mean value theorem, for $A|u| < \frac{1}{2}\sigma_n$,

$$\left|\widehat{\widetilde{\phi}}_n(u) - e^{-u^2/2}\right| \le \left\{e^{-u^2/2} + \left|\widehat{\widetilde{\phi}}(u) - e^{-u^2/2}\right|\right\} \frac{2A|u|^3}{\sigma_n},$$

and so

$$\begin{aligned}\left|\widehat{\widetilde{\phi}}(u) - e^{-u^2/2}\right| &\le e^{-u^2/2}\, \frac{2A|u|^3}{\sigma_n}\left(1 - \frac{2A|u|^3}{\sigma_n}\right)^{-1} \\ &\le e^{-u^2/2}\frac{4A|u|^3}{\sigma_n} \\ &\le B\sigma_n^{-1}\end{aligned}$$

if $|u|^3 < \sigma_n/4A$ for some constant B.

Similarly, if P_n is a reciprocal polynomial, then as in the derivation of (4.18), there are constants $A, B > 0$ such that

$$\left|\widehat{\widetilde{\phi}}_n(u) - e^{-u^2/2}\right| \le B\sigma_n^{-2}$$

whenever $|u| < A\sigma_n^{1/2}$. Finally, if (1.15) is satisfied, then there are constants $A, B > 0$ with

$$\left|\widehat{\widetilde{\phi}}_n(u) - e^{-u^2/2}\right| \le B\sigma_n^{-3}$$

whenever $|u| < A\sigma_n^{3/5}$.

To extend these estimates to all of $\mathbb{R}$ we need the following result.

LEMMA 4.2. *Suppose that m_n is a probability measure, $n = 1, 2, \dots$, and there is a sequence (β_n) with $\lim \beta_n = 0$ so that*

$$\left|\widehat{\widetilde{\phi}}_n(u) - e^{-u^2/2}\right| < \beta_n$$

whenever $|u| \le A|\log \beta_n|$ for some $A > 0$. Then

$$\overline{\lim}_{n\to\infty}\, \beta_n^{-1}\|\widehat{\widetilde{\phi}}_n - e^{-(\cdot)^2/2}\|_\infty \le 1.$$

Proof. Take $0 < \epsilon < 1$. Choose n large enough so that

$$2|\log(\beta_n\epsilon)| < \alpha^{-2}A^2\, |\log \beta_n|^2.$$

Take any u in $\mathbb{R}$ with $|u| > A|\log \beta_n|$. Then for some integer $k \ge 1$,

$$\alpha^{-1}A|\log \beta_n| < \alpha^{-k}|u| \le A|\log \beta_n|.$$

Putting $v = \alpha^{-k}|u|$, we have

$$v^2 > \alpha^{-2}A^2|\log \beta_n|^2 > 2|\log(\beta_n\epsilon)|,$$

and so

$$e^{-v^2/2} < \beta_n\epsilon.$$

Since $|\widehat{\widetilde{\phi}}_n(v) - e^{-v^2/2}| < \beta_n$, recalling (3.4) gives

$$\left|\widehat{\widetilde{\phi}}_n(u)\right| \le \left|\widehat{\widetilde{\phi}}(v)\right| < \beta_n(1+\epsilon).$$

Also $e^{-u^2/2} < e^{-v^2/2} < \beta_n\epsilon$, and so

$$\left|\widehat{\widetilde{\phi}}_n(u) - e^{-u^2/2}\right| < \beta_n(1+2\epsilon).$$

For any u with $|u| \le A|\log\beta_n|$ we have $|\widehat{\widetilde{\phi}}_n(u) - e^{-u^2/2}| < \beta_n$, and thus $\|\widehat{\widetilde{\phi}}_n - e^{-(\cdot)^2/2}\|_\infty \le \beta_n(1+2\epsilon)$ for all $u \in \mathbb{R}$. The result follows. □

Proof of Theorem 1.3. Theorem 1.3 follows from Lemma 4.2 and the preceding discussions. □

5. Convergence in the time domain. From Theorems 1.1 and 1.2 we can deduce the convergence of $\widetilde{m}_n$ and $\widetilde{\phi}_n$ to the Gaussian function G in the time domain only in the weak sense of (1.7). In this section we shall show that under mild assumptions on $(r_{n,j})$ in Theorem 1.2, both $\widetilde{m}_n$ and $\widetilde{\phi}_n$ have a "nice" shape, which ensures that the convergence is uniform. We consider two possibilities for the shape. For a continuous function ψ, we say ψ is *bell-shaped* if $\psi \ge 0$, $\lim_{x\to\pm\infty}\psi(x) = 0$, and there are two points $\alpha < \beta$ such that ψ is convex on $(-\infty, \alpha]$ and $[\beta, \infty)$ and concave on $[\alpha, \beta]$. We say that ψ is *logconcave* if it is supported on a closed interval, $\psi > 0$, and $\log\psi$ is concave on its interior. Neither of these properties implies the other. We note that in both cases there is a point γ such that ψ is increasing on $(-\infty, \gamma]$ and decreasing on $[\gamma, \infty)$. We also note that logconcavity is equivalent to *total positivity* of order 2, which says that for any $x_1 < x_2$ and $y_1 < y_2$,

$$\begin{vmatrix} \psi(x_1 - y_1) & \psi(x_1 - y_2) \\ \psi(x_2 - y_1) & \psi(x_2 - y_2) \end{vmatrix} \ge 0.$$

The following lemma shows that for a sequence of bell-shaped or logconcave functions, asymptotic normality implies uniform convergence. The result was stated in [5] for the case of logconcave functions, but no proof was given.

LEMMA 5.1. *Suppose that* (g_n) *is a sequence of continuous functions with* $\int_{-\infty}^{\infty} g_n = 1$, *which are either bell-shaped or logconcave, and for each* $x \in \mathbb{R}$,

$$\lim_{n\to\infty}\int_{-\infty}^{x} g_n = \int_{-\infty}^{x} G. \tag{5.1}$$

Then g_n *converges to* G *uniformly on* $\mathbb{R}$.

Proof. By (5.1), for any interval $I \subset \mathbb{R}$,

$$\lim_{n\to\infty}\int_I g_n = \int_I G. \tag{5.2}$$

Take $\epsilon > 0$. Then

$$\lim_{n\to\infty}\int_{-3\epsilon}^{-\epsilon} g_n = \int_{-3\epsilon}^{-\epsilon} G, \qquad \lim_{n\to\infty}\int_{-\epsilon}^{\epsilon} g_n = \int_{-\epsilon}^{\epsilon} G.$$

Since $\int_{-3\epsilon}^{-\epsilon} G < \int_{-\epsilon}^{\epsilon} G$, we have $\int_{-3\epsilon}^{-\epsilon} g_n < \int_{-\epsilon}^{\epsilon} G$ for large enough n. Similarly, for large enough n, $\int_{\epsilon}^{3\epsilon} g_n < \int_{-\epsilon}^{\epsilon} G$. So for large enough n, there are points $-3\epsilon < a_n < -\epsilon <$

$b_n < \epsilon < c_n < 3\epsilon$ with $g_n(a_n) < g_n(b_n) > g_n(c_n)$. For any such n, $\max_{x\in\mathbb{R}} g_n(x)$ occurs only for $x \in (-3\epsilon, 3\epsilon)$. For if $\max_{x\in\mathbb{R}} g_n(x) = g_n(\alpha)$ for $\alpha \le -3\epsilon$, then $g_n(\alpha) > g_n(a_n) < g_n(b_n) > g_n(c_n)$, which contradicts the shape of g_n. Similarly, $\max_{x\in\mathbb{R}} g_n(x)$ cannot occur for $x \ge 3\epsilon$.

Again take $\epsilon > 0$. Choose $\delta > 0$ such that $|G(x) - G(y)| < \epsilon$ whenever $|x - y| < \delta$. Take a function $B \ge 0$ with support in $[0, \delta]$, $\int_0^\delta B = 1$, and $||\widehat{B}||_1 < \infty$. Then

$$\lim_{n\to\infty} \int_{-\infty}^{\infty} B(x-a) g_n(x)dx = \int_{-\infty}^{\infty} B(x-a)G(x)dx$$

uniformly in $a \in \mathbb{R}$. To see this, choose $A > 0$ so that $\int_{|u|>A} |\widehat{B}(u)|du < \epsilon$, and choose N so that

$$|\widehat{g}_n(u) - \widehat{G}(u)| < \epsilon \quad \text{for all } n > N,\ u \in [-A, A].$$

Then for all $n > N$,

$$\begin{aligned}
&\left| \int_{-\infty}^{\infty} B(x-a) g_n(x)dx - \int_{-\infty}^{\infty} B(x-a)G(x)dx \right| \\
&= \left| \int_{-\infty}^{\infty} e^{-iau} \widehat{B}(u)\widehat{g}_n(u)du - \int_{-\infty}^{\infty} e^{-iau} \widehat{B}(u)\widehat{G}(u)du \right| \\
&\le \int_{|u|>A} |\widehat{B}(u)|\ |\widehat{g}_n(u)|du + \int_{-A}^{A} |\widehat{g}_n(u) - \widehat{G}(u)|\ |\widehat{B}(u)|du \\
&+ \int_{|x|>A} |\widehat{B}(u)|\ |\widehat{G}(u)|du < \epsilon(2 + ||\widehat{B}||_1),
\end{aligned}$$

on noting that $|\widehat{g}_n(u)| \le \int_{-\infty}^{\infty} g_n(u)du = 1$.

Take $z < 0$. Choose N so that for all $n > N$, g_n is increasing on $(-\infty, z]$ and

$$\left| \int_{-\infty}^{\infty} B(x-a) g_n(x)dx - \int_{-\infty}^{\infty} B(x-a)G(x)dx \right| < \epsilon$$

for all $a \in \mathbb{R}$. For $y \le z$, $n > N$,

$$\begin{aligned}
\int_{-\infty}^{\infty} B(x-y+\delta) g_n(x)dx &= \int_{y-\delta}^{y} B(x-y+\delta) g_n(x)dx \\
&\le \int_{y-\delta}^{y} B(x-y+\delta) g_n(y)dx \\
&= g_n(y) \int_{-\infty}^{\infty} B = g_n(y).
\end{aligned}$$

Also for $n > N$,

$$\begin{aligned}
\int_{-\infty}^{\infty} B(x-y+\delta) g_n(x)dx &> \int_{-\infty}^{\infty} B(x-y+\delta) G(x)dx - \epsilon \\
&> \int_{-\infty}^{\infty} B(x-y+\delta) G(y)dx - 2\epsilon \\
&= G(y) - 2\epsilon.
\end{aligned}$$

Thus $g_n(y) > G(y) - 2\epsilon$ for all $n > N$. Similarly, for $y + \delta \le z$, $g_n(y) < G(y) + 2\epsilon$ for all $n > N$. Thus g_n converges to G uniformly on $(-\infty, z - \delta]$. A similar argument holds for $z > 0$, and so g_n converges to G uniformly outside any open interval containing 0.

Once again take $\epsilon > 0$ and choose $\delta > 0$ so that $|G(x) - G(y)| < \frac{\epsilon}{2}$ for $|x - y| \le 2\delta$. Choose N so that for $n > N$, $|g_n(x) - G(x)| < \frac{\epsilon}{2}$ for all $|x| \ge \delta$, and $\max g_n(x)$ occurs only for x in $(-\delta, \delta)$. Take any $n > N$ and x in $(-\delta, \delta)$. Then either $g_n(x) \ge g_n(-\delta)$ or $g_n(x) \ge g_n(\delta)$. Now $g_n(\delta) > G(\delta) - \frac{\epsilon}{2} > G(x) - \epsilon$ and similarly $g_n(-\delta) > G(x) - \epsilon$. Thus $g_n(x) > G(x) - \epsilon$. So we have shown that for any $\epsilon > 0$, there exists an integer N such that for all $n > N$ and all $x \in \mathbb{R}$, $g_n(x) > G(x) - \epsilon$.

Now suppose that g_n does not converge uniformly to G on $\mathbb{R}$. Then there is a number $k > 0$ and a sequence (x_n) with $\lim x_n = 0$ so that for arbitrarily large n,

$$g_n(x_n) > G(x_n) + k \quad \text{and} \quad \log g_n(x_n) > \log G(x_n) + k. \tag{5.3}$$

Choose points $0 < a < a + h < a + 2h < 1$. Then $2G(a + h) > G(a) + G(a + 2h)$ and $2G(-a - h) > G(-a) + G(-a - 2h)$. So for large enough n,

$$2g_n(a + h) > g_n(a) + g_n(a + 2h), \tag{5.4}$$

$$2g_n(-a - h) > g_n(-a) + g_n(-a - 2h). \tag{5.5}$$

Next choose $0 < 2\delta < a$ so that $|G(x) - G(y)| < k/3$ whenever $|x - y| \le \delta$. For large enough n, $x_n + 2\delta < a$ and $x_n + \delta/2 > 0$. Since $g_n \to G$ uniformly on $[\delta/2, \infty)$ and $|G(x_n + \delta) - G(x_n + 2\delta)| < k/3$, we have for large enough n,

$$|g_n(x_n + \delta) - g_n(x_n + 2\delta)| < \frac{k}{2}. \tag{5.6}$$

Also we have $G(x_n + \delta) < G(x_n) + k/3$, and so for large enough n,

$$g_n(x_n + \delta) < G(x_n) + \frac{k}{2}. \tag{5.7}$$

Hence for large enough n, by (5.6) and (5.7),

$$2g_n(x_n + \delta) < g_n(x_n + 2\delta) + G(x_n) + k.$$

Therefore, by (5.3), we see that for arbitrarily large n,

$$2g_n(x_n + \delta) < g_n(x_n) + g_n(x_n + 2\delta). \tag{5.8}$$

Now suppose g_n is bell-shaped. Choose n so that $x_n > -a$, $x_n + 2\delta < a$, and (5.4), (5.5), and (5.8) are satisfied. Let α, β be such that g_n is convex on $(-\infty, \alpha]$ and $[\beta, \infty)$ and concave on $[\alpha, \beta]$. By (5.4) and (5.5), $\beta > a$ and $\alpha < -a$. So g_n is concave on $[-a, a]$, which contradicts (5.8).

Next suppose that g_n is logconcave. A similar (but simpler) argument to that above shows that (5.8) can be replaced by

$$2 \log g_n(x + \delta) < \log g_n(x_n) + \log g_n(x_n + 2\delta),$$

which again gives a contradiction. □

We remark that the uniform convergence of g_n to G on $\mathbb{R}$ and the condition $\int_{-\infty}^{\infty} g_n = 1 = \int_{-\infty}^{\infty} G$ imply that $g_n \to G$ in $L^p(\mathbb{R})$ as $n \to \infty$ for all p, $1 \le p \le \infty$. Since convergence in $L^1(\mathbb{R})$ implies (5.1), the converse of Lemma 5.1 also holds.

From Lemma 5.1 we now derive the uniform convergence of $\widetilde{m}_n$ to G under an extra condition on the numbers $(r_{n,j})$ as in Theorem 1.4.

THEOREM 5.2. *We assume the conditions of Theorem* 1.4. *Then*

$$\lim_{n\to\infty}\left\{\sigma_n a_{n,k} - G\left(\frac{k-\mu_n}{\sigma_n}\right)\right\} = 0 \tag{5.9}$$

uniformly over k *in* $\mathbb{Z}$.

Proof. Since all $r_{n,j}$ lie in the sector $|\arg z| \le \frac{\pi}{3}$, it follows that the matrix $(a_{n,i-j})$ is totally positive of order 2. Hence $a_{n,k} \ge 0$ and

$$a_{n,k}^2 \ge a_{n,k-1}a_{n,k+1}, \quad k = 1,\dots,n-1, \ \ n = 1,2,\dots\ . \tag{5.10}$$

For $n = 1,2,\dots$, we define ψ_n as follows. Without loss of generality we may assume $a_{n,0}a_{n,n} \ne 0$, and it follows from (5.10) that $a_{n,k} > 0$, $k = 0,\dots,n$. We define ψ_n on $[-\mu_n/\sigma_n, (n-\mu_n)/\sigma_n]$ to be the piecewise linear function with knots $(j-\mu_n)/\sigma_n$, $j = 0,\dots,n$, satisfying

$$\psi_n\left(\frac{j-\mu_n}{\sigma_n}\right) = \log(\sigma_n a_{n,j}), \quad j = 0,1,\dots,n.$$

From (5.10), ψ_n is concave on $[-\mu_n/\sigma_n, (n-\mu_n)/\sigma_n]$. We now extend ψ_n to a continuous concave function on (α,β), where $\alpha = -(\mu_n+1)/\sigma_n$, $\beta = (n-\mu_n+1)/\sigma_n$, and

$$\lim_{x\to\alpha^+}\psi_n(x) = \lim_{x\to\beta^-}\psi_n(x) = -\infty.$$

For $n = 1,2,\dots$, we define

$$g_n(x) = \begin{cases} e^{\psi_n(x)}, & \alpha < x < \beta, \\ 0 & \text{otherwise.} \end{cases}$$

Clearly, g_n is logconcave, and

$$g_n\left(\frac{j-\mu_n}{\sigma_n}\right) = \sigma_n a_{n,j}, \quad j = 0,1,\dots,n.$$

As in Theorem 1.2, we define measures m_n, $n = 1,2,\dots$, by

$$m_n(\{k\}) = a_{n,k}, \quad k = 0,1,\dots,n,$$

and it follows that (m_n) is asymptotically normal. We note that for $k \in \mathbb{Z}$,

$$\int_{-\infty}^{\frac{k-\mu_n}{\sigma_n}} d\widetilde{m}_n = \sum_{j=0}^{k} a_{n,j},$$

where we put $a_{n,j} = 0$ for $j > n$. It follows from (5.15) that as $n \to \infty$,

$$\int_{-\infty}^{x} g_n - \int_{-\infty}^{x} d\widetilde{m}_n = O(\sigma_n^{-1})$$

uniformly in x. We can then apply Lemma 5.1 to the sequence of functions $g_n/\int_{-\infty}^{\infty} g_n$ to show that this sequence converges to G on $\mathbb{R}$. Hence g_n converges uniformly to G on $\mathbb{R}$, which by (5.15) gives (5.9). ∎

We now consider the uniform convergence of the normalized m_n-scaling functions $\widetilde{\phi}_n$ to G.

THEOREM 5.3. *Assume the conditions of Theorem* 1.5. *Then* $\widetilde{\phi}_n \to G$ *as* $n \to \infty$ *uniformly on* $\mathbb{R}$.

Proof. It follows from the work of Goodman and Micchelli (see [8]) and the properties of totally positive matrices (see [2]) that the functions ϕ_n, and hence $\widetilde{\phi}_n$, are bell-shaped. The result then follows from Theorem 1.1, Theorem 1.2, and Lemma 5.1. □

We remark that if the set of all $r_{n,j}$ lies in Re $z \geq 0$, then the condition that it also lies in D_γ for some $\gamma \in [0, \frac{\pi}{2})$ is equivalent to requiring that for some $\beta \in [0, \frac{\pi}{2})$ the set of all $r_{n,j}$ lying outside the sector $|\arg z| \leq \beta$ is bounded and bounded away from zero. In [4], Chui and Wang consider convergence of the sequence $(\widetilde{\phi}_n)$ as in Theorem 5.3 under the assumption that the polynomial $\sum_{k=0}^n a_{n,k} z^k$ is reciprocal and all $r_{n,j}$ are real and positive. They also assume that for $n = 1, 2, \dots$, $r_{n,j} = 1$ for at least Kn values of j for some fixed $K > 0$. They prove convergence in L^p, $1 \leq p < \infty$, which we have noted is weaker than uniform convergence.

We shall finish the paper by considering the order of uniform convergence for both the measures and the corresponding scaling functions. We first need to extend concepts of bell-shaped and logconcave to discrete measures. Suppose m is a probability measure on $\mathbb{Z}$ with $m(\{j\}) = a_j$, $j \in \mathbb{Z}$. We say m is *bell-shaped* if there are integers $k \leq \ell$ such that

$$\begin{aligned} 2a_j &\leq a_{j-1} + a_{j+1}, \quad j \leq k-1 \text{ and } j \geq \ell + 1, \\ 2a_j &\geq a_{j-1} + a_{j+1}, \quad k \leq j \leq \ell. \end{aligned}$$

We say m in *logconcave* if

$$a_j^2 \geq a_{j-1} a_{j+1}, \quad j \in \mathbb{Z}.$$

LEMMA 5.4. *For* $n = 1, 2, \dots$, *let* m_n *be a probability measure on* $\{0, 1, \dots, n\}$ *given by* $m_n(\{k\}) = a_{n,k}$, $k = 0, 1, \dots, n$, *which is either bell-shaped or logconcave, with mean* μ_n *and standard derivation* σ_n. *Suppose that for some* $K > 0$ *and* $r \geq 1$,

$$\left| \widehat{\widetilde{m}}_n(u) - e^{-u^2/2} \right| \leq K \sigma_n^{-r} \quad \text{for } |u| \leq K \sigma_n. \tag{5.11}$$

Then as $n \to \infty$,

$$\max_{k=0,\dots,n} \left| \sigma_n a_{n,k} - G\left(\frac{k - \mu_n}{\sigma_n} \right) \right| = O(\sigma_n^{-s}), \tag{5.12}$$

where $s = \min\{\frac{r}{2}, \frac{2}{3}\}$.

Proof. Take a nonnegative function N with support in $[-1, 1]$, $\int_{-\infty}^{\infty} N = 1$, $\|\widehat{N}\|_1 < \infty$, and for some $A > 0$,

$$|\widehat{N}(u)| \leq A(1 + |u|)^{-3r-1}, \quad u \in \mathbb{R}.$$

Take $0 < \delta < 1/2$. Let $B_1(x) := \delta^{-1} N(x/\delta)$ and $B_2(x) := \delta^{-1} N(x/\delta - 4)$. Then B_1 and B_2 have supports on $[-\delta, \delta]$ and $[3\delta, 5\delta]$, respectively, and $\int_{-\infty}^{\infty} B_1 = \int_{-\infty}^{\infty} B_2 = 1$. So

$$\int_{-\infty}^{\infty} B_1 G > G(\delta), \quad \int_{-\infty}^{\infty} B_2 G < G(3\delta).$$

and hence

$$\begin{aligned}\int_{-\infty}^{\infty} B_1 G - \int_{-\infty}^{\infty} B_2 G &> G(\delta) - G(3\delta)\\ &> |G'(\delta)|2\delta\\ &> |G''(\delta)|2\delta^2\\ &> |G''(1/2)|2\delta^2.\end{aligned}$$

Also for $j = 1, 2$,

$$\begin{aligned}\left|\int_{-\infty}^{\infty} B_j d\widetilde{m}_n - \int_{-\infty}^{\infty} B_j G\right| &= \left|\int_{-\infty}^{\infty} \widehat{B}_j(-u)(\widehat{\widetilde{m}}_n(u) - \widehat{G}(u))du\right|\\ &\le \int_{|u|\ge K\sigma_n} (|\widehat{\widetilde{m}}_n(u)| + \widehat{G}(u))|\widehat{B}_j(-u)|du\\ &\quad + \frac{K}{\sigma_n^r}\int_{-K\sigma_n}^{K\sigma_n} |\widehat{B}_j(u)|du\\ &\le 2\int_{|u|>K\sigma_n} |\widehat{N}(\delta u)|du + \frac{K}{\sigma_n^r}\int_{-\infty}^{\infty} |\widehat{N}(\delta u)|du\\ &= \frac{2}{\delta}\int_{|u|\ge K\delta\sigma_n} |\widehat{N}(u)|du + \frac{K}{\delta\sigma_n^r}\int_{-\infty}^{\infty} |\widehat{N}(u)|du\\ &\le \frac{C}{\delta(K\delta\sigma_n)^{3r}} + \frac{C}{\delta\sigma_n^r}\end{aligned}$$

for some $C > 0$. Choosing $\delta = c\sigma_n^{\beta-1}$ for some $\frac{1}{3} \le \beta < 1$, and $c > 1$, gives

$$\left|\int_{-\infty}^{\infty} B_j d\widetilde{m}_n - \int_{-\infty}^{\infty} B_j G\right| \le \frac{D}{c\sigma_n^{r+\beta-1}} \tag{5.13}$$

for some $D > 0$. Then

$$\begin{aligned}\int_{-\infty}^{\infty} B_1 d\widetilde{m}_n &> \int_{-\infty}^{\infty} B_1 G - \frac{D}{c\sigma_n^{r+\beta-1}}\\ &> \int_{-\infty}^{\infty} B_2 G + \left|G''\left(\frac{1}{2}\right)\right|2\delta^2 - \frac{D}{c\sigma_n^{r+\beta-1}}\\ &> \int_{-\infty}^{\infty} B_2 d\widetilde{m}_n + \frac{|G''(\frac{1}{2})|2c^2}{\sigma_n^{2-2\beta}} - \frac{2D}{c\sigma_n^{r+\beta-1}}\ .\end{aligned} \tag{5.14}$$

Now for $n = 1, 2, \dots$, choose a continuous function g_n, which is bell-shaped or logconcave as m_n is bell-shaped or logconcave, respectively, and satisfies

$$g_n\left(\frac{j-\mu}{\sigma_n}\right) = \sigma_n a_{n,j}, \quad j = 0, 1, \dots, n. \tag{5.15}$$

If m_n is logconcave, then this can be done as in the proof of Theorem 5.2, while if m_n is bell-shaped we can take g_n to be simply the piecewise linear interpolant. Note that if, for some constant b, $g_n \ge b$ on the support of B_j, $j = 1$ or 2, then $\int_{-\infty}^{\infty} B_j d\widetilde{m}_n$ bounds the product of b and a Riemann sum for B_j over its support with

interval length σ_n^{-1}. This Riemann sum equals a Riemann sum for N over $[0,1]$ with interval length $\delta^{-1}\sigma_n^{-1}$, which differs from $\int_0^1 N$ by $O(\delta^{-2}\sigma_n^{-2})$. Thus, by the uniform boundedness of g_n, we have

$$\int B_j d\widetilde{m}_n \geq b + O(\delta^{-2}\sigma_n^{-2}),$$

and similarly the result holds with $\geq$ replaced by $\leq$. Thus if $g_n(x) \leq g_n(y)$ for all $x \in [-\delta, \delta]$, $y \in [3\delta, 5\delta]$, we have

$$\int_{-\infty}^{\infty} B_1 d\widetilde{m}_n \leq \int_{-\infty}^{\infty} B_2 d\widetilde{m}_n + \frac{a}{\delta^2\sigma_n^2} = \int_{-\infty}^{\infty} B_2 d\widetilde{m}_n + \frac{a}{c^2\sigma_n^{2\beta}}$$

for a fixed constant a. Choosing $\beta = 2/3$ and c large enough, this would contradict (5.14), and so there are points $-\delta < b_n < \delta$, $3\delta < c_n < 5\delta$ with $g_n(b_n) > g_n(c_n)$. Similarly, we can choose b_n so that there is a point a_n in $(-5\delta, -3\delta)$ with $g_n(a_n) < g_n(b_n)$. As in the proof of Lemma 5.1, it follows from the shape of g_n that the maximum of $g_n(x)$ occurs only for x in $(-5\delta, 5\delta)$. So we have shown that for a constant a, maximum of $g_n(x)$ occurs for x in $(-a\sigma_n^{-1/3}, a\sigma_n^{1/3})$ for $n = 1, 2, \ldots$.

Now take $\delta = \sigma_n^{\beta-1}$ for some $1/3 \leq \beta < 1$ and $\gamma \geq a\sigma_n^{-1/3} + \delta$. Let $B(x) = \delta^{-1}N(\delta^{-1}(x-\gamma))$ so that B has support on $[\gamma - \delta, \gamma + \delta]$. As in (5.13)

$$\left| \int_{-\infty}^{\infty} B d\widetilde{m}_n - \int_{-\infty}^{\infty} BG \right| \leq \frac{D}{\sigma_n^{r+\beta-1}}$$

for some $D > 0$. Since g_n is decreasing on $[a\sigma_n^{-1/3}, \infty)$, for a constant $b > 0$,

$$\begin{aligned} g_n(\gamma - \delta) &\geq \int_{-\infty}^{\infty} B d\widetilde{m}_n - \frac{b}{\delta^2\sigma_n^2} \\ &\geq \int_{-\infty}^{\infty} BG - \frac{b}{\delta^2\sigma_n^2} - \frac{D}{\sigma_n^{r+\beta-1}} \\ &\geq G(\gamma + \delta) - \frac{b}{\sigma_n^{2\beta}} - \frac{D}{\sigma_n^{r+\beta-1}} \ . \end{aligned}$$

Since $|G'(\tau)| < 1$ for all τ in $\mathbb{R}$, $|G(x) - G(y)| \leq |x - y|$ for all $x, y \in \mathbb{R}$. So $G(\gamma + \delta) \geq G(\gamma - \delta) - 2\delta$, and so

$$g_n(\gamma - \delta) \geq G(\gamma - \delta) - \frac{b}{\sigma_n^{2\beta}} - \frac{D}{\sigma_n^{r+\beta-1}} - 2\delta.$$

Similarly,

$$g_n(\gamma + \delta) \leq G(\gamma + \delta) + \frac{b}{\sigma_n^{2\beta}} + \frac{D}{\sigma_n^{r+\beta-1}} + 2\delta.$$

Thus for all $x \geq a\sigma_n^{-1/3} + 2\delta$,

$$|g_n(x) - G(x)| \leq \frac{b}{\sigma_n^{2\beta}} + \frac{D}{\sigma_n^{r+\beta-1}} + \frac{2}{\sigma_n^{1-\beta}}.$$

For $r \geq 4/3$, put $\beta = 1/3$ to give

$$|g_n(x) - G(x)| = 0(\sigma_n^{-\frac{2}{3}}).$$

For $1 \le r \le 4/3$, put $\beta = 1 - r/2$ to give

$$|g_n(x) - G(x)| = 0(\sigma_n^{-\frac{r}{2}}).$$

Similarly, the result holds for $x \le -a\sigma_n^{-\frac{1}{3}} - 2\delta$. Thus for a constant $b > a$,

$$\sup\{|g_n(x) - G(x)| : |x| \ge b\sigma_n^{-\frac{1}{3}}\} = O(\sigma_n^{-s}) \tag{5.16}$$

for s as in the statement of Lemma 5.4. Note that for any $\delta > 0$ and $x, y \in (-\delta, \delta)$,

$$|G(x) - G(y)| \le |G''(0)|\delta|x - y| \le \delta|x - y|. \tag{5.17}$$

Take any $x \in (-b\sigma_n^{-\frac{1}{3}}, b\sigma_n^{\frac{-1}{3}})$. Then either

$$g_n(x) \ge g_n(b\sigma_n^{-\frac{1}{3}}) \quad \text{or} \quad g_n(x) \ge g_n(-b\sigma_n^{-\frac{1}{3}}).$$

Suppose the former. Then

$$\begin{aligned} g_n(x) \ge g_n(b\sigma_n^{-\frac{1}{3}}) &> G(b\sigma_n^{-\frac{1}{3}}) - O(\sigma_n^{-s}) \\ &> G(x) - O(\sigma_n^{-s}) - 2(b\sigma_n^{-\frac{1}{3}})^2. \end{aligned}$$

The same holds similarly for the latter case. Thus

$$\sup\{g_n(x) - G(x) : |x| \le b\sigma_n^{-\frac{1}{3}}\} = O(\sigma_n^{-s}). \tag{5.18}$$

Now note, as in the proof of Lemma 5.1, that if g_n is bell-shaped, then for all large enough n, g_n is concave on $[-\frac{2}{3}, \frac{2}{3}]$. Since concavity implies logconcavity, g_n is logconcave on $[-\frac{2}{3}, \frac{2}{3}]$ for all large enough n. By (5.16) and the mean value theorem,

$$\sup\left\{|\log g_n(x) - \log G(x)| : b\sigma_n^{-\frac{1}{3}} \le |x| \le \frac{2}{3}\right\} = O(\sigma_n^{-s}).$$

Take $0 \le x \le b\sigma_n^{-\frac{1}{3}}$ and n so large that $b\sigma_n^{-\frac{1}{3}} \le \frac{2}{9}$. Then

$$\begin{aligned} \log g_n(x) &\le 2\log g_n(x + b\sigma_n^{-\frac{1}{3}}) - \log g_n(x + 2b\sigma_n^{-\frac{1}{3}}) \\ &\le 2\log G(x + b\sigma_n^{-\frac{1}{3}}) - \log G(x + 2b\sigma_n^{-\frac{1}{3}}) + O(\sigma_n^{-s}) \\ &\le \log G(x) + |\log G(x + b\sigma_n^{-\frac{1}{3}}) - \log G(x)| \\ &\qquad + |\log G(x + b\sigma_n^{-\frac{1}{3}}) - \log G(x + 2b\sigma_n^{-\frac{1}{3}})| + O(\sigma_n^{-s}) \\ &\le \log G(x) + O(\sigma_n^{-\frac{2}{3}}) + O(\sigma_n^{-s}). \end{aligned}$$

A similar argument holds for $-b\sigma_n^{-\frac{1}{3}} \le x \le 0$, and applying the mean value theorem gives

$$\sup\{G(x) - g_n(x) : |x| \le b\sigma_n^{-\frac{1}{3}}\} = O(\sigma_n^{-3}). \tag{5.19}$$

Combining (5.16), (5.18), and (5.19) and recalling (5.15) then gives the result. □

Proof of Theorem 1.4. Theorem 1.4 follows from Proposition 4.1 and Lemma 5.4. □

To consider the order of uniform convergence for the scaling functions, we need the following analogue of Lemma 5.4. This can be proved in a similar manner to Lemma 5.4, but the proof is simpler, in particular because there is no restriction on the range of u as in (5.11).

LEMMA 5.5. *Suppose that (g_n) is a sequence of continuous functions, which are either bell-shaped or logconcave with $\int_{-\infty}^{\infty} g_n = 1$ and $\|\widehat{g}_n(u) - e^{-u^2/2}\|_\infty < \alpha_n$ for $n = 1, 2, \dots$, where $\lim_{n\to\infty} \alpha_n = 0$. Then as $n \to \infty$,*

$$\|g_n - G\|_\infty = O(\alpha_n^{\frac{1}{2}}).$$

Proof of Theorem 1.5. Theorem 1.5 follows from Theorem 1.3 and Lemma 5.5. □

WIGNER MEASURES IN THE DISCRETE SETTING: HIGH-FREQUENCY ANALYSIS OF SAMPLING AND RECONSTRUCTION OPERATORS*

FABRICIO MACIÀ†

Abstract. The goal of this article is to determine how the oscillation and concentration effects developed by a sequence of functions in $\mathbb{R}^d$ are modified by the action of sampling and reconstruction operators on regular grids. Our analysis is performed in terms of Wigner and defect measures, which provide a quantitative description of the high-frequency behavior of bounded sequences in $L^2(\mathbb{R}^d)$. We actually present explicit formulas that make possible the computation of such measures for sampled/reconstructed sequences. As a consequence, we are able to characterize sampling and reconstruction operators that preserve or filter the high-frequency behavior of specific classes of sequences. The proofs of our results rely on the construction and manipulation of Wigner measures associated to sequences of discrete functions.

Key words. Wigner measures, sampling and reconstruction, high-frequency analysis, concentration and oscillation, weak convergence, weak compactness, shift-invariant spaces

1. Introduction.

1.1. Statement of the problem: Oscillation and concentration under the effect of sampling and reconstruction. A central problem in numerical analysis and signal theory is that of reconstructing a function $u(x)$ defined in $\mathbb{R}^d$ from a discrete set of measurements taken on an uniform grid of step size h. These discrete values are typically obtained by applying to the function u a *sampling operator* S_φ^h of the type

$$S_\varphi^h u(n) := \frac{1}{h^d} \int_{\mathbb{R}^d} u(x) \overline{\varphi\left(\frac{x}{h} - n\right)} dx$$

for some *sampling function* φ. One then tries to recover u by means of a *reconstruction* (or *interpolation*) *operator* T_ψ^h, which associates to a sequence of discrete values $U := (U_n)$ a function

$$T_\psi^h U(x) := \sum_{n \in \mathbb{Z}^d} U_n \psi\left(\frac{x}{h} - n\right);$$

here ψ is some fixed *reconstruction function*. This process usually provides only an approximation $u^h := T_\psi^h S_\varphi^h u$ of the original function u, with an error that vanishes as h tends to zero. Such reconstruction schemes have been the subject of intensive study from the point of view of both approximation theory and numerical analysis.

Here we shall be concerned with the *high-frequency* approximation properties of those operators; that is, we shall study how the scheme $T_\psi^h S_\varphi^h$ is able to capture (or filter) *oscillation* and *concentration*-like phenomena on the functions it is intended to approximate. More generally, we shall be interested in clarifying how the high-frequency behavior of a sequence of reconstructed functions depends on the profiles φ, ψ and the sampling rate h chosen.

Before giving a more precise statement of our objectives, let us first illustrate the above discussion with two specific examples: consider $f_k(x) := k^{d/2}\rho(k(x-x_0))$ and $g_k(x) := \rho(x)e^{ikx\cdot\xi^0}$ with $\rho \in L^2(\mathbb{R}^d)$; the sequence (f_k) concentrates around the point x_0 as $k \to \infty$, whereas (g_k) oscillates in the direction ξ^0. The results we shall present in this paper are aimed at understanding to what extent the sequences $(T_\psi^{h_k} S_\varphi^{h_k} f_k)$ and $(T_\psi^{h_k} S_\varphi^{h_k} g_k)$ reproduce the same behavior as (f_k) and (g_k) (i.e., if concentration and oscillation persist) for a given sequence (h_k) of positive reals that tends to zero (the sampling steps) and some choice of φ and ψ.

Perhaps the simplest convenient setting in which to formulate our results is provided by the notion of *defect measure*, an object that gives a quantitative description of what we shall understand by concentration and oscillation effects and whose definition we next recall. Let (u_k) be a weakly converging sequence in the space $L^2(\mathbb{R}^d)$; denote by u its weak limit and remark that the densities $|u_k - u|^2$ are uniformly bounded in $L^1(\mathbb{R}^d)$. Helly's compactness theorem then ensures that some subsequence $(|u_{k_n} - u|^2)$ weakly converges in the set of positive Radon measures,[1] or, in other words, that there exists a positive measure ν on $\mathbb{R}^d$ such that

$$\int_{\mathbb{R}^d} \phi(x)|u_{k_n}(x) - u(x)|^2 dx \to \int_{\mathbb{R}^d} \phi(x) d\nu(x) \quad \text{as } n \to \infty$$

for every $\phi \in C_c(\mathbb{R}^d)$. When the above convergence takes place without extracting a subsequence we say that ν is the *defect measure* of the sequence (u_k).

Immediately from this definition one deduces the following general principle: if ν is the defect measure of a sequence (u_k) and $\omega \subset \mathbb{R}^d$ is an open subset, then there is an equivalence between $\nu(\omega) = 0$ and the fact that $u_k|_\omega$ converges strongly to $u|_\omega$ in $L^2_{\text{loc}}(\omega)$. Thus, the support of ν is precisely the set where strong convergence fails, that is, the set where oscillations and concentrations take place.

But defect measures are also able to detect concentration and oscillatory phenomena and give quantitative information about them. Consider the sequences (f_k), (g_k) previously defined; they both weakly converge to zero in $L^2(\mathbb{R}^d)$, and it is easy to check that their respective defect measures are $\|\rho\|^2_{L^2(\mathbb{R}^d)}\delta_{x_0}$ and $|\rho(x)|^2 dx$. Notice that, in the first case, the defect measure actually captures the concentration of the sequence around the point $x = x_0$. In the complementary of that point, where the sequence converges strongly to zero, the measure vanishes. In the second example, the defect measure is uniformly distributed on $\mathbb{R}^d$, this being consistent with the fact that strong convergence does not take place in any subset of $\mathbb{R}^d$.

Let us point out that the analysis of concentration and oscillation effects developed by a sequence of functions is a central issue in many problems of the calculus of variations and partial differential equations. A number of applications of defect

[1] From now on, we shall use the term *measure* as an abbreviation of the longer *Radon measure*. Recall that the space of Radon measures $\mathcal{M}(\mathbb{R}^d)$ is identified, by Riesz's theorem, with the space of continuous linear functionals on $C_c(\mathbb{R}^d)$.

measures may be found in the analysis of variational problems with loss of compactness performed by Lions in [11, 12].[2]

Consider a sequence (u_k), weakly converging to zero in $L^2(\mathbb{R}^d)$; sample it using a profile φ and form the reconstructed sequence

$$v_k := T_\psi^{h_k} S_\varphi^{h_k} u_k$$

for some given ψ and some sequence (h_k) of positive reals tending to zero. The functions v_k are bounded in $L^2(\mathbb{R}^d)$ and tend weakly to zero, provided φ and ψ satisfy suitable hypotheses (see Lemma 3.1 in section 3 below). Suppose furthermore that the densities $|v_k|^2$ weakly converge to the defect measure $\nu_{\varphi,\psi}$.

One of the main issues addressed in this article is that of understanding the relations existing between the defect measure $\nu_{\varphi,\psi}$, the profiles φ, ψ, and the sequences (u_k), (h_k). Among these, we point out the following:

A. Is there a formula, valid for any sequence (u_k), relating $\nu_{\varphi,\psi}$ to the defect measure ν only in terms of the profiles φ and ψ?

B. Given (u_k), characterize the profiles φ and ψ such that $\nu_{\varphi,\psi} = 0$. This is the problem of *filtering* since, as we have discussed before, $\nu_{\varphi,\psi} = 0$ is equivalent to the strong local convergence to zero of the sequence $(T_\psi^{h_k} S_\varphi^{h_k} u_k)$.

C. Similarly, characterize the profiles φ and ψ such that $\nu_{\varphi,\psi} = \nu$ for a given (u_k).

D. Finally, characterize the profiles that give $\nu_{\varphi,\psi} = \nu$ *for every* (u_k).

We shall prove that the answer to question A is negative. This is due to the fact that the measure $\nu_{\varphi,\psi}$ is sensitive to the characteristic directions of oscillation of the sequence (u_k), whereas ν is unable to distinguish them. As we have seen above, the defect measure of the oscillating sequence (g_k) equals $|\rho(x)|^2 dx$ independently of the vector ξ^0; that is not the case for $\nu_{\varphi,\psi}$. Indeed, under additional assumptions on φ and ψ we prove (see Theorem 1.3 and Corollary 1.4) that

$$\nu_{\varphi,\psi}(x) = \sum_{k\in\mathbb{Z}^d} |\widehat{\psi}(\xi^0 + 2\pi k)|^2 |\widehat{\varphi}(\xi^0)|^2 |\rho(x)|^2 dx.$$

Thus the measure $\nu_{\varphi,\psi}$ is ξ^0-dependent and cannot be expressed solely in terms of ν, φ, and ψ. Note that $\nu_{\varphi,\psi}$ is identically zero as soon as any of $\sum_{k\in\mathbb{Z}^d} |\widehat{\psi}(\xi^0 + 2\pi k)|^2$ or $\widehat{\varphi}(\xi^0)$ is null. Analogously, the profiles that give $\nu_{\varphi,\psi} = \nu$ are precisely those which satisfy

$$\sum_{k\in\mathbb{Z}^d} |\widehat{\psi}(\xi^0 + 2\pi k)|^2 |\widehat{\varphi}(\xi^0)|^2 = 1.$$

Therefore, in order to understand how $\nu_{\varphi,\psi}$ is built, we must have at our disposal an object that is able to distinguish between oscillatory phenomena at different directions.

1.2. Wigner measures. This refinement is provided by the theory of *Wigner measures*.[3] Given a bounded sequence in $L^2(\mathbb{R}^d)$ one associates to it a measure $\mu(x,\xi)$

[2] We also refer to Evans's notes [4] for an exposition of some additional applications as well as a discussion of other measure-theoretical objects (such as, for example, Young measures) designed to study the failure of strong convergence.

[3] This object is present in the work of Wigner on semiclassical quantum mechanics [20]. Recently, Wigner measures have gained interest since the works of, for example, Gérard [6], Lions and Paul [13], and Markowich, Mauser, and Poupaud [14]. Related objects are the *microlocal defect measures* or *H-measures*, introduced independently by Gérard [5] and Tartar [18].

on $\mathbb{R}^d \times \mathbb{R}^d$ which describes the concentration and oscillation effects (these are the respective roles of the variables x and ξ) occurring at some characteristic length-scale. This measure takes into account the characteristic speeds as well as the directions of propagation of oscillations. One way of defining them consists in replacing the density $|u(x)|^2$ involved in the definition of the defect measure by the phase space (microlocal) density,

$$m^\varepsilon[u](x,\xi) := \frac{1}{(2\pi\varepsilon)^d}\overline{u(x)}\widehat{u}(\xi/\varepsilon)e^{ix\cdot\xi/\varepsilon}, \tag{1.1}$$

where $\widehat{u}$ is the Fourier transform of u and ε is a positive constant. The $(2\pi)^{-d}$ factor in the definition of $m^\varepsilon[u]$ is placed to have

$$\int_{\mathbb{R}^d} m^\varepsilon[u](x,\xi)d\xi = |u(x)|^2, \qquad \int_{\mathbb{R}^d} m^\varepsilon[u](x,\xi)dx = \frac{|\widehat{u}(\xi/\varepsilon)|^2}{(2\pi\varepsilon)^d}. \tag{1.2}$$

Thus, the function $m^\varepsilon[u]$ may be looked at as a joint physical space–Fourier space "density," in spite of the fact that $m^\varepsilon[u]$ is not positive in general. However, limits of these quantities are positive measures.

THEOREM 1.1. *Let (u_k) be a bounded sequence in $L^2(\mathbb{R}^d)$ and let (ε_k) be a sequence of positive numbers tending to zero. Then it is possible to extract a subsequence (u_{k_n}) such that, for every test function $a \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$,*

$$\lim_{n\to\infty} \int_{\mathbb{R}^d\times\mathbb{R}^d} a(x,\xi)m^{\varepsilon_{k_n}}[u_{k_n}](x,\xi)dxd\xi = \int_{\mathbb{R}^d\times\mathbb{R}^d} a(x,\xi)d\mu(x,\xi), \tag{1.3}$$

where μ is a finite positive measure on $\mathbb{R}^d \times \mathbb{R}^d$.

A measure $\mu \in \mathcal{M}_+(\mathbb{R}^d\times\mathbb{R}^d)$ is called the *Wigner measure* of the sequence (u_k) at scale (ε_k) whenever the limit (1.3) holds without extracting a subsequence. Different proofs of Theorem 1.1 may be found in [8, 13, 7]. Let us point out that other quadratic densities may be used to define Wigner measures. For instance, in [13] μ is obtained by replacing $m^\varepsilon[u]$ in the limit (1.3) by the more familiar *Wigner transform*:

$$w^\varepsilon[u](x,\xi) := \int_{\mathbb{R}^d} u\left(x-\varepsilon\frac{p}{2}\right)\overline{u\left(x+\varepsilon\frac{p}{2}\right)}e^{ip\cdot\xi}\frac{dp}{(2\pi)^d}. \tag{1.4}$$

It is also possible to consider *wave-packet (Husimi) transforms*. Of course, all of these methods are equivalent (the same limit is obtained); see the discussion in [8].

The Wigner measure encodes all the information contained in the defect measure, provided the sequence (u_k) oscillates at frequencies of the order of ε_k^{-1}. We state this more precisely in the following proposition (see [8, 13]).

PROPOSITION 1.2. *If μ is the Wigner measure at scale (ε_k) of a sequence (u_k) and ν is the measure obtained as the weak limit in $\mathcal{M}_+(\mathbb{R}^d)$ of the densities $|u_k|^2dx$, then the identity*

$$\nu(x) = \int_{\mathbb{R}^d} \mu(x,d\xi)$$

*holds, provided (u_k) is ε_k-*oscillatory:

$$\limsup_{k\to\infty} \int_{|\xi|>R/\varepsilon_k} |\widehat{u_k}(\xi)|^2 d\xi \to 0 \quad \text{as } R\to\infty. \tag{1.5}$$

Notice that condition (1.5) actually expresses that the energy of the Fourier transform of u_k is concentrated in a ball of radius R/ε_k, which should be understood as the requirement that the sequence (u_k) does not oscillate at length scales finer than ε_k.

To illustrate this discussion it may be helpful to look at explicit computations. The Wigner measure at scale (ε_k) of the concentrating sequence (f_k) defined at the beginning of this section is given by

$$\mu(x,\xi) = \begin{cases} \|\rho\|^2_{L^2(\mathbb{R}^d)}\delta_{x_0}(x)\otimes\delta_0(\xi) & \text{if } \varepsilon_k k\to 0,\\ \delta_{x_0}(x)\otimes|\widehat{\rho}(\xi)|^2\dfrac{d\xi}{(2\pi)^d} & \text{if } \varepsilon_k = k^{-1},\\ 0 & \text{if } \varepsilon_k k\to\infty, \end{cases} \tag{1.6}$$

while for the oscillating sequence (g_k) it can be checked to be

$$\mu(x,\xi) = \begin{cases} |\rho(x)|^2dx\otimes\delta_0(\xi) & \text{if } \varepsilon_k k\to 0,\\ |\rho(x)|^2dx\otimes\delta_{\xi^0}(\xi) & \text{if } \varepsilon_k = k^{-1},\\ 0 & \text{if } \varepsilon_k k\to\infty. \end{cases} \tag{1.7}$$

These examples show the importance of the choice of the scale (ε_k). When this scale is taken to be coarser than the characteristic length-scale k^{-1} of oscillation/concentration, it is no longer true that the projection on the first component of their Wigner measures coincides with the defect measure. On the other hand, in the case $\varepsilon_k k \to 0$ (the scale chosen is much smaller than the actual oscillation scale) the Wigner measure is not able to capture the direction of oscillation. Hence, to obtain a complete description, the scale (ε_k) must be taken of the same order as that of the oscillations.

Wigner measures turn out to be the correct tools for comparing the high-frequency behavior of the sequences (u_k) and $(T^{h_k}_\psi S^{h_k}_\varphi u_k)$.

1.3. Computation of Wigner and defect measures. Given a sequence of sampling steps (h_k), it seems clear that the functions $T^{h_k}_\psi S^{h_k}_\varphi u_k$ will not develop oscillation and concentration effects of characteristic sizes asymptotically smaller than h_k. Most commonly, these functions will form an h_k-oscillatory sequence;[4] consequently, only Wigner measures at scales coarser than or of the same order as (h_k) will be considered.

In order to establish explicit formulas, we shall require additional hypotheses on φ, ψ and on the Wigner measures involved. Nevertheless, in order to simplify the statement of our results, in this introduction we shall impose the following (more restrictive) condition on the admissible profiles:

$$|\gamma(x)| \le C(1+|x|)^{-d-\varepsilon} \quad \text{for every } x\in\mathbb{R}^d \text{ and some } C,\varepsilon>0. \tag{1.8}$$

More general results may be found in section 7.

We prove the following.

THEOREM 1.3. *Let φ, ψ satisfy* (1.8). *Suppose (u_k) is a bounded sequence in $L^2(\mathbb{R}^d)$ and that μ is its Wigner measure at scale (h_k). Suppose, moreover, that the measures*

$$|\widehat{\varphi}(\xi+2\pi n)|^2\mu(x,\xi+2\pi n) \tag{1.9}$$

[4]However, this may fail for some pathological examples (see section 5.3).

are mutually singular for $n \in \mathbb{Z}^d$.

Then the Wigner measure at scale (h_k) *of the sequence* $(T_\psi^{h_k} S_\varphi^{h_k} u_k)$ *is given by*

$$\mu_{\varphi,\psi}(x,\xi) = |\widehat{\psi}(\xi)|^2 \sum_{k\in\mathbb{Z}^d} |\widehat{\varphi}(\xi+2\pi n)|^2 \mu(x,\xi+2\pi n).$$

From this, one deduces the following corollary.

COROLLARY 1.4. *If, moreover,* $|T_\psi^{h_k} S_\varphi^{h_k} u_k|^2 dx$ *weakly converges to a measure* $\nu_{\varphi,\psi}$, *then*

$$\nu_{\varphi,\psi}(x) = \int_{\mathbb{R}^d} \sum_{k\in\mathbb{Z}^d} |\widehat{\psi}(\xi+2\pi k)|^2 |\widehat{\varphi}(\xi)|^2 \mu(x,d\xi).$$

This shows, in particular, that a formula relating $\nu_{\varphi,\psi}$ and the weak limit ν of $|u_k|^2 dx$ does not exist unless (u_k) is h_k-oscillatory and μ is of the form $\nu(x)\otimes\sigma(\xi)$. It also shows that $\nu = \nu_{\varphi,\psi}$ if and only if $\sum_{k\in\mathbb{Z}^d} |\widehat{\psi}(\xi+2\pi k)|^2 |\widehat{\varphi}(\xi)|^2 = 1$ for $\tilde{\mu}$-almost every $\xi \in \mathbb{R}^d$, where $\tilde{\mu} := \int \mu(\cdot, d\xi)$. Consequently, there do not exist profiles φ, ψ satisfying (1.8) such that ν equals $\nu_{\varphi,\psi}$ for every h_k-oscillatory sequence (u_k).

On the other hand, Theorem 1.3 implies that question A above does have a positive answer in terms of Wigner measures, at least when restricted to the class of sequences which satisfy (1.9). That condition, roughly speaking, imposes a restriction on the size of the region in frequency space where an admissible sequence fails to converge strongly to zero. Below, we shall compare it with that appearing in Shannon's sampling theorem.

The above results will be obtained as corollaries of the more general Theorems 7.1 and 7.3. Profiles that belong to negative-order Sobolev spaces or that fail to satisfy the localization hypothesis (1.8) are allowed. However, this will require us to impose compatibility conditions on the Wigner measure μ.

As an illustration of the range of results that will be obtained in this more general setting, we present an *asymptotic version* of *Shannon's sampling theorem*.[5] It corresponds to taking as sampling profile $\varphi = \delta_0$, the Dirac delta at the origin, and as reconstruction function $\widehat{\psi} := \mathbf{1}_Q$, where $Q := [-\pi,\pi)^d$. Notice that $S_{\delta_0}^h u(n) = u(hn)$ is the discretization operator, whereas the T_ψ^h corresponds to band-limited reconstruction.

THEOREM 1.5. *Let* (u_k) *be a bounded sequence in* $L^2(\mathbb{R}^d)$ *and denote by* μ *its Wigner measure at scale* (h_k). *Suppose, in addition, that* $u_k \in H^s(\mathbb{R}^d)$ *for some* $s > d/2$ *and*

$$\begin{aligned} &\text{(i)} && (1-h_k^2\Delta_x)^{s/2} u_k \quad \textit{are uniformly bounded in } L^2(\mathbb{R}^d).\\ &\text{(ii)} && \mu(\mathbb{R}^d \times (\partial Q + 2\pi n)) = 0 \quad \textit{for } n \in \mathbb{Z}^d.\\ &\text{(iii)} && \mu(x,\xi+2\pi n), \quad n\in\mathbb{Z}^d, \quad \textit{are mutually singular measures.} \end{aligned} \tag{1.10}$$

Then the Wigner measure at scale (h_k) *of* $(T_\psi^{h_k} S_{\delta_0}^{h_k} u_k)$ *is*

$$\mu_{\delta_0,\psi}(x,\xi) = \mathbf{1}_Q(\xi) \sum_{n\in\mathbb{Z}^d} \mu(x,\xi+2\pi n). \tag{1.11}$$

Moreover, if $|T_\psi^{h_k} S_{\delta_0}^{h_k} u_k|^2 dx$ *and* $|u_k|^2 dx$ *weakly converge to* ν_S *and* ν, *respectively, then*

$$\nu_S(x) = \int_{\mathbb{R}^d} \mu(x,d\xi) = \nu(x).$$

[5]See section 3.1 for a statement of Shannon's original sampling theorem.

Thus, unlike the operators considered in Theorem 1.3, the composition of discretization and band-limited reconstruction preserves the defect measure for a large class of sequences.

Notice that, by the Sobolev imbedding theorem, $S_{\delta_0}^{h_k} u_k$ is well-defined. Actually, (1.10.i) ensures that the sequence of discretizations is square-summable and, consequently, that $(T_\psi^{h_k} S_{\delta_0}^{h_k} u_k)$ is bounded in $L^2(\mathbb{R}^d)$ and h_k-oscillatory (for a more complete result, we refer to Lemma 3.1). Condition (1.10.ii) appears because $\widehat{\psi}$ is not continuous; we shall discuss its necessity in section 4.4. Finally, (1.10.iii) should be understood as the analogue of Shannon's original band-limited condition in this context.

To conclude this short description, let us present how the above results may be refined when the sequence (u_k) is known to be ε_k-oscillatory and the sampling rate (h_k) is taken to satisfy $h_k/\varepsilon_k \to 0$. As can be expected, much more precision is gained.

THEOREM 1.6. *Suppose φ, ψ satisfy* (1.8) *and (u_k) is an ε_k-oscillatory, bounded sequence in $L^2(\mathbb{R}^d)$. If μ is its Wigner measure at scale (ε_k), then the corresponding measure of the sequence $(T_\psi^{h_k} S_\varphi^{h_k} u_k)$ is*

$$\mu_{\varphi,\psi} = |\widehat{\psi}(0)|^2 |\widehat{\varphi}(0)|^2 \mu.$$

Moreover, if the densities a $|T_\psi^{h_k} S_\varphi^{h_k} u_k|^2 dx$ and $|u_k|^2 dx$ weakly converge to $\nu_{\varphi,\psi}$ and ν, respectively, then

$$\nu_{\varphi,\psi}(x) = \sum_{n\in\mathbb{Z}^d} |\widehat{\psi}(2\pi n)|^2 |\widehat{\varphi}(0)|^2 \nu(x).$$

This theorem holds under much more general conditions on φ and ψ (see Theorem 7.6) and gives a positive answer to question A, provided we consider only ε_k-oscillatory sequences.

An immediate consequence of the above result is that zero-mean sampling profiles φ (i.e., with $\widehat{\varphi}(0) = 0$, as a wavelet, for instance) completely filter any oscillations that occur at scales much coarser than the sampling rate h_k. For such a profile, $\nu_{\varphi,\psi} = 0$ for every ε_k-oscillatory sequence. An analogous phenomenon occurs for reconstruction profiles satisfying $\widehat{\psi}(2\pi n) = 0$ for every $n \in \mathbb{Z}^d$.

On the other hand, a sufficient condition to have equality between $\nu_{\varphi,\psi}$ and ν is that $|\widehat{\varphi}(0)| = |\widehat{\psi}(0)| = 1$ and $|\widehat{\psi}(2\pi n)| = 0$ for $n \neq 0$.

1.4. Strategy of proof: Wigner measures in the discrete setting. The proof of the results we have presented above will be achieved by analyzing separately the sampling and reconstruction operators S_φ^h and T_ψ^h. In order to develop this strategy, it is necessary to deal with the concept of *Wigner measure associated to a sequence of discrete functions*. We shall introduce it by means of a discrete analogue of the transform $m^\varepsilon[\cdot]$. We detail this in the following paragraph.

To a discrete square-summable function $U \in L^2(h\mathbb{Z}^d)$, where $L^2(h\mathbb{Z}^d)$ stands for the space of the functions U defined on $\mathbb{Z}^d$ with values in $\mathbb{C}$ such that the norm

$$\|U\|_h := \left(h^d \sum_{n\in\mathbb{Z}^d} |U_n|^2 \right)^{1/2}$$

is finite, we associate

$$M^\varepsilon[U](x,\xi) := \frac{h^{2d}}{(2\pi\varepsilon)^d} \sum_{m\in\mathbb{Z}^d} \overline{U_m} \widehat{U}\left(\frac{h}{\varepsilon}\xi\right) e^{im\cdot(h/\varepsilon)\xi} \delta_{hm}(x). \tag{1.12}$$

Here, δ_{hm} is the Dirac mass centered at the point hm, and $\widehat{U}$ denotes the discrete Fourier transform

$$\widehat{U}(\xi) := \sum_{n\in\mathbb{Z}^d} U_n e^{-in\cdot\xi},$$

which, as is well known, is a $2\pi\mathbb{Z}^d$-periodic function in $L^2_{\rm loc}(\mathbb{R}^d)$. The discrete transform $M^\varepsilon[U]$ may be related to the continuous $m^\varepsilon[u]$ by noticing that

$$M^\varepsilon[U] = m^\varepsilon[T^h_{\delta_0}U], \quad \text{where } T^h_{\delta_0}U(x) = h^d \sum_{n\in\mathbb{Z}^d} U^h_n \delta_{hn}(x). \tag{1.13}$$

This is meaningful, since $m^\varepsilon[u]$ is well-defined for any tempered distribution $u \in \mathcal{S}'(\mathbb{R}^d)$.

In order to simplify our language we make the following definition.

DEFINITION 1.7. *Let $h = (h_k)$ be a scale. We shall call a sequence (U^{h_k}) h_k-bounded if and only if $U^{h_k} \in L^2(h_k\mathbb{Z}^d)$ and $\|U^{h_k}\|_{h_k} \le C$ for every $k \in \mathbb{N}$.*

One has the following convergence result (which is not a direct consequence of Theorem 1.1).

PROPOSITION 1.8. *Let (h_k), (ε_k) be scales such that (h_k/ε_k) is bounded and let (U^{h_k}) be an h_k-bounded sequence of discrete functions. Then $(M^{\varepsilon_k}[U^{h_k}])$ is bounded in $\mathcal{S}'(\mathbb{R}^d\times\mathbb{R}^d)$, and given any of its convergent subsequences $(U^{h_{k_n}})$, there exists a positive measure μ such that*

$$\lim_{n\to\infty} \langle M^{\varepsilon_{k_n}}[U^{h_{k_n}}], a\rangle_{\mathcal{S}'\times\mathcal{S}} = \int_{\mathbb{R}^d\times\mathbb{R}^d} a(x,\xi)d\mu(x,\xi) \tag{1.14}$$

for every $a \in \mathcal{S}(\mathbb{R}^d\times\mathbb{R}^d)$.

This will be proved as a corollary of the more general Proposition 3.4, which in turn follows from the analysis of Wigner measures associated to functions in negative-order Sobolev spaces that is performed in section 8. As in the continuous setting, we say that a measure μ is the *Wigner measure at scale* (ε_k) of a sequence of discrete functions (U^{h_k}) if the limit (1.14) holds for the whole sequence.

Remark 1.9. (i) When (h_k/ε_k) is unbounded, it may happen that $M^{\varepsilon_k}[U^{h_k}]$ is not bounded in $\mathcal{S}'(\mathbb{R}^d\times\mathbb{R}^d)$.

(ii) If $h_k/\varepsilon_k \to c > 0$, then μ is not finite. Indeed, it is periodic (with respect to the lattice $(2\pi/c)\mathbb{Z}^d$) in the ξ variable.

(iii) However, when $h_k/\varepsilon_k \to 0$, the Wigner measure μ is finite, as in the continuous case.

With this tool at our disposal, we are able to compare the Wigner measure of a sequence of discrete functions (U^{h_k}) with that of a reconstructed sequence $(T^{h_k}_\psi U^{h_k})$. Analogously, we may compute Wigner measures of sequences of sampled discrete functions $(S^{h_k}_\varphi u_k)$ in terms of those corresponding to the original sequence (u_k). These are, respectively, the contents of Theorems 4.6 and 4.2.

1.5. Plan of the article. Results and assumptions concerning the operators S^h_φ and T^h_ψ are collected in section 3.

In section 4, the problem of computing Wigner measures for sequences of sampled or reconstructed functions is addressed. Formulas for Wigner measures at scales of the same order as the sampling/reconstruction step (h_k) are presented in Theorems 4.6 and 4.2. Theorems 1.3 and 1.5 then easily follow from those two results. We also

point out the relationships existing between these Wigner measures and the concept of *Wigner series* introduced in [14, 9].

The problem of the computation of defect measures of sequences of the form $(T_\psi^{h_k} U^{h_k})$ is considered in section 5; the main results are presented in Proposition 5.8 and Corollary 5.9.

In section 6 we investigate Wigner measures at scales (ε_k) satisfying $h_k/\varepsilon_k \to 0$. Explicit formulas are presented in Theorems 6.1 and 6.2, from which Theorem 1.6 immediately follows.

The composition of sampling and reconstruction is studied in section 7, where the main results of this article are proved.

Finally, section 8 contains the elements from the theory of Wigner measures on which the proofs of most of the results of this article are based. Propositions 8.1 and 8.3, which extend the theory of Wigner measures to sequences in Sobolev spaces of negative order, are systematically used throughout this paper.

2. Notation and conventions. We briefly present some notation that will be used throughout this article.

$B(x;R)$ will denote the open ball with radius R of $\mathbb{R}^d$ centered at the point x. $\mathbf{1}_A$ will denote the characteristic function of a set $A \subseteq \mathbb{R}^d$.

We write Γ to denote the lattice $2\pi\mathbb{Z}^d$. A function f defined on $\mathbb{R}^d$ is Γ-periodic if $f(x+\gamma) = f(x)$ for every $\gamma \in \Gamma$ and every $x \in \mathbb{R}^d$.

We adopt the following convention for the Fourier transform:

$$\widehat{u}(\xi) := \int_{\mathbb{R}^d} u(x) e^{-ix\cdot\xi} dx.$$

Given a measurable function $\varphi(\xi)$, the *Fourier multiplier* of symbol φ is the operator $\varphi(D_x)$ formally defined by

$$\varphi(D_x)u(x) := \int_{\mathbb{R}^d} \varphi(\xi)\widehat{u}(\xi) e^{ix\cdot\xi} \frac{d\xi}{(2\pi)^d} = \check{\varphi} * u(x),$$

$\check{\varphi}$ being the inverse Fourier transform of φ.

A particularly important Fourier multiplier is the *Bessel potential* $\langle D_x \rangle$ of symbol

$$\langle \xi \rangle := (1 + |\xi|^2)^{1/2}.$$

Next, we recall the definition of some function spaces.

As usual, $\mathcal{S}(\mathbb{R}^d)$ denotes the space of *rapidly decreasing functions* and $\mathcal{S}'(\mathbb{R}^d)$ stands for its dual, the space of *tempered distributions*.

Given $r \in \mathbb{R}$, $H^r(\mathbb{R}^d)$, the *Sobolev space* of order r, consists of the distributions $u \in \mathcal{S}'(\mathbb{R}^d)$ such that $\langle D_x \rangle^r u \in L^2(\mathbb{R}^d)$.

The weighted space $L^2(\mathbb{R}^d; \langle x \rangle^r)$ is that of the functions $u \in L^1_{\mathrm{loc}}(\mathbb{R}^d)$ such that

$$\|u\|_{L^2(\mathbb{R}^d;\langle x\rangle^r)} := \left(\int_{\mathbb{R}^d} |u(x)|^2 \langle x \rangle^r dx \right)^{1/2} < \infty.$$

The analogous definition is understood for $L^\infty(\mathbb{R}^d; \langle x \rangle^r)$.

By $C^\infty(\mathbb{R}^d; \langle x \rangle^r)$ we intend the space of functions $u \in C^\infty(\mathbb{R}^d)$ such that

$$\|\partial_x^\alpha u\|_{L^\infty(\mathbb{R}^d;\langle x\rangle^r)} < \infty \quad \text{for every multi-index } \alpha \in \mathbb{N}^d.$$

$C_0(\mathbb{R}^d)$ denotes the spaces of continuous functions on $\mathbb{R}^d$ vanishing at infinity.

Given an open set $\Omega \subseteq \mathbb{R}^d$, $\mathcal{M}_+(\Omega)$ is the set of *positive Radon measures* on Ω, which can be identified through Riesz's theorem to the set of positive functionals on $C_c(\Omega)$, the space of continuous functions on Ω with compact support.

In order to lighten our writing, we shall write $\mathcal{S}$ and $\mathcal{S}'$ instead of $\mathcal{S}(\mathbb{R}^d_x \times \mathbb{R}^d_\xi)$ and $\mathcal{S}'(\mathbb{R}^d_x \times \mathbb{R}^d_\xi)$, respectively.

For a measurable function $f : \mathbb{R}^d \to \mathbb{C}$, we use the notation

$$D_f := \{x \in \mathbb{R}^d : f \text{ is not continuous at } x\}.$$

An important, perhaps nonstandard, definition is that of a scale.

DEFINITION 2.1. *A* scale (ε_k) *is a sequence of positive numbers that tends to zero as* $k \to \infty$.

Given two scales (h_k) and (ε_k), the notation $h_k \ll \varepsilon_k$ and $h_k \sim \varepsilon_k$ will be used to indicate that $\lim_{k\to\infty} h_k/\varepsilon_k = 0$ and $\lim_{k\to\infty} h_k/\varepsilon_k = c > 0$, respectively.

Finally, we shall always denote

$$Q := [-\pi, \pi)^d.$$

3. Sampling and reconstruction.

3.1. Definitions and examples. We now describe the sampling and reconstruction operators we are going to consider. Given a distribution $\varphi \in \mathcal{S}'(\mathbb{R}^d)$ we set, for every $n \in \mathbb{Z}^d$ and $h > 0$,

$$\varphi_n^h(x) := \varphi\left(\frac{x}{h} - n\right).$$

The *reconstruction* (or *synthesis*) *operator* T_φ^h, acting on discrete functions U of $\mathbb{Z}^d$, is defined to be

$$T_\varphi^h U(x) := \sum_{n\in\mathbb{Z}^d} U_n \varphi_n^h(x). \tag{3.1}$$

This expression is well-defined for finitely supported discrete functions. When φ is a continuous function such that $\varphi(0) = 1$ and $\varphi(k) = 0$ for $k \in \mathbb{Z}^d \setminus \{0\}$, then $T_\varphi^h U$ is actually a function that *interpolates* the discrete values U_n on the grid $h\mathbb{Z}^d$, i.e., $T_\varphi^h U(hn) = U_n$ for all $n \in \mathbb{Z}^d$.

Analogously, the *sampling* (or *analysis*) *operator* S_φ^h, a priori only acting on functions $u \in \mathcal{S}(\mathbb{R}^d)$, is defined as follows: $S_\varphi^h u$ is the discrete function given by

$$S_\varphi^h u(n) := h^{-d} \langle \overline{\varphi_n^h}, u \rangle_{\mathcal{S}'(\mathbb{R}^d)\times\mathcal{S}(\mathbb{R}^d)}.$$

When $\varphi = \delta_0$, we obtain the usual *discretization* operator: $S_{\delta_0}^h u(n) = u(hn)$ for every $n \in \mathbb{Z}^d$.

Indeed, these sampling/reconstruction schemes include several well-known procedures on regular grids. Among many others we may cite the following:

- *Cardinal B-splines.* The B-spline of order zero is the function $\varphi(x) := \mathbf{1}_{[-1/2,1/2]^d}(x)$; the function $T_\varphi^h U$ is just the piecewise constant interpolation of the discrete function U on the grid $h\mathbb{Z}^d$. The B-spline of order 1,

$$\varphi(x) = \mathbf{1}_{[-1/2,1/2]^d} * \mathbf{1}_{[-1/2,1/2]^d} = \prod_{j=1}^d (1 - |x_j|)_+,$$

gives rise to the piecewise linear interpolation operator. Analogously, B-splines of order $r \in \mathbb{N}$ are defined iterating this convolution r times. These are $C^{r-1}(\mathbb{R}^d)$ functions supported in $[-r/2, r/2]^d$, taking the value 1 at the origin. More details may be found, for instance, in [2].

- *Band-limited sampling/reconstruction.* This corresponds to the profile

$$\varphi(\xi) := \prod_{j=1}^{d} \operatorname{sinc}(\xi_j),$$

where the *cardinal sine function* is defined by

$$\operatorname{sinc}(t) := \frac{\sin \pi t}{\pi t}.$$

It is easy to check that $\widehat{\varphi}(\xi) = \mathbf{1}_Q(\xi)$. This profile is relevant because of *Shannon's sampling theorem*: *a function u belongs to the space*

$$V^h := \{u \in L^2(\mathbb{R}^d) : \operatorname{supp} \widehat{u} \subset [-\pi/h, \pi/h)^d\} = \operatorname{range}(T_\varphi^h)$$

if and only if

$$u = \sum_{n \in \mathbb{Z}^d} u(hn) \varphi_n^h.$$

In particular, such functions are determined by their values on the grid $h\mathbb{Z}^d$.

- *Wavelets.* Take $h_k := 2^{-k}$ for every $k \in \mathbb{Z}$. A function $\psi \in L^2(\mathbb{R}^d)$ is a wavelet, provided $\{\psi_n^{h_k} : n \in \mathbb{Z}^d,\ k \in \mathbb{Z}\}$ is an orthonormal basis of $L^2(\mathbb{R}^d)$. For more details on wavelets and the closely related *multiresolution analyses*, the reader may see [10, 16].

Additional examples and references (from the viewpoint of signal theory) may be found in the survey [19].

3.2. Boundedness properties. In order to ensure that the sampling and reconstruction operators are bounded, we shall make the assumption (BP_s) below:

$$\text{(BP_s)} \qquad \begin{gathered} \varphi \in H^s(\mathbb{R}) \text{ and, for some } B > 0, \\ \tau_{\langle D_x \rangle^s \varphi}(\xi) := \sum_{k \in \mathbb{Z}^d} |\langle \xi + 2\pi k \rangle^s \widehat{\varphi}(\xi + 2\pi k)|^2 \le B \quad \text{for a.e. } \xi \in \mathbb{R}^d. \end{gathered}$$

LEMMA 3.1. *Suppose $\varphi \in \mathcal{S}'(\mathbb{R}^d)$. Then the following are equivalent:*

(i) *φ satisfies* (BP_s).

(ii) *There exists $B > 0$ such that*

$$\|\langle hD_x \rangle^s T_\varphi^h U\|_{L^2(\mathbb{R}^d)} \le \sqrt{B} \|U\|_{L^2(h\mathbb{Z}^d)} \tag{3.2}$$

holds uniformly for $h > 0$ and $U \in L^2(h\mathbb{Z}^d)$.

(iii) *There exists $B > 0$ such that*

$$\|S_\varphi^h u\|_{L^2(h\mathbb{Z}^d)} \le \sqrt{B} \|\langle hD_x \rangle^{-s} u\|_{L^2(\mathbb{R}^d)} \tag{3.3}$$

holds uniformly for $h > 0$ and $u \in H^{-s}(\mathbb{R}^d)$.

Moreover, whenever (i), (ii), *or* (iii) *is fulfilled, the smallest constant B for which any of the above assertions holds is precisely $\|\tau_{\langle D_x\rangle^s\varphi}\|_{L^\infty(Q)}$.*

Proof. To see why (i) and (ii) are equivalent, first observe that, given any $\varphi \in H^s(\mathbb{R}^d)$, the following identity holds:

$$T^h_\varphi = \langle hD_x\rangle^{-s} T^h_{\langle D_x\rangle^s\varphi}. \tag{3.4}$$

To check this, simply notice that

$$\widehat{T^h_\varphi U}(\xi) = h^d\widehat{\varphi}(h\xi)\sum_{n\in\mathbb{Z}^d} U_n e^{-ihn\cdot\xi} = \widehat{\varphi}(h\xi)h^d\widehat{U}(h\xi),$$

and hence

$$\widehat{T^h_\varphi U}(\xi) = \langle h\xi\rangle^{-s}\langle h\xi\rangle^s\widehat{\varphi}(h\xi)h^d\widehat{U}(h\xi) = \langle hD_x\rangle^{\widehat{-s}}\widehat{T^h_{\langle D_x\rangle^s\varphi}U}(\xi).$$

Since $\langle D_x\rangle^s\varphi \in L^2(\mathbb{R}^d)$ and

$$\|\langle hD_x\rangle^s T^h_\varphi U\|_{L^2(\mathbb{R}^d)} = \|T^h_{\langle D_x\rangle^{-s}\varphi}U\|_{L^2(\mathbb{R}^d)}$$

it suffices to deal with the case $s = 0$. But it is a well-known result (see, for instance, [3, 17]) that for $\varphi \in L^2(\mathbb{R}^d)$, (i) and (ii) are equivalent and that $\|T^h_\varphi\| = \|\tau_\varphi\|_{L^\infty(\mathbb{R}^d)}$ whenever T^h_φ is bounded.

Statements (ii) and (iii) are equivalent because of the following duality relation:

$$(\langle hD_x\rangle^s T^h_\varphi U, \langle hD_x\rangle^{-s}u)_{L^2(\mathbb{R}^d)} = (U, S^h_\varphi u)_{L^2(h\mathbb{Z}^d)},$$

which holds for every $u \in H^{-s}(\mathbb{R}^d)$ and $U \in L^2(h\mathbb{Z}^d)$. This is simple to check:

$$\begin{aligned}(\langle hD_x\rangle^s T^h_\varphi U, \langle hD_x\rangle^{-s}u)_{L^2(\mathbb{R}^d)} &= \sum_{n\in\mathbb{Z}^d} U_n\int_{\mathbb{R}^d}\langle hD_x\rangle^s\varphi^h_n(x)\overline{\langle hD_x\rangle^{-s}u(x)}dx\\ &= \sum_{n\in\mathbb{Z}^d} U_n\langle\varphi^h_n,\overline{u}\rangle_{H^s(\mathbb{R}^d)\times H^{-s}(\mathbb{R}^d)}\\ &= h^d\sum_{n\in\mathbb{Z}^d} U^h_n\overline{S^h_\varphi u(n)}. \qquad \square\end{aligned}$$

Remark 3.2. For $s \le 0$, estimate (3.2) implies that

$$\|\langle\varepsilon D_x\rangle^s T^h_\varphi U^h\|_{L^2(\mathbb{R}^d)} \le \sqrt{B}\|U^h\|_{L^2(h\mathbb{Z}^d)}, \tag{3.5}$$

as soon as $h/\varepsilon \le 1$, as can be easily checked by taking Fourier transforms.

A sufficient condition for (BP_s) in terms of decay on φ is given next.

LEMMA 3.3. *Suppose $\varphi \in H^s(\mathbb{R}^d)$ satisfies, for some $\varepsilon > 0$,*

$$\int_{\mathbb{R}^d}|\langle D_x\rangle^s\varphi(x)|^2(1+|x|)^{d+\varepsilon}dx < \infty. \tag{3.6}$$

Then $\widehat{\varphi}$ and $\tau_{\langle D_x\rangle^s\varphi}$ are continuous functions. In particular, (BP_s) *always holds for such a φ.*

Proof. It follows along the lines of [16, Lemma II.7]. Under condition (3.6), $\langle\xi\rangle^s\widehat{\varphi} \in H^{d/2+\varepsilon/2}(\mathbb{R}^d)$; Sobolev's imbedding theorem then ensures that $\langle\xi\rangle^s\widehat{\varphi}$ is a

continuous function, and hence so is $\widehat{\varphi}$. The continuity of $\tau_{\langle D_x\rangle^s\varphi}$ is a consequence of the fact that, whenever $\chi \in C_c^\infty(\mathbb{R}^d)$ satisfies $\sum_{n\in\mathbb{Z}^d} |\chi(\xi+2\pi n)| \geq 1$, the expression

$$\left[\sum_{n\in\mathbb{Z}^d} \|u\chi(\cdot+2\pi n)\|^2_{H^s(\mathbb{R}^d)}\right]^{1/2}$$

defines an equivalent norm in $H^s(\mathbb{R}^d)$, $s \geq 0$. This actually proves that

$$\sum_{n\in\mathbb{Z}^d} \sup_{\xi\in\mathbb{R}^d} |\langle\xi\rangle^s \widehat{\varphi}(\xi)\chi(\xi+2\pi n)|^2 < \infty.$$

In particular, the series defining $\tau_{\langle D_x\rangle^s\varphi}$ is uniformly convergent and the claim then follows. □

Condition (3.6) automatically holds for profiles φ such that

$$|\langle D_x\rangle^s\varphi(x)| \leq C(1+|x|)^{-d-\varepsilon} \quad \text{for every } x\in\mathbb{R}^d \text{ and some } C,\varepsilon>0; \tag{3.7}$$

in particular, the hypothesis (1.8) we assumed in the introduction implies (BP_s) for $s=0$.

Now we can prove a general result from which Proposition 1.8 immediately follows.

PROPOSITION 3.4. *Suppose φ satisfies* (BP_s) *and we are given scales (h_k), (ε_k) such that (h_k/ε_k) is bounded. If (U^{h_k}) is an h_k-bounded sequence of discrete functions, then the distributions $m^{\varepsilon_k}[T^{h_k}_\varphi U^{h_k}]$ are uniformly bounded in $\mathcal{S}'$. Moreover, the limit of any weakly convergent subsequence is a positive measure.*

The proof of this is a direct consequence of Remark 3.2 and the general result established in Proposition 8.1.

3.3. Bases and projections. Below, we recall some results from approximation theory that will be needed in what follows. These results deal with the range in $H^s(\mathbb{R}^d)$ of the reconstruction operator T^h_φ; we denote this space by V^h_φ and assume that it is equipped with the (equivalent) norm $\|\langle hD_x\rangle^s\cdot\|_{L^2(\mathbb{R}^d)}$.

The space V^h_φ is a *principal shift invariant* (PSI) space. When any of the conditions of Lemma 3.1 are satisfied, the family $\{h^{-d/2}\varphi^h_n : n\in\mathbb{Z}^d\}$ is said to form a *Bessel system* for V^h_φ.

The next lemma clarifies how the function $\tau_{\langle D_x\rangle^s\varphi}$ characterizes further basis properties of the functions φ^h_n.

LEMMA 3.5. *Let $\varphi\in\mathcal{S}'(\mathbb{R}^d)$ satisfy* (BP_s). *Then*

(i) *$\{h^{-d/2}\varphi^h_n : n\in\mathbb{Z}^d\}$ is an orthonormal basis of V^h_φ if and only if*

$$\tau_{\langle D_x\rangle^s\varphi}(\xi) = 1 \quad \textit{for a.e. } \xi\in\mathbb{R}^d;$$

(ii) *$\{h^{-d/2}\varphi^h_n : n\in\mathbb{Z}^d\}$ is a* Riesz basis[6] *of V^h_φ if and only if there exist constants A, $B>0$ such that*

$$A \leq \tau_{\langle D_x\rangle^s\varphi}(\xi) \leq B \quad \textit{for a.e. } \xi\in\mathbb{R}^d.$$

[6]This means that there exist constants $A,B>0$ such that

$$A\|U\|^2_{L^2(h\mathbb{Z}^d)} \leq \|T^h_\varphi U\|^2_{H^s(\mathbb{R}^d)} \leq B\|U\|^2_{L^2(h\mathbb{Z}^d)}$$

for all $U\in L^2(h\mathbb{Z}^d)$. This is equivalent to the existence of a linear isomorphism $R: V^h \to V^h$ such that $\{h^{-d/2}R\varphi^h_n : n\in\mathbb{Z}^d\}$ forms an orthonormal basis of $H^s(\mathbb{R}^d)$. This property is sometimes also referred to as $(\varphi^h_n)_{n\in\mathbb{Z}^d}$ forming a *stable frame* in $H^s(\mathbb{R}^d)$.

Proof. It follows from (3.4) that the operator $\langle hD_x\rangle^s$ is a unitary isomorphism from V_φ^h onto the range of $T^h_{\langle D_x\rangle^s\varphi}$. Hence $\{h^{-d/2}\varphi_n^h : n\in\mathbb{Z}^d\}$ is an orthonormal (resp., Riesz) basis of V_φ^h if and only if $\{h^{-d/2}(\langle D_x\rangle^s\varphi)_n^h : n\in\mathbb{Z}^d\}$ is an orthonormal (resp., Riesz) basis of $V^h_{\langle D_x\rangle^s\varphi}$. Thus, the lemma need only be proved for profiles $\varphi\in L^2(\mathbb{R}^d)$; this is a well-known result (see, for instance, [17]). ∎

We shall also need the following expression for the orthogonal projection onto V_φ^h.

LEMMA 3.6. *Let $\varphi\in\mathcal{S}'(\mathbb{R}^d)$ satisfy* (BP_s). *The orthogonal projection $P_\varphi^h : H^s(\mathbb{R}^d)\to V_\varphi^h$ equals $P_\varphi^h = T_\varphi^h S^h_{\widetilde{\langle D_x\rangle^s\varphi}}\langle hD_x\rangle^s$, where, for $f\in L^2(\mathbb{R}^d)$, $\tilde f\in L^2(\mathbb{R}^d)$ is defined by*

$$\widehat{\tilde f}(\xi) := \begin{cases} \dfrac{\widehat f(\xi)}{\tau_f(\xi)} & \text{if } \tau_f(\xi)\neq 0,\\ 0 & \text{otherwise.}\end{cases}$$

Proof. The proof of the result for $s=0$ may be found in [3, Theorem 2.9]. We limit ourselves to this case by noticing that

$$P_\varphi^h = \langle hD_x\rangle^{-s}P^h_{\langle hD_x\rangle^s\varphi}\langle hD_x\rangle^s,$$

since, as we have seen in (3.4), the range of T_φ^h equals that of $\langle hD_x\rangle^{-s}T^h_{\langle hD_x\rangle^s\varphi}$, and $\langle hD_x\rangle^s$ is an orthogonal mapping. Using the L^2-result we obtain

$$P_\varphi^h = \langle hD_x\rangle^{-s}T^h_{\langle hD_x\rangle^s\varphi}S^h_{\widetilde{\langle D_x\rangle^s\varphi}}\langle hD_x\rangle^s = T_\varphi^h S^h_{\widetilde{\langle D_x\rangle^s\varphi}}\langle hD_x\rangle^s,$$

as claimed. ∎

4. High-frequency analysis: $h\sim\varepsilon$.

4.1. Reduction to the case $h=\varepsilon$. In this section we analyze the effect of sampling and reconstruction on Wigner measures at scales (ε_k) of the same order of the sampling/reconstruction rate (h_k) (i.e., such that (h_k/ε_k) is bounded).

First notice that it suffices to treat the case $\varepsilon_k = h_k$; the more general case can be obtained by a proper rescaling. This is due to the identity

$$m^\varepsilon[u](x,\xi) = (h/\varepsilon)^d m^h[u](x,(h/\varepsilon)\xi),$$

which clearly implies the following lemma.

LEMMA 4.1. *Suppose $h_k/\varepsilon_k\to c>0$. Then $m^{\varepsilon_k}[u_k]$ converges in $\mathcal{S}'$ if and only if $m^{h_k}[u_k]$ does. Their respective limits μ_c and μ are related through*

$$\mu_c(x,\xi) = c^d\mu(x,c\xi). \tag{4.1}$$

When $h_k=\varepsilon_k$, the transforms $M^{h_k}[U^{h_k}]$ are Γ-periodic in the variable ξ; hence, so are their limiting Wigner measures.

4.2. Sampling. We start by exploring the effect of sampling on the structure of Wigner measures. The computation of the Wigner measure at scale (h_k) of a sequence of samples $(S_\varphi^{h_k}u_k)$ is done in the following theorem; it is applicable whenever the hypothesis (D) below is fulfilled:

$$\operatorname*{essup}_{\xi\in Q}\sum_{|n|\geq R}|\langle\xi+2\pi n\rangle^s\widehat\varphi(\xi+2\pi n)|^2\to 0 \quad\text{as } R\to\infty. \tag{D}$$

Notice that profiles with the property (3.6) immediately verify (D).

Before stating our result, it is important to notice that the Fourier transform of a profile φ satisfying condition (BP_s) is an element of $L^2_{\mathrm{loc}}(\mathbb{R}^d)$. In particular, it is only defined modulo sets of zero Lebesgue measure. Thus, when dealing with pointwise properties of $\widehat{\varphi}$, we shall systematically assume that a precise representative of the class of $\widehat{\varphi}$ has, once and for all, been chosen.

For instance, the Wigner measures μ of the sequences (u_k) in Theorem 4.2 below will be assumed to satisfy conditions (MS) and (ND):

(MS) $\quad |\widehat{\varphi}(\xi+2\pi n)|^2\mu(x,\xi+2\pi n), \quad n\in\mathbb{Z}^d, \quad$ are mutually singular measures.

(ND) $$\mu(\mathbb{R}^d\times\overline{D_{\widehat{\varphi}}})=0,$$

where, recall, $D_{\widehat{\varphi}}$ stands for the set of discontinuity points of $\widehat{\varphi}$. These conditions must be understood to hold for the same representative of $\widehat{\varphi}$.

THEOREM 4.2. *Let (h_k) be a scale and take φ satisfying* (BP_s) *and* (D). *Let (u_k) be a sequence in $H^{-s}(\mathbb{R}^d)$ such that $(\langle h_kD_x\rangle^{-s}u_k)$ is bounded, and suppose that $m^{h_k}[u_k]$ converges to a Wigner measure μ that fulfills* (ND), (MS).

Then $M^{h_k}[S^{h_k}_{\varphi}u_k]$ converges to the Wigner measure μ^{φ} given by

$$\mu^{\varphi}(x,\xi)=\sum_{n\in\mathbb{Z}^d}|\widehat{\varphi}(\xi+2\pi n)|^2\mu(x,\xi+2\pi n). \tag{4.2}$$

Remark 4.3. (i) As pointed out above, formula (4.6) holds for the same precise representative of the Fourier transform $\widehat{\varphi}$ which was chosen in (ND) and (MS).

(ii) The necessity of hypotheses (ND) and (MS) will be discussed in section 4.4.

(iii) Condition (D) may be replaced by the assumption that $(\langle h_kD_x\rangle^{-s}u_k)$ is h_k-oscillatory. This will be made clear in the proof of the theorem.

The proof of this theorem is postponed to the end of this section.

The expression (4.2) may be related to the concept of *Wigner series* introduced in [14, 9]. Recall that given $u\in\mathcal{S}'(\mathbb{R}^d)$, the *Wigner series* of u at scale ε is defined by

$$w^{\varepsilon}_S[u](x,\xi):=\frac{1}{(2\pi)^d}\sum_{n\in\mathbb{Z}^d}u(x-\varepsilon\pi n)\overline{u}(x+\varepsilon\pi n)e^{in\cdot\xi}.$$

It is easy to check that $w^{\varepsilon}_S[u](x,\xi)=\sum_{n\in\mathbb{Z}^d}w^{\varepsilon}[u](x,\xi+2\pi n)$.[7]

When (u_k) is bounded in $L^2(\mathbb{R}^d)$, is ε_k-oscillatory, and possesses a Wigner measure at scale (ε_k), then the following relation holds:

$$\lim_{k\to\infty}\int_{\mathbb{R}^d\times\mathbb{R}^d}a(x,\xi)w^{\varepsilon_k}_S[u_k](x,\xi)dxd\xi=\int_{\mathbb{R}^d\times\mathbb{R}^d}\sum_{n\in\mathbb{Z}^d}a(x,\xi+2\pi n)d\mu(x,\xi) \tag{4.3}$$

for $a\in\mathcal{S}$; see [1].

Theorem 4.2 has a simple interpretation in terms of Wigner series: the measure μ^{φ} may be obtained as the limit of the Wigner series

$$w^{h_k}_S[\widehat{\varphi}(h_kD_x)u_k].$$

[7] See (1.4) for the definition of the Wigner transform $w^{\varepsilon}[u]$.

This is due to the fact that, under any of the hypotheses (D), $(\widehat{\varphi}(h_k D_x)u_k)$ is h_k-oscillatory. Besides, as a consequence of Proposition 8.3, the Wigner measure at scale (h_k) of $(\widehat{\varphi}(h_k D_x)u_k)$ is given by $|\widehat{\varphi}(\xi)|^2\mu(x,\xi)$. The assertion then follows from (4.3).

As was already mentioned in the introduction, condition (MS) is a restriction on the support of the measure $|\widehat{\varphi}(\xi)|^2\mu(x,\xi)$. Two extremal cases in which it is trivially satisfied are the following:

(i) $\widehat{\varphi}|_{\mathbb{R}^d\setminus Q} \equiv 0$; in this case (MS) holds independently of what μ is.

(ii) The sequence (u_k) is *asymptotically band-limited*; i.e., its Wigner measures at scale (h_k) are concentrated on the cube $\overline{Q}$. For those sequences, condition (MS) only involves the behavior of μ on the boundary ∂Q: it essentially expresses that the restrictions of μ to parallel sides of ∂Q do not overlap (i.e., are mutually singular). A sufficient condition for this is, for instance,

$$\limsup_{k\to\infty} \int_{\mathbb{R}^d\setminus Q_R} \left|\widehat{u_k}\left(\frac{\xi}{h_k}\right)\right|^2 \frac{d\xi}{(2\pi h_k)^d} \to 0 \quad \text{as } R\to\infty, \tag{4.4}$$

where $Q_R := [-\pi, \pi - 1/R)^d$.

Remark 4.4. In any of the above cases, we have

$$\mathbf{1}_Q(\xi)\mu^{\varphi}(x,\xi) = |\widehat{\varphi}(\xi)|^2\mu(x,\xi).$$

Hence, the restriction of μ^{φ} to $\mathbb{R}^d \times Q$ coincides with μ if and only if $|\widehat{\varphi}(\xi)|^2 = 1$ for μ-almost every $\xi \in \overline{Q}$.

The specific choice $\varphi = \delta_0$ corresponds to the analysis of *discretization*, for then $S^h_{\delta_0}u(n) = u(hn)$. Theorem 4.2 takes the following simple form.

COROLLARY 4.5. *Let (h_k) be a scale and let (u_k) be a sequence in $H^s(\mathbb{R}^d)$, for some $s > d/2$, such that $(\langle h_k D_x\rangle^s u_k)$ is bounded. If μ is its Wigner measure at scale (h_k) and the measures $\mu(x,\xi+2\pi n)$ are mutually singular, then Wigner measure μ^{δ_0} corresponding to the sequence of discretizations is the periodization:*

$$\mu^{\delta_0}(x,\xi) = \sum_{n\in\mathbb{Z}^d} \mu(x,\xi+2\pi n).$$

In other words, μ^{δ_0} is the limit of the Wigner series $w^{h_k}_S[u_k]$.

This corollary is particularly useful in the explicit computation of Wigner measures for discrete functions. As an example, consider the concentrating and oscillating sequences we defined in the introduction, $f_k(x) = k^{d/2}\rho(k(x-x_0))$ and $g_k(x) := \rho(x)e^{ikx\cdot\xi^0}$ with $\rho \in L^2(\mathbb{R}^d)$. Using identities (1.6) and (1.7) we obtain, for (f_k) and (g_k), respectively,

$$\mu^{\delta_0}(x,\xi) = \delta_{x_0}(x) \otimes \sum_{n\in\mathbb{Z}} |\widehat{\rho}(\xi+2\pi n)|^2 \frac{d\xi}{(2\pi)^d}$$

if, for instance, $\operatorname{supp}\widehat{\rho} \subset Q$, and

$$|\rho(x)|^2 dx \otimes \sum_{n\in\mathbb{Z}^d} \delta_{\xi^0+2\pi n}(\xi), \tag{4.5}$$

with no assumption on ρ.

4.3. Reconstruction. Now we deal with the reconstruction operator T^h_φ; it modifies the high-frequency behavior of a sequence of discrete functions in the following way.

THEOREM 4.6. *Let (h_k) be a scale and (U^{h_k}) an h_k-bounded sequence; take φ satisfying* (BP_s). *If $M^{h_k}[U^{h_k}]$ converges to the Wigner measure μ which verifies* (ND), *then $m^{h_k}[T^{h_k}_\varphi U^{h_k}]$ converges to a Wigner measure μ_φ given by*

$$\mu_\varphi(x,\xi) = |\widehat{\varphi}(\xi)|^2 \mu(x,\xi). \tag{4.6}$$

The proof of Theorem 4.6 is based on explicit formulas for the Fourier transforms of $T^h_\varphi U$. As we have already seen,

$$\widehat{T^h_\varphi U}(\xi) = \widehat{\varphi}(h\xi) h^d \widehat{U}(h\xi) \tag{4.7}$$

for any $U \in L^2(h\mathbb{Z}^d)$. The following remark ensures that Proposition 8.3 can be applied in the proof below.

Remark 4.7. If $\varphi \in H^s(\mathbb{R}^d)$ satisfies (BP_s), then $\widehat{\varphi} \in L^\infty(\mathbb{R}^d; \langle\xi\rangle^s)$.

Proof of Theorem 4.6. Just notice that (4.7) can be rewritten as

$$T^h_\varphi U^h = \widehat{\varphi}(hD_x) T^h_{\delta_0} U^h.$$

The hypotheses made on φ and μ allow us to apply Proposition 8.3 (see Remark 4.7) and conclude the proof. □

Identity (4.6) expresses how the measure μ is modulated by the profile φ; the necessity of the hypothesis (ND) for this result is discussed in section 4.4 as well.

Since μ is Γ-periodic in ξ, formula (4.6) suggests that μ may be compared to the periodization of μ_φ with respect to the variable ξ.

COROLLARY 4.8. *Let φ, (U^{h_k}), μ, and μ_φ be as in Theorem* 4.6. *Then the periodization*

$$\mu_{\varphi,s}(x,\xi) := \sum_{n\in\mathbb{Z}^d} \langle \xi + 2\pi n\rangle^{2s} \mu_\varphi(x, \xi + 2\pi n) \tag{4.8}$$

is a well-defined[8] *measure, Γ-periodic in ξ, that satisfies*

$$\mu_{\varphi,s}(x,\xi) = \tau_{\langle D_x\rangle^s \varphi}(\xi)\mu(x,\xi). \tag{4.9}$$

In particular,

(i) *if $\tau_{\langle D_x\rangle^s\varphi}(\xi) = 1$ except for ξ in a set of zero μ-measure, then $\mu_{\varphi,s} = \mu$;*

(ii) *$\tau_{\langle D_x\rangle^s\varphi} \equiv 1$ if and only if the identity $\mu_{\varphi,s} = \mu$ holds for every sequence (U^{h_k}).*

Proof. Since $|\langle\xi\rangle^s \widehat{\varphi}(\xi)|^2$ is a nonnegative continuous function, the series defining $\tau_{\langle D_x\rangle^s\varphi}(\xi)$ converges absolutely for every ξ on the support of μ (which consists of continuity points for $\widehat{\varphi}(\xi)$). Thus, by the dominated convergence theorem,

$$\int_{\mathbb{R}^d\times\mathbb{R}^d} a(x,\xi)\tau_{\varphi,s}(\xi)d\mu(x,\xi) = \sum_{n\in\mathbb{Z}^d} \int_{\mathbb{R}^d\times\mathbb{R}^d} a(x,\xi)|\langle\xi+2\pi n\rangle^s \widehat{\varphi}(\xi+2\pi n)|^2 d\mu(x,\xi)$$

[8] The limit defining the sum (4.8) is understood to exist for the weak convergence of measures in $\mathcal{M}_+(\mathbb{R}^d\times\mathbb{R}^d)$.

for every $a \in C_c(\mathbb{R}^d \times \mathbb{R}^d)$. Now, taking into account (4.6) and the fact that μ is Γ-periodic in ξ, we find that

$$\int_{\mathbb{R}^d\times\mathbb{R}^d} a(x,\xi)\tau_{\varphi,s}(\xi)d\mu(x,\xi) = \sum_{n\in\mathbb{Z}^d}\int_{\mathbb{R}^d\times\mathbb{R}^d} a(x,\xi)\langle\xi+2\pi n\rangle^{2s}d\mu_\varphi(x,\xi+2\pi n),$$

and the first part of the result follows.

Statement (i) as well as the "only if" part of (ii) are trivial. To obtain the necessity in (ii), just consider sequences of discrete functions whose Wigner measures are of the form $\mu(x,\xi) = \nu(x)\otimes\sum_{n\in\mathbb{Z}^d}\delta_{\xi^0+2\pi n}$ (as (4.5), for instance). Clearly, for $\mu_{\varphi,s} = \mu$ to hold for such a measure, we must have $\tau_{\langle D_x\rangle^s\varphi}(\xi^0) = 1$. □

Remark 4.9. (i) Because of Lemma 3.5, if relation $\mu_{\varphi,s} = \mu$ holds for every h_k-bounded sequence of discrete functions, then the profile φ has the following property: $\{h^{-d/2}\varphi_n^h : n \in \mathbb{Z}^d\}$ is an orthonormal family in $H^s(\mathbb{R}^d)$ for every $h > 0$.

(ii) However, the converse is not true: if φ gives rise to an orthonormal family, then $\tau_{\langle D_x\rangle^s\varphi}(\xi) = 1$ holds outside a set of null Lebesgue measure. If μ is supported on that set, identity $\mu_{\varphi,s} = \mu$ may not hold.

As in the preceding section, our result has an interpretation in terms of Wigner series. Under the conditions of Theorem 4.6, the measure $\mu_{\varphi,s}$ may be obtained as the limit of the functions

$$w_S^{h_k}[\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k}],$$

as $k\to\infty$, provided $(\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k})$ is h_k-oscillatory. Note, however, that this may not be the case for certain profiles φ (see section 5.3).

In particular, Corollary 4.8 shows that the limits of $w_S^{h_k}[T_\varphi^{h_k}U^{h_k}]$ and $M^{h_k}[U^{h_k}]$ coincide if we choose, for instance, $\varphi := \mathbf{1}_{[-1/2,1/2)^d}$.

4.4. The necessity of the hypotheses of Theorems 4.2 and 4.6. Formulas (4.6) and (4.2) may not hold when $\widehat{\varphi}$ is not continuous and the Wigner measure μ does not vanish on the closure of the set of discontinuity points $D_{\widehat{\varphi}}$. We illustrate this with two one-dimensional examples where

$$\varphi(x) = \frac{\sin\pi x}{\pi x}.$$

We will chose $\mathbf{1}_Q$ as the representative of $\widehat{\varphi}$ for which the counterexamples will be built.

1. *Necessity of condition* (ND) *in Theorem* 4.6. Take U^h to be the sequence discrete function of $L^2(h\mathbb{Z}^d)$ given by their Fourier transforms:

$$\widehat{U^h}(\xi) := \frac{1}{h}\sum_{n\in\mathbb{Z}}\mathbf{1}_{(-1,1)}\left(\frac{\xi-(2n+1)\pi}{h}\right).$$

Then, denoting by μ the Wigner measure at scale h of (U^h),

$$|\widehat{\varphi}(\xi)|^2\mu(x,\xi) = \frac{\sin^2(x)}{\pi^2x^2}dx\otimes\delta_{-\pi}(\xi).$$

This measure differs from μ_φ, which is given by

$$\mu_\varphi(x,\xi) = \frac{\sin^2(x/2)}{\pi^2x^2}dx\otimes[\delta_\pi(\xi)+\delta_{-\pi}(\xi)].$$

Remark 4.10. (i) The particular choice of the representative of $\widehat{\varphi}$ does not play a role. Theorem 4.6 still fails if we take as representative of $\widehat{\varphi}$ the characteristic functions of $(-\pi,\pi)^d$ or $[-\pi,\pi]^d$.

(ii) In particular, this example shows that even the two projections on x and ξ of the measures μ and μ_φ may differ.

(iii) This also shows that the periodization in ξ of μ_φ does not necessarily coincide with μ, even when $\tau_\varphi = 1$, as is the case here. Thus the conclusion of Corollary 4.8 may fail when $\widehat{\varphi}$ is not continuous.

Our following counterexample to Theorem 4.2 is based on the same principle.

2. *Necessity of condition* (ND) *in Theorem* 4.2. Define

$$\widehat{v^h}(\xi) := \mathbf{1}_{(-1,1)}(\xi + \pi/h).$$

Then, denoting by μ the Wigner measure at scale h of (v^h),

$$\sum_{n\in\mathbb{Z}} |\widehat{\varphi}(\xi+2\pi n)|^2 \mu(x,\xi+2\pi n) = \frac{\sin^2(x)}{\pi^2 x^2} dx \otimes \sum_{n\in\mathbb{Z}} \delta_{(2n+1)\pi}(\xi),$$

and this is different from μ^φ, which is precisely

$$\mu^\varphi(x,\xi) = \frac{\sin^2(x/2)}{\pi^2 x^2} dx \otimes \sum_{n\in\mathbb{Z}} \delta_{(2n+1)\pi}(\xi).$$

Finally, we investigate hypothesis (MS). Now we set $\varphi := \delta_0$.

3. *Necessity of condition* (MS) *in Theorem* 4.2. Define

$$\widehat{v^h}(\xi) := \mathbf{1}_Q(h\xi) \sum_{n\in\mathbb{Z}} \mathbf{1}_{(-1,1)}(\xi - (2n+1)\pi).$$

Clearly, as in our first example, the periodization of the Wigner measure of (v^h) is

$$\sum_{k\in\mathbb{Z}^d} \mu(x,\xi+2\pi n) = \frac{\sin^2(x/2)}{\pi^2 x^2} dx \otimes \sum_{k\in\mathbb{Z}} \delta_{(2n+1)\pi}(\xi).$$

However, the sequence of discretizations $(S^h_{\delta_0} v^h)$ has the following one:

$$\mu^{\delta_0}(x,\xi) = \frac{\sin^2(x)}{\pi^2 x^2} dx \otimes \sum_{n\in\mathbb{Z}} \delta_{(2n+1)\pi}(\xi).$$

The verification of these statements easily follows from (1.6), identity (8.5), and Lemma 8.13.

4.5. A Poisson summation formula and proof of Theorem 4.2. The computation of the Fourier transform of $S^h_\varphi u$ is given by the following identity.

LEMMA 4.11. *Let φ satisfy* (BP_s) *and let $u \in H^{-s}(\mathbb{R}^d)$. Then the Fourier transform of $S^h_\varphi u$ is*

$$h^d \sum_{n\in\mathbb{Z}^d} S^h_\varphi u(n) e^{-ihn\cdot\xi} = \sum_{n\in\mathbb{Z}^d} \overline{\widehat{\varphi}(h\xi+2\pi n)}\, \widehat{u}\left(\xi + \frac{2\pi}{h} n\right), \tag{4.10}$$

the convergence of the first series being in $L^2_{loc}(\mathbb{R}^d)$*, while the second takes place in* $L^1_{loc}(\mathbb{R}^d)$.

Proof. Begin by noticing that $\overline{\widehat{\varphi}}\widehat{u} \in L^1(\mathbb{R}^d)$, and thus

$$\Pi^h(\xi) := \sum_{n\in\mathbb{Z}^d} \overline{\widehat{\varphi}(h\xi + 2\pi n)}\widehat{u}(\xi + 2\pi/hn)$$

is a well-defined $(2\pi/h)\mathbb{Z}^d$-periodic $L^1_{\rm loc}(\mathbb{R}^d)$ function, the series defining it being absolutely convergent in $L^1_{\rm loc}(\mathbb{R}^d)$. We can compute its Fourier coefficients:

$$\begin{aligned}\int_{[-\pi/h,\pi/h)^d} \Pi^h(\xi)e^{ihn\cdot\xi}\frac{h^d d\xi}{(2\pi)^d} &= \sum_{k\in\mathbb{Z}^d}\int_Q \overline{\widehat{\varphi}(\xi+2\pi k)}\widehat{u}\left(\frac{\xi+2\pi k}{h}\right)e^{in\cdot\xi}\frac{d\xi}{(2\pi)^d}\\ &= \int_{\mathbb{R}^d}\overline{\widehat{\varphi}(\xi)}\widehat{u}\left(\frac{\xi}{h}\right)e^{in\cdot\xi}\frac{d\xi}{(2\pi)^d}\\ &= \int_{\mathbb{R}^d}\overline{h^d\widehat{\varphi}(h\xi)e^{-ihn\cdot\xi}}\widehat{u}(\xi)\frac{d\xi}{(2\pi)^d}\\ &= \langle\overline{\varphi_n^h}, u\rangle_{\mathcal{S}'\times\mathcal{S}} = h^d S^h_\varphi u(n).\end{aligned}$$

Lemma 3.1 proves that $S^h_\varphi u$ is square-summable and, consequently,

$$\Pi^h(\xi) = \sum_{n\in\mathbb{Z}^d} h^d S^h_\varphi u(n)e^{-ihn\cdot\xi},$$

the sum being understood in the L^2-sense. This is precisely formula (4.10). □

Remark 4.12. Identity (4.10) may be viewed as a generalization of the *Poisson summation formula*. Taking as φ the Dirac delta δ_0, we obtain

$$h^d\sum_{n\in\mathbb{Z}^d} u(hn)e^{-ihn\cdot\xi} = \sum_{n\in\mathbb{Z}^d}\widehat{u}\left(\xi+\frac{2\pi}{h}n\right)$$

for every $u\in H^s(\mathbb{R}^d)$ with $s > d/2$.

Proof of Theorem 4.2. The proof will be done in two steps.

Step 1. We first establish the result for sequences such that $\widehat{\varphi}(\xi)\widehat{u_k}(\xi/h_k)$ has support in a ball $B(0;R)$ for every $k\in\mathbb{N}$. We claim that the following formula holds:

$$T^{h_k}_{\delta_0} S^{h_k}_\varphi u_k(x) = \sum_{|n|\le R+\pi\sqrt{d}} e^{-2\pi i n\cdot x/h_k}\overline{\widehat{\varphi}}(h_k D_x)u_k(x).$$

This is obtained by applying the inverse Fourier transform to both sides of identity (4.10) and remarking that only summands satisfying $|n|\le R+\pi\sqrt{d}$ must be considered because of the condition on the support of $\widehat{\varphi}\,\widehat{u_k}(\cdot/h_k)$. The Wigner measures of the functions

$$e^{-2\pi i n\cdot x/h_k}\overline{\widehat{\varphi}}(h_k D_x)u_k(x)$$

are precisely (cf. Proposition 8.3 and Remark 4.7)

$$|\widehat{\varphi}(\xi+2\pi n)|^2\mu(x,\xi+2\pi n).$$

By hypothesis, they are mutually singular so, by Lemma 8.13, we deduce that the measure μ^φ obtained as the limit of $m^{h_k}[T^{h_k}_{\delta_0}S^{h_k}_\varphi u_k]$ is given by (4.2).

Step 2. We prove the result in the general case by taking advantage of hypothesis (D). Let $\chi \in C_c^\infty(\mathbb{R}^d)$ be a cut-off function identically equal to one in the unit ball $B(0;1)$. Denote by $S^{h_k}_{\varphi,R}u_k$ the truncation given by

$$\begin{aligned}\widehat{S^{h_k}_{\varphi,R}u_k}(\xi) &:= S^{h_k}_{\varphi}\chi\left(\widehat{\frac{h_kD_x}{R}}\right)u_k(\xi)\\ &= \frac{1}{(h_k)^d}\sum_{n\in\mathbb{Z}^d}\overline{\widehat{\varphi}(\xi+2\pi n)}\chi\left(\frac{\xi+2\pi n}{R}\right)\widehat{u_k}\left(\frac{\xi+2\pi n}{h_k}\right).\end{aligned}$$

Then, by the first step we have just proved, $M^{h_k}[S^{h_k}_{\varphi,R}u]$ converges to

$$\mu^{\varphi}_R(x,\xi) := \sum_{n\in\mathbb{Z}^d}\left|\widehat{\varphi}(\xi+2\pi n)\chi\left(\frac{\xi+2\pi n}{R}\right)\right|^2\mu(x,\xi+2\pi n). \tag{4.11}$$

We claim that (D) implies the following:

$$\limsup_{k\to\infty}\|S^{h_k}_{\varphi}u_k - S^{h_k}_{\varphi,R}u_k\|^2_{L^2(h_k\mathbb{Z}^d)} \to 0 \quad \text{as } R\to\infty. \tag{4.12}$$

It is sufficient to realize that

$$S^{h_k}_{\varphi}u_k - S^{h_k}_{\varphi,R}u_k = S^{h_k}_{\psi_R}u_k$$

for $\widehat{\psi_R} := \overline{\chi(\cdot/R)}\widehat{\varphi}$. The norm of $S^{h_k}_{\psi_R}$ is precisely (cf. Lemma 3.1)

$$\operatorname*{essup}_{\xi\in Q}\sum_{n\in\mathbb{Z}^d}\left|\langle\xi+2\pi n\rangle^s\widehat{\varphi}(\xi+2\pi n)\chi\left(\frac{\xi+2\pi n}{R}\right)\right|^2,$$

which tends to zero as $R\to 0$.

Lemma 8.12 then ensures that μ^{φ}_R weakly converge to μ^{φ}. Identity (4.11) means that

$$\int_{\mathbb{R}^d\times\mathbb{R}^d}a(x,\xi)d\mu^{\varphi}_R(x,\xi) = \int_{\mathbb{R}^d\times\mathbb{R}^d}\sum_{k\in\mathbb{Z}^d}a(x,\xi+2\pi n)|\widehat{\varphi}(\xi)|^2|\chi(\xi/R)|^2d\mu(x,\xi)$$

for every test function $a\in\mathcal{S}$. Passing to limits as $R\to\infty$ in the above identity, we obtain the claimed result.

Notice that the same argument may be applied if, instead of condition (D), we have that $(\langle h_kD_x\rangle^{-s}u_k)$ is h_k-oscillatory. This is because (4.12) may be estimated from above by

$$\limsup_{k\to\infty}\left\|\langle h_kD_x\rangle^{-s}\left(1-\chi\left(\frac{h_kD_x}{R}\right)\right)u_k\right\|^2_{L^2(\mathbb{R}^d)} \to 0 \quad \text{as } R\to\infty$$

because of Lemma 3.1 and the h_k-oscillation hypothesis. □

5. Computation of defect measures.

5.1. Relations between defect and Wigner measures in the discrete setting. In this paragraph, we establish the analogue of Proposition 1.2 in the discrete setting. In particular, we present conditions that ensure that the projection on the x-component of a Wigner measure may be obtained as the limit of quadratic densities of the type

$$E^h[U^h](x) := h^d \sum_{n\in\mathbb{Z}^d} |U_n^h|^2 \delta_{hn}(x).$$

PROPOSITION 5.1. *Let (h_k) be a scale and (U^{h_k}) an h_k-bounded sequence. Suppose that $(M^{h_k}[U^{h_k}])$ converges to μ as $k\to\infty$. Then, for every $\phi\in C_c(\mathbb{R}^d)$,*

$$\int_{\mathbb{R}^d\times Q} \phi(x)d\mu(x,\xi) = \lim_{k\to\infty} (h_k)^d \sum_{n\in\mathbb{Z}^d} \phi(h_k n)|U_n^{h_k}|^2. \tag{5.1}$$

If (ε_k) is a scale such that $h_k \ll \varepsilon_k$ and the transforms $M^{\varepsilon_k}[U^{h_k}]$ converge to μ, then (5.1) *holds, provided (U^{h_k}) is* ε_k-oscillatory, *i.e.,*

$$\limsup_{k\to\infty} (h_k)^d \int_{Q\setminus B(0;h_k/\varepsilon_k R)} |\widehat{U^{h_k}}(\xi)|^2 d\xi \to 0 \quad \text{as } R\to\infty. \tag{5.2}$$

In view of Proposition 5.1, one might think that Wigner measures at scales coarser than h_k are unnecessary. However, as the next result shows, if (U^{h_k}) is ε_k-oscillatory for such a scale, then the Wigner measure at scale (h_k) does not give any information about the oscillation effects.

PROPOSITION 5.2. *Let (h_k) and (ε_k) be scales such that $h_k \ll \varepsilon_k$. For every ε_k-oscillatory, h_k-bounded sequence (U^{h_k}) such that $M^{h_k}[U^{h_k}] \rightharpoonup \mu$ as $k\to\infty$, we have*

$$\mu(x,\xi) = \nu(x) \otimes \sum_{k\in\mathbb{Z}^d} \delta_{2\pi k}(\xi),$$

where ν is the weak limit in $\mathcal{M}_+(\mathbb{R}^d)$ of the measures $E^{h_k}[U^{h_k}]$.

The Wigner measure also gathers the information on the densities $|\mathcal{F}^{\varepsilon_k}U^{h_k}(\xi)|^2$; indeed, these converge to the projection on ξ of the Wigner measure, provided that no energy is lost at infinity.

PROPOSITION 5.3. *Let (h_k) and (ε_k) be scales such that h_k/ε_k is bounded. Suppose that (U^{h_k}) is* compact at infinity*,*

$$\limsup_{k\to\infty} (h_k)^d \sum_{|h_k n|>R} |U_n^{h_k}|^2 \to 0 \quad \text{as } R\to\infty, \tag{5.3}$$

and that $M^{\varepsilon_k}[U^{h_k}] \rightharpoonup \mu$ as $k\to\infty$. Then

$$\int_{\mathbb{R}^d\times\mathbb{R}^d} \psi(\xi)d\mu(x,\xi) = \lim_{k\to\infty} \int_{\mathbb{R}^d} \psi(\xi)|\mathcal{F}^{\varepsilon_k}U^{h_k}(\xi)|^2 d\xi$$

for every $\psi\in C_c(\mathbb{R}^d)$.

The proof of Propositions 5.1 and 5.3 requires the following preliminary result, which explains how the transform $M^{\varepsilon}[U^h]$ of a discrete function U^h can be localized.

LEMMA 5.4. *Let $U^h \in L^2(h\mathbb{Z}^d)$ and let φ, $\phi \in C_c^\infty(\mathbb{R}^d)$. Then for every $a \in \mathcal{S}(\mathbb{R}^d \times \mathbb{R}^d)$ the following holds:*

$$\lim_{k\to\infty} \left| \langle M^{\varepsilon_k}[U^{h_k}], |\phi(x)|^2\varphi(\xi)\rangle_{\mathcal{S}'\times\mathcal{S}} - (h_k)^d \int_{\mathbb{R}^d} |\widehat{\phi U^{h_k}}(\xi)|^2 \varphi\left(\frac{\varepsilon_k}{h_k}\xi\right) \frac{d\xi}{(2\pi)^d} \right| = 0.$$

Proof. First note that, as a consequence of relation (1.13) and Lemma 8.5, we have

$$\lim_{k\to\infty} |\langle M^{\varepsilon_k}[U^{h_k}], |\phi(x)|^2\varphi(\xi)\rangle_{\mathcal{S}'\times\mathcal{S}} - \langle M^{\varepsilon_k}[\phi U^{h_k}], \psi(x)\varphi(\xi)\rangle_{\mathcal{S}'\times\mathcal{S}}| = 0 \tag{5.4}$$

for every test function $\psi \in C_c^\infty(\mathbb{R}^d)$ such that $\psi(x) = 1$ for $x \in \operatorname{supp}\phi$. Now, (8.2.i) and (1.13), together with Plancherel's formula for the discrete Fourier transform, yield

$$\begin{aligned}\langle M^{\varepsilon_k}[\phi U^{h_k}], \psi(x)\varphi(\xi)\rangle_{\mathcal{S}'\times\mathcal{S}} &= \langle \phi(x) T_{\delta_0}^{h_k} U^{h_k}, \varphi(\varepsilon_k D_x)\phi(x) T_{\delta_0}^{h_k} U^{h_k}\rangle_{\mathcal{S}'\times\mathcal{S}} \\ &= (h_k)^{2d} \int_{\mathbb{R}^d} |\widehat{\phi U^{h_k}}(h_k\xi)|^2 \varphi(\varepsilon_k\xi) \frac{d\xi}{(2\pi)^d},\end{aligned}$$

and the result follows. □

Proof of Proposition 5.1. Identity (5.1) in the case $h_k = \varepsilon_k$ is a direct consequence of the identity

$$\int_Q M^h[U](x,\xi)d\xi = E^h[U^h](x)$$

and the fact that, due to the Γ-periodicity in ξ of $M^{h_k}[U^{h_k}]$ and μ, one has

$$\lim_{k\to\infty} \int_{\mathbb{R}^d\times Q} \phi(x) M^{h_k}[U^{h_k}](x,\xi)dxd\xi = \int_{\mathbb{R}^d\times Q} \phi(x)d\mu(x,\xi)$$

for every $\phi \in C_c^\infty(\mathbb{R}^d)$.

Next we analyze the case $h_k/\varepsilon_k \to 0$. Given functions $\phi, \chi \in C_c^\infty(\mathbb{R}^d)$, and using Lemma 5.4 and periodization in the variable ξ, we find

$$\int_{\mathbb{R}^d\times\mathbb{R}^d} |\phi(x)|^2\chi(\xi)d\mu(x,\xi) = \lim_{k\to\infty} (h_k)^d \int_Q |\widehat{\phi U^{h_k}}(\xi)|^2 \sum_{n\in\mathbb{Z}^d} \chi\left(\frac{\varepsilon_k}{h_k}(\xi + 2\pi n)\right) \frac{d\xi}{(2\pi)^d}. \tag{5.5}$$

Choose a function $\chi \in C_c^\infty(\mathbb{R}^d)$ such that

$$\begin{aligned}\chi(\xi) &= 1 \quad \text{for } |\xi| \le 1, \\ \chi(\xi) &= 0 \quad \text{for } |\xi| \ge 2, \\ 0 \le \chi(\xi) &\le 1 \quad \text{for } \xi \in \mathbb{R}^d,\end{aligned}$$

and set $\chi_R(\xi) := \chi(\xi/R)$ for every $R > 0$. With such a test function and $h_k/\varepsilon_k < \pi/R$ we have $\chi_R(\frac{\varepsilon_k}{h_k}(\xi + 2\pi n)) = \chi_R(\frac{\varepsilon_k}{h_k}\xi) \le 1$ for every $\xi \in Q$. Then, taking this into account in (5.5) and using Plancherel's formula, the following is obtained:

$$\lim_{k\to\infty} \left| (h_k)^d \int_Q |\widehat{\phi U^{h_k}}(\xi)|^2 \frac{d\xi}{(2\pi)^d} - \int_{\mathbb{R}^d\times\mathbb{R}^d} |\phi(x)|^2\chi_R(\xi)d\mu(x,\xi) \right| \le M(R),$$

where

$$M(R) := \limsup_{k\to\infty} (h_k)^d \int_{\mathbb{R}^d} \left(1 - \chi_R\left(\frac{\varepsilon_k}{h_k}(\xi + 2\pi n)\right)\right) |\widehat{\phi U^{h_k}}(\xi)|^2 \frac{d\xi}{(2\pi)^d}.$$

Identity (5.1) is obtained by letting R tend to ∞, noticing that (5.2) implies that $M(R) \to 0$ as $R \to \infty$. □

Proof of Proposition 5.2. Since $(U^{h_k})_{k\in\mathbb{N}}$ is ε_k-oscillatory, we have

$$\limsup_{k\to\infty} \int_{Q\setminus B(0;\delta)} |\widehat{\phi U^{h_k}}(\xi)|^2 d\xi = 0$$

for every $\delta > 0$ and $\phi \in C_c^\infty(\mathbb{R}^d)$. Using Lemma 5.4 below, we obtain, for every $\varphi \in C_c^\infty(Q \setminus \{0\})$,

$$0 = \lim_{k\to\infty} \int_Q \varphi(\xi) |\widehat{\phi U^{h_k}}(\xi)|^2 \frac{d\xi}{(2\pi)^d} = \int_{\mathbb{R}^d\times Q} |\phi(x)|^2 \varphi(\xi) d\mu(x,\xi).$$

In particular, μ is concentrated on the set $\mathbb{R}^d \times \{0\}$. Since $\mu(\cdot \times Q) = \nu(x)$ by Proposition 5.1, we find that, because of the periodicity, $\mu(\mathbb{R}^d \times \cdot) = \nu(\mathbb{R}^d) \sum_{k\in\mathbb{Z}^d} \delta_{2\pi k}(\xi)$, and this restricts μ to being equal to $\nu \otimes \sum_{k\in\mathbb{Z}^d} \delta_{2\pi k}$. □

Proof of Proposition 5.3. Since the densities $|\mathcal{F}^{\varepsilon_k} U^{h_k}|^2$ are uniformly bounded in $L^1(\mathbb{R}^d)$ (and consequently in $\mathcal{M}(\mathbb{R}^d)$) it suffices to prove the result for test functions $\psi \in C_c^\infty(\mathbb{R}^d)$. Let χ and χ_R be defined as in the proof of Proposition 5.1. Because of Lemma 5.4 the following holds for every $\psi \in \mathcal{S}(\mathbb{R}^d)$:

$$\int_{\mathbb{R}^d\times\mathbb{R}^d} |\chi_R(x)|^2 \psi(\xi) d\mu(x,\xi) = \lim_{k\to\infty} \int_{\mathbb{R}^d} \psi(\xi) |\mathcal{F}^{\varepsilon_k} \chi_R U^{h_k}(\xi)|^2 d\xi.$$

Since $|\chi_R(x)|^2 \to 1$ as $R \to \infty$ for every $x \in \mathbb{R}^d$, we have to show only that

$$\lim_{R\to\infty} \int_{\mathbb{R}^d\times\mathbb{R}^d} |\chi_R(x)|^2 \psi(\xi) d\mu(x,\xi) = \lim_{k\to\infty} \int_{\mathbb{R}^d} \psi(\xi) |\mathcal{F}^{\varepsilon_k} U^{h_k}(\xi)|^2 d\xi.$$

This appears as a consequence of the identity

$$\begin{aligned}
&\int_{\mathbb{R}^d} \psi(\xi)(|\mathcal{F}^{\varepsilon_k} U^{h_k}(\xi)|^2 - |\mathcal{F}^{\varepsilon_k} \chi_R U^{h_k}(\xi)|^2) d\xi \\
&\quad = \int_{\mathbb{R}^d} \psi(\xi)[\mathcal{F}^{\varepsilon_k}(U^{h_k} - \chi_R U^{h_k})(\xi)]\overline{\mathcal{F}^{\varepsilon_k} U^{h_k}(\xi)} d\xi \\
&\qquad + \int_{\mathbb{R}^d} \psi(\xi) \mathcal{F}^{\varepsilon_k} \chi_R U^{h_k}(\xi) \overline{[\mathcal{F}^{\varepsilon_k}(U^{h_k} - \chi_R U^{h_k})(\xi)]} d\xi,
\end{aligned}$$

which implies

$$\begin{aligned}
&\limsup_{k\to\infty} \left| \int_{\mathbb{R}^d} \psi(\xi)(|\mathcal{F}^{\varepsilon_k} U^{h_k}(\xi)|^2 - |\mathcal{F}^{\varepsilon_k} \chi_R U^{h_k}(\xi)|^2) d\xi \right| \\
&\qquad \le C_\psi \limsup_{k\to\infty} \|U^{h_k} - \chi_R U^{h_k}\|^2_{L^2(h\mathbb{Z}^d)}.
\end{aligned}$$

Since the U^{h_k} are compact at infinity, the second term in the above estimate tends to zero as R tends to infinity, and thus

$$\left| \limsup_{k\to\infty} \int_{\mathbb{R}^d} \psi(\xi) |\mathcal{F}^{\varepsilon_k} U^{h_k}(\xi)|^2 - \int_{\mathbb{R}^d\times\mathbb{R}^d} |\chi_R(x)|^2 \psi(\xi) d\mu(x,\xi) \right| \to 0 \quad \text{as } R \to \infty.$$

One easily deduces from this that the measures $|\mathcal{F}^{\varepsilon_k} U^{h_k}(\xi)|^2 d\xi$ converge in $\mathcal{M}_+(\mathbb{R}^d)$ to the measure $\int_{\mathbb{R}^d} \mu(dx, \cdot)$, as claimed. □

5.2. Defect measures of reconstructed sequences. Let (U^{h_k}) be h_k-bounded and $\varphi \in H^s(\mathbb{R}^d)$ some profile satisfying (BP_s). As a consequence of Lemma 3.1, the sequence of densities

$$|\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k}|^2$$

is uniformly bounded in $L^1(\mathbb{R}^d)$. Hence, Helly's compactness theorem ensures that, extracting a subsequence if necessary, there exists a measure $\nu_\varphi \in \mathcal{M}_+(\mathbb{R}^d)$ such that

$$\lim_{k\to\infty} \int_{\mathbb{R}^d} \phi(x) |\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k}(x)|^2 dx = \int_{\mathbb{R}^d\times Q} \phi(x) d\nu_\varphi(x).$$

The main issue addressed in this section is that of clarifying how ν_φ depends on the sequence (U^{h_k}) and the profile φ. We shall see that a formula relating ν_φ and the limit of $E^{h_k}[U^{h_k}]$ does not exist in general. However, such a formula may be established in terms of the Wigner measure of (U^{h_k}).

Suppose that $M^{h_k}[U^{h_k}]$ converges to μ. Then Theorem 4.6 may be applied to obtain that, provided $\mu(\mathbb{R}^d \times \overline{D_{\widehat{\varphi}}}) = 0$, one has

$$m^{h_k}[T_\varphi^{h_k} U^{h_k}] \rightharpoonup |\widehat{\varphi}(\xi)|^2 \mu(x,\xi).$$

In general, we are only able to ensure (see Proposition 1.7 in [9])

$$\nu_\varphi(x) \geq \int_{\mathbb{R}^d} |\langle \xi\rangle^s \widehat{\varphi}(\xi)|^2 \mu(x, d\xi),$$

and equality holds whenever $(\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k})$ is h_k-oscillatory. Note, however, that this is not always the case. At the end of this section we provide an example of profile φ and a sequence (U^{h_k}) for which $(\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k})$ fails to be h_k-oscillatory. Nevertheless, the following simple sufficient condition for h_k-oscillation holds.

PROPOSITION 5.5. *$(\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k})$ is h_k-oscillatory whenever* (D) *holds.*

This immediately follows from the following lemma.

LEMMA 5.6. *$(\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k})$ is h_k-oscillatory if and only if*

$$\limsup_{k\to\infty} (h_k)^d \int_Q \sigma_\varphi^R(\xi) |\widehat{U^{h_k}}(\xi)|^2 d\xi \to 0 \quad \text{as } R \to \infty,$$

where

$$\sigma_\varphi^R(\xi) := \sum_{|n|\geq R} |\langle \xi + 2\pi n\rangle^s \widehat{\varphi}(\xi + 2\pi n)|^2.$$

Proof. Start by noticing that

$$\int_{|\xi|\geq R/h_k} |\widehat{\langle h_k D_x\rangle^s T_\varphi^{h_k}} U^{h_k}(\xi)|^2 d\xi = \int_{|\xi|\geq R} (h_k)^d |\langle \xi\rangle^s \widehat{\varphi}(\xi) \widehat{U^{h_k}}(\xi)|^2 d\xi.$$

Periodizing in ξ, we get

$$\begin{aligned}\int_Q \sigma_\varphi^{R+\sqrt{d}\pi}(\xi) |\widehat{U^{h_k}}(\xi)|^2 d\xi &\leq \int_{|\xi|\geq R} |\langle \xi\rangle^s \widehat{\varphi}(\xi) \widehat{U^{h_k}}(\xi)|^2 d\xi \\ &\leq \int_Q \sigma_\varphi^{R-\sqrt{d}\pi}(\xi) |\widehat{U^{h_k}}(\xi)|^2 d\xi,\end{aligned}$$

and the claim follows. □

Hence, h_k-oscillation is obtained if φ decays at infinity at a uniform rate. For more general φ, it is still possible to obtain sufficient conditions; however, these depend on the particular sequence of discrete functions to be reconstructed.

PROPOSITION 5.7. *Suppose*

$$\text{(5.6)}\qquad \begin{aligned} &\text{(i)}\quad \mu(\mathbb{R}^d \times \overline{D_{\tau_{\langle D_x\rangle^s\varphi}}}) = 0;\\ &\text{(ii)}\quad (U^{h_k}) \text{ is compact at infinity.}\end{aligned}$$

Then $(\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k})$ *is* h_k*-oscillatory.*

Proof. For the sake of simplicity, we prove the result for $s = 0$, the proof in the general case being identical. Taking into account the periodicity of the densities involved, Proposition 5.3 ensures that

$$\text{(5.7)}\qquad \lim_{k\to\infty} (h_k)^d \int_Q \psi(\xi)|\widehat{U^{h_k}}(\xi)|^2 d\xi = \int_{\mathbb{R}^d\times Q} \psi(\xi) d\mu(x,\xi)$$

for every $\psi \in C_c(\mathbb{R}^d)$, and the claim follows. Since $\mu(\mathbb{R}^d \times \overline{D_{\tau_\varphi}}) = 0$, necessarily $\mu(\mathbb{R}^d \times \overline{D_{\sigma_\varphi^R}})$ is null for every $R > 0$. From classical results on weak convergence of measures, one deduces that relation (5.7) also holds for $\psi = \sigma_\varphi^R$. Hence, by the dominated convergence theorem,

$$\lim_{R\to\infty}\lim_{k\to\infty} (h_k)^d \int_Q \sigma_\varphi^R(\xi)|\widehat{U^{h_k}}(\xi)|^2 d\xi = \lim_{R\to\infty}\int_{\mathbb{R}^d\times Q} \sigma_\varphi^R(\xi) d\mu(x,\xi) = 0,$$

and the result follows. □

Combining Propositions 5.5, 5.7, and 1.2, we obtain the following result.

PROPOSITION 5.8. *Suppose that at least one of either* (D) *or* (5.6) *is satisfied and that* $\mu(\mathbb{R}^d \times \overline{D_{\widehat{\varphi}}}) = 0$. *Then*

$$\text{(5.8)}\qquad \lim_{k\to\infty} \int_{\mathbb{R}^d} \phi(x)|\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k}|^2 dx = \int_{\mathbb{R}^d\times\mathbb{R}^d} \phi(x)|\langle\xi\rangle^s \widehat{\varphi}(\xi)|^2 d\mu(x,\xi)$$

for every $\phi \in C_c(\mathbb{R}^d)$.

As anticipated above, (5.8) shows that the knowledge of the weak limit of the measures $E^{h_k}[U^{h_k}]$ and the profile φ are not enough, in general, to reconstruct the weak limit of the densities $|\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k}|^2 dx$. However, when the sequence of discrete functions under consideration is ε_k-oscillatory for some scale coarser than the reconstruction step h_k, there does exist a formula that relates both limits, as follows.

COROLLARY 5.9. *Let* (U^{h_k}) *be an* h_k*-bounded,* ε_k*-oscillatory sequence such that* $(E^{h_k}[U^{h_k}])$ *weakly converges to a measure* ν. *Suppose, moreover, that* $\widehat{\varphi}$ *is continuous at* Γ *and that any of* (D) *or* (5.6) *is satisfied. Then the densities* $|\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k}|^2$ *weakly converge to the measure*

$$\nu_\varphi(x) = \left(\sum_{n\in\mathbb{Z}^d} |\langle 2\pi n\rangle^s \widehat{\varphi}(2\pi n)|^2\right)\nu(x).$$

Proof. Using Proposition 5.2, we find that any Wigner measure at scale h_k of (U^{h_k}) equals

$$\mu(x,\xi) = \nu(x) \otimes \sum_{n\in\mathbb{Z}^d} \delta_{2\pi n}(\xi).$$

Since $\mu(\mathbb{R}^d \times \overline{D_{\widehat{\varphi}}}) = 0$, Proposition 5.8 is applicable and gives

$$|\langle h_k D_x\rangle^s T_\varphi^{h_k} U^{h_k}|^2 dx \rightharpoonup \tau_{\langle D_x\rangle^s \varphi}(0)\nu(x) \quad \text{as } k \to \infty,$$

as claimed. □

Note that condition (5.6.i) reduces in this setting to the requirement that $\tau_{\langle D_x\rangle^s\varphi}$ is continuous at $\xi = 0$.

5.3. A counterexample to *h*-oscillation. Here we construct a function $\varphi \in L^2(\mathbb{R})$ satisfying (BP_s) such that $\widehat{\varphi}$ is continuous but

$$\|\sigma_\varphi^R\|_{L^\infty(Q)} = 1 \quad \text{for every } R > 0.$$

With such a profile, we show that theres exist a sequence of discrete functions (U^h) such that $(T_\varphi^h U^h)$ is not h-oscillatory.

To construct φ, define $t_n := e^{-n}$ for $n = 0, 1, 2\ldots$ and let ψ_n be the piecewise linear function given for $n \geq 1$ by

$$\psi_n(t) := \begin{cases} \dfrac{t - t_{n+1}}{t_n - t_{n+1}} & \text{if } t \in (t_{n+1}, t_n), \\ \dfrac{t - t_{n-1}}{t_n - t_{n-1}} & \text{if } t \in (t_n, t_{n-1}), \\ 0 & \text{otherwise.} \end{cases}$$

Clearly $\sum_{n=1}^\infty \psi_n(t) = 1$ for $t \in (0, t_1)$, and the sum vanishes for $t \leq 0$. Defining

$$\widehat{\varphi}(\xi) := \sqrt{\sum_{n=1}^\infty \psi_n(\xi - 2\pi n)},$$

we obtain $\varphi \in L^2(\mathbb{R})$, $\widehat{\varphi} \in C(\mathbb{R})$, and $\tau_\varphi(\xi) = \sum_{n=1}^\infty \psi_n(\xi)$ for every $\xi \in Q$.

Moreover

$$\sigma_\varphi^n(\xi) = \begin{cases} 1 & \text{if } \xi \in (0, t_{n+1}), \\ 0 & \text{if } \xi \leq 0. \end{cases}$$

Thus $\|\sigma_\varphi^R\|_{L^\infty(Q)} = 1$ for every $R > 0$.

If we choose discrete functions $U^h \in L^2(h\mathbb{Z})$ such that

$$\widehat{U^h}(\xi) = h^{-1} \sum_{n\in\mathbb{Z}} \mathbf{1}_{(0,h)}(\xi + 2\pi n),$$

then for the φ constructed above we obtain

$$\lim_{h\to 0} \int_Q \sigma_\varphi^R(\xi) h |\widehat{U^h}(\xi)|^2 d\xi = 1 \quad \text{for every } R > 0.$$

This proves that $(T_\varphi^h U^h)$ is not h-oscillatory.

6. High-frequency analysis: $h \ll \varepsilon$. Here we shall investigate the structure of Wigner measures at scales (ε_k) asymptotically coarser than the sampling/reconstruction rate (h_k).

In the next two theorems, we suppose that φ satisfies (BP_s) and $\widehat{\varphi}$ *is continuous in a neighborhood of* $\xi = 0$. Moreover, (h_k) and (ε_k) will be scales such that $h_k \ll \varepsilon_k$.

THEOREM 6.1. *Suppose that* (U^{h_k}) *is* h_k*-bounded and* $M^{\varepsilon_k}[U^{h_k}]$ *converges to the Wigner measure* μ*. Then* $m^{\varepsilon_k}[T_\varphi^{h_k} U^{h_k}]$ *converges to a measure* μ_φ *given by*

$$\mu_\varphi(x,\xi) = |\widehat{\varphi}(0)|^2 \mu(x,\xi). \tag{6.1}$$

The proof of this result is completely analogous to that of Theorem 4.6.

Concerning the sampling operators, the situation is much similar.

THEOREM 6.2. *Let* (u_k) *be a sequence in* $H^{-s}(\mathbb{R}^d)$ *such that* $(\langle h_k D_x\rangle^{-s} u_k)$ *is bounded in* $L^2(\mathbb{R}^d)$ *and* ε_k*-oscillatory.*

(i) *Then* $(S_\varphi^{h_k} u_k)$ *is* ε_k*-oscillatory.*

(ii) *Suppose moreover that* $m^{\varepsilon_k}[u_k]$ *converges to a Wigner measure* μ*. Then* $M^{\varepsilon_k}[S_\varphi^{h_k} u_k]$ *converges to the Wigner measure* μ^φ *given by*

$$\mu^\varphi = |\widehat{\varphi}(0)|^2 \mu. \tag{6.2}$$

Proof. To prove the first part of the theorem, begin by noticing that, by the Cauchy–Schwarz inequality and Lemma 4.11, for almost every $\xi \in \mathbb{R}^d$,

$$\begin{aligned}
|\widehat{S_\varphi^{h_k} u_k}(\xi)|^2 &= \left| \frac{1}{(h_k)^d} \sum_{n\in\mathbb{Z}^d} \overline{\widehat{\varphi}(\xi + 2\pi n)} \widehat{u_k}\left(\frac{\xi + 2\pi n}{h_k}\right)\right|^2 \\
&\le \frac{\|\tau_{\langle D_x\rangle^s \varphi}\|_{L^\infty(Q)}}{(h_k)^{2d}} \sum_{n\in\mathbb{Z}^d} \left| \langle \xi + 2\pi n\rangle^{-s} \widehat{u_k}\left(\frac{\xi + 2\pi n}{h_k}\right)\right|^2.
\end{aligned}$$

Thus

$$\begin{aligned}
&\int_{Q\setminus B(0;h_k/\varepsilon_k R)} (h_k)^d |\widehat{S_\varphi^{h_k} u_k}(\xi)|^2 d\xi \\
&\quad \le \|\tau_{\langle D_x\rangle^s \varphi}\|_{L^\infty(Q)} \int_{Q\setminus B(0;R/\varepsilon_k)} \sum_{n\in\mathbb{Z}^d} |\langle h_k\xi + 2\pi n\rangle^{-s}\, \widehat{u_k}(\xi + 2\pi n)|^2 d\xi \\
&\quad \le \|\tau_{\langle D_x\rangle^s \varphi}\|_{L^\infty(Q)} \int_{\mathbb{R}^d\setminus B(0;R/\varepsilon_k)} |\langle h_k\xi\rangle^{-s}\, \widehat{u_k}(\xi)|^2 d\xi,
\end{aligned}$$

and this clearly proves that $(S_\varphi^{h_k} u_k)$ is ε_k-oscillating as soon as $(\langle h_k D_x\rangle^{-s} u_k)$ is.

The proof of identity (6.2) is essentially identical to that of Theorem 4.2. A completely analogous argument to that used in Step 2 of that proof allows us to consider only sequences such that $\widehat{\varphi}(h_k/\varepsilon_k\cdot)\widehat{u_k}(\cdot/\varepsilon_k)$ is supported in a ball $B(0;R)$. This hypothesis, together with Lemma 4.11, implies that, for h_k/ε_k small enough,

$$(h_k)^d \widehat{S_\varphi^{h_k} u_k}\left(\frac{h_k}{\varepsilon_k}\xi\right) = \overline{\widehat{\varphi}\left(\frac{h_k}{\varepsilon_k}\xi\right)} \widehat{u_k}(\xi/\varepsilon_k);$$

that is, only one summand is involved. Then the result follows from Proposition 8.3 exactly as in the proof of Theorem 4.2. ∎

We conclude with a simple remark.

COROLLARY 6.3. *Under the assumptions and notation of Theorems* 6.1 *and* 6.2*, the following hold:*

(i) *If φ has zero mean (i.e., $\widehat{\varphi}(0) = 0$), then the Wigner measure at scale (ε_k) of any sequence $(T_\varphi^{h_k} U^{h_k})$ or $(S_\varphi^{h_k} u_k)$ vanishes identically. In particular, this is the case if φ is a wavelet.*[9]

(ii) *$\mu_\varphi = \mu^\varphi = \mu$ always holds for profiles such that $|\widehat{\varphi}(0)| = 1$.*

7. Wigner measures of sampled/reconstructed sequences. Now we are able to describe Wigner measures of sequences of the form $T_\psi^h S_\varphi^h u$. In its full generality, our result requires several compatibility hypotheses, which we describe below. First of all,

$$\text{(7.1)}\qquad \begin{aligned} &\text{(i)}\quad \psi \text{ and } \varphi \text{ satisfy } (\mathrm{BP}_s) \text{ with exponents } s' \text{ and } s \text{ respectively;}\\ &\text{(ii)}\quad \varphi \text{ satisfies (D).}\end{aligned}$$

The admissible sequences will be assumed to be such that

$$\text{(7.2)}\qquad u_k \in H^{-s}(\mathbb{R}^d), \quad \text{and} \quad (\langle h_k D_x\rangle^{-s} u_k) \text{ is bounded in } L^2(\mathbb{R}^d),$$

and their Wigner measures must satisfy the following compatibility conditions for some precise representatives of $\widehat{\psi}$ and $\widehat{\varphi}$:

$$\text{(7.3)}\qquad \begin{aligned} &\text{(i)}\quad \mu \text{ fulfills (ND).}\\ &\text{(ii)}\quad \int_{\mathbb{R}^d\times\mathbb{R}^d} \mathbf{1}_{\overline{D_{\widehat{\psi}}}}(\xi + 2\pi n)|\widehat{\varphi}(\xi)|^2 d\mu(x,\xi) = 0, \quad n \in \mathbb{Z}^d.\\ &\text{(iii)}\quad \mu \text{ satisfies (MS).}\end{aligned}$$

Combining Theorems 4.6 and 4.2 we obtain the following theorem.

THEOREM 7.1. *Let ψ and φ be functions satisfying* (7.1)*; let (h_k) be a scale and let (u_k) be a sequence satisfying* (7.2)*. Suppose, moreover, that $m^{h_k}[u_k]$ converges to a Wigner measure μ that satisfies* (7.3)*.*

Then $m^{h_k}[T_\psi^{h_k} S_\varphi^{h_k} u_k]$ converges to the measure $\mu_{\varphi,\psi}$ given by

$$\text{(7.4)}\qquad \int_{\mathbb{R}^d\times\mathbb{R}^d} a(x,\xi)\, d\mu_{\varphi,\psi}(x,\xi) = \int_{\mathbb{R}^d\times\mathbb{R}^d} \sum_{n\in\mathbb{Z}^d} a(x,\xi+2\pi n)|\widehat{\psi}(\xi+2\pi n)|^2 |\widehat{\varphi}(\xi)|^2 d\mu(x,\xi)$$

for every $a \in C_c(\mathbb{R}^d \times \mathbb{R}^d)$.

Proof. Hypothesis (7.3.ii) expresses that the closure of the set of discontinuity points of $\widehat{\psi}$ is a null set for the Wigner measure of $S_\varphi^{h_k} u_k$,

$$\sum_{k\in\mathbb{Z}^d} |\widehat{\varphi}(\xi+2\pi n)|^2 \mu(x,\xi+2\pi n).$$

Hence, Theorem 4.6 is applicable, and we conclude that the distributions $m^{h_k}[T_\psi^{h_k} S_\varphi^{h_k} u_k]$ converge to the measure

$$|\widehat{\psi}(\xi)|^2 \sum_{n\in\mathbb{Z}^d} |\widehat{\varphi}(\xi+2\pi n)|^2 \mu(x,\xi+2\pi n).$$

Since $|\widehat{\psi}(\xi)|^2$ is integrable with respect to the finite measure $|\widehat{\varphi}|^2\mu$ (this is again due to (7.3.ii)), its periodization is integrable as well, and formula (7.4) follows. ∎

[9] See, for instance, [10, Proposition 2.1].

Remark 7.2. (i) When $\widehat{\psi}$ and $\widehat{\varphi}$ verify (3.6), then hypotheses (7.1), (7.3.i), and (7.3.ii) are immediately satisfied.

(ii) (7.1.ii) may be replaced by the requirement that $(\langle h_k D_x\rangle^{-s} u_k)$ be h_k-oscillatory.

From formula (7.4) one sees at once that, taking $\psi = \varphi = \delta_0$, one has that $\mu_{\varphi,\psi}$ is the periodization in ξ of the Wigner measure μ. Hence, $\mu_{\varphi,\psi}$ coincides with the limit of the Wigner series corresponding to (u_k).

When $\widehat{\psi}$ and $|\widehat{\varphi}|^2\mu$ vanish off Q it is easy to check that formula (7.4) takes the simple form

$$\mu_{\varphi,\psi}(x,\xi) = |\widehat{\psi}(\xi)|^2 |\widehat{\varphi}(\xi)|^2 \mu(x,\xi).$$

It is also clear that as soon as $|\widehat{\varphi}(\xi)|^2\mu(x,\xi)$ is not null outside Q, the measures $\mu_{\varphi,\psi}$ and μ will in general differ.

Concerning defect measures, combining Proposition 5.8 and the previous theorem, we obtain the following.

THEOREM 7.3. *Under the notation of Theorem* 7.1 *the following holds: if*

$$|\langle h_k D_x\rangle^{s'} T_\psi^{h_k} S_\varphi^{h_k} u_k|^2 dx \text{ weakly converges to a measure } \nu_{\varphi,\psi}$$

and ψ *verifies* (D)*, then*

$$\nu_{\varphi,\psi}(x) = \int_{\mathbb{R}^d_\xi} \sum_{n\in\mathbb{Z}^d} |\langle \xi + 2\pi n\rangle^{s'} \widehat{\psi}(\xi + 2\pi n)|^2 |\widehat{\varphi}(\xi)|^2 \mu(x, d\xi). \tag{7.5}$$

Remark 7.4. (i) The conclusion of the theorem still holds if condition "ψ satisfies (D)" is replaced by (5.6).

(ii) Theorems 1.3 and 1.5 follow immediately from Theorems 7.1 and 7.3.

With formula (7.5) at our disposal, we are now able to answer, in a quite general way, questions A–D addressed in the introduction. Of course, the answer to A is negative, since, in general, μ is not trivial in its ξ-component; concerning the problem of filtering, we immediately get the necessary and sufficient condition

$$c_{\varphi,\psi}(\xi) := |\widehat{\varphi}(\xi)|^2 \sum_{n\in\mathbb{Z}^d} |\langle \xi + 2\pi n\rangle^{s'} \widehat{\psi}(\xi + 2\pi n)|^2 = 0 \quad \text{for } \mu\text{-a.e. } \xi \in \mathbb{R}^d.$$

Analogously, $c_{\varphi,\psi}(\xi) = 1$ for μ-almost every $\xi \in \mathbb{R}^d$ characterizes the profiles that give $\nu_{\varphi,\psi} = \nu$. To answer D, we must, of course, assume that $\widehat{\varphi}$ and $\tau_{\langle D_x\rangle^{s'}\widehat{\psi}}$ are continuous (which, as we know, is the case if (3.6) holds). In that case, we have the equality $\nu_{\varphi,\psi} = \nu$ for every admissible sequence if and only if

$$|\widehat{\varphi}(\xi)|^2 = \frac{1}{\tau_{\langle D_x\rangle^{s'}\psi}(\xi)} \quad \text{for every } \xi \in \mathbb{R}^d \quad \text{with } \tau_{\langle D_x\rangle^{s'}\psi}(\xi) \neq 0.$$

The sampling profile φ cannot be an $L^2(\mathbb{R}^d)$ function, since $|\widehat{\varphi}|^2$ is necessarily periodic. When $\varphi = \delta_0$ and ψ generates an orthonormal basis in the sense of Lemma 3.5 we always have $\nu_{\varphi,\psi} = \nu$. If ψ merely generates a Riesz basis, $A\nu \leq \nu_{\varphi,\psi} \leq B\nu$ holds instead.

The above results may be used to compute Wigner measures of the *orthogonal projections* $P_\psi^{h_k} u_k$ of a given sequence (u_k) on the shift-invariant space defined by the range of $T_\psi^{h_k}$. As we have seen in Lemma 3.6, P_ψ^h may be written as the composition

of T_ψ^h with $S_\varphi^h\langle hD_x\rangle^s$ for a sampling profile $\varphi := \widetilde{\langle D_x\rangle^s\psi}$. Hence, Theorem 7.1 gives the following.

COROLLARY 7.5. *For ψ satisfying* (3.6) *and (u_k) such that* (7.2) *and* (MS) *hold, the defect measures of the sequence $(P_\psi^{h_k}u_k)$ is given by*

$$\nu_{P_\psi}(x) = \int_{\mathbb{R}^d} \frac{\mathbf{1}_\psi(\xi)}{\tau_{\langle D_x\rangle^s\psi}(\xi)} |\langle\xi\rangle^s\widehat{\psi}(\xi)|^2\mu(x,d\xi),$$

where $\mathbf{1}_\psi(\xi)$ denotes the characteristic function of the set of $\xi\in\mathbb{R}^d$ such that $\tau_{\langle D_x\rangle^s\psi}(\xi)\neq 0$.

In particular, when ψ gives rise to an orthonormal family, we obtain the simple formula (cf. Lemma 3.5)

$$\nu_{P_\psi}(x) = \int_{\mathbb{R}^d} |\langle\xi\rangle^s\widehat{\psi}(\xi)|^2\mu(x,d\xi).$$

To conclude, we shall see how the above results may be refined when the sequence $(\langle h_kD_x\rangle^{-s}u_k)$ is assumed to be ε_k-oscillatory at some scale $h_k\ll\varepsilon_k$. The assumptions of φ and ψ are weaker:

(7.6)
- (i) ψ and φ satisfy (BP_s) with exponents s' and s, respectively.
- (ii) $\widehat{\psi}$, $\widehat{\varphi}$ are continuous in a neighborhood of $\xi=0$.
- (iii) $\tau_{\langle D_x\rangle^{s'}\psi}$ is continuous at $\xi=0$.

Theorems 6.1 and 6.2 and Corollary 5.9 then give the following.

THEOREM 7.6. *Let ψ and φ be functions satisfying* (7.6)*, let (h_k), (ε_k) be scales with $h_k\ll\varepsilon_k$, and let (u_k) be a sequence such that* (7.2) *holds and $(\langle h_kD_x\rangle^{-s}u_k)$ is ε_k-oscillatory. Suppose, moreover, that $m^{\varepsilon_k}[u_k]$ converges to a Wigner measure μ.*

Then $m^{\varepsilon_k}[T_\psi^{h_k}S_\varphi^{h_k}u_k]$ converges to the measure $\mu_{\varphi,\psi}$ given by

$$\mu_{\varphi,\psi}(x,\xi) = |\widehat{\psi}(0)|^2|\widehat{\varphi}(0)|^2\mu(x,\xi).$$

Moreover, if $|\langle h_kD_x\rangle^{s'}T_\psi^{h_k}S_\varphi^{h_k}u_k|^2dx$ weakly converges to a measure $\nu_{\varphi,\psi}$, then

$$\nu_{\varphi,\psi}(x) = \sum_{n\in\mathbb{Z}^d} |\langle 2\pi n\rangle^{s'}\widehat{\psi}(2\pi n)|^2|\widehat{\varphi}(0)|^2\nu(x),$$

where ν is the weak limit of the densities $|\langle h_kD_x\rangle^{-s}u_k|^2dx$.

Hence, when a sequence possesses a characteristic oscillation scale (ε_k) (that is the meaning of the ε_k-oscillation condition), choosing a sampling/reconstruction rate (h_k) asymptotically finer than (ε_k) allows us to completely capture its oscillation/concentration behavior (modulo a constant that depends only on ψ and φ).

Filtering in that case can be achieved only by means of a sampling profile φ with zero mean ($\widehat{\varphi}(0)=0$) or a reconstruction profile such that $\widehat{\psi}$ vanishes at Γ.

8. Tools from the theory of Wigner measures. The main tools from the theory of Wigner measures used in this article are Propositions 8.1 and 8.3 below. The first of these is an extension of Theorem 1.1 to bounded sequences in Sobolev spaces.

PROPOSITION 8.1. *Let (ε_k) be a scale and let (u_k) be a sequence of functions in $H^{-s}(\mathbb{R}^d)$ for some $s\geq 0$ satisfying*

(8.1) $\qquad \|\langle\varepsilon_kD_x\rangle^{-s}u_k\|_{L^2(\mathbb{R}^d)}$ *are uniformly bounded in k.*

Then the sequence of distributions $(m^{\varepsilon_k}[u_k])$ is uniformly bounded in $\mathcal{S}'$. Moreover, any of its weakly converging subsequences tends to a positive measure.

As we have done so far, a measure $\mu \in \mathcal{M}_+(\mathbb{R}^d \times \mathbb{R}^d)$ will be called the *Wigner measure at scale* (ε_k) of a sequence (u_k) (satisfying the hypotheses of Proposition 8.1) provided $m^{\varepsilon_k}[u_k] \rightharpoonup \mu$ in $\mathcal{S}'$ as $k \to \infty$.

Remark 8.2. (i) When $s > 0$, condition (8.1) is stronger than just requiring that (u_k) is bounded in $H^{-s}(\mathbb{R}^d)$.

(ii) Let (h_k) be a scale such that $h_k \ll \varepsilon_k$. If $\|\langle h_k D_x\rangle^{-s} u_k\|_{L^2(\mathbb{R}^d)} \leq C$ for every $k \in \mathbb{N}$, then $\|\langle \varepsilon_k D_x\rangle^{-s} u_k\|_{L^2(\mathbb{R}^d)}$ is uniformly bounded as well.

(iii) The same result holds if $m^\varepsilon[\cdot]$ is replaced by the Wigner transform (1.4).

The second main result of this section is a localization formula for Wigner measures which was used several times in this article.

PROPOSITION 8.3. *Let (ε_k), (h_k) be scales and let (u_k) be a sequence in $H^{-s}(\mathbb{R}^d)$, $s \geq 0$, satisfying* (8.1). *Suppose that ϕ is a Borel function such that $\phi \in L^\infty(\mathbb{R}^d; \langle\xi\rangle^r)$, $r \in \mathbb{R}^d$. If $m^{\varepsilon_k}[u_k]$ converges to μ, then $m^{\varepsilon_k}[\phi(h_k D_x)u_k]$ converges to a Wigner measure μ_ϕ which has the following properties:*

(i) *If $h_k = \varepsilon_k$ and $\mu(\mathbb{R}^d \times \overline{D_\phi}) = 0$, D_ϕ being the set of points where ϕ is not continuous, then*

$$\mu_\phi(x,\xi) = |\phi(\xi)|^2 \mu(x,\xi).$$

(ii) *If $h_k \ll \varepsilon_k$ and ϕ is continuous in a neighborhood of $\xi = 0$, then*

$$\mu_\phi = |\phi(0)|^2 \mu.$$

When applied to $\phi(\xi) := \langle\xi\rangle^s$, this result gives the following.

Remark 8.4. Let (ε_k), (h_k), and (u_k) be as in Proposition 8.3. Suppose $m^{\varepsilon_k}[u_k]$ converges to μ. Then $m^{\varepsilon_k}[\langle h_k D_x\rangle^{-s} u_k]$ converges to the measure μ_s given by

$$\begin{array}{ll} \mu_s(x,\xi) = \langle\xi\rangle^{-2s}\mu(x,\xi) & \text{if } h_k = \varepsilon_k, \\ \mu_s = \mu & \text{if } h_k \ll \varepsilon_k. \end{array}$$

In particular (cf. Theorem 1.1), $\langle\xi\rangle^{-2s}\mu$ (resp., μ) is a finite measure when $h_k = \varepsilon_k$ (resp., $h_k \ll \varepsilon_k$).

For the convenience of the reader, we give detailed proofs of both results; they follow the ideas present in the existing literature on the subject (see [6, 13, 8, 9]). Proposition 8.1 will be proved in section 8.2. We shall essentially show that truncation of the high frequencies of a sequence satisfying (8.1) implies ξ-variable localization of the corresponding $m^\varepsilon[\cdot]$. Then we conclude by applying Theorem 1.1 to the localized sequence.

Proposition 8.3 is proved in section 8.3; in section 8.4, we describe two results useful for the computation of Wigner measures (Lemmas 8.12 and 8.13).

8.1. First properties of $m^\varepsilon[u]$. We begin by discussing three alternative ways of computing $m^\varepsilon[u]$ that may be used when u is merely a tempered distribution. First note that, given a $u \in \mathcal{S}'(\mathbb{R}^d)$, it makes sense to consider the distribution $m^\varepsilon[u]$ given by (1.1), since the Fourier transform of u is well-defined. Actually $m^\varepsilon[u] \in \mathcal{S}'$.

1. The action of $m^\varepsilon[u]$ on a test function $a \in \mathcal{S}$ is given by any of the following formulas (see [7]):

$$\langle m^\varepsilon[u], a\rangle_{\mathcal{S}'\times\mathcal{S}} = \begin{cases} \langle \overline{u}, a(x, \varepsilon D_x)u\rangle_{\mathcal{S}'(\mathbb{R}^d)\times\mathcal{S}(\mathbb{R}^d)}, & \text{(i)} \\ \displaystyle\int_{\mathbb{R}^d}\int_{\mathbb{R}^d} \frac{1}{\varepsilon^d} k_a\left(x, \frac{x-p}{\varepsilon}\right) u(p)\overline{u(x)}\,dp\,dx, & \text{(ii)} \end{cases} \tag{8.2}$$

where $a(x, \varepsilon D_x)$ is the *semiclassical pseudodifferential operator* of symbol a,

$$a(x, \varepsilon D_x)u(x) = \int_{\mathbb{R}^d} a(x, \varepsilon\xi)\widehat{u}(\xi)e^{ix\cdot\xi}\frac{d\xi}{(2\pi)^d}, \tag{8.3}$$

and the kernel $k_a(x, p)$ is the inverse Fourier transform of a with respect to ξ,

$$k_a(x, p) := \int_{\mathbb{R}^d} a(x, \xi)e^{ip\cdot\xi}\frac{d\xi}{(2\pi)^d}.$$

Formula (8.2.i) makes sense because the operator $a(x, \varepsilon D_x)$ continuously maps $\mathcal{S}'(\mathbb{R}^d)$ into $\mathcal{S}(\mathbb{R}^d)$ whenever $a \in \mathcal{S}$ (see, for instance, [15]). The integral in (8.2.ii) must, of course, be understood in distributional sense.

2. The distribution $m^\varepsilon[u]$ may be computed through the rescaled Fourier transform

$$\mathcal{F}^\varepsilon u(\xi) := \frac{1}{(2\pi\varepsilon)^{d/2}}\widehat{u}\left(\frac{\xi}{\varepsilon}\right), \tag{8.4}$$

using the identity

$$m^\varepsilon[u](x, \xi) = \overline{m^\varepsilon[\mathcal{F}^\varepsilon u](\xi, -x)}. \tag{8.5}$$

This follows from a direct computation from the definition (1.1).

3. Now we present two localization formulas.

LEMMA 8.5. *Let $u \in \mathcal{S}'(\mathbb{R}^d)$, $\phi \in C^\infty(\mathbb{R}^d; \langle x\rangle^r)$ for some $r \in \mathbb{R}$ and $a \in \mathcal{S}$. Then there exists $r_1^\sigma, r_2^\sigma \in \mathcal{S}$ such that*

$$\langle m^\varepsilon[\phi u], a\rangle_{\mathcal{S}'\times\mathcal{S}} = \langle|\phi(x)|^2 m^\varepsilon[u], a\rangle_{\mathcal{S}'\times\mathcal{S}} + \varepsilon\langle m^\varepsilon[u], r_1^\varepsilon\rangle_{\mathcal{S}'\times\mathcal{S}},$$
$$\langle m^\varepsilon[\phi(hD_x)u], a\rangle_{\mathcal{S}'\times\mathcal{S}} = \left\langle\left|\phi\left(\frac{h}{\varepsilon}\xi\right)\right|^2 m^\varepsilon[u], a\right\rangle_{\mathcal{S}'\times\mathcal{S}} + \varepsilon\langle m^\varepsilon[u], r_2^{h/\varepsilon}\rangle_{\mathcal{S}'\times\mathcal{S}}.$$

Moreover, the test functions r_1^σ, r_2^σ are uniformly bounded in $\mathcal{S}$ for $0 < \sigma \le 1$.

This holds as a consequence of standard results on symbolic calculus for semiclassical pseudodifferential operators; see, for instance, [15]. Note that Proposition 8.3 is not a consequence of this result, since the multiplier $\phi(hD_x)$ there may have a nonsmooth symbol.

8.2. Boundedness of the transforms $m^\varepsilon[u]$. The following lemmas are used to establish the boundedness in $\mathcal{S}'$ of the sequence $(m^{\varepsilon_k}[u_k])$, provided (u_k) satisfies the hypotheses of Proposition 8.1.

LEMMA 8.6. *For every $u \in L^2(\mathbb{R}^d; \langle x\rangle^r)$ and $a \in \mathcal{S}$ the following estimate holds:*

$$|\langle m^\varepsilon[u], a\rangle_{\mathcal{S}'\times\mathcal{S}}| \le \|u\|^2_{L^2(\mathbb{R}^d;\langle x\rangle^r)} \int_{\mathbb{R}^d} \sup_{x\in\mathbb{R}^d} |k_a(x, p)\langle x - \varepsilon p\rangle^{-r/2}\langle x\rangle^{-r/2}|dp.$$

Proof. Use formula (8.2.ii) to write

$$\langle m^\varepsilon[u], a\rangle_{\mathcal{S}'\times\mathcal{S}} = \int_{\mathbb{R}^d}\int_{\mathbb{R}^d} k_a(x, p)u(x - \varepsilon p)\overline{u(x)}dpdx,$$

noticing that this integral makes sense as $k_a \in \mathcal{S}$. Multiply and divide the integrand above by $\langle x - \varepsilon p\rangle^{r/2}\langle x\rangle^{r/2}$ to obtain, by Hölder's inequality,

$$|\langle m^\varepsilon[u], a\rangle_{\mathcal{S}'\times\mathcal{S}}| \le \int_{\mathbb{R}^d} \sup_{x\in\mathbb{R}^d} |k_a(x, p)\langle x - \varepsilon p\rangle^{-r/2}\langle x\rangle^{-r/2}| \int_{\mathbb{R}^d} |u_r(x - \varepsilon p)\overline{u_r(x)}|dxdp,$$

where we have set $u_r(x) := \langle x\rangle^{r/2}u(x)$. The conclusion follows from another application of Hölder's inequality. □

If $u \in H^{-s}(\mathbb{R}^d)$, then $\mathcal{F}^\varepsilon u \in L^2(\mathbb{R}^d; \langle\xi\rangle^{-2s})$. Clearly,

$$\|\langle \varepsilon D_x\rangle^{-s}u\|^2_{L^2(\mathbb{R}^d)} = \|\mathcal{F}^\varepsilon u\|^2_{L^2(\mathbb{R}^d;\langle\xi\rangle^{-2s})}. \tag{8.6}$$

Thus, taking identity (8.5) into account, we obtain, using the preceding lemma,

$$|\langle m^\varepsilon[u], a\rangle_{\mathcal{S}'\times\mathcal{S}}| \le \|\langle \varepsilon D_x\rangle^{-s}u\|^2_{L^2(\mathbb{R}^d)} \int_{\mathbb{R}^d} \sup_{\xi\in\mathbb{R}^d} |\widehat{a}(q,\xi)\langle\xi+\varepsilon q\rangle^s\langle\xi\rangle^s| \frac{dq}{(2\pi)^d}, \tag{8.7}$$

where $\widehat{a}(q,\xi)$ denotes the Fourier transform in x of the function $a(x,\xi)$.

LEMMA 8.7. *For every $s \ge 0$ there exists a constant $C_{s,d} > 0$ such that*

$$|\langle m^\varepsilon[u], a\rangle_{\mathcal{S}'\times\mathcal{S}}| \le C_{s,d}\|\langle \varepsilon D_x\rangle^{-s}u\|^2_{L^2(\mathbb{R}^d)} \int_{\mathbb{R}^d} \sup_{\xi\in\mathbb{R}^d} |\widehat{a}(q,\xi)\langle\xi\rangle^{2s}|\langle\varepsilon q\rangle^s dq \tag{8.8}$$

holds for every $u \in H^{-s}(\mathbb{R}^d)$ and every $a \in \mathcal{S}$.

Proof. This is obtained through the simple inequality $\langle\xi+q\rangle^s \le C_{s,d}\langle\xi\rangle^s\langle q\rangle^s$, which holds when $s \ge 0$. □

Notice that whenever $a \in \mathcal{S}$, the integrals $\int_{\mathbb{R}^d} \sup_{\xi\in\mathbb{R}^d} |\widehat{a}(q,\xi)\langle\xi\rangle^{2s}|\langle\varepsilon q\rangle^s dq$ are uniformly bounded for $0 < \varepsilon \le 1$. Consequently, we get the following corollary.

COROLLARY 8.8. *Let (ε_k) and (u_k) satisfy the hypotheses of Proposition* 8.1. *Then the sequence $(m^{\varepsilon_k}[u_k])$ is bounded in $\mathcal{S}'$.*

Estimate (8.8) immediately gives the following.

Remark 8.9. Lemma 8.7 shows that $m^\varepsilon[u]$ acts continuously on test functions a in the closure of $\mathcal{S}$ for the norm

$$[a]_s := \int_{\mathbb{R}^d} \sup_{\xi\in\mathbb{R}^d} |\widehat{a}(q,\xi)\langle\xi\rangle^{2s}|\langle q\rangle^s dq < \infty. \tag{8.9}$$

This closure contains the space

$$\Sigma^s := \{\langle D_x\rangle^s\langle\xi\rangle^{2s}a \in C_0(\mathbb{R}^d\times\mathbb{R}^d) : [a]_s < \infty\}. \tag{8.10}$$

Remark 8.10. Consequently, if (u_k) is as in Proposition 8.1 and $(m^{\varepsilon_k}[u_k])$ converges weakly in $\mathcal{S}'$, then $\langle m^{\varepsilon_k}[u], a\rangle$ converges as well for every $a \in \Sigma^s$.

Proof of Proposition 8.1. The boundedness of the sequence $(m^{\varepsilon_k}[u_k])$ was proved in Corollary 8.8. Suppose now that the distributions $m^{\varepsilon_k}[u_k]$ weakly converge to some $\mu \in \mathcal{S}'$. We next show by means of a localization argument that μ is a positive distribution and thus, due to Schwartz's theorem, a positive Radon measure.

Take $\phi \in \mathcal{S}(\mathbb{R}^d_\xi)$; Lemma 8.5 gives

$$\lim_{k\to\infty} \langle m^{\varepsilon_k}[\phi(\varepsilon_k D_x)u_k], a\rangle_{\mathcal{S}'\times\mathcal{S}} = \int_{\mathbb{R}^d\times\mathbb{R}^d} a(x,\xi)|\phi(\xi)|^2 d\mu(x,\xi)$$

for every $a \in \mathcal{S}$. Since $(\phi(\varepsilon_k D_x)u_k)$ is a bounded sequence in $L^2(\mathbb{R}^d)$, Theorem 1.1 ensures that $|\phi(\xi)|^2\mu$ is a positive Radon measure (and hence a positive distribution). But $\phi \in \mathcal{S}(\mathbb{R}^d_\xi)$ is arbitrary, so μ itself is positive and we obtain the desired result. □

Notice that a very similar proof would give a version of Proposition 8.1 in the context of weighted spaces $L^2(\mathbb{R}^d; \langle x\rangle^r)$.

8.3. Proof of Proposition 8.3. The key ingredient in the proof of the proposition is the following auxiliary result.

LEMMA 8.11. *Under the assumptions of Proposition* 8.3*,*

$$\lim_{k\to\infty}\left|\left\langle m^{\varepsilon_k}[\phi(h_kD_x)u_k]-\left|\phi\left(\frac{h_k}{\varepsilon_k}\xi\right)\right|^2 m^{\varepsilon_k}[u_k],a\right\rangle\right|=0 \tag{8.11}$$

holds for every $a\in\mathcal{S}$ if any of the following conditions hold:

(i) *$h_k=\varepsilon_k$ and a vanishes on the set of discontinuity points of ϕ.*

(ii) *$h_k\ll\varepsilon_k$ and ϕ is continuous at $\xi=0$.*

Proof. Take $a\in\mathcal{S}$ and set $\Phi_k(\xi):=\phi(h_k/\varepsilon_k\xi)$. From relations (8.5), (8.2.i), and (8.7) we obtain

$$\left|\left\langle m^{\varepsilon_k}[\phi(h_kD_x)u_k]-\left|\phi\left(\frac{h_k}{\varepsilon_k}\xi\right)\right|^2 m^{\varepsilon_k}[u_k],a\right\rangle\right|\le M_k(a)\|\langle\varepsilon_kD_x\rangle^{-s}u_k\|^2_{L^2(\mathbb{R}^d)},$$

where

$$M_k(a):=\int_{\mathbb{R}^d}\sup_{\xi\in\mathbb{R}^d}|\widehat{a}(q,\xi)\Phi_k(\xi)[\Phi_k(\xi+\varepsilon_kq)-\Phi_k(\xi)]\langle\xi+\varepsilon_kq\rangle^s\langle\xi\rangle^s|\frac{dq}{(2\pi)^d}; \tag{8.12}$$

recall that $\widehat{a}(q,\xi)$ stands for the Fourier transform of $a(x,\xi)$ in x.

We now must prove that $M_k(a)\to0$ as $k\to\infty$. First we check this for test functions a belonging to the smaller class:

$$\widehat{\mathcal{D}}:=\{a\in\mathcal{S}:\widehat{a}\in C_c^\infty(\mathbb{R}^d\times\mathbb{R}^d)\}.$$

Take $R>0$ such that $\operatorname{supp}a$ is contained in $B(0;R)\times B(0;R)$.

When $k\in\mathbb{N}$ is sufficiently large, $\varepsilon_k\le1$ and

$$\frac{h_k}{\varepsilon_k}(\xi+\varepsilon_kq)\in B(0;2R\sup h_k/\varepsilon_k)\quad\text{for every } q,\xi\in B(0;R). \tag{8.13}$$

Suppose now that (i) holds. If C_ϕ denotes the set of points where ϕ is continuous, then $\Phi_k=\phi$ is uniformly continuous over $C_\phi\cap B(0;R)$ and, consequently,

$$\sup_{q,\xi\in B(0;R)}\mathbf{1}_{C_\phi}(\xi)|\phi(\xi+\varepsilon_kq)-\phi(\xi)|\to0\quad\text{as } k\to\infty$$

because of (8.13).

On the other hand, when $h_k/\varepsilon_k\to0$ and ϕ is continuous at $\xi=0$, again as a consequence of (8.13),

$$\sup_{\xi,q\in B(0;R)}\left|\phi\left(\frac{h_k}{\varepsilon_k}(\xi+\varepsilon_kq)\right)-\phi\left(\frac{h_k}{\varepsilon_k}\xi x\right)\right|\le2\sup_{\xi\in B(0;2h_k/\varepsilon_kR)}|\phi(\xi)-\phi(0)|\to0$$

as $k\to\infty$.

Thus, in either case,

$$\sup_{\xi\in\mathbb{R}^d}|\widehat{a}(q,\xi)\Phi_k(\xi)[\Phi_k(\xi+\varepsilon_kq)-\Phi_k(\xi)]\langle\xi+\varepsilon_kq\rangle^s\langle\xi\rangle^s|\to0\quad\text{as } k\to\infty$$

for every $q\in\mathbb{R}^d$. Lebesgue's dominated convergence theorem gives the convergence to zero of the integrals (8.12). The density of $\widehat{\mathcal{D}}$ in $\mathcal{S}$ concludes the proof of the lemma. ∎

Proof of Proposition 8.3. To prove (i) and (ii) it only needs to be checked that, for any $a \in C_c^\infty(\mathbb{R}^d \times \mathbb{R}^d)$ (if $\varepsilon_k = h_k$, we further require that $a|_{\mathbb{R}^d \times \overline{D_\phi}} \equiv 0$), the functions $|\phi(h_k/\varepsilon_k \xi)|^2 a(x,\xi)$ belong to the class Σ^s. If so, then

$$\lim_{k\to\infty} \left\langle \left| \phi\left(\frac{h_k}{\varepsilon_k}\xi\right)\right|^2 m^{\varepsilon_k}[u_k], a \right\rangle_{\mathcal{S}'\times\mathcal{S}} = \int_{\mathbb{R}^d\times\mathbb{R}^d} |\phi(c\,\xi)|^2 a(x,\xi) d\mu$$

holds with $c := \lim h_k/\varepsilon_k$ because of Remark 8.10. The conclusion would then follow from identity (8.11).

First, notice that $|\phi(h_k/\varepsilon_k \cdot)|^2 a$ are compactly supported and infinitely differentiable in x. When $\varepsilon_k = h_k$ we must verify that $|\phi|^2 a \in \Sigma^s$, which is clearly the case if $a|_{\mathbb{R}^d\times\overline{D_\phi}} \equiv 0$, for then $|\phi|^2 a$ is continuous in ξ.

On the other hand, if $h_k \ll \varepsilon_k$ and ϕ is merely continuous in a ball $B(0;\delta)$, then, for k large enough, $\operatorname{supp} a \subset B(0; h_k/\varepsilon_k \delta)$, and consequently $\phi(h_k/\varepsilon_k \cdot)$ is continuous on $\operatorname{supp} a$. ∎

8.4. Additional properties. The next approximation result is sometimes useful in the computation of Wigner measures.

LEMMA 8.12. *Let (u_k) and (u_k^N) be sequences in $H^{-s}(\mathbb{R}^d)$, $s \geq 0$, satisfying* (8.1) *with the same bound and*

$$\limsup_{k\to\infty} \|\langle \varepsilon_k D_x\rangle^{-s}(u_k - u_k^N)\|_{L^2(\mathbb{R}^d)} \to 0 \quad \text{as } N \to \infty.$$

Suppose that $m^{\varepsilon_k}[u_k]$ and $m^{\varepsilon_k}[u_k^N]$ converge, respectively, to μ and μ_N. Then

$$\mu_N \rightharpoonup \mu \quad \text{in } \mathcal{M}_+(\mathbb{R}^d\times\mathbb{R}^d) \quad \text{as } N \to \infty.$$

Proof. This is a simple consequence of the identity

$$\begin{aligned}\langle m^{\varepsilon_k}[u_k] - m^{\varepsilon_k}[u_k^N], a\rangle_{\mathcal{S}'\times\mathcal{S}} = {} & \langle \overline{u_k^N}, a(x,\varepsilon_k D_x)(u_k - u_k^N)\rangle_{\mathcal{S}'\times\mathcal{S}} \\ & + \langle \overline{(u_k - u_k^N)}, a(x,\varepsilon_k D_x) u_k\rangle_{\mathcal{S}'\times\mathcal{S}}.\end{aligned}$$

This gives an estimate:

$$|\langle m^{\varepsilon_k}[u_k] - m^{\varepsilon_k}[u_k^N], a\rangle_{\mathcal{S}'\times\mathcal{S}}| \leq C \|\langle \varepsilon_k D_x\rangle^{-s}(u_k - u_k^N)\|_{L^2(\mathbb{R}^d)};$$

taking limits as $k \to \infty$, we obtain

$$\left| \int_{\mathbb{R}^d\times\mathbb{R}^d} a(x,\xi)(d\mu - d\mu_N)\right| \leq C \limsup_{k\to\infty} \|\langle \varepsilon_k D_x\rangle^{s}(u_k - u_k^N)\|_{L^2(\mathbb{R}^d)},$$

and the result follows, since the measures μ_N and μ are equibounded. ∎

We conclude this section with an almost orthogonality result.

LEMMA 8.13. *Let (u_k) and (v_k) be sequences in $H^{-s}(\mathbb{R}^d)$, $s \geq 0$, satisfying* (8.1) *for some scale (ε_k). Suppose that μ and ν, their Wigner measures at scale (ε_k), are mutually singular. Then $m^{\varepsilon_k}[u_k + v_k]$ converges to $\mu + \nu$.*

Proof. A proof of this result for $s = 0$ may be found in [6] or [13]. For the general case, it suffices to take into account Remark 8.4 to conclude that the Wigner measures of $\langle \varepsilon_k D_x\rangle^{-s} u_k$ and $\langle \varepsilon_k D_x\rangle^{-s} v_k$ are $\langle \xi\rangle^{-2s}\mu$ and $\langle \xi\rangle^{-2s}\nu$. These are clearly mutually singular, and thus the aforementioned L^2-version of the present result gives

$$m^{\varepsilon_k}[\langle \varepsilon_k D_x\rangle^{-s}(u_k + v_k)] \rightharpoonup \langle \xi\rangle^{-2s}\mu + \langle \xi\rangle^{-2s}\nu$$

and finally

$$m^{\varepsilon_k}[u_k + v_k] \rightharpoonup \langle\xi\rangle^{2s}(\langle\xi\rangle^{-2s}\mu + \langle\xi\rangle^{-2s}\nu) = \mu + \nu,$$

as claimed. □

Acknowledgments. This article extends and improves some of the results of the author's Ph.D. thesis. He is grateful for the guidance of his Ph.D. advisor Enrique Zuazua. Much of this work was done at the Département de Mathématiques et Applications of the École Normale Supérieure, Paris, where the author spent the 2002–2003 academic year as a post-doctorate fellow. He wishes to acknowledge the hospitality of this institution. Finally, he would like to thank Patrick Gérard for many helpful discussions and suggestions.

EXISTENCE OF MINIMIZERS IN INCREMENTAL ELASTO-PLASTICITY WITH FINITE STRAINS*

ALEXANDER MIELKE†

Abstract. We consider elasto-plastic deformations of a body which is subjected to a time-dependent loading. The model includes fully nonlinear elasticity as well as the multiplicative split of the deformation gradient into an elastic part and a plastic part. Using the energetic formulation for this rate-independent process we derive a time-incremental problem, which is a minimization problem with respect to the deformation and the plastic variables. We provide assumptions on the constitutive laws of the material which guarantee that the incremental problem can be solved for as many time steps as desired. The methods relies on the polyconvexity of the so-called condensed energy functional and on a priori estimates for the plastic variables using the dissipation distance.

Key words. nonlinear elasticity, plasticity, polyconvexity, time-incremental minimization problems, energetic formulation

1. Introduction.

The mathematical theory of linearized elasto-plasticity was developed in the 1970s by Moreau [Mor74, Mor76] and subsequently developed further up to efficient numerical implementations; see, e.g., [Joh76, HaR95]. This theory relies on the additive decomposition

$$\varepsilon = \frac{1}{2}(\mathrm{D}u + \mathrm{D}u^{\mathsf{T}}) = \varepsilon_{\mathrm{elast}} + \varepsilon_{\mathrm{plast}}$$

of the linearized strain tensor ε, where $u : \Omega \to \mathbb{R}^d$ denotes the displacement. Moreover, the energy is assumed to be a quadratic functional such that the problem takes the form of a quasi-variational inequality. More general approaches with nonlinear hardening laws and viscoplastic effects can be found in [BeF96, Alb98, ACZ99, Che01a, Che01b, Nef02].

With this work we want to start a mathematical investigation of elasto-plasticity which allows for large strains and which is based on the multiplicative decomposition

$$F = \mathrm{D}\varphi = F_{\mathrm{elast}}F_{\mathrm{plast}}. \tag{1.1}$$

Here, $\varphi : \Omega \to \mathbb{R}^d$ is the deformation of the body $\Omega \subset \mathbb{R}^d$. The energy $\mathcal{E}$ stored in a deformed body depends only on the elastic part F_{elast} of the deformation tensor and suitable hardening parameters $p \in \mathbb{R}^m$, but not on the plastic part F_{plast}, which is contained in $\mathrm{SL}(\mathbb{R}^d)$ or another Lie group $\mathfrak{G}$ contained in $\mathrm{GL}_+(\mathbb{R}^d) = \{\, P \in \mathbb{R}^{d\times d} \mid \det P > 0 \,\}$. The energy functional takes the form

$$\mathcal{E}(t, \varphi, (F_{\mathrm{plast}}, p)) = \int_\Omega W(x, \mathrm{D}\varphi(x)F_{\mathrm{plast}}(x)^{-1}, p(x))\,\mathrm{d}x - \langle \ell(t), \varphi\rangle,$$

where the external loading $\ell(t)$ is given via

$$\langle \ell(t), \varphi \rangle = \int_\Omega f_{\text{ext}}(t,x) \cdot \varphi(x)\,\mathrm{d}x + \int_\Gamma g_{\text{ext}}(t,x) \cdot \varphi(x)\,\mathrm{d}a.$$

To model the plastic effects, one prescribes either a plastic flow law or, equivalently, a dissipation potential $\Delta : \Omega \times \mathrm{T}(\mathfrak{G} \times \mathbb{R}^m) \to [0,\infty]$. We consider $\Delta(x,\cdot,\cdot)$ as an infinitesimal metric which defines the global dissipation distance $D(x,\cdot,\cdot)$ on $\mathfrak{G} \times \mathbb{R}^m$. Thus, the second ingredient to our material model is the dissipation distance between two internal states $z_j = (F^{(j)}_{\text{plast}}, p_j) : \Omega \to \mathrm{SL}(\mathbb{R}^d) \times \mathbb{R}^m$:

$$\mathcal{D}(z_1,z_2) = \int_\Omega D(x, (F^{(1)}_{\text{plast}}(x), p_1(x)),\, (F^{(2)}_{\text{plast}}(x), p_2(x)))\,\mathrm{d}x.$$

Allowing for finite strains, we are forced to abolish convexity assumptions on the stored-energy density W, since it has to be frame indifferent (i.e., $W(x,RF,z) = W(x,F,z)$ for $R \in \mathrm{SO}(\mathbb{R}^d)$) and enforce local invertibility (i.e., $W(F) = \infty$ for $F \notin \mathrm{GL}_+(\mathbb{R}^d)$). It was a major breakthrough in [Bal77] when it was discovered that these conditions are compatible with quasi-convexity and polyconvexity. The aim of this work is to show that it is possible to find constitutive functions W (being polyconvex) and Δ which, on the one hand, satisfy all the above-mentioned natural, physical conditions of finite-strain elasticity as well as the multiplicative plastic decomposition (1.1) (giving rise to the Lie group structure for $P = F_{\text{plast}}$) and, on the other hand, allow for a mathematical existence theory.

We follow the work found in [MiT99, MTL02, Mie02, Mie03a, MiR03], which shows that rate-independent evolution for elastic materials with internal variables ("standard generalized materials") can be formulated by energy principles as follows. A pair $(\varphi, z) : [0,T] \times \Omega \to \mathbb{R}^d \times \mathrm{SL}(\mathbb{R}^d) \times \mathbb{R}^m$ is called a solution of the elasto-plastic process associated with $\mathcal{E}(t,\cdot,\cdot)$ and $\mathcal{D}$ if *stability* (S) and the *energy inequality* (E) hold:

(S) For all $t \in [0,T]$ we have
$\mathcal{E}(t,\varphi(t),z(t)) \le \mathcal{E}(t,\widetilde{\varphi},\widetilde{z}) + \mathcal{D}(z(t),\widetilde{z})$ for all admissible states $(\widetilde{\varphi},\widetilde{z})$.

(E) For all $s,t \in [0,T]$ with $s < t$ we have
$$\mathcal{E}(s,\varphi(s),z(s)) + \mathrm{Diss}(z,[s,t]) \le \mathcal{E}(t,\varphi(t),z(t)) - \int_s^t \langle \dot{\ell}(\tau,\varphi(\tau)) \rangle\,\mathrm{d}\tau.$$

So far, we are not able to provide existence results for (S)–(E) in the present elasto-plastic setting. However, analogous models in phase transformations [MTL02, MiR03], in delamination [KMR03], in micromagnetism [Kru02, RoK04], and in fracture [FrM93, FrM98, DMT02] have been treated with mathematical success. In these works two major restrictions had to be made: (i) $\mathcal{E}$ has to be convex in the strains (leading to infinitesimal strains), and (ii) the internal variable z has to lie in a closed convex subset of a Banach space. In finite-strain elasto-plasticity these two assumptions are clearly violated. For a more general nonlinear version we refer to [MaM03], where severe compactness assumptions are used to construct solutions. So far it is not clear how this compactness can be established in elasto-plasticity; however, in [MiM04] the first steps are being taken by introducing a suitable regularization.

Since most of the above-mentioned existence results are based on time-incremental approximations we devote this work to an existence theory for the following incremental problem (IP). The hope is that after having developed a suitable existence theory

for (IP) that the methods in [MaM03] could be adjusted to pass to the limit for step size tending to 0 and thus find solutions for (S)–(E).

(IP) For given $t_0 = 0 < t_1 < \cdots < t_N = T$ and z_0, find incrementally, for $k = 1, \dots, N$,

$$(\varphi_k, z_k) \in \operatorname*{Arg\,min}_{(\varphi,z)} [\mathcal{E}(t_k, \varphi, z) + \mathcal{D}(z_{k-1}, z)].$$

Here "Arg min" denotes the set of all global minimizers. Hence, (IP) consists of k minimization problems which are coupled via the dissipation distance. The problem in solving (IP) is that the minimization at the kth step involves the solution z_{k-1} from the previous step. For solving the N minimization problems in (IP) it needs a careful bookkeeping of the properties of the solutions; in particular we have to control the integrability conditions of P_k and P_k^{-1} independently of k. This will be done by the help of the dissipation distance $\mathcal{D}$, whereas the elastic energy $\mathcal{E}$ is used to control the Sobolev norm of φ_k.

Such incremental minimization problems are heavily used in the engineering community (cf. [OrR99, OrS99, MSS99, ORS00, MiL03, MSL02, HaH03]), which justifies studying (IP) in its own right. In fact, existence and nonexistence for (IP) relates to questions of formation of microstructure, localization, or failure; see the discussions in [Mie03a, Mie04]. The failure mechanisms in elasto-plasticity are currently an active research area. However, the aim of our work is to provide examples and to isolate general conditions which exclude these failures. In fact, there are many commercial codes for the numerical simulation of plastic processes (like deep drawing) which are expected to describe nice solutions in regions where no failure arises. We want to contribute to the challenging task of providing a mathematical understanding of these models and hopefully improve the numerical simulation techniques.

The plan of the paper is as follows. In section 2 we introduce the notions of finite-strain elasto-plasticity in detail and establish the relation between the classical flow rules of elasto-plasticity with our energetic formulation (S)–(E). For a more extensive and mechanical treatment we refer to [Mie03a]. In section 3 we start the mathematical analysis by studying the incremental problem (IP) in specific function spaces $\mathcal{F} \times \mathcal{Z}$. To start with, we establish a rather general result which says that any solution $(\varphi_k, z_k)_{k=1,\dots,N}$ of (IP) is stable in the sense of (S) and satisfies a two-sided discretized energy inequality replacing (E).

The key to the analysis of (IP) is realizing that the internal variables $z = (F_{\text{plast}}, p)$ occur under the integral over the body Ω only in a local fashion. Hence, it is possible to minimize in (IP) with respect to z pointwise in $x \in \Omega$. This leads to the condensed energy density

$$W^{\text{cond}}(z_{\text{old}}; F) = \min\{W(FP, p) + D(z_{\text{old}}, (P, p)) \mid (P, p) \in \mathrm{SL}(\mathbb{R}^d) \times \mathbb{R}^m\}.$$

In [CHM02, Mie03a] it is shown that W^{cond} has also mechanical significance, as it contains the effective information of the interplay between energy storage through W and the dissipation mechanism through D. The first major assumption for our existence theory is that $W^{\text{cond}}((\mathbf{1}, p_*); \cdot) : \mathbb{R}^{d\times d} \to \mathbb{R}_\infty$ is polyconvex. The second major assumption is that the condensed energy density W^{cond} and the dissipation distance D are coercive:

$$W^{\text{cond}}((\mathbf{1}, p_*); F) \geq c|F|^{q_F} - C \quad \text{and} \quad D((\mathbf{1}, p_*), (P, p)) \geq c|P|^{q_P} - C.$$

If the growth exponents satisfy $\frac{1}{q_P} + \frac{1}{q_F} \le \frac{1}{q} < \frac{1}{d}$, then the existence of solutions $(\varphi_k, F^{(k)}_{\text{plast}}, p_k)$ for (IP) is obtained with $\varphi_k \in \mathrm{W}^{1,q}(\Omega, \mathbb{R}^d)$ and $F^{(k)}_{\text{plast}} \in \mathrm{L}^{q_P}(\Omega, \mathbb{R}^{d\times d})$.

In section 4 we supply a specific two-dimensional example in which all assumptions can be checked explicitly and are fulfilled for suitable parameter values. Thus, we provide a first existence theory for a multidimensional elasto-plastic incremental problem in the geometric nonlinear case.

In section 5 we treat a one-dimensional example where again the existence theory for (IP) can be carried out explicitly. Using this example we discuss the difficulties in proving the existence of solutions for the time-continuous problem (S)–(E) by letting the step size of the time discretizations go to 0. In section 6, using the very specific properties of the one-dimensional case (like $\operatorname{div}\sigma = 0 \implies \sigma = \text{const.}$), we finally prove a convergence result for the incremental solution which implies that the time-continuous problem (S)–(E) has a solution as well.

2. Elasto-plasticity at finite strain. We consider an elastic body $\Omega \subset \mathbb{R}^d$ which is bounded and has a Lipschitz boundary $\partial\Omega$. A deformation is a mapping $\varphi : \Omega \to \mathbb{R}^d$ such that the deformation gradient $F(x) = \mathrm{D}\varphi(x)$ exists for a.e. $x \in \Omega$ and satisfies

$$F(x) \in \mathrm{GL}_+(\mathbb{R}^d) = \{\, F \in \mathbb{R}^{d\times d} \mid \det F > 0 \,\}.$$

The internal plastic state at a material point $x \in \Omega$ is described by the plastic tensor $P = F_{\text{plast}} \in \mathrm{GL}_+(\mathbb{R}^d)$ and a possibly vector-valued hardening variable $p \in \mathbb{R}^m$. We write the shorthand $z = (P, p)$ to denote the set of all plastic variables. The major assumption in finite-strain elasto-plasticity is the multiplicative decomposition of the deformation gradient F into an elastic and a plastic part,

$$F = F_{\text{elast}} F_{\text{plast}} = F_{\text{elast}} P. \tag{2.1}$$

The point of this decomposition is that the elastic properties will depend only on F_{elast}, whereas previous plastic transformations through P are completely forgotten. However, the hardening variable p will record changes in P and may influence the elastic properties.

The deformation process is governed by two principles. First, we have energy storage which gives rise to the equilibrium equations, and, second, we have dissipation due to plastic transformations which give rise to the plastic flow rule. Energy storage is described by the Gibbs energy

$$\mathcal{E}(t, \varphi, z) = \int_\Omega W(x, \mathrm{D}\varphi(x), z(x))\,\mathrm{d}x - \langle \ell(t), \varphi\rangle, \tag{2.2}$$

where $\langle \ell(t), \varphi\rangle = \int_\Omega f_{\text{ext}}(t,x)\cdot\varphi(x)\,\mathrm{d}x + \int_{\Gamma_{\text{Neu}}} g_{\text{ext}}(t,x)\cdot\varphi(x)\,\mathrm{d}a(x)$ denotes the loading depending on the process time $t \in [0, T]$. The major constitutive assumption is the multiplicative decomposition

$$W(x, F, (P, p)) = \widehat{W}(x, FP^{-1}, p). \tag{2.3}$$

From now on we drop the variable x for notational convenience. However, the whole theory and analysis works in the inhomogeneous case as well.

The dissipation effects are usually modeled by prescribing yield surfaces. For our purpose it is more convenient and mathematically clearer to start on the other side, namely, the dissipation metric. In mechanics this metric is called dissipation

potential, since the dissipational friction forces are obtained from it via differentiation with respect to the plastic rates. We emphasize that the natural setup for the plastic transformation $P \in \mathrm{GL}_+(\mathbb{R}^d)$ is that of an element of a Lie group $\mathfrak{G} \subset \mathrm{GL}_+(\mathbb{R}^d)$. A usual assumption is incompressibility, which gives $\mathfrak{G} = \mathrm{SL}(\mathbb{R}^d) = \{ P \mid \det P = 1 \}$. However, $\mathfrak{G} = \mathrm{GL}_+(\mathbb{R}^d)$ or a single-slip system $\mathfrak{G} = \{ \mathbf{1} + \gamma e_1 \otimes e_2 \mid \gamma \in \mathbb{R} \}$ may also be possible. A dissipation potential is a mapping

$$\Delta : \Omega \times \mathrm{T}(\mathfrak{G} \times \mathbb{R}^m) \to [0, \infty], \tag{2.4}$$

which is called a dissipation metric if it is continuous and $\Delta(x, (P,p), \cdot)$ is convex and positively homogeneous of degree 1:

$$\Delta(x, (P,p), \alpha(\dot P, \dot p)) = \alpha \Delta(x, (P,p), (\dot P, \dot p)) \text{ for } \alpha \geq 0. \tag{2.5}$$

(Again we will drop the variable x for notational convenience.) This condition leads to rate-independent material behavior. One assumes, together with the multiplicative decomposition (2.1), *plastic indifference*:

$$\Delta((P\widehat P, p), (\dot P \widehat P, \dot p)) = \Delta((P,p), (\dot P, \dot p)) \text{ for all } \widehat P \in \mathfrak{G}. \tag{2.6}$$

This amounts in the existence of a function $\widehat\Delta : \mathbb{R}^m \times \mathbb{R}^m \times \mathfrak{g} \to [0, \infty]$ such that

$$\Delta((P,p), (\dot P, \dot p)) = \widehat\Delta(p, \dot p, \dot P P^{-1}). \tag{2.7}$$

Here $\mathfrak{g} = \mathrm{T}_{\mathbf{1}}\mathfrak{G}$ is the Lie algebra associated with the Lie group $\mathfrak{G}$, and $\dot P P^{-1}$ is strictly speaking the right translation of $\dot P(t) \in \mathrm{T}_{P(t)}\mathfrak{G}$ to $\mathfrak{g} = \mathrm{T}_{\mathbf{1}}\mathfrak{G}$.

An important feature of our theory is the induced dissipation distance D on $\mathfrak{G} \times \mathbb{R}^m$ defined via (recall $z = (P,p)$)

$$D(z_0, z_1) = \inf \left\{ \int_0^1 \Delta(z(s), \dot z(s)) \, \mathrm{d}s \mid z \in \mathrm{C}^1([0,1], \mathfrak{G} \times \mathbb{R}^m), z(0) = z_0, z(1) = z_1 \right\}. \tag{2.8}$$

It is important to note that we didn't assume symmetry (i.e., $\Delta(z, -\dot z) \neq \Delta(z, \dot z)$ is allowed), which would contradict hardening. Thus, $D(\cdot, \cdot)$ will not be symmetric either. However, we will often use the triangle inequality

$$D(z_1, z_3) \leq D(z_1, z_2) + D(z_2, z_3), \tag{2.9}$$

which is immediate from the definition. Plastic difference implies that the dissipation distance satisfies

$$D((P_1, p_1), (P_2, p_2)) = D((\mathbf{1}, p_1), (P_2 P_1^{-1}, p_2)). \tag{2.10}$$

Integration over the body Ω gives the total dissipation between two internal states $z_j : \Omega \to \mathfrak{G} \times \mathbb{R}^m$ via

$$\mathcal{D}(z_0, z_1) = \int_\Omega D(z_0(x), z_1(x)) \, \mathrm{d}x. \tag{2.11}$$

To make the energetic formulation mathematically rigorous we define the set of kinematically admissible deformations via

$$\mathcal{F} = \{ \varphi \in \mathrm{W}^{1,q}(\Omega; \mathbb{R}^d) \mid \varphi|_{\Gamma_{\mathrm{Dir}}} = \varphi_{\mathrm{Dir}} \}, \tag{2.12}$$

where $\Gamma_{\rm Dir} = \partial\Omega/\Gamma_{\rm Neu}$ is a part of the boundary with positive surface measure. Moreover, $\varphi_{\rm Dir} = \widehat{\varphi}|_{\Gamma_{\rm Dir}}$, where $\widehat{\varphi} \in {\rm C}^1(\overline{\Omega};\mathbb{R}^d)$ with ${\rm D}\widehat{\varphi}(x) \in {\rm GL}_+(\mathbb{R}^d)$ for all $x \in \overline{\Omega}$. The integrability power q in ${\rm W}^{1,q}$ will be chosen larger than the space dimension d in order to apply the theory of polyconvexity. The loading can then be considered as a function $\ell : [0,T] \to {\rm W}^{1,q}(\Omega,\mathbb{R}^d)^*$, where * denotes the dual space (space of all continuous linear forms).

The set of admissible internal states is simply

$$\mathcal{Z} = \{\, z : \Omega \to \mathfrak{G} \times \mathbb{R}^m \mid z \text{ measurable} \,\}. \tag{2.13}$$

Because of the image space, which is a manifold, it is not clear whether it is reasonable to consider $\mathcal{Z}$ as a subset of a Banach space like $L^1(\Omega,\mathbb{R}^{d\times d}\times\mathbb{R}^m)$. It rather seems natural to equip $\mathcal{Z}$ with the metric $\mathcal{D}$ and use arguments of general metric spaces. Nevertheless, our analysis will be based on states $z = (P,p) \in \mathcal{Z}$ with $P \in {\rm L}^{q_P}(\Omega,\mathbb{R}^{d\times d})$ for a suitable $q_P > 1$. However, the topology on the set $\mathcal{Z}$ will not be important.

DEFINITION 2.1. *A process $(\varphi,z) : [0,T] \to \mathcal{F}\times\mathcal{Z}$ is called a solution of the elasto-plastic problem defined via $\mathcal{E}(t,\cdot,\cdot)$ and $\mathcal{D}$ if the stability condition* (S) *and the energy inequality* (E) *hold:*

(S) *For all $t \in [0,T]$ we have*
$\mathcal{E}(t,\varphi(t),z(t)) \le \mathcal{E}(t,\widetilde{\varphi},\widetilde{z}) + \mathcal{D}(z(t),\widetilde{z})$ *for all $(\widetilde{\varphi},\widetilde{z}) \in \mathcal{F}\times\mathcal{Z}$.*

(E) *For all $s,t \in [0,T]$ with $s < t$ we have*

$$\mathcal{E}(t,\varphi(t),z(t)) + {\rm Diss}(z,[s,t]) \le \mathcal{E}(s,\varphi(s),z(s)) - \int_s^t \langle \dot{\ell}(r),\varphi(r)\rangle \,{\rm d}r. \tag{2.14}$$

Here $-\int_s^t \langle \dot{\ell},\varphi\rangle \,{\rm d}r = \int_s^t \langle \ell,\dot{\varphi}\rangle \,{\rm d}r - \langle \ell,\varphi\rangle|_s^t$ is called the reduced work of the external forces, since $\mathcal{E}$ denotes the Gibbs energy instead of the Helmholtz energy. The dissipation is defined as

$${\rm Diss}(z,[s,t]) = \sup\left\{ \sum_{j=1}^N \mathcal{D}(z(t_{j-1}),z(t_j)) \mid N \in \mathbb{N}, s \le t_0 < \cdots < t_N \le t \right\}$$

for general processes, which equals ${\rm Diss}(z,[s,t]) = \int_s^t \int_\Omega \Delta(z(r,x),\dot{z}(r,x)) \,{\rm d}x \,{\rm d}t$ for differentiable processes.

The major advantage of the energetic formulation via (S) and (E) is that derivatives of neither the constitutive functions W and Δ nor the solution $({\rm D}\varphi,z)$ are needed. Nevertheless, (S) and (E) are strong enough to determine the physically relevant solutions. We refer to [MiT03] for uniqueness results under additional convexity assumptions. Moreover, it is shown in [Mie03a] that sufficiently smooth solutions (φ,z) of (S) and (E) satisfy the classical equations of elasto-plasticity, namely, the *equilibrium equation*

$$\begin{cases} -\operatorname{div} T(t,x) = f_{\rm ext}(t,x) & \text{in } \Omega, \\ \varphi(t,x) = Y_{\rm Dir}(x) & \text{on } \Gamma_{\rm Dir}, \\ T(t,x)\nu(x) = g_{\rm ext}(t,x) & \text{on } \Gamma_{\rm Neu}, \end{cases} \tag{2.15}$$

with $T(t,x) = \frac{\partial}{\partial F} W({\rm D}\varphi(t,x),z(t,x)) = \frac{\partial}{\partial F_{\rm elast}} \widehat{W}({\rm D}\varphi(t,x)P(t,x)^{-1},p(t,x))P(t,x)^{-\mathsf{T}}$, and the *flow rule*

$$0 \in \partial_{\dot{z}}^{\rm sub} \Delta(z(t,x),\dot{z}(t,x)) - Q(t,x), \tag{2.16}$$

where $\partial^{\rm sub}_{\dot z}\Delta(z,\dot z)$ denotes the subgradient of the convex function $\Delta(z,\cdot):\mathrm{T}_z(\mathfrak{G}\times\mathbb{R}^m)\to[0,\infty]$ and Q is the driving force thermodynamically conjugated to z, i.e.,

$$Q=-\frac{\partial}{\partial(P,p)}W(F,(P,p))=\left(P^{-\mathsf{T}}F^{\mathsf{T}}\frac{\partial}{\partial F_{\rm elast}}\widehat{W}(FP^{-1},p)P^{-\mathsf{T}},-\frac{\partial}{\partial p}\widehat{W}(FP{-}1,p)\right).$$

Defining the elastic domain as $\mathbb{Q}(z)=\partial^{\rm sub}_{\dot z}\Delta(z,0)\subset\mathrm{T}^*_z(\mathfrak{G}\times\mathbb{R}^m)$, the Legendre–Fenchel transform shows that (2.16) is equivalent to

$$\dot z\in\partial\mathcal{X}_{\mathbb{Q}(z)}(Q)=\mathrm{N}_Q\mathbb{Q}(z). \tag{2.17}$$

If $\mathbb{Q}(z)$ is given by a yield function Φ in the form

$$\mathbb{Q}(z)=\{\,Q\mid\Phi(z,Q)\le 0\,\}$$

and $\frac{\partial}{\partial Q}\Phi(z,Q)\neq 0$ at $\Phi(z,Q)=0$, then (2.17) can be reformulated via the Karush–Kuhn–Tucker conditions

$$\dot z=\lambda\frac{\partial}{\partial Q}\Phi(z,Q),\quad \lambda\ge 0,\quad \Phi(z,Q)\le 0,\quad \lambda\Phi(z,Q)=0.$$

3. Incremental problems. Until now no existence theory for the time-continuous problem (S)–(E) was available, except for the case $d=1$ given in section 5 below. Following the abstract developments in [MiT03] and the applications of the same energetic approach to models for shape-memory alloys [MTL02, MiR03], it is clear that for proving existence results for the highly nonlinear problem (S)–(E) it is essential to provide an existence theory for suitable associated time-discretized problems. Moreover, such incremental problems are the basis of all engineering simulations and, hence, provide a first step to the mathematical understanding of elasto-plasticity.

It was realized in [OrR99, ORS00, CHM02, Mie03a, Mie04] that existence of solutions for the incremental problem is not to be expected in general situations. In fact, nonexistence can be connected either with failure of the material due to localization (e.g., in shear bands) or fracture or with formation of microstructure in material domains of positive measure. Here we present constitutive assumptions which allow us to prove existence of solutions for each incremental step.

We now start with the mathematical analysis and recall that $\mathcal{F}$ and $\mathcal{Z}$ are defined in (2.12) and (2.13), respectively. Consider a time discretization $0=t_0<t_1<\cdots<t_{N-1}<t_N=T$ of the interval $[0,T]$. Moreover, assume that an initial state $(\varphi_0,z_0)\in\mathcal{F}\times\mathcal{Z}$ is given which is stable according to (S) at $t=0$.

(IP) Incremental Problem:
For $k=1,\dots,N$ find $(\varphi_k,z_k)\in\mathcal{F}\times\mathcal{Z}$ such that
$(\varphi_k,z_k)\in\operatorname{Arg\,min}\{\,\mathcal{E}(t_k,\varphi,z)+\mathcal{D}(z_{k-1},z)\mid(\varphi,z)\in\mathcal{F}\times\mathcal{Z}\,\}$. (3.1)

Here "Arg min" denotes the set of global minimizers. The main point is to show that this set is nonempty, i.e., there exists $(\varphi_k,z_k)\in\mathcal{F}\times\mathcal{Z}$ such that

$$\mathcal{E}(t_k,\varphi_k,z_k)+\mathcal{D}(z_{k-1},z_k)=\inf\{\,\mathcal{E}(t_k,\varphi,z)+\mathcal{D}(z_{k-1},z)\mid(\varphi,z)\in\mathcal{F}\times\mathcal{Z}\,\}.$$

We say that the minimum of $\mathcal{E}(t_k,\cdot,\cdot)+\mathcal{D}(z_{k-1},\cdot)$ is attained at the minimizer (φ_k,z_k).

Before we start the analysis of (IP) we first establish a result which emphasizes the fact that the given incremental problem is the most natural one. In particular, it

illuminates the positive role of the dissipation distance $\mathcal{D}$, which is difficult to characterize, as it is defined only implicitly via Δ in (2.8). However, replacing $\mathcal{D}(z_{k-1}, z)$ in (IP) by some approximation (e.g., $\Delta(z_{k-1}, z_k - z)$) would destroy at least one of the three estimates provided in (i) and (ii) below.

THEOREM 3.1. *Let $(\varphi_k, z_k)_{k=0,\dots,N}$ be any solution of* (IP). *Then the following discrete versions of* (S) *and* (E) *hold:*

(i) *For $k = 0, \dots, N$ the state (φ_k, z_k) is stable at t_k, i.e.,*

$$\mathcal{E}(t_k, \varphi_k, z_k) \le \mathcal{E}(t_k, \widetilde{\varphi}, \widetilde{z}) + \mathcal{D}(z_k, \widetilde{z}) \text{ for all } (\widetilde{\varphi}, \widetilde{z}) \in \mathcal{F} \times \mathcal{Z}.$$

(ii) *For all $s, t \in \{ t_j \mid j = 0, 1, \dots, N \}$ with $s < t$ we have*

$$\begin{aligned} -\int_s^t \langle \dot{\ell}(r), \varphi^{\mathrm{cl}}(r) \rangle \, \mathrm{d}r &\le \mathcal{E}(t, \varphi^{\mathrm{cr}}(t), z^{\mathrm{cr}}(t)) + \mathrm{Diss}(z^{\mathrm{cr}}, [s,t]) - \mathcal{E}(s, \varphi^{\mathrm{cr}}(s), z^{\mathrm{cr}}(s)) \\ &\le -\int_s^t \langle \dot{\ell}(r), \varphi^{\mathrm{cr}}(r) \rangle \, \mathrm{d}r. \end{aligned}$$

Here, φ^{cr} and φ^{cl} are the piecewise constant interpolants which are continuous from the right "cr" and from the left "cl", i.e., $\varphi^{\mathrm{cr}}(t) = \varphi_{k-1}$ for $t \in [t_{k-1}, t_k)$ and $\varphi^{\mathrm{cl}}(t) = \varphi_k$ for $t \in (t_{k-1}, t_k]$ with $\varphi^{\mathrm{cr}}(t_N) = \varphi_N$ and $\varphi^{\mathrm{cl}}(t_0) = \varphi_0$. Hence,

$$\int_{t_j}^{t_k} \langle \dot{\ell}(r), \varphi^{\mathrm{cr}}(r) \rangle \, \mathrm{d}r = \sum_{i=j+1}^{k} \langle \ell(t_i) - \ell(t_{i-1}), \varphi_{i-1} \rangle,$$

and with the same notation for z^{cr} we have $\mathrm{Diss}(z^{\mathrm{cr}}, [t_j, t_k]) = \sum_{i=j+1}^{k} \mathcal{D}(z_{i-1}, z_i)$.

The proof does not need any specific assumptions on the function space $\mathcal{F} \times \mathcal{Z}$ or on the functionals $\mathcal{E}$ and $\mathcal{D}$, since it assumes the existence of a solution. Essential to the proof are the minimization property and the triangle inequality (2.9) for $\mathcal{D}$.

Proof. To simplify the proof we write $y_k = (\varphi_k, z_k)$ and $\widetilde{y} = (\widetilde{\varphi}, \widetilde{z})$.

(i) For arbitrary $\widetilde{y} \in \mathcal{F} \times \mathcal{Z}$ and $k \in \{1, \dots, N\}$ we have

$$\begin{aligned} &\mathcal{E}(t_k, \widetilde{y}) + \mathcal{D}(z_k, \widetilde{z}) = \mathcal{E}(t_k, \widetilde{y}) + \mathcal{D}(z_{k-1}, \widetilde{z}) + \mathcal{D}(z_k, \widetilde{z}) - \mathcal{D}(z_{k-1}, \widetilde{z}) \\ &\ge \mathcal{E}(t_k, y_k) + \mathcal{D}(z_{k-1}, z_k) + \mathcal{D}(z_k, \widetilde{z}) - \mathcal{D}(z_{k-1}, \widetilde{z}) \ge \mathcal{E}(t_k, y_k), \end{aligned}$$

where the first estimate follows since y_k is a minimizer and the second estimate follows from the triangle inequality for $\mathcal{D}$.

(ii) The lower estimate follows since y_{i-1} is stable at t_{i-1}:

$$\begin{aligned} &-\int_{t_{i-1}}^{t_i} \langle \dot{\ell}(r), \varphi^{\mathrm{cl}}(r) \rangle \, \mathrm{d}r = -\langle \ell(t_i), \varphi_i \rangle + \langle \ell(t_{i-1}), \varphi_i \rangle \\ &= \mathcal{E}(t_i, y_i) - \mathcal{E}(t_{i-1}, y_i) = \mathcal{E}(t_i, y_i) - \mathcal{E}(t_{i-1}, y_{i-1}) + \mathcal{E}(t_{i-1}, y_{i-1}) - \mathcal{E}(t_{i-1}, y_i) \\ &\le \mathcal{E}(t_i, y_i) - \mathcal{E}(t_{i-1}, y_{i-1}) + \mathcal{D}(z_{i-1}, z_i). \end{aligned}$$

Summing over i from $j+1$ to k gives the lower estimate. The upper estimate follows similarly since y_i is a minimizer at t_i:

$$\mathcal{E}(t_i, y_i) - \mathcal{E}(t_{i-1}, y_{i-1}) + \mathcal{D}(z_{i-1}, z_i) \le \mathcal{E}(t_i, y_{i-1}) - \mathcal{E}(t_{i-1}, y_{i-1}) = -\int_{t_{i-1}}^{t_i} \langle \dot{\ell}, \varphi^{\mathrm{cr}} \rangle \, \mathrm{d}r.$$

Thus, the result is proved. ∎

We now study the existence of solutions to (IP). For this we need specific properties of the space $\mathcal{F} \times \mathcal{Z}$ and strong conditions on the functionals $\mathcal{E}$ and $\mathcal{D}$. In each time step we have to solve the global minimization problem for the functional $\mathcal{I}_k : \mathcal{F} \times \mathcal{Z} \to \mathbb{R}_\infty$, given as

$$\mathcal{I}_k(\varphi, z) := \int_\Omega [W(\mathrm{D}\varphi(x), z(x)) + D(z_{k-1}(x), z(x))]\,\mathrm{d}x - \langle \ell(t_k), \varphi \rangle. \tag{3.2}$$

The special structure here is that $z \in \mathcal{Z}$ occurs under the integral only with its point values and that no derivatives of z appear. We note that $\mathcal{I}_k : \mathcal{F} \times \mathcal{Z} \to \mathbb{R}_\infty$ is not lower semicontinuous because of the geometric nonlinearity coming from the multiplicative decomposition, i.e., $W(F, (P, p)) = \widehat{W}(FP^{-1}, p)$. It is shown in [FKP94, LDR00] that lower semicontinuity of $\mathcal{I}_k$ implies cross-quasi-convexity of

$$(F, P, p) \mapsto W(F, (P, p)) + D(z_{k-1}(x), (P, p)),$$

which in turn implies convexity in $z = (P, p)$. However, this can only be achieved if $F_{\mathrm{elast}} \mapsto \widehat{W}(F_{\mathrm{elast}})$ is convex, but this contradicts the standard axioms of finite-strain elasto-plasticity; see [CHM02] and below.

Of course, lower semicontinuity of $\mathcal{I}_k$ is not necessary, and we may obtain minimizers without it. The idea is that we can minimize with respect to z for each point $x \in \Omega$ separately. To prepare the following result we define the *condensed energy density*

$$W^{\mathrm{cond}}(z_{\mathrm{old}}; F) = \min\{\, W(F, z) + D(z_{\mathrm{old}}, z) \mid z \in \mathfrak{G} \times \mathbb{R}^m \,\}$$

and the condensed functional

$$\mathcal{I}_k^{\mathrm{cond}}(\varphi) = \int_\Omega W^{\mathrm{cond}}(z_{k-1}(x); \mathrm{D}\varphi(x))\,\mathrm{d}x - \langle \ell(t_k), \varphi \rangle.$$

According to [EkT76, Chap. VIII, sect. 1.6] we can choose a measurable *update function*

$$\begin{aligned} &z^{\mathrm{upd}} : (\mathfrak{G} \times \mathbb{R}^m) \times \mathbb{R}^{d\times d} \to \mathfrak{G} \times \mathbb{R}^m \text{ with} \\ &z^{\mathrm{upd}}(z_{\mathrm{old}}; F) \in Z(z_{\mathrm{old}}; F) := \operatorname{Arg\,min}\{\, W(F, z) + D(z_{\mathrm{old}}, z) \mid z \in \mathfrak{G} \times \mathbb{R}^m \,\}, \end{aligned}$$

i.e., $W^{\mathrm{cond}}(z_{\mathrm{old}}; F) = (W(F, z) + D(z_{\mathrm{old}}, z))|_{z = z^{\mathrm{upd}}(z_{\mathrm{old}}; F)}$.

LEMMA 3.2. *Let W and D be nonnegative, measurable functions, such that for each $(z_{\mathrm{old}}; F)$ the function $z \mapsto W(F, z) + D(z_{\mathrm{old}}, z)$ is coercive. Then W^{cond} and z^{upd} as above are well defined. Moreover, we have the following:*

(a) *For all $(\varphi, z) \in \mathcal{F} \times \mathcal{Z}$ we have $\mathcal{I}_k^{\mathrm{cond}}(\varphi) \le \mathcal{I}_k(\varphi, z)$ with equality if and only if $z(x) \in Z(z_{k-1}(x); \mathrm{D}\varphi(x))$ for a.a. $x \in \Omega$.*

(b) *A pair $(\varphi, z) \in \mathcal{F} \times \mathcal{Z}$ minimizes $\mathcal{I}_k$ in (3.2) if and only if φ is a minimizer of $\mathcal{I}_k^{\mathrm{cond}} : \mathcal{F} \to \mathbb{R}_\infty$ and $z(x) \in Z(z_{k-1}(x); \mathrm{D}\varphi(x))$ for a.a. $x \in \Omega$.*

(c) *If $\widetilde{\varphi} \in \mathcal{F}$ minimizes $\mathcal{I}_k^{\mathrm{cond}}$ and $\widetilde{z} \in \mathcal{Z}$ satisfies $\widetilde{z}(x) = z^{\mathrm{upd}}(z_{k-1}(x); \mathrm{D}\widetilde{\varphi}(x))$, then $(\widetilde{\varphi}, \widetilde{z})$ minimizes $\mathcal{I}_k$.*

Proof. Part (a) is obvious, as $W^{\mathrm{cond}}(z_{k-1}; F) \le W(F, z) + D(z_{k-1}, z)$.

For part (b) first assume that $(\varphi, z) \in \mathcal{F} \times \mathcal{Z}$ minimizes $\mathcal{I}_k$ and let $A = \{\, x \in \Omega \mid z(x) \in Z(z_{k-1}(x); \mathrm{D}\varphi(x)) \,\}$. Outside of A we can change z, while keeping φ fixed, such that the integrand $W + D$ becomes strictly smaller. However, decreasing an integrand strictly on a set of positive measure decreases the integral $\mathcal{I}_k$. Hence, A must have measure 0.

Assume that φ minimizes $\mathcal{I}^{\mathrm{cond}}$ and that $z \in \mathcal{Z}$ is given such that A has full measure in Ω. Then $W^{\mathrm{cond}} = W + D$ on A implies $\mathcal{I}_k^{\mathrm{cond}}(\varphi) = \mathcal{I}_k(\varphi, z)$. With part (a) we conclude that (φ, z) minimizes $\mathcal{I}_k$.

Part (c) is obtained exactly the same way, as now $A = \Omega$. ∎

This simple lemma shows that each step in the incremental problem (IP) reduces to a classical variational problem of nonlinear elasticity. Using the multiplicative decomposition (2.3) and the plastic indifference of the dissipation (2.10) we immediately see that W^{cond} satisfies

$$W^{\mathrm{cond}}((P_{\mathrm{old}}, p_{\mathrm{old}}); F) = W^{\mathrm{cond}}((\mathbf{1}, p_{\mathrm{old}}); FP_{\mathrm{old}}^{-1}), \tag{3.3}$$

and thus it is uniquely determined by $W^{\mathrm{cond}}((\mathbf{1}, \cdot); \cdot) : \mathbb{R}^m \times \mathbb{R}^{d\times d} \to \mathbb{R}_\infty$. Similarly, we may choose z^{upd} such that it satisfies

$$z^{\mathrm{upd}}((P_{\mathrm{old}}, p_{\mathrm{old}}); F) = z^{\mathrm{upd}}((\mathbf{1}, p_{\mathrm{old}}); FP_{\mathrm{old}}^{-1}) \begin{pmatrix} P_{\mathrm{old}} & 0 \\ 0 & 1 \end{pmatrix}. \tag{3.4}$$

We now list all assumptions which are stated in terms of W^{cond} and D. Thus, the assumptions are quite implicit, since in practice the stored-energy density W and the dissipation potential Δ are given. From Δ one has to calculate the dissipation distance $D(\cdot, \cdot)$ and then the condensed energy density W^{cond}. However, currently there are no conditions on W and Δ which are known to be sufficient for our conditions. In the next section we provide an example where all these conditions are satisfied.

$$\begin{cases} \text{(i)} & W^{\mathrm{cond}}((\mathbf{1}, \cdot); \cdot) : \mathbb{R}^m \times \mathbb{R}^{d\times d} \to [0, \infty] \text{ and } D(\cdot, \cdot) : (\mathfrak{G} \times \mathbb{R}^m)^2 \to [0, \infty] \\ & \text{are lower semicontinuous.} \\ \text{(ii)} & \text{For each } p \in \mathbb{R}^m \text{ the function } W^{\mathrm{cond}}((\mathbf{1}, p), \cdot) : \mathbb{R}^{d\times d} \to [0, \infty] \\ & \text{is polyconvex.} \\ \text{(iii)} & \text{There exist } C, c > 0, p_* \in \mathbb{R}^m \text{ and exponents } q_F, q_P \geq 1 \text{ such that} \\ & \qquad D((\mathbf{1}, p_*), (P, p)) \geq c|P|^{q_P} - C \\ & \text{for all } (P, p), \text{and} \\ & \qquad W^{\mathrm{cond}}((\mathbf{1}, p); F) \geq c|F|^{q_F} - C \\ & \text{for all } (F, P, p) \text{ with } D((\mathbf{1}, p_*), (P, p)) < \infty. \\ \text{(iv)} & z^{\mathrm{upd}}((\mathbf{1}, \cdot); \cdot) : \mathbb{R}^m \times \mathbb{R}_+^{d\times d} \to \mathfrak{G} \times \mathbb{R}^m \text{ is Borel measurable.} \end{cases} \tag{3.5}$$

Note that we do not need any additional assumptions on W or Δ.

THEOREM 3.3. *Let the assumptions* (3.5) *be satisfied such that additionally*

$$\frac{1}{q_F} + \frac{1}{q_P} \leq \frac{1}{q} < \frac{1}{d}$$

holds, where q occurs in the definition of $\mathcal{F}$ in (2.12).

Then, for each $z_0 \in \mathcal{Z}$ with $\mathcal{D}((\mathbf{1}, p_*), z_0) = \int_\Omega D((\mathbf{1}, p_*), (P_0(x), p_0(x)))\,\mathrm{d}x < \infty$ and each $\ell \in \mathrm{C}^0([0, T], \mathrm{W}^{1,q}(\Omega, \mathbb{R}^d)^*)$ the incremental problem (IP) *(see* (3.1)*) has a solution $((\varphi_k, z_k))_{k=1,\ldots,N}$ with*

$$\varphi_k \in \mathcal{F} \subset \mathrm{W}^{1,q}(\Omega, \mathbb{R}^d) \quad \textit{and} \quad z_k = z^{\mathrm{upd}}(z_{k-1}; \mathrm{D}\varphi_k(\cdot)) \in \mathcal{Z} \cap \mathrm{L}^{q_P}(\Omega, \mathbb{R}^{d\times d}).$$

Proof. Obviously, the result is proved by induction over $k = 1, 2, \ldots, N$.

For the kth step we assume that $z_{k-1} \in \mathcal{Z}$ is known to satisfy $\mathcal{D}((\mathbf{1}, p_*), z_{k-1}) < \infty$, which certainly holds for $k = 1$. With (3.5)(iii) we conclude $P_{k-1} \in \mathrm{L}^{q_P}(\Omega, \mathbb{R}^{d\times d})$. By Lemma 3.2, the kth minimization problem for $\mathcal{I}_k$ (cf. (3.2)) reduces to minimization of $\mathcal{I}_k^{\mathrm{cond}} : \mathcal{F} \to \mathbb{R}_\infty$, where $\mathcal{I}_k^{\mathrm{cond}}(\varphi) = \int_\Omega W_k(x, \mathrm{D}\varphi(x))\,\mathrm{d}x - \langle \ell(t_k), \varphi\rangle$ with

$$W_k(x, F) = W^{\mathrm{cond}}(z_{k-1}(x); F) = W^{\mathrm{cond}}((\mathbf{1}, p_{k-1}(x)); FP_{k-1}(x)^{-1}).$$

Clearly, $W_k : \Omega \times \mathbb{R}^{d\times d} \to [0, \infty]$ is measurable in x and lower semicontinuous in F. Moreover, by (3.5)(iii) we have the lower bound

$$\begin{aligned} W_k(x, F) &\geq c|FP_{k-1}(x)^{-1}|^{q_F} - C \\ &\geq \frac{cq_F}{q}|F|^q - c\left(\frac{q_F}{q} - 1\right)|P_{k-1}(x)|^{q_F q/(q_F - q)} - c, \end{aligned}$$

where we have used $|FP^{-1}| \geq |F|/|P|$ and $|a/b|^{q_F} \geq ra^{q_F/r} - (r-1)b^{q_F/(r-1)}$ with $r = q_F/q > 1$. Using the assumption $\frac{1}{q_P} \leq \frac{1}{q} - \frac{1}{q_F}$ we conclude $W_k(x, F) \geq \widetilde{c}|F|^q - h(x)$ for $\widetilde{c} > 0$ and $h \in \mathrm{L}^1(\Omega)$. Hence, W_k is coercive.

Moreover, the minors (of order s) of the product FP_{k-1}^{-1} are in fact linear combinations of products of the minors (of order s) of F and P_{k-1}^{-1}. Since by (3.5)(ii) W^{cond} is polyconvex we conclude that $F \mapsto W_k(x, F)$ is polyconvex as well.

The existence theory of Ball [Bal76, Bal77] provides $\varphi_k \in \mathcal{F} \subset \mathrm{W}^{1,q}(\Omega, \mathbb{R}^d)$ such that $\mathcal{I}_k^{\mathrm{cond}}(\varphi_k) = \inf\{\, \mathcal{I}_k^{\mathrm{cond}}(\varphi) \mid \varphi \in \mathcal{F}\,\}$. By Lemma 3.2 we see that (φ_k, z_k) with $z_k = z^{\mathrm{upd}}(z_{k-1}; \mathrm{D}\varphi_k) \in \mathcal{Z}$ minimizes $\mathcal{I}_k : \mathcal{F} \times \mathcal{Z} \to \mathbb{R}_\infty$.

To finish the induction we have to show $\mathcal{D}((\mathbf{1}, p_*), z_k) < \infty$. To see this we use the triangle inequality for $\mathcal{D}$ and the minimization property of (φ_k, z_k) in the form of the energy estimate as in part (ii) of Theorem 3.1. We have

$$\begin{aligned} &\mathcal{D}((\mathbf{1}, p_*), z_k) \leq \mathcal{D}((\mathbf{1}, p_*), z_{k-1}) + \mathcal{D}(z_{k-1}, z_k) \\ &\leq \mathcal{D}((\mathbf{1}, p_*), z_{k-1}) + \mathcal{I}_{k-1}^{\mathrm{cond}}(\varphi_{k-1}) - \mathcal{I}_k^{\mathrm{cond}}(\varphi_k) + \langle \ell(t_{k-1}) - \ell(t_k), \varphi_{k-1}\rangle < \infty. \end{aligned}$$

This concludes the induction step, and hence the whole proof. ∎

4. A two-dimensional example. The purpose of this section is to supply a multidimensional example with $\mathfrak{G} = \mathrm{SL}(\mathbb{R}^d)$ where all assumptions of the previous section can be fulfilled. Unfortunately, our example only works in $d = 2$, since it depends on the fact that everything can be calculated explicitly.

We consider the isotropic elastic energy density

$$W : \left\{ \begin{array}{rcl} \mathbb{R}^{2\times 2} & \to & \mathbb{R}_\infty, \\ F & \mapsto & \frac{1}{\alpha}(\nu_1^\alpha + \nu_2^\alpha) + V(\det F), \end{array} \right. \tag{4.1}$$

where $\nu_1, \nu_2 \geq 0$ are the two singular values of F (i.e., the eigenvalues of $(F^{\mathsf{T}}F)^{1/2}$) and $V : \mathbb{R} \to [0, \infty]$ is convex and continuous and satisfies

$$V(\delta) = \infty \text{ for } \delta \leq 0, \quad V(\delta) \nearrow \infty \text{ for } \delta \searrow 0.$$

For the plastic variables we take $z = (P, p) \in \mathrm{SL}(2) \times \mathbb{R}$ with the dissipation metric

$$\Delta(P, p, \dot{P}, \dot{p}) = \left\{ \begin{array}{ll} A'(p)\|\dot{P}P^{-1}\| & \text{for } \dot{p} \geq \|\dot{P}P^{-1}\|, \\ \infty & \text{else.} \end{array} \right. \tag{4.2}$$

Here, $\|\cdot\|$ denotes the classical Euclidean norm on $\mathfrak{g} \subset \mathbb{R}^{2\times 2}$, i.e., $\|\xi\|^2 = \sum_{i,j=1}^{2} \xi_{ij}^2$, and $A(p) = \mathrm{e}^{\beta p}$ for $\beta > 0$. The associated dissipation distance D is plastically invariant and isotropic, i.e.,

$$D((RP_0\widehat{P}, p_0), (RP_1\widehat{P}, p_1)) = D((P_0, p_0), (P_1, p_1))$$

for all arguments. From the analysis in [Mie02, HMM03, Mie03a] we know that

$$D((\mathbf{1}, p_0), (E(s), p_1)) = \begin{cases} \mathrm{e}^{\beta(p_0+\sqrt{2}|s|)} - \mathrm{e}^{\beta p_0} & \text{for } p_1 \geq p_0+\sqrt{2}|s|, \\ \infty & \text{else,} \end{cases} \tag{4.3}$$

where $E(s) = \mathrm{diag}(\mathrm{e}^s, \mathrm{e}^{-s})$, and, for all $R, \widehat{R} \in \mathrm{SO}(2)$,

$$D((\mathbf{1}, p_0), (RE(s)\widehat{R}, p_1)) \geq D((\mathbf{1}, p_0), (E(s), p_1)). \tag{4.4}$$

With this information, it is shown in [Mie03a] that the condensed stored-energy density takes the form

$$W^{\mathrm{cond}}((\mathbf{1}, p); F) = \min_{s\in\mathbb{R}} \frac{1}{\alpha}((\mathrm{e}^{-s}\nu_1)^\alpha + (\mathrm{e}^s\nu_2)^\alpha) + V(\nu_1\nu_2) + \mathrm{e}^{p\beta}(\mathrm{e}^{\sqrt{2}\beta|s|} - 1).$$

To see this, one uses the isotropy of W and D together with (4.4) to deduce that the minimum in W^{cond} with $F = \mathrm{diag}(\nu_1, \nu_2)$ is attained for $P = E(s) = \mathrm{diag}(\mathrm{e}^s, \mathrm{e}^{-s})$ for some $s \in \mathbb{R}$.

The minimum over $s \in \mathbb{R}$ can be evaluated explicitly if we choose $\beta = \alpha/\sqrt{2}$. This gives the final form

$$W^{\mathrm{cond}}((\mathbf{1}, p); F) = V(\nu_1\nu_2) - \mathrm{e}^{\alpha p/\sqrt{2}} + \begin{cases} \frac{2}{\alpha}\sqrt{\nu_1^\alpha(\nu_2^\alpha + b_p)} & \text{for } \nu_1^\alpha \geq \nu_2^\alpha + b_p, \\ \frac{1}{\alpha}(\nu_1^\alpha + \nu_2^\alpha + b_p) & \text{for } |\nu_1^\alpha - \nu_2^\alpha| \leq b_p, \\ \frac{2}{\alpha}\sqrt{\nu_2^\alpha(\nu_1^\alpha + b_p)} & \text{for } \nu_2^\alpha \geq \nu_1^\alpha + b_p, \end{cases}$$

where $b_p = \alpha\mathrm{e}^{\alpha p/\sqrt{2}}$. Moreover, the update functions can be given explicitly as well. With the auxiliary function

$$S(\nu, p) = \begin{cases} -\frac{1}{2\alpha}\log\frac{\nu_1^\alpha}{\nu_2^\alpha + b_p} & \text{for } \nu_1^\alpha \geq \nu_2^\alpha + b_p, \\ 0 & \text{for } |\nu_1^\alpha - \nu_2^\alpha| \leq b_p, \\ \frac{1}{2\alpha}\log\frac{\nu_2^\alpha}{\nu_1^\alpha + b_p} & \text{for } \nu_2^\alpha \geq \nu_1^\alpha + b_p, \end{cases}$$

we find the update functions (for $\det F = \nu_1\nu_2 > 0$)

$$P^{\mathrm{upd}}((\mathbf{1}, p_0); F) = R_F^{-1}E(S(\nu, p_0))R_F \quad \text{and} \quad p^{\mathrm{upd}}((\mathbf{1}, p_0); F) = p_0 + \sqrt{2}|S(\nu, p_0)|,$$

where $\nu_1, \nu_2 > 0$ and R_F are defined via $F = \widehat{R}\,\mathrm{diag}(\nu_1, \nu_2)R_F$ with $\widehat{R}, R_F \in \mathrm{SO}(2)$. Both update functions are locally Lipschitz continuous since R_F is uniquely defined where $S(\nu, p) \neq 0$.

We summarize the properties of W^{cond} and D in the following proposition, which establishes the conditions (3.5).

PROPOSITION 4.1. *Let W and Δ be defined as above with $\beta = \alpha/\sqrt{2}$. Then the following hold:*

(i) $W^{\mathrm{cond}}((\mathbf{1}, \cdot); \cdot) : \mathbb{R} \times \mathbb{R}^{2\times 2} \to \mathbb{R}_\infty$ *is continuous and* $D(\cdot, \cdot) : (\mathrm{SL}(2) \times \mathbb{R})^2 \to [0, \infty]$ *is lower semicontinuous.*

(ii) *For $\alpha \geq 2$ and $p \in \mathbb{R}$ the function $W^{\mathrm{cond}}((\mathbf{1},p);\cdot) : \mathbb{R}^{2\times d} \to \mathbb{R}_\infty$ is polyconvex.*

(iii) *For all $F \in \mathbb{R}^{2\times 2}, p_*, p \in \mathbb{R}$, and $P \in \mathrm{SL}(2)$ with $D((\mathbf{1},p_*),(P,p)) < \infty$ we have*

$$D((\mathbf{1},p_*),(P,p)) \geq \frac{\mathrm{e}^{\alpha p_*/\sqrt{2}}}{2}\Big(\|P\|^\alpha - 1\Big),$$
$$W^{\mathrm{cond}}((\mathbf{1},p);F) \geq \frac{1}{\alpha}\Big(\sqrt{b_p}\, 2^{1-\alpha/2}\, \|F\|^{\alpha/2} - b_p\Big).$$

(iv) *The update function $z^{\mathrm{upd}} = (P^{\mathrm{upd}}, p^{\mathrm{upd}})$ is continuous.*

Proof. Parts (i) and (iv) are immediate from the definitions and formulas. Part (ii) is the most difficult part; its proof is given in [Mie03b].

To prove the lower estimates in (iii) we first note that $P \in \mathrm{SL}(2)$ has the form $P = R_1 \operatorname{diag}(g, 1/g) R_2 = R_1 E(\log g) R_2$. With (4.3) and (4.4) we obtain

$$D((\mathbf{1},p_*),(P,p)) \geq \mathrm{e}^{\alpha p_*/\sqrt{2}}(\mathrm{e}^{\alpha|\log g|} - 1).$$

Using $\|P\| = \sqrt{g^2 + 1/g^2} \leq \sqrt{2}\max\{g, 1/g\} = \sqrt{2}\mathrm{e}^{|\log g|}$ gives the first estimate. For the second estimate we use the explicit form of $W^{\mathrm{cond}}((\mathbf{1},p);F)$ and $V \geq 0$ to find the lower estimate $\frac{2}{\alpha}\sqrt{b_p}(\max\{\nu_1,\nu_2\})^{\alpha/2}$. With $\|F\| = \sqrt{\nu_1^2+\nu_2^2} \leq \sqrt{2}\max\{\nu_1,\nu_2\}$ the desired estimate follows. ∎

Thus, we have shown that this example satisfies the assumptions (3.5) for $\alpha \geq 2$ with $q_F = \alpha/2$ and $q_P = \alpha$. Hence, Theorem 3.3 is applicable if

$$\frac{1}{2} = \frac{1}{d} > \frac{1}{q} \geq \frac{1}{q_F} + \frac{1}{q_P} = \frac{3}{\alpha}$$

holds. We summarize the existence result for this example in the following statement.

THEOREM 4.2. *Let $d = 2$ and $\mathfrak{G} = \mathrm{SL}(2)$. With $\alpha > 6$ and $\beta = \alpha/\sqrt{2}$ let $W : \mathbb{R}^{2\times 2} \to [0,\infty]$ and $\Delta : \mathrm{T}(\mathfrak{G}\times\mathbb{R}) \to [0,\infty]$ be defined via (4.1) and (4.2), respectively. Assume that there exists a $p_* \in \mathbb{R}$ such that the initial condition $z_0 \in \mathcal{Z}$ satisfies $\mathcal{D}((\mathbf{1},p_*),z_0) < \infty$ and let $q = \alpha/3$.*

Then for each $\ell : [0,T] \to (\mathrm{W}^{1,\alpha/3}(\Omega,\mathbb{R}^2))^*$ the incremental problem (IP) (see (3.1)) has a solution $((\varphi_k,z_k))_{k=1,\dots,N} \in (\mathcal{F}\times\mathcal{Z})^N$. Moreover, there exists a constant C which depends only on α, ℓ, and z_0, but neither on the partition $t_1,\dots,t_N$ nor on the solution, such that

$$\|\varphi_k\|_{\mathrm{W}^{1,\alpha/3}} + \|P_k\|_{\mathrm{L}^\alpha} + \|\mathrm{e}^{\alpha p_k/\sqrt{2}}\|_{\mathrm{L}^1} \leq C \text{ for } k = 1,\dots,N.$$

5. A one-dimensional example. The one-dimensional case is quite special and much simpler for two reasons. First, polyconvexity is equivalent to convexity, and, second, the equilibrium equation is an ordinary differential equation which can be solved easily. Nevertheless this case is interesting, since we will be able to discuss the problems with convergence for step size going to 0 of the incremental solutions towards a solution of the time-continuous problem (S)–(E); see (2.14). We will see that general arguments, which are available in higher space dimensions as well, are not sufficient. In section 6, using the special one-dimensional structure, we then prove convergence (of a subsequence) and obtain finally an existence result for (S)–(E).

Again we treat a special case, but far more general constitutive laws W and Δ could be considered. We let

$$W(F) = \begin{cases} \frac{1}{\alpha}(F^\alpha + F^{-\alpha}) & \text{for } F > 0, \\ \infty & \text{else,} \end{cases}$$

$\mathfrak{G} = \mathrm{GL}_+(1) = (0,\infty)$, $z = (P,p) \in \mathfrak{G} \times \mathbb{R}$, and

$$\Delta((P,p),(\dot P,\dot p)) = \begin{cases} \alpha \mathrm{e}^{\alpha p}\dot p & \text{for } \dot p \geq |\dot P/P|, \\ \infty & \text{else.} \end{cases}$$

As in the previous section (see also [Mie03a]), we obtain the dissipation distance

$$\mathcal{D}((P_0,p_0),(P_1,p_1)) = \begin{cases} \mathrm{e}^{\alpha p_1} - \mathrm{e}^{\alpha p_0} & \text{for } p_1 \geq p_0 + |\log P_1/P_0|\,, \\ \infty & \text{else.} \end{cases}$$

From this we find the condensed stored-energy density

$$W^{\mathrm{cond}}((1,p);F) = \frac{1}{\alpha}\begin{cases} 2\sqrt{1+b_pF^\alpha} - b_p & \text{for } F^\alpha \geq b_p + F^{-\alpha}, \\ F^\alpha + F^{-\alpha} & \text{for } |F^\alpha - F^{-\alpha}| \leq b_p, \\ 2\sqrt{1+b_pF^{-\alpha}} - b_p & \text{for } F^{-\alpha} \geq b_p + F^\alpha, \\ \infty & \text{for } F \leq 0, \end{cases} \tag{5.1}$$

where $b_p = \alpha \mathrm{e}^{\alpha p}$. For $F > 0$ the update functions read

$$P^{\mathrm{upd}}((1,p);F) = \begin{cases} F/(1+b_pF^\alpha)^{1/(2\alpha)} & \text{for } F^\alpha \geq b_p + F^{-\alpha}, \\ 1 & \text{for } |F^\alpha - F^{-\alpha}| \leq b_p, \\ F\,(1+b_pF^{-\alpha})^{1/(2\alpha)} & \text{for } F^{-\alpha} \geq b_p + F^\alpha; \end{cases}$$

$$z^{\mathrm{upd}}((1,p);F) = p + \left|\log P^{\mathrm{upd}}((1,p);F)\right|.$$

As in section 4 we see that the abstract theory of section 3 applies for $\alpha > 3$ since $q_F = \alpha/2$ and $q_P = \alpha$ in condition (3.5).

We consider the one-dimensional domain $\Omega = (0,1) \subset \mathbb{R}^1$. The space $\mathcal{F}^q$ of admissible deformation may be either $\mathcal{F}^q_{\mathrm{displ}} = \mathrm{W}^{1,q}_0(\Omega) = \{\,\varphi \in \mathrm{W}^{1,q}(\Omega) \mid \varphi(0) = \varphi(1) = 0\,\}$ or $\mathcal{F}^q_{\mathrm{tract}} = \{\,\varphi \in \mathrm{W}^{1,q}(\Omega) \mid \varphi(0) = 0\,\}$. The loading takes the form

$$\langle \ell(t), \varphi\rangle = \int_0^1 h_{\mathrm{ext}}(t,x)\varphi(x)\,\mathrm{d}x + \sigma_1(t)\varphi(1) = \int_0^1 H_{\mathrm{ext}}(t,x)\varphi'(x)\,\mathrm{d}x,$$

where $H_{\mathrm{ext}}(t,x) = \sigma_1(t) + \int_x^1 h_{\mathrm{ext}}(t,\widetilde{x})\,\mathrm{d}\widetilde{x}$ and $\varphi'(x) = \mathrm{D}\varphi(x) \in \mathbb{R}^{1\times 1}$. At this point it suffices to assume $H_{\mathrm{ext}} \in \mathrm{C}^0([0,T]\times\overline{\Omega})$.

PROPOSITION 5.1. *Fix $\alpha > 3$ and $p_* \in \mathbb{R}$. Then the above one-dimensional model generates an incremental problem* (IP) *as above, and* (IP) *has, for each $z_0 \in \mathcal{Z}$ with $\mathcal{D}((1,p_*),z_0) < \infty$, a unique solution $(\varphi_k,z_k)_{k=1,\dots,N}$.*

Moreover, there exists $C > 0$, which depends only on α, ℓ, and z_0, such that

$$\|\varphi_k\|_{\mathrm{W}^{1,\alpha/3}} + \|P_k\|_{\mathrm{L}^\alpha} + \|P_k^{-1}\|_{\mathrm{L}^\alpha} + \|\mathrm{e}^{\alpha p_k}\|_{\mathrm{L}^1} \leq C \text{ for } k = 1,\dots,N. \tag{5.2}$$

Proof. Using Lemma 3.2 φ_k is a minimizer of the condensed functional $\mathcal{I}^{\mathrm{cond}}_k$ which is based on W^{cond}; see (5.1). Because of $\alpha > 3$, this density, and hence the functional $\mathcal{I}^{\mathrm{cond}}_k$, is strictly convex. Hence, φ_k is uniquely defined for given z_{k-1} and t_k.

For given F and z_{k-1}, the set $\operatorname{Arg\,min}\{\,W(FP)+D(z_{k-1},(P,p))\,|\,(P,p) \in (0,\infty)\times\mathbb{R}\,\}$ contains just one point. Hence, z_k is also uniquely defined. By induction we conclude uniqueness of the whole solution to (IP).

Estimate (5.2) follows the standard energy estimates as given in section 3. ∎

Finally we want to discuss the problem of establishing convergence for the step size $\max\{\, t_k - t_{k-1} \mid k = 1, \dots, N \,\}$ going to 0. In [MiT99, MTL02, MiT03, MaM03] conditions are given which guarantee that from the sequence of the piecewise constant interpolants

$$(\varphi_{\mathrm{cr}}^N, z_{\mathrm{cr}}^N) : \left\{ \begin{array}{ccc} [0,T) & \to & \mathcal{F} \times \mathcal{Z}, \\ t & \mapsto & \sum_{k=0}^{N-1} \chi_{[t_k, t_{k+1})}(t)(\varphi^k, z^k) \end{array} \right. \tag{5.3}$$

a subsequence can be extracted which converges to a solution $(\varphi, z) : [0,T] \to \mathcal{F} \times \mathcal{Z}$ of the time-continuous problem (S)–(E); see (2.14). The dissipation $\mathcal{D}$ can be used to bound possible oscillations in time yielding temporal compactness. The problem is to control possible spatial oscillation, i.e., in $x \in \Omega$.

A crucial tool developed there (see also [Efe03, MaM03, MiR03]) is the set of stable states

$$\mathcal{S}_{[0,T]} = \{\, (t, \varphi, z) \in [0,T] \times \mathcal{F} \times \mathcal{Z} \mid \text{ for all } \widetilde{\varphi}, \widetilde{z} : \mathcal{E}(t, \varphi, z) \le \mathcal{E}(t, \widetilde{\varphi}, \widetilde{z}) + \mathcal{D}(z, \widetilde{z}) \,\}.$$

The important condition in the abstract theory developed in the above-mentioned papers is that any limit $(\varphi, z) : [0,T] \to \mathcal{F} \times \mathcal{Z}$ of the subsequence $(\varphi^{N_m}(t), z^{N_m}(t)) \to (\varphi(t), z(t))$ occurs in a topology in which the stable set $\mathcal{S}_{[0,T]}$ is closed. We want to study this question in our explicit one-dimensional example now.

For simplicity, we restrict ourselves to the traction case $\mathcal{F} = \mathcal{F}_{\mathrm{tract}}^{\alpha/3}$, which allows us to characterize $\mathcal{S}_{[0,T]}$ explicitly. A similar result was obtained already in [Mie03a].

LEMMA 5.2. *In the above one-dimensional example $(t, \varphi, P, p) \in \mathcal{S}_{[0,T]}$ if and only if for a.a. $x \in \Omega$ we have*

$$|(\varphi'/P)^\alpha - (\varphi'/P)^{-\alpha}| \le \alpha \mathrm{e}^{\alpha p} \text{ and } ((\varphi'/P)^{\alpha-1} - (\varphi'/P)^{-\alpha-1})/P = H_{\mathrm{ext}}(t, \cdot). \tag{5.4}$$

Proof. Stability of (t, φ, z) is equivalent to the fact that (φ, z) is a global minimizer of $J : (\widetilde{\varphi}, \widetilde{z}) \mapsto \mathcal{E}(t, \widetilde{\varphi}, \widetilde{z}) + \mathcal{D}(z, \widetilde{z})$. Minimizing with respect to $\widetilde{z} \in \mathcal{Z}$ leads to the condensed functional

$$J^{\mathrm{cond}} : \widetilde{\varphi} \mapsto \int_\Omega W^{\mathrm{cond}}(z(x); \widetilde{\varphi}'(x)) \, \mathrm{d}x - \langle \ell(t), \widetilde{\varphi} \rangle.$$

For $\widetilde{\varphi} = \varphi$ we know that this minimum is attained for $\widetilde{z} = z$, and hence we know

$$W^{\mathrm{cond}}(z(x); \varphi'(x)) = W(\varphi'(x)/P(x)) \text{ for a.a. } x \in \Omega. \tag{5.5}$$

This gives the first condition in (5.4).

Since φ minimizes J^{cond} we have $\mathrm{D}J^{\mathrm{cond}}(\varphi) = 0$, which implies the second condition in (5.4), after using (5.5) once again. Thus, we conclude that (5.4) is necessary. The sufficiency follows from the convexity. ∎

Defining the two-dimensional subsets $M(t,x)$ of $\mathbb{R}^3$ via

$$M(t,x) = \Big\{ (F,P,p) \in (0,\infty)^2 \times \mathbb{R} \;\Big|\; \begin{array}{l} \big|(\frac{F}{P})^\alpha - (\frac{F}{P})^{-\alpha}\big| \le \alpha \mathrm{e}^{\alpha p}, \\ (\frac{F}{P})^{\alpha-1} - (\frac{F}{P})^{-\alpha-1} = P\, H_{\mathrm{ext}}(t,x) \Big\} \subset \mathbb{R}^3, \end{array}$$

the stability condition (5.4) can be reformulated as

$$(\varphi'(x), P(x), p(x)) \in M(t,x) \text{ for a.a. } x \in \Omega.$$

We note that the sets $M(t,x)$ are closed but not convex in $\mathbb{R}^3$. Hence, $\mathcal{S}_{[0,T]}$ is closed in the strong topology of $[0,T]\times\mathcal{F}\times\mathcal{Z}\subset\mathbb{R}\times \mathrm{W}^{1,\alpha/3}(\Omega)\times \mathrm{L}^\alpha(\Omega)\times \mathrm{L}^\alpha(\Omega)$.

However, $\mathcal{S}_{[0,T]}$ is not closed in the weak topology of this Banach space. Yet, so far the a priori estimate (5.2) is the only one available, and from it we obtain just weak convergence (at fixed times $t\in[0,T]$):

$$
\begin{aligned}
\varphi^{N_m}(t) &\rightharpoonup \varphi(t) && \text{in } \mathrm{W}^{1,\alpha/3}(\Omega),\\
\frac{\partial}{\partial x}(\varphi^{N_m}(t))P^{N_m}(t)^{-1} &\rightharpoonup F_{\mathrm{elast}}(t) && \text{in } \mathrm{L}^\alpha(\Omega),\\
P^{N_m}(t) &\rightharpoonup P(t) && \text{in } \mathrm{L}^\alpha(\Omega),\\
P^{N_m}(t)^{-1} &\rightharpoonup K(t) && \text{in } \mathrm{L}^\alpha(\Omega),\\
z^{N_m}(t) &\rightharpoonup p(t) && \text{in } \mathrm{L}^\alpha(\Omega).
\end{aligned}
\tag{5.6}
$$

However, this does not imply $\varphi'(t,x)/P(t,x)=F_{\mathrm{elast}}(t,x)$ or $P(t,x)^{-1}=K(t,x)$ for a.a. $x\in\Omega$, which would be needed to conclude from $((\varphi^{N_m})',P^{N_m},p^{N_m})\in M(t,x)$ the desirable condition $(\varphi',P,p)\in M(t,x)$.

Thus, the convergence of the incremental solutions can be shown only by establishing convergence in stronger topologies. Below we will show that the solutions $(\frac{\mathrm{d}}{\mathrm{d}x}\varphi^k,P_k,p_k)$ converge pointwise in $[0,T]\times\Omega$.

Before providing this result, we want to mention another abstract approach to obtain strong convergence, which is implemented in section 7 of [MiT03]. It relies on the reduced problem where only the internal variable z is kept, whereas the deformation φ is minimized out. We define

$$
\mathcal{I}^{\mathrm{red}}(t,z)=\min\{\,\mathcal{E}(t,\varphi,z)\mid\varphi\in\mathcal{F}\,\}.
$$

In the case of $\mathcal{F}=\mathcal{F}^{\alpha/3}_{\mathrm{tract}}$ this minimization can be made explicit, since $\mathcal{E}$ contains φ only via φ'. We denote by W^* the Legendre–Fenchel transform of W, i.e.,

$$
W^*(\sigma)=\sup\{\,\sigma F-W(F)\mid F\in\mathbb{R}\,\}.
\tag{5.7}
$$

Then $W^*:\mathbb{R}\to\mathbb{R}$ is convex and satisfies $W^*(\sigma)\sim\frac{1}{\alpha_+}\sigma^{\alpha_+}$ for $\sigma\to+\infty$ and $W^*(\sigma)\sim-\frac{1}{\alpha_-}(-\sigma)^{\alpha_-}$ for $\sigma\to-\infty$, where $\alpha_\pm=\frac{\alpha}{\alpha\mp1}$. Moreover, a simple calculation gives

$$
\mathcal{I}^{\mathrm{red}}(t,z)=-\int_0^1 W^*(H_{\mathrm{ext}}(t,x)P(x))\,\mathrm{d}x.
$$

Unfortunately, this functional is concave in P. Hence, the strong convergence theory in the uniformly convex case is not applicable.

6. Convergence in the one-dimensional case. To derive a convergence result we use the very specific structure of the one-dimensional traction problem with $\mathcal{F}=\mathcal{F}^{\alpha/3}_{\mathrm{tract}}$. As already used in Lemma 5.2 the incremental problem has the special property that it can be solved independently for each point $x\in\Omega$ to obtain $(F_k,P_k,p_k)=(\frac{\mathrm{d}}{\mathrm{d}x}\varphi_k(x),P_k(x),p_k(x))$ as the solution of the finite-dimensional, x-dependent minimization problem

$$
\begin{aligned}
&(F_k(x),P_k(x),p_k(x))\\
&\in \operatorname*{Arg\,min}_{(F,P,p)\in\mathbb{R}^3} W(F/P)-H_{\mathrm{ext}}(t_k,x)F+D((P_{k-1}(x),p_{k-1}(x)),(P,p)),
\end{aligned}
$$

which has a unique solution.

We now additionally assume $z_0 = (P_0, p_0) \in \mathrm{C}^0(\overline{\Omega}, \mathbb{R}^2)$ with $P_0(x) > 0$ for all $x \in \overline{\Omega}$. Moreover, the loading should satisfy $H_{\mathrm{ext}} \in \mathrm{C}^1([0,T] \times \overline{\Omega})$. Using energy estimates as for Proposition 5.1, we find a constant $C > 0$, which is independent of $x \in \overline{\Omega}$ and the time discretization, such that all incremental solutions satisfy

$$|F_k(X)| + |P_k(x)| + |1/P_k(x)| + |p_k(x)| \le C \tag{6.1}$$

for all $x \in \overline{\Omega}$ and $k = 0, 1, \dots, N$.

From now on we omit the x-dependence in most cases and use the shorthand $H_k = H_{\mathrm{ext}}(t_k, x)$. Introducing the logarithm $\gamma = \log P$ and eliminating F, we are left with the following incremental problem in $\mathbb{R}^2$:

$$(\gamma_k, p_k) \in \operatorname{Arg\,min}\{\, D((\mathrm{e}^{\gamma_{k-1}}, p_{k-1}), (\mathrm{e}^{\gamma}, p)) - W^*(\mathrm{e}^{\gamma} H_k) \mid \gamma, p \in \mathbb{R} \,\}.$$

Because of the special form of D, this reduces to a scalar problem

$$\begin{aligned} &\gamma_k \in \operatorname{Arg\,min}\{\, \mathrm{e}^{\alpha(p_{k-1} + |\gamma - \gamma_{k-1}|)} - W^*(\mathrm{e}^{\gamma} H_k) \mid \gamma \in \mathbb{R} \,\}, \\ &p_k = p_{k-1} + |\gamma_k - \gamma_{k-1}|. \end{aligned} \tag{6.2}$$

This problem can be solved almost explicitly by using monotonicity arguments relying on the total ordering of the real line.

The essential scalar variable is $\zeta_{k-1}^{\pm} = \gamma_{k-1} \mp p_{k-1} + \log(\pm H_k)$, which allows us to write the iteration (6.2) in the form

$$\begin{pmatrix} \gamma_k \\ p_k \end{pmatrix} = \begin{cases} \begin{pmatrix} \Gamma_+(\zeta_{k-1}^+) - \log H_k \\ \Gamma_+(\zeta_{k-1}^+) - \zeta_{k-1}^+ \end{pmatrix} & \text{if } \Gamma_+(\zeta_{k-1}^+) > \gamma_{k-1} + \log H_k, \\ \begin{pmatrix} \gamma_{k-1} \\ p_{k-1} \end{pmatrix} & \text{if } \Gamma_+(\zeta_{k-1}^+) \le \gamma_{k-1} + \log |H_k| \le \Gamma_-(\zeta_{k-1}^-), \\ \begin{pmatrix} \Gamma_-(\zeta_{k-1}^-) - \log(-H_k) \\ \zeta_{k-1}^- - \Gamma_-(\zeta_{k-1}^-) \end{pmatrix} & \text{if } \Gamma_-(\zeta_{k-1}^-) < \gamma_{k-1} + \log(-H_k), \end{cases} \tag{6.3}$$

where $\Gamma_{\pm}(\zeta) = \operatorname{Arg\,min}\{\, \mathrm{e}^{\pm\alpha(\gamma - \zeta)} - W^*(\pm \mathrm{e}^{\gamma}) \mid \gamma \in \mathbb{R} \,\}$.

We call the first case, where $\gamma_k > \gamma_{k-1}$, plastic loading and the third case, where $\gamma_k < \gamma_{k-1}$, plastic unloading. In the second case the plastic variables do not change. The major observation is that if in a time interval the solution stays either always in cases one and two or always in cases two and three, then the solution can be calculated directly from the initial data when entering this time interval and the loading history, but one does not need to know the solution in between. In particular, the number of steps done in between is irrelevant. We now make this precise.

With $\Gamma_{\pm}(\zeta) \sim \alpha_{\pm}\zeta$ for $\zeta \to -\infty$, $\alpha_- < 1 < \alpha_+$, and the a priori estimate (6.1) we find a constant $H^* > 0$ such that $|H_k| \le H^*$ implies that the second case (no change in the plastic variables) occurs. We now decompose the time interval $[0,T]$ into a finite number of subintervals $J_m = [\tau_{m-1}, \tau_m]$ with $0 = \tau_0 \le \tau_1 < \tau_2 < \cdots < \tau_M = T$ such that $H^* + (-1)^m H(t) \ge 0$ for all $t \in J_m$. For the given time discretization $0 = t_0 < t_1 < \cdots < t_N = T$ we define, for $m = 1, \dots, M$, the exit times $t_{j_m} \in J_m$ of the subintervals J_m via

$$j_0 = 0 \quad \text{and} \quad j_m = \max\{\, k \mid t_k \le \tau_m \,\}.$$

On the subintervals J_m we change the loading H_k into a monotone version $\widetilde{H}_k$, which is defined for $t_k \in J_m$ via

$$\widetilde{H}_k = (-1)^m \max\{\, (-1)^m H(t_n) \mid n \in \{j_{m-1}, \dots, k\} \,\}. \tag{6.4}$$

Hence $(-1)^m \widetilde{H}_k$ is nondecreasing for $k = j_{m-1}, \dots, j_m$.

By induction over the subintervals and by induction over the number of steps inside each subinterval, we obtain the following representation formula.

PROPOSITION 6.1. *Let m be even and $t_k \in J_m$. Then the solution takes the form*

$$\begin{pmatrix} \gamma_k \\ p_k \end{pmatrix} = \begin{pmatrix} \Gamma_+(\gamma_{j_{m-1}} - p_{j_{m-1}} + \log \widetilde{H}_k) - \log \widetilde{H}_k \\ \Gamma_+(\gamma_{j_{m-1}} - p_{j_{m-1}} + \log \widetilde{H}_k) - \gamma_{j_{m-1}} + p_{j_{m-1}} - \log \widetilde{H}_k \end{pmatrix}. \tag{6.5}$$

A similar formula using Γ_- holds for m odd; cf. (6.3).

Finally, we obtain the desired convergence result, which is formulated in terms of functions over $x \in \Omega = (0,1) \subset \mathbb{R}^1$.

THEOREM 6.2. *Consider the one-dimensional traction problem of section* 5 *with $\alpha > 2$ and $H_{\mathrm{ext}} \in \mathrm{C}^1([0,T] \times \overline{\Omega})$. Then there exists a function $(\varphi, P, p) \in \mathrm{C}^0([0,T], \mathrm{W}^{1,\infty}(\Omega) \times \mathrm{L}^\infty(\Omega)^2)$, which is a solution of* (S)–(E) *(cf.* (2.14)*). Moreover, there exists a constant $C > 0$ such that for each time discretization $0 = t_0 < t_1 < \cdots < t_N = T$ the unique solution $(\varphi_k, P_k, p_k)_{k=0,\ldots,N}$ of the incremental problem* (3.1) *satisfies, for $k = 1, \ldots, N$,*

$$\|\varphi(t_k,\cdot) - \varphi_k\|_{\mathrm{W}^{1,\infty}} + \|P(t_k,\cdot) - P_k\|_{\mathrm{L}^\infty} + \|p(t_k,\cdot) - p_k\|_{\mathrm{L}^\infty} \\ \leq C \max\{\, t_n - t_{n-1} \mid n = 1, \ldots, k \,\}.$$

Proof. We use the fact that Proposition 6.1 can be applied in a uniform manner for $x \in \overline{\Omega}$.

First, consider the division into subintervals J_m. Since H_{ext} is continuous, the sets Σ_+ and Σ_- with

$$\Sigma_\pm = \{\, (t,x) \in [0,T] \times \overline{\Omega} \mid \pm H_{\mathrm{ext}}(t,x) \geq H^* \,\}$$

are strictly separated. Because of this, the only restrictions to the subintervals are $J_m(x) \supset \Sigma_+ \cap ([0,T] \times \{x\})$ for even m and $J_m(x) \supset \Sigma_- \cap ([0,T] \times \{x\})$ for odd m. Hence, it is possible to choose the intervals piecewise constant on a finite number of subintervals $\Omega_l = (x_{l-1}, x_l)$. In particular, the number of time intervals $J_m(x)$, $m = 1, \ldots, M_l$, is bounded from above.

Second, we apply the formula (6.5). To show convergence we define the function $\widetilde{H}_{\mathrm{ext}}$ as in (6.4):

$$\widetilde{H}_{\mathrm{ext}}(t,x) = (-1)^m \max\{\, (-1)^m H_{\mathrm{ext}}(s,x) \mid s \in J_m(x) \cap [0,t] \,\}.$$

By Lipschitz continuity of $H_{\mathrm{ext}}(\cdot, x)$ we obtain

$$|\widetilde{H}_k(x) - \widetilde{H}_{\mathrm{ext}}(t_k,x)| \leq C_1 \delta_k \quad \text{with } \delta_k = \max\{\, t_n - t_{n-1} \mid n = 1, \ldots, k \,\}$$

for a constant C_1 independent of $x \in \Omega$ and the partition.

Now, we may take a sequence of partitions $0 < t_1^{N_l} < \cdots < t_{N_l}^{N_l}$ such that the fineness $\widetilde{\delta}_l := \delta_{N_l}^{N_l}$ tends to 0. Now, the exit points $t_{j_m^l(x)}^{N_l}$ have a distance to the end points $\tau_m(x)$ of the intervals $J_m(x)$ of at most $\widetilde{\delta}_l$. Moreover, by induction over m we find that $(\gamma_{j_m^l(x)}(x), p_{j_m^l(x)}(x))$ converges for $l \to \infty$. The limits, called $(\widetilde{\gamma}_m(x), \widetilde{p}_m(x))$, satisfy the recursion

$$\begin{pmatrix} \widetilde{\gamma}_m \\ \widetilde{p}_m \end{pmatrix} = \begin{pmatrix} \Gamma_+(\widetilde{\gamma}_{m-1} - \widetilde{p}_{m-1} + \log \widetilde{H}_{\mathrm{ext}}(\tau_m)) - \log \widetilde{H}_{\mathrm{ext}}(\tau_m) \\ \Gamma_+(\widetilde{\gamma}_{m-1} - \widetilde{p}_{m-1} + \log \widetilde{H}_{\mathrm{ext}}(\tau_m)) - \widetilde{\gamma}_{m-1} + \widetilde{p}_{m-1} - \log \widetilde{H}_{\mathrm{ext}}(\tau_m) \end{pmatrix}$$

for even m and similarly for odd m. The error is bounded by $C_2\widetilde{\delta}_l$, since $\Gamma_\pm$ are Lipschitz continuous.

Third, we define the function $(\gamma, p) : [0,T] \times \Omega \to \mathbb{R}^2$ via

$$\begin{pmatrix} \gamma(t,x) \\ p(t,x) \end{pmatrix} = \begin{pmatrix} \Gamma_+(\widetilde{\gamma}_{m-1}(x) - \widetilde{p}_{m-1}(x) + \log \widetilde{H}_{\rm ext}(t,x)) - \log \widetilde{H}_{\rm ext}(t,x) \\ \Gamma_+(\widetilde{\gamma}_{m-1}(x) - \widetilde{p}_{m-1}(x) + \log \widetilde{H}_{\rm ext}(t,x)) - \widetilde{\gamma}_{m-1}(x) + \widetilde{p}_{m-1}(x) - \log \widetilde{H}_{\rm ext}(t,x) \end{pmatrix}$$

for $t \in J_m(x)$. By our construction the incremental solutions $(t_k^{N_l}, \gamma_k^{N_l}(x), p_k^{N_l}(x))$ converge to $(t, \gamma(t,x), p(t,x))$ with an error bounded by $C_3\delta_l$, uniformly on $[0,T] \times \Omega$.

Finally, it remains to show that (γ, p) define a solution of (S)–(E). Let $\widehat{F}(P,H)$ be the unique minimizer of $F \mapsto W(F/P) - HF$. Then the desired function (φ, P, p) is obtained from (γ, p) via

$$P(t,x) = \mathrm{e}^{\gamma(t,x)} \quad \text{and} \quad \varphi(t,x) = \int_0^x \widehat{F}(P(t,\xi), H_{\rm ext}(t,\xi))\,\mathrm{d}\xi.$$

Since the function $\widehat{F}$ is also Lipschitz continuous, we obtain uniform convergence of the (unique) incremental solutions towards this limit function. Now we use the abstract theorem, Theorem 3.1, which guarantees that the incremental solutions are stable and satisfy the discrete version of the energy inequality. The characterization of the stable sets in Lemma 5.2 show that uniform limits (with pointwise convergence almost everywhere) are stable again, i.e., $(t, \varphi(t), P(t), p(t)) \in \mathcal{S}_{[0,T]}$ for each $t \in [0,T]$. Thus, (S) is established.

Similarly, we start from the discrete energy inequality (ii) in Theorem 3.1 for the incremental solutions (φ^{N_l}, z^{N_l}). For $l \to \infty$ the uniform convergence guarantees that all terms converge:

$$\mathcal{E}(t, \varphi(t), z(t)) + \mathrm{Diss}(z, [s,t]) = \mathcal{E}(s, \varphi(s), z(s)) - \int_s^t \int_\Omega \partial_t H_{\rm ext}(\tau,\xi) \partial_x \varphi(\tau,\xi)\,\mathrm{d}\xi\,\mathrm{d}\tau.$$

For the convergence of the dissipation, uniform convergence is not sufficient. There we use that the piecewise constant interpolants $P^{\rm cr}(\cdot, x)$ are monotone in t when restricted to the subintervals $J_m(x)$ and that $p^{\rm cr}(\cdot, x)$ is always monotone. This, together with the uniform convergence, implies convergence of the dissipation as well. This establishes (E) as an energy equality. ∎

RENORMALIZED ENTROPY SOLUTIONS FOR QUASI-LINEAR ANISOTROPIC DEGENERATE PARABOLIC EQUATIONS*

MOSTAFA BENDAHMANE† AND KENNETH H. KARLSEN†‡

Abstract. We prove the well-posedness (existence and uniqueness) of renormalized entropy solutions to the Cauchy problem for quasi-linear anisotropic degenerate parabolic equations with L^1 data. This paper complements the work by Chen and Perthame [*Ann. Inst. H. Poincaré Anal. Non Linéaire*, 20 (2003), pp. 645–668], who developed a pure L^1 theory based on the notion of kinetic solutions.

Key words. degenerate parabolic equation, quasi-linear, anisotropic diffusion, entropy solution, renormalized solution, uniqueness, existence

1. Introduction.

We consider the Cauchy problem for quasi-linear anisotropic degenerate parabolic equations with L^1 data. This convection–diffusion-type problem is of the form

$$\partial_t u + \operatorname{div} f(u) = \nabla \cdot (a(u)\nabla u) + F, \qquad u(0,x) = u_0(x), \tag{1.1}$$

where $(t,x) \in (0,T) \times \mathbf{R}^d$; $T > 0$ is fixed; div and ∇ are with respect to $x \in \mathbf{R}^d$; and $u = u(t,x)$ is the scalar unknown function that is sought. The (initial and source) data $u_0(x)$ and $F(t,x)$ satisfy

$$u_0 \in L^1(\mathbf{R}^d), \qquad F \in L^1((0,T) \times \mathbf{R}^d). \tag{1.2}$$

The diffusion function $a(u) = (a_{ij}(u))$ is a symmetric $d \times d$ matrix of the form

$$a(u) = \sigma(u)\sigma(u)^\top \geq 0, \qquad \sigma \in \left(L^\infty_{\mathrm{loc}}(\mathbf{R})\right)^{d \times K}, \qquad 1 \leq K \leq d, \tag{1.3}$$

and hence has entries

$$a_{ij}(u) = \sum_{k=1}^{K} \sigma_{ik}(u)\sigma_{jk}(u), \qquad i,j = 1,\dots,d.$$

The inequality in (1.3) means that for all $u \in \mathbf{R}$

$$\sum_{i,j=1}^{d} a_{ij}(u)\lambda_i\lambda_j \geq 0 \qquad \forall \lambda = (\lambda_1,\dots,\lambda_d) \in \mathbf{R}^d.$$

Finally, the convection flux $f(u)$ is a vector-valued function that satisfies

$$f(u) = (f_1(u),\dots,f_d(u)) \in \left(\mathrm{Lip}_{\mathrm{loc}}(\mathbf{R})\right)^d. \tag{1.4}$$

It is well known that (1.1) possesses discontinuous solutions and that weak solutions are not uniquely determined by their initial data (the scalar conservation law is a special case of (1.1)). Hence (1.1) must be interpreted in the sense of entropy solutions [16, 20, 21]. In recent years the isotropic diffusion case, for example, the equation

$$\partial_t u + \operatorname{div} f(u) = \Delta A(u), \quad A(u) = \int_0^u a(\xi)\, d\xi, \quad 0 \le a \in L^\infty_{\mathrm{loc}}(\mathbf{R}), \tag{1.5}$$

has received much attention, at least when the data are regular enough (say $L^1 \cap L^\infty$) to ensure $\nabla A(u) \in L^2$. Various existence results for entropy solutions of (1.5) (and (1.1)) can be derived from the work by Vol'pert and Hudjaev [21]. Some general uniqueness results for entropy solutions have been proved in the one-dimensional context by Wu and Yin [22] and Bénilan and Touré [2]. In the multidimensional context a general uniqueness result is more recent and was proved by Carrillo [6, 5] using Kružkov's doubling-of-variables device. Various extensions of his result can be found in [4, 13, 14, 15, 17, 18, 19]; see also [7] for a different approach. Explicit "continuous dependence on the nonlinearities" estimates were proved in [10]. In the literature just cited it is essential that the solutions u possess the regularity $\nabla A(u) \in L^2$. This excludes the possibility of imposing general L^1 data, since it is well known that in this case one cannot expect that much integrability.

The general anisotropic diffusion case (1.1) is more delicate and was successfully solved only recently by Chen and Perthame [9]. Chen and Perthame introduced the notion of kinetic solutions and provided a well-posedness theory for (1.1) with L^1 data. Using their kinetic framework, explicit continuous dependence and error estimates for $L^1 \cap L^\infty$ entropy solutions were obtained in [8]. With the only assumption that the data belong to L^1, we cannot expect a solution of (1.1) to be more than L^1. Hence it is in general impossible to make distributional sense to (1.1) (or its entropy formulation). In addition, as already mentioned above, we cannot expect $\sqrt{a(u)}\nabla u$ to be square-integrable, which seems to be an essential condition for uniqueness. Both these problems were elegantly dealt with in [9] using the kinetic approach.

The purpose of the present paper is to offer an alternative "pure" L^1 well-posedness theory for (1.1) based on a notion of renormalized entropy solutions and the classical Kružkov method [16]. The notion of renormalized solutions was introduced by DiPerna and Lions in the context of Boltzmann equations [11]. This notion (and a similar one called entropy solutions) was then adapted to nonlinear elliptic and parabolic equations with L^1 (or measure) data by various authors. We refer to [3] for some recent results in this context and a list of relevant references. Bénilan, Carrillo, and Wittbold [1] introduced a notion of renormalized Kružkov entropy solutions for scalar conservation laws with L^1 data and proved the existence and uniqueness of such solutions. Their theory generalizes the Kružkov well-posedness theory for L^∞ entropy solutions [16].

Motivated by [1, 3] and [9], we introduce herein a notion of renormalized entropy solutions for (1.1) and prove its well-posedness. Let us illustrate our notion of an L^1 solution on the isotropic diffusion equation (1.5) with initial data $u|_{t=0} = u_0 \in L^1$. To this end, let $T_l : \mathbf{R} \to \mathbf{R}$ denote the truncation function at height $l > 0$ and let $\zeta(z) = \int_0^z \sqrt{a(\xi)}\, d\xi$. A renormalized entropy solution of (1.5) is a function $u \in L^\infty(0,T; L^1(\mathbf{R}^d))$ such that (i) $\nabla \zeta(T_l(u))$ is square-integrable on $(0,T) \times \mathbf{R}^d$ for any $l > 0$; (ii) for any convex C^2 entropy-entropy flux triple (η, q, r), with η' bounded and $q' = \eta' f'$, $r' = \eta' a$, there exists for any $l > 0$ a nonnegative bounded Radon

measure μ_l on $(0,T)\times\mathbf{R}^d$, whose total mass tends to zero as $l\uparrow\infty$, such that

$$\begin{aligned}(1.6)\qquad &\partial_t\eta(T_l(u))+\operatorname{div}q(T_l(u))-\Delta r(T_l(u))\\ &\qquad\le -\eta''(T_l(u))\,|\nabla\zeta(T_l(u))|^2+\mu_l(t,x)\quad\text{in }\mathcal{D}'((0,T)\times\mathbf{R}^d).\end{aligned}$$

Roughly speaking, (1.6) expresses the entropy condition satisfied by the truncated function $T_l(u)$. Of course, if u is bounded by M, choosing $l>M$ in (1.6) yields the usual entropy formulation for u, i.e., a bounded renormalized entropy solution is an entropy solution. However, in contrast to the usual entropy formulation, (1.6) makes sense also when u is merely L^1 and possibly unbounded. Intuitively the measure μ_l should be supported on $\{|u|=l\}$ and carry information about the behavior of the "energy" on the set where $|u|$ is large. The requirement is that the energy should be small for large values of $|u|$, that is, the total mass of the renormalization measure μ_l should vanish as $l\uparrow\infty$. This is essential for proving uniqueness of a renormalized entropy solution. Being explicit, the existence proof reveals that

$$\mu_l((0,T)\times\mathbf{R}^d)\le\int_{\{|u_0|>l\}}|u_0|\,dx\to 0\quad\text{as } l\uparrow\infty.$$

We prove existence of a renormalized entropy solution to (1.1) using an approximation procedure based on artificial viscosity [21] and bounded data. We derive a priori estimates and pass to the limit in the approximations.

Uniqueness of renormalized entropy solutions is proved by adapting the doubling-of-variables device due to Kružkov [16]. In the first order case, the uniqueness proof of Kružkov depends crucially on the fact that

$$\nabla_x\Phi(x-y)+\nabla_y\Phi(x-y)=0,\qquad \Phi\text{ smooth function on }\mathbf{R}^d,$$

which allows for a cancellation of certain singular terms. The proof herein for the second order case relies in addition crucially on the following identity involving the Hessian matrices of $\Phi(x-y)$:

$$\nabla_{xx}\Phi(x-y)+2\nabla_{xy}\Phi(x-y)+\nabla_{yy}\Phi(x-y)=0,$$

which, when used together with the parabolic dissipation terms (like the one found in (1.6)), allows for a cancellation of certain singular terms involving the second order operator in (1.1). Compared to [9], our uniqueness proof is new even in the case of bounded entropy solutions.

The remaining part of this paper is organized as follows: In section 2 we introduce the notion of a renormalized entropy solution for (1.1) and state our main well-posedness theorem. The proof of this theorem is given in section 3 (uniqueness) and section 4 (existence).

2. Definitions and statement of main result. We start by defining an entropy-entropy flux triple.

DEFINITION 2.1 (entropy-entropy flux triple). *For any convex C^2 entropy function $\eta:\mathbf{R}\to\mathbf{R}$, the corresponding entropy fluxes*

$$q=(q_1,\dots,q_d):\mathbf{R}\to\mathbf{R}^d\quad\textit{and}\quad r=(r_{ij}):\mathbf{R}\to\mathbf{R}^{d\times d}$$

are defined by $q'(u)=\eta'(u)f'(u)$ and $r'(u)=\eta'(u)a(u)$. We will refer to (η,q,r) as an entropy-entropy flux triple.

For $1 \le k \le K$ and $1 \le i \le d$, we let

$$\zeta_{ik}(u) = \int_0^u \sigma_{ik}(\xi)\, d\xi, \qquad \zeta_k(u) = (\zeta_{1k}(u), \dots, \zeta_{dk}(u)),$$

and for any $\psi \in C(\mathbf{R})$

$$\zeta_{ik}^{\psi}(u) = \int_0^u \psi(\xi)\sigma_{ik}(\xi)\, d\xi, \qquad \zeta_k^{\psi}(u) = \left(\zeta_{1k}^{\psi}(u), \dots, \zeta_{dk}^{\psi}(u)\right).$$

Let us introduce the following set of vector fields:

$$\begin{aligned} &L^2(0,T;L^2(\mathrm{div};\mathbf{R}^d)) \\ &\quad = \left\{ w = (w_1, \dots, w_d) \in \left(L^2((0,T)\times\mathbf{R}^d)\right)^d : \mathrm{div} w \in L^2((0,T)\times\mathbf{R}^d) \right\}. \end{aligned}$$

Following [9] we define an entropy solution as follows.

DEFINITION 2.2 (entropy solution). *An entropy solution of* (1.1) *is a measurable function* $u : (0,T)\times\mathbf{R}^d \to \mathbf{R}$ *satisfying the following conditions:*

(D.1) $u \in L^\infty(0,T;L^1(\mathbf{R}^d)) \cap L^\infty((0,T)\times\mathbf{R}^d)$.

(D.2) *For any* $k = 1, \dots, K$, $\zeta_k(u) \in L^2(0,T;L^2(\mathrm{div};\mathbf{R}^d))$.

(D.3) *(chain rule) For any* $k = 1, \dots, K$ *and* $\psi \in C(\mathbf{R})$,

$$\mathrm{div}\zeta_k^{\psi}(u) = \psi(u)\mathrm{div}\zeta_k(u)$$

a.e. in $(0,T)\times\mathbf{R}^d$ *and in* $L^2((0,T)\times\mathbf{R}^d)$.

(D.4) *Define the parabolic dissipation measure* $n_l^{u,\psi}(t,x)$ *by*

$$n^{u,\psi}(t,x) = \psi(u(t,x)) \sum_{k=1}^{K} \left(\mathrm{div}\zeta_k(u(t,x))\right)^2.$$

For any entropy-entropy flux triple (η, q, r),

$$\begin{aligned} &\partial_t \eta(u) + \sum_{i=1}^{d} \partial_{x_i} q_i(u) - \sum_{i,j=1}^{d} \partial^2_{x_i x_j} r_{ij}(u) \\ &\qquad - \eta'(u)F \le -n^{u,\eta''} \quad \text{in } \mathcal{D}'((0,T)\times\mathbf{R}^d). \end{aligned} \tag{2.1}$$

(D.5) $\operatorname{ess\,lim}_{t\downarrow 0} \|u(t,\cdot) - u_0\|_{L^1(\mathbf{R}^d)} = 0$.

An important contribution of Chen and Perthame [9] is to make explicit the point that the chain rule (D.3) should be included in the definition of an entropy solution in the anisotropic diffusion case. They also note that (D.3) is automatically fulfilled when $a(u)$ is a diagonal matrix, and can then be deleted from Definition 2.2. This applies to the isotropic case (1.5).

Uniqueness of an entropy solution in the sense of Definition 2.2 was proved in [9] using a kinetic formulation and regularization by convolution. The present paper offers an alternative proof based on the more classical Kružkov method of doubling the variables [16].

Let us mention that (D.4) implies that the following Kružkov-type entropy condition holds for all $c \in \mathbf{R}$ (here $A'_{ij}(\cdot) = a_{ij}(\cdot)$):

$$\begin{aligned}&\partial_t |u-c| + \sum_{i=1}^{d} \partial_{x_i} \Big[\operatorname{sign}(u-c)\,(f_i(u) - f_i(c)) \Big] \\ &\quad - \sum_{i,j=1}^{d} \partial^2_{x_i x_j} \Big[\operatorname{sign}(u-c)\,(A_{ij}(u) - A_{ij}(c)) \Big] - \operatorname{sign}(u-c)\,F \le 0.\end{aligned} \tag{2.2}$$

In the isotropic case (1.5), (2.2) simplifies to

$$\partial_t |u-c| + \operatorname{div} \Big[\operatorname{sign}(u-c)\,(f(u) - f(c)) \Big] - \Delta\, |A(u) - A(c)| \le 0. \tag{2.3}$$

After Carrillo's work [6, 5], it is known that (2.3) implies uniqueness in the isotropic case (1.5). In the anisotropic case (1.1), (2.2) is not sufficient for uniqueness. Indeed, it is necessary to explicitly include the parabolic dissipation measure in the entropy condition, as is done in (D.4).

As we discussed in section 1, for unbounded L^1 solutions Definition 2.2 is in general not meaningful. In [9] the authors use a notion of kinetic solutions to handle this problem. It is the purpose of this paper to use instead a notion of renormalized entropy solutions. Before we can introduce this notion, let us recall the definition of the (Lipschitz continuous) truncation function $T_l : \mathbf{R} \to \mathbf{R}$ at height $l > 0$:

$$T_l(u) = \begin{cases} -l, & u < -l, \\ u, & |u| \le l, \\ l, & u > l. \end{cases} \tag{2.4}$$

We then suggest the following notion of an L^1 solution.

DEFINITION 2.3 (renormalized entropy solution). *A renormalized entropy solution of* (1.1) *is a measurable function* $u : (0,T) \times \mathbf{R}^d \to \mathbf{R}$ *satisfying the following conditions:*

(D.1) $u \in L^\infty(0,T; L^1(\mathbf{R}^d))$.

(D.2) *For any* $k = 1, \dots, K$, $\zeta_k(T_l(u)) \in L^2(0,T; L^2(\operatorname{div}; \mathbf{R}^d))$ *for all* $l > 0$.

(D.3) *(renormalized chain rule) For any* $k = 1, \dots, K$ *and* $\psi \in C(\mathbf{R})$,

$$\operatorname{div} \zeta_k^\psi(T_l(u)) = \psi(T_l(u)) \operatorname{div} \zeta_k(T_l(u))$$

a.e. in $(0,T) \times \mathbf{R}^d$ *and in* $L^2((0,T) \times \mathbf{R}^d)$ *for all* $l > 0$.

(D.4) *For* $l > 0$, *introduce the renormalized parabolic dissipation measure*

$$n_l^{u,\psi}(t,x) = \psi(T_l(u(t,x))) \sum_{k=1}^{K} \Big(\operatorname{div} \zeta_k(T_l(u(t,x))) \Big)^2.$$

For any $l > 0$ *and any entropy-entropy flux triple* (η, q, r), *with* $|\eta'|$ *bounded by* K *(for some given* K*), there exists a nonnegative bounded Radon measure* $\mu_l^{u,K}$ *on* $(0,T) \times \mathbf{R}^d$ *such that*

$$\begin{aligned}&\partial_t \eta(T_l(u)) + \sum_{i=1}^{d} \partial_{x_i} q_i(T_l(u)) - \sum_{i,j=1}^{d} \partial^2_{x_i x_j} r_{ij}(T_l(u)) \\ &\quad - \eta'(T_l(u)) F \le -n_l^{u,\eta''} + \mu_l^{u,K} \quad \text{in } \mathcal{D}'((0,T) \times \mathbf{R}^d).\end{aligned} \tag{2.5}$$

(D.5) *The total mass of the renormalization measure* $\mu_l^{u,K}$ *vanishes as* $l \uparrow \infty$*:*

$$\lim_{l\uparrow\infty} \mu_l^{u,K}((0,T)\times\mathbf{R}^d) = 0.$$

(D.6) $\operatorname{ess\,lim}_{t\downarrow 0} \|u(t,\cdot) - u_0\|_{L^1(\mathbf{R}^d)} = 0.$

Note that since $T_l(u) \in L^\infty((0,T)\times\mathbf{R}^d)$, the terms in (2.5) are all well defined. Moreover, if a renormalized entropy solution u belongs to $L^\infty((0,T)\times\mathbf{R}^d)$, then it is also an entropy solution in the sense of Definition 2.2 (let $l \uparrow \infty$ in Definition 2.3).

Our well-posedness result is contained in the following theorem, which is proved in section 3 (uniqueness) and section 4 (existence).

THEOREM 2.1 (well-posedness). *Suppose that* (1.2)*,* (1.3)*, and* (1.4) *hold. Then there exists a unique renormalized entropy solution* u *of* (1.1)*.*

It is worthwhile mentioning that Theorem 2.1 holds under merely local regularity assumptions on $f(u)$, $a(u)$. Moreover, $a(u)$ can be discontinuous, which is of interest in some applications [4].

Remark 2.1. In the isotropic case it is not necessary to include the chain rule (D.3) as a part of Definition 2.3, since it is then automatically fulfilled. Indeed, let $0 \le \sigma \in L^\infty_{\mathrm{loc}}(\mathbf{R})$ and $\psi \in L^\infty_{\mathrm{loc}}(\mathbf{R})$. Set

$$\beta(z) = \int_0^z \sigma(\xi)\,d\xi, \qquad \beta^\psi(z) = \int_0^z \psi(\xi)\sigma(\xi)\,d\xi.$$

Then, for any measurable function $u(x)$ such that $\partial_{x_i}\beta(T_l(u)) \in L^1_{\mathrm{loc}}(\mathbf{R}^d)$, for some fixed $i = 1,\dots,d$, there holds

$$\partial_{x_i}\beta^\psi(T_l(u(x))) = \psi(T_l(u(x)))\partial_{x_i}\beta(T_l(u(x))) \tag{2.6}$$

for a.e. $x \in \mathbf{R}^d$ and in $L^2_{\mathrm{loc}}(\mathbf{R}^d)$ for all $l > 0$. To establish (2.6) we can apply the proof in [9] to the function $v := \beta(T_l(u)) \in L^\infty(\mathbf{R})$, which satisfies $\partial_{x_i} v \in L^1_{\mathrm{loc}}(\mathbf{R}^d)$.

Remark 2.2 (the initial condition). In Definition 2.3 of a renormalized entropy solution we require that the initial condition at $t = 0$ be satisfied in the strong L^1 sense. When proving convergence of approximate solution sequences without having BV estimates at our disposal, it can be difficult to verify condition (D.6) for a limit function. To have a more flexible framework, the initial condition can be included into the renormalized entropy formulation, that is, delete condition (D.6) and require instead that the renormalized entropy inequality in (2.5) hold in $\mathcal{D}'([0,T)\times\mathbf{R}^d)$. In this case, the Radon measure $\mu_l^{u,K}$ should be bounded on $[0,T)\times\mathbf{R}^d$ and satisfy $\lim_{l\uparrow\infty}\mu_l^{u,K}([0,T)\times\mathbf{R}^d) = 0$. Such a weak formulation of the initial condition is much easier to verify for limits of certain approximate solution sequences. This point was made explicit in [12]; see also [13] for degenerate parabolic equations. To prove Theorem 2.1 with a weak formulation of the initial condition we simply have to combine the proof of Theorem 3.1 below with a straightforward adaptation of the arguments in [12, 13] (we leave the details to the reader). Of course, the comments above also apply to Definition 2.3 of an entropy solution.

3. Uniqueness of renormalized entropy solution. For the uniqueness proof, we need a C^1 approximation of $\operatorname{sign}(\cdot)$ and a corresponding C^2 approximation of the Kružkov entropy flux $|\cdot - c|$, $c \in \mathbf{R}$.

For $\varepsilon > 0$, set

$$\operatorname{sign}_\varepsilon(\xi) = \begin{cases} -1, & \xi < -\varepsilon, \\ \sin\left(\frac{\pi}{2\varepsilon}\xi\right), & |\xi| \le \varepsilon, \\ 1, & \xi > \varepsilon. \end{cases} \tag{3.1}$$

For each $c \in \mathbf{R}$, the corresponding entropy function

$$u \mapsto \eta_\varepsilon(u,c) = \int_c^u \operatorname{sign}_\varepsilon(\xi - c)\, d\xi$$

is convex and belongs to $C^2(\mathbf{R})$ with $\eta_\varepsilon'' \in C_c(\mathbf{R})$ and $|\eta_\varepsilon'| \le 1$ (so that the constant K appearing in Definition 2.3 is 1). Moreover, η_ε is symmetric in the sense that $\eta_\varepsilon(u,c) = \eta_\varepsilon(c,u)$ and

$$\eta_\varepsilon(u,c) \to \eta(u,c) := |u-c| \quad \text{as } \varepsilon \downarrow 0.$$

For each $c \in \mathbf{R}$ and $1 \le i,j \le d$, we define the entropy flux functions

$$\begin{aligned} u \mapsto q_i^\varepsilon(u,c) &= \int_c^u \operatorname{sign}_\varepsilon(\xi - c)\, f_i'(\xi)\, d\xi, \\ u \mapsto r_{ij}^\varepsilon(u,c) &= \int_c^u \operatorname{sign}_\varepsilon(\xi - c)\, A_{ij}'(\xi)\, d\xi, \end{aligned} \tag{3.2}$$

where $A_{ij}'(\cdot) = a_{ij}(\cdot)$ for $1 \le i,j \le d$. Then as $\varepsilon \downarrow 0$

$$\begin{aligned} q_i^\varepsilon(u,c) &\to q_i(u,c) := \operatorname{sign}(u-c)\,(f_i(u) - f_i(c)), \\ r_{ij}^\varepsilon(u,c) &\to r_{ij}(u,c) := \operatorname{sign}(u-c)\,(A_{ij}(u) - A_{ij}(c)) \end{aligned} \tag{3.3}$$

for $1 \le i,j \le d$. Let $q^\varepsilon = (q_1^\varepsilon, \dots, q_d^\varepsilon)$, $r^\varepsilon = \left(r_{ij}^\varepsilon\right)$, and similarly for q, r.

We are now ready to prove uniqueness of renormalized entropy solutions.

THEOREM 3.1 (uniqueness). *Suppose that* (1.3) *and* (1.4) *hold. Let u and v be renormalized entropy solutions of* (1.1) *with data $F \in L^1((0,T)\times\mathbf{R}^d)$, $u_0 \in L^1(\mathbf{R}^d)$ and $G \in L^1((0,T)\times\mathbf{R}^d)$, $v_0 \in L^1(\mathbf{R}^d)$, respectively. Then for a.e. $t \in (0,T)$,*

$$\begin{aligned} &\|u(\cdot,t) - v(\cdot,t)\|_{L^1(\mathbf{R}^d)} \\ &\quad \le \|u_0 - v_0\|_{L^1(\mathbf{R}^d)} + \int_0^t \|F(s,\cdot) - G(s,\cdot)\|_{L^1(\mathbf{R}^d)}\, ds. \end{aligned} \tag{3.4}$$

In particular, (1.1) *admits at most one renormalized entropy solution.*

Proof. We shall prove (3.4) using Kružkov's doubling-of-variables method [16]. When it is notationally convenient we drop the domain of integration.

Let $(\eta_\varepsilon, q_i^\varepsilon, r_{ij}^\varepsilon)$ be the entropy flux triple defined above, and denote by μ_l^u, μ_l^v the corresponding renormalization measures.

From the definition of a renormalized entropy solution for $u = u(t,x)$,

$$\begin{aligned} &\int \left(\eta_\varepsilon(T_l(u),c)\partial_t\phi + \sum_{i=1}^d q_i^\varepsilon(T_l(u),c)\partial_{x_i}\phi + \sum_{i,j=1}^d r_{ij}^\varepsilon(T_l(u),c)\partial_{x_ix_j}^2\phi \right) dx\,dt \\ &\quad - \int \operatorname{sign}_\varepsilon(T_l(u) - c)\, F(t,x)\phi\, dx\,dt \\ &\quad \ge \int n^{u,\operatorname{sign}_\varepsilon'(\cdot - c)}(t,x)\phi\, dx\,dt - \int \phi\, d\mu_l^u(t,x) \end{aligned} \tag{3.5}$$

for all $c \in \mathbf{R}$, for all $l > 0$, and for every $0 \le \phi = \phi(t,x) \in \mathcal{D}((0,T) \times \mathbf{R}^d)$.

From the definition of a renormalized entropy solution for $u = u(s,y)$,

$$
\begin{aligned}
&\int \left(\eta_\varepsilon(T_l(v),c)\partial_s\phi + \sum_{i=1}^d q_i^\varepsilon(T_l(v),c)\partial_{y_j}\phi + \sum_{i,j=1}^d r_{ij}^\varepsilon(T_l(v),c)\partial^2_{y_iy_j}\phi \right) dy\,ds \\
&\quad - \int \operatorname{sign}_\varepsilon (T_l(v)-c)\, G(s,y)\phi\, dy\,ds \\
&\qquad \ge \int n^{v,\operatorname{sign}'_\varepsilon(c-\cdot)}(s,y)\phi\, dy\,ds - \int \phi\, d\mu_l^v(s,y)
\end{aligned} \tag{3.6}
$$

for all $c \in \mathbf{R}$, for all $l > 0$, and for every $0 \le \phi = \phi(s,y) \in \mathcal{D}((0,T) \times \mathbf{R}^d)$.

Choose $c = T_l(v(s,y))$ in (3.5) and integrate over (s,y). Choose $c = T_l(u(t,x))$ in (3.6) and integrate over (t,x). Then adding the two resulting inequalities yields

$$
\begin{aligned}
&\int \Bigg(\eta_\varepsilon(T_l(u),T_l(v))\,(\partial_t+\partial_s)\,\phi \\
&\quad + \sum_{i=1}^d \left[q_i^\varepsilon(T_l(u),T_l(v))\partial_{x_i}\phi + q_i^\varepsilon(T_l(v),T_l(u))\partial_{y_i}\phi \right] \\
&\quad + \sum_{i,j=1}^d \left[r_{ij}^\varepsilon(T_l(u),T_l(v))\partial^2_{x_ix_j}\phi + r_{ij}^\varepsilon(T_l(v),T_l(u))\partial^2_{y_iy_j}\phi \right] \Bigg) dx\,dt\,dy\,ds \\
&\qquad - \int \operatorname{sign}_\varepsilon (T_l(u)-T_l(v))\,(F(t,x)-G(s,y))\; dx\,dt\,dy\,ds \\
&\qquad\quad \ge \int \left(n^{u,\operatorname{sign}'_\varepsilon(\cdot-c)}(t,x) + n^{v,\operatorname{sign}'_\varepsilon(\cdot-c)}(s,y) \right) \phi\, dx\,dt\,dy\,ds \\
&\qquad\qquad - \int \phi(t,x,s,y)\, d\mu_l^u(t,x)\, dy\,ds \\
&\qquad\qquad\quad - \int \phi(t,x,s,y)\, d\mu_l^v(s,y)\, dx\,dt,
\end{aligned} \tag{3.7}
$$

where $\phi = \phi(t,x,s,y)$ is any nonnegative function in $\mathcal{D}(((0,T) \times \mathbf{R}^d)^2)$.

We introduce next a standard mollifier sequence $\omega_\rho : \mathbf{R} \times \mathbf{R}^d \to \mathbf{R}$, $\rho > 0$, and take our test function $\phi = \phi(t,x,s,y)$ to be of the form

$$
\phi(t,x,s,y) = \varphi\left(\frac{t+s}{2}, \frac{x+y}{2}\right)\omega_\rho\left(\frac{t-s}{2}, \frac{x-y}{2}\right), \qquad \varphi \in \mathcal{D}((0,T)\times\mathbf{R}^d), \qquad 0 \le \varphi \le 1.
$$

With this choice, we have $(\partial_t+\partial_s)\,\phi = (\partial_t+\partial_s)\,\varphi\left(\frac{t+s}{2}, \frac{x+y}{2}\right)\omega_\rho\left(\frac{t-s}{2}, \frac{x-y}{2}\right)$ and $(\nabla_x+\nabla_y)\,\phi = (\nabla_x+\nabla_y)\,\varphi\left(\frac{t+s}{2}, \frac{x+y}{2}\right)\omega_\rho\left(\frac{t-s}{2}, \frac{x-y}{2}\right)$.

Introduce the Hessian matrices

$$
\nabla_{xx}\phi = \left(\partial^2_{x_ix_j}\phi\right), \quad \nabla_{xy}\phi = \left(\partial^2_{x_iy_j}\phi\right), \quad \nabla_{yy}\phi = \left(\partial^2_{y_iy_j}\phi\right).
$$

Then one can check that the following crucial matrix equality holds:

$$
(\nabla_{xx} + 2\nabla_{xy} + \nabla_{yy})\,\phi = (\nabla_{xx} + 2\nabla_{xy} + \nabla_{yy})\,\varphi\left(\frac{t+s}{2}, \frac{x+y}{2}\right)\omega_\rho\left(\frac{t-s}{2}, \frac{x-y}{2}\right).
$$

Note that the two latter properties imply that for $1 \le i \le d$,

$$
\begin{aligned}
&q_i^\varepsilon(T_l(u),T_l(v))\partial_{x_i}\phi + q_i^\varepsilon(T_l(v),T_l(u))\partial_{y_i}\phi \\
&\quad = q_i^\varepsilon(T_l(u),T_l(v))\left(\partial_{x_i}+\partial_{y_i}\right)\varphi\left(\frac{t+s}{2},\frac{x+y}{2}\right)\omega_\rho\left(\frac{t-s}{2},\frac{x-y}{2}\right) \\
&\qquad + \left[q_i^\varepsilon(T_l(v),T_l(u)) - q_i^\varepsilon(T_l(u),T_l(v))\right]\partial_{y_i}\phi,
\end{aligned}
\tag{3.8}
$$

and for $1 \le i,j \le d$,

$$
\begin{aligned}
&r_{ij}^\varepsilon(T_l(u),T_l(v))\partial^2_{x_ix_j}\phi + r_{ij}^\varepsilon(T_l(v),T_l(u))\partial^2_{y_iy_j}\phi \\
&\quad = r_{ij}^\varepsilon(T_l(u),T_l(v))\left(\partial^2_{x_ix_j}+2\partial^2_{x_iy_j}+\partial^2_{y_iy_j}\right)\varphi\left(\frac{t+s}{2},\frac{x+y}{2}\right)\omega_\rho\left(\frac{t-s}{2},\frac{x-y}{2}\right) \\
&\qquad - 2r_{ij}^\varepsilon(T_l(u),T_l(v))\partial^2_{x_iy_j}\phi \\
&\qquad\quad + \left[r_{ij}^\varepsilon(T_l(v),T_l(u)) - r_{ij}^\varepsilon(T_l(u),T_l(v))\right]\partial^2_{y_iy_j}\phi.
\end{aligned}
\tag{3.9}
$$

We also have

$$
\begin{aligned}
&-\int \phi(t,x,s,y)\,d\mu_l^u(t,x)\,dy\,ds \\
&\qquad \ge -\int \omega_\rho\left(\frac{t-s}{2},\frac{x-y}{2}\right)\,dy\,ds\,d\mu_l^u(t,x) \ge -\mu_l^u((0,T)\times\mathbf{R}^d)
\end{aligned}
\tag{3.10}
$$

and similarly

$$
-\int \phi(t,x,s,y)\,d\mu_l^v(s,y)\,dx\,dt \ge -\mu_l^v((0,T)\times\mathbf{R}^d). \tag{3.11}
$$

Insertion of (3.8)–(3.11) into (3.7) gives

$$
\begin{aligned}
&\int\Bigg(\eta_\varepsilon(T_l(u),T_l(v))\left(\partial_t+\partial_s\right)\varphi\left(\frac{t+s}{2},\frac{x+y}{2}\right) \\
&\qquad + \sum_{i=1}^d q_i^\varepsilon(T_l(u),T_l(v))\left(\partial_{x_i}+\partial_{y_i}\right)\varphi\left(\frac{t+s}{2},\frac{x+y}{2}\right) \\
&\qquad + \sum_{i,j=1}^d r_{ij}^\varepsilon(T_l(u),T_l(v))\left(\partial^2_{x_ix_j}+2\partial^2_{x_iy_j}+\partial^2_{y_iy_j}\right)\varphi\left(\frac{t+s}{2},\frac{x+y}{2}\right)\Bigg) \\
&\qquad\qquad \times \omega_\rho\left(\frac{t-s}{2},\frac{x-y}{2}\right)\,dx\,dt\,dy\,ds \\
&\qquad - \int \operatorname{sign}_\varepsilon\left(T_l(u)-T_l(v)\right)\left(F(t,x)-G(s,y)\right)\,dx\,dt\,dy\,ds \\
&\quad \ge E_1(\varepsilon)+E_2(\varepsilon)+E_3(\varepsilon)-\mu_l^v((0,T)\times\mathbf{R}^d)-\mu_l^v((0,T)\times\mathbf{R}^d),
\end{aligned}
\tag{3.12}
$$

where $E_j(\varepsilon) = \int I_j(\varepsilon)\,dx\,dt\,dy\,ds$, $j = 1, 2, 3$, with

$$
\begin{aligned}
I_1(\varepsilon) &= \left(n^{u,\operatorname{sign}'_\varepsilon(\cdot-c)}(t,x) + n^{v,\operatorname{sign}'_\varepsilon(\cdot-c)}(s,y)\right)\phi,\\
I_2(\varepsilon) &= 2\sum_{i,j=1}^{d} r_{ij}^{\varepsilon}(T_l(u),T_l(v))\partial^2_{x_iy_j}\phi,\\
I_3(\varepsilon) &= \sum_{i=1}^{d}\left[q_i^{\varepsilon}(T_l(u),T_l(v)) - q_i^{\varepsilon}(T_l(v),T_l(u))\right]\partial_{y_i}\phi\\
&\qquad + \sum_{i,j=1}^{d}\left[r_{ij}^{\varepsilon}(T_l(u),T_l(v)) - r_{ij}^{\varepsilon}(T_l(v),T_l(u))\right]\partial^2_{y_iy_j}\phi.
\end{aligned}
$$

Clearly, we have $\lim_{\varepsilon\downarrow 0} E_3(\varepsilon) = 0$ and

$$
\lim_{\varepsilon\downarrow 0} E_2(\varepsilon) = \int 2\sum_{i,j=1}^{d} r_{ij}(T_l(u),T_l(v))\partial^2_{x_iy_j}\phi\,dx\,dt\,dy\,ds. \tag{3.13}
$$

Our goal now is to show that

$$
\lim_{\varepsilon\downarrow 0} E_1(\varepsilon) + \lim_{\varepsilon\downarrow 0} E_2(\varepsilon) \geq 0. \tag{3.14}
$$

To this end, note first that, since $\operatorname{sign}'_\varepsilon(\cdot) \geq 0$,

$$
I_1(\varepsilon) \geq 2\sum_{k=1}^{K} \operatorname{sign}'_\varepsilon\left(T_l(u) - T_l(v)\right)\operatorname{div}_x\zeta_k(T_l(u))\operatorname{div}_y\zeta_k(T_l(v))\phi,
$$

so that

$$
\begin{aligned}
E_1(\varepsilon) \geq \int 2\sum_{k=1}^{K} &\operatorname{sign}'_\varepsilon\left(T_l(u) - T_l(v)\right)\operatorname{div}_x\zeta_k(T_l(u))\\
&\times \operatorname{div}_y\zeta_k(T_l(v))\phi\,dx\,dt\,dy\,ds.
\end{aligned}
$$

Invoking the chain rule (D.3) in Definition 2.3 (we can do this since $\operatorname{sign}'_\varepsilon(\cdot)$ belongs to $C(\mathbf{R})$), we have for $1 \leq k \leq K$

$$
\operatorname{sign}'_\varepsilon\left(T_l(u) - T_l(v)\right)\operatorname{div}_y\zeta_k(T_l(v)) = \operatorname{div}_y\zeta_k^{\operatorname{sign}'_\varepsilon(T_l(u)-\cdot)}(T_l(v)). \tag{3.15}
$$

If we now use (3.15), then we have

$$
E_1(\varepsilon) \geq \int 2\sum_{k=1}^{K} \operatorname{div}_x\zeta_k(T_l(u))\operatorname{div}_y\zeta_k^{\operatorname{sign}'_\varepsilon(T_l(u)-\cdot)}(T_l(v))\phi\,dx\,dt\,dy\,ds.
$$

Integration by parts in y yields

$$\begin{aligned}
E_1(\varepsilon) \geq \int 2 \sum_{k=1}^{K} \sum_{i,j=1}^{d} & \partial_{x_i} \zeta_{ik}(T_l(u)) \\
& \times \partial_{y_j} \left(\int_{T_l(u)}^{T_l(v)} \operatorname{sign}'_\varepsilon (T_l(u) - \xi)\, \sigma_{jk}(\xi)\, d\xi \right) \phi \, dx\, dt\, dy\, ds \\
= - \int 2 \sum_{k=1}^{K} \sum_{i,j=1}^{d} & \partial_{x_i} \zeta_{ik}(T_l(u)) \\
& \times \left(\int_{T_l(u)}^{T_l(v)} \operatorname{sign}'_\varepsilon (T_l(u) - \xi)\, \sigma_{jk}(\xi)\, d\xi \right) \partial_{y_j} \phi \, dx\, dt\, dy\, ds.
\end{aligned}$$

For $1 \leq k \leq K$ and $1 \leq j \leq d$, define the function $\psi^\varepsilon_{jk} : \mathbf{R} \to \mathbf{R}$ by

$$\psi^\varepsilon_{jk}(\eta) = \int_{\eta}^{T_l(v)} \operatorname{sign}'_\varepsilon (\eta - \xi)\, \sigma_{jk}(\xi)\, d\xi.$$

Since $\operatorname{sign}'_\varepsilon(\cdot) \in C(\mathbf{R})$ and $\sigma_{jk}(\cdot) \in L^\infty_{\mathrm{loc}}(\mathbf{R})$, we have $\psi^\varepsilon_{jk}(\cdot) \in C(\mathbf{R})$ and the chain rule can therefore be used.

Using the chain rule (D.3) in Definition 2.3 and then doing integration by parts in x, we derive

$$\begin{aligned}
E_1(\varepsilon) &\geq - \int 2 \sum_{k=1}^{K} \sum_{i,j=1}^{d} \partial_{x_i} \zeta_{ik}(T_l(u)) \psi^\varepsilon_{jk}(T_l(u)) \partial_{y_j} \phi \, dx\, dt\, dy\, ds \\
&= - \int 2 \sum_{k=1}^{K} \sum_{i,j=1}^{d} \partial_{x_i} \zeta_{ik}^{\psi^\varepsilon_{jk}}(T_l(u)) \partial_{y_j} \phi \, dx\, dt\, dy\, ds \\
&= - \int 2 \sum_{k=1}^{K} \sum_{i,j=1}^{d} \partial_{x_i} \left(\int_{T_l(v)}^{T_l(u)} \psi^\varepsilon_{jk}(\xi) \sigma_{ik}(\xi)\, d\xi \right) \partial_{y_j} \phi \, dx\, dt\, dy\, ds \\
&= \int 2 \sum_{k=1}^{K} \sum_{i,j=1}^{d} \left(\int_{T_l(v)}^{T_l(u)} \psi^\varepsilon_{jk}(\xi) \sigma_{ik}(\xi)\, d\xi \right) \partial^2_{x_i y_j} \phi \, dx\, dt\, dy\, ds.
\end{aligned}$$

Observe that for a.e. $\eta \in \mathbf{R}$

$$\lim_{\varepsilon \downarrow 0} \psi^\varepsilon_{jk}(\eta) = -\operatorname{sign}(\eta - T_l(v))\, \sigma_{jk}(\eta),$$

so that by the dominated convergence theorem we have for a.e. (t, x, s, y)

$$\lim_{\varepsilon \downarrow 0} \int_{T_l(v)}^{T_l(u)} \psi^\varepsilon_{jk}(\xi) \sigma_{ik}(\xi)\, d\xi = - \int_{T_l(v)}^{T_l(u)} \operatorname{sign}(\xi - T_l(v))\, \sigma_{jk}(\xi) \sigma_{ik}(\xi)\, d\xi.$$

Hence, after another application of the dominated convergence theorem,

$$\begin{aligned}\lim_{\varepsilon\downarrow 0} E_1(\varepsilon) \geq -\int 2\sum_{k=1}^{K}\sum_{i,j=1}^{d}\left(\int_{T_l(v)}^{T_l(u)} \operatorname{sign}\left(\xi - T_l(v)\right)\sigma_{jk}(\xi)\sigma_{ik}(\xi)\,d\xi\right)\\ \times \partial^2_{x_i y_j}\phi\,dx\,dt\,dy\,ds\\ = -\int 2\sum_{i,j=1}^{d} r_{ij}(T_l(u),T_l(v))\partial^2_{x_i y_j}\phi\,dx\,dt\,dy\,ds.\end{aligned} \tag{3.16}$$

Finally, adding (3.16) to (3.13) yields (3.14).

Summing up, sending $\varepsilon \downarrow 0$ in (3.12) gives

$$\begin{aligned}&\int \Big(I_{\text{time}} + I_{\text{conv}} + I_{\text{diff}}\Big)(t,x,s,y)\omega_\rho\left(\frac{t-s}{2},\frac{x-y}{2}\right)dx\,dt\,dy\,ds\\ &\quad -\int \operatorname{sign}\left(T_l(u)-T_l(v)\right)\left(F(t,x)-G(s,y)\right)\\ &\qquad \times \omega_\rho\left(\frac{t-s}{2},\frac{x-y}{2}\right)\varphi\left(\frac{t+s}{2},\frac{x+y}{2}\right)dx\,dt\,dyds\\ &\quad \geq -\mu_l^u((0,T)\times\mathbf{R}^d) - \mu_l^v((0,T)\times\mathbf{R}^d),\end{aligned} \tag{3.17}$$

where

$$I_{\text{time}}(t,x,s,y) = \left|T_l(u(t,x)) - T_l(v(s,y))\right|\left(\partial_t+\partial_s\right)\varphi\left(\frac{t+s}{2},\frac{x+y}{2}\right),$$

$$I_{\text{conv}}(t,x,s,y) = \sum_{i=1}^{d} q_i(T_l(u(t,x)),T_l(v(s,y)))\left(\partial_{x_i}+\partial_{y_i}\right)\varphi\left(\frac{t+s}{2},\frac{x+y}{2}\right),$$

$$I_{\text{diff}}(t,x,s,y) = \sum_{i,j=1}^{d} r_{ij}(T_l(u),T_l(v))\left(\partial^2_{x_i x_j} + 2\partial^2_{x_i y_j} + \partial^2_{y_i y_j}\right)\varphi\left(\frac{t+s}{2},\frac{x+y}{2}\right).$$

Let us introduce the change of variables

$$\tilde{x} = \frac{x+y}{2}, \quad \tilde{t} = \frac{t+s}{2}, \quad z = \frac{x-y}{2}, \quad \tau = \frac{t-s}{2},$$

which maps $(0,T)\times\mathbf{R}^d\times(0,T)\times\mathbf{R}^d$ into

$$\Omega = \mathbf{R}^d\times\mathbf{R}^d\times\left\{(\tilde{t},\tau)\;\middle|\; 0\leq\tilde{t}+\tau\leq T,\quad 0\leq\tilde{t}-\tau\leq T\right\}.$$

Observe that

$$\left(\partial_t+\partial_s\right)\varphi\left(\frac{t+s}{2},\frac{x+y}{2}\right) = \varphi_{\tilde{t}}(\tilde{t},\tilde{x}), \qquad \left(\nabla_x+\nabla_y\right)\varphi(t,x,s,y) = \nabla_{\tilde{x}}\varphi(\tilde{t},\tilde{x}).$$

This change of variables diagonalizes also the operator $\nabla_{xx}+2\nabla_{xy}+\nabla_{yy}$:

$$\left(\nabla_{xx}+2\nabla_{xy}+\nabla_{yy}\right)\varphi\left(\frac{t+s}{2},\frac{x+y}{2}\right) = \nabla_{\tilde{x}\tilde{x}}\varphi(\tilde{t},\tilde{x}).$$

Keeping in mind that

$$x = \tilde{x} + z, \quad y = \tilde{x} - z, \quad t = \tilde{t} + \tau, \quad s = \tilde{t} - \tau,$$

we may now estimate (3.17) as

$$\begin{aligned} &\int_\Omega \Big(I_{\text{time}} + I_{\text{conv}} - I_{\text{diff}} \Big)(\tilde{t}, \tilde{x}, \tau, z) \omega_\rho(\tau, z)\, d\tilde{t}\, d\tilde{x}\, d\tau\, dz \\ &\qquad \geq - \int_\Omega \big| F(\tilde{t} + \tau, \tilde{x} + z) - G(\tilde{t} - \tau, \tilde{x} - z) \big| \, \omega_\rho(\tau, z)\, d\tilde{x}\, d\tilde{t}\, d\tau\, dz - o(1/l), \end{aligned} \tag{3.18}$$

where

$$\begin{aligned} I_{\text{time}}(\tilde{t}, \tilde{x}, \tau, z) &= \big| T_l(u(\tilde{t} + \tau, \tilde{x} + z)) - T_l(v(\tilde{t} - \tau, \tilde{x} - z)) \big| \, \varphi_{\tilde{t}}(\tilde{t}, \tilde{x}), \\ I_{\text{conv}}(\tilde{t}, \tilde{x}, \tau, z) &= \sum_{i=1}^d q_i \left(T_l(u(\tilde{t} + \tau, \tilde{x} + z)), T_l(v(\tilde{t} - \tau, \tilde{x} - z)) \right) \partial_{\tilde{x}_i} \varphi(\tilde{t}, \tilde{x}), \\ I_{\text{diff}}(\tilde{t}, \tilde{x}, \tau, z) &= \sum_{i,j=1}^d r_{ij} \left(T_l(u(\tilde{t} + \tau, \tilde{x} + z)), T_l(v(\tilde{t} - \tau, \tilde{x} - z)) \right) \partial^2_{\tilde{x}_i \tilde{x}_j} \varphi. \end{aligned}$$

Sending $\rho \downarrow 0$ in (3.18) yields

$$\begin{aligned} &\int \Bigg(|T_l(u) - T_l(v)| \, \partial_t \varphi + \sum_{i=1}^d q_i \left(T_l(u), T_l(v) \right) \partial_{x_i} \varphi \\ &\qquad + \sum_{i,j=1}^d r_{ij} \left(T_l(u), T_l(v) \right) \partial^2_{x_i x_j} \varphi \Bigg) \, dx\, dt \\ &\qquad\qquad \geq - \int |F(t,x) - G(t,x)| \, \varphi \, dx\, dt - o(1/l). \end{aligned} \tag{3.19}$$

By standard arguments (choosing a sequence of functions $0 \leq \varphi \leq 1$ from $\mathcal{D}((0,T) \times \mathbf{R}^d)$ that converges to $\mathbf{1}_{(0,t) \times \mathbf{R}^d}$ and using the initial conditions for u, v in the sense of, say, (D.6) in Definition 2.3, it follows from (3.19) that for a.e. $t \in (0,T)$

$$\begin{aligned} &\int_{\mathbf{R}^d} |T_l(u(t,x)) - T_l(v(t,x))| \, dx \\ &\qquad \leq \int_{\mathbf{R}^d} |T_l(u_0) - T_l(v_0)| \, dx + \int_0^t \int_{\mathbf{R}^d} |F(s,x) - G(s,x)| \, dx\, ds + o(1/l). \end{aligned} \tag{3.20}$$

Equipped with (D.5) in Definition 2.3 for u and v, sending $l \uparrow \infty$ in (3.20) finally yields the L^1 stability property (3.4). ∎

4. Existence of renormalized entropy solution. The purpose of this section is to prove the following theorem.

THEOREM 4.1 (existence). *Suppose that* (1.2), (1.3), *and* (1.4) *hold. Then there exists at least one renormalized entropy solution u of* (1.1).

We divide the proof into two steps.

Step 1 (bounded data). Suppose the data u_0 and F are bounded and integrable functions. Repeating the proof in [9] we find that there exists a unique entropy solution u to (1.1) (interpreted in the sense of Definition 2.2), and this entropy solution can

be constructed by the vanishing viscosity method [21]. For us it remains to prove that this entropy solution is also a renormalized entropy solution in the sense of Definition 2.3. To this end, let u_ρ be the unique classical (say $C^{1,2}$) solution to the uniformly parabolic problem

$$\begin{aligned} &\partial_t u_\rho + \operatorname{div} f(u_\rho) = \nabla \cdot (a(u_\rho)\nabla u_\rho) + \rho \Delta u_\rho + F, \qquad \rho > 0, \\ &u_\rho(x,0) = u_0(x). \end{aligned} \tag{4.1}$$

Equipped with the a priori estimates in [21], Chen and Perthame [9] proved

$$u_\rho \to u \quad \text{a.e. and in } C(0,T;L^1(\mathbf{R}^d)) \text{ as } \rho \downarrow 0, \tag{4.2}$$

where u is the unique entropy solution to (1.1).

For any C^2 function S and $\left(q_i^S\right)' = S' f_i'$, $\left(r_{ij}^S\right)' = S' a_{ij}$ for $1 \le i,j \le d$, multiplying the equation in (4.1) by $S'(u_\rho)$ yields

$$\begin{aligned} &\partial_t S(u_\rho) + \sum_{i=1}^d \partial_{x_i} q_i^S(u_\rho) - \sum_{i,j=1}^d \partial^2_{x_i x_j} r_{ij}^S(u_\rho) - \rho \Delta S(u_\rho) \\ &\quad - S'(u_\rho) F(u_\rho) = -\left(n_\rho^{S''} + m_\rho^{S''}\right)(t,x), \end{aligned} \tag{4.3}$$

where the parabolic dissipation measure $n_{n,\rho}^{S''}(t,x)$ is defined by

$$n_\rho^{S''}(t,x) = \sum_{k=1}^K \left(\sum_{i=1}^d \partial_{x_i} \zeta_{ik}^{S''}(u(t,x)) \right)^2,$$

and the entropy dissipation measure $m_\rho^{S''}(t,x)$ is defined by

$$m_\rho^{S''}(t,x) = \rho S''(u_\rho) \left|\nabla u_\rho\right|^2.$$

An easy approximation argument reveals that (4.3) continues to hold for any function $S \in W^{2,\infty}(\mathbf{R})$.

Inserting $S(u) = \frac{1}{l}\int_0^u T_l(\xi)\xi$ into (4.3) and then sending $l \downarrow 0$, we get the well-known estimate

$$\|u_\rho\|_{L^\infty(0,T;L^1(\mathbf{R}^d))} \le \|u_0\|_{L^1(\mathbf{R}^d)} + \|F\|_{L^1((0,T)\times\mathbf{R}^d)}. \tag{4.4}$$

We need to derive some additional a priori estimates (involving (2.4)) that are independent of ρ and $\|u_0\|_{L^\infty(\mathbf{R}^d)}$, $\|F\|_{L^\infty((0,T)\times\mathbf{R}^d)}$.

LEMMA 4.1. *For any $l > 0$, we have*

$$\int_{(0,T)\times\mathbf{R}^d} \left(\sum_{k=1}^K \left(\sum_{i=1}^d \partial_{x_i} \zeta_{ik}(T_l(u_\rho)) \right)^2 + \rho \left|\nabla T_l(u_\rho)\right|^2 \right) dx\, dt \le C_l$$

for some constant C_l that is independent of ρ but not l. More precisely,

$$C_l = l\left(\|u_0\|_{L^1(\mathbf{R}^d)} + \|F\|_{L^1((0,T)\times\mathbf{R}^d)} \right).$$

Proof. Introduce the function

$$S(u) = \int_0^u T_l(\xi)\, d\xi = \begin{cases} \frac{|u|^2}{2}, & |u| \le l, \\ l\,|u| - \frac{l^2}{2}, & |u| > l. \end{cases}$$

The lemma follows by choosing this $S(\cdot)$ in (4.3). ∎

LEMMA 4.2. *For any $l > 0$ and any $\delta > 0$,*

$$\frac{1}{\delta}\int_{\{l<|u_\rho|<l+\delta\}}\left(\sum_{k=1}^{K}\left(\sum_{i=1}^{d}\partial_{x_i}\zeta_{ik}(u_\rho)\right)^2+\rho\,|\nabla u_\rho|^2\right)dx\,dt\le\mathcal{E}(l) \tag{4.5}$$

for some bounded function $\mathcal{E}(\cdot)$ on $\mathbf{R}_+$ that is independent of ρ,δ and satisfies $\lim_{l\uparrow\infty}\mathcal{E}(l)=0$.

If the data u_0, F are bounded and $l > M := \|u_0\|_{L^\infty(\mathbf{R}^d)} + \|F\|_{L^\infty((0,T)\times\mathbf{R}^d)}$, then $\mathcal{E}(l) = 0$.

Proof. Let us define the function $S(\cdot)$ by $S(0) = 0$ and

$$S'(u)=\frac{1}{\delta}\left(T_{l+\delta}(u)-T_l(u)\right)=\begin{cases}-1, & u<-l-\delta,\\ \frac{-u-l}{\delta}, & -l-\delta<u<-l,\\ 0, & -l<u<l,\\ \frac{u-l}{\delta}, & l<u<l+\delta,\\ 1, & u>l+\delta.\end{cases}$$

Inserting this S into (4.3) gives

$$\begin{aligned}&\frac{1}{\delta}\int_{\{l<|u_\rho|<l+\delta\}}\left(\sum_{k=1}^{K}\left(\sum_{i=1}^{d}\partial_{x_i}\zeta_{ik}(u_\rho)\right)^2+\rho\,|\nabla u_\rho|^2\right)dx\,dt\\ &\quad\le\int_{\{|u_0|>l\}}|u_0|\,dx+\int_{\{|u_\rho|>l\}}|F|\,dx\,dt:=\mathcal{E}(l).\end{aligned} \tag{4.6}$$

Since $u_0\in L^1(\mathbf{R}^d)$, $F\in L^1((0,T)\times\mathbf{R}^d)$, and, thanks to (4.4), u_ρ is uniformly (in ρ) bounded in $L^1((0,T)\times\mathbf{R}^d)$, we have $\mathcal{E}(l)\to 0$ as $l\uparrow\infty$.

If the data u_0, F are bounded, then it is well known that $\|u_\rho\|_{L^\infty((0,T)\times\mathbf{R}^d)}\le M$, where M is defined in the lemma. We observe that if $l > M$, then $S(u_0) = 0$ and $S'(u_\rho) = 0$. Hence we deduce $\mathcal{E}(l) = 0$. ∎

Let us choose a particular $S = S_{\eta,h}$ in (4.3) of the form

$$\begin{aligned}&S_{\eta,h}(0)=0, && S'_{\eta,h}=\eta' h',\\ &\eta\in C^2(\mathbf{R}), && \eta''\ge 0, \qquad |\eta'|\le K,\\ &h\in C^2(\mathbf{R}), && \operatorname{supp}(h')\subset[-l,l].\end{aligned}$$

This gives

$$\begin{aligned}&\partial_t S_{\eta,h}(u_\rho)+\sum_{i=1}^{d}\partial_{x_i}q_i^{S_{\eta,h}}(u_\rho)-\sum_{i,j=1}^{d}\partial^2_{x_ix_j}r_{ij}^{S_{\eta,h}}(u_\rho)-\rho\Delta S_{\eta,h}(u_\rho)\\ &\quad-S'_{\eta,h}(u_\rho)F(u_\rho)=-\left(n_\rho^{\eta''h'}+\mu_\rho^{\eta'h''}\right)(t,x),\end{aligned} \tag{4.7}$$

where

$$\begin{aligned}\mu_\rho^{\eta'h''}(t,x)&:=-\left(n_\rho^{\eta'h''}+m_\rho^{\eta'h''}\right)(t,x)\\ &=-\eta'(u_\rho)h''(u_\rho)\left(\sum_{k=1}^{K}\left(\sum_{i=1}^{d}\partial_{x_i}\zeta_{ik}(u_\rho)\right)^2+\rho\,|\nabla u_\rho|^2\right).\end{aligned}$$

Let $h_{l,\delta} : \mathbf{R} \to \mathbf{R}$ denote the function defined by $h_{l,\delta}(0) = 0$ and

$$h'_{l,\delta}(u) = \begin{cases} 1, & |u| < l, \\ \frac{l+\delta-|u|}{\delta}, & l < |u| < l+\delta, \\ 0, & |u| > l+\delta. \end{cases}$$

Clearly,

$$h_{l,\delta}(u) \to T_l(u), \qquad h'_{l,\delta}(u) \to \mathbf{1}_{\{|u|<l\}} \tag{4.8}$$

for any $u \in \mathbf{R}$. The idea is to choose $h = h_{n,l}$ in (4.7) and then let $\delta \downarrow 0$. To this end, let us first define the Radon measure $\mu^K_{l,\rho,\delta}$ on $(0,T) \times \mathbf{R}^d$ by

$$d\mu^K_{l,\rho,\delta}(t,x) := \frac{K}{\delta} \mathbf{1}_{\{l<|u_\rho|<l+\delta\}} \left(\sum_{k=1}^K \left(\sum_{i=1}^d \partial_{x_i} \zeta_{ik}(u_\rho) \right)^2 + \rho \, |\nabla u_\rho|^2 \right) dx \, dt,$$

that is, for any Borel set $E \subset (0,T) \times \mathbf{R}^d$,

$$\mu^K_{l,\rho,\delta}(E) = \frac{K}{\delta} \int_{E \cap \{l<|u_\rho|<l+\delta\}} \left(\sum_{k=1}^K \left(\sum_{i=1}^d \partial_{x_i} \zeta_{ik}(u_\rho) \right)^2 + \rho \, |\nabla u_\rho|^2 \right) dx \, dt.$$

Then, by Lemma 4.2, $\mu^K_{l,\rho,\delta}((0,T) \times \mathbf{R}^d) \le \mathcal{E}(l)$. Consequently, we may assume that

$$\begin{aligned} &\mu^K_{l,\rho,\delta} \overset{\star}{\rightharpoonup} \mu^K_{l,\rho} \qquad \text{in the sense of measures on } (0,T) \times \mathbf{R}^d \text{ as } \delta \downarrow 0, \\ &\mu^K_{l,\rho} \overset{\star}{\rightharpoonup} \mu^K_l \qquad \text{in the sense of measures on } (0,T) \times \mathbf{R}^d \ \rho \downarrow 0 \end{aligned} \tag{4.9}$$

for some nonnegative bounded Radon measure μ^K_l satisfying

$$\mu^K_l((0,T) \times \mathbf{R}^d) \le \mathcal{E}(l) \to 0 \quad \text{as } l \uparrow \infty. \tag{4.10}$$

For any $0 \le \phi \in \mathcal{D}((0,T) \times \mathbf{R}^d)$, thanks to (4.8) and the convexity of η,

$$\begin{aligned} &\lim_{\delta \downarrow 0} \int_{(0,T)\times\mathbf{R}^d} n_\rho^{\eta'' h'_{l,\delta}}(t,x) \phi \, dx \, dt \\ &\qquad \ge \int_{(0,T)\times\mathbf{R}^d} \eta''(T_l(u_\rho)) \sum_{k=1}^K \left(\sum_{i=1}^d \partial_{x_i} \zeta_{ik}(T_l(u_\rho)) \right)^2 \phi \, dx \, dt. \end{aligned} \tag{4.11}$$

Again because of (4.8), it can be easily checked that as $\delta \downarrow 0$ (recall $q' = \eta' f'$ and $r' = \eta' a$)

$$\begin{aligned} &S_{\eta,h_{l,\delta}}(u) \to \eta(T_l(u)), \qquad S'_{\eta,h_{l,\delta}}(u) \to \eta'(T_l(u)), \\ &q^{S_{\eta,h_{l,\delta}}}(u) \to q(T_l(u)), \qquad r^{S_{\eta,h_{l,\delta}}}(u) \to r(T_l(u)) \end{aligned} \tag{4.12}$$

for any $u \in \mathbf{R}$.

Inserting $h = h_{l,\delta}$ into (4.7) and using $|\eta'| \le K$, (4.9), (4.11), (4.12) when sending $\delta \downarrow 0$, we get

$$\begin{aligned}
&\partial_t \eta(T_l(u_\rho)) + \sum_{i=1}^{d} \partial_{x_i} q_i(T_l(u_\rho)) - \sum_{i,j=1}^{d} \partial^2_{x_i x_j} r_{ij}(T_l(u_\rho)) \\
&\qquad - \rho \Delta \eta(T_l(u_\rho)) - \eta'(T_l(u_\rho)) F \\
&\le -\eta''(T_l(u_\rho)) \sum_{k=1}^{K} \left(\sum_{i=1}^{d} \partial_{x_i} \zeta_{ik}(u_\rho) \right)^2 + \mu^K_{l,\rho} \quad \text{in } \mathcal{D}'((0,T)\times \mathbf{R}^d).
\end{aligned} \tag{4.13}$$

Equipped with (4.9), passing to the limit $\rho \downarrow 0$ in (4.13) yields that u satisfies the entropy condition (2.5).

It remains to prove that the chain rule (D.3) in Definition 2.3 holds. For any $\psi \in C(\mathbf{R})$, the classical chain rule gives for $k = 1, \dots, K$

$$\sum_{i=1}^{d} \partial_{x_i} \zeta^{\psi}_{ik}(T_l(u_\rho)) = \psi(T_l(u_\rho)) \sum_{i=1}^{d} \partial_{x_i} \zeta_{ik}(T_l(u_\rho)) \qquad \forall l > 0.$$

As in [9], the proof is to observe that this equality continues to hold in the limit as $\rho \downarrow 0$ since u_ρ converges strongly and $\sum_{i=1}^{d} \partial_{x_i} \zeta_{ik}(T_l(u_\rho))$ weakly.

Step 2 (unbounded data). Suppose the data u_0 and F satisfy (1.2). For $n > 1$, introduce the truncated data $u_{0,n} = T_n(u_0)$ and $F_n = T_n(F)$. We have $u_{0,n} \to u_0$, $F_n \to F$ in L^1 as $n \uparrow \infty$. Thanks to the L^1 contraction property of the solution operator to (4.1), $\{u_n\}_{n>1}$ is a Cauchy sequence in $C(0,T;L^1(\mathbf{R}^d))$ and has a limit point u. From Step 1 we know that each u_n is a renormalized entropy solution of (1.1) with u_0 and F replaced by $u_{0,n}$ and F_n, respectively. Denote by $\mu^K_{l,n}$ the corresponding renormalization measure. Lemma 4.1 and (4.10) imply that the following n-independent a priori estimates hold for each $l > 0$:

$$\begin{aligned}
&\|u_n\|_{L^\infty(0,T;L^1(\mathbf{R}^d))} \le \|u_0\|_{L^1(\mathbf{R}^d)} + \|F\|_{L^1((0,T)\times\mathbf{R}^d)}, \\
&\sum_{k=1}^{K} \Big(\mathrm{div} \zeta_k(T_l(u_n)) \Big)^2 = \sum_{k=1}^{K} \left(\sum_{i=1}^{d} \partial_{x_i} \zeta_{ik}(T_l(u_n)) \right)^2 \le C_l, \\
&\mu^K_{l,n}((0,T)\times\mathbf{R}^d) \le \int_{\{|u_0|>l\}} |u_0| \, dx + \int_{\{|u_n|>l\}} |F| \, dx\, dt
\end{aligned}$$

for some constant C_l depending on l but not n. Equipped with these estimates and the strong convergence $u_n \to u$, we can repeat the steps in the above limiting process for the viscous approximations $\{u_\rho\}_{\rho>0}$ and prove that the limit point u of $\{u_n\}_{n>1}$ is a renormalized entropy solution of (1.1), with the renormalization measure $\mu^{u,K}_l$ being a limit point of $\{\mu^K_{l,n}\}_{n>1}$. This completes the proof of Theorem 4.1.

Acknowledgment. This work was done while MB visited the Centre of Mathematics for Applications (CMA) at the University of Oslo, Norway, and he is grateful for the hospitality.

Γ-CONVERGENCE THROUGH YOUNG MEASURES*

PABLO PEDREGAL†

Abstract. We present a general framework to treat Γ-convergence of functionals through Young measures and through slicing decomposition. After dealing with a general situation where functionals are defined in Lebesgue spaces, we concentrate on the gradient case. Explicit computations are possible, in this case, when the sequence of functions determining the functionals has a special property. We illustrate the method by examining several well-known situations. More than these examples, emphasis in this paper is placed on the method itself and its generality.

Key words. slicing decomposition, joint Young measure, lower semicontinuity

AMS subject classifications. 49J45, 74Q05

DOI. 10.1137/S0036141003425696

1. Introduction. Γ-convergence of functionals is an important method for dealing with sequences of functionals and for understanding their limiting properties. It was originally introduced in the pioneering works [9], [10]. See [8] for a formal and more complete analysis. It is closely related to homogenization, G- and H-convergence (see [6], [11], [15], [16]), as well as variational problems and techniques (see [3], [7]). Many examples and applications are scattered throughout the literature, but [1] is a nice account of the application of all these ideas to optimal design and shape optimization. See also [5]. In this work, we would like to start a systematic treatment of Γ-convergence through the study of the underlying Young measures associated to relevant sequences. A major tool is the slicing measure decomposition (see [2], [12]).

To explain our perspective, suppose we have a sequence of integral functionals

$$I_j(u) = \int_\Omega W(a_j(x), u(x))\, dx, \quad u \in \mathcal{A},$$

where $\Omega \subset \mathbf{R}^N$ is a bounded, regular domain, $a_j : \Omega \to \mathbf{R}^m$, and $\mathcal{A}$ is some weakly closed subset of a certain reflexive Lebesgue space. The integrand

$$W(\lambda, \rho) : \mathbf{R}^m \times \mathbf{R}^d \to \mathbf{R}$$

is assumed to be continuous to begin with. Under coercivity for W with respect to ρ, the Γ-limit of the sequence of functional $\{I_j\}$ is defined by putting

$$I(u) = \inf \left\{ \liminf_{j\to\infty} I_j(u_j) : u_j \rightharpoonup u \right\}, \tag{1.1}$$

and it represents the right notion of variational convergence of functionals. A prime objective in many situations is to provide an explicit, integral form for $I(u)$, and doing so amounts to describing how the new integrand can be determined and computed from the sequence $\{a_j\}$. The procedure, carried out in many cases which can be

found in the references given above, essentially consists in finding a lower bound in (1.1), in the form of an integral functional, set up in such a way that will eventually become the Γ-limit, because that lower bound will in fact be an equality for a certain, cleverly chosen sequence $u_j \rightharpoonup u$ for any u. We would like to describe how this whole procedure can be done in a more-or-less systematic way through Young measures.

The key idea is to work with the joint Young measure corresponding to pairs $\{(a_j, u_j)\}$, where $u_j \rightharpoonup u$. But since $\{a_j\}$ is given and cannot be changed in any way, by means of the slicing decomposition we keep the Young measure associated with $\{a_j\}$ and work with the part of the joint measure coming from $\{u_j\}$. Notice that the joint Young measure will not, in general, be a product measure, and therefore a main issue is to understand the connection and relationship between their respective Young and joint Young measures.

Let

$$W(\lambda, \rho) : \mathbf{R}^m \times \mathbf{R}^d \to \mathbf{R}$$

be a continuous integrand such that

$$\begin{aligned} c\left(|\rho|^p - 1\right) \leq W(a_j(x), \rho) \leq C\left(|\rho|^p + 1\right), \\ |W(\lambda_1, \rho) - W(\lambda_2, \rho)| \leq w(|\lambda_1 - \lambda_2|)\, |\rho|^p \end{aligned}$$

for some $C > c > 0$, $p > 1$, a.e. $x \in \Omega$ and all j. The function w is continuous and $w(0) = 0$. Notice that an explicit x dependence of W can be incorporated into a_j so that, without loss of generality, we can assume no explicit dependence on x.

Let $\{a_j\}$ be weakly convergent in $L^q(\Omega)$ for some $q > 1$ and let $\sigma = \{\sigma_x\}_{x\in\Omega}$ be its underlying Young measure. Define the integrand

$$\psi(x, \rho) : \Omega \times \mathbf{R}^d \to \mathbf{R}$$

by putting

$$\psi(x, \rho) = \min_{\varphi} \left\{ \int_{\mathbf{R}^m} CW(x, \varphi(\lambda))\, d\sigma_x(\lambda) : \rho = \int_{\mathbf{R}^m} \varphi(\lambda)\, d\sigma_x(\lambda) \right\}.$$

We will show that ψ is well-defined in the sense that this infimum is indeed a minimum. CW is the convexification of W with respect to ρ. Notice that ψ is defined through a variational problem with respect to the Young measure corresponding to the sequence $\{a_j\}$, which determines the sequence of functionals $\{I_j\}$.

THEOREM 1.1. *Under the above hypotheses, the* Γ*-limit of* $\{I_j\}$ *is given by*

$$I(u) = \int_\Omega \psi(x, u(x))\, dx.$$

In section 3 we include various typical examples where one can explicitly calculate the density ψ by exploiting optimality conditions.

The situation where functionals depend on gradients is much more interesting,

$$I_j(u) = \int_\Omega W(a_j(x), \nabla u(x))\, dx, \quad u \in \mathcal{A},$$

and this time $\mathcal{A}$ is a weakly closed subset of a certain reflexive Sobolev space. A result similar to the previous one is valid only under a main, additional, structural

assumption on the sequence $\{a_j\}$. This property, called the "average gradient property" (AGP), roughly says that averages of gradients over level sets of a_j are gradients themselves. A more rigorous treatment can be found in section 4. The integrand W is assumed to enjoy the same properties as above. Suppose that $\{a_j\}$ is weakly convergent in $L^q(\Omega)$ for some $q > 1$ and that it verifies AGP, and let $\sigma = \{\sigma_x\}_{x\in\Omega}$ be its underlying Young measure. Define the integrand

$$\psi(x, \rho) : \Omega \times \mathbf{R}^d \to \mathbf{R}$$

by putting

$$\psi(x,\rho) = \min_{\varphi} \left\{ \int_{\mathbf{R}^m} CW(x, \varphi(\lambda))\, d\sigma_x(\lambda) : \rho = \int_{\mathbf{R}^m} \varphi(\lambda)\, d\sigma_x(\lambda), \right.$$
$$\left. \varphi(a_j(y)) \text{ is a gradient in } y \right\}.$$

A more precise definition of ψ is discussed later (section 4).

THEOREM 1.2. *If the sequence $\{a_j\}$ verifies AGP, the Γ-limit of $\{I_j\}$ is given by*

$$I(u) = \int_\Omega \psi(x, \nabla u(x))\, dx.$$

Some typical examples are explored in section 5 to illustrate the method.

2. The case without derivatives. In this section we treat and prove our main result for the most simple situation where the functionals do not depend explicitly on derivatives so that

$$I_j(u) = \int_\Omega W(a_j(x), u(x))\, dx,$$

where u belongs to some weakly closed subset of a certain Sobolev space. Ω is assumed to be a bounded, regular domain. More explicitly our assumptions on

$$W(\lambda, \rho) : \mathbf{R}^m \times \mathbf{R}^d \to \mathbf{R}$$

and the sequence $\{a_j\}$ are as follows:

1. $\{a_j\}$ is a weakly convergent sequence in $L^q(\Omega)$ for some $q > 1$.
2. W is uniformly coercive in ρ for all j with an exponent $p > 1$ and is uniformly bounded from above by the same power so that

$$c\,(|\rho|^p - 1) \le W(a_j(x), \rho) \le C\,(|\rho|^p + 1)$$

for some $C > c > 0$, all j, and a.e. $x \in \Omega$. Under this hypothesis, every sequence $\{u_j\}$ such that $\{I_j(u_j)\}$ is bounded from above will be bounded in $L^p(\Omega)$, and thus, possibly for a subsequence, it will converge weakly to some $u \in L^p(\Omega)$.

3. W is uniformly continuous in λ as indicated earlier:

$$|W(\lambda_1, \rho) - W(\lambda_2, \rho)| \le w(|\lambda_1 - \lambda_2|)\, |\rho|^p\,,$$

where w is continuous and $w(0) = 0$.

We have assumed no explicit, inhomogeneous dependence of W on $x \in \Omega$ but have pointed out that there is no loss of generality. Our aim is a description of the Γ-limit

$$I(u) = \inf \left\{ \liminf_{j\to\infty} I_j(u_j) : u_j \rightharpoonup u \text{ in } L^p(\Omega) \right\}.$$

Let u be given in $L^p(\Omega)$, and let $\{u_j\}$ be such that $\{I_j(u_j)\}$ is a nonincreasing sequence of numbers and $u_j \rightharpoonup u$ in $L^p(\Omega)$. Let $\sigma = \{\sigma_x\}_{x\in\Omega}$ be the Young measure associated with $\{a_j\}$ and let $\nu = \{\nu_x\}_{x\in\Omega}$ be the Young measure corresponding to the pairs $\{(a_j, u_j)\}$. Notice that

$$\operatorname{supp}(\sigma_x) \subset \mathbf{R}^m, \quad \operatorname{supp}(\nu_x) \subset \mathbf{R}^m \times \mathbf{R}^d.$$

At this point we invoke the slicing measure decomposition or disintegration.

THEOREM 2.1 (see [2], [12]). *Let ν be a nonnegative, finite Radon measure on $\mathbf{R}^{n+m}$, and let σ be its canonical projection onto $\mathbf{R}^n$ ($\sigma(E) = \nu(E \times \mathbf{R}^m)$). For σ-a.e. $x \in \mathbf{R}^n$ there exists a probability measure μ_x on $\mathbf{R}^m$ such that*

1. *the map*

$$x \mapsto \int_{\mathbf{R}^m} f(x,y)\, d\mu_x(y)$$

is σ-measurable for every bounded, continuous f;

2. *for every bounded, continuous function f*

$$\int_{\mathbf{R}^{n+m}} f(x,y)\, d\nu(x,y) = \int_{\mathbf{R}^n} \left(\int_{\mathbf{R}^m} f(x,y)\, d\mu_x(y) \right) d\sigma(x).$$

An enlightened way of shortening the statement of this theorem is to write

$$\nu(x,y) = \mu_x(y) \otimes \sigma(x).$$

Hence, in our situation, we can write

$$\nu_x = \mu_{\lambda,x} \otimes \sigma_x \tag{2.1}$$

for a.e. $x \in \Omega$ and every $\lambda \in \operatorname{supp}(\sigma_x)$. Each $\mu_{\lambda,x}$ is a certain probability measure with support contained in $\mathbf{R}^d$.

On the other hand, the representation in terms of Young measures always yields something smaller.

THEOREM 2.2 (see [13]). *If $\{z_j\}$ is a sequence of measurable functions with associated Young measure $\nu = \{\nu_x\}_{x\in\Omega}$, then*

$$\liminf_{j\to\infty} \int_E \psi(x, z_j(x))\, dx \geq \int_E \int_{\mathbf{R}^m} \psi(x,\lambda)\, d\nu_x(\lambda)\, dx$$

for every Carathéodory function ψ, bounded from below, and every measurable subset $E \subset \Omega$.

By using this fact, we obtain

$$\begin{aligned} \lim_{j\to\infty} \int_\Omega W(a_j(x), u_j(x))\, dx &\geq \int_\Omega \int_{\mathbf{R}^m \times \mathbf{R}^d} W(\lambda,\rho)\, d\nu_x(\lambda,\rho)\, dx \\ &= \int_\Omega \int_{\mathbf{R}^m} \int_{\mathbf{R}^d} W(\lambda,\rho)\, d\mu_{\lambda,x}(\rho)\, d\sigma_x(\lambda)\, dx. \end{aligned}$$

We also have the constraint on the first moment

$$u(x) = \int_{\mathbf{R}^m \times \mathbf{R}^d} \rho \, d\nu_x(\lambda, \rho) = \int_{\mathbf{R}^m} \int_{\mathbf{R}^d} \rho \, d\mu_{\lambda,x}(\rho) \, d\sigma_x(\lambda).$$

If we set

$$\varphi(\lambda, x) = \int_{\mathbf{R}^d} \rho \, d\mu_{\lambda,x}(\rho), \tag{2.2}$$

so that

$$u(x) = \int_{\mathbf{R}^m} \varphi(\lambda, x) \, d\sigma_x(\lambda), \tag{2.3}$$

we can go further down in our lower estimate by putting

$$\int_\Omega \int_{\mathbf{R}^m} \int_{\mathbf{R}^d} W(\lambda, \rho) \, d\mu_{\lambda,x}(\rho) \, d\sigma_x(\lambda) \, dx \geq \int_\Omega \int_{\mathbf{R}^m} CW(\lambda, \varphi(\lambda, x)) \, d\sigma_x(\lambda) \, dx,$$

where CW indicates the convex hull of W with respect to ρ. We can therefore write

$$I(u) \geq \inf_\varphi \left\{ \int_\Omega \int_{\mathbf{R}^m} CW(\lambda, \varphi(\lambda, x)) \, d\sigma_x(\lambda) \, dx : \varphi \text{ verifies (2.2) and (2.3) for some admissible } \nu \text{ as in (2.1)} \right\}.$$

One main step is to isolate the key requirements on the vector fields φ in the previous infimum without any reference to the measures $\mu_{\lambda,x}$ in (2.1), bearing in mind that we will later have to produce a sequence converging weakly to u for which all these inequalities are indeed equalities. In this general context, there is essentially no structural condition on φ so that we go further down by estimating

$$I(u) \geq \inf_\varphi \left\{ \int_\Omega \int_{\mathbf{R}^m} CW(\lambda, \varphi(\lambda, x)) \, d\sigma_x(\lambda) \, dx : u(x) = \int_{\mathbf{R}^m} \varphi(\lambda, x) \, d\sigma_x(\lambda) \right\}.$$

Because of the local nature of the Young measure, we see that this lower bound for $I(u)$ is an integral functional. Indeed if we define the integrand

$$\psi(x, \rho) : \Omega \times \mathbf{R}^d \to \mathbf{R}$$

by putting

$$\psi(x, \rho) = \inf_\varphi \left\{ \int_{\mathbf{R}^m} CW(x, \varphi(\lambda)) \, d\sigma_x(\lambda) : \rho = \int_{\mathbf{R}^m} \varphi(\lambda) \, d\sigma_x(\lambda) \right\}, \tag{2.4}$$

then, by interchanging the inf operation with the integral over Ω,

$$I(u) \geq \int_\Omega \psi(x, u(x)) \, dx.$$

Our goal is to show that we have, in fact, equality

$$I(u) = \int_\Omega \psi(x, u(x)) \, dx.$$

LEMMA 2.3. *The infimum in* (2.4) *is always attained.*

Proof. Notice that this lemma amounts to showing that a variational principle of the type

$$\text{Minimize in } \varphi: \quad \int_{\mathbf{R}^m} F(\lambda, \varphi(\lambda))\, d\sigma(\lambda)$$

subject to

$$\rho = \int_{\mathbf{R}^m} \varphi(\lambda)\, d\sigma(\lambda)$$

always has optimal solutions where σ is a given probability measure supported in $\mathbf{R}^m$ and F is a continuous integrand that is convex and coercive in the second variable. One could invoke Lebesgue spaces with respect to measures different from the usual Lebesgue measures (see [2]). Instead, in this simple context, it is easier to use the same slicing measure technique.

Let $\{\varphi_j\}$ be minimizing, and let φ be its weak limit. Define a measure ν supported on $\mathbf{R}^m \times \mathbf{R}^d$ by putting

$$\langle G, \nu \rangle = \lim_{j\to\infty} \int_{\mathbf{R}^m} G(\lambda, \varphi_j(\lambda))\, d\sigma(\lambda) \tag{2.5}$$

for any continuous G. It is clear that the projection of ν over $\mathbf{R}^m$ is σ. By the slicing measure decomposition we claim that, by the convexity of F,

$$\begin{aligned}
\lim_{j\to\infty} \int_{\mathbf{R}^m} F(\lambda, \varphi_j(\lambda))\, d\sigma(\lambda) &= \int_{\mathbf{R}^m} \int_{\mathbf{R}^d} F(\lambda, \rho)\, d\mu^\lambda(\rho)\, d\sigma(\lambda) \\
&\geq \int_{\mathbf{R}^m} F\left(\lambda, \int_{\mathbf{R}^d} \rho\, d\mu^\lambda(\rho)\right) d\sigma(\lambda) \\
&= \int_{\mathbf{R}^m} F(\lambda, \varphi(\lambda))\, d\sigma(\lambda).
\end{aligned}$$

Notice that applying (2.5) to $G(\lambda, \rho) = g(\lambda)\rho$ for arbitrary g, we conclude that the first moment of μ^λ is precisely the weak limit φ. □

Proof of Theorem 1.1. Let u be given. For a.e. $x \in \Omega$, by Lemma 2.3, we find $\varphi_0(\lambda, x)$ such that

$$\begin{aligned}
\psi(x, u(x)) &= \int_{\mathbf{R}^m} CW(\lambda, \varphi_0(\lambda, x))\, d\sigma_x(\lambda), \\
u(x) &= \int_{\mathbf{R}^m} \varphi_0(\lambda, x)\, d\sigma_x(\lambda).
\end{aligned}$$

It is also true that for every pair $(\lambda, x) \in \mathbf{R}^m \times \Omega$ we can find a probability measure $\mu_{\lambda,x}$ supported in $\mathbf{R}^d$ such that

$$\begin{aligned}
CW(\lambda, \varphi_0(\lambda, x)) &= \int_{\mathbf{R}^d} W(\lambda, \rho)\, d\mu_{\lambda,x}(\rho), \\
\varphi_0(\lambda, x) &= \int_{\mathbf{R}^d} \rho\, d\mu_{\lambda,x}(\rho).
\end{aligned}$$

In fact, it is a direct consequence of Carathéodory's theorem (see [7]) that we can take

$$\mu_{\lambda,x} = \sum_{l=0}^{d} t_{\lambda,x,l}\delta_{z_{\lambda,x,l}}, \qquad t_{\lambda,x,l} \geq 0, \sum_{l=0}^{d} t_{\lambda,x,l} = 1$$

for certain vectors $z_{\lambda,x,l}$. We conclude that

$$\int_{\Omega} \psi(x,u(x))\,dx = \int_{\Omega}\int_{\mathbf{R}^m}\int_{\mathbf{R}^d} W(\lambda,\rho)\,d\mu_{\lambda,x}(\rho)\,d\sigma_x(\lambda)\,dx.$$

Take the family of probability measures

$$\nu_x = \mu_{\lambda,x} \otimes \sigma_x. \tag{2.6}$$

Our main task consists in finding a sequence $\{u_j\}$ so that $\nu = \{\nu_x\}_{x\in\Omega}$ is the Young measure associated with $\{(a_j,u_j)\}$ and

$$\lim_{j\to\infty}\int_{\Omega} W(a_j(x),u_j(x))\,dx = \int_{\Omega}\psi(x,u(x))\,dx, \tag{2.7}$$

as desired. Notation becomes cumbersome but the leading argument is quite transparent, we believe.

An important issue here is that we are not entitled to change the sequence $\{a_j\}$ so that it is the sequence $\{u_j\}$ that must adapt itself to $\{a_j\}$. We will be using the next lemma. It is modeled after Lemma 7.9 in [13], but this time for a general, positive Radon measure. Its proof is based on the Lebesgue differentiation theorem, which is also valid for Radon measures (see, for instance, Corollary 2.23 in [2]). $B(\lambda,r)$ is, as usual, the ball centered at λ and radius r.

LEMMA 2.4. *Let σ be a positive, Radon measure in an open set D in $\mathbf{R}^d$. Let $N \subset D$ be a subset of σ-null measure. For $r_j : D\setminus N \to \mathbf{R}^+$ and $\{f_i\} \subset L^1(D,\sigma)$, there exist a set of points $\{\lambda_k^{(j)}\} \subset D\setminus N$ and positive numbers $\{\epsilon_k^{(j)}\}$, $\epsilon_k^{(j)} \leq r_j(\lambda_k^{(j)})$, such that*

$$\left\{B(\lambda_k^{(j)},\epsilon_k^{(j)})\right\} \text{ are pairwise disjoint for each } j,$$

$$\sigma\left(D\setminus \cup_k B(\lambda_k^{(j)},\epsilon_k^{(j)})\right) = 0 \quad \text{for each } j,$$

$$\int_D \xi(\lambda) f_i(\lambda)\,d\sigma(\lambda) = \lim_{j\to\infty}\sum_k f_i(\lambda_k^{(j)})\int_{B(\lambda_k^{(j)},\epsilon_k^{(j)})}\xi(\lambda)\,d\sigma(\lambda)$$

for every i and every $\xi \in L^\infty(D,\sigma)$.

Choose a dense, countable family of functions $\{W_i(\lambda,\rho)\}_{i=1,2,\ldots}$ vanishing at infinity. Put $W_0 \equiv W$. Consider the countable family of functions $\left\{\overline{W}_i(x)\right\}_{i=0,1,\ldots}$ defined by

$$\overline{W}_i(x) = \int_{\mathbf{R}^m}\tilde{W}_i(\lambda,x)\,d\sigma_x(\lambda),$$

$$\tilde{W}_i(\lambda,x) = \int_{\mathbf{R}^d} W_i(\lambda,\rho)\,d\mu_{\lambda,x}(\rho).$$

Apply the preceding lemma to Ω, the Lebesgue measure, $r_j(x)=1$, $N=\emptyset$, and the family $\{\overline{W}_i\}$ to conclude that we can find $\{x_k^{(j)}\}$ and $\{\epsilon_k^{(j)}\}$ such that

$$\left\{B(x_k^{(j)},\epsilon_k^{(j)})\right\} \text{ are pairwise disjoint for each } j,$$

$$\left|\Omega\setminus \cup_k B(x_k^{(j)},\epsilon_k^{(j)})\right|=0 \quad \text{for each } j,$$

$$\int_\Omega \xi(x)\int_{\mathbf{R}^m}\int_{\mathbf{R}^d} W_i(\lambda,\rho)\,d\mu_{\lambda,x}(\rho)\,d\sigma_x(\lambda)\,dx=\lim_{j\to\infty}\sum_k \overline{W}_i(x_k^{(j)})\int_{B(x_k^{(j)},\epsilon_k^{(j)})}\xi(x)\,dx$$

for all $\xi\in L^\infty(\Omega)$.

Apply Lemma 2.4 once again, this time to the Radon measures $\sigma_k^{(j)}\equiv\sigma_{x_k^{(j)}}$, $r_s(\lambda)=\epsilon_k^{(j)}$, $N=\emptyset$ and the family $\{\tilde{W}_i(\cdot,x_k^{(j)})\}$. Conclude that there exists a collection of points $\{\lambda_{k,r}^{(j,s)}\}$ and $\delta_{k,r}^{(j,s)}<\epsilon_k^{(j)}$ such that

$$\left\{B(\lambda_{k,r}^{(j,s)},\delta_{k,r}^{(j,s)})\right\} \quad \text{are pairwise disjoint for each } j,\ k, \text{ and } s,$$

$$\sigma_k^{(j)}\left(\mathbf{R}^m\setminus\cup_r B(\lambda_{k,r}^{(j,s)},\delta_{k,r}^{(j,s)})\right)=0 \quad \text{for every } j,\ k, \text{ and } s,$$

$$\int_{\mathbf{R}^m}\tilde{W}_i(\lambda,x_k^{(j)})\,d\sigma_k^{(j)}(\lambda)=\lim_{s\to\infty}\sum_r \tilde{W}_i(\lambda_{k,r}^{(j,s)},x_k^{(j)})\,\sigma_k^{(j)}\left(B(\lambda_{k,r}^{(j,s)},\delta_{k,r}^{(j,s)})\right)$$

for all k, j and i.

By our previous remark about Carathéodory's theorem,

$$\mu_{\lambda_{k,r}^{(j,s)},x_k^{(j)}}=\sum_{l=0}^d t_{k,r,l}^{(j,s)}\delta_{z_{k,r,l}^{(j,s)}},\quad t_{k,r,l}^{(j,s)}\ge 0, \sum_{l=0}^d t_{k,r,l}^{(j,s)}=1.$$

Take any partition of the set

$$\Lambda_{k,r}^{(j,s)}=\left\{a_j\in B(\lambda_{k,r}^{(j,s)},\delta_{k,r}^{(j,s)})\right\}\cap B(x_k^{(j)},\epsilon_k^{(j)})$$

in $d+1$ disjoint subsets, $\Lambda_{k,r,l}^{(j,s)}$, of relative (Lebesgue) measures $t_{k,r,l}^{(j,s)}$, and define $u_{j,s}$ on these subsets as $z_{k,r,l}^{(j,s)}$, respectively. Notice that

$$\lim_{j\to\infty}\sup_k\lim_{s\to\infty}\sup_r\left(\sigma_k^{(j)}\left(B(\lambda_{k,r}^{(j,s)},\delta_{k,r}^{(j,s)})\right)-\frac{\left|\Lambda_{k,r}^{(j,s)}\right|}{\left|B(x_k^{(j)},\epsilon_k^{(j)})\right|}\right)=0.$$

Take $\{\xi_n\}$ to be a dense, countable subset of continuous functions including the function identically 1 over Ω. For any such continuous ξ_n and any j and s, we have that the integrals

$$R_{n,i,j,s}=\int_\Omega \xi_n(x)W_i(a_j(x),u_{j,s}(x))\,dx$$

can be decomposed as follows:

$$\begin{aligned}
R_{n,i,j,s} &= \sum_k \sum_r \int_{\Lambda_{k,r}^{(j,s)}} \xi_n(x) W_i(\lambda_{k,r}^{(j,s)}, u_{j,s}(x))\, dx + d_{n,i,j,s} \\
&= \sum_k \sum_r \sum_l \int_{\Lambda_{k,r,l}^{(j,s)}} \xi_n(x)\, dx\, W_i(\lambda_{k,r}^{(j,s)}, z_{k,r,l}^{(j,s)}) + d_{n,i,j,s} \\
&= \sum_k \sum_r \int_{\Lambda_{k,r}^{(j,s)}} \xi_n(x)\, dx\, \tilde{W}_i(\lambda_{k,r}^{(j,s)}, x_k^{(j)}) + d_{n,i,j,s} \\
&= \sum_k \int_{B(x_k^{(j)}, \epsilon_k^{(j)})} \xi_n(x)\, dx \sum_r \tilde{W}_i(\lambda_{k,r}^{(j,s)}, x_k^{(j)}) \sigma_k^{(j)} \left(B(\lambda_{k,r}^{(j,s)}, \delta_{k,r}^{(j,s)}) \right) + d_{n,i,j,s}.
\end{aligned}$$

$d_{n,i,j,s}$ designates different sequences of numbers such that

$$\lim_{j\to\infty} \lim_{s\to\infty} d_{n,i,j,s} = 0$$

for all i and n. By our previous choices through Lemma 2.4, we can suitably choose $s = s(j)$ and have that the Young measure corresponding to $\{(a_j, u_j)\}$, $u_j = u_{j,s(j)}$, is precisely ν. Furthermore, by redoing all the previous computations for $\xi \equiv 1$ and W (for this we need the uniform continuity with respect to λ), it is elementary to check that (2.7) holds. In particular $\{u_j\}$ is bounded in $L^p(\Omega)$. □

An interesting consequence of our theorem is the following.

COROLLARY 2.5. *The Γ-limit of the initial functionals I_j depends upon the sequence $\{a_j\}$ only through its underlying Young measure.*

3. Some examples. What is quite remarkable is that in specific examples the computation of the density in (2.4) for the Γ-limit can be explicitly calculated. We will look at two typical, nontrivial examples.

Notice, to begin with, that if the sequence $\{a_j\}$ converges strongly to a, then the variational problem (2.4) is trivial since $\sigma_x = \delta_{a(x)}$, and we get

$$\psi(x, u(x)) = CW(a(x), u(x)).$$

On the other hand, solving (2.4) and overlooking the dependence on x amounts to being able to find the optimal solutions of problems of the type

$$\text{Minimize in } \varphi: \quad \int_{\mathbf{R}^m} F(\lambda, \varphi(\lambda))\, d\sigma(\lambda)$$

subject to

$$\rho = \int_{\mathbf{R}^m} \varphi(\lambda)\, d\sigma(\lambda),$$

where σ is a given probability measure supported in $\mathbf{R}^m$ and $F : \mathbf{R}^m \times \mathbf{R}^d \to \mathbf{R}$ is coercive and convex in the second variable. Since we know that there are always optimal solutions, these can be found by examining optimality conditions in many cases. The form of these will obviously depend on the probability measure σ.

Let us take

$$I_j(u) = \int_\Omega a_j(x)\, |u(x)|^2\, dx,$$

where $a_j : \Omega \to \mathbf{R}$ and $u : \Omega \to \mathbf{R}^d$ and $a_j \geq \alpha > 0$. The family of probability measures appearing in (2.4) is precisely the Young measure associated with $\{a_j\}$. In this example we know that those are supported in $\mathbf{R}$, more precisely in $(\alpha, +\infty)$. By Corollary 2.5 we can specify $\sigma = \{\sigma_x\}$ instead of a_j. The simplest nontrivial example corresponds, overlooking the dependence on x, to

$$\sigma = t\delta_a + (1-t)\delta_b$$

for $t \in (0,1)$ and $\alpha < a < b$. Since in this case the only relevant values in the optimization problem to find the density for the Γ-limit are $\varphi(a)$ and $\varphi(b)$, let us put for simplicity

$$A = \varphi(a), \quad B = \varphi(b).$$

Then we must solve

$$\text{Minimize in } (A,B): \quad ta\,|A|^2 + (1-t)b\,|B|^2$$

subject to

$$\rho = tA + (1-t)B.$$

The optimal solution is easily found to be

$$A = \frac{b}{tb + (1-t)a}\rho, \quad B = \frac{a}{tb + (1-t)a}\rho,$$

and hence the value of the infimum is

$$\frac{ab}{tb + (1-t)a}\,|\rho|^2.$$

In particular if $\{a_j\}$ generates the Young measure

$$\sigma_x = t(x)\delta_a + (1-t(x))\delta_b,$$

then the Γ-limit is

$$I(u) = \int_\Omega \frac{ab}{t(x)b + (1-t(x))a}\,|u(x)|^2\,dx.$$

Let us now assume that $\{a_j\}$ generates the Lebesgue measure restricted to the interval (a,b), where again $\alpha < a < b$. Then we should solve the variational problem

$$\text{Minimize in } \varphi: \quad \int_a^b y\,|\varphi(y)|^2\,dy$$

subject to

$$\rho = \int_a^b \varphi(y)\,dy.$$

By looking at optimality conditions, we find that the optimal $\varphi(y)$ is

$$\varphi(y) = \frac{1}{\log\frac{b}{a}}\frac{1}{y}\rho,$$

and the value of the infimum is

$$\frac{1}{\log \frac{b}{a}} |\rho|^2 .$$

In this case the Γ-limit is

$$I(u) = \frac{1}{\log \frac{b}{a}} \int_a^b |u(x)|^2 \, dx.$$

Another such interesting example corresponds to having

$$d\sigma_x(y) = \chi_{(a,b)}(y) f(x,y) \, dy$$

for a certain $f(x,y)$.

In connection with this last family of examples, consider the case of homogenization of integrals in the periodic case

$$I_j(u) = \int_Q W(jx, u(x)) \, dx,$$

where

$$W(y,\rho) : Q \times \mathbf{R}^d \to \mathbf{R}$$

is Q-periodic in y, and Q is the unit cube in $\mathbf{R}^d$. In this case we can take

$$a_j : Q \to Q, \quad a_j(x) = jx - [jx],$$

where brackets $[\cdot]$ indicate the integer part. It is well known (see Riemann–Lebesgue lemma [7], [13]) that the Young measure associated with $\{a_j\}$ is the Lebesgue measure restricted to Q. Thus the variational problem defining the homogenized functional

$$\psi(\rho) : \mathbf{R}^d \to \mathbf{R}$$

is

$$\text{Minimize in } \varphi : \quad \int_Q CW(y, \varphi(y)) \, dy$$

subject to

$$\rho = \int_Q \varphi(y) \, dy,$$

where CW is the convexification with respect to the u variable. When CW is smooth then optimality conditions may be used to determine explicitly the integrand $\psi(\rho)$ as in the examples above. Explicit dependence of W on x can also be allowed and nonperiodic examples can also be studied.

4. The gradient case. We would like to explore how the previous analysis may be adapted to deal with an explicit dependence on gradients of the integrand defining the functionals I_j. We thus assume

$$I_j(u) = \int_\Omega W(a_j(x), \nabla u(x)) \, dx. \tag{4.1}$$

The same technical assumptions on W as in the nongradient case hold:

$$c\left(|\rho|^p-1\right)\le W(a_j(x),\rho)\le C\left(|\rho|^p+1\right),$$
$$|W(\lambda_1,\rho)-W(\lambda_2,\rho)|\le w(|\lambda_1-\lambda_2|)\,|\rho|^p$$

for some $C>c>0$, all j, a.e. $x\in\Omega$, and some exponent $p>1$. We will restrict our attention here to the scalar case where $u:\Omega\to\mathbf{R}$ and leave the more complicated vector case for a future work [14]. Note that

$$a_j:\Omega\to\mathbf{R}^m,\quad W:\mathbf{R}^m\times\mathbf{R}^N\to\mathbf{R}$$

if Ω is a regular, bounded domain in $\mathbf{R}^N$. Assume that $\{a_j\}$ is uniformly bounded in some Lebesgue space.

Let $u\in W^{1,p}(\Omega)$ be given, and let $u_j\rightharpoonup u$ in $W^{1,p}(\Omega)$. Let

$$\nu=\{\nu_x\}_{x\in\Omega},\quad \nu_x=\mu_{\lambda,x}\otimes\sigma_x \tag{4.2}$$

be the Young measure associated with the pairs $\{(a_j,\nabla u_j)\}$, where $\sigma=\{\sigma_x\}_{x\in\Omega}$ is the one corresponding to $\{a_j\}$. Notice that the lower bound for the case without derivatives is again valid. Indeed if

$$\varphi(\lambda,x)=\int_{\mathbf{R}^N}\rho\,d\mu_{\lambda,x}(\rho),\qquad \nabla u(x)=\int_{\mathbf{R}^m}\varphi(\lambda,x)\,d\sigma_x(\lambda), \tag{4.3}$$

then a lower bound for the Γ-limit is

$$\inf_{\varphi}\left\{\int_\Omega\int_{\mathbf{R}^m}CW(\lambda,\varphi(\lambda,x))\,d\sigma_x(\lambda)\,dx\right\}, \tag{4.4}$$

where φ is admissible as indicated above. The key issue here is how to determine admissibility for the fields $\varphi(\lambda,x)$ in terms not only of σ, but also of the sequence a_j itself. Because of this fact, a general result such as Lemma 2.3 in this situation should be more involved. The difficulties are related to the ones we encounter when trying to adjust the gradients of several components (vector gradients) at the same time. This is due to the fact that we cannot modify the sequence $\{a_j\}$ in the least. Notice that the condition

$$\varphi(\lambda,x)=\int_{\mathbf{R}^N}\rho\,d\mu_{\lambda,x}(\rho)$$

essentially says that admissible vector fields φ should be "averages" of gradients over a partition of Ω related to the sequence $\{a_j\}$. As far as we can tell there is no explicit characterization of such property since we do not know how to reconstruct a gradient field from its averages over certain known sets so as to "patch" them together. This can only be done when there is some adjustment between the admissible fields φ in (4.4) and the sequence $\{a_j\}$. We would like, however, to explore how the proof of Theorem 1.1 can be redone in the gradient situation. The only case where we can proceed to compute the Γ-limit, always by reproducing the proof of Theorem 1.1, corresponds to the situation when the infimum in (4.4) over all admissible φ's equals the infimum over the fields satisfying a certain property related to the sequence $\{a_j\}$ itself. One such situation occurs when the sequence $\{a_j\}$ has the AGP. A rigorous way of formalizing this property follows. Formalities are related to the fact that this property needs to be defined locally. B stands for the unit ball in $\mathbf{R}^N$.

Definition 4.1. *We say that the sequence $\{a_j\}$ verifies the AGP (with respect to the exponent p) if $\sigma=\{\sigma_x\}_{x\in\Omega}$ is its corresponding Young measure and for a.e. $x\in\Omega$ whenever*

1. $r_j \searrow 0$ *and* $\{a_j(x + r_j y)\}$, $y \in B$, *generates* σ_x;
2. *for all* j

$$\left\{B(\lambda_k^{(j)}, r_k^{(j)})\right\} \text{ are pairwise disjoint,}$$
$$r_k^{(j)} < r_j \text{ for all } k,$$
$$\sigma_x\left(\mathbf{R}^m \setminus \cup_k B(\lambda_k^{(j)}, r_k^{(j)})\right) = 0;$$

3. $v \in W^{1,p}(B)$,

then if we define

$$\Omega_k^{(j)} = \left\{y \in B : a_j(x + r_j y) \in B(\lambda_k^{(j)}, r_k^{(j)})\right\}$$

and

$$V_j(y) = \frac{1}{\left|\Omega_k^{(j)}\right|} \int_{\Omega_k^{(j)}} \nabla v(z)\, dz, \quad y \in \Omega_k^{(j)},$$

it is true that

$$\| curl V_j\|_{W^{-1,q}(B)} \to 0$$

as $j \to \infty$.

This is a precise way (probably not the only one) of formalizing the heuristic idea that averages of gradients over "level sets" of $\{a_j\}$ are themselves gradients. As such, it has been specifically tailored to redo the proof of Theorem 1.1 in the gradient case. We will describe some important explicit examples in the next section.

If we define the density

$$\psi(x, \rho) : \Omega \times \mathbf{R}^N \to \mathbf{R}$$

by putting, just as before,

(4.5)
$$\psi(x, \rho) = \inf_{\varphi} \left\{ \int_{\mathbf{R}^m} CW(\lambda, \varphi(\lambda))\, d\sigma_x(\lambda) : \rho = \int_{\mathbf{R}^m} \varphi(\lambda)\, d\sigma_x(\lambda), \text{ and whenever} \right.$$
$$r_j \searrow 0 \text{ is such that } \{a_j(x + r_j y)\} \text{ generates } \sigma_x,$$
$$\left. \| \operatorname{curl} (\varphi(a_j(x + r_j y)))\|_{W^{-1,q}(B)} \to 0 \right\},$$

then we claim that the Γ-limit is

$$I(u) = \int_\Omega \psi(x, \nabla u(x))\, dx. \tag{4.6}$$

LEMMA 4.2. *If* $\{a_j\}$ *verifies the AGP, then the class of admissible fields in the infimum in* (4.5) *is identical to the class for the infimum in* (4.4) *for a.e.* $x \in \Omega$.

Proof. Let $\varphi(\lambda, x)$ be as in (4.3), where

$$\nu_x = \mu_{\lambda,x} \otimes \sigma_x$$

is the slicing measure decomposition of the Young measure associated to the pairs

$\{(a_j, \nabla u_j)\}$ for certain gradients $\{\nabla u_j\}$. The point x is regarded here as a parameter. We know that if $r_j \searrow 0$ is such that the sequence $\{a_j(x + r_j y)\}$, for $y \in B$, generates σ_x (the localization property of Young measures; see [13]) and

$$\Omega_k^{(j)} = \left\{ y \in B : a_j(x + r_j y) \in B(\lambda_k^{(j)}, r_k^{(j)}) \right\},$$
$$\sigma_x \left(\mathbf{R}^m \setminus \cup_k B(\lambda_k^{(j)}, r_k^{(j)}) \right) = 0,$$
$$\left\{ B(\lambda_k^{(j)}, r_k^{(j)}) \right\} \text{ pairwise disjoint for all } j, \quad r_k^{(j)} < r_j,$$

then

$$\sup_k \left| \frac{1}{\left| \Omega_k^{(j)} \right|} \int_{\Omega_k^{(j)}} \nabla u_j(z)\, dz - \varphi(\lambda_k^{(j)}, x) \right| \to 0 \quad \text{as } j \to \infty.$$

This is one important property of the slicing measure decomposition. Consequently if V_j is taken as in Definition 4.1 for the gradients ∇u_j, after a standard diagonal argument, we have

$$\| V_j(y) - \varphi(a_j(x + r_j y), x) \|_{L^p(B)} \to 0 \quad \text{as } j \to \infty,$$

where

$$\| \operatorname{curl}_y V_j(y) \|_{W^{-1,q}(B)} \to 0.$$

This certainly implies that

$$\| \operatorname{curl}_y \varphi(a_j(x + r_j y), x) \|_{W^{-1,q}(B)} \to 0. \qquad \square$$

In the next lemma we gather several elementary or well-known facts.

LEMMA 4.3.

1. *Every probability measure supported in* $\mathbf{R}^N$ *can be generated by a sequence of gradients (the scalar case; see* [13]*).*
2. *If* $\| curl V_j \|_{W^{-1,q}(\Omega)} \to 0$*, there exists a sequence* $\{U_j\}$*, bounded in* $W^{1,p}(\Omega)$*, such that*
$$\| \nabla U_j - V_j \|_{L^p(\Omega)} \to 0.$$
3. *If* $\| U_j - V_j \|_{L^p(\Omega)} \to 0$*, then the two sequences* $\{U_j\}$ *and* $\{V_j\}$ *generate the same Young measure* [13].

Proof of Theorem 1.2. We are now ready to prove Theorem 1.2. We follow closely the same procedure as in the proof of Theorem 1.1. The key change refers to the fact that by Lemma 4.2, the field φ_0 is locally (almost) a gradient in λ. Thus, by item 1 of Lemma 4.3, and for j, k fixed, the family of probability measures

$$\nu_k^{(j)}(y) = \mu_{\lambda_{k,r}^{(j,s)}, x_k^{(j)}} \otimes \sigma_{x_k^{(j)}}$$

for $y \in \Lambda_{k,r}^{(j,s)}$, where as before

$$\Lambda_{k,r}^{(j,s)} = \left\{ y \in B : a_j(x_k^{(j)} + \epsilon_k^{(j)})y) \in B(\lambda_{k,r}^{(j,s)}, \delta_{k,r}^{(j,s)}) \right\} \cap B,$$

is a gradient Young measure in B because its first moment is, by construction,

$$\varphi_0\left(a_j(x_k^{(j)}+\epsilon_k^{(j)})y), x_k^{(j)}\right),$$

and this field is essentially a gradient (the characterization of Young measures; see [13]). Hence, the sequence $\{u_{j,s}\}$ in the proof of Theorem 1.1 can be taken such that

$$\lim_{j\to\infty}\lim_{s\to\infty}\|\operatorname{curl} u_{j,s}\|_{W^{-1,q}(\Omega)}\to 0.$$

Keep in mind that the integral of φ_0 against σ is also a gradient. We conclude by applying items 2 and 3 of Lemma 4.3 to the pairs $\left\{(a_j, u_{j,s(j)})\right\}$ for an appropriate subsequence. □

Because x in (4.3) is like a parameter, finding explicitly the density for the Γ-limit (always under the AGP) amounts to solving problems of the type

$$\text{Minimize in } \varphi: \quad \int_{\mathbf{R}^m} F(\lambda,\varphi(\lambda))\,d\sigma(\lambda)$$

subject to

$$\rho=\int_{\mathbf{R}^m}\varphi(\lambda)\,d\sigma(\lambda),$$
$$\|\operatorname{curl}\,(\varphi(a_j(y))\|_{W^{-1,q}(D)}\to 0,$$

where a_j is defined in D, and it generates σ as a homogeneous Young measure.

Notice that a fact as Corollary 2.5 cannot hold in this situation because the underlying structure of the sequence $\{a_j\}$ is embedded in the definition of the density for the Γ-limit.

5. Some examples for the gradient case. One of the simplest examples we can consider is the gradient version of our first example in section 3 in two dimensions:

$$I_j(u)=\int_\Omega a_j(x)\,|\nabla u(x)|^2\,dx,$$

where $\Omega\subset\mathbf{R}^2$, $a_j(x)=\chi(jx\cdot n)a+(1-\chi(jx\cdot n))b$, n is a unit vector, χ is the characteristic function of the interval $(0,t)$ over $(0,1)$ extended by periodicity, and a and b are such that $0<a<b$. The Γ-limit can be computed explicitly if $\{a_j\}$ verifies the AGP. Since in this example the Young measure associated with $\{a_j\}$ is homogeneous and supported only in $\{a,b\}$, verifying AGP reduces to checking that if

$$V_j^a=\int_{\{a_j=a\}\cap B}\nabla v(z)\,dz,$$
$$V_j^b=\int_{\{a_j=b\}\cap B}\nabla v(z)\,dz$$

for any $v\in H^1(B)$, then

$$(V_j^a-V_j^b)\cdot Tn\to 0$$

as $j\to\infty$, where T is the counterclockwise $\pi/2$ rotation. In this particular case, because of the divergence theorem,

$$(V_j^a-V_j^b)\cdot Tn=\int_{\partial B_j}v(z)\otimes n(z)\,dS(z)-\int_{\partial B\setminus\partial B_j}v(z)\otimes n(z)\,dS(z),$$

where ∂B_j is the intersection of the region where $a_j = a$ with ∂B. It is clear that as j grows larger and larger,

$$(V_j^a - V_j^b) \cdot Tn \to 0.$$

In this way, since $\sigma = t\delta_a + (1-t)\delta_b$ is the (homogeneous) Young measure generated by $\{a_j\}$, the density for the Γ-limit is defined through the optimization problem

$$\text{Minimize in } (A, B): \quad ta\,|A|^2 + (1-t)b\,|B|^2$$

subject to

$$\rho = tA + (1-t)B, \quad (A-B) \cdot Tn = 0.$$

Notice that for an admissible vector field φ,

$$\varphi(a_j(x)) = \chi(jx \cdot n)\varphi(a) + (1 - \chi(jx \cdot n))\varphi(b),$$

and the condition of this field being a gradient amounts to having

$$(\varphi(a) - \varphi(b)) \cdot Tn = 0.$$

We have put $A = \varphi(a)$, $B = \varphi(b)$ as before.

After some elementary, algebraic computations, we find the optimal value

$$\psi(\rho) = (ta + (1-t)b)\,|\rho|^2 - \frac{(b-a)^2 t(1-t)}{(1-t)a + tb}(\rho \cdot n)^2.$$

As expected, we can also write

$$\psi(\rho) = \rho^T H \rho,$$

where

$$H = (ta + (1-t)b)\mathbf{1} - \frac{(b-a)^2 t(1-t)}{(1-t)a + tb} n \otimes n$$

is the associated, effective, or homogenized tensor. $\mathbf{1}$ is the identity matrix. We can iterate this procedure to find the Γ-convergence of higher-order laminates (see [1]).

Another typical example is

$$I_j(u) = \int_Q W(jx, \nabla u(x))\,dx,$$

where Q is the unit cube in $\mathbf{R}^2$, $W(y, \rho)$ is Q-periodic in y, and we have the bounds

$$c\left(|\rho|^2 - 1\right) \le W(y, \rho) \le C\left(|\rho|^2 + 1\right)$$

for $0 < c < C$ and all $y \in Q$ as well as the uniform continuity in the y variable. In this case we take, as in section 3,

$$a_j : Q \to Q, \quad a_j(x) = jx - [jx].$$

We also know that the Young measure associated with $\{a_j\}$ is the Lebesgue measure restricted to Q (homogeneous). In this example, the AGP is also easy to check since

for a given $v \in H^1(B)$, the fields V_j in Definition 4.1 (when $\lim_{j\to\infty} jr_j = +\infty$) converge strongly in $L^p(B)$ to the average of ∇v over B due to periodicity. Since this limit is a constant vector, the AGP holds.

To compute the density for the Γ-limit, we need to examine the requirement about

$$\operatorname{curl}_y(\varphi(a_j(x + r_j y), x))$$

converging to zero. In this case, due to homogeneity, the x-dependence is irrelevant. If r_j is such that $s_j = jr_j$ converges to $+\infty$, then we need to determine the fields $\varphi : \mathbf{R}^2 \to \mathbf{R}^2$ such that

$$\operatorname{curl}_y(\varphi(s_j y - [s_j y]) \to 0.$$

Clearly, we can consider φ as Q-periodic, and then if $z = s_j y$,

$$\operatorname{curl}_y(\varphi(s_j y)) = s_j \operatorname{curl}_z \varphi(z),$$

so that since $s_j \to +\infty$, we conclude that $\varphi = \nabla\xi$ for some (possibly nonperiodic) field ξ. The optimization problem defining the density for the Γ-limit is

$$\text{Minimize in } \xi : \quad \int_Q CW(y, \nabla\xi(y))\, dy$$

subject to

$$\rho = \int_Q \nabla\xi(y)\, dy, \quad \nabla\xi,\ Q\text{-periodic.}$$

By an elementary change, we can reformulate the problem as

$$\text{Minimize in } \xi : \quad \int_Q CW(y, \rho + \nabla\xi(y))\, dy$$

for all $\xi \in H^1(Q)$, Q-periodic. This is the typical cell problem in homogenization of multiple integrals for the scalar case [4].

MULTILEVEL CHARACTERIZATIONS OF ANISOTROPIC FUNCTION SPACES*

GEORGE KYRIAZIS†

Abstract. We present a general method for extending decomposition systems of $L_2(\mathbb{R}^d)$ to decomposition systems for the anisotropic Triebel–Lizorkin and Besov spaces, $F_{p,q}^{\alpha,s}$ and $B_{p,q}^{\alpha,s}$, respectively, for the full range of the indexes. Our approach is based on techniques from harmonic analysis and relies on the boundedness of almost diagonal operators on appropriate sequence spaces. Typical examples of such decomposition systems are the various wavelet-type unconditional bases for $L_2(\mathbb{R}^d)$.

Key words. anisotropic function spaces, almost diagonal operators, unconditional bases, wavelets

1. Introduction.

Multilevel-basis characterizations of function spaces are important in many applications since they frequently lead to simple characterizations of the spaces in terms of discrete norms applied to the coefficients with respect to that basis. In this context, wavelet-type characterizations of the various isotropic Triebel–Lizorkin and Besov spaces have established themselves as a very useful tool in many fields such as statistics, image processing, and the numerical solutions of elliptic PDEs. In recent years, however, a renewed interest in pseudodifferential operators and Fourier multipliers acting on spaces with different degrees of smoothness in the various coordinate directions, as well as applications of nonlinear approximation, has lead to the study of the more general classes of anisotropic function spaces.

To describe our results we first introduce the standard multi-index notation. In particular, for every $x = (x_1, \dots, x_d) \in \mathbb{R}^d$ and $\beta = (\beta_1, \dots, \beta_d) \in \mathbb{N}_0^d$ ($\mathbb{N}_0 := \mathbb{N} \cup \{0\}$, $d \geq 1$), we let $x^\beta := x_1^{\beta_1} \cdots x_d^{\beta_d}$, $|\beta| := \beta_1 + \cdots + \beta_d$, $\beta! := \beta_1! \cdots \beta_d!$, and $(\cdot)^{(\beta)} := \frac{\partial^{|\beta|}(\cdot)}{\partial^{\beta_1} x_1 \cdots \partial^{\beta_d} x_d}$. Also, if $x, y \in \mathbb{R}^d$, we define $xy := x_1 y_1 + \cdots + x_d y_d$.

We recall that an anisotropy on $\mathbb{R}^d$ is a vector $\alpha = (a_i, \dots, a_d)$ of positive numbers such that $a_1 + \cdots + a_d = d$ and we let $\alpha_{\min} := \min\{a_i : 1 \leq i \leq d\}$ and $\alpha_{\max} := \max\{a_i : 1 \leq i \leq d\}$. If $t \geq 0$ and $x \in \mathbb{R}^d$ the anisotropic dilation is defined by

$$t^\alpha x := (t^{a_1} x_1, \dots, t^{a_d} x_d),$$

and for every $s \in \mathbb{R}$ we use the notation $t^{s\alpha} x := (t^s)^\alpha x$.

Let α be an anisotropy on $\mathbb{R}^d$, which will be fixed for the rest of the article, and $\lambda > 1$. For every $k = (k_1, \dots, k_d) \in \mathbb{Z}^d$, $j \in \mathbb{Z}$, we define the parallelepiped $I_{j,k}^\alpha$ to be the image of the cube $k + [0,1)^d$ under anisotropic dilation by $\lambda^{-j\alpha}$, namely,

$$I_{j,k}^\alpha := \lambda^{-ja_1}[k_1, k_1 + 1) \times \cdots \times \lambda^{-ja_d}[k_d, k_d + 1),$$

*Received by the editors March 31, 2003; accepted for publication (in revised form) January 16, 2004; published electronically July 29, 2004.

†Department of Mathematics and Statistics, University of Cyprus, P.O. Box 20537, 1678 Nicosia, Cyprus (kyriazis@ucy.ac.cy).

and we use the notation $x_{I^\alpha_{j,k}} := (\lambda^{-ja_1}k_1, \dots, \lambda^{-ja_d}k_d)$ for its lower left corner. The volume of a parallelepiped I will be denoted by $|I|$ ($|I^\alpha_{j,k}| = \lambda^{-jd}$) and we define $\ell(I) := |I|^{1/d}$ its average sidelength. Then, for every $j \in \mathbb{N}_0$ the set $\mathcal{D}_j := \{I^\alpha_{j,k} : k \in \mathbb{Z}^d\}$ forms a disjoint partition of $\mathbb{R}^d$ and we define $\mathcal{D} := \cup_{j\in\mathbb{Z}}\mathcal{D}_j$ and $\mathcal{D}_+ := \cup_{j\in\mathbb{N}_0}\mathcal{D}_j$.

We denote by $\mathcal{S} := \mathcal{S}(\mathbb{R}^d)$ the Schwartz space of infinitely differentiable, rapidly decreasing functions on $\mathbb{R}^d$ and by $\mathcal{S}' := \mathcal{S}'(\mathbb{R}^d)$ its dual, the space of tempered distributions. The Fourier transform $\widehat{f}$ of an integrable function is defined by

$$\widehat{f}(\xi) = \int_{\mathbb{R}^d} f(x)e^{-ix\xi}\,dx,$$

while its inverse is defined by $\check{f}(\xi) = (2\pi)^{-d}\widehat{f}(-\xi)$. Duality now extends the Fourier transform and thus its inverse uniquely from $\mathcal{S}$ to $\mathcal{S}'$. Finally, we use $\langle f, \eta\rangle$ for the standard inner product $\int f\overline{\eta}$ of two functions, when this makes sense, and the same notation is employed for the action of a distribution $f \in \mathcal{S}'$ on $\overline{\eta} \in \mathcal{S}$.

Let now E be a finite set and $\Psi := \{\psi^e_I : e \in E, I \in \mathcal{D}_+\}$ be a decomposition system for $L_2(\mathbb{R}^d)$ with dual functionals $\tilde{\Psi} := \{\widetilde{\psi}^e_I : e \in E, I \in \mathcal{D}_+\}$, that is, for every $f \in L_2(\mathbb{R}^d)$

$$f = \sum_{e\in E}\sum_{I\in\mathcal{D}_+} \langle f, \widetilde{\psi}^e_I\rangle\psi^e_I. \tag{1.1}$$

Our goal is to study sufficient conditions on $\Psi, \tilde{\Psi}$ so that they form a decomposition system for the inhomogeneous anisotropic Triebel–Lizorkin and Besov spaces. We would like also to characterize the membership of a distribution f in these spaces by the size of the coefficients $\{\langle f, \widetilde{\psi}^e_I\rangle\}_{I,e}$. In particular, we shall prove that under certain smoothness and oscillation assumptions on the families $\Psi, \tilde{\Psi}$, depending on the parameters $s \in \mathbb{R}, 0 < p < \infty$, and $0 < q \le \infty$ (see Theorem 4.1), if $f \in F^{\alpha,s}_{p,q}$, then (1.1) holds in the distributional sense (and in the sense of $F^{\alpha,s}_{p,q}$ when $q \ne \infty$). In addition, we have

$$\|f\|_{F^{\alpha,s}_{p,q}} \approx \sum_{e\in E}\Big\|\Big(\sum_{I\in\mathcal{D}_+}(|I|^{-s/d}|\langle f, \widetilde{\psi}^e_I\rangle|\tilde{\chi}_I)^q\Big)^{1/q}\Big\|_{L_p}, \tag{1.2}$$

where $\tilde{\chi}_I := |I|^{-1/2}\chi_I$ is the characteristic function of I normalized in L_2. Here we have adopted the notation $A \approx B$, which means that there exist constants $C_1, C_2 > 0$ such that $C_1A \le B \le C_2A$. The equivalence constants C_1 and C_2 in (1.2) depend on d, p, q, and s. On other occasions, the reader will have to consult the text to understand the parameters on which the equivalence constants depend on. Throughout the paper, the constants are denoted by C and they may vary at every occurrence.

Similarly (for suitable $\Psi, \tilde{\Psi}$) we shall prove (see Theorem 4.2) that for every $f \in B^{\alpha,s}_{p,q}$, $s \in \mathbb{R}, 0 < p, q \le \infty$, the representation (1.1) holds in the distributional sense (and in the sense of $B^{\alpha,s}_{p,q}$ when $p, q \ne \infty$). Also,

$$\|f\|_{B^{\alpha,s}_{p,q}} \approx \sum_{e\in E}\Bigg(\sum_{m\in\mathbb{N}_0}\Bigg(\sum_{I\in\mathcal{D}_m}\big(|I|^{-s/d+1/p-1/2}|\langle f, \widetilde{\psi}^e_I\rangle|\big)^p\Bigg)^{q/p}\Bigg)^{1/q} \tag{1.3}$$

with the usual modifications when $q = \infty$ or $p = \infty$.

This type of question is well studied in the isotropic cases, especially within the wavelet theory; for a full account see [FJW], [M], [HW], and [K] and the references therein.

Multiscale characterizations for the anisotropic Besov $B^{\alpha,s}_{p,q}$ spaces were given in [GHT], [GT], [H], and [L], by means of compactly supported wavelet bases for $0 < p, q \le \infty$, and $s > 0$ and in the special case where α and s are related by (2.6). In these references Besov spaces are defined via the modulus of smoothness; consequently the techniques used have their roots in approximation theory, and they are not applicable to the Triebel–Lizorkin spaces. In our paper we prefer to define both scales of Besov and Triebel–Lizorkin spaces in a unified way by means of Calderon's reproducing formula. We note that in the case of Besov spaces the two definitions lead to the same spaces for $s > d(\frac{1}{p} - 1)_+$ (see [D]). In particular, our goal is to present a general method for extending decomposition systems (or unconditional bases) of $L_2(\mathbb{R}^d)$, which are usually easier to construct, to decomposition systems (or unconditional bases) for the inhomogeneous anisotropic Besov and Triebel–Lizorkin spaces. As a consequence we establish wavelet characterizations for the $F^{\alpha,s}_{p,q}$ and $B^{\alpha,s}_{p,q}$ spaces for the full range of the indexes and for any sufficiently decaying wavelet bases. As an additional byproduct of our results we point out that the whole apparatus of nonlinear approximation by bases functions (see [De]) becomes available for these spaces as well, with possible applications in numerical methods dealing with semielliptic differential operators. Finally, we note that our results hold also for the homogeneous versions of the anisotropic Besov and Triebel–Lizorkin spaces with minor modifications.

The outline of the paper is as follows. In section 2 we give the definitions of the anisotropic $F^{\alpha,s}_{p,q}$ and $B^{\alpha,s}_{p,q}$ spaces and we briefly review some of their main properties. In section 3 we study the boundedness of almost diagonal operators on the sequence spaces $f^{\alpha,s}_{p,q}$ and $b^{\alpha,s}_{p,q}$, a subject that is important by itself, since it can be used for the study of the boundedness of Calderon–Zygmund-type operators on the $F^{\alpha,s}_{p,q}$ and $B^{\alpha,s}_{p,q}$ spaces. In section 4 we present the main results of our paper, and finally in section 5 we apply these results within the framework of wavelet bases. Some technical lemmas have been included in the appendix section 6.

2. Anisotropic function spaces. Let $\alpha = (a_1, \dots, a_d)$ be our fixed anisotropy. An anisotropic distance associated to α is a continuous function $u : \mathbb{R}^d \to \mathbb{R}$ such that $u(x) > 0, x \neq 0$, and $u(t^\alpha x) = tu(x), t > 0$; typical examples are given by

$$u_p(x) = \left(\sum_{i=1}^{d} |x_i|^{p/a_i} \right)^{1/p}, \quad x \in \mathbb{R}^d,\ 0 < p < \infty.$$

It is well known that any two anisotropic distances are equivalent and that there exists a $C^\infty(\mathbb{R}^d \setminus \{0\})$ anisotropic distance function (see [Y]), which we denote by $|\cdot|_\alpha$. We also recall that any anisotropic distance satisfies a quasi-triangular inequality, and in particular there exists $c_\alpha > 1$ such that $|x + y|_\alpha \le c_\alpha(|x|_\alpha + |y|_\alpha), x, y \in \mathbb{R}^d$.

To define the various function spaces that we are interested in we consider $\lambda > 1$, which will be fixed for the rest of this section, and we further assume that

$$\{x \in \mathbb{R}^d : |x|_\alpha \le \lambda\} \subset [-\pi, \pi]^d. \tag{2.1}$$

(This assumption is needed to establish the anisotropic version of Calderon's reproducing formula (2.12).)

Let now $\varphi_0 \in \mathcal{S}$ be such that

$$\text{supp } \widehat{\varphi_0} \subset \{\xi \in \mathbb{R}^d : |\xi|_\alpha \leq \lambda\} \quad \text{and} \quad \widehat{\varphi_0}(\xi) = 1 \text{ if } |\xi|_\alpha \leq 1. \tag{2.2}$$

We let also

$$\widehat{\varphi}(\xi) := \widehat{\varphi}_0(\xi) - \widehat{\varphi}_0(\lambda^\alpha \xi), \quad \xi \in \mathbb{R}^d, \tag{2.3}$$

and we define $\varphi_\nu(x) := \lambda^{\nu d}\varphi(\lambda^{\nu\alpha}x), x \in \mathbb{R}^d$, $\nu \in \mathbb{N}$. Then it is easily seen that

$$\sum_{\nu\in\mathbb{N}_0} \widehat{\varphi_\nu}(\xi) = 1, \quad \xi \in \mathbb{R}^d. \tag{2.4}$$

Let $s \in \mathbb{R},\ 0 < p < \infty,\ 0 < q \leq \infty$; the anisotropic Triebel–Lizorkin space $F^{\alpha,s}_{p,q}$ is defined to be the set of all $f \in \mathcal{S}'$ such that

$$\|f\|_{F^{\alpha,s}_{p,q}} := \left\| \left(\sum_{\nu\in\mathbb{N}_0} (\lambda^{\nu s}|\varphi_\nu * f|)^q \right)^{1/q} \right\|_{L_p} < \infty, \tag{2.5}$$

(with the usual modification for $q = \infty$).

We note that by varying the indices s, α, p, q we recover most of the classical isotropic and anisotropic spaces. For instance, if $1 < p < \infty$ and $(s_1, \ldots, s_d) \in \mathbb{N}^d$, then the anisotropic Sobolev space

$$W_p^{(s_1,\ldots,s_d)}(\mathbb{R}^d) := \left\{ f \in \mathcal{S}' : \|f\|_{L_p(\mathbb{R}^d)} + \sum_{j=1}^d \left\| \frac{\partial^{s_j} f}{\partial x_j^{s_j}} \right\|_{L_p(\mathbb{R}^d)} \right\}$$

is identified with $F^{\alpha,s}_{p,2}$ (see [ST]), where α, s are defined by

$$\frac{1}{s} = \frac{1}{d}\left(\frac{1}{s_1} + \cdots + \frac{1}{s_d}\right), \quad \alpha = \left(\frac{s}{s_1}, \ldots, \frac{s}{s_d}\right). \tag{2.6}$$

It also trivially seen that if $s = s_1 = \cdots = s_d$, then $F^{\alpha,s}_{p,q}$ coincides with the isotropic space $F^s_{p,q}$ (see [T]).

In a similar vein, for $s \in \mathbb{R},\ 0 < p, q \leq \infty$, the anisotropic Besov space $B^{\alpha,s}_{p,q}$ is defined to be the set of all $f \in \mathcal{S}'$ such that

$$\|f\|_{B^{\alpha,s}_{p,q}} := \left(\sum_{\nu\in\mathbb{N}_0} (\lambda^{\nu s}\big\|\varphi_\nu * f\big\|_{L_p})^q \right)^{1/q} < \infty \tag{2.7}$$

(with the usual modification for $q = \infty$).

In the literature it is customary to use $\lambda = 2$; nevertheless, from standard estimates (similar to the ones in [T] section 2.3.2) it is not hard to prove that the above definitions are independent of $\lambda > 1$.

Associated to the Triebel–Lizorkin and Besov spaces are the sequence spaces $f^{\alpha,s}_{p,q}$ and the $b^{\alpha,s}_{p,q}$, respectively.

For $s \in \mathbb{R}$, $0 < p < \infty$, and $0 < q \leq \infty$, $f^{\alpha,s}_{p,q}$ is defined to be the space of all complex-valued sequences $h := (h_I)_{I\in\mathcal{D}_+}$ such that

$$\|h\|_{f^{\alpha,s}_{p,q}} := \left\| \left(\sum_{I\in\mathcal{D}_+} (|I|^{-s/d}|h_I|\tilde{\chi}_I)^q \right)^{1/q} \right\|_{L_p} < \infty,$$

where $\tilde{\chi}_I(x) := |I|^{-1/2}\chi_I(x)$, (with the usual modification for $q = \infty$).

Similarly, if $s \in \mathbb{R}$, and $0 < p, q \leq \infty$, $b_{p,q}^{\alpha,s}$ is defined to be the space of all complex-valued sequences $h := (h_I)_{I \in \mathcal{D}_+}$ such that

$$\|h\|_{b_{p,q}^{\alpha,s}} := \left(\sum_{j \in \mathbb{N}_0} \left(\sum_{I \in \mathcal{D}_j} \left(|I|^{-s/d+1/p-1/2} |h_I| \right)^p \right)^{q/p} \right)^{1/q} < \infty$$

(with the usual modification for $p = \infty$ or $q = \infty$).

Regarding the notation of the $F_{p,q}^{\alpha,s}, B_{p,q}^{\alpha,s}, f_{p,q}^{\alpha,s}$, and $b_{p,q}^{\alpha,s}$ spaces, we point out that the anisotropy α appears only implicitly in their definitions, either in the construction of φ or in the description of the parallelepipeds in $\mathcal{D}_+$. Therefore, as mentioned in the introduction, we consider that α is a fixed anisotropy throughout this article, and we are concerned only with the range of the other three indexes s, p, q.

Multiplying (2.4) by $\widehat{f}$ and inverting the Fourier transform we get that for every $f \in \mathcal{S}'$

$$f = \sum_{\nu \in \mathbb{N}_0} \varphi_\nu * f, \tag{2.8}$$

in the sense of $\mathcal{S}'$. We are interested in a discretized and more useful, for our purposes, version of (2.8). Working toward this we recall from [Di] that one can construct functions $\phi_0, \widetilde{\phi}_0, \phi, \widetilde{\phi} \in \mathcal{S}$ satisfying

$$\begin{aligned} &\operatorname{supp} \widehat{\phi_0}, \widehat{\widetilde{\phi}_0} \subset \{\xi : |\xi|_\alpha \leq \lambda\}, \\ &\operatorname{supp} \widehat{\phi}, \widehat{\widetilde{\phi}} \subset \left\{ \xi : \frac{1}{\lambda} \leq |\xi|_\alpha \leq \lambda \right\}, \end{aligned}$$

and such that

$$\sum_{\nu \in \mathbb{N}_0} \overline{\widehat{\widetilde{\phi}_\nu}(\xi)} \widehat{\phi_\nu}(\xi)(\xi) = 1, \quad \xi \in \mathbb{R}^d, \tag{2.9}$$

where as before $\phi_\nu(x) := \lambda^{\nu d} \phi(\lambda^{\nu\alpha} x)$ and $\widetilde{\phi}_\nu(x) := \lambda^{\nu d} \widetilde{\phi}(\lambda^{\nu\alpha} x)$, $x \in \mathbb{R}^d, \nu \in \mathbb{N}$. Similarly to (2.8) we get that for every $f \in \mathcal{S}'$

$$f = \sum_{\nu \in \mathbb{N}_0} \eta_\nu * \phi_\nu * f, \tag{2.10}$$

in the sense of $\mathcal{S}'$, where $\eta_\nu(x) := \overline{\widetilde{\phi}_\nu(-x)}$. This is the so-called Calderon's reproducing formula. The advantage of formula (2.10) over (2.8) is that we can further analyze the smooth terms $\eta_\nu * \phi_\nu * f, \nu \in \mathbb{N}_0$. Using techniques reminiscent of the Shannon sampling theorem, one can show (see [Di]) that for every $f \in \mathcal{S}'$

$$\eta_\nu * \phi_\nu * f(x) = \sum_{I \in \mathcal{D}_\nu} \langle f, \widetilde{\phi}_I \rangle \phi_I(x), \quad x \in \mathbb{R}^d, \nu \in \mathbb{N}_0, \tag{2.11}$$

where for every parallelepiped $I \in \mathcal{D}$,

$$\phi_I(\cdot) := |I|^{-1/2} \phi \left(\frac{\cdot - x_I}{\ell(I)^\alpha} \right), \quad \widetilde{\phi}_I(\cdot) := |I|^{-1/2} \widetilde{\phi} \left(\frac{\cdot - x_I}{\ell(I)^\alpha} \right).$$

It follows that every distribution $f \in F^{\alpha,s}_{p,q}$ (or $B^{\alpha,s}_{p,q}$) can be represented in the form

$$f = \sum_{\nu\in\mathbb{N}_0} \sum_{I\in\mathcal{D}_\nu} \langle f, \widetilde{\phi}_I\rangle \phi_I = \sum_{I\in\mathcal{D}_+} \langle f, \widetilde{\phi}_I\rangle \phi_I, \tag{2.12}$$

in the sense of $\mathcal{S}'$.

Moreover, the coefficients

$$s_I(f) := \langle f, \widetilde{\phi}_I\rangle, \quad I \in \mathcal{D}_+,$$

in (2.12) contain all the necessary information to determine whether a distribution belongs in the class of anisotropic Triebel–Lizorkin or Besov spaces. In particular, it was established in [Di] that if $s \in \mathbb{R}, 0 < p < \infty$, $0 < q \le \infty$, and $\varsigma := (s_I(f))_I$, then

$$\|f\|_{F^{\alpha,s}_{p,q}} \approx \|\varsigma\|_{f^{\alpha,s}_{p,q}}. \tag{2.13}$$

Similarly, if $s \in \mathbb{R}$ and $0 < p, q \le \infty$ (see [Di]), then

$$\|f\|_{B^{\alpha,s}_{p,q}} \approx \|\varsigma\|_{b^{\alpha,s}_{p,q}}. \tag{2.14}$$

We note that Dintelmann considered in [Di] only the case where $\lambda = 2$, along the lines of the isotropic cases established in [FJ]; however, his results follow almost verbatim for any $\lambda > 1$.

To establish (1.2) and (1.3) we first need to study the boundedness of almost diagonal operators on the spaces $f^{\alpha,s}_{p,q}$ and $b^{\alpha,s}_{p,q}$.

3. Almost diagonal matrices. In this section we are interested in giving sufficient conditions on a matrix

$$(a_{IJ})_{I,J\in\mathcal{D}_+}$$

so that it gives rise to a bounded operator $\mathbf{A}$ on $f^{\alpha,s}_{p,q}$ or $b^{\alpha,s}_{p,q}$. Similar to the isotropic cases (see [FJ]), we say that $\mathbf{A}$ is almost diagonal on $f^{\alpha,s}_{p,q}(b^{\alpha,s}_{p,q})$ if there exist $\epsilon > 0$ such that

$$|a_{IJ}| \le C\omega_{IJ}(\epsilon), \quad I, J \in \mathcal{D}_+,$$

with

$$\omega_{IJ}(\epsilon) = \left(\frac{\ell(I)}{\ell(J)}\right)^s \left(1 + \frac{|x_I - x_J|_\alpha}{\max(\ell(I),\ell(J))}\right)^{-\mathcal{J}-\epsilon} \min\left[\left(\frac{\ell(I)}{\ell(J)}\right)^{(d+\epsilon)/2}, \left(\frac{\ell(J)}{\ell(I)}\right)^{(d+\epsilon)/2+\mathcal{J}-d}\right],$$

where $\mathcal{J} := d/\min(1,p,q)$ for $f^{\alpha,s}_{p,q}$ and $\mathcal{J} := d/\min(1,p)$ for $b^{\alpha,s}_{p,q}$.

A basic tool in proving that almost diagonal matrices are bounded on $f^{\alpha,s}_{p,q}$ $(b^{\alpha,s}_{p,q})$ is the strong maximal operator $M_t, t > 0$, defined by

$$M_t(f)(x) := \left(\sup_{Q\ni x} |Q|^{-1} \int_Q |f(y)|^t \, dy\right)^{1/t}, \tag{3.1}$$

where the supremum is taken with respect to all rectangles with sides parallel to the coordinate axes. It is known that if $0 < p < \infty$, $0 < q \le \infty$, and $0 < t < \min\{p, q\}$, then for any sequence of functions $(f_j)_{j\in\mathbb{Z}}$

$$\left\| \left(\sum_{j\in\mathbb{Z}} M_t(f_j)^q \right)^{1/q} \right\|_{L_p} \le C \left\| \left(\sum_{j\in\mathbb{Z}} |f_j|^q \right)^{1/q} \right\|_{L_p}. \tag{3.2}$$

In the case where the sup in (3.1) is taken over, all cubes with sides parallel to the coordinate axes (3.2) is a well-known result of Fefferman and Stein [FS], while for the anisotropic case we refer the reader to [ST].

PROPOSITION 3.1. *Let $0 < p < \infty, 0 < q \le \infty$, and $s \in \mathbb{R}$. An almost diagonal operator on $f^{\alpha,s}_{p,q}$ is bounded.*

Proof. Let $\mathbf{A}$ be an almost diagonal operator on $f^{\alpha,s}_{p,q}$ associated with the matrix $(a_{IJ})_{I,J\in\mathcal{D}_+}$. We recall that

$$\|\mathbf{A}\|_{f^{\alpha,s}_{p,q}\to f^{\alpha,s}_{p,q}} := \sup_{\|h\|_{f^{\alpha,s}_{p,q}}\le 1} \|\mathbf{A}h\|_{f^{\alpha,s}_{p,q}},$$

where

$$(\mathbf{A}h)_I = \sum_{J\in\mathcal{D}_+} a_{IJ} h_J.$$

(The series is absolutely convergent; see proof below.) It follows that

$$\begin{aligned} \|\mathbf{A}h\|_{f^{\alpha,s}_{p,q}} &= \left\| \left(\sum_{I\in\mathcal{D}_+} (|I|^{-s/d} |(\mathbf{A}h)_I| \tilde{\chi}_I)^q \right)^{1/q} \right\|_{L_p} \\ &\le \left\| \left(\sum_{I\in\mathcal{D}_+} \left(|I|^{-s/d} \sum_{J\in\mathcal{D}_+} |a_{IJ}||h_J| \tilde{\chi}_I \right)^q \right)^{1/q} \right\|_{L_p} \\ &\le C(\sigma_1 + \sigma_2), \end{aligned} \tag{3.3}$$

where

$$\sigma_1 := \left\| \left(\sum_{I\in\mathcal{D}_+} \left(|I|^{-s/d} \sum_{|J|\le|I|} |a_{IJ}||h_J| \tilde{\chi}_I \right)^q \right)^{1/q} \right\|_{L_p}$$

and

$$\sigma_2 := \left\| \left(\sum_{I\in\mathcal{D}_+} \left(|I|^{-s/d} \sum_{|J|>|I|} |a_{IJ}||h_J| \tilde{\chi}_I \right)^q \right)^{1/q} \right\|_{L_p}.$$

To estimate σ_1, since $|J| \le |I|$,

$$|a_{IJ}| \le C \left(\frac{\ell(I)}{\ell(J)} \right)^{s+\frac{(d-\epsilon)}{2}-\mathcal{J}} \left(1 + \frac{|x_I - x_J|_\alpha}{\ell(I)} \right)^{-\mathcal{J}-\epsilon}. \tag{3.4}$$

Let $\mu_I := |I|^{-s/d}\tilde{\chi}_I$ and $0 < t < \min\{1, p, q\}$ be such that $\mathcal{J} + \frac{\epsilon}{2} > d/t$. Using Lemmas 6.4 and 6.8 we obtain

$$\begin{aligned}
\sigma_1 &\leq C\bigg\|\bigg(\sum_{I\in\mathcal{D}_+}\bigg(\sum_{|J|\leq|I|}\bigg(\frac{\ell(I)}{\ell(J)}\bigg)^{s+\frac{(d-\epsilon)}{2}-\mathcal{J}}\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(I)}\bigg)^{-\mathcal{J}-\epsilon}|h_J|\mu_I\bigg)^q\bigg)^{\frac{1}{q}}\bigg\|_{L_p}\\
&= C\bigg\|\bigg(\sum_{n\in\mathbb{N}_0}\sum_{I\in\mathcal{D}_n}\bigg(\sum_{m\geq n}\lambda^{(m-n)(s+\frac{(d-\epsilon)}{2}-\mathcal{J})}\sum_{J\in\mathcal{D}_m}(1+\lambda^n|x_I-x_J|_\alpha)^{-\mathcal{J}-\epsilon}|h_J|\mu_I\bigg)^q\bigg)^{\frac{1}{q}}\bigg\|_{L_p}\\
&\leq C\bigg\|\bigg(\sum_{n\in\mathbb{N}_0}\sum_{I\in\mathcal{D}_n}\bigg(\sum_{m\geq n}\lambda^{(m-n)(s+\frac{(d-\epsilon)}{2}-\mathcal{J}+\frac{d}{t})}M_t\bigg(\sum_{J\in\mathcal{D}_m}|h_J|\chi_J\bigg)\mu_I\bigg)^q\bigg)^{\frac{1}{q}}\bigg\|_{L_p}\\
&= C\bigg\|\bigg(\sum_{n\in\mathbb{N}_0}\bigg(\sum_{m\geq n}\lambda^{(m-n)(-\frac{\epsilon}{2}-\mathcal{J}+\frac{d}{t})}M_t\bigg(\sum_{J\in\mathcal{D}_m}|h_J|\mu_J\bigg)\bigg)^q\bigg)^{\frac{1}{q}}\bigg\|_{L_p}\\
&\leq C\bigg\|\bigg(\sum_{n\in\mathbb{N}_0}\bigg(M_t\bigg(\sum_{I\in\mathcal{D}_n}|h_I|\mu_I\bigg)\bigg)^q\bigg)^{\frac{1}{q}}\bigg\|_{L_p}\\
&\leq C\|h\|_{f^{\alpha,s}_{p,q}},
\end{aligned}$$

where in the last inequality we used the maximal inequality (3.2).

When $|J| > |I|$, we have that

$$|a_{IJ}| \leq C\bigg(\frac{\ell(I)}{\ell(J)}\bigg)^{s+\frac{(d+\epsilon)}{2}}\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(J)}\bigg)^{-\mathcal{J}-\epsilon}. \tag{3.5}$$

Employing Lemmas 6.4 and 6.8 once more we get

$$\begin{aligned}
\sigma_2 &\leq C\bigg\|\bigg(\sum_{I\in\mathcal{D}_+}\bigg(\sum_{|J|>|I|}\bigg(\frac{\ell(I)}{\ell(J)}\bigg)^{s+\frac{(d+\epsilon)}{2}}\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(J)}\bigg)^{-\mathcal{J}-\epsilon}|h_J|\mu_I\bigg)^q\bigg)^{\frac{1}{q}}\bigg\|_{L_p}\\
&= C\bigg\|\bigg(\sum_{n\in\mathbb{N}_0}\sum_{I\in\mathcal{D}_n}\bigg(\sum_{m<n}\lambda^{(m-n)(s+\frac{(d+\epsilon)}{2})}\sum_{J\in\mathcal{D}_m}\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(J)}\bigg)^{-\mathcal{J}-\epsilon}|h_J|\mu_I\bigg)^q\bigg)^{\frac{1}{q}}\bigg\|_{L_p}\\
&\leq C\bigg\|\bigg(\sum_{n\in\mathbb{N}_0}\sum_{I\in\mathcal{D}_n}\bigg(\sum_{m<n}\lambda^{(m-n)(s+\frac{(d+\epsilon)}{2})}M_t\bigg(\sum_{J\in\mathcal{D}_m}|h_J|\chi_J\bigg)\mu_I\bigg)^q\bigg)^{\frac{1}{q}}\bigg\|_{L_p}\\
&= C\bigg\|\bigg(\sum_{n\in\mathbb{N}_0}\bigg(\sum_{m<n}\lambda^{(m-n)\frac{\epsilon}{2}}M_t\bigg(\sum_{J\in\mathcal{D}_m}|h_J|\mu_J\bigg)\bigg)^q\bigg)^{\frac{1}{q}}\bigg\|_{L_p}\\
&\leq C\bigg\|\bigg(\sum_{n\in\mathbb{N}_0}\bigg(M_t\bigg(\sum_{I\in\mathcal{D}_n}|h_I|\mu_I\bigg)\bigg)^q\bigg)^{\frac{1}{q}}\bigg\|_{L_p}\\
&\leq C\|h\|_{f^{\alpha,s}_{p,q}}.
\end{aligned}$$

Putting the two estimates for σ_1 and σ_2 in (3.3) the result follows. □

Similar to the previous proposition for the Besov spaces we have the following.

PROPOSITION 3.2. *Let $0 < p, q \leq \infty$, and $s \in \mathbb{R}$. An almost diagonal operator on $b^{\alpha,s}_{p,q}$ is bounded.*

Proof. Let $\mathbf{A}$ be an almost diagonal operator on $b^{\alpha,s}_{p,q}$ associated with the matrix $(a_{IJ})_{I,J\in\mathcal{D}_+}$. As before, we need to prove that

$$\|\mathbf{A}\|_{b^{\alpha,s}_{p,q}\to b^{\alpha,s}_{p,q}} := \sup_{\|h\|_{b^{\alpha,s}_{p,q}}\le 1} \|\mathbf{A}h\|_{b^{\alpha,s}_{p,q}} < \infty.$$

We shall consider only $0 < p, q < \infty$; the cases $p = \infty$ or $q = \infty$ follow similarly.

Let $h \in b^{\alpha,s}_{p,q}$. To simplify our notation we define $\gamma := s/d - (1/p - 1/2)$ and $\tilde{h}_J := |J|^{-\gamma} h_J$. Since $(\mathbf{A}h)_I = \sum_{J\in\mathcal{D}_+} a_{IJ} h_J$,

$$\begin{aligned}
\|\mathbf{A}h\|^q_{b^{\alpha,s}_{p,q}} &= \sum_{m\in\mathbb{N}_0} \Bigg(\sum_{I\in\mathcal{D}_m} \big(|I|^{-\gamma} |(\mathbf{A}h)_I|\big)^p \Bigg)^{q/p} \\
&\le \sum_{m\in\mathbb{N}_0} \Bigg(\sum_{I\in\mathcal{D}_m} \Bigg(\sum_{J\in\mathcal{D}_+} (|J|/|I|)^\gamma |a_{IJ}||\tilde{h}_J| \Bigg)^p \Bigg)^{q/p} \\
&\le C(\sigma_1^q + \sigma_2^q)
\end{aligned}$$

with

$$\sigma_1 := \Bigg(\sum_{m\in\mathbb{N}_0} \Bigg(\sum_{I\in\mathcal{D}_m} \Bigg(\sum_{|J|\le|I|} (|J|/|I|)^\gamma |a_{IJ}||\tilde{h}_J| \Bigg)^p \Bigg)^{q/p} \Bigg)^{1/q}$$

and

$$\sigma_2 := \Bigg(\sum_{m\in\mathbb{N}_0} \Bigg(\sum_{I\in\mathcal{D}_m} \Bigg(\sum_{|J|>|I|} (|J|/|I|)^\gamma |a_{IJ}||\tilde{h}_J| \Bigg)^p \Bigg)^{q/p} \Bigg)^{1/q}.$$

Case I. $1 \le p < \infty$. For σ_1 using (3.4), Minkowski's inequality, and Lemmas 6.6 and 6.8

$$\begin{aligned}
\sigma_1^q &\le \sum_{m\in\mathbb{N}_0} \Bigg(\sum_{I\in\mathcal{D}_m} \Bigg(\sum_{n\ge m} \sum_{J\in\mathcal{D}_n} (|J|/|I|)^\gamma |a_{IJ}||\tilde{h}_J| \Bigg)^p \Bigg)^{q/p} \\
&\le \sum_{m\in\mathbb{N}_0} \Bigg(\sum_{I\in\mathcal{D}_m} \Bigg(\sum_{n\ge m} \sum_{J\in\mathcal{D}_n} (|J|/|I|)^{\gamma - \frac{s}{d} - \frac12 + \frac{\mathcal{J}}{d} + \frac{\epsilon}{2d}} \Bigg(1 + \frac{|x_I - x_J|_\alpha}{\ell(I)} \Bigg)^{-\mathcal{J}-\epsilon} |\tilde{h}_J| \Bigg)^p \Bigg)^{q/p} \\
&\le C \sum_{m\in\mathbb{N}_0} \Bigg(\sum_{n\ge m} \lambda^{(m-n)(\mathcal{J} - \frac{d}{p} + \frac{\epsilon}{2})} \Bigg(\sum_{I\in\mathcal{D}_m} \Bigg(\sum_{J\in\mathcal{D}_n} \Bigg(1 + \frac{|x_I - x_J|_\alpha}{\ell(I)} \Bigg)^{-\mathcal{J}-\epsilon} |\tilde{h}_J| \Bigg)^p \Bigg)^{\frac1p} \Bigg)^q \\
&\le C \sum_{m\in\mathbb{N}_0} \Bigg(\sum_{n\ge m} \lambda^{(m-n)(\mathcal{J} - \frac{d}{p} + \frac{\epsilon}{2} - \frac{d}{p'})} \Bigg(\sum_{J\in\mathcal{D}_n} |\tilde{h}_J|^p \Bigg)^{1/p} \Bigg)^q \\
&\le C \sum_{m\in\mathbb{N}_0} \Bigg(\sum_{I\in\mathcal{D}_m} \big(|I|^{-s/d + (1/p - 1/2)} |h_I|\big)^p \Bigg)^{q/p} = C\|h\|^q_{b^{\alpha,s}_{p,q}}
\end{aligned}$$

since $\mathcal{J} - \frac{d}{p} + \frac{\epsilon}{2} - \frac{d}{p'} = \mathcal{J} - d + \frac{\epsilon}{2} > 0$.

Similarly, using (3.5), Minkowski's inequality, and Lemma 6.7 we obtain

$$\begin{aligned}
\sigma_2^q &\le \sum_{m\in\mathbb{N}_0}\bigg(\sum_{I\in\mathcal{D}_m}\bigg(\sum_{n<m}\sum_{J\in\mathcal{D}_n}(|J|/|I|)^{\gamma}|a_{IJ}||\tilde{h}_J|\bigg)^p\bigg)^{q/p}\\
&\le \sum_{m\in\mathbb{N}_0}\bigg(\sum_{I\in\mathcal{D}_m}\bigg(\sum_{n<m}\sum_{J\in\mathcal{D}_n}(|J|/|I|)^{\gamma-\frac{s}{d}-\frac12-\frac{\epsilon}{2d}}\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(J)}\bigg)^{-\mathcal{J}-\epsilon}|\tilde{h}_J|\bigg)^p\bigg)^{q/p}\\
&\le C\sum_{m\in\mathbb{N}_0}\bigg(\sum_{n<m}\lambda^{(m-n)(-\frac{d}{p}-\frac{\epsilon}{2})}\bigg(\sum_{I\in\mathcal{D}_m}\bigg(\sum_{J\in\mathcal{D}_n}\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(J)}\bigg)^{-\mathcal{J}-\epsilon}|\tilde{h}_J|\bigg)^p\bigg)^{\frac1p}\bigg)^q\\
&\le C\sum_{m\in\mathbb{N}_0}\bigg(\sum_{n<m}\lambda^{(m-n)(-\frac{\epsilon}{2})}\bigg(\sum_{J\in\mathcal{D}_n}|\tilde{h}_J|^p\bigg)^{1/p}\bigg)^q\\
&\le C\sum_{m\in\mathbb{N}_0}\bigg(\sum_{I\in\mathcal{D}_m}\big(|I|^{-s/d+(1/p-1/2)}|h_I|\big)^p\bigg)^{q/p}=C\|h\|^q_{b^{\alpha,s}_{p,q}},
\end{aligned}$$

where in the last inequality we applied Lemma 6.8. Putting the estimates for σ_1 and σ_2 together we get the desired result for $1\le p<\infty$.

Case II. $p\le 1$. Similar to the previous case,

$$\begin{aligned}
\sigma_1^q &\le C\sum_{m\in\mathbb{N}_0}\bigg(\sum_{J\in\mathcal{D}_n}\sum_{n\ge m}\sum_{I\in\mathcal{D}_m}\lambda^{(m-n)(\mathcal{J}-\frac{d}{p}+\frac{\epsilon}{2})p}\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(I)}\bigg)^{-\mathcal{J}p-\epsilon p}|\tilde{h}_J|^p\bigg)^{q/p}\\
&\le C\sum_{m\in\mathbb{N}_0}\bigg(\sum_{J\in\mathcal{D}_n}\sum_{n\ge m}\lambda^{(m-n)(\mathcal{J}-\frac{d}{p}+\frac{\epsilon}{2})p}|\tilde{h}_J|^p\bigg)^{q/p}\\
&= C\sum_{m\in\mathbb{N}_0}\bigg(\sum_{n\ge m}\lambda^{(m-n)(\mathcal{J}-\frac{d}{p}+\frac{\epsilon}{2})p}\sum_{J\in\mathcal{D}_n}|\tilde{h}_J|^p\bigg)^{q/p}\\
&\le C\sum_{m\in\mathbb{N}_0}\bigg(\sum_{I\in\mathcal{D}_m}\big(|I|^{-s/d+(1/p-1/2)}|h_I|\big)^p\bigg)^{q/p}=C\|h\|^q_{b^{\alpha,s}_{p,q}},
\end{aligned}$$

where in the last inequality we used that $\mathcal{J}-\frac{d}{p}+\frac{\epsilon}{2}>0$.

Finally, from Lemmas 6.5 and 6.8,

$$\begin{aligned}
\sigma_2^q &\le C\sum_{m\in\mathbb{N}_0}\bigg(\sum_{n<m}\sum_{J\in\mathcal{D}_n}\sum_{I\in\mathcal{D}_m}\lambda^{(m-n)(\gamma-\frac{s}{d}-\frac12-\frac{\epsilon}{2d})dp}\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(J)}\bigg)^{-\mathcal{J}p-\epsilon p}|\tilde{h}_J|^p\bigg)^{q/p}\\
&\le C\sum_{m\in\mathbb{N}_0}\bigg(\sum_{n<m}\sum_{J\in\mathcal{D}_n}\lambda^{(m-n)(-\frac{\epsilon p}{2})}|\tilde{h}_J|^p\bigg)^{q/p}\\
&\le C\sum_{m\in\mathbb{N}_0}\bigg(\sum_{I\in\mathcal{D}_m}\big(|I|^{-s/d+(1/p-1/2)}|h_I|\big)^p\bigg)^{q/p}=C\|h\|^q_{b^{\alpha,s}_{p,q}}.
\end{aligned}$$

This concludes the proof of the proposition. □

Let now $r_1,r_2\in\mathbb{R}$, $M>0$, and $(\theta_I)_{I\in\mathcal{D}_+}$ and $(\eta_I)_{I\in\mathcal{D}_+}$ be families of functions on $\mathbb{R}^d$ that satisfy

$$\int_{\mathbb{R}^d}\theta_I(x)x^\beta\,dx=0,\ \beta\alpha\le r_1,\ |I|<1, \tag{3.6}$$

$$|\theta_I(x)| \le C|I|^{-\frac{1}{2}}\left(1+\frac{|x-x_I|_\alpha}{\ell(I)}\right)^{-M},\ I\in\mathcal{D}_+, \tag{3.7}$$

$$|\theta_I^{(\beta)}(x)| \le C|I|^{-\frac{1}{2}-\frac{\beta\alpha}{d}}\left(1+\frac{|x-x_I|_\alpha}{\ell(I)}\right)^{-M},\ \beta\alpha\le r_2+\alpha_{\max},\ I\in\mathcal{D}_+, \tag{3.8}$$

and

$$\int_{\mathbb{R}^d}\eta_I(x)x^\beta\,dx=0,\quad \beta\alpha\le r_2,\ |I|<1, \tag{3.9}$$

$$|\eta_I(x)| \le C|I|^{-\frac{1}{2}}\left(1+\frac{|x-x_I|_\alpha}{\ell(I)}\right)^{-M},\ I\in\mathcal{D}_+, \tag{3.10}$$

$$|\eta_I^{(\beta)}(x)| \le C|I|^{-\frac{1}{2}-\frac{\beta\alpha}{d}}\left(1+\frac{|x-x_I|_\alpha}{\ell(I)}\right)^{-M},\ \beta\alpha\le r_1+\alpha_{\max},\ I\in\mathcal{D}_+, \tag{3.11}$$

where (3.6), (3.11) and (3.8), (3.9) are void if $r_1<0$ or $r_2<0$, respectively.

Assuming that r_1, r_2 and M are sufficiently large and using Lemma 6.3 (or Remark 6.1 instead, if $|I|=|J|=1$ or when either of r_1, r_2 are negative), it is easily seen that the infinite matrix

$$\mathbf{A}:=(\langle\theta_I,\eta_J\rangle)_{I,J\in\mathcal{D}_+} \tag{3.12}$$

gives rise to a bounded operator on the f- and b-spaces. In particular, we have the following.

COROLLARY 3.1. *Let $0<p<\infty, 0<q\le\infty$, $s\in\mathbb{R}$, and $\mathcal{J}:=d/\min\{1,p,q\}$. Let also $(\theta_I)_{I\in\mathcal{D}_+},(\eta_I)_{I\in\mathcal{D}_+}$ be families of functions satisfying* (3.6)–(3.11) *for some $r_1,r_2\in\mathbb{R}$ and $M>0$. If $r_1>s$, $r_2>\mathcal{J}-d-s$, and $M>\max\{\mathcal{J},d+r_1,d+r_2\}$, then the matrix $\mathbf{A}$ in* (3.12) *defines a bounded operator on $f^{\alpha,s}_{p,q}$.*

COROLLARY 3.2. *Let $0<p,q\le\infty$, $s\in\mathbb{R}$, and $\mathcal{J}:=d/\min\{1,p\}$. We also assume that $(\theta_I)_{I\in\mathcal{D}_+},(\eta_I)_{I\in\mathcal{D}_+}$ are families of functions satisfying* (3.6)–(3.11) *for some $r_1,r_2\in\mathbb{R}$ and $M>0$. If $r_1>s$, $r_2>\mathcal{J}-d-s$, and $M>\max\{\mathcal{J},d+r_1,d+r_2\}$, then the matrix $\mathbf{A}$ in* (3.12) *defines a bounded operator on $b^{\alpha,s}_{p,q}$.*

4. Decomposition systems for function spaces. We start this section by giving two fundamental lemmas that will help us address the convergence of the series in (2.12).

LEMMA 4.1. *Let $s\in\mathbb{R}$, $0<p<\infty$, $0<q\le\infty$, and $\mathcal{J}:=d/\min\{1,p,q\}$. If $(\theta_I)_{I\in\mathcal{D}_+}$ satisfies* (3.6)–(3.8) *for some $r_1,r_2\in\mathbb{R}$ with $r_1>\mathcal{J}-d-s$, $r_2>s$, and $M>\max\{\mathcal{J},d+r_1,d+r_2\}$, then for every $d:=(d_I)_{I\in\mathcal{D}_+}\in f^{\alpha,s}_{p,q}$ the series $\sum_{I\in\mathcal{D}_+}d_I\theta_I$ converges in $\mathcal{S}'$ (and in $F^{\alpha,s}_{p,q}$ for $q\ne\infty$) and*

$$\Big\|\sum_{I\in\mathcal{D}_+}d_I\theta_I\Big\|_{F^{\alpha,s}_{p,q}}\le C\|d\|_{f^{\alpha,s}_{p,q}}. \tag{4.1}$$

Proof. To establish that the series $\sum_{I\in\mathcal{D}_+}d_I\theta_I$ converges in $\mathcal{S}'$ it is sufficient to prove that for every $\eta\in\mathcal{S}$ we have $|\sum_{I\in\mathcal{D}_+}d_I\langle\theta_I,\eta\rangle|<\infty$. For this, one has to use that

$$|\langle\theta_I,\eta\rangle|\le C\ell(I)^{r_1+d/2}(1+|x_I|_\alpha)^{-M}, \tag{4.2}$$

which is an immediate consequence of Lemma 6.3 (or Remark 6.1 if $|I|=1$ or $r_1<0$). We leave the details to the reader and we refer to [K], where we have worked out the full details for the isotropic case, which is similar.

To prove (4.1) we define $c_{IJ} := \langle \theta_I, \widetilde{\phi}_J \rangle$. Then

$$s_J(f) := \langle f, \widetilde{\phi}_J \rangle = \sum_{I \in \mathcal{D}_+} d_I \langle \theta_I, \widetilde{\phi}_J \rangle = \sum_{I \in \mathcal{D}_+} d_I c_{IJ}, \quad J \in \mathcal{D}.$$

In other words, if $\mathbf{C} := (c_{IJ})_{I,J \in \mathcal{D}}$ and $\varsigma := (s_J(f))_J$, we have

$$\varsigma = \mathbf{C}^T d,$$

where $\mathbf{C}^T$ is the transpose of the matrix $\mathbf{C}$. Applying Corollary 3.1 we get that $\mathbf{C}^T$ is an almost diagonal matrix on $f^{\alpha,s}_{p,q}$, and therefore bounded. Thus, from (2.13), it follows that

$$\|f\|_{F^{\alpha,s}_{p,q}} \approx \|\varsigma\|_{f^{\alpha,s}_{p,q}} = \|\mathbf{C}^T d\|_{f^{\alpha,s}_{p,q}} \leq C \|d\|_{f^{\alpha,s}_{p,q}}.$$

Finally we note that once (4.1) has been established it follows that for $q \neq \infty$ the series $\sum_{I \in \mathcal{D}_+} d_I \theta_I$ converges in the sense of $F^{\alpha,s}_{p,q}$, since its tail $\sum_{|I| \geq N} d_I \theta_I$ converges strongly to 0, as $N \to \infty$. □

Similarly, in the case of Besov spaces we have the following lemma.

LEMMA 4.2. *Let $s \in \mathbb{R}$, $0 < p, q \leq \infty$, and $\mathcal{J} := d/\min\{1, p\}$. If $(\theta_I)_{I \in \mathcal{D}_+}$ satisfies* (3.6)–(3.8) *for some $r_1, r_2 \in \mathbb{R}$, with $r_1 > \mathcal{J} - d - s$, $r_2 > s$, and $M > \max\{\mathcal{J}, d + r_1, d + r_2\}$, then for every $d := (d_I)_{I \in \mathcal{D}_+} \in B^{\alpha,s}_{p,q}$ the series $\sum_{I \in \mathcal{D}_+} d_I \theta_I$ converges in $\mathcal{S}'$ (and in $B^{\alpha,s}_{p,q}$ for $p, q \neq \infty$) and*

$$\left\| \sum_{I \in \mathcal{D}_+} d_I \theta_I \right\|_{B^{\alpha,s}_{p,q}} \leq C \|d\|_{b^{\alpha,s}_{p,q}}. \tag{4.3}$$

Proof. For the convergence of the series $\sum_{I \in \mathcal{D}_+} d_I \theta_I$ we note that since $d \in b^{\alpha,s}_{p,q}$, then $|d_I| \leq C|I|^{s/d+1/2-1/p}$, $I \in \mathcal{D}_+$. Using now this estimate it is not hard to see that the series converges absolutely. Again we refer the reader to [K], where we have worked out the details for the isotropic case. As far as the proof of (4.3) is concerned it is identical to the one of (4.1) since under our assumptions the matrix $\mathbf{C}^T$ is bounded on $b^{\alpha,s}_{p,q}$. □

Now let E be a finite set and $\Psi := \{\psi^e_I : e \in E, I \in \mathcal{D}_+\}$ be a decomposition system for $L_2(\mathbb{R}^d)$ with dual functionals $\tilde{\Psi} := \{\widetilde{\psi}^e_I : e \in E, I \in \mathcal{D}_+\}$; that is, for every $f \in L_2(\mathbb{R}^d)$

$$f = \sum_{e \in E} \sum_{I \in \mathcal{D}_+} \langle f, \widetilde{\psi}^e_I \rangle \psi^e_I.$$

We further assume that for every $e \in E$, the families $(\widetilde{\psi}^e_I)_{I \in \mathcal{D}_+}$ and $(\psi^e_I) I \in \mathcal{D}_+$ satisfy (3.6)–(3.8) and (3.9)–(3.11), respectively, with $r_{\tilde{\Psi}}$ instead of r_1 and r_Ψ instead of r_2. In particular for every $I \in \mathcal{D}_+$, we assume that

$$\int_{\mathbb{R}^d} x^\beta \psi^e_I(x)\, dx = 0, \quad \beta\alpha \leq r_{\tilde{\Psi}}, \ |I| < 1, \tag{4.4}$$

$$|\psi^e_I(x)| \leq C|I|^{-\frac{1}{2}} \left(1 + \frac{|x - x_I|_\alpha}{\ell(I)}\right)^{-M}, \tag{4.5}$$

$$|(\psi^e_I)^{(\beta)}(x)| \leq C|I|^{-\frac{1}{2} - \frac{\beta\alpha}{d}} \left(1 + \frac{|x - x_I|_\alpha}{\ell(I)}\right)^{-M}, \quad \beta\alpha \leq r_\Psi + \alpha_{\max}, \tag{4.6}$$

and

$$\int_{\mathbb{R}^d} x^\beta \widetilde{\psi}_I^e(x)\,dx = 0, \quad \beta\alpha \le r_\Psi,\ |I| < 1, \tag{4.7}$$

$$|\widetilde{\psi}_I^e(x)| \le C|I|^{-\frac{1}{2}}\left(1 + \frac{|x - x_I|_\alpha}{\ell(I)}\right)^{-M}, \tag{4.8}$$

$$|(\widetilde{\psi}_I^e)^{(\beta)}(x)| \le C|I|^{-\frac{1}{2}-\frac{\beta\alpha}{d}}\left(1 + \frac{|x - x_I|_\alpha}{\ell(I)}\right)^{-M}, \quad \beta\alpha \le r_{\widetilde{\Psi}} + \alpha_{\max}, \tag{4.9}$$

where $M > 0$ and $r_{\widetilde{\Psi}}, r_\Psi \in \mathbb{R}$. Of course (4.4), (4.9) and (4.6), (4.7) are void if $r_{\widetilde{\Psi}} < 0$ or $r_\Psi < 0$, respectively.

We note that for every $I \in \mathcal{D}_+$ since $\phi_I \in L_2(\mathbb{R}^d)$,

$$\phi_I = \sum_{e\in E}\sum_{J\in\mathcal{D}_+} \langle \phi_I, \widetilde{\psi}_J^e\rangle \psi_J^e. \tag{4.10}$$

Moreover, if $\psi_J^e, \widetilde{\psi}_J^e, J \in \mathcal{D}_+, e \in E$, satisfy (4.4)–(4.9) with $r_{\widetilde{\Psi}} > \mathcal{J} - d - s$ and $r_\Psi > s$, it is not hard to see that the sequence $(\langle \phi_I, \widetilde{\psi}_J^e\rangle)_{J\in\mathcal{D}_+} \in f_{p,q}^{\alpha,s}$ for $\mathcal{J} := d/\min\{1,p,q\}$ (or $b_{p,q}^{\alpha,s}$ for $\mathcal{J} := d/\min\{1,p\}$). It follows from Lemmas 4.1 and 4.2 that the convergence in (4.10) can be also considered in the sense of $F_{p,q}^{\alpha,s}$ or $B_{p,q}^{\alpha,s}$, respectively.

Also, for every $f \in F_{p,q}^{\alpha,s}$ (or $B_{p,q}^{\alpha,s}$) from (2.12) we get that

$$\begin{aligned} f &= \sum_{I\in\mathcal{D}_+} \langle f, \widetilde{\phi}_I\rangle \phi_I = \sum_{I\in\mathcal{D}_+}\sum_{e\in E}\sum_{J\in\mathcal{D}_+} \langle f, \widetilde{\phi}_I\rangle\langle \phi_I, \widetilde{\psi}_J^e\rangle \psi_J^e \\ &= \sum_{e\in E}\sum_{J\in\mathcal{D}_+}\sum_{I\in\mathcal{D}_+} \langle f, \widetilde{\phi}_I\rangle\langle \phi_I, \widetilde{\psi}_J^e\rangle \psi_J^e \\ &= \sum_{e\in E}\sum_{J\in\mathcal{D}_+} \langle f, \widetilde{\psi}_J^e\rangle \psi_J^e, \end{aligned}$$

where all identities above are considered in the distributional sense. To justify the third equality, we note that our assumptions guarantee that for every $e \in E$ the sequence

$$(d_J^e)_{J\in\mathcal{D}_+} := \Big(\sum_{I\in\mathcal{D}_+} |\langle f, \widetilde{\phi}_I\rangle||\langle \phi_I, \widetilde{\psi}_J^e\rangle|\Big)_{J\in\mathcal{D}_+}$$

belongs in $f_{p,q}^{\alpha,s}$ (or $b_{p,q}^{\alpha,s}$). Similar now to Lemma 4.1 (or Lemma 4.2), it follows that for every $\eta \in \mathcal{S}$

$$\sum_{J\in\mathcal{D}_+} |d_J^e||\langle \psi_J^e, \eta\rangle| < \infty,$$

which allows us to interchange the order of the summations.

THEOREM 4.1. *Let $s \in \mathbb{R}$, $0 < p < \infty$, $0 < q \le \infty$, and $\mathcal{J} := d/\min\{1,p,q\}$. Let also $\Psi, \widetilde{\Psi}$ be a decomposition system for $L_2(\mathbb{R}^d)$ satisfying (4.4)–(4.9) for some $r_\Psi, r_{\widetilde{\Psi}} \in \mathbb{R}$ with $r_\Psi > s$, $r_{\widetilde{\Psi}} > \mathcal{J} - d - s$, and $M > \max\{\mathcal{J}, d + r_\Psi, d + r_{\widetilde{\Psi}}\}$. Then, for every $f \in F_{p,q}^{\alpha,s}$,*

$$f = \sum_{e\in E}\sum_{I\in\mathcal{D}_+} \langle f, \widetilde{\psi}_I^e\rangle \psi_I^e, \tag{4.11}$$

in the sense of $\mathcal{S}'$ *(and in* $F^{\alpha,s}_{p,q}$ *for* $q \neq \infty$*). Moreover,*

$$\|f\|_{F^{\alpha,s}_{p,q}} \approx \sum_{e\in E} \|(\langle f, \widetilde{\psi}^e_I\rangle)_I\|_{f^{\alpha,s}_{p,q}}. \tag{4.12}$$

Proof. Taking into account our discussion above we only have to establish (4.12). From (4.11) we get that for every $I \in \mathcal{D}_+$

$$\langle f, \widetilde{\phi}_I\rangle = \sum_{e\in E}\sum_{J\in\mathcal{D}_+} \langle f, \widetilde{\psi}^e_J\rangle\langle \psi^e_J, \widetilde{\phi}_I\rangle = \sum_{e\in E}\sum_{J\in\mathcal{D}_+} a^e_{JI}\tilde{a}^e_J(f), \tag{4.13}$$

where

$$\tilde{a}^e_J(f) := \langle f, \widetilde{\psi}^e_J\rangle, \quad a^e_{JI} := \langle \psi^e_J, \widetilde{\phi}_I\rangle, \quad I, J \in \mathcal{D}_+, e \in E.$$

Then, if $\tilde{a}_e := (\tilde{a}^e_I(f))_{I\in\mathcal{D}_+}$ and $\mathbf{A}^e := (a^e_{IJ})_{I,J\in\mathcal{D}_+}$, we can express (4.13) in the form

$$\varsigma = \sum_{e\in E} \mathbf{A}^T_e \tilde{a}_e,$$

where as before $\varsigma := (s_I(f))_{I\in\mathcal{D}_+}$.

Similarly, if we define $\tilde{a}^e_{JI} := \langle \phi_J, \widetilde{\psi}^e_I\rangle, I, J \in \mathcal{D}_+$, then

$$\tilde{a}^e_I(f) = \langle f, \widetilde{\psi}^e_I\rangle = \sum_{J\in\mathcal{D}_+} \langle f, \widetilde{\phi}_J\rangle\langle \phi_J, \widetilde{\psi}^e_I\rangle = \sum_{J\in\mathcal{D}_+} \tilde{a}^e_{JI} s_J(f), \quad I \in \mathcal{D}_+.$$

Setting $\tilde{\mathbf{A}}^e := (\tilde{a}^e_{IJ})_{I,J\in\mathcal{D}_+}$ it follows that for every $e \in E$

$$\tilde{a}_e = \tilde{\mathbf{A}}^T_e \varsigma.$$

Employing now Corollary 3.1 we get that the matrices $\tilde{\mathbf{A}}^T_e, \mathbf{A}^T_e, e \in E$, are bounded on $f^{\alpha,s}_{p,q}$ and therefore

$$\begin{aligned}\|\varsigma\|_{f^{\alpha,s}_{p,q}} &= \left\| \sum_{e\in E} \mathbf{A}^T_e \tilde{a}_e \right\|_{f^{\alpha,s}_{p,q}} \leq C \sum_{e\in E} \|\mathbf{A}^T_e \tilde{a}_e\|_{f^{\alpha,s}_{p,q}} \leq C \sum_{e\in E} \|\tilde{a}_e\|_{f^{\alpha,s}_{p,q}} \\ &= C \sum_{e\in E} \|\tilde{\mathbf{A}}^T_e \varsigma\|_{f^{\alpha,s}_{p,q}} \leq C\|\varsigma\|_{f^{\alpha,s}_{p,q}}.\end{aligned}$$

This concludes the proof of the theorem. ∎

THEOREM 4.2. *Let* $s \in \mathbb{R}$, $0 < p, q < \infty$, *and* $\mathcal{J} := d/\min\{1, p\}$. *Let also* $\Psi, \widetilde{\Psi}$ *be a decomposition system for* $L_2(\mathbb{R}^d)$ *satisfying* (4.4)–(4.9) *for some* $r_\Psi, r_{\widetilde{\Psi}} \in \mathbb{R}$ *with* $r_\Psi > s$, $r_{\widetilde{\Psi}} > \mathcal{J} - d - s$, *and* $M > \max\{\mathcal{J}, d + r_\Psi, d + r_{\widetilde{\Psi}}\}$. *Then, for every* $f \in B^{\alpha,s}_{p,q}$,

$$f = \sum_{e\in E}\sum_{I\in\mathcal{D}_+} \langle f, \widetilde{\psi}^e_I\rangle \psi^e_I,$$

in the sense of $\mathcal{S}'$ *(and in* $B^{\alpha,s}_{p,q}$ *for* $p, q \neq \infty$*). Moreover,*

$$\|f\|_{B^{\alpha,s}_{p,q}} \approx \sum_{e\in E} \|(\langle f, \widetilde{\psi}^e_I\rangle)_I\|_{b^{\alpha,s}_{p,q}}. \tag{4.14}$$

Proof. Again we only have to demonstrate (4.14). One has to proceed as in the previous theorem and use Corollary 3.2 instead of Corollary 3.1 to establish that the matrices $\tilde{\mathbf{A}}^T_e, \mathbf{A}^T_e, e \in E$, are bounded on $b^{\alpha,s}_{p,q}$. We leave the details to the reader. ∎

5. Wavelet characterizations of function spaces. Let $\alpha = (a_1, \dots, a_d)$ be a given anisotropy and $\mathbf{M} = \operatorname{diag}(\lambda^{a_1}, \dots, \lambda^{a_d})$ be a diagonal matrix for some fixed $\lambda > 1$. Since $a_1 + \cdots + a_d = d$ we note that $\det \mathbf{M} = \lambda^d$ while for every $j \in \mathbb{N}$ the action of $\mathbf{M}^j$ on $\mathbb{R}^d$ can also be expressed by means of the anisotropic dilation by $\lambda^{j\alpha}$, i.e., for every $x = (x_1, \dots, x_d) \in \mathbb{R}^d$,

$$\mathbf{M}^j x = \lambda^{j\alpha} x = (\lambda^{ja_1} x_1, \dots, \lambda^{ja_d} x_d).$$

A biorthogonal wavelet basis associated to the matrix $\mathbf{M}$ is generated by a couple of scaling functions ψ^0, $\widetilde{\psi}^0$ which, among other assumptions, satisfy the dilation equations

$$\psi^0(x) = |\det \mathbf{M}|^{1/2} \sum_{k \in \mathbb{Z}^d} b_k \psi^0(\mathbf{M}x - k), \quad x \in \mathbb{R}^d,$$
$$\widetilde{\psi}^0(x) = |\det \mathbf{M}|^{1/2} \sum_{k \in \mathbb{Z}^d} c_k \widetilde{\psi}^0(\mathbf{M}x - k), \quad x \in \mathbb{R}^d,$$

for some sequence of complex numbers $(b_k)_k, (c_k)_k \in \ell_2(\mathbb{Z}^d)$, and they have biorthogonal shifts, i.e.,

$$\langle \psi^0(\cdot - k), \widetilde{\psi}^0(\cdot - n) \rangle = \delta_{k,n}, \quad k, n \in \mathbb{Z}.$$

Now let $E = (0, 1, \dots, \lambda^d - 1)$ and $E_0 = E \setminus \{0\}$. Associated to ψ^0 and $\widetilde{\psi}^0$ there exist two families of wavelet functions,

$$\Psi := \{\psi^e : e \in E_0\} \quad \text{and} \quad \widetilde{\Psi}_0 := \{\widetilde{\psi}^e : e \in E\}.$$

Following the wavelet literature for every $I \in \mathcal{D}, e \in E$, we also define

$$\psi_I^e(\cdot) := |I|^{-1/2} \psi^e \left(\frac{\cdot - x_I}{\ell(I)^\alpha} \right), \quad \widetilde{\psi}_I^e(\cdot) := |I|^{-1/2} \widetilde{\psi}^e \left(\frac{\cdot - x_I}{\ell(I)^\alpha} \right). \tag{5.1}$$

In particular, if $I := I_{j,k}^\alpha, k \in \mathbb{Z}^d, j \in \mathbb{Z}$, we note that

$$\psi_I^e(\cdot) = |\det \mathbf{M}^j|^{1/2} \psi^e(\mathbf{M}^j x \cdot - k), \quad \widetilde{\psi}_I^e(\cdot) = |\det \mathbf{M}^j|^{1/2} \widetilde{\psi}^e(\mathbf{M}^j x - k).$$

Then the collection of functions

$$W_0 := \{\psi_I^0, \widetilde{\psi}_I^0 : I \in \mathcal{D}_0, \} \cup \{\psi_I^e, \widetilde{\psi}_I^e : I \in \mathcal{D}_+, e \in E_0\}$$

constitutes a Riesz basis for $L_2(\mathbb{R}^d)$. In particular, for every $f \in L_2(\mathbb{R}^d)$ there exist unique coefficients $\langle f, \widetilde{\psi}_I^e \rangle, I \in \mathcal{D}_+,\ e \in E$, such that

$$f = \sum_{I \in \mathcal{D}_0} \langle f, \widetilde{\psi}_I^0 \rangle \psi_I^{\mathbf{0}} + \sum_{e \in E_0} \sum_{I \in \mathcal{D}_+} \langle f, \widetilde{\psi}_I^e \rangle \psi_I^e \tag{5.2}$$

and

$$\|f\|_{L_2(\mathbb{R}^d)} \approx \Big(\sum_{I\in\mathcal{D}_0} |\langle f, \widetilde{\psi}^0_I\rangle|^2 \Big)^{1/2} + \Big(\sum_{e\in E_0} \sum_{I\in\mathcal{D}_+} |\langle f, \widetilde{\psi}^e_I\rangle|^2 \Big)^{1/2}. \tag{5.3}$$

The construction of such a basis is a delicate matter and in the case of compactly supported wavelet bases it requires that

$$\lambda^{a_i} \in \mathbb{N}, \quad i = 1, \dots, d. \tag{5.4}$$

This in turn forces us to deal only with anisotropies $\alpha = (a_1, \dots, a_d)$ for which there exist $\lambda > 1$ such that (5.4) holds. As it turns out this is equivalent to requiring

$$(a_1, \dots, a_d) \in \mu \log \mathbb{N}^d \text{ for some } \mu > 0. \tag{5.5}$$

In particular, it is not hard to see that (5.5) holds for all anisotropies $\alpha \in \mathbb{Q}^d_+$. We refer the reader to [GT] for the proof of these facts and a complete analysis regarding the construction of anisotropic wavelet bases.

Standard assumptions on the functions $\{\psi^e, \widetilde{\psi}^e : e \in E\}$ include

$$\int_{\mathbb{R}^d} x^\beta \psi^e(x)\, dx = 0, \quad |\beta| \le r_1,\ e \in E_0,$$
$$\int_{\mathbb{R}^d} x^\beta \widetilde{\psi}^e(x)\, dx = 0, \quad |\beta| \le r_2,\ e \in E_0,$$

and

$$|(\psi^e)^{(\beta)}(x)| \le C(1 + |x|_\alpha)^{-M}, \quad |\beta| \le r_2 + m, e \in E,$$
$$|(\widetilde{\psi}^e)^{(\beta)}(x)| \le C(1 + |x|_\alpha)^{-M}, \quad |\beta| \le r_1 + m, e \in E,$$

where $M > 0$, $m \ge 0$, and $r_1, r_2 \in \mathbb{N}_0$. By requiring that r_1, r_2, m, and M are sufficiently large it is readily seen that the families $\{\psi^e_I : e \in E, I \in \mathcal{D}_+\}$, $\{\widetilde{\psi}^e_I : e \in E, I \in \mathcal{D}_+\}$ satisfy the assumptions of Theorems 4.1 and 4.2 and therefore form decomposition systems for the anisotropic Triebel–Lizorkin and Besov spaces. Moreover, the uniqueness of the wavelet coefficients in (5.2) shows that they constitute unconditional bases for these spaces.

6. Appendix: Inequalities. Throughout this section we assume that $\alpha = (a_1, \dots, a_d)$ is a fixed anisotropy. We start with the following version of Taylor's formula, which was given in [F].

LEMMA 6.1. *Let $r \ge 0$ and $f : \mathbb{R}^d \to C$ be a function such that $f^{(\beta)}$ exists for all $\beta \in \mathbb{N}^d_0$ with $\beta\alpha \le r + \alpha_{\max}$. Then, there is a constant C such that for every $x, y \in \mathbb{R}^d$*

$$f(x) = \sum_{\beta\alpha \le r} f^{(\beta)}(y) \frac{(x-y)^\beta}{\beta!} + R_r(x),$$

where

$$|R_r(x)| \le C \sum_{\beta\alpha > r}^{r+\alpha_{\max}} |x-y|^{\beta\alpha}_\alpha \sup_{|z-y|_\alpha \le |x-y|_\alpha} |f^{(\beta)}(z)|.$$

LEMMA 6.2. *Let $J \in \mathcal{D}_+$ and $x_1 \in \mathbb{R}^d$. If η, θ are functions on $\mathbb{R}^d$ such that for some $r \geq 0$ and $M > d + r$ satisfy*

$$\int_{\mathbb{R}^d} x^\beta \eta(x)\, dx = 0, \quad \beta\alpha \leq r, \tag{6.1}$$

$$|\eta(x)| \leq C|J|^{-\frac{1}{2}} \left(1 + \frac{|x - x_1|_\alpha}{\ell(J)}\right)^{-M}, \tag{6.2}$$

and

$$|\theta^{(\beta)}(x)| \leq C\big(1 + |x|_\alpha\big)^{-M}, \quad \beta\alpha \leq r + \alpha_{\max}; \tag{6.3}$$

then,

$$|\langle \theta, \eta \rangle| \leq C|J|^{r/d+1/2}(1 + |x_1|_\alpha)^{-M}.$$

Proof. Although the proof of the lemma is typical, we give a full account of it for the sake of completeness. We recall that there exists $c_\alpha \geq 1$ such that for every $x, y \in \mathbb{R}^d$, $|x + y|_\alpha \leq c_\alpha(|x|_\alpha + |y|_\alpha)$ and that for every $\beta \in \mathbb{N}_0^d$, $|x^\beta| = \prod_{i=1}^d (|x_i|^{1/a_i})^{a_i\beta_i} \leq \prod_{i=1}^d (\sum_{j=1}^d |x_j|^{1/a_j})^{a_i\beta_i} \leq (\sum_{j=1}^d |x_j|^{1/a_j})^{\beta\alpha} \leq C|x|_\alpha^{\beta\alpha}$.

From the moment condition of η we have

$$\begin{aligned}
|\langle \theta, \eta \rangle| &= \left| \int_{\mathbb{R}^d} \theta(y)\overline{\eta(y)}\, dy \right| \\
&= \left| \int_{\mathbb{R}^d} \left[\theta(y) - \sum_{\beta\alpha \leq r} \frac{(y - x_1)^\beta}{\beta!} \theta^{(\beta)}(x_1)\right] \overline{\eta(y)}\, dy \right| \\
&\leq \int_{\mathbb{R}^d} \left| \theta(y) - \sum_{\beta\alpha \leq r} \frac{(y - x_1)^\beta}{\beta!} \theta^{(\beta)}(x_1) \right| |\eta(y)|\, dy.
\end{aligned}$$

We will integrate over $A := \{y : |y - x_1|_\alpha \geq 1\}$ and A^c separately. For the integral over A, from (6.3)

$$\begin{aligned}
&\int_A |\theta(y) - \sum_{\beta\alpha \leq r} \frac{(y - x_1)^\beta}{\beta!} \theta^{(\beta)}(x_1)||\eta(y)|\, dy \\
&\quad \leq C|J|^{-1/2} \int_A (1 + |y|_\alpha)^{-M} \left(1 + \frac{|y - x_1|_\alpha}{\ell(J)}\right)^{-M} dy \\
&\qquad + C|J|^{-1/2} \int_A |y - x_1|_\alpha^r \big(1 + |x_1|_\alpha\big)^{-M} \left(1 + \frac{|y - x_1|_\alpha}{\ell(J)}\right)^{-M} dy \\
&\quad =: B_1 + B_2.
\end{aligned}$$

For B_1, we first consider the case where $|y|_\alpha \leq |x_1|_\alpha / 2c_\alpha$. Then, $|y - x_1|_\alpha \geq |x_1|_\alpha / 2c_\alpha$ and $\frac{|y - x_1|_\alpha}{\ell(J)} \geq \frac{1 + |y - x_1|_\alpha}{2\ell(J)} \geq C\frac{1 + |x_1|_\alpha}{\ell(J)}$. It follows that

$$\begin{aligned}
&|J|^{-1/2} \int_{A \cap \{|y|_\alpha \leq |x_1|_\alpha / 2c_\alpha\}} (1 + |y|_\alpha)^{-M} \left(1 + \frac{|y - x_1|_\alpha}{\ell(J)}\right)^{-M} dy \\
&\leq C|J|^{M/d-1/2}(1 + |x_1|_\alpha)^{-M} \int_A (1 + |y|_\alpha)^{-M}\, dy \qquad (6.4) \\
&\leq C|J|^{M/d-1/2}(1 + |x_1|_\alpha)^{-M}.
\end{aligned}$$

If $|y|_\alpha > |x_1|_\alpha/2c_\alpha$, then $(1+|y|_\alpha)^{-M} \le C(1+|x_1|_\alpha)^{-M}$, and hence we have

$$\begin{aligned} &|J|^{-1/2}\int_{A\cap\{|y|_\alpha>|x_1|_\alpha/2c_\alpha\}}(1+|y|_\alpha)^{-M}\left(1+\frac{|y-x_1|_\alpha}{\ell(J)}\right)^{-M}dy \\ &\le C|J|^{-1/2}(1+|x_1|_\alpha)^{-M}\int_{|y-x_1|_\alpha\ge 1}\left(\frac{|y-x_1|_\alpha}{\ell(J)}\right)^{-M}dy \qquad (6.5)\\ &\le C|J|^{M/d-1/2}(1+|x_1|_\alpha)^{-M}. \end{aligned}$$

For B_2, using that $|y-x_1|_\alpha \ge 1$, we have

$$\begin{aligned} B_2 &\le C|J|^{M/d-1/2}(1+|x_1|_\alpha)^{-M}\int_{|y-x_1|_\alpha\ge 1}|y-x_1|_\alpha^{-M+r}\,dy \qquad (6.6)\\ &\le C|J|^{M/d-1/2}(1+|x_1|_\alpha)^{-M}. \end{aligned}$$

Since $|J|\le 1$ and $M-d/2 > r+d/2$, from (6.4)–(6.6), we find

$$\int_A |\theta(y)-\sum_{\beta\alpha\le r}\frac{(y-x_1)^\beta}{\beta!}\theta^{(\beta)}(x_1)||\eta(y)|\,dy \le C|J|^{r/d+1/2}(1+|x_1|_\alpha)^{-M}.$$

Next, we estimate the integral over $A^c=\{y : |y-x_1|_\alpha < 1\}$. From Taylor's formula we know that

$$\begin{aligned} |\theta(y)-\sum_{\beta\alpha\le r}\frac{(y-x_1)^\beta}{\beta!}\theta^{(\beta)}(x_1)| &\le C\sum_{\beta\alpha>r}^{r+\alpha_{\max}}|y-x_1|_\alpha^{\beta\alpha}\sup_{|z-x_1|_\alpha\le|y-x_1|_\alpha}|\theta^{(\beta)}(z)|\\ &\le C|y-x_1|_\alpha^r\sup_{|z-x_1|_\alpha\le|y-x_1|_\alpha}(1+|z|_\alpha)^{-M}\\ &\le C|y-x_1|_\alpha^r(1+|x_1|_\alpha)^{-M}, \end{aligned}$$

where in the second inequality we used the fact that $|y-x_1|_\alpha\le 1$ and in the last that $|x_1|_\alpha \le c_\alpha(|z-x_1|_\alpha+|z|_\alpha)\le c_\alpha(1+|z|_\alpha)$. It follows that

$$\begin{aligned} &\int_{A^c}|\theta(y)-\sum_{\beta\alpha\le r}\frac{(y-x_1)^\beta}{\beta!}\theta^{(\beta)}(x_1)||\eta(y)|\,dy\\ &\le C|J|^{-1/2}\int_{A^c}|y-x_1|_\alpha^r(1+|x_1|_\alpha)^{-M}\left(1+\frac{|y-x_1|_\alpha}{\ell(J)}\right)^{-M}dy\\ &\le C|J|^{r/d-1/2}(1+|x_1|_\alpha)^{-M}\int_{A^c}\left(1+\frac{|y-x_1|_\alpha}{\ell(J)}\right)^{-M+r}dy\\ &\le C|J|^{r/d+1/2}(1+|x_1|_\alpha)^{-M}. \qquad \square \end{aligned}$$

Using dilations and translations we now easily get the following.

LEMMA 6.3. *Let $I,J\in\mathcal{D}$ with $|J|\le|I|$. We also assume that η_J,θ_I are functions on $\mathbb{R}^d$ such that for some $r\ge 0$ and $M>d+r$ satisfy*

$$\int_{\mathbb{R}^d}x^\beta\eta_J(x)\,dx=0,\quad \beta\alpha\le r, \qquad (6.7)$$

$$|\eta_J(x)|\le C|J|^{-\frac12}\left(1+\frac{|x-x_J|_\alpha}{\ell(J)}\right)^{-M}, \qquad (6.8)$$

and

$$|(\theta_I)^{(\beta)}(x)| \le C|I|^{-\frac{1}{2}-\frac{\beta\alpha}{d}}\left(1+\frac{|x-x_I|_\alpha}{\ell(I)}\right)^{-M}, \quad \beta\alpha \le r+\alpha_{\max}. \tag{6.9}$$

Then,

$$|\langle \theta_I, \eta_J\rangle| \le C\left(\frac{|J|}{|I|}\right)^{r/d+1/2}\left(1+\frac{|x_I-x_J|_\alpha}{\ell(I)}\right)^{-M}.$$

Remark 6.1. In the absence of zero moments, that is, if $|J| \le |I|$ and

$$|\eta_J(x)| \le C|J|^{-\frac{1}{2}}\left(1+\frac{|x-x_J|_\alpha}{\ell(J)}\right)^{-M},$$
$$|\theta_I(x)| \le C|I|^{-\frac{1}{2}}\left(1+\frac{|x-x_I|_\alpha}{\ell(I)}\right)^{-M},$$

$M > d$, then using similar arguments as in the proof of the previous lemma it is easy to show that

$$|\langle \theta_I, \eta_J\rangle| \le C\left(\frac{|J|}{|I|}\right)^{1/2}\left(1+\frac{|x_I-x_J|_\alpha}{\ell(I)}\right)^{-M}. \tag{6.10}$$

LEMMA 6.4. *Let $0 < t \le 1$ and $M > d/t$. For any sequence of complex numbers $(h_J)_{J\in\mathcal{D}_m}$, $m \in \mathbb{Z}$, and $x \in I \in \mathcal{D}$, we have*

$$\sum_{J\in\mathcal{D}_m}|h_J|\left(1+\frac{|x_I-x_J|_\alpha}{\max(\ell(I),\ell(J))}\right)^{-M} \le C\max\left\{\left(\frac{|I|}{|J|}\right)^{\frac{1}{t}},1\right\}M_t\Big(\sum_{J\in\mathcal{D}_m}|h_J|\chi_J\Big)(x).$$

Proof. Without loss of generality we assume that $x_I = 0$.

Case I. $|I| \le 2^{-md}$. We let $\delta := M/d - 1/t > 0$, and for each $j \in \mathbb{N}$ we define $\Omega_j := \{J \in \mathcal{D}_m : \lambda^{j-1} < \lambda^m|x_J|_\alpha \le \lambda^j\}$, while $\Omega_0 := \{J \in \mathcal{D}_m : \lambda^m|x_J|_\alpha \le 1\}$. If $x \in I$, then

$$\sum_{J\in\mathcal{D}_m}|h_J|\big(1+\lambda^m|x_J|_\alpha\big)^{-M} = \sum_{j=0}^{\infty}\sum_{J\in\Omega_j}|h_J|\big(1+\lambda^m|x_J|_\alpha\big)^{-M}$$
$$\le C\sum_{j=0}^{\infty}\sum_{J\in\Omega_j}|h_J|\lambda^{-jM} = C\sum_{j=0}^{\infty}\lambda^{-jd/t-j\delta d}\sum_{J\in\Omega_j}|h_J|$$
$$\le C\sup_{j\ge0}\lambda^{-jd/t}\sum_{J\in\Omega_j}|h_J| \le C\Big(\sup_{j\ge0}\lambda^{-jd}\sum_{J\in\Omega_j}|h_J|^t\Big)^{1/t}$$
$$= C\Big(\sup_{j\ge0}\lambda^{-jd}\lambda^{md}\int\Big(\sum_{J\in\Omega_j}|h_J|\chi_J\Big)^t\Big)^{1/t}$$
$$\le C\Big(\sup_{j\ge0}\frac{1}{|\cup_{J\in\Omega_j}J|}\int_{\cup_{J\in\Omega_j}J}\Big(\sum_{J\in\Omega_j}|h_J|\chi_J\Big)^t\Big)^{1/t}$$
$$\le CM_t\Big(\sum_{J\in\mathcal{D}_m}|h_J|\chi_J\Big)(x).$$

Case II. $|I| > \lambda^{-md}$. Let us assume that $\ell(I) = \lambda^{-n}$, $n < m$. For $j \in \mathbb{N}_+$ we define $\Omega_j := \{J \in \mathcal{D}_m : \lambda^{j-1} < \lambda^n |x_J|_\alpha \leq \lambda^j\}$, while for $j = 0$ we set $\Omega_0 := \{J \in \mathcal{D}_m : \lambda^n |x_J|_\alpha \leq 1\}$. Then for every $x \in I$ we have

$$\begin{aligned}
&\sum_{J\in\mathcal{D}_m} |h_J|\big(1+\lambda^n|x_J|_\alpha\big)^{-M} = \sum_{j=0}^{\infty}\sum_{J\in\Omega_j} |h_J|\big(1+\lambda^n|x_J|_\alpha\big)^{-M}\\
&\leq C\sum_{j=0}^{\infty}\sum_{J\in\Omega_j} |h_J|\lambda^{-jM} = C\sum_{j=0}^{\infty}\lambda^{-jd/t-j\delta d}\sum_{J\in\Omega_j}|h_J|\\
&\leq C\sup_{j\geq 0}\lambda^{-jd/t}\sum_{J\in\Omega_j}|h_J| \leq C\bigg(\sup_{j\geq 0}\lambda^{-jd}\sum_{J\in\Omega_j}|h_J|^t\bigg)^{1/t}\\
&= C\bigg(\sup_{j\geq 0}\lambda^{-jd}\lambda^{md}\int\Big(\sum_{J\in\Omega_j}|h_J|\chi_J\Big)^t\bigg)^{1/t}\\
&\leq C\lambda^{(m-n)d/t}\bigg(\sup_{j\geq 0}\frac{1}{|\cup_{J\in\Omega_j}J|}\int_{\cup_{J\in\Omega_j}J}\Big(\sum_{J\in\Omega_j}|h_J|\chi_J\Big)^t\bigg)^{1/t}\\
&\leq C\lambda^{(m-n)d/t}M_t\Big(\sum_{J\in\mathcal{D}_m}|h_J|\chi_J\Big)(x). \qquad \square
\end{aligned}$$

LEMMA 6.5. *Let $m, n \in \mathbb{Z}$ with $m \geq n$. If $J \in \mathcal{D}_n$ and $M > d$, then*

$$\sum_{I\in\mathcal{D}_m}\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(J)}\bigg)^{-M} \leq C\lambda^{(m-n)d}.$$

Proof. We have

$$\sum_{I\in\mathcal{D}_m}\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(J)}\bigg)^{-M} = \lambda^{(m-n)M}\sum_{j\in\mathbb{Z}^d}\big(\lambda^{m-n}+|\lambda^m x_J - j|_\alpha\big)^{-M}.$$

Using now the fact that for every $\rho \geq 1$ and $M > d$,

$$\sum_{j\in\mathbb{Z}^d}(\rho+|j|_\alpha)^{-M} \leq C\rho^{d-M},$$

the result follows. $\square$

LEMMA 6.6. *Let $M > d$, $1 \leq p \leq \infty$, and $m, n \in \mathbb{Z}$ be such that $n \geq m$. If $(d_J)_{J\in\mathcal{D}_n}$ is a sequence of complex numbers, then*

$$\bigg(\sum_{I\in\mathcal{D}_m}\bigg(\sum_{J\in\mathcal{D}_n}\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(I)}\bigg)^{-M}|d_J|\bigg)^p\bigg)^{1/p} \leq C\lambda^{(n-m)d/p'}\bigg(\sum_{J\in\mathcal{D}_n}|d_J|^p\bigg)^{1/p},$$

where $1/p + 1/p' = 1$.

Proof. We note that for every $I, \Delta \in \mathcal{D}_m$, and $J \in \mathcal{D}_n$ with $J \subset \Delta$,

$$\bigg(1+\frac{|x_I-x_\Delta|_\alpha}{\ell(I)}\bigg) \leq C\bigg(1+\frac{|x_I-x_J|_\alpha}{\ell(I)}\bigg).$$

Also, for every $I \in \mathcal{D}_m$, $\mathcal{D}_m = \{\Delta : \Delta = I + j\lambda^{-m\alpha}, j \in \mathbb{Z}^d\}$. Using these two facts we find

$$\begin{aligned}
&\Big(\sum_{I\in\mathcal{D}_m} \Big(\sum_{J\in\mathcal{D}_n} \Big(1 + \frac{|x_I - x_J|_\alpha}{\ell(I)}\Big)^{-M} |d_J|\Big)^p\Big)^{1/p} \\
&= \Big(\sum_{I\in\mathcal{D}_m} \Big(\sum_{\Delta\in\mathcal{D}_m} \sum_{\substack{J\in\mathcal{D}_n \\ J\subset\Delta}} \Big(1 + \frac{|x_I - x_J|_\alpha}{\ell(I)}\Big)^{-M} |d_J|\Big)^p\Big)^{1/p} \\
&\le C\Big(\sum_{I\in\mathcal{D}_m} \Big(\sum_{\Delta\in\mathcal{D}_m} \sum_{\substack{J\in\mathcal{D}_n \\ J\subset\Delta}} \Big(1 + \frac{|x_I - x_\Delta|_\alpha}{\ell(I)}\Big)^{-M} |d_J|\Big)^p\Big)^{1/p} \\
&= C\Big(\sum_{I\in\mathcal{D}_m} \Big(\sum_{j\in\mathbb{Z}^d} (1+|j|_\alpha)^{-M} \sum_{\substack{J\in\mathcal{D}_n \\ J\subset I+j\lambda^{-m\alpha}}} |d_J|\Big)^p\Big)^{1/p} \\
&\le C \sum_{j\in\mathbb{Z}^d} (1+|j|_\alpha)^{-M} \Big(\sum_{I\in\mathcal{D}_m} \Big(\sum_{\substack{J\in\mathcal{D}_n \\ J\subset I+j\lambda^{-m\alpha}}} |d_J|\Big)^p\Big)^{1/p} \\
&\le C\lambda^{(n-m)d/p'} \sum_{j\in\mathbb{Z}^d} (1+|j|_\alpha)^{-M} \Big(\sum_{I\in\mathcal{D}_m} \sum_{\substack{J\in\mathcal{D}_n \\ J\subset I+j\lambda^{-m\alpha}}} |d_J|^p\Big)^{1/p} \\
&\le C\lambda^{(n-m)d/p'} \Big(\sum_{J\in\mathcal{D}_n} |d_J|^p\Big)^{1/p},
\end{aligned}$$

where we used Minkowski's and Hölder's inequalities. □

In a similar vein we have the following lemma. (We leave the proof to the reader.)

LEMMA 6.7. *Let $M > d$, $1 \le p \le \infty$, and $m, n \in \mathbb{Z}$ be such that $m \ge n$. If $(d_J)_{J\in\mathcal{D}_n}$ is a sequence of complex numbers, then*

$$\Big(\sum_{I\in\mathcal{D}_m} \Big(\sum_{J\in\mathcal{D}_n} \Big(1 + \frac{|x_I - x_J|_\alpha}{\ell(J)}\Big)^{-M} |d_J|\Big)^p\Big)^{1/p} \le C\lambda^{(m-n)d/p} \Big(\sum_{J\in\mathcal{D}_n} |d_J|^p\Big)^{1/p}.$$

Finally, we close the appendix by stating a very useful result, used repeatedly in the proofs of section 3.

LEMMA 6.8. *Let $\lambda > 1$, $\theta > 0$, and $0 < q \le \infty$. If $a_n, b_n \ge 0$, $n \in \mathbb{Z}$, satisfy*

$$0 \le b_n \le \sum_{m\le n} \lambda^{(m-n)\theta} a_m,$$

then

$$\Big(\sum_{n\in\mathbb{Z}} b_n^q\Big)^{1/q} \le C\Big(\sum_{n\in\mathbb{Z}} a_n^q\Big)^{1/q}.$$

ON THE EGUCHI–OKI–MATSUMURA EQUATION FOR PHASE SEPARATION IN ONE SPACE DIMENSION*

TAKAO HANADA†, NAOYUKI ISHIMURA‡, AND MASAAKI NAKAMURA§

Abstract. Eguchi–Oki–Matsumura equations are introduced to describe the dynamics of pattern formation that arises from phase separation in some binary alloys. The model extends the well-known Cahn–Hilliard equation and consists of coupled two functions; one is the local concentration and the other is the local degree of order. We show the existence of a solution, its asymptotic profile, and in part the structure of steady state solutions. Computational studies are also given.

Key words. pattern formation, phase separation, Eguchi–Oki–Matsumura model

1. Introduction.

There has been much interest in the dynamics of pattern formation resulting from phase separation, which is commonly observed in many physical contexts; we recall, for example, certain binary alloys and polymer mixtures. Cahn and Hilliard [4], based on a continuum model in thermodynamics, made a phenomenological approach to explain such kinetics and derive the fourth-order partial differential equations (PDEs), known as the Cahn–Hilliard equation. Many studies have been performed on this equation and much progress has been achieved so far from various points of view. For more information and background materials, see [1], [2], [3], [6], [7], [8], [9], [11], [21], [22], [23], [24], [25] and the references therein.

Eguchi, Oki, and Matsumura [10], in an attempt to theoretically investigate such pattern formation, introduced a system of equations, referred to here as EOM equations. This motion law is derived from the first principles of thermodynamics of irreversible process under appropriate assumptions on the free energy, and it generalizes the formulation settled by Cahn and Hilliard. The EOM equation extends the Cahn–Hilliard equation and consists of coupled two phase fields, one the local concentration and the other the local degree of order. After performance of a suitable scaling of parameters, presented later, EOM equations in one space dimension, with which we are mainly concerned, are expressed as follows:

$$
\begin{cases}
u_t = -\varepsilon^2 u_{xxxx} + ((a+v^2)u)_{xx} & \text{in } 0<x<l, \quad t>0,\\
v_t = v_{xx} + (b-u^2-v^2)v & \text{in } 0<x<l, \quad t>0,\\
u_x = u_{xxx} = v_x = 0 & \text{at } x=0 \text{ and } l, \quad t>0,\\
u|_{t=0} = u_0, \quad v|_{t=0} = v_0 & \text{on } 0\le x\le l,
\end{cases}
\tag{1.1}
$$

where $u = u(x,t)$ and $v = v(x,t)$ denote unknown functions related to the local concentration and the local degree of order, respectively. The total concentration of u is conserved under the evolution of (1.1). Namely, we have

$$\frac{1}{l}\int_0^l u(x,t)\,dx = m,$$

where m is a constant. Given initial data u_0, v_0 should satisfy required compatibility conditions:

$$(u_0)_x = (u_0)_{xxx} = (v_0)_x = 0 \qquad \text{at } x = 0,\, l, \quad \text{and } \frac{1}{l}\int_0^l u_0(x)\,dx = m.$$

Positive constants ε, a depend on the temperature, and $b \in \boldsymbol{R}$ is the principal parameter which increases from negative to positive as the temperature decreases from above to below the critical temperature. We focus our attention, however, on the case of positive b, since the negative b turns out to enjoy rather trivial behaviors.

As a special case of EOM equations, we observe that if $v \equiv 0$, then (1.1) reduces to

$$\begin{cases} u_t = -\varepsilon^2 u_{xxxx} + a u_{xx} & \text{in } 0 < x < l, \quad t > 0, \\ u_x = u_{xxx} = 0 & \text{at } x = 0 \text{ and } l, \quad t > 0, \\ (1/l)\int_0^l u\,dx = m. \end{cases}$$

This is the famous Cahn–Hilliard equation in its simplest form (if we especially allow $a < 0$). If we put $u \equiv m$ in (1.1), then we recover

$$\begin{cases} v_t = v_{xx} + (b - m^2 - v^2)v & \text{in } 0 < x < l, \quad t > 0, \\ v_x = 0 & \text{at } x = 0 \text{ and } l, \quad t > 0, \end{cases}$$

which is deduced from the Ginzburg–Landau theory for superconductivity.

Motivated partly by works concerning the Cahn–Hilliard equation [8], [11], [25], we expect that the solution $(u(x,t), v(x,t))$ for (1.1) converges as $t \to \infty$ to the solution $(u(x), v(x))$ for the steady state problem

$$\begin{cases} -\varepsilon^2 u_{xxxx} + ((a + v^2)u)_{xx} = 0 & \text{in } 0 < x < l, \\ v_{xx} + (b - u^2 - v^2)v = 0 & \text{in } 0 < x < l, \\ u_x = u_{xxx} = v_x = 0 & \text{at } x = 0 \text{ and } l, \\ (1/l)\int_0^l u\,dx = m. \end{cases} \tag{1.2}$$

We remark that (1.2) always has a solution $u \equiv m$ and $v \equiv 0$. If $b \le 0$, then it can be seen that this is the only solution to (1.2) by virtue of the maximum principle. If $b > m^2$, (1.2) has another solution $u \equiv m$ and $v \equiv \pm\sqrt{b - m^2}$. We call these solutions trivial. Solutions that are different from trivial ones will be called nontrivial solutions of the EOM equations; in other words, solution (u, v) to (1.2), both of which are not simultaneously constants, will be referred to as nontrivial solutions.

In this article, we are concerned with the local solvability, the asymptotic behavior of solutions to (1.1), and the structure of steady state solutions to (1.2). It is exhibited that the local degree of order v plays a key role in producing phase separation in the EOM model. Our main analytical achievements are summarized as follows.

THEOREM 1.1. *Suppose that* $u_0, v_0 \in H^2(0,l)$ *with* $(u_0)_x = (v_0)_x = 0$ *at* $x = 0, l$ *and* $(1/l)\int_0^l u_0\,dx = m$. *Then, for each* $T > 0$, *there exists a unique solution* (u,v) *to* (1.1) *such that*

$$u \in L^2((0,T);H^4(0,l)) \cap L^\infty([0,T);H^2(0,l)),$$
$$v \in L^2((0,T);H^2(0,l)) \cap L^\infty([0,T);H^1(0,l)).$$

For any initial data above, the solution (u,v) *converges as* $t \to \infty$ *to a solution of the steady state problem* (1.2).

There is at least one monotone nontrivial steady state solution of (1.2) *if we assign suitably large* b *and* m^2. *Moreover, for any integer* $k \geq 2$ *and for appropriately chosen large* b *and* m^2 *depending on* k, (1.2) *has at least one nonmonotone nontrivial steady state solution, each of whose derivatives changes sign exactly* $(k-1)$ *times.*

The values of b and m^2 stated in the theorem will be clarified in the course of proof.

For related results concerning EOM equations, see [17], [20].

We briefly outline the idea of proof. To obtain the local in time solution, a standard Galerkin method is employed. The global existence then follows by a priori estimates, with the aid of a Lyapunov functional; the free energy of the system serves as a Lyapunov functional, which is given by

$$F[u,v] := \int_0^l \left(\frac{\varepsilon^2}{2}u_x^2 + \frac{1}{2}v_x^2 + \frac{a}{2}u^2 + \frac{1}{4}v^4 - \frac{b}{2}v^2 + \frac{1}{2}u^2v^2\right) dx. \tag{1.3}$$

Note that $F[u,v]$ is well defined for (u,v) of the function class specified in Theorem 1.1. A direct calculation leads to

$$\frac{d}{dt}F[u,v](t) = -\int_0^l \{-\varepsilon^2 u_{xxx} + ((a+v^2)u)_x\}^2\,dx - \int_0^l v_t^2\,dx \leq 0 \tag{1.4}$$

for any solution (u,v) to (1.1).

Every solution is proved to converge to a steady state. Depending on the value of parameters b and m, EOM equations have various steady state solutions, which numerical investigation in section 5 clearly illustrates. Section 4 shows analytically the existence of nontrivial steady state solutions of EOM equations.

We quickly review the derivation of (1.1) for completeness of our exposition. Following [10], we begin with the total free energy:

$$F_{\mathrm{EOM}}[u,v] = \int_\Omega \left(\frac{H}{2}|\nabla u|^2 + \frac{K}{2}|\nabla v|^2 + f(u,v)\right) dx,$$

where $\Omega \subset \boldsymbol{R}^3$ represents a bounded domain and physical constants H, K mean the surface energy per unit area, which depend on the temperature. The function $f(u,v)$ stands for the density of the bulk free energy assumed to be given by

$$f(u,v) = \frac{a}{2}u^2 + \frac{1}{4}v^4 - \frac{b}{2}v^2 + \frac{g}{2}u^2v^2,$$

where positive constants a, g depend on the temperature and b denotes the principal parameter. Here we confine ourselves to considering the one-dimensional case and put $\Omega = (0,l)$. We make a scaling of variables. Define

$$\sqrt{\frac{g}{K}}u \to u, \quad \frac{1}{\sqrt{K}}v \to v, \quad \frac{a}{gK} \to a, \quad \frac{b}{K} \to b$$

and divide F_{EOM} by K^2. Then the functional (1.3) is discovered with $\varepsilon^2 = H/gK$. We remark that we have just rearranged the constants while retaining the role of the principal parameter b.

2. Existence of solutions. First we deal with the solvability of the problem (1.1). To establish the local in time existence, we implement a standard Galerkin approximation method.

Let $\mathcal{F}$ denote the complete orthonormal system in $L^2(0,l)$ with the even periodic boundary condition:

$$\mathcal{F} := \left\{ \frac{1}{\sqrt{l}}, \sqrt{\frac{2}{l}} \cos\frac{\pi x}{l}, \sqrt{\frac{2}{l}} \cos\frac{2\pi x}{l}, \dots, \sqrt{\frac{2}{l}} \cos\frac{n\pi x}{l}, \dots \right\}.$$

For every integer $N > 0$, let W_N be a linear space spanned by $\{1/\sqrt{l}, \sqrt{2/l}\cos(\pi x/l), \dots, \sqrt{2/l}\cos(N\pi x/l)\}$ and P_N denote the orthogonal projector in $L^2(0,l)$ onto W_N; namely,

$$P_N : L^2(0,l) \to W_N := \mathrm{Span} \left\{ \frac{1}{\sqrt{l}}, \sqrt{\frac{2}{l}} \cos\frac{\pi x}{l}, \dots, \sqrt{\frac{2}{l}} \cos\frac{N\pi x}{l} \right\}.$$

To be precise, for every even periodic $f \in L^2(0,l)$, we define

$$P_N f(x) := \frac{1}{\sqrt{l}} f^0 + \sum_{n=1}^{N} f^n \sqrt{\frac{2}{l}} \cos\frac{n\pi x}{l},$$

where

$$f^0 := \frac{1}{\sqrt{l}} \int_0^l f(x)\,dx \quad \text{and} \quad f^n := \int_0^l f(x) \sqrt{\frac{2}{l}} \cos\frac{n\pi x}{l}\,dx.$$

We are then looking for an approximate solution $(u_N(x,t), v_N(x,t))$ to (1.1) given by

$$\begin{aligned} u_N(x,t) &= m + \sum_{n=1}^{N} u^n(t) \sqrt{\frac{2}{l}} \cos\frac{n\pi x}{l} \\ &\quad (u^0(t) = \sqrt{l}m \text{ is used without possible confusion}), \\ v_N(x,t) &= \frac{1}{\sqrt{l}} v^0(t) + \sum_{n=1}^{N} v^n(t) \sqrt{\frac{2}{l}} \cos\frac{n\pi x}{l}. \end{aligned}$$

That is, u_N, v_N are interpreted as W_N-valued functions on $[0,T)$ for some $T > 0$, which satisfy

$$\begin{cases} (u_N)_t = -\varepsilon^2 (u_N)_{xxxx} + a(u_N)_{xx} + P_N((v_N)^2 u_N)_{xx} & \text{in } 0 < x < l,\ 0 < t < T, \\ (v_N)_t = (v_N)_{xx} + b v_N - P_N(((u_N)^2 + (v_N)^2) v_N) & \text{in } 0 < x < l,\ 0 < t < T, \\ u_N|_{t=0} = P_N u_0,\ v_N|_{t=0} = P_N v_0 & \text{on } 0 \le x \le l. \end{cases}$$

If we write up the equations for each component, then we discover

$$
\begin{aligned}
\frac{du^n(t)}{dt} &= -\varepsilon^2 \left(\frac{n\pi}{l}\right)^4 u^n(t) - a\left(\frac{n\pi}{l}\right)^2 u^n(t) \\
&\quad - \frac{1}{2l}\left(\frac{n\pi}{l}\right)^2 \sum_{G(n_1,n_2,n_3;n)}^{*} \iota_{n_1}\iota_{n_2}\iota_{n_3} v^{n_1}(t)v^{n_2}(t)u^{n_3}(t), \\
\frac{dv^n(t)}{dt} &= -\left(\frac{n\pi}{l}\right)^2 v^n(t) + bv^n(t) \\
&\quad - \frac{1}{2l} \sum_{G(n_1,n_2,n_3;n)}^{*} \iota_{n_1}\iota_{n_2}\iota_{n_3}\iota_n (u^{n_1}(t)u^{n_2}(t) + v^{n_1}(t)v^{n_2}(t))v^{n_3}(t) \\
&\qquad (\iota_0 := 2^{-1/2} \quad \text{and} \quad \iota_n := 1 \text{ for } n \geq 1), \\
u^n(0) &= \int_0^l u_0(x)\sqrt{\frac{2}{l}}\cos\frac{n\pi x}{l}\,dx \qquad \text{for } n \geq 1, \\
v^n(0) &= \begin{cases} (1/\sqrt{l})\int_0^l v_0(x)\,dx & \text{for } n = 0, \\ \int_0^l v_0(x)\sqrt{2/l}\cos(n\pi x/l)\,dx & \text{for } n \geq 1. \end{cases}
\end{aligned} \tag{2.1}
$$

Here we have defined

$$
\begin{aligned}
G(n_1,n_2,n_3;n) := \{0 \leq n_1, n_2, n_3 \leq N \,|\, & n_1 + n_2 + n_3 = \pm n \\
\text{or } \ n_1 - n_2 + n_3 = \pm n \quad & \text{or } n_1 + n_2 - n_3 = \pm n \quad \text{or } n_1 - n_2 - n_3 = \pm n\},
\end{aligned}
$$

and the summation $\sum^*$ indicates that the multiplicity is taken into account; for example, if $(n_1,n_2,n_3;n) = (1,1,1;1)$, then $\sum^* v^1(t)v^1(t)u^1(t) = 3v^1(t)v^1(t)u^1(t)$, since three equations in the definition of G are satisfied. If $(n_1,n_2,n_3;n) = (0,0,0;0)$, then the multiplication by eight is made.

The system of equations (2.1) has a unique solution on $[0,T_N)$ for some $T_N > 0$. The passage to the limit $N \to \infty$ is based on a priori estimates on (u_N, v_N). Here we refer to various a priori estimates established for the solution (u,v) to (1.1) in the next section, which are principally applicable as well to the truncated systems with necessary modifications. For instance, an upper bound for v_N is estimated as

$$
\|v_N(t)\|^2 := \int_0^l v_N(x,t)^2\,dx = \sum_{i=0}^{N} v^i(t)^2 \leq \limsup_{N\to\infty} \|v_N(t)\|^2 \leq \|v(t)\|^2 \leq 2bl,
$$

where the last inequality is expressed in Lemma 3.1. Note also that norm $\|\cdot\|$ is consistent with those defined there.

In addition, the time evolution of the Lyapunov functional $F[u_N, v_N](t)$ is calculated to be

$$
\begin{aligned}
&\frac{d}{dt}F[u_N,v_N](t) \\
&\quad = -\int_0^l \{-\varepsilon^2 (u_N)_{xxx} + (au_N + P_N(u_N(v_N)^2))_x\}^2\,dx - \int_0^l ((v_N)_t)^2\,dx \leq 0.
\end{aligned}
$$

After performing an integration with respect to t, we infer that $\|u_N(t)\|$, $\|(u_N)_x(t)\|$, $\|(v_N)_x(t)\|$ and therefore $\max|u_N(\cdot,t)|$ and $\max|v_N(\cdot,t)|$ are uniformly bounded by constants which depend on $H^1(0,l)$-norms of the initial data u_0 and v_0 but are independent of N.

We are thus able to let $N \to \infty$; in particular, we have $\liminf_{N\to\infty} T_N \geq T > 0$ for some $T > 0$. Uniform bounds of $H^1(0,l)$-norms enable us to repeat the local solvability procedure and continue the solution. We remark that the linear parts of (2.1) are good terms. In summary, our existence results are formulated as follows.

PROPOSITION 2.1. *Suppose that* $u_0, v_0 \in H^1(0,l)$ *with* $(u_0)_x = (v_0)_x = 0$ *at* $x = 0, l$ *and* $(1/l)\int_0^l u_0\,dx = m$. *Then, for each* $T > 0$, *there exists a unique solution* (u,v) *to* (1.1) *such that*

$$u \in L^2((0,T); H^3(0,l)) \cap L^\infty([0,T); H^1(0,l)),$$
$$v \in L^2((0,T); H^2(0,l)) \cap L^\infty([0,T); H^1(0,l)).$$

Further regularities claimed in Theorem 1.1 are standard consequences of a priori estimates depicted as lemmas in the subsequent section.

We next deal with the long-term behavior of the solution (u,v) to (1.1). This is a rather routine inference by virtue of the Lyapunov functional $F[u,v]$.

Since the solution (u,v) exists for any $T > 0$, integration of (1.4) with respect to t yields

$$\limsup_{t\to\infty} F[u,v](t) + \int_0^\infty d\tau \int_0^l (\{-\varepsilon^2 u_{xxx} + ((a+v^2)u)_x\}^2 + v_t^2)\,dx \leq F[u_0,v_0].$$

Taking into account that $F[u,v]$ is bounded below, we conclude that there is a sequence $t_1 < t_2 < \cdots < t_n < \cdots \to \infty$ for which

$$\begin{cases} (-\varepsilon^2 u_{xxx} + ((a+v^2)u)_x)(t_n) \to 0 \\ (v_{xx} + (b - u^2 - v^2)v)(t_n) \to 0 \end{cases} \qquad \text{as } n \to \infty.$$

That is, (u,v) tends to an element of the ω-limit set of (u_0,v_0), on which $F[u,v]$ is constant; namely, (u,v) converges to an equilibrium solution of the steady state problem (1.2).

3. A priori estimates. We turn our attention to some a priori estimates, which are needed to prove the existence and to determine the asymptotic profile of the solution (u,v) to (1.1). For brevity of presentation, we introduce the following function spaces:

$$E_T := \{(u,v) \in L^2((0,T); H^4(0,l)) \times L^2((0,T); H^2(0,l)) \mid u_x = u_{xxx} = v_x = 0 \text{ at } x = 0, l\},$$

$$E_0 := \left\{ (u_0,v_0) \in (H^2(0,l))^2 \,\middle|\, (u_0)_x = (v_0)_x = 0 \text{ at } x = 0, l,\ \frac{1}{l}\int_0^l u_0\,dx = m \right\},$$

where $T > 0$. The norms of $L^p(0,l)$ $(1 \leq p \leq \infty)$ are denoted by $\|\cdot\|_p$ and $\|\cdot\| := \|\cdot\|_2$. The inequalities $\|\cdot\|_p \leq l^{(q-p)/q}\|\cdot\|_q$ $(1 < p \leq q \leq \infty)$ are easily checked. Furthermore, C_0 stand for various constants depending only on the initial data and constants ε^2, a, b, which may differ from line to line. We understand that C_0 is independent of t.

First we provide a bound for v.

LEMMA 3.1. *There holds*

$$\|v(t)\|_\infty \leq \max\{\|v_0\|_\infty, \sqrt{b}\} \qquad \textit{for } 0 < t < T.$$

We recall once again that $b \geq 0$ is assumed.

Proof. Take an arbitrarily small $\delta > 0$ and suppose there exists first $0 \le t < T$, $0 \le x \le l$ such that

$$\|v_0\|_\infty \le \sqrt{b} + \delta \le v(x,t) = \max_{0\le y\le l} v(y,t).$$

The other case $v(x,t) = \min_{0\le y\le l} v(y,t) \le -\sqrt{b} - \delta \le -\|v_0\|$ proceeds similarly. We then find that

$$0 \le v_t(x,t) = v_{xx}(x,t) + (b - u(x,t)^2 - v(x,t)^2)v(x,t) \le (b - (\sqrt{b}+\delta)^2)v(x,t) < 0,$$

a contradiction. Since δ is arbitrary, we are done. □

We can say further that for any initial data $(u_0, v_0) \in E_0$ and for every $\delta > 0$, there exists T_δ such that $\|v(t)\|_\infty \le (1+\delta)\sqrt{b}$ for $t \ge T_\delta$. We may thus assume without loss of generality that $\|v_0\|_\infty \le \sqrt{2b}$ from the beginning. Note also that this especially leads to $\|v(t)\|_p \le l^{1/p}\sqrt{2b}$ for any $1 \le p \le \infty$.

LEMMA 3.2. *For any initial data $(u_0, v_0) \in E_0$, the solution $(u, v) \in E_T$ to (1.1) verifies*

$$\|u(t)\|,\ \|u_x(t)\|,\ \|v_x(t)\| \le C_0$$

for $0 < t < T$, and moreover

$$\|u(t)\|_\infty \le C_0.$$

Proof. We employ the Lyapunov functional introduced in (1.3). We assert that for $0 < t < T$

$$F[u,v](t) + \int_0^t d\tau \int_0^l (\{-\varepsilon^2 u_{xxx} + ((a+v^2)u)_x\}^2 + v_t^2)\, dx \le F[u_0, v_0],$$

from which the first three estimates hold. Thanks to the inequality

$$\|w\|_\infty \le \frac{1}{\sqrt{l}}\|w\| + \sqrt{l}\|w_x\| \qquad \text{for } w \in H^1(0,l),$$

we arrive at the last estimate. □

LEMMA 3.3. *It follows that for any $0 \le t \le s \le T$*

$$\int_t^s (\|u_{xx}(\tau)\|^2 + \|u_x(\tau)\|^2 + \|v_x(\tau)\|^2)\, d\tau \le C_0(1 + (s-t)).$$

Proof. Multiplying the first and the second equation of (1.1) by u and v, respectively, and integrating by parts, we infer that

$$\begin{aligned}
\frac{1}{2}\frac{d}{dt}\|u(t)\|^2 + \varepsilon^2\|u_{xx}(t)\|^2 &= -\int_0^l ((a+v^2)u)_x u_x\, dx \\
&= -a\|u_x(t)\|^2 - \|(u_x v)(t)\|^2 - 2\int_0^l u u_x v v_x\, dx \\
&\le -a\|u_x(t)\|^2 + \|(uv_x)(t)\|^2 \le -a\|u_x(t)\|^2 + C_0^2\|v_x(t)\|^2, \\
\frac{1}{2}\frac{d}{dt}\|v(t)\|^2 + \|v_x(t)\|^2 &= \int_0^l (b - u^2 - v^2)v^2\, dx \le b\|v(t)\|^2 \le 2lb^2,
\end{aligned}$$

where the use of $\|u(t)\|_\infty \le C_0$ and $\|v(t)\|_\infty \le \sqrt{2b}$ is made. We compute

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}(\|u(t)\|^2 + (C_0^2+1)\|v(t)\|^2) + \varepsilon^2\|u_{xx}(t)\|^2 + a\|u_x(t)\|^2 + \|v_x(t)\|^2 \\ \le b^2(C_0^2+1) =: C_0,\end{aligned}$$

and hence we have

$$\begin{aligned}\|u(s)\|^2 + (C_0^2+1)\|v(s)\|^2 + 2\int_t^s (\varepsilon^2\|u_{xx}(\tau)\|^2 + a\|u_x(\tau)\|^2 + \|v_x(\tau)\|^2)\,d\tau \\ \le \|u(t)\|^2 + (C_0^2+1)\|v(t)\|^2 + C_0(s-t) =: C_0(1+(s-t)),\end{aligned}$$

from where the lemma follows. □

Next we are going to derive higher derivative estimates. Our intention is to achieve bounds represented explicitly in terms of t.

LEMMA 3.4. *There holds for any* $0 \le t \le s \le T$,

$$\int_t^s (\|u_{xxx}(\tau)\|^2 + \|v_{xx}(\tau)\|^2)\,d\tau \le C_0(1+(s-t)).$$

Proof. This time we multiply the first and the second equation of (1.1) by u_{xx} and v_{xx}, respectively; we deduce that

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\|u_x(t)\|^2 + \varepsilon^2\|u_{xxx}(t)\|^2 \\ &\quad = -\int_0^l ((a+v^2)u)_{xx}u_{xx}\,dx = -a\|u_{xx}(t)\|^2 + \int_0^l (uv^2)_x u_{xxx}\,dx \\ &\quad \le -a\|u_{xx}(t)\|^2 + \frac{\varepsilon^2}{2}\|u_{xxx}(t)\|^2 + \frac{1}{2\varepsilon^2}\int_0^l (u_x v^2 + 2uvv_x)^2\,dx \\ &\quad \le -a\|u_{xx}(t)\|^2 + \frac{\varepsilon^2}{2}\|u_{xxx}(t)\|^2 + C_0(\|u_x(t)\|^2 + \|v_x(t)\|^2), \\ &\frac{1}{2}\frac{d}{dt}\|v_x(t)\|^2 + \|v_{xx}(t)\|^2 = -\int_0^l (b-u^2-v^2)vv_{xx}\,dx \\ &\quad = \int_0^l \{(b-u^2-v^2)v_x^2\,dx - (u^2+v^2)_x vv_x\}\,dx \\ &\quad = \int_0^l \{(b-3v^2)v_x^2 - u^2v_x^2 - 2uu_xvv_x\}\,dx \\ &\quad \le \int_0^l \{(b-3v^2)v_x^2 + u_x^2v^2\}\,dx \le 2b(\|u_x(t)\|^2 + \|v_x(t)\|^2).\end{aligned}$$

Adding these inequalities, we have

$$\frac{1}{2}\frac{d}{dt}(\|u_x(t)\|^2 + \|v_x(t)\|^2) + \frac{\varepsilon^2}{2}\|u_{xxx}(t)\|^2 + \|v_{xx}(t)\|^2 \le C_0(\|u_x(t)\|^2 + \|v_x(t)\|^2).$$

An integration with respect to t combined with Lemmas 3.2 and 3.3 finishes the proof of Lemma 3.4. □

Finally we formalize the next lemma.

LEMMA 3.5. *There hold for any* $0 \le t \le s \le T$

$$\|u_{xx}(t)\|^2 \le C_0(1+t), \quad \int_t^s \|u_{xxxx}(\tau)\|^2\,d\tau \le C_0(1+(s-t)).$$

Proof. We multiply the equation of u by u_{xxxx} and integrate by parts to obtain

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|u_{xx}(t)\|^2 + \varepsilon^2\|u_{xxxx}(t)\|^2 &= \int_0^l (au+uv^2)_{xx}u_{xxxx}\,dx\\ &\le -a\|u_{xxx}(t)\|^2 + \frac{\varepsilon^2}{2}\|u_{xxxx}(t)\|^2 + \frac{1}{2\varepsilon^2}\int_0^l ((uv^2)_{xx})^2\,dx\\ &\le -a\|u_{xxx}(t)\|^2 + \frac{\varepsilon^2}{2}\|u_{xxxx}(t)\|^2\\ &\qquad + C_0(\|u_{xx}(t)\|^2 + \|v_{xx}(t)\|^2 + \|(u_xv_x)(t)\|^2 + \|v_x(t)^2\|^2).\end{aligned}$$

To handle the last term, we appeal to the inequality

$$\|u_x(t)\|_\infty \le \sqrt{l}\|u_{xx}(t)\|, \quad \|v_x(t)\|_\infty \le \sqrt{l}\|v_{xx}(t)\|,$$

which is valid in light of $u_x = v_x = 0$ at the boundary; it then follows that

$$\begin{aligned}\|(u_xv_x)(t)\|^2 \le l\|u_{xx}(t)\|^2\|v_x(t)\|^2 \le C_0\|u_{xx}(t)\|^2,\\ \|v_x(t)^2\|^2 \le C_0\|v_{xx}(t)\|^2.\end{aligned}$$

To sum up, we have accomplished

$$\frac{1}{2}\frac{d}{dt}\|u_{xx}(t)\|^2 + \frac{\varepsilon^2}{2}\|u_{xxxx}(t)\|^2 + a\|u_{xxx}(t)\|^2 \le C_0(\|u_{xx}(t)\|^2 + \|v_{xx}(t)\|^2).$$

The integral estimates of the previous two lemmas now imply the conclusion we desired. □

4. Structure of steady solutions. In this section, the structure of steady state solutions to EOM equations is analyzed; we want to seek for solutions $u = u(x)$ and $v = v(x)$ which verify (1.2).

Numerical investigation presented in section 5 strongly indicates that there really exist nontrivial steady state solutions to EOM equations for certain parameter values. We recall that nontrivial solutions are defined as those for (1.2) other than trivial solutions mentioned in section 1; namely, they are solutions (u, v) to (1.2), both of which are not simultaneously constants. The aim of this section is to confirm analytically these numerical observations. Our results are as follows and extend our previous establishments [15].

PROPOSITION 4.1. *For suitably assigned large b and m^2, there exists at least one monotone nontrivial steady state solution for EOM equations. Furthermore, for any integer $k \ge 2$ and for appropriately large b and m^2 depending on k, EOM equations have nonmonotone nontrivial steady state solutions, each of whose derivatives changes sign exactly $(k-1)$ times.*

The large values of b and m^2 stated in Proposition 4.1 can be computed explicitly, for which we do not go into detail. We also remark that our result should be compared to [5], where the fact is described that nonmonotonic functions cannot be a local minimizer for a single Cahn–Hilliard-type functional.

The proof is carried out from the variational point of view and divided into several steps. First we notice that although (1.2) is a system of equations of fourth order, it has a second-order variational structure; the solution to (1.2) is given by the critical point of a functional (1.3) among the function space

$$\mathcal{A} := \left\{ (u,v) \in (H^1(0,l))^2 \;\middle|\; \frac{1}{l}\int_0^l u\,dx = m \right\}.$$

We have the next lemma, whose proof is given in a similar way as in Lemma 3.1 of [25], and we may safely omit it.

LEMMA 4.2. *Problem* (1.2) *is equivalent to the problem of finding the critical points of functional* $F[u,v]$ *defined by* (1.3) *over* $\mathcal{A}$.

Step 1. Existence of nontrivial global minimizer.

We immediately obtain

$$\begin{aligned}\frac{1}{l}F[m,0] &= \frac{a}{2}m^2,\\ \frac{1}{l}F[m,\pm\sqrt{b-m^2}] &= \frac{a}{2}m^2-\frac{1}{4}(b-m^2)^2 \quad \text{if } b>m^2.\end{aligned}$$

Since F is bounded below on $\mathcal{A}$, our task of constructing at least one nontrivial steady state solution is to find a test function $(u,v)\in\mathcal{A}$ such that

$$\frac{1}{l}F[u,v] < \frac{a}{2}m^2-\frac{1}{4}(b-m^2)^2. \tag{4.1}$$

The minimization procedure then works well to produce at least one nontrivial steady state solution, which is global minimizer of (1.3) over $\mathcal{A}$.

To accomplish this, we prepare

$$\begin{aligned}u(x) &= m-\delta\cos\frac{\pi x}{l},\\ v(x) &= \pm\sqrt{b-\left(m-\delta\cos\frac{\pi x}{l}\right)^2},\end{aligned} \tag{4.2}$$

where $\delta>0$ is a parameter and we assign $b>(m+\delta)^2$. Clearly $(u,v)\in\mathcal{A}$ and we compute

$$\begin{aligned}\frac{1}{l}F[u,v] = \frac{a}{2}\,m^2 &-\frac{1}{4}(b-m^2)^2+(\varepsilon^2(\pi/l)^2+a)\frac{\delta^2}{4}\\ &+\frac{\delta^2\pi^2}{2l^2}\int_0^l\frac{(m-\delta\cos(\pi x/l))^2\sin^2(\pi x/l)}{b-(m-\delta\cos(\pi x/l))^2}\,dx-\frac{m^2\delta^2}{2}-\frac{3\delta^4}{32}+\frac{\delta^2}{4}(b-m^2).\end{aligned}$$

If we further set $b=2m^2$ and $\delta=m/4$, then we infer that

$$\begin{aligned}\frac{1}{l}F[u,v] = \frac{1}{l}F[m,\pm\sqrt{b-m^2}] &-\frac{131}{2^{13}}m^4\\ &+\left(\frac{\varepsilon^2(\pi/l)^2+a}{64}+\frac{\pi^2}{32l^2}\int_0^l\frac{(4-\cos(\pi x/l))^2\sin^2(\pi x/l)}{32-(4-\cos(\pi x/l))^2}\,dx\right)m^2,\end{aligned}$$

from which we conclude that (4.1) holds, taking larger m if necessary.

Step 2. Monotonicity of the global minimizer.

Our intention is to show the monotonicity of the global minimizer (u,v) obtained in Step 1. Since there is a cross-term $\int_0^l 2^{-1}u^2v^2\,dx$ in the functional $F[u,v]$, a simple direct application of usual rearrangements is insufficient. We have, however, the next lemma.

LEMMA 4.3. *Suppose* $f,g\in H^1(0,l)$. *Let* f^i *and* g^d *denote the monotone increasing and decreasing rearrangement of* f *and* g, *respectively. Then*

$$\int_0^l f^i g^d\,dx \le \int_0^l fg\,dx,$$

where the equality holds if and only if $(f,g) \equiv (f^i, g^d)$ *or* (f^d, g^i).

Suppose additionally f, g *are both nonnegative (or nonpositive). Then*

$$\int_0^l (f^i)^2 (g^d)^2 \, dx \le \int_0^l f^2 g^2 \, dx,$$

where the equality holds if and only if $(f,g) \equiv (f^i, g^d)$ *or* (f^d, g^i). *If the sign of* (f,g) *is opposite, then* (f^i, g^i) *or* (f^d, g^d) *brings the same conclusion.*

We recall that the monotone increasing rearrangement f^i of $f \in H^1(0,l)$ is defined as follows. For $c \in \boldsymbol{R}$, put

$$I_c := \{x \in (0,l) \,|\, f(x) \ge c\},$$
$$I_c^i := \begin{cases} \{l - |I_c| \le x \le l\} & \text{if } I_c \ne \emptyset, \\ \emptyset & \text{if } I_c = \emptyset, \end{cases}$$

where $|I_c|$ denotes the Lebesgue measure of the interval I_c. We then have

$$f^i(x) = \sup\{c \in \boldsymbol{R} \,|\, x \in I_c^i\} \qquad \text{for } 0 \le x \le l.$$

The monotone decreasing rearrangement is defined similarly.

The next properties of rearrangements are well known [19]:

$$\begin{aligned} &\int_0^l (f^i)_x^2 \, dx \le \int_0^l f_x^2 \, dx, \\ &\int_0^l (f^i)^p \, dx = \int_0^l f^p \, dx \quad \text{if } f \ge 0,\ p > 0. \end{aligned} \tag{4.3}$$

The proof of our lemma is rather standard. Approximating f by step functions, we see that it suffices to deduce the lemma in the case of sequences, which is known to be true [18]. We omit the details.

Now we return to our problem. Taking account of (4.3) and Lemma 4.3, we assert that the monotonicity of the global minimizer (u,v) follows at once if (u,v) are both simultaneously taken to be nonnegative (or nonpositive). Indeed, suppose (u,v) are nonnegative. Performing the monotone increasing and decreasing rearrangement for u and v, respectively, we derive that

$$F[u^i, v^d] \le F[u,v] = \min_{\mathcal{A}} F,$$

from which we establish that $(u,v) \equiv (u^i, v^d)$ or (u^d, v^i).

It remains to prove that (u,v) are both taken to be nonnegative (or nonpositive). Suppose $m = l^{-1} \int_0^l u \, dx > 0$. Then $|\{x \,|\, u(x) > 0\}| > 0$ and we note that u solves

$$\begin{aligned} -\varepsilon^2 u_{xx} + (a + v^2)u &= \beta \qquad \text{in } 0 < x < l, \\ u_x &= 0 \qquad \text{at } x = 0 \text{ and } l \end{aligned}$$

for some constant $\beta \in \boldsymbol{R}$. Since $|\{x \,|\, u(x) > 0\}| > 0$, the sign of constant β must be positive, which certainly holds at the maximum point in $\{x \,|\, u(x) > 0\}$. We recall that $a > 0$. If there happens $|\{x \,|\, u(x) < 0\}| > 0$, then a similar reasoning as above applied to the minimum point of u (< 0) implies $\beta < 0$, which is a contradiction.

We therefore conclude that u has the same sign as m. If we further put $v^+(x) = \max\{v(x), -v(x)\} \geq 0$, then we observe

$$F[u, v^+] = F[u, v] = \min_{\mathcal{A}} F,$$

from which we find that (u, v) are nonnegative.

Step 3. Existence of multi-bump solutions.

Now, utilizing this monotone nontrivial solution, for every integer $k \geq 2$, we construct nontrivial solutions (u^k, v^k) to (1.2), whose derivatives u^k_x and v^k_x change sign exactly $(k-1)$ times, respectively. To obtain these solutions, we divide the interval $[0, l]$ into k subpieces $[(i-1)l/k, il/k]$ $(i = 1, 2, \ldots, k)$. On the first subinterval $[0, l/k]$, the minimization procedure formulated in Step 1 works if b and m^2 are suitably large enough and there exists at least one monotone nontrivial solution (u^k, v^k) to the equations of (1.2) with $u^k_x = v^k_x = 0$ at $x = 0$ and l/k. These are monotone functions. We define inductively on $i = 1, 2, \ldots, k$ that

$$u^k(x) = \begin{cases} u^k(x - ((i-1)l/k)), & i \text{ is odd}, \\ u^k(-x + (il/k)), & i \text{ is even}, \end{cases}$$

on each subintervals $[(i-1)l/k, il/k]$. v^k is extended similarly onto $[0, l]$. Such constructed (u^k, v^k) clearly solves (1.2) and fulfills our requirements.

The proof of Proposition 4.1 is finally completed. □

5. Computational study. In this section we treat the computational research for EOM equations. The detailed exposition is given in another work [16]; here we just incorporate several results. Note that our discretization scheme is motivated partially by [12], [13], [14], whose principal target is to cultivate a stable reasonable numerical scheme for computing the Cahn–Hilliard equation.

Let $x_k = k\Delta x$ $(k = 0, 1, \ldots, n)$ with $\Delta x = l/n$. The discretized free energy $F^n[U, V]$ for the approximations (U_k, V_k) of $(u(x_k, t), v(x_k, t))$ is expressed as

$$F^n[U, V] = \sum\nolimits_t \left(\frac{\varepsilon^2}{4}((\nabla_+ U_k)^2 + (\nabla_- U_k)^2) + \frac{1}{4}((\nabla_+ V_k)^2 + (\nabla_- V_k)^2) \right.$$
$$\left. + \frac{a}{2}U_k^2 + \frac{1}{4}V_k^4 - \frac{b}{2}V_k^2 + \frac{1}{2}U_k^2 V_k^2 \right) \Delta x.$$

Here ∇_+ and ∇_- denote the forward and backward difference in x, respectively:

$$\nabla_+ U_k = \frac{1}{\Delta x}(U_{k+1} - U_k), \quad \nabla_- U_k = \frac{1}{\Delta x}(U_k - U_{k-1}).$$

Furthermore, $\sum_t$ represents the trapezoidal summation formula defined by

$$\sum\nolimits_t U_k^2 = \frac{1}{2}U_0^2 + \sum_{k=1}^{n-1} U_k^2 + \frac{1}{2}U_n^2.$$

Now, for the approximations $(\bar{U}_k, \bar{V}_k)$ of $(u(x_k, t + \Delta t), v(x_k, t + \Delta t))$, we mainly adopt the implicit scheme as follows:

$$\frac{\bar{U}_k - U_k}{\Delta t} = \nabla^2 \left(-\varepsilon^2 \nabla^2 \frac{\bar{U}_k + U_k}{2} + a\frac{\bar{U}_k + U_k}{2} + \frac{\bar{U}_k \bar{V}_k + U_k V_k}{2} \frac{\bar{V}_k + V_k}{2} \right),$$
$$\frac{\bar{V}_k - V_k}{\Delta t} = \nabla^2 \frac{\bar{V}_k + V_k}{2} + b\frac{\bar{V}_k + V_k}{2} - \frac{\bar{U}_k \bar{V}_k + U_k V_k}{2} \frac{\bar{U}_k + U_k}{2} - \frac{\bar{V}_k{}^2 + V_k^2}{2} \frac{\bar{V}_k + V_k}{2},$$

FIG. 5.1. *Convergence to a monotone steady state solution.*

where $\nabla^2 := \nabla_+\nabla_-$ stands for the second-order central difference in x. With this implicit scheme, we deduce that the discretized total concentration is conserved and the discretized free energy is decreasing:

$$\sum\nolimits_t \bar{U}_k = \sum\nolimits_t U_k, \qquad F^n[\bar{U}, \bar{V}] \le F^n[U, V].$$

We supplement our solver, however, by the explicit scheme, since our current problem is in a sense stable by virtue that $a > 0$ and the implicit one is a little complicated to implement.

$$\frac{\bar{U}_k - U_k}{\Delta t} = -\varepsilon^2\nabla^4 U_k + \nabla^2((a + V_k^2)U_k),$$
$$\frac{\bar{V}_k - V_k}{\Delta t} = \nabla^2 V_k + (b - U_k^2 - V_k^2)V_k.$$

In this case, the dissipation of the free energy holds only approximately; nevertheless, it is whole enough for our purposes.

The discretized boundary conditions should be fixed as

$$\begin{aligned}
&U_{-1} = U_1, \quad U_{n-1} = U_{n+1} \quad \text{in place of } u_x = 0 \text{ at } x = 0 \text{ and } l,\\
&V_{-1} = V_1, \quad V_{n-1} = V_{n+1} \quad \text{in place of } v_x = 0 \text{ at } x = 0 \text{ and } l,\\
&U_{-2} = U_2, \quad U_{n-2} = U_{n+2} \quad \text{in place of } u_{xxx} = 0 \text{ at } x = 0 \text{ and } l.
\end{aligned}$$

We focus our interest on the question of whether the variety of steady state solutions exists. In the following, constants are taken to be

$$l = 1, \quad \varepsilon = 1, \quad a = m = \frac{1}{4}.$$

Several steady solutions are illustrated in the following figures.

Figure 5.1 depicts the convergence of a solution (u, v) for (1.1) to a monotone steady state solution. We set $b = 16/25$ and as initial function we employ

$$u_0(x) = m,$$
$$v_0(x) = \sqrt{b - m^2} - \frac{1}{1000}\cos(\pi x).$$

The computation is implemented under the mesh size $\Delta x = 1/64$ and $\Delta t = 1/256$ up to the time interval $0 \le t \le 4096$.

The monotone steady state solution corresponds to the case $k = 1$ in Theorem 1.1. It is numerically unstable with respect to the perturbation on initial data.

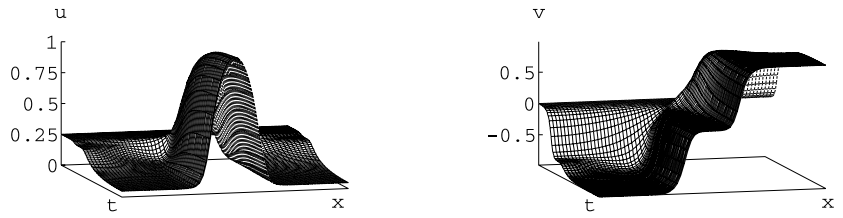

FIG. 5.2. *Convergence to a nonmonotone steady state solution.*

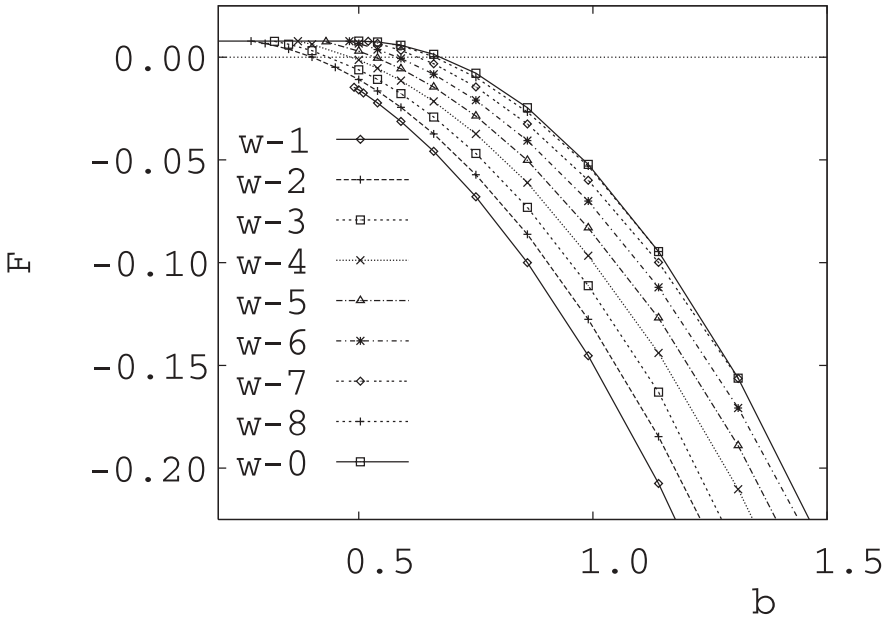

FIG. 5.3. *Energy diagram of steady state solutions.*

Figure 5.2, on the other hand, illustrates the convergence to a nonmonotone steady state solution. We set $b = 0.99$, and as initial functions we take

$$u_0(x) = m,$$
$$v_0(x) = -\frac{1}{1000}\cos(\pi x).$$

The implementation data are the same as those of Figure 5.1, performed during the time interval $0 \le t \le 128$.

The limiting function is related to the case $k = 2$ in Theorem 1.1; however, the function v is monotone increasing in Figure 5.2. This apparent discrepancy is easily reconciled because the sign of v is irrespective to the problem. We hasten to remark that the nonmonotone steady solution, which is constructed in Theorem 1.1 with $k = 2$, also is numerically realized.

Finally, we exhibit the energy diagram of various steady state solutions in Figure 5.3. Here the notation $w{-}i$ $(i = 0, 1, \ldots, 8)$ means the steady state solution to

(1.1), which is akin to the one with $k = i + 1$ described in Theorem 1.1.

It is observed that the energy of the monotone steady state solution dominates others. The detailed investigation, including the problem of the stability, will be deferred to another work.

Acknowledgments. We are grateful to Professor Hiroshi Fujita for his interest in this research. Thanks are also due to anonymous referees for pointing out mistakes in the first version of the manuscript and for valuable comments. In addition, the discussion in the Creation and Sustenance of Diversity workshop held at the International Institute for Advanced Study, Kyoto, was very fruitful.

STABLE STATIONARY PATTERNS AND INTERFACES ARISING IN REACTION-DIFFUSION SYSTEMS*

YOSHIHITO OSHITA†

Abstract. We study reaction-diffusion systems with FitzHugh–Nagumo-type nonlinearity. We consider the rich structures of stable stationary solutions for two different parameter scalings with the corresponding limiting problems. We study the complex phase separation patterns and derive the stationary interface equation for the limiting problems.

Key words. sharp interface, microscopic structure, Young measure

DOI. 10.1137/S0036141002406722

1. Introduction.

In this paper, we study the singular limiting behavior of some stable steady states of a class of reaction-diffusion systems:

$$(E)^{\mu}_{\varepsilon,D} \qquad \begin{cases} u_t = \varepsilon^2 \Delta u + f(u) - \dfrac{\varepsilon}{\mu} v & \text{in } \Omega \times \mathbb{R}^+, \\ \tau v_t = D\Delta v + u - m - \gamma v & \text{in } \Omega \times \mathbb{R}^+, \\ \dfrac{\partial u}{\partial n} = \dfrac{\partial v}{\partial n} = 0 & \text{on } \partial\Omega \times \mathbb{R}^+, \end{cases}$$

where $\Omega \subset \mathbb{R}^N$ $(N \geq 2)$ is a bounded domain with the smooth boundary $\partial\Omega$; $\partial/\partial n$ is the normal derivative on $\partial\Omega$; $\varepsilon, \mu \ll 1$ and $D \gg 1$ are positive parameters; γ and τ are positive constants; $f(u) = -W'(u)$ ($W \in C^2(\mathbb{R})$ is a double-well potential such that $W(\pm 1) = 0$ and $W(s) > 0$ for $s \neq \pm 1$); and m is a constant between two global minima of W, namely,

$$m \in (-1, 1). \tag{A1}$$

The system $(E)^{\mu}_{\varepsilon,D}$ describes, for instance, wave propagation in excitable media such as a Belousov–Zhabotinskii reaction, pattern formation in population genetics, propagation of signals along a nerve axon or cardiac tissue, etc. They are referred to as FitzHugh–Nagumo equations and have been studied extensively. (See, for instance, [3, 4, 5, 10, 15] and the references therein.)

We construct stable stationary solutions of $(E)^{\mu}_{\varepsilon,D}$ and study a behavior of them in two cases:

(i) $\varepsilon \to 0$ for fixed D, μ and

(ii) $\varepsilon \to 0, D \to \infty$ for fixed μ.

Although the Allen–Cahn equation

$$u_t = \Delta u + f(u)$$

with homogeneous Neumann data does not have nonconstant stable stationary solutions, $(E)^{\mu}_{\varepsilon,D}$ provides a rich structure, that is, a formation of nontrivial stationary

patterns. We construct stationary solutions of $(E)^{\mu}_{\varepsilon,D}$ by using variational methods although $(E)^{\mu}_{\varepsilon,D}$ is not a gradient flow associated to some functional. For a proof of stability of such stationary solutions, we can apply the result of [16]. This paper is mostly concerned with variational problems for functionals with parameters ε, D, and μ and asymptotic behavior of minimizers.

Here we compare our case with one in [16]. In [16], it was shown that there are stable stationary solutions (u, v) such that the total variation of u is very large when $\varepsilon \sim \mu \ll 1$ and D is of order 1. On the other hand, we see that in both (i) and (ii), there is a limiting variational problem with a positive parameter μ. Then we study the μ-parametrized limiting functionals in the limit $\mu \to 0$, and we see that, in the case of (i), minimizers of the μ-parametrized limiting functional have the large total variation when μ is small.

Finally we derive the Euler–Lagrange equation of the singular limiting problem and it turns out to be a balance condition on the interface between the local effects of curvature and the effect of the nonlocal term. We will see that, in the case of (ii), the above balance condition on the interface coincides with the result of [5]. (See Remark 2.3 below.)

We make the following conditions on f:

(f1) $f \in C^1(\mathbb{R})$.

(f2) f has just three zeros, $f(\pm 1) = f(a) = 0$, $a \in (-1, 1)$, and satisfies $f'(\pm 1) < 0$, $f'(a) > 0$.

(f3) $\int_{-1}^{1} f(v)\, dv = 0$.

(f4) f has the polynomial growth at infinity, that is, there exist constants $s \in [1, \infty)$ and $c_1, c_2, R > 0$ such that

$$c_1|u|^s \le |f(u)| \le c_2|u|^s \quad \text{for all } |u| \ge R.$$

We use the following notation. $(\cdot, \cdot)$ denotes L^2-inner product, $\langle u \rangle$ is the mean value of $u \in L^1(\Omega)$ on Ω,

$$\int_\Omega |Du| := \sup \left\{ \int_\Omega \sum_{i=1}^{N} u D_i g_i \, dx \,;\, g = (g_1, \dots, g_N) \in C_0^1(\Omega, \mathbb{R}^N), |g| \le 1 \right\}$$

is the total variation of $u \in L^1(\Omega)$, $BV(\Omega)$ is the Banach space of functions $u \in L^1(\Omega)$ with

$$\|u\|_{BV} := \int_\Omega u \, dx + \int_\Omega |Du| < \infty,$$

$|\cdot|$ is the n-dimensional Lebesgue measure, and $P_\Omega(G)$ denotes the perimeter of $G \subset \Omega$ with respect to Ω. Denote by ∂' the relative boundary with respect to Ω.

For an oriented smooth hypersurface, we define the second fundamental form so that the principal curvatures and mean curvature of S^{N-1} are negative if the normal vector orients to the center. In this paper, the mean curvature denotes the sum of all principal curvatures.

2. Main results. The original problem has three independent parameters ε, D, and μ with given constants τ, γ, and m. Theorem 2.1 concerns two scalings for fixed μ, that is, $\varepsilon \to 0$ with fixed D, and $\varepsilon \to 0$, $D \to \infty$. To state the main results, define

$$c_0 := \frac{\sqrt{2}}{\int_{-1}^{1} \sqrt{W(s)}\, ds}.$$

Remark 2.1. The constant c_0 can be characterized as follows when f is smooth. Indeed, it is known that if, in addition, f is smooth, then there exist a constant $\delta > 0$ and smooth functions $U : \mathbb{R} \times (-\delta, \delta) \to \mathbb{R}$, $c : (-\delta, \delta) \to \mathbb{R}$ such that

$$U_{xx}(x,V) + c(V)U_x(x,V) + f(U(x,V)) = V, \quad x \in \mathbb{R}, V \in (-\delta,\delta),$$
$$U(-\infty,V) = h_-(V), \quad U(+\infty,V) = h_+(V), \quad c(0) = 0,$$

where $h_\pm(V)$, $V \in (-\delta,\delta)$ are two solutions of $f(\cdot) = V$ which are smooth in V and satisfy $h_\pm(0) = \pm 1$. This means that for each $V \in (-\delta,\delta)$, $u(x,t) = U(x - c(V)t, V)$ is a traveling wave solution of the equation

$$u_t = u_{xx} + f(u) - V, \quad x \in \mathbb{R}, \ \ t \in \mathbb{R},$$

which converges to $h_\pm(V)$ as $x \to \pm\infty$ ($c = c(V)$ represents the speed of the traveling wave solution). See [2, 5, 8, 9] and references therein. Then it is easy to see that there holds

$$c_0 = \left.\frac{dc}{dV}\right|_{V=0}.$$

Our first result is the following.

THEOREM 2.1. *Assume* (A1) *and* (f1)–(f4). *Then the following hold:*

(i) *Let $D = 1$. Then for any sequence $\varepsilon_n \to 0$, there exists a subsequence $\varepsilon_k = \varepsilon_{n_k} \to 0$ and stable stationary solutions (u_k, v_k) of $(E)^\mu_{\varepsilon_k,D}$ such that u_k converges strongly in $L^1(\Omega)$ to a solution of*

$$(P)^\mu \qquad \begin{cases} \min\limits_{u\in\mathcal{G}} B^\mu(u), \quad B^\mu(u) := \left[\dfrac{2}{c_0}P_\Omega(\{u=1\}) + \dfrac{1}{2\mu}(K(u-m),u-m)\right], \\ \mathcal{G} := \{u \in BV(\Omega)\,;\, |u(x)| = 1 \quad \textit{for almost all } x \in \Omega\}, \end{cases}$$

where

$$K := (-\Delta + \gamma)^{-1} \tag{2.1}$$

is the Green operator with a homogeneous Neumann boundary condition.

(ii) *For any sequence $\varepsilon_n \to 0$, $D_n \to \infty$, there exist subsequences $\varepsilon_k = \varepsilon_{n_k} \to 0$, $D_k = D_{n_k} \to \infty$ such that for each k, $(E)^\mu_{\varepsilon_k,D_k}$ has a stable stationary solution (u_k, v_k) which has the property that u_k converges strongly in $L^1(\Omega)$ to a solution of*

$$(\widetilde{P})^\mu \qquad \min_{u\in\mathcal{G}} \widetilde{B}^\mu(u), \quad \widetilde{B}^\mu(u) := \left[\frac{2}{c_0}P_\Omega(\{u=1\}) + \frac{1}{2\mu\gamma}|\Omega|(\langle u\rangle - m)^2\right],$$

where $\mathcal{G}$ is the same as in $(P)^\mu$.

The method used to prove Theorem 2.1 is based on the Γ-convergence result for a sequence of functionals of Modica–Mortola type. Such a method was first applied to such problems as the van der Waals–Cahn–Hilliard model or the phase transition model in the gradient theory of fluids (see [11]). Note that such problems are gradient flows associated to some functionals, but our problem $(E)^\mu_{\varepsilon,D}$ is not.

$(P)^\mu$ and $(\widetilde{P})^\mu$ are the geometric minimization problems with a parameter dependence, which determine the location of interior boundary layers. (Here we call $\Gamma = \partial'\{u = 1\}$ a sharp interface for $u \in \mathcal{G}$.) We are interested in the following two problems: the asymptotic behavior, as $\mu \to 0$, of solutions of $(P)^\mu$ and $(\widetilde{P})^\mu$,

and finding a geometric interface equation for minimizers. Theorem 2.2 concerns the parameter dependence of solutions of $(P)^\mu$ and $(\widetilde{P})^\mu$. In Theorem 2.3, we derive the geometric interface equation associated with the solutions of $(P)^\mu$ and $(\widetilde{P})^\mu$. Note that we obtain it without the technique of the matched asymptotic expansion.

THEOREM 2.2. (i) *Let u^μ be a solution of $(P)^\mu$. Then for any sequence $\mu_k \to 0$, (u^μ) generates the Young measure $\nu = (\nu_x)_{x\in\Omega}$ such that*

$$\nu_x = \frac{1-m}{2}\delta_{-1} + \frac{1+m}{2}\delta_1 \quad \textit{for almost all } x \in \Omega.$$

Furthermore, there holds

$$C_1\mu^{-1/3} \le P_\Omega(\{u^\mu = 1\}) \le C_2\mu^{-1/3}, \quad \mu \in (0,1), \tag{2.2}$$

where C_1, C_2 are positive constants (independent of μ).

(ii) *Let $\widetilde{u}^\mu$ be a solution of $(\widetilde{P})^\mu$. There holds*

$$P_\Omega(\{\widetilde{u}^\mu = 1\}) \le C_3, \quad \mu \in (0,1),$$

for a positive constant C_3 (independent of μ). Furthermore, for any sequence $\mu_n \to 0$, there exists a subsequence $\mu_k \to 0$ that has the following properties:

(1) *there exists a positive constant C_4 such that*

$$\frac{1}{\mu_k}(\langle \widetilde{u}^{\mu_k}\rangle - m)^2 \le \frac{C_4}{|\log \mu_k|}, \quad k = 1, 2, \dots,$$

(2) *$\widetilde{u}^{\mu_k}$ converges strongly in $L^1(\Omega)$ to a solution u^* of*

$$\begin{cases} \min\limits_{u\in\mathcal{M}} P_\Omega(\{u=1\}), \\ \mathcal{M} := \left\{ u \in \mathcal{G}\,;\, \displaystyle\int_\Omega u\,dx = m|\Omega| \right\}. \end{cases}$$

In particular, $(\widetilde{u}^{\mu_k})$ generates the Young measure $\nu_x = \delta_{u^*(x)}$ for almost every $x \in \Omega$.

Remark 2.2. From Theorem 2.2, the solutions (u_k, v_k) in Theorem 2.1 are not spatially constant for large k.

We see that a phase separation with fine structures occurs in the scaling (i) of Theorem 2.2, in the sense that we may construct a sequence of solutions that converges to a pattern with an arbitrarily large perimeter if we choose sufficiently small μ. For variational problems with two scales, see, for example, [1, 7, 13].

THEOREM 2.3. (i) *For fixed $\mu > 0$, let u be a solution of $(P)^\mu$ and $\Gamma = \partial'\{u = 1\}$. Assume that Γ is smooth in a neighborhood U of $x_0 \in \Gamma$. Then there holds*

$$\mu H = c_0 v \quad \textit{on } \Gamma \cap U,$$

where H is the mean curvature of Γ (when the normal vector points from $\{u = -1\}$ to $\{u = +1\}$) and v is the solution of

$$\begin{cases} (-\Delta + \gamma)v = u - m & \textit{in } \Omega, \\ \dfrac{\partial v}{\partial n} = 0 & \textit{on } \partial\Omega. \end{cases}$$

(ii) *For fixed $\mu > 0$, let $\widetilde{u}$ be a solution of $(\widetilde{P})^\mu$ and $\widetilde{\Gamma} = \partial'\{\widetilde{u} = 1\}$. Assume that $\widetilde{\Gamma}$ is smooth in a neighborhood U of $x_0 \in \widetilde{\Gamma}$. Then there holds*

$$\mu H = \frac{c_0}{\gamma}(\langle \widetilde{u} \rangle - m) \quad \text{on } \widetilde{\Gamma} \cap U,$$

where H is the mean curvature of $\widetilde{\Gamma}$.

Remark 2.3. Theorem 2.3(ii) implies that solutions of $(\widetilde{P})^\mu$ typically involve a partition of Ω into regions separated by surfaces of a constant mean curvature. In [5], the authors obtained a limiting free boundary problem from an Allen–Cahn equation with a nonlocal term, which arises as a limit of a reaction-diffusion system. Then we see that any smooth surface that corresponds to a stationary solution of the motion law obtained in [5] has also a constant mean curvature.

Hereafter, for the sake of notational simplicity, we will use the same letters C to denote some positive constants whose values may vary from line to line. This notational convention does not apply to such letters as $C_1, C_2, C_3, \ldots$.

3. Proof of Theorem 2.1. In this section, we prove Theorem 2.1. For simplicity, we show the claim when

$$m = 0$$

is satisfied since we can prove in other cases by the same manner. Denote by $(-D\Delta + \gamma)^{-1}$ the Green operator of $-D\Delta + \gamma$ with the homogeneous Neumann boundary condition. Define a functional

$$I^\mu_{\varepsilon,D}(u) := \int_\Omega \left\{ \frac{\varepsilon^2}{2}|\nabla u|^2 + W(u) \right\} dx + \frac{\varepsilon}{2\mu}((-D\Delta + \gamma)^{-1}u, u)$$

for $u \in H^1(\Omega)$. Let $u_{\varepsilon,D} \in H^1(\Omega)$ be a critical point of $I^\mu_{\varepsilon,D}$ and let $v_{\varepsilon,D} := (-D\Delta + \gamma)^{-1}u_{\varepsilon,D}$. Then $u_{\varepsilon,D}$ satisfies the Euler–Lagrange equation

$$\varepsilon^2 \Delta u_{\varepsilon,D} + f(u_{\varepsilon,D}) - \frac{\varepsilon}{\mu}(-D\Delta + \gamma)^{-1}u_{\varepsilon,D} = 0,$$

which means that $(u_{\varepsilon,D}, v_{\varepsilon,D})$ is a stationary solution of $(E)^\mu_{\varepsilon,D}$. Moreover, by the result of section 3 in [16], $(u_{\varepsilon,D}, v_{\varepsilon,D})$ is stable for all ε if $\tau = 0$ and for $\varepsilon < \tau^{-1}\mu\gamma^2$ if $\tau > 0$. (The condition $\tau \cdot \frac{\varepsilon}{\mu} < \gamma^2$ is sufficient for stability but need not be necessary.) Consider the minimization problem

$$(P)^\mu_{\varepsilon,D} \qquad \min_{u \in H^1(\Omega)} I^\mu_{\varepsilon,D}(u).$$

Noting that the H^1-norm is weakly lower semicontinuous, $(-D\Delta + \gamma)^{-1}$ is compact and continuous on $L^2(\Omega)$, and $I^\mu_{\varepsilon,D}$ is coercive, the problem $(P)^\mu_{\varepsilon,D}$ has a solution $u_{\varepsilon,D}$. To establish Theorem 2.1, it remains to show the behavior of $u_{\varepsilon,D}$ in the limit as $\varepsilon \to 0$ or $\varepsilon \to 0$ and $D \to \infty$.

Define a functional $a^\mu_{\varepsilon,D} : L^1(\Omega) \to [0, \infty]$ for $\varepsilon, \mu, D > 0$ as follows:

$$a^\mu_{\varepsilon,D}(u) := \begin{cases} \varepsilon^{-1} I^\mu_{\varepsilon,D}(u) & \text{for } u \in H^1(\Omega), \\ \infty & \text{otherwise.} \end{cases}$$

We obtain the following lemma.

LEMMA 3.1. *Let $D = 1$. Then*

(1) *for any $\varepsilon_k \to 0$, and $u_k \to u$ weakly in $L^2(\Omega)$ and strongly in $L^1(\Omega)$, there holds*

$$\liminf_{k\to\infty} a^{\mu}_{\varepsilon_k, D}(u_k) \geq b^{\mu}(u);$$

(2) *for any $u \in L^2(\Omega)$, there exist sequences $\varepsilon_k \to 0$ and $u_k \to u$ weakly in $L^2(\Omega)$ and strongly in $L^1(\Omega)$ such that*

$$b^{\mu}(u) \geq \limsup_{k\to\infty} a^{\mu}_{\varepsilon_k, D}(u_k),$$

where

$$b^{\mu}(u) := \begin{cases} B^{\mu}(u) = 2(c_0)^{-1} P_{\Omega}(\{u = 1\}) + (2\mu)^{-1}(Ku, u) & \text{for } u \in \mathcal{G}, \\ \infty & \text{for } u \in L^1(\Omega)\backslash\mathcal{G}. \end{cases}$$

(The definitions of B^{μ} and $\mathcal{G}$ are in Theorem 2.1(i)*, and K is defined in* (2.1)*.)*

LEMMA 3.2. *The following two properties hold:*

(1) *For any $\varepsilon_k \to 0$, $D_k \to \infty$, and $u_k \to u$ weakly in $L^2(\Omega)$ and strongly in $L^1(\Omega)$, there holds*

$$\liminf_{k\to\infty} a^{\mu}_{\varepsilon_k, D_k}(u_k) \geq \widetilde{b}^{\mu}(u);$$

(2) *for any $u \in L^2(\Omega)$, there exist sequences $\varepsilon_k \to 0$, $D_k \to \infty$, and $u_k \to u$ weakly in $L^2(\Omega)$ and strongly in $L^1(\Omega)$ such that*

$$\widetilde{b}^{\mu}(u) \geq \limsup_{k\to\infty} a^{\mu}_{\varepsilon_k, D_k}(u_k),$$

where

$$\widetilde{b}^{\mu}(u) := \begin{cases} \widetilde{B}^{\mu}(u) = 2(c_0)^{-1} P_{\Omega}(\{u = 1\}) + |\Omega|(2\mu\gamma)^{-1}\langle u\rangle^2 & \text{for } u \in \mathcal{G}, \\ \infty & \text{for } u \in L^1(\Omega)\backslash\mathcal{G}. \end{cases}$$

($\widetilde{B}^{\mu}$ is defined in Theorem 2.1(ii)*.)*

Proof of Lemmas. First recall Modica–Mortola theorem, namely, a sequence $(E^{\varepsilon})_{0<\varepsilon\leq 1}$ of functionals on $L^1(\Omega)$ such that

$$E^{\varepsilon}(u) := \begin{cases} \displaystyle\int_{\Omega} \left(\frac{\varepsilon}{2}|\nabla u|^2 + \frac{1}{\varepsilon} W(u) \right) dx & \text{for } u \in H^1(\Omega), \\ \infty & \text{for } u \in L^1(\Omega)\backslash H^1(\Omega). \end{cases} \tag{3.1}$$

Γ converges to

$$E(u) := \begin{cases} 2(c_0)^{-1} P_{\Omega}(\{u = 1\}) & \text{for } u \in \mathcal{G}, \\ \infty & \text{for } u \in L^1(\Omega)\backslash\mathcal{G}\ . \end{cases}$$

That is,

(i) for any $\varepsilon_k \to 0$, and $u_k \to u$ strongly in $L^1(\Omega)$, there holds

$$\liminf_{k\to\infty} E^{\varepsilon_k}(u_k) \geq E(u);$$

(ii) for any $u \in L^1(\Omega)$, there exist sequences $\varepsilon_k \to 0$ and $u_k \to u$ strongly in $L^1(\Omega)$ such that

$$E(u) \geq \limsup_{k\to\infty} E^{\varepsilon_k}(u_k).$$

Note that in (ii), for $u \in \mathcal{G}$, we may choose u_k such that $\|u_k\|_{L^\infty(\Omega)} = 1$. (For example, see [17].) Hence we may assume that $u_k \rightharpoonup u$ weakly in $L^2(\Omega)$.

Noting that if $u_k \rightharpoonup u$ weakly in $L^2(\Omega)$, then

$$(Ku_k, u_k) \to (Ku, u) \quad \text{as } k \to \infty.$$

Lemma 3.1 follows.

To verify Lemma 3.2, it suffices to see that for any sequences $\varepsilon_k \to 0$, $D_k \to \infty$, and $u_k \to u$ weakly in $L^2(\Omega)$ and strongly in $L^1(\Omega)$, there holds

$$(T_k u_k, u_k) \to \frac{|\Omega|\langle u\rangle^2}{\gamma} \quad \text{as } k \to \infty, \tag{3.2}$$

where T_k is the Green operator of $-D_k\Delta + \gamma$ with homogeneous Neumann boundary data. Indeed, we may consider only the case $u_k \in H^1(\Omega)$ since other cases are trivial. In the case $u \notin \mathcal{G}$, by the above Γ-convergence result,

$$\liminf_{k\to\infty} a^\mu_{\varepsilon,D}(u_k) = \infty;$$

hence the assertion follows by the penalty term. Thus we may assume that $u \in \mathcal{G} \subset L^2(\Omega)$.

To see the above property (3.2), denote $0 = \lambda_1 < \lambda_2 \leq \cdots \leq \lambda_i \leq \cdots \to \infty$ the eigenvalues of $-\Delta$ on Ω with homogeneous Neumann boundary condition and let $(\phi_i)_{i=1}^\infty$ be the corresponding eigenfunctions with $\|\phi_i\|_{L^2(\Omega)} = 1$. We may assume that $D_k \geq 1$ for all $k \geq 1$. Expanding u_k and u in terms of (ϕ_i), we have

$$u_k = \sum_{i=1}^\infty a_i^{(k)}\phi_i, \quad u = \sum_{i=1}^\infty a_i\phi_i,$$

where $a_i^{(k)} = (u_k, \phi_i)$ and $a_i = (u, \phi_i)$. Note that

$$a_1 = |\Omega|^{-\frac{1}{2}} \int_\Omega u\, dx$$

and

$$(T_k u_k, u_k) = \frac{(a_1^{(k)})^2}{\gamma} + \sum_{i\geq 2} \frac{(a_i^{(k)})^2}{D_k\lambda_i + \gamma}.$$

Here we estimate

$$\begin{aligned} 0 \leq \sum_{i\geq 2} \frac{(a_i^{(k)})^2}{D_k\lambda_i + \gamma} &\leq 2\sum_{i\geq 2} \frac{(a_i^{(k)} - a_i)^2}{\lambda_i + \gamma} + 2\sum_{i\geq 2} \frac{(a_i)^2}{D_k\lambda_i + \gamma} \\ &= 2\left(K\left(\sum_{i\geq 2} a_i^{(k)}\phi_i - \sum_{i\geq 2} a_i\phi_i\right), \sum_{i\geq 2} a_i^{(k)}\phi_i - \sum_{i\geq 2} a_i\phi_i\right) \\ &\quad + 2\sum_{i\geq 2} \frac{(a_i)^2}{D_k\lambda_i + \gamma}. \end{aligned} \tag{3.3}$$

Since

$$\sum_{i\geq 2} a_i^{(k)}\phi_i \rightharpoonup \sum_{i\geq 2} a_i\phi_i, \quad k\to\infty,$$

weakly in $L^2(\Omega)$, the first term of the right-hand side of (3.3) goes to 0 as $k\to\infty$. Moreover, since

$$\frac{(a_i)^2}{D_k\lambda_i+\gamma} \leq \frac{(a_i)^2}{\lambda_i+\gamma}, \quad \sum_{i\geq 2}\frac{(a_i)^2}{\lambda_i+\gamma} < \infty,$$

the second term of the right-hand side of (3.3) also goes to 0 as $k\to\infty$ by the Lebesgue dominated convergence theorem. Hence

$$\lim_{k\to\infty}\sum_{i\geq 2}\frac{(a_i^{(k)})^2}{D_k\lambda_i+\gamma} = 0.$$

Noting that $a_1^{(k)}\to a_1$ as $k\to\infty$, we have

$$\lim_{k\to\infty}(T_k u_k, u_k) = \frac{(a_1)^2}{\gamma} = \frac{|\Omega|\langle u\rangle^2}{\gamma},$$

as desired. The proof is complete. □

To show Theorem 2.1(i), it is sufficient to see that for any sequence $\varepsilon_n\to 0$, there exists a subsequence $\varepsilon_k\to 0$ such that $u_{\varepsilon_k,D}\to u^*$ weakly in $L^2(\Omega)$ and strongly in $L^1(\Omega)$. Indeed, by Lemma 3.1(1), there holds

$$b^\mu(u^*) \leq \liminf_{k\to\infty} a^\mu_{\varepsilon_k,D}(u_{\varepsilon_k,D}).$$

On the other hand, by Lemma 3.1(2), for any $u\in\mathcal{G}$, there exists a sequence u_k such that

$$\limsup_{k\to\infty} a^\mu_{\varepsilon_k,D}(u_k) \leq b^\mu(u).$$

Hence we have $b^\mu(u^*)\leq b^\mu(u)$, which means that u^* is a solution of $(P)^\mu$.

It remains to see the existence of a subsequence ε_k such that $u_{\varepsilon_k,D}$ converges to some u^* weakly in $L^2(\Omega)$ and strongly in $L^1(\Omega)$. Note that there holds by the assumption (f4), for some positive constants C_5, C_6,

$$\begin{aligned}\int_\Omega |u|^{s+1}\,dx &\leq \int_\Omega (C_5 + C_6 W(u))\,dx\\ &\leq C_5|\Omega| + C_6\varepsilon E^\varepsilon(u),\end{aligned}$$

where E^ε is defined in (3.1). Furthermore, by constructing a comparison function, it is easy to see that for some constant $C>0$, independent of $\varepsilon\in(0,1]$ and $D\geq 1$,

$$E^\varepsilon(u_{\varepsilon,D}) \leq a^\mu_{\varepsilon,D}(u_{\varepsilon,D}) = \frac{1}{\varepsilon} I^\mu_{\varepsilon,D}(u_{\varepsilon,D}) \leq C.$$

Hence it follows that $(u_{\varepsilon,D})_{0<\varepsilon\leq 1}$ is bounded in $L^2(\Omega)$ and that by the Modica–Mortola theorem, $(u_{\varepsilon,D})_{0<\varepsilon\leq 1}$ is relatively compact in $L^1(\Omega)$. Thus the claim follows. The proof of Theorem 2.1(i) is complete.

Similarly, we establish Theorem 2.1(ii) by using Lemma 3.2. □

4. Asymptotic behavior of solutions. In this section, we prove Theorem 2.2.

Proof of Theorem 2.2(i). For simplicity, we show the claim when there hold

$$\frac{c_0}{4} = 1 \text{ and } \gamma = 1,$$

since we can prove other cases by the same manner. We will show that our solution u^μ oscillates rapidly with the average wave length of order $\mu^{\frac{1}{3}}$ when μ goes to zero.

First we give an upper bound for the minimal energy. Define the function oscillating in a one-dimensional direction as follows. Let r be the solution of

$$\begin{array}{ll} -r''(s) = q(s) - m & \text{for } 0 < s < 1, \\ r(s+1) = r(s), r'(s+1) = r'(s) & \text{for all } s \in \mathbb{R}, \end{array}$$

where

$$q(s) := \begin{cases} +1, & s < [s] + \frac{1+m}{2}, \\ -1, & [s] + \frac{1+m}{2} \le s. \end{cases}$$

Letting $Q_\mu(x) := q(x_1/\mu^{\frac{1}{3}})$ and $R_\mu(x) := r(x_1/\mu^{\frac{1}{3}})$, there holds

$$-\Delta(\mu^{\frac{2}{3}} R_\mu) = Q_\mu - m.$$

Let $W_\mu := K(Q_\mu - m)$, that is, W_μ is the solution of

$$\begin{cases} -\Delta W_\mu + W_\mu = Q_\mu - m & \text{in } \Omega, \\ \dfrac{\partial W_\mu}{\partial n} = 0 & \text{on } \partial\Omega. \end{cases}$$

Then there holds $W_\mu = \mu^{\frac{2}{3}} R_\mu - X_\mu - Y_\mu$, where X_μ, Y_μ are the solutions of

$$\begin{cases} -\Delta X_\mu + X_\mu = 0 & \text{in } \Omega, \\ \dfrac{\partial X_\mu}{\partial n} = \dfrac{\partial}{\partial n}(\mu^{\frac{2}{3}} R_\mu) & \text{on } \partial\Omega, \end{cases}$$

and

$$\begin{cases} -\Delta Y_\mu + Y_\mu = \mu^{\frac{2}{3}} R_\mu & \text{in } \Omega, \\ \dfrac{\partial Y_\mu}{\partial n} = 0 & \text{on } \partial\Omega, \end{cases}$$

respectively. Since $P_\Omega(\{Q_\mu = 1\}) = O(\mu^{-\frac{1}{3}})$ and $\|W_\mu\|_{L^2(\Omega)} = O(\mu^{\frac{2}{3}})$ as $\mu \to 0$, one obtains the upper bound for $(P)^\mu$, that is, $B^\mu(u^\mu) \le C\mu^{-\frac{1}{3}}$, in particular,

$$(K(u^\mu - m), u^\mu - m) \le C\mu^{\frac{2}{3}}, \quad P_\Omega(\{u^\mu = 1\}) \le C\mu^{-\frac{1}{3}}. \tag{4.1}$$

To see a Young measure associated with u^μ, choose any sequence $\mu_l \to 0$. Then by the fundamental existence theorem, for a subsequence μ_k, we may assume that (u^{μ_k}) generates a Young measure $\nu = (\nu_x)_{x\in\Omega}$. Since $u^{\mu_k}(x) = 1$ or $u^{\mu_k}(x) = -1$ for almost all $x \in \Omega$, there exists a measurable function $\varphi : \Omega \to [0,1]$ such that $\nu_x = (1 - \varphi(x))\delta_{-1} + \varphi(x)\delta_1$ for almost every $x \in \Omega$. Then since

$$\int_{-\infty}^{\infty} \lambda \, d\nu_x(\lambda) = 2\varphi(x) - 1,$$

we have $u^{\mu_k} \rightharpoonup 2\varphi - 1$ weakly in $L^2(\Omega)$. Thus as $k \to \infty$,

$$(K(u^{\mu_k} - m), u^{\mu_k} - m) \to (K(2\varphi - 1 - m), 2\varphi - 1 - m) = 0$$

by (4.1). Therefore $\varphi(x) \equiv \frac{1+m}{2}$ for almost all $x \in \Omega$.

It remains to see the lower bound in (2.2). The key estimate to see this is the following interpolation inequality.

LEMMA 4.1. *There exist positive constants β_1 and δ_1 such that for all $0 < \delta \le \delta_1$ and $u \in \mathcal{G}$,*

$$\beta_1 \le \delta P_\Omega(\{u = 1\}) + \delta^{-2}(K(u - m), u - m). \tag{4.2}$$

This is obtained by standard arguments used in [6]. (A similar inequality was also proved in [12].) For the one-dimensional case, see [14]. Then we have the following.

COROLLARY 4.2. (1)

$$\min_{u \in \mathcal{G}} B^\mu(u) \ge \frac{1}{2}\beta_1 \mu^{-\frac{1}{3}}.$$

(2) *For any $u \in \mathcal{G}$ such that*

$$(K(u - m), u - m) \le \left(\frac{\delta_1}{2}\right)^2,$$

there holds

$$[P_\Omega(\{u = 1\})]^2 \cdot (K(u - m), u - m) \ge \frac{9}{64}. \tag{4.3}$$

By (4.3) and the upper bound (4.1), we obtain the estimates with a uniform constant $C > 0$,

$$(K(u^\mu - m), u^\mu - m) \ge C\mu^{\frac{2}{3}},$$
$$P_\Omega(\{u^\mu = 1\}) \ge C\mu^{-\frac{1}{3}}$$

for all $\mu \in (0, 1)$. The proof is complete. □

Proof of Theorem 2.2(ii). Here, for simplicity, we show the claim when there hold

$$\frac{c_0}{4\gamma}|\Omega| = 1 \text{ and } m = 0,$$

since we can prove other cases by the same manner. Let $\widetilde{p}^\mu := \dfrac{c_0}{2}\widetilde{B}^\mu(\widetilde{u}^\mu)$. Choose $u_0 \in L^1(\Omega)$ such that $\langle u_0 \rangle = 0$ and $W(u_0) = 0$ (i.e., $u_0(x) = -1$ or $u_0(x) = +1$) for almost all $x \in \Omega$. Then

$$\widetilde{p}^\mu \le P_\Omega(\{u_0 = 1\}) = C,$$

where C is a constant independent of μ. Moreover, by the definition of $\widetilde{p}^\mu$, the function $\mu \mapsto \widetilde{p}^\mu$ is nonincreasing and hence differentiable at almost every number $\mu \in (0, 1)$. We will find the sequence $\mu_k \to 0$ satisfying the conditions (1) and (2) in Theorem 2.2(ii). For $0 < \mu_1 < \mu_0$,

$$\begin{aligned} C \ge \widetilde{p}^{\mu_1} - \widetilde{p}^{\mu_0} &\ge \int_{\mu_1}^{\mu_0} \left| \frac{d}{d\mu}\widetilde{p}^\mu \right| d\mu \\ &\ge \operatorname*{ess\,inf}_{\mu_1 < \mu < \mu_0} \mu \left| \frac{d}{d\mu}\widetilde{p}^\mu \right| \left| \log \frac{\mu_1}{\mu_0} \right|. \end{aligned} \tag{4.4}$$

Thus we infer that

$$\mu_k \left| \frac{d}{d\mu} \widetilde{p}^{\mu} \right| \le \frac{C}{|\log \mu_k|}$$

for a suitable sequence $\mu_k \to 0$. Hence, noting Lemma 7.2 in [18], there holds

$$\mu_k^{-1} \langle \widetilde{u}^{\mu_k} \rangle^2 = \mu_k \left| \frac{\partial \widetilde{B}^{\mu}}{\partial \mu}(\widetilde{u}^{\mu_k}) \right| \le \mu_k \left| \frac{d}{d\mu} \widetilde{p}^{\mu} \right| \le \frac{C}{|\log \mu_k|}. \tag{4.5}$$

We may assume that $\widetilde{u}^{\mu_k} \to u^*$ strongly in $L^1(\Omega)$. (Note that $\widetilde{u}^{\mu_k}$ is bounded in $BV(\Omega)$ and the compactness of the embedding $BV(\Omega) \hookrightarrow L^1(\Omega)$.) Then $W(u^*(x)) = 0$ almost every $x \in \Omega$. Furthermore, by (4.5), we have

$$\langle u^* \rangle = \frac{1}{|\Omega|} \lim_{k \to \infty} \int_{\Omega} \widetilde{u}^{\mu_k} \, dx = 0,$$

that is, $u_0 \in \mathcal{M}$. It remains to show that the minimality of $P_{\Omega}(\{u = 1\})$ in $\mathcal{M}$. For any $u \in \mathcal{M}$, by the definition of $\widetilde{u}^{\mu_k}$,

$$P_{\Omega}(\{\widetilde{u}^{\mu_k} = 1\}) + \frac{1}{\mu_k} \langle \widetilde{u}^{\mu_k} \rangle^2 \le P_{\Omega}(\{u = 1\}).$$

Taking the limit $k \to \infty$, we obtain by the weak lower semicontinuity of the total variation in L^1 topology,

$$P_{\Omega}(\{u^* = 1\}) \le \liminf_{k \to \infty} P_{\Omega}(\{\widetilde{u}^{\mu_k} = 1\}) \le P_{\Omega}(\{u = 1\}).$$

The proof is complete. □

5. Stationary sharp interfaces. In this section, we prove Theorem 2.3. First we give some notation and preliminaries. Let

$$F : B \to \mathbb{R}^N, \quad B := \{z \in \mathbb{R}^{N-1}; \, |z| < 1\},$$

be a parametrized (smooth) hypersurface and let $\Gamma := \{F(z); \, z \in B\} \subset \mathbb{R}^N$ be the corresponding hypersurface. We identify functions on Γ with functions on B. For a given surface F, we use the following notation. Let (g_{ij}) represent the first fundamental form, and let $g^{ij} = (g_{ij})^{-1}$ be the coefficients of the inverse of the matrix (g_{ij}). Let

$$ds := \sqrt{|g|} \, dz,$$

where $|g| = \det(g_{ij})$.

Let $\mathbf{n} = \mathbf{n}(z)$ be the normal vector and let (ℓ_{ij}) represent the second fundamental form. Let $H := \kappa_1 + \cdots + \kappa_{N-1}$ be the mean curvature, where $\kappa_1, \ldots, \kappa_{N-1}$ are the principal curvatures.

Given a parametrized surface F, let $\overline{\alpha}$ be a "variation" of F with "velocity" $\Phi \cdot \mathbf{n}$, namely, $\overline{\alpha}(\eta)$ is a parametrized surface for each $\eta \in (-\delta, \delta)$, $\delta > 0$, such that

$$\overline{\alpha}(\eta)(z) = \alpha(\eta, z) := F(z) + \eta \Phi(z) \mathbf{n}(z), \quad (\eta, z) \in (-\delta, \delta) \times B,$$

for a given scalar function $\Phi : B \to \mathbb{R}$. Let

$$A(F) := \int_{\Gamma} ds = \int_{B} \sqrt{|g|} \, dz$$

be the area of F.

The first variation of the area is given by the following standard lemma. (We omit the proof.)

LEMMA 5.1.

$$\left.\frac{dA(\overline{\alpha}(\eta))}{d\eta}\right|_{\eta=0} = \int_\Gamma \Phi H\, ds.$$

Proof of Theorem 2.3(i). Here, for simplicity, we show the claim when $\frac{c_0}{2\mu} = 1$ is satisfied since we can prove in other cases by the same manner. For $u \in \mathcal{G}$ and a function $v \in H^1(\Omega)$, let

$$e(u,v) := P_\Omega(\{u=1\}) - \int_\Omega \left[\frac{1}{2}(|\nabla v|^2 + \gamma v^2) - (u-m)v\right] dx.$$

Remark 5.1. For any $u \in \mathcal{G}$, there holds

$$\begin{aligned}\frac{c_0}{2}B^\mu(u) &= P_\Omega(\{u=1\}) + \frac{1}{2}(K(u-m), u-m)\\ &= \max_{v\in H^1(\Omega)} e(u,v),\end{aligned}$$

where the maximum in the right-hand side is attained at v if and only if $v = K(u-m)$. Let $\overline{\beta} = \overline{\beta}(\eta)$ be a smooth path in $\mathcal{G}$ such that

$$\overline{\beta}(0) = u.$$

We call $\overline{\beta}$ a variation of u. We identify the velocity vector

$$\left.\frac{d}{d\eta}\overline{\beta}\right|_{\eta=0}$$

with a section $\Phi\mathbf{n} = \Phi(s)\mathbf{n}(s)$, $s \in \Gamma$ of the normal bundle of Γ. Given a smooth function $v, \Psi : \Omega \to \mathbb{R}$, choose a smooth map $\varrho : V \times \Omega \to \mathbb{R}$ such that

$$\varrho(0,x) = v(x), \quad \frac{\partial\varrho}{\partial\eta}(0,x) = \Psi(x).$$

We call $\overline{\varrho}(\eta) := \varrho(\eta,\cdot)$ a variation of v with velocity Ψ.

Claim 1.

$$\left.\frac{d}{d\eta}e(\overline{\beta}(\eta),\overline{\varrho}(\eta))\right|_{\eta=0} = \int_\Gamma (H-2v)\Phi\, ds + \int_\Omega [-\nabla v\cdot\nabla\Psi - \gamma\Psi + (u-m)\Psi]\, dx.$$

Proof. We calculate the first variation of e, that is,

$$\left.\frac{d}{d\eta}e(\overline{\beta}(\eta),\overline{\varrho}(\eta))\right|_{\eta=0} = \left.\frac{d}{d\eta}e(\overline{\beta}(\eta),v)\right|_{\eta=0} + \left.\frac{d}{d\eta}e(u,\overline{\varrho}(\eta))\right|_{\eta=0}. \tag{5.1}$$

By Lemma 5.1,

$$\left.\frac{d}{d\eta}P_\Omega(\overline{\beta}(\eta)=1)\right|_{\eta=0} = \int_\Gamma H\Phi\, ds.$$

Similarly,

$$\begin{aligned}\left.\frac{d}{d\eta}\int_\Omega \overline{\beta}(\eta)v\, dx\right|_{\eta=0} &= -2\int_\Gamma v\Phi\, ds,\\ \left.\frac{d}{d\eta}e(u,\overline{\varrho}(\eta))\right|_{\eta=0} &= \int_\Omega [-\nabla v\cdot\nabla\Psi - \gamma\Psi + (u-m)\Psi]\, dx.\end{aligned}$$

Hence by (5.1), the claim follows. ∎

If u is a solution of $(P)^\mu$, for any variation $\overline{\beta}(\eta), \overline{\varrho}(\eta)$, the quantity

$$\frac{d}{d\eta} e(\overline{\beta}(\eta), \overline{\varrho}(\eta))\Big|_{\eta=0}$$

must vanish; hence there holds

$$H - 2v = 0$$

on Γ. The proof is complete. □

Proof of Theorem 2.3(ii). For simplicity, we show the claim when there hold

$$\frac{c_0}{2\mu\gamma} = 1 \text{ and } m = 0,$$

since we can prove in other cases by the same manner. Then

$$\frac{c_0}{2}\widetilde{B}^\mu(u) = P_\Omega(\{u = 1\}) + \frac{1}{2|\Omega|}\left(\int_\Omega u\,dx\right)^2.$$

On the other hand,

$$\frac{d}{d\eta}\left(\int_\Omega \overline{\beta}(\eta)\,dx\right)^2\Big|_{\eta=0} = -2\int_\Omega u\,dx \int_\Gamma 2\Phi\,ds.$$

Hence if u is a solution of $(\widetilde{P})^\mu$, then by Lemma 5.1, there holds $H - 2\langle u\rangle = 0$ on Γ. The proof is complete. □

6. Remarks on the sharp interface problems. In this section, we give some remarks about the problems $(P)^\mu$ and $(\widetilde{P})^\mu$. Throughout this section, we set for simplicity

$$c_0 := 2,\ \gamma := \frac{1}{2},\ |\Omega| := 1.$$

We study the lower bound in Theorem 2.2(i). Define

$$\alpha := \inf\left\{\liminf_{k\to\infty} \mu_k^{\frac{1}{3}} B^{\mu_k}(u^{\mu_k})\,;\ \mu_k \to 0\right\} > 0.$$

Here α depends only on N, Ω, and m. By an argument similar to the one used in section 4, we have

$$\beta := \inf\left\{\liminf_{k\to\infty}\left[\mu_k^{-\frac{2}{3}}(\langle u_k\rangle - m)^2 + S(u_k)\right]\ ;\ \mu_k \to 0, u_k \in \mathcal{G}\right\} > 0,$$

where

$$S(u) := \frac{3}{2}[P_\Omega(\{u = 1\})]^{\frac{2}{3}} \cdot [(K(u - \langle u\rangle), u - \langle u\rangle)]^{\frac{1}{3}}.$$

Proposition 6.1. *There holds*

$$\alpha \geq \beta.$$

Proof. Let $\mu_k \to 0$ and $u^{\mu_k} \in \mathcal{G}$ be sequences such that

$$\lim_{k\to\infty} \mu_k^{\frac{1}{3}} B^{\mu_k}(u^{\mu_k}) = \alpha.$$

Then

$$\liminf_{k\to\infty}\left\{\mu_k^{-\frac{2}{3}}(\langle u^{\mu_k}\rangle - m)^2 + S(u^{\mu_k})\right\} \leq \alpha.$$

Hence $\beta \leq \alpha$. □

Next we give an upper bound for α using the functional defined as follows:

$$S^*(u) := \frac{3}{2}[P_\Omega(\{u=1\})]^{\frac{2}{3}} \cdot [((-\Delta)^{-1}(u-m), u-m)]^{\frac{1}{3}}$$

for $u \in \mathcal{M}$. Here, $(-\Delta)^{-1}$ denotes the Green operator of $-\Delta$ acting on $\{u \in L^2(\Omega)\,;\, \int_\Omega u\,dx = 0\}$ with homogeneous Neumann data.

As in the proof of Theorem 2.2 and Proposition 6.1, we obtain

$$\begin{aligned}\alpha^* := \inf \Bigg\{ &\liminf_{k\to\infty} \left[\mu_k^{\frac{1}{3}} P_\Omega(\{u_k=1\}) + \frac{1}{2}\mu_k^{-\frac{2}{3}}((-\Delta)^{-1}(u_k-m), u_k-m)\right]; \\ &\mu_k \to 0 \text{ and } u_k \in \mathcal{M}\Bigg\} \\ \geq \beta^* > 0,\end{aligned}$$

where

$$\beta^* := \inf_{u\in\mathcal{M}} S^*(u).$$

Remark 6.1. If

$$\alpha^* > \beta^*, \tag{6.1}$$

then β^* is attained at some $u^* \in \mathcal{M}$, that is, $S^*(u^*) = \beta^*$. Moreover, the condition (6.1) is necessary and sufficient for the BV-boundedness of all minimizing sequences for S^* in $\mathcal{M}$.

Proof. To see that (6.1) is necessary, let u_μ^* be a solution of

$$\min_{u\in\mathcal{M}} \left\{ P_\Omega(\{u=1\}) + \frac{1}{2\mu}((-\Delta)^{-1}(u-m), u-m)\right\}.$$

Choose a sequence $\mu_k \to 0$ such that

$$\alpha^* = \lim_{k\to\infty} \left\{ \mu_k^{\frac{1}{3}} P_\Omega(\{u_k=1\}) + \frac{1}{2}\mu_k^{-\frac{2}{3}}((-\Delta)^{-1}(u_k-m), u_k-m)\right\}$$

with $u_k = u_{\mu_k}^*$. If $\beta^* \geq \alpha^*$, then u_k is a minimizing sequence for S^* in $\mathcal{M}$. On the other hand, by an argument similar to the one used in the proof of Theorem 2.2, we have for a uniform constant C,

$$P_\Omega(\{u_k=1\}) \geq C\mu_k^{-\frac{1}{3}}.$$

Hence u_k is unbounded in $BV(\Omega)$.

We will see that (6.1) is sufficient. Suppose that $\alpha^* > \beta^*$. Assume by contradiction that u_k is a minimizing sequence for S^* in $\mathcal{M}$ such that

$$P_\Omega(\{u_k=1\}) \to \infty,$$

as $k \to \infty$. Let

$$\mu_k := \frac{((-\Delta)^{-1}(u_k-m), u_k-m)}{P_\Omega(\{u_k=1\})} \leq \frac{C}{[P_\Omega(\{u_k=1\})]^3} \to 0. \tag{6.2}$$

Then

$$\begin{aligned}\alpha^* &\le \lim_{k\to\infty}\left\{\mu_k^{\frac{1}{3}}P_\Omega(\{u_k=1\})+\frac{1}{2}\mu_k^{-\frac{2}{3}}((-\Delta)^{-1}(u_k-m),u_k-m)\right\}\\ &= \lim_{k\to\infty} S^*(u_k)\\ &= \beta^*,\end{aligned}$$

which is a contradiction. □

PROPOSITION 6.2. *Assume* $\Omega = Q := (0,1)^N$. *Then*

$$\alpha \le \beta^* := \inf_{u\in\mathcal{M}} S^*(u).$$

Proof. It is easily seen that $\alpha \le \alpha^*$. Hence it is sufficient to show that $\alpha^* = \beta^*$. Assume by contradiction that $\alpha^* > \beta^*$. Then by Remark 6.1, there exists a minimizer u_1 for S^* in $\mathcal{M}$. By rescaling the axially symmetric and periodic extension of u_1, we will construct a minimizing sequence u_k for S^* in $\mathcal{M}$ such that

$$P_\Omega(\{u_k=1\}) \to \infty.$$

Indeed, let u^* be the function on $\mathbb{R}^N$ which satisfies $u^*|_Q = u_1$ and is axially symmetric about the hyperplanes $\{x_i = 0\}$, $1 \le i \le N$, and invariant under the translations generated by two times of the fundamental vectors. Let

$$u_k(x) := u^*(2^{k-1}x), \quad x \in Q, \tag{6.3}$$

for $k \ge 2$. Then $u_k \in \mathcal{M}$. We claim that

$$\begin{aligned}P_\Omega(\{u_k=1\}) &= 2^{k-1}P_\Omega(\{u_1=0\}),\\ ((-\Delta)^{-1}(u_k-m),u_k-m) &= \left(\frac{1}{2}\right)^{2(k-1)}((-\Delta)^{-1}(u_1-m),u_1-m),\end{aligned}$$

and hence $S^*(u_k) = \beta^*$. To see the first equality, note that the contribution to the perimeter of $\{u^*=1\}$ on the hyperplanes $\{x_i = k\}$, $k = 1,2,\dots,n$ $(n \in \mathbb{N})$, vanishes because of the symmetry. Thus we have $P_{nQ}(\{u^*=1\}) = n^N P_Q(\{u^*=1\})$. The claim follows by a scaling argument. Therefore u_k is a minimizing sequence for S^*, which is unbounded in $BV(Q)$. This is a contradiction by Remark 6.1. □

Hereafter let $N = 2$, $\Omega = Q := (0,1)^2$. Now we have the following.

DEFINITION 6.3. $u \in \mathcal{G}$ *is called planar if* $u = u(x,y)$ *depends only on* x.

We show the following.

PROPOSITION 6.4. *There exists a constant* $m \in (0,1)$ *and a sequence* $\mu_k \to 0$ *such that every solution* u^{μ_k} *of* $(P)^{\mu_k}$ *is not planar.*

Proof. We construct comparison functions as follows. Let $m = 1 - \frac{2}{n^2}$ $(n = 2,3,\dots)$ and

$$u_1(x,y) := \begin{cases} -1, & \max\{|x|,|y|\} \le \dfrac{1}{n},\\ +1 & \text{otherwise.}\end{cases}$$

Then $\langle u_1\rangle = m$. We write u_1 as

$$u_1 = m + \sum_{\substack{i,j\ge 0\\(i,j)\ne(0,0)}} a_{i,j}\phi_{i,j},$$

where

$$\phi_{i,j} := 2\cos i\pi x \cdot \cos j\pi y, \quad i,j \geq 0, (i,j) \neq (0,0),$$

and

$$a_{i,j} := \begin{cases} -\dfrac{4}{ij\pi^2} \sin\dfrac{i\pi}{n} \cdot \sin\dfrac{j\pi}{n}, & i \geq 1, j \geq 1, \\ -\dfrac{4}{i\pi n} \sin\dfrac{i\pi}{n}, & i \geq 1, j = 0, \\ -\dfrac{4}{j\pi n} \sin\dfrac{j\pi}{n}, & i = 0, j \geq 1, \end{cases}$$

are Fourier coefficients. Noting that if $i \equiv k \pmod{n}$, then

$$\sin^2\frac{i\pi}{n} = \sin^2\frac{k\pi}{n} \leq \frac{(k\pi)^2}{n^2},$$

we estimate for $\lambda_{i,j} := \pi^2(i^2+j^2)$ $(i,j \geq 1)$,

$$\begin{aligned} \sum_{i,j\geq 1} \frac{(a_{ij})^2}{\lambda_{i,j}} &= \sum_{i,j\geq 1} \frac{16}{\pi^6} \frac{\sin^2\frac{i\pi}{n}\sin^2\frac{j\pi}{n}}{i^2j^2(i^2+j^2)} \\ &\leq \frac{16}{\pi^2 n^4} \sum_{k,l=1}^{n} \sum_{i,j\geq 0} \frac{k^2l^2}{(ni+k)^2(nj+l)^2[(ni+k)^2+(nj+l)^2]} \\ &= \frac{16}{\pi^2 n^4} \sum_{k,l=1}^{n} \left[\sum_{i,j\geq 1} \frac{k^2l^2}{(ni+k)^2(nj+l)^2[(ni+k)^2+(nj+l)^2]} \right. \\ &\quad + \frac{1}{k^2+l^2} + \sum_{j=1}^{\infty} \frac{l^2}{(nj+l)^2[k^2+(nj+l)^2]} \\ &\quad \left. + \sum_{i=1}^{\infty} \frac{k^2}{(ni+k)^2[(ni+k)^2+l^2]} \right] \\ &\leq C\frac{(\log n)^2}{n^4}, \end{aligned}$$

where C is a constant independent of n. Estimating other terms similarly, we get

$$((-\Delta)^{-1}(u_1 - m), u_1 - m) \leq \alpha_0 \frac{(\log n)^2}{n^4}.$$

Hence noting that $P_Q(\{u_1 = 1\}) = \frac{2}{n}$, we see that for any $\delta \in (0,1)$, there exists a constant α_1 such that

$$(\alpha \leq \beta^* \leq) S^*(u_1) \leq \frac{\alpha_1}{n^{2-\delta}}$$

for large n. Define u_k as (6.3) in the proof of Proposition 6.2, and define μ_k as (6.2).

We estimate

$$\begin{aligned}\limsup_{k\to\infty} \mu_k^{\frac{1}{3}} B^{\mu_k}(u^{\mu_k}) &\le \lim_{k\to\infty} \left\{ \mu_k^{\frac{1}{3}} P_\Omega(\{u_k = 1\}) + \frac{1}{2}\mu_k^{-\frac{2}{3}}((-\Delta)^{-1}(u_k - m), u_k - m) \right\} \\ &= \lim_{k\to\infty} S^*(u_k) \\ &\le \frac{\alpha_1}{n^{2-\delta}}. \qquad (6.4)\end{aligned}$$

Completion of the proof of Proposition 6.4. To the contrary, assume that each $(P)^{\mu_k}$ has a planar solution u^{μ_k}. Then to get a lower bound, we apply the following.

LEMMA 6.5. *Let $u \in \mathcal{G}$ be planar and let*

$$m' := \int_Q u\,dxdy, \quad L := P_Q(\{u = 1\}).$$

Then

$$S(u) \ge \frac{3}{2}\left(\frac{L}{L+1}\right)^{\frac{2}{3}} \left(\frac{C_0}{12}\right)^{\frac{1}{3}} \min\{1 - m', 1 + m'\}^{\frac{2}{3}},$$

where $C_0 = \frac{2\pi^2}{2\pi^2+1}$. □

Letting $m_k := \langle u^{\mu_k} \rangle$ and $L_k := P_Q(\{u^{\mu_k} = 1\})$, we have

$$\begin{aligned} C &\ge \mu_k^{\frac{1}{3}} B^{\mu_k}(u^{\mu_k}) \\ &\ge \mu_k^{-\frac{2}{3}}(m_k - m)^2 + S(u^{\mu_k}) \\ &\ge \mu_k^{-\frac{2}{3}}(m_k - m)^2 + \frac{3}{2}\left(\frac{L_k}{L_k+1}\right)^{\frac{2}{3}} \left(\frac{C_0}{12}\right)^{\frac{1}{3}} (1 - m_k)^{\frac{2}{3}}, \end{aligned}$$

which implies that $\lim_{k\to\infty} m_k = m$, and hence $L_k \ge 1$ for large k. Thus taking the limit $k \to \infty$, we have

$$\begin{aligned}\liminf_{k\to\infty} \mu_k^{\frac{1}{3}} B^{\mu_k}(u^{\mu_k}) &\ge \frac{3}{2}\left(\frac{1}{2}\right)^{\frac{2}{3}} \left(\frac{C_0}{12}\right)^{\frac{1}{3}} (1 - m)^{\frac{2}{3}} \\ &=: \alpha_2 n^{-\frac{4}{3}},\end{aligned}$$

which contradicts the upper bound (6.4) for large n. Proposition 6.4 has been proved. □

Proof of Lemma 6.5. Without loss of generality, we may assume that $m' \in [0, 1]$.

Since the second eigenvalue of $-\frac{d^2}{dx^2}$ acting on $H^2(0,1)$ with homogeneous Neumann data is π^2, we have

$$(K(u - m'), u - m') \ge \frac{\pi^2}{\pi^2 + \frac{1}{2}}((-\Delta)^{-1}(u - m'), u - m').$$

Writing $u(x, y) = g(x)$, let $0 < x_1 < x_2 < \cdots < x_L < 1$ be the discontinuity points of g in the interval $(0, 1)$. Here $L = P_\Omega(\{u = 1\})$. Then we estimate

$$S(u) \ge \frac{3}{2} L^{\frac{2}{3}} (C_0)^{\frac{1}{3}} [((-\Delta)^{-1}(u - m'), u - m')]^{\frac{1}{3}}. \qquad (6.5)$$

Letting $\psi \in C^1[0,1]$ be the (weak) solution of

$$\begin{cases} -\psi'' = g - m', & 0 < x < 1, \\ \psi'(0) = \psi'(1) = 0, \end{cases}$$

we have

$$((-\Delta)^{-1}(u-m'), u-m') = \int_0^1 \psi(g-m')\,dx = \int_0^1 (\psi'(x))^2\,dx.$$

To complete the proof of Lemma 6.5, we show the following.

LEMMA 6.6. *Let $u : [0,1] \to \mathbb{R}$ be a piecewise linear function such that $u'(x)$ is constant on each interval (x_i, x_{i+1}) and takes c_i, where $0 = x_0 < x_1 < \cdots < x_L < x_{L+1} = 1$ and $c_i \in \mathbb{R}$. Then*

$$\int_0^1 u^2\,dx \geq \frac{1}{12}\left(\sum_{i=0}^{L} \frac{1}{|c_i|}\right)^{-2}.$$

Proof. Since $u'(x) = c_i$ for $x_i < x < x_{i+1}$, it follows that

$$\int_{x_i}^{x_{i+1}} u^2\,dx = \int_{x_i}^{x_{i+1}} \left(c_i\left(x - \frac{x_i + x_{i+1}}{2}\right) + \frac{u(x_i) + u(x_{i+1})}{2}\right)^2 dx \geq \frac{c_i^2}{12}(x_{i+1} - x_i)^3.$$

Summing over i, we get

$$\begin{aligned} \int_0^1 u^2\,dx &\geq \frac{1}{12}\sum_{i=0}^{L} \frac{1}{|c_i|}(|c_i|(x_{i+1} - x_i))^3 \\ &\geq \frac{1}{12}\left(\sum_{i=0}^{L} \frac{1}{|c_i|}\right)^{-2}. \end{aligned}$$

Here in the second inequality we used the Jensen's inequality. □

Completion of the proof of Lemma 6.5. Applying Lemma 6.6 to ψ', we have

$$((-\Delta)^{-1}(u-m'), u-m') \geq \frac{(1-m')^2}{12}(L+1)^{-2}. \tag{6.6}$$

Combining (6.5) and (6.6), the proof is complete. □

Finally we remark on the problem $(\widetilde{P})^\mu$.

Remark 6.2. We think that typical interfaces for solutions of $(\widetilde{P})^\mu$ should be lines or circles when $N = 2$. We believe that, for m sufficiently close to 1, and μ small, an interface approximated by a circle of a small radius, centered near the points on the boundary, which have the maximum mean curvature, should arise as in Cahn–Hilliard theory. We remark that phase separation with circular interfaces are observed in experiments of block copolymer (see [15]).

Example. Let $m = 0.8$ and $\Omega = (0,1)^2$. If u is planar, then

$$\widetilde{B}^\mu(u) \geq \min\left\{\frac{0.04}{\mu}, 1\right\}.$$

On the other hand, if $u \in \mathcal{G}$ has the circular interface such that $u(x,y) = -1$ for $x^2 + y^2 < \frac{0.4}{\pi}$ and $u = +1$, otherwise,

$$\widetilde{B}^\mu(u) \leq \frac{\sqrt{0.4\pi}}{2} \sim 0.56.$$

Hence solutions for $(\widetilde{P})^\mu$ are not planar.

Acknowledgments. I would like to thank Professor G. Weiss for showing me the private communication [12], Professor D. Hilhorst for introducing me the paper [5], and the referee for carefully reading the manuscript.

VISCOUS SHOCK WAVE TO A GAS-SOLID FREE BOUNDARY PROBLEM FOR COMPRESSIBLE GAS*

FEIMIN HUANG‡, AKITAKA MATSUMURA†, AND XIAODING SHI§

Abstract. We continue to study the large time behavior of the solution to a gas-solid free boundary problem for a one-dimensional model system of compressible viscous gas proposed by us in [*SIAM J. Math. Anal.*, 34 (2003), pp. 1331–1355], where the travelling wave and the rarefaction wave were investigated. In this paper we prove the asymptotic stability of the superposition of a travelling wave and a viscous shock wave under some smallness conditions. The asymptotic behavior of the free boundary is also obtained. The proof is given by the elementary energy estimate.

Key words. viscous shock wave, gas-solid free boundary, compressible gas

1. Introduction. In this paper, we continue to study the large time behavior of the solution to a gas-solid free boundary problem for a one-dimensional model system of compressible viscous gas proposed by us in [4]. The free boundary value problem reads in the *Eulerian* coordinates as

$$
\begin{cases}
\tilde{\rho}_t + (\tilde{\rho}\tilde{u})_{\tilde{x}} = 0 & \text{in } \tilde{x} > X(t),\\
(\tilde{\rho}\tilde{u})_t + (\tilde{\rho}\tilde{u}^2 + \tilde{p})_{\tilde{x}} = \mu\tilde{u}_{\tilde{x}\tilde{x}} & \text{in } \tilde{x} > X(t),\\
\tilde{\rho}(X(t),t) = \rho_b,\\
\mu\tilde{u}_{\tilde{x}}(X(t),t) = \dfrac{\rho_b\bar{\rho}}{\bar{\rho}-\rho_b}\tilde{u}^2(X(t),t),\\
\dfrac{dX(t)}{dt} = \dfrac{\rho_b}{\rho_b-\bar{\rho}}\tilde{u}(X(t),t), & X(0) = 0,\\
(\tilde{\rho},\tilde{u})|_{(+\infty,t)} = (\rho_+,u_+),\\
(\tilde{\rho},\tilde{u})|_{t=0} = (\rho_0,u_0),
\end{cases}
\tag{1.1}
$$

where $\tilde{\rho}(\tilde{x},t)$ denotes the density of gas, $\tilde{u}(\tilde{x},t)$ denotes the velocity, and $\tilde{p} = \tilde{\rho}^\gamma$ $1 \le \gamma \le 3$ denotes the pressure; where the viscosity coefficient μ and the density $\bar{\rho}$ of the solid are given positive constants; and where

$$
\rho_b < \bar{\rho}, \qquad \frac{dX(t)}{dt} < 0. \tag{1.2}
$$

As shown in [4], the part $\tilde{x} > X(t)$ is filled by the gas with the density $\tilde{\rho}(\tilde{x},t)$ and velocity $\tilde{u}(\tilde{x},t)$ satisfying the conservation of the mass and momentum, the part $\tilde{x} < X(t)$ is filled by the solid with the constant density $\bar{\rho}$ and zero velocity, and the phase transition from the solid to the gas occurs on the free boundary $\tilde{x} = X(t)$. It

is interesting to compare our free boundary problem (1.1), (1.2) with the previous ones. In all previous works (e.g., Kazhikhov [8], Nagasawa [16]) they assume $\frac{dX(t)}{dt} = \tilde{u}(X(t),t)$. In this case, if we introduce the Lagrangian mass coordinates, we can reformulate the problem to that with the fixed boundary. On the other hand, in our case we cannot do it, which gives us a major difficulty. For the related free boundary problem, see [4, 6, 8, 16] and references therein.

Now let us turn to our free boundary problem (1.1), (1.2). In [4] we proved the free boundary problem (1.1), (1.2) admits a travelling wave under some conditions. We then proved the asymptotic stability of the superposition of a travelling wave and a rarefaction wave under some smallness conditions. However, the viscous shock wave case was left open, and the asymptotic behavior of the free boundary $\tilde{x} = X(t)$ is not obtained yet.

In this paper we investigate the case when the asymptotic state is given by the combination of a travelling wave and a viscous shock wave. We further show the asymptotic behavior of the free boundary $\tilde{x} = X(t)$. The main novelty of this paper is to determine the phase shift of the viscous shock wave. As we know, it is difficult to locate the phase shift even for the viscous scalar conservation laws with boundary (see [9, 10]). For 2×2 compressible Navier–Stokes equations with the fixed boundary, Matsumura and Mei [12] developed a new technique to calculate the shift. In their case, only conservation of mass was used to determine the shift. Because the problem (1.1), (1.2) is a free boundary problem, our case is much more difficult than [12] in many aspects. Since the velocity $\tilde{u}(\tilde{x},t)$ on the free boundary is unknown, conservation of momentum has to be used here. Our main difficulty comes from the free boundary $\tilde{x} = X(t)$. To treat the free boundary problem more easily, we study it in the Lagrangian coordinates instead of Eulerian coordinates. The free boundary in the Lagrangian coordinates (x,t) becomes $x = x(t) = \bar{\rho}X(t)$. When the initial data is closed to the superposition of a travelling wave with speed $\bar{s} < 0$ and a 2-viscous shock wave, we expect the free boundary $x = x(t)$ to tend to $x = \bar{s}t +$ constant as t tends to infinity. To overcome the main difficulty from the free boundary, we manipulate both conservation laws, and then the phase shift α is explicitly determined. Furthermore, the asymptotic behavior of the free boundary is consequently given after the large time behavior of the solution is obtained. Namely, $x(t) - \bar{s}t$ converges to a constant as time tends to infinity. We note that our results naturally include the case that the asymptotic state is given by a single travelling wave. This case was also considered in [4]; however, the asymptotic behavior of the free boundary $x = x(t)$ was not yet obtained there. In this sense, we also improve some results of [4]. We now formulate our main result.

As in [4], we transform (1.1) into the problem in the Lagrangian coordinates:

$$
\begin{cases}
v_t - u_x = 0, & x > x(t),\ t > 0,\\
u_t + p(v)_x = \mu\left(\dfrac{u_x}{v}\right)_x, & x > x(t),\ t > 0,\\
v(x(t),t) = v_b,\\
\mu u_x(x(t),t) = \dfrac{v_b}{v_b - \bar{v}}u^2(x(t),t),\\
\dfrac{dx(t)}{dt} = \dfrac{1}{\bar{v} - v_b}u(x(t),t), & x(0) = 0,\\
(v,u)|_{(+\infty,t)} = (v_+,u_+) = \left(\dfrac{1}{\rho_+},u_+\right),\\
(v,u)|_{t=0} = (v_0,u_0), & v_0(0) = v_b,
\end{cases}
\tag{1.3}
$$

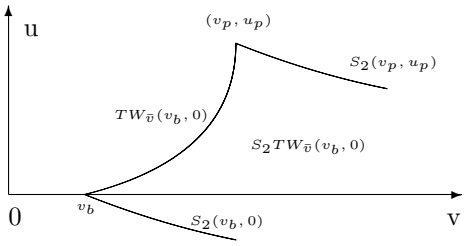

FIG. 1.1.

where $v = \frac{1}{\rho}$, $p(v) = v^{-\gamma}$, $1 \le \gamma \le 3$, and $x(t) = \bar\rho X(t)$. By the argument of [4], a new travelling wave solution (simply denoted by TW-solution) exists for the free boundary problem (1.1), (1.2). For any $0 < \bar v < v_b < +\infty$, the TW-curve with the parameter $\bar v$ through the point $(v_b, 0)$ is defined by

(1.4)
$$TW_{\bar v}(v_b, 0) = \{(v,u); u = (v-\bar v)^{\frac12}(p(v_b)-p(v))^{\frac12},\ u^2 < (v-\bar v)^2|p'(v)|,\ v > v_b\}.$$

This shows that for any $(v_*, u_*) \in TW_{\bar v}(v_b, 0)$ there exists a travelling wave solution $(V_T, U_T)(\xi)$, $\xi = x - \bar s t$, satisfying

$$\begin{cases} -\bar s V_T' - U_T' = 0, \\ -\bar s U_T' + p(V_T)' = \mu\left(\dfrac{U_T'}{V_T}\right)', \end{cases} \tag{1.5}$$

with

$$\begin{cases} V_T(0) = v_b, \qquad U_T(0) = u_b, \qquad \mu U_T'(0) = v_b(v_b - \bar v)\bar s^2, \\ V_T(+\infty) = v_*, \qquad U_T(+\infty) = u_*, \end{cases} \tag{1.6}$$

where

$$\bar s = \frac{u_b}{\bar v - v_b}, \qquad u_b = \frac{\bar v - v_b}{\bar v - v_*}u_*. \tag{1.7}$$

That is, the TW-solution $(V_T, U_T)(\xi)$ connects (v_b, u_b) and (v_*, u_*). On the other hand, it is known that the 2-shock curve $S_2(v_b, 0)$ through the point $(v_b, 0)$ is

$$S_2(v_b, 0) = \{(v,u); u = -s_b(v - v_b),\ v > v_b\}, \qquad s_b = \sqrt{\frac{p(v_b)-p(v)}{v - v_b}}, \tag{1.8}$$

and $S_2(v_p, u_p)$ through the point (v_p, u_p) is

$$S_2(v_p, u_p) = \{(v,u); u = u_p - s_p(v - v_p),\ v > v_p\}, \qquad s_p = \sqrt{\frac{p(v_p)-p(v)}{v - v_p}}, \tag{1.9}$$

where

$$u_p = (v_p - \bar v)^{\frac12}(p(v_b)-p(v_p))^{\frac12}, \qquad u_p^2 = (v_p - \bar v)^2|p'(v_p)|. \tag{1.10}$$

We define $S_2TW_{\bar v}(v_b,0)$ as the domain surrounded by curves $TW_{\bar v}(v_b,0)$, $S_2(v_b,0)$, and $S_2(v_p,u_p)$ (see Figure 1.1).

Now let us turn to the asymptotic behavior of the solution. When the right end state (v_+,u_+) of (1.3) belongs to the region $S_2TW_{\bar v}(v_b,0)$ in the phase plane, the solution of (1.3) is expected to tend to the superposition of a TW-solution and a 2-viscous shock wave as t tends to infinity. Our aim is to justify the above conjecture. Our result is, roughly speaking, as follows.

If $(v_+,u_+)\in S_2TW_{\bar v}(v_b,0)$, then there exists $(v_*,u_*)\in TW_{\bar v}(v_b,0)$ such that $(v_+,u_+)\in S_2(v_*,u_*)$, and the superposition of the TW-solution connecting (v_b,u_b) with (v_*,u_*) and the 2-viscous shock wave connecting (v_*,u_*) with (v_+,u_+) is stable, provided that $|v_*-v_b|$ is small. That is, the TW-solution is necessarily weak; however, the 2-viscous shock wave is not necessarily weak.

Finally, we note that when the free boundary $\tilde x = X(t)$ is fixed as a straight line, the problem (1.1), (1.2) becomes the so-called inflow problem (see [4]). We refer the reader to [3, 11, 15, 17] for the inflow problem.

Our plan for this paper is as follows. In section 2, we give some known results on the travelling wave and the viscous shock wave; in section 3, we study the phase shift of the viscous shock wave; in section 4, we state our main result; in section 5, we reformulate the original problem to a new initial-boundary value problem; in section 6, we show the local existence of the solution; in section 7, we establish the a priori estimates and prove our main result.

Notation. Throughout this paper, several positive generic constants are denoted by c, C without confusion. For function spaces, $L^p(\Omega)$, $1\le p\le\infty$, denotes a usual Lebesgue space on $\Omega\subset R=(-\infty,\infty)$ with its norm

$$\|f\|_{L^p(\Omega)}=\left(\int_\Omega |f(x)|^p dx\right)^{\frac1p},\quad 1\le p<\infty,\qquad \|f\|_{L^\infty(\Omega)}=\sup_\Omega |f(x)|. \tag{1.11}$$

$H^l(\Omega)$ denotes the lth order Sobolev space with its norm

$$\|f\|_l=\left(\sum_{j=0}^{l}\|\partial_x^j f\|^2\right)^{\frac12}\quad \text{when } \|\cdot\|:=\|\cdot\|_{L^2(\Omega)}. \tag{1.12}$$

The domain Ω will often be abbreviated without confusion.

2. Preliminaries. In this section we recall some properties of the travelling wave solution and the viscous shock wave. From [4], we have the following result of the travelling wave solution.

LEMMA 2.1. *For any given $\bar v$, v_b, and v_* with $0<\bar v<v_b<v_*$, let u_* be the number such that $(v_*,u_*)\in TW_{\bar v}(v_b,0)$. Then there exists a unique solution $(V_T,U_T)(\xi)$, $\xi=x-\bar s t$, to (1.5) and (1.6) satisfying $0<v_b<V_T(\xi)<v_*$, $V_T'>0$, where $\bar s$ and u_b are given by (1.7). Furthermore, fix $\bar v$ and v_b, and let $v_*-v_b=\delta$; then there exist positive constants $\delta_0>0$ and $c_0>0$ such that, for any $\delta\le\delta_0$,*

$$|V_T(\xi)-v_*|=O(\delta)e^{-\frac{c_0}{\sqrt\delta}\xi},\qquad |U_T(\xi)-u_*|=O(\delta^{\frac32})e^{-\frac{c_0}{\sqrt\delta}\xi}, \tag{2.1}$$

and

$$(u_*,\bar s,u_b)=O(\delta^{\frac12}),\qquad V_T'=O(\delta^{\frac12})e^{-\frac{c_0}{\sqrt\delta}\xi},\qquad V_T''=O(1)e^{-\frac{c_0}{\sqrt\delta}\xi}. \tag{2.2}$$

On the other hand, it is well known that for any point (v_*, u_*) with $v_* > 0$, if $(v_+, u_+) \in S_2(v_*, u_*)$, then there exists a unique viscous shock profile $(v, u) = (V_s, U_s)(\eta = x - st)$, $s = \sqrt{\frac{p(v_*)-p(v_+)}{v_+-v_*}} > 0$, satisfying $(V_s, U_s)(-\infty) = (v_*, u_*)$, $(V_s, U_s)(+\infty) = (v_+, u_+)$ up to a shift. Namely, (V_s, U_s) satisfies

$$\begin{cases} -sV_s' - U_s' = 0, \\ -sU_s' + p(V_s)' = \mu\left(\dfrac{U_s'}{V_s}\right)', \\ (V_s, U_s)(-\infty) = (v_*, u_*), \\ (V_s, U_s)(+\infty) = (v_+, u_+), \end{cases} \tag{2.3}$$

which yields

$$\frac{s\mu V_s'}{V_s} = -s^2 V_s - p(V_s) - b \equiv: h(V_s), \tag{2.4}$$

where $b = -s^2 v_* - p(v_*) = -s^2 v_+ - p(v_+)$. Thus, we have the following lemma.

LEMMA 2.2. *Let (v_*, u_*) be a point in the phase plane with $v_* > 0$. Suppose that $(v_+, u_+) \in S_2(v_*, u_*)$; then there exists a unique shock profile $(V_s, U_s)(\eta = x - st)$, $s = \sqrt{\frac{p(v_*)-p(v_+)}{v_+-v_*}} > 0$, up to a shift, which connects (v_*, u_*) and (v_+, u_+) and satisfies* (2.3) *and*

$$\begin{aligned} &0 < v_* < V_s(\eta) < v_+, u_+ < U_s(\eta) < u_*, h(V_s) > 0, V_s' = \frac{V_s h(V_s)}{s\mu} > 0, \\ &(|V_s(\eta) - v_*|, |U_s(\eta) - u_*|) = O(1)|v_+ - v_*|e^{-c_-|\eta|} \quad \text{as } \eta \to -\infty, \\ &(|V_s(\eta) - v_+|, |U_s(\eta) - u_+|) = O(1)|v_+ - v_*|e^{-c_+|\eta|} \quad \text{as } \eta \to +\infty, \end{aligned} \tag{2.5}$$

where $c_- = \frac{v_*|p'(v_*)+s^2|}{\mu s} > 0$, $c_+ = \frac{v_+|p'(v_+)+s^2|}{\mu s} > 0$.

3. Phase shift. This section is devoted to the phase shift of the viscous shock profile. When $(v_+, u_+) \in S_2 TW_{\bar v}(v_b, 0)$, there is $(v_*, u_*) \in TW_{\bar v}(v_b, 0)$ such that $(v_+, u_+) \in S_2(v_*, u_*)$, and the asymptotic behavior of the solution to (1.3) is expected to be the superposition of a TW-solution $(V_T, U_T)(\xi)$, $\xi = x - \bar s t$, connecting (v_b, u_b) with (v_*, u_*) and a 2-viscous shock wave $(V_s, U_s)(\eta)$, $\eta = x - st$, connecting (v_*, u_*) with (v_+, u_+), where

$$\bar s = \frac{u_*}{\bar v - v_*}, \qquad u_b = \frac{\bar v - v_b}{\bar v - v_*}u_*, \qquad s = \sqrt{\frac{p(v_*) - p(v_+)}{v_+ - v_*}}. \tag{3.1}$$

We consider the situation where the initial data $(v_0(x), u_0(x))$ are given in a neighborhood of $(V_T(x) + V_s(x - \beta) - v_*, U_T(x) + U_s(x - \beta) - u_*)$ for some large constant $\beta > 0$. That is, we ask the viscous shock wave to be suitably far from the boundary initially. We now try to locate the phase shift α such that the asymptotic state of the solution (v, u) to (1.3) is given by $(V_T(x - x(t)) + V_s(x - st + \alpha - \beta) - v_*, U_T(x - x(t)) + U_s(x - st + \alpha - \beta) - u_*)$.

To investigate the phase shift α, we consider a coordinate transformation

$$t = t, \quad y = x - x(t), \tag{3.2}$$

in which we can make the free boundary problem (1.3) easier to handle. Let $x(t) = \bar{s}t + \gamma(t)$. Then we rewrite (1.3) as

$$
\begin{cases}
v_t - (\bar{s} + \gamma'(t))v_y - u_y = 0, & y > 0,\ t > 0,\\
u_t - (\bar{s} + \gamma'(t))u_y + p(v)_y = \mu\left(\dfrac{u_y}{v}\right)_y, & y > 0,\ t > 0,\\
v(0,t) = v_b,\\
\mu u_y(0,t) = \dfrac{v_b}{v_b - \bar{v}}u^2(0,t),\\
\dfrac{d\gamma(t)}{dt} = \dfrac{1}{\bar{v} - v_b}u(0,t) - \bar{s}, & \gamma(0) = 0,\\
(v,u)|_{(+\infty,t)} = (v_+, u_+),\\
(v,u)(y,0) = (v_0,u_0)(y), & v_0(0) = v_b.
\end{cases}
\tag{3.3}
$$

On the other hand, Lemma 2.1 yields the TW-solution $(V_T, U_T)(y)$ connecting (v_b, u_b), and (v_*, u_*) satisfies

$$
\begin{cases}
-\bar{s}V_{Ty} - U_{Ty} = 0, & y > 0,\\
-\bar{s}U_{Ty} + p(V_T)_y = \mu\left(\dfrac{U_{Ty}}{V_T}\right)_y, & y > 0,\\
V_T(0) = v_b, \quad U_T(0) = u_b,\\
\mu U_{Ty}(0) = v_b(v_b - \bar{v})\bar{s}^2,\\
(V_T, U_T)|_{(+\infty)} = (v_*, u_*).
\end{cases}
\tag{3.4}
$$

In the new coordinate system (y,t), the asymptotic shock wave should take the form

$$
(V_s, U_s)(y,t) = (V_s, U_s)(y + x(t) - st + \alpha - \beta).
\tag{3.5}
$$

Note that $x(t)$ is an unknown function, and it is very difficult to determine the phase shift α if we directly use the form (3.5). Since the free boundary $x(t)$ is expected to tend to $\bar{s}t + \text{const}$ as t tends to infinity, we use the shock profile

$$
(\bar{V}_s, \bar{U}_s)(y,t) = (V_s, U_s)(y - (s - \bar{s})t + \alpha - \beta)
\tag{3.6}
$$

instead of the profile (3.5) and then estimate the L^1 distance between (V_s, U_s) and $(\bar{V}_s, \bar{U}_s)$. By Lemma 2.2, the shock profile (3.6) satisfies

$$
\begin{cases}
\bar{V}_{st} - \bar{s}\bar{V}_{sy} - \bar{U}_{sy} = 0, & y > 0,\ t > 0,\\
\bar{U}_{st} - \bar{s}\bar{U}_{sy} + p(\bar{V}_s)_y = \mu\left(\dfrac{\bar{U}_{sy}}{\bar{V}_s}\right)_y, & y > 0,\ t > 0,\\
(\bar{V}_s, \bar{U}_s)(-\infty,t) = (v_*, u_*),\\
(\bar{V}_s, \bar{U}_s)(+\infty,t) = (v_+, u_+).
\end{cases}
\tag{3.7}
$$

Let

$$
\begin{aligned}
w(y,t) &= v(y,t) - V_T(y) - V_s(y,t) + v_*,\\
z(y,t) &= u(y,t) - U_T(y) - U_s(y,t) + u_*,
\end{aligned}
\tag{3.8}
$$

and

$$
\begin{aligned}
\bar{w}(y,t) &= v(y,t) - V_T(y) - \bar{V}_s(y,t) + v_*,\\
\bar{z}(y,t) &= u(y,t) - U_T(y) - \bar{U}_s(y,t) + u_*.
\end{aligned}
\tag{3.9}
$$

Then we have from (3.3)–(3.4), (3.7), and (3.9)

$$\begin{cases} \bar{w}_t - \bar{s}\bar{w}_y - \bar{z}_y = \gamma'(t)v_y, & y>0,\ t>0,\\ \bar{z}_t - \bar{s}\bar{z}_y + P_y - Q_y = \gamma'(t)u_y, & y>0,\ t>0, \end{cases} \tag{3.10}$$

where

$$\begin{aligned} P(y,t) &= p(v(y,t)) - p(V_T(y)) - p(\bar{V}_s(y,t)) + p(v_*),\\ Q(y,t) &= \mu\left(\frac{u_y(y,t)}{v(y,t)} - \frac{U_{Ty}(y)}{V_T(y)} - \frac{\bar{U}_{sy}(y,t)}{\bar{V}_s(y,t)}\right). \end{aligned} \tag{3.11}$$

Integrating $(3.10)_1$ over R_+ yields

$$\begin{aligned} \frac{d}{dt}\int_0^\infty \bar{w}(y,t)dy &= -\bar{s}\bar{w}(0,t) - \bar{z}(0,t) + \gamma'(t)(v_+ - v_b)\\ &= -\bar{s}(v_* - \bar{V}_s(0,t)) - (u(0,t) - u_b)\\ &\quad + (\bar{U}_s(0,t) - u_*) + \gamma'(t)(v_+ - v_b)\\ &= (s-\bar{s})(v_* - \bar{V}_s(0,t)) + \gamma'(t)(v_+ - \bar{v}), \end{aligned} \tag{3.12}$$

where we have used the fact that

$$\bar{U}_s(0,t) - u_* = s(v_* - \bar{V}_s(0,t)), \qquad u(0,t) - u_b = \gamma'(t)(\bar{v} - v_b). \tag{3.13}$$

In the same fashion, integrating $(3.10)_2$ over R_+, by the fact that

$$-s(\bar{U}_s(0,t) - u_*) + p(\bar{V}_s(0,t)) - p(v_*) = \mu\frac{\bar{U}_{sy}(0,t)}{\bar{V}_s(0,t)}, \tag{3.14}$$

yields

$$\begin{aligned} \frac{d}{dt}\int_0^\infty \bar{z}(y,t)dy &= -\bar{s}\bar{z}(0,t) + P(0,t) - Q(0,t) + \gamma'(t)(u_+ - u(0,t))\\ &= -u_b\gamma'(t) + (s-\bar{s})(u_* - \bar{U}_s(0,t))\\ &\quad + \gamma'(t)(u(0,t) + u_b) + \gamma'(t)(u_+ - u(0,t))\\ &= u_+\gamma'(t) + (s-\bar{s})(u_* - \bar{U}_s(0,t)). \end{aligned} \tag{3.15}$$

Here we are very lucky that the term $\gamma'(t)u(0,t)$ is cancelled in (3.15). Integrating (3.12) and (3.15) over $(0,t)$ gives

$$\int_0^\infty \bar{w}(y,t)dy = \gamma(t)(v_+ - \bar{v}) + (s-\bar{s})\int_0^t v_* - \bar{V}_s(0,t)dt + \int_0^\infty \bar{w}(y,0)dy, \tag{3.16}$$

$$\int_0^\infty \bar{z}(y,t)dy = \gamma(t)u_+ + (s-\bar{s})\int_0^t u_* - \bar{U}_s(0,t)dt + \int_0^\infty \bar{z}(y,0)dy. \tag{3.17}$$

On the other hand, we compute

$$\begin{aligned} &\int_0^\infty \bar{V}_s(y,t) - V_s(y,t)dy\\ &\quad = -\int_0^\infty\int_0^1 V_{sy}(y + \bar{s}t - st + \alpha - \beta + \theta\gamma(t))d\theta dy \times \gamma(t)\\ &\quad = -\int_0^1 [v_+ - V_s(\bar{s}t - st + \alpha - \beta + \theta\gamma(t))]d\theta \times \gamma(t)\\ &\quad = (v_* - v_+)\gamma(t) + \sigma(t) \end{aligned} \tag{3.18}$$

and

$$\int_0^\infty \bar{U}_s(y,t) - U_s(y,t)dy = (u_* - u_+)\gamma(t) - s\sigma(t), \tag{3.19}$$

where

$$\sigma(t) = \sigma(\gamma,t) = \int_0^1 [V_s(\bar{s}t - st + \alpha - \beta + \theta\gamma(t)) - v_*]d\theta \times \gamma(t). \tag{3.20}$$

It is noted that $\bar{s}t + \theta\gamma(t) < 0$ holds for any $0 \le \theta \le 1$ due to $\bar{s} < 0$ and $x(t) < 0$. Thus, if $\alpha - \beta < 0$, then $\sigma(t)$ has the following estimate:

$$|\sigma(t)| \le C|\gamma(t)|e^{-c_-|-st+\alpha-\beta|}. \tag{3.21}$$

From (3.16)–(3.19), we have

$$\begin{aligned}\int_0^\infty w(y,t)dy &= \int_0^\infty \bar{w}(y,t)dy + \int_0^\infty \bar{V}_s(y,t) - V_s(y,t)dy\\ &= \gamma(t)(v_* - \bar{v}) + (s - \bar{s})\int_0^t v_* - \bar{V}_s(0,t)dt\\ &\quad + \int_0^\infty w(y,0)dy + \sigma(t),\end{aligned} \tag{3.22}$$

$$\begin{aligned}\int_0^\infty z(y,t)dy &= \int_0^\infty \bar{z}(y,t)dy + \int_0^\infty \bar{U}_s(y,t) - U_s(y,t)dy\\ &= \gamma(t)u_* + (s - \bar{s})\int_0^t u_* - \bar{U}_s(0,t)dt\\ &\quad + \int_0^\infty z(y,0)dy - s\sigma(t).\end{aligned} \tag{3.23}$$

Combining (3.22) and (3.23) implies

$$\begin{aligned}&u_*\int_0^\infty w(y,t)dy - (v_* - \bar{v})\int_0^\infty z(y,t)dy\\ &\quad = a(s - \bar{s})\int_0^t (v_* - \bar{V}_s(0,t))dt\\ &\qquad + \int_0^\infty [u_* w(y,0) - (v_* - \bar{v})z(y,0)]dy + a\sigma(t),\end{aligned} \tag{3.24}$$

where $a = u_* + s(v_* - \bar{v}) > 0$. Expecting $[u_*\int_0^\infty w(y,t)dy - (v_* - \bar{v})\int_0^\infty z(y,t)dy]|_{t=+\infty} = 0$, $\sigma(t)|_{t=+\infty} = 0$ yields

$$\begin{aligned}I(\alpha) &:= a(s - \bar{s})\int_0^\infty (v_* - V_s(\bar{s}t - st + \alpha - \beta))dt\\ &\quad + u_*\int_0^\infty [v_0(y) - V_T(y) - V_s(y + \alpha - \beta) + v_*]dy\\ &\quad - (v_* - \bar{v})\int_0^\infty [u_0(y) - U_T(y) - U_s(y + \alpha - \beta) + u_*]dy\\ &= 0.\end{aligned} \tag{3.25}$$

Since

$$\begin{aligned} I'(\alpha) &= a(v_* - V_s(\alpha-\beta)) - a(v_+ - V_s(\alpha-\beta)) \\ &= a(v_* - v_+) < 0, \end{aligned} \tag{3.26}$$

the equality $0 = I(\alpha) = I(0) + a(v_* - v_+)\alpha$ determines α by

$$\begin{aligned} \alpha &= -\frac{1}{a(v_*-v_+)} I(0) \\ &= -\frac{1}{a(v_*-v_+)} \Big\{ a(s-\bar{s}) \int_0^\infty (v_* - V_s(\bar{s}t - st - \beta))dt \\ &\qquad + u_* \int_0^\infty [v_0(y) - V_T(y) - V_s(y-\beta) + v_*]dy \\ &\qquad - (v_* - \bar{v}) \int_0^\infty [u_0(y) - U_T(y) - U_s(y-\beta) + u_*]dy \Big\}. \end{aligned} \tag{3.27}$$

Substituting (3.25) into (3.24) gives

$$\begin{aligned} & u_* \int_0^\infty w(y,t)dy - (v_* - \bar{v}) \int_0^\infty z(y,t)dy \\ &\quad = -a(s-\bar{s}) \int_t^\infty (v_* - V_s(\bar{s}t - st + \alpha - \beta))dt + a\sigma(t) \\ &\quad =: A(t) + a\sigma(t). \end{aligned} \tag{3.28}$$

4. Main result. Let

$$\begin{aligned} V(y,t;\alpha,\beta) &= V_T(y) + V_s(y + x(t) - st + \alpha - \beta) - v_*, \\ U(y,t;\alpha,\beta) &= U_T(y) + U_s(y + x(t) - st + \alpha - \beta) - u_*, \end{aligned} \tag{4.1}$$

where $\alpha = \alpha(\beta)$ is given by (3.27). We suppose that for some $\beta > 0$,

$$v_0(y) - V(y,0;0,\beta) \in H^1 \cap L^1, \qquad u_0(y) - U(y,0;0,\beta) \in H^1 \cap L^1. \tag{4.2}$$

Set

$$(\Phi_0, \Psi_0)(y) = -\int_y^\infty (v_0(y) - V(y,0;0,\beta), u_0(y) - U(y,0;0,\beta))dy. \tag{4.3}$$

Assume that

$$(\Phi_0, \Psi_0) \in L^2. \tag{4.4}$$

We now give our main result.

THEOREM 4.1. *Suppose that* $1 \le \gamma \le 3$ *and* $(v_+, u_+) \in S_2 TW_{\bar{v}}(v_b, 0)$. *Then there exists* (v_*, u_*) *such that* $(v_*, u_*) \in TW_{\bar{v}}(v_b, 0)$ *and* $(v_+, u_+) \in S_2(v_*, u_*)$. *Assume that* (4.2) *and* (4.4) *hold and*

$$(\gamma - 1)^2 (v_+ - v_*) < 2\gamma v_*. \tag{4.5}$$

Then there exists a positive constant δ_0 *such that for any given* $0 < v_* - v_b = \delta < \delta_0$, *if*

$$\sqrt{\beta} \|\Phi_0, \Psi_0\|_2 + e^{-\frac{2}{5}c_-\beta} < \delta^2, \tag{4.6}$$

then (3.3) *has a unique global solution* $((v,u)(y,t),\gamma(t))$ *satisfying*

$$v(y,t)-V(y,t;\alpha,\beta)\in C^0([0,\infty),H^1)\cap L^2(0,\infty;H^1), \tag{4.7}$$

$$u(y,t)-U(y,t;\alpha,\beta)\in C^0([0,\infty),H^1)\cap L^2(0,\infty;H^2), \tag{4.8}$$

$$\gamma(t)\in C^1[0,\infty), \tag{4.9}$$

and

$$\sup_{y\in\Re_+}|(v,u)(y,t)-(V,U)(y,t;\alpha,\beta)|\longrightarrow 0 \quad \text{as } t\to+\infty, \tag{4.10}$$

where $\alpha=\alpha(\beta)$ *is determined by* (3.27). *Furthermore,* $\gamma(t)$ *converges to a constant* Γ *as* $t\to\infty$, *where*

$$\begin{aligned}\Gamma=\frac{1}{\bar v-v_*}\Big\{&(s-\bar s)\int_0^\infty[v_*-V_s(-(s-\bar s)t+\alpha-\beta)]dt\\&+\int_0^\infty[v_0(y)-V_T(y)-V_s(y+\alpha-\beta)+v_*]dy\Big\}.\end{aligned} \tag{4.11}$$

Remark 4.2. In Theorem 4.1, the strength of the viscous shock wave is not necessarily weak. For general pressure p, the same result could be easily proved by the same argument if the strength of the viscous shock wave is suitably small.

5. Reformulated system. Let

$$\phi(y,t)=-\int_y^\infty w(y,t)dy=-\int_y^\infty[v(y,t)-V(y,t;\alpha,\beta)]dy,$$
$$\psi(y,t)=-\int_y^\infty z(y,t)dy=-\int_y^\infty[u(y,t)-U(y,t;\alpha,\beta)]dy.$$

We put the perturbation by

$$\begin{aligned}v(y,t)&=\phi_y(y,t)+V(y,t;\alpha,\beta),\\u(y,t)&=\psi_y(y,t)+U(y,t;\alpha,\beta).\end{aligned} \tag{5.1}$$

Note that the viscous shock profile $(V_s,U_s)(y,t)$ of (3.5) satisfies, from Lemma 2.2,

$$\begin{cases}V_{st}-(\bar s+\gamma')V_{sy}-U_{sy}=0, & y>0,\ t>0,\\ U_{st}-(\bar s+\gamma')U_{sy}+p(V_s)_y=\mu\left(\dfrac{U_{sy}}{V_s}\right)_y, & y>0,\ t>0,\\ (V_s,U_s)(-\infty,t)=(v_*,u_*),\\ (V_s,U_s)|_{(+\infty,t)}=(v_+,u_+).\end{cases} \tag{5.2}$$

Substituting (3.4), (5.1)–(5.2) into (3.3) and integrating the system on $[y,+\infty)$, we have

$$\begin{cases}\phi_t-(\bar s+\gamma')\phi_y-\psi_y=(V_T(y)-v_*)\gamma',\\ \psi_t-(\bar s+\gamma')\psi_y+p(V+\phi_y)-p(V_T)-p(V_s)+p(v_*)\\ \quad=\mu\left(\dfrac{U_y+\psi_{yy}}{V+\phi_y}-\dfrac{U_{Ty}}{V_T}-\dfrac{U_{sy}}{V_s}\right)+(U_T(y)-u_*)\gamma'.\end{cases} \tag{5.3}$$

We now investigate the initial and boundary conditions of the reformulated system (5.3). By the definition, the initial data satisfies

$$\begin{aligned}\phi(\xi,0) &= -\int_y^{+\infty}[v_0(y)-V(y,0;\alpha,\beta)]dy\\ &= \Phi_0(y)+\int_y^{\infty}\int_0^{\alpha}V_s'(y+\theta-\beta)d\theta dy \qquad (5.4)\\ &= \Phi_0(y)+\int_0^{\alpha}[v_+-V_s(y+\theta-\beta)]d\theta =: \phi_0(y),\end{aligned}$$

$$\psi(y,0)=\Psi_0(y)+\int_0^{\alpha}[u_+-U_s(y+\theta-\beta)]d\theta =: \psi_0(y). \qquad (5.5)$$

Furthermore, we have the following property of $\phi_0(y)$ and $\psi_0(y)$.

PROPOSITION 5.1. *Under assumptions* (4.2) *and* (4.4)*, there exists a positive constant* $C_0>0$ *such that the initial perturbations* $(\phi_0,\psi_0)\in H^2$*, and it satisfies*

$$\|(\phi_0,\psi_0)\|_2 \le C_0(\sqrt{\beta}\|(\Phi_0,\Psi_0)\|_2+e^{-\frac{1}{2}c_-\beta}). \qquad (5.6)$$

Proof. From (3.27), we have

$$|\alpha| \le C(|\Phi_0|+|\Psi_0|+e^{-c_-|st+\beta|}) \le C(\|\Phi_0\|_2+\|\Psi_0\|_2+e^{-c_-\beta}). \qquad (5.7)$$

Thus by the same argument of [3, Proposition 3.1], Proposition 5.1 is proved. ∎

We now show the boundary conditions. Let $B(\gamma,t)=\bar{s}t-st+\alpha-\beta+\gamma(t)$ and $\sigma(\gamma,t)=\sigma(t)$. By (3.3), (3.22), and (3.23), we have

$$\gamma'(t) = \frac{1}{\bar{v}-v_b}(\psi_y(0,t)+U_s(B(\gamma,t))-u_*), \qquad (5.8)$$

$$\begin{aligned}\phi(0,t) &= -\gamma(t)(v_*-\bar{v})-(s-\bar{s})\int_0^t[v_*-\bar{V}_s(0,t)]dt+\phi_0(0)-\sigma(t)\\ &=: C(\gamma,t)+\phi_0(0)-\sigma(t),\end{aligned} \qquad (5.9)$$

and

$$\begin{aligned}\psi_t(0,t) &= \frac{U_s(B(\gamma,t))}{v_b-\bar{v}}\psi_y(0,t)+\left[(s-\bar{s})+\frac{U_s(B(\gamma,t))}{v_b-\bar{v}}\right](U_s(B(\gamma,t))-u_*)\\ &=: D(\gamma,t)\psi_y(0,t)+E(\gamma,t).\end{aligned} \qquad (5.10)$$

We note that

$$\phi_y(0,t)=v_*-V_s(B(\gamma,t)) \qquad (5.11)$$

holds as a compatibility condition when we substitute (5.8)–(5.9) into $(5.3)_1$. Thus

our reformulated system is

$$
\begin{cases}
\phi_t - (\bar{s}+\gamma')\phi_y - \psi_y = (V_T(y)-v_*)\gamma', \\
\psi_t - (\bar{s}+\gamma')\psi_y + p(V+\phi_y) - p(V_T) - p(V_s) + p(v_*) \\
\quad = \mu\left(\dfrac{U_y+\psi_{yy}}{V+\phi_y} - \dfrac{U_{Ty}}{V_T} - \dfrac{U_{sy}}{V_s}\right) + (U_T(y)-u_*)\gamma', \\
(\phi,\psi)(y,0) = (\phi_0,\psi_0)(y), \\
\phi(0,t) = C(\gamma,t) + \phi_0(0) - \sigma(t), \\
\psi(0,t) = \psi_0(0) + \displaystyle\int_0^t D(\gamma,t)\psi_y(0,t)dt + \int_0^t E(\gamma,t)dt, \\
\gamma'(t) = \dfrac{1}{\bar{v}-v_b}(\psi_y(0,t) + U_s(B(\gamma,t)) - u_*), \quad \gamma(0) = 0.
\end{cases} \tag{5.12}
$$

6. Local existence. For any interval $I \subset \Re_+$, we define the solution space $X(I)$ by

$$
\begin{aligned}
X(I) = \Big\{ & (\phi,\psi) \in C^0(I;H^2);\ \phi_y \in L^2(I;H^1), \\
& \psi_y \in L^2(I;H^2),\ \sup_{t\in I} \|(\phi,\psi)(t)\|_2 \le \varepsilon_1 \Big\},
\end{aligned} \tag{6.1}
$$

where $\varepsilon_1 = \frac{1}{2}v_b$. Let

$$
N(t) = \sup_{0\le\tau\le t}(\|\phi(\tau)\|_2 + \|\psi(\tau)\|_2), \qquad N_0 = \|\phi_0\|_2 + \|\psi_0\|_2. \tag{6.2}
$$

By the Sobolev embedding theorem, for $(\phi,\psi) \in X([0,T])$, one obtains

$$
(V+\phi_y)(y,t) \ge v_b - \|\phi_y\|_1 \ge \frac{1}{2}v_b, \qquad (y,t) \in \Re_+ \times [0,T], \tag{6.3}
$$

which ensures that the system (5.12) is uniformly nonsingular on $[0,T]$. We have the following proposition.

PROPOSITION 6.1 (local existence). *For any $\tau \ge 0$, consider the problem*

$$
\begin{cases}
\phi_t - (\bar{s}+\gamma')\phi_y - \psi_y = (V_T(y)-v_*)\gamma', \\
\psi_t - (\bar{s}+\gamma')\psi_y + p(V+\phi_y) - p(V_T) - p(V_s) + p(v_*) \\
\quad = \mu\left(\dfrac{U_y+\psi_{yy}}{V+\phi_y} - \dfrac{U_{Ty}}{V_T} - \dfrac{U_{sy}}{V_s}\right) + (U_T(y)-u_*)\gamma', \\
(\phi,\psi)|_{t=\tau} = (\phi_\tau,\psi_\tau)(y) \in H^2, \\
\phi(0,t) = C(\gamma,t) + \phi_0(0) - \sigma(\gamma,t), \quad t \ge \tau, \\
\psi(0,t) = \psi_0(0) + \displaystyle\int_0^t D(\gamma,t)\psi_y(0,t)dt + \int_0^t E(\gamma,t)dt, \quad t \ge \tau, \\
\gamma'(t) = \dfrac{1}{\bar{v}-v_b}(\psi_y(0,t) + U_s(B(\gamma,t)) - u_*), \quad \gamma(\tau) = \gamma_\tau.
\end{cases} \tag{6.4}
$$

Then there exist positive constants $\delta_0 > 0$ and $C_1 > 0$ independent of τ such that, for any $0 < \delta \le \delta_0$, $\varepsilon \in (0, \frac{\varepsilon_2}{C_0}]$, $\varepsilon_2 = O(\delta) \ll \varepsilon_1$, and β satisfying $e^{-c_-\beta} < \varepsilon_2$, there exists a positive constant T_0 depending on ε_2 but not on τ such that, if $\|(\phi_\tau,\psi_\tau)\|_2 \le \varepsilon$,

$|\gamma(\tau)| \le |\bar{s}\tau|$, *then problem* (6.4) *has a unique solution* $(\phi,\psi) \in X([\tau,\tau+T_0])$, $\gamma(t) \in C^1[\tau,\tau+T_0]$ *satisfying* $\|(\phi,\psi)(t)\|_2 \le C_1\varepsilon$ *and* $|\gamma(t)| \le |\bar{s}|t$ *for* $t \in [\tau,\tau+T_0]$.

Proof. Without loss of generality, let $\tau = 0$. By the characteristic method, ϕ has the explicit form

$$\begin{aligned}\phi(y,t) = \phi_0(\bar{x}_0) &+ \int_0^t \psi_y(\bar{x}_0 - x(\tau),\tau)d\tau \\ &+ \int_0^t \gamma'(\tau)(V_T(\bar{x}_0 - x(\tau)) - v_*)d\tau, \quad \text{if } y \ge -x(t),\end{aligned} \tag{6.5}$$

and

$$\begin{aligned}\phi(y,t) = C(\gamma(\bar{t}_0),\bar{t}_0) + \phi_0(0) - \sigma(\gamma(\bar{t}_0),\bar{t}_0) + \int_{\bar{t}_0}^t \psi_y(x(\bar{t}_0) - x(\tau),\tau)d\tau \\ + \int_{\bar{t}_0}^t \gamma'(\tau)(V_T(x(\bar{t}_0) - x(\tau)) - v_*)d\tau \quad \text{if } 0 \le y \le -x(t),\end{aligned} \tag{6.6}$$

where $\bar{x}_0 = y + x(t)$ and $\bar{t}_0 = x^{-1}(y + x(t))$. We note that the inverse function of $x(t)$ exists because $|\gamma'(t)| \le C(\|\psi(t)\|_2 + e^{-c-\beta}) \le 2C\varepsilon_2$ is small.

On the other hand, $(6.4)_2$ is regarded as the initial-boundary value problem for the parabolic equation of ψ:

$$\begin{cases} \psi_t - \dfrac{\mu}{V+\phi_y}\psi_{yy} = g := g(\phi_y,\gamma,\gamma',\psi_y), \\ \psi(0,t) = \psi_0(0) + \displaystyle\int_0^t D(\gamma,t)\psi_y(0,t)dt + \int_0^t E(\gamma,t)dt, \\ \psi|_{t=0} = \psi_0, \end{cases} \tag{6.7}$$

where

$$\begin{aligned}g(\phi_y,\gamma,\gamma',\psi_y) = (\bar{s}+\gamma')\psi_y &- (p(V+\phi_y) - p(V_T) - p(V_s) + p(v_*)) \\ &+ \mu\left(\frac{U_y}{V+\phi_y} - \frac{U_{Ty}}{V_T} - \frac{U_{sy}}{V_s}\right) + (U_T(y) - u_*)\gamma'\end{aligned}$$

and

$$\gamma(t) = \int_0^t \frac{1}{\bar{v} - v_b}(\psi_y(0,\tau) + U_s(B(\gamma,t)) - u_*)d\tau. \tag{6.8}$$

We now approximate $(\phi_0,\psi_0) \in H^2$ by $(\phi_{0k},\psi_{0k}) \in H^3$ such that

$$(\phi_{0k},\psi_{0k}) \to (\phi_0,\psi_0), \quad \text{strongly in } H^2, \tag{6.9}$$

as $k \to \infty$ and $\|(\phi_{0k},\psi_{0k})\|_2 \le \frac{3}{2}\varepsilon$ holds for any k.

We will use the iteration method to prove Proposition 6.1. We define the sequence $\{(\phi_k^{(n)}(y,t),\psi_k^{(n)}(y,t),\gamma_k^{(n)}(t))\}$ for each k so that

$$(\phi_k^{(0)},\psi_k^{(0)})(y,t) = (\phi_{0k},\psi_{0k})(y), \tag{6.10}$$

and $\gamma_k^{(0)}(t)$ is the solution of the following ODE:

$$\gamma'(t) = \frac{1}{\bar{v} - v_b}(\psi_{0ky}(0) + U_s(B(\gamma,t)) - u_*), \qquad \gamma(0) = 0, \tag{6.11}$$

and for a given $((\phi_k^{(n-1)}, \psi_k^{(n-1)})(y,t), \gamma_k^{(n-1)}(t))$, $\psi_k^{(n)}$ is a solution to

$$
\begin{cases}
\psi_{kt}^{(n)} - \dfrac{\mu \psi_{kyy}^{(n)}}{V_k^{(n-1)} + \phi_{ky}^{(n-1)}} = g^{(n-1)} = g(\phi_{ky}^{(n-1)}, \gamma_k^{(n-1)}, \gamma_{kt}^{(n-1)}, \psi_{ky}^{(n-1)}), \\
\psi_k^{(n)}(0,t) = \psi_{0k}(0) + \displaystyle\int_0^t D(\gamma_k^{(n-1)}, t)\psi_{ky}^{(n)}(0,t)dt + \int_0^t E(\gamma_k^{(n-1)}, t)dt \\
\qquad\qquad - \displaystyle\int_0^t [h(\gamma_k^{(n-1)}, \psi_{ky}^{(n)}) - h(\gamma_k^{(n-1)}, \psi_{ky}^{(n-1)})]|_{y=0} dt, \\
\psi_k^{(n)}|_{t=0} = \psi_{0k},
\end{cases} \tag{6.12}
$$

$\gamma_k^{(n)}(t)$ is a solution to

$$
\gamma_{kt}^{(n)}(t) = \frac{1}{\bar{v} - v_b}(\psi_{ky}^{(n)}(0,t) + U_s(B(\gamma_k^{(n)}, t)) - u_*), \qquad \gamma_k^{(n)}(0) = 0, \tag{6.13}
$$

and $\phi_k^{(n)}(y,t)$ is a solution to

$$
\begin{cases}
\phi_{kt}^{(n)} - (\bar{s} + \gamma_{kt}^{(n)})\phi_{ky}^{(n)} - \psi_{ky}^{(n)} = (V_T(y) - v_*)\gamma_{kt}^{(n)}, \\
\phi_k^{(n)}(0,t) = C(\gamma_k^{(n)}, t) + \phi_0(0) - \sigma(\gamma_k^{(n)}, t), \\
\phi_k^{(n)}(y,0) = \phi_{0k};
\end{cases} \tag{6.14}
$$

i.e.,

$$
\phi_k^{(n)}(y,t) = \begin{cases}
C(\gamma_k^{(n)}(\bar{t}_k^{(n)}), \bar{t}_k^{(n)}) + \phi_{0k}(0) - \sigma(\gamma_k^{(n)}(\bar{t}_k^{(n)}), \bar{t}_k^{(n)}) \\
\quad + \displaystyle\int_{\bar{t}_k^{(n)}}^t \psi_{ky}^{(n)}(x_k^{(n)}(\bar{t}_k^{(n)}) - x_k^{(n)}(\tau), \tau)d\tau \\
\quad + \displaystyle\int_{\bar{t}_k^{(n)}}^t [\gamma_k^{(n)}(\tau)]'[V_T(x_k^{(n)}(\bar{t}_k^{(n)}) - x_k^{(n)}(\tau)) - v_*]d\tau \\
\text{if } 0 \le y \le -x_k^{(n)}(t), \\
\phi_{0k}(\bar{x}_k^{(n)}) + \displaystyle\int_0^t \psi_{ky}^{(n)}(\bar{x}_k^{(n)} - x_k^{(n)}(\tau), \tau)d\tau \\
\quad + \displaystyle\int_0^t [\gamma_k^{(n)}(\tau)]'[V(\bar{x}_k^{(n)} - x_k^{(n)}(\tau)) - v_*]d\tau \\
\text{if } y \ge -x_k^{(n)}(t),
\end{cases} \tag{6.15}
$$

where

$$
\begin{gathered}
x_k^{(n)}(t) = \bar{s}t + \gamma_k^{(n)}(t), \\
\bar{t}_k^{(n)} = (x_k^{(n)})^{-1}(y + x_k^{(n)}(t)), \qquad \bar{x}_k^{(n)} = y + x_k^{(n)}(t), \\
h(\gamma, \psi_y) = \bar{s}\psi_y + \frac{\psi_y + U_s(B(\gamma,t)) - u_*}{\bar{v} - v_b}(\psi_y + u_b - u_*),
\end{gathered} \tag{6.16}
$$

and $V_k^{(0)} = v_b - \phi_{ky}^{(0)}$, $V_k^{(n)} = V_T + V_s(y + B(\gamma_k^{(n)}, t)) - v_*$, $n \ge 1$. Since (6.14) contains only the index n, by the same argument of (5.11), we have $\phi_{ky}^{(n)}(0,t) =$

$v_* - V_s(B(\gamma_k^{(n)}, t))$, which infers

$$(V_k^{(n)} + \phi_{ky}^{(n)})(0,t) = v_b, \quad n \geq 0. \tag{6.17}$$

Since ε_2 is small, by the principle of contraction mapping, it is easy to prove there exist $C_1 > 2$ and positive time $t_0(\varepsilon_2) \ll 1$ such that, if $g^{(n-1)} \in C(0, t_0; H^2)$ and $\psi_{0k} \in H^3$, there exists a unique-local solution $\psi_k^{(n)}$ to (6.12) satisfying

$$\psi_k^{(n)} \in C(0, t_0; H^3) \cap C^1(0, t_0; H^1) \cap L^2(0, t_0; H^4)$$

and $\sup_{y \in R_+ \times (0,t_0)} |\psi_k^{(n)}(y,t)| \leq C_1\varepsilon$.

Thus, if $(\|\phi_k^{(n-1)}\|_2, \|\psi_k^{(n-1)}\|_2) \leq C_1\varepsilon$, multiplying (6.12) by $\psi_k^{(n)}$ and integrating it over R_+, we have

$$\begin{aligned} &\|\psi_k^{(n)}\|_t^2 + \frac{\mu}{v_+}\|\psi_{ky}^{(n)}\|^2 \\ &\qquad \leq C(\varepsilon)(1 + \|\psi_k^{(n)}\|^2) + \frac{1}{4}\|\psi_{kyy}^{(n)}\|^2. \end{aligned} \tag{6.18}$$

Multiplying (6.12) by $-\psi_{kyy}^{(n)}$ and integrating it over $\mathbb{R}_+$, one has

$$\|\psi_{ky}^{(n)}\|_t^2 + \frac{\mu}{v_+}\|\psi_{kyy}^{(n)}(t)\|^2 \leq C(\varepsilon)(1 + \|\psi_{ky}^{(n)}\|^2). \tag{6.19}$$

Combining (6.18) and (6.19) gives, if T_0 is chosen suitably small,

$$\|\psi_k^{(n)}\|_1 \leq C_1\varepsilon \quad \text{if } t < T_0. \tag{6.20}$$

Differentiating (6.12) with respect to y, multiplying by $-\psi_{kyyy}^{(n)}$, and integrating over R_+, we have

$$\|\psi_{kyy}^{(n)}\|_t^2 + \frac{\mu}{v_+}\|\psi_{kyyy}^{(n)}(t)\|^2 + 2\psi_{kyt}^{(n)}\psi_{kyy}^{(n)}\Big|_{y=0} \leq C(\varepsilon). \tag{6.21}$$

Substituting (6.16), (6.17) into (6.12) yields, on the boundary $y = 0$,

$$\psi_{kyy}^{(n)} = e_1[\psi_{ky}^{(n)}]^2 + e_2\psi_{ky}^{(n)} + e_3, \tag{6.22}$$

where the coefficients e_i, $i = 1, 2, 3$, depend only on $\gamma_k^{(n-1)}$ and t. Thus the integration of (6.21) over $(0,t)$ and using (6.22) give

$$\|\psi_{kyy}^{(n)}\|^2 \leq C_1\varepsilon. \tag{6.23}$$

On the other hand, a direct estimate on (6.15) yields

$$\|\phi_k^{(n)}(t)\|_2 \leq C_1\varepsilon. \tag{6.24}$$

Therefore, $(\|\phi_k^{(n)}\|_2, \|\psi_k^{(n)}\|_2) \leq C_1\varepsilon$. From (6.13), it is easy to see that $\gamma_k^{(n)}(t) \in C^1([0, T_0])$ and $|\gamma_k^{(n)}(t)| \leq C_1\varepsilon(t - \tau) + \gamma_\tau \leq |\bar{s}|t$. By the classical method of the contraction mapping principle, $(\phi_k^{(n)}, \psi_k^{(n)})$ is a Cauchy sequence in $C(0, t_0; H^3)$. Thus we have a solution $(\phi_k(y,t), \psi_k(y,t))$, $\gamma_k(t)$ by letting n tend to infinity. In the same way, letting $k \to \infty$, we obtain the desired unique-local solution $(\phi(y,t), \psi(y,t), \gamma(t))$ to (6.4). We omit the details. ∎

7. A priori estimates. This section is devoted to the a priori estimates. Throughout this section, we use c, C to denote the positive constants which are independent of T, β, and α. We first rewrite the system (5.12) as

$$
\begin{cases}
\phi_t - (\bar{s}+\gamma')\phi_y - \psi_y = (V_T(y)-v_*)\gamma', \\
\psi_t - (\bar{s}+\gamma')\psi_y - f(V)\phi_y - \dfrac{\mu}{V}\psi_{yy} = F + G + (U_T(y)-u_*)\gamma', \\
(\phi,\psi)(y,0) = (\phi_0,\psi_0)(y), \\
\phi(0,t) = C(\gamma,t) + \phi_0(0) - \sigma(t), \\
\psi(0,t) = \psi_0(0) + \displaystyle\int_0^t D(\gamma,t)\psi_y(0,t)dt + \int_0^t E(\gamma,t)dt, \\
\gamma'(t) = \dfrac{1}{\bar{v}-v_b}(\psi_y(0,t) + U_s(0,t) - u_*), \quad \gamma(0) = 0,
\end{cases} \tag{7.1}
$$

where

$$
f(V) = f(V_s,V_T) = -p'(V) + \frac{h(V_s)}{V} + \frac{g(V_T)}{V}, \tag{7.2}
$$

$$
h(V_s) = \frac{\mu s V_s'}{V_s}, \qquad g(V_T) = \frac{\mu\bar{s}V_T'}{V_T}, \tag{7.3}
$$

$$
\begin{aligned}
F = &-\{p(V+\phi_y) - p(V) - p'(V)\phi_y\} \\
&+ (h(V_s)\phi_y + g(V_T)\phi_y)\left(\frac{1}{V+\phi_y} - \frac{1}{V}\right) + \mu\psi_{yy}\left(\frac{1}{V+\phi_y} - \frac{1}{V}\right),
\end{aligned} \tag{7.4}
$$

$$
G = -\{p(V) - p(V_s) - p(V_T) + p(v_*)\} + h(V_s)\frac{V_T - v_*}{V+\phi_y} + g(V_T)\frac{V_s - v_*}{V+\phi_y}. \tag{7.5}
$$

It is easy to see that

$$
|F| = O(|\phi_y|^2 + |\phi_y|\cdot|\psi_{yy}|). \tag{7.6}
$$

Proposition 7.1 (a priori estimates). *There exist positive constants δ_0 and $C_2 > 0$ such that if $0 < v_* - v_b = \delta < \delta_0$ and $(\phi,\psi) \in X([0,T])$, $\gamma(t) \in C^1[0,T]$ is a solution of (7.1) for some positive T satisfying $|\gamma(t)| \le |\bar{s}|t$ and $(N(T), e^{-\frac{1}{5}c_-\beta}) = O(\delta)$, then (ϕ,ψ) satisfies the a priori estimates*

$$
\|(\phi,\psi)(t)\|_2^2 + \int_0^t \{\|\phi_y\|_1^2 + \|\psi_y\|_2^2\}d\tau \le C_2(\delta^{-2}\|(\phi_0,\psi_0)\|_2^2 + \delta^2), \tag{7.7}
$$

$$
\int_0^t \left|\frac{d}{dt}\|\phi_y\|^2\right| + \left|\frac{d}{dt}\|\psi_y\|^2\right| d\tau \le C_2(\delta^{-2}\|(\phi_0,\psi_0)\|_2^2 + \delta^2). \tag{7.8}
$$

Before proving Proposition 7.1, we first give some lemmas.

Lemma 7.2. *For $0 \le t \le T$, the following holds:*

$$
\begin{gathered}
\psi(0,t) = -\bar{s}\phi(0,t) + \frac{A(t) + s\sigma(t)}{v_* - \bar{v}}, \\
\phi_y(0,t) = v_* - V_s(0,t), \\
\psi_{yy}(0,t) = A_1\psi_y(0,t)^2 + A_2(t)\psi_y(0,t) + A_3(t),
\end{gathered} \tag{7.9}
$$

$$
(|A(t)|, |A'(t)|, |\sigma(t)|, |\sigma'(t)|) \le Ce^{-c_-(st+\beta)}, \quad \bar{s} < 0, \quad |\bar{s}| = O(\delta^{\frac{1}{2}}),
$$

$$
\begin{aligned}
&\phi(0,t)\psi(0,t) \geq -\frac{3}{4}\bar{s}\phi(0,t) - Ce^{-c_-(st+\beta)},\\
&\psi(0,t)^2 \leq C\delta\phi^2(0,t) + Ce^{-c_-(st+\beta)},\\
&\delta^{\frac{1}{2}}\gamma'^2 \leq \varepsilon_3\|\psi_y\|^2 + C(\varepsilon_3)\delta\|\psi_{yy}\|^2 + Ce^{-c_-(st+\beta)},\\
&\phi_y(0,t)^2 \leq Ce^{-c_-(st+\beta)}, \quad |\psi(0,t)\phi_y(0,t)| \leq C(\psi(0,t)^2 + \phi_y(0,t)^2),\\
&|\psi_y(0,t)\psi(0,t)| \leq \varepsilon_3(\delta^{\frac{1}{2}}\phi(0,t)^2 + \|\psi_y\|^2)\\
&\qquad\qquad + C(\varepsilon_3)(\delta\|\psi_{yy}\|^2 + \delta^{-\frac{1}{2}}e^{-c_-(st+\beta)}),\\
&\psi_y(0,t)\psi_t(0,t) \geq \frac{u_*}{2(v_b-\bar{v})}\psi_y(0,t)^2 - Ce^{-c_-(st+\beta)} - C\delta^2\gamma'^2,
\end{aligned}
\tag{7.10}
$$

where ε_3 is an arbitrary positive constant and

$$
\begin{aligned}
&A_1 = \frac{v_b}{\mu(v_b-\bar{v})}, \qquad A_2(t) = \frac{2(u_b + U_s(0,t) - u_*)v_b}{\mu(v_b-\bar{v})},\\
&A_3(t) = \frac{v_b(u_b + U_s(0,t) - u_*)^2 - v_b u_b^2}{\mu(v_b-\bar{v})} - U_{sy}(0,t).
\end{aligned}
$$

Proof. In view of the boundary conditions of (7.1), we have (3.28) because α is determined by (3.27). By (3.28), we get

$$
u_*\phi(0,t) - (v_* - \bar{v})\psi(0,t) = -A(t) - s\sigma(t), \tag{7.11}
$$

which is equivalent to the first term of (7.9). It is noted that our boundary conditions of the reformulated system (7.1) are derived from the original boundary conditions of (3.3). To the contrary, it is easy to verify that (3.3) holds from (7.1). By the boundary conditions of (3.3), the other terms of (7.9) are easily proved.

On the other hand, the first term of (7.10) is easy from Lemmas 2.1–2.2, (3.20), and (3.28) because α is small due to Proposition 5.1. For the fourth term of (7.10), we compute by (7.1) and Lemma 2.2

$$
\begin{aligned}
\delta^{\frac{1}{2}}\gamma'^2 &\leq \delta^{\frac{1}{2}}(\psi_y^2(0,t) + Ce^{-c_-(st+\beta)})\\
&\leq \varepsilon_3\|\psi_y\|^2 + C(\varepsilon_3)\delta\|\psi_{yy}\|^2 + Ce^{-c_-(st+\beta)}.
\end{aligned}
$$

In a similar way, we can also get the other terms of (7.10). We omit the proofs here. ∎

Let $x' = \bar{s} + \gamma'$; then $0 > x' \geq -\frac{1}{2}\bar{s}$ and $|x'| = O(\delta^{\frac{1}{2}})$. We now establish the a priori estimates.

LEMMA 7.3. *There exists a positive constant δ_0 which depends only on $\bar{v}$, v_b, and v_+. For any given $0 < v_* - v_b = \delta < \delta_0$, the following holds:*

$$
\begin{aligned}
&\|(\phi,\psi)(t)\|^2 + \int_0^t \|\psi_y\|^2 d\tau + \int_0^t\int_0^\infty V_{sy}\psi^2 dydt + \int_0^t \delta^{\frac{1}{2}}\phi^2(o,t)dt\\
&\leq C\left\{\|(\phi_0,\psi_0)\|^2 + \delta^4 + \delta^2\int_0^t \|\phi_y\|^2 d\tau\right.\\
&\qquad \left. + \delta\int_0^t \|\psi_{yy}\|^2 dt + N(T)\int_0^t [\|\phi_y\|^2 + \|\psi_{yy}\|^2]d\tau\right\}.
\end{aligned}
\tag{7.12}
$$

Proof. Multiplying $(7.1)_1$ by ϕ and $(7.1)_2$ by $f(V)^{-1}\psi$, then we have

$$\begin{aligned}&\left(\frac{1}{2}\phi^2\right)_t-\left(\frac{x'}{2}\phi^2\right)_y-(\phi\psi)_y+\left(\frac{1}{2f(V)}\psi^2\right)_t-\left(\frac{1}{2f(V)}\right)_t\psi^2-\frac{x'}{2}\left(\frac{\psi^2}{f(V)}\right)_y\\&+\frac{x'}{2}\psi^2\left(\frac{1}{f(V)}\right)_y-\left(\frac{\mu}{Vf(V)}\psi_y\psi\right)_y+\frac{\mu}{Vf(V)}\psi_y^2+\left(\frac{\mu}{Vf(V)}\right)_y\psi_y\psi\\&=(F+G)\psi f(V)^{-1}+\gamma'(V_T(y)-v_*)\phi+\gamma'(U_T(y)-u_*)\psi f(V)^{-1}.\end{aligned}\tag{7.13}$$

By the definition of $f(V)$ and Lemma 2.1, one has

$$\begin{aligned}&\left|\left(\frac{\mu}{Vf(V)}\right)_y\psi_y\psi\right|\\&\le\left|\frac{\mu|K'(V_s)|+C\delta}{(Vf(V))^2}V_{sy}\psi_y\psi\right|+C(|V_T'|+|\bar{s}V_T''|)|\psi_y\psi|\\&\le\bar{\varepsilon}\frac{\mu}{Vf(V)}\psi_y^2+\frac{\mu K'(V_s)^2+C\delta}{4\bar{\varepsilon}K(V_s)^3}V_{sy}^2\psi^2+C(|V_T'|^2+\bar{s}^2|V_T''|^2)\psi^2,\end{aligned}\tag{7.14}$$

for any $\bar{\varepsilon}>0$ which will be determined later, where

$$K(V_s)=-p'(V_s)V_s+h(V_s).$$

Substituting this inequality into (7.13) yields

$$\begin{aligned}&\left\{\frac{1}{2}\phi^2+\frac{1}{2f(V)}\psi^2\right\}_t+(Z(V_s)-C\delta)V_{sy}\psi^2+(1-\bar{\varepsilon})\frac{\mu}{Vf(V)}\psi_y^2\\&\quad-\left\{\frac{x'}{2}\phi^2+\phi\psi+\frac{\mu}{Vf(V)}\psi_y\psi+\frac{x'}{2f(V)}\psi^2\right\}_y\\&\le(F+G)\psi f(V)^{-1}+\gamma'(V_T(y)-v_*)\phi\\&\quad+\gamma'(U_T(y)-u_*)\psi f(V)^{-1}+C(\delta^{\frac{1}{2}}V_T'+\delta|V_T''|)\psi^2,\end{aligned}\tag{7.15}$$

where

$$Z(V_s)=\frac{s}{2}\frac{K(V_s)-V_sK'(V_s)}{K(V_s)^2}-\frac{\mu K'(V_s)^2V_{sy}}{4\bar{\varepsilon}K(V_s)^3}.\tag{7.16}$$

Let $1\le\gamma\le3$; if we choose

$$\max\left\{\frac{(\gamma-1)^2(v_+-v_*)}{2\gamma v_*},\frac{1}{2}\right\}\le\bar{\varepsilon}<1,\tag{7.17}$$

then by the argument of [3, 12] we have

$$Z(V_s)\ge C_3>0.\tag{7.18}$$

Thus integration of (7.15) over $[0,+\infty)\times[0,t]$ yields, if $\delta<\frac{1}{2}C_3$,

$$\int_0^{+\infty}\left\{\frac{\phi^2}{2}+\frac{\psi^2}{2f(V)}\right\}dy+\int_0^t\int_0^{+\infty}\frac{1}{2}Z(V_s)V_{sy}\psi^2dyd\tau$$

$$
\begin{aligned}
&+\int_0^t\int_0^{+\infty}\frac{\mu\psi_y^2}{2Vf(V)}dyd\tau+\int_0^t\left[\frac{x'}{2}\phi^2+\phi\psi\right](0,t)dt\\
&\le C\int_0^{+\infty}\{\phi_0^2+\psi_0^2\}dy+\left|\int_0^t\left[\frac{\mu\psi_y\psi}{Vf(V)}+\frac{x'}{2f(V)}\psi^2\right](0,t)d\tau\right|\\
&+C\int_0^t\int_0^{+\infty}(|F|+|G|)|\psi|dyd\tau+C\delta^{\frac12}\int_0^t\int_0^{\infty}(V_T'+\delta^{\frac12}|V_T''|)\psi^2dyd\tau\\
&+\int_0^t\int_0^{+\infty}\gamma'(V_T(y)-v_*)\phi+\gamma'(U_T(y)-u_*)\psi f(V)^{-1}dyd\tau.
\end{aligned}\tag{7.19}
$$

We estimate the right-hand sides of (7.19). We compute

$$
\begin{aligned}
&\int_0^\infty\int_0^\infty|G|dydt\\
&\le\int_0^\infty\int_0^\infty|V_s(y+x(t)-st+\alpha-\beta)-v_*||V_T(y)-v_*|dydt\\
&\le C\int_0^\infty\int_0^{st+\beta-\alpha-x(t)}\delta e^{-c_0\frac{y}{\sqrt\delta}}e^{-c_-|y+x(t)-st+\alpha-\beta|}dydt\\
&\quad+C\int_0^\infty\int_{st+\beta-\alpha-x(t)}^\infty\delta e^{-c_0\frac{y}{\sqrt\delta}}dydt\le C\delta e^{-c_-\beta}\le C\delta^6,
\end{aligned}\tag{7.20}
$$

$$
\begin{aligned}
&\int_0^\infty(V_T'+\delta^{\frac12}|V_T''|)\psi^2dy\le C\int_0^\infty(V_T'+\delta^{\frac12}|V_T''|)(\psi^2(0,t)+y\|\psi_y\|^2)dy\\
&\le C\delta\psi^2(0,t)+C\delta^{\frac32}\|\psi_y\|^2,
\end{aligned}\tag{7.21}
$$

and

$$
\begin{aligned}
&\int_0^\infty|\gamma'(V_T(y)-v_*)\phi|dy\\
&\le C\int_0^\infty|\gamma'(V_T(y)-v_*)|(|\phi(0,t)|+y^{\frac12}\|\phi_y\|)dy\\
&\le C\delta^{\frac32}(\gamma'^2+\phi^2(0,t))+C\delta^2\|\phi_y\|^2.
\end{aligned}\tag{7.22}
$$

Similar to (7.22), we also have

$$
\int_0^\infty|\gamma'(U_T(y)-u_*)\psi f(V)^{-1}|dy\le C\delta^2(\|\psi_y\|^2+\gamma'^2+\psi^2(0,t)).\tag{7.23}
$$

We now estimate the terms from the boundary. We calculate from (7.10)

$$
\frac{x'}{2}\phi^2+\phi\psi\ge-\frac14\bar s\phi^2(0,t)-Ce^{-c_-(st+\beta)}\ge c_1\delta^{\frac12}\phi^2(0,t)-Ce^{-c_-(st+\beta)},\tag{7.24}
$$

$$
\begin{aligned}
&\left|\frac{\mu}{Vf(V)}\psi_y(0,t)\psi(0,t)\right|\\
&\le\varepsilon_3(\delta^{\frac12}\phi(0,t)^2+\|\psi_y\|^2)+C(\varepsilon_3)(\delta\|\psi_{yy}\|^2+\delta^{-\frac12}e^{-c_-(st+\beta)}).
\end{aligned}\tag{7.25}
$$

Since $e^{-c_-\beta}=O(\delta^5)$, we have

$$
\delta^{-\frac12}e^{-c_-\beta}\le C\delta^4.\tag{7.26}
$$

Thus there exists a positive constant $\delta_0 > 0$. For any $\delta < \delta_0$, if we choose $\varepsilon_3 \le \frac{1}{2}c_1$, then the estimate (7.12) holds from (7.6), (7.10), and (7.19)–(7.26). Hence Lemma 7.3 is proved. □

LEMMA 7.4. *It follows that*

$$\begin{aligned}\|\phi_y\|^2 + \int_0^t \|\phi_y\|^2 d\tau \le C\delta \int_0^t \|\psi_{yy}\|^2 dt \\ + C\left\{\|(\phi_0,\psi_0)\|_1^2 + \delta^4 + N(T)\int_0^t [\|\phi_y\|^2 + \|\psi_y\|_1^2]d\tau\right\}.\end{aligned} \tag{7.27}$$

Proof. From the system (7.1), we have

$$\begin{aligned}\frac{\mu}{V}\phi_{yt} - x'\frac{\mu}{V}\phi_{yy} + f(V)\phi_y + x'\psi_y \\ = \psi_t - F - G + \frac{\mu}{V}\gamma' V_T' - \gamma'(U_T(y) - u_*).\end{aligned} \tag{7.28}$$

Multiplying (7.28) by ϕ_y yields

$$\begin{aligned}\left(\frac{\mu}{2V}\phi_y^2\right)_t - \frac{(s-x')\mu}{2V^2}V_{sy}\phi_y^2 - \left\{x'\frac{\mu}{2V}\phi_y^2\right\}_y - \frac{\mu x'}{2V^2}V_y\phi_y^2 + f(V)\phi_y^2 + x'\psi_y\phi_y \\ = \psi_t\phi_y - (F+G)\phi_y + \frac{\mu}{V}\gamma' V_T'\phi_y - \gamma'(U_T(y) - u_*)\phi_y.\end{aligned} \tag{7.29}$$

The system $(7.1)_1$ gives

$$\begin{aligned}\psi_t\phi_y = (\psi\phi_y)_t - \psi\phi_{yt} = (\psi\phi_y)_t - \psi(x'\phi_{yy} + \psi_{yy} + \gamma' V_T') \\ = (\psi\phi_y)_t - (x'\psi\phi_y)_y - (\psi\psi_y)_y - \gamma'\psi V_T' + x'\psi_y\phi_y + \psi_y^2,\end{aligned} \tag{7.30}$$

and Lemma 2.1 and the Cauchy inequality yield

$$|\gamma'(U_T(y) - u_*)\phi_y| \le C\delta\phi_y^2 + C\delta^2\gamma'^2 e^{-\frac{c_0}{\sqrt{\delta}}y}. \tag{7.31}$$

Substituting (7.30)–(7.31) into (7.29), we get

$$\begin{aligned}\left(\frac{\mu}{2V}\phi_y^2 - \psi\phi_y\right)_t + \left(f(V) - \frac{h(V_s)}{2V} - C\delta^{\frac{1}{2}}\right)\phi_y^2 + \left\{\psi\psi_y + x'\psi\phi_y - \frac{\mu x'}{2V}\phi_y^2\right\}_y \\ \le \psi_y^2 - (F+G)\phi_y + \frac{\mu}{V}\gamma' V_T'\phi_y - \gamma' V_T'\psi + C\delta^2\gamma'^2 e^{-\frac{c_0}{\sqrt{\delta}}y}.\end{aligned} \tag{7.32}$$

Note that (7.2) gives

$$f(V) - \frac{h(V_s)}{2V} > -p'(V) \ge -p'(v_+), \tag{7.33}$$

and the boundary terms of (7.32) are investigated in Lemma 7.2. Thus integrating (7.32) over $[0,+\infty)\times[0,t]$ and using (7.6), (7.20), Lemmas 7.2–7.3, and the inequalities

$$\int_0^{+\infty} |\psi\phi_y| dy \le \frac{\mu}{4v_+}\|\phi_y(t)\|^2 + \frac{v_+}{\mu}\|\psi\|^2, \tag{7.34}$$

$$\int_0^{\infty} \left|\frac{\mu}{V}\gamma' V_T'\phi_y\right| dy \le C\delta^{\frac{1}{2}}\|\phi_y\|^2 + C\delta\gamma'^2, \tag{7.35}$$

$$\int_0^{\infty} |\gamma' V_T'\psi| dy \le C\delta(\gamma'^2 + \psi(0,t)^2) + C\delta^{\frac{3}{2}}\|\psi_y\|^2, \tag{7.36}$$

we get (7.27). Thus Lemma 7.4 is proved. □

LEMMA 7.5. *It follows that*

$$\begin{aligned}\|\psi_y(t)\|^2 + \int_0^t \|\psi_{yy}\|^2 d\tau + \delta^{\frac{1}{2}} \int_0^t \psi_y(0,t)^2 dt \\ \le C\left\{ \|(\phi_0,\psi_0)\|_1^2 + \delta^4 + N(T)\int_0^t \left[\|\phi_y(\tau)\|^2 + \|\psi_y(\tau)\|_1^2\right] d\tau \right\}.\end{aligned} \tag{7.37}$$

Proof. Multiplying $(7.1)_2$ by $-\psi_{yy}$, one obtains

$$\begin{aligned}(-\psi_y\psi_t)_y + \left(\frac{\psi_y^2}{2}\right)_t + \left(\frac{x'}{2}\psi_y^2\right)_y + f(V)\phi_y\psi_{yy} + \frac{\mu}{V}\psi_{yy}^2 \\ = -(F+G)\psi_{yy} - \gamma'(U_T(y)-u_*)\psi_{yy}.\end{aligned} \tag{7.38}$$

The Cauchy inequality yields

$$|f(V)\phi_y\psi_{yy}| \le \frac{\mu}{4v_+}\psi_{yy}^2 + C\phi_y^2, \tag{7.39}$$

and (7.6) and the Cauchy inequality yield

$$|F\psi_{yy}| \le C(|\phi_y|^2 + |\phi_y|\cdot|\psi_{yy}|)|\psi_{yy}| \le C|\phi_y|(|\phi_y|^2 + |\psi_{yy}|^2), \tag{7.40}$$

$$|G\psi_{yy}| \le \frac{\mu}{4v_+}\psi_{yy}^2 + C|G|, \tag{7.41}$$

$$|\gamma'(U_T(y)-u_*)\psi_{yy}| \le \frac{\mu}{4v_+}\psi_{yy}^2 + C\delta^3{\gamma'}^3 e^{-\frac{c_0}{\sqrt{\delta}}y}. \tag{7.42}$$

Substituting (7.39)–(7.42) into (7.38), we have

$$\begin{aligned}\frac{1}{2}(\psi_y^2)_t + \left\{\frac{x'}{2}\psi_y^2 - \psi_y\psi_t\right\}_y + \frac{\mu}{4v_+}\psi_{yy}^2 \\ \le C\phi_y^2 + C|\phi_y|(|\phi_y|^2 + |\psi_{yy}|^2) + C\delta^3{\gamma'}^3 e^{-\frac{c_0}{\sqrt{\delta}}y}.\end{aligned} \tag{7.43}$$

The boundary terms of (7.43) are estimated in Lemma 7.2. Thus integrating (7.43) over $[0,+\infty)\times[0,t]$ and using Lemmas 7.2 and 7.4 and the fact that $x' < 0$, we get the estimate (7.37). □

From Lemmas 7.3–7.5, we get the following inequality.

LEMMA 7.6. *It follows that*

$$\|(\phi,\psi)(t)\|_1^2 + \int_0^t \left\{\|\phi_y\|^2 + \|\psi_y\|_1^2\right\} d\tau \le C\{\|(\phi_0,\psi_0)\|_1^2 + \delta^4\}. \tag{7.44}$$

LEMMA 7.7. *It follows that*

$$\begin{aligned}\|\phi_{yy}(t)\|^2 + \int_0^t \|\phi_{yy}\|^2 d\tau \le C\delta^{-2}\{\|(\phi_0,\psi_0)\|_2^2 + \delta^4\} \\ + C\left\{\int_0^t \|F_y\|^2 d\tau + \delta\int_0^t \|\psi_{yyy}\|^2 d\tau\right\}.\end{aligned} \tag{7.45}$$

Proof. Differentiating (7.28) with respect to y, one gets

$$\begin{aligned}&\frac{\mu}{V}\phi_{yyt}-\frac{\mu V_y}{V^2}\phi_{yt}-x'\frac{\mu}{V}\phi_{yyy}+x'\frac{\mu V_y}{V^2}\phi_{yy}+f(V)\phi_{yy}+f(V)_y\phi_y+x'\psi_{yy}\\&\quad=\psi_{yt}-F_y-G_y+\frac{\mu}{V}\gamma' V_T''-\frac{\mu V_y}{V^2}\gamma' V_T'-\gamma' U_T'.\end{aligned}\tag{7.46}$$

Multiplying (7.46) by ϕ_{yy}, we have

$$\begin{aligned}&\left(\frac{\mu}{2V}\phi_{yy}^2\right)_t+\left(f(V)-\frac{h(V_s)}{2V}-C\delta^{\frac12}\right)\phi_{yy}^2-\left(\frac{x'\mu}{2V}\phi_{yy}^2\right)_y\\&\quad-\frac{\mu V_y}{V^2}\phi_{yt}\phi_{yy}+f(V)_y\phi_{yy}\phi_y+x'\psi_{yy}\phi_{yy}\\&\quad\le\psi_{yt}\phi_{yy}-(F_y+G_y)\phi_{yy}+\left(\frac{\mu}{V}\gamma' V_T''-\frac{\mu V_y}{V^2}\gamma' V_T'-\gamma' U_T'\right)\phi_{yy}.\end{aligned}\tag{7.47}$$

Using Lemmas 2.1 and 7.2 and the Cauchy inequality, we obtain

$$\begin{aligned}\left|\frac{\mu V_y}{V^2}\phi_{yt}\phi_{yy}\right|&=\left|\frac{\mu V_y}{V^2}(x'\phi_{yy}+\psi_{yy}+\gamma' V_T')\phi_{yy}\right|\\&\le\frac18|p'(v_+)|\phi_{yy}^2+C(\psi_{yy}^2+\delta^{\frac12}\gamma'^2V_T'),\end{aligned}\tag{7.48}$$

$$|f(V)_y\phi_{yy}\phi_y|\le\frac18|p'(v_+)|\phi_{yy}^2+C\phi_y^2,\tag{7.49}$$

$$|F_y\phi_{yy}|\le\frac18|p'(v_+)|\phi_{yy}^2+C|F_y|^2,\tag{7.50}$$

$$\begin{aligned}\psi_{yt}\phi_{yy}&=(\psi_y\phi_{yy})_t-\psi_y\phi_{yyt}=(\psi_y\phi_{yy})_t-(\psi_y\phi_{yt})_y+\phi_{yt}\psi_{yy}\\&=(\psi_y\phi_{yy})_t-(\psi_y\phi_{yt})_y+x'\phi_{yy}\psi_{yy}+\psi_{yy}^2+\gamma' V_T'\psi_{yy},\end{aligned}\tag{7.51}$$

$$\left|\left(\frac{\mu}{V}\gamma' V_T''-\frac{\mu V_y}{V^2}\gamma' V_T'-\gamma' U_T'\right)\phi_{yy}\right|\le\frac18|p'(v_+)|\phi_{yy}^2+C\gamma'^2e^{-\frac{c_0}{\sqrt\delta}y}.\tag{7.52}$$

Substituting (7.48)–(7.52) into (7.47), we have

$$\begin{aligned}&\left(\frac{\mu}{2V}\phi_{yy}^2-\psi_y\phi_{yy}\right)_t+\frac14|p'(v_+)|\phi_{yy}^2+\left(\psi_y\phi_{yt}-\frac{x'\mu}{2V}\phi_{yy}^2\right)_y\\&\quad\le2\psi_{yy}^2+C\gamma'^2e^{-\frac{c_0}{\sqrt\delta}y}+C|G_y|^2.\end{aligned}\tag{7.53}$$

Similar to (7.20), we have

$$|G_y|\le H+C\delta\phi_{yy},\tag{7.54}$$

where H satisfies

$$\int_0^t\int_0^\infty|H|dydt\le C\delta^{\frac12}e^{-c_-\beta}\le C\delta^5.\tag{7.55}$$

Since

$$\phi_{yy}|_{y=0}=\frac{1}{x'}(\phi_{yt}-\psi_{yy}-\gamma' V_T')|_{y=0},$$

Lemma 7.2 and the Cauchy inequality yield

$$\left|\frac{x'\mu}{2V}\phi_{yy}(0,t)^2\right| \le C(\delta^{\frac{1}{2}}\gamma'^2 + \delta^4 e^{-c_- st} + \delta^{-2}\|\psi_{yy}\|^2 + \delta\|\psi_{yyy}\|^2), \tag{7.56}$$

where we have used the fact that $\phi_{yt} = -V_s'(0,t)$. Note that $|\psi_y\phi_{yt}|(0,t)$ is controlled by $\delta\psi_y(0,t)^2$ and $\delta^{-1}\phi_{yt}(0,t)^2$. Thus integrating (7.53) over $[0,+\infty)\times[0,t]$ and making use of Lemmas 7.2 and 7.6 and (7.54)–(7.56), we obtain the inequality (7.45). Lemma 7.7 is proved. ∎

LEMMA 7.8. *It follows that*

$$\begin{aligned}&\|\psi_{yy}(t)\|^2 + \int_0^t \|\psi_{yyy}\|^2 d\tau \\ &\quad\le C\delta^{-2}\{\|(\phi_0,\psi_0)\|_2^2 + \delta^4\} + C\int_0^t \|F_y(\tau)\|^2 d\tau.\end{aligned} \tag{7.57}$$

Proof. Differentiating $(7.1)_2$ with respect to y and multiplying the derivative by $-\psi_{yyy}$, we have

$$\begin{aligned}&\left(\frac{1}{2}\psi_{yy}^2\right)_t + \left(\frac{x'}{2}\psi_{yy}^2 - \psi_{yt}\psi_{yy}\right)_y + f(V)\phi_{yy}\psi_{yyy} + f(V)_y\phi_y\psi_{yyy} \\ &\quad + \frac{\mu}{V}\psi_{yyy}^2 - \frac{\mu}{V^2}V_y\psi_{yy}\psi_{yyy} = -(F_y + G_y + \gamma' U_T')\psi_{yyy}.\end{aligned} \tag{7.58}$$

The Cauchy inequality and Lemma 2.1 yield

$$|f(V)\phi_{yy}\psi_{yyy}| \le C|\phi_{yy}|^2 + \frac{\mu}{8v_+}|\psi_{yyy}|^2, \tag{7.59}$$

$$|f(V)_y\phi_y\psi_{yyy}| \le C|\phi_y|^2 + \frac{\mu}{8v_+}|\psi_{yyy}|^2, \tag{7.60}$$

$$(|F_y| + |G_y|)|\psi_{yyy}| \le C\left(|F_y|^2 + G_y^2 + \frac{\mu}{8v_+}|\psi_{yyy}|^2\right), \tag{7.61}$$

$$|\gamma' U_T'\psi_{yyy}| \le C\delta^3\gamma'^2 e^{-\frac{c_0}{\sqrt{\delta}}y} + \frac{\mu}{8v_+}|\psi_{yyy}|^2. \tag{7.62}$$

On the other hand, Lemma 7.2 yields, on the boundary $y = 0$,

$$\begin{aligned}\psi_{yt}\psi_{yy} &= \psi_{yt}(A_1\psi_y^2 + A_2(t)\psi_y + A_3(t)) \\ &= \left(\frac{A_1}{3}\psi_y^3 + \frac{A_2(t)}{2}\psi_y^2 + A_3(t)\psi_y\right)_t - \frac{A_2'(t)}{2}\psi_y^2 - A_3'(t)\psi_y.\end{aligned} \tag{7.63}$$

Here $A_2(t) > 0$ because β is large and $(|A_2'(t)|, |A_3'(t)|) \le Ce^{-c_-(st+\beta)}$.

Substituting (7.54), (7.55), and (7.59)–(7.63) into (7.58), integrating it over $[0,+\infty)\times[0,t]$, and making use of Lemmas 7.6 and 7.7 and the fact that $x' < 0$, we obtain the inequality (7.57). Lemma 7.8 is proved. ∎

Proof of Proposition 7.1. By using the Sobolev embedding theorem and (7.4), we have

$$\begin{aligned}\|F_y\|^2 &\le C\int_0^{+\infty}(\phi_y^4 + \phi_y^2\phi_{yy}^2 + \psi_{yy}^2\phi_{yy}^2 + \psi_{yyy}^2\phi_y^2 + \phi_y^2\psi_{yy}^2)dy \\ &\le C\sup_{y\in\Re_+}\left[\phi_y^2\int_0^{+\infty}(\phi_y^2 + \phi_{yy}^2 + \psi_{yyy}^2 + \psi_{yy}^2)dy + \psi_{yy}^2\int_0^{+\infty}\phi_{yy}^2\,dy\right] \\ &\le CN(T)(\|\phi_y\|_1^2 + \|\psi_y\|_2^2),\end{aligned} \tag{7.64}$$

which, together with Lemmas 7.3–7.8, yields the inequality (7.7). To prove the inequality (7.8), we differentiate the system $(7.1)_1$ with respect to y, multiply it by ϕ_y, and integrate the resulting equality with respect to y to get

$$\frac{d}{dt}\|\phi_y(t)\|^2 = 2\int_0^{+\infty} \psi_{yy}\phi_y dy + 2x'\int_0^{+\infty} \phi_y\phi_{yy}dy + 2\int_0^{\infty} \gamma' V_T'\phi_y dy. \tag{7.65}$$

Integrating (7.65) over $[0,+\infty)$, we get (7.8) for ϕ due to (7.7). In the same way, we can also prove (7.8) for ψ. Proposition 7.1 is proved. □

THEOREM 7.9. *Suppose that the assumptions of Theorem* 4.1 *hold; then the initial-boundary value problem* (7.1) *has a unique global solution* $(\phi,\psi)\in X([0,+\infty))$, $\gamma(t)\in C^1[0,\infty)$ *satisfying the inequalities* (7.7) *and* (7.8) *for any* $t\geq 0$. *Moreover, the solution is asymptotically stable:*

$$\lim_{t\to\infty}\sup_{y\in\Re_+}|(\phi_y,\psi_y)(y,t)| = 0, \qquad \lim_{t\to\infty}\gamma(t) = \Gamma,$$

where Γ *is determined by* (4.11).

Proof. The assumption (4.6) gives $\|\phi_0,\psi_0\|_2 < C_4\delta^2 \leq \varepsilon_4 = \sqrt{C_2(1+C_4^2)}\delta$ due to Proposition 5.1. From Proposition 6.1, there exists a positive time $T_0 = T_0(\varepsilon_4) > 0$ such that a unique local solution $(\phi,\psi)(y,t)$, $\gamma(t)$ of (7.1) exists in $[0,T_0]$ satisfying $(\|\phi\|_2,\|\psi\|_2) \leq C_1C_4\delta^2 \leq \sqrt{C_2(1+C_4^2)}\delta$ and $|\gamma(t)| \leq |\bar{s}|t$. We now assume that for some positive integer $n>1$ there exists a unique local solution $(\phi,\psi)(y,t)$, $\gamma(t)$ of (7.1) in $[0,(n-1)T_0]$ satisfying $(\|\phi\|_2,\|\psi\|_2)(t)\leq\sqrt{C_2(1+C_4^2)}\delta$ and $|\gamma(t)|\leq|\bar{s}|t$. From Proposition 6.1, we know the solution (ϕ,ψ), $\gamma(t)$ can be extended to the interval $[(n-1)T_0,nT_0]$. Furthermore, Proposition 7.1 yields $(\|\phi\|_2,\|\psi\|_2)(t)\leq\sqrt{C_2(1+C_4^2)}\delta = \varepsilon_4$, and $|\gamma(t)|\leq|\bar{s}|t$ still hold when $t\in[(n-1)T_0,nT_0]$. Repeating the above argument, we get the existence of a unique global solution $(\phi,\psi)\in X([0,+\infty))$, $\gamma(t)\in C^1[0,\infty)$ satisfying the inequalities (7.7) and (7.8) for any $t\geq 0$. By (7.7), $\|(\phi_y,\psi_y)(t)\|_1$ tends to zero as time tends to infinity. By the Sobolev embedding theorem, we obtain

$$\sup_{y\in\Re_+}|(\phi_y,\psi_y)(y,t)|\to 0 \quad \text{as } t\to+\infty. \tag{7.66}$$

On the other hand, the boundary condition (5.9) yields

$$\gamma(t)(v_*-\bar{v}) = -\phi(0,t) - (s-\bar{s})\int_0^t [v_* - \bar{V}_s(0,t)]dt + \phi_0(0) - \sigma(t). \tag{7.67}$$

It is noted that $|\phi(0,t)|\leq\|\phi\|_1$ and $\sigma(t)$ tend to zero when $t\to\infty$ due to (7.7) and Lemma 7.2. From (7.67), we have

$$\begin{aligned}\lim_{t\to\infty}\gamma(t) = \Gamma = \frac{1}{\bar{v}-v_*}\Big\{&(s-\bar{s})\int_0^{\infty}[v_* - V_s(\bar{s}t - st + \alpha - \beta)]dt \\ &+ \int_0^{\infty}[v_0(y) - V_T(y) - V_s(y+\alpha-\beta) + v_*]dy\Big\}.\end{aligned} \tag{7.68}$$

Proof of Theorem 4.1. From Theorem 7.9, Theorem 4.1 is obtained at once. □

PLANE-LIKE MINIMAL SURFACES IN PERIODIC MEDIA WITH EXCLUSIONS*

MONICA TORRES†

Abstract. We consider minimal surfaces in a medium with exclusions (voids). This extends the results given in [*Comm. Pure Appl. Math.*, 54 (2001), pp. 1403–1441] to the case of a degenerate metric such that the area of a surface of codimension 1 is measured by neglecting the parts inside the exclusions. We prove that, given any plane in the medium, there is at least one minimal surface that always stays at a bounded distance from the plane. We also explore the connections of this problem with the theory of homogenization of Hamilton–Jacobi equations.

Key words. minimal surfaces, sets of finite perimeter, homogenization, periodic media

AMS subject classification. 35R99

1. Introduction.

The recent results in [14] consider a generalization of the problem of minimal surfaces in periodic media and show that, given a metric with periodic coefficients, there exists a number M so that one can find a minimizer in any strip of width M. The width M is independent of the orientation of the strip. Moreover, the minimizers constructed in [14] have the property that, when folded to the fundamental domain, they are laminations. For a discussion on the history of the problem of constructing minimizers that are asymptotic to a plane we refer the reader to [14] and the references therein.

The goal of this paper is to extend the results of [14] to a situation where the medium has exclusions, i.e., regions for which the metric vanishes. We also discuss the behavior of the minimizers near the exclusions, which is an issue not considered in [14]. Since similar situations of media with exclusions appear naturally in the theory of homogenization, we consider in this paper the relation of the minimizers with the theory of homogenization, and we develop several explicit calculations.

We recall that minimal surfaces can be studied using geometric measure theory (see, e.g., [26, 34]) in which the surfaces are interpreted as currents, i.e., dual to forms. Then the laminations can be interpreted as homologically minimizing currents (see, for instance, [6, 5, 4]). One can also study minimal surfaces by considering the surfaces as boundaries of sets in which the perimeter is defined in a weak sense (see, e.g., [27]).

In this paper we will follow the approach of locally finite perimeter sets, which is the one followed in [14]. For the problem considered in this paper, this approach is more advantageous because the fundamental domain is a manifold with boundary, and the theory of homologically minimizing currents in manifolds with boundary is not readily available to our knowledge. We refer the reader to [27, 25, 2] for a comprehensive survey on the theory of sets of finite perimeter.

The setting of the problem is as follows: the space $\mathbb{R}^n$ is considered as the lattice of cubes $[0,1]^n + \mathbb{Z}^n$ where each cube has an internal exclusion. If I denotes the

†Department of Mathematics, Northwestern University, 2033 Sheridan Rd., Evanston, IL 60208-2730 (torres@math.northwestern.edu).

exclusion contained in $Y = [0,1]^n$, we assume the following:

1. I is compact, connected, and has Lipschitz boundary.
2. The distance between I and the boundary of Y, which we shall denote by α, is strictly positive.
3. Any other exclusion is of the form $I + z$ for some $z \in \mathbb{Z}^n$; i.e., the exclusions are periodic.

Once we have set up the domain for our problem, we proceed to explain our definition of *minimal surface*, which is made precise in section 2. If Σ is a surface in $\mathbb{R}^n$ of codimension one, we consider the following procedure for measuring the area of Σ: the portions that are inside the exclusions do not contribute to the area, and outside the exclusions the area is measured in the standard way. We say that Σ is a *minimal surface* if Σ minimizes area outside the exclusions. This means, loosely speaking, that any compact perturbation to Σ increases its area outside the exclusions.

We can now introduce the main result of this paper, which reads as follows: Under the assumptions 1, 2, and 3 given above, there exists a universal constant C (that depends only on n an α) such that, for every $(n-1)$-dimensional hyperplane Π, we can find a minimal surface Σ satisfying $d(\Pi, \Sigma) \leq C$.

The minimizers constructed in this paper are regular away from the boundaries of the exclusions. This follows directly from standard interior regularity theory for minimal surfaces (see Remark A.2). For the case when the exclusions have C^2 boundaries, the regularity of the minimizers near the boundary of the exclusions is a consequence of [29], where techniques of geometric measure theory are used to prove optimal regularity for codimension one minimal surfaces with a free boundary.

An important property of the surfaces constructed in this paper is that they meet the exclusions orthogonally. This means, loosely speaking, that the intersection of the minimizers with the exclusions looks like two perpendicular hyperplanes (in a small neighborhood). This orthogonality result can be deduced (once we have the regularity of the minimizers up to the boundary of the exclusions) by studying the first variation of the area. An analysis of the Euler–Lagrange equation is done in [31], where numerical and theoretical analysis for minimal surfaces involving two media is performed. We discuss the orthogonality property in section 6, and we explain how it can be obtained from [31]. For a proof of this orthogonality property, in the context of geometric measure theory, we refer the reader to [29].

The existence of plane-like minimizers implies that, in spite of having a heterogeneous media, the minimizer looks like a plane (homogeneous media) when seen from a far distance. This suggests connections with the theory of homogenization of PDEs, which studies the asymptotic behavior of a family of PDEs that oscillate with small period of size $\epsilon > 0$. The last section of this paper begins to explore the connection with the theory of homogenization of Hamilton–Jacobi equations. Hamilton–Jacobi equations arise in optimal control, differential games, geometric optics, calculus of variations, etc., and their solutions are understood in the *viscosity sense*. We refer the reader to [8, 23, 7] and the references therein for the definitions and basic properties of viscosity solutions that we will use in this paper.

The study of asymptotics of solutions of Hamilton–Jacobi equations is a fundamental question, as well as their applications to mathematical sciences. The homogenization of Hamilton–Jacobi equations has been extensively studied (see, for instance, [32, 21, 22, 15, 9]). The homogenized equation is also a Hamilton–Jacobi equation, and the corresponding Hamiltonian, usually denoted by $\overline{H}$, is called the *effective Hamiltonian*. It is a difficult but interesting task to find explicit formulas for $\overline{H}$. The

references [22, 19, 20, 17, 16, 24] contain results in this direction. In this paper, we introduce a particular example, and we perform several explicit computations in search of its corresponding effective Hamiltonian. The homogenization of Hamilton–Jacobi equations in perforated domains was treated in [30], where both the Neumann-type and the Dirichlet boundary value problems were considered. A generalization of [30] has been studied in [1].

The organization of the paper is as follows.

Section 2 contains the proof of the existence of minimizers.

Section 3 uses some subadditivity properties of sets of finite perimeter to define an *infimal minimizer* which is contained in all the other minimizers and satisfies several monotonicity properties. The results presented in section 3 are contained in [14], but for clarity of the exposition we present again the proofs with more detail.

Section 4 deals with the proof of a geometric property that is specific to the infimal minimizer. This property is analogous to the so-called Birkhoff property in Aubry–Mather theory.

Section 5 contains the proof of the main theorem, which relies on the fact that minimizers must satisfy some *density estimates*. The geometric property proven in section 4, together with the density estimates, allows us to prove that the infimal minimizer is contained in a band whose width is independent of the direction of the plane.

Section 6 discusses the behavior of the minimizers near the boundaries of the exclusions.

Section 7 explores the connection with the theory of homogenization of Hamilton–Jacobi equations and contains several explicit computations.

We present at the end an appendix that includes the main definitions concerning sets of finite perimeter, as well as several remarks regarding some conventions and notation that we are using throughout the paper.

2. Existence of minimizers. We proceed now to prove the existence of minimizers. We refer the reader to the appendix for the definition and main properties of sets of finite perimeter. As explained before, our setting in this paper is $\mathbb{R}^n$ with exclusions (voids) that satisfy the three properties stated in the introduction.

We denote I as the exclusion contained in $[0,1]^n$. We let $\mathcal{I}$ denote the union of all exclusions and O its complement; i.e.,

$$\mathcal{I} = \bigcup_{k\in\mathbb{Z}^n} (I+k), \tag{1}$$

$$O = \mathbb{R}^n \backslash \mathcal{I}. \tag{2}$$

We let $\omega \in \mathbb{R}^n$, and we consider first the case when $\omega \in \mathbb{Q}^n$. Given $\tilde{M} \in \mathbb{R}$, we define

$$\Gamma_{\omega,\tilde{M}} = \left\{ x \in \mathbb{R}^n : x \cdot \frac{\omega}{|\omega|} \leq \tilde{M} \right\}, \tag{3}$$

where $\frac{\omega}{|\omega|}$ is the outward unit normal to $\partial\Gamma_{\omega,\tilde{M}}$. We denote T_k as the translation operator by $k \in \mathbb{Z}^n$; that is, $T_k(x) = x+k$, $x \in \mathbb{R}^n$. Given $N \in \mathbb{N}^+$ and $M > 0$, we define

$$\begin{aligned} A_{S_1,S_2} = \{&E : E \text{ is a set of finite perimeter,} \\ &S_1 \subset E \subset S_2, T_{Nk}E = E \ \forall k \in \mathbb{Z}^n, \omega \cdot k = 0\}, \end{aligned} \tag{4}$$

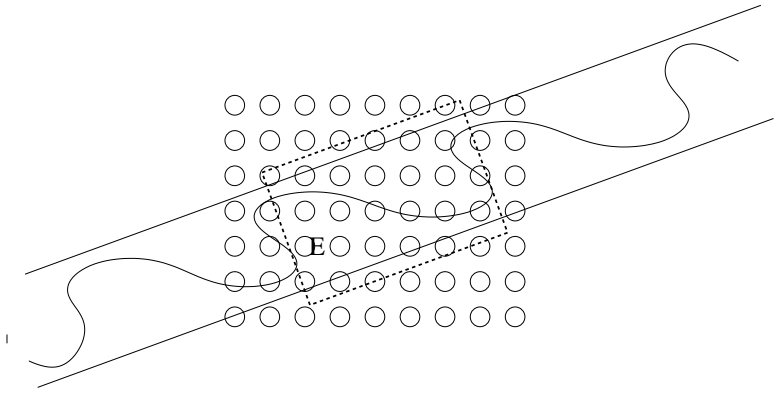

FIG. 1. *Diagram showing parallel plane restrictions and the period for minimization.*

where $S_1 = \Gamma_{\omega,0}$ and $S_2 = \Gamma_{\omega,M}$. We will refer to the sets $\Pi_1 \equiv \{x \in \mathbb{R}^n : x \cdot \omega = 0\}$ and $\Pi_2 \equiv \{x \in \mathbb{R}^n : x \cdot \frac{\omega}{|\omega|} = M\}$ as the parallel plane restrictions. Throughout this paper, we consider (without loss of generality) sets of finite perimeter that satisfy Remark A.1.

Since ω is rational, the sets in A_{S_1,S_2} can be identified with sets in the manifold

$$\Gamma_{\omega,M}/\approx, \tag{5}$$

where $\approx$ is the equivalence relation defined by

$$x \approx y \Longleftrightarrow x = y + Nk \quad \text{for some} \quad k \in \mathbb{Z}^n, \omega \cdot k = 0. \tag{6}$$

The space defined in (5) is $[-\infty, M] \times \mathbb{T}^{n-1}$. Moreover, we can identify the period of the class A_{S_1,S_2} as $[-\epsilon, M+\epsilon] \times \mathbb{T}^{n-1}$ for a fixed $\epsilon > 0$ (see Figure 1). We define

$$\Omega = ([-\epsilon, M+\epsilon] \times \mathbb{T}^{n-1}) \setminus \mathcal{I}. \tag{7}$$

For each set $E \in A_{S_1,S_2}$, we consider

$$J(E) = \int_\Omega |D\varphi_E|, \tag{8}$$

where the measure $|D\varphi_E|$ is introduced in Definition A.4. We let $\beta = \inf_{E \in A_{S_1,S_2}} J(E)$ and $\{E_j\}$ be a sequence such that $J(E_j) \to \beta$. This implies that the sequence $\{\int_\Omega |D\varphi_{E_j}|\}$ is uniformly bounded. Since the exclusions have at least Lipschitz boundary, it follows from Theorem A.2 that $BV(\Omega)$ is relatively compact in $L^1(\Omega)$. Therefore, there exists a convergent subsequence, which we denote again by $\{E_j\}$, in $L^1(\Omega)$. We let $E_0 \in L^1(\Omega)$ be the limit. Using Proposition A.1 we obtain

$$\int_\Omega |D\varphi_{E_0}| \leq \liminf \int_\Omega |D\varphi_{E_j}|.$$

Thus,

$$J(E_0) = \inf_{E \in A_{S_1,S_2}} J(E).$$

We make the following definitions.

DEFINITION 2.1. *Any $E \in A_{S_1,S_2}$ that satisfies $J(E) = J(E_0)$ shall be called a minimizer corresponding to the class A_{S_1,S_2}, or simply a minimizer, when it is not necessary to specify the class.*

DEFINITION 2.2. *We say that the minimizer E is an unconstrained minimizer if there exists a universal constant $\tilde{M} > 0$ such that, for all $M \geq \tilde{M}$ and all $\epsilon \geq 0$, E is a minimizer corresponding to the class $A_{\Gamma_{\omega,-\epsilon},\Gamma_{\omega,M}}$.*

DEFINITION 2.3. *We say that the minimizer E is a class A minimizer if, for any open ball B_R,*

$$\int_{B_R \cap O} |D\varphi_E| = \inf \left\{ \int_{B_R \cap O} |D\varphi_F| : F \text{ is a set of finite perimeter, } \operatorname{spt}(\varphi_F - \varphi_E) \subset B_R \right\}.$$

DEFINITION 2.4. *We say that $\Sigma \subset \mathbb{R}^n$ is* a minimal surface *if $\Sigma = \partial E$, where E is a class A minimizer.*

Remark 2.1. We shall prove later (Proposition 5.2) that if the distance between the two restrictions Π_1 and Π_2 is large enough (independently of the slope of the restrictions), then there exists at least one unconstrained class A minimizer. That is, if the distance between Π_1 and Π_2 is large enough, then the restrictions do not interfere in the minimization, which means that they do not prevent the minimizers from doing "better."

The following lemma tells us that, without loss of generality, we can assume that minimizers are closed sets.

LEMMA 2.1. *If E is a minimizer corresponding to the class A_{S_1,S_2}, then there exists a closed set $\tilde{E}$, which is also a minimizer for the class A_{S_1,S_2}.*

Proof. Define $\tilde{E} = E \cup \partial E$ (see Definition A.8). We have that $\tilde{E}$ is closed. We need to prove that $\tilde{E}$ and E differ (outside the exclusions) on a set of $\mathcal{L}^n$-measure zero. Since the restrictions Π_1 and Π_2 have $\mathcal{L}^n$-measure zero, we need only to consider the set $\mathcal{K} \equiv \partial E \cap O \cap B_{\Pi_1,\Pi_2}$, where B_{Π_1,Π_2} is the open slab enclosed by Π_1 and Π_2. Since E minimizes area outside the exclusions, it follows from Lemma A.5 that if $x \in \mathcal{K}$ has density γ_x, then $0 < \gamma_x < 1$ (see Definition A.6 for the definition of density of a point), which implies that such x is not a Lebesgue point for φ_E. Therefore, from Definition A.6 we obtain that $\mathcal{L}^n(\mathcal{K}) = 0$. We can now prove that $\tilde{E}$ is a minimizer, which is a consequence of the fact that the sets E and $\tilde{E}$ differ (outside the exclusions) on a set of $\mathcal{L}^n$-measure zero. In fact, if $V \subset O$ is any open set, we have

$$\begin{aligned}
\int_V |D\varphi_E| &= \sup \left\{ \int_V \varphi_E \operatorname{div} g : g \in C_0^1(V;\mathbb{R}^n), \quad |g(x)| \leq 1, \quad \text{for} \quad x \in V \right\} \\
&= \sup \left\{ \int_V \varphi_{\tilde{E}} \operatorname{div} g : g \in C_0^1(V;\mathbb{R}^n), \quad |g(x)| \leq 1, \quad \text{for} \quad x \in V \right\} \\
&= \int_V |D\varphi_{\tilde{E}}|,
\end{aligned}$$

which proves that both measures coincide outside the exclusions. ∎

Remark 2.2. From now on, we shall assume that minimizers are closed sets.

We now proceed to prove that a minimizer (minus the exclusions) is connected for the case when the exclusions are simply connected sets and have at least C^1

boundaries. We remark that we do not need the connectivity of the minimizers in any of the proofs in this paper, but we present the result since it is interesting by itself.

LEMMA 2.2. *Let E be a minimizer corresponding to the class A_{S_1,S_2}. Assume that the exclusions are simply connected and have at least C^1 boundaries; then $E \cap O$ is connected.*

Proof. We let $\tilde{E} = E \cap O$. We prove that $\tilde{E}_{int}$ is connected. We proceed by contradiction and assume that

$$\tilde{E}_{int} = A \cup B, \tag{9}$$

where A,B are two disjoints open sets. Since $\Gamma_{\omega,0} \cap O$ is connected, it must be contained in either A or B. We assume that $\Gamma_{\omega,0} \cap O \subset A$, and we let $F = \mathbb{R}^n \setminus \tilde{E}$. Since E minimizes area outside the exclusions it follows that the points in ∂F have uniform density; i.e., there exists a universal constant C such that

$$|F \cap B(x,r)| \geq Cr^n, \quad x \in \partial F, \quad r \leq r_0, \tag{10}$$

for some small enough universal constant r_0. We prove this claim in Lemma A.6. We now proceed to prove that (10) implies that we can approximate $\tilde{E}_{int}$ from inside with smooth sets. We recall (see [2]) that sets of finite perimeter in $\mathbb{R}^n$ can be approximated in measure by open sets with smooth boundaries in such a way that we also have convergence of perimeters to perimeters. It is not, in general, possible to approximate a set of finite perimeter E by C^∞ sets contained inside E, nor it is possible from outside (see [27, p. 24] for a counterexample). However, in our case, we prove in Lemma A.7 that we can find sequences of sets $\{A_t\}$, $\{B_t\}$ with smooth boundaries satisfying

$$A_t \subset\subset A, \quad B_t \subset\subset B \tag{11}$$

and

$$\mathrm{Per}(A \cup B) = \lim_{t\to 0} \mathrm{Per}(A_t \cup B_t), \quad A_t \to A \quad B_t \to B \quad \text{in measure.} \tag{12}$$

From (11), (12), and the lower semicontinuity property given in Proposition A.1 we obtain

$$\begin{aligned} \mathrm{Per}(A \cup B) &= \lim_{t\to 0} \mathrm{Per}(A_t \cup B_t) \\ &= \lim_{t\to 0} \mathrm{Per}(A_t) + \lim_{t\to 0} \mathrm{Per}(B_t) \\ &\geq \mathrm{Per}(A) + \mathrm{Per}(B). \end{aligned}$$

This is a contradiction since we can eliminate B and obtain a set with less perimeter. ∎

3. Infimal minimizer. The minimizer we have just constructed may not be unique. However, we can prove the existence of an infimal minimizer, that is, a minimizer that is contained in any other minimizer. The results presented in this section are contained in [14], but, for clarity of the exposition, we present here the proofs with more detail.

In this section, Ω denotes the set defined in (7).

THEOREM 3.1. *There exists $E_* \in A_{S_1,S_2}$ such that, if E is any other minimizer, then $E_* \subset E$. We refer to E_* as the infimal minimizer.*

Proof. We denote $\mathcal{B}$ as the set of all minimizers. We have that $\mathcal{B} \subset L^1(\Omega)$. If $E_1, E_2 \in \mathcal{B}$, by Theorem A.4 we have

$$\text{Per}(E_1 \cap E_2, \Omega) + \text{Per}(E_1 \cup E_2, \Omega) \leq \text{Per}(E_1, \Omega) + \text{Per}(E_2, \Omega). \tag{13}$$

Since $E_1 \cup E_2$ is an admissible set we have $\text{Per}(E_1 \cup E_2, \Omega) \geq \text{Per}(E_1, \Omega)$. Since $\text{Per}(E_1, \Omega) = \text{Per}(E_2, \Omega)$ and using inequality (13), it follows that

$$\text{Per}(E_1 \cap E_2, \Omega) \leq \text{Per}(E_1, \Omega),$$

which implies that $E_1 \cap E_2$ is also a minimizer. Since we can uniformly bound the perimeters of minimizers in Ω, it follows from Proposition A.1 and Theorem A.2 that $\mathcal{B}$ is a compact subset of $L^1(\Omega)$. Since $L^1(\Omega)$ is separable, $\mathcal{B}$ is also separable. We let $\{E_j\}$ denote a dense subset of $\mathcal{B}$, and we define

$$\tilde{E_n} = \bigcap_{j=1}^{n} E_j.$$

Since $\tilde{E_n}$ is a minimizer and $\tilde{E}_{n+1} \subset \tilde{E_n}$ with $|\tilde{E_1} \cap \Omega| < \infty$, it follows that $|\tilde{E_n} \cap \Omega| \to |\bigcap_{n=1}^{\infty} \tilde{E_n} \cap \Omega|$, and therefore $\tilde{E_n} \to \bigcap_{n=1}^{\infty} \tilde{E_n}$ in $L^1(\Omega)$. We define

$$E_* = \bigcap_{n=1}^{\infty} \tilde{E_n}.$$

By Proposition A.1

$$\text{Per}(E_*, \Omega) \leq \liminf \text{Per}(\tilde{E_n}, \Omega),$$

which implies that E_* is a minimizer.

If E denotes any other minimizer we claim that $|(E_* \backslash E) \cap \Omega| = 0$. We proceed by contradiction and assume this is not true; i.e., $|(E_* \backslash E) \cap \Omega| > \delta > 0$. Since $\{E_j\}$ is a dense subset of $\mathcal{B}$, we can find E_k such that $|(E_k \backslash E) \cap \Omega| < \frac{\epsilon}{2}, \epsilon < \delta$. We choose N large enough such that $\tilde{E_N} \subset E_k$ and $|(E_* \backslash \tilde{E_N}) \cap \Omega| < \frac{\epsilon}{2}$. We have

$$\begin{aligned} |(E_* \backslash E) \cap \Omega| &\leq |(E_* \backslash \tilde{E_N}) \cap \Omega| + |(\tilde{E_N} \backslash E) \cap \Omega| \\ &\leq |(E_* \backslash \tilde{E_N}) \cap \Omega| + |(E_k \backslash E) \cap \Omega| \\ &\leq \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon < \delta, \end{aligned}$$

which is a contradiction. Since E and E_* are both minimizers and are closed, if follows from Remark A.1 that $E_* \subset E$. ∎

COROLLARY 3.1. *The infimal minimizer is unique.*

We let $M_1 < 0$ and $M_2 > 0$ be such that $T_2 := \Gamma_{\omega, M_2} \subset S_2$. We have $T_1 := \Gamma_{\omega, M_1} \subset S_1$ and $T_1 \subset T_2$. The following proposition shall be used later to establish properties of the infimal minimizer.

PROPOSITION 3.1. *If E is a minimizer corresponding to the class A_{S_1, S_2} and L a minimizer corresponding to the class A_{T_1, T_2}, then*

(a) *$E \cap L$ is a minimizer corresponding to the class A_{T_1, T_2};*

(b) *$E \cup L$ is a minimizer corresponding to the class A_{S_1, S_2};*

(c) $E_{*, T_1, T_2} \subset E_{*, S_1, S_2}$.

Proof. We note that $E \cup L \in A_{S1,S2}$ and $E \cap L \in A_{T_1,T_2}$. Using Theorem A.4 and since $\mathrm{Per}(E,\Omega) \le \mathrm{Per}(E \cup L,\Omega)$, it follows that

$$\begin{aligned}\mathrm{Per}(E \cap L,\Omega) + \mathrm{Per}(E,\Omega) &\le \mathrm{Per}(E \cap L,\Omega) + \mathrm{Per}(E \cup L,\Omega)\\ &\le \mathrm{Per}(E,\Omega) + \mathrm{Per}(L,\Omega),\end{aligned}$$

which implies that $\mathrm{Per}(E \cap L,\Omega) \le \mathrm{Per}(L,\Omega)$; i.e., $E \cap L$ is a minimizer in the class A_{T_1,T_2}. In the same way we prove (b). In order to prove (c) we note that, by (a), $E_{*,T_1,T_2} \cap E_{*,S_1,S_2}$ is a minimizer corresponding to the class A_{T_1,T_2}, and hence

$$\begin{aligned}&E_{*,T_1,T_2} \subset (E_{*,T_1,T_2} \cap E_{*,S_1,S_2})\\ \Rightarrow\ &E_{*,T_1,T_2} \subset E_{*,S_1,S_2}. \qquad \square\end{aligned}$$

4. Birkhoff property. We denote E as the infimal minimizer corresponding to the class A_{S_1,S_2}. We recall that T_k denotes the translation operator by $k \in \mathbb{Z}^n$; that is, $T_k(x) = x + k$, $x \in \mathbb{R}^n$. The infimal minimizer satisfies an important geometric property (quite analogous to the property called Birkhoff in Aubry–Mather theory), which is proven in [14].

LEMMA 4.1. *If $k \in \mathbb{Z}^n$, we have the following:*

(a) *If $k \cdot \omega \le 0$, then $T_k E \subset E$.*

(b) *If $k \cdot \omega \ge 0$, then $E \subset T_k E$.*

Proof. (a) We let $T_1 = T_k(S_1)$ and $T_2 = T_k(S_2)$, where as before $S_1 = \{x \in \mathbb{R}^n : x \cdot \omega \le 0\}$ and $S_2 = \{x \in \mathbb{R}^n : x \cdot \omega \le M\}$. If $k \cdot \omega \le 0$ we have that $T_1 \subset S_1$, $T_2 \subset S_2$, and $T_1 \subset T_2$. We note that $T_k E$ is the infimal minimizer in A_{T_1,T_2}. By Proposition 3.1(c) we have $T_k E \subset E$.

(b) If $k \cdot \omega \ge 0$, we have that $S_1 \subset T_1$, $S_2 \subset T_2$, and $T_1 \subset T_2$. Since $T_k E$ is the infimal minimizer in A_{T_1,T_2}, by Proposition 3.1(c) it follows that $E \subset T_k E$. $\square$

We make the following important observation.

Remark 4.1. From (a) and (b) above, we have that if $k \cdot \omega = 0$, then $T_k E = E$. This implies that even though in the minimization of (8) the size of the period of the candidate sets is given by the number N (recall the definition (4)), the infimal minimizer E has indeed a periodicity that depends only on the slope of the restrictions.

DEFINITION 4.1. *Given any two hyperplanes Π and $\tilde{\Pi}$ parallel to the restrictions, we denote $B_{\Pi,\tilde{\Pi}}$ as the open* slab *enclosed by Π and $\tilde{\Pi}$.*

The following two results are needed in order to handle the exclusions. They play the analogous role that the lower estimates in [14] play for the case without exclusions.

LEMMA 4.2. *If $\mathcal{C} \subset B_{\Pi_1,\Pi_2}$ is a cube of edge length $l \ge 5$ with sides parallel to the coordinate axis and integer vertices, we have the following:*

(a) *If $\mathcal{C} \subset (\mathbb{R}^n \backslash E)$, then there exists $0 < M_a < M$ such that $E \subset \Gamma_{w,M_a}$.*

(b) *If $\mathcal{C} \subset E$, then there exist $0 < M_b < M$ such that $\Gamma_{w,M_b} \subset E$.*

Proof. (a) We denote $\tilde{\Pi}$ as the hyperplane parallel to the restrictions Π_1 and Π_2 in such a way that the intersection $\tilde{\Pi} \cap \mathcal{C}$ consists only of the edge of $\mathcal{C}$ that is closer to the lower restriction Π_1. The equation of $\tilde{\Pi}$ is $x \cdot \frac{\omega}{|\omega|} = \tilde{M}$ for some $0 < \tilde{M} < M$. We define

$$\mathcal{D} = \bigcup_{\omega \cdot k \ge 0} T_k C. \tag{14}$$

If $\omega \cdot k \ge 0$, we claim that $T_k C \subset \mathbb{R}^n \setminus E$. In fact, if this is not true, there exist $x \in C$, $y \in E$ such that $T_k(x) = y$. Then $T_{-k}(y) = x$, which is a contradiction since

Lemma 4.1 implies $T_{-k}E \subset E$. We conclude that the set $\mathcal{D} \subset \mathbb{R}^n \setminus E$. We note that $\mathcal{D}$ contains the set $\{x \cdot \frac{\omega}{|\omega|} \geq \tilde{M} + \sqrt{n}\}$. If we define $M_a = \tilde{M} + \sqrt{n}$, we obtain that $E \subset \Gamma_{w,M_a}$.

(b) We denote $\tilde{\Pi}$ as the hyperplane parallel to the restrictions Π_1 and Π_2 in such a way that the intersection $\tilde{\Pi} \cap \mathcal{C}$ consists only of the edge of $\mathcal{C}$ that is closer to the upper restriction Π_2. The equation of $\tilde{\Pi}$ is $x \cdot \frac{\omega}{|\omega|} = \tilde{M}$ for some $0 < \tilde{M} < M$. We define

$$\mathcal{G} = \bigcup_{\omega \cdot k \leq 0} T_k C. \tag{15}$$

If $\omega \cdot k \leq 0$, it follows from Lemma 4.1 that $T_k E \subset E$, and therefore $T_k C \subset E$. We conclude that $\mathcal{G} \subset E$. We note that $\mathcal{G}$ contains the set $\{x \cdot \frac{\omega}{|\omega|} \leq \tilde{M} - \sqrt{n}\}$. If we define $M_b = \tilde{M} - \sqrt{n}$, we obtain $\Gamma_{w,M_b} \subset E$. ∎

We use the previous lemma to prove the following proposition.

PROPOSITION 4.1. *If $\mathcal{C} \subset B_{\Pi_1,\Pi_2}$ is a cube of edge length $l \geq 5$, with sides parallel to the coordinate axis and integer vertices, then we cannot have $\mathcal{C} \subset E$.*

Proof. We proceed by contradiction. We let M_b be the number given by Lemma 4.2(b), and we define $\Pi_b = \{x \in \mathbb{R}^n : x \cdot \frac{\omega}{|\omega|} = M_b\}$. By subtracting a small number $\epsilon > 0$ to M_b, if necessary, we can assume that $|\omega| M_b \in \mathbb{Q}$. Since $l \geq 5$, there exists $p \in \mathbb{Z}^n$ such that $p \in C \cap \Gamma_{w,M_b}$. We define $M_c = p \cdot \frac{\omega}{|\omega|}$, and we take $k \in \{x \cdot \frac{\omega}{|\omega|} = M_b - M_c\} \cap \mathbb{Z}^n$ (which can be chosen because $|\omega|(M_b - M_c) \in \mathbb{Q}$). Since $M_b - M_c = k \cdot \frac{\omega}{|\omega|}$ we have

$$\begin{aligned} T_{-k}(\Pi_b) &= \left\{ x - k : x \cdot \frac{\omega}{|\omega|} = M_b \right\} \\ &= \left\{ y : y \cdot \frac{\omega}{|\omega|} = M_b - k \cdot \frac{\omega}{|\omega|} \right\} \\ &= \left\{ y : y \cdot \frac{\omega}{|\omega|} = M_c \right\} := \Pi_c. \end{aligned}$$

The plane Π_c divides E in two parts, say E_1 and E_2, where $\Pi_1 \subset E_1$ and $\Pi_b \subset E_2$. We consider now the set $E_1 \cup T_{-k}(E_2 \backslash B_{\Pi_b,\Pi_c})$. Clearly, this set is also a minimizer contained (and not equal) in E. This contradicts the fact that E is the infimal minimizer, that is, a minimizer that is contained in any other minimizer. ∎

5. Proof of the main theorem. We proceed in this section to prove the main theorem. We recall that we are considering $\mathbb{R}^n$ as the lattice $[0,1]^n + \mathbb{Z}^n$ with periodic exclusions; i.e., each cube $[0,1]^n + k$ with $k \in \mathbb{Z}^n$ has an internal exclusion. If I denotes the exclusion contained $Y = [0,1]^n$, we assume the following:

1. I is compact, connected, and has Lipschitz boundary.
2. The distance between I and the boundary of Y, which we denote by α, is strictly positive.
3. Any other exclusion is of the form $I + z$ for some $z \in \mathbb{Z}^n$; i.e., the exclusions are periodic.

Remark 5.1. From now on, given the restrictions S_1 and S_2, *we work with the unique infimal minimizer E corresponding to the class A_{S_1,S_2}.*

Remark 5.2. In order to clarify exposition we use the same C to denote different universal constants.

We now state the main theorem.

THEOREM 5.1. *Assume that the exclusions satisfy* $1, 2$, *and* 3 *above. Then there exists a universal constant* C *(that depends only on* n *and* α*) such that, for every* $(n-1)$*-dimensional hyperplane* Π*, we can find a minimal surface* Σ *satisfying* $d(\Pi, \Sigma) \leq C$.

We recall from Definition 2.4 that a surface Σ is a minimal surface if it is the boundary of a class A minimizer (recall Definition 2.3), which means that any compact perturbation to Σ will increase its area outside the exclusions. The tool used to prove Theorem 5.1 is essentially a covering argument. This argument is similar to the one used in [14] to obtain the theorem for the case without exclusions. However, in our case we need to make several adjustments in order to extend the theorem to the case with exclusions. Lemmas 5.1, 5.3, and 5.4 are needed to handle the presence of exclusions. Using these lemmas we prove Propositions 5.1 and 5.2. Then Theorem 5.1 follows, for the case ω rational, from Proposition 5.3. Finally, we consider the case ω irrational at the end of this section.

LEMMA 5.1. *We let* E *denote the infimal minimizer corresponding to the class* A_{S_1,S_2}*, and we let* $x \in \partial E$*. If* Q_q *is a closed cube of edge length* q *(or a closed ball of radius* q*) containing* x *and such that* $Q_q \cap \Pi_1 = \emptyset$ *and* $Q_q \cap \Pi_2 = \emptyset$*, then*

$$\mathrm{Per}(E, Q_q^0 \cap O) \leq C q^{n-1},$$

where Q_q^0 *denotes the interior of the set* Q_q.

Proof. We can consider the set E as a candidate in the class with a period large enough (choosing N large enough in the definition (4)) in such a way that Q_q is completely contained inside the period $[0, M] \times \mathbb{T}^{n-1}$. Using Remark 4.1, it follows that the set E is a minimizer for the new class. Proceeding as in Lemmas A.1 and A.2 we can prove that, for almost every $0 < s < q$,

$$\mathrm{Per}(E \backslash Q_s, Q_q^0 \cap O) = \mathrm{Per}(E, (Q_q^0 \backslash Q_s) \cap O) + \mathcal{H}_{n-1}(\partial Q_s \cap E \cap O). \tag{16}$$

(In fact, we can use Lemma A.1 with $f(x) = \varphi_E$, $A = (Q_q^0 \backslash Q_s) \cap O$, and $\Omega = Q_q^0 \cap O$.) Since E is a minimizer we have

$$\mathrm{Per}(E, Q_q^0 \cap O) \leq \mathrm{Per}(E \backslash Q_s, Q_q^0 \cap O). \tag{17}$$

From (16) and (17) we obtain that, for almost every $0 < s < q$,

$$\begin{aligned} \mathrm{Per}(E, Q_q^0 \cap O) &\leq \mathrm{Per}(E, (Q_q^0 \backslash Q_s) \cap O) + \mathcal{H}_{n-1}(\partial Q_s \cap E \cap O) \\ &\leq \mathrm{Per}(E, (Q_q^0 \backslash Q_s) \cap O) + C s^{n-1}. \end{aligned} \tag{18}$$

We now choose a sequence $\{s_j\} \to q$ such that (18) holds for each s_j. If we let $j \to \infty$, we conclude that $\int_{Q_q^0 \cap O} |D\varphi_E| \leq C q^{n-1}$. We note that we can use $C = 2n$ if Q_q is a cube and $C = n w_n$ (where w_n is the volume of the n-dimensional unit ball) if Q_q is a ball. □

LEMMA 5.2. *We let* E *denote the infimal minimizer corresponding to the class* A_{S_1,S_2}*, and we let* $y \in \partial E$*. We assume that there exists* $\tilde{r} > 0$ *that satisfies* $B(y, \tilde{r}) \cap \Pi_1 = \emptyset$*,* $B(y, \tilde{r}) \cap \Pi_2 = \emptyset$*, and* $B(y, \tilde{r}) \subset O$*. Then there exists a universal constant* $C > 0$ *such that, for all* $r \leq \tilde{r}$*,*

$$\int_{B(y,r)} |D\varphi_E| \geq C r^{n-1}. \tag{19}$$

Proof. Since E minimizes area outside the exclusions we have, for all $r \leq \tilde{r}$,

$$\int_{B(y,r)} |D\varphi_E| \leq \mathcal{H}_{n-1}(E \cap \partial B(y,r)). \tag{20}$$

We define $V(r) = |E \cap B(y,r)|$, $r \leq \tilde{r}$. Using the isoperimetric inequality given in Lemma A.3 we have that

$$|E \cap B(y,r)| \leq C[\mathrm{Per}(E \cap B(y,r))]^{\frac{n}{n-1}}. \tag{21}$$

From Lemma A.2 and using (20) and (21) it follows that, for almost every $r \leq \tilde{r}$,

$$\begin{aligned} |E \cap B(y,r)| &\leq C[\mathrm{Per}(E \cap B(y,r), \mathbb{R}^n)]^{\frac{n}{n-1}} \\ &= C[\mathrm{Per}(E, B(y,r)) + \mathcal{H}_{n-1}(E \cap \partial B(y,r))]^{\frac{n}{n-1}} \\ &\leq C[\mathcal{H}_{n-1}(E \cap \partial B(y,r))]^{\frac{n}{n-1}}. \end{aligned}$$

Due to Remark A.1 it follows that $V(r) > 0$ for all $r \leq \tilde{r}$. Since $V'(r) = \mathcal{H}_{n-1}(E \cap \partial B(y,r))$ we have, for almost every $r \leq \tilde{r}$,

$$V(r) \leq CV'(r)^{\frac{n}{n-1}}. \tag{22}$$

If we divide (22) by $V(r)$, we obtain $C \leq V(r)^{\frac{1-n}{n}} V'(r) = (V(r)^{\frac{1}{n}})'$. If we integrate, we obtain $V(r)^{\frac{1}{n}} \geq Cr$; i.e.,$V(r) \geq Cr^n$ for all $r \leq \tilde{r}$. In the same way we can prove that $|(\mathbb{R}^n \backslash E) \cap B(y,r)| \geq Cr^n$,$r \leq \tilde{r}$. The isoperimetric inequality stated in Lemma A.4 gives us

$$\begin{aligned} \min\{|(\mathbb{R}^n \backslash E) \cap B(y,r)|, |E \cap B(y,r)|\} &\leq C \left(\int_{B(y,r)} |D\varphi_E| \right)^{\frac{n}{n-1}} \\ &\Rightarrow \\ Cr^n &\leq \left(\int_{B(y,r)} |D\varphi_E| \right)^{\frac{n}{n-1}}. \end{aligned}$$

We conclude that

$$\int_{B(y,r)} |D\varphi_E| \geq Cr^{n-1}.$$

This completes the proof of the lemma. □

LEMMA 5.3. *We let E denote the infimal minimizer for the class A_{S_1,S_2}, and we take $x \in \partial E \cap O$. We assume that $x \in Y$, where $Y = [0,1]^n + k$ for some $k \in \mathbb{Z}^n$, and we denote I as the exclusion contained in Y. We assume also that Y does not intersect the parallel plane restrictions Π_1 and Π_2. Then $\partial E \cap \partial Y_\alpha \neq \emptyset$, where $Y_\alpha = \{x \in Y : d(x,I) \geq \frac{\alpha}{2}\}$.*

Proof. We proceed by contradiction and assume that $\partial E \cap Y_\alpha = \emptyset$. This implies that $Y_\alpha \subset E_{int}$ or $Y_\alpha \subset \mathbb{R}^n \backslash E$. Assume that $Y_\alpha \subset E_{int}$. We define $\tilde{E} = E \cup Y$. From Lemma 5.2 it follows that $\tilde{E}$ has strictly less area than E, which is a contradiction. If we assume now that $Y_\alpha \subset \mathbb{R}^n \backslash E$, then we can define $\tilde{E} = E \setminus Y$. Again, Lemma 5.2 implies that the set $\tilde{E}$ has strictly less area than E, which is a contradiction. We conclude that $\partial E \cap \partial Y_\alpha \neq \emptyset$. □

LEMMA 5.4. *We let E denote the infimal minimizer corresponding to the class A_{S_1,S_2}, and we let $x \in \partial E \cap O$. We assume that $x \in Y$, where $Y = [0,1]^n + k$ for*

some $k \in \mathbb{Z}^n$. We assume also that Y is far away from the parallel plane restrictions Π_1 and Π_2. Then there exists a cube $\mathcal{C}_x$ of edge length 2 and a universal constant $\beta > 0$, such that $x \in \mathcal{C}_x$ and $\mathcal{C}_x$ contains at least $\beta > 0$ amount of area, where β is a universal constant.

Proof. From Lemma 5.3 there exists $y \in \partial E \cap Y$ such that $d(y, I) \geq \frac{\alpha}{2}$, where I is the exclusion contained in Y. If we make a dyadic decomposition of Y, we get 2^n cubes of side $\frac{1}{2}$ contained in Y. The point y must be contained in one of these dyadic cubes, say $\tilde{Y}$. Both Y and $\tilde{Y}$ have a common vertex, say v. We denote $\mathcal{C}_x$ as the cube of edge length 2 with its center in v. We note that $B(y, \frac{\alpha}{4})$ satisfies the hypothesis of Lemma 5.3, and thus we obtain the existence of the required constant β (in fact, $\beta = C(\frac{\alpha}{4})^n$). This completes the proof of the lemma. □

We shall use Vitali's covering lemma (see [25, Chapter 1]).

LEMMA 5.5. *Let $\mathcal{F}$ be any collection of nondegenerate closed cubes in $\mathbb{R}^n$ with edges parallel to the coordinate axis and satisfying*

$$\sup\{\text{diagonal} \quad \mathcal{C} : \mathcal{C} \in \mathcal{F}\} < \infty.$$

Then there exists a countable family $\mathcal{G}$ of disjoints cubes in $\mathcal{F}$ such that

$$\bigcup_{\mathcal{C} \in \mathcal{F}} \mathcal{C} \subset \bigcup_{\mathcal{C} \in \mathcal{G}} \hat{\mathcal{C}},$$

where $\hat{\mathcal{C}}$ is concentric with $\mathcal{C}$, and with edge length five times the edge length of $\mathcal{C}$.

Proof. The proof is the same as with balls, using the fact that the cubes are oriented in the same way as the coordinate axis. □

We have the following.

Remark 5.1. If we have a cube $\mathcal{C}$ in $\mathbb{R}^n$ of edge length l, then we can have at most $3^n - 1$ cubes of edge length l that intersect $\mathcal{C}$ without intersecting among themselves in a set of positive measure.

We now prove the following.

PROPOSITION 5.1. *There exists a universal constant $\tilde{M}$ such that for all $M \geq \tilde{M}$, if E denotes the infimal minimizer corresponding to A_{S_1,S_2}, where $S_1 = \Gamma_{\omega,0}$ and $S_2 = \Gamma_{\omega,M}$, then $d(\Pi_1, \partial E) < \tilde{M}$.*

Proof. We define $\tau = 5$, and we fix λ to be a multiple of 2τ and satisfying

$$\lambda > \frac{2^{2n} n \tau^n (3^n - 1)}{\beta}. \tag{23}$$

We let $\tilde{M} = 2\lambda\sqrt{n}$, and we note that $2\lambda\sqrt{n}$ is the length of the diagonal of the cube of edge length 2λ. We fix $M \geq \tilde{M}$ and denote E as the infimal minimizer corresponding to the class A_{S_1,S_2}, where $S_1 = \Gamma_{\omega,0}$ and $S_2 = \Gamma_{\omega,M}$. Our choice of λ allows us to fit a cube $\tilde{\mathcal{C}}$ of edge length 2λ in between $\Pi_1 = \{x \in \mathbb{R}^n : x \cdot \omega = 0\}$ and $\Pi_2 = \{x \in \mathbb{R}^n : x \cdot \frac{\omega}{|\omega|} = M\}$, with $\tilde{\mathcal{C}}$ having integer vertices, and edges parallel to the coordinate axis and intersecting Π_1 in a line. We claim that

$$d(\partial E, \Pi_1) < \tilde{M}. \tag{24}$$

We let $\mathcal{C}$ be the cube of edge length λ that is concentric with the cube $\tilde{\mathcal{C}}$. One of the following must happen:

1. $\mathcal{C} \subset \mathbb{R}^n \backslash E$. In this case, Lemma 4.2(a) implies the inequality (24).

2. $\mathcal{C} \cap E \neq \emptyset$. In this case, due to Proposition 4.1, we cannot have $\mathcal{C} \subset E$. Therefore, $\mathcal{C}$ must intersect ∂E.

For each $x \in \partial E \cap O \cap \mathcal{C}$ we denote $\mathcal{C}_x$ as the cube of edge length 2 constructed in Lemma 5.4. Therefore, we have a cover $\{\cup \mathcal{C}_x\}$ for $\partial E \cap \mathcal{C} \cap O$. By Lemma 5.5 we can extract a countable disjoint family $\{\mathcal{C}_i\}$ such that

$$\bigcup \mathcal{C}_x \subset \bigcup \hat{\mathcal{C}}_i, \tag{25}$$

where $\hat{\mathcal{C}}_i$ is concentric with $\mathcal{C}_i$ and has edge length 2τ. From Lemma 5.1 we have

$$\int_{(\cup \mathcal{C}_i) \cap O} |D\varphi_E| \leq 2n(2\lambda)^{n-1}. \tag{26}$$

From (26) and Lemma 5.4 it follows that the disjoint family has a finite number of cubes, say K, given by

$$K \leq \frac{2^n n \lambda^{n-1}}{\beta}. \tag{27}$$

Since λ is a multiple of 2τ, we can divide $\mathcal{C}$ in $\frac{\lambda^n}{(2\tau)^n}$ cubes of edge length 2τ, each cube having integer vertices and edges parallel to the coordinate axis. We note that the cubes do not intersect in sets of positive measure. Let us refer to this collection of cubes as $\mathcal{B}$. By Remark 5.1, out of the collection $\mathcal{B}$, at most

$$\frac{(3^n - 1)2^n n \lambda^{n-1}}{\beta} \tag{28}$$

intersect ∂E. Due to our choice of λ, we have

$$\frac{(3^n - 1)2^n n \lambda^{n-1}}{\beta} < \frac{\lambda^n}{(2\tau)^n}.$$

This implies that there exists $\mathcal{C}' \in \mathcal{B}$ such that $\mathcal{C}' \cap \partial E = \emptyset$. Due to Proposition 4.1 we must have $\mathcal{C}' \subset \mathbb{R}^n \backslash E$, and the inequality (24) follows from Lemma 4.2(a). ∎

We have the following.

PROPOSITION 5.2. *If E denotes the infimal minimizer corresponding to A_{S_1,S_2}, where $S_1 = \Gamma_{\omega,0}$ and $S_2 = \Gamma_{\omega,2\lambda\sqrt{n}}$, then E is an unconstrained minimizer.*

Proof. From inequality (24) we have that, for all $M > \tilde{M} = 2\lambda\sqrt{n}$, E is a minimizer for the class $A_{\Gamma_{\omega,0},\Gamma_{\omega,M}}$. We fix $\gamma > 0$. We claim that E is a minimizer for the class $A_{\Gamma_{\omega,-\gamma},\Gamma_{\omega,\tilde{M}}}$. We proceed by contradiction and assume this is not true. Therefore, the infimal minimizer, say $\tilde{E}$, corresponding to the class $A_{\Gamma_{\omega,-\gamma},\Gamma_{\omega,\tilde{M}}}$ has less perimeter than E. We choose $k \in \mathbb{Z}^n$ in such a way that $\Gamma_{\omega,0} \subset T_k\tilde{E}$. We obtain a contradiction since $T_k\tilde{E}$ is contained in the class $A_{\Gamma_{\omega,0},\Gamma_{\omega,\tilde{M}+k\cdot\frac{w}{|w|}}}$ and has less perimeter than E, which is a minimizer for this class. ∎

PROPOSITION 5.3. *If E denotes the infimal minimizer corresponding to A_{S_1,S_2}, where $S_1 = \Gamma_{\omega,0}$ and $S_2 = \Gamma_{\omega,2\lambda\sqrt{n}}$, then E is a class A minimizer.*

Proof. We let L denote any set that coincides with E outside the ball B_{R-1}. We consider E as competing in a class with a period and distance between the plane restrictions large enough so that B_{R-1} is completely contained in one period. In order to do this, we choose $M > 0$ and N in (4) large enough in such a way that B_{R-1}

is contained in the period $[-M,M]\times\mathbb{T}^{n-1}$ corresponding to the class $A_{\Gamma_{\omega,-M},\Gamma_{\omega,M}}$. Using Proposition 5.2 and Remark 4.1 it follows that E is a minimizer in this new class, and therefore $\mathrm{Per}(E,B_R\cap O)\le \mathrm{Per}(L,B_R\cap O)$. Since R is arbitrary, the proposition follows. □

This completes the proof of Theorem 5.1 for the case ω rational.

5.1. The case ω irrational. We now proceed to consider the case when the slope ω of the plane is irrational. Given $\omega\in\mathbb{R}^n\backslash\mathbb{Q}^n$, there exists a sequence $\{\omega_j\}\in\mathbb{Q}^n$ with $\omega_j\to\omega$. For each ω_j, we let $\{E_{\omega_j}\}$ denote the corresponding class A minimizers given by Theorem 5.1. From Lemma 5.1 we have

$$\mathrm{Per}(E_{\omega_j},B_R\cap O)\le CR^{n-1}.$$

Thus, $\{E_{\omega_j}\}$ has a subsequence that is convergent in $L^1(B_R\cap O)$. By applying the diagonal procedure, we obtain a subsequence of $\{E_{\omega_j}\}$ (which we will denote again as $\{E_{\omega_j}\}$) and a set E_ω such that $E_{\omega_j}\to E_\omega$ in $L^1_{loc}(\mathbb{R}^n\cap O)$. We need to check that E_ω is a class A minimizer. We let L denote any set that coincides with E_w outside the ball B_{R-1}. We define, for each j and $R\le r\le R+1$,

$$F_j^r=\begin{cases} L & \text{in} \quad B_r,\\ E_j & \text{in} \quad B_{R+1}\setminus\overline{B}_r.\end{cases}$$

Since each E_j is a class A minimizer we have

$$\begin{aligned}\int_{B_{R+1}\cap O}|D\varphi_{E_j}| &\le \int_{B_{R+1}\cap O}|D\varphi_{F_j^r}|\\ &=\int_{B_r\cap O}|D\varphi_L|+\int_{\partial B_r\cap O}|D\varphi_{F_j^r}|+\int_{(B_{R+1}\setminus\overline{B}_r)\cap O}|D\varphi_{E_j}|\\ &=\int_{B_r\cap O}|D\varphi_L|+\int_{\partial B_r\cap O}|(\varphi_L)^r_{tr}-(\varphi_{E_j})^r_{tr}|d\mathcal{H}_{n-1}\\ &\quad+\int_{(B_{R+1}\setminus\overline{B}_r)\cap O}|D\varphi_{E_j}|,\end{aligned}$$

where $(\varphi_L)^r_{tr}$ and $(\varphi_{E_j})^r_{tr}$ are the traces (see Theorem A.3) of φ_L and φ_{E_j} on ∂B_r, respectively. We recall that, for almost every $R\le r\le R+1$, the traces $(\varphi_L)^r_{tr}$ and $(\varphi_{E_j})^r_{tr}$ coincide with the corresponding characteristic functions (see [27]). Using this fact and passing the last term in the right-hand side of the previous inequality to the left we obtain, for almost every $R\le r\le R+1$,

$$\int_{B_r\cap O}|D\varphi_{E_j}|\le\int_{B_r\cap O}|D\varphi_L|+\int_{\partial B_r\cap O}|\varphi_L-\varphi_{E_j}|d\mathcal{H}_{n-1}. \tag{29}$$

We have the identity

$$\int_{(B_{R+1}\setminus\overline{B}_R)\cap O}|\varphi_{E_j}-\varphi_L|=\int_R^{R+1}\int_{\partial B_r\cap O}|\varphi_{E_j}-\varphi_L|d\mathcal{H}_{n-1}dr. \tag{30}$$

Since $E_w=L$ in $B_{R+1}\setminus\overline{B_R}$ it follows that $E_j\to L$ in $L^1((B_{R+1}\setminus\overline{B}_R)\cap O)$. This implies that (30) converges to 0 as $j\to\infty$, and therefore there exists a subsequence of $\{E_j\}$ (that we shall denote again as E_j) such that, for almost every $R\le r\le R+1$,

$$\int_{\partial B_r\cap O}|\varphi_{E_j}-\varphi_L|d\mathcal{H}_{n-1}\to 0. \tag{31}$$

From (29) and (31), it follows that, for almost every $R \le r \le R+1$,

$$\limsup_{r\to o} \int_{B_r\cap O} |D\varphi_{E_j}| \le \int_{B_r\cap O} |D\varphi_L|, \tag{32}$$

and hence

$$\begin{aligned}\int_{B_r\cap O} |D\varphi_{E_w}| &\le \liminf \int_{B_r\cap O} |D\varphi_{E_j}| \\ &\le \int_{B_r\cap O} |D\varphi_L|.\end{aligned}$$

Since $L = E_w$ in $B_{R+1} \setminus \overline{B}_R$ we conclude that

$$\int_{B_R\cap O} |D\varphi_{E_w}| \le \int_{B_R\cap O} |D\varphi_L|, \tag{33}$$

which proves that E_w is a class A minimizer. Clearly, we also have $d(E_w, \Pi_1) \le 2\lambda\sqrt{n}$. □

6. Behavior of the minimizers near the boundaries of the exclusions. It is an easy exercise to check that, for $n = 2$, minimizers must enter the exclusions *orthogonally*. In higher dimensions, the analogous result can be deduced (once we have the regularity of the minimizers up to the boundary of the exclusions) by studying the first variation of the area. An analysis of the Euler–Lagrange equation is done in [31], and we explain in this section how to use the results in [31] to obtain the fact that the minimizers must enter the exclusions *orthogonally*. For a proof of this orthogonality property, using techniques of geometric measure theory, we refer the reader to [29]. When the exclusions have C^2 boundary, the regularity of the minimizers near the boundaries of the exclusions is proven in [29].

In order to show how the orthogonality result follows from the work in [31], we must first recall that the minimal surface problem can also be studied by considering the surfaces as graphs of functions (nonparametric approach; cf. [27]). We can think of the nonparametric minimal surface problem as the problem of minimizing the energy among a class of functions with fixed boundary data and where the density at each point is one. In [31], the nonparametric minimal surface problem involving two different media is considered (the density at each point is given by a positive, piecewise smooth function), and the Euler–Lagrange equation is derived from the variational form. The solution has a jump across the interface that separates the two media, and a jump condition is derived that generalizes Snell's law to higher dimensions.

For the case $n = 2$, following [31] we consider a two-dimensional domain $D = [a, b] \times [c, d]$, and we seek a function $u(x, y)$ which minimizes the functional

$$\begin{aligned} E(u) &= \int_D c(x, y, u(x, y))\sqrt{1 + |Du(x, y)|^2}\,dx\,dy, \\ u(x, y)|_{\partial D} &= u_0(x, y), \end{aligned} \tag{34}$$

where $u_0(x, y)$ is a given boundary condition and $c(x, y, z)$ is a positive piecewise smooth function which has a finite jump across a surface $S = \{(x, y, z) : g(x, y, z) = 0\}$. We assume that the graph of the minimizer of (34) intersects the surface S at a curve Γ. We denote γ as the projection of Γ on the (x, y)-plane. The curve γ divides the set D in two regions, D_1 and D_2. It is proven in [31] that if the surface S can

be expressed locally as the graph of the function $z = \phi(x, y)$, then the jump of the derivatives of $u(x, y)$ across the surface S must satisfy the following generalized Snell's law in three dimensions (which can be extended to higher dimensions):

$$c^- \mathbf{n_1} \cdot \mathbf{m}|_\Gamma = c^+ \mathbf{n_2} \cdot \mathbf{m}|_\Gamma, \tag{35}$$

where c^- and c^+ are the weights of the two different media, $\mathbf{n_i} = \frac{(-u_x, -u_y, 1)}{\sqrt{1+u_x^2+u_y^2}}$ are the normal directions of the surface $u(x, y)$ in D_i, $i = 1, 2$, and $\mathbf{m} = \frac{(-\phi_x, -\phi_y, 1)}{\sqrt{1+\phi_x^2+\phi_y^2}}$ is the unit normal direction of S.

We note that if we consider the case $c^- = \epsilon$, $c^+ = 1$ and then compute the limit in (35) as $\epsilon \to 0$ we obtain

$$\mathbf{n_2} \cdot \mathbf{m}|_\Gamma = 0, \tag{36}$$

which implies that $\mathbf{n_2}$ and $\mathbf{m}$ are orthogonal vectors. We conclude from this that the minimizer E meets (on its regular points) the boundary of the exclusions orthogonally.

7. Connection with homogenization of Hamilton–Jacobi equations. In this section we explore some connections with the theory of homogenization of Hamilton–Jacobi equations. We first recall some of the main issues concerning the homogenization of Hamilton–Jacobi equations, and then we present the connection with the degenerate metric considered earlier.

We consider, for each $0 < \epsilon \leq 1$, the viscosity solution u^ϵ of the following problem:

$$H\left(Du^\epsilon, \frac{x}{\epsilon}\right) = 0 \text{ in } \mathbb{R}^n, \tag{37}$$

where $H : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ is a periodic function in the second variable. Under a suitable hypothesis (see, for instance, [22]) we can homogenize (37); i.e., the sequence of viscosity solutions $\{u^\epsilon\}$ converges as $\epsilon \to 0$ to the viscosity solution u of the averaged problem

$$\overline{H}(Du) = 0 \text{ in } \mathbb{R}^n,$$

where $\overline{H} : \mathbb{R}^n \to \mathbb{R}$ is defined as follows: for each $p \in \mathbb{R}^n$, $\overline{H}(p)$ is the unique number for which the PDE

$$\begin{aligned} H(p + D_y v, y) &= \overline{H}(p) \text{ in } \mathbb{R}^n, \\ v &\text{ is } [0, 1]^n\text{-periodic} \end{aligned} \tag{38}$$

has a viscosity solution.

As explained in the introduction, the function $\overline{H}$ is called the effective Hamiltonian, and an interesting endeavor is to study the structure of $\overline{H}$ in order to find explicit formulas for it. This is still largely an open problem, and [22, 19, 20, 24, 17, 16] contain results in this direction. The goal of this section is to provide a particular example of (37) for which we can explicitly compute the limiting function u.

We recall our earlier consideration of $\mathbb{R}^n$ as the lattice of cubes $[0, 1]^n + \mathbb{Z}^n$ where each cube of side 1 has an internal exclusion. The exclusions satisfy properties 1, 2, and 3 stated in the introduction. In this section we work with surfaces of codimension $(n - 1)$, i.e., curves, instead of surfaces of codimension 1.

We fix $x \in \mathbb{R}^n$, and for each $0 < \epsilon \leq 1$ we consider the sequence of lattices $\epsilon([0, 1]^n + \mathbb{Z}^n)$. We let $\mathcal{J}$ denote the set of all curves joining the origin with x. We

use the degenerate metric introduced in this paper to measure the length of each curve $l \in \mathcal{J}$. The length of l at the scale ϵ, that is, when we consider l as residing in the configuration $\epsilon([0,1]^n + \mathbb{Z}^n)$, is obtained by neglecting the portions inside the exclusions. This length depends on ϵ since the configuration of the lattice changes as we let $\epsilon \to 0$. We let l_ϵ denote the curve of minimal length and denote this optimal length by $d_\epsilon(0,x)$. We shall refer to the number $d_\epsilon(0,x)$ as the *smallest distance between* 0 *and* x *at the scale* ϵ.

We define, for each $0 < \epsilon \leq 1$, the sequence of functions

$$u^\epsilon(x) = d_\epsilon(0,x), \quad x \in \mathbb{R}^n. \tag{39}$$

We have the following.

THEOREM 7.1. *If* $\mathcal{I}$ *denotes the union of all exclusions and* $O = \mathbb{R}^n \backslash \mathcal{I}$, *then*

$$\begin{cases} |Du_\epsilon| = 1 & \text{in} \quad \epsilon O, \\ u_\epsilon & \text{is constant on each connected component of} \quad \epsilon\mathcal{I}. \end{cases} \tag{40}$$

Proof. Without loss of generality we can assume $\epsilon = 1$. We define

$$v(x) = d_1(x,0), \quad x \in \mathbb{R}^n. \tag{41}$$

$v(x)$ is the smallest distance from x to the origin, and since we compute the length of a path $l \in \mathcal{J}$ by neglecting the portions inside the exclusions, we have that v is constant on each exclusion, which is connected. We prove now that v solves the eikonal equation $|Dv| = 1$ in the viscosity sense outside the exclusions. We prove first that v is a viscosity subsolution of $|Du| = 1$. If φ is a C^1 function such that $v - \varphi$ has a local maximum at the point $x_0 \in O$, we need to prove that $|D\varphi(x_0)| \leq 1$. Since $v - \varphi$ has a local maximum at x_0 it follows that $v(x) - v(x_0) \leq \varphi(x) - \varphi(x_0)$ for all x in a neighborhood of x_0. Therefore, for all z satisfying $|z| = 1$ and for all h small enough, we have

$$\begin{aligned} v(x_0 + hz) - v(x_0) \leq \varphi(x_0 + hz) - \varphi(x_0) &= \int_0^h \frac{d}{ds}\varphi(x_0 + sz) \\ &= \int_0^h D\varphi(x_0 + sz) \cdot z ds \leq \int_0^h D\varphi(x_0) \cdot z ds + Ch^2. \end{aligned}$$

If we define $z_0 = -\frac{D\varphi(x_0)}{|D\varphi(x_0)|}$, then

$$v(x_0 + hz_0) - v(x_0) \leq -\int_0^h |D\varphi(x_0)| ds + Ch^2 = -h|D\varphi(x_0)| + Ch^2. \tag{42}$$

We now use the fact that v is a Lipschitz function, and from (42) we obtain

$$h|D\varphi(x_0)| \leq v(x_0) - v(x_0 + hz_0) + Ch^2 \leq |hz_0| + Ch^2,$$

and hence

$$|D\varphi(x_0)| \leq 1 + Ch.$$

By letting $h \to 0$, we conclude that $|D\varphi(x_0)| \leq 1$. We now prove that v is a supersolution. If φ is a C^1 function such that $v - \varphi$ has a local minimum at the point $x_0 \in O$,

we need to prove that $|D\varphi(x_0)| \geq 1$. Since $v-\varphi$ has a local minimum at x_0, it follows that $v(x)-v(x_0) \geq \varphi(x)-\varphi(x_0)$ for all x in a neighborhood of x_0. Therefore, if h is small enough, we have

$$v(x_0+hz)-v(x_0) \geq \varphi(x_0+hz)-\varphi(x_0) = \int_0^h \frac{d}{ds}\varphi(x_0+sz) = \int_0^h D\varphi(x_0+sz)\cdot z ds$$

$$\geq \int_0^h D\varphi(x_0)\cdot z ds - Ch^2 \geq -h|D\varphi(x_0)| - Ch^2 \tag{43}$$

for all $|z|=1$. We fix h small enough. We note that $v(x_0)=\inf_{|z|=1}\{h+v(x_0+hz)\}$, and hence there exists a point z_0 such that $v(x_0+hz_0)+h \leq v(x_0)+h^2$. From (43) we obtain $h|D\varphi(x_0)| \geq v(x_0)-v(x_0+hz_0)-Ch^2 \geq h-h^2-Ch^2$, and hence $|D\varphi(x_0)| \geq 1-h-Ch$. Letting $h \to 0$ we obtain $|D\varphi(x_0)| \geq 1$. □

From standard theory of viscosity solutions we have that $\{u_\epsilon\}$ contains a subsequence that converges uniformly to a function u_0. Constructing the PDE that u_0 solves (i.e., the homogenization of (40)) is difficult. We present in this section some partial results toward this homogenization.

We proceed to compute u_0 *for the particular case* $n=2$ and we assume, in addition to properties 1, 2, and 3 given in the introduction, that the exclusions are *balls of radius* ρ. Given two fixed points P and Q in the plane, we let $l_\epsilon^\rho(P,Q)$ denote the optimal path joining P and Q at the scale ϵ. We denote $d_\epsilon^\rho(P,Q)$ as the length of $l_\epsilon^\rho(P,Q)$. The behavior of $d_\epsilon^\rho(P,Q)$ depends on the value of ρ, where $0<\rho\leq\frac{1}{2}$ (we note that the radius of the exclusions at the scale ϵ is $\epsilon\rho$). We have, for any $0<\epsilon\leq 1$,

$$0 \leq d_\epsilon^\rho(P,Q) \leq |P-Q|_2. \tag{44}$$

Thus, fixing ρ and letting $\epsilon \to 0$ it follows that $\{d_\epsilon^\rho(P,Q)\}$ contains a subsequence that converges to a number, say $d_0^\rho(P,Q)$.

If we assume that X and Y are centers of exclusions at the scale ϵ, we can replace $l_\epsilon^\rho(X,Y)$ inside the exclusions with lines so that this optimal path is composed of a sequence of segments. We can classify (after a suitable translation and/or rotation) these segments in the following four categories:

1. a segment joining the points $(0,0)$ and $(\frac{i}{\epsilon},\frac{j}{\epsilon})$, where $i,j\in\mathbb{Z}^+$ are relatively prime and $j<i$;
2. the segment joining the points $(0,0)$ and $(\frac{1}{\epsilon},0)$;
3. the segment joining the points $(0,0)$ and $(0,\frac{1}{\epsilon})$;
4. the segment joining $(0,0)$ and $(\frac{1}{\epsilon},\frac{1}{\epsilon})$.

We identify a segment of type 1 with the pair $[i,j]$, a segment of types 2 or 3 with $[1,0]$, and a segment of type 4 with $[1,1]$. Therefore, any optimal path joining two points that are centers of exclusions is composed of a sequence of segments belonging to the set

$$\mathcal{P} = \{[i,j] : i,j\in\mathbb{Z}^+, i,j \quad \text{are relatively prime, } j<i\} \cup \{[1,1]\} \cup \{[1,0]\}.$$

We prove in the next theorem that if ρ is large enough, then the optimal path joining two centers of exclusions is composed only of segments of the type $[1,0]$.

THEOREM 7.2. *If* $\rho > \frac{2-\sqrt{2}}{2}$ *then, for any* $0<\epsilon\leq 1$, *the optimal path connecting two points that are centers of exclusions is composed only of segments of the type* $[1,0]$. *Moreover, if* P *and* Q *are any two points, we have that*

$$\lim_{\epsilon\to 0} d_\epsilon^\rho(P,Q) = (1-2\rho)|P-Q|_1.$$

Proof. We fix $\epsilon > 0$, and thus in this proof we work in the domain $\epsilon([0,1]^n + \mathbb{Z}^n)$. We denote $X = (x_1, x_2)$ and $Y = (y_1, y_2)$ as two points that are centers of exclusions. We can assume, without loss of generality, that $y_1 \geq x_1$ and $y_2 \geq x_2$. We proceed by contradiction and assume that $l_\epsilon^\rho(X,Y)$ has a segment of the type 1 or 4. Therefore, the path $l_\epsilon^\rho(X,Y)$ contains a segment joining the points $\epsilon(i+\frac{1}{2}, j+\frac{1}{2})$ and $\epsilon(i+\frac{1}{2}+m, j+\frac{1}{2}+n)$, where $n \leq m$, $n \geq 2$, and m and n are prime relative to each other. Since $l_\epsilon^\rho(X,Y)$ is the optimal path we have that

$$\begin{aligned} m(\epsilon - 2\epsilon\rho) + n(\epsilon - 2\epsilon\rho) &\geq \sqrt{\epsilon^2 m^2 + \epsilon^2 n^2} - 2\epsilon\rho, \\ m(1-2\rho) + n(1-2\rho) &\geq \sqrt{m^2+n^2} - 2\rho, \\ m + n - \sqrt{m^2+n^2} &\geq 2(m+n-1)\rho, \\ \Rightarrow \rho &\leq \frac{m+n-\sqrt{m^2+n^2}}{2(m+n-1)}. \end{aligned}$$

We claim that $\frac{m+n-\sqrt{m^2+n^2}}{2(m+n-1)} \leq \frac{2-\sqrt{2}}{2}$. To prove this, we consider the function $f(x) = \frac{x+n-\sqrt{x^2+n^2}}{2(x+n-1)}$ and its derivative $f'(x) = \frac{1}{2}\frac{n^2-\sqrt{x^2+n^2}+x-xn}{\sqrt{n^2+x^2}(x+n+1)^2}$. We note that $f'(x) \leq 0$ if $x \geq 0$. This implies that f is decreasing, and thus $f(m) \leq f(n)$. By a simple substitution it follows that $f(n) = \frac{2n-\sqrt{2}n}{2(2n-1)} = \frac{2-\sqrt{2}}{2}(\frac{n}{2n-1}) \leq \frac{2-\sqrt{2}}{2}$ (since $\frac{n}{2n-1} \leq 1$). Hence, $\rho \leq f(m) \leq \frac{2-\sqrt{2}}{2}$, which contradicts the fact that $\rho > \frac{2-\sqrt{2}}{2}$. This proves the first part of the theorem. Because of the above result, we can explicitly compute $d_\epsilon^\rho(X,Y)$:

$$\begin{aligned} d_\epsilon^\rho(X,Y) &= \frac{y_2 - x_2}{\epsilon}(\epsilon - 2\epsilon\rho) + \frac{y_1 - x_1}{\epsilon}(\epsilon - 2\epsilon\rho) \\ &= (1-2\rho)[(y_2 - x_2) + (y_1 - x_1)] \\ &= (1-2\rho)|Y - X|_1. \end{aligned} \tag{45}$$

We now denote P and Q as any two points in the plane. If P' and Q' are the closest centers of exclusions to P and Q, respectively, we have

$$d_\epsilon^\rho(P',Q') - \sqrt{2}\epsilon \leq d_\epsilon^\rho(P,Q) \leq d_\epsilon^\rho(P',Q') + \sqrt{2}\epsilon.$$

From (45) we have

$$(1-2\rho)|P'-Q'|_1 - \sqrt{2}\epsilon \leq d_\epsilon^\rho(P,Q) \leq (1-2\rho)|P'-Q'|_1 + \sqrt{2}\epsilon.$$

Using the triangle inequality, again

$$\begin{aligned} (1-2\rho)(|P-Q|_1 - 2\sqrt{2}\epsilon) - \sqrt{2}\epsilon \leq d_\epsilon^\rho(P,Q) \\ \leq (1-2\rho)(|P-Q|_1 + 2\sqrt{2}\epsilon) + \sqrt{2}\epsilon. \end{aligned}$$

Letting $\epsilon \to 0$ yields

$$\begin{aligned} 1 - 2\rho \leq \frac{d_0^\rho(P,Q)}{|P-Q|_1} &\leq 1 - 2\rho \\ \Rightarrow \\ d_0^\rho(P,Q) &= (1-2\rho)|P-Q|_1. \end{aligned}$$ □

We now wish to study the behavior of the optimal path as $\rho \to 0$. As ρ decreases, new paths (new segments of the collection $\mathcal{P}$) become available. For each

segment $[i,j]$ there exists a critical radius $\rho_{[i,j]}$, which is the largest radius for which $d_1^{\rho_{[i,j]}}((0,0),(i,j)) = \sqrt{i^2+j^2}$.

Since $\mathcal{P}$ is countable, we can enumerate the sequence $\{\rho_{[i,j]}\}$ in such a way that the coordinate i is always increasing. We have the following lemma.

LEMMA 7.1. $\lim_{i\to\infty} \rho_{[i,j]} = 0$.

Proof. We recall that $[i,j]$ represents the segment joining $(0,0)$ with (i,j). We denote by $P = (p_1,p_2)$ the closest point (other than the extremes) with integer coordinates to the segment, and we denote this distance as d. The point P satisfies the equation $|\frac{i}{j} - \frac{p_1}{p_2}| = \frac{1}{jp_2}$, that is, $|ip_2 - jp_1| = 1 = A(p)$, where $A(p)$ is the area of the parallelogram spanned by (i,j) and (p_1,p_2). Hence we have that $\frac{1}{2} = d\frac{\sqrt{i^2+j^2}}{2}$, which implies that $d = \frac{1}{\sqrt{i^2+j^2}}$. We define $l = \sqrt{i^2+j^2}$, $l_1 = \sqrt{p_1^2+p_2^2}$, and $l_2 = \sqrt{(i-p_1)^2+(j-p_2)^2}$. Solving the equation $l - 2\rho = l_1 + l_2 - 4\rho$ for ρ, we obtain the critical radius for which the segment joining $(0,0)$ with (i,j) is a better path than the one joining the points $(0,0),(p_1,p_2)$, and (i,j). We have that $\rho = \frac{l_1+l_2-l}{2}$. Since $l_1 + l_2 \le 2d + l$ it follows that $\rho \le \frac{2d+l-l}{2} = d = \frac{1}{\sqrt{i^2+j^2}}$. Since $\rho_{[i,j]} \le \rho$ the lemma holds. ∎

An easy computation gives us $\rho_{[1,1]} = \frac{2-\sqrt{2}}{2}$, $\rho_{[2,1]} = \frac{1+\sqrt{2}-\sqrt{5}}{2}$, and $\rho_{[3,1]} = \frac{1+\sqrt{5}-\sqrt{10}}{2}$. We have the following theorem.

THEOREM 7.3. *Let P, Q be any two points in the plane. Then we have the following:*

(a) *If $\frac{1+\sqrt{2}-\sqrt{5}}{2} < \rho \le \frac{2-\sqrt{2}}{2}$, we have*

$$\lim_{\epsilon\to 0} d_\epsilon^\rho(P,Q) = |P-Q|_{1,1},$$

where $|\cdot|_{1,1} : \mathbb{R}^2 \to \mathbb{R}^+$ is given by

$|(x,y)|_{1,1} = (\sqrt{2}-1)|x| + (1-2\rho)|y|$ *if* $|x| \le |y|$ *and*

$|(x,y)|_{1,1} = (\sqrt{2}-1)|y| + (1-2\rho)|x|$ *if* $|y| \le |x|$.

(b) *If $\frac{1+\sqrt{5}-\sqrt{10}}{2} < \rho \le \frac{1+\sqrt{2}-\sqrt{5}}{2}$, we have*

$$\lim_{\epsilon\to 0} d_\epsilon^\rho(P,Q) = |P-Q|_{2,1},$$

where $|\cdot|_{2,1} : \mathbb{R}^2 \to \mathbb{R}^+$ is given by

$|(x,y)|_{2,1} = (1-2\rho)|x| + (\sqrt{5}-2+2\rho)|y|$ *if* $|y| \le \frac{|x|}{2}$,

$|(x,y)|_{2,1} = (2\sqrt{2}-\sqrt{5}-2\rho)|y| + (\sqrt{5}-\sqrt{2})|x|$ *if* $\frac{|x|}{2} < |y| \le |x|$,

$|(x,y)|_{2,1} = (1-2\rho)|y| + (\sqrt{5}-2-2\rho)|x|$ *if* $|y| \ge 2|x|$, *and*

$|(x,y)|_{2,1} = (2\sqrt{2}-\sqrt{5}+2\rho)|x| + (\sqrt{5}-\sqrt{2})|y|$ *if* $|x| \le |y| < 2|x|$.

Moreover, $|\cdot|_{1,1}$ and $|\cdot|_{2,1}$ define norms in $\mathbb{R}^2$.

Proof. We denote $X = (x_1,x_2)$ and $Y = (y_1,y_2)$ as centers of exclusions (at the scale ϵ). We can assume that $x_1 \le y_1$ and $x_2 \le y_2$. In order to prove (a), we consider first the case when $y_2 - x_2 \le y_1 - x_1$. Solving the equation $\sqrt{5} - 2\rho = \sqrt{2} + 1 - 4\rho$, we obtain $\rho = \frac{\sqrt{2}+1-\sqrt{5}}{2}$, the critical radius for which the next segment $[2,1]$ becomes available. Therefore, if ρ belongs to the interval given in (a), the only paths available are $[1,0]$ and $[1,1]$. Thus, the optimal path $l_\epsilon^\rho(X,Y)$ has as many segments $[1,1]$ as possible, since for this interval $[1,1]$ is better than two segments of type $[1,0]$. Hence,

we can compute $d_\epsilon^\rho(X,Y)$ explicitly, and we obtain

$$\begin{aligned} d_\epsilon^\rho(X,Y) &= \frac{y_2-x_2}{\epsilon}(\sqrt{2}\epsilon - 2\epsilon\rho) + \frac{(y_1-x_1)-(y_2-x_2)}{\epsilon}(\epsilon - 2\epsilon\rho) \\ &= (\sqrt{2}-1)(y_2-x_2) + (1-2\rho)(y_1-x_1) \\ &= |Y-X|_{1,1}. \end{aligned}$$

The case $y_2 - x_2 \geq y_1 - x_1$ is computed in the same way, except that we interchange the roles of the coordinates. To prove (a) we can proceed now in exactly the same way (provided that $|\cdot|_{1,1}$ is a norm) as in Theorem 7.2. We need to check that $|\cdot|_{1,1}$ defines a norm in $\mathbb{R}^2$. We need only to show that the triangle inequality holds, and there are several cases to verify.

We let $(x,y),(w,z)$ be any two points in the plane, and we consider the case $|y| \leq |x|$, $|w| \leq |z|$ and $|x+w| \leq |y+z|$. We need to prove that $(\sqrt{2}-1)|x+w|+(1-2\rho)|y+z| \leq (\sqrt{2}-1)(|y|+|w|)+(1-2\rho)(|x|+|z|)$; that is, $(\sqrt{2}-1)(|x+w|-|y|-|w|)+(1-2\rho)(|y+z|-|x|-|z|) \leq 0$. Using the triangle inequality for real numbers we can see that the last inequality is true since $|x|-|y| \geq 0$ and $1-2\rho > \sqrt{2}-1$ for ρ in the interval given in (a).

Considering now the case $|y| \leq |x|$, $|w| \geq |z|$, and $|x+w| \leq |y+z|$, we need to prove that $(\sqrt{2}-1)|x+w|+(1-2\rho)|y+z| \leq (\sqrt{2}-1)(|y|+|z|)+(1-2\rho)(|x|+|w|)$; that is, $(\sqrt{2}-1)(|x+w|-|y|-|z|)+(1-2\rho)(|y+z|-|x|-|w|) \leq 0$. Using the triangle inequality for real numbers we can see that the last inequality is true.

Proceeding to the case $|y| \leq |x|$, $|w| \leq |z|$, and $|x+w| \geq |y+z|$, we need to prove that $(\sqrt{2}-1)|y+z|+(1-2\rho)|x+w| \leq (\sqrt{2}-1)(|y|+|w|)+(1-2\rho)(|x|+|z|)$; that is, $(\sqrt{2}-1)(|y+z|-|y|-|w|)+(1-2\rho)(|x+w|-|x|-|z|) \leq 0$. Using the triangle inequality for real numbers we can see that the last inequality is true since $|z|-|w| \geq 0$ and $1-2\rho > \sqrt{2}-1$ for ρ in the interval given in (a).

Finally, we check that $|y| \leq |x|$, $|w| \geq |z|$, and $|x+w| \geq |y+z|$. We need to prove that $(\sqrt{2}-1)|y+z|+(1-2\rho)|x+w| \leq (\sqrt{2}-1)(|y|+|z|)+(1-2\rho)(|x|+|w|)$; that is, $(\sqrt{2}-1)(|y+z|-|y|-|z|)+(1-2\rho)(|x+w|-|x|-|w|) \leq 0$, which is true due to the triangle inequality. There are four more cases corresponding to $|y| \geq |x|$, but they are proven in the same way. The unit ball for this norm is a polygon with eight edges as shown in Figure 2.

To prove (b) we note that by solving the equation $\sqrt{10}-2\rho = \sqrt{5}+1-4\rho$ we obtain $\rho = \frac{\sqrt{5}+1-\sqrt{10}}{2}$, the critical radius for which the next segment $[3,1]$ becomes available. If $p > 0$ and $q \geq 0$ are two integers satisfying $-p+2q \leq 0$, then, for ρ in the interval given in (b), the best path joining $(0,0)$ with (p,q) consists only of segments of the type $[2,1]$ and $[1,0]$. Furthermore, this path takes as many $[2,1]$ segments as possible and then completes the trajectory with segments $[1,0]$. If $-p+2q > 0$ and $q < p$, the best path consists only of segments of the type $[2,1]$ and $[1,1]$, and this path takes as many $[2,1]$ segments as possible and then completes the trajectory with segments $[1,1]$. Thus, we can compute $d_\epsilon^\rho(X,Y)$ exactly as before and proceed as in Theorem 7.2. The unit ball for $|\cdot|_{2,1}$ is a polygon with 16 edges as shown in Figure 2. □

The following theorem gives an asymptotic behavior of d_0^ρ.

THEOREM 7.4. *Let P, Q be any two points in the plane. Then*

$$\lim_{\rho \to 0} d_0^\rho(P,Q) = |P-Q|_2.$$

Proof. We denote X and Y as two points that are centers of exclusions (at the scale ϵ). The optimal path $l_\epsilon^\rho(X,Y)$ intersects a finite numbers of balls, say N. We

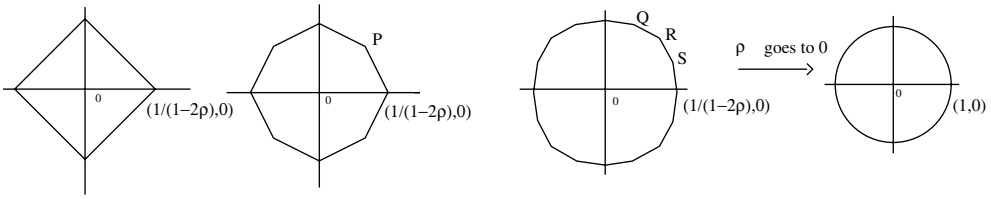

FIG. 2. *Unit balls for limiting norms.* $P = R = (\frac{1}{\sqrt{2}-2\rho}, \frac{1}{\sqrt{2}-2\rho})$, $Q = (\frac{1}{\sqrt{5}-2\rho}, \frac{2}{\sqrt{5}-2\rho})$, $S = (\frac{2}{\sqrt{5}-2\rho}, \frac{1}{\sqrt{5}-2\rho})$.

define

$$\tilde{d}^{\rho}_{\epsilon}(X,Y) = d^{\rho}_{\epsilon}(X,Y) + (N-1)(2\epsilon\rho). \tag{46}$$

Since the distance between two centers of exclusions is at least ϵ it follows that

$$\begin{aligned} N &\leq \frac{\tilde{d}^{\rho}_{\epsilon}(X,Y)}{\epsilon} + 1 \\ \Rightarrow N - 1 &\leq \frac{\tilde{d}^{\rho}_{\epsilon}(X,Y)}{\epsilon}. \end{aligned} \tag{47}$$

Hence, using (46) and (47) we obtain

$$\begin{aligned} d^{\rho}_{\epsilon}(X,Y) &\geq \tilde{d}^{\rho}_{\epsilon}(X,Y) - \frac{\tilde{d}^{\rho}_{\epsilon}(X,Y)}{\epsilon}(2\epsilon\rho) \\ &= \tilde{d}^{\rho}_{\epsilon}(X,Y)(1-2\rho) \\ &\geq (1-2\rho)|X-Y|_2. \end{aligned} \tag{48}$$

We denote P' and Q' as the closest points to P and Q, respectively (at the scale ϵ), in such a way that both P' and Q' are centers of exclusions. We have

$$d^{\rho}_{\epsilon}(P',Q') - \sqrt{2}\epsilon \leq d^{\rho}_{\epsilon}(P,Q) \leq |P-Q|_2.$$

Using (48), we obtain

$$(1-2\rho)|P'-Q'|_2 - \sqrt{2}\epsilon \leq d^{\rho}_{\epsilon}(P,Q) \leq |P-Q|_2.$$

Using the triangle inequality we have

$$(1-2\rho)(|P-Q|_2 - \sqrt{2}\epsilon) - \sqrt{2}\epsilon \leq d^{\rho}_{\epsilon}(P,Q) \leq |P-Q|_2.$$

Letting $\epsilon \to 0$ we have

$$1 - 2\rho \leq \frac{d^{\rho}_{0}(P,Q)}{|P-Q|_2} \leq 1.$$

This implies

$$\lim_{\rho \to 0} d^{\rho}_{0}(P,Q) = |P-Q|_2. \qquad \square$$

Figure 2 shows the unit balls of norms d^{ρ}_{0} for the cases $\frac{2-\sqrt{2}}{2} < \rho < 0.5$, $\frac{1+\sqrt{2}-\sqrt{5}}{2} < \rho \leq \frac{2-\sqrt{2}}{2}$, and $\frac{1+\sqrt{5}-\sqrt{10}}{2} < \rho \leq \frac{1+\sqrt{2}-\sqrt{5}}{2}$. Our results suggest that

as ρ gets smaller the behavior of the unit ball changes, though it is always polygonal with more and mores edges until it becomes a circle in the limit. That is, *as* $\rho \to 0$, *the sequence of norms converges to the Euclidean norm.*

Remark 7.1. The norms d_0^ρ can be thought of as an example of the so-called stable norms (see, for instance, [33, 28, 11, 6, 10, 5, 4] and the references therein). However, in this paper we are interested in looking at these norms in the context of Hamilton–Jacobi equations in order to provide an explicit example of homogenization of Hamilton–Jacobi equations. As mentioned earlier, finding explicit formulas for the effective Hamiltonian $\overline{H}$ is essentially still an open problem.

Remark 7.2. Theorems 7.2 and 7.3 provide, for $n = 2$, an explicit formula for u_0, which is the uniform limit of the solutions of (40). The homogenization of (40) is difficult to achieve. The construction of the corresponding effective Hamiltonian $\overline{H}$ does not follow from [30] due to the behavior of the functions u^ϵ on the boundaries of the exclusions.

Appendix A.

We refer to the standard references [27, 25, 2] for the details related to the theory of sets of finite perimeter.

DEFINITION A.1. *Throughout this paper, we denote* $B(x,r)$ *as the open ball centered at* x *and radius* r *(we shall also use the notation* B_r *when* $x = 0$*). We denote* $\mathcal{H}_k$ *as the* k*-dimensional Hausdorff measure in* $\mathbb{R}^n$*, and* $\mathcal{L}^n$ *denotes the Lebesgue measure in* $\mathbb{R}^n$*. We recall that* $\mathcal{H}_n = \mathcal{L}^n$*. At times we shall denote* $|E|$ *as the* $\mathcal{L}^n$*-Lebesgue measure of* E*.*

DEFINITION A.2 (see [27, p. 4]). *We let* $\Omega \subset \mathbb{R}^n$ *denote an open set. If* $f \in L^1(\Omega)$*, we define*

$$\int_\Omega |Df| = \sup\left\{\int_\Omega f \mathrm{div} g : g \in C_0^1(\Omega;\mathbb{R}^n), \quad |g(x)| \le 1, \quad \text{for} \quad x \in \Omega\right\}.$$

DEFINITION A.3. *A function* $f \in L^1(\Omega)$ *is said to have bounded variation in* Ω *if* $\int_\Omega |Df| < \infty$*. We define* $BV(\Omega)$ *as the space of all functions in* $L^1(\Omega)$ *with bounded variation. With the norm* $|f|_{BV} = |f|_{L^1(\Omega)} + \int_\Omega |Df|$*,* $BV(\Omega)$ *is a Banach space. If* $f \in BV(\Omega)$*, then* Df*, the gradient of* f *in the sense of distributions, is a vector valued Radon measure in* Ω *with total variation* $|Df|$*. Thus we may extend the definition of* $\int_A |Df|$ *to include cases where* $A \subset \Omega$ *is not necessarily open.*

DEFINITION A.4. *If* E *denotes a Borel set, we define the perimeter of* E *in* Ω *as*

$$\mathrm{Per}(E,\Omega) = \int_\Omega |D\varphi_E|,$$

where φ_E *is the characteristic function of the set* E*. If* $\mathrm{Per}(E,\Omega) < \infty$ *for every bounded open set* Ω*, then* E *is called a set of locally finite perimeter in* $\mathbb{R}^n$*. For simplicity, we will denote a set of locally finite perimeter in* $\mathbb{R}^n$ *simply as a* set of finite perimeter*. Also, at times we shall denote* $\mathrm{Per}(E,\mathbb{R}^n)$ *simply as* $\mathrm{Per}(E)$*.*

DEFINITION A.5 (see [27, p. 43]). *Let* E *be a set of finite perimeter. We call the* reduced boundary *of* E*, denoted as* $\partial^* E$*, the set of all points* $x \in \mathrm{supp}|D\varphi_E|$ *such that*

- $\int_{B(x,r)} |D\varphi_E| > 0$ *for all* $r > 0$*;*
- *the limit* $\nu(x) = \lim_{r\to 0} \dfrac{\int_{B(x,r)} D\varphi_E}{\int_{B(x,r)} |D\varphi_E|}$ *exists;*
- $|\nu(x)| = 1$.

DEFINITION A.6. *For every $\gamma \in [0,1]$ and every $\mathcal{L}^n$-measurable set $E \subset \mathbb{R}^n$, we define*

$$E_\gamma = \left\{ x \in \mathbb{R}^n : \lim_{r \to 0} \frac{|B(x,r) \cap E|}{|B(x,r)|} = \gamma \right\}, \tag{49}$$

the set of all points with density γ. If E is a set of finite perimeter, then (cf. [2]*) the limit in* (49) *exists for $\mathcal{H}_{n-1}$-almost every x. The sets E_1 and E_0 are the measure theoretic interior and exterior of E, respectively.*

DEFINITION A.7. *We say that the set of finite perimeter E has* least area *in the open set Ω if*

$$\int_\Omega |D\varphi_E| = \inf \left\{ \int_\Omega |D\varphi_F| : F \text{ is a set of finite perimeter, } \operatorname{support}(\varphi_F - \varphi_E) \subset \Omega \right\}.$$

DEFINITION A.8. *If E is a set of finite perimeter, we denote ∂E as the topological boundary of E. We note that $E_{int} \subset E_1$ and $E_{out} \subset E_0$, where E_{int} denotes the topological interior of the set E, and $E_{out} = (\mathbb{R}^n \setminus E)_{int}$. We define*

$$\partial^s E = \mathbb{R}^n \setminus (E_0 \cup E_1).$$

The set $\partial^s E$ is called the essential boundary *of E. We have*

$$\partial^* E \subset E_{\frac{1}{2}} \subset \partial^s E$$

and

$$\mathcal{H}_{n-1}(\partial^s E \setminus \partial^* E) = 0.$$

We have that

$$|D\varphi_E| = \mathcal{H}_{n-1}|_{\partial^* E}. \tag{50}$$

Remark A.1. When considering functions in BV we are really considering equivalence classes of functions, and changing a function on a set of measure zero gives the same function. The same is true for sets of finite perimeter, and, therefore, since we are concerned only with equivalence classes of sets, *we assume throughout this paper that a set of finite perimter E is the representative given by Theorem* A.1. With this convention, there is no ambiguity when speaking of the topological boundary of a set of finite perimeter.

Remark A.2. Standard interior regularity theory [12, 13, 26, 27, 18] implies that, if $n \leq 7$ and E is a set of finite perimeter that has least area in the open set Ω, then $\partial E \cap \Omega$ is a smooth surface. If $n > 7$, $\partial E \cap \Omega$ can have singularities, but they have zero $\mathcal{H}_k$-measure for any $k > n - 8$. At times we will use the word "surface" to denote the boundary of a set of finite perimeter, although this boundary could have singularities.

PROPOSITION A.1 (see [27, p. 7]). *If $\{f_j\}$ denote a sequence of functions in $BV(\Omega)$ that converge in $L^1_{loc}(\Omega)$ to a function f, then the following semicontinuity property holds:*

$$\int_\Omega |Df| \leq \liminf_{j \to \infty} \int_\Omega |Df_j|.$$

THEOREM A.1 (see [27, p. 42]). *If E is a Borel set, then there exists a Borel set $\tilde{E}$ equivalent to E (that is, differs only by a set of $\mathcal{L}^n$-measure zero) and such that*

$$0 < |\tilde{E} \cap B(x,r)| < \omega_n r^n$$

for all $x \in \partial\tilde{E}$ and all $r > 0$, where ω_n is the measure of the unit ball in $\mathbb{R}^n$.

THEOREM A.2 (see [27, p. 17]). *If Ω is a bounded open set in $\mathbb{R}^n$ with Lipschitz continuous boundary, then sets of functions uniformly bounded in a BV norm are relatively compact in $L^1(\Omega)$.*

Since we are regarding $BV(\Omega)$ as a subset of $L^1(\Omega)$, it makes no sense to talk about the value of a BV function on sets of measure zero. However, it is important to be able to talk about the value of a BV function on the boundary of a set even though such a boundary may have measure zero; that is, we need a notion of *trace of a BV function on the boundary of the set*. The following theorem provides such a trace, which depends on the value of the function on the surroundings of the set.

THEOREM A.3 (see [27, p. 37]). *If Ω is a bounded open set with Lipschitz continuous boundary $\partial\Omega$ and $f \in BV(\Omega)$, then there exists a function $f_{tr} \in L^1(\partial\Omega)$ such that, for $\mathcal{H}_{n-1}$-almost all $x \in \partial\Omega$,*

$$\lim_{r\to 0} \int_{B(x,r)\cap\Omega} |f(z) - f_{tr}(x)|dz = 0,$$

and f_{tr} is called the trace function.

THEOREM A.4 (see [27, p. 172]). *We let A and B denote two sets of finite perimeter. If Ω is any open set, then*

$$\mathrm{Per}(A \cap B, \Omega) + \mathrm{Per}(A \cup B, \Omega) \le \mathrm{Per}(A, \Omega) + \mathrm{Per}(B, \Omega).$$

Proof. We let f, g be two smooth functions with $0 \le f \le 1$, $0 \le g \le 1$. We define $\Psi = f + g - fg$ and $\Phi = fg$. We note that

$$\int_\Omega |D\Psi| \le \int_\Omega (1-f)|Dg| + \int_\Omega (1-g)|Df|,$$
$$\int_\Omega |D\Phi| \le \int_\Omega f|Dg| + \int_\Omega g|Df|.$$

This implies

$$\int_\Omega |D\Phi| + \int_\Omega |D\Psi| \le \int_\Omega |Df| + \int_\Omega |Dg|. \tag{51}$$

We can find [27] sequences of smooth functions f_j and g_j such that $f_j \to \varphi_A$, $g_j \to \varphi_B$ in $L^1(\Omega)$ and $\int_\Omega |Df_j| \to \int_\Omega |D\varphi_A|$, $\int_\Omega |Dg_j| \to \int_\Omega |D\varphi_B|$. Since $\Psi_j = f_j + g_j - f_j g_j \to \varphi_{A\cup B}$, $\Phi_j = f_j g_j \to \varphi_{A\cap B}$, the theorem follows from (51) and Proposition A.1. ∎

THEOREM A.5 (see [27, p. 173]). *Let $E = E_1 \cup E_2$, and let $\mathcal{H}_{n-1}(\overline{E}_1 \cap \overline{E}_2) = 0$. Then for any open set A we have*

$$\int_A |D\varphi_E| = \int_A |D\varphi_{E_1}| + \int_A |D\varphi_{E_2}|. \tag{52}$$

Moreover, if E has least area in A, the same is true for E_1 and E_2.

LEMMA A.1 (see [27, p. 28]). *Let $f \in BV(\Omega)$. If $A \subset\subset \Omega$ is an open set with Lipschitz continuous boundary ∂A, then $f|_A$ and $f|_{\Omega\setminus\overline{A}}$ belong to $BV(A)$ and $BV(\Omega\setminus\overline{A})$, respectively, and*

$$\int_{\partial A} |Df| = \int_{\partial A} |f_A^- - f_A^+| d\mathcal{H}_{n-1},$$

where $f_A^- = (f_A)_{tr}$ and $f_A^+ = (f|_{\Omega\setminus\overline{A}})_{tr}$, the traces on ∂A of $f|_A$ and $f|_{\Omega\setminus\overline{A}}$, respectively.

LEMMA A.2. *If E is a set of finite perimeter and $x \in \mathbb{R}^n$, then, for almost every r,*

$$\mathrm{Per}(E \cap B(x,r), \mathbb{R}^n) = \mathrm{Per}(E, B(x,r)) + \mathcal{H}_{n-1}(E \cap \partial B(x,r)).$$

Proof. We denote

$$F(x) = \begin{cases} \varphi_E(x), & x \in B(x,r), \\ 0, & x \in \mathbb{R}^n \setminus B(x,r). \end{cases} \tag{53}$$

From Lemma A.1 and using (53) we have

$$\int_{\mathbb{R}^n} |DF| = \int_{B(x,r)} |D\varphi_E| + \int_{\partial B(x,r)} |(\varphi_E)_{tr}| d\mathcal{H}_{n-1}. \tag{54}$$

The lemma follows from (54) since $\int_{\mathbb{R}^n} |DF| = \mathrm{Per}(E \cap B(x,r), \mathbb{R}^n)$ and $\varphi_E = (\varphi_E)_{tr}$ for almost every r. ∎

LEMMA A.3 (see [27, p. 25]). *If E is a set of finite perimeter and $x \in \mathbb{R}^n$, then, for every r,*

$$|E|^{\frac{n-1}{n}} \le C(n)\mathrm{Per}(E, \mathbb{R}^n).$$

LEMMA A.4 (see [27, p. 25]). *If E is a set of finite perimeter and $x \in \mathbb{R}^n$, then, for every r,*

$$\min\{|E \cap B(x,r)|, |(\mathbb{R}^n \setminus E) \cap B(x,r)|\}^{\frac{n-1}{n}} \le C(n) \int_{B(x,r)} |D\varphi_E|.$$

LEMMA A.5. *Let E be a set of finite perimeter that minimizes area in the open set Ω. If $x \in \partial E \cap \Omega$ has density γ_x (see Definition A.6), then $0 < \gamma_x < 1$.*

Proof. We take $x \in \partial E \cap \Omega$. Let $r_0 > 0$ such that $B(x, r_0) \subset \Omega$. We now prove that there exist universal constants C_1, C_2 such that, for all $r \le r_0$,

$$|B(x,r) \cap E| \ge C_1 r^n, \quad |B(x,r) \cap (\mathbb{R}^n \setminus E)| \ge C_2 r^n. \tag{55}$$

The computation that gives the first part of (55) is contained in the proof of Lemma 5.2. The second part (i.e., for the complement of E) is proven in the same way, and we present here again the argument since (55) is a fundamental property of minimal surfaces. We let $F = \mathbb{R}^n \setminus E$. For all $r \le r_0$ we have

$$\int_{B(x,r)} |D\varphi_F| \le \mathcal{H}_{n-1}(F \cap \partial B(x,r)). \tag{56}$$

We define $V(r) = |F \cap B(x,r)|$, $r \le r_0$. Using the isoperimetric inequality given in Lemma A.3 we have that

$$|F \cap B(x,r)| \le C[\mathrm{Per}(F \cap B(x,r), \mathbb{R}^n)]^{\frac{n}{n-1}}.$$

Proceeding as in Lemma A.2 we can prove that $\mathrm{Per}(F \cap B(x,r), \mathbb{R}^n) = \mathrm{Per}(F, B(x,r)) + \mathcal{H}_{n-1}(F \cap \partial B(x,r))$ for almost every $r \le r_0$, and hence

$$\begin{aligned} |F \cap B(x,r)| &\le C[\mathrm{Per}(F \cap B(x,r), \mathbb{R}^n)]^{\frac{n}{n-1}} \\ &= C[\mathrm{Per}(F, B(x,r)) + \mathcal{H}_{n-1}(F \cap \partial B(x,r))]^{\frac{n}{n-1}} \\ &\le C[\mathcal{H}_{n-1}(F \cap \partial B(x,r))]^{\frac{n}{n-1}}. \end{aligned}$$

Due to Remark A.1 it follows that $V(r) > 0$ for all $r \le r_0$. Since $V'(r) = \mathcal{H}_{n-1}(F \cap \partial B(x,r))$ we have , for almost every $r \le r_0$,

$$V(r) \le CV'(r)^{\frac{n}{n-1}}. \tag{57}$$

If we divide (57) by $V(r)$ and integrate we obtain $V(r)^{\frac{1}{n}} \ge Cr$; i.e.,$V(r) \ge Cr^n$. Now, from (55) we have

$$C_1 r^n \le |B(x,r) \cap E| = |B(x,r)| - |B(x,r) \cap (\mathbb{R}^n \setminus E)| \le |B(x,r)| - C_2 r^n.$$

Therefore

$$0 < \tilde{C}_1 \le \frac{|B(x,r) \cap E|}{|B(x,r)|} \le \tilde{C}_2 < 1,$$

where $\tilde{C}_1$ and $\tilde{C}_2$ are two universal constants. Taking limit as $r \to 0$ and from Definition A.6 we obtain that $0 < \gamma_x < 1$. ∎

LEMMA A.6. *If E is a minimizer corresponding to the class A_{S_1,S_2}, and if the exclusions have at least C^1 boundaries, then there exists a universal constant C such that the set $F \equiv \mathbb{R}^n \setminus (E \cap O)$ satisfies*

$$|F \cap B(x,r)| \ge Cr^n \tag{58}$$

for all $x \in \partial F$, $r \le r_0$, where r_0 is a universal constant.

Proof. We take $x \in \partial F$ and $r < \frac{\alpha}{2}$. We have different situations according to the location of $B(x,r)$. In each case, however, the density estimate (58) can be obtained as in Lemma A.5 from the isoperimetric inequality given in Lemma A.3. In fact, if $B(x,r)$ does not intersect any exclusion or the parallel plane restrictions, then we proceed exactly as in Lemma A.5. We consider now the cases

1. $B(x,r)$ intersects Π_1 (the lower parallel plane restriction) and/or an exclusion.
2. $B(x,r)$ intersects Π_2 (the upper parallel plane restriction) and/or an exclusion.

In case 1, we proceed as in Lemma A.5 with $V(r) = |F \cap B(x,r) \cap O|$, applying the isoperimetric inequality given in Lemma A.3 to the domain $|F \cap B(x,r) \cap O|$. In order to estimate $\mathrm{Per}(F \cap B(x,r) \cap O)$ we use the fact that ∂E is a free boundary (in the sense that we do not impose any restriction as to how the minimizer E meets the exclusions), and hence $\mathrm{Per}(F, B(x,r) \cap O) \le \mathcal{H}_{n-1}(\partial B(x,r) \cap F \cap O)$. If $B(x,r)$ intersects the exclusion I, then (while computing $\mathrm{Per}(F \cap B(x,r) \cap O)$) we can estimate $H_{n-1}(\partial I \cap B(x,r) \cap F)$ by performing a change of variables to flatten the boundary of the exclusion. In case 2, if $B(x,r)$ intersects Π_2 and more than half the ball $B(x,r)$ is

outside the restrictions, then (58) is clear, but, if not, then we consider $B(x, \frac{r}{2})$, and we proceed as in case 1. □

LEMMA A.7. *Let E be a set of finite perimeter in $\mathbb{R}^n$, and let $F = \mathbb{R}^n \setminus E$. If there exists a universal constant C such that*

$$|F \cap B(x,r)| \geq Cr^n \tag{59}$$

for all $x \in \partial F$ and all $r \leq \tilde{r}$, then there exists a sequence of C^∞ sets $E_{\epsilon_k} \subset\subset E$ converging in measure to E and such that

$$\lim_{\epsilon_k \to 0} \mathrm{Per}(E_{\epsilon_k}, \mathbb{R}^n) = \mathrm{Per}(E, \mathbb{R}^n).$$

Proof. The proof of this lemma is an improvement of Theorem 3.42 in [2] under the extra condition (59). In fact, we consider the standard mollified functions $u_\epsilon = \varphi_E * \rho_\epsilon$ and $v_\epsilon = \varphi_F * \rho_\epsilon$, where spt $\rho \subset B_1$, $\rho \equiv 1$ on $B(x, \frac{1}{2})$, and $\rho_\epsilon = \frac{1}{\epsilon^n}\rho(\frac{\cdot}{\epsilon})$. We note that $u_\epsilon + v_\epsilon = 1$. If $x \in \partial F$ and $\epsilon < \tilde{r}$, we obtain from (59)

$$\begin{aligned} v_\epsilon(x) &= \frac{1}{\epsilon^n} \int_{B(x,\epsilon)\cap F} \rho\left(\frac{x-y}{\epsilon}\right) dy \\ &\geq \frac{1}{\epsilon^n} \int_{B(x,\frac{\epsilon}{2})\cap F} \rho\left(\frac{x-y}{\epsilon}\right) dy \\ &= \frac{1}{\epsilon^n} \left| B\left(x, \frac{\epsilon}{2}\right) \cap F \right| \\ &\geq C\epsilon^{-n}\epsilon^n = C. \end{aligned}$$

Therefore, we can choose t close enough to 1 so that

$$\{v_\epsilon < 1 - t\} = \{u_\epsilon > t\} \subset\subset E. \tag{60}$$

Using an exercise problem in [2, p. 39] we have that, for almost every $t \in (0, 1)$,

$$\lim_{\epsilon \to 0} \mathrm{Per}(\{u_\epsilon > t\}, \mathbb{R}^n) = \mathrm{Per}(E, \mathbb{R}^n). \tag{61}$$

Hence, we choose t such that (60) and (61) holds, and we define $E_{\epsilon_k} \equiv \{u_{\epsilon_k} > t\}$. We can now conclude as in [2]. □

Acknowledgments. I am greatly indebted to Luis A. Caffarelli for introducing me to this subject. I am also very thankful to Lawrence C. Evans, Rafael de la Llave, Ovidiu Savin, and the referees for many useful comments. The proof of Lemma A.7 was communicated by Luigi Ambrosio.

CONVEXIFIED GAUSS CURVATURE FLOW OF SETS: A STOCHASTIC APPROXIMATION*

HITOSHI ISHII† AND TOSHIO MIKAMI‡

Abstract. We construct a discrete stochastic approximation of a convexified Gauss curvature flow of boundaries of bounded open sets in an anisotropic external field. We also show that a weak solution to the PDE which describes the motion of a bounded open set is unique and is a viscosity solution of it.

Key words. convexified Gauss curvature flow, stochastic approximation, weak solution, viscosity solution

AMS subject classifications. 53C44, 35K65, 60D05

DOI. 10.1137/S0036141002420509

1. Introduction.

Gauss curvature flow is known as a mathematical model of the wearing process of a convex stone rolling on a beach and has been studied by many authors (see, e.g., [2, 3, 6, 7, 11, 14, 16, 23]).

In the last few years we have been generalizing the theory of Gauss curvature flow to a class of nonconvex sets.

In [17] we studied the existence and the uniqueness of a viscosity solution to the PDE that describes the time evolution of a nonconvex graph by a convexified Gauss curvature (see (1.10) for the PDE).

In [20] we proposed and studied the discrete stochastic approximations of evolving functions which are generalizations of those considered in [17], proved the existence and the uniqueness of a weak solution to the PDE which appears as the continuum limit of discrete stochastic processes, and discussed under what conditions a weak solution to the PDE is a viscosity solution of it.

In [19] we studied the existence and the uniqueness of the motion (or time evolution) of a nonconvex compact set which evolves by a convexified Gauss curvature in $\mathbf{R}^N$ ($N \geq 2$), by the level set approach in the theory of viscosity solutions (see, e.g., [5, 10, 23] for the level set approach; also see [1]).

We introduce the notion of the motion of a smooth oriented closed hypersurface by a convexified Gauss curvature.

Let M be a smooth oriented closed hypersurface in $\mathbf{R}^N$ and ν be a smooth vector field over M of unit normal vectors. For $x \in M$, let T_xM denote the tangent space of M at x, and let $A_x : T_xM \mapsto T_xM$ denote the Weingarten map at x defined by the following:

$$A_x(e) = -D_e\nu \quad \text{for } e \in T_xM, \tag{1.1}$$

where $D_e\nu$ denotes the derivative of ν with respect to e. Recall that the principal

curvatures $\kappa_1, \dots, \kappa_{N-1}$ of M at x are the eigenvalues of the symmetric map A_x and the Gauss curvature $K(x)$ of M at x is given by $\det A_x$.

Let C be the convex hull $\operatorname{co} M$ of M. We define $\sigma : M \mapsto \{0, 1\}$ by

$$\sigma(x) = \begin{cases} 1 & \text{if } x \in M \cap \partial C, \\ 0 & \text{otherwise} \end{cases} \tag{1.2}$$

and call $\sigma(x)K(x)$ the *convexified* Gauss curvature of M at x.

The motion of a smooth oriented closed hypersurface by a convexified Gauss curvature is the curvature flow:

$$v = -\sigma K \nu, \tag{1.3}$$

where ν denotes the unit outward normal vector field on the hypersurface and v denotes the velocity of the hypersurface.

Let $(A_x)_+$ denote the positive part of the symmetric map A_x. $K_+(x) := \det\{(A_x)_+\}$ is called the *positive part* of the Gauss curvature of M at x, and the following holds:

$$\sigma(x)K(x) = \sigma(x)K_+(x). \tag{1.4}$$

Remark 1.1. For $x \in M$,

$$\det\{(A_x)_+\} = \operatorname{Det}_+(A_x) := \begin{cases} \det A_x & \text{if } A_x \text{ is nonnegative definite,} \\ 0 & \text{otherwise.} \end{cases}$$

The discrete approximation of a smooth simple closed convex curve which evolves as the curvature flow was considered by Girão and is useful in the numerical analysis (see [13] and the references therein). We refer to [12] and the references therein for the recent development of this topic.

The discrete stochastic approximation of the curvature flow of smooth simple closed convex curves is given in [18], where the model and the approach are completely different from those in this paper.

In this paper we propose and study the discrete stochastic approximation of a convexified Gauss curvature flow of boundaries of bounded open sets in an anisotropic external field:

$$v = -R(\nu)\sigma K \nu, \tag{1.5}$$

where $R : \mathbf{S}^{N-1} \mapsto [0, \infty)$ controls the anisotropy of an external field (see (1.3) for notation).

This is important since a stone on a beach is not always convex. Equation (1.5) also gives a mathematical model of the wearing process of a stone which is hit by several kinds of matter from different directions or a stone which has a fine microstructure consisting of anisotropic materials.

Our result in this paper is the first one in the case $N \geq 3$, among random and nonrandom results, which gives a discrete approximation of the motion of a bounded open set, in $\mathbf{R}^N$, by Gauss curvature.

Therefore the construction of a nonrandom version of such an approximation as above in the case $N \geq 3$ is an open problem, although the stochastic approximation is more realistic than a nonrandom one in that a stone rolling on a beach moves randomly.

We briefly describe what we proved in [20] and then discuss the results in this paper more precisely to compare a convexified Gauss curvature flow of graphs with that of closed hypersurfaces. Put $n := N - 1$.

For $x \in \mathbf{R}^n$ and $u : \mathbf{R}^n \mapsto \mathbf{R}$, the following set is called the subdifferential of u at x:

$$\partial u(x) := \{p \in \mathbf{R}^n : u(y) - u(x) \geq p \cdot (y - x) \text{ for all } y \in \mathbf{R}^n\}, \tag{1.6}$$

where $\cdot$ denotes the inner product in $\mathbf{R}^n$. Let $L^1(\mathbf{R}^n : [0, \infty), dx)$ denote the set of measurable functions $\varphi : \mathbf{R}^n \mapsto [0, \infty)$ for which $\int_{\mathbf{R}^n} |\varphi(x)| dx < \infty$.

Alexandrov–Bakelman's generalized curvature introduced in the following played a crucial role in [20].

DEFINITION 1.1 (see, e.g., [4, section 9.6]). *Let $\overline{R} \in L^1(\mathbf{R}^n : [0, \infty), dx)$ and $u \in C(\mathbf{R}^n)$. For $A \in B(\mathbf{R}^n)$(:=Borel σ-field of $\mathbf{R}^n$), put*

$$\overline{w}(\overline{R}, u, A) := \int_{\cup_{x \in A} \partial u(x)} \overline{R}(y) dy. \tag{1.7}$$

(It is known that $\overline{w}(\overline{R}, u, \cdot) : B(\mathbf{R}^n) \mapsto [0, \infty)$ is completely additive.)

For $\overline{R} \in L^1(\mathbf{R}^n : [0, \infty), dx)$, we showed the existence and the uniqueness of a solution $u \in C([0, \infty) \times \mathbf{R}^n)$ to the following equation (see [20, Theorem 1]): for any $\varphi \in C_o(\mathbf{R}^n)$ and any $t \geq 0$,

$$\int_{\mathbf{R}^n} \varphi(x)(u(t, x) - u(0, x)) dx = \int_0^t ds \int_{\mathbf{R}^n} \varphi(x) \overline{w}(\overline{R}, u(s, \cdot), dx). \tag{1.8}$$

The existence of a continuous solution to (1.8) was given by the continuum limit of the infinite particle systems $\{(Z_m(t, z))_{z \in \mathbf{Z}^n/m}\}_{t \geq 0}$ that satisfies the following: for any $t \geq 0$ and any $z \in \mathbf{Z}^n/m$,

$$P(Z_m(t + \Delta t, z) - Z_m(t, z) > 0) = m^n E[\overline{w}(\overline{R}, \hat{Z}_m(t, \cdot), \{z\})] \Delta t + o(\Delta t) \tag{1.9}$$

as $\Delta t \to 0$ ($m \geq 1$), where $\mathbf{Z}^n/m := \{z/m | z \in \mathbf{Z}^n\}$ and $\hat{Z}_m(t, \cdot)$ denotes a convex envelope of the function $z \mapsto Z_m(t, z)$, i.e., the graph of the boundary of the convex hull, in $\mathbf{R}^N$, of the set $\{(z, y) | z \in \mathbf{Z}^n/m, y \geq Z_m(t, z)\}$.

In [20, Theorem 2], we proved that a continuous solution u to (1.8) sweeps in time $t > 0$ a region with volume given by $t \cdot \overline{w}(\overline{R}, u(0, \cdot), \mathbf{R}^n)$ and that, for continuous solutions u and v to (1.8) with $v(0, \cdot) = \hat{u}(0, \cdot)$, $\hat{u}(t, \cdot)$ is different from $v(t, \cdot)$ at time $t > 0$ in general if $u(0, \cdot) \neq \hat{u}(0, \cdot)$.

We also showed that a continuous solution to (1.8) is a viscosity solution of the following PDE (see [20, Theorem 3]):

$$\partial_t u(t, x) = \chi(u, Du(t, x), t, x) \overline{R}(Du(t, x)) \mathrm{Det}_+(D^2 u(t, x)) \text{ on } (0, \infty) \times \mathbf{R}^n, \tag{1.10}$$

where $Du(t, x) := (\partial u(t, x)/\partial x_i)_{i=1}^n$, $D^2 u(t, x) := (\partial^2 u(t, x)/\partial x_i \partial x_j)_{i,j=1}^n$, and

$$\chi(u, p, t, x) := \begin{cases} 1 & \text{if } p \in \partial u(t, x), \\ 0 & \text{otherwise} \end{cases}$$

(see Remark 1.1 for notation). Here $\partial u(t, x)$ denotes the subdifferential of the function $x \mapsto u(t, x)$. Conversely, we discussed under what conditions a viscosity solution to (1.10) is a solution to (1.8).

Remark 1.2. Suppose that u in (1.10) is twice differentiable in x. Then putting

$$\nu = \left(\frac{(Du(t,x), -1)}{(|Du(t,x)|^2 + 1)^{1/2}} \right)_{x \in \mathbf{R}^n}$$

in (1.3),

$$\chi(u, Du(t,x), t, x)(1 + |Du(t,x)|^2)^{-(n+2)/2} \mathrm{Det}_+(D^2 u(t,x))$$

is the convexified Gauss curvature of $\{(y, u(t,y)) | y \in \mathbf{R}^n\}$ at x.

Next we briefly discuss what we study in this paper.

Let F be a closed convex set in $\mathbf{R}^N$. For $x \in \partial F$, put

$$N_F(x) := \{p \in \mathbf{S}^{N-1} | F \subset \{y | \langle y - x, p \rangle \leq 0\}\},$$

where $\langle \cdot, \cdot \rangle$ denotes the inner product in $\mathbf{R}^N$.

Let $L^1(\mathbf{S}^{N-1} : [0, \infty), d\mathcal{H}^{N-1})$ denote the set of measurable functions $\phi : \mathbf{S}^{N-1} \mapsto [0, \infty)$ for which $\int_{\mathbf{S}^{N-1}} |\varphi(p)| d\mathcal{H}^{N-1}(p) < \infty$, where $d\mathcal{H}^{N-1}$ denotes the $(N-1)$-dimensional Hausdorff outer measure.

To consider a convexified Gauss curvature flow of bounded open sets by the level set approach, we introduce new types of measures.

DEFINITION 1.2. *Let u be a bounded function from a subset of $\mathbf{R}^N$ to $\mathbf{R}$, and $R \in L^1(\mathbf{S}^{N-1} : [0, \infty), d\mathcal{H}^{N-1})$.*

(i) *Let $r \in \mathbf{R}$. For $B \in B(\mathbf{R}^N)$, put*

$$\omega_r(R, u, B) := \int_{\cup_{x \in B \cap \partial A} N_{A^-}(x)} R(p) d\mathcal{H}^{N-1}(p), \tag{1.11}$$

where $A = \mathrm{co}\ u^{-1}([r, \infty))$ and A^- denotes the closure of the set A.

(ii) *For $B \in B(\mathbf{R}^N)$, put*

$$\mathbf{w}(R, u, B) := \int_{\mathbf{R}} dr \omega_r(R, u, B), \tag{1.12}$$

provided the right-hand side is well defined.

Remark 1.3. (i) If $\partial(\mathrm{co}\ u^{-1}([r, \infty)))$ is smooth at x, then $N_{(\mathrm{co}\ u^{-1}([r,\infty)))^-}(x)$ is the set of a unit outward normal vector on $\partial(\mathrm{co}\ u^{-1}([r, \infty)))$ at x. Otherwise $N_{(\mathrm{co}\ u^{-1}([r,\infty)))^-}(x)$ consists of more than one point. (ii) $\omega_r(R, u, \cdot) : B(\mathbf{R}^N) \mapsto [0, \infty)$ in (1.11) is completely additive (see [4, p. 31, Theorem 5.1]). (iii) For u and r in Definition 1.2, the $(N-1)$-dimensional Hausdorff outer measure of the following set is zero (see [4, p. 30, Lemma 5.2]):

$$\cup_{x \in \partial(\mathrm{co}\ u^{-1}([r,\infty)))} \{p \in N_{(\mathrm{co}\ u^{-1}([r,\infty)))^-}(x) : \{x\} \subsetneq \{y \in \mathbf{R}^N : \langle y - x, p \rangle = 0\} \cap (\mathrm{co}\ u^{-1}([r, \infty)))^-\}.$$

When it is not confusing, we write $\omega_r(R, u, dx) = \omega_r(u, dx)$ and $\mathbf{w}(R, u, dx) = \mathbf{w}(u, dx)$ for the sake of simplicity.

The existence and the uniqueness of a solution to the following equation are given in section 2.

DEFINITION 1.3. *Let $T \in [0, \infty]$ and $R \in L^1(\mathbf{S}^{N-1} : [0, \infty), d\mathcal{H}^{N-1})$. A family of bounded open sets $\{D(t)\}_{t \in [0,T)}$ in $\mathbf{R}^N$ is called a convexified Gauss curvature flow in an (R-)anisotropic external field on $[0, T)$ if*

$$D(t) = (\mathrm{co}\ D(t)) \cap D(0) \quad \text{for } t \in [0, T) \tag{1.13}$$

and if the following holds: for any $\varphi \in C_o(\mathbf{R}^N)$ *and any* $t \in [0,T)$,

$$\int_{\mathbf{R}^N} \varphi(x)(I_{D(0)}(x) - I_{D(t)}(x))dx = \int_0^t ds \int_{\mathbf{R}^N} \varphi(x)\omega_1(R, I_{D(s)}(\cdot), dx), \tag{1.14}$$

where $I_A(x) = 1$ *if* $x \in A$ *and* $= 0$ *if* $x \notin A$ *for the set* A.

We also show the existence and the uniqueness of a solution $u \in C_b([0,T) \times \mathbf{R}^N)$ to the following: for any $\varphi \in C_o(\mathbf{R}^N)$ and any $t \in [0,T)$,

$$\int_{\mathbf{R}^N} \varphi(x)(u(0,x) - u(t,x))dx = \int_0^t ds \int_{\mathbf{R}^N} \varphi(x)\mathbf{w}(R, u(s,\cdot), dx). \tag{1.15}$$

The existence of $\{I_{D(t)}\}_{t\geq 0}$ in Definition 1.3 is shown by the continuum limit of a class of particle systems $\{(Y_m(t,z))_{z\in\mathbf{Z}^N/m}\}_{t\geq 0}$ that satisfies the following: for any $t \geq 0$ and any $z \in \mathbf{Z}^N/m$,

$$P(Y_m(t+\Delta t, z) - Y_m(t,z) < 0) = m^N E[\omega_1(Y_m(t,\cdot), \{z\})]\Delta t + o(\Delta t) \tag{1.16}$$

as $\Delta t \to 0$ $(m \geq 1)$ (see Theorem 2.1 in section 2).

The existence and the uniqueness of a solution to (1.15) are given by the continuum limit of the linear combinations of solutions to (1.14) with $D(0) = u(0,\cdot)^{-1}((r,\infty))$ for $r \in \mathbf{R}$ (see Corollary 2.3 in section 2).

We also discuss the properties of $\{D(t)\}_{t\geq 0}$ in Definition 1.3 (see Theorem 2.4 in section 2).

For $p \in \mathbf{R}^N$ and an $(N \times N)$-symmetric real matrix X, put

$$G(p,X) := \begin{cases} |p| \det\left\{\left(-(I_N - \bar{p}\otimes\bar{p})\frac{X}{|p|}(I_N - \bar{p}\otimes\bar{p}) + \bar{p}\otimes\bar{p}\right)_+\right\} & \text{if } p \neq o, \\ 0 & \text{if } p = o \end{cases} \tag{1.17}$$

(see Remark 1.1 for notation), where I_N denotes the $(N \times N)$-identity matrix and $\bar{p} := p/|p|$.

Suppose that a smooth oriented hypersurface M in $\mathbf{R}^N$ is given by $M = \{y \in \mathbf{R}^N \mid \varphi(y) = a,\ D\varphi(y) \neq o\}$ for some $\varphi \in C^2(\mathbf{R}^N)$ and $a \in \mathbf{R}$ and that the vector field ν is given by $\nu_x = D\varphi(x)/|D\varphi(x)|$. Regard the tangent space, T_xM, as the orthogonal complement of ν_x, and let $E_x := \operatorname{span} \nu_x$ and id_{E_x} denote the identity map on E_x. Then the map

$$A_x \oplus \mathrm{id}_{E_x} : \mathbf{R}^N \equiv T_xM \oplus E_x \to T_xM \oplus E_x$$

has a matrix representation

$$-(I_N - \bar{p}\otimes\bar{p})\frac{X}{|p|}(I_N - \bar{p}\otimes\bar{p}) + \bar{p}\otimes\bar{p},$$

with $p = D\varphi(x)$ and $X = D^2\varphi(x)$. Therefore, if $D\varphi(x) \neq o$, then

$$K(x) = \det\left(-(I_N - \bar{p}\otimes\bar{p})\frac{X}{|p|}(I_N - \bar{p}\otimes\bar{p}) + \bar{p}\otimes\bar{p}\right), \tag{1.18}$$

$$K_+(x) = \frac{G(p,X)}{|p|}. \tag{1.19}$$

For $\{D(t)\}_{t\geq 0}$ in Definition 1.3, we show that $I_{D(t)}(x)$ and $I_{D(t)^-}(x)$ are, respectively, a viscosity supersolution and a viscosity subsolution of the following PDE (see Theorem 2.5 in section 2):

$$\partial_t u(t,x) + R\left(\frac{Du(t,x)}{|Du(t,x)|}\right)\sigma^-(u, Du(t,x), t, x)G(Du(t,x), D^2u(t,x)) = 0 \tag{1.20}$$

(where $(t,x) \in (0,\infty)\times \mathbf{R}^N$). Here

$$\sigma^-(u,p,t,x) := \begin{cases} 1 & \text{if } u(t,\cdot) < u(t,x) \text{ on } H(p,x) \text{ and } p \in \mathbf{R}^N \setminus \{o\}, \\ 0 & \text{otherwise,} \end{cases} \tag{1.21}$$

where

$$H(p,x) := \{y \in \mathbf{R}^N \setminus \{x\} \mid \langle y - x, p\rangle \leq 0\}. \tag{1.22}$$

Moreover, we show that a continuous solution to (1.15) is a viscosity solution of (1.20) (see Corollary 2.6 in section 2).

$G(p, -I_N) = |p|^{2-N}$ for $p \neq o$. Indeed, take $p_1, \ldots, p_{N-1} \in \mathbf{S}^{N-1}$ so that $\{p_1, \ldots, p_{N-1}, \bar{p}\}$ is an orthonormal basis of $\mathbf{R}^N$. Then $p_1, \ldots, p_{N-1}$ and $\bar{p}$ are eigenvectors of $(I_N - \bar{p}\otimes\bar{p})^2 = I_N - \bar{p}\otimes\bar{p}$ and $\bar{p}\otimes\bar{p}$, with an eigenvalue 1, respectively. Therefore $G(p,X)$ is not continuous at $p = o$. However, $G(p,X)$ should be continuous if we use the standard approach for a viscosity solution (see [8]). This is why we use the modified definition of a viscosity solution to (1.20) from [21] (see Remark 1.5).

We first introduce the set of admissible test functions. We denote by $\mathcal{F}$ the set of all functions $f \in C^2([0,\infty))$ for which $f'' > 0$ on $(0,\infty)$ and

$$\lim_{r\downarrow 0} \frac{f(r)}{r^N} = 0. \tag{1.23}$$

Let Ω be an open subset of $(0,\infty)\times\mathbf{R}^N$. A function $\varphi \in C^2(\Omega)$ is called admissible in Ω if for any $(\hat{t},\hat{x}) \in \Omega$ for which $D\varphi$ vanishes, there exists $f \in \mathcal{F}$ such that as $(t,x) \to (\hat{t},\hat{x})$,

$$|\varphi(t,x) - \varphi(\hat{t},\hat{x}) - \partial_t\varphi(\hat{t},\hat{x})(t-\hat{t})| \leq f(|x-\hat{x}|) + o(|t-\hat{t}|). \tag{1.24}$$

We denote by $\mathcal{A}(\Omega)$ the set of all admissible functions in Ω.

Remark 1.4. $f(r) = r^{N+1} \in \mathcal{F}$ and $\varphi(t,x) = f(|x-\hat{x}|) \in \mathcal{A}((0,\infty)\times\mathbf{R}^N)$ for any $\hat{x} \in \mathbf{R}^N$.

DEFINITION 1.4 (viscosity solution). *Let $0 < T \leq \infty$ and set $\Omega := (0,T)\times\mathbf{R}^N$, and put $R(o/|o|) := 0$.*

(i) *A function $u \in LSC(\Omega)$ is called a viscosity supersolution of* (1.20) *in Ω if whenever $\varphi \in \mathcal{A}(\Omega)$, $(s,y) \in \Omega$, and $u - \varphi$ attains a local minimum at (s,y); then*

$$\partial_t\varphi(s,y) + R\left(\frac{D\varphi(s,y)}{|D\varphi(s,y)|}\right)\sigma^+(u, D\varphi(s,y), s, y)G(D\varphi(s,y), D^2\varphi(s,y)) \geq 0, \tag{1.25}$$

where

$$\sigma^+(u,p,s,y) := \begin{cases} 1 & \text{if } u(s,\cdot) \leq u(s,y) \text{ on } H(p,y) \text{ and } p \in \mathbf{R}^N \setminus \{o\}, \\ 0 & \text{otherwise.} \end{cases} \tag{1.26}$$

(ii) *A function $u \in USC(\Omega)$ is called a viscosity subsolution of* (1.20) *in* Ω *if whenever* $\varphi \in \mathcal{A}(\Omega)$, $(s,y) \in \Omega$, *and* $u - \varphi$ *attains a local maximum at* (s,y), *then*

$$\partial_t \varphi(s,y) + \sigma^-(u, D\varphi(s,y), s, y) R\left(\frac{D\varphi(s,y)}{|D\varphi(s,y)|}\right) G(D\varphi(s,y), D^2\varphi(s,y)) \le 0. \tag{1.27}$$

(iii) *A function $u \in C(\Omega)$ is called a viscosity solution of* (1.20) *in* Ω *if it is a viscosity supersolution and a viscosity subsolution of* (1.20) *in* Ω.

Remark 1.5. (i) $\sigma^+(u,p,s,y) \ge \sigma^-(u,p,s,y)$ for all $u : \Omega \mapsto \mathbf{R}$ and all $(p,s,y) \in \mathbf{R}^N \times \Omega$. (ii) Let $\mathcal{A}_0(\Omega)$ denote the set of all $\phi_1(t) + \phi_2(x) \in \mathcal{A}(\Omega)$ such that $x \mapsto G(D\phi_2(x), D^2\phi_2(x))$ is continuous in Ω. Then one can replace, in Definition 1.4, $\mathcal{A}(\Omega)$ by $\mathcal{A}_0(\Omega)$ (see [19]). (iii) For any $f \in \mathcal{F}$ and $\hat{x} \in \mathbf{R}^N$, $\varphi(t,x) = f(|x - \hat{x}|) \in \mathcal{A}_0((0,\infty) \times \mathbf{R}^N)$.

In section 2 we state our main results, which will be proved in section 4. In section 3 we give technical lemmas.

2. Main result. In this section we give our main result.

We give two assumptions to state the stochastic process which approximates the solution to (1.13)–(1.14).

(A.0). D is a nonempty bounded open set in $\mathbf{R}^N$ such that Vol(∂D) :=the Lebesgue measure of the boundary ∂D of D is zero.

(A.1). $R \in L^1(\mathbf{S}^{N-1} : [0,\infty), d\mathcal{H}^{N-1})$ and $||R||_{L^1(\mathbf{S}^{N-1})} = 1$.

Take $K > 0$ so that co $D \subset [-K+1, K-1]^N$ (see (1.2) for notation). For $m \ge 1$, put

$$\mathcal{S}_m := \{I_A : [-K,K]^N \cap (\mathbf{Z}^N/m) \mapsto \{0,1\} | A \subset [-K,K]^N \cap \mathbf{Z}^N/m\} \tag{2.1}$$

(see (1.14) for notation), and

$$D_m := D \cap (\mathbf{Z}^N/m). \tag{2.2}$$

For x, $z \in \mathbf{Z}^N/m$, and $v \in \mathcal{S}_m$, put

$$v_{m,z}(x) := \begin{cases} v(x) & \text{if } x \ne z, \\ 0 & \text{if } x = z, \end{cases}$$

and for $f : \mathcal{S}_m \mapsto \mathbf{R}$, put

$$A_m f(v) := m^N \sum_{z \in [-K,K]^N \cap (\mathbf{Z}^N/m)} \omega_1(R, v, \{z\})\{f(v_{m,z}) - f(v)\}. \tag{2.3}$$

Let $m \ge 1$ and $\{y_m(k,\cdot)\}_{k \ge 0}$ be a Markov chain on $\mathcal{S}_m$ such that $y_m(0,\cdot) = I_{D_m}(\cdot)$ and such that the following holds: for any $k \ge 0$ and any $z \in [-K,K]^N \cap (\mathbf{Z}^N/m)$,

$$P(y_m(k+1,\cdot) = (y_m(k,\cdot))_{m,z} | y_m(0,\cdot), \dots, y_m(k,\cdot)) = \omega_1(R, y_m(k,\cdot), \{z\}). \tag{2.4}$$

Let $\{\Delta_k\}_{k \ge 0}$ be independent, exponentially distributed random variables with parameter one and be independent of $\{y_m(k,\cdot)\}_{k \ge 0}$. Put

$$Y_m(t,\cdot) := y_m(k,\cdot) \qquad \text{if} \quad \frac{1}{m^N} \sum_{i=-1}^{k-1} \Delta_i \le t < \frac{1}{m^N} \sum_{i=-1}^{k} \Delta_i, \tag{2.5}$$

where $\Delta_{-1} := 0$.

Then $\{Y_m(t,\cdot)\}_{t\geq 0}$ is a Markov process on $\mathcal{S}_m$ $(m \geq 1)$, with the generator A_m, such that $Y_m(0,z) = I_{D_m}(z)$ $(z \in [-K,K]^N \cap (\mathbf{Z}^N/m))$ (see [9, p. 162]).

Remark 2.1. (i) If $y_m(k,\cdot) \not\equiv 0$, then

$$\sum_{z\in[-K,K]^N\cap(\mathbf{Z}^N/m)} \omega_1(R, y_m(k,\cdot), \{z\}) = 1.$$

(ii) If $\omega_1(R, y_m(k,\cdot), \{z\}) > 0$, then $z \in \partial\{\text{co } y_m(k,\cdot)^{-1}(1)\} \cap y_m(k,\cdot)^{-1}(1)$.

(iii) $y_m(k,\cdot) \equiv 0$ if and only if $k \geq \#D_m$:=the cardinal number of the set D_m, a.s.

For $(t,x) \in [0,\infty) \times [-K,K]^N$, put also

$$X_m(t,x) := I_{(\text{co } Y_m(t,\cdot)^{-1}(1))^o \cap D}(x), \tag{2.6}$$

where A^o denotes the interior of the set $A \subset \mathbf{R}^N$.

Then $\{X_m(t,\cdot)\}_{t\geq 0}$ is a stochastic process on

$$\mathcal{S} := \{f \in L^2([-K,K]^N) : ||f||_{L^2([-K,K]^N)} \leq (2K)^N\}, \tag{2.7}$$

which is a complete separable metric space by the metric

$$d_{\mathcal{S}}(f,g) := \sum_{k=1}^{\infty} \frac{\min(|\langle f-g, e_k\rangle_{L^2([-K,K]^N)}|, 1)}{2^k}. \tag{2.8}$$

Here $\{e_k\}_{k\geq 1}$ denotes a complete orthonomal basis of $L^2([-K,K]^N)$.

The following is our main result.

THEOREM 2.1. *Suppose that* (A.0)–(A.1) *hold. Then there exists a unique solution* $\{D(t)\}_{t\geq 0}$ *to* (1.13)–(1.14) *with* $D(0) = D$ *on* $[0,\infty)$ *such that* $I_{D(\cdot)}(\cdot) \in C([0,\infty) : L^2([-K,K]^N))$ *and such that the following holds: for any* $\gamma > 0$,

$$\lim_{m\to\infty} P\left(\sup_{t\geq 0} ||X_m(t,\cdot) - I_{D(t)}(\cdot)||_{L^2([-K,K]^N)} \geq \gamma\right) = 0. \tag{2.9}$$

We recall the definition of Hausdorff metric: for compact sets A and $B \subset \mathbf{R}^N$,

$$d_H(A,B) := \max(\max_{p\in A} dist(p,B), \max_{q\in B} dist(q,A)). \tag{2.10}$$

As a corollary, we obtain the following.

COROLLARY 2.2. *Suppose that* (A.0)–(A.1) *hold and that* D *is convex. Then for a unique solution* $\{D(t)\}_{t\geq 0}$ *to* (1.13)–(1.14) *with* $D(0) = D$ *on* $[0,\infty)$, *the following holds: for any* $T \in [0, \text{Vol}(D))$ *and any* $\gamma > 0$,

$$\lim_{m\to\infty} P\left(\sup_{0\leq t\leq T} d_H(\partial(\text{co } Y_m(t,\cdot)^{-1}(1)), \partial D(t)) \geq \gamma\right) = 0. \tag{2.11}$$

We introduce the assumption on the initial function in (1.15).

(A.2). $h \in C_b(\mathbf{R}^N)$. For any $r \in \mathbf{R}$, the set $h^{-1}((r,\infty))$ is bounded or $\mathbf{R}^N$.

Then one can easily obtain the following from Theorem 2.1.

COROLLARY 2.3. *Suppose that* (A.1)–(A.2) *hold. Then there exists a unique continuous solution* $\{u(t,\cdot)\}_{t\geq 0}$ *to* (1.15) *with* $u(0,\cdot) = h(\cdot)$ *on* $[0,\infty)$. *In addition, for any* $r \in \mathbf{R}$, $\{u(t,\cdot)^{-1}((r,\infty))\}_{t\geq 0}$ *is a unique solution to* (1.13)–(1.14) *with* $D(0) =$

$h^{-1}((r,\infty))$ *on* $[0,\infty)$. *In particular,* $\{u(t,\cdot)^{-1}((r,\infty))\}_{t\ge 0}$ *depends only on the set* $u(0,\cdot)^{-1}((r,\infty))$.

The following theorem collects some elementary properties of solutions to (1.13)–(1.14).

THEOREM 2.4. *Suppose that* (A.0)–(A.1) *hold. Let* $\{D(t)\}_{t\ge 0}$ *be a unique solution to* (1.13)–(1.14) *with* $D(0)=D$ *on* $[0,\infty)$. *Then the following holds.*

(a) $t\mapsto D(t)$ *is nonincreasing on* $[0,\infty)$.

(b) *For any* $t\le T^*:=\mathrm{Vol}(D(0))$,

$$\mathrm{Vol}(D(0)\backslash D(t))=t. \tag{2.12}$$

(c) $D(t)=\emptyset$ *for* $t\ge T^*$.

(d) *Let* $\{D_1(t)\}_{t\ge 0}$ *be a solution to* (1.13)–(1.14) *on* $[0,\infty)$ *such that* $D_1(0)$ *is a bounded, convex, open set which contains* D. *Then*

$$D(t)\subset D_1(t) \quad \text{for all } t\ge 0, \tag{2.13}$$

where the equality holds if and only if $D(0)=D_1(0)$.

Under

$$R\in C(S^{N-1}:[0,\infty)), \tag{A.3}$$

we give the relation between the solution to (1.13)–(1.14) and the viscosity solution of (1.20).

THEOREM 2.5. *Suppose that* (A.0)–(A.1) *and* (A.3) *hold. Then for a unique solution* $\{D(t)\}_{t\ge 0}$ *to* (1.13)–(1.14) *with* $D(0)=D$ *on* $[0,\infty)$, $I_{D(t)}(x)$ *and* $I_{D(t)^-}(x)$ *are a viscosity supersolution and a viscosity subsolution to* (1.20) *in* $(0,\infty)\times\mathbf{R}^N$, *respectively.*

As a corollary, we obtain the following.

COROLLARY 2.6. *Suppose that* (A.1)–(A.3) *hold. Then a continuous solution* $\{u(t,\cdot)\}_{t\ge 0}$ *to* (1.15) *with* $u(0,\cdot)=h(\cdot)$ *on* $[0,\infty)$ *is a viscosity solution to* (1.20) *in* $(0,\infty)\times\mathbf{R}^N$.

3. Lemmas. In this section we give lemmas which will be used in the next section.

We extend $Y_m(t,\cdot)$ as a function on $\mathbf{R}^N$ so that

$$\overline{Y}_m(t,x)=\begin{cases} 0 & (x\in D^c\cap(\mathbf{Z}^N/m)),\\ Y_m(t,[mx]/m) & (x=(x_i)_{i=1}^N\in\mathbf{R}^N),\end{cases} \tag{3.1}$$

where $[mx]:=([mx_i])_{i=1}^N$ and $[mx_i]$ denotes an integer for which $[mx_i]\le mx_i<[mx_i]+1$.

Remark 3.1. For $z\in[-K,K]^N\cap(\mathbf{Z}^N/m)$,

$$Y_m(t,z)=m^N\int_{\{x\in\mathbf{R}^N\,|\,[mx]=mz\}}\overline{Y}_m(t,x)dx.$$

LEMMA 3.1. *Suppose that* (A.0)–(A.1) *hold. Then* $\{\overline{Y}_m(\cdot,\cdot)\}_{m\ge 1}$ *is tight in* $D([0,\infty):\mathcal{S})$, *and any weak limit point of* $\{\overline{Y}_m(\cdot,\cdot)\}_{m\ge 1}$ *belongs to the set* $C([0,\infty):\mathcal{S})$.

Proof. Since $\mathcal{S}$ is compact and since $t\mapsto\overline{Y}_m(t,x)$ is nonincreasing for any $x\in\mathbf{R}^N$, we only have to show the following (see [9, p. 129, Corollary 7.4, and p. 148, Theorem

10.2]): for any $\eta > 0$ and $T > 0$, there exists $\delta > 0$ such that for any i for which $1 \le i \le [T/\delta] + 1$,

$$\lim_{m\to\infty} P(||\overline{Y}_m(i\delta,\cdot) - \overline{Y}_m((i-1)\delta,\cdot)||_{L^1([-K,K]^N)} \ge \eta) = 0. \tag{3.2}$$

Indeed, for any s and t for which $(i-1)\delta \le s \le t \le i\delta$,

$$\overline{Y}_m(s,x) - \overline{Y}_m(t,x) = 0 \text{ or } 1$$

and

$$\begin{aligned} d_{\mathcal{S}}(\overline{Y}_m(t,\cdot),\overline{Y}_m(s,\cdot))^2 &\le ||\overline{Y}_m(t,\cdot) - \overline{Y}_m(s,\cdot)||^2_{L^2([-K,K]^N)} \\ &= ||\overline{Y}_m(i\delta,\cdot) - \overline{Y}_m((i-1)\delta,\cdot)||_{L^1([-K,K]^N)}. \end{aligned}$$

For $\delta < \eta/2$ and $m \ge 1$, by Chebyshev's inequality and Ito's formula (see [15]),

$$\begin{aligned} &P(||\overline{Y}_m(i\delta,\cdot) - \overline{Y}_m((i-1)\delta,\cdot)||_{L^1([-K,K]^N)} \ge \eta) \\ &\le \left(\frac{2}{\eta}\right)^2 E\left[\left| \sum_{z\in D_m} (Y_m(i\delta,z) - Y_m((i-1)\delta,z))\frac{1}{m^N} \right.\right. \\ &\qquad \left.\left. + \int_{(i-1)\delta}^{i\delta} \omega_1(Y_m(s,\cdot),D_m)ds \right|^2\right] \\ &= \left(\frac{2}{\eta}\right)^2 m^{-N} E\left[\int_{(i-1)\delta}^{i\delta} \omega_1(Y_m(s,\cdot),D_m)ds\right] \\ &\le \left(\frac{2}{\eta}\right)^2 m^{-N}\delta \to 0 \quad \text{as } m\to\infty \end{aligned} \tag{3.3}$$

(see (2.2) for notation). Indeed,

$$\begin{aligned} &||\overline{Y}_m(i\delta,\cdot) - \overline{Y}_m((i-1)\delta,\cdot)||_{L^1([-K,K]^N)} \\ &= -\sum_{z\in D_m} (Y_m(i\delta,z) - Y_m((i-1)\delta,z))\frac{1}{m^N} - \int_{(i-1)\delta}^{i\delta} \omega_1(Y_m(s,\cdot),D_m)ds \\ &\qquad + \int_{(i-1)\delta}^{i\delta} \omega_1(Y_m(s,\cdot),D_m)ds. \qquad \square \end{aligned}$$

LEMMA 3.2. *Suppose that* (A.0)–(A.1) *hold. Then there exist a subsequence* $\{m_k\}_{k\ge1} \subset \mathbf{N}$ *and stochastic processes* $\{\overline{Y}_{1,m_k}(\cdot,\cdot)\}_{k\ge1}$ *on a probability space* $(\Omega_1, \mathbf{B}_1, P_1)$ *such that the probability law of* $\overline{Y}_{1,m_k}(\cdot,\cdot)$ *is the same as that of* $\overline{Y}_{m_k}(\cdot,\cdot)$ *for all* $k \ge 1$, *and such that* $\{\overline{Y}_{1,m_k}(\cdot,\cdot)\}_{k\ge1}$ *is convergent in* $D([0,\infty) : \mathcal{S})$, P_1*-a.s., and such that the following holds* P_1*-a.s.: for any* $T > 0$ *and* $\varphi \in C([-K,K]^N)$,

$$\begin{aligned} \sup_{0\le t\le T} &\left| \sum_{z\in D_{m_k}} \varphi + (z)(Y_{1,m_k}(t,z) - Y_{1,m_k}(0,z))\left(\frac{1}{m_k}\right)^N \right. \\ &\left. + \int_0^t \sum_{z\in D_{m_k}} \varphi(z)\omega_1(Y_{1,m_k}(s,\cdot),\{z\})ds \right| \to 0 \quad \text{as } k\to\infty. \end{aligned} \tag{3.4}$$

Here Y_{1,m_k} is defined from $\overline{Y}_{1,m_k}$ in the same way as in Remark 3.1.

Proof. By Lemma 3.1 and Skorohod's theorem (see [9, p. 102, Theorem 1.8]), there exist a subsequence $\{m_{0,k}\}_{k\geq 1} \subset \mathbf{N}$ and stochastic processes $\{\overline{Y}_{1,m_{0,k}}(\cdot,\cdot)\}_{k\geq 1}$ on a probability space $(\Omega_1, \mathbf{B}_1, P_1)$ such that the probability law of $\overline{Y}_{1,m_{0,k}}(\cdot,\cdot)$ is the same as that of $\overline{Y}_{m_{0,k}}(\cdot,\cdot)$ for all $k \geq 1$, and such that $\{\overline{Y}_{1,m_{0,k}}(\cdot,\cdot)\}_{k\geq 1}$ is convergent in $D([0,\infty) : \mathcal{S})$, P_1-a.s.

As in (3.3), by Doob–Kolmogorov's inequality (see [15]), for any $T > 0$ and $\varphi \in C([-K,K]^N)$,

$$E_1\left[\sup_{0\leq t\leq T}\left|\sum_{z\in D_{m_{0,k}}}\varphi(z)(Y_{1,m_{0,k}}(t,z)-Y_{1,m_{0,k}}(0,z))\left(\frac{1}{m_{0,k}}\right)^N + \int_0^t \sum_{z\in D_{m_{0,k}}}\varphi(z)\omega_1(Y_{1,m_{0,k}}(s,\cdot),\{z\})ds\right|^2\right] \to 0 \quad \text{as } k\to\infty. \tag{3.5}$$

Since an L^2-convergent sequence of random variables has an a.s. convergent subsequence, and since $C([-K,K]^N)$ is separable, one can complete the proof by the diagonal method. □

When it is not confusing, we write $\overline{Y}_{1,m_k} = \overline{Y}_{m_k}$ and $Y_{1,m_k} = Y_{m_k}$ on $(\Omega_1, \mathbf{B}_1, P_1)$ for the sake of simplicity.

Take $x_0 \in D$ and $r_0 > 0$ so that $U_{4r_0}(x_0) := \{y \in \mathbf{R}^N : |x_0 - y| < 4r_0\} \subset D$, and put $U_0 := U_{2r_0}(x_0)$. Then

$$V_0 := \inf_{x\in\partial U_0} \mathrm{Vol}(U_{3r_0}(x_0) \cap H(x_0 - x, x)) > 0. \tag{3.6}$$

It is easy to see that $V_0 = \mathrm{Vol}(U_{3r_0}(x_0) \cap H(p, x_0 - 2r_0 p))$ for any $p \in \mathbf{S}^{N-1}$.

Put also, on $(\Omega_1, \mathbf{B}_1, P_1)$,

$$\tau_m := \inf\{t > 0 | Y_{1,m}(t,z) = 0 \text{ for some } z \in (\mathbf{Z}^N/m) \cap U_0\}. \tag{3.7}$$

Then for any $k \geq 1$, there exists a random point $z_{m_k} \in (\mathbf{Z}^N/m) \cap U_0$ such that

$$Y_{1,m_k}(\tau_{m_k}-, z_{m_k}) - Y_{1,m_k}(\tau_{m_k}, z_{m_k}) = 1.$$

Additionally, the following holds:

$$Y_{1,m_k}(0,z) - Y_{1,m_k}(\tau_{m_k}, z) = 1 \quad \text{for all } z \in D_{m_k} \cap H(x_0 - z_{m_k}, z_{m_k}).$$

Since $U_{3r_0}(x_0) \subset D$, $Y_{1,m_k}(0,z) - Y_{1,m_k}(\tau_{m_k}, z) = 0$ or 1, and

$$\sum_{z\in D_{m_k}} (Y_{1,m_k}(0,z) - Y_{1,m_k}(\tau_{m_k}, z))\left(\frac{1}{m_k}\right)^N \sim \tau_{m_k}$$

for sufficiently large $k \geq 1$ from (3.4), the following holds.

LEMMA 3.3. *Suppose that* (A.0)–(A.1) *hold. Then*

$$P_1\left(V_0 \leq \liminf_{k\to\infty} \tau_{m_k} \leq \limsup_{k\to\infty} \tau_{m_k} \leq \mathrm{Vol}(D)\right) = 1. \tag{3.8}$$

Proof. By (3.4), for any $t > \mathrm{Vol}(D)$,

$$\begin{aligned}(3.9)\qquad &\limsup_{k\to\infty}\{\min(\tau_{m_k}, t)\}\\ &= \limsup_{k\to\infty}\int_0^{\min(\tau_{m_k},t)} \omega_1(Y_{m_k}(s,\cdot), D_{m_k})ds\\ &\le \limsup_{k\to\infty}\sum_{z\in D_{m_k}}(Y_{m_k}(0,z) - Y_{m_k}(\min(\tau_{m_k},t),z))\left(\frac{1}{m_k}\right)^N \le \mathrm{Vol}(D)\end{aligned}$$

P_1-a.s. We also have

$$\begin{aligned}(3.10)\qquad V_0 &\le \liminf_{k\to\infty}\sum_{z\in D_{m_k}}(Y_{m_k}(0,z) - Y_{m_k}(\tau_{m_k},z))\left(\frac{1}{m_k}\right)^N\\ &\le \liminf_{k\to\infty}\int_0^{\tau_{m_k}} \omega_1(Y_{m_k}(s,\cdot), D_{m_k})ds = \liminf_{k\to\infty}\tau_{m_k} \quad P_1\text{-a.s.} \qquad \square\end{aligned}$$

The following lemma can be proved in the same way as in [4, section 5.2], and the proof is omitted.

LEMMA 3.4. *Suppose that* (A.1) *holds. Let F and $F_m (m \ge 1)$ be closed convex sets in $\mathbf{R}^N$ such that ∂F and $\partial F_m (m \ge 1)$ are closed hypersurfaces and such that $d_H(F_m, F) \to 0$ as $m \to \infty$. Then $\omega_1(I_{F_m}(\cdot), dx)$ weakly converges to $\omega_1(I_F(\cdot), dx)$ as $m \to \infty$, that is, for any $\varphi \in C_o(\mathbf{R}^N)$,*

$$(3.11)\qquad \lim_{m\to\infty}\int_{\mathbf{R}^N}\varphi(x)\omega_1(I_{F_m}(\cdot), dx) = \int_{\mathbf{R}^N}\varphi(x)\omega_1(I_F(\cdot), dx).$$

We denote by $X(\cdot,\cdot) \in C([0,\infty) : \mathcal{S})$ the P_1-a.s. limit of $\overline{Y}_{1,m_k}(\cdot,\cdot)$ as $k \to \infty$ (see Lemma 3.2 for notation). Then we have the following.

LEMMA 3.5. *Suppose that* (A.0)–(A.1) *hold. Then there exists a solution $\{D(t)\}_{t\in[0,V_0)}$ to* (1.13)–(1.14) *on $[0, V_0)$ such that the following holds P_1-a.s.:*

$$(3.12)\qquad X(t,x) = I_{D(t)}(x), \quad dx\text{-a.e.} \quad \text{for all } t \in [0, V_0)$$

(see (3.6) *for notation).*

Proof. We introduce local coordinates so that we can reduce the study of the time evolution of $\partial(\mathrm{co}\, Y_{m_k}(t,\cdot)^{-1}(1))$ on $[0, V_0)$ to that of convex functions in all local coordinates.

For (x_0, r_0) in (3.6) and any $p \in \mathbf{S}^{N-1}$, let $C(x_0, r_0; p)$ denote a semi-infinite cylinder

$$\{x_0 + rp + x : r \ge 0, |x| \le r_0, \langle x, p\rangle = 0, x \in \mathbf{R}^N\}$$

which can be obtained by moving an $(N-1)$-dimensional ball

$$\{x_0 + x : |x| \le r_0, \langle x, p\rangle = 0, x \in \mathbf{R}^N\}$$

in the positive direction of p.

Take $p_1, \ldots, p_{k_0} \in \mathbf{S}^{N-1}$ for some $k_0 \in \mathbf{N}$ so that

$$\mathrm{co}\ D \subset \cup_{i=1}^{k_0} C(x_0, r_0; p_i).$$

For $i = 1, \dots, k_0$, take $\{q_{i1}, \dots, q_{i(N-1)}\}$ so that $\{q_{i1}, \dots, q_{i(N-1)}, p_i\}$ is an orthonormal basis in $\mathbf{R}^N$, and put

$$C_{m_k}(t) := \text{co } Y_{m_k}(t, \cdot)^{-1}(1). \tag{3.13}$$

For $x = (x_j)_{j=1}^{N-1} \in \mathbf{R}^{N-1}$ for which $|x| \le 2r_0$, also put

$$\tilde{X}_{m_k,i}(t,x) := -\sup\left\{ r > 0 | x_0 + rp_i + \sum_{j=1}^{N-1} q_{ij}x_j \in C_{m_k}(t) \right\}. \tag{3.14}$$

Since the set $C_{m_k}(t)$ is convex and since

$$\inf\left\{ \left(\sum_{j=1}^{N-1} |x_j|^2 \right)^{1/2} : x_0 + rp_i + \sum_{j=1}^{N-1} q_{ij}x_j \in C_{m_k}(t) \text{ for some } r > 0 \right\} \ge \frac{7r_0}{4}$$

for $m_k \ge 8\sqrt{N}/r_0$ and $t \in [0, \tau_{m_k})$, and since $t \mapsto Y_{m_k}(t, \cdot)$ is nonincreasing, $\tilde{X}_{m_k,i}(t, \cdot)$ ($m_k \ge 8\sqrt{N}/r_0$, $t \in [0, \tau_{m_k})$) are bounded convex functions on $\{x \in \mathbf{R}^{N-1} : |x| \le 7r_0/4\}$.

It is known that a uniformly bounded set of convex functions with a common domain is compact as the set of continuous functions defined on K for every compact subset K of the interior of their domain (see [4, section 3.3]).

Therefore, by Lemma 3.3 and the diagonal method, there exists a subsequence $\{\tilde{X}_{\tilde{m}_k,i}(t, \cdot)\}_{k\ge1}$ of $\{\tilde{X}_{m_k,i}(t, \cdot)\}_{k\ge1}$ and a convex function $\tilde{X}_i(t, \cdot)$ such that for any $t \in \mathbf{Q} \cap [0, V_0)$ and $i = 1, \dots, k_0$,

$$\lim_{k\to\infty} \sup_{x\in\mathbf{R}^{N-1}, |x|\le 3r_0/2} |\tilde{X}_{\tilde{m}_k,i}(t,x) - \tilde{X}_i(t,x)| = 0. \tag{3.15}$$

(Notice that $\{\tilde{m}_k\}_{k\ge1}$ can be random.)

It is clear that there exists a nonincreasing family of compact convex sets $\{\tilde{C}(t)\}_{t\in\mathbf{Q}\cap[0,V_0)}$ such that for any $t \in \mathbf{Q} \cap [0, V_0)$,

$$\lim_{k\to\infty} d_H(C_{\tilde{m}_k}(t), \tilde{C}(t)) = 0, \tag{3.16}$$

$$\tilde{X}_i(t,x) = -\sup\left\{ r > 0 | x_0 + rp_i + \sum_{j=1}^{N-1} q_{ij}x_j \in \tilde{C}(t) \right\}$$

for all $i = 1, \dots, k_0$, and $x = (x_k)_{k=1}^{N-1} \in \mathbf{R}^{N-1}$ for which $|x| \le 3r_0/2$.

In particular,

$$D \subset \tilde{C}(0) \quad \text{(by (2.2))}, \tag{3.17}$$

$$\lim_{k\to\infty} ||X_{1,\tilde{m}_k}(t, \cdot) - I_{\tilde{C}(t)^o \cap D}(\cdot)||_{L^2([-K,K]^N)} = 0$$

for all $t \in \mathbf{Q} \cap [0, V_0)$, where $X_{1,\tilde{m}_k}$ is defined by $Y_{1,\tilde{m}_k}$ in the same way as in (2.6). When it is not confusing, we write $X_{1,\tilde{m}_k} = X_{\tilde{m}_k}$ on $(\Omega_1, \mathbf{B}_1, P_1)$ for the sake of simplicity.

The following also holds: for all $t \in [0, V_0) \cap \mathbf{Q}$,

$$\lim_{k\to\infty} ||\overline{Y}_{\tilde{m}_k}(t, \cdot) - X_{\tilde{m}_k}(t, \cdot)||_{L^2([-K,K]^N)} = 0. \tag{3.18}$$

Indeed, if $X_m(t,x) \neq \overline{Y}_m(t,x)$, then

$$dist(x, \partial(C_m(t)^o \cap D)) \leq \frac{N^{1/2}}{m},$$

and by (3.16), the volume of the $(N^{1/2}/\tilde{m}_k)$-neighborhood of the set $\partial D \cup \partial C_{\tilde{m}_k}(t)$ converges to zero as $k \to \infty$ for $t \in [0, V_0) \cap \mathbf{Q}$.

For $t \in [0, V_0)\backslash\mathbf{Q}$, put

$$\tilde{C}(t) := \cap_{s \in \mathbf{Q} \cap [0,t)} \tilde{C}(s). \tag{3.19}$$

Then, by (3.17)–(3.19), the following holds P_1-a.s.:

$$X(t,x) = I_{\tilde{C}(t)^o \cap D}(x), \quad dx\text{-a.e.}, \quad \text{for all } t \in [0, V_0), \tag{3.20}$$

since $\{\overline{Y}_{\tilde{m}_k}\}_{k \geq 1}$ is a subsequence of a convergent sequence $\{\overline{Y}_{m_k}\}_{k \geq 1}$ and since $X \in C([0,\infty) : \mathcal{S})$ is the P_1-a.s. limit, in $D([0,\infty) : \mathcal{S})$, of $\overline{Y}_{m_k}$ as $k \to \infty$, and since $\{\tilde{C}(t)\}_{t \in [0,V_0) \cap \mathbf{Q}}$ is nonincreasing in t.

Put

$$D(t) := \tilde{C}(t)^o \cap D. \tag{3.21}$$

Then (1.13) holds for all $t \in [0, V_0)$, since $D = D(0)$ by (3.17) and since

$$D(t) \supset \{\text{co } (\tilde{C}(t)^o \cap D)\} \cap D = (\text{co } D(t)) \cap D \supset D(t) \cap D = D(t).$$

On $[0, V_0)$,

$$\omega_1(I_{\tilde{C}(t)}(\cdot), dx) = \omega_1(I_{D(t)}(\cdot), dx), \quad dt\text{-a.e.}, \tag{3.22}$$

since

$$\tilde{C}(t)\backslash(\text{co } D(t))^- \subset \tilde{C}(t)\backslash D(t)^- \subset D^c$$

by (3.21), where D^c denotes a complement of D, and since

$$\int_0^{V_0} \omega_1(I_{\tilde{C}(s)}(\cdot), D^c) ds = \int_{D^c} (I_{D(0)}(x) - I_{D(V_0)}(x)) dx = 0$$

by (3.4), (3.20)–(3.21), and Lemma 3.4.

Here we used the fact that (3.16) holds except for at most countably many $t \in [0, V_0)$. Indeed, $t \mapsto C_{\tilde{m}_k}(t)$ is nonincreasing and (3.16) holds for all $t \in \mathbf{Q} \cap [0, V_0)$. Therefore, if $C_{\tilde{m}_k}(t)$ does not converge to $\tilde{C}(t)$ as $k \to \infty$, then $(\tilde{C}(t)\backslash\tilde{C}(t+))^o$ is not empty and has a positive Lebesgue measure by (3.19), where $\tilde{C}(t+) := \cup_{s>t} \tilde{C}(s)$. Besides, $(\tilde{C}(t)\backslash\tilde{C}(t+))^o$ are disjoint for different t.

Hence, (1.14) holds for all $t \in [0, V_0)$ from (3.4), Lemma 3.4, and (3.20)–(3.22). □

The following lemma, which can be proved by the translation invariance of the solution to (1.13)–(1.14), implies the uniqueness of the solution to (1.13)–(1.14).

LEMMA 3.6. *Suppose that* (A.1) *holds. For* $T > 0$, *if* $\{D_i(t)\}_{0 \leq t < T}$ $(i = 1, 2)$ *are solutions to* (1.13)–(1.14) *on* $[0, T)$ *for which* $D_1(0) \subset D_2(0)$ *and if* (A.0) *holds for* $D = D_i(0)$ $(i = 1, 2)$, *then* $D_1(t) \subset D_2(t)$ *for all* $t \in [0, T)$. *In particular, for all* $t \in [0, \min(\text{Vol}(D_1(0)), T))$,

$$dist(D_1(t), D_2(t)^c) \geq dist(D_1(0), D_2(0)^c). \tag{3.23}$$

Proof. For each $t \geq 0$, put

$$\tilde{D}(t) := D_1(t)^- \cap D_2(t)^c, \quad u_i(t,\cdot) := I_{D_i(t)}(\cdot), \quad u_i^-(t,\cdot) := I_{D_i(t)^-}(\cdot),$$

$$N_i(t) := \cup_{x \in \partial \tilde{D}(t) \cap \partial D_i(t)} \{p \in S^{N-1} | \sigma^+(u_i, -p, t, x) = 1\}$$

($i = 1, 2$). Then $N_2(t) \subset N_1(t)$.

Take a nondecreasing sequence $\{\eta_m\}_{m \geq 1}$ of nondecreasing C^1-functions such that

$$\eta_m(r) = 0 \quad \text{for all } r \leq 0, \quad \eta_m(r) = 1 \quad \text{for all } r \geq \frac{1}{m}, \tag{3.24}$$

and for $r \in \mathbf{R}$, put

$$\zeta_m(r) = \int_0^r \eta_m(s) ds. \tag{3.25}$$

Then since $t \mapsto u_i(t,x)$ and $t \mapsto u_i^-(t,x)$ are, respectively, right and left continuous for any $x \in \mathbf{R}^N$, for $t \in [0, \min(\mathrm{Vol}(D_1(0)), T))$ and $x \in \mathbf{R}^N$,

$$\begin{aligned} &\zeta_m(u_1^-(t,x) - u_2(t,x) - 1) - \zeta_m(u_1^-(0,x) - u_2(0,x)) \\ &= \int_0^t \zeta_m(u_1^-(s,x) - u_2(s,x) - s/t)(u_1^-(ds,x) - u_2(ds,x)) \\ &\qquad -\frac{1}{t}\int_0^t \eta_m(u_1^-(s,x) - u_2(s,x) - s/t) ds. \end{aligned} \tag{3.26}$$

Since $\zeta_m \geq 0$, $D_1(0) \subset D_2(0)$, and $N_2(s) \subset N_1(s)$, we have

$$\begin{aligned} 0 \leq &\int_0^t ds \int_{\mathbf{R}^N} \zeta_m(u_1^-(s,x) - u_2(s,x) - s/t) \\ &\qquad \times (\omega_1(u_2(s,\cdot), dx) - \omega_1(u_1(s,\cdot), dx)) \\ &\qquad -\frac{1}{t}\int_0^t ds \int_{\mathbf{R}^N} \eta_m(u_1^-(s,x) - u_2(s,x) - s/t) dx \\ \to &\int_0^t (1 - s/t)(\omega_1(u_2(s,\cdot), \tilde{D}(s)) - \omega_1(u_1(s,\cdot), \tilde{D}(s))) ds \\ &\qquad -\frac{1}{t}\int_0^t ds \int_{\tilde{D}(s)} dx \quad (\text{as } m \to \infty) \\ \leq &-\frac{1}{t}\int_0^t ds \int_{\tilde{D}(s)} dx, \end{aligned} \tag{3.27}$$

which implies the first assertion of this lemma.

Suppose that (3.23) does not hold. Then there exists $a \in (0, dist(D_1(0), D_2(0)^c))$ such that

$$\inf\{dist(D_1(t), D_2(t)^c) | t \in [0, \min(\mathrm{Vol}(D_1(0)), T))\} < a.$$

Take $p_a \in \mathbf{S}^{N-1}$ and $t_a \in [0, \min(\mathrm{Vol}(D_1(0)), T))$ so that

$$ap_a + D_1(t_a) \not\subset D_2(t_a).$$

Since $ap_a + D_1(0) \subset D_2(0)$ and $\{ap_a + D_1(t)\}_{0\le t<T}$ is a solution to (1.13)–(1.14) on $[0,T)$, this contradicts the first assertion of this lemma. □

Take $\varphi \in C^2(\mathbf{R}^N)$ for which $D\varphi(x_o) \neq 0$ for some $x_o \in \mathbf{R}^N$. Put

$$f_N := \frac{D\varphi(x_o)}{|D\varphi(x_o)|}, \quad (g_1 \cdots g_N) := I_N - f_N \otimes f_N. \tag{3.28}$$

Take $\{f_1, \ldots, f_{N-1}\}$ so that $\{f_1, \ldots, f_N\}$ is an orthonormal basis of $\mathbf{R}^N$. Then the following holds.

LEMMA 3.7.

(i) $\langle g_i, f_N \rangle = 0$ $(1 \le i \le N)$.

(ii) *For i for which $\partial_i\varphi(x_o) := \partial\varphi(x_o)/\partial x_i \neq 0$,*

$$g_i = -\sum_{k\neq i} \frac{\partial_k\varphi(x_o)}{\partial_i\varphi(x_o)} g_k.$$

(iii) $\mathrm{span}(g_1, \ldots, g_N) = \mathrm{span}(f_1, \ldots, f_{N-1})$.

(iv) $D(D\varphi(x_o)/|D\varphi(x_o)|)(\mathbf{R}^N) \subset \mathrm{span}(g_1, \ldots, g_N)$. *As a mapping on* $\mathrm{span}(g_1, \ldots, g_N)$, *eigenvalues and eigenvectors of* $(g_1 \cdots g_N)(D^2\varphi(x_o)/|D\varphi(x_o)|)(g_1 \cdots g_N)$ *are the same as those of* $D(D\varphi(x_o)/|D\varphi(x_o)|)$. *In particular, all eigenvalues of* $D(D\varphi(x_o)/|D\varphi(x_o)|)$ *are real.*

(v) *If eigenvalues* $\lambda_1 \le \cdots \le \lambda_{N-1}$ *of* $-D(D\varphi(x_o)/|D\varphi(x_o)|)$ *as a mapping on* $\mathrm{span}(g_1, \ldots, g_N)$ *are nonnegative, then*

$$\prod_{i=1}^{N-1} \lambda_i = \frac{G(D\varphi(x_o), D^2\varphi(x_o))}{|D\varphi(x_o)|}. \tag{3.29}$$

Proof. It is easy to see that (i) and (ii) hold. Take i for which $\partial_i\varphi(x_o) \neq 0$. Then, by (i) and (ii), we have only to show, to prove (iii), that $\{g_j\}_{j\neq i}$ is independent. Suppose that for $j = 1, \ldots, N$,

$$\sum_{k\neq i} \lambda_k \left(\delta_{kj} - \frac{\partial_k\varphi(x_o)\partial_j\varphi(x_o)}{|D\varphi(x_o)|^2} \right) = 0. \tag{3.30}$$

Putting $j = i$ in (3.30), we obtain

$$\sum_{k\neq i} \lambda_k \frac{\partial_k\varphi(x_o)\partial_i\varphi(x_o)}{|D\varphi(x_o)|^2} = 0,$$

from which

$$\sum_{k\neq i} \lambda_k \partial_k\varphi(x_o) = 0. \tag{3.31}$$

Putting $j \neq i$ in (3.30), we obtain

$$\lambda_j - \partial_j\varphi(x_o) \sum_{k\neq i} \lambda_k \frac{\partial_k\varphi(x_o)}{|D\varphi(x_o)|^2} = 0,$$

from which $\lambda_j = 0$ for $j \neq i$, by (3.31).

We prove (iv). It is easy to see that

$$D\left(\frac{D\varphi(x_o)}{|D\varphi(x_o)|}\right) = (g_1 \cdots g_N)\frac{D^2\varphi(x_o)}{|D\varphi(x_o)|}. \tag{3.32}$$

Hence

$$D\left(\frac{D\varphi(x_o)}{|D\varphi(x_o)|}\right)\left(\sum_{i=1}^N x_i g_i\right) = \lambda \sum_{i=1}^N x_i g_i$$

if and only if

$$(g_1 \cdots g_N)\frac{D^2\varphi(x_o)}{|D\varphi(x_o)|}(g_1 \cdots g_N)\left(\sum_{i=1}^N x_i g_i\right) = \lambda \sum_{i=1}^N x_i g_i,$$

since

$$(g_1 \cdots g_N)^2 = (g_1 \cdots g_N). \tag{3.33}$$

Put $P := (f_1 \cdots f_N)$ and $Q := (f_1 \cdots f_{N-1})$, and let Q^* and o_{N-1} denote the transposed matrix of Q and the $(N-1)$-dimensional zero vector, respectively. The proof of (v) is divided into the following.

Step I. The eigenvalues of

$$-(I_N - f_N \otimes f_N)\frac{D^2\varphi(x_o)}{|D\varphi(x_o)|}(I_N - f_N \otimes f_N) + f_N \otimes f_N$$

are those of

$$\begin{pmatrix} -Q^* D(\frac{D\varphi(x_o)}{|D\varphi(x_o)|})Q & o_{N-1} \\ o_{N-1}^* & 1 \end{pmatrix}.$$

Step II. The eigenvalues of $Q^* D(D\varphi(x_o)/|D\varphi(x_o)|)Q$ are those of $D(D\varphi(x_o)/|D\varphi(x_o)|)$ on $\mathrm{span}(g_1, \ldots, g_N)$.

Proof of Step I. Denote by O_{N-1} the $(N-1)\times(N-1)$-zero matrix. For $\lambda \in \mathbf{R}$,

$$\begin{aligned}
&\det\left(-(I_N - f_N \otimes f_N)\frac{D^2\varphi(x_o)}{|D\varphi(x_o)|}(I_N - f_N \otimes f_N) + f_N \otimes f_N - \lambda I_N\right) \\
&= \det\left(-\begin{pmatrix} I_{N-1} & o_{N-1} \\ o_{N-1}^* & 0 \end{pmatrix} P^* \frac{D^2\varphi(x_o)}{|D\varphi(x_o)|} P \begin{pmatrix} I_{N-1} & o_{N-1} \\ o_{N-1}^* & 0 \end{pmatrix}\right. \\
&\qquad \left. + \begin{pmatrix} O_{N-1} & o_{N-1} \\ o_{N-1}^* & 1 \end{pmatrix} - \lambda I_N\right) \\
&= \det\left(\begin{pmatrix} -Q^* \frac{D^2\varphi(x_o)}{|D\varphi(x_o)|} Q & o_{N-1} \\ o_{N-1}^* & 1 \end{pmatrix} - \lambda I_N\right)
\end{aligned}$$

since

$$P^*P = I_N, \quad P\begin{pmatrix} O_{N-1} & o_{N-1} \\ o_{N-1}^* & 1 \end{pmatrix} P^* = f_N \otimes f_N.$$

Equations (3.28) and (3.32) complete the proof since $\langle f_i, f_N \rangle = 0$ if $i \neq N$.

Proof of Step II. Let $x = (x_i)_{i=1}^{N-1} \in \mathbf{R}^{N-1}$ and $\lambda \in \mathbf{R}$. Suppose that

$$Q^* D\left(\frac{D\varphi(x_o)}{|D\varphi(x_o)|}\right) Qx = \lambda x. \tag{3.34}$$

Then

$$QQ^* D\left(\frac{D\varphi(x_o)}{|D\varphi(x_o)|}\right)\left(\sum_{1\le i\le N-1} x_i f_i\right) = \lambda \sum_{1\le i\le N-1} x_i f_i.$$

Hence, by (3.32),

$$D\left(\frac{D\varphi(x_o)}{|D\varphi(x_o)|}\right) \sum_{1\le i\le N-1} x_i f_i = \lambda \sum_{1\le i\le N-1} x_i f_i \tag{3.35}$$

since, by (iii),

$$QQ^*(I_N - f_N \otimes f_N) = I_N - f_N \otimes f_N.$$

It is easy to see that (3.35) implies (3.34) since $Q^*Q = I_{N-1}$. □

For $i = 1, \dots, N$, put

$$y_i(x) := \left((\delta_{ij} - 1)\frac{\partial_j \varphi(x)}{|D\varphi(x)|} + \delta_{ij}\varphi(x)\right)_{j=1}^{N}.$$

Then we have the following.

LEMMA 3.8. *Suppose that all eigenvalues of $D(D\varphi(x_o)/|D\varphi(x_o)|)$ are nonpositive. Then, for $i = 1, \dots, N$,*

$$\frac{\partial_i \varphi(x_o)}{|D\varphi(x_o)|} G(D\varphi(x_o), D^2\varphi(x_o)) = \det(Dy_i(x_o)). \tag{3.36}$$

Proof. For the sake of simplicity, we assume that $i = N$.

We first consider the case when $\partial_N \varphi(x_o) \neq 0$. By (ii) in Lemma 3.7, it is easy to see that the following holds:

$$\begin{aligned} A &:= \begin{pmatrix} I_{N-1} & o_{N-1} \\ -\frac{D\varphi(x_o)^*}{\partial_N \varphi(x_o)} & \end{pmatrix} Dy_N(x_o) \\ &= D\left(-\frac{D\varphi(x_o)}{|D\varphi(x_o)|}\right) + \begin{pmatrix} O_{N-1} & o_{N-1} \\ -D\varphi(x_o)^* & \end{pmatrix}. \end{aligned} \tag{3.37}$$

By Lemma 3.7 (i) and (iv), the eigenvalues and eigenvectors of $D(-D\varphi(x_o)/|D\varphi(x_o)|)$ on $\operatorname{span}(g_1, \dots, g_N)$ are real and are also those of the matrix A.

Therefore, by (iii) in Lemma 3.7, the matrix A has a real eigenvalue λ and a real eigenvector $x_\lambda \notin \operatorname{span}(g_1, \dots, g_N)$. Indeed, by (3.32),

$$A\mathbf{e}_N \in (-\partial_N \varphi(x_o))\mathbf{e}_N + \operatorname{span}(g_1, \dots, g_N),$$

where $\mathbf{e}_N := (\delta_{jN})_{j=1}^N$. Besides, $\mathbf{e}_N \notin \operatorname{span}(g_1, \dots, g_N)$ since $\partial_N \varphi(x_o) \neq 0$.

We show that $\lambda = -\partial_N \varphi(x_o)$. Put

$$x_\lambda := x_g + a\mathbf{e}_N \quad (x_g \in \operatorname{span}(g_1, \dots, g_N), a \neq 0), \tag{3.38}$$

which is possible since $\mathrm{span}(\mathbf{e}_N, g_1, \dots, g_N) = \mathbf{R}^N$ by (iii) in Lemma 3.7. Then

$$(-\partial_N \varphi(x_o))a\mathbf{e}_N = \lambda a \mathbf{e}_N \tag{3.39}$$

by (i) in Lemma 3.7 since $Ax_\lambda = \lambda x_\lambda$ and since $\mathbf{e}_N$ and $\{g_1, \dots, g_N\}$ are independent. This implies that $\lambda = -\partial_N \varphi(x_o)$.

Suppose that $\partial_N \varphi(x_o) = 0$. Then, by (3.32) and (i) in Lemma 3.7, for $x \in \mathbf{R}^N$,

$$\langle f_N, Dy_N(x_o)x\rangle = \left\langle f_N, D\left(-\frac{D\varphi(x_o)}{|D\varphi(x_o)|}\right)x\right\rangle = 0. \tag{3.40}$$

Hence $Dy_N(x_o)(\mathbf{R}^N)$ is at most $(N-1)$-dimensional and (3.36) holds. □

4. Proofs. In this section we prove the results in section 2.

Proof of Theorem 2.1. By Lemmas 3.1–3.6, there exists a unique (nonrandom) solution $\{D(t)\}_{0\le t<V_0}$ (see (3.6) for notation) of (1.13)–(1.14) on $[0, V_0)$ such that $I_{D(\cdot)} \in C([0, V_0) : \mathcal{S})$ and such that the following holds: for any $T \in [0, V_0)$ and $\gamma > 0$,

$$\lim_{m\to\infty} P\left(\sup_{0\le t\le T} d_{\mathcal{S}}(\overline{Y}_m(t,\cdot), I_{D(t)}(\cdot)) \ge \gamma\right) = 0. \tag{4.1}$$

Therefore

$$\lim_{m\to\infty} P\left(\sup_{0\le t\le T} ||\overline{Y}_m(t,\cdot) - I_{D(t)}(\cdot)||_{L^2([-K,K]^N)} \ge \gamma\right) = 0, \tag{4.2}$$

since, for $m \ge 1$ and $t \in [0, T]$,

$$\begin{aligned} &||\overline{Y}_m(t,\cdot) - I_{D(t)}(\cdot)||^2_{L^2([-K,K]^N)} \\ &= \int_{[-K,K]^N} (\overline{Y}_m(t,x) - 2\overline{Y}_m(t,x)I_{D(t)}(x) + I_{D(t)}(x))dx. \end{aligned}$$

We prove that the following holds:

$$\lim_{m\to\infty} P\left(\sup_{0\le t\le T} ||X_m(t,\cdot) - I_{D(t)}(\cdot)||_{L^2([-K,K]^N)} \ge \gamma\right) = 0. \tag{4.3}$$

For any s and t for which $0 \le s < t \le T$,

$$\begin{aligned} &||X_m(t,\cdot) - I_{D(t)}(\cdot)||_{L^2([-K,K]^N)} \\ &\le ||X_m(t,\cdot) - X_m(s,\cdot)||_{L^2([-K,K]^N)} + ||X_m(s,\cdot) - \overline{Y}_m(s,\cdot)||_{L^2([-K,K]^N)} \\ &\quad + ||\overline{Y}_m(s,\cdot) - I_{D(s)}(\cdot)||_{L^2([-K,K]^N)} + ||I_{D(s)}(\cdot) - I_{D(t)}(\cdot)||_{L^2([-K,K]^N)}. \end{aligned} \tag{4.4}$$

Let $U_{-N^{1/2}/m}(D) := \{x \in D | dist(x, D^c) > N^{1/2}/m\}$. Then

$$\begin{aligned} &||X_m(t,\cdot) - X_m(s,\cdot)||^2_{L^2([-K,K]^N)} = ||X_m(t,\cdot) - X_m(s,\cdot)||_{L^1([-K,K]^N)} \\ &\le 2^N \sum_{z\in D_m} (Y_m(s,z) - Y_m(t,z))\frac{1}{m^N} + \mathrm{Vol}(D\backslash U_{-N^{1/2}/m}(D)) \end{aligned} \tag{4.5}$$

(see (2.2) for notation). Indeed, if $x = (x_i)_{i=1}^N \in U_{-N^{1/2}/m}(D)\backslash(\mathrm{co}\ Y_m(t,\cdot)^{-1}(1))$, then $Y_m(t,z) = 0$ for some $z = (z_i)_{i=1}^N \in \mathbf{Z}^N/m$ for which $|x_i - z_i| \le 1/m$ for all $i = 1, \dots, N$.

In the same way as in (3.5), by (4.5), for any $\gamma > 0$, there exists $\delta > 0$ such that the following holds: for any $s \in [0, T - \delta]$,

$$\lim_{m\to\infty} P\left(\sup_{s\le s_1\le s+\delta} ||X_m(s_1,\cdot) - X_m(s,\cdot)||_{L^2([-K,K]^N)} \ge \gamma\right) = 0. \tag{4.6}$$

Since, for any $t \in [0, V_0)$, any subsequence of $\{C_m(t)\}_{m\ge1}$ has a convergent subsequence (see (3.13)–(3.16)),

$$\lim_{m\to\infty} ||\overline{Y}_m(t,\cdot) - X_m(t,\cdot)||_{L^2([-K,K]^N)} = 0 \tag{4.7}$$

for all $t \in [0, V_0)$, P_1-a.s. (see the discussion after (3.18)). Hence, for any $\gamma > 0$,

$$\lim_{m\to\infty} P(||\overline{Y}_m(s,\cdot) - X_m(s,\cdot)||_{L^2([-K,K]^N)} \ge \gamma) = 0. \tag{4.8}$$

$I_{D(\cdot)} \in C([0, V_0) : L^2([-K, K]^N))$ since

$$||I_{D(s)}(\cdot) - I_{D(t)}(\cdot)||^2_{L^2([-K,K]^N)} = \int_{[-K,K]^N} I_{D(s)}(x)dx - \int_{[-K,K]^N} I_{D(t)}(x)dx$$

and since $t \mapsto \int_{[-K,K]^N} I_{D(t)}(x)dx$ is continuous on $[0, V_0)$.

Equation (4.2) and the discussion after (4.3) show that (4.3) is true.

Recall Lemmas 3.2 and 3.3 and the notation therein. For $T < V_0$, take $x_0 \in D(T)$ and r_0 so that $U_{4r_0}(x_0) \subset D(T)$. For sufficiently large $k \ge 1$,

$$U_{3r_0}(x_0) \subset (\text{co } Y_{m_k}(T,\cdot)^{-1}(1))^o \cap D, \quad P_1\text{-a.s.},$$

since

$$\lim_{k\to\infty} ||X_{m_k}(T,\cdot) - I_{D(T)}(\cdot)||_{L^2([-K,K]^N)} = 0, \quad P_1\text{-a.s.}$$

by Lemma 3.2 and (4.7) (see the discussion below (4.2)). Hence in the same way as in Lemma 3.3,

$$\begin{aligned} V_0 &\le \liminf_{k\to\infty} \sum_{z\in D_{m_k}} (Y_{m_k}(T,z) - Y_{m_k}(\tau_{m_k},z))\frac{1}{m_k^N} \\ &\le \liminf_{k\to\infty} (\tau_{m_k} - T) \quad P_1\text{-a.s.}, \end{aligned} \tag{4.9}$$

which implies that (4.3) holds for $T < 2V_0$. Repeating the same procedure as above and then letting $r_0 \downarrow 0$, (4.3) holds for all $T < T^* := \text{Vol}(D)$.

Put

$$D(t) = \emptyset \quad \text{for } t \ge T^*. \tag{4.10}$$

Then $I_{D(\cdot)} \in C([0,\infty) : L^2([-K, K]^N))$ and $\{D(t)\}_{t\ge0}$ is a unique solution to (1.13)–(1.14) on $[0,\infty)$ by Lemma 3.6, since $t \mapsto I_{D(t)}$ is nonincreasing and since

$$\text{Vol}(D(t)) = \text{Vol}(D(0)) - t \downarrow 0 \quad \text{as } t \uparrow T^* \tag{4.11}$$

by (1.14).

We prove (2.9). By (4.11), for $\gamma > 0$,

$$\text{Vol}(D(t)) \le \left(\frac{\gamma}{4}\right)^2 \quad \text{for } t \ge t_\gamma := T^* - \left(\frac{\gamma}{4}\right)^2. \tag{4.12}$$

Therefore

$$\begin{aligned} &P\left(\sup_{t\ge 0} ||X_m(t,\cdot) - I_{D(t)}(\cdot)||_{L^2([-K,K]^N)} \ge \gamma\right) \\ &\le P\left(\sup_{0\le t\le t_\gamma} ||X_m(t,\cdot) - I_{D(t)}(\cdot)||_{L^2([-K,K]^N)} \ge \gamma\right) \\ &\qquad + P\left(\sup_{t\ge t_\gamma} ||X_m(t,\cdot) - I_{D(t)}(\cdot)||_{L^2([-K,K]^N)} \ge \gamma\right) \\ &\le 2P\left(\sup_{0\le t\le t_\gamma} ||X_m(t,\cdot) - I_{D(t)}(\cdot)||_{L^2([-K,K]^N)} \ge \frac{\gamma}{2}\right) \to 0 \quad (\text{as } m\to\infty) \end{aligned} \tag{4.13}$$

since for $t \ge t_\gamma$,

$$\begin{aligned} &||X_m(t,\cdot) - I_{D(t)}(\cdot)||_{L^2([-K,K]^N)} \\ &\le ||X_m(t_\gamma,\cdot)||_{L^2([-K,K]^N)} + ||I_{D(t_\gamma)}(\cdot)||_{L^2([-K,K]^N)} \\ &\le ||X_m(t_\gamma,\cdot) - I_{D(t_\gamma)}(\cdot)||_{L^2([-K,K]^N)} + 2||I_{D(t_\gamma)}(\cdot)||_{L^2([-K,K]^N)}. \end{aligned}$$ □

Proof of Corollary 2.2. Since D is convex,

$$(\text{co } Y_m(t,\cdot)^{-1}(1))^o \cap D = (\text{co } Y_m(t,\cdot)^{-1}(1))^o =: D_m(t).$$

For $T < T^*(= \text{Vol}(D))$, take $x_0 \in D(T)$ and r_0 so that $U_{4r_0}(x_0) \subset D(T)$ (see (3.6) for notation). Then, for sufficiently large m, $U_{3r_0}(x_0) \subset D_m(0)$.

Consider cones

$$\text{cone}(x) := \text{co } (\{x\} \cup U_0^-) \quad (x \in D^-)$$

(see (3.6) for notation), and for $r > 0$, put

$$V(r) := \inf_{x\in\partial D} \text{Vol}(\text{cone}(x) \cap H(x_0 - x, x + r(x_0 - x))), \tag{4.14}$$

$$V_m(r) := \inf_{x\in\partial D_m(0)} \text{Vol}(\text{cone}(x) \cap H(x_0 - x, x + r(x_0 - x))). \tag{4.15}$$

Then for $\gamma > 0$ and sufficiently large $m \ge 1$, by Theorem 2.1,

$$\begin{aligned} &P\left(\sup_{0\le t\le T} d_H(\partial D_m(t), \partial D(t)) \ge \gamma\right) \\ &\le P\Bigg(||I_{D_m(T)}(\cdot) - I_{D(T)}(\cdot)||^2_{L^2([-K,K])} \ge V_0) \\ &\qquad + P(U_0 \subset D_m(T), \sup_{0\le t\le T} d_H(\partial D_m(t), \partial D(t)) \ge \gamma\Bigg) \\ &\to 0 \quad (\text{as } m\to\infty) \end{aligned} \tag{4.16}$$

(see (3.6) for notation). Indeed,

$$P\left(U_0 \subset D_m(T),\ \sup_{0\le t\le T} d_H(\partial D_m(t), \partial D(t)) \ge \gamma\right)$$
$$\le P\left(\sup_{0\le t\le T} ||I_{D_m(t)}(\cdot) - I_{D(t)}(\cdot)||^2_{L^2([-K,K])} \ge \min(V(\gamma), V_m(\gamma))\right),$$

and $V_m(\gamma) \ge V(\gamma)$ for all $m \ge 1$. □

Proof of Corollary 2.3. For $r \in \mathbf{R}$, let $\{D_r(t)\}_{t\ge 0}$ denote the unique solution of (1.13)–(1.14) with $D_r(0) = h^{-1}((r,\infty))$ on $[0,\infty)$. Notice that

$$D_r(\cdot) = \begin{cases} \mathbf{R}^N & \text{if } r < \inf\{h(x)|x \in \mathbf{R}^N\}, \\ \emptyset & \text{if } r \ge \sup\{h(x)|x \in \mathbf{R}^N\}. \end{cases} \tag{4.17}$$

Put

$$u(t,x) := \sup\{r \in \mathbf{R}|x \in D_r(t)\}. \tag{4.18}$$

Then, for all $t \ge 0$ and $r \in \mathbf{R}$ for which $D_r(t) \ne \emptyset$, $\mathbf{R}^N$,

$$u(t,\cdot)^{-1}((r,\infty)) = D_r(t), \tag{4.19}$$

since $D_r(t) = D_{r+}(t) := \cup_{\tilde r > r} D_{\tilde r}(t)$ by (1.13).

Indeed, $D_r(0) = D_{r+}(0)$ and $D_r(t) \supset D_{\tilde r}(t)$ for $\tilde r > r$ by Lemma 3.6. If $\tilde r - r$ is positive and is sufficiently small, then $D_{\tilde r}(t) \ne \emptyset$ by (b) in Theorem 2.4, and

$$\int_{\mathbf{R}^N} (I_{D_{\tilde r}(t)}(x) - I_{D_r(t)}(x))dx = \int_{\mathbf{R}^N} (I_{D_{\tilde r}(0)}(x) - I_{D_r(0)}(x))dx \uparrow 0 \quad (\text{as } \tilde r \to r). \tag{4.20}$$

By Lemma 3.6 and (4.19), u is continuous.

For $m \ge 1$, put

$$k_{m,1} := [m \sup\{h(y)|y \in \mathbf{R}^N\}],$$
$$k_{m,0} := [m \inf\{h(y)|y \in \mathbf{R}^N\}] - 1.$$

Then

$$\sum_{k_{m,0}\le k\le k_{m,1}} \frac{k}{m}\left(I_{D_{\frac{k}{m}}(t)}(x) - I_{D_{\frac{k+1}{m}}(t)}(x)\right) \tag{4.21}$$
$$= \sum_{k_{m,0}< k\le k_{m,1}} \frac{1}{m} I_{D_{\frac{k}{m}}(t)}(x) - \frac{k_{m,1}+1}{m} I_{D_{\frac{k_{m,1}+1}{m}}(t)}(x) + \frac{k_{m,0}}{m} I_{D_{\frac{k_{m,0}}{m}}(t)}(x).$$

Since $I_{D_{\frac{k_{m,1}+1}{m}}(t)}(x) \equiv 0$ and since $I_{D_{\frac{k_{m,0}}{m}}(t)}(x) \equiv 1$, the following holds: for any $\varphi \in C_o(\mathbf{R}^N)$ and any $t \ge 0$,

$$\int_{\mathbf{R}^N} \varphi(x) \left[\sum_{k_{m,0}\le k\le k_{m,1}} \frac{k}{m}\left(I_{D_{\frac{k}{m}}(0)}(x) - I_{D_{\frac{k+1}{m}}(0)}(x)\right)\right. \tag{4.22}$$
$$\left. - \sum_{k_{m,0}\le k\le k_{m,1}} \frac{k}{m}\left(I_{D_{\frac{k}{m}}(t)}(x) - I_{D_{\frac{k+1}{m}}(t)}(x)\right)\right] dx$$
$$= \int_0^t ds \left[\sum_{k_{m,0}< k\le k_{m,1}} \frac{1}{m} \int_{\mathbf{R}^N} \varphi(x)\omega_1\left(I_{D_{\frac{k}{m}}(s)}(\cdot), dx\right)\right].$$

Letting $m \to \infty$ in (4.22), one can show that u is a solution to (1.15) by Lemma 3.4 since

$$\omega_1\left(I_{D_{\frac{[mr]+1}{m}}(s)}(\cdot), dx\right) \to \omega_1(I_{D_r(s)}(\cdot), dx) \quad \text{weakly as } m \to \infty$$

and since

$$\omega_1(I_{D_r(s)}(\cdot), dx) = \omega_r(u(s,\cdot), dx),$$

except for at most countably many $r \in (\inf\{u(s,y)|y \in \mathbf{R}^N\}, \sup\{u(s,y)|y \in \mathbf{R}^N\})$.

Indeed,

$$\cup_{\tilde{r}>r}\{\text{co } u(s,\cdot)^{-1}((\tilde{r},\infty))\}^- = \text{co } u(s,\cdot)^{-1}((r,\infty)) \tag{4.23}$$

since $D_r(s) = D_{r+}(s)$ (see (4.19)–(4.20)) and since for $\tilde{r} > r$,

$$\begin{aligned}&\text{co } u(s,\cdot)^{-1}((\tilde{r},\infty)) \subset \{\text{co } u(s,\cdot)^{-1}((\tilde{r},\infty))\}^- \\ &\subset \text{co } u(s,\cdot)^{-1}([\tilde{r},\infty)) \subset \text{co } u(s,\cdot)^{-1}((r,\infty)).\end{aligned}$$

Besides, except for at most countably many r,

$$\{\text{co } u(s,\cdot)^{-1}((r,\infty))\}^- = \text{co } u(s,\cdot)^{-1}([r,\infty)) \tag{4.24}$$

since the sets $(\text{co } u(s,\cdot)^{-1}([r,\infty))\backslash\{\text{co } u(s,\cdot)^{-1}((r,\infty))\}^-)$ are disjoint for different r and since $(\text{co } u(s,\cdot)^{-1}([r,\infty))\backslash\{\text{co } u(s,\cdot)^{-1}((r,\infty))\}^-)$ is not empty if and only if it has a positive Lebesgue measure.

Let $v \in C([0,\infty) \times \mathbf{R}^N)$ be a solution to (1.15) with $v(0,\cdot) = h(\cdot)$. Then for $m \geq 1$, $r \in [\inf\{h(y)|y \in \mathbf{R}^N\}, \sup\{h(y)|y \in \mathbf{R}^N\})$, and $\varphi \in C_o(\mathbf{R}^N)$ and $t \geq 0$,

$$\begin{aligned}&\int_{\mathbf{R}^N} \varphi(x)\{\eta_m(v(0,x)-r) - \eta_m(v(t,x)-r)\}dx \\ &= \int_0^t ds \int_{\mathbf{R}} \frac{d\eta_m(\tilde{r}-r)}{d\tilde{r}} d\tilde{r} \int_{\mathbf{R}^N} \varphi(x)\omega_{\tilde{r}}(v(s,\cdot), dx)\end{aligned} \tag{4.25}$$

(see (3.24) for notation).

Let $m \to \infty$ in (4.25). Then we see that $\tilde{D}_r(t) := v(t,\cdot)^{-1}((r,\infty))$ is a solution to (1.14) on $[0,\infty)$ by Lemma 3.4. Indeed, in the same way as in (4.23), one can show that the following holds:

$$\cup_{\tilde{r}>r}\text{co } v(s,\cdot)^{-1}([\tilde{r},\infty)) = \text{co } v(s,\cdot)^{-1}((r,\infty)). \tag{4.26}$$

We prove that $v(t,\cdot)^{-1}((r,\infty))$ satisfies (1.13). For $x \in (\text{co } \tilde{D}_r(t)) \cap \tilde{D}_r(0)$, take $\delta > 0$ so that $U_\delta(x) \subset (\text{co } \tilde{D}_r(t)) \cap \tilde{D}_r(0)$. Then $U_\delta(x) \subset \text{co } \tilde{D}_r(s)$ for all $s \leq t$. Hence, by (1.14), for any $\varphi \in C_o(\mathbf{R}^N)$ such that $\varphi \equiv 0$ in $U_\delta(x)^c$,

$$\int_{\mathbf{R}^N} \varphi(y)\{I_{\tilde{D}_r(0)}(y) - I_{\tilde{D}_r(t)}(y)\}dy = \int_0^t ds \int_{\mathbf{R}^N} \varphi(y)\omega_1(I_{\tilde{D}_r(s)}(\cdot), dy) = 0, \tag{4.27}$$

which implies that $x \in (U_\delta(x) \subset)\tilde{D}_r(t)$. Hence (1.13) holds.

The uniqueness of u follows from that of $D_r(\cdot)$ for all r. □

Theorem 2.4 is an easy consequence of Theorem 2.1 and Lemma 3.6, and we omit the proof.

Proof of Theorem 2.5.

Step I. We first show that $u(t,x) := I_{D(t)}(x)$ is a viscosity supersolution of (1.20) in $(0,\infty)\times\mathbf{R}^N$.

Let $\psi \in \mathcal{A}((0,\infty)\times\mathbf{R}^N)$ and assume that $u-\psi$ attains a local minimum at $(t_0,x_0)\in(0,\infty)\times\mathbf{R}^N$. Without loss of generality, we may assume that $u(t_0,x_0)=\psi(t_0,x_0)$ and that $u(t,x)>\psi(t,x)$ for all $(t,x)\in(0,\infty)\times\mathbf{R}^N\setminus\{(t_0,x_0)\}$ (see [8]).

If $x_0\notin\partial(\text{co } D(t_0))\cap\partial D(t_0)$, then $\partial_t\psi(t_0,x_0)\geq 0$.

Indeed, $t\mapsto u(t,x_0)$ is constant if t_0-t is a sufficiently small positive number, from which $\psi(t_0,x_0)>\psi(t,x_0)$ for such t.

Suppose that $x_0\in\partial(\text{co } D(t_0))\cap\partial D(t_0)$. Then $u(t_0,x_0)=0$, and $D\psi(t_0,x_0)=o$ or $\sigma^+(u,D\psi(t_0,x_0),t_0,x_0)=1$.

Indeed, if $D\psi(t_0,x_0)\neq o$, then for y for which $y+x_0\notin H(D\psi(t_0,x_0),x_0)$ and for $r>0$, by the mean value theorem, there exists $\theta\in(0,1)$ such that

$$u(t_0,x_0+ry)>\psi(t_0,x_0+ry)=\psi(t_0,x_0)+r\langle D\psi(t_0,x_0+\theta ry),y\rangle>0,$$

provided r is sufficiently small, by the continuity of $D\psi$.

Case 1. We first consider the case when $D\psi(t_0,x_0)=o$. We may assume that there exist $f\in\mathcal{F}$ and $\varphi_1\in C^2((0,\infty))$ such that

$$\psi(t,x)=-f(|x-x_0|)-\varphi_1(t) \tag{4.28}$$

(see [21]).

For $A>0$ and $i\geq 2$, put

$$\psi_{i,A}(t,x)=\psi(t,x)-A\{|t-t_0|^2+|x-x_0|^i\}. \tag{4.29}$$

Then

$$\partial_t\psi_{i,A}(t_0,x_0)=\partial_t\psi(t_0,x_0),\quad D\psi_{i,A}(t_0,x_0)=D\psi(t_0,x_0), \tag{4.30}$$

and

$$\begin{aligned} U^+_{i,A,\varepsilon} &:= \{(t,x)\in(0,\infty)\times\mathbf{R}^N \,|\, \psi_{i,A}(t,x)+\varepsilon>u(t,x)\} \\ &\subset U_{(2^{i/2}\varepsilon/A)^{1/i}}((t_0,x_0)) \end{aligned} \tag{4.31}$$

($\varepsilon\in(0,A)$), and the following holds: for $t\geq 0$,

$$\lim_{x\to x_0} G(D\psi_{N,A}(t,x),D^2\psi_{N,A}(t,x))=NA. \tag{4.32}$$

We argue by contradiction. We consider $\psi_{N,A}$ instead of ψ. When it is not confusing, we omit $_{N,A}$ for the sake of simplicity.

Assume that the following holds:

$$\partial_t\psi(t_0,x_0)<0. \tag{4.33}$$

By reselecting $A>0$ sufficiently small and $\varepsilon>0$ sufficiently small compared to A if necessary, we may assume that $U_{(2^{i/2}\varepsilon/A)^{1/i}}((t_0,x_0))\subset(0,\infty)\times\mathbf{R}^N$, that

$$\partial_t\psi(t,x)+R\left(\frac{D\psi(t,x)}{|D\psi(t,x)|}\right)G(D\psi(t,x),D^2\psi(t,x))+\varepsilon<0 \quad \text{on } U^+_\varepsilon, \tag{4.34}$$

and that

$$U_\varepsilon^+ = \cup_{t>0}\{t\} \times (\psi(t,\cdot)^{-1}((-\varepsilon,\infty)) \cap D(t)^c). \tag{4.35}$$

We may also assume that $x \mapsto \psi(t,x)$ is strictly concave on U_ε^+; hence $x \mapsto (\psi(s,x), D\psi(s,x)/|D\psi(s,x)|)$ is one-to-one on some neighborhood of $\partial\psi(s,\cdot)^{-1}((-\varepsilon,\infty)) \cap D(s)^c$, provided $\psi(s,\cdot)^{-1}((-\varepsilon,\infty)) \cap D(s)^c \neq \emptyset$.

Indeed, if $\psi(s,\cdot)^{-1}((-\varepsilon,\infty)) \cap D(s)^c \neq \emptyset$, then $-\varepsilon$ is not the maximum of $\psi(s,\cdot)$ on $\psi(s,\cdot)^{-1}((-\varepsilon,\infty)) \cap D(s)^c$ and hence $D\psi(s,\cdot) \neq o$ on some neighborhood of $\partial\psi(s,\cdot)^{-1}((-\varepsilon,\infty)) \cap D(s)^c$.

For $t \geq 0$ and m and $k \geq 1$,

$$\begin{aligned}\int_{\mathbf{R}^N} &(\zeta_k(\eta_m(\psi(t,x)+\varepsilon) - u(t,x)) \\ &\quad - \zeta_k(\eta_m(\psi(0,x)+\varepsilon) - u(0,x)))dx \\ = \int_{\mathbf{R}^N} dx \int_0^t \Big(&- \zeta_k(\eta_m(\psi(s,x)+\varepsilon) - u(s,x))u(ds,x) \\ &+ \eta_k(\eta_m(\psi(s,x)+\varepsilon) - u(s,x))\frac{d\eta_m(\psi(s,x)+\varepsilon)}{dr}\partial_s\psi(s,x)ds\Big)\end{aligned} \tag{4.36}$$

(see (3.24)–(3.25) for notation).

Letting $k \to \infty$ in (4.36), by (4.31) and (4.35),

$$\begin{aligned}0 \leq \int_0^t ds \Bigg\{ &\int_{\psi(s,\cdot)^{-1}((-\varepsilon,\infty))\cap D(s)^c} \eta_m(\psi(s,x)+\varepsilon)\omega_1(u(s,\cdot),dx) \\ &+ \int_{\psi(s,\cdot)^{-1}((-\varepsilon,-\varepsilon+1/m))\cap D(s)^c} \frac{d\eta_m(\psi(s,x)+\varepsilon)}{dr}\partial_s\psi(s,x)dx\Bigg\}.\end{aligned} \tag{4.37}$$

For s for which $\psi(s,\cdot)^{-1}((-\varepsilon,-\varepsilon+1/m))\cap D(s)^c \neq \emptyset$ and sufficiently large $m \geq 1$, by Lemma 3.8 and (4.34),

$$\begin{aligned}&\int_{\psi(s,\cdot)^{-1}((-\varepsilon,-\varepsilon+1/m))\cap D(s)^c} \frac{d\eta_m(\psi(s,x)+\varepsilon)}{dr}\partial_s\psi(s,x)dx \\ &< -\int_{-\varepsilon}^{-\varepsilon+1/m} \frac{d\eta_m(r+\varepsilon)}{dr}dr \int_{\{\frac{-D\psi(s,x)}{|D\psi(s,x)|}:x\in\partial\psi(s,\cdot)^{-1}((r,\infty))\cap D(s)^c\}} (R(p) \\ &\qquad + \varepsilon\sup\{G(D\psi(s,x), D^2\psi(s,x)) : (s,x) \in U_\varepsilon^+\}^{-1})d\mathcal{H}^{N-1}(p) \\ &\to -\int_{\cup_{r>-\varepsilon}\{\frac{-D\psi(s,x)}{|D\psi(s,x)|}:x\in\partial\psi(s,\cdot)^{-1}((r,\infty))\cap D(s)^c\}} (R(p) + \varepsilon\sup\{G(D\psi(s,x), \\ &\qquad D^2\psi(s,x)) : (s,x) \in U_\varepsilon^+\}^{-1})d\mathcal{H}^{N-1}(p) \quad (\text{as } m \to \infty).\end{aligned} \tag{4.38}$$

Equations (4.37)–(4.38) contradict

$$\begin{aligned}&\{p \in \mathbf{S}^{N-1} : \sigma^+(u,-p,s,x) = 1 \text{ for some } x \in \psi(s,\cdot)^{-1}((-\varepsilon,\infty)) \cap D(s)^c\} \\ &\subset \cup_{r>-\varepsilon}\left\{-\frac{D\psi(s,x)}{|D\psi(s,x)|} : x \in \partial\psi(s,\cdot)^{-1}((r,\infty)) \cap D(s)^c\right\}\end{aligned}$$

since

$$\eta_m(\psi(s,x)+\varepsilon) \to 1 \quad \text{if } x \in \psi(s,\cdot)^{-1}((-\varepsilon,\infty)), \text{ as } m \to \infty.$$

Case 2. Next we consider the case when $\sigma^+(u, D\psi(t_0,x_0), t_0, x_0) = 1$. By (ii)–(iv) in Lemma 3.7, all eigenvalues of $-D(D\psi(t_0,x_0)/|D\psi(t_0,x_0)|)$ are nonnegative since the function $x \mapsto \psi(t_0,x)$ takes a maximum $\psi(t_0,x_0)$ on the set $\{x_0 + y \in \mathbf{R}^N | \langle y, D\psi(t_0,x_0)\rangle = 0\}$.

For $A > 0$, all eigenvalues of $-D(D\psi_{2,A}(t_0,x_0)/|D\psi_{2,A}(t_0,x_0)|)$ as a mapping on the set $\{y \in \mathbf{R}^N | \langle y, D\psi_{2,A}(t_0,x_0)\rangle = 0\}$ are greater than or equal to $2A/|D\psi(t_0,x_0)|$ (see (3.32)–(3.33)) since, in Lemma 3.7, 1 and $f_1, \ldots, f_{N-1}$ are an eigenvalue and eigenvectors of $(g_1 \cdots g_N)$, respectively.

We argue by contradiction. Assume that the following holds:

$$\partial_t\psi(t_0,x_0) + R\left(\frac{D\psi(t_0,x_0)}{|D\psi(t_0,x_0)|}\right)G(D\psi(t_0,x_0), D^2\psi(t_0,x_0)) < 0. \tag{4.39}$$

We consider $\psi_{2,A}$ instead of ψ. When it is not confusing, we omit $_{2,A}$ for the sake of simplicity. By reselecting A, $\varepsilon > 0$ if necessary, we may assume that (4.34)–(4.35) hold.

One can also assume, in $U_{(2\varepsilon/A)^{1/2}}((t_0,x_0))$, that $\partial_i\psi(s,x) \neq 0$ and all eigenvalues of $-D(D\psi(s,x)/|D\psi(s,x)|)$ as a mapping on the set $\{y \in \mathbf{R}^N | \langle y, D\psi(s,x)\rangle = 0\}$ are greater than or equal to $A/|D\psi(t_0,x_0)|$, and $x \mapsto y_i(s,x)$ is one-to-one for some $i \in \{1, \ldots, N\}$ by the inverse function theorem, (v) in Lemma 3.7, and Lemma 3.8.

In the same way as in (4.36)–(4.38), we obtain a contradiction.

Step II. We show that $u^-(t,x) = I_{D(t)^-}(x)$ is a viscosity subsolution of (1.20).

Let $\psi \in \mathcal{A}((0,\infty)\times\mathbf{R}^d)$ and assume that $u^- - \psi$ attains a maximum at $(t_0,x_0) \in (0,\infty)\times\mathbf{R}^d$. We may assume as well that $u^-(t_0,x_0) = \psi(t_0,x_0)$, so that $u^-(t,x) < \psi(t,x)$ for all $(t,x) \in (0,\infty)\times\mathbf{R}^d \setminus \{(t_0,x_0)\}$ (see [8]).

Since $t \mapsto u^-(t,x)$ is nonincreasing, $\partial_t\psi(t_0,x_0) \leq 0$.

Hence we have only to consider the case when the following holds: $D\psi(t_0,x_0) \neq o$, and

$$\sigma^-(u^-, D\psi(t_0,x_0), t_0, x_0) = 1, \quad R\left(\frac{D\psi(t_0,x_0)}{|D\psi(t_0,x_0)|}\right)G(D\psi(t_0,x_0), D^2\psi(t_0,x_0)) > 0.$$

In particular, $u^-(t_0,x_0) = 1$. By adding to ψ the function $(t,x) \mapsto A\{|t-s|^2+|x-y|^2\}$, with a sufficiently small $A > 0$, if necessary, we may assume that

$$U_\varepsilon^- := \{(t,x) \in (0,\infty)\times\mathbf{R}^d | \psi(t,x) - \varepsilon < u^-(t,x)\} \quad (\varepsilon > 0) \tag{4.40}$$

is contained in the set $U_{(\varepsilon/A)^{1/2}}((t_0,x_0))$.

We argue by contradiction. Assume that the following holds:

$$\partial_t\psi(t_0,x_0) + R\left(\frac{D\psi(t_0,x_0)}{|D\psi(t_0,x_0)|}\right)G(D\psi(t_0,x_0), D^2\psi(t_0,x_0)) > 0. \tag{4.41}$$

By reselecting $\varepsilon > 0$ if necessary, we may assume that

$$\partial_t\psi(t,x) + R\left(\frac{D\psi(t,x)}{|D\psi(t,x)|}\right)G(D\psi(t,x), D^2\psi(t,x)) - \varepsilon > 0, \tag{4.42}$$

and $u^-(t,x) = 1$ on U_ε^- by the continuity of ψ.

Put $\tilde{\eta}_m(r) = \eta_m(r + 1/m)$ for $r \in \mathbf{R}$ and $m \geq 1$. In the same way as in Step I, considering $u^-(t,x) - \tilde{\eta}_m(\psi(t,x) - 1 - \varepsilon)$ instead of $\eta_m(\psi(t,x) + \varepsilon) - u(t,x)$, we obtain a contradiction. □

Proof of Corollary 2.6. We first show that u is a viscosity supersolution of (1.20) in $(0,\infty)\times\mathbf{R}^N$. Let $\varphi\in\mathcal{A}((0,\infty)\times\mathbf{R}^N)$ and assume that $u-\varphi$ attains a minimum at $(t_0,x_0)\in(0,\infty)\times\mathbf{R}^N$. We may assume that $u(t_0,x_0)=\varphi(t_0,x_0)$, so that $u(t,x)>\varphi(t,x)$ for all $(t,x)\in(0,\infty)\times\mathbf{R}^N\setminus\{(t_0,x_0)\}$ (see [8]). By subtracting a constant, we may assume that $\varphi\le u<0$.

Put $r_0:=\varphi(t_0,x_0)$ and

$$u_r(t,x):=I_{u^{-1}(t,\cdot)((r,0))}(x)\quad(r<0). \tag{4.43}$$

Then

$$u_{r_0}(t,x)\ge\frac{\varphi(t,x)}{|r_0|}+1\quad\text{for all }(t,x)\in(0,\infty)\times\mathbf{R}^N, \tag{4.44}$$

where the equality holds if and only if $(t,x)=(t_0,x_0)$.

Since u_r is a viscosity supersolution of (1.20) in $(0,\infty)\times\mathbf{R}^N$ by Corollary 2.3 and Theorem 2.5, and since

$$\sigma^+(u_{r_0},D(\varphi(t_0,x_0)/|r_0|+1),t_0,x_0)=\sigma^+(u,D\varphi(t_0,x_0),t_0,x_0),$$

(1.25) holds.

Next we show that u is a viscosity subsolution of (1.20) in $(0,\infty)\times\mathbf{R}^N$. Let $\varphi\in\mathcal{A}((0,\infty)\times\mathbf{R}^d)$ and assume that $u-\varphi$ attains a maximum at $(t_1,x_1)\in(0,\infty)\times\mathbf{R}^d$. We may assume as well that $u(t_1,x_1)=\varphi(t_1,x_1)$, so that $u(t,x)<\varphi(t,x)$ for all $(t,x)\in(0,\infty)\times\mathbf{R}^d\setminus\{(t_1,x_1)\}$ (see [8]).

By adding a constant, we may assume that $\varphi\ge u>0$.

Put $r_1:=\varphi(t_1,x_1)$ and

$$u_r^-(t,x):=I_{u^{-1}(t,\cdot)([r,\infty))}(x)\quad(r<0). \tag{4.45}$$

Then

$$u_{r_1}^-(t,x)\le\frac{\varphi(t,x)}{r_1}\quad\text{for all }(t,x)\in(0,\infty)\times\mathbf{R}^N, \tag{4.46}$$

where the equality holds if and only if $(t,x)=(t_1,x_1)$.

Since u_r^- is a viscosity subsolution of (1.20) in $(0,\infty)\times\mathbf{R}^N$ by Corollary 2.3 and Theorem 2.5, and since

$$\sigma^-(u_{r_1}^-,D(\varphi(t_1,x_1)/r_1),t_1,x_1)=\sigma^-(u,D\varphi(t_1,x_1),t_1,x_1),$$

(1.27) holds. □

PROPAGATION OF VISCOUS SHOCK WAVES AWAY FROM THE BOUNDARY*

CHIU-YA LAN†, HUEY-ER LIN†, TAI-PING LIU‡, AND SHIH-HSIEN YU§

Abstract. We study the propagation of shock waves away from the boundary for viscous conservation law. Our main purpose is to obtain pointwise description of the perturbation of the shock profile. We show that there are different convergence rates for the region between the boundary and the shock and the region ahead of the shock. The dependence of these rates on the shock strength, viscosity, and initial perturbation is studied. There are two mechanisms which govern the solution behavior: the compressibility of the shock and the presence of the boundary. We introduce an iteration scheme to decouple these two effects. Thus near the boundary we use the Green's function for the initial-boundary value problem of the equation linearized around the boundary value; away from the boundary we use the Green's function for the initial-value problem of the equation linearized around the shock profile. To focus on our main ideas, we study the Burgers equation, for which the Green's functions have explicit forms. Our new approach should be applicable to more general situations such as the system of viscous conservation laws.

Key words. time asymptotic, pointwise approach, shock location

1. Introduction.

The purpose of this paper is to study the effect of the boundary on the time asymptotic behavior of the propagation of shock waves for the viscous conservation law

$$u_t + f(u)_x = u_{xx}.$$

We are interested in the interplay of the effects of boundary, nonlinearity through the strength of the shock, and the initial data. We will consider the case when the flux is strongly nonlinear: $f''(u) \neq 0$. For simplicity we consider the Burgers equation. The situation is simpler when the shock is propagating toward the boundary and becomes the boundary layer. We consider the case when the shock is propagating away from the boundary. Thus we will study the stability of a viscous shock profile for the initial-boundary value problem

$$u_t + uu_x = u_{xx}, \tag{1.1}$$

$$u(-L-t,t) = u_-, \qquad u(\infty,t) = -u_- \equiv u_+, \tag{1.2}$$

$$u(x,0) = \phi(x) + \bar{u}(x), \qquad \bar{u}(-L) = u_- - \phi(-L), \tag{1.3}$$

$$\phi(x) \equiv -u_- \tanh\frac{(u_- x)}{2},$$

where $\phi(x)$ is a stationary shock wave solution of the Burgers equation and $L > 0$ is a given constant.

To highlight the effect of the boundary, we will carry out the detailed analysis for the case when the initial perturbation is small and has algebraic decay. Since we are interested in the time asymptotic behavior, we assume that the shock is initially not located near the boundary; i.e. L is large:

$$\bar{u}(x) = O(1)e^{-\frac{L}{d}}(1+x+L)^{-\alpha}, \tag{1.4}$$

$$\bar{u}_x(x) = O(1)e^{-\frac{L}{d}}(1+x+L)^{-\alpha-1}, \quad \alpha > 1,\ d \geq 1. \tag{1.5}$$

In this case, the boundary effect and the presence of the shock give rise to convergence at an exponential rate for the region between the shock and the boundary, and at an algebraic rate for the region around and ahead of the shock. The choice of algebraic decaying initial data is also motivated by the study of the system of conservation laws, for which the wave interactions of distinct characteristic families give rise to waves of algebraic rates [1].

There have been works on the boundary effects using the energy method [3], [2], [5]. Our pointwise approach extends that of [4], which studies the propagation of stationary shocks. For the pointwise approach, one needs to use the exact solution representation, that is, make use of the Green's functions. In this regard, the present study introduces an important new analytical device for separating the nonlinearity effect of the shock from that of the boundary. Specifically, for the region around the boundary we use the Green's function for the initial-boundary value problem but ignore the presence of the shock. For the region away from the boundary we use the Green's function for the equation linearized around the shock, ignoring the presence of the boundary. The advantage is the simplicity of the forms of these Green's functions and the clarity of the different roles played by the boundary and the shock on the asymptotic behavior of the solutions. This avoids the potentially complicated construction of the Green's function with the presence of both the boundary and the shock. This new methodology was raised first in the unpublished work [6], and is applicable in principle to systems, a task we will pursue in the future.

There are three parts in this paper: first, we obtain preliminary pointwise estimates, particularly the boundary estimate of the solution of (1.1), (1.2), and (1.3) around a viscous shock wave. The boundary estimate thus obtained allows us to locate, time-asymptotically, the shock profile. With the shock location determined, we then study the time asymptotic behavior of the perturbation. We show that the perturbation decays exponentially for the region between the boundary and the shock, and algebraically for the region ahead of the shock. Finally, in the last section we remark on the different roles played by the nonlinearity, viscosity, boundary, and initial data in the time asymptotic behavior of the solutions.

2. Boundary estimate. In this section we will obtain the boundary estimate. Since the shift of the shock location due to the perturbation and the boundary is not known a priori, we therefore will not try to properly shift the shock. Thus the interior estimate given in this section is rough and there is no time decay. However, the boundary estimate given here is optimal and will be crucial in the next section in determining the shock shift. For simplicity in the analysis, we will take the shock to be of finite strength; in fact, we assume that $u_- = 1$ and the initial data to be

$$\bar{u}(x) = O(1)e^{-L}(1+x+L)^{-\alpha}, \qquad \bar{u}_x(x) = O(1)e^{-L}(1+x+L)^{-\alpha-1}.$$

Set the perturbation with zero boundary value to be $v(x,t)$:

$$v(x,t) \equiv u(x,t) - \phi(x) - \Psi(x,t),$$
$$\Psi(x,t) = (1-\phi(-L-t))(1+x+L+t)^{-\alpha}.$$

Then $v(x,t)$ satisfies

$$v_t + (\phi v)_x - v_{xx} = -\left(\frac{v^2}{2} + \Psi v\right)_x - \Psi_t - \left(\phi\Psi + \frac{\Psi^2}{2}\right)_x + \Psi_{xx}, \tag{2.1}$$

$$v(-L-t,t) = 0, \qquad v(\infty,t) = 0, \tag{2.2}$$

$$\begin{cases} v(x,0) = \bar{u}(x) - \Psi(x,0) = O(1)e^{-L}(1+x+L)^{-\alpha}, & v(-L,0) = 0, \\ v_x(x,0) = O(1)e^{-L}(1+x+L)^{-\alpha-1}. \end{cases} \tag{2.3}$$

As mentioned before, we separate the space-time domain into two parts: the region near the boundary, $x \in [-L-t, -(L+t)/2)$, and that away from the boundary, $x \geq -(L+t)/2$.

Region I. For $x \in [-L-t, -(L+t)/2)$, we use the Green's function $K^B(x,t;y,\sigma)$ for

$$w_t + w_x = w_{xx}, \tag{2.4}$$

$$w(-L-t,t) = 0, \qquad w(\infty,t) = 0. \tag{2.5}$$

The following expression of the Green's function is easily obtained by converting, through reflection, the initial-boundary problem into the initial value problem for which the Green's function is the translated heat kernel:

$$k(x,t) \equiv e^{-\frac{x^2}{4t}}/\sqrt{4\pi t}.$$

LEMMA 2.1. *The Green's function $K^B(x,t;y,\sigma)$ for* (2.4) *and* (2.5) *is*

$$K^B(x,t;y,\sigma) = k(x-y-(t-\sigma),t-\sigma) - k(x+y-t+3\sigma+2L,t-\sigma)e^{-2(y+L+\sigma)}.$$

We represent the solution $v(x,t)$ of (2.1), (2.2), and (2.3) using this Green's function. Multiply K^B with (2.1) and integrate the equation to yield

$$\begin{aligned} v(x,t) = &\int_{-L}^{\infty} K^B(x,t;y,0)v(y,0)dy \\ &+ \int_0^t \int_{-L-\sigma}^{\infty} K_y^B(x,t;y,\sigma)\left[(\phi(y)-1+\Psi(y,\sigma))v(y,\sigma) + \frac{v(y,\sigma)^2}{2}\right]dyd\sigma \\ &+ \int_0^t \int_{-L-\sigma}^{\infty} K^B(x,t;y,\sigma)\left\{-\Psi_\sigma - \left(\phi\Psi + \frac{\Psi^2}{2}\right)_y + \Psi_{yy}\right\}(y,\sigma)dyd\sigma. \end{aligned} \tag{2.6}$$

Region II. For $x \geq -(L+t)/2$, we focus on the shock profile and consider the Green's function $G(x,t;y,\sigma)$ for the initial value problem

$$w_t + (\phi(x)w)_x - w_{xx} = 0, \quad -\infty < x < \infty. \tag{2.7}$$

The Green's function for this is easily obtained from Hopf–Cole transformation. It is also easy to see that the Green's function is the weighted heat kernels, as stated in the corollary below; cf. [1].

LEMMA 2.2. *The Green's function $G(x,t;y,\sigma)$ for (2.7) is*

$$
\begin{aligned}
G(x,t;y,\sigma) &= -\int_{-\infty}^{y} g_x(x,t;\xi,\sigma)d\xi \\
&= g(x,t;y,\sigma) + \frac{\int_{-\infty}^{y} \sinh(\frac{x-\xi}{2})k(x-\xi,t-\sigma)e^{-\frac{t-\sigma}{4}}d\xi}{2\cosh^2\frac{x}{2}},
\end{aligned}
\tag{2.8}
$$

where

$$
g(x,t;y,\sigma) \equiv \frac{\cosh(\frac{y}{2})}{\cosh(\frac{x}{2})}k(x-y,t-\sigma)e^{-\frac{t-\sigma}{4}} \tag{2.9}
$$

is the Green's function for

$$
w_t + \phi(x)w_x - w_{xx} = 0.
$$

COROLLARY 2.3. *The Green's function $g(x,t;y,\sigma)$ of $w_t+\phi(x)w_x-w_{xx}=0$ can be viewed as a weighted heat kernel:*

$$
\begin{aligned}
&\text{for } x>0,\ y>0, \quad g(x,t;y,\sigma) = O(1)k(x-y+(t-\sigma),t-\sigma),\\
&\text{for } x>0,\ y<0, \quad g(x,t;y,\sigma) = O(1)e^{-|x|}k(x-y-(t-\sigma),t-\sigma),\\
&\text{for } x<0,\ y<0, \quad g(x,t;y,\sigma) = O(1)k(x-y-(t-\sigma),t-\sigma),\\
&\text{for } x<0,\ y>0, \quad g(x,t;y,\sigma) = O(1)e^{-|x|}k(x-y+(t-\sigma),t-\sigma).
\end{aligned}
$$

More precisely, $g(x,t;y,\sigma)$ can be written as the following two equivalent expressions:

$$
g(x,t;y,\sigma) = \begin{cases} \dfrac{1+e^{y}}{1+e^{x}}k(x-y-(t-\sigma),t-\sigma), \\ \dfrac{1+e^{-y}}{1+e^{-x}}k(x-y+(t-\sigma),t-\sigma). \end{cases}
$$

With the second Green's function, we obtain a representation for the solution that is different from (2.6):

$$
\begin{aligned}
v(x,t) = &\int_{-L}^{\infty} G(x,t;y,0)v(y,0)dy \\
&-\int_0^t G(x,t;-L-\sigma,\sigma)v_y(-L-\sigma,\sigma)d\sigma \\
&+\int_0^t\int_{-L-\sigma}^{\infty} G_y(x,t;y,\sigma)\left(\Psi(y,\sigma)v(y,\sigma)+\frac{v(y,\sigma)^2}{2}\right)dyd\sigma \\
&+\int_0^t\int_{-L-\sigma}^{\infty} G(x,t;y,\sigma)\left\{-\Psi_\sigma-\left(\phi\Psi+\frac{\Psi^2}{2}\right)_y+\Psi_{yy}\right\}(y,\sigma)dyd\sigma.
\end{aligned}
\tag{2.10}
$$

We study the solution $v(x,t)$ for (2.1), (2.2), and (2.3) by the following iterations: for $x\in[-L-t,-(L+t)/2)$,

$$
\begin{aligned}
v^0(x,t) = &\int_{-L}^{\infty} K^B(x,t;y,0)v(y,0)dy \\
&+\int_0^t\int_{-L-\sigma}^{\infty} K^B(x,t;y,\sigma)\left\{-\Psi_\sigma-\left(\phi\Psi+\frac{\Psi^2}{2}\right)_y+\Psi_{yy}\right\}(y,\sigma)dyd\sigma;
\end{aligned}
\tag{2.11}
$$

for $x \geq -(L+t)/2$,

$$
\begin{aligned}
v^0(x,t) = &\int_{-L}^{\infty} G(x,t;y,0)v(y,0)dy \\
&- \int_0^t G(x,t;-L-\sigma,\sigma)v_y^0(-L-\sigma,\sigma)d\sigma \\
&+ \int_0^t \int_{-L-\sigma}^{\infty} G(x,t;y,\sigma)\left\{-\Psi_\sigma - \left(\phi\Psi + \frac{\Psi^2}{2}\right)_y + \Psi_{yy}\right\}(y,\sigma)dyd\sigma;
\end{aligned} \tag{2.12}
$$

for $x \in [-L-t, -(L+t)/2)$, $n \geq 1$,

$$
\begin{aligned}
v^n(x,t) = &\int_{-L}^{\infty} K^B(x,t;y,0)v(y,0)dy \\
&+ \int_0^t \int_{-L-\sigma}^{\infty} K_y^B(x,t;y,\sigma) \\
&\qquad \cdot \left[(\phi(y) - 1 + \Psi(y,\sigma))v^{n-1}(y,\sigma) + \frac{v^{n-1}(y,\sigma)^2}{2}\right] dyd\sigma \\
&+ \int_0^t \int_{-L-\sigma}^{\infty} K^B(x,t;y,\sigma)\left\{-\Psi_\sigma - \left(\phi\Psi + \frac{\Psi^2}{2}\right)_y + \Psi_{yy}\right\}(y,\sigma)dyd\sigma;
\end{aligned} \tag{2.13}
$$

for $x \geq -(L+t)/2$, $n \geq 1$,

$$
\begin{aligned}
v^n(x,t) = &\int_{-L}^{\infty} G(x,t;y,0)v(y,0)dy \\
&- \int_0^t G(x,t;-L-\sigma,\sigma)v_y^n(-L-\sigma,\sigma)d\sigma \\
&+ \int_0^t \int_{-L-\sigma}^{\infty} G_y(x,t;y,\sigma)\left(\Psi(y,\sigma)v^{n-1}(y,\sigma) + \frac{v^{n-1}(y,\sigma)^2}{2}\right) dyd\sigma \\
&+ \int_0^t \int_{-L-\sigma}^{\infty} G(x,t;y,\sigma)\left\{-\Psi_\sigma - \left(\phi\Psi + \frac{\Psi^2}{2}\right)_y + \Psi_{yy}\right\}(y,\sigma)dyd\sigma.
\end{aligned} \tag{2.14}
$$

From the expression of $\Psi(x,t)$ at the beginning of this section, we have

$$
\Psi_t + \left(\phi\Psi + \frac{\Psi^2}{2}\right)_x - \Psi_{xx} = O(1)e^{-L-t}(1+x+L+t)^{-\alpha}.
$$

The first step is to estimate v^0, for which we need the following lemmas. Lemma 2.4 follows from straightforward computations. In Lemma 2.5 both algebraic and exponential rates are described, and we need to consider various regions in the (x,t) space in its proof.

LEMMA 2.4. *For $x \in [-L-t, 0)$,*

$$
\int_{-L}^{\infty} k(x-y-t,t)e^{-L}(1+y+L)^{-\alpha}dy \leq Ce^{-\frac{L}{2}}e^{-\frac{|x|}{2}}e^{-\frac{t}{4}}, \tag{2.15}
$$

$$
\begin{aligned}
&\int_0^t \int_{-L-\sigma}^{\infty} k(x-y-(t-\sigma),t-\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma \\
&\qquad \leq e^{-\frac{L}{2}}e^{-\frac{|x|}{2}}e^{-\frac{t}{4}}.
\end{aligned} \tag{2.16}
$$

LEMMA 2.5. *For $x \geq -(L+t)/2$ and $r > 1$,*

$$\int_0^t G(x,t;-L-\sigma,\sigma)e^{-\frac{L}{2r}}e^{-\frac{L+\sigma}{2}}d\sigma \leq Ce^{-\frac{L}{2r}}e^{-\frac{|x|}{2}}. \tag{2.17}$$

$$\begin{aligned}&\int_0^t\int_{-L-\sigma}^{\infty} G(x,t;y,\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\\ &\qquad\leq C\begin{cases} e^{-L}e^{-|x|}+e^{-\frac{L}{2}}e^{-\frac{|x|}{2}}(1+t)^{-\alpha} & \text{if } x\in[-(L+t)/2,0),\\ e^{-\frac{L}{2}}e^{-\frac{|x|}{2}}+e^{-L}(1+x+L+t)^{-\alpha} & \text{if } x\geq 0.\end{cases}\end{aligned} \tag{2.18}$$

$$\begin{aligned}&\int_{-L}^{\infty} G(x,t;y,0)e^{-L}(1+y+L)^{-\alpha}dy\\ &\qquad\leq C\begin{cases} e^{-\frac{L}{2}}e^{-\frac{|x|}{2}} & \text{if } x\in[-(L+t)/2,0),\\ e^{-L}e^{-|x|}+e^{-L}(1+x+L+t)^{-\alpha} & \text{if } x\geq 0.\end{cases}\end{aligned} \tag{2.19}$$

Proof. From (2.8)

$$G(x,t;y,\sigma) = O(1)\left\{e^{-\frac{|x|}{2}}e^{\frac{|y|}{2}}k(x-y,t-\sigma)e^{-\frac{t-\sigma}{4}}+e^{-|x|}\right\}$$

and so we have (2.17)

$$\begin{aligned}&\int_0^t G(x,t;-L-\sigma,\sigma)e^{-\frac{L}{2r}}e^{-\frac{L+\sigma}{2}}d\sigma\\ &\quad\leq C\left\{\int_0^t e^{-\frac{|x|}{2}}k(x+L+\sigma,t-\sigma)e^{-\frac{t-\sigma}{4}}e^{-\frac{L}{2r}}d\sigma+\int_0^t e^{-|x|}e^{-\frac{L}{2r}}e^{-\frac{L+\sigma}{2}}d\sigma\right\}\\ &\quad\leq Ce^{-\frac{L}{2r}}e^{-\frac{|x|}{2}}.\end{aligned}$$

Similarly,

$$\begin{aligned}&\int_0^t\int_{-L-\sigma}^{\infty} G(x,t;y,\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\\ &\qquad=\int_0^t\int_{-L-\sigma}^{\infty} g(x,t;y,\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\\ &\qquad\quad+\int_0^t\int_{-L-\sigma}^{\infty} O(1)e^{-|x|}e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\equiv g_1+g_2,\end{aligned}$$

where g_2 is obtained by straightforward computation,

$$g_2=\int_0^t\int_{-L-\sigma}^{\infty} O(1)e^{-|x|}e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\leq Ce^{-|x|}e^{-L},$$

and from Corollary 2.3, when $x\in[-(L+t)/2,-t/2)$,

$$\begin{aligned}g_1&=\int_0^t\int_{-L-\sigma}^{\infty} g(x,t;y,\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\\ &\leq C\left\{\int_0^t\int_{-L-\sigma}^{0} k(x-y-(t-\sigma),t-\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\right.\\ &\qquad\left.+\int_0^t\int_0^{\infty} e^{-|x|}k(x-y+(t-\sigma),t-\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\right\}\end{aligned}$$

$$\le C\left\{\int_0^t\int_{-L-\sigma}^0 \frac{1}{\sqrt{4\pi(t-\sigma)}}e^{-\frac{(x-y)^2}{4(t-\sigma)}+\frac{(x-y)}{2}-\frac{t-\sigma}{4}}e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma \right.$$
$$\left. +\int_0^t e^{-|x|}e^{-L-\sigma}d\sigma\right\}$$
$$\le C\left\{e^{-\frac{L}{2}}e^{-\frac{|x|}{2}}e^{-\frac{t}{4}}+e^{-L}e^{-|x|}\right\}$$
$$\le Ce^{-\frac{L}{2}}e^{-\frac{|x|}{2}}e^{-\frac{t}{4}};$$

when $x\in[-t/2,0)$,

$$g_1\le C\left\{e^{-\frac{L}{2}}e^{-\frac{|x|}{2}}e^{-\frac{t}{4}}\right.$$
$$+\int_0^{\frac{t}{4}}\left(\int_0^{\frac{t-\sigma}{8}}+\int_{\frac{t-\sigma}{8}}^{\infty}\right)$$
$$e^{-|x|}k(x-y+(t-\sigma),t-\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma$$
$$\left.+\int_{\frac{t}{4}}^t\int_0^{\infty}e^{-|x|}k(x-y+(t-\sigma),t-\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\right\}$$
$$\le C\left\{e^{-\frac{L}{2}}e^{-\frac{|x|}{2}}e^{-\frac{t}{4}}\right.$$
$$+\int_0^{\frac{t}{4}}e^{-|x|}e^{-\frac{(x-\frac{(t-\sigma)}{8}+(t-\sigma))^2}{4(t-\sigma)}}e^{-L-\sigma}(1+L+\sigma)^{-\alpha}d\sigma$$
$$+\int_0^{\frac{t}{4}}e^{-|x|}e^{-L-\sigma}\left(1+\frac{t}{8}+L+\frac{7\sigma}{8}\right)^{-\alpha}d\sigma$$
$$\left.+\int_{\frac{t}{4}}^t e^{-|x|}e^{-L-\sigma}(1+L+\sigma)^{-\alpha}d\sigma\right\}$$
$$\le C\left\{e^{-\frac{L}{2}}e^{-\frac{|x|}{2}}e^{-\frac{t}{4}}+e^{-L}e^{-\frac{|x|}{2}}(1+t)^{-\alpha}\right\};$$

and when $x\ge 0$,

$$g_1\le C\left\{\int_0^t\int_{-L-\sigma}^0 e^{-|x|}k(x-y-(t-\sigma),t-\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\right.$$
$$\left.+\int_0^t\int_0^{\infty}k(x-y+(t-\sigma),t-\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\right\}$$
$$\le C\left\{e^{-\frac{L}{2}}e^{-\frac{|x|}{2}}e^{-\frac{t}{4}}\right.$$
$$+\int_0^t\left(\int_0^{\frac{x}{2}}+\int_{\frac{x}{2}}^{x+\frac{t-\sigma}{2}}+\int_{x+\frac{t-\sigma}{2}}^{\infty}\right)$$
$$\left.k(x-y+(t-\sigma),t-\sigma)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha}dyd\sigma\right\}$$

$$
\begin{aligned}
&\le C\left\{e^{-\frac{L}{2}}e^{-\frac{|x|}{2}}e^{-\frac{t}{4}}\right.\\
&\quad+\int_0^t e^{-\frac{(x-(x/2)+(t-\sigma))^2}{4(t-\sigma)}}e^{-L-\sigma}d\sigma+\int_0^t e^{-\frac{((t-\sigma)/2)^2}{4(t-\sigma)}}e^{-L-\sigma}\left(1+\frac{x}{2}+L+\sigma\right)^{-\alpha}d\sigma\\
&\quad\left.+\int_0^t e^{-L-\sigma}\left(1+x+\frac{t}{2}+L+\frac{\sigma}{2}\right)^{-\alpha}d\sigma\right\}\\
&\le C\left\{e^{-\frac{L}{2}}e^{-\frac{|x|}{2}}e^{-\frac{t}{4}}+e^{-L}e^{-\frac{x}{4}}e^{-\frac{t}{4}}+e^{-L}e^{-\frac{t}{16}}(1+x+L)^{-\alpha}\right.\\
&\quad\left.+e^{-L}(1+x+L+t)^{-\alpha}\right\}\\
&\le C\left\{e^{-\frac{L}{2}}e^{-\frac{|x|}{2}}e^{-\frac{t}{4}}+e^{-L}(1+x+L+t)^{-\alpha}\right\}.
\end{aligned}
$$

By adding g_1 and g_2 we obtain (2.18).

The estimate for (2.19) is similar to that for (2.18) so we omit the detail. □

LEMMA 2.6. *For $0\le x+L+t\le 1$, there exists a constant $C>0$ such that*

$$
\begin{aligned}
|K^B(x,t;y,\sigma)|\le C&\frac{|x+L+t|}{\sqrt{t-\sigma}}\\
&\cdot\int_{-1}^1 k\left(\frac{y+L+\sigma+\theta(x+L+t)}{1.5},t-\sigma\right)d\theta e^{-(y+L+\sigma)-(t-\sigma)},
\end{aligned}
$$

and

$$
\begin{aligned}
|K_y^B(x,t;y,\sigma)|\le C&\frac{|x+L+t|}{\sqrt{t-\sigma}}\left(1+\frac{1}{\sqrt{t-\sigma}}\right)\\
&\cdot\int_{-1}^1 k\left(\frac{y+L+\sigma+\theta(x+L+t)}{1.5},t-\sigma\right)d\theta e^{-(y+L+\sigma)-(t-\sigma)}.
\end{aligned}
$$

Proof. Let $X=x+L+t$ and $Y=y+L+\sigma$, $0\le X\le 1$. Then the estimates of K^B and K_y^B follow from the following expressions:

$$
\begin{aligned}
K^B&=k(x-y-(t-\sigma),t-\sigma)-k(x+y-t+3\sigma+2L,t-\sigma)e^{-2(y+L+\sigma)}\\
&=[k(Y-X,t-\sigma)-k(Y+X,t-\sigma)]e^{(X-Y)-(t-\sigma)}\\
&=-X\int_{-1}^1 k_Y(Y+\theta X,t-\sigma)d\theta e^{(X-Y)-(t-\sigma)}\\
&=O(1)\frac{X}{\sqrt{t-\sigma}}\int_{-1}^1 k\left(\frac{Y+\theta X}{1.5},t-\sigma\right)d\theta e^{-Y-(t-\sigma)},\\
K_y^B&=[k_Y(Y-X,t-\sigma)-k_Y(Y+X,t-\sigma)]e^{(X-Y)-(t-\sigma)}-K^B\\
&=-X\int_{-1}^1 k_{YY}(Y+\theta X,t-\sigma)d\theta e^{(X-Y)-(t-\sigma)}-K^B\\
&=O(1)\frac{X}{\sqrt{t-\sigma}}\left(1+\frac{1}{\sqrt{t-\sigma}}\right)\int_{-1}^1 k\left(\frac{Y+\theta X}{1.5},t-\sigma\right)d\theta e^{-Y-(t-\sigma)}.
\end{aligned}
$$

□

With the above lemmas we are now ready to estimate the leading term v^0 of iterations (2.11)–(2.14).

PROPOSITION 2.7. *There exist constants $C_0 > 0$ and $r > 1$ such that*

$$v^0(x,t) \le C_0 \begin{cases} e^{-\frac{L}{2r}} e^{-\frac{|x|}{2}} |x+L+t| & \text{for } x \in [-L-t, -L-t+1], \\ e^{-\frac{L}{2r}} e^{-\frac{|x|}{2}} & \text{for } x \in [-L-t, 0), \\ e^{-\frac{L}{2r}} e^{-\frac{|x|}{2}} + e^{-\frac{L}{2}} (1+x+L+t)^{-\alpha} & \text{for } x \ge 0, \end{cases}$$

$$v^0_x(-L-t,t) \le C_0 e^{-\frac{L}{2r}} e^{-\frac{L+t}{2}}.$$

Proof. From the property of K^B in Lemma 2.6, we have, for $x \in [-L-t, -L-t+1]$,

$$\begin{aligned} &\int_0^t \int_{-L-\sigma}^{\infty} K^B(x,t;y,\sigma) e^{-L-\sigma} (1+y+L+\sigma)^{-\alpha} dy d\sigma \\ &\qquad \le C|x+L+t| e^{-s(L+t)}, \quad 0 < s < 1, \end{aligned} \tag{2.20}$$

and by Fubini's theorem and integration by parts, with $X = x+L+t$, $Y = y+L$,

$$\begin{aligned} &\left| \int_{-L}^{\infty} K^B(x,t;y,0) v(y,0) dy \right| \\ &\quad = \left| \int_0^{\infty} [k(Y-X,t) - k(Y+X,t)] e^{(X-Y)-t} v(Y,0) dY \right| \\ &\quad = \left| \int_0^{\infty} \int_{-1}^{1} (-X) \partial_Y k(Y+\theta X, t) d\theta e^{(X-Y)-t} v(Y,0) dY \right| \\ &\quad = \left| (-X) \int_{-1}^{1} \int_0^{\infty} \partial_Y k(Y+\theta X, t) e^{(X-Y)-t} v(Y,0) dY d\theta \right| \\ &\quad = \left| X \int_{-1}^{1} \int_0^{\infty} k(Y+\theta X, t) [-e^{(X-Y)-t} v(Y,0) + e^{(X-Y)-t} v_Y(Y,0)] dY d\theta \right| \\ &\quad \le CXe^{-L} e^{-t}. \end{aligned} \tag{2.21}$$

Here we have used $|v(Y,0)| + |v_Y(Y,0)| = O(1)e^{-L}$ from (2.3). In particular we have from (2.20) and (2.21) that $v^0(-L-t,t) = 0$ and

(2.22)

$$\begin{aligned} &v^0_x(-L-t,t) \\ &= \lim_{x+L+t \to 0^+} \left\{ \int_{-L}^{\infty} \frac{K^B(x,t;y,0)}{|x+L+t|} v(y,0) dy \right. \\ &\qquad \left. + \int_0^t \int_{-L-\sigma}^{\infty} \frac{K^B(x,t;y,\sigma)}{|x+L+t|} \left\{ -\Psi_\sigma - \left(\phi\Psi + \frac{\Psi^2}{2} \right)_y + \Psi_{yy} \right\} dy d\sigma \right\} \\ &\le Ce^{-L-t} \\ &\quad + \int_0^t \int_{-L-\sigma}^{\infty} \frac{C}{\sqrt{t-\sigma}} \int_{-1}^{1} k\left(\frac{(x+L+t)\theta + (y+L+\sigma)}{1.5}, t-\sigma \right) e^{-(y+L+\sigma)-(t-\sigma)} d\theta \\ &\qquad \cdot \left\{ -\Psi_\sigma - \left(\phi\Psi + \frac{\Psi^2}{2} \right)_y + \Psi_{yy} \right\} dy d\sigma \\ &\le Ce^{-s(L+t)}, \quad 0 < s < 1. \end{aligned}$$

Since $K^B(x,t;y,\sigma) \le k(x-y-(t-\sigma), t-\sigma)$, we may apply Lemmas 2.4 and 2.5 and (2.20)–(2.22) by letting $s = \frac{1}{2} + \frac{1}{2r}$ for $r > 1$. This proves the lemma. ∎

Remark 2.8. For general initial data (1.4) with $d > 1$, v^0 is estimated as

$$v^0(x,t) \le O(1) \begin{cases} |x+L+t| e^{-\frac{|x|}{2d}} e^{-\frac{L+t}{2d}} & \text{for } x \in [-L-t, -L-t+1], \\ e^{-\frac{|x|}{2d}} e^{-\frac{L}{2d}} & \text{for } x \in [-L-t, 0), \\ e^{-\frac{|x|}{2}} \max\{e^{-\frac{L}{d}}, e^{-\frac{L}{2}}\} + (1+x+L+t)^{-\alpha} e^{-\frac{L}{d}} & \text{for } x \ge 0, \end{cases}$$

$$v^0_x(-L-t,t) \le O(1) e^{-\frac{L}{2d}} e^{-\frac{(L+t)}{2d}}.$$

Our main theorem of this section, Theorem 2.13 on the solution $v(x,t)$, will be proved by induction. The general procedure is to estimate v^n for all $n \in N$. The ansatz is more complicated than that of v^0 because of nonlinearity in (2.1) and the singularity in $K^B_y(x,t;y,\sigma)$ and $G_y(x,t;y,\sigma)$. To deal with the singularity, we need the following lemmas.

LEMMA 2.9. *For $|x+L+t| < 1$ and L large, there exists a positive constant C such that*

$$\int_0^t \int_{-L-\sigma}^{-L-\sigma+4} |K^B_y(x,t;y,\sigma)|(y+L+\sigma) e^{-|y|} dy d\sigma \le C|x+L+t| e^{-\frac{|x|}{2}} e^{-\frac{L}{2}}, \tag{2.23}$$

$$\int_0^t \int_{-L-\sigma+4}^{0} |K^B_y(x,t;y,\sigma)| e^{-|y|} dy d\sigma \le C|x+L+t| e^{-\frac{|x|}{2}} e^{-\frac{L}{2}}, \tag{2.24}$$

$$\int_0^t \int_{0}^{\infty} |K^B_y(x,t;y,\sigma)| dy d\sigma \le C|x+L+t| e^{-\frac{|x|}{2}} e^{-\frac{L}{2}}. \tag{2.25}$$

Proof. If $t > 1$,

$$\begin{aligned} &\int_0^t \int_{-L-\sigma}^{-L-\sigma+4} |K^B_y(x,t;y,\sigma)|(y+L+\sigma) e^{-|y|} dy d\sigma \\ &\quad = \left(\int_0^{t-1} + \int_{t-1}^t \right) \int_{-L-\sigma}^{-L-\sigma+4} |K^B_y(x,t;y,\sigma)|(y+L+\sigma) e^{-|y|} dy d\sigma \\ &\quad \equiv J_1 + J_2. \end{aligned}$$

If $X = x+L+t$, $Y = y+L+\sigma$, and $L > 0$ is large, then from the property of K^B_y in Lemma 2.6 we have

$$\begin{aligned} J_1 &= \int_0^{t-1} \int_{-L-\sigma}^{-L-\sigma+4} |K^B_y(x,t;y,\sigma)|(y+L+\sigma) e^{-|y|} dy d\sigma \\ &\le \int_0^{t-1} \int_0^4 C \frac{X}{\sqrt{t-\sigma}} \left(1 + \frac{1}{\sqrt{t-\sigma}}\right) \int_{-1}^1 k\left(\frac{Y+\theta X}{1.5}, t-\sigma\right) d\theta \\ &\qquad e^{-Y-(t-\sigma)} Y e^{(Y-L-\sigma)} dY d\sigma \\ &\le \int_0^{t-1} CX d\sigma e^{-(L+t)} \quad (t-\sigma > 1,\ 0 < Y < 4) \\ &\le CX(t-1) e^{-(L+t)} \le CX e^{x/2} e^{-\frac{L}{2}}, \\ J_2 &= \int_{t-1}^t \int_{-L-\sigma}^{-L-\sigma+4} |K^B_y(x,t;y,\sigma)|(y+L+\sigma) e^{-|y|} dy d\sigma \\ &\le \int_{t-1}^t \int_{-L-\sigma}^{-L-\sigma+4} K^B(x,t;y,\sigma)(y+L+\sigma) e^{-|y|} dy d\sigma \end{aligned}$$

$$+\int_{t-1}^{t}\int_{0}^{2X}|k_Y(Y-X,t-\sigma)-k_Y(Y+X,t-\sigma)|e^{-Y-(t-\sigma)}Ye^{(Y-L-\sigma)}dYd\sigma$$
$$+\int_{t-1}^{t}\int_{2X}^{4}|k_Y(Y-X,t-\sigma)-k_Y(Y+X,t-\sigma)|e^{-Y-(t-\sigma)}Ye^{(Y-L-\sigma)}dYd\sigma$$
$$\equiv j_1+j_2+j_3.$$

The terms j_1, j_2, and j_3 are estimated using Lemma 2.6:

$$j_1=\int_{t-1}^{t}\int_{-L-\sigma}^{-L-\sigma+4}|K^B(x,t;y,\sigma)|(y+L+\sigma)e^{-|y|}dyd\sigma$$
$$\le C\int_{t-1}^{t}\int_{0}^{4}\frac{X}{\sqrt{t-\sigma}}\int_{-1}^{1}k\left(\frac{Y+\theta X}{1.5},t-\sigma\right)d\theta e^{-Y-(t-\sigma)}Ye^{(Y-L-\sigma)}dYd\sigma$$
$$\le C\int_{t-1}^{t}\frac{X}{\sqrt{t-\sigma}}d\sigma e^{-(L+t)}$$
$$\le C|x+L+t|e^{x/2}e^{-\frac{L}{2}},$$
$$j_2=\int_{t-1}^{t}\int_{0}^{2X}|k_Y(Y-X,t-\sigma)-k_Y(Y+X,t-\sigma)|e^{-Y-(t-\sigma)}Ye^{(Y-L-\sigma)}dYd\sigma$$
$$\le C\int_{t-1}^{t}\int_{0}^{2X}\frac{2X}{\sqrt{t-\sigma}}k\left(\frac{Y-X}{2},t-\sigma\right)e^{-Y-(t-\sigma)}e^{(Y-L-\sigma)}dYd\sigma$$
$$\le C\int_{t-1}^{t}\frac{2X}{\sqrt{t-\sigma}}d\sigma e^{-(L+t)}$$
$$\le C|x+L+t|e^{x/2}e^{-\frac{L}{2}},$$
$$j_3=\int_{t-1}^{t}\int_{2X}^{4}|k_Y(Y-X,t-\sigma)-k_Y(Y+X,t-\sigma)|e^{-Y-(t-\sigma)}Ye^{(Y-L-\sigma)}dYd\sigma$$
$$=\int_{t-1}^{t}\int_{2X}^{4}\left|-X\int_{-1}^{1}k_{YY}(Y+\theta X,t-\sigma)d\theta\right|e^{-Y-(t-\sigma)}Ye^{(Y-L-\sigma)}dYd\sigma$$
$$\le C\int_{t-1}^{t}\int_{2X}^{4}\int_{-1}^{1}\frac{X}{t-\sigma}k\left(\frac{Y+\theta X}{1.5},t-\sigma\right)d\theta e^{-Y-(t-\sigma)}Ye^{(Y-L-\sigma)}dYd\sigma$$
$$\le C\int_{t-1}^{t}\int_{2X}^{4}\frac{XY}{t-\sigma}k\left(\frac{Y}{3},t-\sigma\right)e^{-(L+t)}dYd\sigma$$
$$\le C\int_{t-1}^{t}\frac{X}{\sqrt{t-\sigma}}d\sigma e^{-(L+t)}$$
$$\le C|x+L+t|e^{x/2}e^{-\frac{L}{2}}.$$

Thus we have obtained (2.23) for $t>1$. For $t\le 1$ the calculation is the same as for J_2 and is omitted.

Next, for $0\le X\le 1$ and $Y\ge 4$, K_y^B in Lemma 2.6 satisfies

$$|K_y^B(x,t;y,\sigma)|\le C\frac{X}{\sqrt{t-\sigma}}\left(1+\frac{1}{\sqrt{t-\sigma}}\right)k\left(\frac{Y-1}{1.5},t-\sigma\right)e^{-Y-(t-\sigma)}$$
$$\le CXk\left(\frac{Y-1}{2},t-\sigma\right)e^{-Y-(t-\sigma)},$$

and therefore

$$\begin{aligned}
&\int_0^t \int_{-L-\sigma+4}^0 |K_y^B(x,t;y,\sigma)| e^{-|y|} dy d\sigma \\
&\quad \le \int_0^t \int_4^{L+\sigma} CXk\left(\frac{Y-1}{2}, t-\sigma\right) e^{-Y-(t-\sigma)} e^{(Y-L-\sigma)} dY d\sigma \\
&\quad \le CX \int_0^t d\sigma e^{-(L+t)} = CXte^{-(L+t)} \\
&\quad \le C|x+L+t|e^{x/2} e^{-\frac{L}{2}},
\end{aligned}$$

and

$$\begin{aligned}
&\int_0^t \int_0^\infty |K_y^B(x,t;y,\sigma)| dy d\sigma \\
&\quad \le \int_0^t \int_0^\infty C|x+L+t| k\left(\frac{y+L+\sigma-1}{2}, t-\sigma\right) e^{-(y+L+\sigma)-(t-\sigma)} dy d\sigma \\
&\quad \le C|x+L+t|te^{-(L+t)} \le C|x+L+t|e^{-\frac{|x|}{2}} e^{-\frac{L}{2}}.
\end{aligned}$$

This establishes (2.24), (2.25) and completes the proof of the lemma. □

LEMMA 2.10. *For $x \in [-L-t, -(L+t)/2)$, $D > 1$,*

$$\int_0^t \int_{-L-\sigma}^0 k(x-y-(t-\sigma), t-\sigma) e^y dy d\sigma = O(1)te^x, \tag{2.26}$$

$$\int_0^t \int_0^\infty k(x-y-(t-\sigma), t-\sigma) e^{-y/2} dy d\sigma = O(1)\sqrt{t}e^x, \tag{2.27}$$

$$\int_0^t \int_0^\infty k(x-y-(t-\sigma), t-\sigma)(1+y+L+\sigma)^{-\alpha} dy d\sigma = O(1)\sqrt{t}e^x, \tag{2.28}$$

$$\int_0^t \int_{-L-\sigma}^0 \frac{1}{\sqrt{t-\sigma}} k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right) e^{x-y} e^{-|y|} dy d\sigma = O(1)\sqrt{t}e^x, \tag{2.29}$$

$$\int_0^t \int_0^\infty \frac{1}{\sqrt{t-\sigma}} k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right) e^{x-y} e^{-\frac{|y|}{2}} dy d\sigma = O(1)\sqrt{t}e^x, \tag{2.30}$$

$$\begin{aligned}
&\int_0^t \int_0^\infty \frac{1}{\sqrt{t-\sigma}} k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right) e^{x-y} (1+y+L+\sigma)^{-\alpha} dy d\sigma \\
&\quad = O(1)\sqrt{t}e^x.
\end{aligned} \tag{2.31}$$

Proof. The last three estimates, (2.29), (2.30), and (2.31), are obvious from

$$\int_{-\infty}^\infty k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right) dy = O(1).$$

The first three estimates, (2.26), (2.27), and (2.28), are obtained from the following equations, which hold for $x < 0$:

$$\begin{aligned}
&\int_{-L-\sigma}^0 k(x-y-(t-\sigma), t-\sigma) e^y dy \\
&\quad = \int_{-L-\sigma}^0 k(x-y+(t-\sigma), t-\sigma) e^x dy \le e^x,
\end{aligned}$$

$$\int_0^\infty k(x-y-(t-\sigma),t-\sigma)e^{-y/2}dy$$
$$= \int_0^\infty \frac{1}{\sqrt{4\pi(t-\sigma)}} e^{-\frac{x^2}{4(t-\sigma)}+\frac{x}{2}-y-\frac{t-\sigma}{4}}dy$$
$$= \frac{1}{\sqrt{4\pi(t-\sigma)}} e^{-\frac{(x-(t-\sigma))^2}{4(t-\sigma)}} \le \frac{1}{\sqrt{4\pi(t-\sigma)}} e^x,$$
$$\int_0^\infty k(x-y-(t-\sigma),t-\sigma)(1+y+L+\sigma)^{-\alpha}dy$$
$$\le \int_0^\infty k(x-(t-\sigma),t-\sigma)e^{-y/2}(1+y+L+\sigma)^{-\alpha}dy$$
$$\le Ck(x-(t-\sigma),t-\sigma) \le \frac{C}{\sqrt{t-\sigma}} e^x. \qquad \square$$

LEMMA 2.11. *For $x \ge -(L+t)/2$,*

$$\int_0^t \int_{-L-\sigma}^0 |g_x(x,t;y,\sigma)|e^{y/2}dyd\sigma = O(1)e^{-\frac{|x|}{2}}, \tag{2.32}$$

$$\int_0^t \int_0^\infty |g_x(x,t;y,\sigma)|e^{-y/2}dyd\sigma = O(1)e^{-\frac{|x|}{2}}. \tag{2.33}$$

Proof. These estimates follow immediately from the inequality

$$|g_x(x,t;y,\sigma)| \le \frac{4}{\sqrt{t-\sigma}}\left(1+\frac{1}{\sqrt{t-\sigma}}\right) e^{-\frac{1}{2}(|x|-|y|)} e^{-\frac{t-\sigma}{4}} e^{-\frac{(x-y)^2}{8(t-\sigma)}}. \qquad \square$$

LEMMA 2.12. *For $x \ge -(L+t)/2$,*

$$\int_0^t \int_0^\infty |g_x(x,t;y,\sigma)|(1+y+L+\sigma)^{-2\alpha}dyd\sigma$$
$$= O(1)\begin{cases} e^{-\frac{|x|}{2}}(1+t)^{-2\alpha+1} & \text{if } x \in [-(L+t)/2, 0), \\ (1+x+L+t)^{-\alpha} & \text{if } x \ge 0. \end{cases} \tag{2.34}$$

Proof. First we note that

$$g_x(x,t;y,\sigma)$$
$$= -\frac{1}{2}\tanh\frac{x}{2} g(x,t;y,\sigma) - \frac{(x-y)}{2(t-\sigma)} g(x,t;y,\sigma)$$
$$= O(1)\begin{cases} \left(1+\frac{1}{\sqrt{t-\sigma}}\right)e^{-|x|}k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right) & \text{for } x<0,\ y>0, \\ \left(1+\frac{1}{\sqrt{t-\sigma}}\right)k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right) & \text{for } x>0,\ y>0, \end{cases} \quad \text{for } D>1.$$

This yields, for $x \in [-(L+t)/2, -t/2]$,

$$\begin{aligned}
&\int_0^t \int_0^\infty |g_x(x,t;y,\sigma)|(1+y+L+\sigma)^{-2\alpha} dyd\sigma \\
&\quad \le C \int_0^t \int_0^\infty \left(1+\frac{1}{\sqrt{t-\sigma}}\right) e^{-|x|} k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right) \\
&\qquad\qquad \cdot (1+y+L+\sigma)^{-2\alpha} dyd\sigma \\
&\quad \le Ce^{-|x|} \int_0^t \left(1+\frac{1}{\sqrt{t-\sigma}}\right)(1+L+\sigma)^{-2\alpha} d\sigma \\
&\quad \le Ce^{-|x|} = O(1)e^{-\frac{|x|}{2}} e^{-\frac{t}{4}};
\end{aligned}$$

for $x \in (-t/2, 0)$,

$$\begin{aligned}
&\int_0^t \int_0^\infty |g_x(x,t;y,\sigma)|(1+y+L+\sigma)^{-2\alpha} dyd\sigma \\
&\quad \le C \left\{ \int_0^{\frac{t}{4}} \left(\int_0^{\frac{t-\sigma}{8}} + \int_{\frac{t-\sigma}{8}}^\infty \right) \left(1+\frac{1}{\sqrt{t-\sigma}}\right) e^{-|x|} k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right) \right. \\
&\qquad\qquad \cdot (1+y+L+\sigma)^{-2\alpha} dyd\sigma \\
&\qquad + \int_{\frac{t}{4}}^t \int_0^\infty \left(1+\frac{1}{\sqrt{t-\sigma}}\right) e^{-|x|} k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right) \\
&\qquad\qquad \left. \cdot (1+y+L+\sigma)^{-2\alpha} dyd\sigma \right\} \\
&\quad \le Ce^{-\frac{|x|}{2}} (1+t)^{-2\alpha+1};
\end{aligned}$$

and, for $x \ge 0$,

$$\begin{aligned}
&\int_0^t \int_0^\infty |g_x(x,t;y,\sigma)|(1+y+L+\sigma)^{-2\alpha} dyd\sigma \\
&\quad \le C \int_0^t \left(\int_0^{\frac{x}{2}} + \int_{\frac{x}{2}}^{x+\frac{t-\sigma}{2}} + \int_{x+\frac{t-\sigma}{2}}^\infty \right) \left(1+\frac{1}{\sqrt{t-\sigma}}\right) \\
&\qquad\qquad \cdot k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right)(1+y+L+\sigma)^{-2\alpha} dyd\sigma \\
&\quad \equiv A_1 + A_2 + A_3.
\end{aligned}$$

As in the proof of Lemma 2.5, we have broken the above integral into the terms A_1, A_2, and A_3 according to various regions. The estimates for these terms are straightforward:

$$\begin{aligned}
A_1 &= \int_0^t \int_0^{\frac{x}{2}} \left(1+\frac{1}{\sqrt{t-\sigma}}\right) k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right)(1+y+L+\sigma)^{-2\alpha} dyd\sigma \\
&\le C \int_0^t \left(1+\frac{1}{\sqrt{t-\sigma}}\right) e^{-\frac{(\frac{x}{2}+t-\sigma)^2}{4D(t-\sigma)}} (1+L+\sigma)^{-2\alpha} d\sigma \\
&\le Ce^{-\frac{x}{4D}} \left(\int_0^{\frac{t}{2}} + \int_{\frac{t}{2}}^t \right) e^{-\frac{t-\sigma}{4D}} \left(1+\frac{1}{\sqrt{t-\sigma}}\right)(1+L+\sigma)^{-2\alpha} d\sigma \\
&\le Ce^{-\frac{x}{4D}} (e^{-\frac{t}{8D}} + (1+L+t)^{-2\alpha})
\end{aligned}$$

$$\le C(1+x+L+t)^{-2\alpha},$$

$$A_2 = \int_0^t \int_{\frac{x}{2}}^{x+\frac{t-\sigma}{2}} \left(1+\frac{1}{\sqrt{t-\sigma}}\right) k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right)(1+y+L+\sigma)^{-2\alpha} dy d\sigma$$

$$\le C\int_0^t \left(1+\frac{1}{\sqrt{t-\sigma}}\right) e^{-\frac{(\frac{t-\sigma}{2})^2}{4D(t-\sigma)}} \left(1+\frac{x}{2}+L+\sigma\right)^{-2\alpha} d\sigma$$

$$= C\left(\int_0^{\frac{t}{2}} + \int_{\frac{t}{2}}^t\right)\left(1+\frac{1}{\sqrt{t-\sigma}}\right) e^{-\frac{t-\sigma}{16D}}(1+x+L+\sigma)^{-2\alpha} d\sigma$$

$$\le C\left[e^{-\frac{t}{32D}}(1+x+L)^{-2\alpha}\int_0^{\frac{t}{2}}\left(1+\frac{1}{\sqrt{t-\sigma}}\right)d\sigma \right.$$

$$\left. + (1+x+L+t)^{-2\alpha}\int_{\frac{t}{2}}^t \left(1+\frac{1}{\sqrt{t-\sigma}}\right) e^{-\frac{t-\sigma}{16D}} d\sigma\right]$$

$$\le C(1+x+L+t)^{-2\alpha},$$

$$A_3 = \int_0^t \int_{x+\frac{t-\sigma}{2}}^{\infty} \left(1+\frac{1}{\sqrt{t-\sigma}}\right) k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right)(1+y+L+\sigma)^{-2\alpha} dy d\sigma$$

$$\le C\int_0^t \left(1+\frac{1}{\sqrt{t-\sigma}}\right)\left(1+x+L+\frac{t}{2}+\frac{\sigma}{2}\right)^{-2\alpha} d\sigma$$

$$\le C(1+x+L+t)^{-2\alpha+1}.$$

By adding A_1, A_2, and A_3 we obtain (2.34) in the case $x \ge 0$. □

Finally, we can establish the basic structure of the global solution of the problem (2.1), (2.2), and (2.3).

THEOREM 2.13. *Suppose that L is sufficiently large. Then there exists a global solution $v(x,t)$ of* (2.1), (2.2), *and* (2.3) *satisfying the following estimate:*

$$v(x,t) = O(1)e^{-\frac{L}{2r}} \begin{cases} e^{-\frac{|x|}{2}}|x+L+t| & \text{for } x \in [-L-t, -L-t+1], \\ e^{-\frac{|x|}{2}} & \text{for } x \in [-L-t, 0), \\ e^{-\frac{|x|}{2}} + (1+x+L+t)^{-\alpha} & \text{for } x \ge 0. \end{cases} \tag{2.35}$$

Moreover, $v_x(-L-t,t)$ exists and has the estimate

$$v_x(-L-t,t) = O(1)e^{-\frac{L}{2r}}e^{-\frac{(L+t)}{2}}, \quad r>1. \tag{2.36}$$

Proof. From Proposition 2.7. we have proved that v^0 satisfies estimates (2.35) and (2.36). Now, suppose that $v^n(x,t)$, for any $n \le k$, satisfies estimate (2.35). We define a weighted super norm $|||\cdot|||$ as follows:

$$|||y||| \equiv \sup_{\substack{t\ge 0 \\ -L-t\le x<0}} \frac{|y(x,t)|}{e^{-\frac{|x|}{2}}} + \sup_{\substack{t\ge 0 \\ x\ge 0}} \frac{|y(x,t)|}{e^{-\frac{|x|}{2}} + (1+x+L+t)^{-\alpha}}.$$

Let

$$\delta^n(x,t) \equiv v^n(x,t) - v^{n-1}(x,t) \quad \text{for } n \ge 1;$$

then it suffices to show that δ^n is a geometric sequence by induction. We have the following representation for δ^n's:

for $x \in [-L-t, -(L+t)/2)$,

$$\delta^1(x,t) = \int_0^t \int_{-L-\sigma}^{\infty} K_y^B(x,t;y,\sigma)\left[(\phi - 1 + \Psi)v^0 + \frac{(v^0)^2}{2}\right](y,\sigma)dyd\sigma; \tag{2.37}$$

for $x \geq -(L+t)/2$,

$$\begin{aligned}\delta^1(x,t) = &-\int_0^t G(x,t;-L-\sigma,\sigma)\delta_y^1(-L-\sigma,\sigma)d\sigma \\ &+\int_0^t \int_{-L-\sigma}^{\infty} G_y(x,t;y,\sigma)\left[\frac{(v^0)^2}{2} + \Psi v^0\right](y,\sigma)dyd\sigma;\end{aligned} \tag{2.38}$$

for $x \in [-L-t, -(L+t)/2)$, $n \geq 1$,

$$\begin{aligned}\delta^{n+1}(x,t) = &\int_0^t \int_{-L-\sigma}^{\infty} K_y^B(x,t;y,\sigma) \\ &\cdot \left[(\phi - 1 + \Psi)\delta^n + \frac{\delta^n(v^n + v^{n-1})}{2}\right](y,\sigma)dyd\sigma;\end{aligned} \tag{2.39}$$

and, for $x \geq -(L+t)/2$, $n \geq 1$,

$$\begin{aligned}\delta^{n+1}(x,t) = &-\int_0^t G(x,t;-L-\sigma,\sigma)\delta_y^{n+1}(-L-\sigma,\sigma)d\sigma \\ &+\int_0^t \int_{-L-\sigma}^{\infty} G_y(x,t;y,\sigma)\left[\Psi\delta^n + \frac{\delta^n(v^n + v^{n-1})}{2}\right](y,\sigma)dyd\sigma.\end{aligned} \tag{2.40}$$

Since $\Psi(x,t) \leq 1 - \phi(x)$, either less than e^x if $-L-t \leq x \leq 0$ or 2 if $x > 0$, and

$$\begin{aligned}|K_y^B(x,t;y,\sigma)| &\leq K^B + (|k_Y(Y-X,t-\sigma)| + |k_Y(Y+X,t-\sigma)|)e^{(X-Y)-(t-\sigma)} \\ &\leq C\left\{k(x-y-(t-\sigma),t-\sigma)\right. \\ &\qquad \left. + \frac{1}{\sqrt{t-\sigma}}k\left(\frac{x-y+(t-\sigma)}{D}, t-\sigma\right)e^{x-y}\right\} \quad \text{for all } D > 1,\end{aligned}$$

we have from Lemma 2.10 and (2.37) that, for $x \in [-L-t, -(L+t)/2)$,

$$\begin{aligned}|\delta^1(x,t)| &\leq C_0 \int_0^t \int_{-L-\sigma}^{0} |K_y^B(x,t;y,\sigma)| \\ &\qquad \cdot \left[|||v^0|||e^{-|y|/2}(2(1-\phi(y))) + \frac{1}{2}|||v^0|||e^{-\frac{L}{2r}}e^{-|y|}\right]dyd\sigma \\ &\quad + C_0 \int_0^t \int_0^{\infty} |K_y^B(x,t;y,\sigma)| \\ &\qquad \cdot \left[|||v^0|||(e^{-|y|/2} + (1+y+L+\sigma)^{-\alpha})2(1-\phi(y))\right. \\ &\qquad \left. + \frac{1}{2}|||v^0|||e^{-\frac{L}{2r}}\left(e^{-|y|/2} + (1+y+L+\sigma)^{-\alpha}\right)^2\right]dyd\sigma \\ &\leq C|||v^0|||\int_0^t \int_{-L-\sigma}^{0} |K_y^B(x,t;y,\sigma)| \cdot e^{-\frac{|y|}{2}}\left(e^{-|y|} + e^{-\frac{L}{2r}}e^{-|y|/2}\right)dyd\sigma\end{aligned} \tag{2.41}$$

$$
\begin{aligned}
&+ C|||v^0||| \int_0^t \int_0^\infty |K_y^B(x,t;y,\sigma)| \\
&\qquad \cdot \left[\left(e^{-|y|/2} + (1+y+L+\sigma)^{-\alpha} \right) \right. \\
&\qquad \left. + e^{-\frac{L}{2r}} \left(e^{-|y|} + (1+y+L+\sigma)^{-2\alpha} \right) \right] dyd\sigma \\
&\le C e^{-\frac{L}{2r}} e^{-\frac{|x|}{2}} |||v^0|||.
\end{aligned}
$$

From Lemma 2.9 and the fact that $\phi(x) - 1 + \Psi(x,t) = O(1)|x+L+t|e^{-|x|}$, for $-L-t \le x < 0$, we obtain, for $x \in [-L-t, -L-t+1)$,

$$
\begin{aligned}
|\delta^1(x,t)| &\le C \int_0^t \int_{-L-\sigma}^{-L-\sigma+4} |K_y^B(x,t;y,\sigma)|(y+L+\sigma) \\
&\qquad \cdot |||v^0|||e^{-|y|/2} \left[e^{-|y|} + \frac{1}{2} e^{-\frac{L}{2r}} e^{-\frac{|y|}{2}} \right] dyd\sigma \\
&+ C \int_0^t \int_{-L-\sigma+4}^0 |K_y^B(x,t;y,\sigma)| \\
&\qquad \cdot \left[|||v^0|||e^{-|y|/2}(2(1-\phi(y))) + \frac{1}{2}|||v^0|||e^{-\frac{L}{2r}} e^{-|y|} \right] dyd\sigma \\
&+ C \int_0^t \int_0^\infty |K_y^B(x,t;y,\sigma)| \\
&\qquad \cdot \left[|||v^0||| \left(e^{-|y|/2} + (1+y+L+\sigma)^{-\alpha} \right) 2(1-\phi(y)) \right. \\
&\qquad \left. + \frac{1}{2}|||v^0|||e^{-\frac{L}{2r}} \left(e^{-|y|/2} + (1+y+L+\sigma)^{-\alpha} \right)^2 \right] dyd\sigma \\
&\le C|x+L+t|e^{-\frac{L}{2r}} e^{-\frac{|x|}{2}} |||v^0|||.
\end{aligned}
\tag{2.42}
$$

This yields $\delta^1(-L-t,t) = 0$. Furthermore, similar to (2.22) and the proof of Lemma 2.9, with $X = x+L+t$, $Y = y+L+\sigma$, we have that

$$
\begin{aligned}
&|\delta_x^1(-L-t,t)| \\
&\quad = \left| \lim_{x+L+t \to 0^+} \int_0^t \int_{-L-\sigma}^\infty \frac{-K^B(x,t;y,\sigma)}{|x+L+t|} \left[(\phi - 1 + \Psi)v^0 + \frac{(v^0)^2}{2} \right](y,\sigma) dyd\sigma \right. \\
&\qquad + \lim_{X \to 0^+} \int_0^t \int_{-L-\sigma}^\infty \frac{(k_Y(Y-X,t-\sigma) - k_Y(Y+X,t-\sigma))}{X} e^{X-Y-(t-\sigma)} \\
&\qquad\qquad \left. \cdot \left[(\phi - 1 + \Psi)v^0 + \frac{(v^0)^2}{2} \right](y,\sigma) dyd\sigma \right| \\
&\quad \le C e^{-\frac{L}{2r}} e^{-\frac{L+t}{2}} |||v^0|||.
\end{aligned}
\tag{2.43}
$$

Also, from Lemmas 2.5, 2.11, and 2.12, equations (2.38), (2.43), and the fact that

$$
G_y(x,t;y,\sigma) = -g_x(x,t;y,\sigma),
$$

we have, for $x \ge -(L+t)/2$,

$$
\begin{aligned}
|\delta^1(x,t)| \le C\Bigg\{ & \int_0^t |G(x,t;-L-\sigma,\sigma)|\,|||v^0|||e^{-\frac{L}{2r}}e^{-(L+\sigma)/2}d\sigma \\
& + \int_0^t\int_{-L-\sigma}^0 |G_y(x,t;y,\sigma)| \\
& \qquad \cdot\left[|||v^0|||e^{-\frac{|y|}{2}}e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha} + \frac{1}{2}|||v^0|||e^{-\frac{L}{2r}}e^{-|y|}\right]dyd\sigma \\
& + \int_0^t\int_0^\infty |G_y(x,t;y,\sigma)| \\
& \qquad \cdot\Big[|||v^0|||\left(e^{-\frac{|y|}{2}} + (1+y+L+\sigma)^{-\alpha}\right)e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha} \\
& \qquad\quad + |||v^0|||e^{-\frac{L}{2r}}(e^{-|y|} + (1+y+L+\sigma)^{-2\alpha})\Big]dyd\sigma\Bigg\} \\
\le Ce^{-\frac{L}{2r}}|||v^0|||\Bigg\{ & \begin{array}{ll} e^{-\frac{|x|}{2}} & \text{for } x\in[-(L+t)/2,0), \\ e^{-\frac{|x|}{2}} + (1+x+L+t)^{-\alpha} & \text{for } x\ge 0. \end{array}
\end{aligned}
\tag{2.44}
$$

Inequalities (2.41) and (2.44) imply that

$$
|||\delta^1||| \le Ce^{-\frac{L}{2r}}|||v^0|||. \tag{2.45}
$$

Similarly, we have from the induction hypothesis that, for $x\in[-L-t,-L-t+1)$,

(2.46)

$$
\begin{aligned}
|\delta^{n+1}(x,t)| \le & C|||\delta^n||| \\
& \cdot\Bigg\{\int_0^t\int_{-L-\sigma}^{-L-\sigma+4} |K_y^B(x,t;y,\sigma)|(y+L+\sigma)e^{-\frac{|y|}{2}}\left(e^{-|y|}+e^{-\frac{L}{2r}}e^{-\frac{|y|}{2}}\right)dyd\sigma \\
& + \int_0^t\int_{-L-\sigma+4}^0 |K_y^B(x,t;y,\sigma)|e^{-\frac{|y|}{2}}\left(e^{-|y|}+e^{-\frac{L}{2r}}e^{-\frac{|y|}{2}}\right)dyd\sigma \\
& + \int_0^t\int_0^\infty |K_y^B(x,t;y,\sigma)|\left(e^{-\frac{|y|}{2}} + (1+y+L+\sigma)^{-\alpha}\right) \\
& \qquad \cdot\left[4 + e^{-\frac{L}{2r}}\left(e^{-\frac{|y|}{2}} + (1+y+L+\sigma)^{-\alpha}\right)\right]dyd\sigma\Bigg\} \\
\le & C|x+L+t|||\delta^n|||e^{-\frac{L}{2r}}e^{-\frac{|x|}{2}}.
\end{aligned}
$$

Thus

$$
|\delta_x^{n+1}(-L-t,t)| \le C|||\delta^n|||e^{-\frac{L}{2r}}e^{-\frac{L+t}{2}}; \tag{2.47}
$$

and, for $x\in[-L-t,-(L+t)/2)$,

$$
\begin{aligned}
|\delta^{n+1}(x,t)| \le & C|||\delta^n||| \\
& \cdot\Bigg\{\int_0^t\int_{-L-\sigma}^0 |K_y^B(x,t;y,\sigma)|e^{-\frac{|y|}{2}}\left(e^{-|y|}+e^{-\frac{L}{2r}}e^{-\frac{|y|}{2}}\right)dyd\sigma \\
& + \int_0^t\int_0^\infty |K_y^B(x,t;y,\sigma)|\left(e^{-\frac{|y|}{2}} + (1+y+L+\sigma)^{-\alpha}\right) \\
& \qquad \cdot\left[4 + e^{-\frac{L}{2r}}\left(e^{-\frac{|y|}{2}} + (1+y+L+\sigma)^{-\alpha}\right)\right]dyd\sigma\Bigg\} \\
\le & C|||\delta^n|||e^{-\frac{L}{2r}}e^{-\frac{|x|}{2}};
\end{aligned}
\tag{2.48}
$$

for $x \geq -(L+t)/2$,

$$
\begin{aligned}
|\delta^{n+1}(x,t)| \leq C|||\delta^n|||
&\cdot \Bigg\{ \int_0^t |G(x,t;-L-\sigma,\sigma)| e^{-\frac{L}{2r}} e^{-(L+\sigma)/2} d\sigma \\
&+ \int_0^t \int_{-L-\sigma}^0 |G_y(x,t;y,\sigma)| e^{-\frac{|y|}{2}} \\
&\qquad \cdot \left[e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha} + e^{-\frac{L}{2r}} e^{-\frac{|y|}{2}} \right] dy d\sigma \\
&+ \int_0^t \int_0^\infty |G_y(x,t;y,\sigma)| \left(e^{-\frac{|y|}{2}} + (1+y+L+\sigma)^{-\alpha} \right) \\
&\qquad \cdot \Big[e^{-L-\sigma}(1+y+L+\sigma)^{-\alpha} \\
&\qquad\quad + e^{-\frac{L}{2r}} \left(e^{-\frac{|y|}{2}} + (1+y+L+\sigma)^{-\alpha} \right) \Big] dy d\sigma \Bigg\} \\
&\leq C e^{-\frac{L}{2r}} |||\delta^n||| \begin{cases} e^{-\frac{|x|}{2}} & \text{for } x \in [-(L+t)/2, 0), \\ e^{-\frac{|x|}{2}} + (1+x+L+t)^{-\alpha} & \text{for } x \geq 0. \end{cases}
\end{aligned} \tag{2.49}
$$

From the inequalities (2.47), (2.48), and (2.49) we conclude that

$$
|||\delta^{n+1}||| \leq C|||\delta^n|| e^{-\frac{L}{2r}}, \tag{2.50}
$$

$$
|\delta_x^{n+1}(-L-t,t)| \leq C|||\delta^n||| e^{-\frac{L}{2r}} e^{-\frac{L+t}{2}}, \quad 1 \leq n \leq k. \tag{2.51}
$$

Thus, when L is sufficiently large, $|||\delta^n|||$ and $|\delta_x^{n+1}(-L-t,t)|$ are geometric sequences and

$$
|||v^{k+1} - v^0||| \leq \sum_{n=0}^{k} |||\delta^{n+1}||| \leq \sum_{n=0}^{\infty} \left(C e^{-\frac{L}{2r}} \right)^{n+1} |||v^0||| \leq \frac{1}{2} |||v^0|||, \tag{2.52}
$$

which means, by induction, that for all n, v^n satisfy the estimates (2.35) and (2.36), and there exists

$$
v(x,t) \equiv \lim_{n \to \infty} v^n(x,t)
$$

satisfying (2.35), (2.36), (2.6), and (2.10). ∎

From the above estimate of $v(x,t)$ and $v_x(-L-t,t)$, we obtain the estimate of the solution $u(x,t)$ for (1.1), (1.2), and (1.3).

THEOREM 2.14. *Suppose that L is sufficiently large. Then, there exists a global solution $u(x,t)$ of* (1.1), (1.2), *and* (1.3) *such that*

$$
u(x,t) = \phi(x) + O(1) e^{-\frac{L}{2r}} \begin{cases} e^{-\frac{|x|}{2}} & \text{for } x \in [-L-t, 0), \\ e^{-\frac{|x|}{2}} + (1+x+L+t)^{-\alpha} & \text{for } x \geq 0. \end{cases} \tag{2.53}
$$

Moreover, $u_x(-L-t,t)$ exists and has the estimate

$$
u_x(-L-t,t) = O(1) e^{-\frac{L}{2r}} e^{-\frac{(L+t)}{2}}, \quad r > 1. \tag{2.54}
$$

Remark 2.15. For general initial data (1.4) with $d > 1$, we also obtain the structure of global solution in time as follows:

$$u(x,t) = \phi(x) + O(1)e^{-\frac{L}{2d}} \begin{cases} e^{-\frac{|x|}{2d}} & \text{for } x \in [-L-t, 0), \\ e^{-\frac{|x|}{2}} + (1+x+L+t)^{-\alpha} & \text{for } x \geq 0, \end{cases}$$

$$u_x(-L-t,t) = O(1)e^{-\frac{L}{2d}} e^{-\frac{(L+t)}{2d}}.$$

The computation is similar to those in section 3 and is therefore omitted.

3. Time asymptotic stability. In this section, we will study the time asymptotic behavior of the solution for (1.1), (1.2), and (1.3). For that, we need to locate the time asymptotic position of the shock profile through the conservation law.

As a consequence of the boundary estimate (2.54), we have

$$\begin{aligned} \frac{d}{dt}\int_{-L-t}^{\infty} u(x,t) - \phi(x)dx &= (1 - \phi(-L-t)) - u_x(-L-t,t) \\ &\leq O(1)e^{-\frac{L}{6}} e^{-\frac{L+t}{2}}, \end{aligned}$$

and therefore

$$\lim_{t\to\infty} \int_{-L-t}^{\infty} u(x,t) - \phi(x)dx$$

exists. We thus obtain the time asymptotic shift x_0 of the shock location

$$x_0 \equiv \frac{\lim_{t\to\infty} \int_{-L-t}^{\infty} u(x,t) - \phi(x)dx}{u_+ - u_-} = O(1)e^{-\frac{L}{6}} e^{-\frac{L}{2}}, \tag{3.1}$$

where u_-, u_+ are the end states of the stationary Burgers shock and here are taken to be $u_- = -u_+ = 1$.

Now, consider the new variables

$$\mathbf{v}(x,t) \equiv u(x,t) - \phi(x + x_0), \tag{3.2}$$

$$w(x,t) \equiv -\int_x^{\infty} \mathbf{v}(r,t)dr. \tag{3.3}$$

Then

$$\begin{aligned} w(-L-t,t) &= -\int_{-L-t}^{\infty} u(x,t) - \phi(x+x_0)dx \\ &= -\int_{-L-t}^{\infty} u(x,t) - \phi(x)dx + \int_{-\infty}^{\infty} \phi(x+x_0) - \phi(x)dx \\ &\quad - \int_{-\infty}^{-L-t} \phi(x+x_0) - \phi(x)dx \\ &= -\int_{-L-t}^{\infty} u(x,t) - \phi(x)dx + O(1)e^{-L-t} + x_0(u_+ - u_-) \\ &\leq O(1)e^{-\frac{L}{6}} e^{-\frac{L+t}{2}}, \end{aligned}$$

$$\begin{aligned} w_x(-L-t,t) &= u(-L-t,t) - \phi(-L-t+x_0) \\ &= 1 - \phi(-L-t+x_0) = O(1)e^{-L-t} \leq O(1)e^{-\frac{L}{6}} e^{-\frac{L+t}{2}}, \end{aligned}$$

$$\begin{aligned} w_{xx}(-L-t,t) &= u_x(-L-t,t) - \phi'(-L-t+x_0) \\ &= O(1)e^{-\frac{L}{6}} e^{-\frac{L+t}{2}}. \end{aligned}$$

And the initial value for $w(x,t)$ satisfies

$$\begin{aligned} w(x,0) &= -\int_x^\infty u(r,0) - \phi(r+x_0)dr \\ &\le \frac{C}{\alpha-1}e^{-L}(1+x+L)^{-\alpha+1} + \int_x^\infty \phi(r) - \phi(r+x_0)dr \\ &\le Ce^{-L}(1+x+L)^{-\alpha+1} + C\begin{cases} |x_0|, & -L \le x \le 0, \\ |x_0|e^{-|x|}, & x > 0, \end{cases} \\ w_x(x,0) &= u(x,0) - \phi(x+x_0) \\ &\le O(1)(e^{-L}(1+x+L)^{-\alpha} + |x_0|e^{-|x|}). \end{aligned}$$

In summary, $w(x,t)$ satisfies

$$w_t + \phi(x+x_0)w_x - w_{xx} = \frac{-\mathbf{v}^2(x,t)}{2}, \tag{3.4}$$

$$w(x,0) \le O(1)\begin{cases} e^{\frac{-L}{2}-\frac{L}{6}}, & -L \le x \le 0, \\ e^{\frac{-L}{2}-\frac{L}{6d}}(x+L+1)^{-\alpha+1}, & x > 0,\ d \gtrsim 1, \end{cases}$$

$$w_x(x,0) \le O(1)\begin{cases} e^{\frac{-L}{2}-\frac{L}{6}}, & -L \le x \le 0, \\ e^{\frac{-L}{2}-\frac{L}{6d}}(x+L+1)^{-\alpha}, & x > 0,\ d \gtrsim 1, \end{cases}$$

$$w(-L-t,t) \le O(1)e^{\frac{-(L+t)}{2}}e^{\frac{-L}{6}},$$

$$w_x(-L-t,t) \le O(1)e^{\frac{-(L+t)}{2}}e^{\frac{-L}{6}},$$

$$w_{xx}(-L-t,t) \le O(1)e^{\frac{-(L+t)}{2}}e^{\frac{-L}{6}},$$

$$|x_0| \le O(1)e^{\frac{-L}{2}}e^{\frac{-L}{6}},$$

where $d \gtrsim 1$ means that $d > 1$ and is close to 1.

To simplify the boundary condition, we set

$$\begin{aligned} &\bar{w}(x,t) \equiv w(x,t) - R(x,t), \\ &\text{where} \quad R(x,t) = w(-L-t,t)e^{-(x+L+t)}. \end{aligned} \tag{3.5}$$

Then it follows from (3.4) and previous estimates that

$$\begin{aligned} &\bar{w}_t + \phi(x+x_0)\bar{w}_x - \bar{w}_{xx} + \frac{1}{2}\bar{w}_x^2 + \bar{w}_x R_x \\ &\quad + R_t + \phi(x+x_0)R_x - R_{xx} + \frac{1}{2}R_x^2 = 0, \end{aligned} \tag{3.6}$$

$$\bar{w}(-L-t,t) = 0, \tag{3.7}$$

$$\bar{w}(x,0) \le O(1)\begin{cases} e^{\frac{-L}{2}-\frac{L}{6}}, & -L-t \le x \le 0, \\ e^{\frac{-L}{2}-\frac{L}{6d}}(x+L+1)^{-\alpha+1}, & x > 0,\ d \gtrsim 1, \end{cases} \tag{3.8}$$

$$\bar{w}_x(x,0) \le O(1)\begin{cases} e^{\frac{-L}{2}-\frac{L}{6}}, & -L-t \le x \le 0, \\ e^{\frac{-L}{2}-\frac{L}{6d}}(x+L+1)^{-\alpha}, & x > 0,\ d \gtrsim 1. \end{cases} \tag{3.9}$$

As before, we have two different representations for the solution in two different regions.

Region I: $x \in [-L-t, -(L+t)/2)$. We have from (3.6) that

$$\begin{aligned}\bar{w}(x,t) = &\int_{-L}^{\infty} K^B(x,t;y,0)\bar{w}(y,0)dy\\ &+\int_0^t\int_{-L-\sigma}^{\infty} K^B(1-\phi(y+x_0))\bar{w}_y dyd\sigma\\ &-\int_0^t\int_{-L-\sigma}^{\infty} K^B\frac{(\bar{w}_y)^2}{2}dyd\sigma\\ &-\int_0^t\int_{-L-\sigma}^{\infty} K^B\bar{w}_y R_y dyd\sigma\\ &-\int_0^t\int_{-L-\sigma}^{\infty} K^B\left[R_\sigma+\phi(y+x_0)R_y-R_{yy}+\frac{1}{2}R_y^2\right]dyd\sigma.\end{aligned} \tag{3.10}$$

Region II: $x \geq \frac{-L-t}{2}$. We have from (3.6) that

$$\begin{aligned}\bar{w}(x,t) = &\int_{-L}^{\infty} \bar{g}(x,t;y,0)\bar{w}(y,0)dy\\ &-\int_0^t \bar{g}(x,t;-L-\sigma,\sigma)\bar{w}_y(-L-\sigma,\sigma)d\sigma\\ &-\int_0^t\int_{-L-\sigma}^{\infty} \bar{g}\frac{(\bar{w}_y)^2}{2}dyd\sigma\\ &-\int_0^t\int_{-L-\sigma}^{\infty} \bar{g}\bar{w}_y R_y dyd\sigma\\ &-\int_0^t\int_{-L-\sigma}^{\infty} \bar{g}\left[R_\sigma+\phi(y+x_0)R_y-R_{yy}+\frac{1}{2}R_y^2\right]dyd\sigma,\end{aligned} \tag{3.11}$$

where $\bar{g}(x,t;y,\sigma) \equiv g(x+x_0,t;y+x_0,\sigma)$.

And, as before, we use the following iterations:
for $(-L-t) \leq x < (-L-t)/2$,

$$\begin{aligned}\bar{w}^0(x,t) = &\int_{-L}^{\infty} K^B(x,t;y,0)\bar{w}(y,0)dy\\ &-\int_0^t\int_{-L-\sigma}^{\infty} K^B\left[R_\sigma+\phi(y+x_0)R_y-R_{yy}+\frac{1}{2}R_y^2\right]dyd\sigma;\end{aligned}$$

for $x \geq (-L-t)/2$,

$$\begin{aligned}\bar{w}^0(x,t) = &\int_{-L}^{\infty} \bar{g}(x,t;y,0)\bar{w}(y,0)dy\\ &-\int_0^t \bar{g}(x,t;-L-\sigma,\sigma)\bar{w}^0_y(-L-\sigma,\sigma)d\sigma\\ &-\int_0^t\int_{-L-\sigma}^{\infty} \bar{g}\left[R_\sigma+\phi(y+x_0)R_y-R_{yy}+\frac{1}{2}R_y^2\right]dyd\sigma;\end{aligned}$$

for $(-L-t) \leq x < (-L-t)/2$, $n \geq 0$,

$$\bar{w}^{n+1}(x,t) = \int_{-L}^{\infty} K^B(x,t;y,0)\bar{w}^n(y,0)dy$$

$$
\begin{aligned}
&+\int_0^t\int_{-L-\sigma}^{\infty} K^B(1-\phi(y+x_0))\bar{w}_y^n dyd\sigma\\
&-\int_0^t\int_{-L-\sigma}^{\infty} K^B\frac{(\bar{w}_y^n)^2}{2}dyd\sigma\\
&-\int_0^t\int_{-L-\sigma}^{\infty} K^B\bar{w}_y^n R_y dyd\sigma\\
&-\int_0^t\int_{-L-\sigma}^{\infty} K^B\left[R_\sigma+\phi(y+x_0)R_y-R_{yy}+\frac{1}{2}R_y^2\right]dyd\sigma;
\end{aligned}
$$

for $x \geq (-L-t)/2$, $n \geq 0$,

$$
\begin{aligned}
\bar{w}^{n+1}(x,t) = &\int_{-L}^{\infty} \bar{g}(x,t;y,0)\bar{w}^n(y,0)dy\\
&-\int_0^t \bar{g}(x,t;-L-\sigma,\sigma)\bar{w}_y^{n+1}(-L-\sigma,\sigma)d\sigma\\
&-\int_0^t\int_{-L-\sigma}^{\infty} \bar{g}\frac{(\bar{w}_y^n)^2}{2}dyd\sigma\\
&-\int_0^t\int_{-L-\sigma}^{\infty} \bar{g}\bar{w}_y^n R_y dyd\sigma\\
&-\int_0^t\int_{-L-\sigma}^{\infty} \bar{g}\left[R_\sigma+\phi(y+x_0)R_y-R_{yy}+\frac{1}{2}R_y^2\right]dyd\sigma.
\end{aligned}
$$

It is noted that

$$
\bar{w}^m(x,0) = \bar{w}(x,0) \quad \text{for all } m \in \mathbf{N}, \tag{3.12}
$$

$$
R_x(x,t) = -R(x,t) \quad \text{and} \quad |R_t(x,t)| \leq O(1)e^{\frac{-(L+t)}{2}}e^{\frac{-L}{6}}e^{-(x+L+t)} \tag{3.13}
$$

by (3.5). We will show that the boundary value is unchanged through the iteration. The proof of Lemma 3.1 contains the essential estimate for that.

LEMMA 3.1.

$$
\bar{w}^0(-L-t,t) = 0. \tag{3.14}
$$

Proof. Let $X = x+L+t\,(\geq 0)$ and $Y = y+L+\sigma\,(\geq 0)$. $K^B(x,t;y,\sigma)$ can be represented as

$$
K^B(x,t;y,\sigma) = [k(Y-X,t-\sigma)-k(Y+X,t-\sigma)]e^{(X-Y)-(t-\sigma)}. \tag{3.15}
$$

Then by (3.15) and Fubini's theorem,

$$
\begin{aligned}
&\left|\int_{-L}^{\infty} K^B(x,t;y,0)\bar{w}(y,0)dy\right|\\
&\quad=\left|(-X)\int_{-L}^{\infty}\int_{-1}^{1}\partial_y k(Y-\theta X,t)d\theta e^{(X-Y)-t}\bar{w}(y,0)dy\right|\\
&\quad=\left|(-X)\int_{-1}^{1}\int_{-L}^{\infty}\partial_y k(Y-\theta X,t)e^{(X-Y)-t}\bar{w}(y,0)dyd\theta\right|\\
&\quad=\left|X\int_{-1}^{1}\int_{-L}^{\infty} k(Y-\theta X,t)\left[-e^{(X-Y)-t}\bar{w}(y,0)+e^{(X-Y)-t}\bar{w}_y(y,0)\right]dyd\theta\right|
\end{aligned}
$$

$$
\begin{aligned}
&= \left| X \int_{-1}^{1} \int_{-L}^{\infty} \frac{1}{\sqrt{4\pi t}} e^{\frac{-(Y-X)^2}{4t}} e^{\frac{-2XY(1-\theta)}{4t}} e^{\frac{X^2(1-\theta^2)}{4t}} \right. \\
&\qquad \left. \cdot \left[-e^{(X-Y)-t} \bar{w}(y,0) + e^{(X-Y)-t} \bar{w}_y(y,0) \right] dy d\theta \right| \\
&\le X e^{\frac{X^2}{4t}} \int_{-1}^{1} e^{\frac{-X^2\theta^2}{4t}} \int_{-L}^{\infty} k(x-y-t,t)[|\bar{w}(y,0)| + |\bar{w}_y(y,0)|] dy d\theta, \\
&\le O(1) X e^{\frac{X^2}{4t}} e^{\frac{x}{2}} e^{\frac{-t}{4}} e^{\frac{-L}{6}},
\end{aligned}
$$

and

$$
\begin{aligned}
&\left| \int_0^t \int_{-L-\sigma}^{\infty} K^B(x,t;y,\sigma) R_\sigma dy d\sigma \right| \\
&\quad = \left| (-X) \int_0^t \int_{-L-\sigma}^{\infty} \int_{-1}^{1} \partial_y k(Y-\theta X, t-\sigma) d\theta e^{(X-Y)-(t-\sigma)} R_\sigma dy d\sigma \right| \\
&\quad = \left| (-X) \int_0^t \int_{-1}^{1} \int_{-L-\sigma}^{\infty} \partial_y k(Y-\theta X, t-\sigma) e^{(X-Y)-(t-\sigma)} R_\sigma dy d\theta d\sigma \right| \\
&\quad \le O(1) X \int_0^t \int_{-1}^{1} \int_{-L-\sigma}^{\infty} \frac{1}{(t-\sigma)} e^{\frac{-(Y-\theta X)^2}{4\bar{d}(t-\sigma)}} e^{(x-y)} \\
&\qquad\qquad \cdot e^{\frac{-(L+\sigma)}{2}} e^{\frac{-L}{6}} e^{-(y+L+\sigma)} dy d\theta d\sigma \\
&\quad \le O(1) X e^x \int_0^t \int_{-1}^{1} \frac{e^{\sigma/2}}{\sqrt{t-\sigma}} d\theta d\sigma e^{\frac{L}{2} - \frac{L}{6}} \\
&\quad \le O(1) X e^x \sqrt{t} e^{\frac{t}{2}} e^{\frac{L}{2} - \frac{L}{6}}, \quad \text{where } \bar{d} > 1,
\end{aligned}
$$

which imply (3.14). □

The leading ansatz for the solution $\bar{w}(x,t)$ is provided by the estimate for $\bar{w}^0(x,t)$, for which we need the following lemmas. They are analogous to Lemmas 2.4 and 2.5, with additional attention to the property of time decay.

LEMMA 3.2. *For $x \ge (-L-t)/2$,*

$$
\int_0^t \bar{g}(x,t;-L-\sigma,\sigma) e^{\frac{-\sigma}{2}} e^{\frac{-L}{2} - \frac{L}{6}} d\sigma \le O(1) e^{\frac{-|x|}{4}} e^{\frac{-3t}{16}} e^{\frac{-L}{4} - \frac{L}{6}}, \tag{3.16}
$$

$$
\left| \int_0^t \bar{g}_x(x,t;-L-\sigma,\sigma) e^{\frac{-\sigma}{2}} e^{\frac{-L}{2} - \frac{L}{6}} d\sigma \right| \le O(1) e^{\frac{-|x|}{4}} e^{\frac{-3t}{16}} e^{\frac{-L}{4} - \frac{L}{6}}. \tag{3.17}
$$

Proof. First we notice that, for $y < 0$,

$$
\begin{aligned}
\bar{g}_x(x,t;y,\sigma) &= \frac{1}{\sqrt{4\pi(t-\sigma)}} \frac{-(1+e^{y+x_0}) e^{x+x_0}}{(1+e^{x+x_0})^2} e^{\frac{-(x-y-(t-\sigma))^2}{4(t-\sigma)}} \\
&\quad + \frac{1}{\sqrt{4\pi(t-\sigma)}} \frac{1+e^{y+x_0}}{1+e^{x+x_0}} \frac{-2(x-y-(t-\sigma))}{4(t-\sigma)} e^{\frac{-(x-y-(t-\sigma))^2}{4(t-\sigma)}} \\
&\equiv \bar{g}_{1x} + \bar{g}_{2x}.
\end{aligned} \tag{3.18}
$$

Since

$$
\int_0^t \bar{g}(x,t;-L-\sigma,\sigma) e^{\frac{-\sigma}{2}} e^{\frac{-L}{2} - \frac{L}{6}} d\sigma
$$

$$= O(1)\frac{1}{1+e^x}\int_0^t \frac{1}{\sqrt{4\pi(t-\sigma)}} e^{\frac{-(x+L+\sigma-(t-\sigma))^2}{4(t-\sigma)}} \cdot e^{\frac{-\sigma}{2}} e^{\frac{-L}{2}-\frac{L}{6}} d\sigma$$

$$= O(1)\frac{e^{\frac{x}{4}}}{1+e^x}\int_0^t \frac{1}{\sqrt{t-\sigma}} e^{\frac{-[x+L+\sigma-(1/2)(t-\sigma)]^2}{4(t-\sigma)}} e^{\frac{-3}{16}(t-\sigma)} e^{\frac{-\sigma}{4}} d\sigma e^{\frac{-L}{4}-\frac{L}{6}}$$

$$\le O(1)\frac{e^{\frac{x}{4}}}{1+e^x} e^{\frac{-3t}{16}} e^{\frac{-L}{4}-\frac{L}{6}},$$

the first estimate is proved. Set

$$\eta = \frac{x+L+\sigma-\frac{1}{2}(t-\sigma)}{\sqrt{4(t-\sigma)}},$$

$$\Rightarrow d\eta = \left(\frac{3/2}{\sqrt{4(t-\sigma)}} + 2\frac{x+L+\sigma-(1/2)(t-\sigma)}{(4(t-\sigma))^{\frac{3}{2}}}\right) d\sigma.$$

Then

$$\left|\int_0^t \bar{g}_x(x,t;-L-\sigma,\sigma) e^{\frac{-\sigma}{2}} e^{\frac{-L}{2}-\frac{L}{6}} d\sigma\right|$$

$$= \left| O(1)\frac{1}{1+e^x}\int_0^t \left(1+\frac{-2(x+L+\sigma-(t-\sigma))}{4(t-\sigma)}\right)\frac{e^{\frac{-(x+L+\sigma-(t-\sigma))^2}{4(t-\sigma)}}}{\sqrt{4(t-\sigma)}} \right.$$

$$\left. \cdot e^{\frac{-\sigma}{2}} e^{\frac{-L}{2}-\frac{L}{6}} d\sigma \right|$$

$$= \left| O(1)\frac{e^{\frac{x}{4}}}{1+e^x}\int_0^t \left(-\frac{3/2}{\sqrt{4(t-\sigma)}} - 2\frac{x+L+\sigma-(1/2)(t-\sigma)}{(4(t-\sigma))^{\frac{3}{2}}}\right) \right.$$

$$\cdot e^{\frac{-[x+L+\sigma-(1/2)(t-\sigma)]^2}{4(t-\sigma)}} e^{(-3/16)(t-\sigma)} e^{\frac{-\sigma}{4}} d\sigma e^{\frac{-L}{4}-\frac{L}{6}}$$

$$\left. + O(1)\frac{e^{\frac{x}{4}}}{1+e^x}\int_0^t \frac{1}{\sqrt{t-\sigma}} e^{\frac{-[x+L+\sigma-(1/2)(t-\sigma)]^2}{4(t-\sigma)}} e^{(-3/16)(t-\sigma)} e^{\frac{-\sigma}{4}} d\sigma e^{\frac{-L}{4}-\frac{L}{6}} \right|$$

$$\le O(1)\frac{e^{\frac{x}{4}}}{1+e^x} e^{\frac{-3t}{16}} e^{\frac{-L}{4}-\frac{L}{6}}. \qquad \square$$

LEMMA 3.3. *For* $x \ge \frac{(-L-t)}{2}$,

$$\int_{-L}^{\infty} \bar{g}(x,t;y,0)\bar{w}(y,0)dy$$

$$\le O(1)\begin{cases} e^{\frac{x}{4}} e^{\frac{-3t}{16}} e^{\frac{-L}{4}-\frac{L}{6}} + e^{\frac{2x}{3}}(x+t+L+1)^{-\alpha+1} e^{\frac{-L}{2}}, & \frac{-L-t}{2} \le x \le 0, \\ (x+t+L+1)^{-\alpha+1} e^{\frac{-L}{4}-\frac{L}{6d}}, & x > 0. \end{cases}$$

Proof. We have

$$\int_{-L}^{\infty} \bar{g}(x,t;y,0)\bar{w}(y,0)dy$$

$$
\begin{aligned}
&= \int_{-L}^{0} \frac{1}{\sqrt{4\pi t}} \frac{1+e^{y+x_0}}{1+e^{x+x_0}} e^{\frac{-(x-t-y)^2}{4t}} \bar{w}(y,0)dy \\
&\quad + \int_{0}^{\infty} \frac{1}{\sqrt{4\pi t}} \frac{1+e^{-(y+x_0)}}{1+e^{-(x+x_0)}} e^{\frac{-(x+t-y)^2}{4t}} \bar{w}(y,0)dy \\
&\equiv I_1 + I_2.
\end{aligned}
$$

The estimate of I_1 is straightforward by (3.8):

$$
\begin{aligned}
|I_1| &= O(1)\frac{1}{1+e^x} e^{-\frac{L}{2}-\frac{L}{6}} \int_{-L}^{0} \frac{e^{\frac{-(x-t-y)^2}{4t}}}{\sqrt{4\pi t}} dy \\
&\le O(1)\frac{1}{1+e^x} e^{-\frac{L}{2}-\frac{L}{6}} \cdot e^{\frac{x}{4}} e^{\frac{L}{4}} e^{\frac{-3t}{16}} \int_{-L}^{0} \frac{e^{\frac{-(x-t/2-y)^2}{4t}}}{\sqrt{4\pi t}} dy \\
&\le O(1) e^{\frac{-|x|}{4}} e^{\frac{-3t}{16}} e^{\frac{-L}{4}-\frac{L}{6}}.
\end{aligned}
$$

For the estimate of I_2, we have the following cases:

Case 1. For $x \ge 0$,

$$
\begin{aligned}
|I_2| &\le O(1) e^{\frac{-L}{2}-\frac{L}{6d}} \\
&\quad \cdot \left(\int_0^{\frac{(x+t)}{3}} + \int_{\frac{(x+t)}{3}}^{\infty} \right) \frac{1}{\sqrt{4\pi t}} e^{\frac{-(x+t-y)^2}{4t}} (y+L+1)^{-\alpha+1} dy.
\end{aligned}
$$

Since

$$
\begin{aligned}
&\int_0^{\frac{(x+t)}{3}} \frac{1}{\sqrt{4\pi t}} e^{\frac{-(x+t-y)^2}{4t}} (y+L+1)^{-\alpha+1} dy \\
&\qquad \le O(1) \int_{\frac{x+t}{3\sqrt{t}}}^{\frac{x+t}{\sqrt{4t}}} e^{-\eta^2} d\eta \le O(1) e^{\frac{-2x}{9}} e^{\frac{-t}{9}}, \\
&\int_{\frac{(x+t)}{3}}^{\infty} \frac{1}{\sqrt{4\pi t}} e^{\frac{-(x+t-y)^2}{4t}} (y+L+1)^{-\alpha+1} dy \\
&\qquad \le O(1)(x+t+L+1)^{-\alpha+1},
\end{aligned}
$$

we have

$$
|I_2| \le O(1)(x+t+L+1)^{-\alpha+1} e^{\frac{-L}{2}}.
$$

Case 2. For $-t < x < 0$,

$$
\begin{aligned}
|I_2| &\le O(1) e^x e^{\frac{-L}{2}} e^{\frac{-L}{6d}} \cdot \left(\int_0^{\frac{(x+t)}{3}} + \int_{\frac{(x+t)}{3}}^{\infty} \right) \frac{1}{\sqrt{4\pi t}} e^{\frac{-(x+t-y)^2}{4t}} (y+L+1)^{-\alpha+1} dy. \\
&\le O(1) \left(e^{x-\frac{2x}{9}} e^{\frac{-t}{9}} e^{\frac{-L}{2}-\frac{L}{6d}} + e^x (x+t+L+1)^{-\alpha+1} e^{\frac{-L}{2}-\frac{L}{6d}} \right) \\
&\le O(1) e^{\frac{-2|x|}{3}} (x+t+L+1)^{-\alpha+1} e^{\frac{-L}{2}}.
\end{aligned}
$$

Case 3. For $x \le -t$,

$$
|I_2| \le O(1) e^x e^{\frac{-L}{2}-\frac{L}{6d}} \int_0^{\infty} \frac{1}{\sqrt{4\pi t}} e^{\frac{-(x+t-y)^2}{4t}} (y+L+1)^{-\alpha+1} dy
$$

$$\le O(1)e^{x}e^{\frac{-L}{2}-\frac{L}{6d}}\int_{-\infty}^{\frac{x+t}{\sqrt{4t}}}e^{-\eta^2}d\eta$$
$$\le O(1)e^{\frac{x}{2}}e^{\frac{-t}{4}}e^{\frac{-L}{2}-\frac{L}{6d}}.$$

Combining the estimates for I_1 and I_2, the lemma is proved. □

LEMMA 3.4. *For* $x \ge \frac{(-L-t)}{2}$,

$$\int_0^t\int_{-L-\sigma}^{\infty}\bar{g}(x,t;y,\sigma)e^{\frac{-L}{6}}e^{\frac{-(L+\sigma)}{2}}e^{-(y+L+\sigma)}dyd\sigma \le O(1)e^{\frac{-|x|}{4}}e^{-\frac{3t}{16}}e^{\frac{-L}{4}-\frac{L}{6}}.$$

Proof.

$$\begin{aligned}&\int_0^t\int_{-L-\sigma}^{\infty}\bar{g}(x,t;y,\sigma)e^{\frac{-L}{6}}e^{\frac{-(L+\sigma)}{2}}e^{-(y+L+\sigma)}dyd\sigma\\ &\le O(1)\left(\frac{e^{\frac{x}{4}}}{1+e^{x}}\int_0^t\int_{-L-\sigma}^{0}\frac{1}{\sqrt{4\pi(t-\sigma)}}e^{\frac{-\left(x-y-\frac{(t-\sigma)}{2}\right)^2}{4(t-\sigma)}}e^{\frac{-y}{4}}e^{\frac{-3}{16}(t-\sigma)}\right.\\ &\qquad\cdot e^{\frac{-L}{6}}e^{\frac{-(L+\sigma)}{2}}e^{-(y+L+\sigma)}dyd\sigma\\ &\quad+\frac{e^{\frac{-x}{2}}}{1+e^{-x}}\int_0^t\int_0^{\infty}\frac{1}{\sqrt{4\pi(t-\sigma)}}e^{\frac{-(x-y)^2}{4(t-\sigma)}}e^{\frac{y}{2}}e^{\frac{-(t-\sigma)}{4}}\\ &\qquad\left.\cdot e^{\frac{-L}{6}}e^{\frac{-(L+\sigma)}{2}}e^{-(y+L+\sigma)}dyd\sigma\right)\\ &\le O(1)e^{\frac{-|x|}{4}}e^{-\frac{3t}{16}}e^{\frac{-L}{4}-\frac{L}{6}}.\end{aligned}$$ □

LEMMA 3.5. *For* $-L-t \le x \le \frac{-L-t}{2}$ *and* $1<D<2$,

$$\int_0^t\int_{-L-\sigma}^{\infty}\frac{1}{(t-\sigma)}e^{\frac{-(Y-X)^2}{4D(t-\sigma)}}e^{x-y}\cdot e^{\frac{-L}{6}}e^{\frac{-(L+\sigma)}{2}}e^{-(y+L+\sigma)}dyd\sigma \le O(1)e^{\frac{x}{2}}e^{\frac{-L}{6}}.$$

Proof. The calculation is divided into two parts: For $-L-\sigma \le y < 0$,

$$\begin{aligned}&\int_0^t\int_{-L-\sigma}^{0}\frac{1}{(t-\sigma)}e^{\frac{-(Y-X)^2}{4D(t-\sigma)}}e^{x-y}\cdot e^{\frac{-L}{6}}e^{\frac{-(L+\sigma)}{2}}e^{-(y+L+\sigma)}dyd\sigma\\ &\le\int_0^t\int_{-L-\sigma}^{0}\frac{1}{(t-\sigma)}e^{\frac{-(x-y+(t-\sigma))^2}{4D(t-\sigma)}}e^{x-y}\cdot e^{\frac{-L}{6}}e^{\frac{y}{2}}dyd\sigma\\ &=\int_0^t\int_{-L-\sigma}^{0}\frac{1}{(t-\sigma)}e^{\frac{-[x-y+(1-D)(t-\sigma)]^2}{4D(t-\sigma)}}e^{\frac{x}{2}}e^{\frac{-(2-D)}{4}(t-\sigma)}dyd\sigma e^{\frac{-L}{6}}\\ &\le O(1)e^{\frac{x}{2}}e^{\frac{-L}{6}},\end{aligned}$$

and for $y \ge 0$,

$$\int_0^t\int_0^{\infty}\frac{1}{(t-\sigma)}e^{\frac{-(Y-X)^2}{4D(t-\sigma)}}e^{x-y}\cdot e^{\frac{-L}{6}}e^{\frac{-(L+\sigma)}{2}}e^{-(y+L+\sigma)}dyd\sigma$$

$$= \int_0^t \int_0^\infty \frac{1}{(t-\sigma)} e^{\frac{-(x-y)^2}{4D(t-\sigma)} - \frac{x}{2D} + \frac{y}{2D} - \frac{(t-\sigma)}{4D}} e^{x-y} \cdot e^{\frac{-L}{6}} e^{\frac{-(L+\sigma)}{2}} e^{-(y+L+\sigma)} dyd\sigma$$
$$\le O(1) e^{(1-\frac{1}{2D})x} e^{\frac{-t}{4D}} e^{-L-\frac{L}{2}-\frac{L}{6}}. \qquad \square$$

Now, we are ready to study the solution through iterations. We first estimate $\bar{w}^0(x,t)$. From the representation of $\bar{w}^0(x,t)$,

$$|\bar{w}^0(x,t)| \le O(1) \left(\int_{-L}^\infty k(x-y-t,t)|\bar{w}(y,0)|dy \right.$$
$$\left. + \int_0^t \int_{-L-\sigma}^\infty k(x-y-(t-\sigma);t-\sigma) e^{\frac{-(L+\sigma)}{2}} e^{\frac{-L}{6}} e^{-(y+L+\sigma)} dyd\sigma \right)$$
$$\le O(1) e^{\frac{x}{2}} e^{\frac{-L}{6}} \quad \text{for } -L-t \le x < \frac{-L-t}{2}.$$

Based on the relation

$$K_x^B(x,t;y,\sigma) + K_y^B(x,t;y,\sigma)$$
$$= 2K^B(x,t;y,\sigma) - 2\partial_y k(Y-X,t-\sigma) e^{(X-Y)-(t-\sigma)} \tag{3.19}$$

and the facts that $K^B(x,t;y=\infty,\sigma) = 0$ and $\bar{w}(-L,0) = 0$, by integration by parts, we have that

$$\left| \int_{-L}^\infty K_x^B(x,t;y,0)\bar{w}(y,0)dy \right|$$
$$\le O(1) \int_{-L}^\infty k(x-y-t,t)|(-\bar{w}(y,0) + \bar{w}_y(y,0))|dy$$
$$\le O(1) e^{\frac{x}{2}} e^{\frac{-t}{4}} e^{\frac{-L}{6}}.$$

From

$$K_x^B(x,t;y,\sigma) = K^B(x,t;y,\sigma)$$
$$+ \left(\frac{(Y-X)}{2(t-\sigma)} \frac{e^{\frac{-(Y-X)^2}{4(t-\sigma)}}}{\sqrt{4\pi(t-\sigma)}} + \frac{(Y+X)}{2(t-\sigma)} \frac{e^{\frac{-(Y+X)^2}{4(t-\sigma)}}}{\sqrt{4\pi(t-\sigma)}} \right) e^{x-y} \tag{3.20}$$
$$\equiv K^B(x,t;y,\sigma) + K^\star(x,t;y,\sigma)$$

and

$$|K^\star(x,t;y,\sigma)| \le O(1) \frac{1}{(t-\sigma)} e^{\frac{-(Y-X)^2}{4D(t-\sigma)}} e^{x-y}, \tag{3.21}$$

where $D > 1$ and is close to 1, we have, by Lemma 3.5,

$$\left| \int_0^t \int_{-L-\sigma}^\infty K_x^B \left[R_\sigma + \phi(y+x_0)R_y - R_{yy} + \frac{1}{2}R_y^2 \right] dyd\sigma \right|$$
$$\le O(1) \left(\int_0^t \int_{-L-\sigma}^\infty k(x-y-(t-\sigma),t-\sigma) e^{\frac{-L}{6}} e^{\frac{-(L+\sigma)}{2}} e^{-(y+L+\sigma)} dyd\sigma \right.$$
$$\left. + \int_0^t \int_{-L-\sigma}^\infty \frac{1}{t-\sigma} e^{\frac{-(Y-X)^2}{4D(t-\sigma)}} e^{x-y} e^{\frac{-L}{6}} e^{\frac{-(L+\sigma)}{2}} e^{-(y+L+\sigma)} dyd\sigma \right)$$
$$\le O(1) e^{\frac{x}{2}} e^{\frac{-L}{6}}.$$

Therefore,

$$|\bar{w}_x^0(x,t)| \le O(1)e^{\frac{x}{2}}e^{\frac{-L}{6}} \quad \text{for } -L-t \le x < \frac{-L-t}{2},$$

and, in particular,

$$|\bar{w}_x^0(-L-t,t)| \le O(1)e^{\frac{-t}{2}}e^{\frac{-L}{2}-\frac{L}{6}}.$$

Then by Lemmas 3.2, 3.3, and 3.4,

$$|\bar{w}^0(x,t)| \le O(1)\begin{cases} e^{\frac{x}{4}}e^{\frac{-3t}{16}}e^{\frac{-L}{4}-\frac{L}{6}} + e^{\frac{2x}{3}}(x+t+L+1)^{-\alpha+1}e^{\frac{-L}{2}} & \text{for } \dfrac{-L-t}{2} \le x \le 0, \\ (x+t+L+1)^{-\alpha+1}e^{\frac{-L}{4}-\frac{L}{6d}} & \text{for } x>0. \end{cases}$$

Also note that

$$\begin{aligned} \bar{g}_x + \bar{g}_y = {} & \frac{-1}{4}\frac{1}{\cosh^2((x+x_0)/2)}\frac{1}{\sqrt{4\pi(t-\sigma)}}e^{\frac{-(x-y-(t-\sigma))^2}{4(t-\sigma)}} \\ & + \frac{1}{4}\frac{1}{\cosh^2((x+x_0)/2)}\frac{1}{\sqrt{4\pi(t-\sigma)}}e^{\frac{-(x-y+(t-\sigma))^2}{4(t-\sigma)}}, \end{aligned} \tag{3.22}$$

$\bar{g}(x,t,\infty,\sigma) = 0$ and $\bar{w}(-L-t,t) = 0$. Then by Lemmas 3.2 and 3.4, (3.13), and (3.22),

$$\begin{aligned} & |\bar{w}_x^0(x,t)| \\ & \le O(1)\Bigg(\int_{-L}^{\infty} \bar{g}(x,t;y,0)|\bar{w}_y(y,0)|dy \\ & \quad + e^{-|x|}\int_{-L}^{\infty}\frac{1}{\sqrt{4\pi t}}\left(e^{\frac{-(x-y-t)^2}{4t}} + e^{\frac{-(x-y+t)^2}{4t}}\right)|\bar{w}(y,0)|dy \\ & \quad + \left|\int_0^t \bar{g}_x(x,t;-L-\sigma,\sigma)\bar{w}_y^0(-L-\sigma,\sigma)d\sigma\right| \\ & \quad + \int_0^t \bar{g}(x,t;-L-\sigma,\sigma)e^{\frac{-(L+\sigma)}{2}}e^{\frac{-L}{6}}d\sigma \\ & \quad + \int_0^t\int_{-L-\sigma}^{\infty}\bar{g}(x,t;y,\sigma)e^{\frac{-L}{6}}e^{\frac{-(L+\sigma)}{2}}e^{-(y+L+\sigma)}dyd\sigma \\ & \quad + \int_0^t\int_{-L-\sigma}^{\infty}\frac{e^{-|x|}}{\sqrt{t-\sigma}}\left(e^{\frac{-(x-y-(t-\sigma))^2}{4(t-\sigma)}} + e^{\frac{-(x-y+(t-\sigma))^2}{4(t-\sigma)}}\right) \\ & \qquad\qquad \cdot e^{\frac{-L}{6}}e^{\frac{-(L+\sigma)}{2}}e^{-(y+L+\sigma)}dyd\sigma\Bigg) \\ & \le O(1)\begin{cases} e^{\frac{-L}{4}-\frac{L}{6d}}\left[e^{\frac{-|x|}{4}}e^{\frac{-3t}{16}} + e^{\frac{-2|x|}{3}}(x+t+L+1)^{-\alpha+1}\right] & \text{for } \dfrac{-(L+t)}{2} < x \le 0, \\ e^{\frac{-L}{4}-\frac{L}{6d}}[(x+t+L+1)^{-\alpha} + e^{-|x|}(x+t+L+1)^{-\alpha+1}] & \text{for } x>0. \end{cases} \end{aligned}$$

With these, we can now formulate our main theorem.

THEOREM 3.6. *Suppose that L is sufficiently large and $\alpha > 1$. Then the solution $\bar{w}(x,t)$ for (3.6)–(3.9) satisfies*

(3.23)
$$|\bar{w}(x,t)| \le C_0 \cdot \begin{cases} e^{\frac{-|x|}{4}} e^{\frac{-t}{8}} e^{\frac{-L}{4}} + e^{\frac{-|x|}{2}} (x+t+L+1)^{-\alpha+1} e^{\frac{-L}{4}}, & -L-t \le x \le 0, \\ (x+t+L+1)^{-\alpha+1} e^{\frac{-L}{4}}, & x > 0, \end{cases}$$

(3.24)
$$|\bar{w}_x(x,t)| \le C_0 \cdot \begin{cases} e^{\frac{-|x|}{4}} e^{\frac{-t}{8}} e^{\frac{-L}{4}} + e^{\frac{-|x|}{2}} (x+t+L+1)^{-\alpha+1} e^{\frac{-L}{4}}, & -L-t \le x \le 0, \\ (x+t+L+1)^{-\alpha} e^{\frac{-L}{4}} + e^{\frac{-|x|}{3}} (x+t+L+1)^{-\alpha+1} e^{\frac{-L}{4}}, & x > 0, \end{cases}$$

where $C_0 > 0$ is a constant.

Remark 3.7. The theorem induces that the decay rate of $v(x,t) = u(x,t) - \phi(x + x_0)$ is also of the form (3.24).

Before proving the theorem, we need the following lemmas to study the nonlinear terms in the iterations.

LEMMA 3.8. *For $x \ge (-L-t)/2$,*

$$\int_0^t \int_{-L-\sigma}^0 \bar{g} e^{-|y|} (y+\sigma+L+1)^{-2\alpha+2} dy d\sigma \le O(1) \begin{cases} e^{\frac{-|x|}{2}} e^{\frac{-t}{8}} t (L+1)^{-2\alpha+2} + e^{\frac{-|x|}{2}} (x+t+L+1)^{-\alpha+1} & \text{for } \dfrac{-L-t}{2} \le x \le 0, \\ e^{\frac{-|x|}{3}} (x+t+L+1)^{-\alpha+1} & \text{for } x > 0, \end{cases}$$

$$\left| \int_0^t \int_{-L-\sigma}^0 \bar{g}_x e^{-|y|} (y+\sigma+L+1)^{-2\alpha+2} dy d\sigma \right| \le O(1) \begin{cases} e^{\frac{-|x|}{2}} e^{\frac{-t}{8}} (t+\sqrt{t}) (L+1)^{-2\alpha+2} + e^{\frac{-|x|}{2}} (x+t+L+1)^{-\alpha+1} \\ \qquad \text{for } \dfrac{-L-t}{2} \le x \le 0, \\ e^{\frac{-|x|}{3}} (x+t+L+1)^{-\alpha+1} \quad \text{for } x > 0. \end{cases}$$

Proof. Recall that $\bar{g}$ is a simple translation of g. From (2.9)

$$\begin{aligned} &\int_0^t \int_{-L-\sigma}^0 \bar{g} e^{-|y|} (y+\sigma+L+1)^{-2\alpha+2} dy d\sigma \\ &\le O(1) e^{\frac{-|x|}{2}} \int_0^t \int_{-L-\sigma}^0 \frac{e^{\frac{-(x-y)^2}{4(t-\sigma)}}}{\sqrt{4\pi(t-\sigma)}} e^{\frac{-|y|}{2}} e^{\frac{-(t-\sigma)}{4}} (y+\sigma+L+1)^{-2\alpha+2} dy d\sigma \\ &= O(1) e^{\frac{-|x|}{2}} \int_0^t \left(\int_{-L-\sigma}^{\frac{-L-\sigma}{2}} + \int_{\frac{-L-\sigma}{2}}^0 \right) \frac{e^{\frac{-(x-y)^2}{4(t-\sigma)}}}{\sqrt{4\pi(t-\sigma)}} e^{\frac{-|y|}{2}} e^{\frac{-(t-\sigma)}{4}} (y+\sigma+L+1)^{-2\alpha+2} dy d\sigma \\ &\le O(1) e^{\frac{-|x|}{2}} \int_0^t e^{\frac{-(t-\sigma)}{4}} e^{\frac{-L-\sigma}{4}} d\sigma \\ &\quad + O(1) e^{\frac{-|x|}{2}} \int_0^t e^{\frac{-(t-\sigma)}{4}} \left(\frac{L+\sigma}{2} + 1 \right)^{-2\alpha+2} d\sigma. \end{aligned}$$

This proves the first estimate. From (3.18)

$$\left|\int_0^t\int_{-L-\sigma}^0 \bar{g}_x e^{-|y|}(y+\sigma+L+1)^{-2\alpha+2}dyd\sigma\right|$$
$$\le O(1)e^{\frac{-|x|}{2}}\int_0^t\int_{-L-\sigma}^0\left(1+\frac{1}{\sqrt{t-\sigma}}\right)\frac{e^{\frac{-(x-y)^2}{4r(t-\sigma)}}}{\sqrt{t-\sigma}}e^{\frac{-|y|}{2}}e^{\frac{-(t-\sigma)}{4}}(y+\sigma+L+1)^{-2\alpha+2}dyd\sigma,$$

where $r>1$ and is close to 1. From this the second estimate follows easily. □

LEMMA 3.9. *For $x\ge(-L-t)/2$,*

$$\int_0^t\int_0^\infty \bar{g}e^{\frac{-|y|}{3}}(y+\sigma+L+1)^{-2\alpha+1}dyd\sigma$$
$$\le O(1)\begin{cases} e^{\frac{-2|x|}{3}}e^{\frac{-t}{9}}t(L+1)^{-2\alpha+1}+e^{\frac{-2|x|}{3}}(x+t+L+1)^{-\alpha} & \text{for } \dfrac{-L-t}{2}\le x\le 0,\\ e^{\frac{-|x|}{3}}(x+t+L+1)^{-\alpha} & \text{for } x>0,\end{cases}$$

$$\int_0^t\int_0^\infty \bar{g}_x e^{\frac{-|y|}{3}}(y+\sigma+L+1)^{-2\alpha+1}dyd\sigma$$
$$\le O(1)\begin{cases} e^{\frac{-2|x|}{3}}e^{\frac{-t}{9}}(t+\sqrt{t})(L+1)^{-2\alpha+1}+e^{\frac{-2|x|}{3}}(x+t+L+1)^{-\alpha}\\ \qquad\qquad \text{for } \dfrac{-L-t}{2}\le x\le 0,\\ e^{\frac{-|x|}{3}}(x+t+L+1)^{-\alpha} \quad \text{for } x>0.\end{cases}$$

Proof. Since for $x\le 0$,

$$\int_0^t\int_0^\infty \bar{g}e^{\frac{-|y|}{3}}(y+\sigma+L+1)^{-2\alpha+1}dyd\sigma$$
$$\le O(1)e^{\frac{-2|x|}{3}}\int_0^t\int_0^\infty\frac{1}{\sqrt{4\pi(t-\sigma)}}e^{\frac{-[x-y+\frac{1}{3}(t-\sigma)]^2}{4(t-\sigma)}}e^{\frac{-2(t-\sigma)}{9}}(y+\sigma+L+1)^{-2\alpha+1}dyd\sigma$$
$$\le O(1)e^{\frac{-2|x|}{3}}\left(e^{\frac{-t}{9}}t(L+1)^{-2\alpha+1}+(x+t+L+1)^{-\alpha}\right),$$

and for $x>0$,

$$\int_0^t\int_0^\infty \bar{g}e^{\frac{-|y|}{3}}(y+\sigma+L+1)^{-2\alpha+1}dyd\sigma$$
$$\le O(1)e^{\frac{-|x|}{3}}\int_0^t\int_0^\infty\frac{1}{\sqrt{4\pi(t-\sigma)}}e^{\frac{-[x-y+\frac{1}{3}(t-\sigma)]^2}{4(t-\sigma)}}e^{\frac{-2(t-\sigma)}{9}}(y+\sigma+L+1)^{-2\alpha+1}dyd\sigma$$
$$= O(1)e^{\frac{-|x|}{3}}\int_0^t\left(\int_0^{\frac{x+(t-\sigma)/3}{2}}+\int_{\frac{x+(t-\sigma)/3}{2}}^\infty\right)\frac{e^{\frac{-[x-y+\frac{1}{3}(t-\sigma)]^2}{4(t-\sigma)}}}{\sqrt{4\pi(t-\sigma)}}e^{\frac{-2(t-\sigma)}{9}}$$
$$\cdot(y+\sigma+L+1)^{-2\alpha+1}dyd\sigma$$
$$\le O(1)e^{\frac{-|x|}{3}}\left(\int_0^t e^{\frac{-[x+\frac{1}{3}(t-\sigma)]^2}{16(t-\sigma)}}e^{\frac{-2(t-\sigma)}{9}}(\sigma+L+1)^{-2\alpha+1}d\sigma\right.$$
$$\left.+\int_0^t e^{\frac{-2(t-\sigma)}{9}}(x+t+\sigma+L+1)^{-2\alpha+1}d\sigma\right)$$
$$\le O(1)e^{\frac{-|x|}{3}}(x+t+L+1)^{-\alpha},$$

the first estimate is proved. Due to (3.18),

$$\left|\int_0^t\int_0^\infty \bar g_x e^{\frac{-|y|}{3}}(y+\sigma+L+1)^{-2\alpha+1}dyd\sigma\right|$$
$$\le O(1)e^{\frac{-|x|}{3}}\int_0^t\int_0^\infty\left(1+\frac{1}{\sqrt{t-\sigma}}\right)\frac{e^{\frac{-[x-y+\frac{1}{3}(t-\sigma)]^2}{4r(t-\sigma)}}}{\sqrt{t-\sigma}}e^{\frac{-2(t-\sigma)}{9}}(y+\sigma+L+1)^{-2\alpha+1}dyd\sigma,$$

where $r>1$ and is close to 1. The second estimate then follows easily as the first. ∎

LEMMA 3.10. *For $x\ge(-L-t)/2$,*

$$\int_0^t\int_0^\infty \bar g(y+\sigma+L+1)^{-2\alpha}dyd\sigma\, e^{\frac{-L}{6}}$$
$$\le O(1)\begin{cases} e^{\frac{-|x|}{2}}e^{\frac{-t}{2}}e^{\frac{-L}{6}}+e^{\frac{-|x|}{2}}(x+t+L+1)^{-\alpha}e^{\frac{-L}{6}} & \text{for } \dfrac{-L-t}{2}\le x\le 0,\\ (x+t+L+1)^{-\alpha}e^{\frac{-L}{6}} & \text{for } x>0.\end{cases}$$
$$\int_0^t\int_0^\infty \bar g_x(y+\sigma+L+1)^{-2\alpha}dyd\sigma\, e^{\frac{-L}{6}}$$
$$\le O(1)\begin{cases} e^{\frac{-|x|}{2}}e^{\frac{-t}{2}}\sqrt{t}\,e^{\frac{-L}{6}}+e^{\frac{-|x|}{2}}(x+t+L+1)^{-\alpha}e^{\frac{-L}{6}} & \text{for } \dfrac{-L-t}{2}\le x\le 0,\\ (x+t+L+1)^{-\alpha}e^{\frac{-L}{6}} & \text{for } x>0.\end{cases}$$

Proof. For convenience, let

$$P_3\equiv\int_0^t\int_0^\infty \bar g(y+\sigma+L+1)^{-2\alpha}dyd\sigma\, e^{\frac{-L}{6}}.$$

When $-t<x\le 0$

$$P_3\le O(1)e^x\cdot\left(\int_0^{\frac{x+t}{r_1}}+\int_{\frac{x+t}{r_1}}^t\right)\int_0^\infty\frac{1}{\sqrt{4\pi(t-\sigma)}}e^{\frac{-[x+(t-\sigma)-y]^2}{4(t-\sigma)}}(y+\sigma+L+1)^{-2\alpha}dyd\sigma\, e^{\frac{-L}{6}}$$
$$\equiv O(1)(P_{31}^-+P_{32}^-),$$

where $r_1>1$, with

$$P_{31}^-=O(1)e^x\int_0^{\frac{x+t}{r_1}}\left(\int_0^{\frac{1}{r_2}(1-\frac{1}{r_1})(x+t)}+\int_{\frac{1}{r_2}(1-\frac{1}{r_1})(x+t)}^\infty\right)\frac{e^{\frac{-[x+(t-\sigma)-y]^2}{4(t-\sigma)}}}{\sqrt{4\pi(t-\sigma)}}$$
$$\cdot(y+\sigma+L+1)^{-2\alpha}dyd\sigma e^{\frac{-L}{6}}$$
$$\le O(1)e^{\frac{-|x|}{2}}(x+t+L+1)^{-\alpha}e^{\frac{-L}{6}},$$

where $r_2>1$, and

$$P_{32}^-=O(1)e^x\int_{\frac{x+t}{r_1}}^t(\sigma+L+1)^{-2\alpha}d\sigma\cdot e^{\frac{-L}{6}}$$
$$\le O(1)e^x(x+t+L+1)^{-\alpha}e^{\frac{-L}{6}}.$$

When $x \le -t$, it is obvious that

$$P_3 \le O(1)e^x e^{\frac{-L}{6}} \le O(1)e^{\frac{x}{2}} e^{\frac{-t}{2}} e^{\frac{-L}{6}}.$$

When $x > 0$, we have

$$\begin{aligned} P_3 &\le O(1)\int_0^t \left(\int_0^{\frac{x+(t-\sigma)}{2}} + \int_{\frac{x+(t-\sigma)}{2}}^{\infty} \right) \frac{e^{\frac{-[x+(t-\sigma)-y]^2}{4(t-\sigma)}}}{\sqrt{4\pi(t-\sigma)}} (y+\sigma+L+1)^{-2\alpha} dy d\sigma e^{\frac{-L}{6}} \\ &\le O(1)(x+t+L+1)^{-\alpha} e^{\frac{-L}{6}}. \end{aligned}$$

The first estimate is proved. As in the previous two lemmas, the second estimate follows due to (3.18). □

Proof of Theorem 3.6. We will prove the theorem by induction. Suppose that $\bar{w}^m(x,t)$ and $\bar{w}^m_x(x,t)$ satisfy the estimates (3.23) and (3.24) for all $m \le n$. We will show that the sequence

$$\bar{\delta}^m(x,t) \equiv \bar{w}^m(x,t) - \bar{w}^{m-1}(x,t), \quad m \ge 1,$$

is geometric in the weighted norm

$$\begin{aligned} |||h||| \equiv & \sup_{\substack{-L-t\le x\le 0 \\ t>0}} \frac{|h(x,t)|}{e^{\frac{-|x|}{4}} e^{\frac{-t}{8}} + e^{\frac{-|x|}{2}} (x+t+L+1)^{-\alpha+1}} \\ & + \sup_{\substack{x>0 \\ t>0}} \frac{|h(x,t)|}{(x+t+L+1)^{-\alpha+1}} \\ & + \sup_{\substack{-L-t\le x\le 0 \\ t>0}} \frac{|h_x(x,t)|}{e^{\frac{-|x|}{4}} e^{\frac{-t}{8}} + e^{\frac{-|x|}{2}} (x+t+L+1)^{-\alpha+1}} \\ & + \sup_{\substack{x>0 \\ t>0}} \frac{|h_x(x,t)|}{(x+t+L+1)^{-\alpha} + e^{\frac{-|x|}{3}} (x+t+L+1)^{-\alpha+1}}. \end{aligned}$$

From the estimates on $\bar{w}^0$ preceding (3.22), we have, by (3.12), for $(-L-t) \le x < (-L-t)/2$,

$$\begin{aligned} \bar{\delta}^1(x,t) = & \int_0^t \int_{-L-\sigma}^{\infty} K^B (1-\phi(y+x_0)) \bar{w}^0_y dy d\sigma \\ & - \int_0^t \int_{-L-\sigma}^{\infty} K^B \frac{(\bar{w}^0_y)^2}{2} dy d\sigma \\ & - \int_0^t \int_{-L-\sigma}^{\infty} K^B \bar{w}^0_y R_y dy d\sigma; \end{aligned}$$

for $x \ge (-L-t)/2$,

$$\begin{aligned} \bar{\delta}^1(x,t) = & - \int_0^t \bar{g}(x,t;-L-\sigma,\sigma) \bar{\delta}^1_y(-L-\sigma,\sigma) d\sigma \\ & - \int_0^t \int_{-L-\sigma}^{\infty} \bar{g} \frac{(\bar{w}^0_y)^2}{2} dy d\sigma \\ & - \int_0^t \int_{-L-\sigma}^{\infty} \bar{g} \bar{w}^0_y R_y dy d\sigma; \end{aligned}$$

for $(-L-t) \le x < (-L-t)/2$, $m \ge 1$,

$$\begin{aligned}\bar{\delta}^{m+1}(x,t) = &\int_0^t \int_{-L-\sigma}^{\infty} K^B(1-\phi(y+x_0))\bar{\delta}_y^m dyd\sigma \\ &- \int_0^t \int_{-L-\sigma}^{\infty} K^B \bar{\delta}_y^m \frac{(\bar{w}_y^m + \bar{w}_y^{m-1})}{2} dyd\sigma \\ &- \int_0^t \int_{-L-\sigma}^{\infty} K^B \bar{\delta}_y^m R_y dyd\sigma;\end{aligned}$$

for $x \ge (-L-t)/2$, $m \ge 1$,

$$\begin{aligned}\bar{\delta}^{m+1}(x,t) = &- \int_0^t \bar{g}(x,t;-L-\sigma,\sigma)\bar{\delta}_y^{m+1}(-L-\sigma,\sigma)d\sigma \\ &- \int_0^t \int_{-L-\sigma}^{\infty} \bar{g}\bar{\delta}_y^m \frac{(\bar{w}_y^m + \bar{w}_y^{m-1})}{2} dyd\sigma \\ &- \int_0^t \int_{-L-\sigma}^{\infty} \bar{g}\bar{\delta}_y^m R_y dyd\sigma.\end{aligned}$$

Region I: $\{-L-t \le x < (-L-t)/2\}$. Since

$$\left| \int_0^t \int_{-L-\sigma}^{\infty} K^B(1-\phi(y+x_0))\bar{\delta}_y^n dyd\sigma \right| \le O(1) e^{\frac{x}{2}} |||\bar{\delta}^n|||,$$

$$\left| \int_0^t \int_{-L-\sigma}^{\infty} K^B \bar{\delta}_y^n R_y dyd\sigma \right| \le O(1) e^{\frac{x}{2}} e^{\frac{-t}{8}} e^{\frac{-L}{6}} |||\bar{\delta}^n|||$$

and

$$\begin{aligned}&\left| \int_0^t \int_{-L-\sigma}^{\infty} K^B \bar{\delta}_y^n \frac{(\bar{w}_y^n + \bar{w}_y^{n-1})}{2} dyd\sigma \right| \\ &\le O(1) \left(\int_0^t \int_{-L-\sigma}^{0} K^B \left[e^{\frac{-|y|}{4}} e^{\frac{-\sigma}{8}} + e^{\frac{-|y|}{2}} (y+\sigma+L+1)^{-\alpha+1} \right]^2 e^{\frac{-L}{4}} dyd\sigma \right. \\ &\qquad \left. + \int_0^t \int_0^{\infty} K^B \left[(y+\sigma+L+1)^{-\alpha} + e^{\frac{-|y|}{3}} (y+\sigma+L+1)^{-\alpha+1} \right]^2 e^{\frac{-L}{4}} dyd\sigma \right) \\ &\cdot |||\bar{\delta}^n||| \le O(1) e^{\frac{x}{2}} e^{\frac{-L}{4}} \cdot |||\bar{\delta}^n|||,\end{aligned}$$

we have, for $-L-t \le x < (-L-t)/2$,

$$|\bar{\delta}^{n+1}(x,t)| \le O(1) e^{\frac{x}{2}} |||\bar{\delta}^n|||. \tag{3.25}$$

Moreover, similar to Lemma 3.1, we have, from (3.15) and Fubini's theorem, that

$$\bar{\delta}^m(-L-t,t) = 0 \tag{3.26}$$

for all $1 \le m \le (n+1)$. This and (3.12) mean that the boundary value and initial value are kept in the iterations.

Based on (3.20), (3.21), and straightforward calculation, we can obtain

$$\left| \int_0^t \int_{-L-\sigma}^{0} K^\star \bar{\delta}_y^n \frac{(\bar{w}_y^n + \bar{w}_y^{n-1})}{2} dyd\sigma \right|$$

$$
\begin{aligned}
&\le O(1)\left(\int_0^t\int_{-L-\sigma}^0 |K^\star| e^{\frac{-|y|}{2}} e^{\frac{-\sigma}{4}} e^{\frac{-L}{4}} dyd\sigma\right.\\
&\quad+\int_0^t\int_{-L-\sigma}^0 |K^\star|\left[e^{-|y|}(y+\sigma+L+1)^{-2\alpha+2}\right.\\
&\qquad\qquad\left.+e^{\frac{-|y|}{2}-\frac{|y|}{4}} e^{\frac{-\sigma}{8}}(y+\sigma+L+1)^{-\alpha+1}\right]\\
&\qquad\cdot e^{\frac{-L}{4}} dyd\sigma\\
&\quad+\int_0^t\int_0^\infty |K^\star|\left[(y+\sigma+L+1)^{-\alpha}\right.\\
&\qquad\qquad\left.\left.+e^{\frac{-|y|}{3}}(y+\sigma+L+1)^{-\alpha+1}\right]^2 e^{\frac{-L}{4}} dyd\sigma\right)\cdot |||\bar\delta^n|||\\
&\le O(1)e^{\frac{x}{2}} e^{\frac{-L}{4}}\cdot |||\bar\delta^n|||,
\end{aligned}
$$

$$
\left|\int_0^t\int_{-L-\sigma}^\infty K^\star(1-\phi(y+x_0))\bar\delta_y^n dyd\sigma\right| \le O(1)e^{(1-\frac{1}{2D})x}|||\bar\delta^n|||,
$$

and

$$
\left|\int_0^t\int_{-L-\sigma}^\infty K^\star\bar\delta_y^n R_y dyd\sigma\right| \le O(1)e^{(1-\frac{1}{2D})x} e^{\frac{-L}{6}}\cdot |||\bar\delta^n|||.
$$

Hence, for $-L-t\le x<(-L-t)/2$

$$
|\bar\delta_x^{n+1}(x,t)| \le O(1)e^{\frac{x}{2}} e^{\frac{-L}{6}} |||\bar\delta^n|||, \tag{3.27}
$$

and, in particular,

$$
|\bar\delta_x^{n+1}(-L-t,t)| \le O(1)e^{\frac{-t}{2}} e^{\frac{-L}{2}-\frac{L}{6}}\cdot |||\bar\delta^n|||. \tag{3.28}
$$

Region II: $\{x\ge(-L-t)/2\}$. Substituting (3.28) into the following integrals and then by Lemma 3.2, we can obtain

$$
\left|\int_0^t \bar g(x,t;-L-\sigma,\sigma)\bar\delta_y^{n+1}(-L-\sigma,\sigma)d\sigma\right| \le O(1)e^{\frac{-|x|}{4}} e^{\frac{-3t}{16}} e^{\frac{-L}{4}-\frac{L}{6}} |||\bar\delta^n|||,
$$

and

$$
\left|\int_0^t \bar g_x(x,t;-L-\sigma,\sigma)\bar\delta_y^{n+1}(-L-\sigma,\sigma)d\sigma\right| \le O(1)e^{\frac{-|x|}{4}} e^{\frac{-3t}{16}} e^{\frac{-L}{4}-\frac{L}{6}} |||\bar\delta^n|||.
$$

From Lemmas 3.8–3.10, we have, by straightforward calculations,

$$
\begin{aligned}
&\left|\int_0^t\int_{-L-\sigma}^\infty \bar g\bar\delta_y^n \frac{(\bar w_y^n+\bar w_y^{n-1})}{2} dyd\sigma\right|\\
&\le O(1)\left(\int_0^t\int_{-L-\sigma}^0 \bar g\left[e^{\frac{-|y|}{4}} e^{\frac{-\sigma}{8}}+e^{\frac{-|y|}{2}}(y+\sigma+L+1)^{-\alpha+1}\right]^2 e^{\frac{-L}{4}} dyd\sigma\right.\\
&\qquad\left.+\int_0^t\int_0^\infty \bar g\left[e^{\frac{-|y|}{3}}(y+\sigma+L+1)^{-\alpha+1}+(y+\sigma+L+1)^{-\alpha}\right]^2 e^{\frac{-L}{4}} dyd\sigma\right)\\
&\quad\cdot|||\bar\delta^n|||\\
&\le O(1)|||\bar\delta^n|||e^{\frac{-L}{6}}\begin{cases} e^{\frac{-|x|}{2}}e^{\frac{-t}{8}}+e^{\frac{-|x|}{2}}(x+t+L+1)^{-\alpha+1}, & \dfrac{-L-t}{2}<x\le 0,\\ e^{\frac{-|x|}{3}}(x+t+L+1)^{-\alpha+1}+(x+t+L+1)^{-\alpha}, & x>0,\end{cases}
\end{aligned}
$$

and $|\int_0^t \int_{-L-\sigma}^{\infty} \bar{g}_x \bar{\delta}_y^n \frac{(\bar{w}_y^n + \bar{w}_y^{n-1})}{2} dyd\sigma|$ is also bounded by the same estimates as above, and

$$\left| \int_0^t \int_{-L-\sigma}^{\infty} \bar{g} \bar{\delta}_y^n R_y dyd\sigma \right| \le O(1) e^{\frac{-|x|}{4}} e^{\frac{-3t}{16}} e^{\frac{-L}{2} - \frac{L}{6}} |||\bar{\delta}^n|||,$$
$$\left| \int_0^t \int_{-L-\sigma}^{\infty} \bar{g}_x \bar{\delta}_y^n R_y dyd\sigma \right| \le O(1) e^{\frac{-|x|}{4}} e^{\frac{-3t}{16}} e^{\frac{-L}{2} - \frac{L}{6}} |||\bar{\delta}^n|||.$$

Therefore, for $x > (-L-t)/2$,

$$|\bar{\delta}^{n+1}(x,t)|, |\bar{\delta}_x^{n+1}(x,t)| \le O(1)|||\bar{\delta}^n|||e^{\frac{-L}{6}} \cdot \begin{cases} e^{\frac{-|x|}{4}} e^{\frac{-t}{8}} + e^{\frac{-|x|}{2}} (x+t+L+1)^{-\alpha+1}, & \frac{-L-t}{2} < x \le 0, \\ e^{\frac{-|x|}{3}} (x+t+L+1)^{-\alpha+1} + (x+t+L+1)^{-\alpha}, & x > 0. \end{cases} \tag{3.29}$$

From (3.25), (3.27), and (3.29),

$$|||\bar{\delta}^{n+1}||| \le C e^{\frac{-L}{6}} |||\bar{\delta}^n|||. \tag{3.30}$$

Similar estimates also yield

$$|||\bar{\delta}^1||| \le C e^{\frac{-L}{6}} |||\bar{w}^0|||. \tag{3.31}$$

Consequently, when L is sufficiently large, $\{|||\bar{\delta}^m|||\}$ is a geometric sequence such that

$$|||\bar{w}^{n+1} - \bar{w}^0||| \le \sum_{m=1}^{n+1} |||\bar{\delta}^m||| < \frac{1}{2} |||\bar{w}^0|||, \tag{3.32}$$

which implies that $\bar{w}^{n+1}(x,t)$ and $\bar{w}_x^{n+1}(x,t)$ satisfy the required bounds. By mathematical induction, the theorem is true for all $m \in \mathbf{N}$. As a result, there exists a subsequence converging to a limit $\bar{w}(x,t)$ which is the solution of the initial-boundary problem (3.6)–(3.9). The proof is completed. □

4. Effect of nonlinearity, boundary and initial data. In Theorem 3.6, we show that there are three different convergence rates to the shock: exponential near the boundary, exponential in space and algebraic in time $(1+t)^{-\alpha+1}$ behind and near the shock, and algebraic $(1+x+L+t)^{-\alpha}$ in front of the shock. This is so when initial data decays slowly (e.g., algebraically). On the other hand, similar computations show that when initial data decays faster than $e^{-|x|}$, the solution doesn't converge in space as fast as the initial data. The convergence rate is exponential but depends on the viscosity ε and the nonlinearity, that is, the strength $2|u_-|$ of the shock. Thus, consider the initial-boundary value problem

$$u_t + uu_x = \varepsilon u_{xx}, \tag{4.1}$$
$$u(-L-t,t) = u_-, \qquad u(\infty,t) = -u_-, \tag{4.2}$$
$$u(x,0) = \phi_\varepsilon(x) + \bar{u}_\varepsilon(x), \qquad \bar{u}_\varepsilon(-L) = u_- - \phi_\varepsilon(-L), \tag{4.3}$$
$$\phi_\varepsilon(x) \equiv -u_- \tanh\left(\frac{u_- x}{2\varepsilon}\right).$$

As before, we use two different Green's functions for two divided space-time domains, respectively:

I. Near the boundary, we represent the solutions using the Green's function

$$K^{B,\varepsilon}(x,t;y,\sigma) = \frac{1}{\sqrt{4\pi\varepsilon(t-\sigma)}}\left(e^{-\frac{(x-y-u_-(t-\sigma))^2}{4\varepsilon(t-\sigma)}} - e^{-\frac{(x+y+2L-u_-t+(2+u_-)\sigma)^2}{4\varepsilon(t-\sigma)}} e^{-\left(\frac{1+u_-}{\varepsilon}\right)(y+L+\sigma)}\right)$$

of the initial-boundary value problem with viscosity $\varepsilon > 0$

$$w_t + u_- w_x = \varepsilon w_{xx},$$
$$w(-L-t,t) = 0, \qquad w(\infty,t) = 0.$$

II. In the domain which is far away from the boundary, we represent the solutions using the Green's function G^ε for the initial value problem for $w_t + (\phi_\varepsilon(x)w)_x = \varepsilon w_{xx}$:

$$G^\varepsilon(x,t;y,\sigma) = g^\varepsilon(x,t;y,\sigma) + \frac{\int_{-\infty}^{y} \sinh\left(\frac{u_-(x-\xi)}{2\varepsilon}\right) k_\varepsilon(x-\xi,t-\sigma) e^{-\frac{u_-^2(t-\sigma)}{4\varepsilon}} d\xi}{2\cosh^2\frac{u_- x}{2\varepsilon}},$$

where

$$g^\varepsilon(x,t;y,\sigma) \equiv \frac{\cosh\left(\frac{u_- y}{2\varepsilon}\right)}{\cosh\left(\frac{u_- x}{2\varepsilon}\right)} k_\varepsilon(x-y,t-\sigma) e^{-\frac{u_-^2(t-\sigma)}{4\varepsilon}}$$

is the Green's function for

$$w_t + \phi_\varepsilon(x) w_x - \varepsilon w_{xx} = 0$$

and $k_\varepsilon(x,t) \equiv e^{-\frac{x^2}{4\varepsilon t}}/\sqrt{4\pi\varepsilon t}$ is the heat kernel. Of course, we also use the Green's function $\bar{g}^\varepsilon$ for

$$w_t + \phi_\varepsilon(x + x_0^\varepsilon) w_x = \varepsilon w_{xx}$$

to represent the solution in this region, where x_0^ε is the translation and

$$\bar{g}^\varepsilon(x,t;y,\sigma) = g^\varepsilon(x + x_0^\varepsilon, t; y + x_0^\varepsilon, \sigma).$$

As before, the convergence rate is dictated by the effect of the initial data and boundary for $x \geq -(L+t)/2$:

$$\int_{-L}^{\infty} \bar{g}^\epsilon(x,t;y,0)\bar{w}_y(y,0)dy, \tag{4.4}$$

$$\int_0^t \bar{g}_x^\epsilon(x,t;-L-\sigma,\sigma)\bar{w}_y(-L-\sigma,\sigma)d\sigma, \quad \bar{w} \text{ defined as in (3.5).} \tag{4.5}$$

For the particular initial data with the critical decay

$$\bar{u}_\varepsilon(x) = \begin{cases} (u_- - \phi_\varepsilon(-L))e^{-\frac{u_-(x+L)}{\varepsilon}}, & -L \leq x \leq 0, \\ 0, & x > 0, \end{cases}$$

and therefore

$$\bar{w}_x(x,0) = O(1)\begin{cases} e^{-(\frac{u_-}{\varepsilon}L)\beta}, & -L \leq x \leq 0, \\ e^{-(\frac{u_-}{\varepsilon}L)\beta} e^{-\frac{u_-|x|}{\varepsilon}}, & x > 0, \end{cases} \qquad \text{for some } \beta \text{ between } \tfrac{1}{2} \text{ and } 1;$$

then the convergence rates in space and time are those given by the integral (4.4) and (4.5) and are of the order

$$O(1)e^{-\frac{u_-|x|}{2r\varepsilon}}e^{-\frac{u_-^2 t}{4r\varepsilon}} \quad \text{for any fixed } r > 1.$$

Assuming that the initial perturbation has faster decay, for instance, in the extreme case, is of compact support, then the solutions converge no faster than $e^{-u_-|x|/2r\varepsilon}$ in space and $e^{-u_-^2 t/4r\varepsilon}$ in time. In other words, in this case, the nonlinearity $|u_-|$ and the viscosity ε dictate the convergence rate. Note that the effects of viscosity and nonlinearity are different for space and time decay. In the limiting case of hyperbolic conservation law, $\varepsilon \to 0$, perturbation with compact support will decay to zero in finite time T, which is large when the shock strength is small. This is consistent with the above estimate in that the convergence rate is infinite in the limit $\varepsilon \to 0$. For data with either algebraic or exponential decay, the convergence of solution between the boundary and the shock,

$$O(1)e^{-\frac{u_-|x|}{2\varepsilon}}e^{-\frac{u_-^2 t}{4\varepsilon}},$$

depends solely on the nonlinearity and viscosity. This is so because of the effect of the boundary.

Acknowledgment. This work was done while the first two authors visited the Department of Mathematics, Stanford University. They would like to express their sincere gratitude for the hospitality they received there.

ON THE SOBOLEV SPACE THEORY OF PARABOLIC AND ELLIPTIC EQUATIONS IN C^1 DOMAINS*

KYEONG-HUN KIM† AND N. V. KRYLOV†

Abstract. Existence and uniqueness results are given for second-order parabolic and elliptic equations with variable coefficients in C^1 domains in Sobolev spaces with weights allowing the derivatives of solutions to blow up near the boundary. The "number" of derivatives can be negative and fractional. The coefficients of parabolic equations are only assumed to be measurable in time.

Key words. parabolic equations, C^1 domains, Sobolev spaces with weights

AMS subject classifications. 35K20, 35J15

1. Introduction.

In this article we deal with the Sobolev space theory of second-order parabolic and elliptic equations in C^1 domains. Since the boundary is not supposed to be regular enough we have to look for solutions in function spaces with weights allowing derivatives of our solutions to blow up near the boundary. In the framework of Hölder spaces such a setting leads to investigating so-called intermediate (or interior) Schauder estimates, which originated in [2]. For results about these estimates the reader is referred to [2], [4], [5] (elliptic case) and [3], [13] (parabolic case).

The main source of our interest in the Sobolev space theory comes from the theory of stochastic partial differential equations (SPDEs). There the Hölder space approach seems not to allow one to obtain results of reasonable generality. On the contrary, the Sobolev space approach works quite well. However, the Sobolev spaces without weights turn out to be trivially inappropriate. Therefore, even if we investigate SPDEs in smooth domains we need to work with weights. Then, naturally, we first need to understand what happens if we are dealing with usual parabolic equations rather than SPDEs. Interestingly, if one studies the problem under natural assumptions, then it becomes irrelevant whether the domain is C^1 or C^∞ (see Theorem 2.12). This is how we ended up with C^1 domains.

Various Sobolev spaces with weights (say, in domains with irregular boundaries or even in the whole space) and their applications to partial differential equations have long been investigated. We do not want to even try to present all relevant references, some of which can be found in [1]. The reader can find some references related to the subject of this article in the papers [9], [14], [15], and [16], the results of which are extensively used in what follows.

Our main results are stated in section 2 and consist of Theorem 2.10 and Theorem 2.14, on solvability of parabolic equations in domains and half-spaces, respectively; Theorem 2.11, treating elliptic equations; and Theorem 2.12, allowing us to reduce the case of general C^1 domains to the case of C^∞ domains. Notice that in Theorem 2.10 we consider only bounded domains; however, actually, the result is

†127 Vincent Hall, University of Minnesota, Minneapolis, MN 55455 (khkim@math.umn.edu, krylov@math.umn.edu).

also true for the domains Ω which are uniformly C^1 smooth in a natural sense. It is assumed usually in the L_p-theory of parabolic equations that the leading coefficients are continuous in the closure of the domain. In our results the coefficients are only assumed to be measurable in t and may substantially oscillate near the boundary.

In section 3 we prove some auxiliary results, and in section 4 the solvability in half-spaces is investigated and Theorem 2.14 is proved. Then in section 5, Theorems 2.10 and 2.11 are proved. The final section, section 6, is devoted to the proof of Theorem 2.12.

It is certainly worth saying that formally speaking, at least under heavier smoothness assumptions on the domain, the continuity of leading coefficients, and the rate with which lower order coefficients are allowed to grow near the boundary, Theorem 2.10 can be obtained from Theorem 4.1 of [14] after deleting all stochastic terms and then claiming that in this situation the restriction $p \geq 2$ can be relaxed to $p > 1$. However, while reading somewhat sketchy proofs in [14] we came to the conclusion that the argument based on renormalization of spaces may be wrong. This is why we decided to give independent proofs in a more general situation but only for the deterministic case. SPDEs will be considered in a subsequent article.

In this paper, as usual $\mathbb{R}^d$ stands for the Euclidean space of points $x = (x^1, \dots, x^d)$, $B_r(x) = \{y \in \mathbb{R}^d : |x-y| < r\}$, $B_r = B_r(0)$, $\mathbb{R}^d_+ = \{x \in \mathbb{R}^d : x^1 > 0\}$. For $i = 1, \dots, d$, multi-indices $\alpha = (\alpha_1, \dots, \alpha_d)$, $\alpha_i \in \{0, 1, 2, \dots\}$, and functions $u(x)$ we set

$$u_{x^i} = \partial u / \partial x^i = D_i u, \quad D^\alpha u = D_1^{\alpha_1} \times \cdots \times D_d^{\alpha_d} u, \quad |\alpha| = \alpha_1 + \cdots + \alpha_d.$$

2. Main results. Let Ω be an open set in $\mathbb{R}^d$, $\Omega \neq \mathbb{R}^d$. First, we consider the equation

$$u_t(t,x) = a^{ij}(t,x) u_{x^i x^j}(t,x) + b^i(t,x) u_{x^i}(t,x) + c(t,x) u(t,x) + f(t,x) \tag{2.1}$$

given for $x \in \Omega$, $t \geq 0$.

Take an increasing function $\omega_0(\varepsilon)$ defined on $[0, \infty)$ and such that $\omega_0(\varepsilon) \downarrow 0$ as $\varepsilon \downarrow 0$. Also take some numbers $r_0, K_0 \in (0, \infty)$.

Assumption 2.1. The domain Ω is of class C^1_u. In other words, for any $x_0 \in \partial\Omega$, there exists a one-to-one continuously differentiable mapping Ψ of $B_{r_0}(x_0)$ onto a domain $G \subset \mathbb{R}^d$ such that

(i) $G_+ := \Psi(B_{r_0}(x_0) \cap \Omega) \subset \mathbb{R}^d_+$ and $\Psi(x_0) = 0$;
(ii) $\Psi(B_{r_0}(x_0) \cap \partial\Omega) = G \cap \{y \in \mathbb{R}^d : y^1 = 0\}$;
(iii) $\|\Psi\|_{C^1(B_{r_0}(x_0))} \leq K_0$ and $|\Psi^{-1}(y_1) - \Psi^{-1}(y_2)| \leq K_0 |y_1 - y_2|$ for any $y_i \in G$;
(iv) for $x_1, x_2 \in B_{r_0}(x_0)$, we have $|\Psi_x(x_1) - \Psi_x(x_2)| \leq \omega_0(|x_1 - x_2|)$.

To state our assumptions on a, b, c we introduce the following notation. Set

$$\rho(x) = \rho_\Omega(x) = \operatorname{dist}(\mathrm{x}, \partial\Omega), \quad \rho(\mathrm{x}, \mathrm{y}) = \rho_\Omega(\mathrm{x}, \mathrm{y}) = \rho(\mathrm{x}) \wedge \rho(\mathrm{y})$$

and according to [2] and [5] for $\sigma \in \mathbb{R}$, $\alpha \in (0,1)$, and $k = 0, 1, 2, \dots$ introduce

$$[f]^{(\sigma)}_k = [f]^{(\sigma)}_{k,\Omega} = \sup_{|\beta|=k} \sup_{x \in \Omega} \rho^{k+\sigma}(x) |D^\beta f(x)|,$$

$$[f]^{(\sigma)}_{k+\alpha} = [f]^{(\sigma)}_{k+\alpha,\Omega} = \sup_{|\beta|=k} \sup_{x,y \in \Omega} \rho^{k+\alpha+\sigma}(x,y) \frac{|D^\beta f(x) - D^\beta f(y)|}{|x-y|^\alpha}, \tag{2.2}$$

$$|f|^{(\sigma)}_k = |f|^{(\sigma)}_{k,\Omega} = \sum_{j=0}^k [f]^{(\sigma)}_{j,\Omega}, \quad |f|^{(\sigma)}_{k+\alpha} = |f|^{(\sigma)}_{k+\alpha,\Omega} = |f|^{(\sigma)}_{k,\Omega} + [f]^{(\sigma)}_{k+\alpha,\Omega}.$$

Remark 2.2. We did not specify what kind of derivatives are $D^\beta f$. These are either classical derivatives or Sobolev ones. In the latter case, of course, instead of sup we should have used ess sup. Also, it is worth pointing out that the norms $|\cdot|_\gamma^{(\sigma)}$ introduced for all $\gamma \geq 0$ and $\sigma \in \mathbb{R}$ possess quite peculiar properties if γ is not an integer and $\gamma+\sigma < 0$. In that case, for instance, $[f]_\gamma^{(\sigma)} = \infty$ unless $D^\beta f \equiv 0$ whenever $|\beta| = [\gamma]$, so that it may happen that $|f|_\nu^{(\sigma)} < \infty$ for a $\nu > \gamma$ but $|f|_\gamma^{(\sigma)} = \infty$.

We also fix a function $\delta_0(\tau) \geq 0$ defined on $[0,\infty)$ such that $\delta_0(\tau) > 0$ unless $\tau \in \{0,1,2,\ldots\}$. For $\tau \geq 0$ define

$$\tau+ = \tau + \delta_0(\tau).$$

Finally, fix some constants

$$\delta, K \in (0,\infty), \quad \gamma \in \mathbb{R}, \quad p \in (1,\infty).$$

Assumption 2.3. (i) The functions a, b, c are Borel measurable in (t,x), $a^{ij} = a^{ji}$.

(ii) For any $t > 0, x \in \Omega$, and $\lambda \in \mathbb{R}^d$,

$$\delta|\lambda|^2 \leq a^{ij}(t,x)\lambda^i\lambda^j \leq K|\lambda|^2. \tag{2.3}$$

(iii) For each $t > 0$,

$$|a(t,\cdot)|_{|\gamma|+}^{(0)} + |b(t,\cdot)|_{|\gamma|+}^{(1)} + |c(t,\cdot)|_{|\gamma|+}^{(2)} \leq K.$$

Assumption 2.4. (i) The function $a(t,\cdot)$ is continuous at any point $x \in \Omega$ uniformly with respect to t.

(ii) There is a control on the behavior of a, b, and c near $\partial\Omega$, namely,

$$\lim_{\substack{\rho(x)\to 0,\\ x\in\Omega}} \sup_{\substack{y\in\Omega,\\ |x-y|\leq\rho(x,y)}} \sup_t |a(t,x)-a(t,y)| = 0. \tag{2.4}$$

$$\lim_{\substack{\rho(x)\to 0,\\ x\in\Omega}} \sup_t [\rho(x)|b(t,x)| + \rho^2(x)|c(t,x)|] = 0.$$

Remark 2.5. Equation (2.4) has very little to do with the uniform continuity of a in Ω (which is assumed, for instance, in [14]) and, for that matter, even with its pointwise continuity. For instance, if $\delta \in (0,1)$, $d = 1$, and $\Omega = \mathbb{R}_+$, then the function $a(x)$ equal to $2 + \sin(|\ln x|^\delta)$ for $0 < x \leq 1/2$ satisfies (2.4).

Indeed, if $x, y > 0$ and $|x-y| \leq x \wedge y$, then

$$|a(x) - a(y)| = |x-y||a'(\xi)|,$$

where ξ lies between x and y. In addition, $|x-y| \leq x \wedge y \leq \xi \leq 2(x \wedge y)$, and $\xi|a'(\xi)| \leq |\ln[2(x \wedge y)]|^{\delta-1} \to 0$ as $x \wedge y \to 0$. The function $a(x)$ also satisfies Assumption 2.3 for any γ if we change it appropriately for $x > 1/2$.

To proceed further we state a version of well-known results from [4] and [12], which we discuss in section 6.

LEMMA 2.6. *There is a bounded real-valued function ψ defined in $\bar\Omega$ such that*

(i) *$\psi(x) > 0$ in Ω, $\psi = 0$ on $\partial\Omega$, and for any $\varepsilon > 0$ the function ψ is bounded away from zero on the set $\{x \in \Omega : \rho(x) \geq \varepsilon\}$;*

(ii) *ψ_x is uniformly continuous in $\bar\Omega$, and $|\psi_x(x)| \geq 1$ on $\partial\Omega$;*

(iii) *for any multi-index* α *we have*

$$\sup_{\Omega} \rho^{|\alpha|}(x)|D^{\alpha}\psi_x(x)| < \infty.$$

(iv) *for any multi-index* $\alpha \neq 0$ *we have* $\rho^{|\alpha|}(x)|D^{\alpha}\psi_x(x)| \to 0$ *as* $x \in \Omega$ *and* $\rho(x) \to 0$.

Remark 2.7. In the part of a neighborhood of $\partial\Omega$ lying in Ω the functions ψ and ρ are comparable in the following sense.

For $x \in \Omega$, the ratio $\psi(x)/\rho(x)$ equals $\psi_{x^i}(\xi)\tau^i$, where $\tau^i = (x^i - x_0^i)/|x - x_0|$, x_0 is one of the closest points to x on $\partial\Omega$, and ξ is a point between x and x_0. It follows from (iii) that $\psi(x) \leq N\rho(x)$, where N is independent of x. On the other hand, (ii) implies that

$$\psi_{x^i}(\xi)\tau^i = \psi_{x^i}(x_0)\tau^i + o(|x - x_0|) = |\psi_x(x_0)| + o(|x - x_0|) \geq 1 + o(|x - x_0|).$$

It follows that, if $\rho(x)$ is small enough, then $\rho(x) \leq 2\psi(x)$. Thus, there exists an $\varepsilon > 0$ such that in $\{x \in \Omega : \rho(x) \leq \varepsilon\}$ we have $(1/2)\rho(x) \leq \psi(x) \leq N\rho(x)$.

Also notice that the functions ψ and ρ are comparable in Ω if Ω is bounded. Therefore, in many situations one can interchange $\psi(x)$ and $\rho(x)$. An advantage of using ψ on some occasions is that this function is infinitely differentiable. For instance, we prove the following fact in section 3.

LEMMA 2.8. *Let* ψ *be a function as in Lemma* 2.6 *and let* Ω *be bounded. Let* $\mu \in \mathbb{R}$, $\tau \geq 0$, $\kappa \leq \sigma$, *and either* $\sigma + [\tau] \geq 0$ *or* $\tau \in \{0, 1, 2 \ldots\}$. *Then* (i) $|\psi^{-\kappa}|_{\tau}^{(\sigma)} < \infty$; (ii) *for any function* a *we have* $|a|_{\tau}^{(\sigma)} \leq N|\psi^{\sigma}a|_{\tau}^{(0)}$ *and* $|\psi^{\mu}a|_{\tau}^{(\sigma)} \leq N|a|_{\tau}^{(\mu+\sigma)}$, *where* N *is independent of* a.

To describe the assumptions on f we use the Banach spaces introduced in [15]. Let $\xi \in C_0^{\infty}(\mathbb{R}_+)$ be a function satisfying

$$\sum_{n=-\infty}^{\infty} \xi(e^{n+t}) > 0 \quad \forall t \in \mathbb{R}. \tag{2.5}$$

For $x \in \Omega$ and $n \in \mathbb{Z} = \{0, \pm 1, \ldots\}$ define

$$\zeta_n(x) = \xi(e^n\psi(x)).$$

Observe that, due to (2.5), we have $\sum_n \zeta_n \geq \text{const} > 0$ in Ω. Also in Ω by virtue of Lemma 2.6(i)–(iii) we have

$$\zeta_n \in C_0^{\infty}(\Omega), \quad |D^m\zeta_n(x)| \leq Ne^{mn}, \tag{2.6}$$

where N is independent of n and x. For any distribution u on Ω, the first relation in (2.6) allows us to define $u\zeta_n$ as a distribution on $\mathbb{R}^d$ (equal to zero outside of Ω).

Now, for $\theta, \gamma \in \mathbb{R}$, let $H_{p,\theta}^{\gamma}(\Omega)$ be the set of all distributions u on Ω such that

$$\|u\|_{H_{p,\theta}^{\gamma}(\Omega)}^p := \sum_{n \in \mathbb{Z}} e^{n\theta}\|\zeta_{-n}(e^n\cdot)u(e^n\cdot)\|_{H_p^{\gamma}}^p < \infty, \tag{2.7}$$

where $H_p^{\gamma} = (1 - \Delta)^{-\gamma/2}L_p(\mathbb{R}^d, dx)$.

Remark 2.9. It is known (see, for instance, [15]) that up to equivalent norms the space $H_{p,\theta}^{\gamma}(\Omega)$ is independent of the choice of ξ and ψ if Ω is bounded and, if γ is a

nonnegative integer, then $H^\gamma_{p,\theta}(\Omega)$ is the space of all distributions u on Ω such that $\rho^{|\alpha|+(\theta-d)/p}D^\alpha u \in L_p(\Omega, dx)$, $|\alpha| \le \gamma$, provided with a natural norm.

For convenience we may assume that $\xi(t) = 0$ if $t \le \sup_\Omega \psi$. In that case $\zeta_n = 0$ for $n \le 0$ and the sum in (2.7) can be taken only over $n \le -1$.

Denote

$$\mathbb{H}^\gamma_{p,\theta}(\Omega, T) = L_p((0,T), H^\gamma_{p,\theta}(\Omega)), \quad U^\gamma_{p,\theta}(\Omega) = \psi^{1-2/p}H^{\gamma-2/p}_{p,\theta}(\Omega),$$

and by $\mathfrak{H}^\gamma_{p,\theta}(\Omega, T)$ we denote the space of all functions $u \in \psi\mathbb{H}^\gamma_{p,\theta}(\Omega, T)$ such that, for some $u_0 \in U^\gamma_{p,\theta}(\Omega)$ and $f \in \psi^{-1}\mathbb{H}^{\gamma-2}_{p,\theta}(\Omega, T)$, we have

$$(u(t), \phi) = (u_0, \phi) + \int_0^t (f(s), \phi)\, ds \quad \forall t \le T, \phi \in C_0^\infty(\Omega).$$

Naturally, we denote $u_t = f$ and $u(0) = u_0$. The norm in $\mathfrak{H}^\gamma_{p,\theta}(\Omega, T)$ is introduced by

$$\|u\|_{\mathfrak{H}^\gamma_{p,\theta}(\Omega,T)} = \|\psi^{-1}u\|_{\mathbb{H}^\gamma_{p,\theta}(\Omega,T)} + \|\psi u_t\|_{\mathbb{H}^{\gamma-2}_{p,\theta}(\Omega,T)} + \|u(0)\|_{U^\gamma_{p,\theta}(\Omega)}.$$

Finally, let $\mathfrak{H}^\gamma_{p,\theta,0}(\Omega, T) = \mathfrak{H}^\gamma_{p,\theta}(\Omega, T) \cap \{u : u(0) = 0\}$.

From this point on, we assume that

$$d - 1 < \theta < d - 1 + p.$$

Here is our first main result.

THEOREM 2.10. *Let Ω be bounded and $T \in [0, \infty)$. Then under the above assumptions,*

(i) *for any $f \in \psi^{-1}\mathbb{H}^\gamma_{p,\theta}(\Omega, T)$ and $u_0 \in U^{\gamma+2}_{p,\theta}(\Omega)$, (2.1) with initial data u_0 admits a unique solution u in the class $\mathfrak{H}^{\gamma+2}_{p,\theta}(\Omega, T)$;*

(ii) *for this solution*

$$\|\psi^{-1}u\|_{\mathbb{H}^{\gamma+2}_{p,\theta}(\Omega,T)} \le Ne^{NT}\left(\|u_0\|_{U^{\gamma+2}_{p,\theta}(\Omega)} + \|\psi f\|_{\mathbb{H}^\gamma_{p,\theta}(\Omega,T)}\right), \tag{2.8}$$

where the constant N is independent of T, f, and u_0.

The following theorem is obtained in section 5 rather easily from Theorem 2.10. It extends Theorem 5.1 of [15], in which there is the requirement that $c \le -c_0/\rho(x)$ with a sufficiently large constant c_0. On the other hand, it should be noted that in [15] there are no restrictions on θ and no assumptions on the smoothness of Ω.

THEOREM 2.11. *Let Ω be bounded and the above assumptions be satisfied. Let a, b, c be independent of t and let c_0 be a sufficiently large constant (actually, any constant bigger than N from (2.8)). Then for any $f \in \psi^{-1}H^\gamma_{p,\theta}(\Omega)$ there is a unique $u \in \psi H^{\gamma+2}_{p,\theta}(\Omega)$ such that, in Ω,*

$$a^{ij}u_{x^ix^j} + b^iu_{x^i} + (c - c_0)u + f = 0. \tag{2.9}$$

Furthermore,

$$\|\psi^{-1}u\|_{H^{\gamma+2}_{p,\theta}(\Omega)} \le N\|\psi f\|_{H^\gamma_{p,\theta}(\Omega)}, \tag{2.10}$$

where the constant N is independent of f.

One of important ingredients in the proof of Theorem 2.10 is the following result, which allows us to reduce the case of general C^1 domains to the case of C^∞ domains. For $\varepsilon > 0$ set

$$\Omega_\varepsilon = \{x \in \Omega : \psi(x) > \varepsilon\}.$$

THEOREM 2.12. *There is an $\varepsilon > 0$ and a C^∞ diffeomorphism $\mu : \Omega_\varepsilon \to \Omega$ such that, for $\nu = \mu^{-1}$,*

(i) *the functions μ_x and ν_x are uniformly continuous in Ω_ε and Ω, respectively;*

(ii) *for any $n = 0, 1, 2, \dots$, we have $|\mu_x|^{(0)}_{n,\Omega_\varepsilon} + |\nu_x|^{(0)}_{n,\Omega} < \infty$;*

(iii) *for any multi-index $\alpha \neq 0$ we have $(\psi(x) - \varepsilon)^{|\alpha|} D^\alpha \mu_x(x) \to 0$ as $x \in \Omega_\varepsilon$ and $\psi(x) - \varepsilon \downarrow 0$;*

(iv) *for any multi-index $\alpha \neq 0$ we have $\rho^{|\alpha|} D^\alpha \nu_x(x) \to 0$ as $x \in \Omega$ and $\rho(x) \downarrow 0$;*

(v) *in the part of a neighborhood of $\partial\Omega_\varepsilon$ lying in Ω_ε we have $\psi(\mu(x)) = \psi(x) - \varepsilon$;*

(vi) *if Ω is bounded, then $\rho_\Omega \leq N \rho_{\Omega_\varepsilon}(\nu)$ in Ω and $\rho_{\Omega_\varepsilon} \leq N \rho_\Omega(\mu)$ in Ω_ε, where N is a finite constant.*

The proof of Theorem 2.10 is also based on the following result for $\mathbb{R}^d_+$. Below, the spaces $H^\gamma_{p,\theta}$, $\mathbb{H}^\gamma_{p,\theta}(T)$, and $\mathfrak{H}^\gamma_{p,\theta}(T)$ are taken from [9]. They are defined on the basis of (2.7), where we formally take $\Omega = \mathbb{R}^d_+$ and $\psi(x) = x^1$, so that $\zeta_{-n}(e^n x) = \xi(x^1) =: \zeta(x)$ and

$$\|u\|^p_{H^\gamma_{p,\theta}} := \sum_{n \in \mathbb{Z}} e^{n\theta} \|u(e^n \cdot)\zeta\|^p_{H^\gamma_p} < \infty.$$

As in [9] by M^α we denote the operator of multiplying by $(x^1)^\alpha$ and $M = M^1$.

Remark 2.13 (see [9]). If $\gamma = 0, 1, 2, \dots$, then $\|u\|^p_{H^\gamma_{p,\theta}}$ is equivalent to

$$\sum_{|\alpha| \leq \gamma} \int_{\mathbb{R}^d_+} (x^1)^{\theta - d} |(x^1)^{|\alpha|} D^\alpha u(x)|^p \, dx.$$

THEOREM 2.14. *Let $\Omega = \mathbb{R}^d_+$, $\omega \in (0, \infty)$, $T \in (0, \infty]$. Drop Assumption 2.4 and instead suppose that*

$$|a(t,x) - a(t,y)| + x^1 |b(t,x)| + (x^1)^2 |c(t,x)| \leq \omega$$

whenever $t > 0$, $x, y \in \Omega$, and $|x - y| \leq x^1 \wedge y^1$. Suppose that all other assumptions are satisfied.

Then there exists an $\omega_0 \in (0,1)$ depending only on δ, p, θ, γ, $|\gamma|+$, and K, such that, if $\omega \leq \omega_0$, then

(i) *for any $f \in M^{-1}\mathbb{H}^\gamma_{p,\theta}(T)$ and $u_0 \in U^{\gamma+2}_{p,\theta}$, (2.1) with initial data u_0 admits a unique solution u in the class $\mathfrak{H}^{\gamma+2}_{p,\theta}(T)$;*

(ii) *for this solution*

$$\|M^{-1}u\|_{\mathbb{H}^{\gamma+2}_{p,\theta}(T)} \leq N \left(\|u_0\|_{U^{\gamma+2}_{p,\theta}} + \|Mf\|_{\mathbb{H}^\gamma_{p,\theta}(T)} \right), \tag{2.11}$$

where the constant N depends only on $p, \delta, \theta, \gamma$, $|\gamma|+$, and K.

3. Auxiliary results. The goal of this section is to write multidimensional versions of the results of section 3 in [6] and to develop certain techniques for dealing with the norms $|\cdot|^{(\sigma)}_\gamma$. In the following lemma, no restriction on θ is needed. One can prove

that its statement also holds true if one replaces $\mathbb{R}^d_+$ and $H^\gamma_{p,\theta}$ with Ω and $H^\gamma_{p,\theta}(\Omega)$, respectively. However, such a modification is of no use for us because we needed the lemma as it is stated and the norms in $H^\gamma_{p,\theta}(\mathbb{R}^d_+)$ and $H^\gamma_{p,\theta}$ are not equivalent (since ψ is bounded).

LEMMA 3.1. *Let constants $C, \delta \in (0,\infty)$, a function $u \in H^\gamma_{p,\theta}$, and q be the smallest integer such that $|\gamma| + 2 \le q$.*

(i) *Let $\eta_k \in C^\infty(\mathbb{R}^d_+)$, $k = 1, 2, \dots$, satisfy*

$$\sum_k M^{|\alpha|} |D^\alpha \eta_k| \le C \quad in \quad \mathbb{R}^d_+ \tag{3.1}$$

for any multi-index α such that $0 \le |\alpha| \le q$. Then

$$\sum_k \|\eta_k u\|^p_{H^\gamma_{p,\theta}} \le N C^p \|u\|^p_{H^\gamma_{p,\theta}},$$

where the constant N is independent of u, θ, and C.

(ii) *If in addition to the condition in* (i)

$$\sum_k \eta_k^2 \ge \delta \quad on \quad \mathbb{R}^d_+, \tag{3.2}$$

then

$$\|u\|^p_{H^\gamma_{p,\theta}} \le N \sum_k \|\eta_k u\|^p_{H^\gamma_{p,\theta}}, \tag{3.3}$$

where the constant N is independent of u and θ.

Proof. (i) One may assume that $C = 1$ because one can replace η_k with η_k/C. Then since different functions ξ generate equivalent norms, we have

$$\sum_k \|\eta_k u\|^p_{H^\gamma_{p,\theta}} \le N \sum_n e^{n\theta} \sum_k \|u(e^n\cdot)\zeta\eta_{kn}\|^p_{H^\gamma_p},$$

where $\eta_{kn} = \eta_k(e^n\cdot)\zeta$. Furthermore, observe that by the Leibniz rule

$$I_{n\alpha} := \sum_k |D^\alpha \eta_{kn}(x)| \le N \sum_k \sum_{|\beta|+|\gamma|=|\alpha|} e^{n|\beta|} |D^\beta \eta_k|(e^n x)\, |D^\gamma \zeta(x)|$$

and that on the support of ζ we have $e^{n|\beta|} \le N(e^n x^1)^{|\beta|}$. Then, upon recalling (3.1), we see that $I_{n\alpha}$ are bounded by a constant independent of $x \in \mathbb{R}^d$, $n \in \mathbb{Z}$, and α such that $|\alpha| \le q$.

It follows by Theorem 2.1 and Remark 2.1 of [7] that, for each n,

$$\sum_k \|u(e^n\cdot)\zeta\eta_{kn}\|^p_{H^\gamma_p} \le N \|u(e^n\cdot)\zeta\|^p_{H^\gamma_p}.$$

Formally speaking, to use Theorem 2.1 in [7], we need condition (3.1) to be satisfied for all multi-indices α rather than only such that $|\alpha| \le q$. That it suffices to dominate these quantities for $|\alpha| \le q$ follows by inspecting the argument in [7]. Hence,

$$\sum_k \|\eta_k u\|^p_{H^\gamma_{p,\theta}} \le N \sum_n e^{n\theta} \|u(e^n\cdot)\zeta\|^p_{H^\gamma_p} \le N \|u\|^p_{H^\gamma_{p,\theta}}.$$

This proves (i) and allows us to use the same argument as in Remark 2.1 of [7]. Assertion (i) means that the operator mapping $u \in H^\gamma_{p,\theta}$ into $(\eta_k u, k = 1, 2, \ldots) \in \ell_p(H^\gamma_{p,\theta})$ is bounded. Its dual is also bounded, which means that (due to the arbitrariness of p, γ, θ we do not use new parameters for dual spaces) if $\sum_k \|g_k\|^p_{H^\gamma_{p,\theta}} < \infty$, then $\sum_k \eta_k g_k \in H^\gamma_{p,\theta}$ and

$$\left\| \sum_k \eta_k g_k \right\|^p_{H^\gamma_{p,\theta}} \leq N \sum_k \|g_k\|^p_{H^\gamma_{p,\theta}}. \tag{3.4}$$

Under the condition in (ii), it turns out that here in place of η_k one can take $\tilde{\eta}_k := \eta_k/\bar{\eta}$, where $\bar{\eta} = \sum_i \eta_i^2$. Indeed, it is easy to deduce from (3.1) and the inequality $\sum |ab| \leq \sum |a|(\sum |b|)$ that $M^{|\alpha|} D^\alpha \bar{\eta}$ is bounded if $0 \leq |\alpha| \leq q$. Then one gets the same property for $1/\bar{\eta}$ by relying on (3.2). This makes it clear that $\tilde{\eta}_k$ satisfy (3.1) with certain C. Finally, by taking $\tilde{\eta}_k = \eta_k / \sum_i \eta_i^2$ and $\eta_k u$ in place of η_k and g_k, respectively, in (3.4) we get (3.3). The lemma is proved.

Remark 3.2. In Lemma 3.1 we assumed that $u \in H^\gamma_{p,\theta}$. In this connection it is important to observe that the above proof shows also that if the right-hand side of (3.3) is finite, then $u \in H^\gamma_{p,\theta}$.

Notice that the first inequality in (3.5) below is written for η_k^4 and not for η_k^2 as in Lemma 3.1. The purpose of this is to have the possibility to apply Lemma 3.1 to η_k^2 in place of η_k. In this connection it is useful to have in mind that $\sum |ab| \leq \sum |a|(\sum |b|)$ and $\sum a^2 \leq (\sum |a|)^2$.

LEMMA 3.3. *For each $\varepsilon > 0$ and $q = 1, 2, \ldots$ there exist nonnegative functions $\eta_k \in C_0^\infty(\mathbb{R}^d_+)$, $k = 1, 2, \ldots$, such that* (i) *on $\mathbb{R}^d_+$ for each multi-index α with $1 \leq |\alpha| \leq q$ we have*

$$\sum_k \eta_k^4 \geq 1, \quad \sum_k \eta_k \leq N(d), \quad \sum_k M^{|\alpha|} |D^\alpha \eta_k| \leq \varepsilon; \tag{3.5}$$

(ii) *for any k and $x, y \in \operatorname{supp} \eta_k$ we have $|x - y| \leq N(x^1 \wedge y^1)$, where $N = N(d, q, \varepsilon) \in [1, \infty)$.*

Proof. Let

$$\mathbb{R}^{d-1} = \bigcup_{k=1}^\infty Q_k$$

be a decomposition of $\mathbb{R}^{d-1}$ into disjoint unit cubes Q_k. Mollify the indicator function of each Q_k in such a way that thus obtained function χ_k vanish outside of the twice dilated Q_k (naturally, with center of dilation being that of Q_k). Then

$$\delta \leq \sum_k \chi_k^2 \leq \left(\sum_k \chi_k \right)^2 \leq N$$

on $\mathbb{R}^{d-1}$ for some constants $\delta, N \in (0, \infty)$ depending only on d. Furthermore, by Lemma 3.2 of [6] there exists a nonnegative function $\xi \in C_0^\infty(\mathbb{R}_+)$ such that assertion (i) of the present lemma holds for $d = 1$ with the collection $\{\xi(e^n x) : n \in \mathbb{Z}\}$ in place of $\{\eta_k(x) : k = 1, 2, \ldots\}$.

Then write $x=(x^1,x')$, fix a constant $r\in(0,1)$ to be specified later, and introduce

$$\tau_k(x')=\chi_k(rx'),\quad \eta_{nk}(x)=\xi(e^nx^1)\tau_k(e^nx').$$

Then (first sum with respect to k)

$$\delta\leq\sum_{n,k}\eta_{nk}^4\leq\left(\sum_{n,k}\eta_{nk}\right)^4\leq N \tag{3.6}$$

on $\mathbb{R}^d_+$ for some constants $\delta,N\in(0,\infty)$ depending only on d.

Now, for $1\leq|\alpha|\leq q$ and some constants $c_{\beta\gamma}$, we have

$$M^{|\alpha|}D^\alpha\eta_{nk}(x)=(x^1)^{|\alpha|}e^{n|\alpha|}\sum_{\beta+\gamma=\alpha}c_{\beta\gamma}\xi^{(\beta_1)}(e^nx^1)(D^\gamma\tau_k)(e^nx').$$

Hence,

$$\sum_{n,k}|M^{|\alpha|}D^\alpha\eta_{nk}(x)|\leq\sum_{\beta+\gamma=\alpha}c_{\beta\gamma}I_1(\gamma)I_2(\alpha,\beta),$$

where

$$I_1(\gamma)=\sup_{x'}\sum_k|D^\gamma\tau_k(x')|=r^{|\gamma|}\sup_{x'}\sum_k|D^\gamma\chi_k(x')|,$$

$$I_2(\alpha,\beta)=\sup_{t\geq0}\sum_n t^{|\alpha|}e^{n|\alpha|}|\xi^{(\beta_1)}(e^nt)|=\sup_{t\in\mathbb{R}}\sum_n e^{(n+t)|\alpha|}|\xi^{(\beta_1)}(e^{n+t})|.$$

Obviously I_1 is finite. That I_2 is also finite is seen from its representation as the supremum of a continuous 1-periodic function. Moreover, if $\gamma=0$, then $c_{\beta\gamma}\neq0$ only if $\beta_1=|\alpha|$, in which case $c_{\beta\gamma}=1$ and, by the construction of ξ, we have $I_2(\alpha,\beta)\leq\varepsilon$. It follows that

$$\sum_{n,k}|M^{|\alpha|}D^\alpha\eta_{nk}(x)|\leq N(d)\varepsilon+N(\varepsilon,q,d)r. \tag{3.7}$$

We renumber the set $\{\eta_{kn}:n=0,\pm1,\dots,k=1,2,\dots\}$ and write it as $\{\eta_k:k=1,2,\dots\}$. Then from (3.7) we see how to choose r to satisfy the last inequality in (3.5) with $N(d)\varepsilon$ in place of ε.

Equation (3.6) shows that $N(d)\eta_k$, with an appropriate $N(d)$, satisfy the first two inequalities in (3.5). However, ε in (3.5) will be replaced with $N(d)\varepsilon$. This is, of course, irrelevant since from the very beginning we could take a smaller constant instead of ε. This proves (i).

To prove (ii) notice that if $x,y\in\operatorname{supp}\eta_{0k}$, then $x^1,y^1\in\operatorname{supp}\xi$ and x^1,y^1 are separated away from zero and bounded above, whereas $x',y'\in\operatorname{supp}\tau_k$, so that $|x'-y'|$ is bounded above independently of k. In that case $|x-y|\leq N(d,q,\varepsilon)(x^1\wedge y^1)$. This relation is dilation invariant and therefore holds for any n,k, and $x,y\in\operatorname{supp}\eta_{nk}$. The lemma is proved.

LEMMA 3.4. *Let $0\leq\gamma\leq\tau$, $\sigma_1,\sigma_2,\sigma,\kappa\in\mathbb{R}$, and*

$$\textit{either}\quad[\gamma]+\sigma\geq0,\quad[\gamma]+\sigma_1+\sigma_2\geq0\quad\textit{or}\quad\gamma\in\{0,1,2,\dots\}.$$

Then, with $N = N(\gamma, \sigma, \sigma_1, \sigma_2, d)$, we have

$$|a|_\gamma^{(\sigma)} \le N|a|_\tau^{(\sigma)}, \quad |ab|_\gamma^{(\sigma_1+\sigma_2)} \le N|a|_\gamma^{(\sigma_1)}|b|_\gamma^{(\sigma_2)},$$
$$|a|_{\gamma+1}^{(\kappa)} \le N(|a|_0^{(\kappa)} + |a_x|_\gamma^{(\kappa+1)}), \quad |a|_0^{(\kappa)} + |a_x|_\gamma^{(\kappa+1)} \le N|a|_{\gamma+1}^{(\kappa)}.$$

This result is quite standard (for various particular cases of it we refer to [2] and [5]) and is based on simple manipulations. We only mention three main ingredients.

The first is that if we take the sup in (2.2) only over $x, y \in \Omega$ such that $4|x-y| \le \rho(x,y)$, then the norm $|\cdot|_{k+\alpha}^{(\sigma)}$ will be replaced with an equivalent one provided that $k + \sigma \ge 0$. This is because $\rho^{k+\sigma}(x,y) \le \rho^{k+\sigma}(x)$ and $\rho(x,y)/|x-y| \le 4$ when $4|x-y| \ge \rho(x,y)$. This replacement allows one to connect x, y by a straight segment lying in Ω and use that $(\rho(x,y)/|x-y|)^\alpha$ increases with α.

The second ingredient is the observation that if $4|x-y| \le \rho(x,y)$, then $(1/2)\rho(x) \le \rho(x,y) \le \rho(x)$, and one can raise this inequality to any power. The third ingredient is the Leibniz rule.

The following interpolation lemma is a particular case of Proposition 4.2 of [13] (also see www.math.iastate.edu/lieb/book/errata.pdf) stated in more general form and for norms based on parabolic distances. Various versions of the lemma also can be found in many other places (see, for instance, [2] and [5]).

LEMMA 3.5. *If $0 \le \kappa \le \tau < \infty$, then*

$$|a|_\kappa^{(0)} \le N(\kappa, \tau, d) \left(\sup_\Omega |a|\right)^{1-\kappa/\tau} \left(|a|_\tau^{(0)}\right)^{\kappa/\tau}.$$

Notice that we only need Lemma 3.5 for $\Omega = \mathbb{R}^d_+$. The next result for $\Omega = \mathbb{R}^d_+$ bears on multiplicators in $H^\gamma_{p,\theta}$.

LEMMA 3.6. *Let $p \in (1,\infty)$, $\gamma, \theta \in \mathbb{R}$. Then there exists a constant $N = N(\gamma, |\gamma|+, p, d)$ such that if $f \in H^\gamma_{p,\theta}$ and a is a function with finite norm $|a|^{(0)}_{|\gamma|+,\mathbb{R}^d_+}$, then*

$$\|af\|_{H^\gamma_{p,\theta}} \le N|a|^{(0)}_{|\gamma|+,\mathbb{R}^d_+} \|f\|_{H^\gamma_{p,\theta}}. \tag{3.8}$$

In addition, if $\gamma = 0, 1, 2, \dots$, then

$$\|af\|_{H^\gamma_{p,\theta}} \le N \sup_{\mathbb{R}^d_+} |a| \, \|f\|_{H^\gamma_{p,\theta}} + N\|f\|_{H^{\gamma-1}_{p,\theta}} \sup_{\mathbb{R}^d_+} \sup_{1 \le |\alpha| \le \gamma} |M^{|\alpha|} D^\alpha a|. \tag{3.9}$$

Proof. Since the norms in $H^\gamma_{p,\theta}$ constructed from different ζ are equivalent, we have

$$\|af\|^p_{H^\gamma_{p,\theta}} \le N \sum_n e^{n\theta} \|\zeta(\cdot)a(e^n\cdot)\zeta(\cdot)f(e^n\cdot)\|^p_{H^\gamma_p}.$$

Furthermore, for any n (see, for instance, Lemma 5.2 in [8]),

$$\|\zeta(\cdot)a(e^n\cdot)\zeta(\cdot)f(e^n\cdot)\|_{H^\gamma_p} \le N|a(e^n\cdot)\zeta|_{B^{|\gamma|+}} \|f(e^n\cdot)\zeta\|_{H^\gamma_p} =: I,$$

where $|\cdot|_{B^\nu}$ is a natural Hölder's norm in $\mathbb{R}^d$. Now we use, first, that for functions with support belonging to that of ζ the norm $|\cdot|_{B^\nu}$ is equivalent to $|\cdot|_\nu^{(0)}$, then the multiplicative property of $|\cdot|_\nu^{(0)}$ from Lemma 3.4 and, finally, the simple fact that the

norms $|\cdot|^{(0)}_{\nu}$ are dilation invariant. Then we see that

$$I \leq N|a(e^n\cdot)\zeta|^{(0)}_{|\gamma|+,\mathbb{R}^d_+}\|f(e^n\cdot)\zeta\|_{H^\gamma_p} \leq N|a|^{(0)}_{|\gamma|+,\mathbb{R}^d_+}|\zeta|^{(0)}_{|\gamma|+,\mathbb{R}^d_+}\|f(e^n\cdot)\zeta\|_{H^\gamma_p}.$$

Assertion (3.8) easily follows from these inequalities. Inequality (3.9) is straightforward due to Remark 2.13. The lemma is proved.

Now we give a result that will allow us to use change of variables.

LEMMA 3.7. *Let Ω', Ω'' be domains in $\mathbb{R}^{d'}$ and $\mathbb{R}^{d''}$, respectively, constants $N_1, N_2 \in [1,\infty)$, $\sigma \geq 0$, $\gamma = k+\varepsilon$, where $k = 0,1,\dots$ and $\varepsilon \in [0,1)$. Let a be a function on Ω' with $|a|^{(\sigma)}_{\gamma,\Omega'} < \infty$ and let $\mu : \Omega'' \to \Omega'$ be a Lipschitz continuous mapping with Lipschitz constant N_1 such that $\rho_{\Omega''} \leq N_2\rho_{\Omega'}(\mu)$ on Ω'' and $|\mu_x|^{(0)}_{(\gamma-1)_+,\Omega''} < \infty$. Then*

$$|a(\mu)|^{(\sigma)}_{\gamma,\Omega''} \leq N(\gamma,\sigma,d)N_3|a|^{(\sigma)}_{\gamma,\Omega'}, \tag{3.10}$$

where $N_3 = N_3(k,\varepsilon,\sigma) = N_2^{\gamma+\sigma}N_1^{\varepsilon}(1+|\mu_x|^{(0)}_{(\gamma-1)_+,\Omega''})^k$.

Proof. The result is trivial if $k = \varepsilon = 0$ since $\rho_{\Omega''} \leq N_2\rho_{\Omega'}(\mu)$ and $\sigma \geq 0$. If $k = 0$ and $\varepsilon \in (0,1)$, estimate (3.10) follows after observing that for $x, y \in \Omega''$ we have

$$\rho^{\varepsilon+\sigma}_{\Omega''}(x,y)\frac{|a(\mu(x)) - a(\mu(y))|}{|x-y|^\varepsilon} \leq N_2^{\gamma+\sigma}[a]^{(\sigma)}_{\gamma,\Omega'}\frac{|\mu(x)-\mu(y)|^\varepsilon}{|x-y|^\varepsilon} \leq N_2^{\gamma+\sigma}N_1^{\varepsilon}[a]^{(\sigma)}_{\gamma,\Omega'}.$$

We now use the induction on k. Assume that $k = n+1$ and (3.10) holds with $n+\varepsilon$ in place of γ, where $n = 0,1,2,\dots$ and $\varepsilon \in [0,1)$. Observe that

$$(a(\mu(x)))_{x^i} = a_{y^j}(\mu(x))\mu^j_{x^i}(x).$$

Then by the induction hypotheses and Lemma 3.4 we obtain

$$\begin{aligned}|(a(\mu))_x|^{(\sigma+1)}_{\gamma-1,\Omega''} &\leq N|(a_x(\mu))|^{(\sigma+1)}_{\gamma-1,\Omega''}|\mu_x|^{(0)}_{\gamma-1,\Omega''}\\ &\leq NN_3(k-1,\varepsilon,\sigma+1)|a_x|^{(\sigma+1)}_{\gamma-1,\Omega'}|\mu_x|^{(0)}_{\gamma-1,\Omega''} \leq NN_3(k,\varepsilon,\sigma)|a|^{(\sigma)}_{\gamma,\Omega'}.\end{aligned}$$

By using again Lemma 3.4 and the fact that $|a(\mu)|^{(\sigma)}_{0,\Omega''}$ admits the same estimate (recall that $N_1, N_2 \geq 1$), we see that (3.10) holds with $k = n+1$. The lemma is proved.

Proof of Lemma 2.8. (i) Owing to the first assertion of Lemma 3.4 we have $|\psi^{-\kappa}|^{(\sigma)}_{\tau} \leq N|\psi^{-\kappa}|^{(\sigma)}_{n}$, where n is any integer $\geq \tau$. Therefore, it suffices to concentrate on $\tau \in \{0,1,\dots\}$. Furthermore, since Ω is bounded and $\kappa \leq \sigma$, we have $|\psi^{-\kappa}|^{(\sigma)}_{\tau} \leq N|\psi^{-\kappa}|^{(\kappa)}_{\tau}$. Hence we may assume in addition that $\kappa = \sigma$.

Now first let $\sigma \geq 0$. In Lemma 3.7 take $\Omega' = \mathbb{R}_+$, $\Omega'' = \Omega$, and $\mu = \psi$. Then the assumption $\rho_{\Omega''} \leq N_2\rho_{\Omega'}(\mu)$ is satisfied since Ω is bounded, and it remains only to note that, obviously, $a(x) := x^{-\sigma}$, $x > 0$, satisfies $|a|^{(\sigma)}_{\tau,\Omega'} < \infty$ for any $\tau = 0,1,2,\dots$.

If $\sigma < 0$, assertion (i) follows by induction on τ on the basis of the case $\sigma \geq 0$ and the Leibniz rule:

$$\begin{aligned}0 = \psi^{|\gamma|}D^\gamma(\psi^\sigma\psi^{-\sigma}) &= \psi^{|\gamma|+\sigma}D^\gamma(\psi^{-\sigma})\\ &\quad + \sum_{\substack{\alpha+\beta=\gamma,\\ |\alpha|<|\gamma|}} c^\gamma_{\alpha\beta}[\psi^{|\alpha|+\sigma}D^\alpha(\psi^{-\sigma})]\psi^{|\beta|-\sigma}D^\beta(\psi^\sigma),\end{aligned}$$

where $|\gamma| \geq 1$ and $c^\gamma_{\alpha\beta}$ are certain constants.

To prove assertion (ii) notice that by (i) and the second assertion of Lemma 3.4 we have

$$|a|_\tau^{(\sigma)} = |\psi^{-\sigma}\psi^\sigma a|_\tau^{(\sigma)} \le N|\psi^{-\sigma}|_\tau^{(\sigma)}|\psi^\sigma a|_\tau^{(0)} \le N|\psi^\sigma a|_\tau^{(0)}.$$

Also

$$|\psi^\mu a|_\tau^{(\sigma)} \le N|\psi^\mu|_\tau^{(-\mu)}|a|_\tau^{(\mu+\sigma)} \le N|a|_\tau^{(\mu+\sigma)},$$

provided that $[\tau]-\mu \ge 0$ or $\tau \in \{0,1,2,\dots\}$. However, if none of these conditions holds, then $\mu = k\alpha$, where k is an integer ≥ 2 and $0 < \alpha \le [\tau]$. Then, for $\mu(i) = i\alpha$, we have

$$|\psi^{\mu(i+1)}a|_\tau^{(\sigma)} = |\psi^\alpha(\psi^{\mu(i)}a)|_\tau^{(\sigma)} \le N|\psi^{\mu(i)}a|_\tau^{(\alpha+\sigma)}$$

and the rest is obvious. The lemma is proved.

The following lemma about implicit functions will be used on few occasions.

LEMMA 3.8. *Let $n = 1,2,\dots$, $G \subset \mathbb{R}^d$ be a domain and let $d(x)$ be a nonnegative function on G. Let $E(r,x)$ be an $\mathbb{R}^{d_1}$-valued n times continuously differentiable function given in an open set of points $(r,x) \in \mathbb{R}^{d_1+d}$, $r \in \mathbb{R}^{d_1}$, $x \in \mathbb{R}^d$, whose projection on $\mathbb{R}^d$ is G. Assume that for each $x \in G$ there exists a unique solution $r(x)$ of the equation $E(r,x) = 0$. Denote $z(x) = (r(x),x)$ and assume that for $x \in G$ the matrix $E_r(z(x))$ is invertible and the inverse matrix is bounded on G. Finally, assume that*

$$d^{|\alpha|-1}(x)(D^\alpha E)(z(x)) \tag{3.11}$$

is bounded in G for any α such that $n \ge |\alpha| \ge 1$, where, as usual, D^α stands for the derivative of order α in all variables (on that occasion of function E depending on $z = (r,x)$). Then

(i) *it holds that*

$$d^{|\alpha|-1}(x)D^\alpha r(x) \tag{3.12}$$

is bounded in G for any α such that $n \ge |\alpha| \ge 1$;

(ii) *if the sets $\{x \in G : d(x) < \varepsilon\}$ are nonempty for any $\varepsilon > 0$ and if $n \ge 2$ and (3.11) tends to zero as $d(x) \to 0$ for any α such that $n \ge |\alpha| \ge 2$, then (3.12) tends to zero as $d(x) \to 0$ for any α such that $n \ge |\alpha| \ge 2$.*

Proof. (i) It is well known that $r(x)$ is n times continuously differentiable in G and

$$E_{r^j}(z(x))r^j_{x^i}(x) = -E_{x^i}(z(x)). \tag{3.13}$$

It follows that (3.12) is bounded for $|\alpha| = 1$. Assume that it is bounded for $1 \le |\alpha| \le m$, where $m \in \{1,2,\dots,n-1\}$. By differentiating (3.13) we find for $x \in G$ that

$$\begin{aligned} E_{r^j}(z(x))d^{|\alpha|}(x)D^\alpha r^j_{x^i}(x) &= -d^{|\alpha|}(x)D^\alpha\big(E_{x^i}(z(x))\big) \\ &\quad + \sum_{\substack{|\beta|\le|\alpha|-1,\\ |\beta|+|\gamma|=|\alpha|}} c^\alpha_{\beta\gamma}\big[d^{|\beta|}(x)D^\beta r^j_{x^i}(x)\big]d^{|\gamma|}(x)D^\gamma\big(E_{r^j}(z(x))\big), \end{aligned} \tag{3.14}$$

where $c^\alpha_{\beta\gamma}$ are some constants. Owing to the induction hypotheses, we see that to prove the boundedness of (3.12) for $|\alpha| = m+1$ it suffices to prove that $d^{|\alpha|}(x)D^\alpha\big(E_z(z(x))\big)$ is bounded whenever $|\alpha| \le m$.

Observe that $D^\alpha\big(E_z(z(x))\big)$ is represented as the sum of certain constants times terms of the type

$$(D^\beta E_z)(z(x))D^{\gamma_1}z^{i_1}(x)\times\cdots\times D^{\gamma_{|\beta|}}z^{i_{|\beta|}}(x), \tag{3.15}$$

where $|\gamma_i|\geq 1$, $|\gamma_1|+\cdots+|\gamma_{|\beta|}|=|\alpha|$ and z^i, $i=1,\dots,d_1+d$, is the ith coordinate of $z=(r,x)$. Being multiplied by $d^{|\alpha|}(x)$ expression (3.15) is written as

$$d^{|\beta|}(x)(D^\beta E_z)(z(x))d^{|\gamma_1|-1}(x)D^{\gamma_1}z^{i_1}(x)\times\cdots\times d^{\gamma_{|\beta|}-1}(x)D^{\gamma_{|\beta|}}z^{i_{|\beta|}}(x). \tag{3.16}$$

If $|\alpha|\leq m$, then $|\gamma_k|\leq m$ and $d^{|\gamma_k|-1}(x)D^{\gamma_k}z^{i_k}(x)$ is bounded in both cases if $z^{i_k}=r^j$ (by the induction hypotheses) or $z^{i_k}=x^j$ (trivially). Hence the boundedness of (3.11) implies that of (3.16) and finishes the proof of (i).

To prove (ii), first examine (3.14) for $|\alpha|=1$. The first term on the right goes to zero as $d(x)\to 0$ due to the assumption about (3.11) and the fact that r_x is bounded. The treatment of the second term is no different since for β there is only one possibility: $\beta=0$. Next, assume that (3.12) tends to zero as $d(x)\to 0$ for $|\alpha|=2,\dots,m$ ($m\leq n-1$) and, to make one step forward, take α in (3.14) with $|\alpha|=m$.

Notice that in the second term on the right in (3.14) the terms with $|\beta|\geq 1$ tend to zero as $d(x)\to 0$ by the induction hypotheses since $|\beta|+1\leq m$. It follows that to complete the induction it suffices to prove that $d^{|\alpha|}(x)D^\alpha\big(E_z(z(x))\big)\to 0$ if $|\alpha|=m$.

We go back to (3.16) and observe that if $2\leq|\gamma_k|(\leq m)$, then $d^{|\gamma_k|-1}(x)D^{\gamma_k}z^{i_k}(x)\to 0$ as $d(x)\to 0$ in both cases if $z^{i_k}=r^j$ (by the induction hypotheses) or $z^{i_k}=x^j$ (being identically zero). Taking into account assertion (i) we see that it remains only to analyze the terms of type (3.16) with $|\gamma_1|=\cdots=|\gamma_{|\beta|}|=1$. However, for those terms we have $|\beta|=|\alpha|\geq 1$ and they tend to zero by assumption. The lemma is proved.

4. Proof of Theorem 2.14. We closely follow the proof of Theorem 2.16 of [6]. As usual we may assume that $u_0=0$ and $T=\infty$ and, since for $a^{ij}=\delta^{ij}$ and $b=0$ and $c=0$ the result is known from [9], we need only prove the existence of an ω_0, such that the a priori estimate (2.11) holds given that the solution already exists and $\omega\leq\omega_0$. Below, unless explicitly expressed otherwise, we use notation N for various constants which may vary from one occurrence to another and depend only on the data as they should according to the statement of the theorem.

Case 1. $|\gamma|\notin\{0,1,2,\dots\}$. Take the least integer $q\geq|\gamma|+4$. Also take an $\varepsilon\in(0,1)$ to be specified later and take a sequence of functions η_k, $k=1,2,\dots$, from Lemma 3.3 corresponding to ε,q. Then by Lemma 3.1, we have

$$\|M^{-1}u\|^p_{\mathbb{H}^{\gamma+2}_{p,\theta}}\leq N\sum_{k=1}^\infty\|M^{-1}u\eta_k^2\|^p_{\mathbb{H}^{\gamma+2}_{p,\theta}}. \tag{4.1}$$

For any k let x_k be a point in $\operatorname{supp}\eta_k$ and $a_k(t)=a(t,x_k)$. Owing to (2.1), we have

$$(u\eta_k^2)_t=a_k^{ij}(u\eta_k^2)_{x^ix^j}+M^{-1}f_k,$$

where

$$\begin{aligned}f_k=&(a^{ij}-a_k^{ij})\eta_k^2Mu_{x^ix^j}-2a_k^{ij}M(\eta_k^2)_{x^i}u_{x^j}-a_k^{ij}M^{-1}uM^2(\eta_k^2)_{x^ix^j}\\&+\eta_k^2Mb^iu_{x^i}+\eta_k^2M^2cM^{-1}u+Mf\eta_k^2.\end{aligned}$$

It follows from [9] that for each k

$$\|M^{-1}u\eta_k^2\|^p_{\mathbb{H}^{\gamma+2}_{p,\theta}} \le N\|f_k\|^p_{\mathbb{H}^{\gamma}_{p,\theta}}. \tag{4.2}$$

Furthermore, by Lemmas 3.6 and 3.5 after denoting $\gamma' = |\gamma| + \delta_0(|\gamma|)/2$ and $\delta_1 = \delta_0(|\gamma|)/(2|\gamma| + 2\delta_0(|\gamma|))$ (> 0), we get

$$\begin{aligned}\|(a^{ij} - a_k^{ij})\eta_k^2 M u_{x^ix^j}\|_{\mathbb{H}^{\gamma}_{p,\theta}} &\le N\|\eta_k M u_{x^ix^j}\|_{\mathbb{H}^{\gamma}_{p,\theta}} \sup_{t\ge 0} |(a^{ij} - a_k^{ij})(t,\cdot)\eta_k|^{(0)}_{\gamma',\mathbb{R}^d_+}\\ &\le N\|\eta_k M u_{x^ix^j}\|_{\mathbb{H}^{\gamma}_{p,\theta}} \sup_{[0,\infty)\times\mathbb{R}^d_+} |(a^{ij} - a_k^{ij})\eta_k|^{\delta_1}.\end{aligned}$$

Observe that for any k and $x, y \in \operatorname{supp}\eta_k$ we have $|x - y| \le N(\varepsilon)(x^1 \wedge y^1)$, where $N(\varepsilon) = N(d, q, \varepsilon)$, and one can easily find not more than $N(\varepsilon) + 2 \le 3N(\varepsilon)$ points x_i lying on the straight segment connecting x and y and including x and y, such that $|x_i - x_{i+1}| \le x_i^1 \wedge x_{i+1}^1$. It follows from our assumptions that

$$\sup_{[0,\infty)\times\mathbb{R}^d_+} |(a^{ij} - a_k^{ij})\eta_k| \le NN(\varepsilon)\omega.$$

Similarly,

$$\|\eta_k^2 M b^i u_{x^i}\|_{\mathbb{H}^{\gamma}_{p,\theta}} + \|\eta_k^2 M^2 c M^{-1}u\|_{\mathbb{H}^{\gamma}_{p,\theta}} \le NN(\varepsilon)\omega^{\delta_1}\left(\|\eta_k u_x\|_{\mathbb{H}^{\gamma}_{p,\theta}} + \|\eta_k M^{-1}u\|_{\mathbb{H}^{\gamma}_{p,\theta}}\right).$$

Coming back to (4.2) and (4.1) and using Lemma 3.1, we conclude

$$\begin{aligned}\|M^{-1}u\|^p_{\mathbb{H}^{\gamma+2}_{p,\theta}} &\le NN(\varepsilon)\omega^{p\delta_1}\left(\|Mu_{xx}\|^p_{\mathbb{H}^{\gamma}_{p,\theta}} + \|u_x\|^p_{\mathbb{H}^{\gamma}_{p,\theta}} + \|M^{-1}u\|^p_{\mathbb{H}^{\gamma}_{p,\theta}}\right)\\ &\quad + NC^p\left(\|u_x\|^p_{\mathbb{H}^{\gamma}_{p,\theta}} + \|M^{-1}u\|^p_{\mathbb{H}^{\gamma}_{p,\theta}}\right) + N\|Mf\|^p_{\mathbb{H}^{\gamma}_{p,\theta}},\end{aligned} \tag{4.3}$$

where

$$C = \sup_{\mathbb{R}^d_+}\sup_{|\alpha|\le q-2}\sum_{k=1}^{\infty} M^{|\alpha|}(|D^\alpha(M(\eta_k^2)_x)| + |D^\alpha(M^2(\eta_k^2)_{xx})|).$$

By construction, we have $C \le N\varepsilon$. Furthermore (see, for instance, [9]),

$$\|u_x\|_{H^{\gamma}_{p,\theta}} \le N\|M^{-1}u\|_{H^{\gamma+1}_{p,\theta}}, \quad \|Mu_{xx}\|_{H^{\gamma}_{p,\theta}} \le N\|M^{-1}u\|_{H^{\gamma+2}_{p,\theta}}. \tag{4.4}$$

Hence (4.3) yields

$$\|M^{-1}u\|^p_{\mathbb{H}^{\gamma+2}_{p,\theta}} \le N_1(N(\varepsilon)\omega^{p\delta_1} + \varepsilon^p)\|M^{-1}u\|^p_{\mathbb{H}^{\gamma+2}_{p,\theta}} + N\|Mf\|^p_{\mathbb{H}^{\gamma}_{p,\theta}}.$$

We finally choose first ε and then ω_0 so that $N_1(N(\varepsilon)\omega^{p\delta_1} + \varepsilon^p) \le 1/2$ for $\omega \le \omega_0$ and finish the proof of the theorem in the case under consideration.

Case 2. $\gamma \in \{0, 1, 2, \ldots\}$. If $\gamma = 0$, (4.3) obviously holds with $\delta_1 = 1$ and C defined by the same formula in which we drop the supremum with respect to α and take $\alpha = 0$. After this one can follow the previous arguments word for word. If γ is a positive integer, one can proceed as in [6] by induction on γ on the basis of (3.9). We leave the details to the reader.

Case 3. $\gamma \in \{-1, -2, \dots\}$. In this case instead of proving a priori estimates we prove the theorem directly. As above we may assume that $u_0 = 0$.

We proceed by induction on γ and assume that there exists an $\omega_0 > 0$ such that the theorem holds for $\gamma + 1$ in place of γ. We will see that the same ω_0 suits γ. The possibility to start the induction from $\gamma = -1$ is justified by the above result.

Let $\omega \leq \omega_0$. Then the operator $\mathcal{R}$ which maps $f \in M^{-1}\mathbb{H}^{\gamma+1}_{p,\theta}$ into the solution $u \in \mathfrak{H}^{\gamma+3}_{p,\theta,0}$ of (2.1) is well defined and bounded.

Take an $f \in M^{-1}\mathbb{H}^{\gamma}_{p,\theta}$ and recall that $d - 1 < \theta < d - 1 + p$, so that according to Corollary 2.12 of [9] we have the representation

$$f = MD_k f^k,$$

where $f^k \in M^{-1}\mathbb{H}^{\gamma+1}_{p,\theta}$, $k = 1, 2, \dots, d$, and

$$\sum_{k=1}^{d} \|Mf^k\|_{\mathbb{H}^{\gamma+1}_{p,\theta}} \leq N\|Mf\|_{\mathbb{H}^{\gamma}_{p,\theta}}. \tag{4.5}$$

Now let

$$w^k = \mathcal{R}f^k, k = 1, 2, \dots, d, \quad v = MD_k w^k.$$

Owing to the induction hypothesis, (4.4), and (4.5) we have

$$\|M^{-1}v\|_{\mathbb{H}^{\gamma+2}_{p,\theta}} \leq \sum_k \|w^k_x\|_{\mathbb{H}^{\gamma+2}_{p,\theta}} \leq N \sum_k \|M^{-1}w^k\|_{\mathbb{H}^{\gamma+3}_{p,\theta}} \leq N\|Mf\|_{\mathbb{H}^{\gamma}_{p,\theta}}.$$

Furthermore, as is easy to check,

$$v_t = a^{ij}v_{x^i x^j} + b^i v_{x^i} + cv + f + \bar{f}$$

with

$$\begin{aligned} M\bar{f} = {} & Mw^k_{x^i x^j} MD_k a^{ij} + w^k_{x^i} M^2 D_k b^i + M^{-1}w^k M^3 D_k c \\ & - 2a^{i1} M w^k_{x^k x^i} - w^k_{x^k} M b^1. \end{aligned}$$

In addition,

$$|MD_k a|_{|\gamma+1|,\mathbb{R}^d_+} = |MD_k a|_{|\gamma|-1,\mathbb{R}^d_+} \leq N|a|_{|\gamma|,\mathbb{R}^d_+} \leq NK,$$

$$|M^2 D_k b|_{|\gamma+1|,\mathbb{R}^d_+} = |M^2 D_k b|_{|\gamma|-1,\mathbb{R}^d_+} \leq N|b|^{(1)}_{|\gamma|,\mathbb{R}^d_+},$$

and similar estimates hold for $M^3 D_k c$, a, and Mb. Hence from the construction of w^k, (4.4), Lemma 3.6, and (4.5) we infer that

$$\|M\bar{f}\|_{\mathbb{H}^{\gamma+1}_{p,\theta}} \leq N\|Mf\|_{\mathbb{H}^{\gamma}_{p,\theta}}.$$

Finally, we can define $\bar{u} = \mathcal{R}(\bar{f})$ and $u = v - \bar{u}$. Then u belongs to $\mathfrak{H}^{\gamma+2}_{p,\theta,0}$ and satisfies (2.1), and (2.11) follows from the above estimates.

To prove the uniqueness of solutions take an $u \in \mathfrak{H}^{\gamma+2}_{p,\theta,0}$ and assume that it satisfies (2.1) in $(0, \infty) \times \mathbb{R}^d_+$ with $f = 0$. Notice that

$$(\eta_k u)_t = a^{ij}(\eta_k u)_{x^i x^j} + b^i(\eta_k u)_{x^i} + c(\eta_k u) + \tilde{f}, \tag{4.6}$$

where

$$\tilde{f} = -2a^{ij}\eta_{kx^i}u_{x^j} - (a^{ij}\eta_{kx^ix^j} + b^i\eta_{kx^i})u.$$

As is easy to see, $\tilde{f} \in L_p((0,\infty), H_p^{\gamma+1}) =: \mathbb{H}_p^{\gamma+1}$. (Here we use the notation from [8].) Furthermore, (4.6) will not change if we change arbitrarily a, b, c outside of the support of η_k. We do this preserving the uniform ellipticity and smoothness of a, b, c in the whole space, and then by a well-known regularity result we get that (4.6) about $\eta_k u$ is uniquely solvable in $\mathbb{H}_p^{\gamma+2}$ for any $\tilde{f} \in \mathbb{H}_p^{\gamma}$ and also uniquely solvable in $\mathbb{H}_p^{\gamma+3}$ for any $\tilde{f} \in \mathbb{H}_p^{\gamma+1}$. Actually, it is hard to find an exact reference to this "well-known" result, but refer to Remark 5.6 of [8], where one must throw away all stochastic terms and then notice that one can apply this remark for all $p \in (1,\infty)$ rather than $p \in [2,\infty)$. The latter assumption on p in [8] is only related to the presence of stochastic terms.

From the uniqueness in $\mathbb{H}_p^{\gamma+2}$ and the solvability in $\mathbb{H}_p^{\gamma+3}$ we conclude that $\eta_k u \in \mathbb{H}_p^{\gamma+3}$. Since η_k has compact support, we also have $\eta_k u \in \mathbb{H}_{p,\theta}^{\gamma+3}$, $M^{-1}\eta_k u \in \mathbb{H}_{p,\theta}^{\gamma+3}$, and $\eta_k u \in \mathfrak{H}_{p,\theta,0}^{\gamma+3}$. This and the induction hypotheses allow us to get from (4.6) that

$$\|\eta_k M^{-1}u\|_{\mathbb{H}_{p,\theta}^{\gamma+3}}^p \le N\|M\eta_{kx^i}a^{ij}u_{x^j}\|_{\mathbb{H}_{p,\theta}^{\gamma+1}}^p + N\|(a^{ij}M^2\eta_{kx^ix^j} + Mb^iM\eta_{kx^i})M^{-1}u\|_{\mathbb{H}_{p,\theta}^{\gamma+1}}^p.$$

By summing up these estimates with respect to k and using Lemmas 3.1, 3.4, and 3.6 and the fact that $M^{-1}u \in \mathbb{H}_{p,\theta}^{\gamma+2}$, we obtain that $\|M^{-1}u\|_{\mathbb{H}_{p,\theta}^{\gamma+3}} < \infty$, that is, $u \in \mathfrak{H}_{p,\theta,0}^{\gamma+3}$. That $u = 0$ now follows from the induction hypotheses.

The theorem is proved.

5. Proof of Theorems 2.10 and 2.11.

Proof of Theorem 2.10. We split the proof into three steps.

Step 1. First we claim that we may assume that $\partial\Omega$ is infinitely differentiable. To prove the claim, use Theorem 2.12 and notice that, as we know from Theorem 3.2 of [15], due to assertions (i) and (ii) of Theorem 2.12, the mappings μ and ν induce one-to-one linear bounded mappings of the spaces $H_{p,\theta}^{\gamma}(\Omega)$ onto $H_{p,\theta}^{\gamma}(\Omega_\varepsilon)$ and vice versa. Therefore, proving that a function $u \in \mathfrak{H}_{p,\theta}^{\gamma+2}(\Omega,T)$ satisfies (2.1) with initial condition u_0 and admits estimate (2.8) is equivalent to proving that the function $\tilde{u} := u(\mu)$ satisfies the corresponding equation in $(0,T)\times\Omega_\varepsilon$, belongs to $\mathfrak{H}_{p,\theta}^{\gamma+2}(\Omega_\varepsilon,T)$, and admits the natural modification of estimate (2.8). The equation for $\tilde{u}$ is

$$\tilde{u}_t = \tilde{a}^{ij}\tilde{u}_{x^ix^j} + \tilde{b}^i\tilde{u}_{x^i} + \tilde{c}\tilde{u} + \tilde{f}, \tag{5.1}$$

where

$$\tilde{a}^{ij}(t,x) = \bar{a}^{ij}(t,\mu(x)), \quad \tilde{b}^i(t,x) = \bar{b}^i(t,\mu(x)),$$
$$\bar{a}^{ij} = a^{kr}\nu_{x^k}^i\nu_{x^r}^j, \quad \bar{b}^i = a^{kr}\nu_{x^kx^r}^i + b^k\nu_{x^k}^i,$$
$$\tilde{c}(t,x) = c(t,\mu(x)), \quad \tilde{f}(t,x) = f(t,\mu(x)).$$

Since the matrix $\nu_x(\mu)$ and its inverse μ_x are bounded, (5.1) is uniformly parabolic.

Furthermore, by Lemma 3.4,

$$|\bar{a}(t,\cdot)|^{(0)}_{|\gamma|+} \le N|a(t,\cdot)|^{(0)}_{|\gamma|+}(|\nu_x|^{(0)}_{|\gamma|+})^2 \le N_1,$$
$$|\bar{b}(t,\cdot)|^{(1)}_{|\gamma|+} \le N|a(t,\cdot)|^{(0)}_{|\gamma|+}|\nu_{xx}|^{(1)}_{|\gamma|+} + N|b(t,\cdot)|^{(1)}_{|\gamma|+}|\nu_x|^{(0)}_{|\gamma|+} \le N_1,$$

where N_1 is independent of t. Also observe that in a bounded C^1 domain every function having bounded first derivatives satisfies the Lipschitz condition. Then from the above estimates by Lemma 3.7 we conclude that $\tilde{a}, \tilde{b}, \tilde{c}$ satisfy Assumption 2.3 relative to Ω_ε with certain strictly positive and finite constants in place of δ and K.

The function $\tilde{a}(t,x)$ is obviously continuous inside of Ω_ε uniformly in t, so that Assumption 2.4(i) is satisfied. Also, obviously the part of Assumption 2.4(ii) concerning $\tilde{c}$ is satisfied. It is satisfied for $\tilde{b}$ as well since (cf. Theorem 2.12(iv)) $\rho_\Omega(x)(|b(t,x)| + |\nu_{xx}(x)|) \to 0$ as long as $t > 0$ and $\Omega \ni x \to \partial\Omega$, which implies that, under the same conditions, $\rho_\Omega|\bar{b}| \to 0$ and if $x \in \Omega_\varepsilon$ and $t > 0$ and $\rho_{\Omega_\varepsilon}(x) \to 0$, then $\rho_{\Omega_\varepsilon}(x)|\tilde{b}(t,x)| \to 0$.

It remains to check (2.4) for $\tilde{a}$. This turns out to be a more tedious albeit elementary task. Observe that for $x, y \in \Omega_\varepsilon$,

$$\begin{aligned}|\tilde{a}(t,x) - \tilde{a}(t,y)| &= |\bar{a}(t,\mu(x)) - \bar{a}(t,\mu(y))| \\ &\le N|a(t,\mu(x)) - a(t,\mu(y))| + N|\nu_x(\mu(x)) - \nu_x(\mu(y))|.\end{aligned}$$

Here the last term goes to zero as $x - y \to 0$ due to the uniform continuity of μ and ν_x no matter whether x, y approach $\partial\Omega_\varepsilon$ or not. Furthermore, if $x, y \in \Omega_\varepsilon$ and $|x - y| \le \rho_{\Omega_\varepsilon}(x,y)$, then

$$|\mu(x) - \mu(y)| \le N|x - y| \le N\rho_{\Omega_\varepsilon}(x,y) \le N\rho_\Omega(\mu(x),\mu(y)).$$

Therefore, to check that $|\tilde{a}(t,x) - \tilde{a}(t,y)| \to 0$ uniformly in t as $\Omega_\varepsilon \ni x \to \partial\Omega_\varepsilon$ and $|x - y| \le \rho_{\Omega_\varepsilon}(x,y)$ it suffices to prove that, for any constant N_1,

$$\lim_{\substack{\rho(x)\to 0,\\ x\in\Omega}} \sup_{\substack{y\in\Omega,\\ |x-y|\le N_1\rho(x,y)}} \sup_t |a(t,x) - a(t,y)| = 0, \tag{5.2}$$

which is given for $N_1 = 1$ by Assumption 2.4.

By way of getting a contradiction assume that (5.2) is false. Then there exists a point $x_0 \in \partial\Omega$, a $\tau > 0$, and sequences $x_n, y_n \in \Omega$ and $t_n > 0$ such that $x_n, y_n \to x_0$, $|x_n - y_n| \le N_1\rho(x_n,y_n)$, and

$$|a(t_n,x_n) - a(t_n,y_n)| \ge \tau.$$

Take the mapping Ψ from Assumption 2.1 and a number $k = 1, 2, \dots$ to be specified later and define

$$\bar{x}_n(i) = \Psi(x_n)i/k + \Psi(y_n)(k-i)/k, \quad x_n(i) = \Psi^{-1}(\bar{x}_n(i)), \quad i = 0, 1, \dots, k.$$

As is easy to see, due to Assumption 2.1, we have $B_{r_0/K_0} \cap \mathbb{R}^d_+ \subset \Psi(B_{r_0}(x_0) \cap \Omega)$. Therefore, for all large n, which we only concentrate on, we have $x_n(i) \in B_{r_0}(x_0) \cap \Omega$. Furthermore, for $x \in \partial\Omega$ close to x_0, we have

$$\bar{x}^1_n(i) \le |\bar{x}_n(i) - \Psi(x)| \le K_0|x_n(i) - x|.$$

By taking the inf over $x \in B_{r_0}(x_0) \cap \partial\Omega$, we get that $\bar{x}_n^1(i) \le K_0 \rho(x_n(i))$. Similarly, if $z \in \partial\mathbb{R}^d_+$ and z is close to 0, then $\rho(x_n(i)) \le |x_n(i) - \Psi^{-1}(z)| \le K_0 |\bar{x}_n(i) - z|$, which after taking the inf over z yields $\rho(x_n(i)) \le K_0 \bar{x}_n^1(i)$.

Now, notice that the sequence $\bar{x}_n^1(i)$ is monotone in i so that, for $i = 0, 1, \dots, k-1$,

$$\bar{x}_n^1(k) \wedge \bar{x}_n^1(0) \le \bar{x}_n^1(i+1) \wedge \bar{x}_n^1(i).$$

It follows that, for $i = 0, 1, \dots, k-1$,

$$\begin{aligned}
|x_n(i+1) - x_n(i)| &\le K_0 |\bar{x}_n(i+1) - \bar{x}_n(i)| = K_0 k^{-1} |\Psi(x_n) - \Psi(y_n)| \\
&\le K_0^2 k^{-1} |x_n - y_n| \le K_0^2 k^{-1} N_1 \rho(x_n(k), x_n(0)) \\
&\le K_0^3 k^{-1} N_1 [\bar{x}_n^1(k) \wedge \bar{x}_n^1(0)] \le K_0^3 k^{-1} N_1 [\bar{x}_n^1(i+1) \wedge \bar{x}_n^1(i)] \\
&\le K_0^4 k^{-1} N_1 \rho(x_n(i+1), x_n(i)).
\end{aligned}$$

The latter is less than $\rho(x_n(i+1), x_n(i))$ if $k \ge K_0^4 N_1$. With such a k by Assumption 2.4 we conclude

$$|a(t_n, y_n) - a(t_n, x_n)| \le \sum_{i=0}^{k-1} |a(t_n, x_n(i+1)) - a(t_n, x_n(i+1))| \to 0,$$

which is the contradiction in question. Thus indeed in the rest of the proof we may assume that $\partial\Omega$ is infinitely differentiable.

Step 2. We establish a priori estimate (2.8) assuming that $u \in \mathfrak{H}^{\gamma+2}_{p,\theta}(\Omega, T)$ satisfies (2.1). Let $x_0 \in \partial\Omega$ and Ψ be a function from Assumption 2.1. By Step 1 we may assume that Ψ is infinitely differentiable with bounded derivatives.

Define $r = r_0/K_0$ and fix smooth functions $\eta \in C_0^\infty(B_r), \varphi \in C^\infty(\mathbb{R})$ such that $\eta = 1$ in $B_{r/2}$ and $\varphi(t) = 1$ for $t \le -3$ and $\varphi(t) = 0$ for $t \ge -1$ and $0 \ge \varphi' \ge -1$. As we noted above, $\Psi(B_{r_0}(x_0))$ contains B_r. For $k = 1, 2, \dots$, $t > 0$, $x \in \mathbb{R}^d_+$ introduce $\varphi_k(x) = \varphi(k^{-1} \ln x^1)$,

$$\hat{a}_k := \tilde{a}\eta(x)\varphi_k + (1 - \eta\varphi_k)I, \quad \hat{b}_k := \tilde{b}\eta\varphi_k, \quad \hat{c}_k := \tilde{c}\eta\varphi_k,$$

where the functions $\tilde{a}, \tilde{b}$, and $\tilde{c}$ are taken from (5.1) with Ψ and Ψ^{-1} instead of ν and μ, respectively. By using Lemma 3.4 one can check that $\hat{a}_k, \hat{b}_k, \hat{c}_k$ satisfy Assumptions 2.3 with $\Omega = \mathbb{R}^d_+$ and some new constant $\delta', K' \in (0, \infty)$ independent of k and x_0.

Take the ω_0 from Theorem 2.14 corresponding to $\delta', p, \theta, \gamma, |\gamma|+$, and K'. We also fix a $k > 0$ such that

$$|\hat{a}_k(t,x) - \hat{a}_k(t,y)| + x^1 |\hat{b}_k(t,x)| + (x^1)^2 |\hat{c}_k(t,x)| \le \omega_0$$

whenever $t > 0, x, y \in \mathbb{R}^d_+$ and $|x - y| \le x^1 \wedge y^1$. The fact that this condition holds with $\tilde{a}, \tilde{b}, \tilde{c}$ in place of $\hat{a}_k, \hat{b}_k, \hat{c}_k$ if x^1 and y^1 are small enough is proved in Step 1. That multiplying by φ_k preserves the needed property for small x^1 and y^1 and also extends it for all x^1 and y^1 follows from the fact that $\varphi(k^{-1} \ln x^1) = 0$ for $x^1 \ge e^{-k}$ and

$$|\varphi(k^{-1} \ln x^1) - \varphi(k^{-1} \ln y^1)| = k^{-1} \xi^{-1} |\varphi'(k^{-1} \ln \xi)| \cdot |x^1 - y^1| \le k^{-1},$$

where ξ is a point between x^1 and y^1, so that $|x^1 - y^1| \le x^1 \wedge y^1 \le \xi$. Now we fix a $\rho_0 < r_0$ such that

$$\Psi(B_{\rho_0}(x_0)) \subset B_{r/2} \cap \{x : x^1 \le e^{-3k}\}.$$

Let ζ be a smooth function with support in $B_{\rho_0}(x_0)$ and denote $v := (u\zeta)(\Psi^{-1})$ and continue v as zero in $\mathbb{R}^d_+ \setminus \Psi(B_{\rho_0}(x_0))$. Since $\eta\varphi_k = 1$ on $\Psi(B_{\rho_0}(x_0))$, the function v satisfies

$$v_t = \hat{a}^{ij}_k v_{x^i x^j} + \hat{b}^i_k v_{x^i} + \hat{c}_k v + \hat{f},$$

where $\hat{f} = \tilde{f}(\Psi^{-1})$, $\tilde{f} = -2a^{ij}u_{x^i}\zeta_{x^j} - ua^{ij}\zeta_{x^i x^j} - ub^i\zeta_{x^i} + \zeta f$. Similar to what was said in the beginning of Step 1, we have $v \in \mathfrak{H}^{\gamma+2}_{p,\theta}(T)$. It follows from Theorem 2.14 that for any $t \le T$,

$$\|M^{-1}v\|_{\mathbb{H}^{\gamma+2}_{p,\theta}(t)} \le N\|M\hat{f}\|_{\mathbb{H}^{\gamma}_{p,\theta}(t)} + N\|u_0(\Psi^{-1})\zeta(\Psi^{-1})\|_{U^{\gamma+2}_{p,\theta}}.$$

To transform this estimate we observe that by Theorem 3.2 in [15], for any $\nu, \alpha \in \mathbb{R}$ and $g \in \psi^{-\alpha}H^{\nu}_{p,\theta}(\Omega)$ with support in $B_{\rho_0}(x_0)$,

$$\|\psi^{\alpha}g\|_{H^{\nu}_{p,\theta}(\Omega)} \sim \|M^{\alpha}g(\Psi^{-1})\|_{H^{\nu}_{p,\theta}}.$$

Then we find

$$\begin{aligned}\|\psi^{-1}u\zeta\|_{\mathbb{H}^{\gamma+2}_{p,\theta}(\Omega,t)} &\le N\|M^{-1}v\|_{\mathbb{H}^{\gamma+2}_{p,\theta}(t)} \le N\|a\zeta_x\psi u_x\|_{\mathbb{H}^{\gamma}_{p,\theta}(\Omega,t)}\\ &+ N\|a\zeta_{xx}\psi u\|_{\mathbb{H}^{\gamma}_{p,\theta}(\Omega,t)} + \|\zeta_x\psi bu\|_{\mathbb{H}^{\gamma}_{p,\theta}(\Omega,t)}\\ &+ N\|\zeta\psi f\|_{\mathbb{H}^{\gamma}_{p,\theta}(\Omega,t)} + \|\zeta u_0\|_{U^{\gamma+2}_{p,\theta}(\Omega)}.\end{aligned}$$

Next we use a natural counterpart of Lemma 3.6 for general domains, which is stated as Theorem 3.1 in [15]. We also use that, by Lemma 2.8, Assumption 2.3(iii) implies that $|\psi b(t,\cdot)|^{(0)}_{|\gamma|+}$ is bounded on $[0,T]$. Then we conclude

$$\begin{aligned}\|\psi^{-1}u\zeta\|_{\mathbb{H}^{\gamma+2}_{p,\theta}(\Omega,t)} &\le N\|\psi u_x\|_{\mathbb{H}^{\gamma}_{p,\theta}(\Omega,t)} + N\|u\|_{\mathbb{H}^{\gamma}_{p,\theta}(\Omega,t)}\\ &+ N\|\psi f\|_{\mathbb{H}^{\gamma}_{p,\theta}(\Omega,t)} + N\|u_0\|_{U^{\gamma+2}_{p,\theta}(\Omega)}.\end{aligned}$$

Note that the above constants ρ_0, k, δ', K', and N are independent of x_0. Therefore, to estimate the norm $\|\psi^{-1}u\|_{\mathbb{H}^{\gamma+2}_{p,\theta}(\Omega,t)}$, one introduces a partition of unity $\zeta_{(i)}, i = 0,1,2,\dots,N$, such that $\zeta_{(0)} \in C_0^{\infty}(\Omega)$ and $\zeta_{(i)} \in C_0^{\infty}(B_{\rho_0}(x_i))$, $x_i \in \partial\Omega$, for $i \ge 1$. Then one estimates $\|\psi^{-1}u\zeta_{(0)}\|_{\mathbb{H}^{\gamma+2}_{p,\theta}(\Omega,t)}$ using Theorem 5.1 in [8] and the other norms as above. By summing up those estimates one gets

$$\begin{aligned}\|\psi^{-1}u\|_{\mathbb{H}^{\gamma+2}_{p,\theta}(\Omega,t)} &\le N\|\psi u_x\|_{\mathbb{H}^{\gamma}_{p,\theta}(\Omega,t)} + N\|u\|_{\mathbb{H}^{\gamma}_{p,\theta}(\Omega,t)}\\ &+ N\|\psi f\|_{\mathbb{H}^{\gamma}_{p,\theta}(\Omega,t)} + N\|u_0\|_{U^{\gamma+2}_{p,\theta}(\Omega)}.\end{aligned} \tag{5.3}$$

Furthermore, we know from Theorem 4.1 of [15] (cf. also (4.4)) that

$$\|\psi u_x\|_{H^{\gamma}_{p,\theta}(\Omega)} \le N\|u\|_{H^{\gamma+1}_{p,\theta}(\Omega)}.$$

Therefore (5.3) yields

$$\|u\|^p_{\mathfrak{H}^{\gamma+2}_{p,\theta}(\Omega,t)} \le N\|u\|^p_{\mathbb{H}^{\gamma+1}_{p,\theta}(\Omega,t)} + N\|\psi f\|^p_{\mathbb{H}^{\gamma}_{p,\theta}(\Omega,t)} + N\|u_0\|^p_{U^{\gamma+2}_{p,\theta}(\Omega)}.$$

Now (2.8) follows from inequality (2.21) of [16] and Gronwall's inequality. Actually, there is a restriction that $p \ge 2$ in inequality (2.21) of [16], but by inspecting the proofs

of Theorem 4.2 and Theorem 7.1 in [8] one can easily check that in our (deterministic) case the result holds for all $p > 1$.

Step 3. The a priori estimate from Step 2 combined with the method of continuity shows that it remains only to prove solvability in the case of the heat equation. At this moment the fact that the domain is infinitely smooth turns out to be extremely handy.

Since $C_0^\infty(\Omega)$ is dense in $U^{\gamma+2}_{p,\theta}(\Omega)$, it suffices to concentrate on $u_0 \in C_0^\infty(\Omega)$. Then passing from u to $u - u_0$ we see that we may assume $u_0 = 0$. Again using the fact that $C_0^\infty(\Omega)$ is dense in the spaces $H^\kappa_{q,\tau}(\Omega)$ we easily convince ourselves that it suffices to consider only f's that are bounded on $\Omega \times [0,T]$ along with each derivative in (t,x) and vanish if x is in a neighborhood of the boundary of Ω.

In that case it is well known (see, for instance, Theorem 4.5.2 in [10]) that there exists a classical solution u of the heat equation with zero boundary and initial data. Moreover, u is infinitely differentiable and each of its derivatives in (t,x) is bounded.

Next, it turns out that u/ψ is infinitely differentiable and has bounded derivatives. Indeed, this is a local property which is preserved under C^∞ transformations of coordinates. Moreover, inside of Ω the property is obvious and near the boundary points it follows after flattening the boundary from the formula

$$v(x)/x^1 = \int_0^1 v_{x^1}(rx^1, x^2, \dots, x^d)\, dr,$$

valid for any smooth function v on $\bar{\mathbb{R}}^d_+$ vanishing for $x^1 = 0$. In particular, we infer that $\psi^{|\alpha|} D^\alpha(\psi^{-1}u)$ is bounded for any multi-index α. Hence, by Proposition 2.2 in [15] we conclude that $u \in \mathfrak{H}^{\gamma+2}_{p,\theta}(\Omega, T)$. The theorem is proved.

Proof of Theorem 2.11. Let $u \in \psi H^{\gamma+2}_{p,\theta}(\Omega)$ be a solution of (2.9). Observe that, due to Theorem 3.1 of [15] and Lemma 2.8(i) implying that $|\psi^{2/p}|^{(0)}_\tau < \infty$ for all $\tau \geq 0$, we have $u \in U^{\gamma+2}_{p,\theta}(\Omega)$. Furthermore, $v := ue^{c_0 t}$ satisfies (2.1) with $fe^{c_0 t}$ in place of f. For v estimate (2.8) becomes

$$g(T)\|u/\psi\|_{H^{\gamma+2}_{p,\theta}(\Omega)} \leq N_1 e^{N_1 T}\left(\|u/\psi\|_{H^{\gamma+2}_{p,\theta}(\Omega)} + g(T)\|\psi f\|_{H^{\gamma}_{p,\theta}(\Omega)}\right),$$

where

$$g(T) = \left(\int_0^T e^{ptc_0}\, dt\right)^{1/p}.$$

If $c_0 > N_1$, then the ratio $N_1 e^{N_1 T}/g(T)$ tends to zero as $T \to \infty$. Then after finding a T such that this ratio is less than $1/2$ one gets (2.10).

Having thus proved the a priori estimate (2.10), we can proceed as in Steps 1 and 3 of the above proof of Theorem 2.10. The theorem is proved.

6. Proof of Theorem 2.12. First we discuss Lemma 2.6. Its assertions (i)–(iii) are stated as Lemma 2.8 in [4] and one finds all the assertions for $|\alpha| = 1$ in Theorems 1.3 and 2.1 of [12]. Since the lemma plays a crucial role in the present article, we give a short proof.

Lemma 2.8 of [4] is obtained on the basis of Lemma 2.3 of [4], and assertion (iv) of our Lemma 2.6 is obtained by analyzing the proof of Lemma 2.3 of [4], which treats a generalization of the following. Given a C^1 function f on $\mathbb{R}^{d-1}$ with compact support

and a $\varphi \in C_0^\infty(\mathbb{R}^{d-1})$, for $x = (x^1, x') \in \mathbb{R}^d_+$, introduce

$$F(x) = (x^1)^{1-d} \int_{\mathbb{R}^{d-1}} f(y')\varphi((x'-y')/x^1)\,dy' = \int_{\mathbb{R}^{d-1}} f(x'-x^1y')\varphi(y')\,dy'.$$

We have

$$F_{x^j}(x) = \int_{\mathbb{R}^{d-1}} f_{y^j}(x'-x^1y')\varphi(y')\,dy', \quad j = 2,\dots,d, \tag{6.1}$$

$$F_{x^1}(x) = -\int_{\mathbb{R}^{d-1}} f_{y^i}(x'-x^1y')y^i\varphi(y')\,dy', \tag{6.2}$$

$$|F_x(x)| \le N \sup_{y'} |f_{y'}(y')|. \tag{6.3}$$

Furthermore, by induction one easily gets that for any multi-index $\alpha \neq 0$

$$\begin{aligned}(MD)^\alpha F(x) &:= (MD_1)^{\alpha_1} \times \cdots \times (MD_d)^{\alpha_d} F(x)\\ &= (x^1)^{1-d} \int_{\mathbb{R}^{d-1}} f(y')\varphi_\alpha((x'-y')/x^1)\,dy' = \int_{\mathbb{R}^{d-1}} f(x'-x^1y')\varphi_\alpha(y')\,dy',\end{aligned}$$

where $\varphi_\alpha \in C_0^\infty(\mathbb{R}^{d-1})$ and $\int \varphi_\alpha\,dy' = 0$. Applying this to (6.1) and (6.2) we obtain

$$(MD)^\alpha F_{x^i}(x) = \int_{\mathbb{R}^{d-1}} f_{y^j}(x'-x^1y')\varphi_{ij\alpha}(y')\,dy',$$

where $\varphi_{ij\alpha} \in C_0^\infty(\mathbb{R}^{d-1})$ and $\int \varphi_{ij\alpha}\,dy' = 0$ if $\alpha \neq 0$. It follows that if $\alpha \neq 0$, then

$$\begin{aligned}(MD)^\alpha F_{x^i}(x) &= \int_{\mathbb{R}^{d-1}} [f_{y^j}(x'-x^1y') - f_{y^j}(x')]\varphi_{ij\alpha}(y')\,dy',\\ |(MD)^\alpha F_{x^i}(x)| &\le N \sup_{y':|y'|\le x^1R} |f_x(x'+y') - f_x(x')|,\\ |(x^1)^{|\alpha|} D^\alpha F_x(x)| &\le N \sup_{y':|y'|\le x^1R} |f_x(x'+y') - f_x(x')|, \qquad (6.4)\end{aligned}$$

where R is such that $\operatorname{supp}\varphi \in B_R$.

Now, if a portion of $\partial\Omega$ is given by the equation $x^1 = f(x')$ and Ω near this portion lies in $x^1 > f(x')$, then there the function ψ is constructed after Lemma 2.5 of [4] by means of solving the equation

$$x^1 = \psi(x) + F(\varepsilon\psi(x), x') \tag{6.5}$$

under the additional harmless assumptions that $\int \varphi\,dy' = 1$. The constant $\varepsilon > 0$ is chosen in such a way that $\varepsilon|F_{x^1}| \le 1/2$, so that (6.5) admits a smooth solution by the implicit function theorem. In that case also, for the function $E(r,x) := r + F(\varepsilon r, x') - x^1$, we have $E_r \le -1/2$. By Lemma 3.8 and estimates (6.3) and (6.4) we conclude that assertion (iv) of Lemma 2.6 holds for ψ defined from (6.5). For general C^1 domains one constructs ψ by "piecing together such local definitions of ψ by partitions of unity" (see [4]); one can find more detail in [11] and [12].

Proof of Theorem 2.12. This proof consists of five steps.

Step 1. First we construct $\mu(x)$ near the boundary of Ω_ε as a mapping that moves $x \in \Omega_\varepsilon = \{\psi > \varepsilon\}$ along the straight line $x(r) = x - r\psi_x(x)$ toward $\partial\Omega$ to a point y at which $\psi(y) = \psi(x) - \varepsilon$. The value of $\varepsilon > 0$ will be taken in a special way.

To make a preliminary choice, notice that we can take 2ψ in place of ψ, so that without losing generality we may assume that for an $\bar{\varepsilon} > 0$, we have $|\psi_x| > 1$ in $\Omega \setminus \Omega_{\bar{\varepsilon}}$. Then recalling that r_0 and K_0 are the constants from Assumption 2.1, define

$$M = \sup_{\Omega} |\psi_x|, \quad R = 10K_0^2 M^2,$$

and only concentrate on ε satisfying

$$0 < \varepsilon < (\bar{\varepsilon}/R) \wedge (r_0/(8K_0^2 M)). \tag{6.6}$$

Keeping in mind that $\psi(x)$ is equivalent to $\rho(x)$ near $\partial\Omega$ and that ψ_x is uniformly continuous, choose ε (satisfying (6.6) and) such that

$$x, y \in \bar{\Omega} \setminus \Omega_{R\varepsilon}, |x - y| \leq 2M\varepsilon \Longrightarrow \rho(x) < \frac{r_0}{2K_0^2}, \quad |\psi_x(x) - \psi_x(y)| \leq \frac{1}{8K_0^2 M}. \tag{6.7}$$

Next, for $x \in \bar{\Omega} \setminus \Omega_{R\varepsilon}$ and $r \in \mathbb{R}$ such that $x - r\psi_x(x) \in \bar{\Omega} \setminus \Omega_{R\varepsilon}$, introduce the functions

$$u = u(r, x) = x - r\psi_x(x), \quad E(r, x) = \psi(u) - \psi(x) + \varepsilon.$$

Observe that if $x, u(r, x) \in \bar{\Omega} \setminus \Omega_{R\varepsilon}$ and $|r| \leq 2\varepsilon$, then $|x - u| \leq 2M\varepsilon$ and $|\psi_x(u)| \geq 1$ (owing to $R\varepsilon \leq \bar{\varepsilon}$; see (6.6)) and

$$\begin{aligned} E_r(r, x) = &- \psi_{x^i}(x)\psi_{x^i}(u) = -|\psi_x(u)|^2 \\ &+ \big(\psi_{x^i}(u) - \psi_{x^i}(x)\big)\psi_{x^i}(u) \leq -1 + M/(8K_0^2 M) < -1/2. \end{aligned}$$

Hence, in this range of r, the functions $\psi(u(r, x))$ and $E(r, x)$ are strictly locally decreasing in r. In particular, if $x \in \partial\Omega$, then on the interval $-2\varepsilon \leq r < 0$ we have $\psi(u(r, x)) > |r|/2$. Hence $u(-2\varepsilon, x) \in \Omega_\varepsilon$, so that any point on $\partial\Omega$ can be connected by a straight line with a point in Ω_ε.

Furthermore, it is seen that for any $x \in \Omega_\varepsilon \setminus \Omega_{R\varepsilon}$ we have $E(0, x) = \varepsilon$ and there is a unique $r = r(x) \in (0, 2\varepsilon)$ such that

$$\varepsilon \geq E(r, x) > 0 \quad \text{for} \quad r \in [0, r(x)), \quad E(r(x), x) = 0. \tag{6.8}$$

Now we apply Lemma 3.8 to $G = \Omega_\varepsilon \setminus \bar{\Omega}_{R\varepsilon}$ and $d = \rho_{\Omega_\varepsilon}$. Notice that in G every derivative of $\psi(x)$ is bounded and that d on G is comparable with $\psi(x) - \varepsilon$ (cf. Remark 2.7). Also we introduce

$$u(x) = u(r(x), x) = x - r(x)\psi_x(x)$$

and notice that by definition $\psi(x) - \varepsilon = \psi(u(x))$ and the latter is comparable with $\rho(u(x))$. Then we see that instead of dealing with (3.11) it suffices to treat

$$(\psi(x) - \varepsilon)^{|\alpha|-1}(D^\alpha \psi)(u(x)),$$

which equals

$$\psi^{|\alpha|-1}(u(x))(D^\alpha \psi)(u(x)),$$

and the latter is bounded on G for any $\alpha \neq 0$ and, for $|\alpha| \geq 2$, tends to zero as $\psi(x) - \varepsilon = \psi(u(x)) \downarrow 0$ by Lemma 2.6.

Thus, by Lemma 3.8 we have that $(\psi(x)-\varepsilon)^{|\alpha|-1}D^\alpha r(x)$ is bounded in $\Omega_\varepsilon \setminus \Omega_{R\varepsilon}$ for any $\alpha \neq 0$ and, for $|\alpha| \geq 2$, tends to zero as $\psi(x)-\varepsilon \downarrow 0$.

Step 2. Now we can define μ in Ω_ε. Observe that $R > 10$, so that $1/(R-2) < 5/(4R)$ and there is an infinitely differentiable function $\kappa(t)$, $t \in \mathbb{R}$, such that $\kappa(t) = 1$ for $t \leq 2$, $\kappa(t) = 0$ for $t \geq R$, and $0 \leq -\kappa' \leq 5/(4R)$. In Ω_ε we define

$$\mu(x) = x - r(x)\kappa(\psi(x)/\varepsilon)\psi_x(x). \tag{6.9}$$

Strictly speaking, for $x \in \Omega_{R\varepsilon}$ the above formula has no sense since we have not defined $r(x)$ for $x \in \Omega_{R\varepsilon}$, but for those x we have $\psi(x) > R\varepsilon$, so that $\kappa(\psi(x)/\varepsilon) = 0$ and in that case we set by definition $\mu(x) = x$. Certainly, assertions (ii), (iii), (v), and (vi) hold in what concerns μ. Assertion (i) for μ follows from the formula

$$r_{x^i}(x)\psi_{x^j}(u)\psi_{x^j}(x) = \psi_{x^i}(u) - \psi_{x^i}(x) - r(x)\psi_{x^j}(u)\psi_{x^ix^j}(x), \tag{6.10}$$

which holds for $x \in \Omega_\varepsilon \setminus \Omega_{R\varepsilon}$ with $u = u(x)$ and which yields, first, the modulus of continuity of $r(x)$ and then that of $r_x(x)$ in $\Omega_\varepsilon \setminus \Omega_{R\varepsilon}$.

Step 3. Next, we come to defining ν. To be sure that μ is locally one-to-one, we fine tune the choice of ε in the following way. Observe that in $\Omega_\varepsilon \setminus \Omega_{R\varepsilon}$ as we know, $r(x) \in (0, 2\varepsilon)$ so that $r \leq 2\psi$ in $\Omega_\varepsilon \setminus \Omega_{R\varepsilon}$ and the last term in (6.10) is less than $2M\psi\psi_{x^ix^j}$. Furthermore, $\psi\psi_{xx}$ can be made arbitrary small in $\Omega \setminus \Omega_{R\varepsilon}$ on the account of appropriate choice of ε. Therefore, (6.10) and the estimates in the beginning of the proof (remember $|u-x| \leq 2\varepsilon M$) show that for sufficiently small ε we have

$$|r_x| \leq 2|\psi_x(u) - \psi_x(x)| + 1/(4MK_0^2) \leq 1/(2MK_0^2)$$

in $\Omega_\varepsilon \setminus \Omega_{R\varepsilon}$.

Now, by differentiating (6.9) in the direction of a unit vector $e \in \mathbb{R}^d$ we obtain in $\Omega_\varepsilon \setminus \Omega_{R\varepsilon}$ that

$$\begin{aligned} |\mu_{(e)}(x) - e| &\leq |r_{(e)}(x)|\kappa(\psi/\varepsilon)M + 2\varepsilon|\kappa'(\psi/\varepsilon)|M^2/\varepsilon + 2\psi|\psi_{x(e)}| \\ &\leq 1/(2K_0^2) + 10M^2/(4R) + 2\psi|\psi_{x(e)}| = 3/(4K_0^2) + 2\psi|\psi_{x(e)}|. \end{aligned}$$

By reducing further ε we arrive at a situation in which

$$|\mu_{(e)}(x) - e| \leq 4/(5K_0^2) < 1 \tag{6.11}$$

in $\Omega_\varepsilon \setminus \Omega_{R\varepsilon}$ and, actually, in Ω_ε since the first expression is zero in $\Omega_{R\varepsilon}$.

Estimate (6.11) allows us to solve the equation

$$\mu(\nu(x)) - x = 0 \tag{6.12}$$

near any point $x_0 = \mu(y_0)$ with $y_0 \in \Omega_\varepsilon$ (and the solution satisfying $\nu(x_0) = y_0$ is unique). Furthermore,

$$\rho^{|\alpha|-1}(x)(D^\alpha\mu)(\nu(x)) = \rho^{|\alpha|-1}(\mu(y))D^\alpha\mu(y)|_{y=\nu(x)}$$

and, due to the part of assertion (ii) proved for μ, the latter is bounded. Also observe that, for any solution of (6.12) and $x \in \Omega \setminus \Omega_{R\varepsilon}$, we have $\nu(x) \in \Omega_\varepsilon \setminus \Omega_{R\varepsilon}$ (otherwise $\mu(\nu(x)) = \nu(x)$), so that, by virtue of (6.8) and the fact that $0 \leq \kappa \leq 1$, we have

$$\psi(x) = \psi(\mu(\nu(x))) \geq \psi(u(\nu(x))) = \psi(\nu(x)) - \varepsilon.$$

It follows that if $\Omega \ni x \to \partial\Omega$, then $y = \nu(x) \to \partial\Omega_\varepsilon$ and

$$|\rho^{|\alpha|-1}(\mu(y))D^\alpha \mu(y)| \le N\psi^{|\alpha|-1}(\mu(y))D^\alpha\mu(y)| \to 0,$$

as have been pointed out above. This and Lemma 3.8 applied to (6.12) would have finished the proof of the theorem if we already knew that $\nu(x)$ was uniquely defined in Ω.

Step 4. To show that $\nu(x)$ is indeed uniquely defined in Ω, we first prove that

$$\Omega' := \mu(\Omega_\varepsilon) = \Omega. \tag{6.13}$$

Referring to (6.11), we conclude that Ω' is an open subset of Ω. On the other hand, if $y_n \in \Omega'$ and $y \in \Omega$ and $y_n \to y$, then for $x_n \in \Omega_\varepsilon$ such that $\mu(x_n) = y_n$ we have

$$x_n - y_n = r(x_n)\kappa(\psi(x_n)/\varepsilon)\psi_x(x_n).$$

Since the right-hand side is bounded, there is a subsequence $x_{n'}$ converging to a point $x \in \bar\Omega_\varepsilon$.

It turns out that $x \in \Omega_\varepsilon$. Indeed, if $x \in \partial\Omega_\varepsilon$, then $\kappa(\psi(x_{n'})/\varepsilon) = 1$ for all large n' and $\psi(x_{n'}) = \psi(y_{n'}) + \varepsilon$, so that $\psi(x) = \psi(y) + \varepsilon$. Here $y \in \Omega$ and $\psi(y) > 0$, implying $\psi(x) > \varepsilon$ and contradicting $x \in \partial\Omega_\varepsilon$.

By passing to the limit in $\mu(x_{n'}) = y_{n'}$ we now see that $\mu(x) = y$ and $y \in \Omega'$. This means that Ω' is not only open but also is closed in the relative topology of Ω. It follows that Ω' is the union of some connected components of Ω. In addition, since as was noted above, any point on $\partial\Omega$ can be connected by a straight line with a point in Ω_ε, each connected component of Ω contains points of Ω_ε and thus points of Ω'. We have proved (6.13).

Step 5. It remains to prove that the mapping μ is one-to-one. To this end we make the final adjustment of ε which gives us the possibility of connecting close points in Ω_ε by paths of length comparable with the distance between the points. So far the relation of ε to r_0 and K_0 did not play much of a role. Now it becomes crucial.

As is easy to see, due to Assumption 2.1 for any $x_0 \in \partial\Omega$, we have $B_{r_0/K_0} \cap \mathbb{R}^d_+ \subset \Psi(B_{r_0}(x_0) \cap \Omega)$. Furthermore, the function $\psi(\Psi^{-1})$ is continuously differentiable in the closure of $B_{r_0/K_0} \cap \mathbb{R}^d_+$ and vanishes on the set $\{y^1 = 0\} \cap B_{r_0/K_0}$, so that its gradient on this set is parallel to the y^1 axis. It follows that for sufficiently small $\varepsilon > 0$ the angle, which the gradient of $\psi(\Psi^{-1})$ makes with the y^1 axis on the surface $\{\psi(\Psi^{-1}) = \varepsilon\} \cap B_{r_0/K_0}$, is as small as we like. We make it so small that any two points $y_1, y_2 \in \{\psi(\Psi^{-1}) > \varepsilon\} \cap B_{r_0/K_0}$ could be connected by a path lying in $\{\psi(\Psi^{-1}) > \varepsilon\} \cap B_{r_0/K_0}$ and consisting of two straight segments of total length $\le (10/9)|y_1 - y_2|$.

Next, if $x_1, x_2 \in \Omega$ and

$$\rho(x_1) < r_0/(2K_0^2) \quad \text{and} \quad |x_1 - x_2| < r_0/(2K_0^2),$$

then there is an $x_0 \in \partial\Omega$ such that

$$x_1, x_2 \in B_{r_0/K_0^2}(x_0) \cap \Omega$$

and the images y_1 and y_2 of x_1, x_2 under Ψ lie in $B_{r_0/K_0} \cap \mathbb{R}^d_+$ and $|y_1 - y_2| \le K_0|x_1 - x_2|$. If in addition $x_1, x_2 \in \Omega_\varepsilon$, then by the above paragraph there is a path in Ω_ε connecting x_1 and x_2 and having length $\le K_0(10/9)|y_1 - y_2| \le (10/9)K_0^2|x_1 - x_2|$.

Now, assume that $\mu(x_1) = \mu(x_2)$ for some $x_i \in \Omega_\varepsilon$. If $x_1, x_2 \in \Omega_{R\varepsilon}$, then $\mu(x_1) = x_1 = \mu(x_2) = x_2$. If, say $x_1 \in \Omega \setminus \Omega_{R\varepsilon}$, then (see (6.7)) we have $\rho(x_1) < r_0/(2K_0^2)$ and

$$|x_1 - x_2| = |r(x_1)\kappa(\psi(x_1)/\varepsilon)\psi_x(x_1) - r(x_2)\kappa(\psi(x_2)/\varepsilon)\psi_x(x_2)|$$
$$\leq |r(x_1)\kappa(\psi(x_1)/\varepsilon)\psi_x(x_1)| + |r(x_2)\kappa(\psi(x_2)/\varepsilon)\psi_x(x_2)| \leq 4M\varepsilon.$$

In addition (see (6.6)) $4M\varepsilon < r_0/(2K_0^2)$, so that the points x_1 and x_2 can be connected by a path $s(t)$, $t \in [0,1]$, lying in Ω_ε and having length $\leq (10/9)K_0^2|x_1 - x_2|$. In light of (6.11), we obtain

$$|x_1 - x_2| = |\mu(x_1) - \mu(x_2) - (x_1 - x_2)| \leq \int_0^1 |(\mu(s(t)))' - s'(t)|\,dt$$
$$\leq 4/(5K_0^2)\int_0^1 |s'(t)|\,dt \leq (8/9)|x_1 - x_2|,$$

implying that $|x_1 - x_2| = 0$. We see that the conditions $\mu(x_1) = \mu(x_2)$ and $x_1, x_2 \in \Omega_\varepsilon$ imply that $x_1 = x_2$. Therefore, $\nu = \mu^{-1}$ is well defined indeed and the theorem is proved.

Acknowledgments. The authors are sincerely grateful to the referees for useful comments and suggestions.

INFINITE JACOBI MATRICES WITH UNBOUNDED ENTRIES: ASYMPTOTICS OF EIGENVALUES AND THE TRANSFORMATION OPERATOR APPROACH*

JAN JANAS† AND SERGUEI NABOKO‡

Abstract. In this paper the exact asymptotics of eigenvalues $\lambda_n(J)$, $n \to \infty$, of a class of unbounded self-adjoint Jacobi matrices J with discrete spectrum are given. Their calculation is based on a successive diagonalization approach—a new version of the classical transformation operator method. The approximations of the transformation operator are constructed step by step using a successive diagonalization procedure, which results in higher order approximations of the $\lambda_n(J)$.

Key words. unbounded Jacobi operator, asymptotics of eigenvalues, transformation operator, successive diagonalization

1. Introduction. In this work we consider a class of infinite Jacobi matrices acting in $l^2 = l^2(\mathbb{N})$. Although the class we study looks rather special, it is large enough to contain examples of physical interest. More precisely we investigate the asymptotics of the energy spectrum of a molecule in the homogeneous electric field. The asymptotics of the spectrum are obtained via a general successive diagonalization method which seems to be of independent interest and can be used for other Jacobi matrices with discrete spectrum. We emphasize that the special class of Jacobi matrices under consideration has been chosen for simplicity only. Our goal is to present the general ideas of the method, avoiding tedious calculations and complicated formulations.

Recall that an essentially self-adjoint Jacobi matrix

$$J = \begin{pmatrix} q_1 & \lambda_1 & 0 & 0 & \cdots \\ \lambda_1 & q_2 & \lambda_2 & 0 & \cdots \\ 0 & \lambda_2 & q_3 & \lambda_3 & \cdots \\ 0 & 0 & \lambda_3 & q_4 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix},$$

which is a relatively compact perturbation of the diagonal operator Q (given by $Qf_n = q_n f_n$ in the canonical basis f_n of l^2) under suitable conditions on its entries, has a compact resolvent and so its spectrum is discrete. A simple sufficient condition for the discreteness of the spectrum of J was given, for example, in [19] and says

$$\text{if } \lim_n \inf \frac{q_n^2}{\lambda_n^2 + \lambda_{n-1}^2} > 2, \text{ then } J \text{ has discrete spectrum}$$

(we assume that $\lambda_n > 0$). Another sufficient condition for discreteness of the spectrum of J was obtained in [36] (using continuous fraction representation of the Weyl function

of J). The class of J we consider below has bounded weights λ_n and $q_n = n^2 + c_1 n + O(1)$. The idea of successive diagonalization uses two general ingredients.

First, for a given compact perturbation R of a diagonal self-adjoint operator D ($De_n = \mu_n e_n$, where e_n is an orthonormal basis in a Hilbert space) we assume that (a) dist $(\mu_k, \mu_l) \geq \varepsilon_0 > 0$ if $k \neq l$ and at least k or l is large enough, and (b) R is a band matrix in the basis e_n. We stress that R can be non-self-adjoint (as it will be in our situation of self-adjoint Jacobi matrices). Under the above assumption $\sigma(D+R)$ is obviously discrete and the eigenvalues $\lambda_k(D+R) = \mu_k + O(\|R^* e_n\|)$. In this way we are able to control the distance $|\lambda_k(D+R) - \mu_k|$. Note that even for a rank-one R it may happen that the above distance can be an arbitrary l^1 sequence (see Example 2.3).

Second, we look for a diagonal matrix that is similar to the original J modulo some compact band matrix (in the same basis f_n).

This idea in some important features goes back to the old method of transformation operator presented by Delsarte [10], Delsarte and Lions [11], Marchenko [32], Levitan [30], and Naimark [33]. It was applied to calculate the exact asymptotics of the eigenvalues of Sturm–Liouville operators with smooth coefficients. However, we do not try to find exactly the transformation operator; instead, a successive approximation procedure is suggested. A somewhat similar idea of approximate similarity was used by Rosenblum in his remarkable paper [34] on asymptotics of the eigenvalues of some pseudodifferential operators. But our class of unbounded Jacobi matrices is quite different from the one of pseudodifferential operators considered by Rosenblum. Note that in this way we have to leave the class of self-adjoint operators, but we stay in the class of band matrices that are a weak perturbation of the diagonal matrix. We repeat this procedure several times (successive diagonalization), obtaining finally as weak perturbation of the diagonal operator, as we require. This allows us to find the value of the eigenvalues $\lambda_n(J)$ with arbitrary precision as $n \to \infty$. In this paper we restrict ourselves to three steps to avoid the tedious calculation necessary for higher order approximation. Although we concentrate on finding asymptotics of $\lambda_n(J)$, the approach also works simultaneously for computing approximate formulas of the eigenvectors of J. Surely this is a natural consequence of realization of the transformation operator idea. Actually, the spectral analysis of infinite self-adjoint Jacobi matrices is a classical topic related to the theory of orthogonal polynomials [1], [2], [3], [4], [8]. Numerous methods were elaborated on for studies of spectral problems for various classes of Jacobi matrices in $l^2(\mathbb{N})$ and $L^2(\mathbb{Z})$; see [12], [13], [14], [15], [16], [19], [20], [21], [22], [23], [24], [25], [26], [27], [35].

Note that calculation of exact asymptotics of eigenvalues of ordinary differential operators is a classical problem studied by Birkhoff and Tamarkin and for partial differential operators by Weyl. The same question about the asymptotics of eigenvalues can be investigated for difference operators (Jacobi matrices).

In turn, in physical models it is important to analyze the influence of physical parameters on the spectrum of Hamiltonians. Since the exact calculation of their eigenvalues is usually impossible, it is of considerable interest to study the appearance of the parameters in different terms of asymptotics of the eigenvalues. This allows better understanding of the role of parameters in the spectral picture of Hamiltonians and therefore in the corresponding physical model as well.

Let us also recall that Jacobi matrices appear in applications to many fields, including quantum mechanics, quantum optics, solid state physics, and numerical analysis. Already classical operators of creation a and annihilation $a^+ = a^*$ of quan-

tum physics can be represented by the nonsymmetric Jacobi matrix (a_{ij}) with only one nonzero diagonal $a_{ij} = \sqrt{i-1}\delta_{ij+1}$, where δ_{ij} is the Kronecker delta function. In quantum optics, Hamiltonians in simple models can be represented by polynomials in a and a^+. Therefore in a suitable orthonormal basis they are given by Hermitian band matrices. In some cases such models can be reduced to symmetric Jacobi matrices, for example, in the case of the Jaynes–Cumming model without rotating wave approximation (RWA) studied in [31]. In turn, in solid state physics models appear as Jacobi matrices with almost periodic entries [9].

The paper is organized as follows. In section 2 the first abstract fact is proved. The above-mentioned three steps of successive diagonalization are presented in section 3. Finally, the application to a physical model is considered briefly in section 4.

2. Preliminaries. Before proceeding further let us recall some notation and notions. Let $\{f_n\}_{n=1}^{\infty}$ be the canonical orthonormal basis in $l^2 = l^2(\mathbb{N})$. For given sequences $\{\lambda_n\}_{n=1}^{\infty}$, $\{q_n\}_{n=1}^{\infty}$ of real numbers one defines the Jacobi matrix J by $J = SD + DS^* + Q$, where D and Q are the diagonal operators defined by $\{\lambda_n\}_{n=1}^{\infty}$ and $\{q_n\}_{n=1}^{\infty}$, respectively, and the unilateral shift is defined by $Sf_n = f_{n+1}$. As mentioned, the class of Jacobi operators we study in this paper is given by $q_n = n^2 + c_1 n + c_2 n^{-1} + c_3 n^{-2} + O(\frac{1}{n^3})$, $\lambda_n = g + b_1 n^{-1} + b_2 n^{-2} + O(\frac{1}{n^3})$, where all c_j, b_j are real and such that $\lambda_n \neq 0$ (as usual). We omit the zero order term in q_n since it produces the shift of the spectrum only. The physical motivation for so special a choice of q_n and λ_n will be given in section 4. Denote by $J(= J(g, b_1, b_2, c_1, c_2, c_3))$ the Jacobi operator induced by the above sequences. The spectrum of J is obviously discrete and consists of the eigenvalues $\{\lambda_k(J)\}_{k=1}^{\infty}$ [18].

In what follows $\Sigma_{1/p}$ $(p > 0)$ stands for the weak ideal of Schatten–von Neumann compact operators T such that their singular numbers $s_k(T)$ satisfy estimates $s_k(T) = O(\frac{1}{k^p})$ [5]. Below $\| \|$ denotes the operator norm and $[A, B] := AB - BA$ is the commutator of operators A and B.

We start by proving a folklore-type, simple lemma, which will be used as a tool of successive approximation of the eigenvalues $\lambda_k(J)$.

LEMMA 2.1. *Let D be a self-adjoint diagonal operator in a Hilbert space H given by $De_n = \mu_n e_n$, where $\{e_n\}$ is an orthonormal basis of eigenvectors in H and simple eigenvalues $\mu_n \to \infty$ are ordered by $|\mu_i| \leq |\mu_{i+1}|$. Assume that*

$$\text{(i)} \quad \textit{dist}\,(\mu_i, \mu_k) \geq \varepsilon_0 \textit{ for some } \varepsilon_0 > 0 \textit{ and all } i \neq k.$$

If R is a compact (not necessary self-adjoint) operator in H, then the operator $T = D + R$ has discrete spectrum when the complex eigenvalues $\lambda_n(T)$ of T are numerated properly. Moreover, for large values of n the eigenvalues of T are simple and $\lambda_n(T)$ satisfy the estimates $\lambda_n(T) = \mu_n + O(\|R^* e_n\|)$.[1]

Proof. Let

$$K_n := \{\lambda \in \mathbb{C},\ |\lambda - \mu_n| \leq r_n\}$$

with $r_n = O(\|R^* e_n\|)$. We claim two facts. First, there exists a collection of the eigenvalues of T such that for arbitrary n the distance between μ_n and an eigenvalue of T from the collection fulfills the estimate $O(\|R^* e_n\|)$, as $n \to \infty$. Second, all the eigenvalues of T belong to the collection and therefore satisfy the estimates of

[1] The above formula induces a proper numeration of $\lambda_n(T)$ which does not coincide in general with monotonic ordering of their moduli, due to possible jumps of the signs of μ_n.

Lemma 2.1 after a proper numeration. Note that the above inessential complicated formulation appears due to not fixed signs of μ_n.

To prove the first fact we find numbers $r_n < \varepsilon_0/2$ such that for large n in the disc K_n there is exactly one simple eigenvalue of T. Below we essentially follow the idea of the proof of the stability of the multiplicity from [5]. For $\lambda \in \mathbb{C} \setminus \sigma(D)$ we have

$$(T-\lambda)^{-1} = [I + (D-\lambda)^{-1}R]^{-1}(D-\lambda)^{-1}. \tag{2.1}$$

Assume that for $n \gg 1$ we have chosen r_n such that

$$(*)\sup\|(D-\lambda)^{-1}R\| \le \frac{1}{3}, \quad \lambda \in \Gamma_n, \text{where } \Gamma_n = \partial K_n.$$

Since $r_n < \varepsilon_0/2$, using (2.1) and (i) we see that $\sigma(T) \cap \Gamma_n = \phi$. Fix large n for which $(*)$ holds. Now we follow more or less standard reasoning. Let P_T and P_D be the Riesz projections given by

$$P_T := -\frac{1}{2\pi i}\int_{\Gamma_n}(T-\lambda)^{-1}d\lambda, \quad P_D := -\frac{1}{2\pi i}\int_{\Gamma_n}(D-\lambda)^{-1}d\lambda = (\cdot, e_n)e_n.$$

Denote $F_\lambda := (D-\lambda)^{-1}R$. Then using (2.1) we have

$$P_T = P_D - \frac{1}{2\pi i}\int_{\Gamma_n}\left[\sum_{k=1}^{\infty}(-1)^k F_\lambda^k\right](D-\lambda)^{-1}d\lambda.$$

Due to $(*)$ one can estimate

$$\|P_T - P_D\| \le \frac{1}{2\pi}|\Gamma_n| \sup_{\Gamma_n}\sum_{k=1}^{\infty}\|F_\lambda\|^k r_n^{-1} = \sup_{\Gamma_n}[\|F_\lambda\|(1-\|F_\lambda\|)^{-1}] \le 1/2.$$

Hence rank P_T = rank $P_D = 1$. Therefore there is in K_n exactly one eigenvalue of T provided one can find r_n for which $(*)$ is satisfied.

Consider the Schmidt decomposition $R = \sum_{k=1}^{\infty} s_k(R)(\cdot, \varphi_k)\psi_k$, where $\{\varphi_n\}$ and $\{\psi_n\}$ are some orthonormal bases in H and $s_k(R)$ are the singular numbers of the compact operator R [5], [28]. Let $P_n := (\cdot, e_n)e_n$ and $P_n^\perp := I - P_n$.

Then $\|R^*(D-\overline{\lambda})^{-1}\| \le \|R^*(D-\overline{\lambda})^{-1}P_n\| + \|R^*(D-\overline{\lambda})^{-1}P_n^\perp\|$. However,

$$\|R^*(D-\overline{\lambda})^{-1}P_n\| = \|R^* e_n\| r_n^{-1}, \quad \lambda \in \Gamma_n. \tag{2.2}$$

On the other hand, for $f \in H$

$$\begin{aligned}\|R^*(D-\overline{\lambda})^{-1}P_n^\perp f\|^2 &= \sum_{k=1}^{\infty} s_k(R)^2 |(P_n^\perp(D-\overline{\lambda})^{-1}P_n^\perp f, \psi_k)|^2 \\ &\equiv \sum_{k=1}^{N} s_k(R)^2|\cdots|^2 + \sum_{k=N+1}^{\infty} s_k(R)^2|\cdots|^2.\end{aligned}$$

Since $\|P_n^\perp(D-\overline{\lambda})^{-1}P_n^\perp\| \le 2\varepsilon_0^{-1}$ (remember that $r_n \le \varepsilon_0/2$) and $\lambda \in \Gamma_n$,

$$\sum_{k=N+1}^{\infty} s_k(R)^2 |(P_n^{\perp}(D-\overline{\lambda})^{-1}P_n^{\perp}f,\psi_k)|^2$$

$$\leq s_{N+1}(R)^2 \cdot (2\varepsilon_0^{-1}\|f\|)^2 \leq \frac{1}{32}\|f\|^2 \tag{2.3}$$

for N sufficiently large.

Fix such a large value of N. Then $|(P_n^{\perp}(D-\overline{\lambda})^{-1}P_n^{\perp}f,\psi_k)|^2 \to 0$ as $n\to\infty$ (uniformly in $\lambda\in\Gamma_n$ and f in the unit ball) and $k=1,\dots,N$.

Indeed, if $Q_L=\sum_{l=1}^{L}P_l$, then

$$\begin{aligned}|(P_n^{\perp}(D-\overline{\lambda})^{-1}P_n^{\perp}f,\psi_k)| &\leq |(P_n^{\perp}(D-\overline{\lambda})^{-1}P_n^{\perp}f,Q_L\psi_k)| \\ &\quad + |(P_n^{\perp}(D-\overline{\lambda})^{-1}P_n^{\perp}f,(I-Q_L)\psi_k)| \\ &\leq \sum_{l=1}^{L}|(P_n^{\perp}(D-\overline{\lambda})^{-1}P_n^{\perp}f,P_l\psi_k)| + 2\varepsilon_0^{-1}\|(I-Q_L)\psi_k\|\cdot\|f\|. \end{aligned} \tag{2.4}$$

The second term from the above line can be made arbitrarily small by choosing L sufficiently large. For such fixed L and k each term $|(P_n^{\perp}(D-\overline{\lambda})^{-1}P_n^{\perp}f,P_l\psi_k)|$, $1\leq l\leq L$, obviously tends to zero uniformly in f from the unit ball as $n\to\infty$ (since $\sup_{\lambda\in\Gamma_n}\|P_l(D-\overline{\lambda})^{-1}\|\to 0$ as $n\to\infty$). Fix L so large that

$$2(2/\varepsilon_0)^2\sum_{k=1}^{N}s_k(R)^2\|(I-Q_L)\psi_k\|^2 \leq \frac{1}{32}.$$

For such large fixed L and $n\gg 1$ and $\lambda\in\Gamma_n$,

$$\sum_{k=1}^{N}s_k(R)^2|(P_n^{\perp}(D-\overline{\lambda})^{-1}P_n^{\perp}f,\psi_k)|^2 \leq \frac{1}{32}\|f\|^2. \tag{2.5}$$

Put $r_n=12\|R^*e_n\|$. Combining (2.2), (2.3), (2.4), and (2.5), we obtain the desired estimate $(*)$ (since all the above estimates were uniform with respect to $\lambda\in\Gamma_n$ and $\frac{1}{12}+\sqrt{\frac{1}{32}+\frac{1}{32}}=\frac{1}{3}$).

To prove the second fact, choose the radii $R_n\to+\infty$, $n\to\infty$, such that the circles $\Gamma_{R_n}:=\{z,|z|=R_n\}$ satisfy the estimates $\operatorname{dist}(\Gamma_{R_n},\sigma(D))\geq\varepsilon_0/4$ (using assumption (i)). As above, we want to prove the new estimate (compare to $(*)$) for large n,

$$\sup\|(\mathrm{D}-\lambda)^{-1}R\|\leq\frac{1}{3},\qquad \lambda\in\Gamma_{R_n}. \tag{2.6}$$

Since $s_k(R)\to 0$, as $k\to\infty$,

$$\sum_{k=N+1}^{\infty}s_k(R)^2|(P_n^{\perp}(\mathrm{D}-\overline{\lambda})^{-1}P_n^{\perp}f,\psi_k)|^2 \leq s_{N+1}(R)^2(4\varepsilon_0^{-1})^2\|f\|^2 \leq \frac{1}{4}\|f\|^2 \tag{2.7}$$

for N sufficiently large. Fix such N. To complete the proof it is enough to estimate

$$\sum_{k=1}^{N}s_k(R)^2|(P_n^{\perp}(\mathrm{D}-\overline{\lambda})^{-1}P_n^{\perp}f,\psi_k)|^2.$$

If $\lambda \in \Gamma_{R_n}$ we have

$$\|(\mathrm{D}-\overline{\lambda})^{-1}P_n^{\perp}f\|^2 = \sum_{l=1}^{\infty}|(P_n^{\perp}f,e_l)|^2|\mu_l-\lambda|^{-2} \le \sum_{l=1}^{\infty}|(P_n^{\perp}f,e_l)|^2(4\varepsilon_0^{-1})^2.$$

Since $|\mu_l+R_n|^{-2}+|\mu_l-R_n|^{-2}\to 0$, as $n\to\infty$, for $l=1,2,\dots$, we get

$$\sum_{k=1}^{N} s_k(R)^2|(P_n^{\perp}(\mathrm{D}-\overline{\lambda})^{-1}P_n^{\perp}f,\psi_k)|^2 = o(1)N\|f\|^2 \tag{2.8}$$

as $n\to\infty$. Here $o(1)$ tends to zero uniformly in f when $n\to\infty$. Finally (2.7) and (2.8) imply the desired estimate (2.6) for large n.

Our second fact will be proved once we show that for the discs $K(0,R_n)$ of radius R_n and the center at zero that

$$\sharp(K(0,R_n)\cap\sigma(T)) = \sharp(K(0,R_n)\cap\sigma(\mathrm{D})) \tag{2.9}$$

for n sufficiently large.

Note that due to the separation assumption (i), the circles Γ_n separate pairs of neighboring eigenvalues of D and therefore they do the same for neighboring eigenvalues of T for sufficiently large n. Finally, combining (2.9) and the formula $r_n = 12\|Re_n^*\|$ we get the desired asymptotic estimates $\lambda_n(T)=\mu_n+O(\|R^*e_n\|)$. It remains to prove (2.9). As above, it is enough to show that $\|P_T-P_{\mathrm{D}}\|<1$, where P_T (resp., P_{D}) are the Riesz projections corresponding to $\sigma(T)\cap K(0,R_n)$ ($\sigma(\mathrm{D})\cap K(0,R_n)$, resp.).

Applying (2.6) we have

$$\begin{aligned}\|P_T-P_{\mathrm{D}}\| &\le \frac{1}{2\pi}\int_{\Gamma_{R_n}}\|(D-\lambda)^{-1}R(T-\lambda)^{-1}\||d\lambda| \\ &\le \frac{1}{2\pi}\cdot\frac{3}{2}\int_{\Gamma_{R_n}}\|(\mathrm{D}-\lambda)^{-1}R(\mathrm{D}-\lambda)^{-1}\||d\lambda|.\end{aligned}$$

We claim that

$$\lim_n \int_{\Gamma_{R_n}}\|(\mathrm{D}-\lambda)^{-1}R(\mathrm{D}-\lambda)^{-1}\||d\lambda| = 0. \tag{2.10}$$

First observe that by the separation condition

$$\int_{\Gamma_{R_n}}\|(\mathrm{D}-\lambda)^{-1}R(\mathrm{D}-\lambda)^{-1}\||d\lambda| \le \|R\|\int_{\Gamma_{R_n}}\|(\mathrm{D}-\lambda)^{-1}\|^2|d\lambda| \le C\|R\| \tag{2.11}$$

for some positive C, $n=1,2,\dots$.

Fix $\varepsilon>0$ for which $C\cdot\varepsilon \ll 1$ and choose M so large that

$$R = R_\varepsilon + \sum_{k=1}^{M} s_k(R)(\dots,\varphi_k)\psi_k, \text{ where } \|R_\varepsilon\|\le\varepsilon. \tag{2.12}$$

Using (2.11) and (2.12), the above claim is reduced to the convergence

$$\lim_n \int_{\Gamma_{R_n}}\|(\mathrm{D}-\lambda)^{-1}(\langle\cdot,\varphi_k\rangle)\psi_k(\mathrm{D}-\lambda)^{-1}\||d\lambda| = 0,\ k=1,\dots,M.$$

Below we omit the index k. Applying the Cauchy–Schwarz inequality, it is enough to prove that for any $\varphi \in H$

$$\lim_n \int_{\Gamma_{R_n}} \|(\mathrm{D}-\lambda)^{-1}\varphi\|^2 |d\lambda| = 0. \tag{2.13}$$

The above integral can be estimated easily:

$$\begin{aligned}\int_{\Gamma_{R_n}} \|(\mathrm{D}-\lambda)^{-1}\varphi\|^2 |d\lambda| &= \int_{\Gamma_{R_n}} \sum_{k=1}^{\infty} |(\varphi, e_k)|^2 |(\mu_k-\lambda)^{-2}||d\lambda| \\ &= \sum_{k=1}^{\infty} |(\varphi, e_k)|^2 \int_{\Gamma_{R_n}} |(\mu_k-\lambda)^{-2}||d\lambda|.\end{aligned}$$

As it has been noticed above,

$$\int_{\Gamma_{R_n}} |(\mu_k-\lambda)^{-2}||d\lambda| \le \int_{\Gamma_{R_n}} \|(\mathrm{D}-\lambda)^{-1}\|^2 |d\lambda| \le C$$

for all n and k. On the other hand, for large n and some positive constant C_1,

$$\int_{\Gamma_{R_n}} |(\mu_k-\lambda)^{-2}||d\lambda| \le C_1 \int_{\Gamma_{R_n}} |\lambda|^{-2} |d\lambda| = O(R_n^{-1})$$

(uniformly in k). Combining the last two estimates we obtain the relation (2.13). This completes the proof of Lemma 2.1. □

Remark 2.2. A similar result holds in the case in which the eigenvalues $\{\mu_n\}$ of D are not simple. If $|\mu_l| \le |\mu_{l+1}|$ and $P_{\{\mu_l\}}$ is the orthogonal projection on the space of eigenvectors corresponding to μ_l, and n_l stands for the multiplicity of μ_l, then the eigenvalues $\lambda_{n(l)}(T)$ (counted properly with algebraic multiplicity) satisfy for $l \gg 1$

$$\lambda_{n(l)}(T) = \mu_l + O(\|R^* P_{\{\mu_l\}}\|),$$

where $n_1 + \cdots + n_{l-1} < n(l) \le n_1 + \cdots + n_l$. In the applications given in the next section we shall need estimates: $\|R^* e_n\| = O(\frac{1}{n^p})$, $p > 0$. Note that the above estimate on R cannot be replaced by $R \in \Sigma_{1/p}$.

Indeed, one can add to a given operator D a diagonal operator $R = \mathrm{diag}(\frac{1}{n_k^p})$, where n_k is an arbitrary permutation of $\mathbb{N}$. It is clear that by a proper choice of the permutation n_k we have $R \in \Sigma_{1/p}$, but we are not able to prove any estimates of $\mathrm{dist}(\lambda_n(T), \mu_n)$ $(T = D + R)$, only its decreasing to 0, as n tends to infinity.

Moreover, even for rank-one perturbation of R, the statement $\lambda_n(T) - \mu_n = O(\frac{1}{n^p})$ does not hold true.

Example 2.3. Indeed, choose the operator T in l^2 given by $T = \mathrm{D} + (\cdot, \varphi)\varphi$, where $\mathrm{D}e_n = ne_n$, $\varphi \in l^2, \|\varphi\| = 1$; i.e., $R = (\cdot, \varphi)\varphi$. Straightforward calculation shows that in the interval $(n, n+1)$ there exists exactly one eigenvalue λ_n of T satisfying the following condition:

$$\sum_{k=1}^{\infty} |\varphi_k|^2 (k - \lambda_n)^{-1} = -1, \tag{2.14}$$

where $\varphi = \sum_{k=1}^{\infty} \varphi_k e_k$, and the Fourier coefficients $\varphi_n \neq 0$ for all $_n$.

We have for fixed n

$$|\varphi_n|^2(n-\lambda_n)^{-1}+|\varphi_{n+1}|^2(n+1-\lambda_n)^{-1}+\sum_{k\neq n,n+1}|\varphi_k|^2(k-\lambda_n)^{-1}=-1.$$

However,

$$\sum_{k\neq n,n+1}\varphi_k^2(k-\lambda_n)^{-1}|\leq 2\sum_{k\neq n}|\varphi_k|^2|n-k|^{-1}=o(1)\quad\text{as}\quad n\to\infty.$$

Thus

$$-1+o(1)=|\varphi_n|^2(n-\lambda_n)^{-1}+|\varphi_{n+1}|^2(n+1-\lambda_n)^{-1}\geq|\varphi_n|^2(n-\lambda_n)^{-1}$$

and so $\lambda_n-n=|\lambda_n-n|\leq|\varphi_n|^2(1+o(1))$.

It follows that $\lim_n(\lambda_n-n)=0$, which in turn implies equality $-1+o(1)=|\varphi_n|^2(n-\lambda_n)^{-1}+o(1)$. Therefore $|\varphi_n|^2(\lambda_n-n)^{-1}=1+o(1)$. However, we know only that $|\varphi_n|^2\in l^1$ and so λ_n-n can tend to zero as an arbitrary l^1 sequence (exactly like $|\varphi_n|^2$).

Before we turn to some applications of Lemma 2.1 let us define by $\Sigma^b_{1/p}$ the set of all operators in H that are in $\Sigma_{1/p}$ and possess a band-type matrix in the basis $\{e_n\}_{n=1}^\infty$ of the eigenvectors of D. Consider a band-type operator R of the following form: $R=\sum_{k=-N}^N S^k\Lambda_k$, where Λ_k are diagonal operators and $S^{-k}:=S^{*^k}$, $k>0$. It will be proved below that $R\in\Sigma^b_{1/p}$ iff the diagonal operators Λ_k are defined by sequences from l^p (for $k=-N,\dots,N$).

PROPOSITION 2.3. *Let R be a compact operator that has a band matrix representation (r_{ij}) of width N in the basis $\{e_n\}$.*

Then $R\in\Sigma_{1/p}$ iff $r_{ii+k}=O(i^{-p})$, $k=-N,\dots,N$.

Proof. Let $R=\sum_{k=-N}^N\Lambda_kS^k$. If $r_{ii+k}=O(i^{-p})$ for all k, then $\Lambda_k\in\Sigma_{1/p}$ and so $R\in\Sigma_{1/p}$. On the other hand, if $R\in\Sigma_{1/p}$ and is given by the above formula, then $S^NR=\sum_{k=0}^{2N}\tilde\Lambda_kS^k$, where $\tilde\Lambda_k:=S^N\Lambda_{k-N}S^{*^N}$. Since $S^NR\in\Sigma_{1/p}$, it follows that its singular numbers satisfy estimates $s_k(S^NR)=O(k^{-p})$, and applying [18, Cor. 3.2] we know that the same estimate holds for its eigenvalues $\lambda_k(S^NR)=O(k^{-p})$. Hence $\tilde\Lambda_o\in\Sigma_{1/p}$ (note that the matrix S^NR is lower triangular). It follows that $\Lambda_{-N}\in\Sigma_{1/p}$ and also (by symmetry) that $\Lambda_N\in\Sigma_{1/p}$. Therefore $\sum_{k=-N+1}^{N-1}\Lambda_kS^k\in\Sigma_{1/p}$ and so on. The proof is complete. □

Below we also shall need the following elementary result.

PROPOSITION 2.4. *Let $W=I+K$, where K is a compact operator. If $0\in\sigma(W)$, then for any small $\varepsilon>0$ there exists a natural number $N=N(\varepsilon)$ such that $W+\varepsilon Q_N$ is invertible; here Q_N is the orthogonal projection in H onto $[e_1,\dots,e_N]$, and e_n is the orthonormal basis in H.*

Proof. Choose $\varepsilon>0$ so small that $W+\varepsilon I$ is invertible. Then $W+\varepsilon Q_N=[I+\varepsilon(Q_N-I)(W+\varepsilon I)^{-1}](W+\varepsilon I)$. Since $(W+\varepsilon I)^{-1}=(1+\varepsilon)^{-1}I+K_\varepsilon$, for a certain compact K_ε, it follows that $\|(Q_N-I)K_\varepsilon\|\to0$, as $N\to\infty$. Therefore $W+\varepsilon Q_N$ is invertible for N sufficiently large (as the product of two invertible operators). □

3. Successive diagonalization and the eigenvalues of Jacobi matrices. In this section a general method of successive diagonalization will be applied to J_g. The choice of the special class of J,s (in what follows we omit the letter g in J_g) is motivated by applications that will be given in section 4. The method seems strong enough (as will become clear from its proof) for possible applications to other classes of

Jacobi matrices with dominating diagonal. However, the method admits its simplest form for $\alpha > 2\beta + 1$, where α is the power order of the diagonal growth and β is the power order of the weight growth. We hope to consider this and other situations in a future paper. The procedure of the successive diagonalization method is the following.

Step 1. We look for self-adjoint diagonal operators $\tilde{J}_1,\ \Lambda_1$, where $\Lambda_1 \in \Sigma_1^b$ such that for anti-Hermitian $T_1 := \Lambda_1 S - S^*\Lambda_1$ we have

$$\tilde{J}_1(I + T_1) \doteq (I + T_1)J, \tag{3.1}$$

and the equality $\doteq$ means one modulo Σ_1^b. By this notation $J \doteq \Lambda^2 + c_1\Lambda + g(S + S^*)$. Assumptions on $\tilde{J}_1$ and T_1 imply (using (3.1)) that

$$\tilde{J}_1 - \Lambda^2 - c_1\Lambda \in \Sigma_1^b. \tag{3.2}$$

This can be easily checked by looking at the main diagonal entries of the difference of the left- and right-hand sides of (3.1). In turn, the first lower diagonal entries of the difference between the left- and right-hand sides of (3.1) are obtained by grouping all the terms of the difference that contain only S. Denoting this difference by A_1 we get that

$$A_1 \doteq \tilde{J}_1\Lambda_1 S - gS - \Lambda_1 S\Lambda^2 - c_1\Lambda_1 S\Lambda.$$

We search for Λ_1 satisfying the condition

$$\tilde{J}_1\Lambda_1 S - gS - \Lambda_1 S\Lambda^2 - c_1\Lambda_1 S\Lambda \in \Sigma_1^b. \tag{3.3}$$

It means

$$\Lambda_1(\tilde{J}_1 S - S\Lambda^2 - c_1 S\Lambda) - gS \in \Sigma_1^b. \tag{3.4}$$

If we define $\tilde{J}_1 := \Lambda^2 + c_1\Lambda$ (see (3.2)), then using the elementary identities

$$[\Lambda, S] = S,\ [\Lambda^2, S] = (2\Lambda - I)S, \tag{3.5}$$

the condition (3.4) can be written as

$$\Lambda_1[2\Lambda - I + c_1]S - gS \in \Sigma_1^b. \tag{3.6}$$

The inclusion (3.6) implies the choice

$$\Lambda_1 := \frac{g}{2}\Lambda^{-1}.$$

Observe that the first upper diagonal entries of the same difference are given by collecting all the terms of the difference that contain only S^*. Moreover, if B_1 denotes the above collection, then one can easily check (again using (3.1), and (3.6)) that

$$B_1 \doteq S^*[2\Lambda - I + c_1]\Lambda_1 - gS^*. \tag{3.7}$$

Hence $B_1 - A_1^* \in \Sigma_1^b$ and our choice of Λ_1 gives simultaneously that $B_1 \in \Sigma_1^b$. Concerning terms containing S^2 or S^{*^2} (in (3.1)), all of them belong to Σ_1^b already. The above choice of $\tilde{J}_1$ and Λ_1 implies the condition (2.1). Now we obtain the first three terms (in power asymptotic expansion) of $\lambda_n(J)$. Indeed, we rewrite (3.1) as

$$K_1 + \tilde{J}_1(I + T_1) = (I + T_1)J$$

for a certain $K_1 \in \Sigma_1^b$. Since $I + T_1$ is invertible (because $T_1^* = -T_1$), $J = (I + T_1)^{-1}[\tilde{J}_1 + K_1(I + T_1)^{-1}](I + T_1)$ and so

$$\{\lambda_n(J)\}_{n=1}^{\infty} = \sigma(J) = \sigma(\tilde{J}_1 + K_1(I + T_1)^{-1}).$$

Applying Lemma 2.1 with $R = K_1(I + T_1)^{-1}$ and $D = \tilde{J}_1 = \Lambda^2 + c_1\Lambda$ we have

$$\lambda_n(J) = n^2 + c_1 n + O(n^{-1}).$$

Due to the above choices and the form of R it is clear that $\|R^* e_n\| = O(\frac{1}{n})$.

Step 2. We look for new self-adjoint diagonal operators $\tilde{J}_2, \Lambda_1 \in \Sigma_1^b$, and $\Lambda_2 \in \Sigma_{1/2}^b$ such that for

$$T_1 := \Lambda_1 S - S^* \Lambda_1, \qquad T_2 := \Lambda_2 S^2 + S^{*^2} \Lambda_2$$

we have

$$\tilde{J}_2(I + T_1 + T_2) \doteq (I + T_1 + T_2)J, \tag{3.8}$$

where $\doteq$ means the equality modulo $\Sigma_{1/2}^b$.

Below diagonal operators Λ_j, band operators T_j and equalities $\doteq$ will have slightly different meanings at each of Steps 2 and 3. We keep the same notation for similar notions for reader convenience to avoid complicated symbols, hoping it will not lead to misunderstanding. Again in the new notation,

$$J \doteq \Lambda^2 + c_1\Lambda + c_2\Lambda^{-1} + g(S + S^*) + b_1(S\Lambda^{-1} + \Lambda^{-1}S^*).$$

Note that Λ_1 can be different from Λ_1 given in the first step, but for reader convenience we keep the same notation as above. Moreover, anticipating consequences of the above assumptions and (3.8) we also impose the following smoothness condition on Λ_1:

$$\Lambda_1 - S^*\Lambda_1 S \in \Sigma_{1/2}^b. \tag{3.9}$$

The operators Λ_j and $\tilde{J}_2$ will be chosen more precisely than in Step 1. Comparing the main diagonal entries of the difference between the left- and the right-hand side of (3.8) we put

$$\tilde{J}_2 = \Lambda^2 + c_1\Lambda + c_2\Lambda^{-1}. \tag{3.10}$$

One can check that the diagonal part of the above difference has the form $\tilde{J}_2 - \Lambda^2 - c_1\Lambda - c_2\Lambda^{-1} - g(\Lambda_1 - S^*\Lambda_1 S)$ modulo $\Sigma_{1/2}^b$. This clarifies the choice of $\tilde{J}_2$ in (3.10) and the condition (3.9)

As in the first step we collect all the terms of the difference of both sides of (3.8) containing only S and we obtain using (3.10)

$$\begin{aligned} A_2 &:= \tilde{J}_2\Lambda_1 S - (SD + \Lambda_1 SQ + \Lambda_2 S^2 DS^*) \doteq \tilde{J}_2\Lambda_1 S - (DS + \Lambda_1 SQ) \\ &= -DS + [2\Lambda - I + c_1]\Lambda_1 S, \end{aligned} \tag{3.11}$$

Again, as in the first step one can check that for the term B_2 which appears at the difference of both sides of (3.8) with terms containing only S^*,

$$A_2 \doteq B_2^*. \tag{3.12}$$

In turn collecting all terms, which appear on both sides of (3.8), containing only S^2, we have

$$C_2 := \tilde{J}_2\Lambda_2 S^2 - \Lambda_1 S^2 D - \Lambda_2 S^2 Q.$$

By the same token, for terms containing only S^{*^2} we have

$$D_2 := \tilde{J}_2 S^{*^2}\Lambda_2 + S^*\Lambda_1 D S^* - S^{*^2}\Lambda_2 Q.$$

Direct computation shows that again

$$D_2 \doteq C_2^*. \tag{3.13}$$

Combining (3.12) and (3.13) it is obvious that the condition $B_2 \in \Sigma_{1/2}^b$ (resp., $D_2 \in \Sigma_{1/2}^b$) holds provided one can check that $A_2 \in \Sigma_{1/2}^b$ (resp., $C_2 \in \Sigma_{1/2}^b$). First we are going to satisfy the condition $A_2 \in \Sigma_{1/2}^b$. Using (3.10) the claim $A_2 \in \Sigma_{1/2}^b$ is equivalent to $(2\Lambda - I + c_1)\Lambda_1 - D \in \Sigma_{1/2}^b$. The above equation suggests that the simplest choice of Λ_1 is

$$\Lambda_1 := D(2\Lambda - I + c_1 I)^{-1}. \tag{3.14}$$

Note that Λ_1 defined by (3.14) satisfies both conditions $\Lambda_1 \in \Sigma_1^b$ and $\Lambda_1 - S^*\Lambda_1 S \in \Sigma_{1/2}^b$. Put

$$\Lambda_2 := g\Lambda_1[4\Lambda + 2c_1 - 4]^{-1} \tag{3.15}$$

to ensure that $C_2 \in \Sigma_{1/2}^b$.

If for a certain k it happens that $2k - 2 + c_1 = 0$, then one can put $\Lambda_1 e_k = 0$. This makes no problem in checking all the above conditions. (Finite dimensional perturbations in the canonical basis are allowed.) Since $\Lambda_1 \in \Sigma_1^b$, we see that $\Lambda_2 \in \Sigma_{1/2}$. Using the formulas (3.14) and (3.15) one can verify that $C_2 \in \Sigma_{1/2}^b$. Since we can reverse the implication in the above reasoning, the desired equality (3.8) holds. Therefore there is $K_2 \in \Sigma_{1/2}^b$ such that

$$K_2 + \tilde{J}_2(I + T_1 + T_2) = (I + T_1 + T_2)J.$$

By Proposition 2.4 we can find a finite dimensional projection Q such that $I + T_1 + T_2 + \varepsilon Q$ is invertible for some $\varepsilon > 0$. Since $\tilde{J}_2 Q - QJ$ is a finite rank band matrix, the above equality can be written as

$$\tilde{K}_2 + \tilde{J}_2(I + T_1 + T_2 + \varepsilon Q) = (I + T_1 + T_2 + \varepsilon Q)J$$

for a certain $\tilde{K}_2 \in \Sigma_{1/2}^b$. We can repeat the reasoning given at the end of Step 1 and applying Lemma 2.1 we have

$$\lambda_n(J) = n^2 + c_1 n + c_2 n^{-1} + O(n^{-2}). \tag{3.16}$$

Step 3. One might think that the method of diagonalization presented in the above steps carries over easily to the third step. This is not the case, however, as we shall see below. At this step we look again for new self-adjoint diagonal operators

$\Lambda_j \in \Sigma_{1/j}$ $(j = 1, 2, 3)$ and $\tilde{\Lambda}_2 \in \Sigma_{1/2}$ such that for $T_j = \Lambda_j S^j - S^{*^j}\Lambda_j$ $(j = 1, 3)$ and $T_2 = \Lambda_2 S^2 + S^{*^2}\tilde{\Lambda}_2$,

$$\tilde{J}_3(I + T_1 + T_2 + T_3) - (I + T_1 + T_2 + T_3)J \in \Sigma_{1/3}, \tag{3.17}$$

where $\tilde{J}_3$ is a diagonal operator given by

$$\tilde{J}_3 = \Lambda^2 + c_1\Lambda + c_2\Lambda^{-1} + \Delta \quad \text{for a certain } \Delta \in \Sigma_{1/2}. \tag{3.18}$$

Note that at this step the diagonalizing matrix $I+T_1+T_2+T_3$ not only has one upper and one lower diagonal more (than in Step 2) but also loses its symmetry with respect to the main diagonal. Using (3.17) we will determine (similarly as in the above steps) $\Lambda_j, \tilde{\Lambda}_2$, and Δ. In what follows $\doteq$ stands for the equality modulo $\Sigma_{1/3}$. Comparing the diagonal entries of both sides of (3.17) we can write

$$\tilde{J}_3 \doteq \Lambda^2 + c_1\Lambda + c_2\Lambda^{-1} + c_3\Lambda^{-2} + \Lambda_1 SDS^* - S^*\Lambda_1 SD.$$

Following the ideas presented in the above steps we also need some extra smoothing assumptions on Λ_1 and Λ_2. Namely, in what follows we assume that

(3.19)
(a) $[\Lambda_1, S] \in \Sigma^b_{1/2}$, (b) $[\Lambda_2, S] \in \Sigma^b_{1/3}$, (c) $[\tilde{\Lambda}_2, S] \in \Sigma^b_{1/3}$, (d) $\tilde{\Lambda}_2 - \Lambda_2 \in \Sigma^b_{1/3}$.

Substituting $D \doteq gI + b_1\Lambda^{-1} + b_2\Lambda^{-2}$ into the above formula for $\tilde{J}_3$ we obtain (using (3.19) (a)) that $\Delta = c_3\Lambda^{-2} + g(\Lambda_1 - S^*\Lambda_1 S)$. Then we can express $\tilde{J}_3$ as

$$\tilde{J}_3 := \Lambda^2 + c_1\Lambda + c_2\Lambda^{-1} + c_3\Lambda^{-2} + g(\Lambda_1 - S^*\Lambda_1 S). \tag{3.20}$$

Similarly as in the second step one can verify (by using (3.19) (c), (d) and assumptions $\Lambda_j \in \Sigma_{1/j}$ $(j = 1, 2, 3)$, $\tilde{\Lambda}_2 \in \Sigma_{1/2}$) that the coefficients A_3 and E_3 (resp., $\tilde{A}_3$ and $\tilde{B}_3$) of the difference of the left- and right-hand sides of (3.16) at S and S^3 (resp., S^* and S^{*^3}) satisfy $\tilde{A}_3 \doteq A^*_3$, $\tilde{B}_3 \doteq E^*_3$. As calculations to be given below show, the situation for the coefficients at S^2 and S^{*^2} terms is not so symmetric. This is exactly the reason for introducing two slightly different diagonal matrices Λ_2 and $\tilde{\Lambda}_2$. Below we shall see that $\tilde{\Lambda}_2 \doteq \Lambda_2$. Note that (3.19) (c) follows from (3.19) (b) and (d). In what follows we shall find formulas for Λ_j, $j = 1, 2, 3$, and $\tilde{\Lambda}_2$. These formulas will be derived from the basic equation (3.17). First we look for Λ_1, Λ_2. Since $\Lambda_j \in \Sigma_{1/j}$ and due to the definition of $\tilde{J}_3$, and J_g, we seek $\Lambda_j (j = 1, 2)$ in the form

$$\Lambda_1 := a\Lambda^{-1} + b\Lambda^{-2} + c\Lambda^{-3}, \tag{3.21}$$

$$\Lambda_2 := d\Lambda^{-2} + e\Lambda^{-3} \tag{3.22}$$

for some constants a, b, c, d, e to be determined below. The ansatz for Λ_1, Λ_2 follows straightforwardly from simple analysis of (3.24) and (3.26) (see below). The proper formula for the matrix $\tilde{\Lambda}_2$ will be given by formula (3.30). It turns out that (3.17) defines the above constants uniquely. Indeed, by looking at terms of (3.17) containing only S we see that

$$(\Lambda^2 + c_1\Lambda + c_2\Lambda^{-1})\Lambda_1 S - SD - \Lambda_1 S(\Lambda^2 + c_1\Lambda + c_2\Lambda^{-1}) - \Lambda_2 S^2 DS^* \doteq 0. \tag{3.23}$$

Using again the commutation formulas (3.5) and $[\Lambda^{-1}, S] = -S\Lambda^{-1}(\Lambda + I)^{-1}$, one can check that (3.23) is equivalent to

$$\Lambda_1[2\Lambda + (c_1 - 1)I] - gI - b_1\Lambda^{-1} - (b_1 + b_2)\Lambda^{-2} \doteq 0. \tag{3.24}$$

In turn by collecting all terms of (3.17) containing only S^2 we have

$$(\Lambda^2 + c_1\Lambda)\Lambda_2 S^2 - \Lambda_1 S^2 D - \Lambda_2 S^2(\Lambda^2 + c_1\Lambda) \doteq 0. \tag{3.25}$$

Since $S^2\Lambda^{-1} \doteq (\Lambda^{-1} + 2\Lambda^{-2})S^2$ one can verify that (3.25) is equivalent to

$$\Lambda_2[4(\Lambda - I) + 2c_1 I] \doteq \Lambda_1(gI + b_1\Lambda^{-1}). \tag{3.26}$$

By substituting expressions (3.21) into (3.24) one gets in particular that $a = g/2$. The explicit solution of (3.24), (3.26) is given by the following formulas:

$$\Lambda_1 := [gI + b_1\Lambda^{-1} + (b_1 + b_2)\Lambda^{-2}][2\Lambda + c_1 - 1]^{-1} \quad (\text{modulo } \Sigma_{1/4}),$$

$$\Lambda_2 := \Lambda_1(gI + b_1\Lambda^{-1})[4\Lambda - (4 - 2c_1)I]^{-1} \quad (\text{modulo } \Sigma_{1/4}). \tag{3.27}$$

Again in formula (3.27) possible two zero of the denominators are inessential and can be removed similarly as in Step 2 (both diagonal operators are defined to be equal to zero for critical indexes). One can compute Λ_1, Λ_2 using (3.27) in the form of (3.21), (3.22), respectively; however, it is necessary only if we want to obtain an approximate formula for the eigenvectors of J.

What about $\tilde{\Lambda}_2$ and Λ_3? By grouping all terms with S^{*^2} of (3.17) we have

$$(\Lambda^2 + c_1\Lambda)S^{*^2}\tilde{\Lambda}_2 + S^*\Lambda_1 D S^* - S^{*^2}\tilde{\Lambda}_2(\Lambda^2 + c_1\Lambda) \doteq 0. \tag{3.28}$$

Using the standard commutator formulas for $[S^{*^2}, \Lambda^2]$ and $[S^{*^2}, \Lambda]$ we rewrite (3.28) into the equivalent form

$$\tilde{\Lambda}_2[4(\Lambda - I) + 2c_1 I] \doteq \Lambda_1(gI + b_1\Lambda^{-1}) + g(S\Lambda_1 S^* - \Lambda_1). \tag{3.29}$$

Thus

$$\tilde{\Lambda}_2 \doteq \Lambda_1[4(\Lambda - I) + 2c_1 I]^{-1}(gI + b_1\Lambda^{-1}) = \Lambda_2 \tag{3.30}$$

because $g(S\Lambda_1 S^* - \Lambda_1) \in \Sigma^b_{1/2}$. However, (3.29) is not sufficiently precise: substitution of Λ_2 instead of $\tilde{\Lambda}_2$ into (3.28) contradicts it. Indeed, due to the multiplier Λ in the left-hand side of (3.29) we should calculate $\tilde{\Lambda}_2$ modulo $\Sigma_{1/4}$ but $\tilde{\Lambda}_2 = \Lambda_2$ modulo $\Sigma_{1/3}$ only because $(\Lambda_1 - S\Lambda_1 S^*)$ belongs to $\Sigma_{1/2}$ and not to $\Sigma_{1/3}$ in general! Moreover, one can choose $\tilde{\Lambda}_2 = \Lambda_2$ iff $\Lambda_1 - S\Lambda_1 S^* \in \Sigma_{1/3}$.

Now by collecting all terms with S^3 we have

$$(\Lambda^2 + c_1\Lambda)\Lambda_3 S^3 - \Lambda_2 S^3 b - \Lambda_3 S^3(\Lambda^2 + c_1\Lambda) \doteq 0. \tag{3.31}$$

Applying the relations $[S^3, \Lambda^2] = -3(2\Lambda - 3)S^3$, $[S^3, \Lambda] = -3S^3$, we see that (3.31) is equivalent to $6\Lambda_3\Lambda \doteq g\Lambda_2$. The last equation has the solution $\Lambda_3 := g\Lambda_2(6\Lambda)^{-1}$. In turn by bringing together all terms of (3.17) that contain S^{*^3}, one easily finds that the sum of these terms must belong to $\Sigma^b_{1/3}$ because $\tilde{\Lambda}_2 \doteq \Lambda_2$ and $\tilde{\Lambda}_2 - S\tilde{\Lambda}_2 S^* \in \Sigma_{1/3}$. Note

that the above explicit formulas for Λ_j and $\tilde{\Lambda}_2$ also imply that all the requirements concerning $\Lambda_j (j = 1, 2, 3)$ and $\tilde{\Lambda}_2$ (in particular assumptions (3.19) (a), (b), (c), (d)) are satisfied. Finally, since all the above equations are equivalent to suitable ones, we check that the above choice of $T_j (j = 1, 2, 3)$ leads to the desired relation (3.17). By repeating the reasoning given at the end of Step 1 we obtain the following more precise asymptotics of the eigenvalues of J.

THEOREM 3.1. *The asymptotic formula for $\lambda_n(J_g)$ is given by*

$$\lambda_n(J_g) = n^2 + c_1 n + c_2 n^{-1} + c_3 n^{-2} + \frac{g^2}{2} n^{-2} + O(n^{-3}). \tag{3.32}$$

Proof. It is enough to use the formula (3.20) and observe that $\Lambda_1 - S^* \Lambda_1 S \doteq \frac{g}{2} \Lambda^{-2}$ (use here (3.27) for the matrix Λ_1). □

Remark 3.2. Surely one can continue this process of successive diagonalization of J. We have stopped after making three steps because the weights λ_n and the diagonal q_n are known only up to $O(n^{-3})$.

Moreover, the idea of successive diagonalization can be applied for other classes of Jacobi operators with uniformly separated discrete spectrum (at least provided the main diagonal has more than one order higher-power-like growth compared to off-diagonal terms). Observe that one can use the same method to approximate the eigenvectors f_k of J for large indices k. In the next section we give an application of Theorem 3.1 to spectral analysis of energy spectrum of a molecule in the homogeneous electric field, which motivated our special choice of J entries.

Remark 3.3. It seems somewhat surprising that the influence of the zero order term $g(S + S^*)$ in J causes only the minus second order variation of the eigenvalues (see [36]).

4. Application to asymptotics of the energy spectrum of a molecule in a homogeneous electric field. This section contains an application of Theorem 3.1 to a polar molecule of symmetric top type in a homogeneous electric field [6], [7], [17]. The Hamiltonian of a symmetric pendulum has the form

$$\hat{H}_o = \frac{\hat{L}^2}{2I} + \left(\frac{1}{2I_3} - \frac{1}{2I} \right) \hat{L}^2_{z'},$$

where $\hat{L}^2$ (resp., $\hat{L}^2_z$) are the operators of the full moment (resp., its projection on the z'-axis) acting in $L^2(\mathbb{R}^3)$, and I, I_3 are the corresponding inertia moments. It turns out that $\hat{H}_o$ has eigenfunctions ϕ^n_{mk} coinciding (up to the normalization constant) with the generalized spherical function $D^n_{mk}(a, b, c)$, where $(a, b, c) \in (0, 2\pi)x(0, \pi)x(0, 2\pi)$. More precisely,

$$\phi^n_{mk}(a, b, c) = \sqrt{(2n + 1)/8\pi^2} D^n_{mk}(a, b, c),$$

$k, m = -n, \ldots, 0, \ldots, n$. The eigenvalues of $\hat{H}_o$ corresponding to ϕ^n_{mk} are given by

$$E_{n,|k|} = \frac{h^2}{2I} n(n + 1) + \frac{h^2}{2} \left(\frac{1}{I_3} - \frac{1}{I} \right) k^2;$$

here h is the Planck constant. Let $\hat{V} = -dE(t)\cos b$ be the potential energy of the perturbation by the electric field $E(t)$ directed along the z-axis (in the fixed coordinate system (x, y, z) connected with the pendulum), where d is the dipole moment of the

molecule and b is the angle between the axes z and z'. For more physical details of the model, see [17].

It turns out that the full Hamiltonian $\hat{H} := \hat{H}_o + \hat{V}$ can be reduced in the basis ϕ^n_{mk} to a Jacobi matrix $J_{\tilde{g}}$, where $\tilde{g} = dE(t)$ is the constant of interaction for fixed time t. More precisely, for fixed indices $k, m \in \mathbb{Z}$, the diagonal and the weights of $J_{\tilde{g}}$, after straightforward calculations in the basis ϕ^n_{km}, are given by

$$q_n = \frac{h^2}{2I} n(n+1) + \frac{h^2}{2}\left(\frac{1}{I_3} - \frac{1}{I}\right) k^2 - \tilde{g}\frac{mk}{n(n+1)},$$

$$\lambda_n = \frac{-\tilde{g}}{(n+1)(2n+1)} |[((n+1)^2 - m^2)((n+1)^2 - k^2)]|^{1/2}.$$

These calculations use the explicit form of the matrix elements of $\hat{V}$ in the basis ϕ^n_{mk} as the Clebsch–Gordan coefficients c^{rt}_{klmn}; see [31]. Namely, we have

$$(\hat{V}\phi^n_{mk}, \phi^p_{rs}) = -dE(t) c^{nm}_{1r0m} c^{nk}_{1p0k} \delta_{mr} \delta_{ks}.$$

Although the study of this type of molecule in an electric field is of special interest, our goal in this paper is rigorous mathematical analysis of related classes of unbounded Jacobi matrices only. It is clear that $J_{\tilde{g}}$ is of the form considered in Theorem 3.1. Applying Theorem 3.1 we immediately obtain the following result.

THEOREM 4.1. *The asymptotics as $n \to \infty$ of the energy spectrum $E_n(k, m)$ (for fixed integer numbers k, m) are given by*

$$E_n(k,m) = \frac{h^2}{2I} n^2 + \frac{h^2}{2I} n + \frac{h^2}{2}\left(\frac{1}{I_2} - \frac{1}{I}\right) k^2 + \left(\frac{\tilde{g}mk + I\frac{\tilde{g}^2}{(4h^2)}}{n^2}\right) + O\left(\frac{1}{n^3}\right), \ n \to \infty.$$

Acknowledgments. We thank Bozena Skoczylas for her valuable help in preparation of the manuscript. We appreciate A. Laptev's useful comments and information about the paper by Rosenblum. We also are grateful to E. Tur for helpful discussion related to the physical aspect of the problem.

A SHARP DECAY ESTIMATE FOR POSITIVE NONLINEAR WAVES*

ALBERTO BRESSAN† AND TONG YANG‡

Abstract. We consider a strictly hyperbolic, genuinely nonlinear system of conservation laws in one space dimension. A sharp decay estimate is proved for the positive waves in an entropy weak solution. The result is stated in terms of a partial ordering among positive measures, using symmetric rearrangements and a comparison with a solution of Burgers's equation with impulsive sources.

Key words. hyperbolic conservation laws, positive nonlinear waves, Burgers's equation

AMS subject classifications. 35L65

DOI. 10.1137/S0036141003427774

1. Introduction.

Consider a strictly hyperbolic system of n conservation laws

$$u_t + f(u)_x = 0 \tag{1.1}$$

and assume that all characteristic fields are genuinely nonlinear. Call $\lambda_1(u) < \cdots < \lambda_n(u)$ the eigenvalues of the Jacobian matrix $A(u) \doteq Df(u)$. We shall use bases of left and right eigenvectors $l_i(u)$, $r_i(u)$ normalized so that

$$\nabla\lambda_i(u)\, r_i(u) \equiv 1\,, \qquad\qquad l_i(u)\, r_j(u) = \begin{cases} 1 & \text{if} \quad i = j, \\ 0 & \text{if} \quad i \neq j. \end{cases} \tag{1.2}$$

Given a function $u : \mathbb{R} \mapsto \mathbb{R}^n$ with small total variation following [BC], [B], one can define the measures μ^i of i-waves in u as follows. Since $u \in BV$, its distributional derivative $D_x u$ is a Radon measure. We define μ^i as the measure such that

$$\mu^i \doteq l_i(u) \cdot D_x u \tag{1.3}$$

restricted to the set where u is continuous, while, at each point x where u has a jump, we define

$$\mu^i\big(\{x\}\big) \doteq \sigma_i\,, \tag{1.4}$$

where σ_i is the strength of the i-wave in the solution of the Riemann problem with data $u^- = u(x-)$, $u^+ = u(x+)$. In accordance with (1.2), if the solution of the Riemann problem contains the intermediate states $u^- = \omega_0, \omega_1, \ldots, \omega_n = u^+$, the strength of the i-wave is defined as

$$\sigma_i \doteq \lambda_i(\omega_i) - \lambda_i(\omega_{i-1}). \tag{1.5}$$

Observing that

$$\sigma_i = l_i(u^+) \cdot (u^+ - u^-) + O(1) \cdot |u^+ - u^-|^2,$$

we can find a vector $l_i(x)$ such that

$$\big|l_i(x) - l_i\big(u(x+)\big)\big| = \mathcal{O}(1)\cdot\big|u(x+) - u(x-)\big|, \tag{1.6}$$

$$\sigma_i = l_i(x)\cdot\big(u(x+) - u(x-)\big). \tag{1.7}$$

We can thus define the measure μ^i equivalently as

$$\mu^i \doteq l_i\cdot D_x u\,, \tag{1.8}$$

where $l_i(x) = l_i\big(u(x)\big)$ at points where u is continuous, while $l_i(x)$ is some vector which satisfies (1.6)–(1.7) at points of jump. For all $x\in\mathbb{R}$ there holds

$$\Big|l_i(x) - l_i\big(u(x)\big)\Big| = \mathcal{O}(1)\cdot\big|u(x+) - u(x-)\big|\,. \tag{1.9}$$

We call μ^{i+}, μ^{i-}, respectively, the positive and negative parts of μ^i, so that

$$\mu^i = \mu^{i+} - \mu^{i-}, \qquad\qquad |\mu^i| = \mu^{i+} + \mu^{i-}. \tag{1.10}$$

It is our purpose to prove a sharp estimate on the decay of the density of the measures μ^{i+}. This will be achieved by introducing a partial ordering within the family of positive Radon measures. In the following, $meas(A)$ denotes the Lebesgue measure of a set A.

Definition 1. *Let μ,μ' be two positive Radon measures. We say that $\mu\preceq\mu'$ if and only if*

$$\sup_{meas(A)\leq s}\mu(A) \;\leq\; \sup_{meas(B)\leq s}\mu'(B) \qquad\qquad \text{for every } s>0\,. \tag{1.11}$$

In some sense, the above relation means that μ' is more singular than μ. Namely, it has a greater total mass, concentrated on regions with higher density. Notice that the usual order relation

$$\mu\leq\mu' \qquad \text{if and only if} \qquad \mu(A)\leq\mu'(A) \quad \text{for every} \quad A\subset\mathbb{R} \tag{1.12}$$

is much stronger. Of course $\mu\leq\mu'$ implies $\mu\preceq\mu'$, but the converse does not hold.

Following [BC], [B], together with the measures μ^i, we define the Glimm functionals

$$V(u) \doteq \sum_i |\mu^i|(\mathbb{R})\,, \tag{1.13}$$

$$Q(u) \doteq \sum_{i<j}\big(|\mu^j|\otimes|\mu^i|\big)\big\{(x,y)\,;\;x<y\big\} + \sum_i\big(\mu^{i-}\otimes|\mu^i|\big)\big\{(x,y)\,;\;x\neq y\big\}\,. \tag{1.14}$$

Now let $u=u(t,x)$ be an entropy weak solution of (1.1). If the total variation of u is small and the constant C_0 is large enough, it is well known that the quantities

$$Q(t) \doteq Q\big(u(t)\big)\,, \qquad\qquad \Upsilon(t) \doteq V\big(u(t)\big) + C_0\,Q\big(u(t)\big) \tag{1.15}$$

are nonincreasing in time. The decrease in Q controls the amount of interaction, while the decrease in Υ controls both the interaction and the cancellation in the solution.

An accurate estimate on the measure μ^{i+}_t of positive i-waves in $u(t,\cdot)$ will be obtained by a comparison with a solution of Burgers's equation with source terms.

THEOREM 1. *For some constant κ and for every small BV solution $u = u(t,x)$ of the system* (1.1) *the following holds. Let $w = w(t,x)$ be the solution of the scalar Cauchy problem with impulsive source term*

$$w_t + (w^2/2)_x = -\kappa\,\mathrm{sgn}(x)\cdot\frac{d}{dt}Q\big(u(t)\big)\,, \tag{1.16}$$

$$w(0,x) = \mathrm{sgn}(x)\cdot\sup_{meas(A)<2|x|}\frac{\mu_0^{i+}(A)}{2}\,. \tag{1.17}$$

Then, for every $t \geq 0$,

$$\mu_t^{i+} \preceq D_x w(t)\,. \tag{1.18}$$

As shown in the next section, the initial data in (1.17) represents the *odd rearrangement* of the function $v_i(x) \doteq \mu_0^{i+}\big(]-\infty,x]\big)$. The above theorem improves the earlier estimate derived in [BC]. For a scalar conservation law with strictly convex flux, a classical decay estimate was proved by Oleinik [O]. In the case of genuinely nonlinear systems, results related to the decay of nonlinear waves were also obtained in [GL], [L1], [L2], [L3], [BG]. An application of the present analysis can be found in [BY], where Theorem 1 plays a key role in the estimate of the rate of convergence of vanishing viscosity approximations.

2. Lower semicontinuity. Let μ be a positive Radon measure on $\mathbb{R}$, so that $\mu \doteq D_x v$ is the distributional derivative of some bounded, nondecreasing function $v : \mathbb{R} \mapsto \mathbb{R}$. We can decompose

$$\mu = \mu^{\mathrm{sing}} + \mu^{ac}$$

as the sum of a singular and an absolutely continuous part, w.r.t. Lebesgue measure. The absolutely continuous part corresponds to the usual derivative $z \doteq v_x$, which is a nonnegative $\mathbf{L}^1$ function defined at a.e. point. We shall denote by $\hat{z}$ the *symmetric rearrangement* of z, i.e., the unique even function such that

$$\hat{z}(x) = \hat{z}(-x)\,, \qquad \hat{z}(x) \geq \hat{z}(x') \quad \text{if} \quad 0 < x < x'\,, \tag{2.1}$$

$$\mathrm{meas}\Big(\big\{x\,;\ \hat{z}(x) > c\big\}\Big) = \mathrm{meas}\Big(\big\{x\,;\ z(x) > c\big\}\Big) \qquad \text{for every } c > 0\,. \tag{2.2}$$

Moreover, we define the *odd rearrangement* of v as the unique function $\hat{v}$ such that (Figure 1)

$$\hat{v}(-x) = -\hat{v}(x)\,, \qquad \hat{v}(0+) = \frac{1}{2}\mu^{\mathrm{sing}}(\mathbb{R})\,, \tag{2.3}$$

$$\hat{v}(x) = \hat{v}(0+) + \int_0^x z(y)\,dy \qquad \text{for } x > 0\,. \tag{2.4}$$

By construction, the function $\hat{v}$ is convex for $x < 0$ and concave for $x > 0$.

The relation between the odd rearrangement $\hat{v}$ and the partial ordering (1.10) is clarified by the following result, which is an easy consequence of the definitions.

PROPOSITION 1. *Let $\mu = D_x v$ and $\mu' = D_x v'$ be positive Radon measures. Call $\hat{v}, \hat{v}'$ the odd rearrangements of v, v', respectively. Then $\mu \preceq D_x\hat{v} \preceq \mu$ and moreover*

$$\hat{v}(x) = \mathrm{sgn}(x)\cdot\sup_{meas(A)\leq 2|x|}\frac{\mu(A)}{2}\,, \tag{2.5}$$

$$\mu \preceq \mu' \qquad \textit{if and only if} \qquad \hat{v}(x) \leq \hat{v}'(x) \quad \textit{for all } x > 0\,. \tag{2.6}$$

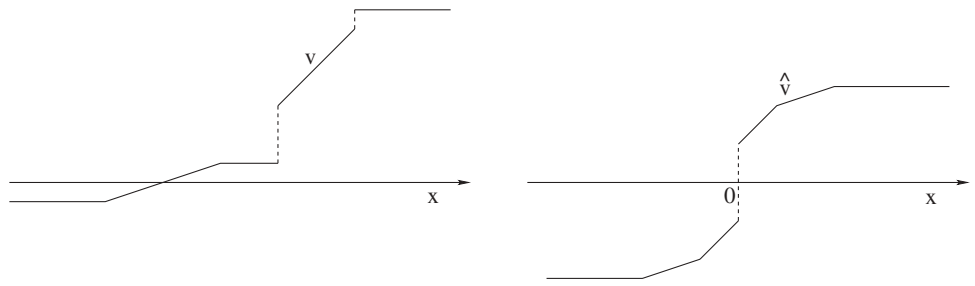

FIG. 1.

Two more results will be used in what follows. By the restriction of a measure μ to a set J, we mean the measure

$$(\mu\lfloor J)(A) \doteq \mu(A \cap J)\,.$$

PROPOSITION 2. *Let μ, μ' be positive measures. Consider any finite partition $\mathbb{R} = J_1 \cup \cdots \cup J_N$. If the restrictions of μ, μ' to each set J_ℓ satisfy $\mu\lfloor J_\ell \preceq \mu'\lfloor J_\ell$, then $\mu \preceq \mu'$.*

PROPOSITION 3. *Assume that $\mu \preceq D_s w$ for some nondecreasing odd function w. If $|\mu^\sharp - \mu|(\mathbb{R}) \leq \varepsilon$, then*

$$\mu^\sharp \preceq D_s \left[w + \mathrm{sgn}(s) \cdot \frac{\varepsilon}{2} \right] .$$

The next result is concerned with the lower semicontinuity of the partial ordering $\preceq$ w.r.t. weak convergence of measures.

PROPOSITION 4. *Consider a sequence of measures μ_ν converging weakly to a measure μ. Assume that the positive parts satisfy $\mu_\nu^+ \preceq D w_\nu$ for some odd, nondecreasing functions $s \mapsto w_\nu(s)$, concave for $s > 0$. Let w be the odd function such that*

$$w(s) \doteq \liminf_{\nu \to \infty} w_\nu(s) \qquad\qquad \text{for } \ s > 0\,.$$

Then the positive part of μ satisfies

$$\mu^+ \preceq D_s w\,. \tag{2.7}$$

Proof. By possibly taking a subsequence, we can assume that $w_\nu(s) \to w(s)$ for all $s \neq 0$. Moreover, we can assume the weak convergence

$$\mu_\nu^+ \rightharpoonup \tilde{\mu}^+\,, \qquad\qquad \mu_\nu^- \rightharpoonup \tilde{\mu}^-$$

for some positive measures $\tilde{\mu}^+$, $\tilde{\mu}^-$. We thus have

$$\mu = \tilde{\mu}^+ - \tilde{\mu}^-\,, \qquad \mu^+ \leq \tilde{\mu}^+\,, \qquad \mu^- \leq \tilde{\mu}^-\,. \tag{2.8}$$

By (2.8) it suffices to prove that $\tilde{\mu}^+ \preceq D_s w$, i.e.,

$$\mathrm{meas}\,(A) \leq 2s \qquad \Longrightarrow \qquad \tilde{\mu}^+(A) \leq 2w(s) \tag{2.9}$$

for every $s > 0$ and every Borel measurable set $A \subset \mathbb{R}$. If (2.9) fails, there exists $s > 0$ and a set A such that

$$\mathrm{meas}\,(A) = 2s\,, \qquad \tilde{\mu}^+(A) > 2w(s) = 2 \lim_{\nu \to \infty} w_\nu(s).$$

Since w is continuous for $s > 0$, we can choose an open set $A' \supseteq A$ such that, setting $s' \doteq \text{meas}\,(A')/2$, one has $2w(s') < \tilde{\mu}^+(A)$. By the weak convergence $\mu^+_\nu \rightharpoonup \tilde{\mu}^+$ one obtains

$$\tilde{\mu}^+(A') \leq \liminf_{\nu\to\infty} \mu^+_\nu(A') \leq 2w(s') < \tilde{\mu}^+(A)\,,$$

reaching a contradiction. Hence (2.9) must hold. □

Toward the proof of Theorem 1 we shall need a lower semicontinuity property for wave measures, similar to what was proved in [BaB]. In the following, C_0 is the same constant as in (1.15).

LEMMA 1. *Consider a sequence of functions u_ν with uniformly small total variation and call μ^{i+}_ν the corresponding measures of positive i-waves. Let $s \mapsto w_\nu(s)$, $\nu \geq 1$, be a sequence of odd, nondecreasing functions, concave for $s > 0$, such that*

$$\mu^{i+}_\nu \preceq D_s\Big[w_\nu + C_0\,\text{sgn}(s)\big(Q_0 - Q(u_\nu)\big)\Big] \tag{2.10}$$

for some Q_0. Assume that $u_\nu \to u$ and $w_\nu \to w$ in $\mathbf{L}^1_{\text{loc}}$. Then the measure of positive i-waves in u satisfies

$$\mu^{i+} \preceq D_s\Big[w + C_0\,\text{sgn}(s)\big(Q_0 - Q(u)\big)\Big]\,. \tag{2.11}$$

Proof. The main steps follow the proof of Theorem 10.1 in [B].

1. By possibly taking a subsequence we can assume that $u_\nu(x) \to u(x)$ for every x and that the measures of total variation converge weakly, say,

$$|\mu_\nu| \doteq \big|D_x u_\nu\big| \rightharpoonup \mu^\sharp \tag{2.12}$$

for some positive Radon measure $\mu^\sharp$. In this case one has $\mu^\sharp \geq |\mu|$, in the sense of (1.12).

2. Let any $\varepsilon > 0$ be given. Since the total mass of $\mu^\sharp$ is finite, one can select finitely many points $y_1, \ldots, y_N$ such that

$$\mu^\sharp\big(\{x\}\big) < \varepsilon \qquad \text{for all} \quad x \notin \{y_1, \ldots, y_N\}. \tag{2.13}$$

We now choose disjoint open intervals $I_k \doteq]y_k - \rho,\ y_k + \rho[$ such that

$$\mu^\sharp\big(I_k \setminus \{y_k\}\big) < \frac{\varepsilon}{N}, \qquad k = 1, \ldots, N. \tag{2.14}$$

Moreover, we choose $R > 0$ such that

$$\bigcup_{k=1}^N I_k \subset [-R, R], \qquad \mu^\sharp\big(]-\infty, -R] \cup [R, \infty[\big) < \varepsilon. \tag{2.15}$$

Because of (2.13), we can now choose points $p_0 < -R < p_1 < \cdots < R < p_r$ which are continuity points for u and for every u_ν, such that

$$\mu^\sharp\big(\{p_h\}\big) = 0, \qquad u_\nu(p_h) \to u(p_h) \qquad \text{for all} \ \ h = 0, \ldots, r \tag{2.16}$$

and such that either

$$p_h - p_{h-1} < \frac{\varepsilon}{N}\,, \qquad p_{h-1} < y_k < p_h, \qquad [p_{h-1}, p_h] \subset I_k \tag{2.17}$$

for some $k \in \{1, \dots, N\}$, or else

$$|\mu|\big([p_{h-1}, p_h]\big) \leq \mu^\sharp\big([p_{h-1}, p_h]\big) < \varepsilon. \tag{2.18}$$

Call $J_h \doteq [p_{h-1}, p_h]$. If (2.18) holds, by weak convergence for some ν_0 sufficiently large one has

$$|\mu_\nu|(J_h) < \varepsilon \qquad \text{for all} \quad \nu \geq \nu_0. \tag{2.19}$$

On the other hand, if (2.17) holds, from (2.14) it follows that

$$|\mu|\big(J_h \setminus \{y_k\}\big) \leq \mu^\sharp\big(J_h \setminus \{y_k\}\big) < \frac{\varepsilon}{N}\,. \tag{2.20}$$

In the remainder of the proof, the main strategy is as follows.

- On the intervals $J_{h(k)}$ containing a point y_k of large oscillation, we first replace each u_ν by a piecewise constant function $\bar u_\nu$ having a single jump at y_k. The relations between the corresponding measures μ^i_ν and $\bar\mu^i_\nu$ are given by Lemma 10.2 in [B]. Then we take the limit as $\nu \to \infty$.
- On the remaining intervals J_h with small oscillation, we replace the left eigenvectors $l_i(u_\nu)$ by a constant vector $l_i(u^*_h)$. Then we use Proposition 4 to estimate the limit as $\nu \to \infty$.

3. We first take care of the intervals J_h containing a point y_k of large oscillation, so that (2.17) holds. For each $k = 1, \dots, N$, let $h = h(k) \in \{1, \dots, r\}$ be the index such that $y_k \in J_h \doteq [p_{h-1},\ p_h]$. For every $\nu \geq 1$ consider the function

$$\bar u_\nu(x) \doteq \begin{cases} u_\nu(x) & \text{if} \quad x \notin \cup_k J_{h(k)}, \\ u_\nu(p_{h(k)-1}) & \text{if} \quad x \in]p_{h(k)-1},\ y_k[, \\ u_\nu(p_h) & \text{if} \quad x \in [y_k,\ p_{h(k)}]. \end{cases}$$

Observe that all functions $u, \bar u_\nu$ are continuous at every point $p_0, \dots, p_r$ and have jumps at $y_1, \dots, y_N$. Call $\bar\mu^i_\nu$, $i = 1, \dots, n$, the corresponding measures, defined as in (1.8) with u replaced by $\bar u_\nu$. Clearly $\bar\mu^i_\nu = \mu^i_\nu$ outside the intervals $J_{h(k)}$ of large oscillation. By Lemma 10.2 at page 203 in [B], there holds

$$Q(\bar u_\nu) \leq Q(u_\nu), \qquad\qquad V(\bar u_\nu) + C_0\, Q(\bar u_\nu) \leq V(u_\nu) + C_0 \cdot Q(u_\nu),$$

$$\bar\mu^{i+}_\nu(\mathbb{R}) - \mu^{i+}_\nu(\mathbb{R}) \ \leq\ C_0\,\big[Q(u_\nu) - Q(\bar u_\nu)\big].$$

As a consequence, from (2.10) we deduce

$$\bar\mu^{i+}_\nu \preceq D_s\Big[T^\varepsilon w_\nu + C_0\,\mathrm{sgn}(s)\big(Q_0 - Q(\bar u_\nu)\big)\Big]\,, \tag{2.21}$$

where

$$T^\varepsilon w(s) \doteq \begin{cases} w(s + \varepsilon/2) & \text{if} \quad s > 0, \\ w(s - \varepsilon/2) & \text{if} \quad s < 0. \end{cases}$$

Indeed, all the mass which in μ^{i+}_ν lies on the set

$$\Omega \doteq \bigcup_{k=1}^N J_{h(k)}\,, \qquad\qquad J_h \doteq [p_{h-1},\ p_h]$$

is replaced in $\bar\mu^{i+}_\nu$ by point masses at $y_1,\ldots,y_N$. We obtain (2.21) by observing that, by (2.17), $meas(\Omega)<\varepsilon$. Moreover, the increase in the total mass is $\leq C_0\big[Q(u_\nu)-Q(\bar u_\nu)\big]$.

Since $u_\nu(p_h)\to u(p_h)$ for every h, there holds

$$\begin{aligned}\Big|\mu^i\big(\{y_k\}\big)-\bar\mu^i_\nu\big(\{y_k\}\big)\Big| &= \mathcal{O}(1)\cdot\Big\{\big|u(y_k-)-u(p_{h(k)-1})\big|+\big|u(y_k+)-u(p_{h(k)})\big|\\ &\qquad +\big|u(p_{h(k)-1})-u_\nu(p_{h(k)-1})\big|+\big|u(p_{h(k)})-u_\nu(p_{h(k)})\big|\Big\}\\ &= \mathcal{O}(1)\cdot\frac{\varepsilon}{N}\end{aligned}\tag{2.22}$$

for each $k=1,\ldots,N$ and all ν sufficiently large. By construction we also have

$$|\bar\mu^i_\nu|\big(J_{h(k)}\setminus\{y_k\}\big)=0,\qquad |\mu^i|\big(J_{h(k)}\setminus\{y_k\}\big)=\mathcal{O}(1)\cdot\frac{\varepsilon}{N}\,.\tag{2.23}$$

4. Next, call $\mathcal{S}\doteq\big\{h\,;\ \mu^\sharp(J_h)<\varepsilon\big\}$ the family of intervals where the oscillation of every u_ν is small, so that (2.18) holds. If $h\in\mathcal{S}$, for every $x,y\in J_h$ and ν sufficiently large, one has

$$\big|u_\nu(x)-u_\nu(y)\big|\leq|\mu_\nu|(J_h)<\varepsilon,$$

$$\big|u(x)-u(y)\big|\leq|\mu|(J_h)\leq\mu^\sharp(J_h)<\varepsilon.$$

Set $u^*_h\doteq u(p_h)$. By the pointwise convergence $u_\nu(p_h)\to u(p_h)$ and the two above estimates it follows that

$$\big|u_\nu(x)-u^*_h\big|<\varepsilon,\qquad \big|u(x)-u^*_h\big|<\varepsilon\qquad\text{for all }\ x\in J_h\,.\tag{2.24}$$

5. We now introduce the measures $\hat\mu^i_\nu$ such that

$$\hat\mu^i_\nu\doteq l_i(u^*_h)\cdot D_xu_\nu$$

restricted to each interval J_h, $h\in\mathcal{S}$, where the oscillation is small, while

$$\hat\mu^i_\nu=\bar\mu^i_\nu$$

on each interval $J_h=J_{h(k)}$ where the oscillation is large. Observe that the restriction of $\hat\mu^i_\nu$ to $J_{h(k)}$ consists of a single mass at the point y_k. Namely, $\hat\mu^i_\nu\big(\{y_k\}\big)$ is precisely the size of the ith wave in the solution of the Riemann problem with data $u^-=u_\nu(p_{h(k)-1})$, $u^+=u_\nu(p_{h(k)})$.

We define $\hat w_\nu$ as the nondecreasing odd function such that

$$\hat w_\nu(s)\ \doteq\ \sup_{meas(A)\leq 2s}\frac{\hat\mu^{i+}_\nu(A)}{2}\,,\qquad s>0.\tag{2.25}$$

By possibly taking a further subsequence we can assume the convergence

$$Q(\bar u_\nu)\to\overline{Q}\,,\qquad \hat\mu^i_\nu\rightharpoonup\hat\mu^i\,,\qquad \hat w_\nu(s)\to\hat w(s)\,.$$

Using (2.16), we can apply Proposition 4 on each interval J_h and obtain

$$\hat\mu^{i+}\preceq D_s\hat w\,.\tag{2.26}$$

6. Observe that, by (2.24) and (2.19),

$$|\hat\mu^i_\nu - \mu^i_\nu|(J_h) = \mathcal{O}(1)\cdot\varepsilon\,\mu^\sharp(J_h), \qquad\qquad h\in\mathcal{S}. \tag{2.27}$$

From (2.21) and the definition of $\hat w_\nu$ at (2.25) it thus follows that

$$\hat w_\nu(s) \leq T^\varepsilon w_\nu(s) + C_0\big[Q_0 - Q(\bar u_\nu)\big] + \mathcal{O}(1)\cdot\varepsilon, \qquad\qquad s>0\,. \tag{2.28}$$

Letting $\nu\to\infty$ we obtain

$$\hat w(s) \leq T^\varepsilon w(s) + C_0[Q_0 - \overline{Q}] + \mathcal{O}(1)\cdot\varepsilon, \qquad\qquad s>0\,, \tag{2.29}$$

$$\overline{Q} = \lim_{\nu\to\infty} Q(\bar u_\nu) \geq \lim_{\nu\to\infty} Q(u_\nu) - \mathcal{O}(1)\cdot\varepsilon \geq Q(u) - \mathcal{O}(1)\cdot\varepsilon\,, \tag{2.30}$$

because of the lower semicontinuity of the functional $u\mapsto Q(u)$. From (2.26), (2.29), and (2.30) we deduce

$$\hat\mu^{i+} \preceq D_s\Big[T^\varepsilon w + \mathrm{sgn}(s)\,\big(C_0[Q_0 - Q(u)] + \mathcal{O}(1)\cdot\varepsilon\big)\Big]\,.$$

By (2.22)–(2.24), our construction of the measure $\hat\mu^i$ achieves the property

$$\big|\mu^{i+} - \hat\mu^{i+}\big|(\mathbb{R}) = \mathcal{O}(1)\cdot\varepsilon\,.$$

Hence, by Proposition 3,

$$\mu^{i+} \preceq D_s\Big[T^\varepsilon w + \mathrm{sgn}(s)\,\big(C_0[Q_0 - Q(u)] + \mathcal{O}(1)\cdot\varepsilon\big)\Big]\,.$$

Since $\varepsilon>0$ was arbitrary, this proves (2.11). □

3. A decay estimate. The second basic ingredient in the proof is the following lemma, which refines the estimate in [BC].

LEMMA 2. *For some constant $\kappa>0$ the following holds. Let $u=u(t,x)$ be any entropy weak solution of* (1.1)*, with initial data $u(0,x)=\bar u(x)$ having small total variation. Then the measure μ^{i+}_t of positive i-waves in $u(t,\cdot)$ can be estimated as follows.*

Let $w:[0,\tau[\,\times\mathbb{R}\mapsto\mathbb{R}$ be the solution of Burgers's equation

$$w_t + (w^2/2)_x = 0 \tag{3.1}$$

with initial data

$$w(0,x) = \mathrm{sgn}(x)\cdot\sup_{meas(A)\leq 2|x|}\frac{\mu^{i+}_0(A)}{2}\,. \tag{3.2}$$

Set

$$w(\tau,x) = w(\tau-,\ x) + \kappa\,\mathrm{sgn}(x)\cdot\big[Q(\bar u) - Q\big(u(\tau)\big)\big]\,. \tag{3.3}$$

Then

$$\mu^{i+}_\tau \preceq D_x w(\tau)\,. \tag{3.4}$$

Proof. The main steps follow the proof of Theorem 10.3 in [B]. We first prove the estimate (3.3) under the following additional hypothesis.

(H) There exist points $y_1 < \cdots < y_m$ such that the initial data $\bar u$ is smooth outside such points, constant for $x < y_1$ and $x > y_m$, and the derivative component $l_i(u)\, u_x$ is constant on each interval $]y_\ell,\, y_{\ell+1}[$. Moreover, the Glimm functional $t \mapsto Q\big(u(t)\big)$ is continuous at $t = \tau$.

1. The solution $u = u(t,x)$ can be obtained as the limit of front tracking approximations. In particular, we can consider a particular converging sequence $(u_\nu)_{\nu\geq 1}$ of ε_ν-approximate solutions with the following additional properties:

(i) Each i-rarefaction front x_α travels with the characteristic speed of the state on the right:

$$\dot x_\alpha = \lambda_i\big(u(x_\alpha+)\big).$$

(ii) Each i-shock front x_α travels with a speed strictly contained between the right and the left characteristic speeds:

$$\lambda_i\big(u(x_\alpha+)\big) < \dot x_\alpha < \lambda_i\big(u(x_\alpha-)\big). \tag{3.5}$$

(iii) As $\nu \to \infty$, the interaction potentials satisfy

$$Q\big(u_\nu(0,\cdot)\big) \to Q(\bar u). \tag{3.6}$$

2. Let u_ν be an approximate solution constructed by the front tracking algorithm. By a *(generalized) i-characteristic* we mean an absolutely continuous curve $x = x(t)$ such that

$$\dot x(t) \in \big[\lambda_i(u_\nu(t,x-)),\ \lambda_i(u_\nu(t,x+))\big]$$

for a.e. t. If u_ν satisfies the above properties (i)–(ii), then the i-characteristics are precisely the polygonal lines $x : [0,\tau] \mapsto \mathbb{R}$ for which the following holds. For a suitable partition $0 = t_0 < t_1 < \cdots < t_m = \tau$, on each subinterval $[t_{j-1},\, t_j]$ either $\dot x(t) = \lambda_i\big(u_\nu(t,x)\big)$, or else x coincides with a wave front of the ith family. For a given terminal point $\bar x$ we shall consider the *minimal backward i-characteristic* through $\bar x$, defined as

$$y(t) = \min\big\{x(t)\,;\quad x \ \text{ is an } i\text{-characteristic},\quad x(\tau) = \bar x\big\}.$$

Observe that $y(\cdot)$ is itself an i-characteristic. By (3.5), it cannot coincide with an i-shock front of u on any nontrivial time interval.

In connection with the exact solution u, we define an i-characteristic as a curve

$$t \mapsto x(t) = \lim_{\nu\to\infty} x_\nu(t)$$

which is the limit of i-characteristics in a sequence of front tracking solutions $u_\nu \to u$.

3. Let $\varepsilon > 0$ be given. If the assumption (H) holds, the measure μ^{i+}_τ of i-waves in $u(\tau)$ is supported on a bounded interval and is absolutely continuous w.r.t. Lebesgue measure. We can thus find a piecewise constant function ψ^τ with jumps at points $x_1(\tau) < \bar x_2(\tau) < \cdots < \bar x_N(\tau)$ such that

$$\int \left|\frac{d\mu^{i+}_\tau}{dx} - \psi^\tau\right| dx < \varepsilon\,, \qquad \int_{x_j(\tau)}^{x_{j+1}(\tau)} \left(\frac{d\mu^{i+}_\tau}{dx} - \psi^\tau\right) dx = 0, \qquad j = 1,\dots,N-1\,. \tag{3.7}$$

To prove the lemma in this special case, relying on Proposition 2, it thus suffices to find i-characteristics $t \mapsto x_j(t)$ such that the following hold (Figure 2):

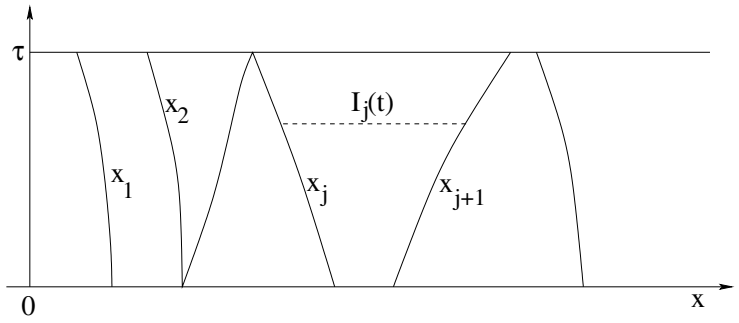

FIG. 2.

(i) For each $j = 1, \dots, N$, the function ψ^τ is constant on the interval $\big]x_j(\tau), x_{j+1}(\tau)\big[$ and (3.7) holds. Moreover, either $x_j(0) = x_{j+1}(0)$, or else the derivative component $\psi^0 \doteq l^i(u)u_x(0,\cdot)$ is constant on the interval $\big]x_j(0), x_{j+1}(0)\big[$.

(ii) An estimate corresponding to (3.3)–(3.4) holds restricted to each subinterval $\big[x_j(\tau),\ x_{j+1}(\tau)\big[$.

We need to explain in more detail this last statement. Define

$$I_j(t) \doteq \big[x_j(t),\, x_{j+1}(t)\big[\,, \qquad\qquad \Delta_j \doteq \big\{(t,x)\,;\quad t\in[0,\tau]\,,\quad x\in I_j(t)\big\}\,.$$

For each j, we denote by Γ_j the total amount of wave interaction within the domain Δ_j. This is defined as in [B], first for a sequence of front tracking approximations u_ν, then taking a limit as $\nu\to\infty$. Furthermore, we define the constant values

$$\psi_j^\tau \doteq \psi^\tau(x), \qquad\qquad x\in I_j(\tau)\,,$$

$$\psi_j^0 \doteq \psi^0(x), \qquad\qquad x\in I_j(0).$$

Call

$$\sigma_j^0 \doteq \lim_{t\to 0+} \mu^{i+}\big(I_j(t)\big)$$

the initial amount of positive i-waves inside the interval I_j.

For each interval I_j, we consider on one hand the function w_j^τ corresponding to (3.2)–(3.3), namely,

$$w_j^\tau(s) \doteq \min\left\{\sigma_j^0\,,\ \frac{s}{\tau + (\psi_j^0)^{-1}}\right\} + \kappa\Gamma_j\cdot \mathrm{sgn}(s)\,.$$

Here $(\psi_j^0)^{-1} \doteq 0$ in the case where $x_j(0) = x_{j+1}(0)$. This may happen when the initial data has a jump at $x_j(0)$, and the corresponding measure μ^{i+} has a Dirac mass (with infinite density) at that point.

On the other hand, we look at the nondecreasing, odd function η_j such that

$$\eta_j(s) \doteq \min\Big\{\psi_j^\tau\, s,\quad \psi_j^\tau\big[x_{j+1}(\tau) - x_j(\tau)\big]\Big\}, \qquad\qquad s>0\,.$$

Our basic goal is to prove that (Figure 3)

$$\eta_j(s) \le w_j^\tau(s) \qquad\qquad \text{for all } s>0\,. \tag{3.8}$$

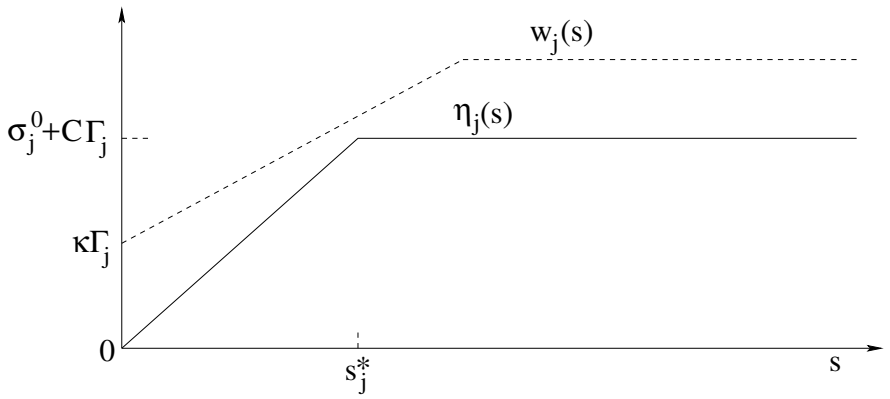

FIG. 3.

Indeed, by (3.7), for $s > 0$ one has

$$\sup_{meas(A)\leq 2s} \frac{\mu_\tau^{i+}\big(A\cap I_j(\tau)\big)}{2} \leq \eta_j(s) + \varepsilon_j$$

with

$$\sum_j \varepsilon_j < \varepsilon\,.$$

Proving (3.8) for each j will thus imply

$$\mu_\tau^{i+} \preceq w(\tau,x) = w(\tau-,\ x) + \kappa\,\mathrm{sgn}(x)\cdot\big[Q(\bar u) - Q\big(u(\tau)\big) + \mathcal{O}(1)\cdot\varepsilon\big]\,.$$

Since $\varepsilon > 0$ was arbitrary, this establishes the lemma under the additional assumptions (H).

4. We now work toward a proof of (3.8), in three cases.

Case 1: $\sigma_j^0 = 0$.

Case 2: $x_j(0) = x_{j+1}(0)$ and $\sigma_j^0 > 0$.

Case 3: $x_j(0) < x_{j+1}(0)$ and $\sigma_j^0 = \big(x_{j+1}(0) - x_j(0)\big)\,\psi_j^0 > 0$.

In Case 1 the proof is easy. Indeed, the total amount of positive i-waves in $I_j(\tau)$ is here bounded by a constant times the total amount of interaction taking place inside the domain Δ_j, i.e.,

$$\mu_\tau^{i+}\big(I_j(\tau)\big) \leq C_0\cdot\Gamma_j$$

for some constant C_0. On the other hand

$$w_j^\tau(s) = \kappa\Gamma_j\cdot\mathrm{sgn}(s)\,.$$

Choosing $\kappa > C_0$ we achieve (3.8).

5. Since Case 2 can be obtained from Case 3 in the limit as $x_{j+1} - x_j \to 0$, we shall only give a proof for Case 3.

We can again distinguish two cases. If the amount of interaction Γ_j is large compared with the initial amount of i-waves, say

$$\Gamma_j \geq \frac{1}{6C_0}\sigma_j^0\,,$$

then the bound (3.8) is readily achieved choosing $\kappa > 8C_0$. Indeed, for $s > 0$ we have

$$\eta_j(s) \leq \frac{1}{2}\,\mu_\tau^{i+}\big(I_j(\tau)\big) \leq C_0\Gamma_j + \sigma_j^0 \leq 7C_0\,\Gamma_j\,.$$

The more difficult case to analyze is when Γ_j is small, say

$$\Gamma_j < \sigma_j^0/6C_0\,. \tag{3.9}$$

Looking at Figure 3, it clearly suffices to prove (3.8) for the single value

$$s = s_j^* \doteq \frac{x_{j+1}(\tau) - x_j(\tau)}{2}\,.$$

Equivalently, calling

$$z_j(t) \doteq x_{j+1}(t) - x_j(t)$$

the length of the interval $I_j(t)$ and

$$\sigma_j^\tau \doteq \mu_\tau^{i+}\big(I_j(\tau)\big) = z_j(\tau)\,\psi_j^\tau$$

the total amount of positive i-waves inside $I_j(\tau)$, we need to show that

$$\sigma_j^\tau \leq 2\kappa\Gamma_j + \min\left\{\sigma_j^0\,,\quad \frac{2s_j^*}{\tau + (\psi_j^0)^{-1}}\right\}\,. \tag{3.10}$$

By the approximate conservation of i-waves over the region Δ_j, we can write

$$\sigma_j^\tau \leq \sigma_j^0 + C_0\Gamma_j\,. \tag{3.11}$$

Using (3.11) in (3.10), our task is reduced to showing that

$$\sigma_j^\tau \leq 2\kappa\Gamma_j + \frac{2s_j^*}{\tau + (\psi_j^0)^{-1}} \tag{3.12}$$

for a suitably large constant κ. Because of (3.11), it suffices to show that

$$\begin{aligned} z_j(\tau) &\geq (\sigma_j^0 - C'\Gamma_j)\big(\tau + (\psi_j^0)^{-1}\big) \\ &= \big[z_j(0) + \tau\sigma_j^0\big] - C'\big(\tau + (\psi_j^0)^{-1}\big)\,\Gamma_j \end{aligned} \tag{3.13}$$

for a suitable constant C'.

6. We now prove (3.13). Notice that, by genuine nonlinearity and the normalization (1.2), if no other waves were present in the region Δ_j we would have $\Gamma_j = 0$ and

$$\frac{d}{dt}z_j(t) \equiv \sigma_j^0\,.$$

In this case, the equality would hold in (3.13).

To handle the general case, we represent the solution u as a limit of front tracking approximations u_ν, where for each $\nu \geq 1$ the function $u_\nu(0,\cdot)$ contains exactly ν rarefaction fronts equally spaced along the interval $I_j(0)$ (Figure 4). Each of these fronts has initial strength $\sigma_\alpha(0) = \sigma_j^0/\nu$. For $\alpha = 1,\ldots,\nu$, let $y_\alpha(t) \in I_j(t)$ be the

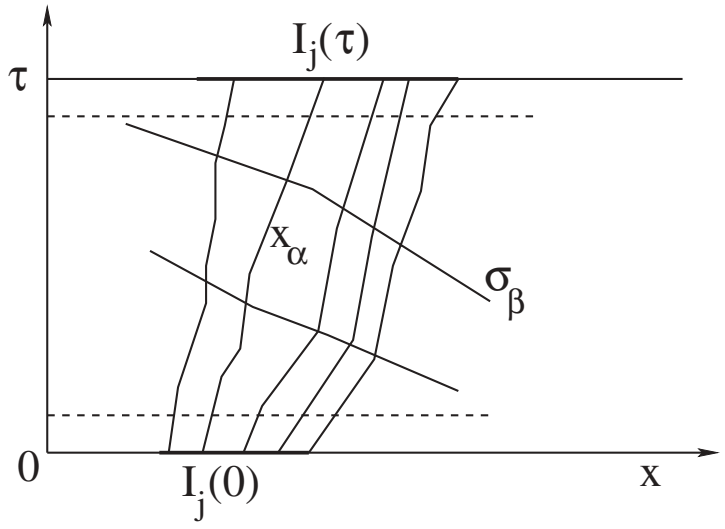

FIG. 4.

location of one of these fronts at time $t \in [0,\tau]$, and let $\sigma_\alpha(t) > 0$ be its strength. Moreover, call

$$J_\alpha(t) \doteq \big[y_\alpha(t)\,,\ y_{\alpha+1}(t)\big]\,, \qquad\qquad \Delta_\alpha \doteq \big\{(t,x)\,;\ \ t\in[0,\tau]\,,\ \ x\in J_\alpha(t)\big\}\,,$$

and let Γ_α be the total amount of interaction in u_ν taking place inside the domain Δ_α.

We define a subset of indices $\mathcal{I} \subseteq \{1,\dots,\nu\}$ by setting $\alpha \in \mathcal{I}$ if

$$5C_0\Gamma_\alpha > \sigma_\alpha(0) = \sigma_j^0/\nu\,. \tag{3.14}$$

Observe that, if $\alpha \notin \mathcal{I}$, then

$$\left|\frac{\sigma_\alpha(t)}{\sigma_\alpha(0)} - 1\right| < \frac{1}{2} \qquad \text{for all } t\in[0,\tau]\,.$$

In particular, if $\alpha, \alpha+1 \notin \mathcal{I}$, then the interval $J_\alpha(t)$ is well defined for all $t\in[0,\tau]$. Its length

$$z_\alpha(t) \doteq y_{\alpha+1}(t) - y_\alpha(t)$$

satisfies the differential inequality

$$\frac{d}{dt} z_\alpha(t) \geq W_\alpha(t) - C_1 \cdot \sum_{\beta\in\mathcal{C}_\alpha(t)} |\sigma_\beta| \tag{3.15}$$

for some constant C_1. Here

$$\begin{aligned} W_\alpha(t) &\doteq \big[\text{amount of } i\text{-waves inside the interval } J_\alpha(t)\big] \\ &\geq \sigma_\alpha(0) - C_0\Gamma_\alpha\,, \end{aligned} \tag{3.16}$$

while $\mathcal{C}_\alpha(t)$ refers to the set of all wave fronts of different families which are crossing the interval J_α at time t. Calling W'_α the total amount of waves of families $\neq i$ which lie inside $J_\alpha(0)$, we can now write

(3.17)
$$\int_0^\tau \left(\sum_{\beta \in \mathcal{C}_\alpha(t)} |\sigma_\beta| \right) dt \leq \Big(\max_{t\in[0,\tau]} z_\alpha(t) \Big) \cdot \frac{2\nu}{\sigma_j^0} \cdot \Gamma_\alpha + \mathcal{O}(1) \cdot \tau \Gamma_\alpha + \mathcal{O}(1) \cdot \left(\frac{z_j(0)+1}{\nu} \right) W'_\alpha.$$

Indeed, by strict hyperbolicity, every front σ_β of a different family can spend at most a time $\mathcal{O}(1) \cdot z_\alpha$ inside J_α. Either it is located inside J_α already at time $t = 0$, or else, when it enters, it crosses y_α or $y_{\alpha+1}$. In this case, since $\alpha, \alpha+1 \notin \mathcal{I}$, by (3.14) it will produce an interaction of magnitude $|\sigma_\beta\, \sigma_\alpha| \geq |\sigma_\beta \cdot \sigma_j^0|/2\nu$. The second term on the right-hand side of (3.17) takes care of the new wave fronts which are generated through interactions inside J_α. The last term takes into account wave fronts of different families that initially lie already inside J_α at time $t = 0$. Integrating (3.15) over the time interval $[0, \tau]$ and using (3.16)–(3.17) one obtains

$$z_\alpha(\tau) \;\geq\; z_\alpha(0) + \tau \frac{\sigma_j^0}{\nu} - \mathcal{O}(1) \cdot \tau \Gamma_\alpha - \mathcal{O}(1) \cdot \Big(\max_{t\in[0,\tau]} z_\alpha(t) \Big) \cdot \frac{2\nu}{\sigma_j^0} \cdot \Gamma_\alpha - \mathcal{O}(1) \cdot \left(\frac{z_j(0)+1}{\nu} \right) W'_\alpha.$$

(3.18)

7. To proceed in our analysis, we now show that

$$\max_{t\in[0,\tau]} z_\alpha(t) \leq 2\, z_\alpha(\tau)\,. \tag{3.19}$$

Indeed, let $\tau' \in [0, \tau]$ be the time where the maximum is attained. If our claim (3.19) does not hold, there would exist a first time $\tau'' \in [\tau', \tau]$ such that $z_\alpha(\tau'') = z_\alpha(\tau')/2$. From (3.15) and the assumption $W_\alpha(t) \geq 0$ it follows that

$$\int_{\tau'}^{\tau''} C_1 \sum_{\beta \in \mathcal{C}_\alpha(t)} |\sigma_\beta|\, dt \geq \frac{z_\alpha(\tau')}{2}\,. \tag{3.20}$$

Using the smallness of the total variation, a contradiction is now obtained as follows. Call

$$\Phi(t) \doteq C_0 Q(t) + \sum_{k_\beta \neq i} \phi_{k_\beta}\big(t, x_\beta(t)\big)\, |\sigma_\beta|\,,$$

where the sum ranges over all fronts of strength σ_β located at x_β, of a family $k_\beta \neq i$. The weight functions ϕ_j are defined as

$$\phi_j(t,x) \doteq \begin{cases} 0 & \text{if} \quad x > y_{\alpha+1}(t)\,, \\ \frac{y_{\alpha+1}(t) - x}{y_{\alpha+1}(t) - y_\alpha(t)} & \text{if} \quad x \in \big[y_\alpha(t),\; y_{\alpha+1}(t)\big]\,, \\ 1 & \text{if} \quad x < y_\alpha(t) \end{cases}$$

in the case $j > i$, while

$$\phi_j(t,x) \doteq \begin{cases} 1 & \text{if} \quad x > y_{\alpha+1}(t)\,, \\ \frac{x - y_\alpha(t)}{y_{\alpha+1}(t) - y_\alpha(t)} & \text{if} \quad x \in \big[y_\alpha(t),\; y_{\alpha+1}(t)\big]\,, \\ 0 & \text{if} \quad x < y_\alpha(t) \end{cases}$$

in the case $j < i$. Because of the term $C_0 Q(t)$, the functional Φ is nonincreasing at times of interactions. Moreover, outside interaction times a computation entirely similar to the one on page 213 of [B] now yields

$$-\frac{d}{dt}\Phi(t) \geq \sum_{\beta\in\mathcal{C}_\alpha(t)} |\sigma_\beta| \cdot \frac{c_0}{z(t)} \tag{3.21}$$

for some small constant $c_0 > 0$ related to the gap between different characteristic speeds. From (3.20) and (3.21), respectively, we now deduce

$$\int_{\tau'}^{\tau''} \sum_{\beta\in\mathcal{C}_\alpha(t)} |\sigma_\beta|\, dt \geq \frac{z_\alpha(\tau')}{2C_1}\,,$$

$$\int_{\tau'}^{\tau''} \sum_{\beta\in\mathcal{C}_\alpha(t)} |\sigma_\beta|\, dt \leq \int_{\tau'}^{\tau''} \left|\frac{d\Phi(t)}{dt}\right| \cdot \frac{z_\alpha(\tau')}{c_0}\, dt \leq \frac{\Phi(\tau')}{c_0}\, z_\alpha(\tau')\,.$$

Since $\Phi(t) = \mathcal{O}(1)\cdot \text{Tot.Var.}\big\{u(t)\big\}$, by the smallness of the total variation we can assume $\Phi(\tau') < 2C_1/c_0$. In this case, the two above inequalities yield a contradiction.

8. Using (3.19), from (3.18) we obtain

$$\begin{aligned}
z_j(\tau) &= \sum_{1\leq\alpha\leq\nu} z_\alpha(\tau) \geq \sum_{\alpha\notin\mathcal{I}} z_\alpha(\tau) \\
&\geq \sum_{\alpha\notin\mathcal{I}} \left\{ \frac{z_\alpha(0) + \tau\sigma_j^0/\nu}{1 + C_2(\nu/\sigma_j^0)\Gamma_\alpha} - \mathcal{O}(1)\cdot\tau\Gamma_j - \mathcal{O}(1)\cdot\left(\frac{z_j(0)+1}{\nu}\right) W'_\alpha \right\} \\
&\geq \sum_{\alpha\notin\mathcal{I}} \left(z_\alpha(0) + \tau\frac{\sigma_j^0}{\nu}\right)\left(1 - C_2\frac{\nu}{\sigma_j^0}\Gamma_\alpha\right) - \mathcal{O}(1)\cdot\tau\Gamma_j - \mathcal{O}(1)\cdot\frac{z_j(0)+1}{\nu} \\
&\geq \sum_{\alpha\notin\mathcal{I}} \left(z_\alpha(0) + \tau\frac{\sigma_j^0}{\nu}\right) - C_2\frac{z_j(0)}{\sigma_j^0}\Gamma_j - \mathcal{O}(1)\cdot\tau\Gamma_j - \mathcal{O}(1)\cdot\frac{z_j(0)+1}{\nu}\,. \qquad (3.22)
\end{aligned}$$

By (3.14) the cardinality of the set $\mathcal{I}$ satisfies

$$\#\mathcal{I}\cdot\frac{\sigma_j^0}{5C_0\nu} \leq \sum_{\alpha\in\mathcal{I}} \Gamma_\alpha \leq \Gamma_j;$$

hence

$$\frac{\#\mathcal{I}}{\nu} \leq \frac{5C_0}{\sigma_j^0}\Gamma_j\,.$$

In turn, this implies

$$\begin{aligned}
\sum_{\alpha\notin\mathcal{I}} \left(z_\alpha(0) + \tau\frac{\sigma_j^0}{\nu}\right) &\geq \big(z_j(0) + \tau\sigma_j^0\big)\left(1 - \frac{\#\mathcal{I}}{\nu}\right) \\
&\geq \big(z_j(0) + \tau\sigma_j^0\big) - 5C_0\Gamma_j\frac{z_j(0)}{\sigma_j^0}\Gamma_j - 5C_0\tau\Gamma_j\,. \qquad (3.23)
\end{aligned}$$

Using (3.23) in (3.22), observing that

$$\frac{z_j(0)}{\sigma_j^0} = \frac{x_{j+1}(0) - x_j(0)}{\sigma_j^0} = (\psi_j^0)^{-1},$$

and letting $\nu \to \infty$, we conclude

$$z_j(\tau) \geq \big(z_j(0) + \tau\sigma_j^0\big) - \mathcal{O}(1) \cdot (\psi_j^0)^{-1}\Gamma_j - \mathcal{O}(1) \cdot \tau\Gamma_j\,.$$

This establishes (3.13) for a suitable constant C'.

9. In the general case, without the assumptions (H), the lemma is proved by an approximation argument. We construct a convergent sequence of initial data $\bar u_\nu \to \bar u$ which satisfy (H) and such that

$$\bar u_\nu \to \bar u\,, \qquad Q(\bar u_\nu) \to Q(\bar u)\,, \qquad \big|\mu^{i+}_{\nu,0} - \mu^{i+}_0\big| \to 0\,.$$

Calling w_ν the solution of (3.1) with initial data

$$w_\nu(0,x) = \mathrm{sgn}(x) \cdot \sup_{meas(A)\leq 2|x|} \frac{\mu^{i+}_{\nu,0}(A)}{2}\,,$$

by the previous analysis we have

$$\mu^{i+}_{\nu,\tau_\nu} \preceq D_x\Big[w_\nu(\tau_\nu-) + \mathrm{sgn}(x) \cdot \big[Q(\bar u_\nu) - Q(u_\nu(\tau_\nu))\big]\Big]\,.$$

Observe that $w_\nu(\tau_\nu-) \to w(\tau-)$ in $\mathbf{L}^1_{\rm loc}$. Choosing $\kappa \geq C_0$, by the lower semicontinuity result stated in Lemma 1 we now conclude

$$\mu^{i+}_\tau \preceq D_x\Big[w(\tau-) + \kappa\,\mathrm{sgn}(x) \cdot \big[Q(\bar u) - Q(u(\tau))\big]\Big]\,. \qquad \square$$

4. Proof of the main theorem. Using the previous lemmas, we now give a proof of Theorem 1. For a given interval $[0,\tau]$, the solution of the impulsive Cauchy problem (1.17)–(1.18) can be obtained as follows. Consider a partition $0 = t_0 < t_1 < \cdots < t_N = \tau$. Construct an approximate solution by requiring that $w(0,x) = \hat v_i(x)$,

$$w_t + (w^2/2)_x = 0 \tag{4.1}$$

on each subinterval $[t_{k-1}, t_k[$, while

$$w(t_k, x) = w(t_k-\,,\ x) + \kappa\,\mathrm{sgn}(x) \cdot \big[Q(t_{k-1}) - Q(t_k)\big]\,. \tag{4.2}$$

We then consider a sequence of partitions $0 = t^\nu_0 < t^\nu_1 < \cdots < t^\nu_{N_\nu} = \tau$, and the corresponding solutions w_ν. If the mesh of the partitions approaches zero, i.e.,

$$\lim_{\nu\to\infty} \sup_k |t^\nu_k - t^\nu_{k-1}| = 0\,,$$

then the approximate solutions w_ν converge to a unique limit, which yields the solution of (1.17)–(1.18).

Call $\mathcal{F}$ the set of nondecreasing odd functions, concave for $x > 0$. This set is positively invariant for the flow of Burgers's equation (4.1). Moreover, this flow is order preserving. Namely, if $w, w' \in \mathcal{F}$ are solutions of (4.1) with initial data such that $w(0,x) \leq w'(0,x)$ for all $x > 0$, then also

$$w(t,x) \leq w'(t,x) \qquad\qquad \text{for all}\ \ t, x > 0\,.$$

Equivalently,

$$D_x w(0) \preceq D_x w'(0) \qquad \Longrightarrow \qquad D_x w(t) \preceq D_x w'(t)$$

for every $t > 0$. For each fixed ν, we can apply Lemma 2 on each subinterval $[t^\nu_{k-1}, t^\nu_k]$ and obtain

$$\mu^{i+}_{t^\nu_k} \preceq D_x w_\nu(t^\nu_k) \qquad \Longrightarrow \qquad \mu^{i+}_{t^\nu_{k+1}} \preceq D_x w_\nu(t^\nu_{k+1})\,.$$

By induction on k, this yields

$$\mu^{i+}_\tau \preceq D_x w_\nu(\tau)\,, \tag{4.3}$$

where w_ν is the approximate solution constructed according to (4.1)–(4.2). Letting $\nu \to \infty$ and using Lemma 1, we achieve a proof of Theorem 1. □

5. Examples.

Example 1. Consider first the scalar case. Let $u = u(t,x)$ be a solution of Burgers's equation with smooth initial data

$$u_t + (u^2/2)_x = 0\,, \qquad\qquad u(0,x) = \bar u(x)\,.$$

Define the function w as the solution to

$$w_t + (w^2/2)_x = 0\,, \qquad\qquad w(0,x) = \mathrm{sgn}(x) \cdot \sup_{meas(A)<2|x|} \int_A \frac{\bar u_x(y)}{2}\, dy\,.$$

This corresponds to (1.16)–(1.17) with $Q \equiv 0$. According to Oleinik's estimate we now have $u_x(t,x) \le 1/t$ for all $t > 0$, and a.e. $x \in \mathbb{R}$. Of course, this reflects the fact that, along each characteristic with $\dot x = u\big(t, x(t)\big)$, the gradient satisfies

$$\frac{d}{dt} u_x\big(t, x(t)\big) = -\frac{1}{u_x^2\big(t, x(t)\big)}\,. \tag{5.1}$$

A better estimate on $u_x\big(t, x(t)\big)$ when it is positive, based on (5.1), is

$$u_x\big(t, x(t)\big) \le \frac{1}{t + \big[\bar u_x(x(0))\big]^{-1}}\,. \tag{5.2}$$

According to (1.18), for every $t > 0$ we have the relation

$$\mu^+_t \preceq D_x w(t)\,, \tag{5.3}$$

which includes the additional information (5.2). This relation is sharp in the sense that the converse inequality

$$D_x w(t) \preceq \mu^+_t$$

also holds, as long as no positive waves are cancelled by interacting with shocks.

Analogous results are valid for scalar equations with more general flux:

$$u_t + f(u)_x = 0, \qquad\qquad u(0,x) = \bar u(x)\,,$$

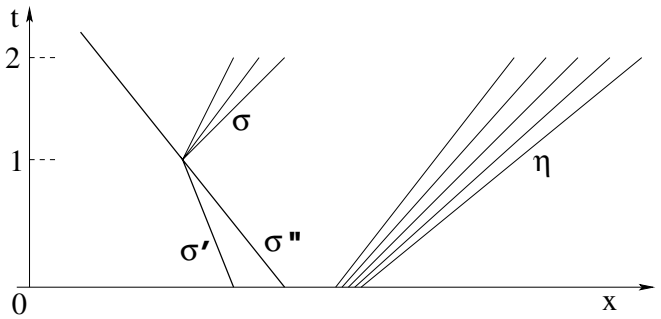

FIG. 5.

under the assumption of genuine nonlinearity $f'' > 0$. Notice that in this case the normalization (1.2) yields $r(u) = 1/f''(u)$, $l(u) = f''(u)$. As long as the solution $u(t,\cdot)$ remains smooth, the corresponding wave measure is thus defined as

$$\mu_t(A) = \int_A f''\big(u(t,x)\big) \cdot u_x(t,x)\, dx\,.$$

Example 2. Consider the p-system in Lagrangean coordinates (see [Sm])

$$v_t - u_x = 0\,, \qquad u_t + (K/v^\gamma)_x = 0\,.$$

Here $K > 0$ and $\gamma \geq 1$ are constants. Consider a solution which initially contains two approaching 1-shocks and a 2-rarefaction (Figure 5). Assume that at time $t = 1$ the two shocks interact. As shown in [Sm], the Riemann problem is then solved in terms of a 1-shock and a 2-rarefaction. Let us look at the measure of positive 2-waves in the solution. Let η be the strength of the centered rarefaction. During the interval $t \in [0,1[$ the density of rarefaction waves decays, as in the scalar case. At time $t = 1$ a new centered rarefaction is created by the interaction. Calling σ', σ'' the strengths of the incoming shocks, the strength σ of this new rarefaction will satisfy

$$\sigma \leq \kappa \cdot |\sigma'\sigma''| \doteq \tilde\sigma \tag{5.4}$$

for a suitable constant $\kappa > 0$. Notice that the decrease in the interaction potential at time $t = 1$ is $\Delta Q = -|\sigma'\sigma''|$. The values of the corresponding function $w = w(t,x)$ in (1.16)–(1.18) at various times are illustrated in Figure 6. For $t \in [0,1[$ the estimate (1.18) is sharp, in the sense that

$$D_x w(t) \preceq \mu_t^{2+} \preceq D_x w(t)\,. \tag{5.5}$$

The first relation in (5.5) will fail for $t \geq 1$ if $\tilde\sigma < \sigma$. The accuracy of our estimate in this case depends essentially on the careful choice of the constant κ in (5.4). In particular, if we could choose κ so that $\sigma = \kappa|\sigma'\sigma''|$, then both relations in (5.5) would remain valid for all times $t \geq 0$.

Remark. Concerning compression waves, an estimate of the form (1.18) could be derived also for the negative part of the measures μ_t^i. In this case, μ_t^{i-} can be compared with the gradient $D_x w$ of an odd, nonincreasing solution of a perturbed Burgers's equation. However, the result does not appear to be very interesting. Indeed, as time progresses negative waves become ever more singular and a bound such as (1.18)

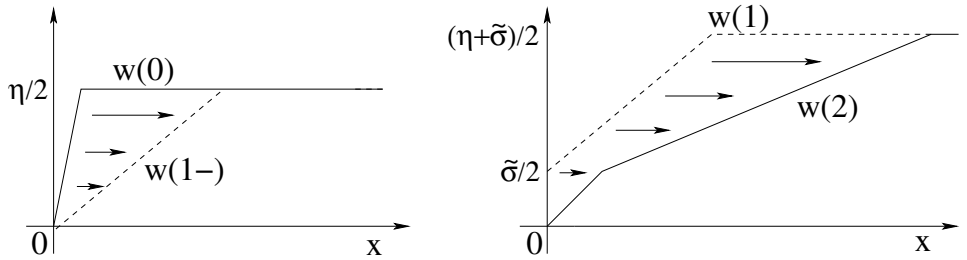

FIG. 6.

retains little content. For large times, a much better way to estimate negative waves is to analyze their cancellation with positive waves of the same family, as in [L1], [L2].

ATTRACTION DOMAINS OF DEGENERATE SINGULAR EQUILIBRIA IN QUASI-LINEAR ODES*

RICARDO RIAZA†

Abstract. The present paper addresses stability properties of singular equilibria arising in a given family of quasi-linear ODEs. These ODEs model continuous-time methods for root-finding problems and their singular equilibria are *degenerate* in the sense that the linearization of the system at equilibrium yields a singular matrix pencil. The analysis is based upon a normal form defined by a codimension-one regular system coupled with a singular scalar equation. The key step is the formulation of certain codimension-one Lyapunov matrix equations which incorporate the relevant singular information and allow for the construction of Lyapunov functions supporting the stability analysis. This approach makes it possible to state precisely the asymptotic stability of such degenerate equilibria, and provides a local estimation of the corresponding attraction domains. An application to the computation of singular DC operating points in nonlinear circuits is discussed.

Key words. implicit ODE, singularity, normal form, stability of equilibria, matrix equation, Lyapunov function, root-finding, nonlinear circuit

1. Introduction.

Consider the implicit differential system

$$y' = \xi(y,z) \tag{1a}$$

$$zz' = \zeta(y,z), \tag{1b}$$

where $y \in \mathbb{R}^{n-1}$, $z \in \mathbb{R}$, and the functions $\xi(y,z)$, $\zeta(y,z)$ are sufficiently smooth.

System (1) arises as a local normal form for quasi-linear ODEs $A(u)u' = f(u)$ (where A and f are sufficiently smooth matrix- and vector-valued functions) around a *singular point* satisfying $\det A(u^*) = 0$ and $(\det A)'(u^*)v \neq 0$, $\forall v \in \mathrm{Ker}A(u^*) - \{0\}$ [11, 16, 19, 22]. It is also closely related to certain singular differential-algebraic equations (DAEs) [3, 4, 17]. These singular equations are relevant in problems arising in magnetohydrodynamics, electrical circuits, or power system theory, to name a few [5, 6, 15, 23].

Singularities of the normal form (1) are located in the hyperplane $z = 0$, and can be classified (see [3, 4, 6, 12, 13, 17, 19, 23] and references therein) into *pseudo-equilibria* (defined by the condition $\zeta(y,0) = 0$), *forward impasse points* ($\zeta(y,0) < 0$), or *backward impasse points* ($\zeta(y,0) > 0$). Smooth solutions may be defined through pseudoequilibrium points, whereas a pair of trajectories collapse when reaching an impasse point, either in forward or backward time direction.

The present work is focused on stability issues concerning *singular equilibria* of (1), characterized by the pair of conditions $\xi(y,0) = 0$, $\zeta(y,0) = 0$. Within the context of semiexplicit DAEs, these singular equilibria have been analyzed in [3] under an assumption of regularity on the matrix pencil (see [18] and references therein for

background on this topic) describing the linearization of the problem. For system (1), this matrix pencil would read $\mu C - D$, μ being a complex parameter, whereas $C = \mathrm{diag}\{I_{n-1}, 0\}$ and D is the Jacobian matrix of the right-hand side of (1) evaluated at equilibrium; regularity of the matrix pencil means that there exists a μ_0 such that $\mu_0 C - D$ is invertible, allowing for the definition of a Kronecker index for the pencil.

In contrast, the present paper will address *degenerate* singular equilibria, displaying a singular pencil in the linearization. Specifically, we will consider ODEs of the form

$$y' = Hy + \beta(y, z), \tag{2a}$$

$$zz' = \lambda z^2 + y^T G y + \gamma(y, z), \tag{2b}$$

where $H,\ G \in \mathbb{R}^{(n-1)\times(n-1)}$, G being symmetric, and $\lambda \in \mathbb{R}$. The functions $\beta(y, z)$ and $\gamma(y, z)$ are $O(\|(y, z)\|)^2$ and $O(\|(y, z)\|)^3$, respectively. Singularity of the matrix pencil arising in the linearization at the origin would in this situation follow from the vanishing of the last row of $\mu C - D$ for any μ, with the above-explained notation.

System (2), with $H = -I_{n-1},\ \lambda = -1/2$, is proved in [19] to describe a normal form around a singular equilibrium of the so-called continuous Newton method (see [18, 20, 21] and the bibliography therein)

$$-J(u)u' = f(u) \tag{3}$$

for sufficiently smooth $f : \mathbb{R}^n \to \mathbb{R}^n$, J being the Jacobian matrix of f. Euler discretization of (3) yields the classical Newton iteration for root-finding and optimization problems. The interest of a continuous-time scheme in this setting stems from its better properties regarding global issues and singular problems, together with the fact that a unique continuous system may lead to different iterative techniques, including damped and accelerated versions of basic methods, through the use of different integration schemes. Therefore, the same continuous-time study may be of interest for a wide family of discrete-time techniques [21].

A singular equilibrium of (3) is defined by the pair of conditions $f(u^*) = 0$ and $\mathrm{rk}J(u^*) < n$, together with the assumption that u^* is a limit point of the set where J is invertible. Singular roots arise for instance in predictor-corrector continuation methods [1], and are mapped into the origin in the normal form (2) [19]. In the discrete-time context of the classical Newton method, several results concerning the existence of locally cone-shaped regions of attraction for these singular zeroes were proved in [8, 10, 14] and references therein. Continuous-time extensions have been addressed in [18, 20], and applications of this approach to the original discrete-time setting can be found in [21].

Nevertheless, several issues in this direction remain open. In section 2, we analyze the actual local shape of attraction domains of degenerate equilibria of (2) and the dynamic phenomena which are responsible for these local shapes. Under certain assumptions, the attraction domain comprises a cone-shaped region, but the actual domain may be larger, which may have important implications regarding the use of (3) and related discretizations in singular root-finding problems. This local shape will be shown to be intimately linked with the nature of singularities surrounding the equilibrium and, in particular, with the backward or forward nature of nearby impasse points. The analysis will be supported on the use of several Lyapunov functions, based in turn on certain $(n-1)$-dimensional Lyapunov matrix equations constructed from the "regular" part (2a) but incorporating the relevant information from the singular

equation (2b). An application to the computation of singular DC operating points in nonlinear circuits is discussed in section 3.

The reader is referred to [2] for background on semiflows, invariance, and Lyapunov functions. Useful facts coming from matrix analysis and involving, in particular, the Lyapunov matrix equation can be found in [9].

2. Dynamics around degenerate equilibria. System (2) and, in particular, the continuous Newton method, define a (possibly not complete) flow Φ on the set of regular points

$$\mathcal{X} = \{(y,z) \in \mathbb{R}^{n-1} \times \mathbb{R} \ / z \neq 0\}. \tag{4}$$

Nevertheless, in order to analyze the behavior of this flow near the origin, the reader should avoid simply considering an "extension" of this flow to $\mathcal{X} \cup \{0\}$ by adding $\Phi(t,0) = 0$ for $t \in \mathbb{R}$, since the resulting extension of Φ may not be well defined as a flow. Therefore, our present approach will be based on the fact that well-defined, complete semiflows are induced by (2) on certain positively invariant subsets of $\mathcal{X}$; asymptotic stability of the origin may then be precisely addressed for such semiflows.

Inspired on convergence results for singular equilibria of Newton's method [8, 10, 14, 18, 20], one may conjecture if these asymptotic stability results for (2) may follow from the assumption that λ and the spectral abscissa

$$\alpha = \max_{\mu \in \sigma(H)} \operatorname{Re} \mu \tag{5}$$

are negative. Note that, for the continuous Newton method, it is $\alpha = -1,\ \lambda = -1/2$. System (7) in section 2.1 will prove that this conjecture is false in general. It is shown in section 2.2 that, at least, the conditions $\alpha < 0,\ \lambda < 0$ make it possible to prove that nearby trajectories remain on a given neighborhood of the origin as long as they are defined.

If the matrix G is positive definite, then the assumptions $\alpha < 0,\ \lambda < 0$ suffice indeed to guarantee the asymptotic convergence to the origin of all trajectories emanating from *regular* points within a given neighborhood of the equilibrium. This is illustrated by the case $\eta > 0$ in section 2.1, and proved in general in section 2.3. The local attraction domains of such singular roots are therefore significantly larger than a cone-shaped region, making those solutions more easily computable through Newton-based techniques.

Nevertheless, without the positive definiteness of G, this nice behavior will not be displayed. It will be shown in section 2.4 that, under the dominance condition $\alpha < \lambda < 0$, there exists a cone-shaped region with vertex in the origin which is positively invariant and asymptotically convergent to the degenerate equilibrium. Compared with previous approaches in this direction (see [18] and references therein), the Lyapunov function method used to prove this result will additionally give a hint for the estimation of the actual local shape of the attraction domain. An example is provided by the case $\eta < 0$ in section 2.1.

Particularization of these results for the continuous Newton method and an application in circuit theory can be found in sections 2.5 and 3, respectively.

2.1. A glimpse. Consider the vector field $f(y,z) = (y, z^2 + 2\eta y^2)$, with $(y,z) \in \mathbb{R}^2,\ \eta \in \mathbb{R}$. The continuous Newton method (3) reads $y' = -y,\ 4\eta y y' + 2zz' = -z^2 - 2\eta y^2$ or, equivalently,

$$y' = -y, \tag{6a}$$

$$zz' = -(1/2)z^2 + \eta y^2, \tag{6b}$$

which has the form depicted in (2), with $Hy = -y,\ \lambda = -1/2,\ y^T G y = \eta y^2, \beta = \gamma = 0$. The origin may be easily shown to be a degenerate singular equilibrium regardless of the value of $\eta \in \mathbb{R}$. Nevertheless, this parameter strongly influences the dynamic behavior around the origin, as discussed below.

Note that the particular value $\eta = 0$ yields a removable singularity, since (6) would amount in this case to $y' = -y,\ z' = -z/2$, leading to an asymptotically stable equilibrium in the classical sense. This nongeneric phenomenon has been analyzed in [18, 20, 21] and will not be considered further here.

Case $\eta > 0$. Solutions of (6) read

$$\begin{aligned} y(t) &= y_0 e^{-t}, \\ z(t) &= \mathrm{sg}(z_0)\sqrt{z_0^2 e^{-t} + 2\eta y_0^2 (e^{-t} - e^{-2t})}. \end{aligned}$$

Trajectories with $z_0 \neq 0$ are well defined for all $t \geq 0$, since the radicand is always positive. Furthermore, every initial point with $z_0 \neq 0$ converges to the origin. This means that the domain of attraction of the origin is the set of regular points, showing that of singular roots in Newton-based techniques may be significantly larger than a locally cone-shaped set.

Concerning general systems of the form (2), this behavior will be shown in section 2.3 to follow from the positive definiteness of G, together with the assumptions $\lambda < 0$, $\alpha < 0$. The first condition forces all singularities in a neighborhood of the equilibrium to behave as backward impasse points, and amounts in this example to $\eta > 0$. Trajectories are then repelled by the singular manifold and must evolve towards the equilibrium.

Case $\eta < 0$. In this case, if we rewrite the radicand as $(z_0^2 + 2\eta y_0^2)e^{-t} - 2\eta y_0^2 e^{-2t}$, it is not difficult to check that initial points (y_0, z_0) in the cone-shaped region

$$\{(y_0, z_0) \in \mathbb{R}^2 : z_0^2 + 2\eta y_0^2 \geq 0\} \ \equiv\ \{(y_0, z_0) \in \mathbb{R}^2 : |y_0| \leq |z_0|/\sqrt{2|\eta|}\}$$

guarantee that the radicand remains positive and, therefore, trajectories are well defined for all positive t. It is also easy to check that all these solutions converge to the origin.

On the contrary, the condition $z_0^2 + 2\eta y_0^2 < 0 \equiv |y_0| > |z_0|/\sqrt{2|\eta|}$ yields a positive collapse-time

$$t^* = \ln\left(\frac{2\eta y_0^2}{z_0^2 + 2\eta y_0^2}\right),$$

beyond which trajectories are not defined. Note that $2\eta y_0^2 < z_0^2 + 2\eta y_0^2 < 0$ and, therefore, $t^* > 0$. This means that trajectories outside the cone evolve towards a forward impasse point, where they cease to exist. This directional convergence phenomenon will be shown in section 2.4 to be a general property of systems of the form (2) with $\alpha < \lambda < 0$ and, in particular, of the continuous Newton method. The actual local shape of the attraction domain can be estimated with the Lyapunov function approach discussed there.

A generalization of (6). If we finally consider the system

$$y' = \alpha y, \tag{7a}$$

$$z z' = \lambda z^2 + \eta y^2, \tag{7b}$$

with $\eta < 0$, $\lambda < \alpha < 0$, it may be shown that solutions are

$$y(t) = y_0 e^{\alpha t},$$
$$z(t) = \mathrm{sg}(z_0)\sqrt{\left(z_0^2 + \frac{\eta}{\lambda-\alpha}y_0^2\right)e^{2\lambda t} - \frac{\eta}{\lambda-\alpha}y_0^2 e^{2\alpha t}}.$$

Now, any $y_0 \neq 0$ yields a positive escape time

$$t^* = \frac{\ln\left(1 + \frac{(\lambda-\alpha)z_0^2}{\eta y_0^2}\right)}{2(\alpha-\lambda)},$$

where it is to be noted that both $(\lambda-\alpha)z_0^2/\eta y_0^2$ and $\alpha - \lambda$ are positive. This means that only the z-coordinate curve is convergent to the origin and suggests that the dominance condition $\alpha < \lambda < 0$ is a key requirement in the phenomenon of directional stability.

2.2. Positive invariance with $\boldsymbol{\alpha < 0}$, $\boldsymbol{\lambda < 0}$. As a preliminary result let us recall that, writing as $\mu_1, \dots, \mu_n$ the n (not necessarily distinct) real eigenvalues of an $n \times n$ symmetric matrix A, and denoting

$$\eta_A = \min\{\mu_1, \dots, \mu_n\}, \tag{8a}$$
$$\kappa_A = \max\{\mu_1, \dots, \mu_n\}, \tag{8b}$$

then $\eta_A|x|^2 \leq x^\tau A x \leq \kappa_A|x|^2$ for any vector $x \in \mathbb{R}^n$, $|\ |$ standing for the Euclidean norm.

PROPOSITION 1. *Consider a quasi-linear ODE of the form* (2) *with* $\lambda < 0$. *Assume that the spectral abscissa defined in* (5) *verifies* $\alpha < 0$, *and denote* $\tilde{\kappa} = \max\{\kappa_G, 0\} \geq 0$, *where* κ *is defined as in* (8b). *Let* P *be the positive definite solution of the* $(n-1)$*-dimensional Lyapunov matrix equation*

$$PH + H^T P = 2(-\tilde{\kappa} + \lambda)I_{n-1}. \tag{9}$$

Then, there exists $r_0 > 0$ *such that*

$$V(y,z) = y^T P y + z^2 \tag{10}$$

satisfies $V' \leq 0$ *on* $\{x = (y,z) \in \mathcal{X} \ / \ |x| \leq r_0\}$. *Hence, for* $0 < V_0 < \min_{|x|=r_0} V(y,z)$, *the level sets* $\{x = (y,z) \in \mathcal{X} \ / \ V(y,z) \leq V_0\}$ *are positively invariant.*

Proof. The derivative of V along trajectories of (2) reads

$$V' = y^T(PH + H^T P)y + 2[y^T P\beta(y,z) + \lambda z^2 + y^T G y + \gamma(y,z)].$$

Now, using (9) and the fact that $y^T G y \leq \tilde{\kappa}|y|^2$, we have

$$\begin{aligned} V' &\leq 2[(-\tilde{\kappa} + \lambda)|y|^2 + y^T P\beta(y,z) + \lambda z^2 + \tilde{\kappa}|y|^2 + \gamma(y,z)] \\ &= 2[\lambda(|y|^2 + z^2) + y^T P\beta(y,z) + \gamma(y,z)]. \end{aligned}$$

Let $r_\beta,\ c_\beta,\ r_\gamma,\ c_\gamma$ be positive constants such that

$$|x| \leq r_\beta \Rightarrow |\beta(x)| \leq c_\beta|x|^2,$$
$$|x| \leq r_\gamma \Rightarrow |\gamma(x)| \leq c_\gamma|x|^3,$$

and define

$$r_0 = \min\left\{ r_\beta,\ r_\gamma,\ \frac{|\lambda|}{\kappa_P c_\beta + c_\gamma} \right\}.$$

Then, $|x| \le r_0$ implies that

$$|y^T P\beta(y,z) + \gamma(y,z)| \le |y|\kappa_P c_\beta |x|^2 + c_\gamma |x|^3 \le r_0(\kappa_P c_\beta + c_\gamma)|x|^2 \le |\lambda||x|^2$$

and, therefore, $V' \le 0$. Positive invariance of the level sets $\{x = (y,z) \in \mathcal{X} \ / \ V(y,z) \le V_0\}$ follows from [2, Theorem 18.2]. □

Denoting

$$\tilde{P} = \begin{pmatrix} P & 0 \\ 0 & 1 \end{pmatrix},$$

the level sets $\{x = (y,z) \in \mathcal{X} \ / \ V(y,z) \le V_0\}$ can be alternatively described in terms of the Hilbert norm

$$\|x\| = \sqrt{x^T \tilde{P} x} \equiv \sqrt{y^T P y + z^2} = \sqrt{V(y,z)}. \tag{11}$$

To this end, let us define

$$\mathcal{B}(0,\rho) \ = \{x \in \mathbb{R}^n \ / \ \|x\| \le \rho\}, \tag{12a}$$

$$\mathcal{B}^+(0,\rho) = \{x = (y,z) \in \mathbb{R}^n \ / \ \|x\| \le \rho,\ z > 0\}, \tag{12b}$$

$$\mathcal{B}^-(0,\rho) = \{x = (y,z) \in \mathbb{R}^n \ / \ \|x\| \le \rho,\ z < 0\}, \tag{12c}$$

$$\mathcal{B}^\pm(0,\rho) = \mathcal{B}^+(0,\rho) \cup \mathcal{B}^-(0,\rho) = \mathcal{B}(0,\rho) \cap \mathcal{X}. \tag{12d}$$

From the relations $\eta_{\tilde{P}}|x|^2 \le \|x\|^2 \le \kappa_{\tilde{P}}|x|^2$, it is easy to check that $\min_{|x|=r_0} V(y,z) = \eta_{\tilde{P}} r_0^2$. Defining $\rho_0 = \sqrt{\eta_{\tilde{P}}}\, r_0$, the following result can be immediately derived from Proposition 1.

COROLLARY 1. *If $\alpha < 0$ and $\lambda < 0$, system (2) induces a semiflow Φ on $\mathcal{B}^\pm(0,\rho)$ for all positive $\rho < \rho_0$.*

Note that $\mathcal{B}^\pm(0,\rho)$ excludes points in the hyperplane $z = 0$. From the result above the reader should not conclude that, in general, trajectories evolve towards the origin; note that there might be forward impasse points on $z = 0$ attracting solutions in finite time. In this situation, the additional dominance condition $\alpha < \lambda < 0$ (verified, in particular, by the continuous Newton method), allows one to prove the existence of a locally cone-shaped region which is positively invariant and asymptotically convergent to the origin, as shown in section 2.4. Nevertheless, in the particular case in which the origin is entirely surrounded by backward impasse points, then the origin is actually a stable attractor for the dynamics on $\mathcal{B}^\pm(0,\rho)$, without the need for the above-mentioned dominance condition. This simpler case, associated with the positive definiteness of G, is considered in section 2.3.

2.3. Completeness and asymptotic stability with positive definite G.

THEOREM 1. *Consider the quasi-linear ODE (2). Assume that $\alpha < 0$, $\lambda < 0$, and that G is positive definite. Then, there exists a positive $\rho_1 < \rho_0$ such that the semiflow Φ induced by (2) on $\mathcal{B}^\pm(0,\rho_1)$ is complete; that is, all solutions are defined on the time interval $[0,\infty)$. Furthermore, $\lim_{t\to\infty} \Phi(t,x_0) = 0$ for all x_0 in $\mathcal{B}^\pm(0,\rho_1)$.*

Proof. The key aspect here is that the smallness of ρ_1 must guarantee that all singularities in $\mathcal{B}(0,\rho_1)-\{0\}$ are backward impasse points. To achieve this, choose any positive r_1 satisfying

$$r_1 < \min\left\{r_0, \frac{\eta_G}{c_\gamma}\right\}, \tag{13}$$

where $\eta_G > 0$ since G is positive definite, and define $\rho_1 = \sqrt{\eta_{\tilde{P}}}r_1$. Hence, if $\|(y,0)\| \leq \rho_1 = \sqrt{\eta_{\tilde{P}}}r_1$, then $|y| \leq \|(y,0)\|/\sqrt{\eta_{\tilde{P}}} \leq r_1$ and $|\gamma(y,0)| \leq c_\gamma|y|^3 \leq c_\gamma r_1|y|^2 < \eta_G|y|^2$ (note that $y=0$ is excluded). This implies that $\gamma(y,0) > -\eta_G|y|^2$ and, since $y^TGy \geq \eta_G|y|^2$,

$$y^TGy + \gamma(y,0) > 0,\ (y,0) \in \mathcal{B}(0,\rho_1)-\{0\},$$

showing that all singularities in $\mathcal{B}(0,\rho_1)-\{0\}$ are backward impasse points. This fact will suffice to prove that all trajectories are well defined in $[0,\infty)$.

Suppose that $x_0 = (y_0,z_0) \in \mathcal{B}^+(0,\rho_1)$ is such that the trajectory emanating from this point is defined for a maximal positive time $t^+(x_0) < \infty$ (the reasoning in $\mathcal{B}^-(0,\rho_1)$ would be entirely analogous). In this situation, [2, Proposition 10.12] shows that for every compact set $\mathcal{C}$ on $\mathcal{B}^+(0,\rho_1)$ there would exist a time $t_0 < t^+(x_0)$ such that $\Phi(t,x_0) \notin \mathcal{C}$ for $t > t_0$. If we define $\mathcal{C}_\varepsilon = \{(y,z) \in \mathcal{B}^+(0,\rho_1) \ / \ z \geq \varepsilon\}$, for every $\varepsilon > 0$ there would exist a $t_0(\varepsilon)$ such that $z(t) < \varepsilon$ if $t > t_0(\varepsilon)$. This shows that, under the assumption $t^+(x_0) < \infty$, it would be $\lim_{t\to t^+(x_0)} z(t) = 0$.

Nevertheless, the positive definiteness of G precludes $z(t)$ from reaching the set $z=0$ in finite time, as shown below. Since $|\gamma(y,z)| \leq c_\gamma r_1|x|^2 \leq \eta_G|x|^2$, we have $\gamma \geq -\eta_G|x|^2$ and, therefore,

$$\lambda z^2 + y^TGy + \gamma(y,z) \geq \lambda z^2 + \eta_G|y|^2 - \eta_G(|y|^2+z^2) = (\lambda-\eta_G)z^2.$$

This means that the real-valued function $(\lambda z^2 + y^TGy + \gamma(y,z))/z$ is bounded below by $(\lambda-\eta_G)z$ on $\mathcal{B}^+(0,\rho_1)$. Since orbits do not leave $\mathcal{B}^+(0,\rho_1)$ due to Proposition 1, the z-component of the trajectory emanating from (y_0,z_0), with $z_0 > 0$, satisfies $z(t) \geq z_0 e^{(\lambda-\eta_G)t} > 0$ for all finite t, in contradiction with $\lim_{t\to t^+(x_0)} z(t) = 0$. This proves that $t^+(x_0) = \infty$ and, since x_0 is arbitrary, the semiflow is complete on $\mathcal{B}^\pm(0,\rho_1)$.

In this situation, the function V defined in (10) behaves as a classical Lyapunov function, since limit points verifying $z=0$, $y \neq 0$ are ruled out by the backward nature of impasse points in $\mathcal{B}(0,\rho_1)$. Hence, $\Phi(t,x_0) \to 0$ as $t \to \infty$, for all x_0 in $\mathcal{B}^\pm(0,\rho_1)$. ∎

Under the hypotheses of Theorem 1, the semiflow Φ may be safely extended to $\mathcal{B}^\pm(0,\rho_1)\cup\{0\}$ by adding $\Phi(t,0) = 0$ for $t \in [0,\infty)$, the origin being an asymptotically stable equilibrium of the resulting semiflow. In applications concerning the continuous Newton method, this situation yields a domain of attraction for a singular root which comprises all regular points within a usual ball about the degenerate equilibrium, as compiled in item 1 of Theorem 3 in section 2.5. An example of this nice behavior is given by the case $V_0 = 0$ in the nonlinear circuit presented in section 3.

2.4. Directional convergence with $\alpha < \lambda < 0$ and arbitrary G. If G is not positive definite, forward impasse points of system (2) may (and actually will, if G is not positive semidefinite) be displayed around the origin, precluding the application of the results discussed in section 2.3. Nevertheless, Proposition 1 and Corollary 1

can be strengthened under the additional dominance condition $\alpha < \lambda < 0$, which is satisfied in particular by the continuous Newton method, for which $\alpha = -1$, $\lambda = -1/2$.

In this direction, note that the condition $\alpha < \lambda$ implies that $H - \lambda I_{n-1}$ is an asymptotically stable matrix, since $\sigma(H-\lambda I_{n-1}) = \{\mu-\lambda \,/\, \mu \in \sigma(H)\}$, and, therefore, the condition $\alpha = \max_{\mu\in\sigma(H)} \operatorname{Re}\mu < \lambda$ yields $\max_{\mu\in\sigma(H)} \operatorname{Re}(\mu-\lambda) < 0$. This fact guarantees that the matrix equation (14) below has indeed a positive definite solution.

THEOREM 2. *Consider a quasi-linear ODE* (2) *with* $\alpha < \lambda < 0$, *and let* Q *be the positive definite solution of the* $(n-1)$*-dimensional Lyapunov matrix equation*

$$Q(H - \lambda I_{n-1}) + (H - \lambda I_{n-1})^T Q = -I_{n-1}. \tag{14}$$

Then, for every $\theta > 0$ *(satisfying additionally* $\theta < 1/\sqrt{2|\eta_G|}$ *if* $\eta_G < 0$, *where* η_G *is defined as in* (8a)), *there exists a positive* $\rho(\theta) < \rho_0$ *such that*

$$U(y,z) = y^T Q y - \theta^2 z^2 \tag{15}$$

satisfies $U' \le 0$ *on* $\partial\mathcal{K}(0,\theta) \cap \mathcal{B}^{\pm}(0,\rho(\theta))$, *where*

$$\mathcal{K}(0,\theta) = \{(y,z) \in \mathbb{R}^{n-1}\times\mathbb{R} : y^T Q y \le \theta^2 z^2\}, \tag{16}$$

and $\partial\mathcal{K}(0,\theta)$ *stands for the boundary* $\{(y,z) \in \mathbb{R}^{n-1}\times\mathbb{R} : y^T Q y = \theta^2 z^2\}$. *Hence, the set* $\mathcal{K}(0,\theta) \cap \mathcal{B}^{\pm}(0,\rho(\theta))$ *is positively invariant for the semiflow* Φ *defined in Corollary* 1. *Furthermore, the restriction of* Φ *to* $\mathcal{K}(0,\theta) \cap \mathcal{B}^{\pm}(0,\rho(\theta))$ *is complete, and* $\lim_{t\to\infty} \Phi(t,x_0) = 0$ *for all* x_0 *in* $\mathcal{K}(0,\theta) \cap \mathcal{B}^{\pm}(0,\rho(\theta))$.

Proof. The derivative of U along trajectories of (2) reads

$$U' = y^T(QH + H^T Q)y + 2[y^T Q\beta(y,z) - \theta^2(\lambda z^2 + y^T G y + \gamma(y,z))].$$

In the boundary $\partial\mathcal{K}(0,\theta)$, it is $U = 0$ or, equivalently, $\theta^2 z^2 = y^T Q y$. Therefore, in $\partial\mathcal{K}(0,\theta)$ we have

$$\begin{aligned} y^T(QH + H^T Q)y - 2\lambda\theta^2 z^2 &= y^T(QH + H^T Q)y - 2\lambda y^T Q y \\ &= y^T[Q(H - \lambda I_{n-1}) + (H - \lambda I_{n-1})^T Q]y = -|y|^2, \end{aligned}$$

yielding

$$\begin{aligned} U' &= -|y|^2 - 2\theta^2 y^T G y + 2[y^T Q\beta(y,z) - \theta^2\gamma(y,z)] \\ &\le -|y|^2 - 2\theta^2\eta_G|y|^2 + 2[y^T Q\beta(y,z) - \theta^2\gamma(y,z)]. \end{aligned}$$

In light of the restriction imposed on θ when $\eta_G < 0$, we always have $-1 - 2\theta^2\eta_G < 0$. The property $U' \le 0$, together with the other claims in the theorem, follows then from the choice of $\rho(\theta)$ in a way such that $2|y^T Q\beta(y,z) - \theta^2\gamma(y,z)| \le (1 + 2\theta^2\eta_G)|y|^2$ whenever $U = 0$, $\|x\| \le \rho(\theta)$. Details are straightforward and are left to the reader. ∎

2.5. The continuous Newton method at singular roots: Attraction domains.

THEOREM 3. *Consider the normal form* (2) *for the continuous Newton method around a singular equilibrium, for which* $H = -I_{n-1}$, $\lambda = -1/2$. *Then, the solution of the Lyapunov matrix equation* (14) *reads* $Q = I_{n-1}$. *Depending on the inertia of* G *in* (2b), *the following sets are included in the attraction domain of the origin,* $\mathcal{A}(0)$, *according to Theorems* 1 *and* 2*:*

1. *If $\eta_G > 0$, that is, if G is positive definite, then there exists a positive ρ_1 such that*

$$\mathcal{B}^{\pm}(0,\rho_1) \subset \mathcal{A}(0),$$

   $\mathcal{B}^{\pm}$ being defined in (12b).
2. *If $\eta_G \leq 0$, that is, if G is not positive definite, then for every positive $\theta < 1/\sqrt{2|\eta_G|}$ there exists a positive $\rho(\theta)$ such that the Euclidean cone $\mathcal{K}(0,\theta) = \{(y,z) \in \mathbb{R}^{n-1} \times \mathbb{R} : |y|^2 \leq \theta^2 z^2\}$ verifies that*

$$\mathcal{K}(0,\theta) \cap \mathcal{B}^{\pm}(0,\rho(\theta)) \subset \mathcal{A}(0).$$

   In the particular case $\eta_G = 0$, the result holds for any $\theta > 0$.

Note that the cone-shaped regions described in the second item of Theorem 3 are also included in the attraction domain of cases with positive definite G, but in this situation the first item yields a wider estimation of the local domain. It is also worth remarking that weak problems, for which these results may be improved, are not considered here (see [18, 20] and references therein). In cases with nonpositive definite G, the limit value $\theta = 1/\sqrt{2|\eta_G|}$ may provide a rather nice estimation of the actual extension of the cone-shaped region convergent to a singular root in the continuous Newton method. This value will also be shown to play a role in discrete-time counterparts of this method, particularly in the classical Newton iteration. This is illustrated, together with several additional features of these techniques, in a nonlinear circuit example addressed in section 3.

3. Bifurcation points of nonlinear circuits. The circuit displayed in Figure 1 includes an independent current source I_0, a linear capacitor C, two linear resistors R_1 and R_2, a nonlinear voltage-controlled current source (VCCS) with a quadratic characteristic $i = v^2$ (v being the voltage drop across the resistor R_1), a Josephson junction, and an independent voltage source V_0. The Josephson junction consists of two superconductors separated by an oxide barrier [7], and can be considered as a nonlinear inductor characterized by the differential relation $\phi' = v_J$, where ϕ denotes the magnetic flux in the junction, together with a (simplified) sinusoidal current-flux relation $i_J = \sin\phi$. As shown in Figure 1, most parameters in the circuit have been normalized for simplicity.

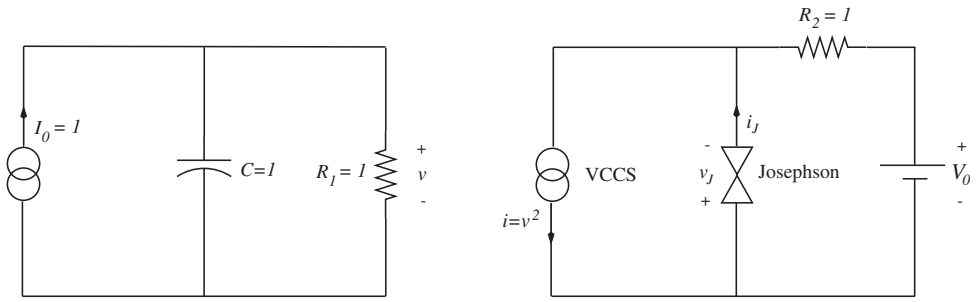

FIG. 1. *Nonlinear circuit.*

The dynamics of this circuit can be described in terms of the capacitor charge q and the flux ϕ in the Josephson junction through the ODE

$$q' = -q + 1, \tag{17a}$$

$$\phi' = q^2 - \sin\phi - V_0, \tag{17b}$$

whereas the continuous Newton method for the right-hand side of (17) can be written as

$$q' = -q + 1, \tag{18a}$$

$$\cos\phi\ \phi' = -q^2 + 2q - \sin\phi - V_0. \tag{18b}$$

Singularities of this quasi-linear ODE are defined by the condition $\cos\phi = 0$, which yields $\phi = \pi/2 + k\pi,\ k \in \mathbb{Z}$. Note that the location of singularities does not depend on the value of V_0. Singular equilibria will be displayed only if $\sin\phi = \pm 1$ at equilibrium (defined by $q = 1$, $\sin\phi = 1 - V_0$), that is, if $V_0 = 0$ or $V_0 = 2$. It can be checked that these values yield saddle-node bifurcations for (17) at $q = 1$, $\phi = \pi/2 + 2k\pi,\ k \in \mathbb{Z}$, for $V_0 = 0$, and $q = 1$, $\phi = -\pi/2 + 2k\pi,\ k \in \mathbb{Z}$, for $V_0 = 2$.

Let us consider the behavior of the continuous Newton method (18) regarding these singular operating points, focusing on

(a) $q = 1$, $\phi = \pi/2$ for $V_0 = 0$;
(b) $q = 1$, $\phi = -\pi/2$ for $V_0 = 2$.

In both cases, the normal form (2) can be easily computed through the coordinate change

$$y = q - 1, \tag{19a}$$

$$z = \cos\phi, \tag{19b}$$

with $\phi \in (0, \pi)$ for (a) and $\phi \in (-\pi, 0)$ for (b). Some simple computations lead to

$$y' = -y, \tag{20a}$$

$$zz' = -(1/2)z^2 \pm y^2 + \text{h.o.t.} \tag{20b}$$

The "+" sign in (20b) corresponds to (a), whereas the "−" case is obtained in (b). Note that the quadratic terms of (20b) are those of (6b) with $\eta = 1$ and $\eta = -1$, respectively.

Case (a). Singularities near the equilibrium $q = 1$, $\phi = \pi/2$, for $V_0 = 0$, are backward impasse points and, in light of the results in section 2.3 (see also item 1 in Theorem 3), every regular point sufficiently close to the singular equilibrium must evolve towards the origin. Computer simulations indicate that this is actually the case: Figure 2(a) displays an estimation of the attraction domain of this singular operating point. Note that the boundary of the attraction domain is partially defined by the straight lines $\phi = -\pi/2$ and $\phi = 3\pi/2$, which correspond to singularities of the quasi-linear ODE (18).

Case (b). Concerning the equilibrium $q = 1$, $\phi = -\pi/2$, for $V_0 = 2$, it follows from the results discussed in section 2.4 and compiled in item 2 of Theorem 3 that, for all $\theta < 1/\sqrt{2}$, there must exist a $\rho(\theta)$ defining a region of the form $y^2 \le \theta^2 z^2$ positively invariant and convergent to the origin. In the limit case $\theta = 1/\sqrt{2}$, the set

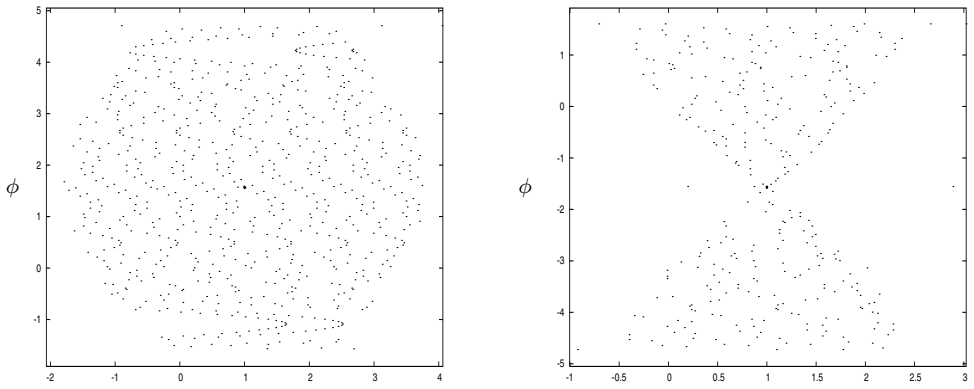

FIG. 2. *Domains of attraction of the continuous Newton method:* (a) *equilibrium at* $(1, \pi/2)$*,* $V_0 = 0$*;* (b) *equilibrium at* $(1, -\pi/2)$*,* $V_0 = 2$*.*

$y^2 = (1/2)z^2$ reads, in the original coordinates q, ϕ and using (19),

$$(q-1)^2 = (1/2)\cos^2\phi, \quad -\pi < \phi < 0. \tag{21}$$

This curve is plotted in Figure 2(b), together with a computer estimation of the attraction domain of the singular equilibrium. The figure clearly indicates that (21) provides, in this case, an accurate estimation of the boundary of the attraction domain near the degenerate solution. It is worth remarking that, as we move away from the singularity, the incidence of higher order terms becomes more significant and the divergence between the curve representing (21) and the boundary of the attraction domain is more apparent. Equation (21) is not plotted for $\phi < -\pi$ and $\phi > 0$ since the coordinate change (19) remains valid only for $-\pi < \phi < 0$. attraction domain is clearly delimited by the straight lines

With illustrative purposes, let us briefly address this directional convergence phenomenon in the discrete-time setting. Figure 3(a) displays the set of points which converge in the classical Newton iteration (obtained as the Euler discretization of (18) with stepsize 1) to the degenerate equilibrium without crossing the singular manifold; that is, the iteration is truncated for any orbit which jumps from one side of the singular manifold to the other (a jump which is allowed by the discrete-time nature of the method). The curve (21) again provides an accurate estimation of the boundary of the attraction domain for this truncated iteration.

The computer estimation of the actual local domain of attraction of the singular equilibrium for the discrete-time method is shown in Figure 3(b). This domain comprises not only the one shown in (a), but also those points which converge to the solution after crossing the singular manifold. For instance, the initial point $q = 2.5,\ \phi = -0.5$ may be shown to "jump over" the singular manifold in the first iteration step, reaching $q = 1.0,\ \phi = -3.6571$ and then evolving towards the singular root without additional jumps. Note that the first iteration step is exact in the q-component due to the decoupled and linear nature of (18a).

Although additional details in this direction are beyond the purposes of the present paper, let us finally remark here that this approach provides a linearly con-

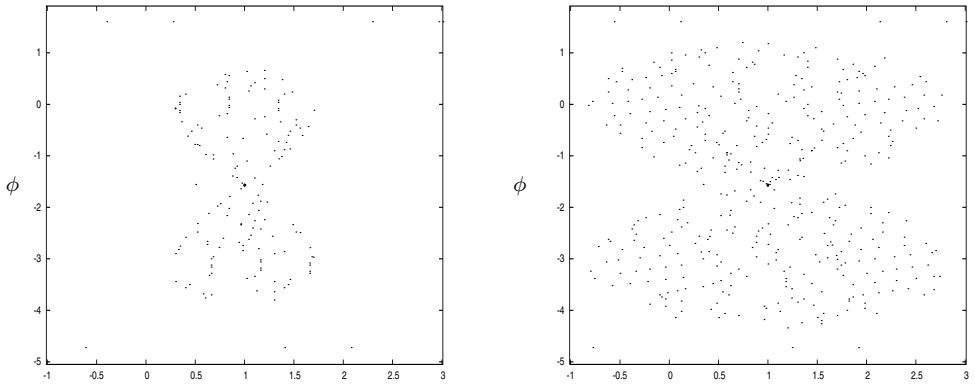

FIG. 3. *Local domains of attraction of* $(1, -\pi/2)$*:* (a) *truncated and* (b) *standard discrete-time Newton method,* $V_0 = 2$.

vergent iteration to the singular root. This follows from the value $\lambda = -1/2$ in the normal form (2b): Euler discretization with stepsize 1 places an eigenvalue at $1/2$ in the linearized discrete-time system. Quadratic convergence to singular roots may be recovered through the use of certain Runge–Kutta discretizations; see [21].
