Using Lemma 3.2, Korn's inequality, and the compact embedding of $X_T(\Omega, I)$ into $L^2(\Omega)^3$ [28], the bilinear form b is coercive on V. Consequently, the Friedrichs extension B associated with the triple $(V, \mathcal{H}, b)$ (with $\mathcal{H}$ defined as in the proof of Lemma 3.3) is invertible with a compact inverse. Again denote by A the Friedrichs extension of the triple $(V, \mathcal{H}, a)$. Clearly $A = B - (1+\omega^2)K$, where the continuous operator K is defined by

$$K(u,H)^\top = (u,0)^\top.$$

Writing

$$(1+\omega^2)^{-1}B^{-1}A = (1+\omega^2)^{-1}I - B^{-1}K,$$

we conclude as in Lemma 3.3, since $B^{-1}K$ is a compact operator. ∎

Similarly to Theorem 3.5, the converse of Lemma 4.4 holds under some conditions on ω.

THEOREM 4.6. *Assume that ω^2 is not an eigenvalue of $-\Delta_I^{Neu}$. If $(u_\omega, H) \in V$ is a solution of* (3.9) *with F defined by* (3.8) *and a, V defined in Lemma* 4.4, *then* $\mathrm{div} H = 0$ *and u, E, H are solutions of* (2.9), (2.10), *and* (2.11) *with the boundary conditions* (2.6) *and* (2.7) *when $u = \frac{u_\omega}{i\omega}$, E is given by* (3.1), *and $\sigma, D, B = 0$ are defined by* (2.8).

4.3. Equivalence between the -formulation and the -formulation. The goal of this section is to show that the displacement and electric fields obtained by the E-formulation and the H-formulation are identical.

THEOREM 4.7. *Let u_1, E_1, H_1 (resp., u_2, E_2, H_2) be the solutions of* (2.9), (2.10), *and* (2.11) *with the boundary conditions* (2.6) *and* (2.7) *obtained by the E-formulation (resp., H-formulation). If $\omega^2 \notin S_0$ (cf. Lemma 4.2), then $u_1 = u_2$ and $E_1 = E_2$.*

Proof. Denote $u = u_1 - u_2$ and $E = E_1 - E_2$. Since u_1, E_1 and u_2, E_2 satisfy (2.9) and (2.11), u, E satisfy

$$\begin{aligned}
&\mathrm{Div}\sigma + \omega^2 u = 0 \text{ in } \Omega,\\
&\mathbf{curl}\, H + i\omega D = 0 \text{ in } \Omega,\\
&\mathbf{curl}\, E = 0 \text{ in } \Omega,
\end{aligned}$$

where $\sigma = \sigma_1 - \sigma_2, and D = D_1 - D_2$ are given by (2.8). Therefore $E = \nabla\chi$, with $\chi \in H_0^1(\Omega)$ and the pair $(u, \chi) \in H_0^1(\Omega)^4$ is a solution of (4.4) with $F = 0$. By Lemma 4.2, we conclude that $u = 0$ and $\chi = 0$. ∎

Remark 4.8. The magnetic fields obtained by the E-formulation and the H-formulation cannot be identical, since the one obtained by the E-formulation does not necessarily satisfy the Gauge conditions.

5. Singularities of some elliptic systems. It is well known that the singularities of elliptic systems in Ω are produced by the corners and edges of Ω. Here we briefly describe the corner and edge singularities of the operator Δ_μ^{Neu} and of the 4×4 system (4.2)–(4.3) with Dirichlet boundary conditions. For the sake of brevity we restrict ourselves to a minimal description and refer the reader to the pioneer work [15] or standard books [11, 7, 18] for more details.

5.1. Corner singularities. Fix a corner $c \in \mathcal{C}$ of Ω and denote by (ρ_c, ϑ_c) the spherical coordinates centered at c. Denote by Γ_c the infinite polyhedral cone which coincides with Ω near c. Let G_c be the intersection of Γ_c with the unit sphere centered at c.

For any $\lambda \in \mathbb{C}$, let us set

$$S^\lambda(\Gamma_c) = \left\{ \psi(x) = \rho_c^\lambda \sum_{q=0}^{Q} (\log\rho_c)^q \psi_q(\vartheta_c) : \psi_q \in H^1(G_c) \right\}.$$

The set $\Lambda_\mu^{Neu}(\Gamma_c)$ of corner singular exponents of the operator Δ_μ^{Neu} in Γ_c is the set of $\lambda \in \mathbb{C}$ such that there exists a nonpolynomial solution $\Psi \in S^\lambda(\Gamma_c)$ of

$$\Delta_\mu \Psi = \mathrm{div}(\mu\nabla\Psi) = 0 \text{ in } \Gamma_c, \tag{5.1}$$

$$\mu\nabla\Psi \cdot n = 0 \text{ on } \partial\Gamma_c\,. \tag{5.2}$$

We denote by $Z^{\lambda}_{Neu}(\Gamma_c, \mu)$ the space of these solutions.

Similarly for the 4×4 system (4.2)–(4.3) with Dirichlet boundary conditions, its set $\Lambda^{Dir}_{C,\epsilon,e}(\Gamma_c)$ of corner singular exponents is the set of $\lambda \in \mathbb{C}$ such that there exists a nonpolynomial solution $(u, \chi) \in S^{\lambda}(\Gamma_c)^4$ of

$$\left\{ \begin{array}{ll} \operatorname{div}(\epsilon \nabla \chi + e\gamma(u)) = 0 & \text{in } \Gamma_c, \\ \operatorname{Div}\left(C\gamma(u) - e^{\top}\nabla\chi\right) = 0 & \text{in } \Gamma_c, \\ \chi = 0, u = 0 & \text{on } \partial\Gamma_c. \end{array} \right. \tag{5.3}$$

The space of these solutions is denoted by $Z^{\lambda}_{Dir}(\Gamma_c, C, \epsilon, e)$.

5.2. Edge singularities. Fix an edge $a \in \mathcal{A}$ of Ω and denote by $\Gamma_a \times \mathbb{R}$ the infinite polyhedral cone which coincides with Ω near a (Γ_a is then a two-dimensional sector). Denote by (r_a, θ_a, z_a) the cylindrical coordinates along a. Let G_a be the intersection of Γ_a with the unit sphere $r_a = 1$.

As before, for any $\lambda \in \mathbb{C}$ let us set

$$S^{\lambda}(\Gamma_a) = \left\{ \psi(x) = r_a^{\lambda} \sum_{q=0}^{Q} (\log r_a)^q \psi_q(\theta_a) : \psi_q \in H^1(G_a) \right\}.$$

The set $\Lambda^{Neu}_{\mu}(\Gamma_a)$ of corner singular exponents of the operator Δ^{Neu}_{μ} in Γ_a is the set of $\lambda \in \mathbb{C}$ such that there exists a nonpolynomial solution $\Psi \in S^{\lambda}(\Gamma_a)$ of

$$\begin{array}{l} \operatorname{div}_2(\mu_2 \nabla_2 \Psi) = 0 \text{ in } \Gamma_a, \\ \mu_2 \nabla_2 \Psi \cdot n = 0 \text{ on } \partial\Gamma_a, \end{array}$$

where div_2 (resp., ∇_2) means the two-dimensional divergence (resp., gradient) and μ_2 is the 2×2 matrix obtained from μ by dropping the third line and the third column of μ.

We denote by $Z^{\lambda}_{Neu}(\Gamma_a, \mu)$ the space of these solutions.

In the same way, the set $\Lambda^{Dir}_{C,\epsilon,e}(\Gamma_a)$ of edge singular exponents of the 4×4 system (4.2)–(4.3) with Dirichlet boundary conditions is the set of $\lambda \in \mathbb{C}$ such that there exists a nonpolynomial solution $(u, \chi) \in S^{\lambda}(\Gamma_a)^4$ of

$$\left\{ \begin{array}{ll} \tilde{\operatorname{div}}(\epsilon \tilde{\nabla} \chi + e\tilde{\gamma}(u)) = 0 & \text{in } \Gamma_a, \\ \tilde{\operatorname{Div}}\left(C\tilde{\gamma}(u) - e^{\top}\tilde{\nabla}\chi\right) = 0 & \text{in } \Gamma_a, \\ \chi = 0, u = 0 & \text{on } \partial\Gamma_a, \end{array} \right. \tag{5.4}$$

where the sign $\tilde{}$ means that all derivatives in the z_a-variable are replaced by zero. The space of these solutions is denoted by $Z^{\lambda}_{Dir}(\Gamma_a, C, \epsilon, e)$.

6. Corner and edge singularities when is positive definite. Our goal is to describe the corner and edge singularities of the (regularized) problem (3.9). These singularities are obtained using some ideas from [4, 5, 6].

Let us start with the corner singularities.

6.1. Corner singularities. Fix a corner $c \in \mathcal{C}$ of Ω. We drop the index c in the above considerations. As usual we are looking for solutions of the homogeneous problem in the space

$$\mathbf{S}_T^\lambda(\Gamma,\mu) = \Big\{(u,H) \in H^1_{0,loc}(\Gamma)^3 \times X_{T,loc}(\Gamma,\mu) : \operatorname{div}(\mu H) \in H^1_{loc}(\Gamma),\\ u(x) = \rho^\lambda \sum_{q=0}^{Q} (\log\rho)^q U_q(\vartheta),\\ H(x) = \rho^\lambda \sum_{q=0}^{Q} (\log\rho)^q H_q(\vartheta)\Big\},$$

the index *loc* meaning that the properties hold in all bounded domains far from c. This means that we look for a nonpolynomial solution $(u,H) \in \mathbf{S}_T^\lambda(\Gamma,\mu)$ of

$$\left\{\begin{array}{ll} \mathbf{curl}\left(\epsilon^{-1}\left(\mathbf{curl}\, H + e\gamma(u)\right)\right) - \mu\nabla\operatorname{div}(\mu H) = 0 & \text{in } \Gamma,\\ \operatorname{Div}\left(C\gamma(u) + e^\top\epsilon^{-1}e\gamma(u) + e^\top\epsilon^{-1}\,\mathbf{curl}\, H\right) = 0 & \text{in } \Gamma,\\ u = 0 & \text{on } \partial\Gamma,\\ \mu H\cdot n = 0 & \text{on } \partial\Gamma,\\ \mu\nabla(\operatorname{div}(\mu H))\cdot n = 0 & \text{on } \partial\Gamma,\\ \epsilon^{-1}\left(\mathbf{curl}\, H + e\gamma(u)\right)\times n = 0 & \text{on } \partial\Gamma. \end{array}\right. \tag{6.1}$$

If a nontrivial solution exists, then we say that λ is a corner exponent.

Inspired by [4, 5, 6], this problem is split up into three subproblems by introducing the auxiliary unknowns

$$\psi = -\epsilon^{-1}\left(\mathbf{curl}\, H + e\gamma(u)\right)$$

and

$$q = \operatorname{div}(\mu H).$$

With this notation, problem (6.1) is equivalent to looking for $q, (\psi,u), H$ successive solutions of

$$\left\{\begin{array}{ll} \operatorname{div}(\mu\nabla q) = 0 & \text{in } \Gamma,\\ \mu\nabla q\cdot n = 0 & \text{on } \partial\Gamma, \end{array}\right. \tag{6.2}$$

$$\left\{\begin{array}{ll} \mathbf{curl}\,\psi = -\mu\nabla q & \text{in } \Gamma,\\ \operatorname{div}(\epsilon\psi + e\gamma(u)) = 0 & \text{in } \Gamma,\\ \operatorname{Div}\left(C\gamma(u) - e^\top\psi\right) = 0 & \text{in } \Gamma,\\ \psi\times n = 0, u = 0 & \text{on } \partial\Gamma, \end{array}\right. \tag{6.3}$$

$$\left\{\begin{array}{ll} \mathbf{curl}\, H = -\epsilon\psi - e\gamma(u) & \text{in } \Gamma,\\ \operatorname{div}(\mu H) = q & \text{in } \Gamma,\\ \mu H\cdot n = 0 & \text{on } \partial\Gamma. \end{array}\right. \tag{6.4}$$

This means that three types of singularities may appear:

Type 1: $q = 0$, $\psi = u = 0$, and H is a general solution of (6.4).

Type 2: $q = 0$, (ψ,u) is a general solution of (6.3), and H is a particular solution of (6.4).

Type 3: q is a general solution of (6.2), (ψ, u) is a particular solution of (6.3), and H is a particular solution of (6.4).

These three types of singularities may be described with the help of the corner singularities of the operator Δ_μ^{Neu} and of the 4×4 elliptic system (4.2)–(4.3) with Dirichlet boundary conditions described in subsection 4.1.

Since for our problem (3.9) $\operatorname{div}(\mu H) = 0$ and is then regular, we do not describe the singularities of Type 3 because they cannot occur for any solution of (3.9).

The singularities of Type 1 are obtained exactly as in Lemma 5.1 of [5] since only the magnetic field H is involved.

LEMMA 6.1. *Assume that $\lambda \neq -1$. Then $(u, H) \in \mathbf{S}_T^\lambda(\Gamma, \mu)$ is a singularity of type 1 if and only if $\lambda + 1$ belongs to $\Lambda_\mu^{Neu}(\Gamma)$ and $H = \nabla\Phi$, with $\Phi \in Z_{Neu}^{\lambda+1}(\Gamma, \mu)$.*

The situation is different for singularity of Type 2 since the coupling between the elasticity system and Maxwell's equations appear via problem (6.3).

LEMMA 6.2. *Assume that $\lambda \neq -1$. Then $(u, H) \in \mathbf{S}_T^\lambda(\Gamma, \mu)$ is a singularity of type 2 if and only if λ belongs to $\Lambda_{C,\epsilon,e}^{Dir}(\Gamma)$, $\psi = \nabla\chi$, with $(u, \chi) \in Z_{Dir}^\lambda(\Gamma, C, \epsilon, e)$, and H is given by*

$$H = \frac{1}{\lambda + 1} \left(a \times \mathbf{x} + \nabla r \right), \tag{6.5}$$

where $a = -(\epsilon\psi + e\gamma(u))$ and $r \in S^{\lambda+1}(\Gamma)$ is solution of

$$\left\{ \begin{array}{ll} \operatorname{div}(\mu\nabla r) = -\operatorname{div}(\mu(a \times \mathbf{x})) & \textit{in } \Gamma, \\ \mu\nabla r \cdot n = -\mu(a \times \mathbf{x}) \cdot n & \textit{on } \partial\Gamma. \end{array} \right. \tag{6.6}$$

Proof. As

$$\mathbf{curl}\, \psi = 0 \text{ in } \Gamma,$$

there exists $\chi \in S^\lambda(\Gamma)$ such that

$$\psi = \nabla\chi \text{ in } \Gamma.$$

From (6.3) we deduce that

$$\left\{ \begin{array}{ll} \operatorname{div}(\epsilon\nabla\chi + e\gamma(u)) = 0 & \text{in } \Gamma, \\ \operatorname{Div}\left(C\gamma(u) - e^\top \nabla\chi\right) = 0 & \text{in } \Gamma, \\ \chi = 0, u = 0 & \text{on } \partial\Gamma. \end{array} \right.$$

In view of section 5, we deduce that $(u, \chi) \in Z_{Dir}^\lambda(\Gamma, C, \epsilon, e)$.

Now we readily check that H in the form (6.5) is a solution of (6.4) if and only if r is a solution of (6.6), whose solution exists by Theorem 4.14 of [23] and because $\mathbf{curl}(a \times \mathbf{x}) = (\lambda + 1)a$. ∎

LEMMA 6.3. *There is no corner singularity of Type 2 in the strip $\Re\lambda \in \left]-1, 0\right]$.*

Proof. By Theorem 1 of [16] (see Remark 2 of [16], or Theorem 2 of [17]), the set $\Lambda_{C,\epsilon,e}^{Dir}(\Gamma) \cap [-1, 0]$ is empty. We conclude by Lemma 6.2. ∎

Since the singularities of our problem (3.9) have to be locally in $X_T(\Gamma, \mu)$, among the singular exponents described above we select the subset Λ_c of $\lambda > -\frac{3}{2}$ such that there exists $(u, H) \in \mathbf{S}_T^\lambda(\Gamma, \mu)$ solution of (6.1) such that

$$\chi(u, H) \in X_T(\Gamma, \mu),$$

where χ is a cut-off function equal to 1 near c. This last condition implies the following constraints for our first two types of singularities (see [5, 6]):

Type 1: $\lambda+1 \in \Lambda_{\mu}^{Neu}(\Gamma)$ and since $\Lambda_{\mu}^{Neu}(\Gamma) \cap [-1,0]$ is empty, by Lemma 5.4 of [5] we get the condition $\lambda > -1$.

Type 2: $\lambda \in \Lambda_{C,\epsilon,e}^{Dir}(\Gamma)$ and by the condition $\chi u \in H^1(\Gamma)^3$, we get $\lambda > -\frac{1}{2}$. By Lemma 6.3, we arrive at the condition $\lambda > 0$.

In conclusion, the set of corner singular exponents is

$$\Lambda_c = \{\lambda > -1 : \lambda+1 \in \Lambda_{\mu}^{Neu}(\Gamma_c)\} \cup \{\lambda > 0 : \lambda \in \Lambda_{C,\epsilon,e}^{Dir}(\Gamma_c)\}.$$

6.2. Edge singularities. Fix an edge $a \in \mathcal{A}$ of Ω and drop the index a. As before, we are looking for solutions of the homogeneous piezoelectric system (6.1) in $\Gamma \times \mathbb{R}$. For the elasticity system or Maxwell's equations, the system obtained in the Cartesian coordinates (x, y, z) (according to the notation introduced in section 5, the z-axis contains the edge a) is split up into two independent problems in Γ_a. Here the coupling between these systems prevents this splitting. Therefore we simply follow the approach of the previous subsection. Namely, we search nonpolynomial solutions (u, H) of (6.1) independent of the z-variable and in the space

$$\begin{aligned}\mathbf{S}_T^{\lambda}(\Gamma,\mu) = \Big\{ &(u,H) \in H^1_{0,loc}(\Gamma\times\mathbb{R})^3 \times X_{T,loc}(\Gamma\times\mathbb{R},\mu) : \operatorname{div}(\mu H) \in H^1_{loc}(\Gamma\times\mathbb{R}),\\ &u(x,y,z) = r^{\lambda}\sum_{q=0}^{Q}(\log r)^q U_q(\theta),\\ &H(x,y,z) = r^{\lambda}\sum_{q=0}^{Q}(\log r)^q H_q(\theta)\Big\};\end{aligned}$$

the index *loc* here means that the properties hold in all bounded domains far from a.

Then we introduce the auxiliary unknowns ψ and q defined as before but here independent of the variable z. This leads to the successive problems (6.2), (6.3), and (6.4) (where all derivatives in z are equal to zero). As before, singularities of Types 1, 2, and 3 appear. The singularities of Type 3 are not studied for the same reason as before. We now describe the singularities of Type 1 (compare with Lemma 6.1).

LEMMA 6.4. *Assume that $\lambda \neq -1$. Then $(u, H) \in \mathbf{S}_T^{\lambda}(\Gamma,\mu)$ is an edge singularity of type 1 if and only if $\lambda+1$ belongs to $\Lambda_{\mu}^{Neu}(\Gamma)$, $u = 0$ and*

$$H = (\nabla_2\Phi, 0)^{\top},$$

with $\Phi \in Z_{Neu}^{\lambda+1}(\Gamma,\mu)$.

Proof. As

$$\mathbf{curl}\, H = \begin{pmatrix} \partial_2 H_3 \\ -\partial_1 H_3 \\ \partial_1 H_2 - \partial_2 H_1 \end{pmatrix} = 0,$$

the third component H_3 is constant and the field

$$h = \begin{pmatrix} H_1 \\ H_2 \end{pmatrix}$$

has a two-dimensional zero curl. Therefore there exists Φ such that $h = \nabla_2\Phi$, and we conclude as in Lemma 6.1. $\square$

Let us continue with singularities of Type 2.

LEMMA 6.5. *Assume that $\lambda \neq -1$ and $\lambda \neq 0$. Then $(u, H) \in \mathbf{S}_T^\lambda(\Gamma, \mu)$ is an edge singularity of Type 2 if and only if λ belongs to $\Lambda^{Dir}_{C,\epsilon,e}(\Gamma)$, $\psi = (\nabla_2\chi, 0)^\top$, with $(u, \chi) \in Z^\lambda_{Dir}(\Gamma, C, \epsilon, e)$ and H given by*

$$H = \begin{pmatrix} \frac{a_3 x_2}{\lambda} \\ \frac{a_3 x_1}{\lambda} \\ \frac{a_1 x_2 - a_2 x_1}{\lambda+1} \end{pmatrix} + (\nabla_2 r, 0)^\top, \tag{6.7}$$

where $a = -(\epsilon\psi + e\gamma(u))$ and $r \in S^{\lambda+1}(\Gamma)$ is the solution of

$$\left\{ \begin{array}{ll} \operatorname{div}_2(\mu\nabla_2 r) = -\operatorname{div}_2\left(\mu\begin{pmatrix} \frac{a_3 x_2}{\lambda} \\ \frac{a_3 x_1}{\lambda} \end{pmatrix}\right) & \text{in } \Gamma, \\ \mu\nabla r \cdot n = -\mu\begin{pmatrix} \frac{a_3 x_2}{\lambda} \\ \frac{a_3 x_1}{\lambda} \end{pmatrix} \cdot n & \text{on } \partial\Gamma. \end{array} \right. \tag{6.8}$$

Proof. As in the previous lemma, since $\operatorname{\mathbf{curl}}\psi = 0$ in Γ, there exists $\chi \in S^\lambda(\Gamma)$ such that

$$\psi = (\nabla_2\chi, 0)^\top \text{ in } \Gamma.$$

From (6.3) we deduce that

$$\left\{ \begin{array}{ll} \operatorname{div}(\epsilon\nabla\chi + e\gamma(u)) = 0 & \text{in } \Gamma, \\ \operatorname{Div}\left(C\gamma(u) - e^\top\nabla\chi\right) = 0 & \text{in } \Gamma, \\ \chi = 0, u = 0 & \text{on } \partial\Gamma. \end{array} \right.$$

This means that $(u, \chi) \in Z^\lambda_{Dir}(\Gamma, C, \epsilon, e)$ owing to section 5 (recalling that u and χ are independent of the z-variable).

As in Lemma 6.2, we easily check that H in the form (6.7) is a solution of (6.4) if and only if r is a solution of (6.8), whose existence follows from Theorem 4.14 of [23]. $\square$

In summary we may formulate the following corollary.

COROLLARY 6.6. *The set Λ_a of edge exponents associated with a is given by*

$$\Lambda_a = \{\lambda > -1 : \lambda + 1 \in \Lambda^{Neu}_\mu(\Gamma_a)\} \cup \{\lambda > 0 : \lambda \in \Lambda^{Dir}_{C,\epsilon,e}(\Gamma_a)\}.$$

7. Regularity results. In this section, we describe regularity results of a solution u, H, E of our time-harmonic piezoelectric system. These results use its weak formulation obtained above, are based on the knowledge of corner and edge singularities of these formulation described in the previous section, and rely on the application of Mellin's techniques as in [4, 5].

For the sake of brevity, we do not describe singular decomposition of such a solution. Using the techniques from [4, 5], for sufficiently smooth data we may obtain a decomposition of u, H, E into a regular part and a singular one.

7.1. The case positive definite. Before stating our regularity results, let us introduce the following notation: For any corner $c \in \mathcal{C}$ introduce

$$\lambda_{c,u} = \min\{\lambda > 0 : \lambda \in \Lambda^{Dir}_{C,\epsilon,e}(\Gamma_c)\},$$
$$\lambda_{c,H} = \min\{\lambda : \lambda \in \Lambda_c\}.$$

Similarly, for any edge $a \in \mathcal{A}$ define

$$\lambda_{a,u} = \min\{\lambda > 0 : \lambda \in \Lambda^{Dir}_{C,\epsilon,e}(\Gamma_a)\},$$
$$\lambda_{a,H} = \min\{\lambda : \lambda \in \Lambda_a\}.$$

Finally, we set

$$\tau_u := \min\left(\min_{a\in\mathcal{A}} \lambda_{a,u}, \frac{1}{2} + \min_{c\in\mathcal{C}} \lambda_{c,u}\right),$$
$$\tau_H := \min\left(\min_{a\in\mathcal{A}} \lambda_{a,H}, \frac{1}{2} + \min_{c\in\mathcal{C}} \lambda_{c,H}\right).$$

We remark that τ_u does not depend on μ.

THEOREM 7.1. *Let* $(u_\omega, H) \in H^1_0(\Omega)^3 \times X_T(\Omega,\mu)$ *be a solution of problem* (3.9), *with* J *and* f *smooth enough. Then we have*

$$u_\omega \in H^{1+\tau}(\Omega)^3 \ \forall \tau < \tau_u, \tag{7.1}$$
$$H \in H^{\tau}(\Omega)^3 \ \forall \tau < \tau_H. \tag{7.2}$$

Proof. Mellin's techniques directly imply that

$$(u_\omega, H) \in H^{\tau}(\Omega)^6 \ \forall \tau < \tau_H.$$

The extra regularity for u_ω follows from the description of the singularities of problem (3.9) made in section 6, where we see that the regularity of u_ω is only determined by the singularity of type 2. ∎

COROLLARY 7.2. *Assume that* J *and* f *are smooth. Let* u, E, H *be solutions of* (2.8), (2.9), (2.10), *and* (2.11) *with the boundary conditions* (2.6) *and* (2.7) *obtained by Theorem* 3.5. *Then* u *has the regularity* (7.1), H *has the regularity* (7.2), *and* E *satisfies*

$$E \in H^{\tau}(\Omega)^3 \ \forall \tau < \tau_u. \tag{7.3}$$

Proof. The previous lemma directly yields the regularity for u and H. By (3.1), E has the regularity of $\mathbf{curl}\, H + i\omega e\gamma(u)$. Since the singularities of type 1 for H are gradient, the regularity of E is only determined by the singularities of type 2. ∎

7.2. The case = 0. Here, to solve our piezoelectric system we may use either the E-formulation or the H-formulation. Both formulations give the same regularity for u and E, which is quite natural since generically they are identical (see Theorem 4.7).

THEOREM 7.3. *Let* $(u_\omega, \varphi) \in H^1_0(\Omega)^4$ *be a solution of problem* (4.4) *with* J *and* f *smooth enough; then we have*

$$(u_\omega, \varphi) \in H^{1+\tau}(\Omega)^4 \ \forall \tau < \tau_u, \tag{7.4}$$

where τ_u *is defined as before.*

Proof. Since the system associated with (4.4) is the strongly elliptic system (4.2)–(4.3) with Dirichlet boundary conditions, the mentioned regularity result follows from Theorem 5.11 of [7]. ∎

COROLLARY 7.4. *Assume that* J *and* f *are smooth. Let* u, E, H *be solutions of* (2.8), (2.9), (2.10), *and* (2.11) *with the boundary conditions* (2.6) *and* (2.7) *obtained by Theorem* 4.3. *Then* u *has the regularity* (7.1) *and* E *satisfies* (7.3).

Proof. This is a direct consequence of the previous theorem since $E = \frac{1}{i\omega}\nabla\varphi$. ◻

For the H-formulation, the arguments of the previous subsection directly give the next results.

THEOREM 7.5. *Let* $(u_\omega, H) \in H_0^1(\Omega)^3 \times X_T(\Omega, I)$ *be a solution of problem* (3.9) *in the sense of Lemma* 4.4 *with* J *and* f *smooth enough. Then the regularity results* (7.1)–(7.2) *hold,* τ_H *being defined as before but with* $\mu = I$.

COROLLARY 7.6. *Assume that* J *and* f *are smooth. Let* u, E, H *be solutions of* (2.8)*,* (2.9)*,* (2.10)*, and* (2.11) *with the boundary conditions* (2.6) *and* (2.7) *obtained by Theorem* 4.6*. Then* u *has the regularity* (7.1)*,* H *has the regularity* (7.2)*, and* E *satisfies* (7.3).

8. Numerical examples of edge singular exponents. To illustrate our theoretical results, we give some edge singular exponents of our piezoelectric system corresponding to some illustrative materials when $c_{45} = c_{16} = c_{26} = c_{36} = 0$, $c_{11} = c_{22}$, $c_{44} = c_{55}$, $c_{66} = \frac{c_{11}-c_{12}}{2}$, $\epsilon_{11} = \epsilon_{22}$, and $\epsilon_{12} = 0$. We further consider a dihedral cone $\Gamma_a \times \mathbb{R}$ such that the edge a of this cone (corresponding to the axis $z = 0$) is parallel to the poling direction x_3. In that case, the system (5.4) reduces to the following 4×4 system (see, for instance, [19]):

$$\begin{aligned}
&\begin{pmatrix} c_{11}\partial_1^2 + \frac{c_{11}-c_{12}}{2}\partial_2^2 & \frac{c_{11}+c_{12}}{2}\partial_1\partial_2 \\ \frac{c_{11}+c_{12}}{2}\partial_1\partial_2 & \frac{c_{11}-c_{12}}{2}\partial_1^2 + c_{11}\partial_2^2 \end{pmatrix}\begin{pmatrix} u_1 \\ u_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \text{ in } \Gamma_a,\\
&\begin{pmatrix} c_{44}\Delta & e_{15}\Delta \\ -e_{15}\Delta & \epsilon_{11}\Delta \end{pmatrix}\begin{pmatrix} u_3 \\ \chi \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \quad \text{in } \Gamma_a,\\
&\chi = 0, u = 0 \quad \text{on } \partial\Gamma_a,
\end{aligned}$$

where, as usual, $\Delta = \partial_1^2 + \partial_2^2$. Setting $v = c_{44}u_3 + e_{15}\chi$ and $w = -e_{15}u_3 + \epsilon_{11}\chi$, this system is equivalent to

$$\begin{aligned}
&\begin{pmatrix} c_{11}\partial_1^2 + \frac{c_{11}-c_{12}}{2}\partial_2^2 & \frac{c_{11}+c_{12}}{2}\partial_1\partial_2 \\ \frac{c_{11}+c_{12}}{2}\partial_1\partial_2 & \frac{c_{11}-c_{12}}{2}\partial_1^2 + c_{11}\partial_2^2 \end{pmatrix}\begin{pmatrix} u_1 \\ u_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \text{ in } \Gamma_a,\\
&\Delta v = 0 \text{ in } \Gamma_a,\\
&\Delta w = 0 \text{ in } \Gamma_a,\\
&u_1 = u_2 = v = w = 0 \text{ on } \partial\Gamma_a.
\end{aligned}$$

This last system is decoupled into a 2×2 system of the isotropic elasticity for the pair (u_1, u_2) (with Lamé coefficients given by $\lambda = c_{12}$ and $\mu = \frac{c_{11}-c_{12}}{2}$) with Dirichlet boundary conditions and two Dirichlet problems for v and w. For this last Dirichlet problem, it is well known that the singular exponents are given by $\frac{l\pi}{\omega}$, with $l \in \mathbb{N}$, when ω is the interior opening of Γ_a. On the other hand, the singular exponents of the isotropic elasticity are also well known and are the set of $\lambda \in \mathbb{C}$ such that (see, for instance, [12])

$$k^2 \sin(\lambda\omega)^2 = \lambda^2 \sin(\omega)^2,$$

with $k = \frac{3c_{11}-c_{12}}{c_{11}+c_{12}}$.

The zeros of this equation can be easily computed using a Newton method. Figures 8.1 and 8.2 show the real part of the singular exponents in the strip $\Re\lambda \in (0, 2)$ for all values of $\omega \in (0, 2\pi]$ for the piezoelectric materials PZT-4 and $BaTiO_3$ in black lines. In these figures, the gray lines correspond to the curves $\frac{l\pi}{\omega}$, for $l = 1, 2, 3$. From these figures, we may conclude that for these materials the strongest singular

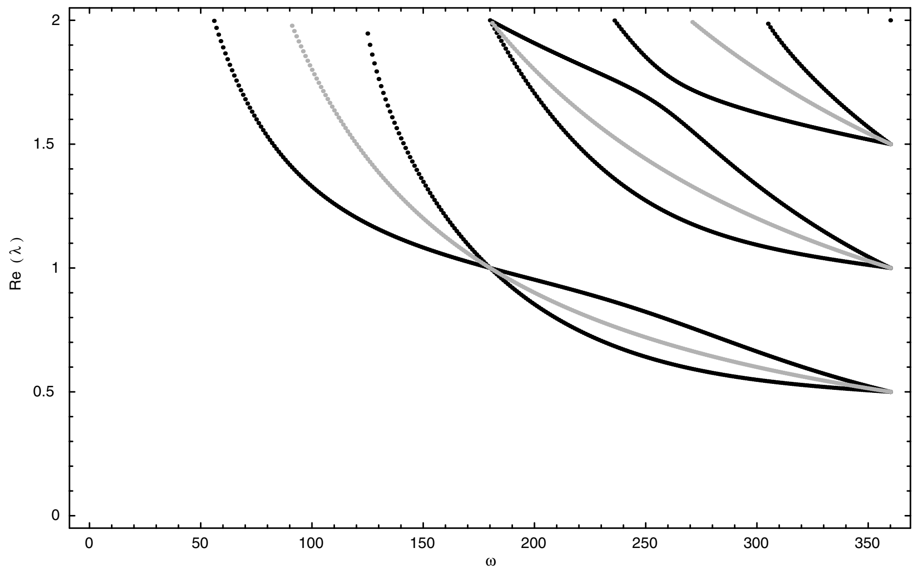

FIG. 8.1. *The edge exponents for the* PZT*-4.*

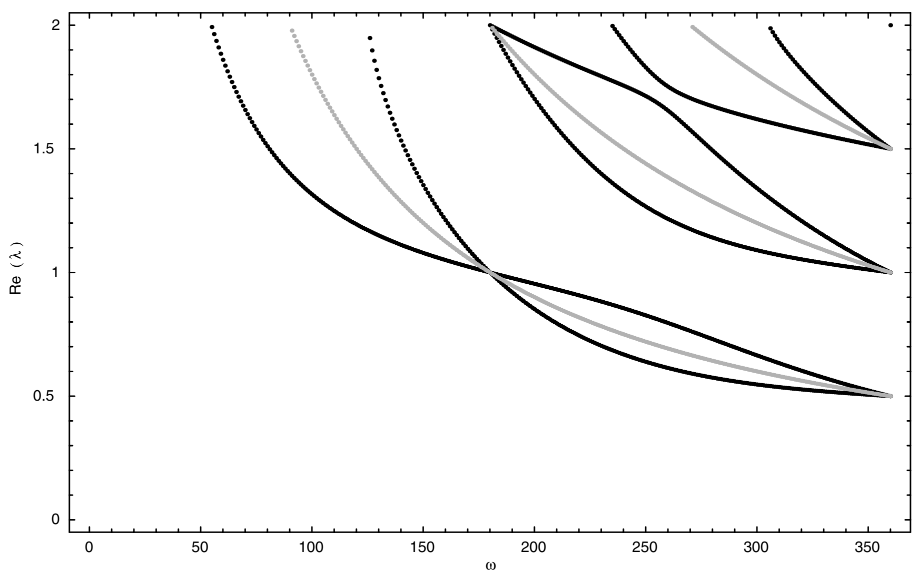

FIG. 8.2. *The edge exponents for the* $BaTiO_3$*.*

exponent λ_0 (strongest in the sense that $\Re\lambda_0$ is minimal) is always the one coming from the 2×2 system of elasticity and that $\Re\lambda_0 > 1/2$ (see Theorem 2.2 of [22]). This last property implies the $H^{3/2}$-regularity (resp., $H^{1/2}$-regularity) for u (resp., for E) along the edge. Note further that the curves obtained for the PZT-4 are similar to the ones shown in Figure 4b of [29] (in that paper, the singular exponents are obtained using an extension of Lekhnitskii's representation for elastic solids).

Remark 8.1. If the edge is not parallel to the poling direction, then the above decoupling phenomenon does not appear. The calculation of the edge singular exponents is then more complicated and will be done using a finite element method. This will be done in a forthcoming paper [20].

9. Conclusions. We have investigated a general time-harmonic piezoelectric system, which contains as special cases standard models like ceramics. We developed the appropriate formalism in order to get existence and uniqueness results of weak solutions in the case when the magnetic permeability matrix is positive definite (case of the $BaTiO_3$) and the case when the magnetic permeability matrix is equal to zero (case of the PZT). In the latter case, we gave two different formulations: the E-formulation and the H-formulation. For this second one, Gauge conditions are introduced as for eddy current problem. We further show that generically these two formulations yield the same solutions. We described the corner and edge singularities of our general system and deduced some regularity results. Some edge singular exponents were given in order to illustrate our theoretical results.

APPLICATION OF THE REALIZATION OF HOMOGENEOUS SOBOLEV SPACES TO NAVIER–STOKES*

LORENZO BRANDOLESE†

Abstract. Molecule spaces have been introduced by Furioli and Terraneo [*Funkcial. Ekvac.*, 45 (2002), pp. 141–160] to study some local behavior of solutions to the Navier–Stokes equations. In this paper we give a new characterization of these spaces and simplify Furioli and Terraneo's result. Our analysis also provides a persistence result for Navier–Stokes in a subspace of $L^2(\mathbb{R}^3, (1+|x|^2)^\alpha dx)$, $\alpha < 5/2$, which fills a gap between previously known results in the weighted-L^2 setting and those on the pointwise decay of the velocity field at infinity. Our main tool is the realization of homogeneous Sobolev spaces introduced by Bourdaud.

1. Introduction. Consider the Navier–Stokes equations for a viscous incompressible fluid in the three-dimensional space and not submitted to external forces:

$$\text{(NS)} \qquad \begin{cases} \partial_t u + (u\cdot\nabla)u = \Delta u - \nabla p, \\ \nabla\cdot u = 0, \\ u(x,0) = a(x). \end{cases}$$

Here $u = (u_1, u_2, u_3)$ is the velocity field and p is the pressure, both defined in $\mathbb{R}^3 \times [0,\infty[$. Moreover, $\nabla\cdot u = \sum_{j=1}^3 \partial_j u_j$ and $(u\cdot\nabla)u = \sum_{j=1}^3 u_j\partial_j u$.

If $a \in L^2(\mathbb{R}^3)$, then we have known for a very long time that a *weak* solution to (NS) exists such that $u \in L^\infty(]0,\infty[, L^2(\mathbb{R}^3))$ and $\nabla u \in L^2(]0,\infty[, L^2(\mathbb{R}^3))$. If we know, in addition, that the initial datum is well localized in $\mathbb{R}^3$, then these conditions, of course, do not give us so much information on the spatial localization of $u(t)$ during the evolution. Then the natural problem arises of finding the functional spaces that would provide the good setting for obtaining such information. Several papers have been written on this topic; see, e.g., [14], [9], [10], [13], [1], [16] and the references therein. In particular, it was shown in [14] that the condition $a \in L^2(\mathbb{R}^3, (1+|x|^2)^\delta dx)$ $(0 \le \delta \le \frac{3}{2})$ is conserved during the evolution, for a suitable class of weak solutions. Here and below, this weighted-L^2 space is equipped with the natural norm $\left(\int |a(x)|^2(1+|x|^2)^\delta\, dx\right)^{1/2}$. As far as we deal with data belonging to general weighted-L^2 spaces, it seems difficult to improve the upper bound on δ.

When dealing with *strong* solutions to (NS) one can obtain sharper conclusions on the localization of u. For example, assuming that $a \in L^1 \cap L^2(\mathbb{R}^3)$, He [13] proves, among other things, that $u(t)$ belongs to $L^2(\mathbb{R}^3, (1+|x|^2)^2 dx)$ at least in some time interval $[0,T]$, $T > 0$ (and uniformly in $[0,+\infty[$, under a supplementary smallness assumption). In a slightly different context, we would also like to mention the work of Miyakawa [17], in which it is shown that $u(x,t) \sim |x|^{-\alpha} t^{-\beta/2}$ as $|x| \to \infty$ or $t \to \infty$,

for all $\alpha, \beta \geq 0$ and $1 \leq \alpha + \beta \leq 4$, under suitable assumptions on a. The main tool here is the application of the contraction mapping theorem to the integral equation

$$u(t) = e^{t\Delta}a - \int_0^t \nabla \cdot e^{(t-s)\Delta}\mathbb{P}(u \otimes u)(s)\, ds, \tag{IE}$$

where $e^{t\Delta}$ is the heat semigroup and $\mathbb{P}$ is the Leray–Hopf projector onto the solenoidal vector fields, defined by $\mathbb{P}f = f - \nabla\Delta^{-1}(\nabla \cdot f)$, where $f = (f_1, f_2, f_3)$. Note that (IE), together with the divergence-free condition $\nabla \cdot a = 0$, is equivalent to (NS) under very general assumptions (see [11]).

If we compare the results on the spatial localization contained in [13] and [17], we see that Miyakawa's results seem to give a slightly better conclusion. Indeed, [17] tells us that the condition $a(x) \sim |x|^{-4}$ at infinity is conserved during the evolution (furthermore, $|x|^{-4}$ is known to be the optimal decay in the generic case), whereas, according to [13], the condition $u(t) \in L^2(\mathbb{R}^3, (1+|x|^2)^2 dx)$ only tells us, formally, that $u(t) \sim |x|^{-7/2}$ at infinity. Then there is a small gap between the results on the pointwise decay and those in the weighted-L^2 setting.

The first purpose of this paper is to obtain a persistence result in suitable subspaces of $L^2(\mathbb{R}^3, (1+|x|^2)^\alpha dx)$, for all $0 \leq \alpha < \frac{5}{2}$, which, at least formally, will allow us to recover the optimal decay of the velocity field. To do this, rather than establishing a new theorem we shall give a new interpretation of a known result by Furioli and Terraneo on the molecules of the Hardy space [12]. More precisely, let us introduce the space Z_δ of functions (or vector fields) f such that

$$f \in L^2(\mathbb{R}^3, (1+|x|^2)^{\delta-2} dx), \tag{1.1}$$

$$\nabla f \in L^2(\mathbb{R}^3, (1+|x|^2)^{\delta-1} dx), \tag{1.2}$$

$$\Delta f \in L^2(\mathbb{R}^3, (1+|x|^2)^{\delta} dx). \tag{1.3}$$

We provide such space with its natural norm. We will prove the following theorem (announced, in a weaker form, in [5]).

THEOREM 1.1. *Let $\frac{1}{2} \leq \delta < \frac{9}{2}$ and let $a \in Z_\delta$ be a solenoidal vector field. Then there exists $T > 0$ such that* (IE) *possesses a unique strong solution $u \in C([0,T], Z_\delta)$.*

The restriction $\delta < \frac{9}{2}$ is consistent with the spatial spreading effect of the velocity field described, e.g., in [6]: we cannot have $u \in C([0,T], Z_{9/2})$ unless the initial data have some symmetry properties. As we shall see, the elements of Z_δ are $o(|x|^{-\delta+1/2})$ at infinity. Hence the correspondence between this result and those on the pointwise decay is not merely formal. The condition $\delta \geq \frac{1}{2}$ is physically reasonable since it prevents $u \to \infty$ as $|x| \to \infty$.

In section 3 we show that Theorem 1.1 is essentially equivalent to (but slightly improves) the result by Furioli and Terraneo [12]. Their motivation was different and this is probably the reason why the relation between their *space of molecules* X_δ (defined below) and the more natural space Z_δ is not found in [12]; motivated by the problem of the unicity of mild solutions in *critical spaces* (i.e., homogeneous spaces of degree -1), they studied the Navier–Stokes equations in $\Delta^{-1}\mathcal{H}^1$, which is the space made of all distributions vanishing at infinity and such that their Laplacian belongs to the Hardy space $\mathcal{H}^1(\mathbb{R}^3)$. As discussed also in [15], such space gives a useful insight of solutions to the Navier–Stokes equations. Indeed, if a solution u satisfies $\Delta u \in \mathcal{H}^1(\mathbb{R}^3)$, then $u \in L^3(\mathbb{R}^3)$, $\nabla \otimes u \in L^{3/2}$, and $(u \cdot \nabla)u \in \mathcal{H}^1(\mathbb{R}^3)$ (this is a consequence of the so-called div-curl lemma as stated in [7]). Furthermore, $\nabla p \in \mathcal{H}^1(\mathbb{R}^3)$ (this follows from the classical relation $\Delta p = \sum_{h,k=1}^3 \partial_h\partial_k(u_h u_k)$ and the boundedness of the Riesz transforms in the Hardy space). Thus, the three terms which contribute to $\partial_t u$ in (NS) have the same regularity.

Moreover, the Hardy space has a very simple structure, due to its well-known atomic decomposition. Hence, solving the equations in $\Delta^{-1}\mathcal{H}^1$ yields a natural decomposition of the flow into simple "building blocks." Furioli and Terraneo considered the converse problem of studying the evolution of each building block. The result of [12] essentially states that if Δu is a *molecule* of the Hardy space (in a sense close to that of Coifman and Weiss [8]) at the beginning of the evolution, then this property remains true for a certain time. To do this they introduced, for $\delta > \frac{3}{2}$, the space X_δ defined as the set of all tempered distributions f vanishing at infinity such that $\Delta f \in L^2(\mathbb{R}^3, (1+|x|^2)^\delta dx)$ and $\int x^\alpha \Delta f(x)\, dx = 0$ for all $\alpha \in \mathbb{N}^3$ such that $\alpha_1 + \alpha_2 + \alpha_3 < \delta - \frac{3}{2}$. The norm of X_δ is defined by

$$||f||^2_{X_\delta} \equiv \int |\Delta f(x)|^2 (1+|x|^2)^\delta \, dx.$$

Furioli and Terraneo's theorem then is stated as Theorem 1.1, with X_δ instead of Z_δ, and with the additional restrictions $\frac{3}{2} < \delta < \frac{9}{2}$ and $\delta \neq \frac{5}{2}, \frac{7}{2}$. The condition $\delta > \frac{3}{2}$ is important for the embedding $X_\delta \subset \Delta^{-1}\mathcal{H}^1$. However, P.-G. Lemarié-Rieusset noticed that the condition $\delta \neq \frac{5}{2}, \frac{7}{2}$ can be removed. Their paper is technical and relies on the theory of *local* Muckenhoupt weights.

The second purpose of this paper is to provide a simpler proof of their result. Indeed, in section 4 we remark that the Fourier transform of X_δ is closely related to the realization "à la Bourdaud" [3] of the homogeneous Sobolev space $\dot{H}^\delta$. The operators involved in (IE) turn out to be Fourier pointwise multipliers of the realized spaces. Therefore the estimates that are needed to establish the boundedness of the bilinear operator $B(u,v)(t) = \int_0^t \nabla \cdot e^{(t-s)\Delta}\mathbb{P}(u \otimes v)(s)\, ds$ in $C([0,T], X_\delta)$ become very natural. The conclusion of the proof is a simple application of the contraction mapping theorem.

The idea of using Bourdaud's results on realized spaces in this way (or analogous results by Youssfi [20] for the realized homogeneous Besov spaces) seems to be new. Since this argument does not directly rely on the divergence-free condition or the matricial structure of $\mathbb{P}$, it can be easily applied to more general equations. Moreover, we feel that providing evidence of the relation between the localization problem of the velocity field and Furioli and Terraneo's molecules provides a better understanding of [12].

The spatial localization of the velocity field in different weighted-Lebesgue spaces is studied in [19]. After the first version of this paper was completed, the author was notified by H.-O. Bae and B. J. Jin that their preprint [2] also improves the spatial decay results of [13] and [14] and provides solutions to (NS) in $L^2(\mathbb{R}^3, (1+|x|^2)^\alpha dx)$, $0 \leq \alpha < \frac{5}{2}$. Their method is a refinement of the weighted estimates of He and Xin [14] and is quite different than ours. The assumptions on the data are also different: Bae and Jin deal with less regular data, but they put more stringent assumptions on their spatial localization.

2. Some properties of the space . For $\delta \geq 0$ we introduce the space L^2_δ of all functions $f \in L^2(\mathbb{R}^3, (1+|x|^2)^\delta dx)$ such that $\int x^\alpha f(x)\, dx = 0$ for all $\alpha \in \mathbb{N}^3$, with $0 \leq |\alpha| < \delta - \frac{3}{2}$ (where $|\alpha| = \alpha_1 + \alpha_2 + \alpha_3$). There are of course no moment conditions for $0 \leq \delta \leq \frac{3}{2}$. Note that L^2_δ is well defined because of the embedding of $L^2(\mathbb{R}^3, (1+|x|^2)^\delta dx)$ into $L^1(\mathbb{R}^3, w_\delta(x)dx)$, for $\delta > \frac{3}{2}$. Here and below, for $\delta > \frac{3}{2}$, we set $w_\delta(x) = (1+|x|)^{[\delta-3/2]}$ if $\delta - \frac{3}{2} \notin \mathbb{N}$ (where $[\cdot]$ denotes the integer part), and $w_\delta(x) = (1+|x|)^{\delta-5/2}$ otherwise.

LEMMA 2.1. *Let $\delta \geq 0$. We have $f \in L^2_\delta$ if and only if f can be decomposed as*

$$f = g + \sum_{j=0}^{\infty} f_j,$$

where g and f_j belong to $L^2(\mathbb{R}^3)$, $\operatorname{supp} g \subset \{|x| \leq 1\}$, $\operatorname{supp} f_j \subset \{2^{j-1} \leq |x| \leq 2^{j+1}\}$, and

$$\begin{aligned} &\|f_j\|_2 \leq \epsilon_j 2^{-j\delta}, \qquad \text{with} \quad \epsilon_j \in \ell^2(\mathbb{N}), \\ &\int x^\alpha g(x)\,dx = \int x^\alpha f_j(x)\,dx = 0, \qquad \text{if } \alpha \in \mathbb{N}^3, \quad 0 \leq |\alpha| < \delta - \frac{3}{2}, \end{aligned} \tag{2.1}$$

and where the series converges a.e. in $\mathbb{R}^3$ and in L^2_δ.

Proof. The result is obvious for $0 \leq \delta \leq \frac{3}{2}$, so we may assume $\delta > \frac{3}{2}$. We start with a bad choice, namely

$$\tilde{g}(x) = f(x) I_{|x|\leq 1} \quad \text{and} \quad \tilde{f}_j(x) = f(x) I_{2^j \leq |x| \leq 2^{j+1}} \qquad (j = 0, 1, \ldots),$$

where I denotes the indicator function. Letting $\tilde{f}_{-1} = \tilde{g}$, we set

$$J(j,\alpha) = \int x^\alpha \tilde{f}_j(x)\,dx.$$

Since $|\alpha| < \delta - \frac{3}{2}$, the series $\sum_j J(j,\alpha)$ converges and $\sum_{j=-1}^{\infty} J(j,\alpha) = 0$. We now introduce a family of functions $\psi_\beta \in C_0^\infty(\mathbb{R}^3)$, supported in $\frac{1}{2} \leq |x| \leq 1$ and such that

$$\int x^\alpha \psi_\beta(x)\,dx = \delta_{\alpha,\beta} \qquad (\alpha, \beta \in \mathbb{N}^3, \quad |\alpha|, |\beta| < \delta - \tfrac{3}{2}),$$

with $\delta_{\alpha,\beta} = 0$ or 1 if $\alpha \neq \beta$ or $\alpha = \beta$, respectively (we may define ψ_β, e.g., through the tensorial product of suitable $C_0^\infty(\mathbb{R})$ functions).

Now let

$$c(j,\alpha) \equiv J(j,\alpha) + J(j+1,\alpha) + \cdots,$$

and set, for $j = -1, 0, \ldots,$

$$f_j(x) = \tilde{f}_j(x) - \sum_\beta \Big(c(j,\beta) 2^{-(3+|\beta|)j} \psi_\beta(2^{-j}x) - c(j+1,\beta) 2^{-(3+|\beta|)(j+1)} \psi_\beta(2^{-j-1}x) \Big),$$

the summation being taken over all $\beta \in \mathbb{N}^3$ such that $0 \leq |\beta| < \delta - \frac{3}{2}$.

Since $|J(j,\alpha)| \leq 2^{j|\alpha|} 2^{3j/2 - j\delta} \tilde{\epsilon}_j$ for some $\tilde{\epsilon}_j \in \ell^2(\mathbb{N})$, we have $|c(j,\alpha)| \leq 2^{j|\alpha|} 2^{3j/2-j\delta} \bar{\epsilon}_j$, with $\bar{\epsilon}_j \in \ell^2(\mathbb{N})$. One now easily checks that $\sum_{j=-1}^{\infty} f_j = \sum_{j=-1}^{\infty} \tilde{f}_j = f$ a.e. in $\mathbb{R}^3$ and that g and f_j satisfy (2.1).

The converse is immediate. Note that if g and f_j satisfy the above conditions, then $\sum f_j$ must converge also in the $L^1(\mathbb{R}^3, w_\delta(x)dx)$ norm ($\delta > \frac{3}{2}$) by Hölder's inequality, and this ensures the condition on the moments of f. Lemma 2.1 follows. $\square$

A similar decomposition applies to Z_δ.

LEMMA 2.2. *Let $\delta \geq 0$. We have $f \in Z_\delta$ if and only if*

$$f = g + \sum_{j=0}^{\infty} f_j,$$

with

$$\begin{aligned}
&\operatorname{supp} g \subset \{|x| \leq 1\}, && \operatorname{supp} f_j \subset \{2^{j-2} \leq |x| \leq 2^{j+2}\}, && \\
&g, \nabla g, \Delta g \in L^2(\mathbb{R}^3), && ||f_j||_2 \leq \epsilon_j 2^{2j} 2^{-j\delta}, && \epsilon_j \in \ell^2(\mathbb{N}), \\
&||\nabla f_j||_2 \leq \bar{\epsilon}_j 2^j 2^{-j\delta}, && ||\Delta f_j||_2 \leq \tilde{\epsilon}_j 2^{-j\delta}, && \bar{\epsilon}_j, \tilde{\epsilon}_j \in \ell^2(\mathbb{N}),
\end{aligned} \tag{2.2}$$

and where the series converges a.e. in $\mathbb{R}^3$ and in Z_δ.

If $\delta > \frac{7}{2}$, then Z_δ is continuously embedded in $L^1(\mathbb{R}^3)$. In this case we have $\int f = 0$ if and only if we may choose g and f_j satisfying, in addition, $\int g = \int f_j = 0$ ($j = 0, 1, \ldots$).

Proof. It is obvious that if (2.2) holds, then $f = g + \sum_{j=0}^{\infty} f_j$ belongs to Z_δ. Conversely, let φ and ψ be two compactly supported smooth functions, such that 0 does not belong to the support of ψ and $1 \equiv \varphi(x) + \sum_{j=0}^{\infty} \psi(2^{-j}x)$. If we set $g(x) = f(x)\varphi(x)$ and $f_j(x) = f(x)\psi(2^{-j}x)$, then we have $\nabla f_j(x) = \psi(2^{-j}x)\nabla f(x) + 2^{-j}(\nabla\psi)(2^{-j}x)f(x)$ and

$$\Delta f_j(x) = \psi(2^{-j}x)\Delta f(x) + 2^{-j+1}(\nabla\psi)(2^{-j}x) \cdot \nabla f(x) + 2^{-2j}(\Delta\psi)(2^{-j}x)f(x).$$

Decomposition (2.2) then directly follows from the definition of Z_δ.

If $\delta > \frac{7}{2}$, then $Z_\delta \subset L^1(\mathbb{R}^3)$ as checked with Hölder's inequality. In this case, when $\int f = 0$, we can modify the definition of g and f_j reproducing the proof of Lemma 2.1 (with $|\alpha| = |\beta| = 0$) and get the vanishing integral conditions. Lemma 2.2 follows. $\square$

We finish our study of Z_δ with the following lemma.

LEMMA 2.3. *Let $\delta \geq \frac{1}{2}$. Then Z_δ is an algebra with respect to the pointwise product. More precisely, if f and h belong to Z_δ, then $fh \in Z_{2\delta-1/2} \subset Z_\delta$.*

Proof. The condition $\delta \geq \frac{1}{2}$ ensures that if $f \in Z_\delta$, then f vanishes at infinity. Indeed, we have the following bound:

$$|f(x)| \leq C(1 + |x|)^{-\delta+1/2}\epsilon(x), \tag{2.3}$$

where $\epsilon(x)$ is a bounded function vanishing at infinity. This is seen by applying Lemma 2.2 and writing, for $x \in \operatorname{supp} f_j$, $f_j(x) = \int |x-y|^{-1}\Delta f_j(y)\,dy$. Then applying Hölder's inequality and the last of (2.2) we get for $x \in \operatorname{supp} f_j$, $|f_j(x)| \leq \epsilon_j 2^{-j\delta}2^{j/2}$ with $\epsilon_j \in \ell^2(\mathbb{N})$ and our claim follows.

Another useful estimate (which follows interpolating ∇f_j between $||\Delta f_j||_2$ and $||f_j||_\infty$) is

$$\left(\int_{2^j \leq |x| \leq 2^{j+1}} |\nabla f(x)|^4 dx\right)^{1/4} \leq \epsilon_j 2^{j/4 - j\delta}, \qquad \text{with } \epsilon_j \in \ell^2(\mathbb{N}).$$

Using this, we immediately see that if f and h belong to Z_δ, then $fh \in L^2(\mathbb{R}^3, (1 + |x|^2)^{2\delta-5/2}dx)$, $\nabla(fh) \in L^2(\mathbb{R}^3, (1 + |x|^2)^{2\delta-3/2}dx)$, and $\Delta(fh) \in L^2(\mathbb{R}^3, (1 + |x|^2)^{2\delta-\frac{1}{2}}dx)$. Therefore $fh \in Z_{2\delta-1/2} \subset Z_\delta$ and, moreover,

$$||fh||_{Z_{2\delta-1/2}} \leq C||f||_{Z_\delta}||h||_{Z_\delta}. \qquad \square$$

3. Characterization of molecule spaces. We defined the molecule space X_δ in the introduction for $\delta > \frac{3}{2}$. These spaces can be defined also for $\frac{1}{2} < \delta \le \frac{3}{2}$ by simply dropping the moment conditions on Δf (it should be observed that the embedding $X_\delta \subset \Delta^{-1}\mathcal{H}^1(\mathbb{R}^3)$ breaks down for $\delta \le \frac{3}{2}$, but for the sake of brevity we refer to X_δ as a "molecule space" also in this case). In this section we study the relation between the spaces Z_δ and X_δ.

PROPOSITION 3.1. *We have*

$$X_\delta = Z_\delta, \qquad \text{if } \frac{1}{2} < \delta < \frac{7}{2} \quad \text{and} \quad \delta \neq \frac{3}{2}, \frac{5}{2}, \tag{3.1}$$

$$X_\delta = Z_\delta \cap \left\{ f \in L^1(\mathbb{R}^3) \,:\, \int f = 0 \right\}, \qquad \text{if } \frac{7}{2} < \delta < \frac{9}{2} \tag{3.2}$$

(with norm equivalence).

Note that $\delta = \frac{3}{2}, \frac{5}{2}, \frac{7}{2}$ are excluded. The proof of Proposition 3.1 will only give $Z_\delta \subset X_\delta$ in this case. Let us shed some light on this point with an example. Let $j,k = 1,2,3$ and $f \in L^2(\mathbb{R}^3)$ such that $\Delta f = \partial_j \partial_k g$, where $g(x) = (4\pi)^{-3/2} e^{-|x|^2/4}$. Then $f \in X_{7/2}$ but $f \notin X_\delta$ for $\delta > \frac{7}{2}$, since $\int x_j x_k \Delta f(x)\, dx \neq 0$. Moreover, computing the inverse Fourier transform as in [17] from the identity $\widehat{f}(\xi) = \xi_j \xi_k |\xi|^{-2} e^{-|\xi|^2}$, one checks after some computations that the integral $\int |f(x)|^2 (1+|x|^2)^{3/2}\, dx$ diverges so that $f \notin Z_{7/2}$.

Proof of Proposition 3.1. Throughout the proof $\alpha \in \mathbb{N}^3$. Note that because of our restrictions $\delta - \frac{3}{2}$ is not an integer.

First step: The embedding $X_\delta \subset Z_\delta$. Let $f \in X_\delta$. Applying Lemma 2.1 to Δf and using the fact that f vanishes at infinity, we see that we may write

$$f = \frac{c}{|x|} * p + \sum_{j=0}^{\infty} \frac{c}{|x|} * q_j, \tag{3.3}$$

c being an absolute constant. Here p and q_j are compactly supported L^2-functions, satisfying

$$\begin{aligned}
&\operatorname{supp} p \subset \{|x| \le 1\},\\
&\operatorname{supp} q_j \subset \{2^{j-1} \le |x| \le 2^{j+1}\},\\
&||q_j||_2 \le \epsilon_j 2^{-j\delta}, \qquad \epsilon_j \in \ell^2(\mathbb{N}),\\
&\int x^\alpha p(x)\, dx = \int x^\alpha q_j(x)\, dx = 0, \qquad \text{if } |\alpha| < \delta - \frac{3}{2}.
\end{aligned} \tag{3.4}$$

Let us show that, for all $f \in X_\delta$ and $2^j \le |x| \le 2^{j+1}$, we have

$$|f(x)| \le \bar{\epsilon}_j 2^{j/2} 2^{-j\delta}, \qquad \text{with } \bar{\epsilon}_j \in \ell^2(\mathbb{N}). \tag{3.5}$$

To prove (3.5) we set $P = \frac{1}{|\cdot|} * p$, $Q_j = \frac{1}{|\cdot|} * q_j$ $(j = 0, 1, \ldots)$, and $d = [\delta - \frac{3}{2}]$ (we set $d = -1$ if $\frac{1}{2} < \delta < \frac{3}{2}$). Then we have

$$|Q_j(x)| \le C \epsilon_j 2^{-j(\delta - 1/2)}, \qquad \text{if } |x| \le 4 \cdot 2^j, \tag{3.6}$$

$$|Q_j(x)| \le C |x|^{-(d+2)} \epsilon_j 2^{(d+5/2-\delta)j}, \qquad \text{if } |x| \ge 4 \cdot 2^j. \tag{3.7}$$

The first bound follows from the localization of q_j and Hölder's inequality. Let us prove (3.7); we start by introducing the Taylor polynomial $y \mapsto T_x(y)$ of degree d

centered at x of the function $1/|y|$ (we set $T_x(y) \equiv 0$ for $\frac{1}{2} < \delta < \frac{3}{2}$). Then for $|x| \geq 4 \cdot 2^j$ and $y \in \operatorname{supp} q_j$ we may write, using the last of (3.4),

$$|Q_j(x)| = \left| \int \left(\frac{1}{|x-y|} - T_x(-y) \right) q_j(y)\, dy \right| \leq C|x|^{-d-2} \int |y|^{d+1} |q_j(y)|\, dy.$$

Here the inequality follows from the Taylor formula and the fact that the $(d+1)$-order derivatives of $y \mapsto 1/|y|$ are bounded in a ball centered at x and radium $|x|/2$, up to a constant, by $|x|^{-d-2}$. The bound (3.7) now follows from Hölder's inequality.

Similar arguments allow us to see that $|P(x)| \leq C(1+|x|)^{-(d+2)}$. Summing up on these inequalities immediately yields (3.5).

Condition (3.6) also ensures that $\int_{|x|\leq 1} |f|^2$ is finite. Then using (3.5) we get

$$\int |f(x)|^2 (1+|x|^2)^{\delta-2}\, dx < \infty. \tag{3.8}$$

We now need some bounds for ∇f. We start from $-\nabla f(x) = \frac{cx}{|x|^3} * p + \sum_{j=0}^\infty \frac{cx}{|x|^3} * q_j$, and we set $R_j = (x/|x|^3) * q_j$ $(j = 0, 1, \ldots)$ and $R_{-1} = (x/|x|^3) * p$. Then for $j \geq -1$,

$$|R_j(x)| \leq C|x|^{-(d+3)} \epsilon_j 2^{(d+5/2-\delta)j}, \qquad \text{if } |x| \geq 4 \cdot 2^j, \tag{3.9}$$

$$\left(\int_{|x|\leq 4\cdot 2^j} |R_j(x)|^4\, dx \right)^{1/4} \leq C\epsilon_j 2^{j/4} 2^{-j\delta}. \tag{3.10}$$

Indeed, (3.9) again easily follows using the vanishing of the moments of q_j and the Taylor formula. The proof of (3.10) deserves a more detailed explanation: for $|x| \leq 4 \cdot 2^j$ we write

$$\frac{x}{|x|^3} * q_j(x) = \theta_j * q_j(x), \qquad \text{where} \quad \theta_j(x) = \frac{x}{|x|^3} I_{\{|x|\leq 6\cdot 2^j\}}.$$

Then (3.10) comes from $||\theta_j * q_j||_4 \leq ||\theta_j||_{4/3} ||q_j||_2 \leq C 2^{j/4} ||q_j||_2$.

Now, for $j \geq 1$ we write $-\frac{1}{c}\nabla f = \sum_{k=-1}^{j-2} R_k + \sum_{k=j-1}^\infty R_k \equiv A_j + B_j$. Using (3.9) we get

$$\left(\int_{2^j \leq |x| \leq 2^{j+1}} |A_j(x)|^2\, dx \right)^{1/2} \leq C\tilde\epsilon_j 2^j 2^{-j\delta}, \qquad \text{with } \tilde\epsilon_j \in \ell^2(\mathbb{N}).$$

On the other hand, applying Hölder and Minkowski inequalities and (3.10) yields

$$\left(\int_{2^j \leq |x| \leq 2^{j+1}} |B_j(x)|^2\, dx \right)^{1/2} \leq C'\tilde\epsilon_j 2^j 2^{-j\delta}, \qquad \text{with } \tilde\epsilon_j \in \ell^2(\mathbb{N}).$$

Since we obviously have $\int_{|x|\leq 2} |\nabla f|^2 < \infty$, we thus see that

$$\int |\nabla f(x)|^2 (1+|x|^2)^{\delta-1}\, dx < \infty. \tag{3.11}$$

This last inequality, condition (3.8), and the definition of the X_δ norm yield the injection $X_\delta \subset Z_\delta$.

Second step: The elements of X_δ, $\frac{7}{2} < \delta < \frac{9}{2}$ have vanishing integral. Assume now $\frac{7}{2} < \delta < \frac{9}{2}$. Then the moments of p and q_j vanish up to the order two. Moreover, our previous estimates imply that P and Q_j belong to $L^1(\mathbb{R}^3)$. We thus see, e.g., via the Fourier transform (using the fact that $\widehat{p}(\xi)$ and $\widehat{q}_j(\xi)$ vanish at the origin together with their derivatives up to the order two and letting $\xi \to 0$) that $\int P(x)\,dx = \int Q_j(x)\,dx = 0$ for all positive integers j. Moreover, the series $\sum Q_j$ converges in the L^1-norm by (3.6)–(3.7) yielding $\int f = 0$.

Third step: The converse inclusion. Let $f \in Z_\delta$. In the case $\frac{7}{2} < \delta < \frac{9}{2}$ we assume $\int f = 0$. The bound $||f||_{X_\delta} < \infty$ is obvious. By Lemma 2.2 we have $f = g + \sum_{j=0}^{\infty} f_j$, such that (2.2) holds (with $\int g = \int f_j = 0$ for all $j \geq 0$ if $\frac{7}{2} < \delta < \frac{9}{2}$).

We claim that

$$\int x^\alpha \Delta g(x)\,dx = \int x^\alpha \Delta f_j(x)\,dx = 0, \qquad 0 \leq |\alpha| < \delta - \tfrac{3}{2},$$

for all $j \geq 0$ (there are no moment conditions for $\frac{1}{2} < \delta < \frac{3}{2}$). Indeed, since g and f_j are compactly supported, when applying the Green formula all the boundary terms vanish and we obtain (e.g., for f_j, when $\frac{7}{2} < \delta < \frac{9}{2}$)

$$\int x^\alpha \Delta f_j(x)\,dx = 2 \int f_j(x)\,dx, \qquad \text{if} \quad x^\alpha = x_1^2,\ x_2^2, \text{ or } x_3^2,$$

and $\int x^\alpha \Delta f_j(x)\,dx = 0$; otherwise ($|\alpha| \leq [\delta - \frac{3}{2}]$). Our claim then follows.

Moreover, by Hölder's inequality,

$$\sum_{j=0}^{\infty} ||x^\alpha \Delta f_j||_1 < \infty, \qquad 0 \leq |\alpha| < \delta - \tfrac{3}{2}.$$

Summing on j we get $\int x^\alpha \Delta f(x)\,dx = 0$.

To conclude that $f \in X_\delta$ it remains to check that f vanishes at infinity. This was done in (2.3). ◻

4. Proof of Theorem 1.1. The boundedness of the operator $\nabla e^{t\Delta}\mathbb{P}$ in X_δ ($\frac{3}{2} < \delta < \frac{9}{2}$), $\delta \neq \frac{5}{2}, \frac{7}{2}$ is a fundamental step of [12]. Lemma 4.1 provides a short proof of this fact. Our main tool will be the *realization* of homogeneous Sobolev spaces introduced by Bourdaud. Note that $\nabla e^{t\Delta}\mathbb{P}$ is a matrix operator acting on vector fields. But its matricial structure has no special role in what follows, since we shall establish all the relevant estimates componentwise.

LEMMA 4.1. *Let $\frac{1}{2} < \delta < \frac{9}{2}$, $\delta \neq \frac{3}{2}, \frac{5}{2}, \frac{7}{2}$. The operator $\nabla e^{t\Delta}\mathbb{P}$ is bounded from Z_δ to X_δ for all $t > 0$, with operator norm $O(t^{-1/2})$ as $t \to 0$.*

Proof. Let $f \in Z_\delta$. If $\frac{7}{2} < \delta < \frac{9}{2}$, then we introduce a function h such that

$$f(x) = cg(x) + h(x), \qquad \text{where } g(x) = (4\pi)^{-3/2} e^{-|x|^2/4}$$

and the constant c is chosen in a such way that $\int h(x)\,dx = 0$. If, instead, $\frac{1}{2} < \delta < \frac{7}{2}$, $\delta \neq \frac{3}{2}, \frac{5}{2}$, then we simply set $f(x) = h(x)$. In any case, we deduce from Proposition 3.1 that $h \in X_\delta$ and $||h||_{X_\delta} \leq C||f||_{Z_\delta}$ for some constant C depending only on δ.

We start showing that $\nabla e^{t\Delta}\mathbb{P}g$ belongs to X_δ for all $0 \leq \delta < \frac{9}{2}$. Note that the components of $(\nabla e^{t\Delta}\mathbb{P}g)\widehat{\ }(\xi)$ are given by

$$\mathrm{i}\xi_h\left(\delta_{j,k} - \frac{\xi_j \xi_k}{|\xi|^2}\right) \exp(-(t+1)|\xi|^2) \qquad (j,h,k = 1,2,3, \quad \delta_{j,k} = 0 \text{ or } 1),$$

and the inverse Fourier transform can be easily computed (see, e.g., [17]). We immediately find that $\nabla e^{t\Delta}\mathbb{P}g$ is a smooth function in $\mathbb{R}^3$, such that

$$|\partial^\alpha \nabla e^{t\Delta}\mathbb{P}g(x)| \le C_\alpha (1+|x|)^{-(4+|\alpha|)} \qquad \text{for all } \alpha \in \mathbb{N}^3.$$

This bound implies that $e^{t\Delta}\mathbb{P}\nabla g \in Z_\delta$, for $0 \le \delta < \frac{9}{2}$. But $\int \nabla e^{t\Delta}\mathbb{P}g = 0$ (the Fourier transform of the integrand vanishes at the origin) and thus $\nabla e^{t\Delta}\mathbb{P}g$ belongs, more precisely, to X_δ.

Let us now prove that $\nabla e^{t\Delta}\mathbb{P}h$ does also belong to X_δ. The only difficulty is for $\frac{3}{2} < \delta < \frac{9}{2}$, $\delta \ne \frac{5}{2}, \frac{7}{2}$. Indeed, if $\frac{1}{2} < \delta < \frac{3}{2}$, then one observes that the weight $(1+|x|^2)^\delta$ belongs to the Muckenhoupt class A_2; see [18]. This implies that $\mathbb{P}$, and more generally the Riesz transforms, are bounded in $L^2(\mathbb{R}^3, (1+|x|^2)^\delta dx)$. Since $\nabla e^{t\Delta}\mathbb{P}$ and the Laplacian commute, the result easily follows applying this remark to Δh.

To deal with the case $\delta > \frac{3}{2}$, we start by recalling that the Sobolev space H^δ is defined by

$$||q||^2_{H^\delta} \equiv \int |\widehat{q}(\xi)|^2 (1+|\xi|^2)^\delta \, d\xi$$

and that $H^\delta \subset C^{\delta - 3/2}$ (the Hölder–Zygmund space). Thus, stating that h belongs to X_δ is equivalent to stating that

$$q(\xi) \equiv |\xi|^2 \widehat{h}(\xi) \in H^\delta \qquad \text{and} \qquad \partial^\alpha q(0) = 0 \quad \text{ for all } 0 \le |\alpha| \le \left[\delta - \frac{3}{2}\right].$$

These two conditions on q can be expressed by saying that q belongs to $L^2(\mathbb{R}^3) \cap \dot{H}^\delta_{rel}$, where $\dot{H}^\delta_{rel}$ is the realization of the homogeneous Sobolev space $\dot{H}^\delta$ (see Bourdaud [3]). Recall that $\dot{H}^\delta_{rel}$ can be injected into $\mathcal{S}'(\mathbb{R}^3)$ (this would not be true for $\dot{H}^\delta$, which is instead a space of tempered distributions modulo polynomials) and hence the notion of pointwise multipliers makes sense in the realized space. It follows from the result of [3] that $m(\xi) \equiv \xi_j/|\xi|$ is a multiplier for $\dot{H}^\delta_{rel}$ (any homogeneous function of degree 0 which is smooth outside the origin is indeed a multiplier for this space).

Since $h \in X_\delta$, the components of $|\xi|^2 \widehat{\mathbb{P}h}(\xi)$, which are given by $(\delta_{j,k} - \xi_j \xi_k |\xi|^{-2}) q(\xi)$, belong to $L^2(\mathbb{R}^3) \cap \dot{H}^\delta_{rel}$. Hence, $\mathbb{P}h \in X_\delta$. Moreover, $\mathrm{i}\xi_h e^{-t|\xi|^2} \in \mathcal{S}(\mathbb{R}^3)$ is also a multiplier of $\dot{H}^\delta_{rel}$ (with norm $c/\sqrt{t}$). Then we get $||\nabla e^{t\Delta}\mathbb{P}f||_{X_\delta} \le Ct^{-1/2}||f||_{Z_\delta}$ and Lemma 4.1 is thus proven. □

Our last lemma deals with the case $\delta = \frac{1}{2}$.

Lemma 4.2. *The operator $\nabla e^{t\Delta}\mathbb{P}$ is bounded in $Z_{1/2}$ for all $t > 0$, with operator norm $O(t^{-1/2})$ as $t \to 0$.*

Proof. Following Miyakawa's notations, we denote by $F(x,t)$ the kernel of the operator $\nabla e^{t\Delta}\mathbb{P}$. Then we know that $F(x,t) = t^{-2}\Phi(x/\sqrt{t})$, where Φ is smooth in $\mathbb{R}^3$ and $|\Phi(x)| \le C(1+|x|)^{-4}$ (see again [17] for more details). Let us show that $||\Phi * f||_{Z_{1/2}} \le C||f||_{Z_{1/2}}$. Then the conclusion will follow from a simple rescaling argument.

Let $f \in Z_{1/2}$ and write $f = g + \sum_{j=0}^\infty f_j$, where g and f_j satisfy (2.2). We also know that $|f_j(x)| \le \epsilon_j$ for all $x \in \operatorname{supp} f_j$ (we saw this right after (2.3)), with $\epsilon_j \in \ell^2(\mathbb{N})$. We obviously have $\Phi * g \in Z_{1/2}$ and $\Phi * f \in L^\infty(\mathbb{R}^3)$. Now let $2^k \le |x| \le 2^{k+1}$ ($k \in \mathbb{N}$, $k \ge 3$). Using the decay of Φ we see that $\Phi * f_j$ is bounded by $C\epsilon_j 2^{-4k}2^{3j}$ ($j \le k-3$) and $C\epsilon_j 2^{-j}$ ($j \ge k+3$). Thus $|\Phi * f(x)| \le \tilde{\epsilon}_k$, with $\tilde{\epsilon}_k \in \ell^2(\mathbb{N})$, and we conclude that $\int |\Phi * f(x)|^2 (1+|x|^2)^{-3/2} \, dx$ is finite.

Moreover, by Young's inequality,

$$\begin{aligned}
&\int |\nabla\Phi * f(x)|^2(1+|x|^2)^{-1/2}dx \\
&\qquad \le C\biggl(\int |\Phi(x)|(1+|x|)^{1/2}dx\biggr)^2 \int |\nabla f(x)|^2(1+|x|^2)^{-1/2}dx, \\
&\int |\Delta\Phi * f(x)|^2(1+|x|^2)^{1/2}dx \\
&\qquad \le C\biggl(\int |\Phi(x)|(1+|x|)^{1/2}dx\biggr)^2 \int |\Delta f(x)|^2(1+|x|^2)^{1/2}dx
\end{aligned}$$

(we also used $(1+|x|)^{-1/2} \le c(1+|y|)^{-1/2}(1+|x-y|)^{1/2}$ in the first inequality and $(1+|x|)^{1/2} \le c(1+|y|)^{1/2}(1+|x-y|)^{1/2}$ in the second inequality). Lemma 4.2 now follows. ∎

Proof of Theorem 1.1. The proof is based on the application of Kato's standard iteration argument in the space $C([0,T],Z_\delta)$. Let us write (IE) in the compact form $u(t) = e^{t\Delta}a - B(u,u)$, where $B(u,v) = \int_0^t \nabla \cdot e^{(t-s)\Delta}\mathbb{P}(u \otimes v)(s)\,ds$.

By Lemmas 4.1 and 4.2, and using the fact that Z_δ is a pointwise algebra for $\delta \ge \frac{1}{2}$, we see that the bilinear operator B is bounded in $C([0,T],Z_\delta)$ for $\frac{1}{2} \le \delta < \frac{9}{2}$, $\delta \ne \frac{3}{2}, \frac{5}{2}, \frac{7}{2}$, (the continuity with respect to the time variable is straightforward). Moreover, $\|B(u,v)\|_\delta \le C_T \|u\|_\delta\, \|v\|_\delta$, where $\|w\|_\delta \equiv \sup_{t\in[0,T]} ||w(t)||_{Z_\delta}$ and $C_T = O(T^{1/2})$ as $t \to 0$. We get the same conclusion for $\delta = \frac{3}{2}, \frac{5}{2}, \frac{7}{2}$ if we use the continuous embedding $Z_\delta \subset Z_{\delta'}$ $(\delta \ge \delta')$ and the stronger version of Lemma 2.3. For example,

$$\|B(u,v)\|_{3/2} \le C\|B(u,v)\|_2 \le CT^{1/2}\|u\|_{5/4}\|v\|_{5/4} \le CT^{1/2}\|u\|_{3/2}\|v\|_{3/2},$$

and a similar argument can be used for $\delta = \frac{5}{2}, \frac{7}{2}$.

Since $e^{t\Delta}a$ belongs to $C([0,T],Z_\delta)$ if $a \in Z_\delta$ for all $\delta \ge 0$, as is easily checked, we see that the fixed point argument applies in $C([0,T],Z_\delta)$, at least if $T > 0$ is small enough. ∎

We state as a corollary a slight improvement of Furioli and Terraneo's theorem.

Corollary 4.3. *Let $\frac{1}{2} < \delta < \frac{9}{2}$ and $a \in X_\delta$. Then there exists $T > 0$ such that* (IE) *can be uniquely solved in $C([0,T],X_\delta)$.*

Proof. The result is true for $\frac{1}{2} < \delta < \frac{7}{2}$ and $\delta \ne \frac{3}{2}, \frac{5}{2}$ because of the identification between X_δ and Z_δ. For $\frac{7}{2} < \delta < \frac{9}{2}$ we use the fact that every divergence-free vector field which is in $L^1(\mathbb{R}^3)$ must have a vanishing integral. Hence the existence and unicity result for (IE) in X_δ again follows from the corresponding result in Z_δ and the last conclusion of Proposition 3.1.

In the case $\delta = \frac{3}{2}$ we can observe that if $u, v \in C([0,T],X_{3/2})$, then $B(u,v)$ belongs, e.g., to $C([0,T],Z_2)$, which is contained in $C([0,T],X_{3/2})$. A similar argument can be used for $\delta = \frac{5}{2}, \frac{7}{2}$ and the conclusion easily follows. ∎

As claimed in the introduction, the restriction $\delta < \frac{9}{2}$ cannot be removed in Theorem 1.1. Indeed, if u is a solution to (IE) such that $u \in C([0,T],Z_{9/2})$, for some $T > 0$, then the initial datum must satisfy the conditions of Dobrokhotov and Shafarevich: $\int (a_j a_k) = 0$ if $j \ne k$ and $\int a_1^2 = \int a_2^2 = \int a_3^2$. This is due to the fact that the localization condition $a \in L^2(\mathbb{R}^3, (1+|x|^2)^{5/2}dx)$ is not conserved during the evolution (see [6]). For the same reason, the condition $a \in X_\delta$, $\delta > \frac{9}{2}$ breaks down (in general). But we do not know if the condition $a \in X_{9/2}$ (or $a \in X_{1/2}$) propagates.

We conclude by observing that spatially localized flows $u(t)$, belonging to Z_δ and X_δ with $\delta > \frac{9}{2}$, do, however, exist. Examples of such flows can be found in [4].

Acknowledgment. The author would like to thank the three referees for their remarks and useful comments, which helped him to improve the first version of this paper in a number of ways.

WILSON BASES FOR GENERAL TIME-FREQUENCY LATTICES*

GITTA KUTYNIOK† AND THOMAS STROHMER‡

Abstract. Motivated by a recent generalization of the Balian–Low theorem and by new research in wireless communications, we analyze the construction of Wilson bases for general time-frequency lattices. We show that orthonormal Wilson bases for $L^2(\mathbb{R})$ can be constructed for any time-frequency lattice whose volume is $\frac{1}{2}$. We then focus on the spaces $\ell^2(\mathbb{Z})$ and $\mathbb{C}^L$ which are the preferred settings for numerical and practical purposes. We demonstrate that with a properly adapted definition of Wilson bases the construction of orthonormal Wilson bases for general time-frequency lattices also holds true in these discrete settings. In our analysis we make use of certain metaplectic transforms. Finally, we discuss some practical consequences of our theoretical findings.

Key words. Wilson basis, metaplectic transform, Gabor frame, Schrödinger representation, time-frequency lattice

1. Introduction. Gabor systems have become a popular tool, both in theory and in applications; e.g., see [12, 18, 13]. However, one drawback is that due to the *Balian–Low theorem* it is impossible to construct (orthogonal) Gabor bases for $L^2(\mathbb{R})$ with good time-frequency localization [18]. In [33, 9] it has been shown that a modification of Gabor bases, so-called *Wilson bases*, provide a means to circumvent the Balian–Low theorem. Indeed, there exist orthogonal Wilson bases for $L^2(\mathbb{R})$ whose basis functions have exponential decay in time and frequency. These Wilson bases can be constructed from certain tight Gabor frames with redundancy 2.

Gabor frames are usually associated with rectangular time-frequency lattices, but they can also be defined for general nonseparable lattices; see, e.g., [10, 17, 11, 28]. Recently it has been shown that such a generalization of Gabor frames to general time-frequency lattices does not enable us to overcome the Balian–Low theorem [19, 2]. This leads naturally to the question of whether it is possible to extend the construction of Wilson bases to general time-frequency lattices.

Another motivation for the research presented in this paper has its origin in wireless communication. Orthogonal frequency division multiplexing (OFDM) is a wireless transmission technology employing a set of transmission functions which is usually associated with a rectangular time-frequency lattice [14]. The connection to Gabor theory is given by the fact that the collection of transmission pulses in OFDM can be interpreted as a Gabor system; see [27, 30]. The density of the associated rectangular time-frequency lattice can be seen as a measure of the spectral efficiency in terms of number of bits transmitted per Hertz per second. The necessary condition of linear independence of the transmission functions implies that we are dealing with either an undersampled or a critically sampled Gabor system.

For wireless channels that are time-dispersive (due to multipath) and frequency-dispersive (due to the Doppler effect), good time-frequency localization of the transmission pulses is essential to mitigate the interferences caused by the dispersion of the channel [27, 30]. The ideal set of transmission pulses should therefore possess (i) good time-frequency localization and (ii) maximize the spectral efficiency; i.e., the transmission functions should correspond to a (critically sampled) Gabor basis for $L^2(\mathbb{R})$. As we know, the Balian–Low theorem prohibits these conditions to be fulfilled simultaneously.

Recently it has been shown that in case of time-frequency dispersive channels the performance of OFDM can be improved when using general time-frequency lattices, in particular hexagonal-type lattices [31]. In a nutshell, lattices that are adapted to the shape of the Wigner distribution of the transmission pulses allow for a better "packing" of the time-frequency plane, which in turn can be used to either achieve higher data rates or improve interference robustness of the associated so-called Lattice-OFDM system.

One variation of OFDM (for rectangular lattices) is called offset quadrature amplitude modulation (OQAM) OFDM. It corresponds to using a Wilson basis as a set of transmission functions [4]. OQAM-OFDM achieves maximal spectral efficiency and allows for transmission functions with good time-frequency localization. As in the case of standard OFDM, it would be potentially useful for time-frequency dispersive channels to extend OQAM-OFDM to general time-frequency lattices in order to improve the robustness of OQAM-OFDM against interference even further. Thus we again arrive at the problem of constructing Wilson bases for general nonseparable time-frequency lattices.

Yet another motivation comes from filter bank theory, more precisely cosine-modulated filter banks [6]. We know that discrete-time Wilson bases correspond to a special class of cosine-modulated filter banks (see [6]). In light of the improvements gained by using general time-frequency lattices in OFDM [31], it would be interesting to analyze if the construction of cosine-modulated filter banks can be extended to general time-frequency lattices. A positive answer to this question might lead to a more efficient encoding of signals and images.

Since our goal to construct Wilson bases for general time-frequency lattices is in part motivated by applied problems and since any numerical implementation of Wilson bases is based on a discrete model, our analysis will not only concern $L^2(\mathbb{R})$ but also comprise the spaces $\ell^2(\mathbb{Z})$ and $\mathbb{C}^L$. Furthermore, $\ell^2(\mathbb{Z})$ is the appropriate setting when Wilson bases are utilized as filter banks, since in this case one deals with sampled, thus discrete-time, signals.

1.1. Notation. We assume that the reader is familiar with the theory of Gabor frames and refer to [18] for background and details.

A lattice Λ in $\mathbb{R}^d$ is a discrete subgroup with compact quotient; i.e., there exists a matrix $A \in GL(d, \mathbb{R})$ such that $\Lambda = A\mathbb{Z}^d$. The matrix A is called the (nonunique) generator matrix for Λ. The volume of Λ is $\mathrm{vol}(\Lambda) = |\det(A)|$. Two lattices, which play a crucial role in OFDM design (see [31]), are the rectangular lattice Λ_R and the hexagonal lattice Λ_H. A generator matrix for Λ_R is given by

$$A_R = \begin{bmatrix} T & 0 \\ 0 & F \end{bmatrix},$$

and a generator matrix for Λ_H is given by

$$A_H = \begin{bmatrix} \frac{\sqrt{2}}{\sqrt[4]{3}}T & \frac{\sqrt{2}}{2\sqrt[4]{3}}T \\ 0 & \frac{\sqrt[4]{3}}{\sqrt{2}}F \end{bmatrix},$$

where $T, F > 0$. An easy calculation shows that both lattices Λ_R and Λ_H have the same volume TF. A normal form for matrices, which we will use in the following, is the so-called Hermite normal form [20]. We say that a matrix $A = [\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}]$ is in *Hermite normal form* if $c = 0$, $a, d > 0$, and $0 \le b < a$. For example, both matrices A_R and A_H are in Hermite normal form.

For $(x, y) \in \mathbb{R}^2$ and $g \in L^2(\mathbb{R})$, let $g_{x,y}$ be defined by

$$g_{x,y}(t) = e^{2\pi i y t} g(t - x).$$

We denote by $\mathcal{G}(g, \Lambda)$ the system of functions given by

$$g_{\lambda,\mu}(t) = g(t - \lambda) e^{2\pi i t \mu}, \qquad (\lambda, \mu) \in \Lambda.$$

As usual, the *redundancy* of $\mathcal{G}(g, \Lambda)$ is given by $\frac{1}{\mathrm{vol}(\Lambda)}$.

As in [18], we define the *Schrödinger representation* $\rho : \mathbb{H} \to \mathcal{U}(L^2(\mathbb{R}))$ by

$$\rho(x, y, z) g(t) = e^{2\pi i z} e^{-\pi i x y} e^{2\pi i y t} g(t - x).$$

Note that

$$g_{x,y} = e^{\pi i x y} \rho(x, y, 1) g. \tag{1.1}$$

Furthermore, we use the following notation from [18] (with slight changes):

$$\mathcal{J} = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}, \quad \mathcal{B}_b = \begin{bmatrix} b & 0 \\ 0 & \frac{1}{b} \end{bmatrix}, \quad \mathcal{C}_c = \begin{bmatrix} 1 & 0 \\ c & 1 \end{bmatrix}.$$

$\mathcal{F}$ and $^\wedge$ denote the Fourier transform, $\mathcal{F}^{-1}$ and $^\vee$ denote the inverse Fourier transform. The dilation is given by $\mathcal{D}_b f(t) = |b|^{\frac{1}{2}} f(bt)$ and the "chirp" operator is defined via $\mathcal{N}_c f(t) = e^{-\pi i c t^2} f(t)$, where $b, c \in \mathbb{R}$ and $f \in L^2(\mathbb{R})$.

Metaplectic transforms will turn out to be a very useful tool in our analysis. For the study of the discrete and finite case, we need a result on metaplectic transforms from [24]. Since this thesis is not easy to access, we present the result here in the slightly weaker version we will use, together with the necessary definitions and notations. The result will be stated in the situation of a general locally compact abelian group G with dual group $\widehat{G}$, group multiplication denoted by $+$, and action of $\widehat{G}$ on G denoted by $\langle x, \chi \rangle$ for $x \in G$ and $\chi \in \widehat{G}$. The cases we are interested in later on are $G = \mathbb{Z}$ and $G = \mathbb{Z}_L$. We will usually write a metaplectic transform σ in the matrix notation $\sigma = [\begin{smallmatrix} \alpha & \beta \\ \gamma & \delta \end{smallmatrix}] \in \mathrm{Hom}(G \times \widehat{G})$, which means that $\alpha \in \mathrm{Hom}(G)$, $\beta \in \mathrm{Hom}(\widehat{G}, G)$, $\gamma \in \mathrm{Hom}(G, \widehat{G})$, and $\delta \in \mathrm{Hom}(\widehat{G})$. Then the *adjoint* σ^* is defined by $\langle (x, \chi), \sigma^*(y, \pi) \rangle = \langle \sigma(x, \chi), (y, \pi) \rangle$ for all $(x, \chi), (y, \pi) \in G \times \widehat{G}$. Let η be defined by $\eta = [\begin{smallmatrix} 0 & -I_{\widehat{G}} \\ I_G & 0 \end{smallmatrix}] \in \mathrm{Hom}(G \times \widehat{G}, \widehat{G} \times G)$, where the above definition concerning the matrix notation has to be adapted in an obvious way, and where I_G and $I_{\widehat{G}}$ denote the identity on G and $\widehat{G}$, respectively. Then σ is called *symplectic* if $\sigma^* \eta \sigma = \eta$. If $\zeta \in \mathrm{Hom}(G \times \widehat{G}, \widehat{G} \times G)$, then ψ is a *second degree character* of $G \times \widehat{G}$ associated to

ζ if $\psi((x,\chi)+(y,\pi)) = \psi(x,\chi)\psi(y,\pi)\,\langle (x,\chi),\zeta(y,\pi)\rangle$ for all $(x,\chi),(y,\pi) \in G \times \widehat{G}$. Moreover, for $(x,\chi) \in G \times \widehat{G}$ and $g \in L^2(G)$, let $g_{x,\chi}$ be defined by

$$g_{x,\chi}(t) = \chi(t)g(t-x),$$

which generalizes the previous definition.

We can now state the version of [24, Theorem 1.1.28] which we will employ in sections 3 and 4.

THEOREM 1.1. *Let* $\sigma := [\begin{smallmatrix} \alpha & \beta \\ \gamma & \delta \end{smallmatrix}] \in \mathrm{Hom}(G \times \widehat{G})$ *be symplectic and let* ψ_ζ *be a second degree character of* $G \times \widehat{G}$ *associated to*

$$\zeta := \sigma^* \begin{bmatrix} 0 & 0 \\ I_G & 0 \end{bmatrix} \sigma - \begin{bmatrix} 0 & 0 \\ I_G & 0 \end{bmatrix} \in \mathrm{Hom}(G \times \widehat{G}, \widehat{G} \times G).$$

If U *is defined by*

$$Uf(t) := \int_{\widehat{G}} f(\alpha t + \beta\omega)\psi_\zeta^{-1}(t,\omega)d\omega,$$

then we have

$$(Uf)_{x,\chi}(t) = \psi_\zeta^{-1}(x,\chi)Uf_{\sigma(x,\chi)}(t), \quad (x,\chi) \in G \times \widehat{G}.$$

2. Wilson bases for general lattices—the continuous case. We first show that all lattices in $\mathbb{R}^2$ which are important for applications, such as the rectangular lattice, the hexagonal lattice, and lattices whose generator matrix has rational entries, possess a uniquely determined matrix in Hermite normal form, which we will call the *canonical generator matrix*. In particular, we characterize exactly those lattices which possess a generator matrix in Hermite normal form.

We then show that it is possible to construct orthonormal Wilson bases for time-frequency lattices Λ with $\mathrm{vol}(\Lambda) = \frac{1}{2}$ which possess a generator matrix in Hermite normal form. In principle Wilson systems can be defined for lattices Λ with $\mathrm{vol}(\Lambda) \neq \frac{1}{2}$; however, so far all known constructions of *orthogonal Wilson bases* for $L^2(\mathbb{R})$ are strictly tied to lattices with volume $\frac{1}{2}$. In light of this fact, throughout this paper a Wilson system will always be associated with a time-frequency lattice of volume $\frac{1}{2}$.

LEMMA 2.1. *Let* Λ *be a lattice in* $\mathbb{R}^2$. *Then the following conditions are equivalent.*

(i) $P_2(\Lambda)$ *is discrete, where* $P_2 : \mathbb{R}^2 \to \mathbb{R}$, $(x,y) \mapsto y$.

(ii) *There exists a generator matrix* A *for* Λ *which is in Hermite normal form.*

If one of these conditions is satisfied, the matrix A *is uniquely determined.*

Proof. Let

$$A' = \begin{bmatrix} a' & b' \\ c' & d' \end{bmatrix}$$

be an arbitrary generator matrix for Λ.

First we prove that (ii) implies (i). By (ii), there exists a matrix

$$A = \begin{bmatrix} a & b \\ 0 & d \end{bmatrix},$$

which is in Hermite normal form and which satisfies $A\mathbb{Z}^2 = \Lambda$. Thus $P_2(\Lambda) = d\mathbb{Z}$, which yields (i).

Next we show (i) $\Rightarrow$ (ii). For this, we construct a matrix

$$A = \begin{bmatrix} a & b \\ 0 & d \end{bmatrix},$$

which satisfies the claimed properties. Without loss of generality we assume that $d' \neq 0$ (if $d' = 0$ and $c' \neq 0$ we could change the columns of A'). We begin with the following observation. Assume that $\frac{c'}{d'}$ is not rational. Since $P_2(\Lambda)$ is a nontrivial discrete, additive subgroup of $\mathbb{R}$, hence a lattice, there exists $s \in \mathbb{R}\backslash\{0\}$ such that $P_2(\Lambda) = s\mathbb{Z}$. Thus $c' = sm$ and $d' = sn$ for some $m, n \in \mathbb{Z}$, a contradiction. This implies that the quotient $\frac{c'}{d'}$ is rational. Setting $\frac{c'}{d'} = \frac{k}{l}$, $k, l \in \mathbb{Z}$ with $\gcd(k, l) = 1$, and factoring out $\frac{d'}{l}$, without loss of generality we can assume that A' is of the form

$$A' = r \begin{bmatrix} a' & b' \\ c' & d' \end{bmatrix},$$

with $a', b', r \in \mathbb{R}$ and $c', d' \in \mathbb{Z}$. Now we proceed as follows. First we set $p := \gcd(c', d') > 0$. We then obtain

$$A' \begin{bmatrix} \pm\frac{d'}{p} \\ \mp\frac{c'}{p} \end{bmatrix} = \begin{bmatrix} \pm\frac{r\det(A')}{p} \\ 0 \end{bmatrix} \in \Lambda,$$

since $\frac{c'}{p}, \frac{d'}{p} \in \mathbb{Z}$. Hence we can define a by $a := \left|\frac{r\det(A')}{p}\right| > 0$.

In a second step we compute b and d. Since $\frac{c'}{p}$ and $\frac{d'}{p}$ are relative prime, there exist $m, n \in \mathbb{Z}$ such that $\frac{c'}{p}m + \frac{d'}{p}n = 1$ (see [22, Theorem 4.4]). Hence $c'm + d'n = p$ and we obtain

$$A' \begin{bmatrix} m \\ n \end{bmatrix} = \begin{bmatrix} r(a'm + b'n) \\ rp \end{bmatrix} \in \Lambda.$$

Now let $k \in \mathbb{Z}$ be chosen in such a way that $0 \leq r(a'm + b'n) + ka < a$ and define $b := ka + r(a'm + b'n)$ and $d := rp$. Without loss of generality we can assume that $d > 0$, since otherwise we just take $-m$ and $-n$ instead of m and n. Then

$$\begin{bmatrix} b \\ d \end{bmatrix} = \begin{bmatrix} r(a'm + b'n) \\ rp \end{bmatrix} + k \begin{bmatrix} a \\ 0 \end{bmatrix} \in \Lambda$$

and $|ad| = |\frac{r\det(A')}{p}|rp = |r^2\det(A')|$. This proves that A generates Λ and is in Hermite normal form.

At last we prove that the matrix in condition (ii) is uniquely determined. For this, assume there exist $a, b, d, a', b', d' \in \mathbb{R}$ with $a, a', d, d' > 0$, $0 \leq b < a$, and $0 \leq b' < a'$ such that

$$\Lambda = A\mathbb{Z}^2 = A'\mathbb{Z}^2, \tag{2.1}$$

where

$$A = \begin{bmatrix} a & b \\ 0 & d \end{bmatrix} \quad \text{and} \quad A' = \begin{bmatrix} a' & b' \\ 0 & d' \end{bmatrix}.$$

By (2.1), there exist $m, n \in \mathbb{Z}$ with $a' = ma + nb$ and $0 = nd$, which implies that $a' = ma$. Again by (2.1), we can find $k, l \in \mathbb{Z}$ such that $b' = ka + lb$ and $d' = ld$. Since

$\mathrm{vol}(\Lambda) = |ad| = |a'd'|$, we obtain $|ml| = 1$. Now $a, a', d, d' > 0$ implies that $a = a'$, $d = d'$, and $l = 1$. Finally, applying this to $b' = ka + lb$ and using that $0 \leq b < a$ and $0 \leq b' < a'$ yields $b = b'$. Thus, we have shown that $A = A'$, which completes the proof. □

In the following, we restrict our attention to lattices which possess a generator matrix in Hermite normal form. All results in the situation $L^2(\mathbb{R})$ could be derived (in the same manner, but with much more technical effort) for general lattices, but with little or no practical benefit.

Definition 2.2. *Let Λ be a lattice in $\mathbb{R}^2$ which satisfies the conditions of Lemma* 2.1. *Then the uniquely determined generator matrix A of Lemma* 2.1 *is called the* canonical generator matrix *for Λ.*

Now let Λ be a lattice with $\mathrm{vol}(\Lambda) = \frac{1}{2}$ which possesses a generator matrix in Hermite normal form. Using the definition of a canonical generator matrix, we define a Wilson system associated with Λ as follows.

Definition 2.3. *If $\mathcal{G}(g, \Lambda) \subseteq L^2(\mathbb{R})$ is a Gabor system of redundancy* 2 *and*

$$A = \begin{bmatrix} a & b \\ 0 & d \end{bmatrix}$$

is the canonical generator matrix for the lattice Λ, then the associated Wilson system $\mathcal{W}(g, \Lambda, L^2(\mathbb{R})) = \{\psi^\Lambda_{m,n}\}_{m\in\mathbb{Z}, n\geq 0}$ *consists of the functions*

$$\begin{aligned} \psi^\Lambda_{m,0} &= g_{2ma,0} && \text{if } n = 0, \\ \psi^\Lambda_{m,n} &= \tfrac{1}{\sqrt{2}} e^{-\pi i b d n^2} (g_{ma+nb,nd} + g_{ma-nb,-nd}) && \text{if } n \neq 0,\ m+n \text{ even}, \\ \psi^\Lambda_{m,n} &= \tfrac{i}{\sqrt{2}} e^{-\pi i b d n^2} (g_{ma+nb,nd} - g_{ma-nb,-nd}) && \text{if } n \neq 0,\ m+n \text{ odd}. \end{aligned}$$

If the system $\mathcal{W}(g, \Lambda, L^2(\mathbb{R}))$ is an orthonormal basis for $L^2(\mathbb{R})$ we call it a Wilson (orthonormal) basis.

We will see that this definition reduces to the usual definition of Wilson systems. For this, we consider the rectangular lattice

$$\Gamma = \{(\tfrac{m}{2}, n)\}_{m,n\in\mathbb{Z}}.$$

It is an easy calculation to show that the canonical generator matrix for Γ is

$$A = \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & 1 \end{bmatrix}.$$

Thus, for each $g \in L^2(\mathbb{R})$, the Wilson system $\mathcal{W}(g, \Gamma, L^2(\mathbb{R}))$ consists indeed of the functions

$$\begin{aligned} \psi^\Gamma_{m,0} &= g_{m,0} && \text{if } n = 0, \\ \psi^\Gamma_{m,n} &= \tfrac{1}{\sqrt{2}} (g_{m/2,n} + g_{m/2,-n}) && \text{if } m+n \text{ is even}, \\ \psi^\Gamma_{m,n} &= \tfrac{i}{\sqrt{2}} (g_{m/2,n} - g_{m/2,-n}) && \text{if } m+n \text{ is odd}, \end{aligned}$$

which coincides with the usual definition of Wilson systems; cf., for instance, [18, Definition 8.5.1]. Notice that we will fix the notation Γ for the remainder.

We will make use of the following well-known theorem about a Wilson system for rectangular lattices to constitute an orthonormal basis (e.g., cf. [3, Theorem 4.1]).

Theorem 2.4. *Suppose that $g \in L^2(\mathbb{R})$ is such that*

(i) $\hat{g}$ *is real-valued and*

(ii) $\{g_{m/2,n}\}_{m,n\in\mathbb{Z}}$ *is a tight Gabor frame for* $L^2(\mathbb{R})$ *with frame bound* 2.

Then the system $\mathcal{W}(g,\Gamma,L^2(\mathbb{R}))$ *is a Wilson orthonormal basis for* $L^2(\mathbb{R})$.

We are now ready to extend the construction of Wilson bases for time-frequency lattices which possess a generator matrix in Hermite normal form.

THEOREM 2.5. *Let* Λ *be a lattice in* $\mathbb{R}^2$ *with* $\mathrm{vol}(\Lambda)=\frac{1}{2}$ *and canonical generator matrix*

$$A=\begin{bmatrix} a & b\\ 0 & d\end{bmatrix}.$$

Define U *by*

$$U:=\mathcal{D}_{1/d}\circ\mathcal{F}\circ\mathcal{N}_{-b/d}\circ\mathcal{F}^{-1}. \tag{2.2}$$

Let $g\in L^2(\mathbb{R})$ *be such that*

(i) $\widehat{Ug}$ *is real-valued and*

(ii) $\{g_{ma+nb,nd}\}_{m,n\in\mathbb{Z}}$ *is a tight frame for* $L^2(\mathbb{R})$ *with frame bound* 2.

Then the system $\mathcal{W}(g,\Lambda,L^2(\mathbb{R}))$ *is a Wilson orthonormal basis for* $L^2(\mathbb{R})$.

Proof. We will reduce our claim to Theorem 2.4 by using a metaplectic transform. We define $\mathcal{A}$ by

$$\mathcal{A}=\begin{bmatrix} d & -b\\ 0 & 2a\end{bmatrix}.$$

Then, for all $m,n\in\mathbb{Z}$, we have

$$\mathcal{A}(ma+nb,nd)=\left(\tfrac{1}{2}m,n\right). \tag{2.3}$$

Since $\mathcal{A}\in\mathrm{Sp}(2,\mathbb{R})$, we can apply [15, Theorem 4.51] and write

$$\mathcal{A}=B_d(-\mathcal{J})C_{b/d}\mathcal{J}.$$

By [18, Example 9.4.1] we obtain

$$\rho(x,y,1)g=U^{-1}\rho(\mathcal{A}(x,y),1)(Ug), \tag{2.4}$$

with U defined in (2.2). Using (1.1), (2.3), and (2.4), we compute

$$\begin{aligned} g_{ma+nb,nd}&=e^{\pi i(ma+nb)nd}\rho(ma+nb,nd,1)g\\ &=e^{\pi i(ma+nb)nd}U^{-1}\rho(\mathcal{A}(ma+nb,nd),1)(Ug)\\ &=e^{\pi i(ma+nb)nd}U^{-1}\rho(\tfrac{1}{2}m,n,1)(Ug). \end{aligned}$$

Using (1.1) again, we obtain

$$g_{ma+nb,nd}=e^{\pi i(ma+nb)nd}e^{-\pi i\frac{1}{2}mn}U^{-1}(Ug)_{\frac{m}{2},n}=e^{\pi ibdn^2}U^{-1}(Ug)_{\frac{m}{2},n}. \tag{2.5}$$

Since multiplication by a phase factor and applying a unitary operator to a tight frame preserves tightness (and frame bounds), it follows that condition (ii) is equivalent to $\{(Ug)_{m/2,n}\}_{m,n\in\mathbb{Z}}$ being a tight frame with frame bound 2. We need not deal with condition (i), since this states already that $\widehat{Ug}$ is real-valued. Applying Theorem 2.4 yields that the Wilson system $\mathcal{W}(Ug,\Gamma,L^2(\mathbb{R}))$ is an orthonormal basis.

Using now the metaplectic transform, i.e., (2.5), and the fact that U is a unitary operator, finishes the proof. □

We will conclude this section by providing an example which shows how we can compute a Wilson basis with excellent time-frequency localization for a special lattice, but this calculation can also be done for an arbitrary lattice.

Here we consider the hexagonal lattice Λ_H with generator matrix

$$A_H = \begin{bmatrix} \frac{\sqrt{2}}{\sqrt[4]{3}} & \frac{\sqrt{2}}{2\sqrt[4]{3}} \\ 0 & \frac{\sqrt[4]{3}}{\sqrt{2}} \end{bmatrix}.$$

This lattice was also used in [31]. Observe that since we have $0 \leq \frac{\sqrt{2}}{2\sqrt[4]{3}} < \frac{\sqrt{2}}{\sqrt[4]{3}}$, the matrix A_H is already the canonical generator matrix for Λ_H. First we define the function $h \in L^2(\mathbb{R})$ by

$$h(x) = (2\nu)^{\frac{1}{4}} e^{-\nu\pi x^2}.$$

By [18, Theorem 7.5.3], the set $\{h_{m/2,n}\}_{m,n\in\mathbb{Z}}$ is a frame for $L^2(\mathbb{R})$. Let S denote its frame operator and consider the function $\varphi \in L^2(\mathbb{R})$ given by

$$\varphi = \sqrt{2}\mathcal{F} \circ S^{-\frac{1}{2}} h. \tag{2.6}$$

Using [3, Theorem 4.6], this function coincides with the function considered in [9, section 4]. There it was shown that φ satisfies conditions (i) and (ii) of Theorem 2.4 and hence yields a Wilson basis in the sense of Theorem 2.4. Moreover, φ has exponential decay in time and frequency. To obtain a generating function for a Wilson basis with respect to Λ_H in the sense of Theorem 2.5, first observe that by the proof of Theorem 2.5, we only need to compute the function $g = U^{-1}\varphi$, where U is defined in (2.2). Then g automatically satisfies conditions (i) and (ii) of Theorem 2.5, and hence the system $\mathcal{W}(g, A_H, L^2(\mathbb{R}))$ is a Wilson orthonormal basis by Theorem 2.5. Thus we define $g \in L^2(\mathbb{R})$ by

$$g = \mathcal{F} \circ \mathcal{N}_{\frac{1}{\sqrt{3}}} \circ \mathcal{F}^{-1} \circ \mathcal{D}_{\frac{\sqrt[4]{3}}{\sqrt{2}}} \varphi = \sqrt{2}\mathcal{F} \circ \mathcal{N}_{\frac{1}{\sqrt{3}}} \circ \mathcal{D}_{\frac{\sqrt{2}}{\sqrt[4]{3}}} \circ S^{-\frac{1}{2}} h.$$

Let us mention that the function g has exponential decay in time and frequency. Thus we obtain a Wilson basis with respect to the lattice Λ with very good time-frequency localization. As already mentioned above, this procedure can be applied to an arbitrary lattice, hence we obtain a Wilson basis with excellent time-frequency localization for any lattice.

3. Wilson bases for general lattices—the discrete case. In this section we analyze the construction of Wilson bases for general time-frequency lattices for functions defined on $\ell^2(\mathbb{Z})$. The reasons for considering the setting $\ell^2(\mathbb{Z})$ are that, on the one hand, several applications such as filter bank design in digital signal processing deal directly with a discrete setting [6] and, on the other hand, even those problems that arise in the "continuous" setting of $L^2(\mathbb{R})$ require a discrete model for their numerical treatment. Thus, with these practical aspects in mind, throughout this section we naturally consider only lattices whose generator matrices have rational entries, since any implementation is intrinsically restricted to such "rationally" generated lattices. Another natural setting for numerical implementations is of course

$\mathbb{C}^L$ (which can be identified with the space of L-periodic sequences). We will analyze that case in the next section.

Before we proceed we define Gabor systems and Wilson systems on $\ell^2(\mathbb{Z})$ for general time-frequency lattices Λ with $\mathrm{vol}(\Lambda) = \frac{1}{2}$. First we prove that each lattice possesses a generator matrix of some particular form.

LEMMA 3.1. *Let Λ be a lattice in $\mathbb{Z} \times \mathbb{R}$ with generator matrix A given by*

$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \qquad \text{with } a, b \in \mathbb{Z},\ c, d \in \mathbb{Q}, \text{ and } \det(A) = \frac{1}{2},$$

and denote $c = \frac{p}{q}, d = \frac{p'}{q'}$ with $\gcd(p,q) = \gcd(p',q') = 1$, $p, q, p', q' \in \mathbb{Z}$. Then Λ possesses a uniquely determined generator matrix of the form

$$A' = \begin{bmatrix} \frac{N}{2} & b' \\ 0 & \frac{1}{N} \end{bmatrix}, \tag{3.1}$$

where $N = \frac{qq'}{\gcd(pq',p'q)}$ and $b' \in \mathbb{Z}$, $0 \le b' < \frac{N}{2}$.

Proof. We assume that $c \neq 0$, otherwise (3.1) is automatically satisfied. We first show that A can be written as

$$A = \begin{bmatrix} a & b \\ \frac{r}{N} & \frac{s}{N} \end{bmatrix}, \tag{3.2}$$

with integers r, s, N, such that $\gcd(r,s) = 1$.

Let $c = \frac{p}{q}, d = \frac{p'}{q'}$ with $p, p', q, q' \in \mathbb{Z}$, denote $N' := qq', \tilde{c} := pq', \tilde{d} := p'q$, and write $z = \gcd(\tilde{c}, \tilde{d})$. Since $a, b, \tilde{c}, \tilde{d} \in \mathbb{Z}$ and since

$$\mathrm{vol}(\Lambda) = \frac{1}{2} \Rightarrow a\tilde{d} - b\tilde{c} = \frac{N'}{2},$$

it follows that $\frac{N'}{2} \in \mathbb{Z}$. A necessary and sufficient condition for the equation $a\tilde{d} - b\tilde{c} = \frac{N'}{2}$ to have an integer solution in a and b is that $\gcd(\tilde{c}, \tilde{d}) | \frac{N'}{2}$ (see [22, Theorem 8.1]), hence $z | \frac{N'}{2}$. Denote $z' := \frac{N'}{2z}, r := \frac{\tilde{c}}{z}, s := \frac{\tilde{d}}{z}$. Then $c = \frac{r}{2z'}, d = \frac{s}{2z'}$ with $z' \in \mathbb{Z}$, and $\gcd(r,s) = 1$. By a proper choice of the signs of c and d we can always assume that z' is positive. By writing $N := 2z' \in \mathbb{Z}$ we see that A can indeed be written as in (3.2).

Now, assuming that A is of the form (3.2), we compute

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} Nd \\ -Nc \end{bmatrix} = \begin{bmatrix} N(ad - bc) \\ 0 \end{bmatrix} = \begin{bmatrix} \frac{N}{2} \\ 0 \end{bmatrix}.$$

Since $\gcd(r,s) = 1$ there exist integers m, n with $mr + ns = 1$. For such a pair (m,n) we denote $b' = am + bn$ and obtain

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} m \\ n \end{bmatrix} = \begin{bmatrix} am + bn \\ \frac{r}{N}m + \frac{s}{N}n \end{bmatrix} = \begin{bmatrix} b' \\ \frac{1}{N} \end{bmatrix}.$$

If $b' < 0$ or $b' \ge \frac{N}{2}$, we substitute the vector obtained by

$$\begin{bmatrix} b' \\ \frac{1}{N} \end{bmatrix} + k \begin{bmatrix} \frac{N}{2} \\ 0 \end{bmatrix} = \begin{bmatrix} b' + k\frac{N}{2} \\ \frac{1}{N} \end{bmatrix},$$

where $k \in \mathbb{Z}$ is chosen in such a way that $0 \leq b' + k\frac{N}{2} < \frac{N}{2}$. Consequently the matrix

$$\begin{bmatrix} \frac{N}{2} & b' \\ 0 & \frac{1}{N} \end{bmatrix} \tag{3.3}$$

generates the lattice Λ. Finally, since $\frac{N}{2}$ and b' are integers and $0 \leq b' < \frac{N}{2}$, the generator matrix in (3.3) is indeed of the form (3.1).

The fact that this is a unique representation follows immediately from the condition $0 \leq b' < \frac{N}{2}$. $\square$

Definition 3.2. *Let Λ be a lattice in $\mathbb{Z} \times \mathbb{R}$. Then the uniquely determined matrix A' of Lemma* 3.1 *is called the* canonical generator matrix *for Λ.*

In the following we will regard such a lattice as being in $\mathbb{Z} \times \mathbb{T}$ by considering $\Lambda = \{\frac{N}{2}m + bn, e^{2\pi i \frac{n}{N}}\}_{m\in\mathbb{Z},n=0,\dots,N-1}$. This is a very natural approach since, for all $k \in \mathbb{Z}$, we have

$$(\tfrac{N}{2}m + bn, \tfrac{1}{N}n + k) = (\tfrac{N}{2}(m - 2bk) + b(n + kN), \tfrac{1}{N}(n + kN)).$$

Hence the lattice $A'\mathbb{Z}^2$ is invariant under adding integers to the second component. Moreover, it is sufficient to restrict to the index set $\mathbb{Z} \times \{0, \dots, N-1\}$ since, for all $0 \leq n' < N$ and $k \in \mathbb{Z}$,

$$(\tfrac{N}{2}m + b(n' + kN), (n' + kN) \mod N) = (\tfrac{N}{2}(m + 2bk) + bn', n'),$$

which implies

$$\{(\tfrac{N}{2}m + bn, n \mod N)\}_{m,n\in\mathbb{Z}} = \{(\tfrac{N}{2}m + bn, n)\}_{m\in\mathbb{Z},n=0,\dots,N-1}$$

in the sense of sets.

Using the definition of canonical generator matrices we can now define Gabor systems for $\ell^2(\mathbb{Z})$.

Definition 3.3. *Let Λ be a lattice in $\mathbb{Z} \times \mathbb{T}$ with canonical generator matrix A given by*

$$A = \begin{bmatrix} \frac{N}{2} & b \\ 0 & \frac{1}{N} \end{bmatrix},$$

and let $g \in \ell_2(\mathbb{Z})$. Then the associated Gabor system $\{g_{m\frac{N}{2}+nb,n\frac{1}{N}}\}_{m\in\mathbb{Z},n=0,\dots,N-1}$ is given by

$$g_{m\frac{N}{2}+nb,n\frac{1}{N}}(l) = g(l - (m\tfrac{N}{2} + nb))e^{\frac{2\pi i l n}{N}}, \qquad l \in \mathbb{Z}.$$

We first give the definition of a Wilson basis associated with a lattice with diagonal canonical generator matrix, i.e., with $b = 0$ (in this special case the definition coincides with the one given in [5]).

Definition 3.4. *Let Λ be a lattice in $\mathbb{Z} \times \mathbb{T}$ with canonical generator matrix A given by*

$$A = \begin{bmatrix} \frac{N}{2} & 0 \\ 0 & \frac{1}{N} \end{bmatrix},$$

and let $g \in \ell_2(\mathbb{Z})$. Then the Wilson system $\mathcal{W}(g, \Lambda, \ell_2(\mathbb{Z})) = \{\psi_{m,n}\}_{m\in\mathbb{Z},n=0,\dots,\frac{N}{2}}$ is given by

$$\psi^{\Lambda}_{m,n} = g_{mN,n\frac{1}{N}} \qquad \text{if } m \in \mathbb{Z},\ n = 0, \tfrac{N}{2},$$

and for $m \in \mathbb{Z}$, $n = 1, \dots, \frac{N}{2} - 1$,

$$\begin{aligned}\psi^{\Lambda}_{m,n} &= \tfrac{1}{\sqrt{2}}(g_{m\frac{N}{2},n\frac{1}{N}} + g_{m\frac{N}{2},-n\frac{1}{N}}) \quad \textit{if } m+n \textit{ is even},\\ \psi^{\Lambda}_{m,n} &= \tfrac{i}{\sqrt{2}}(g_{m\frac{N}{2},n\frac{1}{N}} - g_{m\frac{N}{2},-n\frac{1}{N}}) \quad \textit{if } m+n \textit{ is odd}.\end{aligned}$$

The Zak transform, which can be defined for any locally compact abelian group (cf. [26]), will be employed to prove equivalent conditions for the Wilson system to form an orthonormal basis. In particular, we need the Zak transform on $\mathbb{T}$ with respect to the uniform lattice $K = \{e^{2\pi i \frac{2k}{N}} : k = 0, \dots, \frac{N}{2} - 1\}$ in $\mathbb{T}$, which is defined on the set of square-integrable functions on $\{e^{2\pi i t} : t \in [0, \frac{2}{N})\} \times \{0, \dots, \frac{N}{2} - 1\}$ by

$$Zf(e^{2\pi i t}, y) = \sum_{k=0}^{\frac{N}{2}-1} f(e^{2\pi i (t + \frac{2k}{N})}) e^{2\pi i \frac{2k}{N} y}.$$

The proof of the following proposition is inspired by the proof of [9, Proposition 5.2].

PROPOSITION 3.5. *Let* $g \in \ell_2(\mathbb{Z})$ *be such that* $\hat{g}$ *is real-valued and consider the lattice* Λ *with canonical generator matrix given by*

$$\begin{bmatrix} \frac{N}{2} & 0 \\ 0 & \frac{1}{N} \end{bmatrix}.$$

Then the following conditions are equivalent.

(i) $\{g_{m\frac{N}{2},n\frac{1}{N}}\}_{m\in\mathbb{Z},n=0,\dots,N-1}$ *is a tight frame for* $\ell_2(\mathbb{Z})$ *with frame bound* 2.

(ii) *We have* $|Z\hat{g}(e^{2\pi i t}, y)|^2 + |Z\hat{g}(e^{2\pi i (t+\frac{1}{N})}, y)|^2 = N$ *a.e.*

(iii) *For all* $j \in \{0, \dots, N-1\}$, *we have* $\sum_{l=0}^{N-1} \hat{g}(e^{2\pi i (t + \frac{l}{N})}) \hat{g}(e^{2\pi i (t + \frac{l+2j}{N})}) = N\delta_{j,0}$ *a.e.*

(iv) $\mathcal{W}(g, \Lambda, \ell_2(\mathbb{Z}))$ *is an orthonormal basis for* $\ell_2(\mathbb{Z})$.

Proof. Throughout this proof we choose the normalized Haar measure on $\mathbb{T}$, i.e., $m(E) = \int_0^1 1_E(e^{2\pi i t}) dt$, for all measurable $E \subseteq \mathbb{T}$ and the counting measure on its dual group $\widehat{\mathbb{T}} = \mathbb{Z}$. This choice ensures that the Plancherel formula for $\mathbb{T}$ holds.

Since we will mainly work in the Fourier domain, we first need to compute the Fourier transform of the elements of the Gabor system for the following calculations:

$$\begin{aligned}\widehat{g_{m\frac{N}{2},n\frac{1}{N}}}(e^{2\pi i t}) &= \sum_{l\in\mathbb{Z}} e^{2\pi i \frac{n}{N} l} g(e^{2\pi i (l - m\frac{N}{2})}) e^{-2\pi i l t}\\ &= e^{2\pi i \frac{mn}{2}} e^{-2\pi i t m \frac{N}{2}} \sum_{l\in\mathbb{Z}} g(e^{2\pi i l}) e^{-2\pi i l (t - \frac{n}{N})}\\ &= (-1)^{mn} \hat{g}_{n\frac{1}{N}, -m\frac{N}{2}}(e^{2\pi i t}).\end{aligned}$$

(i) $\Leftrightarrow$ (ii): Since the Fourier transform is a unitary operator, the Gabor system $\{g_{m\frac{N}{2},\frac{1}{N}n}\}_{m\in\mathbb{Z},n=0,\dots,N-1}$ is a tight frame for $\ell_2(\mathbb{Z})$ with frame bound 2 if and only if the Gabor system $\{\hat{g}_{n\frac{1}{N},m\frac{N}{2}}\}_{m\in\mathbb{Z},n=0,\dots,N-1}$ is a tight frame for $L^2(\mathbb{T})$ with frame bound 2. Then we write this set as the disjoint union $\{\hat{g}_{n\frac{2}{N},m\frac{N}{2}}\}_{m\in\mathbb{Z},n=0,\dots,\frac{N}{2}-1} \cup \{(T_{-\frac{1}{N}}\hat{g})_{n\frac{2}{N},m\frac{N}{2}}\}_{m\in\mathbb{Z},n=0,\dots,\frac{N}{2}-1} =: G_1 \cup G_2$, and let S_i denote the frame operator for G_i, $i = 1, 2$.

First we compute the frame operator S_1. For all $f \in L^2(\mathbb{T})$, using the Poisson summation formula [16, Theorem 4.42] applied to $H = \{e^{2\pi i k \frac{2}{N}} : k = 0, \dots, \frac{N}{2} - 1\}$, we obtain

$$
\begin{aligned}
S_1 f(e^{2\pi i t}) &= \sum_{m\in\mathbb{Z}} \sum_{n=0}^{\frac{N}{2}-1} \left\langle f, \hat{g}_{n\frac{2}{N}, m\frac{N}{2}} \right\rangle \hat{g}_{n\frac{2}{N}, m\frac{N}{2}}(e^{2\pi i t}) \\
&= \sum_{m\in\mathbb{Z}} \sum_{n=0}^{\frac{N}{2}-1} \int_0^1 f(e^{2\pi i s}) \overline{\hat{g}(e^{2\pi i (s - n\frac{2}{N})})} e^{-2\pi i m \frac{N}{2} s} ds \, \hat{g}(e^{2\pi i (t - n\frac{2}{N})}) e^{2\pi i m \frac{N}{2} t} \\
&= \sum_{n=0}^{\frac{N}{2}-1} \left[\sum_{m\in\mathbb{Z}} (\widehat{f\overline{T_{n\frac{2}{N}}\hat{g}}})(m\tfrac{N}{2}) e^{2\pi i m \frac{N}{2} t} \right] \hat{g}(e^{2\pi i (t - n\frac{2}{N})}) \\
&= \sum_{n=0}^{\frac{N}{2}-1} \tfrac{2}{N} \sum_{k=0}^{\frac{N}{2}-1} (f\overline{T_{n\frac{2}{N}}\hat{g}})(e^{2\pi i (t + k\frac{2}{N})}) \hat{g}(e^{2\pi i (t - n\frac{2}{N})}).
\end{aligned}
$$

Applying now the Zak transform yields

$$
\begin{aligned}
Z(S_1 f)(e^{2\pi i t}, y) &= \sum_{l=0}^{\frac{N}{2}-1} \tfrac{2}{N} \sum_{n,k=0}^{\frac{N}{2}-1} f(e^{2\pi i (t + \frac{2k+2l}{N})}) \overline{\hat{g}(e^{2\pi i (t + \frac{2k+2l-2n}{N})})} \hat{g}(e^{2\pi i (t + \frac{2l-2n}{N})}) e^{2\pi i \frac{2l}{N} y} \\
&= \tfrac{2}{N} \sum_{l,n,k=0}^{\frac{N}{2}-1} f(e^{2\pi i (t + \frac{2l+2n}{N})}) \overline{\hat{g}(e^{2\pi i (t + \frac{2l}{N})})} \hat{g}(e^{2\pi i (t + \frac{2l-2k}{N})}) e^{2\pi i \frac{2(l-k+n)}{N} y} \\
&= \tfrac{2}{N} \sum_{l=0}^{\frac{N}{2}-1} \overline{\hat{g}(e^{2\pi i (t + \frac{2l}{N})})} \left[\sum_{k=0}^{\frac{N}{2}-1} \hat{g}(e^{2\pi i (t + \frac{2l-2k}{N})}) e^{-2\pi i \frac{2k}{N} y} \right] \\
&\qquad \cdot \left[\sum_{n=0}^{\frac{N}{2}-1} f(e^{2\pi i (t + \frac{2n+2l}{N})}) e^{2\pi i \frac{2n}{N} y} \right] e^{2\pi i \frac{2l}{N} y} \\
&= \tfrac{2}{N} \overline{Z(\hat{g})(e^{2\pi i t}, y)} Z(\hat{g})(e^{2\pi i t}, y) Z(f)(e^{2\pi i t}, y).
\end{aligned}
$$

To compute the Zak transform of S_2, we can use the previous calculation, which yields

$$
\begin{aligned}
Z(S_2 f)(e^{2\pi i t}, y) &= \tfrac{2}{N} Z(f)(e^{2\pi i t}, y) |Z(T_{-\frac{1}{N}}\hat{g})(e^{2\pi i t}, y)|^2 \\
&= \tfrac{2}{N} Z(f)(e^{2\pi i t}, y) |Z(\hat{g})(e^{2\pi i (t + \frac{1}{N})}, y)|^2,
\end{aligned}
$$

since

$$
Z(T_{-\frac{1}{N}}\hat{g})(e^{2\pi i t}, y) = \sum_{k=0}^{\frac{N}{2}-1} \hat{g}(e^{2\pi i (t + \frac{2k}{N} + \frac{1}{N})}) e^{2\pi i \frac{2k}{N} y} = Z(\hat{g})(e^{2\pi i (t + \frac{1}{N})}, y).
$$

Hence (i) is equivalent to

$$
\begin{aligned}
2Z(f)(e^{2\pi i t}, y) &= Z((S_1 + S_2) f)(e^{2\pi i t}, y) \\
&= \tfrac{2}{N} Z(f)(e^{2\pi i t}, y) \left[|Z(\hat{g})(e^{2\pi i t}, y)|^2 + |Z(\hat{g})(e^{2\pi i (t + \frac{1}{N})}, y)|^2 \right] \text{ a.e.,}
\end{aligned}
$$

which holds if and only if (ii) is satisfied.

(ii) $\Leftrightarrow$ (iii): The following properties of the Zak transform will be exploited several times. The reconstruction formula

$$\sum_{y=0}^{\frac{N}{2}-1} Zf(e^{2\pi it},y) = \sum_{k=0}^{\frac{N}{2}-1} f(e^{2\pi i(t+\frac{2k}{N})}) \sum_{y=0}^{\frac{N}{2}-1} e^{2\pi i\frac{2k}{N}y} = \tfrac{N}{2} f(e^{2\pi it})$$

holds a.e., since $\sum_{y=0}^{\frac{N}{2}-1} e^{2\pi i\frac{2k}{N}y} \neq 0$ if and only if $k=0$ by [21, Lemma 23.29] and, if $k=0$, then $\sum_{y=0}^{\frac{N}{2}-1} e^{2\pi i\frac{2k}{N}y} = \frac{N}{2}$. Moreover, we will use that

$$Z\hat{g}(e^{2\pi i(t+\frac{2l}{N})},y) = \sum_{k=0}^{\frac{N}{2}-1} f(e^{2\pi i(t+\frac{2k+2l}{N})})e^{2\pi i\frac{2k}{N}y} = e^{-2\pi i\frac{2l}{N}y} Z\hat{g}(e^{2\pi it},y).$$

The idea is to write the equation in (iii) in terms of the Zak transform. Using the fact that $\hat{g}$ is real-valued, we compute

$$\begin{aligned}
&\sum_{l=0}^{N-1} \hat{g}(e^{2\pi i(t+\frac{l}{N})})\hat{g}(e^{2\pi i(t+\frac{l+2j}{N})})\\
&= \frac{4}{N^2}\sum_{l=0}^{N-1}\sum_{x=0}^{\frac{N}{2}-1} Z\hat{g}(e^{2\pi i(t+\frac{l}{N})},x)\sum_{y=0}^{\frac{N}{2}-1}\overline{Z\hat{g}(e^{2\pi i(t+\frac{l+2j}{N})},y)}\\
&= \frac{4}{N^2}\sum_{k,x,y=0}^{\frac{N}{2}-1}\Big[Z\hat{g}(e^{2\pi i(t+\frac{2k}{N})},x)\overline{Z\hat{g}(e^{2\pi i(t+\frac{2k+2j}{N})},y)}\\
&\quad + Z\hat{g}(e^{2\pi i(t+\frac{2k+1}{N})},x)\overline{Z\hat{g}(e^{2\pi i(t+\frac{2k+2j+1}{N})},y)}\Big]\\
&= \frac{4}{N^2}\sum_{x,y=0}^{\frac{N}{2}-1}\left[\sum_{k=0}^{\frac{N}{2}-1} e^{-2\pi i\frac{2k}{N}(x-y)}\right] e^{2\pi i\frac{2j}{N}y}\Big[Z\hat{g}(e^{2\pi it},x)\overline{Z\hat{g}(e^{2\pi it},y)}\\
&\quad + Z\hat{g}(e^{2\pi i(t+\frac{1}{N})},x)\overline{Z\hat{g}(e^{2\pi i(t+\frac{1}{N})},y)}\Big]\\
&= \frac{2}{N}\sum_{x=0}^{\frac{N}{2}-1}\Big[|Z\hat{g}(e^{2\pi it},x)|^2 + |Z\hat{g}(e^{2\pi i(t+\frac{1}{N})},x)|^2\Big] e^{2\pi i\frac{2j}{N}x}\\
&= \frac{2}{N}\Big[|Z\hat{g}(e^{2\pi it},\cdot)|^2 + |Z\hat{g}(e^{2\pi i(t+\frac{1}{N})},\cdot)|^2\Big]^{\vee}(j),
\end{aligned}$$

where the inverse Fourier transform is taken in $\mathbb{Z}_{N/2}$. This shows that (iii) is equivalent to

$$\frac{2}{N}\Big[|Z\hat{g}(e^{2\pi it},\cdot)|^2 + |Z\hat{g}(e^{2\pi i(t+\frac{1}{N})},\cdot)|^2\Big]^{\vee}(j) = N\delta_{j,0}. \tag{3.4}$$

If (ii) holds, then

$$\frac{2}{N}\Big[|Z\hat{g}(e^{2\pi it},\cdot)|^2 + |Z\hat{g}(e^{2\pi i(t+\frac{1}{N})},\cdot)|^2\Big]^{\vee}(j) = \frac{2}{N}N\sum_{x=0}^{\frac{N}{2}-1} e^{2\pi i\frac{2j}{N}x} = N\delta_{j,0},$$

which is (3.4). On the other hand, the inverse Fourier transform is injective. This proves that (3.4) holds if and only if (ii) is true and thus (ii) $\Leftrightarrow$ (iii).

(iii) $\Leftrightarrow$ (iv): First we remark that $\mathcal{W}(g, \Lambda, \ell_2(\mathbb{Z}))$ is an orthonormal basis if and only if the set

$$\Psi := \{T_{nN} f_m : m = 1, \dots, N,\ n \in \mathbb{Z}\},$$

where

$$\begin{aligned} f_1(x) &= g(x), \\ f_N(x) &= g_{0,\frac{N}{2}}(x), \\ f_{2l+k}(x) &= \frac{(-1)^{kl}}{\sqrt{2}}(g_{k\frac{N}{2},\frac{l}{N}} + (-1)^{k+l} g_{k\frac{N}{2},-\frac{l}{N}}),\ l = 1, \dots, \tfrac{N}{2}-1,\ k = 0, 1, \end{aligned}$$

is an orthonormal basis, since these elements differ from the elements in $\mathcal{W}(g, \Lambda, \ell_2(\mathbb{Z}))$ only by factors of absolute value 1. Next, notice that to prove (iv) it is sufficient and necessary that

$$\|T_{nN} f_m\|_2 = 1, \quad m = 1, \dots, L,\ n \in \mathbb{Z} \tag{3.5}$$

and

$$\sum_{m=1}^{L} \sum_{n \in \mathbb{Z}} \langle h_1, T_{nN} f_m \rangle \langle T_{nN} f_m, h_2 \rangle = \langle h_1, h_2 \rangle \quad \text{for all } h_1, h_2 \in \ell_2(\mathbb{Z}). \tag{3.6}$$

We start by dealing with (3.5). Using the Plancherel theorem, we compute

$$1 = \|T_{nN} f_1\|_2^2 = \|\hat{g}\|_2^2 = \int_0^1 \hat{g}(e^{2\pi i t}) \hat{g}(e^{2\pi i t}) dt,$$

$$1 = \|T_{nN} f_N\|_2^2 = \|\hat{g}_{\frac{N}{2},0}\|^2 = \int_0^1 \hat{g}(e^{2\pi i t}) \hat{g}(e^{2\pi i t}) dt,$$

and, for $m = 2, \dots, N-1$,

$$\begin{aligned} 1 &= \|T_{nN} f_m\|_2^2 \\ &= \|\tfrac{1}{\sqrt{2}}(\hat{g}_{\frac{l}{N},-k\frac{N}{2}} + (-1)^{k+l} \hat{g}_{-\frac{l}{N},-k\frac{N}{2}})\|_2^2 \\ &= \frac{1}{2}\int_0^1 |e^{-2\pi i \frac{kN}{2} t}|^2 |\hat{g}(e^{2\pi i (t-\frac{l}{N})}) + (-1)^{k+l} \hat{g}(e^{2\pi i (t+\frac{l}{N})})|^2 dt \\ &= \frac{1}{2}\int_0^1 \Big[|\hat{g}(e^{2\pi i (t-\frac{l}{N})})|^2 + |\hat{g}(e^{2\pi i (t+\frac{l}{N})})|^2 + (-1)^{k+l} \hat{g}(e^{2\pi i (t-\frac{l}{N})}) \overline{\hat{g}(e^{2\pi i (t+\frac{l}{N})})} \\ &\quad + (-1)^{k+l} \overline{\hat{g}(e^{2\pi i (t-\frac{l}{N})})} \hat{g}(e^{2\pi i (t+\frac{l}{N})})\Big] dt. \end{aligned}$$

Since $\hat{g}$ is real-valued, we can continue the last computation and obtain that

$$1 = \|T_{nN} f_m\|_2^2 = \|\hat{g}\|_2^2 + (-1)^{k+l} \int_0^1 \hat{g}(e^{2\pi i t}) \hat{g}(e^{2\pi i (t+\frac{2l}{N})}) dt.$$

Combining the above computations, we have proved that (3.5) holds if and only if

$$(3.7)\qquad \int_0^1 \hat{g}(e^{2\pi it})\hat{g}(e^{2\pi i(t+\frac{2j}{N})})dt = \delta_{j,0} \quad \text{for all } j \in \{0,\dots,N-1\}.$$

Now we turn to the study of condition (3.6). Using the Plancherel formula and the Poisson summation formula [16, Theorem 4.42] applied to $H = \{e^{2\pi i\frac{k}{N}} : k = 0,\dots,N-1\}$, we obtain

$$\begin{aligned}
&\sum_{m=1}^{N}\sum_{n\in\mathbb{Z}} \langle h_1, T_{nN}f_m\rangle \langle T_{nN}f_m, h_2\rangle \\
&= \sum_{m=1}^{N}\sum_{n\in\mathbb{Z}} \left\langle \widehat{h_1}, \widehat{T_{nN}f_m}\right\rangle \left\langle \widehat{T_{nN}f_m}, \widehat{h_2}\right\rangle \\
&= \sum_{m=1}^{N}\sum_{n\in\mathbb{Z}} \int_0^1 (\widehat{h_1}\overline{\widehat{f_m}})(e^{2\pi it}) \int_0^1 (\widehat{f_m}\overline{\widehat{h_2}})(e^{2\pi is})e^{-2\pi isNn}ds\, e^{2\pi itNn}dt \\
&= \sum_{m=1}^{N} \int_0^1 (\widehat{h_1}\overline{\widehat{f_m}})(e^{2\pi it}) \left[\sum_{n\in\mathbb{Z}} (\widehat{f_m}\overline{\widehat{h_2}})\hat{}\,(Nn)e^{2\pi itNn}\right] dt \\
&= \sum_{m=1}^{N} \int_0^1 (\widehat{h_1}\overline{\widehat{f_m}})(e^{2\pi it}) \tfrac{1}{N}\sum_{r=0}^{N-1} (\widehat{f_m}\overline{\widehat{h_2}})(e^{2\pi i(t+\frac{r}{N})})\, dt,
\end{aligned}$$

which equals $\langle h_1, h_2\rangle$ if and only if

$$(3.8)\qquad \sum_{m=1}^{N} \overline{\widehat{f_m}(e^{2\pi it})}\widehat{f_m}(e^{2\pi i(t+\frac{r}{N})}) = N\delta_{r,0} \quad \text{for all } r \in \{0,\dots,N-1\}.$$

Setting $\mathbb{L} := \{-\frac{N}{2}+1,\dots,-1,1,\dots,\frac{N}{2}-1\}$, we compute

$$\begin{aligned}
&\sum_{m=1}^{N} \overline{\widehat{f_m}(e^{2\pi it})}\widehat{f_m}(e^{2\pi i(t+\frac{r}{N})}) \\
&= \hat{g}(e^{2\pi it})\hat{g}(e^{2\pi i(t+\frac{r}{N})}) + \hat{g}_{\frac{N}{2},0}(e^{2\pi it})\hat{g}_{\frac{N}{2},0}(e^{2\pi i(t+\frac{r}{N})}) + \frac{1}{2}\sum_{l=1}^{\frac{N}{2}-1}\sum_{k=0}^{1} [\overline{\hat{g}_{\frac{l}{N},-k\frac{N}{2}}(e^{2\pi it})} \\
&\quad + (-1)^{k+l}\overline{\hat{g}_{-\frac{l}{N},-k\frac{N}{2}}(e^{2\pi it})}][\hat{g}_{\frac{l}{N},-k\frac{N}{2}}(e^{2\pi i(t+\frac{r}{N})}) + (-1)^{k+l}\hat{g}_{-\frac{l}{N},-k\frac{N}{2}}(e^{2\pi i(t+\frac{r}{N})})] \\
&= \hat{g}(e^{2\pi it})\hat{g}(e^{2\pi i(t+\frac{r}{N})}) + \hat{g}(e^{2\pi i(t-\frac{N}{2})})\hat{g}(e^{2\pi i(t+\frac{r}{N}-\frac{N}{2})}) \\
&\quad + \frac{1}{2}\sum_{l=1}^{\frac{N}{2}-1}\sum_{k=0}^{1} e^{-2\pi ik\frac{N}{2}\frac{r}{N}}[\hat{g}(e^{2\pi i(t-\frac{l}{N})}) \\
&\quad + (-1)^{k+l}\hat{g}(e^{2\pi i(t+\frac{l}{N})})][\hat{g}(e^{2\pi i(t-\frac{l}{N}+\frac{r}{N})}) + (-1)^{k+l}\hat{g}(e^{2\pi i(t+\frac{l}{N}+\frac{r}{N})})] \\
&= \hat{g}(e^{2\pi it})\hat{g}(e^{2\pi i(t+\frac{r}{N})}) + \hat{g}(e^{2\pi i(t-\frac{N}{2})})\hat{g}(e^{2\pi i(t+\frac{r}{N}-\frac{N}{2})}) \\
&\quad + \frac{1}{2}\sum_{l=1}^{\frac{N}{2}-1}\sum_{k=0}^{1} (-1)^{kr}[\hat{g}(e^{2\pi i(t-\frac{l}{N})})\hat{g}(e^{2\pi i(t-\frac{l}{N}+\frac{r}{N})}) + \hat{g}(e^{2\pi i(t+\frac{l}{N})})\hat{g}(e^{2\pi i(t+\frac{l}{N}+\frac{r}{N})}) \\
&\quad + (-1)^{k+l}(e^{2\pi i(t-\frac{l}{N})})\hat{g}(e^{2\pi i(t+\frac{l}{N}+\frac{r}{N})}) + \hat{g}(e^{2\pi i(t+\frac{l}{N})})\hat{g}(e^{2\pi i(t-\frac{l}{N}+\frac{r}{N})}))]
\end{aligned}$$

$$= \hat{g}(e^{2\pi it})\hat{g}(e^{2\pi i(t+\frac{r}{N})}) + \sum_{l\in\mathbb{L}} \hat{g}(e^{2\pi i(t+\frac{l}{N})})\hat{g}(e^{2\pi i(t+\frac{l}{N}+\frac{r}{N})}) \left[\frac{1+(-1)^r}{2}\right]$$
$$+ \sum_{l\in\mathbb{L}} (-1)^l \hat{g}(e^{2\pi i(t+\frac{l}{N})})\hat{g}(e^{2\pi i(t-\frac{l}{N}+\frac{r}{N})}) \left[\frac{1+(-1)^{r+1}}{2}\right]$$
$$+\hat{g}(e^{2\pi i(t-\frac{N}{2})})\hat{g}(e^{2\pi i(t+\frac{r}{N}-\frac{N}{2})}).$$

If r is even, i.e., $r = 2j$, we obtain

$$\sum_{m=1}^{N} \overline{\widehat{f_m}(e^{2\pi it})}\widehat{f_m}(e^{2\pi i(t+\frac{r}{N})}) = \sum_{l=0}^{N-1} \hat{g}(e^{2\pi i(t+\frac{l}{N})})\hat{g}(e^{2\pi i(t+\frac{l}{N}+\frac{2j}{N})}),$$

and if r is odd, i.e., $r = 2j+1$, we obtain

$$\begin{aligned}
&\sum_{m=1}^{N} \overline{\widehat{f_m}(e^{2\pi it})}\widehat{f_m}(e^{2\pi i(t+\frac{r}{N})}) \\
&= \hat{g}(e^{2\pi it})\hat{g}(e^{2\pi i(t+\frac{r}{N})}) + \hat{g}(e^{2\pi i(t-\frac{N}{2})})\hat{g}(e^{2\pi i(t+\frac{r}{N}-\frac{N}{2})}) \\
&\quad + \sum_{l\in\mathbb{L}} (-1)^l \hat{g}(e^{2\pi i(t+\frac{l}{N})})\hat{g}(e^{2\pi i(t-\frac{l}{N}+\frac{r}{N})}) \\
&= 0.
\end{aligned}$$

This shows that (3.6) holds if and only if

$$\sum_{l=0}^{N-1} \hat{g}(e^{2\pi i(t+\frac{l}{N})})\hat{g}(e^{2\pi i(t+\frac{l+2j}{N})}) = N\delta_{j,0}.$$

Moreover, this equation implies equation (3.7), since

$$\begin{aligned}
\int_0^1 \hat{g}(e^{2\pi it})\hat{g}(e^{2\pi i(t+\frac{2j}{N})})dt &= \int_0^{\frac{1}{N}} \sum_{l=0}^{N-1} \hat{g}(e^{2\pi i(t+\frac{l}{N})})\hat{g}(e^{2\pi i(t+\frac{l+2j}{N})})dt \\
&= \int_0^{\frac{1}{N}} N\delta_{j,0}dt = \delta_{j,0}.
\end{aligned}$$

This shows (iii) $\Leftrightarrow$ (iv), and hence the theorem is proved. $\square$

Now we will study the case of a general time-frequency lattice.

PROPOSITION 3.6. *Let Λ be a lattice in $\mathbb{Z}\times\mathbb{T}$ with $\mathrm{vol}(\Lambda) = \frac{1}{2}$ with canonical generator matrix A given by*

$$A = \begin{bmatrix} \frac{N}{2} & b \\ 0 & \frac{1}{N} \end{bmatrix}.$$

Let $g \in \ell_2(\mathbb{Z})$, let $m_0, n_0 \in \mathbb{Z}$ be chosen such that $\frac{N}{2}m_0 + bn_0 = \gcd(\frac{N}{2}, b) =: c$, and let U be defined on $\ell_2(\mathbb{Z})$ by

$$Uf(k) = f(k)e^{\pi i \frac{n_0}{cN}k^2}.$$

Then

$$g_{m\frac{N}{2}+nb,n\frac{1}{N}}(l) = C(m,n)U(U^{-1}g)_{m\frac{N}{2}+nb,-m\frac{n_0}{2c}-n\frac{bn_0}{cN}+n\frac{1}{N}}(l), \quad l \in \mathbb{Z},$$

where $C(m,n) = e^{\pi i \frac{n_0}{cN}(m\frac{N}{2}+nb)^2}$.

Proof. Let $\sigma \in \mathrm{Hom}(\mathbb{Z}\times\mathbb{T})$ be defined by

$$\sigma = \begin{bmatrix} I_{\mathbb{Z}} & 0 \\ -\frac{n_0}{cN} & I_{\mathbb{T}} \end{bmatrix}.$$

It is easy to check that σ is symplectic on $\mathbb{Z}\times\mathbb{T}$. In order to apply Theorem 1.1, we need to compute a second degree character of $\mathbb{Z}\times\mathbb{T}$ associated to $\zeta = \sigma^*\kappa_0\sigma - \kappa_0$, where κ_0 is defined by

$$\kappa_0 = \begin{bmatrix} 1 & 1 \\ I_{\mathbb{Z}} & 0 \end{bmatrix} \in \mathrm{Hom}(\mathbb{Z}\times\mathbb{T}, \mathbb{T}\times\mathbb{Z}).$$

First we note that $\sigma^*(z,n) = (ze^{2\pi i(-\frac{n_0}{cN})n}, n)$, since

$$\langle (m,t), \sigma^*(z,n)\rangle = \langle \sigma(m,t),(z,n)\rangle = z^m(e^{2\pi i(-\frac{n_0}{cN})m}t)^n = \left\langle (m,t), (ze^{2\pi i(-\frac{n_0}{cN})n}, n)\right\rangle.$$

Thus

$$\zeta(n,z) = (\sigma^*\kappa_0\sigma - \kappa_0)(n,z) = \sigma^*\kappa_0(n, e^{2\pi i(-\frac{n_0}{cN})n}z) - (1,n) = (e^{2\pi i(-\frac{n_0}{cN})n}, 0).$$

The map

$$\psi : \mathbb{Z}\times\mathbb{T}\to\mathbb{T}, \quad \psi(m,t) = e^{-\pi i \frac{n_0}{cN}m^2}$$

is a second degree character associated to ζ as the following calculation shows:

$$\begin{aligned} \psi(m,t)\psi(n,z)\langle (m,t),\zeta(n,z)\rangle &= e^{-\pi i\frac{n_0}{cN}m^2} e^{-\pi i\frac{n_0}{cN}n^2} e^{2\pi i(-\frac{n_0}{cN})mn} \\ &= e^{-\pi i \frac{n_0}{cN}(m+n)^2} \\ &= \psi((m,t)+(n,z)). \end{aligned}$$

Next notice that

$$\sigma(m\tfrac{N}{2}+nb, n\tfrac{1}{N}) = (m\tfrac{N}{2}+nb, -m\tfrac{n_0}{2c} - n\tfrac{bn_0}{cN} + n\tfrac{1}{N}). \tag{3.9}$$

Now we can apply Theorem 1.1, which proves the claim. □

Next we define a Wilson basis associated with a lattice with arbitrary canonical generator matrix. For this, the following mapping will turn out to be very useful.

LEMMA 3.7. *Let* $\frac{N}{2}, b \in \mathbb{Z}$ *with* $0 \le b < \frac{N}{2}$, *and let* $m_0, n_0 \in \mathbb{Z}$ *be chosen such that* $\frac{N}{2}m_0 + bn_0 = \gcd(\frac{N}{2}, b) =: c$. *Further, let* $d := \mathrm{lcm}(\frac{N}{2}, b)$. *Then the mapping* $\varphi : \mathbb{Z}^2 \to \mathbb{Z}^2$ *defined by*

$$\varphi(m,n) = \begin{cases} (m,n) & : \ b = 0, \\ (mm_0 - \frac{2d}{N}n, mn_0 + \frac{d}{b}n) & : \ b \neq 0 \end{cases}$$

is bijective and, for all $m \in \mathbb{Z}$, *we have*

$$\{(m, n \bmod 2c) : (m,n) \in \varphi^{-1}(\mathbb{Z}\times\{0,\dots,N-1\})\} = \{m\}\times\{0,\dots,2c-1\}$$

with

$$|\{n : (m,n)\in\varphi^{-1}(\mathbb{Z}\times\{0,\dots,N-1\})\}| = 2c.$$

Proof. We only need to study the case $b \neq 0$. For this, let $(m,n),(m',n') \in \mathbb{Z}^2$ be such that $\varphi(m,n) = \varphi(m',n')$. Then

$$\tfrac{N}{2}(mm_0 - \tfrac{2d}{N}n) + b(mn_0 + \tfrac{d}{b}n) = \tfrac{N}{2}(m'm_0 - \tfrac{2d}{N}n') + b(m'n_0 + \tfrac{d}{b}n'),$$

which holds if and only if

$$m(\tfrac{N}{2}m_0 + bn_0) = m'(\tfrac{N}{2}m_0 + bn_0),$$

and hence $m = m'$. This implies

$$(-\tfrac{2d}{N}n, \tfrac{d}{b}n) = (-\tfrac{2d}{N}n', \tfrac{d}{b}n'),$$

which yields $n = n'$. This proves that φ is injective.

To show that φ is surjective, let $(k,l) \in \mathbb{Z}^2$ and consider $M := \frac{N}{2}k + bl$. It is well known that there exists some $m \in \mathbb{Z}$ with $M = mc$. Furthermore, we have

$$\{(p,q) \in \mathbb{Z}^2 : \tfrac{N}{2}p + bq = mc\} = \{(mm_0 - \tfrac{2d}{N}n, mn_0 + \tfrac{d}{b}n) : n \in \mathbb{Z}\},$$

since $\frac{N}{2}p + bq = \frac{N}{2}p' + bq'$ if and only if $\frac{N}{2}(p-p') = b(q'-q)$. This yields the existence of some $n \in \mathbb{Z}$ with

$$\varphi(m,n) = (mm_0 - \tfrac{2d}{N}n, mn_0 + \tfrac{d}{b}n) = (k,l).$$

Secondly, we will prove the second part of the lemma. First observe that $m,n \in \mathbb{Z}$ satisfy

$$\varphi(m,n) \in \mathbb{Z} \times \{0,\dots,N-1\} \tag{3.10}$$

if and only if they satisfy

$$-\tfrac{b}{d}n_0m \le n \le -\tfrac{b}{d}n_0m + \tfrac{b}{d}(N-1) = 2c - \tfrac{b}{d}n_0m - \tfrac{b}{d}.$$

Hence, for each fixed $m \in \mathbb{Z}$, the set of $n \in \mathbb{Z}$ such that (3.10) is satisfied equals

$$S_m := \{\lceil -\tfrac{b}{d}n_0m \rceil, \dots, \lfloor 2c - \tfrac{b}{d}n_0m - \tfrac{b}{d} \rfloor\}.$$

To finish the proof we claim that

$$|S_m| = 2c \quad \text{for all } m \in \mathbb{Z}. \tag{3.11}$$

For this, fix $m \in \mathbb{Z}$ and let $k \in \mathbb{Z}$ and $l \in \{0,\dots,\frac{d}{b}-1\}$ be such that $-n_0m = k\frac{d}{b} + l$. Then we obtain $\lceil -\frac{b}{d}n_0m \rceil = k$ if $l = 0$ and otherwise $\lceil -\frac{b}{d}n_0m \rceil = k+1$. Moreover, we have

$$\lfloor 2c - \tfrac{b}{d}n_0m - \tfrac{b}{d} \rfloor = \left\lfloor 2c + k + \frac{l-1}{\frac{d}{b}} \right\rfloor,$$

which equals $2c + k - 1$ if $l = 0$ and otherwise $2c + k$. Thus the second part of the lemma is proved. ∎

Note that the following definition reduces to Definition 3.4 in the case of a diagonal canonical generator matrix.

DEFINITION 3.8. *Let Λ be a lattice in $\mathbb{Z} \times \mathbb{T}$ with canonical generator matrix A given by*

$$A = \begin{bmatrix} \frac{N}{2} & b \\ 0 & \frac{1}{N} \end{bmatrix}.$$

Let $g \in \ell_2(\mathbb{Z})$, and let φ be defined as in Lemma 3.7. *Then the Wilson system $\mathcal{W}(g,\Lambda,\ell_2(\mathbb{Z})) = \{\psi_{m,n}\}_{m\in\mathbb{Z},n=0,\dots,\frac{N}{2}}$ is given by*

$$\psi^{\Lambda}_{m,n} = g_{\varphi_1(2m,n)\frac{N}{2}+\varphi_2(2m,n)b,\varphi_2(2m,n)\frac{1}{N}} \qquad \text{if } m\in\mathbb{Z},\ n=0,\tfrac{N}{2},$$

and for $m \in \mathbb{Z}$, $n = 1,\dots,\frac{N}{2}-1$,

$$\begin{aligned}
\psi^{\Lambda}_{m,n} &= \tfrac{1}{\sqrt{2}}(g_{\varphi_1(m,n)\frac{N}{2}+\varphi_2(m,n)b,\varphi_2(m,n)\frac{1}{N}} \\
&\quad + g_{\varphi_1(m,-n)\frac{N}{2}+\varphi_2(m,-n)b,\varphi_2(m,-n)\frac{1}{N}}) \quad \text{if } m+n \text{ is even,}\\
\psi^{\Lambda}_{m,n} &= \tfrac{i}{\sqrt{2}}(g_{\varphi_1(m,n)\frac{N}{2}+\varphi_2(m,n)b,\varphi_2(m,n)\frac{1}{N}} \\
&\quad - g_{\varphi_1(m,-n)\frac{N}{2}+\varphi_2(m,-n)b,\varphi_2(m,-n)\frac{1}{N}}) \quad \text{if } m+n \text{ is odd.}
\end{aligned}$$

The following theorem gives an equivalent condition for a Wilson system with respect to an arbitrary time-frequency lattice to form an orthonormal basis in terms of a frame condition for the associated Gabor system.

THEOREM 3.9. *Let Λ be a lattice in $\mathbb{Z}\times\mathbb{T}$ with canonical generator matrix A given by*

$$A = \begin{bmatrix} \frac{N}{2} & b \\ 0 & \frac{1}{N} \end{bmatrix}.$$

Let $g \in \ell_2(\mathbb{Z})$ be such that $\widehat{U^{-1}g}$ is real-valued, let $M := 2c$, and let U and φ be defined as in Proposition 3.6 *and Lemma* 3.7, *respectively. Then the following conditions are equivalent.*

(i) $\{g_{m\frac{N}{2}+nb,n\frac{1}{N}}\}_{m\in\mathbb{Z},n=0,\dots,N-1}$ *is a tight frame for $\ell_2(\mathbb{Z})$ with frame bound* 2.

(ii) $\{(U^{-1}g)_{m\frac{M}{2},n\frac{1}{M}}\}_{m\in\mathbb{Z},n=0,\dots,M-1}$ *is a tight frame for $\ell_2(\mathbb{Z})$ with frame bound* 2.

(iii) $\mathcal{W}(U^{-1}g,\frac{M}{2}\mathbb{Z}\times\frac{1}{M}\{0,\dots,M-1\},\ell_2(\mathbb{Z}))$ *is an orthonormal basis for $\ell_2(\mathbb{Z})$.*

(iv) $\mathcal{W}(g,\Lambda,\ell_2(\mathbb{Z}))$ *is an orthonormal basis for $\ell_2(\mathbb{Z})$.*

Proof. Let σ be defined as in the proof of Proposition 3.6 and let $\varphi = (\varphi_1,\varphi_2)$. Then we compute

$$\begin{aligned}
&\sigma(\varphi_1(m,n)\tfrac{N}{2}+\varphi_2(m,n)b,\varphi_2(m,n)\tfrac{1}{N})\\
&= (\varphi_1(m,n)\tfrac{N}{2}+\varphi_2(m,n)b, -\varphi_1(m,n)\tfrac{n_0}{2c}-\varphi_2(m,n)\tfrac{bn_0}{cN}+\varphi_2(m,n)\tfrac{1}{N})\\
&= (m(\tfrac{N}{2}m_0+bn_0)+n(-\tfrac{2d}{N}\tfrac{N}{2}+\tfrac{d}{b}b), m(-\tfrac{n_0}{2c}m_0-\tfrac{bn_0}{cN}n_0+\tfrac{1}{N}n_0)\\
&\quad +n(\tfrac{2d}{N}\tfrac{n_0}{2c}-\tfrac{d}{b}\tfrac{bn_0}{cN}+\tfrac{d}{b}\tfrac{1}{N}))\\
&= (mc, mn_0(\tfrac{1}{N}-\tfrac{1}{cN}(\tfrac{N}{2}m_0+bn_0))+n\tfrac{d}{bN})\\
&= (m\tfrac{M}{2}, n\tfrac{1}{M}),
\end{aligned}$$

where in the last step we used $cd = \frac{N}{2}b$. Using Lemma 3.7, the equivalence of (i) and (ii) now follows immediately from Proposition 3.6 and (3.9), since U is unitary and $|C(m,n)| = 1$. Proposition 3.5 proves (ii) $\Leftrightarrow$ (iii). Therefore it remains to prove the equivalence of (iii) and (iv). For this, we will use the following implication of Proposition 3.6:

$$\begin{aligned}
U(U^{-1}g)_{m\frac{M}{2},n\frac{1}{M}} &= U(U^{-1}g)_{\sigma(\varphi_1(m,n)\frac{N}{2}+\varphi_2(m,n)b,\varphi_2(m,n)\frac{1}{N})}\\
&= C(\varphi(m,n))^{-1} g_{\varphi_1(m,n)\frac{N}{2}+\varphi_2(m,n)b,\varphi_2(m,n)\frac{1}{N}}.
\end{aligned}$$

Further, notice that $C(\varphi(m,n))^{-1}$ does not depend on the sign of n, since

$$C(\varphi(m,n))^{-1} = e^{-\pi i \frac{n_0}{cN}(\varphi_1(m,n)\frac{N}{2}+\varphi_2(m,n)b)^2} = e^{-\pi i \frac{n_0}{cN} m^2 (m_0 \frac{N}{2}+n_0 b)^2} = e^{-\pi i \frac{n_0}{N} m^2 c^2}.$$

The definition of a Wilson basis, the fact that U is a unitary operator, and the fact that $|C(\varphi(m,n))| = 1$ yields the result. □

4. Wilson bases for general lattices—the finite case. The space $\mathbb{C}^L$ has several advantages over $\ell^2(\mathbb{Z})$ when constructing numerical methods for practical time-frequency analysis, which often allow a further acceleration of numerical algorithms; e.g., see [1, 29, 32].

Before defining Gabor systems and Wilson systems for $\mathbb{C}^L$ for general time-frequency lattices, we first prove that each such lattice not only possesses a uniquely determined generator matrix in Hermite normal form (which was already proved in [20]), but in our situation this matrix attains a special form.

LEMMA 4.1. *Let Λ be a lattice in $\mathbb{Z}_L \times \mathbb{Z}_L$ with generator matrix A given by*

$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \qquad \text{with } a,b,c,d \in \mathbb{N}, \text{ and } \det(A) = \frac{L}{2},$$

and denote $p = \gcd(c,d)$ if $c \neq 0$ and $p = d$ if $c = 0$. Then Λ possesses a uniquely determined generator matrix of the form

$$A' = \begin{bmatrix} \frac{L}{2p} & b' \\ 0 & p \end{bmatrix}, \tag{4.1}$$

where $p = \gcd(c,d)$ and $0 \leq b' < \frac{L}{2p}$.

Proof. Let $p = \gcd(c,d)$ with $c = qp, d = rp$ and note that $p|\frac{L}{2}$ since $\det(A) = ad - bc = (ar - bq)p = \frac{L}{2}$. Since $\frac{d}{p} = r$ and $\frac{-c}{p} = -q$, we have

$$A \begin{bmatrix} r \\ -q \end{bmatrix} = \begin{bmatrix} \frac{L}{2p} \\ 0 \end{bmatrix}. \tag{4.2}$$

Furthermore, we claim that there exists a $z \in \mathbb{Z}$ with $0 \leq z < \frac{L}{2p}$ such that the point $\left[\begin{smallmatrix} z \\ p \end{smallmatrix}\right]$ belongs to Λ. This can be seen as follows: The condition $\left[\begin{smallmatrix} z \\ p \end{smallmatrix}\right] \in \Lambda$ is equivalent to the existence of $m, n \in \mathbb{Z}$ such that

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} m \\ n \end{bmatrix} = \begin{bmatrix} z \\ p \end{bmatrix}. \tag{4.3}$$

Consider the equation $cm + dn = p$ and substitute $c = qp, d = rp$, then $qpm + rpn = p$, hence $qm + rn = 1$. Since r and q are relative prime, there exist $m, n \in \mathbb{Z}$ such that $qm + rn = 1$ (see, e.g., [22, Theorem 4.4]). Thus (4.3) holds for $z \in \mathbb{Z}$, but we still have to show that it holds under the condition $0 \leq z < \frac{L}{2p}$. We can write $z = b' + k\frac{L}{2p}$ with $0 \leq b' < \frac{L}{2p}$ and $k \in \mathbb{Z}$. Hence

$$\begin{bmatrix} z \\ p \end{bmatrix} = \begin{bmatrix} b' \\ p \end{bmatrix} + k \begin{bmatrix} \frac{L}{2p} \\ 0 \end{bmatrix}.$$

Since $\left[\begin{smallmatrix} \frac{L}{2p} \\ 0 \end{smallmatrix}\right] = A\left[\begin{smallmatrix} r \\ -q \end{smallmatrix}\right]$ by (4.2), it follows that $\left[\begin{smallmatrix} b' \\ p \end{smallmatrix}\right] \in \Lambda$. Consequently the matrix

$$A' = \begin{bmatrix} \frac{L}{2p} & b' \\ 0 & p \end{bmatrix}$$

(which satisfies $\det(A') = \frac{L}{2}$) generates Λ.

The fact that this matrix is uniquely determined is an immediate consequence from the condition $0 \leq b' < \frac{L}{2p}$. $\square$

DEFINITION 4.2. *Let Λ be a lattice in $\mathbb{Z}_L \times \mathbb{Z}_L$. Then the uniquely determined matrix A' of Lemma* 4.1 *is called the* canonical generator matrix *for Λ.*

Using the notion of a canonical generator matrix, we first give the definition of a Gabor system.

DEFINITION 4.3. *Let Λ be a lattice in $\mathbb{Z}_L \times \mathbb{Z}_L$ with canonical generator matrix A given by*

$$A = \begin{bmatrix} \frac{L}{2p} & b \\ 0 & p \end{bmatrix}.$$

Set $M = 2p, N = \frac{L}{p}$ and let g be some L-periodic function on $\mathbb{Z}$. Then the associated Gabor system is given by $\{g_{ma+nb,nd}\}_{m=0,\dots,M-1,n=0,\dots,N-1}$, where

$$g_{ma+nb,nd}(l) = g(l-(ma+nb))e^{2\pi i lnd/L}, \qquad l = 0,\dots,L-1.$$

Next we define a Wilson basis associated with a lattice with diagonal canonical generator matrix in the following way.

DEFINITION 4.4. *Let Λ be a lattice in $\mathbb{Z}_L \times \mathbb{Z}_L$ with canonical generator matrix A given by*

$$A = \begin{bmatrix} \frac{L}{2p} & 0 \\ 0 & p \end{bmatrix}$$

and let g be some L-periodic function on $\mathbb{Z}$. Then the Wilson system $\mathcal{W}(g,\Lambda,\mathbb{C}^L) = \{\psi_{m,n}\}_{(m,n)\in I}$, where $I = \{0,\dots,p-1\} \times \{0, \frac{L}{2p}\} \cup \{0,\dots,2p-1\} \times \{1,\dots,\frac{L}{2p}-1\}$, is given by

$$\psi^{\Lambda}_{m,n} = g_{m\frac{L}{p},np} \qquad \text{if } m = 0,\dots,p-1,\ n = 0, \tfrac{L}{2p},$$

and for $m = 0,\dots,2p-1$, $n = 1,\dots,\frac{L}{2p}-1$,

$$\psi^{\Lambda}_{m,n} = \tfrac{1}{\sqrt{2}}(g_{m\frac{L}{2p},np} + g_{m\frac{L}{2p},-np}) \quad \text{if } m+n \text{ is even,}$$
$$\psi^{\Lambda}_{m,n} = \tfrac{i}{\sqrt{2}}(g_{m\frac{L}{2p},np} - g_{m\frac{L}{2p},-np}) \quad \text{if } m+n \text{ is odd.}$$

Also in the finite case we will employ the Zak transform. This time we will use the Zak transform on the group $\mathbb{Z}_L$ with respect to the uniform lattice $K = \{2pk : k = 0,\dots,\frac{L}{2p}-1\}$ in $\mathbb{Z}_L$, which is defined on the set of square-integrable functions on the set $\{0,\dots,2p-1\} \times \{0,\dots,\frac{L}{2p}-1\}$ by

$$Zf(x,y) = \sum_{k=0}^{\frac{L}{2p}-1} f(x+2pk)e^{2\pi i \frac{2pk}{L}y},$$

where we associate $\mathbb{Z}_L$ with $\{0,\dots,L-1\}$.

The following proposition is the analogue to Proposition 3.5 for the space $\mathbb{C}^L$.

PROPOSITION 4.5. *Let g be some L–periodic function on $\mathbb{Z}$ such that $\hat{g}$ is real-valued and consider the lattice Λ with canonical generator matrix given by*

$$\begin{bmatrix} \frac{L}{2p} & 0 \\ 0 & p \end{bmatrix}.$$

Then the following conditions are equivalent.

(i) $\{g_{m\frac{L}{2p},np}\}_{m=0,\dots,2p-1,n=0,\dots,\frac{L}{p}-1}$ *is a tight frame for* $\mathbb{C}^L$ *with frame bound* 2.
(ii) *We have* $|Z\hat{g}(x,y)|^2 + |Z\hat{g}(x+p,y)|^2 = \frac{1}{p}$ *a.e.*
(iii) *For all* $j = 0,\dots,\frac{L}{2p}-1$ *and* $y \in \mathbb{Z}_L$, *we have* $\sum_{l=0}^{\frac{L}{p}-1} \hat{g}(y+lp)\hat{g}(y+lp+2jp) = \frac{1}{p}\delta_{j,0}$.
(iv) $\mathcal{W}(g,\Lambda,\mathbb{C}^L)$ *is an orthonormal basis for* $\mathbb{C}^L$.

Proof. The proof, while lengthy, is very similar to the proof of Proposition 3.5. In fact, with obvious adaptations, such as using the normalized Haar measure on $\mathbb{Z}_L$, i.e., $m(E) = \frac{1}{L}\sum_{x\in\mathbb{Z}_L} 1_E(x)$ for all $E \subseteq \mathbb{Z}_L$, and replacing Zak transforms and Fourier transforms by their corresponding finite counterparts, the proof carries over almost line by line. We therefore leave this part to the reader. ∎

Now we will turn our attention to general time-frequency lattices. Here the situation is slightly more involved compared to $\ell^2(\mathbb{Z})$.

Let Λ be a lattice in $\mathbb{Z}_L \times \mathbb{Z}_L$ with canonical generator matrix A given by

$$A = \begin{bmatrix} \frac{L}{2p} & b \\ 0 & p \end{bmatrix}.$$

Then we choose $\alpha,\beta,m_0,n_0 \in \mathbb{Z}$ such that

$$\alpha\frac{L}{2p}m_0 + \alpha b n_0 + \beta p n_0 \tag{4.4}$$

attains its minimal positive value. Assume that there exists a choice of α,β,m_0,n_0 such that $(\frac{L}{2p}m_0 + bn_0)(pn_0) < 0$ and $(\alpha\frac{L}{2p})(\alpha b+\beta p) > 0$. In the other cases we have to change the signs of the later defined γ and δ accordingly. In the following we will restrict our analysis to the case where $|\alpha| = 1$. For the remainder of this section let α,β,m_0,n_0 be defined in this way. Now we regard α and β as elements of $\mathbb{Z}_L$. For the sake of brevity we set

$$c := \gcd(\alpha\tfrac{L}{2p}, \alpha b + \beta p), \quad d := \operatorname{lcm}(\alpha\tfrac{L}{2p}, \alpha b + \beta p),$$

and

$$s := \gcd(\tfrac{L}{2p}m_0 + bn_0, pn_0), \quad t := \operatorname{lcm}(\tfrac{L}{2p}m_0 + bn_0, pn_0).$$

The minimality condition for (4.4) shows that

$$\alpha\frac{L}{2p}m_0 + \alpha b n_0 + \beta p n_0 = c = s. \tag{4.5}$$

We further define $\gamma,\delta \in \mathbb{Z}_L$ by

$$\gamma := \frac{t}{\frac{L}{2p}m_0 + bn_0} \quad \text{and} \quad \delta := -\frac{t}{pn_0},$$

and $\sigma \in \operatorname{Hom}(\mathbb{Z}_L \times \mathbb{Z}_L)$ by

$$\sigma = \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix}.$$

PROPOSITION 4.6. *Let* Λ *be a lattice in* $\mathbb{Z}_L \times \mathbb{Z}_L$ *with canonical generator matrix* A *given by*

$$A = \begin{bmatrix} \frac{L}{2p} & b \\ 0 & p \end{bmatrix}.$$

Let σ be defined as in the preceding paragraph, and let U on the space of L-periodic functions on $\mathbb{Z}$ be defined by

$$Uf(k) = \sum_{l \in \mathbb{Z}_L} f(\alpha k + \beta l) e^{-\pi i(\alpha\gamma k^2 + \beta\delta l^2)(L+1)/L} e^{-2\pi i \beta\gamma k l/L}.$$

Then

$$g_{m\frac{L}{2p}+nb,np}(l) = C(m,n) U (U^{-1} g)_{\sigma(m\frac{L}{2p}+nb,np)}(l),$$

where $C(m,n) = e^{-\pi i(\alpha\gamma m^2+\beta\delta n^2)(L+1)/L} e^{-2\pi i\beta\gamma mn/L}$.

Before moving on to the proof of this statement we point out that the operator U in Proposition 4.6 is no longer a simple chirp operator as for the case $\ell^2(\mathbb{Z})$; cf. Proposition 3.6. This difference and the different form of σ necessitate a somewhat different proof for the case $\mathbb{C}^L$.

Proof. In order to apply Theorem 1.1 we need to check whether $\sigma = (\sigma_1, \sigma_2)$ is symplectic. For this, we have to show that, for all $(x,y),(x',y') \in \mathbb{Z}_L \times \mathbb{Z}_L$,

$$e^{-2\pi i\sigma_2(x,y)\sigma_1(x',y')/L} e^{2\pi i \sigma_2(x',y')\sigma_1(x,y)/L} = e^{-2\pi i x'y/L} e^{2\pi i xy'/L}. \tag{4.6}$$

We have

$$\begin{aligned} &e^{-2\pi i\sigma_2(x,y)\sigma_1(x',y')/L} e^{2\pi i \sigma_2(x',y')\sigma_1(x,y)/L} \\ &= e^{-2\pi i(\gamma x+\delta y)(\alpha x'+\beta y')/L} e^{2\pi i(\gamma x'+\delta y')(\alpha x+\beta y)/L} \\ &= e^{2\pi i(\alpha\delta-\beta\gamma)(xy'-x'y)/L} \end{aligned}$$

and

$$\begin{aligned} \alpha\delta - \beta\gamma &= -\frac{\alpha t}{pn_0} - \frac{\beta t}{\frac{L}{2p}m_0 + bn_0} \\ &= \frac{-t}{(\frac{L}{2p}m_0+bn_0)(pn_0)}(\alpha(\tfrac{L}{2p}m_0+bn_0)+\beta pn_0). \end{aligned}$$

By (4.5),

$$\alpha\delta - \beta\gamma = \frac{-st}{(\frac{L}{2p}m_0+bn_0)(pn_0)} = 1,$$

since $(\frac{L}{2p}m_0+bn_0)(pn_0) < 0$. This proves that (4.6) is satisfied, which shows that σ is indeed symplectic. Moreover, a short computation analogous to the one in the proof of Proposition 3.6 shows that

$$\zeta(k,l) = (\sigma^*\kappa_0\sigma - \kappa_0)(k,l) = (\alpha\gamma k + \beta\gamma l, \beta\gamma k + \beta\delta l).$$

Now it is easy to check (compare also [24, Example 1.1.34 (iii)]) that

$$\psi : \mathbb{Z}_L^2 \to \mathbb{T}, \quad \psi(k,l) = e^{\pi i(\alpha\gamma k^2+\beta\delta l^2)(L+1)/L} e^{2\pi i\beta\gamma kl/L}$$

is a second degree character associated to ζ. Applying Theorem 1.1 now finishes the proof. $\square$

As in the discrete case we need to define a special bijective map in order to give the definition of a Wilson basis associated with a lattice with arbitrary canonical generator matrix.

LEMMA 4.7. *Let* $\frac{L}{2p}, b \in \mathbb{Z}_L$ *with* $0 \leq b < \frac{L}{2p}$ *and let* $\alpha, \beta, m_0, n_0, c, d$ *be defined as before. Then the mapping* $\varphi : \mathbb{Z}^2 \to \mathbb{Z}^2$ *defined by*

$$\varphi(m,n) = \begin{cases} (m,n) & : \quad b = 0, \\ (mm_0 - \frac{2pd}{\alpha L} n, mn_0 + \frac{d}{\alpha b + \beta p} n) & : \quad b \neq 0 \end{cases}$$

is bijective and we have

$$\{(m \bmod \tfrac{L}{c}, n \bmod 2c) : (m,n) \in \varphi^{-1}(\{0, \dots, 2p-1\} \times \{0, \dots, \tfrac{L}{p} - 1\})\}$$

$$= \{0, \dots, \tfrac{L}{c} - 1\} \times \{0, \dots, 2c - 1\}.$$

Proof. The proof of this lemma is very similar to the proof of Lemma 3.7; we therefore omit it. □

Note that the following definition reduces to Definition 4.4 in the case of a diagonal canonical generator matrix.

DEFINITION 4.8. *Let* Λ *be a lattice in* $\mathbb{Z}_L \times \mathbb{Z}_L$ *with canonical generator matrix* A *given by*

$$A = \begin{bmatrix} \frac{L}{2p} & b \\ 0 & p \end{bmatrix}.$$

Let g *be some* L*-periodic function on* $\mathbb{Z}$*, and let* φ *be defined as in Lemma* 4.7*. Then the Wilson system* $\mathcal{W}(g, \Lambda, \mathbb{C}^L) = \{\psi_{m,n}\}_{(m,n) \in I}$*, where* $I = \{0, \dots, p-1\} \times \{0, \frac{L}{2p}\} \cup \{0, \dots, 2p-1\} \times \{1, \dots, \frac{L}{2p} - 1\}$*, is given by*

$$\psi^{\Lambda}_{m,n} = g_{\varphi_1(2m,n)\frac{L}{2p} + \varphi_2(2m,n)b, \varphi_2(2m,n)p} \qquad \text{if } m = 0, \dots, p-1, \ n = 0, \tfrac{L}{2p},$$

and for $m = 0, \dots, 2p-1$*,* $n = 1, \dots, \frac{L}{2p} - 1$*,*

$$\begin{aligned} \psi^{\Lambda}_{m,n} &= \tfrac{1}{\sqrt{2}}(g_{\varphi_1(m,n)\frac{L}{2p} + \varphi_2(m,n)b, \varphi_2(m,n)p} \\ &\quad + g_{\varphi_1(m,-n)\frac{L}{2p} + \varphi_2(m,-n)b, \varphi_2(m,-n)p}) \quad \text{if } m+n \text{ is even}, \\ \psi^{\Lambda}_{m,n} &= \tfrac{i}{\sqrt{2}}(g_{\varphi_1(m,n)\frac{L}{2p} + \varphi_2(m,n)b, \varphi_2(m,n)p} \\ &\quad - g_{\varphi_1(m,-n)\frac{L}{2p} + \varphi_2(m,-n)b, \varphi_2(m,-n)p}) \quad \text{if } m+n \text{ is odd}. \end{aligned}$$

The following theorem is the analogue to Theorem 3.9 for the space $\mathbb{C}^L$.

THEOREM 4.9. *Let* Λ *be a lattice in* $\mathbb{Z}_L \times \mathbb{Z}_L$ *with canonical generator matrix* A *given by*

$$A = \begin{bmatrix} \frac{L}{2p} & b \\ 0 & p \end{bmatrix}.$$

Let g *be some* L*-periodic function on* $\mathbb{Z}$ *such that* $\widehat{U^{-1}g}$ *is real-valued, let* $M := 2p$*,* $N := \frac{L}{p}$*,* $q := \frac{L}{2c}$*,* $\tilde{M} := 2q$*,* $\tilde{N} := \frac{L}{q}$*, and let* U *and* φ *be defined as in Proposition* 4.6 *and Lemma* 4.7*, respectively. Then the following conditions are equivalent.*

(i) $\{g_{m\frac{L}{2p}+nb,np}\}_{m=0,\dots,M-1,n=0,\dots,N-1}$ *is a tight frame for* $\mathbb{C}^L$ *with frame bound* 2.

(ii) $\{(U^{-1}g)_{m\frac{L}{2q},nq}\}_{m=0,\dots,\tilde{M}-1,n=0,\dots,\tilde{N}-1}$ *is a tight frame for* $\mathbb{C}^L$ *with frame bound* 2.

(iii) $\mathcal{W}(U^{-1}g,\frac{L}{2q}\mathbb{Z}_L\times q\mathbb{Z}_L,\mathbb{C}^L)$ *is an orthonormal basis for* $\mathbb{C}^L$.

(iv) $\mathcal{W}(g,\Lambda,\mathbb{C}^L)$ *is an orthonormal basis for* $\mathbb{C}^L$.

Proof. Let σ be defined as before and let $\varphi=(\varphi_1,\varphi_2)$. Then we compute

$$\begin{aligned}
&\sigma(\varphi_1(m,n)\tfrac{L}{2p}+\varphi_2(m,n)b,\varphi_2(m,n)p)\\
&=(\alpha(\varphi_1(m,n)\tfrac{L}{2p}+\varphi_2(m,n)b)+\beta\varphi_2(m,n)p,\gamma(\varphi_1(m,n)\tfrac{L}{2p}+\varphi_2(m,n)b)+\delta\varphi_2(m,n)p)\\
&=(m(\alpha\tfrac{L}{2p}m_0+\alpha bn_0+\beta pn_0)+n(-\alpha\tfrac{L}{2p}\tfrac{2pd}{\alpha L}+\alpha b\tfrac{d}{\alpha b+\beta p}+\beta p\tfrac{d}{\alpha b+\beta p}),\\
&\quad m(\gamma\tfrac{L}{2p}m_0+\gamma bn_0+\delta pn_0)+n(-\gamma\tfrac{L}{2p}\tfrac{2pd}{\alpha L}+\gamma b\tfrac{d}{\alpha b+\beta p}+\delta p\tfrac{d}{\alpha b+\beta p}))\\
&=(mc,m(\tfrac{t}{\frac{L}{2p}m_0+bn_0}(\tfrac{L}{2p}m_0+bn_0)-\tfrac{t}{pn_0}pn_0)\\
&\quad+n(-\tfrac{t}{\frac{L}{2p}m_0+bn_0}\tfrac{d}{\alpha}+\tfrac{t}{\frac{L}{2p}m_0+bn_0}\tfrac{bd}{\alpha b+\beta p}-\tfrac{t}{pn_0}\tfrac{pd}{\alpha b+\beta p}))\\
&=(mc,ntd(\tfrac{-\alpha bpn_0-\beta p^2n_0+\alpha bpn_0-\alpha p\frac{L}{2p}m_0-\alpha pbn_0}{\alpha(\frac{L}{2p}m_0+bn_0)(\alpha b+\beta p)pn_0}))\\
&=(mc,-ntdp\tfrac{\alpha\frac{L}{2p}m_0+\alpha bn_0+\beta pn_0}{\alpha(\frac{L}{2p}m_0+bn_0)(\alpha b+\beta p)pn_0})\\
&=(mc,-ntp\tfrac{cd}{\alpha(\frac{L}{2p}m_0+bn_0)(\alpha b+\beta p)pn_0})\\
&=(mc,-nt\tfrac{\frac{L}{2}}{(\frac{L}{2p}m_0+bn_0)pn_0})\\
&=(mc,n\tfrac{L}{2c}),
\end{aligned}$$

where in the last step we used (4.5) and $st=-(\frac{L}{2p}m_0+bn_0)pn_0$. Since $|\alpha|=1$, we have $c=s=\gcd(\alpha\frac{L}{2p},\alpha b+\beta p)$ is a factor of $\frac{L}{2p}$ and hence of $\frac{L}{2}$. Using Lemma 4.7, the equivalence of (i) and (ii) follows immediately from Proposition 4.6, since U is unitary and $|C(m,n)|=1$. Proposition 4.5 proves (ii) $\Leftrightarrow$ (iii). Therefore it remains to prove the equivalence of (iii) and (iv). For this, we will use the following implication of Proposition 4.6:

$$\begin{aligned}
U(U^{-1}g)_{m\frac{L}{2q},nq}&=U(U^{-1}g)_{\sigma(\varphi_1(m,n)\frac{L}{2p}+\varphi_2(m,n)b,\varphi_2(m,n)p)}\\
&=C(\varphi(m,n))^{-1}g_{\varphi_1(m,n)\frac{L}{2p}+\varphi_2(m,n)b,\varphi_2(m,n)p}.
\end{aligned}$$

An easy but tedious calculation shows that $C(\varphi(m,n))^{-1}$ does not depend on the sign of n. The definition of a Wilson basis, the fact that U is a unitary operator, and the fact that $|C(\varphi(m,n))|=1$ yields the result. ∎

Tight Gabor frames in $\mathbb{C}^L$ can be constructed in the same way as for $\ell^2(\mathbb{Z})$ and $L^2(\mathbb{R})$ by using the "inverse square root trick." Furthermore, it has been shown in [25] that for properly localized windows the dual window constructed in $\mathbb{C}^L$ by "sampling and periodization" of the frame $\{g_{ma,nb}\}$ converges to the dual window $S^{-1}g$ with increasing sampling rate and increasing periodization interval; see [25] for details. This result can be easily extended to tight windows. We refer also to [23, 30, 7] for related results and leave the details to the reader. To obtain tight Gabor frames in $\mathbb{C}^L$ that satisfy the required conditions of the theorem above and have good time-frequency localization, one can thus essentially proceed analogous to the example at the end of section 2.

5. Conclusion. We have demonstrated that orthonormal Wilson bases for $L^2(\mathbb{R})$ (with excellent time-frequency localization) can be constructed for general time-frequency lattices. Of course any numerical implementation has to be done in a discrete setting. Somewhat longer proofs establish a similar result for the spaces $\ell^2(\mathbb{Z})$ and $\mathbb{C}^L$ for nonrectangular time-frequency lattices. The approach based on metaplectic transforms used in this paper suggests that the main results can be extended to the setting of symplectic time-frequency lattices on general locally compact abelian groups.

Furthermore, our results imply that from a practical viewpoint it is indeed possible to extend OQAM-OFDM or cosine-modulated filter banks to general time-frequency lattices. Moreover, we expect that the benefits of using general time-frequency lattices will be even more pronounced for images and higher-dimensional signals. Our expectation is based on the fact that in the theory of sphere packings (and sphere coverings) the advantages of the optimal sphere packing over the packing associated with the rectangular lattices increases significantly with the dimension of the space [8].

An interesting research problem is thus to investigate how to extend the results in this paper to $L^2(\mathbb{R}^d)$ for nonsymplectic lattices as well as to find optimal time-frequency lattices in $\mathbb{R}^{2d}$ for $d > 1$. One possibility for defining an "optimal" time-frequency lattice is to fix the function g to be a Gaussian, say, and then find that time-frequency lattice of fixed density which minimizes the condition number of the associated Gabor frame operator as indicated in [31].

Acknowledgment. We thank the referees for valuable comments and suggestions which led to an improvement of the results and presentation in this paper.

A HIGHER ORDER ASYMPTOTIC PROBLEM RELATED TO PHASE TRANSITIONS*

ROGER MOSER†

Abstract. An asymptotic analysis of a family of functionals used in the van der Waals–Cahn–Hilliard theory of phase transitions gives rise to a generalized area functional in the limit. We examine a family of related higher order functionals on a three-dimensional domain. The expected limit in this case is a generalization of the Willmore functional. An analysis of the problem under a monotonicity assumption supports this conjecture.

Key words. phase transitions, Willmore functional, generalized surfaces

1. Introduction.

Suppose $\Omega \subset \mathbb{R}^3$ is an open domain. For $\epsilon > 0$ and $u \in H^1_{\mathrm{loc}}(\Omega)$, consider the functional

$$E_\epsilon(u) = \int_\Omega \left(\frac{\epsilon}{2} |\nabla u|^2 + \frac{1}{4\epsilon}(1-u^2)^2 \right) dx.$$

These and similar functionals are used in the van der Waals–Cahn–Hilliard theory of phase transitions as a model for the energy of phase interfaces. In this context, but also as an independent problem, it is interesting to study the asymptotic behavior of E_ϵ as $\epsilon \searrow 0$. Such an analysis was first done by Modica and Mortola [14, 15] in the framework of Γ-convergence. Related results have been obtained by Modica [12, 13], Sternberg [22], and many others. The limit functional for this asymptotic problem turns out to be (up to a constant multiple) an area functional for generalized surfaces (or generalized submanifolds for similar problems in other dimensions) in Ω.

The asymptotic behavior of critical points of E_ϵ under a volume constraint—in other words, solutions of

$$\epsilon \Delta u + \frac{1}{\epsilon}(1-u^2)u = \lambda \quad \text{in } \Omega, \tag{1.1}$$

where λ is a constant—have been studied by Hutchinson and Tonegawa [9]. This theory again identifies the area functional as the limit of E_ϵ, but it also gives some information about the behavior of the left-hand side of (1.1) as $\epsilon \searrow 0$. In fact, the quantity

$$\tau_\epsilon(u) = \epsilon \Delta u + \frac{1}{\epsilon}(1-u^2)u$$

converges to the mean curvature of the limit surface in some sense, at least if solutions of (1.1) or similar equations are considered. The results have been extended by Tonegawa [23] to the case of sufficiently regular nonconstant right-hand sides in (1.1).

If the limit of τ_ϵ corresponds to the mean curvature, then one might expect that the functionals

$$T_\epsilon(u) = \frac{1}{4\epsilon}\int_\Omega (\tau_\epsilon(u))^2\,dx$$

for $u \in H^2_{\mathrm{loc}}(\Omega)$ converge to a generalized version of the Willmore functional. (For an immersed C^2-surface $\Sigma \subset \Omega$ with mean curvature vector H, the Willmore functional is defined by

$$W(\Sigma) = \frac{1}{4}\int_\Sigma |H|^2\,d\mathcal{H}^2,$$

where $\mathcal{H}^2$ is the two-dimensional Hausdorff measure; see Willmore [24] for a discussion.) We study the asymptotic behavior of T_ϵ as $\epsilon \searrow 0$ in this paper. Although we cannot answer the question implied above in full generality, our results indicate strongly that the Willmore functional is indeed the limit of T_ϵ.

This problem is related to a conjecture of De Giorgi [6] about the Γ-convergence of similar functionals. A problem of this type has also been studied in a paper by Bellettini and Mugnai [5] for two-dimensional domains and under the assumption of radial symmetry.

For technical reasons, we assume that $\Omega = \Omega' \times \mathbb{R}$ for our main result, where $\Omega' \subset \mathbb{R}^2$ is an open domain. We then work in the space of all functions $u \in H^2_{\mathrm{loc}}(\Omega)$ satisfying

$$\frac{\partial u}{\partial x^3} \geq 0.$$

This condition simplifies the analysis of the problem. Some of the tools we use also work without this restriction, but it appears that a satisfactory analysis of the full problem also requires some additional arguments.

Before we state our results, we introduce some notation and terminology. We denote the Lebesgue measure in Ω by $\mathcal{L}^3$ and the m-dimensional Hausdorff measure by $\mathcal{H}^m$. If we have a countably m-rectifiable set $\Sigma \subset \Omega$, then $T_x\Sigma$ denotes the approximate tangent space of Σ at x. This approximate tangent space exists $\mathcal{H}^m$-almost everywhere on Σ. If $\phi \in C^1(\Omega, \mathbb{R}^3)$, then $\operatorname{div}_\Sigma \phi$ denotes the divergence of ϕ with respect to Σ. That is, if we write proj_V for the (3×3)-matrix of the orthogonal projection onto a linear subspace V of $\mathbb{R}^3$, then

$$\operatorname{div}_\Sigma \phi(x) = \operatorname{trace}(\operatorname{proj}_{T_x\Sigma}\nabla\phi(x))$$

wherever the approximate tangent space exists. We also write $\operatorname{proj}_V^\perp$ for the matrix of the orthogonal projection onto the orthogonal complement of V.

THEOREM 1.1. *Suppose $\Omega = \Omega' \times \mathbb{R}$ for some open set $\Omega' \subset \mathbb{R}^2$. For $\epsilon > 0$, suppose $u_\epsilon \in H^2_{\mathrm{loc}}(\Omega)$ such that*

$$\frac{\partial u_\epsilon}{\partial x^3} \geq 0$$

$\mathcal{L}^3$-almost everywhere in Ω. If

$$\liminf_{\epsilon \searrow 0}(E_\epsilon(u_\epsilon) + T_\epsilon(u_\epsilon)) < \infty,$$

then there exists a sequence $\epsilon_k \searrow 0$ with the following properties.

(i) *There exist a relatively closed, countably* 2*-rectifiable set* $\Sigma \subset \Omega$ *and an upper semicontinuous function* $\theta : \Sigma \to [2\sqrt{2}/3, \infty)$ *such that*

$$\lim_{k\to\infty} \frac{\epsilon_k}{2} \int_\Omega \eta |\nabla u_{\epsilon_k}|^2 \, dx = \lim_{k\to\infty} \frac{1}{4\epsilon_k} \int_\Omega \eta (1-u_{\epsilon_k}^2)^2 \, dx = \frac{1}{2} \int_\Sigma \eta\theta \, d\mathcal{H}^2$$

for every $\eta \in C_0^0(\Omega)$.

(ii) *The sequence* $\{u_{\epsilon_k}\}$ *converges* $\mathcal{L}^3$*-almost everywhere to a function* $u : \Omega \to \{-1, 1\}$ *that is locally constant in* $\Omega\backslash\Sigma$.

(iii) *There exists an* $\mathcal{H}^2$*-measurable function* $H : \Sigma \to \mathbb{R}^3$ *with* $H(x) \perp T_x\Sigma$ *for* $\mathcal{H}^2$*-almost every* $x \in \Sigma$*, such that*

$$\int_\Sigma (\operatorname{div}_\Sigma \phi + \phi \cdot H)\theta \, d\mathcal{H}^2 = 0$$

for every $\phi \in C_0^1(\Omega, \mathbb{R}^3)$ *and*

$$\frac{1}{4} \int_\Sigma |H|^2 \theta \, d\mathcal{H}^2 \le \liminf_{k\to\infty} T_{\epsilon_k}(u_{\epsilon_k}).$$

The proof of Theorem 1.1 rests on two pillars: a theory of a generalized Willmore functional on the one hand, and estimates of the terms of E_ϵ on the other hand. The generalized Willmore functional we use gives in particular a direct link between the functionals T_ϵ and the classical Willmore functional. But to apply the theory successfully, it is important to show that the terms

$$\frac{\epsilon}{2}|\nabla u_\epsilon|^2$$

are bounded by the other contribution to $E_\epsilon(u_\epsilon)$,

$$\frac{1}{4\epsilon}(1-u_\epsilon^2)^2,$$

in an appropriate sense, at least in the limit. Such estimates are also important in the works of Hutchinson and Tonegawa [9], Tonegawa [23], and Bellettini and Mugnai [5]. Apart from these estimates, however, we use relatively little information about the structure of the problem. This means that our methods can also be applied to other problems. For instance, it is not difficult to see that similar results can be obtained if the potential given by the function $(1-u^2)^2$ is replaced by another two-well potential. (We leave it to the reader to verify the details.) Similar tools as we use here have also been applied to a problem related to harmonic maps in [17].

We conclude the introduction by pointing out that the Willmore functional can always be approximated by T_ϵ for sufficiently smooth surfaces. Suppose, e.g., that $U \subset \mathbb{R}^3$ is a bounded, open set with C^2-regular boundary. Choose a function $\chi \in C^2(\mathbb{R}^3)$ with $\chi \equiv 1$ on $\Sigma = \partial U$, such that the distance function $\operatorname{dist}(\,\cdot\,, \Sigma)$ is of class C^2 in a neighborhood of $\operatorname{supp}\chi$. Then the functions

$$u_\epsilon(x) = \begin{cases} \chi(x)\tanh\left(\frac{\operatorname{dist}(x,\Sigma)}{\sqrt{2}\epsilon}\right) & \text{if } x \notin U, \\ -\chi(x)\tanh\left(\frac{\operatorname{dist}(x,\Sigma)}{\sqrt{2}\epsilon}\right) & \text{if } x \in U \end{cases}$$

satisfy

$$\lim_{\epsilon\searrow 0} \frac{\epsilon}{2} \int_\Omega \eta |\nabla u_\epsilon|^2 \, dx = \lim_{\epsilon\searrow 0} \frac{1}{4\epsilon} \int_\Omega \eta(1-u_\epsilon^2)^2 \, dx = \frac{\sqrt{2}}{3} \int_\Sigma \eta \, d\mathcal{H}^2$$

for any $\eta \in C_0^0(\mathbb{R}^3)$ and

$$\frac{2\sqrt{2}}{3} W(\Sigma) = \lim_{\epsilon \searrow 0} T_\epsilon(u_\epsilon).$$

The proof consists of the obvious computations and the observation that the function $v(s) = \tanh(s/(\sqrt{2}\epsilon))$ solves

$$v'' + (1 - v^2)v = 0.$$

2. A generalization of the Willmore functional. We need a few tools from geometric measure theory, among them some concepts from [16, 18, 17] that can be regarded as variants of the notion of varifolds (cf. Simon [20] and Allard [1]). Similar tools have been developed by Ambrosio and Soner [4] and Lin [10]. Yet in none of these papers are they quite in the right form for the problem we study here; therefore we present the theory from the beginning. Because it might also be of independent interest, we consider arbitrary dimensions $n \geq 2$. In this section, we assume that Ω is an open set in $\mathbb{R}^n$.

Let $\mathcal{S}$ be the set of all symmetric, positive semidefinite real $(n \times n)$-matrices. We write $\mathcal{M}(\Omega)$ for the set of all pairs $M = (\mu, \nu)$, such that

- μ is a Radon measure on Ω (with nonnegative values),
- ν is a Radon measure on Ω with values in $\mathcal{S}$, and
- there exists a function $\sigma \in L^\infty(\mu, \mathcal{S})$ such that $\nu = \mu \llcorner \sigma$.

If $M = (\mu, \nu) \in \mathcal{M}(\Omega)$, we define the linear functional

$$\delta M(\phi) = \int_\Omega \left(\operatorname{div} \phi \, d\mu - \frac{\partial \phi^\alpha}{\partial x^\beta} \, d\nu_{\alpha\beta} \right)$$

on $C_0^1(\Omega, \mathbb{R}^n)$. Here and throughout the paper we use a summation convention: a repeated Greek index indicates a summation over its range.

Examples.

(i) Suppose $\Sigma \subset \Omega$ is a countably m-rectifiable set and

$$\theta \in L^1_{\mathrm{loc}}(\mathcal{H}^m \llcorner \Sigma, [0, \infty)).$$

Define $M = (\mu, \nu)$, where

$$\mu = (\mathcal{H}^m \llcorner \Sigma) \llcorner \theta \tag{2.1}$$

and

$$\nu = \mu \llcorner \sigma \tag{2.2}$$

for $\sigma(x) = \operatorname{proj}^\perp_{T_x\Sigma}$. Then

$$\delta M(\phi) = \int_\Sigma (\operatorname{div}_\Sigma \phi) \theta \, d\mathcal{H}^m.$$

(ii) If $\epsilon > 0$ and $u \in H^2_{\mathrm{loc}}(\Omega)$, define

$$\mu = \mathcal{L}^n \llcorner \left(\frac{\epsilon}{2} |\nabla u|^2 + \frac{1}{4\epsilon}(1 - u^2)^2 \right) \tag{2.3}$$

(where $\mathcal{L}^n$ is the Lebesgue measure in Ω), and

$$\nu_{\alpha\beta} = \epsilon\mathcal{L}^n \llcorner \left(\frac{\partial u}{\partial x^\alpha}\frac{\partial u}{\partial x^\beta}\right). \tag{2.4}$$

Then the pair $M = (\mu, \nu)$ satisfies

$$\delta M(\phi) = \int_\Omega \phi \cdot \nabla u\, \tau_\epsilon(u)\, dx.$$

(iii) Other examples of possible applications are given in [16, 18, 17].

The examples indicate that the space $\mathcal{M}(\Omega)$ can provide a connection between the functionals E_ϵ and the (generalized) area functional. The following notion also gives a relation between T_ϵ and the Willmore functional.

Definition 2.1. *The functional W on $\mathcal{M}(\Omega)$ given by*

$$W(M) = \frac{1}{4}\sup\left\{(\delta M(\phi))^2 :\ \phi \in C_0^1(\Omega, \mathbb{R}^n) \text{ with } \int_\Omega \phi^\alpha\phi^\beta\, d\nu_{\alpha\beta} \le 1\right\}$$

is called the generalized Willmore functional*. We write*

$$\mathcal{W}(\Omega) = \{M \in \mathcal{M}(\Omega) :\ W(M) < \infty\}.$$

Examples.

(i) Suppose $\Sigma \subset \Omega$ is countably m-rectifiable and $\theta \in L^1_{\mathrm{loc}}(\mathcal{H}^m \llcorner \Sigma, [0,\infty))$, such that there exists an $\mathcal{H}^m$-measurable function $H : \Sigma \to \mathbb{R}^n$ with

$$H(x) \perp T_x\Sigma \tag{2.5}$$

for $\mathcal{H}^m$-almost every $x \in \Sigma$ and

$$\int_\Sigma (\operatorname{div}_\Sigma \phi + \phi \cdot H)\theta\, d\mathcal{H}^m = 0$$

for every $\phi \in C_0^1(\Omega, \mathbb{R}^n)$. If $M = (\mu, \nu)$ is defined by (2.1) and (2.2), then

$$W(M) = \frac{1}{4}\int_\Sigma |H|^2\theta\, d\mathcal{H}^m.$$

But if (2.5) is not satisfied $\mathcal{H}^m$-almost everywhere, then $W(M) = \infty$.

(ii) If $\epsilon > 0$ and $u \in H^2_{\mathrm{loc}}(\Omega)$, and if $M = (\mu, \nu)$ is given by (2.3) and (2.4), then

$$\begin{aligned}(\delta M(\phi))^2 &= \left(\int_\Omega \phi \cdot \nabla u\, \tau_\epsilon(u)\, dx\right)^2 \\ &\le \left(\int_\Omega (\tau_\epsilon(u))^2\, dx\right)\left(\int_\Omega (\phi \cdot \nabla u)^2\, dx\right) = 4T_\epsilon(u)\int_\Omega \phi^\alpha\phi^\beta\, d\nu_{\alpha\beta}.\end{aligned}$$

Thus $W(M) \le T_\epsilon(u)$.

In the rest of the section we analyze measure pairs in $\mathcal{W}(\Omega)$. We first show that a representation of δM by an $\mathbb{R}^n$-valued function H as in the first example always exists for $M \in \mathcal{W}(\Omega)$.

Proposition 2.2. *Suppose that $M = (\mu, \nu) \in \mathcal{W}(\Omega)$, and let $\sigma \in L^\infty(\mu, \mathcal{S})$ be the function such that $\nu = \mu \llcorner \sigma$. Then there exists a μ-measurable function $H = (H^1, \ldots, H^n) : \Omega \to \mathbb{R}^n$ with $H^\beta \sigma_{\alpha\beta} \in L^1_{\mathrm{loc}}(\mu)$ for $\alpha = 1, \ldots, n$, such that*

$$\delta M(\phi) = -\int_\Omega \phi^\alpha H^\beta \, d\nu_{\alpha\beta} \tag{2.6}$$

for every $\phi \in C^1_0(\Omega, \mathbb{R}^n)$ and

$$H(x) \perp \ker \sigma(x) \tag{2.7}$$

for μ-almost every $x \in \Omega$. Moreover,

$$W(M) = \frac{1}{4} \int_\Omega H^\alpha H^\beta \, d\nu_{\alpha\beta}. \tag{2.8}$$

Any other function satisfying (2.6) *and* (2.7) *agrees with H except possibly on a μ-null set.*

Proof. The functional δM on $C^1_0(\Omega, \mathbb{R}^n)$ satisfies

$$\begin{aligned} |\delta M(\phi)| &\le 2 \left(W(M) \int_\Omega \phi^\alpha \phi^\beta \, d\nu_{\alpha\beta} \right)^{1/2} \\ &\le 2 \|\phi\|_{C^0(\overline{\Omega})} (W(M) \|\sigma\|_{L^\infty(\mu)} \mu(\operatorname{supp} \phi))^{1/2}. \end{aligned} \tag{2.9}$$

Hence there exists a continuous extension to $C^0_0(\Omega, \mathbb{R}^n)$, represented by an $\mathbb{R}^n$-valued Radon measure h on Ω. Moreover, this measure is absolutely continuous with respect to μ. By the Radon–Nikodým theorem there exists a unique function $\hat{H} \in L^1_{\mathrm{loc}}(\mu, \mathbb{R}^n)$ such that $h = \mu \llcorner \hat{H}$. In other words, we have

$$\delta M(\phi) = \int_\Omega \phi \cdot \hat{H} \, d\mu$$

for any $\phi \in C^1_0(\Omega, \mathbb{R}^n)$. Now we consider the first inequality in (2.9) again. Any $\psi \in L^\infty(\mu, \mathbb{R}^n) \cap L^2(\mu, \mathbb{R}^n)$ with

$$\int_\Omega \psi^\alpha \psi^\beta \, d\nu_{\alpha\beta} = 0$$

can be approximated by a sequence of vector fields $\psi_i \in C^1_0(\Omega, \mathbb{R}^n)$ such that, as $i \to \infty$, $\|\psi_i - \psi\|_{L^2(\mu)} \to 0$ (because μ is a Radon measure). Hence

$$\left| \int_\Omega \psi \cdot \hat{H} \, d\mu \right| = \lim_{i \to \infty} \left| \int_\Omega \psi_i \cdot \hat{H} \, d\mu \right| \le 2\sqrt{W(M)} \limsup_{i \to \infty} \left(\int_\Omega \psi_i^\alpha \psi_i^\beta \, d\nu_{\alpha\beta} \right)^{1/2} = 0.$$

It follows that $\hat{H}(x) \perp \ker \sigma(x)$ for μ-almost every $x \in \Omega$. In particular there is a function $H : \Omega \to \mathbb{R}^n$, unique up to a μ-null set, such that (2.7) holds and

$$X \cdot \hat{H}(x) = -X^\alpha H^\beta(x) \sigma_{\alpha\beta}(x)$$

for μ-almost every $x \in \Omega$ and every $X \in \mathbb{R}^n$. This H satisfies (2.6). Only (2.8) remains to be proved.

The inequality

$$W(M) \leq \frac{1}{4} \int_\Omega H^\alpha H^\beta \, d\nu_{\alpha\beta}$$

follows directly from the definition of the functional W. To show the converse inequality, we approximate H by a sequence of functions $H_i \in C_0^1(\Omega, \mathbb{R}^n)$ such that

$$\lim_{i\to\infty} \int_\Omega (H^\alpha - H_i^\alpha)(H^\beta - H_i^\beta) \, d\nu_{\alpha\beta} = 0.$$

Then we have

$$W(M) \geq \frac{\left(\int_\Omega H^\alpha H_i^\beta \, d\nu_{\alpha\beta}\right)^2}{4\int_\Omega H_i^\alpha H_i^\beta \, d\nu_{\alpha\beta}}$$

for every i (provided that the denominator on the right-hand side does not vanish). For $i \to \infty$, we obtain the desired inequality. □

DEFINITION 2.3. *If $M = (\mu, \nu)$ is in $\mathcal{W}(\Omega)$ and $H : \Omega \to \mathbb{R}^n$ satisfies* (2.6) *and* (2.7)*, then H is called the* generalized mean curvature *of M. For any Borel set $A \subset \Omega$, we write*

$$W(M; A) = \frac{1}{4} \int_A H^\alpha H^\beta \, d\nu_{\alpha\beta}.$$

DEFINITION 2.4. *Suppose $M^{(k)} = (\mu^{(k)}, \nu^{(k)}) \in \mathcal{W}(\Omega)$ for $k \in \mathbb{N}$, and $M = (\mu, \nu) \in \mathcal{W}(\Omega)$. We say that $M^{(k)}$* converges weakly *to M and we write $M^{(k)} \rightharpoonup M$ if*

$$\sup_{k\in\mathbb{N}} W(M^{(k)}) < \infty$$

and, for every $\eta \in C_0^0(\Omega)$,

$$\int_\Omega \eta \, d\mu = \lim_{k\to\infty} \int_\Omega \eta \, d\mu^{(k)} \quad \textit{and} \quad \int_\Omega \eta \, d\nu = \lim_{k\to\infty} \int_\Omega \eta \, d\nu^{(k)}.$$

We say that $M^{(k)}$ converges strongly *to M and we write $M^{(k)} \to M$ if $M^{(k)} \rightharpoonup M$ and*

$$W(M) \geq \limsup_{k\to\infty} W(M^{(k)}).$$

Remark. The following is an immediate consequence of the definition of W: if $M^{(k)} \rightharpoonup M$, then

$$W(M) \leq \liminf_{k\to\infty} W(M^{(k)}).$$

Thus if $M^{(k)} \to M$, then

$$W(M) = \lim_{k\to\infty} W(M^{(k)}).$$

The space $\mathcal{W}(\Omega)$ is quite large. For instance, it contains measure pairs corresponding to countably rectifiable sets in Ω of any dimension. For some of the results in this section we have to consider a smaller subspace. We write $\mathcal{W}_m(\Omega)$ for the set of all pairs $M = (\mu, \nu) \in \mathcal{W}(\Omega)$ that satisfy

$$\operatorname{trace} \nu \leq (n-m)\mu. \tag{2.10}$$

In order to obtain some idea of what this condition means, consider an M that belongs to a rectifiable set Σ as in the examples above. Then (2.10) is satisfied if and only if the dimension of Σ is at least m.

For $M = (\mu, \nu) \in \mathcal{W}_m(\Omega)$, in particular if $m = 2$, we want to examine the behavior of quantities of the form $r^{-m}\mu(B_r(x_0))$ as $r \searrow 0$, where $B_r(x_0)$ denotes the open ball in $\mathbb{R}^n$ of center x_0 and radius r. The following lemma gives an inequality which is useful for that purpose. It is a variant of a result that is well known for many related theories. (Cf. Allard [1], Price [19], and Simon [21]. There are many other papers with results of this kind.)

LEMMA 2.5. *Suppose $M = (\mu, \nu) \in \mathcal{W}_m(\Omega)$ has the generalized mean curvature H. For $x_0 \in \Omega$ and $0 < \rho < \operatorname{dist}(x_0, \partial\Omega)$, set*

$$\Phi_M(x_0, \rho) = \rho^{-m}\left(\mu(B_\rho(x_0)) + \frac{1}{m}\int_{B_\rho(x_0)} (x^\alpha - x_0^\alpha)H^\beta(x)\, d\nu_{\alpha\beta}(x)\right).$$

If $0 < s \leq r < \operatorname{dist}(x_0, \partial\Omega)$, then

$$\Phi_M(x_0, s) \leq \Phi_M(x_0, r) + I,$$

where

$$I = \int_{B_r(x_0)\setminus B_s(x_0)} \left(\frac{(x^\alpha - x_0^\alpha)(x^\beta - x_0^\beta)}{|x - x_0|^{m+2}} + \frac{(x^\alpha - x_0^\alpha)H^\beta(x)}{m|x - x_0|^m}\right) d\nu_{\alpha\beta}(x).$$

Proof. We assume for simplicity that $x_0 = 0$. Suppose $\psi \in C_0^1(B_1(0))$ is a nonnegative function. For $\rho > 0$, set $\psi_\rho(x) = \psi(x/\rho)$. Insert now $\phi(x) = \psi_\rho(x)x$ into (2.6). The resulting equation is

$$\begin{aligned}\int_\Omega \psi_\rho(n\, d\mu - \operatorname{trace} d\nu) + \frac{1}{\rho}\int_\Omega x \cdot \nabla\psi(x/\rho)\, d\mu(x)&\\ - \int_\Omega \left(\frac{x^\alpha}{\rho}\frac{\partial\psi}{\partial x^\beta}(x/\rho) - x^\alpha H^\beta(x)\psi_\rho(x)\right) d\nu_{\alpha\beta}(x) &= 0.\end{aligned}$$

Thus (2.10) implies

$$\begin{aligned}m\int_\Omega \psi_\rho d\mu + \frac{1}{\rho}\int_\Omega x \cdot \nabla\psi(x/\rho)\, d\mu(x)&\\ - \int_\Omega \left(\frac{x^\alpha}{\rho}\frac{\partial\psi}{\partial x^\beta}(x/\rho) - x^\alpha H^\beta(x)\psi_\rho(x)\right) d\nu_{\alpha\beta}(x) &\leq 0.\end{aligned}$$

It follows that

$$\begin{aligned}\frac{d}{d\rho}\left(\rho^{-m}\int_\Omega \psi_\rho\, d\mu + \frac{1}{m}\int_\Omega \psi_\rho(x)x^\alpha H^\beta(x)\, d\nu_{\alpha\beta}(x)\right)&\\ \geq -\rho^{-m-2}\int_\Omega \left(x^\alpha\frac{\partial\psi}{\partial x^\beta}(x/\rho) + \frac{1}{m}x \cdot \nabla\psi(x/\rho)x^\alpha H^\beta(x)\right) d\nu_{\alpha\beta}(x).&\end{aligned} \tag{2.11}$$

If ψ is of the form $\psi(x) = \eta(|x|)$ for some $\eta \in C^1(\mathbb{R})$ with $\eta \equiv 0$ in $[1, \infty)$, the right-hand side of (2.11) is

$$-\rho^{-m-2} \int_\Omega \eta'(|x|/\rho) \left(\frac{x^\alpha x^\beta}{|x|} + \frac{1}{m} |x| x^\alpha H^\beta(x) \right) d\nu_{\alpha\beta}(x).$$

For

$$\Phi_\psi(\rho) = \rho^{-m} \left(\int_{B_\rho(x_0)} \psi_\rho d\mu + \frac{1}{m} \int_{B_\rho(x_0)} \psi_\rho x^\alpha H^\beta(x)\, d\nu_{\alpha\beta}(x) \right),$$

it follows that

$$\begin{aligned}\Phi_\psi(r) - \Phi_\psi(s) &\geq - \int_s^r \rho^{-m-2} \int_\Omega \eta'(|x|/\rho) \left(\frac{x^\alpha x^\beta}{|x|} + \frac{1}{m} |x| x^\alpha H^\beta(x) \right) d\nu_{\alpha\beta}(x)\, d\rho \\ &= \int_\Omega \int_s^r \rho^{-m} \frac{d}{d\rho} \eta(|x|/\rho)\, d\rho \left(\frac{x^\alpha x^\beta}{|x|^2} + \frac{1}{m} x^\alpha H^\beta(x) \right) d\nu_{\alpha\beta}(x).\end{aligned}$$

We have

$$\int_s^r \rho^{-m} \frac{d}{d\rho} \eta(|x|/\rho)\, d\rho = r^{-m} \eta(|x|/r) - s^{-m} \eta(|x|/s) + m \int_s^r \rho^{-m-1} \eta(|x|/\rho)\, d\rho. \tag{2.12}$$

If we approximate the characteristic function of the interval $(-\infty, 1)$ by a sequence of C^1-functions and insert these approximations instead of η into (2.12), the right-hand side converges to 0 if $|x| \geq r$ or $|x| < s$ and to

$$r^{-m} + m \int_{|x|}^r \rho^{-m-1}\, d\rho = |x|^{-m}$$

if $|x| \in [s, r)$. The claim of the lemma now follows from Lebesgue's convergence theorem. □

LEMMA 2.6. *Suppose $M = (\mu, \nu) \in \mathcal{W}_2(\Omega)$ and $\sigma \in L^\infty(\mu, \mathcal{S})$ such that $\nu = \mu \llcorner \sigma$. Then for any $\delta > 0$ and for any pair of concentric balls $B_s(x_0) \subset B_r(x_0) \subset \Omega$, the inequality*

$$(1 - \delta) s^{-2} \mu(B_s(x_0)) \leq (1 + \delta) r^{-2} \mu(B_r(x_0)) + \left(\frac{1}{4} + \frac{\|\sigma\|_{L^\infty(\mu)}}{2\delta} \right) W(M; B_r(x_0))$$

holds.

Proof. We use Lemma 2.5 and the estimates

$$\begin{aligned}&\frac{1}{2\rho^2} \left| \int_{B_\rho(x_0)} (x^\alpha - x_0^\alpha) H^\beta(x)\, d\nu_{\alpha\beta}(x) \right| \\ &\qquad \leq \frac{1}{2\rho^2} \left(\int_{B_\rho(x_0)} (x^\alpha - x_0^\alpha)(x^\beta - x_0^\beta)\, d\nu_{\alpha\beta}(x) \right)^{1/2} \left(\int_{B_\rho(x_0)} H^\alpha H^\beta\, d\nu_{\alpha\beta} \right)^{1/2} \\ &\qquad \leq \delta \rho^{-2} \mu(B_\rho(x_0)) + \frac{\|\sigma\|_{L^\infty(\mu)}}{4\delta} W(M; B_\rho(x_0))\end{aligned}$$

and

$$\begin{aligned}&\left| \int_{B_r(x_0) \setminus B_s(x_0)} \frac{(x^\alpha - x_0^\alpha) H^\beta(x)}{2|x - x_0|^2}\, d\nu_{\alpha\beta}(x) \right| \\ &\qquad \leq \int_{B_r(x_0) \setminus B_s(x_0)} \frac{(x^\alpha - x_0^\alpha)(x^\beta - x_0^\beta)}{|x - x_0|^4}\, d\nu_{\alpha\beta}(x) + \frac{1}{16} \int_{B_r(x_0) \setminus B_s(x_0)} H^\alpha H^\beta\, d\nu_{\alpha\beta}.\end{aligned}$$

It now suffices to combine the inequalities. ◻

If $M = (\mu, \nu) \in \mathcal{W}_2(\Omega)$, we conclude from Lemma 2.6 that $\mu(\{x\}) = 0$ for every $x \in \Omega$. Hence

$$\lim_{r \searrow 0} W(M; B_r(x)) = 0.$$

Thus it also follows from Lemma 2.6 that the 2-density

$$\Theta_M(x) = \lim_{r \searrow 0} r^{-2} \mu(B_r(x)) \tag{2.13}$$

exists for every $x \in \Omega$. Moreover, the function Θ_M defined by (2.13) has the following property.

LEMMA 2.7. *Let $M^{(k)} = (\mu^{(k)}, \nu^{(k)}) \in \mathcal{W}_2(\Omega)$ for $k \in \mathbb{N}$, and $M = (\mu, \nu) \in \mathcal{W}_2(\Omega)$ such that $M^{(k)} \to M$. Suppose $\sigma^{(k)} \in L^\infty(\mu^{(k)}, \mathcal{S})$ are the functions such that $\nu^{(k)} = \mu^{(k)} \llcorner \sigma^{(k)}$. Let $x_k \in \Omega$ with $x_k \to x_0 \in \Omega$ as $k \to \infty$. If*

$$\sup_{k \in \mathbb{N}} \|\sigma^{(k)}\|_{L^\infty(\mu^{(k)})} < \infty,$$

then

$$\Theta_M(x_0) \geq \limsup_{k \to \infty} \Theta_{M^{(k)}}(x_k).$$

Remark. It follows in particular that Θ_M is upper semicontinuous.

Proof. Let $\epsilon > 0$. There exists a radius $r > 0$ such that

$$\Theta_M(x_0) \geq r^{-2} \mu(\overline{B_r(x_0)}) - \epsilon$$

and

$$W(M; \overline{B_r(x_0)}) \leq \epsilon.$$

Hence

$$\Theta_M(x_0) \geq r^{-2} \limsup_{k \to \infty} \mu^{(k)}(B_r(x_0)) - \epsilon$$

and

$$\limsup_{k \to \infty} W(M^{(k)}; B_r(x_0)) \leq \epsilon.$$

Now Lemma 2.6 implies that

$$\Theta_{M^{(k)}}(x_0) \leq (1+\delta) r^{-2} \mu^{(k)}(B_r(x_0)) + C\left(1 + \frac{1}{\delta}\right)\epsilon$$

for any $\delta \in (0, 1]$ and any sufficiently large k, where C is a number that depends only on

$$\sup_{k \in \mathbb{N}} \|\sigma^{(k)}\|_{L^\infty(\mu^{(k)})}.$$

Thus

$$\limsup_{k \to \infty} \Theta_{M^{(k)}}(x_0) \leq (1+\delta)(\Theta_M(x_0) + \epsilon) + C\left(1 + \frac{1}{\delta}\right)\epsilon.$$

Since ϵ and δ are arbitrary, the claim follows. ◻

For a fixed $M = (\mu, \nu) \in \mathcal{W}_2(\Omega)$ and a fixed point $x_0 \in \Omega$, we now consider the rescaled measure pairs $M^{x_0,r} = (\mu^{x_0,r}, \nu^{x_0,r}) \in \mathcal{W}_2(\Omega^{x_0,r})$, where $\Omega^{x_0,r} = r^{-1}(\Omega - x_0)$, defined by

$$\int_{\Omega^{x_0,r}} \eta \, d\mu^{x_0,r} = r^{-2} \int_{\Omega} \eta((x - x_0)/r) \, d\mu(x)$$

and

$$\int_{\Omega^{x_0,r}} \eta \, d\nu^{x_0,r} = r^{-2} \int_{\Omega} \eta((x - x_0)/r) \, d\nu(x)$$

for all $\eta \in C_0^0(\Omega^{x_0,r})$. We have

$$\lim_{r \searrow 0} \mu^{x_0,r}(B_R(0)) = \lim_{r \searrow 0} r^{-2} \mu(B_{Rr}(x_0)) = R^2 \Theta_M(x_0)$$

for almost any $R > 0$. If $\phi \in C_0^1(\mathbb{R}^n, \mathbb{R}^n)$, then

$$\delta M^{x_0,r}(\phi) = r^{-1} \delta M(\phi((x - x_0)/r))$$

for any r that is large enough so that $\operatorname{supp} \phi \subset \Omega^{x_0,r}$. If $R > 0$ is such that $\operatorname{supp} \phi \in B_R(0)$, then it follows that

$$|\delta M^{x_0,r}(\phi)| \leq 2 \sup_{\mathbb{R}^n} |\phi| \left(\|\sigma\|_{L^\infty(\mu)} r^{-2} \mu(B_{Rr}(x_0)) W(M; B_{Rr}(x_0)) \right)^{1/2} \to 0$$

as $r \searrow 0$ (where $\sigma \in L^\infty(\mu, \mathcal{S})$ is such that $\nu = \mu \llcorner \sigma$).

We infer that we can choose a sequence $r_k \searrow 0$ such that $M^{x_0,r_k} \to M^*$ for some $M^* = (\mu^*, \nu^*) \in \mathcal{W}_2(\mathbb{R}^n)$ with $\delta M^* = 0$ (in the sense that the restrictions of M^{x_0,r_k} to any bounded domain in $\mathbb{R}^n$ converge strongly to the corresponding restrictions of M^*). Moreover, any given sequence $r_k \searrow 0$ has a subsequence with this property.

Definition 2.8. *Any measure pair $M^* \in \mathcal{W}_2(\Omega)$ obtained by a limit process as described above is called a* tangent measure pair *of M at x_0.*

Lemma 2.9. *Suppose $M^* = (\mu^*, \nu^*)$ is a tangent measure pair of $M = (\mu, \nu) \in \mathcal{W}_2(\Omega)$ at $x_0 \in \Omega$. Then $r^{-2}\mu^*(B_r(0)) = \Theta_M(x_0)$ for any $r > 0$.*

Proof. For all but countably many $r > 0$, we have

$$\mu^*(B_r(0)) = \lim_{k \to \infty} \mu^{x_0,r_k}(B_r(0)) = \lim_{k \to \infty} r_k^{-2} \mu(B_{rr_k}(x_0)) = r^2 \Theta_M(x_0).$$

By Lemma 2.5, the quantity $r^{-2}\mu^*(B_r(0))$ is nondecreasing; hence the identity holds even for all $r > 0$. □

Lemma 2.10. *Suppose $M^* = (\mu^*, \nu^*) \in \mathcal{W}_2(\mathbb{R}^n)$ satisfies $\delta M^* = 0$ and*

$$r^{-2}\mu^*(B_r(0)) = s^{-2}\mu^*(B_s(0)) \tag{2.14}$$

for every pair of positive numbers r, s. Then the set

$$S(M^*) = \{x \in \mathbb{R}^n : \Theta_{M^*}(x) \geq \Theta_{M^*}(0)\}$$

is a linear subspace of $\mathbb{R}^n$. If $\mu^* \neq 0$, then $\dim S(M^*) \leq 2$, and the following three conditions are equivalent:

(i) $\dim S(M^*) = 2$,

(ii) $\mu^*(\mathbb{R}^n \backslash S(M^*)) = 0$,

(iii) $\mu^* = \pi^{-1}\Theta_{M^*}(0)\mathcal{H}^2 \llcorner S(M^*)$ *and* $\nu^* = \operatorname{proj}^{\perp}_{S(M^*)} \mu^*$.

Proof. We may assume $\mu^* \neq 0$. Let $\sigma^* \in L^\infty(\mu^*, \mathcal{S})$ be the function such that $\nu^* = \mu^* \llcorner \sigma^*$. Then (2.14) and Lemma 2.5 imply that $x \in \ker \sigma^*(x)$ for μ^*-almost every $x \in \mathbb{R}^n$. If $x_0 \in \mathbb{R}^n$ and $r > 0$, Lemma 2.5 also implies

$$\Theta_{M^*}(x_0) + \int_{B_r(x_0)} \frac{(x^\alpha - x_0^\alpha)(x^\beta - x_0^\beta)}{|x - x_0|^4}\, d\nu^*_{\alpha\beta}(x) \\ \leq r^{-2}\mu^*(B_r(x_0)) \leq r^{-2}\mu^*(B_{r+|x_0|}(0)) = \left(1 + \frac{|x_0|}{r}\right)^{-2} \Theta_{M^*}(0).$$

Letting $r \to \infty$, we see that $\Theta_{M^*}(x_0) \leq \Theta_{M^*}(0)$, and $\Theta_{M^*}(x_0) = \Theta_{M^*}(0)$ only if $x - x_0 \in \ker \sigma^*(x)$ for μ^*-almost every $x \in \mathbb{R}^n$.

Let $x_0 \in S(M^*)$. Then it follows that $x_0 \in \ker \sigma^*(x)$ for μ^*-almost every $x \in \mathbb{R}^n$. Let $\eta \in C_0^1(\mathbb{R}^n)$; then

$$\frac{d}{dt}\int_{\mathbb{R}^n} \eta(x + tx_0)\, d\mu^*(x) = \int_{\mathbb{R}^n} x_0 \cdot \nabla\eta(x + tx_0)\, d\mu^*(x) \\ = \int_{\mathbb{R}^n} x_0^\alpha \frac{\partial \eta}{\partial x^\beta}(x + tx_0)\, d\nu^*_{\alpha\beta}(x) = 0,$$

because $\delta M^* = 0$. That is, the measure μ^* is invariant under translations in the direction of x_0. It follows that $S(M^*)$ is a linear subspace of $\mathbb{R}^n$. Moreover, this translation invariance and (2.14) imply $\dim S(M^*) \leq 2$, and they also imply the equivalence of (i) and (ii). Obviously, (iii) implies (ii). Thus it remains to show that (ii) implies (iii).

For the rest of the proof, we assume that $S(M^*) = \mathbb{R}^2 \times \{0\}$ for simplicity. We also assume that $\mu^*(\mathbb{R}^n \backslash S(M^*)) = 0$. We already know that $\nu^*_{1\alpha} = \nu^*_{2\alpha} = 0$ for $\alpha = 1, \ldots, n$. Now for $\xi \in C_0^1(\mathbb{R}^2)$ and $\zeta \in C_0^1(\mathbb{R}^{n-2})$, consider a vector field of the form

$$\phi(x^1, \ldots, x^n) = \xi(x^1, x^2)\zeta(x^3, \ldots, x^n)e_\alpha,$$

where $\alpha \geq 3$ and e_α is the αth standard unit vector in $\mathbb{R}^n$. Because $\delta M^* = 0$, we have

$$\int_{\mathbb{R}^2 \times \{0\}} \xi(x^1, x^2) \left(\frac{\partial \zeta}{\partial x^\alpha}(0)\, d\mu^*(x) - \frac{\partial \zeta}{\partial x^\beta}(0)\, d\nu^*_{\alpha\beta}(x)\right) = 0.$$

If we choose ζ such that $(0, 0, \frac{\partial \zeta}{\partial x^3}, \ldots, \frac{\partial \zeta}{\partial x^n}) = e_\beta$, it follows that $\nu^*_{\alpha\beta} = 0$ for $\alpha \neq \beta$ and

$$\nu^*_{33} = \cdots = \nu^*_{nn} = \mu^*.$$

This shows (iii) and concludes the proof. $\square$

PROPOSITION 2.11. *If $M = (\mu, \nu) \in \mathcal{W}_2(\Omega)$, then the set*

$$\Sigma = \{x \in \Omega \colon\ \Theta_M(x) > 0\}$$

is countably 2-rectifiable. If $\sigma \in L^\infty(\mu, \mathcal{S})$ is such that $\nu = \mu \llcorner \sigma$, then $\sigma(x) = \mathrm{proj}^\perp_{T_x\Sigma}(x)$ for μ-almost every $x \in \Sigma$.

Proof. Let Σ_0 be the set of all points $x \in \Sigma$ such that σ and Θ_M are approximately continuous at x with respect to μ. Then $\mu(\Sigma \backslash \Sigma_0) = 0$. Suppose $x_0 \in \Sigma_0$. Let

$M^* = (\mu^*, \nu^*)$ be a tangent measure pair of M at x_0. From Lemmas 2.7 and 2.9 it follows that

$$\Theta_{M^*}(x) \geq \Theta_M(x_0) = \Theta_{M^*}(0) > 0$$

for μ^*-almost every $x \in \mathbb{R}^n$. Thus the set $S(M^*)$ defined in Lemma 2.10 is a two-dimensional linear subspace of $\mathbb{R}^n$. Moreover,

$$\mu^* = \pi^{-1}\Theta_M(x_0)\mathcal{H}^2 \llcorner S(M^*)$$

and

$$\nu^* = \mathrm{proj}^{\perp}_{S(M^*)}\mu^*.$$

Because σ is approximately continuous at x_0, we have $\sigma(x_0) = \mathrm{proj}^{\perp}_{S(M^*)}$. In particular the tangent measure pair M^* is unique. The claims now follow from standard arguments from geometric measure theory (cf. Federer [7] or Simon [20]). $\square$

3. Energy estimates. We now assume again that Ω is a three-dimensional domain, that is, $\Omega \subset \mathbb{R}^3$. For $\epsilon > 0$, we examine functions $u \in H^2_{\mathrm{loc}}(\Omega)$ such that $E_\epsilon(u)$ and $T_\epsilon(u)$ are finite. We first derive a few inequalities that will be useful when we consider the limit $\epsilon \searrow 0$ later in this section.

All of the inequalities we prove here are of a local character. Throughout the section, we assume that $\Omega_0 \subset \Omega$ is an open, bounded set such that its closure is contained in Ω.

LEMMA 3.1. *There exists a constant C such that for any $\epsilon > 0$ and any $u \in H^2_{\mathrm{loc}}(\Omega)$, the set*

$$\Omega_1 = \{x \in \Omega_0 \colon\ |u(x)| \geq 1\}$$

satisfies

$$\int_{\Omega_1} \left(\frac{\epsilon}{2}|\nabla u|^2 + \frac{1}{4\epsilon}(1-u^2)^2\right) dx \leq C\epsilon^2(T_\epsilon(u) + E_\epsilon(u)).$$

Proof. Choose a cutoff function $\eta \in C_0^\infty(\Omega)$ with $0 \leq \eta \leq 1$ and $\eta \equiv 1$ in Ω_0. Define

$$\Omega_1^+ = \{x \in \Omega \colon\ u(x) \geq 1\}$$

and

$$\Omega_1^- = \{x \in \Omega \colon\ u(x) \leq -1\}.$$

Then

$$\begin{aligned}
\epsilon \int_{\Omega_1^+} \eta^2 |\nabla u|^2\, dx &= \epsilon \int_{\Omega_1^+} \eta^2 \nabla(u-1)\cdot\nabla u\, dx \\
&= \frac{1}{\epsilon}\int_{\Omega_1^+} \eta^2 (u-1)(1-u^2)u\, dx - \int_{\Omega_1^+} \eta^2(u-1)\tau_\epsilon(u)\, dx \\
&\quad - 2\epsilon \int_{\Omega_1^+} \eta(u-1)\nabla\eta\cdot\nabla u\, dx \\
&\leq \epsilon^2 T_\epsilon(u) + \frac{1}{\epsilon}\int_{\Omega_1^+} \eta^2[(u-1)^2 + (u-1)(1-u^2)u]\, dx \\
&\quad + \frac{\epsilon}{2}\int_{\Omega_1^+} \eta^2|\nabla u|^2\, dx + 2\epsilon\|\nabla\eta\|_{L^\infty(\Omega)} \int_{\Omega_1^+} (u-1)^2\, dx.
\end{aligned}$$

In Ω_1^+, we have $(u-1)^2 \le \frac{1}{4}(1-u^2)^2$ and

$$(u-1)^2 + (u-1)(1-u^2)u = (1-u^2)^2 \left[\frac{1}{(u+1)^2} - \frac{u}{u+1}\right] \le -\frac{1}{4}(1-u^2)^2.$$

Thus

$$\int_{\Omega_1^+} \eta^2 \left(\frac{\epsilon}{2}|\nabla u|^2 + \frac{1}{4\epsilon}(1-u^2)^2\right) dx \le \epsilon^2 T_\epsilon(u) + 2\epsilon^2 \|\nabla\eta\|_{L^\infty(\Omega)} E_\epsilon(u).$$

The same computations work for Ω_1^- instead of Ω_1^+, and the claim follows. ∎

LEMMA 3.2. *There exists a constant C such that for every $x_0 \in \Omega_0$ and $\epsilon > 0$ with $B_{2\epsilon}(x_0) \subset \Omega_0$, and for every $u \in H^2_{\mathrm{loc}}(\Omega)$,*

$$\int_{B_\epsilon(x_0)} \left(\frac{\epsilon}{2}|\nabla u|^2 + \frac{1}{4\epsilon}(1-u^2)^2\right) dx \le C\epsilon^2 (E_\epsilon(u) + T_\epsilon(u) + 1).$$

Proof. Set

$$\tilde{u}(x) = \begin{cases} 1 & \text{if } u(x) \ge 1, \\ u(x) & \text{if } -1 < u(x) < 1, \\ -1 & \text{if } u(x) \le -1. \end{cases}$$

In view of Lemma 3.1, it suffices to show that

$$\int_{B_\epsilon(x_0)} \left(\frac{\epsilon}{2}|\nabla \tilde{u}|^2 + \frac{1}{4\epsilon}(1-\tilde{u}^2)^2\right) dx \le C\epsilon^2 (E_\epsilon(u) + T_\epsilon(u) + 1).$$

Choose a cutoff function $\eta \in C_0^\infty(B_{2\epsilon}(x_0))$ with $0 \le \eta \le 1$ and $\eta \equiv 1$ in $B_\epsilon(x_0)$, such that $|\nabla\eta| \le 2/\epsilon$. Then

$$\begin{aligned} \epsilon \int_\Omega \eta^2 |\nabla\tilde{u}|^2\, dx &= \epsilon \int_\Omega \eta^2 \nabla\tilde{u} \cdot \nabla u\, dx \\ &= \frac{1}{\epsilon}\int_\Omega \eta^2 \tilde{u}(1-u^2)u\, dx - \int_\Omega \eta^2 \tilde{u}\tau_\epsilon(u)\, dx - 2\epsilon \int_\Omega \eta\tilde{u}\nabla\eta\cdot\nabla u\, dx. \end{aligned}$$

We have

$$-\int_\Omega \eta^2 \tilde{u}\tau_\epsilon(u)\, dx \le \epsilon^2 T_\epsilon(u) + \frac{1}{\epsilon}\int_{B_{2\epsilon}(x_0)} \tilde{u}^2\, dx \le \epsilon^2 T_\epsilon(u) + \frac{32}{3}\pi\epsilon^2$$

and

$$-2\epsilon \int_\Omega \eta\tilde{u}\nabla\eta\cdot\nabla u\, dx = -2\epsilon\int_\Omega \eta\tilde{u}\nabla\eta\cdot\nabla\tilde{u}\, dx - 2\epsilon\int_{\Omega_1} \eta\tilde{u}\nabla\eta\cdot\nabla u\, dx,$$

where

$$\Omega_1 = \{x \in \Omega\colon\ |u(x)| \ge 1\}.$$

Moreover,

$$\begin{aligned} -2\epsilon\int_\Omega \eta\tilde{u}\nabla\eta\cdot\nabla\tilde{u}\, dx &\le \frac{\epsilon}{2}\int_\Omega \eta^2|\nabla\tilde{u}|^2\, dx + 2\epsilon\int_{B_{2\epsilon}(x_0)} |\nabla\eta|^2\, dx \\ &\le \frac{\epsilon}{2}\int_\Omega \eta^2|\nabla\tilde{u}|^2\, dx + \frac{256}{3}\pi\epsilon^2 \end{aligned}$$

and

$$-2\epsilon \int_{\Omega_1} \eta \tilde{u} \nabla \eta \cdot \nabla u \, dx \leq \epsilon \int_{\Omega_1} \eta^2 |\nabla u|^2 \, dx + \epsilon \int_{B_{2\epsilon}(x_0)} |\nabla \eta|^2 \, dx$$
$$\leq C_1 \epsilon^2 (E_\epsilon(u) + T_\epsilon(u) + 1)$$

by Lemma 3.1 for a constant C_1 that depends only on Ω and Ω_0. Finally, we have $\tilde{u}(1-u^2)u \leq 1$ in Ω; hence

$$\frac{1}{\epsilon} \int_\Omega \eta^2 \tilde{u}(1-u^2)u \, dx \leq \frac{32}{3} \pi \epsilon^2.$$

We also have

$$\frac{1}{\epsilon} \int_{B_\epsilon(x_0)} (1-\tilde{u}^2)^2 \, dx \leq \frac{4}{3} \pi \epsilon^2.$$

Combining all the estimates, we obtain the desired inequality. ∎

LEMMA 3.3. *For any $K > 0$ there exist two constants $C, r > 0$ with the following properties. Suppose $u \in H^2_{\mathrm{loc}}(\Omega)$ and $0 < \epsilon \leq \frac{1}{2} \operatorname{dist}(\Omega_0, \partial\Omega)$ such that*

$$E_\epsilon(u) + T_\epsilon(u) \leq K. \tag{3.1}$$

Then

$$\sup_{\Omega_0} |u| \leq C.$$

Moreover,

$$\operatorname*{osc}_{B_{r\epsilon}(x_0)} u \leq \frac{1}{4}$$

for any $x_0 \in \Omega_0$.

Proof. Suppose $x_0 \in \Omega$ and $0 < \epsilon \leq \frac{1}{2} \operatorname{dist}(\Omega_0, \partial\Omega)$. If (3.1) is satisfied, then by Lemma 3.2 (applied to a different Ω_0),

$$\int_{B_\epsilon(x_0)} \left(\frac{\epsilon}{2} |\nabla u|^2 + \frac{1}{4\epsilon}(1-u^2)^2 \right) dx \leq C_1 \epsilon^2$$

for a constant C_1 that depends only on Ω, Ω_0, and K. Define

$$v(x) = u(\epsilon x + x_0).$$

Then

$$\frac{1}{2} \int_{B_1(0)} \left(|\nabla v|^2 + \frac{1}{2}(1-v^2)^2 \right) dx \leq C_1 \tag{3.2}$$

and

$$\frac{1}{4} \int_{B_1(0)} (\Delta v + (1-v^2)v)^2 \, dx \leq T_\epsilon(u) \leq K. \tag{3.3}$$

It follows from (3.2) that

$$\|v\|_{H^1(B_1(0))} \leq C_2 = C_2(\Omega, \Omega_0, K).$$

According to the Sobolev embedding theorem,

$$\|v\|_{L^6(B_1(0))} \leq C_3 = C_3(\Omega, \Omega_0, K).$$

Then (3.3) implies

$$\|\Delta v\|_{L^2(B_1(0))} \leq C_4 = C_4(\Omega, \Omega_0, K).$$

Hence

$$\|v\|_{H^2(B_{1/2}(0))} \leq C_5 = C_5(\Omega, \Omega_0, K),$$

and therefore

$$\|v\|_{C^{0,1/2}(\overline{B_{1/2}(0)})} \leq C_6 = C_6(\Omega, \Omega_0, K)$$

by the Sobolev embedding theorem. Now both inequalities in the claim of the lemma follow from the last inequality. □

The next lemma provides two of the key estimates for the proof of Theorem 1.1. The first inequality of the lemma is related to estimates of what is called the "discrepancy function" by Hutchinson and Tonegawa [9], Bellettini and Mugnai [5], and others. The second one will help to exploit the condition $\frac{\partial u_\epsilon}{\partial x^3} \geq 0$ in Theorem 1.1.

Lemma 3.4. *For any $\delta > 0$ and any $K > 0$ there exist three numbers $\epsilon_0 > 0$, $c > 0$, and $R > 0$ with the following property. Suppose $0 < \epsilon \leq \epsilon_0$ and $\eta \in C_0^1(\Omega_0)$ with $0 \leq \eta \leq K$ and*

$$\sup_{\Omega_0} |\nabla \eta| \leq \frac{c}{\epsilon}.$$

Suppose further $u \in H^2_{\mathrm{loc}}(\Omega)$ such that

$$E_\epsilon(u) + T_\epsilon(u) \leq K$$

and

$$\sup_{x_0 \in \operatorname{supp} \eta} \left(\frac{1}{\epsilon} \int_{B_{R\epsilon}(x_0) \cap \Omega} (\tau_\epsilon(u))^2 \, dx \right) \leq c.$$

Then

$$\int_{\Omega_0} \eta \left[\frac{\epsilon}{2} |\nabla u|^2 - \frac{1}{4\epsilon}(1 - u^2)^2 \right] dx \leq \delta. \tag{3.4}$$

Furthermore, there exists a universal constant C such that

$$\int_{\Omega_0} \eta(\epsilon |\nabla u| - C) \left| \frac{\partial u}{\partial x^3} \right| dx \leq \delta. \tag{3.5}$$

Proof. We argue by contradiction. Suppose that the first claim (about inequality (3.4)) were false for two given numbers $\delta > 0$ and $K > 0$. Then there would exist three sequences $\epsilon_k \searrow 0$, $c_k \searrow 0$, and $R_k \to \infty$, as well as corresponding functions $\eta_k \in C_0^1(\Omega_0)$ with $0 \leq \eta_k \leq K$ and

$$\sup_{\Omega_0} |\nabla \eta_k| \leq \frac{c_k}{\epsilon_k},$$

and $u_k \in H^2_{\mathrm{loc}}(\Omega)$ with

$$E_{\epsilon_k}(u_k) + T_{\epsilon_k}(u_k) \leq K$$

and

$$\sup_{x_0 \in \operatorname{supp} \eta_k} \left(\frac{1}{\epsilon_k} \int_{B_{R_k \epsilon_k}(x_0) \cap \Omega} (\tau_{\epsilon_k}(u_k))^2 \, dx \right) \leq c_k,$$

such that

$$\limsup_{k \to \infty} \int_{\Omega_0} \eta_k \left[\frac{\epsilon_k}{2} |\nabla u_k|^2 - \frac{1}{4\epsilon_k}(1 - u_k^2)^2 \right] dx > \delta.$$

Define

$$\Omega_k^+ = \left\{ x \in \Omega \colon\ u_k(x) > \frac{1}{2} \right\}, \quad \Omega_k^- = \left\{ x \in \Omega \colon\ u_k(x) < -\frac{1}{2} \right\},$$

and

$$\Omega_k^0 = \left\{ x \in \Omega \colon\ -\frac{1}{2} \leq u_k(x) \leq \frac{1}{2} \right\}.$$

Suppose $x_0 \in \Omega_k^0$. By Lemma 3.3, there exists some $r > 0$, depending only on Ω, Ω_0, and K, such that $|u_k| \leq 3/4$ in $B_{r\epsilon_k}(x_0)$. Thus

$$\frac{1}{4\epsilon_k} \int_{B_{\epsilon_k}(x_0)} (1 - u_k^2)^2 \, dx \geq C_1 \epsilon_k^2 \tag{3.6}$$

for a constant $C_1 > 0$ that depends only on Ω, Ω_0, and K. By Vitali's covering lemma, there exists a finite set of points $x_1^k, \ldots, x_{I_k}^k \in \Omega_k^0 \cap \operatorname{supp} \eta_k$, such that

$$\Omega_k^0 \cap \operatorname{supp} \eta_k \subset \bigcup_{i=1}^{I_k} B_{5\epsilon_k}(x_i^k),$$

but

$$B_{\epsilon_k}(x_i^k) \cap B_{\epsilon_k}(x_j^k) = \emptyset \quad \text{for } i \neq j.$$

By (3.6), we have

$$I_k \leq \frac{C_2}{\epsilon_k^2}$$

for a constant C_2 that depends only on Ω, Ω_0, and K.

Fix now some $R \geq 5$. For $k \in \mathbb{N}$ and $1 \leq i \leq I_k$, choose two cutoff functions $\xi_i^k \in C_0^\infty(B_{2R\epsilon_k}(x_i^k))$ with $0 \leq \xi_i^k \leq 1$ and $\xi_i^k \equiv 1$ in $B_{R\epsilon_k}(x_i^k)$, and $\zeta_i^k \in C_0^\infty(B_{4R\epsilon_k}(x_i^k))$ with $0 \leq \zeta_i^k \leq 1$ and $\zeta_i^k \equiv 1$ in $B_{2R\epsilon_k}(x_i^k)$, such that

$$|\nabla \xi_i^k| \leq \frac{2}{R\epsilon_k} \quad \text{and} \quad |\nabla \zeta_i^k| \leq \frac{1}{R\epsilon_k}.$$

Set

$$\xi^k = \max_{1\le i\le I_k} \xi_i^k.$$

This is a Lipschitz function with $0 \le \xi^k \le 1$ and $\xi^k \equiv 1$ on $\Omega_k^0 \cap \operatorname{supp} \eta_k$. Moreover, $\operatorname{supp} \xi^k$ is contained in the set

$$U_k = \big\{x \in \Omega\colon\ \operatorname{dist}(x, \Omega_k^0 \cap \operatorname{supp} \eta_k) < 2R\epsilon_k\big\}.$$

We also have

$$|\nabla \xi^k| \le \frac{2}{R\epsilon_k}.$$

Next, we define

$$\psi_i^k = \frac{\zeta_i^k[1-(1-\xi^k)^2]}{\sum_{j=1}^{I_k} \zeta_j^k}$$

in U_k and $\psi_i^k = 0$ in $\Omega \backslash U_k$. Then we have

$$\sum_{i=1}^{I_k} \psi_i^k = 1 - (1-\xi^k)^2.$$

Moreover,

$$|\nabla \psi_i^k| \le \frac{C_3}{\epsilon_k}$$

for a constant C_3 that depends only on R.

We have

$$\begin{aligned}\epsilon_k \int_{\Omega_k^+} \eta_k (1-\xi^k)^2 |\nabla u_k|^2\, dx = {} & \frac{1}{\epsilon_k} \int_{\Omega_k^+} \eta_k (1-\xi^k)^2 (u_k - 1)(1-u_k^2) u_k\, dx \\ & - \int_{\Omega_k^+} \eta_k (1-\xi^k)^2 (u_k-1) \tau_{\epsilon_k}(u_k)\, dx \\ & - \epsilon_k \int_{\Omega_k^+} (1-\xi^k)^2 (u_k - 1) \nabla \eta_k \cdot \nabla u_k\, dx \\ & + 2\epsilon_k \int_{\Omega_k^+} \eta_k (1-\xi^k)(u_k-1) \nabla \xi^k \cdot \nabla u_k\, dx.\end{aligned}$$

It is easy to see that

$$\lim_{k\to\infty} \left(\epsilon_k \int_{\Omega_k^+} (1-\xi^k)^2 (u_k-1) \nabla \eta_k \cdot \nabla u_k\, dx \right) = 0$$

and

$$\limsup_{k\to\infty} \left(2\epsilon_k \int_{\Omega_k^+} \eta_k (1-\xi^k)(u_k-1) \nabla \xi^k \cdot \nabla u_k\, dx \right) \le \frac{C_4}{R}$$

for a constant C_4 that depends only on K. Moreover,

$$\lim_{k\to\infty}\int_{\Omega_k^+}\eta_k(1-\xi^k)^2(u_k-1)\tau_{\epsilon_k}(u_k)\,dx=0.$$

We also have

$$\frac{1}{\epsilon_k}\int_{\Omega_k^+}\eta_k(1-\xi^k)^2(u_k-1)(1-u_k^2)u_k\,dx\le-\frac{1}{3\epsilon_k}\int_{\Omega_k^+}\eta_k(1-\xi^k)^2(1-u_k^2)^2\,dx$$

for every k. Similar estimates hold for Ω_k^- instead of Ω_k^+. It follows that

$$\limsup_{k\to\infty}\int_{\Omega_0}\eta_k(1-\xi^k)^2\left[\frac{\epsilon_k}{2}|\nabla u_k|^2+\frac{1}{4\epsilon_k}(1-u_k^2)^2\right]dx\le\frac{C_5}{R}$$

for a constant C_5 that depends only on K. If we choose R such that

$$R\ge\frac{2C_5}{\delta},$$

then we have

$$\limsup_{k\to\infty}\sum_{i=1}^{I_k}\int_{\Omega_0}\eta_k\psi_i^k\left[\frac{\epsilon_k}{2}|\nabla u_k|^2-\frac{1}{4\epsilon_k}(1-u_k^2)^2\right]dx\ge\frac{\delta}{2}.$$

Hence for infinitely many values of k (we may assume without loss of generality: for any k) there is an index $i_0(k)\in\{1,\dots,I_k\}$ such that

$$\int_{\Omega_0}\eta_k\psi_{i_0(k)}^k\left[\frac{\epsilon_k}{2}|\nabla u_k|^2-\frac{1}{4\epsilon_k}(1-u_k^2)^2\right]dx\ge\frac{\delta\epsilon_k^2}{2C_2}.$$

Define $\tilde{x}_k=x_{i_0(k)}^k$ and

$$v_k(x)=u_k(\epsilon_k x+\tilde{x}_k).$$

Moreover, define

$$\tilde{\psi}_k(x)=\psi_{i_0(k)}^k(\epsilon_k x+\tilde{x}_k).$$

Let $r>0$. By Lemma 3.2, we have

$$\frac{1}{2}\int_{B_r(0)}\left(|\nabla v_k|^2+\frac{1}{2}(1-v_k^2)^2\right)dx\le C_6r^3$$

for a constant C_6 that depends only on Ω, Ω_0, and K, whenever k is large enough. Furthermore,

$$\int_{B_r(0)}(\Delta v_k+(1-v_k^2)v_k)^2\,dx\le\frac{1}{\epsilon_k}\int_{B_{R_k\epsilon_k}(\tilde{x}_k)}(\tau_{\epsilon_k}(u_k))^2\,dx\le c_k\to 0$$

as $k\to\infty$. By Lemma 3.3, there exists a number C_7, depending only on K, such that $|v_k|\le C_7$ in $B_r(0)$ for any sufficiently large k. The number $r>0$ is arbitrary. Thus a subsequence of $\{v_k\}$ converges to a bounded solution of

$$\Delta v+(1-v^2)v=0\quad\text{in }\mathbb{R}^3. \tag{3.7}$$

The convergence is strong in $H^1(B_r(0))$ for every $r > 0$. Because $\nabla\tilde{\psi}_k$ is uniformly bounded, we may assume that $\tilde{\psi}_k \to \psi$ uniformly, where $\psi : B_{4R}(0) \to [0,1]$ is a continuous function. Moreover, we may assume $\tilde{x}_k \to x_0 \in \Omega_0$. Because of the gradient bound for η_k, the functions $\eta_k(\epsilon_k x + \tilde{x}_k)$ converge uniformly to a constant $a \in [0, K]$ after we have picked another subsequence. It follows that

$$\frac{a}{2}\int_Q \psi\left(|\nabla v|^2 - \frac{1}{2}(1-v^2)^2\right) dx \geq \frac{\delta}{2C_2} > 0.$$

However, it was proved by Modica [11] that a bounded solution of (3.7) satisfies

$$|\nabla v|^2 \leq \frac{1}{2}(1-v^2)^2$$

pointwise. This gives a contradiction, and (3.4) follows.

To prove (3.5), we use the same method. There exists a constant C such that any bounded solution of (3.7) satisfies

$$|\nabla v| \leq C.$$

(To prove this, one can first estimate the energy in balls of radius 1 with the methods from the proof of Lemma 3.2 and then apply standard regularity results for elliptic equations.) In particular

$$(|\nabla v| - C)\left|\frac{\partial v}{\partial x^3}\right| \leq 0.$$

The rest of the proof is similar to the above. We omit the details. ∎

4. Proof of Theorem 1.1. In this section we prove Theorem 1.1. Some of the facts we establish are also true without the assumption $\frac{\partial u_\epsilon}{\partial x^3} \geq 0$; therefore we work first without this condition and impose it only later.

We assume that $u_\epsilon \in H^2_{\text{loc}}(\Omega)$ are functions such that

$$\liminf_{\epsilon \searrow 0}(E_\epsilon(u_\epsilon) + T_\epsilon(u_\epsilon)) < \infty.$$

We can choose a sequence $\epsilon_k \searrow 0$ such that

$$\limsup_{k\to\infty}(E_\epsilon(u_\epsilon) + T_\epsilon(u_\epsilon)) < \infty.$$

We will choose a subsequence of $\{\epsilon_k\}$ several times in the proof. We will always denote the subsequence by $\{\epsilon_k\}$ again for convenience.

We consider the measure pairs $M^{(k)} = (\mu^{(k)}, \nu^{(k)}) \in \mathcal{W}(\Omega)$ defined by

$$\mu^{(k)} = \mathcal{L}^3 \llcorner \left(\frac{\epsilon_k}{2}|\nabla u_{\epsilon_k}|^2 + \frac{1}{4\epsilon_k}(1-u_{\epsilon_k}^2)^2\right)$$

and

$$\nu^{(k)}_{\alpha\beta} = \epsilon_k \mathcal{L}^3 \llcorner \left(\frac{\partial u_{\epsilon_k}}{\partial x^\alpha}\frac{\partial u_{\epsilon_k}}{\partial x^\beta}\right).$$

We have

$$\limsup_{k\to\infty}(\mu^{(k)}(\Omega) + W(M^{(k)})) < \infty;$$

thus we may assume that (after passing to a subsequence)

$$M^{(k)} \rightharpoonup M$$

for some $M = (\mu, \nu) \in \mathcal{W}(\Omega)$ with

$$W(M) \leq \liminf_{k\to\infty} W(M^{(k)}) \leq \liminf_{k\to\infty} T_{\epsilon_k}(u_{\epsilon_k}).$$

(The second inequality follows from the same computations as in the examples of section 2.) We also consider the Radon measures

$$h_k = \frac{1}{\epsilon_k}\mathcal{L}^3 \llcorner (\tau_{\epsilon_k}(u_{\epsilon_k}))^2$$

on Ω. We have

$$\limsup_{k\to\infty} h_k(\Omega) < \infty;$$

hence we may assume that $h_k \to h$ for a Radon measure h on Ω.

Lemma 4.1. *Every $x_0 \in \Omega$ satisfies $\mu(\{x_0\}) = 0$.*

Proof. Suppose we have $\mu(\{x_0\}) > 0$ for some $x_0 \in \Omega$. For $\phi \in C_0^1(B_1(0), \mathbb{R}^3)$ and $r > 0$, set

$$\phi_r(x) = \phi((x - x_0)/r).$$

We have

$$\int_\Omega \left(\operatorname{div}\phi_r\, d\mu - \frac{\partial\phi_r^\alpha}{\partial x^\beta}\, d\nu_{\alpha\beta} + \phi_r^\alpha H^\beta\, d\nu_{\alpha\beta}\right) = 0,$$

where H is the generalized mean curvature of M. Hence

$$\int_\Omega \left(\operatorname{div}\phi((x-x_0)/r)\, d\mu(x) - \frac{\partial\phi^\alpha}{\partial x^\beta}((x-x_0)/r)\, d\nu_{\alpha\beta}(x)\right) = -r\int_\Omega \phi^\alpha((x-x_0)/r)H^\beta(x)\, d\nu_{\alpha\beta}(x) \to 0$$

as $r \searrow 0$. On the other hand, the left-hand side converges to

$$\operatorname{div}\phi(0)\,\mu(\{x_0\}) - \frac{\partial\phi^\alpha}{\partial x^\beta}(0)\,\nu_{\alpha\beta}(\{x_0\}).$$

It follows that $\operatorname{trace}\nu(\{x_0\}) = 3\mu(\{x_0\})$. But this is impossible because

$$\operatorname{trace}\nu^{(k)} \leq 2\mu^{(k)},$$

and this contradiction completes the proof. □

Lemma 4.2. $M \in \mathcal{W}_2(\Omega)$.

Proof. We need to prove that

$$\operatorname{trace}\nu \leq \mu. \tag{4.1}$$

To this end, we choose a function $\phi \in C_0^1(\Omega)$ with $\phi \geq 0$. For a fixed $\delta > 0$, let ϵ_0, c, and R be the numbers from Lemma 3.4 belonging to δ and

$$K = \sup_{k\in\mathbb{N}}(E_{\epsilon_k}(u_{\epsilon_k}) + T_{\epsilon_k}(u_{\epsilon_k})) + \sup_\Omega \phi.$$

Define

$$V_0^{c/2} = \{x \in \Omega : \ h(\{x\}) \geq c/2\}$$

and

$$V_r^{c/2} = \bigcup_{x \in V_0^{c/2}} B_r(x)$$

for $r > 0$. The set $V_0^{c/2}$ is finite. Because of Lemma 4.1, there exists a number $r_0 > 0$ such that $\mu(V_{r_0}^{c/2}) \leq \delta$. Moreover, we have

$$\frac{1}{\epsilon_k} \int_{B_{R\epsilon_k}(x_0)} (\tau_{\epsilon_k}(u_{\epsilon_k}))^2 \, dx < c$$

for any $x_0 \in \operatorname{supp} \phi \backslash V_{r_0/2}^{c/2}$ and any sufficiently large k. If $\psi \in C^1(\Omega)$ is a function with $0 \leq \psi \leq 1$, $\psi \equiv 0$ in $V_{r_0/2}^{c/2}$, and $\psi \equiv 1$ outside of $V_{r_0}^{c/2}$, we can apply Lemma 3.4 to ϵ_k, u_k, and $\eta = \phi\psi$ for every sufficiently large k. It follows that

$$\int_\Omega \phi\psi \operatorname{trace} d\nu \leq \int_\Omega \phi\psi \, d\mu + \delta.$$

Thus

$$\int_\Omega \phi \operatorname{trace} d\nu \leq \int_\Omega \phi \, d\mu + \delta(1 + K).$$

Since δ is arbitrary, we conclude that (4.1) holds. $\square$

We now consider the functions

$$v_\epsilon = \frac{1}{\sqrt{2}} \left(u_\epsilon - \frac{u_\epsilon^3}{3} \right).$$

We have

$$\nabla v_\epsilon = \frac{1}{\sqrt{2}} (1 - u_\epsilon^2) \nabla u_\epsilon;$$

thus

$$\int_\Omega |\nabla v_\epsilon| \, dx \leq \int_\Omega \left(\frac{\epsilon}{2} |\nabla u_\epsilon|^2 + \frac{1}{4\epsilon} (1 - u_\epsilon^2)^2 \right) \, dx = E_\epsilon(u_\epsilon)$$

by Young's inequality. From the theory of functions of bounded variation and sets of bounded perimeter (see, e.g., Giusti [8] or Ambrosio, Fusco, and Pallara [3]), it follows that there exists a subsequence of $\{\epsilon_k\}$ such that $\mathcal{L}^3$-almost everywhere in Ω,

$$v_{\epsilon_k} \to v,$$

where $v : \Omega \to \{-\sqrt{2}/3, \sqrt{2}/3\}$ is a function such that the set

$$U = \left\{ x \in \Omega : \ v(x) = -\frac{\sqrt{2}}{3} \right\}$$

is of finite perimeter (in Ω). Moreover, the reduced boundary $\partial^* U$ satisfies

$$\frac{2\sqrt{2}}{3}\mathcal{H}^2 \llcorner \partial^* U \leq \mu.$$

For every point $x \in \partial^* U$, we have

$$\lim_{r \searrow 0} r^{-2}\mathcal{H}^2(\partial^* U \cap B_r(x_0)) = \pi.$$

Hence

$$\Theta_M(x) \geq \frac{2\sqrt{2}}{3}\pi.$$

By Lemma 2.7, the same inequality holds for any point in the relative closure of $\partial^* U$ in Ω, which we denote by $\overline{\partial^* U}$. Thus

$$\overline{\partial^* U} \subset \Sigma = \left\{ x \in \Omega \colon \Theta_M(x) \geq \frac{2\sqrt{2}}{3}\pi \right\}.$$

The set Σ is relatively closed. According to Proposition 2.11, it is countably 2-rectifiable. If $\nu = \mu \llcorner \sigma$, then

$$\sigma(x) = \mathrm{proj}^{\perp}_{T_x\Sigma}$$

μ-almost everywhere on Σ (which is also $\mathcal{H}^2$-almost everywhere on Σ). In particular,

$$\mathrm{trace}\, \nu \llcorner \Sigma = \mu \llcorner \Sigma.$$

The function v is locally constant on $\Omega \backslash \Sigma$ after we have changed it on an $\mathcal{L}^3$-null set.

The most difficult part of the proof of Theorem 1.1 is to show that $\mu(\Omega \backslash \Sigma) = 0$. To this end, we now use the additional assumption $\Omega = \Omega' \times \mathbb{R}$ and

$$\frac{\partial u_\epsilon}{\partial x^3} \geq 0 \tag{4.2}$$

$\mathcal{L}^3$-almost everywhere in Ω. Then we use arguments based on an idea of Ambrosio and Cabré [2].

Lemma 4.3. $\mu(\Omega \backslash \Sigma) = 0$.

Proof. Suppose $\eta \in C^2_0(\Omega \backslash \Sigma)$ is a nonnegative function, the support of which is contained in one of the connected components of $\Omega \backslash \Sigma$. Then we have either $u_{\epsilon_k}(x) \to -1$ for $\mathcal{L}^3$-almost every $x \in \mathrm{supp}\, \eta$ or $u_{\epsilon_k}(x) \to 1$ for $\mathcal{L}^3$-almost every $x \in \mathrm{supp}\, \eta$. We may assume without loss of generality that the limit is 1. Thus

$$\int_{\mathrm{supp}\, \eta} u_{\epsilon_k}\, dx \to \mathcal{L}^3(\mathrm{supp}\, \eta)$$

by Lebesgue's convergence theorem.

For $t \geq 0$, define

$$\eta_t(x^1, x^2, x^3) = \eta(x^1, x^2, x^3 - t).$$

We calculate

$$\begin{aligned}\frac{d}{dt}\int_\Omega \eta_t\,d\mu &= -\int_\Omega \frac{\partial\eta}{\partial x^3}(x^1,x^2,x^3-t)\,d\mu(x)\\ &= -\int_\Omega \frac{\partial\eta}{\partial x^\beta}(x^1,x^2,x^3-t)\,d\nu_{3\beta}(x)+\int_\Omega \eta_t H^\beta\,d\nu_{3\beta}.\end{aligned}$$

We have

$$\left|\int_\Omega \frac{\partial\eta}{\partial x^\beta}(x^1,x^2,x^3-t)\,d\nu_{3\beta}(x)\right| \le \lim_{k\to\infty}\left(\epsilon_k\int_\Omega |\nabla\eta(x^1,x^2,x^3-t)||\nabla u_{\epsilon_k}|\frac{\partial u_{\epsilon_k}}{\partial x^3}\,dx\right).$$

Using Lemma 3.4 and arguments similar to those in the proof of Lemma 4.2, we find that the right-hand side is at most

$$C\|\nabla\eta\|_{L^\infty(\Omega)}\lim_{k\to\infty}\int_{\operatorname{supp}\eta_t}\frac{\partial u_{\epsilon_k}}{\partial x^3}\,dx$$

for a universal constant C. Moreover, for any $\lambda>0$, we have

$$\begin{aligned}\left|\int_\Omega \eta_t H^\beta\,d\nu_{3\beta}\right| &\le \left(\int_\Omega \eta_t^2\,d\nu_{33}\right)^{1/2}\left(\int_\Omega H^\alpha H^\beta\,d\nu_{\alpha\beta}\right)^{1/2}\\ &\le \lambda W(M)+\frac{1}{\lambda}\lim_{k\to\infty}\left(\epsilon_k\int_\Omega \eta_t^2\left(\frac{\partial u_{\epsilon_k}}{\partial x^3}\right)^2\,dx\right)\\ &\le \lambda W(M)+\frac{C}{\lambda}\|\eta\|^2_{L^\infty(\Omega)}\lim_{k\to\infty}\int_{\operatorname{supp}\eta_t}\frac{\partial u_{\epsilon_k}}{\partial x^3}\,dx.\end{aligned}$$

Because of (4.2),

$$\int_0^\infty\int_{\operatorname{supp}\eta_t}\frac{\partial u_{\epsilon_k}}{\partial x^3}\,dx\,dt \le \int_{\operatorname{supp}\eta}(1-u_{\epsilon_k})\,dx.$$

Thus for $T>0$, we have a number C_1 such that

$$\begin{aligned}\int_\Omega \eta\,d\mu &\le \int_\Omega \eta_T\,d\mu+\lambda TW(M)+C_1\left(1+\frac{1}{\lambda}\right)\lim_{k\to\infty}\int_{\operatorname{supp}\eta}(1-u_{\epsilon_k})\,dx\\ &= \int_\Omega \eta_T\,d\mu+\lambda TW(M).\end{aligned}$$

Because λ is arbitrary and because $\mu(\Omega)<\infty$, it follows that

$$\int_\Omega \eta\,d\mu \le \liminf_{T\to\infty}\int_\Omega \eta_T\,d\mu = 0.$$

We conclude that $\mu(\Omega\backslash\Sigma)=0$. □

It follows from Lemma 4.3 and the existence of the 2-density Θ_M that μ is absolutely continuous with respect to $\mathcal{H}^2\llcorner\Sigma$. More precisely,

$$\mu=\pi^{-1}(\mathcal{H}^2\llcorner\Sigma)\llcorner\Theta_M.$$

Together with $\operatorname{trace}\nu=\mu$, this implies part (i) of Theorem 1.1 for $\theta=\Theta_M$. We have already proved (ii). Part (iii) follows from Proposition 2.2 and the facts we know about the structure of M. This concludes the proof of Theorem 1.1.

DIFFEOMORPHISMS AND NONLINEAR HEAT FLOWS*

L. C. EVANS†, O. SAVIN†, AND W. GANGBO‡

Abstract. We show that the gradient flow $\mathbf{u}$ on L^2 generated by the energy functional $I[\mathbf{u}] := \int_U \Phi(\det D\mathbf{u})\,dx$ for vector-valued mappings is in some sense "integrable," meaning that (i) the inverse Jacobian $\beta := (\det D\mathbf{u})^{-1}$ satisfies a scalar nonlinear diffusion equation, and (ii) we can recover $\mathbf{u}$ by solving an ODE determined by β.

Key words. quasi convexity, gradient flow, Jacobian

1. Introduction.

1.1. Gradient flows for quasi-convex energies. This paper is a contribution to the mostly unsolved problem of understanding the gradient flow dynamics on L^2 generated by integral functionals having the form

$$I[\mathbf{v}] := \int_U F(D\mathbf{v})\,dx, \tag{1.1}$$

defined for functions $\mathbf{v} : U \to \mathbb{R}^m$, where U is an open subset of $\mathbb{R}^n$. The gradient $D\mathbf{v}$ belongs to $\mathbb{M}^{m\times n}$, the space of $m \times n$ matrices, and we are given the nonlinearity $F : \mathbb{M}^{m\times n} \to (-\infty, +\infty]$.

Quasi convexity. As is well known, the critical assumption for the existence of minimizers of $I[\cdot]$, subject to appropriate boundary conditions, is that F be *quasi-convex* in the sense of C. B. Morrey, Jr. This is the condition that

$$\int_U F(A)\,dx \le \int_U F(A + D\mathbf{v})\,dx \tag{1.2}$$

for all matrices $A \in \mathbb{M}^{m\times n}$ and all C^1 functions $\mathbf{v} : U \to \mathbb{R}^m$ vanishing on ∂U.

Dynamics. As the existence and (partial) regularity theories for minimizers are fairly well understood, it has long seemed natural to turn attention to related dynamical problems. The corresponding flow on L^2 generated by $I[\cdot]$ is the initial-value problem for the system of PDEs

$$\begin{cases} \mathbf{u}_t = \operatorname{div}(DF(D\mathbf{u})) & (t > 0), \\ \mathbf{u} = \mathbf{u}^0 & (t = 0), \end{cases} \tag{1.3}$$

with appropriate boundary conditions.

Given the quasi-convexity hypothesis (1.2), the system (1.3) is parabolic, at least in some weak sense. However, it is extremely nonlinear, so much so that it remains to date a challenging open problem to prove existence of even weak solutions, to understand uniqueness issues, and/or to show partial regularity.

Time-step approximations. One obvious approach is to approximate by an implicit *time-step approximation*. For this, we fix a step size $h > 0$ and recursively find $\mathbf{u}_{k+1}$ to minimize

$$I_k[\mathbf{v}] := \frac{1}{2}\int_U |\mathbf{v} - \mathbf{u}_k|^2\,dx + h\int_U F(D\mathbf{v})\,dx, \tag{1.4}$$

with appropriate boundary conditions, given $\mathbf{u}_k$. The Euler–Lagrange equations read

$$\begin{cases} \frac{\mathbf{u}_{k+1}-\mathbf{u}_k}{h} = \operatorname{div}(DF(D\mathbf{u}_{k+1})) \qquad (k = 0, 1, \dots), \\ \qquad \mathbf{u}_0 = \mathbf{u}^0. \end{cases} \tag{1.5}$$

This procedure generates a strong candidate for an approximation to the full dynamics (1.3). The fundamental point is that under our quasi-convexity assumption we can in fact iteratively find minimizers of (1.4).

The really hard task is passing to limits as $h \to 0$. Since our approximations $\mathbf{u}_k$ are minimizers, and not just critical points, of $I_k[\cdot]$, the expectation and hope is that we obtain in the limit some sort of reasonable weak solution of (1.3). It has, however, proved in practice impossible to carry out this program in general, owing to the usual problem in nonlinear PDE that we do not have very good uniform estimates on the approximate solutions $\mathbf{u}_k$. (The paper [E] demonstrates a completely different minimization principle, but we have not been able to exploit this usefully.)

1.2. Nonlinearities depending only on the determinant. This paper documents some progress in this matter for the case $m = n$ and nonlinearities F with the special structure

$$F(P) = \Phi(\det P) \qquad (P \in \mathbb{M}^{n\times n}), \tag{1.6}$$

where Φ is a convex function and "det" means determinant. Such a nonlinearity is quasi-convex, and it has long been known that for the static calculus of variations the particular hypothesis (1.6) has strong implications; see, for instance, Dacorogna [D].

We begin by reviewing the issue of minimizing the functional

$$I[\mathbf{v}] := \int_U F(D\mathbf{v})\,dx = \int_U \Phi(\det D\mathbf{v})\,dx \tag{1.7}$$

among mappings $\mathbf{v} = (v^1, \dots, v^n)$ from a connected, open set $U \subset \mathbb{R}^n$ into $\mathbb{R}^n$. We write the gradient matrix of $\mathbf{v}$ as

$$D\mathbf{v} = \begin{pmatrix} v^1_{x_1} & \dots & v^1_{x_n} \\ \vdots & \ddots & \vdots \\ v^n_{x_1} & \dots & v^n_{x_n} \end{pmatrix}.$$

If $\mathbf{u} = (u^1, \dots, u^n)$ is a smooth minimizer of $I[\cdot]$, subject to boundary conditions which for the moment we do not specify, then $\mathbf{u}$ solves the Euler–Lagrange system of PDEs

$$\operatorname{div}(DF(D\mathbf{u})) = \operatorname{div}(\Phi'(\det D\mathbf{u})(\operatorname{cof} D\mathbf{u})^T) = 0, \tag{1.8}$$

where $\operatorname{cof} D\mathbf{u}$ is the cofactor matrix formed from $D\mathbf{u}$. To derive (1.8) we employed the formula

$$\frac{\partial \det P}{\partial p_i^k} = (\operatorname{cof} P)_i^k \qquad (1 \le i, k \le n) \tag{1.9}$$

for the $n \times n$ matrix P, whose (i,k) entry is denoted p_i^k. Likewise, $(\operatorname{cof} P)_i^k$ means the (i,k) entry of $\operatorname{cof} P$. Formula (1.9) is a consequence of the matrix identity

$$(\operatorname{cof} P)^T P = I \det P, \tag{1.10}$$

but for any C^2 function $\mathbf{w} = (w^1, \dots, w^n)$ we have

$$\operatorname{div}((\operatorname{cof} D\mathbf{w})^T) \equiv 0; \tag{1.11}$$

that is,

$$(\operatorname{cof} D\mathbf{w})^k_{i,x_i} = 0 \qquad (k = 1, \dots, n).$$

Therefore (1.8) implies

$$0 = \Phi''(\det D\mathbf{u}) D(\det D\mathbf{u})(\operatorname{cof} D\mathbf{u})^T. \tag{1.12}$$

In view of (1.10), our multiplying (1.10) by $D\mathbf{u}$ gives

$$0 = \Phi''(\det D\mathbf{u}) D(\det D\mathbf{u})(\det D\mathbf{u}) = \frac{1}{2}\Phi''(\det D\mathbf{u}) D(\det D\mathbf{u})^2.$$

Assuming next the strict convexity condition that $\Phi'' > 0$, we deduce that $(\det D\mathbf{u})^2$ is constant within U. Thus, if $\mathbf{u}$ is smooth, we conclude that

$$\det D\mathbf{u} \equiv C \quad \text{within} \quad U \tag{1.13}$$

for some constant C.

1.3. A gradient flow. We study in this paper the corresponding "heat flow" governed by the function $I[\cdot]$, that is, the system of PDEs

$$\mathbf{u}_t = \operatorname{div}(DF(D\mathbf{u})) = \operatorname{div}(\Phi'(\det D\mathbf{u})(\operatorname{cof} D\mathbf{u})^T), \tag{1.14}$$

plus appropriate initial and boundary conditions, detailed later.

We are especially interested in the case that $\Phi(d) < \infty$ for $d > 0$, $\Phi(d) = \infty$ for $d < 0$, and $\lim_{d\to 0^+} \Phi(d) = +\infty$. Then (1.14) enforces the constraint

$$\det D\mathbf{u} > 0.$$

We can hope therefore that for each time t the mapping $x \mapsto y = \mathbf{u}(x,t)$ is a diffeomorphism, with inverse $y \mapsto x = \mathbf{v}(y,t)$. And since the static problem, recalled in section 1.1, is so simple, we hope as well that the analysis of the system (1.14) may not be so complicated.

This is in fact so, for as we will see in section 2, the quantity

$$\beta := (\det D\mathbf{u})^{-1} > 0, \tag{1.15}$$

regarded as a function of y and t, solves the nonlinear parabolic PDE

$$\beta_t = \operatorname{div}\left(\Phi''\left(\frac{1}{\beta}\right)\frac{D\beta}{\beta^2}\right) = \operatorname{div}\left(\beta\Psi'(\beta)D\beta\right) \tag{1.16}$$

with Neumann boundary conditions, where

$$\Psi(d) := d\Phi\left(\frac{1}{d}\right) \quad \text{for } d > 0.$$

Now (1.16) is singular in regimes where $\beta \to 0$ or ∞, but the maximum principle implies that if the initial data β^0 is bounded away from 0 and ∞, then so is the solution.

We will show furthermore that given β, the solution of (1.16) with appropriate initial conditions, we can then recover the mappings $\mathbf{u}$ by solving a system of ODEs governed by β and proving then that the PDE (1.14) holds. In this sense, we can regard the parabolic system of PDEs (1.14) as being somehow "integrable."

1.4. Outline. Our paper introduces in section 2 the formal computations showing how (1.16) results from (1.14). Section 3 then reverses this process to provide careful proofs: we start with the solution β of the nonlinear diffusion equation and build from it the mappings $\mathbf{u}(\cdot, t)$ for $t > 0$.

Section 4 introduces some interesting variants of our construction, the first for more general integrands than in (1.7). We discuss also a situation when the range of the initial mapping $\mathbf{u}^0$ is a proper subset W_0 of the target V. In this case we can design Φ so that the flow "fills up" V in finite time. Interesting complications occur if U and V are not in fact diffeomorphic.

The concluding section 5 introduces and analyzes a related "time-stepping" dynamic variational principle. This discussion will make much clearer the connections between our PDE (1.16) and (1.14).

2. Calculations for smooth solutions.

Suppose now U is a smooth, open, bounded, connected subset of $\mathbb{R}^n$, and

$$\mathbf{u} : \bar{U} \times [0, \infty) \to \mathbb{R}^n$$

is smooth, $\mathbf{u} = (u^1, \dots, u^n)$. In this section we suppose as well that $\mathbf{u}$ solves the system (1.14). Let $\mathbf{u}^0 = \mathbf{u}(\cdot, 0)$ denote the initial mapping.

2.1. Changing variables.

Suppose that for each time $t \geq 0$, the mapping

$$\mathbf{u}(\cdot, t) : \bar{U} \to \bar{V}$$

is a diffeomorphism, where $V \subset \mathbb{R}^n$ is a fixed open subset of $\mathbb{R}^n$. We can then invert the relationship

$$y = \mathbf{u}(x, t) \qquad (x \in \bar{U}, y \in \bar{V}) \tag{2.1}$$

to give

$$x = \mathbf{v}(y, t) \qquad \text{for } \mathbf{v} := \mathbf{u}^{-1}. \tag{2.2}$$

Set

$$\beta(y, t) := \det D\mathbf{v}(y, t) = (\det D\mathbf{u}(x, t))^{-1}. \tag{2.3}$$

2.2. A PDE for . Our main observation is that β solves a scalar, nonlinear diffusion equation.

THEOREM 2.1. *We have*

$$\begin{cases} \beta_t = \operatorname{div}\left(\Phi''\left(\frac{1}{\beta}\right)\frac{1}{\beta^2}D\beta\right) & \textit{in } V\times(0,\infty), \\ \frac{\partial\beta}{\partial\nu} = 0 & \textit{on } \partial V\times(0,\infty), \end{cases} \tag{2.4}$$

ν denoting the unit outward-pointing normal vectorfield to ∂V.

Proof. 1. Fix any time $T>0$ and select a smooth function $\zeta : \bar{V}\times[0,T]\to\mathbb{R}$ such that

$$\zeta(\cdot,0)\equiv\zeta(\cdot,T)\equiv 0. \tag{2.5}$$

Then, employing (2.1), we compute

$$\begin{aligned} &\int_0^T\int_V \beta\zeta_t + D_y\left(\Phi'\left(\frac{1}{\beta}\right)\right)\cdot D_y\zeta\, dydt \\ &= \int_0^T\int_U \left[\beta(\mathbf{u},t)\zeta_t(\mathbf{u},t) + D_x\left(\Phi'\left(\frac{1}{\beta}\right)\right)(D\mathbf{u})^{-1}\cdot D_y\zeta\right]\frac{dx}{\beta(\mathbf{u},t)}\,dt \\ &= \int_0^T\int_U \frac{\partial}{\partial t}(\zeta(\mathbf{u},t)) - D_y\zeta\cdot\mathbf{u}_t + D_x\left(\Phi'\left(\frac{1}{\beta}\right)\right)\frac{(D\mathbf{u})^{-1}}{\beta}\cdot D_y\zeta\, dxdt \\ &= -\int_0^T\int_U D_y\zeta\cdot\left[\mathbf{u}_t - D_x\left(\Phi'\left(\frac{1}{\beta}\right)\right)\frac{(D\mathbf{u})^{-1}}{\beta}\right]\, dxdt. \end{aligned} \tag{2.6}$$

Now our PDE (1.14) reads

$$\mathbf{u}_t = \operatorname{div}_x(\Phi'(\det D\mathbf{u})\det D\mathbf{u}(D\mathbf{u})^{-1}) = D_x\left(\Phi'\left(\frac{1}{\beta}\right)\right)\frac{(D\mathbf{u})^{-1}}{\beta},$$

since $\operatorname{div}((\det D\mathbf{u})(D\mathbf{u})^{-1}) = \operatorname{div}(\operatorname{cof} D\mathbf{u}^T)\equiv 0$. Consequently the expression within the square brackets in the last term of (2.6) vanishes. So

$$\int_0^T\int_V \beta\zeta_t + D_y\left(\Phi'\left(\frac{1}{\beta}\right)\right)\cdot D_y\zeta\, dydt = 0$$

for all test functions ζ as above.

2. If also $\zeta\equiv 0$ on $\partial V\times[0,T]$, we may integrate by parts to deduce

$$\beta_t + \operatorname{div}_y\left(D_y\Phi'\left(\frac{1}{\beta}\right)\right)\equiv 0, \tag{2.7}$$

and this is the PDE in (2.4). Now drop the assumption that $\zeta = 0$ on the boundary and again integrate by parts:

$$\int_0^T\int_{\partial V}\frac{\partial}{\partial\nu}\left(\Phi'\left(\frac{1}{\beta}\right)\right)\zeta\, d\mathcal{H}^{n-1}\, dt = 0.$$

It follows that

$$\frac{\partial}{\partial\nu}\left(\Phi'\left(\frac{1}{\beta}\right)\right) = -\Phi''\left(\frac{1}{\beta}\right)\frac{\partial\beta}{\partial\nu}\equiv 0 \quad \text{on} \quad \partial V\times(0,T).$$

Since $\Phi''>0$, the proof is done. $\square$

2.3. Recovering the mapping u from . We next address the question of how to recover the mapping $\mathbf{u}$ from knowledge of β. One possibility is for each time t to try to find $x \mapsto \mathbf{u}(x,t)$ solving

$$\begin{cases} \beta(\mathbf{u}(x,t),t)\det D\mathbf{u}(x,t) \equiv 1 & \text{in } \bar{U}, \\ \mathbf{u}(\cdot,t) \in \operatorname{Diff}(\bar{U},\bar{V}), \end{cases} \tag{2.8}$$

where $\operatorname{Diff}(\bar{U},\bar{V})$ denotes the set of all diffeomorphisms of $\bar{U}$ onto $\bar{V}$. As we will discuss later in section 5, this approach works, provided U and V are convex sets.

However, there is a simpler construction available. First, define the new nonlinearity

$$\Psi(d) := d\Phi\left(\frac{1}{d}\right) \qquad (d > 0). \tag{2.9}$$

Then

$$\Psi'(d) = \Phi\left(\frac{1}{d}\right) - \frac{1}{d}\Phi'\left(\frac{1}{d}\right), \quad \Psi''(d) = \frac{1}{d^3}\Phi''\left(\frac{1}{d}\right); \tag{2.10}$$

and so $\Psi : (0,\infty) \to \mathbb{R}$ is convex.

Next, perform these calculations:

$$\begin{aligned} \mathbf{u}_t &= \operatorname{div}_x(\Phi'(\det D\mathbf{u})\det D\mathbf{u}(D\mathbf{u})^{-1}) \\ &= D_x(\Phi'(\det D\mathbf{u}))\cdot(\det D\mathbf{u}(D\mathbf{u})^{-1}) \\ &= \Phi''(\det D\mathbf{u})D_x(\det D\mathbf{u})\cdot(\det D\mathbf{u}(D\mathbf{u})^{-1}) \\ &= \Phi''\left(\frac{1}{\beta}\right)\frac{1}{\beta}D_x\left(\frac{1}{\beta}\right)(D\mathbf{u})^{-1} \\ &= -\Phi''\left(\frac{1}{\beta}\right)\frac{1}{\beta^3}D_x\beta(D\mathbf{u})^{-1} \\ &= -\Psi''(\beta)D_y\beta = -D_y\Psi'(\beta). \end{aligned} \tag{2.11}$$

This computation suggests that we fix a point $x \in \bar{U}$ and then solve the ODE

$$\begin{cases} \dot{\mathbf{y}}(t) = -\Psi''(\beta(\mathbf{y}(t),t))D\beta(\mathbf{y}(t),t) & \text{for } t > 0, \\ \mathbf{y}(0) = y = \mathbf{u}^0(x), \end{cases} \tag{2.12}$$

where $\dot{} = \frac{d}{dt}$. Then by uniqueness of solutions we have $\mathbf{u}(x,t) = \mathbf{y}(t)$ for $t \geq 0$.

3. Building diffeomorphisms. The formal calculations from the previous section done with, we turn now to building rigorously a smooth solution

$$\mathbf{u} : \bar{U} \times [0,\infty) \to \bar{V}$$

of our system

$$\begin{cases} \mathbf{u}_t = \operatorname{div}(\Phi'(\det D\mathbf{u})(\operatorname{cof} D\mathbf{u})^T) & \text{in } \bar{U} \times (0,\infty), \\ \mathbf{u} = \mathbf{u}^0 \quad \text{on } \bar{U} \times \{t = 0\}, \\ \mathbf{u}(\cdot,t) \in \operatorname{Diff}(\bar{U},\bar{V}) \end{cases} \tag{3.1}$$

under some additional assumptions.

3.1. Hypotheses. We require that the initial mapping $\mathbf{u}^0 : \bar{U} \to \bar{V}$ be a diffeomorphism, mapping ∂U onto ∂V. We write

$$\beta^0 := \det D\mathbf{v}^0 \tag{3.2}$$

for $\mathbf{v}^0 := (\mathbf{u}^0)^{-1}$ and assume that there exist positive constants $0 < C_1 \leq C_2$ such that

$$C_1 \leq \beta^0 \leq C_2 \quad \text{on } \bar{V}. \tag{H1}$$

We ask also that the following *compatibility condition* hold:

$$\frac{\partial \beta^0}{\partial \nu} = 0 \quad \text{on} \quad \partial V. \tag{H2}$$

Finally we require that Φ be smooth and convex on $(0, \infty)$, with the lower bound

$$\Phi''\left(\frac{1}{\beta}\right) > 0 \quad \text{for } C_1 \leq \beta \leq C_2. \tag{H3}$$

3.2. Solving PDE and ODE. In view of (H1), (H2), the initial/boundary-value problem

$$\begin{cases} \beta_t = \operatorname{div}\left(\Phi''\left(\frac{1}{\beta}\right)\frac{D\beta}{\beta^2}\right) & \text{in } V \times (0,\infty), \\ \frac{\partial \beta}{\partial \nu} = 0 & \text{on } \partial V \times [0,\infty), \\ \beta = \beta^0 & \text{on } \bar{V} \times \{t = 0\} \end{cases} \tag{3.3}$$

has a unique, smooth solution β, with

$$0 < C_1 \leq \beta \leq C_2 \qquad \text{in } \bar{V} \times [0, \infty). \tag{3.4}$$

Next, for each $y \in \bar{V}$, solve the ODE (2.12):

$$\begin{cases} \dot{\mathbf{y}}(t) = -\Psi''(\beta(\mathbf{y}(t),t))D\beta(\mathbf{y}(t),t) & \text{for } t > 0, \\ \mathbf{y}(0) = y. \end{cases} \tag{3.5}$$

We write $\mathbf{y}(t) = \mathbf{y}(t, y)$ to display dependence on the initial point y.

THEOREM 3.1. (i) *For each given $x \in \bar{U}$, the* ODE (3.5) *has a unique solution $\mathbf{y} : [0, \infty) \to \bar{V}$, existing for all times $t \geq 0$.*

(ii) *If $y \in \partial V$, then $\mathbf{y}(t) \in \partial V$ for all times $t \geq 0$.*

(iii) *For each $t \geq 0$, the mapping*

$$\mathbf{u}(x,t) := \mathbf{y}(t, \mathbf{u}^0(x)) \qquad (x \in \bar{U},\ t \geq 0) \tag{3.6}$$

is a smooth diffeomorphism from $\bar{U}$ to $\bar{V}$, mapping ∂U onto ∂V.

Proof. Since $\frac{\partial \beta}{\partial \nu} = 0$ on ∂V, $D\beta$ is tangent to ∂V and consequently the flow does not leave $\bar{V}$. In particular, if $\mathbf{u}^0(x) \in \partial V$, then $\mathbf{x}(t) \in \partial V$ for times $t \geq 0$.

Assertion (iii) is standard. ∎

Define $\mathbf{u} : \bar{U} \times [0, \infty) \to \bar{V}$ by (3.6) and set $\mathbf{v}(\cdot, t) := \mathbf{u}^{-1}(\cdot, t)$ for each time $t \geq 0$.

THEOREM 3.2. (i) *We have*

$$\beta \equiv \det D\mathbf{v}. \tag{3.7}$$

(ii) *Furthermore,* $\mathbf{u}$ *solves the system of* PDEs (2.1)*, and the mapping*

$$t \mapsto \int_U \Phi(\det D\mathbf{u})(x,t)\,dx$$

is nonincreasing.

Proof. 1. As before, set $\alpha = \det D\mathbf{u}$, $\alpha = \alpha(x,t)$. Then

$$\alpha_t = \alpha D_x \mathbf{u}_t (D\mathbf{u})^{-1}. \tag{3.8}$$

Now

$$\mathbf{u}_t = -D_y \Psi'(\beta)$$

and so

$$D_x \mathbf{u}_t = -D_y^2 \Psi'(\beta)(D_x \mathbf{u}).$$

Hence

$$\alpha_t = -\alpha \Delta_y \Psi'(\beta). \tag{3.9}$$

Next, regarding $\beta = \beta(\mathbf{u},t)$ as a function of (x,t), we have

$$\begin{aligned}
(\alpha\beta)_t &= \alpha_t \beta + \alpha\beta_t + \alpha D_y\beta \cdot \mathbf{u}_t \\
&= -\alpha\beta\Delta_y\Psi'(\beta) + \alpha \operatorname{div}(\Psi''(\beta)\beta D_y\beta) - \alpha D_y\beta \cdot (\Psi''(\beta) D_y \beta) \\
&= 0.
\end{aligned}$$

Since $\alpha\beta \equiv 1$ at $t = 0$, we deduce that

$$\beta = \alpha^{-1} = \det D\mathbf{v}.$$

2. We have shown that $\beta \equiv \det D\mathbf{v}$, where $\mathbf{v} = \mathbf{u}^{-1}$ and $\mathbf{u}$ is defined by (3.6). We then return to the computation (2.11) to deduce that

$$\mathbf{u}_t = \dot{\mathbf{x}} = -\Psi''(\beta) D\beta = \operatorname{div}(\Phi'(\det D\mathbf{u})(\operatorname{cof} D\mathbf{u})^T). \tag{3.10}$$

Finally let us calculate

$$\begin{aligned}
\frac{d}{dt}\int_U \Phi(\det D\mathbf{u})\,dx &= \frac{d}{dt}\int_V \Phi\left(\frac{1}{\beta}\right)\beta\,dy \\
&= \int_V \left(\Phi\left(\frac{1}{\beta}\right) - \frac{1}{\beta}\Phi'\left(\frac{1}{\beta}\right)\right)\beta_t\,dy \\
&= \int_V \Psi'(\beta)\operatorname{div}(\beta\Psi''(\beta)D\beta)\,dy \\
&= -\int_V \Psi''(\beta)^2\beta|D\beta|^2\,dy \le 0. \qquad \square
\end{aligned}$$

4. Some variants.

4.1. More general nonlinearities. Our methods extend with little difficulty to the functional

$$I[\mathbf{v}] := \int_U \Phi(f(\mathbf{v})\det D\mathbf{v})\,dx \tag{4.1}$$

for Φ as before and $f : \bar{V} \to (0,\infty)$.

Euler–Lagrange equation. The corresponding Euler–Lagrange equation is

$$-\operatorname{div}(\Phi'(f \det D\mathbf{u}) f (\operatorname{cof} D\mathbf{u})^T) + \Phi'(f \det D\mathbf{u})(\det D\mathbf{u}) Df = 0,$$

which simplifies to read

$$\Phi''(f \det D\mathbf{u}) D(f \det D\mathbf{u}) f (\operatorname{cof} D\mathbf{u})^T = 0. \tag{4.2}$$

As in section 1.1 this implies that

$$f(\mathbf{u}) \det D\mathbf{u} \equiv C \quad \text{within} \quad U$$

for some constant C.

A gradient flow. The evolution associated with (4.1) is

$$\mathbf{u}_t - \operatorname{div}(\Phi'(f \det D\mathbf{u}) f (\operatorname{cof} D\mathbf{u})^T) + \Phi'(f \det D\mathbf{u})(\det D\mathbf{u}) Df = 0, \tag{4.3}$$

plus initial and boundary conditions.

As before, assume $\mathbf{v} := \mathbf{u}^{-1}$ exists and write

$$\beta := \det D\mathbf{v}.$$

THEOREM 4.1. *We have*

$$\begin{cases} \beta_t = -\operatorname{div}\left(\Phi''\left(\frac{f}{\beta}\right) f D\left(\frac{f}{\beta}\right)\right) & \text{in } V \times (0,\infty), \\ \frac{\partial}{\partial \nu}\left(\frac{f}{\beta}\right) = 0 & \text{on } \partial V \times (0,\infty). \end{cases} \tag{4.4}$$

Proof. 1. Fix any time $T > 0$ and select a smooth function $\zeta : \bar{V} \times [0,T] \to \mathbb{R}$ satisfying (2.5).

Then

$$\begin{aligned} &\int_0^T \int_V \beta\zeta_t + D_y\left(\Phi'\left(\frac{f}{\beta}\right)\right) \cdot D_y\zeta f \, dydt \\ &= \int_0^T \int_U \left[\beta(\mathbf{u},t)\zeta_t(\mathbf{u},t) + D_x\left(\Phi'\left(\frac{f}{\beta}\right)\right)(D\mathbf{u})^{-1} \cdot D_y\zeta f\right] \frac{dx}{\beta(\mathbf{u},t)} \, dt \\ &= \int_0^T \int_U \frac{\partial}{\partial t}(\zeta(\mathbf{u},t)) - D_y\zeta \cdot \mathbf{u}_t + D_x\left(\Phi'\left(\frac{f}{\beta}\right)\right)\frac{(D\mathbf{u})^{-1}}{\beta} \cdot D_y\zeta f \, dxdt \\ &= -\int_0^T \int_U D_y\zeta \cdot \left[\mathbf{u}_t - D_x\left(\Phi'\left(\frac{f}{\beta}\right)\right)\frac{(D\mathbf{u})^{-1}}{\beta} f\right] \, dxdt. \end{aligned} \tag{4.5}$$

But according to (4.3), we have

$$\begin{aligned} \mathbf{u}_t &= D(\Phi'(f \det D\mathbf{u})) f (\det D\mathbf{u})(D\mathbf{u})^{-1} \\ &= D\left(\Phi'\left(\frac{f}{\beta}\right)\right)\frac{f}{\beta}(D\mathbf{u})^{-1}. \end{aligned} \tag{4.6}$$

Consequently the expression within the square brackets in the last term of (4.5) vanishes. ∎

4.2. "Filling up" the target domain. An interesting variant of our construction is as follows. Select $\mathbf{u}^0 : \bar{U} \to \bar{W}_0$ to be a diffeomorphism, where $W_0 \subset\subset V$ is given. We will choose Φ and $\mathbf{u}$ so that

$$\begin{cases} W(t) := \mathbf{u}(U,t) & (t \geq 0), \\ W(0) = W_0 \end{cases} \tag{4.7}$$

expands to "fill up" the target V in finite time.

For this, let us take $m > 0$ and

$$\Phi(d) := \begin{cases} \frac{1}{m} d^{-m} & (d > 0), \\ +\infty & (d \leq 0). \end{cases}$$

Therefore

$$\Psi(d) = d\Phi\left(\frac{1}{d}\right) = \frac{1}{m} d^{m+1}$$

for $d > 0$. Then β solves the porous medium equation

$$\beta_t = \operatorname{div}(\Psi''(\beta)\beta D\beta) = \Delta(\beta^{m+1}).$$

5. Connections with optimal mass transfer problems. As noted in the introduction, the time-step minimization method (1.4) and (1.5) provides an extremely natural approximation method, but one which we have not been able to prove converges. This section recalls more about this procedure, to highlight the connections with Monge–Kantorovich mass transfer theory.

We are primarily motivated by Otto [O] and Jordan, Kinderlehrer, and Otto [J-K-O]. The novelty of Otto's paper [O] was to interpret (5.8) as a gradient flux of the "entropy" $S(\beta) := \int_V \Psi(\beta) dy$ with respect to the Wasserstein distance.

5.1. Time-step approximations. Assume for this section that U and V are two bounded, open, *convex* sets with smooth boundaries.

We discuss a time-discrete algorithm for the flow

$$\begin{cases} \mathbf{u}_t = \operatorname{div}(DF(D\mathbf{u})), \\ \mathbf{u}(\cdot,0) = \mathbf{u}_0, \\ \mathbf{u}(\cdot,t) \in \operatorname{Diff}(\bar{U},\bar{V}), \end{cases} \tag{5.1}$$

where, as before,

$$F(P) = \begin{cases} \Phi(\det P), & \det P > 0, \\ +\infty, & \det P \leq 0. \end{cases}$$

The system (5.1) is a gradient flux of the functional $I[\cdot]$ with respect to the L^2-metric. In section 2 we have shown that (5.1) is related to (1.16), which, as we will recall below, is the gradient flow governed by $\int_V \Psi(\beta)\, dy$ with respect to the Wasserstein distance. The algorithm which we discuss is another way to view that relation.

A discrete-time approximation. First, let us fix a time-step size $h > 0$. We introduce the implicit scheme of recursively finding $\mathbf{u}_{k+1}$ to solve

$$\begin{cases} \frac{\mathbf{u}_{k+1}-\mathbf{u}_k}{h} = \operatorname{div}(DF(D\mathbf{u}_{k+1})), \\ \mathbf{u}_{k+1} \in \operatorname{Diff}(\bar{U},\bar{V}), \end{cases} \tag{5.2}$$

given $\mathbf{u}_k$. More precisely, set

$$I_k[\mathbf{v}] := \frac{1}{2}\int_U |\mathbf{v}-\mathbf{u}_k|^2\,dx + h\int_U F(D\mathbf{v})\,dx. \tag{5.3}$$

We intend to find $\mathbf{u}_{k+1}$ to be the unique minimizer of

$$\min_{\mathbf{v}}\{I_k[\mathbf{v}] \mid \mathbf{v}\in \mathrm{Diff}(\bar{U},\bar{V})\}. \tag{5.4}$$

Changing variables. Since our nonlinearity F is neither coercive nor convex, standard calculus of variations methods do not apply. However, recent papers by Gangbo and Van der Putten [G-VP] and Maroofi [Ma] demonstrate how to exploit the special structure of $F(P)=\Phi(\det P)$ to find minimizers.

Indeed, if we apply a change of variables $y=\mathbf{u}(x)$ and set $\beta := \det(D\mathbf{u}^{-1})$, $\beta_k := \det(D\mathbf{u}_k^{-1})$, we discover that

$$I_k[\mathbf{v}] = \frac{1}{2}\int_V |y-\mathbf{u}_k(\mathbf{v}^{-1}(y))|^2 dy + h\int_V \Psi(\beta)\,dy.$$

Consequently

$$\begin{aligned}
&\min_{\mathbf{v}\in\mathrm{Diff}(\bar{U},\bar{V})} I_k[\mathbf{v}]\\
&= \inf_\beta\left\{h\int_V \Psi(\beta)\,dy + \inf_{\mathbf{v}}\left\{\frac{1}{2}\int_V |y-\mathbf{u}_k(\mathbf{v}^{-1}(y))|^2 dy \mid \beta=\det(D\mathbf{v}^{-1})\right\}\right\}\\
&= \inf_\beta\left\{h\int_V \Psi(\beta)\,dy + \inf_{\mathbf{w}}\left\{\frac{1}{2}\int_V |y-\mathbf{w}(y)|^2 dy \mid \beta_k=\beta(\mathbf{w})\det D\mathbf{w}\right\}\right\}\\
&= \inf_\beta\left\{h\int_V \Psi(\beta)\,dy + W_2^2(\beta_k,\beta)\right\},
\end{aligned} \tag{5.5}$$

where W_2, the *Wasserstein distance* between two Borel measures μ and ν, is defined as

$$W_2^2(\mu,\nu) := \frac{1}{2}\inf_{\gamma\in\Gamma(\mu,\nu)}\iint |x-y|^2 d\gamma(x,y).$$

Here $\Gamma(\mu,\nu)$ is the set of Borel measures γ on $\mathbb{R}^{2n}$ that have μ and ν as their marginals. The notation $W_2^2(\beta_k,\beta)$ means that we have identified β with the measure whose density is β.

We assume for $k=0$ that

$$\int_V \beta_0\,dy = 1,$$

where $\beta_0=\det D\mathbf{u}_0^{-1}$. This reduces the last three problems in (5.5) to minimization problems over $\mathcal{P}_a(V)$, the set of probability densities supported in V.

Define the new functional

$$J_k(\beta) := W_2^2(\beta,\beta_k) + h\int_V \Psi(\beta)\,dy. \tag{5.6}$$

Now $W_2^2(\beta_k,\cdot)$ is convex and is weakly-$*$ lower semicontinuous. Since Ψ is strictly convex, we see also that $\beta\to\int_V\Psi(\beta)\,dy$ is a strictly convex functional of β and is weakly-$*$ lower semicontinuous on subsets of L^1 that are weakly-$*$ compact. Consequently, the minimization problem

$$\inf_{\beta \in \mathcal{P}_a(V)} J_k(\beta) \tag{5.7}$$

has a unique solution β_{k+1}.

5.2. Time-step approximations for . This subsection quickly reviews a time-discrete algorithm based on the Wasserstein distance for solving

$$\begin{cases} \beta_t = \operatorname{div}\Big(\beta D[\Psi'(\beta)]\Big), \\ \beta(\cdot, 0) = \beta_0. \end{cases} \tag{5.8}$$

Let us now deal with the following nonlinear problem appearing in (5.5), where we replace β by β_{k+1}. We study the minimization problem

$$\inf_{\mathbf{v}} \left\{ \int_V |y - \mathbf{v}(y)|^2 dy \mid \beta_k = \beta_{k+1}(\mathbf{v}) \det D\mathbf{v} \right\}, \tag{5.9}$$

which, thanks to the Monge–Kantorovich theory, is known to admit a unique minimizer $\mathbf{v}_{k+1}$ (see Brenier [B]). Furthermore, $\mathbf{v}_{k+1}$ is the gradient of a convex function $\psi_{k+1} : \bar{V} \to \mathbb{R}$, satisfying the Monge–Ampere problem

$$\beta_k = \beta_{k+1}(D\psi_{k+1}) \det D^2\psi_{k+1}, \quad D\psi_{k+1}(\bar{V}) = \bar{V} \tag{5.10}$$

in the sense that

$$D\psi_{k+1} : \bar{V} \to \bar{V} \text{ a.e.} \quad \text{and} \quad \int_V f(D\psi_{k+1})\beta_k \, dx = \int_V f\beta_{k+1} \, dy \tag{5.11}$$

for all $f \in C(\mathbb{R}^n)$. Equivalently, if ϕ_{k+1} is the Legendre transform of ψ_{k+1}, then

$$D\phi_{k+1} : \bar{V} \to \bar{V} \text{ a.e.} \qquad \text{and} \qquad \int_V g(D\phi_{k+1})\beta_{k+1} \, dy = \int_V g\beta_k \, dx \tag{5.12}$$

for all $g \in C(\mathbb{R}^n)$. We write that

$$(D\psi_{k+1})_{\#}\beta_k = \beta_{k+1}, \quad (D\phi_{k+1})_{\#}\beta_{k+1} = \beta_k,$$

the symbol # denoting push-forward. Agueh [A] has shown that

$$C_1 \le \beta_{k+1} \le C_2, \tag{5.13}$$

provided

$$C_1 \le \beta_k \le C_2 \tag{5.14}$$

for constants $0 < C_1 \le C_2$

The Euler–Lagrange equations of (5.7) read

$$D\phi_{k+1}(y) = y + hD[\Psi'(\beta_{k+1}(y))], \tag{5.15}$$

and we conclude from (5.15) that

$$\beta_{k+1}(y) = (\Psi^*)'\left(\left(\phi_{k+1}(y) - \frac{|y|^2}{2}\right)/h\right), \tag{5.16}$$

where Ψ^* is the Legendre transform of Ψ.

Assume that $\beta_k \in C^{l,\alpha}(\bar{V})$ for some $\alpha > 0$ and some integer $l \geq 0$. By (5.16), $\beta_{k+1} \in W^{1,\infty}(V) \subset C^{0,\alpha}(\bar{V})$. Regularity theory for the Monge–Ampere equations (see [C1], [C2], [C3], [C4]) and (5.10) imply that $\psi_{k+1}, \phi_{k+1} \in C^{2,\alpha}(\bar{V})$. This and (5.16) demonstrate that $\beta_{k+1} \in C^{2,\alpha}(\bar{V})$. Thus

$$\gamma_{k+1} := D\phi_{k+1} \circ D\phi_k \circ \cdots \circ D\phi_1 \in C^{l+1,\alpha}(\bar{V}, \bar{V}).$$

The map

$$\mathbf{u}_{k+1} = \gamma_{k+1} \circ \mathbf{u}_0$$

is then the unique solution to (5.2), and $\mathbf{u}_{k+1} \in C^{l+1,\alpha}(\bar{U}, \bar{V})$ if $\mathbf{u}_0 \in C^{l+1,\alpha}(\bar{U}, \bar{V})$.

We record next that the time-step approximations converge as $h \to 0$.

THEOREM 5.1. *For $h > 0$, inductively define β_{k+1} to be the unique minimizer of $J_k[\cdot]$ over $\mathcal{P}_a(V)$. Set*

$$\beta^h(y,t) = \begin{cases} \beta_0(y) & \text{if} \quad t = 0, \\ \beta_k(y) & \text{if} \quad t \in ((k-1)h, kh]. \end{cases}$$

Fix $T > 0$ and assume that $T = Mh$ for an integer $M > 0$.

Then the following hold:

(i) *For each test function $\eta \in C_c^2$, we have*

$$\left| \int_{V_T} \partial_t^h \eta (\beta^h - \beta_0)\, dxdt + \int_{V_T} \operatorname{div}\Big(\beta^h D[\Psi'(\beta^h)]\Big)\, dxdt \right| \leq C_\eta h,$$

where $\partial_t^h \eta(x,t) = (\eta(x,t+h) - \eta(x,t))/h$ and $V_T = V \times (0,T)$.

(ii) *There exists a subsequence $\{h_m\}_{m=1}^\infty$ converging to 0 and $\beta \in L^1(V_T)$ such that $\{\beta^{h_m}\}_{m=1}^\infty$ converges to β. Furthermore, β satisfies the parabolic equation (5.8).*

5.3. Time-step approximations for u. Finally, we return to the approximation scheme (5.2) and consider the convergence problem as $h \to 0$.

We first record some uniform estimates.

THEOREM 5.2. *Fix $h > 0$ and inductively define $\mathbf{u}_{k+1}$ to be the unique minimizer of $I_k[\cdot]$ over $\operatorname{Diff}(\bar{U}, \bar{V})$. Define*

$$\mathbf{u}^h(\cdot,t) = \begin{cases} \mathbf{u}_0(\cdot) & \text{if} \quad t = 0, \\ \mathbf{u}_k(\cdot) & \text{if} \quad t \in ((k-1)h, kh]. \end{cases}$$

Fix $T > 0$ and assume that $T = Mh$ for an integer $M > 0$. Set $U_T = U \times (0,T)$.

Then the following hold:

(i) *For each $t \in [0,T]$ we have that $\mathbf{u}^h(\cdot,t) \in \operatorname{Diff}(\bar{U}, \bar{V}) \cap C^{l+1,\alpha}(\bar{U}, \mathbb{R}^n)$ and there are constants $C_1, C_2 > 0$ depending only on $\mathbf{u}_0$ such that*

$$C_1 \leq \det D(\mathbf{u}^h)^{-1} \leq C_2.$$

(ii) *There exists a constant $C > 0$, depending only on $\mathbf{u}_0$, such that*

$$\sum_{k=0}^{M-1} \int_U |\mathbf{u}_{k+1} - \mathbf{u}_k|^2\, dx \leq Ch.$$

(iii) *For each test function* $\mathbf{v} \in C^2$, *we have*

(5.17)
$$\left| \int_{U_T} \mathbf{u}^h \cdot \mathbf{v}_t - DF(D\mathbf{u}^h) : D\mathbf{v}\, dxdt + \int_U \mathbf{u}_0 \cdot \mathbf{v}(\cdot, 0)\, dx \right| \leq \frac{h}{2} C\sqrt{T} ||\mathbf{v}_t||_{L^\infty(U_T)}.$$

Proof. 1. Set $\beta_0 = \det D\mathbf{u}_0^{-1}$. Since $\mathbf{u}_0 \in \mathrm{Diff}(\bar{U}, \bar{V})$ we have that

$$0 < C_1 := \min_{\bar{V}} \beta_0, C_2 := \max_{\bar{V}} \beta_0 < +\infty.$$

According to the discussion above, we can choose inductively $\mathbf{u}_{k+1}$ to be the unique minimizer of I_k over $\mathrm{Diff}(\bar{U}, \bar{V})$.

2. The inequality $I_k(\mathbf{u}_{k+1}) \leq I_k(\mathbf{u}_k)$ implies that

$$\sum_{k=0}^{M-1} I_k(\mathbf{u}_{k+1}) \leq \sum_{k=0}^{M-1} I_k(\mathbf{u}_k).$$

Therefore

(5.18)
$$\frac{1}{2} \sum_{k=0}^{M-1} \int_V |\mathbf{u}_{k+1} - \mathbf{u}_k|^2 dx \leq h \int_U \Phi(\det D\mathbf{u}_0) - \Phi(\det D\mathbf{u}_M) dx \leq 2h|U| \max_{[\frac{1}{C_2}, \frac{1}{C_1}]} |\Phi|.$$

This proves (ii).

3. Suppose now that $\mathbf{v} \in C^2$, and set $t_k = kh$, $\mathbf{v}_k = \mathbf{v}(\cdot, kh)$, and $U_k = U \times (t_k, t_{k+1})$. Then

$$\int_{U_T} \mathbf{u}^h \cdot \mathbf{v}_t - DF(D\mathbf{u}^h) : D\mathbf{v}\, dxdt = \sum_{k=0}^{M-1} \int_{U_k} \mathbf{u}_{k+1} \cdot \mathbf{v}_t\, dxdt - DF(D\mathbf{u}_{k+1}) : D\mathbf{v}\, dxdt.$$

We recall that $(\mathbf{u}_{k+1} - \mathbf{u}_k)/h = \mathrm{div}(DF(D\mathbf{u}_{k+1}))$ and continue to calculate that

$$\begin{aligned}
\int_{U_T} \mathbf{u}^h \cdot \mathbf{v}_t - DF(D\mathbf{u}^h) : D\mathbf{v}\, dxdt &= \sum_{k=0}^{M-1} \int_{U_k} \mathbf{u}_{k+1} \cdot \mathbf{v}_t + \left(\frac{\mathbf{u}_{k+1} - \mathbf{u}_k}{h} \right) \cdot \mathbf{v}\, dxdt \\
&= \sum_{k=0}^{M-1} \int_U \mathbf{u}_{k+1} \cdot (\mathbf{v}_{k+1} - \mathbf{v}_k)\, dx \\
&\quad + \int_U (\mathbf{u}_{k+1} - \mathbf{u}_k) \cdot \mathbf{v}_k\, dx \\
&\quad + \sum_{k=0}^{M-1} \int_U \left(\frac{\mathbf{u}_{k+1} - \mathbf{u}_k}{h} \right) \cdot \left(\int_{t_k}^{t_{k+1}} \mathbf{v} - \mathbf{v}_k\, dt \right) dx \\
&= \int_U \mathbf{u}_M \cdot \mathbf{v}_M - \mathbf{u}_0 \cdot \mathbf{v}_0\, dx \\
&\quad + \sum_{k=0}^{M-1} \int_U \left(\frac{\mathbf{u}_{k+1} - \mathbf{u}_k}{h} \right) \cdot \left(\int_{t_k}^{t_{k+1}} \mathbf{v} - \mathbf{v}_k\, dt \right) dx.
\end{aligned}$$

Taking into account $\mathbf{v}_M = \mathbf{v}(T) = 0$ and

$$\left|\int_{t_k}^{t_{k+1}} \mathbf{v} - \mathbf{v}_k \, dt\right| \leq \frac{h^2}{2} \max_{U_T} |\mathbf{v}_t|,$$

we conclude that

$$\begin{aligned}
&\left|\int_{U_T} \mathbf{u}^h \cdot \mathbf{v}_t - DF(D\mathbf{u}^h) : D\mathbf{v} \, dxdt + \int_U \mathbf{u}_0 \cdot \mathbf{v}(\cdot, 0) \, dx\right| \\
&\qquad \leq \frac{h}{2} \, ||\mathbf{v}_t||_{L^\infty} \sum_{k=0}^{M-1} \int_U |\mathbf{u}_{k+1} - \mathbf{u}_k| \, dx \\
&\qquad \leq \frac{h}{2} \, ||\mathbf{v}_t||_{L^\infty(U_T)} \left(\sum_{k=0}^{M-1} \int_U |\mathbf{u}_{k+1} - \mathbf{u}_k|^2 \, dx\right)^{\frac{1}{2}} M^{\frac{1}{2}}. \qquad (5.19)
\end{aligned}$$

We combine (5.18) and (5.19) to finish up the proof of (iii). ☐

This theorem provides some uniform estimates, but it remains an unsolved problem to show that as $h \to 0$, the approximation $\mathbf{u}^h$ converges somehow to a solution $\mathbf{u}$ of (1.3). One particular issue is that we do not know if the gradients $D\mathbf{u}^h$ converge strongly in L^2.

Our belief is that although the scheme (5.2), (5.3), and (5.4) is obviously extremely natural, we do not currently know how fully to exploit the minimization structure. We have here a problem in the "time-dependent calculus of variations," but we do not have enough experience to understand, for instance, the proper choices of comparison functions to employ in our variational principles. The direct PDE and ODE methods in sections 2 and 3 provide a way around this difficulty for the special case of the nonlinearity (1.6).

IMMEDIATE REGULARIZATION AFTER BLOW-UP*

MAREK FILA†, HIROSHI MATANO‡, AND PETER POLÁČIK§

Abstract. We study solutions of some supercritical parabolic equations which blow up in finite time but continue to exist globally in the weak sense. We show that the minimal continuation becomes regular immediately after the blow up time, and if it blows up again, it can only do so finitely many times.

Key words. nonlinear heat equation, blow up, regularity

AMS subject classifications. 35K57, 35B65

DOI. 10.1137/040613299

1. Introduction.

We consider the problem

$$\text{(P)}\qquad \begin{cases} u_t = \Delta u + f(u), & x \in B_1,\ t > 0, \\ u = 0, & x \in \partial B_1,\ t > 0, \\ u(x,0) = u_0(x)\ (= U_0(|x|)\,), & x \in B_1, \end{cases}$$

where $B_1 = \{x \in \mathbb{R}^N : |x| < 1\}$, $U_0 \in C([0,1])$, $U_0 \geq 0$ with $U_0(1) = 0$, and either

$$f(u) = \lambda e^u, \quad \lambda > 0, \quad 3 \leq N \leq 9 \tag{1.1}$$

or

$$f(u) = u^p, \quad \frac{N+2}{N-2} < p < p^*, \quad N \geq 3, \tag{1.2}$$

where

$$p^* = \begin{cases} \infty & \text{if} \quad N \leq 10, \\ 1 + \frac{4}{N-4-2\sqrt{N-1}} & \text{if} \quad N > 10. \end{cases}$$

In the case of the exponential nonlinearity (1.1), we shall further assume that $U_0(r)$ is a nonincreasing function on $[0,1]$.

We shall show that if a solution blows up in a finite time $t = T < \infty$ but continues to exist as a weak solution for $t > T$, then this extended solution becomes regular immediately after the blow up time T, that is, it possesses no singularity in the time

interval $T < t < T^*$ for some $T^* \in (T, \infty]$. Here, by an extended solution we mean the so-called minimal continuation, whose meaning will be clarified later.

Let us now give a more detailed description of the result together with some history of the problem. Global unbounded weak solutions of (P) with $f(u) = u^p$, $p \geq \frac{N+2}{N-2}$, were discovered in [16]. These solutions are characterized as the limit of an increasing sequence of global classical solutions $0 < u_1 < u_2 < u_3 < \cdots$ such that each u_k belongs to the domain of attraction of the stable stationary solution $u = 0$ (that is, $u_k \to 0$ as $t \to \infty$) and such that $\lim_{k\to\infty} u_k$ lies on the boundary of this domain of attraction.

The monotonicity of the sequences and the standard Kaplan-type estimate for the approximating classical solutions yield uniform bounds on certain integrals; hence the limit functions are indeed time-global weak solutions. Moreover, these weak solutions are necessarily unbounded on the time interval $[0, \infty)$, since otherwise they would remain classical for all $t > 0$ and converge to some positive stationary solution as $t \to \infty$, but the assumption $p \geq \frac{N+2}{N-2}$ and the Pohozaev identity imply nonexistence of positive stationary solutions. Consequently, one of the following alternatives occurs for each of these global weak solutions:

(a) the solution blows up in finite time;

(b) the solution remains smooth for all $t > 0$ and tends to infinity as $t \to \infty$.

For a long time it was not known which of the two alternatives really occurs. Much later Galaktionov and Vázquez [4] concluded that (a) is always the case, provided that

$$\frac{N+2}{N-2} < p \left(< 1 + \frac{6}{N-10} \quad \text{if} \quad N > 10 \right).$$

It follows from [4] and a recent result of Mizoguchi [15] that (a) holds for all $p > (N+2)/(N-2)$, $N > 2$. By *blow up in finite time* we mean that there is $T \in (0, \infty)$ such that

$$\lim_{t \to T} \|u(\cdot, t)\|_{L^\infty(B_1)} = \infty,$$

and we call T the *blow up time* of solution u. The above-mentioned global weak solutions thus have continuation beyond the blow up time in a certain sense.

Note that such continuation is not possible if $1 < p \leq \frac{N+2}{N-2}$. Indeed it is known that in this range of p every blow up is complete in the sense that the minimal (proper) continuation for t larger than the blow up time T is infinite everywhere in $B_1 \times (T, \infty)$. See [1, 4] for details. Note also that the same is true for any $p > 1$ if $u_t \geq 0$.

In the case of exponential nonlinearity (1.1), global unbounded weak solutions were constructed in [9] for a certain range of λ and later in [3] for a larger range of λ. It was also proved in [3] that global unbounded weak solutions blow up in finite time.

For both (1.1) and (1.2), it is still an open question whether the weak continuation beyond the blow up time is unique or not. However, one can define uniquely the so-called minimal continuation, and this is what we study in the present paper.

Now, given a global weak solution u, we define the set of *regular time moments* by

$$\mathcal{R} := \{t_0 > 0 : \ u \text{ is a classical solution on some time interval around } t = t_0\}$$

and the *set of singular time moments* by $\mathcal{S} = (0, \infty) \setminus \mathcal{R}$. By Lemma 2.6 in subsection

2.1, we see that $\mathcal{S} = \mathcal{B}$, where

$$\mathcal{B} := \left\{ t_0 > 0 \,:\, \limsup_{t \to t_0} \|u(\cdot, t)\|_{L^\infty(B_1)} = \infty \right\}.$$

Our main goal is to show that $\mathcal{B}$ is a finite set. This in particular implies that the solution recovers smoothness immediately after blow-up, and it remains smooth until $t = \infty$ or until the next blow-up occurs. We also give an example of a limit L^1-solution for which $\mathcal{B}$ is a singleton.

Previously some examples of "peaking solutions"—that is, solutions which blow up at $t = T$ and become smooth for $t > T$— have been known for the Cauchy problem in $\mathbb{R}^N$ (see [9, 4, 12]). In [9] and [4], examples of peaking solutions are constructed by simply gluing backward self-similar solutions (i.e., self-similar solutions that are defined for $-\infty < t < T$ and blow up at $t = T$) and forward self-similar solutions (i.e., self-similar solutions that are defined for $T < t < \infty$ and blow up at $t = T$) sharing the same blow up profile at the blow up time T. However, this method does not work for problems in bounded domains since self-similar solutions do not satisfy reasonable boundary conditions on a fixed boundary. In [13, 14], examples of solutions with multiple blow up time are constructed for the power case (1.2). These earlier works only give some examples of peaking solutions, and it has not been known whether or not global weak solutions in general behave like peaking solutions—more precisely, whether or not immediate regularization always occurs after blow-up. Our result in the present paper shows that every minimal continuation beyond blow-up has this property.

It should be noted that our result does not follow from standard parabolic estimates. Indeed, once a solution u blows up, say at $t = T$, then its blow up profile $u(x, T)$ may no longer belong to the function space in which problem (P) is well-posed; therefore, a standard bootstrap argument does not improve the regularity so much. See Remark 3.4 for details.

This paper is organized as follows. In section 2, we define limit L^1-solutions and derive various estimates for these solutions. Among other things we show that limit L^1-solutions belong to $C([0, \infty); H^1(B_1))$.

In section 3, we state our main result (Theorem 3.1). We then prove the main theorem in sections 4 and 5. The proof relies heavily on the zero-number properties of parabolic equations. Note that, as we are dealing with solutions with singularities, the zero-number is no longer monotone nonincreasing but a slightly weaker property holds (see Lemma 4.1 and Remark 4.3).

In section 6, we consider the case of exponential nonlinearity (1.1) and prove the existence of a peaking solution that blows up exactly once and remains smooth thereafter (Theorem 6.1). This result is proved by showing that a singular heteroclinic connection between certain equilibrium solutions of (P) has this property. As far as the authors know, no example of peaking solution was known previously for the exponential nonlinearity (1.1) in a bounded domain.

2. Preliminaries. Hereafter, for notational simplicity, we sometimes write the solution of (P) as $u(r, t)$ rather than $u(x, t)$, where r stands for $|x|$. This is the case in some part of subsections 2.3–2.5 and much of section 3.

2.1. Definition of L^1-solutions.

DEFINITION 2.1. *By an* L^1-solution *on an interval* $[0, T_0]$ *we mean a function* $u \in C([0, T_0];\, L^1(B_1))$ *such that* $f(u) \in L^1(Q_{T_0})$, $Q_{T_0} := B_1 \times (0, T_0)$ *and such that* *the equality*

$$\int_{B_1} (u(x,t)\Psi(x,t) - u_0(x)\Psi(x,0))\, dx - \int_0^t \int_{B_1} u\Psi_t \, dx\, ds$$
$$= \int_0^t \int_{B_1} (u\Delta\Psi + f(u)\Psi)\, dx\, ds$$

holds for any $0 < t \le T_0$ *and* $\Psi \in C^2(\overline{Q}_{T_0})$ *with* $\Psi = 0$ *on* $\partial\Omega \times [0, T_0]$. *By a* global L^1-solution *we mean a function* $u \in C([0,\infty);\, L^1(B_1))$ *which is an* L^1*-solution on* $[0, T_0]$ *for every* $T_0 > 0$.

Definition 2.2. *By a* limit L^1-solution *we mean a global* L^1*-solution which can be approximated by global classical solutions in the following way: There is a sequence* $\{u_{0,n}\}$ *in* $C(\overline{B}_1)$ *such that*

$$u_{0,n} \to u_0 \quad \text{in } C(\overline{B}_1) \tag{2.1}$$

and that the solution u_n *of* (P) *with* $u(\cdot,0) = u_{0,n}$ *exists globally for* $t \ge 0$ *and satisfies*

$$\begin{aligned} u_n(\cdot,t) &\to u(\cdot,t) && \text{in } L^1(B_1) \quad \text{for every } t > 0, \\ f(u_n) &\to f(u) && \text{in } L^1((B_1) \times (0,t)) \quad \text{for every } t > 0. \end{aligned} \tag{2.2}$$

We refer to any such sequence $\{u_n\}$ *as an* approximating sequence *for* u. *We call a limit* L^1*-solution a* minimal L^1-solution *if it has an approximating sequence that is pointwise nondecreasing in* n.

Remark 2.3. We do not need to assume in Definition 2.2 that $u(x,t)$ is a global L^1-solution. In fact, by condition (2.2), the limit function $u(x,t)$ automatically satisfies the integral identity in Definition 2.1. To see that u belongs to $C([0,\infty);\, L^1(B_1))$, recall that any approximating sequence of classical solutions u_n satisfies

$$u_n(\cdot,t) = e^{t\Delta}\, u_{0,n} + \int_0^t e^{(t-\tau)\Delta} f(u_n(\cdot,\tau))\, d\tau.$$

Letting $n \to \infty$ and using (2.2), we obtain

$$u(\cdot,t) = e^{t\Delta}\, u_0 + \int_0^t e^{(t-\tau)\Delta} f(u(\cdot,\tau))\, d\tau.$$

This proves the continuity $t \mapsto u(\cdot,t)$ in $L^1(B_1)$.

Remark 2.4. Condition (2.2) is automatically fulfilled if the approximating sequence u_n is monotone nondecreasing in n. In fact, the standard Kaplan estimate gives uniform bounds for $\|u_n(\cdot,t)\|_{L^1(B_1)}$ and $\|f(u_n)\|_{L^1(B_1\times[0,T_0])}$; hence (2.2) follows from the monotone convergence theorem.

Though we require only (2.1) and (2.2) for the approximating sequence u_n, the actual convergence takes place in a much stronger sense, as we shall see in Proposition 2.12.

The next lemma shows that any limit L^1-solution is a classical solution until it blows up.

Lemma 2.5. *Let* u *and* $\tilde{u}$ *be, respectively, a limit* L^1*-solution and a classical solution of* (P) *sharing the same initial data* u_0, *and denote by* $[0,T)$ *the maximal interval of existence for* $\tilde{u}$. *Then* $u = \tilde{u}$ *for* $0 \le t < T$. *Moreover, any approximating sequence* $\{u_n\}$ *for* u *satisfies*

$$u_n(\cdot,t) \to u(\cdot,t) \quad \text{in } C^2(\overline{B}_1) \quad \text{for each } t \in (0,T).$$

Proof. By the well-posedness of (P) in the space $C(\overline{B}_1)$, convergence (2.1) implies $u_n(\cdot,t) \to \tilde{u}(\cdot,t)$ in $C(\overline{B}_1)$ locally uniformly in $t \in (0,T)$. This, together with (2.2), yields $\tilde{u}(x,t) = u(x,t)$ for $0 \le t < T$. The C^2 convergence is a consequence of parabolic estimates. ◻

LEMMA 2.6. *Let u be a limit L^1-solution and suppose that*

$$\sup_{t_1<t<t_2} \|u(\cdot,t)\|_{L^\infty(B_1)} < \infty \tag{2.3}$$

for some $0 \le t_1 < t_2$. Then u is "regular" (i.e., a classical solution) in the interval $t_1 < t < t_2$.

Proof. By the same limiting argument as in Remark 2.3, we get

$$u(\cdot,t) = e^{(t-t_1)\Delta}\, u(\cdot,t_1) + \int_{t_1}^{t} e^{(t-\tau)\Delta} f(u(\cdot,\tau))d\tau$$

for $t \in [t_1,t_2)$. Since u is bounded we obtain $u \in C((t_1,t_2);\, C^1(\overline{B}_1))$; hence $f(u) \in C((t_1,t_2);\, C^1(\overline{B}_1))$. Using the parabolic estimates again, we see that u is a classical solution for $t_1 < t < t_2$. ◻

Another consequence of parabolic estimates is the following.

LEMMA 2.7. *Let u be a minimal L^1-solution satisfying* (2.3) *for some $0 \le t_1 < t_2$. Then any nondecreasing approximating sequence $\{u_n\}$ satisfies*

$$u_n(\cdot,t) \to u(\cdot,t) \quad \text{in } C^2(\overline{B}_1)$$

for each $t \in (t_1,t_2)$.

2.2. A pointwise Kaplan-type bound. It is well known that all global classical solutions of (P) satisfy certain integral estimates called Kaplan estimates (see [8]). In this subsection we introduce a multiscale version of Kaplan's technique and derive a useful pointwise bound for global weak solutions of (P). Our technique, which applies to radially decreasing solutions, is a slightly modified version of the one found in [11]. Note that, in the case of power nonlinearity (1.2), the same pointwise bound can also be derived by a totally different technique and it holds for any radially symmetric solutions that are not necessarily decreasing in r (see subsection 2.4 and also [10]).

To begin with, let us consider problem (P) where $u_0(x) \ge 0$ is a continuous function on $\overline{B}_1$ vanishing on ∂B_1 and $f : \mathbb{R} \to \mathbb{R}$ is a C^2 function satisfying

$$f'' > 0, \qquad \int_L^\infty \frac{du}{f(u)} < \infty \tag{2.4}$$

for some $L \ge 0$.

Next let μ be the second eigenvalue (the first positive eigenvalue) for the Laplacian in B_1 under the Neumann boundary conditions and under radial symmetry:

$$\begin{cases} \eta''(r) + \dfrac{N-1}{r}\eta'(r) = -\mu\eta(r), & 0 < r < 1, \\ \eta'(0) = \eta'(1) = 0. \end{cases} \tag{2.5}$$

More precisely, μ is a positive number such that there exists a function $\eta = \eta(r)$ satisfying (2.5) along with the condition

$$\eta'(r) < 0, \quad 0 < r < 1, \quad \eta(0) = 1,\ 0 > \eta(1).$$

Clearly these conditions determine both μ and η uniquely. For each $R \in (0,1]$, we set

$$\psi_R(x) = \eta(R^{-1}|x|) - \eta(1).$$

Then it is easily seen that ψ_R satisfies

$$\begin{cases} \Delta\psi_R = -\dfrac{\mu}{R^2}(\psi_R - C), & x \in B_R, \\ \psi_R > 0, & x \in B_R, \\ \psi_R = \dfrac{\partial \psi_R}{\partial n} = 0, & x \in \partial B_R. \end{cases}$$

Here the constant $C := -\eta(1)$ satisfies

$$\int_{B_R} \psi_R(x)\, dx = C|B_R|,$$

where

$$B_R := \{x \in \mathbb{R}^N \;:\; |x| < R\}, \quad |B_R| := \int_{B_R} dx.$$

Now we define a function $h_R(t)$ by

$$h_R(t) = \frac{1}{\int_{B_R} \psi_R\, dx} \int_{B_R} \psi_R(x) u(x,t)\, dx.$$

Then a simple computation shows that

$$\begin{aligned} \left(\int_{B_R} \psi_R\, dx\right) h_R'(t) &= \int \psi_R u_t\, dx \\ &= \int \psi_R \left(\Delta u + f(u)\right)\, dx \\ &= \int (\Delta \psi_R) u + \psi_R f(u)\, dx \\ &= \int_{B_R} \psi_R f(u)\, dx - \frac{\mu}{R^2} \int (\psi_R - C) u\, dx, \end{aligned}$$

provided that u is smooth. Thus, by Jensen's inequality, we get

$$h_R'(t) \geq f(h_R(t)) - \frac{\mu}{R^2} h_R(t) + \frac{\mu}{R^2} \frac{1}{|B_R|} \int_{B_R} u(x,t)\, dx. \tag{2.6}$$

If, in particular, $u \geq 0$, we have

$$h_R'(t) \geq f(h_R(t)) - \frac{\mu}{R^2}\, h_R(t).$$

The above inequality yields the following lemma.

LEMMA 2.8. *Let f satisfy* (2.4). *If u is a nonnegative classical solution of* (P) *defined for all $t \geq 0$, then*

$$h_R(t) \leq \rho_R, \quad t \geq 0,\ 0 < R \leq 1,$$

where ρ_R is the largest root of the equation

$$f(\rho) - \frac{\mu}{R^2}\, \rho = 0.$$

The well-known Kaplan's eigenfunction method (see [8]) consists in testing the equation in (P) by the first eigenfunction φ_1 of the Laplacian under the Dirichlet boundary condition where one chooses $\varphi_1 > 0$ such that $\int_{B_1} \varphi_1(x)\,dx = 1$. This yields a bound for $\int_{B_1} u(x,t)\varphi_1(x)\,dx$. In our case, testing by ψ_R with various $R > 0$ gives a localized version of such a bound.

Example 1. If $f(u) = \lambda e^u$, where $\lambda > 0$, then one easily sees

$$\rho_R \le \log \frac{\mu}{\lambda R^2} + \log\log \frac{\mu}{\lambda R^2} + \log \frac{e}{e-1}. \tag{2.7}$$

Example 2. If $f(u) = u^p$, where $p > 1$, then

$$\rho_R = \left(\frac{\mu}{R^2}\right)^{1/(p-1)}. \tag{2.8}$$

Remark 2.9. Mizoguchi [11] uses $\varphi_1(R^{-1}x)$ instead of ψ_R (for the power case (1.2)). This gives a slightly better constant μ, provided that solution u is radially decreasing. On the other hand, our choice of ψ_R has an advantage of yielding a more refined bound in subsection 2.5.

2.3. Basic estimates for the exponential. In this subsection we assume that

$$f(u) = \lambda e^u, \quad N > 2, \tag{2.9}$$

and that $u_0(x) = U_0(|x|)$ with

$$U_0 \in C^1([0,1]), \quad U_0' \le 0, \quad U_0(1) = 0. \tag{2.10}$$

Then $\partial u/\partial r \le 0$ for $r \ge 0$ and $t > 0$; hence Lemma 2.8 and (2.7) yield

$$0 \le u(r,t) \le \log \frac{\mu}{\lambda r^2} + \log\log \frac{\mu}{\lambda r^2} + \log \frac{e}{e-1}, \tag{2.11}$$

since $u(r,t) \le h_r(t)$. Consequently, for each $1 \le q < N/2$, there is a constant $M_q > 0$ such that

$$\|u\|_{L^q(B_1)} \le M_q, \quad \|\lambda e^u\|_{L^q(B_1)} \le M_q. \tag{2.12}$$

Next we recall that, for each $0 < \beta < 1$,

$$\|e^{t\Delta}\varphi\|_{X_\beta} \le C_\beta\, t^{-\beta}\|\varphi\|_{L^q}, \quad t > 0,$$

where $X_\beta = W_0^{2\beta,q}(B_1)$ and Δ denotes the Laplace operator in B_1 under the Dirichlet boundary conditions. Therefore, if v is a solution of the equation

$$v_t = \Delta v + g(x,t), \quad x \in B_1,\ t \ge 0 \tag{2.13}$$

under the Dirichlet boundary conditions, then from the expression

$$v(\cdot, t+\delta) = e^{\delta\Delta} v(\cdot,t) + \int_0^\delta e^{(\delta-\tau)\Delta} g(\cdot, t+\tau)\,d\tau$$

we get the estimate

$$\|v(\cdot,t+\delta)\|_{X_\beta} \le C_\beta\,\delta^{-\beta}\|v(\cdot,t)\|_{L^q} + \frac{C_\beta}{1-\beta}\,\delta^{1-\beta} \sup_{\tau\in(0,\delta)} \|g(\cdot,t+\tau)\|_{L^q}.$$

Combining this and (2.12), we obtain

$$\|u(\cdot, t+\delta)\|_{X_\beta} \le C_\beta M_q \left(\delta^{-\beta} + \frac{\delta^{1-\beta}}{1-\beta}\right), \quad t \ge 0,$$

for any $0 < \beta < 1$. Hence the following lemma holds.

LEMMA 2.10. *Assume* (2.9) *and* (2.10). *Let u be a classical solution of* (P) *defined for all $t \ge 0$. Then for each $\delta > 0$ there is a (universal) constant $A_{\delta,q,\beta} > 0$ independent of u such that*

$$\|u(\cdot, t)\|_{X_\beta} \le A_{\delta,q,\beta}, \quad \delta \le t < \infty.$$

Now choose q close enough to $N/2$ and β close enough to 1 so that the embedding

$$W_0^{2\beta,q}(B_1) \subset H_0^1(B_1) \tag{2.14}$$

is compact. This is possible since $N > 2$. Then Lemma 2.10 implies the following lemma.

LEMMA 2.11. *Let the assumptions of Lemma* 2.10 *be satisfied. Then for each $\delta > 0$ there exists a compact set $K_\delta \subset H_0^1(B_1)$ independent of u such that*

$$u(\cdot, t) \in K_\delta, \quad \delta \le t < \infty.$$

Consequently,

$$\|u(\cdot, t)\|_{H_1} \le C_\delta, \quad \delta \le t < \infty, \tag{2.15}$$

for some universal constant C_δ.

The next proposition shows that the convergence of approximating classical solutions to a limit L^1-solution takes place in a much stronger topology than (2.2).

PROPOSITION 2.12. *Assume* (2.9) *and* (2.10). *Let u be a limit L^1-solution and let $\{u_n\}$ be an approximating sequence for u. Then*

(i) *for each $t > 0$*

$$u_n(\cdot, t) \to u(\cdot, t) \quad \text{in } H_0^1(B_1), \qquad e^{u_n(\cdot,t)} \to e^{u(\cdot,t)} \quad \text{in } L^q(B_1)$$

for any $1 \le q < N/2$. Consequently, the estimates (2.12), (2.15) *hold for limit L^1-solutions;*

(ii) $u \in C((0,\infty); H_0^1(B_1))$;

(iii) *for each $t > 0$*

$$u_n(\cdot, t) \to u(\cdot, t) \quad \text{in } C^2_{loc}(\overline{B}_1 \setminus \{0\}).$$

Proof. By Lemma 2.5 and assumption (2.10) we have $\partial u/\partial r < 0$ for $0 < r \le 1$ and for $0 < t < T$, where T is the blow up time for u. Therefore, u_n satisfies the same inequality for n sufficiently large and for t sufficiently small (hence for all $t > 0$). Consequently the pointwise bound (2.11) holds for u_n with n sufficiently large. Combining this bound, the Lebesgue convergence theorem, and the former half of Lemma 2.11 (with u replaced by u_n), we obtain (i). Statement (ii) is a consequence of the continuity of $u(\cdot, t)$ in $L^1(B_1)$ and the fact that $u(\cdot, t)$ belongs to the compact set $K_\delta \subset H_0^1(B_1)$. Statement (iii) follows from bound (2.11) and local parabolic estimates for u_n. $\square$

COROLLARY 2.13. *Let u and u_n be as in Proposition* 2.12. *Then*

$$J[u_n] \to J[u] \quad \text{as } n \to \infty;$$

hence $J[u(\cdot,t)]$ is monotone nonincreasing in t, where

$$J[u] = \int_{B_1} \left(\frac{1}{2}|\nabla u|^2 - \lambda e^u \right) dx.$$

Proof. Since u_n is a classical solution, $J[u_n(\cdot,t)]$ is monotone nonincreasing in t. Letting $n \to \infty$ and using Proposition 2.12(i), we obtain the desired result. ◻

Next we show that (2.6) holds for any limit L^1-solution u. This will play a key role in subsection 2.5.

PROPOSITION 2.14. *Assume* (2.9) *and* (2.10). *Let u be a nonnegative limit L^1-solution of* (P). *Then*

$$h_R'(t) \geq \lambda e^{h_R(t)} - \frac{\mu}{R^2} h_R(t) + \frac{\mu}{R^2} \frac{1}{|B_R|} \int_{B_R} u(x,t)\, dx. \tag{2.16}$$

Proof. By (2.12) and the standard a priori estimate for the linear problem (2.13) with $g \in L^\infty((0,\infty); L^q)$, we have

$$u \in C^\gamma_{loc}((0,\infty); W^{2\beta,q}(B_1))$$

for any $0 < \gamma < 1 - \beta$ and any $1 < q < N/2$. Choosing q sufficiently close to $N/2$ and using the Sobolev embedding theorem, we see that

$$u \in C^\gamma_{loc}((0,\infty); L^r(B_1))$$

for any $1 < r < \infty$ and any $0 < \gamma < \min\{1, N/(2r)\}$. In view of this and the inequality

$$|e^u - e^v| \leq (e^u + e^v)|u - v|$$

along with bound (2.12), we get

$$e^u \in C^\gamma_{loc}((0,\infty); L^q(B_1))$$

for any $1 < q < N/2$ and for some appropriate exponent $0 < \gamma < 1$ depending on q. Again using the standard a priori estimates for (2.13) with Hölder continuous $g(\cdot,t)$, we obtain

$$u \in C^1((0,\infty); L^q(B_1)) \cap C((0,\infty); W^{2,q}(B_1))$$

for any $1 < q < N/2$. Therefore all the computations we used to derive (2.6) for classical solutions can be justified for limit L^1-solutions. This completes the proof. ◻

2.4. Basic estimates for the power. In this subsection we assume

$$f(u) = u^p, \quad N > 2, \quad p > \frac{N+2}{N-2}, \tag{2.17}$$

and that $U_0 \in C[0,1]$. Then Corollary 3.3 and Remark 3.5 in [10] show that any limit L^1-solution satisfies

$$|u(r,t)| \leq Cr^{-2/(p-1)} \quad \text{for } \ 0 \leq t < \infty \tag{2.18}$$

for some constant $C > 0$. In the special case where U_0 satisfies (2.10), a similar but more explicit pointwise bound

$$0 \le u(r,t) \le \left(\frac{\mu}{\lambda r^2}\right)^{1/(p-1)} \tag{2.19}$$

follows also from Lemma 2.8 and (2.8). These bounds imply that for each $1 \le q < \frac{N(p-1)}{2p}$, there is a constant $M_q > 0$ such that

$$\|u^p\|_{L^q(B_1)} \le M_q,$$

which is an analogue of (2.12) in the exponential case. Arguing as before, we see that Lemma 2.10 holds for the power case (1.2). Choosing q close enough to $N(p-1)/2p$ and β close enough to 1 we obtain the compact embedding (2.14). Arguing as before, we can derive the same results as Proposition 2.12 and Corollary 2.13. More precisely, we have the following proposition.

PROPOSITION 2.15. *Assume* (2.17) *and that $U_0(r)$ is a continuous function on* $[0,1]$. *Let u be a limit L^1-solution and let $\{u_n\}$ be an approximating sequence for u. Then for each $t > 0$,*

$$u_n(\cdot,t) \to u(\cdot,t) \quad in\ H_0^1(B_1) \cap L^q(B_1) \cap C^2_{loc}(\overline{B}_1 \setminus \{0\})$$

for any $1 \le q < \frac{N(p-1)}{2}$. Furthermore,

$$u \in C((0,\infty);\, H_0^1(B_1))$$

and $J[u(\cdot,t)]$ is monotone nonincreasing in t, where

$$J[u] = \int_{B_1} \left(\frac{1}{2}|\nabla u|^2 - \frac{1}{p+1}|u|^{p+1}\right) dx.$$

Note that the monotonicity assumption in (2.10) is not needed in the above proposition since (2.18) holds for any bounded initial data U_0.

2.5. Refined bound for the exponential. The following lemma gives an upper bound sharper than (2.11).

LEMMA 2.16. *Assume* (2.9) *and* (2.10). *Let u be a limit L^1-solution of* (P). *Suppose for some $0 < R \le 1$, $C_1 > 0$, $t_0 \in \mathbb{R}$, and $a > 0$,*

$$u(R,t) \ge \log\frac{1}{R^2} - C_1 \quad for\ \ t_0 \le t \le t_0 + aR^2. \tag{2.20}$$

Then

$$u(R,t_0) \le \log\frac{1}{R^2} + \alpha, \tag{2.21}$$

where α is a constant given by

$$\int_\alpha^\infty \frac{dk}{\lambda e^k - \mu(k + C_1)} = a. \tag{2.22}$$

Proof. By the assumptions we have

$$\frac{1}{|B_R|}\int_{B_R} u\,dx \ge \log\frac{1}{R^2} - C_1.$$

Combining this with (2.16), we obtain

$$h_R' \geq \lambda e^{h_R} - \frac{\mu}{R^2}\left(h_R - \log\frac{1}{R^2} + C_1\right).$$

Setting $k(t) := h_R(t) - \log(1/R^2)$, we get

$$k' \geq \frac{1}{R^2}\,(\lambda e^k - \mu k - \mu C_1).$$

It follows that

$$\int_{k(t_0)}^{k(t)} \frac{dk}{\lambda e^k - \mu(k + C_1)} \geq \frac{t - t_0}{R^2}, \quad t_0 \leq t \leq t_0 + aR^2.$$

Consequently, we have either

$$k(t_0) \leq k^*,$$

where k^* is the largest zero of the function

$$k \;\mapsto\; \lambda e^k - \mu(k + C_1),$$

or $k(t_0) > k^*$ and

$$\int_{k(t_0)}^{\infty} \frac{dk}{\lambda e^k - \mu(k + C_1)} \geq a.$$

Here we understand $k^* = -\infty$ if the function $\lambda e^k - \mu(k+C_1)$ has no zero. Now define $\alpha \in \mathbb{R}$ by (2.22). From the previous inequality it is clear that

$$k(t_0) \leq \alpha.$$

This proves (2.21). □

2.6. Characterization of the singular set. Now recall the definition of the sets $\mathcal{R}, \mathcal{S}, \mathcal{B}$ introduced in Introduction. Namely, $\mathcal{R}$ denotes the set of $t_0 > 0$ such that solution u stays classical around $t = t_0$, $\mathcal{S} := (0, \infty) \setminus \mathcal{R}$ denotes the set of "singular time moments," and

$$\mathcal{B} := \left\{ t_0 > 0 \,:\, \limsup_{t \to t_0} \|u(\cdot, t)\|_{L^\infty(B_1)} = \infty \right\}.$$

By Lemma 2.6, we have $\mathcal{S} = \mathcal{B}$. If $t_0 > 0$ is such that

$$\limsup_{t \nearrow t_0} \|u(\cdot, t)\|_{L^\infty(B_1)} < \infty,$$

then Lemma 2.6 and the local existence theorem for (P) imply that u can be continued as a classical solution beyond $t = t_0$; hence $t_0 \notin \mathcal{B}$. Therefore, $\mathcal{B}$ coincides with the set

$$\left\{ t_0 > 0 \,:\, \limsup_{t \nearrow t_0} \|u(\cdot, t)\|_{L^\infty(B_1)} = \infty \right\}.$$

In the case where u is a minimal L^1-solution, then it is easily seen that

$$\|u(\cdot,t_1)\|_{L^\infty(B_1)} < \infty$$

implies u is regular in some interval $t_1 \le t < t_1+\delta$, where $\delta > 0$ depends only on $\|u(\cdot,t_1)\|_{L^\infty}$. Therefore, if $t_0 > 0$ is such that

$$\liminf_{t\nearrow t_0} \|u(\cdot,t)\|_{L^\infty(B_1)} < \infty,$$

then $t_0 \notin \mathcal{B}$. Consequently the following lemma holds.

LEMMA 2.17. *If u is a minimal L^1-solution of* (P)*, then*

$$\mathcal{B} = \left\{ t_0 > 0 \;:\; \lim_{t\nearrow t_0} \|u(\cdot,t)\|_{L^\infty(B_1)} = \infty \right\}. \tag{2.23}$$

Finally, note that the pointwise bounds (2.11) and (2.18) show that singularity can occur only near the origin, both in the exponential case (1.1) and the power case (1.2). These pointwise bounds and local parabolic estimates for the approximating sequence $\{u_n\}$ imply that $u(x,t)$ is smooth in $(B_1 \setminus \{0\}) \times (0,\infty)$.

3. Main result.

3.1. Statement and remarks. Let I be an interval (open, half-open, or closed) with endpoints a, b, $-\infty \le a < b \le \infty$, and let f be a continuous function on I. We define the *zero-number* of f by

$$\begin{aligned}\mathcal{Z}_I(f) = \sup\{n \in \mathbb{N} \;:\; &\text{there are} \quad a < x_0 < x_1 < \cdots < x_n < b \\ &\text{such that} \quad f(x_i)f(x_{i+1}) < 0 \quad \text{for} \quad 0 \le i < n\}\end{aligned}$$

if f changes sign in I and $\mathcal{Z}_I(f) = 0$ otherwise.

THEOREM 3.1. *Let u be a minimal L^1-solution of problem* (P) *which blows up in a finite time T, and let either* (1.1) *or* (1.2) *be satisfied. Assume that the initial data $U_0(|x|)$ satisfy*

$$U_0 \in C([0,1]), \quad U_0(r) \ge 0 \ (0 \le r \le 1).$$

In case (1.1)*, assume further that $U_0(r)$ is nonincreasing in $0 \le r \le 1$. Then, there exists a positive integer k such that*

$$\mathcal{B} = \{t_i\}_{i=1}^k,$$

$$t_1 = T < t_2 < \cdots < t_k < \infty.$$

Consequently, the solution is regular except at $t = t_i$ $(i = 1, 2, \ldots, k)$. Moreover, the following estimate holds:

$$2k - 1 \le j := \min_{0<t<T} \mathcal{Z}_{[0,1]}\big(u_t(\cdot,t)\big). \tag{3.1}$$

In particular, if $U_0 \in C^2([0,1])$, then

$$2k - 1 \le j_0 := \mathcal{Z}_{[0,1]}\left(U_0'' + \frac{N-1}{r}U_0' + f(U_0)\right). \tag{3.2}$$

Remark 3.2. Since $w := u_t$ satisfies $w(1,t) = 0$ and a parabolic equation of the form

$$w_t = w_{rr} + \frac{N-1}{r} w_r + a(r,t)w,$$

the zero-number $\mathcal{Z}_{[0,1]}(u_t(\cdot,t))$ is nonincreasing in t and is finite for every $0 < t < T$. See [2] for details. Consequently, the minimum on the right-hand side of (3.1) is well-defined and is a finite integer. It is also clear that $j \le j_0$.

Remark 3.3. In order for the solution u to be a global L^1-solution, it should necessarily hold that $j > 0$. Indeed, if $j = 0$, this means that the solution satisfies $u_t(r,t) \ge 0$ $(0 \le r \le 1)$ for t close to T. By the result of [1], this means a complete blow-up; therefore, the solution cannot be continued as an L^1-solution beyond the blow up time T.

Remark 3.4. The above theorem means that the solution recovers smoothness immediately after the blow up time. Note that this result does not follow from standard parabolic estimates. Indeed, at the time of blow-up, some of the solutions may have a singularity of the form $\log(1/|x|^2) + C$ (in case (1.1)) or of the form $C|x|^{-2/(p-1)}$ (in case (1.2)), as exemplified by certain self-similar solutions. When such singularities occur, the solution profile $u(x,T)$ no longer belongs to the space where (P) is well-posed (for example, $L^q(B_1)$ with $q > \frac{(N-1)p}{2}$ in case (1.2)); therefore, parabolic regularization alone cannot bring the solution back to the space where (P) is well-posed. Thus smoothness does not follow automatically. Indeed the singular stationary solution φ^* defined below is an example of a weak solution that never becomes regular. (Since φ^* is not a minimal L^1-solution, there is no contradiction with the above theorem.)

Remark 3.5. By Lemma 2.17, we have $\lim_{t \nearrow t_0} \|u(\cdot,t)\|_{L^\infty} = \infty$ for every $t_0 \in \mathcal{B}$. However, we do not know whether or not this always implies that $\|u(\cdot,t_0)\|_{L^\infty} = \infty$. Since our equation has a supercritical nonlinearity, some subtle behavior may occur near the origin at the time of blow-up.

Incidentally, for an equation similar to (P), Pierre [17] found explicit examples of peaking solutions that blow up arbitrarily many times. He observed that

$$u(x,t) := \frac{1}{|x|^2 + \psi(t)}$$

is an L^1-solution of the equation

$$u_t = \Delta u + g(|x|,t)u^2, \quad g(r,t) := 2N - \psi'(t) - \frac{8r^2}{r^2 + \psi(t)} ,$$

provided ψ is a nonnegative C^1-function and $N > 4$. Obviously, u blows up at each time t such that $\psi(t) = 0$.

4. Further preliminaries.

4.1. Singular stationary solutions. In the proof of Theorem 3.1, the so-called singular stationary solution plays an important role. The equation

$$u_{rr} + \frac{N-1}{r} u_r + f(u) = 0, \quad r > 0, \tag{4.1}$$

has an explicit singular solution φ^* if either $f(u) = \lambda e^u$, $N \geq 3$ or $f(u) = u^p$, $N \geq 3$, $p > N/(N-2)$. Namely,

$$\varphi^*(r) = \log \frac{2(N-2)}{\lambda r^2} \tag{4.2}$$

in the former case, and

$$\varphi^*(r) = K r^{-\frac{2}{p-1}} \tag{4.3}$$

with

$$K = \left(\frac{2}{(p-1)^2} ((N-2)p - N) \right)^{\frac{1}{p-1}}$$

in the latter case. The assumption that $N \leq 9$ in (1.1) or $p < p^*$ in (1.2) guarantees the existence of a forward self-similar solution of the problem

$$\begin{cases} u_t = u_{rr} + \dfrac{N-1}{r} u_r + f(u), & r, t > 0, \\ u_r(0,t) = 0, & t > 0, \\ u(r,0) = \varphi^*(r), & r > 0, \end{cases} \tag{S}$$

which is regular for $r \geq 0$, $t > 0$ (cf. [4, 19, 18]). This forward self-similar solution is needed in our proof of Theorem 3.1.

Another notable feature of the critical dimension $N = 9$ for $f(u) = \lambda e^u$ and the critical power $p = p^*$ for $f(u) = u^p$ is that under assumption (1.1) or (1.2), it is well known (cf. [7]) that the graph of any smooth solution of (4.1) intersects with the graph of the singular solution φ^* infinitely many times, while this is not the case if $N > 9$ (in the exponential case) or $p > p^*$ (in the power case). This property will also be used in our proof of Theorem 3.1.

4.2. Zero-number properties for singular solutions. It is well known that if u and v are classical solutions of (P), then $\mathcal{Z}_{[0,1]}(u(\cdot,t) - v(\cdot,t))$ is a nonincreasing function of t. This is because $w := u - v$ satisfies a parabolic equation of the form

$$w_t = w_{rr} + \frac{N-1}{r} w_r + a(r,t) w.$$

Moreover, each time the function $r \mapsto u(r,t) - v(r,t)$ develops a degenerate zero somewhere in $[0,1]$, the above zero-number drops at least by 1. See [2] for details. It is easily seen that the same is true if u is a classical solution and $v = \varphi^*$, since $u(r,t) - \varphi^*(r)$ always have the same sign (i.e., negative) near $r = 0$. However, if u is an L^1-solution, then both u and φ^* may have a singularity at $r = 0$, and this makes the situation a bit more complicated. Nonetheless, a slightly weaker version of the above property still holds.

LEMMA 4.1. *Let $u(r,t)$ be a limit L^1-solution of* (P) *and let $\varphi^*(r)$ be the singular stationary solution. Let $t^* > 0$ and suppose that there exists a sequence $0 < \tau_1 < \cdots < \tau_k < t^*$ such that $u(r,\tau_i) - \varphi^*(r)$ has a degenerate zero in $(0,1]$ for $i = 1, 2, \ldots, k$. Then*

$$\mathcal{Z}_{[0,1]}(u(\cdot,t^*) - \varphi^*) \leq \mathcal{Z}_{[0,1]}(u(\cdot,0) - \varphi^*) - k. \tag{4.4}$$

Here we understand that $k = 0$ if there is no such τ_i in the interval $(0, t^*)$.

Proof. Let u_n be an approximating sequence for u, and let $t_0 \in (0,T)$ be such that $t_0 < \tau_1$ and that $u(r,t_0) - \varphi^*(r)$ has no degenerate zero in the interval $[0,1]$. Such t_0 exists since u is a classical solution for $0 \le t < T$; therefore, the function $r \mapsto u(r,t) - \varphi^*(r)$ can have a degenerate zero at most for a discrete set of values of t (see [2]). Then, since we have

$$u_n(\cdot,t_0) \to u(\cdot,t_0) \quad \text{in } C^2(\overline{B}_1)$$

by Lemma 2.5, the simplicity of the zeros of $u(r,t_0) - \varphi^*(r)$ implies

$$\mathcal{Z}_{[0,1]}(u_n(\cdot,t_0) - \varphi^*) = \mathcal{Z}_{[0,1]}(u(\cdot,t_0) - \varphi^*) \tag{4.5}$$

for n sufficiently large. On the other hand, Propositions 2.12 and 2.15 yield the convergence

$$u_n(\cdot,t^*) \to u(\cdot,t^*) \quad \text{in } C^2_{loc}(\overline{B}_1 \setminus \{0\}).$$

Consequently, we obtain

$$\mathcal{Z}_{[0,1]}(u_n(\cdot,t^*) - \varphi^*) \ge \mathcal{Z}_{[0,1]}(u(\cdot,t^*) - \varphi^*) \tag{4.6}$$

for n sufficiently large if the right-hand side is finite and

$$\lim_{n\to\infty} \mathcal{Z}_{[0,1]}(u_n(\cdot,t^*) - \varphi^*) = \infty \tag{4.7}$$

if the right-hand side of (4.6) is infinite. However, (4.7) is ruled out by (4.5) and the nonincrease of $\mathcal{Z}_{[0,1]}(u_n(\cdot,t^*) - \varphi^*)$, so we have (4.6).

Now let $r_i \in (0,1]$ $(i = 1,2,\ldots,k)$ be such that the function $r \mapsto u(r,\tau_i) - \varphi^*(r)$ has a degenerate zero at $r = r_i$. Suppose first that $r_i < 1$ $(i = 1,2,\ldots,k)$. (This is always true if $f(u) = u^p$, $p > 1$ or if $f(u) = \lambda e^u$, $\lambda > 0$, $\lambda \ne 2(N-2)$.) Choose a_i, b_i such that $0 < a_i < r_i < b_i < 1$ and that

$$u(a_i,\tau_i) - \varphi^*(a_i) \ne 0, \quad u(b_i,\tau_i) - \varphi^*(b_i) \ne 0 \quad \text{for} \quad i = 1,\ldots,k.$$

Next choose $\epsilon > 0$ sufficiently small so that $u(r,t) - \varphi^*(r) \ne 0$ for $r = a_i$, $\tau_i - \epsilon \le t \le \tau_i + \epsilon$ and $r = b_i$, $\tau_i - \epsilon \le t \le \tau_i + \epsilon$. We denote these two line segments by γ_i, $\tilde{\gamma}_i$. Since $u(r,t) - \varphi^*(r)$ has a degenerate zero at $(r,t) = (r_i,\tau_i)$ and since this function does not vanish on γ_i, $\tilde{\gamma}_i$, we have

$$\mathcal{Z}_{[a_i,b_i]}(u(\cdot,\tau_i - \epsilon) - \varphi^*) > \mathcal{Z}_{[a_i,b_i]}(u(\cdot,\tau_i + \epsilon) - \varphi^*). \tag{4.8}$$

Here we can choose $\epsilon > 0$ in such a way that the functions $u(\cdot,t_i \pm \epsilon) - \varphi^*$ have only simple zeros in the interval $[a_i,b_i]$ and that the intervals $[\tau_i - \epsilon, \tau_i + \epsilon]$, $i = 1,\ldots,k$, are mutually disjoint. This is possible since degenerate zeros can occur only at a discrete set of time t. Then,

$$\mathcal{Z}_{[a_i,b_i]}(u_n(\cdot,\tau_i \pm \epsilon) - \varphi^*) = \mathcal{Z}_{[a_i,b_i]}(u(\cdot,\tau_i \pm \epsilon) - \varphi^*)$$

for n sufficiently large; hence,

$$\mathcal{Z}_{[a_i,b_i]}(u_n(\cdot,\tau_i - \epsilon) - \varphi^*) > \mathcal{Z}_{[a_i,b_i]}(u_n(\cdot,\tau_i + \epsilon) - \varphi^*).$$

Moreover, since $u(r,t) - \varphi^*(r)$ does not vanish on γ_i, $\tilde{\gamma}_i$, the same is true for $u_n(r,t) - \varphi^*(r)$ for n sufficiently large. This and the above inequality imply that the function

$r \mapsto u_n(r,t) - \varphi^*(r)$ has a degenerate zero in $[a_i, b_i]$ for some $t \in (\tau_i - \epsilon, \tau_i + \epsilon)$. Consequently, at least k degenerate zeros occur in the time interval $[t_0, t^*]$; hence

$$\mathcal{Z}_{[0,1]}(u_n(\cdot, t^*) - \varphi^*) \le \mathcal{Z}_{[0,1]}(u_n(\cdot, t_0) - \varphi^*) - k.$$

Combining this inequality with (4.5) and (4.6), we obtain

$$\mathcal{Z}_{[0,1]}(u(\cdot, t^*) - \varphi^*) \le \mathcal{Z}_{[0,1]}(u(\cdot, t_0) - \varphi^*) - k.$$

Since u is a classical solution for $0 \le t < T$, we have

$$\mathcal{Z}_{[0,1]}(u(\cdot, t_0) - \varphi^*) \le \mathcal{Z}_{[0,1]}(u(\cdot, 0) - \varphi^*).$$

This and the previous inequality prove the lemma if $r_i < 1$ $(i = 1, 2, \ldots, k)$.

Consider the possibility $r_i = 1$ for some $i \in \{1, 2, \ldots, k\}$, which can occur only if $f(u) = \lambda e^u$ and $\lambda = 2(N-2)$. In this case, $u(t, \cdot) - \varphi^*$ satisfies the Dirichlet condition $u(1,t) - \varphi^*(1) = 0$. Therefore, choosing a_i as above (so that $u(t, a_i) - \varphi^*(a_i) \ne 0$ for $t \approx \tau_i$) we still obtain (4.8). We can now proceed similarly as before. ∎

Remark 4.2. Since $\mathcal{Z}_{[0,1]}(u(\cdot, t_0) - \varphi^*) < \infty$, the left-hand side of (4.4) is finite even if $\mathcal{Z}_{[0,1]}(u(\cdot, 0) - \varphi^*) = \infty$.

Remark 4.3. Note that the left-hand side of (4.4) is not necessarily monotone nonincreasing in t. This is because some intersection points between the graph of $r \mapsto u(r,t)$ and that of $\varphi^*(r)$ may escape to infinity (at $r = 0$) and later emerge from infinity repeatedly.

4.3. Rescaled equations. As usual, rescaling arguments provide useful information about the behavior of solutions near the blow up point. In the case of the exponential nonlinearity (1.1), we use the rescaling

$$w(y,s) = w^\theta(y,s) = u(r,t) + \log(\theta - t), \quad y = \frac{r}{\sqrt{\theta - t}}, \quad s = -\log(\theta - t), \tag{4.9}$$

where θ is any positive number. Then (P) is converted into the following problem:

$$(\mathrm{R}_e) \qquad \begin{cases} w_s = \dfrac{1}{\rho}(\rho w_y)_y + \lambda e^w - 1, & 0 < y < e^{s/2},\ s > -\log\theta, \\ w_y(0,s) = 0,\ w(e^{s/2}, s) = -s, & s > -\log\theta, \\ w(y, -\log\theta) = u_0(\sqrt{\theta}\, y) + \log\theta, & 0 \le y \le \theta^{-1/2}, \end{cases}$$

where

$$\rho(y) = y^{N-1} e^{-y^2/4}.$$

In the case of the power nonlinearity 1.2, we use the rescaling

$$w^\theta(y,s) = (\theta - t)^{1/(p-1)} u(r,t) \tag{4.10}$$

with y and s as before. Then, (P) is converted into

$$(\mathrm{R}_p) \qquad \begin{cases} w_s = \dfrac{1}{\rho}(\rho w_y)_y + w^p - \dfrac{1}{p-1} w, & 0 < y < e^{s/2},\ s > -\log\theta, \\ w_y(0,s) = 0,\ w(e^{s/2}, s) = 0, & s > -\log\theta, \\ w(y, -\log\theta) = \theta^{1/(p-1)} u_0(\sqrt{\theta}\, y), & 0 \le y \le \theta^{-1/2}. \end{cases}$$

Note that, in contrast to the usual setup, we do not assume that $\theta = T$, the blow up time of solution u. In fact, in our later argument, we shall need to consider the case $\theta > T$; thus, w may possess singularity in finite time. However, for the time being we assume that w is a classical solution of (R_e) or (R_p) and shall later use a limiting argument to deal with singular solutions.

Energy functionals corresponding to (R_e) and (R_p) are, respectively, the following:

$$E_e[w](s) := \int_0^{e^{s/2}} \left(\frac{1}{2}w_y^2 - \lambda e^w + w\right)\rho\, dy,$$
$$E_p[w](s) := \int_0^{e^{s/2}} \left(\frac{1}{2}w_y^2 - \frac{1}{p+1}w^{p+1} + \frac{1}{2(p-1)}w^2\right)\rho\, dy.$$

As is well known, E_p is a Lyapunov functional for (R_p). More precisely,

$$\frac{d}{ds}E_p[w](s) \le -\int_0^{e^{s/2}} w_s^2\,\rho\, dy, \quad s > -\log\theta; \tag{4.11}$$

hence, $E_p[w](s)$ is monotone decreasing in s. The same is true of E_e, at least for large s, as shown in the following lemma.

Lemma 4.4. *Let w be a global classical solution of* (R_e). *Then there is $s_0 < 1$ such that*

$$\frac{d}{ds}E_e[w](s) \le -\int_0^{e^{s/2}} w_s^2\rho\, dy, \quad s \ge s_0. \tag{4.12}$$

Proof. By direct computations we obtain

$$\begin{aligned}\frac{d}{ds}E_e[w](s) = &-\int_0^{e^{s/2}} w_s^2\rho\, dy\\ &-\left(w_y + \frac{1}{4}e^{s/2}w_y^2 + \frac{\lambda}{2}e^{-s/2} + \frac{1}{2}se^{s/2}\right)\rho\,\Big|_{y=e^{s/2}}.\end{aligned}$$

Since

$$w_y + \frac{1}{4}e^{s/2}w_y^2 \ge -e^{-s/2},$$

it suffices to choose s_0 such that $s_0 e^{s_0} > 2 - \lambda$. ∎

In the case of the power nonlinearity (1.2), the global existence of w^θ for all large s implies that $E_p[w^\theta](s) \ge 0$ (see [6]). Integrating (4.11) with respect to s, we obtain

$$\int_{s_1}^{s_2}\int_0^{e^{s/2}} (w_s^\theta)^2\rho\, dy\, ds \le E_p[w^\theta](s_1) - E_p[w^\theta](s_2).$$

Letting $s_2 \to \infty$ and using the boundedness of $E_p[w^\theta]$, we obtain

$$\int_{s_1}^{\infty}\int_0^{e^{s/2}} (w_s^\theta)^2\rho\, dy\, ds < \infty \tag{4.13}$$

(cf. Proposition 7.1 of [10]). As a matter of fact, the same estimate holds for any limit L^1-solutions. More precisely, we have the following lemma.

LEMMA 4.5. *Let u be a limit L^1-solution of* (P) *for the power nonlinearity* (1.2) *and let w^θ be as in* (4.10) *for some $\theta > 0$. Then* (4.13) *holds for any $s_1 > -\log\theta$.*

Proof. Let u_n be an approximating sequence for u. Then w_n^θ satisfies the same estimate as (4.13) for $n = 1, 2, 3, \dots$, where the bound does not depend on n. Letting $n \to \infty$ and using Fatou's lemma, we obtain (4.13). ∎

COROLLARY 4.6. *Let u and w^θ be as in Lemma* 4.5. *Then $w^\theta(y,s)$ approaches stationary solutions of* (R_p) *as $s \to \infty$ locally uniformly in $y > 0$. More precisely, the ω limit set of w^θ is contained in the set of solutions of*

$$\frac{1}{\rho}(\rho\, w_y)_y + w^p - \frac{1}{p-1} w = 0, \quad y > 0. \tag{4.14}$$

Proof. Estimate (2.18) yields

$$w^\theta(y,s) \le C y^{-2/(p-1)}. \tag{4.15}$$

This pointwise bound and parabolic regularization imply that, for any $M > 0$, the derivatives of w^θ are uniformly Hölder continuous in y in the region

$$y \in I_M := [M^{-1}, M], \quad s \ge s_1$$

for s_1 sufficiently large. Consequently $w^\theta(\cdot, s)$ remains in a compact set of $C^2(I_M)$ as s varies over $[s_1, \infty)$. Furthermore, the uniform Hölder continuity of w_s^θ and (4.13) imply that

$$w_s^\theta(y,s) \to 0 \quad \text{as} \quad s \to \infty$$

uniformly in $y \in I_M$. The conclusion of the lemma now follows immediately. ∎

In the case of the exponential nonlinearity (1.1), pointwise estimates of w^θ are much more difficult to obtain. However, under certain special circumstances we have an analogue of the above corollary.

LEMMA 4.7. *Let u be a limit L^1-solution of* (P) *for the exponential nonlinearity* (1.1) *and let w^θ be as in* (4.9). *Suppose that for some $0 < r_0 \le 1$, $C_1 > 0$, and $0 < t_1 < t_2$,*

$$u(r,t) \ge \log\frac{1}{r^2} - C_1 \quad \textit{for} \ \ 0 < r \le r_0,\ t_1 \le t \le t_2. \tag{4.16}$$

Then, for any $\theta \in (t_1, t_2)$, the solution $w^\theta(y,s)$ approaches stationary solutions of (R_e) *as $s \to \infty$ locally uniformly in $y > 0$. More precisely, the ω limit set of w^θ is contained in the set of solutions of*

$$\frac{1}{\rho}(\rho\, w_y)_y + \lambda e^w - 1 = 0, \quad y > 0. \tag{4.17}$$

Proof. By choosing a suitable constant $a > 0$, we see that

$$u(r,t) \ge \log\frac{1}{r^2} - C_1, \qquad t_0 \le t \le t_0 + ar^2$$

for any $0 < r \le r_0,\ t_1 \le t_0 \le \theta$. By Lemma 2.16, we have

$$u(r,t) \le \log\frac{1}{r^2} + \alpha, \qquad \text{for } 0 < r \le r_0,\ t_1 \le t \le \theta.$$

Therefore, w^θ satisfies

$$\log\frac{1}{y^2} - C_1 \le w^\theta(y,s) \le \log\frac{1}{y^2} + \alpha \tag{4.18}$$

for $0 < y \le r_0\, e^{s/2}$ and for all large s. Thus, once we have estimate (4.13), the same argument as in the proof of Corollary 4.6 will yield the conclusion of the lemma.

In order to prove (4.13), it suffices to show that $E_e[w^\theta](s)$ is bounded from below as $s \to \infty$. We have

$$\begin{aligned} E_e[w^\theta](s) &\ge \int_0^{e^{s/2}} (-\lambda e^{w^\theta} + w^\theta)\rho\, dy \\ &= \int_0^{r_0 e^{s/2}} (-\lambda e^{w^\theta} + w^\theta)\rho\, dy + \int_{r_0 e^{s/2}}^{e^{s/2}} (-\lambda e^{w^\theta} + w^\theta)\rho\, dy. \end{aligned}$$

The second integral is easily shown to converge to zero, as $s \to \infty$, thanks to the fact that $y \mapsto w(y,s)$ is decreasing (recall that in case (1.1) we assume that U_0 is nonincreasing). The first integral can be estimated using (4.18):

$$\begin{aligned} \int_0^{r_0 e^{s/2}} (-\lambda e^{w^\theta} + w^\theta)\rho\, dy &\ge \int_0^{e^{s/2}} \left(-\lambda e^{\log(1/y^2)+\alpha} + \log\frac{1}{y^2} - C_1\right)\rho\, dy \\ &= \int_0^{e^{s/2}} \left(-\lambda e^{\alpha}\frac{1}{y^2} + \log\frac{1}{y^2} - C_1\right) y^{N-1} e^{-y^2/4}\, dy. \end{aligned}$$

It is easily seen that the above integral remains bounded as $s \to \infty$. The lemma is proved. ∎

4.4. Singular stationary solutions for the rescaled equation. The singular stationary solution φ^* defined in (4.2) (resp., (4.3)) is also a singular stationary solution for the rescaled equation (4.17) (resp., (4.14)). That is, we have

$$\frac{1}{\rho}(\rho\,\varphi^*_y)_y + \lambda e^{\varphi^*} - 1 = 0, \quad 0 < y < \infty$$

$$\left(\text{ resp., } \frac{1}{\rho}(\rho\,\varphi^*_y)_y - \frac{1}{p-1}\,\varphi^* + (\varphi^*)^p = 0, \quad 0 < y < \infty \right).$$

In Corollary 4.6 and Lemma 4.7, we are not excluding the possibility that w^θ approaches a singular stationary solution as $s \to \infty$.

The following lemmas show that there is no singular stationary solution that lies above φ^*.

LEMMA 4.8. *Let φ^* be as in* (4.2) *and $\rho(y) = y^{N-1}e^{-\frac{y^2}{4}}$. If ψ is a solution of* (4.17) *satisfying $\psi \ge \varphi^*$, then $\psi = \varphi^*$.*

Proof. Suppose $\Phi := \psi - \varphi^* > 0$ for $0 < y < \infty$. Then $(\rho\,\Phi_y)_y < 0$ because Φ satisfies

$$(\rho\Phi_y)_y + \lambda\rho\left(e^{\psi} - e^{\varphi^*}\right) = 0.$$

Define a new space variable $z = z(y)$ by

$$z = \int_1^y \frac{d\xi}{\rho(\xi)}.$$

Then $(\rho\,\Phi_y)_y < 0$ $(y > 0)$ is equivalent to $\Phi_{zz} < 0$ $(-\infty < z < \infty)$. Therefore, Φ is a strictly concave function of z on $\mathbb{R}$, but this is impossible since $\Phi > 0$. ∎

LEMMA 4.9. *Let φ^* be as in* (4.3). *If ψ is a solution of* (4.14) *satisfying $\psi \geq \varphi^*$, then $\psi = \varphi^*$.*

Proof. Suppose $\Phi := \frac{\psi}{\varphi^*} > 1$ for $y \in (0,\infty)$. Then $(\sigma\,\Phi_y)_y < 0$ because Φ satisfies

$$(\sigma\Phi_y)_y + K^{p-1}\frac{\sigma}{y^2}\,(\Phi^p - \Phi) = 0,$$

where

$$\sigma(y) := y^{-\frac{4}{p-1}}\rho(y) = y^{N-1-\frac{4}{p-1}}\,e^{-\frac{y^2}{4}}.$$

The rest of the proof is the same as in the proof of Lemma 4.8 since our assumption $p > \frac{N+2}{N-2}$ implies $2 - N + \frac{4}{p-1} < 0$. ∎

5. Proof of the main theorem. In this section we prove Theorem 3.1. We begin with the following lemma.

LEMMA 5.1. *Under the assumptions of Theorem* 3.1*, the set $\mathcal{B}$ is decomposed into a disjoint union of finitely many closed intervals:*

$$\mathcal{B} = \bigcup_{i=1}^{k} A_i,$$

where $A_i = [t_i^1, t_i^2]$ or $A_i = \{t_i\}$ for $1 \leq i \leq k$, and A_k may also be of the form $[t_k, \infty)$.

Proof. By the definition of $\mathcal{B}$, it is clear that this set is closed. What we have to show is that the number of connected components of $\mathcal{B}$ does not exceed $(j+1)/2$.

Suppose $\mathcal{B}$ has at least k connected components. Then, considering that $u(x,t)$ is a classical solution for $t \notin \mathcal{B}$, and in view of (2.23), we can find a sequence of numbers

$$0 < \tau_1 < t_1 = T < \tau_2 < t_2 < \cdots < \tau_k < t_k$$

such that u is regular in the time interval $[\tau_i, t_i)$ and that

$$\lim_{t \nearrow t_i} u(0,t) = \infty.$$

Therefore, there exists $\tilde{\tau}_i \in (\tau_i, t_i)$ such that

$$u(0,\tau_1) < u(0,\tilde{\tau}_1) > u(0,\tau_2) < u(0,\tilde{\tau}_2) > \cdots < u(0,\tilde{\tau}_k).$$

Now let u_n be an approximating sequence for u. Then by Lemma 2.7 and the above inequality, we have

$$u_n(0,\tau_1) < u_n(0,\tilde{\tau}_1) > u_n(0,\tau_2) < u_n(0,\tilde{\tau}_2) > \cdots < u_n(0,\tilde{\tau}_k)$$

for n sufficiently large. It follows that $(u_n)_t(0,t)$ changes sign at least $2(k-1)$ times. Since $\mathcal{Z}_{[0,1]}((u_n)_t(\cdot,t))$ drops at least by 1 each time $(u_n)_t(0,t)$ changes sign, we have

$$\mathcal{Z}_{[0,1]}((u_n)_t(\cdot,\tilde{\tau}_k)) \leq \mathcal{Z}_{[0,1]}((u_n)_t(\cdot,\tau_1)) - 2(k-1).$$

Letting $n \to \infty$, we obtain

$$\mathcal{Z}_{[0,1]}(u_t(\cdot,\tilde{\tau}_k)) \leq \mathcal{Z}_{[0,1]}(u_t(\cdot,\tau_1)) - 2(k-1); \tag{5.1}$$

see Remark 5.2. Since τ_1 can be chosen arbitrarily close to $t_1 := T$, the right-hand side of (5.1) can be replaced by $j - 2(k-1)$. Moreover, since u does not blow up completely at $t = t_k$, we have

$$\mathcal{Z}_{[0,1]}(u_t(\cdot, \tilde{\tau}_k)) \geq 1$$

(cf. Remark 3.3). Combining this and (5.1), we obtain

$$1 \leq j - 2(k-1).$$

The lemma is proved. □

Remark 5.2. In obtaining (5.1) above, we have used the fact that the pointwise convergence $v_n(r) \to v(r)$ implies

$$\liminf_{n\to\infty} \mathcal{Z}_{(0,1]}(v_n) \geq \mathcal{Z}_{(0,1]}(v),$$

and that the equality holds if $v(r)$ has only simple zeros in the interval $0 \leq r \leq 1$. Thus (5.1) holds if $u_t(r, \tau_1)$ has only simple zeros in $0 \leq r \leq 1$. Since $u_t(r,t)$ can have a degenerate zero only for a discrete set of values of $t \in (0,T)$, we can always assume without loss of generality that $\tau_1 \in (0,T)$ has the above property.

Now we are ready to prove our main theorem.

Proof of Theorem 3.1. We show by contradiction that $A_1 = \{T\}$. Suppose $A_1 \supset [T, T+\delta]$ for some $\delta > 0$. By Lemma 4.1, $u(r,t) - \varphi^*(r)$ can have a degenerate zero in $0 < r \leq 1$ only at finitely many values of t. Therefore, we can find an interval $[\tau_1, \tau_2] \subset [T, T+\delta]$ (with $\tau_1 < \tau_2$) such that $u(r,t) - \varphi^*(r)$ has no degenerate zero for any $t \in [\tau_1, \tau_2]$. This means that the graph of $r \mapsto u(r,t)$ and that of $\varphi^*(r)$ always intersect transversally as t varies over the interval $[\tau_1, \tau_2]$; hence these intersection points are smooth functions of t. The number of the intersection points is uniformly bounded, as we see in Remark 4.2, but it may not be constant since some intersection points may escape into $r = 0$ (where $\varphi^* = \infty$) or emerge from $r = 0$ as t varies (see Remark 4.3). Nonetheless, by replacing $[\tau_1, \tau_2]$ with its suitable subinterval, if necessary, we may assume without loss of generality that the number of the intersection points is constant as t varies over $[\tau_1, \tau_2]$. Consequently, there exists $r_0 > 0$ such that either

$$u < \varphi^*, \quad r \in (0, r_0],\ t \in [\tau_1, \tau_2], \tag{5.2}$$

or

$$u > \varphi^*, \quad r \in (0, r_0],\ t \in [\tau_1, \tau_2]. \tag{5.3}$$

If (5.2) holds, the approximating sequence u_n satisfies

$$\begin{aligned} &u_n(r, \tau_1) < \varphi^*(r), \quad r \in (0, r_0], \\ &u_n(r_0, t) \leq u(r_0, t), \quad t \in [\tau_1, \tau_2], \end{aligned}$$

for $n = 1, 2, 3, \ldots$ since $u_1 < u_2 < u_3 < \cdots \to u$. Let $\tilde{u}$ be the solution of the initial value problem (S) introduced in subsection 4.1. Then since both u and $\tilde{u}$ are smooth outside $r = 0$, there exists some $\delta_0 > 0$ such that $u(r_0, t) < \tilde{u}(r_0, t - \tau_1)$ for $t \in [\tau_1, \tau_1 + \delta_0]$. By the comparison principle we have

$$u_n(r,t) < \tilde{u}(r, t - \tau_1), \quad r \in (0, r_0],\ t \in [\tau_1, \tau_1 + \delta_0],$$

for $n = 1, 2, 3, \ldots$. Letting $n \to \infty$, we obtain

$$u(r,t) \le \tilde{u}(r, t - \tau_1), \quad r \in (0, r_0],\ t \in [\tau_1, \tau_1 + \delta_0].$$

This implies that u is regular for $\tau_1 < t \le \tau_1 + \delta_0$, contradicting our assumption that $[T, T+\delta] \subset \mathcal{B}$.

Next we consider the case where (5.3) holds. We fix $\theta \in (\tau_1, \tau_2)$ arbitrarily and rescale u using the backward self-similar variables as in (4.9) (for the exponential case (1.1)) or as in (4.10) (for the power case (1.2)). Then the rescaled solution $w^\theta(y,s)$ satisfies (R_e) or (R_p), depending on the nonlinearity.

By Lemma 4.7 (in the case of the exponential nonlinearity) or by Corollary 4.6 (in the case of the power nonlinearity), $w^\theta(y,s)$ must approach stationary solutions as $s \to \infty$ locally uniformly in $y > 0$. Inequality (5.3) implies that w^θ can only approach stationary solutions that lie above φ^*. However, Lemmas 4.8 and 4.9 state that there is no stationary solution strictly above φ^*. Therefore,

$$w^\theta(y,s) \to \varphi^*(y) \quad \text{as} \quad s \to \infty \tag{5.4}$$

locally uniformly in $y > 0$. We shall show that this convergence cannot occur. We consider the exponential case and the power case separately.

First, let us consider the exponential case (1.1). Fix $t_0 \in (0, T)$ such that

$$\mathcal{Z}_{(0,1)}(u(\cdot, t_0) - \varphi^*) =: m_0 < \infty \tag{5.5}$$

and such that the function $r \mapsto u(r, t_0) - \varphi^*(r)$ has no degenerate zero in $0 < r \le 1$. For each $a > 0$, let $\varphi_a(r)$ be the solution of

$$\begin{cases} \varphi'' + \dfrac{N-1}{r}\varphi' + \lambda e^\varphi = 0, \quad r > 0, \\ \varphi_a'(0) = 0, \quad \varphi_a(0) = a. \end{cases} \tag{5.6}$$

In other words, $\varphi_a(|x|)$ is a stationary solution of (1.1) in $\mathbb{R}^N$. It is known that, under the assumption $3 \le N \le 9$,

$$\varphi_a(r) \to \varphi^*(r) \quad \text{as} \quad a \to \infty \tag{5.7}$$

locally uniformly in $r > 0$ and that

$$\mathcal{Z}_{(0,\infty)}(\varphi_a - \varphi^*) = \infty; \tag{5.8}$$

see [7]. The convergences (5.7) and (5.5) yield

$$\mathcal{Z}_{[0,1)}(u(\cdot, t_0) - \varphi_a) \in \{m_0, m_0 + 1\} \tag{5.9}$$

for all large a. On the other hand, by (5.8), we can choose $s = s_1$ large enough so that

$$\mathcal{Z}_{(0,\eta(s_1))}(\varphi_1 - \varphi^*) > m_0 + 1,$$

where $\eta(s) = e^{s/2}$. Then this and convergence (5.4) imply that

$$\mathcal{Z}_{(0,\eta(s_1))}(w^\theta(\cdot, s) - \varphi_1) > m_0 + 1$$

for all large s; hence

$$\mathcal{Z}_{(0,\eta(s))}(w^{\theta}(\cdot,s)-\varphi_1) > m_0+1.$$

Fix $s_2 \geq s_1$ large enough so that the above inequality holds for $s=s_2$, (5.9) holds for $a=1+s_2$, and $t_2 := \theta - e^{-s_2} > t_0$. Then the above inequality can be rewritten as

$$\mathcal{Z}_{(0,1/\sqrt{\mu})}(u^{\mu}(\cdot,t_2)-\varphi_1) > m_0+1,$$

where

$$u^{\mu}(r,t) = u(\sqrt{\mu}r,t)+\log\mu, \quad \mu=\theta-t_2.$$

Applying the rescaling $v(r)\mapsto v(r/\sqrt{\mu})-\log\mu$ to both u^{μ} and φ_1 and using the fact that

$$\varphi_1(r/\sqrt{\mu})-\log\mu = \varphi_a(r), \quad a=1-\log\mu = 1+s_2,$$

we obtain

$$\mathcal{Z}_{[0,1)}(u(\cdot,t_2)-\varphi_a) > m_0+1.$$

This, however, contradicts (5.9) since $\mathcal{Z}_{[0,1)}(u(\cdot,t)-\varphi_a)$ is monotone nonincreasing in t. This contradiction proves the assertion $A_1=\{T\}$ for the exponential case (1.1).

In the power case (1.2), the argument goes completely parallel to the above. The only difference is that φ^* has now form (4.3) instead of (4.2), φ_a is the solution of the problem

$$\begin{cases} \varphi''+\dfrac{N-1}{r}\varphi'+\varphi^p=0, \quad r>0,\\ \varphi_a'(0)=0, \quad \varphi_a(0)=a, \end{cases}$$

and the rescaling that we use is

$$u^{\mu}(r,t) = \mu^{\frac{1}{p-1}}u(\sqrt{\mu}r,t).$$

The rest of the proof is the same as in the exponential case. Thus we have $A_1=\{T\}$ both for the power case and the exponential case.

The same argument shows that the sets $A_2,\dots,A_k$ are all singletons. $\square$

6. Example of a peaking solution. In this section we consider (P) with the exponential nonlinearity (1.1) and prove the existence of a minimal L^1-solution that blows up exactly once.

THEOREM 6.1. *There exists an initial function u_0 such that the assumptions of Theorem 3.1 are satisfied in case (1.1) with $j=1$. This means that $\mathcal{B}=\{T\}$.*

We first recall some known properties of equilibria of (P) in case (1.1). The stationary problem corresponding to (P) is equivalent to

$$\text{(E)} \qquad \begin{cases} \phi_{rr}+\dfrac{N-1}{r}\phi_r+\lambda e^{\phi}=0, \qquad r\in(0,1),\\ \phi_r(0)=0, \qquad \phi(1)=0. \end{cases}$$

PROPOSITION 6.2 ([5, 7]; see Figure 1). *Denote by S the solution set of the parameterized problem (E):*

$$S=\{(\phi,\lambda) : \lambda\in\mathbb{R}^+ \textit{ and } \phi \textit{ is a solution of } \text{(E)}\}.$$

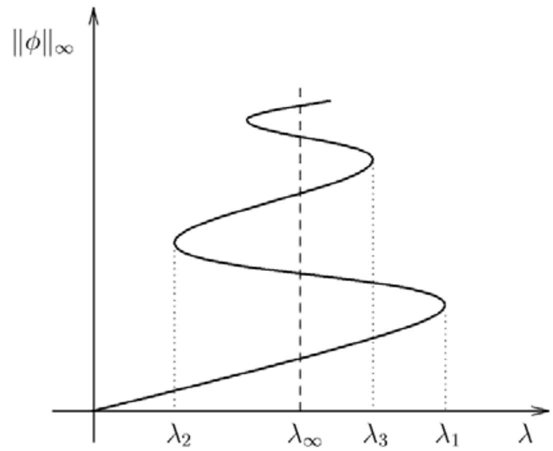

FIG. 1.

Then there exists a smooth curve

$$s \mapsto (\phi(s), \lambda(s)) : \mathbb{R}^+ \to C(\overline{B}_1(0)) \times \mathbb{R}^+$$

such that $S = \{(\phi(s), \lambda(s)) : s > 0\}$ *and that*

$$\sup_{x \in B_1(0)} \phi(s)(x) = \phi(s)(0) = s.$$

Moreover, the following holds:

(a) $\lim_{s\to 0} \lambda(s) = 0$, $\lim_{s\to\infty} \lambda(s) = \lambda_\infty := 2(N-2)$.

(b) *The set of all zeros of* $\lambda'(\cdot)$ *is given by a sequence* $0 < s_1 < s_2 < s_3 < \cdots \to \infty$ *and the critical values* $\lambda_j = \lambda(s_j)\,(j = 1, 2, 3, \dots)$ *satisfy*

$$\lambda_1 > \lambda_3 > \cdots > \lambda_{2j+1} \searrow \lambda_\infty, \quad \lambda_2 < \lambda_4 < \cdots < \lambda_{2j+2} \nearrow \lambda_\infty.$$

(c) *For each* $\lambda \le \lambda_1$ *define*

$$\phi_i^\lambda = \phi(\tilde{s}_i) \ \ (i = 0, 1, \dots),$$

where $\tilde{s}_0 < \tilde{s}_1 < \cdots$ *is the sequence of all points* s *with* $\lambda(s) = \lambda$. *This sequence is finite if* $\lambda \ne \lambda_\infty$ *and infinite if* $\lambda = \lambda_\infty$.

Next we recall the existence of a special blow up solution which can be continued globally as an L^1-solution.

PROPOSITION 6.3 (see [3]). *For any* $\lambda \in (\lambda_2, \lambda_3]$ *there is* u_0 *such that the solution* $u(\cdot, t)$ *of* (P) *has the following properties:*

(i) $u(\cdot, t)$ *blows up in finite time.*

(ii) $u(\cdot, t)$ *is a minimal* L^1*-solution.*

(iii) $u(\cdot, t)$ *is defined (as a classical solution of* (P)*) on the interval* $(-\infty, T)$ *for* $u(\cdot, t) \to \phi_2$ *in* C^1 *as* $t \to -\infty$.

(iv)

$$\frac{u_t(\cdot, t)}{\|u_t(\cdot, t)\|_{C^1(B_1)}} \to \psi_2 \quad \text{in } C^1(B_1) \quad \text{as} \quad t \to -\infty,$$

where ψ_2 is a normalized eigenfunction of

$$\begin{aligned} &\Delta\psi + \lambda e^{\phi_2(|x|)}\psi + \mu\psi = 0, \qquad x \in B_1, \\ &\psi = 0, \qquad x \in \partial B_1, \end{aligned}$$

corresponding to the second eigenvalue μ_2.

For (i)–(iii), see Theorem 3.4 in [3]. For (iv), see the proof of Lemma 3.6 (in particular, (3.14)) of the same paper.

Theorem 6.1 follows now from Proposition 6.3 because $\mathcal{Z}_{[0,1]}(\psi_2) = 1$ and ψ_2 has no degenerate zeros (thus $\mathcal{Z}_{[0,1]}(u_t(\cdot, t)) = 1$ for large negative t).

LARGE-TIME BEHAVIOR FOR VISCOUS AND NONVISCOUS HAMILTON–JACOBI EQUATIONS FORCED BY ADDITIVE NOISE*

NICOLAS DIRR† AND PANAGIOTIS E. SOUGANIDIS‡

Abstract. We study the large-time behavior of the solutions to viscous and nonviscous Hamilton–Jacobi equations with additive noise and periodic spatial dependence. Under general structural conditions on the Hamiltonian, we show the existence of unique up to constants, global-in-time solutions, which attract any other solution.

Key words. Hamilton–Jacobi equations with additive noise, large-time behavior, Lipschitz regularity for Hamilton–Jacobi equations

AMS subject classifications. 35R60, 49L25, 35B40

DOI. 10.1137/040611896

1. Introduction.

We are interested in the long-time behavior of solutions to equations of the form

$$\mathrm{d}u - (\mathrm{tr}(A(x)D^2u) - H(Du,x))\mathrm{d}t + \mathrm{d}W(x,t) = 0 \quad \text{in } \mathbb{R}^n \times (t_0,\infty), \tag{1.1}$$

where $t_0 \in \mathbb{R}$ is arbitrary,

$$H \in C^{0,1}_{\mathrm{loc}}(\mathbb{R}^n \times \mathbb{R}^n) \quad \text{is } \mathbb{Z}^n\text{-periodic with respect to } x, \tag{1.2}$$

and, if S^n and $\mathcal{M}^{n\times m}$ are, respectively, the spaces of $n \times n$ symmetric and $n \times m$ matrices,

$$A \in C^{0,1}(\mathbb{R}^n; S^n) \text{ is } \mathbb{Z}^n\text{-periodic} \tag{1.3}$$

and

$$\text{there exists a } \mathbb{Z}^n\text{-periodic } \sigma \in C^{0,1}(\mathbb{R}^n;\mathcal{M}^{n\times m}) \text{ such that } A = \sigma\sigma^T. \tag{1.4}$$

Here we use the standard notation $C^{0,1}$ and $C^{0,1}_{\mathrm{loc}}$ for the spaces of Lipschitz continuous and locally Lipschitz continuous functions.

We note that (1.4) immediately implies that A is degenerate elliptic, i.e., for all $x, \xi \in \mathbb{R}^n \times \mathbb{R}^n$,

$$(A(x)\xi,\xi) \geq 0.$$

If A is uniformly elliptic, i.e., there exists $\nu > 0$ such that for all $x, \xi \in \mathbb{R}^n \times \mathbb{R}^n$,

$$(A(x)\xi,\xi) \geq \nu|\xi|^2,$$

then (1.4) holds. As a matter of fact, the latter is true also if A is degenerate elliptic and $A \in C^{1,1}(\mathbb{R}^n; S^n)$.

Let $(\Omega, \mathcal{F}, P)$ be a standard probability space and

$$\Delta = \{(s,t) \in \mathbb{R}^2 : s \leqq t\}.$$

For each $(s,t) \in \Delta$, denote by $W(x,t,s,\omega)$ the increment of the random variable $W(x,\cdot,\omega)$ in the interval $[s,t]$. Then $W(x,t,s,\omega)$ has the form

$$W(x,t,s,\omega) = \sum_{i=1}^{M} F_i(x)(W_i(t,\omega) - W_i(s,\omega)), \tag{1.5}$$

where, for each $i = 1, \dots, M$,

$$W_i \text{ is a Brownian motion and } F_i \in C^2(\mathbb{R}^n) \text{ is } \mathbb{Z}^n\text{-periodic.} \tag{1.6}$$

In our analysis we do not need to assume that the Brownian motions $W_1, \dots, W_M$ are mutually independent. Indeed, throughout the paper, we use the fact that $W = (W_1, \dots, W_M)$ is continuous with respect to t almost surely in ω with increments in time which are independent and identically distributed over disjoint time intervals, and that, for all $\epsilon > 0$ and $\ell \in \mathbb{N}$,

$$\mathbb{P}\left(\sup_{t \in [0,\, l]} |W(t) - W(0)| < \epsilon \right) > 0. \tag{1.7}$$

In view of this, our analysis extends to any random forcing $\zeta(x,t,\omega)$ for which a notion of time integral $Z(x,t,s,\omega) = \int_s^t \zeta(x,\rho)\mathrm{d}\rho$ is defined in such a way that Z has the aforementioned properties. Moreover, using discontinuous viscosity solutions, it is possible to extend our analysis to equations driven by certain jump processes, such as, for example, kicking force (see [IK]). In order to keep the presentation short, we focus here on the Brownian case.

Our results hold for all initial data and initial times and for all realizations of the noise in Ω_C, the set of continuous paths of the Brownian motion, which has full measure ($\mathbb{P}(\Omega_C) = 1$), or a smaller set $\tilde{\Omega}$, also of full measure, to be defined later.

Throughout the paper we write $\mathbb{T} = [0,1]^n$, we denote by $C(\mathbb{T})$ the space of $\mathbb{Z}^n$-periodic continuous real-valued functions, and we use the seminorm $|||\cdot|||$ defined, for each $u \in C(\mathbb{T})$, by

$$|||w||| = \inf_{c \in \mathbb{R}} \|w - c\|,$$

where $\|\cdot\|$ is the usual *sup*-norm.

The deterministic version of (1.1), i.e., the equation

$$u_t - \operatorname{tr}\left(A(x)D^2u\right) + H(Du,x) = 0 \quad \text{in} \quad \mathbb{R}^n \times (t_0,\infty), \tag{1.8}$$

plays a fundamental role in our analysis.

Indeed our main result says that, under some additional assumptions on A, H and $F = (F_1, \dots, F_M)$, if (1.8) has a unique up to constants, periodic-in-space, and global-in-time attracting solution, then so does (1.1). In other words, there exists a unique up to constants, periodic with respect to x solution $u_{inv} : \mathbb{R}^n \times \mathbb{R} \times \Omega \to \mathbb{R}$ of (1.1) such that, if u is another solution of (1.1), then

$$\lim_{t\to\infty} |||u(\cdot,t) - u_{inv}(\cdot,t)||| = 0. \tag{1.9}$$

We briefly explain the strategy of the proof. The theory of a fully nonlinear stochastic PDE developed by Lions and one of the authors in [LS1], [LS2], and [LS3], which applies to more general equations, allows us to define pathwise solutions to (1.1). These can be expressed, using a simple transformation, as solutions of a PDE with random coefficients.

The comparison principle for viscosity solutions to (viscous) Hamilton–Jacobi equations implies that the distance between two solutions driven by the same noise cannot increase. Moreover, whenever the excursions of the Brownian motion remain small throughout a time interval, the solutions to (1.1) and (1.8) stay close. In view of (1.9), which holds for solutions of (1.8), the latter converge, as $t \to \infty$ to a unique up to constants attractive solution. It follows that the distance between solutions measured in the seminorm $|||\cdot|||$ decreases throughout such intervals. On the other hand, the independent increments property of W and (1.7) imply that, as $t \to \infty$, there exist enough intervals of small excursions for W. Hence the difference of any two solutions of (1.1) measured in $|||\cdot|||$ tends to 0 as $t \to \infty$. The claim then follows in a standard way.

An important step in showing that the solutions to the deterministic and stochastic equations stay close to each other in intervals of small excursions of the Brownian motion is the fact that, after times of order one, the solutions to (1.1) become Lipschitz continuous with respect to x, with a Lipschitz constant depending on the realization of the noise and not the initial datum. This fact, which is of independent interest, is the main technical result in the paper.

When the equation is of first order, i.e., $A \equiv 0$, the Lipschitz bound follows from the growth conditions on the Hamiltonian, which yield uniform L^∞-bounds on the solutions. For second-order equations, i.e., when $A \not\equiv 0$, there are two distinct cases. When H is superquadratic with respect to the gradient, it is again possible to obtain universal L^∞-bounds on the solutions. The Lipschitz estimate then follows as in the first-order case. When the Hamiltonian is superlinear but not superquadratic, the estimate is more delicate. In this case it is necessary to obtain the Lipschitz bound without using a priori L^∞-bounds for nonnegative solutions, which may not exist. Typically (see, e.g., Barles [B], Crandall, Lions, and Souganidis [CLS], and Lions [L]), the Lipschitz bounds depend on the spatial oscillations of the initial datum, a fact which is not enough for the argument here. We overcome this difficulty by obtaining uniform, after time of order one, estimates on the spacial oscillations of the solutions.

The problem under consideration in this paper is a "toy" example for far more complex models in, for example, phase transitions and growth processes (the so-called KPZ (Kadar–Parisi–Zhang) equation) and fluid mechanics (the stochastically forced Navier–Stokes equation).

The stochastic KPZ equation

$$\mathrm{d}u - \left(\epsilon \Delta u - |Du|^2\right) \mathrm{d}t - \mathrm{d}W = 0$$

is obtained by linearizing the forced mean curvature flow for small gradients and large force. Our results apply directly to this equation with additive forcing and more general operators.

Another concrete example to which our results apply is the stochastic Burgers equation with additive noise. Indeed, if $u \in C(\mathbb{R} \times (0,\infty))$ solves the stochastic Hamilton–Jacobi equation

$$\mathrm{d}u + (u_x)^2 \mathrm{d}t - \mathrm{d}W = 0,$$

then $v = u_x$ solves the Burgers equation

$$\mathrm{d}v + (v^2)_x \mathrm{d}t - \mathrm{d}W_x = 0. \tag{1.10}$$

The unique up to constants random attractor of the Hamilton–Jacobi equation yields a unique invariant measure for the Burgers equation.

Invariant measures for (1.10) and other closely related equations have been the object of extensive study. We refer to E et al. [EKMS], Iturriaga and Khanin [IK], Gomes et al. [GIKP] for the Burgers equation and Mattingly [M1], [M2] for the Navier–Stokes equation with stochastic forcing.

The large-time behavior of solutions of (1.8) depends strongly on whether $A \equiv 0$ or is uniformly elliptic, while very little is known in the degenerate case. When $A \equiv 0$, the problem was studied by Fathi [F], Roquejoffre [R], and Namah and Roquejoffre [NR1], [NR2], the most general results being the ones of Barles and Souganidis [BS2]. The behavior of (1.8) for uniformly elliptic A was studied by Barles and Souganidis [BS3].

When $A = 0$ and H is periodic in time, it was shown by Barles and Souganidis [BS1] (see also Fathi and Mather [FM]) that there are no global attracting solutions. As a matter of fact, phenomena like period doubling can occur. In the uniformly elliptic case, however, it was shown in [BS3] that there exists a unique up to constants attracting solution. Of course, the basic difference between the degenerate and uniformly elliptic settings is that, in the latter case, the equation admits a strong maximum principle.

It follows from our results that even when the equation does not have a strong maximum principle, the stochastic noise is sufficiently irregular for the solutions to lose dependence on the initial data, while this is not true in general for a deterministic time-dependent perturbation.

The proofs in our paper are based on general arguments from the theory of viscosity solutions. This allows us to consider general Hamiltonians H and matrices A. In view of the generality of our assumptions, this paper extends previous works of Iturriaga and Khanin [IK], E et al. [EKMS], and Gomes et al. [GIKP], which consider strictly convex Hamiltonians, and in [GIKP], a space independent uniformly elliptic second-order operator. If the Hamiltonian is strictly convex, the solution of (1.1) can be expressed as the value function of a control problem. The asymptotic behavior of the solutions then reduces to the study of the corresponding controlled stochastic and ordinary differential equations. Here, instead of convexity, we assume some form of asymptotic convexity of the level sets of H. Moreover, in the viscous case, the matrix A can be degenerate elliptic and may depend on space.

We remark that Gomes et al. [GIKP] show that attracting solutions for strictly convex Hamiltonians and $A = \epsilon I$ converge to attracting solutions of the first-order equation. A similar convergence result holds in our case for general A's.

The paper is organized as follows. In section 2 we introduce the notion of solution, we state all the assumptions and the main theorems of the paper, and we prove some preliminary facts. In section 3 we prove the existence of an attracting solution u_{inv} on $\mathbb{R}^n \times (-\infty, \infty)$, assuming that we have the Lipschitz regularization property discussed earlier. Section 4 is devoted to the proof of this property.

2. Assumptions, preliminaries, and results. We begin with the notion of a solution of (1.1). For this, we need the equation

$$v_t - \mathrm{tr}(A(x)D^2 v) + H(Dv + DW(x,t,t_0), x) = \mathrm{tr}(A(x)D^2 W(x,t,t_0)). \tag{2.1}$$

DEFINITION 2.1. *A function* $u : \mathbb{R}^n \times [a,b] \times \Omega \to \mathbb{R}$ *is a viscosity solution of* (1.1) *if, for all* $[t_0, t_1] \subseteq [a,b]$, *the function*

$$v(x,t,\omega) = u(x,t,\omega) - W(x,t,t_0,\omega)$$

is a viscosity solution of (2.1) *in* $\mathbb{R}^n \times [t_0, t_1]$.

This definition coincides with the more general notion of stochastic viscosity solutions in [LS1], [LS2], [LS3]. Notice that when $A \equiv 0$, for the definition we only need $F \in C^1$. When A is uniformly elliptic and sufficiently smooth—for example, when A has constant coefficients—then it is possible to give an alternative definition requiring less differentiability of the F. Indeed, consider the solution w of the linear stochastic PDE

$$\begin{cases} \mathrm{d}w(x,t,t_0) - \mathrm{tr}(A(x)D^2 w(x,t,t_0))\mathrm{d}t = \mathrm{d}W(x,t), \\ w(x,t_0,t_0) = 0. \end{cases}$$

The basic regularity theory for uniformly parabolic linear equations yields, for some $C > 0$, the estimate

$$\|w(\cdot,t,t_0)\|_{C^2(\mathbb{T})} \le C(\|W\|_{C^{0,\alpha}([t_0,t_1])} + \|F\|_{C^{2,\alpha}(\mathbb{T})}).$$

In this case we say that u is a viscosity solution of (1.1) if $v = u - w(\cdot,\cdot,t_0)$ solves

$$v_t - \mathrm{tr}(A(x)D^2 v) + H\big(Dv + Dw(x,t,t_0), x\big) = 0 \text{ in } \mathbb{R}^n \times [t_0, t_1].$$

Next we state a proposition which asserts the existence and uniqueness of pathwise solutions of (1.1). Since the result is an immediate consequence of the theory of viscosity solutions (see [CIL], [B]) and Definition 2.1, we omit the proof.

PROPOSITION 2.2. *Assume* (1.2), (1.3), (1.4), (1.5), *and* (1.6). *For all* $\omega \in \Omega_C$, $s \in \mathbb{R}$, *and* $u \in C(T)$, *there exists a unique stochastic viscosity solution* $u(\cdot,\cdot,s,\omega) \in C\big(\mathbb{R}^n \times [s,\infty)\big)$ *of* (1.1) *such that* $u(\cdot,s,s,\omega) = u$.

Throughout the paper we denote by $S^{W,A}(t,s)(u)$ the stochastic viscosity solution of (1.1) starting with initial datum u at s. The solution to (1.8) is denoted by $S^{0,A}(t,s)(u)$. When $A \equiv 0$ and the context allows it, we write $S^W(t,s)$ and $S^0(t,s)$ to denote the solution operators to (1.1) and (1.8), respectively. Finally, whenever it does not create any ambiguity, we write $S^{W,A}(t,s)$ for both $S^{W,A}(t,s)$ and $S^{0,A}(t,s)$.

Since it will be used later, we note here that, as an immediate consequence of Proposition 2.2, both $S^{0,A}(t,s)$ and $S^{W,A}(t,s)$ commute with constants, i.e., for all $c \in \mathbb{R}^n$,

$$S^{W,A}(t,s)(v+c) = S^{W,A}(t,s)(v) + c. \tag{2.2}$$

We proceed with the assumptions on the Hamiltonian H, which we will be using in this paper.

$$\begin{cases} \text{There exist } K > 0 \text{ and } q > 1 \text{ such that for all } (p,x) \in \mathbb{R}^n \times \mathbb{R}^n, \\ \qquad\qquad H(p,x) \ge K^{-1}|p|^q - K. \end{cases} \tag{2.3}$$

$$\begin{cases} \text{There exist } R_0 > 0 \text{ and a strictly increasing } \Phi \in C\big([0,\infty),[0,\infty)\big) \\ \text{with } \Phi(0) = 0, \text{ such that for all } (p,x) \in \mathbb{R}^n \times \mathbb{R}^n \text{ with } |p| \ge R_0, \\ \qquad\qquad D_pH(p,x)\cdot p - H(p,x) \ge \Phi(|p|). \end{cases} \tag{2.4}$$

$$\text{(2.5)}\qquad \begin{cases}\text{There exist } R_0 \text{ and } B > 0 \text{ such that for all } (p,x) \in \mathbb{R}^n \times \mathbb{R}^n\\ \text{with } |p| \geq R_0, -D_x H(p,x) \cdot p \leq B|p|^2(D_p H(p,x) \cdot p - H(p,x)).\end{cases}$$

(2.6)

$$\begin{cases}\text{There exist } R_0 > 0 \text{ and a strictly increasing } \Phi \in C([0,\infty);[0,\infty)) \text{ with } \Phi(0) = 0,\\ \text{ such that for some } \delta > 0, G(r) = \Phi(r)r^{-(1+\delta)} \text{ is increasing,}\\ G(r) \to \infty \ \text{ as } r \to \infty, \text{ and for all } (p,x) \in \mathbb{R}^n \times \mathbb{R}^n \text{ with } |p| \geq R_0,\\ \qquad\qquad D_p H(p,x) \cdot p - H(p,x) \geq \Phi(|p|).\end{cases}$$

$$\text{(2.7)}\qquad \begin{cases}\text{There exists } C > 0 \text{ such that for all } (p,x) \in \mathbb{R}^n \times \mathbb{R}^n \text{ with } |p| \geq R_0,\\ \qquad\qquad -D_x H(p,x) \cdot p \leq C(D_p H(p,x) \cdot p - H(p,x)).\end{cases}$$

$$\text{(2.8)}\qquad \limsup_{|p|\to\infty}(D_p H(p,x) \cdot p - H(p,x))^{-1}|D_p H(p,x)| = 0 \ \text{ uniformly in } x \in \mathbb{R}^n.$$

$$\text{(2.9)}\qquad \sup_{x\in\mathbb{R}^n} \limsup_{|p|\to\infty} \left(D_p H(p,x) \cdot p - H(p,x)\right)^{-1} |p||D_p H(p,x)| < \infty.$$

$$\text{(2.10)}\qquad \begin{cases}\text{There exist a unique } \lambda \in \mathbb{R} \text{ and a unique up to constants } U \in C(\mathbb{T}),\\ \text{both depending on } A \text{ and } H, \text{ such that for each } v \in C(\mathbb{T}) \text{ and } t_0 \in \mathbb{R},\\ \text{there exists } c \in \mathbb{R} \text{ such that}\\ \lim_{N\to\infty} \sup_{x\in\mathbb{T}} \left|S^{0,A}(t_0+N,t_0)(v) - (U+c) - \lambda N\right| = 0.\end{cases}$$

Assumptions (2.4) and (2.6) state that the level sets of H as a function of p become convex for large $|p|$. This asymptotic condition is crucial for obtaining Lipschitz bounds which do not depend on the initial data and is much weaker than requiring the Hamiltonian to be convex in p.

The sole purpose of (2.8) and (2.9) is to ensure that the Hamiltonian in (2.1), which arises after incorporating the noise, still satisfies the growth assumptions (2.3), (2.4), (2.5) in the nonviscous case and (2.3), (2.6), (2.7) in the viscous case, with constants which may depend on t_0, t, and ω.

Among all the above, the most important assumption is (2.10). It states that the corresponding deterministic equation has a global attractor, which consists—up to constants—of a single trajectory. We refer to the introduction for a discussion concerning this fact and to [BS1], [BS2], and [BS3] for results yielding (2.10) as well as an extensive list of references.

The main result of this paper is the next theorem. The strategy for the proof of the first part was outlined in the introduction. As we explain later in this section the second part is a simple consequence of the first and the stability properties of the viscosity solutions.

THEOREM 2.3. *Assume* (1.2), (1.5), (1.6), (2.3), *and* (2.10). *There exists* $\widetilde{\Omega} \subseteq \Omega$ *with* $\mathbb{P}(\widetilde{\Omega}) = 1$ *such that for every* $\omega \in \widetilde{\Omega}$, *the following hold:*

(i) *If* $A \equiv 0$ *and, in addition,* (2.4), (2.5), *and* (2.8) *hold, or if* $A \not\equiv 0$ *satisfies* (1.3), (1.4) *and, in addition,* (2.6), (2.7), (2.9) *hold and* $F_i \in C^3(\mathbb{T})$, *there exists a unique up to constants solution* $u_{inv}(\cdot,\cdot,\omega) \in C(\mathbb{R}; C^{0,1}(\mathbb{T}))$ *of* (1.1) *attracting any other solution, i.e., for any* $v \in C(\mathbb{T})$ *and* $s \in \mathbb{R}$,

$$\lim_{t\to\infty} \|\!|u_{inv}(\cdot,t,\omega) - S^W(t,s)(v)(\cdot)|\!\|= 0.$$

(ii) *Assume that* $A = \epsilon \tilde{A}$ *is uniformly elliptic and satisfies* (1.3). *If* $u^{\epsilon}_{inv}(\cdot, \cdot, \omega)$ *and* ${u_{inv}}^0(\cdot, \cdot, \omega)$ *are the unique up to constants invariant solutions of* (1.1) *corresponding to* $\epsilon > 0$ *and* $\epsilon = 0$, *respectively, then for any* $[a, b] \subset (-\infty, +\infty)$,

$$\lim_{\epsilon \to 0} \sup_{t \in [a,b]} |||u^{\epsilon}_{inv}(\cdot, t, \omega) - u^{0}_{inv}(\cdot, t, \omega)||| = 0.$$

As was already mentioned in the introduction, for $A \equiv 0$ and $H(p) = |p|^2$ this result was first proved by [EKMS] in one dimension and by [IK] in all dimensions for general strictly convex H and uniformly elliptic x-independent A. Our assumptions allow, however, to consider nonconvex Hamiltonians and degenerate elliptic A. For example, H can have the form

$$H(p, x) = |p|^2 \widehat{H}(\hat{p}, x),$$

where, for $p \in \mathbb{R}^n \setminus \{0\}$, $\hat{p} = |p|^{-1} p$, and $\widehat{H}$ is periodic in x and uniformly bounded away from 0. It is straightforward to check that all structural assumptions on H hold. Moreover, it is proved in [BS2] and [BS3] that for each $v \in C(\mathbb{T})$, $S^0(t)(v)$ has a limit as $t \to \infty$. The up to constants uniqueness of the asymptotic limit of the deterministic equation is here an assumption, which holds, for example, if $\widehat{H}$ is independent of x.

Most of the growth conditions on H are needed for the following lemma, which plays a central role in the paper. In fact, this lemma is of independent interest, as it extends known regularity results for viscous Hamilton–Jacobi equations.

For $(t_1, t_2) \in \Delta$, we write

$$C_W(t_1, t_2, \omega) = \max_i \sup_{t \in [t_1, t_2]} \left| \int_{t_1}^{t} \mathrm{d}W_i(s, \omega) \right|. \tag{2.11}$$

We have the following.

LEMMA 2.4. *Assume* (1.2), (1.3), (1.4), (1.5), (1.6), (2.3) *and either* (2.6), (2.7), (2.9), *and* $F_i \in C^3(\mathbb{T})$ *if* $A \not\equiv 0$ *is degenerate elliptic, or* (2.4), (2.5), *and* (2.8) *if* $A \equiv 0$. *For all* $\omega \in \Omega_C$ *and* $(s, t) \in \Delta$, *there exists* $L(s, t, \omega) > 0$ *such that for all* $v \in C(\mathbb{T})$,

$$\inf_{c \in \mathbb{R}} \|S^{W,A}(t, s)(v) - c\|_{C^{0,1}(\mathbb{T})} \leq L(s, t, \omega).$$

Moreover, there exists $\hat{L} : (0, \infty) \times (0, \infty) \to (0, \infty)$ *which is increasing with respect to the second argument, such that*

$$\text{if } C_W(s, t, \omega) \leq K, \quad \text{then } L(s, t, \omega) \leq \widehat{L}(t - s, K).$$

It follows from Lemma 2.4 that solutions to (1.1) are Lipschitz continuous in space with Lipschitz constant independent of the initial datum. For solutions of the deterministic time-independent equation (1.8), the lemma holds with an L which depends only on $|t - s|$.

The claim about the vanishing viscosity limit asserted in Theorem 2.3 is a simple consequence of our results and standard arguments from the theory of viscosity solutions. Indeed, Lemma 2.4 yields that the family $({u^{\epsilon}}_{inv})_{\epsilon > 0}$ is uniformly Lipschitz continuous on any given compact time interval. A simple diagonalization argument yields a subsequence which converges uniformly on compact intervals to a viscosity solution u of (1.1) with $A \equiv 0$. Lemma 3.7 below then asserts that we must have $u(x, t) = u^0_{inv}(x, t) + c(t)$. However, since both u and u^0_{inv} are solutions, the constant c cannot depend on time. Therefore the whole family $({u^{\epsilon}}_{inv})_{\epsilon > 0}$ converges up to constants to u^0_{inv}.

3. Proofs. We begin with a number of preliminary lemmas which summarize some of the key properties of the solutions of (1.1). The first lemma is an immediate consequence of the definition of a solution and the comparison principle for viscosity solutions (see [CIL]); hence we omit its proof.

LEMMA 3.1. *For all u, $v \in C(\mathbb{T})$ and $(s,t) \in \Delta$,*

$$\|S^{W,A}(t,s)(u) - S^{W,A}(t,s)(v)\|_{C(\mathbb{T})} \leq \|u - v\|_{C(\mathbb{T})}.$$

For $v_0 \in C^{0,1}(\mathbb{T})$ and $(t_1, t_2) \in \Delta$ we denote by

$$L_A(t_1,t_2) = \sup_{s\in[t_1,t_2]} \|DS^{0,A}(s,t_1)(v_0)\|$$

the uniform Lipschitz constant of the solution of the deterministic equation.

We also write C_A and C_0 for the constants

$$C_A = \max_{x\in\mathbb{T},\ |p|\leq L_A(t_1,t_2)} \big(|D_pH(p,x)|+1\big)\|F\|_{C^3(\mathbb{T})} \quad \text{if} \quad A \not\equiv 0$$

and

$$C_0 = \max_{x\in\mathbb{T},\ |p|\leq L_{A\equiv 0}(t_1,t_2)} (|D_pH(p,x)| \ +1)\|F\|_{C^2(\mathbb{T})} \quad \text{if} \quad A \equiv 0.$$

LEMMA 3.2. *Let $v_0 \in C^{0,1}(\mathbb{T})$ and $(t_1, t_2) \in \Delta$. Then*

$$\big\|S^{0,A}(t_2,t_1)(v_0) - S^{W,A}(t_2,t_1)(v_0)\big\| \leq (t_2 - t_1)\, C_A \,\|F\|\, C_W(t_1,t_2,\omega).$$

Proof. 1. To simplify the presentation we assume that $t_1 = 0,\ t_2 = T$ and we use the notation $C = C_A \,\|F\|_{L^\infty}\, C_W(t_1,t_2,\omega)$, $u = S^{W,A}(v_0)$, and $v = S^{0,A}(v_0)$.

2. Arguing by contradiction, we assume that there exists $(x_0, t_0) \in \mathbb{T}\times(0,T)$ such that, possibly after exchanging the role of u and v, $u(x_0,t_0) - v(x_0,t_0) - Ct_0 > 0$. Standard arguments from the theory of viscosity solutions (see [CIL]) then yield $\eta > 0$ and $(X_\alpha, p_\alpha, x_\alpha, t_\alpha)$, $(Y_\alpha, p_\alpha, y_\alpha, s_\alpha) \in S^n \times \mathbb{R}^n \times \mathbb{R}^n \times (0,T)$ such that, as $\alpha \to \infty$,

$$\begin{cases} |t_\alpha - s_\alpha| + \alpha|y_\alpha - x_\alpha|^2 \to 0, \quad \mathrm{tr}\,(A(y_\alpha)Y_\alpha) - \mathrm{tr}\,(A(x_\alpha)X_\alpha) \leq L\alpha|x_\alpha - y_\alpha|^2, \\ C + \eta(T-t_\alpha)^{-2} + H(p_\alpha,x_\alpha) - \mathrm{tr}(A(x_\alpha)X_\alpha) \\ \leq -\eta(T-s_\alpha)^{-2} + H(p_\alpha + DW(y_\alpha,s_\alpha),y_\alpha) - \mathrm{tr}\,(A(y_\alpha)Y_\alpha)\,. \end{cases}$$

The (degenerate) ellipticity of A, the choice of C, and the above inequalities contradict the fact that $\eta > 0$. ∎

Note that the above estimates depend on the Lipschitz constant of the deterministic equation. Hence to use this lemma, it is necessary to have a universal bound on those Lipschitz constants, like the one asserted by Lemma 2.4.

The next claim strengthens the assertion of (2.10), which asserts only pointwise convergence as $t \to \infty$ of the solution operator $S^{0,A}(t,s)$ acting on $C(\mathbb{T})$. It turns out that this convergence is uniform with respect to the initial data.

LEMMA 3.3. *Assume* (2.10) *and the hypotheses of Lemma* 2.4 *hold. There exists a unique up to constants function $U_A^* \in C^{0,1}(\mathbb{T})$ such that, for all $t \in \mathbb{R}$,*

$$\lim_{k\to\infty}\left(\sup_{v\in C^0(\mathbb{T})} |||S^{0,A}(t,-k)(v) - U_A^*|||\right) = 0.$$

Proof. 1. Since the deterministic equation does not depend on time, we may take $t = 0$. Assume that, for some $\delta > 0$, there exist $(v_k)_{k\in\mathbb{N}} \in C(\mathbb{T})$ such that

$$\||S^{0,A}(0,-k)(v_k) - U_A^*\|| \geq \delta \quad \text{for all } k \in \mathbb{N}, \tag{3.1}$$

where U_A^* is the unique (up to constants) limit which exists in view of (2.10).

2. The Lipschitz continuity asserted in Lemma 2.4 yields constants c_k such that the family $(\hat{v}_k)_{k\in\mathbb{N}}$ defined by

$$\hat{v}_k = S^{0,A}(-k+1,-k)(v_k) - c_k$$

is bounded in $C^{0,1}$ and thus compact in $C(\mathbb{T})$. Hence there exists a subsequence $k_m \to \infty$ such that $\widehat{v}_{k_m} \to \hat{v}$ in C^0.

3. Consider the family of maps $S_k : C(\mathbb{T}) \to C(\mathbb{T})$ given by

$$S_k(v) = S^{0,A}(0,-k+1)(v).$$

The contraction property yields that, as $m \to \infty$,

$$\|S_{k_m}(\hat{v}) - S_{k_m}(\hat{v}_{k_m})\| \to 0.$$

But (2.10) implies that

$$\||S_{k_m}(\hat{v}) - U_A^*\|| \to 0.$$

Hence, $S_{k_m}(\hat{v}_{k_m}) \to U_A^*$, a contradiction to (3.1). □

The next result concerns a technical property of the Brownian motion which is a consequence of the fact that the increments are independent and identically distributed. This property plays a fundamental role in our analysis as well as that of [EKMS], [IK], and [GIKP]. To state it, we need the following definition.

DEFINITION 3.4. *Fix $l, m \in \mathbb{N}$ and $k \in \mathbb{Z}$. An interval $[kl,(k+1)l]$ is called an (l,m)-small noise interval if*

$$\sup_{t\in[kl,(k+1)l]} \sup_{1\leq i\leq M} |W_i(t) - W_i(kl)| \leq \frac{1}{m}.$$

We have the following.

LEMMA 3.5. *For almost every path and for any $(l,m) \in \mathbb{N}\times\mathbb{N}$, there are two sequences of integers $(k_i^{l,m,\pm})_{i\in\mathbb{N}}$ such that $k_i^{l,m,\pm} \to \pm\infty$, as $i \to \infty$, and $[k_i^{l,m,\pm} l,(k_i^{l,m,\pm}+1)l]$ are (l,m)-small noise intervals.*

Proof. 1. We present the argument only for positive values of k.

2. Let

$$A_k^{l,m} = \left\{\omega : \sup_{kl\leq t\leq (k+1)l} \sup_{1\leq i\leq M} |W_i(t) - W_i(kl)| \leq \frac{1}{m}\right\}.$$

The increments $W(t)-W(kl)$ of the Brownian motion $W(t) = (W_1(t),\ldots,W_M(t))$ on the interval $[kl,(k+1)l]$ are independent and identically distributed. Hence the events $(A_k^{l,m})_{k\in\mathbb{N}}$ are independent and $\mathbb{P}(A_k^{l,m})$ is strictly positive and independent of k. The second Borel–Cantelli lemma then yields that

$$\mathbb{P}(\{\omega \in A_k^{l,m} \text{ for infinitely many } k\}) = 1. \qquad \square$$

The subset $\tilde{\Omega}$ of Ω of full measure in which our result holds consists of all of continuous paths which have, for each $(l,m) \in \mathbb{N} \times \mathbb{N}$, infinitely many (l,m)-small noise intervals for both positive and negative times. The precise definition of $\tilde{\Omega}$ is

$$\tilde{\Omega} = \Omega_C \cap_{(l,m)\in\mathbb{N}\times\mathbb{N}} (\cap_{j=1}^{\infty} \cup_{k=j}^{\infty} A_k^{l,m}) \cap (\cap_{j=1}^{\infty} \cup_{k=j}^{\infty} A_{-k}^{l,m}).$$

Next we use Lemmas 2.4, 3.2, 3.3, and 3.5 to establish the following.

LEMMA 3.6. *Fix $\omega \in \widetilde{\Omega}$, t_0 and $\delta > 0$. There exists $k_0 = k_0(\omega) \in \mathbb{N}$ such that for all $k \geq k_0(\omega)$ and $u,\ v \in C(\mathbb{T})$,*

$$|||S^{W,A}(t_0, t_0 - k)(u) - S^{W,A}(t_0, t_0 - k)(v)||| \leq \delta, \text{ and}$$
$$|||S^{W,A}(t_0 + k, t_0)(u) - S^{W,A}(t_0 + k, t_0)(v)||| \leq \delta.$$

Proof. 1. Since both estimates are proved similarly, here we establish only the second.

2. Lemma 3.3 yields an $M > 0$ such that for any initial datum $\hat{u}$ and any $m \in \mathbb{N}$,

$$|||S^{0,A}(m + M, m)(\widehat{v}) - U_A^*||| < \delta/4. \tag{3.2}$$

Here we use the fact that, since the deterministic equation is independent of time,

$$\sup_{\hat{v}} |||S^{0,A}(m + M, m)(\hat{v}) - U_A^*||| = \sup_{\hat{v}} |||S^{0,A}(M, 0)(\hat{v}) - U_A^*|||.$$

3. If C_A is the constant in Lemma 3.2 for the Lipschitz constant $L = \widehat{L}(1,1)$, choose $m \in \mathbb{N}$ such that $4MC_A\|F\| < \delta m$ and recall that Lemma 3.5 yields an $(M+1,m)$-small noise interval $[j(M+1),(j+1)(M+1)]$ contained in $(t_0,+\infty)$.

Fix $k_0(\omega)$ such that $t_0 + k_0(\omega) > (j+1)M$. It follows that the small noise interval is contained in $(t_0, t_0 + k_0(\omega))$].

4. Let $t_M^- = j(M+1)$ and $t_M^+ = (j+1)(M+1)$. Since $[t_M^-, t_M^- + 1]$ is contained in the small noise interval, Lemma 2.4 asserts that

$$u_0 = S^{W,A}(t_M^- + 1, t_0)(u) \quad \text{and} \quad v_0 = S^{W,A}(t_M^- + 1, t_0)(v)$$

are Lipschitz continuous with Lipschitz constant $L = \widehat{L}(1,1)$.

Applying again Lemma 2.4, we find that the last statement holds on the entire interval $[t_M^- + 1, (t_M^- + 1) + M]$, which has length M.

5. Using (3.2) and Lemma 3.2, we find

$$\begin{aligned}
&|||S^{W,A}(t_M^+, t_M^- + 1)(u_0) - S^{W,A}(t_M^+, t_M^- + 1)(v_0)||| \\
&\quad \leq |||S^{W,A}(t_M^+, t_M^- + 1)(u_0) - S^{0,A}(t_M^+, t_M^- + 1)(u_0)||| \\
&\qquad + |||S^{W,A}(t_M^+, t_M^- + 1)(v_0) - S^{0,A}(t_M^+, t_M^- + 1)(v_0)||| \\
&\qquad + |||S^{0,A}(t_M^+, t_M^- + 1)(u_0) - U_A^*||| + |||S^{0,A}(t_M^+, t_M^- + 1)(v_0) - U_A^*||| \\
&\quad \leq 4(\delta/4).
\end{aligned}$$

The contraction property guarantees now that the estimate holds for all later times $t > t_M^+$. ◻

Next we construct the global attracting solution u_{inv}^A.

LEMMA 3.7. *Fix $\omega \in \widetilde{\Omega}$. For all $u_0 \in C(T)$ and all $t \in \mathbb{R}$, the limit*

$$\widetilde{u}(\cdot, t) = \lim_{k\to\infty} S^{W,A}(t, -k)(u_0)(\cdot) \tag{3.3}$$

exists in $C(\mathbb{T})$ *and is unique up to constants. Moreover, for any* $t_1 < t_2$*, there exists* $c(t_1, t_2) \in \mathbb{R}$ *such that*

$$S^{W,A}(t_2, t_1)(\tilde{u}(t_1)) = \widetilde{u}(t_2) + c(t_2, t_1). \tag{3.4}$$

Proof. 1. Lemma 3.6 yields that the family $(u_k(\cdot, t))_{k\in\mathbb{N}}$ defined by

$$u_k(\cdot, k) = S^{W,A}(t, -k)(u_0)(\cdot)$$

is a Cauchy sequence with respect to the seminorm $|||\cdot|||$ for each fixed t. Therefore there exist constants $c_k(t)$ such that the sequence $u_k(\cdot, t) - c_k(t)$ converges in $C(\mathbb{T})$.

2. The identity (3.4) is a consequence of the C^0-continuity of the semigroup. ◻

We are now in a position to present the proof of Theorem 2.3.

Proof. In view of Lemma 3.6 and Lemma 3.7, it remains to show that there exists $c(t)$ such that the function $\tilde{v} = \tilde{u} - c$ satisfies, for all $t_1 < t_2$,

$$S^{W,A}(t_2, t_1)(\widetilde{v}(\cdot, t_1))(\cdot) = \widetilde{v}(\cdot, t_2).$$

Let $t_1 < t_2 < 0$. The semigroup property and (3.4) yield

$$S^{W,A}(0, t_1)(\widetilde{u}(\cdot, t_1)) = S^{W,A}(0, t_2)\left(\widetilde{u}(\cdot, t_2) + c(t_2, t_1)\right).$$

It follows that

$$c(t_2, t_1) = c(0, t_1) - c(0, t_2).$$

Similar expressions for $t_2 < 0 < t_1$ and $t_2,\ t_1 > 0$ yield the existence of a solution on $(-\infty, \infty)$ by setting

$$u_{inv}(x, t) = \widetilde{u}(x, t) + c(t),\ \ c(t) = c(\max\{t, 0\}, \min\{t, 0\}). \qquad ◻$$

4. The proof of the Lipschitz bounds. The proof of Lemma 2.4 is long and technical. To simplify the presentation, we divide it into a number of lemmas.

We remind the reader that the sole purpose of assumptions (2.8) and (2.9) is to ensure that the Hamiltonian in (2.1), which arises after incorporating the noise, still satisfies the growth assumptions (2.3), (2.4), (2.5) in the nonviscous case and (2.3) and (2.6), (2.7) in the viscous case, with constants depending on the noise only through the expression in (2.11). Therefore, we will usually omit the dependence of the Hamiltonian in (2.1) on t and ω, thus keeping the notation simple.

The first step towards the universal Lipschitz bound is a universal L^∞-bound for nonnegative solutions. This is the object of the following lemma.

LEMMA 4.1. *Fix* $\omega \in \Omega_C$*,* $u_0 \in C(\mathbb{T})$*, and* $s \in \mathbb{R}$ *and assume* (2.3) *and* $A \equiv 0$*. Let* u *be the solution of* (2.1) *on* $\mathbb{R} \times [s, T]$ *with* $u(\cdot, s) = u_0$*. For all* $t \geq s$*, there exists a positive constant* $C(s, t, \omega)$*, which is independent of the initial datum* u_0 *and depends on* ω *only through the expression in* (2.11)*, such that*

$$\|u(\cdot, t) - \min u_0\| \leq C(s, t, \omega).$$

Proof. 1. If H satisfies (2.3), a straightforward calculation yields that so does $\bar{H}(p, x, t) = H(p + DW(x, t, s, \omega), x)$ with a constant depending on $\|W\|_{C^\infty(\mathbb{T}\times[0,T])}$.

Without loss of generality, we may assume that $u_0(0) = \min_{\mathbb{T}} u_0 = 0$ and $s = 0$. The extension to the general case is straightforward.

2. For sufficiently large $C = C(K) > 0$, the function

$$g(x,t) = C|x|^{q/(q-1)} t^{-1/(q-1)} + Kt + 1$$

is a supersolution of (2.1).

Indeed, for C large,

$$\begin{aligned} &-C(q-1)^{-1}(|x|t^{-1})^{q/q-1} + K + H(Cq(q-1)^{-1}(|x|t^{-1})^{1/q-1}D|x|, x) \\ &\quad \geq C(q-1)^{-1}(|x|t^{-1})^{q/q-1}(K^{-1}q(qC)^{q-1}(q-1)^{1-q} - 1) - K + K \geq 0. \end{aligned}$$

For t small enough we clearly have $g(\cdot,t) \geq u(\cdot,t)$. Since the infimum of a family of supersolutions is also a supersolution, it follows that

$$\bar{g}(x,t) = \inf_{z \in \mathbb{Z}^n} g(x - z, t)$$

is a periodic supersolution of (2.1). ◻

When $A \not\equiv 0$, a universal L^∞-bound for nonnegative solutions is available only for Hamiltonians H with superquadratic growth in p. Indeed, we have the following.

Lemma 4.2. *Fix $\omega \in \Omega_C$ and $u_0 \in C(\mathbb{T})$ and assume that* (2.3) *holds with $q > 2$. Let u solve* (2.1) *on $\mathbb{R}^n \times [s,T]$ with $u(\cdot,s) = u_0$. For $(s,t) \in \Delta$ there exists a constant $C(s,t,\omega)$, independent of the initial datum and depending on ω only via* (2.11)*, such that*

$$\|u(\cdot,t) - \min u_0\| \leq C(s,t,\omega).$$

Before we present the proof, we remark that it is not expected, as follows from the discussion below, to have a universal bound on the L^∞-norm for nonnegative solutions of the viscous Hamilton–Jacobi equations with quadratic or subquadratic growth H. Indeed, for $c > 0$, consider the function $u_c : \mathbb{R}^n \times [0,T] \to \mathbb{R}$ defined by

$$u_c(x,t) = \frac{n}{2}\ln(t+c) + (4(t+c))^{-1}|x|^2 - \frac{n}{2}\ln(c),$$

which is an exact nonnegative solution to

$$u_t - \Delta u + |Du|^2 = 0.$$

It is immediate that, for each $c > 0$, $\min u_c(x,0) = 0$, $u_c(\cdot,t) \geq 0$ for all $t \geq 0$ and $\lim_{c\to 0} u_c(x,1) = +\infty$. However, the oscillation of $u_c(x,1)$ on each bounded subset of $\mathbb{R}^n$ is bounded uniformly in c.

The above solutions were obtained by applying the Hopf–Cole transform to fundamental solutions of the heat equation at time $t + c$. By applying the Hopf–Cole transformation to periodic solutions of the heat equation, it is possible to construct counterexamples in the periodic case in a similar way.

Now we prove Lemma 4.2.

Proof. 1. To simplify the presentation, we assume throughout the proof that $s = 0$ and write u_0 for $u(\cdot,0)$. Finally, as before, we assume that $\min u_0 = 0$.

2. Let

$$\beta = q - 2 > 0, \quad \gamma = (1-\theta)(q-2)(q-1)^{-1}, \quad \text{and} \quad \alpha = \gamma - 1 + 2\theta,$$

where $\theta \in (0, 2^{-1})$ is chosen so that $\alpha > 0$.

3. For $a, b > 0$ consider the function $G_{a,b} : \mathbb{R}^n \times (0,\infty) \to \mathbb{R}$ given by

$$G_{a,b}(x,t) = Kt + 2b \max_{\mathbb{T}} \operatorname{tr}(A) t^{\gamma} + at^{\alpha} + b\gamma|x|^2 t^{\gamma-1}.$$

It is immediate that for any $x \neq 0$, $\lim_{t\to 0} G_{a,b}(x,t) = +\infty$. Hence, for t small,

$$G_{a,b} \geq u_0.$$

4. The constants a, b may be chosen so that $G_{a,b}$ is a supersolution of (2.1). Indeed, since $D^2|x|^2 = 2I$, it remains to show only that

$$R_{a,b}(x,t) = a\alpha t^{\alpha-1} + |x|^2 t^{\gamma-2}\big(K^{-1}(2b\gamma)^q (|x|t^{-\theta})^{q-2} - \gamma(1-\gamma)b\big) > 0.$$

If $|x| \geqq t^{\theta}$, it is possible to find b, depending on q, θ, and K but not on a, so that $R_{a,b} > 0$.

If $|x| \leq t^{\theta}$, it is possible to choose a so that

$$R_{a,b}(x,t) \geq (a\alpha - \gamma(1-\gamma)b)t^{\alpha-1} > 0.$$

5. A periodic supersolution can be constructed as the infimum of supersolutions exactly as in the first-order case. $\square$

We remark that since

$$\inf_{\mathbb{T}} u(t,\cdot) \geq -Kt + \inf_{\mathbb{T}} u(0,\cdot)$$

and the equations commute with constants, Lemmas 4.1 and 4.2 yield automatically a bound on the oscillation

$$\operatorname{osc}(u(\cdot,t)) = \sup_{\mathbb{T}} u(\cdot,t) - \inf_{\mathbb{T}} u(\cdot,t).$$

Thus a bound on the oscillation is a weaker statement than the bounds on the L^{∞}-norm of nonnegative solutions asserted by the previous lemmas. We summarize these comments in the following corollary.

COROLLARY 4.3. *Fix $\omega \in \Omega_C$. Under the assumptions of either Lemma* 4.1 *or Lemma* 4.2*, there exists a positive constant $C(s,t,\omega)$, depending on ω only through $C_W(s,t,\omega)$ as in* (2.11)*, such that for all $(s,t) \in \Delta$ and $u_0 \in C(\mathbb{T})$,*

$$\operatorname{osc}(S^{W,A}(t,s)) \leq C(s,t,\omega).$$

The following lemma completes the proof of Lemma 2.4 in the first-order case.

LEMMA 4.4. *If* (2.4), (2.5), *and* (2.8) *hold and u solves* (1.1) *on $\mathbb{R}^n \times [s,T]$ with $A \equiv 0$, then for all $t \in [s,T]$, $u(\cdot,t)$ is Lipschitz continuous with a Lipschitz constant bounded by $L(s,t,\omega)$, which is nonincreasing for $s < t < s+1$ and depends only on* (2.11)*, H, and $\sup_{t'\in[s,T]} \|u(\cdot,t')\|$.*

Proof. 1. For almost all ω, there exists a $K(t,s,\omega) > 0$ such that if $|p| > K(t,s,\omega)$, there exist $B, R_0 > 0$ such that

$$\widetilde{H}(p,x,t,\omega) = H(p + DW(x,t,s,\omega), x)$$

satisfies (2.4) and (2.5) for fixed ω uniformly in $t \in [s,T]$. Again this is the place where (2.8) is used. In order to simplify notation, next we suppress the dependence of $\tilde{H}$ on t, s, and ω and write simply $\widetilde{H}(p,x)$. Finally, we choose $s = 0$.

2. Following [CLS] (note that (2.4) and (2.5) are (G2) and (3.2) in [CLS]), we consider the solution φ of

$$\varphi'(t) = \varphi(t)\Phi(\varphi(t)^{-1}), \tag{4.1}$$

where Φ is the increasing function in (2.4).

3. For $\lambda > 0$ let

$$z(x,t) = -\varphi(t)e^{-\lambda u(x,t)}.$$

It follows that

$$z_t - G(Dz, z, x) - \varphi'\varphi^{-1}z = 0,$$

where

$$G(p,z,x) = (\lambda z)\widetilde{H}(-(\lambda z)^{-1}p, x).$$

Note that if $q = -(\lambda z)^{-1}p$, then

$$D_z G(p,z,x) = \lambda\big(\widetilde{H}(q,x) - qD_p\widetilde{H}(q,x)\big)$$

and

$$D_x G(p,z,x) = \lambda z D_x\widetilde{H}(q,x) = -|p|\,|q|^{-1}D_x\widetilde{H}(q,x).$$

4. If, for some $C > 0$,

$$w(x,y,t) = z(x,t) - z(y,t) - C|x-y|$$

has a positive maximum M at (x_0, y_0, t_0), then in particular $x_0 \neq y_0$, so $|x-y|$ is smooth in a neighborhood of (x_0,y_0,t_0).

Using the definition of the viscosity solutions with $p = C(x_0 - y_0)|x_0 - y_0|^{-1}$ and noting that $p = C\hat{p}$, we find

$$\begin{aligned} 0 &\leq G(p, z(x_0,t_0), x_0) - G(p, z(y_0,t_0), y_0) + \varphi'(\varphi^{-1})(t_0)(z(x_0,t_0) - z(y_0,t_0)) \\ &= \int_0^1 [|x_0 - y_0|\hat{p}\cdot D_x G(p, z(r), x(r)) + D_z G(p, z(r), x(r))(z(x_0,t_0) - z(y_0,t_0))]\mathrm{d}r \\ &\quad + \varphi'(\varphi^{-1})(t_0)\big(z(x_0,t_0) - z(y_0,t_0)\big), \end{aligned}$$

where

$$q(r) = -(\lambda z(r))^{-1}p, \quad x(r) = y_0 + r(x_0 - y_0), \quad z(r) = z(y_0,t_0) + r(z(x_0,t_0) - z(y_0,t_0)).$$

Hence

$$\begin{aligned} 0 \leq &\int_0^1 \Big(-C|q(r)|^{-1}|x_0 - y_0|\hat{q}(r)\cdot D_x\widetilde{H}\big(q(r), x(r)\big)\Big)\mathrm{d}r \\ &+ \varphi'(\varphi^{-1})(t_0)\big(z(x_0,t_0) - z(y_0,t_0)\big) \\ &- \lambda\big(z(x_0,t_0) - z(y_0,t_0)\big)\int_0^1 \big(q(r)\cdot D_q\widetilde{H}(q(r), x(r)) - \widetilde{H}(q(r), x(r))\big)\mathrm{d}r. \end{aligned}$$

Assume next that C is such that

$$C \geq \lambda \sup_{\mathbb{T}} |z| R_0 \geq \lambda \varphi e^{\|u^-\|} R_0,$$

so that $|q| \geq R_0$ and, hence, $D_q\widetilde{H} \cdot q - \widetilde{H} \geqq 0$, and recall that $\varphi'(\varphi)^{-1} \geqq 0$.

Since by assumption

$$z(x_0, t_0) - z(y_0, t_0) \geq C|x_0 - y_0|,$$

there exists, in view of (2.5), a constant $B > 0$ such that

$$0 \leq \left(\int_0^1 (B - \lambda) g(r) \mathrm{d}r + \varphi'(t_0)(\varphi(t_0))^{-1} \right) \left(z(x_0, t_0) - z(y_0, t_0) \right),$$

where

$$g(r) = q(r) \cdot D_q\widetilde{H}(q(r), x(r)) - \widetilde{H}(q(r), x(r)).$$

Choosing $\lambda = B + 1$ and using (2.4) and (4.1), we find

$$0 \leq (z(x_0, t_0) - z(y_0, t_0)) \int_0^1 [\Phi(\varphi^{-1}(t_0)) - \Phi(|q(r)|)] \mathrm{d}r.$$

Recalling that $|q| = Ce^{\lambda u}(\lambda\varphi)^{-1}$ and that Φ is strictly increasing, we obtain, for $C > \lambda e^{\lambda \|u^-\|_\infty}$, the desired contradiction. ◻

We continue with the Lipschitz bound in the second-order case. Here we argue using the classical Bernstein method, which yields a universal Lipschitz bound depending only on the oscillation of the initial datum.

In the subquadratic but superlinear case, we will use this bound iteratively to obtain a bound for the oscillation which is independent of the initial datum (see Lemma 4.7). Of course, for a superquadratic Hamiltonian, the oscillation is easily bounded by Lemma 4.2, so the Lipschitz bound follows directly from Lemma 4.5.

To this end, let $\varphi : [s, T] \to [0, \infty)$ be a solution of the ordinary differential inequality

$$\varphi_t \leq \min(\varphi^{1/2}, 1), \quad \varphi(s) = 0. \tag{4.2}$$

LEMMA 4.5. *Let u solve* (2.1) *on $\mathbb{T} \times [s, T]$ and assume that*

$$\tilde{H}(p, x, t, s, \omega) = H(p + DW(x, t, s, \omega), x) - \operatorname{tr}\left(A(x) D^2 W(x, t, s, \omega)\right)$$

satisfies (2.3), (2.6), *and* (2.7) *on* $[s, T]$. *There exist $\kappa \in [0, 1)$ and $C_{R_0} > 0$, both independent of the initial datum $u(\cdot, s)$, such that for all $t \in [s, T]$,*

$$\|Du(\cdot, t)\| \leq \varphi(t)^{-1/2} C_{R_0} (1 + \operatorname{osc}(u(\cdot, s))^\kappa). \tag{4.3}$$

The fact that $\kappa < 1$ is very critical, since it implies that even if the oscillation is large initially, it will be much smaller at the end of the time interval. It follows from the proof that for δ as in (2.6), $\kappa(\delta) \to 1$ as $\delta \to 0$. Therefore the method does not apply to Hamiltonians with just linear growth.

Further, notice that the constants in (2.3), (2.6), and (2.7) depend on the realization of the noise in a given time interval, but only through (2.11), so they are bounded if the interval is a small noise interval.

Finally, we remark that it is straightforward to check that the particular equation

$$u_t - \epsilon\Delta u + |Du + DW(x,t,s,\omega)|^2 = 0$$

satisfies the conditions of Lemma 4.5.

For the proof of Lemma 4.5 we need a rough a priori bound on the oscillation. To this end, let

$$L(\omega) = \sup_{(x,y,t)\,\in\,\mathbb{R}^n\times\mathbb{R}^n\times[s,T]} |H(DW(x,t,s,\omega),x) - H(DW(y,t,s,\omega),y)|.$$

Note that the dependence on ω is through (2.11).

LEMMA 4.6. *For all $(s,t)\in\Delta$, we have*

$$\operatorname{osc}(u(\cdot,t)) \le \operatorname{osc}(u(\cdot,s)) + L|t-s|.$$

Proof. The estimate follows directly from the fact that

$$\operatorname{osc}(u(\cdot,t))_t = \left(\sup_{\mathbb{T}} u(\cdot,t) - \inf_{\mathbb{T}} u(\cdot,t)\right)_t \le L. \qquad \square$$

We continue with the proof of Lemma 4.5, which uses some of the techniques of [CLS].

Proof. 1. To simplify things we assume that $s=0$. The functions $v(\cdot,t) = u(\cdot,t)+Kt$ and $u(\cdot,t)$ have the same Lipschitz constant and v solves an equation with a nonnegative Hamiltonian. We may therefore assume that the Hamiltonian is nonnegative, i.e., $K=0$. Moreover, to simplify the presentation, we drop the dependence on ω and write $\tilde{H}(p,x,t)$ instead of $\tilde{H}(p,x,t,0,\omega)$. Finally, we write

$$O_0 = \operatorname{osc}(u(\cdot,0)).$$

2. Let $m(t)$ and $x_m(t)$ denote, respectively, the maximum of the function $u(\cdot,t)$ and the point where the maximum is assumed, i.e., for all $x\in\mathbb{T}$,

$$m(t) = u(x_m(t),t) \ge u(x,t).$$

Then

$$|u(x,t)-m(t)| \le \operatorname{osc}(u(\cdot,t)) \le \operatorname{diam}(\mathbb{T})\|Du(\cdot,t)\|.$$

Since $\tilde{H}\ge 0$, we know that

$$m_t(t) = u_t(x_m(t),t) = [\operatorname{tr}(A(x_m(t))D^2u(x_m(t),t)) - \tilde{H}(0,x_m(t),t)] \le 0.$$

3. For $\lambda>0$ consider the function

$$z(x,t) = \varphi(t)|Du(x,t)|^2 + \lambda(m(t)-u(x,t)).$$

Let (x_0,t_0) be a point where z achieves its maximum. The goal is to show that there exist $\lambda>0$ such that either $t_0=0$ or $|Du(x_0,t_0)|\le R_0$.

In order to keep the presentation simple, in what follows we assume that A is the identity matrix. The modifications needed for general A are straightforward, so we omit them.

4. If either $t_0 = 0$ or $|Du(x_0, t_0)| \leq R_0$, then

$$z(x,t) \leq R_0^2 + \lambda(O_0 + LT).$$

Hence, for all $(x,t) \in \mathbb{T} \times [0,T]$,

$$\varphi(t)|Du(x,t)|^2 \leq R_0^2 + \lambda(O_0 + LT) + \lambda(u(x,t) - m(t)) \leq R_0^2 + \lambda(O_0 + LT).$$

Assume that

$$O_0 \geq 1 + LT.$$

It then follows that for all $(x,t) \in \mathbb{T} \times [0,T]$,

$$\varphi(t)^{1/2}|Du(x,t)| \leq (R_0^2 + \lambda(O_0 + LT))^{1/2} \leq (R_0^2 + 2\lambda O_0)^{1/2}.$$

Since R_0 is given, we may assume that $\lambda \geq R_0$. The above estimate then can be simplified to read

$$\|Du(\cdot,t)\| \leq C\,\lambda\varphi(t)^{-1/2}(1 + \left(O_0\lambda^{-1}\right)^{1/2}). \tag{4.4}$$

5. Assume that $t_0 > 0$ and $|Du(t_0, x_0)| > R_0$. The classical calculations associated with Bernstein's method then yield the following sequence of inequalities, where C is the constant in (2.7) and where z and $\tilde{H}$ are evaluated at (x_0, t_0) and $(Du(x_0,t_0), x_0, t_0)$:

$$\begin{aligned}
0 &\leq z_t - \Delta z = \lambda m_t - \lambda(u_t - \Delta u) \\
&\quad + 2\varphi Du \cdot D(u_t - \Delta u) - 2\varphi|D^2u|^2 + \varphi_t|Du|^2 \\
&\leq \lambda\tilde{H} - 2\varphi Du \cdot D\tilde{H} - 2\varphi|D^2u|^2 + \varphi_t|Du|^2 \\
&\leq \lambda\tilde{H} - \lambda Du \cdot D_p\tilde{H} - 2\varphi Du \cdot D_x\tilde{H} + \varphi_t|Du|^2 \\
&\leq -(\lambda - C)\Phi(|Du|) + \varphi_t|Du|^2.
\end{aligned}$$

If $3\lambda \geq 4C$, then

$$0 \leq -\lambda\Phi(|\operatorname{grad} u|) + 4\varphi_t|\operatorname{grad} u|^2.$$

Dividing by $|Du|^{1+\delta}$, we obtain, always at (x_0, t_0),

$$0 \leq -\lambda G(|Du|) + 4\varphi_t|Du|^{1-\delta}.$$

Consider the set

$$D_{R_0} = \{(x,t) \in \mathbb{T} \times [0,T] \ : \ |\operatorname{grad} u(x,t)| \geq R_0\}$$

and let

$$\lambda_0 = \sup_{(x,t) \in D_{R_0}} 4\varphi_t(t)G(|Du(x,t)|)^{-1}|Du(x,t)|^{1-\delta}. \tag{4.5}$$

If we choose $\lambda > \lambda_0$, then it is impossible for the Bernstein function z to have an interior maximum, unless at the maximum we have $|Du| \leq R_0$, in which case (4.4) holds. It remains to show that λ_0 depends only on the data.

6. Let $(\bar{x}, \bar{t})$ be such that

$$\lambda_0 = 4\phi_t(\bar{t})(G(|Du(\bar{x}, \bar{t})|))^{-1}|Du(\bar{x}, \bar{t})|^{1-\delta}.$$

If such $(\bar{x}, \bar{t})$ does not exist, we argue using approximate maximizers—we leave the details to the reader. Moreover, since $\phi_t(0) = 0$, if $\lambda_0 > 0$, then $\bar{t} > 0$.

Choose $\lambda \in (\lambda_0, 2\lambda_0)$. Using (4.4) and (4.5), we find, for some universal constant $C > 0$, which is independent of λ and the initial datum, that

$$|Du(\bar{x}, \bar{t})| \leq C\, \varphi_t(\bar{t})(G(|Du(\bar{x}, \bar{t})|)\varphi(\bar{t}))^{-1/2}|Du(\bar{x}, \bar{t})|^{1-\delta}(1 + (O_0\lambda^{-1})^{1/2}).$$

Note that since $G(|Du(\bar{x}, \bar{t})|) \geq G(R_0)$ and $\varphi_t \leq \varphi^{1/2}$,

$$|Du(\bar{x}, \bar{t})|^{\delta} \leq C(1 + (O_0\lambda^{-1})^{1/2}).$$

Inserting the above in (4.5) and using (4.2) yield, for a different universal constant C,

$$\lambda_0 \leq C(1 + (O_0\lambda^{-1})^{1/2})^{(1-\delta)/\delta} \leq 2^{(1-\delta)/\delta}C(1 + (O_0{\lambda_0}^{-1})^{(1-\delta)/2\delta}).$$

7. We may assume that

$$2^{(1-\delta)/\delta+1}C \leq \lambda_0,$$

and hence

$$\lambda_0 \leq C(O_0{\lambda_0}^{-1})^{(1-\delta)/2\delta},$$

which implies

$$\lambda_0 \leq CO_0^{(1-\delta)(1+\delta)^{-1}}.$$

It follows that there exists $\rho \in (0, 1)$, independent of the initial condition, such that

$$\lambda_0 \leq CO_0^{1-\rho}.$$

Inserting a λ with $\lambda \in (\lambda_0, 2\lambda_0)$ in (4.4) yields (4.3). $\square$

We conclude with a lemma which provides a universal bound on the oscillation via a bootstrap procedure.

LEMMA 4.7. *Assume the hypotheses of Lemma* 4.5. *There exists a universal constant C, which is independent of the initial datum, such that, after time $T = 1$, the oscillation of u is bounded by C.*

Proof. 1. Since we may assume that $\varphi(t) \geq t^{\beta}$ for some $\beta > 0$, we find that if $\mathrm{osc}(u(\cdot, 0))$ is sufficiently large, then Lemma 4.5 asserts the existence of $\hat{\kappa} \in (0, 1)$ and $C > 1$ such that, after a time interval of length τ,

$$\mathrm{osc}(u(\cdot, t + \tau)) \leq C\tau^{-\beta}(\mathrm{osc}(u(\cdot, t)))^{\hat{\kappa}}.$$

If the oscillation at some time is already bounded by a power of the universal constant C, there is nothing to prove. Therefore we assume that

$$\text{if } \hat{C} = C^{2(1-\hat{\kappa})^{-1}}, \ \text{ then } \ \mathrm{osc}(u) \geq \widehat{C}.$$

If $2\kappa = (1+\hat{\kappa}) < 2$, we obtain the simpler recursion

$$\operatorname{osc}(u(\cdot, t+\tau)) \le \tau^{-\beta}(\operatorname{osc}(u(\cdot, t)))^{\kappa}.$$

2. Choose a sufficiently small $\beta_1 > 0$, let $\bar{\kappa} = \beta\beta_1 + \kappa < 1$, and consider the recursively defined sequences

$$O_l = O_{l-1}^{\bar{\kappa}} \quad \text{and} \quad \tau_l = O_{l-1}^{-\beta_1}.$$

If the numbers O_l are given by $O_l = O_0^{(\bar{\kappa})^l}$, it follows that

$$\operatorname{osc}\left(u\left(\cdot, \sum_{i=0}^{l} \tau_i\right)\right) \le \max(\widehat{C}, O_l).$$

3. Let l_M be the smallest integer such that $O_{l_M} \le 2\widehat{C}$. Then

$$O_{l_M-1} = O_0^{\bar{\kappa}^{(l_M-1)}} \ge 2\widehat{C} \quad \text{and} \quad O_{l_M} \ge (2\widehat{C})^{\bar{\kappa}}.$$

Recall that O_0 and l_M are sufficiently large, β_1 is sufficiently small, $0 \le l \le l_M$, and define

$$s_l = B^{(\bar{\kappa})^{-l}} \quad \text{and} \quad B = (O_{l_M})^{-\beta_1}.$$

We have

$$\sum_{l=0}^{l_M} \tau_l = \sum_{l=0}^{l_M} (O_0^{-\beta_1})^{(\bar{\kappa})^{l-l_M+l_M}} = \sum_{l=0}^{l_M} ((O_0^{-\beta_1})^{(\bar{\kappa}^{l_M})})^{(\bar{\kappa})^{l-l_M}} = \sum_{l=0}^{l_M} s_l,$$

and, since $\bar{\kappa} < 1$,

$$(\bar{\kappa})^{-l}((\bar{\kappa})^{-1} - 1) \ge r(\bar{\kappa}) = (\bar{\kappa})^{-1}((\bar{\kappa})^{-1} - 1) > 0.$$

Moreover

$$B = (O_{l_M})^{-\beta_1} \le (2\widehat{C})^{-\bar{\kappa}\beta_1} < 1.$$

Therefore

$$s_{l+1}{s_l}^{-1} = B^{(\bar{\kappa})^{-(l+1)} - (\bar{\kappa})^{-l}} \le B^{r(\bar{\kappa})} < 1.$$

Thus the series $\sum \tau_l$ converges by comparison with the geometric series. Note that the powers β_1, κ are independent of the length of the a priori chosen time interval. ∎

GLOBAL EXISTENCE OF CLASSICAL SOLUTIONS FOR THE TWO-DIMENSIONAL OLDROYD MODEL VIA THE INCOMPRESSIBLE LIMIT*

ZHEN LEI† AND YI ZHOU‡

Abstract. In this paper, we will study the Oldroyd model describing fluids with viscoelastic properties. Global classical solutions for the two-dimensional incompressible Oldroyd model with small initial displacements are shown to exist via the incompressible limit. The main difficulty is the lack of the damping mechanism on the deformation tensor.

Key words. incompressible limit, global existence, Oldroyd model

AMS subject classifications. 76A05, 76D03

DOI. 10.1137/040618813

1. Introduction. In the context of hydrodynamics, the motion of the fluid flow is classically described by a time-dependent family of orientation preserving diffeomorphisms $x(t, X)$, $0 \le t < T$. Material points X in the reference configuration are deformed to the spatial position $x(t, X)$ at time t. The deformation tensor F is defined as

$$F(t, X) = \frac{\partial x}{\partial X}(t, X).$$

When we work in the Eulerian coordinate, we define $H(t, x)$ such that $H(t, x(t, X)) = F(t, X)$. With no ambiguity, we will not distinguish these two notations and always use the notation F in this paper.

Applying the chain rule, we see that $F(t, x)$ satisfies the following transport equation (see [17], for example):

$$\partial_t F + u \cdot \nabla F = \nabla u F,$$

which stands for $\partial_t F_{ij} + u \cdot \nabla F_{ij} = \partial_k u_i F_{kj}$. We point out that in this paper we will use the notation $F_{ij} = \frac{\partial x_i}{\partial X_j}$, $(\nabla \cdot F)_i = \partial_j F_{ij}$, and $(\nabla u)_{ij} = \frac{\partial u_i}{\partial x_j}$, and summation over repeated indices will always be understood.

The nonlinear viscoelastic fluid system of the compressible Oldroyd model takes the following form:

$$(1.1) \qquad \begin{cases} \partial_t \rho + u \cdot \nabla \rho + \rho \nabla \cdot u = 0, \\ \partial_t u + u \cdot \nabla u + \lambda^2 \frac{p'(\rho)}{\rho} \nabla \rho = \frac{\mu}{\rho}(\Delta u + \nabla(\nabla \cdot u)) + \frac{1}{\rho} \nabla \cdot (\rho F F^T), \\ \partial_t F + u \cdot \nabla F = \nabla u F, \end{cases}$$

where ρ is the density, u is the fluid velocity, $p(\rho)$ is a given equation of state independent of the large parameter λ with $p'(\rho) > 0$ for $\rho > 0$, and F is the deformation tensor introduced above. We emphasize that the solutions will depend on the value of the parameter λ; however, with the exception of the statements of the main theorems, the dependence will not be displayed for reasons of notational convenience.

On the other hand, the nonlinear viscoelastic fluid system of the incompressible Oldroyd model is a distinctly different system of the unknowns (u, F, q) given by

$$\begin{cases} \nabla \cdot u = 0, \\ \partial_t u + u \cdot \nabla u + \nabla q = \mu \Delta u + \nabla \cdot (FF^T), \\ \partial_t F + u \cdot \nabla F = \nabla u F, \end{cases} \tag{1.2}$$

where the density in the undeformed reference configuration has been set equal to one. The scalar pressure q, the deformation tensor F, and the fluid velocity u must be determined with u satisfying the constraint $\nabla \cdot u = 0$. For more details, one should see [14, 15].

One expects, under appropriate conditions on the initial data, that the solutions ρ^λ, $\lambda^2 \frac{1}{\rho^\lambda} \nabla p^\lambda$, u^λ, F^λ of the compressible system (1.1) converge to the solutions 1, ∇q, u, F of the incompressible system (1.2) as $\lambda \longrightarrow \infty$. It is well known that long time behavior of solutions to the viscoelastic equations depends on strong dispersive estimates [8, 9, 11, 20]. For the wave equation, the generalized energy method, based on the Lorentz invariance and global Sobolev inequalities, provides an elegant and efficient means of combining energy and decay estimates; see [8, 9], for example. Recently Sideris and Thomases [21] studied an elastodynamic system which is not Lorentz invariant in three space dimensions via the incompressible limit through the use of weighted Sobolev inequalities involving the smaller number of generators (also in [3, 4]). Because of the presence of the damping term in the momentum equation, the Oldroyd model we study in this paper is neither Lorentz invariant nor scaling invariant; thus their methods do not work in our situation. In fact, the main difficulty for system (1.2) is the lack of the damping mechanism on F. This is different from the cases studied in [16], where the contribution of the strain rate in the constitutive equation is ignored, and in [2, 7, 13], where a linear damping term is present.

On the other hand, one can easily check the energy law

$$\frac{1}{2} \frac{d}{dt} \int_\Omega (|u|^2 + |F|^2) \, dx = -\mu \|\nabla u\|^2, \tag{1.3}$$

which gives the dissipation to the whole incompressible system. This is the reason that Lin, Liu, and Zhang can prove the global existence for small initial displacements in [15]. With the aid of the identities $\det\ F = 1$ and $\nabla \cdot F^T = 0$, they obtained the estimates of the linear terms by transforming them into nonlinear terms. Motivated by their ideas, we believe that local solutions of the compressible system (1.1) should be uniform stable and converge to a global solution of the limiting incompressible system (1.2).

In this paper, we first prove that classical local solutions of the equations of motion exist for sufficiently small disturbances from the general incompressible initial data. This result depends on a modified method of [10], where Klainerman and Majda developed a general theory to study the incompressible limit of compressible fluids in general framework of quasi-linear hyperbolic systems depending on a large parameter. Their method can also be extended to cover the viscous equations. But since the deformation tensor F in system (1.2) is not "fast scale" (in the sense of [10]), our system does not satisfy their structural conditions.

We also prove the uniform stability of the local existence family which yields a lifespan of the compressible system (1.1) and allows for convergence to a global solution of the limiting incompressible equations by means of compactness arguments. The strength of this convergence improves with the degree of incompressibility satisfied by the initial data.

It is well known that many fluids do not satisfy the Newtonian law. There have been many attempts to capture different phenomena for non-Newtonian fluids; see [5, 6, 12, 16, 18, 19], for example. The fluid of Oldroyd type is one of the classical non-Newtonian fluids with memory. When additional damping mechanisms are added, many mathematical results concerning these systems are proved [2, 7, 13, 16]. When the damping mechanism on the deformation tensor F is lost, recently Lin, Liu, and Zhang [15] proved the global existence of classical solutions for the two-dimensional incompressible Oldroyd model by introducing the induced stress to find the dissipation of the system. But it is of interest to see the incompressible system mathematically justified as a limit of the slightly compressible system. However, the two-dimensional inviscid case is still open.

The paper is organized as follows. In section 2, we state the main results of this paper. In section 3, we get the dispersive energy estimates since the local existence and the uniform stability estimates of the solutions of the compressible system (1.1) have been established in [13]. The dispersive energy estimates will allow us to take the limit to obtain a global solution to the incompressible Oldroyd system in section 4.

2. Statements of main results. To avoid complications at the boundary, we concentrate below on the periodic case where $x \in \mathsf{T}^2$, the two-dimensional torus. In fact the whole space problem and the Dirichlet problem of smooth bounded domain can also be treated, at the expense of complicating the proofs below. In the following, $\|\cdot\|$, $\|\cdot\|_s$, and $\|\cdot\|_\infty$ will denote the norms in $L^2(\mathsf{T}^2)$, $H^s(\mathsf{T}^2)$, and $L^\infty(\mathsf{T}^2)$, respectively.

Define

$$E_s(U(t)) = \|\lambda(\rho-1)\|_s^2 + \|u\|_s^2 + \|F-\overline{F}\|_s^2,$$

$$\widetilde{E}_s(U(t)) = \sum_{|\alpha|\le s}\int_{\mathsf{T}^2}\left(\lambda^2\frac{p'(\rho)}{\rho}|\nabla^\alpha(\rho-1)|^2 + \rho|\nabla^\alpha u|^2 + \rho|\nabla^\alpha(F-\overline{F})|^2\right)\,dx, \tag{2.1}$$

where $U(t) = (\rho,\ u,\ F)$ and $\overline{F}$ is a constant 2×2 matrix with $\det(\overline{F}) = 1$. It is obvious that if $|\rho-1|$ is small, we have

$$E_s(U(t)) \sim \widetilde{E}_s(U(t)). \tag{2.2}$$

THEOREM 2.1. *Consider the compressible Oldroyd model* (1.1) *with the following initial datum in* $H^{s+1}(\mathsf{T}^2)$ *(integer* $s\ge 4$*):*

$$\rho^\lambda(0,x) = 1 + \widetilde{\rho}_0^\lambda(x),\quad u^\lambda(0,x) = u_0(x) + \widetilde{u}_0^\lambda(x),\quad F^\lambda(0,x) = F_0(x) + \widetilde{F}_0^\lambda(x), \tag{2.3}$$

where $u_0(x)$, $F_0(x)$ *satisfy the incompressible constraints*

$$\nabla\cdot u_0 = 0,\quad \nabla\cdot F_0^T = 0,\quad \det F_0 = 1, \tag{2.4}$$

(where $\nabla \cdot F_0^T = 0$ *means* $\partial_j (F_0)_{ji} = 0,\ i = 1, 2,$ *as was pointed out before) and* $\widetilde{\rho}_0^\lambda(x),\ \widetilde{u}_0^\lambda(x),\ \widetilde{F}_0^\lambda(x)$ *are assumed to satisfy*

$$\|\widetilde{\rho}_0^\lambda(x)\|_s \le \delta_0/\lambda^2, \quad \|\widetilde{u}_0^\lambda(x)\|_{s+1} \le \delta_0/\lambda, \quad \|\widetilde{F}_0^\lambda(x)\|_s \le \delta_0/\lambda, \quad \delta_0 \ \ \textit{small}. \tag{2.5}$$

Then the following statements hold.

Uniform stability: There exist fixed constants T_0 *and* κ *independent of* λ *such that a unique classical* C^2 *solution* $(\rho^\lambda, u^\lambda, F^\lambda)$ *of the compressible Oldroyd system* (1.1) *exists for all large* λ *on the time interval* $[0, T_0]$*. Furthermore, the solution family satisfies*

$$E_s(U^\lambda(t)) + E_{s-1}(\partial_t U^\lambda(t)) + \mu \int_0^{T_0} (\|\nabla u^\lambda\|_s^2 + \|\nabla \partial_t u^\lambda\|_{s-1}^2)\ dt \le \kappa \tag{2.6}$$

for all $t \in [0, T_0]$*. Moreover, we have*

$$E_s(U^\lambda(t)) + \mu \int_0^{T_0} \|\nabla u^\lambda\|_s^2\ dt \le 4(\|u_0\|_s^2 + \|F_0 - \overline{F}\|_s^2), \tag{2.7}$$

provided λ *is appropriately large and* $t \in [0, T_0]$*.*

Local existence for incompressible system. There exist functions $u,\ F$ *with* $\|u\|_s + \|F\|_s \le \kappa,\ t \in [0, T_0]$*, such that*

$$\begin{cases} \rho^\lambda \longrightarrow 1 \ \ in \ \ L^\infty(0, T_0; H^s) \cap Lip([0, T_0], H^{s-1}), \\ (u^\lambda, F^\lambda) \longrightarrow (u, F) \ \ weakly^* \ \ in \ \ L^\infty(0, T_0; H^s) \cap Lip([0, T_0], H^{s-1}), \\ (u^\lambda, F^\lambda) \longrightarrow (u, F) \ \ in \ \ C([0, T_0], H^{s-\epsilon}), \end{cases} \tag{2.8}$$

where ϵ *is an arbitrarily small positive constant. The function* (u, F) *is a* C^2 *solution of equations of the incompressible Oldroyd type*

$$\begin{cases} \nabla \cdot u = 0, \\ P\{\partial_t u + u \cdot \nabla u - \mu \Delta u - \nabla \cdot (F F^T)\} = 0, \\ \partial_t F + u \cdot \nabla F = \nabla u F, \end{cases} \tag{2.9}$$

with the initial datum

$$u(0, x) = u_0(x), \qquad F(0, x) = F_0(x), \tag{2.10}$$

which satisfy the constraints (2.4)*, where* P *is the* L^2*-projection on the divergence-free vector fields.*

Remark 2.1. If we denote

$$\partial_t u + u \cdot \nabla u - \mu \Delta u - \nabla \cdot (F F^T) = \nabla q,$$

then we have

$$\frac{1}{\rho^\lambda} \lambda^2 \nabla p(\rho^\lambda) \longrightarrow \nabla q \ \ weakly^* \ in \ \ L^\infty(0, T_0; H^{s-2}) \cap L^2(0, T_0; H^{s-1})$$

which means that $\lambda^2 (\|\nabla \rho^\lambda\|_{s-2} + \int_0^t \|\nabla \rho^\lambda\|_{s-1}^2\ dt)$ is uniformly bounded in $t \in [0, T_0]$.

We can use the method originally for general quasi-linear hyperbolic systems and viscous equations developed by Klainerman and Majda [10] and modified for the case when the “slow scale” F has no damping mechanism (see [13]).

THEOREM 2.2. *Consider the solutions of the two-dimensional compressible Oldroyd model obtained in Theorem* 2.1. *Suppose that the initial datum additionally satisfies*

$$\|u_0\|_s + \|F_0 - \overline{F}\|_s < \varepsilon, \tag{2.11}$$

where ε *is a positive constant and*

$$\overline{F} = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}.$$

Suppose further that the disturbances from $(1,\ u_0,\ F_0)$ *satisfy* (2.5). *If* ε *is sufficiently small, then for every fixed* $\overline{T} > 0$, *the solution* $(\rho^\lambda,\ u^\lambda,\ F^\lambda)$ *satisfies the following estimates:*

$$\begin{aligned} &E_s(U^\lambda(t)) + \mu \int_0^t \|\nabla u^\lambda\|_s^2 \, dt \le C\varepsilon^2, \qquad t \in [0, T^\lambda), \\ &E_{s-1}(\partial_t U^\lambda(t)) + \mu \int_0^t \|\nabla \partial_t u^\lambda\|_{s-1}^2 \, dt \le C \exp Ct, \quad 0 \le t \le \overline{T}, \end{aligned} \tag{2.12}$$

where $T^\lambda > \overline{T}$ *and* $T^\lambda \longrightarrow \infty$ *as* $\lambda \longrightarrow \infty$.

We point out that the uniform bounds for the initial energy in (2.5) imply, in the limit as $\lambda \longrightarrow \infty$, that the initial deformation is driven toward incompressibility. Since the bounds on the energy from Theorem 2.2 are uniform in λ, we will be able to take the limit as λ goes to infinity to obtain a global solution to the equations of incompressible Oldroyd type (1.2).

THEOREM 2.3. *Consider the two-dimensional incompressible system of Oldroyd type* (1.2) *with the initial datum* (2.10) *which satisfies the constraints* (2.4) *and* (2.11). *Then there exists a unique global classical solution* (u, F) *which satisfies*

$$\|u\|_s + \|F - \overline{F}\|_s \le C\varepsilon, \tag{2.13}$$

provided ε *is sufficiently small.*

3. Dispersive energy estimates and proof of Theorem 2.2. In this section we will derive the dispersive energy estimates and prove Theorem 2.2. We refer the reader to [13] for the proof of Theorem 2.1. As a result, we have

$$\|\lambda(\rho^\lambda - 1)\|_s^2 + \|u^\lambda\|_s^2 + \|F^\lambda - \overline{F}\|_s^2 \le 4(\|u_0\|_s^2 + \|F_0 - \overline{F}\|_s^2) \le 4\varepsilon^2, \tag{3.1}$$

$$\begin{aligned} &\|\lambda \rho_t^\lambda\|_{s-1} + \|\lambda \nabla \cdot u^\lambda\|_{s-1} + \|\partial_t u^\lambda\|_{s-1} + \|\partial_t F^\lambda\|_{s-1} \\ &\qquad + |\lambda^2 \nabla \rho^\lambda\|_{s-2} + \int_0^t \|\lambda^2 \nabla \rho^\lambda\|_{s-1}^2 + \|\nabla \partial_t \dot{u}^\lambda\|_{s-1}^2 \, dt \le \kappa \end{aligned} \tag{3.2}$$

provided λ is appropriately large and $0 \le t \le T_0$. In fact, noting (2.6) and (2.7), we need only to check the bound of the term $\|\lambda \nabla \cdot u^\lambda\|_{s-1}$. We rewrite the first equation of (1.1) as

$$\nabla \cdot u^\lambda = \partial_t \rho^\lambda + u^\lambda \cdot \nabla(\rho^\lambda - 1) + (\rho^\lambda - 1)\nabla \cdot u^\lambda.$$

Thus by using the Sobolev imbedding and Lemma 3.2 below, we obtain

$$\begin{aligned}\|\lambda\nabla\cdot u^\lambda\|_{s-1} \le C(&\|\lambda\partial_t\rho^\lambda\|_{s-1} + \|\lambda(\rho^\lambda-1)\|_{s-1}\|\nabla\cdot u^\lambda\|_\infty\\ &+\|\nabla\cdot u^\lambda\|_{s-1}\|\lambda(\rho^\lambda-1)\|_\infty\\ &+\|\nabla(\rho^\lambda-1)\|_{s-1}\|u^\lambda\|_\infty + \|u^\lambda\|_{s-1}\|\nabla(\rho^\lambda-1)\|_\infty)\\ \le C(&\|\lambda\partial_t\rho^\lambda\|_{s-1} + \|\lambda(\rho^\lambda-1)\|_s),\end{aligned}$$

which gives the desired bound.

Before proving Theorem 2.2, we first show the following proposition, which is essential and will be used to get the dispersive energy estimates.

PROPOSITION 3.1. *If we set the density in the undeformed reference configuration equal to one, then we have*

$$\partial_j(\rho F_{ji}) = 0 \tag{3.3}$$

for $i = 1, 2$.

Proof. Noting the identity

$$\partial_{X_j}[(\det F)F^{-T}]_{ij} = 0, \qquad i = 1, 2,$$

we can use the conservation law of mass $\rho\cdot\det F = 1$ to get

$$\begin{aligned}\frac{1}{\rho}\nabla\cdot(\rho FF^T)_i &= \det F\frac{\partial X_k}{\partial x_j}\partial_{X_k}(\rho FF^T)_{ij}\\ &= \det F F^{-T}_{jk}\partial_{X_k}(\rho F_{il}F^T_{lj})\\ &= \partial_{X_k}(F^{-T}_{jk}F_{il}F^T_{lj})\\ &= \partial_{X_k}F_{ik}\\ &= F_{jk}\partial_j F_{ik},\end{aligned}$$

and hence

$$\partial_j(\rho F_{ji}) = 0$$

for $i = 1, 2$.

We are now ready to move to the proof of the main results of this section. As it is rather long, we divide it into four steps.

Proof of Theorem 2.2.

Step 1. Define

$$(\dot\rho, \dot u, \dot F) = (\rho - 1, u, F - \overline{F}). \tag{3.4}$$

One can rewrite system (1.1) as

$$\begin{cases}\partial_t\dot\rho + \dot u\cdot\nabla\dot\rho + \rho\nabla\cdot\dot u = 0,\\ \partial_t\dot u + \dot u\cdot\nabla\dot u + \lambda^2\frac{p'(\rho)}{\rho}\nabla\dot\rho = \frac{\mu}{\rho}(\Delta\dot u + \nabla(\nabla\cdot\dot u))\\ \qquad\qquad + \frac{1}{\rho}\nabla\cdot(\rho\dot F\dot F^T) + \frac{1}{\rho}\nabla\cdot(\rho\dot F\overline{F}^T + \rho\overline{F}\dot F^T),\\ \partial_t\dot F + \dot u\cdot\nabla\dot F = \nabla\dot u\dot F + \nabla\dot u\overline{F}.\end{cases} \tag{3.5}$$

We will use the so-called energy method. Let $U(t,x) = (\rho(t,x), u(t,x), F(t,x))$ be a local solution of the compressible Oldroyd model (1.1) obtained in Theorem 2.1. Start by applying the derivative D^α, $|\alpha| \le s$, to the system (3.5). We have

$$
\left\{
\begin{aligned}
&\partial_t D^\alpha \dot\rho + \dot u \cdot \nabla D^\alpha \dot\rho + \rho \nabla \cdot D^\alpha \dot u \\
&\qquad + [D^\alpha(\dot u \cdot \nabla \dot\rho) - \dot u \cdot \nabla D^\alpha \dot\rho] + [D^\alpha(\rho\nabla \cdot \dot u) - \rho \nabla \cdot D^\alpha \dot u] = 0,\\
&\partial_t D^\alpha \dot u + \dot u \cdot \nabla D^\alpha \dot u + \ \lambda^2 \tfrac{p'(\rho)}{\rho} \nabla D^\alpha \dot\rho \\
&\qquad - \ \tfrac{\mu}{\rho}(\Delta D^\alpha \dot u + \nabla\nabla\cdot D^\alpha \dot u) + [D^\alpha(\dot u \cdot \nabla \dot u) - \dot u \cdot \nabla D^\alpha \dot u]\\
&\qquad + \ \lambda^2[D^\alpha(\tfrac{p'(\rho)}{\rho}\nabla\dot\rho) - \tfrac{p'(\rho)}{\rho}\nabla D^\alpha \dot\rho]\\
&\quad = \tfrac{1}{\rho}\nabla\cdot D^\alpha(\rho \dot F \dot F^T) + \tfrac{1}{\rho}\nabla \cdot D^\alpha(\rho \dot F \overline{F}^T + \rho \overline{F}\dot F^T)\\
&\qquad + [D^\alpha(\tfrac{\mu}{\rho}(\Delta \dot u + \nabla\nabla\cdot \dot u)) - \tfrac{\mu}{\rho}(\Delta D^\alpha \dot u + \nabla\nabla\cdot D^\alpha \dot u)]\\
&\qquad + [D^\alpha(\tfrac{1}{\rho}\nabla\cdot(\rho\dot F\dot F^T)) - \ \tfrac{1}{\rho}\nabla\cdot D^\alpha(\rho \dot F \dot F^T)]\\
&\qquad + [D^\alpha(\tfrac{1}{\rho}\nabla\cdot(\rho \dot F\overline{F}^T + \rho\overline{F}\dot F^T)) - \tfrac{1}{\rho}\nabla\cdot D^\alpha(\rho\dot F\overline{F}^T + \rho \overline{F}\dot F^T)],\\
&\partial_t D^\alpha \dot F + \dot u \cdot \nabla D^\alpha \dot F + [D^\alpha(\dot u \cdot \nabla \dot F) - \dot u \cdot \nabla D^\alpha \dot F]\\
&\quad = \nabla D^\alpha \dot u \dot F + \nabla D^\alpha \dot u \overline{F} + [D^\alpha(\nabla \dot u \dot F) - \nabla D^\alpha \dot u \dot F].
\end{aligned}
\right. \tag{3.6}
$$

Next we proceed with the energy method by taking the L^2 inner product of (3.6) with $\lambda^2\frac{p'(\rho)}{\rho}D^\alpha\dot\rho$, $\rho D^\alpha \dot u$, and $\rho D^\alpha \dot F$, respectively. Then after integration by parts we obtain

$$
\frac{1}{2}\frac{d}{dt}\widetilde{E}(D^\alpha U(t)) + \mu(\|D^\alpha \nabla \dot u\|^2 + \|D^\alpha \nabla\cdot \dot u\|^2) = \sum_{1\le j\le 9} I_j, \tag{3.7}
$$

where

$$
I_1 = \frac{1}{2}\int_{\mathsf{T}^2}\left[\lambda^2 |D^\alpha\dot\rho|^2 \partial_t \frac{p'(\rho)}{\rho} + (|D^\alpha \dot u|^2 + |D^\alpha \dot F|^2)\partial_t \rho\right] dx, \tag{3.8}
$$

$$
I_2 = \frac{1}{2}\int_{\mathsf{T}^2}\left[\lambda^2 |D^\alpha\dot\rho|^2 \nabla\cdot\left(\frac{p'(\rho)}{\rho}\dot u\right) + (|D^\alpha \dot u|^2 + |D^\alpha \dot F|^2)\nabla\cdot(\rho \dot u)\right] dx, \tag{3.9}
$$

$$
I_3 = \lambda^2 \int_{\mathsf{T}^2} p''(\rho) D^\alpha \dot\rho D^\alpha \dot u \cdot \nabla \rho \, dx, \tag{3.10}
$$

$$
I_4 = \int_{\mathsf{T}^2}[D^\alpha \dot u_i \partial_j D^\alpha(\rho \dot F_{ik}\dot F_{jk}) + \rho D^\alpha \dot F_{ik}\partial_j D^\alpha u_i \dot F_{jk}] \, dx, \tag{3.11}
$$

$$
\begin{aligned}
I_5 = -\lambda^2 \int_{\mathsf{T}^2} &\frac{p'(\rho)}{\rho}\{[D^\alpha(\dot u \cdot \nabla\dot\rho) - \dot u \cdot \nabla D^\alpha \dot\rho] + [D^\alpha(\rho\nabla\cdot \dot u) - \rho\nabla\cdot D^\alpha \dot u]\}D^\alpha\dot\rho\\
&+ \rho\left[D^\alpha\left(\frac{p'(\rho)}{\rho}\nabla\dot\rho\right) - \frac{p'(\rho)}{\rho}\nabla D^\alpha\dot\rho\right]\cdot D^\alpha \dot u \, dx,
\end{aligned} \tag{3.12}
$$

$$
I_6 = -\int_{\mathsf{T}^2}\rho\{[D^\alpha(\dot u\cdot\nabla\dot u) - \dot u \cdot \nabla D^\alpha \dot u]\cdot D^\alpha \dot u + [D^\alpha(\dot u \cdot \nabla \dot F) - \dot u \cdot \nabla D^\alpha \dot F]_{ik} D^\alpha \dot F_{ik}\} \, dx, \tag{3.13}
$$

$$I_7 = \int_{\mathsf{T}^2} \rho \left[D^\alpha \left(\frac{\mu}{\rho}(\Delta \dot{u} + \nabla\nabla \cdot \dot{u}) \right) - \frac{\mu}{\rho}(\Delta D^\alpha \dot{u} + \nabla\nabla \cdot D^\alpha \dot{u}) \right] \cdot D^\alpha \dot{u}\ dx, \tag{3.14}$$

$$\begin{aligned} I_8 = \int_{\mathsf{T}^2} & \rho \left[D^\alpha \left(\frac{1}{\rho} \nabla \cdot (\rho \dot{F} \dot{F}^T) \right) - \frac{1}{\rho} \nabla \cdot D^\alpha (\rho \dot{F} \dot{F}^T) \right] \cdot D^\alpha \dot{u} \\ & + \rho \left[D^\alpha \left(\frac{1}{\rho} \nabla \cdot (\rho \dot{F} \overline{F}^T + \rho \overline{F} \dot{F}^T) \right) - \frac{1}{\rho} \nabla \cdot D^\alpha (\rho \dot{F} \overline{F}^T + \rho \overline{F} \dot{F}^T) \right] \\ & \cdot D^\alpha \dot{u} + \rho [D^\alpha (\nabla \dot{u} \dot{F}) - \nabla D^\alpha \dot{u} \dot{F}]_{ik} D^\alpha \dot{F}_{ik}\ dx, \end{aligned} \tag{3.15}$$

$$I_9 = \int_{\mathsf{T}^2} \nabla \cdot D^\alpha (\rho \dot{F} \overline{F}^T + \rho \overline{F} \dot{F}^T) D^\alpha \dot{u} + \rho \partial_j D^\alpha \dot{u}^i \overline{F}_{jk} D^\alpha \dot{F}_{ik}\ dx. \tag{3.16}$$

To estimate the quantities I_j, $1 \le j \le 9$, we need the following lemma.

LEMMA 3.2. *Assume $f,\ g \in H^s(\mathsf{T}^2)$. Then for any multi-index $\alpha = (\alpha_1, \dots, \alpha_n)$, $|\alpha| \le s$, we have*

$$\|\nabla^\alpha (fg)\| \le C(\|f\|_\infty \|\nabla^\alpha g\| + \|g\|_\infty \|\nabla^\alpha f\|),$$

$$\|\nabla^\alpha (fg) - f \nabla^\alpha g\| \le C(\|\nabla f\|_\infty \|g\|_{s-1} + \|g\|_\infty \|\nabla f\|_{s-1}).$$

LEMMA 3.3. *If $f : R^n \longrightarrow R$ is a smooth function, then for any positive integer s and constant $M > 0$, we have*

$$\|\nabla f(u)\|_{s-1} \le C \|\nabla u\|_{s-1}$$

for all $\|u\|_s \le M$, where C depends only on s, n, M, and f.

We refer the reader to [1, 10] for the proof of the above two lemmas. Now let us estimate the right side of (3.7) term by term.

By Sobolev imbedding,

$$\begin{aligned} |I_1| &\le C \|\partial_t \rho\|_\infty \int_{\mathsf{T}^2} [\lambda^2 |D^\alpha \dot{\rho}|^2 + |D^\alpha \dot{u}|^2 + |D^\alpha \dot{F}|^2]\ dx \\ &\le C\lambda^{-1} \|\lambda \partial_t \rho\|_{s-2} \int_{\mathsf{T}^2} [\lambda^2 |D^\alpha \dot{\rho}|^2 + |D^\alpha \dot{u}|^2 + |D^\alpha \dot{F}|^2]\ dx \\ &\le C\lambda^{-1} (\|\lambda D^\alpha \dot{\rho}\|^2 + \|D^\alpha \dot{u}\|^2 + \|D^\alpha \dot{F}\|^2). \end{aligned} \tag{3.17}$$

Similarly, we estimate I_2 and I_3 as follows:

$$\begin{aligned} |I_2| &\le C(\|\nabla \cdot \dot{u}\|_\infty + \|\nabla \dot{\rho}\|_\infty) \int_{\mathsf{T}^2} [\lambda^2 |D^\alpha \dot{\rho}|^2 + |D^\alpha \dot{u}|^2 + |D^\alpha \dot{F}|^2]\ dx \\ &\le C\lambda^{-1} (\|\lambda \nabla \dot{\rho}\|_{s-2} + \|\lambda \nabla \cdot \dot{u}\|_{s-2}) \int_{\mathsf{T}^2} [\lambda^2 |D^\alpha \dot{\rho}|^2 + |D^\alpha \dot{u}|^2 + |D^\alpha \dot{F}|^2]\ dx \\ &\le C\lambda^{-1} (\|\lambda D^\alpha \dot{\rho}\|^2 + \|D^\alpha \dot{u}\|^2 + \|D^\alpha \dot{F}\|^2), \end{aligned} \tag{3.18}$$

$$\begin{aligned} |I_3| &\le C\lambda^{-1} \|\lambda^2 \nabla \rho\|_{s-2} \int_{\mathsf{T}^2} |\lambda D^\alpha \dot{\rho}|^2 + |D^\alpha \dot{u}|^2\ dx \\ &\le C\lambda^{-1} (\|\lambda D^\alpha \dot{\rho}\|^2 + \|D^\alpha \dot{u}\|^2). \end{aligned} \tag{3.19}$$

Step 2. Estimates for I_k, with $k \geq 4$ when $D^\alpha = \nabla^\alpha$, $|\alpha| = s$ and $\alpha = 0$.

First, we let $D^\alpha = \nabla^\alpha,\ |\alpha| = s,\ s \geq 4$. We can use Lemma 3.2 and integration by parts to get

$$|I_4| \leq C\|\nabla \dot{u}\|_s \|\dot{F}\|_\infty \|\nabla^\alpha \dot{F}\| \leq C\varepsilon(\|\nabla \dot{u}\|_s^2 + \|\Delta \dot{F}\|_{s-2}^2). \tag{3.20}$$

We now use Lemmas 3.2 and 3.3 to estimate I_5 to I_8.

$$\begin{aligned} |I_5| \leq& C\lambda^{-1}\|\lambda\dot{\rho}\|_s[(\|\lambda^2\nabla\dot{\rho}\|_{s-1}\|\nabla\dot{u}\|_\infty + \|\lambda^2\nabla\dot{\rho}\|_\infty\|\nabla\dot{u}\|_{s-1}) \\ &\qquad\qquad + (\|\lambda\nabla\dot{\rho}\|_{s-1}\|\lambda\nabla\cdot\dot{u}\|_\infty + \|\lambda\nabla\dot{\rho}\|_\infty\|\lambda\nabla\dot{u}\|_{s-1})] \\ &+ C\lambda^{-1}\|\dot{u}\|_s\|\lambda^2\nabla\dot{\rho}\|_\infty\|\lambda\nabla\dot{\rho}\|_{s-1} \\ \leq& C\lambda^{-1}(\|\lambda^2\nabla\dot{\rho}\|_{s-1}^2 + \|\lambda\dot{\rho}\|_s^2 + \|\dot{u}\|_s^2). \end{aligned} \tag{3.21}$$

By a similar argument, we have

$$\begin{aligned} |I_6| &\leq C[\|\dot{u}\|_s\|\nabla\dot{u}\|_\infty\|\nabla\dot{u}\|_{s-1} + \|\nabla^\alpha\dot{F}\|(\|\nabla\dot{F}\|_\infty\|\nabla\dot{u}\|_{s-1} + \|\nabla\dot{F}\|_{s-1}\|\nabla\dot{u}\|_\infty)] \\ &\leq C\varepsilon(\|\nabla\dot{u}\|^2 + \|\nabla\dot{u}\|_s^2 + \|\Delta\dot{F}\|_{s-2}^2), \end{aligned} \tag{3.22}$$

$$|I_7| \leq C\|\dot{u}\|_s(\|\nabla\dot{\rho}\|_\infty\|\Delta\dot{u}\|_{s-1} + \|\nabla\dot{\rho}\|_{s-1}\|\Delta\dot{u}\|_\infty) \leq C\lambda^{-1}(\|\dot{u}\|_s^2 + \|\nabla\dot{u}\|_s^2), \tag{3.23}$$

$$\begin{aligned} |I_8| \leq& C\|\nabla^\alpha\dot{u}\|(\|\nabla\dot{\rho}\|_{s-1}\|\nabla\cdot(\rho\dot{F}\dot{F}^T)\|_\infty + \|\nabla\dot{\rho}\|_\infty\|\nabla\cdot(\rho\dot{F}\dot{F}^T)\|_{s-1} \\ &+ \|\nabla\dot{\rho}\|_{s-1}\|\nabla(\rho\dot{F})\|_\infty + \|\nabla\dot{\rho}\|_\infty\|\nabla(\rho\dot{F})\|_{s-1}) \\ &+ C\|\nabla^\alpha\dot{F}\|(\|\nabla\dot{u}\|_\infty\|\nabla\dot{F}\|_{s-1} + \|\nabla\dot{u}\|_{s-1}\|\nabla\dot{F}\|_\infty) \\ \leq& C\lambda^{-1}(\|\nabla^\alpha\dot{u}\|^2 + \|\lambda\dot{\rho}\|_s^2) + C\varepsilon(\|\nabla\dot{u}\|_{s-1}^2 + \|\Delta\dot{F}\|_{s-2}^2). \end{aligned} \tag{3.24}$$

At last, we estimate I_9 as follows:

$$\begin{aligned} I_9 &= \int_{\mathsf{T}^2} \nabla\cdot\nabla^\alpha\rho(\dot{F}\overline{F}^T + \overline{F}\dot{F}^T)\nabla^\alpha\dot{u} + \rho\partial_j\nabla^\alpha\dot{u}^i\overline{F}_{jk}\nabla^\alpha\dot{F}_{ik}\,dx \\ &= -\int_{\mathsf{T}^2} \overline{F}_{ik}\partial_j\nabla^{\alpha-1}(\rho\dot{F}_{jk})\nabla\nabla^\alpha\dot{u}_i \\ &\quad + [\partial_j\nabla^\alpha\dot{u}_i\nabla^\alpha(\rho\dot{F}_{ik}\overline{F}_{jk}) - \rho\partial_j\nabla^\alpha\dot{u}_i\nabla^\alpha\dot{F}_{ik}\overline{F}_{jk}]\,dx. \end{aligned}$$

Noting (3.3), we have

$$\begin{aligned} |I_9| &\leq C\lambda^{-1}(\|\nabla\dot{u}\|_s^2 + \|\lambda\dot{\rho}\|_s^2) + C\|\nabla\dot{u}\|_s(\|\nabla\dot{\rho}\|_{s-1}\|\dot{F}\|_\infty + \|\nabla^{\alpha-1}\dot{F}\|\|\nabla\dot{\rho}\|_\infty) \\ &\leq C\lambda^{-1}(\|\nabla\dot{u}\|_s^2 + \|\lambda\dot{\rho}\|_s^2 + \|\Delta\dot{F}\|_{s-2}^2). \end{aligned} \tag{3.25}$$

On the other hand, when $|\alpha| = 0$, we have $I_5 = I_6 = I_7 = I_8 = 0$. Furthermore, if we go back to (3.11) and (3.16), we find

$$I_4 = \int_{\mathsf{T}^2} [\dot{u}_i\partial_j(\rho\dot{F}_{ik}\dot{F}_{jk}) + \rho\dot{F}_{ik}\partial_j u_i\dot{F}_{jk}]\,dx = 0,$$

$$\begin{aligned} I_9 &= \int_{\mathsf{T}^2} \dot{u}_i\overline{F}_{ik}\partial_j(\rho\dot{F}_{jk}) - \rho\partial_j\dot{u}_i\dot{F}_{ik}\overline{F}_{jk} + \rho\partial_j\dot{u}_i\overline{F}_{jk}\dot{F}_{ik}\,dx \\ &= \int_{\mathsf{T}^2} \dot{u}_i\overline{F}_{ik}\partial_j(\rho\overline{F}_{jk})\,dx \\ &= -\int_{\mathsf{T}^2} \dot{u}_i\overline{F}_{ik}\partial_j(\dot{\rho}\overline{F}_{jk})\,dx. \end{aligned}$$

Thus, we have

$$|I_9| \le C\lambda^{-1}(\|\nabla\dot u\|^2 + \|\lambda\dot\rho\|^2). \tag{3.26}$$

By adding up all these estimates (3.17)–(3.26), we have thus far obtained

$$\begin{aligned}&\frac{d}{dt}[\widetilde{E}(U(t)) + \widetilde{E}(\nabla^s U(t))] + \mu(\|\nabla\dot u\|_s^2 + \|\nabla\cdot\dot u\|_s^2)\\ &\quad\le C\lambda^{-1}(\|\lambda^2\nabla\dot\rho\|_{s-1}^2 + E_s(U(t)) + C\varepsilon\|\Delta\dot F\|_{s-2}^2).\end{aligned} \tag{3.27}$$

At this stage, it is clear we need to estimate the second term on the right side of the above inequality.

We introduce

$$w = u - \frac{1}{\mu}\Delta^{-1}\nabla^\perp\cdot(\rho\dot F), \tag{3.28}$$

where $\nabla^\perp = (-\partial_2, \partial_1)^T$. Noting (3.2), (3.3), and

(3.29)
$$\nabla\nabla^\perp\cdot\rho\dot F = \Delta\begin{pmatrix}\rho\dot F_{21} & -\rho\dot F_{11}\\ \rho\dot F_{22} & -\rho\dot F_{12}\end{pmatrix} + \begin{pmatrix}-\partial_{2i}(\rho\dot F_{i1}) & \partial_{1i}(\rho\dot F_{i1})\\ -\partial_{2i}(\rho\dot F_{i2}) & \partial_{1i}(\rho\dot F_{i2})\end{pmatrix} + \nabla^2(\rho\dot F_{12} - \rho\dot F_{21}),$$

we find that

$$\|\Delta\dot F\| \le C(\|\nabla\Delta\dot u\| + \|\nabla\Delta w\|) + C\lambda^{-1}\|\lambda\dot\rho\|_2 + \|\nabla^2(\rho\dot F_{12} - \rho\dot F_{21})\|, \tag{3.30}$$

(3.31)
$$\|\nabla^{s-2}\Delta\dot F\| \le C(\|\nabla\Delta\dot u\|_{s-2} + \|\nabla\Delta w\|_{s-2}) + C\lambda^{-1}\|\lambda\dot\rho\|_s + \|\nabla^2(\rho\dot F_{12} - \rho\dot F_{21})\|_{s-2}.$$

From the conservation law of mass $\rho\cdot\det(\dot F + \overline{F}) = 1$ we have

$$\rho\dot F_{21} - \rho\dot F_{12} = 1 - \rho + \rho\dot F_{12}\dot F_{21} - \rho\dot F_{11}\dot F_{22}. \tag{3.32}$$

Thus, we have

$$\|\nabla^2(\rho\dot F_{12} - \rho\dot F_{21})\|_{s-2} \le C\lambda^{-1}\|\lambda\dot\rho\|_s + C\varepsilon\|\Delta\dot F\|_{s-2}. \tag{3.33}$$

Combining (3.30), (3.31), (3.32), and (3.33), we obtain

$$\|\Delta\dot F\|_{s-2} \le C\lambda^{-1}\|\lambda\dot\rho\|_s + C(\|\nabla\Delta\dot u\|_{s-2} + \|\nabla\Delta w\|_{s-2}). \tag{3.34}$$

Now, substituting (3.34) into (3.27), we finally arrive at

$$\begin{aligned}&\frac{d}{dt}[\widetilde{E}(U(t)) + \widetilde{E}(\nabla^s U(t))] + \mu(\|\nabla\dot u\|_s^2 + \|\nabla\cdot\dot u\|_s^2)\\ &\quad\le C\lambda^{-1}(\|\lambda^2\nabla\dot\rho\|_{s-1}^2 + E_s(U(t)) + C\varepsilon\|\nabla\Delta w\|_{s-2}^2).\end{aligned} \tag{3.35}$$

To get the dispersive a priori energy estimates of the solutions of the compressible Oldroyd system (1.1), it is clear we also need an equation of w.

Step 3. Estimates for $\|\Delta w\|_{s-2}$ and $E_s(U(t))$.

With the aid of (3.3), one can rewrite the momentum equation (the second equation of (3.5)) as

$$\partial_t \dot u + \dot u\cdot\nabla\dot u + \lambda^2\frac{1}{\rho}\nabla p = \frac{\mu}{\rho}\Delta w + \frac{\mu}{\rho}\nabla\nabla\cdot\dot u + \frac{1}{\rho}\nabla\cdot(\rho\dot F\dot F^T) - \frac{1}{\rho}\nabla\rho. \tag{3.36}$$

On the other hand, from the first and third equations of (3.5) we have

$$\partial_t(\rho\dot F) + \dot u\cdot\nabla(\rho\dot F) = \nabla\dot u(\rho\dot F) + \nabla\dot u\rho\overline{F} - \nabla\cdot\dot u(\rho\dot F). \tag{3.37}$$

By applying Δ to (3.36) and $-\frac{1}{\mu}\nabla^\perp\cdot$ to (3.37) and then adding up the resulting equation, we find

$$\partial_t\Delta w + \dot u\cdot\nabla\Delta w + \lambda^2\frac{1}{\rho}\nabla\Delta p - \frac{\mu}{\rho}\Delta^2 w - \frac{\mu}{\rho}\nabla\nabla\cdot\Delta\dot u = h, \tag{3.38}$$

where

$$\begin{aligned} h_i =& -[\Delta(\dot u\cdot\nabla\dot u_i) - \dot u\cdot\nabla\Delta\dot u_i] - \lambda^2\left[\Delta\left(\frac{1}{\rho}\partial_i p\right) - \frac{1}{\rho}\partial_i\Delta p\right] \\ &+ \frac{1}{\mu}[\partial_1\dot u_k\partial_k(\rho\dot F_{i2}) - \partial_2\dot u_k\partial_k(\rho\dot F_{i1})] \\ &+ \left[\Delta\left(\frac{\mu}{\rho}\Delta w_i\right) - \frac{\mu}{\rho}\Delta^2 w_i\right] + \left[\Delta\left(\frac{\mu}{\rho}\partial_i\nabla\cdot\dot u\right) - \frac{\mu}{\rho}\partial_i\nabla\cdot\Delta\dot u\right] \\ &+ \Delta\left[\frac{1}{\rho}\partial_j(\rho\dot F\dot F^T)_{ij} - \frac{1}{\rho}\partial_i\rho\right] - \frac{1}{\mu}\nabla_j^\perp[\nabla\dot u\rho\dot F + \nabla\dot u\rho\overline{F} - \nabla\cdot\dot u\rho\dot F]_{ij} \end{aligned} \tag{3.39}$$

for $i = 1, 2$.

By taking the L^2 inner product of (3.38) with $\rho\Delta w$, we can use integration by parts to obtain

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\|\rho\Delta w\|^2 + \mu\|\nabla\Delta w\|^2 =& \frac{1}{2}\int_{\mathbb{T}^2}(\nabla\cdot(\rho\dot u) + \partial_t\rho)|\Delta w|^2dx - \mu(\nabla\cdot\Delta\dot u, \nabla\cdot\Delta w) \\ &+ (\lambda^2\Delta p, \Delta\nabla\cdot w) + (\rho h, \Delta w). \end{aligned} \tag{3.40}$$

We can use (3.2) to get

$$\left|\frac{1}{2}\int_{\mathbb{T}^2}(\nabla\cdot(\rho\dot u + \partial_t\rho))|\Delta w|^2dx\right| \le C\lambda^{-1}\|\Delta w\|^2. \tag{3.41}$$

On the other hand, from a direct computation we have

$$\nabla\cdot(\nabla^\perp\cdot\rho\dot F) = \partial_{1i}\dot F_{i2} - \partial_{2i}\dot F_{i1} = \Delta\rho. \tag{3.42}$$

Thus we have

$$-\mu(\nabla\cdot\Delta\dot u, \nabla\cdot\Delta w) \le -\mu\|\nabla\cdot\Delta\dot u\|^2 + C\lambda^{-1}(\|\lambda\dot\rho\|_2^2 + \|\nabla\Delta\dot u\|^2). \tag{3.43}$$

We now estimate the term $(\rho h, \Delta w)$ in (3.40) where h is given in (3.39). First, we use integration by parts to get

$$\begin{aligned} &\left|(-[\Delta(\dot u\cdot\nabla\dot u_i) - \dot u\cdot\nabla\Delta\dot u_i] - \frac{1}{\mu}\nabla_j^\perp[\nabla\dot u\rho\dot F + \nabla\dot u\rho\overline{F} - \nabla\cdot\dot u\rho\dot F]_{ij}, \rho\Delta w_i)\right| \\ &\le \|\Delta w\|_\infty\|\nabla^2\dot u\|\|\nabla\dot u\| + C\|\nabla\Delta w\|\|\nabla\dot u\|\|\dot F\|_\infty + \frac{1}{\mu}\|\nabla\Delta w\|\|\nabla\dot u\| \\ &\le C\varepsilon(\|\nabla\dot u\|^2 + \|\nabla^2\dot u\|^2) + \frac{\mu}{2}\|\nabla\Delta w\|^2 + \frac{2}{\mu^3}\|\nabla\dot u\|^2. \end{aligned} \tag{3.44}$$

We can use the integration by parts to estimate the third term of $(\rho h, \Delta w)$ as follows:

$$|([\partial_1 \dot{u}_k \partial_k \dot{F}_{2i} - \partial_2 \dot{u}_k \partial_k \dot{F}_{1i}], \rho\Delta w_i)| \leq C\varepsilon(\|\nabla \dot{u}\|^2 + \|\nabla\Delta w\|^2) + C\lambda^{-1}(\|\Delta w\|^2 + \|\dot{F}\|^2). \tag{3.45}$$

Finally, with the aid of (3.34), we estimate the rest terms of $(\rho h, \Delta w)$ as follows:

$$\begin{aligned}
&\bigg(-\lambda^2\left[\Delta\left(\frac{1}{\rho}\partial_i p\right) - \frac{1}{\rho}\partial_i\Delta p\right] + \left[\Delta\left(\frac{\mu}{\rho}\Delta w_i\right) - \frac{\mu}{\rho}\Delta^2 w_i\right]\\
&\quad + \Delta\left[\frac{1}{\rho}\partial_j(\rho\dot{F}\dot{F}^T)_{ji} + \frac{1}{\rho}\partial_i\rho\right], \rho\Delta w_i\bigg)\\
&\leq C\lambda^{-1}\|\Delta w\|(\|\lambda^2\nabla^2\rho\|\|\lambda\nabla\rho\|_\infty + \|\nabla\Delta w\|\|\lambda\nabla\rho\|_\infty + \|\Delta w\|_\infty\|\lambda\nabla^2\rho\|)\\
&\quad + C\varepsilon\|\nabla\Delta w\|\|\Delta\dot{F}\| + C\lambda^{-1}\|\nabla\Delta w\|(\|\lambda\Delta\rho\| + \|\lambda\nabla\rho\|\|\lambda\nabla\rho\|_\infty)\\
&\leq C\lambda^{-1}(\|\Delta w\|^2 + \|\lambda\dot{\rho}\|_2^2 + \|\nabla\Delta w\|^2) + C\varepsilon(\|\nabla\Delta w\|^2 + \|\nabla\Delta\dot{u}\|^2).
\end{aligned} \tag{3.46}$$

Summing up (3.44)–(3.46), we obtain

$$\begin{aligned}
|(\rho h, \Delta w)| &\leq C\varepsilon(\|\nabla\dot{u}\|^2 + \|\nabla\Delta\dot{u}\|^2 + \|\nabla\Delta w\|^2)\\
&\quad + C\lambda^{-1}(\|\Delta w\|^2 + \|\lambda\dot{\rho}\|_2^2 + \|\dot{F}\|^2) + \frac{\mu}{2}\|\nabla\Delta w\|^2 + \frac{2}{\mu^3}\|\nabla\dot{u}\|^2.
\end{aligned} \tag{3.47}$$

To estimate the term $(\lambda^2\Delta p, \Delta\nabla\cdot w)$, we use the decomposition

$$(\lambda^2\Delta p, \Delta\nabla\cdot w) = (\lambda^2\Delta p, \Delta\nabla\cdot\dot{u}) - \frac{1}{\mu}(\lambda^2\Delta p, \nabla\cdot(\nabla^\perp\cdot\rho\dot{F})). \tag{3.48}$$

By multiplying the second equation of system (3.5) by ρ and then applying the divergence operator to the resulting equation, we obtain

$$\lambda^2\Delta p = -\nabla\cdot(\rho\partial_t\dot{u}) + 2\mu\Delta\nabla\cdot\dot{u} - \nabla\cdot(\rho\dot{u}\cdot\nabla\dot{u}) + \nabla\cdot(\nabla\cdot(\rho\dot{F}\dot{F}^T)) - 2\Delta\rho, \tag{3.49}$$

where we used the equality (3.42). Substituting (3.49) into (3.48), one obtains

$$\begin{aligned}
|(\lambda^2\Delta p, \Delta\nabla\cdot w)| &= \bigg|\bigg(-\nabla\cdot(\rho\partial_t\dot{u}) + 2\mu\Delta\nabla\cdot\dot{u} - \nabla\cdot(\rho\dot{u}\cdot\nabla\dot{u})\\
&\qquad + \nabla\cdot(\nabla\cdot(\rho\dot{F}\dot{F}^T)) - 2\Delta\rho, \Delta\nabla\cdot\dot{u} - \frac{1}{\mu}\Delta\rho\bigg)\bigg|\\
&\leq 2\mu\|\Delta\nabla\cdot\dot{u}\|^2 + C\lambda^{-1}(\|\lambda\dot{\rho}\|_2^2 + \|\lambda\Delta\nabla\cdot\dot{u}\|^2 + \|\Delta\dot{F}\|^2\\
&\quad + \|\nabla\cdot\partial_t\dot{u}\|^2 + \|\nabla\nabla\cdot\dot{u}\|^2) + C\varepsilon(\|\Delta\dot{F}\|^2 + \|\nabla\dot{u}\|^2)\\
&\leq 2\mu\|\Delta\nabla\cdot\dot{u}\|^2 + C\lambda^{-1}\|\lambda\dot{\rho}\|_2^2\\
&\quad + C\varepsilon(\|\nabla\dot{u}\|^2 + \|\nabla\Delta\dot{u}\|^2 + \|\nabla\Delta w\|^2) + C\lambda^{-1},
\end{aligned} \tag{3.50}$$

where in the last inequality we used (3.2).

Finally, substituting (3.41), (3.43), (3.47), and (3.50) into (3.40), we arrive at

$$\begin{aligned}
\frac{d}{dt}\|\rho\Delta w\|^2 + \mu\|\nabla\Delta w\|^2 &\leq C\lambda^{-1}(\|\Delta w\|^2 + \|\lambda\dot{\rho}\|_2^2 + \|\dot{F}\|^2) + C\varepsilon(\|\nabla\dot{u}\|^2 + \|\nabla\Delta\dot{u}\|^2)\\
&\quad + \frac{4}{\mu^3}\|\nabla\dot{u}\|^2 + 2\mu\|\Delta\nabla\cdot\dot{u}\|^2 + C\lambda^{-1}.
\end{aligned} \tag{3.51}$$

To estimate the higher order derivatives of w, we apply ∇^{s-2} to (3.38) to obtain

$$\partial_t\nabla^{s-2}\Delta w+\nabla^{s-2}(\dot u\cdot\nabla\Delta w)+\lambda^2\nabla^{s-2}\left(\frac{1}{\rho}\nabla\Delta p\right)-\nabla^{s-2}\left(\frac{\mu}{\rho}\Delta^2 w+\frac{\mu}{\rho}\Delta\nabla\nabla\cdot\dot u\right)$$
$$=\nabla^{s-2}h.$$

Then by taking the L^2 inner product of the resulting equation with $\rho\nabla^{s-2}\Delta w$, we have

(3.52)
$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\rho\nabla^{s-2}\Delta w\|^2+\mu\|\nabla^{s-2}\nabla\Delta w\|^2\\
&=\mu(\nabla^{s-2}\nabla\nabla\cdot\Delta\dot u,\nabla^{s-2}\Delta w)+\frac{1}{2}\int_{\mathbb{T}^2}(\nabla\cdot(\rho\dot u)+\partial_t\rho)|\nabla^{s-2}\Delta w|^2dx\\
&+(\nabla^{s-2}h,\rho\nabla^{s-2}\Delta w)-(\nabla^{s-2}(\dot u\nabla\cdot\Delta w)-\dot u\nabla^{s-2}\nabla\cdot\Delta w,\rho\nabla^{s-2}\Delta w)\\
&+\left(\nabla^{s-2}\left(\frac{\mu}{\rho}\Delta^2w+\frac{\mu}{\rho}\Delta\nabla\nabla\cdot\dot u\right)-\left(\frac{\mu}{\rho}\nabla^{s-2}\Delta^2w+\frac{\mu}{\rho}\nabla^{s-2}\Delta\nabla\nabla\cdot\dot u\right),\rho\nabla^{s-2}\Delta w\right)\\
&+\lambda^2(\nabla^{s-2}\Delta p,\nabla^{s-2}\Delta\nabla\cdot w)-\lambda^2\left(\nabla^{s-2}\left(\frac{1}{\rho}\nabla\Delta p\right)-\frac{1}{\rho}\nabla^{s-2}\nabla\Delta p,\rho\nabla^{s-2}\Delta w\right).
\end{aligned}$$

In what follows, we will estimate the above terms separately. First, similar to getting (3.41) and (3.43), we have

$$\begin{aligned}
&\mu(\nabla^{s-2}\nabla\nabla\cdot\Delta\dot u,\nabla^{s-2}\Delta w)+\frac{1}{2}\int_{\mathbb{T}^2}(\nabla\cdot(\rho\dot u)+\partial_t\rho)|\nabla^{s-2}\Delta w|^2dx\\
&\quad\le-\mu\|\nabla^{s-2}\nabla\cdot\Delta\dot u\|^2+C\lambda^{-1}(\|\lambda\dot\rho\|_s^2+\|\nabla^{s-2}\Delta w\|^2+\|\nabla^{s-2}\nabla\Delta\dot u\|^2).
\end{aligned}\tag{3.53}$$

By using Lemma 3.2, we can estimate the second term of the third line (3.52) as

$$(\nabla^{s-2}(\dot u\nabla\cdot\Delta w)-\dot u\nabla^{s-2}\nabla\cdot\Delta w,\rho\nabla^{s-2}\Delta w)\le C\varepsilon\|\nabla\Delta w\|_{s-2}^2.\tag{3.54}$$

By integration by parts, we can estimate the fourth line of (3.52) as follows:

$$\begin{aligned}
&\left|\left(\nabla^{s-2}\left(\frac{\mu}{\rho}\Delta^2w+\frac{\mu}{\rho}\Delta\nabla\nabla\cdot\dot u\right)-\left(\frac{\mu}{\rho}\nabla^{s-2}\Delta^2w+\frac{\mu}{\rho}\nabla^{s-2}\Delta\nabla\nabla\cdot\dot u\right),\rho\nabla^{s-2}\Delta w\right)\right|\\
&=\left|\left(\nabla^{s-2}\left(\nabla\frac{\mu}{\rho}\Delta\nabla w+\nabla\frac{\mu}{\rho}\nabla\nabla\nabla\cdot\dot u\right)\right.\right.\\
&\quad\left.\left.-\left(\nabla\frac{\mu}{\rho}\nabla^{s-2}\nabla\Delta w+\nabla\frac{\mu}{\rho}\nabla^{s-2}\nabla\nabla\nabla\cdot\dot u\right),\rho\nabla^{s-2}\Delta w\right)\right|\\
&\quad+\left|\left(\nabla^{s-2}\left(\frac{\mu}{\rho}\Delta\nabla w+\frac{\mu}{\rho}\nabla\nabla\nabla\cdot\dot u\right)\right.\right.\\
&\quad\quad\left.\left.-\left(\frac{\mu}{\rho}\nabla^{s-2}\nabla\Delta w+\frac{\mu}{\rho}\nabla^{s-2}\nabla\nabla\nabla\cdot\dot u\right),\nabla\left(\rho\nabla^{s-2}\Delta w\right)\right)\right|\\
&\le C\lambda^{-1}(\|\lambda\dot\rho\|_s^2+\|\nabla\Delta w\|_{s-2}^2).
\end{aligned}$$
(3.55)

Noting that $p = p(\rho)$, by using Lemmas 3.2 and 3.3, we can similarly estimate the last line of (3.52) as follows:

$$
\begin{aligned}
&\left|-\lambda^2\left(\nabla^{s-2}\nabla\left(\frac{1}{\rho}\Delta p\right)-\frac{1}{\rho}\nabla^{s-2}\nabla\Delta p,\rho\nabla^{s-2}\Delta w\right)\right| \\
&= \lambda^2\left|\left(\nabla^{s-2}\nabla\left(\nabla\frac{1}{\rho}\nabla p\right)-\nabla\frac{1}{\rho}\nabla^{s-2}\nabla\nabla p,\rho\nabla^{s-2}\Delta w\right)\right. \\
&\quad\left.+\left(\nabla^{s-2}\nabla\left(\frac{1}{\rho}\nabla p\right)-\frac{1}{\rho}\nabla^{s-2}\nabla\nabla p,\nabla(\rho\nabla^{s-2}\Delta w)\right)\right| \\
&\le C\lambda^{-1}(\|\lambda^2\nabla\rho\|_{s-2}\|\lambda\dot\rho\|_s\|\nabla^{s-2}\Delta w\|+\|\lambda^2\nabla\rho\|_{s-2}\|\lambda\dot\rho\|_s\|\nabla^{s-2}\Delta\nabla w\|) \\
&\le C\lambda^{-1}(\|\lambda\dot\rho\|_s^2+\|\Delta\nabla w\|_{s-2}^2),
\end{aligned}
\tag{3.56}
$$

where in the last inequality we used (3.2).

In order to estimate the term $(\nabla^{s-2}h,\rho\nabla^{s-2}\Delta w)$, we go back to (3.39). It is rather easy to see that

$$
|(-\nabla^{s-2}[\Delta(\dot u\cdot\nabla\dot u_i)-\dot u\cdot\nabla\Delta\dot u_i],\rho\nabla^{s-2}\Delta w_i)|\le C\varepsilon(\|\nabla\dot u\|_s^2+\|\nabla\Delta w\|_{s-2}^2),
\tag{3.57}
$$

$$
\begin{aligned}
\left|\left(\lambda^2\nabla^{s-2}\left[\Delta\left(\frac{1}{\rho}\partial_i p\right)-\frac{1}{\rho}\partial_i\Delta p\right],\rho\nabla^{s-2}\Delta w_i\right)\right| &\le C\lambda^{-1}\|\nabla^{s-2}\nabla\Delta w\|\|\lambda^2\nabla\rho\|_{s-2}\|\lambda\dot\rho\|_s \\
&\le C\lambda^{-1}(\|\nabla^{s-2}\nabla\Delta w\|^2+\|\lambda\dot\rho\|_s^2),
\end{aligned}
\tag{3.58}
$$

$$
\left|\left(\frac{1}{\mu}\nabla^{s-2}[\partial_1\dot u_k\partial_k(\rho\dot F_{i2})-\partial_2\dot u_k\partial_k(\rho\dot F_{i1})],\rho\nabla^{s-2}\Delta w_i\right)\right|\le C\varepsilon(\|\nabla^{s-2}\nabla\Delta w\|^2+\|\nabla\dot u\|_s^2),
\tag{3.59}
$$

$$
\begin{aligned}
&\left|\left(\nabla^{s-2}\left[\Delta\left(\frac{\mu}{\rho}\Delta w_i\right)-\frac{\mu}{\rho}\Delta^2 w_i\right]+\nabla^{s-2}\left[\Delta\left(\frac{\mu}{\rho}\partial_i\nabla\cdot\dot u\right)-\frac{\mu}{\rho}\partial_i\nabla\cdot\Delta\dot u\right],\rho\nabla^{s-2}\Delta w_i\right)\right| \\
&\qquad\le C\lambda^{-1}(\|\lambda\dot\rho\|_s^2+\|\nabla\Delta w\|_{s-2}^2+\|\nabla\dot u\|_s^2),
\end{aligned}
\tag{3.60}
$$

$$
\begin{aligned}
&\left|\left(\nabla^{s-2}\Delta\left[\frac{1}{\rho}\partial_j(\rho\dot F\dot F^T)_{ij}+\frac{1}{\rho}\partial_i\rho\right],\rho\nabla^{s-2}\Delta w\right)\right| \\
&\quad\le C\varepsilon(\|\nabla\Delta w\|_{s-2}^2+\|\Delta\dot F\|_{s-2}^2)+C\lambda^{-1}(\|\lambda\dot\rho\|_s^2+\|\nabla\Delta w\|_{s-2}^2) \\
&\quad\le C\varepsilon(\|\nabla\Delta w\|_{s-2}^2+\|\nabla\dot u\|_s^2)+C\lambda^{-1}\|\lambda\dot\rho\|_s^2,
\end{aligned}
\tag{3.61}
$$

$$
\begin{aligned}
&\left|\left(\frac{1}{\mu}\nabla^{s-2}\nabla_j^\perp[\nabla\dot u\rho\dot F+\nabla\dot u\rho\overline{F}-\nabla\cdot\dot u\rho\dot F]_{ij},\rho\nabla^{s-2}\Delta w_i\right)\right| \\
&\quad\le C\varepsilon\|\nabla\dot u\|_{s-2}^2+\frac{\mu}{2}\|\nabla^{s-2}\nabla\Delta w\|^2+\frac{2}{\mu^3}\|\nabla^{s-2}\nabla\dot u\|_{s-2}^2.
\end{aligned}
\tag{3.62}
$$

Thus, combining (3.57) through (3.62), we have

$$
\begin{aligned}
|(\nabla^{s-2}h,\rho\nabla^{s-2}\Delta w)| &\le C\lambda^{-1}\|\lambda\dot\rho\|_s^2+C\varepsilon(\|\nabla\dot u\|_s^2+\|\nabla\Delta w\|_{s-2}^2) \\
&\quad+\frac{\mu}{2}\|\nabla^{s-2}\nabla\Delta w\|^2+\frac{2}{\mu^3}\|\nabla^{s-2}\nabla\dot u\|^2.
\end{aligned}
\tag{3.63}
$$

provided λ is appropriately large.

Finally we estimate the last remaining term $\lambda^2(\nabla^{s-2}\Delta p, \nabla^{s-2}\Delta\nabla\cdot w)$ in (3.52). Noting (3.2) and (3.42), we can use (3.28) and (3.49) to get

$$\begin{aligned}\lambda^2(\nabla^{s-2}\Delta p, \nabla^{s-2}\Delta\nabla\cdot w) &= \frac{1}{\mu}(\nabla^{s-2}\nabla\cdot(\rho\partial_t\dot{u}), \nabla^{s-2}\Delta\rho)\\ &\quad + (\nabla^{s-1}\nabla\cdot(\rho\partial_t\dot{u}), \nabla^{s-3}\Delta\nabla\cdot\dot{u})\\ &\quad + \Big(2\mu\nabla^{s-2}\Delta\nabla\cdot\dot{u} - \nabla^{s-2}\nabla\cdot(\rho\dot{u}\cdot\nabla\dot{u}) + 2\nabla^{s-2}\Delta\rho\\ &\qquad + \nabla^{s-2}\nabla\cdot(\nabla\cdot\rho\dot{F}\dot{F}^T), \nabla^{s-2}\Delta\nabla\cdot\dot{u} + \frac{1}{\mu}\nabla^{s-2}\Delta\rho\Big)\\ &\le C\mu\|\nabla\dot{u}\|_s^2 + C\varepsilon\|\nabla\Delta w\|_{s-2}^2\\ &\quad + C\lambda^{-1}(\|\lambda\dot{\rho}\|_s^2 + \|\nabla\cdot\partial_t\dot{u}\|_{s-1}^2) + C\lambda^{-1}.\end{aligned} \tag{3.64}$$

Combining (3.51) through (3.56), (3.63), and (3.64), we obtain

$$\begin{aligned}&\frac{d}{dt}(\|\rho\Delta w\|^2 + \|\rho\nabla^{s-2}\Delta w\|^2) + \mu\|\nabla\Delta w\|_{s-2}^2\\ &\quad\le C\lambda^{-1}(E_s(U(t) + \|\nabla\cdot\partial_t\dot{u}\|_{s-1}^2 + \|\Delta w\|_s^2)) + C\left(\mu + \frac{1}{\mu^3}\right)\|\nabla\dot{u}\|_s^2 + C\lambda^{-1}.\end{aligned} \tag{3.65}$$

Multiplying inequality (3.35) by an appropriately large constant $M(\frac{1}{\mu^3}+\mu)$ and then adding up the resulting inequality with (3.65), we obtain

$$\begin{aligned}&\frac{d}{dt}[\widetilde{E}(U(t)) + \widetilde{E}(\nabla^s U(t)) + \|\rho\Delta w\|^2 + \|\rho\nabla^{s-2}\Delta w\|^2] + (\|\nabla\dot{u}\|_s^2 + \|\nabla\Delta w\|_{s-2}^2)\\ &\quad\le C\lambda^{-1}(1 + \|\lambda^2\nabla\rho\|_{s-1}^2 + \|\nabla\cdot\partial_t\dot{u}\|_{s-1}^2) + C\lambda^{-1}[E_s(U(t)) + \|\Delta w\|_{s-2}^2].\end{aligned} \tag{3.66}$$

Noting (3.2), one can use Gronwall's inequality to obtain

$$\widetilde{E}(U(t)) + \widetilde{E}(\nabla^s U(t)) + \int_0^t \|\nabla\dot{u}\|_s^2\,dt \le 2[\widetilde{E}(U(0)) + \widetilde{E}(\nabla^s U(0))] + \lambda^{-1}\widetilde{E}(U(t)) \tag{3.67}$$

for $0 \le t \le T_\lambda$, with $T_\lambda = \lambda^{1-\delta}$ ($\delta < 1$ is a small positive constant), provided λ is sufficiently large. Noting (2.2) and

$$\widetilde{E}(U(0)) + \widetilde{E}(\nabla^s U(0)) \le 2(\|u_0\|_s^2 + \|F_0 - \overline{F}\|_s^2) + \lambda^{-2},$$

we have

$$E(U(t)) + E(\nabla^s U(t)) + \int_0^t \|\nabla\dot{u}\|_s^2\,dt \le C(\|u_0\|_s^2 + \|F_0 - \overline{F}\|_s^2) + \lambda^{-2} \le C\varepsilon^2, \tag{3.68}$$

provided λ is sufficiently large and $0 \le t \le T_\lambda$, which gives the proof of the first inequality of (2.2).

Step 4. Estimate for $E_{s-1}(\partial_t U(t))$.

Let $D^\alpha = \partial_t \nabla^{\alpha-1}$, $|\alpha| = s$ in (3.7). In this case we do not need the decay. We proceed as before. A similar process for (3.17)–(3.19) yields

$$|I_1| + |I_2| + |I_3| \le C\lambda^{-1} E(\partial_t \nabla^{s-1} U(t)). \tag{3.69}$$

To estimate I_4, we now return to (3.11) and write

$$I_4 = \int_{\mathsf{T}^2} [-\partial_t \nabla^{s-1} \partial_j \dot{u}_i \partial_t \nabla^{s-1} (\rho \dot{F}_{ik} \dot{F}_{jk}) + \rho \partial_t \nabla^{s-1} \dot{F}_{ik} \partial_t \partial_j \nabla^{s-1} u_i \dot{F}_{jk}] \, dx.$$

Thus,

$$|I_4| \le C\varepsilon E_{s-1}(\partial_t U(t)) + \frac{\mu}{8} \|\partial_t \nabla^{s-1} \nabla \dot{u}\|^2. \tag{3.70}$$

For the term I_5, one can use Lemmas 3.2 and 3.3 to estimate it as follows:

$$\begin{aligned} |I_5| \le\ & C\lambda^2 [\|\partial_t \nabla^{s-1} \dot{\rho}\| (\|\nabla \dot{u}\|_\infty \|\partial_t \nabla \dot{\rho}\|_{s-2} + \|\partial_t \nabla \dot{\rho}\|_\infty \|\nabla \dot{u}\|_{s-2} \\ & + \|\partial_t \nabla \dot{u}\|_\infty \|\nabla \dot{\rho}\|_{s-2} + \|\partial_t \nabla \dot{u}\|_{s-2} \|\nabla \dot{\rho}\|_\infty) \\ & + \|\partial_t \nabla^{s-1} \dot{u}\| (\|\nabla \dot{\rho}\|_\infty \|\partial_t \nabla \dot{\rho}\|_{s-2} + \|\partial_t \nabla \dot{\rho}\|_\infty \|\nabla \dot{\rho}\|_{s-2})] \\ \le\ & C\varepsilon (\|\lambda \partial_t \nabla^{s-1} \dot{\rho}\|^2 + \|\partial_t \nabla^{s-1} \dot{u}\|^2 + \|\lambda \partial_t \dot{\rho}\|^2 + \|\partial_t \dot{u}\|^2). \end{aligned} \tag{3.71}$$

Similarly, for the terms I_6, I_7, I_8, one can estimate them as follows:

$$|I_6| \le C\varepsilon (\|\partial_t \nabla^{s-1} \dot{u}\|^2 + \|\partial_t \nabla^{s-1} \dot{F}\|^2), \tag{3.72}$$

$$|I_7| \le C\varepsilon \lambda^{-1} (\|\nabla^{s-1} \partial_t \dot{u}\|^2 + \|\nabla^s \partial_t \dot{u}\|^2 + \|\lambda \partial_t \nabla^{s-1} \dot{\rho}\|^2), \tag{3.73}$$

$$|I_8| \le C\varepsilon (\|\partial_t \nabla^{s-1} \dot{u}\|^2 + \|\partial_t \nabla^{s-1} \dot{F}\|^2 + \|\lambda \partial_t \nabla^{s-1} \dot{\rho}\|^2), \tag{3.74}$$

$$|I_9| \le C\varepsilon (\|\partial_t \nabla^{s-1} \dot{F}\|^2 + \|\lambda \partial_t \nabla^{s-1} \dot{\rho}\|^2) + \frac{\mu}{8} \|\partial_t \nabla^s \dot{u}\|^2. \tag{3.75}$$

On the other hand, when $D^\alpha = \partial_t$, by using (3.3) one obtains

$$\begin{aligned} |I_9| &= \left| \int_{\mathsf{T}^2} \partial_{tj} (\rho \overline{F}_{ik} \dot{F}_{jk}) \partial_t \dot{u}^i - \partial_{jt} \dot{u}^i \partial_t (\rho \dot{F}_{ik} \overline{F}_{jk}) + \rho \partial_{jt} \dot{u}^i \overline{F}_{jk} \partial_t \dot{F}_{ik} \ dx \right| \\ &= \left| \int_{\mathsf{T}^2} -\partial_{tj} \rho \overline{F}_{jk} \overline{F}_{ik} \partial_t \dot{u}^i - \partial_{jt} \dot{u}^i \partial_t \rho \dot{F}_{ik} \overline{F}_{jk} \ dx \right| \\ &\le C\lambda^{-1} (\|\lambda \partial_t \dot{\rho}\|^2 + \|\lambda \nabla \partial_t \dot{\rho}\|^2 + \|\partial_t \dot{u}\|^2). \end{aligned}$$

Thus, we have

$$\frac{1}{2} \frac{d}{dt} \widetilde{E}(\partial_t U(t)) + \mu \|\nabla \partial_t \dot{u}\|^2 \le C\varepsilon E(\partial_t U(t)) + \frac{\mu}{2} \|\nabla \partial_t \dot{u}\|^2, \tag{3.76}$$

provided λ is sufficiently large.

By summing up (3.69)–(3.76), we arrive at

$$\frac{d}{dt} [\widetilde{E}(\partial_t U(t)) + \widetilde{E}(\partial_t \nabla^{s-1} U(t))] + \mu \|\nabla \partial_t \dot{u}\|_{s-1}^2 \le C\varepsilon E_{s-1}(\partial_t U(t)). \tag{3.77}$$

Noting (2.4), (2.5), and (2.11), we have

$$\begin{aligned} E_{s-1}(\partial_t U(0)) &\le C\|\lambda(u_0+\widetilde{u}_0^\lambda)\nabla\widetilde{\rho}_0^\lambda\|_{s-1}^2 + \|\lambda(\widetilde{\rho}_0^\lambda+1)\nabla\cdot\widetilde{u}_0^\lambda\|_{s-1}^2 + \|\lambda^2\nabla\widetilde{\rho}_0^\lambda\|_{s-1}^2 \\ &\quad + \|\nabla(\nabla\cdot\widetilde{u}_0^\lambda) + \nabla\cdot[(1+\widetilde{\rho}_0^\lambda)(F_0+\widetilde{F}_0^\lambda)(F_0+\widetilde{F}_0^\lambda)^T]\|_{s-1}^2 \\ &\quad + \|(\Delta(u_0+\widetilde{u}_0^\lambda))\|_{s-1}^2 + \|(u_0+\widetilde{u}_0^\lambda)\cdot\nabla(u_0+\widetilde{u}_0^\lambda)\|_{s-1}^2 \\ &\quad + \|(u_0+\widetilde{u}_0^\lambda)\cdot\nabla(F_0+\widetilde{F}_0^\lambda) - \nabla(u_0+\widetilde{u}_0^\lambda)(F_0+\widetilde{F}_0^\lambda)\|_{s-1} \\ &\le C(\delta_0^2 + \|u_0\|_{s+1}^2 + \|F_0-\overline{F}\|_s^2). \end{aligned} \tag{3.78}$$

Combining (3.77) and (3.78), one can use Gronwall's inequality to get

$$\widetilde{E}(\partial_t U(t)) + \widetilde{E}(\partial_t\nabla^{s-1}U(t)) + \mu\int_0^t \|\nabla\partial_t\dot{u}\|_{s-1}^2\,dt \le C\exp C\varepsilon t \tag{3.79}$$

for $0 \le t \le T_\lambda$.

This completes the proof of Theorem 2.2.

4. Proof of Theorem 2.3. In this section, we will tie everything together and complete the proof Theorem 2.3. For every $\overline{T} > 0$, we have from section 3 that

$$\begin{aligned} &E_s(U^\lambda(t)) \le C\varepsilon^2, \qquad t\in[0,T^\lambda), \\ &E_{s-1}(\partial_t U^\lambda(t)) \le C\exp Ct, \qquad 0\le t\le \overline{T}, \end{aligned} \tag{4.1}$$

provided $\lambda > C\overline{T}\exp C\overline{T}$ is sufficiently large.

We have, as $\lambda \longrightarrow \infty$, that $\rho^\lambda \longrightarrow 1$ in $L^\infty(0,\overline{T};H^s)\cap Lip([0,\overline{T}],H^{s-1})$. Moreover, a standard compactness argument based on the Lions–Aubin lemma (see [23], for example) implies that any subsequence of $(u^\lambda,\ F^\lambda)$ has a subsequence with a limit $(u,\ F)$ with $(u, F-\overline{F}) \in L^\infty(0,\overline{T};H^s)\cap C([0,\overline{T}],H^{s-\epsilon})$ and $(u_t,F_t)\in L^\infty(0,\overline{T};H^{s-1})$, where ϵ is a small positive constant. Now let $\phi(t,x)$ and $\varphi(t,x)$ be two smooth test functions with compact supports in $[0,\overline{T}]$ and $\nabla\cdot\phi = 0$. Then

$$\begin{aligned} &\int_0^{\overline{T}}\int_{\mathsf{T}^2}\phi\left(\partial_t\dot{u}^\lambda + \dot{u}^\lambda\cdot\nabla\dot{u}^\lambda - \frac{\mu}{\rho^\lambda}\Delta\dot{u}^\lambda - \frac{\mu}{\rho^\lambda}\nabla\nabla\cdot\dot{u}^\lambda - \frac{1}{\rho^\lambda}\nabla\cdot\rho^\lambda\dot{F}^\lambda(\dot{F}^\lambda)^T \right.\\ &\qquad\qquad \left. - \frac{1}{\rho^\lambda}\nabla\cdot[\rho^\lambda\dot{F}^\lambda\overline{F}^T + \rho^\lambda\overline{F}(\dot{F}^\lambda)^T]\right)\,dxdt \\ &= \int_0^{\overline{T}}\int_{\mathsf{T}^2} -\phi\lambda^2\nabla\int_1^{\rho^\lambda}\frac{p'(\xi)}{\xi}\,d\xi\,dxdt \\ &= 0 \end{aligned} \tag{4.2}$$

and

$$\int_0^{\overline{T}}\int_{\mathsf{T}^2}\varphi(\partial_t\dot{F}^\lambda + \dot{u}^\lambda\cdot\nabla\dot{F}^\lambda - \nabla\dot{u}^\lambda\dot{F}^\lambda - \nabla\dot{u}^\lambda\overline{F})\,dxdt = 0.$$

On the other hand, from the first equation of system (1.1), we have

$$\nabla\cdot\dot{u}^\lambda = \partial_t\dot{\rho}^\lambda + \dot{u}^\lambda\cdot\nabla\dot{\rho}^\lambda + \dot{\rho}^\lambda\nabla\cdot\dot{u}^\lambda.$$

Let $\lambda \longrightarrow \infty$. We obtain that (u,F) satisfies (2.9) and (2.10) in time interval $t\in[0,\overline{T}]$. By the uniqueness of the classical solution of system (2.9), (2.10), it follows that the convergence is in fact valid for the sequences u^λ and F^λ themselves. Since $\overline{T}$ is arbitrary, (u,F) in fact is the unique global classical solution of the incompressible Oldroyd system (1.2) with the initial data (2.10).

Acknowledgment. The first author would like to thank Professor Chun Liu for many helpful discussions and suggestions.

OSCILLATING SOLUTIONS OF INCOMPRESSIBLE MAGNETOHYDRODYNAMICS AND DYNAMO EFFECT*

DAVID GÉRARD-VARET†

Abstract. We are interested in the stability properties of some solutions of viscous incompressible magnetohydrodynamics equations. These solutions are highly oscillating, with frequency involving a small parameter ε. They arise in the study of small-scale dynamo mechanisms. We prove both nonlinear stability and instability results, depending on the time scale under consideration.

Key words. magnetohydrodynamics, dynamo theory, oscillations

AMS subject classifications. 35Q30, 35Q35

DOI. 10.1137/S0036141004444603

1. Introduction. This paper deals with some oscillatory solutions of the equations of magnetohydrodynamics (MHD). It is motivated by the study of small-scale dynamo mechanisms. Before we state precisely our main results, let us first specify the general framework.

The incompressible MHD equations read in a dimensionless form:

$$\begin{cases} \partial_t u + u \cdot \nabla u + \nabla p - \dfrac{1}{\mathrm{Re}} \Delta u = \operatorname{curl} b \times b + f, \\ \partial_t b - \operatorname{curl}(u \times b) - \dfrac{1}{\mathrm{Rm}} \Delta b = 0, \\ \operatorname{div}\, u = \operatorname{div}\, b = 0. \end{cases} \tag{1.1}$$

They describe the evolution of an incompressible and electrically conducting fluid. They are derived from the incompressible Navier–Stokes equations, the Maxwell equations, and Ohm's law in a conducting medium (see [15]). Functions

$$u = u(t, \mathrm{x}) \in \mathbb{R}^3, \quad b = b(t, \mathrm{x}) \in \mathbb{R}^3, \quad f = f(t, \mathrm{x}) \in \mathbb{R}^3$$

model, respectively, the fluid velocity, the magnetic field, and an additional forcing term; for instance, due to convection. The space and time variables are $t \in \mathbb{R}^+$, $\mathrm{x} = (x, y, z) \in \mathbb{R}^3$. We denote

$$\Delta = \partial_x^2 + \partial_y^2 + \partial_z^2, \quad \nabla = (\partial_x, \partial_y, \partial_z)^t,$$

and for any $v = (v_1(\mathrm{x}), v_2(\mathrm{x}), v_3(\mathrm{x}))^t \in \mathbb{R}^3$,

$$\operatorname{div}\, v = \partial_x v_1 + \partial_y v_2 + \partial_z v_3, \quad \operatorname{curl} v = (\partial_y v_3 - \partial_z v_2, \partial_z v_1 - \partial_x v_3, \partial_x v_2 - \partial_y v_1)^t.$$

Constants Re and Rm are called hydrodynamic and magnetic Reynolds numbers. To lighten the notation, we will assume in what follows that Re = Rm = 1. Note that the divergence-free condition on b is preserved by (1.1b). As soon as it is satisfied initially, it is satisfied for all positive times.

Roughly speaking, *dynamo theory* deals with the stability of solutions

$$(u, b) = (u(t, \mathrm{x}), 0)$$

of system (1.1). More precisely, it studies the generation of magnetic field from the fluid flow u. The basic idea is that the "self-excited" term $\mathrm{curl}\,(u \times b)$ may amplify the magnetic field in the manner of an instability. As long as the fluid motion is strong enough, this transfer from kinetic to magnetic energy may thus prevent the decay of the magnetic field, despite the dissipation term $-\Delta b$.

It is widely accepted that dynamo action takes place in the Earth, in the sun, and in many other planets and stars. Therefore, the understanding of dynamo mechanisms is a major physical issue. It has been the subject of an expansive literature: we refer to the recent review papers by Gilbert [8] and Fearn [5] for a good introduction and appropriate lists of references. Note that most of these references are limited to *kinematic dynamos*: the Laplace force is neglected, and only the induction equation (1.1b) is considered, at imposed velocity u.

Among the mechanisms that have been identified, one of the most famous is the so-called *alpha effect*. It is based on a *scale separation*: the velocity and magnetic fields are assumed to vary on (turbulent) time and length scales τ and l, much smaller than the typical macro scales T and L. Introducing the ratios $\lambda = \tau/T \ll 1$ and $\beta = l/L \ll 1$, one can write this with little formalism:

$$\begin{aligned} u &\approx u_* \left(t, \mathrm{x}, \lambda^{-1} t,\, \beta^{-1}\mathrm{x}\right) \;+\; \bar{u}\,(t, \mathrm{x})\,, \\ b &\approx b_* \left(t, \mathrm{x}, \lambda^{-1} t,\, \beta^{-1}\mathrm{x}\right) \;+\; \bar{b}\,(t, \mathrm{x})\,, \end{aligned} \tag{1.2}$$

where u_* (resp., b_*) is the fluctuating part of the field, and $\bar{u}$ (resp., $\bar{b}$) is its mean part. The basic idea is that the "average" of the fluctuating term $\mathrm{curl}\,(u_* \times b_*)$ can have a destabilizing effect on the mean field $\bar{b}$, generating a dynamo.

This idea was first introduced by Parker [13] in 1955, and in a geophysical context by Braginsky [2]. It has been generalized by Steenbeck, Krause, and Rädler [16]. Let us also mention the important works [14] and [3] on periodic dynamos. Note that the alpha effect has since been confirmed experimentally [17].

The present paper is a small step towards the mathematical study of this mechanism. Namely, we will investigate the stability properties of solutions $(u, 0)$ of (1.1) given by

$$(u, 0) = (\varepsilon^{-1} u^\varepsilon, 0), \quad u^\varepsilon(t, \mathrm{x}) = U(\varepsilon^{-4} t, \varepsilon^{-2}\mathrm{x}), \tag{1.3}$$

where $U = U(\tau, \theta)$ satisfies

$$U \in H^\infty \left(\mathbb{T} \times \mathbb{T}^3\right)^3, \quad \int_{\mathbb{T}\times\mathbb{T}^3} U = 0, \quad \mathrm{div}_\theta\, U = 0. \tag{1.4}$$

Remark 1. The set $\mathcal{P}$ of profiles U satisfying (1.4) is a Fréchet space, where the topology is induced by the family of norms

$$\|U\|_m^2 = \sum_{(\omega,\xi)\in\mathbb{Z}^4} \left(|\omega|^2 + |\xi|^2\right)^m |\hat{U}(\omega, \xi)|^2, \quad m \geq 0,$$

where $\hat{U}$ is the Fourier transform with respect to (τ, θ). We denote by $d_{\mathcal{P}}$ a metric defining this topology.

Remark 2. We assume that $\varepsilon \ll 1$ and that $\int U = 0$, which means we consider fast oscillations with zero mean flow. This is reminiscent of the (somehow crude) modeling of turbulence that we have in mind.

Remark 3. The amplitude and time and length scales in (1.3) are classical (see [8]). In short, one can say using the notation of (1.2) that they correspond to the case

$$|u_*| \gg |\bar{u}|, \quad |b_*| \ll |\bar{b}|.$$

Indeed, the oscillatory part $u_* = \varepsilon^{-1}u^\varepsilon$ of the velocity field is $O(\varepsilon^{-1})$, bigger than the $O(1)$ potential mean part $\bar{u}$. On the contrary, our choices $O(\varepsilon^4)$ and $O(\varepsilon^2)$ for time and length scales of u^ε ensure small amplitude for the oscillatory part of b. This can be seen formally from (1.1b), as the oscillation $b_* = b_*(t, \mathrm{x}, \tau = \varepsilon^{-4}t, \theta = \varepsilon^{-2}\mathrm{x})$ satisfies

$$\varepsilon^{-4}\left(\partial_\tau b_* - \Delta_\theta b_*\right) = o(1).$$

We emphasize that other choices for solutions u^ε are possible. In particular, it would be interesting to study oscillating fields with larger wavelength, so as to emphasize the role of the hyperbolic part of (1.1).

We will show that solutions u^ε given by (1.3) *are stable on times $t = O(1)$ and "generically" unstable on times $t \sim |\ln(\varepsilon)|$.* Substituting $u = \varepsilon^{-1}u^\varepsilon + v$ into (1.1), we will rather work with the system

$$\begin{cases} \partial_t v + \varepsilon^{-1}u^\varepsilon \cdot \nabla v + \varepsilon^{-1} v \cdot \nabla u^\varepsilon + v \cdot \nabla v + \nabla p - \Delta v = \operatorname{curl} b \times b, \\ \partial_t b - \varepsilon^{-1}\operatorname{curl}(u^\varepsilon \times b) - \operatorname{curl}(v \times b) - \Delta b = 0, \\ \operatorname{div} v = \operatorname{div} b = 0. \end{cases} \tag{1.5}$$

Note that for all $\varepsilon > 0$ and all divergence-free fields $v_0^\varepsilon, b_0^\varepsilon \in L^2\left(\mathbb{R}^3\right)^3$, system (1.5) has global weak solutions

$$v, b \in L^\infty_{loc}\left(\mathbb{R}^+;\, L^2\left(\mathbb{R}^3\right)\right)^3 \cap L^2_{loc}(\mathbb{R}^+;\, \dot{H}^1(\mathbb{R}^3))^3,$$

with initial data $v_0^\varepsilon, b_0^\varepsilon$. Indeed, u^ε and its derivatives are bounded functions, so that a classical Leray-type existence theorem for MHD equations extends easily to (1.5).

We will first prove the following stability result.

THEOREM 1.1 (nonlinear stability result). *Let $U \in \mathcal{P}$, and let $\{u^\varepsilon\}_{\varepsilon>0}$ satisfy* (1.3). *Let $m \in \mathbb{N}$, and let v_0, b_0 be in $H^\infty\left(\mathbb{R}^3\right)^3$ divergence-free.*

For all $T \geq 0$, there exist $\delta > 0$, $\varepsilon_0 > 0$ such that if

$$m \geq 1 \quad \text{or} \quad \|(v_0, b_0)\|_{H^{1/2}} \leq \delta,$$

the Cauchy problem (1.5) *with initial data $\varepsilon^m v_0, \varepsilon^m b_0$ has a unique solution*

$$v^\varepsilon, b^\varepsilon \in C^0\left([0,T];\, H^\infty\left(\mathbb{R}^3\right)\right)^3$$

for all $\varepsilon < \varepsilon_0$. Moreover, it satisfies the following for a positive constant C, large s, and small enough ε:

$$\sup_{0\leq t\leq T} \|(v^\varepsilon, b^\varepsilon)(t,\cdot)\|_{L^2} \;\leq\; C\,\varepsilon^m\,\|(v_0,b_0)\|_{H^s},$$
$$\sup_{0\leq t\leq T} \|(v^\varepsilon, b^\varepsilon)(t,\cdot)\|_{L^\infty} \;\leq\; C\,\varepsilon^m\,\|(v_0,b_0)\|_{H^s}.$$

We will then prove the following instability result.

THEOREM 1.2 (nonlinear instability result). *There exists a dense and open subset Ω of $\mathcal{P}$ such that*

- *for all* $U \in \Omega$, *and* $\{u^\varepsilon\}_{\varepsilon>0}$ *satisfying* (1.3), *and*
- *for all* $m \in \mathbb{N}$,

one can find $\delta > 0$, *times* $t(\varepsilon) = O(|\ln(\varepsilon)|)$, *and families of solutions* $\{(v^\varepsilon, b^\varepsilon)^t\}_{\varepsilon>0}$ *of* (1.5) *with*

$$v^\varepsilon, b^\varepsilon \in C^0\left(\mathbb{R}^+; H^\infty\left(\mathbb{R}^3\right)\right)^3,$$

$$\| \partial_{\mathrm{x}}^\alpha (v^\varepsilon, b^\varepsilon)|_{t=0} \|_{L^2} \le C_\alpha\, \varepsilon^{m-2|\alpha|+1} \quad \forall \alpha \in \mathbb{N}^3,$$

and

$$\|b^\varepsilon|_{t=t(\varepsilon)}\|_{L^2} \ge \delta.$$

Remark 4. Note that the lower bound in Theorem 1.2 applies to b^ε, which is exactly the mathematical expression of an alpha effect: small-scale velocity u^ε generates destabilization of $b = 0$.

Remark 5. Theorem (1.2) extends and justifies linear computations carried in [8]. It is also reminiscent of the classical linear computations of Roberts [14] on periodic dynamos. In [14] Roberts studied the equation

$$\partial_t b + \mathrm{curl}\,(u^\varepsilon \times b) - \nu\varepsilon\Delta b = 0, \quad u^\varepsilon = U\left(\varepsilon^{-1}t, \varepsilon^{-1}\mathrm{x}\right),$$

for U periodic with zero mean. He showed an instability result for ν large enough. However, his analysis, which relied heavily on perturbation theory, does not adapt to our nonlinear framework. Henceforth, we use a drastically different approach, based on energy estimates.

The paper is structured as follows. In section 2, we introduce an auxiliary singular system. This system involves additional variables, which take into account the dependence of $(v^\varepsilon, b^\varepsilon)$ on $\varepsilon^{-4}t$, $\varepsilon^{-2}\mathrm{x}$. We construct approximate solutions of this system (section 2.1) and perform a priori estimates (section 2.2). The proof of Theorem 1.1 follows (section 2.3). In section 3, we focus on the instability mechanism. We show that the approximate solutions of section 2 have generically exponential growth (section 3.1) and give precise estimates on this growth (section 3.2). We end with the proof of Theorem 1.2 (section 3.3).

2. Singular system. From the structure of the small-scale flow u^ε, we expect solutions $v^\varepsilon, b^\varepsilon$ of (1.5) to exhibit rapid oscillations, involving $\varepsilon^{-4}t$ and $\varepsilon^{-2}\mathrm{x}$. In particular, we expect the derivatives of $v^\varepsilon, b^\varepsilon$ to behave badly. Hence, we do not expect good H^s energy estimates on system (1.5). To override this difficulty, we will follow ideas of nonlinear geometric optics (cf. [10]): we will work directly in the class of solutions of the type

$$(v^\varepsilon, b^\varepsilon)^t(t,\mathrm{x}) = V^\varepsilon\left(t, \mathrm{x}, \varepsilon^{-4}t, \varepsilon^{-2}\mathrm{x}\right), \tag{2.1}$$

where $V^\varepsilon = V^\varepsilon(t,\mathrm{x},\tau,\theta)$ is periodic in τ and θ. We will get Sobolev bounds on V^ε, which will allow us to control v^ε, b^ε in L^2 and L^∞ (cf. Theorem 1.2).

We introduce the following singular system, of unknown $V = (w, \beta)^t$:

$$\begin{cases} \partial_t V + \varepsilon^{-4}\partial_\tau V + \varepsilon^{-1}(B_{\mathrm{x}} + \varepsilon^{-2}B_\theta)(\tilde{U}, V) + \dfrac{1}{2}(B_{\mathrm{x}} + \varepsilon^{-2}B_\theta)(V,V) \\[2mm] \qquad - \left(\nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta\right)^2 V = \left(\left(\nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta\right) p,\, 0\right)^t, \\[2mm] \mathrm{Div}_{\mathrm{x}} V + \varepsilon^{-2}\mathrm{Div}_\theta V = 0, \end{cases} \tag{2.2}$$

with $\tilde{U} := (U,0)^t$, $U = U(\tau,\theta) \in \mathcal{P}$, where for all $V = (w,\beta)$, $\tilde{V} = (\tilde{w},\tilde{\beta})$,

$$B_{\mathrm{x}}(V,\tilde{V}) := \begin{pmatrix} \mathrm{div}_{\mathrm{x}}\left(w \otimes \tilde{w} - \beta \otimes \tilde{\beta}\right) + \mathrm{div}_{\mathrm{x}}\left(\tilde{w} \otimes w - \tilde{\beta} \otimes \beta\right) \\ -\mathrm{curl}_{\mathrm{x}}\left(w \times \tilde{\beta}\right) - \mathrm{curl}_{\mathrm{x}}\left(\tilde{w} \times \beta\right) \end{pmatrix},$$

$$B_{\theta}(V,\tilde{V}) := \begin{pmatrix} \mathrm{div}_{\theta}\left(w \otimes \tilde{w} - \beta \otimes \tilde{\beta}\right) + \mathrm{div}_{\theta}\left(\tilde{w} \otimes w - \tilde{\beta} \otimes \beta\right) \\ -\mathrm{curl}_{\theta}\left(w \times \tilde{\beta}\right) - \mathrm{curl}_{\theta}\left(\tilde{w} \times \beta\right) \end{pmatrix},$$

and where

$$\mathrm{Div}_{\mathrm{x}} = \begin{pmatrix} \mathrm{div}_{\mathrm{x}} & \\ & \mathrm{div}_{\mathrm{x}} \end{pmatrix}, \quad \mathrm{Div}_{\theta} = \begin{pmatrix} \mathrm{div}_{\theta} & \\ & \mathrm{div}_{\theta} \end{pmatrix}.$$

Note that the quadratic terms in (1.5a) satisfy

$$u^{\varepsilon} \cdot \nabla v + v \cdot \nabla u^{\varepsilon} = \mathrm{div}\ (u^{\varepsilon} \otimes v) + \mathrm{div}\ (v \otimes u^{\varepsilon}),$$

$$\mathrm{curl}\, b \times b = b \cdot \nabla b - \frac{1}{2}\nabla|b|^2 = \mathrm{div}\ (b \otimes b) - \frac{1}{2}\nabla|b|^2,$$

using the fact that v, b are divergence-free. We thus see that any regular solution V^{ε} of (2.2) provides a solution $v^{\varepsilon}, b^{\varepsilon}$ of (1.5) through identity (2.1).

2.1. Approximate solutions. *Up to the end of the section, we fix time $T > 0$, and $m \in \mathbb{N}$.* For any

$$f = f(t,\mathrm{x},\tau,\theta) = \sum_{\omega,k} f_{\omega,k}(t,\mathrm{x})\, e^{i(\omega\tau + k\cdot\theta)},$$

we denote $\overline{f} = f_{0,0}$, $f_* = f - \overline{f}$.

We first construct approximate solutions of (2.2) of the following type:

$$\begin{aligned} V^{\varepsilon}(t,\mathrm{x},\tau,\theta) &\approx \varepsilon^m \sum \varepsilon^i V^i(t,\mathrm{x},\tau,\theta), \\ p^{\varepsilon}(t,\mathrm{x},\tau,\theta) &\approx \varepsilon^{m-1} \sum \varepsilon^i p^i(t,\mathrm{x},\tau,\theta), \end{aligned} \tag{2.3}$$

where for all $i \geq 0$,

$$\left(V^i, p^i\right)^t = (w^i, \beta^i, p^i)^t \in C^{\infty}\left([0,T];\ H^{\infty}\left(\mathbb{R}^3 \times \mathbb{T} \times \mathbb{T}^3\right)\right)^7, \quad \int \overline{p}^i(t,\cdot) = 0.$$

We plug approximation (2.3) into the system (2.2). We identify terms of order ε^{m+i-4} in (2.2a) and of order ε^{m+i-2} in (2.2b). This yields, for all $i \geq 0$,

$$\begin{cases} (\partial_\tau - \Delta_\theta)V^i = F^i, \\ \mathrm{Div}_\theta V^i = -\mathrm{Div}_{\mathrm{x}} V^{i-2}, \end{cases} \tag{S_i}$$

where $V^j := 0$, $p^j := 0$ for $j < 0$, and

$$\begin{aligned} F^i = &-(\partial_t - \Delta_{\mathrm{x}})V^{i-4} - B_{\mathrm{x}}\left(\tilde{U}, V^{i-3}\right) + \left(\mathrm{div}_{\mathrm{x}}\nabla_\theta + \mathrm{div}_\theta\nabla_{\mathrm{x}}\right)V^{i-2} \\ &- \sum_{j+J=i-m-4} B_{\mathrm{x}}\left(V^j, V^J\right) - \sum_{j+J=i-m-2} B_\theta\left(V^j, V^J\right) - B_\theta\left(\tilde{U}, V^{i-1}\right) \\ &+ \left(\nabla_\theta p^{i-1}, 0\right)^t + \left(\nabla_{\mathrm{x}} p^{i-3}, 0\right)^t. \end{aligned} \tag{2.4}$$

Note that (S_0) is equivalent to $V_*^0 \equiv 0$. For $i \geq 0$, we take the oscillatory part of (S_{i+1}) and the average of (S_{i+4}). We get

$$(T_i) \qquad \begin{cases} (\partial_\tau - \Delta_\theta) V_*^{i+1} = \left(\nabla_\theta p_*^i, 0\right)^t - B_\theta\left(\tilde{U}, \overline{V}^i\right) + G_*^i, \\ \mathrm{Div}_\theta V_*^{i+1} = -\mathrm{Div}_{\mathrm{x}} V_*^{i-1}, \\ (\partial_t - \Delta_{\mathrm{x}})\overline{V}^i = \left(\nabla_{\mathrm{x}} \overline{p}^{i+1}, 0\right)^t - \overline{B_{\mathrm{x}}\left(\tilde{U}, V_*^{i+1}\right)} - \displaystyle\sum_{j+J=i-m} \overline{B_{\mathrm{x}}\left(V^j, V^J\right)}, \\ \mathrm{Div}_{\mathrm{x}} \overline{V}^i = 0, \end{cases}$$

where $G_*^i := F_*^{i+1} - (\nabla_\theta p_*^i, 0)^t + B_\theta(\tilde{U}, \overline{V}^i)$ depends only on $V^0, \ldots, V^{i-1}$, V_*^i, and $\nabla_{\mathrm{x}} p_*^{i-1}$.

Thus, introducing

$$X^i := \left(\overline{V}^i, V_*^{i+1}, p_*^i, \overline{p}^{i+1}\right),$$

(T_i) can be seen as a system of unknown X^i, with data depending on $X^0, X^1, \ldots, X^{i-1}$. We will show inductively on $i \geq 0$ the solvability of (T_i).

Case $i = 0$. Recall that $V_*^0 \equiv 0$. As $\overline{p}^0$ does not appear in systems (T_i), we can also assume $\overline{p}^0 \equiv 0$. System (T_0) depends on the values of m.

- $m = 0$. The system (T_0) reads

$$\begin{cases} (\partial_\tau - \Delta_\theta) V_*^1 = \left(\nabla_\theta p_*^0, 0\right)^t - B_\theta\left(\tilde{U}, \overline{V}^0\right), \\ \mathrm{Div}_\theta V_*^1 = 0, \\ (\partial_t - \Delta_{\mathrm{x}})\overline{V}^0 = \left(\nabla_{\mathrm{x}} \overline{p}^1, 0\right)^t - \overline{B_{\mathrm{x}}\left(\tilde{U}, V_*^1\right)} - B_{\mathrm{x}}\left(\overline{V}^0, \overline{V}^0\right), \\ \mathrm{Div}_{\mathrm{x}} \overline{V}^0 = 0. \end{cases}$$

Applying Div_θ to $(T_0\mathrm{a})$ and using $(T_0\mathrm{b})$ leads to

$$(\Delta_\theta p_*^0, 0)^t = \mathrm{Div}_\theta B_\theta\big(\tilde{U}, \overline{V}^0\big).$$

As the second component of the right-hand side is $\mathrm{div}_\theta\, \mathrm{curl}_\theta\big(U \times \overline{\beta}^0\big) \equiv 0$, such an equation has a unique solution:

$$(p_*^0, 0)^t = \Delta_\theta^{-1} \mathrm{Div}_\theta B_\theta\big(\tilde{U}, \overline{V}^0\big). \tag{2.5}$$

Here, Δ_θ^{-1} denotes the inverse of Δ_θ in the set of L^2 periodic functions of (τ, θ) with zero average in θ. Thus, we are left with

$$\begin{cases} (\partial_\tau - \Delta_\theta) V_*^1 = L_\theta \overline{V}^0, \\ (\partial_t - \Delta_{\mathrm{x}})\overline{V}^0 = \left(\nabla_{\mathrm{x}} \overline{p}^1, 0\right)^t - \overline{B_{\mathrm{x}}\left(\tilde{U}, V_*^1\right)} - B_{\mathrm{x}}\left(\overline{V}^0, \overline{V}^0\right), \\ \mathrm{Div}_{\mathrm{x}} \overline{V}^0 = 0, \end{cases}$$

where

$$L_\theta \overline{V}^0 := \nabla_\theta \Delta_\theta^{-1} \mathrm{Div}_\theta B_\theta \left(\tilde{U}, \overline{V}^0\right) - B_\theta \left(\tilde{U}, \overline{V}^0\right).$$

Note that

$$V_*^1 = (\partial_\tau - \Delta_\theta)^{-1} L_\theta \overline{V}^0, \tag{2.6}$$

where $(\partial_\tau - \Delta_\theta)^{-1}$ denotes the inverse of $\partial_\tau - \Delta_\theta$ in the set of L^2 periodic functions of (τ, θ) with zero average in θ. We end up with

$$\begin{cases} (\partial_t - \Delta_{\mathrm{x}})\overline{V}^0 = \left(\nabla_{\mathrm{x}} \overline{p}^1, 0\right)^t - \overline{B_{\mathrm{x}}\left(\tilde{U}, (\partial_\tau - \Delta_\theta)^{-1} L_\theta \overline{V}^0\right)} - B_{\mathrm{x}}\left(\overline{V}^0, \overline{V}^0\right), \\ \mathrm{Div}_{\mathrm{x}} \overline{V}^0 = 0. \end{cases} \tag{2.7}$$

This last system is of the type (1.1), up to the additional linear term

$$\mathcal{A}\overline{V}^0 := -\overline{B_{\mathrm{x}}\left(\tilde{U}, (\partial_\tau - \Delta_\theta)^{-1} L_\theta \overline{V}^0\right)}.$$

Classical existence results for smooth solutions of Navier–Stokes-type equations extend without difficulty (see [7]). In particular, there exists $\delta = \delta(T)$ such that for all

$$\overline{V}_0^0 \in H^\infty\left(\mathbb{R}^3\right)^6, \quad \mathrm{Div}_{\mathrm{x}} \overline{V}_0^0 = 0, \quad \|\overline{V}_0^0\|_{H^{1/2}} \le \delta,$$

system (2.7) has a unique solution

$$\left(\overline{V}^0, \overline{p}^1\right) \in C^\infty\left([0,T];\ H^\infty\left(\mathbb{R}^3\right)\right)^7, \quad \int \overline{p}^1(t,\cdot) = 0,$$

with $\overline{V}^0|_{t=0} = \overline{V}_0^0$. Together with (2.5) and (2.6), this provides a unique solution

$$X^0 = \left(\overline{V}^0, V_*^1, p_*^0, \overline{p}^1\right)$$

of system (T_0).

- $m \ge 1$. The situation is even simpler, as the quadratic term disappears. We are left with

$$\begin{cases} (\partial_t - \Delta_{\mathrm{x}})\overline{V}^0 = \left(\nabla_{\mathrm{x}} \overline{p}^1, 0\right)^t + \mathcal{A}\overline{V}^0, \\ \mathrm{Div}_{\mathrm{x}} \overline{V}^0 = 0, \end{cases} \tag{2.8}$$

which has regular solutions

$$\left(\overline{V}^0, p^1\right)^t \in C^0\left(\mathbb{R}^+;\ H^\infty\left(\mathbb{R}^3\right)\right)^7, \quad \int \overline{p}^1(t,\cdot) = 0$$

for any initial data $\overline{V}_0^0$ in $H^\infty\left(\mathbb{R}^3\right)^6$, $\mathrm{Div}_{\mathrm{x}} \overline{V}^0 = 0$.

Case $i \ge 1$. The solvability of (T_i) is proved inductively. Let $i \ge 1$, and let $X^0, \dots, X^{i-1}$ solve $(T_0), \dots, (T_{i-1})$ on the time interval $[0,T]$. Applying Div_θ to $(T_i\mathrm{a})$ and using $(T_i\mathrm{b})$ leads to

$$(\Delta_\theta p_*^i, 0)^t = \mathrm{Div}_\theta\left(B_\theta\left(\tilde{U}, \overline{V}^i\right) - G_*^i\right) - (\partial_\tau - \Delta_\theta)\, \mathrm{Div}_{\mathrm{x}} V_*^{i-1}. \tag{2.9}$$

To solve (T_i), we need to verify that the right-hand side of (2.9) has zero second component. This compatibility condition ensures that the magnetic component of our approximation remains divergence-free. It is reminiscent to the fact that $\operatorname{div} b = 0$ is preserved by (1.5b).

If we denote $G^i_* = \left(g^i_*, h^i_*\right)^t$, then (2.9) has a unique solution if and only if

$$\mathrm{div}_\theta h^i_* = -(\partial_\tau - \Delta_\theta)\mathrm{div}_\mathrm{x} \beta^{i-1}_*,$$

i.e.,

$$\mathrm{div}_\theta h^i_* = -\mathrm{div}_\mathrm{x} h^{i-2}_*. \tag{2.10}$$

The expression of h^i_* yields

$$\begin{aligned}
\mathrm{div}_\theta h^i_* &= \mathrm{div}_\theta \bigg(-(\partial_t - \Delta_\mathrm{x})\beta^{i-3} + \left(\mathrm{div}_\mathrm{x}\nabla_\theta + \mathrm{div}_\theta\nabla_\mathrm{x}\right)\beta^{i-1} \\
&\qquad + \mathrm{curl}_\mathrm{x}\left(U \times \beta^{i-2}\right) + \mathrm{curl}_\mathrm{x} \sum_{j+J=i-m-3} w^j \times \beta^J \bigg) \\
&= -(\partial_t - \Delta_\mathrm{x})\mathrm{div}_\theta \beta^{i-3} + \left(\mathrm{div}_\mathrm{x}\nabla_\theta + \mathrm{div}_\theta\nabla_\mathrm{x}\right)\mathrm{div}_\theta \beta^{i-1} \\
&\qquad - \mathrm{div}_\mathrm{x}\mathrm{curl}_\theta \left(U \times \beta^{i-2}\right) - \mathrm{div}_\mathrm{x}\mathrm{curl}_\theta \sum_{j+J=i-m-3} w^j \times \beta^J.
\end{aligned}$$

Using that $\mathrm{div}_\theta \beta^i = -\mathrm{div}_\mathrm{x}\beta^{i-2}$ for all i and $\mathrm{div}_\mathrm{x}\mathrm{curl}_\mathrm{x} \equiv 0$, we get

$$\begin{aligned}
\mathrm{div}_\theta h^i_* = -\mathrm{div}_\mathrm{x} \bigg(&-(\partial_t - \Delta_\mathrm{x})\beta^{i-5} + \left(\mathrm{div}_\mathrm{x}\nabla_\theta + \mathrm{div}_\theta\nabla_\mathrm{x}\right)\beta^{i-3} \\
&+ \mathrm{curl}_\theta\left(U \times \beta^{i-2}\right) + \mathrm{curl}_\mathrm{x}\left(U \times \beta^{i-4}\right) \\
&+ \mathrm{curl}_\theta \sum_{j+J=i-m-3} w^j \times \beta^J + \mathrm{curl}_\mathrm{x} \sum_{j+J=i-m-5} w^j \times \beta^J \bigg),
\end{aligned}$$

which is exactly (2.10). Hence,

$$\left(p^i_*, 0\right)^t = \Delta_\theta^{-1}\mathrm{Div}_\theta B_\theta\left(\tilde{U}, \overline{V}^i\right) + H^i_*, \tag{2.11}$$

where H^i_* depends only on $X^0, \ldots, X^{i-1}$. Solving $(T_i\mathrm{a})$ yields in turn

$$V^{i+1}_* = (\partial_\tau - \Delta)^{-1} L_\theta \overline{V}^i + I^i_*,$$

where I^i_* depends only on $X^0, \ldots, X^{i-1}$. We are left with equations of the following type:

$$\begin{cases}
(\partial_t - \Delta_\mathrm{x})\overline{V}^i = \left(\nabla_\mathrm{x}\overline{p}^{i+1}, 0\right)^t + \mathcal{A}\,\overline{V}^i + \overline{J}^i \\
\qquad\qquad - \delta_{0m}\left(B_\mathrm{x}\left(\overline{V}^0, \overline{V}^i\right) + B_\mathrm{x}\left(\overline{V}^i, \overline{V}^0\right)\right), \\
\mathrm{Div}_\mathrm{x}\overline{V}^i = 0,
\end{cases} \tag{2.12}$$

where δ_{0m} is the Kronecker symbol, and where

$$\overline{J}^i \in C^\infty\left([0,T];\ H^\infty\left(\mathbb{R}^3\right)\right)^6$$

depends on $X^0, \dots, X^{i-1}$. This system is linear and of parabolic type. It follows easily that for all initial data $\overline{V}^i|_{t=0} = \overline{V}^i_0$ in $H^\infty\left(\mathbb{R}^3\right)^6$, $\mathrm{Div_x}\overline{V}^i_0 = 0$, such a system has a unique solution

$$\left(\overline{V}^i, \overline{p}^i\right) \in C^\infty\left([0,T];\, H^\infty\left(\mathbb{R}^3\right)\right)^7, \quad \int \overline{p}^i(t,\cdot) = 0.$$

Back to system (T_i), this ends the induction.

2.2. A priori estimates. We now establish some stability estimates on systems of type (2.2) that will be used in sections 2.3 and 3.3. More precisely, let $\{T^\varepsilon\}_{\varepsilon>0}$ be a family of times, and let $\left\{V^\varepsilon_{app}\right\}_{\varepsilon>0}$, $\{F^\varepsilon\}_{\varepsilon>0}$ be families of functions satisfying,

$$\forall\varepsilon, \quad V^\varepsilon_{app}, F^\varepsilon_{app} \in C\left([0,T^\varepsilon];\, H^\infty\left(\mathbb{T}\times\mathbb{T}^3\times\mathbb{R}^3\right)\right)^6,$$

and such that

$$\sup_{\varepsilon}\sup_{0\le t\le T^\varepsilon}\left\|\partial_t^\alpha\partial_{\mathrm{x},\tau,\theta}^\beta V^\varepsilon_{app}(t,\cdot)\right\|_{L^\infty} \le C_{\alpha,\beta} \quad \forall\alpha,\beta. \tag{2.13}$$

We define

$$U^\varepsilon := \tilde{U} + \varepsilon V^\varepsilon_{app}, \quad \tilde{U} = (U,0)^t, \quad U \in \mathcal{P},$$

and we consider the following equations:

$$\begin{cases} \partial_t V + \varepsilon^{-4}\partial_\tau V + \varepsilon^{-1}(B_\mathrm{x} + \varepsilon^{-2}B_\theta)(U^\varepsilon, V) + \dfrac{1}{2}(B_\mathrm{x} + \varepsilon^{-2}B_\theta)(V,V) \\ \qquad -\left(\nabla_\mathrm{x} + \varepsilon^{-2}\nabla_\theta\right)^2 V = \left(\left(\nabla_\mathrm{x} + \varepsilon^{-2}\nabla_\theta\right)p,\, 0\right)^t + F^\varepsilon, \\ \mathrm{Div_x}V + \varepsilon^{-2}\mathrm{Div}_\theta V = 0. \end{cases} \tag{2.14}$$

We distinguish between the low-frequency part V_l and the high-frequency part V_h of V. We introduce $\chi = \chi(\zeta,\xi) \in C^\infty\left(\mathbb{R}^3\times\mathbb{T}^3\right)$ such that

$$\begin{aligned} \chi(\zeta,\xi) &= 1 \quad \text{for } |\zeta+\xi| \le \delta, \\ \chi(\zeta,\xi) &= 0 \quad \text{for } |\zeta+\xi| \ge 2\delta, \end{aligned}$$

where δ is a fixed number satisfying $0 < \delta < 1/4$. Then we set

$$V_l = \chi(\varepsilon^2 D_\mathrm{x}, D_\theta)V, \quad p_l = \chi(\varepsilon^2 D_\mathrm{x}, D_\theta)p, \quad V_h = V - V_l, \quad p_h = p - p_l,$$

where for any f, $\chi(\varepsilon^2 D_\mathrm{x}, D_\theta)f$ is the Fourier multiplier defined as

$$\mathcal{F}\left(\chi(\varepsilon^2 D_\mathrm{x}, D_\theta)f\right)(\zeta,\xi) = \chi(\varepsilon^2\zeta,\xi)\mathcal{F}(f)(\zeta,\xi),$$

$\mathcal{F}$ being the Fourier transform with respect to x and θ. Finally, we define for all $s \in N$ and for all $t \in [0,T^\varepsilon]$

$$\begin{aligned} \Psi_s(V;t) &:= \|V_l(t)\|^2_{H^s} + \varepsilon^2\|V_h(t)\|^2_{H^s} + \int_0^t \|\left(\nabla_\mathrm{x} + \varepsilon^{-2}\nabla_\theta\right)V_l(u)\|^2_{H^s}\,du \\ &\qquad + \varepsilon^{-2}\int_0^t \|V_h(u)\|^2_{H^s}\,du + \varepsilon^{-2}\int_0^t \|(\varepsilon^2\nabla_\mathrm{x} + \nabla_\theta)V_h(u)\|^2_{H^s}\,du, \\ \alpha_s(V;t) &= \sup_{0\le u\le t}\Psi_s(V;u). \end{aligned}$$

We show the following.

Proposition 2.1. *Let $V \in C^0\left([0,T^\varepsilon]; H^\infty\right)^6$, satisfying* (2.14). *Then the following inequality holds, for all $s \geq 5$, for ε small enough:*

$$\alpha_s(V;t) \leq \mathcal{C}_s\left(\alpha_s(V;0) + \varepsilon^6 \int_0^t \|F_h^\varepsilon(u)\|_{H^s}^2\, du + \int_0^t \|F_l^\varepsilon(u)\|_{H^s}^2\, du \right. \\ \left. + (1+\alpha_s(V;t)) \int_0^t \alpha_s(V;u)\, du \, + \, \alpha_s(V;t)^2\right). \tag{2.15}$$

Proof. We start with an L^2 estimate on (2.14).

L^2 estimates.

- *Estimates on V_h.* We apply $\left(1-\chi\left(\varepsilon^2 D_{\mathrm{x}}, D_\theta\right)\right)$ to (2.14). Multiplication by V_h and integration yield

$$\|V_h(t)\|_{L^2}^2 + \varepsilon^{-4}\int_0^t \|(\varepsilon^2\nabla_{\mathrm{x}} + \nabla_\theta)V_h\|_{L^2}^2 \leq \|V_h(0)\|_{L^2}^2 \\ + \frac{\|U^\varepsilon\|_\infty}{\varepsilon^3}\int_0^t \|V\|_{L^2}\, \|(\varepsilon^2\nabla_{\mathrm{x}} + \nabla_\theta)V_h\|_{L^2} \\ + \int_0^t \|V\otimes V\|_{L^2}\, \|(\nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta)V_h\|_{L^2} + \int_0^t \|F_h^\varepsilon\|_{L^2}\, \|V_h\|_{L^2}.$$

Recall that notation $V\otimes V$ refers to the matrix $(V_j\, V_k)_{j,k}$.

By the Plancherel formula,

$$\|(\varepsilon^2\nabla_{\mathrm{x}} + \nabla_\theta)V_h\|_{L^2}^2 = \frac{1}{(2\pi)^6}\int |\varepsilon^2\zeta + \xi|^2 |\mathcal{F}(V_h)(\zeta,\xi)|^2 d\zeta d\xi \\ \geq \frac{\delta^2}{(2\pi)^6}\int |\mathcal{F}(V_h)(\zeta,\xi)|^2 d\zeta d\xi = \delta^2 \|V^h\|_{L^2}^2.$$

Hence, for ε small enough,

$$\|V_h(t)\|_{L^2}^2 + \varepsilon^{-4}\int_0^t \|V_h\|_{L^2}^2 + \varepsilon^{-4}\int_0^t \|(\varepsilon^2\nabla_{\mathrm{x}} + \nabla_\theta)V_h\|_{L^2}^2 \leq C\biggl(\|V_h(0)\|_{L^2}^2 \\ + \varepsilon^{-2}\int_0^t \|V_l\|_{L^2}^2 + \int_0^t \|V\otimes V\|_{L^2}^2 + \varepsilon^4\int_0^t \|F_h^\varepsilon\|_{L^2}^2\biggr). \tag{2.16}$$

- *Estimates on V_l.* The low-frequency part V_l satisfies

$$\partial_t V_l - (\nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta))^2 V_l = -\left((\nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta)p_l, 0\right)^t \\ - \frac{1}{2}\chi(\varepsilon^2 D_{\mathrm{x}}, D_\theta)\left(B_{\mathrm{x}} + \varepsilon^{-2}B_\theta\right)(V,V) \, - \, \varepsilon^{-1}\chi(\varepsilon^2 D_{\mathrm{x}}, D_\theta)\, \left(B_{\mathrm{x}} + \varepsilon^{-2}B_\theta\right)(U^\varepsilon, V).$$

The key observation is that

$$\chi(\varepsilon^2 D_{\mathrm{x}}, D_\theta)\left(B_{\mathrm{x}} + \varepsilon^{-2}B_\theta\right)(U^\varepsilon, V) = \chi(\varepsilon^2 D_{\mathrm{x}}, D_\theta)\left(B_{\mathrm{x}} + \varepsilon^{-2}B_\theta\right)(\tilde{U}, V_h) \\ + \varepsilon\, \chi(\varepsilon^2 D_{\mathrm{x}}, D_\theta)\left(B_{\mathrm{x}} + \varepsilon^{-2}B_\theta\right)(V_{app}^\varepsilon, V).$$

Indeed,

$$\begin{aligned}\text{supp } \mathcal{F}\left(\left(B_{\mathrm{x}}+\varepsilon^{-2}B_\theta\right)\left(\tilde{U},V_l\right)\right) &\subset \text{ supp } \mathcal{F}(U) \ + \ \text{ supp } \mathcal{F}(V_l)\\ &\subset \bigcup_{\xi'\in\mathbb{Z}^3-\{0\}} \{(0,\xi')\} \ + \ \left\{(\zeta,\xi),\ |\varepsilon^2\zeta+\xi|\le 2\delta\right\}\\ &\subset \left\{(\zeta,\xi), \quad |\varepsilon^2\zeta+\xi|\ge 1-2\delta\right\}\end{aligned}$$

As $\delta < 1/4$, we get

$$\text{supp } \mathcal{F}(U) \ + \ \text{ supp } \mathcal{F}(V_l) \ \subset \ \left\{(\zeta,\xi), \quad |\varepsilon^2\zeta+\xi| > 2\delta\right\}$$

so that

$$\chi(\varepsilon^2 D_{\mathrm{x}}, D_\theta)\left(B_{\mathrm{x}}+\varepsilon^{-2}B_\theta\right)(\tilde{U},V_l)=0.$$

We end with the following energy estimates:

$$\begin{aligned}\|V_l(t)\|_{L^2}^2 + \int_0^t \|(\nabla_{\mathrm{x}}+\varepsilon^{-2}\nabla_\theta)V_l\|_{L^2}^2 \le C\Big(&\|V_l(0)\|_{L^2}^2\\ &+\varepsilon^{-2}\int_0^t \|V_h\|_{L^2}^2 + \int_0^t \|V_l\|_{L^2}^2 + \int_0^t \|V\otimes V\|_{L^2}^2 + \int_0^t \|F_l^\varepsilon\|_{L^2}^2\Big).\end{aligned}$$

Combining with (2.16), we get

$$\Psi_0(V;t) \le C\Big(\Psi_0(V;0)+\int_0^t \|V_l\|_{L^2}^2+\int_0^t \|V\otimes V\|_{L^2}^2+\varepsilon^6\int_0^t \|F_h^\varepsilon\|_{L^2}^2+\int_0^t \|F_l^\varepsilon\|_{L^2}^2\Big).$$

H^s *estimates.* We do not detail the derivation of the H^s estimates, $s\ge 1$. They follow from differentiating system (2.14) and applying the same argument as above. We get, for all s and for small enough ε,

$$\begin{aligned}\Psi_s(V;t) \ \le \ C_s\Big(&\Psi_s(V;0)+\int_0^t \|V_l\|_{H^s}^2 + \int_0^t \|V\otimes V\|_{H^s}^2\\ &+\varepsilon^6\int_0^t \|F_h^\varepsilon\|_{H^s}^2 + \int_0^t \|F_l^\varepsilon\|_{H^s}^2\Big).\end{aligned}\tag{2.17}$$

It remains to handle the quadratic terms. As $s \ge 5 > 7/2$, $H^s\left(\mathbb{R}^3\times\mathbb{T}\times\mathbb{T}^3\right)$ is a Banach algebra. Hence, we obtain the bounds

$$\begin{aligned}\int_0^t \|V_l\otimes V_h\|_{H^s}^2 &\le \int_0^t \|V_l\|_{H^s}^2\|V_h\|_{H^s}^2\\ &\le \left(\sup_{0\le u\le t}\|V_l(u)\|_{H^s}^2\right)\left(\int_0^t \|V_h\|_{H^s}^2\right)\end{aligned}$$

and, in the same way,

$$\int_0^t \|V_l\otimes V_l\|_{H^s}^2 \le \left(\sup_{0\le u\le t}\|V_l(u)\|_{H^s}^2\right)\left(\int_0^t \|V_l\|_{H^s}^2\right),$$

$$\int_0^t \|V_h \otimes V_h\|_{H^s}^2 \leq \left(\sup_{0\leq u\leq t} \varepsilon^2 \|V_h(u)\|_{H^s}^2\right) \left(\varepsilon^{-2}\int_0^t \|V_h\|_{L^2}^2\right).$$

If we inject these bounds in (2.17), we obtain

$$\Psi_s(V;t) \leq C_s \left(\Psi_s(V;0) + \varepsilon^6 \int_0^t \|F_h^\varepsilon(u)\|_{H^s}^2 du + \int_0^t \|F_l^\varepsilon(u)\|_{H^s}^2 du \right.$$
$$\left. + (1+\alpha_s(V;t)) \int_0^t \Psi_s(V;u)du + \alpha_s(V;t)\Psi_s(V;t)\right). \tag{2.18}$$

Bound (2.15) follows. This ends the proof of the proposition.

2.3. Proof of Theorem 1.1. We now turn to the proof of Theorem 1.1. Let $\overline{V}_0 = (v_0, b_0)$ in $H^\infty\left(\mathbb{R}^3\right)^6$, such that $\mathrm{Div}_{\mathrm{x}}\overline{V}_0 = 0$. From computations of section 2.1, we infer the existence of $\delta > 0$, such that if

$$m \geq 1 \quad \text{or} \quad \|\overline{V}_0\|_{H^{1/2}} \leq \delta, \tag{2.19}$$

there exist approximate solutions of (2.2), indexed by $n \in \mathbb{N}$,

$$V_{app}^{\varepsilon,n} = \varepsilon^m \left(\overline{V}^0(t,\mathrm{x}) + \sum_{i=1}^n \varepsilon^i V^i\left(t,\mathrm{x},\tau,\theta\right) + \varepsilon^{n+1} V_*^{n+1}\right), \tag{2.20}$$

$$p_{app}^{\varepsilon,n} = \varepsilon^m \left(p_*^0(t,\mathrm{x},\tau,\theta) + \sum_{i=1}^n \varepsilon^i p^i\left(t,\mathrm{x},\tau,\theta\right) + \varepsilon^{n+1} \overline{p}^{n+1}\right), \tag{2.21}$$

with $\overline{V}^0|_{t=0} = \overline{V}_0$, and $\overline{V}^i|_{t=0} = 0$ for $i \geq 1$. Profiles V^i and p^i are found using the recursion of the previous section. They satisfy

$$\begin{cases} \partial_t V_{app}^{\varepsilon,n} + \varepsilon^{-4}\partial_\tau V_{app}^{\varepsilon,n} + \varepsilon^{-1}\left(B_{\mathrm{x}} + \varepsilon^{-2}B_\theta\right)(\tilde{U}, V_{app}^{\varepsilon,n}) \\ \qquad + \dfrac{1}{2}\left(B_{\mathrm{x}} + \varepsilon^{-2}B_\theta\right)(V_{app}^{\varepsilon,n}, V_{app}^{\varepsilon,n}) - \left(\nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta\right)^2 V_{app}^{\varepsilon,n} \\ \qquad = -\left(\left(\nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta\right) p_{app}^{\varepsilon,n},\, 0\right)^t + R_{app}^{\varepsilon,n}, \\ \left(\mathrm{Div}_{\mathrm{x}} \,+\, \varepsilon^{-2}\mathrm{Div}_\theta\right) V_{app}^{\varepsilon,n} = r_{app}^{\varepsilon,n}, \end{cases} \tag{2.22}$$

where for all $s, \alpha \in \mathbb{N}$, the remainders $R_{app}^{\varepsilon,n}$ and $r_{app}^{\varepsilon,n}$ satisfy the following estimates:

$$\sup_{0\leq t\leq T^\varepsilon} \|\partial_t^\alpha R_{app}^{\varepsilon,n}(t)\|_{H^s} \leq C_{\alpha,s}\,\varepsilon^{m+n-2}, \qquad \sup_{0\leq t\leq T^\varepsilon} \|\partial_t^\alpha r_{app}^{\varepsilon,n}(t)\|_{H^s} \leq C_{\alpha,s}\,\varepsilon^{m+n}. \tag{2.23}$$

We want the second equation of (2.22) to become homogeneous. This is useful in the energy estimates for getting rid of the gradient pressure term. We need to build a function W_{app}^ε, "sufficiently small," such that

$$\left(\mathrm{Div}_{\mathrm{x}} \,+\, \varepsilon^{-2}\mathrm{Div}_\theta\right) W_{app}^\varepsilon = -r_{app}^{\varepsilon,n}.$$

A natural attempt to do so would be to look for W_{app}^ε in the form

$$W_{app}^\varepsilon = \begin{pmatrix} \nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta & \\ & \nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta \end{pmatrix} \Psi^\varepsilon, \tag{2.24}$$

with

$$-\left(\nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta\right)^2 \Psi^\varepsilon = r^{\varepsilon,n}_{app}. \tag{2.25}$$

However, it is not obvious that (2.25) has a solution. Indeed, the operator $-(\nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta)^2$ is not elliptic: its symbol $(\zeta + \varepsilon^{-2}\xi)^2$ cancels for all $\zeta = -\varepsilon^{-2}\xi,\ \xi \in \mathbb{Z}$.

To get rid of this difficulty, we must again distinguish between average and oscillations, and between low frequencies and high frequencies. We first notice that

$$r^{\varepsilon,n}_{app} = \varepsilon^{m+n}\mathrm{Div}_{\mathrm{x}}\left(V^n_* + \varepsilon V^{n+1}_*\right) = r^{\varepsilon,n}_{app,*}.$$

Then we infer from the regularity of $V^{\varepsilon,n}_{app}$ that

$$\begin{aligned}
&\|\partial_t^\alpha\partial_\tau^\beta V^{\varepsilon,n}_{app,*,l}(t,\cdot,\tau,\cdot)\|^2_{H^s}\\
&\le \frac{1}{(2\pi)^6}\int_{\{|\varepsilon^2\zeta+\xi|\,\le\,2\delta\}}(1+|\zeta|^2+|\xi|^2)^s\,\left|\mathcal{F}(\partial_t^\alpha\partial_\tau^\beta V^{\varepsilon,n}_{app,*}(t,\cdot,\tau,\cdot))\right|^2\,d\zeta d\xi\\
&\le \frac{1}{(2\pi)^6}\int_{\{|\zeta|\,\ge\,(1-2\delta)\,\varepsilon^{-2}\}}(1+|\zeta|^2+|\xi|^2)^s\,\left|\mathcal{F}(\partial_t^\alpha\partial_\tau^\beta V^{\varepsilon,n}_{app,*}(t,\cdot,\tau,\cdot))\right|^2\,d\zeta d\xi\\
&\le C_k\,\varepsilon^{4k}\,\|\partial_t^\alpha\partial_\tau^\beta V^{\varepsilon,n}_{app}(t,\cdot,\tau,\cdot)\|_{H^{s+k}} = O(\varepsilon^{4k}) \qquad \forall k>0.
\end{aligned} \tag{2.26}$$

Thus, redefining

$$V^{\varepsilon,n}_{app} := \overline{V}^{\varepsilon,n}_{app} + V^{\varepsilon,n}_{app,*,h},$$

we see that $V^{\varepsilon,n}_{app}$ still satisfies a system of type (2.22), with estimates (2.23), and the new remainder $r^{\varepsilon,n}_{app}$ is such that

$$r^{\varepsilon,n}_{app,l} = 0.$$

In particular, the function W^ε_{app} given by (2.24), (2.25) is well-defined and is bounded by

$$\|\partial_t^\alpha W^\varepsilon_{app}\|_{H^{s-1}} \le C_{\alpha,s}\,\varepsilon^2\,\|\partial_t^\alpha r^\varepsilon_{app}\|_{H^s} \quad \forall \alpha, s.$$

Finally, we set $V^\varepsilon_{app} = V^{\varepsilon,n}_{app} + W^\varepsilon_{app}$. This solves

$$(2.27)\qquad \begin{cases} \partial_t V^\varepsilon_{app} + \varepsilon^{-4}\partial_\tau V^\varepsilon_{app} + \varepsilon^{-1}\left(B_{\mathrm{x}} + \varepsilon^{-2}B_\theta\right)(\tilde{U}, V^\varepsilon_{app}) \\ \qquad\qquad + \dfrac{1}{2}\left(B_{\mathrm{x}} + \varepsilon^{-2}B_\theta\right)(V^\varepsilon_{app}, V^\varepsilon_{app}) - \left(\nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta\right)^2 V^\varepsilon_{app} \\ \qquad\qquad = -\left(\left(\nabla_{\mathrm{x}} + \varepsilon^{-2}\nabla_\theta\right)p^\varepsilon_{app},\, 0\right)^t + R^\varepsilon_{app}, \\ \mathrm{Div}_{\mathrm{x}} V \;+\; \varepsilon^{-2}\mathrm{Div}_\theta V = 0, \end{cases}$$

where

$$(2.28)\qquad \sup_{0\le t\le T^\varepsilon} \|R^\varepsilon_{app}(t)\|_{H^s} \le C_s\,\varepsilon^{m+n-2} \quad \forall s.$$

We can now use the results of section 2.2. We fix $n \ge 4$, $s \ge 5$ and assume (2.19). For ε small enough, we will show the existence of a solution of (2.2), $V^\varepsilon \in C^0\left([0,T];\, H^\infty\left(\mathbb{R}^3\times\mathbb{T}\times\mathbb{T}^3\right)\right)^6$, $V^\varepsilon|_{t=0} = \varepsilon^m\overline{V}_0$.

The local existence theory of smooth solutions for (2.2) is classical (see, for instance, [11]). For all $\varepsilon > 0$, there exists a unique maximal solution

$$V^\varepsilon \in C^0\left([0,T^\varepsilon_*);\, H^\infty\left(\mathbb{R}^3\times\mathbb{T}\times\mathbb{T}^3\right)\right)^6, \quad V^\varepsilon|_{t=0} = \varepsilon^m\overline{V}_0.$$

Moreover, the lifespan T^ε_* satisfies one of the following conditions:

- $T^\varepsilon_* \ge T$,
- $T^\varepsilon_* < T$ and $\liminf_{t\to T^\varepsilon_*} \|V^\varepsilon(t)\|_{H^s} \to +\infty$.

It is enough to show that the second possibility does not occur for small enough ε. Let $T^\varepsilon < \min(T^\varepsilon_*, T)$, and define $W^\varepsilon := V^\varepsilon - V^\varepsilon_{app}$ on $[0,T^\varepsilon]$. Then W^ε is a solution of (2.14), where V^ε_{app} defined above satisfies (2.13), and $F^\varepsilon = R^\varepsilon_{app}$ satisfies (2.28).

We apply Proposition 2.1. This yields, for ε small enough,

$$(2.29)\qquad \alpha_s(W^\varepsilon;t) \le C\Bigg(\varepsilon^{2m+4} + \alpha_s(W^\varepsilon;0) + (1+\alpha_s(W^\varepsilon;t))\int_0^t \alpha_s(W^\varepsilon;u)du \\ + \alpha_s(W^\varepsilon;t)^2\Bigg).$$

Note that $W^\varepsilon|_{t=0} = \varepsilon^m\overline{V}_0 - V^\varepsilon_{app}|_{t=0}$ satisfies

$$\overline{W}^\varepsilon|_{t=0} = 0, \quad \|W^\varepsilon_*|_{t=0}\|_{H^s} = O(\varepsilon^{m+1}).$$

As in (2.26), we deduce that

$$(2.30)\qquad \|W^\varepsilon_l|_{t=0}\|_{H^s} = O(\varepsilon^k) \quad \forall k$$

and that

$$\alpha_s(W^\varepsilon;0) = O(\varepsilon^{2m+4}).$$

We introduce

$$T(\varepsilon) := \sup\left\{t\in[0,T^\varepsilon), \quad \alpha_s(W^\varepsilon;t) < \varepsilon^{2m+3}\right\}.$$

For $\varepsilon > 0$ small enough, $T(\varepsilon)$ is well-defined and positive. Moreover, using (2.29), for all $t < T(\varepsilon)$,

$$(1-\varepsilon^{2m+3})\,\alpha_s(W^\varepsilon;t) \le C\left(\varepsilon^{2m+4} \;+\; (1+\varepsilon^{2m+3})\int_0^t \alpha_s(W^\varepsilon;u)du\right).$$

The Gronwall's lemma implies, for all $t < T(\varepsilon)$, $\alpha_s(W^\varepsilon;t) \le C'\,\varepsilon^{2m+4}$. This last inequality shows that $T(\varepsilon) = T^\varepsilon$, and that

$$\sup_{0\le t\le T^\varepsilon} \alpha_s(W^\varepsilon;t) \;\le\; C''\varepsilon^{2m+4}.$$

In particular, we get

$$\sup_{0\le t\le T^\varepsilon} \|W^\varepsilon(t,\cdot)\|_{H^s} \le C\varepsilon^{m+1}.$$

Back to $V^\varepsilon = V^\varepsilon_{app} + W^\varepsilon$, we obtain, for all s,

$$\begin{aligned}\sup_{0\le t\le T^\varepsilon}\|V^\varepsilon(t,\cdot)\|_{H^s} &\le \sup_{0\le t\le T^\varepsilon}\|V^\varepsilon_{app}(t,\cdot)\|_{H^s} + \sup_{0\le t\le T^\varepsilon}\|W^\varepsilon(t,\cdot)\|_{H^s}\\ &\le\; C\varepsilon^m\|\overline{V}_0\|_{H^s}.\end{aligned} \tag{2.31}$$

This yields $T^\varepsilon_* \ge T$ and shows the existence on $[0,T]$ of a smooth solution V^ε with initial data $\overline{V}_0$.

As explained at the beginning of section 2, this provides a smooth solution

$$(v^\varepsilon, b^\varepsilon)^t(t,\mathrm{x}) = V^\varepsilon\left(t,\mathrm{x},\varepsilon^{-4}t,\varepsilon^{-2}\mathrm{x}\right)$$

of (1.5), with initial data $(\varepsilon^m v_0, \varepsilon^m b_0)^t$. Uniqueness of the solution $(v^\varepsilon, b^\varepsilon)$ is a direct consequence of its regularity. Finally, the estimates of the theorem follow from (2.31). This ends the proof.

3. Instability mechanism. We now begin the description of the instability mechanism leading to Theorem 1.2. As we will see, this mechanism is connected to the behavior of the WKB solutions (2.3).

3.1. Spectral analysis. To understand the instability process requires the study of system (2.8), satisfied by $V^0 = \overline{V}^0(t,\mathrm{x})$ when $m \ge 1$. This system reads

$$\begin{cases}\partial_t\overline{w}^0 = \mathcal{A}_1\overline{w}^0 + \nabla_{\mathrm{x}}\overline{p}^1 + \Delta_{\mathrm{x}}\overline{w}^0,\\ \partial_t\overline{\beta}^0 = \mathcal{A}_2\overline{\beta}^0 + \Delta_{\mathrm{x}}\overline{\beta}^0,\\ \mathrm{div}_{\mathrm{x}}\overline{w}^0 = \mathrm{div}_{\mathrm{x}}\overline{\beta}^0 = 0,\end{cases} \tag{3.1}$$

where the operators

$$\mathcal{A}_1\overline{w} = \mathrm{div}_{\mathrm{x}}(A_1\overline{w}), \quad \mathcal{A}_2\overline{\beta} = \mathrm{curl}_{\mathrm{x}}(A_2\overline{\beta})$$

involve the linear operators $A_1 \in \mathcal{L}\left(\mathbb{R}^3, \mathcal{M}_3\left(\mathbb{R}\right)\right)$, $A_2 \in \mathcal{L}\left(\mathbb{R}^3,\mathbb{R}^3\right)$. They are defined in the following way: for all $b \in \mathbb{R}^3$,

$$\begin{aligned}A_1 b &= -\int_{\tau,\theta}\left((\partial_\tau - \Delta_\theta)^{-1}\left(\nabla_\theta\Delta_\theta^{-1}\mathrm{div}^2_\theta(U\otimes b) \;-\; \mathrm{div}_\theta\left(U\otimes b\right)\right)\right)\otimes U,\\ A_2 b &= \int_{\tau,\theta} U\times\left((\partial_\tau - \Delta_\theta)^{-1}\mathrm{curl}_\theta(U\times b)\right).\end{aligned}$$

As

$$\mathrm{div}_\theta(U\otimes b) = b\cdot\nabla_\theta U = \mathrm{curl}_\theta(U\times b),$$

we deduce $\mathrm{div}^2_\theta(U\otimes b)=0$ and

$$A_1 b = \int_{\tau,\theta} \otimes\Big((\partial_\tau-\Delta_\theta)^{-1}\mathrm{curl}_\theta\,(U\times b)\Big)\otimes U.$$

Then

$$\begin{aligned}\mathcal{A}_1 a &= -\mathrm{div}_{\mathrm{x}}\int_{\tau,\theta}\Big((\partial_\tau-\Delta_\theta)^{-1}\mathrm{curl}_\theta\,(U\times b)\Big)\otimes U\\ &= \int_{\tau,\theta} U\cdot\nabla_{\mathrm{x}}(\partial_\tau-\Delta_\theta)^{-1}\mathrm{curl}_\theta(U\times b) = -\mathcal{A}_2 b.\end{aligned}$$

If we relabel, for all $b\in\mathbb{R}^3$,

$$Ab = \int_{\tau,\theta} U\times\Big((\partial_\tau-\Delta_\theta)^{-1}\mathrm{curl}_\theta(U\times b)\Big),$$

the system on $\overline{V}^0$ eventually reads

$$\begin{cases}\partial_t\overline{w}^0 = -\mathrm{curl}_{\mathrm{x}}A\,\overline{w}^0+\nabla_{\mathrm{x}}\overline{p}^1+\Delta_{\mathrm{x}}\overline{w}^0,\\ \partial_t\overline{\beta}^0 = \mathrm{curl}_{\mathrm{x}}A\,\overline{\beta}^0+\Delta_{\mathrm{x}}\overline{\beta}^0,\\ \mathrm{div}_{\mathrm{x}}\overline{w}^0 = \mathrm{div}_{\mathrm{x}}\overline{\beta}^0=0.\end{cases}\tag{3.2}$$

Remark 6. In the physicists' community, the matrix A is often denoted α, which motivates the expression *alpha effect*.

We focus on solutions of (3.2) with initial data $(0,\overline{\beta}_0)^t$, $\mathrm{div}_{\mathrm{x}}\,\overline{\beta}_0=0$. Thus, $\overline{w}_0=0$ for all times, and the divergence-free condition $\mathrm{div}_{\mathrm{x}}\overline{\beta}^0=0$ is fulfilled for all times. If we set $b^0:=\overline{\beta}^0$, we are left with the study of

$$\partial_t b^0 - \mathrm{curl}_{\mathrm{x}}\left(Ab^0\right) - \Delta_{\mathrm{x}} b^0 = 0.\tag{3.3}$$

We first state some properties of the matrix A.

Lemma 3.1. *For all $U\in\mathcal{P}$, the matrix $A=A(U)$ is real-symmetric. Moreover, the set*

$$\Omega = \{U\in\mathcal{P},\quad A(U)\ \textit{has simple nonzero eigenvalues}\}$$

is dense and open in $\mathcal{P}$.

Proof. Using the Fourier coefficients of U, we compute, for all $b\in\mathbb{R}^3$,

$$A\,b = \sum_{\substack{(\omega,k)\in\mathbb{Z}^4\\(\omega,k)\neq 0}} \frac{\hat{U}(\omega,k)\times\hat{U}(-\omega,-k)\,(-ib\cdot k)}{i\omega+|k|^2}.\tag{3.4}$$

Note that the change of indices $(\omega, k) \to (\omega' = -\omega, k' = -k)$ yields

$$\begin{aligned} A\,b &= \sum_{(\omega',k')} \frac{\hat{U}(-\omega',-k') \times \hat{U}(\omega',k')\,(ib\cdot k')}{-i\omega' + |k'|^2} \\ &= \sum_{(\omega',k')} \frac{\hat{U}(\omega',k') \times \hat{U}(-\omega',-k')\,(-ib\cdot k')}{-i\omega' + |k'|^2}, \end{aligned}$$

so that

$$A\,b = \int_{\mathbb{T}^4} U \times (-\partial_\tau - \Delta_\theta)^{-1} \mathrm{curl}_\theta\,(U \times b)\,. \tag{3.5}$$

As U is real-valued, $\hat{U}(-\omega,-k) = \hat{U}^*(\omega,k)$, where the asterisk denotes complex conjugation. We deduce, for all $b \in \mathbb{R}^3$,

$$\begin{aligned} A^*\,b &= \sum_{(\omega,k)} \frac{\hat{U}^*(\omega,k) \times \hat{U}^*(-\omega,-k)\,(ib\cdot k)}{-i\omega + |k|^2} \\ &= \sum_{(\omega,k)} \frac{\hat{U}(-\omega,-k) \times \hat{U}(\omega,k)\,(ib\cdot k)}{-i\omega + |k|^2} \\ &= \sum_{(\omega',k')} \frac{\hat{U}(\omega',k') \times \hat{U}(-\omega',-k')\,(-ib\cdot k')}{i\omega' + |k'|^2} = \alpha\,b, \end{aligned}$$

so that α is real. Then we compute

$$\begin{aligned} A\,b\cdot\tilde{b} &= \int_{\mathbb{T}^4} \Big(U \times (\partial_\tau - \Delta_\theta)^{-1} \mathrm{curl}_\theta\,(U\times b) \Big) \cdot \tilde{b} \\ &= -\int_{\mathbb{T}^4} (U \times \tilde{b}) \cdot \Big((\partial_\tau - \Delta_\theta)^{-1} \mathrm{curl}_\theta\,(U\times b) \Big) \\ &= -\int_{\mathbb{T}^4} (U \times \tilde{b}) \cdot \Big(\mathrm{curl}_\theta\,(\partial_\tau - \Delta_\theta)^{-1}\,(U\times b) \Big) \\ &= -\int_{\mathbb{T}^4} \Big((-\partial_\tau - \Delta_\theta)^{-1} \mathrm{curl}_\theta \Big(U\times\tilde{b}\Big) \Big) \cdot \Big(U\times b \Big) \\ &= \int_{\mathbb{T}^4} \Big(U \times (-\partial_\tau - \Delta_\theta)^{-1} \mathrm{curl}_\theta \Big(U\times\tilde{b}\Big) \Big) \cdot b = \alpha\,\tilde{b}\cdot b \end{aligned}$$

using (3.5). Thus, A is symmetric.

From (3.4), we deduce that

$$\mathcal{P} \mapsto \mathcal{M}_3\,(\mathbb{R})\,, \quad U \mapsto A(U)$$

is continuous. This clearly implies that Ω is open in $\mathcal{P}$. Let $\varepsilon > 0$, and $U \in \mathcal{P} - \Omega$. Let

$$U^n(\tau,\theta) = \sum_{|\omega|+|k|\le n} \hat{U}(\omega,k)\,e^{i(\omega\tau + k\cdot\theta)}.$$

There exists N, such that $d_{\mathcal{P}}\left(U, U^N\right) < \varepsilon/2$. If $U^N \in \Omega$, we are done. Otherwise, we consider

$$\tilde{U} = U^N \; + \; \sum_{i=1}^{3} \delta_i \, V^i, \quad \delta_i > 0 \quad \forall i,$$

where

$$\begin{aligned} V^1(\theta_1,\theta_2,\theta_3) = \Big(& \cos((N+1)\theta_2), \sin((N+1)\theta_1), \\ & \cos((N+1)\theta_1) + \sin((N+1)\theta_2) \Big)^t, \\ V^2(\theta_1,\theta_2,\theta_3) = \Big(& \sin((N+2)\theta_3), \sin((N+2)\theta_1) + \cos((N+2)\theta_3), \\ & \cos((N+2)\theta_1) \Big)^t, \\ V^3(\theta_1,\theta_2,\theta_3) = \Big(& \sin((N+3)\theta_3) + \cos((N+3)\theta_2), \cos((N+3)\theta_3), \\ & \sin((N+3)\theta_2) \Big)^t. \end{aligned}$$

Note that the V^i's are special cases of the famous ABC flows [1] of the type

$$\begin{aligned} V(\theta_1,\theta_2,\theta_3) = \Big(& C\sin(M\theta_3) + B\cos(M\theta_2), A\sin(M\theta_1) + C\cos(M\theta_3), \\ & B\sin(M\theta_2) + A\cos(M\theta_1) \Big)^t. \end{aligned}$$

They satisfy the Beltrami property that $\operatorname{curl} u = k\, u$, $k > 0$. A simple calculation shows that

$$A(\tilde{U}) = A(U^N) - \delta_1 \begin{pmatrix} 1 & & \\ & 1 & \\ & & 0 \end{pmatrix} - \delta_2 \begin{pmatrix} 1 & & \\ & 0 & \\ & & 1 \end{pmatrix} - \delta_3 \begin{pmatrix} 0 & & \\ & 1 & \\ & & 1 \end{pmatrix}.$$

Thus, for appropriate choices of δ_1, δ_2, δ_3, one has

$$A(\tilde{U}) \in \Omega, \quad d_{\mathcal{P}}\left(U^n, \tilde{U}\right) < \varepsilon/2,$$

so that $d_{\mathcal{P}}(U, \tilde{U}) < \varepsilon$. Thus, Ω is dense, which ends the proof of the lemma.

We can now perform a spectral analysis of (3.3).

Proposition 3.2. *Let Ω be the subset of $\mathcal{P}$ defined in Lemma* 3.1. *For all U in Ω, there exist $\zeta^0 \in \mathbb{R}^3$, $\delta > 0$, and two smooth functions*

$$\Lambda_+ : B(\zeta^0, \delta) \mapsto \mathbb{R}_*^+, \quad \hat{b} : B(\zeta^0, \delta) \mapsto \left(\mathbb{C}_*\right)^3,$$

such that for all $\zeta \in B(\zeta^0, \delta)$,

$$b^\zeta(t, \mathrm{x}) \; = \; \hat{b}(\zeta) \, \exp\left(\Lambda_+(\zeta)\, t\right) \, \exp\left(i\zeta \cdot \mathrm{x}\right)$$

is a divergence-free solution of (3.3). *Moreover, one can assume that Λ has a non-degenerate maximum over $B(\zeta^0, \delta)$ at ζ^0.*

Proof. Let U in Ω. We apply the Fourier transform to (3.3): we get, for all $\zeta \in \mathbb{R}^3$,

$$\partial_t \mathcal{F}\left(b^0\right)(t,\zeta) = A^\zeta A\,\mathcal{F}\left(b^0\right)(t,\zeta) - |\zeta|^2 \mathcal{F}\left(b^0\right)(t,\zeta),$$

where,

$$\forall \zeta \in \mathbb{R}^3, \quad A^\zeta = \begin{pmatrix} 0 & -i\zeta_3 & i\zeta_2 \\ i\zeta_3 & 0 & -i\zeta_1 \\ -i\zeta_2 & i\zeta_1 & 0 \end{pmatrix}$$

is the matrix corresponding to cross-product by $i\zeta$. As A is real-symmetric, there exists an orthogonal matrix P with $P^t A\, P = \operatorname{diag}(\alpha_1, \alpha_2, \alpha_3)$, $\alpha_i \in \mathbb{R}$. Introducing $\xi = P^t \zeta$, $\tilde{b}(t,\xi) = P^t \mathcal{F}(b^0)(t,\zeta)$, the previous equation reads

$$\partial_t\, \tilde{b}(t,\xi) = A^\xi D\, \tilde{b}(t,\xi) - |\xi|^2\, \tilde{b}(t,\xi). \tag{3.6}$$

A rapid calculation shows that the eigenvalues λ of $A^\xi D - |\xi|^2 I_d$ satisfy $\lambda = -|\xi|^2$ or

$$\left(\lambda + |\xi|^2\right)^2 \;=\; \xi_1^2 \alpha_2\alpha_3 \;+\; \xi_2^2\alpha_1\alpha_3 \;+\; \xi_3^2 \alpha_1\alpha_2. \tag{3.7}$$

As $U \in \Omega$, the α_i's are distinct and nonzero. Consequently, the products $\alpha_i\alpha_j$, $i \neq j$, are also distinct and nonzero. Let

$$f(\xi) := \xi_1^2\alpha_2\alpha_3 \;+\; \xi_2^2\alpha_1\alpha_3 \;+\; \xi_3^2\alpha_1\alpha_2, \quad \mathcal{U} := \{\xi,\ f(\xi) > 0\}.$$

There are two possibilities:

- All the α_i's have the same sign. Then all the $\alpha_i\alpha_j$, $i \neq j$, are positive, and $\mathcal{U}$ is $\mathbb{R}^3_*$.
- The α_i's have different signs. Then among the products $\alpha_i\alpha_j$, $i \neq j$, two are negative and one is positive—for instance, $\alpha_2\alpha_3$. In this case, $\mathcal{U}$ is the cone $\{|\xi_1|^2 > -\frac{\alpha_1\alpha_3}{\alpha_2\alpha_3}|\xi_2|^2 - \frac{\alpha_1\alpha_2}{\alpha_2\alpha_3}|\xi_3|^2\}$.

On $\mathcal{U}$, one can define

$$\lambda_\pm(\xi) = \pm f(\xi)^{1/2} \;-\; |\xi|^2.$$

Note that $\lambda_+(\xi)$ takes positive values for some ξ. Indeed, if $\bar{\xi}$ is such that $f(\bar{\xi}) > 0$, then

$$\lambda_+\left(\delta\bar{\xi}\right) = \delta f\left(\bar{\xi}\right)^{1/2} \;-\; \delta^2\left|\bar{\xi}\right|^2$$

is positive for $\delta > 0$ small enough. Moreover, using $\lambda_+(\xi) \xrightarrow{|\xi|\to+\infty} -\infty$, we deduce that λ_+ has a global positive maximum in $\mathcal{U}$, say at $\xi = \xi^0$. As ξ^0 is a critical point, we obtain

$$\begin{aligned} 0 = \lambda_+'(\xi^0) &= \frac{1}{2} f(\xi^0)^{-1/2}\nabla f(\xi^0) \;-\; 2\xi^0 \\ &= f(\xi^0)^{-1/2}\begin{pmatrix} \alpha_2\alpha_3 & & \\ & \alpha_1\alpha_3 & \\ & & \alpha_1\alpha_2 \end{pmatrix}\xi^0 - 2\xi^0. \end{aligned}$$

Up to reindex the eigenvalues, this implies that

$$2 f(\xi^0)^{1/2} = \alpha_2\alpha_3, \quad \xi^0 = (\xi_1^0, 0, 0)^t. \tag{3.8}$$

Then we compute

$$\lambda_+''(\xi^0) = -\frac{1}{2} f(\xi^0)^{-3/2} \nabla f(\xi^0) \otimes \nabla f(\xi^0) + \frac{1}{2} f(\xi^0)^{-1/2} f''(\xi^0) - 2I_d,$$

and using (3.8) leads to

$$\lambda_+''(\xi^0) = \begin{pmatrix} -\frac{1}{2f(\xi^0)^{3/2}}(\xi_1^0)^2 & & \\ & \frac{\alpha_1\alpha_3}{f(\xi^0)^{1/2}} - 2 & \\ & & \frac{\alpha_1\alpha_2}{f(\xi^0)^{1/2}} - 2 \end{pmatrix}.$$

In particular, $\det(\lambda_+''(\xi^0)) \neq 0$, which means that the maximum at ξ^0 is nondegenerate.

Let $\delta > 0$ such that $B(\xi^0, \delta) \subset \mathcal{U}$. For all $\xi \in B(\xi^0, \delta)$, $\lambda_+(\xi)$ has multiplicity 1 as an eigenvalue of $A^\xi D$. Therefore, classical smooth dependence results on eigenvalues and eigenvectors yield the existence of a smooth function $\tilde{b} : B(\xi^0, \delta) \mapsto (\mathbb{C}_*)^3$ such that

$$A^\xi D\, \tilde{b}(\xi) = \lambda_+(\xi)\, \tilde{b}(\xi).$$

Back to original variables, we define

$$\zeta^0 = P\xi^0, \quad \Lambda_\pm(\zeta) = \lambda_\pm(P^t\zeta), \quad \hat{b}(\zeta) = P\tilde{b}(P^t\zeta),$$

so that

$$\left(A^\xi A - |\zeta|^2\right) \hat{b}(\zeta) = \Lambda_+(\zeta)\, \hat{b}(\zeta).$$

This shows that, for all $\zeta \in B(\zeta^0)$,

$$b^\zeta(t, \mathrm{x}) \;=\; \hat{b}(\zeta)\, e^{i\Lambda(\zeta)t}\, e^{i\zeta\cdot \mathrm{x}}$$

solves (3.3). Note also that b^ζ is divergence-free, as $\zeta \cdot \hat{b}(\zeta) = 0$. This ends the proof of the proposition.

3.2. Construction of unstable wavepackets. Thanks to Proposition 3.2, we are now able to build approximate solutions having exponential growth. More precisely, we show the following.

PROPOSITION 3.3. *Let $U \in \Omega$. There exists $\lambda^0 > 0$, and for every integer $n \in \mathbb{N}$ families $\{X^i = (\overline{V}^i, V_*^{i+1}, p_*^i, \overline{p}^{i+1})\}_{0\le i\le n}$ such that:*

(i) *For all i, X^i satisfies (T_i).*

(ii) *As $t \to +\infty$, $V^0 = \overline{V}^0 = (0, \overline{\beta}^0)$ has the asymptotic behavior*

$$\|\overline{\beta}^0(t,\cdot)\|_{L^2} \;\sim\; \frac{C}{\sqrt{t}} e^{\lambda^0 t}. \tag{3.9}$$

(iii) *For all $i = km + l$, with $l \in \{0, \dots, m-1\}$, for all $\alpha, s \in \mathbb{N}$, and for all t,*

$$\|\partial_t^\alpha X^i(t,\cdot)\|_{H^s} \le \frac{C_{\alpha,i,s}}{\sqrt{1+t}^{k+1}}\, t^l\, e^{(k+1)\lambda^0 t}, \quad C_{\alpha,i,s} > 0. \tag{3.10}$$

Proof. We treat separately the cases $i = 0$, $1 \le i \le m-1$, and $i \ge m$ (for which (T_i) includes quadratic terms).

Construction of X^0. We first use Proposition 3.2 to build X^0. Let

$$\Lambda_\pm : B(\zeta^0,\delta) \mapsto \mathbb{R}_*^+, \quad \hat{b} : B(\zeta^0,\delta) \mapsto (\mathbb{C}_*)^3$$

as in Proposition 3.3. As $\Lambda^0 := \Lambda_+(\zeta^0)$ is a nondegenerate maximum, one can assume, up to take a smaller δ, that

$$\Lambda_+(\zeta) = \Lambda_+(\zeta^0) + \nabla_\zeta \Lambda_+(\zeta^0)\cdot(\zeta-\zeta^0) - |\zeta-\zeta^0|^2 \frac{\alpha(\zeta-\zeta^0)}{2}, \tag{3.11}$$

where $0 < \underline{\alpha} < \alpha(\cdot) < \overline{\alpha}$ in $B(0,\delta)$. We extend functions $\Lambda_\pm$ and $\hat{b}$ to

$$B_\delta := B(\zeta^0,\delta) \cup B(-\zeta^0,\delta)$$

by the following: for all $\zeta \in B(-\zeta^0,\delta)$,

$$\Lambda_\pm(\zeta) := \Lambda_\pm(-\zeta), \quad \hat{b}(\zeta) := \hat{b}(-\zeta)^*.$$

With this continuation,

$$b^\zeta(t,\mathrm{x}) = \hat{b}(\zeta)\, e^{\Lambda_+(\zeta)t}\, e^{i\zeta\cdot\mathrm{x}} \tag{3.12}$$

is a divergence-free solution of (3.3) for all ζ in B_δ. Now let ϕ be a smooth real-valued function supported in B_δ, such that $\phi(\zeta^0) = 1$, $\phi(-\zeta) = \phi(\zeta)^*$. We set

$$\overline{\beta}^0(t,\mathrm{x}) = \int_{B_\delta} \phi(\zeta)\,\hat{b}(\zeta)\, e^{\Lambda_+(\zeta)t}\, e^{i\zeta\cdot\mathrm{x}}\, d\zeta. \tag{3.13}$$

Then we define $\overline{V}^0 := (0,\overline{\beta}^0)^t$, V_*^1 by (2.6), and $X^0 = (\overline{V}^0, V_*^1, 0, 0)$. From the properties of b^ζ, we deduce easily that $\overline{V}^0$ satisfies (3.2), and consequently that X^0 solves (T_0). Finally, points (ii) and (iii) of the proposition are derived from standard computations involving (3.11). For the sake of brevity, we do not detail these computations and refer to [4] for complete treatment in a very similar framework.

Construction of X^i, $1 \le i \le m-1$. Let X^0 be defined as above, and for $1 \le i \le m-1$, let X^i be defined inductively by the following: *X^i is the solution of (T_i) with $\overline{V}^i|_{t=0} = 0$.* As seen in section 3.1, such a definition makes sense. We show by induction on $i \ge 0$ the following property:

(P_i): *Function X^i has an expression of the type*

$$\begin{aligned} X^i(t,\mathrm{x},\tau,\theta) &\\ = \int_{B_\delta} &\left(P^{i,+}_{\zeta,\tau,\theta}(t)\, e^{\Lambda_+(\zeta)t} + P^{i,-}_{\zeta,\tau,\theta}(t)\, e^{\Lambda_-(\zeta)t} + P^{i,-}_{\zeta,\tau,\theta}(t)\, e^{-|\zeta|^2 t}\right) e^{i\zeta\cdot\mathrm{x}} d\zeta, \end{aligned} \tag{3.14}$$

where $P^{i,\pm}_{\zeta,\tau,\theta}$, $P^{i,0}_{\zeta,\tau,\theta}$ are polynomials in t, of degree $\le i$, with coefficients smooth and compactly supported in $B_\delta \times \mathbb{T} \times \mathbb{T}^3$.

- *Case* $i = 0$. (P_0) is true by definition of X^0.
- *Case* $i \ge 1$. Let $i \ge 1$, and assume $(P_0), \dots, (P_{i-1})$. Recall that

$$\begin{aligned} \left(p_*^i, 0\right)^t &= \Delta_\theta^{-1} \mathrm{Div}_\theta B_\theta\left(\tilde{U}, \overline{V}^i\right) + H_*^i, \\ V_*^{i+1} &= (\partial_\tau - \Delta)^{-1} L_\theta \overline{V}^i + I_*^i, \end{aligned}$$

where H_*^i, I_*^i are i-linear in $(X^0,\dots,X^{i-1})$. Thus, X^i is of type (3.14) as soon as $\overline{V}^i$ and $\overline{p}^{i+1}$ are.

These functions satisfy

$$\begin{cases}\partial_t \overline{V}^i = \begin{pmatrix}-\mathrm{curl}_{\mathrm{x}} A & \\ & \mathrm{curl}_{\mathrm{x}} A\end{pmatrix} V^i + \Delta_{\mathrm{x}} V^i + \left(\nabla_{\mathrm{x}} \overline{p^{i+1}}, 0\right)^t + \overline{J}^i, \\ \mathrm{Div}_{\mathrm{x}} V^i = 0. \end{cases} \tag{3.15}$$

Taking the curl of the first line of (3.15) yields

$$\overline{p}^{i+1} = -(\Delta_{\mathrm{x}})^{-1}\, \overline{J}^i_1,$$

which shows that

$$\overline{p}^{i+1}(t,\mathrm{x}) = \int_{B_\delta} \left(Q^{i,+}_\zeta(t)\, e^{\Lambda_+(\zeta)t} + Q^{i,-}_\zeta(t)\, e^{\Lambda_-(\zeta)t} + Q^{i,0}_\zeta(t)\, e^{-|\zeta|^2 t}\right) e^{i\zeta\cdot x} d\zeta,$$

where $Q^{i,\pm}_\zeta$, $Q^{i,0}_\zeta$ are polynomials in t, of degree $\le i-1$, with coefficients smooth and compactly supported in B_δ.

Replacing $\overline{p}^{i+1}$ by its expression leads to

$$\begin{cases}\partial_t \overline{V}^i = \begin{pmatrix}-\mathrm{curl}_{\mathrm{x}} A & \\ & \mathrm{curl}_{\mathrm{x}} A\end{pmatrix} \overline{V}^i + \Delta_{\mathrm{x}} \overline{V}^i + \overline{K}^i, \\ \mathrm{Div}_{\mathrm{x}} \overline{V}^i = 0, \end{cases}$$

where $\overline{K}^i$ is i-linear on $(X^0,\dots,X^{i-1})$. We define

$$\mathcal{V}^i(t,\zeta) := \mathcal{F}\left(\overline{V}^i\right)(t,\zeta),$$

which satisfies

$$\partial_t \mathcal{V}^i(t,\zeta) = \begin{pmatrix}-A^\zeta A & \\ & A^\zeta A\end{pmatrix} - |\xi|^2 \mathcal{V}^i(t,\zeta) + \mathcal{K}^i(t,\zeta),$$

$$\mathcal{K}^i(t,\zeta) = R^{i,+}_\zeta(t)\, e^{\Lambda_+(\zeta)t} + R^{i,-}_\zeta(t)\, e^{\Lambda_-(\zeta)t} + R^{i,0}_\zeta(t)\, e^{-|\zeta|^2 t},$$

where $R^{i,\pm}_\zeta$, $R^{i,0}_\zeta$ are polynomials in t, of degree $\le i-1$, smooth and compactly supported in B_δ.

At fixed ζ, such an equation is an ordinary differential system of the type

$$\frac{d}{dt}\mathcal{V} + M\mathcal{V} = S^+(t)e^{\Lambda_+ t} + S^-(t)e^{\Lambda_- t} + S^0(t)e^{\Lambda^0 t},$$

where Λ_+, Λ_-, Λ_0, which stand for $\Lambda_+(\zeta)$, $\Lambda_-(\zeta)$, $-|\zeta|^2$, are simple eigenvalues of the matrix M, which stands for $\left(\begin{smallmatrix}-A^\zeta A & \\ & A^\zeta A\end{smallmatrix}\right)$. It is well known that the solution

$$\mathcal{V}(t) = \int_0^t e^{M(t-s)} \left(S^+(s)e^{\Lambda^+ s} + S^-(s)e^{\Lambda^- s} + S^0(s)e^{\Lambda^0 s}\right) ds$$

with $\mathcal{V}(0) = 0$ is of the type

$$\mathcal{V}(t) = T^+(t)e^{\Lambda^+ t} + T^-(t)e^{\Lambda^- t} + T^0(t)e^{\Lambda^0 t},$$

where $T^\pm$ (resp., T^0) is a polynomial such that $\deg T^\pm \leq \deg S^\pm + 1$ (resp., $\deg T^0 \leq \deg S^0 + 1$).

Back to the original system, (P_i) follows, which ends the induction. Point (iii) is again a classical consequence of expression (3.14) and (3.11).

Construction of X^i, $i \geq m$. As $i \geq m$, quadratic terms enter system (T_i). More precisely, one checks that

- H^i_* and I^i_* are made of terms that are i-linear in $(X^0, \dots, X^{i-1})$, and of quadratic terms that involve the pairs $\{V^j, V^J\}$ with $j + J = i - m - 1$, or $i - m - 3$;
- $\overline{J}^i$ and $\overline{K}^i$ are made of terms that are i-linear in $(X^0, \dots, X^{i-1})$, and of quadratic terms involving the pairs $\{V^j, V^J\}$ with $j + J = i - m$, $i - m - 1$ or $i - m - 3$.

Note that

$$\Lambda_+(j\zeta^0) \,<\, j\,\Lambda_+(\zeta^0) \quad \forall 2 \leq j \leq n,$$

so that up to take δ smaller, one can assume that for all $2 \leq j \leq n$ and for all $\zeta_1, \dots, \zeta_j$ in B_δ,

$$\Lambda_+(\zeta_1 + \cdots + \zeta_j) \,<\, \Lambda_+(\zeta_1) \,+ \cdots +\, \Lambda_+(\zeta_j).$$

Under this assumption, one can show inductively that for general $i = km + l$, $k \geq 0$, $1 \leq l \leq m - 1$, the solution X^i of (T_i) with $\overline{V}^i|_{t=0} = 0$ has an expression of the type

$$X^i(t, \mathrm{x}, \tau, \theta) = \sum_{j=1}^{k+1} \int_{B_\delta^{j+1}} Y^{i,j}(\zeta_1, \dots, \zeta_j, \tau, \theta, t)\, e^{i(\zeta_1 + \cdots + \zeta_j)\cdot \mathrm{x}}\, d\zeta_1 \dots d\zeta_j$$
$$+ \int_{B_\delta^{k+1}} P^i(\zeta_1, \dots, \zeta_{k+1}, \tau, \theta, t)\, e^{(\Lambda_+(\zeta_1) + \cdots + \Lambda_+(\zeta_{k+1}))\, t}\, e^{i(\zeta_1 + \cdots + \zeta_{k+1})\cdot \mathrm{x}}\, d\zeta_1 \dots d\zeta_{k+1},$$

where

- P^i is a polynomial in t, of degree $\leq l$, with coefficients smooth and compactly supported.
- $Y^{i,j}$ is a finite sum of terms of the form

  $$Y^i_{\Lambda_1, \dots, \Lambda_j}(\zeta_1, \dots, \zeta_j, \tau, \theta, t) = Q^i_{\Lambda_1, \dots, \Lambda_j}(\zeta_1, \dots, \zeta_j, \tau, \theta, t)\, e^{(\Lambda_1(\zeta_1) + \cdots + \Lambda_j(\zeta_{k+1}))\, t},$$

  with $Q^i_{\Lambda_1, \dots, \Lambda_j}$ polynomial in t, and $\Lambda_1(\zeta_0) + \cdots + \Lambda_j(\zeta_0) < (k+1)\Lambda_+(\zeta^0)$.

We do not detail this induction, as it is very similar to the previous one and tedious. Once this expression for X^i is obtained, the estimate follows; see [4] for details.

3.3. Proof of Theorem 1.2. We now turn to the proof of the instability theorem, Theorem 1.2. We adapt ideas of [9], encountered in the stability study of Euler and Prandtl equations (see also [6, 12]).

Let k_0 in $\mathbb{N}^*$ to be chosen later, let $m \geq 1$, and let $n = k_0 m$. Let $U \in \Omega$, and take profiles $X^0, \dots, X^n$ as in Proposition 3.3. We have in particular

$$\varepsilon^m \|\overline{V}^0(t, \cdot)\|_{L^2} = \varepsilon^m \|\overline{\beta}^0(t, \cdot)\|_{L^2} \geq \frac{C_0\, \varepsilon^m\, e^{\lambda^0 t}}{(1+t)^{1/2}}.$$

We define

$$\mathcal{E}(t) := \frac{C_0\, \varepsilon^m\, e^{\lambda^0 t}}{(1+t)^{1/2}}$$

and $T^\varepsilon > 0$ such that $\mathcal{E}(T^\varepsilon) = 1$. Note that $T^\varepsilon = O(|\ln(\varepsilon)|)$. Moreover, thanks to point (iii) of Proposition (3.3), we get, for all $i = km + l$, $l \in \{0, \dots, m-1\}$, and for all α, s, t,

$$\begin{aligned}
\varepsilon^{m+i} \|\partial_t^\alpha X^i(t)\|_{H^s} &\le C\, \frac{\varepsilon^{m+i} e^{(k+1)\lambda_0 t}}{\sqrt{1+t}^{k+1}}\, t^l, \\
&\le C\, \left(\frac{\varepsilon^m e^{\lambda_0 t}}{\sqrt{1+t}}\right)^{k+1}\, (\varepsilon t)^l, \\
&\le C'\, \mathcal{E}(t)^{k+1}\, (\varepsilon t)^l.
\end{aligned} \tag{3.16}$$

As in section 2.3, we define $V_{app}^{\varepsilon,n}$ and $p_{app}^{\varepsilon,n}$ by (2.3), so that they satisfy equations of type (2.14). Thanks to (3.16), it is easy to check that

$$\|\overline{R}_{app}^{\varepsilon,n}(t)\|_{H^s} \le C_s\, \mathcal{E}(t)^{k_0 - 2},$$

$$\|R_{app,*}^{\varepsilon,n}(t)\|_{H^s} \le C_s\, \varepsilon^{-2}\, \mathcal{E}(t)^{k_0-2},$$

$$\|\partial_t^\alpha r_{app}^{\varepsilon,n}(t,\cdot)\|_{H^s} \le C'_{s,\alpha}\, \left(\varepsilon^m\, \mathcal{E}(t)^{k_0+1} \;+\; \varepsilon\, \mathcal{E}(t)^{k_0+1}\right).$$

The Fourier transform of V^n and V^{n+1} has compact support in ζ, so that $r_{app}^{\varepsilon,n} = \varepsilon^{m+n}(V_*^n + \varepsilon V_*^{n+1})$ is such that $r_{app,l}^{\varepsilon,n} = 0$. As in section 2.3, we can then define W_{app}^ε by (2.24), (2.25) and set $V_{app}^\varepsilon = V_{app}^{\varepsilon,n} + W_{app}^\varepsilon$. This solves (2.27), where the remainder R_{app}^ε satisfies, for all $t \in [0, T^\varepsilon]$,

$$\|\overline{R}_{app}^{\varepsilon}(t)\|_{H^s} \;+\; \varepsilon^2 \|R_{app,*}^\varepsilon(t)\|_{H^s} \;\le C_s\, \mathcal{E}(t)^{k_0-2}. \tag{3.17}$$

We deduce (as in (2.26))

$$\begin{aligned}
\|R_{app,l}^\varepsilon(t)\|_{H^s} &\le \|\overline{R}_{app,l}^{\varepsilon}(t)\|_{H^s} \;+\; \|R_{app,*,l}^\varepsilon(t)\|_{H^s} \\
&\le \|\overline{R}_{app}^{\varepsilon}(t)\|_{H^s} \;+\; C\,\varepsilon^2\, \|R_{app}^\varepsilon(t)\|_{H^{s+1/2}} \\
&\le C'_s\, \mathcal{E}(t)^{k_0-2}.
\end{aligned} \tag{3.18}$$

Conclusion. We fix $s \ge 5$, $\eta > 0$ to be chosen later. With the notation of Proposition 2.1, (2.15), we choose $k_0 > \max(4, 2 + \lambda^{-1}\mathcal{C}_s)$. Let V^ε be the solution of (2.2), with initial data $V^\varepsilon|_{t=0} = V_{app}^\varepsilon|_{t=0}$. Let $W^\varepsilon = V^\varepsilon - V_{app}^\varepsilon$, and let

$$T(\varepsilon) = \sup\left\{t \in [0, T^\varepsilon], \quad \forall u \in [0,t],\ \alpha_s(W^\varepsilon; u) \le 1/2\right\}.$$

We apply Proposition 2.1 to W^ε. This yields, for all $t \in [0, T(\varepsilon))$,

$$\alpha_s(W^\varepsilon; t) \le 2\mathcal{C}_s \int_0^t \alpha_s(W^\varepsilon; u)du + \frac{4}{3}\mathcal{C}_s \left(\varepsilon^6 \int_0^t \|R_{app,h}^\varepsilon(u)\|_{H^s}^2 du \right.$$
$$\left. + \int_0^t \|R_{app,l}^\varepsilon(u)\|_{H^s}^2 du\right).$$

We deduce from (3.18) that

$$\alpha_s(W^\varepsilon;t) \leq 2\mathcal{C}_s \int_0^t \alpha_s(W^\varepsilon;u)du \,+\, C_s\,\mathcal{E}(t)^{2(k_0-2)}.$$

With our choice for k_0, Gronwall's lemma implies

$$\alpha_s(W^\varepsilon;t) \leq\, C_s\,\mathcal{E}(t)^{2(k_0-2)}.$$

For $t^\varepsilon = T^\varepsilon - \sigma$, σ independent of ε, large enough,

$$C_s\,\mathcal{E}(t)^{2(k_0-2)} \,<\, e^{-2(k_0-2)\lambda^0\sigma} < \frac{1}{4}.$$

This shows that $T(\varepsilon) \geq t^\varepsilon$ and that

$$\|W_l^\varepsilon(t^\varepsilon)\|_{H^s}^2 + \varepsilon^2\|W^\varepsilon(t^\varepsilon)\|_{H^s}^2 < \exp(-2\lambda^0\sigma) \quad \forall s.$$

Recall also that, up to consider a larger σ,

$$\|V_{app}^\varepsilon - \overline{V}^0\|_{H^s}^2 \,\leq\, e^{-2\lambda^0\sigma}.$$

We can now conclude the proof of Theorem 1.2. We introduce

$$\begin{aligned}(v^\varepsilon, b^\varepsilon)^t(t,\mathrm{x}) &= V^\varepsilon\left(t,\mathrm{x},\varepsilon^{-4}t,\varepsilon^{-2}\mathrm{x}\right)\\ &= (w^\varepsilon,\beta^\varepsilon)\left(t,\mathrm{x},\varepsilon^{-4}t,\varepsilon^{-2}\mathrm{x}\right),\end{aligned}$$

which is solution of the original system (1.5). Rapid computations lead to

$$\begin{aligned}\|b^\varepsilon(t)\|_{L^2_\mathrm{x}}^2 &\geq \|\beta^\varepsilon(t)\|_{L^2_{\mathrm{x},\tau,\theta}}^2 \,-\, C\,\varepsilon^2\|\beta^\varepsilon(t)\|_{H^1_{\mathrm{x},\tau,\theta}}^2\\ &\geq \|\overline{\beta}_l^\varepsilon(t)\|_{L^2_\mathrm{x}}^2 \,-C\,\varepsilon^2\|\beta^\varepsilon(t)\|_{H^1_{\mathrm{x},\tau,\theta}}^2\\ &\geq \frac{\varepsilon^m}{2}\|\overline{\beta}_l^0(t)\|_{L^2_\mathrm{x}}^2 \,-\, C'\Big(\|\overline{V}_{app,l}^\varepsilon(t) - \varepsilon^m\overline{V}_{app,l}^0(t)\|_{L^2_\mathrm{x}}^2 + \|\overline{W}_l^\varepsilon(t)\|_{L^2_\mathrm{x}}^2\\ &\quad + \varepsilon^2\left(\varepsilon^m\|\overline{\beta}^0(t)\|_{H^1_\mathrm{x}}^2 + \|V_{app}^\varepsilon(t) - \varepsilon^m\overline{V}_{app}^0(t)\|_{H^1_{\mathrm{x},\tau,\theta}}^2 + \|W^\varepsilon(t)\|_{H^1_{\mathrm{x},\tau,\theta}}^2\right)\Big),\end{aligned}$$

where C and C' are positive constants independent of ε and η. As the Fourier transform of $\overline{\beta}^0$ has compact support, we deduce that

$$\overline{\beta}^0 = \overline{\beta}_l^0, \quad \|\overline{\beta}^0\|_{H^1_\mathrm{x}} \,\leq\, R\,\|\overline{\beta}^0\|_{L^2_\mathrm{x}}$$

for some $R > 0$.

Using previous bounds, this yields, for ε small enough,

$$\|b^\varepsilon(t)\|_{L^2}^2 \,\geq\, C_0\,e^{-\lambda^0\sigma} \,-\, C_1\,e^{-2\lambda^0\sigma} \,\geq\, \delta > 0,$$

up to consider a larger σ. Theorem 1.2 follows.

Acknowledgments. I wish to express my gratitude to B. Desjardins and E. Dormy, for careful reading of the manuscript and helpful comments.

OPTIMAL RATE OF CONVERGENCE OF THE BENCE–MERRIMAN–OSHER ALGORITHM FOR MOTION BY MEAN CURVATURE*

KATSUYUKI ISHII†

Abstract. Bence, Merriman, and Osher proposed an algorithm for computing the motion a hypersurface by mean curvature in terms of solutions of the usual heat equation, continually reinitialized after short time steps. In this paper, applying some techniques of asymptotic analysis for the Allen–Cahn equation, we give a rate of convergence of their algorithm for the motion of a smooth and compact hypersurface by mean curvature. We also consider the special case of a circle evolving by curvature and show that our rate is optimal.

Key words. motion by mean curvature, numerical algorithm, rate of convergence, optimality

DOI. 10.1137/04061862X

1. Introduction.

In 1992, Bence, Merriman, and Osher proposed in [2] an algorithm for computing the motion of a hypersurface by its mean curvature. It is described as follows.

Given a closed set $C_0 \subset \mathbb{R}^N$, we solve the initial-value problem for the heat equation

$$\begin{cases} u_t - \Delta u = 0 & \text{in } (0,+\infty)\times\mathbb{R}^N, \\ u(0,x) = \begin{cases} 1, & x \in C_0, \\ -1, & x \in \mathbb{R}^N \setminus C_0. \end{cases} \end{cases} \tag{1.1}$$

Fix a time step $h > 0$ and set

$$C_1 = \{x \in \mathbb{R}^N \mid u(h,x) \geq 0\}.$$

Next we solve (1.1) with C_0 replacing C_1 and define a new set C_2 with the solution u replaced by that of (1.1) with the new initial data. Repeating this procedure, we have a sequence $\{C_k\}_{k=0,1,\ldots}$ of closed sets in $\mathbb{R}^N$. Then we define

$$C_t^h = C_k \quad \text{if } kh \leq t < (k+1)h,\ k = 0,1,\ldots,$$

for $t \geq 0$. Letting $h \searrow 0$, we obtain

$$\partial C_t^h \longrightarrow \Gamma_t,\ \Gamma_0 = \partial C_0,$$

and Γ_t moves by its $((N-1)$-times) mean curvature.

The convergence of the Bence–Merriman–Osher (BMO) algorithm was proved by Mascarenhas [19], Evans [5], Barles and Georgelin [1], and Goto, Ishii, and Ogawa [10]. The generalizations of this algorithm were considered by Ishii [14], Ishii, Pires,

and Souganidis [16], Ishii and Ishii [15], Vivier [23], and Leoni [18]. However, to the author's knowledge, there are a few results on the rate of convergence of the BMO algorithm. In [22] Ruuth gave an error estimate for the case of the planar graph on $[0,h]$. Ishii and Nakamura [17] proved that the Hausdorff distance between the motion by mean curvature Γ_t and the approximate interface $\Gamma_t^h := \partial C_t^h$ is an order of $h^{1/2}$ as $h \searrow 0$. This estimate is valid before the onset of singularities, but not optimal.

The purpose of this paper is to show the optimal rate of convergence of the BMO algorithm, valid before the onset of singularities, for the Hausdorff distance between Γ_t and Γ_t^h. In fact, assuming $\{\Gamma_t\}_{0\le t<T_0}$ is the motion of a smooth and compact hypersurface by mean curvature, we prove that, for any $T < T_0$,

$$\sup_{t\in[0,T]} d_H(\Gamma_t, \Gamma_t^h) \le Lh,$$

where L is a constant depending on T, but independent of small $h > 0$, and d_H denotes the Hausdorff distance. This estimate is optimal and improves that of [17].

Both of the order in h and the optimality are the consequence of the maximum principle and the explicit constructions of sub- and supersolutions of (1.1), which are inspired by the asymptotic analysis of solutions of the Allen–Cahn equation (see, e.g., Fife [7] and de Mottoni and Schatzman [4]). As for the relation between the BMO algorithm and the Allen–Cahn equation, from the viewpoint of the splitting methods in numerical analysis, Vivier [23] first pointed out that we may think the Allen–Cahn equation is an approximation of the BMO algorithm. Leoni [18] and Goto, Ishii, and Ogawa [10] gave the proofs of the convergence of the BMO algorithm and a generalized scheme by applying some techniques of the asymptotic analysis for the Allen–Cahn equation. The arguments in this paper also rely on them.

This paper is organized as follows. In section 2 we discuss the formal asymptotic expansion of the radially symmetric solution of (1.1). To derive formally the equation of the motion of the interface, we consider the asymptotic behavior as $t \searrow 0$ of the zero of the solution of (1.1). In section 3 we construct sub- and supersolutions of (1.1) by using some functions provided by the formal asymptotic expansion. We treat the nonradial case in subsection 3.2 and the radial case in subsection 3.3. Section 4 is devoted to the rate of convergence of the BMO algorithm to the motion of a smooth and compact hypersurface by mean curvature. The arguments in sections 3–4 are very similar to those in [18], although Leoni considered in her paper a different situation from ours. In section 5, we return to the special case of a circle evolving by curvature. By the radial symmetry, we have only to consider the asymptotic behavior of the radius R_h of the approximate circle as $h \searrow 0$. In subsection 5.1 we obtain the short-time asymptotics of R_h. In subsection 5.2 we formally derive a corrector for R_h. Based on these results, in subsection 5.3 we obtain the behavior of R_h and show the optimality of our estimate obtained in section 4. The considerations of section 5 are motivated by Nochetto, Paolini, and Verdi [20]. In [20] they obtained the optimal error estimate of the approximate interface given by the solution of a variational inequality to the smooth motion by mean curvature. The appendix is devoted to the proof of a lemma given in section 2.

In the following of this paper, we denote by K various constants depending only on known ones, and the notation $g = O(f)$ means that $|g| \le K'f$ for some constant $K' > 0$ independent of small $t > 0$.

2. Formal asymptotic expansion to the radial case. In this section we briefly discuss the formal asymptotic expansion to the simplest situation, the radially symmetric solution of (1.1) as $t \searrow 0$. Even though this presentation is only formal, it shows us several crucial aspects for the constructions of sub- and supersolutions of (1.1) in the next section. For each $x_0 \in \mathbb{R}^N$, put $B(x_0, R) = \{x \in \mathbb{R}^N \mid |x - x_0| < R\}$.

If $u = u(t, r)$ $(r = |x|)$ and $C_0 = \overline{B(0, R)}$, then the problem (1.1) turns to

$$\text{(2.1)} \qquad \begin{cases} \mathcal{L}u := u_t - u_{rr} - \dfrac{N-1}{r} u_r = 0 & \text{in } (0, +\infty) \times (0, +\infty), \\ u_r(t, 0) = 0, \quad t > 0, \\ u(0, r) = \begin{cases} 1, & r \in [0, R], \\ -1, & r \in (R, +\infty). \end{cases} \end{cases}$$

Set $\widetilde{\Gamma}_0 = \partial B(0, R)$ and $\widetilde{\Gamma}_t = \{x \in \mathbb{R}^N \mid u(t, |x|) = 0\}$ for $t > 0$. Then we can easily verify that $\widetilde{\Gamma}_t$ is a sphere in $\mathbb{R}^N$.

As to the behavior of the solution of (2.1) away from $\widetilde{\Gamma}_t$, we have the following.

LEMMA 2.1. *For any $\delta \in (0, R/2)$, there exist $M_0 > 0$ and $t_0 \in (0, 1)$ such that, for all $t \in (0, t_0)$,*

$$\begin{aligned} &1 - M_0 e^{-\delta^2/32t} \le u(t, r) \le 1 \quad \textit{for all } 0 \le r \le R - \delta, \\ &-1 \le u(t, r) \le -1 + M_0 e^{-\delta^2/32t} \quad \textit{for all } r \ge R + \delta. \end{aligned}$$

See Goto, Ishii, and Ogawa [10, Proposition 6.1] for the proof. From this lemma, it is sufficient for us to consider the asymptotics of the solution of (2.1) near $\widetilde{\Gamma}_t$. Fix $\delta \in (0, R/2)$ and take $t_0 > 0$ so small that Lemma 2.1 holds. Let $\widetilde{\phi}(t)$ be the radius of $\widetilde{\Gamma}_t$. We assume that the solution u of (2.1) is approximated by the following formal series in $(t, r) \in (0, t_0) \times (R - \delta, R + \delta)$:

$$\text{(2.2)} \quad u(t, r) = \sum_{j=0}^{+\infty} t^{j/2} U_j \left(t, \frac{\widetilde{d}(t, r)}{2\sqrt{t}} \right), \qquad \widetilde{\phi}(t) = \sum_{j=0}^{+\infty} t^j \phi_j(t), \qquad \widetilde{\phi}(0) = \phi_0(0) = R.$$

Here U_j and ϕ_j are assumed to be bounded in $(0, t_0) \times (R - \delta, R + \delta)$ for each $j \in \mathbb{N} \cup \{0\}$ and $\widetilde{d}(t, r)$ is the signed distance function to $\widetilde{\Gamma}_t$ given by

$$\widetilde{d}(t, r) = \widetilde{\phi}(t) - r.$$

Before choosing U_j and ϕ_j $(j \in \mathbb{N} \cup \{0\})$, we give a lemma on the effect of the diffusion on $\partial B(0, R)$. Select $\widetilde{r} \ge 0$ so that $u(t, R - \widetilde{r}) = 0$. Then $\widetilde{r} = \widetilde{\phi}(0) - \widetilde{\phi}(t)$ and it is the normal distance between $\partial B(0, R)$ and $\widetilde{\Gamma}_t$.

LEMMA 2.2. *We have*

$$\widetilde{r} = \frac{(N-1)t}{R} + \frac{(N-1)(3N-1)t^2}{6R^3} + O(t^3) \quad \textit{as } t \searrow 0.$$

See the appendix for the proof. By this lemma, we formally have

$$\widetilde{\phi}' \Big|_{t=0} = - \widetilde{r}' |_{t=0} = - \frac{N-1}{R},$$

where $' = d/dt$. This suggests that we may set $\phi_0(t) = \phi(t)$, where $\phi(t) = \sqrt{R^2 - 2(N-1)t}$ and it solves

$$\text{(2.3)} \qquad \phi'(t) = - \frac{N-1}{\phi(t)} \quad \text{for } t > 0, \ \phi(0) = R.$$

Using Lemma 2.2 and the definition of ϕ, we can estimate the distance between $\partial B(0,\phi(t))$ and $\widetilde{\Gamma}_t$ for small $t>0$.

PROPOSITION 2.3. *Let $\phi(t)=\sqrt{R^2-2(N-1)t}$ and let $\widetilde{r}$ be the normal distance between $\partial B(0,R)$ and $\widetilde{\Gamma}_t$. Then*

$$\widetilde{r}-(R-\phi(t))=\frac{(N-1)t^2}{3R^3}+O(t^3) \quad \textit{as } t\searrow 0.$$

Remark 2.1. Ruuth [22, Chapter 4] obtained a similar result to this proposition in the case of the graph in $\mathbb{R}^2$.

Proof of Proposition 2.3. It is easily seen by Taylor expansion to ϕ around $t=0$ that

$$\phi(t)=R-\frac{(N-1)t}{R}-\frac{(N-1)^2t^2}{2R^2}+O(t^3) \quad \text{as } t\searrow 0.$$

Hence, we have the result by using Lemma 2.2 and this expansion. ∎

We choose U_j and ϕ_j ($j\in\mathbb{N}\cup\{0\}$) of (2.2). First, we do some ϕ_j's. It is seen that, as $t\searrow 0$,

$$\begin{aligned}
&\widetilde{r}-(R-\phi(t))=-\sum_{j=1}^{+\infty}t^j\phi_j(t),\\
&\frac{1}{R}\approx\frac{1}{\widetilde{\phi}(t)}=\frac{1}{\phi(t)}\left\{1-\sum_{j=1}^{+\infty}t^j\frac{\phi_j(t)}{\phi(t)}+\left(\sum_{j=1}^{+\infty}t^j\frac{\phi_j(t)}{\phi(t)}\right)^2-\cdots\right\}.
\end{aligned}$$

It follows from these relations and Proposition 2.3 that

$$-\sum_{j=1}^{+\infty}t^j\phi_j(t)=\frac{t^2(N-1)}{3(\phi(t))^3}\left\{1-\sum_{j=1}^{+\infty}t^j\frac{\phi_j(t)}{\phi(t)}+\left(\sum_{j=1}^{+\infty}t^j\frac{\phi_j(t)}{\phi(t)}\right)^2-\cdots\right\}^3+O(t^3)$$

for sufficiently small $t>0$. Comparing the coefficients of t^j ($j=1,2$) on both sides, we have

$$t\text{−term}:\phi_1(t)=0,\ t^2\text{−term}:\phi_2(t)=-\frac{N-1}{3(\phi(t))^3}.$$

We omit the choices of ϕ_j's ($j\geq 3$).

Second, we select some U_j's. We set $\widetilde{\phi}(t)=\phi(t)+t^2\phi_2(t)$ for simplicity. Put $\rho=\widetilde{d}/2\sqrt{t}$. Since $r=\phi-(2\sqrt{t}\rho-t^2\phi_2)$, we get

$$\frac{1}{r}=\frac{1}{\phi-(2\sqrt{t}\rho-t^2\phi_2)}=\frac{1}{\phi}\sum_{j=0}^{+\infty}\left\{\frac{1}{\phi}\left(2\sqrt{t}\rho-t^2\phi_2\right)\right\}^j \quad \text{for small } t>0. \tag{2.4}$$

Besides we easily see that

$$d_t=\phi'+2t\phi_2+t^2\phi_2',\ d_r=-1,\ d_{rr}=0.$$

Thus we use (2.2), (2.4) and these identities to compute that

$$
\begin{aligned}
\mathcal{L}u = &-\frac{1}{4t}\left(U_{0,\rho\rho}+2\rho U_{0,\rho}\right)+\frac{1}{\sqrt{t}}\left\{\frac{U_{0,\rho}}{2}\left(\phi'+\frac{N-1}{\phi}\right)-\left(\frac{1}{4}U_{1,\rho\rho}+\frac{\rho}{2}U_{1,\rho}-\frac{1}{2}U_1\right)\right\}\\
&+\left\{\frac{(N-1)\rho U_{0,\rho}}{\phi^2}+\frac{U_{1,\rho}}{2}\left(\phi'+\frac{N-1}{\phi}\right)-\left(\frac{1}{4}U_{2,\rho\rho}+\frac{\rho}{2}U_{2,\rho}-U_2\right)\right\}\\
&+\sqrt{t}\left\{U_{0,\rho}\phi_2+U_{1,t}+(N-1)\left(\frac{2\rho^2}{\phi^3}U_{0,\rho}+\frac{\rho U_{1,\rho}}{\phi^2}\right)+\frac{U_{2,\rho}}{2}\left(\phi'+\frac{N-1}{\phi}\right)\right.\\
&\qquad\left.-\left(\frac{1}{4}U_{3,\rho\rho}+\frac{\rho}{2}U_{3,\rho}-\frac{3}{2}U_3\right)\right\}+\cdots\\
= &\ 0,
\end{aligned}
$$

where $U_{i,\rho}=\partial U_i/\partial\rho$ and$U_{i,\rho\rho}=\partial^2 U_i/\partial\rho^2$.

We compare the coefficients of $t^{j/2}$ $(j=-2,-1,0,1,2,\ldots)$. In the case of the t^{-1}-term, we can derive

$$
U_{0,\rho\rho}+2\rho U_{0,\rho}=0 \quad \text{on } \mathbb{R}^1. \tag{2.5}
$$

Taking Lemma 2.1 into account, we impose the following condition on U_0:

$$
U_0(t,\rho)\longrightarrow\begin{cases}1 & \text{as } \rho\to+\infty,\\ -1 & \text{as } \rho\to-\infty\end{cases}\qquad \text{for any small } t>0. \tag{2.6}
$$

Then we have

$$
U_0=U_0(\rho)=\frac{2}{\sqrt{\pi}}\int_0^\rho e^{-s^2}ds. \tag{2.7}
$$

As for the $t^{-1/2}$-term, by (2.3) we obtain

$$
\frac{1}{4}U_{1,\rho\rho}+\frac{\rho}{2}U_{1,\rho}-\frac{1}{2}U_1=0 \quad \text{on } \mathbb{R}^1. \tag{2.8}
$$

Since the rate of convergence (2.6) is faster than the exponential one, combining Lemma 2.1 with this fact, we have the following condition on U_1:

$$
U_1(t,\rho)\longrightarrow 0 \quad \text{as } \rho\to\pm\infty \quad \text{for any small } t>0. \tag{2.9}
$$

Therefore we have $U_1\equiv 0$ because the uniqueness of solutions of (2.8) under (2.9) holds in the class of bounded functions.

In the case of the $t^{j/2}$-term $(j=0,1)$, from (2.3) and the fact that $U_1\equiv 0$ we get

$$
\frac{1}{4}U_{2,\rho\rho}+\frac{\rho}{2}U_{2,\rho}-U_2=\frac{(N-1)\rho U_{0,\rho}}{\phi^2} \quad \text{on } \mathbb{R}^1, \tag{2.10}
$$

$$
\frac{1}{4}U_{3,\rho\rho}+\frac{\rho}{2}U_{3,\rho}-\frac{3}{2}U_3=(N-1)\left(2\rho^2-\frac{1}{3}\right)\frac{U_{0,\rho}}{\phi^3} \quad \text{on } \mathbb{R}^1. \tag{2.11}
$$

By the same reason as above, the following condition is imposed on U_j's $(j=2,3)$:

$$
U_j(t,\rho)\longrightarrow 0 \quad \text{as } \rho\to\pm\infty \quad \text{for any small } t>0. \tag{2.12}
$$

Solving (2.10) and (2.11) under (2.12), we obtain

$$
U_2(t,\rho)=-\frac{(N-1)\rho e^{-\rho^2}}{\sqrt{\pi}(\phi(t))^2}, \qquad U_3(t,\rho)=-\frac{4(N-1)\rho^2 e^{-\rho^2}}{3\sqrt{\pi}(\phi(t))^3}. \tag{2.13}
$$

We omit selecting U_j $(j\geq 4)$.

Remark 2.2. In the above discussion, we have not applied the Fredholm alternative to derive the equation of the motion of the interface, which is used to do so in the case of the Allen–Cahn equation (see, e.g., Fife [7], de Mottoni and Schatzman [4], and Nochetto, Paolini, and Verdi [20]), because such equations as (2.8) under (2.9) have only the trivial solution. For this reason, we have used other methods such as Lemma 2.2 and Proposition 2.3 to determine ϕ_0, ϕ_1, and ϕ_2.

3. Subsolutions and supersolutions. We construct sub- and supersolutions of (1.1) in $(kh,(k+1)h)\times\mathbb{R}^N$ for $h>0$ and $k\in\mathbb{N}\cup\{0\}$. These functions will be used in sections 4 and 5 to derive the optimal rate of convergence of the BMO algorithm.

In this and the next section we assume that $\{\Gamma_t\}_{0\le t<T_0}$ is a motion of a smooth and compact hypersurface by mean curvature. The precise assumption on $\{\Gamma_t\}_{0\le t<T_0}$ is given in subsection 3.1. In addition, the existence, uniqueness, and behavior of $\{\Gamma_t\}_{0\le t<T_0}$ are mentioned in Remark 4.1 of section 4.

3.1. Signed distance function. For each $t\in[0,T_0)$, the signed distance function $d=d(t,x)$ to Γ_t is defined by

$$d\,(t,x)=\begin{cases}\operatorname{dist}\,(x,\Gamma_t) & \text{for } x\in D_t^+,\\ 0 & \text{for } x\in\Gamma_t,\\ -\operatorname{dist}\,(x,\Gamma_t) & \text{for } x\in D_t^-,\end{cases}\tag{3.1}$$

where D_t^+ denotes the bounded domain enclosed by Γ_t and $D_t^-=\mathbb{R}^N\backslash(D_t^+\cup\Gamma_t)$. Then d satisfies

$$d_t=\Delta d\quad\text{on } \Gamma_t,\ t>0.\tag{3.2}$$

For any $T\in(0,T_0)$ and $\delta>0$, let $\mathcal{N}_\delta$ be the tubular neighborhood of $\{(t,x)\in[0,T]\times\mathbb{R}^N\mid x\in\Gamma_t\}$:

$$\mathcal{N}_\delta:=\{(t,x)\in[0,T]\times\mathbb{R}^N\mid |d(t,x)|\le\delta\}.$$

We assume that $\{\Gamma_t\}_{0\le t<T_0}$ is so smooth that, for any $T<T_0$, there exists a $\delta>0$ satisfying

$$d_t,d_{x_i},d_{x_ix_j},d_{x_ix_jt},d_{x_ix_jx_k},d_{x_ix_jx_kx_l}\in L^\infty(\mathcal{N}_{5\delta})\quad\text{for } i,j,k,l=1,\dots,N.\tag{3.3}$$

It follows from this condition that for any $(t,x)\in\mathcal{N}_{5\delta}$, there is a unique $y(t,x)\in\Gamma_t$ satisfying

$$|d(t,x)|=|x-y(t,x)|.\tag{3.4}$$

Let $\widetilde{\kappa}=\widetilde{\kappa}(t,x)$ be the sum of the square of all principal curvatures at $x\in\Gamma_t$. Define

$$\kappa^s=\kappa^s(t,x):=\widetilde{\kappa}(t,y(t,x))\quad\text{for } (t,x)\in\mathcal{N}_{5\delta}.$$

Then (3.3) yields that

$$\kappa^s,\kappa^s_t,\kappa^s_{x_i},\kappa^s_{x_ix_j}\in L^\infty(\mathcal{N}_{5\delta})\quad\text{for } i,j=1,2,\dots,N.\tag{3.5}$$

Moreover, we observe by this property that there exists a $\kappa_1>0$ such that

$$|d_t-\Delta d-\kappa^s d|\le\kappa_1 d^2\quad\text{on } \mathcal{N}_{5\delta}.\tag{3.6}$$

For the details to (3.2)–(3.6), see, e.g., Chen [3], Gilbarg and Trudinger [9], and Paolini and Verdi [21].

3.2. Nonradial case. In this subsection we construct a sub- and a supersolution of (1.1) in $(kh,(k+1)h)\times\mathbb{R}^N$ for each $h>0$ and $k\in\mathbb{N}\cup\{0\}$.

We modify slightly the signed distance function d in (3.1). For any $(t,x)\in\mathcal{N}_{5\delta}$, $k\in\mathbb{N}\cup\{0\}$, and $\alpha_k\geq 0$, set

$$\underline{d}_k(t,x)=d(t,x)-\alpha_k h^2,\qquad \overline{d}_k(t,x)=d(t,x)+\alpha_k h^2.$$

We introduce smooth functions η and ζ satisfying

$$\eta(r)=\begin{cases} r, & s\leq\delta,\\ 2\delta, & s\geq 3\delta,\\ -2\delta, & s\leq -3\delta,\end{cases}\quad 0\leq\eta'\leq 1,\ |\eta''|\leq\frac{M_1}{\delta},\tag{3.7}$$

$$\zeta(r)=\begin{cases} 1, & |s|\leq\delta,\\ 0, & |s|\geq 3\delta,\end{cases}\quad 0\leq\zeta\leq 1,\ |\zeta'|\leq\frac{M_1}{\delta},\ |\zeta''|\leq\frac{M_1}{\delta^2},\tag{3.8}$$

where M_1 is a constant independent of δ. Motivated by the formal discussion in section 2, we define $\underline{u}$ and $\overline{u}$ by

$$\begin{aligned}\underline{u}\,(t,x)=U_0\left(\frac{\eta(\underline{d}_k(t,x))}{2\sqrt{t-kh}}\right)&+(t-kh)\zeta(\underline{d}_k(t,x))U_2\left(t,x,\frac{\underline{d}_k(t,x)}{2\sqrt{t-kh}}\right)\\ &-(t-kh)^{3/2}U_3-U_4\alpha_k h^2\sqrt{t-kh},\end{aligned}\tag{3.9}$$

$$\begin{aligned}\overline{u}\,(t,x)=U_0\left(\frac{\eta(\overline{d}_k(t,x))}{2\sqrt{t-kh}}\right)&+(t-kh)\zeta(\overline{d}_k(t,x))U_2\left(t,x,\frac{\overline{d}_k(t,x)}{2\sqrt{t-kh}}\right)\\ &+(t-kh)^{3/2}U_3+U_4\alpha_k h^2\sqrt{t-kh}\end{aligned}\tag{3.10}$$

in $(kh,(k+1)h)\times\mathbb{R}^N$ and $k\in\mathbb{N}\cup\{0\}$. Here $U_2=U_2(t,x,\rho)$ is given by

$$U_2(t,x,\rho)=-\frac{1}{\sqrt{\pi}}\kappa^s(t,x)\rho e^{-\rho^2},\tag{3.11}$$

and U_3 and U_4 are positive constants selected later. At $t=kh$, we set

$$\underline{u}(kh,x)=\begin{cases}1 & \text{if } \underline{d}_k(kh,x)\geq 0,\\ -1 & \text{if } \underline{d}_k(kh,x)<0,\end{cases}\qquad \overline{u}(kh,x)=\begin{cases}1 & \text{if } \overline{d}_k(kh,x)\geq 0,\\ -1 & \text{if } \overline{d}_k(kh,x)<0.\end{cases}\tag{3.12}$$

We note that U_2 satisfies

$$\frac{1}{4}U_{2,\rho\rho}+\frac{\rho}{2}U_{2,\rho}-U_2=\kappa^s\rho U_{0,\rho}\quad\text{for } (t,x)\in\mathcal{N}_{5\delta},\ \rho\in\mathbb{R}^1.\tag{3.13}$$

PROPOSITION 3.1. *Let d satisfy* (3.3) *for some $\delta>0$. Then there exist $h_1>0$, $U_3>0$, and $U_4>0$ such that for each $h\in(0,h_1)$, $k\in\mathbb{N}\cup\{0\}$, and $\alpha_k\geq 0$, $\underline{u}$ and $\overline{u}$ are, respectively, a subsolution and a supersolution of* (1.1) *in $(kh,(k+1)h)\times\mathbb{R}^N$.*

Proof. We set $k=0$ and prove the subsolution case.

For the notational simplicity, put $\underline{\rho}=\underline{d}_0/2\sqrt{t}$, $\underline{z}(t,x)=\eta(\underline{d}_0(t,x))$, and $\rho_{\underline{z}}=\underline{z}/2\sqrt{t}$. We denote by $\mathbb{L}$

$$\mathbb{L}u=u_t-\Delta u\quad\text{for } u=u(t,x).$$

It is seen by calculations that

$$\begin{aligned}\mathbb{L}\underline{u}=&-\frac{1}{4t}(U_{0,\rho\rho}|D\underline{z}|^2+2\rho_{\underline{z}}U_{0,\rho})+\frac{U_{0,\rho}}{2\sqrt{t}}(\underline{z}_t-\Delta\underline{z})-\zeta\left\{\frac{1}{4}U_{2,\rho\rho}|D\underline{d}_0|^2+\frac{\rho}{2}U_{2,\rho}-U_2\right\}\\ &+\sqrt{t}\left\{\zeta U_{2,\rho}(\underline{d}_{0,t}-\Delta\underline{d}_0)+\zeta'U_{2,\rho}|D\underline{d}_0|^2+\zeta\langle DU_{2,\rho},D\underline{d}_0\rangle\right\}\\ &+t\{\zeta(U_{2,t}-\Delta U_2)+\zeta'U_2(\underline{d}_{0,t}-\Delta\underline{d}_0)\}-\frac{3}{2}\sqrt{t}U_3-\frac{U_4\alpha_0h^2}{2\sqrt{t}},\end{aligned}$$

where $Df=(f_{x_1},\ldots,f_{x_N})$. We divide our consideration into two cases.

Case 1. $|\underline{d}_0(t,x)| \le \delta$.

In this case, $\eta = \zeta = 1$. Thus $\underline{z} = \underline{d}_0$, $\rho_{\underline{z}} = \underline{\rho}$ and

$$(3.14)\ |D\underline{z}| = |D\underline{d}_0| = |Dd| = 1, \qquad \underline{z}_t - \Delta\underline{z} = \underline{d}_{0,t} - \Delta\underline{d}_0 = d_t - \Delta d \quad \text{on } \mathcal{N}_{5\delta}.$$

Moreover, we observe that

$$(3.15)\quad \sup_{\substack{\rho\in\mathbb{R}^1\\ l=0,2}} |\rho^l U_{0,\rho}| + \sup_{(t,x)\in\mathcal{N}_{5\delta},\rho\in\mathbb{R}^1} (|U_2| + |U_{2,\rho}| + |U_{2,t}| + |\Delta U_2| + |DU_{2,\rho}|) \le K.$$

Here we have used (3.3) and (3.5) to obtain the boundedness for the second term on the left-hand side of this inequality.

It follows from (2.5), (3.3), (3.14), and (3.15) that

$$\mathbb{L}\underline{u} \le \frac{U_{0,\rho}}{2\sqrt{t}}(d_t - \Delta d) - \left\{\frac{1}{4}U_{2,\rho\rho} + \frac{\rho}{2}U_{2,\rho} - U_2\right\} + \sqrt{t}\left\{K(1+\sqrt{t}) - \frac{3}{2}U_3\right\} - \frac{U_4\alpha_0 h^2}{2\sqrt{t}}.$$

We see by the positivity of $U_{0,\rho}$, (3.6) and (3.13) that

$$\frac{U_{0,\rho}}{2\sqrt{t}}(d_t - \Delta d) - \left\{\frac{1}{4}U_{2,\rho\rho} + \frac{\rho}{2}U_{2,\rho} - U_2\right\} \le 2\sqrt{t}\kappa_1\underline{\rho}^2 U_{0,\rho} + \frac{U_{0,\rho}}{2\sqrt{t}}(\kappa^s + 2\kappa_1 d)\alpha_0 h^2.$$

Using (3.5), (3.15) and this inequality, we get

$$\mathbb{L}\underline{u} \le \sqrt{t}\left(K(1+\sqrt{t}) - \frac{3}{2}U_3\right) + \frac{h^2}{2\sqrt{t}}(U_{4,1}(U_{4,2} + 2\kappa_1\delta) - U_4)\alpha_0,$$

where $U_{4,1} = \|U_{0,\rho}\|_{L^\infty(\mathbb{R})}$ and $U_{4,2} = \|\kappa^s\|_{L^\infty(\mathcal{N}_{5\delta})}$. Therefore we can take

$$U_3 \ge \frac{4}{3}K, \qquad U_4 \ge U_{4,1}(U_{4,2} + 2\kappa_1\delta)$$

to obtain

$$\mathbb{L}\underline{u} \le 0 \quad \text{in } \{(t,x) \in (0,h)\times\mathbb{R}^N \mid |\underline{d}_0(t,x)| \le \delta\}.$$

Case 2. $|\underline{d}_0(t,x)| \ge \delta$.

In this case, $|\underline{z}| \ge \delta$. Then we see by (3.3), (3.5), and (3.7) that

$$(3.16)\qquad \begin{aligned} &|\rho_{\underline{z}}^l U_{0,\rho}(\rho_{\underline{z}})| + |U_2(t,x,\underline{\rho})| + |U_{2,\rho}(t,x,\underline{\rho})| + |U_{2,t}(t,x,\underline{\rho})| \\ &\quad + |\Delta U_2(t,x,\underline{\rho})| + |DU_{2,\rho}(t,x,\underline{\rho})| \le Ke^{-\delta^2/8t} \end{aligned}$$

for small $t > 0$ and $l = 0,1,2,3$. By (3.3) and (3.7) we get

$$|w_t - \Delta w| \le K \quad (w = z, \underline{d}_0).$$

Using (2.5), (3.8), (3.13), (3.16) and this estimate, we obtain

$$\mathbb{L}\underline{u} \le Ke^{-\delta^2/8t} - \frac{3\sqrt{t}}{2}U_3.$$

We choose $h_1 > 0$ so small that $e^{-\delta^2/8t} \le \sqrt{t}$ for all $t \in (0,h_1)$. Hence, letting $U_3 \ge 2K/3$ and $U_4 \ge 0$, we have

$$\mathbb{L}\underline{u} \le 0 \quad \text{in } \{(t,x) \in (0,h)\times\mathbb{R}^N \mid |\underline{d}_0(t,x)| \ge \delta\}$$

for all $h \in (0,h_1)$.

Consequently, taking a large $U_3 > 0$ and setting $U_4 = U_{4,1}(U_{4,2} + 2\kappa_1\delta)$, we obtain

$$\mathbb{L}\underline{u} \leq 0 \quad \text{in } (0,h) \times \mathbb{R}^N$$

for all $h \in (0, h_1)$. The supersolution case can be shown by a method similar to the above.

For the case $k \geq 1$, we can show the assertion of this proposition by using the same h_1, U_3, and U_4 as in the case $k = 0$. $\square$

3.3. Radial case. This subsection is devoted to the construction of a sub- and a supersolution of (1.1) which are radially symmetric. We recall that if $u = u(t,r)$ $(r = |x|)$ and $C_0 = B(0,R)$, then the problem (1.1) turns to (2.1). We assume $N = 2$ to simplify our arguments.

For any $R > 0$, put

$$\begin{aligned} \phi(t) &= \sqrt{R^2 - 2t},\ \phi_1(t) = \frac{1}{3(\phi(t))^3} \quad \text{on } [0,h], \\ \widetilde{d}(t,r) &= \phi(t) - t^2\phi_1(t) - r \quad \text{on } [0,h] \times \mathbb{R}^1. \end{aligned} \tag{3.17}$$

Let η and ζ be the same functions as (3.7) and (3.8), respectively. Set $z(t,r) = \eta(\widetilde{d}(t,r))$ and define $\underline{u}$ and $\overline{u}$ by

$$\underline{u}(t,r) = U_0\left(\frac{z(t,r)}{2\sqrt{t}}\right) + \zeta(\widetilde{d}(t,r))\left\{tU_2\left(t, \frac{\widetilde{d}(t,r)}{2\sqrt{t}}\right) + t^{3/2}U_3\left(t, \frac{\widetilde{d}(t,r)}{2\sqrt{t}}\right)\right\} - t^2U_4, \tag{3.18}$$

$$\overline{u}(t,r) = U_0\left(\frac{z(t,r)}{2\sqrt{t}}\right) + \zeta(\widetilde{d}(t,r))\left\{tU_2\left(t, \frac{\widetilde{d}(t,r)}{2\sqrt{t}}\right) + t^{3/2}U_3\left(t, \frac{\widetilde{d}(t,r)}{2\sqrt{t}}\right)\right\} + t^2U_4 \tag{3.19}$$

for $t > 0$, $r \in \mathbb{R}^1$. Here U_2, U_3 are given by (2.13) and U_4 is a constant selected later. At $t = 0$, we put

$$\underline{u}(0,r) = \overline{u}(0,r) = \begin{cases} 1, & \text{if } \widetilde{d}(0,r) \geq 0, \\ -1, & \text{if } \widetilde{d}(0,r) < 0. \end{cases} \tag{3.20}$$

PROPOSITION 3.2. *Fix $\delta \in (0, R/5 \wedge 1)$. Then there exist $h_2 > 0$ and $U_4 > 0$ such that for each $h \in (0, h_2)$, $\underline{u}$ and $\overline{u}$ are, respectively, a subsolution and a supersolution of* (2.1) *in $(0,h) \times \mathbb{R}^1$. In addition, they satisfy the boundary condition of* (2.1).

Proof. We assume $k = 0$ and prove the subsolution case. Set $\rho_z = z/2\sqrt{t}$ and $\widetilde{\rho} = \widetilde{d}/2\sqrt{t}$ for the notational simplicity.

It is observed by calculations that

$$\begin{aligned} \mathcal{L}\underline{u} = &-\frac{1}{4t}\left(U_{0,\rho\rho}z_r^2 + 2\rho_z U_{0,\rho}\right) + \frac{U_{0,\rho}}{2\sqrt{t}}\left(z_t - z_{rr} - \frac{1}{r}z_r\right) - \zeta\left(\frac{1}{4}U_{2,\rho\rho}\widetilde{d}_r^2 + \frac{\widetilde{\rho}}{2}U_{2,\rho} - U_2\right) \\ &+ \sqrt{t}\zeta\left\{U_{2,\rho}\left(\widetilde{d}_t - \widetilde{d}_{rr} - \frac{1}{r}\widetilde{d}_r\right) - \left(\frac{1}{4}U_{3,\rho\rho}\widetilde{d}_r^2 + \frac{\widetilde{\rho}}{2}U_{3,\rho} - \frac{3}{2}U_3\right)\right\} \\ &+ t\left[\zeta\left\{U_{2,t} + \sqrt{t}U_{3,t} + \frac{U_{3,\rho}}{2}\left(\widetilde{d}_t - \widetilde{d}_{rr} - \frac{1}{r}\widetilde{d}_r\right)\right\} - 2U_4\right] \\ &- 2\zeta'\widetilde{d}_r\left\{tU_{2,\rho}\frac{\widetilde{d}_r}{2\sqrt{t}} + t^{3/2}U_{3,\rho}\frac{\widetilde{d}_r}{2\sqrt{t}}\right\} \\ &+ t\left\{\zeta'\left(\widetilde{d}_t - \widetilde{d}_{rr} - \frac{1}{r}\widetilde{d}_r\right) - \zeta''\widetilde{d}_r^2\right\}(U_2 + \sqrt{t}U_3). \end{aligned}$$

We divide our consideration into two cases.

Case 1. $|\widetilde{d}(t,r)| \le \delta$.

In this case, $\eta = \zeta = 1$. Thus $z = \widetilde{d}$, $\rho_z = \widetilde{\rho}$ and

$$w_r = -1,\ w_t - w_{rr} - \frac{1}{r}w_r = \phi' - 2t\phi_1 - t^2\phi_1' + \frac{1}{r} \quad \text{for } w = z, \widetilde{d}. \tag{3.21}$$

Moreover, we see from (2.13) and (3.17) that

$$\sup_{\substack{\rho\in\mathbb{R}^1\\ l=0,1,2,3}} |\rho^l U_{0,\rho}| + \sup_{\substack{t\in[0,R^2/4],\rho\in\mathbb{R}^1\\ j=2,3,l=0,1,2,3}} \left(|\rho^l U_j| + |\rho^l U_{j,\rho}| + |U_{j,t}|\right) \le K. \tag{3.22}$$

By (2.5), (3.21), and this boundedness, we have

$$\begin{aligned}\mathcal{L}u \le{}& \frac{U_{0,\rho}}{2\sqrt{t}}\left(\phi' - 2t\phi_1 - t^2\phi_1' + \frac{1}{r}\right) - \left(\frac{1}{4}U_{2,\rho\rho} + \frac{\widetilde{\rho}}{2}U_{2,\rho} - U_2\right)\\ &+ t^{1/2}\left\{U_{2,\rho}\left(\phi' - 2t\phi_1 - t^2\phi_1' + \frac{1}{r}\right) - \left(\frac{1}{4}U_{3,\rho\rho} + \frac{\widetilde{\rho}}{2}U_{3,\rho} - \frac{3}{2}U_3\right)\right\}\\ &+ \frac{tU_{3,\rho}}{2}\left(\phi' - 2t\phi_1 - t^2\phi_1' + \frac{1}{r}\right) + t(K - 2U_4).\end{aligned}$$

We estimate $\phi' - 2t\phi_1 - t^2\phi_1' + 1/r$. We remark that $\widetilde{d} = 2\sqrt{t}\widetilde{\rho}$ and $r = \phi - (2\sqrt{t}\widetilde{\rho} + t^2\phi_1)$. It follows from (3.17) that there exists an $h_2 \in (0,\delta)$ such that $\phi(t) \ge 4\delta$ and $t^2\phi_1(t) \le \delta$ for $t \in (0,h_2)$. Thus we get $2\sqrt{t}|\widetilde{\rho}| + t^2\phi_1 \le 2\delta$ and

$$\frac{1}{r} \le \frac{1}{\phi}\left\{1 + \frac{1}{\phi}(2\sqrt{t}\widetilde{\rho} + t^2\phi_1) + \frac{1}{\phi^2}(2\sqrt{t}\widetilde{\rho} + t^2\phi_1)^2\right\} + \frac{1}{3\delta\phi^3}(2\sqrt{t}|\widetilde{\rho}| + t^2\phi_1)^3$$

for all $t \in (0,h_2)$. Since ϕ satisfies $\phi' + 1/\phi = 0$ and ϕ_1' is bounded, we observe that

$$\phi' - 2t\phi_1 - t^2\phi_1' + \frac{1}{r} \le \frac{2\sqrt{t}\widetilde{\rho}}{\phi^2} + \frac{4t\widetilde{\rho}^2}{\phi^3} - 2t\phi_1 + \frac{8t^{3/2}|\widetilde{\rho}|^3}{3\delta\phi^3} + Kt^2. \tag{3.23}$$

We observe from the positivity of $U_{0,\rho}$ on $\mathbb{R}^1$, (2.10), (2.11), (3.22), and this estimate that

$$\begin{aligned}&\frac{U_{0,\rho}}{2\sqrt{t}}\left(\phi' - 2t\phi_1 - t^2\phi_1' + \frac{1}{r}\right) - \left(\frac{1}{4}U_{2,\rho\rho} + \frac{\widetilde{\rho}}{2}U_{2,\rho} - U_2\right)\\ &\qquad -\sqrt{t}\left(\frac{1}{4}U_{3,\rho\rho} + \frac{\widetilde{\rho}}{2}U_{3,\rho} - \frac{3}{2}U_3\right) \le U_{0,\rho}(Kt\widetilde{\rho}^3 + Kt^{3/2}) \le tK(1+\sqrt{t}).\end{aligned}$$

In addition, (3.22) and (3.23) yield that

$$t^{1/2}U_{2,\rho}\left(\phi' - 2t\phi_1 - t^2\phi_1' + \frac{1}{r}\right) + \frac{tU_{3,\rho}}{2}\left(\phi' - 2t\phi_1 - t^2\phi_1' + \frac{1}{r}\right) \le Kt.$$

Therefore we obtain

$$\mathcal{L}\underline{u} \le t(K(1+\sqrt{t}) - 2U_4).$$

Consequently, taking U_4 sufficiently large, we obtain

$$\mathcal{L}\underline{u} \le 0 \quad \text{in } \{(t,r) \in (0,h) \times \mathbb{R}^1 \mid |\widetilde{d}(t,r)| \le \delta\}$$

for all $h \in (0,h_2)$.

Case 2. $|\widetilde{d}(t,r)| \geq \delta$.

In this case, $|z| \geq \delta$. Then we see by (2.13) that

$$|\rho_z^l U_{0,\rho}(\rho_z)| + |\widetilde{\rho}^l U_j(t,\widetilde{\rho})| + |\widetilde{\rho}^l U_{j,\rho}(t,\widetilde{\rho})| + |U_{j,t}(t,\widetilde{\rho})| \leq K e^{-\delta^2/8t} \tag{3.24}$$

for small $t > 0$, $j = 2, 3$, and $l = 0, 1, 2, 3$. Then it is easily observed by the fact that $\delta \leq r \leq R + 3\delta$ and by (3.7) and (3.17) that

$$\left| w_t - w_{rr} - \frac{1}{r} w_r \right| \leq K \quad \text{for } w = z, \widetilde{d}.$$

Thus we apply (3.7), (3.8), (3.24), and this inequality to obtain

$$\mathcal{L}\underline{u} \leq K e^{-\delta^2/8t} - 2tU_4.$$

Taking $h_2 > 0$ smaller if necessary, we have $e^{-\delta^2/8t} \leq t$ for all $t \in (0, h_2)$. Thus we choose $U_4 \geq K/2$ to have

$$\mathcal{L}\underline{u} \leq 0 \quad \text{in } \{(t,r) \in (0,h) \times \mathbb{R}^1 \mid |\widetilde{d}(t,r)| \geq \delta\}$$

for all $h \in (0, h_2)$.

Consequently, taking $U_4 > 0$ large and $h_2 > 0$ small, we obtain

$$\mathcal{L}\underline{u} \leq 0 \quad \text{in } (0,h) \times \mathbb{R}^1$$

for all $h \in (0, h_2)$. Since $\underline{u}(t,r) = U_0(\delta/\sqrt{t}) - t^2 U_4$ for $0 \leq r \ll 1$, it is easily verified that $\underline{u}_r(t,0) = 0$. The supersolution case can be shown in a similar way. ∎

4. Rate of convergence. In this section we consider the rate of convergence of the BMO algorithm to the motion of a smooth and compact hypersurface by mean curvature.

To state our theorem, we rewrite the BMO algorithm as follows. Let $\Gamma_0 \subset \mathbb{R}^N$ be a smooth and compact hypersurface and $C_0 \subset \mathbb{R}^N$ the compact set such that $\partial C_0 = \Gamma_0$. Fix a time step $h > 0$. Let $u^h = u^h(t,x)$ be the solution of

$$\begin{cases} u_t^h = \Delta u^h \quad \text{in } (kh, (k+1)h) \times \mathbb{R}^N, \\ u^h(kh, x) = \begin{cases} 1, & x \in C_k, \\ -1, & x \in \mathbb{R}^N \setminus C_k, \end{cases} \\ C_k = \begin{cases} \text{the above set } C_0 & \text{for } k = 0, \\ \left\{ x \in \mathbb{R}^N \;\middle|\; \lim\limits_{t \to kh-} u^h(t,x) \geq 0 \right\} & \text{for } k = 1, 2, \ldots. \end{cases} \end{cases} \tag{4.1}$$

Set

$$C_t^h = \begin{cases} \{x \in \mathbb{R}^N \mid u^h(t,x) \geq 0\} & \text{for } t \neq kh, \\ C_k & \text{for } t = kh, \end{cases}$$

$$\Gamma_t^h = \partial C_t^h (= \{x \in \mathbb{R}^N \mid u^h(t,x) = 0\}). \tag{4.2}$$

We note that C_{kh}^h coincides with C_k defined in the introduction and that Γ_t^h is a smooth and compact hypersurface for each $t \geq 0$, $h > 0$. Furthermore, there exists an $R_0 > 0$ such that $\Gamma_t^h \subset \overline{B(0, R_0)}$ for all $t \geq 0$ and $h > 0$ (see Barles and Georgelin [1, Lemma 5.1]). Using this formulation, we have the following theorem.

Theorem 4.1. *Let* $\{\Gamma_t\}_{0\le t<T_0}$ *be a smooth and compact motion by mean curvature satisfying* (3.3). *Let* Γ_t^h *be defined by* (4.2). *Then, for any* $T \in (0, T_0)$, *there exist* $h_0 > 0$ *and* $L > 0$ *such that*

$$\sup_{t\in[0,T]} d_H\left(\Gamma_t^h, \Gamma_t\right) \le Lh \tag{4.3}$$

for all $h \in (0, h_0)$. *Here* $d_H(A, B)$ *denotes the Hausdorff distance between* A, $B \subset \mathbb{R}^N$.

Remark 4.1. On the existence, uniqueness, and behavior of a motion by mean curvature $\{\Gamma_t\}_{0\le t<T_0}$, the following results are known. Assume that Γ_0 is the boundary of class $C^{k,\alpha}$ of a bounded domain ($k \ge 2, 0 < \alpha < 1$).

(i) For some $T_0 = T_0(\Gamma_0) > 0$, there uniquely exists a smooth and compact motion by mean curvature $\{\Gamma_t\}_{0\le t<T_0}$ starting from Γ_0. Moreover, the signed distance function d defined by (3.1) is of class $C^{(k+\alpha)/2,k+\alpha}(\mathcal{N}_{\delta_0})$ for some small $\delta_0 > 0$ (see Evans and Spruck [6]).

(ii) If $N = 2$ or Γ_0 is convex, then the motion $\{\Gamma_t\}_{0\le t<T_0}$ can be extended up to $T_0 = T_{max}$, where T_{max} is the extinction time for Γ_t (see Gage and Hamilton [8], Grayson [11], and Huisken [13]). In other cases the singularities may appear before Γ_t shrinks to a point (see, e.g., Grayson [12]).

Therefore (4.3) is valid before Γ_t shrinks to a point or develops the singularities.

Proof of Theorem 4.1. Set $k = 0$, $u = u^h$ and let $\underline{u}$ and $\overline{u}$ be defined by (3.9) and (3.10), respectively. Define

$$\underline{\Sigma}_t^h := \{x \in \mathbb{R}^N \mid \underline{u}(t,x) = 0\}, \qquad \underline{\Theta}_t^h := \{x \in \mathbb{R}^N \mid \underline{d}_0(t,x) = 0\},$$
$$\overline{\Sigma}_t^h := \{x \in \mathbb{R}^N \mid \overline{u}(t,x) = 0\}, \qquad \overline{\Theta}_t^h := \{x \in \mathbb{R}^N \mid \overline{d}_0(t,x) = 0\}.$$

Note that these sets are smooth and compact hypersurfaces.

Step 1. We prove that there exist $h_{0,1} > 0$, L_1 and $L_2 > 0$ such that

$$d_H(\underline{\Theta}_t^h, \underline{\Sigma}_t^h),\ d_H(\overline{\Theta}_t^h, \overline{\Sigma}_t^h) \le (L_1 h\alpha_0 + L_2)h^2 \tag{4.4}$$

for all $t \in (0, h)$ and $h \in (0, h_{0,1})$.

We easily see from (3.15) that there exists an $h_{0,1} = h_{0,1} > 0$ such that

$$|\underline{d}_0(t,x)| < 2\sqrt{t} \quad \text{on } \underline{\Sigma}_t^h \cup \underline{\Theta}_t^h \tag{4.5}$$

for all $t \in [0, h)$ and $h \in (0, h_{0,1})$. Moreover, taking $h_{0,1}$ smaller if necessary, we observe that for any $t \in (0, h_{0,1})$ and $x \in \mathbb{R}^N$ satisfying $|\underline{d}_0(t,x)| \le 2\sqrt{t}$,

$$\langle D\underline{u}(t,x), D\underline{d}_0(t,x)\rangle \ge \frac{U_{0,\rho}(1)}{2\sqrt{t}} - Kt \ge \frac{1}{10\sqrt{\pi t}}. \tag{4.6}$$

Let $\underline{x} \in \underline{\Theta}_t^h$ and take $\underline{y} \in \underline{\Sigma}_t^h$ so that $\underline{y} = \underline{x} + |\underline{x} - \underline{y}| D\underline{d}_0(t, \underline{x})$. Applying the mean value theorem, we obtain

$$\begin{aligned} 0 = \underline{u}(t,\underline{y}) &= \underline{u}(t,\underline{x}) + \langle D\underline{u}(t, \theta\underline{x} + (1-\theta)\underline{y}), \underline{y} - \underline{x}\rangle \quad (0 < \theta < 1) \\ &= -t^{3/2}U_3 - U_4\alpha_0 h^2\sqrt{t} + |\underline{x} - \underline{y}|\langle D\underline{u}(t, \theta\underline{y} + (1-\theta)\underline{x}), D\underline{d}_0(t,\underline{x})\rangle. \end{aligned}$$

It is easily seen that $D\underline{d}_0(t,\underline{x}) = Dd(t, \theta\underline{y} + (1-\theta)\underline{x})$. Hence we can use (4.6) to have $|\underline{x} - \underline{y}| \le 10\sqrt{\pi}t(U_4\alpha_0 h^2 + tU_3)$ and thus

$$\sup_{x\in\underline{\Theta}_t^h} \operatorname{dist}(x, \underline{\Sigma}_t^h) \le (L_1 h\alpha_0 + L_2)h^2,$$

where $L_1 = 10\sqrt{\pi}U_4$, $L_2 = 10\sqrt{\pi}U_3$ and U_3, U_4 are the same constants as in Proposition 3.1. Similarly, we can show that

$$\sup_{x\in\underline{\Sigma}_t^h} \operatorname{dist}(x, \underline{\Theta}_t^h),\ \sup_{x\in\overline{\Theta}_t^h} \operatorname{dist}(x, \overline{\Sigma}_t^h),\ \sup_{x\in\overline{\Sigma}_t^h} \operatorname{dist}(x, \overline{\Theta}_t^h) \le (L_1 h\alpha_0 + L_2)h^2.$$

Hence we obtain (4.4).

Step 2. We show that there exists an $h_0 > 0$ such that

$$d_H(\Gamma_t, \Gamma_t^h) \le \{(1 + L_1 h)\alpha_0 + L_2\}h^2 \quad \text{for all } t \in (0, h) \text{ and } h \in (0, h_0). \tag{4.7}$$

Let $h_1 > 0$ be given in Proposition 3.1. Set $h_0 = \min\{h_{0,1}, h_1\}$ and fix $h \in (0, h_0)$. Since it is easily verified by (3.12) that $\underline{u}(0, x) \le u(0, x) \le \overline{u}(0, x)$ on $\mathbb{R}^N$, we have $\underline{u}(t, x) \le u(t, x) \le \overline{u}(t, x)$ on $[0, h) \times \mathbb{R}^N$ by Proposition 3.1 and the comparison principle for the heat equation. This implies that

$$\Gamma_t^h \subset \{x \in \mathbb{R}^N \mid \underline{u}(t, x) \le 0 \le \overline{u}(t, x)\} \quad \text{for all } t \in [0, h), \tag{4.8}$$

that is, Γ_t^h lies between $\underline{\Sigma}_t^h$ and $\overline{\Sigma}_t^h$.

For any $x \in \Gamma_t$, we can find an $\underline{x} \in \underline{\Theta}_t^h$ such that $\operatorname{dist}(x, \underline{\Theta}_t^h) = \alpha_0 h^2 = |x - \underline{x}|$. From Step 1, we have

$$\operatorname{dist}(x, \underline{\Sigma}_t^h) \le |x - \underline{x}| + \operatorname{dist}(\underline{x}, \underline{\Sigma}_t^h) \le \{(1 + L_1 h)\alpha_0 + L_2\}h^2$$

for all $t \in [0, h)$. Since $x \in \Gamma_t$ is arbitrary, we get

$$\sup_{x\in\Gamma_t} \operatorname{dist}(x, \underline{\Sigma}_t^h) \le \{(1 + L_1 h)\alpha_0 + L_2\}h^2 \quad \text{for all } t \in [0, h). \tag{4.9}$$

Similarly, we can show that

$$\sup_{x\in\Gamma_t} \operatorname{dist}(x, \overline{\Sigma}_t^h) \le \{(1 + L_1 h)\alpha_0 + L_2\}h^2 \quad \text{for all } t \in [0, h), \tag{4.10}$$

with the same L_1, L_2 as above.

Hence, using (4.8)–(4.10), we obtain

$$\sup_{x\in\Gamma_t} \operatorname{dist}(x, \Gamma_t^h) \le \max\left\{\sup_{x\in\Gamma_t} \operatorname{dist}(x, \overline{\Sigma}_t^h), \sup_{x\in\Gamma_t} \operatorname{dist}(x, \underline{\Sigma}_t^h)\right\} \le \{(1 + L_1 h)\alpha_0 + L_2\}h^2$$

for all $t \in (0, h)$.

Since Γ_t also lies between $\underline{\Sigma}_t^h$ and $\overline{\Sigma}_t^h$, by the same argument as above, we get

$$\sup_{x\in\Gamma_t^h} \operatorname{dist}(x, \Gamma_t) \le \max\left\{\sup_{x\in\overline{\Sigma}_t^h} \operatorname{dist}(x, \Gamma_t), \sup_{x\in\underline{\Sigma}_t^h} \operatorname{dist}(x, \Gamma_t)\right\} \le \{(1 + L_1 h)\alpha_0 + L_2\}h^2$$

for all $t \in (0, h)$. Therefore we obtain (4.7).

Step 3. We consider the case $k = 1$. Put $\alpha_1 = (1+L_1 h)\alpha_0 + L_2$ and fix $h \in (0, h_0)$. Then we can see by Proposition 3.1 that $\underline{u}$ and $\overline{u}$ are, respectively, a subsolution and a supersolution of (1.1) in $(h, 2h) \times \mathbb{R}^N$. Since Γ_t^h moves continuously in t in the sense of the Hausdorff distance (cf. Goto, Ishii, and Ogawa [10, Corollary 3.1]), we observe by (4.7) that

$$\Gamma_h^h \subset \{x \in \mathbb{R}^N \mid \underline{d}_1(h, x) \le 0 \le \overline{d}_1(h, x)\}.$$

It is easily seen by (3.12) and this inclusion that $\underline{u}(h,x) \le u(h,x) \le \overline{u}(h,x)$ on $\mathbb{R}^N$, and hence we obtain $\underline{u}(t,x) \le u(t,x) \le \overline{u}(t,x)$ on $[h,2h) \times \mathbb{R}^N$ by the comparison principle for the heat equation. Therefore applying the argument in Step 2, we have

$$d_H(\Gamma_t, \Gamma_t^h) \le \{(1+L_1h)\alpha_1 + L_2\}h^2 \quad \text{for all } t \in [h,2h).$$

Step 4. We select $m \in \mathbb{N}$ satisfying $mh \le T < (m+1)h$ for each $h \in (0,h_0)$ and repeat the arguments in Steps 2–3 inductively. Set

$$\alpha_k = (1+L_1h)\alpha_{k-1} + L_2 \quad \text{for } k = 1,2,\dots,m.$$

Then it follows from Proposition 3.1 that $\underline{u}$ and $\overline{u}$ are, respectively, a subsolution and a supersolution of (1.1) in $(kh,(k+1)h) \times \mathbb{R}^N$. Since we can verify from (3.12) that $\underline{u}(kh,x) \le u(kh,x) \le \overline{u}(kh,x)$ on $\mathbb{R}^N$, we have $\underline{u}(t,x) \le u(t,x) \le \overline{u}(t,x)$ on $[kh,(k+1)h) \times \mathbb{R}^N$ by the comparison principle for the heat equation. Thus we obtain

$$d_H(\Gamma_t, \Gamma_t^h) \le \{(1+L_1h)\alpha_k + L_2\}h^2 \quad \text{for all } t \in [kh,(k+1)h) \text{ and } k = 0,1,2,\dots,m$$

by an argument similar to Step 2.

Step 5. We estimate the sequence $\{\alpha_k\}_{1\le k\le m}$. Since $\alpha_0 \ge 0$ is arbitrary, we can take $\alpha_0 = 0$. Then we observe from the definition of α_k that

$$\begin{aligned}\alpha_k &= (1+L_1h)\alpha_{k-1} + L_2 = (1+L_1h)^2\alpha_{k-2} + L_2\{1+(1+L_1h)\}\\ &= \cdots\\ &= L_2\sum_{l=1}^{k}(1+L_1h)^{l-1} \le L_2\frac{(1+L_1h)^m - 1}{L_1h}.\end{aligned}$$

By the choice of m, we get

$$\alpha_k \le \frac{L_2(e^{L_1T_0}-1)}{L_1h} \le \frac{L_2T_0e^{L_1T_0}}{h} \qquad \text{for } k = 0,1,\dots,m.$$

Thus we obtain

$$\sup_{t\in[0,T]} d_H(\Gamma_t,\Gamma_t^h) \le \left\{(1+L_1)L_2T_0e^{L_1T_0} + L_2\right\}h$$

for all $h \in (0,h_0)$. Therefore the proof is completed. □

5. Optimality. This section is devoted to the optimality for the estimate in Theorem 4.1. For this purpose, we consider a circle evolving by curvature.

Let $C_0 = \{x \in \mathbb{R}^2 \mid |x| \le 1\}$ and fix a time step $h > 0$. Let u^h be the radially symmetric solution of (4.1). Then we can easily verify that for any $t > 0$, Γ_t^h defined in (4.2) is a circle centered at the origin, and we denote by $R_h(t)$ the radius of Γ_t^h. Put $\phi(t) = \sqrt{1-2t}$ and let $\Gamma_t = \partial B(0,\phi(t))$. Take $\delta \in (0,1/5)$ and set

$$T_{max} = \frac{1}{2},\ T_\delta = \frac{1}{2} - \frac{25\delta^2}{2},\ m = \left[\frac{T_\delta}{h}\right], \tag{5.1}$$

where T_{max} is the extinction time for Γ_t and $[s]$ denotes the Gauss symbol for $s \in \mathbb{R}$. Applying Theorem 4.1, we see that for each $\delta \in (0,1/5)$, there exist $h_2 > 0$ and $M_1 > 0$ such that

$$\sup_{t\in[0,T_\delta]} |R_h(t) - \phi(t)| \le M_1h \quad \text{for all } h \in (0,h_2). \tag{5.2}$$

In the remainder of this section we consider a more precise behavior of R_h as $h \searrow 0$ than (5.2) and show that the estimate of Theorem 4.1 is optimal. Our main result of this section is stated as follows.

THEOREM 5.1. *For each $\delta \in (0, 1/5)$, there exist $h_0 > 0$ and $L > 0$ such that*

$$|R_h(t) - (\phi(t) - t^2\phi_1^0(t))| \le Lt^{5/2} \quad \text{for } t \in [t, h], \tag{5.3}$$

$$|R_h(t) - (\phi(t) - h\varphi(t))| \le Lh^{3/2} \quad \text{for } t \in [h, T_\delta] \tag{5.4}$$

for all $h \in (0, h_0)$. Here $\phi_1^0(t)$, $\varphi(t)$ are given by

$$\phi_1^0(t) = \frac{1}{3(\phi(t))^3}, \qquad \varphi(t) = -\frac{\log\phi(t)}{3\phi(t)}.$$

This theorem shows that Γ_t^h moves faster than Γ_t.

As a corollary of Theorem 5.1, we obtain an estimate of the distance between Γ_t and Γ_t^h.

COROLLARY 5.2. *For each $\delta \in (0, 1/5)$, there exist $h_1 \in (0, h_0)$, $\overline{L} > 0$, and $\underline{L} > 0$ such that*

$$\underline{L}t^2 \le d_H(\Gamma_t, \Gamma_t^h) \le \overline{L}t^2 \quad \text{for } t \in [0, h], \tag{5.5}$$

$$\underline{L}th \le d_H(\Gamma_t, \Gamma_t^h) \le \overline{L}th \quad \text{for } t \in [h, T_\delta] \tag{5.6}$$

for all $h \in (0, h_1)$.

This corollary shows that in the case where $\{\Gamma_t\}_{t\ge 0}$ is a motion of a smooth and compact hypersurface by mean curvature, the linear rate in h is optimal to the convergence of the BMO algorithm.

We prepare some functions which will be used in the following subsections. For $k = 0, 1, 2, \ldots, m$, we define

$$\phi^k(t) = \sqrt{(R_h(kh))^2 - 2t}, \; \phi_1^k(t) = \frac{1}{3(\phi^k(t))^3} \quad \text{for } t \in [0, h]. \tag{5.7}$$

Note that $\phi^0 = \phi$ and $(\phi^k)' = -1/\phi^k$ in $(0, h)$. It is easily seen by (5.2) and these facts that, for any $\delta > 0$, there exists an $h_0 > 0$ such that

$$\frac{1}{3(1+\delta)^3} \le \phi_1^k(t) \le \frac{1}{3\cdot(3\delta)^3}, \qquad \frac{1}{(1+\delta)^5} \le (\phi_1^k)'(t) \le \frac{1}{(3\delta)^5} \tag{5.8}$$

for all $t \in [0, h]$, $k = 0, 1, \ldots, m$, and $h \in (0, h_0)$.

5.1. Short-time asymptotics of . In this subsection, we prove the following theorem suggested by Proposition 2.3.

THEOREM 5.3. *There exist $h_3 > 0$ and $L_1 > 0$ such that*

$$|R_h(t + kh) - (\phi^k(t) - t^2\phi_1^k(t))| \le L_1 t^{5/2}$$

for all $t \in [0, h)$, $k = 0, 1, \ldots, m$, and $h \in (0, h_3)$.

Proof. Set $k = 0$ and $u = u^h$ for simplicity. Define $\widetilde{\phi}(t) = \phi(t) - t^2\phi_1^0(t)$ and $\widetilde{d}(t, r) = \widetilde{\phi}(t) - r$. Let $\underline{u}$ and $\overline{u}$ be defined by (3.18) and (3.19), respectively. Let h_2 be given in Proposition 3.2. Since $\underline{u}(0, r) = \overline{u}(0, r) = u(0, r)$ on $\mathbb{R}^1$ by (3.20), applying Proposition 3.2 and the comparison principle for the heat equation, we get

$$\underline{u}(t, r) \le u(t, r) \le \overline{u}(t, r) \quad \text{in } [0, h) \times \mathbb{R}^1 \tag{5.9}$$

for all $h \in (0, h_2)$. Let $\underline{\phi} = \underline{\phi}(t)$ and $\overline{\phi} = \overline{\phi}(t)$ be the zero of $\underline{u}(t, \cdot)$ and $\overline{u}(t, \cdot)$, respectively. Then it follows from (5.9) and (5.12) that

$$\underline{\phi}(t) \le R_h(t) \le \overline{\phi}(t) \quad \text{for all } t \in [0, h) \text{ and } h \in (0, h_2) \tag{5.10}$$

for all $h \in (0, h_2)$.

We estimate $\underline{\phi}$ and $\overline{\phi}$. At first, it is easily seen by (3.22) that there exists an $h_3 \in (0, \delta^2/4 \wedge h_2)$ such that

$$-t^2 U_4 = \underline{u}(t, \widetilde{\phi}(t)) < 0 = \underline{u}(t, \underline{\phi}(t)) < \underline{u}(t, \widetilde{\phi}(t) - 2t^2), \tag{5.11}$$

$$\underline{u}_r(t, r) \le -\frac{U_{0,\rho}(1)}{2\sqrt{t}} + Kt \le -\frac{U_{0,\rho}(1)}{4\sqrt{t}} < 0 \tag{5.12}$$

for all $t \in (0, h_3)$ and $r \in \mathbb{R}$ satisfying $|\widetilde{d}(t, r)| \le 2\sqrt{t} (\le \delta)$. Here we have used (3.22) to derive these estimates. Thus we can observe from (5.11) and (5.12) that

$$\widetilde{\phi}(t) - Kt^{5/2} \le \underline{\phi}(t) \le \widetilde{\phi}(t) \quad \text{for all } t \in (0, h) \text{ and } h \in (0, h_3). \tag{5.13}$$

We can also show similarly that

$$\widetilde{\phi}(t) \le \overline{\phi}(t) \le \widetilde{\phi}(t) + Kt^{5/2} \quad \text{for all } t \in (0, h) \text{ and } h \in (0, h_3). \tag{5.14}$$

Combining (5.13), (5.14) with (5.10) and setting $L_1 = K$, we obtain the result for $k = 0$.

In the case $k \ge 1$, let η be defined by (3.7) and set

$$\widetilde{d}^k(t, r) = \phi^k(t) - t^2 \phi_1^k(t) - r, \qquad z^k(t, r) = \eta(\widetilde{d}^k(t, r)).$$

We define $\underline{u}^k$ and $\overline{u}^k$ by (3.18)–(3.20) with replacing $\widetilde{d}$, z with $\widetilde{d}^k$, z^k, respectively. Then we can check that Proposition 3.2 holds for these $\underline{u}^k$ and $\overline{u}^k$ for any $h \in (0, h_2)$ and small $h_2 > 0$. Since we can easily verify that the choices of h_2 and h_3 depend only on $\delta \in (0, 1/5)$, we can apply the above argument to obtain the result. ◻

5.2. Derivation of a corrector for . In this subsection we formally calculate $R_h(t) - \phi(t)$ and find a corrector for $R_h(t)$ on each time interval $[kh, (k+1)h)$ $(k \in \mathbb{N} \cup \{0\})$. By Theorem 5.3, we see that

$$|R_h(\bar{t}) - (\phi(\bar{t}) - \bar{t}^2 \phi_1^0(\bar{t}))| \le L_1 \bar{t}^{5/2} \qquad \text{for all } \bar{t} \in [0, h] \text{ and } h \in (0, h_3). \tag{5.15}$$

Next we compute $R_h(\bar{t} + h) - \phi(\bar{t} + h)$ for $\bar{t} \in [0, h]$. Theorem 5.3 yields that $|R_h(\bar{t} + h) - (\phi^1(\bar{t}) - \bar{t}^2 \phi_1^1(\bar{t}))| \le L_1 \bar{t}^{5/2}$ for all $\bar{t} \in [0, h_3]$. From (5.15) and this estimate, we have

$$\begin{aligned} R_h(\bar{t} + h) - \phi(\bar{t} + h) &\ge \phi^1(\bar{t}) - \bar{t}^2 \phi_1^1(\bar{t}) - \phi(\bar{t} + h) - L_1 \bar{t}^{5/2} \\ &= \sqrt{(R_h(h))^2 - 2\bar{t}} - \sqrt{1 - 2(\bar{t} + h)} - \bar{t}^2 \phi_1^1(\bar{t}) + L_1 \bar{t}^{5/2} \\ &\ge \sqrt{(\phi(h) - h^2 \phi_1^0(h) - L_1 h^{5/2})^2 - 2\bar{t}} - \sqrt{(\phi(h))^2 - 2\bar{t}} - \bar{t}^2 \phi_1^1(\bar{t}) - L_1 \bar{t}^{5/2} \\ &=: I_1 - I_2 - \bar{t}^2 \phi_1^1(\bar{t}) - L_1 \bar{t}^{5/2}. \end{aligned} \tag{5.16}$$

We observe by Taylor expansion to I_1 and I_2 around $\bar{t} = 0$ that

$$
(5.17)\quad \begin{aligned} I_1 - I_2 = &-h^2\phi_1^0(h) - L_1h^{5/2} - \frac{(h^2\phi_1^0(h) + L_1h^{5/2})\bar{t}}{\phi(h)(\phi(h) - h^2\phi_1^0(h) - L_1h^{5/2})} \\ &- \int_0^{\bar{t}} \left(\frac{(\bar{t}-s)}{\{(\phi(h) - h^2\phi_1^0(h) - L_1h^{5/2})^2 - 2s\}^{3/2}} - \frac{(\bar{t}-s)}{\{(\phi(h))^2 - 2s\}^{3/2}} \right) ds. \end{aligned}
$$

It follows from

$$
(5.18)\qquad \left(\frac{1}{1-r}\right)^3 \le 1 + 8r \quad \text{for all } |r| \ll 1
$$

that

$$
\begin{aligned} &\frac{1}{\{(\phi(h) - h^2\phi_1^0(h) - L_1h^{5/2})^2 - 2s\}^{3/2}} \\ &\quad \le \frac{1}{\{(\phi(h))^2 - 2s\}^{3/2}} \left(1 + \frac{8(h^2\phi_1^0(h) + L_1h^{5/2})(2\phi(h) - h^2\phi_1^0(h) - L_1h^{5/2})}{(\phi(h))^2 - 2s}\right) \end{aligned}
$$

for any $s \in [0, h]$ and small $h > 0$. By using this inequality, we have

$$
\begin{aligned} I_1 - I_2 \ge &-h^2\phi_1^0(h) - L_1h^{5/2} - \frac{\bar{t}(h^2\phi_1^0(h) + L_1h^{5/2})}{\phi(h)(\phi(h) - h^2\phi_1^0(h) - L_1h^{5/2})} \\ &- \frac{4\bar{t}^2(h^2\phi_1^0(h) + L_1h^{5/2})(2\phi(h) - h^2\phi_1^0(h) - L_1h^{5/2})}{\{(\phi(h))^2 - 2\bar{t}\}^{5/2}}. \end{aligned}
$$

In addition, since we also see by (5.18) that

$$
\frac{1}{\phi(h) - h^2\phi_1^0(h) - L_1h^{5/2}} \le \frac{1}{\phi(h)}\left(1 + \frac{8(h^2\phi_1^0(h) + L_1h^{5/2})}{\phi(h)}\right)
$$

for any small $h > 0$, noting that $h^2\phi_1^0(h) + L_1h^{5/2} > 0$ and $(\phi(h))^2 - 2\bar{t} \ge (\phi(2h))^2$ on $[0, h]$, we get

$$
(5.19)\quad \begin{aligned} I_1 - I_2 \ge &-h^2\phi_1^0(h) - L_1h^{5/2} \\ &- \bar{t}h^2\left\{\left(\frac{1}{(\phi(h))^2} + \frac{8h\phi(h)}{(\phi(2h))^5}\right)\phi_1^0(h) + \frac{8h^2(\phi_1^0(h))^2}{(\phi(h))^3}\right\} \\ &- \bar{t}\left\{\left(\frac{1}{(\phi(h))^2} + \frac{8h\phi(h)}{(\phi(2h))^5} + \frac{16h^2\phi_1^0(h)}{(\phi(h))^3}\right)L_1h^{5/2} + \frac{8(L_1h^{5/2})^2}{(\phi(h))^3}\right\}. \end{aligned}
$$

Setting

$$
\begin{aligned} \phi_1^1 &= \left(\frac{1}{(\phi(h))^2} + \frac{8h\phi(h)}{(\phi(2h))^5}\right)\phi_1^0(h) + \frac{8h^2(\phi_1^0(h))^2}{(\phi(h))^3}, \\ \mathcal{L}^1 &= \left(\frac{1}{(\phi(h))^2} + \frac{8h\phi(h)}{(\phi(2h))^5} + \frac{16h^2\phi_1^0(h)}{(\phi(h))^3}\right)L_1h^{5/2} + \frac{8(L_1h^{5/2})^2}{(\phi(h))^3}, \end{aligned}
$$

we obtain

$$
R_h(\bar{t} + h) - \phi(\bar{t} + h) \ge -h^2\phi_1^0(h) - \bar{t}^2\phi_1^1(\bar{t}) - \bar{t}h^2\phi_2^1 - L_1h^{5/2} - L_1\bar{t}^{5/2} - \mathcal{L}^1\bar{t}
$$

for all $\bar{t} \in [0, h]$ and small $h > 0$.

To consider the case $k = 2, 3, \ldots, m$, we define

$$\psi^k = \psi_1^k + h\psi_2^k,\ \psi_1^k = \sum_{l=0}^{k} \phi_1^l(h),\ \psi_2^k = \sum_{l=0}^{k} \phi_2^l,\ L_2^k = h\sum_{l=0}^{k} \mathcal{L}^l \tag{5.20}$$

$$(\phi_2^0 = 0, \mathcal{L}^0 = 0),$$

$$\phi_2^l = \left(\frac{1}{(\phi(lh))^2} + \frac{8h\phi(lh)}{(\phi((l+1)h))^5}\right)\psi^{l-1} + \frac{8h^2(\psi^{l-1})^2}{(\phi(lh))^3}, \tag{5.21}$$

$$\begin{aligned}\mathcal{L}^l = {}& \left(\frac{1}{(\phi(lh))^2} + \frac{8h\phi(lh)}{(\phi((l+1)h))^5} + \frac{16h^2\psi^{l-1}}{(\phi(lh))^3}\right)(L_1 lh^{5/2} + L_2^{l-1}) \\ & + \frac{8(L_1 lh^{5/2} + L_2^{l-1})^2}{(\phi(lh))^3}.\end{aligned} \tag{5.22}$$

Assume that for $k \geq 2$,

$$\begin{aligned}& R_h(\bar{t} + (k-1)h) - (\phi(\bar{t} + (k-1)h) \\ & \quad \geq -h^2\psi^{k-2} - \bar{t}^2\phi_1^{k-1}(\bar{t}) - \bar{t}h^2\phi_2^{k-1} - L_1(k-1)h^{5/2} - L_1\bar{t}^{5/2} - L_2^{k-2} - \mathcal{L}^{k-1}\bar{t}\end{aligned}$$

for all $\bar{t} \in [0, h]$. Since by Theorem 5.3 we have $|R_h(\bar{t}+kh) - (\phi^k(\bar{t}) - \bar{t}^2\phi_1^k(\bar{t}))| \leq L_1\bar{t}^{5/2}$ for all $\bar{t} \in [0, h_2]$, similar calculations to (5.16) yield

$$\begin{aligned}& R_h(\bar{t} + kh) - \phi(\bar{t} + kh) \\ & \geq \sqrt{(\phi(kh) - h^2\psi^{k-1} - L_1kh^{5/2} - L_2^{k-1})^2 - 2\bar{t}} - \sqrt{(\phi(kh))^2 - 2\bar{t}} - \bar{t}^2\phi_1^k(\bar{t}) - L_1\bar{t}^{5/2} \\ & =: I_4 - \bar{t}^2\phi_1^k(\bar{t}) - L_1\bar{t}^{5/2}.\end{aligned}$$

Replacing $h^2\phi_1^0(h)$ and $L_1h^{5/2}$ with, respectively, $h^2\psi^{k-1}$ and $L_1kh^{5/2} + L_2^{k-1}$ in the case $k = 1$, we get

$$I_4 \geq -h^2\psi^{k-1} - \bar{t}^2\phi_1^k(\bar{t}) - \bar{t}h^2\phi_2^k - L_1kh^{5/2} - L_1\bar{t}^{5/2} - L_2^{k-1} - \mathcal{L}^k\bar{t}.$$

Thus we have

$$\begin{aligned}R_h(\bar{t} + kh) - \phi(\bar{t} + kh) \geq {}& -h^2\psi^{k-1} - \bar{t}^2\phi_1^k(\bar{t}) - \bar{t}h^2\phi_2^k \\ & - kL_1h^{5/2} - L_1\bar{t}^{5/2} - L_2^{k-1} - \mathcal{L}^k\bar{t}\end{aligned}$$

for all $\bar{t} \in [0, h]$ and small $h > 0$.

Similarly, we can observe that

$$\begin{aligned}R_h(\bar{t} + kh) - \phi(\bar{t} + kh) \leq {}& -h^2\psi^{k-1} - \bar{t}^2\phi_1^k(\bar{t}) - \bar{t}h^2\phi_2^k \\ & + L_1kh^{5/2} + L_1\bar{t}^{5/2} + L_2^k + \mathcal{L}^k\bar{t}\end{aligned}$$

for all $\bar{t} \in [0, h]$, $k \in \mathbb{N} \cup \{0\}$ and small $h > 0$. Therefore we obtain

$$\begin{aligned}& |R_h(\bar{t} + kh) - \{\phi(\bar{t} + kh) - (h^2\psi^{k-1} + \bar{t}^2\phi_1^k(\bar{t}) + \bar{t}h^2\phi_2^k)\}| \\ & \quad \leq L_1kh^{5/2} + L_1\bar{t}^{5/2} + L_2^k + \mathcal{L}^k\bar{t}\end{aligned} \tag{5.23}$$

for all $t \in [0, h]$, $k \in \mathbb{N} \cup \{0\}$ and small $h > 0$. This inequality shows that the term $h^2\psi^{k-1} + \bar{t}^2\phi_1^k(\bar{t}) + \bar{t}h^2\phi_2^k$ is a (formal) corrector for $R_h(t)$.

5.3. Proofs of Theorem 5.1 and Corollary 5.2. This subsection is devoted to the estimates and the limits of ψ_1^k, ψ_2^k, L_2^k, and $\mathcal{L}^k$ and the proofs of Theorem 5.1 and Corollary 5.2. Remember that we have taken $\delta \in (0, 1/5)$ and set T_{max}, T_δ, and m as in (5.1).

PROPOSITION 5.4. *Let $\varphi_1(t) = (1/\phi(t) - 1)/3$. Then there exist $h_3 > 0$ and $M_3 > 0$ such that*

$$\sup_{t\in[0,T_\delta]} |\varphi_1(t) - h\psi_1^{[t/h]}| \leq M_3 h \quad \text{for all } h \in (0, h_3).$$

Proof. We remark that $\varphi_1(t) = \frac{1}{3}\int_0^t \frac{1}{(\phi(s))^3} ds$. Set $k = [t/h]$. It is easily seen by the definition of ϕ_1^k in (5.20) and $kh \leq T_{max}$ that

$$|\varphi_1(t) - h\psi_1^{[t/h]}| \leq \frac{1}{3}\left|\int_0^{kh} \frac{1}{(\phi(s))^3} ds - h\sum_{l=0}^{k} \frac{1}{(\phi(lh))^3}\right| + \frac{h}{3(\phi(T_\delta))^3}$$
$$+ \frac{T_{max}}{3} \max_{0\leq l\leq k} \left|\frac{1}{(\phi(lh))^3} - \frac{1}{\{(R_h(lh))^2 - 2h\}^{3/2}}\right|.$$

Since $1/(\phi(t))^3$ is increasing in t, we easily observe that

$$\left|\int_0^{kh} \frac{1}{(\phi(s))^3} ds - h\sum_{l=0}^{k} \frac{1}{(\phi(lh))^3}\right| \leq \left(\frac{1}{(\phi(T_\delta))^3} - \frac{1}{(\phi(0))^3}\right) h.$$

Combining (5.2) with this inequality, we have the result. $\square$

We obtain the estimates for ψ_2^k by the following lemma.

LEMMA 5.5. *There exist $h_4 > 0$, $M_4 > 0$, and $M_5 > 0$ such that*

$$M_4(kh)^2 \leq h^2\psi_2^k \leq M_5$$

for $k = 0, 1, \ldots, m$ and $h \in (0, h_4)$.

Proof. The definition of ψ_1^k in (5.20) yields that

$$0 < \psi_1^1 \leq \cdots \leq \psi_1^m. \tag{5.24}$$

Besides we easily see that

$$\alpha := \sup_{0\leq l\leq m, h>0} \max\left\{\frac{1}{(\phi(lh))^2}, \frac{8\phi(lh)}{(\phi((l+1)h))^5}, \frac{8}{(\phi(lh))^3}\right\} < +\infty.$$

Thus, for $l = 1, 2, \ldots, m$, ϕ_2^l satisfies

$$\phi_2^l \leq \alpha\{(1+h)\psi^{l-1} + h^2(\psi^{l-1})^2\}. \tag{5.25}$$

We estimate ϕ_2^l by using (5.21) and this inequality.

First, for sufficiently small $h > 0$ we get $\psi_2^0(h) = \phi_2^0(h) \leq 1$ and

$$\phi_2^1 \leq \alpha(2 + h).$$

Fix $k = 2, 3, \ldots, m$ and let $l = 2, 3, \ldots, k$. From the fact $m = [T_\delta/h]$ we remark that

$$(1 + \alpha h(2+h))^l \leq (1 + \alpha h(2+h))^m \leq e^{3\alpha T_{max}} \tag{5.26}$$

for $l = 2, 3, \dots, m$ and $h \in (0,1)$. Taking (5.24) and this estimate into account, we choose $h_4 \in (0,1)$ such that for any $h \in (0, h_4)$,

$$h(\psi_1^m + h\psi_1^1) \le M_{5,1},\ M_{5,1}h \le M_{5,1}e^{3\alpha T_{max}}h \le 1, \tag{5.27}$$

where $M_{5,1} = \varphi_1(T_\delta) + 1$.

It follows from (5.21) with $l = 2$ and (5.25) that

$$\phi_2^2 \le \alpha\{(1+h)(\psi_1^1 + h\psi_2^1) + h^2(\psi_1^1 + h\psi_2^1)^2\}.$$

We easily see by (5.27) that $h^2(\psi_1^1 + h\psi_2^1) \le M_{5,1}h \le 1$. Thus we get

$$\phi_2^2 \le \alpha(2+h)(\psi_1^1 + h\psi_2^1). \tag{5.28}$$

In the case of $l = 3$, since $\psi^2 = \psi_1^2 + h\psi_2^1 + h\phi_2^2$, we see by (5.24), (5.25), and (5.28) that

$$\phi_2^3 \le \alpha[(1+h)(1+\alpha h(2+h))(\psi_1^2 + h\psi_2^1) + h^2\{(1+\alpha h(2+h))(\psi_1^2 + h\psi_2^1)\}^2].$$

Using (5.26) and (5.27), we get

$$h^2(1+\alpha h(2+h))(\psi_1^2 + h\psi_2^1) \le M_{5,1}e^{3\alpha T_{max}}h \le 1.$$

Therefore we have

$$\phi_2^3 \le \alpha(2+h)(1+\alpha h(2+h))(\psi_1^2 + h\psi_2^1). \tag{5.29}$$

As to the case of $l = 4$, note that $\psi^3 = \psi_1^3 + h\psi_2^1 + h(\phi_2^2 + \phi_2^3)$. Hence it is observed by (5.25)–(5.29) and a similar argument that

$$\phi_2^4 \le \alpha(2+h)(1+\alpha h(2+h))^2(\psi_1^3 + h\psi_2^1).$$

By repeating this procedure, we can show that

$$\phi_2^l \le \alpha(2+h)(1+\alpha h(2+h))^{l-2}(\psi_1^{l-1} + h\psi_2^1) \quad \text{for } l = 4, \dots, k.$$

Summing up $l = 0$ to $l = k$ and using (5.27), we get

$$h^2\psi_2^k = h^2\sum_{l=0}^{k}\phi_2^l \le 3\alpha(1 + M_{5,1}e^{3\alpha T_{max}}) \quad \text{for } h \in (0, h_4).$$

Setting $M_5 = 3\alpha(1 + M_{5,1}e^{3\alpha T_{max}})$, we have an upper bound for $h^2\psi_2^k$.

As for a lower bound for $h^2\psi_2^k$, we observe from the definition of ϕ_2^l in (5.21) and (5.8) that

$$\phi_2^l \ge \frac{\psi^l}{(\phi(lh))^2} \ge \frac{l\phi_1^0(0)}{(\phi(0))^2} \ge \frac{l}{3(1+\delta)^3}.$$

Thus, putting $M_4 = 1/6(1+\delta)^3$, we obtain $h^2\psi_2^k \ge M_4(kh)^2$. $\square$

We use this lemma to prove the following.

PROPOSITION 5.6. *Let $\varphi_2(t) = -\log\phi(t)/3\phi(t) - \varphi_1(t)$. Then there exist $h_5 > 0$ and $M_6 > 0$ such that*

$$\sup_{t\in[0,T_\delta]} |\varphi_2(t) - h^2\psi_2^{[t/h]}| \le M_6 h \quad \text{for all } h \in (0, h_5).$$

Proof. We easily see that φ_2 is a unique solution of

$$\varphi_2(t) = \int_0^t \frac{\varphi_1(s) + \varphi_2(s)}{(\phi(s))^2} ds.$$

For each $t \in [0, T_\delta]$, set $k = [t/h]$. It is easily observed from the definition of ψ_2^k in (5.20) and Lemma 5.5 that

$$\begin{aligned} |\varphi_2(t) - h^2 \psi_2^{[t/h]}| \le\ & (1 + Kh) \left\{ \left| \int_0^t \frac{\varphi_1(s)}{(\phi(s))^2} ds - h \sum_{l=0}^{k} \frac{h\psi_1^l}{(\phi(lh))^2} \right| \right. \\ & \left. + \left| \int_0^t \frac{\varphi_2(s)}{(\phi(s))^2} ds - h \sum_{l=0}^{k} \frac{h^2\psi_2^l}{(\phi(lh))^2} \right| \right\} + Kh \\ =:\ & (1 + Kh)(I_1 + I_2) + Kh. \end{aligned}$$

Since $1/(\phi(t))^2$ (resp., ψ^k) is increasing with respect to t (resp., k), we have

$$\int_{lh}^{(l+1)h} \frac{h\psi_1^{[s/h]}}{(\phi(s))^2} ds \le \frac{h^2 \psi_1^{l+1}}{(\phi((l+1)h))^2}.$$

Using Proposition 5.4 and this inequality, we calculate

$$\begin{aligned} I_1 &= \left| \int_0^{kh} \frac{\varphi_1(s) - h\psi_1^{[s/h]} + h\psi_1^{[s/h]}}{(\phi(s))^2} ds - h \sum_{l=0}^{k} \frac{h\psi_1^l}{(\phi(lh))^2} + \int_{kh}^{t} \frac{\varphi_1(s)}{(\phi(s))^2} ds \right| \\ &\le Kh \int_0^{kh} \frac{ds}{(\phi(s))^2} + h \left| \sum_{l=0}^{k} \frac{h\psi_1^{l+1}}{(\phi((l+1)h))^2} - \sum_{l=0}^{k} \frac{h\psi_1^l}{(\phi(lh))^2} \right| + Kh \\ &\le Kh. \end{aligned}$$

Similarly we can show that

$$I_2 \le \int_0^t \frac{|\varphi_2(s) - h^2\psi_2^{[s/h]}|}{(\phi(s))^2} ds + Kh.$$

Therefore we obtain

$$|\varphi_2(t) - h^2\psi_2^{[t/h]}| \le Kh + (1 + Kh) \int_0^t \frac{|\varphi_2(s) - h^2\psi_2^{[s/h]}|}{(\phi(s))^2} ds.$$

We apply the Gronwall inequality to get

$$|\varphi_2(t) - h^2\psi_2^{[t/h]}| \le Kh \exp\left((1 + Kh) \int_0^{T_\delta} \frac{ds}{(\phi(s))^2} \right)$$

for all $t \in [0, T_\delta]$ and small $h > 0$. Thus we have the result. ◻

Finally we obtain the bounds for $\mathcal{L}^k$ and L_2^k.

PROPOSITION 5.7. *There exist $h_6 > 0$ and $M_7 > 0$ such that*

$$\mathcal{L}^k \le M_7(kh)h^{3/2}, \qquad L_2^k \le M_7(kh)^2 h^{3/2}$$

for all $k = 1, 2, \ldots, m$ and $h \in (0, h_6)$.

Proof. The proof is similar to that of Lemma 5.5.

It follows from (5.2) and Proposition 5.4 that

$$\alpha := \sup_{0\le l\le m, h>0} \max\left\{\frac{1}{(\phi(lh))^2}, \frac{8\phi(lh)}{(\phi((l+1)h)^5}, \frac{16h\psi^l}{(\phi(lh))^3}, \frac{8}{(\phi(lh))^3}\right\} < +\infty.$$

Thus, for $l = 1, 2, \ldots, m$, $\mathcal{L}^l$ satisfies

$$\mathcal{L}^l \le \alpha\{(1+h)(L_1 lh^{5/2} + L_2^{l-1}) + (L_1 lh^{5/2} + L_2^{l-1})^2\}. \tag{5.30}$$

We estimate $\mathcal{L}^l$ by using (5.22) and this inequality.

First, for sufficiently small $h \in (0, 1)$, we have

$$\mathcal{L}^1 \le \alpha(2+h)L_1 h^{5/2} \le M_{7,1}h^{5/2},\ M_{7,1} = 3\alpha L_1.$$

Fix $k = 2, 3, \ldots, m$ and let $l = 2, 3, \ldots, k$. In view of

$$(1 + \alpha h(2+h))^l \le (1 + \alpha h(2+h))^m \le e^{3\alpha T_{max}} \tag{5.31}$$

for $l = 2, 3, \ldots, m$ and $h \in (0, 1)$, we can choose $h_6 \in (0, 1)$ such that for any $h \in (0, h_6)$,

$$e^{3\alpha T_{max}}(T_{max}L_1 + M_{7,1}h)h^{3/2} \le 1. \tag{5.32}$$

It is easily seen from (5.20) that $L_2^1 = h\mathcal{L}^1 \le M_{7,1}h^{7/2}$. Thus we get, by (5.30),

$$\mathcal{L}^2 \le \alpha\{(1+h)(2L_1h^{5/2} + M_{7,1}h^{7/2}) + (2L_1h^{5/2} + M_{7,1}h^{7/2})^2\}. \tag{5.33}$$

We easily observe by (5.32) that $2L_1h^{5/2} + M_{7,1}h^{7/2} \le 1$. Hence we have

$$\mathcal{L}^2 \le \alpha(2+h)(2L_1h^{5/2} + M_{7,1}h^{7/2}) \le 3\alpha(L_1 + M_{7,1}h)(2h)h^{3/2}. \tag{5.34}$$

In the case of $l = 3$, since $L_2^2 = h(\mathcal{L}^1 + \mathcal{L}^2)$, we see by (5.30) that

$$\begin{aligned}\mathcal{L}^3 \le \alpha[&(1+h)(1+\alpha h(2+h))(3L_1h^{5/2} + M_{7,1}h^{7/2})\\ &+\{(1+\alpha h(2+h))(3L_1h^{5/2} + M_{7,1}h^{7/2})\}^2].\end{aligned}$$

Using (5.31) and (5.32), we obtain

$$(1+\alpha h(2+h))(3L_1h^{5/2} + M_{7,1}h^{7/2}) \le e^{3\alpha T_{max}}(T_{max}+1)L_1h^{3/2} \le 1.$$

Thus we get

$$\mathcal{L}^3 \le \alpha(2+h)(1+\alpha h(2+h))(3L_1h^{5/2} + M_{7,1}h^{7/2}) \le 3\alpha e^{3\alpha T_{max}}(L_1 + M_{7,1}h)(3h)h^{3/2}.$$

We repeat the above arguments to obtain

$$\mathcal{L}^l \le \alpha(2+h)(1+\alpha h(2+h))^{l-2}(L_1 lh^{5/2} + M_{7,1}h^{7/2}) \le M_7(lh)h^{3/2} \tag{5.35}$$

for $M_7 = 3\alpha e^{3\alpha T_{max}}(L_1 + M_{7,1})$. From this estimate, we get

$$L_2^k = h\sum_{l=1}^{k} \mathcal{L}^l \le M_7(kh)^2h^{3/2}$$

for all $k = 0, 1, \ldots, m$ and $h \in (0, h_5)$. $\square$

We observe from Propositions 5.4–5.7 that

$$0 \le h^2\psi^{k-1} + \bar{t}^2\phi_1^k(\bar{t}) + \bar{t}h^2\phi_2^k \le Kh,\ 0 \le L_1kh^{5/2} + L_1\bar{t}^{5/2} + L_2^k + \mathcal{L}^k\bar{t} \le Kh^{3/2}$$

for all $\bar{t} \in [0, h)$, $k = 0, 1, \ldots, m$. Thus (5.23) rigorously holds for sufficiently small $h > 0$.

Proof of Theorem 5.1. In the case $k = 0$, (5.3) is obtained by Theorem 5.3. Thus we assume $k \ge 1$ and prove (5.4).

Noting that $\varphi = \varphi_1 + \varphi_2$, in view of Propositions 5.4–5.7, we can find an $h_0 > 0$ so small that

$$|R_h(t) - (\phi(t) - h\varphi(t))| \le Kh^2 + Kh^{3/2} \le Lh^{3/2} \tag{5.36}$$

for some large $L > 0$ and all $t \in [0, T_\delta]$ and $h \in (0, h_0)$. ☐

Proof of Corollary 5.2. In the case $k = 0$, we have (5.5) by (5.3). Thus we may assume $k \ge 1$ and $kh \le t < (k+1)h$. Let $h_0 > 0$ be given in Theorem 5.1.

Using (5.8), (5.23), Lemma 5.5, and Proposition 5.7, we have

$$\begin{aligned} R_h(t) - \phi(t) &\le -kKh^2 - M_4(kh)^2h - K(t-kh)^2 \\ &\qquad + kL_1h^{5/2} + L_1(t-kh)^{5/2} + M_7(kh)^2h^{3/2} + M_7(t-kh)(kh)h^{3/2} \\ &\le -(K - L_1h^{1/2})(kh^2 + (t-kh)^2) - (M_4 - 2M_7h^{1/2})(kh)^2h \\ &\le -(K - L_1h^{1/2})(kh^2 + (t-kh)^2) \end{aligned}$$

for any $h \in (0, h_0)$ satisfying $M_4 \ge 2M_7h^{1/2}$. Take $h_1 \in (0, h_0)$ such that $2M_7h^{1/2} \le M_4$ and $Lh^{1/2} \le K/2$. Since we get, from $kh \ge t - h$,

$$kh^2 + (t-kh)^2 \ge \frac{1}{2}kh^2 + \frac{1}{2}kh^2 \ge \frac{1}{2}(t-h)h + \frac{1}{2}kh^2 \ge \frac{1}{2}th,$$

setting $\underline{L} = K/4$, we obtain

$$R_h(t) - \phi(t) \le -\underline{L}th.$$

Similarly we can show that

$$R_h(t) - \phi(t) \ge -\overline{L}th \quad \text{for all } t \in [h, T_\delta] \text{ and } h \in (0, h_1)$$

for some $\overline{L} > 0$. From these two estimates, we have (5.6). ☐

6. Appendix. We give the proof of Lemma 2.2.

Proof of Lemma 2.2. Put $\widetilde{r} = vt$. Then it follows from Evans [5, Theorem 4.1] that $|v - (N-1)/R| \le Kt^{1/2}$ for any small $t > 0$. Hence we estimate v as $t \searrow 0$ more precisely. In the following we always assume that $t > 0$ is sufficiently small.

To simplify our consideration, we treat the following problem instead of (2.1):

$$\begin{cases} u_t - \Delta u = 0 & \text{in } (0, +\infty) \times \mathbb{R}^N, \\ u(0, x) = \begin{cases} 1, & x \in \overline{B(z_0, R)}, \\ 0, & x \in \mathbb{R}^N \setminus \overline{B(z_0, R)}, \end{cases} \end{cases} \tag{6.1}$$

where $z_0 = (0, \ldots, 0, R) \in \mathbb{R}^N$. We note that, in this setting, $C_t^h = \{x \in \mathbb{R}^N \mid u(t, x) \ge 1/2\}$. Then the solution u of (6.1) can be represented as

$$u(t, x) = \frac{1}{(4\pi t)^{N/2}} \int_{B(z_0, R)} e^{-|y-x|^2/4t} dy.$$

Set $x_0 = (0, \ldots, 0, vt)$ with $v \geq 0$ and assume that $u(t, x_0) = 1/2$. Then

$$\frac{1}{2} = \frac{1}{(4\pi t)^{N/2}} \int_{\overline{B(z_0,R)}} e^{-(|y'|^2+|y_N-vt|^2)/4t} dy.$$

Since the lower hemisphere of $\partial B(z_0, R)$ can be written as

$$y_N = R - \sqrt{R^2 - |y'|^2} \quad (y = (y', y_N) \in \partial B(z_0, R),\ y' \in \overline{B'(0,R)}),$$

where $B'(0,R) = \{x' \in \mathbb{R}^{N-1} \mid |x'| < R\}$, we observe that

$$\frac{1}{2} = \frac{1}{(4\pi t)^{N/2}} \int_{\overline{B'(0,R)}} e^{-|y'|^2/4t} \int_{\overline{R-\sqrt{R^2-|y'|^2}}}^{+\infty} e^{-|y_N-vt|^2/4t} dy_N dy' + O(e^{-K/t}).$$

Changing the variable by setting $z' = y'/2\sqrt{t}$, $z_N = (y_N - vt)/2\sqrt{t}$, we compute that

$$\frac{1}{2} = \frac{1}{\pi^{N/2}} \int_{\overline{B'(0,R/2\sqrt{t})}} e^{-|z'|^2} \left\{ \int_0^{+\infty} - \int_0^{\sqrt{t}(g(t,z')-v/2)} \right\} e^{-|z_N|^2} dz_N dz' + O(e^{-K/t}).$$

Here $g(t, z')$ is defined by

$$g(t,z') = \frac{1}{2t}(R - \sqrt{R^2 - 4t|z'|^2}) = \frac{|z'|^2}{R} + \frac{t|z'|^4}{R^3} + O\left(\frac{t^2|z'|^6}{R^5}\right). \tag{6.2}$$

Since

$$\frac{1}{\pi^{N/2}} \int_{\overline{B'(0,R/2\sqrt{t})}} e^{-|z'|^2} \int_0^{+\infty} e^{-|z_N|^2} dz_N dz' = \frac{1}{2} - O(e^{-K/t}),$$

we deduce that

$$\frac{1}{\pi^{N/2}} \int_{\overline{B'(0,R/2\sqrt{t})}} e^{-|z'|^2} \int_0^{\sqrt{t}(g(t,z')-v/2)} e^{-|z_N|^2} dz_N dz' = O(e^{-K/t}).$$

Using Taylor expansion to the function $\int_0^s e^{-|z_N|^2} dz_N$ around $s = 0$, we can observe that

$$\frac{1}{\pi^{N/2}} \int_{\overline{B'(0,R/2\sqrt{t})}} e^{-|z'|^2} \left\{ (2g(t,z') - v) - \frac{t}{12}(2g(t,z') - v)^3 \right\} = O(t^2). \tag{6.3}$$

By the way, lengthy calculations yield that

$$\int_{\overline{B'(0,R/2\sqrt{t})}} e^{-|z'|^2} |z'|^{2k} dz' = \pi^{(N-1)/2} \prod_{l=1}^{k} \frac{N+2l-3}{2} - O(e^{-K/t}). \tag{6.4}$$

We use this estimate to compute the left-hand side of (6.3). Combining (6.2) with (6.4) with $k = 1, 2$, we get

$$\frac{1}{\pi^{(N-1)/2}} \int_{\overline{B'(0,R/2\sqrt{t})}} e^{-|z'|^2} (2g(t,z') - v) dz' = \frac{N-1}{R} + \frac{(N^2-1)t}{2R^3} - v + O(e^{-K/t}).$$

We note that

$$(2g(t,z') - v)^3 = \frac{8|z'|^6}{R^3} - \frac{12v|z'|^4}{R^2} + \frac{6v^2|z'|^2}{R} - v^3 + tP(t, |z'|),$$

where $tP(t,|z'|)$ is the remainder term satisfying

$$\int_{\mathbb{R}^{N-1}} e^{-|z'|^2} P(t,|z'|)dz' = O(1).$$

We use (6.4) with $k = 0, 1, 2, 3$ and this estimate to obtain

$$\begin{aligned} &\frac{t}{12\pi^{(N-1)/2}} \int_{B'(0,R/2\sqrt{t})} e^{-|z'|^2} (2g(t,z') - v)^3 dz' \\ &\quad = \frac{(N+3)(N^2-1)t}{12R^3} - \frac{(N^2-1)t}{4R^2} v + \frac{(N-1)t}{4R} v^2 - \frac{t}{12} v^3 + O(t^2). \end{aligned}$$

Therefore we obtain the following:

$$\frac{N-1}{R} - \frac{(N^2-1)(N-3)t}{12R^3} - v + \frac{(N^2-1)t}{4R^2} v - \frac{(N-1)t}{4R} v^2 + \frac{t}{12} v^3 = O(t^2).$$

Let $G(v)$ be the left-hand side of this estimate. We find a root v^* of $G(v) = 0$ near $v_0 = (N-1)/R$ and consider $v^* - v_0$. We easily see that

$$G(v_0 + s) = \frac{(N-1)(3N-1)t}{6R^3} - \left(1 - \frac{(N-1)t}{2R^2}\right) s + \frac{t}{12} s^3. \tag{6.5}$$

Set

$$v_1 = v_1(t) := \frac{(N-1)(3N-1)t}{6R^3 - 3R(N-1)t}.$$

It is observed by (6.5) that

$$G(v_0 + 2v_1) < 0 < G(v_0 + v_1) \le Kt^4, \qquad -1 \le \frac{dG}{dv}(v_0 + s) \le -\frac{1}{2} \text{ for } s \in [0, 2v_1).$$

Hence there exists a root v^* of $G(v) = 0$ satisfying $0 < v^* - (v_0 + v_1) \le Kt^4$. Thus we conclude that

$$\left| v^* - \left(v_0 + \frac{(N-1)(3N-1)t}{6R^3} \right) \right| \le Kt^2.$$

In the case of $G(v) = O(t^2)$, we can obtain the result of Lemma 2.2 by slightly modifying the above argument. $\square$

IDENTIFICATION OF OPERATORS WITH BANDLIMITED SYMBOLS*

W. KOZEK† AND G. E. PFANDER‡

Abstract. Underspread and overspread operators are Hilbert–Schmidt operators with strictly bandlimited Kohn–Nirenberg symbols. In this paper, we prove a classical conjecture concerning the necessity of the underspread condition for the identifiability of such operator classes, and, in doing so, we exhibit a new uncertainty principle phenomenon in the time-frequency analysis of operators.

Key words. underspread and overspread operators, Gabor frame operators, bandlimited Kohn–Nirenberg symbol, spreading function

AMS subject classifications. 42C02, 47G02, 81S02

DOI. 10.1137/S0036141003433437

1. Introduction.

Identification of incompletely known linear operators based on the observation of a restricted number of input and corresponding output signals is an important goal in many applied sciences. In *communications engineering*, for instance, identifying the transmission channel can help to adjust signal synthesis at the transmitter and signal analysis at the receiver. This is possible in wired communications, since a linear *time-invariant* system is a convolution operator and—leaving numerical instability of deconvolution aside—is completely determined by its action on a single function.

Underspread and overspread operators on the other hand are *time-varying* Hilbert–Schmidt operators. They act on a space of d-dimensional signals, but the corresponding kernels of time-varying operators are essentially $2d$-dimensional so that a single observation of its action cannot uniquely determine the operator unless one has additional a priori knowledge of the operator class at hand in the form of certain constraints.

Hilbert–Schmidt operators can be represented as a weighted superposition of *translation operators* T_t, $t \in \mathbb{R}$, with $T_t f(x) = f(x-t)$, $x \in \mathbb{R}^d$, and *modulation operators* M_ν, $\nu \in \widehat{\mathbb{R}}$, with $M_\nu f(x) = f(x)e^{2\pi i \nu \cdot x}$, $x \in \mathbb{R}^d$, i.e., as an operator valued integral

$$H = \int\int \eta_H(t,\nu)\, T_t M_\nu \, dt\, d\nu\,. \tag{1.1}$$

Underspread and overspread operators are characterized by the property that the support of their *spreading function* η_H in (1.1) is contained in a rectangular parallelepiped. Such an operator is called *underspread* if the volume of the rectangular parallelepiped does not exceed one, and it is *overspread* otherwise, conditions which are intimately related to uncertainty phenomena in time-frequency analysis. The Kohn–Nirenberg symbol of a Hilbert–Schmidt operator is the symplectic Fourier transformation of the

‡School of Engineering and Science, International University Bremen, 28759 Bremen, Germany (g.pfander@iu-bremen.de).

respective spreading function, and, consequently, it is bandlimited in the case of an underspread or overspread operator.

The identification of underspread and overspread operators is important in various areas of electrical engineering and applied mathematics, including radar/sonar measurements and mobile radio communications, which we now briefly describe.

The principle of *radar/sonar measurements* is to send out a signal modulated onto an electromagnetic/acoustic wave and to deduce information about a (generally) moving target from an echo of the signal [Sko80]. In simple *range-Doppler estimation* the target is modeled as a pure time-frequency shift and distance ("range") and velocity ("Doppler-shift") are estimated. A more precise model of the physical phenomenon is the *doubly spread target model*. Here, the reflection is described as a continuous superposition of time-frequency shifts which arise since the target causes different reflections whose distance and velocity vary over a certain interval of the real-line. Unambiguous identification of the target was realized to depend on the product of the range and Doppler uncertainty, a fact that led to the terminology of underspread and overspread targets [Gre68]. Qualitatively speaking, overspread targets are those where the inherent uncertainty of the model is larger than the amount of information gathered by observing the reflected signal [VT71].

In *mobile radio communication*, the transmitted signal typically undergoes multiple reflections with different time-delay (corresponding to translation operators) and Doppler-shift (corresponding to modulation operators). The action of such channels on the signal can be modeled by underspread and overspread operators [VT71]. In order to obtain reliable communication, it is necessary to gather knowledge about channels by means of observations of transmitted and received signals to identify the channel operator (channel sounding) [MMH$^+$02, MGO03, LKS03].

Starting in the late 1950s, Thomas Kailath analyzed the identifiability of operators with restricted time and frequency spread [Kai59, Kai62, Kai63]. In engineering terms and without detailing a mathematical setup, Kailath proclaimed that a collection of communication channels which are characterized by having common maximum delay a and common maximum Doppler spread b would be identifiable by a single input signal if and only if $ab \leq 1$, i.e., if and only if the operator class is underspread. To prove the necessity of the underspread condition, Kailath provided ingenious arguments based on the comparison of the degrees of freedom of operators (which approximate underspread operators) and degrees of freedom of the output signal. To compare finite dimensions, Kailath used the theoretical construct of a bandlimited input signal with finite duration.

Being aware of the mathematical shortcomings of his approach, and understanding the work of Slepian, Landau, and Pollak on "the dimensions of the space of essentially time- and bandlimited functions" [SP61, LP61, LP62], Kailath conjectured that the underspread condition $ab \leq 1$ is necessary in general [Kai62].

We shall prove Kailath's conjecture in section 3 of this paper using the mathematical framework which is described in section 2. In section 4, we shall describe connections between the critical density in Gabor theory and the *critical spread* $ab = 1$ in the theory of operators with bandlimited symbols. We prove an identification result for Gabor frame operators in section 4.1 and relate this result and Kailath's conjecture to uncertainty principles in time-frequency analysis in section 4.2.

In section 5, we shall extend our identifiability result to higher dimensions and include classes of operators which have restricted but not necessarily rectangular spreading support. These results are based on the representation theory of the re-

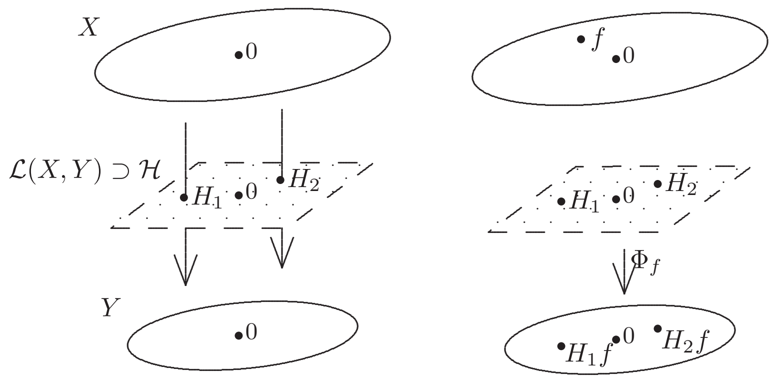

FIG. 2.1. *The goal of operator identification: Find $f \in X$ such that $\Phi_f : \mathcal{H} \longrightarrow Y$ is bounded and stable.*

duced Weyl–Heisenberg group, a fact which indicates close connections of our results to quantum mechanics.

2. Preliminaries. The goal of operator/system identification is to locate, for given normed linear spaces X and Y and a normed linear space of bounded linear operators $\mathcal{H} \subset \mathcal{L}(X, Y)$, an element $f \in X$ which induces a bounded and stable linear map $\Phi_f : \mathcal{H} \longrightarrow Y,\ H \mapsto Hf$ (see Figure 2.1). Consequently, we call $\mathcal{H}$ *identifiable by $f \in X$ if there exist $A, B > 0$ with $A\,\|H\|_{\mathcal{H}} \leq \|Hf\|_Y \leq B\,\|H\|_{\mathcal{H}}$ for all $H \in \mathcal{H}$.*

In sections 2.1 and 2.2, we shall describe the operator spaces $\mathcal{H}$, the domain spaces X, and the target spaces Y that are considered in this paper. In section 2.3, we shall present some techniques from Gabor analysis which will be used in this paper.

2.1. Hilbert–Schmidt operators with bandlimited symbols. We shall use Hilbert–Schmidt operators which act on the Hilbert space $L^2(\mathbb{R}^d)$ of complex valued and square integrable functions as a model of physical time-varying linear systems, as they appear in radar and in mobile communications [FL96, Yoo02, Str05].

A Hilbert–Schmidt operator $H : L^2(\mathbb{R}^d) \longrightarrow L^2(\mathbb{R}^d)$ is given by

$$Hf(x) = \int \kappa_H(x,t) f(t)\, dt = \int \kappa_H(x, x-t) f(x-t)\, dt \quad \text{(a.e.)},$$

with kernel $\kappa_H \in L^2(\mathbb{R}^{2d})$. The space of Hilbert–Schmidt operators $HS(L^2(\mathbb{R}^d))$ is itself a Hilbert space with inner product $\langle H_1, H_2 \rangle_{\mathrm{HS}} = \langle \kappa_{H_1}, \kappa_{H_2} \rangle_{L^2}$ [Die70, Gaa73].

Underspread and overspread operators are Hilbert–Schmidt operators which satisfy two constraints: First, they have restricted delay; i.e., $\kappa_H(x, x-t)$ vanishes for large $|t|$, say, for $|t| > \frac{a}{2} > 0$. Consequently, if f satisfies $\operatorname{supp} f \subseteq [0, T]$, then $\operatorname{supp} Hf \subseteq [-\frac{a}{2}, T+\frac{a}{2}]$. Second, underspread and overspread operators have the property that they are almost time-invariant, i.e., that their characteristics change only slowly over time. A comparison to the time-invariant convolution operators K given by $Kf(x) = \int \kappa_K(t) f(x-t)\, dt$—whose kernel κ_K is independent of the time variable x—leads us to quantify the *slow variance* of an operator H by means of a Paley–Wiener-type support condition on its spreading function which is given by

$$\eta_H(t, \nu) = \int \kappa_H(x, x-t) e^{-2\pi i \nu x}\, dx \quad \text{(a.e.)}.$$

In fact, underspread and overspread operators have the property that $\eta_H(t,\nu)$ vanishes for large $|\nu|$, say, for $|\nu| > \frac{b}{2} > 0$.

Combining the aforementioned time and frequency spread conditions on H leads to the condition

$$\operatorname{supp}\eta_H \subseteq Q_{a,b} = \left[-\frac{a}{2},\frac{a}{2}\right]^d \times \left[-\frac{b}{2},\frac{b}{2}\right]^d \tag{2.1}$$

for some $a,b>0$. An operator which satisfies (2.1) for $a,b>0$ is called underspread if $ab\le 1$ and overspread if $ab>1$.

The spreading function η_H of a Hilbert–Schmidt operator H leads to a representation of H as an operator valued integral by means of (1.1). Here and in the following, operator valued integrals shall be interpreted weakly, i.e., $\int H(z)dzf,\ f\in L^2(\mathbb{R})$, is given by means of

$$\left\langle \int H(z)dzf,\, g\right\rangle_{L^2(\mathbb{R}^d)} = \int \langle H(z)f,g\rangle_{L^2(\mathbb{R}^d)}\,dz \quad \text{for all } g\in L^2(\mathbb{R}^d).$$

Equation (1.1) illustrates that support restrictions on η_H reflect limitations on the maximal time and frequency shifts which the input signals undergo, a fact which emphasizes the usefulness of η_H in the time-frequency analysis of operators.

Note that condition (2.1) on a Hilbert–Schmidt operator H is a band-limitation on its Kohn–Nirenberg symbol σ_H which is given by

$$\sigma_H(x,\xi) = \int \kappa_H(x,x-y)\,e^{-2\pi i y\xi}\,dy = \int\!\!\int \eta_H(t,\nu)e^{2\pi i(x\nu - t\xi)}\,dt\,d\nu \quad \text{(a.e.)} \tag{2.2}$$

[KN65, Fol89].

To prove that a class of Hilbert–Schmidt operators whose spreading functions satisfy (2.1) for fixed $a,b>0$ with $ab\le 1$ is identifiable necessitates the use of *Shah distributions* (also called *combfunctions* or *delta trains*) $⧢_a = \sum_{n\in\mathbb{Z}^d}\delta_{an}$, $a>0$ as identifiers (see section 2.2). Since not all Hilbert–Schmidt operators in $\mathcal{L}(L^2(\mathbb{R}^d),L^2(\mathbb{R}^d))$ can be extended to a space of distributions containing the Shah distribution, we need to restrict ourselves to operators which satisfy a regularity condition on their kernels. Here, we choose Hilbert–Schmidt operators with kernels in the Feichtinger algebra $S_0(\mathbb{R}^{2d})$, a Banach algebra of test functions which is discussed in detail in section 2.2. In fact, if $\kappa_H\in S_0(\mathbb{R}^{2d})$, then the Hilbert–Schmidt operator H extends to $S_0'(\mathbb{R}^d)$ with $⧢_a\in S_0'(\mathbb{R}^d)$ [FZ98]. We set

$$\mathcal{H} = \left\{H\in HS(L^2(\mathbb{R}^d)):\ \kappa_H\in S_0(\mathbb{R}^{2d})\right\}, \tag{2.3}$$

and, as discussed above, we consider operator classes with restricted spreading; i.e., we consider operator classes of the form

$$\mathcal{H}_M = \{H\in\mathcal{H}:\ \operatorname{supp}\,\eta_H\subseteq M\}\,,\quad M\subset\mathbb{R}^d\times\widehat{\mathbb{R}}^d. \tag{2.4}$$

Note that $\mathcal{H}$ and $\mathcal{H}_M$, $M\subset\mathbb{R}^d\times\widehat{\mathbb{R}}^d$, are not closed as linear subspaces of the space of Hilbert–Schmidt operators, and that $\mathcal{H}_M\subseteq\mathcal{H}_{M'}$ if $M\subseteq M'$.

2.2. The Feichtinger algebra. Introduced in [Fei81], Feichtinger's Banach algebra $S_0(\mathbb{R}^d)$ of test functions gained popularity in the growing field of Gabor analysis, which is discussed in section 2.3. The usefulness of $S_0(\mathbb{R}^d)$ stems from the fact that it is the smallest Banach space allowing a meaningful time-frequency analysis, which, as a consequence, extends to its respectively large dual Banach space $S_0'(\mathbb{R}^d)$. In fact, the L^2-Fourier transform, the modulation operators M_ν, $\nu \in \widehat{\mathbb{R}}^d$, and the translation operators T_t, $t \in \mathbb{R}^d$, which are all unitary on the Hilbert space $L^2(\mathbb{R}^d)$, are isometric isomorphisms on the Feichtinger algebra $S_0(\mathbb{R}^d)$ and, therefore, on its dual $S_0'(\mathbb{R}^d)$. The Feichtinger algebra $S_0(\mathbb{R}^d)$ can be continuously embedded in any Banach space with these properties and which contains at least one, and therefore all, nontrivial Schwartz function [FZ98].

Note that we chose to work with the Banach spaces $S_0(\mathbb{R}^d)$ and $S_0'(\mathbb{R}^d)$ rather than with the Fréchet space of Schwartz functions $\mathcal{S}(\mathbb{R}^d) \subset S_0(\mathbb{R}^d)$ and its dual $\mathcal{S}'(\mathbb{R}^d) \supset S_0'(\mathbb{R}^d)$ of tempered distributions for the convenience of expressing continuity (boundedness) and openness (stability) of linear operators by means of norm inequalities. We would like to point out that the results in this paper are consequences of the structure of the identification problem at hand and not of topological subtleties.

There exist various ways of defining $S_0(\mathbb{R}^d)$, and equally many different equivalent norms for $S_0(\mathbb{R}^d)$. Here, we shall give a definition based on the space of Lebesgue measurable and integrable functions $L^1(\mathbb{R}^d)$, the space of Fourier transforms of functions in $L^1(\mathbb{R}^d)$, which is denoted by $A(\mathbb{R}^d)$ and which is equipped with the Banach-space structure of $L^1(\mathbb{R}^d)$ by means of $\|\widehat{f}\|_A = \|f\|_{L^1}$ [Kat76], and the space of absolutely summable sequences $l^1(\mathbb{Z}^d)$.

The *Feichtinger algebra* $S_0(\mathbb{R}^d)$ coincides with the *Wiener amalgam space* $W(A(\mathbb{R}^d), l^1(\mathbb{Z}^d))$. Consequently, we have $f \in S_0(\mathbb{R}^d)$ if and only if f is locally in $A(\mathbb{R}^d)$ with global decay of l^1-type; i.e., given any compactly supported $\psi \in A(\mathbb{R}^d)$ with $\sum_{n\in\mathbb{Z}^d} T_n\psi = 1$ we have $f \in S_0(\mathbb{R}^d)$ if and only if $\sum_{n\in\mathbb{Z}^d} \|f \cdot T_n\psi\|_A < \infty$, and

$$\|f\|_{S_0} = \sum_{n\in\mathbb{Z}^d} \|f \cdot T_n\psi\|_A$$

is a norm on $S_0(\mathbb{R}^d)$. Moreover, $S_0(\mathbb{R}^d)$ is a Banach algebra under convolution and pointwise multiplication.

The dual space $S_0'(\mathbb{R}^d)$ of the Feichtinger algebra satisfies $S_0'(\mathbb{R}^d) = W(A'(\mathbb{R}^d), l^\infty(\mathbb{Z}^d))$ since the class of compactly supported functions in $A(\mathbb{R}^d)$ is dense in $A(\mathbb{R}^d)$ [FG85]. Hence, $S_0'(\mathbb{R}^d)$ contains *Dirac's delta* $\delta : f \mapsto f(0)$ and *Shah distributions* $⧢_a = \sum_{n\in\mathbb{Z}^d} \delta_{an}$, where $\delta_{na} = T_{na}\delta$ and $a > 0$. We set $⧢ = ⧢_1$.

2.3. Gabor analysis. Most techniques applied in this paper originate from Gabor analysis.

Gabor introduced the concept of coherent states to electrical engineering independently of quantum theory [Gab46, Grö01]. Hence, we shall simply call the family

$$(g, a, b) = \{M_{kb}T_{la}g\}_{k,l\in\mathbb{Z}^d}$$

of coherent states a *Gabor system*.

One of the basic results of Gabor analysis is the fact that there exists $g \in L^2(\mathbb{R}^d)$ such that (g, a, b) is an orthonormal basis for $L^2(\mathbb{R}^d)$ if and only if $ab = 1$. For example, the Gabor system $(\mathbf{1}_{[0,a)}, a, b)$ is an orthonormal basis for $L^2(\mathbb{R}^d)$, where $\mathbf{1}_A(x) = 1$ for $x \in A$ and $\mathbf{1}_A(x) = 0$ else.

If $ab > 1$, the system (g, a, b) is not complete. However, if $ab > 1$, then there exists $g \in L^2(\mathbb{R})$ such that the (g, a, b)-synthesis map $D_g : l^2(\mathbb{Z}^2) \longrightarrow L^2(\mathbb{R})$, $\{c_{k,l}\} \mapsto \sum c_{k,l}M_{kb}T_{la}g$ is well-defined, bounded, and stable; i.e., (g, a, b) is a Riesz basis for its closed linear span, $\overline{\mathrm{span}(g,a,b)}$, in $L^2(\mathbb{R}^d)$; hence, there exist $A, B > 0$ such that

$$A\|\{c_{k,l}\}\|_{l^2} \leq \| \sum_{k,l\in\mathbb{Z}^d} c_{k,l} M_{kb} T_{la} g \|_{L^2} \leq B\|\{c_{k,l}\}\|_{l^2} \quad \text{for all } \{c_{k,l}\} \in l^2(\mathbb{Z}^{2d}). \tag{2.5}$$

For $ab < 1$, the system (g,a,b), $g \in L^2(\mathbb{R})$, is overcomplete; i.e., there exists a nontrivial coefficient sequence $\{c_{k,l}\} \in l^2(\mathbb{Z}^{2d}) \setminus \{0\}$ such that $\sum c_{k,l} M_{kb} T_{la} g = 0$ in $L^2(\mathbb{R}^d)$. Nevertheless, for an appropriate choice of g, e.g., g being a Gaussian, the (g,a,b)-analysis operator $C_g = D_g^* : L^2(\mathbb{R}) \longrightarrow l^2(\mathbb{Z}^2)$, $f \mapsto \{\langle f, M_{kb} T_{la} g\rangle\}$ is well-defined, bounded, and stable; i.e., (g,a,b) forms a frame for $L^2(\mathbb{R}^d)$; hence, there exist $A, B > 0$ such that

$$A\|f\|_{L^2}^2 \leq \sum |\langle f, M_{kb} T_{la} g\rangle|^2 \leq B\|f\|_{L^2}^2 \quad \text{for all } f \in L^2(\mathbb{R}^d)\,. \tag{2.6}$$

As a consequence of (2.6), every $f \in L^2(\mathbb{R}^d)$ has a stable representation

$$f = \sum_k \sum_l c_{k,l} M_{kb} T_{la} g \;\text{ in } L^2(\mathbb{R}^d)$$

in terms of the frame (g,a,b), where the coefficients $\{c_{k,l}\} \in l^2(\mathbb{Z}^2)$ can be chosen by means of inner products, i.e., $c_{k,l} = \langle f, M_{kb} T_{la} \gamma\rangle$, where (γ, a, b) is a so-called dual frame of (g,a,b).

More details on time-frequency analysis with some relevance to this paper can be found in [Grö01].

Operator-theoretic applications of Gabor theory as presented in this paper have drawn increasing interest in applied harmonic analysis; see, for example, [Dau88, HRT97, FK98, Koz98, RT98, Lab01, FN03, CG03, Hei03, GLM04].

3. Identification of underspread and overspread operators. We shall first prove Kailath's conjecture for operators acting on functions defined on the real-line, i.e., we choose $d = 1$. The identification problem is given by the operator space $\mathcal{H}_{Q_{a,b}}$, $a, b > 0$, which is defined in (2.3) and (2.4), where $M = Q_{a,b} = [-\frac{a}{2}, \frac{a}{2}]\times[-\frac{b}{2}, \frac{b}{2}]$. The linear space $\mathcal{H}_{Q_{a,b}}$ is equipped with the Hilbert–Schmidt norm and its elements map $X = S_0'(\mathbb{R})$ to $Y = L^2(\mathbb{R})$ [FK98].

The Lebesgue measure $a{\cdot}b$ of the set $Q_{a,b}$ plays a crucial role in determining the identifiability of $\mathcal{H}_{Q_{a,b}}$. The main result of our paper is the following.

THEOREM 3.1. *The set $\mathcal{H}_{Q_{a,b}}$ is identifiable; i.e., there is $f \in S_0'(\mathbb{R})$ such that $\Phi_f : \mathcal{H}_{Q_{a,b}} \longrightarrow L^2(\mathbb{R})$ is bounded and stable, where $\mathcal{H}_{Q_{a,b}}$ is equipped with the Hilbert–Schmidt norm if and only if $ab \leq 1$.*

First, we shall give a proof of the long-understood identifiability of $\mathcal{H}_{Q_{a,b}}$ for $ab \leq 1$.

3.1. Sufficiency of $\quad \leq 1$ for the identifiability of $\mathcal{H}_{\quad a,b}$. Our proof of the sufficiency of the underspread condition is based on the unitarity of the Zak transformations $Z_c : L^2(\mathbb{R}) \longrightarrow L^2(Q_{c,\frac{1}{c}})$, $c > 0$, which are defined by

$$Z_c f(t,\nu) = c^{\frac{1}{2}} \sum_{n\in\mathbb{Z}} f(t - cn) e^{2\pi i c n \nu} \quad \text{(for almost every) } (t,\nu) \in Q_{c,\frac{1}{c}}$$

and the following lemma.

Lemma 3.2. *For $H \in \mathcal{H}$ we have*

$$Z_c \circ H\text{Ш}_c(t,\nu) = c^{-\frac{1}{2}} \sum_{n\in\mathbb{Z}} \sum_{m\in\mathbb{Z}} \eta_H(t - cn, \nu - \tfrac{m}{c}) e^{2\pi i(\nu - \frac{m}{c})t}, \quad (t,\nu) \in Q_{c,\frac{1}{c}}\,.$$

Proof. For $x \in \mathbb{R}$ we have $H\text{Ш}_c(x) = \langle \text{Ш}_c, \kappa_H(x,\cdot)\rangle = \sum_{k\in\mathbb{Z}} \kappa_H(x, ck)$. Using in succession the Tonelli–Fubini theorem, the formula

$$\kappa_H(x,y) = \int \eta_H(x - y, \nu) e^{2\pi i \nu x}\, d\nu, \quad (x,y) \in \mathbb{R}^2,$$

two substitutions, and the Poisson summation formula [Grö01, p. 250], we obtain for $(t,\nu) \in Q_{c,\frac{1}{c}}$ that

$$\begin{aligned} Z_c \circ H\text{Ш}_c(t,\nu) &= c^{\frac{1}{2}} \sum_{l\in\mathbb{Z}} \sum_{k\in\mathbb{Z}} \kappa_H(t - cl, ck) e^{2\pi i cl\nu} \\ &= c^{\frac{1}{2}} \sum_{l\in\mathbb{Z}} \sum_{k\in\mathbb{Z}} \int \eta_H(t - cl - ck, \omega) e^{2\pi i(cl\nu + \omega(t - cl))}\, d\omega \\ &\overset{\substack{\xi=\nu+\omega \\ n=k+l}}{=} c^{\frac{1}{2}} \sum_{n\in\mathbb{Z}} \sum_{m\in\mathbb{Z}} \int \eta_H(t - cn, \xi + \nu) e^{2\pi i(\xi+\nu)t} e^{-2\pi i cl\xi}\, d\xi \\ &= c^{-\frac{1}{2}} \sum_{n\in\mathbb{Z}} \sum_{m\in\mathbb{Z}} \eta_H(t - cn, \nu - \tfrac{m}{c}) e^{2\pi i(\nu - \frac{m}{c})t}. \qquad \square \end{aligned}$$

A standard periodization argument leads to the sufficiency of $ab \leq 1$ for the identifiability of $\mathcal{H}_{Q_{a,b}}$. In fact, the following theorem shows that for $f = \text{Ш}_a \in S_0'(\mathbb{R})$ we have $\Phi_f : \mathcal{H}_{Q_{a,b}} \longrightarrow L^2(\mathbb{R})$, where $\mathcal{H}_{Q_{a,b}}$ is equipped with the Hilbert–Schmidt norm, is bounded, and is stable whenever $ab \leq 1$.

Theorem 3.3. *The operator family $\mathcal{H}_M = \{H \in \mathcal{H} : \ \operatorname{supp} \eta_H \subseteq M\}$ can be identified with the identifier Ш_c if and only if the interior M° of M satisfies*

$$M^\circ \ \cap \bigcup_{(m,n)\in\mathbb{Z}^2\setminus\{(0,0)\}} \Big(M^\circ + (cn, \tfrac{m}{c}) \Big) = \emptyset, \tag{3.1}$$

i.e., if and only if M° is contained in a fundamental domain of the lattice $c\mathbb{Z} \times \frac{1}{c}\mathbb{Z}$. In particular, $\mathcal{H}_{Q_{a,b}}$, $a, b > 0$, is identifiable with Ш_c if and only if $a \leq c$ and $ab \leq 1$.

Note that Theorem 3.3 classifies all sets M with the property that $\mathcal{H}_M$ can be identified using the tempered distribution Ш_c, $c > 0$. No result regarding the necessity of the underspread condition $ab \leq 1$ for the identifiability of $\mathcal{H}_{Q_{a,b}}$ by any other $f \in S_0'(\mathbb{R})$ has been obtained.

Figure 3.1 is a picture proof of Theorem 3.3 for $M = Q_{c,\frac{1}{c}}$, $c > 0$. Details in the case $c = 1$ are given below.

Proof of Theorem 3.3. For ease of notation, we shall only provide a proof of Theorem 3.3 for $c = 1$. The general case follows from Theorem 5.4.

First, we show that if (3.1) holds, then Ш identifies $\mathcal{H}_M$. Set $Q = Q_{1,1}$ and let $A_{m,n} = M^\circ \cap \big(Q + (m,n)\big)$ and $B_{m,n} = A_{m,n} - (m,n) \subseteq Q$. Then $B_{m,n} \cap B_{m',n'} = \emptyset$ for $(m,n) \neq (m',n')$, since else $M^\circ \cap \big(M^\circ + (m - m', n - n')\big) \neq \emptyset$. Further, the spreading function η_H of each $H \in \mathcal{H}_M$ is continuous, and, therefore, $\eta_H(t,\nu) = 0$ for all $(t,\nu) \notin \bigcup_{m,n} A_{m,n}$. We conclude that $\{(t,\nu) \in Q : \ Z \circ H\text{Ш}(t,\nu) \neq 0\} \subseteq$

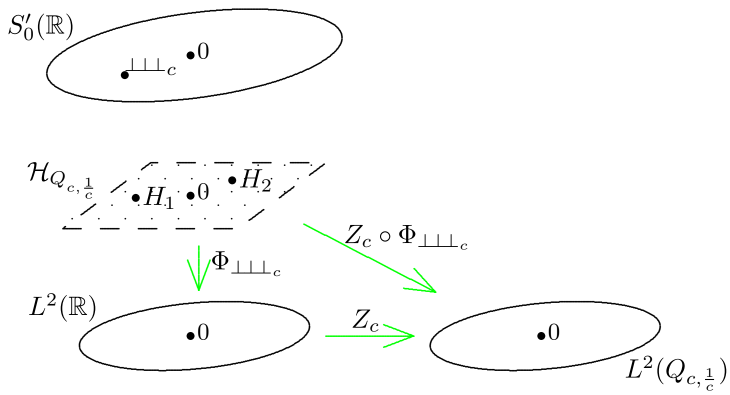

FIG. 3.1. *Sketch of the proof of the identifiability of $\mathcal{H}_{Q_{c,\frac{1}{c}}}$, $c > 0$, using as identifier Ш_c. The Zak transform Z_c is unitary and, therefore, bounded and stable, and $Z_c \circ \Phi_{\text{Ш}_c}$ maps $\mathcal{H}_{Q_{c,\frac{1}{c}}}$ into $L^2(Q_{c,\frac{1}{c}})$ and is bounded and stable as well. We conclude that $\Phi_{\text{Ш}_c}$ is bounded and stable on $\mathcal{H}_{Q_{c,\frac{1}{c}}}$, i.e., Ш_c identifies $\mathcal{H}_{Q_{c,\frac{1}{c}}}$.*

$\bigcup_{m,n} B_{m,n} \subseteq Q$. For $H \in \mathcal{H}_M$ we calculate

$$\begin{aligned}\|H\|_{HS} &= \|\eta_H\|_{L^2(\mathbb{R}\times\widehat{\mathbb{R}})} = \sum_{m,n} \|\eta_H\|_{L^2(A_{m,n})} = \sum_{m,n} \|T_{(-m,-n)}\eta_H\|_{L^2(B_{m,n})} \\ &= \sum_{m,n} \|Z \circ H\text{Ш}\|_{L^2(B_{m,n})} = \|Z \circ H\text{Ш}\|_{L^2(Q)} = \|H\text{Ш}\|_{L^2(\mathbb{R})} \\ &= \|\Phi_{\text{Ш}} H\|_{L^2(\mathbb{R})}\,; \qquad (3.2)\end{aligned}$$

and, by definition, $\mathcal{H}_M$ allows identification with identifier Ш.

Let us now assume that $M^\circ \cap \bigcup_{(m,n)\neq 0} M^\circ{+}(m,n) \neq \emptyset$ and show that $\mathcal{H}_M$ is not identifiable. In this case, there exists $(t_0, \nu_0) \in M^\circ \cap \bigcup_{(m,n)\neq 0} \big(M^\circ{+}(m,n)\big)$, $\frac{1}{2} > \epsilon > 0$, and $(n_0, m_0) \in \mathbb{Z}^{2d}$ with $B_\epsilon(t_0,\nu_0) \subset M^\circ \cap \big(M^\circ{+}(n_0,m_0)\big)$, where $B_\epsilon(t_0,\nu_0) = \{(t,\nu) : \|(t,\nu) - (t_0,\nu_0)\|_\infty < \epsilon\}$. Hence $B_\epsilon(t_0 - n_0, \nu_0 - m_0) \subset M^\circ$. Choose $0 \neq \widetilde{\eta} \in A(\mathbb{R}^{2d}) \subset S_0(\mathbb{R}^{2d})$ with supp $\widetilde{\eta} \subset B_\epsilon(t_0,\nu_0)$, and define $H \in \mathcal{H}_M$ by means of $\eta(t,\nu) = \widetilde{\eta}(t,\nu) - \widetilde{\eta}(t+n_0, \nu+m_0)e^{2\pi i t m_0} \not\equiv 0$, $(t,\nu) \in \mathbb{R}\times\widehat{\mathbb{R}}$. We obtain

$$\begin{aligned}Z\circ H\text{Ш}(t,\nu) &= \sum_{m,n\in\mathbb{Z}} \eta(t{-}n, \nu{-}m)e^{2\pi i(\nu-m)t} \\ &= \sum_{m,n\in\mathbb{Z}} \Big(\widetilde{\eta}(t{-}n, \nu{-}m) - \widetilde{\eta}(t{-}n{+}n_0, \nu{-}m{+}m_0)e^{2\pi i(t-n)m_0}\Big)\, e^{2\pi i(\nu-m)t} \\ &= \Big(\sum_{m,n\in\mathbb{Z}} \widetilde{\eta}(t{-}n, \nu{-}m)e^{2\pi i(\nu-m)t}\Big) \\ &\quad -\Big(\sum_{m,n\in\mathbb{Z}} \widetilde{\eta}(t{+}n_0{-}n, \nu{+}m_0{-}m)e^{2\pi i(t+n_0)m_0}e^{2\pi i(\nu-m)t}\Big) \;=\; 0\,.\end{aligned}$$

The injectivity of the Zak transformation implies $H\text{Ш} = 0$, contradicting the injectivity of $\Phi_{\text{Ш}}$ and therefore the identifiability of $\mathcal{H}_M$ by Ш. ∎

Note that equation (3.2) implies that $\Phi_{\text{Ш}}$, which is a priori defined on $\mathcal{H}_M = \{H \in \mathcal{H} : \text{ supp}\, \eta_H \subseteq M\} \subset \mathcal{H} \subset HS(L^2(\mathbb{R}))$, where M is a fundamental do-

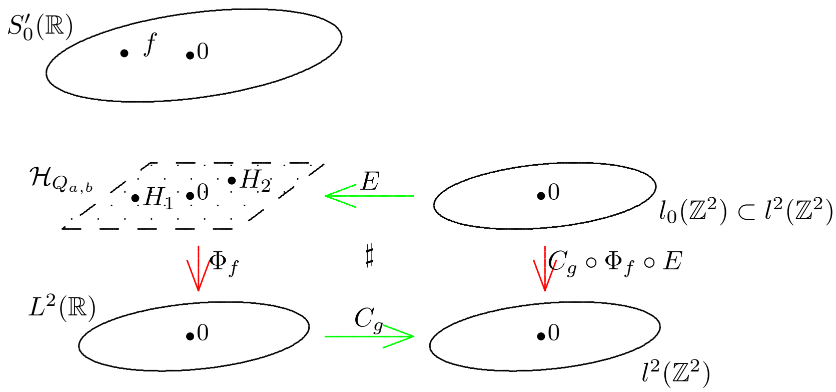

FIG. 3.2. *Sketch of the proof that $\mathcal{H}_{Q_{a,b}}$ is not identifiable if $ab > 1$. We show that for all $f \in S_0'(\mathbb{R})$, the bounded operator $C_g \circ \Phi_f \circ E$ is not stable. The synthesis operator E and the analysis operator C_g are stable, hence, stability of $C_g \circ \Phi_f \circ E$ must fail at Φ_f.*

main of $\mathbb{Z}\times\mathbb{Z}$, can be isometrically extended to its HS-closure $\overline{\mathcal{H}_M} = \{H \in HS(L^2(\mathbb{R})) : \operatorname{supp} \eta_H \subseteq M\}$. Certainly, not all $H \in HS(L^2(\mathbb{R}))$ extend in this fashion to $S_0'(\mathbb{R})$, and, hence, we must continue to focus our attention on operators with kernels in the Feichtinger algebra, i.e., on operator classes contained in $\mathcal{H} = \big\{H \in HS(L^2(\mathbb{R})) : \kappa_H \in S_0(\mathbb{R}^2)\big\}$.

3.2. Necessity of ≤ 1 for the identifiability of $\mathcal{H}_{a,b}$. We shall show that for $ab > 1$ and *every* $f \in S_0'(\mathbb{R})$, the well-defined operator $\Phi_f : \mathcal{H}_{Q_{a,b}} \longrightarrow L^2(\mathbb{R})$ is *not* stable.

To obtain this result, we shall equip $l_0(\mathbb{Z}^2)$ with the topology induced by the l^2-norm and use the fact that $ab > 1$ to construct a bounded and stable synthesis operator $E:\ l_0(\mathbb{Z}^2) \to \mathcal{H}_M$ in Lemma 3.4, and a bounded and stable (g, a', b')-analysis operator $C_g : L^2(\mathbb{R}) \longrightarrow l^2(\mathbb{Z}^2)$ in the proof of Theorem 3.6, with the property that the compositions

$$C_g \circ \Phi_f \circ E:\ l_0(\mathbb{Z}^2) \longrightarrow l^2(\mathbb{Z}^2), \quad f \in S_0'(\mathbb{R}),$$

are not stable. The stability of E and C_g implies that all operators $\Phi_f : \mathcal{H}_{Q_{a,b}} \longrightarrow L^2(\mathbb{R})$, $f \in S_0'(\mathbb{R})$, must not be stable, showing that $\mathcal{H}_{Q_{a,b}}$ is not identifiable for $ab > 1$ (see Figure 3.2).

We shall now construct the aforementioned synthesis operator E. For $ab > 1$, we choose $\lambda \in \mathbb{R}$ with $1 < \lambda^4 < a\,b$. Using a product-convolution operator $P : f \mapsto (f * \eta_1)\,\check{\eta}_2$ as prototype operator, we define the embedding operator E by means of

$$E:\ l_0(\mathbb{Z}^2) \to \mathcal{H}_M, \quad \{\sigma_{k,l}\} \mapsto \sum_{k,l} \sigma_{k,l}\ M_{k\lambda\alpha} T_{l\lambda\beta} P T_{-l\lambda\beta} M_{-k\lambda\alpha}\,,$$

where we chose $\alpha = \frac{1}{a}$ and $\beta = \frac{1}{b}$ for simplicity of notation. The choice of λ allows us to construct $P \in \mathcal{H}_{Q_{a,b}}$ in Lemma 3.4 such that $\{M_{k\lambda\alpha} T_{l\lambda\beta} P T_{-l\lambda\beta} M_{-k\lambda\alpha}\}_{k,l\in\mathbb{Z}}$ is a Riesz basis for its closed linear space in the Hilbert space of Hilbert–Schmidt operators, and, as consequence of (2.5), E is stable. In addition to the Riesz property, P is designed in Lemma 3.4 to satisfy a time-frequency localization property which will play a central role in the proof of our main result.

LEMMA 3.4. *Fix $\lambda > 1$ with $1 < \lambda^4 < a\,b$ and choose $\eta_1, \eta_2 \in \mathcal{S}(\mathbb{R})$ with values in $[0,1]$ and*

$$\eta_1(t) = \begin{cases} 1 & \text{for } |t| \le \frac{a}{2\lambda}, \\ 0 & \text{for } |t| \ge \frac{a}{2} \end{cases} \quad \text{and} \quad \eta_2(\nu) = \begin{cases} 1 & \text{for } |\nu| \le \frac{b}{2\lambda}, \\ 0 & \text{for } |\nu| \ge \frac{b}{2}. \end{cases}$$

The operator $P \in \mathcal{H}_{Q_{a,b}}$ defined by $\eta_P = \eta_1 \otimes \eta_2$ has the following properties:

(a) *The synthesis operator*

$$E: \ l_0(\mathbb{Z}^2) \to \mathcal{H}_M, \quad \{\sigma_{k,l}\} \mapsto \sum_{k,l} \sigma_{k,l}\ M_{k\lambda\alpha} T_{l\lambda\beta} P T_{-l\lambda\beta} M_{-k\lambda\alpha} \tag{3.3}$$

is well-defined, bounded, and stable.

(b) *The operator $P \in \mathcal{H}_M$ is a time-frequency localization operator in the following sense: There exist functions $d_1, d_2 : \mathbb{R} \to \mathbb{R}_0^+$ which decay rapidly at infinity and which have the property that for all $f \in S_0'(\mathbb{R})$ we have $|Pf(x)| \le \|f\|_{S_0'}\, d_1(x)$, $x \in \mathbb{R}$, and $|\widehat{Pf}(\xi)| \le \|f\|_{S_0'}\, d_2(\xi)$, $\xi \in \widehat{\mathbb{R}}$.*

Proof. (a) Observe that for any $(s,\omega) \in \mathbb{R}\times\widehat{\mathbb{R}}$ and $f \in S_0(\mathbb{R})$ we have

$$\begin{aligned} M_\omega T_s P T_{-s} M_{-\omega} f &= \int\!\!\int \eta_P(t,\nu) M_\omega T_s\, T_t M_\nu\, T_{-s} M_{-\omega} f \, dt\, d\nu \\ &= \int\!\!\int \eta_P(t,\nu) e^{2\pi i(\omega t - s\nu)} T_t M_\nu f\, dt\, d\nu. \end{aligned}$$

Hence, for E defined in (3.3) and any $\{\sigma_{k,l}\} \in l_0(\mathbb{Z}^2)$, we have $E\{\sigma_{k,l}\} \in \mathcal{H}_{Q_{a,b}}$ with

$$\eta_{E\{\sigma_{k,l}\}}(t,\nu) = \eta_P(t,\nu) \sum_{k,l\in\mathbb{Z}} \sigma_{k,l}\, e^{2\pi i(k\lambda\alpha t - l\lambda\beta\nu)}, \quad (t,\nu) \in \mathbb{R}\times\widehat{\mathbb{R}}. \tag{3.4}$$

We consider $l_0(\mathbb{Z}^2)$ as a subspace of $l^2(\mathbb{Z}^2)$ and observe that E is stable, since

$$\|E\{\sigma_{k,l}\}\|_{HS} = \|\eta_{E\{\sigma_{k,l}\}}\|_{L^2} \ge \|\eta_{E\{\sigma_{k,l}\}}\, \mathbf{1}_{[-\frac{a}{2\lambda},\frac{a}{2\lambda}]\times[-\frac{b}{2\lambda},\frac{b}{2\lambda}]}\|_{L^2} = \frac{ab}{\lambda^2}\, \|\{\sigma_{k,l}\}\|_{l^2}.$$

The boundedness of E follows from a similar calculation.

(b) For $f \in S_0(\mathbb{R})$ and $x \in \mathbb{R}$ we have

$$\begin{aligned} |Pf(x)| &= \left| \int\!\!\int \eta_P(t,\nu) e^{2\pi i\nu x} f(x-t)\, dt\, d\nu \right| \\ &= \left| \int \eta_2(\nu) e^{2\pi i\nu x}\, d\nu \right| \ \left| \int \eta_1(t) f(x-t)\, dt \right| \\ &\le |\widehat{\eta}_2(-x)|\ \ \|f\|_{S_0'} \|\eta_1\|_{S_0}. \end{aligned} \tag{3.5}$$

The function $d_1(x) = |\widehat{\eta}_2(-x)|\, \|\eta_1\|_{S_0}$ decays rapidly at infinity, i.e., $d_1(x) \to 0$ as $|x| \to \infty$ faster than any power of $\frac{1}{x}$, since $\widehat{\eta}_2 \in \mathcal{S}(\mathbb{R})$. Further, the inequality $|Pf(x)| \le \|f\|_{S_0'}\, d_1(x)$, $x \in \mathbb{R}$, extends to general $f \in S_0'(\mathbb{R})$, since $S_0(\mathbb{R})$ is w*-dense in $S_0'(\mathbb{R})$.

To establish a rapidly decaying bound on $|\widehat{Pf}|$, $f \in S_0'(\mathbb{R}^d)$, we first assume $f \in S_0(\mathbb{R})$ and calculate for $\xi \in \widehat{\mathbb{R}}$

$$\begin{aligned}
|\widehat{Pf}(\xi)| &= \left| \int \widehat{\eta}_2(-x) \int \eta_1(t) f(x-t)\, dt\, e^{-2\pi i \xi x}\, dx \right| \\
&= \left| \int \widehat{\eta}_2(-x) \int \widehat{\eta}_1(\gamma) \widehat{f}(\gamma) e^{-2\pi i x(\xi-\gamma)}\, d\gamma\, dx \right| \\
&= \left| \int \eta_2(\xi-\gamma) \widehat{\eta}_1(\gamma) \widehat{f}(\gamma)\, d\gamma \right| \qquad (3.6) \\
&\leq \|f\|_{S_0'} \|\eta_2(\xi - \cdot) \widehat{\eta}_1(\cdot)\|_{S_0}. \qquad (3.7)
\end{aligned}$$

The application of the theorem of Tonelli and Fubini to obtain (3.6) is valid for $f \in S_0(\mathbb{R})$, and the validity of (3.7) extends once more to general $f \in S_0'(\mathbb{R})$.

We claim that $d_2(\xi) = \|\eta_2(\xi - \cdot)\widehat{\eta}_1(\cdot)\|_{S_0}$ is rapidly decaying. Since the Feichtinger algebra $S_0(\mathbb{R})$ equals the Wiener amalgam space $W(A(\mathbb{R}), l^1(\mathbb{Z}))$, we choose $\widehat{\varphi} \in \mathcal{S}(\mathbb{R}) \subset A(\mathbb{R})$ with supp $\widehat{\varphi} \subseteq [-1,+1]$, and $\sum_{n\in\mathbb{Z}} \mathrm{T}_n \widehat{\varphi} \equiv 1$, and observe that $(\|\widehat{\eta}_1 \cdot \mathrm{T}_n \widehat{\varphi}\,\|_A)_{n\in\mathbb{Z}}$ decays rapidly, i.e., for any $k \in \mathbb{N}$ there exists $C_k > 0$ such that

$$\left\|g \cdot \mathrm{T}_n \widehat{\varphi}\right\|_A = \int \left| \int \eta_1(x) e^{-2\pi i x n} \varphi(t-x)\, dx \right| dt \leq C_k (1+n^2)^{-k/2},\ n \in \mathbb{Z} \qquad (3.8)$$

[Grö01, p. 228]. For $k \in \mathbb{N}$ we choose C_k satisfying (3.8) and calculate

$$\begin{aligned}
d_2(\xi) = \|\eta_2(\xi - \cdot)\widehat{\eta}_1(\cdot)\|_{S_0} &\leq C \sum_{n\in\mathbb{Z}} \|\,\mathrm{T}_n \widehat{\varphi}(\cdot)\ \eta_2(\xi - \cdot)\widehat{\eta}_1(\cdot)\|_A \\
&= C \sum_{\xi-1-\frac{b}{2}<n<\xi+1+\frac{b}{2}} \|\,\mathrm{T}_n \widehat{\varphi}(\cdot)\ \eta_2(\xi - \cdot)\widehat{\eta}_1(\cdot)\|_A \\
&\leq C\, \|\eta_2\|_A \sum_{\xi-1-\frac{b}{2}<n<\xi+1+\frac{b}{2}} \|\,\mathrm{T}_n \widehat{\varphi}(\cdot)\ \widehat{\eta}_1(\cdot)\|_A \\
&\leq C\, C_k\, \|\eta_2\|_A \left\lceil 2+b \right\rceil \left(1 + \min\left\{ \left\lceil \xi - 1 - \frac{b}{2} \right\rceil^2, \left\lfloor \xi + 1 + \frac{b}{2} \right\rfloor^2 \right\} \right)^{-k/2} \\
&\leq \widetilde{C} (1+\xi^2)^{-k/2}. \qquad \square
\end{aligned}$$

Lemma 3.5 is technical but of upmost importance in the proof of Theorem 3.6. It generalizes the fact that $m \times n$ matrices with $m < n$ have a nontrivial kernel and, therefore, are not stable, to operators acting on $l^2(\mathbb{Z}^2)$. In fact, the bi-infinite matrices $M = (m_{j',j})_{j',j\in\mathbb{Z}^2}$ considered in Lemma 3.5 are not dominated by its diagonal $m_{j,j}$—which would correspond to square matrices—but by a skewdiagonal $m_{j,\lambda j}$, with $\lambda > 1$.

LEMMA 3.5. *Given $M = (m_{j',j}) : l^2(\mathbb{Z}^2) \to l^2(\mathbb{Z}^2)$. If there exists a monotonically decreasing function $w : \mathbb{R}_0^+ \to \mathbb{R}_0^+$ with $w(x) = O\left(x^{-2-\delta}\right)$, $\delta > 0$, and constants $\lambda > 1$ and $K_0 > 0$ with $|m_{i,j}| < w(\|\lambda j' - j\|_\infty)$ for $\|\lambda j' - j\|_\infty > K_0$, then M is not stable.*

Proof. First, we show that if $w : \mathbb{R}_0^+ \to \mathbb{R}_0^+$ with $w(x) = O\left(x^{-2-\delta}\right)$ is monotonically decreasing, then

$$\sum_{K\geq 1} K \sum_{k\geq K} k\, w(k)^2 < \infty\,. \qquad (3.9)$$

Inequality (3.9) is proven using the Riemann integral criterium for sums. To this end, we pick continuous $v \in L^\infty(\mathbb{R}^+)$ with $w(x) \leq v(x) x^{-2-\delta}$ and observe that

$$\sum_{K\geq 1} K \sum_{k\geq K} k\, w(k)^2 \leq \int_0^\infty x \int_x^\infty y\, w(y)^2\, dy\, dx \leq \int_0^\infty x \int_x^\infty v(y)^2 y^{-3-2\delta}\, dy\, dx$$
$$\leq \frac{\|v\|_\infty^2}{2+2\delta} \int_0^\infty x^{-1-2\delta}\, dx < \infty\,.$$

Now, we shall use (3.9) to show that $\inf_{x\in l^2(\mathbb{Z}^2)}\{\frac{\|Mx\|_{l^2}}{\|x\|_{l^2}}\} = 0$. To this end, fix $\epsilon > 0$ and pick $K_1 > K_0$ with

$$\sum_{K\geq K_1} K \left(\sum_{k\geq K} k\, w(k)^2 \right) \leq 2^{-6}\epsilon^2\,.$$

Pick $N \in \mathbb{N}$ with $\widetilde{N} := \lceil \frac{N}{\lambda} \rceil + K_1 < N$ and define

$$\widetilde{M} = (m_{j',j})_{\|j'\|_\infty \leq \widetilde{N}, \|j\| \leq N} : \mathbb{C}^{(2N+1)^2} \to \mathbb{C}^{(2\widetilde{N}+1)^2}.$$

The matrix $\widetilde{M}$ has a nontrivial kernel since $(2\widetilde{N}+1)^2 < (2N+1)^2$, so we can choose $\widetilde{x} \in \mathbb{C}^{(2N+1)}$ with $\|\widetilde{x}\|_2 = 1$ and $\widetilde{M}\widetilde{x} = 0$. Define $x \in l^2(\mathbb{Z}^2)$ according to $x_j = \widetilde{x}_j$ if $\|j\|_\infty \leq N$ and $x_j = 0$ otherwise.

By construction we have $\|x\|_{l^2} = 1$, and $(Mx)_{j'} = 0$ for $\|j'\|_\infty \leq \widetilde{N}$.

To estimate $(Mx)_{j'}$ for $\|j'\|_\infty > \widetilde{N}$, we fix $K > K_1$ and $j' \in \mathbb{Z}^d$ with $\|j'\|_\infty = \lceil \frac{N}{\lambda} \rceil + K$. We have $\|\lambda j'\|_\infty \geq N + K\lambda$ and $\|\lambda j' - j\|_\infty \geq K\lambda \geq K$ for all $j \in \mathbb{Z}^d$ with $\|j\|_\infty \leq N$, and, therefore,

$$|(Mx)_j'|^2 = \left| \sum_{\|j\|_\infty \leq N} m_{j',j} x_j \right|^2 \leq \|x\|_2^2 \sum_{\|j\|_\infty \leq N} |m_{j',j}|^2$$
$$\leq \sum_{\|j\|_\infty \leq N} w(\|\lambda j' - j\|_\infty)^2 \leq \sum_{\|j\|_\infty \geq K} w(\|j\|_\infty)^2$$
$$= 2^2 \sum_{k\geq K} 2k\, w(k)^2 = 2^3 \sum_{k\geq K} k\, w(k)^2.$$

Finally, we can compute

$$\|Mx\|_{l^2}^2 = \sum_{j'\in\mathbb{Z}^d} |(Mx)_j'|^2 \quad = \sum_{\|j'\|_\infty \geq \lceil \frac{N}{\lambda} \rceil + K_1} |(Mx)_{j'}|^2$$
$$= \; 2^3 \sum_{\|j'\|_\infty \geq \lceil \frac{N}{\lambda} \rceil + K_1} \sum_{k \geq \|j'\|_\infty} k\, w(k)^2 \leq 2^6 \sum_{K \geq \lceil \frac{N}{\lambda} \rceil + K_1} K \sum_{k\geq K} k\, w(k)^2 \leq \epsilon^2$$

and obtain $\|Mx\|_{l^2} \leq \epsilon$. Since ϵ was chosen arbitrarily and $\|x\|_{l^2} = 1$, we have $\inf_{x\in l^2(\mathbb{Z}^2)}\{\frac{\|Mx\|_{l^2}}{\|x\|_{l^2}}\} = 0$ and M is not stable. $\square$

Now all pieces are in place to state and prove the main contribution of this paper.

THEOREM 3.6. *For $a, b > 0$ with $ab > 1$, $\mathcal{H}_{Q_{a,b}}$ is not identifiable.*

Proof. Fix $a, b > 0$ with $ab > 1$ and choose λ, η_1, η_2, P, and E as in Lemma 3.4.

To construct the aforementioned stable (g, a', b')-analysis operator C_g, we choose as Gabor atom the Gaussian $g_0 : \mathbb{R} \to \mathbb{R}^+, \quad x \mapsto e^{-\pi x^2}$. Lyubarskii [Lyu92], and Seip [Sei92], and Seip and Wallstén [SW92] have shown that $(g_0, a', b') = \{M_{ka'}T_{lb'}g_0\}$ is a frame for any $a', b' > 0$ with $a'b' < 1$, and, hence, we conclude that the analysis map given by

$$C_{g_0} : L^2(\mathbb{R}) \to l^2(\mathbb{Z}^2), \quad f \mapsto \big\{\langle f, M_{k\lambda^2\alpha}T_{l\lambda^2\beta}g_0\rangle\big\}_{k,l}$$

is bounded and stable since $\lambda^2\beta \cdot \lambda^2\alpha = \frac{\lambda^4}{ab} < 1$.

Let us now fix $f \in S_0'(\mathbb{R})$ and consider the composition

$$\begin{array}{ccccccc} l_0(\mathbb{Z}^2) & \overset{E}{\to} & \mathcal{H}_M & \overset{\Phi_f}{\to} & L^2 & \overset{C_{g_0}}{\to} & l^2(\mathbb{Z}^2) \\ \{\sigma_{k,l}\} & \mapsto & E\{\sigma_{k,l}\} & \mapsto & E\{\sigma_{k,l}\}\, f & \mapsto & \big\{\, \langle\, E\{\sigma_{k,l}\}\, f,\ M_{k'\lambda^2\alpha}T_{l'\lambda^2\beta}g_0 \,\rangle\, \big\}_{k',l'} \, . \end{array}$$

The bi-infinite matrix

$$M = \Big(m_{k',l',k,l}\Big) = \Big(\langle\, M_{k\lambda\alpha}T_{l\lambda\beta}PT_{-l\lambda\beta}M_{-k\lambda\alpha}f,\ M_{k'\lambda^2\alpha}T_{l'\lambda^2\beta}g_0 \,\rangle\Big)$$

represents the operator $C_{g_0} \circ \Phi_f \circ E$ with respect to the canonical basis of $l^2(\mathbb{Z}^2)$, since

$$\begin{aligned} \Big(C_{g_0} \circ \Phi_f \circ E\ \{\sigma_{k,l}\}\Big)_{k',l'} &= \Big\langle \sum_{k,l} \sigma_{k,l} M_{k\lambda\alpha}T_{l\lambda\beta}PT_{-l\lambda\beta}M_{-k\lambda\alpha}f,\ M_{k'\lambda^2\alpha}T_{l'\lambda^2\beta}g_0 \Big\rangle \\ &= \sum_{k,l} \langle\, M_{k\lambda\alpha}T_{l\lambda\beta}PT_{-l\lambda\beta}M_{-k\lambda\alpha}f,\ M_{k'\lambda^2\alpha}T_{l'\lambda^2\beta}g_0 \,\rangle\, \sigma_{k,l} \\ &= \sum_{k,l} m_{k',l',k,l}\ \sigma_{k,l}\, . \end{aligned}$$

In order to use Lemma 3.5 to show that M, and, therefore, $C_{g_0} \circ \Phi_f \circ E$, is not stable, we have to obtain bounds on the matrix entries of M. Lemma 3.4(b) will provide us with these bounds. In fact, for $k, l, k', l' \in \mathbb{Z}$, we have

$$\begin{aligned} |m_{k',l',k,l}| &= \big|\langle\, M_{k\lambda\alpha}T_{l\lambda\beta}PT_{-l\lambda\beta}M_{-k\lambda\alpha}f,\ M_{k'\lambda^2\alpha}T_{l'\lambda^2\beta}\, g_0 \,\rangle\big| \\ &\le \langle\, T_{l\lambda\beta}\, |PT_{-l\lambda\beta}M_{-k\lambda\alpha}f|\, ,\ T_{l'\lambda^2\beta}\, |g_0|\, \rangle \\ &\le \|f\|_{S_0'}\ d_1 * g_0\, (\lambda\beta(\lambda l' - l))\, , \end{aligned}$$

and

$$\begin{aligned} |m_{k',l',k,l}| &= \big|\langle\, T_{k\lambda\alpha}M_{-l\lambda\beta}\big(PT_{-l\lambda\beta}M_{-k\lambda\alpha}f\big)\widehat{\ },\ T_{k'\lambda^2\alpha}M_{-l'\lambda^2\beta}\, \widehat{g_0} \,\rangle\big| \\ &\le \langle\, T_{k\lambda\alpha}\, \big|\big(PT_{-l\lambda\beta}M_{-k\lambda\alpha}f\big)\widehat{\ }\big|\ ,\ T_{k'\lambda^2\alpha}\, |g_0|\, \rangle \\ &\le \|f\|_{S_0'}\ d_2 * g_0(\lambda\alpha(\lambda k' - k)). \end{aligned}$$

In these calculations, we used that $g_0 \ge 0$, $\widehat{g_0} = g_0$, and $g_0(-x) = g_0(x)$, as well as the Parseval–Plancherel identity. Since d_1, d_2, and g_0 decay rapidly, so do $d_1 * g_0$ and $d_2 * g_0$. We set

$$w(x) = \|f\|_{S_0'}\ \max\big\{d_1 * g_0(\lambda\beta x),\ d_1 * g_0(-\lambda\beta x),\ d_2 * g_0(\lambda\alpha x),\ d_2 * g_0(-\lambda\alpha x)\big\}$$

and obtain $|m_{k',l',k,l}| \leq w\big(\max\{|\lambda k' - k|,\ |\lambda l' - l|\}\big)$ with $w(x) = O\,(x^{-n})$ for $n \in \mathbb{N}$. Lemma 3.5 implies that M is not stable, and, by construction, we can conclude that $C_{g_0} \circ \Phi_f \circ E$, and thus Φ_f is not stable. ∎

Note that Lemma 3.5 is crucial for the understanding of Theorem 3.6: For any $f \in S_0'$, the operator $C_g \circ \Phi_f \circ E : l_0(\mathbb{Z}^2) \longrightarrow l^2(\mathbb{Z}^2)$, and, therefore, the operator $\Phi_f : \mathcal{H}_{Q_{a,b}} \longrightarrow L^2(\mathbb{R})$, is not stable as a result of the nonquadratic structure of the canonical matrix representation of $C_g \circ \Phi_f \circ E$. The validity of Lemma 3.5 does not depend on the choice of (reasonable) topologies on domain and range; in fact, a more general version of Lemma 3.5 can be found in [Pfa05].

4. Gabor frame operators, underspread operators, and uncertainty. The proof of Kailath's conjecture in section 3 relies strongly on the existence of a Schwartz function $g \in \mathcal{S}(\mathbb{R})$ such that (g, a, b) is a Gabor frame for given $a, b > 0$ with $ab < 1$. In section 4.1 we shall discuss the role of the critical density $ab = 1$ in the identification of Gabor frame operators and analogies of underspread and Gabor frame operators. Interpretations of the results in sections 3 and 4.1 as consequences of uncertainty in time-frequency analysis are given in section 4.2.

As in section 3, we choose to work in section 4 in the one-dimensional setting.

4.1. Identification of Gabor frame operators. For appropriate $g, h \in L^2(\mathbb{R})$, e.g., for $g, h \in S_0(\mathbb{R})$, and $a, b > 0$, the *Gabor frame operator* $S_{g,h}^{a,b} : L^2(\mathbb{R}) \longrightarrow L^2(\mathbb{R})$ is given by

$$S_{g,h}^{a,b} f = D_h \circ C_g\ f = \sum_{k,l \in \mathbb{Z}} \langle f, M_{kb} T_{la} g \rangle\, M_{kb} T_{la} h\,, \quad f \in L^2(\mathbb{R})\,.$$

Let us compare the spreading function representation of Hilbert–Schmidt operators given in (1.1) with *Janssen's representation* of the Gabor frame operator, which is

$$S_{g,h}^{a,b} f = (ab)^{-1} \sum_{m,n \in \mathbb{Z}} \big\langle h, M_{\frac{m}{a}} T_{\frac{n}{b}} g \big\rangle\, M_{\frac{m}{a}} T_{\frac{n}{b}} f\,, \quad f \in L^2(\mathbb{R})$$

[Jan95, Grö01]. Both types of operators are superpositions of time-frequency shifts, and, hence, we shall refer to the tempered distribution

$$(ab)^{-1} \sum_{m,n \in \mathbb{Z}} \big\langle h, M_{\frac{m}{a}} T_{\frac{n}{b}} g \big\rangle\ \delta_{\frac{n}{b}} \otimes \delta_{\frac{m}{a}} \in S_0'(\mathbb{R} \times \widehat{\mathbb{R}})$$

as spreading function of the Gabor frame operator $S_{g,h}^{a,b}$.

On a formal level, the relationship between Gabor frame operators and underspread and overspread operators is striking: the spreading functions of Gabor frame operators are supported (as distributions) on a full rank lattice $\frac{1}{b}\mathbb{Z} \times \frac{1}{a}\mathbb{Z}$ in the time-frequency plane $\mathbb{R} \times \widehat{\mathbb{R}}$, whereas the spreading functions of underspread and overspread operators are supported on a fundamental domain of such a lattice (see Figure 4.1). The duality of *compact* and *discrete* locally compact abelian groups suggests that results in the theory of underspread and overspread operators might lead to analogous results in Gabor analysis, and vice versa.

The correspondence of underspread and overspread operators to Gabor frame operators has not yet been fully explored. To initiate research in this direction, we shall show in Theorem 4.1 that identifiability of a canonically defined class of Gabor frame operators with fixed lattice $a\mathbb{Z} \times b\mathbb{Z}$ is equivalent to the existence of $f \in L^2(\mathbb{R})$ such that (f, a, b) is a Gabor frame for $L^2(\mathbb{R})$. As in section 3, we need to define a

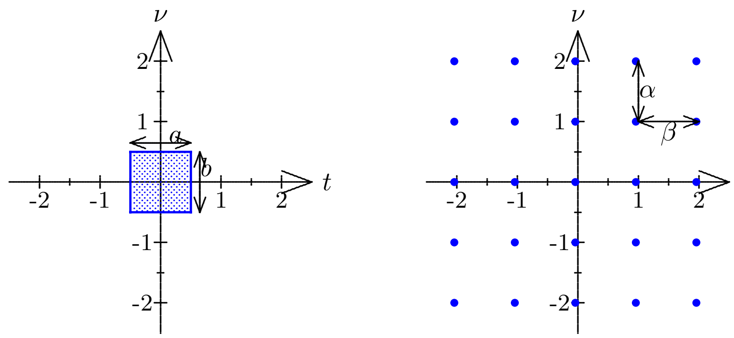

FIG. 4.1. *Support of the spreading symbol of an underspread or overspread operator and distributional support of the spreading symbol of a Gabor frame operator.*

domain X and classes of Gabor frame operators $\mathcal{S}^{a,b}$ with some care in order to have X sufficiently large to allow identification for $ab \leq 1$, and X small enough to allow for an easy proof of the nonidentifiability in case of $ab > 1$.

We choose as domain the Wiener space $W(\mathbb{R})$, i.e.,

$$X = W(\mathbb{R}) = W(L^\infty(\mathbb{R}), l^1(\mathbb{Z})) = \left\{ f \in L^2(\mathbb{R}) : \|f\|_W = \sum_{k\in\mathbb{Z}} \|f \cdot 1_{[k,k+1)}\|_\infty < \infty \right\},$$

as range, once more, $Y = L^2(\mathbb{R})$, and, for $a, b > 0$, we consider the operator class

$$\mathcal{S}^{a,b} = \left\{ S^{a,b}_{g,h} : \ g \in L^2(\mathbb{R}), \ h \in W(\mathbb{R}) \right\} \quad \text{with} \quad \|S^{a,b}_{g,h}\|_{\mathcal{S}^{a,b}} = \left\| \left\{ \left\langle h, M_{\frac{m}{a}} T_{\frac{n}{b}} g \right\rangle \right\} \right\|_{l^2}.$$

We have

$$\|S^{a,b}_{g,h} f\|_{L^2} \leq \sqrt{(a+1)(b+1)} \ \|f\|_W \ \|S^{a,b}_{g,h}\|_{\mathcal{S}^{a,b}}$$

[Grö01, p. 107], and, therefore, $\mathcal{S}^{a,b} \subset \mathcal{L}\left(W(\mathbb{R}), L^2(\mathbb{R})\right)$ and $\{\Phi_f : \ f \in W(\mathbb{R})\} \subset \mathcal{L}\left(\mathcal{S}^{a,b}, L^2(\mathbb{R}^d)\right)$, where $\Phi_f : S^{a,b}_{g,h} \mapsto S^{a,b}_{g,h} f$.

THEOREM 4.1. *$\mathcal{S}^{a,b}$ is identifiable if and only if $ab \leq 1$. Moreover, for any a, b with $ab > 1$ and any $f \in W(\mathbb{R})$ there exist $g \in L^2(\mathbb{R})$ and $h \in W(\mathbb{R})$ such that $S^{a,b}_{g,h} f = 0$.*

Note that identification of $\mathcal{S}^{a,b}$ does not require us to uncover g and h in $S^{a,b}_{g,h}$, but only to obtain the coefficients $\left\{ \left\langle h, M_{\frac{n}{a}} T_{\frac{m}{b}} g \right\rangle \right\}$ in Janssen's representation of the Gabor frame operator $S^{a,b}_{g,h}$.

Proof of Theorem 4.1. To show the identifiability of $\mathcal{S}^{a,b}$ for $ab \leq 1$, we use the fact that for any $ab \leq 1$ there exists $f \in W(\mathbb{R})$ such that $(f, a, b) = \{M_{kb} T_{la} f\}$ is a frame for $L^2(\mathbb{R})$. For example, if $ab < 1$, we may choose the Gaussian $f = g_0 : \mathbb{R} \to \mathbb{R}^+$, $x \mapsto e^{-\pi x^2}$, with $g_0 \in \mathcal{S}(\mathbb{R}) \subset W(\mathbb{R})$ and for $ab = 1$ we could choose $f = \mathbf{1}_{[0,a)} \in W(\mathbb{R})$. The Ron–Shen duality principle implies that (f, a, b) is a frame for $L^2(\mathbb{R})$ if and only if $(f, \frac{1}{b}, \frac{1}{a})$ is a Riesz basis for its closed linear span in $L^2(\mathbb{R})$, i.e., if and only if there exist $A, B > 0$ such that for all $\{d_{m,n}\} \in l^2(\mathbb{Z}^2)$ we have

$$A\|\{d_{m,n}\}\|_{l^2} \leq \| \sum_{m,n\in\mathbb{Z}} d_{m,n} M_{\frac{m}{a}} T_{\frac{n}{b}} f\|_{L^2} \leq B\|\{d_{m,n}\}\|_{l^2} \tag{4.1}$$

[RS97, Grö01]. Replacing $\{d_{m,n}\}$ by $\{\langle h, M_{\frac{m}{a}} T_{\frac{n}{b}} g\rangle\} \in l^2(\mathbb{Z}^2)$ in (4.1) shows that any f with (f, a, b) is a frame for $L^2(\mathbb{R})$ identifies $\mathcal{S}^{a,b}$.

We shall now show that for any $a, b > 0$ with $ab > 1$ and any $f \in W(\mathbb{R})$ there exist $g \in L^2(\mathbb{R})$ and $h \in W(\mathbb{R})$ such that $S^{a,b}_{g,h} \in \mathcal{S}^{a,b} \setminus \{0\}$ and $S^{a,b}_{g,h} f = 0$, contradicting that f identifies $\mathcal{S}^{a,b}$. Fix $a, b > 0$ with $ab > 1$ and $f \in W(\mathbb{R})$ and pick $g \in L^2(\mathbb{R})$ such that $g \perp \overline{\text{span}(f, a, b)}$, and, therefore, $f \perp \overline{\text{span}(g, a, b)}$. Let $h = g_0 \in W(\mathbb{R})$ be the Gaussian defined above and observe that $(g_0, \frac{1}{b}, \frac{1}{a})$ is a frame for $L^2(\mathbb{R})$ since $\frac{1}{ab} < 1$. Hence, $\{\langle h, M_{\frac{m}{a}} T_{\frac{n}{b}} g\rangle\} = \{e^{2\pi i \frac{mn}{ab}} \overline{\langle g, M_{-\frac{m}{a}} T_{-\frac{n}{b}} h\rangle}\} \in l^2(\mathbb{Z}^2) \setminus \{0\}$, i.e., $S^{a,b}_{g,h} \in \mathcal{S}^{a,b}$, $\|S^{a,b}_{g,h}\| \neq 0$, but $S^{a,b}_{g,h} f = \sum \langle f, T_{am} M_{bn} g\rangle\, T_{am} M_{bn} h = 0$. □

4.2. Uncertainty. Theorem 4.1 illustrates a strong relationship of critical density in Gabor analysis to the identification of canonically defined classes of Gabor frame operators. The critical density phenomenon in Gabor analysis is well known to be rooted in uncertainty in time-frequency analysis:

- functions cannot be arbitrarily well localized simultaneously in time and frequency, i.e., in phase space, and we can therefore exclude the possibility that there exist Gabor systems (g, a, b) which are Riesz bases for $L^2(\mathbb{R})$ if $ab < 1$, and
- functions cannot represent an area in phase space of volume larger than one in the sense that one cannot construct complete Gabor frames (g, a, b) for $L^2(\mathbb{R})$ if $ab > 1$.

Due to the first of the two limitations described above, Folland refers to a rectangle of volume one in phase space as a "minimal rectangle in phase space" [FS97].

Theorem 3.1 describes a new interpretation of minimal rectangles which plays a role in the time-frequency analysis of operators: an operator, whose spreading symbol is known to be supported in a rectangle in the time-frequency plane, can be identified if the rectangle has volume less than or equal to one, and cannot be identified if the rectangle has volume greater than one. Note that this phenomenon is not a direct consequence of the fact that we cannot construct functions which are arbitrarily well localized in phase space, since, in fact, there exist no support restrictions for the construction of operator symbols or spreading functions in phase space.

Theorems 3.1 and 4.1 can also be viewed as pull-backs of the critical density phenomenon of "phase space expansions" as described in [Lan93] to operator theory. Any operator output signal can carry only a restricted amount of time-frequency structured information, and therefore any output signal can be used only to resolve a limited amount of information from an operator. Theorem 3.1 illustrates that this amount of information corresponds to a *minimal rectangle in the spreading domain*. Theorem 4.1 shows that the resolvable amount of information of operators, whose spreading functions have discrete distributional support contained in a lattice $\frac{1}{b}\mathbb{Z}\times\frac{1}{a}\mathbb{Z}$, is connected to the sparsity of the lattice. In fact, all information inherent in such an operator can be resolved using a single test signal if and only if $ab \leq 1$. Note that in the latter case, the Kohn–Nirenberg symbol, which is the symplectic Fourier transformation of the spreading function, is $a\times b$ periodic, i.e., is the periodization of a function supported on a *minimal rectangle of size* $ab \leq 1$ *in phase space*.

We would like to add that the physical interpretation of the uncertainty principle as a limit to the achievable precision when measuring position and momentum of quantum mechanical objects parallels the identifiability result for underspread and overspread operators nicely, since the latter tells us that we will not be able to identify an overspread operator no matter how smartly a signal is chosen to test the system.

The uncertainty principle phenomena discussed above, among others, can be found in [Fef83, Dau92, Lan93, BHW98, Grö01, Grö03].

5. Generalized spreading constraints. We shall now extend the results stated in section 3 to higher dimensions and to nonrectangular spreading support sets.

Similarly to the one-dimensional case, we have

$$\mathcal{H} = \mathcal{H}(\mathbb{R}^d) = \left\{H \in HS(L^2(\mathbb{R}^d)) :\ \kappa_H \in S_0(\mathbb{R}^{2d})\right\} \subset \mathcal{L}\left(S_0'(\mathbb{R}^d), L^2(\mathbb{R}^d)\right).$$

Once more, we shall use a Zak transformation, namely, $Z : L^2(\mathbb{R}^d) \longrightarrow L^2(\mathbb{R}^d \times \widehat{R}^d)$, $Zf(t,\nu) = \sum_{n\in\mathbb{Z}^d} f(t-n)e^{2\pi i n\cdot\nu}$ for almost every $(t,\nu) \in Q = Q_{1,1}$, and the Shah distribution $⊥⊥⊥ = ⊥⊥⊥_1$. Adjusting Lemma 3.2 accordingly, we obtain

$$Z \circ H⊥⊥⊥(t,\nu) = \sum_{n,m\in\mathbb{Z}^d} \eta_H(t-n,\nu-m)e^{2\pi i(\nu-m)\cdot t} \quad \text{for all } (t,\nu) \in \left[-\frac{1}{2},\frac{1}{2}\right]^{2d}, \tag{5.1}$$

an identity which leads immediately to the following.

THEOREM 5.1. *$\mathcal{H}_M = \{H \in \mathcal{H} :\ \operatorname{supp} \eta_H \subseteq M\}$ is identifiable with identifier $⊥⊥⊥$ if and only if $M^\circ \cap \bigcup_{(m,n)\in\mathbb{Z}^{2d}\setminus(0,0)} \left(M^\circ + (m,n)\right) = \emptyset$.*

The proof of Theorem 5.1 is similar to the proof of Theorem 3.3 and is therefore omitted.

A straightforward generalization of either Theorem 3.3 or Theorem 5.1 leads to the identifiability of $\mathcal{H}_{\mathcal{D}Q}$, $Q = Q_{1,1} = [-\frac{1}{2},\frac{1}{2}]^{2d}$ in the case that $\mathcal{D}$ is a diagonal matrix with diagonal $(a_1,\ldots,a_d,\frac{1}{a_1},\ldots,\frac{1}{a_d}) \in (\mathbb{R}^+)^{2d}$. This observation leads us to the question for which general diagonal or nondiagonal, volume preserving matrices $\mathcal{A} \in SL(2d,\mathbb{R})$ is the operator space $\mathcal{H}_{\mathcal{A}Q}$ identifiable.

The underlying idea of obtaining identifiability results on $\mathcal{H}_{\mathcal{A}Q}$ for nondiagonal matrices $\mathcal{A} \in SL(2d,\mathbb{R})$ is to use the canonical correspondence of elements in $\mathcal{H}_{\mathcal{A}Q}$ with elements in $\mathcal{H}_Q$ given by a coordinate transformation in the spreading domain. Theorem 5.3 states that for symplectic $\mathcal{A}$, there exist unitary operators $O_\mathcal{A}$ on $L^2(\mathbb{R}^d)$, such that the following formal calculation of operator valued integrals holds for all $H \in \mathcal{H}_{\mathcal{A}Q}$. Note that here we set $\mu(t,\nu) = M_\nu T_t$ to obtain

$$\begin{aligned}
H &= \int\int \eta_H(t,\nu)\, M_\nu T_t\ dt\, d\nu = \int\int \eta_H(t,\nu)\ \mu(t,\nu)\, dt\, d\nu \\
&= \int\int \eta_H(\mathcal{A}(t,\nu))\ \mu(\mathcal{A}(t,\nu))\ dt\, d\nu = \int\int \eta_H(\mathcal{A}(t,\nu))\ O_\mathcal{A}\mu(t,\nu)O_\mathcal{A}{}^*\ dt\, d\nu \\
&= O_\mathcal{A} \int\int \eta_{H_\mathcal{A}}(t,\nu)\ \mu(t,\nu)\ dt\, d\nu\ O_\mathcal{A}{}^* = O_\mathcal{A}\ H_\mathcal{A}\ O_\mathcal{A}{}^*,
\end{aligned} \tag{5.2}$$

where $\eta_{H_\mathcal{A}} = \eta_H \circ \mathcal{A}$ and $H_\mathcal{A} \in \mathcal{H}_Q$. We shall see that the *intertwining* operators $O_\mathcal{A} \in U\big(L^2(\mathbb{R}^d)\big)$ in (5.2) extend to $S_0'(\mathbb{R}^d)$ and act isomorphically on $S_0(\mathbb{R}^d)$. The identifiability of $\mathcal{H}_Q$ leads therefore to the identifiability of $\mathcal{H}_{\mathcal{A}Q}$ using as identifier the tempered distribution $O_\mathcal{A}⊥⊥⊥ \in S_0'(\mathbb{R}^d)$. See Figure 5.1 for an illustration of this approach.

To gather all $\mathcal{A} \in SL(2d,\mathbb{R})$ which allow for calculations similar to those in (5.2), we turn to the representation theory of the reduced Weyl–Heisenberg group $\mathbb{H}_d^{red}$, which is identical to $\mathbb{R}^d \times \widehat{\mathbb{R}}^d \times \mathbb{T}$ in topology and Haar measure. The group operation on the reduced Weyl–Heisenberg group is

$$\big(t,\nu,e^{2\pi i s}\big) \cdot \big(t',\nu',e^{2\pi i s'}\big) = \big(t+t',\nu+\nu',e^{2\pi i(s+s'+\frac{1}{2}(t'\cdot\nu - t\cdot\nu'))}\big),$$

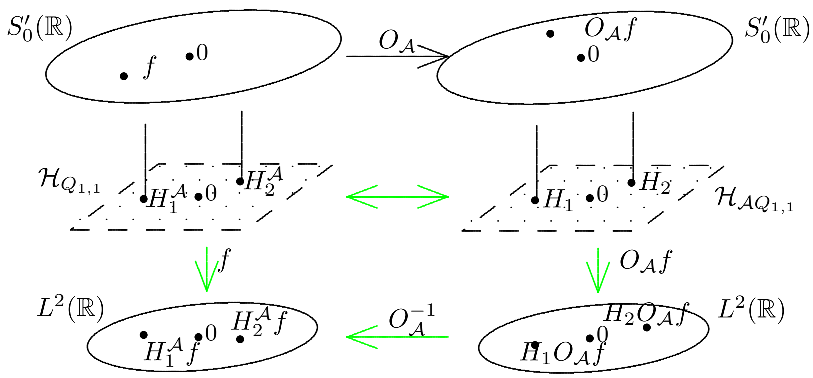

FIG. 5.1. *Identifiability of $\mathcal{H}_{\mathcal{A}Q}$, $\mathcal{A} \in Sp(d,\mathbb{R})$, based on the existence of an intertwining operator $O_{\mathcal{A}}$.*

and its Schrödinger representation on the space of unitary operators on $L^2(\mathbb{R}^d)$ is given by

$$\begin{array}{lllllllll}
\rho: & \mathbb{H}_d^{red} & \to & U\big(L^2(\mathbb{R}^d)\big) & & & & & \\
& (t,\nu,s) & \mapsto & \rho(t,\nu,s): & L^2(\mathbb{R}) & \to & L^2(\mathbb{R}) & & \\
& & & & f & \mapsto & \rho(t,\nu,e^{2\pi i s})f: & \mathbb{R}^d & \to \quad \mathbb{R}^d \\
& & & & & & & x & \mapsto \quad e^{2\pi i(\nu\cdot x)+s} f(x+t)\ .
\end{array}$$

Representing H once more as operator valued integral, we obtain

$$\begin{aligned}
H = \int\!\!\int \eta_H(t,\nu) M_\nu T_t \, dt\, d\nu \ &= \ \int_{\mathbb{R}^d}\int_{\widehat{\mathbb{R}}^d}\int_0^1 \eta_H(t,\nu)\rho(-t,\nu,0)\, dt\, d\nu\, ds \\
= \int_{\mathbb{H}_d^{red}} e^{-2\pi i s}\eta_H(-t,\nu)\rho(t,\nu,e^{2\pi i s})\, d\mu(t,\nu,s) \ &= \ \rho(\eta_H^\circ),
\end{aligned}$$

where $\eta_H^\circ(t,\nu,e^{2\pi i s}) = e^{-2\pi i s}\eta_H(-t,\nu)$. In other words, a Hilbert–Schmidt operator H with $\eta_H \in L^1(\mathbb{R}^{2d})$ is the integrated Schrödinger representations of η_H° with respect to the reduced Weyl–Heisenberg group $\mathbb{H}_d^{red}$ [Fol89, Grö01].

Before listing the relevant results from representation theory in Theorem 5.3, it is now time to define the symplectic group.

DEFINITION 5.2. *The symplectic group $Sp(d,\mathbb{R})$ consists of those matrices $\mathcal{A} \in SL(2d,\mathbb{R})$ that satisfy $\mathcal{A}^\star \left(\begin{smallmatrix} 0 & -I_d \\ I_d & 0 \end{smallmatrix}\right) \mathcal{A} = \left(\begin{smallmatrix} 0 & -I_d \\ I_d & 0 \end{smallmatrix}\right)$, where I_d is the $d\times d$ identity matrix.*

Theorem 5.3(a) outlines the scope of our approach [Fol89]. Part (c) delivers intertwining operators for equivalent representations $\rho \circ \mathcal{A}$ and ρ. Parts (d), (e), (f), and (g) describe these operators as products of some elementary operators. This characterization shows us that the a priori Hilbert space theory applies to the Feichtinger algebra setup used in this paper (see part (h)). Part (i) covers shifts of the spreading support which allow us to extend Theorem 5.4 to affine linear coordinate transformations.

For ease of notation we shall not distinguish between the matrix $\mathcal{A}$ and the corresponding linear map; i.e., we have $\mathcal{A}(t,\nu) = \big((t,\nu)\cdot\mathcal{A}^t\big)^t$.

THEOREM 5.3.

(a) *Let S operate on $\mathbb{H}_d^{red}$. The induced map $\rho_S = \rho\circ S : \mathbb{H}_d^{red} \longrightarrow U\left(L^2(\mathbb{R}^d)\right)$ is an unitary representation of $\mathbb{H}_d^{red}$ which is unitarily equivalent to the irre-*

ducible Schrödinger representation ρ; i.e., there exists an unitary intertwining operator O such that $O\rho(g)O^* = \rho_S(g)$ for all $g \in HW_d^{red}$ if and only if there exists $\mathcal{A} \in Sp(d,\mathbb{R})$ with $S = \widetilde{\mathcal{A}}$, where $\widetilde{\mathcal{A}}$ is given by $\widetilde{\mathcal{A}} : \mathbb{H}_d^{red} \longrightarrow \mathbb{H}_d^{red}, (t,\nu,e^{2\pi is}) \mapsto (\mathcal{A}(t,\nu), e^{2\pi is})$.

(b) *Let $\mathcal{A} \in Sp(d,\mathbb{R})$ and let $\rho_{\mathcal{A}} = \rho \circ \widetilde{\mathcal{A}}$. Then $\rho_{\mathcal{A}}(f) = \rho(f \circ \mathcal{A}^{-1})$ for $f \in L^1(\mathbb{H}_d^{red})$.*

(c) *For $\mathcal{A} \in Sp(d,\mathbb{R})$ there exists a unitary operator $O_{\mathcal{A}}$ on $L^2(\mathbb{R}^d)$, with $O_{\mathcal{A}}HO_{\mathcal{A}}^* = \rho(\eta(H)^\circ \circ \widetilde{\mathcal{A}}^{-1})$ for all $H \in HS(L^2(\mathbb{R}^d))$ with $\eta(H) \in L^1(\mathbb{R}^{2d})$.*

(d) *The matrix $\mathcal{I} = \left(\begin{smallmatrix} 0 & I_d \\ -I_d & 0 \end{smallmatrix}\right)$ together with the subgroups*

$$N = \left\{ \left(\begin{smallmatrix} I_d & 0 \\ A & I_d \end{smallmatrix}\right), A = A^* \right\} \quad \text{and} \quad D = \left\{ \left(\begin{smallmatrix} A & 0 \\ 0 & A^{*-1} \end{smallmatrix}\right), A \in GL(n,\mathbb{R}) \right\}$$

of $Sp(d,\mathbb{R})$ generate $Sp(d,\mathbb{R})$.

(e) *For $\mathcal{A} = \left(\begin{smallmatrix} 0 & I_d \\ -I_d & 0 \end{smallmatrix}\right)$ we have $\mu \circ \mathcal{A}(t,\nu) = \mu(\mathcal{A}(t,\nu)) = \mathcal{F}^{-1}\mu(t,\nu)\mathcal{F}$.*

(f) *For $\mathcal{A} = \left(\begin{smallmatrix} I_d & 0 \\ A & I_d \end{smallmatrix}\right)$ with $A = A^*$ define C_A through $C_Af(x) = e^{-\pi i x^TAx}f(x)$. Then we have $\mu \circ \mathcal{A}(t,\nu) = \mu(\mathcal{A}(t,\nu)) = C_A \circ \mu(t,\nu) \circ C_A^*$.*

(g) *For $\mathcal{A} = \left(\begin{smallmatrix} A & 0 \\ 0 & A^{*-1} \end{smallmatrix}\right)$ let U_A be defined by setting $U_Af(x) = |\det A|^{-\frac{1}{2}}f(A^{-1}x)$. Then $\mu \circ \mathcal{A}(t,\nu) = \mu(\mathcal{A}(t,\nu)) = U_A \circ \mu(t,\nu) \circ U_A^*$.*

(h) *The unitary operators $\mathcal{F}$, C_A, and U_A restrict and extend to $S_0(\mathbb{R})$ and $S_0'(\mathbb{R})$, respectively.*

(i) *Set $L_{(a,b)} : \mathbb{R}^d \times \widehat{\mathbb{R}}^d \longrightarrow \mathbb{R}^d \times \widehat{\mathbb{R}}^d, (t,\nu) \mapsto (a+t, b+\nu)$. Then*

$$\mu \circ L_{(a,b)}(t,\nu) = e^{2\pi i\nu a}\mu(a,b)\mu(t,\nu) = e^{2\pi ibt}\mu(t,\nu)\mu(a,b).$$

For details on representation theoretic background, see [Fol89, FK98, Grö01]. Using Theorem 5.3, we obtain the following.

THEOREM 5.4. *Let $S = L_{(a,b)} \circ \mathcal{A}$, $\mathcal{A} \in Sp(d,\mathbb{R})$. Then $\mathcal{H}_M$ is identifiable if and only if $\mathcal{H}_{SM}$ is identifiable.*

Proof. Assume that $\mathcal{H}_M$ is identifiable with $f_M \in S_0'(\mathbb{R}^d)$. Theorem 5.3 provides us with an unitary operator $O_{\mathcal{A}}$ on $L^2(\mathbb{R}^d)$ which extends to $S_0'(\mathbb{R}^d)$. We claim that $O_{\mathcal{A}}f_M \in S_0'(\mathbb{R}^d)$ identifies $\mathcal{H}_{SM}$. To see this, observe that for all $H \in \mathcal{H}_{SM}$ we have

$$\begin{aligned}
H &= \int\int \eta_H(t,\nu)\ \mu(t,\nu)\,dt\,d\nu \\
&= \int\int \eta_H\big(\mathcal{A}(t,\nu)+(a,b)\big)\ \mu\big(\mathcal{A}(t,\nu)+(a,b)\big)\,dt\,d\nu \\
&= \int\int \eta_H\big(\mathcal{A}(t,\nu)+(a,b)\big)\ e^{2\pi ia(Ct+D\nu)}\mu(a,b)\mu(\mathcal{A}(t,\nu))\ dt\,d\nu \\
&= \int\int \eta_H\big(\mathcal{A}(t,\nu)+(a,b)\big)e^{2\pi ia(Ct+D\nu)}\ \mu(a,b)O_{\mathcal{A}}\mu(t,\nu){O_{\mathcal{A}}}^*\ dt\,d\nu \\
&= \mu(a,b)O_{\mathcal{A}}\int\int \eta_{H_{\mathcal{A},(a,b)}}(t,\nu)\ \mu(t,\nu)\ dt\,d\nu\ {O_{\mathcal{A}}}^* \\
&= \mu(a,b)O_{\mathcal{A}}\ H_{\mathcal{A},(a,b)}\ {O_{\mathcal{A}}}^*,
\end{aligned}$$

and

$$\begin{aligned}
&\|H\,O_{\mathcal{A}}f_M\|_{L^2(\mathbb{R}^d)} = \|{O_{\mathcal{A}}}^*\mu(a,b)^*HO_{\mathcal{A}}f_M\|_{L^2(\mathbb{R}^d)} \\
&= \|H_{\mathcal{A},(a,b)}f_M\|_{L^2(\mathbb{R}^d)} = \|\eta_{H_{\mathcal{A},(a,b)}}\|_{L^2(\mathbb{R}^{2d})} = \|\eta_H\|_{L^2(\mathbb{R}^{2d})} \equiv \|H\|_{HS}. \qquad \square
\end{aligned}$$

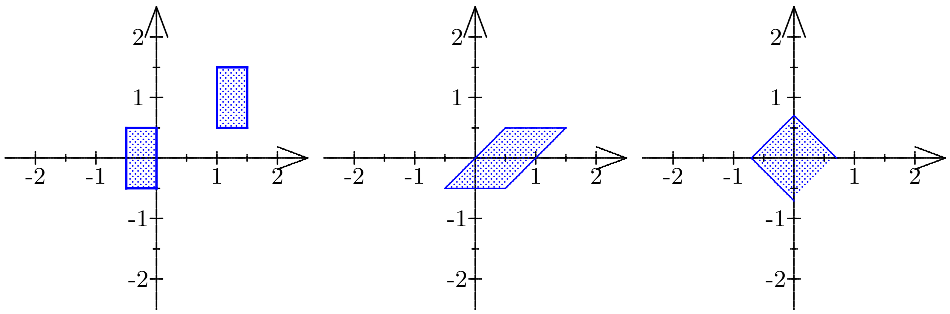

FIG. 5.2. *Examples of sets M such that H_M is identifiable.*

Theorems 3.3 and 5.4 imply that the exemplary spreading support sets M given Figure 5.2 define identifiable operator classes H_M.

For $M = Q$, we can identify $\mathcal{H}_{SQ}$ using the identity in the following.

COROLLARY 5.5. *Let $S = L_{(a,b)} \circ \mathcal{A}$ for some $(a,b) \in \mathbb{R}^d \times \widehat{\mathbb{R}}^d$ and $\mathcal{A} = \left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right) \in Sp(d,\mathbb{R})$. Then for $H \in \mathcal{H}_{SQ}$ and for $(t,\nu) \in \operatorname{supp}(\eta_H)$*

$$e^{2\pi i a\cdot(Ct+Dv)+\nu t} Z \circ O_S \circ H \circ O^*_{S}{\perp\!\perp\!\perp}(t,\nu) = \eta_H(\mathcal{A}^{-1}(t-a,\nu-b)).$$

We have shown that identifiability is robust with respect to symplectic coordinate transformations in the spreading domain. This result is rooted in the representation theory of the Weyl–Heisenberg group. Theorem 5.3(i) shows that this approach can not be extended to obtain insights on nonsymplectic coordinate transformations.

Nevertheless, we should note that for $\mathcal{A} \in SL(2d,\mathbb{R})$ the condition $\mathcal{A} \in Sp(d,\mathbb{R})$ is not necessary for $\mathcal{H}_{\mathcal{A}Q}$ to be identifiable. In fact, the diagonal matrix $\mathcal{D}$ with diagonal $(2,\, \frac{1}{2},\, 1,\, 1)$ has the property $\mathcal{D} \in SL(4,\mathbb{R}) \setminus Sp(2,\mathbb{R})$, but $\mathcal{H}_{\mathcal{D}Q}$ is identifiable since $\mathcal{D}Q$ is a fundamental domain of the symplectic lattice $\left(\begin{smallmatrix} A & 0 \\ 0 & A^{*-1} \end{smallmatrix}\right)\mathbb{Z}^4$ with $A = \left(\begin{smallmatrix} 1 & 0 \\ \frac{1}{2} & 1 \end{smallmatrix}\right)$, and therefore an application of Theorems 5.1 and 5.4 is permissible.

For similar results on nonsymplectic lattices in Gabor theory see [Bek04, HW01, HW04].

Acknowledgments. We would like to thank Georg Zimmermann for many fruitful discussions regarding Kailath's conjecture and slowly time-varying operators in general. Further, we thank the anonymous reviewer for many suggestions that helped to improve the clarity and readability of this paper.

STABILITY OF LARGE-AMPLITUDE SHOCK PROFILES OF GENERAL RELAXATION SYSTEMS*

CORRADO MASCIA† AND KEVIN ZUMBRUN‡

Abstract. Building on previous analyses carried out in [Mascia and Zumbrun, *Indiana Univ. Math. J.*, 51 (2002), pp. 773–904] and [Mascia and Zumbrun, *Arch. Ration. Mech. Anal.*, 172 (2004), pp. 93–131], we establish $L^1 \cap H^2 \to L^p$ nonlinear orbital stability, $1 \leq p \leq \infty$, with sharp rates of decay, of large-amplitude Lax-type shock profiles for a general class of relaxation systems that includes most models in common use, under the necessary conditions of strong spectral stability, i.e., stable point spectrum of the linearized operator about the wave, transversality of the profile, and hyperbolic stability of the associated ideal shock. In particular, our results apply to standard moment-closure systems, answering a question left open in Mascia and Zumbrun (2002). The argument combines the basic nonlinear stability argument introduced in Mascia and Zumbrun (2002) with an improved "Goodman-style" weighted energy estimate similar to but substantially more delicate than that used in Mascia and Zumbrun (2004) to treat large-amplitude profiles of systems with real viscosity.

Key words. relaxation systems, stability of traveling waves

AMS subject classifications. 35L60, 35B30, 35B45, 35L65, 76L05

DOI. 10.1137/S0036141004435844

1. Introduction. In [24], a detailed study was carried out on linearized and nonlinear stability of traveling front solutions, or shock profiles

$$(u,v)(x,t) = (\bar{u},\bar{v})(x-st), \qquad \lim_{z\to\pm\infty}(\bar{u},\bar{v}) = (u_\pm, v_\pm) = (u_\pm, v^*(u_\pm)), \tag{1.1}$$

of relaxation systems

$$\begin{cases} u_t + f(u,v)_x = 0, \\ v_t + g(u,v)_x = q(u,v), \end{cases} \tag{1.2}$$

$u,\ f \in \mathbb{R}^n$, $v,\ g,\ q \in \mathbb{R}^r$, where

$$\operatorname{Re}\sigma(q_v(u,v^*(u))) < 0$$

along a smooth *equilibrium manifold* $v = v^*(u)$ defined by $q(u,v^*(u)) = 0$.

The linearized results obtained in [24] are extremely general and appear to be optimal. However, the nonlinear results are restricted to arbitrary-amplitude profiles of special, discrete kinetic models, defined as systems (1.2) for which f and g are linear, and small-amplitude profiles of general, simultaneously symmetrizable models, defined as systems (1.2) for which there exists a smooth, symmetric positive definite matrix function $A^0 = A^0(u,v)$ for which A^0A and A^0Q are symmetric, where $A := (df^t, dg^t)^t$ and $Q := (0, dq^t)^t$.

The first result is quite satisfactory and has important applications to the physically interesting class of systems obtained by discretization of kinetic models such as Boltzmann or Vlasov–Poisson equations. On the other hand, the equally important class of systems obtained by moment-closure approximation of kinetic models is not contained in the class of discrete kinetic models, and so the question of large-amplitude stability for these models was left open in [24]; indeed, as discussed in Remark 1.16 of [24], it was not at all clear from the analysis of [24] whether this was a technical artifact or represented a true qualitative difference in behavior between these two types of approximation. Moreover, even the requirement of simultaneous symmetrizability appears to be overly restrictive in the large-amplitude case. As described in [33], many systems of physical interest are simultaneously symmetrizable along the equilibrium manifold $v = v^*(u)$, including (standard versions of) both discrete and moment-closure approximations of kinetic models; however, so far as we can see, simultaneous symmetrizability does not typically hold away from equilibrium, in particular along a shock profile, as assumed in [24].[1] This distinction is unimportant in the small-amplitude case, for which the argument of [24] goes through by continuity assuming only simultaneous symmetrizability at the endstates $(u_-, v^*(u_-))$;[2] however, it becomes significant in the large-amplitude case, for which profiles may feature arbitrarily large excursions from equilibrium.

The difficulty in the analysis of the general case was control of higher-derivative source terms arising in the nonlinear iteration through Taylor expansion of the variable coefficient matrix $A = (df^t, dg^t)^t$. Such terms do not arise in the case of discrete kinetic models, for which A is constant, and this made it possible to carry out the entire nonlinear stability analysis using linearized (i.e., Green function) estimates alone. In the general case, we found it necessary to augment these bounds with coupled energy estimates in order to close the iteration, and these estimates, as implemented in [24], used both global symmetrizability and the small-amplitude assumption in important ways. In particular, these assumptions were used to guarantee that the perturbation equations be locally dissipative everywhere along the shock profile, whereas, in the present, large-amplitude case, the perturbation equations are in general dissipative only near plus or minus spatial infinity.

Similar difficulties arose in the closely related study [25] of stability of shock profiles for real viscosity models, initially limiting this analysis also to the small-amplitude, globally symmetrizable case. Recently, however, these obstacles were overcome and the corresponding restrictions removed in [27] by the introduction of a modified energy estimate incorporating "Goodman-type" weighted norms in the style of [12]. As discussed in [39, 40], these quantify the observation that transverse convection relative to the shock profile already yields a complementary type of dissipation near the inner shock layer by rapidly sweeping signals to plus or minus spatial infinity, where they then decay under the effects of the local dissipativity guaranteed by (A1)–(A2).

In this paper, we show that a similar approach can be applied in the relaxation case to yield a satisfactory nonlinear stability theory applying to large-amplitude profiles of the physically correct class of systems that are simultaneously symmetrizable *at equilibrium*—indeed, to the considerably more general class of equations that was considered in the linearized analysis of [24].

---

[1] This corrects a misstatement in [24, Remark 1.15], where the calculations of [33] were misquoted as asserting global simultaneous symmetrizability.

[2] Specifically, in the notation of [24, Lemma 7.4], the key property $\mathrm{Re}\,(kA - A^0Q) > 0$ persists under perturbation.

This brings the analysis of [24] to a satisfying conclusion, putting under a common framework most of the relaxation models typically studied, and in particular resolving in the negative the question posed in [24] of whether there might be a true qualitative difference in behavior between discrete and moment-closure approximations of kinetic models. We point out that our results yield new information even in the case of (non-globally-symmetrizable) discrete kinetic models, since we require significantly less regularity on the data ($L^1 \cap H^2$ vs. $W^{3,1} \cap W^{3,\infty}$). Also, the low norm decay rates, L^p for $1 \le p < 2$, are new for general models even in the small-amplitude case.

A substantial new difficulty in the relaxation as compared to the real viscosity case is that the hyperbolic characteristic speeds corresponding to eigenvalues of $(df^t, dg^t)^t$ are by the subcharacteristic condition (a necessary condition for dissipativity condition (A2); see [24, 32]) necessarily of both positive and negative signs, whereas in the case of real viscosity, hyperbolic modes were assumed to be all of one sign, i.e., strictly upwind or strictly downwind. Since weights are chosen to decay exponentially in the direction of propagation, this means that a single scalar weight no longer suffices in the relaxation case, and the introduction of a matrix of distinct diagonal weights leads to off-diagonal error terms that grow exponentially in both the amplitude of the shock and in an arbitrary constant C_* determining the amount of dissipation on the inner layer with respect to the chosen weight.

At first sight, it is hard to see how such an argument could ever close, since good terms of order C_* generate bad terms of exponential order in C_*. Remarkably, the energy estimates *can* close by a refinement of the hyperbolic compensation argument of [17, 30]: namely, the observation (Lemma 2.3 below) that the same "compensating matrix" K used to complete the partial dissipation provided by the semiparabolic matrix B may be used at the same time to eliminate off-diagonal terms of essentially arbitrary size. The details of this argument may be found in sections 2 and 3.

We now describe our results in more detail. Of system (1.2), we assume the following structural properties:

(A1) *Symmetrizability of* $A(u,v) = (df^t, dg^t)^t$*:* there exists a C^3 positive definite matrix-valued function $A^0(u,v)$ such that A^0A is symmetric.

(A2) *Dissipativity at the equilibrium states* $(u_\pm, v^*(u_\pm))$*:* for some $\theta > 0$,

$$\operatorname{Re}\sigma(i\xi A_\pm + Q_\pm) \le \frac{-\theta|\xi|^2}{1+|\xi|^2} \qquad \forall\, \xi \in \mathbb{R},$$

where $A_\pm := A(u_\pm, v^*(u_\pm))$, $Q_\pm := Q(u_\pm, v^*(u_\pm))$, and $Q(u,v) := (0, dq(u,v))^t$.

Condition (A1) is connected with well-posedness of (1.2), while (A2) is connected with time-asymptotic stability of equilibrium states $(u_\pm, v^*(u_\pm))$ [17]. As discussed variously in [5, 17, 33, 35], sufficient conditions for (A2) are either simultaneous symmetrizability, A^0Q symmetric, or else weak dissipativity, $Q(A^0)^{-1} \le 0$ and $(Q(A^0)^{-1})_{22} < 0$,[3] together with *genuine coupling*:

$$\text{No eigenvector of } A_\pm \text{ lies in the kernel of } Q_\pm. \tag{1.3}$$

Hereafter, set $s = 0$ (changing to coordinates moving with the shock), so that (1.1) becomes a standing-wave solution. Regarding the profile $(\bar u, \bar v)$, we assume the following:

[3] That is, $\tilde Q := Q(A^0)^{-1} =$ block-diag $\{0, \tilde q\}$ with $\tilde q < 0$, whence we may replace $\tilde Q$ with $\operatorname{Re}\tilde Q$ and proceed as in the simultaneously symmetrizable case, noting that $\ker A^0 \operatorname{Re}\tilde Q = \ker A^0\tilde Q = (I_{n-r}, 0)$, whence (1.3) is preserved. The example $\tilde q = \begin{pmatrix} 0 & a \\ -a & 1 \end{pmatrix}$, $a \ne 0$, shows that $\tilde q > 0$ is necessary, since $\operatorname{Re}\sigma\tilde q < 0$ but $\operatorname{Re}\tilde q =$ block-diag $\{0, \tilde q\}$ is only semidefinite.

(H0) $f,\, g,\, q \in C^3$.

(H1) The eigenvalues of $A(x) := (df^t, dg^t)^t(\bar u, \bar v)(x)$ are (i) different from 0 and (ii) of constant multiplicity.

(H2) (i) The eigenvalues $a_j^{*\pm}$ of $A_\pm^* := df^*(u_\pm)$, $f^*(u) := f(u, v^*(u))$, are real and different from 0;[4] moreover, (ii) when ordered with increasing size, they satisfy the *strict Lax characteristic conditions* [19]

$$a_{p-1}^{*-} < 0 < a_p^{*-}, \quad a_p^{*+} < 0 < a_{p+1}^{*+}$$

for some $1 \le p \le n$ (the principal characteristic field of the shock).

(H3) *Dynamical stability:* the *Liu–Majda determinant condition* [20, 21, 22, 23]

$$\Delta := \det(r_1^{*-}, \dots, r_{p-1}^{*-}, [u], r_{p+1}^{*+}, r_n^{*+}) \neq 0 \tag{1.4}$$

is satisfied, where $r_j^{*\pm}$ denote the eigenvectors of $A_\pm^*$ associated with $a_j^{*\pm}$, and $[u] := u_+ - u_-$ denotes the jump in u across the shock.

(H4) *Structural stability:* the profile $(\bar u, \bar v)(\cdot)$ is a transverse connection of the associated standing-wave ODE, in particular, therefore, locally unique up to translation.

(H5) *Strong spectral stability:* the point spectrum of the linearized operator $\mathcal{L}$ about the wave is contained in $\{\lambda : \operatorname{Re}\lambda < 0\} \cup \{0\}$.

Condition (H0) gives the regularity needed both for our analysis here and in order to apply the linearized bounds of [24]. Condition (H1)(i) is a standard assumption [34, 38, 24] ensuring that the standing-wave ODE be of nondegenerate type [24]. It is not clearly necessary, however, and at least for discrete kinetic models it can be relaxed, as we discuss in section 4; indeed, in that setting it is rather unnatural. Condition (H1)(ii) is a technical assumption that was used in the pointwise Green function analysis of [24]; at the expense of some detail in the pointwise description of linearized behavior, it may be removed altogether [39]. Constant multiplicity holds automatically for discrete kinetic models, but for moment-closure models may be difficult to verify. Together, (A1) and (H1)(ii) are equivalent to semisimplicity plus constant multiplicity of $\sigma(A)$. Condition (H2)(i) expresses hyperbolicity and noncharacteristicity of the associated "equilibrium system"

$$u_t + f^*(u)_x = 0 \tag{1.5}$$

obtained from (1.2) by formal Chapman–Enskog expansion at the endstates u_-, u_+ with respect to the corresponding ideal shock (u_-, u_+) of (1.5). Note that hyperbolicity of the equilibrium system is not required *along the profile*, thus allowing applications to interesting nonhyperbolic situations as discussed in [16, 1, 2]. Condition (H2)(ii) restricts attention for simplicity to the standard case of a classical, Lax-type

[4] This differs from hypothesis (H2) of [24], in which the eigenvalues were also required to be distinct. However, it was noted in Remark 1.12 of [24] that this requirement may be dropped when $A_\pm^*$ and $Q_\pm$ are simultaneously symmetrizable, with essentially no change in either results or notation; the same argument shows that this requirement may likewise be dropped in the general case, at the expense of further complications (specifically, the matrix-valued diffusion waves $e^{(x-a_j^{*\pm})^2(4\pi\beta_j^{*\pm}t)^{-1}}$ of the remark must be replaced by the fundamental solution of $v_t + a_j^{*\pm}v_x = \beta_j^{*\pm}v_{xx}$, where $\beta_j^{*\pm} := l_j^{*\pm t}B^{*\pm}r_j^{*\pm}$ are no longer necessarily diagonal, and the matrix-valued error-functions appearing in excited term E by its spatial integral; finally, though the precise form of scattering term S in [24, Proposition 1.10] is no longer clear, it is easily verified that it satisfies pointwise bounds yielding the same rates of $L^q \to L^p$ decay as needed for subsequent stability arguments).

shock (u_-, u_+) of (1.5); the treatment of nonclassical over- and undercompressive shocks we leave for the future.[5]

Conditions (H3)–(H5) are together equivalent to the *Evans function condition*:

($\mathcal{D}$) The Evans function $D(\cdot)$ associated with $\mathcal{L}$ has precisely one zero on $\{\lambda : \operatorname{Re}\lambda \geq 0\}$ (necessarily at $\lambda = 0$).[6]

The generalized spectral stability condition ($\mathcal{D}$) was shown in [24] to be necessary and sufficient for linearized stability under assumptions (A1)–(A2) and (H0)–(H2); the main point of this paper is to show that these conditions are sufficient also for nonlinear stability. The conditions (H3) and (H4) correspond to the classical physical notions of dynamical and structural stability (see, e.g., [3]), whereas (H5) encodes heretofore neglected relaxation effects; for further discussion in the closely related viscous case, see [38] and especially [27]. All three of conditions (H3)–(H5) hold automatically in the small-amplitude case; see [21, 22, 23, 34, 24, 28], respectively.

DEFINITION 1.1. *For a profile $\bar{U} = (\bar{u}, \bar{v})$ that is* (*as in the Lax case*) *unique up to translation, we define* nonlinear orbital stability *as convergence of $U = (u, v)(\cdot, t)$ as $t \to \infty$ to a translate $\bar{U}(\cdot - \delta(t))$, where $\delta(\cdot)$ is an appropriately chosen function describing shock location, for any solution U of* (1.2) *with initial data sufficiently close in some norm to the original profile $\bar{U}$.*

Then the main result of this paper is as follows.

THEOREM 1.2. *Let $\bar{U} = (\bar{u}, \bar{v})$ be a profile* (1.1) *of a relaxation system* (1.2), *under assumptions* (A1)–(A2) *and* (H0)–(H5). *Then $\bar{U}$ is nonlinearly orbitally stable from $L^1 \cap H^2$ to L^p for all $p \geq 2$.*

More precisely, for initial perturbations $U_0 := \tilde{U}_0 - \bar{U}$ with $|U_0|_{L^1 \cap H^2}$ sufficiently small, the solution $\tilde{U} = (\tilde{u}, \tilde{v})(x, t)$ of (1.2) *with initial data $\tilde{U}_0$ satisfies*

$$|\tilde{U}(x,t) - \bar{U}(x - \delta(t))|_{L^p} \leq C|U_0|_{L^1 \cap H^2} (1+t)^{-\frac{1}{2}(1-\frac{1}{p})} \tag{1.6}$$

for all $1 \leq p \leq \infty$, for some $\delta(t)$ satisfying

$$|\dot{\delta}(t)| \leq C|U_0|_{L^1 \cap H^2} (1+t)^{-\frac{1}{2}} \qquad \textit{and} \qquad |\delta(t)| \leq C|U_0|_{L^1 \cap H^2}.$$

Remark 1.3. Useful geometric necessary conditions for viscous stability have been obtained in [36, 38, 11] in the simultaneously symmetrizable case A^0Q symmetric using the stability index of [10, 4]. Strengthened, *signed* versions $\Delta > 0$ (under appropriate normalization) of the dynamical stability condition (1.4), these readily yield examples of spectrally unstable large-amplitude profiles, similarly to the strictly parabolic case (see, e.g., [7, 10, 38, 42]). This shows that the stability conditions assumed in Theorem 1.2 are not vacuous in the large-amplitude case. Moreover, as discussed in [38, section 6.2], the signed version of the Majda condition can serve as a physical selection principle in situations, for neither of the classical criteria of structural or dynamical stability suffice. As discussed further in [27, 38], it is an extremely interesting open problem which of the stability conditions (H3) and (H5) is in practice most restrictive.

Similarly, as in the small-amplitude case, Theorem 1.2 is obtained by a nonlinear iteration combining the linearized decay rates of [24] with an appropriate auxiliary

[5]See [24] for a linearized analysis and [41, 38, 13] for related nonlinear analyses in the viscous or viscous-dispersive case.

[6]For a precise definition of the Evans function and a proof of the equivalence of ($\mathcal{D}$) and (H3)–(H5), see [24] or [38, Appendix A2].

energy estimate controlling higher derivatives. Following [24], define the nonlinear perturbation $U = (u, v)$ by

$$U(x,t) := \tilde{U}(x + \delta(t), t) - \bar{U}(x), \tag{1.7}$$

where $\tilde{U} = (\tilde{u}, \tilde{v})$ is a solution of (1.2) and the "shock location" δ is to be determined later. Evidently, decay of U is equivalent to nonlinear orbital stability, as described in (1.6). Then the key energy estimate, and the main technical contribution of the paper, is as follows.

Proposition 1.4. *Under the hypotheses of Theorem* 1.2*, let* $U_0 \in H^2$*, and suppose that, for* $0 \le t \le T$*, both the supremum of* $|\dot{\delta}|$ *and the* $H^1 \cap W^{1,\infty}$ *norm of the perturbation* $U = (u, v)^t$ *defined by* (1.7) *remain bounded by a sufficiently small constant* $\zeta > 0$*. Then, for all* $0 \le t \le T$ *and some* $\theta > 0$*,*

$$|U|_{H^2}^2(t) \le Ce^{-\theta t}|U_0|_{H^2}^2 + C\int_0^t e^{-\theta(t-s)}(|U|_{L^2}^2 + \dot{\delta}^2)(s)ds. \tag{1.8}$$

Inequality (1.8), expressing exponential damping of high frequencies, improves the weaker bound

$$|U|_{H^2}^2(t) + \int_0^t |U_x|_{H^1}^2(s)ds \le C(\zeta^2 + |U_0|_{H^2}^2) + C\int_0^t (|U|_{H^1}^2 + \dot{\delta}^2)(s)ds \tag{1.9}$$

stated for the small-amplitude case in [24]. As discussed in [39, 40] in the context of real viscosity systems, both bounds follow from the same string of energy estimates; similar inequalities hold in the real viscosity case.

With estimate (1.9), Theorem 1.2 follows for high norms L^p, $2 \le p \le \infty$, by exactly the same argument used in [24] to treat the small-amplitude case, for the proof of (1.9) was the single place in [24] where the small-amplitude assumption was actually used. See [24, section 7], or [27, section 4] in the real viscosity case. For completeness, we give in section 4 a simplified version of this argument based on the improved estimate (1.8) of Proposition 1.4, which suffices for low norms L^p, $1 \le p < 2$, as well.

Remark 1.5. We have here restricted our attention for simplicity to the study of Lax-type shocks. Nonclassical over- and undercompressive shocks may be treated similarly under further restrictions on the initial data; see [14, 29] for analyses in the parabolic (resp., hyperbolic–parabolic) case.

The paper is outlined as follows. In section 2, we give the preliminary lemmas needed in the analysis. In section 3, we carry out the proof of Proposition 1.4, and in section 4 we prove Theorem 1.2. Finally, in section 5, we discuss the complementary characteristic case.

2. Preliminaries. As in [27], our starting point consists of the following two lemmas.

Lemma 2.1 (see [26]). *Under assumptions* (A1)–(A2)*,* (H0)–(H2)*, standing wave solutions* (1.1) *satisfy*

$$|(d/dx)^k \bar{U} - U_\pm| \le C|\bar{U}_x| \le Ce^{-\theta|x|}, \quad k = 0, \ldots, 4, \tag{2.1}$$

as $x \to \pm\infty$*, for some* $\theta > 0$*,* $U_\pm = (u_\pm, v_\pm) = (u_\pm, v^*(u_\pm))$*.*

Proof. Equivalently, the standing-wave equations may be expressed as a nondegenerate ODE with hyperbolic rest points; see [24, proof of Lemma 1.2]. ∎

LEMMA 2.2 (see [30]). *Let A and Q denote simultaneously symmetrizable matrices and A^0 their symmetrizer, with $A^0Q \le 0$.*

Then genuine coupling (1.3) *is equivalent to one of the following conditions:*

(K0) *There exists $\theta > 0$ such that $\operatorname{Re}\sigma(i\xi A + Q) \le \frac{-\theta|\xi|^2}{1+|\xi|^2}$ for all $\xi \in \mathbb{R}$;*

(K1) *There exists a smooth skew-symmetric matrix-valued function $K(A, Q, A^0)$ such that $\operatorname{Re}\left(A^0Q - KA\right) < 0$;*

(K2) block-diag $LQR < 0$, *where $L := O^t(A^0)^{\frac{1}{2}}$ and $R := L^{-1} = (A^0)^{-\frac{1}{2}}O$ are matrices of left and right eigenvectors of A block-diagonalizing LAR, with O orthonormal. Here,* block-diag M *denotes the matrix formed from the diagonal blocks of M, with each block of dimension equal to the multiplicity of corresponding eigenvalues of LAR.*

Note that strictly dissipativity assumption (A2) corresponds to condition (K0) at the asymptotic states $(u_\pm, v^*(u_\pm))$ with respect to the matrices $A_\pm$ and $Q_\pm$.

Proof. These and other useful equivalent formulations are established in [30]. The main implication for our purposes, (K2) $\Rightarrow$ (K1), follows readily from Lemma 2.3, below, by first converting to the case of symmetric A, Q by the transformations $A \to ((A^0)^{\frac{1}{2}}AA^0)^{-\frac{1}{2}}$, $Q \to ((A^0)^{\frac{1}{2}}QA^0)^{-\frac{1}{2}}$, from which the original result follows by the fact that $M > 0 \Leftrightarrow (A^0)^{\frac{1}{2}}M(A^0)^{\frac{1}{2}} > 0$, then converting by an orthonormal change of coordinates to the case that A is diagonal and Q symmetric. Variable multiplicity eigenvalues may be handled by partition of unity/interpolation, noting that $\operatorname{Re}(Q - KA) < 0$ persists under perturbation.

Under the assumed symmetry of LQR, (K0) $\Rightarrow$ (K2) follows by Taylor expansion at infinity of the spectrum of the symbol $i\xi A + Q$, from which we may deduce

$$\operatorname{Re}\sigma(\text{ block-diag}\, LQR) < 0;$$

see, e.g., [24, Appendix B]. That (K1) $\Rightarrow$ (K0) follows upon rearrangement of energy estimate

$$\langle (A^0 + |\xi|^2 A^0 - i\xi K)w, (\lambda + i\xi A + |\xi|^2 B)w\rangle = 0.$$

Finally, (K2) $\Leftrightarrow$ (1.3) is clear. ∎

For our purposes, we shall require the following slight extension of Lemma 2.2, whose proof gives at the same time an explicit description of K of which we shall later make important use. We note that an equivalent version of this result was obtained independently and previously to ours by Humpherys [15].

LEMMA 2.3. *Let D be diagonal, with real entries appearing with prescribed multiplicity in order of increasing size, and let Q be arbitrary. Then there exists a smooth skew-symmetric matrix-valued function $K(D, Q)$ such that*

$$\operatorname{Re}\,(Q - KD) = \operatorname{Re}\text{block-diag}\, Q,$$

where block-diag Q *denotes the block-diagonal part of Q, with blocks of dimension equal to the multiplicity of the corresponding eigenvalues of D.*

Proof. It is straightforward to check that the symmetric matrix $\operatorname{Re} KD = (\frac{1}{2})(KD - D^tK)$ may be prescribed arbitrarily on off-diagonal blocks by setting $K_{ij} := (a_i - a_j)^{-1}M_{ij}$, where M_{ij} is the desired block, $i \ne j$. Choosing $M = \operatorname{Re} Q$, we obtain $\operatorname{Re}(Q - KD) = \operatorname{Re}$ block-diag (Q) as claimed. ∎

We shall also need the following two elementary results.

LEMMA 2.4. *Given* (A2)*, there exist block-diagonalizing matrices* $L_\pm$*,* $R_\pm$*,* $LAR_\pm$ *block-diagonal,* $LR_\pm = I$*, such that*

$$\text{block-diag}\, LQR_\pm < 0.$$

(Note: A and Q are not assumed simultaneously symmetrizable as in Lemma 2.2.)

Proof. Again, $\operatorname{Re}\sigma(\text{block-diag}\, \tilde{L}Q\tilde{R}_\pm) < 0$ follows from (A2) by Taylor expansion at infinity of the spectrum of the symbol $i\xi A_\pm + Q_\pm$ for any block-diagonalizing transformations $\tilde{L}_\pm$, $\tilde{R}_\pm$; see [24, Appendix B]. By a standard linear-algebraic lemma (see, e.g., [31, Proposition A.9, p. 361]), $\text{block-diag}\, S^{-1}\tilde{L}Q\tilde{R}S_\pm < 0$, $S_\pm := \text{block-diag}\,\{S_1, \dots, S_k\}_\pm$ for some choice of nonsingular $S_j^\pm$. Taking $L_\pm := S^{-1}\tilde{L}_\pm$, $R_\pm := \tilde{R}S_\pm$, and we are done. □

LEMMA 2.5. *There is a correspondence between symmetric positive definite symmetrizers* A^0*,* A^0A *symmetric, and diagonalizing transformations* L*,* R*,* LAR *diagonal, given by* $A^0 = L^*L$*, or equivalently* $L = O^*(A^0)^{\frac{1}{2}}$*, where* O *is an orthonormal matrix diagonalizing the symmetric matrix* $(A^0)^{\frac{1}{2}}A(A^0)^{-\frac{1}{2}}$*.*

Moreover, the matrix O (*or equivalently* L) *may be chosen with the same degree of smoothness as* A^0 *on any simply connected domain.*

Proof. The first assertion follows by direct calculation. The second is clear in the strictly hyperbolic case, for which the correspondence is also one-to-one; in the general (constant-multiplicity) case, it follows by a standard lemma of Kato [18]. □

Remark 2.6. Lemma 2.5 hints at the strategy we shall follow in carrying out energy estimates, which is to "effectively diagonalize" by the use of a symmetrizer. That is, rather than working with LAR as we should like, we work with $A^0A = L^*LA = L^*(LAR)L$, thereby avoiding the problem that there may exist a nonlinear change of coordinates with Jacobian L. Conjugation by L of course does not affect the energy estimates.

Finally, for convenience of the reader, we recall the standard relations

$$\langle W, SW_x\rangle = -\frac{1}{2}\langle W, S_xW\rangle \tag{2.2}$$

and

$$\frac{1}{2}\langle W_x, KW\rangle_t = \langle W_x, KW_t\rangle + \frac{1}{2}\langle W_x, K_tW\rangle + \frac{1}{2}\langle W, K_xW_t\rangle, \tag{2.3}$$

valid, respectively, for symmetric S and skew-symmetric K.

3. Energy estimates. In this section, we carry out the main work of the paper, establishing Proposition 1.4.

Perturbation equation. Define the nonlinear perturbation $U(x,t) := \tilde{U}(x+\delta(t), t) - \bar{U}(x)$ as in (1.7), where $\delta(t)$ (estimating shock location) is to be determined later; for definiteness, fix $\delta(0) = 0$. Substituting (1.7) into (1.2), we obtain

$$\tilde{U}_t + \tilde{A}\tilde{U}_x - \begin{pmatrix} 0 \\ q \end{pmatrix}(\tilde{U}) = \dot{\delta}\tilde{U}_x,$$

where $\tilde{A} := (df, dg)^t(\tilde{u}, \tilde{v})$, and thereby

$$(\tilde{U} - \bar{U})_t + (\tilde{A}\tilde{U}_x - \bar{A}\bar{U}_x) - \left(\begin{pmatrix} 0 \\ q \end{pmatrix}(\tilde{U}) - \begin{pmatrix} 0 \\ q \end{pmatrix}(\bar{U})\right) = \dot{\delta}(t)\tilde{U}_x,$$

where $\tilde{U}$ now denotes $\tilde{U}(x + \delta(t), t)$ and $\bar{U}$ denotes $\bar{U}(x)$.

Expanding $(\tilde{A}\tilde{U}_x - \bar{A}\bar{U}_x)$ using the quadratic Leibniz relation

$$\tilde{A}\tilde{U}_x - \bar{A}\bar{U}_x = \tilde{A}(\tilde{U}_x - \bar{U}_x) + (\tilde{A} - \bar{A})\bar{U}_x,$$

and Taylor expanding $(\binom{0}{q}(\tilde{U}) - \binom{0}{q}(\bar{U}))$ about $\tilde{U}$, we obtain the basic nonlinear perturbation equation

$$U_t - \tilde{A}U_x - \tilde{Q}U = M_1(U)\bar{U}_x + (0, I_r)^t M_2(U) + \dot{\delta}(t)(\bar{U}_x + U_x), \tag{3.1}$$

where $\tilde{Q} := (0, dq)^t(\tilde{u}, \tilde{v})$ and

$$\begin{aligned} M_1(U) &= \mathcal{O}(|U|) := \tilde{A}(x,t) - \bar{A}(x), \\ M_2(U) &= \mathcal{O}(|U|^2) := \begin{pmatrix} 0 \\ q \end{pmatrix}(\tilde{U}) - \begin{pmatrix} 0 \\ q \end{pmatrix}(\bar{U}) - \tilde{Q}(\tilde{U} - \bar{U}). \end{aligned}$$

Weighting matrix. Let $\tilde{A}^0 := A^0(\tilde{U})$ denote the symmetrizer of $\tilde{A}$ guaranteed by (A1), and factor $\tilde{A}^0\tilde{A} = (\tilde{A}^0)^{\frac{1}{2}}\tilde{O}\tilde{D}\tilde{O}^t(\tilde{A}^0)^{\frac{1}{2}}$, or, equivalently,

$$\tilde{A} = (\tilde{A}^0)^{-\frac{1}{2}}\tilde{O}\tilde{D}\tilde{O}^t(\tilde{A}^0)^{\frac{1}{2}}, \tag{3.2}$$

where $\tilde{O}$ is orthogonal, $\tilde{O}^t = \tilde{O}^{-1}$, and C^3 is a function of (u, v) (see Lemma 2.5) and $\tilde{D} =$ block-diag$\{\tilde{a}_1, \ldots, \tilde{a}_l\}$, where $\tilde{a}_j$ denote the eigenvalues of $\tilde{A}$, indexed in increasing order

$$\tilde{a}_1 \leq \cdots \leq \tilde{a}_k < 0 < \tilde{a}_{k+1} \leq \cdots \leq \tilde{a}_l.$$

Define the "Goodman-type" [12] weighting matrix $\alpha(x) :=$ block-diag$\{\alpha_1, \ldots, \alpha_l\}$, where $\alpha_j > 0$ are defined by ODE

$$\alpha_x = C_* \mathrm{sgn}\, a_j |\bar{U}_x|\, \alpha, \qquad \alpha(0) = 1,$$

with $C_* > 0$ a sufficiently large constant to be determined later. This definition, together with $|a_j| > 0$, (H2)(i), gives the key inequality

$$\alpha_x \bar{D} \geq \theta_1 C_* |\bar{U}_x| \alpha, \tag{3.3}$$

where $\bar{D} =$ block-diag$\{\bar{a}_1, \ldots, \bar{a}_l\}$ and $\bar{a}_j$ are the eigenvalues of $\bar{A}$.

Setting

$$\tilde{A}^0_\alpha := (\tilde{A}^0)^{\frac{1}{2}}\tilde{O}\,\alpha\,\tilde{O}^t(\tilde{A}^0)^{\frac{1}{2}}, \tag{3.4}$$

we have by factorization (3.2) that

$$\tilde{A}^0_\alpha\tilde{A} = [(\tilde{A}^0)^{\frac{1}{2}}\tilde{O}\,\alpha\,\tilde{O}^t(\tilde{A}^0)^{\frac{1}{2}}]\tilde{A} = (\tilde{A}^0)^{\frac{1}{2}}\tilde{O}(\alpha\tilde{D})\tilde{O}^t(\tilde{A}^0)^{\frac{1}{2}}. \tag{3.5}$$

Hence, $\tilde{A}^0_\alpha\tilde{A}$ is symmetric and the symmetric positive definite matrix $\tilde{A}^0_\alpha$ is also a viable symmetrizer for $\tilde{A}$.

Moreover, setting $L := \tilde{O}^t(\tilde{A}^0)^{\frac{1}{2}}$ and $R := (\tilde{A}^0)^{-\frac{1}{2}}\tilde{O}$, by Lemma 2.5 and constant multiplicity of eigenvalues of A, we have the freedom to smoothly (C^3) redefine L and R so that they take on prescribed values at $x \to \pm\infty$. Thus, by Lemma 2.4, we may assume without loss of generality that

$$\mathrm{Re}\ \text{block-diag}\left(\alpha\tilde{O}^t(\tilde{A}^0)^{\frac{1}{2}}\tilde{Q}(\tilde{A}^0)^{-\frac{1}{2}}\tilde{O}\right)_\pm \leq -\theta(C_*) < 0,$$

and thereby, appealing to (2.1), $k=0$,

$$\mathrm{Re}\ \text{block-diag}\big(\alpha\tilde O^t(\tilde A^0)^{\frac12}\tilde Q(\tilde A^0)^{-\frac12}\tilde O\big)\le -\theta(C_*)+C(C_*)\zeta+C|\bar U_x|\alpha, \tag{3.6}$$

where

$$\tilde A^0_\alpha\tilde Q=(\tilde A^0)^{\frac12}\tilde O\big[\alpha\,\tilde O^t(\tilde A^0)^{\frac12}\tilde Q(\tilde A^0)^{-\frac12}\tilde O\big]\tilde O^t(\tilde A^0)^{\frac12},$$

and the exponent θ now refers to the minimum of the constants used elsewhere in the argument and that appear in (2.1). The constants $\theta(C_*)$ and $C(C_*)$ measure the conditioning of matrices α and in fact decay (resp., grow) exponentially with respect to C_*; however, this is unimportant for our argument.

Define

$$K_1:=K\big(\tilde D,\alpha\,\tilde O^t(\tilde A^0)^{\frac12}\tilde Q(\tilde A^0)^{-\frac12}\tilde O+N\big),$$

where $K(\cdot)$ is as in Lemma 2.3, and N is *an arbitrary matrix with* $|N|_{C^1_{x,t}}\le C(C_*)$ *and vanishing on diagonal blocks*, to be determined later. Moreover, let $\tilde K_\alpha$ be the skew-symmetric matrix obtained from K_1 after conjugation by $(\tilde A^0)^{\frac12}\tilde O$, i.e.,

$$\tilde K_\alpha:=(\tilde A^0)^{\frac12}\tilde O K_1\tilde O^t(\tilde A^0)^{\frac12}.$$

For later use, note that, through smooth dependence on $\tilde U=\bar U+U$ and N,

$$|\tilde K_{\alpha,x}|,|\tilde K_{\alpha,t}|\le C(C_*). \tag{3.7}$$

We have, therefore,

$$\begin{aligned}&\mathrm{Re}(-\tilde K_\alpha\tilde A+\tilde A^0_\alpha\tilde Q+(\tilde A^0)^{\frac12}\tilde O N\tilde O^t(\tilde A^0)^{\frac12})\\&\quad=\mathrm{Re}\,(\tilde A^0)^{\frac12}\tilde O\big(-K_1\tilde D+\alpha\,\tilde O^t(\tilde A^0)^{\frac12}\tilde Q(\tilde A^0)^{-\frac12}\tilde O+N\big)\tilde O^t(\tilde A^0)^{\frac12}\\&\quad=\mathrm{Re}\,(\tilde A^0)^{\frac12}\tilde O\,\text{block-diag}\big(\alpha\,\tilde O^t(\tilde A^0)^{\frac12}\tilde Q(\tilde A^0)^{-\frac12}\tilde O\big)\tilde O^t(\tilde A^0)^{\frac12}\\&\quad\le-\theta(C_*)+C(C_*)\zeta+C|\bar U_x|\,\tilde A^0_\alpha\end{aligned} \tag{3.8}$$

by (3.6) together with Lemma 2.3. By (3.3), we have also

$$\begin{aligned}(\tilde A^0)^{\frac12}\tilde O(\alpha_x\tilde D)\tilde O^t(\tilde A^0)^{\frac12}&\ge(\tilde A^0)^{\frac12}\tilde O(\alpha_x\bar D)\tilde O^t(\tilde A^0)^{\frac12}-C(C_*)\,\zeta\\&\ge\theta C_*|\bar U_x|\tilde A^0_\alpha-C(C_*)\,\zeta\end{aligned} \tag{3.9}$$

for possibly still smaller $\theta>0$ (with ζ as defined in the statement of Proposition 1.4).

Friedrichs-type estimate. As in [24], we first perform a standard "Friedrichs-type" estimate for symmetric hyperbolic systems (see [8, 9]), now incorporating the weight α.

Differentiating (3.1) twice with respect to x, we obtain

$$U_{xxt}-(\tilde AU_x)_{xx}-(\tilde QU)_{xx}=(M(U)\bar U_x)_{xx}+(0,I_r)^tM_2(U)_{xx}+\dot\delta(t)(\bar U_{xxx}+U_{xxx}). \tag{3.10}$$

Taking the L^2 inner product $\tilde A^0_\alpha U_{xx}$ against U_{xxt}, we get

$$\frac12\langle\tilde A^0_\alpha U_{xx},U_{xx}\rangle_t=\langle\tilde A^0_\alpha U_{xx},U_{xxt}\rangle+\frac12\langle(\tilde A^0_\alpha)_tU_{xx},U_{xx}\rangle, \tag{3.11}$$

where $\tilde A^0_\alpha$ is defined in (3.4).

The second term can be easily bounded: indeed, using (3.1),

$$|(\tilde{A}^0_\alpha)_t|_{L^\infty} = \left|\frac{dA^0_\alpha}{d\tilde{U}}\right| |\tilde{U}_t| = \left|\frac{dA^0_\alpha}{d\tilde{U}}\right| |U_t| \le C(C_*)[|U|_{W^{1,\infty}} + |\dot{\delta}(t)|(|\bar{U}_x|_{L^\infty} + |U_x|_{L^\infty})],$$

and hence

$$\frac{1}{2}\langle (\tilde{A}^0_\alpha)_t U_{xx}, U_{xx}\rangle \le C(C_*)\,\zeta\,|U_{xx}|^2_{L^2} \tag{3.12}$$

(with ζ as defined in the statement of Proposition 1.4).

Let us consider the first term on the right-hand side of (3.11)

$$\begin{aligned}\langle \tilde{A}^0_\alpha U_{xx}, U_{xxt}\rangle &= \langle \tilde{A}^0_\alpha U_{xx}, (\tilde{A}U_x)_{xx}\rangle + \langle \tilde{A}^0_\alpha U_{xx}, (\tilde{Q}U)_{xx}\rangle \\ &\quad + \langle \tilde{A}^0_\alpha U_{xx}, (M_1(U)\bar{U}_x)_{xx}\rangle + \langle \tilde{A}^0_\alpha U_{xx}, (0, I_r)^t M_2(U)_{xx}\rangle \\ &\quad + \dot{\delta}(t)\,\langle \tilde{A}^0_\alpha U_{xx}, \bar{U}_{xxx} + U_{xxx}\rangle.\end{aligned} \tag{3.13}$$

Differentiating the first of the terms in (3.13), we get

$$\langle \tilde{A}^0_\alpha U_{xx}, (\tilde{A}U_x)_{xx}\rangle = \langle \tilde{A}^0_\alpha U_{xx}, \tilde{A}_{xx}U_x\rangle + 2\langle \tilde{A}^0_\alpha U_{xx}, \tilde{A}_x U_{xx}\rangle + \langle \tilde{A}^0_\alpha U_{xx}, \tilde{A}U_{xxx}\rangle. \tag{3.14}$$

Since

$$\begin{aligned}\tilde{A}_x &= \frac{d\tilde{A}}{d\tilde{U}}(\bar{U}_x + U_x),\\ \tilde{A}_{xx} &= \frac{d^2\tilde{A}}{d\tilde{U}^2}\,(\bar{U}_x\,\bar{U}_x + \bar{U}_x\,U_x + U_x\,\bar{U}_x + U_x\,U_x) + \frac{d\tilde{A}}{d\tilde{U}}\,(\bar{U}_{xx} + U_{xx}),\end{aligned}$$

the first two terms of (3.14) are bounded by

$$\begin{aligned}&\langle \tilde{A}^0_\alpha U_{xx}, \tilde{A}_{xx}U_x\rangle + 2\langle \tilde{A}^0_\alpha U_{xx}, \tilde{A}_x U_{xx}\rangle \le C(C_*)\,(\zeta + \bar{\zeta})\,|U_{xx}|^2_{L^2} \\ &\quad + C(C_*, \bar{\zeta})\,|U_x|^2_{L^2} + \left\langle \tilde{A}^0_\alpha U_{xx}, \frac{d\tilde{A}}{d\tilde{U}}\,\bar{U}_x\,U_{xx}\right\rangle;\end{aligned} \tag{3.15}$$

here, we have used Young's inequality to bound $\langle U_x, U_{xx}\rangle$ with $\bar{\zeta}|U_{xx}|^2_{L^2} + C|U_x|^2_{L^2}$, with $\bar{\zeta} > 0$ chosen such that $\zeta \ll \bar{\zeta} \ll 1$.

Using the symmetry of $\tilde{A}^0_\alpha$ and (2.2) with $S = \tilde{A}^0_\alpha\tilde{A}$, we find that the last term of (3.14) takes the form

$$\langle \tilde{A}^0_\alpha U_{xx}, \tilde{A}U_{xxx}\rangle = \langle U_{xx}, \tilde{A}^0_\alpha\tilde{A}\,U_{xxx}\rangle = -\frac{1}{2}\,\langle U_{xx}, (\tilde{A}^0_\alpha\tilde{A})_x U_{xx}\rangle. \tag{3.16}$$

Recalling (3.5), we have

$$(\tilde{A}^0_\alpha\tilde{A})_x = \frac{d\,(\tilde{A}^0_\alpha\tilde{A})}{d\tilde{U}}(\bar{U}_x + U_x) + (\tilde{A}^0)^{\frac{1}{2}}\tilde{O}\,(\alpha_x\tilde{D})\,\tilde{O}^t(\tilde{A}^0)^{\frac{1}{2}},$$

where, with slight abuse of notation,

$$\frac{d\,(\tilde{A}^0_\alpha\tilde{A})}{d\tilde{U}}\,W = \frac{d\,((\tilde{A}^0)^{\frac{1}{2}}\tilde{O})}{d\tilde{U}}\,W\,\alpha\,\tilde{D}\,\tilde{O}^t(\tilde{A}^0)^{\frac{1}{2}} + (\tilde{A}^0)^{\frac{1}{2}}\tilde{O}\,\alpha\,\frac{d\,(\tilde{D}\,\tilde{O}^t(\tilde{A}^0)^{\frac{1}{2}})}{d\tilde{U}}\,W. \tag{3.17}$$

Hence, we get

$$\begin{aligned}\langle \tilde A^0_\alpha U_{xx}, \tilde A U_{xxx}\rangle &\le -\frac{1}{2}\,\langle U_{xx}, (\tilde A^0)^{\frac12}\,\tilde O\,(\alpha_x \tilde D)\,\tilde O^t (\tilde A^0)^{\frac12} U_{xx}\rangle \\ &\quad + C(C_*)\,\zeta\,|U_{xx}|^2_{L^2} - \frac{1}{2}\left\langle U_{xx}, \frac{d\,(\tilde A^0_\alpha \tilde A)}{d\tilde U}\,\bar U_x\, U_{xx}\right\rangle.\end{aligned} \tag{3.18}$$

Summarizing, the first term on the right-hand side of (3.13) can be estimated by

$$\begin{aligned}\langle \tilde A^0_\alpha U_{xx}, (\tilde A U_x)_{xx}\rangle &\le C(C_*)\,(\zeta+\bar\zeta)\,|U_{xx}|^2_{L^2} + C(C_*,\bar\zeta)\,|U_x|^2_{L^2} \\ &\quad + \left\langle \tilde A^0_\alpha U_{xx}, \frac{d\tilde A}{d\tilde U}\,\bar U_x\, U_{xx}\right\rangle - \frac{1}{2}\,\langle U_{xx}, (\tilde A^0)^{\frac12}\,\tilde O\,(\alpha_x \tilde D)\,\tilde O^t (\tilde A^0)^{\frac12} U_{xx}\rangle \\ &\quad - \frac{1}{2}\left\langle U_{xx}, \frac{d\,(\tilde A^0_\alpha \tilde A)}{d\tilde U}\,\bar U_x\, U_{xx}\right\rangle.\end{aligned} \tag{3.19}$$

The second term in (3.13) can be dealt with similarly: since

$$\tilde Q_x = \frac{d\tilde Q}{d\tilde U}\,(\bar U_x + U_x), \quad \tilde Q_{xx} = \frac{d^2\tilde Q}{d\tilde U^2}\,(\bar U_x\,\bar U_x + \bar U_x\,U_x + U_x\,\bar U_x + U_x\,U_x) + \frac{d\tilde Q}{d\tilde U}\,(\bar U_{xx} + U_{xx}),$$

we have

$$\begin{aligned}\langle \tilde A^0_\alpha U_{xx}, (\tilde Q U)_{xx}\rangle &= \langle \tilde A^0_\alpha U_{xx}, \tilde Q_{xx} U\rangle + 2\langle \tilde A^0_\alpha U_{xx}, \tilde Q_x U_x\rangle + \langle \tilde A^0_\alpha U_{xx}, \tilde Q U_{xx}\rangle \\ &\le C(C_*)\,(\zeta+\bar\zeta)\,|U_{xx}|^2_{L^2} + C(C_*,\bar\zeta)\,|U|^2_{H^1} + \langle \tilde A^0_\alpha U_{xx}, \tilde Q U_{xx}\rangle,\end{aligned} \tag{3.20}$$

with $\bar\zeta$ as in the previous case.

The third term in (3.13) can be estimated by

$$\begin{aligned}\langle \tilde A^0_\alpha U_{xx}, (M_1(U)\bar U_x)_{xx}\rangle &\le C(C_*)\,\bar\zeta\,|U_{xx}|^2_{L^2} + C(C_*,\bar\zeta)\,|U|^2_{H^1} \\ &\qquad + \left\langle \tilde A^0_\alpha U_{xx}, \frac{dM_1}{dU}\,U_{xx}\,\bar U_x\right\rangle.\end{aligned} \tag{3.21}$$

The fourth term in (3.13) is easier: since

$$M_2(U)_{xx} = \frac{d^2 M_2}{dU^2}\,U_x\,U_x + \frac{dM_2}{dU}\,U_{xx},$$

we have (recall that $M_2(U) = \mathcal{O}(|U|^2)$)

$$\langle \tilde A^0_\alpha U_{xx}, (0, I_r)^t\, M_2(U)_{xx}\rangle \le C(C_*)\,\bar\zeta\,|U_{xx}|^2_{L^2} + C(C_*,\bar\zeta)\,|U_x|^2_{L^2}. \tag{3.22}$$

Finally, we estimate the last term in (3.13): $\dot\delta(t)\,\langle \tilde A^0_\alpha U_{xx}, \bar U_{xxx} + U_{xxx}\rangle$. Since

$$\dot\delta(t)\,\langle \tilde A^0_\alpha U_{xx}, \bar U_{xxx}\rangle \le C(C_*)|\dot\delta(t)|\,|U_{xx}|_{L^2} \le C(C_*)\,\bar\zeta\,|U_{xx}|^2_{L^2} + C(C_*,\bar\zeta)|\dot\delta(t)|^2$$

and, using (2.2) with $S = \tilde A^0_\alpha$,

$$\dot\delta(t)\,\langle \tilde A^0_\alpha U_{xx}, U_{xxx}\rangle = -\frac{1}{2}\dot\delta(t)\,\langle U_{xx}, (\tilde A^0_\alpha)_x U_{xx}\rangle \le C(C_*)\,\zeta\,|U_{xx}|^2_{L^2},$$

we have

$$\dot\delta(t)\,\langle \tilde A^0_\alpha U_{xx}, \bar U_{xxx}+U_{xxx}\rangle \le C(C_*)\,\zeta\,|U_{xx}|^2_{L^2}+C(C_*)|\dot\delta(t)|. \tag{3.23}$$

Collecting (3.12), (3.19), (3.20), (3.21), (3.22), and (3.23), we get

$$\begin{aligned}\frac12\langle \tilde A^0_\alpha U_{xx},U_{xx}\rangle_t \le{}& -\frac12\,\langle U_{xx},(\tilde A^0)^{\frac12}\tilde O\,(\alpha_x\tilde D)\,\tilde O^t(\tilde A^0)^{\frac12}U_{xx}\rangle+\langle U_{xx},\tilde A^0_\alpha\tilde Q U_{xx}\rangle\\ &-\frac12\left\langle U_{xx},\frac{d\,(\tilde A^0_\alpha\tilde A)}{d\tilde U}\,\bar U_x\,U_{xx}\right\rangle+\left\langle U_{xx},\tilde A^0_\alpha\left(\frac{d\tilde A}{d\tilde U}\,\bar U_x\,U_{xx}+\frac{dM_1}{dU}\,U_{xx}\,\bar U_x\right)\right\rangle\\ &+C(C_*)\,(\zeta+\bar\zeta)\,|U_{xx}|^2_{L^2}+C(C_*,\bar\zeta)\,(|U|^2_{H^1}+|\dot\delta(t)|^2).\end{aligned}\tag{3.24}$$

Let us consider the term in (3.24) containing $\frac{d\,(\tilde A^0_\alpha\tilde A)}{d\tilde U}$. By (3.17),

$$\begin{aligned}\left\langle U_{xx},\frac{d\,(\tilde A^0_\alpha\tilde A)}{d\tilde U}\,\bar U_x\,U_{xx}\right\rangle &= s\left\langle U_{xx},\frac{d\,((\tilde A^0)^{\frac12}\tilde O)}{d\tilde U}\,\bar U_x\,\alpha\,\tilde D\,\tilde O^t(\tilde A^0)^{\frac12}\,U_{xx}\right\rangle\\ &\quad+\left\langle U_{xx},(\tilde A^0)^{\frac12}\tilde O\,\alpha\,\frac{d\,(\tilde D\,\tilde O^t(\tilde A^0)^{\frac12})}{d\tilde U}\,\bar U_x\,U_{xx}\right\rangle\\ &=\langle U_{xx},(\tilde A^0)^{\frac12}\tilde O\,P_1\,\alpha\,\tilde O^t(\tilde A^0)^{\frac12}\,U_{xx}\rangle\\ &\quad+\langle U_{xx},(\tilde A^0)^{\frac12}\tilde O\,\alpha\,P_2\,\tilde O^t(\tilde A^0)^{\frac12}\,U_{xx}\rangle,\end{aligned}$$

where

$$P_1=\tilde O^t\,(\tilde A^0)^{-\frac12}\,\frac{d\,((\tilde A^0)^{\frac12}\tilde O)}{d\tilde U}\,\bar U_x\,\tilde D\quad\text{and}\quad P_2=\frac{d\,(\tilde D\,\tilde O^t(\tilde A^0)^{\frac12})}{d\tilde U}\,\bar U_x\,(\tilde A^0)^{-\frac12}\,\tilde O.$$

Similarly,

$$\left\langle U_{xx},\tilde A^0_\alpha\left(\frac{d\tilde A}{d\tilde U}\,\bar U_x\,U_{xx}+\frac{dM_1}{dU}\,U_{xx}\,\bar U_x\right)\right\rangle=\langle U_{xx},(\tilde A^0)^{\frac12}\tilde O\,\alpha\,P_3\tilde O^t(\tilde A^0)^{\frac12}\,U_{xx}\rangle,$$

where

$$P_3=\tilde O^t(\tilde A^0)^{\frac12}\,\left(\frac{d\tilde A}{d\tilde U}+\frac{dM_1}{dU}\right)\,\bar U_x.$$

The terms

$$-\frac12\langle U_{xx},(\tilde A^0)^{\frac12}\tilde O\,P_1\,\alpha\,\tilde O^t(\tilde A^0)^{\frac12}\,U_{xx}\rangle+\left\langle U_{xx},(\tilde A^0)^{\frac12}\tilde O\,\alpha\,\left(P_3-\frac12\,P_2\right)\,\tilde O^t(\tilde A^0)^{\frac12}\,U_{xx}\right\rangle$$

can be rewritten as the sum of two terms, one taking into account "off-block-diagonal" parts (meaning off-block-diagonal after conjugation by $(\tilde A^0)^{\frac12}\tilde O$) and the other taking into account "block-diagonal" parts. We denote the first one as

$$\langle U_{xx},(\tilde A^0)^{\frac12}\tilde O N\tilde O^t(\tilde A^0)^{\frac12}U_{xx}\rangle,$$

where $|N|_{C^1(x,t}\le C(C_*)$ indeed holds, since N by definition is of form $J(\tilde U,\alpha,\bar U_x)$ with $J(\cdot)$ smooth, and $|\tilde U|_{C^1(x,t)}\le C\zeta$, $|\alpha|_{C^1(x,t)}\le C_*\sup|\alpha|\le C(C_*)$. The "block-diagonal" parts (meaning block-diagonal after conjugation by $(\tilde A^0)^{\frac12}\tilde O$) of these error terms may be estimated by $C\,\langle U_{xx}, |\bar U_x|\,\tilde A^0_\alpha\, U_{xx}\rangle$ for some constant $C>0$ (independent of α, C_*).

Hence, we get the final form of the Friedrichs-type estimate:

$$\begin{aligned}\frac12\langle \tilde A^0_\alpha U_{xx}, U_{xx}\rangle_t \le &-\frac12\,\langle U_{xx}, (\tilde A^0)^{\frac12}\,\tilde O\,(\alpha_x \tilde D)\,\tilde O^t(\tilde A^0)^{\frac12} U_{xx}\rangle + \langle U_{xx}, \tilde A^0_\alpha \tilde Q U_{xx}\rangle\\ &+\langle U_{xx}, (\tilde A^0)^{\frac12}\tilde O N \tilde O^t (\tilde A^0)^{\frac12} U_{xx}\rangle + C\langle U_{xx}, |\bar U_x|\,\tilde A^0_\alpha U_{xx}\rangle\\ &+C(C_*)\,(\zeta+\bar\zeta)\,|U_{xx}|^2_{L^2} + C(C_*,\bar\zeta)\,(|U|^2_{H^1}+|\dot\delta(t)|^2).\end{aligned}\tag{3.25}$$

Remark 3.1. The treatment of error term N, above, we regard as the most delicate and novel aspect of our argument. Without complete cancellation of off-diagonal terms, we see no way that such a "Goodman-type" estimate can close, due to exponential growth in C_* of $\sup|\alpha|$.

Kawashima-type estimate. Next, we perform a "Kawashima-type" estimate of the type formalized in [17]. Applying (2.3) to $W = U_x$ and $K = \tilde K_\alpha$,

$$\frac12\langle U_{xx}, \tilde K_\alpha U_x\rangle_t = \langle U_{xx}, \tilde K_\alpha U_{xt}\rangle + \frac12\langle U_{xx}, (\tilde K_\alpha)_t U_x\rangle + \frac12\langle U_x, (\tilde K_\alpha)_x U_{xt}\rangle.\tag{3.26}$$

Thanks to (3.7) and to Young's inequality, the second term is easily bounded by

$$\frac12\langle U_{xx}, (\tilde K_\alpha)_t U_x\rangle \le C\,\bar\zeta\,|U_{xx}|^2_{L^2} + C(\bar\zeta, C_*)\,|U_x|^2_{L^2},\tag{3.27}$$

with $\bar\zeta$ as previously chosen.

Differentiating (3.1) with respect to x, we obtain

$$U_{xt} + (\tilde A U_x)_x - (\tilde Q U)_x = (M_1(U)\bar U_x)_x + (0, I_r)^t M_2(U)_x + \dot\delta(t)(\bar U_{xx} + U_{xx}),\tag{3.28}$$

and hence (twice) the last term in (3.26) can be rewritten as

$$\begin{aligned}\langle U_x, (\tilde K_\alpha)_x U_{xt}\rangle = &-\left\langle U_x, (\tilde K_\alpha)_x \frac{d\tilde A}{d\tilde U}(\bar U_x + U_x)\,U_x\right\rangle - \langle U_x, (\tilde K_\alpha)_x \tilde A U_{xx}\rangle\\ &+\left\langle U_x, (\tilde K_\alpha)_x \frac{d\tilde Q}{d\tilde U}(\bar U_x + U_x)\,U_x\right\rangle + \langle U_x, (\tilde K_\alpha)_x \tilde Q\,U_x\rangle\\ &+\left\langle U_x, (\tilde K_\alpha)_x \frac{dM_1}{dU}\,U_x\,\bar U_x\right\rangle + \langle U_x, (\tilde K_\alpha)_x M_1(U)\bar U_{xx}\rangle\\ &+\left\langle U_x, (\tilde K_\alpha)_x (0, I_r)^t\frac{dM_2}{dU}\,U_x\right\rangle + \dot\delta(t)\langle U_x, (\tilde K_\alpha)_x(\bar U_{xx} + U_{xx})\rangle.\end{aligned}$$

All of the terms not containing U_{xx} can be estimated by $C(C_*)(|U|^2_{H^1} + |\dot\delta(t)|^2)$ (having used once more (3.7)). For the remaining terms,

$$-\langle U_x, (\tilde K_\alpha)_x \tilde A U_{xx}\rangle + \dot\delta(t)\langle U_x, (\tilde K_\alpha)_x\, U_{xx}\rangle \le C\,\bar\zeta\,|U_{xx}|^2_{L^2} + C(C_*,\bar\zeta)\,|U_x|^2_{L^2}.$$

Hence,

$$\frac12\langle U_x, (\tilde K_\alpha)_x U_{xt}\rangle \le C\,\bar\zeta\,|U_{xx}|^2_{L^2} + C(C_*,\bar\zeta)(|U|^2_{H^1} + |\dot\delta(t)|^2).\tag{3.29}$$

Inserting (3.28), the first term on the right-hand side of (3.26) becomes

$$\begin{aligned}\langle U_{xx}, \tilde K_\alpha U_{xt}\rangle = &-\left\langle U_{xx}, \tilde K_\alpha \frac{d\tilde A}{d\tilde U}(\bar U_x + U_x)\, U_x\right\rangle - \langle U_{xx}, \tilde K_\alpha\, \tilde A U_{xx}\rangle\\ &+\left\langle U_{xx}, \tilde K_\alpha \frac{d\tilde Q}{d\tilde U}(\bar U_x + U_x)\, U_x\right\rangle + \langle U_{xx}, \tilde K_\alpha\, \tilde Q\, U_x\rangle\\ &+\left\langle U_{xx}, \tilde K_\alpha \frac{dM_1}{dU}\, U_x\, \bar U_x\right\rangle + \langle U_{xx}, \tilde K_\alpha\, M_1(U)\bar U_{xx}\rangle\\ &+\left\langle U_{xx}, \tilde K_\alpha\, (0, I_r)^t \frac{dM_2}{dU}\, U_x\right\rangle + \dot\delta(t)\langle U_{xx}, (\tilde K_\alpha)_x(\bar U_{xx} + U_{xx})\rangle.\end{aligned}$$

The terms containing at least one of $U_x, U, \dot\delta$ can be estimated (applying Young's inequality) by $C(\bar\zeta + \zeta)|U_{xx}|^2_{L^2} + C(\bar\zeta, C_*)(|U|^2_{H^1} + |\dot\delta(t)|^2)$; hence,

$$\begin{aligned}\langle U_{xx}, \tilde K_\alpha U_{xt}\rangle \le &-\langle U_{xx}, \tilde K_\alpha\, \tilde A U_{xx}\rangle + C(\bar\zeta + \zeta)|U_{xx}|^2_{L^2}\\ &+ C(\bar\zeta, C_*)(|U|^2_{H^1} + |\dot\delta(t)|^2).\end{aligned}\tag{3.30}$$

Finally, (3.26), (3.27), (3.29), and (3.30) give

$$\begin{aligned}\frac12\langle U_{xx}, \tilde K_\alpha U_x\rangle_t \le &-\langle U_{xx}, \tilde K_\alpha\, \tilde A U_{xx}\rangle + C(\bar\zeta + \zeta)|U_{xx}|^2_{L^2}\\ &+ C(C_*, \bar\zeta)(|U|^2_{H^1} + |\dot\delta(t)|^2).\end{aligned}\tag{3.31}$$

Adding (3.25) and (3.31), we obtain

$$\begin{aligned}&\frac12(\langle \tilde A^0_\alpha U_{xx}, U_{xx}\rangle_t + \langle U_{xx}, \tilde K_\alpha U_x\rangle)_t \le -\frac12\,\langle U_{xx}, (\tilde A^0)^{\frac12}\tilde O\,(\alpha_x \tilde D)\,\tilde O^t(\tilde A^0)^{\frac12} U_{xx}\rangle\\ &\quad + C\,\langle U_{xx}, |\bar U_x|\,\tilde A^0_\alpha U_{xx}\rangle + \langle U_{xx}, (-\tilde K_\alpha\, \tilde A + \tilde A^0_\alpha \tilde Q + (\tilde A^0)^{\frac12}\tilde O N \tilde O^t(\tilde A^0)^{\frac12})\, U_{xx}\rangle\\ &\quad + C(C_*)\,(\zeta + \bar\zeta)\,|U_{xx}|^2_{L^2} + C(C_*, \bar\zeta)\,(|U|^2_{H^1} + |\dot\delta(t)|^2).\end{aligned}\tag{3.32}$$

Recalling (3.8) and (3.9), we obtain, finally,

$$\begin{aligned}&(\langle \tilde A^0 U_{xx}, U_{xx}\rangle + \langle U_{xx}, \tilde K_\alpha U_x\rangle)_t \le -\,(\theta\, C_* - C)\,\langle U_{xx}, |\bar U_x|\,\tilde A^0_\alpha\, U_{xx}\rangle\\ &\quad + (-\theta(C_*) + C(C_*)(\zeta + \bar\zeta))|U_{xx}|^2_{L^2} + C(\bar\zeta, C_*)(|U|^2_{H^1} + |\dot\delta(t)|^2)\\ &\quad \le -\frac12\theta(C_*)|U_{xx}|^2_{L^2} + C(\bar\zeta, C_*)(|U|^2_{H^1} + |\dot\delta(t)|^2),\end{aligned}\tag{3.33}$$

provided that C_* is taken sufficiently large and $\bar\zeta$, ζ sufficiently small that $C \le \theta C_*$ and $-\theta(C_*) + C(C_*)(\zeta + \bar\zeta) \le -\theta(C_*)/2$.

Given $M > 0$, let us set

$$\mathcal E(U) := \langle \tilde A^0 U_{xx}, U_{xx}\rangle + \langle U_{xx}, \tilde K_\alpha U_x\rangle + M|U|^2_{L^2}.\tag{3.34}$$

Since, for $U \in H^2$, $|U_x|_{L^2}$ can be bounded by $C\left(|U|_{L^2} + |U_{xx}|_{L^2}\right)$ for some $C > 0$, then the functional defined in (3.34) is equivalent to $|U|^2_{H^2}$ if M is large enough. Moreover, from (3.1) it follows that

$$\frac{d|U|^2_{L^2}}{dt} \le C(|U|^2_{H^1} + |\dot\delta(t)|^2).$$

Therefore,

$$\frac{d\mathcal{E}}{dt} \leq -\frac{1}{2}\theta(C_*)\,|U_{xx}|^2_{L^2} + C(|U|^2_{H^1} + |\dot{\delta}(t)|^2)$$

for some $C > 0$. Passing through the Fourier transform, it is easy to see that for $U \in H^2$ there holds

$$|U_x|^2_{L^2} \leq C|U|^2_{L^2} + \frac{1}{C}|U_{xx}|^2_{L^2} \qquad \forall\, C > 0. \tag{3.35}$$

Hence, using $\mathcal{E} \geq C|U_{xx}|^2_{L^2}$ and choosing C big enough in (3.35), we get

$$\frac{d\mathcal{E}}{dt} \leq -\theta\,\mathcal{E} + C(|U|^2_{L^2} + |\dot{\delta}(t)|^2)$$

for some $C, \theta > 0$. Multiplying by $e^{\theta t}$ and integrating in time from 0 to t, we get (1.8), and the proof of Proposition 1.4 is complete.

Remark 3.2. The energy estimate (1.9) can be deduced from (3.33) as follows. Integrating (3.33) from 0 to t yields

$$\begin{aligned}(\langle \tilde{A}^0_\alpha U_{xx}, U_{xx}\rangle + \langle U_{xx}, \tilde{K}_\alpha U_x\rangle)|_0^t + \theta(C_*)\int_0^t |U_{xx}|^2_{L^2}(s)\,ds \\ \leq C(C_*, \bar{\zeta})\int_0^t (|U|^2_{H^1} + |\dot{\delta}|^2)(s)\,ds.\end{aligned}$$

Rearranging, using positive definiteness of $\tilde{A}^0_\alpha$, using Young's inequality to bound

$$\langle U_{xx}, K_\alpha U_x\rangle(t) \leq \bar{\zeta}|U_{xx}|^2_{L^2}(t) + C\bar{\zeta}^{-1}|U_x|^2_{L^2}(t) \leq \bar{\zeta}|U_{xx}|^2_{L^2}(t) + C\bar{\zeta}^{-1}\zeta^2,$$

and recalling, by assumption, that $(\langle \tilde{A}^0_\alpha U_x, U_x\rangle + \langle U_x, \tilde{K}_\alpha U\rangle)(0) \leq C\zeta^2$, we obtain (1.9) as claimed.

4. Nonlinear stability. We now establish Theorem 1.2 on nonlinear stability.

Linearized estimates. Linearizing (1.2) about the stationary solution $(\bar{u}, \bar{v})$, we obtain the linearized equations

$$U_t = \mathcal{L}U := -(AU)_x + QU, \tag{4.1}$$

where

$$A := \begin{pmatrix} df \\ dg \end{pmatrix}(\bar{u}, \bar{v}), \quad Q := \begin{pmatrix} 0 \\ dq(\bar{u}, \bar{v}) \end{pmatrix}, \quad \text{and} \quad U := \begin{pmatrix} u \\ v \end{pmatrix} \qquad (u \in \mathbb{R}^n,\ v \in \mathbb{R}^r).$$

Define the associated Green distribution $G(x, t; y)$ by

$$(\partial_t - \mathcal{L})G(x, t; y) = \delta_{(y,0)}(x, t).$$

We have the following bounds established in [24, Proposition 1.11] and [24, Lemmas 7.1–7.5]. (See also the "notes" below (7.22) of [24], which is used in the short-time estimate for $|e_y(\cdot, t)|_{L^p}$.)

Proposition 4.1 (see [24]). *Assuming* (A1)–(A2) *and* (H0)–(H5), *the Green distribution G may be decomposed as*

$$G = E + \tilde{G} + H, \tag{4.2}$$

where $E(x,t;y)=e(y,t)\,\bar U_x(x)$, *with*

$$
\begin{aligned}
|e_y(\cdot,t)|_{L^p} &\le Ct^{\frac12}(1+t)^{-\frac12(1-\frac1p)-\frac12}, \qquad |e_t(\cdot,t)|_{L^p}\le Ct^{-\frac12(1-\frac1p)},\\
|e_{ty}(\cdot,t)|_{L^p} &\le Ct^{-\frac12(1-\frac1p)-\frac12},\\
\left|\int_{\mathbb{R}}\tilde G(\cdot,t;y)\,f(y)\,dy\right|_{L^p} &\le C(1+t)^{-\frac12(1-\frac1r)}|f|_{L^q},\\
\left|\int_{\mathbb{R}}\tilde G(\cdot,t;y)\,(0,I_r)^t\,f(y)\,dy\right|_{L^p} &\le C(1+t)^{-\frac12(1-\frac1r)-\frac12}|f|_{L^q},\\
\left|\int_{\mathbb{R}}\tilde G_y(\cdot,t;y)\,f(y)\,dy\right|_{L^p} &\le C(1+t)^{-\frac12(1-\frac1r)-\frac12}|f|_{L^q}+Ce^{-\eta t}|f|_{L^p},
\end{aligned}
$$

and

$$
\left|\int_{\mathbb{R}}H(\cdot,t;y)\,f(y)\,dy\right|_{L^p}\le Ce^{-\eta t}|f|_{L^p}
$$

for all $t\ge 0$, *some* C, $\eta>0$, *for any* $1\le r\le p$ *and* $f\in L^q$ *(resp.,* L^p*), where* $1/r+1/q=1+1/p$.

Here, the "excited" component E accounts for contributions in the direction of the translational zero eigenfunction $\bar U_x$, while the "hyperbolic" component H accounts for propagation of signals along hyperbolic characteristics, its time-exponential damping a consequence of the genuine coupling condition (1.3). The reduced Green distribution $\tilde G$, accounting for long-time behavior in the far fields, is approximately a sum of Gaussian signals scattered by the shock layer. For further discussion, see [24].

Proof of Theorem 1.2. We first treat the case $p\ge 2$, afterward extending to $p\le 2$ by a bootstrap argument. ∎

stability, 2 ≤ ≤ ∞. Define the nonlinear perturbation

$$
U(x,t):=\begin{pmatrix}u\\ v\end{pmatrix}(x+\delta(t),t)-\begin{pmatrix}\bar u\\ \bar v\end{pmatrix}(x)=\tilde U(x+\delta(t),t)-\bar U(x),
$$

where $\delta(t)$ (estimating shock location) is to be determined later; for definiteness, fix $\delta(0)=0$. Then

$$
U_t-\mathcal{L}U=N_1(U)_x+(0,I_r)^tN_2(U)+\dot\delta(t)(\bar U_x+U_x),
$$

where

$$
N_j(U,U)=\mathcal{O}(|U|^2)\qquad\text{and}\qquad N_j(U,U)_x=\mathcal{O}(|U||U_x|)
$$

so long as $|U|$ remains bounded. By Duhamel's principle, and the fact that

$$
\int_{\mathbb{R}}G(x,t;y)\bar U_x(y)dy=e^{\mathcal{L}t}\bar U_x(x)=\bar U_x(x),
$$

we have

$$
\begin{aligned}
U(x,t)=\int_{\mathbb{R}}G(x,t;y)U_0(y)\,dy&-\int_0^t\!\!\int_{\mathbb{R}}G_y(x,t-s;y)(N_1(U)+\dot\delta U)(y,s)\,dy\,ds\\
&+\int_0^t\!\!\int_{\mathbb{R}}G(x,t-s;y)(0,I_r)^tN_2(U)(y,s)\,dy\,ds+\delta(t)\bar U_x.
\end{aligned}
$$

Defining the *instantaneous shock location*

$$\delta(t) = -\int_{\mathbb{R}} e(y,t)U_0(y)\,dy + \int_0^t\!\!\int_{\mathbb{R}} e_y(y,t-s)(N_1(U)+\dot{\delta}U)(y,s)\,dy\,ds, \tag{4.3}$$

where E, e are defined as in Proposition 4.1, and recalling decomposition (4.2), we thus obtain the *reduced equations*

$$\begin{aligned} U(x,t) = {} & \int_{\mathbb{R}} (H+\tilde{G})(x,t;y)U_0(y)\,dy \\ & + \int_0^t\!\!\int_{\mathbb{R}} H(x,t-s;y)(N_1(U)_x + (0,I_r)^t N_2(U) + \dot{\delta}U_x)(y,s)\,dy\,ds \\ & - \int_0^t\!\!\int_{\mathbb{R}} \tilde{G}_y(x,t-s;y)(N_1(U)+\dot{\delta}U)(y,s)\,dy\,ds \\ & + \int_0^t\!\!\int_{\mathbb{R}} \tilde{G}(x,t-s;y)(0,I_r)^t N_2(U)\,dy\,ds, \end{aligned} \tag{4.4}$$

and differentiating (4.3) with respect to t and using $|e_y(\cdot,s)|_{L^1} \to 0$ as $t \to 0$,

$$\dot{\delta}(t) = -\int_{\mathbb{R}} e_t(y,t)U_0(y)\,dy + \int_0^t\!\!\int_{\mathbb{R}} e_{yt}(y,t-s)(N_1(U)+\dot{\delta}U)(y,s)\,dy\,ds. \tag{4.5}$$

Define

$$\zeta(t) := \sup_{0\le s\le t,\, 2\le p\le\infty} \big[\, |U(\cdot,s)|_{L^p}(1+s)^{\frac{1}{2}(1-\frac{1}{p})} + |\dot{\delta}(s)|(1+s)^{\frac{1}{2}} + |\delta(s)|\big]. \tag{4.6}$$

We shall establish the following claim.

Claim. *For all $t \ge 0$ for which a solution exists with ζ uniformly bounded by some fixed, sufficiently small constant, there holds*

$$\zeta(t) \le C_2(|U_0|_{L^1\cap H^2} + \zeta(t)^2).$$

From this result, it follows by continuous induction that, provided $|U_0|_{L^1\cap H^2} < 1/4C_2^2$, there holds

$$\zeta(t) \le 2\,C_2|U_0|_{L^1\cap H^2} \tag{4.7}$$

for all $t \ge 0$ such that ζ remains small. By standard short-time theory/local well-posedness in H^2, and the standard principle of continuation, there exists a solution $U(\cdot,t) \in H^2$ on the open time-interval for which $|U|_{H^2}$ remains bounded, and on this interval ζ is well-defined and continuous. Now, let $[0,T)$ be the maximal interval on which $|U|_{H^2}$ remains strictly bounded by some fixed, sufficiently small constant $\delta > 0$. By Proposition 1.4 and the one-dimensional Sobolev bound $|U|_{W^{1,\infty}} \le C|U|_{H^2}$, we have

$$\begin{aligned} |U(t)|_{H^2}^2 & \le C|U(0)|_{H^2}^2 e^{-\theta t} + C\int_0^t e^{-\theta_2(t-\tau)}(|U|_{L^2}^2 + |\dot{\delta}|^2)(\tau)\,d\tau \\ & \le C_2\big(|U(0)|_{H^2}^2 + \zeta(t)^2\big)(1+t)^{-\frac{1}{2}}, \end{aligned} \tag{4.8}$$

and so the solution continues so long as ζ remains small, with bound (4.7), at once yielding existence and the claimed sharp $L^p \cap H^2$ bounds, $2 \le p \le \infty$.

Thus, it remains only to establish the claim above.

Proof of claim. We must show that each of the quantities $|U|_{L^p}(1+s)^{\frac{1}{2}(1-\frac{1}{p})}$, $|\dot\delta|(1+s)^{\frac{1}{2}}$, and $|\delta|$ is separately bounded by

$$C(|U_0|_{L^1\cap H^2}+\zeta(t)^2)$$

for some $C>0$, all $0\le s\le t$, so long as ζ remains sufficiently small. By (4.4)–(4.5), we have

$$\begin{aligned}
|U|_{L^p}(t) \le{}& \left|\int_{\mathbb{R}}(H+\tilde G)(x,t;y)U_0(y)\,dy\right|_{L^p}\\
&+\left|\int_0^t\!\!\int_{\mathbb{R}} H(x,t-s;y)\,N_1(U)_y(y,s)\,dy\,ds\right|_{L^p}\\
&+\left|\int_0^t\!\!\int_{\mathbb{R}} H(x,t-s;y)\,(0,I_r)^t N_2(U)(y,s)\,dy\,ds\right|_{L^p}\\
&+\left|\int_0^t\!\!\int_{\mathbb{R}} H(x,t-s;y)\,\dot\delta\,U_x(y,s)\,dy\,ds\right|_{L^p}\\
&+\left|\int_0^t\!\!\int_{\mathbb{R}} \tilde G_y(x,t-s;y)\,N_1(U)(y,s)\,dy\,ds\right|_{L^p}\\
&+\left|\int_0^t\!\!\int_{\mathbb{R}} \tilde G(x,t-s;y)\,(0,I_r)^t N_2(U)(y,s)\,dy\,ds\right|_{L^p}\\
&+\left|\int_0^t\!\!\int_{\mathbb{R}} \tilde G_y(x,t-s;y)\,\dot\delta\,U(y,s)dy\,ds\right|_{L^p}\\
=:{}& I_a+I_b+I_c+I_d+I_e+I_f+I_g,
\end{aligned}\tag{4.9}$$

(4.10)

$$|\dot\delta|(t)\le\left|\int_{\mathbb{R}} e_t(y,t)\,U_0(y)\,dy\right|+\left|\int_0^t\!\!\int_{\mathbb{R}} e_{yt}(y,t-s)\dot\delta U(y,s)\,dy\,ds\right|=:II_a+II_b,$$

and

(4.11)

$$|\delta|(t)\le\left|\int_{\mathbb{R}} e(y,t)U_0(y)dy\right|+\left|\int_0^t\!\!\int_{\mathbb{R}} e_y(y,t-s)\dot\delta\,U(y,s)\,dy\,ds\right|=:III_a+III_b.$$

We estimate each term in turn, following the approach of [24, 25, 27, 37]. Applying the bounds of Proposition 4.1, we find that the linear term I_a satisfies

$$\begin{aligned}
I_a &\le |U|_{L^p}(t)\left|\int_{\mathbb{R}} H\,U_0\,dy\right|_{L^p}+\left|\int_{\mathbb{R}}\tilde G\,U_0\ dy\right|_{L^p}\\
&\le Ce^{-\theta t}|U_0|_{L^p}+C(1+t)^{-\frac14}|U_0|_{L^1}\le C|U_0|_{L^1\cap H^2}(1+t)^{-\frac14}.
\end{aligned}\tag{4.12}$$

Likewise, applying the bounds of Proposition 4.1 together with definition (4.6) and energy estimate (4.8), we have

$$\begin{aligned} I_b &= \left| \int_0^t\!\!\int_{\mathbb{R}} H\, N_1(U)_y \, dy\, ds \right|_{L^p} \le C \int_0^t e^{-\eta(t-s)} |U|_{L^\infty} |U_x|_{L^p}(s)\, ds \\ &\le C \int_0^t e^{-\eta(t-s)} |U|_{L^\infty} |U|_{H^2}(s)\, ds \le C\zeta(t)^2 \int_0^t e^{-\eta(t-s)} (1+s)^{-\frac34}\, ds \\ &\le C\zeta(t)^2 (1+t)^{-\frac34}, \end{aligned} \tag{4.13}$$

$$\begin{aligned} I_c &= \left| \int_0^t\!\!\int_{\mathbb{R}} H\, (0, I_r)^t N_2(U)\, dy\, ds \right|_{L^p} \le C \int_0^t e^{-\eta(t-s)} |U|_{L^\infty} |U|_{L^p}(s)\, ds \\ &\le C\zeta(t)^2 \int_0^t e^{-\eta(t-s)} (1+s)^{-\frac34}\, ds \le C\zeta(t)^2 (1+t)^{-\frac34}, \end{aligned} \tag{4.14}$$

$$\begin{aligned} I_d &= \left| \int_0^t\!\!\int_{\mathbb{R}} H\, \dot\delta\, U_x \, dy\, ds \right|_{L^p} \le C \int_0^t e^{-\eta(t-s)} |\dot\delta| |U_x|_{L^p}(s)\, ds \\ &\le C\zeta(t)^2 \int_0^t e^{-\eta(t-s)} (1+s)^{-\frac34}\, ds \le C\zeta(t)^2 (1+t)^{-\frac34} \end{aligned} \tag{4.15}$$

(Proposition 4.1, $2 \le p = q \le \infty$, $r = 1$) and

$$\begin{aligned} I_e &= \left| \int_0^t\!\!\int_{\mathbb{R}} \tilde G_y\, N_1(U)\, dy\, ds \right|_{L^p} \le C \int_0^t \big(1+(t-s)\big)^{-\frac12(1-\frac1p)-\frac14} |U|_{L^\infty} |U|_{L^2}(s)\, ds \\ &\le C\zeta(t)^2 \int_0^t \big(1+(t-s)\big)^{-\frac12(1-\frac1p)-\frac14} (1+s)^{-\frac34}\, ds \le C\zeta(t)^2 (1+t)^{-\frac12(1-\frac1p)}, \end{aligned} \tag{4.16}$$

$$\begin{aligned} I_f &= \left| \int_0^t\!\!\int_{\mathbb{R}} \tilde G\, (0, I_r)^t N_2(U)\, dy\, ds \right|_{L^p} \le C \int_0^t \big(1+(t-s)\big)^{-\frac12(1-\frac1p)-\frac14} |U|_{L^\infty} |U|_{L^2}(s)\, ds \\ &\le C\zeta(t)^2 \int_0^t \big(1+(t-s)\big)^{-\frac12(1-\frac1p)-\frac14} (1+s)^{-\frac34}\, ds \le C\zeta(t)^2 (1+t)^{-\frac12(1-\frac1p)}, \end{aligned} \tag{4.17}$$

$$\begin{aligned} I_g &= \left| \int_0^t\!\!\int_{\mathbb{R}} \tilde G_y\, \dot\delta\, U\, dy\, ds \right|_{L^p} \le C \int_0^t \big(1+(t-s)\big)^{-\frac12(1-\frac1p)-\frac14} |\dot\delta| |U|_{L^2}(s)\, ds \\ &\le C\zeta(t)^2 \int_0^t \big(1+(t-s)\big)^{-\frac12(1-\frac1p)-\frac14} (1+s)^{-\frac34}\, ds \le C\zeta(t)^2 (1+t)^{-\frac12(1-\frac1p)} \end{aligned} \tag{4.18}$$

(Proposition 4.1, $2 \le p \le \infty$, $q = 2$). Summing bounds (4.12)–(4.18), we obtain the desired bound on $|U|_{L^p}$.

Similarly, applying the bounds of Proposition 4.1 together with definition (4.6), we find that

$$II_a = \left| \int_{\mathbb{R}} e_t\, U_0\, dy \right| \le |e_t(y,t)|_{L^\infty}(t) |U_0|_{L^1} \le C |U_0|_{L^1} (1+t)^{-\frac12} \tag{4.19}$$

and

(4.20)
$$II_b = \left|\int_0^t\!\!\int_{\mathbb{R}} e_{yt}\,\dot\delta U\,dy\,ds\right| \le \int_0^t |e_{yt}|_{L^2}(t-s)|\dot\delta||U|_{L^2}(s)\,ds$$
$$\le C\zeta(t)^2\int_0^t (t-s)^{-3/4}(1+s)^{-\frac{3}{4}}\,ds \le C\zeta(t)^2(1+t)^{-\frac{1}{2}},$$

while

$$III_a = \left|\int_{\mathbb{R}} e\,U_0\,dy\right| \le |e(y,t)|_{L^\infty}(t)|U_0|_{L^1} \le C|U_0|_{L^1} \tag{4.21}$$

and

$$\begin{aligned} III_b = \left|\int_0^t\!\!\int_{\mathbb{R}} e_y\,\dot\delta U\,dy\,ds\right| &\le \int_0^t |e_y|_{L^2}(t-s)|\dot\delta||U|_{L^2}(s)\,ds \\ &\le C\zeta(t)^2\int_0^t (t-s)^{-\frac{1}{4}}(1+s)^{-\frac{3}{4}}\,ds \le C\zeta(t)^2. \end{aligned} \tag{4.22}$$

Summing (4.19)–(4.20) and (4.21)–(4.22), we obtain the desired bounds on $\dot\delta$ and δ.

This completes the proof of the claim, giving the result for $2 \le p \le \infty$. □

stability, $1 \leq \quad \leq 2$. The source term $\dot\delta\, U_x$ appearing in the reduced equations is convenient for high norm estimates L^p, $p \ge 2$, but (since it would lead to a source term involving higher derivative factor $|U_x|_{L^p}$ not controlled by energy estimates) not for low norm estimates L^p, $1 \le p < 2$. To treat low norms, we redefine

$$U := \tilde U(x,t) - \bar U(x - \delta(t))$$

following [40], which has the effect of replacing $\dot\delta\, U_x$ in the reduced equations with "centering errors"

$$\begin{aligned} S_1(\delta,\dot\delta,U)_x + \begin{pmatrix} 0 \\ I_r \end{pmatrix} S_2(\delta) := &-((A(\bar U(x-\delta)) - A(\bar U(x)))U + \dot\delta(\bar U(x-\delta) - \bar U(x)))_x \\ &+ \delta(Q(\bar U(x-\delta)) - Q(\bar U(x)))U \end{aligned}$$

satisfying

$$\begin{aligned} |S_1(\delta,\dot\delta,U)(y,s)| &\le |\delta|(|U| + |\dot\delta|)e^{-\theta|y|}, \\ |S_1(\delta,\dot\delta,U)_x(y,s)| &\le |\delta|(|U| + |\dot\delta| + |U_x|)e^{-\theta|y|}, \\ |S_2(\delta)(y,s)| &\le |\delta||U|e^{-\theta|y|}, \end{aligned}$$

and therefore

$$\begin{aligned} |S_1|_{L^1} &\le (|U|_{L^\infty} + |\dot\delta|) \le C(1+t)^{-\frac{1}{2}}|U_0|_{L^1\cap H^2}, \\ |(S_1)_x|_{L^1} &\le (|U|_{L^\infty} + |U|_{H^1} + |\dot\delta|) \le C(1+t)^{-\frac{1}{4}}|U_0|_{L^1\cap H^2}, \end{aligned}$$

and

$$|S_2|_{L^1} \le |U|_{L^\infty}|\delta| \le C(1+t)^{-\frac{1}{2}}|U_0|_{L^1\cap H^2}$$

by the previously obtained L^∞ and H^1 estimates, which are unaffected by a spatial shift. Likewise,

$$|N_1(U)|_{W^{1,1}},\ |N_2(U)|_{L^1} \le |U|^2_{H^1} \le C(1+t)^{-\frac{1}{2}}|U_0|_{L^1\cap H^2}.$$

Thus, expressing U by Duhamel's formula similarly to (4.9)–(4.11) and estimating nonlinear terms using the bounds of Proposition 4.1 with $p=1$, $q=1$, we readily obtain the sharp L^1 decay estimate

$$|U|_{L^1} \le C|U_0|_{L^1\cap H^2}$$

and, by interpolation with the previously obtained L^2 bound, the sharp L^p estimate, $1\le p\le 2$ of $|U|_{L^p} \le C(1+t)^{\frac{1}{2}(1-\frac{1}{p})}|U_0|_{L^1\cap H^2}$, as claimed. We omit the details, which are entirely similar to those already carried out.

5. The characteristic case. Finally, we briefly discuss the uniformly characteristic case in which (H1)(i) is violated for a shock profile of a discrete kinetic model. This cannot occur for the simplest examples of the Broadwell or Jin–Xin models, for the reason that it would violate the subcharacteristic condition

$$a_j < a_j^{*\pm} < a_{j+r}, \tag{5.1}$$

which is in turn necessary for strict dissipativity, (A2); see, e.g., [24, 26, 33]. Indeed, this holds in general for models with the property that $r+1$ consecutive characteristics take on only two values ($r+1=2$ for Broadwell; $r+1=(n/2)+1\ge 2$ for Jin–Xin, but the total number of characteristic values is 2), for the subcharacteristic condition (5.1) then implies that $a_p^{*\pm}$ lie between the neighboring characteristic values a_p and a_{p+r}, whence, by the Lax condition $a_p^{*-}>0>a_p^{*+}$, the speed $s=0$ does as well.

This is clearly an accident of low dimension, however, and for general models there is no physical reason that (H1)(i) should be satisfied. Indeed, though it is evidently satisfied generically, there is ample reason to discard this hypothesis, for, discretizing the Boltzmann equations

$$f_t + \xi f_x = \mathcal{Q}(\xi, f), \quad \xi \in \mathbb{R}^1,$$

by velocity ξ, where ξ denotes velocity, $f(\xi,x)$ the probability distribution of speeds at spatial location x, and $\mathcal{Q}(\xi,f)$ a collision term (local in x but nonlocal in ξ), we find as the velocity mesh goes to zero that (H1)(i) is more and more poorly satisfied, so that uniformity of our estimates (or even the ball for which small-amplitude profiles are guaranteed to exist) is lost.

This is hardly the main difficulty in proceeding to the Boltzmann limit, which is rather the reverse problem of unboundedness of the multiplication operator $f\to\xi f$ (in our notation, blowup of the spectrum of A) and the associated lack of spectral gap between zero and the essential spectrum of the operator $A^{-1}Q$ appearing in the standing-wave and eigenvalue ODE; see, e.g., [6]. Nonetheless, it is an issue that arises and should be addressed.

Fortunately, there is a simple fix, at least for discrete kinetic models. Namely, in case characteristics $a_j,\dots,a_k$ coincide with shock speed $s=0$, we may substitute for (H1)(i) the more general hypotheses

$$\mathrm{Re}\ \begin{pmatrix} L_j \cdots L_k \end{pmatrix}\ d\mathcal{Q} \begin{pmatrix} R_j \\ \vdots \\ R_k \end{pmatrix} \le -\theta < 0 \tag{5.2}$$

for some fixed left and right zero eigenbases L_i and R_i, and

$$\ker A \cap \ker d\mathcal{Q} = \emptyset, \tag{5.3}$$

where without loss of generality A is taken to be diagonal. This holds necessarily at $x = \pm\infty$ for some choice of diagonalizing transformation, by strict dissipativity, (A2) (recall that $\operatorname{Re}\sigma(\text{ block-diag}\,\tilde{L}Q\tilde{R}_\pm) < 0$ follows from (A2) by Taylor expansion at infinity of the spectrum of the symbol $i\xi A_\pm + Q_\pm$; likewise, (A2) implies genuine coupling, (1.3), of which (5.3) is a weakened form), hence (H1)(i) is always satisfied in the small-amplitude case. Whether or not it holds globally for physically interesting examples we do not know.

Review of the argument of section 3 shows that auxiliary energy estimate (1.9) goes through under this hypothesis with constant weights $\alpha_j = \alpha_{j+1} = \cdots = \alpha_k \equiv 1$ in the zero-speed modes, since there are no error terms in these modes to be overcome and there is a uniformly good contribution by (5.2). Likewise, review of the arguments of [24] shows that the results obtained there carry through as well, with appropriate modification of the proofs. Namely, (5.2) and (5.3) together imply that

$$\begin{pmatrix} df \\ dQ_j \\ \vdots \\ dQ_k \\ dg_2 \end{pmatrix}, \qquad g =: \begin{pmatrix} g_1 \\ g_2 \end{pmatrix}, \quad g_1 \in \mathbb{R}^{k-j+1},$$

is full rank under some choice of coordinate system, whence we can again rewrite both traveling-wave and eigenvalue/resolvent equations as nondegenerate first-order systems and proceed as before. We omit the details, as this diverges from our main purpose.

Note in particular that we obtain small-amplitude existence for fixed speed s by a minor adjustment of the argument of [24] (namely, fixing the speed, without loss of generality, $s = 0$, and letting endstates vary), without any assumption on the base state other than simplicity of the principal eigenvalue and strong dissipativity; this generalizes earlier results of [34, 24].

For $a_j, \dots, a_k$ close to $s = 0$, we may recover our previous results with uniform estimates by a singular perturbation version of the same argument. It would be interesting to extend this approach to more general relaxation models for which the speeds a_i are not constant, in particular the case for which they are sometimes but not always characteristic.

ANALYSIS OF SOLUTIONS TO THE LAWRENCE–DONIACH SYSTEM FOR LAYERED SUPERCONDUCTORS*

PATRICIA BAUMAN† AND YANGSUK KO‡

Abstract. We consider a coupled Ginzburg–Landau system, the so-called Lawrence–Doniach system, which models layered superconductors as a stack of nonlinearly coupled, parallel two-dimensional superconducting layers, separated by an insulating material or vacuum, in an applied magnetic field. We prove that weak solutions (e.g., energy minimizers) in an appropriate divergence-free gauge are uniformly bounded and continuous and satisfy a priori estimates based on elliptic theory and single layer potentials. Moreover, we show the existence of an upper critical field $\bar{h}$ such that when the modulus of a constant applied magnetic field $\vec{H} = h\vec{v}$ in a direction $\vec{v}$ nontangential to the layers (where $|\vec{v}| = 1$) is greater than $\bar{h}$, the normal (nonsuperconducting) state is the only solution to the Lawrence–Doniach system. It follows from these results and methods developed earlier by Chapman, Du, and Gunzburger [*SIAM J. Appl. Math.,* 55 (1995), pp. 156–174] that under certain assumptions on the relative values of parameters in the model, minimizers of the Lawrence–Doniach energy converge, as the interlayer spacing tends to zero, to minimizers of an appropriate anisotropic Ginzburg–Landau energy in three dimensions. Finally, we derive that $\bar{h} \le C\kappa/\mu$ for all κ sufficiently large and all unit vectors $\vec{v}$ satisfying $\vec{v} \cdot \vec{e_3} \ge \mu > 0$ for the Lawrence–Doniach system, where κ is the Ginzburg–Landau constant for the superconducting material and C is independent of κ and μ.

1. Introduction and statement of main results.

1.1. Background on the Lawrence–Doniach model. The standard Ginzburg–Landau model (cf. [7]) has been well accepted as a macroscopic model for isotropic (and homogeneous) superconductors for temperatures near the critical temperature T_c of the material. However, this model cannot account for the anisotropy of layered or high temperature superconductors. (See [3], [18].) Therefore, alternative models have been developed. One of these is the Lawrence–Doniach model proposed by Lawrence and Doniach [15], whose solutions are analyzed here. Their model describes a layered superconductor as a finite number of infinitely thin parallel superconducting layers, each pair of which is separated by an insulating material or vacuum, occupying a bounded domain in $\mathbb{R}^3$. The model includes Josephson coupling in adjacent superconducting layers and is described by an energy which includes two-dimensional (isotropic) Ginzburg–Landau-type integrals in terms of an order parameter and magnetic potential on each layer, and a three-dimensional integral which includes the global effect of the applied magnetic field on the layered superconductor. The class of layered superconductors includes low-temperature layered superconductors and copper oxide high temperature superconductors (which are composed of layered Perovskite structures).

The scaling parameters most important for characterizing superconducting materials are the coherence length ξ (representing the length scale for spatial variation of the superconducting order parameter $\psi(x)$, whose modulus is the density of superconducting electrons at position x in the reference configuration) and the penetration depth λ (which sets the length scale for electromagnetic response). In layered superconductors with uniaxial symmetry, these quantities are isotropic within the plane of the layers (which we assume is oriented so that it is parallel to the horizontal (x_1x_2) plane), and they take different values along the perpendicular (x_3 axis) direction (namely $\xi_\|, \lambda_\|, \xi_\perp, \lambda_\perp$). The degree of anisotropy, referred to in the physics literature as "quasi-two-dimensionality" varies over a wide range for different layered superconducting materials, depending on the strength of coupling between the adjacent two-dimensional superconducting layers. (A table of these values for various types of layered and high temperature superconducting materials can be found in [11].)

The Lawrence–Doniach model is widely accepted as a model for layered superconductors at temperatures close to the critical temperature T_C and is considered qualitatively correct even for lower temperatures. It is considered a more complete theory than the competing three-dimensional anisotropic Ginzburg–Landau model (described in section 6 of this paper). The latter model occurs as a limit of the Lawrence–Doniach model for layered superconductors in the case in which the coherence length perpendicular to the layers, $\xi_\perp$, is much larger than the layer separation, d, by letting $d/\xi_\perp \to 0$. This limiting process course-grains the layered structure into a continuum in which the anisotropy is incorporated into an effective mass tensor in the three-dimensional reference configuration of the material. The resulting three-dimensional anisotropic Ginzburg–Landau model is physically relevant for layered superconductors in which the coherence length perpendicular to the layers is much less than the interlayer spacing, and it is not expected to be even qualitatively correct at lower temperatures, where this coherence length can become less than or comparable to the layer separation. (See [13].) For layered superconductors in which $\xi_\perp$ is much less than d (as is the case in many high temperature superconductors), it is necessary to take the discrete nature of the layered structure into account. An example of a high temperature superconducting material in which this is the case is $BiSr_2Ca_2Cu_2O_{8+y}$. Thus, the Lawrence–Doniach model is more appropriate for describing $BiSr_2Ca_2Cu_2O_{8+y}$ than the three-dimensional anisotropic Ginzburg–Landau model. (See [11].)

A detailed study comparing the phenomenological Lawrence–Doniach model for layered superconductors to a full-fledged microscopic treatment was done by Klemm, Luther, and Beasley in [13]. An extensive description of experimental results on highly anisotropic layered high temperature superconductors described by the Lawrence–Doniach model can be found in [11]. The experimental observations and physical predictions in these papers motivate a careful study of solutions to the Lawrence–Doniach system (described below) in regimes in which the applied magnetic field $\vec{H} = h\vec{v}$ is allowed to take various directions. To understand why this is important, we note that in standard (isotropic) Ginzburg–Landau models in three dimensions, it is expected that vortices (i.e., superconducting defects) occur in filaments whose cross sections form an Abrikosov triangular lattice, and the qualitative behavior of solutions is similar as we vary the direction of the applied magnetic field. However, in layered superconductors of the type in which the discrete layers must be taken into account, the situation is different: experiments suggest that when the applied magnetic field $\vec{H} = h\vec{v}$ is perpendicular to the horizontal (x_1x_2) plane of the layers, the lateral distance between two vortices of a single flux line in adjacent layers increases on the order of $\cot\theta$, where $\theta = \arcsin(\vec{v}\cdot\vec{e_3})$. As long as θ is not too small, the vortices of single flux lines in adjacent layers have sufficient overlap to form a three-dimensional supercurrent flow pattern that is not very different from the usual Abrikosov vortex. As θ is reduced, there occurs a crossover from Abrikosov-like to staircase-like flux lines at a critical angle. As θ is further reduced, there may be a second critical angle below which the whole length of a flux line is locked into the region between the superconducting layers. Moreover, when θ is zero (so that the applied magnetic field is parallel to the layers), shielding current flows only within individual layers and not between them. (See [11].) The phenomena described above may be related to an interesting conjecture by Beasley, Klemm, and Luther, which we describe later in the introduction, asserting that when $\vec{H} = h\vec{v}$ is parallel to the $x_x x_2$ plane of the layers and the temperature T of the superconductor is sufficiently low, the upper critical modulus $H_{c_3}(v)$ for the Lawrence–Doniach model should be infinite. (See [13].) Physically, this means that no matter how strong the parallel applied magnetic field is, the superconducting material never becomes normal; i.e., it never reaches a state in which superconductivity is completely destroyed and the applied magnetic field has completely penetrated the superconducting layers. It is interesting to note that this kind of behavior is impossible for the three-dimensional anisotropic Ginzburg–Landau model, since methods developed in [9] for the standard isotropic three-dimensional Ginzburg–Landau model can be used to show easily that upper critical fields are uniformly bounded above independent of the direction $\vec{v}$, since the anisotropy governed by the effective mass tensor is not so different qualitatively from the isotropic case in which this tensor is the identity.

Before stating our results, let us introduce the Lawrence–Doniach model and the Euler–Lagrange equations and gauge invariance associated with the model. In the (nondimensionalized) Lawrence–Doniach model, a layered superconductor occupies a bounded domain $\mathcal{D} = \Omega \times (0, S)$ in $\mathbb{R}^3$, where Ω is a bounded Lipschitz domain in $\mathbb{R}^2$ and $S > 0$. The superconducting layers are perpendicular to the x_3 axis and occupy $N+1$ equally spaced planar regions, $\Omega_n = \Omega \times \{ns\}$, in $\mathcal{D}$ for $n = 0, 1, \ldots, N$, where $S = Ns$ and N is a positive integer. Thus, the distance s between adjacent superconducting planes is equal to $\frac{S}{N}$.

We assume throughout this paper that $\vec{H} = (h_1, h_2, h_3)$ is a given constant applied magnetic field, and we write $\vec{H} = h\vec{v}$, where $\vec{v}$ is a unit vector in $\mathbb{R}^3$ and $h \equiv |\vec{H}| \geq 0$. We say that $\vec{H}$ is nontangential if it is nontangential to the layers, i.e., $h > 0$ and $\vec{v}\cdot\vec{e_3} \neq 0$. For each unit vector $\vec{v}$ in $\mathbb{R}^3$, we assume that a fixed smooth divergence-free vector field $\vec{a} : \mathbb{R}^3 \longrightarrow \mathbb{R}^3$ has been chosen such that $\nabla \times \vec{a} = \vec{v}$ in $\mathbb{R}^3$. For example, if $\vec{v} = (v_1, v_2, v_3)$, one can choose $\vec{a(x)} = (v_2 x_3, v_3 x_1 - v_1 x_3, 0)$, and any other choice differs from this by the gradient of a harmonic function on $\mathbb{R}^3$. Thus, $\nabla \times h\vec{a} = h\vec{v} = \vec{H}$ in $\mathbb{R}^3$.

The Lawrence–Doniach energy functional for a layered superconductor in an applied magnetic field $\vec{H}$ in nondimensionalized form (see [4], [6], [13], and [15]) is given by

$$
\begin{aligned}
\mathcal{G}^s_{LD}\left(\{\psi_n\}_{n=0}^N, \vec{A}\right) = {} & s\sum_{n=0}^{N}\int_\Omega \left(\frac{1}{2}\left(|\psi_n|^2 - 1\right)^2 + \left|\left(\frac{\imath}{\kappa}\mathbf{grad} + \mathbf{A}_n\right)\psi_n\right|^2\right) d\mathbf{x} \\
& + s\sum_{n=0}^{N-1}\int_\Omega \sigma\left|\psi_{n+1}\exp\left(-\imath\kappa\int_{ns}^{(n+1)s} A^3 dx_3\right) - \psi_n\right|^2 d\mathbf{x} \\
& + \int_{\mathbb{R}^3}\left|\left(\nabla\times\vec{A}\right) - \vec{H}\right|^2 d\vec{x},
\end{aligned}
\tag{1.1}
$$

where $\mathbf{x} = (x_1, x_2)$ so that $\vec{x} = (x_1, x_2, x_3) = (\mathbf{x}, x_3)$, **grad** denotes the gradient operator with respect to the x_1 and x_2 coordinates, $\imath$ is the imaginary unit, and σ and κ are positive constants. Here, ψ_n is a complex-valued function defined on Ω, called the order parameter for the nth superconducting layer occupying $\Omega_n \equiv \Omega \times \{ns\}$; $\vec{A} = \vec{A}(\vec{x}) = (A^1, A^2, A^3) = (\mathbf{A}, A^3)$ is a vector field defined on $\mathbb{R}^3$, called the magnetic potential; and $\mathbf{A}_n = \mathbf{A}_n(\mathbf{x}) = (A_n^1(\mathbf{x}), A_n^2(\mathbf{x}))$ is a function from $\mathbb{R}^2$ to $\mathbb{R}^2$ defined by $\mathbf{A}_n(\mathbf{x}) = \mathbf{A}(\mathbf{x}, ns) = (A^1(x_1, x_2, ns), A^2(x_1, x_2, ns))$. More precisely, $\mathbf{A}_n(\mathbf{x})$ and $A_n^i(\mathbf{x})$ for $i = 1, 2$ are the traces of $\mathbf{A}$ and A^i, respectively, at $(\mathbf{x}, ns)$ on the plane $\{x_3 = ns\}$ for $n = 0, 1, \ldots, N$. Note that ψ_n is a function whose domain is Ω, even though it represents a physical quantity (the nth order parameter) corresponding to Ω_n. Similarly, $\mathbf{A}_n$ is a function whose domain is $\mathbb{R}^2$, though it corresponds to the trace of $\mathbf{A}$ on the plane $\{x_3 = ns\}$.

Given $\vec{H}$, the Lawrence–Doniach energy is defined on pairs $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big)$ such that

$$
(1.2)\qquad \begin{cases} \{\psi_n\}_{n=0}^N \in \big[H^1(\Omega; \mathbb{C})\big]^{N+1} = \big[\mathcal{H}^1(\Omega)\big]^{N+1} \quad \text{and} \\ \vec{A} \in E \equiv \Big\{ \vec{C} \in H^1_{loc}(\mathbb{R}^3; \mathbb{R}^3) : (\nabla \times \vec{C}) - \vec{H} \in L^2(\mathbb{R}^3; \mathbb{R}^3) \Big\}. \end{cases}
$$

Note that for these pairs it follows from the trace theorem that $\mathbf{A}_n \in H^{\frac{1}{2}}_{loc}\big(\mathbb{R}^2; \mathbb{R}^2\big) \hookrightarrow L^4_{loc}\big(\mathbb{R}^2; \mathbb{R}^2\big)$, so that $\mathcal{G}^s_{LD}\big(\{\psi_n\}_{n=0}^N, \vec{A}\big)$ is well defined and finite. According to the Lawrence–Doniach model, a minimizer or stable equilibrium $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big)$ of the Lawrence–Doniach energy, $\mathcal{G}^s_{LD}$, in $[\mathcal{H}^1(\Omega)]^{N+1} \times E$ corresponds to a physically realistic state of the layered superconductor: $\big|\psi_n(\mathbf{x})\big|^2$ is the density of superconducting electron pairs at position $(\mathbf{x}, ns)$ in the nth superconducting layer Ω_n; $\big(\nabla \times \vec{A}\big)(\vec{x})$ is the induced magnetic field at position $\vec{x}$ in $\mathbb{R}^3$; and $\big(\nabla \times (\nabla \times \vec{A})\big)(\vec{x})$ is the induced current at position $\vec{x}$ in $\mathbb{R}^3$. We note that in the above nondimensionalized model, several dimensional constants have been "nondimensionalized" or scaled from their original values. Thus, $\kappa = \lambda/\xi$, the ratio of the penetration depth and coherence length in the superconducting layers. Also, the nondimensionalized interlayer spacing, s, equals d/λ, where d is the original (dimensionalized) interlayer spacing. (See [4] for more details on the nondimensionalized formulation.) The constant σ is a parameter related to the strength of the interlayer coupling (Josephson coupling) of the layers in the superconducting material.

The Euler–Lagrange equations and natural boundary conditions associated with minimizers or equilibria of the Lawrence–Doniach energy $\mathcal{G}^s_{LD}$, called the Lawrence–Doniach system, are given by

$$
(1.3)\qquad \begin{cases} \text{(a)}\ \Big(\dfrac{\imath}{\kappa}\mathbf{grad} + \mathbf{A}_n\Big)^2 \psi_n + \big(|\psi_n|^2 - 1\big)\psi_n + \mathrm{P}_n = 0 & \text{on } \Omega, \\ \text{(b)}\ \nabla \times \big(\nabla \times \vec{A}\big) = (j_1, j_2, j_3) & \text{in } \mathbb{R}^3, \\ \text{(c)}\ \Big(\dfrac{\imath}{\kappa}\mathbf{grad}\ \psi_n + \mathbf{A}_n \psi_n\Big) \cdot \mathbf{n} = 0 & \text{on } \partial\Omega, \\ \text{(d)}\quad (\nabla \times \vec{A}) - \vec{H} \in L^2(\mathbb{R}^3; \mathbb{R}^3) & \end{cases}
$$

for all $n = 0, 1, \dots, N$, where

$$\mathrm{P}_n = \begin{cases} \sigma\big(\psi_0 - \psi_1 e^{-\imath\phi_0^1}\big) & \text{if } n = 0, \\ \sigma\big(2\psi_n - \psi_{n-1} e^{\imath\phi_{n-1}^n} - \psi_{n+1} e^{-\imath\phi_n^{n+1}}\big) & \text{if } 0 < n < N, \\ \sigma\big(\psi_N - \psi_{N-1} e^{\imath\phi_{N-1}^N}\big) & \text{if } n = N, \end{cases}$$

$$\phi_n^{n+1} = \kappa \int_{ns}^{(n+1)s} A^3\, dx_3 \quad \text{for } n = 0, 1, \dots, N-1,$$

$$j_i = s \sum_{n=0}^{N} \left[\frac{\imath}{2\kappa} \left(\psi_n \frac{\partial \psi_n^*}{\partial x_i} - c.c. \right) - |\psi_n|^2 A_n^i \right] \chi_\Omega(x_1, x_2) dx_1\, dx_2\, \delta_{ns}(x_3) \quad \text{for } i = 1, 2,$$

$$j_3 = \frac{1}{2} s\sigma\kappa\imath \sum_{n=0}^{N-1} \left[\psi_n \psi_{n+1}^* e^{\imath\phi_n^{n+1}} - c.c. \right] \chi_\Omega(x_1, x_2) \chi_{[ns,(n+1)s]}(x_3).$$

Here $\mathbf{n}$ is the outward normal to $\partial\Omega$, * means the complex conjugate, *c.c.* denotes the complex conjugate of the previous term, χ_Ω is the characteristic function for Ω, and $\delta_{ns} \in \mathcal{D}'(\mathbb{R})$ is the delta distribution supported at the point ns. The Lawrence–Doniach system (1.3) is to be interpreted in the weak sense defined by (2.3). Note that j_1 and j_2 are real measures in $\mathbb{R}^3$ supported in $\bigcup_{n=0}^N \overline{\Omega}_n$.

The Lawrence–Doniach energy, $\mathcal{G}_{LD}^s$, in (1.1) and the family of weak solutions of (1.2) and (1.3) are invariant in $[H^1(\Omega)]^{N+1} \times E$ under the gauge transformation

$$\Big(\{\psi_n\}_{n=0}^N, \vec{A}\Big) \longrightarrow \Big(\{\xi_n\}_{n=0}^N, \vec{Q}\Big),$$

where

$$\text{(1.4)} \qquad \begin{cases} \xi_n(\mathbf{x}) = \psi_n(\mathbf{x}) e^{\imath\kappa g(\mathbf{x}, ns)} & \text{in } \Omega, \\ \vec{Q} = \vec{A} + \nabla g & \text{in } R^3 \end{cases}$$

for all $n = 0, 1, \dots, N$ and any $g \in H^2_{loc}(\mathbb{R}^3)$. If $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big) \in [H^1(\Omega)]^{N+1} \times E$ and (1.4) holds for a function $g \in H^2_{loc}(\mathbb{R}^3)$, we say that $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big)$ and $\big(\{\xi_n\}_{n=0}^N, \vec{Q}\big)$ are gauge-equivalent. Note that the Lawrence–Doniach energy and the physical properties of a solution are invariant under this transformation: the density of superconducting electron pairs is $|\psi_n|^2 = |\xi_n|^2$, the induced magnetic field is $\nabla\times\vec{A} = \nabla\times\vec{Q}$, and the current is $\nabla\times\big(\nabla\times\vec{A}\big) = \nabla\times\big(\nabla\times\vec{Q}\big)$.

We prove in section 2 that every pair in $[H^1(\Omega)]^{N+1} \times E$ is gauge-equivalent to a pair $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big)$, satisfying

$$\text{(1.5)} \qquad \begin{aligned} &\Big(\{\psi_n\}_{n=0}^N, \vec{A}\Big) \in [H^1(\Omega)]^{N+1} \times K, \\ &\text{where } K = \Big\{ \vec{C} \in E : \nabla\cdot\vec{C} = 0 \text{ and } \vec{C} - h\vec{a} \in \check{H}^1(\mathbb{R}^3) \cap L^6(R^3; R^3) \Big\}, \end{aligned}$$

which is unique up to uniform rotations: $\psi_n \to \psi_n e^{i\kappa c}$ for $n = 0, \dots, N$, where $c \in R$. (See Lemma 2.1.) Here $\check{H}^1(\mathbb{R}^3)$ denotes the completion of $C_0^\infty(\mathbb{R}^3; \mathbb{R}^3)$ with respect to the norm

$$\|\vec{C}\|_{\check{H}^1(\mathbb{R}^3)} = \left(\int_{\mathbb{R}^3} \big|\nabla\vec{C}\big|^2 d\vec{x} \right)^{\frac{1}{2}},$$

where

$$\nabla\vec{C} = \left(\frac{\partial C_j}{\partial x_i}\right) \text{ and } \left|\nabla\vec{C}\right|^2 = \operatorname{tr}\left[(\nabla\vec{C})^t(\nabla\vec{C})\right].$$

It follows easily that minimizers of $\mathcal{G}^s_{LD}$ (and hence weak solutions) of (1.3) in $[H^1(\Omega)]^{N+1} \times E$ exist. Moreover, for any weak solution of (1.3) in $[H^1(\Omega)]^{N+1} \times E$, g can be chosen so as to obtain a new gauge-equivalent weak solution of (1.3) in $[H^1(\Omega)]^{N+1} \times K$. (This process is called "choosing a gauge.")

The layered superconductor is said to be in a perfect superconducting state if $|\psi_n|^2 = 1$ in Ω for all n, and in the normal (nonsuperconducting) state if $|\psi_n|^2 = 0$ in Ω for all n and $\nabla \times \vec{A} \equiv \vec{H}$ in $\mathbb{R}^3$. In general, it is expected that $|\psi_n| \leq 1$ in Ω for each n; this was proved for a weak solution of (1.2) and (1.3) by Chapman, Du, and Gunzburger in [4] under the assumption that Ω is a smooth simply connected domain, and that the solution is gauge-equivalent to some $\left(\{\psi_n\}_{n=0}^N, \vec{A}\right)$ whose restriction to $\overline{\Omega}^{N+1} \times \overline{\mathcal{D}}$ is continuous, and satisfies $\left(\{\psi_n\}_{n=0}^N, \vec{A}\right) \in [H^1(\Omega)]^{N+1} \times \check{H}^1(\mathbb{R}^3)$,

$$\begin{aligned} &\nabla\cdot\vec{A} = 0 \text{ in } R^3, \\ &\vec{A}\cdot\vec{n} = 0 \text{ on } \partial D \text{ and } \nabla\psi\cdot\vec{n} = 0 \text{ on } \partial\Omega, \end{aligned} \tag{1.6}$$

where $\vec{n}$ is the outer unit normal on ∂D. (See [4, sections 1 and 4].) In addition, they proved that if γ and S are fixed positive numbers, with $\sigma\kappa^2 s^2 = \gamma^{-1}$ and $S = Ns$, and if minimizers of (1.1) satisfy $|\psi_n| \leq 1$ for all $n = 0, 1, \ldots, N$, then there is an extension of $\left(\{\psi_n\}_{n=0}^N, \vec{A}\right)$, denoted by $(\psi^s, \vec{A}^s)$, to $H^1(D) \times E$, such that $(\psi^s, \vec{A}^s)$ forms a minimizing sequence, as $s = s_j \equiv \frac{S}{N_j} \to 0$, for an appropriate anisotropic Ginzburg–Landau energy (which involves the parameters γ and κ) defined on $H^1(D) \times E$. (See (6.1) of section 6 for the definition of this anisotropic Ginzburg–Landau energy.) The proof of this result involved an intricate analysis in which the minimum Lawrence–Doniach energy was shown to converge (as $s \to 0$) to the minimum energy for the anisotropic Ginzburg–Landau model, assuming the above relationship between σ, κ, s, and γ. This result explains why, under certain assumptions on the relative sizes of the parameters σ, κ, and s, the Lawrence–Doniach system "homogenizes" to an anisotropic version of the classical three-dimensional Ginzburg–Landau model as the interlayer spacing s tends to 0.

We remark that the "gauge" (1.6) used in [4] is overdetermined. This is easily adjusted, however, by choosing the gauge (1.5), for example, instead of (1.6), and when this is done, it follows from the work of Chapman, Du, and Gunzburger in [4] that if weak solutions in the gauge (1.5) satisfy $|\psi_n| \leq 1$ in Ω for each n, the convergence result described above as $s \to 0$ holds in the gauge (1.5).

The question of whether minimizers of (1.1) or weak solutions to the Lawrence–Doniach system are gauge-equivalent to a pair whose restriction to $\overline{\Omega}^{N+1} \times \overline{\mathcal{D}}$ is continuous was left open in [4]. This question is nontrivial, since the magnetic potential $\vec{A} = (A^1, A^2, A^3)$ has the property that $\nabla \times \nabla \times \vec{A}$ is given by a measure supported in the layers, for $i = 1, 2$, and thus analysis of the regularity of the trace of A^i on Ω_n, and hence of ψ_n, is nontrivial. This question is of independent interest, since defects in superconductivity (known as vortices) in the nth layer are described by points $\mathbf{x}$ in Ω satisfying $\psi_n(\mathbf{x}) = 0$ (since $|\psi_n(\mathbf{x})|^2$ is the density of superconducting electron pairs in the nth layer at position $(\mathbf{x}, ns)$). This definition of defects makes sense only if higher regularity, such as continuity, of the order parameter ψ_n is proved. In addition, jump discontinuities in the induced magnetic field, $(\nabla \times \vec{A})(\vec{x})$, across the layers (corresponding to bending of the induced magnetic field across the layers) are expected for solutions of the Lawrence–Doniach system. (See [1] and [2].) A rigorous analysis of such properties cannot be done without results on the regularity of $(\nabla \times \vec{A})(\vec{x})$ that identifies how and where jumps will occur across each layer for solutions of the Lawrence–Doniach system.

1.2. Main results and outline of the paper. In this paper, assuming that Ω is a bounded Lipschitz domain in $\mathbb{R}^2$, we prove that $|\psi_n| \leq 1$ almost everywhere in Ω for $n = 0, 1, \ldots, N$ for all weak solutions, without assuming continuity of solutions of the Lawrence–Doniach system. In addition, we prove a priori estimates, which imply that all weak solutions (and in particular, minimizers of the Lawrence–Doniach energy) are gauge-equivalent to a pair satisfying (1.5), whose restriction to $\overline{\Omega}^{N+1} \times \overline{\mathcal{D}}$ is continuous, with $\vec{A}$ piecewise C^1 in $\Omega \times \mathbb{R}$, such that all discontinuities of $\nabla\vec{A}$ in $\Omega \times \mathbb{R}$ occur as jump discontinuities in $\frac{\partial A^i}{\partial x_3}$ for $i = 1, 2$ from above and below at points in Ω_n. Our methods of proof involve elliptic regularity and a priori estimates of single layer potentials. The latter arise because A^1 and A^2 in this gauge have Laplacians given by measures supported in the layers, and hence can be represented as single layer potentials in $\mathbb{R}^3$. A consequence of these results and the methods of Chapman, Du, and Gunzburger is that minimizers of the Lawrence–Doniach energy converge, as the nondimensionalized interlayer spacing s tends to zero, to minimizers of an appropriate anisotropic Ginzburg–Landau energy in three dimensions (provided that $\sigma\kappa^2 s^2 = \gamma^{-1}$ for some $\gamma > 0$). (See section 6.) Another consequence is the existence of a smallest nonnegative number, $\bar{h} = \bar{h}(\vec{v}, \kappa, s, \sigma, S, \Omega) = \frac{1}{\mu}O(\kappa)$, called the upper critical modulus, such that if $h > \bar{h}$ and $\vec{H} = h\vec{v}$, where $\vec{v}$ is a nontangential unit vector in $\mathbb{R}^3$ and $0 < \mu \leq |\vec{v} \cdot \vec{e_3}|$, the only weak solution to the Lawrence–Doniach system is the normal (nonsuperconducting) state, defined by $\psi_n \equiv 0$ for $n = 0, 1, \ldots, N$ and $\nabla \times \vec{A} \equiv \vec{H}$ in $\mathbb{R}^3$. (See (5.1) for a formal definition of $\bar{h}$.)

The infimum of the values $h'' > 0$ such that all normal states are stable for $h > h''$ in an applied magnetic field $\vec{H} = h\vec{v}$ is denoted by $H_{c_3} = H_{c_3}(\vec{v}, \kappa, s, \sigma, S, \Omega)$. (If there are no such values h'', one defines $H_{c_3} = \infty$.) Here, a weak solution is called stable if the Lawrence–Doniach energy has nonnegative second variation at the solution. From our result on the finiteness of $\bar{h} < \infty$ and the fact that the Lawrence–Doniach energy has a minimizer in $[H^1(\Omega)]^{N+1} \times E$, it follows that $H_{c_3} \leq \bar{h} = \frac{1}{\mu}O(\kappa)$ (for each fixed $\vec{v}, \kappa, s, \sigma, S$, and Ω as above), for nontangential applied magnetic fields $\vec{H} = h\vec{v}$. This proves a result conjectured by physicists (see [13] and the references cited there). Note that since μ is the sine of the angle between $\vec{H} = h\vec{v}$ and the x_1x_2 plane when $\vec{v} \cdot \vec{e_3} = \mu$, our upper bound on H_{c_3} blows up as $\mu \to 0$. Moreover, an examination of the proof of this estimate (based on the inequality (5.6) of Lemma 5.4, which involves integral estimates on the two-dimensional layers) shows that our proof of this result does not allow a finite upper bound on H_{c_3} as $\vec{v}$ approaches a direction parallel to the layers.

We remark that Klemm, Luther, and Beasley have predicted that $H_{c_3} = \infty$ at a sufficiently low temperature $T < T_c$ for applied magnetic fields $\vec{H} = h\vec{v}$ in directions $\vec{v}$ that are parallel to the layers, based on a theory that the normal cores in these materials can effectively fit between the layers (so that $|\psi_n| > 0$ in Ω_n for each n) in this case. The behavior of solutions in this regime has been studied recently by Alama, Berlinsky, and Bronsard in [1] for layered superconductors occupying a finite number of parallel infinite strips, under some assumptions on the spatial dependence of the order parameter in each layer and on the magnetic potential $\vec{A}$ in $\mathbb{R}^3$. Since the constants in the Lawrence–Doniach model are temperature dependent, an interesting open problem (that will require a different approach from the one we develop here in Lemma 5.4 and Theorem 5.5) is to compute $H_{c_3} = H_{c_3}(T, \vec{v}, \kappa, s, \sigma, S, \Omega)$ when $\vec{v}$ is parallel to the x_1x_2 plane. We conjecture that $H_{c_3}(v)$ is finite in certain regimes depending on the constants in the Lawrence–Doniach model in parallel fields $\vec{v}$ (since it converges to the three-dimensional Ginzburg–Landau anisotropic model under certain assumptions on these constants), but it may be infinite for parallel fields at certain temperatures (i.e., in other regimes depending on the constants in the Lawrence–Doniach model).

As far as we know, our results on the existence and bounds of the upper critical moduli H_{c_3} and $\bar{h}$ for nontangential applied magnetic fields, $\vec{H} = h\vec{v}$, are the first rigorous results on upper critical moduli for the Lawrence–Doniach system, even in the case of a perpendicular applied magnetic field, $\vec{H} = h\vec{e_3}$.

A detailed summary of our results and the organization of our paper is as follows. In section 2 we prove the maximum principle, $|\psi_n|^2 \leq 1$ on Ω, for all solutions of (1.2) and (1.3), without assuming any continuity of solutions. (See Theorem 2.4.) In addition, we observe that for a solution $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big)$ in the "Coulomb gauge" (1.5), it follows from elliptic regularity theory (since $\nabla\times\big(\nabla\times\vec{A}\big) = -\Delta\vec{A}$ for divergence-free fields in $\mathbb{R}^3$) that A^3 is in $W^{2,q}_{loc}(\mathbb{R}^3)$ for all $q \in (1,\infty)$, and thus A^3 is in $C^{1,\beta}_{loc}(R^3)$ for all $\beta \in (0,1)$. (See Theorem 2.6.)

Unlike the case of A^3, the Laplacians of A^1 and A^2 are singular measures rather than L^p functions. In addition, ψ_n satisfies a nonlinear elliptic equation in Ω involving $\mathbf{A}_n$ for each n, where $\mathbf{A}_n(\cdot)$ is the trace of (A^1, A^2) on $\{x_3 = ns\}$. Therefore, techniques for obtaining higher regularity for the standard Ginzburg–Landau system do not apply. In section 3 we find explicit integral representations of A^1, A^2, A^1_n, and A^2_n involving single layer potentials, and using results from the theory of single layer potentials, we improve the regularity of A^1_n and A^2_n from $H^{\frac{1}{2}}_{loc}(\mathbb{R}^2)$ to $H^1_{loc}(\mathbb{R}^2)$.

In section 4, we use the above result and a bootstrapping method (combining results from the theory of single layer potentials and elliptic theory) to obtain a regularity result, Theorem 4.6, which states that there exist constants $p > 2$ and α in (0,1) such that in the gauge (1.5), all weak solutions of the Lawrence–Doniach system satisfy

$$
\begin{aligned}
&\psi_n \in W^{1,p}\big(\Omega\big) \cap C^{\alpha}\big(\overline{\Omega}\big) \cap C^{2,\alpha}\big(\Omega\big),\\
&A^1_n, A^2_n \in W^{1,p}_{loc}\big(\mathbb{R}^2\big) \cap C^{\alpha}_{loc}\big(\mathbb{R}^2\big) \cap C^1\big(\Omega\big) \cap C^{\infty}\Big(\mathbb{R}^2 \setminus \overline{\Omega}\Big) \text{ for all } n = 0, 1, \ldots, N,\\
&A^1, A^2 \in W^{1,p}_{loc}\big(\mathbb{R}^3\big) \cap C^{\alpha}_{loc}\big(\mathbb{R}^3\big) \cap C^{\infty}\left(\mathbb{R}^3 \Big\backslash \bigcup_{i=o}^{N} \overline{\Omega}_n\right),\\
&\frac{\partial A^i}{\partial x_1} \text{ and } \frac{\partial A^i}{\partial x_2} \in C\big(\Omega \times \mathbb{R}\big) \text{ for } i = 1, 2,\\
&A^3 \in W^{2,q}_{loc}\big(\mathbb{R}^3\big) \cap C^{1,\beta}_{loc}\big(\mathbb{R}^3\big) \text{ for all } q \in (1,\infty) \text{ and } \beta \in (0,1).
\end{aligned}
$$

In addition, for $i = 1, 2$ we prove that A^i is piecewise C^1 in $\Omega \times \mathbb{R}$, with all discontinuities of ∇A^i in $\Omega \times \mathbb{R}$ occurring as jump discontinuities in $\frac{\partial A^i}{\partial x_3}$ from above and below at points in Ω_n where the ith component of the current density in $R^2 \times \{ns\}$, namely, $g^i_n(\mathbf{x}, ns)$ (defined by (3.4)), is nonzero. If Ω is a $C^{1,1}$ domain, we prove that the above results hold for all $p \in (1,\infty)$ and all $\alpha \in (0,1)$, with additional regularity up to the boundary of Ω. (See Theorems 4.4 and 4.6.) Thus ψ_n is continuous in Ω for each n, and the induced magnetic field $\nabla \times \vec{A}$ is continuous in $\Omega \times \mathbb{R}^3$ except at points in Ω_n, where it has jump discontinuities.

In section 5, we prove the existence of $\bar{h} = \bar{h}(\vec{v}, \kappa, s, \sigma, S, \Omega) < \infty$ such that if $h > \bar{h}$, $\vec{v}$ is a nontangential unit vector, and $\vec{H} = h\vec{v}$, any weak solution to the Lawrence–Doniach system is normal (nonsuperconducting). We also prove that $H_{c_3} \leq \bar{h} \leq C\kappa/\mu$ for all κ sufficiently large if $|\vec{v} \cdot \vec{e_3}| \geq \mu > 0$, where C is a positive constant depending only on S and Ω. (See Theorem 5.5 and Corollary 5.6.) The above result generalizes a theorem of Giorgi and Phillips in [9] for the standard Ginzburg–Landau model with $\vec{v} = \vec{e_3}$ as $\kappa \to \infty$ in two and three dimensions.

Finally, in section 6, we describe the three-dimensional anisotropic Ginzburg–Landau model, and conclude as a consequence of Theorem 2.4 and the results of Chapman, Du, and Gunzburger in [4], that if $\sigma\kappa^2 s^2 = \gamma^{-1}$, where $\gamma > 0$ is fixed, then minimizers of the Lawrence–Doniach energy in the gauge (1.5) have an extension to $H^1(D) \times E$ in a divergence-free gauge in $\mathbb{R}^3$ and form a minimizing sequence as $s \to 0$ of the anisotropic Ginzburg–Landau energy. (See Theorem 6.1.)

2. Preliminary results. Throughout this paper, we assume that Ω is a given bounded Lipschitz domain in $\mathbb{R}^2$ and $\vec{H} = h\vec{v}$ is a constant applied magnetic field on $\mathbb{R}^3$ with h, $\vec{v}$, and $\vec{a} = \vec{a}(\vec{x})$ as described in the introduction.

In this section we prove preliminary results on weak solutions of (1.3) and minimizers of the Lawrence–Doniach energy in the gauge $[\mathcal{H}^1(\Omega)]^{N+1} \times K$ defined by (1.5). Recall that $\check{H}^1(\mathbb{R}^3)$ is the completion of $C_0^\infty(\mathbb{R}^3; \mathbb{R}^3)$ with respect to the norm

$$\|\vec{C}\|_{\check{H}^1(\mathbb{R}^3)} = \left(\int_{\mathbb{R}^3} \left|\nabla \vec{C}\right|^2 d\vec{x} \right)^{\frac{1}{2}}.$$

It follows from the Sobolev inequality that each $\vec{C} \in \check{H}^1(\mathbb{R}^3)$ has a representative in $L^6(R^3; R^3)$ such that

$$\|\vec{C}\|_{L^6(\mathbb{R}^3, \mathbb{R}^3)} \leq 2\|\vec{C}\|_{\check{H}^1(\mathbb{R}^3)}. \tag{2.1}$$

Moreover,

$$\|\vec{C}\|^2_{\check{H}^1(\mathbb{R}^3)} = \int_{\mathbb{R}^3} \left(\left|\nabla \cdot \vec{C}\right|^2 + \left|\nabla \times \vec{C}\right|^2 \right) d\vec{x}. \tag{2.2}$$

(See [14].) We need the following lemma to prove that the "Coulomb gauge" (1.5) is an appropriate gauge for weak solutions of (1.3) in $[\mathcal{H}^1(\Omega)]^{N+1} \times E$.

LEMMA 2.1. *Let* $\left(\{\xi_n\}_{n=0}^N, \vec{Q}\right) \in [\mathcal{H}^1(\Omega)]^{N+1} \times E$. *Then there exists a gauge-equivalent pair* $\left(\{\psi_n\}_{n=0}^N, \vec{A}\right)$ *satisfying* (1.5). *Moreover, if* $\left(\{\tilde{\psi}_n\}_{n=0}^N, \tilde{A}\right)$ *is another such pair, then* $\tilde{A} = \vec{A}$ *and there is a constant* $c \in \mathbb{R}$ *such that* $\tilde{\psi}_n = \psi_n e^{\imath\kappa c}$ *for all* $n = 0, 1, \ldots, N$.

Proof. Let $\left(\{\xi_n\}_{n=0}^N, \vec{Q}\right) \in [\mathcal{H}^1(\Omega)]^{N+1} \times E$ be given. Then $\vec{Q} \in H^1_{loc}(\mathbb{R}^3; \mathbb{R}^3)$ and $\nabla \times \vec{Q} - \vec{H} = \nabla \times \left(\vec{Q} - h\vec{a}\right) \in L^2(\mathbb{R}^3; \mathbb{R}^3)$. Set $\vec{u} = \nabla \times \left(\vec{Q} - h\vec{a}\right)$. Since $\vec{u} \in L^2(\mathbb{R}^3; \mathbb{R}^3)$ and $\nabla \cdot \vec{u} = 0$ in $\mathcal{D}'(\mathbb{R}^3)$, Lemma 3.1 of [9] states that there is a unique $\vec{C} \in \check{H}^1(\mathbb{R}^3) \cap L^6(R^3; R^3)$ such that $\nabla \times \vec{C} = \vec{u}$ and $\nabla \cdot \vec{C} = 0$. Set $\vec{A} = \vec{C} + h\vec{a}$. Then $\vec{A} \in H^1_{loc}(\mathbb{R}^3; \mathbb{R}^3)$, $\vec{A} - h\vec{a} = \vec{C} \in \check{H}^1(\mathbb{R}^3) \cap L^6(R^3; R^3)$, and $\nabla \cdot \vec{A} = \nabla \cdot \vec{C} + h\nabla \cdot \vec{a} = 0$

in $\mathbb{R}^3$. Since

$$\begin{aligned}\nabla\times\left(\vec{A}-\vec{Q}\right) &= \nabla\times\left(\vec{A}-h\vec{a}\right)-\nabla\times\left(\vec{Q}-h\vec{a}\right)\\ &= \nabla\times\vec{C}-\vec{u}=\vec{0}\end{aligned}$$

and $\vec{A}-\vec{Q}\in H^1_{loc}(\mathbb{R}^3;\mathbb{R}^3)$, there exists a function g in $H^2_{loc}(\mathbb{R}^3)$ such that $\vec{A}=\vec{Q}+\nabla g$. Set $\psi_n(\mathbf{x})=\xi_n(\mathbf{x})e^{\imath\kappa g(\mathbf{x},ns)}$ for all $\mathbf{x}$ in Ω and for all $n=0,1,\dots,N$. Then the pair $\left(\{\psi_n\}_{n=0}^N,\vec{A}\right)$ is gauge-equivalent to $\left(\{\xi_n\}_{n=0}^N,\vec{Q}\right)$ and $\left(\{\psi_n\}_{n=0}^N,\vec{A}\right)\in[\mathcal{H}^1(\Omega)]^{N+1}\times K$.

Now assume that there is another pair $(\{\tilde{\psi}_n\}_{n=0}^N,\tilde{A})$ in $[\mathcal{H}^1(\Omega)]^{N+1}\times K$, which is gauge-equivalent to $\left(\{\xi_n\}_{n=0}^N,\vec{Q}\right)$; i.e., there is a function $\tilde{g}$ in $H^2_{loc}(\mathbb{R}^3)$ such that $\tilde{A}=\vec{Q}+\nabla\tilde{g}$ and $\tilde{\psi}_n(\mathbf{x})=\xi_n(\mathbf{x})e^{\imath\kappa\tilde{g}(\mathbf{x},ns)}$ for each n. To show that $\vec{A}=\tilde{A}$ and that there is a constant $c\in\mathbb{R}$ such that $\tilde{\psi}_n=\psi_n e^{\imath\kappa c}$ for each n, it is sufficient to prove that $\tilde{g}-g=c$ for some constant $c\in\mathbb{R}$. Set $\tilde{C}=\tilde{A}-h\vec{a}$. Then $\vec{C},\ \tilde{C}\in\check{H}^1(\mathbb{R}^3)\cap L^6(R^3;R^3)$, $\nabla\times\vec{C}=\nabla\times\tilde{C}=\nabla\times\left(\vec{Q}-h\vec{a}\right)\in L^2(\mathbb{R}^3;\mathbb{R}^3)$, and $\nabla\cdot\vec{C}=\nabla\cdot\tilde{C}=0$. By Lemma 3.1 in [9], such a vector field is unique, and hence $\vec{C}=\tilde{C}$. Thus, $\vec{A}=\tilde{A}$ and we have $\nabla g=\nabla\tilde{g}$, so that $\tilde{g}=g+c$ for some constant $c\in\mathbb{R}$. ∎

By Lemma 2.1 and the invariance of the Lawrence–Doniach energy under gauge transformations, the existence of minimizers in $[\mathcal{H}^1(\Omega)]^{N+1}\times E$ is equivalent to the existence of minimizers in $[\mathcal{H}^1(\Omega)]^{N+1}\times K$. Thus we have the following theorem.

THEOREM 2.2. *There exists* $\left(\{\psi_n\}_{n=0}^N,\vec{A}\right)\in[\mathcal{H}^1(\Omega)]^{N+1}\times K$, *which minimizes* $\mathcal{G}^s_{LD}$ *in* $[\mathcal{H}^1(\Omega)]^{N+1}\times E$.

Proof. Let $\{\left(\{\psi^j_n\}_{n=0}^N,\vec{A}^j\right)\}\subset[\mathcal{H}^1(\Omega)]^{N+1}\times E$ be a minimizing sequence for $\mathcal{G}^s_{LD}$. By Lemma 2.1, we may assume that $\vec{A}^j\in K$ for all j without loss of generality. Using (2.1), (2.2), and $\nabla\cdot\vec{A}^j=0$ for all j, it follows that $\left(\{\psi^j_n\}_{n=0}^N,\vec{A}^j-h\vec{a}\right)$ is bounded in $[\mathcal{H}^1(\Omega)]^{N+1}\times\ [\check{H}^1(\mathbb{R}^3)\cap L^6(R^3;R^3)]$ so that there is a weakly convergent subsequence. Let $(\{\psi_n\}_{n=0}^N,\vec{A}-h\vec{a})$ be the weak limit of the subsequence. Since the integrands in (1.1) are each weakly lower semicontinuous in $[\mathcal{H}^1(\Omega)]^{N+1}\times K$, $\mathcal{G}^s_{LD}$ is weakly lower semicontinuous, and thus $\left(\{\psi_n\}_{n=0}^N,\vec{A}\right)$ is a minimizer in the gauge $[\mathcal{H}^1(\Omega)]^{N+1}\times K$. ∎

The weak formulation of (1.3) is

(2.3)

$$\begin{aligned}
&\text{(a)}\quad s\sum_{n=0}^{N}\int_\Omega\left[\left(|\psi_n|^2-1\right)\psi_n\varphi_n^*+\left(\frac{\imath}{\kappa}\mathbf{grad}\ \psi_n+\mathbf{A}_n\psi_n\right)\cdot\left(\frac{\imath}{\kappa}\mathbf{grad}\ \varphi_n+\mathbf{A}_n\varphi_n\right)^*\right]d\mathbf{x}\\
&\qquad+s\sigma\sum_{n=0}^{N-1}\int_\Omega\left[\left(\psi_{n+1}-\psi_n e^{\imath\phi_n^{n+1}}\right)\varphi_{n+1}^*+\left(\psi_n-\psi_{n+1}e^{-\imath\phi_n^{n+1}}\right)\varphi_n^*\right]d\mathbf{x}=0,\\
&\text{(b)}\quad 2\int_{\mathbb{R}^3}\nabla\times\left(\vec{A}-h\vec{a}\right)\cdot\nabla\times\vec{B}\,d\vec{x}+s\sigma\int_{\mathbb{R}^3}\mathrm{I}\cdot B^3\,d\vec{x}\\
&\qquad+s\sum_{n=0}^{N}\int_{\mathbb{R}^2}\chi_{[\Omega\times\{ns\}]}(\mathbf{x},x_3)\left[\frac{\imath}{\kappa}\left(\psi_n^*\,\mathbf{grad}\ \psi_n-c.c.\right)+2\mathbf{A}_n\left|\psi_n\right|^2\right]\cdot\mathbf{B}_n\,d\mathbf{x}=0
\end{aligned}$$

for any $\{\varphi_n\}_{n=0}^N\in[\mathcal{H}^1(\Omega)]^{N+1}$ and $\vec{B}=(B^1,B^2,B^3)\in H^1(\mathbb{R}^3;\mathbb{R}^3)$ with bounded support. Here,

$$
\begin{aligned}
\mathrm{I} &= \imath\kappa \sum_{n=0}^{N-1} \chi_\Omega(\mathbf{x})\chi_{[ns,(n+1)s]}(x_3)\Big(\psi_{n+1}\psi_n^* e^{-\imath\phi_n^{n+1}} - c.c.\Big) \\
&= 2\kappa \sum_{n=0}^{N-1} \chi_\Omega(\mathbf{x})\chi_{[ns,(n+1)s]}(x_3)\Im\Big(\psi_{n+1}^*\psi_n e^{\imath\phi_n^{n+1}}\Big),
\end{aligned} \tag{2.4}
$$

where $\Im$ denotes the imaginary part of the argument and *c.c.* denotes the complex conjugate of the previous term. By a weak solution of (1.3) we mean a pair, $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big) \in [\mathcal{H}^1(\Omega)]^{N+1} \times E$, satisfying (2.3). From Theorem 2.2, we have the following.

COROLLARY 2.3. *There exists* $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big) \in [\mathcal{H}^1(\Omega)]^{N+1} \times K$, *which is a weak solution to the Lawrence–Doniach system* (1.3).

Next we prove that the magnitude of the order parameters of weak solutions to (1.3) is uniformly bounded by 1, which is the density of the perfectly superconducting state. This result generalizes Proposition 4.5 in [4], in which the maximum principle was established under the assumption that ψ_n and $\vec{A}$ are continuous on $\overline{\Omega}$ and $\overline{\mathcal{D}}$ for all $n = 0, 1, \ldots, N$.

THEOREM 2.4. *If* $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big)$ *is a weak solution to* (1.3), *then* $|\psi_n| \le 1$ *almost everywhere in* Ω *for all* $n = 0, 1, \ldots, N$.

Proof. Set $\varphi_n = \big(|\psi_n| - 1\big)_+ d_n$, where $d_n = \frac{\psi_n}{|\psi_n|}$ and where $q_+ = q$ if $q \ge 0$ and $q_+ = 0$ if $q < 0$. Since $\psi_n \in H^1(\Omega;\mathbb{C})$, we have $|\psi_n|$ and $(|\psi_n| - 1)_+$ in $H^1(\Omega)$ (see [10, Chapter 7]), and it follows that $\varphi_n \in H^1(\Omega, \mathbb{C})$ for each n. Let $O_n = \{x \in \Omega : |\psi_n(x)| > 1\}$. Then almost everywhere in O_n, we have

$$
\frac{\imath}{\kappa}\,\mathbf{grad}\,\psi_n + \mathbf{A}_n\psi_n = \frac{\imath}{\kappa} d_n\Big(\mathbf{grad}\ |\psi_n|\Big) + |\psi_n|\left(\frac{\imath}{\kappa}\mathbf{grad}\, d_n + \mathbf{A}_n d_n\right),
$$

$$
\left(\frac{\imath}{\kappa}\,\mathbf{grad}\,\varphi_n + \mathbf{A}_n\varphi_n\right)^* = -\frac{\imath}{\kappa} d_n^*\Big(\mathbf{grad}\ |\psi_n|\Big) + \big(|\psi_n| - 1\big)\left(-\frac{\imath}{\kappa}\mathbf{grad}\, d_n^* + \mathbf{A}_n d_n^*\right),
$$

and

$$
\big(|\psi_n|^2 - 1\big)\psi_n\varphi_n^* = |\psi_n|\,\big(|\psi_n| + 1\big)\big(|\psi_n| - 1\big)^2
$$

so that

$$
\begin{aligned}
&\Re\left\{\left(\frac{\imath}{\kappa}\mathbf{grad}\,\psi_n + \mathbf{A}_n\psi_n\right)\left(\frac{\imath}{\kappa}\mathbf{grad}\,\varphi_n + \mathbf{A}_n\varphi_n\right)^*\right\} \\
&\quad = \frac{1}{\kappa^2}\big|\mathbf{grad}\ |\psi_n|\big|^2 + |\psi_n|\,\big(|\psi_n| - 1\big)\left|\frac{\imath}{\kappa}\mathbf{grad}\, d_n + \mathbf{A}_n d_n\right|^2.
\end{aligned}
$$

Taking the real part of (2.3a), we obtain

$$
\begin{aligned}
& s\sum_{n=0}^{N}\int_{O_n}\left(\frac{1}{\kappa^2}\big|\mathbf{grad}\ |\psi_n|\big|^2 + |\psi_n|\,\big(|\psi_n| - 1\big)\left|\frac{\imath}{\kappa}\mathbf{grad}\, d_n + \mathbf{A}_n d_n\right|^2\right)d\mathbf{x} \\
&+ s\sum_{n=0}^{N}\int_{O_n}|\psi_n|\,\big(|\psi_n| + 1\big)\big(|\psi_n| - 1\big)^2\,d\mathbf{x} \\
&+ s\sigma\sum_{n=0}^{N-1}\Re\left\{\int_\Omega\left(\left(\psi_n - \psi_{n+1}e^{-i\phi_n^{n+1}}\right)\varphi_n^* + \left(\psi_{n+1} - \psi_n e^{i\phi_n^{n+1}}\right)\varphi_{n+1}^*\right)d\mathbf{x}\right\} = 0.
\end{aligned}
$$

We write this as $\mathrm{I}+\mathrm{II}+\mathrm{III}=0$. Note that $\mathrm{I}\geq 0$ and $\mathrm{II}\geq 0$. Rewriting III, we have

$$\mathrm{III} = s\sigma\sum_{n=0}^{N-1}\left[\int_\Omega \Re\left\{\left(\psi_n-\psi_{n+1}e^{-i\phi_n^{n+1}}\right)\psi_n^*\frac{|\psi_n|-1}{|\psi_n|}\chi_{O_n}\right\}\right. \\ \left.+\Re\left\{\left(\psi_{n+1}-\psi_n e^{i\phi_n^{n+1}}\right)\psi_{n+1}^*\frac{|\psi_{n+1}|-1}{|\psi_{n+1}|}\chi_{O_{n+1}}\right\}d\mathbf{x}\right]$$

so that

$$\mathrm{III} = s\sigma\sum_{n=0}^{N-1}\left[\int_{O_n}\left(|\psi_n|^2-\Re\left\{\psi_n^*\psi_{n+1}e^{-i\phi_n^{n+1}}\right\}\right)\frac{|\psi_n|-1}{|\psi_n|}\,d\mathbf{x}\right. \\ \left.+\int_{O_{n+1}}\left(|\psi_{n+1}|^2-\Re\left\{\psi_{n+1}^*\psi_n e^{i\phi_n^{n+1}}\right\}\right)\frac{|\psi_{n+1}|-1}{|\psi_{n+1}|}\,d\mathbf{x}\right].$$

Thus,

$$\mathrm{III} \geq s\sigma\sum_{n=0}^{N-1}\left[\int_{O_n}\big(|\psi_n|-|\psi_{n+1}|\big)\big(|\psi_n|-1\big)\,d\mathbf{x}\right. \\ \left.+\int_{O_{n+1}}\big(|\psi_{n+1}|-|\psi_n|\big)\big(|\psi_{n+1}|-1\big)\,d\mathbf{x}\right].$$

Splitting the domains of integration appropriately, we have

$$\mathrm{III} \geq s\sigma\sum_{n=0}^{N-1}\left[\left(\int_{O_n\cap O_{n+1}}+\int_{O_n\setminus O_{n+1}}\right)\big(|\psi_n|-|\psi_{n+1}|\big)\big(|\psi_n|-1\big)\,d\mathbf{x}\right. \\ \left.+\left(\int_{O_{n+1}\cap O_n}+\int_{O_{n+1}\setminus O_n}\right)\big(|\psi_{n+1}|-|\psi_n|\big)\big(|\psi_{n+1}|-1\big)\,d\mathbf{x}\right].$$

Rearranging the terms in the integrand of the above, we get

$$\mathrm{III} \geq s\sigma\sum_{n=0}^{N-1}\left[\int_{O_n\cap O_{n+1}}\big(|\psi_n|^2-2|\psi_n||\psi_{n+1}|+|\psi_{n+1}|^2\big)\,d\mathbf{x}\right. \\ +\int_{O_n\setminus O_{n+1}}\big(|\psi_n|-|\psi_{n+1}|\big)\big(|\psi_n|-1\big)\,d\mathbf{x} \\ \left.+\int_{O_{n+1}\setminus O_n}\big(|\psi_{n+1}|-|\psi_n|\big)\big(|\psi_{n+1}|-1\big)\,d\mathbf{x}\right].$$

Since $|\psi_n|-|\psi_{n+1}|\geq|\psi_n|-1\geq 0$ on $O_n\setminus O_{n+1}$ and $|\psi_{n+1}|-|\psi_n|\geq|\psi_{n+1}|-1\geq 0$ on $O_{n+1}\setminus O_n$, we have

$$\mathrm{III} \geq s\sigma\sum_{n=0}^{N-1}\left[\int_{O_n\cap O_{n+1}}\big(|\psi_n|-|\psi_{n+1}|\big)^2\right. \\ \left.+\int_{O_n\setminus O_{n+1}}\big(|\psi_n|-1\big)^2+\int_{O_{n+1}\setminus O_n}\big(|\psi_{n+1}|-1\big)^2\right]\geq 0. \tag{2.5}$$

Using (2.5) and the fact that $\mathrm{I} \geq 0$, $\mathrm{II} \geq 0$, and $\mathrm{I} + \mathrm{II} + \mathrm{III} = 0$, we obtain $\mathrm{I} = \mathrm{II} = \mathrm{III} = 0$ so that

$$\sum_{n=0}^{N} \int_{O_n} |\psi_n| \big(|\psi_n| + 1\big)\big(|\psi_n| - 1\big)^2 \, d\mathbf{x} = 0.$$

Therefore, the measure of O_n is zero, i.e., $|\psi_n| \leq 1$ almost everywhere in Ω for all $n = 0, 1, \ldots, N$. $\square$

The above result, namely, $|\psi_n| \leq 1$ for all $n = 0, 1, \ldots, N$, was assumed as a hypothesis in a result of Chapman, Du, and Gunzburger in [4], in which case it was shown that if the parameters in the Lawrence–Doniach system are related by the equation $\gamma\sigma s^2 = \kappa^{-2}$, then minimizers of the Lawrence–Doniach energy (with S fixed and $s = S/N \to 0$), after extending $\{\psi_n\}$ to be defined on $D = \Omega \times (0, S)$ by linear interpolation in x_3 between consecutive layers, form a minimizing sequence for an appropriate anisotropic Ginzburg–Landau energy. (See Lemma 5.5, Theorem 5.1, and Corollary 5.6 of [4].) Thus, our Theorem 2.4 and the results in [4] can be combined to obtain this limiting result without the added hypothesis $|\psi_n| \leq 1$ in Ω for all $n = 0, 1, \ldots, N$. For completeness, we describe the anisotropic Ginzburg–Landau energy and state this consequence in section 6 of this paper.

We need the following lemma, which follows by approximation with smooth functions.

Lemma 2.5. *Let $\vec{C} = (C^1, C^2, C^3) \in H^1_{loc}(\mathbb{R}^3; \mathbb{R}^3)$ such that $\nabla \cdot \vec{C} = 0$ and let $\vec{B} = (B^1, B^2, B^3) \in H^1(\mathbb{R}^3; \mathbb{R}^3)$ with bounded support. Then*

$$\int_{\mathbb{R}^3} \left(\nabla \times \vec{C}\right) \cdot \left(\nabla \times \vec{B}\right) d\vec{x} = \int_{\mathbb{R}^3} \left(\nabla \vec{C}\right) \cdot \left(\nabla \vec{B}\right) d\vec{x}, \tag{2.6}$$

where

$$\left(\nabla \vec{C}\right) \cdot \left(\nabla \vec{B}\right) = \sum_{i=1}^{3} \nabla C^i \cdot \nabla B^i.$$

We can now improve the regularity of A^3, the third component of $\vec{A}$, for weak solutions in the gauge (1.5).

Theorem 2.6. *Let $\left(\{\psi_n\}_{n=0}^N, \vec{A}\right)$ be a weak solution of (1.3) in $[\mathcal{H}^1(\Omega)]^{N+1} \times K$. Then $A^3 \in W^{2,q}_{loc}(\mathbb{R}^3)$ for all $1 < q < \infty$, and thus $A^3 \in C^{1,\beta}_{loc}(\mathbb{R}^3)$ for all $0 < \beta < 1$.*

Proof. Let $\vec{B} = (0, 0, B^3)$ in (2.3b), where $B^3 \in H^1(\mathbb{R}^3)$ with bounded support. Using Lemma 2.5, we have

$$\Delta(A^3 - ha^3) = \Delta A^3 = \frac{s\sigma}{2}\,\mathrm{I} \text{ in } \mathbb{R}^3,$$

where I is the function defined in (2.4). By Theorem 2.4, we have $\frac{s\sigma}{2}\,\mathrm{I} \in L^\infty(\mathbb{R}^3)$. Since $\mathrm{I} = 0$ in $\mathbb{R}^3 \backslash \overline{D}$ and $A \in K$, it follows from this and (1.3) that $A^3 - ha^3$ is the Newtonian potential of $\frac{s\sigma}{2}\,\mathrm{I}$ in $\mathbb{R}^3$. The proof now follows from standard elliptic regularity results and the Sobolev imbedding theorem; see, e.g., [10]. $\square$

3. Integral representations of ^{1} ^{2} ^{1}, and ^{2}. Throughout this section, let $\left(\{\psi_n\}_{n=0}^N, \vec{A}\right)$ denote a weak solution of (1.3) in the gauge (1.5) so that

$$\left(\{\psi_n\}_{n=0}^N, \vec{A}\right) \in [\mathcal{H}^1(\Omega)]^{N+1} \times K.$$

Thus,

$$\vec{A} - h\vec{a} \in \check{H}^1(\mathbb{R}^3), \quad \nabla\cdot(\vec{A} - h\vec{a}) = 0 \quad \text{in } \mathbb{R}^3. \tag{3.1}$$

By choosing an appropriate $\vec{B} = (B^1, B^2, B^3)$ in (2.3b), we obtain

$$\Delta(A^i - ha^i) = j_i \quad \text{in } \mathcal{D}'(\mathbb{R}^3) \tag{3.2}$$

for $i = 1, 2$. Here j_i is the measure defined in (1.3), i.e.,

$$j_i(\varphi) = \sum_{n=0}^{N} \int_{\mathbb{R}^2} g_n^i(\mathbf{x}, ns)\varphi(\mathbf{x}, ns)\, d\mathbf{x} \tag{3.3}$$

for all $\varphi \in C_0^\infty(\mathbb{R}^3)$ and $i = 1, 2$, where

$$g_n^i(\mathbf{x}, ns) \equiv h_n^i(\mathbf{x}) = s\chi_\Omega(\mathbf{x}) \left[\frac{\imath}{2\kappa} \left(\psi_n^* \frac{\partial \psi_n}{\partial x_i} - c.c. \right) + A_n^i \left|\psi_n\right|^2 \right](\mathbf{x}) \tag{3.4}$$

for all $\mathbf{x} \in \mathbb{R}^2$, $n = 0, 1, \ldots, N$, and $i = 1, 2$. Note that $A_n^i \in H_{loc}^{\frac{1}{2}}(\mathbb{R}^2)$ by the trace theorem and that h_n^i is real valued. By Theorem 2.4, $h_n^i \in L^2(\mathbb{R}^2)$ (with support in $\overline{\Omega}$), and hence $g_n^i \in L^2(\mathbb{R}^2 \times \{ns\})$ (with support in $\overline{\Omega}_n$) for all $n = 0, 1, \ldots, N$ and $i = 1, 2$. Thus $j_i \in \mathcal{E}'(\mathbb{R}^3)$ for $i = 1, 2$, where $\mathcal{E}'(\mathbb{R}^3)$ is the class of tempered distributions in $\mathbb{R}^3$.

One can extend j_i to be defined in $C_c(\mathbb{R}^3)$ by formula (3.3), where $C_c(\mathbb{R}^3)$ is the set of continuous functions defined in $\mathbb{R}^3$ with compact support. Let us denote the extension again by j_i. Thus, j_i is a measure in $\mathbb{R}^3$ with support in $\bigcup_{n=0}^N \overline{\Omega}_n$.

For $\vec{x}$ in $\mathbb{R}^3$, let $\Gamma_3(\vec{x}) = \frac{c}{|\vec{x}|}$ be the fundamental solution of Δ in $\mathbb{R}^3$ (so that $c = -\frac{1}{4\pi}$). Define

$$\begin{aligned} [S(g_n^i)](\vec{x}) &= \int_{\mathbb{R}^2 \times \{ns\}} \frac{c}{|\vec{x} - \vec{Q}|} g_n^i(\vec{Q})\, d\sigma(\vec{Q}) \\ &= \int_{\mathbb{R}^2} \frac{c}{\left|\vec{x} - (\mathbf{y}, ns)\right|} h_n^i(\mathbf{y})\, d\mathbf{y}, \end{aligned} \tag{3.5}$$

where $d\sigma$ denotes surface measure on $\mathbb{R}^2 \times \{ns\}$. Note that $S(g_n^i)$ is the single layer potential of g_n^i on $\mathbb{R}^2 \times \{ns\}$. By the L^2 theory of single layer potentials on smooth domains (see [8]), $S(g_n^i) \in W_{loc}^{1,2}(\mathbb{R}^3) \cap C^\infty(\mathbb{R}^3 \backslash \overline{\Omega_n})$.

Our analysis of the regularity of $A^i - ha^i$ for $i = 1, 2$ is based on the following observations.

LEMMA 3.1. *$A^i - ha^i = \Gamma_3 * j_i = \sum_{n=0}^N S(g_n^i)$ in $L_{loc}^2(\mathbb{R}^3)$.*

Proof. Let $\hat{A} = \vec{A} - h\vec{a}$. By (2.3), we have $\Delta \hat{A}^i = j_i$ in $\mathcal{D}'(\mathbb{R}^3)$ for $i = 1, 2$. Thus for all $\varphi \in C_c^\infty(\mathbb{R}^3)$,

$$\begin{aligned} \langle \hat{A}^i, \varphi \rangle &= \langle \Delta\Gamma_3 * \hat{A}^i, \varphi \rangle \\ &= \langle \Gamma_3 * \Delta \hat{A}^i, \varphi \rangle = \langle \Gamma_3 * j_i, \varphi \rangle, \end{aligned}$$

and hence $\hat{A}^i = \Gamma_3 * j_i$ in $\mathcal{D}'(\mathbb{R}^3)$. On the other hand,

$$\begin{aligned} \langle S(g_n^i), \varphi \rangle &= \int_{\mathbb{R}^3} S(g_n^i)(\vec{x})\varphi(\vec{x})\, d\vec{x} \\ &= \int_{\mathbb{R}^3} \varphi(\vec{x}) \int_{\mathbb{R}^2} \frac{c}{\left|\vec{x} - (\mathbf{y}, ns)\right|} h_n^i(\mathbf{y})\, d\mathbf{y}\, d\vec{x}. \end{aligned}$$

Thus (by Fubini's theorem)

$$\begin{aligned}\langle \Gamma_3 * j_i, \varphi\rangle &= \langle j_i * \Gamma_3, \varphi\rangle \\ &= \sum_{n=0}^{N} \int_{\mathbb{R}^2} h_n^i(\mathbf{y}) \int_{\mathbb{R}^3} \frac{c}{|\vec{x}-(\mathbf{y},ns)|}\varphi(\vec{x})\, d\vec{x}\, d\mathbf{y} \\ &= \sum_{n=0}^{N} \int_{\mathbb{R}^3} \varphi(\vec{x}) \int_{\mathbb{R}^2} \frac{c}{|\vec{x}-(\mathbf{y},ns)|} h_n^i(\mathbf{y})\, d\mathbf{y}\, d\vec{x} \\ &= \sum_{n=0}^{N} \int_{\mathbb{R}^3} \varphi(\vec{x})[S(g_n^i)](\vec{x})\, d\vec{x},\end{aligned}$$

and we conclude that $\hat{A}^i = \Gamma_3 * j_i = \sum_{n=0}^N S(g_n^i)$ in $\mathcal{D}'(\mathbb{R}^3)$ for $i = 1,2$. Since $\hat{A}^i$ and $S(g_n^i)$ are in $L^2_{loc}(\mathbb{R}^3)$ for all $n = 0,1,\dots,N$ and $i = 1,2$, it follows that $\hat{A}^i = \sum_{n=0}^N S(g_n^i)$ in $L^2_{loc}(\mathbb{R}^3)$. $\square$

Define $t_n^i \in L^2_{loc}(\mathbb{R}^2 \times \{ns\})$ for all $n = 0,1,\dots,N$ and $i = 1,2$ by

$$\begin{aligned} t_n^i(\mathbf{x}, ns) &= \int_{\mathbb{R}^2\times\{ns\}} \frac{c}{|(\mathbf{x},ns)-\vec{Q}|} g_n^i(\vec{Q})\, d\sigma(\vec{Q}) \\ &= \int_{\mathbb{R}^2} \frac{c}{|\mathbf{x}-\mathbf{y}|} h_n^i(\mathbf{y})\, d\mathbf{y}. \end{aligned} \tag{3.6}$$

We shall need the following notation concerning nontangential limits and nontangential maximal functions on the plane $\{x_3 = ns\}$ for $n = 0,1,\dots,N$ in order to state our next result. Fix any $R > 0$ and assume that $0 < \theta < \frac{\pi}{2}$. Let

$$\Gamma \equiv \Gamma_{R,\theta} = \{\vec{x} \in \mathbb{R}^3 : |\vec{x}| < R \text{ and } |\vec{x}\cdot\vec{e_3}| > |\vec{x}|\cdot\cos\theta\}.$$

Let $\Gamma^+ = \{\vec{x} \in \Gamma : x_3 > 0\}$ and $\Gamma^- = \{\vec{x} \in \Gamma : x_3 < 0\}$. For each $\mathbf{x} \in \mathbb{R}^2$ and $n \in \{0,1,\dots,N\}$, let

$$\Gamma(\mathbf{x}, ns) = \{\vec{y} \in \mathbb{R}^3 : \vec{y} - (\mathbf{x}, ns) \in \Gamma\}.$$

Similarly, let $\Gamma^+(\mathbf{x}, ns) = \{\vec{y} \in \mathbb{R}^3 : \vec{y} - (\mathbf{x}, ns) \in \Gamma^+\}$ and $\Gamma^-(\mathbf{x}, ns) = \{\vec{y} \in \mathbb{R}^3 : \vec{y} - (\mathbf{x}, ns) \in \Gamma^-\}$. Note that $\Gamma(\mathbf{x}, ns)$ is a cone which is nontangential to the plane $\mathbb{R}^2 \times \{ns\}$ at $(\mathbf{x}, ns)$, since $\overline{\Gamma(\mathbf{x}, ns)} \bigcap [\mathbb{R}^2 \times \{ns\}] = \{(\mathbf{x}, ns)\}$.

For a function u defined at all points $\vec{y}$ in $\Gamma(\mathbf{x}, ns)$ with $0 < |y_3 - ns|$ sufficiently small, we define the nontangential limit (n.t. lim) of $u(\vec{y})$ as $\vec{y} \to (\mathbf{x}, ns)$ by

$$\operatorname*{n.t.lim}_{\vec{y}\to(\mathbf{x},ns)} u(\vec{y}) = \lim_{\vec{y}\to(\mathbf{x},ns)} \{u(\vec{y}) : \vec{y} \in \Gamma(\mathbf{x}, ns)\},$$

provided that the limit exists for each $\Gamma = \Gamma_{R,\theta}$ with $0 < \theta < \frac{\pi}{2}$. Similarly, we define

$$\operatorname*{n.t.lim}_{\vec{y}\to(\mathbf{x},ns^+)} u(\vec{y}) \text{ and } \operatorname*{n.t.lim}_{\vec{y}\to(\mathbf{x},ns^-)} u(\vec{y})$$

by replacing $\Gamma(\mathbf{x}, ns)$ in the above definition with $\Gamma^+(\mathbf{x}, ns)$ and $\Gamma^-(\mathbf{x}, ns)$, respectively.

Finally, we define the nontangential maximal function of u at $(\mathbf{x}, ns)$, denoted $u^*(\mathbf{x}, ns) = u^*_{R,\theta}(\mathbf{x}, ns)$, by

$$u^*(\mathbf{x}, ns) = \sup\{|u(\vec{y})| : \vec{y} \in \Gamma(\mathbf{x}, ns)\}$$

for a fixed $R > 0$ and $0 < \theta < \frac{\pi}{2}$.

By standard results on single layer potentials (see [8] and [19]), we have the following.

THEOREM 3.2. *For all $n = 0, 1, \ldots, N$ and $i = 1, 2$, $S(g_n^i) \in W_{loc}^{1,2}(\mathbb{R}^3) \cap C^\infty(\mathbb{R}^3 \backslash \overline{\Omega}_n)$, $t_n^i \in W_{loc}^{1,2}(\mathbb{R}^2 \times \{ns\})$, and t_n^i is the trace of $S(g_n^i)$ on $\mathbb{R}^2 \times \{ns\}$. The nontangential maximal functions of $S(g_n^i)$ and $\nabla S(g_n^i)$ from above and below $\mathbb{R}^2 \times \{ns\}$ are in $L_{loc}^2(\mathbb{R}^2 \times \{ns\})$. In addition, t_n^i and $\mathbf{grad}\, t_n^i$ are the nontangential limits of $S(g_n^i)$ and $\mathbf{grad} S(g_n^i)$, respectively, pointwise almost everywhere in $\mathbb{R}^2 \times \{ns\}$, and in $L_{loc}^2(\mathbb{R}^2 \times \{ns\})$ via the translation $(\mathbf{x}, ns + \epsilon) \to (\mathbf{x}, ns)$ as $\epsilon \to 0$. The gradients of $S(g_n^i)$ and t_n^i satisfy*

$$\begin{aligned}
\nabla S\big(g_n^i\big)(\vec{x}) &= \int_{\mathbb{R}^2 \times \{ns\}} \frac{-c\big(\vec{x} - \vec{Q}\big)}{\big|\vec{x} - \vec{Q}\big|^3} g_n^i\big(\vec{Q}\big)\, d\sigma\big(\vec{Q}\big) \\
&= \int_{\mathbb{R}^2} \frac{-c\big(\vec{x} - (\mathbf{y}, ns)\big)}{\big|\vec{x} - (\mathbf{y}, ns)\big|^3} h_n^i(\mathbf{y})\, d\mathbf{y} \;\; \text{a.e. in } \mathbb{R}^3, \\
(\mathbf{grad}\, t_n^i)(\mathbf{x}, ns) &= P.V. \int_{\mathbb{R}^2 \times \{ns\}} \frac{-c\big((\mathbf{x}, ns) - \vec{Q}\big)}{\big|(\mathbf{x}, ns) - \vec{Q}\big|^3} g_n^i\big(\vec{Q}\big)\, d\sigma\big(\vec{Q}\big) \\
&= P.V. \int_{\mathbb{R}^2} \frac{-c(\mathbf{x} - \mathbf{y})}{|\mathbf{x} - \mathbf{y}|^3} h_n^i(\mathbf{y})\, d\mathbf{y} \;\; \text{a.e. in } \mathbb{R}^2 \times \{ns\},
\end{aligned}$$

and

$$\begin{aligned}
&\underset{\vec{y} \to (\mathbf{x}, ns)}{\text{n.t.lim}}\; \mathbf{grad}\, S\big(g_n^i\big)(\vec{y}) = \mathbf{grad}\, t_n^i(\mathbf{x}, ns), \\
&\underset{\vec{y} \to (\mathbf{x}, ns^+)}{\text{n.t.lim}} \left(\frac{\partial S(g_n^i)}{\partial x_3}\right)(\vec{y}) = \frac{1}{2} g_n^i(\mathbf{x}, ns) = \frac{1}{2} h_n^i(\mathbf{x}), \\
&\underset{\vec{y} \to (\mathbf{x}, ns^-)}{\text{n.t.lim}} \left(\frac{\partial S(g_n^i)}{\partial x_3}\right)(\vec{y}) = -\frac{1}{2} g_n^i(\mathbf{x}, ns) = -\frac{1}{2} h_n^i(\mathbf{x})
\end{aligned}$$

pointwise a.e. in $\mathbb{R}^2 \times \{ns\}$, and in $L_{loc}^2(\mathbb{R}^2 \times \{ns\})$ via the translation $(\mathbf{x}, ns + \epsilon) \to (\mathbf{x}, ns)$, as $\epsilon \to 0$ (or $\epsilon \to 0^+$ or $\epsilon \to 0^-$, respectively). Here P.V. denotes the principal-valued integral.

Define $\mathbf{a}_n(\mathbf{x}) = (a_n^1(\mathbf{x}), a_n^2(\mathbf{x})) = (a^1(\mathbf{x}, ns), a^2(\mathbf{x}, ns))$. A consequence of Lemma 3.1, Theorem 3.2, and the fact that $S(g_n^i) \in C^\infty(\mathbb{R}^3 \backslash \bigcup_{n=0}^N \overline{\Omega}_n)$ is Corollary 3.3.

COROLLARY 3.3. *For all $n = 0, 1, \ldots, N$ and $i = 1, 2$, we have*

$$\begin{aligned}
A_n^i(\mathbf{x}) - h a_n^i(\mathbf{x}) &= t_n^i(\mathbf{x}, ns) + \sum_{\substack{k=0 \\ k \neq n}}^N S(g_k^i)(\mathbf{x}, ns) \\
&= \sum_{k=0}^N \int_{\mathbb{R}^2} \frac{c}{\big|(\mathbf{x}, ns) - (\mathbf{y}, ks)\big|} h_k^i(\mathbf{y})\, d\mathbf{y}
\end{aligned}$$

for almost every $\mathbf{x}$ in $\mathbb{R}^2$. Thus, $A_n^i \in W_{loc}^{1,2}(\mathbb{R}^2)$ for all n and i as above.

Proof. Fix i and n. The formula for $A_n^i - h a_n^i$ follows from Lemma 3.1 and Theorem 3.2. Since a_n^i is smooth, we have $A_n^i \in W_{loc}^{1,2}(\mathbb{R}^2)$. $\square$

Remark 3.4. We remark that if $g_n^i \in L^p(\Omega_n)$ for $2 < p < \infty$, the L^p theory of single layer potentials on C^1 domains gives the results of Theorem 3.2 and Corollary 3.3 with L_{loc}^2 and $W_{loc}^{1,2}$ replaced by L_{loc}^p and $W_{loc}^{1,p}$ throughout. (See [8].)

4. Higher regularity of solutions to the Lawrence–Doniach system. Throughout this section, let $\left(\{\psi_n\}_{n=0}^N, \vec{A}\right)$ denote a weak solution of (1.3) in the Coulomb gauge (1.5). In Corollary 3.3, we improved the regularity of A_n^i for $i = 1, 2$ from $H_{loc}^{\frac{1}{2}}(\mathbb{R}^2)$ to $W_{loc}^{1,2}(\mathbb{R}^2)$. In this section, we use this improved regularity together with the L^p theory of single layer potentials and elliptic estimates to prove higher regularity of ψ_n, $\mathbf{A}_n$, and $\vec{A}$. In particular, we prove that ψ_n and $\mathbf{A}_n$ are C^1 in Ω for each n, A^1 and A^2 are continuous in $\mathbb{R}^3$ and piecewise C^1 in $\Omega \times \mathbb{R}$, and all discontinuities in the gradient of A^i for $i = 1, 2$ occur as jump discontinuities in $\frac{\partial A^i}{\partial x_3}$ at those points of Ω_n at which $g_n^i \neq 0$.

Although our only assumption on Ω throughout this paper is that it is a bounded Lipschitz domain, we also state the regularity results, which hold when Ω is a bounded $C^{1,1}$ domain, and which are of independent interest, since most of the literature on Ginzburg–Landau equations has been written for the case of bounded smooth domains.

Lemma 4.1. *$\psi_n \in W_{loc}^{2,2}(\Omega) \cap W^{1,p}(\Omega) \cap C^\alpha(\overline{\Omega})$ for some $2 < p < \infty$, $0 < \alpha < 1$, and for all $n = 0, 1, \ldots, N$. Moreover, if Ω is a $C^{1,1}$ domain, then $\psi_n \in W^{2,2}(\Omega) \cap W^{1,q}(\Omega) \cap C^\beta(\overline{\Omega})$ for all $1 < q < \infty$ and $0 < \beta < 1$.*

Proof. Let **div** denote the divergence operator with respect to the x_1 and x_2 coordinates. By (1.5), Theorem 2.6, and Corollary 3.3, $\mathbf{div}\mathbf{A}_n = \frac{\partial A_n^1}{\partial x_1} + \frac{\partial A_n^2}{\partial x_2}$ is well defined and is in $C_{loc}^\beta(\mathbb{R}^2)$ for all $0 < \beta < 1$. Using this result, we can rewrite (1.3a) and (1.3c) as follows:

$$\begin{cases} \dfrac{1}{\kappa^2}\Delta\psi_n = F_n & \text{in } \Omega, \\ \dfrac{\partial\psi_n}{\partial\mathbf{n}} = G_n & \text{in } \partial\Omega \end{cases} \tag{4.1}$$

for all $n = 0, 1, \ldots, N$, where

$$\begin{cases} F_n = \left(|\psi_n|^2 - 1\right)\psi_n + \dfrac{2i}{\kappa}\mathbf{A}_n \cdot \mathbf{grad}\,\psi_n + \dfrac{\imath}{\kappa}\psi_n\mathbf{div}\mathbf{A}_n + |\mathbf{A}_n|^2\psi_n + P_n, \\ G_n = i\kappa(\psi_n\mathbf{A}_n)\cdot\mathbf{n} \end{cases} \tag{4.2}$$

for all $n = 0, 1, \ldots, N$, and where P_n is the bounded function defined in (1.3). By Theorem 2.4 and Corollary 3.3, $F_n \in L^{2-\varepsilon}(\Omega)$ for all $0 < \epsilon < 1$, and thus $\psi_n \in W_{loc}^{2,2-\epsilon}(\Omega)$ by interior elliptic estimates. It follows that $F_n \in L_{loc}^2(\Omega)$ and $\psi_n \in W_{loc}^{2,2}(\Omega) \cap W^{1,2}(\Omega) \cap L^\infty(\Omega)$ for all $n = 0, 1, \ldots, N$.

Set $w = \Gamma_2 * \chi_\Omega F_n$, where Γ_2 is the fundamental solution for the Laplacian in $\mathbb{R}^2$. By interior elliptic estimates, $w \in W_{loc}^{2,2-\varepsilon}(\mathbb{R}^2) \bigcap W_{loc}^{2,2}(\Omega)$ for all $0 < \epsilon < 1$. Hence $\frac{\partial w}{\partial x_j} \in W_{loc}^{1,2-\epsilon}(\mathbb{R}^2) \cap L_{loc}^q(\mathbb{R}^2)$ for all $0 < \epsilon < 1$ and $1 < q < \infty$, and $w \in C_{loc}^\beta(\mathbb{R}^2)$ for all $0 < \beta < 1$ by Sobolev imbedding. Since $\nabla[(\frac{\partial w}{\partial x_j})^q] = q(\frac{\partial w}{\partial x_j})^{q-1} \cdot \nabla(\frac{\partial w}{\partial x_j}) \in L_{loc}^{2-\epsilon}(\mathbb{R}^2)$ by Holder's inequality, we have $(\frac{\partial w}{\partial x_j})^q \in W_{loc}^{1,2-\epsilon}(\mathbb{R}^2)$ for all $1 < q < \infty$ and $0 < \epsilon < 1$. Similarly, since $A_n^i \in W_{loc}^{1,2}(\mathbb{R}^2) \subset L_{loc}^q(\mathbb{R}^2)$ for all $1 < q < \infty$, $0 < \epsilon < 1$, and $i = 1, 2$, $\nabla[(A_n^i)^q] = q(A_n^i)^{q-1} \cdot \nabla A_n^i \in L_{loc}^{2-\epsilon}(\mathbb{R}^2)$, and hence $(A_n^i)^q \in W_{loc}^{1,2-\epsilon}(\mathbb{R}^2)$ for all $1 < q < \infty$ and $0 < \epsilon < 1$. Thus the traces of ∇w and A_n^i are in $L^q(\partial\Omega)$ for all $1 < q < \infty$ and $G_n \in L^q(\partial\Omega)$ for all $1 < q < \infty$.

Now set $U = \psi_n - w$. Then $U \in W^{1,2}(\Omega) \cap W_{loc}^{2,2}(\Omega)$, $\Delta U = 0$ in Ω, and $\nabla U \cdot \mathbf{n} = G_n - \nabla w \cdot \mathbf{n} \equiv \tilde{G}_n \in L^q(\partial\Omega)$ for all $1 < q < \infty$. By existence-uniqueness results (up to an additive constant) on the Neumann problem in $W^{1,r}(\Omega)$ with compatible L^r

Neumann data in bounded Lipschitz domains for $1 < r < 2+\epsilon_0$, where ϵ_0 is a positive constant depending only on the domain (see [5], [12], [16], and [19]), we conclude that $U \in W^{1,p}(\Omega)$ for some $p \in (2, 2+\epsilon_0)$, and thus $\psi_n \in W^{2,2}_{loc}(\Omega) \cap W^{1,p}(\Omega) \cap C^{\alpha}(\overline{\Omega})$ for $\alpha = 1 - \frac{2}{p}$ by Sobolev imbedding.

If Ω is a $C^{1,1}$ domain, since $\tilde{G}_n$ is in $L^q(\partial\Omega)$, existence-uniqueness results for the Neumann problem in C^1 domains with L^q Neumann data imply that $U \in W^{1,q}(\Omega)$ for all $1 < q < \infty$. (See [8].) Thus $\psi_n \in W^{1,q}(\Omega)$ for all $1 < q < \infty$, and it follows from this and Corollary 3.3 that $G_n \in H^{\frac{1}{2}}(\partial\Omega)$ and $F_n \in L^2(\Omega)$. Thus, $\psi_n \in W^{2,2}(\Omega)$ by the elliptic regularity theory for $C^{1,1}$ domains. The desired result in this case now follows by Sobolev imbedding. $\square$

For the remainder of this section, let $p \in (2,\infty)$ and $\alpha \in (0,1)$ denote the constants of Lemma 4.1.

LEMMA 4.2. *For all $n = 0, 1, \ldots, N$ and $i = 1, 2$, $A^i_n \in W^{1,p}_{loc}(\mathbb{R}^2) \cap C^{\alpha}_{loc}(\mathbb{R}^2)$. Moreover, if Ω is a $C^{1,1}$ domain, then $A^i_n \in W^{1,q}_{loc}(\mathbb{R}^2) \cap C^{\beta}_{loc}(\mathbb{R}^2)$ for all $1 < q < \infty$ and $0 < \beta < 1$.*

Proof. Fix n and i as above. By (3.4), Theorem 2.4, Corollary 3.3, Lemma 4.1, and the Sobolev imbedding theorem, we have $g^i_n \in L^p(\mathbb{R}^2 \times \{ns\})$ with suppt $g^i_n \in \overline{\Omega}_n$. Since t^i_n is the trace of $S(g^i_n)$ on $\mathbb{R}^2 \times \{ns\}$, it follows from Remark 3.4 that $t^i_n \in W^{1,p}_{loc}(\mathbb{R}^2 \times \{ns\})$. By Corollary 3.3, we have $A^i_n \in W^{1,p}_{loc}(\mathbb{R}^2)$ and thus $A^i_n \in C^{\alpha}_{loc}(\mathbb{R}^2)$.

If Ω is a $C^{1,1}$ domain, then Lemma 4.1 implies that $g^i_n \in L^q(\mathbb{R}^2 \times \{ns\})$ for all $1 < q < \infty$, and thus $A^i_n \in W^{1,q}_{loc}(\mathbb{R}^2) \cap C^{\beta}_{loc}(\mathbb{R}^2)$ in this case. $\square$

The additional regularity obtained for A^i_n and ψ_n in Lemma 4.2 yields additional regularity on A^i for $i = 1, 2$.

LEMMA 4.3. *For $i = 1, 2$, $A^i \in W^{1,p}_{loc}(\mathbb{R}^3) \cap C^{\alpha}_{loc}(\mathbb{R}^3)$. Moreover, if Ω is a $C^{1,1}$ domain, then $A^i \in W^{1,q}_{loc}(\mathbb{R}^3) \cap C^{\beta}_{loc}(\mathbb{R}^3)$ for all $1 < q < \infty$ and $0 < \beta < 1$.*

Proof. Fix i as above. Since $A^i \in W^{1,2}_{loc}(\mathbb{R}^3)$ and ha^i is harmonic in $\mathbb{R}^3$ for $i = 1, 2$, it follows from (1.3) and (1.5) that A^i is harmonic in $\mathbb{R}^3 \setminus \bigcup_{n=0}^{N} \overline{\Omega}_n$ and the trace of A^i on $\mathbb{R}^2 \times \{ns\}$ is in $W^{1,p}_{loc}(\mathbb{R}^2)$ by Lemma 4.2. Thus elliptic regularity in C^1 domains implies that $A^i \in W^{1,p}_{loc}(\mathbb{R}^3) \cap C^{\alpha}_{loc}(\mathbb{R}^3)$. (See [8].)

If Ω is a $C^{1,1}$ domain, the above holds with p and α replaced by q and β for any $1 < q < \infty$ and $0 < \beta < 1$. $\square$

THEOREM 4.4. *$\psi_n \in C^{2,\alpha}(\Omega)$ and, if Ω is a $C^{1,1}$ domain, $\psi_n \in W^{2,q}(\Omega) \cap C^{1,\beta}(\overline{\Omega}) \cap C^{2,\beta}(\Omega)$ for all $1 < q < \infty$ and $0 < \beta < 1$. Moreover, if Ω is a $C^{2,\delta}$ domain with $0 < \delta < 1$, $\psi_n \in C^{2,\delta}(\overline{\Omega})$.*

Proof. By Lemma 4.1, $\psi_n \in W^{1,p}(\Omega) \cap C^{\alpha}(\overline{\Omega})$. By Lemma 4.2 and the Sobolev imbedding theorem, $F_n \in L^p(\Omega)$. It follows from interior elliptic estimates that $\psi_n \in W^{2,p}_{loc}(\Omega)$, and thus $\psi_n \in C^{1,\alpha}(\Omega)$. By this and Theorem 2.6, we have $F_n \in C^{\alpha}(\Omega)$ and thus $\psi_n \in C^{2,\alpha}(\Omega)$.

If Ω is a $C^{1,1}$ domain, then, arguing as above, we have $F_n \in L^q(\Omega)$. By the trace theorem, Lemma 4.1, and Lemma 4.2, we have $G_n \in W^{1-\frac{1}{q},q}(\partial\Omega) \cap C^{\beta}(\partial\Omega)$ for all $1 < q < \infty$, $0 < \beta < 1$, and $n = 0, \ldots, N$. Thus $\psi_n \in W^{2,q}(\Omega) \cap C^{1,\beta}(\overline{\Omega})$ for all $1 < q < \infty$ and $0 < \beta < 1$ by the elliptic regularity theory. It follows that $F_n \in C^{\beta}(\overline{\Omega})$ for all $0 < \beta < 1$ and $\psi_n \in C^{2,\beta}(\Omega)$. Moreover, if $\partial\Omega$ is $C^{2,\delta}$, then $\psi_n \in C^{2,\delta}(\overline{\Omega})$. $\square$

COROLLARY 4.5. *$A^i_n \in C^1(\Omega)$ for all $n = 0, 1, \ldots, n$ and $i = 1, 2$.*

Proof. Fix n and i as above. By Corollary 3.3, it suffices to show that $t^i_n(\cdot, ns) \in C^1(\Omega)$. By (3.4), Lemmas 4.1 and 4.2, and Theorem 4.4, $h^i_n \in L^p(\mathbb{R}^2) \cap C^{\alpha}(\Omega)$. Thus, by Theorem 3.2 and Remark 3.4, $t^i_n(\cdot, ns) \in W^{1,p}_{loc}(\mathbb{R}^2) \subset C^{\alpha}_{loc}(\mathbb{R}^2)$. In addition, for each open set Ω' such that $\overline{\Omega'} \subset\subset \Omega$, there is a constant $C = C(\Omega', \Omega)$ such that

$$|h_n^i(\mathbf{y}) - h_n^i(\mathbf{x})| \leq C|\mathbf{x} - \mathbf{y}|^\alpha \text{ for all } \mathbf{x}, \mathbf{y} \in \Omega'.$$

Recall that

$$t_n^i(\mathbf{x}, ns) = \int_{\mathbb{R}^2} \frac{c}{|\mathbf{x} - \mathbf{y}|} h_n^i(\mathbf{y})\, d\mathbf{y} = \int_\Omega \frac{c}{|\mathbf{x} - \mathbf{y}|} h_n^i(\mathbf{y})\, d\mathbf{y}.$$

To show that $t_n^i(\cdot, ns)$ is C^1 in Ω, we use an argument similar to that found in Lemma 4.2 of [10]. Let $\zeta(\mathbf{x})$ denote $\frac{c}{|\mathbf{x}|}$ and $\eta(t)$ denote a continuously differentiable function such that $0 \leq \eta \leq 1$, $0 \leq \eta' \leq 2$, $\eta(t) = 0$ if $t \leq 1$, and $\eta(t) = 1$ if $t \geq 2$. For $\epsilon > 0$, define $\eta_\epsilon(t)$ to be $\eta\left(\frac{t}{\epsilon}\right)$. Let

$$t_{n,\epsilon}^i(\mathbf{x}, ns) = \int_\Omega \zeta(\mathbf{x} - \mathbf{y}) \cdot \eta_\epsilon(|\mathbf{x} - \mathbf{y}|) \cdot h_n^i(\mathbf{y})\, d\mathbf{y}.$$

Note that $t_{n,\epsilon}^i \in C^1(\mathbb{R}^2)$, and $t_{n,\epsilon}^i(\cdot, ns)$ converges uniformly in compact subsets of Ω to $t_n^i(\cdot, ns)$. For $j = 1, 2$, $\mathbf{x} \in \Omega$, and $\epsilon < \frac{1}{2} dist(\mathbf{x}, \partial\Omega)$, we have

$$\begin{aligned}
\frac{\partial}{\partial x_j}(t_{n,\epsilon}^i)(\mathbf{x}, ns) &= \int_\Omega \frac{\partial}{\partial x_j}(\zeta\eta_\epsilon) h_n^i(\mathbf{y})\, d\mathbf{y} \\
&= \int_\Omega \frac{\partial}{\partial x_j}(\zeta\eta_\epsilon)[h_n^i(\mathbf{y}) - h_n^i(\mathbf{x})]\, d\mathbf{y} + h_n^i(\mathbf{x}) \int_\Omega \frac{\partial}{\partial x_j}(\zeta\eta_\epsilon)\, d\mathbf{y} \\
&= \int_\Omega \frac{\partial}{\partial x_j}(\zeta\eta_\epsilon)[h_n^i(\mathbf{y}) - h_n^i(\mathbf{x})]\, d\mathbf{y} - h_n^i(\mathbf{x}) \int_{\partial\Omega} \zeta(\mathbf{x} - \mathbf{y}) n_j\, dl(\mathbf{y}).
\end{aligned}$$

Here, $\zeta = \zeta(\mathbf{x} - \mathbf{y})$, $\eta_\epsilon = \eta_\epsilon(\mathbf{x} - \mathbf{y})$, n_j is the jth component of the outward unit normal to $\partial\Omega$, and $dl(\mathbf{y})$ is the arclength measure on $\partial\Omega$. Define

$$u_n^{ij}(\mathbf{x}) = \int_\Omega \frac{\partial}{\partial x_j}\big(\zeta(\mathbf{x} - \mathbf{y})\big)\big(h_n^i(\mathbf{y}) - h_n^i(\mathbf{x})\big)\, d\mathbf{y} - h_n^i(\mathbf{x}) \int_{\partial\Omega} \zeta(\mathbf{x} - \mathbf{y}) n_j\, dl(\mathbf{y}).$$

Since $h_n^i \in C^\alpha(\Omega)$, it follows that u_n^{ij} is well defined in Ω, and for each subdomain Ω' as above,

$$\sup \left\{ \left| \frac{\partial}{\partial x_j}(t_{n,\epsilon}^i)(\mathbf{x}, ns) - u_n^{ij}(\mathbf{x}) \right| : \mathbf{x} \in \overline{\Omega'} \right\} \to 0$$

as $\epsilon \to 0$ and thus $u_n^{ij} \in C(\Omega)$ for all i and j in $\{1, 2\}$. We have shown that $t_{n,\epsilon}^i \to t_n^i$ and $\frac{\partial t_{n,\epsilon}^i}{\partial x_j}(\cdot, ns) \to u_n^{ij}$ uniformly on compact subsets of Ω, $u_n^{ij} \in C(\Omega)$, and $t_n^i(\cdot, ns) \in W_{loc}^{1,p}(\mathbb{R}^2) \subset C_{loc}^\alpha(\mathbb{R}^2)$. It follows that $\frac{\partial t_n^i}{\partial x_j}(\cdot, ns) = u_n^{ij}$ in the sense of distributions in Ω, and thus $t_n^i(\cdot, ns) \in C^1(\Omega)$. $\square$

Since A^i and ∇A^i are harmonic in $\mathbb{R}^3 \backslash \bigcup_{n=0}^N \overline{\Omega}_n$ for $i = 1, 2$, the continuity of $\mathbf{grad}\, A_n^i$ in Ω and g_n^i in Ω_n implies that $\frac{\partial A^i}{\partial x_j}$ is continuous up to the boundary in the subdomains of $\Omega' \times \mathbb{R}$ located between two adjacent layers Ω_n, below Ω_0, or above Ω_n, where $\overline{\Omega'} \subset\subset \Omega$. From this and the regularity results proved in sections 3 and 4, we obtain the following.

THEOREM 4.6. *Let $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big)$ be a weak solution of* (1.3) *satisfying* (1.5). *There exist constants $p > 2$ and $0 < \alpha < 1$ such that for all $n = 0, \dots, N$,*

$$\begin{aligned}
&\psi_n \in W^{1,p}(\Omega) \cap C^{2,\alpha}(\Omega) \cap C^{\alpha}(\overline{\Omega}),\\
&A_n^1, A_n^2 \in W^{1,p}_{loc}(\mathbb{R}^2) \cap C^{\alpha}_{loc}(\mathbb{R}^2) \cap C^1(\Omega) \cap C^{\infty}\Big(\mathbb{R}^2 \setminus \overline{\Omega}\Big),\\
&A^1, A^2 \in W^{1,p}_{loc}(\mathbb{R}^3) \cap C^{\alpha}_{loc}(\mathbb{R}^3) \cap C^{\infty}\left(\mathbb{R}^3 \Big\backslash \bigcup_{i=o}^{N} \overline{\Omega}_n\right),\\
&\frac{\partial A^i}{\partial x_1} \text{ and } \frac{\partial A^i}{\partial x_2} \in C(\Omega \times \mathbb{R}) \text{ for } i = 1, 2,\\
&A^3 \in W^{2,q}_{loc}(\mathbb{R}^3) \cap C^{1,\beta}_{loc}(\mathbb{R}^3) \text{ for all } q \in (1, \infty) \text{ and } \beta \in (0, 1).
\end{aligned}$$

In addition, for $i = 1, 2$, A^i is piecewise C^1 in $\overline{\Omega'} \times \mathbb{R}$ for all domains $\Omega' \subset \overline{\Omega'} \subset\subset \Omega$, with all discontinuities of ∇A^i in $\Omega \times \mathbb{R}$ occurring as jump discontinuities in $\frac{\partial A^i}{\partial x_3}$ from above and below at points in Ω_n at which $g_n^i(\mathbf{x}, ns)$ is nonzero. Moreover, if Ω is a $C^{1,1}$ domain, the above results hold for all $1 < p < \infty$ and $0 < \alpha < 1$, and we have, in addition,

$$\begin{aligned}
&\psi_n \in W^{2,q}(\Omega) \cap C^{2,\beta}(\Omega) \cap C^{1,\beta}(\overline{\Omega}),\\
&A_n^1, A_n^2 \in W^{1,q}_{loc}(\mathbb{R}^2) \cap C^{\beta}_{loc}(\mathbb{R}^2),\\
&A^1, A^2 \in W^{1,q}_{loc}(\mathbb{R}^3) \cap C^{\beta}_{loc}(\mathbb{R}^3)
\end{aligned}$$

for all $1 < q < \infty$ and $0 < \beta < 1$.

Proof. The proof follows immediately from elliptic regularity and Theorem 3.2, Lemmas 4.1–4.3, Theorem 4.4, and Corollary 4.5, since $\Delta A^i = \vec{0}$ in $\mathbb{R}^3 \backslash \bigcup_{n=0}^N \overline{\Omega}_n$ for $i = 1, 2$. $\square$

5. Breakdown of superconductivity due to strong magnetic fields. In this section we prove various a priori estimates for solutions of the Lawrence–Doniach system in the gauge (1.5), which generalize results of Giorgi and Phillips (cf. [9]) for the standard (isotropic) Ginzburg–Landau model predicted by physicists (cf. [17]). Using our a priori estimates, we show that the upper critical modulus, $\bar{h}(\vec{v}, \kappa, s, \sigma, S, \Omega)$, is finite when $\vec{v}$ is nontangential to the layers.

Recall that we have assumed $\vec{H}$ is a constant applied magnetic field in $\mathbb{R}^3$ and $\vec{H} = h\vec{v}$, where $|\vec{v}| = 1$ and $h \geq 0$. The vector $\vec{v}$ is called nontangential if $\vec{v} \cdot \vec{e_3} \neq 0$.

We define $\bar{h} = \bar{h}(\vec{v}, \kappa, s, \sigma, S, \Omega)$ by

$$\begin{aligned}
\bar{h} = \inf\{h' > 0 :& \text{ normal states are the only solutions of (1.3)}\\
&\text{for all } h > h' \text{ with } \vec{H} = h\vec{v}\},
\end{aligned} \tag{5.1}$$

with $\bar{h} = \infty$ if there are no such h'.

We begin with the following observation: Let $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big)$ be a weak solution of (1.3). Computing real and imaginary parts of $(\frac{\imath}{\kappa}\mathbf{grad}\ \psi_n + \mathbf{A}_n\psi_n)\psi_n^*$, we have

$$\begin{aligned}
\Re\left[\Big(\frac{\imath}{\kappa}\mathbf{grad}\ \psi_n + \mathbf{A}_n\psi_n\Big)\psi_n^*\right] &= \frac{\imath}{2\kappa}\Big(\psi_n^*\mathbf{grad}\ \psi_n - c.c.\Big) + \mathbf{A}_n|\psi_n|^2,\\
\Im\left[\Big(\frac{\imath}{\kappa}\mathbf{grad}\ \psi_n + \mathbf{A}_n\psi_n\Big)\psi_n^*\right] &= \frac{1}{2\kappa}\mathbf{grad}\ \Big(|\psi_n|^2\Big) = \frac{|\psi_n|}{\kappa}\mathbf{grad}\ (|\psi_n|).
\end{aligned}$$

Thus,

$$\begin{aligned}&\frac{\imath}{\kappa}\textbf{grad }\psi_n + \mathbf{A}_n\psi_n\\ &= \left\{\left[\frac{\imath}{2\kappa}\Big(\psi_n^*\textbf{grad }\psi_n - c.c.\Big) + \mathbf{A}_n\,|\psi_n|^2\right]|\psi_n|^{-1} + \Im\left[\frac{1}{\kappa}\textbf{grad }|\psi_n|\right]\right\}\frac{\psi_n}{|\psi_n|}\end{aligned} \tag{5.2}$$

for almost all $\mathbf{x}$ in $\{\mathbf{x} \in \Omega : \psi_n(\mathbf{x}) \neq 0\}$, which we denote by $\{\psi_n \neq 0\}$. Since $\psi_n \in H^1(\Omega)$, $\textbf{grad }\psi_n = 0$ almost everywhere in $\{\psi_n = 0\}$. (See [10, Lemma 7.7].) Therefore, (5.2) holds almost everywhere in Ω. Now, letting $\varphi_n = \psi_n$ in (2.3a), using (5.2), Theorem 2.4, and the fact that $|\psi_{n+1}|^2 + |\psi_n|^2 - \big(\psi_n\psi_{n+1}^* e^{\imath\phi_n^{n+1}} + c.c.\big) = |\psi_{n+1}e^{-\imath\phi_n^{n+1}} - \psi_n|^2$, we get the following.

Lemma 5.1. *If* $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big)$ *is a weak solution of* (1.3)*, then*

$$\begin{aligned}&\sum_{n=0}^N\int_\Omega\left(\left|\frac{1}{\kappa}\textbf{grad }|\psi_n|\right|^2 + \left|\left[\frac{\imath}{2\kappa}\Big(\psi_n^*\textbf{grad }\psi_n - c.c.\Big) + \mathbf{A}_n\,|\psi_n|^2\right]|\psi_n|^{-1}\right|^2\right)d\mathbf{x}\\ &= \sum_{n=0}^N\int_\Omega\left|\frac{\imath}{\kappa}\textbf{grad }\psi_n + \mathbf{A}_n\psi_n\right|^2 d\mathbf{x}\\ &= \sum_{n=0}^N\int_\Omega\Big(1 - |\psi_n|^2\Big)|\psi_n|^2 - \sigma\sum_{n=0}^{N-1}\int_\Omega\left|\psi_{n+1}e^{-\imath\phi_n^{n+1}} - \psi_n\right|^2 d\mathbf{x}\\ &\leq \sum_{n=0}^N\int_\Omega\Big(1 - |\psi_n|^2\Big)|\psi_n|^2\, d\mathbf{x}\\ &\leq \sum_{n=0}^N\int_\Omega|\psi_n|^2\, d\mathbf{x}.\end{aligned}$$

Recall that $\mathbf{a}_n(\mathbf{x}) = \big(a_n^1(\mathbf{x}), a_n^2(\mathbf{x})\big)$ denotes the trace of the first two components of $\vec{a}(\mathbf{x}, ns)$ on $\mathbb{R}^2$. We need the following lemma.

Lemma 5.2. *Let* $\big(\{\psi_n\}_{n=0}^N, \vec{A}\big)$ *be a weak solution of* (1.3) *satisfying* (1.5)*. There exists a constant M depending only on Ω and S (and hence depending only on $\mathcal{D}$) such that*

$$\sum_{n=0}^N\int_\Omega|\mathbf{A}_n - h\mathbf{a}_n|^2\, d\mathbf{x} \leq M\sum_{n=0}^N\int_\Omega|\psi_n|^2\, d\mathbf{x}.$$

Proof. By Corollary 3.3,

$$A_n^i(\mathbf{x}) - ha_n^i(\mathbf{x}) = \sum_{k=0}^N\int_{\mathbb{R}^2}\frac{c}{\big|(\mathbf{x}, ns) - (\mathbf{y}, ks)\big|}h_k^i(\mathbf{y})\, d\mathbf{y}$$

for $i = 1, 2$. Thus

$$\begin{aligned}\int_\Omega\left|A_n^i - ha_n^i\right|^2 d\mathbf{x} &\leq \tilde{C}N\sum_{k=0}^N\int_\Omega\left|h_k^i\right|^2 d\mathbf{x}\\ &= \tilde{C}N\sum_{k=0}^N\int_{\Omega\times\{ks\}}\left|g_k^i(\mathbf{x}, ks)\right|^2 d\mathbf{x},\end{aligned} \tag{5.3}$$

where $\tilde{C}$ is a constant depending only on Ω. Since $|\psi_n| \leq 1$, it follows from formula (3.4) and Lemma 5.1 that

$$\begin{aligned}\sum_{k=0}^{N} \int_{\Omega\times\{ks\}} \left|g_k^i(\mathbf{x}, ks)\right|^2 \, d\mathbf{x} &\leq s^2 \sum_{k=0}^{N} \int_{\Omega\times\{ks\}} |\psi_k|^2 \, d\mathbf{x} \\ &= S^2 N^{-2} \sum_{k=0}^{N} \int_{\Omega\times\{ks\}} |\psi_k|^2 \, d\mathbf{x}.\end{aligned} \tag{5.4}$$

Summing over $i = 1, 2$ and $n = 0, 1, \ldots, N$ in (5.3) and using (5.4), we obtain

$$\sum_{n=0}^{N} \int_{\Omega} |\mathbf{A}_n - h\mathbf{a}_n|^2 \, d\mathbf{x} \leq \tilde{C} S^2 \sum_{n=0}^{N} \int_{\Omega} |\psi_n|^2 \, d\mathbf{x}.$$

The theorem follows with $M = \tilde{C}S^2$. ◻

LEMMA 5.3. *Let* $\left(\{\psi_n\}_{n=0}^N, \vec{A}\right)$ *be a weak solution of* (1.3) *satisfying* (1.5). *Then*

$$\sum_{n=0}^{N} \int_{\Omega} \left|(\imath \mathbf{grad} + \kappa h \mathbf{a}_n)\psi_n\right|^2 d\mathbf{x} \leq C_1 \kappa^2 \sum_{n=0}^{N} \int_{\Omega} |\psi_n|^2 \, d\mathbf{x},$$

where C_1 is a positive constant depending only on $\mathcal{D}$.

Proof. We write

$$\left(\frac{\imath}{\kappa}\mathbf{grad} + h\mathbf{a}_n\right)\psi_n = \left(\frac{\imath}{\kappa}\mathbf{grad} + \mathbf{A}_n\right)\psi_n - (\mathbf{A}_n - h\mathbf{a}_n)\psi_n. \tag{5.5}$$

Thus, we have

$$\begin{aligned}&\sum_{n=0}^{N} \int_{\Omega} \left|\left(\frac{\imath}{\kappa}\mathbf{grad} + h\mathbf{a}_n\right)\psi_n\right|^2 d\mathbf{x} \\ &\leq 2 \sum_{n=0}^{N} \left[\int_{\Omega} \left|\left(\frac{\imath}{\kappa}\mathbf{grad} + \mathbf{A}_n\right)\psi_n\right|^2 d\mathbf{x} + \int_{\Omega} \left|\mathbf{A}_n - h\mathbf{a}_n\right|^2 |\psi_n|^2 \, d\mathbf{x}\right].\end{aligned}$$

Using this inequality, Theorem 2.4, Lemma 5.1, and Lemma 5.2, we obtain

$$\sum_{n=0}^{N} \int_{\Omega} \left|\left(\frac{\imath}{\kappa}\mathbf{grad} + h\mathbf{a}_n\right)\psi_n\right|^2 d\mathbf{x} \leq 2(1+M) \sum_{n=0}^{N} \int_{\Omega} |\psi_n|^2 \, d\mathbf{x}.$$

The lemma follows with $C_1 = 2(1 + M) = C_1(\mathcal{D})$. ◻

We shall need the following result, which is an extension of Lemma 2.8 of [9]. Note that when $\theta = 0$ in the statement of this result, no positive lower bound on the right-hand side of (5.6) is obtained. This is the reason that our estimate from above on $h_{c_3}(\vec{v})$ (proved on Theorem 5.5) applies only to the case in which $\vec{H} = h\vec{v}$ is nontangential to the layers $\Omega \times \{ns\}$.

LEMMA 5.4. *Given $m > 0$, there is a constant $C_2 = C_2(m, \Omega)$ satisfying $0 < C_2 \leq 1$ such that if $\theta \in \mathbb{R}$, w is a nonzero real number, $\vec{b} = (b^1, b^2, b^3) = (\mathbf{b}, b^3)$ is a vector field in $H^1(\Omega, \mathbb{R}^3)$ satisfying $\left(\nabla \times \vec{b}\right) \cdot \vec{e_3} \equiv \left(\frac{\partial b_2}{\partial x_1} - \frac{\partial b_1}{\partial x_2}\right) \equiv \theta$ in Ω, and $w^2 |\theta| \geq m$, then*

$$C_2 w^2 |\theta| \int_{\Omega} |\zeta|^2 \, d\mathbf{x} \leq \int_{\Omega} \left|(\imath \mathbf{grad} + w^2 \mathbf{b})\zeta\right|^2 d\mathbf{x} \tag{5.6}$$

for all $\zeta \in \mathcal{H}^1(\Omega;\mathbb{C})$.

Proof. If $\theta = 0$, the inequality is trivial. Assume that $\theta \neq 0$.

It was shown by Giorgi and Phillips (see [9, Lemma 2.8]) that, given $m > 0$, there exists $C_2 = C_2(m,\Omega))$, $0 < C_2 \leq 1$, such that if $\lambda^2 \geq m$, then

$$C_2\lambda^2 \int_\Omega |\zeta|^2 \, d\mathbf{x} \leq \int_\Omega \left|(\imath\mathbf{grad} + \lambda^2\mathbf{c})\zeta\right|^2 d\mathbf{x}$$

for all $\zeta \in H^1(\Omega;\mathbb{C})$ and $\mathbf{c} = (c_1, c_2) \in H^1(\Omega;\mathbb{R}^2)$ such that $\frac{\partial c_2}{\partial x_1} - \frac{\partial c_1}{\partial x_2} \equiv 1$ in Ω. Since $\frac{1}{\theta}(\frac{\partial b_2}{\partial x_1} - \frac{\partial b_1}{\partial x_2}) = 1$ in Ω, if $\theta > 0$, we can apply the result of Giorgi and Phillips with $\mathbf{c} = \frac{1}{\theta}\mathbf{b} = \frac{1}{\theta}(b_1, b_2)$ and $\lambda^2 = \theta w^2$ to obtain (5.6). If $\theta < 0$, the result follows from (5.6) for the case just proved, applied to $\theta' = |\theta| = -\theta$, $\vec{b}' = -\vec{b}$, and $\zeta' = -(\mathrm{Re}\zeta) + i(\mathrm{Im}\zeta)$ in $\mathcal{H}^1(\Omega;\mathbb{C})$. $\square$

We can now prove the existence of a finite upper critical modulus, assuming that $\vec{H} = h\vec{v}$, where $\vec{v}$ is a unit vector in $\mathbb{R}^3$ which is nontangential to the superconducting layers, $\Omega \times \{ns\}$.

THEOREM 5.5. *Given* $m > 0$ *and* $0 < \mu < 1$*, there exists a positive constant* $\phi = \phi(m,\mathcal{D})$ *so that if* $\vec{H} = h\vec{v}$ *with* $|\vec{v}| \equiv 1$ *and* $|\vec{v}\cdot\vec{e}_3| \geq \mu$ *and if* $h > \frac{1}{\mu}\max\left(\frac{m}{\kappa}, \phi\kappa\right)$*, then any weak solution to* (1.3) *is a normal state. Thus*

$$\begin{aligned} H_{c_3}(\vec{v},\kappa,s,\sigma,S,\Omega) &\leq \bar{h}(\vec{v},\kappa,s,\sigma,S,\Omega) \\ &\leq \frac{1}{\mu}\max\left(\frac{m}{\kappa}, \phi\kappa\right). \end{aligned}$$

Moreover, the constant ϕ *can be chosen to satisfy* $\phi = \frac{C_1}{C_2}$*, where* $C_1 = C_1(\mathcal{D})$ *and* $C_2 = C_2(m,\Omega)$ *are the constants of Lemmas* 5.3 *and* 5.4*, respectively.*

Proof. Let $\left(\{\psi_n\}_{n=0}^N, \vec{A}\right)$ be a weak solution of (1.3) and assume that $h > \frac{1}{\mu}\max\left(\frac{m}{\kappa}, \phi\kappa\right)$. Note that a weak solution is a normal state if and only if its entire gauge-equivalence class consists of normal states. Thus we may assume without loss of generality that $\left(\{\psi_n\}_{n=0}^N, \vec{A}\right)$ satisfies (1.5). Set $w^2 = h\kappa$. Then, by hypothesis, we have $w^2|\vec{v}\cdot\vec{e}_3| \geq w^2\mu \geq m$. Since $[\nabla\times(\vec{a}(x_1,x_2,ns))]\cdot\vec{e}_3 = \vec{v}\cdot\vec{e}_3$ is constant in Ω for each n, we may apply (5.6) of Lemma 5.4 with $\zeta = \psi_n$, $\vec{b}(x_1,x_2) = \vec{a}(x_1,x_2,ns)$, $\mathbf{b} = \mathbf{a}_n$, and $\theta = \vec{v}\cdot\vec{e}_3$, to get

$$C_2 h\kappa\mu \sum_{n=0}^N \int_\Omega |\psi_n|^2 \, d\mathbf{x} \leq \sum_{n=0}^N \int_\Omega \left|(i\mathbf{grad} + h\kappa\mathbf{a}_n)\psi_n\right|^2 d\mathbf{x}.$$

Using this inequality, Lemma 5.3, and setting $\phi = \frac{C_1}{C_2}$, we have

$$h\sum_{n=0}^N \int_\Omega |\psi_n|^2 \, d\mathbf{x} \leq \frac{\phi\kappa}{\mu}\sum_{n=0}^N \int_\Omega |\psi_n|^2 \, d\mathbf{x}.$$

By hypothesis, $h > \frac{\phi\kappa}{\mu}$. Therefore we have $\int_\Omega |\psi_n|^2 \, d\mathbf{x} = 0$ for all $n = 0, 1, \ldots, N$, and $\psi_n = 0$ almost everywhere in Ω for all n. Using this result and (1.3), we have $\Delta(\vec{A} - h\vec{a}) = -\nabla\times\nabla\times(\vec{A} - h\vec{a}) = 0$. Since $\vec{A} - h\vec{a} \in \check{H}^1(\mathbb{R}^3)$, we conclude that $\vec{A} = h\vec{a}$, and thus $\nabla\times\vec{A} = h\vec{v} = \vec{H}$. $\square$

COROLLARY 5.6. *Assume that* $|\vec{v}| = 1$ *and* $|\vec{v}\cdot\vec{e}_3| \geq \mu > 0$*. There exist positive constants* κ_0 *and* C_0 *depending only on* $\mathcal{D}$ *such that for all* $\kappa \geq \kappa_0$*, we have*

$$H_{c_3}(\vec{v},\kappa,s,\sigma,S,\Omega) \leq \bar{h}(\vec{v},\kappa,s,\sigma,S,\Omega) \leq C_0\cdot\frac{\kappa}{\mu}.$$

Proof. Set $m = 1$ in Theorem 5.5 and let $C_0 = \phi(1, \mathcal{D}) = C_1(\mathcal{D})/C_2(1, \mathcal{D})$. The result follows from Theorem 5.5 if $\kappa \geq \kappa_0 = \phi(1, \mathcal{D})^{-\frac{1}{2}}$. $\square$

6. Homogenization of the Lawrence–Doniach model. For completeness, we conclude this paper by stating a result on the homogenization of solutions of the Lawrence–Doniach system (in the gauge (1.5)) to solutions of a three-dimensional anisotropic Ginzburg–Landau system, which follows from the maximum principle (Theorem 2.4) and results proved by Chapman, Du, and Gunzburger in [4] under the assumption that solutions of the Lawrence–Doniach system satisfy $|\psi_n| \leq 1$ for all n.

The three-dimensional anisotropic Ginzburg–Landau energy (in nondimensionalized form) is given by

$$
\begin{aligned}
\mathcal{G}_{AGL}(\psi, \vec{A}) = &\int_{\mathcal{D}} \frac{1}{2}\left(|\psi|^2 - 1\right)^2 d\vec{x} + \int_{\mathbb{R}^3} \left|\nabla \times (\vec{A} - h\vec{a})\right|^2 d\vec{x} \\
&+ \int_{\mathcal{D}} \left(\left| \left(\frac{\imath}{\kappa} \mathbf{grad} + \mathbf{A} \right) \psi \right|^2 + \frac{1}{\gamma} \left| \left(\frac{\imath}{\kappa} \frac{\partial}{\partial x_3} + A^3 \right) \psi \right|^2 \right) d\vec{x},
\end{aligned}
\tag{6.1}
$$

where κ is the Ginzburg–Landau constant and γ is an anisotropy constant. Here, the order parameter ψ is defined in $\mathcal{D} = \Omega \times (0, S)$ and $(\psi, \vec{A}) \in H^1(\mathcal{D}) \times E$, where E is defined as in (1.2). We remark that the anisotropic Ginzburg–Landau energy $\mathcal{G}_{AGL}$ is invariant under the gauge transformation

$$
(\psi, \vec{A}) \longrightarrow (\xi, \vec{Q}),
$$

where

$$
\begin{cases}
\xi(\vec{x}) = \psi(\vec{x}) e^{\imath\kappa g(\vec{x})}, \\
\vec{Q} = \vec{A} + \nabla g,
\end{cases}
$$

which maps $H^1(\mathcal{D}) \times E$ to itself whenever $g \in H^2_{loc}(\mathbb{R}^3)$. By choosing g appropriately, one obtains $(\xi, \vec{Q}) \in H^1(\mathcal{D}) \times K$, where K is defined as in (1.5), and it follows that minimizers of $\mathcal{G}_{AGL}$ in $H^1(\mathcal{D}) \times E$ exist and are gauge-equivalent to some $(\psi, \vec{A})$ in $H^1(\mathcal{D}) \times K$. Moreover, minimizers are weak solutions of the Euler–Lagrange equations (called the anisotropic equations)

$$
\begin{cases}
\left(\frac{\imath}{\kappa} \mathbf{grad} + \mathbf{A} \right)^2 \psi + \frac{1}{\gamma} \left(\frac{\imath}{\kappa} \frac{\partial}{\partial x_3} + A^3 \right)^2 \psi + \left(|\psi|^2 - 1\right)\psi = 0 \quad \text{in } \mathcal{D}, \\
\nabla \times \left(\nabla \times \vec{A} \right) = (J_1, J_2, J_3) \quad \text{in } \mathbb{R}^3, \\
\left(\frac{\imath}{\kappa} \nabla \psi + \vec{A}\psi \right) \cdot \hat{n} = 0 \quad \text{on } \partial\mathcal{D}, \\
\nabla \times \left(\vec{A} - h\vec{a} \right) \in L^2(\mathbb{R}^3; \mathbb{R}^3),
\end{cases}
\tag{6.2}
$$

where

$$
J_i = \frac{1}{\gamma_i} \left[\frac{\imath}{2\kappa} \left(\psi \frac{\partial \psi^*}{\partial x_i} - c.c. \right) - |\psi|^2 A^i \right] \chi_{\mathcal{D}}
$$

for $i = 1, 2, 3$, and where $\gamma_1 = \gamma_2 = 1$ and $\gamma_3 = \gamma$. Here, $\hat{n}$ is the outward normal to $\partial\mathcal{D}$. More precisely, a minimizer of $\mathcal{G}_{AGL}$ in $H^1(\mathcal{D}) \times K$ satisfies

(6.3)

$$\begin{aligned}
&\int_{\mathcal{D}} \Bigg[(|\psi|^2 - 1)\psi\varphi^* + \left(\frac{\imath}{\kappa}\mathbf{grad}\ \psi + \mathbf{A}\psi\right) \cdot \left(\frac{\imath}{\kappa}\mathbf{grad}\ \varphi + \mathbf{A}\varphi\right)^* \\
&\qquad + \frac{1}{\gamma}\left(\frac{\imath}{\kappa}\frac{\partial\psi}{\partial x_3} + A^3\psi\right)\left(\frac{\imath}{\kappa}\frac{\partial\varphi}{\partial x_3} + A^3\varphi\right)^*\Bigg] d\vec{x} = 0, \\
&2\int_{\mathbb{R}^3} \nabla\times\left(\vec{A} - h\vec{a}\right) \cdot \nabla\times\vec{B}\, d\vec{x} + \int_{\mathbb{R}^3} \chi_{\mathcal{D}}\left[\frac{\imath}{\kappa}(\psi^*\,\mathbf{grad}\ \psi - c.c.) + 2\mathbf{A}\,|\psi|^2\right] \cdot \mathbf{B}\, d\mathbf{x} \\
&\qquad + \int_{\mathbb{R}^3} \chi_{\mathcal{D}}\,\frac{1}{\gamma}\left[\frac{\imath}{\kappa}\left(\psi^*\frac{\partial\psi}{\partial x_3} - c.c.\right) + 2A^3\,|\psi|^2\right] B^3\, d\vec{x} = 0
\end{aligned}$$

for any $\varphi \in \mathcal{H}^1(\mathcal{D})$ and $\vec{B} \in H^1(\mathbb{R}^3;\mathbb{R}^3)$ with bounded support.

As in the case of the Lawrence–Doniach system, one can prove that weak solutions satisfy $|\psi| \le 1$ almost everywhere in $\mathcal{D}$ by choosing an appropriate test function in (6.3).

Assume that the parameters σ, κ, s, and γ are related by

$$\frac{1}{\gamma} = \sigma\kappa^2 s^2. \tag{6.4}$$

(See [4] and [13] for details on the physical meaning of these relationships.) Briefly, the above equation allows one to define $m_\perp$, $\lambda_\perp$, and $\xi_\perp$, the mass of superconducting charge carriers, penetration depth, and coherence length in directions perpendicular to the layers in the dimensionalized Lawrence–Doniach model by

$$\gamma = \frac{m_\perp}{m_\|} = \left(\frac{\lambda_\perp}{\lambda_\|}\right)^2 = \left(\frac{\xi_\perp}{\xi_\|}\right)^2$$

(where $m_\|, \lambda_\|$, and $\xi_\|$ are defined to be their values within the layers for the Lawrence–Doniach model) in such a way that

$$\sigma = \left(\frac{\xi_\perp}{d}\right)^2,$$

and it can be shown that $s \to 0$ in the nondimensionalized Lawrence–Doniach model corresponds to $d/\xi_\perp \to 0$ in the dimensionalized Lawrence–Doniach model. (See [4].) The homogenization of the Lawrence–Doniach model is achieved by fixing the domain $\mathcal{D} = \Omega \times [0, S]$ and letting N go to ∞. Since $sN = S$, there is a set $\mathcal{A}$ of the available values for s, i.e., $\mathcal{A} = \left\{\frac{S}{N} : N = 1, 2, \dots\right\}$. Thus, letting $s \to 0^+$ means that $s \in \mathcal{A}$ and $s \to 0$ by letting $N \to \infty$.

Now let ξ^s denote $\{\xi_n\}_{n=0}^N$ if $s \in \mathcal{A}$ and $\{\xi_n\}_{n=0}^N \in \left[\mathcal{H}^1(\Omega)\right]^{N+1}$. Define $I_s\xi^s$ to be the linear interpolant of ξ^s in the x_3 direction in $\mathcal{D}$ with respect to the superconducting layers $\{\Omega_n\}_{n=0}^N$, i.e.,

$$\left(I_s\xi^s\right)(\mathbf{x}, x_3) = \left(1 - \frac{x_3 - ns}{s}\right)\xi_n(\mathbf{x}) + \frac{x_3 - ns}{s}\,\xi_{n+1}(\mathbf{x}) \tag{6.5}$$

if $(\mathbf{x}, x_3) \in \Omega \times [ns, (n+1)s]$ for all $n = 0, 1, \ldots, N-1$. Thus, we have

$$\begin{aligned} \nabla\big(I_s\xi^s\big) &= \left(\mathbf{grad}\,\big(I_s\xi^s\big), \frac{\partial I_s\xi^s}{\partial x_3}\right) \\ &= \left(\left(1 - \frac{x_3 - ns}{s}\right)\mathbf{grad}\,\xi_n + \frac{x_3 - ns}{s}\mathbf{grad}\,\xi_{n+1}\,, \frac{\xi_{n+1} - \xi_n}{s}\right). \end{aligned} \tag{6.6}$$

It is easy to show that if $\xi^s \in \big[\mathcal{H}^1(\Omega)\big]^{N+1}$, then $I_s\xi^s \in \mathcal{H}^1(\mathcal{D})$.

From Theorem 2.4 of this paper and Theorem 5.1, Lemma 5.5, and Corollary 5.6 of [4] (using the Coulomb gauge (1.5)), we have the following.

THEOREM 6.1. *Let* $\big(\psi^s, \vec{A}^s\big) \in \big[\mathcal{H}^1(\Omega)\big]^{N+1} \times K$ *denote a minimizer of* $\mathcal{G}^s_{LD}$ *in* $\big[\mathcal{H}^1(\Omega)\big]^{N+1} \times E$ *for each* $s \in \mathcal{A}$. *If* (6.4) *is satisfied, then as* $s \to 0^+$, $\big\{\big(I_s\psi^s, \vec{A}^s\big)\big\}_{s\in\mathcal{A}}$ *forms a minimizing sequence of* $\mathcal{G}_{AGL}$ *in* $H^1(\mathcal{D}) \times E$. *Moreover, if* l *and* l_s *denote the minimum values of* $\mathcal{G}_{AGL}$ *and* $\mathcal{G}^s_{LD}$, *respectively, i.e.,*

$$\begin{aligned} l &= \min\big\{\mathcal{G}_{AGL}\big(\xi, \vec{Q}\big) : \big(\xi, \vec{Q}\big) \in \mathcal{H}^1(\mathcal{D}) \times E\big\}, \\ l_s &= \min\big\{\mathcal{G}^s_{LD}\big(\xi^s, \vec{Q}\big) : \big(\xi^s, \vec{Q}\big) \in [\mathcal{H}^1(\Omega)]^{N+1} \times E\big\} \end{aligned}$$

for $s \in \mathcal{A}$, *we have* $l = \lim_{s\to 0^+} l_s = \lim_{s\to 0^+} \mathcal{G}_{AGL}\big(I_s\psi^s, \vec{A}^s\big)$.

CURRENT COUPLING OF DRIFT-DIFFUSION MODELS AND SCHRÖDINGER–POISSON SYSTEMS: DISSIPATIVE HYBRID MODELS*

M. BARO†, H. NEIDHARDT†, AND J. REHBERG†

Dedicated to H. Gajewski on the occasion of his 65th birthday

Abstract. A one-dimensional coupled drift-diffusion dissipative Schrödinger model (hybrid model) is mathematically analyzed. The device domain is split into two parts: one in which the transport is well described by the drift-diffusion equations (classical zone) and another in which a quantum description via dissipative Schrödinger equations (quantum zone) is used. Both system are coupled such that the continuity of the current densities is guaranteed. The electrostatic potential is self-consistently determined by Poisson's equation on the whole device domain. We show that the hybrid model is well posed, and we prove existence of solutions and show their uniform boundedness, provided the distribution functions satisfy a so-called balance condition. The current densities are different from zero in the nonequilibrium case and are uniformly bounded.

Key words. quantum–classical coupling, hybrid models, drift-diffusion models, dissipative Schrödinger systems, Poisson equation, current coupling, semiconductors

1. Introduction.

A basic model for carrier transport in semiconductors was created in 1950 by van Roosbroeck [51]. It describes the transport of electrons and holes by drift and diffusion processes in a self-consistent electrical field. This so-called drift-diffusion model was first used by Gummel [27] to calculate diodes. Since that time, drift-diffusion models have been intensively studied, and there exists extensive literature on them; see [23, 44, 52] and references therein. However, modern semiconductor devices inherently employ quantum effects in their operations, such as tunneling [15, 18, 54], which are well described by stationary or transient Wigner– or Schrödinger–Poisson systems [1, 9, 10, 12, 19, 20, 29, 30, 31, 36, 37, 38, 39, 41, 42, 46, 47, 48, 49, 53]. Unfortunately, the numerical treatment of a Wigner– or Schrödinger–Poisson system is fairly expensive compared to classical models, such as the drift-diffusion model. However, for several devices, such as resonant tunneling diodes [13, 14, 22, 45], the quantum effects occur only in some small spatial parts, while other parts admit a quite reasonable description by approved "classical models," such as drift-diffusion models, etc. Thus one looks for a model that combines a quantum description in parts where it is necessary with a classical description in other parts. The aim is to obtain a model which allows an effective and fast numerical treatment but describes the transport of electrons and holes in the semiconductor device with sufficient accuracy. Models of that type are usually called hybrid models; cf. [2, 6, 7, 16]. In [2, 16] coupled Schrödinger drift-diffusion models are used to simulate the current voltage

characteristic of a resonant tunneling diode. In the following we are interested in an analytical treatment of such models under quite general assumptions, but in a dissipative approximation.

In particular, we consider a one-dimensional stationary hybrid model which consists of a drift-diffusion model in the so-called "classical zone" and a dissipative Schrödinger model in the "quantum zone." Both systems are coupled by the conditions that the Fermi energies of the quantum zone are given by the electrochemical potentials of the classical zone, and the current densities are continuous at the interface points. Moreover, the electrostatic potential is determined self-consistently by a Poisson equation on the whole device domain.

The hybrid model approach, however, evokes several problems. In fact, if one is interested in a current density which is continuous over the whole device, then one has to consider an open quantum system. Indeed, for Schrödinger operators with self-adjoint boundary conditions, the current density is always zero since such operators commute with the complex conjugation. Thus, a continuous nontrivial net current flow through the interface between quantum and classical zones is impossible in this case. Consequently, hybrid models enforce at least non–self-adjoint boundary conditions for the Schrödinger operator to describe the particles in the quantum zone. Such models are introduced in [33, 34, 35]. Further, a nontrivial current density arises in the quantum zone only if the statistical behavior of the quantum system is described by a density matrix, which is different from those of the thermodynamical equilibrium. Hence, one has to find suitable nonequilibrium density matrices.

In more detail, we divide the one-dimensional device domain $\Omega = (a_0, b_0) \subseteq \mathbb{R}$ into a quantum zone $\Omega_q = (a, b)$, $a_0 < a < b < b_0$, and a classical region $\Omega_c = \Omega \setminus \Omega_q$. In the classical region the densities of electrons U^- and holes U^+, as well as the current densities for electrons J^- and holes J^+, respectively, are determined by means of the stationary drift-diffusion equations without generation or recombination [43] (temperature, elementary charge, and Boltzmann's constant scaled to one):

$$U^\pm(x) := N_0(x)^\pm \exp\Big(- V^\pm(x) \pm \phi^\pm(x)\Big) \qquad \text{(density relations)}, \tag{1.1}$$

$$J^\pm(x) := \mp\mu^\pm(x) U^\pm(x) \frac{d}{dx}\phi^\pm(x) \qquad \text{(current relations)}, \tag{1.2}$$

$$\frac{d}{dx} J^\pm = 0 \qquad \text{(continuity equations)}, \tag{1.3}$$

$x \in \Omega_c$. Here and in what follows, the superscript "+" refers to hole quantities and "−" to electron quantities. $N_0^\pm$ denotes the densities of states, $\mu^\pm$ the carrier mobilities, and $\phi^\pm$ the electrochemical potentials. The potentials $V^\pm$ contain the electrostatic potential φ and the band edge-offset potentials $V_h^\pm$, i.e.,

$$V^\pm := V_h^\pm \pm \varphi. \tag{1.4}$$

At the device boundary we impose inhomogeneous Dirichlet boundary conditions on the system (1.1)–(1.3), i.e.,

$$\phi^\pm(a_0) = \phi^\pm_{a_0} \quad \text{and} \quad \phi^\pm(b_0) = \phi^\pm_{b_0}. \tag{1.5}$$

To have a mathematically meaningful description, the system (1.1)–(1.3) requires boundary conditions at the end points a and b of the classical zones (a_0, a) and (b, b_0), too. However, for the hybrid model, a and b are not boundary points but interface points at which the coupling of the drift-diffusion system with the quantum subsystem is realized. Hence, the coupling conditions have to replace the boundary conditions at these interface points. We will develop these interface conditions later in the text.

In the quantum zone a dissipative Schrödinger system is adopted (cf. [3, 33]), which is derived from a quantum transmitting Schrödinger system; see [4, 8] and section B.1 in Appendix B. A dissipative Schrödinger model consists of two dissipative Schrödinger-type operators $H^\pm$ (cf. [34, 35] and section A.1 in Appendix A), arising from the differential expressions

$$H^\pm f = \left(-\frac{1}{2}\frac{d}{dx}\frac{1}{m^\pm}\frac{d}{dx} + V^\pm\right) f, \tag{1.6}$$

where $m^\pm$ denotes the effective mass of the particle under consideration and $V^\pm$ contain the band edge-offsets and the electrostatic potential; see (1.4). Supplemented by the boundary conditions

$$\frac{1}{2m^\pm(a)} f'(a) = -\varkappa_a^\pm f(a) \quad \text{and} \quad \frac{1}{2m^\pm(b)} f'(b) = \varkappa_b^\pm f(b), \tag{1.7}$$

$H^\pm$ are maximal dissipative, and completely non–self-adjoint operators on the Hilbert space $L^2(\Omega_q)$ if $\mathrm{Im}(\varkappa_a^\pm), \mathrm{Im}(\varkappa_b^\pm) > 0$. The coupling constants $\varkappa_a^\pm$ and $\varkappa_b^\pm$ are given by means of the potentials $V^\pm$ at the quantum–classical interface boundaries a and b by

$$\varkappa_a^\pm := i\sqrt{\frac{s^\pm - V^\pm(a)}{2m_a^\pm}} \quad \text{and} \quad \varkappa_b^\pm := i\sqrt{\frac{s^\pm - V^\pm(b)}{2m_b^\pm}}, \tag{1.8}$$

where i denotes the imaginary unit, i.e., $i^2 = -1$, and

$$s^\pm := V_{max}^\pm + \delta_0^\pm, \quad \delta_0^\pm > 0, \tag{1.9}$$

with

$$V_{max}^\pm := \max\{V^\pm(a), V^\pm(b)\}, \tag{1.10}$$

where $\delta_0^\pm$ are given positive constants. Note that $\mathrm{Im}(\varkappa_a^\pm) > 0$ and $\mathrm{Im}(\varkappa_b^\pm) > 0$. The operators $H^\pm$ are maximal dissipative, and the multiplicity of their minimal self-adjoint dilations is 2; cf. [35]. Moreover, the spectrum of minimal self-adjoint dilations coincides with the real line and is purely absolutely continuous. Thus, there exist two generalized eigenfunctions, denoted by $\psi_a^\pm(\lambda, x), \psi_b^\pm(\lambda, x)$, for each dilation operator; see [33] and section A.2 in Appendix A. The particle densities $u^\pm$ and current densities $j^\pm$ are then given by means of the generalized eigenfunctions $\psi_a^\pm(\lambda, x)$, $\psi_b^\pm(\lambda, x)$, assuming Boltzmann distribution, by

$$u^\pm(x) = \sum_{\nu=a,b} \int_{\Lambda^\pm} d\lambda\, n_0^\pm \exp(-\lambda \pm \epsilon_\nu) \, |\psi_\nu(\lambda, x)|^2, \quad x \in \Omega_q, \tag{1.11}$$

$$j^\pm = \sum_{\nu=a,b} \int_{\Lambda^\pm} d\lambda\, n_0^\pm \exp(-\lambda \pm \epsilon_\nu) \, \mathrm{Im}\left(\frac{1}{m(x)} \frac{\partial \psi_\nu(\lambda, x)}{\partial x} \overline{\psi_\nu(\lambda, x)}\right) \tag{1.12}$$

(see [33, 5]), where $n_0^\pm$ are the integrated density of states and

$$\Lambda^\pm := [V_{max}^\pm, V_{max}^\pm + \delta^\pm), \quad 0 < \delta_0^\pm < \delta^\pm \leq \infty. \tag{1.13}$$

The real parameters $\mathfrak{A} := \{\delta_0^\pm, \delta^\pm\}$, $0 < \delta_0^\pm < \delta^\pm \leq \infty$, are called the approximation parameters; see section B.2 in Appendix B.

The construction of the Schrödinger model in the quantum zone is to some extent artificial, since the physical interpretation of the generalized eigenfunctions ψ_a, ψ_b corresponding to the self-adjoint dilations of $H^\pm$ is not a priori clear. However, as pointed out in [4], the dissipative Schrödinger model can be seen as an approximation of the usual Schrödinger scattering model considered elsewhere (see, e.g., [8, 22]), with approximation parameters $\mathfrak{A}$. We will briefly outline this feature in section B.2 of Appendix B.

The Fermi levels $\epsilon_a^\pm$, $\epsilon_b^\pm$ in (1.11), (1.12) are determined by the drift-diffusion model by

$$\phi^\pm(a) = \epsilon_a^\pm \qquad \text{and} \qquad \phi^\pm(b) = \epsilon_b^\pm. \tag{1.14}$$

Thus, the conditions (1.14) couple the drift-diffusion equations (1.1)–(1.3) and the dissipative Schrödinger operators (1.6)–(1.12). This coupling will be called the Fermi coupling. Moreover, we impose the continuity of the drift-diffusion currents $J^\pm$ and the quantum current $j^\pm$, i.e.,

$$J^\pm(a) = j^\pm = J^\pm(b). \tag{1.15}$$

This condition is necessary in order to obtain a physically meaningful model.

In order to have a meaningful description of the semiconductor device, the electrostatic potential φ has to be computed self-consistently by a Poisson equation, i.e.,

$$-\frac{d}{dx}\varepsilon\frac{d}{dx}\varphi(x) = C(x) + \mathcal{U}^+(x) - \mathcal{U}^-(x), \quad x \in \Omega, \tag{1.16}$$

with boundary conditions

$$\varphi(a_0) = \varphi_{a_0} \qquad \text{and} \qquad \varphi(b_0) = \varphi_{b_0}, \tag{1.17}$$

where the carrier densities $\mathcal{U}^\pm$ are given by

$$\mathcal{U}^\pm(x) := \begin{cases} U^\pm(x) & \text{for } x \in \Omega_c, \\ u^\pm(x) & \text{for } x \in \Omega_q, \end{cases} \tag{1.18}$$

and ε, C denote the dielectric permittivity and the doping profile, respectively.

The coupled dissipative Schrödinger (1.6)–(1.12) and drift-diffusion model (1.1)–(1.3) with the coupling conditions (1.14)–(1.18) is called the dissipative hybrid model.

The aim of this paper is to show that the proposed dissipative hybrid model is well posed and admits a solution under natural assumptions for any choice of the approximation parameters $\mathfrak{A}$. The paper is organized as follows. In section 2 we investigate the stationary drift-diffusion system on the disconnected set $\Omega_c = (a_0, a) \cup (b, b_0)$, provided the current densities are given and equal on the different intervals (a_0, a) and (b, b_0). This leads to certain restrictions on the current densities; cf. Lemma 2.2. Section 3 is devoted to the rigorous setup of the dissipative Schrödinger system used in the quantum zone. The dissipative hybrid model is defined in section 4. In section 4.1 the so-called Fermi coupling is explained. Using the Fermi coupling, we show in section 4.2 that the stationary drift-diffusion and the dissipative Schrödinger models admit a current coupling. This result is in fact nontrivial and is based on Proposition 4.1. Using the results of section 4.2, in section 4.3 we rigorously introduce the dissipative hybrid model. Finally, in section 4.4 we consider the coupling with the Poisson equation. The problem of finding a solution to the dissipative hybrid model is reformulated in section 4.4 as a fixed point problem. In section 5 we show that the fixed point problem admits a solution. The existence proof is based on the Leray–Schauder fixed point theorem. Uniqueness is not shown and not expected for physical reasons; cf. [32, 50]. However, it turns out that all solutions are uniformly bounded by a bound that is determined by the data of the problem but independent of the choice of the approximation parameters $\mathfrak{A}$. Moreover, the current densities are nontrivial in the nonequilibrium case. We sum up with some comments in section 6. In section A we give an introduction to dissipative Schrödinger systems and prove some continuity results for the carrier and current density operators. The derivation of the dissipative Schrödinger model from the usual Schrödinger scattering model is exposed in section B.

Notation. By $L^p(\mathcal{O}, X, \mathfrak{m})$, $1 \leq p < \infty$, we denote the space of $\mathfrak{m}$-measurable and p-integrable functions over Borel sets $\mathcal{O} \subseteq \mathbb{R}$ with values in a Banach space X. By $L^\infty(\mathcal{O}, X, \mathfrak{m})$ the space of essentially bounded functions is denoted. If $\mathfrak{m}$ is the Lebesgue measure, then we write $L^p(\mathcal{O}) = L^p(\mathcal{O}, \mathbb{C}, \mathfrak{m})$ and $L^p_{\mathbb{R}}(\mathcal{O}) := L^p(\mathcal{O}, \mathbb{R}, \mathfrak{m})$, $1 \leq p \leq \infty$. For closed sets $\mathcal{O} \subseteq \mathbb{R}$ we denote by $C(\mathcal{O})$ and $C_{\mathbb{R}}(\mathcal{O})$ the spaces of continuous complex- or real-valued functions, respectively, on $\mathcal{O}$ equipped with the supremum norm.

The norm of a Banach or Hilbert space X is indicated by $\|\cdot\|_X$, or simply by $\|\cdot\|$; the scalar product of a Hilbert space X by $(\cdot,\cdot)_X$, or simply by $(\cdot,\cdot)$, where the first argument is the linear one. The dual space is indicated by X^*. By $\mathcal{B}(X, Y)$ the space of all linear bounded operators from the Banach space X to the Banach space Y is denoted with norm $\|\cdot\|_{\mathcal{B}(X,Y)}$. If $X = Y$, then $\mathcal{B}(X, X) = \mathcal{B}(X)$ and $\|\cdot\|_{\mathcal{B}(X,Y)} = \|\cdot\|_{\mathcal{B}(X)}$. If X is a Hilbert space, then $\mathcal{B}_1(X)$ denotes the space of trace class operators. For a densely defined linear operator $A : X \longrightarrow Y$ we denote by A^*, $\mathrm{spec}(A)$, and $\mathrm{res}(A)$ its adjoint, spectrum, and resolvent set, respectively.

Furthermore, for $\mathcal{O} = (a_0, b_0)$ or $\mathcal{O} = (a, b)$ we denote by $W^{1,2}(\mathcal{O})$ the usual Sobolev spaces of complex-valued functions on $\mathcal{O}$. The subspace of elements with homogeneous Dirichlet boundary conditions at the end points of the interval $\mathcal{O} \subseteq \mathbb{R}$ is denoted by $\overset{o}{W}{}^{1,2}(\mathcal{O})$. Its dual with respect to the L^2-pairing is denoted by $W^{-1,2}(\mathcal{O}) = (\overset{o}{W}{}^{1,2}(\mathcal{O}))^*$. If we have in mind only real-valued functions, then we write $W^{1,2}_{\mathbb{R}}(\mathcal{O})$ and $\overset{o}{W}{}^{1,2}_{\mathbb{R}}(\mathcal{O})$.

Moreover, the superscripts "+" and "−" always indicate quantities related to holes and electrons, respectively.

Throughout this paper φ will always denote the electrostatic potential. If needed, we will indicate the dependence of any quantity A on the electrostatic potential φ, or the current density J and the electrostatic potential φ, by writing $A[\varphi]$ or $A[J, \varphi]$, respectively.

2. Classical zone. In this section we consider the stationary drift-diffusion equations (1.1)–(1.3) on the disconnected set Ω_c with boundary conditions (1.5). The boundary conditions at a and b are replaced by the conditions that (i) the current densities at a and b are equal and (ii) these current densities are given. We show in this section that the system is well posed and admits solutions $\phi^\pm$, provided the given current densities are located in some interval around zero, which depends on the fixed electrostatic potential φ. Later on, the given current densities will be the quantum current densities for a fixed potential φ, which is finally determined self-consistently by the Poisson equation.

We assume that the carrier and current densities $U^{\pm}$ and $J^{\pm}$ are given by (1.1) and (1.2), respectively. We make the following assumptions.

ASSUMPTION 2.1.

(C.1) *The effective carrier mobilities $\mu^{\pm}$ are strictly positive and constant on Ω_c.*

(C.2) *The effective density of states $N_0^{\pm}$ are strictly positive constants on Ω_c.*

(C.3) *The boundary values ϕ_{a_0} and ϕ_{b_0} are given constants from $\mathbb{R}$.*

(C.4) *The band-edge offsets $V_h^{\pm}$ are real and continuous functions, i.e., $V_h^{\pm} \in C_{\mathbb{R}}(\overline{\Omega_c})$.*

(C.5) *Generation and recombination are absent.*

Moreover, we will assume throughout this section that the electrostatic potential φ is given and obeys $\varphi \in C_{\mathbb{R}}(\Omega)$. By Assumption (C.4) we get that the potentials $V^{\pm}$ defined by (1.4) satisfy $V^{\pm} \in C_{\mathbb{R}}(\overline{\Omega_c})$.

By (C.5) we obtain the continuity equations (1.3), which imply that the current density $J^{\pm}(x)$ is constant on each subinterval of Ω_c, i.e.,

$$J^{\pm}(x) = J^{\pm}(a), \quad x \in (a_0, a), \quad \text{and} \quad J^{\pm}(x) = J^{\pm}(b), \quad x \in (b, b_0). \tag{2.1}$$

Thus, we deduce

$$J^{\pm}(a) = \mu^{\pm} N_0^{\pm} \frac{e^{-\phi^{\pm}_{a_0}} - e^{-\phi^{\pm}(a)}}{\int_{a_0}^{a} dy\, e^{V^{\pm}(y)}} \tag{2.2}$$

and

$$J^{\pm}(b) = \mu^{\pm} N_0^{\pm} \frac{e^{-\phi^{\pm}(b)} - e^{-\phi^{\pm}_{b_0}}}{\int_{b}^{b_0} dy\, e^{V^{\pm}(y)}}. \tag{2.3}$$

LEMMA 2.2. *Let the electrostatic potential $\varphi \in C_{\mathbb{R}}(\Delta)$ and the current densities $J^{\pm}$ be given. There are solutions $\phi^{\pm} \in C^1_{\mathbb{R}}(\Omega_c)$ of the drift-diffusion equations* (1.1)–(1.3) *satisfying the boundary conditions* (1.5) *and the conditions $J^{\pm}(a) = J^{\pm}(b) = J^{\pm}$ if and only if $J^{\pm} \in (J^{\pm}_{min}, J^{\pm}_{max})$, where*

$$J^{\pm}_{min} := -\mu^{\pm} N_0^{\pm} \frac{e^{\pm\phi^{\pm}_{b_0}}}{\int_{b}^{b_0} dy\, e^{V^{\pm}(y)}}, \quad J^{\pm}_{max} := \mu^{\pm} N_0^{\pm} \frac{e^{\pm\phi^{\pm}_{a_0}}}{\int_{a_0}^{a} dy\, e^{V^{\pm}(y)}}, \tag{2.4}$$

with $V^{\pm}$ given by (1.4). *Moreover, these solutions $\phi^{\pm}$ are unique.*

Proof. Let us first assume that $\phi^{\pm}$ are solutions of the drift-diffusion equations such that $J^{\pm}(a) = J^{\pm}(b) = J^{\pm}$ holds. From (2.2) and (2.3), one gets

$$J^{\pm}(a) < \mu^{\pm} N_0^{\pm} \frac{e^{\pm\phi^{\pm}_{a_0}}}{\int_{a_0}^{a} dy\, e^{V^{\pm}(y)}} = J^{\pm}_{max} \tag{2.5}$$

and

$$J^{\pm}(b) > -\mu^{\pm} N_0^{\pm} \frac{e^{\pm\phi^{\pm}_{b_0}}}{\int_{b}^{b_0} dy\, e^{V^{\pm}(y)}} = J^{\pm}_{min}. \tag{2.6}$$

Thus, $J^{\pm} \in (J^{\pm}_{min}, J^{\pm}_{max})$.

Conversely, if $J^{\pm} \in (J^{\pm}_{min}, J^{\pm}_{max})$, then we can define

$$\phi^-(x) := \begin{cases} -\ln\left(e^{-\phi^-_{a_0}} - \frac{J^-}{\mu^- N^-_0}\int_{a_0}^{x} dy\, e^{V^-(y)}\right) & \text{for } x \in (a_0, a), \\ -\ln\left(e^{-\phi^-_{b_0}} + \frac{J^-}{\mu^- N^-_0}\int_{x}^{b_0} dy\, e^{V^-(y)}\right) & \text{for } x \in (b, b_0), \end{cases} \tag{2.7}$$

and similarly

$$\phi^+(x) := \begin{cases} \ln\left(e^{\phi^+_{a_0}} - \frac{J^+}{\mu^+ N^+_0}\int_{a_0}^{x} dy\, e^{V^+(y)}\right) & \text{for } x \in (a_0, a), \\ \ln\left(e^{\phi^+_{b_0}} + \frac{J^+}{\mu^+ N^+_0}\int_{x}^{b_0} dy\, e^{V^+(y)}\right) & \text{for } x \in (b, b_0). \end{cases} \tag{2.8}$$

A straightforward computation shows that $\phi^{\pm}$ defined by (2.7) and (2.8) are indeed solutions of the drift-diffusion equations (1.1)–(1.3) and satisfy the boundary conditions (1.5). The uniqueness of the solutions follows from the fact that (1.3) is a second order equation for $e^{\phi^{\pm}}$, where the boundary values at $\phi^{\pm}(a_0)$, $\phi^{\pm}(b_0)$ are fixed by (1.5), and $\frac{d}{dx}\phi^{\pm}(a_0)$, $\frac{d}{dx}\phi^{\pm}(b_0)$ are fixed by the conditions $J^{\pm}(a) = J^{\pm}(b) = J^{\pm}$. ∎

It is convenient to introduce the sets

$$\mathcal{E}^- := \left\{ (J^-, \varphi) \in \mathbb{R} \times C_{\mathbb{R}}(\Omega) : \begin{array}{l} 0 < e^{-\phi^-_{a_0}} - \frac{J^-}{\mu^- N^-_0}\int_{a_0}^{a} dx\, e^{V^-(x)} \\ 0 < e^{-\phi^-_{b_0}} + \frac{J^-}{\mu^- N^-_0}\int_{b}^{b_0} dx\, e^{V^-(x)} \end{array} \right\} \tag{2.9}$$

and

$$\mathcal{E}^+ := \left\{ (J^+, \varphi) \in \mathbb{R} \times C_{\mathbb{R}}(\Omega) : \begin{array}{l} 0 < e^{\phi^+_{a_0}} - \frac{J^+}{\mu^+ N^+}\int_{a_0}^{a} dx\, e^{V^+(x)} \\ 0 < e^{\phi^+_{b_0}} + \frac{J^+}{\mu^+ N^+}\int_{b}^{b_0} dx\, e^{V^+(x)} \end{array} \right\}. \tag{2.10}$$

Note that the definitions (2.7) and (2.8) make sense if $(J^{\pm}, \varphi) \in \mathcal{E}^{\pm}$. For pairs $(J^{\pm}, \varphi) \in \mathcal{E}^{\pm}$ we will indicate the dependence of $\phi^{\pm}$ from (2.7), (2.8) on the pairs by writing $\phi^{\pm}[J^{\pm}, \varphi]$.

For $(J^{\pm}, \varphi) \in \mathcal{E}^{\pm}$ the densities $U^{\pm}$ are given by means of (1.1), (2.7), and (2.8) by

$$U^-(x) = \begin{cases} N^-_0 e^{-V^-(x)} \left\{ e^{-\phi^-_{a_0}} - \frac{J^-}{\mu^- N^-_0}\int_{a_0}^{x} dy\, e^{V^-(y)} \right\} & \text{for } x \in (a_0, a), \\ N^-_0 e^{-V^-(x)} \left\{ e^{-\phi^-_{b_0}} + \frac{J^-}{\mu^- N^-_0}\int_{x}^{b_0} dy\, e^{V^-(y)} \right\} & \text{for } x \in (b, b_0), \end{cases} \tag{2.11}$$

and

$$U^+(x) = \begin{cases} N^+_0 e^{-V^+(x)} \left\{ e^{\phi^+_{a_0}} - \frac{J^+}{\mu^+ N^+_0}\int_{a_0}^{x} dy\, e^{V^+(y)} \right\} & \text{for } x \in (a_0, a), \\ N^+_0 e^{-V^+(x)} \left\{ e^{\phi^+_{b_0}} + \frac{J^+}{\mu^+ N^+_0}\int_{x}^{b_0} dy\, e^{V^+(y)} \right\} & \text{for } x \in (b, b_0). \end{cases} \tag{2.12}$$

Clearly the densities $U^{\pm}$ are positive if $(J^{\pm}, \varphi) \in \mathcal{E}^{\pm}$. The operators that assign the densities $U^{\pm}$ to pairs of $(J^{\pm}, \varphi)$, called the classical carrier density operators $\mathcal{D}^{\pm} : \mathcal{E}^{\pm} \longrightarrow L^1_{\mathbb{R}}(\Omega_c)$, are defined by

$$\mathcal{D}^{\pm}[J^{\pm}, \varphi] := U^{\pm}, \qquad (J^{\pm}, \varphi) \in \mathrm{dom}(\mathcal{D}^{\pm}) = \mathcal{E}^{\pm}, \tag{2.13}$$

where $U^{\pm}$ are given by (2.11) and (2.12). Of course, the carrier densities are not only from L^1 but in fact also are continuous functions. However, in section 3 we see that for the quantum densities the adequate function space is L^1. This suggests that we demand the same function space here.

3. Quantum zone. In this section we rigorously define the dissipative Schrödinger system described in the introduction of this paper; see (1.6)–(1.13). To that end we make the following general assumptions.

ASSUMPTION 3.1.

(Q.1) *The effective masses* $m^{\pm}$ *are positive and obey* $m^{\pm}$, $\frac{1}{m^{\pm}} \in L^{\infty}_{\mathbb{R}}(\Omega_q)$.

(Q.2) *The effective masses* $m_a^{\pm}$ *and* $m_b^{\pm}$ *entering the boundary coefficients* $\varkappa_a^{\pm}$ *and* $\varkappa_b^{\pm}$ *(see* (1.8)*) are strictly positive constants.*

(Q.3) *The approximation parameters* $\mathfrak{A} = \{\delta_0^{\pm}, \delta^{\pm}\}$ *entering* $\varkappa_a^{\pm}$ *and* $\varkappa_b^{\pm}$ *via* (1.9) *are strictly positive and obey* $\delta_0^{\pm} < \delta^{\pm} \leq \infty$.

(Q.4) *The band-edge offsets* $V_h^{\pm}$ *are essentially bounded over the whole device domain and continuous in the classical region* (*see also Assumption* (C.4)).

(Q.5) *The distribution functions* $f^{\pm} : \mathbb{R} \longrightarrow \mathbb{R}_+$ *are continuously differentiable and nonincreasing, i.e.,* $\frac{d}{dx} f^{\pm}(x) \leq 0$ *for* $x \in \mathbb{R}$, *such that*

$$D^{\pm}(s) := \sup_{\lambda \in [s,\infty)} f^{\pm}(\lambda)\sqrt{1+\lambda^2} < \infty, \quad s \in \mathbb{R}, \tag{3.1}$$

$$F^{\pm}(s) := \int_s^{\infty} d\lambda\, f^{\pm}(\lambda) < \infty, \quad s \in \mathbb{R}. \tag{3.2}$$

Moreover, the electrostatic potential $\varphi \in C_{\mathbb{R}}(\Omega)$ is assumed to be fixed in this section. The potentials $V^{\pm}$ are defined—as before—by (1.4).

Remark 3.2. Clearly, the reduced Boltzman distribution functions $f^{\pm}(\lambda) = n_0^{\pm}\, e^{-\lambda}$ and the reduced Fermi–Dirac distribution functions $f^{\pm}(\lambda) = n_0^{\pm}\, \ln(1+e^{-\lambda})$, where $n_0^{\pm}$ are the integrated density of states, satisfy assumption (Q.5).

We define the operators $H^{\pm}$ on the Hilbert space $L^2(\Omega_q)$ by

$$\mathrm{dom}(H^{\pm}) = \left\{ g \in W^{1,2}(\Omega_q) : \begin{array}{c} \frac{1}{m^{\pm}} g' \in W^{1,2}(\Omega_q), \\ \frac{1}{2m^{\pm}(a)} g'(a) = -\varkappa_a^{\pm} g(a), \\ \frac{1}{2m^{\pm}(b)} g'(b) = \varkappa_b^{\pm} g(b) \end{array} \right\} \tag{3.3}$$

and

$$(H^{\pm} g)(x) = -\frac{1}{2}\frac{d}{dx}\frac{1}{m^{\pm}(x)}\frac{d}{dx} g(x) + V^{\pm}(x) g(x), \tag{3.4}$$

where the coefficients $\varkappa_a^{\pm}$ and $\varkappa_b^{\pm}$ are given by (1.8). The operators $H^{\pm}$ are maximal dissipative and completely non–self-adjoint, since $\mathrm{Im}(\varkappa_a^{\pm}), \mathrm{Im}(\varkappa_b^{\pm}) > 0$; see [34].

The dissipative operators $H^{\pm}$ are regarded as pseudo-Hamiltonians of an open quantum system; see [17, 3]. By means of the dilation theorem (see, e.g., [21]), there exists a Hilbert space $\mathfrak{K}$ containing $L^2(\Omega_q)$ as a subspace and self-adjoint dilations $K^{\pm}$ on $\mathfrak{K}$ corresponding to the maximal dissipative operators $H^{\pm}$, i.e.,

$$(H^{\pm} - z)^{-1}\psi = P(K^{\pm} - z)^{-1}\psi \qquad \text{for all } \psi \in L^2(\Omega_q),$$

where P denotes the orthogonal projection from the dilation space $\mathfrak{K}$ onto the subspace $L^2(\Omega_q)$. Moreover, the minimality conditions

$$\mathfrak{K} = \operatorname*{clospan}_{z \in \mathbb{C}\setminus\mathbb{R}} \left\{ (K^{\pm} - z)^{-1}\psi,\ \psi \in L^2(\Omega_q) \right\}$$

are satisfied. The minimal self-adjoint dilations $K^{\pm}$ corresponding to the maximal dissipative operators $H^{\pm}$ can be obtained explicitly; see [35] and also section A.2. The spectrum of $K^{\pm}$ is absolutely continuous, is the whole real line, and has multiplicity 2. The incoming eigenfunctions of $K^{\pm}$ are denoted by $\psi_a^{\pm}(x,\lambda)$, $\psi_b^{\pm}(x,\lambda)$; see [35]. The macroscopic quantities such as carrier densities $u^{\pm}$ and current densities $j^{\pm}$ for the open quantum system are then determined by the incoming eigenfunctions of the quasi Hamiltonian and given statistics as in [33] and sections A.3 and A.4 by

$$u^{\pm}(x) = \sum_{\nu=a,b} \int_{\Lambda^{\pm}} d\lambda \; f^{\pm}(\lambda \mp \epsilon_\nu) |\psi_\nu^{\pm}(x,\lambda)|^2, \tag{3.5}$$

$$j^{\pm} = \sum_{\nu=a,b} \int_{\Lambda^{\pm}} d\lambda \; f^{\pm}(\lambda \mp \epsilon_\nu) \mathrm{Im}\left(\frac{1}{m(x)} \frac{\partial \psi_\nu^{\pm}(\lambda,x)}{\partial x} \overline{\psi_\nu^{\pm}(\lambda,x)} \right), \tag{3.6}$$

where $\epsilon_a^{\pm}$, $\epsilon_b^{\pm}$ are given Fermi levels and $\Lambda^{\pm}$ the sets given by (1.13). The current densities $j^{\pm}$ can be expressed by means of the transmission coefficients $0 \le t^{\pm}(\lambda) \le 1$ (see [35] and section A.4 in Appendix A) as

$$j^{\pm} = \frac{1}{2\pi} \int_{\Lambda^{\pm}} d\lambda \; t^{\pm}(\lambda) \Big(f^{\pm}(\lambda \mp \epsilon_a) - f^{\pm}(\lambda \mp \epsilon_b) \Big). \tag{3.7}$$

Clearly the carrier and current densities depend on the electrostatic potential φ since the eigenfunctions $\psi_a^{\pm}$, $\psi_b^{\pm}$ and the intervals $\Lambda^{\pm}$ depend on φ. Moreover, $u^{\pm}$ and $j^{\pm}$ depend on the Fermi energies $\epsilon_a^{\pm}$, $\epsilon_b^{\pm}$. Therefore, we define the carrier density operators $\mathcal{N}^{\pm} : \mathbb{R} \times \mathbb{R} \times C_{\mathbb{R}}(\Omega) \longrightarrow L^1(\Omega_q)$ and current density operators $j^{\pm} : \mathbb{R} \times \mathbb{R} \times C_{\mathbb{R}}(\Omega) \longrightarrow \mathbb{R}$, which assign to the Fermi levels and the electrostatic potential the corresponding carrier and current densities, i.e.,

$$\mathcal{N}^{\pm}[\epsilon_a^{\pm}, \epsilon_b^{\pm}, \varphi] := u^{\pm}(x), \quad (\epsilon_a^{\pm}, \epsilon_b^{\pm}, \varphi) \in \mathrm{dom}(\mathcal{N}^{\pm}) = \mathbb{R} \times \mathbb{R} \times C_{\mathbb{R}}(\Omega), \tag{3.8}$$

and

$$j^{\pm}[\epsilon_a^{\pm}, \epsilon_b^{\pm}, \varphi] := j^{\pm}, \quad (\epsilon_a^{\pm}, \epsilon_b^{\pm}, \varphi) \in \mathrm{dom}(j^{\pm}) = \mathbb{R} \times \mathbb{R} \times C_{\mathbb{R}}(\Omega). \tag{3.9}$$

The carrier density operators admit the estimate (cf. Proposition A.4 of section A.3)

$$\|\mathcal{N}^{\pm}[\epsilon_a^{\pm}, \epsilon_b^{\pm}, \varphi]\|_{L^1(\Omega_q)} \le C^{\pm}[\epsilon_a^{\pm}, \epsilon_b^{\pm}, \varphi] \left(\gamma_1^{\pm} + \gamma_2^{\pm} \sqrt{\|\varphi_{\mp}\|_{L^\infty(\Omega_q)}} \right), \tag{3.10}$$

where φ_+ and φ_- denote the positive and negative parts, respectively, of φ, i.e.,

$$\varphi_-(x) := \max\{0, -\varphi(x)\}, \quad \varphi_+(x) := \max\{0, \varphi(x)\}, \quad x \in \Omega_q. \tag{3.11}$$

The constants $\gamma_1^{\pm}$, $\gamma_2^{\pm}$ are independent of $\epsilon_a^{\pm}$, $\epsilon_b^{\pm}$, and φ. The constants $C^{\pm}[\epsilon_a^{\pm}, \epsilon_b^{\pm}, \varphi]$ are given by

$$C^{\pm}[\epsilon_a^{\pm}, \epsilon_b^{\pm}, \varphi] := \sup_{\lambda \in \Lambda^{\pm}[\varphi]} \max_{\nu=a,b} f^{\pm}(\lambda \mp \epsilon_\nu^{\pm}) \sqrt{1+\lambda^2}, \tag{3.12}$$

where $\Lambda^{\pm}[\varphi]$ denotes the dependence of the intervals $\Lambda^{\pm}$ given by (1.13) on the electrostatic potential φ.

4. Hybrid model. In this section we couple the drift-diffusion model of section 2 and the dissipative Schrödinger model of section 3, which leads to the dissipative hybrid model. This coupling is done in two steps: (i) the Fermi coupling and (ii) the current coupling.

4.1. Fermi coupling. Fermi coupling means to choose the Fermi energies $\epsilon_a^\pm$ and $\epsilon_b^\pm$ in the dissipative Schrödinger model (see (3.5), (3.6)) in an appropriate manner. Let us assume that the electrostatic potential φ and the current densities $J^\pm$ are given and obey $(J^\pm,\varphi) \in \mathcal{E}^\pm$, where $\mathcal{E}^\pm$ are given by (2.9), (2.10). Thus the Fermi potentials $\phi^\pm$ can be defined by means of (2.7) and (2.8). The Fermi levels $\epsilon_a^\pm$ and $\epsilon_b^\pm$ are then determined by

$$\epsilon_a^\pm = \phi^\pm(a) \quad \text{and} \quad \epsilon_b^\pm = \phi^\pm(b).$$

With this choice of the Fermi levels, we may define in accordance with (3.8) and (3.9) the mappings $\mathcal{N}^\pm : \mathcal{E}^\pm \longrightarrow L^1(\Omega_q)$,

$$\mathcal{N}^\pm[J^\pm,\varphi] := \mathcal{N}^\pm[\phi^\pm[J^\pm,\varphi](a), \phi[J^\pm,\varphi](b),\varphi], \quad (J^\pm,\varphi) \in \mathrm{dom}(\mathcal{N}^\pm) = \mathcal{E}^\pm, \tag{4.1}$$

and similar the mappings $j^\pm : \mathcal{E}^\pm \longrightarrow \mathbb{R}$ by

$$j^\pm[J^\pm,\varphi] := j^\pm[\phi^\pm[J^\pm,\varphi](a), \phi^\pm[J^\pm,\varphi](b),\varphi], \quad (J^\pm,\varphi) \in \mathrm{dom}(j^\pm) = \mathcal{E}^\pm. \tag{4.2}$$

4.2. Current coupling. The other condition for the coupling of the dissipative and drift-diffusion model is to impose the continuity of the current densities. More precisely, let the electrostatic potential $\varphi \in C_{\mathbb{R}}(\Omega)$ be given; then the current continuity condition reads

$$J^\pm = j^\pm[J^\pm,\varphi], \quad (J^\pm,\varphi) \in \mathcal{E}^\pm, \tag{4.3}$$

where $j^\pm$ are given by (4.2). Let us first show that condition (4.3) is well posed.

Proposition 4.1. *If Assumptions* 2.1 *and* 3.1 *are satisfied, then for any electrostatic potential $\varphi \in C_{\mathbb{R}}(\Omega)$, the equations* (4.3) *admit unique solutions $J^\pm$ such that $(J^\pm,\varphi) \in \mathcal{E}^\pm$.*

Proof. Since the considerations for holes and electrons are the same, we restrict ourselves in the following to holes and consider only the current continuity equation $J^+ = j^+[J^+,\varphi]$, $(J^+,\varphi) \in \mathcal{E}^+$. The transmission coefficient $t^+(z)$ is holomorphic and bounded by 1 in $z \in \mathbb{C}_-$; see section A.2, equation (A.23). We note that the limit $t^+(\lambda) = \lim_{\beta\uparrow 0} t^+(\lambda - i\beta)$ exists for all $\lambda \in \mathbb{R}$ and is bounded by 1, too. Using the uniqueness theorem for the H^∞-function (cf. Corollary II.4.2 of [26]), we find that this limit is different from zero for a.e. $\lambda \in \mathbb{R}$. Hence the function $t^+(\lambda)$ is different from zero and obeys the estimate

$$0 \le t^+(\lambda) \le 1, \quad \varphi \in C_{\mathbb{R}}(\Omega), \tag{4.4}$$

for a.e. $\lambda \in \mathbb{R}$. Inserting (2.7) and (2.8) into (3.7), we find

$$\begin{aligned} j^+[J^+,\varphi] = \frac{1}{2\pi}\int_{\Lambda^+[\varphi]} d\lambda\, t^+(\lambda)\Bigg\{ f^+\left(\lambda - \ln\left(e^{\phi^+_{a_0}} - \frac{J^+}{\mu^+ N_0^+}\int_{a_0}^a dy\, e^{V^+(y)}\right)\right) \\ -f^+\left(\lambda - \ln\left(e^{\phi^+_{b_0}} + \frac{J^+}{\mu_b^+ N_b^+}\int_b^{b_0} dy\, e^{V^+(y)}\right)\right)\Bigg\}. \end{aligned}$$

Since $\frac{d}{dx}f^+ \le 0$, one gets $\frac{\partial}{\partial J^+} j^+[J^+,\varphi] \le 0$. Hence, if φ is fixed, then the function $j^+[J^+,\varphi]$ is nonincreasing in J^+. By Lemma 2.2 one has $(J^+,\varphi) \in \mathcal{E}^+ \iff J^+ \in (J^+_{min}, J^+_{max})$. If $J^+ \uparrow J^+_{max}$, then $\phi^+[J^+,\varphi](a) \to -\infty$. Using the estimate

$$\int_{\Lambda^+} d\lambda\, t^+(\lambda) f^+(\lambda - \phi^+[J^+,\varphi](a)) \le \int_{V^+_{max} - \phi^+[J^+,\varphi](a)}^\infty d\lambda\, f^+(\lambda),$$

we find

$$\lim_{J^+ \uparrow J^+_{max}} \int_{\Lambda^+} d\lambda\, t^+(\lambda) f^+(\lambda - \phi^+[J^+,\varphi](a)) = 0,$$

which gives

$$(4.5)\quad \begin{aligned} j^+[J^+_{max},\varphi] &:= \lim_{J^+ \uparrow J^+_{max}} j^+[J^+,\varphi] \\ &= -\frac{1}{2\pi} \int_{\Lambda^+} d\lambda\, t^+(\lambda) f^+ \left(\lambda - \ln\left(e^{\phi^+_{b_0}} + \frac{J^+_{max}}{\mu^+ N^+_0} \int_b^{b_0} dy\, e^{V^+(y)}\right)\right). \end{aligned}$$

Similarly, if $J^+ \downarrow J^+_{min}$, then $\phi^+[J^+,\varphi](b) \to -\infty$. Hence

$$\lim_{J^+ \downarrow J^+_{min}} \int_{\Lambda^+} d\lambda\, t^+(\lambda) f^+(\lambda - \phi^+[J^+,\varphi](b)) = 0,$$

which yields

$$(4.6)\quad \begin{aligned} j^+[J^+_{min},\varphi] &:= \lim_{J^+ \downarrow J^+_{min}} j^+[J^+,\varphi] \\ &= \frac{1}{2\pi} \int_{\Lambda^+} d\lambda\, (\lambda) f^+ \left(\lambda - \ln\left(e^{\phi^+_{a_0}} - \frac{J^+_{min}}{\mu^+ N^+_0} \int_{a_0}^{a} dy\, e^{V^+(y)}\right)\right). \end{aligned}$$

Since $j^+[J^+,\varphi]$ is continuous and nonincreasing in J^+, as are $j^+[J^+_{min},\varphi] > 0$ and $j^+[J^+_{max},\varphi] < 0$, one immediately gets that the equation $J^+ = j^+[J^+,\varphi]$ admits a unique solution J^+ for each $\varphi \in C_{\mathbb{R}}(\Omega)$ such that $(J^+,\varphi) \in \mathcal{E}^+$. ∎

4.3. Dissipative hybrid system. If $J^\pm = J^\pm[\varphi]$ are the solutions of (4.3) for a given electrostatic potential $\varphi \in C_{\mathbb{R}}(\Omega)$, then it makes sense to introduce the following quantities of the dissipative hybrid system:

(4.7) $\quad \phi^\pm[\varphi] := \phi^\pm[J^\pm[\varphi],\varphi]$ Fermi potentials (cf. (2.7), (2.8)),

(4.8) $\quad \mathcal{N}^\pm[\varphi] := \mathcal{N}^\pm[J^\pm[\varphi],\varphi]$ dissipative particle density operators (cf. (4.1)),

(4.9) $\quad \mathcal{D}^\pm[\varphi] := \mathcal{D}^\pm[J^\pm[\varphi],\varphi]$ classical density operators (cf. (2.13)).

Moreover, we introduce the hybrid carrier density operators as follows.

DEFINITION 4.2. *Let Assumptions* 2.1 *and* 3.1 *be satisfied. The carrier density operator* $\mathcal{U}^\pm[\cdot] : C_{\mathbb{R}}(\Omega) \longrightarrow L^1_{\mathbb{R}}(\Omega)$ *of the dissipative hybrid system is defined by*

$$(4.10)\qquad \mathcal{U}^\pm[\varphi](x) := \begin{cases} \mathcal{D}^\pm[\varphi](x), & x \in \Omega_c, \\ \mathcal{N}^\pm[\varphi](x), & x \in \Omega_q. \end{cases}$$

In order to couple the hybrid system with the Poisson equation, we need to verify certain properties of the quantities (4.7)–(4.9). In the following lemma we give an L^∞-estimate of the quasi-Fermi potentials $\phi^\pm[\varphi]$ that is uniform in $\varphi \in C_{\mathbb{R}}(\Omega)$.

LEMMA 4.3. *If Assumptions* 2.1 *and* 3.1 *are satisfied, then for any* $\varphi \in C_{\mathbb{R}}(\Omega)$ *one has*

$$(4.11)\qquad \max_{x \in \Omega_c} \{|\phi^\pm[\varphi](x)|\} \le \eta^\pm,$$

where

$$\eta^{\pm} := \max\left\{\left|\phi^{\pm}_{a_0}\right|, \left|\phi^{\pm}_{b_0}\right|\right\}. \tag{4.12}$$

Proof. Assume that $J^+[\varphi] \geq 0$. Since $J^+[\varphi]$ solves (4.3), one gets from (3.7) and the monotonicity of the functions $f^{\pm}$ that

$$f^+(\lambda - \phi^+[\varphi](a)) \geq f^+(\lambda - \phi^+[\varphi](b)), \quad \lambda \in \Lambda^+.$$

Taking into account the monotonicity of f^+, we find that

$$-\phi^+[\varphi](a) \leq -\phi^+[\varphi](b).$$

If $J^+[\varphi] \geq 0$, then $-\phi^+[\varphi](x)$, $x \in \Omega_c$, is nondecreasing. That means we have

$$-\phi^+[\varphi](a_0) \leq -\phi^+[\varphi](a) \quad \text{and} \quad -\phi^+[\varphi](b) \leq -\phi^+[\varphi](b_0).$$

Hence

$$-\phi^+[\varphi](a_0) \leq -\phi^+[\varphi](a) \leq -\phi^+[\varphi](b) \leq -\phi^+[\varphi](b_0),$$

which shows that

$$\max\{|\phi^+[\varphi](a)|, |\phi^+[\varphi](b)|\} \leq \max\{|\phi^+[\varphi](a_0)|, |\phi^+[\varphi](b_0)|\}.$$

If $J^+[\varphi] \leq 0$, then from (3.7) one gets

$$f^+(\lambda - \phi^+[\varphi](a)) \leq f^+(\lambda - \phi^+[\varphi](b)), \quad \lambda \in \Lambda^+,$$

which yields

$$\phi^+[\varphi](a) \leq \phi^+[\varphi](b).$$

Since $\phi^+[\varphi](x)$ is nondecreasing on Ω_c, we find

$$\phi^+[\varphi](a_0) \leq \phi^+[\varphi](a) \leq \phi^+[\varphi](b) \leq \phi^+[\varphi](b_0),$$

which gives

$$\max\{|\phi^+[\varphi](a)|, |\phi^+[\varphi](b)|\} \leq \max\{|\phi^+[\varphi](a_0)|, |\phi^+[\varphi](b_0)|\} = \eta^+.$$

We complete the proof for holes with the remark that the quasi-Fermi potential $\phi^+[\varphi]$ is monotone on each subinterval (a_0, a) and (b, b_0). The proof for electrons is similar. ∎

With the help of Lemma 4.3, we prove an estimate for the carrier density operators.

LEMMA 4.4. *If Assumptions* 2.1 *and* 3.1 *are satisfied, then for any $\varphi \in C_{\mathbb{R}}(\Omega)$ the carrier density operators $\mathcal{N}^{\pm}[\cdot]$ admit the estimates*

$$\|\mathcal{N}^{\pm}[\varphi]\|_{L^1(\Omega_q)} \leq C^{\pm}(V^{\pm}_{max}[\varphi]) \left(\gamma^{\pm}_1 + \gamma^{\pm}_2 \sqrt{\|\varphi_{\mp}\|_{L^\infty(\Omega_q)}}\right), \tag{4.13}$$

where φ_+ and φ_- denote the positive and negative parts, respectively, of φ. The constants $\gamma^{\pm}_1$, $\gamma^{\pm}_2$ are independent of φ; $V^{\pm}_{\max}[\varphi]$ are given by (1.10), *and the functions $C^{\pm}(s)$ are given by*

$$C^{\pm}(s) := D^{\pm}(s - \eta^{\pm})(1 + \eta^{\pm}), \quad s \in \mathbb{R}, \tag{4.14}$$

with $D^{\pm}(\cdot)$ *and* $\eta^{\pm}$ *given by* (3.1) *and* (4.12), *respectively.*

Proof. From (3.10) and (3.12) we get

$$\|\mathcal{N}^{\pm}[\varphi]\|_{L^1(\Omega_q)} \le C^{\pm}[\phi^{\pm}[\varphi](a), \phi^{\pm}[\varphi](b), \varphi] \left(\gamma_1^{\pm} + \gamma_2^{\pm}\sqrt{\|\varphi_{\mp}\|_{L^\infty(\Omega_q)}}\right).$$

Thus, it suffices to show that constants $C^{\pm}[\phi^{\pm}[\varphi](a), \phi^{\pm}[\varphi](b), \varphi]$ are estimated by $C^{\pm}(V^{\pm}_{max}[\varphi])$. Let us consider the case of holes. We find by means of the definition of Λ^+ (see (1.13)) that

$$\sup_{\lambda\in\Lambda^+[\varphi]} \sqrt{1+\lambda^2} f^+(\lambda - \phi^+[\varphi](b)) \le D^+(V^+_{max}[\varphi] - \phi^+[\varphi](b)) \sup_{x\in\mathbb{R}} \left(\frac{1+(x+\phi^+[\varphi](b))^2}{1+x^2}\right)^{1/2}.$$

Since

$$\sup_{x\in\mathbb{R}} \left(\frac{1+(x+\phi^+[\varphi](b))^2}{1+x^2}\right)^{1/2} \le 1 + |\phi^+[\varphi](b)|,$$

we get

$$\sup_{\lambda\in\Lambda^+[\varphi]} \sqrt{1+\lambda^2} f^+(\lambda - \phi^+[\varphi](b)) \le D^+(V^+_{max}[\varphi] - \phi^+[\varphi](b))(1 + |\phi^+[\varphi](b)|).$$

In the same manner, we prove

$$\sup_{\lambda\in\Lambda^+[\varphi]} \sqrt{1+\lambda^2} f^+(\lambda - \phi^+[\varphi](a)) \le D^+(V^+_{max}[\varphi] - \phi^+[\varphi](a))(1 + |\phi^+[\varphi](a)|),$$

which yields

(4.15)

$$C^+[\phi^+[\varphi](a), \phi^+[\varphi](b), \varphi] \le \max_{\nu\in\{a,b\}} \left\{D^+(V^+_{max}[\varphi] - \phi^+[\varphi](\nu))(1 + |\phi^+[\varphi](\nu)|)\right\}.$$

Since $D^+(\cdot)$ is nonincreasing, we complete the proof using Lemma 4.3. The proof for electrons is similar. ∎

Like the carrier densities $\mathcal{N}^{\pm}[\varphi]$, the current densities $J^{\pm}[\varphi]$ also admit an estimate.

LEMMA 4.5. *If Assumptions* 2.1 *and* 3.1 *are satisfied, then for any* $\varphi \in C_{\mathbb{R}}(\Omega)$ *the estimates*

$$|J^{\pm}[\varphi]| \le \frac{1}{\pi} F^{\pm}(V^{\pm}_{max}[\varphi] - \eta^{\pm}) \tag{4.16}$$

are valid, where $V^{\pm}_{max}[\varphi]$ *are defined by* (1.10); $\eta^{\pm}$ *and the functions* $F^{\pm}(\cdot)$ *are given by* (4.12) *and by* (3.2), *respectively.*

Proof. We consider the case of holes. Since $J^+[\varphi]$ is a solution of (4.3), one has $J^+[\varphi] = j^+[J^+[\varphi], \varphi]$, where $j^+[J^+[\varphi], \varphi]$ is defined by (4.2). From (3.7) and the fact that the transmission coefficient $t^+[\varphi](\lambda)$ is uniformly bounded by one, we obtain

$$|J^+[\varphi]| \le \frac{1}{2\pi} \left\{ \int_{\Lambda^+[\varphi]} d\lambda \; f^+(\lambda - \phi^+[\varphi](b)) + f^+(\lambda - \phi^+[\varphi](a)) \right\},$$

which yields

$$|J^+[\varphi]| \leq \frac{1}{2\pi}\left\{F^+(V^+_{max}[\varphi] - \phi^+[\varphi](b)) + F^+(V^+_{max}[\varphi] - \phi^+[\varphi](a))\right\}.$$

By Lemma 4.3 we immediately get (4.16). The case of electrons is handled in a similar way. ∎

The next step is to show the continuity of the current density operator with respect to the electrostatic potential φ.

LEMMA 4.6. *Let Assumptions* 2.1 *and* 3.1 *be satisfied. If* $\varphi, \varphi_n \in C_{\mathbb{R}}(\Omega)$, $n \in \mathbb{N}$, *and* $\lim_{n\to\infty} \|\varphi_n - \varphi\|_{L^\infty(\Omega)} = 0$, *then* $\lim_{n\to\infty} J^\pm[\varphi_n] = J^\pm[\varphi]$.

Proof. We will prove the statement only for holes; the proof for electrons is similar. We set $J := J^+[\varphi]$ and $J_n := J^+[\varphi_n]$, $n \in \mathbb{N}$. If $J_n \not\to J$ as $n \to \infty$, then there is a subsequence $\{J_{n_k}\}_{k\in\mathbb{N}}$ such that $\lim_{k\to\infty} J_{n_k} = J_\infty \neq J$. This results from Lemma 4.5, which shows the uniform boundedness of $\{J_n\}^\infty_{n\in\mathbb{N}}$.

Let us show that $(J_\infty, \varphi) \in \mathcal{E}^+$. Since $(J_n, \varphi_n) \in \mathcal{E}^+$, $n \in \mathbb{N}$, and

$$\lim_{n\to\infty} J^+_{min}[\varphi_n] = J^+_{min}[\varphi] \quad \text{and} \quad \lim_{n\to\infty} J^+_{max}[\varphi_n] = J^+_{max}[\varphi],$$

one has $(J_\infty, \varphi) \notin \mathcal{E}^+$ if and only if either $J_\infty = J^+_{max}[\varphi]$ or $J_\infty = J^+_{min}[\varphi]$. However, this is impossible; namely, if $\lim_{k\to\infty} J_{n_k} = J^+_{max}[\varphi] > 0$, then $\lim_{k\to\infty} j^+[J_{n_k}, \varphi_{n_k}] = j^+[J_\infty, \varphi] \leq 0$; cf. (4.5). Similarly, if $\lim_{k\to\infty} J_{n_k} = J^+_{min}[\varphi] < 0$, then $\lim_{k\to\infty} j^+[J_{n_k}, \varphi_{n_k}] = j^+[J^+_\infty, \varphi] \geq 0$; cf. (4.6).

Since $(J_\infty, \varphi) \in \mathcal{E}^+$, the quantities $\phi^+[J_\infty, \varphi]$ are well defined. One gets $\lim_{k\to\infty} \phi^+[J_{n_k}, \varphi_{n_k}](b) = \phi^+[J_\infty, \varphi](b)$ and $\lim_{k\to\infty} \phi^+[J_{n_k}, \varphi_{n_k}](a) = \phi^+[J_\infty, \varphi](a)$, which yields

$$\lim_{k\to\infty} f^+(\lambda - \phi^+[J_{n_k}, \varphi_{n_k}](\nu)) = f^+(\lambda - \phi^+[J^\pm_\infty, \varphi](\nu)) \qquad \text{for a.e. } \lambda \in \mathbb{R},\ \nu = a, b.$$

From the uniform boundedness of the Fermi potentials (see Lemma 4.3), we obtain from Theorem A.9

$$\lim_{k\to\infty} j^+[J_{n_k}, \varphi_{n_k}] = j^+[J_\infty, \varphi].$$

By $J_{n_k} = j^+[J_{n_k}, \varphi_{n_k}]$ we find

$$J_\infty = \lim_{k\to\infty} J_{n_k} = j^+[J_\infty, \varphi].$$

Since the solution of this equation is unique, one gets $J_\infty = J^+[\varphi]$, which proves the continuity. ∎

Next, let us show that the carrier density operators $\mathcal{U}^\pm[\cdot]$ are continuous. To this end we first prove the continuity of the dissipative carrier density operators $\mathcal{N}^\pm[\cdot]$.

LEMMA 4.7. *Let Assumptions* 2.1 *and* 3.1 *be satisfied. If* $\varphi, \varphi_n \in C_{\mathbb{R}}(\Omega)$, $n \in \mathbb{N}$, *and* $\lim_{n\to\infty} \|\varphi_n - \varphi\|_{L^\infty(\Omega)} = 0$, *then* $\lim_{n\to\infty} \|\mathcal{N}^\pm[\varphi_n] - \mathcal{N}^\pm[\varphi]\|_{L^1(\Omega_q)} = 0$.

Proof. Let $\varphi, \varphi_n \in C_{\mathbb{R}}(\Omega)$, $n \in \mathbb{N}$, with $\lim_{n\to\infty} \|\varphi - \varphi_n\|_{L^\infty(\Omega)}$ be given. From Lemma 4.6 and (2.7), (2.8), we immediately obtain

$$\lim_{n\to\infty} \phi^\pm[\varphi_n](x) = \phi^\pm[\varphi](x) \quad \text{for every } x \in \Omega_c.$$

Hence, we get $\lim_{n\to\infty} f^\pm(\lambda \mp \phi^\pm[\varphi_n](\nu)) = f^\pm(\lambda \mp \phi^\pm[\varphi](\nu))$ for $\nu = a, b$. Taking into account the uniform boundedness of $\phi^\pm$ (cf. Lemma 4.3) and Theorem A.7, one completes the proof. ∎

PROPOSITION 4.8. *Let Assumptions* 2.1 *and* 3.1 *be satisfied. If* $\varphi, \varphi_n \in C_{\mathbb{R}}(\Omega)$, $n \in \mathbb{N}$, *and* $\lim_{n\to\infty} \|\varphi_n - \varphi\|_{L^\infty(\Omega)} = 0$, *then* $\lim_{n\to\infty} \|\mathcal{U}^\pm[\varphi_n] - \mathcal{U}^\pm[\varphi]\|_{L^1(\Omega)} = 0$.

Proof. Taking into account Lemma 4.7, it remains to show that

$$\lim_{n\to\infty} \|\mathcal{D}^\pm[\varphi_n] - \mathcal{D}^\pm[\varphi]\|_{L^1(\Omega_c)} = 0.$$

However, this follows immediately from Lemma 4.6 and (2.11), (2.12). ∎

4.4. Coupling to Poisson's equation: Dissipative hybrid model. In order to have a meaningful model for semiconductors, the electrostatic potential has to be computed self-consistently by a Poisson equation. In this section we pose the Poisson equation on the whole device domain Ω, where the right-hand side depends on the densities of the dissipative hybrid model. This leads to a nonlinear equation for the electrostatic potential φ, which will be reformulated as a fixed point problem.

Concerning the data for Poisson's equation, we make the following assumptions.

ASSUMPTION 4.9.

(P.1) *The doping profile* C *belongs to* $W^{-1,2}_{\mathbb{R}}(\Omega)$.

(P.2) *The dielectric permittivity* ε *is positive and obeys* $\varepsilon, \frac{1}{\varepsilon} \in L^\infty_{\mathbb{R}}(\Omega)$.

By $\widehat{\varphi}$ we denote the function which satisfies $\widehat{\varphi} \in W^{1,2}_{\mathbb{R}}(\Omega)$, $\varepsilon \frac{d}{dx}\widehat{\varphi} \in W^{1,2}_{\mathbb{R}}(\Omega)$, $\widehat{\varphi}(a_0) = \varphi_{a_0}$, and $\widehat{\varphi}(b_0) = \varphi_{b_0}$, and additionally

$$-\frac{d}{dx}\varepsilon(x)\frac{d}{dx}\widehat{\varphi}(x) = 0, \quad x \in \Omega.$$

DEFINITION 4.10. *We define the linear Poisson operator with zero boundary conditions* $\mathcal{P} : \overset{o}{W}{}^{1,2}_{\mathbb{R}}(\Omega) \longrightarrow W^{-1,2}_{\mathbb{R}}(\Omega)$ *by*

$$\langle \mathcal{P}\upsilon, \zeta \rangle := \int_a^b dx\, \varepsilon(x)\, \frac{d\upsilon}{dx}\frac{d\zeta}{dx}, \qquad \upsilon, \zeta \in \overset{o}{W}{}^{1,2}_{\mathbb{R}}(\Omega). \tag{4.17}$$

DEFINITION 4.11. *Assume* $w^\pm \in L^1(\Omega)$. *We say* $\varphi \in W^{1,2}_{\mathbb{R}}(\Omega)$ *satisfies Poisson's equation if* $\zeta := \varphi - \widehat{\varphi} \in \overset{o}{W}{}^{1,2}_{\mathbb{R}}(\Omega)$ *and, additionally, satisfies*

$$\mathcal{P}\zeta = C + w^+ - w^-, \tag{4.18}$$

where the function $w^\pm$ *must be understood in the sense of the embedding* $L^1(\Omega) \hookrightarrow W^{-1,2}_{\mathbb{R}}(\Omega)$

DEFINITION 4.12. *Let Assumptions* 2.1, 3.1, *and* 4.9 *be satisfied. We say an element* $\varphi \in W^{1,2}_{\mathbb{R}}(\Omega)$ *is a solution of the dissipative hybrid model if*

(i) *the carrier densities* $w^\pm \in L^1(\Omega)$ *are given by the hybrid densities, i.e.,* $w^\pm = \mathcal{U}^\pm[\varphi]$ *(cf.* (4.10)*), and*

(ii) *the potential* φ *satisfies Poisson's equation.*

We note that if $\varphi \in W^{1,2}_{\mathbb{R}}(\Omega)$ is a solution of the dissipative hybrid model, then the current densities are given by $J^\pm[\varphi]$.

Let us introduce for each fixed electrostatic potential $\varphi \in C_{\mathbb{R}}(\Omega)$ the map $\mathcal{R}[\varphi] : \overset{o}{W}{}^{1,2}_{\mathbb{R}}(\Omega) \longrightarrow W^{-1,2}_{\mathbb{R}}(\Omega)$,

$$\mathcal{R}[\varphi](\zeta) := \mathcal{P}\zeta + \left\{p^-[\varphi]e^{\zeta} - p^+[\varphi]e^{-\zeta}\right\}, \tag{4.19}$$

where

$$p^-[\varphi](x) := \begin{cases} N_0^- e^{\widehat{\varphi}(x) - V_h^-(x)} \left(e^{-\phi_{a_0}^-} - \frac{J^-[\varphi]}{\mu^- N_0^-} \int_{a_0}^x dy\, e^{V^-(y)} \right), & x \in (a_0, a), \\ 0, & x \in \Omega_q, \\ N_0^- e^{\widehat{\varphi}(x) - V_h^-(x)} \left(e^{-\phi_{b_0}^-} + \frac{J^-[\varphi]}{\mu^- N_0^-} \int_x^{b_0} dy\, e^{V^-(y)} \right), & x \in (b, b_0), \end{cases} \tag{4.20}$$

and

$$p^+[\varphi](x) := \begin{cases} N_0^+ e^{-(\widehat{\varphi}(x) + V_h^+(x))} \left(e^{\phi_{a_0}^+} - \frac{J^+[\varphi]}{\mu^+ N_0^+} \int_{a_0}^x dy\, e^{V^+(y)} \right), & x \in (a_0, a), \\ 0, & x \in \Omega_q, \\ N_0^+ e^{-(\widehat{\varphi}(x) + E_h^+(x))} \left(e^{\phi_{b_0}^+} + \frac{J^+[\varphi]}{\mu^+ N_0^+} \int_x^{b_0} dy\, e^{V^+(y)} \right), & x \in (b, b_0), \end{cases} \tag{4.21}$$

$\varphi \in C_{\mathbb{R}}(\Omega)$, where $V^\pm = V^\pm[\varphi]$ are given by (1.4). We note that $p^\pm[\varphi] \in L^\infty_{\mathbb{R}}(\Omega)$ and that drift-diffusion densities can be written as

$$U^\pm[J^\pm[\varphi], \varphi](x) = p^\pm[\varphi](x) e^{\mp\zeta(x)}, \quad x \in \Omega_c, \tag{4.22}$$

where $\varphi = \zeta + \widehat{\varphi}$ and $U^\pm[J^\pm[\varphi], \varphi]$ are given by (2.11) and (2.12), respectively.

Concerning the next lemma and its proof, we follow the terminology of [24]; in particular, the notions of strong monotonicity and boundedly Lipschitz continuity are used in accordance with Definitions III.1.1 and III.1.2 of [24].

LEMMA 4.13. *Let Assumptions* 2.1 *and* 4.9 *be satisfied. If* $\varphi \in C_{\mathbb{R}}(\Omega)$, *then the operator* $\mathcal{R}[\varphi]$ *is strongly monotone with monotonicity constant* $\frac{1}{\|1/\varepsilon\|_{L^\infty(\Omega)}}$ *and boundedly Lipschitz continuous.*

Proof. We note that the operator $\mathcal{P}$ is linear, is bounded, and obeys

$$\langle \mathcal{P}\zeta, \zeta \rangle \ \geq \ \frac{1}{\|1/\varepsilon\|_{L^\infty(\Omega)}} \|\zeta\|^2_{\overset{o}{W}{}^{1,2}_{\mathbb{R}}(\Omega)}. \tag{4.23}$$

Hence, $\mathcal{P}$ is a strongly monotone operator with monotonicity constant $\frac{1}{\|1/\varepsilon\|_{L^\infty(\Omega)}}$, which maps $\overset{o}{W}{}^{1,2}_{\mathbb{R}}(\Omega)$ onto $W^{-1,2}_{\mathbb{R}}(\Omega)$.

By Proposition 4.1 one has $(J^\pm[\varphi], \varphi) \in \mathcal{E}^\pm$; hence, $p^\pm[\varphi](x) \geq 0$ for $x \in \Omega$. Using this, one verifies that for each $\varphi \in C_{\mathbb{R}}(\Omega)$ the nonlinear operator $T[\varphi] : \overset{o}{W}{}^{1,2}_{\mathbb{R}}(\Omega) \longrightarrow W^{-1,2}_{\mathbb{R}}(\Omega)$,

$$T[\varphi](\zeta) := \left\{ p^-[\varphi] e^{\zeta} - p^+[\varphi] e^{-\zeta} \right\}, \tag{4.24}$$

is monotone. Hence, the sum $\mathcal{R}[\varphi] = \mathcal{P} + T[\varphi]$ is a strongly monotone operator with the same monotonicity constant as $\mathcal{P}$. Since $\mathcal{P}$ is bounded and linear, it is obviously Lipschitz continuous. A straightforward computation shows that $T[\varphi]$ is boundedly Lipschitz continuous, too. Hence the sum $\mathcal{R}[\varphi]$ is also boundedly Lipschitz continuous. ∎

Remark 4.14. From our Lemma 4.13, and Corollary III.2.3 of [24], we obtain that for $\varphi \in C_{\mathbb{R}}(\Omega)$ the operator $\mathcal{R}[\varphi]^{-1} : W^{-1,2}_{\mathbb{R}}(\Omega) \longrightarrow \overset{o}{W}{}^{1,2}_{\mathbb{R}}(\Omega)$ exists, is bounded, and is Lipschitz continuous with a Lipschitz constant not bigger than $\|1/\varepsilon\|_{L^\infty(\Omega)}$.

Let us introduce the mapping $\mathcal{Q} : C_{\mathbb{R}}(\Omega) \longrightarrow W^{1,2}_{\mathbb{R}}(\Omega)$ defined by

$$\mathcal{Q}(\varphi) := \widehat{\varphi} + \mathcal{R}[\varphi]^{-1}(C - \mathcal{N}^-[\varphi] + \mathcal{N}^+[\varphi]), \tag{4.25}$$

where $\varphi \in \mathrm{dom}(\mathcal{Q}) = C_{\mathbb{R}}(\Omega)$ and $\mathcal{N}^{\pm}[\varphi]$ have to be seen as elements from $W_{\mathbb{R}}^{-1,2}(\Omega)$. In what follows we simultaneously regard the mapping $\mathcal{Q}$ also as mapping from $C_{\mathbb{R}}(\Omega)$ into itself by means of the embedding $W_{\mathbb{R}}^{1,2}(\Omega) \hookrightarrow C_{\mathbb{R}}(\Omega)$.

PROPOSITION 4.15. *Let Assumptions* 2.1, 3.1, *and* 4.9 *be satisfied. An element* $\varphi \in W_{\mathbb{R}}^{1,2}(\Omega)$ *is a solution of the dissipative hybrid model if and only if* φ *is a fixed point of the mapping* $\mathcal{Q} : C_{\mathbb{R}}(\Omega) \longrightarrow C_{\mathbb{R}}(\Omega)$.

Proof. Let us assume that $\varphi \in W_{\mathbb{R}}^{1,2}(\Delta)$ is a solution of the dissipative hybrid model. From Definition 4.12 we get

$$\mathcal{P}\zeta = C - \mathcal{U}^{-}[\varphi] + \mathcal{U}^{+}[\varphi], \tag{4.26}$$

where $\varphi = \zeta + \widehat{\varphi}$. By means of the relation (4.22) we have

$$-\mathcal{D}^{-}[\varphi] + \mathcal{D}^{+}[\varphi] = -p^{-}[\varphi]e^{\zeta} + p^{+}[\varphi]e^{-\zeta}, \tag{4.27}$$

and thus, by definition of $\mathcal{U}^{\pm}$ (see (4.10)), we get

$$\mathcal{R}[\varphi](\zeta) = C - \mathcal{N}^{-}[\varphi] + \mathcal{N}^{+}[\varphi]. \tag{4.28}$$

Therefore we obtain

$$\varphi = \widehat{\varphi} + \mathcal{R}[\varphi]^{-1}(C - \mathcal{N}^{-}[\varphi] + \mathcal{N}^{+}[\varphi]), \tag{4.29}$$

which implies $\varphi = \mathcal{Q}[\varphi]$; i.e., φ is a fixed point of $\mathcal{Q}$. The converse statement is proven in a similar manner. ∎

5. Existence.

5.1. Preliminaries. Our final aim is to show that the dissipative hybrid model introduced in the previous section always admits a solution. By Proposition 4.15 this is equivalent to showing that the nonlinear mapping $\mathcal{Q} : C_{\mathbb{R}}(\Omega) \longrightarrow C_{\mathbb{R}}(\Omega)$ admits a fixed point. This will be done by applying the Leray–Schauder fixed point theorem [25, Theorem 11.3]. To this end we consider the nonlinear equation

$$\vartheta = t\mathcal{Q}(\vartheta), \quad \vartheta \in C_{\mathbb{R}}(\Omega), \quad t \in [0,1]. \tag{5.1}$$

Let us introduce the modified carrier density operators $\mathcal{U}_t^{\pm}[\cdot] : C_{\mathbb{R}}(\Omega) \longrightarrow L^1(\Omega)$, $t \in [0,1]$,

$$\mathcal{U}_t^{\pm}[\varphi](x) := \begin{cases} \mathcal{D}^{\pm}[t\varphi](x)e^{\mp(1-t)\varphi(x)}, & x \in \Omega_c, \\ \mathcal{N}^{\pm}[t\varphi](x), & x \in \Omega_q. \end{cases} \tag{5.2}$$

We note that $\mathcal{U}^{\pm}[\varphi] = \mathcal{U}_1^{\pm}[\varphi]$, $\varphi \in C_{\mathbb{R}}(\Omega)$; cf. (4.10).

LEMMA 5.1. *Let Assumptions* 2.1, 3.1, *and* 4.9 *be satisfied. If* $\vartheta \in C_{\mathbb{R}}(\Omega)$ *satisfies* (5.1) *for* $t \in [0,1]$, *then there is an element* $\varphi \in W_{\mathbb{R}}^{1,2}(\Omega)$ *such that* $\vartheta = t\varphi$, *and that* $\zeta := \varphi - \widehat{\varphi} \in \overset{o}{W}{}_{\mathbb{R}}^{1,2}(\Omega)$ *satisfies the modified Poisson equation*

$$\mathcal{P}\zeta = C + \mathcal{U}_t^{+}[\varphi] - \mathcal{U}_t^{-}[\varphi]. \tag{5.3}$$

Proof. The proof of the lemma is essentially the same as the proof of Proposition 4.15. ∎

Having in mind an application of the Leray–Schauder fixed point theorem, one has to show that the mapping $\mathcal{Q}$ is compact, i.e., continuous and maps every bounded set into a precompact one; cf. section 11.2 of [25]. This will be shown by the following lemmata.

LEMMA 5.2. *If Assumptions* 2.1, 3.1, *and* 4.9 *are satisfied, then the mapping* $\mathcal{Q} : C_{\mathbb{R}}(\Omega) \longrightarrow C_{\mathbb{R}}(\Omega)$ *is continuous.*

Proof. Let $\varphi, \varphi_n \in C_{\mathbb{R}}(\Omega)$, $n \in \mathbb{N}$, such that $\lim_{n\to\infty} \|\varphi - \varphi_n\|_{L^\infty(\Omega)} = 0$. We set

$$\psi := C - \mathcal{N}^-[\varphi] + \mathcal{N}^+[\varphi] \in W^{-1,2}_{\mathbb{R}}(\Omega)$$

and

$$\psi_n := C - \mathcal{N}^-[\varphi_n] + \mathcal{N}^+[\varphi_n] \in W^{-1,2}_{\mathbb{R}}(\Omega), \quad n \in \mathbb{N}.$$

By Lemma 4.7 we find $\lim_{n\to\infty} \|\mathcal{N}^\pm[\varphi_n] - \mathcal{N}^\pm[\varphi]\|_{L^1(\Omega)} = 0$, which yields

$$\lim_{n\to\infty} \|\psi_n - \psi\|_{W^{-1,2}(\Omega)} = 0. \tag{5.4}$$

Let us show that

$$\lim_{n\to\infty} \|\mathcal{R}[\varphi_n]^{-1}(\psi_n) - \mathcal{R}[\varphi]^{-1}(\psi)\|_{W^{1,2}(\Omega)} = 0. \tag{5.5}$$

Obviously one has

$$\psi_n - \mathcal{R}[\varphi_n](\mathcal{R}[\varphi]^{-1}(\psi)) = \psi_n - \psi - \left\{\mathcal{R}[\varphi_n](\mathcal{R}[\varphi]^{-1}(\psi)) - \psi\right\}. \tag{5.6}$$

The sequence $\mathcal{R}[\varphi_n] : \overset{o}{W}{}^{1,2}(\Omega) \longrightarrow W^{-1,2}(\Omega)$ converges strongly to $\mathcal{R}[\varphi]$; i.e., for each $\zeta \in \overset{o}{W}{}^{1,2}(\Omega)$ one has $\mathcal{R}[\varphi_n](\zeta) \to \mathcal{R}[\varphi](\zeta)$ as $n \to \infty$. Hence

$$\lim_{n\to\infty} \|\mathcal{R}[\varphi_n](\mathcal{R}[\varphi]^{-1}(\psi)) - \psi\|_{W^{-1,2}(\Omega)} = 0. \tag{5.7}$$

From (5.4), (5.6), and (5.7) we get

$$\lim_{n\to\infty} \|\psi_n - \mathcal{R}[\varphi_n](\mathcal{R}[\varphi]^{-1}(\psi))\|_{W^{-1,2}(\Omega)} = 0. \tag{5.8}$$

Using the representation

$$\mathcal{R}[\varphi_n]^{-1}(\psi_n) - \mathcal{R}[\varphi]^{-1}(\psi) = \mathcal{R}[\varphi_n]^{-1}(\psi_n) - \mathcal{R}[\varphi_n]^{-1}(\mathcal{R}[\varphi_n](\mathcal{R}[\varphi]^{-1}(\psi)))$$

and (5.8), we obtain from Remark 4.14 the relation (5.5), which yields the continuity of $\mathcal{Q}$. ∎

LEMMA 5.3. *If Assumptions* 2.1, 3.1, *and* 4.9 *are satisfied, then the mapping* $\mathcal{Q} : C_{\mathbb{R}}(\Omega) \longrightarrow C_{\mathbb{R}}(\Omega)$ *is compact.*

Proof. By Lemma 5.2 it remains to show that $\mathcal{Q}$ maps a bounded set into a precompact set. To this end we are going to verify that the mapping $\mathcal{Q} : C_{\mathbb{R}}(\Omega) \longrightarrow W^{1,2}(\Omega)$ defined by (4.25) maps bounded sets into bounded sets. The compactness of the embedding $W^{1,2}(\Omega) \hookrightarrow C_{\mathbb{R}}(\Omega)$ then implies the asserted precompactness.

Using the definition (4.25), we get the estimate

$$\|\mathcal{Q}(\varphi)\|_{W^{1,2}(\Omega)} \le \left\{\|\widehat{\varphi}\|_{W^{1,2}(\Omega)} + \|\mathcal{R}[\varphi]^{-1}(C - \mathcal{N}^-[\varphi] + \mathcal{N}^+[\varphi])\|_{\overset{o}{W}{}^{1,2}(\Omega)}\right\}. \tag{5.9}$$

Since, by Lemma 4.13, for each $\varphi \in C_{\mathbb{R}}(\Omega)$ the operator $\mathcal{R}[\varphi]$ is strongly monotone with monotonicity constant $\frac{1}{\|1/\varepsilon\|_{L^\infty(\Omega)}}$, we obtain from Theorem 2.17 of [38] (see also [24]) the estimate

$$\begin{aligned}(5.10)\quad &\|\mathcal{R}[\varphi]^{-1}(C-\mathcal{N}^-[\varphi]+\mathcal{N}^+[\varphi])\|_{\overset{\circ}{W}{}^{1,2}(\Omega)}\\ &\qquad\le \|1/\varepsilon\|_{L^\infty(\Omega)}\|\mathcal{R}[\varphi](0)-(C-\mathcal{N}^-[\varphi]+\mathcal{N}^+[\varphi])\|_{W^{-1,2}(\Omega)}.\end{aligned}$$

Thus we get by (4.19)

$$\mathcal{R}[\varphi](0)=p^-[\varphi]-p^+[\varphi].$$

Hence

$$\begin{aligned}&\|\mathcal{R}[\varphi]^{-1}(C-\mathcal{N}^-[\varphi]+\mathcal{N}^+[\varphi])\|_{\overset{\circ}{W}{}^{1,2}(\Omega)}\\ &\qquad\le \|1/\varepsilon\|_{L^\infty(\Omega)}\left\|\{p^-[\varphi]-p^+[\varphi]\}-(C-\mathcal{N}^-[\varphi]+\mathcal{N}^+[\varphi])\right\|_{W^{-1,2}(\Omega)},\end{aligned}$$

which yields the estimate

$$\begin{aligned}(5.11)\quad &\|\mathcal{R}[\varphi]^{-1}(C-\mathcal{N}^-[\varphi]+\mathcal{N}^+[\varphi])\|_{\overset{\circ}{W}{}^{1,2}(\Omega)}\\ &\qquad\le \beta\left(1+\sum_{s=\pm}\left\{\|p^s[\varphi]\|_{L^1(\Omega)}+\|\mathcal{N}^s[\varphi]\|_{L^1(\Omega_q)}\right\}\right),\end{aligned}$$

where β is some positive constant depending only on the doping profile C, the permittivity function ε, and the norm of the embedding $L^1_{\mathbb{R}}(\Omega)\hookrightarrow W^{-1,2}_{\mathbb{R}}(\Omega)$.

Using the definitions (2.7), (2.8), as well as (4.20) and (4.21), we find the representations

$$p^\pm[\varphi](x)=\begin{cases}N_0^\pm e^{\mp(\widehat{\varphi}(x)\pm V_h^\pm(x))}e^{\pm\phi^\pm[\varphi](x)}, & x\in\Omega_c,\\ 0, & x\in\Omega_q,\end{cases}$$

and taking into account Lemma 4.3, we obtain the estimate

$$\|p^\pm[\varphi]\|_{L^1(\Omega_c)}\le\Gamma_c^\pm,$$

with

$$\Gamma_c^\pm:=N_0^\pm e^{\eta^\pm}\int_{\Omega_c}dx\; e^{-V_h^\pm\mp\widehat{\varphi}(x)}.$$

Hence,

$$(5.12)\qquad \|p^-[\varphi]\|_{L^1(\Omega_c)}+\|p^+[\varphi]\|_{L^1(\Omega_c)}\le\Gamma_c^-+\Gamma_c^+=:\Gamma_c.$$

By Lemma 4.4 we find the estimate

$$\begin{aligned}(5.13)\quad &\|\mathcal{N}^-[\varphi]\|_{L^1(\Omega_q)}+\|\mathcal{N}^+[\varphi]\|_{L^1(\Omega_q)}\\ &\le C^-(V^-_{max}[\varphi])\left(\gamma_1^-+\gamma_2^-\|\varphi_+\|_{L^\infty(\Omega_q)}\right)+C^+(V^+_{max}[\varphi])\left(\gamma_1^++\gamma_2^+\|\varphi_-\|_{L^\infty(\Omega_q)}\right),\end{aligned}$$

where $V^{\pm}_{max}[\varphi]$ are given by (1.10). If $\varphi \in \mathcal{B}_{C_{\mathbb{R}}(\Omega)}(r) := \{\varphi \in C_{\mathbb{R}}(\Omega) : \|\varphi\|_{L^\infty(\Omega)} \le r\}$, then $V^{\pm}_{max}[\varphi] \ge -r - c_h$, where

$$c_h := \max\{\|V_h^+\|_{L^\infty(\Omega)}, \|V_h^-\|_{L^\infty(\Omega)}\}. \tag{5.14}$$

Since the functions $C^{\pm}(\cdot)$ are nonincreasing, we find $C^{\pm}(V^{\pm}_{max}[\varphi]) \le C^{\pm}(-r - c_h)$, which yields

$$\|\mathcal{N}^-[\varphi]\|_{L^1(\Omega_q)} + \|\mathcal{N}^+[\varphi]\|_{L^1(\Omega_q)} \le \Gamma_q(r) \qquad \text{for all } \varphi \in \mathcal{B}_{C_{\mathbb{R}}(\Omega)}(r),\ r > 0, \tag{5.15}$$

where the constant $\Gamma_q(r)$ is given by

$$\Gamma_q(r) := C^-(-r - c_h)\big(\gamma_1^- + \gamma_2^- \sqrt{r}\big) + C^+(-r - c_h)\big(\gamma_1^+ + \gamma_2^+ \sqrt{r}\big).$$

Finally, one gets by (5.9)–(5.15) the estimate

$$\|\mathcal{Q}(\varphi)\|_{W^{1,2}(\Omega)} \le r_0,$$

with

$$r_0 := \|\widehat{\varphi}\|_{\overset{o}{W}{}^{1,2}(\Omega)} + \beta\Big(1 + \Gamma_c + \Gamma_q(r)\Big).$$

Hence $\mathcal{Q}(\mathcal{B}_{C_{\mathbb{R}}(\Omega)}(r)) \subseteq \mathcal{B}_{W^{1,2}(\Omega)}(r_0)$; i.e., the mapping $\mathcal{Q}$ maps bounded sets into bounded sets of $W^{1,2}(\Omega)$. Since the embedding $W^{1,2}(\Omega) \hookrightarrow C_{\mathbb{R}}(\Omega)$ is compact, we deduce the precompactness of the set $\mathcal{Q}(\mathcal{B}_{C_{\mathbb{R}}(\Omega)}(r))$, which completes the proof. $\square$

5.2. A priori estimates. Our next aim is to investigate solutions of (5.3) and to verify certain a priori estimates for them.

LEMMA 5.4. *Let Assumptions* 2.1, 3.1, *and* 4.9 *be satisfied. If* $\varphi \in W^{1,2}_{\mathbb{R}}(\Omega)$, *and if* $\zeta := \varphi - \widehat{\varphi} \in \overset{o}{W}{}^{1,2}_{\mathbb{R}}$ *satisfies* (5.3) *for some* $t \in [0, 1]$, *then there exists a constant* M *independent of* φ *and* t *such that*

$$\varphi(x) \le M \left\{1 + C^+(t\varphi_{max} - c_h)\sqrt{1 + \|\varphi_-\|_{L^\infty(\Omega_q)}}\right\}, \tag{5.16}$$

$$-\varphi(x) \le M \left\{1 + C^-(-t\varphi_{min} - c_h)\sqrt{1 + \|\varphi_+\|_{L^\infty(\Omega_q)}}\right\} \tag{5.17}$$

for all $x \in \Omega$, *where*

$$\varphi_{max} := \max\{\varphi(a), \varphi(b)\} \quad \text{and} \quad \varphi_{min} := \min\{\varphi(a), \varphi(b)\}, \tag{5.18}$$

$\varphi_\pm$ *denotes the positive and negative parts of* φ, *and* c_h *is given by* (5.14).

Proof. We set $d := \mathcal{P}^{-1}C \in \overset{o}{W}{}^{1,2}_{\mathbb{R}}(\Omega)$. Since $\zeta := \varphi - \widehat{\varphi}$ is a solution of (5.3), one has

$$\mathcal{P}(\zeta - d) = \mathcal{U}_t^+[\varphi] - \mathcal{U}_t^-[\varphi].$$

Since the right-hand side of the above equation is in $L^1(\Omega)$, one gets that $g := \zeta - d \in \overset{o}{W}{}^{1,2}_{\mathbb{R}}(\Omega)$, $\varepsilon g' \in W^{1,1}_{\mathbb{R}}(\Omega)$, and

$$-\frac{d}{dx}\varepsilon(x)\frac{d}{dx}g(x) = \mathcal{U}_t^+[\varphi](x) - \mathcal{U}_t^-[\varphi](x)$$

for a.e. $x \in \Omega$. We remark that

$$\mathcal{P}(\zeta - d) = -\frac{d}{dx}\varepsilon(x)\frac{d}{dx}g.$$

Let $\Omega_0 = (x_0, x_1) \subseteq \Omega$ be given such that $\zeta(x_0) = \zeta(x_1) = 0$ and $\zeta(x) > 0$ for $x \in \Omega_0$. We set

$$g^+(x) = \int_{x_0}^{x} dy\, \frac{1}{\varepsilon(y)} \int_{x_0}^{y} dz\, \mathcal{U}_t^+[\varphi](z), \quad x \in \Omega_0.$$

Obviously, one has

$$\frac{d}{dx}\varepsilon(x)\frac{d}{dx}h(x) = \mathcal{U}_t^-[\varphi](x)$$

for a.e. $x \in \Omega_0$, where $h(x) := g(x) + g^+(x) = \zeta(x) - d(x) + g^+(x)$, $x \in \Omega_0$. Using the maximum principle [25, Theorem 8.1] we obtain

$$\sup_{x \in \Omega_0} h(x) \leq \max\{h(x_0), h(x_1)\},$$

which yields

$$\zeta(x) \leq d(x) + \max\{-d(x_0), -d(x_1) + g^+(x_1)\}, \quad x \in \Omega_0.$$

Thus

$$\zeta(x) \leq 2\|d\|_{L^\infty(\Omega)} + g^+(x_1), \quad x \in \Omega_0. \tag{5.19}$$

For $x \in \Omega_c \cap \Omega_0$ there is, by (5.2),

$$\mathcal{U}_t^+[\varphi](x) = N_0^+ e^{\phi^+[t\varphi](x)} e^{-\widehat{\varphi}(x) - V_h^+(x)} e^{-\zeta(x)}.$$

By Lemma 4.3 and $\zeta(x) \geq 0$, $x \in \Omega_0$, we get

$$\mathcal{U}_t^+[\varphi](x) \leq N_0^+ e^{\eta^+} e^{-\widehat{\varphi}(x) - V_h^+(x)}, \quad x \in \Omega_c \cap \Omega_0,$$

which yields the estimate

$$\int_{\Omega_0 \cap \Omega_c} dz\, \mathcal{U}_t^+[\varphi](z) \leq N_0^+ e^{\eta^+} \int_{\Omega_0 \cap \Omega_c} dz\, e^{-\widehat{\varphi}(z) - V_h^+(z)}.$$

Hence, we obtain the estimate

$$\begin{aligned} g^+(x_1) &\leq \|1/\varepsilon\|_{L^1(\Omega_0)} \int_{\Omega_0} dz\, \mathcal{U}_t^+[\varphi](z) \\ &\leq \|1/\varepsilon\|_{L^1(\Omega_0)} \left(\int_{\Omega_0 \cap \Omega_q} dz\, \mathcal{U}_t^+[\varphi](z) + e^{\eta^+} N_0^+ \int_{\Omega_0 \cap \Omega_c} dz\, e^{-\widehat{\varphi}(z) - V_h^+(z)} \right). \end{aligned}$$

Inserting this estimate into (5.19), one finds positive constants M_1^+, M_2^+ independent of φ and t such that the inequality

$$\zeta(x) \leq M_1^+ + M_2^+ \int_{\Omega_q} dz\, \mathcal{U}_t^+[\varphi](z) \tag{5.20}$$

holds for $x \in \Omega_+ := \{x \in \Omega : \zeta(x) > 0\}$.

In the same manner we find positive constants M_1^-, M_2^-, which are independent of φ and t, such that

$$-\zeta(x) \le M_1^- + M_2^- \int_{\Omega_q} dz\, \mathcal{U}_t^-[\varphi](z) \tag{5.21}$$

for $x \in \Omega_- := \{x \in \Omega : \zeta(x) < 0\}$.

Since

$$\int_{\Omega_q} dz\, \mathcal{U}_t^\pm[\varphi](z) = \|\mathcal{N}^\pm[t\varphi]\|_{L^1(\Omega_q)},$$

we obtain from Lemma 4.4 and (5.20), (5.21) the existence of positive constants M^+, M^-, which do not depend on φ and t, such that

$$\zeta(x) \le M^+ \left(1 + C^+(V_{max}^+[t\varphi])\sqrt{1 + \|\varphi_-\|_{L^\infty(\Omega_q)}}\right) \tag{5.22}$$

for all $x \in \Omega_+$ and

$$-\zeta(x) \le M^- \left(1 + C^-(V_{max}^-[t\varphi])\sqrt{1 + \|\varphi_+\|_{L^\infty(\Omega_q)}}\right) \tag{5.23}$$

for all $x \in \Omega_-$.

Since $\zeta(x) \le 0$ for $x \in \Omega \setminus \Omega_+$ and $-\zeta(x) \le 0$ for $x \in \Omega \setminus \Omega_-$, we obtain from (5.22) and (5.23) that in fact these relations are valid for each $x \in \Omega$.

Taking into account the estimates $V_{max}^+[t\varphi] \ge t\varphi_{max} - c_h$, $V_{max}^-[t\varphi] \ge -t\varphi_{min} - c_h$ (cf. (5.14) and (5.18)), we get—since $C^\pm(\cdot)$ is nonincreasing—the estimates

$$C^+(V^+[t\varphi]) \le C^\pm(t\varphi_{max} - c_h) \quad \text{and} \quad C^-(V^-[t\varphi]) \le C^\pm(-t\varphi_{min} - c_h).$$

Finally, using the estimates $\pm\varphi(x) \le \pm\zeta(x) + \|\widehat{\varphi}\|_{L^\infty(\Omega)}$, $x \in \Omega$, and $t \in [0,1]$, we immediately obtain from (5.22) and (5.23) the estimates (5.16), (5.17) for some constant M. ∎

COROLLARY 5.5. *Let Assumptions* 2.1, 3.1, *and* 4.9 *be satisfied. If* $\varphi \in W_{\mathbb{R}}^{1,2}(\Omega)$ *and if* $\zeta := \varphi - \widehat{\varphi} \in \overset{o}{W}{}_{\mathbb{R}}^{1,2}(\Omega)$ *satisfies* (5.3) *for some* $t \in [0,1]$, *then*

$$\|\varphi_+\|_{L^\infty(\Omega_q)} \le M \left(1 + C^+(t\varphi_{max} - c_h)\sqrt{1 + \|\varphi_-\|_{L^\infty(\Omega_q)}}\right) \tag{5.24}$$

and

$$\|\varphi_-\|_{L^\infty(\Omega_q)} \le M \left(1 + C^-(-t\varphi_{max} - c_h)\sqrt{\|1 + \|\varphi_+\|_{L^\infty(\Omega_q)}}\right). \tag{5.25}$$

Proof. Since $\varphi_{min} \le \varphi_{max}$, one has $-t\varphi_{max} \le -t\varphi_{min}$, $t \in [0,1]$. Taking into account the fact that the functions $C^\pm(\cdot)$ are nonincreasing, we obtain from Lemma 5.4 the estimates (5.24) and (5.25). ∎

5.3. Main theorem. Using Corollary 5.5, we aim to show that all solutions of (5.3) are included in a uniform ball; that is, there is an $r_0 > 0$ such that

$$\mathfrak{L} := \left\{\vartheta \in C_{\mathbb{R}}(\Omega) : \vartheta = t\mathcal{Q}_\infty(\vartheta), \quad t \in [0,1]\right\} \subseteq \mathcal{B}_{C_{\mathbb{R}}(\Omega)}(r_0). \tag{5.26}$$

For this last step we need the following additional balance condition.

ASSUMPTION 5.6 (balance condition). *Let the distribution functions $f^{\pm}$ satisfy the assumption* (Q.5). *We say that the distribution functions $f^{\pm}$ obey the balance condition if*

$$G(x,y) := \sup_{s \geq 0} \left\{ D^{+}(s+x) D^{-}(-s+y)^{1/2} + D^{+}(-s+x)^{1/2} D^{-}(s+y) \right\} < \infty$$

for $x, y \in \mathbb{R}$, where $D^{\pm}(\cdot)$ are defined by (3.1).

Remark 5.7. The Boltzmann and the Fermi–Dirac distributions satisfy the balance condition; see Remark 3.2.

Indeed, let $f^{\pm}(\cdot)$ be the Boltzmann distribution function, i.e., $f^{\pm}(\lambda) = e^{-\lambda}$, $\lambda \in \mathbb{R}$. Using the definition (3.1), we get that $D^{\pm}(\lambda) = e^{-\lambda}\sqrt{1+\lambda^2}$, $\lambda \in \mathbb{R}$. A straightforward computation shows that

$$G(x,y) = \sup_{s \geq 0} \left\{ e^{-\frac{s}{2} - x - y} g(x,y,s) \right\}$$

for $x, y \in \mathbb{R}$, where

$$g(x,y,s) := \left(\sqrt{1+(s+x)^2}\sqrt{1+(s-y)^2} + \sqrt{1+(s-x)^2}\sqrt{1+(s+y)^2} \right).$$

Obviously, one has $G(x,y) < \infty$ for $x, y \in \mathbb{R}$. Hence, the balance condition holds.

The verification of the balance condition for Fermi–Dirac distribution functions is easier than for Boltzmann distributions since their growth at minus infinity is linear and not exponential, as for Boltzmann distributions.

THEOREM 5.8. *Let Assumptions* 2.1, 3.1, *and* 4.9 *be satisfied. If the balance condition, i.e., Assumption* 5.6, *is valid, then for any choice of the approximation parameters $\mathfrak{A} = \{\delta_0^{\pm}, \delta^{\pm}\}$, $0 < \delta_0^{\pm} < \delta^{\pm} \leq \infty$,*

(i) *a solution $\varphi \in W^{1,2}_{\mathbb{R}}(\Omega)$ of dissipative hybrid model in the sense of Definition* 4.12 *exists, and*

(ii) *there is an $r_0 \in (0,\infty)$ independent of the approximation parameters $\{\delta_0^{\pm}, \delta^{\pm}\}$ such that any solution $\varphi \in W^{1,2}_{\mathbb{R}}(\Omega)$ of the dissipative hybrid model obeys $\|\varphi\|_{L^\infty(\Omega)} \leq r_0$.*

The corresponding current densities $J^{\pm}[\varphi]$ of a solution $\varphi \in W^{1,2}_{\mathbb{R}}(\Omega)$ of the dissipative hybrid model are different from zero if and only if the boundary values of the quasi-Fermi potentials are different, i.e., $\phi^{\pm}_{a_0} \neq \phi^{\pm}_{b_0}$, provided the distribution functions $f^{\pm}(\cdot)$ are strictly decreasing.

Proof. To prove (i) it is enough to show that $\mathcal{Q} : C_{\mathbb{R}}(\Omega) \longrightarrow C_{\mathbb{R}}(\Omega)$ has a fixed point; see Proposition 4.15. To prove this we use the Leray–Schauder fixed point theorem. Since by Lemmas 5.2 and 5.3 the mapping $\mathcal{Q}$ is continuous and compact, it remains to show that the set $\mathfrak{L}$ defined by (5.26) is uniformly bounded in $t \in [0,1]$. If $\varphi \in \mathfrak{L}$, then by Lemma 5.1 it satisfies (5.3). If $\varphi \in \mathfrak{L}$ satisfies (5.3), then the estimates of Corollary 5.5 hold.

Let us assume that $\varphi_{max} \geq 0$. Using the estimate $1 + \|\varphi_{\pm}\|^{1/2}_{L^\infty(\Omega_q)} \leq \sqrt{2}\left(1 + \|\varphi_{\pm}\|_{L^\infty(\Omega_q)}\right)^{1/2}$, we obtain from Corollary 5.5 the estimates

$$1 + \|\varphi_{+}\|_{L^\infty(\Omega_q)} \leq r_1 \left(1 + C^{+}\sqrt{1 + \|\varphi_{-}\|_{L^\infty(\Omega_q)}}\right), \tag{5.27}$$

$$1 + \|\varphi_{-}\|_{L^\infty(\Omega_q)} \leq r_1 \left(1 + C^{-}\sqrt{1 + \|\varphi_{+}\|_{L^\infty(\Omega_q)}}\right), \tag{5.28}$$

where r_1 is a positive constant independent of $\varphi \in \mathfrak{L}$. Moreover, we used abbreviations $C^{\pm} := C^{\pm}(\pm t\varphi_{max} - c_h)$. Inserting (5.28) into (5.27), we find a positive constant r_2, which does not depend on φ and t, such that

$$\|\varphi_+\|_{L^\infty(\Omega_q)} \leq r_2 \left(1 + C^+\sqrt{C^-}\right)^{4/3},$$

where we used the fact that $C^+ \leq C^+(-c_h)$, since $\varphi_{max} \geq 0$.

Further, by definition (4.14) we get

$$\begin{aligned} C^+\sqrt{C^-} &= C^+(t\varphi_{max} - c_h)\sqrt{C^-(-t\varphi_{max} - c_h)} \\ &= (1+\eta^+)\sqrt{1+\eta^-}D^+(t\varphi_{max} - c_h - \eta^+)D^-(-t\varphi_{max} - c_h - \eta^-)^{1/2}. \end{aligned}$$

Taking into account the balance condition (Assumption 5.6) and $\varphi_{max} \geq 0$, we get

$$C^+\sqrt{C^-} \leq (1+\eta^+)\sqrt{1+\eta^-}G(-c_h - \eta^+, -c_h - \eta^-),$$

which shows that there is a positive constant r_3 independent of $\varphi \in \mathfrak{L}$ and $t \in [0,1]$ such that

$$\|\varphi_+\|_{L^\infty(\Omega_q)} \leq r_3.$$

Since $0 \leq \varphi_{max} \leq \|\varphi_+\|_{L^\infty(\Omega_q)}$, we have $-t\varphi_{max} \geq -t\|\varphi_+\|_{L^\infty(\Omega_q)} \geq -\|\varphi_+\|_{L^\infty(\Omega_q)} \geq -r_3$, $t \in [0,1]$. By the monotonicity of $C^-(\cdot)$ we obtain $C^-(-t\varphi_{max} - c_h) \leq C^-(-r_3)$. Using Corollary 5.5, we finally get the existence of a positive constant r_4, which does not depend on $\varphi \in \mathfrak{L}$ and t, such that

$$\|\varphi_-\|_{L^\infty(\Omega_q)} \leq r_4.$$

Hence $\|\varphi\|_{L^\infty(\Omega_a)} \leq r_+ := \max\{r_3, r_4\}$, which shows that the $\mathfrak{L}_q := \{\varphi \restriction \Omega_q : \varphi \in \mathfrak{L}\} \subseteq \mathcal{B}_{C_{\mathbb{R}}(\Omega_q)}(r_+)$, provided $\varphi_{max} \geq 0$.

In a similar manner one shows that there exists a positive constant r_- independent of $t \in [0,1]$ such that $\mathfrak{L}_q := \{\varphi \restriction \Omega_q : \varphi \in \mathfrak{L}\} \subseteq \mathcal{B}_{C_{\mathbb{R}}(\Omega_q)}(r_-)$, provided $\varphi_{max} \leq 0$.

Thus, we get that $\mathfrak{L}_q \subseteq \mathcal{B}_{C_{\mathbb{R}}(\Omega_q)}(r_q)$, $r_q := \max\{r_+, r_-\}$. In particular, we have $-r_q \leq \varphi_{min} \leq \varphi_{max} \leq r_q$. Using Lemma 5.4, we find

$$\varphi(x) \leq M\left(1 + C^+(-r_q - c_h)\left(1 + r_q^{1/2}\right)\right) =: r_5$$

and

$$-\varphi(x) \leq M\left(1 + C^-(-r_q - c_h)\left(1 + r_q^{1/2}\right)\right) =: r_6$$

for all $x \in \Omega$. Setting $r_0 = \max\{r_5, r_6\}$, we conclude that $\|\varphi\|_{L^\infty(\Omega)} \leq r_0$. Hence, $\mathfrak{L} \subseteq B_{C_{\mathbb{R}}(\Omega)}(r_0)$. Since r_0 depends only on quantities entering Assumptions 2.1, 3.1, 4.9, and 5.6, but is independent of $t \in [0,1]$, the uniform boundedness of the set $\mathfrak{L}$ is verified. Hence the Leray–Schauder fixed point theorem implies the existence of a solution of a dissipative hybrid model. Assertion (ii) is verified.

To prove the last assertion, we note that in accordance with (3.7) the current density for holes $J^+[\varphi]$ satisfies the equation

$$J^+[\varphi] = \frac{1}{2\pi}\int_{\Lambda^+[\varphi]} d\lambda\, t^+[\varphi](\lambda)\left\{f^+(\lambda - \phi^+[\varphi](a)) - f^+(\lambda - \phi^+[\varphi](b))\right\},$$

where $t^+[\varphi](\lambda)$ is the transmission coefficient. Notice that $t^+[\varphi](\lambda) \geq 0$ for a.e. $\lambda \in \mathbb{R}$. If $J^+[\varphi] \geq 0$, then $-\phi^+[\varphi](x)$, $x \in \Omega_q$, is nondecreasing such that $-\phi^+[\varphi](a) \leq -\phi^+[\varphi](b)$. Hence

$$f^+(\lambda - \phi^+[\varphi](a)) - f^+(\lambda - \phi^+[\varphi](b)) \geq 0.$$

If $J^+[\varphi] = 0$, then

$$f^+(\lambda - \phi^+[\varphi](a)) - f^+(\lambda - \phi^+[\varphi](b)) = 0$$

for a.e. $\lambda \in \Lambda^+[\varphi]$. Since the distribution functions $f^\pm(\cdot)$ are strictly decreasing, one gets $\phi^+[\varphi](a) = \phi^+[\varphi](b)$. If $J^+[\varphi] = 0$, then $\phi^+[\varphi](a_0) = \phi^+[\varphi](a)$ and $\phi^+[\varphi](b) = \phi^+[\varphi](b_0)$, which yields $\phi^+_{a_0} = \phi^+[\varphi](a_0) = \phi^+[\varphi](b_0) = \phi^+_{b_0}$. We proceed similarly if $J^+[\varphi] \leq 0$. Conversely, if $\phi^+_{a_0} = \phi^+_{b_0}$ and $J^+[\varphi] \geq 0$, then $-\phi^+_{a_0} = -\phi^+[\varphi](a_0) \leq -\phi^+[\varphi](a) \leq -\phi^+_b[\varphi](b) \leq -\phi^+[\varphi](b_0) = -\phi^+_{b_0} = -\phi^+_{a_0}$, which yields $J^+[\varphi] = 0$. We act similarly if $J^+[\varphi] \leq 0$. The proof for electrons is similar. $\square$

6. Comments. We analyzed a dissipative hybrid model, which consists of a coupled drift-diffusion model and dissipative Schrödinger operators. The electrostatic potential is determined by a Poisson equation on the whole device domain. We showed that the coupled system is well posed and always admits a solution, provided Assumptions 2.1, 3.1, 4.9, and 5.6 are satisfied; see Theorem 5.8. The proof is based on a Leary–Schauder fixed point argument, which does not give uniqueness of solution. In fact, uniqueness is in general not expected.

Let us comment on the results as follows:

1. The dissipative Schrödinger model considered in section 3 is to some extent artificial since the physical interpretation of the generalized eigenfunctions $\psi^\pm_a$, $\psi^\pm_b$ of the minimal self-adjoint dilations $K^\pm$ is not a priori clear. However, as has been shown in [4], for fixed energy there are two channels which fit into the picture of the more commonly used quantum transmitting Schrödinger equation (B.1); see (B.8) and (B.9). Using this fact, one can consider the dissipative Schrödinger model as an approximation by means of a proper choice of the distribution functions for the dissipative system. The approximation we consider here is outlined in section B.2 and depends on the approximation parameters $\mathfrak{A} = \{\delta_0, \delta\}$; see (B.10) and (B.11). We note that other approximations can be chosen, which then leads to a different dissipative hybrid model.
   Moreover, the dissipative Schrödinger model allows us to use the Lax–Philip scattering techniques to prove the continuity of the carrier and current density operator; see section A.2. The Lax–Phillips scattering theory is simpler than that of the Schrödinger operators corresponding to the Schrödinger operator (B.1); see also [4].
   In the dissipative approximation presented in section B.2, we considered only wave functions with energy larger than V_{max} since they are the current carrying states. The inclusion of the states with energies smaller than V_{max} is so far an open problem.
2. The drift-diffusion model we consider here is based on Boltzmann statistics (see (1.1)–(1.3)), which leads to explicit expressions for the electrochemical potentials $\phi^\pm$; see (2.7) and (2.8). The case of Fermi–Dirac statistics may be considered in the same fashion. However, one loses the explicit expressions.

3. Here we treated the bipolar case, where electrons and holes interact via the Poisson equation only. To prove the existence of solutions, the statistical distribution functions $f^{\pm}$ have to satisfy the balance condition (Assumption 5.6), which is satisfied for the common distribution functions; see Remark 5.7. The unipolar case, where only one particle species is considered, is even simpler. In this case the balance condition is redundant, and the existence of a solution is easily obtained by the estimate (3.10) of the density and applying the maximum principle to Poisson's equation.
4. Theorem 5.8 shows that the solutions of a dissipative hybrid model are contained in a ball with radius r_0. Following the proof of the theorem, one can derive this radius explicitly.
5. In Theorem 5.8 we showed that the current densities of the dissipative hybrid model are equal to zero if and only if $\phi^{\pm}_{a_0} = \phi^{\pm}_{b_0}$, i.e., in thermal equilibrium. In this case the electrochemical potentials $\phi^{\pm}$ are constant, and thus the statistical operators $\varrho^{\pm}$ are given by functions of the corresponding self-adjoint dilation $K^{\pm}$, i.e., $\varrho^{\pm} = \mathfrak{f}^{\pm}(K^{\pm})$ with $\mathfrak{f}^{\pm}(\lambda) = f^{\pm}(\lambda \mp \phi^{\pm})\chi_{\Lambda^{\pm}}(\lambda)$, where $\phi^{\pm}$ are the constant electrochemical potentials. One may expect that the solution of the dissipative hybrid model in thermal equilibrium is unique. However, this is so far an open problem.

Appendix A. Dissipative Schrödinger systems. Let us give a short introduction to the theory of dissipative Schrödinger systems; for details see [3, 5, 35, 33]. We start with some facts on Schrödinger-type operators.

A.1. Schrödinger-type operators. Let the conditions $0 < m \in L^{\infty}_{\mathbb{R}}(\Omega_q)$, $\frac{1}{m} \in L^{\infty}_{\mathbb{R}}(\Omega_q)$, be satisfied, where $\Omega_q = (a,b)$. Moreover, let $V \in L^{\infty}_{\mathbb{R}}(\Omega_q)$ and $\varkappa_a, \varkappa_b \in \mathbb{C}_+$, where $\mathbb{C}_+ := \{z \in \mathbb{C} : \mathrm{Im}(z) > 0\}$, be given. The Schrödinger-type operator H is defined by

$$(Hg)(x) := -\frac{1}{2}\frac{d}{dx}\frac{1}{m}\frac{d}{dx}g(x) + V(x)g(x), \quad x \in \Omega_q, \quad g \in \mathrm{dom}(H), \tag{A.1}$$

where its domain is given by

$$\mathrm{dom}(H) := \left\{ g \in W^{1,2}(\Omega_q) : \begin{array}{c} \frac{1}{m}g' \in W^{1,2}(\Omega_q), \\ \frac{1}{2m(a)}g'(a) = -\varkappa_a g(a), \\ \frac{1}{2m(b)}g'(b) = \varkappa_b g(b) \end{array} \right\}. \tag{A.2}$$

The operator H is maximal dissipative and completely non–self-adjoint on the Hilbert space $L^2(\Omega_q)$; that is, the operator does not possess self-adjoint parts. Its spectrum consists only of discrete eigenvalues in the lower half-plane [34].

In the following we are going to prove some continuity results for the operator H with respect to the potential V and the boundary coefficients $\varkappa_a$, $\varkappa_b$. To this end we introduce

$$\mathcal{T} := \mathbb{C}_+ \times \mathbb{C}_+ \times L^{\infty}(\Omega_q),$$

and write—if needed—$H[\tau]$ for $\tau = (\varkappa_a, \varkappa_b, V) \in \mathcal{T}$ to indicate the dependence of the maximal dissipative operator on the potential V and the boundary coefficients $\varkappa_a$, $\varkappa_b$. Moreover, for $\tau, \tau_n \in \mathcal{T}$, $n \in \mathbb{N}$, we write $\lim_{n\to\infty} \tau_n = \tau$ if

$$\lim_{n\to\infty} \left(|\varkappa_{a,n} - \varkappa_a| + |\varkappa_{b,n} - \varkappa_b| + \|V_n - V\|_{L^{\infty}(\Omega)} \right) = 0. \tag{A.3}$$

Remark A.1. Let the electrostatic potential $\varphi \in C_{\mathbb{R}}(\Omega)$ be given and assume that the band-edge offset potentials $V_h^{\pm}$ satisfy Assumption 3.1 (Q.4). Then the triples $\tau^{\pm} = (\varkappa_a^{\pm}, \varkappa_b^{\pm}, V^{\pm})$, where $\varkappa_a^{\pm}$, $\varkappa_b^{\pm}$ are given by (1.8) and $V^{\pm}$ by (1.4), are well defined, and there is $\tau^{\pm} \in \mathcal{T}$. Thus the operators $H^{\pm}$ defined by (3.3), (3.4) are of the form (A.1), (A.2). Moreover, $\varphi, \varphi_n \in C_{\mathbb{R}}(\Omega)$, $n \in \mathbb{N}$, with $\lim_{n\to\infty} \|\varphi_n - \varphi\|_{L^\infty(\Omega)} = 0$ implies $\lim_{n\to\infty} \tau_n^{\pm} = \tau^{\pm}$, where

$$\tau_n^{\pm} := (\varkappa_a^{\pm}[\varphi_n], \varkappa_b^{\pm}[\varphi_n], V^{\pm}[\varphi_n]) \quad \text{and} \quad \tau^{\pm} := (\varkappa_a^{\pm}[\varphi], \varkappa_b^{\pm}[\varphi], V^{\pm}[\varphi]),$$

where $\varkappa_a^{\pm}[\varphi]$, $\varkappa_b^{\pm}[\varphi]$, $V^{\pm}[\varphi]$ indicates the dependence of the coupling constants $\varkappa_a^{\pm}$, $\varkappa_b^{\pm}$ and the potential $V^{\pm}$ on the electrostatic potential φ; cf. (1.8) and (1.4).

A.2. Dilation and Lax–Phillips scattering. The constants $\varkappa_a, \varkappa_b \in \mathbb{C}_+$ can be written as

$$\varkappa_a = q_a + i\frac{\alpha_a^2}{2} \quad \text{and} \quad \varkappa_b = q_b + i\frac{\alpha_b^2}{2}, \tag{A.4}$$

where $\alpha_a, \alpha_b > 0$.

Since the operator H is maximal dissipative, it admits a minimal self-adjoint dilation K on some dilation space $\mathfrak{K}$; see [21]. We choose the dilation space $\mathfrak{K}$,

$$\mathfrak{K} := L^2(\mathbb{R}_-, \mathbb{C}^2) \oplus L^2(\Omega_q) \oplus L^2(\mathbb{R}_+, \mathbb{C}^2). \tag{A.5}$$

To describe the minimal dilation K in $\mathfrak{K}$ we set

$$\vec{g} := g_- \oplus g \oplus g_+, \tag{A.6}$$

where $g \in L^2(\Omega_q)$, and where

$$g_-(x) := \begin{pmatrix} g_-^b(x) \\ g_-^a(x) \end{pmatrix} \in L^2(\mathbb{R}_-, \mathbb{C}^2) \quad \text{and} \quad g_+(x) := \begin{pmatrix} g_+^b(x) \\ g_+^a(x) \end{pmatrix} \in L^2(\mathbb{R}_+, \mathbb{C}^2) \tag{A.7}$$

for $x \in \mathbb{R}_-$ and $x \in \mathbb{R}_+$, respectively.

THEOREM A.2. *Let $(\varkappa_a, \varkappa_b, V) \in \mathcal{T}$ be given. Then the operator K defined by*

$$\mathrm{dom}(K) := \left\{ \vec{g} \in \mathcal{K} : \begin{array}{c} g_\pm \in W^{1,2}(\mathbb{R}_\pm, \mathbb{C}^2),\ g, \frac{1}{m}g' \in W^{1,2}(\Omega_q), \\ \frac{1}{2m(b)}g'(b) - q_b g(b) = \alpha_b \frac{g_-^b(0) + g_+^b(0)}{2}, \\ i\alpha_b g(b) = g_+^b(0) - g_-^b(0), \\ \frac{1}{2m(a)}g'(a) + q_a g(a) = \alpha_a \frac{g_-^a(0) + g_+^a(0)}{2}, \\ i\alpha_a g(a) = g_-^a(0) - g_+^a(0) \end{array} \right\} \tag{A.8}$$

and

$$K\vec{g} := -i\frac{d}{dx}g_- \oplus \left(-\frac{1}{2}\frac{d}{dx}\frac{1}{m}\frac{d}{dx} + V \right) g \oplus -i\frac{d}{dx}g_+, \qquad \vec{g} \in \mathrm{dom}(K), \tag{A.9}$$

is self-adjoint.

Proof. The proof is given in [35, Theorem 4.1]. □

The operator K is a minimal self-adjoint dilation of H, i.e.,

$$(H - z)^{-1}\psi = P(K - z)^{-1}\psi \qquad \text{for all } \psi \in L^2(\Omega_q) \text{ and } z \in \mathbb{C}_+, \tag{A.10}$$

and

$$\mathfrak{K} = \operatorname*{clospan}_{z\in\mathbb{C}\setminus\mathbb{R}} \left\{(K-z)^{-1}\psi,\ \psi \in L^2(\Omega_q)\right\}, \tag{A.11}$$

where P is the orthogonal projection from the dilation space $\mathfrak{K}$ onto the subspace $L^2(\Omega_q)$.

We introduce the unclosed operator $\alpha : L^2(\Omega_q) \to \mathbb{C}^2$,

$$\alpha f = \begin{pmatrix} \alpha_b f(b) \\ -\alpha_a f(a) \end{pmatrix}, \qquad f \in \operatorname{dom}(\alpha) = W^{1,2}(\Omega_q), \tag{A.12}$$

and the boundary operators $T : \operatorname{res}(H) \longrightarrow \mathcal{B}(L^2(\Omega_q), \mathbb{C}^2)$, $T_* : \operatorname{res}(H^*) \longrightarrow \mathcal{B}(L^2(\Omega_q), \mathbb{C}^2)$ defined by

$$\begin{aligned} T(z)g &:= \alpha(H-z)^{-1}g, \quad g \in L^2(\Omega_q), \\ T_*(z)g &:= \alpha(H^*-z)^{-1}g, \quad g \in L^2(\Omega_q). \end{aligned} \tag{A.13}$$

The 2×2 matrix-valued function $\Theta : \operatorname{res}(H^*) \longrightarrow \mathcal{B}(\mathbb{C}^2)$ defined by

$$\Theta(z) = I_{\mathbb{C}^2} - i\alpha T(\overline{z})^* \tag{A.14}$$

is holomorphic, contractive on $\mathbb{C}_-$, and unitary on $\mathbb{R}$. The matrix-valued Θ is called the characteristic function of H; see [21, 35] for motivation and details of this definition.

The incoming generalized eigenfunctions of K, i.e., functions $\vec{\psi}_a = \psi_{a,-} \oplus \psi_a \oplus \psi_{a,+}$ and $\vec{\psi}_b = \psi_{b,-} \oplus \psi_b \oplus \psi_{b,+}$, which satisfy

$$\begin{aligned} -i\frac{d}{dx}\psi_{\nu,-}(\lambda,x) \oplus \left(-\frac{1}{2}\frac{d}{dx}\frac{1}{m}\frac{d}{dx} + V(x)\right)\psi_\nu(,\lambda,x) \oplus -i\frac{d}{dx}\psi_{\nu,+}(\lambda,x) \\ = \lambda\Big(\psi_{\nu,-}(\lambda,x) \oplus \psi_\nu(\lambda,x) \oplus \psi_{\nu,+}(\lambda,x)\Big), \qquad \lambda \in \mathbb{R},\ \nu = a,b, \end{aligned}$$

and the boundary conditions in (A.8), are given by

$$\begin{aligned} \vec{\psi}_\nu(\lambda,x) &= \psi_{\nu,-} \oplus \psi_\nu \oplus \psi_{\nu,+} \\ &= \frac{1}{\sqrt{2\pi}}\Big(e^{i\lambda x}e_\nu \oplus \big(T_*(\lambda)^* e_\nu\big)(x) \oplus e^{i\lambda x}\Theta(\lambda)e_\nu\Big), \qquad \lambda \in \mathbb{R},\ \nu = a,b, \end{aligned} \tag{A.15}$$

$e_b = \left(\begin{smallmatrix}1\\0\end{smallmatrix}\right)$, $e_a = \left(\begin{smallmatrix}0\\1\end{smallmatrix}\right)$; see [35, 5].

The incoming Fourier transform $\Phi_- : \mathfrak{K} \longrightarrow \widehat{\mathfrak{K}_0} := L^2(\mathbb{R};\mathbb{C}^2)$ is then defined by

$$\begin{aligned} \Big(\Phi_- \vec{f}\Big)(\lambda) := &\begin{pmatrix} \int_{-\infty}^0 dx\ \left(f_-(x), \psi_{b,-}(\lambda,x)\right)_{\mathbb{C}^2} \\ \int_{-\infty}^0 dx\ \left(f_-(x), \psi_{a,-}(\lambda,x)\right)_{\mathbb{C}^2} \end{pmatrix} \\ &+ \begin{pmatrix} \int_a^b dx\ \overline{\psi_b(\lambda,x)}\, f(x) \\ \int_a^b dx\ \overline{\psi_a(\lambda,x)}\, f(x) \end{pmatrix} + \begin{pmatrix} \int_0^\infty dx\ \left(f_+(x), \psi_{b,+}(\lambda,x)\right)_{\mathbb{C}^2} \\ \int_0^\infty dx\ \left(f_+(x), \psi_{a,+}(\lambda,x)\right)_{\mathbb{C}^2} \end{pmatrix}, \end{aligned}$$

$\lambda \in \mathbb{R}$, for all $\vec{f} = f_- \oplus f \oplus f_+ \in \mathfrak{K}$. The incoming Fourier transform Φ_- establishes a unitary equivalence between the dilation K and the multiplication operator M with the independent variable λ; see [35, 5].

We introduce the identification operators $J_\pm : \mathfrak{K}_0 \longrightarrow \mathfrak{K}$, $\mathfrak{K}_0 = L^2(\mathbb{R};\mathbb{C}^2)$,

$$\begin{aligned} J_-\vec{f} &:= P_-\vec{f} \oplus 0 \oplus 0, \\ J_+\vec{f} &:= 0 \oplus 0 \oplus P_+\vec{f}, \end{aligned} \qquad \vec{f} \in \mathfrak{K}_0, \tag{A.16}$$

where $P_\pm$ denote the orthogonal projections from $\mathfrak{K}_0$ onto $L^2(\mathbb{R}_\pm, \mathbb{C}^2)$. Let K_0 be the differentiation operator $K_0 = -i\frac{d}{dx}$, defined on $\mathfrak{K}_0$. The Lax–Phillips wave operators,

$$W_\pm := s - \lim_{t\to\pm\infty} e^{itK} J_\pm e^{-itK_0}, \tag{A.17}$$

always exist (see [3, 33]) and are unitary.

By $\mathcal{F} : \mathfrak{K}_0 \longrightarrow \widehat{\mathfrak{K}}_0 = L^2(\mathbb{R}, \mathbb{C}^2)$ we denote the usual Fourier transform

$$(\mathcal{F}\vec{f})(\lambda) := \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} dx\, e^{-ix\lambda} \vec{f}(x), \quad \vec{f} \in \mathfrak{K}_0, \quad \lambda \in \mathbb{R}. \tag{A.18}$$

The incoming Fourier transform Φ_- of K is then expressed by

$$\Phi_- = \mathcal{F}W_-^* : \mathfrak{K} \longrightarrow \widehat{\mathfrak{K}}_0 \tag{A.19}$$

(see [3, 35, 33]).

The Lax–Phillips scattering operator $S : \mathfrak{K}_0 \longrightarrow \mathfrak{K}_0$ is defined by

$$S := W_+^* W_-. \tag{A.20}$$

The scattering operator commutes with K_0, which yields that the operator $\widehat{S} : \widehat{\mathfrak{K}}_0 \longrightarrow \widehat{\mathfrak{K}}_0$,

$$\widehat{S} := \mathcal{F} S \mathcal{F}^*, \tag{A.21}$$

commutes with M. Hence the operator $\widehat{S}$ can be represented as a multiplication operator with a 2×2 matrix-valued function $\{\widehat{S}(\lambda)\}_{\lambda\in\mathbb{R}}$, which is called the scattering matrix, in particular, the Lax–Phillips scattering matrix. It turns out that the scattering matrix can be computed directly from the operator H by means of the characteristic function Θ. In fact, there is

$$S(\lambda) = \Theta(\lambda)^* \tag{A.22}$$

for a.e. $\lambda \in \mathbb{R}$.

The transmission coefficient $t(\lambda)$, $\lambda \in \mathbb{R}$, is then given by

$$t(\lambda) := |(S(\lambda)e_b, e_a)_{\mathbb{C}^2}|^2 = |(e_b, \Theta(\lambda)e_a)_{\mathbb{C}^2}|^2, \tag{A.23}$$

where $e_b, e_a \in \mathbb{C}$ are given by $e_b = \binom{1}{0}$, $e_a = \binom{0}{1}$. Moreover, there is

$$t(\lambda) = |(S(\lambda)e_a, e_b)_{\mathbb{C}^2}|^2$$

(see [35]).

Clearly, all the quantities defined above depend on the triple $\tau = (\varkappa_a, \varkappa_b, V) \in \mathcal{T}$. If needed, we will denote the dependence of any quantity A on $\tau \in \mathcal{T}$ by writing $A[\tau]$.

A.3. Carrier density operator. Let $\tau \in \mathcal{T}$ be given and H be the associated maximal dissipative Schrödinger operator. By means of a so-called density matrix ρ, one can assign a particle density u to each operator H in a unique way. The mapping $\tau \mapsto u$ is then defined as the carrier density operator. In what follows we will discuss this procedure in detail.

A density matrix is an element of the Banach space $L^\infty(\mathbb{R}, \mathcal{B}(\mathbb{C}^2))$ such that its values are self-adjoint and nonnegative 2×2 matrices; i.e., for a.e. $\lambda \in \mathbb{R}$ there is $\rho(\lambda) = \rho(\lambda)^*$ and $\rho(\lambda) \geq 0$. With ρ one associates a bounded multiplication operator $\widehat{\rho} : \widehat{\mathfrak{K}}_0 \longrightarrow \widehat{\mathfrak{K}}_0$ on the Hilbert space $\mathfrak{K}_0 = L^2(\mathbb{R}, \mathbb{C}^2)$ defined by

$$(\widehat{\rho}\vec{f})(\lambda) := \rho(\lambda)\vec{f}(\lambda). \tag{A.24}$$

Using the transformation (A.19), one defines by

$$\varrho := \Phi_-^* \widehat{\rho} \Phi_- \tag{A.25}$$

an operator on the dilation space $\mathfrak{K}$, which is self-adjoint, is nonnegative, and commutes with the dilation K. The operator ϱ is called a density operator or a steady state albeit that ϱ is not a trace class operator. However, it turns out that if the additional condition

$$C_\rho := \sup_{\lambda \in \mathbb{R}} \sqrt{\lambda^2 + 1} \|\rho(\lambda)\|_{\mathcal{B}(\mathbb{C}^2)} < \infty \tag{A.26}$$

is satisfied, then the product ϱP (where P denotes again the projection from $\mathfrak{K}$ onto $L^2(\Omega_q)$) belongs to the trace class; cf. [33]. Using this observation, the following is shown in [3, 35]: for a fixed density matrix ρ satisfying (A.26) and given $\tau \in \mathcal{T}$, there is exactly one function $u \in L^1(\Omega_q)$ satisfying

$$\operatorname{tr}(\varrho M(h)) = \int_{\Omega_q} dx\, u(x)h(x) \quad \text{for all } h \in L^\infty_{\mathbb{R}}(\Omega_q), \tag{A.27}$$

where $M(h)$ is the multiplication operator defined by

$$M(h)\vec{g} := 0 \oplus hg \oplus 0, \quad \vec{g} = g_- \oplus g \oplus g_+ \in \mathfrak{K}, \quad (hg)(x) = h(x)g(x), \quad x \in \Omega_q$$

(see [35]). We note that condition (A.26) implies $\varrho M(h) \in \mathcal{B}_1(\mathfrak{K})$ for each $h \in L^\infty_{\mathbb{R}}(\Omega_q)$.

Remark A.3. Let $f^\pm$ be distribution functions obeying Assumption 3.1 (Q.5). We define the density matrices $\rho^\pm$ by

$$\rho^\pm(\lambda) = \begin{pmatrix} f^\pm(\lambda \mp \epsilon_b) & 0 \\ 0 & f^\pm(\lambda \mp \epsilon_a) \end{pmatrix} \chi_{\Lambda^\pm}(\lambda),$$

where ϵ_a, ϵ_b are given Fermi levels and $\chi_{\Lambda^\pm}$ denotes the characteristic function of the sets $\Lambda^\pm$; see (1.13). Clearly $\rho^\pm$ satisfy the condition (A.26). In [33] it is shown that the densities $u^\pm$ corresponding to $\rho^\pm$ and $\tau^\pm$, where $\tau^\pm$ are given as in Remark A.1, defined by means of the relation (A.27) coincide with (3.5).

The mapping that assigns the density u to each triple $\tau \in \mathcal{T}$, if the density matrix ρ is given, is called the carrier density operator $\mathcal{N}_\rho$; i.e., $\mathcal{N}_\rho : \mathcal{T} \longrightarrow L^1(\Omega_q)$ is defined by

$$\int_{\Omega_q} dx\, \mathcal{N}_\rho[\tau](x)h(x) = \operatorname{tr}(\varrho[\tau]M(h)) \qquad \text{for all } h \in L^\infty(\Omega_q) \text{ and each } \tau \in \mathcal{T},$$

where $\varrho[\tau]$ indicates the dependence of ϱ given by (A.25) on τ.

PROPOSITION A.4. *Let $\tau = \{\varkappa_a, \varkappa_b, V\} \in \mathcal{T}_+$. If the density matrix $\rho \in L^\infty(\mathbb{R}, \mathcal{B}(\mathbb{C}^2))$ satisfies the condition* (A.26) *and the boundary coefficients obey* $\mathrm{Re}(\varkappa_a) \le 0$ *and* $\mathrm{Re}(\varkappa_b) \le 0$*, then*

$$\|\mathcal{N}_\rho[\tau]\|_{L^1(\Omega_q)} \le C_\rho \left(3 + \left[8 + 4\sqrt{\|m\|_{L^\infty(\Omega_q)}}(b-a)\right]\sqrt{1 + \|V_-\|_{L^\infty(\Omega_q)}}\right), \tag{A.28}$$

where $V_-(x) := \max\{0, -V(x)\}$, $x \in \Omega_q$, and C_ρ is given by (A.26).

Proof. In [4, Lemma 6.2] the estimate

$$\|\mathcal{N}_\rho[\tau]\|_{L^1(\Omega_q)} \le C_\rho \left(3 + \left[8 + 4\sqrt{\|m\|_{L^\infty(\Omega_q)}}(b-a)\right]\sqrt{1 + \|V\|_{L^\infty(\Omega_q)}}\right)$$

is proven. The improved estimate (A.28) can be obtained by carefully checking the proof of Lemma 6.2 of [4]. Indeed, by doing so one obtains that the nonnegative part of the potential v moves the spectrum of the operator H to the right-hand side, which yields that it can be neglected. $\square$

We are going to verify the continuity of the carrier density operator in its dependence of τ. To this end we need the following.

PROPOSITION A.5. *Let $\tau, \tau_n \in \mathcal{T}$, $n \in \mathbb{N}$. If $\tau_n \to \tau$ as $n \to \infty$, then*

$$\lim_{n\to\infty} \|(K[\tau_n] - z)^{-1} - (K[\tau] - z)^{-1}\|_{\mathcal{B}_1(\mathfrak{K})} = 0 \tag{A.29}$$

for $z \in \mathbb{C} \setminus \mathbb{R}$.

Proof. At first we show that for each $\vec{g} \in \mathrm{dom}(K[\tau])$ there is a sequence $\{\vec{g}_n\}_{n\in\mathbb{N}}$ such that $\vec{g}_n \in \mathrm{dom}(K[\varkappa_{a,n}, \varkappa_{b,n}, V])$, $\lim_{n\to\infty} \vec{g}_n = \vec{g}$, and $\lim_{n\to\infty} K[\varkappa_{a,n}, \varkappa_{b,n}, V]\vec{g}_n = K[\tau]\vec{g}$ in the sense of $\mathfrak{K}$. Let

$$\vec{g}_n = \vec{g} + \vec{h}_n, \quad n \in \mathbb{N},$$

where

$$\vec{h}_n := 0 \oplus h_n \oplus h_{+,n}, \quad n \in \mathbb{N}.$$

Furthermore, let $\theta(\cdot) : \mathbb{R} \longrightarrow [0,1]$ be a smooth function equal to one in a neighborhood of zero and equal to zero in neighborhood of $y_0 := 2\int_a^b dt\, m(t)$. We set

$$h_n(x) := \theta\left(2\int_a^x dt\, m(t)\right) h_{a,n}(x) + \theta\left(2\int_x^b dt\, m(t)\right) h_{b,n}(x), \quad x \in \Omega_q, \quad n \in \mathbb{N},$$

where

$$h_{a,n}(x) := 2C_{a,n}\int_a^x m(t)dt, \qquad h_{b,n}(x) := -2C_{b,n}\int_x^b m(t)dt, \quad x \in [a,b],$$

and

$$\begin{aligned} C_{a,n} &:= (\alpha_{a,n} - \alpha_a)g_-^a(0) - (\varkappa_{a,n} - \varkappa_a)g(a), \\ C_{b,n} &:= (\alpha_{b,n} - \alpha_b)g_-^b(0) + (\varkappa_{b,n} - \varkappa_b)g(b). \end{aligned}$$

Notice that $\lim_{n\to\infty} C_{a,n} = \lim_{n\to\infty} C_{b,n} = 0$. Further, we set

$$h^a_{+,n}(x) := h^a_{+,n}(0)e^{-x}, \quad x \in \mathbb{R}_+, \quad \text{and} \quad h^b_{+,n}(x) := h^b_{+,n}(0)e^{-x}, \quad x \in \mathbb{R}_+,$$

where

$$h^a_{+,n}(0) := -i(\alpha_{a,n} - \alpha_a)g(a) \quad \text{and} \quad h^b_{+,n}(0) := i(\alpha_{b,n} - \alpha_b)g(b), \quad n \in \mathbb{N}.$$

A straightforward computation shows that $\vec{g}_n \in \mathrm{dom}(K[\varkappa_{a,n}, \varkappa_{b,n}, V])$, $\lim_{n\to\infty} \vec{g}_n = \vec{g}$, and $\lim_{n\to\infty} K[\varkappa_{a,n}, \varkappa_{b,n}, V]\vec{g}_n = K[\tau]\vec{g}$.

Since the sequence $\{\vec{g}_n\}_{n\in\mathbb{N}}$ exists for each $\vec{g} \in \mathrm{dom}(K[\tau])$, one gets by [40, Theorem 2.1] that

$$s - \lim_{n\to\infty} (K[\varkappa_{a,n}, \varkappa_{b,n}, V] - z)^{-1} = (K[\tau] - z)^{-1}. \tag{A.30}$$

The operators $K[\varkappa_{a,n}, \varkappa_{b,n}, V]$, $n \in \mathbb{N}$, and $K[\tau]$ are self-adjoint extensions of the symmetric operator $K_\bullet[V]$ given by

$$\mathrm{dom}(K_\bullet[V]) := \left\{ \vec{g} \in \mathfrak{K} : \begin{array}{c} g_\pm \in W^{1,2}(\mathbb{R}_\pm, \mathbb{C}^2) \quad g, \frac{1}{m}g' \in W^{1,2}(\Omega_q), \\ g(a) = g(b) = 0, \\ \frac{1}{m(a)}g'(a) = \frac{1}{m(b)}g'(b) = 0, \\ g_-(0) = g_+(0) = 0 \end{array} \right\}$$

and

$$K_\bullet[V]\vec{g} := -i\frac{d}{dx}g_- \oplus \left(-\frac{1}{2}\frac{d}{dx}\frac{1}{m}\frac{d}{dx} + V\right) g \oplus -i\frac{d}{dx}g_+, \quad \vec{g} \in \mathrm{dom}(K_\bullet[V]),$$

which has the deficiency indices $\{4, 4\}$. This fact immediately improves the strong convergence (A.30) to the trace class convergence, i.e.,

$$\lim_{n\to\infty} \|(K[\varkappa_{a,n}, \varkappa_{b,n}, V] - z)^{-1} - (K[\tau] - z)^{-1}\|_{\mathcal{B}_1(\mathfrak{K})} = 0.$$

Since $P(K[\tau] - z)^{-1} \in \mathcal{B}_1(\mathfrak{K})$, one gets

$$\lim_{n\to\infty} \|(K[\tau_n] - z)^{-1}(V - V_n)P(K[\tau] - z)^{-1}\|_{\mathcal{B}_1(\mathfrak{K})} = 0.$$

Using the representation

$$\begin{aligned} &(K[\tau_n] - z)^{-1} - (K[\varkappa_{a,n}, \varkappa_{b,n}, V] - z)^{-1} \\ &\quad = (K[\tau_n] - z)^{-1}(V - V_n)P(K[\tau] - z)^{-1} \\ &\qquad + (K[\tau_n] - z)^{-1}(V - V_n)P\left((K[\varkappa_{a,n}, \varkappa_{b,n}, V] - z)^{-1} - (K[\tau] - z)^{-1}\right), \end{aligned}$$

we find

$$\lim_{n\to\infty} \|(K[\tau_n] - z)^{-1} - (K[\varkappa_{a,n}, \varkappa_{b,n}, V] - z)^{-1}\|_{\mathcal{B}_1(\mathfrak{K})} = 0.$$

Finally, taking into account the representation

$$\begin{aligned} &(K[\tau_n] - z)^{-1} - (K[\tau] - z)^{-1} \\ &= (K[\tau_n]-z)^{-1} - (K[\varkappa_{a,n}, \varkappa_{b,n}, V]-z)^{-1} + (K[\varkappa_{a,n}, \varkappa_{b,n}, V]-z)^{-1} - (K[\tau]-z)^{-1}, \end{aligned}$$

we complete the proof. ∎

Proposition A.5 immediately implies the continuity of the incoming Fourier transform.

Proposition A.6. *Let $\tau, \tau_n \in \mathcal{T}$, $n \in \mathbb{N}$. If $\tau_n \longrightarrow \tau$ as $n \to \infty$, then*

$$s - \lim_{n\to\infty} \Phi_-[\tau_n] = \Phi_-[\tau]. \tag{A.31}$$

Proof. Let

$$W_-[\tau_n, \tau] := s - \lim_{t\to-\infty} e^{itK[\tau_n]}e^{-itK[\tau]}.$$

From Proposition A.5 we obtain that

$$s - \lim_{n\to\infty} W_-[\tau_n, \tau] = I_{\mathfrak{K}},$$

which yields

$$w - \lim_{n\to\infty} W_-[\tau_n, \tau]^* = I_{\mathfrak{K}}.$$

Since $W_-[\tau_n, \tau]$ is unitary for each $n \in \mathbb{N}$, we find

$$s - \lim_{n\to\infty} W_-[\tau_n, \tau]^* = I_{\mathfrak{K}}.$$

By the chain rule for wave operators, we obtain

$$W_-[\tau_n] = W_-[\tau_n, \tau]W_-[\tau], \quad n \in \mathbb{N},$$

which gives

$$s - \lim_{n\to\infty} W_-[\tau_n]^* = W_-[\tau]^*. \tag{A.32}$$

Taking into account the representation (A.19), we complete the proof. ∎

Using Proposition A.6, we will now verify the continuity of the carrier density operator.

Theorem A.7. *Let $\tau, \tau_n \in \mathcal{T}$, $n \in \mathbb{N}$. Further, suppose that there is a density matrix $\rho \in L^\infty(\mathbb{R}, \mathcal{B}(\mathbb{C}^2))$ such that $C_\rho < \infty$ and a sequence of density matrices $\{\rho_n\}_{n\in\mathbb{N}}$, $\rho_n \in L^\infty(\mathbb{R}, \mathcal{B}(\mathbb{C}^2))$, such that $\sup_{n\in\mathbb{N}} C_{\rho_n} < \infty$. If $\tau_n \to \tau$ as $n \to \infty$ and*

$$\lim_{n\to\infty} \rho_n(\lambda) = \rho(\lambda)$$

for a.e. $\lambda \in \mathbb{R}$, then

$$\lim_{n\to\infty} \|\mathcal{N}_{\rho_n}[\tau_n] - \mathcal{N}_\rho[\tau]\|_{L^1(\Omega_q)} = 0. \tag{A.33}$$

Proof. We set $\Phi_n := \Phi_-[\tau_n]$ and $\Phi := \Phi_-[\tau]$ as well as

$$\iota_n(\lambda) := (\lambda - i)\rho_n(\lambda) \quad \text{and} \quad \iota(\lambda) := (\lambda - i)\rho(\lambda), \quad \lambda \in \mathbb{R}, \quad n \in \mathbb{N}.$$

From (A.25) we find the representation

$$\varrho_n[\tau_n] - \varrho[\tau] = \Phi_n^* \,\widehat{\iota}_n\, \Phi_n(K_n - i)^{-1} - \Phi^* \,\widehat{\iota}\, \Phi(K - i)^{-1}, \quad n \in \mathbb{N},$$

where $K_n := K[\tau_n]$ and $K := K[\tau]$. Note that $(K-i)^{-1}P \in \mathcal{B}_1(\mathfrak{K})$. Hence we find the estimate

$$\begin{aligned}
&\left\|(\varrho_n[\tau_n] - \varrho[\tau])P_{\mathfrak{h}}^{\mathfrak{K}}\right\|_{\mathcal{B}_1(\mathfrak{K})} \\
&\quad \le C_{\rho_n}\left\|(K_n - i)^{-1} - (K-i)^{-1}\right\|_{\mathcal{B}_1(\mathfrak{K})} + C_{\rho_n}\left\|(\Phi_n - \Phi)(K-i)^{-1}P\right\|_{\mathcal{B}_1(\mathfrak{K},\mathfrak{K}_0)} \\
&\qquad + \left\|(\widehat{\iota}_n - \widehat{\iota})\Phi(K-i)^{-1}P\right\|_{\mathcal{B}_1(\mathfrak{K},\mathfrak{K}_0)} + \left\|(\Phi_n^* - \Phi^*)\,\widehat{\iota}\,\Phi(K-i)^{-1}P\right\|_{\mathcal{B}_1(\mathfrak{K})}.
\end{aligned}$$

The first term on the right-hand side goes to zero by Proposition A.5. The second term tends to zero by Proposition A.6 and $(K-i)^{-1}P \in \mathcal{B}_1(\mathfrak{K})$. By $s-\lim_{n\to\infty}\widehat{\iota}_n = \widehat{\iota}$ and $(K-i)^{-1}P \in \mathcal{B}_1(\mathfrak{K})$ the third term goes to zero. Finally, from Proposition A.6 and the isometry of the incoming Fourier transform we get $s-\lim_{n\to\infty}\Phi_n = \Phi$, which yields that the fourth term converges to zero. Hence we find

$$\lim_{n\to\infty}\|(\varrho_n[\tau_n] - \varrho[\tau])P\|_{\mathcal{B}_1(\mathfrak{K})} = 0.$$

Taking into account (A.27), this proves (A.33). $\square$

A.4. Current density operator. Similar to the carrier density operator, it is possible to introduce a current density operator $j_\rho : \mathcal{T} \longrightarrow \mathbb{R}$ for a given maximal dissipative operator $h[\tau]$ and a density matrix $\rho \in L^\infty(\mathbb{R}, \mathcal{B}(\mathbb{C}^2))$, provided the density matrix satisfies the additional condition

$$L_\rho := \int_{\mathbb{R}} d\lambda\, \mathrm{tr}(\rho(\lambda)) < \infty \tag{A.34}$$

(cf. [3, 5, 35, 33]). In [33] it is shown that the current density operator admits a representation by the so-called current density observable $C[\tau](\lambda)$ at energy $\lambda \in \mathbb{R}$, which is defined by

$$C[\tau](\lambda) := \frac{1}{2\pi}\left(P_a\Theta[\tau](\lambda)P_b - P_b\Theta[\tau](\lambda)P_a\right)\Theta[\tau](\lambda)^*, \quad \tau \in \mathcal{T}, \tag{A.35}$$

where $\Theta[\tau]$ is the characteristic function of the maximal dissipative operator $H[\tau]$ (cf. (A.14) and [5, 33]) and the projections $P_a := (\cdot, e_a)_{\mathbb{C}^2}e_a$, $P_b := (\cdot, e_b)_{\mathbb{C}^2}e_b$ with $e_a = \binom{0}{1}$, $e_b = \binom{1}{0}$. Indeed, if the density matrix ρ satisfies the condition (A.34), then the current density operator $j_\rho[\cdot] : \mathcal{T}_+ \longrightarrow \mathbb{R}$ admits the representation

$$j_\rho[\tau] := \int_{\mathbb{R}} d\lambda\, \mathrm{tr}(\rho(\lambda)C[\tau](\lambda)). \tag{A.36}$$

Since $\|C[\tau](\lambda)\|_{\mathcal{B}(\mathbb{C}^2)} \le \frac{1}{2\pi}$, one gets the estimate

$$|j_\rho[\tau]| \le \frac{1}{2\pi}\int_{\mathbb{R}} d\lambda\, \mathrm{tr}(\rho(\lambda)). \tag{A.37}$$

Remark A.8. In the case when $\rho^\pm$ are given as in Remark A.3, we obtain from (A.36) the expression (3.7), where the transmission coefficients are given by (A.23).

Let us now prove the continuity of the current density operator.

THEOREM A.9. *Let $\tau, \tau_n \in \mathcal{T}$, $n \in \mathbb{N}$. Further, suppose that there is a density matrix $\rho \in L^\infty(\mathbb{R}, \mathcal{B}(\mathbb{C}^2))$ such that $L_\rho < \infty$ (cf.* (A.34)*) and a sequence of density* *matrices* $\{\rho_n\}_{n\in\mathbb{N}}$, $\rho_n \in L^\infty(\mathbb{R},\mathcal{B}(\mathbb{C}^2))$, *such that* $\sup_{n\in\mathbb{N}} L_{\rho_n} < \infty$. *If* $\tau_n \longrightarrow \tau$ *as* $n\to\infty$, $\lim_{n\to\infty}\rho_n(\lambda) = \rho(\lambda)$ *for a.e.* $\lambda\in\mathbb{R}$, *and*

$$\lim_{n\to\infty}\int_{\mathbb{R}} d\lambda\ (\rho_n(\lambda)e,e)_{\mathbb{C}^2} = \int_{\mathbb{R}} d\lambda\ (\rho(\lambda)e,e)_{\mathbb{C}^2} \tag{A.38}$$

for each $e\in\mathbb{C}^2$, *then* $\lim_{n\to\infty} j_{\rho_n}[\tau_n] = j_\rho[\tau]$.

Proof. By Proposition A.5 we obtain that $s-\lim_{n\to\infty} S[\tau_n] = S[\tau]$. This yields

$$\lim_{n\to\infty}\int_{\mathbb{R}} d\lambda\ \left\|(S[\tau_n](\lambda) - S[\tau](\lambda))\vec{f}(\lambda)\right\|^2_{\mathbb{C}^2} = 0$$

for each $\vec{f}\in\widehat{\mathfrak{K}}_0 = L^2(\mathbb{R},\mathbb{C}^2)$. Taking into account (A.22), we obtain

$$\lim_{n\to\infty}\int_{\mathbb{R}} d\lambda\ \left\|(\Theta[\tau_n](\lambda)^* - \Theta[\tau](\lambda)^*)\vec{f}(\lambda)\right\|^2_{\mathbb{C}^2} = 0$$

and

$$\lim_{n\to\infty}\int_{\mathbb{R}} d\lambda\ \left\|(\Theta[\tau_n](\lambda) - \Theta[\tau](\lambda))\vec{f}(\lambda)\right\|^2_{\mathbb{C}^2} = 0$$

for each $\vec{f}\in\widehat{\mathfrak{K}}_0$. Hence

$$\lim_{n\to\infty}\int_{\mathbb{R}} d\lambda\ \left\|(C[\tau_n](\lambda) - C[\tau](\lambda))\vec{f}(\lambda)\right\|^2_{\mathbb{C}^2} = 0 \tag{A.39}$$

for each $\vec{f}\in\widehat{\mathfrak{K}}_0$. Further, we have

$$\begin{aligned}
&\mathrm{tr}(\rho_n(\lambda)C[\tau_n](\lambda)) - \mathrm{tr}(\rho(\lambda)C[\tau](\lambda))\\
&\quad = \mathrm{tr}(\rho_n(\lambda)^{1/2}C[\tau_n]\rho_n(\lambda)^{1/2})_{\mathbb{C}^2} - \mathrm{tr}(\rho^{1/2}(\lambda)C[\tau]\rho^{1/2}(\lambda))_{\mathbb{C}^2}\\
&\quad = \sum_{\nu=a,b}\left\{(C[\tau_n](\lambda)\rho_n(\lambda)^{1/2}e_\nu,\rho_n(\lambda)^{1/2}e_\nu)_{\mathbb{C}^2} - (C[\tau](\lambda)\rho(\lambda)^{1/2}e_\nu,\rho(\lambda)^{1/2}e_\nu)_{\mathbb{C}^2}\right\},
\end{aligned}$$

$\lambda\in\mathbb{R}$. Setting $\vec{f}_{\nu,n}(\lambda) := \rho_n(\lambda)^{1/2}e_\nu$ and $\vec{f}_\nu(\lambda) := \rho(\lambda)^{1/2}e_\nu$, $\nu = a,b$, we get $\vec{f}_{\nu,n},\vec{f}_\nu\in\mathfrak{K}_0$. Using $\|C[\tau](\lambda)\|_{\mathcal{B}(\mathbb{C}^2)}\le\frac{1}{2\pi}$, $\lambda\in\mathbb{R}$, we obtain the estimate

$$\begin{aligned}
&\left|\mathrm{tr}(\rho_n(\lambda)C[\tau_n](\lambda)) - \mathrm{tr}(\rho(\lambda)C[\tau](\lambda))\right|\\
&\quad\le\sum_{\nu=a,b}\frac{1}{2\pi}\left\{\|\vec{f}_{\nu,n}(\lambda)\|_{\mathbb{C}^2} + \|\vec{f}_\nu(\lambda)\|_{\mathbb{C}^2}\right\}\|\vec{f}_{\nu,n}(\lambda) - \vec{f}_\nu(\lambda)\|_{\mathbb{C}^2}\\
&\qquad + \sum_{\nu=a,b}\|\vec{f}_\nu(\lambda)\|_{\mathbb{C}^2}\|(C[\tau_n](\lambda) - C[\tau](\lambda))\vec{f}_\nu(\lambda)\|_{\mathbb{C}^2}.
\end{aligned}$$

We note that $\vec{f}_{\nu,n},\vec{f}_\nu\in\widehat{\mathfrak{K}}_0$, $\nu=a,b$, $n\in\mathbb{N}$. Hence

$$
\begin{aligned}
|j_{\rho_n}[\tau_n] - j_\rho[\tau]| &\le \int_{\mathbb{R}} d\lambda \ |\mathrm{tr}(C[\tau_n](\lambda)\rho_n(\lambda)) - \mathrm{tr}(C[\tau](\lambda)\rho(\lambda))| \\
&\le \frac{1}{2\pi}\left\{\left(\sum_{\nu=a,b}\|\vec{f}_{\nu,n}\|^2_{\widehat{\mathfrak{K}}_0}\right)^{1/2} + \left(\sum_{\nu=a,b}\|\vec{f}_{\nu}\|^2_{\widehat{\mathfrak{K}}_0}\right)^{1/2}\right\}\left(\sum_{\nu=a,b}\|\vec{f}_{\nu,n}-\vec{f}_{\nu}\|^2_{\widehat{\mathfrak{K}}_0}\right)^{1/2} \\
&\quad + \left(\sum_{\nu=a,b}\|\vec{f}_{\nu}\|^2_{\widehat{\mathfrak{K}}_0}\right)^{1/2}\left(\sum_{\nu=a,b}\int_{\mathbb{R}} d\lambda \ \|(C[\tau_n](\lambda)-C[\tau](\lambda))\vec{f}_\nu(\lambda)\|^2_{\mathbb{C}^2}\right)^{1/2},
\end{aligned}
$$

which yields

$$
\begin{aligned}
\text{(A.40)}\quad \left|j_{\rho_n}[\tau_n] - j_\rho[\tau]\right| &\le \left\{L^{1/2}_{\rho_n} + L^{1/2}_{\rho}\right\}\left(\sum_{\nu=a,b}\|\vec{f}_{\nu,n}-\vec{f}_{\nu}\|^2_{\widehat{\mathfrak{K}}_0}\right)^{1/2} \\
&\quad + L^{1/2}_{\rho}\left(\sum_{\nu=a,b}\int_{\mathbb{R}} d\lambda \ \|(C[\tau_n](\lambda)-C[\tau](\lambda))\vec{f}_\nu(\lambda)\|^2_{\mathbb{C}^2}\right)^{1/2}.
\end{aligned}
$$

Since $\rho_n(\lambda) \to \rho(\lambda)$ for a.e. $\lambda \in \mathbb{R}$ as $n \to \infty$, we find $\vec{f}_{\nu,n}(\lambda) \to \vec{f}_\nu(\lambda)$ for a.e. $\lambda \in \mathbb{R}$ as $n \to \infty$. From (A.38) we get that $\lim_{n\to\infty}\|\vec{f}_{\nu,n}\|_{\widehat{\mathfrak{K}}_0} = \|\vec{f}_\nu\|_{\widehat{\mathfrak{K}}_0}$, $\nu = a,b$. By Theorem 13.44 of [28] we get that $\vec{f}_{\nu,n}$ converges weakly to $\vec{f}_\nu$, which implies $\lim_{n\to\infty}\|\vec{f}_{\nu,n}-\vec{f}_\nu\|_{\widehat{\mathfrak{K}}_0} = 0$, $\nu = a,b$. Thus the first term of the right-hand side tends to zero as $n \to \infty$. Taking into account (A.39), we show that the second term of the right-hand side goes to zero as $n \to \infty$. □

Appendix B. Approximation. In the following we will outline in which sense the dissipative Schrödinger system can be regarded as an approximation of the frequently used Schrödinger scattering model in [8, 22] (also known as the quantum transmitting Schrödinger model [4]).

B.1. The quantum transmitting Schrödinger model. Let us briefly review the quantum transmitting Schrödinger model considered, e.g., in [8, 4, 11, 22]. The wave functions $\widetilde{\psi}$ are solutions of the one-dimensional Schrödinger equation

$$
\text{(B.1)}\qquad \left(-\frac{1}{2}\frac{d}{dx}\frac{d}{dx} + \widetilde{V}\right)\widetilde{\psi}(x) = \lambda\widetilde{\psi}(x), \quad x \in \mathbb{R},
$$

where the effective mass m and the potential $\widetilde{V}$ satisfy

$$
m(x) = \begin{cases} m_a, & x \in (-\infty, a),\\ m(x), & x \in \Omega_q,\\ m_b, & x \in (b,\infty),\end{cases} \quad\text{and}\quad \widetilde{V}(x) = \begin{cases} V(a), & x \in (-\infty, a),\\ V(x), & x \in \Omega_q,\\ V(b), & x \in (b,\infty).\end{cases}
$$

Due to the flatness of the potential in the asymptotic regions, the solutions of the Schrödinger equation (B.1) are superpositions of plane waves. In what follows we will refer to quantities in the left asymptotic region $(-\infty, a)$ by the subscript a and, similarly, the subscript b is used for quantities in the right asymptotic region (b, ∞).

For energies $\lambda > V(a)$ and $\lambda > V(b)$ there will be two independent solutions $\widetilde{\psi_a}$, $\widetilde{\psi_b}$ of the Schrödinger equation representing particles incident from the left and right, respectively. In the asymptotic regions they are of the form

$$\widetilde{\psi_a}(\lambda, x) = \frac{1}{\sqrt{2\pi\, v_a(\lambda)}} \begin{cases} e^{ik_a(\lambda)(x-a)} + S_{aa}(\lambda) e^{-ik_a(\lambda)(x-a)}, & x < a, \\ S_{ab}(\lambda) e^{ik_b(\lambda)(x-b)}, & x > b, \end{cases}$$

for $\lambda > V(a)$ and

$$\widetilde{\psi_b}(\lambda, x) = \frac{1}{\sqrt{2\pi\, v_b(\lambda)}} \begin{cases} S_{ba}(\lambda) e^{-ik_a(\lambda)(x-a)}, & x < a, \\ e^{-ik_b(\lambda)(x-b)} + S_{bb}(\lambda) e^{-ik_b(\lambda)(x-b)}, & x > b, \end{cases}$$

for $\lambda > V(b)$, where $k_\nu(\lambda) = [2m_\nu(\lambda - V(\nu))]^{1/2}$, $\nu = a, b$, are the wave vectors; $v_\nu(\lambda) = k_\nu(\lambda)/m_\nu$, $\nu = a, b$, are the group velocities; S_{ab}, S_{ba} the transmission amplitudes; and S_{aa}, S_{bb} the reflection amplitudes.

We note that the Schrödinger equation (B.1) may have bounded states with energies $\lambda < \min\{V(a), V(b)\}$. However, we will neglect theses states in the present considerations.

It is well known that the solutions $\widetilde{\psi}_a$, $\widetilde{\psi}_b$ of the Schrödinger equation (B.1) can be obtained by solving (B.1) on the bounded domain Ω_q with appropriate boundary conditions; see, e.g., [8, 22]. Moreover, the Schrödinger operator induced by (B.1) on $L^2(\mathbb{R};\mathbb{C})$ is completely described by the so-called quantum transmitting boundary family, which is a maximal dissipative operator family on $L^2(\Omega_q, \mathbb{C})$; see [4].

The macroscopic quantities such as carrier density and current density are given by

$$\tilde{u}(x) = \sum_{\nu=a,b} \int_{V(\nu)}^{\infty} d\lambda\, f(\lambda - \epsilon_\nu) |\widetilde{\psi_\nu}(\lambda, x)|^2, \quad x \in \Omega_q, \tag{B.2}$$

$$\tilde{j} = \sum_{\nu=a,b} \int_{V(\nu)}^{\infty} d\lambda\, f(\lambda - \epsilon_\nu) \mathrm{Im} \left(\frac{1}{m(x)} \frac{\partial \widetilde{\psi_\nu}(\lambda, x)}{\partial x} \overline{\widetilde{\psi_\nu}(\lambda, x)} \right), \tag{B.3}$$

where $\epsilon_a, \epsilon_b \in \mathbb{R}$ are given Fermi levels and f is a distribution function such as Boltzmann or Fermi–Dirac; see Remark 3.2.

Let us introduce the transmission coefficient $T(\lambda)$ given by

$$T(\lambda) := \frac{v_b(\lambda)}{v_a(\lambda)} |S_{ba}(\lambda)|^2, \qquad \lambda \in (V_{max}, \infty), \tag{B.4}$$

where $V_{max} = \max\{V(a), V(b)\}$. The current density $\tilde{j}$ can then be written as

$$\tilde{j} = \frac{1}{2\pi} \int_{V_{max}}^{\infty} d\lambda\, T(\lambda) \Big(f(\lambda - \epsilon_a) - f(\lambda - \epsilon_b) \Big) \tag{B.5}$$

(see, e.g., [4, 8, 22]). From (B.5) we observe that only the wave functions $\widetilde{\psi_\nu}(\lambda, x)$, $\nu = a, b$, with energies larger than V_{max}, contribute to the current.

B.2. Dissipative approximation. In [4] it is shown that the Schrödinger model considered in the previous section and the dissipative Schrödinger model coincide for fixed energies. In this section we will use this correspondence to derive a dissipative approximation.

Let $\widetilde{\psi_\nu}$, $\nu = a, b$, be the scattering solutions of the Schrödinger equation (B.1). As already mentioned, only the states with energy above V_{max} contribute to the current density. In what follows we are interested in only these states. Assume that δ is a strictly positive constant. We introduce the discrete energies λ_k, $k = 0, 1, \dots$, by

$$\lambda_k := V_{max} + k\,\delta, \qquad k = 0, 1, \dots .$$

Moreover, we introduce

$$\Lambda_k := [\lambda_{k-1}, \lambda_k), \qquad k = 1, 2, \dots .$$

Therefore, the carrier $\tilde{u}$ and current density $\tilde{j}$ (see (B.2), (B.5)) may be written as

$$\tilde{u}(x) = \sum_{k=1}^{\infty} \tilde{u}_k(x), \quad x \in \Omega, \quad \text{and} \quad \tilde{j} = \sum_{j=1}^{\infty} \tilde{j}_k,$$

where

$$\text{(B.6)} \quad \tilde{u}_k(x) := \int_{\Lambda_k} d\lambda \sum_{\nu=a,b} f(\lambda - \epsilon_\nu) |\widetilde{\psi_\nu}(\lambda, x)|^2, \qquad k = 1, 2, \dots, \quad x \in \Omega,$$

$$\text{(B.7)} \qquad \tilde{j}_k \; := \frac{1}{2\pi} \int_{\Lambda_k} d\lambda\, T(\lambda) \left(f(\lambda - \epsilon_a) - f(\lambda - \epsilon_b) \right), \qquad k = 1, 2, \dots .$$

Let δ_0 be a strictly positive constant with $\delta_0 < \delta$. The constants s_k, $k = 1, 2, \dots$, are given by

$$s_k := \lambda_{k-1} + \delta_0, \qquad k = 1, 2, \dots .$$

Note that $s_k \in \Lambda_j$ for each $k = 1, 2, \dots$. Moreover, we define the complex constants

$$\varkappa_a(s_k) := 2i\, v_a(s_k) = i\sqrt{\frac{s_k - V(a)}{2m_a}}, \qquad \varkappa_a(s_k) := 2i\, v_b(s_k) = i\sqrt{\frac{s_k - V(b)}{2m_b}},$$

where $v_\nu(\lambda)$, $\nu = a, b$, are the group velocities defined in section B.1; see also (1.8). Note that $\mathrm{Im}(\varkappa_a(s_k)), \mathrm{Im}(\varkappa_b(s_k)) > 0$ for all $k = 1, 2, \dots$. The maximal dissipative Schrödinger operators defined by (A.1) and (A.2) by means of $\varkappa_a(s_k)$ and $\varkappa_b(s_k)$ are denoted by $H(s_k)$, $k = 1, 2, \dots$, where the potential V is given and fixed. To each maximal dissipative operator $H(s_k)$ there corresponds a minimal self-adjoint dilation $K(s_k)$ (see (A.8), (A.9) in section A.2) and incoming eigenfunctions $\psi_\nu^{(s_k)}(\lambda, x)$, $\nu = a, b$, $k = 1, 2, \dots$; see (A.15). Moreover, the transmission coefficient (A.23) corresponding to each maximal dissipative operator $H(s_k)$ is denoted by $t^{(s_k)}(\lambda)$, $k = 1, 2, \dots$.

In [4] the following relations between the eigenfunctions $\widetilde{\psi_\nu}$ of section B.1 and $\psi_\nu^{(s_k)}$, $\nu = a, b$, are proven:

$$\text{(B.8)} \quad |\widetilde{\psi_\nu}(s_k, x)|^2 = |\psi_\nu^{(s_k)}(s_k, x)|^2 \quad \text{for all } x \in \Omega_q \text{ and } k = 1, 2, \dots, \text{ where } \nu = a, b.$$

Moreover, for the transmission coefficient T from (B.4) and the transmission coefficients $t^{(s_k)}$, $k = 1, 2, \dots$, there is

$$\text{(B.9)} \qquad T(s_k) = t^{(s_k)}(s_k) \quad \text{for all } k = 1, 2, \dots .$$

Using these relations, we may approximate the carrier densities $\tilde{u}_k$ and the current density $\tilde{j}_k$, $k = 1, 2, \dots$, defined by (B.6) and (B.7), respectively, by

$$\widetilde{u}_k(x) \approx u^{(s_k)}(x) \quad \text{and} \quad \widetilde{j}_k \approx j^{(s_k)}, \quad k = 1, 2, \dots,$$

where

$$\begin{aligned} u^{(s_k)}(x) \quad &:= \int_{\Lambda_k} d\lambda \sum_{\nu=a,b} f(\lambda - \epsilon_\nu)|\psi^{(s_k)}(\lambda, x)|^2, \\ j^{(s_k)} &:= \int_{\Lambda_k} d\lambda\, t^{(s_k)}(\lambda)\left(f(\lambda - \epsilon_a) - f(\lambda - \epsilon_b)\right). \end{aligned}$$

Hence, for large $N \in \mathbb{N}$ we obtain

$$\tilde{u}(x) \approx \sum_{k=1}^{N} u^{s_k}(x) \quad \text{and} \quad \tilde{j} = \sum_{k=1}^{N} j^{(s_k)},$$

where $\tilde{u}$ and $\tilde{j}$ are the carrier and current densities given by (B.2) and (B.3), respectively.

Thus, carrier and current densities are approximated by means of a sequence of carrier densities $u^{(s_k)}$ and currents densities $j^{(s_k)}$, which are determined by a sequence of maximal dissipative operators and given statistics. The quantities δ, δ_0, and N are the approximation parameters.

In the case when we choose the rather rough approximation $N = 1$, we obtain

$$\tilde{u}(x) \approx \int_{\Lambda} d\lambda \sum_{\nu=a,b} f(\lambda - \epsilon_\nu)|\psi_\nu(\lambda, x)|^2 \quad \text{and} \quad \tilde{j} \approx \int_{\Lambda} d\lambda\, t(\lambda)(f(\lambda - \epsilon_a) - f(\lambda - \epsilon_b)),$$

where

$$s := V_{max} + \delta_0, \quad t(\lambda) := t^{(s)}(\lambda), \quad \psi_\nu := \psi_\nu^{(s)}, \tag{B.10}$$

and

$$\Lambda := [V_{max}, V_{max} + \delta), \tag{B.11}$$

for some strictly positive δ, δ_0 with $\delta_0 < \delta$. This is the approximation we consider in this paper; see (1.11)–(1.13) and (3.5)–(3.7).

Acknowledgments. We thank N. Ben Abdallah, P. Degond, and H.-Chr. Kaiser for fruitful discussions and thank the Institute “Mathematiques pour l’Industrie et la Physique” in Toulouse for hospitality and financial support. Moreover, we acknowledge the helpful suggestions and comments received from the referees, which improved the quality of the present article.

ON THE MINIMUM PROBLEM FOR NONCONVEX SCALAR FUNCTIONALS*

SANDRO ZAGATTI†

Abstract. We study the minimum problem for scalar nonconvex functionals defined on Sobolev maps satisfying a Dirichlet boundary condition and refine well-known existence results under standard regularity assumptions.

Key words. minimum problem, weak continuity, extremality

AMS subject classification. 49J45

DOI. 10.1137/040612506

1. Introduction.

We consider functionals of the type

$$\mathcal{F}(u) = \int_\Omega f(x, Du(x))dx,$$

where Ω is an open bounded subset of $\mathbb{R}^n$, the Lagrangian $f = f(x, \xi)$ maps $\Omega \times \mathbb{R}^n$ into $\mathbb{R}$, and the competing real valued maps u vary in suitable Sobolev spaces and satisfy a Dirichlet boundary condition.

Our interest is focused on nonsemicontinuous functionals, corresponding to integrands f which are nonconvex in the second variable. In this case the so-called direct method of the calculus of variations does not guarantee the existence of minimizers and the study of the minimum problem associated to $\mathcal{F}$ requires further techniques based on the theory of differential inclusions and on the study of Hamilton–Jacobi equations.

We describe briefly the idea of the procedure: introduce the lower convex envelope of f with respect to the second variable, usually denoted by f^{**}, and the corresponding relaxed functional

$$\overline{\mathcal{F}}(u) = \int_\Omega f^{**}(x, Du(x))dx;$$

if standard growth conditions on f are assumed, so that the functional is coercive on a suitable Sobolev space, the set S of minimizers of $\overline{\mathcal{F}}$ is nonempty and the solution of the minimum problem for the nonconvex functional $\mathcal{F}$ consists in finding an element $\tilde{u} \in S$ such that

$$f^{**}(x, D\tilde{u}(x)) = f(x, D\tilde{u}(x)) \quad \text{for almost every} \quad x \in \Omega. \tag{1}$$

The realization of this program has seen considerable improvements in the last years and we mention the result contained in [14], [6], [12], [7], [1], [3], and the monograph [8] for a review. In the homogeneous case, corresponding to a Lagrangian f which does not depend explicitly on the variable x, the program sketched above has been performed by different methods. Assuming that coercivity holds, the main hypotheses are the following:

†S.I.S.S.A. Via Beirut 2/4 I-34014 Trieste, Italy (zagatti@sissa.it).

(i) the bipolar f^{**} is affine on each connected component of the set

$$X \doteq \{\xi \in \mathbb{R}^n : f(\xi) > f^{**}(\xi)\}\,; \tag{2}$$

(ii) all the minimizers of $\overline{\mathcal{F}}$ are (classically) differentiable at almost every point $x \in \Omega$.

Condition (i) cannot be avoided. As shown in [4] (see also Theorem 2 in section 3 of this paper), if local affinity on X is violated the nonconvex functional fails to have minimizers for arbitrary boundary data and only in special cases, determined by certain compatibility conditions between the datum and the Lagrangian, the minimum problem can be solved. On the other hand it is an open question to establish if condition (ii) can be weakened or suppressed.

The paper [11] treats the nonhomogeneous case (where f depends explicitly on x), and in order to prove the existence of minimizers the authors impose the conditions listed below.

(a) The map $\xi \mapsto f(x,\xi)$ is affine on each connected component of the set

$$X(x) \doteq \{\xi \in \mathbb{R}^n : f(x,\xi) > f^{**}(x,\xi)\}\,;$$

that is to say, assuming for simplicity that $X(x)$ is connected for every x, there exists a C^1 field m and a continuous function q such that

$$\xi \mapsto f^{**}(x,\xi) = \langle m(x), \xi\rangle + q(x) \quad \text{for every } \xi \in X(x).$$

(b) The boundary of the set on which the divergence of the field m vanishes is zero.

(c) The bipolar f^{**} satisfies a strict convexity condition outside $X(x)$; i.e., there exists a nonnegative increasing function ω, vanishing only in zero, such that

$$f^{**}\left(x, \frac{\xi+\eta}{2}\right) \le \frac{1}{2} f^{**}(x,\xi) + \frac{1}{2} f^{**}(x,\eta) - \omega(|\xi-\eta|),$$

for every $x \in \Omega$ such that $X(x)$ is nonempty, for every $\xi \in E(x)$, and for every $\eta \in \mathbb{R}^n \setminus E(x)$, where $E(x) = \{\xi \in \mathbb{R}^n : f^{**}(x,\xi) = \langle m(x), \xi\rangle + q(x)\}$.

(d) All the minimizers of the relaxed functional are continuous on Ω and classically differentiable almost everywhere on Ω.

In addition, in order to guarantee condition (d), a *uniform strict convexity* condition at infinity is imposed so that, in particular, the set valued map $x \mapsto X(x)$ is necessarily uniformly bounded on Ω.

In this paper we propose a new approach to the problem by using the notion of *integro-maximal minimizer*. We now give a brief description of this method applied to the homogeneous case, where it is more transparent. Assume the coercivity of the functional and that conditions (i) and (ii) hold, and consider the nonempty set S of minimizers of $\overline{\mathcal{F}}$ which is compact with respect to strong convergence in $L^1(\Omega)$. The functional

$$S \ni u \mapsto \int_\Omega u(x)dx$$

is continuous with respect to the same topology and then, by the Weierstrass theorem, there exists an element $\overline{u}$ which maximizes it on S, that is to say,

$$\int_\Omega \overline{u}(x)dx \ge \int_\Omega u(x)dx \quad \forall u \in S.$$

The map $\overline{u}$ minimizes $\mathcal{F}$. Roughly speaking, the maximization of the integral *forces* the gradient of $\overline{u}$ to avoid the interior of the set X defined in (2) and to take values at its boundary so that (1) is satisfied.

In the general nonhomogeneous case, the argument is more elaborate, but essentially analogous.

By this method we are able to refine the results contained in the aforementioned papers. We treat separately the homogeneous and the nonhomogeneous case (sections 3 and 4, respectively) since in the first one, which can be taken as a guide for the general one, the hypotheses are minimal. We stress that in section 3 we give essentially a new proof of results already achieved in other papers and, for completeness, we recall also a well-known result [4] which shows that the local affinity of f^{**} is not only sufficient but also necessary for the existence of minimizers for arbitrary boundary data.

In the nonhomogeneous case (section 4), we improve the result contained in [11] by weakening the assumptions specified above. We maintain (d), and in (a)–(b) we require that m is a continuous Sobolev field satisfying conditions which strictly subsume (b) while condition (c) is suppressed. In addition, we do not need strict convexity at infinity so that the set valued map $\Omega \ni x \mapsto X(x)$ is allowed to be not necessarily uniformly bounded.

2. Preliminaries and notations. We denote, respectively, by $\langle\cdot,\cdot\rangle$ and $|\cdot|$ the inner product and the euclidean norm in $\mathbb{R}^n$. For $x \in \mathbb{R}^n$ and $r > 0$, $B(x,r)$ is the open ball in $\mathbb{R}^n$ of center x and of radius r; $\mu(E)$ denotes the Lebesgue measure of a (Lebesgue measurable) subset E of $\mathbb{R}^n$. Throughout the paper Ω is an open bounded subset of $\mathbb{R}^n$. We use the spaces $L^p(\Omega)$, $W^{1,p}(\Omega,\mathbb{R})$, and $W_0^{1,p}(\Omega,\mathbb{R})$, for $1 \le p \le \infty$, with their usual (strong and weak) topologies and use the precise representative of Sobolev functions as defined in [10]; the conjugate exponent of $p \ge 1$ is written $p' \doteq p/(p-1)$. By 1_E we denote the characteristic function of a subset E of $\mathbb{R}^n$, i.e.,

$$1_E(x) \doteq \begin{cases} 1 \text{ for } & x \in E, \\ 0 \text{ for } & x \in \mathbb{R}^n \setminus E. \end{cases}$$

In the proof of our main result we shall need the following well-known argument (see [9] and [14]).

LEMMA 1. *Let U be an open subset of $\mathbb{R}^n$, $p \in [1,\infty]$, $u \in W^{1,p}(U,\mathbb{R})$, $r > 0$. Assume that there exists a point $x_0 \in U$ such that u is differentiable at x_0 (with differential denoted by $Du(x_0)$). Then there exists $\rho > 0$ and maps $u^+, u^- \in W^{1,p}(U,\mathbb{R})$ with the following properties:*

$$\overline{B(x_0,\rho)} \subseteq U; \tag{3}$$

$$u^\pm - u \in W_0^{1,p}(U,\mathbb{R}); \tag{4}$$

$$u(x) \le u^+(x) \textit{ for a.e. } x \in B(x_0,\rho); \tag{5}$$

$$u(x) \ge u^-(x) \textit{ for a.e. } x \in B(x_0,\rho); \tag{6}$$

$$A^+ \doteq \{x \in U\colon u^+(x) > u(x)\} \textit{ is nonempty and } A^+ \subseteq B(x_0,\rho); \tag{7}$$

$$A^- \doteq \{x \in U\colon u^-(x) < u(x)\} \textit{ is nonempty and } A^- \subseteq B(x_0,\rho); \tag{8}$$

$$\begin{cases} |Du^\pm(x) - Du(x_0)| = r & \textit{for a.e. } x \in A^\pm; \\ Du^\pm(x) = Du(x) & \textit{for a.e. } x \in U \setminus A^\pm; \end{cases} \tag{9}$$

$$\int_\Omega u^+ dx > \int_\Omega u\, dx; \tag{10}$$

(11) $$\int_\Omega u^- dx < \int_\Omega u\, dx;$$

for every field $l \in W^{1,p'}(B(x_0,\rho),\mathbb{R}^n)$, *we have*

(12) $$\int_{B(x_0,\rho)} \langle l, (Du^\pm - Du)\rangle dx = -\int_{B(x_0,\rho)} \operatorname{div}\, l \cdot (u^\pm - u) dx.$$

Proof. We give the proof for the map u^+; it will be clear that the construction of u^- is analogous.

Choose a positive ρ such that (3) is satisfied. Since u is differentiable at x_0 there exists $s > 0$ such that

(13) $$\frac{s}{r} \le \rho$$

and

(14) $$\left| \frac{u(x) - u(x_0) - \langle Du(x_0), x - x_0\rangle}{x - x_0} \right| \le \frac{r}{2} \qquad \forall x \in B\left(x_0, \frac{s}{r}\right).$$

Inserting (13) into (14) we have, in particular,

(15) $$u(x) - u(x_0) - \langle Du(x_0), x - x_0\rangle \ge -\frac{s}{2} \qquad \forall x \in B\left(x_0, \frac{s}{r}\right).$$

Define a map w on $B\left(x_0, \frac{s}{r}\right)$ by setting

(16) $$w(x) \doteq \max\left\{ u(x), u(x_0) + \langle Du(x_0), x - x_0\rangle + \frac{s}{4} - r|x - x_0| \right\}$$

and introduce the set

(17) $$A^+ \doteq \left\{ x \in B\left(x_0, \frac{s}{r}\right) : w(x) > u(x) \right\}.$$

The function u is differentiable and then continuous at the point x_0; since the map

(18) $$B(x_0,\rho) \ni x \mapsto u(x_0) + \langle Du(x_0), x - x_0\rangle + \frac{s}{4} - r|x - x_0|$$

is also continuous at the same point and its value is strictly greater than $u(x_0)$, it follows that the set A^+ is nonempty. In addition the map defined in (18) is Lipschitz continuous and then belongs to $W^{1,\infty}\left(B\left(x_0, \frac{s}{r}\right), \mathbb{R}\right)$, which is contained in $W^{1,p}\left(B\left(x_0, \frac{s}{r}\right), \mathbb{R}\right)$; hence, by Stampacchia's theorem, w belongs to the space $W^{1,p}\left(B\left(x_0, \frac{s}{r}\right), \mathbb{R}\right)$ and we have

(19) $$\begin{cases} Dw(x) = Du(x_0) - rD|x - x_0| \quad \text{for a.e. } x \in A, \\ Dw(x) = Du(x) \quad \text{for a.e. } x \in B\left(x_0, \frac{s}{r}\right) \setminus A. \end{cases}$$

We observe that, for any $x \in B\left(x_0, \frac{s}{r}\right)$ such that $|x - x_0| > \frac{3}{4}\frac{s}{r}$, we have, by (15),

$$\begin{aligned} &u(x_0) + \langle Du(x_0), x - x_0\rangle + \frac{s}{4} - r|x - x_0| \\ &\quad < u(x_0) + \langle Du(x_0), x - x_0\rangle + \frac{s}{4} - \frac{3}{4}s \\ &\quad = u(x_0) + \langle Du(x_0), x - x_0\rangle - \frac{s}{2} \\ &\quad \le u(x). \end{aligned}$$

Hence

$$A^+ \subseteq B\left(x_0, \frac{s}{r}\right) \tag{20}$$

and the map w coincides with u on $B\left(x_0, \frac{s}{r}\right) \setminus \overline{B\left(x_0, \frac{3}{4}\frac{s}{r}\right)}$. By definition (16) and by standard notions on Sobolev functions (see, for example, [10]), this implies that

$$(w-u)\,|_{B\left(x_0, \frac{s}{r}\right)} \in W_0^{1,p}\left(B\left(x_0, \frac{s}{r}\right), \mathbb{R}\right). \tag{21}$$

Now we set

$$u^+(x) \doteq \begin{cases} w(x) & \text{for } x \in B\left(x_0, \frac{s}{r}\right), \\ u(x) & \text{for } x \in U \setminus B\left(x_0, \frac{s}{r}\right). \end{cases} \tag{22}$$

From (16), (20) (and the consideration which follows), (21), and (22) we obtain that u^+ lies in $W^{1,p}(U, \mathbb{R})$. We see now that conditions (4)–(12) hold. Property (4) is a trivial consequence of (16), (21), and (22); (5) follows trivially from definitions (16) and (22). Condition (7) has been already proved and, in order to show (9), we observe that, by (19) and (22), we have that $|Du^+(x) - Du(x_0)| = rD|x - x_0| = r$ for almost every $x \in A$ and that $Du^+(x) = Du(x)$ for almost every $x \in U \setminus A$. Inequality (10) is a consequence of (5) and of the fact that the open set A, being nonempty, has positive measure. Formula (12) follows from (22), (21), and the divergence theorem.

The map u^- can be defined by changing the sign of the second argument in definition (16) and, by analogous arguments, obtaining properties (6), (8), and (11) in place of (5), (7), and (10).

Hence the proof is finished.

3. The homogeneous case. We consider a lower semicontinuous function $f\colon \mathbb{R}^n \to \mathbb{R}$, consider its bipolar f^{**}, and define the set

$$X \doteq \left\{\xi \in \mathbb{R}^d \colon f(\xi) > f^{**}(\xi)\right\}. \tag{23}$$

The lower semicontinuity of f and the continuity of f^{**} imply that X is open.

For $p \in [1, \infty]$ and given $u_0 \in W^{1,p}(\Omega, \mathbb{R})$, we introduce the functionals

$$\mathcal{F}(u) = \int_\Omega f(Du(x))dx, \qquad u \in u_0 + W_0^{1,p}(\Omega, \mathbb{R});$$

$$\overline{\mathcal{F}}(u) = \int_\Omega f^{**}(Du(x))dx, \qquad u \in u_0 + W_0^{1,p}(\Omega, \mathbb{R}).$$

We need the following hypotheses.

Hypothesis H1. The function f^{**} is locally affine on the set X. In other words, for every $\eta \in X$ there exists $r(\eta) > 0$, $m(\eta) \in \mathbb{R}^n$, and $q(\eta) \in \mathbb{R}$ such that $B(\eta, r(\eta)) \subset X$,

$$f^{**}(\xi) = \langle m(\eta), \xi\rangle + q(\eta) \quad \forall \xi \in B(\eta, r(\eta)) \quad \text{and} \tag{24}$$

$$f^{**}(\xi) \geq \langle m(\eta), \xi\rangle + q(\eta) \quad \forall \xi \in \mathbb{R}^n. \tag{25}$$

In our result we require that the set of minimizers of the functional $\overline{\mathcal{F}}$ is nonempty and sequentially compact with respect to the strong topology of $L^1(\Omega)$. In addition we need all minimizers to be classically differentiable almost everywhere in Ω. These facts are ensured by the following conditions (see [3]).

Hypothesis H2.

$$\begin{array}{lll} 1 < p \le n, & \exists\, a,b,c,d > 0: & a|\xi|^p - b \le f(\xi) \le c|\xi|^p + d \quad \forall \xi \in \mathbb{R}^n, \\ n < p < \infty, & \exists\, a,b > 0: & f(\xi) \ge a|\xi|^p - b \quad \forall \xi \in \mathbb{R}^n, \\ p = \infty & \exists\, K > 0: & f(\xi) = +\infty \quad \forall \xi \in \mathbb{R}^n: \ |\xi| \ge K. \end{array}$$

Remark 1. It is well known that the convexity of f^{**} is equivalent to the sequential lower semicontinuity of $\overline{\mathcal{F}}$ with respect to the weak (weak* when $p = \infty$) topology of $W^{1,p}(\Omega, \mathbb{R})$. Hence Hypothesis H2 guarantees that the functional $\overline{\mathcal{F}}$ admits at least one minimizer.

Remark 2. Let $u_0 \in W^{1,p}(\Omega, \mathbb{R})$. If f satisfies H2, by previous considerations the set S of minimizers of $\overline{\mathcal{F}}$ is nonempty. Suppose that there exists $\tilde{u}$ such that $D\tilde{u}(x) \in \mathbb{R}^n \setminus X$ for almost every $x \in \Omega$. Then $\tilde{u}$ is a minimizer of $\mathcal{F}$. Indeed, since $f(\xi) \ge f^{**}(\xi)$ for every $\xi \in \mathbb{R}^n$, we have that $\inf \mathcal{F} \le \min \overline{\mathcal{F}}$. Since $f(D\tilde{u}(x)) = f^{**}(D\tilde{u}(x))$ for almost every $x \in \Omega$, it turns out that

$$\mathcal{F}(\tilde{u}) = \int_\Omega f(D\tilde{u}(x))dx = \int_\Omega f^{**}(D\tilde{u}(x))dx = \min \overline{\mathcal{F}} \le \inf \mathcal{F}.$$

We are ready to prove the main result of this section.

THEOREM 1. *Let $p \in [1, \infty]$ and $u_0 \in W^{1,p}(\Omega, \mathbb{R})$. Let $f : \mathbb{R}^d \to \mathbb{R}$ be a lower semicontinuous function satisfying* H1. *Assume that the set S of minimizers of $\overline{\mathcal{F}}$ is nonempty and sequentially compact with respect to the strong topology of $L^1(\Omega)$. Assume that all the elements of S are differentiable almost everywhere in Ω. Then the functional $\mathcal{F}$ attains its minimum.*

Proof. The functional

$$S \ni u \mapsto \int_\Omega u(x)dx$$

is continuous with respect to the strong topology of $L^1(\Omega)$. Hence, by the Weierstrass theorem, there exists $\overline{u} \in S$ such that

$$\int_\Omega \overline{u}(x)dx \ge \int_\Omega u(x)dx \quad \forall u \in S. \tag{26}$$

Claim. The map $\overline{u}$ minimizes $\mathcal{F}$.

We prove that $D\overline{u}(x)$ lies in the set $\mathbb{R}^n \setminus X$ for every $x \in \Omega$ such that $\overline{u}(x)$ is differentiable at x, so that the claim will be proved by Remark 2.

We argue by contradiction: assume that there exists a point $x_0 \in \Omega$ such that $\overline{u}$ is differentiable at x_0 and $D\overline{u}(x_0) \in X$. Recalling Hypothesis H1, we select $\overline{r}$ in such a way that

$$0 < \overline{r} < r\left(D\overline{u}(x_0)\right). \tag{27}$$

Taking a positive we apply Lemma 1 with Ω, $\overline{u}$, $\overline{r}$ in place of U, u, r, respectively, and obtain a map $\overline{u}^+$ satisfying the following conditions:

$$\overline{u}^+ - \overline{u} \in W_0^{1,p}(\Omega, \mathbb{R}); \tag{28}$$

$$A \doteq \{x \in \Omega \colon \overline{u}^+(x) > \overline{u}(x)\} \text{ is nonempty and } A \subseteq B(x_0, \rho); \tag{29}$$

$$\begin{cases} |D\overline{u}^+(x) - D\overline{u}(x_0)| = \overline{r} & \text{for a.e. } x \in A; \\ D\overline{u}^+(x) = D\overline{u}(x) & \text{for a.e. } x \in \Omega \setminus A; \end{cases} \tag{30}$$

$$\int_\Omega \overline{u}^+(x)dx > \int_\Omega \overline{u}(x)dx; \tag{31}$$

$$\int_A D\overline{u}^+(x)dx = \int_A D\overline{u}(x)dx. \tag{32}$$

We have suppressed the superscript + on the set A^+ and remark that equality (32) follows easily from (12), (29), and (30).

First, we prove that $\overline{u}^+$ lies in S. By (28) it belongs to $\overline{u} + W_0^{1,p}(\Omega, \mathbb{R}) = u_0 + W_0^{1,p}(\Omega, \mathbb{R})$ and we can compute, using (30),

$$\begin{aligned} \overline{\mathcal{F}}(\overline{u}^+) &= \int_{\Omega\setminus A} f^{**}(D\overline{u}^+(x))dx + \int_A f^{**}(D\overline{u}^+(x))dx \\ &= \int_{\Omega\setminus A} f^{**}(D\overline{u}(x))dx + \int_A f^{**}(D\overline{u}^+(x))dx. \end{aligned} \tag{33}$$

Again by (30) and by the choice (27) of $\overline{r}$, we have that

$$D\overline{u}^+(x) \in B\left(D\overline{u}(x_0), r\left(D\overline{u}(x_0)\right)\right) \qquad \text{a.e. in } A. \tag{34}$$

Setting for convenience $m = m\left(D\overline{u}(x_0)\right)$, $q = q\left(D\overline{u}(x_0)\right)$, and using (24), (25), and (32) we have

$$\begin{aligned} \int_A f^{**}(D\overline{u}^+(x))dx &= \int_A \left(\left\langle m, D\overline{u}^+(x)\right\rangle + q\right) dx \\ &= \left\langle m, \int_A D\overline{u}^+(x)dx \right\rangle + q\mu(A) \\ &= \left\langle m, \int_A D\overline{u}(x)dx \right\rangle + q\mu(A) \\ &= \int_A \left(\langle m, D\overline{u}(x)\rangle + q\right) dx \leq \int_A f^{**}(D\overline{u}(x))dx. \end{aligned} \tag{35}$$

Inserting (35) into (33), we have

$$\overline{\mathcal{F}}(\overline{u}^+) = \int_A f^{**}(D\overline{u}^+(x))dx \leq \int_A f^{**}(D\overline{u}(x))dx = \min \mathcal{F}. \tag{36}$$

Hence $\overline{u}^+$ belongs to S so that (31) contradicts (26), and this ends the proof.

Remark 3. In the proof of Theorem 1, in place of the map $\overline{u}$ we may introduce a map $\underline{u} \in S$ such that $\int_\Omega \underline{u}(x)dx \leq \int_\Omega u(x)dx$ for every $u \in S$. By an analogous indirect argument, using the map $\underline{u}^-$ instead of the map $\overline{u}^+$, it can be shown that $\underline{u}$ minimizes $\mathcal{F}$.

According to Theorem 1, the local affinity of f^{**} appears a sufficient condition for the existence of minimizers of $\mathcal{F}$ for arbitrary data. We see now that it is also necessary. This fact is well known and we recall it for completeness. Consider affine boundary data: given $\eta \in \mathbb{R}^n$, set

$$u_\eta(x) \doteq \langle \eta, x \rangle, \qquad x \in \Omega \tag{37}$$

and write

$$\mathcal{F}_\eta(u) = \int_\Omega f(Du(x))dx, \qquad u \in u_\eta + W_0^{1,p}(\Omega, \mathbb{R});$$

$$\overline{\mathcal{F}}_\eta(u) = \int_\Omega f^{**}(Du(x))dx, \qquad u \in u_\eta + W_0^{1,p}(\Omega, \mathbb{R}).$$

We have the following result, the full proof of which is in [4].

THEOREM 2. *Assume that $\mathcal{F}_\eta$ attains its minimum for every $\eta \in \mathbb{R}^n$. Then f^{**} is locally affine on the set X.*

4. The nonhomogeneous case. We consider a lower continuous function $f : \Omega \times \mathbb{R}^n \to \mathbb{R}$ and its bipolar $f^{**} : \Omega \times \mathbb{R}^n \to \mathbb{R}$. For every $x \in \Omega$ we introduce the set

$$X(x) \doteq \{\xi \in \mathbb{R}^n : f(x, \xi) > f^{**}(x, \xi)\}. \tag{38}$$

Given $p \in [1, \infty]$ and $u_0 \in W^{1,p}(\Omega, \mathbb{R})$, we consider the functionals

$$\mathcal{F}(u) = \int_\Omega f(x, Du(x))dx, \qquad u \in u_0 + W^{1,p}(\Omega, \mathbb{R});$$

$$\overline{\mathcal{F}}(u) = \int_\Omega f^{**}(x, Du(x))dx, \qquad u \in u_0 + W^{1,p}(\Omega, \mathbb{R}).$$

We need a version of the affinity condition (H1) introduced in the previous section which refines the one used in [11], which is recalled in points (a)–(b) in the introduction of this paper. We assume that the function f^{**} is continuous on $\Omega \times \mathbb{R}^n$, hence for every $x \in \Omega$ the set $X(x)$ is the countable union of its connected components $X_j(x)$,

$$X(x) = \bigcup_{j=1}^{\infty} X_j(x). \tag{39}$$

Hypothesis H3. For every $j \in \mathbb{N}$ we set

$$\Omega_{X_j} \doteq \{x \in \Omega : X_j(x) \text{ is nonempty}\} \tag{40}$$

and assume that, for every $j \in \mathbb{N}$, there exists a field $m_j \in W^{1,p'}_{\mathrm{loc}}(\Omega_{X_j}, \mathbb{R}^n) \cap C^0(\Omega_{X_j}, \mathbb{R}^n)$ and a map $q_j \in C^0(\Omega_{X_j}, \mathbb{R})$ such that

$$f^{**}(x, \xi) = \langle m_j(x), \xi \rangle + q_j(x) \quad \forall x \in \Omega_{X_j} \text{ and } \forall \xi \in X_j(x) \tag{41}$$

and

$$f^{**}(x, \xi) \geq \langle m_j(x), \xi \rangle + q_j(x) \quad \forall x \in \Omega_{X_j} \text{ and } \forall \xi \in \mathbb{R}^n. \tag{42}$$

We assume that for every j the function $\operatorname{div} m_j$ admits a measurable extension on the whole Ω, still denoted by $\operatorname{div} m_j$, satisfying the following condition:

(43) For every $j \in \mathbb{N}$ and for almost every $x \in \Omega$, there exists an open neighborhood U of x contained in Ω such that either $\operatorname{div} m_j \geq 0$ almost everywhere on U or $\operatorname{div} m_j \leq 0$ almost everywhere on U.

In particular, if the boundary of Ω_{X_j} has measure zero, we may extend $\operatorname{div} m_j$ by zero on $\Omega \setminus \Omega_{X_j}$. We stress that if m_j is of class C^1, condition (43) is automatically satisfied if hypothesis (b) in the introduction holds.

Remark 4. Since f is lower semicontinuous and f^{**} is continuous, the set $X_j(x)$ is open for every $j \in \mathbb{N}$ and for every $x \in \Omega$. Hence, recalling (39) and (40), the set Ω_{X_j} is also open for every j. In particular, given $x_0 \in \Omega_{X_j}$ and $\xi_0 \in X_j(x_0)$, there exists $r > 0$ such that for every $x \in \Omega$ and for every $\xi \in \mathbb{R}^n$ such that $|x - x_0| < r$ and $|\xi - \xi_0| < r$, we have $x \in \Omega_{X_j}$ and $\xi \in X_j(x)$. To see this fact, take $x_0 \in \Omega_{X_j}$ and $\xi_0 \in X_j(x_0)$ and assume, by contradiction, that there exists two sequences (x_k) and (ξ_k) such that $x_k \to x_0$ and $\xi_k \to \xi_0$ and $\xi_k \notin X_j(x_k)$. By the definition of f^{**} and of X_j this means that $f(x_k, \xi_k) = f^{**}(x_k, \xi_k)$, and from this we obtain

$$f(x_0, \xi_0) \leq \liminf f(x_k, \xi_k) = \lim f^{**}(x_k, \xi_k) = f^{**}(x_0, \xi_0).$$

This contradicts that ξ_0 belongs to $X_j(x_0)$. The fact that the Ω_{X_j}'s are open justifies the assumption that m_j belongs to $W^{1,p'}(\Omega_{X_j}, \mathbb{R}^n)$, which is made in Hypothesis H3.

Definition 1. *Fix $j \in \mathbb{N}$. By condition (43) there exists a null set $N \subset \Omega$ such that for every $x \in \Omega \setminus N$ there exists $\rho_x > 0$ such that $\operatorname{div} m_j$ has definite sign almost everywhere on $B(x, \rho)$ for every $\rho \in]0, \rho_x[$. Call $B_j^+(x, \rho)$ the open balls on which $\operatorname{div} m_j \geq 0$ a.e. and $B_j^-(x, \rho)$ the open balls on which $\operatorname{div} m_j \leq 0$ a.e. The collection*

$$\left\{B_j^+(x, \rho), B_j^-(x, \rho) : x \in \Omega, \rho \in]0, \rho_x[\right\}$$

is a Vitali covering of $\Omega \setminus N$, hence, by the Vitali covering lemma, there exists a sequence of positive numbers (ρ_k) and a sequence (x_k) in $\Omega \setminus N$ such that the elements of the countable family

$$\left\{B_j^+(x_k, \rho_k), B_j^-(x_k, \rho_k), k \in \mathbb{N}\right\}$$

are pairwise disjoint and the set

$$(\Omega \setminus N) \setminus \left(\cup_{k \in \mathbb{N}} \left(B_j^-(x_k, \rho_k) \cup B_j^+(x_k, \rho_k)\right)\right)$$

has measure zero.

Now, for every $j \in \mathbb{N}$, we set

$$V_j^+ \doteq \bigcup_{k \in \mathbb{N}} B_j^+(x_k, \rho_k), \qquad V_j^- \doteq \bigcup_{k \in \mathbb{N}} B_j^-(x_k, \rho_k) \tag{44}$$

and define the map

$$\gamma_j \doteq 1_{V_j^+} - 1_{V_j^-}. \tag{45}$$

Clearly, for every $j \in \mathbb{N}$, γ_j belongs to $L^\infty(\Omega, \mathbb{R})$, $|\gamma_j| \equiv 1$ almost everywhere and, by (43), satisfies the following property.

(46) *For every $j \in \mathbb{N}$ and for almost every $x \in \Omega$, there exists an open ball B contained in Ω such that γ_j is constant almost everywhere on B. If $\gamma_j = +1$ a.e. on B, then $\operatorname{div} m_j \geq 0$ a.e. on B; if $\gamma_j = -1$ a.e. on B, then $\operatorname{div} m_j \leq 0$ a.e. on B.*

Remark 5. We stress that the function γ_j does not coincide with the function $\operatorname{sign}(\operatorname{div} m_j)$ since the value zero for $\operatorname{div} m_j$ is treated differently.

Remark 6. Let $u_0 \in W^{1,p}(\Omega, \mathbb{R})$. By Hypothesis H2' below and by the convexity of f^{**} with respect to the second variable, the set S of minimizers of $\overline{\mathcal{F}}$ is nonempty. Assume that there exists $\tilde{u} \in S$ such that $D\tilde{u}(x) \in \mathbb{R}^n \setminus X(x)$ for almost every $x \in \Omega$. Then $\tilde{u}$ is a minimizer of $\mathcal{F}$. Indeed, since $f(x,\xi) \geq f^{**}(x,\xi)$ for every pair $(x,\xi) \in \Omega \times \mathbb{R}^n$, we have that $\inf \mathcal{F} \geq \min \overline{\mathcal{F}}$. Since, by hypothesis, $f^{**}(x, D\tilde{u}(x)) = f(x, D\tilde{u}(x))$ for almost every $x \in \Omega$, we have

$$\mathcal{F}(\tilde{u}) = \int_\Omega f(x, D\tilde{u}(x))dx = \int_\Omega f^{**}(x, D\tilde{u}(x))dx = \min \overline{\mathcal{F}} \leq \inf \mathcal{F}.$$

As in the previous section, we need differentiability almost everywhere of the minimizers of the functional $\overline{\mathcal{F}}$ and the sequential compactness of the set of its minimizers. Such properties are ensured by the generalization of Hypothesis H2 (see the reference quoted there).

Hypothesis H2'.

$$\begin{array}{lll} 1 < p \leq n, & \exists\, a,b,c,d > 0: & a|\xi|^p - b \leq f(x,\xi) \leq c|\xi|^p + d \ \forall (x,\xi) \in \Omega \times \mathbb{R}^n, \\ n < p < \infty, & \exists\, a,b > 0: & f(x,\xi) \geq a|\xi|^p - b \ \forall (x,\xi) \in \Omega \times \mathbb{R}^n, \\ p = \infty, & \exists\, K > 0: & f(x,\xi) = +\infty \ \forall (x,\xi) \in \Omega \times \mathbb{R}^n: \ |\xi| \geq K. \end{array}$$

Example. An easy example of an integrand satisfying the above hypotheses is the following. Let $a \in C(\overline{\Omega})$ be strictly positive for some x and let $m \in W^{1,\frac{4}{3}}(\Omega, \mathbb{R}^n) \cap C(\Omega)$ be such that $\operatorname{div} m$ satisfies condition (43). Then set

$$f(x,\xi) = \big(\xi^2 - a(x)\big)^2 + \langle m(x), \xi \rangle.$$

Clearly f fulfills the requirements (with $p = 4$) and the set $X(x)$, which is nonempty whenever $a(x) > 0$, coincides with the ball $B(0, \sqrt{a(x)})$. Indeed, we have

$$f^{**}(x,\xi) = \begin{cases} \langle m(x), \xi \rangle, & \xi \in X(x), \\ \big(\xi^2 - a(x)\big)^2 + \langle m(x), \xi \rangle, & \xi \in \mathbb{R}^n \setminus X(x). \end{cases}$$

We are ready to prove the main result of this section.

THEOREM 3. *Let $p \in [1,\infty]$ and $u_0 \in W^{1,p}(\Omega, \mathbb{R})$. Let $f : \Omega \times \mathbb{R}^n \to \mathbb{R}$ be a lower semicontinuous function satisfying* H3*. Assume that the set S of minimizers of $\overline{\mathcal{F}}$ is nonempty and sequentially compact with respect to the strong topology of $L^1(\Omega)$. Assume that all the elements of S are differentiable almost everywhere in Ω. Then the functional $\mathcal{F}$ attains its minimum.*

Proof. Recall the properties of the map γ_1 from Definition 1.

Step 1. The functional

$$S \ni u \mapsto \int_\Omega \gamma_1(x) u(x) dx$$

is continuous with respect to the strong topology of $L^1(\Omega)$; hence the set

$$S_1 \doteq \left\{ u_1 \in S : \int_\Omega \gamma_1(x) u_1(x) dx \geq \int_\Omega \gamma_1(x) u(x) dx \ \forall u \in S \right\} \tag{47}$$

is nonempty and sequentially compact with respect to the same topology.

Claim. The set

$$\{x \in \Omega : Du_1(x) \in X_1(x)\}$$

has measure zero for every $u_1 \in S_1$.

We prove that given any $u_1 \in S_1$, $Du_1(x) \in \mathbb{R}^n \setminus X_1(x)$ for every $x \in \Omega$ at which u_1 is differentiable. Assume, by contradiction, that there exists $x_0 \in \Omega$ at which u_1 is differentiable with $Du_1(x_0) \in X_1(x_0)$. Recalling Remark 4, we can find $r > 0$ and $\rho > 0$ such that γ_1 is constant almost everywhere on $B(x_0, \rho)$ and

$$B(x_0, \rho) \subseteq \Omega_{X_1}, \qquad \overline{B(Du_1(x_0), r)} \subseteq X_1(x). \tag{48}$$

Suppose, to fix ideas, that

$$\gamma_1 = +1 \quad \text{a.e. in } B(x_0, \rho); \tag{49}$$

that is to say, recalling Definition 1 and (45),

$$\operatorname{div} m_1 \geq 0 \quad \text{a.e. in } B(x_0, \rho). \tag{50}$$

We apply Lemma 1 with r and ρ chosen above and with the map u_1 in place of u, obtaining a map u_1^+ satisfying (4), (5), (7), (9), (10), and (12). By (9) and (48) we have

$$Du_1^+(x) \in X_1(x) \quad \text{for a.e. } x \in A^+. \tag{51}$$

First we prove that u_1^+ lies in S. Property (4) implies that u_1^+ belongs to $u_1 + W_0^{1,p}(\Omega, \mathbb{R}) = u_0 + W_0^{1,p}(\Omega, \mathbb{R})$. Then, using (41) and (51), we have that

$$f^{**}(x, Du_1^+(x)) = \big\langle m_1(x), Du_1^+(x)\big\rangle + q_1(x) \quad \text{for a.e. } x \in A^+, \tag{52}$$

while (42) and (48) imply that

$$f^{**}(x, Du_1(x)) \geq \langle m_1(x), Du_1(x)\rangle + q_1(x) \quad \text{for a.e. } x \in B(x_0, \rho). \tag{53}$$

Hence (9) and (52) give

$$\begin{aligned} &\int_{B(x_0,\rho)} f^{**}(x, Du_1^+(x))dx \\ &= \int_{B(x_0,\rho)\setminus A^+} f^{**}(x, Du_1^+(x))dx + \int_{A^+} f^{**}(x, Du_1^+(x))dx \\ &= \int_{B(x_0,\rho)\setminus A^+} f^{**}(x, Du_1(x))dx + \int_{A^+} (\langle m_1(x), Du_1^+(x)\rangle + q_1(x))dx, \end{aligned} \tag{54}$$

while (53) gives

$$\begin{aligned} &\int_{B(x_0,\rho)} f^{**}(x, Du_1(x))dx \\ &\geq \int_{B(x_0,\rho)\setminus A^+} f^{**}(x, Du_1(x))dx + \int_{A^+} (\langle m_1(x), Du_1(x)\rangle + q_1(x))dx. \end{aligned} \tag{55}$$

Subtracting (54) from (55) we obtain

$$
\begin{aligned}
&\int_{B(x_0,\rho)} \left(f^{**}(x, Du_1(x))dx - f^{**}(x, Du_1^+(x))\right) dx \\
&\geq \int_{A^+} \langle m_1(x), Du_1(x) - Du_1^+(x)\rangle dx \\
&= \int_{B(x_0,\rho)} \langle m_1(x), Du_1(x) - Du_1^+(x)\rangle dx,
\end{aligned}
\tag{56}
$$

since Du_1 and Du_1^+ agree on $B(x_0,\rho) \setminus A^+$. Remarking that, by Hypothesis H3, the restriction of the field m_1 to the ball $B(x_0,\rho)$ belongs to $W^{1,p'}(B(x_0,\rho),\mathbb{R})$ and that the restrictions of u_1 and u_1^+ to the same ball lie in $W^{1,p}(B(x_0,\rho),\mathbb{R})$ (recall (4)), we have, by (12), (5), (50), and (56), the following.

$$
\begin{aligned}
&\int_{B(x_0,\rho)} (f^{**}(x, Du_1(x)) - f^{**}(x, Du_1^+(x)))dx \\
&\qquad \geq \int_{B(x_0,\rho)} \operatorname{div} m_1(x)(u_1^+(x) - u_1(x))dx \geq 0.
\end{aligned}
$$

Thus,

$$
\int_{B(x_0,\rho)} f^{**}(x, Du_1^+(x))dx \leq \int_{B(x_0,\rho)} f^{**}(x, Du_1(x))dx. \tag{57}
$$

Hence (9) and (57) imply that

$$
\begin{aligned}
\overline{\mathcal{F}}(u_1^+) &= \int_{\Omega\setminus B(x_0,\rho)} f^{**}(x, Du_1^+(x))dx \\
&\quad + \int_{B(x_0,\rho)} f^{**}(x, Du_1^+(x))dx \\
&\leq \int_{\Omega\setminus B(x_0,\rho)} f^{**}(x, Du_1(x)) \\
&\quad + \int_{B(x_0,\rho)} f^{**}(x, Du_1(x))dx \\
&= \overline{\mathcal{F}}(u_1),
\end{aligned}
$$

and it follows that u_1^+ lies in S. Recalling (5), (7), and (49) we have

$$
\int_\Omega \gamma_1(x)u_1^+(x)dx > \int_\Omega \gamma_1(x)u_1(x)dx, \tag{58}
$$

and this contradicts (47).

If, on the contrary, we have

$$
\gamma_1 = -1 \quad \text{a.e. in } B(x_0,\rho), \tag{59}
$$

we proceed analogously defining a map u_1^- as in Lemma 1 and obtaining the same contradiction inserting (6), (8), and (59) into (57) and into (58).

The claim is so proved.

Step 2. Consider now the set

$$S_2 \doteq \left\{u_2 \in S_1 : \int_\Omega \gamma_2(x)u_2(x)dx \geq \int_\Omega \gamma_2(x)u_1(x)dx \quad \forall u_1 \in S_1\right\},$$

which is nonempty and sequentially compact with respect to the strong topology of $L^1(\Omega)$ by the sequential compactness of S_1, the sequential lower semicontinuity of $\overline{\mathcal{F}}$, and the sequential continuity of the map

$$S_1 \ni u_1 \mapsto \int_\Omega \gamma_2(x)u_1(x)dx.$$

We reproduce the arguments of Step 1. Take $u_2 \in S_2$ and assume, by contradiction, that there exists $x_0 \in \Omega$ at which u_2 is differentiable with $Du_2(x_0) \in X_2(x_0)$. Since both $\operatorname{div} m_1$ and $\operatorname{div} m_2$ have sign in a suitably small ball centered at x_0, by the same argument used previously we get a contradiction and obtain that, for every $u_2 \in S_2$, the set

$$\{x \in \Omega : Du_2(x) \in X_2(x)\}$$

has measure zero for every $u_2 \in S_2$. Then, since $S_2 \subseteq S_1$, we have

$$\mu\left(\{x \in \Omega : Du_2(x) \in X_1(x) \cup X_2(x)\}\right) = 0 \quad \forall u_2 \in S_2. \tag{60}$$

Step 3. Iterating the procedure we obtain a sequence (S_k) of nonempty sequentially compact (with respect to strong topology in $L^1(\Omega)$) subsets of S given by

$$S_k \doteq \left\{u_k \in S_{k-1} : \int_\Omega \gamma_k u_k \, dx \geq \int_\Omega \gamma_k u_{k-1} \, dx \quad \forall u_{k-1} \in S_{k-1}\right\},$$

for which we have, as in (60),

$$\mu\left(\left\{x \in \Omega : Du_k(x) \in \cup_{j=1}^k X_j(x)\right\}\right) = 0 \quad \forall u_k \in S_k. \tag{61}$$

Since, by construction,

$$S \supseteq S_1 \supseteq \cdots \supseteq S_k \supseteq S_{k+1} \supseteq \cdots \quad \forall k, \tag{62}$$

the set

$$S_\infty \doteq \bigcap_{k\in\mathbb{N}} S_k \tag{63}$$

is nonempty.

Take an element $u_\infty \in S_\infty$; by (61), (62), and (63) we have that

$$\mu\left(\left\{x \in \Omega : Du_\infty(x) \in \cup_{j=1}^k X_j(x)\right\}\right) = 0 \quad \forall k \in \mathbb{N}.$$

Hence

$$\mu\left(\{x \in \Omega : Du_\infty(x) \in X_j(x)\}\right) = 0 \quad \forall j \in \mathbb{N},$$

and, consequently,

$$\begin{aligned} &\mu\left(\{x \in \Omega : Du_\infty(x) \in X(x)\}\right) \\ &= \mu\left(\bigcup_{j\in\mathbb{N}} \{x \in \Omega : Du_\infty(x) \in X_j(x)\}\right) \\ &\leq \sum_{j\in\mathbb{N}} \mu\left(\{x \in \Omega : Du_\infty(x) \in X_j(x)\}\right) = 0. \end{aligned} \tag{64}$$

Recalling Remark 6, (64) shows that any element of the nonempty set S_∞ is a minimizer of $\mathcal{F}$. This ends the proof.

Remark 7. It is hard to establish if the condition (43) is necessary for the existence of minimizers of the nonconvex functional since, if it is violated, what fails is a contradictory argument. It is clear from the proof of Theorem 3 that the gradient of any minimizer of the relaxed functional (and not only the one of the maximal function $\overline{u}$) must take values away from the open sets contained in $X_j(x)$ in which $\operatorname{div} m_j$ is strictly positive or negative. If not, indeed, it would be possible to reduce the value of the functional by a variation like the one performed in our argument. On the open sets in which $\operatorname{div} m_j$ vanishes, it is the maximization of the integral $\int_\Omega u\,dx$ which forces the gradient to be extremal. If (43) is not fulfilled, the rapid changes of sign of $\operatorname{div} m_j$ may induce oscillations of minimizing sequences so that the gradient of all the minimizers may coalesce inside the "bad" set $X_j(x)$.

GLOBAL SOLUTIONS OF THE HUNTER–SAXTON EQUATION*

ALBERTO BRESSAN† AND ADRIAN CONSTANTIN‡

Abstract. We construct a continuous semigroup of weak, dissipative solutions to a nonlinear partial differential equation modeling nematic liquid crystals. A new distance functional, determined by a problem of optimal transportation, yields sharp estimates on the continuity of solutions with respect to the initial data.

Key words. nonlocal conservation law, global conservative solutions, optimal transportation, dissipative solution

AMS subject classifications. 35D05, 49J20, 76A15

DOI. 10.1137/050623036

1. Introduction.

In this paper we investigate the Cauchy problem

$$u_t + \left(\frac{u^2}{2}\right)_x = \frac{1}{4}\left(\int_{-\infty}^{x} - \int_{x}^{\infty}\right) u_x^2\, dx, \qquad u(0,x) = \bar{u}(x). \tag{1.1}$$

Formally differentiating the above equation with respect to the spatial variable x, we obtain

$$(u_t + uu_x)_x = \frac{1}{2}\, u_x^2, \tag{1.2}$$

whereas yet another differentiation leads to

$$u_{txx} + 2u_x u_{xx} + uu_{xxx} = 0. \tag{1.3}$$

Either of the forms (1.2) and (1.3) of the equation in (1.1) is known as the Hunter–Saxton equation. In this paper we analyze various concepts of solutions for the above equations and construct a semigroup of globally defined solutions. Moreover, we introduce a new distance functional, related to a problem of optimal transportation, which monitors the continuous dependence of solutions on the initial data. The global solutions constructed in this paper are dissipative. It is worthwhile to point out that it is possible (and simpler) to construct a corresponding optimal-transport functional for global energy-conserving solutions—see [BF] for an example of a metric valid for conservative solutions of an equation similar to (1.1).

Physical significance. The Hunter–Saxton equation describes the propagation of waves in a massive director field of a nematic liquid crystal [HS], with the orientation of the molecules described by the field of unit vectors $\mathbf{n}(t,x) = (\cos u(t,x), \sin u(t,x))$, x being the space variable in a reference frame moving with the linearized wave velocity, and t being a slow time variable. The liquid crystal state is a distinct phase

of matter observed between the solid and liquid states. More specifically, liquids are isotropic (that is, with no directional order) and without a positional order of their molecules, whereas the molecules in solids are constrained to point only in certain directions and to be only in certain positions with respect to each other. The liquid crystal phase exists between the solid and the liquid phases—the molecules in a liquid crystal do not exhibit any positional order, but they do possess a certain degree of orientational order. Not all substances can have a liquid crystal phase, e.g., water molecules melt directly from solid crystalline ice to liquid water. Liquid crystals are fluids made up of long rigid molecules, with an average orientation that specifies the local direction of the medium. Their orientation is described macroscopically by a field of unit vectors $\mathbf{n}(t,\mathbf{x})$). There are many types of liquid crystals, depending upon the amount of order in the material. Nematic liquid crystals are invariant under the transformation $\mathbf{n} \mapsto -\mathbf{n}$, in which case $\mathbf{n}$ is called a director field, so that the rodlike molecules have no positional order but tend to point in the same direction (along the director). The director field does not remain the same but generally fluctuates. Obtaining the equation governing the director field represents the crucial point for the modeling of nematic liquid crystals since it is advantageous to study the dynamics of the director field instead of studying the dynamics of all the molecules. The fluctuations of the director field are mainly due to the thermodynamical force caused by elastic deformations in the form of twisting, bending, and splaying (the last being a fan-shaped spreading out from the original direction, bending being a change of direction, while twisting corresponds to a rotation of the direction in planes orthogonal to the axis of rotation). Consider director fields that lie on a circle and depend on a single spatial variable x so that twisting is not allowed. To describe the dynamics of the director field independently of the coupling with the fluid flow, let $u(t,x)$ be the perturbation about a constant value. The asymptotic equation for weakly nonlinear unidirectional waves is precisely (1.2), obtained as the Euler–Lagrange equation of the variational principle

$$\delta \int_{t_1}^{t_2} \int_{\mathbb{R}} (u_t u_x + u u_x^2)\, dx dt = 0$$

for the internal stored energy of deformation of the director field if dissipative effects are neglected (corresponding to the case when inertia effects dominate viscosity)—see [HS] for the details of the derivation. Unlike other studies, in the Hunter–Saxton model the kinetic energy of the director field is not neglected. In the asymptotic regime in which (1.2) is derived (see [HS]), the nondimensionalized kinetic energy density is u_x^2 so that the condition

$$\int_{\mathbb{R}} u_x^2(t,x)\, dx < \infty \tag{1.4}$$

has to hold at any fixed time t for a physically meaningful solution to the Hunter–Saxton equation.

Equation (1.1) is also relevant in other physical situations; e.g., it is a high-frequency limit of the Camassa–Holm equation [DP], a nonlinear shallow water equation [CH, J] modeling solitons [CH, CS] as well as breaking waves [CE].

Geometric interpretation. An interesting aspect of the Hunter–Saxton equation (see [KM]) is the fact that, for spatially periodic functions, it describes geodesic flow on the homogeneous space $\mathrm{Diff}(\mathcal{S})/\mathrm{Rot}(\mathcal{S})$ of the infinite-dimensional Lie group

$\mathrm{Diff}(\mathcal{S})$ of smooth orientation-preserving diffeomorphisms of the unit circle $\mathcal{S}$ modulo the rotations $\mathrm{Rot}(\mathcal{S})$, with respect to the right-invariant homogeneous metric $\langle f,\, g\rangle = \int_{\mathcal{S}} f_x g_x\, dx$. The geometric interpretation of the Hunter–Saxton equation establishes a natural connection with the Camassa–Holm equation, which describes geodesic flow on $\mathrm{Diff}(\mathcal{S})$ with respect to the right-invariant metric $\langle f,\, g\rangle = \int_{\mathcal{S}} (fg + f_x g_x)\, dx$; see [K, CK]. A similar geometric interpretation of (1.1) on the diffeomorphism group of the line holds also for smooth initial data $\bar{u}$ in certain weighted function spaces, but the involved technicalities are more intricate (see [C] for the case of the Camassa–Holm equation).

Integrable structure. The Hunter–Saxton equation has an integrable structure. The equation has a reduction (see [BSS, HZ1]) to a finite-dimensional completely integrable Hamiltonian system whose phase space consists of piecewise linear solutions of the form

$$u(t,x) = \sum_{i=1}^{n} \alpha_i(t)\, |x - x_i(t)|, \tag{1.5}$$

with the constraint

$$\sum_{i=1}^{n} \alpha_i(t) = 0, \tag{1.6}$$

the Hamiltonian being

$$H(x,\alpha) = \frac{1}{2} \sum_{i,j=1}^{n} \alpha_i \alpha_j\, |x_i - x_j|.$$

Due to their lack of regularity, functions of the form (1.5) are not classical solutions of (1.2). Below we will discuss in what sense they are weak solutions of the Hunter–Saxton equation. Let us point out that the constraint (1.6) is the necessary and sufficient condition to ensure that the distributional derivative $x \mapsto u_x(t,x)$ of a function of the form (1.5) belongs to the space $L^2(\mathbb{R})$. Thus (1.4) holds.

In the family of smooth functions $u : \mathbb{R} \mapsto \mathbb{R}$ all of whose derivatives $\partial_x^n u$ decay rapidly as $x \to \pm\infty$, the Hunter–Saxton equation is bi-Hamiltonian [HZ1]. If D^{-1} is the skew-adjoint antiderivative operator given by

$$(D^{-1}f)(x) = \frac{1}{2}\left(\int_{-\infty}^{x} - \int_{x}^{\infty}\right) f(x)\, dx, \qquad f \in \mathcal{D}(\mathbb{R}),$$

the first Hamiltonian form for the Hunter–Saxton equation is

$$u_t = J_1 \frac{\delta \mathcal{H}_1}{\delta u}, \qquad J_1 = u_x D^{-2} - D^{-2} u_x, \qquad \mathcal{H}_1 = \frac{1}{2}\int_{\mathbb{R}} u_x^2\, dx,$$

whereas the second, compatible Hamiltonian structure is

$$u_t = J_2 \frac{\delta \mathcal{H}_2}{\delta u}, \qquad J_2 = D^{-1}, \qquad \mathcal{H}_2 = \frac{1}{2}\int_{\mathbb{R}} u u_x^2\, dx.$$

Moreover, the Hunter–Saxton equation is formally integrable; e.g., it has an associated Lax pair (see [BSS]). However, the complete integrability of the equation has been established only in the previously mentioned case when it reduces to a finite-dimensional dynamical system.

The notion of solution. Physically relevant solutions of the Hunter–Saxton equation need to be of finite kinetic energy so that (1.4) must hold. This leads naturally to functions $u(t,x)$ with distributional derivative $u_x(t,\cdot)$ square integrable at every instant t. Note that the integrability assumption $u_x(t,\cdot) \in L^2(\mathbb{R})$ already imposes a certain degree of regularity on the function u. This suggests that it might be possible to incorporate a reasonably high degree of regularity in the concept of weak solutions to the Hunter–Saxton equation. Let us first consider the concept of weak solutions introduced by Hunter and Zheng [HZ2].

DEFINITION 1.1. *A function $u(t,x)$ defined on $[0,T] \times \mathbb{R}$ is a solution of* (1.2) *if the following hold:*

(i) $u \in C([0,T] \times \mathbb{R}; \mathbb{R})$ *and* $u(0,x) = \bar{u}(x)$ *pointwise on* $\mathbb{R}$.

(ii) *For each $t \in [0,T]$, the map $x \mapsto u(t,x)$ is absolutely continuous with $u_x(t,\cdot) \in L^2(\mathbb{R})$. Moreover, the map $t \mapsto u_x(t,\cdot)$ belongs to the space $L^\infty([0,T]; L^2(\mathbb{R}))$ and is locally Lipschitz continuous on $[0,T]$ with values in $H^{-1}_{loc}(\mathbb{R})$.*

(iii) *Equation* (1.2) *holds in the sense of distributions.*

Here and below, by a mapping f that is locally Lipschitz or locally bounded on $[0,T]$ with values in $H^{-1}_{loc}(\mathbb{R})$ we understand the following: for every $n \geq 1$ there is a constant $K_n \geq 0$ such that

$$\sup_{\{\psi \in \mathcal{D}(-n,n):\ \|\psi\|_{H^1(\mathbb{R})} \leq 1\}} \big|\langle f(t) - f(s), \psi\rangle\big| \leq K_n\, |t-s|, \qquad t,s \in [0,T],$$

respectively,

$$\sup_{\{\psi \in \mathcal{D}(-n,n):\ \|\psi\|_{H^1(\mathbb{R})} \leq 1\}} \big|\langle f(t), \psi\rangle\big| \leq K_n, \qquad t \in [0,T].$$

Here $\mathcal{D}(a,b)$ is the family of smooth functions $f : \mathbb{R} \to \mathbb{R}$ with compact support within $(a,b) \subset \mathbb{R}$.

To a function $u : [0,T] \times \mathbb{R} \to \mathbb{R}$ with the above properties associate the function $F : [0,T] \times \mathbb{R} \to \mathbb{R}$ defined by

$$F(t,x) = \frac{1}{4}\left(\int_{-\infty}^{x} - \int_{x}^{\infty}\right) u_x^2\, dx. \tag{1.7}$$

Then $F \in L^\infty_{loc}([0,T] \times \mathbb{R}; \mathbb{R}) \subset L^2_{loc}([0,T] \times \mathbb{R}; \mathbb{R})$. Moreover, $F_x = \frac{1}{2}\, u_x^2$ so that (1.2) becomes

$$(u_t + uu_x - F)_x = 0 \tag{1.8}$$

in the sense of distributions. Note that $uu_x \in L^2_{loc}([0,T] \times \mathbb{R}; \mathbb{R})$. From (1.8) we infer the existence of a distribution $h(t)$ so that $u_t + uu_x - F = h(t) \otimes 1(x)$, where $1(x)$ stands for the constant function with value 1 on $\mathbb{R}$. If $H(t)$ is a primitive of the distribution $h(t)$, we deduce that the distribution $U = u - H(t) \otimes 1(x)$ satisfies $U_t = u_t - h(t) \otimes 1(x) = F - uu_x \in L^2_{loc}([0,T] \times \mathbb{R}; \mathbb{R})$ and $U_x = u_x \in L^2_{loc}([0,T] \times \mathbb{R}; \mathbb{R})$. Therefore $U \in H^1_{loc}([0,T] \times \mathbb{R})$. Moreover, since $U_t = F - uu_x \in L^\infty_{loc}([0,T]; H^{-1}_{loc}(\mathbb{R}))$ ensures that U is locally Lipschitz as a function from $[0,T]$ to $H^{-1}_{loc}(\mathbb{R})$ and so is u, we deduce that $h(t) \otimes 1(x) = u - U$ shares this property too. But then $h : [0,T] \to \mathbb{R}$ has to be Lipschitz continuous. We infer that $u = U + H(t) \otimes 1(x)$ belongs to the space $H^1_{loc}([0,T] \times \mathbb{R})$. Since requirement (iii) in Definition 1.1 ensures that the identity

$$\int_0^T \int_{\mathbb{R}} \left(\phi_{xt} u + \frac{1}{2}\, \phi_{xx} u^2 - \frac{1}{2}\, \phi u_x^2\right) dx dt = 0$$

holds for every smooth function $\phi : (0,T)\times\mathbb{R} \to \mathbb{R}$ with compact support in $(0,T)\times\mathbb{R}$, we see that the notion of weak solution in the sense of Definition 1.1 is stronger than the concept of weak solution introduced by Hunter and Saxton [HS]. Another useful conclusion that can be drawn from the previous considerations is that for a function u with regularity properties specified in (i)–(ii) of Definition 1.1, requirement (iii) from Definition 1.1 is equivalent to asking that the equation

$$u_t + uu_x = F + h(t) \otimes 1(x) \tag{1.9}$$

hold in the distribution sense for some Lipschitz continuous function $h : [0,T] \to \mathbb{R}$. Any such function h is admissible. Among all these possibilities the most natural one corresponds to the special choice $h \equiv 0$. This leads us to the form (1.1) of the Hunter–Saxton equation.

In the following, we say that a map $t \mapsto u(t,\cdot)$ from $[0,T]$ into $\mathbf{L}^p_{loc}(\mathbb{R})$ is *absolutely continuous* if, for every bounded interval $[a,b]$, the restriction of u to $[a,b]$ is absolutely continuous as a map with values in $\mathbf{L}^p\big([a,b]\big)$. We can thus adopt the following notion of a weak solution.

Definition 1.2. *A function $u(t,x)$ defined on $[0,T]\times\mathbb{R}$ is a solution of* (1.2) *if the following hold:*

(i) *$u \in C([0,T]\times\mathbb{R};\mathbb{R})$ and $u(0,x) = \bar{u}(x)$ pointwise on $\mathbb{R}$.*

(ii) *For each $t \in [0,T]$, the map $x \mapsto u(t,x)$ is absolutely continuous with $u_x(t,\cdot) \in L^2(\mathbb{R})$. Moreover, the map $t \mapsto u_x(t,\cdot)$ belongs to the space $L^\infty([0,T];L^2(\mathbb{R}))$.*

(iii) *The map $t \mapsto u(t,\cdot) \in L^2_{loc}(\mathbb{R})$ is absolutely continuous and satisfies* (1.1) *for almost every $t \in [0,T]$.*

The concept of solution introduced in Definition 1.2 is stronger than that corresponding to Definition 1.1. Indeed, for a function u satisfying all the requirements of Definition 1.2 we infer by (1.1) that $u_{tx} \in L^\infty_{loc}([0,T];H^{-1}_{loc}(\mathbb{R}))$ since $u_t = -uu_x + F$ and uu_x, $F \in L^\infty_{loc}([0,T];L^2_{loc}(\mathbb{R}))$. This yields that the map $t \mapsto u_x(t,\cdot)$ is locally Lipschitz continuous on $[0,T]$ with values in $H^{-1}_{loc}(\mathbb{R})$. We thus recover the apparently missing part from requirement (ii) in Definition 1.1.

We remark that even with this stronger definition, solutions are far from unique. For example, consider the initial data

$$\bar{u}(x) = 0. \tag{1.10}$$

There are now two ways to prolong the solution for times $t > 0$. On one hand, we can define

$$u(t,x) = 0, \qquad x \in \mathbb{R}, \quad t \geq 0. \tag{1.11}$$

On the other hand, the function

$$u(t,x) \doteq \begin{cases} -2t & \text{if} \quad x \leq -t^2 \\ \frac{2x}{t} & \text{if} \quad |x| < t^2 \\ 2t & \text{if} \quad x \geq t^2 \end{cases} \quad \text{for} \quad t \geq 0, \tag{1.12}$$

provides yet another solution. To distinguish between these two solutions, we need to consider the evolution equation satisfied by the "energy density" u_x^2, namely,

$$(u_x^2)_t + (uu_x^2)_x = 0. \tag{1.13}$$

For smooth solutions, the conservation law (1.13) is satisfied pointwise. Notice that the solution defined by (1.10), (1.12) satisfies the additional conservation law (1.13) in the distributional sense, i.e.,

$$\int\int_{\mathbb{R}_+\times\mathbb{R}} \left\{u_x^2\varphi_t + uu_x^2\,\varphi_x\right\} dxdt = 0 \tag{1.14}$$

for every test function $\varphi \in \mathcal{C}_c^1(\mathbb{R}_+\times\mathbb{R})$ whose compact support is contained in the half plane where $t > 0$. On the contrary, the solution defined by (1.10)–(1.11) dissipates energy. More precisely, for every $t_2 \geq t_1 \geq 0$ we have

(1.15)
$$\int_{\mathbb{R}} u_x^2(t_2,x)\,\varphi(t_2,x)\,dx - \int_{\mathbb{R}} u_x^2(t_2,x)\,\varphi(t_2,x)\,dx \leq \int_{t_1}^{t_2}\int_{\mathbb{R}} \left\{u_x^2\,\varphi_t + uu_x^2\varphi_x\right\} dxdt$$

for every test function $\varphi \in \mathcal{C}_c^1(\mathbb{R}_+\times\mathbb{R})$. In what follows, we say that a solution is *dissipative* if (1.15) holds for every $t_2 > t_1 > 0$, $\varphi \in \mathcal{C}_c^1(\mathbb{R}_+\times\mathbb{R})$. Notice that the solution (1.10), (1.12) does not satisfy (1.15) when $t_1 = 2$, $t_2 > 0$.

At this point in the discussion it is worthwhile to point out that the most important feature in the definition of weak solutions is the requirement (1.4). A continuous function $u : [0,T]\times\mathbb{R} \to \mathbb{R}$ with square integrable distributional derivative $u_x(t,\cdot)$ belonging to the space $L^\infty([0,T];L^2(\mathbb{R}))$ is not necessarily bounded, nor does it have a predetermined asymptotic behavior at infinity, as one can see from the example

$$u(t,x) = \begin{cases} |x|^{\frac{1}{5}}\ \sin(|x|^{\frac{1}{5}}) & \text{if} \quad t\geq 0,\ |x|\geq 1,\\ |x|^{\frac{2}{3}}\ \sin(|x|^{\frac{2}{3}}) & \text{if} \quad t\geq 0,\ |x|\leq 1. \end{cases}$$

Nevertheless, the possibility that some additional structural information about the behavior of such functions at infinity might be inferred from some invariance properties of the Hunter–Saxton equation should be ruled out. To do this, consider solutions of the type (1.5) with the constraint (1.6). This type of solution enters into the framework of Definition 1.2, and for any $N(t) > \max\{|x_1(t)|,\dots,|x_n(t)|\}$ we have

$$u_t(t,x) = F(x) \qquad \text{a.e. on} \qquad |x| \geq N(t),$$

so that for all $j \geq N(t)$,

$$u_t(t,j) - u_t(-j) = F(j) - F(-j) = \frac{1}{2}\int_{-j}^{j} u_x^2(t,x)\,dx = \frac{1}{2}\int_{\mathbb{R}} u_x^2(t,x)\,dx. \tag{1.16}$$

But the quantity $I = \frac{1}{2}\int_{\mathbb{R}} u_x^2(t,x)\,dx$ is an invariant (time-independent); cf. [HZ1, BSS]. Moreover, the special form of the solutions guarantees that at every fixed $t \geq 0$,

$$u_\infty(t) \doteq \lim_{x\to\infty} u(t,x) = -\sum_{i=1}^{n} \alpha_i(t)\,x_i(t) = -\lim_{x\to-\infty} u(t,x)$$

and $u_\infty(t) = u(t,j) = -u(t,-j)$ for all $j \geq N(t)$. Thus (1.16) yields

$$u_\infty(t) = u_\infty(0) + \frac{1}{2}\,It, \qquad t \geq 0. \tag{1.17}$$

Unless $I = 0$, in which case u is constant, we see from (1.17) that the asymptotic behavior of the solutions changes with time. On the basis of this set of examples we conclude that the asymptotic behavior of the solutions at infinity should not be prescribed a priori. However, the previous set of examples indicates that a possible restriction would be to require $u \in L^\infty([0,T] \times \mathbb{R})$ if $\bar{u} \in L^\infty(\mathbb{R})$. In this case the space of functions introduced in Definition 1.2 (that is, bounded functions with all the properties specified in Definition 1.2 except the condition that u satisfies (1.1) in $L^2[-n,n]$ for every $n \geq 1$) is a Banach space when endowed with the norm

$$\|u\|_T = \sup_{(t,x)\in[0,T]\times\mathbb{R}} \{|u(t,x)|\} + \operatorname*{ess-sup}_{t\in[0,T]} \int_{\mathbb{R}} u_x^2(t,x)\,dx. \tag{1.18}$$

It is also worth noticing that a function entering the framework of Definition 1.2 has further regularity properties that are not explicitly stated. For example, we have the Hölder continuity property

$$|u(t,x) - u(t,y)| \leq K(t)\sqrt{|x-y|}, \qquad t \geq 0,\ x, y \in \mathbb{R},$$

with $K(t) = \|u_x(t,\cdot)\|_{L^2(\mathbb{R})}$, since

$$|u(t,x) - u(t,y)|^2 = \left|\int_x^y u_x(t,\zeta)\,d\zeta\right|^2 \leq |x-y| \cdot \left|\int_x^y u_x^2(t,\zeta)\,d\zeta\right| \leq |x-y| \int_{\mathbb{R}} u_x^2(t,\zeta)\,d\zeta.$$

2. Global existence of dissipative solutions. For twice continuously differentiable solutions, the derivative $v \doteq u_x$ of the solution u to (1.1) satisfies the equations

$$v_t + uv_x = -\frac{v^2}{2}, \tag{2.1}$$

$$(v^2)_t + (uv^2)_x = 0. \tag{2.2}$$

Define the characteristic $t \mapsto \xi(t,y)$ as the solution to the ODE

$$\frac{\partial}{\partial t}\xi(t,y) = u\big(t,\, \xi(t,y)\big), \qquad \xi(0,y) = y. \tag{2.3}$$

From (1.2) it follows that the evolution of the gradient u_x along each characteristic is described by

$$\frac{d}{dt}\,u_x\big(t,\xi(t,y)\big) = -\frac{1}{2}u_x^2\big(t,\xi(t,y)\big). \tag{2.4}$$

Observe that the solution of the ODE

$$\dot{z} = -z^2/2, \qquad z(0) = z_0$$

is given by

$$z(t) = \frac{2z_0}{2 + tz_0}. \tag{2.5}$$

If $z_0 \geq 0$, this solution is defined for all $t \geq 0$, whereas if $z_0 < 0$, this solution approaches $-\infty$ at the blow-up time

$$T(z_0) = -2/z_0. \tag{2.6}$$

Note that if $\bar{u}(x) \not\equiv 0$, then there is some $x_0 \in \mathbb{R}$ with $\bar{u}(x_0) < 0$ so that the characteristic curve $t \mapsto \xi(t, \bar{u}(x_0))$ will blow up in finite time. Nevertheless, if $\liminf_{x\in\mathbb{R}}\{\bar{u}_x(x)\} > -\infty$, then $T_0 > 0$, where

$$T_0 = \inf_{\{x\in\mathbb{R}:\ \bar{u}_x(x)<0\}} \left\{ \frac{-2}{\bar{u}_x(x)} \right\} \geq 0, \tag{2.7}$$

and on the time interval $[0, T_0)$ the method of characteristics can be used to construct the unique solution of (1.1). Let us describe the construction in detail. From (2.3) we get

$$\frac{\partial}{\partial t}\, \xi_x = u_x(t,\xi) \cdot \xi_x = \frac{2\,\bar{u}_x}{2 + t\,\bar{u}_x} \cdot \xi_x \tag{2.8}$$

since

$$u_x(t, \xi(t,y)) = \frac{2\,\bar{u}_x(y)}{2 + t\,\bar{u}_x(y)} \tag{2.9}$$

in view of (2.4) and the solution formula (2.5). The unique solution of the linear ODE (2.7) with initial data $\xi_x(0,y) = 1$ is given by

$$\xi_x(t,y) = \left(1 + \frac{t}{2}\,\bar{u}_x(y)\right)^2. \tag{2.10}$$

Since $1 + \frac{t}{2}\,\bar{u}_x(y) > 0$ for $t \in [0, T_0)$, relation (2.10) shows that for each $t \in [0, T_0)$ the map $y \mapsto \xi(t,y)$ is an absolutely continuous increasing diffeomorphism of the line. Define the absolutely continuous function φ by

$$\varphi(y) = \frac{1}{4} \int_{\mathbb{R}} \operatorname{sign}(y - x)\,\bar{u}_x^2(x)\,dx \tag{2.11}$$

so that $\varphi_y(y) = \frac{1}{2}\,\bar{u}_x^2(y)$. Note that by (2.10),

$$\xi_{tx} = \bar{u}_x + t\,\frac{\bar{u}_x^2}{2}. \tag{2.12}$$

Since $\xi_t(0,y) = \bar{u}(y)$ as $\xi(0,y) = y$, integration of (2.12) with respect to the spatial variable x yields

$$\xi_t(t,y) = \bar{u}(y) + \frac{t}{4} \int_{\mathbb{R}} \operatorname{sign}(y - x)\,\bar{u}_x^2(x)\,dx \tag{2.13}$$

and thus

$$\xi(t,y) = y + \int_0^t \xi_t(s,y)\,ds = y + t\,\bar{u}(y) + \frac{t^2}{8} \int_{\mathbb{R}} \operatorname{sign}(y - x)\,\bar{u}_x^2(x)\,dx. \tag{2.14}$$

The value of the solution u along the characteristic curve $t \mapsto \xi(t,y)$ is

$$u(t, \xi(t,y)) = \bar{u}(y) + \frac{t}{4} \int_{\mathbb{R}} \operatorname{sign}(y - x)\,\bar{u}_x^2(x)\,dx. \tag{2.15}$$

This relation is obtained by combining (2.13) with (2.3). The increasing diffeomorphism of the line $y \mapsto \xi(t,y)$ given by (2.14) and formula (2.15) yield the unique solution of the Hunter–Saxton equation on the time interval $[0, T_0)$. The above approach works as long as $2 + t\,\bar{u}_x(x) > 0$ but breaks down at $T = T_0$ with T_0 given by (2.7). The reason for the breakdown is that

$$\liminf_{t\uparrow T_0} \left\{ \inf_{x\in\mathbb{R}} u_x(t,x) \right\} = -\infty \tag{2.16}$$

in view of (2.9) and the definition (2.7) of T_0. Note that at $t = T_0$ we might have $\xi_x(t,x) = 0$ for all $x \in (a,b) \subset \mathbb{R}$ so that the map $y \mapsto \xi(t,y)$ is no longer an increasing diffeomorphism of the line. Nevertheless, the previous considerations suggest the following approach in the general case when $\bar{u}_x \in L^2(\mathbb{R})$, covering situations when possibly $T_0 = 0$ as it is the case for, e.g., $\bar{u}(x) = x^{\frac{2}{3}}(1-x)^{\frac{2}{3}}\,\chi_{[0,1]}$. Here χ_A stands for the characteristic function of the set A, defined by $\chi_A(x) = 1$ if $x \in A$ and $\chi_A(x) = 0$ if $x \notin A$.

Let $\bar{u} \in C(\mathbb{R})$ be such that its distributional derivative $\bar{u}_x$ is square integrable. Define $\varphi : \mathbb{R}_+ \times \mathbb{R} \to \mathbb{R}$ by

$$\varphi_y(t,y) = \frac{1}{2}\,\bar{u}_x^2(y)\,\chi_{[\bar{u}_x > -2/t]}(y) \tag{2.17}$$

so that

$$\varphi(t,y) = \frac{1}{4}\int_{[\bar{u}_x > -2/t]} \operatorname{sign}(y-x)\,\bar{u}_x^2(x)\,dx, \qquad t > 0, \tag{2.18}$$

with the understanding that

$$\varphi(0,y) = \frac{1}{4}\int_{\mathbb{R}} \operatorname{sign}(y-x)\,\bar{u}_x^2(x)\,dx.$$

In other words, if $u(t,\xi(t,x_0))$ blows up before $t_0 > 0$, then the point x_0 is not included in the domain of the integral defining $\varphi(t_0,\cdot)$, because

$$T\big(\bar{u}_x(x)\big) > t \qquad \text{if and only if} \qquad \bar{u}_x(x) > -2/t,$$

according to (2.4) and (2.6). Observe that (2.18) and Young's inequality yield

$$\|\varphi(t,\cdot)\|_{L^\infty(\mathbb{R})} \le \frac{1}{4}\int_{\mathbb{R}} \bar{u}_x^2(x)\,dx, \qquad t \ge 0. \tag{2.19}$$

In the (t,x)-plane, the characteristic curve starting at y is obtained as

$$\xi(t,y) = y + t\bar{u}(y) + \int_0^t (t-s)\,\varphi(s,y)\,ds. \tag{2.20}$$

The value of the solution u along this curve is

$$u\big(t,\,\xi(t,y)\big) = \bar{u}(y) + \int_0^t \varphi(s,y)\,ds. \tag{2.21}$$

Observe that for all $t \ge 0$ and $y \in \mathbb{R}$,

$$\xi_t(t,y) = u(t,\xi(t,y)) \tag{2.22}$$

in view of (2.20)–(2.21).

THEOREM 2.1. *Given any absolutely continuous function* $\bar{u} : \mathbb{R} \to \mathbb{R}$ *with derivative* $\bar{u}_x \in L^2(\mathbb{R})$, *the formulas* (2.18)–(2.20) *provide a dissipative solution to* (1.1), *defined for all times* $t \geq 0$.

Proof. We proceed in several steps. First of all, for any fixed $t \geq 0$, the map $y \mapsto \xi(t,y)$ is absolutely continuous since $\varphi_y(t,\cdot) \in L^2(\mathbb{R})$. We claim that for any fixed $t \geq 0$ the map $y \mapsto \xi(t,y)$ is nondecreasing on $\mathbb{R}$ with $\lim_{y\to\pm\infty} \xi(t,y) = \pm\infty$.

Indeed, if $\bar{u}_x(y) > -\frac{2}{t}$, then $\bar{u}_x(y) > -\frac{2}{s}$ for all $s \in [0,t]$ so that $\varphi_y(s,y) = \frac{1}{2}\,\bar{u}_x^2(y)$ for $s \in [0,t]$ by (2.17). Since

$$\xi_y(t,y) = 1 + t\bar{u}_x(y) + \int_0^t (t-s)\,\varphi_y(s,y)\,ds \tag{2.23}$$

we find that in this case

$$\xi_y(t,y) = 1 + t\bar{u}_x(y) + \frac{t^2}{4}\,\bar{u}_x^2(y) = \frac{1}{4}\Big(2 + t\,\bar{u}_x(y)\Big)^2. \tag{2.24}$$

In the remaining cases we have that $\bar{u}_x(y) = -\frac{2}{t_0} \leq -\frac{2}{t}$ for some $t_0 \in (0,t]$. Therefore (2.17) yields $\varphi_y(s,y) = \frac{1}{2}\,\bar{u}_x^2(y)$ for $s \in [0,t_0)$, while $\varphi_y(s,y) = 0$ for $s \in (t_0,t]$. From (2.23) we infer that

$$\xi_y(t,y) = 1 - \frac{2t}{t_0} + \frac{2t - t_0}{t_0} = 0. \tag{2.25}$$

The relations (2.24)–(2.25) confirm the monotonicity of the map $y \mapsto \xi(t,y)$. Since $\xi(0,x) = x$, it remains to prove that $\lim_{y\to\pm\infty} \xi(t,y) = \pm\infty$ for any $t > 0$. Fix $t > 0$. Since $\bar{u}_x \in L^2(\mathbb{R})$, the Lebesgue measure $l(t)$ of the set $\{y \in \mathbb{R} :\ \bar{u}_x(y) \leq -\frac{1}{t}\}$ is finite. On the complement $C(t)$ of this set we obviously have $\bar{u}_x(y) > -\frac{1}{t}$ and thus $\xi_y(t,y) \geq \frac{1}{4}$ by taking into account (2.24). Therefore, given $x_2 > x_1$, we infer that

$$\begin{aligned}\xi(t,x_2) - \xi(t,x_1) &= \int_{x_1}^{x_2} \xi_y(t,y)\,dy \geq \int_{[x_1,x_2]\,\cap\, C(t)} \xi_y(t,y)\,dy \\ &\geq \int_{[x_1,x_2]\,\cap\, C(t)} \frac{1}{4}\,dy \geq \frac{x_2 - x_1 - l(t)}{4}.\end{aligned}$$

This proves the claim about the limiting behavior of $\xi(t,\cdot)$ at $\pm\infty$. While for times t up to the blow-up time T_0, given by (2.7), the map $y \mapsto \xi(t,y)$ is an absolutely continuous diffeomorphism of the real line, for $t \geq T_0$ this map is nondecreasing and onto but is not necessarily a bijection. Nevertheless, we would like to define the solution u by the formula (2.21) for all $t \geq 0$.

To show that u is well-defined via (2.21), due to the monotone and surjective character of the map $y \mapsto \xi(t,y)$, it is sufficient to show that if $\xi(t,y_1) = \xi(t,y_2)$ for some $y_2 > y_1$, then the values of u given by (2.21) are also equal. Indeed, we must have that $\xi(t,y) = \xi(t,y_1)$ for all $y \in [y_1,y_2]$, and a glance at (2.24)–(2.25) confirms that $\bar{u}_x(y) \leq -\frac{2}{t}$ for $y \in [y_1,y_2]$. This means that for every fixed $y \in (y_1,y_2)$ we have $\bar{u}_x(y) = -\frac{2}{t_0(y)}$ for some $t_0(y) \in [0,t]$. Consequently $\varphi_y(s,y) = \frac{1}{2}\,\bar{u}_x^2(y)\,\chi_{[0,t_0(y)]}(s)$ for $s \in [0,t]$, and differentiation of the right-hand side of (2.21) yields

$$\partial_y\left(\bar{u}(y) + \int_0^t \varphi(s,y)\,ds\right) = \bar{u}_x(y) + \int_0^{t_0(y)} \frac{1}{2}\,\bar{u}_x^2(y)\,ds = -\frac{2}{t_0(y)} + \frac{t_0(y)}{2}\,\frac{4}{t_0^2(y)} = 0$$

for $y \in (y_1, y_2)$. In particular, the values of the right-hand side of (2.21) are equal when evaluated at (t, y_1) and at (t, y_2). This proves that u is well-defined.

The next step is to prove that for every $t \geq 0$, the map $y \mapsto u(t,y)$ is continuous on $\mathbb{R}$ with distributional derivative in $L^2(\mathbb{R})$. Given $t \geq 0$ and $y_0 \in \mathbb{R}$, let $I_0 = \{x \in \mathbb{R} : \ \xi(t,x) = y_0\}$. The previously established properties of the map $x \mapsto \xi(t,x)$ ensure that $I_0 = [a,b]$ for some $a \leq b$. For any sequence $y_n \to y_0$, choose $x_n \in \mathbb{R}$ with $\xi(t,x_n) = y_n$. If we show that $\min\{|x_n - a|, |x_n - b|\} \to 0$ as $n \to \infty$, by the continuous dependence on the y-variable of the right-hand side of (2.21), we infer that

$$u(t,y_n) = u(t,\xi(t,n)) \to u(t,\xi(t,a)) = u(t,\xi(t,b)) = u(t,y_0)$$

since $\xi(t,x_n) \to \xi(t,a) = \xi(t,b) = y_0$. Thus $y \mapsto u(t,y)$ would be continuous at y_0. If it would be possible that $\min\{|x_{n_k} - a|, |x_{n_k} - b|\} \geq \varepsilon > 0$ for a sequence $n_k \to \infty$, then

$$|y_{n_k} - y_0| = |\xi(t,x_{n_k}) - \xi(t,a)| = |\xi(t,x_{n_k}) - \xi(t,b)| \geq \min\{y_0 - \xi(t,a-\varepsilon),\, \xi(t,b+\varepsilon)\} > 0$$

must hold by the definition of $[a,b]$ and the monotonicity property of the function $x \mapsto \xi(t,x)$. But this is a contradiction since $y_n \to y_0$ as $n \to \infty$. We therefore proved the continuity of the map $y \mapsto u(t,y)$ for every fixed $y \in \mathbb{R}$. Actually, a glance at the previous considerations confirms the continuity of the map $u : \mathbb{R}_+ \times \mathbb{R} \to \mathbb{R}$ since $\xi : \mathbb{R}_+ \times \mathbb{R} \to \mathbb{R}$ is continuous in view of (2.14). To show that for each $t \geq 0$ the distributional derivative $u_x(t,\cdot)$ belongs to $L^2(\mathbb{R})$, due to the absolute continuity of the nondecreasing surjective map $\xi(t,\cdot) : \mathbb{R} \to \mathbb{R}$, we first show that at every point $y = \xi(t,x)$ where $\xi_x(t,x) > 0$ exists, $u_x(t,y) \in \mathbb{R}$ exists. Indeed, at such a point y the right-hand side of (2.21), formally equal to $u_x(t,\xi(t,x)) \cdot \xi_x(t,x)$, is differentiable with derivative

$$\bar{u}_x(x) + \int_0^t \varphi_y(t,x)\, ds = \bar{u}_x(x) + \frac{t}{2}\, \bar{u}_x^2(x),$$

since in view of (2.24)–(2.25) we must have $\bar{u}_x(x) > -\frac{2}{t}$ and $\varphi_y(s,x) = \frac{1}{2}\, \bar{u}_x^2(x)$ for all $s \in [0,t]$. Since $\xi_y(t,x) = 1 + t\, \bar{u}_x(x) + \frac{t^2}{4}\, \bar{u}_x^2(x)$, we infer that $u_x(t,y)$ exists, being given by the formula

$$u_x(t,y) = \frac{\bar{u}_x(x) + \frac{t}{2}\, \bar{u}_x^2(x)}{1 + t\bar{u}_x(x) + \frac{t^2}{4}\, \bar{u}_x^2(x)} = \frac{\bar{u}_x(x)}{1 + \frac{t}{2}\, \bar{u}_x(x)}, \tag{2.26}$$

where $y = \xi(t,x)$. From (2.26) we deduce that for any interval $[x_1, x_2]$ where $\xi_x(t,x) > 0$ a.e., we have

$$\begin{aligned} \int_{y_1}^{y_2} u_x^2(t,y)\, dy &= \int_{\xi(t,x_1)}^{\xi(t,x_2)} u_x^2(t,\xi(t,x)) \,\cdot\, \xi_x(t,x)\, dx \\ &= \int_{x_1}^{x_2} \frac{\bar{u}_x^2(x)}{\big(1 + \frac{t}{2}\, \bar{u}_x(x)\big)^2} \left(1 + t\, \bar{u}_x(x) + \frac{t^2}{4}\, \bar{u}_x^2(x)\right) dx = \int_{x_1}^{x_2} \bar{u}_x^2(x)\, dx \end{aligned}$$

if $y_1 = \xi(t,x_1)$, $y_2 = \xi(t,x_2)$ and if we take into account (2.24). Summing up over such intervals, we obtain that

$$\int_{\mathbb{R}} u_x^2(t,x)\, dx = \int_{\{\bar{u}_x(x) > -\frac{2}{t}\}} \bar{u}_x^2(x)\, dx. \tag{2.27}$$

In particular, the map $t \mapsto \|u_x(t,\cdot)\|_{L^2(\mathbb{R})}$ is nonincreasing on $\mathbb{R}_+$. Moreover, we also have that

$$\int_{-\infty}^{\xi(t,y)} u_x^2(t,x)\,dx = \int_{\{x\in(-\infty,y]:\ \bar u_x(x) > -\frac{2}{t}\}} \bar u_x^2(x)\,dx$$

and

$$\int_{\xi(t,y)}^{\infty} u_x^2(t,x)\,dx = \int_{\{x\in[y,\infty):\ \bar u_x(x) > -\frac{2}{t}\}} \bar u_x^2(x)\,dx.$$

A comparison with (2.18) yields

$$\varphi(t,y) = \frac{1}{4}\int_{\mathbb{R}} \operatorname{sign}\left(\xi(t,y)-x\right) u_x^2(t,x)\,dx. \tag{2.28}$$

Furthermore, if $\xi_x(t,x) > 0$ exists, relation (2.20) ensures for $y = \xi(t,x)$ the existence of $u_t(t,y)$, given by the formula

$$u_t(t,y) = -\,u_x(t,y)\,u(t,y) + \varphi(t,x)$$

obtained by differentiation and taking into account (2.22). In combination with (2.28), this yields

$$(u_t + uu_x)(t,\xi(t,x)) = \frac{1}{4}\int_{\mathbb{R}} \operatorname{sign}(\xi(t,x)-\zeta)\,u_x^2(t,\zeta)\,d\zeta,$$

which is precisely (1.1) evaluated at $(t,\xi(t,x))$. In view of the previously established properties of the map $x \mapsto \xi(t,x)$ we deduce that the constructed function u satisfies also condition (iii) of Definition 2.1. Since the other properties required by Definition 2.1 were proved above, we conclude that u qualifies as a solution to (1.1) in the sense of Definition 2.1. This completes the proof of Theorem 2.1. $\square$

3. A distance functional. If $\bar u : \mathbb{R} \to \mathbb{R}$ is also bounded, in addition to being continuous and with distributional derivative $\bar u_x \in L^2(\mathbb{R})$, then the global solution $u(t,\cdot)$ constructed in Theorem 2.1 will be bounded at every fixed time $t \geq 0$. More precisely, in view of (2.19) and (2.21) we have that

$$\sup_{t\geq 0,\,x\in\mathbb{R}} \left|u(t,x)\right| \leq \sup_{x\in\mathbb{R}} \left|\bar u(x)\right| + \frac{t}{4}\int_{\mathbb{R}} \bar u_x^2(x)\,dx.$$

Thus, if $\bar u : \mathbb{R} \to \mathbb{R}$ is a bounded continuous function with distributional derivative $\bar u_x \in L^2(\mathbb{R})$, then at each fixed time $t \geq 0$, the solution $u(t,\cdot)$ to (1.1), constructed in Theorem 2.1, belongs to the Banach space $\mathcal{X}$ of bounded continuous functions $f : \mathbb{R} \to \mathbb{R}$ with distributional derivative $f_x \in L^2(\mathbb{R})$, endowed with the norm

$$\|f\|_{\mathcal{X}} = \sup_{x\in\mathbb{R}}\{|f(x)|\} + \left(\int_{\mathbb{R}} f_x^2(x)\,dx\right)^{\frac{1}{2}}.$$

The Banach space $\mathcal{X}$ seems suitable for (1.1)—see also [BZZ], where a construction similar to the one performed in Theorem 2.1 is presented. However, the map $t \mapsto u(t,\cdot)$ is generally not continuous from $\mathbb{R}_+$ to $\mathcal{X}$. Indeed, if for some $\tau > 0$ we have that the set $\{x \in \mathbb{R} :\ \bar u_x(x) = -\frac{2}{\tau}\}$ is of positive Lebesgue measure, then a discontinuity occurs at time $t=\tau$ for the map $t\mapsto u(t,\cdot)\in\mathcal{X}$ since from (2.27) we infer that for $t<\tau$,

$$\int_{\mathbb{R}} u_x^2(t,x)\,dx - \int_{\mathbb{R}} u_x^2(\tau,x)\,dx \geq \int_{\{x\in x:\ \bar u_x(x)=-\frac{2}{\tau}\}} \bar u_x^2(x)\,dx > 0.$$

Our aim will be to construct a distance functional in the space of solutions to (1.1) with respect to which we will have both continuity with respect to time as well as continuity with respect to the initial data for the solutions to (1.1). More precisely, for nonsmooth solutions the conservation law (2.2) is replaced by

$$(v^2)_t + (uv^2)_x = -\mu, \tag{3.1}$$

where μ is the positive measure on the (t,x)-plane defined as

$$\mu(\Omega) = \int_{\{(T(y),\ \xi(T(y),y))\,\in\,\Omega\}} \bar u_x^2(y)\,dy$$

for every open set $\Omega\subset\mathbb{R}_+\times\mathbb{R}$. Here $T(y)$ is the blow-up time along the characteristic curve starting at y, namely,

$$T(y) \doteq \begin{cases} -2/\bar u_x(y) & \text{if} \quad \bar u_x(y)<0,\\ \infty & \text{otherwise.}\end{cases}$$

For any $\bar u\in\mathcal{X}$, we can use the semigroup notation $S_t\bar u \doteq u(t,\cdot)$ to denote the solution of (1.1) constructed in section 2. Indeed

$$S_0\bar u = \bar u, \qquad S_{t+s}\bar u = S_t\big(S_s\bar u\big). \tag{3.2}$$

To prove (3.2), we first show that

$$\xi_1(t+s,y) = \xi_2(t,\xi_1(s,y)), \qquad t,\ s\geq 0,\ \ y\in\mathbb{R}, \tag{3.3}$$

where ξ_2 is the characteristic built upon the initial data $y\mapsto u(s,\xi_1(s,y))$. To check (3.3), we view both expressions as functions of t. At $t=0$ they are both equal to $\xi_1(s,y)$. For $t>0$, differentiation of (3.3) yields

$$\bar u(y) + \int_0^{t+s} \varphi_1(r,y)\,dr = u(s,\xi_1(s,y)) + \int_0^t \varphi_2(r,\xi_1(s,y))\,dr \tag{3.4}$$

in view of (2.20). We use (2.21) to express the right-hand side of (3.4) as

$$\bar u(y) + \int_0^s \varphi_1(r,y)\,dr + \int_0^t \varphi_2(r,\xi_1(s,y))\,dr.$$

Therefore, to get (3.4), which yields (3.3) by integration, it suffices to show that

$$\int_s^{t+s} \varphi_1(r,y)\,dr = \int_0^t \varphi_2(r,\xi_1(s,y))\,dr. \tag{3.5}$$

To prove (3.5), we note that by (2.18),

$$\begin{aligned}\int_0^t \varphi_2(r,\xi_1(s,y))\,dr &= \frac14\int_0^t\int_{\{x:\ u_x(s,x)>-\frac{2}{r}\}} \operatorname{sign}(\xi_1(s,y)-x)\,u_x^2(s,x)\,dx\,dr\\ &= \frac14\int_0^t\int_{\{x:\ u_x(s,\xi_1(s,x))>-\frac{2}{r}\}} \operatorname{sign}(\xi_1(s,y)-\xi_1(s,x))\,u_x^2(s,\xi_1(s,x))\,\partial_x\xi_1(s,x)\,dx\,dr\end{aligned}$$

if we change variables $x \mapsto \xi_1(s,x)$. Now taking (2.9)–(2.10) into account, we infer that

$$\begin{aligned}\int_0^t \varphi_2(r,\xi_1(s,y))\,dr &= \frac{1}{4}\int_0^t \int_{\{x:\; u_x(s,\xi_1(s,x))>-\frac{2}{r}\}} \operatorname{sign}(\xi_1(s,y)-\xi_1(s,x))\,\bar u_x^2(x)\,dx\,dr\\ &= \frac{1}{4}\int_0^t \int_{\{x:\; u_x(s,\xi_1(s,x))>-\frac{2}{r}\}} \operatorname{sign}(y-x)\,\bar u_x^2(x)\,dx\,dr\end{aligned}$$

since the function $x \mapsto \xi_1(s,x)$ is nondecreasing. But

$$u_x(s,\xi_1(s,x)) = \frac{2\,\bar u_x(x)}{2+s\,\bar u_x(x)} > -\frac{2}{r} \quad \text{if and only if} \quad \bar u_x(x) > -\frac{2}{s+r}$$

since the function $y \mapsto \frac{2y}{2+s\,y}$ is strictly increasing for $y > -\frac{2}{s}$, so that in the end we get

$$\begin{aligned}\int_0^t \varphi_2(r,\xi_1(s,y))\,dr &= \frac{1}{4}\int_0^t \int_{\{x:\; \bar u_x(x)>-\frac{2}{r+s}\}} \operatorname{sign}(y-x)\,\bar u_x^2(x)\,dx\,dr\\ &= \frac{1}{4}\int_s^{t+s} \int_{\{x:\; \bar u_x(x)>-\frac{2}{\tau}\}} \operatorname{sign}(y-x)\,\bar u_x^2(x)\,dx\,d\tau\end{aligned} \tag{3.6}$$

where $\tau = r+s$. On the other hand, by (2.18),

$$\int_s^{t+s} \varphi_1(r,y)\,dr = \frac{1}{4}\int_s^{t+s} \int_{\{x:\; \bar u_x(x)>-\frac{2}{\tau}\}} \operatorname{sign}(y-x)\,\bar u_x^2(x)\,dx\,d\tau$$

so that (3.4) holds and (3.3) is proved. Knowing (3.3), to infer $S_{t+s}\bar u = S_t(S_s\bar u)$, it suffices to show that

$$u(t+s,\xi_1(t+s,y)) = u(t,\xi_2(t,\xi_1(s,y))).$$

But, by (2.21), the left-hand side is precisely

$$\begin{aligned}\bar u(y) + \int_0^{t+s} \varphi(r,y)\,dr &= \bar u(y) + \int_0^s \varphi_1(r,y)\,dr\\ &\quad + \int_s^{t+s} \varphi_1(r,y)\,dr = u(s,\xi_1(s,y)) + \int_s^{t+s} \varphi_1(r,y)\,dr,\end{aligned}$$

which, taking into account (3.5), equals

$$u(s,\xi_1(s,y)) + \int_0^t \varphi_2(r,\xi_1(s,y))\,ds = u(t,\xi_2(t,\xi_1(s,y)))$$

in view of (2.21). This completes the proof of (3.2).

Notice that in general the map $t \mapsto S_t\bar u$ is *not* continuous from $[0,\infty[$ into $\mathcal{X}$. It is thus interesting to identify some distance $J(u,v)$ which is well adapted to the evolution generated by (1.1). More precisely, given an arbitrary constant M, in this section we shall construct a functional $J(u,v)$ with the following property: For any initial data $\bar u, \bar v \in \mathcal{X}$ with

$$\|\bar u_x\|_{\mathbf{L}^2} \le M, \qquad \|\bar v_x\|_{\mathbf{L}^2} \le M,$$

the corresponding dissipative solutions u, v constructed in Theorem 2.1 satisfy

$$J(u(t),\ v(t)) \leq e^{C_M\, t} J(\bar{u},\ \bar{v}).$$

To begin the construction, consider the metric space

$$X \doteq (\mathbb{R}^2 \times]-\pi/2,\ \pi/2]) \cup \{\infty\} \tag{3.7}$$

with distance

$$\begin{aligned} d((x,u,w),\ (\tilde{x},\tilde{u},\tilde{w})) \doteq \min\{&|x-\tilde{x}| + |u-\tilde{u}| + \kappa_0\,|w-\tilde{w}|,\\ &\kappa_0\,|\pi/2+w| + \kappa_0|\pi/2+\tilde{w}|\},\\ d((x,u,w),\ \infty) = \kappa_0\,&|\pi/2+w|. \end{aligned} \tag{3.8}$$

Here κ_0 is a suitably large constant, whose precise value will be specified later. Notice that X is obtained from the metric space $\mathbb{R}^2 \times [-\pi/2,\ \pi/2]$ by identifying all points $(x,\ u,\ -\pi/2)$ into a single point, called "∞".

Let $M(X)$ be the space of all bounded Radon measures on X. To each function $u \in H^1_{loc}(\mathbb{R})$ with $u_x \in L^2(\mathbb{R})$ we now associate the measure $\mu^u \in \mathcal{M}(X)$ defined as

$$\mu^u(\{\infty\}) = 0, \qquad \mu^u(A) = \int_{\{x\in\mathbb{R}:\ (x,\,u(x),\,\arctan\ u_x(x)\,)\in A\}} u_x^2(x)\,dx \tag{3.9}$$

for every Borel set $A \subseteq \mathbb{R}^2 \times]-\pi/2,\ \pi/2]$.

As distance between two functions $u, v \in \mathcal{X}$ we now introduce a kind of Kantorovich distance $J(u,v)$ related to an optimal transportation problem. Call $\mathcal{F}$ the family of all triples (ψ, ϕ_1, ϕ_2), where $\phi_1, \phi_2 : \mathbb{R} \mapsto [0,1]$ are simple Borel measurable maps (that is, their range is a finite number of points and the preimage of each such point is a Borel set) and $\psi : \mathbb{R} \mapsto \mathbb{R}$ is a nondecreasing absolute continuous surjective map. Assuming that

$$\phi_1(x)\,u_x^2(x) = \psi'(x)\cdot\phi_2(\psi(x))\,v_x^2(\psi(x)) \qquad \text{for almost every } x\in\mathbb{R}, \tag{3.10}$$

we define

$$\begin{aligned} J^{(\psi,\phi_1,\phi_2)}(u,v) \doteq &\int d((x,\ u(x),\ \arctan u_x(x)),\ (\psi(x),\ v(\psi(x)),\ \arctan v_x(\psi(x))))\\ &\qquad\cdot\phi_1(x)\,u_x^2(x)\,dx\\ &+\int d((x,\ u(x),\ \arctan u_x(x)),\ \infty)\cdot(1-\phi_1(x))\,u_x^2(x)\,dx\\ &+\int d((\psi(x),\ v(\psi(x)),\ \arctan v_x(\psi(x))),\ \infty)\\ &\qquad\cdot(1-\phi_2(\psi(x)))\,v_x^2(\psi(x))\,\psi'(x)\,dx. \end{aligned} \tag{3.11}$$

Observe that (ψ, ϕ_1, ϕ_2) can be regarded as a *transportation plan*, in order to transport the measure μ^u onto the measure μ^v. Since these two positive measures need not have the same total mass, we allow some of the mass to be transferred to the point ∞. More precisely, the mass transferred is $(1-\phi_1)\cdot\mu^u$ and $(1-\phi_2)\cdot\mu^v$. The last two integrals in (3.11) account for the additional cost of this transportation. Integrating (3.10) over the real line, one finds

$$\int_{\mathbb{R}} \phi_1(x)\,u_x^2(x)\,dx = \int_{\mathbb{R}} \phi_2(y)\,v_x^2(y)\,dy.$$

We can thus transport the measure $\phi_1\mu^u$ onto $\phi_2\,\mu^v$ by a map $\Psi : (x,\, u(x)\,\arctan u_x(x)) \mapsto (y,\, v(y),\, \arctan v_x(y))$, with $y = \psi(x)$. The associated cost is given by the first integral in (3.11). In this case the measure $\phi_2\,\mu^v$ is obtained as the push-forward of the measure $\phi_1\mu^u$. We recall that the *push-forward* of a measure μ by a mapping Ψ is defined as $(\Psi\#\mu)(A) \doteq \mu(\Psi^{-1}(A))$ for every measurable set A. Here $\Psi^{-1}(A) \doteq \{z :\ \Psi(z) \in A\}$.

We now define our distance functional by optimizing over all transportation plans, namely,

$$J(u,v) \doteq \inf_{(\psi,\phi_1,\phi_2)} \{J^{(\psi,\phi_1,\phi_2)}(u,v)\}, \tag{3.12}$$

where the infimum is taken over all triples $(\psi,\phi_1,\phi_2) \in \mathcal{F}$ such that (3.10) holds.

To check that (3.12) actually defines a distance, let $u,\ v,\ w \in \mathcal{X}$ be given functions.

1. Let us show that $J(u,v) = J(v,u)$. In order to do this, it is enough to prove that for every triple $(\psi,\ \phi_1,\ \phi_2) \in \mathcal{F}$ satisfying (3.10) and every $\varepsilon > 0$, there is a triple $(\eta,\varphi_1,\varphi_2) \in \mathcal{F}$ satisfying (3.10) such that $\eta : \mathbb{R} \to \mathbb{R}$ is a strictly increasing absolutely continuous bijection and

$$|J^{(\eta,\varphi_1,\varphi_2)}(u,v) - J^{(\psi,\phi_1,\phi_2)}(u,v)| \le \varepsilon. \tag{3.13}$$

Indeed, given $(\psi,\phi_1,\phi_2) \in \mathcal{F}$ satisfying (3.10), define $\tilde{\psi} = \eta^{-1}$, $\tilde{\phi_1} = \varphi_2$, $\tilde{\phi_2} = \varphi_1$. The properties of η ensure the absolute continuity of $\tilde{\psi}$ (see [N]) so that we obtain $J^{(\tilde{\psi},\tilde{\phi_1},\tilde{\phi_2})}(v,u) = J^{(\eta,\varphi_1,\varphi_2)}(u,v)$ by performing the change of variables $x \mapsto \eta(x)$. Since $\varepsilon > 0$ was arbitrary, we infer that $J(v,u) \le J(u,v)$. Interchanging the roles of u and v we get $J(u,v) = J(v,u)$.

To prove (3.13), it is convenient to view $\psi : \mathbb{R} \to \mathbb{R}$ as a maximal monotone multifunction $\psi : \mathbb{R} \mapsto \mathcal{P}(\mathbb{R})$ with domain and range $\mathbb{R}$. Here $\mathcal{P}(\mathbb{R})$ is the family of all subsets of $\mathbb{R}$. The conditions for a multifunction $F : \mathbb{R} \mapsto \mathcal{P}(\mathbb{R})$ to be maximal monotone with domain and range $\mathbb{R}$ may be explicitly written as follows [Z]:

- for every $x \in \mathbb{R}$, the set $F(x) \subset \mathbb{R}$ is nonempty (i.e., the domain of F is $\mathbb{R}$);
- for every $y \in \mathbb{R}$ there is at least some $x \in \mathbb{R}$ with $y \in F(x)$, expressing the fact that the range of F is $\mathbb{R}$;
- there are no couples (x_1,y_1) and (x_2,y_2) with $y_1 \in F(x_1)$ and $y_2 \in F(x_2)$ such that $x_1 < x_2$ and $y_2 < y_1$, meaning that F is monotone;
- if we associate to F its graph $\{(x,y) \in \mathbb{R}^2 :\ y \in F(x)\}$, then this graph has no proper extension satisfying the first three properties (condition defining the maximal monotonicity property).

We recall some important features presented by such maps [AA, Z]:

- the set $F(x)$ is an interval of the form $[a_x,b_x]$ with $a_x \le b_x$ for all $x \in \mathbb{R}$ and $a_x = b_x$ for all $x \in \mathbb{R}$, except perhaps an at most countable set (so F is single-valued with the exception of at most countably many points);
- F is a.e. differentiable, that is, for almost all $x_0 \in \mathbb{R}$ there exists $F'(x_0) \in \mathbb{R}$ such that

$$\lim_{x\to x_0,\, y\in F(x)} \frac{y - F(x_0) - (x-x_0)\,F'(x_0)}{x - x_0} = 0;$$

- we can define the inverse $F^{-1} : \mathbb{R} \to \mathcal{P}(\mathbb{R})$ of F by asking $y \in F^{-1}(x)$ if and only if $x \in F(x)$ and F^{-1} is again a maximal monotone multifunction with domain and range $\mathbb{R}$.

Since the multifunction ψ^{-1} is maximal monotone, let $\{y_n\}$ be the (at most countable) set of points where it is multivalued, that is, $\psi^{-1}(y) = [a_n, b_n]$ with $b_n > a_n$. Then $\psi(x) = y_n$ for $x \in [a_n, b_n]$ and, ψ being absolutely continuous, $\psi_x > 0$ a.e. on $\mathbb{R} - \bigcup_n [a_n, b_n]$ since ψ is strictly increasing on this set. Given $\gamma > 0$, the absolute continuity of $\psi : \mathbb{R} \to \mathbb{R}$ allows us to choose some $\delta > 0$ such that the total variation of ψ over the union of disjoint closed intervals with the sum of their lengths less than δ is less than γ; cf. [BGH]. On each interval $[a_n - \frac{\delta}{2^n}, b_n + \frac{\delta}{2^n}]$ we replace ψ with the linear function η which takes the values $\psi(a_n - \frac{\delta}{2^n})$, respectively, $\psi(b_n + \frac{\delta}{2^n})$, at the endpoints. By the way a_n and b_n were defined, we know that $\psi(b_n + \frac{\delta}{2^n}) > \psi(a_n - \frac{\delta}{2^n})$ so that $\eta'(x)$ is a positive constant on $[a_n - \frac{\delta}{2^n}, b_n + \frac{\delta}{2^n}]$ with

$$\sum_n \int_{a_n - \frac{\delta}{2^n}}^{b_n + \frac{\delta}{2^n}} \eta'(x)\, dx \le \sum_n \left(\psi\left(b_n + \frac{\delta}{2^n}\right) - \psi\left(a_n - \frac{\delta}{2^n}\right)\right) \le \gamma.$$

Setting $\eta(x) = \psi(x)$ for $x \notin [a_n - \frac{\delta}{2^n}, b_n + \frac{\delta}{2^n}]$, we obtain a strictly increasing absolutely continuous bijection $\eta : \mathbb{R} \to \mathbb{R}$. Let us now show that the triple $(\eta, \varphi_1, \varphi_2) \in \mathcal{F}$ satisfies both (3.10) and (3.13), where φ_1, φ_2 are defined by setting $\varphi_1(x) = 0$ for $x \in [a_n - \frac{\delta}{2^n}, b_n + \frac{\delta}{2^n}]$ and $\varphi_1(x) = \phi_1(x)$ for $x \notin [a_n - \frac{\delta}{2^n}, b_n + \frac{\delta}{2^n}]$, while $\varphi_2(\eta(x)) = \phi_2(\psi(x))$ for $x \notin [a_n - \frac{\delta}{2^n}, b_n + \frac{\delta}{2^n}]$ and $\varphi_2(\eta(x)) = 0$ for $x \in [a_n - \frac{\delta}{2^n}, b_n + \frac{\delta}{2^n}]$. On the complement of the set $\bigcup_n [a_n - \frac{\delta}{2^n}, b_n + \frac{\delta}{2^n}]$ relation (3.10) clearly holds a.e. for $(\eta, \varphi_1, \varphi_2)$, being unmodified from (3.10) for (ψ, ϕ_1, ϕ_2). If $x \in [a_n - \frac{\delta}{2^n}, b_n + \frac{\delta}{2^n}]$, then (3.10) for $(\eta, \varphi_1, \varphi_2)$ holds again since both sides are zero as $\varphi_1(x) = \varphi_2(\eta(x)) = 0$ in this case. Finally, to check (3.13), notice that if we denote

$$E_\delta = \bigcup_n \left\{ \left[a_n - \frac{\delta}{2^n}, a_n\right] \cup \left[b_n, b_n + \frac{\delta}{2^n}\right]\right\}, \qquad A = \bigcup_n [a_n, b_n],$$

then

(3.14)
$$|J^{(\eta,\varphi_1,\varphi_2)}(u,v) - J^{(\psi,\phi_1,\phi_2)}(u,v)| \le 2\kappa_0\pi \int_{E_\delta} u_x^2\, dx + 2\kappa_0\pi \int_{E_\delta \cup A} v_x^2(\eta(x))\, \eta'(x)\, dx.$$

Indeed, the distance d is less than $2\kappa_0\pi$ and the integrands in $J^{(\eta,\varphi_1,\varphi_2)}(u,v)$ and $J^{(\psi,\phi_1,\phi_2)}(u,v)$ agree on the complement of the set $\bigcup_n [a_n - \frac{\delta}{2^n}, b_n + \frac{\delta}{2^n}]$ by definition. Also, for almost every $x \in [a_n, b_n]$ we have $\phi_1(x)\, u_x^2 = 0$ by (3.10) as $\psi'(x) = 0$, and $\varphi_1(x) = 0$ by its definition. We obtain (3.14). Since the absolutely continuous map η maps $E_\delta \cup A$ into a set of Lebesgue measure less than γ, and u_x^2, $v_x^2 \in L^1(\mathbb{R})$, from (3.14) we infer (3.13) by choosing $\delta > 0$ and $\gamma > 0$ small enough. This completes the argumentation needed to show that $J(u,v) = J(v,u)$.

2. Choosing $\psi(x) = x$, $\phi_1(x) = \phi_2(x) = 1$, we immediately see that $J(u,u) = 0$. Moreover, we have $J(u,v) > 0$ if $u \ne v$. To check this, note that $J(u,v) = 0$ implies that there is a sequence $(\psi^n, \phi_1^n, \phi_2^n)$ along which $J^{(\psi^n,\phi_1^n,\phi_2^n)}(u,v) \to 0$. The second term in (3.11) yields

$$\left(\frac{\pi}{2} + \arctan u_x(x)\right) (1 - \phi_1^n(x))\, u_x^2(x) \to 0 \quad \text{in} \quad L^1(\mathbb{R}),$$

so that along a subsequence $(1 - \phi_1^{n_k})\, u_x^2 \to 0$ a.e. on $\mathbb{R}$ since $u_x > -\infty$ a.e. On the set $S = \{x \in \mathbb{R} :\ u_x(x) \ne 0\}$ we therefore have $\phi_1^{n_k} \to 1$ a.e. Moreover, the first term in (3.11) forces

$$\begin{aligned} &\phi_1^{n_k}(x)u_x^2(x)\cdot \min\Big\{|x-\psi^{n_k}(x)|+|u(x)-v(\psi^{n_k}(x))| \\ &\qquad\qquad +\kappa_0|\arctan u_x(x)-\arctan v_x(\psi^{n_k}(x))|, \\ &\kappa_0\left[\frac{\pi}{2}+\arctan u_x(x)+\frac{\pi}{2}+\arctan v_x(\psi^{n_k}(x))\right]\Big\}\to 0 \quad \text{in} \quad L^1(\mathbb{R}). \end{aligned} \tag{3.15}$$

Since $u_x>-\infty$ a.e. ensures

$$\frac{\pi}{2}+\arctan u_x(x)+\frac{\pi}{2}+\arctan v_x(\psi^{n_k}(x))\ge \frac{\pi}{2}+\arctan u_x(x)>0 \quad \text{a.e. on} \quad \mathbb{R},$$

we infer from (3.15), by passing to another subsequence, that

$$|x-\psi^{n_k}(x)|+|u(x)-v(\psi^{n_k}(x))|\to 0 \quad \text{a.e. on} \quad S.$$

In view of the continuity of v, $\psi^{n_k}(x)\to x$ a.e. on S guarantees $v(\psi^{n_k}(x))\to v(x)$ a.e. on S so that $u=v$ a.e. on S since also $v(\psi^{n_k}(x))\to u(x)$ a.e. on S. Repeating this argument with the roles of u and v reversed, we find that $u=v$ a.e. on the set $\{x\in\mathbb{R}:\ v_x\neq 0\}$. Combining this with the previous conclusion, we have $u=v$ a.e. on the complement of the set $\{x\in\mathbb{R}: u_x=v_x=0\}$. Since $u_x,\, v_x\in L^2(\mathbb{R})$, this is possible only if $u=v$ on $\mathbb{R}$. Thus $J(u,v)=0$ if and only if $u=v$.

3. Finally, to prove the triangle inequality, it suffices to show that for every choice of $(\psi^\flat,\phi_1^\flat,\phi_2^\flat)$ satisfying (3.10), and of $(\psi^\sharp,\phi_1^\sharp,\phi_2^\sharp)$ satisfying (3.10) for (v,w), the triplet (ψ,ϕ_1,ϕ_2) defined by

$$\psi(x)=\psi^\sharp(\psi^\flat(x)),\quad \phi_1(x)=\phi_1^\flat(x)\cdot\phi_1^\sharp(\psi^\flat(x)),\quad \phi_2(y)=\phi_2^\sharp(y)\cdot\phi_2^\flat(\psi^\flat(x))$$

satisfies (3.10) for (u,w) and

$$J^{(\psi,\phi_1,\phi_2)}(u,w)\le J^{(\psi^\flat,\phi_1^\flat,\phi_2^\flat)}(u,v)+J^{(\psi^\sharp,\phi_1^\sharp,\phi_2^\sharp)}(v,w). \tag{3.16}$$

Notice that composing the relation (3.10) for (v,w) a.e. to the right with $\psi^\flat$, and multiplying the outcome by $\phi_2^\flat\circ\psi^\flat\cdot(\psi^\flat)'$, we infer that (3.10) holds a.e. on $\mathbb{R}$ for (u,w) with our choice of (ψ,ϕ_1,ϕ_2), and we can now concentrate on proving (3.16).

To simplify matters, we introduce the following notation:

$$\begin{aligned} &P_1=(x,\,u,\,\arctan u_x),\quad P_2=(\psi^\flat,\,v\circ\psi^\flat,\,\arctan v_x\circ\psi^\flat),\\ &P_3=(\psi,\,w\circ\psi,\,\arctan w_x\circ\psi),\\ &\qquad m_1=u_x^2,\qquad m_2=v_x^2\circ\psi^\flat\cdot(\psi^\flat)',\qquad m_3=w_x^2\circ\psi\cdot\psi'. \end{aligned}$$

The relations of type (3.10) then yield that a.e. on $\mathbb{R}$,

$$\phi_1^\flat\cdot m_1=\phi_2^\flat\circ\psi^\flat\cdot m_2,\qquad \phi_1^\sharp\circ\psi^\flat\cdot m_2=\phi_2^\sharp\circ\psi\cdot m_3,\qquad \phi_1\cdot m_1=\phi_2\circ\psi\cdot m_3. \tag{3.17}$$

Also,

$$\begin{aligned} J^{(\psi,\phi_1,\phi_2)}(u,w) &= \int_{\mathbb{R}} \{d(P_1,P_3)\cdot\phi_1 m_1 + d(P_1,\infty)\cdot(1-\phi_1)m_1 + d(P_3,\infty) \\ &\qquad \cdot(1-\phi_2\circ\psi)m_3\}\,dx, \\ J^{(\psi^\flat,\phi_1^\flat,\phi_2^\flat)}(u,v) &= \int_{\mathbb{R}} \{d(P_1,P_2)\cdot\phi_1^\flat m_1 + d(P_1,\infty)\cdot(1-\phi_1^\flat)m_1 + d(P_2,\infty) \\ &\qquad \cdot(1-\phi_2^\flat\circ\psi^\flat)m_2\}\,dx, \\ J^{(\psi^\sharp,\phi_1^\sharp,\phi_2^\sharp)}(v,w) &= \int_{\mathbb{R}} \{d(P_2,P_3)\cdot\phi_1^\sharp\circ\psi^b m_1 + d(P_2,\infty)\cdot(1-\phi_1^\sharp\circ\psi^\flat)m_2 + d(P_3,\infty) \\ &\qquad \cdot(1-\phi_2^\sharp\circ\psi)m_3\}\,dx, \end{aligned}$$

the last relation being obtained after the change of variables $x\mapsto\psi^\flat(x)$ in the integral. We will prove (3.16) by deriving an appropriate inequality valid a.e. pointwise between the integrands in the previous expressions. Since

$$(1-\phi_2^\flat\circ\psi^\flat)(1-\phi_1^\sharp\circ\psi^\flat)\geq 0,$$

we have

$$1-\phi_2^\flat\circ\psi^\flat + 1-\phi_1^\sharp\circ\psi^\flat \geq \phi_2^\flat\circ\psi^\flat(1-\phi_1^\sharp\circ\psi^\flat)+\phi_1^\sharp\circ\psi^\flat(1-\phi_2^\flat\circ\psi^\flat).$$

Multiplication of both sides by $d(P_2,\infty)\cdot m_2$ leads to

$$\begin{aligned} &d(P_2,\infty)\cdot(1-\phi_2^\flat\circ\psi^\flat)m_2 + d(P_2,\infty)\cdot(1-\phi_1^\sharp\circ\psi^\flat)m_2 \\ &\quad\geq d(P_2,\infty)\cdot\phi_1^\flat(1-\phi_1^\sharp\circ\psi^\flat)m_1 + d(P_2,\infty)\cdot\phi_1^\sharp\circ\psi^\flat(1-\phi_2^\flat\circ\psi^\flat)m_2 \end{aligned}\tag{3.18}$$

in view of (3.17). Multiply now the inequalities

$$d(P_1,P_2)-d(P_1,\infty)+d(P_2,\infty)\geq 0,\qquad d(P_2,P_3)-d(P_3,\infty)+d(P_2,\infty)\geq 0$$

by $\phi_1^\flat(1-\phi_1^\sharp\circ\psi^\flat)m_1$, respectively, $\phi_1^\sharp\circ\psi^\flat(1-\phi_2^\flat\circ\psi^\flat)m_2$, and add them up. The outcome yields in combination with (3.18) that

$$\begin{aligned} &d(P_1,P_2)\cdot\phi_1^\flat(1-\phi_1^\sharp\circ\psi^\flat)m_1 - d(P_1,\infty)\cdot\phi_1^\flat(1-\phi_1^\sharp\circ\psi^\flat)m_1 \\ &\quad + d(P_2,P_3)\cdot\phi_1^\sharp\circ\psi^\flat(1-\phi_2^\flat\circ\psi^\flat)m_2 + d(P_2,\infty)\cdot(1-\phi_2^\flat\circ\psi^\flat)m_2 \\ &\quad + d(P_2,\infty)\cdot(1-\phi_1^\sharp\circ\psi^\flat)m_2 \geq d(P_3,\infty)\cdot\phi_1^\sharp\circ\psi^\flat(1-\phi_2^\flat\circ\psi^\flat)m_2. \end{aligned}$$

Adding to both sides the quantity

$$\begin{aligned} &d(P_1,\infty)\cdot m_1 + d(P_3,\infty)\cdot m_3 + d(P_1,P_2)\cdot\phi_1^\flat\cdot\phi_1^\sharp\circ\psi^\flat\cdot m_1 - d(P_1,\infty)\cdot\phi_1^\flat \\ &\quad\cdot\phi_1^\sharp\circ\psi^\flat\cdot m_1 + d(P_2,P_3)\cdot\phi_1^\sharp\circ\psi^\flat\cdot\phi_2^\flat\circ\psi^\flat\cdot m_2 - d(P_3,\infty)\cdot\phi_2^\sharp\circ\psi\cdot m_3 \end{aligned}$$

we deduce by (3.17) that the integrand of $J^{(\psi^\flat,\phi_1^\flat,\phi_2^\flat)}(u,v)+J^{(\psi^\sharp,\phi_1^\sharp,\phi_2^\sharp)}(v,w)$, equal a.e. precisely to the left-hand side of the new inequality, is a.e. pointwise larger than

$$\begin{aligned} &d(P_3,\infty)\cdot\phi_1^\sharp\circ\psi^\flat(1-\phi_2^\flat\circ\psi^\flat)m_2 + d(P_1,\infty)\cdot m_1 + d(P_3,\infty)\cdot m_3 \\ &\quad + d(P_1,P_2)\cdot\phi_1^\flat\cdot\phi_1^\sharp\circ\psi^\flat\cdot m_1 - d(P_1,\infty)\cdot\phi_1^\flat\cdot\phi_1^\sharp\circ\psi^\flat\cdot m_1 \\ &\quad + d(P_2,P_3)\cdot\phi_1^\sharp\circ\psi^\flat\cdot\phi_2^\flat\circ\psi^\flat\cdot m_2 - d(P_3,\infty)\cdot\phi_2^\sharp\circ\psi\cdot m_3. \end{aligned}$$

Taking into account (3.17) and the definition $\phi_1 = \phi_1^\flat \cdot \phi_1^\sharp \circ \psi^\flat$, we see that the above expression equals

$$\begin{aligned} &d(P_1,\infty)\cdot(1-\phi_1)m_1 + d(P_3,\infty)\cdot(1-\phi_2\circ\psi)m_3 + (d(P_1,P_2)+d(P_2,P_3)\cdot\phi_1 m_1)\\ &\quad \geq d(P_1,\infty)\cdot(1-\phi_1)m_1 + d(P_3,\infty)\cdot(1-\phi_2\circ\psi)m_3 + d(P_1,P_3)\cdot\phi_1 m_1. \end{aligned}$$

The lower estimate is a.e. precisely the integrand in $J^{(\psi,\phi_1,\phi_2)}(u,w)$, and (3.16) holds. The proof that J satisfies the triangle inequality is therefore complete.

In the remainder of this section we examine how the distance $J(\cdot,\cdot)$ behaves in connection with solutions of (1.1).

Continuity with respect to time. Let $t \mapsto u(t)$ be the solution of (1.1) constructed in section 2. For any fixed $t > 0$, we define a transportation plan of $\mu^{\bar u}$ to $\mu^{u(t)}$ by setting

$$\psi(x) \doteq \xi(t,x), \qquad \phi_1(x) \doteq \begin{cases} 1 & \text{if} \quad T(x) > t, \\ 0 & \text{if} \quad T(x) \leq t, \end{cases} \quad \phi_2(x) \equiv 1. \tag{3.19}$$

Relation (3.6) follows from (2.9)–(2.10) on $\{T(x) > t\}$ and from (2.25) on $\{T(x) \leq t\}$. The cost of this plan is estimated by

$$\begin{aligned} J^{(\psi,\phi_1,\phi_2)}(\bar u,\ u(t)) \leq &\int_{\{T(x)>t\}} \{|x-\xi(t,x)| + |\bar u(x) - u(t,\xi(t,x))| \\ &\qquad + \kappa_0|\arctan \bar u_x(x) - \arctan u_x(t,\xi(t,x))|\}\, \bar u_x^2(x)\,dx \\ &+ \int_{\{T(x)\leq t\}} |\pi/2 + \arctan \bar u_x(x)|\, \bar u_x^2(x)\,dx. \end{aligned} \tag{3.20}$$

By (2.4) we have that a.e.

$$\left|\frac{d}{dt}\arctan u_x\big(t,\xi(t,x)\big)\right| = \left|\frac{\frac{d}{dt}u_x\big(t,\xi(t,x)\big)}{1+u_x^2\big(t,\xi(t,x)\big)}\right| \leq \frac{1}{2}. \tag{3.21}$$

An integration on $[0,t]$ yields

$$|\arctan \bar u_x(x) - \arctan u_x(t,\xi(t,x))| \leq \frac{t}{2}, \qquad t \geq 0. \tag{3.22}$$

On the other hand, using (2.20), we get

$$|x-\xi(t,x)| \leq t\,|\bar u(x)| + \int_0^t (t-s)\,|\varphi(s,x)|\,ds \leq t\,|\bar u(x)| + \frac{t^2}{8}\int_{\mathbb{R}} \bar u_x^2(x)\,dx, \quad t\geq 0,\ x\in\mathbb{R}, \tag{3.23}$$

if we take into account (2.19). From (2.21) and (2.19), we also infer

$$|\bar u(x) - u(t,\xi(t,x))| \leq \int_0^t |\varphi(s,y)|\,dy \leq \frac{t}{4}\int_{\mathbb{R}} \bar u_x^2(x)\,dx, \qquad t\geq 0,\ x\in\mathbb{R}. \tag{3.24}$$

To estimate the last term in (3.20), notice that

$$\{x\in\mathbb{R}:\ T(x)\leq t\} = \left\{x\in\mathbb{R}:\ -\frac{2}{\bar u_x(x)} \leq t\right\} = \left\{x\in\mathbb{R}:\ \bar u_x(x) \leq -\frac{2}{t}\right\}, \qquad t>0. \tag{3.25}$$

Furthermore, since $\lim_{x\to-\infty} x(\frac{\pi}{2}+\arctan x) = -1$, there is a constant $c > 0$ such that

$$0 \le \frac{\pi}{2} + \arctan y \le \frac{c}{|y|}, \qquad y \le -1,$$

whereas

$$\left|\frac{\pi}{2} + \arctan y\right| y^2 \le \pi \qquad \text{if} \quad -1 \le y \le 0,$$

so that

$$\left|\frac{\pi}{2} + \arctan \bar u_x(x)\right| \bar u_x^2(x) \le \pi + c\,|\bar u_x(x)| \qquad \text{if} \quad \bar u_x(x) \le -\frac{2}{t}. \tag{3.26}$$

On the other hand, if $\bar u_x(x) \le -\frac{2}{t}$, then $t^2\bar u_x^2(x) \ge 4$ so that

$$\int_{\{T(x)\le t\}} 1\,dx \le \frac{t^2}{4}\int_{\{T(x)\le t\}} \bar u_x^2(x)\,dx. \tag{3.27}$$

From (3.25)–(3.27) we infer that

$$\int_{\{T(x)\le t\}} \left|\frac{\pi}{2} + \arctan \bar u_x(x)\right| \bar u_x^2(x)\,dx \le \frac{\pi t^2}{4}\|\bar u_x\|_{L^2}^2 + c\int_{\{T(x)\le t\}} |\bar u_x(x)|\,dx$$
$$\le \frac{\pi t^2}{4}\|\bar u_x\|_{L^2}^2 + c\left(\int_{\{T(x)\le t\}} 1\,dx\right)^{\frac12}\left(\int_{\{T(x)\le t\}} \bar u_x^2(x)\,dx\right)^{\frac12} \le \frac{\pi t^2}{4}\|\bar u_x\|_{L^2}^2 + \frac{ct}{2}\,\|\bar u_x\|_{L^2}^2.$$

By (3.20), (3.22)–(3.25), and the previous inequality we conclude

$$J^{(\psi,\phi_1,\phi_2)}(\bar u,\ u(t)) \le \left(\frac{\pi t}{4} + \frac{c+\kappa_0}{2} + \|\bar u\|_{L^\infty} + \frac{t+2}{8}\,\|\bar u_x\|_{L^2}^2\right) t\,\|\bar u_x\|_{L^2}^2, \qquad t \ge 0. \tag{3.28}$$

It is now clear that each semigroup trajectory $t \mapsto S_t\bar u$ is Lipschitz continuous as a map from $[0,\infty[$ into the metric space X equipped with our distance functional J. The Lipschitz constant remains uniformly bounded as $\bar u$ ranges over bounded subsets of X.

Continuity with respect to the initial data. We now consider two distinct solutions and study how the distance $J\big(u(t),\ \tilde u(t)\big)$ varies in time. Recall that the solution $u = u(t,x)$ is computed by (2.20)–(2.22), also in the case where the gradient blows up. The same formula of course holds for $\tilde u$. Let $(\psi_0, \phi_{1,0}, \phi_{2,0})$ be an optimal transportation plan of the measure $\mu^{u(0)}$ to the measure $\mu^{\tilde u(0)}$. In view of the approximation property established in (3.13), we can restrict our attention to the case when ψ_0 is strictly increasing on $\mathbb{R}$. For any $t > 0$, we define a transportation plan $(\psi^t, \phi_1^t, \phi_2^t)$ of the measure $\mu^{u(t)}$ to $\mu^{\tilde u(t)}$ as follows:

$$\psi^t\big(\xi(t,y)\big) \doteq \tilde\xi(t,\ \tilde y) \quad \text{for} \quad \tilde y = \psi_0(y),$$
$$\phi_1^t\big(\xi(t,y)\big) \doteq \begin{cases} \phi_{1,0}(y) & \text{if} \quad T(y) > t \quad \text{and} \quad \widetilde T(\tilde y) > t \quad \text{for } \tilde y = \psi_0(y), \\ 0 & \text{otherwise}, \end{cases}$$
$$\phi_2^t\big(\tilde\xi(t,\ \tilde y)\big) \doteq \begin{cases} \phi_{2,0}(\tilde y) & \text{if} \quad T(y) > t \quad \text{and} \quad \widetilde T(\tilde y) > t \quad \text{for } y = \psi_0^{-1}(\tilde y), \\ 0 & \text{otherwise}. \end{cases}$$

If initially the point y is mapped to $\tilde{y} = \psi_0(y)$, then at any later time $t > 0$ the point $\xi(t, y)$ along the u-characteristic starting from y is sent to the point $\tilde{\xi}(t, \tilde{y})$ along the $\tilde{u}$-characteristic starting from $\tilde{y} = \psi_0(y)$. We thus transport the mass from the point $(\xi(t, y),\ u(t, \xi(t, y)),\ \arctan u_x(t, \xi(t, y)))$ to the corresponding point $(\tilde{\xi}(t, \tilde{y}), \tilde{u}(t, \tilde{\xi}(t, \tilde{y})), \arctan \tilde{u}_x(t, \tilde{\xi}(t, \tilde{y})))$ with $\tilde{y} = \psi_0(y)$, except in the case where blow-up has occurred within time t along one (or both) of the characteristics $\xi(\cdot, y)$, $\tilde{\xi}(\cdot, \tilde{y})$. In this later case, the mass is transported to the point ∞.

To check (3.10), it suffices to show that a.e.

$$\begin{aligned}\phi_1^t(\xi(t, y)) \cdot u_x^2(t, \xi(t, y)) \cdot \xi_x(t, y) = \phi_2^t(\psi^t(\xi(t, y))) \cdot (\psi^t)'(\xi(t, y))\\ \cdot \xi_x(t, y) \cdot u_x^2(t, \psi^t(\xi(t, y))).\end{aligned}$$

Since the relations $\tilde{y} = \psi_0(y)$, $\psi^t(\xi(t, y)) = \tilde{\xi}(t, \tilde{y})$, and $(\psi^t)'(\xi(t, y)) \cdot \xi_x(t, y) = \tilde{\xi}_x(t, \psi_0(y)) \cdot \psi_0'(y)$ all hold a.e., the desired identity holds a.e. on the complement of the set $\{y :\ \tilde{y} = \psi_0(y),\ T(y) > t,\ \tilde{T}(\tilde{y}) > t\}$ where both sides equal zero since $\phi_1^t(\xi(t, y)) = \phi_2^t(\tilde{\xi}(t, \tilde{y})) = 0$. The identity holds also a.e. on the set $\{y :\ \tilde{y} = \psi_0(y), T(y) > t,\ \tilde{T}(\tilde{y}) > t\}$ since there, in view of (2.9)–(2.10), it practically amounts to relation (3.10) for $(\phi_{1,0},\ \phi_{2,0},\ \psi_0)$.

In the following, our main goal is to provide an estimate on the time derivative of the function

$$J(t) = J^{(\psi^t, \phi_1^t, \phi_2^t)}\big(u(t), \tilde{u}(t)\big).$$

Throughout the remainder of this section, by $\{\tilde{T}(\tilde{y}) \gtrless t\}$ we understand the set of all $y \in \mathbb{R}$ such that $\psi_0(y) = \{\tilde{y}\}$ and $\tilde{T}(\tilde{y}) \gtrless t$. Since $u_x^2(t, \xi(t, y)) \cdot \xi_x(t, y) = \bar{u}_x^2(y)$ on $\{T(y) > t\}$ by (2.9)–(2.10) and $\tilde{u}_x^2(t, \tilde{\xi}(t, \tilde{y})) \cdot \tilde{\xi}_x(t, \tilde{y}) = \tilde{u}_x^2(0, \tilde{y})$ on $\{\tilde{T}(\tilde{y}) > t\}$, while $\psi^t(\xi(t, y)) = \tilde{\xi}(t, \tilde{y})$ for $\psi_0(y) = \{\tilde{y}\}$, performing the change of variables $y \mapsto \xi(t, y)$, we see that

$$\begin{aligned}J(t) = \int_{\{T(y)>t,\, \tilde{T}(\tilde{y})>t\}} &\min\{|\xi(t, y) - \tilde{\xi}(t, \tilde{y})| + |u(t, \xi(t, y)) - \tilde{u}(t, \tilde{\xi}(t, \tilde{y}))|\\ &\quad + \kappa_0 |\arctan u_x(t, \xi(t, y)) - \arctan \tilde{u}_x(t, \tilde{\xi}(t, \tilde{y}))|,\\ &\quad \kappa_0(\pi + \arctan u_x(t, \xi(t, y)) + \arctan \tilde{u}_x(t, \tilde{\xi}(t, \tilde{y})))\}\, \phi_{1,0}(y)\, \bar{u}_x^2(y)\, dy\\ &+ \kappa_0 \int_{\{T(y)>t,\, \tilde{T}(\tilde{y})>t\}} \Big(\frac{\pi}{2} + \arctan u_x(t, \xi(t, y))\Big)\, (1 - \phi_{1,0}(y))\, \bar{u}_x^2(y)\, dy\\ &+ \kappa_0 \int_{\{T(y)\le t \text{ or } \tilde{T}(\tilde{y})\le t\}} \Big(\frac{\pi}{2} + \arctan u_x(t, \xi(t, y))\Big)\, \bar{u}_x^2(y)\, dy\\ &+ \kappa_0 \int_{\{T(y)>t,\, \tilde{T}(\tilde{y})>t\}} \Big(\frac{\pi}{2} + \arctan \tilde{u}_x(t, \tilde{\xi}(t,\, \tilde{y}))\Big)\, (1 - \phi_{2,0}(\tilde{y}))\, \tilde{u}_x^2(0, \tilde{y})\, \psi_0'(y)\, dy\\ &+ \kappa_0 \int_{\{T(y)\le t \text{ or } \tilde{T}(\tilde{y})\le t\}} \Big(\frac{\pi}{2} + \arctan \tilde{u}_x(t,\, \tilde{\xi}(t,\, \tilde{y}))\Big)\, \tilde{u}_x^2(0, \tilde{y})\, \psi_0'(y)\, dy.\end{aligned}$$

To simplify notation, let

$$S(t) = \{T(y) > t,\, \tilde{T}(\tilde{y}) > t\}, \qquad S^c(t) = \mathbb{R} - S(t), \tag{3.29}$$

$$\begin{aligned}E(t, y) = \min\{&|u(t, \xi(t, y)) - \tilde{u}(t, \tilde{\xi}(t, \tilde{y}))| + \kappa_0 |\arctan u_x(t, \xi(t, y))\\ &- \arctan \tilde{u}_x(t, \tilde{\xi}(t, \tilde{y}))| + |\xi(t, y) - \tilde{\xi}(t, \tilde{y})|,\\ &\kappa_0(\pi + \arctan u_x(t, \xi(t, y)) + \arctan \tilde{u}_x(t, \tilde{\xi}(t, \tilde{y})))\}.\end{aligned} \tag{3.30}$$

Since for $h \geq 0$ we have

$$S(t+h) \subset S(t), \qquad S^c(t) \subset S^c(t+h), \tag{3.31}$$

we deduce that

(3.32)

$$\begin{aligned}
J(t+h) - J(t) = &\int_{S(t)} (E(t+h,y) - E(t,y))\, \phi_{1,0}(y)\, \bar{u}_x^2(y)\, dy \\
&- \int_{S(t)\setminus S(t+h)} E(t+h,y)\, \phi_{1,0}(y)\, \bar{u}_x^2(y)\, dy \\
&+ \kappa_0 \int_{S(t)} (\arctan u_x(t+h,\xi(t+h,y)) - \arctan u_x(t,\xi(t,y)))(1-\phi_{1,0}(y))\, \bar{u}_x^2(y)\, dy \\
&+ \kappa_0 \int_{S(t)} (\arctan \tilde{u}_x(t+h,\tilde{\xi}(t+h,\tilde{y})) \\
&\qquad - \arctan \tilde{u}_x(t,\tilde{\xi}(t,\tilde{y})))(1-\phi_{2,0}(\tilde{y}))\, \tilde{u}_x^2(0,\tilde{y})\, \psi_0'(y)\, dy \\
&- \kappa_0 \int_{S(t)\setminus S(t+h)} \Big(\frac{\pi}{2} + \arctan u_x(t+h,\xi(t+h,y))\Big)(1-\phi_{1,0}(y))\, \bar{u}_x^2(y)\, dy \\
&- \kappa_0 \int_{S(t)\setminus S(t+h)} \Big(\frac{\pi}{2} + \arctan \tilde{u}_x(t+h,\tilde{\xi}(t+h,\tilde{y}))\Big)(1-\phi_{2,0}(\tilde{y}))\, \tilde{u}_x^2(0,\tilde{y})\, \psi_0'(y)\, dy \\
&+ \kappa_0 \int_{S^c(t)} (\arctan u_x(t+h,\xi(t+h,y)) - \arctan u_x(t,\xi(t,y)))\bar{u}_x^2(y)\, dy \\
&+ \kappa_0 \int_{S^c(t)} (\arctan \tilde{u}_x(t+h,\tilde{\xi}(t+h,\tilde{y})) - \arctan \tilde{u}_x(t,\tilde{\xi}(t,\tilde{y})))\tilde{u}_x^2(0,\tilde{y})\, \psi_0'(y)\, dy \\
&+ \kappa_0 \int_{S^c(t+h)\setminus S^c(t)} \Big(\frac{\pi}{2} + \arctan u_x(t+h,\xi(t+h,y))\Big)\bar{u}_x^2(y)\, dy \\
&+ \kappa_0 \int_{S^c(t+h)\setminus S^c(t)} \Big(\frac{\pi}{2} + \arctan \tilde{u}_x(t+h,\tilde{\xi}(t+h,\tilde{y}))\Big)\, \tilde{u}_x^2(0,\tilde{y})\, \psi_0'(y)\, dy.
\end{aligned}$$

Noticing that $S(t) \setminus S(t+h) = S(t) \cap S^c(t+h) = S^c(t+h) \setminus S^c(t)$, we see that the combination of the fifth and ninth terms above, with that of the sixth and tenth, added to the second term, amount to

(3.33)

$$\begin{aligned}
&\kappa_0 \int_{S(t)\setminus S(t+h)} \Big(\frac{\pi}{2} + \arctan u_x(t+h,\xi(t+h,y))\Big)\, \phi_{1,0}(y)\, \bar{u}_x^2(y)\, dy \\
&\quad + \kappa_0 \int_{S(t)\setminus S(t+h)} \Big(\frac{\pi}{2} + \arctan \tilde{u}_x(t+h,\tilde{\xi}(t+h,\tilde{y}))\Big)\, \phi_{2,0}(\tilde{y})\, \tilde{u}_x^2(0,\tilde{y})\, \psi_0'(y)\, dy \\
&\quad - \int_{S(t)\setminus S(t+h)} E(t+h,y)\, \phi_{1,0}(y)\, \bar{u}_x^2(y)\, dy \\
&= \kappa_0 \int_{S(t)\setminus S(t+h)} (\pi + \arctan u_x(t+h,\xi(t+h,y)) \\
&\qquad\qquad + \arctan \tilde{u}_x(t+h,\tilde{\xi}(t+h,\tilde{y})))\phi_{1,0}(y)\, \bar{u}_x^2(y)\, dy \\
&\quad - \int_{S(t)\setminus S(t+h)} E(t+h,y)\, \phi_{1,0}(y)\, \bar{u}_x^2(y)\, dy
\end{aligned}$$

by (3.10) for $(\phi_{1,0},\, \phi_{2,0},\, \psi_0)$. In view of (3.29)–(3.30), on $S(t)\setminus S(t+h)$ we have that

$$E(t+h,y)=\pi+\arctan u_x(t+h,\xi(t+h,y))+\arctan \tilde u_x(t+h,\tilde\xi(t+h,\tilde y))$$

since at least one of the expressions $u_x(t+h,\xi(t+h,y))$ and $\tilde u_x(t+h,\tilde\xi(t+h,\tilde y))$ is precisely $-\infty$ on this set. Thus the whole expression (3.33) is identically zero. Therefore (3.32) yields

(3.34)

$$\begin{aligned}
J(t+h)-J(t) &= \int_{S(t)} (E(t+h,y)-E(t,y))\,\phi_{1,0}(y)\,\bar u_x^2(y)\,dy\\
&+\kappa_0\int_{S(t)}(\arctan u_x(t+h,\xi(t+h,y))-\arctan u_x(t,\xi(t,y)))(1-\phi_{1,0}(y))\,\bar u_x^2(y)\,dy\\
&+\kappa_0\int_{S(t)}(\arctan \tilde u_x(t+h,\tilde\xi(t+h,\tilde y))\\
&\qquad -\arctan \tilde u_x(t,\tilde\xi(t,\tilde y)))(1-\phi_{2,0}(\tilde y))\tilde u_x^2(0,\tilde y)\psi_0'(y)\,dy\\
&+\kappa_0\int_{S^c(t)}(\arctan u_x(t+h,\xi(t+h,y))-\arctan u_x(t,\xi(t,y)))\bar u_x^2(y)\,dy\\
&+\kappa_0\int_{S^c(t)}(\arctan \tilde u_x(t+h,\tilde\xi(t+h,\tilde y))-\arctan \tilde u_x(t,\tilde\xi(t,\tilde y)))\tilde u_x^2(0,\tilde y)\,\psi_0'(y)\,dy.
\end{aligned}$$

In view of (3.29), we have $S^c(t)=\{T(y)\le t\}\cup\{\tilde T(\tilde y)\le t\}$. On the set $\{T(y)\le t\}$ we have $\arctan u_x(t+h,\xi(t+h,y))=\arctan u_x(t,\xi(t,y))=-\infty$ so that in the fourth term in (3.34) only the integral over $\{T(y)>t,\,\tilde T(\tilde y)\le t\}$ might have a nonzero contribution. Thus the second and fourth terms in (3.34) combine to

$$\begin{aligned}
(3.35)\qquad &\kappa_0\int_{\{T(y)>t\}}(\arctan u_x(t+h,\xi(t+h,y))-\arctan u_x(t,\xi(t,y)))\\
&\qquad\times(1-\phi_{1,0}(y))\,\bar u_x^2(y)\,dy\\
&+\kappa_0\int_{\{\tilde T(\tilde y)\le t<T(y)\}}(\arctan u_x(t+h,\xi(t+h,y))-\arctan u_x(t,\xi(t,y)))\\
&\qquad\times\phi_{1,0}(y)\,\bar u_x^2(y)\,dy.
\end{aligned}$$

Similarly, the third and fifth terms combine to

$$\begin{aligned}
(3.36)\quad &\kappa_0\int_{\{\tilde T(\tilde y)>t\}}(\arctan \tilde u_x(t+h,\xi(t+h,\tilde y))\\
&\qquad-\arctan \tilde u_x(t,\xi(t,\tilde y)))(1-\phi_{2,0}(\tilde y))\,\tilde u_x^2(0,\tilde y)\,\psi_0'(y)\,dy\\
&+\kappa_0\int_{\{T(y)\le t<\tilde T(\tilde y)\}}(\arctan \tilde u_x(t+h,\xi(t+h,\tilde y))\\
&\qquad-\arctan \tilde u_x(t,\xi(t,\tilde y)))\,\phi_{2,0}(\tilde y)\,\tilde u_x^2(0,\tilde y)\,\psi_0'(y)\,dy.
\end{aligned}$$

To transform suitably the first term in (3.34), let us denote by $E^1(t,y)$ the first expression in the minimum (3.30), and by $E^2(t,y)$ the second. If $E(t,y)=E^2(t,y)$, then

(3.37)

$$\begin{aligned}
E(t+h,y)-E(t,y)\le \kappa_0\,&(\arctan u_x(t+h,\xi(t+h,y))-\arctan u_x(t,\xi(t,y))\\
&+\arctan \tilde u_x(t+h,\tilde\xi(t+h,\tilde y))-\arctan \tilde u_x(t,\tilde\xi(t,\tilde y))),
\end{aligned}$$

since $E(t+h,y) \le E^2(t+h,y)$. On the other hand, if $E(t,y) = E^1(t,y)$, then the triangle inequality and the relation $E(t+h,y) \le E^1(t+h,y)$ ensure that

$$\begin{aligned}(3.38)\quad E(t+h,y) - E(t,y) \le& \left|\xi(t+h,y) - \xi(t,y) + \tilde{\xi}(t+h,\tilde{y}) - \tilde{\xi}(t,\tilde{y})\right| \\ &+ \left|u(t+h,\xi(t+h,y)) - \tilde{u}(t+h,\tilde{\xi}(t+h,\tilde{y})) - u(t,\xi(t,y)) + \tilde{u}(t,\xi(t,\tilde{y}))\right| \\ &+ \kappa_0 \left| \arctan u_x(t+h,\xi(t+h,y)) - \arctan u_x(t,\xi(t,y)) \right. \\ &\qquad \left. + \arctan \tilde{u}_x(t+h,\tilde{\xi}(t+h,\tilde{y})) - \arctan \tilde{u}_x(t,\tilde{\xi}(t,\tilde{y}))\right|.\end{aligned}$$

Letting $h \downarrow 0$ in (3.34), and taking into account (3.38) and the considerations preceding it, we deduce that

(3.39)

$$\begin{aligned}\limsup_{h\downarrow 0} \frac{J(t+h)-J(t)}{h} \le& \kappa_0 J_0(t) + \int_{S(t)} \phi_{1,0}(y)\, \bar{u}_x^2(y) \left|\frac{d}{dt}\,\xi(t,y) - \frac{d}{dt}\,\tilde{\xi}(t,\psi_0(y))\right| dy \\ &+ \int_{S(t)} \phi_{1,0}(y)\, \bar{u}_x^2(y) \left|\frac{d}{dt}\,u(t,\xi(t,y)) - \frac{d}{dt}\,\tilde{u}(\tilde{\xi}(t,\psi_0(y)))\right| dy \\ &+ \kappa_0 \int_{S(t)} \phi_{1,0}(y)\, \bar{u}_x^2(y) \left|\frac{d}{dt} \text{ arctan } u_x(t,\xi(t,y)) - \frac{d}{dt} \text{ arctan } \tilde{u}_x(\tilde{\xi}(t,\psi_0(y)))\right| dy,\end{aligned}$$

where

$$\begin{aligned}J_0(t) =& \int_{[T(y)>t]} (1-\phi_{1,0}(y)) \left[\frac{d}{dt} \text{ arctan } u_x(t,\xi(t,y))\right] \bar{u}_x^2(y)\, dy \\ &+ \int_{[\tilde{T}(\tilde{y})>t]} (1-\phi_{2,0}(\tilde{y})) \left[\frac{d}{dt} \text{ arctan } \tilde{u}_x(t,\xi(t,\tilde{y}))\right] \tilde{u}_x^2(0,\tilde{y})\, d\tilde{y} \\ &+ \int_{[\tilde{T}(\tilde{y})\le t<T(y)]} \phi_{1,0}(y) \left[\frac{d}{dt} \text{ arctan } u_x(t,\xi(t,y))\right] \bar{u}_x^2(y)\, dy \\ &+ \int_{[T(y)\le t<\tilde{T}(\tilde{y})]} \phi_{2,0}(\tilde{y}) \left[\frac{d}{dt} \text{ arctan } \tilde{u}_x(t,\xi(t,\tilde{y}))\right] \tilde{u}_x^2(0,\tilde{y})\, d\tilde{y} \le 0,\end{aligned}$$

the last inequality being true by (2.4).

Before proceeding with further analysis of (3.39), we establish a few a priori bounds. From (2.22) we get

$$(3.40)\qquad \left|\frac{d}{dt}\,\xi(t,y) - \frac{d}{dt}\,\tilde{\xi}(t,\tilde{y})\right| = |u(t,\xi(t,y)) - \tilde{u}(t,\tilde{\xi}(t,\tilde{y}))|.$$

Also, note that if $v = \arctan z(t)$ and $\dot{z} = -\frac{z^2}{2}$, then

$$\dot{v} = -\frac{z^2}{2+2z^2} = -\frac{1}{2}\sin^2 v.$$

Since $|\sin^2\alpha - \sin^2\beta| \le |\alpha-\beta|$ by the mean-value theorem as $|(\sin^2 z)'| = 2|\sin z\, \cos z| = |\sin(2z)| \le 1$, we infer three useful facts if we set $z = u_x(t,\xi(t,x))$. First of all,

$$(3.41)\qquad \frac{d}{dt} \arctan u_x(t,\xi(t,y)),\ \frac{d}{dt} \arctan \tilde{u}_x(t,\tilde{u}(t,\tilde{\xi}(t,\tilde{y}))) \le 0.$$

Second,

$$\begin{aligned}(3.42)\qquad &\left|\frac{d}{dt}\ \text{arctan}\ u(t,\xi(t,y)) - \frac{d}{dt}\ \text{arctan}\ \tilde{u}(t,\tilde{\xi}(t,\tilde{y}))\right|\\ &\le \frac{1}{2}\,|\arctan u_x(t,\xi(t,y)) - \arctan \tilde{u}_x(t,\tilde{\xi}(t,\tilde{y}))|.\end{aligned}$$

Furthermore, if $\arctan z \le -\frac{\pi}{4}$, then $\sin(\arctan z) \in [-1, -\frac{1}{\sqrt{2}}]$, so that

$$(3.43)\qquad \frac{d}{dt}\arctan u_x(t,\xi(t,y)) \le -\frac{1}{4} \quad \text{if} \quad \arctan u_x(t,\xi(t,y)) \le -\frac{\pi}{4}.$$

On the other hand, using first (2.21) and then (2.18), we have

$$\begin{aligned}
&\left|\frac{d}{dt}\,u(t,\xi(t,y_0)) - \frac{d}{dt}\,\tilde{u}(t,\tilde{\xi}(t,\tilde{y}_0))\right| = |\varphi(t,y_0) - \tilde{\varphi}(t,\tilde{y}_0)|\\
&\quad = \frac{1}{4}\Big|\int_{\{T(y)>t\}} \text{sign}(y_0-y)\,\bar{u}_x^2(y)\,dy - \int_{\{\tilde{T}(\tilde{y})>t\}} \text{sign}(\tilde{y}_0-\tilde{y})\,\tilde{u}_x^2(0,\tilde{y})\,d\tilde{y}\Big|\\
&\quad = \frac{1}{4}\Big|\int_{-\infty}^{y_0} \bar{u}_x^2(y)\chi_{[T(y)>t]}dy - \int_{-\infty}^{\tilde{y}_0} \tilde{u}_x^2(0,\tilde{y})\,\chi_{[\tilde{T}(\tilde{y})>t]}d\tilde{y}\\
&\qquad - \int_{y_0}^{\infty} \bar{u}_x^2(y)\chi_{[T(y)>t]}dy - \int_{\tilde{y}_0}^{\infty} \tilde{u}_x^2(0,\tilde{y})\,\chi_{[\tilde{T}(\tilde{y})>t]}d\tilde{y}\Big|\\
&\quad = \frac{1}{4}\Big|\int_{-\infty}^{y_0} \bar{u}_x^2(y)\chi_{[T(y)>t]}dy - \int_{-\infty}^{y_0} \tilde{u}_x^2(0,\psi_0(y))\,\chi_{[\tilde{T}(\tilde{y})>t]}\,\psi_0'(y)\,dy\\
&\qquad - \int_{y_0}^{\infty} \bar{u}_x^2(y)\chi_{[T(y)>t]}dy - \int_{y_0}^{\infty} \tilde{u}_x^2(0,\psi_0(y))\,\chi_{[\tilde{T}(\tilde{y})>t]}\,\psi_0'(y)\,dy\Big|\\
&\quad = \frac{1}{4}\Big|\int_{-\infty}^{y_0}(1-\phi_{1,0}(y)+\phi_{1,0}(y))\bar{u}_x^2(y)\chi_{[T(y)>t]}dy\\
&\qquad - \int_{-\infty}^{y_0}(1-\phi_{2,0}(\psi_0(y))+\phi_{2,0}(\psi_0(y)))\tilde{u}_x^2(0,\psi_0(y))\,\chi_{[\tilde{T}(\tilde{y})>t]}\,\psi_0'(y)\,dy\\
&\qquad - \int_{y_0}^{\infty}(1-\phi_{1,0}(y)+\phi_{1,0}(y))\bar{u}_x^2(y)\chi_{[T(y)>t]}dy\\
&\qquad - \int_{y_0}^{\infty}(1-\phi_{2,0}(\psi_0(y))+\phi_{2,0}(\psi_0(y)))\tilde{u}_x^2(0,\psi_0(y))\,\chi_{[\tilde{T}(\tilde{y})>t]}\,\psi_0'(y)\,dy\Big|
\end{aligned}$$

after performing in the next to last step in two of the integrals the change of variables $\tilde{y} = \psi_0(y)$. Since equation (3.10) for $(\psi_0, \phi_{1,0}, \phi_{2,0})$ ensures that $\phi_{1,0}(y)\,\bar{u}_x^2(y) = \phi_{2,0}(\psi_0(y))\,\tilde{u}_x^2(0,\psi_0(y))\,\psi_0'(y)$ a.e. on $S(t)$, we deduce that

$$\begin{aligned}(3.44)\qquad &\Big|\frac{d}{dt}\,u(t,\xi(t,y_0)) - \frac{d}{dt}\,\tilde{u}(t,\tilde{\xi}(t,\tilde{y}_0))\Big|\\
&\le \frac{1}{4}\int_{[T(y)>t]}(1-\phi_{1,0}(y))\,\bar{u}_x^2(y)\,dy + \frac{1}{4}\int_{[\tilde{T}(\tilde{y})>t]}(1-\phi_{2,0}(\tilde{y}))\tilde{u}_x^2(0,\tilde{y})\,d\tilde{y}\\
&\quad + \frac{1}{4}\int_{[\tilde{T}(\tilde{y})\le t<T(y)]} \phi_{1,0}(y)\,\bar{u}_x^2(y)\,dy + \frac{1}{4}\int_{[T(y)\le t<\tilde{T}(\tilde{y})]} \phi_{2,0}(\tilde{y})\,\tilde{u}_x^2(0,\tilde{y})\,d\tilde{y}.\end{aligned}$$

Let us now introduce the following sets:

$$
\begin{aligned}
S_1 &= \Big\{y \in \mathbb{R}:\ \arctan\, u_x(t,\xi(t,y)) \le -\frac{\pi}{4} \quad \text{and} \quad \arctan\, \tilde{u}_x(t,\tilde{\xi}(t,\tilde{y})) \le -\frac{\pi}{4}\Big\},\\
S_2 &= \Big\{y \in \mathbb{R}:\ \arctan\, u_x(t,\xi(t,y)) > -\frac{\pi}{4} \quad \text{and} \quad \arctan\, \tilde{u}_x(t,\tilde{\xi}(t,\tilde{y})) > -\frac{\pi}{4}\Big\},\\
S_3 &= \Big\{y \in \mathbb{R}:\ \arctan\, u_x(t,\xi(t,y)) > -\frac{\pi}{4} \ge \arctan\, \tilde{u}_x(t,\tilde{\xi}(t,\tilde{y}))\Big\},\\
S_4 &= \Big\{y \in \mathbb{R}:\ \arctan\, \tilde{u}_x(t,\tilde{\xi}(t,\tilde{y})) > -\frac{\pi}{4} \ge \arctan\, u_x(t,\xi(t,y))\Big\}.
\end{aligned}
$$

The integral on the right-hand side of (3.44) over S_1 is, in view of (3.43), bounded from above by $|J_0(t)| = -\,J_0(t)$. The integral over S_2 is, in view of the formula for $J(t)$ preceding relation (2.29), bounded from above by $\frac{J(t)}{\pi\kappa_0}$. To evaluate the contribution over the integral over S_3, notice that the same formula for $J(t)$ yields

$$
\begin{aligned}
J(t) \ge{}& \kappa_0 \int_{S(t)\,\cap\, S_3} (\arctan u_x(t,\xi(t,y)) - \arctan \tilde{u}_x(t,\tilde{\xi}(t,\tilde{y})))\, \phi_{1,0}(y)\, \bar{u}_x^2(y)\, dy\\
&+ \kappa_0 \int_{S(t)\,\cap\, S_3} \Big(\frac{\pi}{2} + \arctan u_x(t,\xi(t,y))\Big)\, (1-\phi_{1,0}(y))\, \bar{u}_x^2(y)\, dy\\
&+ \kappa_0 \int_{S^c(t)\,\cap\, S_3} \Big(\frac{\pi}{2} + \arctan u_x(t,\xi(t,y))\Big)\, \bar{u}_x^2(y)\, dy\\
&+ \kappa_0 \int_{S(t)\,\cap\, S_3} \Big(\frac{\pi}{2} + \arctan \tilde{u}_x(t,\tilde{\xi}(t,\ \tilde{y}))\Big)\, (1-\phi_{2,0}(\tilde{y}))\, \tilde{u}_x^2(0,\tilde{y})\, \psi_0'(y)\, dy\\
&+ \kappa_0 \int_{S^c(t)\,\cap\, S_3} \Big(\frac{\pi}{2} + \arctan \tilde{u}_x(t,\ \tilde{\xi}(t,\ \tilde{y}))\Big)\, \tilde{u}_x^2(0,\tilde{y})\, \psi_0'(y)\, dy.
\end{aligned}
$$

Using (3.10), the sum of the first and fourth terms is larger than

$$
\begin{aligned}
&\kappa_0 \int_{S(t)\,\cap\, S_3} \Big(\frac{\pi}{2} + \arctan u_x(t,\xi(t,y))\Big)\, \tilde{u}_x^2(0,\tilde{y})\, \psi_0'(y)\, dy\\
&\quad\ge \frac{\kappa_0\pi}{4} \int_{S(t)\,\cap\, S_3} \tilde{u}_x^2(0,\tilde{y})\, \psi_0'(y)\, dy = \frac{\kappa_0\pi}{4} \int_{S(t)\,\cap\, S_3} \tilde{u}_x^2(0,\tilde{y})\, d\tilde{y}\\
&\quad\ge \frac{\kappa_0\pi}{4} \int_{S(t)\,\cap\, S_3} (1-\phi_{2,0}(\tilde{y}))\, \tilde{u}_x^2(0,\tilde{y})\, d\tilde{y} = \frac{\kappa_0\pi}{4} \int_{[\tilde{T}(\tilde{y})>t]\,\cap\, S_3} (1-\phi_{2,0}(\tilde{y}))\, \tilde{u}_x^2(0,\tilde{y})\, d\tilde{y},
\end{aligned}
$$

with the last equality enforced by $S_3 \subset [T(y) > t]$. The second term is bounded from below by

$$
\begin{aligned}
&\frac{\kappa_0\pi}{4} \int_{S(t)\cap\, S_3} (1-\phi_{1,0}(y))\, \bar{u}_x^2(y)\, dy = \frac{\kappa_0\pi}{4} \int_{[T(y)>t]\cap\, S_3} (1-\phi_{1,0}(y))\, \bar{u}_x^2(y)\, dy\\
&-\frac{\kappa_0\pi}{4} \int_{[T(y)>t\ge\tilde{T}(\tilde{y})]\cap\, S_3} (1-\phi_{1,0}(y))\bar{u}_x^2(y)dy = \frac{\kappa_0\pi}{4} \int_{[T(y)>t]\cap S_3} (1-\phi_{1,0}(y))\bar{u}_x^2(y)\, dy\\
&-\frac{\kappa_0\pi}{4} \int_{[T(y)>t\ge\tilde{T}(\tilde{y})]\cap S_3} \bar{u}_x^2(y)dy + \frac{\kappa_0\pi}{4} \int_{[T(y)>t\ge\tilde{T}(\tilde{y})]\cap S_3} \phi_{1,0}(y)\bar{u}_x^2(y)dy
\end{aligned}
$$

if we recall (3.10). The third term is bounded from below by

$$
\frac{\kappa_0\pi}{4} \int_{S^c(t)\,\cap\, S_3} \bar{u}_x^2(y)\, dy \ge \frac{\kappa_0\pi}{4} \int_{[T(y)>t\ge\tilde{T}(\tilde{y})]\,\cap\, S_3} \bar{u}_x^2(y)\, dy.
$$

Summing up, we get

$$J(t) \geq \frac{\kappa\pi}{4}\Bigg\{ \int_{[T(y)>t]\cap S_3} (1-\phi_{1,0}(y))\bar{u}_x^2(y)dy + \int_{[\tilde{T}(\tilde{y})>t]\cap S_3} (1-\phi_{2,0}(\tilde{y}))\tilde{u}_x^2(0,\tilde{y})\,d\tilde{y}$$

$$+ \int_{[\tilde{T}(\tilde{y})\leq t<T(y)]\cap S_3} \phi_{1,0}(y)\bar{u}_x^2(y)dy + \int_{[T(y)\leq t<\tilde{T}(\tilde{y})]\cap S_3} \phi_{2,0}(\tilde{y})\tilde{u}_x^2(0,\tilde{y})d\tilde{y}\Bigg\},$$

since the last term on the right is zero as $S_3 \subset [T(y) > t]$. A similar relation holds with S_4 instead of S_3. Consequently, putting together all this information about the various inequalities valid on the disjoint sets S_1, S_2, S_3, and S_4, we conclude by (3.44) that

$$\left|\frac{d}{dt}\,u(t,\xi(t,y_0)) - \frac{d}{dt}\,\tilde{u}(t,\tilde{\xi}(t,\tilde{y}_0))\right| \leq -J_0(t) + \frac{3J(t)}{\kappa_0\pi}. \tag{3.45}$$

To obtain now a suitable estimate on

$$\limsup_{h\downarrow 0}\frac{J(t+h)-J(t)}{h} = \limsup_{h\downarrow 0}\int_{S(t)} \frac{E(t+h,y)-E(t,y)}{h}\phi_{1,0}(y)\,\bar{u}_x^2(y)\,dy + \kappa_0\,J_0(t) \tag{3.46}$$

we distinguish two cases. If $E(t,y)$ is the second component $E^2(t,y)$ of the minimum in (3.30), then by (3.37) and (3.41) we can estimate the contribution of the first term in (3.46) by zero from above. On the other hand, if the minimum is $E^1(t,y)$, then the first integral term in (3.46) is not larger (pointwise) than the nonnegative expression

$$\left(E(t,y) + \frac{3J(t)}{\kappa_0\pi} - J_0(t)\right)\,\phi_{1,0}(y)\,\bar{u}_x^2(y)$$

in view of the estimates (3.40), (3.42), and (3.45). We conclude that

$$\limsup_{h\downarrow 0}\frac{J(t+h)-J(t)}{h} \leq J(t) + \left(\frac{3J(t)}{\kappa_0\pi} - J_0(t)\right)\,\|\bar{u}_x^2\|_{L^1(\mathbb{R})} + \kappa_0\,J_0(t).$$

Since $J_0(t) \leq 0$, choosing the constant $\kappa_0 \doteq \|\bar{u}_x^2\|_{\mathbf{L}^1(\mathbb{R})}$ we now have

$$\frac{d}{dt}J^{(\psi^t,\phi_1^t,\phi_2^t)}(u(t),\,v(t)) \leq 2\,J^{(\psi^t,\phi_1^t,\phi_2^t)}(u(t),\,v(t)).$$

Optimizing over all triples $(\psi^0,\phi_1^0,\phi_2^0)$ we conclude

$$J(u(t),\,v(t)) \leq J(u(0),\,v(0))\,e^{2t}, \quad t \geq 0. \tag{3.47}$$

Summing up the considerations made above, we proved the following result.

THEOREM 3.1. *The trajectories $t \mapsto u(t)$ of* (1.1) *constructed in Theorem* 2.1 *are locally Lipschitz continuous as maps from $[0,\infty)$ into the metric space $\mathcal{X}$ equipped with the distance functional J. Moreover, the distance between two trajectories is also locally Lipschitz continuous as a map from $[0,\infty)$ into $\mathcal{X}$.*

4. Concluding remarks. The following example shows that, in some sense, our distance functional J in (3.11) is "sharp." Indeed, the convergence of the initial data in $\mathbf{L}^\infty(\mathbb{R}) \cap \mathbf{L}^1(\mathbb{R})$ together with the weak convergence of the derivatives $\bar u_x$ and $\bar u_x^2$ in $\mathbf{L}^2(\mathbb{R})$ does not guarantee the convergence of the corresponding solutions at later times $t > 0$.

Example 1. Consider the functions $f, g : [0,1] \mapsto [0,1]$ defined as

$$f(x) \doteq \begin{cases} 1-2x & \text{if } x \in [0,\ 1/2], \\ 0 & \text{if } x \in [1/2,\ 1], \end{cases} \qquad g(x) \doteq \begin{cases} 1-3x & \text{if } x \in [0,\ 1/6], \\ 1/2 & \text{if } x \in [1/6,\ 1/2], \\ 1-x & \text{if } x \in [1/2,\ 1]. \end{cases}$$

Observe that

$$\int_0^1 f'(x)\,dx = \int_0^1 g'(x)\,dx = -1, \qquad \int_0^1 \big[f'(x)\big]^2\,dx = \int_0^1 \big[g'(x)\big]^2\,dx = 2.$$

Next, consider the function

$$h(x) \doteq \begin{cases} 1-|x| & \text{if } |x| \le 1, \\ 0 & \text{if } |x| \ge 1, \end{cases}$$

and define the sequences of initial values

$$\bar u_n(x) = \begin{cases} h(x) & \text{if } x \notin [0,1], \\ h(i/n) + \frac{1}{n} f(nx-i+1) & \text{if } x \in \left[\frac{i-1}{n},\ \frac{i}{n}\right], \quad i = 1,\dots,n, \end{cases}$$
$$\bar v_n(x) = \begin{cases} h(x) & \text{if } x \notin [0,1], \\ h(i/n) + \frac{1}{n} g(nx-i+1) & \text{if } x \in \left[\frac{i-1}{n},\ \frac{i}{n}\right], \quad i = 1,\dots,n. \end{cases}$$

Letting $n \to \infty$ we now have the strong convergence $\big\|\bar u_n - \bar v_n\big\|_{\mathbf{L}^\infty(\mathbb{R})} \to 0$. Moreover, by construction it is easy to see that at each point $x \in [0,1]$,

$$\lim_{n\to\infty} \int_0^x \big((\bar u_n)_x(y) - (\bar v_n)_x(y)\big)\,dy = \lim_{n\to\infty} \int_0^x \big((\bar u_n)_x^2(y) - (\bar v_n)_x^2(y)\big)\,dy = 0$$

so that in $\mathbf{L}^2[0,1]$ one has the weak convergence

$$(\bar u_n)_x - (\bar v_n)_x \rightharpoonup 0, \qquad (\bar u_n)_x^2 - (\bar v_n)_x^2 \rightharpoonup 0,$$

since both sequences are bounded in $\mathbf{L}^2[0,1]$ and the previous observation identifies the zero function as the only possible weak limit. However,

$$u(t) \doteq \lim_{n\to\infty} u_n(t) \;\neq\; \lim_{n\to\infty} v_n(t) \doteq v(t)$$

for every $t \in (2/3, 1)$, where $T = 2/3$ is the time at which the gradients of the functions v_n blow up. The last assertion follows at once from (2.27).

We also would like to highlight the importance of requiring that the transport map ψ in (3.10) be monotone nondecreasing. If in (3.11) we were to take the minimization over all maps ψ, not necessarily monotone, we would obtain the classical Kantorovich–Rubinstein distance between measures, which generates the weak topology on the space of bounded, positive measures [V]. By restricting ourselves to monotone nondecreasing maps ψ, the corresponding distance functional generates a much stronger topology.

Example 2. Consider the sequence of Lipschitz functions

$$u^m(x) \doteq \begin{cases} 0 & \text{if } x \notin [0,1], \\ x-(i-1)/m & \text{if } (i-1)/m \le x \le (2i-1)/2m, \\ i/m - x & \text{if } (2i-1)/2m \le x \le i/m, \end{cases} \qquad i=1,\dots,m.$$

In this case, $u_x = \pm 1$ and $\arctan u_x = \pm\pi/4$. The corresponding measures μ^{u^m} defined at (3.9) converge weakly to the measure μ on $\mathbb{R}^2 \times [-\pi/2,\ \pi/2]$ defined as

$$\mu(A) \doteq \frac{1}{2}\,\text{meas}\Big\{x\in[0,1];(x,\,0,\,\pi/4)\in A\Big\} + \frac{1}{2}\,\text{meas}\Big\{x\in[0,1]\,;\ \ (x,\,0,\,-\pi/4)\in A\Big\}.$$

In particular, these measures form a Cauchy sequence in the Kantorovich metric. However, these same functions u^m do not form a Cauchy sequence with respect to the distance J. Indeed, let $m<n$. Notice that in our case $\kappa_0 \doteq \|\bar u_x^2\|_{\mathbf{L}^1(\mathbb{R})} = 1$. Consider the open intervals

$$I_i^{m+} = \left]\frac{i-1}{m},\frac{2i-1}{2m}\right[, \qquad\qquad I_i^{m-} = \left]\frac{2i-1}{2m},\frac{i}{m}\right[,$$

where u_x^m takes the values $+1$ and -1, respectively. Define the intervals I_j^{n+}, I_j^{n-} similarly. Now consider any transportation plan (ψ,ϕ_1,ϕ_2) relating u^m to u^n via (3.10), with ψ nondecreasing. For each $i=1,\dots,m$, call ν_i the number of distinct intervals I_j^{n+} which intersect the image $\psi(I_i^{m+})$. Since ψ is monotone, if $\nu_i\ge 2$, this implies that the image $\psi(I_i^{m+})$ entirely covers at least ν_i-1 distinct intervals I_j^{n-}. Because $u_x^m=1$ on I_i^{m+} and $u_x^n=-1$ on each I_j^{n-}, on the union of these intervals I_j^{n-} we have $\arctan u_x^m(\psi(x)) = -\arctan u_x^n(x) = \frac{\pi}{4}$ so that the integrand contribution from the first two parts of (3.11) is pointwise larger than $\frac{\pi}{2}\phi_1(x)+\frac{\pi}{4}\,(1-\phi_1(x))\ge\frac{\pi}{4}$, which therefore accounts for a cost $\ge \pi(\nu_i-1)/8n$. Next, if $\nu_1+\cdots+\nu_m = n^* < n$, there must be $n-n^*$ intervals $I^{n+}_{j(1)},\dots,I^{n+}_{j(n^*-n)}$ which do not intersect any of the sets $\psi(I_i^{m+})$ for $i=1,\dots,m$. These intervals must be contained in the image of some I_i^{m-}, or in the image of the set $\psi\big(\mathbb{R}\setminus[0,1]\big)$, where $u^m\equiv 0$. This accounts for a cost $\ge \pi(n-n^*)/4n$.

The above argument shows that, for any $m<n$, the cost of any transportation plan relating u^m to u^n is bounded below by

$$J^{(\psi,\phi_1,\phi_2)}(u^m,u^n) \ge \frac{\pi}{8n}\cdot\max\left\{\sum_{i=1}^m(\nu_i-1),\ n-\sum_{i=1}^m\nu_i\right\} \ge \frac{\pi}{8n}\cdot\frac{n-m}{2}.$$

For any fixed m, the right-hand side approaches $\pi/16$ as $n\to\infty$. Therefore, the above is not a Cauchy sequence in our transportation metric.

Acknowledgment. The authors are grateful to both referees for useful comments.

AN INVERSE PROBLEM FOR MAXWELL'S EQUATIONS IN BI-ISOTROPIC MEDIA*

SHUMIN LI†

Abstract. In this paper, we consider Maxwell's equations in a bi-isotropic and inhomogeneous medium. We discuss an inverse problem of determining the coefficients ε, ζ, μ in the constitutive relations from a finite number of interior measurements. We prove a Lipschitz stability estimate for the inverse problem by applying the argument on the basis of Carleman estimate.

Key words. inverse problem, Maxwell's equations, bi-isotropic, magnetoelectric, Carleman estimate, stability

1. Introduction and main results.

We consider Maxwell's equations in a bi-isotropic and inhomogeneous medium:

$$\begin{cases} \partial_t D(x,t) - \nabla \times H(x,t) = 0, & (x,t) \in Q, \\ \partial_t B(x,t) + \nabla \times E(x,t) = 0, & (x,t) \in Q, \\ \nabla \cdot D(x,t) = \nabla \cdot B(x,t) = 0, & (x,t) \in Q, \\ D(x,0) = d(x), \quad B(x,0) = b(x), & x \in \Omega, \\ \nu(x) \times E(x,t) = q(x,t), & (x,t) \in \Sigma, \end{cases} \tag{1.1}$$

with the constitutive relations

$$\begin{cases} D(x,t) = \varepsilon(x)E(x,t) + \zeta(x)H(x,t), & (x,t) \in Q, \\ B(x,t) = \zeta(x)E(x,t) + \mu(x)H(x,t), & (x,t) \in Q. \end{cases} \tag{1.2}$$

Here and henceforth $x = (x_1, x_2, x_3) \in \mathbb{R}^3$, $\partial_t = \frac{\partial}{\partial t}$, $\partial_k = \frac{\partial}{\partial x_k}$ for $k = 1, 2, 3$, $\nabla = (\partial_1, \partial_2, \partial_3)^{\mathrm{T}}$, Δ is the Laplacian in x, $Q = \Omega \times (-T, T)$, Ω is a bounded domain in $\mathbb{R}^3$ with C^2-boundary $\partial\Omega$, $\Sigma = \partial\Omega \times (-T, T)$ and $\nu(x) = (\nu_1(x), \nu_2(x), \nu_3(x))^{\mathrm{T}}$ is the outward unit normal vector to $\partial\Omega$ at x. In (1.1),

$$\begin{aligned} D(x,t) &= (D_1(x,t), D_2(x,t), D_3(x,t))^{\mathrm{T}} : && \text{the electric flux density,} \\ B(x,t) &= (B_1(x,t), B_2(x,t), B_3(x,t))^{\mathrm{T}} : && \text{the magnetic flux density,} \\ E(x,t) &= (E_1(x,t), E_2(x,t), E_3(x,t))^{\mathrm{T}} : && \text{the electric field,} \\ H(x,t) &= (H_1(x,t), H_2(x,t), H_3(x,t))^{\mathrm{T}} : && \text{the magnetic field.} \end{aligned}$$

$d(x)$, $b(x)$, $q(x,t)$ are given vector-valued functions and $\varepsilon(x)$, $\zeta(x)$, $\mu(x)$ are real-valued functions. Here and henceforth $\cdot^{\mathrm{T}}$ denotes the transposes of vectors or matrices under the consideration.

Our consideration is based on some physical background. In fact, there exist materials which can exhibit the magnetoelectric effect. For example, we can consider

some magnetic crystals such as antiferromagnetic Cr_2O_3 and ferromagnetic $GaFeO_3$ (cf. [24, 21]). For details, we refer to [24, 5, 21, 22]. The constitutive relations for magnetoelectric media can be written in the following form (cf. [24, 5]):

$$\begin{cases} D = \overline{\varepsilon}E + \overline{\zeta}H, \\ B = \overline{\zeta}^{\mathrm{T}}E + \overline{\mu}H, \end{cases}$$

where the three 3×3 matrices $\overline{\varepsilon}$, $\overline{\mu}$, and $\overline{\zeta}$ are the permittivity tensor, the permeability tensor, and the Dzyaloshinskii magnetoelectric tensor, respectively. This paper is concerned with the bi-isotropic case, that is, $\overline{\varepsilon} = \varepsilon\mathbf{I}_3$, $\overline{\zeta} = \zeta\mathbf{I}_3$, and $\overline{\mu} = \mu\mathbf{I}_3$, where ε, ζ and μ are real-valued functions of x and $\mathbf{I}_3$ denotes the 3×3 unit matrix.

In this paper, we first consider the following.

Inverse problem: Let $\omega \subset \Omega$ satisfy $\partial\Omega \subset \partial\omega$ and $T > 0$ be suitably given. Then determine $\varepsilon(x)$, $\zeta(x)$, $\mu(x)$ for $x \in \Omega$ from the observation data

$$D(x,t), \quad B(x,t), \qquad (x,t) \in Q_\omega \equiv \omega \times (-T,T).$$

To the author's best knowledge, in the existing papers, inverse problems of determining all the coefficients for Maxwell's equations are mainly considered for the classical isotropic case. The purpose of this paper is to prove the Lipschitz stability for the inverse problem in a more general media. For other inverse problems for Maxwell's equations, we refer to Romanov [26], Romanov and Kabanikhin [27], Sun and Uhlmann [28], Yamamoto [29, 30], and Li and Yamamoto [23].

To state our main results, we introduce the notations. For the coefficients ε, ζ, μ in the constitutive relations (1.2), we set $\epsilon = (\varepsilon, \zeta, \mu)$. By $D[\epsilon;\Phi](\cdot)$, $B[\epsilon;\Phi](\cdot)$, $E[\epsilon;\Phi](\cdot)$, and $H[\epsilon;\Phi](\cdot)$, we denote the solution of (1.1) and (1.2) with the initial and boundary conditions $\Psi \equiv (d, b, q)$.

To guarantee the uniqueness in the inverse problem, we will use two sets of initial and boundary data: $\Phi(j) = \left(d^j, b^j, q^j\right)$, $j = 1, 2$. For the sake of convenience, we assume that d^j, b^j, and q^j $(j = 1, 2)$ are sufficiently smooth and satisfy sufficient compatibility conditions so that $D[\epsilon;\Phi]$, $B[\epsilon;\Phi] \in \left(W^{2,\infty}(Q)\right)^3$. Denote by $\mathbb{G}$ the 12×9 matrix

$$\begin{pmatrix} 0 & e_1\times d^1 & e_1\times b^1 & 0 & e_2\times d^1 & e_2\times b^1 & 0 & e_3\times d^1 & e_3\times b^1 \\ e_1\times d^1 & e_1\times b^1 & 0 & e_2\times d^1 & e_2\times b^1 & 0 & e_3\times d^1 & e_3\times b^1 & 0 \\ 0 & e_1\times d^2 & e_1\times b^2 & 0 & e_2\times d^2 & e_2\times b^2 & 0 & e_3\times d^2 & e_3\times b^2 \\ e_1\times d^2 & e_1\times b^2 & 0 & e_2\times d^2 & e_2\times b^2 & 0 & e_3\times d^2 & e_3\times b^2 & 0 \end{pmatrix},$$

where $e_1 = (1,0,0)^{\mathrm{T}}$, $e_2 = (0,1,0)^{\mathrm{T}}$, and $e_3 = (0,0,1)^{\mathrm{T}}$.

For $W = (w_1, w_2, \ldots, w_n)^{\mathrm{T}}$, we set $|W|^2 = \sum_{k=1}^n |w_k|^2$. Furthermore, $L^2(\Omega)$, $H^1(Q_\omega)$, etc. denote usual Sobolev spaces.

Let $\lambda = \inf_{x\in\overline{\Omega}} |x|$ and $\Lambda = \sup_{x\in\overline{\Omega}} |x|$. We assume that

$$0 < \Lambda^2 < 2\lambda^2. \tag{1.3}$$

We introduce an admissible set of unknown coefficients $\epsilon = (\varepsilon, \zeta, \mu)$, $\widetilde{\epsilon} = \left(\widetilde{\varepsilon}, \widetilde{\zeta}, \widetilde{\mu}\right)$:

$$\mathcal{U} = \mathcal{U}_{M,\theta_0,\theta_1,\epsilon_0} = \big\{(\varepsilon,\zeta,\mu) \in (C^2(\overline{\Omega}))^3 : \quad (\varepsilon,\zeta,\mu) = \epsilon_0 \text{ on } \partial\Omega;$$

$$\|\varepsilon\|_{C^2(\overline{\Omega})}, \|\zeta\|_{C^2(\overline{\Omega})}, \|\mu\|_{C^2(\overline{\Omega})}, \|\nabla(\varepsilon\mu-\zeta^2)\|_{(C(\overline{\Omega}))^3} < M; \varepsilon, \mu, \varepsilon\mu-\zeta^2 > \theta_1 \text{ on } \overline{\Omega};$$

$$\tfrac{x\cdot\nabla(\varepsilon\mu-\zeta^2)}{2(\epsilon\mu-\zeta^2)} > -\theta_0 \text{ on } \overline{\Omega}; \|D[\epsilon;\Phi(j)]\|_{(W^{2,\infty}(Q))^3}, \|B[\epsilon;\Phi(j)]\|_{(W^{2,\infty}(Q))^3} < M \text{ for } j=1,2\big\},$$

where the constants $M > 0$, $0 < \theta_0 < 1$, $\theta_1 > 0$ and a smooth vector-valued function $\epsilon_0 = (\varepsilon_0, \zeta_0, \mu_0)$ on $\partial\Omega$ are given. Furthermore, we take a positive constant β such that

$$0 < \beta < \frac{-\lambda\sqrt{\theta_1} + \sqrt{\lambda^2\theta_1 + 4\theta_1^2(1-\theta_0)}}{2M\theta_1}. \tag{1.4}$$

The following is our main result.

THEOREM 1.1 (stability). *We assume* (1.3), (1.4), *and*

$$\frac{\sqrt{\Lambda^2 - \lambda^2}}{\beta} < T. \tag{1.5}$$

Furthermore, we assume that there exists a constant $\theta_2 > 0$ *such that*

$$\text{the absolute value of one of the } 9 \times 9 \text{ minors of } \mathbb{G}(x) \ge \theta_2, \quad \text{for all } x \in \overline{\Omega}. \tag{1.6}$$

Then there exists a constant $K = K(\Omega, T, \Phi(1), \Phi(2), M, \theta_0, \theta_1, \theta_2, \epsilon_0) > 0$ *such that*

$$\|\widetilde{\varepsilon} - \varepsilon\|_{L^2(\Omega)} + \|\widetilde{\zeta} - \zeta\|_{L^2(\Omega)} + \|\widetilde{\mu} - \mu\|_{L^2(\Omega)} \le K\Theta \tag{1.7}$$

for all $\epsilon = (\varepsilon, \zeta, \mu) \in \mathcal{U}$ *and* $\widetilde{\epsilon} = (\widetilde{\varepsilon}, \widetilde{\zeta}, \widetilde{\mu}) \in \mathcal{U}$, *where*

$$\begin{aligned}\Theta = \sum_{j=1}^{2}\{&\|\partial_t(D[\epsilon;\Phi(j)] - D[\widetilde{\epsilon};\Phi(j)])\|_{(H^1(Q_\omega))^3} \\ &+ \|\partial_t(B[\epsilon;\Phi(j)] - B[\widetilde{\epsilon};\Phi(j)])\|_{(H^1(Q_\omega))^3}\}.\end{aligned} \tag{1.8}$$

We will provide a proof of Theorem 1.1 in section 3 by applying the argument on the basis of Carleman estimate and the energy conservation law. The method of applying Carleman estimate (i.e., a weighted L^2-estimate) to inverse problems was invented by Bukhgeim and Klibanov [3]. For developments of this method, we refer to Bukhgeim [2]; Imanuvilov, Isakov, and Yamamoto [9]; Imanuvilov and Yammamoto [10, 11, 12]; Isakov [14, 15]; Khaĭdarov [17, 18]; Klibanov [19]; and Yamamoto [30, 31]. In section 2, we will state a key Carleman estimate.

For similar inverse problems, we refer to [9] for a Lamé system and [12] for an acoustic equation. In [9, 12], the stability estimate is of Hölder's type. Due to the energy conservation law (3.2) in Lemma 3.1 (ii), we gain here Lipschitz stability estimate (1.7), which is one main achievement.

Furthermore, in Theorem 2.1 in [9], the H^5-norms of observation data are needed in the stability estimate. Here we need at most H^2-norms. There are two reasons. First, in the proof of Theorem 2.1 in [9], higher-order (the second, third, fourth) derivatives with respect to t are used as in [12]. Instead of using higher-order derivatives with respect to t, we use energy estimate (3.1) similarly to [10]. Second, the solution to the corresponding initial-value/boundary-value problem, has only three components in [9]. In this paper, there are in total six components of the vector-valued functions D and B. On the other hand, there are three unknown coefficients both in [9] and in this paper so that we can reduce the order of t-derivatives.

Remark 1.1. In Theorem 1.1, we have to assume a monotonicity condition about the wave speed $(\varepsilon\mu - \zeta^2)^{-(1/2)}$:

$$\frac{x \cdot \nabla(\varepsilon\mu - \zeta^2)}{2(\epsilon\mu - \zeta^2)} > -\theta_0 \text{ on } \overline{\Omega}. \tag{1.9}$$

We may be able to replace (1.9) by a weaker condition, but it is extremely difficult to search for sharpest conditions for deriving a Carleman estimate which is the main tool for our proof. Condition (1.9) is a sufficient condition for the pseudoconvexity, which is a sharp sufficient condition for a Carleman estimate (e.g., [6, 15]), and a similar condition is assumed in the existing references (cf. [4, 9, 12, 13, 15, 16, 17, 20]). In this paper, further searches will not be made for a more general condition than (1.9). In particular, if $\varepsilon\mu - \zeta^2$ is close to a constant function, then (1.9) holds true. Furthermore, we note that similar conditions to (1.3)–(1.5) are adopted in [9].

Remark 1.2. Condition (1.6) enables us to obtain sufficient information from the observation data in order to determine the unknown coefficients and we should a posteriori choose initial data meeting (1.6). It is a common feature in inverse problems with a finite number of measurements that such conditions should be satisfied by initial data (e.g., [9, 10, 12]). There exist initial data satisfying (1.6). For example, we take $d^1(x) = e_3$, $b^1(x) = d^2(x) = e_2$, $b^2(x) = e_1$ for $x \in \overline{\Omega}$. In fact, the 9×9 minor formed by rows 1, 2, 3, 4, 5, 9, 10, 11, and 12 satisfies (1.6) if we take $0 < \theta_2 < 1$.

Remark 1.3. By setting

$$\mathbb{A}_0 = \begin{pmatrix} \varepsilon\mathbf{I}_3 & \zeta\mathbf{I}_3 \\ \zeta\mathbf{I}_3 & \mu\mathbf{I}_3 \end{pmatrix}, \quad \mathbb{A}_k = \begin{pmatrix} 0 & A_k \\ -A_k & 0 \end{pmatrix}, \quad k = 1, 2, 3,$$

$$A_1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix}, \quad A_2 = \begin{pmatrix} 0 & 0 & -1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad A_3 = \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

and $U = (E_1, E_2, E_3, H_1, H_2, H_3)^{\mathrm{T}}$, Maxwell's equations with the constitutive relations (1.2) can be written as

$$\mathbb{A}_0 \partial_t U + \sum_{k=1}^{3} \mathbb{A}_k \partial_k U = 0.$$

It is obvious that $\mathbb{A}_0^{\mathrm{T}} = \mathbb{A}_0$ and $\mathbb{A}_k^{\mathrm{T}} = \mathbb{A}_k$ $(k = 1, 2, 3)$. Moreover, $\mathbb{A}_0$ is a 6×6 positive definite matrix if there exists a constant θ_1 such that ϵ, μ, $\epsilon\mu - \zeta^2 \geq \theta_1$. Therefore, for initial-value/boundary-value problem (1.1) and (1.2), we can refer to the results on symmetric hyperbolic equations.

This paper consists of two more sections. In section 2, we will show a Carleman estimate for Maxwell's equations in bi-isotropic media. In section 3, we will complete the proof of Theorem 1.1.

2. Carleman estimates for Maxwell's equations. Reducing Maxwell's equations to a weakly coupled system of hyperbolic equations and applying a Carleman estimate in the H^{-1}-norms, we will establish a Carleman estimate for Maxwell's equations in bi-isotropic media. For such methods, we can refer to [9, 30].

First, we show a Carleman estimate in the H^{-1}-norms for a second order hyperbolic equation which is proved in [9].

For β and λ, we define the functions $\varphi = \varphi(x, t)$ by

$$\varphi(x, t) = \mathrm{e}^{\varrho(|x|^2 - \beta^2 t^2 - \lambda^2)} \tag{2.1}$$

with some large $\varrho > 0$. For $(\varepsilon, \zeta, \mu) \in \mathcal{U}$, we set

$$\xi = \varepsilon\mu - \zeta^2 \quad \text{on } \overline{\Omega}. \tag{2.2}$$

By $(\varepsilon, \zeta, \mu) \in \mathcal{U}$ and (1.4), we can verify that $a = \xi^{1/2}$ satisfies the conditions $-\theta_0 < \frac{x\cdot\nabla a}{a}$ and $2|\nabla a|\lambda\beta + a^2\beta^2 < 1 - \theta_0$ on $\overline{\Omega}$ (cf. (2.2) and (2.3) in [9]). Furthermore, we note that our weight function φ coincides with that in [9] (cf. (4.3) in [9]).

Proposition 2.1 (see [9]). *Let $\varphi(x,t)$ be given by* (2.1) *and the domain Ω satisfy* (1.3). *We assume that $(\varepsilon, \zeta, \mu) \in \mathcal{U}$ and $0 < T < \frac{\lambda}{\beta}$, where β satisfies* (1.4). *Let $u \in H_0^2(Q)$ satisfy*

$$\xi(x)\left[\partial_t^2 u(x,t)\right] - \Delta u(x,t) = \widetilde{g} + \partial_t g_0 + \sum_{k=1}^{3} \partial_k g_k,\ (x,t) \in Q,$$

where ξ is defined by (2.2). *Then there is $K_1 > 0$ such that for all $s > K_1$,*

$$\int_Q s|u|^2 \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t \le K_1 \int_Q \left(\frac{1}{s^2}|\widetilde{g}|^2 + \sum_{k=0}^{3} |g_k|^2\right) \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t.$$

For the proof of Proposition 2.1, we refer to Theorem 3.2 and section 4 in [9] and section 3.4 in [15]. For similar results, we can refer to Proposition 2.1 in [12] which is derived from Theorem 1.1 in Imanuvilov [8]. Furthermore, we can refer to Ruiz [25]. For Carleman estimate in the H^{-1}-norms for parabolic equations, we refer to [11]. As for Carleman estimate in the L^2-norms, we refer to Hörmander [6, 7], Isakov [15, 16].

Now we state a Carleman estimate for Maxwell's equations, which is the main ingredient for the proof of Theorem 1.1. We will prove it by applying Proposition 2.1.

Theorem 2.2. *Let $\varphi(x,t)$ be given by* (2.1) *and the domain Ω satisfy* (1.3). *We assume that $\epsilon = (\varepsilon, \zeta, \mu) \in \mathcal{U}$ and $0 < T < \frac{\lambda}{\beta}$, where β satisfies* (1.4). *Let D, $B \in \left(H_0^1(Q)\right)^3$ satisfy*

$$\partial_t D - \nabla \times H = R_1, \quad \partial_t B + \nabla \times E = R_2, \tag{2.3}$$

$$D = \varepsilon E + \zeta H, \quad B = \zeta E + \mu H, \tag{2.4}$$

$$\nabla \cdot D = r_1, \quad \nabla \cdot B = r_2 \tag{2.5}$$

in Q. Then there exist $s_0 = s_0(\varrho) > 0$ and $K_2 = K_2(s_0, \beta, \varrho, M, \theta_0, \theta_1, \Omega, T) > 0$ such that for $s > s_0$

$$\begin{aligned} &s\int_Q \left(|D|^2 + |E|^2 + |B|^2 + |H|^2\right) \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t \\ &\quad \le K_2 \sum_{k=1}^{2} \int_Q \left(|r_k|^2 + |R_k|^2\right) \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t. \end{aligned} \tag{2.6}$$

Proof. By the density argument, it suffices to prove (2.6) for D, $B \in \left(C_0^\infty(Q)\right)^3$ satisfying (2.3)–(2.5).

By $\epsilon \in \mathcal{U}$, we have $\xi > \theta_1$ on $\overline{\Omega}$ where ξ is defined by (2.2). By (2.4) and direct calculations, we have

$$E = \gamma_1 D + \gamma_2 B, \quad H = \gamma_2 D + \gamma_3 B, \qquad \text{in } Q, \tag{2.7}$$

where

$$\gamma_1 = \frac{\mu}{\xi}, \quad \gamma_2 = -\frac{\zeta}{\xi}, \quad \gamma_3 = \frac{\varepsilon}{\xi} \qquad \text{on } \overline{\Omega}. \tag{2.8}$$

Moreover, by $\epsilon \in \mathcal{U}$, we have $\gamma_k \in C^2\left(\overline{\Omega}\right)$ for $k = 1, 2, 3$ and

$$\gamma_1\gamma_3 - \gamma_2^2 = \frac{1}{\xi} > 0 \qquad \text{on } \overline{\Omega}. \tag{2.9}$$

Differentiating the second equality in (2.7) with respect to t, in terms of (2.3), (2.7), and (2.9), we have

$$\begin{aligned}
\partial_t H &= \gamma_2 \left(\partial_t D\right) + \gamma_3 \left(\partial_t B\right) \\
&= \gamma_2 \left(\nabla \times H + R_1\right) + \gamma_3 \left(-\nabla \times E + R_2\right) \\
&= \gamma_2 \left[\nabla \times \left(\gamma_2 D + \gamma_3 B\right) + R_1\right] + \gamma_3 \left[-\nabla \times \left(\gamma_1 D + \gamma_2 B\right) + R_2\right] \\
&= \left(\gamma_2^2 - \gamma_1\gamma_3\right)\left(\nabla \times D\right) + \Upsilon(D, B) + \gamma_2 R_1 + \gamma_3 R_2 \\
&= -\frac{1}{\xi}\left(\nabla \times D\right) + \Upsilon(D, B) + \gamma_2 R_1 + \gamma_3 R_2 \qquad \text{in } Q,
\end{aligned}$$

where $\Upsilon(D, B) = \gamma_2 \left[(\nabla\gamma_2) \times D + (\nabla\gamma_3) \times B\right] + \gamma_3 \left[-\left(\nabla\gamma_1\right) \times D - (\nabla\gamma_2) \times B\right]$. For the fourth equality, we have used

$$\nabla \times (\alpha A) = \alpha\left(\nabla \times A\right) + (\nabla\alpha) \times A \qquad \text{on } \overline{\Omega} \tag{2.10}$$

for $\alpha \in C^1\left(\overline{\Omega}\right)$ and $A \in \left(C^1\left(\overline{\Omega}\right)\right)^3$. Therefore, differentiating the first equation of (2.3) with respect to t, we obtain

$$\begin{aligned}
\partial_t R_1 &= \partial_t^2 D - \nabla \times \left(\partial_t H\right) = \partial_t^2 D - \nabla \times \left[-\frac{1}{\xi}(\nabla \times D) + \Upsilon(D, B) + \gamma_2 R_1 + \gamma_3 R_2\right] \\
&= \partial_t^2 D + \frac{1}{\xi}[\nabla \times (\nabla \times D)] + \left[\nabla\left(\frac{1}{\xi}\right)\right] \times (\nabla \times D) - \nabla \times \left[\Upsilon(D, B) + \gamma_2 R_1 + \gamma_3 R_2\right]
\end{aligned}$$

in Q. In the third equality, we have used (2.10). Then by $\nabla \times (\nabla \times D) = -\Delta D + \nabla\left(\nabla \cdot D\right)$ and the first equation of (2.5), we have

$$\partial_t^2 D - \frac{1}{\xi}\Delta D = -\left[\nabla\left(\frac{1}{\xi}\right)\right] \times (\nabla \times D) - \frac{1}{\xi}\nabla r_1 + \nabla \times \left[\Upsilon(D, B) + \gamma_2 R_1 + \gamma_3 R_2\right] + \partial_t R_1$$

in Q. Hence we can apply Proposition 2.1 and obtain that there exist $s_1 = s_1(\varrho) > 0$ and $C_1 > 0$ such that for $s > s_1$

$$s\int_Q |D|^2 \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t \le C_1 \int_Q \left(|r_1|^2 + |D|^2 + |B|^2 + |R_1|^2 + |R_2|^2\right) \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t. \tag{2.11}$$

Here and henceforth, $C_k (k = 1, 2, \dots)$ denote generic positive constants which may depend on $s_l (l = 0, 1, 2, \dots)$, ϱ, M, θ_0, θ_1, ϵ_0, λ, Λ, β, Ω, T, Σ, χ_1, χ_2, δ, η, t_1, t_2, $\left\|d^1\right\|_{\left(C^1(\overline{\Omega})\right)^3}$, $\left\|d^2\right\|_{\left(C^1(\overline{\Omega})\right)^3}$, $\left\|b^1\right\|_{\left(C^1(\overline{\Omega})\right)^3}$, $\left\|b^2\right\|_{\left(C^1(\overline{\Omega})\right)^3}$, but are independent of s and ϑ.

Similarly to (2.11), we can obtain that there exist $s_2 = s_2(\varrho) > 0$ and $C_2 > 0$ such that for $s > s_2$

$$s\int_Q |B|^2 \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t \le C_2 \int_Q \left(|r_2|^2 + |D|^2 + |B|^2 + |R_1|^2 + |R_2|^2\right) \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t. \tag{2.12}$$

By (2.7), (2.11), and (2.12), we see that there exist $s_0 = s_0(\varrho) > 0$ and $C_3, C_4 > 0$ such that for $s > s_0$

$$s\int_Q \left(|D|^2+|E|^2+|B|^2+|H|^2\right) \mathrm{e}^{2s\varphi}\mathrm{d}x\mathrm{d}t \le C_3 s\int_Q \left(|D|^2+|B|^2\right)\mathrm{e}^{2s\varphi}\mathrm{d}x\mathrm{d}t$$
$$\le C_4\int_Q \left(|r_1|^2+|r_2|^2+|R_1|^2+|R_2|^2\right)\mathrm{e}^{2s\varphi}\mathrm{d}x\mathrm{d}t.$$

The proof of Theorem 2.2 is finished. □

The following is a Carleman estimate for a first-order differential equation.

PROPOSITION 2.3 (see [9]). *Let $\varphi(x,t)$ be given by* (2.1). *Then there exists $K_3 > 0$ such that for $s > K_3$*

$$\int_\Omega s|w|^2\mathrm{e}^{2s\varphi(x,0)}\mathrm{d}x \le K_3\sum_{j=1}^{3}\int_\Omega |\partial_j w|^2\mathrm{e}^{2s\varphi(x,0)}\mathrm{d}x \quad \textit{for all } w\in C_0^1\left(\overline{\Omega}\right). \tag{2.13}$$

We can prove Proposition 2.3 directly by integral by parts (e.g., Lemma 3.6 in [9]).

3. Proof of Theorem 1.1. We divide the proof into five steps.

Step 1. First we show a lemma, the first part of which is proved by the argument in [10] and Carleman estimate (2.6) for Maxwell's equations in bi-isotropic media.

LEMMA 3.1. *Let $\varphi(x,t)$ be given by* (2.1) *and the domain Ω satisfy* (1.3). *We assume that $\epsilon = (\varepsilon,\zeta,\mu)\in\mathcal{U}$ and $0 < T < \frac{\lambda}{\beta}$, where β satisfies* (1.4). *Let D, $B\in\left(H^1(Q)\right)^3$ satisfy* (2.3)–(2.5) *and $D = B = 0$ on Σ. Then we have the following.*

(i) *There exist $s_3 = s_3(\varrho) > 0$ and $K_4 = K_4(s_3,\beta,\varrho,M,\theta_0,\theta_1,\Omega,T) > 0$ such that*

$$\int_\Omega \left[|D(\cdot,0)|^2+|B(\cdot,0)|^2\right]\mathrm{e}^{2s\varphi(\cdot,0)}\mathrm{d}x \le K_4\sum_{k=1}^{2}\int_Q\left(|r_k|^2+|R_k|^2\right)\mathrm{e}^{2s\varphi}\mathrm{d}x\mathrm{d}t \tag{3.1}$$

for $s > s_3$, provided that D, $B\in\left(H_0^1(Q)\right)^3$.

(ii) *There exists $K_5 = K_5(M,\theta_0,\theta_1,\Omega,T) > 0$ such that*

$$\begin{aligned}&\int_\Omega \left[|D(\cdot,t_2)|^2+|B(\cdot,t_2)|^2\right]\mathrm{d}x\\ &\quad\le K_5\left\{\int_\Omega\left[|D(\cdot,t_1)|^2+|B(\cdot,t_1)|^2\right]\mathrm{d}x+\int_{Q_\star}\left(|R_1|^2+|R_2|^2\right)\mathrm{d}x\mathrm{d}t\right\}\end{aligned} \tag{3.2}$$

for $-T\le t_1,t_2\le T$, where $Q_\star = \Omega\times(\min\{t_1,t_2\},\max\{t_1,t_2\})\subseteq Q$.

We note that in (ii) D, B need not vanish on $\Omega\times\{\pm T\}$.

Proof. It is obvious that (3.2) holds for $-T\le t_1 = t_2\le T$. In the following, we assume that $t_1\ne t_2$ and $t_1,t_2\in[-T,T]$. Let

$$\iota = \begin{cases}1, & t_2 > t_1,\\ -1, & t_2 < t_1,\end{cases} \tag{3.3}$$

and ξ, γ_1, γ_2, γ_3 be defined by (2.2) and (2.8). As in the proof of Theorem 2.2, by $\epsilon\in\mathcal{U}$ and (2.4), we have $\gamma_k\in C^2\left(\overline{\Omega}\right)$ for $k = 1,2,3$, (2.7) and (2.9). By D, $B\in\left(H^1(Q)\right)^3$ and (2.7), we have E, $H\in\left(H^1(Q)\right)^3$. Furthermore, by $D = B = 0$ on Σ and (2.7), we have $E = H = 0$ on Σ.

By (2.3) and (2.7), it is easy to see that

$$(\partial_t D)\cdot(\gamma_1 D+\gamma_2 B)-(\nabla\times H)\cdot E=R_1\cdot(\gamma_1 D+\gamma_2 B)\qquad \text{in } Q, \tag{3.4}$$

$$(\partial_t B)\cdot(\gamma_2 D+\gamma_3 B)+(\nabla\times E)\cdot H=R_2\cdot(\gamma_2 D+\gamma_3 B)\qquad \text{in } Q. \tag{3.5}$$

Adding (3.4) and (3.5), we have

$$\partial_t\mathcal{B}+\nabla\cdot(E\times H)=R_1\cdot(\gamma_1 D+\gamma_2 B)+R_2\cdot(\gamma_2 D+\gamma_3 B) \tag{3.6}$$

in Q, where we set

$$\mathcal{B}\equiv\frac{1}{2}\left[\gamma_1|D|^2+2\gamma_2\,(D\cdot B)+\gamma_3|B|^2\right]. \tag{3.7}$$

Here we have used $(\nabla\times E)\cdot H-(\nabla\times H)\cdot E=\nabla\cdot(E\times H)$ in Q. Therefore, for $s\ge 0$, we have

$$I_l=I_r, \tag{3.8}$$

where

$$I_l\equiv\int_{t_1}^{t_2}\int_\Omega\left[\partial_t\mathcal{B}+\nabla\cdot(E\times H)\right]\mathrm{e}^{2s\varphi-\iota t}\mathrm{d}x\mathrm{d}t,$$

$$I_r\equiv\int_{t_1}^{t_2}\int_\Omega\left[R_1\cdot(\gamma_1 D+\gamma_2 B)+R_2\cdot(\gamma_2 D+\gamma_3 B)\right]\mathrm{e}^{2s\varphi-\iota t}\mathrm{d}x\mathrm{d}t.$$

Integrating by parts and using $E=H=0$ on Σ, we have

$$\begin{aligned}
I_l&=\int_\Omega\mathcal{B}\left(\cdot,t_2\right)\mathrm{e}^{2s\varphi(\cdot,t_2)-\iota t_2}\mathrm{d}x-\int_\Omega\mathcal{B}\left(\cdot,t_1\right)\mathrm{e}^{2s\varphi(\cdot,t_1)-\iota t_1}\mathrm{d}x\\
&\quad-\int_{t_1}^{t_2}\int_\Omega\left\{-\iota\mathcal{B}+2s\left[(\partial_t\varphi)\,\mathcal{B}+(E\times H)\cdot(\nabla\varphi)\right]\right\}\mathrm{e}^{2s\varphi-\iota t}\mathrm{d}x\mathrm{d}t\\
&\ge\int_\Omega\mathcal{B}\left(\cdot,t_2\right)\mathrm{e}^{2s\varphi(\cdot,t_2)-\iota t_2}\mathrm{d}x-\int_\Omega\mathcal{B}\left(\cdot,t_1\right)\mathrm{e}^{2s\varphi(\cdot,t_1)-\iota t_1}\mathrm{d}x\\
&\quad+\int_{Q_\star}\mathcal{B}\mathrm{e}^{2s\varphi-\iota t}\mathrm{d}x\mathrm{d}t-C_5\mathrm{e}^T s\int_{Q_\star}\left(|\mathcal{B}|+|E|^2+|H|^2\right)\mathrm{e}^{2s\varphi}\mathrm{d}x\mathrm{d}t\quad\text{for } s\ge 0.
\end{aligned} \tag{3.9}$$

For the inequality in (3.9), we have used (3.3) and definition (2.1) of φ. By (2.9) and (3.7), there exist C_6, $C_7>0$ such that

$$C_6\left(|D|^2+|B|^2\right)\le\mathcal{B}\le C_7\left(|D|^2+|B|^2\right)\quad\text{in } Q. \tag{3.10}$$

Therefore, by (3.9) and (3.10), we have

$$\begin{aligned}
I_l&\ge C_6\mathrm{e}^{-T}\int_\Omega\left[|D(\cdot,t_2)|^2+|B(\cdot,t_2)|^2\right]\mathrm{e}^{2s\varphi(\cdot,t_2)}\mathrm{d}x\\
&\quad-C_7\mathrm{e}^T\int_\Omega\left[|D(\cdot,t_1)|^2+|B(\cdot,t_1)|^2\right]\mathrm{e}^{2s\varphi(\cdot,t_1)}\mathrm{d}x\\
&\quad+C_6\mathrm{e}^{-T}\int_{Q_\star}\left(|D|^2+|B|^2\right)\mathrm{e}^{2s\varphi}\mathrm{d}x\mathrm{d}t\\
&\quad-C_8\mathrm{e}^T s\int_{Q_\star}\left(|D|^2+|E|^2+|B|^2+|H|^2\right)\mathrm{e}^{2s\varphi}\mathrm{d}x\mathrm{d}t\quad\text{for } s\ge 0.
\end{aligned} \tag{3.11}$$

By the inequality $2|ab| \le \vartheta a^2 + b^2/\vartheta$ for $\vartheta > 0$, we obtain

$$I_r \le C_9 \mathrm{e}^T \int_{Q_\star} \left[\vartheta \left(|D|^2 + |B|^2 \right) + \frac{1}{\vartheta} \left(|R_1|^2 + |R_2|^2 \right) \right] \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t \tag{3.12}$$

for $\vartheta > 0$ and $s \ge 0$. Hence, by (3.8), (3.11), and (3.12), choosing $\vartheta > 0$ sufficiently small and fixing it, we have

$$\begin{aligned} &\int_\Omega \left[|D(\cdot, t_2)|^2 + |B(\cdot, t_2)|^2 \right] \mathrm{e}^{2s\varphi(\cdot, t_2)} \mathrm{d}x \\ &\quad \le C_{10} \left\{ \int_\Omega \left[|D(\cdot, t_1)|^2 + |B(\cdot, t_1)|^2 \right] \mathrm{e}^{2s\varphi(\cdot, t_1)} \mathrm{d}x \right. \\ &\qquad + \int_{Q_\star} \left(|R_1|^2 + |R_2|^2 \right) \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t \\ &\qquad \left. + s \int_{Q_\star} \left(|D|^2 + |E|^2 + |B|^2 + |H|^2 \right) \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t \right\} \end{aligned} \tag{3.13}$$

for $s \ge 0$. Taking $s = 0$ in (3.13), we obtain (3.2).

Next, we will complete the proof of (3.1). Since $D, B \in \left(H_0^1(Q) \right)^3$, we can apply Theorem 2.2, so that (2.6) holds for sufficiently large $s > 0$. Therefore, taking $t_2 = 0$, $t_1 = T$ in (3.13), and using $Q_\star \subseteq Q$ and (2.6), we see that there exist $s_3 = s_3(\varrho) > 0$ and $K_4 = K_4(s_3, \beta, \varrho, M, \theta_0, \theta_1, \Omega, T) > 0$ such that (3.1) holds for $s > s_3$.

The proof of Lemma 3.1 is complete. $\square$

Step 2. As in [9], by (1.3) and (1.5), we can assume that $0 < T < \frac{\lambda}{\beta}$, where β satisfies (1.4).

By $\epsilon, \widetilde{\epsilon} \in \mathcal{U}$, we have $\xi \equiv \varepsilon\mu - \zeta^2 > \theta_1$, $\widetilde{\xi} \equiv \widetilde{\varepsilon}\widetilde{\mu} - \widetilde{\zeta}^2 > \theta_1$ on $\overline{\Omega}$. By the constitutive relations (1.2), we have

$$\begin{aligned} E[\epsilon; \Phi(j)] &= \gamma_1 D[\epsilon; \Phi(j)] + \gamma_2 B[\epsilon; \Phi(j)], \\ H[\epsilon; \Phi(j)] &= \gamma_2 D[\epsilon; \Phi(j)] + \gamma_3 B[\epsilon; \Phi(j)], \\ E[\widetilde{\epsilon}; \Phi(j)] &= \widetilde{\gamma}_1 D[\widetilde{\epsilon}; \Phi(j)] + \widetilde{\gamma}_2 B[\widetilde{\epsilon}; \Phi(j)], \\ H[\widetilde{\epsilon}; \Phi(j)] &= \widetilde{\gamma}_2 D[\widetilde{\epsilon}; \Phi(j)] + \widetilde{\gamma}_3 B[\widetilde{\epsilon}; \Phi(j)] \quad \text{in } Q, \end{aligned} \tag{3.14}$$

where $j = 1, 2$ and

$$\gamma_1 = \frac{\mu}{\xi}, \quad \gamma_2 = -\frac{\zeta}{\xi}, \quad \gamma_3 = \frac{\varepsilon}{\xi} \qquad \text{on } \overline{\Omega}, \tag{3.15}$$

$$\widetilde{\gamma}_1 = \frac{\widetilde{\mu}}{\widetilde{\xi}}, \quad \widetilde{\gamma}_2 = -\frac{\widetilde{\zeta}}{\widetilde{\xi}}, \quad \widetilde{\gamma}_3 = \frac{\widetilde{\varepsilon}}{\widetilde{\xi}} \qquad \text{on } \overline{\Omega}. \tag{3.16}$$

Furthermore, by $\epsilon, \widetilde{\epsilon} \in \mathcal{U}$, we have γ_k, $\widetilde{\gamma}_k \in C^2(\overline{\Omega})$ for $k = 1, 2, 3$ and

$$\gamma_1\gamma_3 - \gamma_2^2 = \frac{1}{\xi} > 0, \quad \widetilde{\gamma}_1\widetilde{\gamma}_3 - \widetilde{\gamma}_2^2 = \frac{1}{\widetilde{\xi}} > 0, \quad \text{on } \overline{\Omega}. \tag{3.17}$$

We set

$$Y(\cdot; j) = \left\{ \partial_t D[\epsilon; \Phi(j)] - \partial_t D[\widetilde{\epsilon}; \Phi(j)] \right\}(\cdot) \quad \text{in } Q, \tag{3.18}$$

$$Z(\cdot; j) = \left\{ \partial_t B[\epsilon; \Phi(j)] - \partial_t B[\widetilde{\epsilon}; \Phi(j)] \right\}(\cdot) \quad \text{in } Q, \tag{3.19}$$

$$U(\cdot;j) = \gamma_1 Y(\cdot;j) + \gamma_2 Z(\cdot;j), \quad V(\cdot;j) = \gamma_2 Y(\cdot;j) + \gamma_3 Z(\cdot;j) \quad \text{in } Q, \tag{3.20}$$

$$R_3(\cdot;j) = \{\partial_t D[\widetilde{\epsilon};\Phi(j)]\}(\cdot), \quad R_4(\cdot;j) = \{\partial_t B[\widetilde{\epsilon};\Phi(j)]\}(\cdot) \quad \text{in } Q, \tag{3.21}$$

$$f_k = \widetilde{\gamma}_k - \gamma_k \quad \text{on } \overline{\Omega}, \quad k = 1,2,3, \tag{3.22}$$

$$\Psi_1(\cdot;j) = \nabla \times [f_1 R_3(\cdot;j) + f_2 R_4(\cdot;j)] \quad \text{in } Q, \tag{3.23}$$

$$\Psi_2(\cdot;j) = \nabla \times [f_2 R_3(\cdot;j) + f_3 R_4(\cdot;j)] \quad \text{in } Q, \quad j = 1,2,3. \tag{3.24}$$

Then we have $Y(\cdot;j)$, $Z(\cdot;j)$, $U(\cdot;j)$, $V(\cdot;j)$, $R_3(\cdot;j)$, $R_4(\cdot;j) \in \left(W^{1,\infty}(Q)\right)^3$,

$$\partial_t Y(\cdot;j) - \nabla \times V(\cdot;j) = -\Psi_2(\cdot;j), \quad \partial_t Z(\cdot;j) + \nabla \times U(\cdot;j) = \Psi_1(\cdot;j), \tag{3.25}$$

$$Y(\cdot;j) = \varepsilon U(\cdot;j) + \zeta V(\cdot;j), \quad Z(\cdot;j) = \zeta U(\cdot;j) + \mu V(\cdot;j), \tag{3.26}$$

$$\nabla \cdot Y(\cdot;j) = \nabla \cdot Z(\cdot;j) = 0 \quad \text{in } Q. \tag{3.27}$$

In fact, by (3.14) and (3.22), we have

$$\begin{aligned} E[\epsilon;\Phi(j)] - E[\widetilde{\epsilon};\Phi(j)] &= \gamma_1 \{D[\epsilon;\Phi(j)] - D[\widetilde{\epsilon};\Phi(j)]\} \\ &+ \gamma_2 \{B[\epsilon;\Phi(j)] - B[\widetilde{\epsilon};\Phi(j)]\} - f_1 D[\widetilde{\epsilon};\Phi(j)] - f_2 B[\widetilde{\epsilon};\Phi(j)] \quad \text{in } Q, \end{aligned} \tag{3.28}$$

$$\begin{aligned} H[\epsilon;\Phi(j)] - H[\widetilde{\epsilon};\Phi(j)] &= \gamma_2 \{D[\epsilon;\Phi(j)] - D[\widetilde{\epsilon};\Phi(j)]\} \\ &+ \gamma_3 \{B[\epsilon;\Phi(j)] - B[\widetilde{\epsilon};\Phi(j)]\} - f_2 D[\widetilde{\epsilon};\Phi(j)] - f_3 B[\widetilde{\epsilon};\Phi(j)] \quad \text{in } Q. \end{aligned} \tag{3.29}$$

Differentiating (3.28) and (3.29) with respect to t, and using (3.18)–(3.21) and t-independence of γ_1, γ_2, γ_3, we have

$$\{\partial_t E[\epsilon;\Phi(j)] - \partial_t E[\widetilde{\epsilon};\Phi(j)]\}(\cdot) = U(\cdot;j) - f_1 R_3(\cdot;j) - f_2 R_4(\cdot;j) \quad \text{in } Q, \tag{3.30}$$

$$\{\partial_t H[\epsilon;\Phi(j)] - \partial_t H[\widetilde{\epsilon};\Phi(j)]\}(\cdot) = V(\cdot;j) - f_2 R_3(\cdot;j) - f_3 R_4(\cdot;j) \quad \text{in } Q. \tag{3.31}$$

By (1.1), (3.18), and (3.19), we have

$$Y(\cdot;j) = \{\nabla \times H[\epsilon;\Phi(j)] - \nabla \times H[\widetilde{\epsilon};\Phi(j)]\}(\cdot) \quad \text{in } Q, \tag{3.32}$$

$$Z(\cdot;j) = -\{\nabla \times E[\epsilon;\Phi(j)] - \nabla \times E[\widetilde{\epsilon};\Phi(j)]\}(\cdot) \quad \text{in } Q. \tag{3.33}$$

Differentiating (3.32) and (3.33) with respect to t and using (3.23) and (3.24), and (3.30) and (3.31), we can obtain (3.25). By definition (3.15) of γ_1, γ_2, γ_3 and (3.20), direct calculations yield (3.26). Moreover, by (1.1), (3.18), and (3.19), we obtain (3.27). Furthermore, we note that $\|R_3\|_{(W^{1,\infty}(Q))^3}$, $\|R_4\|_{(W^{1,\infty}(Q))^3} \le M$ by $\widetilde{\epsilon} \in \mathcal{U}$.

By $\epsilon, \widetilde{\epsilon} \in \mathcal{U}$, and definitions (3.15), (3.16), and (3.22), we have $f_k \in C_0^1(\overline{\Omega})$ $(k = 1,2,3)$. Therefore, we can apply Proposition 2.3 to f_k $(k = 1,2,3)$. As a result, we have

$$\sum_{k=1}^{3} \int_\Omega |f_k|^2 \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x \le \frac{C_{11}}{s} \sum_{k=1}^{3} \int_\Omega |\nabla f_k|^2 \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x \tag{3.34}$$

for all sufficiently large $s > 0$.

By (1.5) and definition (2.1) of φ, we have

$$\varphi(x,0) \geq 1 \quad \text{and} \quad 0 < \varphi(x,-T) = \varphi(x,T) < 1, \quad x \in \overline{\Omega}. \tag{3.35}$$

Therefore, for any given small $\eta \in (0, 1 - \sup_{x\in\overline{\Omega}} \varphi(x,T))$, we can choose a sufficiently small $\delta = \delta(\eta) > 0$, such that

$$\varphi(x,t) \leq 1 - \eta, \quad (x,t) \in \overline{\Omega} \times ([-T, -T+2\delta] \cup [T-2\delta, T]). \tag{3.36}$$

In order to apply Lemma 3.1, we introduce two cut-off functions χ_1 and χ_2 satisfying $\chi_1 \in C_0^\infty(\Omega)$, $\chi_2 \in C^\infty(\mathbb{R})$, $0 \leq \chi_1(x) \leq 1$ for $x \in \overline{\Omega}$, $0 \leq \chi_2(t) \leq 1$ for $t \in \mathbb{R}$, $\chi_1(x) = 1$ for $x \in \overline{\Omega \backslash \omega}$ and

$$\chi_2(t) = \begin{cases} 0, & t \in [-T, -T+\delta] \cup [T-\delta, T], \\ 1, & t \in [-T+2\delta, T-2\delta]. \end{cases}$$

Step 3. We set $Y_1(\cdot;j) = \chi_1 Y(\cdot;j) \in \left(W^{1,\infty}(Q)\right)^3$, $Z_1(\cdot;j) = \chi_1 Z(\cdot;j) \in \left(W^{1,\infty}(Q)\right)^3$, $U_1(\cdot;j) = \chi_1 U(\cdot;j) \in \left(W^{1,\infty}(Q)\right)^3$, $V_1(\cdot;j) = \chi_1 V(\cdot;j) \in \left(W^{1,\infty}(Q)\right)^3$. Then, by definition of χ_1, (2.10) and (3.25)–(3.27), we have

$$\partial_t Y_1(\cdot;j) - \nabla \times V_1(\cdot;j) = -\chi_1 \Psi_2(\cdot;j) - (\nabla\chi_1) \times V(\cdot;j) \quad \text{in } Q, \tag{3.37}$$

$$\partial_t Z_1(\cdot;j) + \nabla \times U_1(\cdot;j) = \chi_1 \Psi_1(\cdot;j) + (\nabla\chi_1) \times U(\cdot;j) \quad \text{in } Q, \tag{3.38}$$

$$Y_1(\cdot;j) = \varepsilon U_1(\cdot;j) + \zeta V_1(\cdot;j), \quad Z_1(\cdot;j) = \zeta U_1(\cdot;j) + \mu V_1(\cdot;j) \quad \text{in } Q, \tag{3.39}$$

$$\nabla \cdot Y_1(\cdot;j) = (\nabla\chi_1) \cdot Y(\cdot;j), \quad \nabla \cdot Z_1(\cdot;j) = (\nabla\chi_1) \cdot Z(\cdot;j) \quad \text{in } Q, \tag{3.40}$$

$$Y_1(\cdot;j) = Z_1(\cdot;j) = 0 \quad \text{on } \Sigma. \tag{3.41}$$

Therefore, by Lemma 3.1 (ii) and $(\nabla\chi_1)(x) = 0$ for $x \in \Omega \setminus \omega$, we have

$$\begin{aligned} w(t_2;j) \leq c_{12} \Big\{ & w(t_1;j) + \int_Q \Big[\left| -\chi_1 \Psi_2(\cdot;j) - (\nabla\chi_1) \times V(\cdot;j) \right|^2 \\ & + \left| \chi_1 \Psi_1(\cdot;j) + (\nabla\chi_1) \times U(\cdot;j) \right|^2 \Big] \mathrm{d}x\mathrm{d}t \Big\} \\ \leq c_{13} \Big\{ & w(t_1;j) + \int_Q \Big[|\Psi_1(\cdot;j)|^2 + |\Psi_2(\cdot;j)|^2 \Big] \mathrm{d}x\mathrm{d}t \\ & + \int_{Q_\omega} |\nabla\chi_1|^2 \Big[|U(\cdot;j)|^2 + |V(\cdot;j)|^2 \Big] \mathrm{d}x\mathrm{d}t \Big\} \end{aligned} \tag{3.42}$$

for $-T \leq t_1, t_2 \leq T$, where

$$w(t;j) = \int_\Omega \Big[|Y_1(\cdot,t;j)|^2 + |Z_1(\cdot,t;j)|^2 \Big] \mathrm{d}x, \quad t \in [-T,T]. \tag{3.43}$$

By (3.23) and (3.24), $\|R_3(\cdot;j)\|_{(W^{1,\infty}(Q))^3}, \|R_4(\cdot;j)\|_{(W^{1,\infty}(Q))^3} \leq M$, and t-independency of f_k, we have

$$\begin{aligned} \int_Q \Big[|\Psi_1(\cdot;j)|^2 + |\Psi_2(\cdot;j)|^2 \Big] \mathrm{d}x\mathrm{d}t &\leq C_{14} \sum_{k=1}^3 \int_Q \left(|f_k|^2 + |\nabla f_k|^2 \right) \mathrm{d}x\mathrm{d}t \\ &\leq C_{15} \sum_{k=1}^3 \int_\Omega \left(|f_k|^2 + |\nabla f_k|^2 \right) \mathrm{d}x. \end{aligned} \tag{3.44}$$

By definition (1.8) of Θ and (3.18)–(3.20), we have

$$\begin{aligned}&\int_{Q_\omega} |\nabla\chi_1|^2 \left[|U(\cdot;j)|^2 + |V(\cdot;j)|^2\right] \mathrm{d}x\mathrm{d}t \\ &\quad\le C_{16} \int_{Q_\omega} \left[|Y(\cdot;j)|^2 + |Z(\cdot;j)|^2\right] \mathrm{d}x\mathrm{d}t \le C_{17}\Theta^2.\end{aligned} \tag{3.45}$$

Hence, it follows from (3.42), (3.44), and (3.45) that

$$w(t_2;j) \le c_{18}\left[w(t_1;j) + \sum_{k=1}^{3}\int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right)\mathrm{d}x + \Theta^2\right] \tag{3.46}$$

for $-T \le t_1, t_2 \le T$.

Step 4. We set $Y_2(\cdot;j) = \chi_2 Y_1(\cdot;j)$, $Z_2(\cdot;j) = \chi_2 Z_1(\cdot;j)$, $U_2(\cdot;j) = \chi_2 U_1(\cdot;j)$, $V_2(\cdot;j) = \chi_2 V_1(\cdot;j)$. Then, by definitions of χ_1, χ_2, and (3.37)–(3.41), we have $Y_2(\cdot;j)$, $Z_2(\cdot;j)$, $U_2(\cdot;j)$, $V_2(\cdot;j) \in \left(H_0^1(Q)\right)^3$,

$$\begin{gathered}\partial_t Y_2(\cdot;j) - \nabla\times V_2(\cdot;j) = -\chi_1\chi_2\Psi_2(\cdot;j) - \chi_2\left(\nabla\chi_1\right)\times V(\cdot;j) + \left(\partial_t\chi_2\right)Y_1(\cdot;j),\\ \partial_t Z_2(\cdot;j) + \nabla\times U_2(\cdot;j) = \chi_1\chi_2\Psi_1(\cdot;j) + \chi_2\left(\nabla\chi_1\right)\times U(\cdot;j) + \left(\partial_t\chi_2\right)Z_1(\cdot;j),\\ Y_2(\cdot;j) = \varepsilon U_2(\cdot;j) + \zeta V_2(\cdot;j), \quad Z_2(\cdot;j) = \zeta U_2(\cdot;j) + \mu V_2(\cdot;j),\\ \nabla\cdot Y_2(\cdot;j) = \chi_2\left(\nabla\chi_1\right)\cdot Y(\cdot;j), \quad \nabla\cdot Z_2(\cdot;j) = \chi_2\left(\nabla\chi_1\right)\cdot Z(\cdot;j) \quad \text{in } Q.\end{gathered}$$

Therefore, we can apply Lemma 3.1 (i) so that, by $\left(\nabla\chi_1\right)(x) = 0$ for $x \in \Omega\setminus\omega$ and $\left(\partial_t\chi_2\right)(t) = 0$ for $t \in (-T, -T+\delta)\cup(-T+2\delta, T-2\delta)\cup(T-\delta, T)$,

$$\begin{aligned}&\int_\Omega \left[|Y_2(\cdot,0;j)|^2 + |Z_2(\cdot,0;j)|^2\right]\mathrm{e}^{2s\varphi(\cdot,0)}\mathrm{d}x\\ &\le C_{19}\int_Q \Big[\left|-\chi_1\chi_2\Psi_2(\cdot;j) - \chi_2\left(\nabla\chi_1\right)\times V(\cdot;j) + \left(\partial_t\chi_2\right)Y_1(\cdot;j)\right|^2\\ &\qquad + \left|\chi_1\chi_2\Psi_1(\cdot;j) + \chi_2\left(\nabla\chi_1\right)\times U(\cdot;j) + \left(\partial_t\chi_2\right)Z_1(\cdot;j)\right|^2\\ &\qquad + \left|\chi_2\left(\nabla\chi_1\right)\cdot Y(\cdot;j)\right|^2 + \left|\chi_2\left(\nabla\chi_1\right)\cdot Z(\cdot;j)\right|^2\Big]\mathrm{e}^{2s\varphi}\mathrm{d}x\mathrm{d}t\\ &\le C_{20}\Bigg\{\int_Q \left[|\Psi_1(\cdot;j)|^2 + |\Psi_2(\cdot;j)|^2\right]\mathrm{e}^{2s\varphi}\mathrm{d}x\mathrm{d}t\\ &\qquad + \int_{Q_\omega}|\nabla\chi_1|^2\left[|U(\cdot;j)|^2 + |V(\cdot;j)|^2 + |Y(\cdot;j)|^2 + |Z(\cdot;j)|^2\right]\mathrm{e}^{2s\varphi}\mathrm{d}x\mathrm{d}t\\ &\qquad + \left(\int_{-T+\delta}^{-T+2\delta} + \int_{T-2\delta}^{T-\delta}\right)\int_\Omega \left(\partial_t\chi_2\right)^2\left[|Y_1(\cdot;j)|^2 + |Z_1(\cdot;j)|^2\right]\mathrm{e}^{2s\varphi}\mathrm{d}x\mathrm{d}t\Bigg\}\end{aligned} \tag{3.47}$$

for all large $s > 0$. By (2.1) and the definition of λ, we have

$$\varphi(x,t) - \varphi(x,0) = \mathrm{e}^{\varrho\left(|x|^2-\lambda^2\right)}\left(\mathrm{e}^{-\varrho\beta^2t^2} - 1\right) \le \mathrm{e}^{-\varrho\beta^2t^2} - 1 \le 0 \quad \text{for } x \in \overline{\Omega}.$$

Therefore, by (3.23) and (3.24) and $\|R_3(\cdot;j)\|_{(W^{1,\infty}(Q))^3}$, $\|R_4(\cdot;j)\|_{(W^{1,\infty}(Q))^3} \le M$, we have

$$
\begin{aligned}
&\int_Q \left[|\Psi_1(\cdot;j)|^2 + |\Psi_2(\cdot;j)|^2\right] \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t \\
&\quad \le C_{21} \sum_{k=1}^{3} \int_Q \left(|f_k|^2 + |\nabla f_k|^2\right) \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t \\
&\quad \le C_{22} \sum_{k=1}^{3} \int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right) \mathrm{e}^{2s\varphi(\cdot,0)} \left\{ \int_{-T}^{T} \mathrm{e}^{2s[\varphi(\cdot,t)-\varphi(\cdot,0)]} \mathrm{d}t \right\} \mathrm{d}x \\
&\quad \le C_{23} \kappa_1(s) \sum_{k=1}^{3} \int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right) \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x
\end{aligned}
\tag{3.48}
$$

for all $s > 0$, where

$$
\kappa_1(s) = \int_{-T}^{T} \mathrm{e}^{2s\left(\mathrm{e}^{-\varrho\beta^2 t^2}-1\right)} \mathrm{d}t. \tag{3.49}
$$

By (1.8) and (3.18)–(3.20), we have

$$
\begin{aligned}
&\int_{Q_\omega} |\nabla \chi_1|^2 \left[|U(\cdot;j)|^2 + |V(\cdot;j)|^2 + |Y(\cdot;j)|^2 + |Z(\cdot;j)|^2\right] \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t \\
&\quad \le C_{24} \mathrm{e}^{2s\Gamma} \int_{Q_\omega} \left[|Y(\cdot;j)|^2 + |Z(\cdot;j)|^2\right] \mathrm{d}x\mathrm{d}t \le C_{25} \mathrm{e}^{2s\Gamma} \Theta^2
\end{aligned}
\tag{3.50}
$$

for all $s > 0$, where $\Gamma = \sup_{(x,t)\in Q} \varphi(x,t) \ge 1$. By (3.36), (3.43), and (3.46), we have

$$
\begin{aligned}
&\left(\int_{-T+\delta}^{-T+2\delta} + \int_{T-2\delta}^{T-\delta}\right) \int_\Omega (\partial_t \chi_2)^2 \left[|Y_1(\cdot;j)|^2 + |Z_1(\cdot;j)|^2\right] \mathrm{e}^{2s\varphi} \mathrm{d}x\mathrm{d}t \\
&\quad \le C_{26} \mathrm{e}^{2s(1-\eta)} \left(\int_{-T+\delta}^{-T+2\delta} + \int_{T-2\delta}^{T-\delta}\right) w(t;j) \mathrm{d}t \\
&\quad \le 2C_{27} \delta \mathrm{e}^{2s(1-\eta)} \left[w(0;j) + \sum_{k=1}^{3} \int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right) \mathrm{d}x + \Theta^2 \right] \\
&\quad \le C_{28} \delta \mathrm{e}^{-2s\eta} \left\{ \int_\Omega \left[|Y_1(\cdot,0;j)|^2 + |Z_1(\cdot,0;j)|^2\right] \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x \right. \\
&\qquad\qquad \left. + \sum_{k=1}^{3} \int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right) \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x \right\} + C_{29} \mathrm{e}^{2s\Gamma} \Theta^2
\end{aligned}
\tag{3.51}
$$

for all $s > 0$. For the last inequality, we have used the first inequality in (3.35) and definition (3.43) of $w(t;j)$. Moreover, by $\chi_2(0) = 1$ and the definition of $Y_2(\cdot;j)$, $Z_2(\cdot;j)$, we have $Y_2(x,0;j) = Y_1(x,0;j)$ and $Z_2(x,0;j) = Z_1(x,0;j)$ for $x \in \overline{\Omega}$. Hence, substituting (3.48), (3.50), and (3.51) into (3.47), we have

$$
\begin{aligned}
&\int_\Omega \left[|Y_1(\cdot,0;j)|^2 + |Z_1(\cdot,0;j)|^2\right] \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x \\
&\quad = \int_\Omega \left[|Y_2(\cdot,0;j)|^2 + |Z_2(\cdot,0;j)|^2\right] \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x \\
&\quad \le C_{30} \left\{ \delta \mathrm{e}^{-2s\eta} \int_\Omega \left[|Y_1(\cdot,0;j)|^2 + |Z_1(\cdot,0;j)|^2\right] \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x \right. \\
&\qquad\qquad \left. + \kappa_2(s) \sum_{k=1}^{3} \int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right) \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x + \mathrm{e}^{2s\Gamma} \Theta^2 \right\}
\end{aligned}
$$

for all large $s > 0$, where

$$\kappa_2(s) = \kappa_1(s) + \delta e^{-2s\eta}. \tag{3.52}$$

Furthermore, there exists $s_4 > 0$ such that $C_{30}\delta e^{-2s\eta} \le 1/2$ for all $s > s_4$. Therefore, we have

$$\begin{aligned}
&\int_\Omega \left[|Y_1(\cdot,0;j)|^2 + |Z_1(\cdot,0;j)|^2\right] e^{2s\varphi(\cdot,0)}dx \\
&\le 2C_{30}\left[\kappa_2(s)\sum_{k=1}^3\int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right) e^{2s\varphi(\cdot,0)}dx + e^{2s\Gamma}\Theta^2\right] \\
&\le C_{31}\left[\kappa_2(s)\sum_{k=1}^3\int_\Omega |\nabla f_k|^2 e^{2s\varphi(\cdot,0)}dx + e^{2s\Gamma}\Theta^2\right]
\end{aligned} \tag{3.53}$$

for all sufficiently large $s > 0$. For the last inequality in (3.53), we have used (3.34).

Moreover, by the definition of $Y_1(\cdot;j)$, $Z_1(\cdot;j)$, we have

$$Y(\cdot,0;j) = Y_1(\cdot,0;j) + (1-\chi_1)Y(\cdot,0;j),\ Z(\cdot,0;j) = Z_1(\cdot,0;j) + (1-\chi_1)Z(\cdot,0;j) \text{ in } \Omega.$$

Therefore, by $1 - \chi_1(x) = 0$ for $x \in \Omega \setminus \omega$, we have

$$\begin{aligned}
&\int_\Omega \left[|Y(\cdot,0;j)|^2 + |Z(\cdot,0;j)|^2\right] e^{2s\varphi(\cdot,0)}dx \\
&\le C_{32}\left\{\int_\Omega \left[|Y_1(\cdot,0;j)|^2 + |Z_1(\cdot,0;j)|^2\right] e^{2s\varphi(\cdot,0)}dx \right.\\
&\qquad \left. + \int_\omega (1-\chi_1)^2\left[|Y(\cdot,0;j)|^2 + |Z(\cdot,0;j)|^2\right] e^{2s\varphi(\cdot,0)}dx\right\}
\end{aligned} \tag{3.54}$$

for $s > 0$. By the Sobolev embedding theorem (e.g., [1]) and using (1.8) and (3.18) and (3.19), we have

$$\begin{aligned}
&\int_\omega (1-\chi_1)^2\left[|Y(\cdot,0;j)|^2 + |Z(\cdot,0;j)|^2\right] e^{2s\varphi(\cdot,0)}dx \\
&\le C_{33}e^{2s\Gamma}\int_\omega \left[|Y(\cdot,0;j)|^2 + |Z(\cdot,0;j)|^2\right] dx \le C_{34}e^{2s\Gamma}\Theta^2
\end{aligned} \tag{3.55}$$

for all $s > 0$. Substituting (3.53) and (3.55) into (3.54) and summing over $j = 1, 2$, we obtain

$$\begin{aligned}
&\sum_{j=1}^2\int_\Omega \left[|Y(\cdot,0;j)|^2 + |Z(\cdot,0;j)|^2\right] e^{2s\varphi(\cdot,0)}dx \\
&\le C_{35}\left[\kappa_2(s)\sum_{k=1}^3\int_\Omega |\nabla f_k|^2 e^{2s\varphi(\cdot,0)}dx + e^{2s\Gamma}\Theta^2\right]
\end{aligned} \tag{3.56}$$

for all sufficiently large $s > 0$.

Step 5. On the other hand, by (1.1), we have $D[\epsilon;\Phi(j)](\cdot,0) = D[\widetilde{\epsilon};\Phi(j)](\cdot,0) = d^j$, $B[\epsilon;\Phi(j)](\cdot,0) = B[\widetilde{\epsilon};\Phi(j)](\cdot,0) = b^j$ in Ω. Therefore, by (3.28) and (3.29), we have

$$\{E[\epsilon;\Phi(j)] - E[\widetilde{\epsilon};\Phi(j)]\}(\cdot,0) = -f_1 d^j - f_2 b^j \quad \text{in } \Omega, \tag{3.57}$$

$$\{H[\epsilon;\Phi(j)] - H[\widetilde{\epsilon};\Phi(j)]\}(\cdot,0) = -f_2 d^j - f_3 b^j \quad \text{in } \Omega. \tag{3.58}$$

By (3.32), (3.33), (3.57), and (3.58), direct calculations yield

$$\begin{aligned} Y(\cdot,0;j) &= -\nabla\times\left(f_2 d^j + f_3 b^j\right) \\ &= -f_2\left(\nabla\times d^j\right) - f_3\left(\nabla\times b^j\right) - (\partial_1 f_2)\left(e_1\times d^j\right) - (\partial_1 f_3)\left(e_1\times b^j\right) \\ &\quad - (\partial_2 f_2)\left(e_2\times d^j\right) - (\partial_2 f_3)\left(e_2\times b^j\right) - (\partial_3 f_2)\left(e_3\times d^j\right) - (\partial_3 f_3)\left(e_3\times b^j\right) \quad \text{in } \Omega, \\ Z(\cdot,0;j) &= \nabla\times\left(f_1 d^j + f_2 b^j\right) \\ &= f_1\left(\nabla\times d^j\right) + f_2\left(\nabla\times b^j\right) + (\partial_1 f_1)\left(e_1\times d^j\right) + (\partial_1 f_2)\left(e_1\times b^j\right) \\ &\quad + (\partial_2 f_1)\left(e_2\times d^j\right) + (\partial_2 f_2)\left(e_2\times b^j\right) + (\partial_3 f_1)\left(e_3\times d^j\right) + (\partial_3 f_2)\left(e_3\times b^j\right) \quad \text{in } \Omega. \end{aligned}$$

Therefore, by definition of $\mathbb{G}$, we have

$$\mathbb{G}F = \begin{pmatrix} -Y(\cdot,0;1) \\ Z(\cdot,0;1) \\ -Y(\cdot,0;2) \\ Z(\cdot,0;2) \end{pmatrix} - \begin{pmatrix} 0 & \nabla\times d^1 & \nabla\times b^1 \\ \nabla\times d^1 & \nabla\times b^1 & 0 \\ 0 & \nabla\times d^2 & \nabla\times b^2 \\ \nabla\times d^2 & \nabla\times b^2 & 0 \end{pmatrix} \begin{pmatrix} f_1 \\ f_2 \\ f_3 \end{pmatrix} \quad \text{in } \Omega, \tag{3.59}$$

where $F = (\partial_1 f_1, \partial_1 f_2, \partial_1 f_3, \partial_2 f_1, \partial_2 f_2, \partial_2 f_3, \partial_3 f_1, \partial_3 f_2, \partial_3 f_3)^{\mathrm{T}}$. By (1.6) and (3.59), we see that

$$\sum_{k=1}^{3} |\nabla f_k|^2 \le C_{36} |\mathbb{G}F|^2 \le C_{37} \left\{ \sum_{j=1}^{2} \left[|Y(\cdot,0;j)|^2 + |Z(\cdot,0;j)|^2\right] + \sum_{k=1}^{3} |f_k|^2 \right\} \quad \text{in } \Omega.$$

Hence, by (3.34) and (3.56), we have

$$\begin{aligned} &\sum_{k=1}^{3} \int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right) \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x \\ &\le C_{38} \int_\Omega \left\{ \sum_{j=1}^{2} \left[|Y(\cdot,0;j)|^2 + |Z(\cdot,0;j)|^2\right] + \sum_{k=1}^{3} |f_k|^2 \right\} \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x \\ &\le C_{39} \left[\kappa_3(s) \sum_{k=1}^{3} \int_\Omega |\nabla f_k|^2 \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x + \mathrm{e}^{2s\Gamma} \Theta^2 \right] \end{aligned} \tag{3.60}$$

for all sufficiently large $s > 0$, where

$$\kappa_3(s) = \kappa_2(s) + \frac{1}{s}. \tag{3.61}$$

Furthermore, by definitions (3.49), (3.52), and (3.61) of $\kappa_3(s)$, we see that $\lim_{s\to\infty} \kappa_3(s) = 0$. Therefore, there exists $s_5 > 0$ such that $C_{39}\kappa_3(s) \le 1/2$ for $s > s_5$. Therefore, by (3.60), we can obtain that

$$\sum_{k=1}^{3} \int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right) \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x \le 2C_{39} \mathrm{e}^{2s\Gamma} \Theta^2$$

for all sufficiently large $s > 0$. Consequently, by the first inequality in (3.35), we have

$$\begin{aligned} \sum_{k=1}^{3} \int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right) \mathrm{d}x &\le \mathrm{e}^{-2s} \sum_{k=1}^{3} \int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right) \mathrm{e}^{2s\varphi(\cdot,0)} \mathrm{d}x \\ &\le 2C_{39} \mathrm{e}^{2s(\Gamma-1)} \Theta^2 \end{aligned} \tag{3.62}$$

for all sufficiently large $s > 0$. Hence, taking $s > 0$ sufficiently large and fixing it, we obtain that

$$\sum_{k=1}^{3} \int_\Omega |f_k|^2 \mathrm{d}x \le \sum_{k=1}^{3} \int_\Omega \left(|f_k|^2 + |\nabla f_k|^2\right) \mathrm{d}x \le C_{40}\Theta^2. \tag{3.63}$$

Moreover, by direct calculations, we can verify that

$$\begin{aligned}
&\widetilde{\varepsilon} - \varepsilon = \widetilde{\xi} f_3 + \gamma_3 \xi \widetilde{\xi} \left[(\widetilde{\gamma}_2 + \gamma_2) f_2 - \gamma_1 f_3 - \widetilde{\gamma}_3 f_1 \right], \\
&\widetilde{\zeta} - \zeta = -\widetilde{\xi} f_2 - \gamma_2 \xi \widetilde{\xi} \left[(\widetilde{\gamma}_2 + \gamma_2) f_2 - \gamma_1 f_3 - \widetilde{\gamma}_3 f_1 \right], \\
&\widetilde{\mu} - \mu = \widetilde{\xi} f_1 + \gamma_1 \xi \widetilde{\xi} \left[(\widetilde{\gamma}_2 + \gamma_2) f_2 - \gamma_1 f_3 - \widetilde{\gamma}_3 f_1 \right] \quad \text{on } \overline{\Omega}.
\end{aligned}$$

Therefore, by (3.63), we have

$$\|\widetilde{\epsilon} - \epsilon\|_{L^2(\Omega)} + \left\|\widetilde{\zeta} - \zeta\right\|_{L^2(\Omega)} + \|\widetilde{\mu} - \mu\|_{L^2(\Omega)} \le c_{41} \sum_{k=1}^{3} \|f_k\|_{L^2(\Omega)} \le C_{42}\Theta. \tag{3.64}$$

The proof of Theorem 1.1 is complete. $\square$

GLOBAL WEAK SOLUTIONS TO A GENERALIZED HYPERELASTIC-ROD WAVE EQUATION*

G. M. COCLITE†, H. HOLDEN‡, AND K. H. KARLSEN†

Abstract. We consider a generalized hyperelastic-rod wave equation (or generalized Camassa–Holm equation) describing nonlinear dispersive waves in compressible hyperelastic rods. We establish existence of a strongly continuous semigroup of global weak solutions for any initial data from $H^1(\mathbb{R})$. We also present a "weak equals strong" uniqueness result.

Key words. Hyperelastic-rod wave equation, Camassa–Holm equation, weak solutions, existence, uniqueness

AMS subject classifications. 35G25, 35L05, 35A05

DOI. 10.1137/040616711

1. Introduction and statement of main results. In recent years the so-called Camassa–Holm equation [3] has caught a great deal of attention. It is a nonlinear dispersive wave equation that takes the form

$$\frac{\partial u}{\partial t} - \frac{\partial^3 u}{\partial t \partial x^2} + 2\kappa \frac{\partial u}{\partial x} + 3u \frac{\partial u}{\partial x} = 2 \frac{\partial u}{\partial x} \frac{\partial^2 u}{\partial x^2} + u \frac{\partial^3 u}{\partial x^3}, \quad t > 0, \ x \in \mathbb{R}. \tag{1.1}$$

When $\kappa > 0$, this equation models the propagation of unidirectional shallow water waves on a flat bottom, and $u(t,x)$ represents the fluid velocity at time t in the horizontal direction x [3, 22]. The Camassa–Holm equation possesses a bi-Hamiltonian structure (and thus an infinite number of conservation laws) [20, 3] and is completely integrable [3, 1, 11, 6]. Moreover, when $\kappa = 0$ it has an infinite number of solitary wave solutions, called *peakons* due to the discontinuity of their first derivatives at the wave peak, interacting like solitons:

$$u(t,x) = ce^{-|x-ct|}, \qquad c \in \mathbb{R}.$$

The solitary waves with $\kappa > 0$ are smooth, while they become peaked when $\kappa \to 0$. From a mathematical point of view the Camassa–Holm equation is well studied. Local well-posedness results are proved in [7, 21, 24, 30]. It is also known that there exist global solutions for a particular class of initial data and also solutions that blow up in finite time for a large class of initial data [5, 7, 10]. Here blow up means that the slope of the solution becomes unbounded while the solution itself stays bounded. More relevant for the present paper, we recall that existence and uniqueness results for global weak solutions of (1.1) with $\kappa = 0$ have been proved by Constantin and Escher [8], Constantin and Molinet [12], and Xin and Zhang [32, 33], see also Danchin [17, 18].

‡Department of Mathematical Sciences, Norwegian University of Science and Technology, NO–7491 Trondheim, Norway (holden@math.ntnu.no).

Here we are interested in the Cauchy problem for the nonlinear equation

$$\frac{\partial u}{\partial t} - \frac{\partial^3 u}{\partial t \partial x^2} + \frac{\partial}{\partial x}\left(\frac{g(u)}{2}\right) = \gamma\left(2\frac{\partial u}{\partial x}\frac{\partial^2 u}{\partial x^2} + u\frac{\partial^3 u}{\partial x^3}\right), \quad t > 0, \ x \in \mathbb{R}, \tag{1.2}$$

where the function $g : \mathbb{R} \to \mathbb{R}$ and the constant $\gamma \in \mathbb{R}$ are given. Observe that if $g(u) = 2\kappa u + 3u^2$ and $\gamma = 1$, then (1) is the classical Camassa–Holm equation. With $g(u) = 3u^2$, Dai [15, 14, 16] derived (1) as an equation describing finite length, small amplitude radial deformation waves in cylindrical compressible hyperelastic rods, and often referred to it as the hyperelastic-rod wave equation. Stability of solitary waves for this equation was studied in [13]. The constant γ is given in terms of the material constants and the prestress of the rod; we coin (1) the *generalized hyperelastic-rod wave equation*.

In the derivation of the Camassa–Holm equation in the context of the shallow water waves [3, 22], the constant κ is proportional to the square root of water depth. Thus under normal circumstances it is not physical to set $\kappa = 0$. Although strictly speaking one does not have peakons in the shallow water model ($\kappa > 0$), one has them in Dai's model for compressible hyperelastic rods, since in this model $g(u) = 3u^2$ and $\gamma \in \mathbb{R}$. For $\gamma = 0$ and $g(u) = 3u^2$, (1) becomes the regularized wave equation describing surface waves in channel [2]; the solutions are global, the equation has an Hamiltonian structure but is not integrable, and its solitary waves are not solitons.

A difference between the Camassa–Holm equation (1.1) (with $\kappa = 0$) and the generalized hyperelastic-rod wave equation (1) is that (the slope of) solitary wave solutions to (1) can blow up, while they cannot for (1.1). Solitary waves are bounded solutions of (1) of the form $u(t, x) = \varphi(x - ct)$, where c is the wave speed. It is not hard to check that $\varphi(\zeta)$, $\zeta = x - ct$, satisfies the ordinary differential equation $(\varphi')^2 = \frac{c\varphi^2 - G(\phi)}{c - \gamma\varphi}$, where $G(\xi) = \int_0^\xi g(\xi) d\xi$. From this expression it is clear that $|\varphi'|$ can become infinite. Notice, however, that for the Camassa–Holm equation (1.1) (with $\kappa = 0$), for which $G(u) = u^3$, it follows from the above equation that $(\varphi')^2 = \varphi$ (if $\varphi \neq c/\gamma$) and thus any solitary wave (peakon) φ belongs to $W^{1,\infty}$. Notice also that for (1) with $g(u) = 2\kappa u + 3u^2$, the above ordinary differential equation becomes $(\varphi')^2 = \phi^2 \frac{(c-\kappa) - \varphi}{c - \gamma\varphi}$, and choosing $\gamma = \frac{c}{c-\kappa}$, $c \neq \kappa$, we find the peakon solution

$$\varphi(\xi) = (c - \kappa)e^{-\sqrt{\frac{c-\kappa}{c}}|\xi|}. \tag{1.3}$$

From a mathematical point of view the generalized hyperelastic-rod wave equation (1) is much less studied than (1.1). Recently, Yin [34, 35, 36] (see also Constantin and Escher [9]) proved local well-posedness, global well-posedness for a particular class of initial data, and in particular that smooth solutions blow up in finite time (with a precise estimate of the blow-up time) for a large class of initial data. Lopes [28] proved stability of solitary waves for (1) with $\gamma = 1$, while Kalisch [23] studied the stability when $g(u) = 2\kappa u + 3u^3$ and $\gamma \in \mathbb{R}$. Qian and Tang [29] used the bifurcation method to study peakons and periodic cusp waves for (1) with $g(u) = 2\kappa u + au^2$, $\kappa, a \in \mathbb{R}$, $\gamma = 1$. When $a \neq 3$, $a > 0$, $\kappa \neq 0$, they found the following two peakon type solutions: $u(t, x) = \frac{6\kappa}{3-a} \exp\left(-\sqrt{\frac{a}{3}}|x - \frac{6\kappa t}{3-a}|\right)$ and $u(t, x) = \frac{2\kappa}{a+1}\left(3a \exp\left(-\sqrt{\frac{a}{3}}|x - \frac{2\kappa t}{a+1}|\right) - 2\right)$. When $a = 3$ and $\kappa \neq 0$ they also found a peakon type solution of the form $u(t, x) = \frac{3\kappa}{2} \exp(-|x - \frac{\kappa t}{2}|) - \kappa$. For (1) with $g(u) = 3u^2$, Dai [16] has constructed explicitly a variety of traveling waves, including solitary shock (or peakon like) waves. To give an example, suppose $0 < \gamma < 3$ and pick any constant $c > 0$. Then the following peakon like function is a travelling wave solution:

$$u(t,x) = \frac{1}{2}\left(1 - \frac{1}{\gamma}\right)c + \frac{c}{2}\left(\frac{3}{\gamma} - 1\right)\exp\left(-\frac{1}{\sqrt{\gamma}}|x - ct - \zeta|\right),$$

where ζ is a particular constant. Dai refers to this as a supersonic solitary shock wave. Although all the above displayed peakon type solutions belong to $W^{1,\infty}$ they do not all belong to $H^1(\mathbb{R})$ (some of them do not decay to zero at $\pm\infty$) and these cannot be encompassed by our theory.

Up to now there are no global existence results for weak solutions to the generalized hyperelastic-rod wave equation (1). Here we establish the existence of a global weak solution to (1) for any initial function u_0 belonging to $H^1(\mathbb{R})$. Furthermore, we prove the existence of a strongly continuous semigroup, which in particular implies stability of the solution with respect to perturbations of data in the equation as well as perturbation in the initial data. Our approach is based on a vanishing viscosity argument, showing stability of the solution when a regularizing term vanishes. This stability result is new even for the Camassa–Holm equation (1.1). Finally, we prove a "weak equals strong" uniqueness result. Here we follow closely the approach of Xin and Zhang [32] for the Camassa–Holm equation (1.1) with $\kappa = 0$.

Let us be more precise about our results. We shall assume that

$$u|_{t=0} = u_0 \in H^1(\mathbb{R}), \tag{1.4}$$

and

$$g \in \mathrm{Lip}_{\mathrm{loc}}(\mathbb{R}), \qquad g(0) = 0, \qquad \gamma > 0. \tag{1.5}$$

Observe that the case $\gamma = 0$ is much simpler than the one we are considering. Moreover, if $\gamma < 0$, peakons become antipeakons, so we can use a similar argument. The assumption of infinite differentiability of g is made just for convenience. In fact, locally Lipschitz continuity would be sufficient. Define

$$h(\xi) := \frac{1}{2}\big(g(\xi) - \gamma\xi^2\big)$$

for $\xi \in \mathbb{R}$. Rewriting (1) as

$$(1 - \partial_x^2)u_t + \gamma(1 - \partial_x^2)uu_x + \left(h(u) + \frac{\gamma}{2}u_x^2\right)_x = 0, \tag{1.6}$$

we see that (1) formally is equivalent to the elliptic-hyperbolic system

$$\frac{\partial u}{\partial t} + \gamma u\frac{\partial u}{\partial x} + \frac{\partial P}{\partial x} = 0, \quad -\frac{\partial^2 P}{\partial x^2} + P = h(u) + \frac{\gamma}{2}\left(\frac{\partial u}{\partial x}\right)^2. \tag{1.7}$$

Moreover, since $e^{-|x|}/2$ is the Green's function of the operator $-\frac{\partial^2}{\partial x^2} + 1$, (1) is equivalent to the integro-differential equation

$$\frac{\partial u}{\partial t} + \gamma u\frac{\partial u}{\partial x} + \frac{\partial P}{\partial x} = 0, \quad P(t,x) = \frac{1}{2}\int_{\mathbb{R}} e^{-|x-y|}\left(h(u(t,y)) + \frac{\gamma}{2}\left(\frac{\partial u}{\partial x}(t,y)\right)^2\right)dy. \tag{1.8}$$

Motivated by this, we shall use the following definition of weak solution.

DEFINITION 1.1. *We call $u\colon [0,\infty)\times\mathbb{R}\to\mathbb{R}$ a weak solution of the Cauchy problem for* (1) *if*

(*i*) $u\in C([0,\infty)\times\mathbb{R})\cap L^\infty\big((0,\infty);H^1(\mathbb{R})\big)$;

(*ii*) *u satisfies* (1.7) *in the sense of distributions for some* $P\in L^\infty([0,\infty):W^{1,\infty}(\mathbb{R}))$;

(*iii*) $u(0,x)=u_0(x)$, *for every* $x\in\mathbb{R}$;

(*iv*) $\|u(t,\cdot)\|_{H^1(\mathbb{R})}\le\|u_0\|_{H^1(\mathbb{R})}$, *for each* $t>0$.

If, in addition, there exists a positive constant K_1 depending only on $\|u_0\|_{H^1(\mathbb{R})}$ such that

$$\frac{\partial u}{\partial x}(t,x)\le\frac{2}{\gamma t}+K_1,\qquad (t,x)\in(0,\infty)\times\mathbb{R},\tag{1.9}$$

then we call u an admissible weak solution of the Cauchy problem for (1).

Our existence results are collected in the following theorem.

THEOREM 1.2. *There exists a strongly continuous semigroup of solutions associated to the Cauchy problem* (1). *More precisely, there exists a map*

$$\begin{aligned}S\colon[0,\infty)\times(0,\infty)\times\mathcal{E}\times H^1(\mathbb{R})&\longrightarrow C([0,\infty)\times\mathbb{R})\cap L^\infty\big([0,\infty);H^1(\mathbb{R})\big),\\ (t,\gamma,g,u_0)&\mapsto S_t(\gamma,g,u_0),\end{aligned}$$

where

$$\mathcal{E}:=\big\{g\in\mathrm{Lip}_{\mathrm{loc}}(\mathbb{R})\mid g(0)=0\big\}$$

with the following properties:

(*j*) *for each $u_0\in H^1(\mathbb{R})$, $\gamma>0$, $g\in\mathcal{E}$ the map $u(t,x)=S_t(\gamma,g,u_0)(x)$ is an admissible weak solution of* (1);

(*jj*) *it is stable with respect to the initial condition in the following sense, if*

$$u_{0,n}\longrightarrow u_0\ \text{ in } H^1(\mathbb{R}),\ \ \gamma_n\longrightarrow\gamma,\ \ g_n'\longrightarrow g'\ \text{ in } L^\infty(\mathcal{I}),\tag{1.10}$$

then

$$S_t(\gamma_n,g_n,u_{0,n})\longrightarrow S_t(\gamma,g,u_0)\ \text{ in } L^\infty([0,T];H^1(\mathbb{R})),\tag{1.11}$$

for every $\{u_{0,n}\}_{n\in\mathbb{N}}\subset H^1(\mathbb{R})$, $\{\gamma_n\}_{n\in\mathbb{N}}\subset(0,\infty)$, $\{g_n\}_{n\in\mathbb{N}}\subset\mathcal{E}$, $u_0\in H^1(\mathbb{R})$, $\gamma>0$, $g\in\mathcal{E}$, $T>0$, where

$$\mathcal{I}:=\frac{1}{\sqrt{2}}\Big[-\sup_n\|u_{0,n}\|_{H^1(\mathbb{R})},\sup_n\|u_{0,n}\|_{H^1(\mathbb{R})}\Big].$$

Moreover, the following statements hold:

(*k*) *Estimate* (1.9) *is valid with*

$$K_1:=\sqrt{\frac{2}{\gamma}}\bigg(2\max_{|\xi|\le\sqrt{2}\|u_0\|_{H^1(\mathbb{R})}}\big|h(\xi)\big|+\frac{\gamma}{2}\|u_0\|^2_{H^1(\mathbb{R})}\bigg)^{1/2}.$$

(*kk*) *There results*

$$\frac{\partial}{\partial x}S_t(\gamma,g,u_0)\in L^p_{\mathrm{loc}}([0,\infty)\times\mathbb{R}),\tag{1.12}$$

for each $1\le p<3$.

(*kkk*) *The following identity holds in the sense of distributions on* $[0,\infty)\times\mathbb{R}$*:*

$$\frac{\partial}{\partial t}\left(\frac{1}{2}\left[u^2+q^2\right]\right)+\frac{\partial}{\partial x}\left(u\left[\frac{\gamma}{2}q^2+P\right]+\frac{\gamma}{3}u^3-H(u)\right)=-\mu, \tag{1.13}$$

where $u=S_t(\gamma,g,u_0)$*,* $q=\frac{\partial}{\partial x}S_t(\gamma,g,u_0)$*,* $H'=h$*, the defect measure* μ *is a nonnegative Radon measure such that as* $R\to\infty$ *there holds* $Rq\,(q+R)\,\chi_{(-\infty,-R)}(q)\overset{\star}{\rightharpoonup}\mu$ *in the sense of measures and* $\mu([0,\infty)\times\mathbb{R})\le\frac{1}{2}\|u_0\|_{H^1(\mathbb{R})}$*.*

We stress that the existence of a strongly continuous semigroup is new, even for the Camassa–Holm equation itself. In particular, this includes the stability of the solution with respect to perturbations in the initial data and the coefficients in the equation.

As in Xin and Zhang [32, 33] and their study of the Camassa–Holm equation (1.1) with $\kappa=0$, we prove existence of a global weak solution by establishing convergence as $\varepsilon\to 0$ of a sequence of smooth viscous approximate solutions u_ε (see (2.1)). Regarding the limiting process there is a an interesting mathematical issue: we need to prove that the derivative $q_\varepsilon=\partial u_\varepsilon/\partial x$, which a priori is only weakly compact, in fact converges strongly (along a subsequence). Strong convergence of q_ε is needed if we want to send ε to zero in the viscous problem and recover (1). To improve the weak convergence of q_ε to strong convergence we follow [32] closely when using renormalization theory for linear transport equations with nonsmooth coefficients. The idea of renormalization goes back to DiPerna and Lions [19] and it has been developed further and applied by many authors (see Lions [26, 27], Xin and Zhang [32], and the references given therein for relevant information). In the process of improving weak convergence to strong convergence, the higher integrability estimate (1.12) for q_ε is crucial. It ensures that the weak limit of q_ε^2 does not contain singular measures (there are no concentration effects).

Regarding the optimality of (1.12), one should keep in mind that when a solution u blows up (necessarily in the sense that $|\partial u/\partial x|\to\infty$), say at $x=0$, then u must behave like $x^{2/3}$ and $\partial u/\partial x$ like $x^{-1/3}$, since $u(t,\cdot)\in H^1(\mathbb{R})$, in which case $\partial u/\partial x$ belongs to L^p_{loc} if and only if $1\le p<3$.

Denote by u an (admissible) weak solution. If the associated defect measure μ defined in (1.13) vanishes, then we call u an *energy conservative (admissible) weak solution*. Xin and Zhang [33] proved a "weak equals strong" uniqueness result for energy conservative admissible weak solutions of the Camassa–Holm equation (1.1) when $\kappa=0$. Their result also contains the uniqueness result of Constantin and Molinet [12] as a special case.

By slightly adapting the arguments of Xin and Zhang we can also have a "weak equals strong" uniqueness result for the generalized hyperelastic-rod wave equation.

THEOREM 1.3. *Suppose there exists a function* u *such that* (*i*)*,* (*ii*)*, and* (*iii*) *of Definition* 1.1 *hold and that there exists a function* $\beta\in L^2([0,T))$ *for all* $T>0$ *such that* $\left\|\frac{\partial u}{\partial x}(t,\cdot)\right\|_{L^\infty(\mathbb{R})}\le\beta(t)$ *for any* $t\ge 0$*. Then the energy conservative admissible weak solution is unique.*

Due to strong similarities with the proof of Xin and Zhang, we do not prove Theorem 1.3 here and instead ask that the reader consult their paper [33].

Whenever a sufficiently regular solution to (1) can be found (see [9, 16, 29, 34, 35, 36] for some situations where this happens), then Theorem 1.3 ensures that this solution is unique in the class energy conservative admissible weak solutions. Note that peakons are "sufficiently regular." For example, the peakon solution (1.3) is covered by our theory. One should compare Theorem 1.3 with the uniqueness/stability assertion in Theorem 1.2, which states that there is uniqueness in the class of vanishing viscosity solutions.

In passing, we mention that it is apparently not easy to prove existence and uniqueness results for (1) by adapting the methods in [8, 12] for the Camassa–Holm equation, which are based on studying the equation for the "vorticity" $m := (1-\frac{\partial^2}{\partial x^2})u$. In the present context the equation for m reads

$$\frac{\partial m}{\partial t} + \gamma u \frac{\partial m}{\partial x} + 2\gamma \frac{\partial u}{\partial x} m = -\frac{1}{2}\frac{\partial}{\partial x}\big(g(u) - 3\gamma u^2\big). \tag{1.14}$$

In the case of the Camassa–Holm equation (that is, $g(u) = 3u^2$ and $\gamma = 1$), the right-hand side of (1.14) vanishes, and assuming that $m|_{t=0}$ is a bounded nonnegative measure it is not difficult to see that $m(t,\cdot) \in L^1$ remains nonnegative at later times and consequently one can bound $\partial u/\partial x$ in L^∞ and $\partial^2 u/\partial x^2$ in L^1. Using these bounds one can in fact prove the existence and uniqueness of an energy conservative weak solution [8, 12]. In the general case ($g(u)$ is not equal to $3\gamma u^2$), it seems difficult to implement this strategy for proving existence and uniqueness results, and this fact has motivated us to use the "weak convergence" approach.

The remainder of this paper is organized as follows. Section 2 is devoted to stating the viscous problem and a corresponding well-posedness result. In sections 3 and 4 we establish, respectively, an Oleinik type estimate and a higher integrability estimate for the viscous approximants. Section 5 is devoted to proving basic compactness properties for the viscous approximants. Strong compactness of the derivative of the viscous approximants is obtained in section 6, where an existence result for (1) is also stated. In section 7 we prove the uniqueness of the vanishing viscosity limit, this defines a semigroup of solutions as stated in Theorem 1.2. In section 8 we prove the continuity properties of the semigroup.

2. Viscous approximants: Existence and energy estimate. We will prove existence of a weak solution to the Cauchy problem for (1) by proving compactness of a sequence of smooth functions $\{u_\varepsilon\}_{\varepsilon>0}$ solving the following viscous problems (see [4, Theorem 2.3]):

$$\begin{cases} \dfrac{\partial u_\varepsilon}{\partial t} + \gamma u_\varepsilon \dfrac{\partial u_\varepsilon}{\partial x} + \dfrac{\partial P_\varepsilon}{\partial x} = \varepsilon \dfrac{\partial^2 u_\varepsilon}{\partial x^2}, & t>0,\ x\in\mathbb{R},\\ -\dfrac{\partial^2 P_\varepsilon}{\partial x^2} + P_\varepsilon = h(u_\varepsilon) + \dfrac{\gamma}{2}\left(\dfrac{\partial u_\varepsilon}{\partial x}\right)^2, & t>0,\ x\in\mathbb{R},\\ u_\varepsilon(0,x) = u_{\varepsilon,0}(x), & x\in\mathbb{R}. \end{cases} \tag{2.1}$$

We shall assume that

$$\|u_{\varepsilon,0}\|_{H^1(\mathbb{R})} \le \|u_0\|_{H^1(\mathbb{R})},\ \ \varepsilon>0, \quad \text{and} \quad u_{\varepsilon,0}\to u_0 \ \text{in}\ H^1(\mathbb{R}). \tag{2.2}$$

The starting point of our analysis is the following well-posedness result for (2.1).

THEOREM 2.1. *Assume* (1.4) *and* (2.2). *Let* $\varepsilon > 0$, $u_{\varepsilon,0} \in H^\ell(\mathbb{R})$ *and* $\ell \ge 2$. *Then there exists a unique solution* $u_\varepsilon \in C\big(\mathbb{R}; H^\ell(\mathbb{R})\big)$ *to the Cauchy problem* (2.1). *Moreover, for each* $t \ge 0$,

$$\begin{aligned}&\int_{\mathbb{R}}\left(u_\varepsilon^2 + \left(\frac{\partial u_\varepsilon}{\partial x}\right)^2\right)(t,x)dx\\ &\quad + 2\varepsilon\int_0^t\int_{\mathbb{R}}\left(\left(\frac{\partial u_\varepsilon}{\partial x}\right)^2 + \left(\frac{\partial^2 u_\varepsilon}{\partial x^2}\right)^2\right)(s,x)dxds = \|u_{\varepsilon,0}\|^2_{H^1(\mathbb{R})},\end{aligned} \tag{2.3}$$

or

$$\|u_\varepsilon(t,\cdot)\|^2_{H^1(\mathbb{R})} + 2\varepsilon\int_0^t \left\|\frac{\partial u_\varepsilon}{\partial x}(s,\cdot)\right\|^2_{H^1(\mathbb{R})} ds = \|u_{\varepsilon,0}\|^2_{H^1(\mathbb{R})}.$$

Remark 2.2. Due to [25, Theorem 8.5], (2.2) and (2.3), we have for each $t \geq 0$

$$\|u_\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R})} \leq \frac{1}{\sqrt{2}}\,\|u_\varepsilon(t,\cdot)\|_{H^1(\mathbb{R})} \leq \frac{1}{\sqrt{2}}\|u_0\|_{H^1(\mathbb{R})}. \tag{2.4}$$

Proof of Theorem 2.1. From Theorem 2.3 in [4] we infer that (2.1) has a solution $u_\varepsilon \in C(\mathbb{R}; H^\ell(\mathbb{R}))$. Define

$$q_\varepsilon(t,x) := \frac{\partial u_\varepsilon}{\partial x}(t,x).$$

By (2.1), $q_\varepsilon = q_\varepsilon(t,x)$ is the solution of

$$\frac{\partial q_\varepsilon}{\partial t} + \gamma u_\varepsilon \frac{\partial q_\varepsilon}{\partial x} - \varepsilon\frac{\partial^2 q_\varepsilon}{\partial x^2} + \frac{\gamma}{2}q_\varepsilon^2 = h(u_\varepsilon) - P_\varepsilon, \quad q_\varepsilon(0,x) = \frac{\partial u_{\varepsilon,0}}{\partial x}(x), \tag{2.5}$$

for $t > 0$ and $x \in \mathbb{R}$. Multiply (2.1) by u_ε, (2.5) by q_ε, and add the resulting equations. After rearranging a bit, we derive the conservation law

$$\begin{aligned}\frac{\partial}{\partial t}\left(\frac{1}{2}\left[u_\varepsilon^2 + q_\varepsilon^2\right]\right) &+ \frac{\partial}{\partial x}\left(u_\varepsilon\left[\frac{\gamma}{2}q_\varepsilon^2 + P_\varepsilon\right] + \frac{\gamma}{3}u^3 - H(u)\right)\\ &= \frac{\varepsilon}{2}(u_\varepsilon^2 + q_\varepsilon^2)_{xx} - \varepsilon q_\varepsilon^2 - \varepsilon\left(\frac{\partial q_\varepsilon}{\partial x}\right)^2,\end{aligned}$$

where $H' = h$. From this (2.3) follows easily. ∎

3. Viscous approximants: Oleinik type estimate.

LEMMA 3.1. *For each $t > 0$ and $x \in \mathbb{R}$,*

$$\frac{\partial u_\varepsilon}{\partial x}(t,x) \leq \frac{2}{\gamma t} + C_2, \tag{3.1}$$

where $u_\varepsilon = u_\varepsilon(t,x)$ is the unique solution of (2.1), and

$$C_2 := \sqrt{\frac{2}{\gamma}}\left(2\max_{|\xi|\leq\sqrt{2}\|u_0\|_{H^1(\mathbb{R})}}\left|h(\xi)\right| + \frac{\gamma}{2}\|u_0\|^2_{H^1(\mathbb{R})}\right)^{1/2}.$$

Proof. From (2.4),

$$\left\|h(u_\varepsilon)\right\|_{L^\infty([0,\infty)\times\mathbb{R})} \leq \max_{|\xi|\leq\sqrt{2}\|u_0\|_{H^1(\mathbb{R})}}\left|h(\xi)\right| := L_1 < \infty. \tag{3.2}$$

Moreover, since

$$\int_{\mathbb{R}} e^{-|x-y|}dy = 2, \qquad x \in \mathbb{R}, \tag{3.3}$$

again using (2.4), for each $t \geq 0$ and $x \in \mathbb{R}$,

$$|P_\varepsilon(t,x)| \leq L_1 + \frac{\gamma}{4}\left\|\frac{\partial u_\varepsilon}{\partial x}(t,\cdot)\right\|^2_{L^2(\mathbb{R})} \leq L_1 + \frac{\gamma}{4}\|u_0\|^2_{H^1(\mathbb{R})} := L_2.$$

So, denoting $L := L_1 + L_2$, we have, from (2.5),

$$\frac{\partial q_\varepsilon}{\partial t} + \gamma u_\varepsilon \frac{\partial q_\varepsilon}{\partial x} - \varepsilon \frac{\partial^2 q_\varepsilon}{\partial x^2} + \frac{\gamma}{2} q_\varepsilon^2 \leq L. \tag{3.4}$$

Let $f = f(t)$ be the solution of

$$\frac{df}{dt} + \frac{\gamma}{2} f^2 = L, \quad t > 0, \qquad f(0) = \left\|\frac{\partial u_{\varepsilon,0}}{\partial x}\right\|_{L^\infty(\mathbb{R})}. \tag{3.5}$$

Since, by (2.4) and (3.4), $f = f(t)$ is a supersolution of the parabolic initial value problem (2.5), due to the comparison principle for parabolic equations, we get

$$q_\varepsilon(t,x) \leq f(t), \qquad t \geq 0,\ \ x \in \mathbb{R}. \tag{3.6}$$

Finally, consider the map $F(t) := \frac{2}{\gamma t} + \sqrt{\frac{2}{\gamma} L}$, $t > 0$. Observe that $\frac{dF}{dt}(t) + \frac{\gamma}{2} F^2(t) - L = \frac{2\sqrt{2L/\gamma}}{t} > 0$, for any $t > 0$, so that $F = F(t)$ is a supersolution of (3.5). Due to the comparison principle for ordinary differential equations, we get $f(t) \leq F(t)$ for all $t > 0$. Therefore, by this and (3.6), the estimate (3.1) is proven. □

4. Viscous approximants: Higher integrability estimate.

LEMMA 4.1. *Let $0 < \alpha < 1$, $T > 0$, and $a, b \in \mathbb{R}$, $a < b$. Then there exists a positive constant C_3 depending only on $\|u_0\|_{H^1(\mathbb{R})}$, α, T, a and b, but independent of ε, such that*

$$\int_0^T \int_a^b \left|\frac{\partial u_\varepsilon}{\partial x}(t,x)\right|^{2+\alpha} dtdx \leq C_3, \tag{4.1}$$

where $u_\varepsilon = u_\varepsilon(t,x)$ is the unique solution of (2.1).

Proof. The proof is a variant of the proof found in Xin and Zhang [32]. Let $\chi \in C^\infty(\mathbb{R})$ be a cut-off function such that

$$0 \leq \chi \leq 1, \qquad \chi(x) = \begin{cases} 1, & \text{if } x \in [a,b], \\ 0, & \text{if } x \in (-\infty, a-1] \cup [b+1, \infty). \end{cases}$$

Consider also the map $\theta(\xi) := \xi\big(|\xi| + 1\big)^\alpha$, $\xi \in \mathbb{R}$, and observe that, since $0 < \alpha < 1$,

$$\begin{aligned} \theta'(\xi) &= \big((\alpha+1)|\xi| + 1\big)\big(|\xi|+1\big)^{\alpha-1}, \\ \theta''(\xi) &= \alpha \operatorname{sign}(\xi)\, \big(|\xi|+1\big)^{\alpha-2}\big((\alpha+1)|\xi| + 2\big) \\ &= \alpha(\alpha+1)\operatorname{sign}(\xi)\, \big(|\xi|+1\big)^{\alpha-1} + (1-\alpha)\alpha \operatorname{sign}(\xi)\, \big(|\xi|+1\big)^{\alpha-2}, \end{aligned}$$

$$\big|\theta(\xi)\big| \leq |\xi|^{\alpha+1} + |\xi|, \quad \big|\theta'(\xi)\big| \leq (\alpha+1)|\xi| + 1, \quad \big|\theta''(\xi)\big| \leq 2\alpha, \tag{4.2}$$

(4.3)

$$\begin{aligned} \xi\theta(\xi) - \frac{1}{2}\xi^2\theta'(\xi) &= \frac{1-\alpha}{2}\xi^2\big(|\xi|+1\big)^\alpha + \frac{\alpha}{2}\xi^2\big(|\xi|+1\big)^{\alpha-1} \\ &\geq \frac{1-\alpha}{2}\xi^2\big(|\xi|+1\big)^\alpha. \end{aligned}$$

Multiplying (2.5) by $\chi\theta'(q_\varepsilon)$, using the chain rule, and integrating over $\Pi_T := [0,T]\times\mathbb{R}$, we get

$$
\begin{aligned}
(4.4)\qquad &\int_{\Pi_T} \gamma\chi(x) q_\varepsilon \theta(q_\varepsilon)dtdx - \frac{\gamma}{2}\int_{\Pi_T} q_\varepsilon^2 \chi(x)\theta'(q_\varepsilon)dtdx\\
&= \int_{\mathbb{R}} \chi(x)\left(\theta\big(q_\varepsilon(T,x)\big) - \theta\big(q_\varepsilon(0,x)\big)\right)dx - \int_{\Pi_T}\gamma u_\varepsilon \chi'(x)\theta(q_\varepsilon)dtdx\\
&+ \ \varepsilon\int_{\Pi_T} \frac{\partial q_\varepsilon}{\partial x}\chi'(x)\theta'(q_\varepsilon)dtdx + \varepsilon\int_{\Pi_T}\left(\frac{\partial q_\varepsilon}{\partial x}\right)^2\chi(x)\theta''(q_\varepsilon)dtdx\\
&- \int_{\Pi_T}\left(h(u_\varepsilon) - P_\varepsilon\right)\chi(x)\theta'(q_\varepsilon)dtdx.
\end{aligned}
$$

Observe that, by (4.3),

$$
\begin{aligned}
&\int_{\Pi_T} \gamma\chi(x) q_\varepsilon \theta(q_\varepsilon)dtdx - \frac{\gamma}{2}\int_{\Pi_T} q_\varepsilon^2 \chi(x)\theta'(q_\varepsilon)dtdx\\
&= \int_{\Pi_T}\gamma\chi(x)\Big(q_\varepsilon\theta(q_\varepsilon) - \frac{1}{2}q_\varepsilon^2\theta'(q_\varepsilon)\Big)dtdx\\
(4.5)\qquad &\geq \frac{\gamma(1-\alpha)}{2}\int_{\Pi_T}\chi(x) q_\varepsilon^2\big(|q_\varepsilon|+1\big)^\alpha dtdx.
\end{aligned}
$$

Let $t \geq 0$, since $0 < \alpha < 1$, using the Hölder inequality, (2.4) and the first part of (4.2),

$$
\begin{aligned}
(4.6)\qquad \left|\int_{\mathbb{R}}\chi(x)\theta(q_\varepsilon)dx\right| &\leq \int_{\mathbb{R}}\chi(x)\left(|q_\varepsilon|^{\alpha+1} + |q_\varepsilon|\right)dx\\
&\leq \|\chi\|_{L^{2/(1-\alpha)}(\mathbb{R})}\|q_\varepsilon(t,\cdot)\|_{L^2(\mathbb{R})}^{\alpha+1} + \|\chi\|_{L^2(\mathbb{R})}\|q_\varepsilon(t,\cdot)\|_{L^2(\mathbb{R})}\\
&\leq (b-a+2)^{(1-\alpha)/2}\|u_0\|_{H^1(\mathbb{R})}^{\alpha+1} + (b-a+2)^{1/2}\|u_0\|_{H^1(\mathbb{R})},
\end{aligned}
$$

and

(4.7)
$$
\begin{aligned}
\left|\int_{\Pi_T}\gamma u_\varepsilon\chi'(x)\theta(q_\varepsilon)dtdx\right| &\leq \int_{\Pi_T}\gamma|u_\varepsilon||\chi'(x)|\left(|q_\varepsilon|^{\alpha+1}+|q_\varepsilon|\right)dtdx\\
&\leq \int_{\Pi_T}\gamma\|u_\varepsilon(t,\cdot)\|_{L^\infty(\mathbb{R})}|\chi'(x)|\left(|q_\varepsilon|^{\alpha+1}+|q_\varepsilon|\right)dtdx\\
&\leq \gamma\frac{\|u_0\|_{H^1(\mathbb{R})}}{\sqrt{2}}\int_0^T\big(\|\chi'\|_{L^{2/(1-\alpha)}(\mathbb{R})}\|q_\varepsilon(t,\cdot)\|_{L^2(\mathbb{R})}^{\alpha+1}\\
&\qquad + \|\chi'\|_{L^2(\mathbb{R})}\|q_\varepsilon(t,\cdot)\|_{L^2(\mathbb{R})}\big)dt\\
&\leq \gamma T\frac{\|u_0\|_{H^1(\mathbb{R})}}{\sqrt{2}}\big(\|\chi'\|_{L^{2/(1-\alpha)}(\mathbb{R})}\|u_0\|_{H^1(\mathbb{R})}^{\alpha+1}\\
&\qquad + \|\chi'\|_{L^2(\mathbb{R})}\|u_0\|_{H^1(\mathbb{R})}\big).
\end{aligned}
$$

Moreover, observe that

$$
\varepsilon\int_{\Pi_T}\frac{\partial q_\varepsilon}{\partial x}\chi'(x)\theta'(q_\varepsilon)dtdx = -\varepsilon\int_{\Pi_T}\theta(q_\varepsilon)\chi''(x)dtdx,
$$

so, again by the Hölder inequality (2.4) and the first part of (4.2),

$$\begin{aligned}\left|\varepsilon\int_{\Pi_T}\frac{\partial q_\varepsilon}{\partial x}\chi'(x)\theta(q_\varepsilon)dtdx\right| &\le \varepsilon\int_{\Pi_T}|\theta(q_\varepsilon)||\chi''(x)|dtdx\\ &\le \varepsilon\int_{\Pi_T}\left(|q_\varepsilon|^{\alpha+1}+|q_\varepsilon|\right)|\chi''(x)|dtdx\\ &\le \varepsilon\int_0^T\Big(\|\chi''\|_{L^{2/(1-\alpha)}(\mathbb{R})}\|q_\varepsilon(t,\,\cdot\,)\|^{\alpha+1}_{L^2(\mathbb{R})}\\ &\qquad+\|\chi''\|_{L^2(\mathbb{R})}\|q_\varepsilon(t,\,\cdot\,)\|_{L^2(\mathbb{R})}\Big)dt\\ &\le \varepsilon T\Big(\|\chi''\|_{L^{2/(1-\alpha)}(\mathbb{R})}\|u_0\|^{\alpha+1}_{H^1(\mathbb{R})}+\|\chi''\|_{L^2(\mathbb{R})}\|u_0\|_{H^1(\mathbb{R})}\Big).\end{aligned} \tag{4.8}$$

Since $0<\alpha<1$, using (2.3) and the third part of (4.2),

$$\varepsilon\left|\int_{\Pi_T}\left(\frac{\partial q_\varepsilon}{\partial x}\right)^2\chi(x)\theta''(q_\varepsilon)dtdx\right|\le 2\alpha\varepsilon\int_{\Pi_T}\left(\frac{\partial q_\varepsilon}{\partial x}\right)^2dtdx\le\alpha\|u_0\|^2_{H^1(\mathbb{R})}. \tag{4.9}$$

As we showed in the proof of Lemma 3.1, there exists a constant $L>0$ depending only on $\|u_0\|_{H^1(\mathbb{R})}$ such that $\left\|h(u_\varepsilon)-P_\varepsilon\right\|_{L^\infty([0,\infty)\times\mathbb{R})}\le L$, so, since $0<\alpha<1$, using the second part of (4.2),

$$\begin{aligned}&\left|\int_{\Pi_T}\left(h(u_\varepsilon)-P_\varepsilon\right)\chi(x)\theta'(q_\varepsilon)dtdx\right|\\ &\quad\le L\int_{\Pi_T}\chi(x)\left((\alpha+1)|q_\varepsilon|+1\right)dtdx\\ &\quad\le L\int_0^T\left((\alpha+1)\|\chi\|_{L^2(\mathbb{R})}\|q_\varepsilon(t,\,\cdot\,)\|_{L^2(\mathbb{R})}+\|\chi\|_{L^1(\mathbb{R})}\right)dt\\ &\quad\le LT\Big((\alpha+1)(b-a+2)^{1/2}\|u_0\|_{H^1(\mathbb{R})}+(b-a+2)\Big).\end{aligned} \tag{4.10}$$

From (4.4)–(4.10), there exists a constant $c>0$ depending only on $\|u_0\|_{H^1(\mathbb{R})}$, α, $T>0$, a, and b, but independent of ε, such that

$$\frac{\gamma(1-\alpha)}{2}\int_{\Pi_T}|q_\varepsilon|^2\chi(x)\big(|q_\varepsilon|+1\big)^\alpha dtdx\le c. \tag{4.11}$$

Then

$$\int_0^T\int_a^b\left|\frac{\partial u_\varepsilon}{\partial x}(t,x)\right|^{2+\alpha}dtdx\le\int_{\Pi_T}|q_\varepsilon|\chi(x)\left(|q_\varepsilon|+1\right)^{\alpha+1}dtdx\le\frac{2c}{\gamma(1-\alpha)},$$

hence estimate (4.1) is proved. ∎

5. Viscous approximants: Basic compactness.

LEMMA 5.1. *There exists a positive constant C_4 depending only on $\|u_0\|_{H^1(\mathbb{R})}$ such that*

$$\|P_\varepsilon(t,\,\cdot\,)\|_{L^\infty(\mathbb{R})},\ \|P_\varepsilon(t,\,\cdot\,)\|_{L^2(\mathbb{R})},\ \left\|\frac{\partial P_\varepsilon}{\partial x}(t,\,\cdot\,)\right\|_{L^\infty(\mathbb{R})},\ \left\|\frac{\partial P_\varepsilon}{\partial x}(t,\,\cdot\,)\right\|_{L^2(\mathbb{R})}\le C_4, \tag{5.1}$$

where $u_\varepsilon = u_\varepsilon(t,x)$ is the unique solution of (2.1). In particular, $\{P_\varepsilon\}_\varepsilon$ is uniformly bounded in $L^\infty([0,\infty); W^{1,\infty}(\mathbb{R}))$ and $L^\infty([0,\infty); H^1(\mathbb{R}))$.

Proof. Define

$$P_{1,\varepsilon}(t,x) := \frac{\gamma}{4}\int_{\mathbb{R}} e^{-|x-y|} q_\varepsilon^2 dy, \qquad P_{2,\varepsilon}(t,x) := \frac{1}{2}\int_{\mathbb{R}} e^{-|x-y|} h\big(u_\varepsilon(t,y)\big) dy, \tag{5.2}$$

and notice that $P_\varepsilon = P_{1,\varepsilon} + P_{2,\varepsilon}$. By (2.4) and (3.3),

$$P_{1,\varepsilon}(t,x)| \le \frac{\gamma}{4}\|u_\varepsilon(t,\cdot)\|^2_{H^1(\mathbb{R})} \le \frac{\gamma}{4}\|u_0\|^2_{H^1(\mathbb{R})}, \tag{5.3}$$

$$|P_{2,\varepsilon}(t,x)| \le \max_{|\xi| \le \|u_0\|_{H^1(\mathbb{R})}/\sqrt{2}} \big|h(\xi)\big|. \tag{5.4}$$

Moreover, using (3.3) and the Tonelli theorem,

$$\int_{\mathbb{R}} |P_{1,\varepsilon}(t,x)| dx \le \frac{\gamma}{2}\|u_\varepsilon(t,\cdot)\|^2_{H^1(\mathbb{R})} \le \frac{\gamma}{2}\|u_0\|^2_{H^1(\mathbb{R})}. \tag{5.5}$$

From (3.3), (5.3), (5.5), and the Hölder inequality,

$$\int_{\mathbb{R}} |P_{1,\varepsilon}(t,x)|^2 dx \le \|P_{1,\varepsilon}\|_{L^\infty([0,\infty)\times\mathbb{R})}\|P_{1,\varepsilon}(t,\cdot)\|_{L^1(\mathbb{R})} \le \frac{\gamma^2}{8}\|u_0\|^4_{H^1(\mathbb{R})},$$

so that

$$\|P_{1,\varepsilon}(t,\cdot)\|_{L^2(\mathbb{R})} \le \frac{\gamma}{2\sqrt{2}}\|u_0\|^2_{H^1(\mathbb{R})}. \tag{5.6}$$

Using (1.4), (2.4), (3.3), the Tonelli theorem, and the Hölder inequality,

$$\begin{aligned}
\int_{\mathbb{R}} |P_{2,\varepsilon}(t,x)|^2 dx &\le \frac{1}{2}\int_{\mathbb{R}} \left(\int_{\mathbb{R}} e^{-|x-y|} dx\right) \left(h(u_\varepsilon(t,y))\right)^2 dy \\
&\le \left(\max_{|\xi| \le \|u_0\|_{H^1(\mathbb{R})}/\sqrt{2}} \left(h'(\xi)\right)^2\right) \int_{\mathbb{R}} u_\varepsilon^2(t,y) dy \\
&\le \left(\max_{|\xi| \le \|u_0\|_{H^1(\mathbb{R})}/\sqrt{2}} \left(h'(\xi)\right)^2\right) \|u_0\|^2_{H^1(\mathbb{R})}.
\end{aligned} \tag{5.7}$$

Finally, observing

$$\begin{aligned}
\frac{\partial P_{1,\varepsilon}}{\partial x}(t,x) &= \frac{\gamma}{4}\int_{\mathbb{R}} \operatorname{sign}(y-x)\, e^{-|x-y|} \left(q_\varepsilon(t,y)\right)^2 dy, \\
\frac{\partial P_{2,\varepsilon}}{\partial x}(t,x) &= \frac{1}{2}\int_{\mathbb{R}} \operatorname{sign}(y-x)\, e^{-|x-y|} h\big(u_\varepsilon(t,y)\big) dy,
\end{aligned}$$

and recalling $P_\varepsilon = P_{1,\varepsilon} + P_{2,\varepsilon}$, the claim is a direct consequence of (5.3), (5.4), (5.6), and (5.7). ◻

LEMMA 5.2. *There exists a sequence $\{\varepsilon_j\}_{j\in\mathbb{N}}$ tending to zero and a function $u \in L^\infty([0,\infty); H^1(\mathbb{R})) \cap H^1([0,T]\times\mathbb{R})$, for each $T \ge 0$, such that*

$$u_{\varepsilon_j} \rightharpoonup u \quad \text{in } H^1([0,T]\times\mathbb{R}), \text{ for each } T \ge 0, \tag{5.8}$$

$$u_{\varepsilon_j} \to u \quad \text{in } L^\infty_{\mathrm{loc}}([0,\infty)\times\mathbb{R}), \tag{5.9}$$

where $u_\varepsilon = u_\varepsilon(t,x)$ is the unique solution of (2.1).

Proof. Fix $T > 0$. Observe that, from (2.1), $\frac{\partial u_\varepsilon}{\partial t} = \varepsilon \frac{\partial^2 u_\varepsilon}{\partial x^2} - \gamma u_\varepsilon \frac{\partial u_\varepsilon}{\partial x} - \frac{\partial P_\varepsilon}{\partial x}$, so, by (2.4), (2.3), (5.1), and the Hölder inequality,

$$\left\| \frac{\partial u_\varepsilon}{\partial t} \right\|_{L^2([0,T]\times\mathbb{R})} \le \sqrt{\frac{\varepsilon}{2}} \|u_0\|_{L^\infty(\mathbb{R})} + \frac{\gamma\sqrt{T}}{\sqrt{2}} \|u_0\|^2_{L^\infty(\mathbb{R})} + C_4\sqrt{T}. \tag{5.10}$$

Hence $\{u_\varepsilon\}$ is uniformly bounded in $H^1([0,T]\times\mathbb{R}) \cap L^\infty([0,\infty); H^1(\mathbb{R}))$, and (5.8) follows.

Observe that, for each $0 \le s,\, t \le T$,

$$\|u_\varepsilon(t,\cdot) - u_\varepsilon(s,\cdot)\|^2_{L^2(\mathbb{R})} = \int_{\mathbb{R}} \left(\int_s^t \frac{\partial u_\varepsilon}{\partial t}(\tau, x) d\tau \right)^2 dx \le \sqrt{|t-s|} \int_{\Pi_T} \left(\frac{\partial u_\varepsilon}{\partial t}(\tau, x) \right)^2 d\tau dx.$$

Moreover, $\{u_\varepsilon\}$ is uniformly bounded in $L^\infty([0,T]; H^1(\mathbb{R}))$ and $H^1(\mathbb{R}) \subset\subset L^\infty_{\mathrm{loc}}(\mathbb{R}) \subset L^2_{\mathrm{loc}}(\mathbb{R})$, then (5.9) is consequence of [31, Theorem 5]. $\square$

LEMMA 5.3. *The sequence $\{P_\varepsilon\}_\varepsilon$ is uniformly bounded in $W^{1,1}_{\mathrm{loc}}([0,\infty)\times\mathbb{R})$. In particular, there exists a sequence $\{\varepsilon_j\}_{j\in\mathbb{N}}$ tending to zero and a function $P \in L^\infty([0,\infty); W^{1,\infty}(\mathbb{R}))$ such that for each $1 < p < \infty$*

$$P_{\varepsilon_j} \to P \quad \textit{strongly in } L^p_{\mathrm{loc}}([0,\infty)\times\mathbb{R}). \tag{5.11}$$

Proof. We begin by proving that $\left\{\frac{\partial P_\varepsilon}{\partial t}\right\}_\varepsilon$ is uniformly bounded in $L^1_{\mathrm{loc}}([0,\infty)\times\mathbb{R})$. Fix $T > 0$. We claim that

$$\left\{ \frac{\partial P_{1,\varepsilon}}{\partial t} \right\}_\varepsilon \text{ is uniformly bounded in } L^1([0,T]\times\mathbb{R}), \tag{5.12}$$

$$\left\{ \frac{\partial P_{2,\varepsilon}}{\partial t} \right\}_\varepsilon \text{ is uniformly bounded in } L^2([0,T]\times\mathbb{R}), \tag{5.13}$$

where $P_{1,\varepsilon}$ and $P_{2,\varepsilon}$ are defined in (5.2). We begin by proving (5.12). Observe that, from (2.5),

(5.14)
$$\begin{aligned} \frac{\partial P_{1,\varepsilon}}{\partial t}(t,x) &= \frac{\gamma}{2} \int_{\mathbb{R}} e^{-|x-y|} q_\varepsilon \frac{\partial q_\varepsilon}{\partial t} dy \\ &= \frac{\gamma}{2} \int_{\mathbb{R}} e^{-|x-y|} \left(-\gamma q_\varepsilon u_\varepsilon \frac{\partial q_\varepsilon}{\partial x} + \varepsilon q_\varepsilon \frac{\partial^2 q_\varepsilon}{\partial x^2} - \frac{\gamma}{2} q_\varepsilon^3 + q_\varepsilon \left(h(u_\varepsilon) - P_\varepsilon \right) \right) dy. \end{aligned}$$

Using $\frac{\gamma}{2}\frac{\partial}{\partial x}(u_\varepsilon q_\varepsilon^2) = \frac{\gamma}{2} q_\varepsilon^3 + \gamma q_\varepsilon u_\varepsilon \frac{\partial q_\varepsilon}{\partial x}$, $\frac{\partial}{\partial x}\left(q_\varepsilon \frac{\partial q_\varepsilon}{\partial x}\right) = q_\varepsilon \frac{\partial^2 q_\varepsilon}{\partial x^2} + \left(\frac{\partial q_\varepsilon}{\partial x}\right)^2$, (5.14), and integration by parts, we get

$$\begin{aligned} &\frac{\partial P_{1,\varepsilon}}{\partial t}(t,x) \\ &\quad = \frac{\gamma}{4} \int_{\mathbb{R}} e^{-|x-y|} \left(-\frac{\gamma}{2} \frac{\partial}{\partial x}(u_\varepsilon q_\varepsilon^2) + \varepsilon \frac{\partial}{\partial x}\left(q_\varepsilon \frac{\partial q_\varepsilon}{\partial x} \right) - \varepsilon \left(\frac{\partial q_\varepsilon}{\partial x} \right)^2 + q_\varepsilon \left(h(u_\varepsilon) - P_\varepsilon \right) \right) dy \\ &\quad = \frac{\gamma}{4} \int_{\mathbb{R}} e^{-|x-y|} \left(\operatorname{sign}(y-x) \left[\frac{\gamma}{2} u_\varepsilon q_\varepsilon^2 - \varepsilon q_\varepsilon \frac{\partial q_\varepsilon}{\partial x} \right] - \varepsilon \left(\frac{\partial q_\varepsilon}{\partial x} \right)^2 + q_\varepsilon \left(h(u_\varepsilon) - P_\varepsilon \right) \right) dy. \end{aligned}$$

Using (1.4), (2.3), (2.4), (5.1), the Tonelli theorem, and the Hölder inequality,

$$\int_{\mathbb{R}\times\mathbb{R}} e^{-|x-y|}|u_\varepsilon|q_\varepsilon^2 dxdy \le \sqrt{2}\|u_0\|_{H^1(\mathbb{R})}\|u_\varepsilon(t,\cdot)\|^2_{H^1(\mathbb{R})} \le \sqrt{2}\|u_0\|^3_{H^1(\mathbb{R})},$$

$$\begin{aligned}\varepsilon\int_{\Pi_T\times\mathbb{R}} e^{-|x-y|}|q_\varepsilon|\left|\frac{\partial q_\varepsilon}{\partial x}\right| dtdxdy &\le \varepsilon\int_0^T \|u_\varepsilon(t,\cdot)\|^2_{H^1(\mathbb{R})}dt + \varepsilon\int_0^T \left\|\frac{\partial u_\varepsilon}{\partial x}(t,\cdot)\right\|^2_{H^1(\mathbb{R})} dt\\ &\le \left(\varepsilon T + \frac{1}{2}\right)\|u_0\|^2_{H^1(\mathbb{R})},\end{aligned}$$

$$\varepsilon\int_{\Pi_T\times\mathbb{R}} e^{-|x-y|}\left(\frac{\partial q_\varepsilon}{\partial x}\right)^2 dtdxdy \le 2\varepsilon\int_0^T \left\|\frac{\partial u_\varepsilon}{\partial x}(t,\cdot)\right\|^2_{H^1(\mathbb{R})} dt \le \|u_0\|^2_{H^1(\mathbb{R})},$$

$$\begin{aligned}\int_{\mathbb{R}\times\mathbb{R}} e^{-|x-y|}|q_\varepsilon||h(u_\varepsilon)|dxdy &\le \int_{\mathbb{R}} q_\varepsilon^2 dy + \max_{|\xi|\le\|u_0\|_{H^1(\mathbb{R})}/\sqrt{2}} (h'(\xi))^2\int_{\mathbb{R}} u_\varepsilon^2 dy\\ &\le \left(1 + \max_{|\xi|\le\|u_0\|_{H^1(\mathbb{R})}/\sqrt{2}} (h'(\xi))^2\right)\|u_0\|^2_{H^1(\mathbb{R})},\end{aligned}$$

$$\int_{\mathbb{R}\times\mathbb{R}} e^{-|x-y|}|q_\varepsilon||P_\varepsilon|dxdy \le \|u_\varepsilon(t,\cdot)\|^2_{H^1(\mathbb{R})} + \|P_\varepsilon(t,\cdot)\|^2_{L^2(\mathbb{R})} \le \|u_0\|^2_{H^1(\mathbb{R})} + C_4^2.$$

It follows from these estimates that (5.12) holds.

We continue by proving (5.13). Observe that

$$\frac{\partial P_{2,\varepsilon}}{\partial t}(t,x) = \frac{1}{2}\int_{\mathbb{R}} e^{-|x-y|}h'(u_\varepsilon)\frac{\partial u_\varepsilon}{\partial t}dy, \tag{5.15}$$

so, using (1.4), (2.4), the Tonelli theorem, and the Hölder inequality,

$$\left\|\frac{\partial P_{2,\varepsilon}}{\partial t}\right\|^2_{L^2(\Pi_T)} \le \max_{|\xi|\le\|u_0\|_{H^1(\mathbb{R})}/\sqrt{2}} (h'(\xi))^2\left\|\frac{\partial u_\varepsilon}{\partial t}\right\|^2_{L^2(\Pi_T)}. \tag{5.16}$$

Then (5.13) is a direct consequence of (5.10).

Since the bound on $\left\{\frac{\partial P_\varepsilon}{\partial t}\right\}_\varepsilon$ is a consequence of (5.12) and (5.13), the family $\{P_\varepsilon\}_\varepsilon$ is bounded in $W^{1,1}_{\mathrm{loc}}([0,\infty)\times\mathbb{R})$.

Finally, using also Lemma 5.1, we have the existence of a pointwise converging subsequence that is uniformly bounded in $L^\infty([0,\infty)\times\mathbb{R})$. Clearly, this implies (5.11). $\square$

Throughout this paper we use overbars to denote weak limits (the spaces in which these weak limits are taken should be clear from the context and thus they are not always explicitly stated).

LEMMA 5.4. *There exists a sequence $\{\varepsilon_j\}_{j\in\mathbb{N}}$ tending to zero and two functions $q \in L^p_{\mathrm{loc}}([0,\infty)\times\mathbb{R})$, $\overline{q^2} \in L^r_{\mathrm{loc}}([0,\infty)\times\mathbb{R})$ such that*

$$q_{\varepsilon_j} \rightharpoonup q \quad \text{in } L^p_{\mathrm{loc}}([0,\infty)\times\mathbb{R}), \qquad q_{\varepsilon_j} \overset{\star}{\rightharpoonup} q \quad \text{in } L^\infty_{\mathrm{loc}}([0,\infty); L^2(\mathbb{R})), \tag{5.17}$$

$$q^2_{\varepsilon_j} \rightharpoonup \overline{q^2} \quad \text{in } L^r_{\mathrm{loc}}([0,\infty)\times\mathbb{R}), \tag{5.18}$$

for each $1 < p < 3$ and $1 < r < \frac{3}{2}$. Moreover,

$$q^2(t,x) \le \overline{q^2}(t,x) \quad \text{for almost every } (t,x) \in [0,\infty)\times\mathbb{R} \tag{5.19}$$

and

$$\frac{\partial u}{\partial x} = q \quad \text{in the sense of distributions on } [0,\infty)\times\mathbb{R}. \tag{5.20}$$

Proof. Formulas (5.17) and (5.18) are direct consequences of Theorem 2.1 and Lemma 4.1. Inequality (5.19) is true thanks to the weak convergence in (5.18). Finally, (5.20) is a consequence of the definition of q_ε, Lemma 5.2, and (5.17). ∎

In the following, for notational convenience, we replace the sequences $\{u_{\varepsilon_j}\}_{j\in\mathbb{N}}$, $\{q_{\varepsilon_j}\}_{j\in\mathbb{N}}$, $\{P_{\varepsilon_j}\}_{j\in\mathbb{N}}$ by $\{u_\varepsilon\}_{\varepsilon>0}$, $\{q_\varepsilon\}_{\varepsilon>0}$, $\{P_\varepsilon\}_{\varepsilon>0}$, respectively.

In view of (5.17), we conclude that for any $\eta\in C^1(\mathbb{R})$ with η' bounded, Lipschitz continuous on $\mathbb{R}$ and any $1<p<3$ we have

$$\eta(q_\varepsilon) \rightharpoonup \overline{\eta(q)} \quad \text{in } L^p_{\mathrm{loc}}([0,\infty)\times\mathbb{R}), \qquad \eta(q_\varepsilon) \overset{\star}{\rightharpoonup} \overline{\eta(q)} \quad \text{in } L^\infty_{\mathrm{loc}}([0,\infty);L^2(\mathbb{R})). \tag{5.21}$$

Multiplying the equation in (2.5) by $\eta'(q_\varepsilon)$, we get

$$\begin{aligned} &\frac{\partial}{\partial t}\eta(q_\varepsilon) + \frac{\partial}{\partial x}\left(\gamma u_\varepsilon \eta(q_\varepsilon)\right) - \varepsilon\frac{\partial^2}{\partial x^2}\eta(q_\varepsilon) - \varepsilon\eta''(q_\varepsilon)\left(\frac{\partial}{\partial x}\eta(q_\varepsilon)\right)^2 \\ &\quad = \gamma q_\varepsilon \eta(q_\varepsilon) - \frac{\gamma}{2}\eta'(q_\varepsilon)q_\varepsilon^2 + \left(h(u_\varepsilon)-P_\varepsilon\right)\eta'(q_\varepsilon). \end{aligned} \tag{5.22}$$

Lemma 5.5. *For any convex $\eta\in C^1(\mathbb{R})$ with η' bounded, Lipschitz continuous on $\mathbb{R}$, we have*

$$\frac{\partial\overline{\eta(q)}}{\partial t} + \frac{\partial}{\partial x}\left(\gamma u\overline{\eta(q)}\right) \le \gamma\overline{q\eta(q)} - \frac{\gamma}{2}\overline{\eta'(q)q^2} + (h(u)-P)\overline{\eta'(q)}, \tag{5.23}$$

in the sense of distributions on $[0,\infty)\times\mathbb{R}$. Here $\overline{q\eta(q)}$ and $\overline{\eta'(q)q^2}$ denote the weak limits of $q_\varepsilon\eta(q_\varepsilon)$ and $\eta'(q_\varepsilon)q_\varepsilon^2$ in $L^r_{\mathrm{loc}}([0,\infty)\times\mathbb{R})$, $1<r<\frac{3}{2}$, respectively.

Proof. In (5.22), by convexity of η, (1.4), (5.9), (5.17), and (5.18), sending $\varepsilon\to 0$ yields (5.23). ∎

Remark 5.6. From (5.17) and (5.18), it is clear that

$$q = q_+ + q_- = \overline{q_+} + \overline{q_-}, \quad q^2 = (q_+)^2 + (q_-)^2, \quad \overline{q^2} = \overline{(q_+)^2} + \overline{(q_-)^2},$$

almost everywhere in $[0,\infty)\times\mathbb{R}$, where $\xi_+ := \xi\chi_{[0,+\infty)}(\xi)$, $\xi_- := \xi\chi_{(-\infty,0]}(\xi)$, $\xi\in\mathbb{R}$. Moreover, by (3.1) and (5.17),

$$q_\varepsilon(t,x), q(t,x) \le \frac{2}{\gamma t} + C_2, \qquad t\ge 0,\ x\in\mathbb{R}. \tag{5.24}$$

Lemma 5.7. *There holds*

$$\frac{\partial q}{\partial t} + \frac{\partial}{\partial x}(\gamma u q) = \frac{\gamma}{2}\overline{q^2} + h(u) - P \quad \text{in the sense of distributions on } [0,\infty)\times\mathbb{R}. \tag{5.25}$$

Proof. Using (2.5), (5.9), (5.11), (5.17), and (5.18), the result (5.25) follows by $\varepsilon\to 0$ in (2.5). ∎

The next lemma contains a renormalized formulation of (5.25).

LEMMA 5.8. *For any $\eta \in C^1(\mathbb{R})$ with $\eta' \in L^\infty(\mathbb{R})$,*

$$\frac{\partial \eta(q)}{\partial t} + \frac{\partial}{\partial x}\left(\gamma u \eta(q)\right) = \gamma q \eta(q) + \left(\frac{\gamma}{2}\overline{q^2} - \gamma q^2\right)\eta'(q) + \left(h(u) - P\right)\eta'(q), \tag{5.26}$$

in the sense of distributions on $[0,\infty) \times \mathbb{R}$.

Proof. Let $\{\omega_\delta\}_\delta$ be a family of mollifiers defined on $\mathbb{R}$. Denote $q_\delta(t,x) := (q(t,\cdot) \star \omega_\delta)(x)$. Here and in the following all convolutions are with respect to the x variable. According to Lemma II.1 of [19], it follows from (5.25) that q_δ solves

$$\frac{\partial q_\delta}{\partial t} + \gamma u \frac{\partial q_\delta}{\partial x} = \frac{\gamma}{2}\overline{q^2} \star \omega_\delta - \gamma q^2 \star \omega_\delta + h(u) \star \omega_\delta - P \star \omega_\delta + \rho_\delta, \tag{5.27}$$

where the error ρ_δ tends to zero in $L^1_{\mathrm{loc}}([0,\infty) \times \mathbb{R})$. Multiplying (5.27) by $\eta'(q_\delta)$, we get

$$\begin{aligned} \frac{\partial \eta(q_\delta)}{\partial t} + \frac{\partial}{\partial x}\left(\gamma u \eta(q_\delta)\right) = q\eta(q_\delta) &+ \frac{\gamma}{2}\left(\overline{q^2} \star \omega_\delta\right)\eta'(q_\delta) - \gamma\left(q^2 \star \omega_\delta\right)\eta'(q_\delta) \\ &+ \left(h(u) \star \omega_\delta\right)\eta'(q_\delta) - \left(P \star \omega_\delta\right)\eta'(q_\delta) + \rho_\delta \eta'(q_\delta). \end{aligned} \tag{5.28}$$

Using the boundedness of η, η', we can send $\delta \to 0$ in (5.28) to obtain (5.26). The weak time continuity is standard. $\square$

6. Strong convergence of ${}_{\varepsilon}$ and existence for (1). Following [32], in this section we wish to improve the weak convergence of q_ε in (5.17) to strong convergence (and then we have an existence result for (1)). Roughly speaking, the idea is to derive a "transport equation" for the evolution of the defect measure $(\overline{q^2} - q^2)(t,\cdot) \geq 0$, so that if it is zero initially then it will continue to be zero at all later times $t > 0$. The proof is complicated by the fact that we do not have a uniform bound on q_ε from below but merely (5.24) and that in Lemma 4.1 we have only $\alpha < 1$.

LEMMA 6.1. *There holds*

$$\lim_{t\to 0+}\int_{\mathbb{R}} q^2(t,x)dx = \lim_{t\to 0+}\int_{\mathbb{R}} \overline{q^2}(t,x)dx = \int_{\mathbb{R}}\left(\frac{\partial u_0}{\partial x}\right)^2 dx. \tag{6.1}$$

Proof. Since $u \in C(\mathbb{R}_+ \times \mathbb{R})$ (see Lemma 5.2), from (5.20),

$$\begin{aligned} \lim_{t\to 0}\int_{\mathbb{R}} q(t,x)\varphi(x)dx &= -\lim_{t\to 0}\int_{\mathbb{R}} u(t,x)\frac{\partial \varphi}{\partial x}(x)dx \\ &= -\int_{\mathbb{R}} u_0(x)\frac{\partial \varphi}{\partial x}(x)dx = \int_{\mathbb{R}}\frac{\partial u_0}{\partial x}(x)\varphi(x)dx, \end{aligned}$$

for each test function $\varphi \in C^\infty(\mathbb{R})$ with compact support. Due to the boundedness of $\{q_\varepsilon\}_{\varepsilon>0}$ in $L^\infty((0,\infty);L^2(\mathbb{R}))$ we get

$$q(t,\cdot) \rightharpoonup \frac{\partial u_0}{\partial x} \qquad \text{weakly in } L^2(\mathbb{R}) \text{ as } t \to 0+,$$

so

$$\liminf_{t\to 0+}\int_{\mathbb{R}} q^2(t,x)dx \geq \int_{\mathbb{R}}\left(\frac{\partial u_0}{\partial x}(x)\right)^2 dx. \tag{6.2}$$

Moreover, from (2.2), (2.3), (5.9), and (5.18),

$$\int_{\mathbb{R}} u^2(t,x)dx + \int_{\mathbb{R}} \overline{q^2}(t,x)dx \le \int_{\mathbb{R}} u_0^2(x)dx + \int_{\mathbb{R}} \left(\frac{\partial u_0}{\partial x}\right)^2 dx,$$

and, again using the continuity of u (see Lemma 5.2), $\lim_{t\to 0+}\int_{\mathbb{R}} u^2(t,x)dx = \int_{\mathbb{R}} u_0^2 dx$. Hence

$$\limsup_{t\to 0+} \int_{\mathbb{R}} \overline{q^2}(t,x)dx \le \int_{\mathbb{R}} \left(\frac{\partial u_0}{\partial x}\right)^2 dx. \tag{6.3}$$

Clearly, (5.19), (6.2), and (6.3) imply (6.1). ◻

LEMMA 6.2. *For each $R>0$,*

$$\lim_{t\to 0+} \int_{\mathbb{R}} \left(\overline{\eta_R^{\pm}(q)}(t,x) - \eta_R^{\pm}(q(t,x))\right) dx = 0, \tag{6.4}$$

where

$$\eta_R(\xi) := \begin{cases} \frac{1}{2}\xi^2, & \text{if } |\xi| \le R, \\ R|\xi| - \frac{1}{2}R^2, & \text{if } |\xi| > R, \end{cases} \tag{6.5}$$

and $\eta_R^+(\xi) := \eta_R(\xi)\chi_{[0,+\infty)}(\xi)$, $\eta_R^-(\xi) := \eta_R(\xi)\chi_{(-\infty,0]}(\xi)$, $\xi \in \mathbb{R}$.

Proof. Let $R>0$. Observe that

$$\overline{\eta_R(q)} - \eta_R(q) = \frac{1}{2}(\overline{q^2} - q^2) - \left(\overline{f_R(q)} - f_R(q)\right),$$

where $f_R(\xi) := \frac{1}{2}\xi^2 - \eta_R(\xi)$, $\xi\in\mathbb{R}$. Since η_R and f_R are convex,

$$0 \le \overline{\eta_R(q)} - \eta_R(q) = \frac{1}{2}\left(\overline{q^2} - q^2\right) - \left(\overline{f_R(q)} - f_R(q)\right) \le \frac{1}{2}\left(\overline{q^2} - q^2\right).$$

Then, from (6.1), $\lim_{t\to 0+}\int_{\mathbb{R}}\left(\overline{\eta_R(q)}(t,x) - \eta_R(q(t,x))\right)dx = 0$. Since, $\overline{\eta_R^{\pm}(q)} - \eta_R^{\pm}(q) \le \overline{\eta_R(q)} - \eta_R(q)$, the proof is done. ◻

Remark 6.3. Let $R>0$. Then for each $\xi\in\mathbb{R}$

$$\begin{aligned}
\eta_R(\xi) &= \frac{1}{2}\xi^2 - \frac{1}{2}(R-|\xi|)^2\chi_{(-\infty,-R)\cup(R,\infty)}(\xi),\\
\eta_R'(\xi) &= \xi + (R-|\xi|)\operatorname{sign}(\xi)\,\chi_{(-\infty,-R)\cup(R,\infty)}(\xi),\\
\eta_R^+(\xi) &= \frac{1}{2}(\xi_+)^2 - \frac{1}{2}(R-\xi)^2\chi_{(R,\infty)}(\xi),\\
(\eta_R^+)'(\xi) &= \xi_+ + (R-\xi)\chi_{(R,\infty)}(\xi),\\
\eta_R^-(\xi) &= \frac{1}{2}(\xi_-)^2 - \frac{1}{2}(R+\xi)^2\chi_{(-\infty,-R)}(\xi),\\
(\eta_R^-)'(\xi) &= \xi_- - (R+\xi)\chi_{(-\infty,-R)}(\xi).
\end{aligned}$$

LEMMA 6.4. *Assume* (1.4) *and* (2.2). *Then for almost all $t\ge 0$*

$$\int_{\mathbb{R}} \left(\overline{(q_+)^2} - (q_+)^2\right)(t,x)dx \le 2\int_0^t\int_{\mathbb{R}} S(s,x)\left[\overline{q_+}(s,x) - q_+(s,x)\right]dsdx, \tag{6.6}$$

where $S(s,x) := h\big(u(s,x)\big) - P(s,x)$.

Proof. Let $R > C_2$ (see Lemma 3.1). Subtract (5.26) from (5.23) using the entropy η_R^+ (see Lemma 6.2). The result is

$$\begin{aligned}(6.7)\qquad &\frac{\partial}{\partial t}\left(\overline{\eta_R^+(q)}-\eta_R^+(q)\right)+\frac{\partial}{\partial x}\left(\gamma u\left[\overline{\eta_R^+(q)}-\eta_R^+(q)\right]\right)\\ &\quad\le \gamma\left[\overline{q\eta_R^+(q)}-q\eta_R^+(q)\right]-\frac{\gamma}{2}\left[\overline{q^2(\eta_R^+)'(q)}-q^2(\eta_R^+)'(q)\right]\\ &\quad\quad -\frac{\gamma}{2}\left(\overline{q^2}-q^2\right)(\eta_R^+)'(q)+S(t,x)\left[\overline{(\eta_R^+)'(q)}-(\eta_R^+)'(q)\right].\end{aligned}$$

Since η_R^+ is increasing and $\gamma \ge 0$, by (5.19),

$$(6.8)\qquad -\frac{\gamma}{2}\left(\overline{q^2}-q^2\right)(\eta_R^+)'(q)\le 0.$$

Moreover, from Remark 6.3,

$$\begin{aligned}\gamma q\eta_R^+(q)-\frac{\gamma}{2}q^2(\eta_R^+)'(q)&=-\frac{\gamma R}{2}q(R-q)\chi_{(R,\infty)}(q),\\ \overline{\gamma q\eta_R^+(q)}-\frac{\gamma}{2}\overline{q^2(\eta_R^+)'(q)}&=-\frac{\gamma R}{2}\overline{q(R-q)\chi_{(R,\infty)}(q)}.\end{aligned}$$

Therefore, due to (5.24),

$$(6.9)\qquad \gamma q\eta_R^+(q)-\frac{\gamma}{2}q^2(\eta_R^+)'(q)=\overline{q\eta_R^+(q)}-\frac{1}{2}\overline{q^2(\eta_R^+)'(q)}=0,\quad \text{in } \Omega_R:=\left(\tfrac{2}{R-C_2},\infty\right)\times\mathbb{R}.$$

Then from (6.7), (6.8), and (6.9) the following inequality holds in Ω_R:

$$(6.10)\qquad \frac{\partial}{\partial t}\left(\overline{\eta_R^+(q)}-\eta_R^+(q)\right)+\frac{\partial}{\partial x}\left(\gamma u\left[\overline{\eta_R^+(q)}-\eta_R^+(q)\right]\right)\le S(t,x)\left[\overline{(\eta_R^+)'(q)}-(\eta_R^+)'(q)\right].$$

In view of Remark 5.6 and due to (5.24),

$$\eta_R^+(q)=\frac{1}{2}(q_+)^2,\quad (\eta_R^+)'(q)=q_+,\quad \overline{\eta_R^+(q)}=\frac{1}{2}\overline{(q_+)^2},\quad \overline{(\eta_R^+)'(q)}=\overline{q_+},\quad \text{in } \Omega_R.$$

Inserting this into (6.10) and integrating the result over $(\frac{2}{R-C_2},t)\times\mathbb{R}$ gives

$$\begin{aligned}\frac{1}{2}\int_{\mathbb{R}}\left[\overline{(q_+)^2}(t,x)-q_+(t,x)^2\right]dx &\le \int_{\mathbb{R}}\left[\overline{\eta_R^+(q)}(\tfrac{2}{R-C_2},x)-\eta_R^+(q)(\tfrac{2}{R-C_2},x)\right]dx\\ &\quad+\int_{\frac{2}{R-C_2}}^t\int_{\mathbb{R}}S(s,x)\left[\overline{q_+}(s,x)-q_+(s,x)\right]dsdx,\end{aligned}$$

for almost all $t>\frac{2}{R-C_2}$. Sending $R\to\infty$ and using Lemma 6.2, we get (6.6). ∎

Lemma 6.5. *For any $t \ge 0$ and any $R > 0$,*

$$\begin{aligned}(6.11)\qquad &\int_{\mathbb{R}}\left[\overline{\eta_R^-(q)}-\eta_R^-(q)\right](t,x)dx\\ &\quad\le\frac{\gamma R^2}{2}\int_0^t\int_{\mathbb{R}}\overline{(R+q)\chi_{(-\infty,-R)}(q)}dsdx\\ &\quad\quad-\frac{\gamma R^2}{2}\int_0^t\int_{\mathbb{R}}(R+q)\chi_{(-\infty,-R)}(q)dsdx+\gamma R\int_0^t\int_{\mathbb{R}}\left[\overline{\eta_R^-(q)}-\eta_R^-(q)\right]dsdx\\ &\quad\quad+\frac{\gamma R}{2}\int_0^t\int_{\mathbb{R}}\left[\overline{(q_+)^2}-q_+^2\right]dsdx+\int_0^t\int_{\mathbb{R}}S(s,x)\left[\overline{(\eta_R^-)'(q)}-(\eta_R^-)'(q)\right]dsdx.\end{aligned}$$

Proof. Let $R > 0$. By subtracting (5.26) from (5.23), using the entropy η_R^- (see Lemma 6.2), we deduce

$$\begin{aligned}(6.12)\quad &\frac{\partial}{\partial t}\left(\overline{\eta_R^-(q)} - \eta_R^-(q)\right) + \frac{\partial}{\partial x}\left(\gamma u\left[\overline{\eta_R^-(q)} - \eta_R^-(q)\right]\right)\\ &\quad\le \gamma\left[\overline{q\eta_R^-(q)} - q\eta_R^-(q)\right] - \frac{\gamma}{2}\left[\overline{q^2(\eta_R^-)'(q)} - q^2(\eta_R^-)'(q)\right]\\ &\quad\quad - \frac{\gamma}{2}(\overline{q^2} - q^2)(\eta_R^-)'(q) + S(t,x)\left[\overline{(\eta_R^-)'(q)} - (\eta_R^-)'(q)\right].\end{aligned}$$

Since $-R \le (\eta_R^-)' \le 0$ and $\gamma \ge 0$, by (5.19),

$$-\frac{\gamma}{2}\left(\overline{q^2} - q^2\right)(\eta_R^-)'(q) \le \frac{\gamma R}{2}\left(\overline{q^2} - q^2\right). \tag{6.13}$$

Using Remarks 5.6 and 6.3

$$\gamma q\eta_R^-(q) - \frac{\gamma}{2}q^2(\eta_R^-)'(q) = -\frac{\gamma R}{2}q(R+q)\chi_{(-\infty,-R)}(q), \tag{6.14}$$

$$\gamma\overline{q\eta_R^-(q)} - \frac{\gamma}{2}\overline{q^2(\eta_R^-)'(q)} = -\frac{\gamma R}{2}\overline{q(R+q)\chi_{(-\infty,-R)}(q)}. \tag{6.15}$$

Inserting (6.13), (6.14), and (6.15) into (6.12) gives

$$\begin{aligned}&\frac{\partial}{\partial t}\left(\overline{\eta_R^-(q)} - \eta_R^-(q)\right) + \frac{\partial}{\partial x}\left(\gamma u\left[\overline{\eta_R^-(q)} - \eta_R^-(q)\right]\right)\\ &\quad\le -\frac{\gamma R}{2}\overline{q(R+q)\chi_{(-\infty,-R)}(q)} + \frac{\gamma R}{2}q(R+q)\chi_{(-\infty,-R)}(q)\\ &\quad\quad + \frac{\gamma R}{2}\left(\overline{q^2} - q^2\right) + S(t,x)\left[\overline{(\eta_R^-)'(q)} - (\eta_R^-)'(q)\right].\end{aligned}$$

Integrating this inequality over $(0,t)\times\mathbb{R}$ yields

$$\begin{aligned}(6.16)\quad &\int_{\mathbb{R}}\left[\overline{\eta_R^-(q)} - \eta_R^-(q)\right](t,x)dx\\ &\quad\le -\frac{\gamma R}{2}\int_0^t\int_{\mathbb{R}}\overline{q(R+q)\chi_{(-\infty,-R)}(q)}dsdx\\ &\quad\quad + \frac{\gamma R}{2}\int_0^t\int_{\mathbb{R}}q(R+q)\chi_{(-\infty,-R)}(q)dsdx + \frac{R}{2}\int_0^t\int_{\mathbb{R}}\left[\overline{q^2} - q^2\right]dsdx\\ &\quad\quad + \int_0^t\int_{\mathbb{R}}S(s,x)\left[\overline{(\eta_R^-)'(q)} - (\eta_R^-)'(q)\right]dsdx.\end{aligned}$$

Using Remark 6.3,

$$\overline{\eta_R^-(q)} - \eta_R^-(q) = \frac{1}{2}\left(\overline{(q_-)^2} - (q_-)^2\right) + \frac{1}{2}(R+q)^2\chi_{(-\infty,-R)}(q) - \frac{1}{2}\overline{(R+q)^2\chi_{(-\infty,-R)}(q)}.$$

Hence, from Remark 5.6 and (6.16),

$$\begin{aligned}
&\int_{\mathbb{R}} \left[\overline{\eta_R^-(q)} - \eta_R^-(q)\right](t,x)dx \\
&\quad\le -\frac{\gamma R}{2}\int_0^t\int_{\mathbb{R}} \overline{q(R+q)\chi_{(-\infty,-R)}(q)}dsdx \\
&\qquad + \frac{\gamma R}{2}\int_0^t\int_{\mathbb{R}} q(R+q)\chi_{(-\infty,-R)}(q)dsdx + \gamma R\int_0^t\int_{\mathbb{R}}\left[\overline{\eta_R^-(q)} - \eta_R^-(q)\right]dsdx \\
&\qquad - \frac{\gamma R}{2}\int_0^t\int_{\mathbb{R}} (R+q)^2\chi_{(-\infty,-R)}(q)dsdx + \frac{\gamma R}{2}\int_0^t\int_{\mathbb{R}} \overline{(R+q)^2\chi_{(-\infty,-R)}(q)}dsdx \\
&\qquad + \frac{\gamma R}{2}\int_0^t\int_{\mathbb{R}}\left[\overline{(q_+)^2} - q_+^2\right]dsdx + \int_0^t\int_{\mathbb{R}} S(s,x)\left[\overline{(\eta_R^-)'(q)} - (\eta_R^-)'(q)\right]dsdx,
\end{aligned}$$

and applying twice the identity $\frac{R}{2}(R+q)^2 - \frac{R}{2}q(R+q) = \frac{R^2}{2}(R+q)$ we deduce (6.11). ∎

Lemma 6.6. *There holds*

$$\overline{q^2} = q^2 \quad \textit{almost everywhere in } [0,\infty)\times\mathbb{R}. \tag{6.17}$$

Proof. Adding (6.6) and (6.11) yields

$$\begin{aligned}
&\int_{\mathbb{R}}\left(\frac{1}{2}\left[\overline{(q_+)^2} - (q_+)^2\right] + \left[\overline{\eta_R^-(q)} - \eta_R^-(q)\right]\right)(t,x)dx \\
&\quad\le \frac{\gamma R^2}{2}\int_0^t\int_{\mathbb{R}} \overline{(R+q)\chi_{(-\infty,-R)}(q)}dsdx - \frac{\gamma R^2}{2}\int_0^t\int_{\mathbb{R}} (R+q)\chi_{(-\infty,-R)}(q)dsdx \\
&\qquad + \gamma R\int_0^t\int_{\mathbb{R}}\left[\overline{\eta_R^-(q)} - \eta_R^-(q)\right]dsdx + \frac{\gamma R}{2}\int_0^t\int_{\mathbb{R}}\left[\overline{(q_+)^2} - q_+^2\right]dsdx \\
&\qquad + \int_0^t\int_{\mathbb{R}} S(s,x)\left(\left[\overline{q_+} - q_+\right] + \left[\overline{(\eta_R^-)'(q)} - (\eta_R^-)'(q)\right]\right)dsdx.
\end{aligned} \tag{6.18}$$

Arguing as in the proof of Lemma 3.1, there exists a constant $L>0$, depending only on $\|u_0\|_{H^1(\mathbb{R})}$, such that

$$\|S\|_{L^\infty([0,\infty)\times\mathbb{R})} = \left\|h(u) - P\right\|_{L^\infty([0,\infty)\times\mathbb{R})} \le L. \tag{6.19}$$

By Remarks 5.6 and 6.3,

$$q_+ + (\eta_R^-)'(q) = q - (R+q)\chi_{(-\infty,-R)}(q), \quad \overline{q_+} + \overline{(\eta_R^-)'(q)} = q - \overline{(R+q)\chi_{(-\infty,-R)}(q)},$$

so by the convexity of the map $\xi \mapsto \xi_+ + (\eta_R^-)'(\xi)$,

$$0 \le \left[\overline{q_+} - q_+\right] + \left[\overline{(\eta_R^-)'(q)} - (\eta_R^-)'(q)\right] = (R+q)\chi_{(-\infty,-R)}(q) - \overline{(R+q)\chi_{(-\infty,-R)}(q)},$$

and, by (6.19),

$$\begin{aligned}
&S(s,x)\left(\left[\overline{q_+}(s,x) - q_+(s,x)\right] + \left[\overline{(\eta_R^-)'(q)} - (\eta_R^-)'(q)\right]\right) \\
&\quad\le -L\left(\overline{(R+q)\chi_{(-\infty,-R)}(q)} - (R+q)\chi_{(-\infty,-R)}(q)\right).
\end{aligned}$$

Since $\xi \mapsto (R+\xi)\chi_{(-\infty,-R)}(\xi)$ is concave and choosing R large enough,

$$
\begin{aligned}
&\frac{\gamma R^2}{2}\overline{(R+q)\chi_{(-\infty,-R)}(q)} - \frac{\gamma R^2}{2}(R+q)\chi_{(-\infty,-R)}(q)\\
&\quad + S(s,x)\left([\overline{q_+}(s,x) - q_+(s,x)] + \left[\overline{(\eta_R^-)'(q)} - (\eta_R^-)'(q)\right]\right) \qquad (6.20)\\
&\le \left(\frac{\gamma R^2}{2} - L\right)\left(\overline{(R+q)\chi_{(-\infty,-R)}(q)} - (R+q)\chi_{(-\infty,-R)}(q)\right) \le 0.
\end{aligned}
$$

Then, from (6.18) and (6.20),

$$
\begin{aligned}
0 &\le \int_{\mathbb{R}} \left(\frac{1}{2}\left[\overline{(q_+)^2} - (q_+)^2\right] + \left[\overline{\eta_R^-(q)} - \eta_R^-(q)\right]\right)(t,x)dx\\
&\le \gamma R \int_0^t \int_{\mathbb{R}} \left(\frac{1}{2}\left[\overline{(q_+)^2} - q_+^2\right] + \left[\overline{\eta_R^-(q)} - \eta_R^-(q)\right]\right) dsdx,
\end{aligned}
$$

and using the Gronwall inequality and Lemmas 6.1 and 6.2 we conclude that

$$
\int_{\mathbb{R}} \left(\frac{1}{2}\left[\overline{(q_+)^2} - (q_+)^2\right] + \left[\overline{\eta_R^-(q)} - \eta_R^-(q)\right]\right)(t,x)dx = 0, \qquad \text{for each } t > 0.
$$

By the Fatou lemma, Remark 5.6, and (5.19), sending $R \to \infty$ yields

$$
0 \le \int_{\mathbb{R}} \left(\overline{q^2} - q^2\right)(t,x)dx \le 0, \qquad t > 0, \tag{6.21}
$$

and we see that (6.17) holds. ∎

LEMMA 6.7. *Assume* (1.4) *and* (2.2). *Then there exists an admissible weak solution of* (1)*, satisfying conditions* (*k*)*,* (*kk*)*, and* (*kkk*) *of Theorem* 1.2.

Proof. The conditions (*i*), (*iii*), (*iv*) of Definition 1.1 are satisfied, due to (2.2), (2.3) and Lemma 5.2. We have to verify (*ii*). Due to (6.17), we have

$$
q_\varepsilon \to q \qquad \text{in } L^2_{\mathrm{loc}}([0,\infty)\times\mathbb{R}). \tag{6.22}
$$

Clearly (5.9), (5.11), and (6.22) imply that u is a distributional solution of (1.7). Finally, (*k*) and (*kk*) are consequences of Lemmas 3.1 and 4.1, respectively. For (*kkk*) we can argue as in [32], so let us just sketch the proof. From Lemmas 5.8 and 6.6 we get

$$
\frac{\partial \eta_R(q)}{\partial t} + \frac{\partial}{\partial x}\left(\gamma u \eta_R(q)\right) = \gamma q \eta_R(q) - \frac{\gamma}{2} q^2 \eta_R'(q) + (h(u) - P)\,\eta_R'(q). \tag{6.23}
$$

From the definition of η_R,

$$
\begin{aligned}
\gamma\left(q\eta_R(q) - \frac{1}{2}q^2\eta_R'(q)\right) &= \frac{\gamma R}{2}\left(q^2 - Rq\right)\chi_{(R,\infty)}(q) - \frac{\gamma R}{2}\left(q^2 + Rq\right)\chi_{(-\infty,-R)}(q)\\
&=: S_-^R + S_+^R.
\end{aligned}
$$

By (1.9), it follows as in [32] that $\iint_{[0,\infty)\times\mathbb{R}} S_+^R dxdt \le C\|u_0\|_{H^1(\mathbb{R})}$ and thus, by integrating (6.23), $\iint_{[0,\infty)\times\mathbb{R}} S_-^R dxdt \le C$. The latter bound implies that along a subsequence $S_-^R \overset{\star}{\rightharpoonup} \mu$ in the sense of measures as $R \to \infty$, for some nonnegative Radon measure μ. By (1.9), $\iint_{[0,\infty)\times\mathbb{R}} S_+^R dxdt \to 0$ as $R \to \infty$. Hence sending

$R \to \infty$ in (6.23) and adding the result to the equation obtained by multiplying (1) by u, we get (1.13). Finally, integrating (1.13) shows that the total mass of μ is bounded by $\|u_0\|_{H^1(\mathbb{R})}$. $\square$

Remark 6.8. It is possible to prove results similar to those obtained for (1.7) for slightly more general equations of the form

$$\frac{\partial u}{\partial t} + \gamma u \frac{\partial u}{\partial x} + \frac{\partial P}{\partial x} = 0, \quad -\alpha^2 \frac{\partial^2 P}{\partial x^2} + P = h(u) + \frac{\gamma\alpha^2}{2}\left(\frac{\partial u}{\partial x}\right)^2, \tag{6.24}$$

where $\gamma \geq 0$, $\alpha > 0$, and $h\colon \mathbb{R} \to \mathbb{R}$ is any locally Lipschitz continuous function with $h(0) = 0$. The Green function of the operator $-\alpha^2 \frac{\partial^2}{\partial x^2} + 1$ is $e^{-|x|/\alpha}/2$. Formally, by letting $\alpha \to 0$, we recover the conservation law $\frac{\partial u}{\partial t} + \frac{\partial}{\partial x} F(u) = 0$, where the flux $F(u)$ is given by $F'(u) = \gamma u - h'(u)$. Hence (6.24) may be viewed as a new type of regularization for one-dimensional conservation laws. We are currently investigating this singular limit problem.

7. Uniqueness of the viscous limit: the semigroup. Here we prove the existence of the semigroup.

LEMMA 7.1. *There exists a strongly continuous semigroup of solutions associated with the Cauchy problem* (1)

$$S\colon [0,\infty) \times (0,\infty) \times (\mathcal{E} \cap C^\infty(\mathbb{R})) \times H^1(\mathbb{R}) \longrightarrow C([0,\infty) \times \mathbb{R}) \cap L^\infty\big([0,\infty); H^1(\mathbb{R})\big),$$

namely, for each $u_0 \in H^1(\mathbb{R})$, $\gamma > 0$, $g \in \mathcal{E}$ the map $u(t,x) = S_t(\gamma, g, u_0)(x)$ is an admissible weak solution of (1). *Moreover,* (k), (kk), *and* (kkk) *of Theorem* 1.2 *are satisfied.*

Clearly, this lemma is a direct consequence of the following lemma and of the lemmas in the previous sections.

LEMMA 7.2. *Assume* (1.4), (1.5). *Let $\{\varepsilon_n\}_{n\in\mathbb{N}}$, $\{\mu_n\}_{n\in\mathbb{N}} \subset (0,\infty)$ and u, $v \in L^\infty([0,\infty); H^1(\mathbb{R})) \cap H^1([0,T] \times \mathbb{R})$, for each $T \geq 0$, be such that ε_n, $\mu_n \to 0$ and*

$$u_{\varepsilon_n} \to u, \quad u_{\mu_n} \to v, \quad \textit{strongly in } L^\infty_{\mathrm{loc}}([0,\infty); H^1(\mathbb{R})), \tag{7.1}$$

then

$$u = v.$$

Proof. Let $t > 0$, it is not restrictive to assume that

$$\|u_{0,\varepsilon} - u_{0,\mu}\|_{H^1(\mathbb{R})} \leq |\varepsilon - \mu|, \qquad \varepsilon,\ \mu > 0. \tag{7.2}$$

Moreover, passing to subsequences, we can assume that

$$0 < \mu_n < \varepsilon_n < \mu_{n-1}, \qquad n \in \mathbb{N}. \tag{7.3}$$

Indeed, we can argue in the following way: we begin by considering two strictly decreasing subsequences $\{\varepsilon_{n_k}\}_{k\in\mathbb{N}}$, $\{\mu_{n_k}\}_{k\in\mathbb{N}}$. Then we start by defining $\mu_{n_{k_0}} = \mu_{n_0}$, then we continue with $\varepsilon_{n_{k_1}}$ and $\mu_{n_{k_1}}$ in the following way:

$$\varepsilon_{n_{k_1}} = \max\big\{\varepsilon_{n_k};\ \varepsilon_{n_k} < \mu_{n_{k_0}}\big\}, \qquad \mu_{n_{k_1}} = \max\big\{\mu_{n_k};\ \mu_{n_k} < \varepsilon_{n_{k_1}}\big\}.$$

Arguing inductively in this way we find two subsequences $\{\varepsilon_{n_{k_h}}\}_{h\in\mathbb{N}}$, $\{\mu_{n_{k_h}}\}_{h\in\mathbb{N}}$ satisfying (7.3).

From [4, Theorem 3.1] and (7.2), we have that

$$\begin{aligned}
&\|u_\varepsilon(t,\cdot\,) - u_\mu(t,\cdot\,)\|_{H^1(\mathbb{R})}\\
&\quad \le A(t,\varepsilon+\mu)\|u_{0,\varepsilon} - u_{0,\mu}\|_{H^1(\mathbb{R})} + B(t,\varepsilon+\mu)|\varepsilon-\mu|\\
&\quad \le \big(A(t,\varepsilon+\mu) + B(t,\varepsilon+\mu)\big)|\varepsilon-\mu|,
\end{aligned}$$

with

$$A(t,\varepsilon+\mu) = \mathcal{O}\big(e^{t/(\varepsilon+\mu)}\big), \qquad B(t,\varepsilon+\mu) = \mathcal{O}\big(e^{t/(\varepsilon+\mu)}\big),$$

for each ε, $\mu > 0$. Hence

$$\|u_\varepsilon(t,\cdot\,) - u_\mu(t,\cdot\,)\|_{H^1(\mathbb{R})} \le c_1 e^{t/(\varepsilon+\mu)}|\varepsilon-\mu|, \qquad \varepsilon,\mu>0, \tag{7.4}$$

for some constant $c_1 > 0$. Define

$$\varepsilon_{k,n} := \varepsilon_n - k e^{-1/\varepsilon_n^2}, \quad N_n := \big[(\varepsilon_n - \mu_n)e^{1/\varepsilon_n^2}\big], \qquad k,n\in\mathbb{N},$$

where $[\cdot]$ denotes the integer part. Observe that

$$\varepsilon_{N_n,n} \le \mu_n \le \varepsilon_{N_n-1,n}, \quad \mu_n - \varepsilon_{N_n,n} \le e^{-1/\varepsilon_n^2}, \qquad n\in\mathbb{N}, \tag{7.5}$$

and

$$\begin{aligned}
\lim_n \|u_{\varepsilon_{k,n}}(t,\cdot\,) - u_{\varepsilon_n}(t,\cdot\,)\|_{H^1(\mathbb{R})}
&\le c_1 \lim_n e^{t/(\varepsilon_{k,n}+\varepsilon_n)}|\varepsilon_{k,n}-\varepsilon_n|\\
&\le c_1 k \lim_n e^{t/\varepsilon_n} e^{-1/\varepsilon_n^2} = 0,
\end{aligned} \tag{7.6}$$

for each $k\in\mathbb{N}$, in other terms

$$u_{\varepsilon_{k,n}} \to u, \quad \text{strongly in } L^\infty_{\mathrm{loc}}([0,\infty);H^1(\mathbb{R})) \text{ as } n\to\infty, \quad \text{for each } k\in\mathbb{N}. \tag{7.7}$$

Since, from (7.3),

$$\varepsilon_{n+1} < \mu_n < \mu_n + \varepsilon_{N_n,n}, \qquad n\in\mathbb{N},$$

employing (7.5), we have that

$$\begin{aligned}
\lim_n \|u_{\varepsilon_{N_n,n}}(t,\cdot\,) - u_{\mu_n}(t,\cdot\,)\|_{H^1(\mathbb{R})}
&\le c_1 \lim_n e^{t/(\varepsilon_{N_n,n}+\mu_n)}|\varepsilon_{N_n,n}-\mu_n|\\
&\le c_1 \lim_n e^{t/\varepsilon_{n+1}} e^{-1/\varepsilon_n^2} = 0.
\end{aligned} \tag{7.8}$$

Hence

$$u_{\varepsilon_{N_n,n}} \to v, \quad \text{strongly in } L^\infty_{\mathrm{loc}}([0,\infty);H^1(\mathbb{R})) \text{ as } n\to\infty. \tag{7.9}$$

If $\{N_n\}_{n\in\mathbb{N}}$ is bounded, the claim is a direct consequence of (7.7) and (7.9). So we consider the case

$$\lim_n N_n = \infty. \tag{7.10}$$

As before, we define the sequences

$$\mu_{h,n} := \mu_n + he^{-1/\mu_n^2}, \quad M_n := \left[(\varepsilon_n - \mu_n)e^{1/\mu_n^2}\right], \qquad h, n \in \mathbb{N}.$$

Due to (7.3) and (7.10),

$$\lim_n M_n = \infty, \tag{7.11}$$

and, arguing as for (7.7) and (7.9), we are able to prove that

$$\lim_n \|u_{\mu_{h,n}}(t,\cdot) - u_{\mu_n}(t,\cdot)\|_{H^1(\mathbb{R})} = \lim_n \|u_{\mu_{h,n}}(t,\cdot) - v(t,\cdot)\|_{H^1(\mathbb{R})} = 0, \quad h \in \mathbb{N}, \tag{7.12}$$

$$\lim_n \|u_{\mu_{M_n,n}}(t,\cdot) - u_{\varepsilon_n}(t,\cdot)\|_{H^1(\mathbb{R})} = \lim_n \|u_{\mu_{M_n,n}}(t,\cdot) - u(t,\cdot)\|_{H^1(\mathbb{R})} = 0. \tag{7.13}$$

Due to (7.10) and (7.11), we can choose two sequences $\{k_n\}_{n\in\mathbb{N}}$, $\{h_n\}_{n\in\mathbb{N}}$, such that

$$\mu_n \le \mu_{h_n,n}, \varepsilon_{k_n,n} \le \varepsilon_n, \quad |\mu_{h_n,n} - \varepsilon_{k_n,n}| \le c_2 e^{-1/\mu_n^2}, \qquad n \in \mathbb{N}, \tag{7.14}$$

$$\lim_n h_n = \lim_n k_n = \infty, \tag{7.15}$$

for some constant $c_2 > 0$. Observe that

$$\begin{aligned}\|u(t,\cdot) - v(t,\cdot)\|_{H^1(\mathbb{R})} \le\ & \|u(t,\cdot) - u_{\mu_{h,n}}(t,\cdot)\|_{H^1(\mathbb{R})} \\ & + \|u_{\mu_{h,n}}(t,\cdot) - u_{\varepsilon_{k,n}}(t,\cdot)\|_{H^1(\mathbb{R})} \\ & + \|u_{\varepsilon_{k,n}}(t,\cdot) - v(t,\cdot)\|_{H^1(\mathbb{R})}.\end{aligned} \tag{7.16}$$

From (7.9) and (7.13), we have

$$\liminf_{h,n} \|u(t,\cdot) - u_{\mu_{h,n}}(t,\cdot)\|_{H^1(\mathbb{R})} \le \lim_n \|u(t,\cdot) - u_{\mu_{M_n,n}}(t,\cdot)\|_{H^1(\mathbb{R})} = 0, \tag{7.17}$$

$$\liminf_{k,n} \|u_{\varepsilon_{k,n}}(t,\cdot) - v(t,\cdot)\|_{H^1(\mathbb{R})} \le \lim_n \|u_{\varepsilon_{N_n,n}}(t,\cdot) - v(t,\cdot)\|_{H^1(\mathbb{R})} = 0, \tag{7.18}$$

respectively. Finally, from (7.4), (7.14), and (7.15),

$$\begin{aligned}&\liminf_{h,k,n} \|u_{\mu_{h,n}}(t,\cdot) - u_{\varepsilon_{k,n}}(t,\cdot)\|_{H^1(\mathbb{R})} \\ &\quad \le \liminf_n \|u_{\mu_{h_n,n}}(t,\cdot) - u_{\varepsilon_{k_n,n}}(t,\cdot)\|_{H^1(\mathbb{R})} \\ &\quad \le c_1 c_2 \liminf_n e^{-1/\mu_n^2} e^{t(\mu_{h_n,n} + \varepsilon_{k_n,n})} \end{aligned} \tag{7.19}$$

$$\le c_1 c_2 \lim_n e^{-1/\mu_n^2} e^{t(\mu_n)} = 0. \tag{7.20}$$

Clearly, (7.16), (7.17), (7.18), (7.19), imply $u = v$. ∎

8. Stability of the semigroup and proof of Theorem 1.2. Here we prove the stability of the semigroup and then conclude the proof of Theorem 1.2.

LEMMA 8.1. *The semigroup S defined on $[0,\infty) \times (0,\infty) \times (\mathcal{E} \cap C^\infty(\mathbb{R})) \times H^1(\mathbb{R})$ satisfies the stability property* (jj) *of Theorem* 1.2.

Proof. Fix $\varepsilon > 0$. Denote S^ε the semigroup associated to the viscous problem (2.1). Choose $\{u_{0,n}\}_{n\in\mathbb{N}} \subset H^1(\mathbb{R})$, $\{\gamma_n\}_{n\in\mathbb{N}} \subset (0,\infty)$, $\{g_n\}_{n\in\mathbb{N}} \subset \mathcal{E} \cap C^\infty(\mathbb{R})$,

$u_0 \in H^1(\mathbb{R})$, $\gamma > 0$, $g \in \mathcal{E} \cap C^\infty(\mathbb{R})$ satisfying (1.10). The initial data satisfy $u_{0,\varepsilon,n}$, $u_{0,\varepsilon} \in H^\ell(\mathbb{R})$, $\ell \geq 2$, the condition (2.2), and

$$\|u_{0,\varepsilon,n} - u_{0,\varepsilon}\|_{H^1(\mathbb{R})} \leq \|u_{0,n} - u_0\|_{H^1(\mathbb{R})}. \tag{8.1}$$

Finally, write

$$u_{\varepsilon,n} := S^\varepsilon(\gamma_n, g_n, u_{0,n}), \qquad u_n := S(\gamma_n, g_n, u_{0,n}), \qquad u := S(\gamma, g, u_0).$$

Let $t > 0$, then

$$\begin{aligned} \|u_n(t,\cdot) - u(t,\cdot)\|_{H^1(\mathbb{R})} &\leq \|u_n(t,\cdot) - u_{\varepsilon,n}(t,\cdot)\|_{H^1(\mathbb{R})} \\ &\quad + \|u_{\varepsilon,n}(t,\cdot) - u_\varepsilon(t,\cdot)\|_{H^1(\mathbb{R})} + \|u_\varepsilon(t,\cdot) - u(t,\cdot)\|_{H^1(\mathbb{R})}, \end{aligned} \tag{8.2}$$

so

$$\begin{aligned} 0 \leq \liminf_n \|u_n(t,\cdot) - u(t,\cdot)\|_{H^1(\mathbb{R})} &\leq \liminf_{\varepsilon,n} \|u_n(t,\cdot) - u_{\varepsilon,n}(t,\cdot)\|_{H^1(\mathbb{R})} \\ &\quad + \liminf_{\varepsilon,n} \|u_{\varepsilon,n}(t,\cdot) - u_\varepsilon(t,\cdot)\|_{H^1(\mathbb{R})} \\ &\quad + \liminf_{\varepsilon} \|u_\varepsilon(t,\cdot) - u(t,\cdot)\|_{H^1(\mathbb{R})}. \end{aligned} \tag{8.3}$$

From Lemma 5.2 we know that

$$\liminf_{\varepsilon,n} \|u_n(t,\cdot) - u_{\varepsilon,n}(t,\cdot)\|_{H^1(\mathbb{R})} = 0, \tag{8.4}$$

$$\liminf_{\varepsilon} \|u_\varepsilon(t,\cdot) - u(t,\cdot)\|_{H^1(\mathbb{R})} = 0. \tag{8.5}$$

We claim that

$$\liminf_{\varepsilon,n} \|u_{\varepsilon,n}(t,\cdot) - u_\varepsilon(t,\cdot)\|_{H^1(\mathbb{R})} = 0. \tag{8.6}$$

Using [4, Theorem 3.1] and (8.1), we have that

$$\begin{aligned} \|u_{\varepsilon,n}(t,\cdot) - u_\varepsilon(t,\cdot)\|_{H^1(\mathbb{R})} &\leq A(t,\varepsilon)\|u_{0,n} - u_0\|_{H^1(\mathbb{R})} \\ &\quad + B(t,\varepsilon)\big(\|g_n - g\|_{L^\infty(\mathcal{I})} + |\gamma_n - \gamma|\big), \end{aligned} \tag{8.7}$$

with

$$A(t,\varepsilon) = \mathcal{O}(e^{T/\varepsilon}), \qquad B(t,\varepsilon) = \mathcal{O}(e^{T/\varepsilon}), \quad t \in [0,T].$$

Define

$$\varepsilon_n := \frac{T}{|\log(k_n)|}, \qquad k_n := \max\left\{\|u_{0.n} - u_0\|_{H^1(\mathbb{R})}^{1/2}, \|g_n - g\|_{L^\infty(\mathcal{I})}^{1/2}, |\gamma_n - \gamma|^{1/2}\right\},$$

clearly

$$\liminf_{\varepsilon,n} \|u_{\varepsilon,n}(t,\cdot) - u_\varepsilon(t,\cdot)\|_{H^1(\mathbb{R})} \leq \liminf_n \|u_{\varepsilon_n,n}(t,\cdot) - u_{\varepsilon_n}(t,\cdot)\|_{H^1(\mathbb{R})}, \tag{8.8}$$

and

$$\lim_n A(\varepsilon_n, t)\|u_{0,n} - u_0\|_{H^1(\mathbb{R})} = \lim_n B(\varepsilon_n, t)\|g_n - g\|_{L^\infty(\mathcal{I})} = 0. \tag{8.9}$$

Then (8.6) is a consequence of (8.7), (8.8), and (8.9). From (8.3)–(8.6), we get

$$\lim_n \|u_n(t,\cdot) - u(t,\cdot)\|_{H^1(\mathbb{R})} = 0. \qquad \square$$

Proof of Theorem 1.2. The proof is a direct consequence of Lemmas 7.1 and 8.1. $\square$

AN ACCELERATED SPLITTING-UP METHOD FOR PARABOLIC EQUATIONS*

ISTVÁN GYÖNGY† AND NICOLAI KRYLOV‡

Abstract. We approximate the solution u of the Cauchy problem

$$\frac{\partial}{\partial t}u(t,x) = Lu(t,x) + f(t,x), \quad (t,x) \in (0,T] \times \mathbb{R}^d,$$

$$u(0,x) = u_0(x), \quad x \in \mathbb{R}^d,$$

by splitting the equation into the system

$$\frac{\partial}{\partial t}v_r(t,x) = L_r v_r(t,x) + f_r(t,x), \qquad r = 1,2,\dots,d_1,$$

where L, L_r are second order differential operators; f, f_r are functions of t,x such that $L = \sum_r L_r$, $f = \sum_r f_r$. Under natural conditions on solvability in the Sobolev spaces W^m_p, we show that for any $k > 1$ one can approximate the solution u with an error of order δ^k, by an appropriate combination of the solutions v_r along a sequence of time discretization, where δ is proportional to the step size of the grid. This result is obtained by using the time change introduced in [I. Gyöngy and N. Krylov, *Ann. Probab.*, 31 (2003), pp. 564–591], together with Richardson's method and a power series expansion of the error of splitting-up approximations in terms of δ.

Key words. Cauchy problem, parabolic partial differential equations, splitting-up, method of alternative direction, Richardson's method

1. Introduction.

In this paper we are interested in the rate of convergence of splitting-up approximations to the solution of the parabolic, possibly *degenerate,* differential equation with time dependent coefficients

$$\frac{\partial}{\partial t}u(t,x) = Lu(t,x) + f(t,x), \quad (t,x) \in (0,T] \times \mathbb{R}^d, \tag{1.1}$$

with initial condition

$$u(0,x) = u_0(x), \quad x \in \mathbb{R}^d, \tag{1.2}$$

where L is a differential operator of the form

$$L = a^{ij}(t,x)\frac{\partial^2}{\partial x^i x^j} + a^i(t,x)\frac{\partial}{\partial x^i} + a(t,x)$$

and f is a function of $t \geq 0$ and $x \in \mathbb{R}^d$. The first step in the splitting methods is to choose suitable decompositions $L = L_1 + L_2 + \cdots + L_{d_1}$ and $f = f_1 + f_2 + \cdots + f_{d_1}$ for the operator L and the free term f such that each equation

$$\frac{\partial}{\partial t}v_r(t,x) = L_r v_r(t,x) + f_r(t,x), \tag{1.3}$$

$r = 1, 2, \dots, d_1$, is integrable exactly or approximately.

Assume for simplicity that the operators L_r and the free terms f_r, $r = 1, 2, \dots, d_1$, are time independent, and, for fixed $T > 0$ and integer $n \geq 1$, consider the uniform step

$$T_n := \left\{ t_i^n := \frac{iT}{n}, i = 0, 1, 2, \dots, n \right\} \tag{1.4}$$

of step size $\delta := T/n$. Then a splitting-up approximation $u^{(n)}$ for the solution u of (1.1)–(1.2) is defined by

$$u_n(t_i^n) := (\mathbb{S}_\delta^{(d_1)} \dots \mathbb{S}_\delta^{(2)} \mathbb{S}_\delta^{(1)})^i u_0, \qquad i = 0, 1, \dots, n, \tag{1.5}$$

at the grid points. Here $\mathbb{S}_t^{(r)}$ denotes the solution operator of (1.3); i.e., $\mathbb{S}_t^{(r)} \varphi$ is the solution of (1.3) at time t with initial condition φ at $t = 0$. Formula (1.5) means that we take $u^{(n)}(0) = u_0$, and we calculate the approximation at a grid point $t+\delta$ from the approximation $u^{(n)}(t)$ at the previous grid point t, by solving (1.3) for $r = 1, 2, \dots, d_1$ on the same time interval $[0, \delta]$ successively. First we solve the first equation ($r = 1$) on $[0, \delta]$ with initial condition $v_1(0) = u^{(n)}(t)$, and then we solve the second equation, third equation, and so on, on the same interval $[0, \delta]$, by always taking the value at δ of the solution of the previous equation as the initial value for the following equation. Finally we solve the last equation ($r = d_1$) on the interval $[0, \delta]$ with initial condition $v_{d_1}(0) = v_{d_1 - 1}(\delta)$, and the value $v_{d_1}(\delta)$ is the value of the splitting-up approximation at $t + \delta$.

This kind of approximations is well known in numerical analysis, and it has been successfully applied to various types of PDE problems. They are often combined with other numerical methods, such as finite differences, finite elements, etc. Pioneering applications to the heat equation, to hyperbolic equations, and to nonlinear PDEs are presented, for example, in [16], [4], [2], in [29], [9] and in [3], [24], [1], [23], respectively. Many applications and modifications of the splitting-up method have been developed in various applied fields of linear and nonlinear PDEs and ODEs, under a variety of different names, like dimensional splitting, operator splitting, predictor-corrector method, method of alternating directions, fractional step method, Lie–Trotter–Kato formula, Baker–Campbell–Hausdorff formula, Chernoff formula, split Hamiltonian, split-steps, or leapfrog. For guidance in the huge varieties of methods, names, and references we refer the reader to the survey article [13] and books [11], [12].

In the context of semigroups the splitting-up method first appears as Trotter's formula [25], which can be formulated as follows:

$$\lim_{n \to \infty} (e^{tA_{d_1}/n} \dots e^{tA_2/n} e^{tA_1/n})^n z = e^{tA} z \quad \forall z \in \mathbb{B},$$

where $A = A_1 + A_2 + \dots + A_{d_1}$ and A_r are infinitesimal generators of C_0-semigroups of contractions $\{e^{tA} : t \geq 0\}$ and $\{e^{tA_r} : t \geq 0\}$ on a Banach space $\mathbb{B}$, such that the intersection of the domains of the generators is dense in $\mathbb{B}$. Clearly, in the context of Cauchy problems, Trotter's formula states the convergence of the splitting-up approximations defined by the splitting

$$\frac{d}{dt} v_r(t) = A_r v_r(t), \qquad r = 1, 2, \dots, d_1,$$

to the solution of the abstract Cauchy problem

$$\frac{d}{dt} u(t) = Au(t), \quad t \geq 0, \quad u(0) = z.$$

Our main interest in the present paper is to increase the accuracy of the splitting-up approximations for (1.1). It is known that the error of the splitting-up approximations is proportional to δ, the step size. There are, however, modifications of these approximations which are more accurate. A celebrated example is the Strang symmetric scheme

$$u_n(t_i^{(n)}) := (\mathbb{S}_{\delta/2}^{(1)}\mathbb{S}_{\delta/2}^{(2)}\dots\mathbb{S}_{\delta/2}^{(d_1)}\mathbb{S}_{\delta/2}^{(d_1)}\dots\mathbb{S}_{\delta/2}^{(2)}\mathbb{S}_{\delta/2}^{(1)})^i u_0, \qquad i=0,1,\dots,n,$$

whose error is proportional to δ^2. This approximation scheme is presented in [17], [19]. Other symmetric schemes and their generalizations are given in [17], [18], and [6]. All these schemes are of second order accuracy. Inspired by the above example, for given $k \geq 2$ one looks for a composition of splittings

$$\prod_{i=1}^{m}\prod_{j=1}^{d_1}\mathbb{S}_{c^{ij}\delta}^{(j)}, \tag{1.6}$$

with real numbers c^{ij} and integer $m \geq 1$ to be determined, such that

$$u(\delta) - \prod_{i=1}^{m}\prod_{j=1}^{d_1}\mathbb{S}_{c^{ij}\delta}^{(j)}u_0,$$

the local error of the corresponding approximation is proportional to δ^{k+1} in appropriate norms. Such local error leads to a global error, proportional to δ^k; i.e., composition (1.6) represents a method of (at least) *order* k. The conditions on the numbers c^{ij} and m, which lead to splitting methods of high order, have been studied intensively in the literature. Such methods are obtained in [15] for Hamiltonian systems by the Baker–Campbell–Hausdorff formula. Variations of the Trotter formula and the Baker–Campbell–Hausdorff formula are used for linear and for nonlinear equations, respectively, to show the existence of methods of any order (see [13], [21], [22], [26], [28], and the literature therein). An adaptation of the method of *rooted trees* from the theory of Runge–Kutta approximations is used in [14]. By [20] and [27], however, the numbers c^{ij} in each scheme (1.6) of order $k \geq 3$ cannot all be nonnegative. Thus, by [20] and [27], the above splitting methods of order greater than or equal to 3 cannot be used to approximate the solution of partial differential equations of parabolic type. As McLachlan and Quispel write on page 392 of [13]: "... splitting was proposed as a cheap way to retain unconditional stability. Methods with backward time steps can be only conditionally stable; this stumbling block held up the development of high-order compositions for years."

Then the natural question arises as to whether there exists, in the case of parabolic equations, a way different from the multiplicative one to accelerate the convergence to a higher order. One of our main results consists of showing that, using the step size of order δ but organizing the computations differently, it is indeed possible to achieve the accuracy of order δ^k for any k, even if A_r are (degenerate) elliptic operators with coefficients depending on time. In a subsequent article we intend to show that our method is much more universal in the sense that it covers many situations in which method (1.6) works and requires approximately the same amount of work.

In the present paper we use linear combinations of splittings of type (1.5) with different step sizes to achieve arbitrary high accuracy. We prove that for any given $k \geq 0$ there exist absolute constants $b_0, b_1, \dots, b_k$ expressed by simple formulas such that the accuracy of the approximation

$$v_n := b_0 u_n + b_1 u_{2n} + b_2 u_{4n} + \cdots + b_k u_{2^k n} \tag{1.7}$$

is of order δ^{k+1} (see Theorem 2.3 below). Here $u_{2^j n}$ is the splitting-up approximation (1.5) along the grid (1.4), with $2^j n$ in place of n. In particular, if $k = 1$, we have to deal with two step sizes: δ and $\delta/2$, and we get the order of accuracy δ^2. The Strang formula giving the same order of accuracy, generally, also requires working with step size $\delta/2$. By the way, if $A = A_1 + A_2$ and we construct our splitting-up scheme according to $A = (1/2)A_1 + A_2 + (1/2)A_1$, then our approximations just coincide with the Strang one, and there is no need to use linear combinations to get the error of order δ^2. It is also worth noting that the above coefficients $\mathbf{b} = (b_0, \ldots, b_k)$ are given by $\mathbf{b} := \mathbf{e}_1 V^{-1}$, where $\mathbf{e}_1 := (1, 0, 0, \ldots, 0)$ and V^{-1} is the inverse of the $(k+1) \times (k+1)$ Vandermonde matrix $V^{ij} = 2^{-(i-1)(j-1)}$.

Our work is of a purely theoretical nature and, as the referees pointed out, much work yet needs to be done before our results could be used in practical applications. We restricted ourselves to making the first step in attacking Problem 10 on page 492 of [13]: "For systems that evolve in a semigroup, such as the heat equation, develop effective methods of order higher than 2." However, our results show that each time one has *any* algorithm implementing standard splitting-up method to approximate the solutions of the Cauchy problem for degenerate parabolic equations with sufficiently smooth coefficients and free terms, one can improve the rate of convergence to any degree. For instance, we believe that usually in practice one is not doing computations with only one step size, and we show that having, say, three different step sizes, each of which is of order δ of accuracy, and just taking a linear combination of the results, one gets an approximation with error of order δ^3.

We have to admit that we do not know whether our methods can be carried over to quasi-linear equations or to equations in domains. In this connection we note that there is a very active area of developing and applying in practice splitting-up methods for degenerate nonlinear convection-diffusion equations (see, for instance, [5] and references therein). Our equations can be viewed as belonging to this area only if a^{ij} are constant. However, it is perhaps worth mentioning that our methods can be applied to solving systems of (nonlinear) ODEs, and we are in the process of working on this subject.

Inspired by Richardson's method we obtain our results by expanding the error $u - u_n$ of the splitting-up approximation (1.5) in powers of $\delta = T/n$. This is Theorem 2.2, the main theorem of our paper. We use this expansion with $\delta = T/2^j n$, $j = 0, 1, 2, \ldots, k$, and choose the above coefficients $b_0, b_1, \ldots, b_k$ to eliminate the terms of order less than $k + 1$ in the linear combination (1.7).

The main theorem of the present paper is proved by exploiting a new approach of [7] and [8] to splitting-up methods. As we discussed above, the splitting-up approximation (1.5) means that to get the approximation at $t + \delta$ from that at t, one goes back and forth in time d_1 times while solving (1.3), $r = 1, 2, \ldots, d_1$, successively. A basic idea of [7] is to arrange the splitting continuously in forward time direction, and to synchronize it with the original equation by time-scaling. In this way we have differential equations for the rearranged splitting-up approximations and for the time-scaled solution of the original equation, which enables us to use methods of the theory of partial differential equations and not semigroup theory and get an expansion for their difference in terms of powers of δ even if the coefficients depend on time. The method of [7] and [8] appeared in connection with splitting-up for stochastic PDEs.

It is worth mentioning that most likely it is impossible to accelerate the splitting-up method in this more complicated situation.

The paper is organized as follows. In the next section we introduce our general setting but state the results, Theorems 2.3 and 2.2, only for the case of time independent data for the sake of simplicity of presentation. Theorem 2.2 is proved immediately after its formulation on the basis of Theorem 2.3, which in turn is proved in section 4, after we prepare some auxiliary facts in section 3. In section 5 we generalize Theorems 2.3 and 2.2 for time dependent data and derive some consequences valid in the time-homogeneous case as well.

In conclusion we introduce some notation used everywhere below. Throughout the paper $d \geq 1, d_1 \geq 2$ are fixed positive integers, K, T are fixed finite positive constants, and

$$D_i := \frac{\partial}{\partial x^i}, \quad D_{ij} := \frac{\partial^2}{\partial x^i \partial x^j}, \quad D_t := \frac{\partial}{\partial t}.$$

We denote by W_p^m the Sobolev space defined as the closure of C_0^∞ functions $\varphi : \mathbb{R}^d \to \mathbb{R}$ in the norm

$$\|\varphi\|_{m,p} := \left(\sum_{|\gamma| \leq m} \int_{\mathbb{R}^d} |D^\gamma \varphi(x)|^p \, dx \right)^{1/p},$$

where $D^\gamma := D_1^{\gamma_1} \dots D_d^{\gamma_d}$ for multi-indices $\gamma = (\gamma_1, \dots, \gamma_d)$ of length $|\gamma| := \gamma_1 + \gamma_2 + \dots + \gamma_d$. Unless otherwise indicated, we use the summation convention with respect to repeated indices.

2. Formulation of the main results. The case of time independent coefficients. We consider the problem

$$D_t u(t,x) = Lu(t,x) + f(t,x), \qquad t \in (0,T], \ x \in \mathbb{R}^d, \tag{2.1}$$

$$u(0,x) = u_0(x), \quad x \in \mathbb{R}^d, \tag{2.2}$$

where L is an operator of the form

$$L = a^{ij}(t,x) D_{ij} + a^i(t,x) D_i + a(t,x),$$

and f and u_0 are real functions of $(t,x) \in (0,T] \times \mathbb{R}^d$ and of $x \in \mathbb{R}^d$, respectively. We assume that the coefficients a^{ij}, a^i, a and the derivatives $a^{ij}_{x^k}$ of a^{ij} are bounded Borel functions of (t,x). We fix $p \geq 2$ and assume that u_0 and f are measurable and $|u_0|^p$ and $|f|^p$ are integrable over $\mathbb{R}^d$ and over $[0,T] \times \mathbb{R}^d$, respectively.

DEFINITION 2.1. *By a solution of problem* (2.1)–(2.2) *we mean an W_p^1-valued weakly continuous function $u(t) = u(t,\cdot)$ defined on $[0,T]$ such that for all $\phi \in C_0(\mathbb{R}^d)$ and $t \in [0,T]$*

$$\begin{aligned}(u(t,\cdot),\phi) = (u(0,\cdot),\phi) + \int_0^t &[-(a^{ij} D_i u(s), D_j \phi) \\ &+ ((a^i - a^{ij}_{x^j}) D_i u(s) + a u(s) + f_r(s), \phi)] \, ds,\end{aligned}$$

where (,) *denotes the usual inner product in* $L^2(\mathbb{R}^d)$. *Quite often we write* (2.1) *and similar equations in the form*

$$du(t) = (Lu(t) + f(t))\,dt,$$

bearing in mind the differential of u *in* t *only.*

Suppose that we split (2.1) into the equations

$$D_t v(t,x) = L_r v(t,x) + f_r(t,x), \qquad t \in (0,T],\ \ x \in \mathbb{R}^d, \tag{2.3}$$

with

$$L_r := a_r^{ij}(t,x)D_{ij} + a_r^i(t,x)D_i + a_r(t,x), \quad L = \sum_{r=1}^{d_1} L_r, \quad f = \sum_{r=1}^{d_1} f_r,$$

such that these equations are more pleasant from the point of view of numerical methods than the original one. This motivates the multistage splitting method, which we describe below. First we need some assumptions.

Fix an integer $l \geq 1$.

Assumption 2.1 (ellipticity of L_r). For each $r = 1, 2, \ldots, d_1$ for $dt \times dx$-almost every $(t,x) \in [0,T] \times \mathbb{R}^d$

$$a_r^{ij}(t,x)\lambda^i\lambda^j \geq 0$$

for all $(\lambda^1, \lambda^2, \ldots, \lambda^d) \in \mathbb{R}^d$.

Assumption 2.2. (i) The partial derivatives

$$D_t^s D^\rho a_r^{ij}, \quad D_t^s D^\rho a_r^i, \quad D_t^s D^\rho a_r \quad \text{for } i,j = 1,2,\ldots,d,\ r = 1,2,\ldots,d_1$$

exist and by magnitude are bounded by K for all integers $s \geq 0$ and multi-indices ρ, satisfying $2s + |\rho| \leq l$.

(ii) For every integer $s \in [0, l/2]$

$$\sup_{t\in[0,T]} \|D_t^s f_r(t)\|_{l-2s,p} \leq K.$$

(iii) We have $u_0 \in W_p^l$ and $\|u_0\|_{l,p} \leq K$.

It is well known that under the above conditions, (2.1) and (2.3) with initial condition $u(0) = u_0$ admit unique generalized solutions u and v, respectively, which are W_p^l-valued weakly continuous functions of $t \geq 0$ (see, for instance, Theorem 3.1 below). We want to approximate the solution u by using the splitting-up method, i.e., by solving (2.3) successively with appropriate initial conditions on appropriate time intervals. Let us formulate now our splitting-up scheme in the case when the coefficients a_r^{ij}, a_r^i, a_r and free terms f_r are independent of the time variable t.

Set $T_n := \{t_i := iT/n : i = 0,1,2,\ldots,n\}$, $\delta := T/n$ for an integer $n \geq 1$. Then for fixed n we approximate the solution u of (2.1)–(2.2) at $t_i = iT/n$ recursively by $u_n(0) := u_0$,

$$u_n(t_{i+1}) := \mathbb{S}_\delta^{(d_1)} \ldots \mathbb{S}_\delta^{(2)}\mathbb{S}_\delta^{(1)} u_n(t_i), \quad i = 0,1,2,\ldots,n-1, \tag{2.4}$$

where $\mathbb{S}_t^{(r)}\psi := v(t)$ denotes the solution of (2.3) for $t \geq 0$ with initial condition $v(0) = \psi$.

It is known that if Assumptions 2.1 and 2.2 are satisfied with $l = m + 4$, then

$$\max_{t\in T_n} \|u(t) - u_n(t)\|_{m,p} \leq \frac{N}{n}$$

for all $n \geq 1$, where N depends only on d, d_1, T, K, p, m. Moreover, this rate of convergence is sharp (see [8], where this result is a special case of the rate of convergence estimates for stochastic PDEs). In the present paper we want to show that by suitable combinations of splitting-up approximations we can achieve convergence as fast as we wish. We show this by the aid of the following theorem on expansion of u_n in powers of the step size δ.

THEOREM 2.2. *Let $m \geq 0$ and $k \geq 0$ be integers. Let Assumptions 2.1 and 2.2 hold with*

$$l \geq 4 + m + 4k. \tag{2.5}$$

Suppose that the coefficients a_r^{ij}, a_r^i, a_r and the free terms f_r do not depend on t. Then for all $n \geq 1$ and $t \in T_n$ and $x \in \mathbb{R}^d$, the following representation holds:

$$\begin{aligned} u_n(t,x) = {} & u(t,x) + \delta u^{(1)}(t,x) \\ & + \delta^2 u^{(2)}(t,x) + \cdots + \delta^k u^{(k)}(t,x) + R_n^{(k)}(t,x), \end{aligned} \tag{2.6}$$

where the functions $u^{(1)}, \dots, u^{(k)}$ and $R_n^{(k)}$, defined on $[0,T]$, are W_p^m-valued and weakly continuous. Furthermore, $u^{(j)}$, $j = 1, 2, \dots, k$, are independent of n, and

$$\sup_{t\in T_n} \|R_n^{(k)}(t)\|_{m,p} \leq N\delta^{k+1} \tag{2.7}$$

for all n, where N depends only on l, k, d, d_1, K, m, p, T.

Remark 2.1. If $k = 0$ and $p = 2$, the result holds under a weaker restriction on l: $l \geq 3 + m$ (see, for instance [7]). For general $p \geq 2$ and $k = 0$ the result is proved in [8].

We prove Theorem 2.2 in section 4. Now we deduce from it a result on the acceleration of the splitting-up method. Let V denote the square matrix defined by $V^{ij} := 2^{-(i-1)(j-1)}$, $i, j = 1, \dots, k+1$. Notice that the determinant of V is the Vandermonde determinant, generated by $1, 2^{-1}, \dots, 2^{-k}$, and hence it is different from 0. Thus V is invertible. Set $\mathbf{b} := (b_0, b_1, \dots, b_k) := (1, 0, 0, \dots, 0)V^{-1}$, and define

$$v_n(t) := \sum_{j=0}^{k} b_j u_{2^j n}(t), \quad t \in T_n := \left\{ \frac{iT}{n} : i = 0, 1, \dots, n \right\},$$

where $u_{2^j n}$ is the splitting-up approximation based on the grid $T_{2^j n} := \{iT/(2^j n) : i = 0, 1, \dots, 2^j n\}$.

THEOREM 2.3. *Let $m \geq 0$ and $k \geq 0$ be any integers. Let Assumptions* 2.1 and 2.2 *hold with l satisfying* (2.5). *Suppose that the coefficients a_r^{ij}, a_r^i, a_r and the free terms f_r do not depend on t. Then*

$$\max_{t\in T_n} \|v_n(t) - u(t)\|_{m,p} \leq N\delta^{k+1},$$

where N is a constant depending only on l, k, d, d_1, K, m, p, T.

Proof. By Theorem 2.2

$$u_{2^j n} = u + \sum_{i=1}^{k} \frac{\delta^i}{2^{ji}} u^{(i)} + R^{(k)}_{2^j n}, \quad j = 0, 1, \ldots, k.$$

Therefore for all $n \geq 1$

$$v_n = \sum_{j=0}^{k} b_j u_{2^j n} = \left(\sum_{j=0}^{k} b_j \right) u + \sum_{j=0}^{k} \sum_{i=1}^{k} b_j \frac{\delta^i}{2^{ij}} u^{(i)} + \sum_{j=0}^{k} b_j R^{(k)}_{2^j n}$$

$$= u + \sum_{i=1}^{k} \delta^i u^{(i)} \sum_{j=0}^{k} \frac{b_j}{2^{ij}} + \sum_{j=0}^{k} b_j R^{(k)}_{2^{j}n} = u + \sum_{j=0}^{k} b_j R^{(k)}_{2^j n},$$

since $\sum_{j=0}^{k} b_j = 1$ and $\sum_{j=0}^{k} b_j 2^{-ij} = 0$ for $i = 1, 2, \ldots, k$ by the definition of $(b_0, \ldots, b_k)$. Hence $v_n - u = \sum_{j=0}^{k} b_j R^{(k)}_{2^j n}$ and

$$\max_{t \in T_n} \|v_n(t) - u(t)\|_{m,p} = \max_{t \in T_n} \left\| \sum_{j=0}^{k} b_j R^{(k)}_{2^j n}(t) \right\|_{m,p}$$

$$\leq \sum_{j=0}^{k} |b_j| \max_{t \in T_n} \|R^{(k)}_{2^j n}(t)\|_{m,p} \leq N\delta^{k+1},$$

by (2.7), where N is a constant depending only on l, T, K, d, d_1, m, p, k. ◻

Remark 2.2. Assume that $u^{(1)} = 0$ in expansion (2.6). This happens, for example, for Strang's splitting, which is a special case of our splitting-up scheme, as is explained in the Introduction. In this case we need take only k terms in the linear combination to achieve accuracy of order $k + 1$. Namely, we now define $v_n(t)$ by

$$v_n(t) := \sum_{j=0}^{k-1} \lambda_j u_{2^j n}(t), \quad t \in T_n,$$

where

$$(\lambda_0, \lambda_1, \ldots, \lambda_{k-1}) := (1, 0, \ldots, 0)V^{-1},$$

and V is now a $k \times k$ Vandermonde matrix with entries $V_{i1} := 1$, $V_{i,j} := 2^{-(i-1)j}$ for $i = 1, 2, \ldots, k$ and $j = 2, \ldots, k$. Then Theorem 2.3 remains valid, which one can prove in the same way as Theorem 2.3 is proved. For example,

$$v_n(t) := -\frac{1}{3} u_n(t) + \frac{4}{3} u_{2n}(t), \quad t \in T_n,$$

is an approximation of accuracy δ^3 in the case of Strang's splitting.

3. Auxiliary results. Let us consider the PDE

$$du(t, x) = (Lu(t, x) + f(t, x))\, dA(t), \qquad t \in (0, T], \ \ x \in \mathbb{R}^d, \tag{3.1}$$

$$u(0, x) = u_0(x), \quad x \in \mathbb{R}^d, \tag{3.2}$$

where L is an operator of the form

$$L = a^{ij}(t,x)D_{ij} + a^i(t,x)D_i + a(t,x),$$

$A = A(t)$ is a continuous increasing function starting from 0, and f and u_0 are real functions of $(t,x) \in (0,T] \times \mathbb{R}^d$ and of $x \in \mathbb{R}^d$, respectively. Fix an integer $l \geq 0$ and a real number $p \geq 2$. We understand the solution in the spirit of Definition 2.1 and make the following assumptions.

Assumption 3.1 (smoothness of the coefficients). The coefficients of L are measurable. The derivatives in $x \in \mathbb{R}^d$ of the coefficients a^{ij} up to order $2 \vee l$, of the coefficients $a^i(t,x)$ up to order $1 \vee l$, and of $a(t,x)$ up to order l exist for any $t \in (0,\infty)$, and by magnitude are bounded by K.

Assumption 3.2. We have

$$u_0 \in W^l_p, \quad f \in L_p([0,T], W^l_p).$$

Assumption 3.3 (ellipticity of L). For all $t \geq 0$, $x \in \mathbb{R}^d$, and $\lambda \in \mathbb{R}^d$, we have

$$a^{ij}(t,x)\lambda^i\lambda^j \geq 0.$$

Assumption 3.4. The function A is absolutely continuous and

$$\dot{A}(t) := \frac{d}{dt}A(t) \leq K$$

for dt-almost every $t \geq 0$.

The following result is well known in PDE theory (after replacing dA in (3.1) with $\dot{A}\,dt$ we easily get it, for instance, from [10] or from Theorem 3.1 in [7]).

THEOREM 3.1. *Under Assumptions* 3.1, 3.2, 3.3, *and* 3.4 *with* $l \geq 1$ *the Cauchy problem* (3.1)–(3.2) *has a unique generalized solution* u. *If Assumptions* 3.1, 3.2, 3.3, *and* 3.4 *hold with* $l \geq 0$, *and if* u *is a generalized solution of* (3.1)–(3.2), *then for every integer* $l_1 \in [0,l]$

$$\sup_{t\in[0,T]} \|u(t)\|^p_{l_1,p} \leq N\left\{\|u_0\|^p_{l_1,p} + \int_0^T \|f(t)\|^p_{l_1,p}\,dt\right\},$$

where N *is a constant depending only on* T, K, l, p, d.

Under the assumptions of Theorem 3.1 let $\mathcal{R}f$ denote the solution of (3.1) with initial data $u_0 = 0$. Then by virtue of Theorem 3.1

$$\mathcal{R} : L_p([0,T], W^l_p) \to C_w([0,T], W^l_p)$$

is a bounded linear operator, where $C_w([0,T], W^l_p)$ denotes the Banach space of weakly continuous W^l_p-valued functions $u = u(t)$, $t \in [0,T]$ with the norm $\sup_{t\in[0,T]} \|u(t)\|_{l,p}$.

Let us now consider the equation

$$du(t,x) = Lu(t,x)\,dA(t) + g(t,x)\,dH(t), \quad (t,x) \in (0,T] \times \mathbb{R}^d, \tag{3.3}$$

where g is a real-valued function of $(t,x) \in [0,T] \times \mathbb{R}^d$ and H is an absolutely continuous function of $t \in [0,T]$.

Assumption 3.5. We have $g \in L_p([0,T], W_p^{l+2})$, and there exists $g' \in L_p([0,T], W_p^l)$ such that

$$d(g(t),\phi) = (g'(t),\phi)\, dA(t), \quad t \in [0,T],$$

for all $\phi \in C_0(\mathbb{R}^d)$.

LEMMA 3.2. *Under Assumptions* 3.1, 3.3, 3.4, and 3.5 *with* $l \geq 1$, (3.3) *with zero initial data has a unique generalized solution* u. *Moreover,*

$$u = \mathcal{R}(H(Lg - g')) + Hg =: \mathcal{Q}(H,g). \tag{3.4}$$

If Assumptions 3.1, 3.3, 3.4, and 3.5 *hold with* $l \geq 0$, *and* (3.3) *with zero initial data admits a generalized solution* u, *then for every integer* $l_1 \in [0,l]$

$$\begin{aligned} &\sup_{t\in[0,T]} \|u(t)\|_{l_1,p} \\ &\leq N \sup_{t\in[0,T]} |H(t)| \left(\sup_{t\in[0,T]} \|g(t)\|_{l_1,p} + \left\{ \int_0^T (\|g(t)\|_{l_1+2,p}^p + \|g'(t)\|_{l_1,p}^p)\, dt \right\}^{1/p} \right), \end{aligned} \tag{3.5}$$

where N *is a constant depending only on* p, d, K, l, T.

Proof. Note that

$$d((g(t),\phi)H(t)) = (g(t),\phi)\, dH(t) + (g'(t),\phi)H(t)\, dA(t)$$

for all $\phi \in C_0(\mathbb{R}^d)$. Therefore u solves (3.3) when $w(t,x) := u(t,x) - H(t)g(t,x)$ solves

$$dw(t,x) := \{Lw(t,x) + H(t)(Lg(t,x) - g'(t,x))\}\, dA(t).$$

Hence equality (3.4) follows by Theorem 3.1, and it implies (3.5). $\square$

Remark 3.1. We often consider (3.3) when $dH(t)/dt$ is bounded. Then under Assumptions 3.1, 3.3, 3.4, and 3.5 with $l \geq 1$, (3.3) with zero initial data has a unique generalized solution u by Theorem 3.1. By Theorem 3.1 this solution belongs to $C_w([0,T], W_p^l)$, and its norm in this space admits an estimate with a constant depending on the bound for $\dot{H}$ and only the $L_p([0,T], W_p^l)$-norm of g. It is important that the function H enters (3.5) only through $\sup|H|$ and not any characteristic of its derivative; however, for that we pay a price requiring g to have more derivatives.

4. Proof of Theorem 2.2. Throughout this section the assumptions of Theorem 2.2 are supposed to be satisfied. In particular, $l \geq 4$. Fix n and introduce $\delta = T/n$. We use the idea from [7] and [8] of rearranging the splitting method in forward time. We achieve this by considering the equation

$$dw(t,x) = \sum_{r=1}^{d_1} (L_r w(t,x) + f_r)\, dA_r(t), \quad w(0,x) = u_0(x), \tag{4.1}$$

where the time change A_r, $r = 1, \dots, d_1$, is defined by the requirements that $A_r(0) = 0$, $A_r(t)$ be absolutely continuous, and its derivative in time $\dot{A}_r$ be periodic with period $d_1\delta$ and

$$\dot{A}_r(t) = 1_{[r-1,r]}\left(\frac{t}{\delta}\right), \quad t \in [0, d_1\delta] \quad \text{(a.e.)}. \tag{4.2}$$

Instead of the original Cauchy problem (2.1)–(2.2) we consider

$$dv(t,x) = (Lv(t,x) + f)\,dA_0(t), \quad v(0,x) = u_0(x),$$

where

$$A_0(t) := \frac{t}{d_1}. \tag{4.3}$$

Clearly, $v(t) = u(A_0(t))$ and

$$v(d_1 t) = u(t), \quad w(d_1 t) = u_n(t) \quad \text{for all } t \in T_n.$$

Therefore our aim is to show that Theorem 2.2 holds with v and w in place of u, and u_n, respectively, for all $t = id_1\delta$, $i = 0, 1, \dots, n$. To this end first we introduce some notation. We call a sequence of numbers $\alpha = \alpha_1\alpha_2\dots\alpha_i$ a multinumber of length $|\alpha| := i$ if $\alpha_j \in \{0, 1, 2, \dots, d_1\}$. The reader should notice the difference between multinumbers and multi-indices. The set of all multinumbers is denoted by $\mathcal{N}$. For every multinumber α we define a function $B_\alpha : [0,\infty) \to \mathbb{R}$ and a number c_α recursively starting as follows:

$$B_\gamma := \delta^{-1}(A_\gamma - A_0), \quad c_\gamma = 0 \qquad \text{for } \gamma = 0, 1, 2, \dots, d_1. \tag{4.4}$$

If for every multinumber $\beta = \beta_1\dots\beta_i$ of length i the function B_β and the number c_β are defined, then

$$c_{\beta\gamma} := \delta^{-1}\int_0^{d_1\delta} B_\beta(s)\dot{A}_\gamma(s)\,ds, \tag{4.5}$$

$$B_{\beta\gamma}(t) := \delta^{-1}\int_0^t (B_\beta(s)\dot{A}_\gamma(s) - c_{\beta\gamma}\dot{A}_0(s))\,ds \tag{4.6}$$

for $\gamma = 0, 1, 2, \dots, d_1$, where $\dot{A}_\gamma(s) := dA_\gamma(s)/ds$.

Notice that by (4.6) we have

$$B_\beta(t)\,dA_\gamma(t) = c_{\beta\gamma}\,dA_0(t) + \delta\,dB_{\beta\gamma}(t) \tag{4.7}$$

for all multinumbers β and $\gamma = 0, 1, 2, \dots, d_1$. We will often make use of this equality and of the following lemma.

LEMMA 4.1. *For every $\alpha \in \mathcal{N}$ the function B_α is $d_1\delta$-periodic, i.e., $B_\alpha(t + d_1\delta) = B_\alpha(t)$ for all $t \geq 0$, and $B_\alpha(id_1\delta) = 0$ for all integer $i \geq 0$. Moreover, the numbers c_α, the functions $C_\alpha(t) := B_\alpha(\delta t)$, and*

$$\sup_{t\geq 0}|B_\alpha(t)| = \sup_{t\geq 0}|C_\alpha(t)|$$

are finite and do not depend on δ.

Proof. That the first assertion is true for $\alpha = 0, \dots, d_1$ is almost obvious. If it is true for $\alpha = \beta$, where β is a multinumber, then the integrand in (4.6) is $d_1\delta$-periodic, and by definition of $c_{\beta\gamma}$ its integral over the period is zero. It follows that the first assertion holds for $\alpha = \beta\gamma$, so the induction on the length $|\alpha|$ finishes the proof of the first assertion.

To prove the second one we again use the induction on the length $i = |\alpha|$. This statement is true when $|\alpha| = 1$. Assume that it is true for all multinumbers β of length i and notice that, according to (4.2) and (4.3), $\dot{A}_\gamma(\delta s)$ are d_1-periodic in s and independent of δ. Therefore,

$$c_{\beta\gamma} = \frac{1}{\delta}\int_0^{d_1\delta} B_\beta(s)\dot{A}_\gamma(s)\,ds = \int_0^{d_1} C_\beta(s)\dot{A}_\gamma(\delta s)\,ds$$

is independent of δ by the induction hypothesis. Similar argument works for $C_\alpha(t)$. $\square$

We use the notation $\mathcal{R}f$ and $\mathcal{Q}_\alpha g$, $\alpha \in \mathcal{N}$, for the solutions of (3.1) and (3.3), respectively, with zero initial condition and A_0 and B_α in place of A and H, respectively. Notice that, unlike in the case of uniformly parabolic operators, $\mathcal{R}$ and $\mathcal{Q}_\alpha$ do not increase regularity.

The following lemma exhibits our two main technical tools: centering B_α and integrating by parts with respect to t.

LEMMA 4.2. *Take some functions*

$$h \in L_p([0,T], W_p^1), \quad h_r \in L_p([0,T], W_p^1), \quad r = 1, \dots, d_1, \quad h_0 = 0.$$

Let u be a solution of the "equation"

$$du = \sum_{r=1}^{d_1} h_r\,dA_r,$$

$u(0) \in W_p^1$, which is a particular case of (4.1) *when $L_r \equiv 0$. Finally, let $Lu \in L_p([0,T], W_p^1)$. Then for any $\alpha \in \mathcal{N}$*

$$\mathcal{R}(B_\alpha h) = c_{\alpha 0}\mathcal{R}h + \delta\mathcal{Q}_{\alpha 0}h, \tag{4.8}$$

$$\mathcal{Q}_\alpha u = \mathcal{R}(c_{\alpha 0}Lu - c_{\alpha r}h_r) + \delta\mathcal{Q}_{\alpha 0}Lu - \delta\mathcal{Q}_{\alpha r}h_r + B_\alpha u. \tag{4.9}$$

Proof. To prove (4.8) it suffices to use the definitions of $\mathcal{R}$ and $\mathcal{Q}_\beta$ (see Theorem 3.1 and Lemma 3.2) and that by virtue of (4.7) for $\varphi = \mathcal{R}(B_\alpha h)$ we have

$$d\varphi = L\varphi\,dA_0 + B_\alpha h\,dA_0 = L\varphi\,dA_0 + c_{\alpha 0}h\,dA_0 + \delta h\,dB_{\alpha 0}.$$

To prove (4.9) observe that, by definition, $\theta := \mathcal{Q}_\alpha u$ satisfies

$$d\theta = L\theta\,dA_0 + u\,dB_\alpha, \quad \theta(0) = 0.$$

This and (4.7) imply that $\psi := \theta - uB_\alpha$ satisfies $\psi(0) = 0$ and

$$\begin{aligned} d\psi &= L\psi\,dA_0 + LuB_\alpha\,dA_0 - h_rB_\alpha\,dA_r \\ &= L\psi\,dA_0 + c_{\alpha 0}Lu\,dA_0 + \delta Lu\,dB_{\alpha 0} - c_{\alpha r}h_r\,dA_0 - \delta h_r\,dB_{\alpha r}. \end{aligned}$$

Now (4.9) follows from the definitions of $\mathcal{R}$ and $\mathcal{Q}_\beta$. The proof of the lemma is complete. $\square$

Now we introduce some differential operators L_γ and functions f_γ defined for multinumbers γ as follows: $L_0 := 0$, $f_0 := 0$,

$$L_\gamma := L_r, \quad f_\gamma := f_r$$

for $\gamma = r \in \{1, 2, \ldots, d_1\}$, and

$$L_{\gamma 0} := L L_\gamma, \quad L_{\gamma r} := -L_\gamma L_r,$$

$$f_{\gamma 0} := L f_\gamma, \quad f_{\gamma r} := -L_\gamma f_r$$

for $r = 1, 2, \ldots, d_1$.

In this notation we have the following.

LEMMA 4.3. *Let $\alpha, \beta \in \mathcal{N}$ and $2|\beta| + 3 \le l$. Then*

$$\mathcal{Q}_\alpha(L_\beta w + f_\beta) = c_{\alpha r}\mathcal{R}(L_{\beta r} w + f_{\beta r}) + \delta \mathcal{Q}_{\alpha r}(L_{\beta r} w + f_{\beta r}) + B_\alpha(L_\beta w + f_\beta). \tag{4.10}$$

Proof. It follows from formula (4.9) applied to $u := L_\beta w + f_\beta$, when $h_r = L_\beta L_r w + L_\beta f_r$ (remember f_r are independent of t), that the left-hand side of (4.10) equals

$$\mathcal{R}[c_{\alpha 0}(L L_\beta w + L f_\beta) - c_{\alpha r}(L_\beta L_r w + L_\beta f_r)]$$

$$+ \delta \mathcal{Q}_{\alpha 0}(L L_\beta w + L f_\beta) - \delta \mathcal{Q}_{\alpha r}(L_\beta L_r w + L_\beta f_r) + B_\alpha(L_\beta w + f_\beta),$$

which is easily seen to be equal to the right-hand side of (4.10). ∎

We derive from (4.10) one of the most important formulas.

PROPOSITION 4.4. *Let $\kappa \ge 0$ be an integer and $l \ge 2\kappa + 3$. Then*

(4.11)
$$w = v + \sum_{i=1}^{\kappa} \delta^i \sum_{|\alpha|=i} B_\alpha(L_\alpha w + f_\alpha) + \sum_{i=1}^{\kappa} \delta^i \sum_{|\alpha|=i+1} c_\alpha \mathcal{R}(L_\alpha w + f_\alpha) + \delta^{\kappa+1} r^{(\kappa)}$$

for all $t \in [0, d_1 T]$, where

$$r^{(\kappa)} = \sum_{|\alpha|=\kappa+1} \mathcal{Q}_\alpha(L_\alpha w + f_\alpha).$$

Proof. First notice that for $\varphi_0 := w - v$ we have

$$d\varphi_0 = d(w - v) = L\varphi_0 \, dA_0 + \delta(L_r w + f_r)\, dB_r,$$

which proves (4.11) for $\kappa = 0$.

Next we fix a $\kappa \ge 1$ and transform $r^{(i)}$, for $i = 0, \ldots, \kappa - 1$, by applying (4.10) with $\alpha = \beta$ and $|\alpha| = i + 1$ when $f_r \in W_p^{2|\beta|+3}$. Then we get

$$r^{(i)} = \sum_{|\alpha|=i+1, |\beta|=1} c_{\alpha\beta}\mathcal{R}(L_{\alpha\beta} w + f_{\alpha\beta}) + \delta \sum_{|\alpha|=i+1, |\beta|=1} \mathcal{Q}(L_{\alpha\beta} w + f_{\alpha\beta})$$

$$+ \sum_{|\alpha|=i+1} B_\alpha(L_\alpha w + f_\alpha) = \sum_{|\alpha|=i+1} B_\alpha(L_\alpha w + f_\alpha)$$

$$+ \sum_{|\alpha|=i+2} c_\alpha \mathcal{R}(L_\alpha w + f_\alpha) + \delta r^{(i+1)}.$$

This shows how $r^{(0)}, r^{(1)}, \ldots, r^{(\kappa)}$ are related to each other and certainly proves the proposition. ∎

Decomposition (4.11) looks very much like (2.6), the only difference being that the factors of δ^j depend on the approximating function w, and the coefficients of δ^j in the second term on the right contain B_α, which is not a power series in δ. However, observe that we have to estimate the difference $v-w$ only at the points $id_1\delta$ at which all B_α vanish.

Our next step is to "solve" (4.11) with respect to w by the method of successive iterations, that is, by substituting w given by (4.11) into the right-hand side of the same equation. In the process of doing so we encounter only one difficulty, when the second term on the right is plugged into the third and we have to develop expressions like $\mathcal{R}(B_\alpha u)$ into power series in δ. We transform these terms by using (4.8) and (4.10).

First we introduce the notation

$$w_\beta = L_\beta w + f_\beta;$$

observe that in these terms (4.10) is rewritten as

$$\mathcal{Q}_\alpha w_\beta = c_{\alpha r}\mathcal{R}w_{\beta r} + B_\alpha w_\beta + \delta\mathcal{Q}_{\alpha r}w_{\beta r}, \tag{4.12}$$

and note the following.

LEMMA 4.5. *If $\kappa \geq 0$ is an integer and $\alpha,\beta \in \mathcal{N}$ and $2(|\beta|+\kappa)+1 \leq l$, then*

$$\mathcal{R}(B_\alpha w_\beta) = \sum_{i=0}^{\kappa}\delta^i \sum_{|\gamma|=i} c_{\alpha 0\gamma}\mathcal{R}w_{\beta\gamma}$$

$$+\sum_{i=1}^{\kappa}\delta^i \sum_{|\gamma|=i-1} B_{\alpha 0\gamma}w_{\beta\gamma} + \delta^{\kappa+1}\sum_{|\gamma|=\kappa}\mathcal{Q}_{\alpha 0\gamma}w_{\beta\gamma}, \tag{4.13}$$

where for any multinumbers μ,ν

$$\sum_{|\gamma|=0} c_{\nu\gamma}\mathcal{R}w_{\mu\gamma} := c_\nu \mathcal{R}w_\mu, \qquad \sum_{|\gamma|=0} B_{\nu\gamma}w_{\mu\gamma} := B_\nu w_\mu,$$

$$\sum_{|\gamma|=0}\mathcal{Q}_{\nu\gamma}w_{\mu\gamma} := \mathcal{Q}_\nu w_\mu.$$

Proof. If $\kappa = 0$, (4.13) follows from (4.8). If $\kappa \geq 1$, by applying (4.12) repeatedly as in the proof of Proposition 4.4 we find

$$\mathcal{Q}_\alpha w_\beta = \sum_{i=0}^{\kappa-1}\delta^i \sum_{|\gamma|=i+1} c_{\alpha\gamma}\mathcal{R}w_{\beta\gamma}$$

$$+\sum_{i=0}^{\kappa-1}\delta^i \sum_{|\gamma|=i} B_{\alpha\gamma}w_{\beta\gamma} + \delta^\kappa \sum_{|\gamma|=\kappa}\mathcal{Q}_{\alpha\gamma}w_{\beta\gamma}.$$

We use this formula for $\alpha 0$ in place of α and finish the proof by referring to (4.8). ∎

Let $\mathcal{M}$ denote the set of multinumbers $\gamma_1\gamma_2\dots\gamma_i$ with $\gamma_j \in \{1,2,\dots,d_1\}$, $j = 1,2,\dots,i$, and integers $i \geq 1$.

LEMMA 4.6. *The following statements hold:*

(i) *Let* $\gamma = \gamma_1\gamma_2\dots\gamma_i \in \mathcal{M}$ *be such that* $|\gamma| = i \le 1 + l/2$. *Then*

$$L_\gamma = (-1)^{|\gamma|-1}L_{\gamma_1}\dots L_{\gamma_i}, \quad f_\gamma = (-1)^{|\gamma|-1}L_{\gamma_1}\dots L_{\gamma_{i-1}}f_{\gamma_i}.$$

(ii) *Let* $\beta, \gamma \in \mathcal{M}$ *be such that* $|\beta| + |\gamma| \le 1 + l/2$. *Then*

$$L_\beta L_\gamma = -L_{\beta\gamma}, \quad L_\beta f_\gamma = -f_{\beta\gamma}.$$

(iii) *Let* $\alpha \in \mathcal{N}$ *be such that* $\rho := |\alpha| \le 1 + l/2$. *Then there exist constants* $c(\gamma) = c(\alpha, \gamma) \in \{0, \pm 1\}$ *defined for all* $\gamma \in \mathcal{M}$ *with* $|\gamma| = \rho$ *such that*

$$L_\alpha = \sum_{\gamma\in\mathcal{M},|\gamma|=\rho} c(\gamma)L_\gamma, \quad f_\alpha = \sum_{\gamma\in\mathcal{M},|\gamma|=\rho} c(\gamma)f_\gamma. \tag{4.14}$$

Proof. Part (i) follows immediately from the definition of L_γ, f_γ by induction on $|\gamma|$. Part (i) obviously implies part (ii). Part (iii) clearly holds for $\alpha = 0$ and $\alpha = r \in \{1, \dots, d_1\}$. Assume that (4.14) holds for some $\alpha \in \mathcal{N}$, $|\alpha| < 1 + l/2$. Then

$$L_{\alpha r} = -L_\alpha L_r = -\sum_{|\gamma|=|\alpha|} c(\gamma)L_\gamma L_r = \sum_{|\gamma|=|\alpha|} c(\gamma)L_{\gamma r},$$

$$f_{\alpha r} = -L_\alpha f_r = -\sum_{|\gamma|=|\alpha|} c(\gamma)L_\gamma f_r = \sum_{|\gamma|=|\alpha|} c(\gamma)f_{\gamma r}$$

for $r \in \{1, 2, \dots, d_1\}$, and

$$L_{\alpha 0} = LL_\alpha = \sum_{r=1}^{d_1} L_r \sum_{\gamma\in\mathcal{M},|\gamma|=\rho} c(\gamma)L_\gamma = -\sum_{r=1}^{d_1} \sum_{\gamma\in\mathcal{M},|\gamma|=\rho} c(\gamma)L_{r\gamma},$$

$$f_{\alpha 0} = Lf_\alpha = \sum_{r=1}^{d_1} L_r \sum_{\gamma\in\mathcal{M},|\gamma|=\rho} c(\gamma)f_\gamma = -\sum_{r=1}^{d_1} \sum_{\gamma\in\mathcal{M},|\gamma|=\rho} c(\gamma)f_{r\gamma},$$

which proves (iii) by induction on $|\alpha|$. ∎

We introduce sequences $\sigma = (\beta_1, \beta_2, \dots, \beta_i)$ of multinumbers $\beta_j \in \mathcal{M}$, where $i \ge 1$ is any integer, and set $|\sigma| := |\beta_1| + |\beta_2| + \dots + |\beta_i|$. We consider also the "empty sequence" e of length $|e| = 0$, and denote the set of all these sequences by $\mathcal{J}$. For $\sigma = (\beta_1, \beta_2, \dots, \beta_i)$, $i \ge 1$, we define

$$S_\sigma = \mathcal{R}L_{\beta_1} \cdot \ \cdots \ \cdot \mathcal{R}L_{\beta_i},$$

and for $\sigma = e$ we set

$$S_e = \mathcal{R}.$$

Notice that S_σ involves $2|\sigma|$ derivatives with respect to x and a certain number of operators $\mathcal{R}$ which do not increase regularity. Therefore, basically, S_σ has the power of a differential operator of $2|\sigma|$th order. If we have a collection of functions g_ν indexed by a parameter ν taking values in a set A, then we use the notation

$$\sum_{\nu\in A}^{*} g_\nu$$

for any linear combination of g_ν with coefficients independent of the argument of g_ν and of δ. For instance,

$$\sum_A^* S_\sigma w_\gamma = \sum_{(\sigma,\gamma)\in A}^* S_\sigma w_\gamma = \sum_{(\sigma,\gamma)\in A} c(\sigma,\gamma) S_\sigma w_\gamma,$$

where $c(\sigma,\gamma)$ are certain constants independent of δ. These constants are allowed to change from one occurrence to another.

For functions $u = u(t,x) = u(\delta,t,x)$ depending on the parameter δ we write $u = O_m(\delta^\kappa)$ if

$$\sup_\delta \delta^{-\kappa} \sup_{t\in[0,d_1T]} \|u(t)\|_{m,p} < \infty.$$

We also use the following sets:

$$A(i) = \{(\sigma,\beta) : \sigma \in \mathcal{J}, \beta \in \mathcal{M}, |\sigma| + |\beta| \le i\},$$

$$B(i,j) = \{(\alpha,\beta) : \alpha \in \mathcal{N}, \beta \in \mathcal{M}, |\alpha| = i, |\beta| \le j\}.$$

LEMMA 4.7. *Let $\kappa, \mu \ge 0$ be integers and $\alpha \in \mathcal{N}, \beta \in \mathcal{M}$, $\sigma \in \mathcal{J}$. Assume that*

$$2(|\sigma| + |\beta| + \kappa) + \mu + 2 \le l. \tag{4.15}$$

Then

$$S_\sigma(B_\alpha w_\beta) = \sum_{i=0}^{\kappa} \delta^i \sum_{A(|\sigma|+|\beta|+i)}^* S_{\sigma_1} w_{\beta_1}$$

$$+ \sum_{i=1}^{\kappa} \delta^i \sum_{B(|\alpha|+i,|\sigma|+|\beta|+i-1)}^* B_{\alpha_1} w_{\beta_1} + O_\mu(\delta^{\kappa+1}). \tag{4.16}$$

Proof. For $\sigma = e$, when $S_\sigma = \mathcal{R}$, equation (4.16) turns out to be just a different form of (4.13), which is applicable since $2(|\beta| + \kappa) + 1 \le l$. Indeed, owing to Lemma 4.6(iii),

$$\sum_{|\gamma|=i} c_{\alpha 0\gamma} \mathcal{R} w_{\beta\gamma} = \sum_{A(|\sigma|+|\beta|+i)}^* S_{\sigma_1} w_{\beta_1},$$

$$\sum_{|\gamma|=i-1} B_{\alpha 0\gamma} w_{\beta\gamma} = \sum_{B(|\alpha|+i,|\sigma|+|\beta|+i-1)}^* B_{\alpha_1} w_{\beta_1}.$$

Furthermore, for $|\gamma| = \kappa$ (see Remark 3.1)

$$\mathcal{Q}_{\alpha 0\gamma} w_{\beta\gamma} = O_\mu(1) \quad \text{since} \quad 2(|\beta| + \kappa) + \mu + 2 \le l.$$

For $|\sigma| \ge 1$ we proceed by induction on the length $\ell(S_\sigma)$ of $S_\sigma = \mathcal{R}L_{\beta_1} \cdot \cdots \cdot \mathcal{R}L_{\beta_j}$, which we define to be j. If $\ell(S_\sigma) = 1$, then $S_\sigma = \mathcal{R}L_\nu$ for a $\nu \in \mathcal{M}$ with $\nu = \sigma$, and it suffices to notice that

$$S_\sigma(B_\alpha w_\beta) = \mathcal{R}L_\nu(B_\alpha w_\beta) = -\mathcal{R}(B_\alpha w_{\nu\beta}) = -S_e(B_\alpha w_{\beta'}), \tag{4.17}$$

where $\beta' = \nu\beta \in \mathcal{M}$ and $2(|\beta'| + \kappa) + \mu + 2 = 2(|\sigma| + |\beta| + \kappa) + \mu + 2 \le l$.

Assume that (4.16) holds whenever $\ell(S_\sigma) = s$, and take an S_σ such that $\ell(S_\sigma) = s+1$. Then $S_\sigma = \mathcal{R}L_\nu S_{\sigma'}$, where $\nu, \sigma' \in \mathcal{M}$, $|\nu| + |\sigma'| = |\sigma|$, and $\ell(S_{\sigma'}) = s$. Furthermore,

$$2(|\sigma'| + |\beta| + \kappa) + \mu' + 2 \le l,$$

where $\mu' = \mu + 2|\nu|$. By the induction hypothesis,

$$S_{\sigma'}(B_\alpha w_\beta) = \sum_{i=0}^{\kappa} \delta^i \sideset{}{^*}\sum_{A(|\sigma'|+|\beta|+i)} S_{\sigma_1} w_{\beta_1}$$

$$+ \sum_{i=1}^{\kappa} \delta^i \sideset{}{^*}\sum_{B(|\alpha|+i, |\sigma'|+|\beta|+i-1)} B_{\alpha_1} w_{\beta_1} + O_{\mu'}(\delta^{\kappa+1}).$$

We apply $\mathcal{R}L_\nu$ to both parts of this equality and take into account that $L_\nu w_{\beta_1} = -w_{\nu\beta_1}$ and $|\nu| + |\sigma'| = |\sigma|$. Then similarly to (4.17) we get that

$$S_\sigma(B_\alpha w_\beta) = \sum_{i=0}^{\kappa} \delta^i \sideset{}{^*}\sum_{A(|\sigma|+|\beta|+i)} S_{\sigma_1} w_{\beta_1}$$

$$+ \sum_{i=1}^{\kappa} \delta^i \sideset{}{^*}\sum_{B(|\alpha|+i, |\sigma|+|\beta|+i-1)} S_e(B_{\alpha_1} w_{\beta_1}) + O_\mu(\delta^{\kappa+1}). \tag{4.18}$$

Now we transform the second term on the right. Take $(\alpha_1, \beta_1) \in B(|\alpha| + i, |\sigma| + |\beta| + i - 1)$ and notice that then $|\beta_1| \le |\sigma| + |\beta| + i - 1$. Hence, by assumption (4.15),

$$2(|\beta_1| + \kappa - i) + \mu + 2 < l.$$

Therefore, by the result for $\sigma = e$,

$$S_e(B_{\alpha_1} w_{\beta_1}) = \sum_{j=0}^{\kappa-i} \delta^j \sideset{}{^*}\sum_{A(|\beta_1|+j)} S_{\sigma_2} w_{\beta_2}$$

$$+ \sum_{j=1}^{\kappa-i} \delta^j \sideset{}{^*}\sum_{B(|\alpha_1|+j, |\beta_1|+j-1)} B_{\alpha_2} w_{\beta_2} + O_\mu(\delta^{\kappa-i+1}).$$

We substitute this result into (4.18) and obtain (4.16) after collecting the coefficients of δ^{i+j} and noticing that, if $(\alpha_1, \beta_1) \in B(|\alpha| + i, |\sigma| + |\beta| + i - 1)$ and $(\alpha_2, \beta_2) \in B(|\alpha_1| + j, |\beta_1| + j - 1)$, then

$$(\alpha_2, \beta_2) \in B(|\alpha| + i + j, |\sigma| + |\beta| + i + j - 1).$$

This justifies the induction and finishes the proof of the lemma. $\square$

We remind the reader that throughout this section the assumptions of Theorem 2.2 are supposed to be satisfied, and in the following proposition we use the notation

$$B^*(i,j) = \bigcup_{i_1=1}^{i} B(i_1, j).$$

PROPOSITION 4.8. *For any $j = 0, 1, \ldots, k$ we have*

$$w = v + \sum_{i=1}^{j} \delta^i \sum_{A(2i)}^{*} S_\sigma v_\beta + \sum_{i=j+1}^{k} \delta^i \sum_{A(i+j+1)}^{*} S_{\sigma_1} w_{\beta_1}$$

$$+ \sum_{i=1}^{k} \delta^i \sum_{B^*(i,i+j)}^{*} B_{\alpha_1} w_{\beta_1} + O_m(\delta^{k+1}), \tag{4.19}$$

where $v_\beta := L_\beta v + f_\beta$.

Proof. By Proposition 4.4 (notice that, due to (2.5), $l \geq 2k + 3$ and $2(k + 1) + m + 2 \leq l$) we have

$$w = v + \sum_{i=1}^{k} \delta^i \sum_{|\beta|=i} B_\beta w_\beta + \sum_{i=1}^{k} \delta^i \sum_{|\beta|=i+1} c_\beta \mathcal{R} w_\beta + O_m(\delta^{k+1}),$$

which means that (4.19) holds for $j = 0$, since by Lemma 4.6(iii),

$$\sum_{|\beta|=i} B_\beta w_\beta = \sum_{|\beta|=i} B_\beta \sum_{\gamma \in \mathcal{M}, |\gamma|=i} c(\beta, \gamma) w_\gamma = \sum_{B^*(i,i)}^{*} B_{\alpha_1} w_{\beta_1},$$

$$\sum_{|\beta|=i+1} c_\beta \mathcal{R} w_\beta = \sum_{|\beta|=i+1} c_\beta \sum_{\gamma \in \mathcal{M}, |\gamma|=i+1} c(\beta, \gamma) \mathcal{R} w_\gamma = \sum_{A(i+1)}^{*} S_{\sigma_1} w_{\beta_1}.$$

Next, assume that $k \geq 1$ and that (4.19) holds for a $j \in \{0, \ldots, k-1\}$. Transform the first term with $i = j+1$ in the second sum on the right in (4.19) by using Lemma 4.7. To prepare the transformation take $(\sigma_1, \beta_1) \in A(2i) = A(i + j + 1)$ so that $|\sigma_1| + |\beta_1| \leq 2i$ and apply the operator $S_{\sigma_1} L_{\beta_1}$ to both parts of (4.11) with $k - i$ in place of κ. Then we obtain

$$S_{\sigma_1} w_{\beta_1} = S_{\sigma_1} v_{\beta_1} + \sum_{i_1=1}^{k-i} \delta^{i_1} \sum_{|\alpha_1|=i_1} S_{\sigma_1}(B_{\alpha_1} L_{\beta_1} w_{\alpha_1})$$

$$+ \sum_{i_1=1}^{k-i} \delta^{i_1} \sum_{|\alpha_1|=i_1+1} c_{\alpha_1} S_{\sigma_1} L_{\beta_1} \mathcal{R} w_{\alpha_1} + \delta^{k-i+1} r^{(k-i)},$$

where

$$r^{(k-i)} = \sum_{|\alpha|=k-i+1} S_{\sigma_1} L_{\beta_1} \mathcal{Q}_\alpha w_\alpha.$$

Owing to

$$l - 2(k - i + 1 + |\beta_1| + |\sigma_1|) \geq l - 2(k + i + 1)$$
$$\geq l - 2(2k + 1) \geq m + 2,$$

we have $r^{(k-i)} = O_m(1)$. By the way, this is the only place where we need l to be not smaller than $4+m+4k$. Hence by Lemma 4.6(iii),

$$S_{\sigma_1}w_{\beta_1} = S_{\sigma_1}v_{\beta_1} + \sum_{i_1=1}^{k-i}\delta^{i_1} \sideset{}{^*}\sum_{(\alpha_2,\beta_2)\in B(i_1,|\beta_1|+i_1)} S_{\sigma_1}(B_{\alpha_2}w_{\beta_2})$$

$$+\sum_{i_1=1}^{k-i}\delta^{i_1} \sideset{}{^*}\sum_{A(|\sigma_1|+|\beta_1|+i_1+1)} S_{\sigma_2}w_{\beta_2} + O_m(\delta^{k-i+1}) =: J_1+\cdots+J_4. \tag{4.20}$$

Now Lemma 4.7 with $k-i-i_1$ in place of κ and m in place of μ allows us to transform terms entering J_2. For $|\beta_2|\le|\beta_1|+i_1$ we have (remember that $(\sigma_1,\beta_1)\in A(2i)$)

$$2(|\sigma_1|+|\beta_2|+k-i-i_1)+m+2 \le 2(|\sigma_1|+|\beta_1|+k-i)+m+2$$
$$\le 2(i+k)+m+2 \le 4k+m+2 < l.$$

Therefore

$$S_{\sigma_1}(B_{\alpha_2}w_{\beta_2}) = \sum_{i_2=0}^{k-i-i_1}\delta^{i_2} \sideset{}{^*}\sum_{A(|\sigma_1|+|\beta_2|+i_2)} S_{\sigma_3}w_{\beta_3}$$
$$+\sum_{i_2=1}^{k-i-i_1}\delta^{i_2} \sideset{}{^*}\sum_{B(|\alpha_2|+i_2,|\sigma_1|+|\beta_2|+i_2-1)} B_{\alpha_3}w_{\beta_3} + O_m(\delta^{k-i-i_1+1}).$$

We plug this result into J_2 and, in order to collect the coefficients of $\delta^{i_1+i_2}$, notice that for $(\sigma_3,\beta_3)\in A(|\sigma_1|+|\beta_2|+i_2)$ and $(\alpha_2,\beta_2)\in B(i_1,|\beta_1|+i_1)$ it holds that

$$|\sigma_3|+|\beta_3| \le |\sigma_1|+|\beta_2|+i_2 \le |\sigma_1|+|\beta_1|+i_1+i_2.$$

Furthermore, if $(\alpha_3,\beta_3)\in B(|\alpha_2|+i_2,|\sigma_1|+|\beta_2|+i_2-1)$, then

$$|\alpha_3|=|\alpha_2|+i_2=i_1+i_2, \quad |\beta_3|\le|\sigma_1|+|\beta_2|+i_2-1<|\sigma_1|+|\beta_1|+i_1+i_2.$$

It follows that J_2 is written as

$$\sum_{i_1=1}^{k-i}\delta^{i_1}\left(\sideset{}{^*}\sum_{A(|\sigma_1|+|\beta_1|+i_1)} S_{\sigma_2}w_{\beta_2} + \sideset{}{^*}\sum_{B(i_1,|\sigma_1|+|\beta_1|+i_1)} B_{\alpha_2}w_{\beta_2}\right) + O_m(\delta^{k-i+1}),$$

which just amounts to saying that visually in the definition of J_2 one can erase S_{σ_1}, carry all differentiations in it onto w_{β_2}, and still preserve (4.20).

Then we see that

$$\delta^{j+1}\sideset{}{^*}\sum_{A(2j+2)} S_{\sigma_1}w_{\beta_1} = O_m(\delta^{k+1}) + \delta^{j+1}\sideset{}{^*}\sum_{A(2j+2)} S_{\sigma_1}v_{\beta_1}$$
$$+\sum_{i_1=1}^{k-j-1}\delta^{i_1+j+1}\left(\sideset{}{^*}\sum_{A(|\sigma_1|+|\beta_1|+i_1+1)} S_{\sigma_2}w_{\beta_2} + \sideset{}{^*}\sum_{B(i_1,|\sigma_1|+|\beta_1|+i_1)} B_{\alpha_2}w_{\beta_2}\right).$$

Next we notice again that, for $(\sigma_1,\beta_1)\in A(2j+2)$ and $|\sigma_2|+|\beta_2|\le|\sigma_1|+|\beta_1|+i_1+1$, we have $|\sigma_2|+|\beta_2|\le j+2+i_1+j+1$, whereas if $|\beta_2|\le|\sigma_1|+|\beta_1|+i_1$, then $|\beta_2|\le j+1+i_1+j+1$. Therefore, after changing $i_1+j+1\to i$ $(\ge j+2)$, we get

$$\delta^{j+1}\sum_{A(2j+2)}^{*}S_{\sigma_1}w_{\beta_1}=O_m(\delta^{k+1})+\delta^{j+1}\sum_{A(2j+2)}^{*}S_{\sigma_1}v_{\beta_1}$$

$$+\sum_{i=j+2}^{k}\delta^i\left(\sum_{A(i+j+2)}^{*}S_{\sigma_2}w_{\beta_2}+\sum_{B^*(i,i+j+1)}^{*}B_{\alpha_2}w_{\beta_2}\right).$$

This shows that the term with $i=j+1$ in the second sum on the right-hand side in (4.19) can be eliminated at the expense of changing j to $j+1$ in the other terms of (4.19). Thus the induction on j proves the proposition indeed. □

Now we finish the proof of Theorem 2.2. By taking $j=k$ in Proposition 4.8, we find

$$w=v+\sum_{i=1}^{k}\delta^i w^{(i)}+\sum_{B^*(k,2k)}c(\alpha,\beta,\delta)B_\alpha w_\beta+O_m(\delta^{k+1}), \tag{4.21}$$

where

$$w^{(i)}:=\sum_{A(2i)}^{*}S_\sigma v_\beta\in C_w([0,T],W_p^m),\quad i=1,2,\dots,k,$$

are independent of δ and $c(\alpha,\beta,\delta)$ are certain constants. It is not hard to follow our computations in order to see that

$$\sup_{t\in[0,d_1T]}\ \sup_{n,\delta=T/n}\delta^{-(k+1)}\|O_m(\delta^{k+1})(t,\cdot)\|_{m,p}\le N,$$

where the constant N depends only on d,d_1,T,K,k,m,p,l. After that, to finish the proof it remains only to recall that $B_\alpha(jd_1\delta)=0$ for all integers $j\ge0$ and

$$v(d_1t)=u(t),\quad w(d_1t)=u_n(t)\quad\forall t\in T_n=\left\{\frac{iT}{n}:i=0,1,2,\dots,n\right\}.$$

5. The case of time dependent coefficients. We consider here the Cauchy problem (1.1)–(1.2) for time dependent coefficients. We split, as before, the coefficients and the free terms into d_1 terms,

$$a^{ij}=\sum_{r=1}^{d_1}a_r^{ij},\quad a^i=\sum_{r=1}^{d_1}a_r^i,\quad a=\sum_{r=1}^{d_1}a_r,\quad f=\sum_{r=1}^{d_1}f_r;$$

define $\delta=T/n$, $t_i=t_i^n=\delta i$, $T_n=\{t_i:i=0,1,\dots,n\}$; and keep Assumptions 2.1 and 2.2. As before, we also denote $L_r:=a_r^{ij}D_{ij}+a_r^iD_i+a_r$.

One of the splitting-up approximations $u_n(t)$ for $t\in T_n$ is defined as follows. Let $\mathbb{S}_{st}^{(r)}$ be the operator mapping each function φ of an appropriate class into the solution of the problem

$$D_tv(t,x)=d_1L_rv(t,x)+d_1f_r(t,x),\quad t>s,\quad v(s,x)=\varphi(x).$$

Then the approximations are introduced according to

$$u_n(0) := u_0,$$

$$u_n(t_{i+1}) := \mathbb{S}^{(d_1)}_{t_{i\bar{d}},t_{i+1}} \dots \mathbb{S}^{(2)}_{t_{i1},t_{i2}} \mathbb{S}^{(1)}_{t_i,t_{i1}} u_n(t_i), \qquad i = 0, 1, 2, \dots, n, \tag{5.1}$$

where $t_{ij} := t_i + j\delta/d_1$ for $j = 1, 2, \dots, d_1 - 1$, $\bar{d} := d_1 - 1$.

There are many other ways to extend the splitting-up approximations (2.4) to PDEs with time dependent data. Along with (5.1) we also consider another approximation, which has the advantage that in each step we need to solve a time independent PDE, which is usually more convenient in practice than solving time dependent PDEs. This time we define the approximation u_n by

$$u_n(0) := u_0,$$

$$u_n(t^n_{i+1}) := \mathbb{S}^{(d_1)}_{\delta}(t^n_{i+1}) \dots \mathbb{S}^{(2)}_{\delta}(t^n_{i+1}) \mathbb{S}^{(1)}_{\delta}(t^n_{i+1}) u_n(t^n_i), \qquad i = 0, 1, 2, \dots, n, \tag{5.2}$$

where $\mathbb{S}^{(r)}_{\delta}(s)\varphi$ denotes the solution of the problem

$$D_t v(t) = L_r(s) v(t) + f(s), \quad t \geq 0, \qquad v(0) = \varphi, \tag{5.3}$$

with

$$L_r(s) := a^{ij}_r(s,x) D_{ij} + a^i_r(s,x) D_i + a_r(s,x)$$

for $r = 1, 2, \dots, d_1$. Notice that the coefficients of the operators $L_r(s)$ and $f(s)$ are "frozen" at time s; thus (5.3) is a Cauchy problem with time independent data.

We extend Theorem 2.2 as follows.

THEOREM 5.1. *Let $m \geq 0$ and $k \geq 0$ be any integers. Let Assumptions* 2.1 *and* 2.2 *hold with $l \geq 4 + m + 4k$. Let the splitting-up approximation u_n be defined by* (5.1) *or by* (5.2). *Then there exist functions $u^{(j)} \in C_w([0,T], W^m_p)$, $j = 1, 2, \dots, k$, $R^{(k)}_n \in C_w([0,T], W^m_p)$, such that*

$$\begin{aligned} u_n(t,x) &= u(t,x) + \delta u^{(1)}(t,x) \\ &\quad + \delta^2 u^{(2)}(t,x) + \dots + \delta^k u^{(k)}(t,x) + R^{(k)}_n(t,x) \end{aligned} \tag{5.4}$$

for all $t \in T_n$, $x \in \mathbb{R}^d$, and $n \geq 1$. The functions $u^{(j)}$, $j = 1, 2, \dots, k$, are independent of n, and

$$\sup_{t \in [0,T]} \|R^{(k)}_n(t)\|_{m,p} \leq N \delta^{k+1}$$

for all n, where N depends only on k, d, d_1, K, m, p, T.

Clearly Theorem 5.1 implies that we can again accelerate the convergence of the splitting-up approximations by considering

$$v_n(t,\cdot) := \sum_{j=0}^{k} b_j u_{2^j n}(t,\cdot), \quad t \in T_n,$$

where $u_{2^j n}$ for all $j = 0, 1, \dots, k$ are defined by either (5.1) or (5.2).

THEOREM 5.2. *Let $m \geq 0$ and $k \geq 0$ be any integers. Let Assumptions* 2.1 *and* 2.2 *hold with $l \geq 4+m+4k$. Then for all $n \geq 1$*

$$\max_{t\in T_n} \|v_n(t) - u(t)\|_{m,p} \leq N\delta^{k+1},$$

where N is a constant depending only on k, d, d_1, K, m, p, T.

Hence by Sobolev's theorem on embedding W_p^m into C^s, we immediately get the following result.

THEOREM 5.3. *Let $m \geq 0$ and $k \geq 0$ be any integers. Let Assumptions* 2.1 *and* 2.2 *hold with $l \geq 4+m+4k$. Let $s \geq 0$ be an integer such that $m \geq s + d/p$. Then for all $n \geq 1$*

$$\max_{t\in T_n} \sup_{x\in\mathbb{R}^d} \sum_{|\rho|\leq s} |D^\rho v_n(t,x) - D^\rho u(t,x)| \leq N\delta^{k+1},$$

where N is a constant depending only on k, d, d_1, K, m, s, p, T.

We prove Theorem 5.1 by adapting the proof of Theorem 2.2 to the time dependent case. If u_n is defined by (5.1), then we consider the problems

$$dv(t) = \big(L(A_0(t))v(t) + f(A_0(t))\big)\, dA_0(t), \quad v(0) = u_0, \tag{5.5}$$

$$dw(t) = \sum_{r=1}^{d_1} \big(L_r(A_0(t))w(t) + f_r(A_0(t))\big)\, dA_r(t), \quad w(0) = u_0, \tag{5.6}$$

where $A_0(t)$, $A_1(t), A_2(t), \ldots, A_{d_1}(t)$ are defined by (4.2) and (4.3), and $L(A_0(t))$, $L_r(A_0(t))$ mean that we substitute $A_0(t)$ in place of the time variable t of the coefficients of L, L_r.

If u_n is defined by (5.2), then we consider problems (5.5) and (5.6) with absolutely continuous functions $A_0, A_1, \ldots, A_{d_1}$, defined by the following requirements:

$$A_r(0) = 0, \quad \dot{A}_r \text{ is periodic with period } (d_1+1)\delta,$$

$$\dot{A}_r(t) = 1_{[r,r+1]}\left(\frac{t}{\delta}\right), \quad t \in [0, (d_1+1)\delta] \quad \text{for} \quad r = 0, 1, \ldots, d_1. \tag{5.7}$$

By virtue of Theorem 3.1, (5.5) and (5.6) admit unique solutions v and w, respectively. Clearly $v, w \in C_w([0, d'T], W_p^l)$, and

$$v(d't) = u(t), \quad w(d't) = u_n(t) \qquad \forall t \in T_n,$$

where $d' = d_1$ if $A_0, A_1, \ldots, A_{d_1}$ are defined by (4.2) and (4.3), and $d' = d_1 + 1$ if $A_0, A_1, \ldots, A_{d_1}$ are defined by (5.7). Therefore, our aim is to get an equality like (5.1) with v and w in place of u and u_n, respectively.

We treat the cases of two approximations simultaneously and warn the reader that, in order not to repeat the same arguments twice, we are going to use the same notation for some objects that have different meanings in each case. From now on, d' denotes d_1 if we consider the splitting-up approximations u_n defined by (5.1), and it denotes d_1+1 in the case of u_n defined by (5.2). We keep the notation $\mathcal{N}$ for the set of all multinumbers $\alpha = \alpha_1\alpha_2\ldots\alpha_j$ for $\alpha_i \in \{0, 1, 2, \ldots, d_1\}$ and integers $j \geq 1$. We also use the numbers c_α and the functions B_α, defined by (4.4), (4.5), and (4.6), with d' in place of d_1 in (4.5). Observe that, as is easy to see, Lemma 4.1 still holds with d' in place of d_1 in its formulation.

Let $\mathcal{R}f$ and $\bar{\mathcal{R}}f$ denote the solutions of the problems

$$du(t) = (Lu(t) + f(t))\,dt, \quad u(0) = 0,$$

and

$$dv(t) = (\bar{L}v(t) + f(t))\,dA_0(t), \quad v(0) = 0,$$

respectively, where $\bar{L} := L(A_0(t))$, the operator obtained from L by the substitution of $A_0(t)$ in place of t in the coefficients of L. Notice that $\bar{\mathcal{R}}$ depends on n when A_0 is defined by (5.7). Notice also that

$$\overline{\mathcal{R}f}(t,\cdot) := (\mathcal{R}f)(A_0(t),\cdot) = \bar{\mathcal{R}}\bar{f}(t,\cdot), \tag{5.8}$$

where $\bar{f}(t,\cdot) = f(A_0(t),\cdot)$. Let $\bar{Q}_\alpha f$ denote the solution of the problem

$$dv(t) = \bar{L}v(t)\,dA_0(t) + f(t)\,dB_\alpha(t), \quad v(0) = 0.$$

We modify the definition of L_α, f_α, used for time independent operators and free terms, as follows: $L_0 := 0$, $f_0 := 0$,

$$L_\gamma := L_r, \quad f_\gamma := f_r$$

for $\gamma = r \in \{1, 2, \ldots, d_1\}$, and

$$L_{\gamma 0} := LL_\gamma - \dot{L}_\gamma, \quad L_{\gamma r} := -L_\gamma L_r,$$

$$f_{\gamma 0} := Lf_\gamma - \dot{f}_\gamma, \quad f_{\gamma r} := -L_\gamma f_r \tag{5.9}$$

for $r = 1, 2, \ldots, d_1$, where $\dot{f}_\gamma := D_t f_\gamma$ and $\dot{L}_\gamma$ denotes the differential operator which we obtain from L_γ by taking the derivative in t of its coefficients. As is easy to see, L_γ and f_γ are well defined if $2(|\gamma| - 1) \le l$. We use the notation $\bar{L}_\gamma$ and $\bar{f}_\gamma$ for the operator which we obtain from L_γ by substituting $A_0(t)$ in place of t in its coefficients, and for the function obtained from f_γ by the same substitution, respectively. Then we have the following counterpart of Lemma 4.2.

Lemma 5.4. *Take some functions*

$$h \in L_p([0, d'T], W_p^1), \quad h_r \in L_p([0, d'T], W_p^1), \quad r = 0, 1, \ldots, d_1.$$

Let u be a solution of the "equation"

$$du = h_r\,dA_r = \sum_{r=0}^{d_1} h_r\,dA_r$$

with $u(0) \in W_p^1$. Assume that $Lu \in L_p([0, d'T], W_p^1)$. Then for any $\alpha \in \mathcal{N}$

$$\bar{\mathcal{R}}(B_\alpha h) = c_{\alpha 0}\bar{\mathcal{R}}h + \delta\bar{\mathcal{Q}}_{\alpha 0}h,$$

$$\bar{\mathcal{Q}}_\alpha u = \bar{\mathcal{R}}(c_{\alpha 0}\bar{L}u - c_{\alpha r}h_r) + \delta\bar{\mathcal{Q}}_{\alpha 0}\bar{L}u - \delta\bar{\mathcal{Q}}_{\alpha r}h_r + B_\alpha u.$$

The proof of this lemma is an obvious modification of that of Lemma 4.2.

Next, let us use the notation

$$w_\beta = \bar{L}_\beta w + \bar{f}_\beta.$$

Since $w \in C_w([0,d'T],W^l_p)$, the functions w_β are well defined for $2|\beta| \le l$. Under the same condition the coefficients of L_β and f_β have the first derivative in time, and these derivatives are under control. Furthermore, $dw_\beta = h_r\, dA_r$, where, as long as $2|\beta|+3 \le l$, the functions

$$h_0 = (\bar{L}\bar{L}_\beta - \bar{L}_{\beta 0})w + \bar{L}\bar{f}_\beta - \bar{f}_{\beta 0},$$

$$h_r = \bar{L}(\bar{L}_r w + \bar{f}_r), \quad r = 1,\dots,d_1,$$

are bounded W^1_p-valued functions on $[0,d'T]$.

Then in the same way as Lemma 4.2 was used to obtain Lemma 4.3, Proposition 4.4, and Lemma 4.5, we use Lemma 5.4 to get their counterparts, formulated as follows.

LEMMA 5.5. *Let $\alpha,\beta \in \mathcal{N}$. If $2|\beta|+3 \le l$, then*

$$\bar{\mathcal{Q}}_\alpha w_\beta = c_{\alpha r}\bar{\mathcal{R}} w_{\beta r} + \delta \bar{\mathcal{Q}}_{\alpha r} w_{\beta r} + B_\alpha w_\beta.$$

PROPOSITION 5.6. *Let $\kappa \ge 0$ be an integer and $l \ge 2\kappa+3$. Then*

$$w = v + \sum_{i=1}^{\kappa}\delta^i \sum_{|\alpha|=i} B_\alpha w_\alpha + \sum_{i=1}^{\kappa}\delta^i \sum_{|\alpha|=i+1} c_\alpha \bar{\mathcal{R}} w_\alpha + \delta^{\kappa+1}\sum_{|\alpha|=\kappa+1}\bar{\mathcal{Q}}_\alpha w_\alpha. \tag{5.10}$$

LEMMA 5.7. *If $\kappa \ge 0$ is an integer, $\alpha,\beta \in \mathcal{N}$, and $2(|\beta|+\kappa)+1 \le l$, then*

$$\bar{\mathcal{R}}(B_\alpha w_\beta) = \sum_{i=0}^{\kappa}\delta^i \sum_{|\gamma|=i} c_{\alpha 0\gamma}\bar{\mathcal{R}} w_{\beta\gamma}$$

$$+\sum_{i=1}^{\kappa}\delta^i \sum_{|\gamma|=i-1} B_{\alpha 0\gamma} w_{\beta\gamma} + \delta^{\kappa+1}\sum_{|\gamma|=\kappa}\bar{\mathcal{Q}}_{\alpha 0\gamma} w_{\beta\gamma},$$

where for any multinumbers μ,ν

$$\sum_{|\gamma|=0} c_{\nu\gamma}\bar{\mathcal{R}} w_{\mu\gamma} := c_\nu \bar{\mathcal{R}} w_\mu, \quad \sum_{|\gamma|=0} B_{\nu\gamma} w_{\mu\gamma} := B_\nu w_\mu,$$

$$\sum_{|\gamma|=0}\bar{\mathcal{Q}}_{\nu\gamma} w_{\mu\gamma} := \bar{\mathcal{Q}}_\nu w_\mu.$$

In order to iterate (5.10) we introduce the following class of indices. We say that

$$\beta = \gamma^\nu := \gamma_1^{\nu_1}\gamma_2^{\nu_2}\dots\gamma_j^{\nu_j} \tag{5.11}$$

is a *graded multinumber* of length $|\beta| := j+\nu_1+\nu_2+\dots+\nu_j$ if $\gamma_i \in \{1,2,\dots,d_1\}$; $\nu_i \ge 0$ is any integer for $i=1,2,\dots,j$, where $j \ge 1$ is any integer. If $\nu_i = 0$ for some i, then we also write γ_i in place of γ_i^0 in (5.11). Let $\mathcal{K}$ denote the set of all graded multinumbers. For each $\beta = \gamma^\nu = \gamma_1^{\nu_1}\gamma_2^{\nu_2}\dots\gamma_j^{\nu_j} \in \mathcal{K}$ of length $|\beta| \le 1+l/2$ we introduce the following operators and functions:

$$L_\beta = L_{\gamma^\nu} := (-1)^{|\beta|-1} L^{(\nu_1)}_{\gamma_1} L^{(\nu_2)}_{\gamma_2}\cdot\dots\cdot L^{(\nu_j)}_{\gamma_j},$$

$$f_\beta = f_{\gamma^\nu} := (-1)^{|\beta|-1} L^{(\nu_1)}_{\gamma_1}\cdot\dots\cdot L^{(\nu_j-1)}_{\gamma_{j-1}} f^{(\nu_j)}_{\gamma_j}, \tag{5.12}$$

where $f_r^{(s)} := D_t^s f_r$ and $L_r^{(s)}$ denotes the operator which we obtain from L_r by applying the derivation D_t^s to each of its coefficients. By definition, $f_r^{(0)} = f_r$ and $L_r^{(0)} = L_r$. It is easy to see that for $\beta \in \mathcal{N}$, when $\beta = \beta^0 \in \mathcal{K}$, definitions (5.12) are consistent with (5.9).

LEMMA 5.8. *The following statements hold:*

(i) *Let $\beta, \gamma \in \mathcal{K}$ be such that $|\beta| + |\gamma| \le 1 + l/2$. Then*

$$L_\beta L_\gamma = -L_{\beta\gamma}, \quad L_\beta f_\gamma = -f_{\beta\gamma}.$$

(ii) *Let $\alpha \in \mathcal{N}$ be such that $\rho := |\alpha| \le 1 + l/2$. Then there exist constants $c(\gamma) = c(\alpha, \gamma) \in \{0, \pm 1, \pm 2, \dots\}$ defined for all $\gamma \in \mathcal{K}$ with $|\gamma| = \rho$, such that*

$$L_\alpha = \sum_{\gamma \in \mathcal{K}, |\gamma| = \rho} c(\gamma) L_\gamma, \quad f_\alpha = \sum_{\gamma \in \mathcal{K}, |\gamma| = \rho} c(\gamma) f_\gamma. \tag{5.13}$$

Proof. Part (i) follows immediately from the definition (5.12) of L_β, f_β. Part (ii) clearly holds for $\alpha = 0$ and $\alpha = r \in \{1, \dots, d_1\}$. Assume that (5.13) holds for some $\alpha \in \mathcal{N}$, $|\alpha| < 1 + l/2$. Then

$$L_{\alpha r} = -L_\alpha L_r = -\sum_{\beta \in \mathcal{K}, |\beta| = |\alpha|} c(\beta) L_\beta L_r = \sum_{\beta \in \mathcal{K}, |\beta| = |\alpha|} c(\beta) L_{\beta r},$$

$$f_{\alpha r} = -L_\alpha f_r = -\sum_{\beta \in \mathcal{K}, |\beta| = |\alpha|} c(\beta) L_\beta f_r = \sum_{\beta \in \mathcal{K}, |\beta| = |\alpha|} c(\beta) f_{\beta r}$$

for $r \in \{1, 2, \dots, d_1\}$, and

$$L_{\alpha 0} = L L_\alpha - \dot{L}_\alpha = \sum_{r=1}^{d_1} \sum_{\beta \in \mathcal{M}, |\beta| = \rho} c(\beta) L_r L_\beta - \sum_{\gamma^\nu \in \mathcal{M}, |\gamma^\nu| = \rho} c(\gamma^\nu) \dot{L}_{\gamma^\nu},$$

$$f_{\alpha 0} = L f_\alpha - \dot{f}_\alpha = \sum_{r=1}^{d_1} \sum_{\beta \in \mathcal{M}, |\beta| = \rho} c(\beta) L_r f_\beta - \sum_{\gamma^\nu \in \mathcal{M}, |\gamma^\nu| = \rho} c(\gamma^\nu) \dot{f}_{\gamma^\nu}.$$

Hence by using assertion (i) and noticing that

$$\dot{L}_{\gamma^\nu} = \sum_{|\mu|=1} L_{\gamma^{\nu+\mu}}, \quad \dot{f}_{\gamma^\nu} = \sum_{|\mu|=1} f_{\gamma^{\nu+\mu}},$$

we get (5.13) for αr with $r = 0, 1, \dots, d_1$. Thus the induction on the length of α completes the proof. $\square$

For $\beta \in \mathcal{K}$ we write $\bar{L}_\beta$ and $\bar{f}_\beta$, when the time change $A_0(t)$ is done in the coefficients of L_β and in f_β. We set $w_\gamma := \bar{L}_\gamma w + \bar{f}_\gamma$ for $\gamma \in \mathcal{K}$, $|\gamma| \le 1 + l/2$. Notice that Lemma 5.8 has an obvious translation in terms of these functions. Namely, by Lemma 5.8(ii) for every $\alpha \in \mathcal{N}$ such that $\rho := |\alpha| \le 1 + l/2$ there exist constants $c(\gamma) = c(\alpha, \gamma) \in \{0, \pm 1, \pm 2, \dots\}$ defined for all $\gamma \in \mathcal{K}$ with $|\gamma| = \rho$ such that

$$w_\alpha = \sum_{\gamma \in \mathcal{K}, |\gamma| = \rho} c(\gamma) w_\gamma.$$

For every integer $i \ge 1$ we introduce finite sequences $\sigma := (\beta_1, \beta_2, \dots, \beta_i)$ of graded multinumbers $\beta_i \in \mathcal{K}$, and we set $|\sigma| := |\beta_1| + |\beta_2| + \dots + |\beta_i|$. We also introduce the empty sequence e of length $|e| := 0$. The set of all these sequences is denoted by $\mathcal{I}$.

For $\sigma = (\beta_1, \beta_2, \dots, \beta_i)$ with $|\sigma| \le 1 + l/2$ we define

$$S_\sigma := \mathcal{R}L_{\beta_1}\mathcal{R}L_{\beta_2}\cdot\dots\cdot\mathcal{R}L_{\beta_i}, \quad \bar{S}_\sigma := \bar{\mathcal{R}}\bar{L}_{\beta_1}\bar{\mathcal{R}}\bar{L}_{\beta_2}\cdot\dots\cdot\bar{\mathcal{R}}\bar{L}_{\beta_i},$$

and for $|\sigma| = 0$ we set

$$S_e := \mathcal{R}, \quad \bar{S}_e := \bar{\mathcal{R}}.$$

Notice that for any $g \in L_p([0,T], W_p^{2|\sigma|})$

$$\bar{S}_\sigma \bar{g}(t,\cdot) = (S_\sigma g)(A_0(t),\cdot), \tag{5.14}$$

where $\bar{g}(t,\cdot) := g(A_0(t),\cdot)$. This follows from (5.8) by induction on $|\sigma|$. In order to formulate the counterparts of Lemma 4.7 and Proposition 4.8 we use the following sets:

$$A(i) = \{(\sigma,\beta) : \sigma \in \mathcal{I}, \beta \in \mathcal{K}, |\sigma| + |\beta| \le i\},$$

$$B(i,j) = \{(\alpha,\beta) : \alpha \in \mathcal{N}, \beta \in \mathcal{K}, |\alpha| = i, |\beta| \le j\},$$

$$B^*(i,j) = \bigcup_{i_1=1}^{i} B(i_1,j).$$

Remember that if g_ν is a collection of functions indexed by a parameter ν taking values in a set A, then $\sum^*_{\nu\in A} g_\nu$ means any linear combination of g_ν with coefficient independent of the argument of g_ν and of δ.

LEMMA 5.9. *Let $\sigma \in \mathcal{I}$, $\kappa, \mu \ge 0$ be integers, and $\alpha \in \mathcal{N}, \beta \in \mathcal{K}$. Assume that*

$$2(|\sigma| + |\beta| + \kappa) + \mu + 2 \le l.$$

Then

$$\bar{S}_\sigma(B_\alpha w_\beta) = \sum_{i=0}^{\kappa} \delta^i \sum\nolimits^*_{A(|\sigma|+|\beta|+i)} \bar{S}_{\sigma_1} w_{\beta_1}$$

$$+ \sum_{i=1}^{\kappa} \delta^i \sum\nolimits^*_{B(|\alpha|+i, |\sigma|+|\beta|+i-1)} B_{\alpha_1} w_{\beta_1} + O_\mu(\delta^{\kappa+1}).$$

Proof. We can derive this lemma from Lemma 5.7 in the same way that we proved Lemma 4.7. We need only use the sets $\mathcal{K}$ and $\mathcal{I}$ in place of $\mathcal{M}$ and $\mathcal{J}$, and the operators $\bar{\mathcal{R}}$, $\bar{L}_\nu$, $\bar{S}_\sigma$ for $\nu \in \mathcal{K}$, $\sigma \in \mathcal{I}$, in place of $\mathcal{R}$, L_ν, S_σ for $\nu \in \mathcal{M}$, $\sigma \in \mathcal{J}$, respectively. ∎

PROPOSITION 5.10. *Let $k, m \ge 0$ be integers, and*

$$4 + m + 4k \le l.$$

Then for any $j = 0, 1, \dots, k$ we have

$$w = v + \sum_{i=1}^{j} \delta^i \sum\nolimits^*_{A(2i)} \bar{S}_\sigma v_\beta + \sum_{i=j+1}^{k} \delta^i \sum\nolimits^*_{A(i+j+1)} \bar{S}_{\sigma_1} w_{\beta_1}$$

$$+ \sum_{i=1}^{k} \delta^i \sum\nolimits^*_{B^*(i,i+j)} B_{\alpha_1} w_{\beta_1} + O_m(\delta^{k+1}),$$

where $v_\beta := \bar{L}_\beta v + \bar{f}_\beta$.

Proof. The proof of this proposition is a straightforward translation of the proof of the corresponding proposition, Proposition 4.8, in the time independent case. To make this translation we use the sets $\mathcal{K}$ and $\mathcal{I}$ in place of $\mathcal{M}$ and $\mathcal{J}$, and the operators $\bar{\mathcal{R}}$, $\bar{L}_\nu$, $\bar{S}_\sigma$ for $\nu \in \mathcal{K}$, $\sigma \in \mathcal{I}$, in place of $\mathcal{R}$, L_ν, S_σ for $\nu \in \mathcal{M}$, $\sigma \in \mathcal{J}$, respectively. ∎

Now we can finish the proof of Theorem 5.1 as follows. Taking $j = k$ in Proposition 5.10, we get

$$w = v + \sum_{i=1}^{j} \delta^i \sum_{A(2i)} c(\sigma, \beta) \bar{S}_\sigma v_\beta + \sum_{B^*(k,2k)} c(\alpha, \beta, \delta) B_{\alpha_1} w_{\beta_1} + r_\delta, \tag{5.15}$$

where $c(\sigma, \beta)$, $c(\alpha, \beta, \delta)$ are certain constants, r_δ is a function in $C_w([0, d'T], W_p^m)$ for each δ, and

$$\sup_{t \in [0,d'T]} \sup_{n, \delta = T/n} \delta^{-(k+1)} \|r_\delta(t, \cdot)\|_{m,p} \le N.$$

Observe that, in contrast with (4.21), the functions v and $\bar{S}_\sigma v_\beta$ in (5.15) may depend on δ. To proceed further, define $R_n^{(k)}(t, x) := r_\delta(d't, x)$, and

$$u^{(i)} := \sum_{A(2i)} c(\sigma, \beta) S_\sigma u_\beta, \quad i = 1, 2, \dots, k,$$

where $u_\beta := L_\beta u + f_\beta$. Then by virtue of equality (5.14) and the fact that $v(t) = u(A_0(t))$, from (5.15) we get

$$w(t, \cdot) = u(A_0(t), \cdot) + \sum_{i=1}^{j} \delta^i u^{(i)}(A_0(t), \cdot)$$

$$+ \sum_{B^*(k,2k)} c(\alpha, \beta, \delta) B_{\alpha_1}(t) w_{\beta_1}(t, \cdot) + R_n^{(k)} \left(\frac{t}{d'}, \cdot \right).$$

Substituting $d't$ in place of t, we get the required representation (5.1) by taking into account that

$$w(d't) = u_n(t), \quad A_0(d't) = t, \quad B_{\alpha_1}(d't) = 0 \quad \forall t \in T_n.$$

Remark 5.1. Let $1 \le j \le d_1$. Then Theorems 5.1, 5.2, and 5.3 also hold when the operator $\mathbb{S}_\delta^{(r)}(t_{i+1}^n)$ is replaced with $\mathbb{S}_\delta^{(r)}(t_i^n)$ for every $r = 1, 2, \dots, j$ in the definition (5.2) of the splitting-up approximation u_n. To see this we need only repeat the proof of the previous theorem with A_j in place of A_0 in (5.6) and with A_0 and A_j interchanged in (5.5).

Acknowledgment. We express our sincere gratitude to the referees for useful criticism which helped improve the presentation.

PARTIAL REGULARITY FOR A SELECTIVE SMOOTHING FUNCTIONAL FOR IMAGE RESTORATION IN BV SPACE*

YUNMEI CHEN†, M. RAO†, Y. TONEGAWA‡, AND T. WUNDERLI§

Abstract. In this paper we study the partial regularity of a functional on BV space proposed by Chambolle and Lions [*Numer. Math.*, 76 (1997), pp. 167–188] for the purposes of image restoration. The functional is designed to smooth corrupted images using isotropic diffusion via the Laplacian where the gradients of the image are below a certain threshold ϵ and retain edges where gradients are above the threshold using the total variation. Here we prove that if the solution $u \in BV$ of the model minimization problem, defined on an open set Ω, is such that the Lebesgue measure of the set where the gradient of u is below the threshold ϵ is positive, then there exists a nonempty open region E for which $u \in C^{1,\alpha}$ on E and $|\nabla u| < \epsilon$, and $|\nabla u| \geq \epsilon$ on $\Omega \backslash E$ almost everywhere. Thus we indeed have smoothing where $|\nabla u| < \epsilon$.

Key words. bounded variation, selective smooothing, image processing, image restoration, noise removal, partial regularity

1. Introduction.

In the last decade PDE and variational method based diffusion models have grown significantly to tackle the problems of image restoration, reconstruction, and inpainting. The challenging aspect of these problems is to design methods which can filter selectively the noise without losing significant features.

Total variation (TV) based regularization, as first proposed by Rudin, Osher, and Fatemi [17], has proved to be an invaluable tool for preserving edges while reconstructing an image. This method has been studied extensively in [1, 7, 4, 20, 2, 5, 19, 16] and a sequence of papers in the book of [2]. The definition of the total variation seminorm for $u \in L^1(\Omega)$, given by

$$TV(u) = \sup \left\{ \int_\Omega u \,\mathrm{div}(\varphi) dx : \varphi \in C_0^1(\Omega, \mathbf{R}^n), |\varphi| \leq 1 \right\},$$

does not require differentiability or even continuity of u. Thus images with discontinuities are allowed as solutions in the space of $BV(\Omega)$, which is the space of the functions $u \in L^1(\Omega)$ with $TV(u) < \infty$. Moreover, the diffusion resulting from minimizing TV norm is strictly orthogonal to the gradient of the image, and tangential to the edges. This is important for preserving edges while image is smoothed. However, TV-based denoising sometimes causes a *staircasing* effect [6, 7, 8]. The restored image by this regularization can consequently be blocky and even contain false edges.

To overcome this problem and make the filter self-adjustable in order to reap the benefits of isotropic smoothing and TV based regularization, Chambolle and Lions [7]

proposed minimizing the following energy functional for image restoration:

$$\frac{1}{2a}\int_{|\nabla u|<a}|\nabla u|^2dx+\int_{|\nabla u|\geq a}\left(|\nabla u|-\frac{a}{2}\right)+\frac{1}{2}\int_{\Omega}(u-I)^2dx,$$

where I is an observed noisy image, and we want to recover an image u from I, which is related to I by

$$I=u+noise.$$

Using the above functional we then expect to have isotropic diffusion where the image is more uniform ($|\nabla u|<a$) and feature preservation via TV-based diffusion where the boundaries of features are present (the locations where the image gradients most likely have high magnitude: $|\nabla u|\geq a$). It has been shown numerically in [7] that this model is successful in restoring images where homogeneous regions are separated by distinct edges. The purpose of this paper is to prove this mathematically. Our partial regularity results for $a=1$ (without loss of generality) below indicates that the restored image through this model is smooth on the region with smaller gradients. The edges appear at the points where the gradient is larger.

More precisely, consider the problem

$$\min_{u\in BV(\Omega)\cap L^2(\Omega)}\left\{\int_{\Omega}\varphi(Du)+\frac{1}{2}\int_{\Omega}(u-I)^2dx\right\}, \tag{1.1}$$

where φ is the C^1 convex function defined on $\mathbf{R}^n$

$$\varphi(p)=\begin{cases}\frac{1}{2}|p|^2 & \text{if } |p|<1,\\ |p|-\frac{1}{2} & \text{if } |p|\geq 1,\end{cases}$$

$\Omega\subset\mathbf{R}^n$ is a bounded domain with Lipschitz boundary, and $I\in L^\infty(\Omega)\cap BV(\Omega)$ is given.

For $u\in BV(\Omega)$ the gradient of u is a measure Du; it can be decomposed into its absolutely continuous and singular parts with respect to Lebesgue measure, that is,

$$Du=\nabla u\,dx+D^su.$$

See [10] for a complete discussion. Then we define ([12] or [9])

$$J(u)\equiv\int_{\Omega}\varphi(Du)\equiv\int_{\Omega}\varphi(\nabla u)dx+\int_{\Omega}|D^su|$$

with

$$\int_{\Omega}|D^su|\equiv\int_{\Omega}d|D^su|=|D^su|(\Omega).$$

It is important to note ([21] or [12]) that the functional J can also be written as

$$J(u)=\sup_{\phi\in C_0^1(\Omega,\mathbf{R}^n)}\left\{-\int_{\Omega}\left(\frac{1}{2}|\phi|^2+u\,\mathrm{div}(\phi)\right)dx:|\phi(x)|\leq 1\ \forall x\in\Omega\right\}.$$

Using this, we see that the functional J is lower semicontinuous with respect to convergence in $L^1(\Omega)$. Then by a standard argument we can show that there is a unique solution $u \in BV(\Omega) \cap L^2(\Omega)$ to (1.1). Now we are interested as to whether this solution $u \in BV$ is smooth on the region where $|\nabla u| < 1$. If so, it shows that the denoising governed by (1.1) smoothes out lower gradients while preserving the boundaries of features, which are the discontinuities in an image.

We now state the two main partial regularity results of this paper.

THEOREM 1.1. *If u is the solution to (1.1), then for any given $0 < \mu < 1$ there exist positive constants ϵ_0 and κ_0 depending only on n and μ such that if*

$$\frac{1}{|B_r|}\int_{B_r(a)} |Du - l| \le \epsilon_0$$

holds for some ball $B_r(a) \subset\subset \Omega$ and for some $l \in \mathbf{R}^n$, with

$$rC\left(1 + \|I\|_{L^\infty(\Omega)}\right) < \kappa_0 \quad \text{and} \quad |l| < 1 - 2\mu,$$

for some constant C depending only on n and Ω, then

$$|D^s u|(B_{r/2}(a)) = 0 \quad \text{and} \quad |\nabla u| < 1 - \mu \quad \text{on} \quad B_{r/2}(a)$$

and u solves

$$-\Delta u = I - u \quad \text{on} \quad B_{r/2}(a).$$

Hence $u \in C^{1,\alpha}(B_{r/2}(a))$ for any $\alpha < 1$.

THEOREM 1.2. *Let u be as in Theorem (1.1). If $\mathcal{L}^n(\{|\nabla u| < 1\}) > 0$, then there exists a nonempty open region E on which u is $C^{1,\alpha}$, $|\nabla u| < 1$, and u solves*

$$-\Delta u = I - u \quad \text{on} \quad E.$$

In addition we have $|\nabla u| \ge 1$ a.e. on $\Omega \setminus E$.

It is actually straightforward to show that Theorem 1.2 is a direct consequence of Theorem 1.1. Thus from Theorem 1.2, we do indeed have smoothing where $|\nabla u| < 1$.

Here we should point out that partial regularity results were obtained in [3] for minimizers in $BV(\Omega)$ of functionals of the form $\int_\Omega (F(x, Du) + G(x, u))$, where $F(x, p)$ is a convex function in p with $c_1|p| \le F(x, p) \le c_2(1 + |p|)$ for all $p \in \mathbf{R}^n$, F is locally Hölder continuous in x, and $G(x, z)$ satisfies Hölder continuity conditions in both x and z. In our case, $G(x, z) = 1/2(z - I(x))^2$ with only the stated assumption on I, and therefore their results cannot directly be applied in our case. Moreover, our approach is quite different from theirs and can be applied to more general cases.

The partial regularity results for the flow associated with the minimization problem (1) is also discussed in [15] for more general φ. However, these hold only for $\Omega \subset \mathbf{R}^n$ for $n = 1$ and $n = 2$. We also apply some different techniques to get our results.

2. Proof of Theorems 1.1 and 1.2. First we will show that the solution u to (1.1) is in $L^\infty(\Omega)$. To prove this we could consider the time evolution problem corresponding to (1.1), prove an L^∞ bound for the time-dependent solution $u(x, t)$, and then consider the time-asymptotic limit u, which is the solution to (1.1). We would then conclude that $u \in L^\infty(\Omega)$. The following, however, provides a proof of this without having to consider the time evolution of (1.1).

LEMMA 2.1. *If u is the solution to (1.1), then $u \in L^\infty(\Omega)$. In fact, we have $\|u\|_{L^\infty(\Omega)} \le \|I\|_{L^\infty(\Omega)}$.*

Proof. Let φ_ϵ be defined on $\mathbf{R}^n$ by

$$\varphi_\epsilon(p) = \begin{cases} \dfrac{1}{2}|p|^2 & \text{if } |p| < 1, \\ \dfrac{1}{1+\epsilon}|p|^{1+\epsilon} + \left(\dfrac{1}{2} - \dfrac{1}{1+\epsilon}\right) & \text{if } |p| \geq 1 \end{cases}$$

for $\epsilon > 0$, and consider the following minimization problem:

$$\min_{u \in W^{1,1+\epsilon}(\Omega) \cap L^2(\Omega)} \left\{ \int_\Omega \varphi_\epsilon(\nabla u) + \frac{1}{2} \int_\Omega (u - I)^2 dx \right\}.$$

By standard methods, there is a unique solution u_ϵ to this problem. We follow a standard truncation argument where we fix ϵ and $t \geq 0$ and let $v = \min(u_\epsilon, t)$. Noting that $v \in W^{1,1+\epsilon}(\Omega) \cap L^2(\Omega)$ with

$$\nabla v = \begin{cases} \nabla u_\epsilon & \text{if } u_\epsilon < t, \\ 0 & \text{if } u_\epsilon \geq t, \end{cases}$$

we have

$$\int_\Omega \varphi_\epsilon(\nabla u_\epsilon) + \frac{1}{2} \int_\Omega (u_\epsilon - I)^2\, dx \leq \int_\Omega \varphi_\epsilon(\nabla v) + \frac{1}{2} \int_\Omega (v - I)^2 dx, \tag{2.1}$$

and thus after subtracting

$$\int_{\{u_\epsilon \geq t\}} \varphi_\epsilon(\nabla u_\epsilon)\, dx + \int_{\{u_\epsilon \geq t\}} (u_\epsilon - I)^2 dx \leq \int_{\{u_\epsilon \geq t\}} (t - I)^2 dx.$$

Hence

$$\int_{\{u_\epsilon \geq t\}} (u_\epsilon - I)^2 dx \leq \int_{\{u_\epsilon \geq t\}} (t - I)^2 dx.$$

But setting $t = \|I\|_{L^\infty(\Omega)}$ we see that if ess sup $u_\epsilon > t$, then

$$\int_{\{u_\epsilon \geq t\}} (t - I)^2 dx < \int_{\{u_\epsilon \geq t\}} (u_\epsilon - I)^2 dx,$$

which contradicts the above, hence ess sup $u_\epsilon \leq \|I\|_{L^\infty(\Omega)}$. Applying a similar argument to $v = \max(u_\epsilon, -t)$ for $t = \|I\|_{L^\infty(\Omega)}$ we get ess inf $u_\epsilon \geq -\|I\|_{L^\infty(\Omega)}$ and thus $\|u_\epsilon\|_{L^\infty(\Omega)} \leq \|I\|_{L^\infty(\Omega)}$. Furthermore, letting $v = 0$ in (2.1) we see that u_ϵ is bounded in $W^{1,1+\epsilon}(\Omega) \cap L^2(\Omega) \subset BV(\Omega) \cap L^2(\Omega)$ independent of ϵ. Thus there is a $\tilde{u} \in BV(\Omega) \cap L^2(\Omega)$ and a subsequence of $\{u_\epsilon\}$, still denoted by $\{u_\epsilon\}$, such that $u_\epsilon \to \tilde{u}$ strongly in $L^1(\Omega)$, $u_\epsilon \rightharpoonup \tilde{u}$ weakly in $L^2(\Omega)$, and $u_\epsilon \to \tilde{u}$ almost everywhere (a.e.) in Ω. Letting $\epsilon \to 0$ in (2.1), noting that $\varphi(p) \leq \varphi_\epsilon(p)$ for all p, $\int_\Omega \varphi_\epsilon(\nabla v) \to \int_\Omega \varphi(\nabla v)$, lower semicontinuity of the functional $\int_\Omega \varphi(\nabla u)$ defined on $BV(\Omega)$, and weak lower semicontinuity of the second term on the left-hand side, we get

$$\int_\Omega \varphi(\nabla \tilde{u}) + \frac{1}{2} \int_\Omega (\tilde{u} - I)^2 dx \leq \int_\Omega \varphi(\nabla v) + \frac{1}{2} \int_\Omega (v - I)^2 dx$$

for all $v \in W^{1,1+\epsilon}(\Omega) \cap L^2(\Omega)$. We now note [12] that for any $v \in BV(\Omega) \cap L^2(\Omega)$ there exists a sequence v_n in $C^\infty(\overline{\Omega})$ such that

$$\int_\Omega \varphi(\nabla v_n) dx \to \int_\Omega \varphi(\nabla v)$$

and $v_n \to v$ in $L^1(\Omega)$, and since $v \in L^2(\Omega)$ from the construction of v_n [12] we can also take $v_n \to v$ in $L^2(\Omega)$. Therefore we see that the above holds for all $v \in BV(\Omega) \cap L^2(\Omega)$ as well. Hence $\tilde{u}$ solves (1.1). By uniqueness, $\tilde{u} = u$. By the uniform L^∞ bound for u_ϵ and the convergence of u_ϵ to u a.e. in Ω we have $u \in L^\infty(\Omega)$ with $\|u\|_{L^\infty(\Omega)} \le \|I\|_{L^\infty(\Omega)}$ ▯

Throughout the rest of the paper, we fix $\mu > 0$ and unless otherwise stated, all constants depend at most on n, μ, u, Ω, φ, and possibly I.

We begin with a local lower bound estimate for any BV function u and C^1 function h with gradient strictly less than 1.

LEMMA 2.2. *Let $u \in BV(B_r(a))$ for $B_r(a) \subset\subset \Omega$ and $h \in C^1(\overline{B}_r(a))$ with*

$$\sup_{B_r(a)} |\nabla h| \le 1 - \mu;$$

then

$$\int_{B_r(a)} \varphi(Du) - \int_{B_r(a)} \varphi(\nabla h) dx \ge \mu \int_{B_r(a)} |D^s u| + \int_{B_r(a)} \nabla(u-h) \cdot \nabla h dx$$
$$+ \int_{B_r(a)} D^s u \cdot \nabla h + \frac{\mu^2}{2} \int_{B_r(a) \cap \{|\nabla u| \ge 1\}} |\nabla u| dx$$
$$+ \frac{1}{2} \int_{B_r(a) \cap \{|\nabla u| < 1\}} |\nabla(u-h)|^2 dx.$$

Proof. Where $|\nabla u| \ge 1$, we have

$$\begin{aligned} &\varphi(\nabla u) - \varphi(\nabla h) - \nabla(u-h) \cdot \nabla h \\ &= |\nabla u| - \frac{1}{2} + \frac{1}{2}|\nabla h|^2 - \nabla u \cdot \nabla h \\ &\ge \frac{1}{2}(2|\nabla u| - 1 - 2|\nabla u||\nabla h| + |\nabla h|^2) \\ &= \frac{1}{2}(2|\nabla u| - 1 - |\nabla h|)(1 - |\nabla h|) \ge \frac{\mu^2}{2}|\nabla u|. \end{aligned}$$

Where $|\nabla u| < 1$, we have

$$\varphi(\nabla u) - \varphi(\nabla h) - \nabla(u-h) \cdot \nabla h = \frac{1}{2}|\nabla(u-h)|^2.$$

We now obtain the lemma by using

$$\int_{B_r(a)} |D^s u| \ge \int_{B_r(a)} D^s u \cdot \nabla h + \int_{B_r(a)} |D^s u|(1 - |\nabla h|),$$

the assumption on h, and the above estimates. ▯

We now fix $B_{2r}(a) \subset\subset \Omega$. Let v be a Lipschitz function defined on $B_{2r}(a)$ and assume there exists an $l \in \mathbf{R}^n$ with $|l| \le 1 - 2\mu$, such that $\sup_{B_{2r}(a)} |\nabla v - l| \le \beta^{2\delta}$ for $\delta > 0$ and $0 < \beta < 1$ to be chosen later. Also let $\overline{v}$ be defined by $\overline{v}(x) = v(x) - l \cdot x$. Let η_ϵ be the usual mollifier on $\mathbf{R}^n$ and denote $\overline{v}_\beta = \eta_{r\beta} * \overline{v}$ and $v_\beta = \eta_{r\beta} * v$. We then have the following estimates from [18]:

$$\sup_{B_r(a)} |\nabla v_\beta - l| = \sup_{B_r(a)} |\nabla \overline{v}_\beta| \le \beta^{2\delta}, \tag{2.2}$$

$$\sup_{B_r(a)} |v_\beta - v| = \sup_{B_r(a)} |\overline{v}_\beta - \overline{v}| \leq r\beta \sup_{B_r(a)} |\nabla \overline{v}_\beta| \leq r\beta^{1+2\delta}, \tag{2.3}$$

$$\begin{aligned} r^\delta \sup_{B_r(a)} |x-y|^{-\delta} |\nabla v_\beta(x) - \nabla v_\beta(y)| \\ \leq c_1 r^\delta \sup_{B_r(a)} |\nabla v - l| \sup_{x' \neq y'} |x'-y'|^{-\delta} |\eta_1((r\beta)^{-1}x') - \eta_1((r\beta)^{-1}y')| \\ \leq c_2 \beta^{2\delta}\beta^{-\delta} = c_2\beta^\delta. \end{aligned} \tag{2.4}$$

Now for any $\tilde{r} \in [\frac{r}{2}, r]$ there exists a unique solution [11] $w \in H^1(B_{\tilde{r}}(a)) \cap C^{1,\delta}(\overline{B}_{\tilde{r}}(a))$ with $\delta \in (0,1)$ for the problem

$$-\Delta w = I - w \quad \text{on } B_{\tilde{r}}(a), \quad w = v_\beta \quad \text{on } \partial B_{\tilde{r}}(a). \tag{2.5}$$

LEMMA 2.3. *For $I \in L^\infty(\Omega)$, the solution w to* (2.5) *satisfies*

$$\|w\|_{L^\infty(B_{\tilde{r}}(a))} \leq \|v_\beta\|_{L^\infty(\partial B_{\tilde{r}}(a))} + \|I\|_{L^\infty(\Omega)}. \tag{2.6}$$

$$\sup_{B_{\tilde{r}}(a)} |\nabla w - l| \leq c_3(\beta^\delta + r(\|I\|_{L^\infty(\Omega)} + \|v_\beta\|_{L^\infty(\partial B_{\tilde{r}}(a))})) \quad \textit{for any } l \in R^n. \tag{2.7}$$

$$\begin{aligned} \sup_{x,y \in B_{\tilde{r}/2}(a)} \frac{|\nabla w(x) - \nabla w(y)|}{|x-y|^{1/2}} \leq c_4 \Bigg(\frac{1}{r^{n+1/2}} \int_{(\partial B_{\tilde{r}}(a))} |v_\beta| \, d\mathcal{H}^{n-1} \\ + r^{1/2}(\|I\|_{L^\infty(\Omega)} + \|v_\beta\|_{L^\infty(\partial B_{\tilde{r}}(a))}) \Bigg). \end{aligned} \tag{2.8}$$

Proof. Estimate (2.6) is from Theorem 8.16 in [11]. To prove (2.7) and (2.8), we decompose w as $w = w_1 + w_2$, such that

$$-\Delta w_1 = I - w \quad \text{on } B_{\tilde{r}}(a), \quad w_1 = 0 \quad \text{on } \partial B_{\tilde{r}}(a) \tag{2.9}$$

and

$$-\Delta w_2 = 0 \quad \text{on } B_{\tilde{r}}(a), \quad w = v_\beta \quad \text{on } \partial B_{\tilde{r}}(a). \tag{2.10}$$

Let $\tilde{w}_2 \equiv w_2 - v_\beta$. Then $\tilde{w}_2$ solves

$$-\Delta \tilde{w}_2 = -\mathrm{div}(\nabla v_\beta - l) \quad \text{on } B_{\tilde{r}}(a), \quad \tilde{w}_2 = 0 \quad \text{on } \partial B_{\tilde{r}}(a), \tag{2.11}$$

for any $l \in R^n$. Representing the solution of (2.9) using Green's function, i.e., $w_1(x) = \int_{B_{\tilde{r}}(a)} \Gamma(x-y)(I-w)(y)dy$, where Γ is the fundamental solution of Laplace's equation, it is not difficult to get

$$\|\nabla w_1\|_{L^\infty(B_{\tilde{r}}(a))} \leq cr\|I - w\|_{L^\infty(B_{\tilde{r}}(a))}, \tag{2.12}$$

where c is independent of r.

Moreover, by the Stobolev imbedding theorem, Theorem 9.9 in [11], and (2.6),

$$\begin{aligned} \|\nabla w_1\|_{C^{0,1/2}(B_{\tilde{r}}(a))} \leq c\|w_1\|_{W^{2,2n}(B_{\tilde{r}}(a))} \leq c\|I - w\|_{L^{2n}(B_{\tilde{r}}(a))} \\ \leq cr^{1/2}\|I - w\|_{L^\infty(B_{\tilde{r}}(a))} \leq cr^{1/2}(\|v_\beta\|_{L^\infty(\partial B_{\tilde{r}}(a))} + \|I\|_{L^\infty(\Omega)}). \end{aligned} \tag{2.13}$$

Next we shall estimate w_2. Multiplying both sides of (2.11) by $\tilde{w}_2$, and integrating over $B_{\tilde{r}}(a)$, carrying out a simple computation, and using (2.2), we have for any $l \in R^n$,

$$\int_{B_{\tilde{r}}(a)} |\nabla w_2 - l|^2 dx \le c \int_{B_{\tilde{r}}(a)} |\nabla v_\beta - l|^2 dx \le c r^n \beta^{4\delta}, \tag{2.14}$$

where $c > 0$ is a constant independent of r.

Furthermore, applying Theorem 8.16 and 8.33 (with a rescaling argument) in [11] to (2.11), we get the following estimates:

$$\|\tilde{w}_2\|_{L^\infty(B_{\tilde{r}})} \le c \|\nabla v_\beta - l\|_{L^\infty(B_{\tilde{r}})} \tag{2.15}$$

and

$$r^\delta [D\tilde{w}_2]_{C^{0,\delta}(B_{\tilde{r}})} \le c(\|\tilde{w}_2\|_{L^\infty(B_{\tilde{r}})} + \|\nabla v_\beta - l\|_{L^\infty(B_{\tilde{r}})} + r^\delta [Dv_\beta]_{C^{0,\delta}(B_{\tilde{r}})}), \tag{2.16}$$

where $c > 0$ is a constant independent of r. Inserting (2.15) into (2.16), and using (2.2) and (2.4), it yields

$$\begin{aligned} r^\delta [Dw_2]_{C^{0,\delta}(B_{\tilde{r}})} &\le (r^\delta [D\tilde{w}_2]_{C^{0,\delta}(B_{\tilde{r}})} + r^\delta [Dv_\beta]_{C^{0,\delta}(B_{\tilde{r}})}) \\ &\le c(\|\nabla v_\beta - l\|_{L^\infty(B_{\tilde{r}})} + r^\delta [Dv_\beta]_{C^{0,\delta}(B_{\tilde{r}})}) \le c\beta^\delta. \end{aligned} \tag{2.17}$$

Now we can estimate $\sup_{B_{\tilde{r}}(a)} |\nabla w_2 - l|$. Denoting $|B_{\tilde{r}}(a)|^{-1} \int_{B_{\tilde{r}}(a)} f dx$ by $(f)_{B_{\tilde{r}}(a)}$, and using (2.14) and (2.17), we get

$$\begin{aligned} \sup_{B_{\tilde{r}}(a)} |\nabla w_2 - l| &\le \sup_{B_{\tilde{r}}(a)} \{|\nabla w_2 - (\nabla w_2)_{B_{\tilde{r}}(a)}| + |(\nabla w_2)_{B_{\tilde{r}}(a)} - l|\} \\ &\le r^\delta [Dw_2]_{C^{0,\delta}(B_{\tilde{r}})} + |B_{\tilde{r}}(a)|^{-1/2} \left(\int_{B_{\tilde{r}}(a)} |\nabla w_2 - l|^2 \right)^{1/2} dx \le c\beta^\delta; \end{aligned} \tag{2.18}$$

here we used (2.14) and (2.17) in the last inequality.

We then have from (2.6) and (2.18)

$$\begin{aligned} \sup_{B_{\tilde{r}}(a)} |\nabla w - l| &\le \sup_{B_{\tilde{r}}(a)} |\nabla w_2 - l| + \sup_{B_{\tilde{r}}(a)} |\nabla w_1| \\ &\le c_3(\beta^\delta + r(\|I\|_{L^\infty(B_{\tilde{r}}(a))} + \|v_\beta\|_{L^\infty(\partial B_{\tilde{r}}(a))})). \end{aligned}$$

Hence (2.7) is proved. To prove (2.8) we represent w_2 by the Poisson's formula on the ball $B_{\tilde{r}}(a)$, i.e.,

$$w_2(x) = \frac{\tilde{r}^2 - |x|^2}{n\alpha_n r} \int_{\partial B_{\tilde{r}}(a)} \frac{v_\beta(y)}{|x-y|^n} dS_y, \quad x \in B_{\tilde{r}}(a),$$

where α_n represents the volume of n dimensional unit ball. A direct computation leads to the estimate

$$\sup_{B_{\tilde{r}/2}(a)} |D^2 w_2| \le c r^{-n-1} \int_{\partial B_{\tilde{r}}(a)} |v_\beta(y)| dS_y,$$

where $c > 0$ dependents only on n. Then we have

$$\sup_{x,y\in B_{\tilde{r}/2}(a)} \frac{|\nabla w_2(x) - \nabla w_2(y)|}{|x-y|^{1/2}} \leq \left(\sup_{x,y\in B_{\tilde{r}/2}(a)} |D^2 w_2| \right) |x-y|^{1/2} \tag{2.19}$$

$$\leq \frac{c}{r^{n+1/2}} \int_{\partial B_{\tilde{r}}(a))} |v_\beta| \, d\mathcal{H}^{n-1}.$$

Now (2.8) immediately follows from (2.13) and (2.19). ∎

LEMMA 2.4. *Suppose there is a $v \in C^{0,1}(B_{2r}(a))$ and $l \in \mathbf{R}^n$ with $|l| \leq 1-2\mu$, $\sup_{B_{2r}(a)} |\nabla v - l| \leq \beta^{2\delta}$, and $\sup_{B_{2r}(a)} |v| \leq C_u$, where C_u is a constant depending only on u. Let $v_\beta, \tilde{r}$, and w be as in the previous discussion. Then there exists constants c_5 and c_6 such that if $\beta \leq c_5$ and $r(C_u + \|I\|_{L^\infty(\Omega)}) \leq c_6$, then*

$$\int_{B_{\tilde{r}}(a)} \varphi(Du) - \int_{B_{\tilde{r}}(a)} \varphi(\nabla w)dx \geq \int_{\partial B_{\tilde{r}}(a)} (u - v_\beta) \frac{\partial w}{\partial n} \, d\mathcal{H}^{n-1}$$

$$+ \int_{B_{\tilde{r}}(a)} (u-w)(I-w)dx + \mu \int_{B_{\tilde{r}}(a)} |D^s u| + \frac{\mu^2}{2} \int_{B_{\tilde{r}}(a)\cap\{|\nabla u|\geq 1\}} |\nabla u| dx$$

$$+ \frac{1}{2} \int_{B_{\tilde{r}}(a)\cap\{|\nabla u|<1\}} |\nabla(u-w)|^2 dx$$

$$\geq \int_{\partial B_{\tilde{r}}(a)} (u - v_\beta) \frac{\partial w}{\partial n} \, d\mathcal{H}^{n-1} + \frac{1}{2} \int_{B_{\tilde{r}}(a)} (w-I)^2 dx - \frac{1}{2} \int_{B_{\tilde{r}}(a)} (u-I)^2 dx$$

$$+ \mu \int_{B_{\tilde{r}}(a)} |D^s u| + \frac{\mu^2}{2} \int_{B_{\tilde{r}}(a)\cap\{|\nabla u|\geq 1\}} |\nabla u| dx$$

$$+ \frac{1}{2} \int_{B_{\tilde{r}}(a)\cap\{|\nabla u|<1\}} |\nabla(u-w)|^2 dx.$$

Proof. From (2.7)–(2.8), the definition of v_β, and the assumption on l we see that

$$\sup_{B_{\tilde{r}(a)}} |\nabla w| \leq \sup_{B_{\tilde{r}(a)}} |\nabla w - l| + |l|$$

$$\leq c_3(\beta^\delta + r(\|v\|_{L^\infty(\partial B_{\tilde{r}}(a))} + \|I\|_{L^\infty(\Omega)})) + 1 - 2\mu$$

$$\leq c_3(\beta^\delta + r(C_u + \|I\|_{L^\infty(\Omega)})) + 1 - 2\mu.$$

Later, v will be chosen (see, for instance, [14]) to be a Lipschitz approximation of u so that $\|v\|_{L^\infty(B_{2r}(a))}$ can be bounded by a constant C_u depending only on u. Now choose c_5 and c_6 such that $\beta^\delta \leq c_5$ and

$$r(C_u + \|I\|_{L^\infty(\Omega)}) \leq c_6$$

imply

$$c_3(\beta^\delta + r(C_u + \|I\|_{L^\infty(\Omega)})) \leq \mu.$$

Thus

$$\sup_{B_{\tilde{r}(a)}} |\nabla w| \leq 1 - \mu. \tag{2.20}$$

The conditions of Lemma 2.2 now hold for $h = w$. Substituting in w for h in the inequality in Lemma 2.2, integrating by parts, and using Young's inequality for $(u - w)(I - w) = -(u - I)(w - I) + (I - w)^2$ the lemma is proved. ∎

LEMMA 2.5. *If the function $u \in BV(\Omega)$ is solution to* (1.1), *then*

$$\int_{B_r} \varphi(Du) - \int_{B_r} \varphi(Dw) \leq 1/2 \int_{B_r} (w - I)^2 dx$$
$$-1/2 \int_{B_r} (u - I)^2 dx + \int_{\partial B_r} |Tw - Tu| d\mathcal{H}^{n-1}$$

for any $w \in BV(B_r)$, $B_r \subset\subset \Omega$. Here T denotes the trace operator on BV.

Proof. Let $w \in BV(B_r)$ and define

$$\zeta = \begin{cases} w - u & \text{on } B_r, \\ 0 & \text{in } \Omega \backslash \overline{B}_r. \end{cases}$$

Then since u is a solution we have letting $v = u + \zeta$ in (1.1) and using Theorem 1 of section 5.4 in [10],

$$\int_{\Omega} \varphi(Du) + 1/2 \int_{\Omega} (u - I)^2 dx \leq \int_{B_r} \varphi(Dw) + \int_{\partial B_r} |Tw - Tu| d\mathcal{H}^{n-1}$$
$$+ \int_{\Omega \backslash \overline{B}_r} \varphi(Du) + 1/2 \int_{B_r} (w - I)^2 dx + 1/2 \int_{\Omega \backslash B_r} (u - I)^2 dx.$$

Hence

$$\int_{\overline{B}_r} \varphi(Du) + 1/2 \int_{B_r} (u - I)^2 dx \leq \int_{B_r} \varphi(Dw) + 1/2 \int_{B_r} (w - I)^2 dx$$
$$+ \int_{\partial B_r} |Tw - Tu| d\mathcal{H}^{n-1}. \qquad \square$$

We use the above lemma, Lemma 2.4, and estimates (2.2)–(2.4) to obtain the following inequality for the solution u to (1.1).

LEMMA 2.6. *Let v, l be as in Lemma* 2.4 *with*

$$r(C_u + \|I\|_{L^\infty(\Omega)}) \leq c_6,$$

w as in (2.5), *and u a solution to* (1.1). *Then*

$$\int_{B_{\tilde{r}}(a)} |D^s u| + \int_{B_{\tilde{r}(a)} \cap \{|\nabla u| \geq 1\}} |\nabla u| dx + \int_{B_{\tilde{r}(a)} \cap \{|\nabla u| < 1\}} |\nabla (u - w)|^2 dx$$
$$\leq c_7 \int_{\partial B_{\tilde{r}}(a)} |u - v| \, d\mathcal{H}^{n-1} + c_8 r^n \beta^{1+2\delta},$$

where u and v on $\partial B_{\tilde{r}}(a)$ is understood in the sense of trace.

Proof. By the previous lemma with w from (2.5) and Lemma 2.4 we have

$$\int_{\partial B_{\tilde r}(a)} |u - v_\beta|\, d\mathcal{H}^{n-1} \geq \int_{B_{\tilde r}(a)} \varphi(Du) + \frac{1}{2}\int_{B_{\tilde r}(a)} (u - I)^2 dx$$

$$- \int_{B_{\tilde r}(a)} \varphi(\nabla w) dx - \frac{1}{2}\int_{B_{\tilde r}(a)} (w - I)^2 dx$$

$$\geq \int_{\partial B_{\tilde r}(a)} (u - v_\beta)\frac{\partial w}{\partial n}\, d\mathcal{H}^{n-1} + \mu \int_{B_{\tilde r}(a)} |D^s u| + \frac{\mu^2}{2}\int_{B_{\tilde r(a)}\cap\{|\nabla u|\geq 1\}} |\nabla u| dx$$

$$+ \frac{1}{2}\int_{B_{\tilde r(a)}\cap\{|\nabla u|<1\}} |\nabla(u - w)|^2 dx.$$

The lemma is thus proved by using (2.20) and the estimate for $|v - v_\beta|$ from (2.3). ◻

The following first variational formula is from Hardt and Kinderlehrer [12]: if u is a solution to (1.1), then

$$\int_\Omega \sigma \cdot \nabla\zeta dx + \int_\Omega \sigma \cdot \xi |D^s u| = -\int_\Omega (u - I)\zeta dx, \tag{2.21}$$

where ζ is any function in $BV_0(\Omega)$ with $D^s\zeta << |D^s u|$, ξ is the Radon–Nikodym derivative of $D^s\zeta$ with respect to $|D^s u|$, and $\sigma \in L^1(\Omega)$ is the stress tensor defined by

$$\sigma(u) = \begin{cases} \varphi_P(\nabla u) & \text{in } \Omega_a, \\ D^s u/|D^s u| & \text{in } \Omega_s. \end{cases}$$

Here $D^s u/|D^s u|$ denotes the Radon–Nikodym derivative of $D^s u$ with respect to $|D^s u|$ and $\Omega = \Omega_a \cup \Omega_s$ is the decomposition of Ω with respect to the mutually singular measures $\mathcal{L}^n$ and $|D^s u|$. Clearly $|\sigma(u)| \leq 1$. Note that $\sigma(u)$ depends only on u. In the sequel we will write σ instead of $\sigma(u)$ and write the left-hand side of (2.21) as

$$\int_\Omega \sigma \cdot D\zeta.$$

We may also note that if

$$\int_\Omega \sigma \cdot D\zeta = -\int_\Omega (u - I)\zeta dx$$

holds for arbitrary $\zeta \in BV(\Omega)$ for some u where σ is defined as above, then u solves (1.1). In fact, for arbitrary $v \in BV(\Omega)$ we take $\zeta = v - u$, noting that by convexity of φ we have $\varphi(\nabla v) - \varphi(\nabla u) \geq \nabla(v - u) \cdot \varphi_P(\nabla u)$ on Ω_a and that on Ω_s we have

$$\int_{\Omega_s} |D^s v| - \int_{\Omega_s} |D^s u| \geq \int_{\Omega_s} D^s(v - u) \cdot \frac{D^s u}{|D^s u|}.$$

The proof of the lemma below is based on [13], with some necessary modifications.

LEMMA 2.7. *Suppose u is a solution to our minimization problem, $B_{2r}(a) \subset\subset \Omega$, $v \in C^{0,1}(B_{2r}(a))$ with $\sup_{B_{2r}(a)} |\nabla v| \leq 1 - \mu$, and*

$$\mathcal{L}^n(\{u \neq v\} \cap B_\rho(a)) \leq \frac{1}{2}|B_\rho| \quad \textit{for all} \quad r \leq \rho \leq 2r;$$

then there exists positive constants c_9 and c_{10} such that if

$$\mathcal{L}^n(\{u \neq v\} \cap B_{2r}(a)) \leq c_9 r^n,$$

then

$$\|u - v\|_{L^\infty(B_r(a))} \leq c_{10} \left(\mathcal{L}^n(\{u \neq v\} \cap B_{2r}(a))\right)^{\frac{1}{n}}.$$

Proof. First we note that the function φ satisfies $|p| - \lambda \leq \varphi(p) \leq |p|$ for all $p \in \mathbf{R}^n$, some $\lambda > 0$. By convexity of φ we have $\varphi(p) \leq \varphi_P(p) \cdot p + \varphi(0)$ for all $p \in \mathbf{R}^n$. Hence we have

$$|Du| = |\nabla u|dx + |D^s u| \leq \varphi(\nabla u)dx + |D^s u| + \lambda dx$$

$$\leq \varphi_P(\nabla u) \cdot \nabla u dx + |D^s u| + (\lambda + \varphi(0))dx = \sigma \cdot Du + \lambda dx.$$

Let $\theta : \mathbf{R} \to \mathbf{R}$ be a bounded, increasing, piecewise differentiable function with $\theta'(t) \leq 1$ for almost all t. Let $0 < \rho < h$ and

$$\eta(x) = \begin{cases} 1 & \text{in } B_\rho(a), \\ (h-\rho)^{-1}(h - |x-a|) & \text{in } B_h(a) \backslash B_\rho(a), \\ 0 & \text{in } \Omega \backslash B_h(a). \end{cases}$$

Now apply the first variational formula to $\zeta = \eta\theta(u - v)$ to get

$$\int_{B_h(a)} \eta\sigma \cdot D[\theta(u-v)] = (h-\rho)^{-1} \int_{B_h(a)\backslash B_\rho(a)} \sigma \cdot \frac{x-a}{|x-a|}\theta(u-v)dx$$

$$- \int_{B_h(a)} \eta\theta(u-v)(u-I)dx. \tag{2.22}$$

To obtain a lower bound for $\eta\sigma \cdot D[\theta(u - v)]$ we use the above properties of φ. We have $D[\theta(u - v)] = \theta'(u - v)D(u - v)$ and hence by noting the bound of $|\nabla v|$

$$\int_{B_\rho(a)} |D[\theta(u-v)]| \leq \int_{B_\rho(a)} \theta'(u-v)|Du| + \int_{B_\rho(a)} \theta'(u-v)$$

$$\leq \int_{B_\rho(a)} \theta'(u-v)\varphi(Du) + \int_{B_\rho(a)} (\lambda+1)\theta'(u-v)$$

$$\leq \int_{B_\rho(a)} \theta'(u-v)\sigma \cdot Du + \int_{B_\rho(a)} (\lambda+1)\theta'(u-v)$$

$$= \int_{B_\rho(a)} \theta'(u-v)\sigma \cdot D(u-v) + \int_{B_\rho(a)} \theta'(u-v)\sigma \cdot Dv$$

$$+ \int_{B_\rho(a)} (\lambda+1)\theta'(u-v) \leq \int_{B_h(a)} \eta\sigma \cdot D[\theta(u-v)] + \int_{B_h(a)} C_\lambda \theta'(u-v) \tag{2.23}$$

for some constant C_λ depending only on λ. Inserting (2.22) into (2.23), and noting the L^∞ bound for u, we get

$$\int_{B_\rho(a)} |D[\theta(u-v)]|$$

$$\leq (h-\rho)^{-1} \int_{B_h(a)\setminus B_\rho(a)} |\theta(u-v)| dx + C_\lambda |\operatorname{supp} \eta\theta(u-v)|$$

$$+ 2\|I\|_{L^\infty(\Omega)} \int_{B_h(a)} |\theta(u-v)| dx.$$

For $0 < k < s$ we choose θ as

$$\theta(t) = \begin{cases} 0 & \text{for } t \leq k, \\ t-k & \text{for } k < t < s, \\ s-k & \text{for } t \geq s. \end{cases}$$

Now let $A(k,h) \equiv B_h \cap \{u - v > k\}$. Clearly $\operatorname{supp}[\eta\theta(u-v)] \subset A(k,h)$. Thus

$$\int_{B_\rho(a)} |D[\theta(u-v)]|$$

$$\leq ((h-\rho)^{-1} + 2\|I\|_{L^\infty(\Omega)}) \int_{B_h(a)} |\theta(u-v)| dx + C_\lambda |A(k,h)|.$$

By assumption, $|A(0,\rho)| \leq \frac{1}{2}|B_\rho(a)|$ for $r \leq \rho \leq 2r$. Thus we see that

$$\frac{\mathcal{L}^n\{\{\theta(u-v)=0\} \cap B_\rho(a)\}}{|B_\rho(a)|} \geq \frac{1}{2}.$$

We can then apply the isoperimetric inequality for $s > k > 0$ to get

$$(s-k)|A(s,\rho)|^{\frac{n-1}{n}} \leq \left(\int_{B_\rho(a)} |\theta(u-v)|^{\frac{n}{n-1}} dx \right)^{\frac{n-1}{n}}$$

$$\leq c_{11} \int_{B_\rho(a)} |D[\theta(u-v)]|$$

$$\leq c_{12}((h-\rho)^{-1} + \|I\|_{L^\infty(\Omega)}) \int_{B_h(a)} |\theta(u-v)| dx + c_{13}|A(k,h)|.$$

So since $h \leq 2r$ we get

$$(s-k)|A(s,\rho)|^{\frac{n-1}{n}} \leq c_{14}(h-p)^{-1} \int_{B_h(a)} |\theta(u-v)| dx + c_{14}|A(k,h)|.$$

And since

$$\int_{B_h(a)} |\theta(u-v)| dx \leq (s-k)|A(k,h)|,$$

we arrive at

$$|A(s,\rho)|^{\frac{n-1}{n}} \le c_{14}((h-p)^{-1} + (s-k)^{-1})|A(k,h)|$$

for every $r \le \rho < h \le 2r$ and $s > k > 0$. We now apply Lemma 2.1 in [13] to obtain the upper bound.

The lower bound for $u - v$ is obtained by using a similar argument for $0 < k < s < \infty$,

$$\tilde{\theta}(t) = \begin{cases} 0 & \text{for } t \ge -k, \\ -t-k & \text{for } -s < t < -k, \\ s-k & \text{for } t \le -s, \end{cases}$$

and $\tilde{A}(k,h) \equiv B_h \cap \{u - v < -k\}$. The lemma then follows by again applying Lemma 2.1 in [13]. ∎

Now define the energy function

$$\Phi(r,l,x) = \frac{1}{|B_r|}\left\{\int_{B_r(x)\cap\{|\nabla u|\ge 1\}} |\nabla u| dx + \int_{B_r(x)\cap\{|\nabla u|<1\}} |\nabla u - l|^2 dx + \int_{B_r(x)} |D^s u|\right\}.$$

The following theorem provides a decay estimate for Φ.

Theorem 2.8. *If u solves (1.1) with $B_r(a) \subset\subset \Omega$, $l_1 \in \mathbf{R}^n$ with $|l_1| \le 1-\mu$, then there exist positive constants ω, ϵ, κ, c_{37}, c_{38}, and c_{39} such that*

$$\Phi(4r, l_1, a) \le \epsilon$$

and

$$r \le \kappa$$

implies

$$\Phi(\omega r, l_2, a) \le \frac{1}{2}\Phi(4r, l_1, a) + c_{37} r,$$

where

$$|l_1 - l_2| \le c_{38}\Phi(4r, l_1, a)^{\frac{1}{2}} + c_{39} r.$$

Proof. For fixed $\lambda > 0$, define

$$R^\lambda \equiv \{x \in B_{2r}(a) \,|\, \Phi(\rho, l_1, x) \le \lambda \text{ for all } 0 < \rho \le 2r\}.$$

By Vitali's covering theorem, there exist disjoint balls $\{B_{r_i}(x_i)\}_{i=1}^\infty$ such that

$$B_{2r}(a)\backslash R^\lambda \subset \cup_{i=1}^\infty B_{5r_i}(x_i)$$

and $\Phi(r_i, l_1, x_i) \ge \lambda$. Then we have

$$\mathcal{L}^n(B_{2r}(a)\backslash R^\lambda) \le 5^n \sum_{i=1}^\infty |B_{r_i}(x_i)| \le \frac{5^n}{\lambda}|B_{4r}(a)|\Phi(4r, l_1, a).$$

Let $g(x) = u(x) - l_1 \cdot x$. By Poincarè's inequality we have for $x \in R^\lambda$ and $0 < \rho \le 2r$

$$\frac{1}{|B_\rho|}\int_{B_\rho(x)} |g(y) - \overline{g}_{x,\rho}|dy \le \frac{c_{15}}{\rho^{n-1}}\int_{B_\rho(x)} |Dg|$$

$$\le \frac{c_{15}}{\rho^{n-1}}\left\{2\int_{B_\rho(x)\cap\{|\nabla u|\ge 1\}} |\nabla u|dx + \int_{B_\rho(x)} |D^s u|\right.$$

$$\left. + |B_\rho|^{1/2}\left(\int_{B_\rho(x)\cap\{|\nabla u|<1\}} |\nabla u - l_1|^2 dx\right)^{1/2}\right\}$$

$$\le c_{16}\rho\Phi(\rho, l_1, x)^{1/2} \le c_{16}\lambda^{1/2}\rho,$$

where $\overline{g}_{x,\rho} = \frac{1}{|B_\rho|}\int_{B_\rho(x)} g(y)dy$. Then

$$|\overline{g}_{x,\rho/2^{k+1}} - \overline{g}_{x,\rho/2^k}| \le \frac{1}{|B_{\rho/2^{k+1}}|}\int_{B_{\rho/2^{k+1}}(x)} |g(y) - \overline{g}_{x,\rho/2^k}|dy$$

$$\le 2^n \frac{1}{|B_{\rho/2^k}|}\int_{B_{\rho/2^k}(x)} |g(y) - \overline{g}_{x,\rho/2^k}|dy \le c_{17}\rho\lambda^{1/2}/2^k.$$

Since $g(x) = \lim_{\rho\to 0}\overline{g}_{x,\rho}$ for $\mathcal{L}^n$ a.e. $x \in R^\lambda$,

$$|g(x) - \overline{g}_{x,\rho}| \le \sum_{k=1}^{\infty} |\overline{g}_{x,\rho/2^{k+1}} - \overline{g}_{x,\rho/2^k}| \le c_{17}\rho\lambda^{1/2}.$$

For x, $y \in R^\lambda$ with $|x-y| \le 2r$, set $\rho = |x-y|$. Then

$$|\overline{g}_{x,\rho} - \overline{g}_{y,\rho}| \le \frac{1}{|B_\rho(x)\cap B_\rho(y)|}\int_{B_\rho(x)\cap B_\rho(y)} |\overline{g}_{x,\rho} - g(z)| + |g(z) - \overline{g}_{y,\rho}|dz$$

$$\le c_{18}\frac{1}{B_\rho}\left(\int_{B_\rho(x)} |g(z) - \overline{g}_{x,\rho}|dz + \int_{B_\rho(y)} |g(z) - \overline{g}_{y,\rho}|dz\right) \le c_{19}\lambda^{1/2}\rho.$$

So by combining the above, we have

$$|g(x) - g(y)| \le c_{20}\lambda^{1/2}\rho = c_{20}\lambda^{1/2}|x-y|$$

for $\mathcal{L}^n$ a.e. x, $y \in R^\lambda \subset B_{2r}(a)$. Let $\lambda = c_{20}^{-2}\beta^{4\delta}$, so that

$$|u(x) - l_1 \cdot x - u(y) + l_1 \cdot y| = |g(x) - g(y)| \le \beta^{2\delta}|x-y|,$$

and let v be a Lipschitz function defined on $B_{2r}(a)$ such that

$$v = u \text{ on } R^\lambda, \text{ and } \sup_{B_{2r}(a)} |\nabla v - l_1| \le \beta^{2\delta}. \tag{2.24}$$

Such a v exists by a standard extension for a Lipschitz function. Also note that for this choice of v we have $\sup_{B_{2r}(a)} |v| \le C_u$. With the choice of λ, and by choosing

$$\beta = \Phi(4r, l_1, a) \text{ and } \delta = \frac{1}{8(n+1)},$$

we can estimate the size of the nonzero set of $u-v$ as

$$\mathcal{L}^n(B_{2r}(a)\cap\{u\neq v\})\le c_{21}r^n\beta^{-4\delta}\Phi(4r,l_1,a)\le c_{21}r^n\Phi(4r,l_1,a)^{1-4\delta}.$$

We made the choice of δ so that $(1-4\delta)\cdot\frac{n+1}{n}=1+\frac{1}{2n}>1$. Now choose $\tilde r\in[\frac12 r,r]$ so that both

$$\int_{\partial B_{\tilde r(a)}}|u-v|d\mathcal{H}^{n-1}\le\frac{3}{r}\int_{B_{\tilde r(a)}}|u-v|dx$$

and

$$\int_{\partial B_{\tilde r(a)}}|u-\overline{u}_{a,r}-l_1\cdot(x-a)|d\mathcal{H}^{n-1}\le\frac{3}{r}\int_{B_{\tilde r(a)}}|u-\overline{u}_{a,r}-l_1\cdot(x-a)|dx$$

are satisfied. By the choice of $\tilde r$,

$$\int_{\partial B_{\tilde r(a)}}|u-v|d\mathcal{H}^{n-1}\le\frac{3}{r}\|u-v\|_{L^\infty(B_r(a))}\cdot\mathcal{L}^n\{B_r(a)\cap\{u\neq v\}\}.$$

Choose $r(C_u+\|I\|_{L^\infty(\Omega)})\le c_6$. By Lemma 2.7, for $\Phi(4r,l_1,a)\le c_{22}$, we have

$$\frac{1}{r}\|u-v\|_{L^\infty(B_r(a))}\le c_{10}\frac{1}{r}(\mathcal{L}^n(B_{2r}(a)\cap\{u\neq v\}))^{1/n}.$$

Thus

$$\frac{1}{r^n}\int_{\partial B_{\tilde r(a)}}|u-v|d\mathcal{H}^{n-1}\le c_{23}\Phi(4r,l_1,a)^{1+\frac{1}{2n}}.$$

We now apply Lemma 2.6 to the above, using the estimate for the boundary integral of $u-v$, to obtain

$$\begin{aligned}\int_{B_{r\omega}(a)}|D^s u|+\int_{B_{r\omega(a)}\cap\{|\nabla u|\ge1\}}|\nabla u|dx+\int_{B_{r\omega(a)}\cap\{|\nabla u|<1\}}|\nabla(u-w)|^2dx\\ \le c_{24}r^n\left(\Phi(4r,l_1,a)^{1+\frac{1}{2n}}+\Phi(4r,l_1,a)^{1+\frac{1}{4(n+2)}}\right)\end{aligned}\tag{2.25}$$

for any $\omega\le1/2$. Let $l_2\equiv\nabla\omega(a)$. By using the gradient estimate, (2.7)–(2.8), for ω, the choice of $\tilde r$, the definition of v_β, the above bound for v, and Poincarè's inequality,

$$\begin{aligned}|l_1-l_2|&\le\frac{1}{|B_{\tilde r}|}\int_{\partial B_{\tilde r(a)}}|v_\beta-\overline{u}_{a,r}-l_1\cdot(x-a)|d\mathcal{H}^{n-1}+c_{25}r(\|I\|_{L^\infty(\Omega)}+C_u)\\ &\le\frac{1}{|B_{\tilde r}|}\int_{\partial B_{\tilde r(a)}}|v_\beta-u|+|u-\overline{u}_{a,r}-l_1\cdot(x-a)|d\mathcal{H}^{n-1}+c_{25}r(\|I\|_{L^\infty(\Omega)}+C_u)\\ &\le c_{26}\Phi(4r,l_1,a)+\frac{c_{27}}{r^n}\int_{B_r(a)}|Du-l_1|+c_{25}r(\|I\|_{L^\infty(\Omega)}+C_u).\end{aligned}$$

By the Hölder inequality, we obtain $|l_1-l_2|\le c_{28}\Phi(4r,l_1,a)^{1/2}+c_{25}r(\|I\|_{L^\infty(\Omega)}+C_u)$. The last term on the left side of inequality (2.25) satisfies

$$\int_{B_{r\omega}(a)\cap\{|\nabla u|<1\}}|\nabla(u-w)|^2dx\ge\int_{B_{r\omega}(a)\cap\{|\nabla u|<1\}}\frac12|\nabla u-l_2|^2-|\nabla w-l_2|^2dx.$$

Thus by (2.25) and the above inequality,

$$|B_{r\omega}|\Phi(r\omega, l_2, a) \le c_{29} r^n \Phi(4r, l_1, a)^{1+\frac{1}{4(n+2)}} + c_{30} \int_{B_{r\omega}} |\nabla w - l_2|^2 dx. \tag{2.26}$$

To estimate the last term, we again use the estimates for the gradient of w. Note that

$$\begin{aligned}
&\sup_{x,y\in B_{r/4}(a)} \frac{|\nabla w(x) - \nabla w(y)|}{|x-y|^{1/2}} \\
&\le c_4 \frac{1}{r^{n+1/2}} \int_{\partial B_{\tilde{r}(a)}} |v_\beta - \overline{u}_{a,r} - l_1 \cdot (x-a)| d\mathcal{H}^{n-1} \\
&+ c_4 r^{1/2}(\|I\|_{L^\infty(\Omega)} + C_u).
\end{aligned}$$

Therefore, similar to the estimate for $|l_1 - l_2|$, we have

$$\begin{aligned}
&\sup_{x,y\in B_{r/4}(a)} \frac{|\nabla w(x) - \nabla w(y)|}{|x-y|^{1/2}} \\
&\le c_{31}(r^{-1/2}\Phi(4r, l_1, a)^{1/2} + r^{1/2}(\|I\|_{L^\infty(\Omega)} + C_u)).
\end{aligned}$$

Using this we then have

$$\begin{aligned}
&\int_{B_{r\omega}(a)} |\nabla w - l_2|^2 dx \le c_{32}(r\omega)^n\{\omega\Phi(4r, l_1, a) \\
&+ r\Phi(4r, l_1, a)^{1/2}(\|I\|_{L^\infty(\Omega)} + C_u) + r^2(\|I\|_{L^\infty(\Omega)} + C_u)^2\} \\
&\le c_{33}(r\omega)^n\{\omega\Phi(4r, l_1, a) + r(\|I\|_{L^\infty(\Omega)} + C_u)\}.
\end{aligned}$$

Hence by combining the above with (2.26) we arrive at

$$\begin{aligned}
\Phi(r\omega, l_2, a) \le{}& c_{34}\omega^{-n}\Phi(4r, l_1, a)^{1+\frac{1}{4(n+1)}} + c_{35}\omega\Phi(4r, l_1, a) \\
&+ c_{36} r(\|I\|_{L^\infty(\Omega)} + C_u).
\end{aligned}$$

Choose $\omega < 1/4$ so small so that $c_{35}\omega < 1/4$, and again restrict $\Phi(4r, l_1, a)$ so that $c_{34}\omega^{-n}\Phi(4r, l_1, a)^{1+\frac{1}{4(n+1)}} < 1/4$. This now proves the theorem. ◻

We now prove Theorem 1.1 using an iteration argument (see, for example, [14] or [3]).

Proof. Assume that $\frac{1}{|B_r|}\int_{B_r(a)} |Du - l_1| \le \epsilon_0$ for some $l_1 \in \mathbf{R}^n$ with $|l_1| \le 1 - 4\mu$ and for any r with $r \le \kappa$. For each $x \in B_{r/2}(a)$ we have

$$\Phi(r/2, l_1, x) \le 2^n \Phi(r, l_1, a) \le c_{40} \frac{1}{|B_r|} \int_{B_r(a)} |Du - l_1| \le c_{40}\epsilon_0.$$

We will use Theorem 2.8 iteratively. Choose ϵ_0 so small so that $c_{40}\epsilon_0 \le \epsilon$ and restrict

r so that $c_{37}r \leq r/2$. Assume $|l_{j-1}| < 1-2\mu$ and

$$\Phi\left(\left(\frac{\omega}{4}\right)^{j-1}\frac{r}{2}, l_j, x\right) \leq \left(\frac{1}{2}\right)^{j-1}\Phi\left(\frac{r}{2}, l_1, x\right)$$
$$+\sum_{i=1}^{j-1}\left(\frac{1}{2}\right)^{j-1}\omega^{j-i-1}c_{41}r \text{ for } j = 2, \dots, k.$$

We need to show $\Phi\big(\left(\frac{\omega}{4}\right)^{k-1}\frac{r}{2}, l_k, x\big) \leq \epsilon$ and $|l_k| < 1-2\mu$ in order to continue the inductive step. Since $\omega < 1/2$,

$$\sum_{i=1}^{k-1}\left(\frac{1}{2}\right)^{i-1}\omega^{k-i-1} \leq \left(\frac{1}{2}\right)^{k-2}(k-1) \leq c_{42}\left(\frac{1}{2}\right)^{k/2}$$

for all k. By further restricting r, we have

$$\Phi\left(\left(\frac{\omega}{4}\right)^{k-1}\frac{r}{2}, l_k, x\right) \leq \epsilon.$$

Note that

$$|l_k| \leq \sum_{j=1}^{k-1}|l_{j+1}-l_j| + |l_1|$$
$$\leq \sum_{j=1}^{k-1}\left\{c_{38}\Phi\left(\left(\frac{\omega}{4}\right)^{j-1}\frac{r}{2}, l_j, x\right)^{1/2} + c_{39}\left(\frac{\omega}{4}\right)^{j-1}r\right\} + 1 - 4\mu$$
$$\leq c_{38}\sum_{j=1}^{k-1}\left\{\left(\frac{1}{2}\right)^{(j-1)/2}\Phi(\frac{r}{2}, l_1, x)^{1/2} + c_{41}^{1/2}\left(\frac{1}{2}\right)^{j/4}c_{37}^{1/2}r^{1/2}\right\}$$
$$+c_{39}r\sum_{j=1}^{k-1}\left(\frac{\omega}{4}\right)^{j-1} + 1 - 4\mu$$
$$\leq c_{42}\Phi\left(\frac{r}{2}, l_1, x\right)^{1/2} + c_{42}r^{1/2} + 1 - 4\mu.$$

So by restricting ϵ_0 and r again, we see that $|l_k| < 1-2\mu$. Thus we may continue the iterative step indefinitely, giving

$$\lim_{k\to\infty}\left(\Phi\left(\frac{\omega}{4}\right)^k\frac{r}{2}, l_{k+1}, x\right) = 0 \text{ for all } x \in B_{r/2}(a).$$

Thus

$$\lim_{\rho\to 0}\frac{1}{|B_\rho|}\left(\int_{B_\rho(x)}|D^s u| + \int_{B_\rho(x)\cap\{|\nabla u|\geq 1\}}|\nabla u|dx\right) = 0$$

for all $x \in B_{r/2}(a)$. We then have (see, for instance, [10]) $|D^s u|\left(B_{r/2}(a)\right) = 0$ with $|\nabla u| \leq 1-\mu < 1$ a.e. on $B_{r/2}(a)$. By (2.21), u also satisfies the stated equation. ∎

Using Theorem 1.1, we can now easily prove Theorem 1.2.

Proof. Assume that u is a minimizer of (1.1) and that $\tilde{E} = \{|\nabla u| < 1\}$ has positive Lebesgue measure. From standard measure theory (see, for example, [10]),

$$\lim_{r\to 0} \frac{1}{|B_r|} \int_{B_r(x)} |D^s u| = 0 \tag{2.27}$$

for $\mathcal{L}^n$-a.e. $x \in \tilde{E}$. Also, since $|\nabla u| \in L^1(\Omega)$,

$$\lim_{r\to 0} \frac{1}{|B_r|} \int_{B_r(x)} |\nabla u(y) - \nabla u(x)| dx = 0 \tag{2.28}$$

for $\mathcal{L}^n$-a.e. $x \in \tilde{E}$ by Lebesgue's differentiation theorem. Now let E be the set of all points of $\tilde{E}$ for which both (2.27) and (2.28) hold. Clearly $\mathcal{L}^n(\tilde{E}\backslash E) = 0$, $|\nabla u| < 1$ on E, and both (2.27) and (2.28) hold at each point of E. For each fixed $x \in E$, there exists some $\mu_x > 0$ such that

$$|\nabla u(x)| < 1 - 2\mu_x.$$

Then (2.27) and (2.28) combined with Theorem 1.1 show that there exists an r_x such that

$$|D^s u|(B_{r_x}(x)) = 0 \text{ and } |\nabla u| < 1 - \mu_x \text{ on } B_{r_x}(x)$$

and $u \in C^{1,\alpha}(B_{r_x}(x))$, giving $B_{r_x}(x) \subset E$ in particular. Thus E is an open set in Ω with the required properties. □

EXISTENCE AND UNIQUENESS OF SOLUTIONS WITH LOW REGULARITY FOR A CLASS OF NONLINEAR DISPERSIVE EQUATIONS*

OCTAVIAN G. MUSTAFA†

Abstract. Working in Lagrangian coordinates, we prove the existence and uniqueness of solutions for a class of periodic nonlinear dispersive equations with continuously differentiable initial data. This lowers the regularity requirements available for the Cauchy problem by means of the semigroup approach for quasi-linear hyperbolic equations of evolution or by the viscosity method.

Key words. nonlinear dispersive equation, Cauchy problem

AMS subject classifications. 35Q35, 35Q72

1. Introduction.

This paper is devoted to the Cauchy problem

$$u_t + uu_x + \partial_x(1-\partial_x^2)^{-1}(\alpha u^2 + \beta u_x^2) = 0, \qquad x \in \mathbb{R},\ t \geq 0, \tag{1}$$

with

$$u(t, x+1) = u(t, x),\ x \in \mathbb{R},\ t \geq 0, \qquad u(0, x) = u_0(x),\ x \in \mathbb{R}, \tag{2}$$

where α, $\beta \in \mathbb{R}$ are given constants. Nonlinear periodic dispersive equations of this type, obtained for particular values of the constants α and β, has recently attracted a lot of attention in mathematical physics. Setting $\alpha = 1$ and $\beta = \frac{1}{2}$ we obtain the periodic Camassa–Holm equation modeling shallow water waves [1, 4]. This equation, originally derived as a bi-Hamiltonian system with infinitely many conservation laws [18], is also a reexpression of geodesic flow on the diffeomorphism group of the circle [23, 9, 10]. It is a completely integrable infinite-dimensional Hamiltonian system for a large class of initial data [11, 3]. Setting $\alpha = \frac{3}{2}$ and $\beta = 0$ in (1), we obtain the Degasperis–Procesi equation [16], another model for shallow water waves (cf. [17]). Finally, setting $\alpha = 3\beta - \frac{1}{2}$ with $\beta \in \mathbb{R}$, equation (1) particularizes to a model for the propagation of waves through cylindrical hyperelastic rods [15], rewritten as in [14] (see relation (2.2) therein, rescaled with $x \mapsto \frac{x}{\gamma}$). Despite their similar form, as expressed by (1), these three models have very distinct features: only the Camassa–Holm equation and the Degasperis–Procesi equation have an integrable structure (with entirely different, nonequivalent, isospectral problems) and a geometric interpretation in terms of geodesic flow is available only for the Camassa–Holm equation.

Due to its relevance to mathematical physics, the study of the Cauchy problem for (1) is therefore of interest. For initial data $u_0 \in H^s(\mathbb{S})$ (Sobolev spaces of periodic functions), it is known that there exists some $T = T(u_0) > 0$ such that (1) has a unique solution

$$u \in C([0,T); H^s(\mathbb{S})) \cap C^1([0,T); H^{s-1}(\mathbb{S})).$$

This fact was established in [2, 6] for $s \geq 3$ using Kato's semigroup approach for quasi-linear hyperbolic equations. For the validity of the statement for $s > \frac{3}{2}$ by implementing the same approach see [24]. In [21], the viscosity method was used to prove the existence and uniqueness of a solution $u \in C([0,T); H^s(\mathbb{S}))$ for $s > \frac{3}{2}$. For the Degasperis–Procesi equation and for the hyperelastic rod equation, an approach similar to the one devised in [2, 6] works, yielding a unique solution $u \in C([0,T); H^s(\mathbb{S})) \cap C^1([0,T); H^{s-1}(\mathbb{S}))$ for some $T = T(u_0) > 0$, provided $u_0 \in H^s(\mathbb{S})$ with $s > \frac{3}{2}$ (see [14, 27]). Let us note that in general $T < \infty$ for all three models: singularities can develop by u_x becoming unbounded in finite time [5, 7, 8, 14, 22, 27, 28]. Attempts to lower the regularity of the initial data from $u_0 \in H^s(\mathbb{S})$ with $s > \frac{3}{2}$ have been successful in the case of the Camassa–Holm equation by using the special geometric structure of the equation and imposing additional restrictions: $u_0 \in H^1(\mathbb{S})$ with $u_0 - \partial_x^2 u_0$ a positive or negative Radon measure (see [6, 12]). Further results in this direction have been obtained in [25, 26]. The motivation for seeking solutions with lower regularity is not purely academic: it is motivated by the fact that the Camassa–Holm equation, the Degasperis–Procesi equation, and the hyperelastic rod equation have peaked traveling wave solutions [1, 15, 17] and these special solutions play an important role in the dynamics of these models (see [13, 19, 20]).

In this paper, we use Lagrangian coordinates to improve the previously mentioned results by lowering the regularity requirement on the initial data for (1) to the class of continuously differentiable periodic functions. In other words, rather than viewing (1) as describing an evolution at every fixed spatial point x, we track the path of each particle using a diffeomorphism that describes at each instant the location of the particles, the initial state corresponding to the identity diffeomorphism of the real line. Such an approach was successful in proving that the periodic Camassa–Holm equation satisfies the least action principle (see [9, 10]). In contrast to [9, 10], where smooth—$C^\infty(\mathbb{S})$—initial data were of interest, we are concerned here with initial data of class C^1. We will prove that for any $u_0 \in C^1(\mathbb{S})$ there is some $T = T(u_0) > 0$ and a unique solution

$$u \in C([0,T); C^1(\mathbb{S})) \cap C^1([0,T); C(\mathbb{S}))$$

to the Cauchy problem (1). To compare this with the previously described results, note that any function $u_0 \in H^s(\mathbb{S})$ is continuously differentiable if $s > \frac{3}{2}$ but the inclusion is strict. It is also worthwhile to point out that an implementation of Kato's semigroup approach for spaces of continuously differentiable functions, rather than Sobolev spaces, leads to considerable technical difficulties. It is therefore not clear that the same conclusion as ours can be reached by this method.

2. Main result and its proof. Let us denote first by $C_1^1(\mathbb{R})$ the linear space over the real field of all continuously differentiable functions $f : \mathbb{R} \to \mathbb{R}$ that are periodic with period 1. If endowed with the Chebyshev norm

$$\|f\| = \sup_{x\in\mathbb{R}} |f(x)| + \sup_{x\in\mathbb{R}} |f'(x)|\,,$$

$C_1^1(\mathbb{R})$ becomes a Banach space. Let us denote now by $X(\mathbb{R})$ the set of all functions $g \in C^1(\mathbb{R},\mathbb{R})$ such that the derivative g' is periodic of period 1 and $g(1) = g(0) + 1$. Since

$$g(x+1) - g(x) = \int_x^{x+1} g'(s)ds = \int_0^1 g'(s)ds = 1, \qquad x \in \mathbb{R},$$

yields that the difference of two elements of $X(\mathbb{R})$ is a continuously differentiable function which is periodic of period 1, it is obvious that $X(\mathbb{R})$ does not have a linear space structure with respect to the usual sum of functions as an internal operation. However, by introducing the distance

$$d(g_1, g_2) = |g_1(0) - g_2(0)| + \sup_{x\in\mathbb{R}} |g_1'(x) - g_2'(x)|,$$

$X(\mathbb{R})$ becomes a complete metric space.

Certain features of these spaces are established by the next lemmas.

LEMMA 1. *Let $r \in (0,1)$ be fixed. The set U_r given by*

$$U_r = \{g \in X(\mathbb{R}) \mid d(Id, g) < r,\ g'(x) > 0 \text{ for } x \in \mathbb{R}\}$$

is open in $(X(\mathbb{R}), d)$.

Proof. Since $|g(0)| + |1 - g'(x)| < r$ for all real x and g' has the intermediate value property (Darboux property), the inequality

$$|g'(x)| \geq 1 - r$$

yields either $g'(x) \geq 1 - r$ or $g'(x) \leq r - 1$ for all $x \in \mathbb{R}$. Consequently, $g(\mathbb{R}) = \mathbb{R}$ and, due to its monotonicity and smoothness, g is a diffeomorphism of the real line. Further, for $g \in U_r$ fixed, let us consider $\varepsilon \in (0, \frac{1}{2}\min(r - d(Id, g), 1 - r))$. Then, for all $z \in B(g, \varepsilon)$, we have

$$\begin{aligned} |z(0)| + |1 - z'(x)| &\leq |g(0) - z(0)| + |g'(x) - z'(x)| \\ + |g(0)| + |1 - g'(x)| &< \varepsilon + (r - 2\varepsilon) \\ &< r. \end{aligned}$$

Further, since $g'(x) - \varepsilon < z'(x)$ and $g'(x) \geq 1 - r$, we obtain that $z'(t) > \frac{1}{2}(1 - r) > 0$ for all $x \in \mathbb{R}$ yielding $B(g, \varepsilon) \subset U_r$. □

LEMMA 2. *Let $r \in (0,1)$ be fixed. For $\varphi \in U_r$ and $v \in C_1^1(\mathbb{R})$, we have*

$$\varphi^{-1} \in X(\mathbb{R}) \qquad v \circ \varphi^{-1} \in C_1(\mathbb{R}).$$

Here, $C_1(\mathbb{R})$ stands for the Banach space (with Chebyshev norm) of all real-valued continuous functions which are periodic with period 1.

Proof. Since φ is onto to $\mathbb{R}$ and $\varphi(x + 1) = \varphi(x) + 1$, we deduce that

$$\varphi^{-1}(y + 1) = \varphi^{-1}(y) + 1$$

and

$$\begin{aligned} (v \circ \varphi^{-1})(y + 1) &= (v \circ \varphi^{-1})(\varphi(x + 1)) = v(x + 1) = v(x) \\ &= (v \circ \varphi^{-1})(\varphi(x)) = (v \circ \varphi^{-1})(y), \end{aligned}$$

where $y = \varphi(x)$. □

The following lemma allows us to introduce an integral representation that is essential for establishing the main result.

LEMMA 3. *Let $V \in C_1(\mathbb{R})$. There exists a unique $y \in C_1^2(\mathbb{R})$ such that*

$$y - y'' = V \text{ in } \mathbb{R}.$$

Here, $C_1^2(\mathbb{R}) = C_1(\mathbb{R}) \cap C^2(\mathbb{R}, \mathbb{R})$.

Proof. Let us fix $k \in \mathbb{R}$ and consider the boundary value problem

$$\left\{ \begin{array}{c} y'' - y = -V, \ x \in [k, k+1], \\ y(k+1) = y(k), \\ y'(k+1) = y'(k). \end{array} \right. \tag{3}$$

By introducing the matrix

$$A = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

the second order differential equation in (3) can be written as a first order differential system

$$\left\{ \begin{array}{c} z' = Az + w(x), \ x \in [k, k+1] \\ z(k+1) = z(k), \end{array} \right.$$

where

$$z(x) = \begin{pmatrix} y(x) \\ y'(x) \end{pmatrix}, \qquad w(x) = \begin{pmatrix} 0 \\ -V(x) \end{pmatrix}.$$

Using the variation of constants formula, we obtain

$$z(x) = X(x-k)z_k + \int_k^x X(x-s)w(s)ds, \tag{4}$$

where

$$X(x) = \begin{pmatrix} \operatorname{ch} x & \operatorname{sh} x \\ \operatorname{sh} x & \operatorname{ch} x \end{pmatrix}, \qquad z_k = z(k).$$

By imposing that $z_{k+1} = z_k$, formula (4) implies that

$$z_k = [I_2 - X(1)]^{-1} \int_k^{k+1} X(k+1-s)w(s)ds.$$

Formula (4) can now be recast as

$$z(x) = \int_k^{k+1} \left\{ X(x-k)[I_2 - X(1)]^{-1} X(k+1-s) + h(x,s) \right\} w(s)ds,$$

where

$$h(x,s) = \left\{ \begin{array}{c} X(x-s), \ k \le s \le x, \\ 0, \ x < s \le k+1. \end{array} \right.$$

We have used the well-known identity

$$X(x)[X(s)]^{-1} = X(x-s).$$

Straightforward computations that rely on transformations of sums of functions sh, ch into products and vice versa lead us to

$$\begin{cases} y(x) = \displaystyle\int_k^{k+1} G(x-s)V(s)ds, \\ y'(x) = \displaystyle\int_k^{k+1} G'(x-s)V(s)ds, \end{cases} \tag{5}$$

where

$$G(q) = \begin{cases} \dfrac{\text{ch } \left(q - \frac{1}{2}\right)}{2\text{sh } \frac{1}{2}}, \ q \geq 0, \\ \dfrac{\text{ch } \left(q + \frac{1}{2}\right)}{2\text{sh } \frac{1}{2}}, \ q < 0. \end{cases}$$

For $x \in \mathbb{R}$ and $k = [x]$, the periodicity of V allows us to deduce that

$$\begin{cases} y(x) = \displaystyle\int_0^{1} G(x-[x]-s)V(s)ds, \\ y'(x) = \displaystyle\int_0^{1} G'(x-[x]-s)V(s)ds. \end{cases} \tag{6}$$

Here, $[x]$ represents the integer part of x. The proof is complete. □

Let us introduce now the differential system

$$\begin{cases} \partial_t \varphi = v, \\ \partial_t v = P(\varphi, v), \end{cases} \tag{7}$$

where $P(\varphi, v) = -\partial_x(1-\partial_x^2)^{-1}V \circ \varphi$, $V = \alpha(v \circ \varphi^{-1})^2 + \beta(\partial_x(v \circ \varphi^{-1}))^2$ with α, $\beta \in \mathbb{R}$ and $\varphi(t) \in X(\mathbb{R})$, $v(t) \in C_1^1(\mathbb{R})$. According to Lemmas 2 and 3, the system is well-defined. We need also an initial datum:

$$\varphi(0) = Id, \qquad v(0) = v_0 \in C_1^1(\mathbb{R}). \tag{8}$$

Proposition 1. *Let $r \in (0,1)$ and $K > 0$ be fixed. Then, the operator P : $X(\mathbb{R}) \times C_1^1(\mathbb{R}) \to C_1^1(\mathbb{R})$ is Lipschitzian in $U_r \times \overline{B}(v_0, K)$.*

Proof. For $y = (1-\partial_x^2)^{-1}V$, we deduce that $P(\varphi, v) = y' \circ \varphi$, where y' is given by (5). To evaluate the norm of $P(\varphi, v)$, let us notice first that

$$\begin{aligned} P(\varphi, v) + \partial_x P(\varphi, v) &= y' \circ \varphi + (y'' \circ \varphi) \cdot \varphi' \\ &= y' \circ \varphi + ((y - V) \circ \varphi) \cdot \varphi'. \end{aligned}$$

Via the change of variables $s = \varphi(q)$ and the formula $\partial_x(v \circ \varphi^{-1}) = \frac{(\partial_x v) \circ \varphi^{-1}}{(\partial_x \varphi) \circ \varphi^{-1}}$, we obtain

$$\begin{aligned}
y'(\varphi(x)) &= \int_{\varphi(0)}^{\varphi(1)} G'(\varphi(x)-s)V(s)ds = \int_{\varphi(0)}^{\varphi(x)} \frac{\mathrm{sh}\ \left(\varphi(x)-s-\frac{1}{2}\right)}{2\mathrm{sh}\ \frac{1}{2}} V(s)ds \\
&\quad + \int_{\varphi(x)}^{\varphi(1)} \frac{\mathrm{sh}\ \left(\varphi(x)-s+\frac{1}{2}\right)}{2\mathrm{sh}\ \frac{1}{2}} V(s)ds \\
&= \int_0^x \frac{\mathrm{sh}\ \left(\varphi(x)-\varphi(q)-\frac{1}{2}\right)}{2\mathrm{sh}\ \frac{1}{2}} \left[\alpha v^2(q) + \beta\left(\frac{v'(q)}{\varphi'(q)}\right)^2\right] \varphi'(q)dq \\
&\quad + \int_x^1 \frac{\mathrm{sh}\ \left(\varphi(x)-\varphi(q)+\frac{1}{2}\right)}{2\mathrm{sh}\ \frac{1}{2}} \left[\alpha v^2(q) + \beta\left(\frac{v'(q)}{\varphi'(q)}\right)^2\right] \varphi'(q)dq \\
&= P_1(\varphi,v)(x) + P_2(\varphi,v)(x), \qquad x \in [0,1].
\end{aligned}$$

Now, for $\varphi_i \in U_r$, $v_i \in \overline{B}(v_0,K)$, we have

$$\begin{aligned}
&|P_1(\varphi_1,v_1)(x) - P_1(\varphi_2,v_2)(x)| \\
&\leq \int_0^1 |F(a_1,b_1,c_1,d_1,e_1)(q) - F(a_2,b_2,c_2,d_2,e_2)(q)|\, dq,
\end{aligned}$$

where

$$\begin{aligned}
&a_i(q) = \varphi_i(x), \quad b_i(q) = \varphi_i(q), \\
&c_i(q) = v_i(q), \quad\ d_i(q) = \frac{v_i'(q)}{\varphi_i'(q)}, \\
&e_i(q) = \varphi_i'(q)
\end{aligned}$$

for $i = \overline{1,2}$, and $F : \mathbb{R}^5 \to \mathbb{R}$ is given by

$$F(a,b,c,d,e) = \frac{\mathrm{sh}\ \left(a-b-\frac{1}{2}\right)}{2\mathrm{sh}\ \frac{1}{2}} \left(\alpha c^2 + \beta d^2\right) e,$$

with a, b, c, d, $e \in \mathbb{R}$. The quantities $a_i(q)$, $b_i(q)$, $c_i(q)$, $d_i(q)$, $e_i(q)$ are uniformly bounded for $q \in [0,1]$. In fact, since

$$\varphi(q) = \varphi(0) + q - \int_0^q (1-\varphi'(s))ds,$$

we have

$$\begin{aligned}
|a(q)|\,,\ \ |b(q)| &\leq |\varphi(0)| + 1 + \sup_{s\in[0,1]} |1-\varphi'(s)| \\
&< 1 + r, \\
|c(q)| &\leq \|v\|_{C_1^1(\mathbb{R})} \leq \|v_0\|_{C_1^1(\mathbb{R})} + K, \\
|d(q)| &\leq \frac{1}{1-r}\, \|v\|_{C_1^1(\mathbb{R})} \leq \frac{1}{1-r}\left(\|v_0\|_{C_1^1(\mathbb{R})} + K\right)
\end{aligned}$$

and

$$0 < e(q) \leq 1 + \sup_{s\in[0,1]} |1-\varphi'(s)| < 1 + r$$

for all $\varphi \in U_r$, $v \in \overline{B}(v_0, K)$. According to the mean value theorem

$$\begin{aligned}
&|F(a_1,b_1,c_1,d_1,e_1)(q) - F(a_2,b_2,c_2,d_2,e_2)(q)| \\
&\le \sup_{w\in[w_1,w_2]} \|\nabla F(w)\| \left(|a_1(q)-a_2(q)| + |b_1(q)-b_2(q)|\right. \\
&\qquad\qquad \left. + |c_1(q)-c_2(q)| + |d_1(q)-d_2(q)| + |e_1(q)-e_2(q)|\right) \\
&\le \sup_{w\in\mathbb{R}^5,\ \|w\|\le 5C} \|\nabla F(w)\| \left(|a_1(q)-a_2(q)| + |b_1(q)-b_2(q)|\right. \\
&\qquad\qquad \left. + |c_1(q)-c_2(q)| + |d_1(q)-d_2(q)| + |e_1(q)-e_2(q)|\right),
\end{aligned}$$

where

$$w_i = (a_i, b_i, c_i, d_i, e_i)(q) \in \mathbb{R}^5, \qquad i = \overline{1,2},$$

and $C = \max(1+r, \frac{1}{1-r}(\|v_0\|_{C_1^1(\mathbb{R})} + K))$. Before returning to the estimate of $P(\varphi, v)$, we establish that

$$\begin{aligned}
&|a_1(q) - a_2(q)|\,, \ \ |b_1(q) - b_2(q)| \\
&\le |\varphi_1(0) - \varphi_2(0)| + \int_0^{\max(x,q)} |\varphi_1'(s) - \varphi_2'(s)|\, ds \\
&\le d(\varphi_1, \varphi_2)
\end{aligned}$$

and

$$\begin{aligned}
|d_1(q) - d_2(q)| &\le \frac{|v_1'(q) - v_2'(q)|}{\varphi_1'(q)} + |v_2'(q)| \frac{|\varphi_1'(q) - \varphi_2'(q)|}{\varphi_1'(q)\varphi_2'(q)} \\
&\le \frac{1}{1-r} \|v_1 - v_2\|_{C_1^1(\mathbb{R})} + \left(\|v_0\|_{C_1^1(\mathbb{R})} + K\right) \\
&\quad \times \frac{1}{(1-r)^2} d(\varphi_1, \varphi_2) \\
&\le \frac{C}{1-r} D\left((\varphi_1, v_1), (\varphi_2, v_2)\right).
\end{aligned}$$

Here, D denotes the metric in $X(\mathbb{R}) \times C_1^1(\mathbb{R})$, namely,

$$D\left((\varphi_1, v_1), (\varphi_2, v_2)\right) = d(\varphi_1, \varphi_2) + \|v_1 - v_2\|_{C_1^1(\mathbb{R})}\,.$$

It is obvious that $(X(\mathbb{R}) \times C_1^1(\mathbb{R}), D)$ is a complete metric space. Finally,

$$\begin{aligned}
&|P_1(\varphi_1, v_1)(x) - P_1(\varphi_2, v_2)(x)| \\
&\le C(F) \left[3d(\varphi_1, \varphi_2) + \|v_1 - v_2\|_{C_1^1(\mathbb{R})} + \frac{C}{1-r} D\left((\varphi_1, v_1), (\varphi_2, v_2)\right)\right] \\
&\le \left(3 + \frac{C}{1-r}\right) C(F) \cdot D\left((\varphi_1, v_1), (\varphi_2, v_2)\right),
\end{aligned}$$

where $C(F) = \sup_{w\in\mathbb{R}^5,\ \|w\|\le 5C} \|\nabla F(w)\|$. Similar computations, performed for

$P_2(\varphi, v)$ and $\partial_x P(\varphi, v)$, respectively, where

$$\begin{aligned}\partial_x P(\varphi,v)(x) &= (y-V)(\varphi(x))\cdot\varphi'(x)\\ &= [O_1(\varphi,v)(x)+O_2(\varphi,v)(x)]\,\varphi'(x)\\ &\quad -\varphi'(x)\left[\alpha v^2(x)+\beta\left(\frac{v'(x)}{\varphi'(x)}\right)^2\right]\end{aligned}$$

and

$$O_1(\varphi,v)(x) = \int_0^x \frac{\text{ch }\left(\varphi(x)-\varphi(q)-\frac{1}{2}\right)}{2\text{sh }\frac{1}{2}}\left[\alpha v^2(q)+\beta\left(\frac{v'(q)}{\varphi'(q)}\right)^2\right]\varphi'(q)dq,$$

$$O_2(\varphi,v)(x) = \int_x^1 \frac{\text{ch }\left(\varphi(x)-\varphi(q)+\frac{1}{2}\right)}{2\text{sh }\frac{1}{2}}\left[\alpha v^2(q)+\beta\left(\frac{v'(q)}{\varphi'(q)}\right)^2\right]\varphi'(q)dq$$

allow us to complete the proof. □

PROPOSITION 2. *Let $r \in (0,1)$ and $K > 0$ be fixed and denote by c_0 the Lipschitz coefficient of P from Proposition 1. Fix also*

$$0 < T < \min\left(\frac{r}{\|v_0\|_{C_1^1(\mathbb{R})}+K}, \frac{K}{c_0(r+K)+\|P(Id,v_0)\|_{C_1^1(\mathbb{R})}}\right).$$

Then, the initial value problem

$$\begin{cases}\partial_t v = P(\varphi_v, v),\\ v(0) = v_0,\end{cases}$$

where $\varphi_v(t,x) = x + \int_0^t v(s,x)ds$, has a unique solution in $C^1([0,T], C_1^1(\mathbb{R}))$.

Proof. Denote by M the closed ball of radius K and center v_0 in $C([0,T], C_1^1(\mathbb{R}))$ and introduce the operator $\mathcal{T} : C([0,T], C_1^1(\mathbb{R})) \to C([0,T], C_1^1(\mathbb{R}))$ given by

$$(\mathcal{T}v)(t) = v_0 + \int_0^t P(\varphi_v, v)(s)ds, \qquad t \in [0,T].$$

For $v \in M$, we have $v(t) \in C_1^1(\mathbb{R})$ yielding that $\varphi_v(t) \in X(\mathbb{R})$. Furthermore,

$$\begin{aligned}d(Id,\varphi_v(t)) &= |\varphi_v(t,0)| + \sup_{x\in\mathbb{R}}\left|1-\frac{d}{dx}\varphi_v(t,x)\right| \le t\sup_{s\in[0,t]}\|v(s)\|_{C_1^1(\mathbb{R})}\\ &\le T\left(\|v_0\|_{C_1^1(\mathbb{R})}+K\right) < r,\end{aligned}$$

which implies that $\varphi_v(t) \in U_r$ for $t \in [0,T]$. Now,

$$\begin{aligned}&\|(\mathcal{T}v)(t)-v_0\|_{C_1^1(\mathbb{R})}\\ &\le \int_0^T \|P(\varphi_v,v)(s)\|_{C_1^1(\mathbb{R})}\,ds\\ &\le \int_0^T \left(c_0 D((\varphi_v(s),v(s)),(Id,v_0)) + \|P(Id,v_0)\|_{C_1^1(\mathbb{R})}\right)ds\\ &= \int_0^T \left(c_0\left(d(Id,\varphi_v(s)) + \|v_0-v(s)\|_{C_1^1(\mathbb{R})}\right) + \|P(Id,v_0)\|_{C_1^1(\mathbb{R})}\right)ds\\ &\le T\left(c_0(r+K)+\|P(Id,v_0)\|_{C_1^1(\mathbb{R})}\right) < K\end{aligned}$$

and so $\mathcal{T}(M) \subseteq M$. Finally, according to Proposition 1, we have

$$\begin{aligned}
&\|(\mathcal{T}v_1)(t) - (\mathcal{T}v_2)(t)\|_{C_1^1(\mathbb{R})} \\
&\le \int_0^t \|P(\varphi_{v_1}, v_1)(s) - P(\varphi_{v_2}, v_2)(s)\|_{C_1^1(\mathbb{R})}\, ds \\
&\le \int_0^t c_0(1+T) \sup_{q\in[0,s]} \|v_1(q) - v_2(q)\|_{C_1^1(\mathbb{R})}\, ds \\
&\le c_0(1+T) d_k(v_1, v_2) \cdot \frac{e^{kt}-1}{k}
\end{aligned}$$

and, respectively,

$$d_k\left(\mathcal{T}v_1, \mathcal{T}v_2\right) \le \frac{c_0(1+T)}{k} d_k(v_1, v_2),$$

where $k > c_0(1+T)$ is fixed and

$$d_k(v, w) = \sup_{s\in[0,T]} \left(e^{-ks} \sup_{q\in[0,s]} \|v_1(q) - v_2(q)\|_{C_1^1(\mathbb{R})} \right), \qquad v\ ,\ w \in C_1^1(\mathbb{R}).$$

The operator $\mathcal{T}$ being a contraction, the conclusion follows by application of the Banach contraction principle. □

THEOREM 1. *Let v be the solution obtained at Proposition 2. Then, the function $u : [0,T] \times \mathbb{R} \to \mathbb{R}$ given by*

$$u(t,x) = v\left(t, \varphi_v^{-1}(t,x)\right)$$

belongs to $C^1([0,T], C_1(\mathbb{R})) \cap C([0,T], C_1^1(\mathbb{R}))$, is periodic of period 1 with respect to the spatial variable, and satisfies the nonlinear dispersive equation

$$u_t + uu_x + \partial_x(1-\partial_x^2)^{-1}\left(\alpha u^2 + \beta u_x^2\right) = 0, \qquad x \in \mathbb{R},\ t \ge 0,$$

together with the initial datum $u(0) = v_0$.

Proof. The conclusion will be reached in several steps.

Step 1. *$\varphi^{-1}(\cdot, x) \in C^1([0,T], \mathbb{R})$, where $\varphi = \varphi_v$.* Consider $t_1,\ t_2 \in [0,T]$. Then,

$$\begin{aligned}
&\left|\varphi^{-1}(t_1, \varphi(t_2,x)) - \varphi^{-1}(t_2, \varphi(t_2,x))\right| \\
&= \left|\varphi^{-1}(t_1, \varphi(t_2,x)) - \varphi^{-1}(t_1, \varphi(t_1,x))\right| \\
&\le \left| \int_{\varphi(t_1,x)}^{\varphi(t_2,x)} \left|\partial_s \varphi^{-1}(t_1,s)\right| ds \right| \le \frac{1}{1-r} \left|\varphi(t_2,x) - \varphi(t_1,x)\right| \\
&\le \frac{1}{1-r} \left| \int_{t_1}^{t_2} \left|\partial_s \varphi(s,x)\right| ds \right| \le \frac{1}{1-r} \left| \int_{t_1}^{t_2} \|v(s)\|_{C_1^1(\mathbb{R})}\, ds \right| \\
&\le \frac{1}{1-r} \left(\|v_0\|_{C_1^1(\mathbb{R})} + K \right) |t_1 - t_2| .
\end{aligned}$$

Since the estimates are independent of x, by replacing x with $\varphi^{-1}(t_2, x)$, we get

$$\left|\varphi^{-1}(t_1,x) - \varphi^{-1}(t_2,x)\right| \le C\, |t_1 - t_2| . \tag{9}$$

As a Lipschitzian funtion, $\varphi^{-1}(\cdot, x)$ is a.e. differentiable. On the other hand, by differentiating formally with respect to t the identity

$$\varphi^{-1}(t, \varphi(t, x)) = x,$$

we obtain

$$\partial_t \varphi^{-1}(t, \varphi(t, x)) = -\frac{\partial_t \varphi(t, x)}{\partial_x \varphi(t, x)}$$

and, consequently,

$$\partial_t \varphi^{-1}(t, x) = -\frac{\partial_t \varphi(t, \varphi^{-1}(t, x))}{\partial_x \varphi(t, \varphi^{-1}(t, x))} \qquad \text{almost everywhere in } (0, T). \tag{10}$$

The right-hand member of (10) being a continuous function, we have

$$\varphi^{-1}(t, x) = x - \int_0^t \frac{\partial_t \varphi(s, \varphi^{-1}(s, x))}{\partial_x \varphi(s, \varphi^{-1}(s, x))} ds, \qquad t \in [0, T]. \tag{11}$$

The latter formula proves our claim, namely, that φ^{-1} is continuously differentiable with respect to t.

Step 2. $u \in C([0, T], C_1(\mathbb{R}))$ *is Lipschitzian.* We have the following estimates:

$$\begin{aligned} &|u(t_1, x) - u(t_2, x)| \\ &\le \left|v(t_1, \varphi^{-1}(t_1, x)) - v(t_1, \varphi^{-1}(t_2, x))\right| \\ &\quad + \left|v(t_1, \varphi^{-1}(t_2, x)) - v(t_2, \varphi^{-1}(t_2, x))\right| \\ &= I_1(t_1, t_2) + I_2(t_1, t_2), \end{aligned}$$

and

$$\begin{aligned} &I_1(t_1, t_2) \\ &\le \sup_{q \in \mathbb{R}} |\partial_x v(t_1, q)| \cdot \left|\varphi^{-1}(t_1, x) - \varphi^{-1}(t_2, x)\right| \\ &\le \|v(t_1)\|_{C_1^1(\mathbb{R})} C |t_1 - t_2| \le \left(\|v_0\|_{C_1^1(\mathbb{R})} + K\right) C |t_1 - t_2| \\ &\le C^2 |t_1 - t_2|, \end{aligned}$$

$$\begin{aligned} I_2(t_1, t_2) &\le \sup_{t \in [0, T]} \left|\partial_t v(t, \varphi^{-1}(t_2, x))\right| \cdot |t_1 - t_2| \\ &= \sup_{t \in [0, T]} |\partial_x y(t, x)| \cdot |t_1 - t_2| \le c_1 \cdot |t_1 - t_2|, \end{aligned}$$

where, according to (6), we take

$$\begin{aligned} c_1 &\ge \max(|\alpha|, |\beta|) C^2 \int_0^1 |\partial_x G(x - [x] - s)| \, ds \\ &\ge \left(|\alpha| \sup_{q \in \mathbb{R}} |v(t, q)|^2 + \frac{|\beta|}{(1 - r)^2} \sup_{q \in \ R} |\partial_q v(t, q)|^2\right) \\ &\quad \times \int_0^1 |\partial_x G(x - [x] - s)| \, ds. \end{aligned}$$

Step 3. *The family* $\left(\frac{\partial_t\varphi(\cdot,\varphi^{-1}(\cdot,x))}{\partial_x\varphi(\cdot,\varphi^{-1}(\cdot,x))}\right)_{x\in\mathbb{R}}$ *is equicontinuous in* $[0,T]$, that is, the usual ε - δ estimates of continuity are independent of x. Consider $t_1,\ t_2 \in [0,T]$. Then,

$$\begin{aligned}
&\left|\frac{\partial_t\varphi(t_1,\varphi^{-1}(t_1,x))}{\partial_x\varphi(t_1,\varphi^{-1}(t_1,x))} - \frac{\partial_t\varphi(t_2,\varphi^{-1}(t_2,x))}{\partial_x\varphi(t_2,\varphi^{-1}(t_2,x))}\right| \\
&= \left|\frac{v(t_1,\varphi^{-1}(t_1,x))}{\partial_x\varphi(t_1,\varphi^{-1}(t_1,x))} - \frac{v(t_2,\varphi^{-1}(t_2,x))}{\partial_x\varphi(t_2,\varphi^{-1}(t_2,x))}\right| \\
&\leq \frac{\left|v(t_1,\varphi^{-1}(t_1,x) - v(t_2,\varphi^{-1}(t_2,x))\right|}{\partial_x\varphi(t_1,\varphi^{-1}(t_1,x))} \\
&\quad + \left|v(t_2,\varphi^{-1}(t_2,x))\right| \frac{\left|\partial_x\varphi(t_1,\varphi^{-1}(t_1,x)) - \partial_x\varphi(t_2,\varphi^{-1}(t_2,x))\right|}{\partial_x\varphi(t_1,\varphi^{-1}(t_1,x))\partial_x\varphi(t_2,\varphi^{-1}(t_2,x))} \\
&= J_1(t_1,t_2) + J_2(t_1,t_2)
\end{aligned}$$

and

$$J_1(t_1,t_2) \leq \frac{1}{1-r}\left|u(t_1,x) - u(t_2,x)\right| \leq \frac{1}{1-r}\left(C^2 + c_1\right)\left|t_1 - t_2\right|,$$

$$\begin{aligned}
&J_2(t_1,t_2) \\
&\leq \|v(t_2)\|_{C_1^1(\mathbb{R})} \frac{1}{(1-r)^2}\left|\partial_x\varphi(t_1,\varphi^{-1}(t_1,x)) - \partial_x\varphi(t_2,\varphi^{-1}(t_2,x))\right| \\
&\leq \frac{C}{1-r}\left|\partial_x\varphi(t_1,\varphi^{-1}(t_1,x)) - \partial_x\varphi(t_2,\varphi^{-1}(t_2,x))\right|.
\end{aligned}$$

Since the function $\partial_x\varphi$ is periodic with period 1, its restriction to $[0,T]\times\mathbb{R}$ is uniformly continuous, that is, for every $\varepsilon > 0$ there exists $\delta = \delta(\varepsilon) > 0$ such that

$$|\partial_x\varphi(t_1,x_1) - \partial_x\varphi(t_2,x_2)| < \varepsilon$$

for all $t_1,\ t_2 \in [0,T]$ with $|t_1 - t_2| < \delta$ and x_1 , $x_2 \in \mathbb{R}$ with $|x_1 - x_2| < \delta$. Let us denote by $\delta_1 = \delta_1(\varepsilon) > 0$ the quantity $\min\left(\delta, \frac{\delta}{C}\right)$. According to (9), for $t_1,\ t_2 \in [0,T]$ with $|t_1 - t_2| < \delta_1$ we get

$$\left|\partial_x\varphi(t_1,\varphi^{-1}(t_1,x)) - \partial_x\varphi(t_2,\varphi^{-1}(t_2,x))\right| < \varepsilon, \quad x \in \mathbb{R}. \tag{12}$$

All the preceding estimates are independent of x, thus proving our claim.

Step 4. $\varphi^{-1} \in C^1([0,T], C(\mathbb{R},\mathbb{R}))$. Consider $t,\ t+h \in [0,T]$ with $h \neq 0$. Then, formula (11) and the computations in Step 3 yield

$$\begin{aligned}
&\left|\frac{\varphi^{-1}(t+h,x) - \varphi^{-1}(t,x)}{h} - \frac{\partial_t\varphi(t,\varphi^{-1}(t,x))}{\partial_x\varphi(t,\varphi^{-1}(t,x))}\right| \\
&\leq \left|\frac{1}{h}\int_t^{t+h}\left|\frac{\partial_t\varphi(s,\varphi^{-1}(s,x))}{\partial_x\varphi(s,\varphi^{-1}(s,x))} - \frac{\partial_t\varphi(t,\varphi^{-1}(t,x))}{\partial_x\varphi(t,\varphi^{-1}(t,x))}\right| ds\right| \\
&\leq \frac{\varepsilon}{2} + \frac{1}{1-r}\left(C^2 + c_1\right)|h|
\end{aligned}$$

for $|h| < \delta_1\left(\frac{\varepsilon}{2}\right)$. By taking $|h| < \delta_2(\varepsilon) = \min\left(\frac{\varepsilon(1-r)}{2(C^2+c_1)}, \delta_1\left(\frac{\varepsilon}{2}\right)\right)$, we obtain that

$$\left|\frac{\varphi^{-1}(t+h,x)-\varphi^{-1}(t,x)}{h} - \frac{\partial_t\varphi(t,\varphi^{-1}(t,x))}{\partial_x\varphi(t,\varphi^{-1}(t,x))}\right| < \varepsilon, \qquad x \in \mathbb{R}, \tag{13}$$

which proves our claim.

Step 5. $u \in C^1([0,T], C_1(\mathbb{R}))$. Consider t, $t+h \in [0,T]$ with $h \neq 0$. The following estimates hold

$$\begin{aligned}
&\left|\frac{v(t+h,\varphi^{-1}(t+h,x)) - v(t,\varphi^{-1}(t,x))}{h}\right.\\
&\left.-\partial_t v(t,\varphi^{-1}(t,x)) - \partial_x v(t,\varphi^{-1}(t,x)) \cdot \frac{1}{h}\int_{\varphi^{-1}(t,x)}^{\varphi^{-1}(t+h,x)} ds\right|\\
\le &\left|\frac{v(t+h,\varphi^{-1}(t+h,x)) - v(t+h,\varphi^{-1}(t,x))}{h}\right.\\
&\left.-\frac{1}{h}\int_{\varphi^{-1}(t,x)}^{\varphi^{-1}(t+h,x)} \partial_x v(t,\varphi^{-1}(t,x))ds\right|\\
&+\left|\frac{v(t+h,\varphi^{-1}(t,x)) - v(t,\varphi^{-1}(t,x))}{h} - \partial_t v(t,\varphi^{-1}(t,x))\right|\\
\le &\left|\frac{1}{h}\int_{\varphi^{-1}(t,x)}^{\varphi^{-1}(t+h,x)} \left|\partial_x v(t+h,s) - \partial_x v(t,\varphi^{-1}(t,x))\right| ds\right|\\
&+\sup_{q\in\mathbb{R}}\left|\frac{v(t+h,q)-v(t,q)}{h} - \partial_t v(t,q)\right|\\
= &\, E(h) + o(1) \qquad \text{as } h \to 0,
\end{aligned}$$

since $v \in C^1([0,T], C_1^1(\mathbb{R}))$ according to Proposition 2. Similar to the situation described at Step 3, the restriction of function $\partial_x v$ to $[0,T]\times\mathbb{R}$ is uniformly continuous and so

$$\left|\partial_x v(t+h,s) - \partial_x v(t,\varphi^{-1}(t,x))\right| < \varepsilon \tag{14}$$

for $|h|$ small enough provided that $\left|s - \varphi^{-1}(t,x)\right| \le \left|\varphi^{-1}(t+h,x) - \varphi^{-1}(t,x)\right| \le C\,|h|$ is also small. Since

$$E(h) \le \varepsilon\left|\frac{\varphi^{-1}(t+h,x)-\varphi^{-1}(t,x)}{h}\right| \le C\varepsilon, \qquad x \in \mathbb{R},$$

and taking into account (13), our claim is established.

Step 6. $u \in C([0,T], C_1^1(\mathbb{R}))$. We shall confine ourselves to the issue of $\partial_x u \in C([0,T], C_1(\mathbb{R}))$ since $u \in C([0,T], C_1(\mathbb{R}))$ according to Step 2. Consider t_1, $t_2 \in$

$[0, T]$. Then,

$$
\begin{aligned}
&|\partial_x u(t_1, x) - \partial_x u(t_2, x)| \\
\leq\ & \frac{\left|\partial_x v(t_1, \varphi^{-1}(t_1, x)) - \partial_x v(t_2, \varphi^{-1}(t_2, x))\right|}{\partial_x \varphi(t_1, \varphi^{-1}(t_1, x))} \\
&+ \left|\partial_x v(t_2, \varphi^{-1}(t_2, x))\right| \frac{\left|\partial_x \varphi(t_1, \varphi^{-1}(t_1, x)) - \partial_x \varphi(t_2, \varphi^{-1}(t_2, x))\right|}{\partial_x \varphi(t_1, \varphi^{-1}(t_1, x)) \partial_x \varphi(t_2, \varphi^{-1}(t_2, x))} \\
\leq\ & \frac{1}{1-r} \left|\partial_x v(t_1, \varphi^{-1}(t_1, x)) - \partial_x v(t_2, \varphi^{-1}(t_2, x))\right| \\
&+ \frac{C}{1-r} \left|\partial_x \varphi(t_1, \varphi^{-1}(t_1, x)) - \partial_x \varphi(t_2, \varphi^{-1}(t_2, x))\right|.
\end{aligned}
$$

A simple inspection of formulas (12), (14) establishes our claim.

The proof is complete. □

RENORMALIZED ENERGY AND FORCES ON DISLOCATIONS*

PAOLO CERMELLI† AND GIOVANNI LEONI‡

Abstract. In this work we discuss, from a variational viewpoint, the equilibrium problem for a finite number of Volterra dislocations in a plane domain. For a given set of singularities at fixed locations, we characterize elastic equilibrium as the limit of the minimizers of a family of energy functionals, obtained by a finite-core regularization of the elastic-energy functional. We give a sharp asymptotic estimate of the minimum energy as the core radius tends to zero, which allows one to eliminate this internal length scale from the problem. The energy content of a set of dislocations is fully characterized by the regular part of the asymptotic expansion, the so-called renormalized energy, which contains all information regarding self- and mutual interactions between the defects. Thus our result may be considered as the analogue for dislocations of the classical result of Bethuel, Brezis and Hélein for Ginzburg–Landau vortices. We view the renormalized energy as the basic tool for the study of the discrete-to-continuum limit in plasticity of crystals, i.e., the passage from models of isolated defects to theories of continuous distributions of dislocations. The renormalized energy is a function of the defect positions only: we prove that its derivative with respect to the position of a given dislocation is the resultant of the Eshelby stress on that dislocation, which can be identified in turn with the classical Peach–Köhler force.

Key words. dislocations, variational methods, variational techniques for singularities, forces on defects

1. Introduction.

Dislocations are common defects in crystals and influence their behavior in multiple ways. For instance, isolated dislocations generate concentrations of stress which affect the chemical and electronic properties of solids, while the collective motion of large sets of dislocations represents the basic mechanism for plastic slip in ductile solids (cf., e.g., [3], [16], and [23]).

Hence, it is of considerable interest to study the behavior of both isolated and large sets of dislocations.

However, the study of isolated dislocations and of large clusters of defects requires widely different approaches. Problems involving isolated defects involve scales which are typically of the order of the interatomic distances in the crystal, while the characteristic scales involved in the collective behavior of large clusters of dislocations, typically in plasticity, are much larger. A typical example is self-organization of stored dislocations in cell patterns [25]: the characteristic distance between the cell walls is macroscopic, many orders of magnitude larger than the interatomic distances.

Such problems are better studied in terms of dislocation densities, rather than of isolated dislocations, and require the introduction, in the expression for the macroscopic energy of the solid, of terms which depend on the gradients of the (plastic)

strain [1], [15], [18], [19], [20]. These terms are necessarily phenomenological—for instance, energies are assumed to be quadratic in the plastic strain gradients, but such simple choices often lead to unphysical behavior, as shown in [8] for interfacial dislocations in epitaxial films.

At a still larger scale lives classical plasticity: plastic strain gradients are ignored, no internal length scale is introduced, and dislocations are only implicitly taken into account. Classical models cannot describe the self-organization of defects in regular patterns.

Hence, a major open problem in the theory of defects in solids is to correlate the microscopic (isolated defects) and the macroscopic (gradient theories) approaches. Specifically, it would be useful to develop a theoretical framework which allows to characterize the constitutive relations of the continuum models, using the information gained by ab initio models of finite sets of dislocations.

The goal for this paper may be viewed as the first stage of this project: we give a variational formulation of the equilibrium problem for a finite number of dislocations in a plane domain and characterize the energy content of a body with isolated defects in terms of a regular function of the defect configuration, the so-called renormalized energy.

Precisely, consider a finite number of dislocations in an elastic solid: since the stress field induced by a dislocation is short ranged, it is reasonable to work in the approximation of linear elasticity, which may be assumed to be valid sufficiently far from the defect. (This topic has been studied extensively in the literature, and explicit solutions are known in special cases [28], [23], [29].) We restrict attention to plane isotropic elasticity.[1] Let Ω be a regular domain in $\mathbb{R}^2$: in linear elasticity, a displacement of Ω is a regular vector field on Ω, with gradient $\nabla \; = \;$. The equilibrium equations have the form $\operatorname{Div} C[\;(\;)] = 0$ with C a linear operator from $\mathbb{R}^{2\times 2}$ into itself and $(\;) = \frac{1}{2}(\nabla \; + (\nabla \;)^\top)$ the infinitesimal strain tensor.

In this framework, Volterra dislocations may be viewed as singularities of the field . Precisely, fix a finite set of points $\{\;_1, \dots, \;_N\}$ in Ω and a set of vectors $\{\;_1, \dots, \;_N\}$ with $\;_i \in \mathbb{R}^2$: we say that a tensor field on $\Omega \setminus \{\;_1, \dots, \;_N\}$ corresponds to a system of dislocations located at $\{\;_1, \dots, \;_N\}$ with Burgers vectors $\{\;_1, \dots, \;_N\}$ if[2]

$$\begin{cases} \operatorname{Curl} \; = \sum_{i=1}^N \;_i \, \delta_{\;_i} \\ \operatorname{Div} C[\;(\;)] = 0 \end{cases} \quad \text{in } \Omega \tag{1.1}$$

in the sense of distributions, where $(\;) = \frac{1}{2}(\; + \;^\top)$ is the strain associated to .

Solutions of (1.1) are not unique even modulo an infinitesimal rigid motion and, moreover, no variational principle may be associated to (1.1), since the elastic energy of a system of Volterra dislocations is not finite.

Hence, it is necessary to regularize the theory by removing a core $B_\varepsilon(\;_i)$ of radius ε around each dislocation; letting $\Omega_\varepsilon = \Omega \setminus (\cup_{i=1}^N B_\varepsilon(\;_i))$, we solve the family

[1]Point defects in plane elasticity may be effectively used to model straight edge dislocations orthogonal to the plane of strain.

[2]The Curl of a two-dimensional tensor field $\boldsymbol{H}$ is the vector field whose Cartesian components are $(\operatorname{Curl} \boldsymbol{H})_i = (\partial_1 H_{i2} - \partial_2 H_{i1})$.

of minimization problems

$$\min_{\boldsymbol{H}\in H(\ _1,\ldots,\ _N;\Omega_\varepsilon)} \int_{\Omega_\varepsilon} W(\ \ (\ \ ))\, da, \tag{1.2}$$

where $W(\ \ ) = \frac{1}{2}\ \ \cdot C[\ \ ]$ is the elastic energy density,

$$H(\ _1,\ldots,\ _N;\Omega_\varepsilon) = \left\{\ \ \in H(\mathrm{Curl}\,0;\Omega_\varepsilon)\ :\ \int_{\partial B_\varepsilon(\ _i)}\ \ \ ds =\ _i,\quad i=1,\ldots,N\right\},$$

and is the unit tangent vector[3] to $\partial B_\varepsilon(\ _i)$.

Our first result shows that the solutions $\ _\varepsilon$ of (1.2) converge strongly in $L^2_{\mathrm{loc}}(\Omega\setminus\cup_{i=1}^N\{\ _i\};\mathbb{R}^{2\times2})$, as $\varepsilon\to0$, to a solution $\ _0$ of (1.1). This solution is unique modulo a rigid motion. More precisely, we show that

$$\ _\varepsilon \to\ \ _0 = \sum_{i=1}^N\ \ _i + \nabla\ \ _0, \tag{1.3}$$

where $\ _i$ are distributional solutions of (cf. Proposition 3.1),

$$\begin{cases}\mathrm{Curl}\ \ \ = \ _i\,\delta_{\ _i}\\ \mathrm{Div}\,C[\ \ (\ \ )] = 0\end{cases}\qquad \text{in } \mathbb{R}^2,$$

and $\ _0\in H^1(\Omega;\mathbb{R}^2)$ is a regular displacement field which is a minimizer of the functional

$$I_0(\ \ ) := \int_\Omega W(\ \ (\ \ ))\,da + \sum_{i=1}^N \int_{\partial\Omega}\ \ \cdot C[\ \ (\ \ _i)]\ \ \ ds \tag{1.4}$$

on $H^1(\Omega;\mathbb{R}^2)$.

The field $\ _0$ is independent of the internal length scale ε, but its energy is not finite: we obtain a sharp asymptotic estimate as $\varepsilon\to0$ for the minimum energy in (1.2) of the form

(1.5)
$$\int_{\Omega_\varepsilon} W(\ \ (\ \ _\varepsilon))\,da = \sum_{i=1}^N \frac{\mu(\lambda+\mu)}{4\pi(\lambda+2\mu)}|\ _i|^2 \ln\frac{1}{\varepsilon} + F(\ _1,\ldots,\ _N) + O(\varepsilon) + \mathrm{Const.},$$

where λ, μ are the Lamé moduli, and

$$F(\ _1,\ldots,\ _N) = F_{\mathrm{self}}(\ _1,\ldots,\ _N) + F_{\mathrm{int}}(\ _1,\ldots,\ _N) + F_{\mathrm{elastic}}(\ _1,\ldots,\ _N) \tag{1.6}$$

[3]We choose $\boldsymbol{t} = \boldsymbol{n}^\perp$ to be a counterclockwise $\pi/2$-rotation of the outward unit normal $\boldsymbol{n}$ to $\partial B_\varepsilon(\boldsymbol{x}_i)$.

is the *renormalized energy*, with

(1.7)
$$\begin{cases} F_{\mathrm{self}}(\ _1, \dots, \ _N) = \displaystyle\sum_{i=1}^{N} \int_{\Omega \setminus B_R(\ _i)} W(\ (\ _i))\, da + \sum_{i=1}^{N} \frac{\mu(\lambda+\mu)}{4\pi(\lambda+2\mu)} |\ _i|^2 \ln R, \\ F_{\mathrm{int}}(\ _1, \dots, \ _N) = \displaystyle\sum_{i=1}^{N-1} \sum_{j=i+1}^{N} \int_{\Omega} C[\ (\ _i)] \cdot \ (\ _j)\, da, \\ F_{\mathrm{elastic}}(\ _1, \dots, \ _N) = \displaystyle\int_{\Omega} W(\ (\ _0))\, da + \sum_{i=1}^{N} \int_{\partial\Omega} \ _0 \cdot C[\ (\ _i)] \ \ ds, \end{cases}$$

and

$$0 < R < \frac{1}{4} \min\{|\ -\ | : \ \neq \ , (\ ,\ ) \in S \times (S \cup \partial\Omega)\},$$

where $S = \{\ _1, \dots, \ _N\}$. It can be shown that F_{self} is independent of R.

It is important to remark that while for special domains the asymptotic formula

$$\int_{\Omega_\varepsilon} W(\ (\ _\varepsilon))\, da \sim \sum_{i=1}^{N} \frac{\mu(\lambda+\mu)}{4\pi(\lambda+2\mu)} |\ _i|^2 \ln \frac{1}{\varepsilon} \tag{1.8}$$

is classical (see, e.g., [23], [29]) and can be obtained by solving explicitly the Euler equation (1.1) (see [28]), for general domains there are various formal arguments in support of (1.8) but we are not aware of any rigorous derivation prior to ours.

More importantly, the introduction of the renormalized energy in this context appears to be new, and thus our result may be considered as the analogue for dislocations of the classical result of Bethuel, Brezis, and Hélein (see Chapter 2 in [5]; see also [4]) for Ginzburg–Landau vortices. We refer to the monograph [5] for more details about the Ginzburg–Landau functional. (See also [2], [6], [22] and the references contained therein for more recent results.)

Note that the renormalized energy is independent of the core radius and is a function of the defect position which fully characterizes the energy content of a dislocated body. Hence, it provides a basis for the study of the behavior of finite sets of dislocations.

As an example application of these ideas, we prove that the interaction energy F_{int} in $(1.7)_2$ diverges logarithmically with the relative distance between the defects:

$$F_{\mathrm{int}}(\ _1, \dots, \ _N) = \sum_{i=1}^{N-1} \sum_{j=i+1}^{N} \frac{\mu(\lambda+\mu)}{\pi(\lambda+2\mu)} \ _i \cdot \ _j \ln \frac{1}{|\ _i - \ _j|} + O(1)$$

as $|\ _i - \ _j| \to 0$.

When more than one dislocation is present, or an external stress is applied to the dislocated body, defects interact between themselves and with the applied field, by means of the so-called Peach–Köhler force [30]. Since the renormalized energy contains all the information about defect interactions, a natural question is whether it is somehow related to the Peach–Köhler force on dislocations. Indeed, the asymptotic analysis of a regularized Ginzburg–Landau equation, intended to model disclinations in liquid crystals, shows that on a long time scale defects move according to a simple evolution equation, which has the form velocity = force on the defect [21], [27], [26], where the force on the defect is defined as the derivative of the renormalized energy with respect to the defect position.

In this line of thought, we prove the fundamental relation

$$\nabla_{\ \ k} F = -\int_{\partial B_R(\ \ k)} \Big\{ W(\ \ (\ \ _0))\mathbf{1} - \ \ _0^{\top} C[\ \ (\ \ _0)] \Big\} \ \ ds \tag{1.9}$$

for $R < \min_i \frac{1}{2}\mathrm{d}(\ \ _i, \partial\Omega)$, where the integrand $\ \ = W(\ \ (\ \ _0))\mathbf{1} - \ \ _0^{\top} C[\ \ (\ \ _0)]$ is called the Eshelby stress. This object, also known as configurational stress, is usually introduced in continuum mechanics in conjunction with an additional balance law, the configurational balance, when defective structures such as interfaces, cracks, or inclusions are present [18]. The configurational balance governs the evolution of the defect, and the resultant of the Eshelby stress in (1.9) may be identified with the force acting on a defect. In the theory of elastic dislocations, the force on a defect is defined by means of the Peach–Köhler force, and indeed it can be shown that the resultant of the configurational stress coincides with the Peach–Köhler force on a dislocation [7].

Hence, (1.9) shows that the derivative of the renormalized energy coincides with the force on a dislocation.

The idea that the force on a defect is the derivative of the minimum energy with respect to changes of the defect position is the basis of Eshelby's treatment of defects [12], [13], [11]. However, when dislocations are present the energy is not finite, so that Eshelby's approach fails without modifications. Our result may be viewed as the generalization of Eshelby's notion of force on a defect, when bad singularities are associated to the defect itself.

2. The variational problem. Let $\Omega \subset \mathbb{R}^2$ be a simply connected bounded open domain with smooth boundary $\partial\Omega$, with outward unit normal $\ \ $. In the absence of defect, we denote by $\ \ : \Omega \to \mathbb{R}^2$ the *displacement field*, with *displacement gradient* $\nabla\ \ $ and *strain tensor* $\ \ (\ \ ) = \frac{1}{2}\left(\nabla\ \ + (\nabla\ \ )^{\top}\right)$. We write

$$\ \ = C[\ \ ]$$

for the (symmetric) Cauchy stress, with $C : \mathrm{Sym} \to \mathrm{Sym}$ the *elasticity tensor*, a symmetric[4] linear map on the space Sym of symmetric 2×2 tensors. For isotropic materials, the stress has the form

$$C[\ \ ] = \lambda(\mathrm{tr}\ \ )\mathbf{1} + 2\mu\ \ \tag{2.1}$$

with λ, μ the Lamé moduli. The associated *energy functional* is

$$J(\ \ ) = \int_{\Omega} W(\ \ (\ \ ))\, da, \tag{2.2}$$

which is defined on $H^1(\Omega;\mathbb{R}^2)$. Here $W(\ \ ) = \frac{1}{2}\ \ \cdot C[\ \ ]$ is the *strain energy density*, and we assume that the elasticity tensor C is positive definite.[5] In plane elasticity and for isotropic materials this is equivalent to requiring

$$\mu > 0 \quad \text{and} \quad \lambda + \mu > 0. \tag{2.3}$$

[4]That is, $\boldsymbol{E} \cdot C[\boldsymbol{F}] = \boldsymbol{F} \cdot C[\boldsymbol{E}]$ for any $\boldsymbol{E}, \boldsymbol{F} \in \mathrm{Sym}$, where $\cdot$ is the inner product of 2×2 tensors.

[5]This implies that there exist constants $c_1, c_2 > 0$ such that $c_1|\boldsymbol{E}|^2 \le W(\boldsymbol{E}) \le c_2|\boldsymbol{E}|^2$ for any $\boldsymbol{E} \in \mathrm{Sym}$.

In this paper we shall deal with isotropic materials only.

When defects such as dislocations are present, the displacement field is not single-valued, and the equilibrium problem must be formulated in terms of a 2×2 tensor field , defined away from the defects, and such that Curl $= 0$. The field plays the role of displacement gradient but is not necessarily the gradient of a displacement field globally defined on Ω: we will continue to use the denomination *strain tensor* associated to for the symmetric part of , writing

$$(\ ) = \frac{1}{2}\Big(\quad + \quad ^{\top} \Big). \tag{2.4}$$

More precisely, we are interested in situations in which the field has a finite number of singularities in Ω: to this purpose, let $\{ \ _i\}_{i=1,\dots,N}$ be a finite sequence of points in Ω, and for $\varepsilon > 0$ let

$$\Omega_\varepsilon = \Omega \setminus \left(\bigcup_{i=1}^{N} B_\varepsilon(\ _i) \right),$$

and consider the space

$$H(\mathrm{Curl};\Omega_\varepsilon) := \big\{ \quad \in L^2(\Omega_\varepsilon;\mathbb{R}^{2\times 2}) \,:\, \mathrm{Curl} \quad \in L^2(\Omega_\varepsilon;\mathbb{R}^{2\times 2}) \big\}. \tag{2.5}$$

Following [10] we set

$$H(\mathrm{Curl}\,0;\Omega_\varepsilon) := \{ \quad \in H(\mathrm{Curl};\Omega_\varepsilon) \,:\, \mathrm{Curl} \quad = \mathbf{0} \}.$$

We say that $\in H(\mathrm{Curl}\,0;\Omega_\varepsilon)$ corresponds to a *system of dislocations* located at $\ _i$, with *Burgers vectors* $\ _i$ and *cores* $B_\varepsilon(\ _i)$, if

$$\int_{\partial B_\varepsilon(\ _i)} \quad ds = \ _i, \quad i = 1,\dots,N, \tag{2.6}$$

with the unit tangent to $\partial B_\varepsilon(\ _i)$, obtained by rotating counterclockwise by $\pi/2$ the outward unit normal to $\partial B_\varepsilon(\ _i)$. Here we have used the fact that for each $i = 1,\dots,N$ the trace map

$$\mapsto$$

defined on $C^\infty(\overline{\Omega_\varepsilon};\mathbb{R}^{2\times 2})$ extends by continuity to a continuous linear mapping, still denoted , from $H(\mathrm{Curl};\Omega_\varepsilon)$ to $H^{-\frac{1}{2}}(\partial B_\varepsilon(\ _i);\mathbb{R}^2)$. (See, e.g., Theorem 2 in [10].) With an abuse of notation for every $\varphi \in H^{\frac{1}{2}}(\partial B_\varepsilon(\ _i))$ we continue to denote by $\int_{\partial B_\varepsilon(\ _i)} \varphi \quad ds$ the value of the linear mapping applied to φ. We shall denote by $H(\ _1,\dots,\ _N;\Omega_\varepsilon)$ the closed subspace of $H(\mathrm{Curl}\,0;\Omega_\varepsilon)$ of tensor fields corresponding to systems of dislocations with Burgers vectors $\ _i$, i.e.,

$$H(\ _1,\dots,\ _N;\Omega_\varepsilon) := \left\{ \quad \in H(\mathrm{Curl}\,0;\Omega_\varepsilon) \,:\, \int_{\partial B_\varepsilon(\ _i)} \quad ds = \ _i, \quad i = 1,\dots,N \right\}. \tag{2.7}$$

The *strain energy functional* is defined as in the absence of defects (cf. (2.2)),

$$J_\varepsilon(\ ) = \int_{\Omega_\varepsilon} W(\ (\ ))\, da, \tag{2.8}$$

and the associated minimization problem is

$(M_{\boldsymbol{H},\varepsilon})$: minimize the strain energy functional over all systems of dislocations located at given points $(\ _1, \dots, \ _N)$, and with given Burgers vectors $(\ _1, \dots, \ _N)$, i.e., find the solutions of

$$\min_{\boldsymbol{H} \in H(\ _1,\dots, \ _N;\Omega_\varepsilon)} J_\varepsilon(\quad). \tag{2.9}$$

PROPOSITION 2.1. *Assume that the elasticity tensor C satisfies condition* (2.3). *Then*

$$\ _\varepsilon \in H(\ _1, \dots, \ _N; \Omega_\varepsilon)$$

is a minimizer of (2.9) *if and only if* $\ _\varepsilon$ *is a weak solution of the Neumann boundary problem*

$$\begin{cases} \operatorname{Div} C[\ (\ _\varepsilon)] = \mathbf{0} & \text{in } \Omega_\varepsilon, \\ C[\ (\ _\varepsilon)] \ = 0 & \text{on } \partial\Omega_\varepsilon = \partial\Omega \cup \left(\cup_{i=1}^N \partial B_\varepsilon(\ _i)\right). \end{cases} \tag{2.10}$$

Moreover, $\ _\varepsilon$ *is unique modulo an infinitesimal rigid-body motion.*

Proof. Since J_ε is quadratic it follows from standard arguments in the calculus of variations that $\ _\varepsilon$ is a minimizer if and only if it satisfies the weak Euler equation

$$\int_{\Omega_\varepsilon} C[\ _\varepsilon] \cdot \ (\ ) \, da = 0 \qquad \text{for all } \ \in H^1(\Omega_\varepsilon; \mathbb{R}^2). \tag{2.11}$$

Indeed, note that for every $\ , \tilde{\ } \in H(\ _1, \dots, \ _N; \Omega_\varepsilon)$ there exists $\ \in H^1(\Omega_\varepsilon; \mathbb{R}^2)$ such that $\tilde{\ } = \ + \nabla \ $: moreover, for t a real parameter,

$$J_\varepsilon(\ + t\nabla \ ) - J_\varepsilon(\ ) = t \int_{\Omega_\varepsilon} C[\ ] \cdot \ (\ ) \, da + t^2 J_\varepsilon(\nabla \ ),$$

and this proves the assertion.

To prove uniqueness let $\ _\varepsilon$ and $\ '_\varepsilon$ be two solutions of (2.11); then $\ '_\varepsilon = \ _\varepsilon +$ with $\ $ a constant skew-symmetric tensor. Indeed, since $\ _\varepsilon$ and $\ '_\varepsilon$ both belong to $H(\ _1, \dots, \ _N; \Omega_\varepsilon)$, then $\ '_\varepsilon = \ _\varepsilon + \nabla \ $ for some $\ \in H^1(\Omega_\varepsilon; \mathbb{R}^2)$, which satisfies the equation

$$\int_{\Omega_\varepsilon} C[\ (\ )] \cdot \ (\ ) \, da = 0 \qquad \text{for all } \ \in H^1(\Omega_\varepsilon; \mathbb{R}^2);$$

choosing $\ = \ $ and using the strong ellipticity of C, this implies that $\ (\ ) = 0$, and, in turn, that $\ (\ ) = \ + \ $ with $\ $ and $\ $ a constant vector and a constant skew-symmetric tensor, respectively, which proves the assertion. ∎

Remark 2.2. Uniqueness of the solution of (2.9) is guaranteed, for instance, by assuming that the total infinitesimal rotation of the body vanishes, i.e.,

$$\int_{\Omega_\varepsilon} (\ _\varepsilon - \ _\varepsilon^\top) \, da = 0. \tag{2.12}$$

3. Existence for a single dislocation in a ball. In this section we consider the special case where

$$\Omega = B_R(\ _0)$$

and we have a single dislocation located at $\ _0$ and with Burger vector $\ $. We are interested in the asymptotic behavior as $\varepsilon \to 0^+$ and $R \to \infty$ of the solutions of the minimization problem

$$\min_{\boldsymbol{H} \in H(\ ;B_R(\ _0)\setminus B_\varepsilon(\ _0))} \int_{B_R(\ _0)\setminus B_\varepsilon(\ _0)} W(\ (\ ))\, da. \tag{3.1}$$

Proposition 3.1. *Assume that the elasticity tensor C satisfies condition* (2.3) *and let* $\ _{,\varepsilon,R}$ *be the unique solution of* (3.1) *such that*

$$\int_{B_R(\ _0)\setminus B_\varepsilon(\ _0)} (\ _{,\varepsilon,R} - \ ^{\top}_{,\varepsilon,R})\, da = 0. \tag{3.2}$$

Then $\{\ _{,\varepsilon,R}\}$ *converges uniformly on compact subsets of* $\mathbb{R}^2 \setminus \{\ _0\}$ *as* $\varepsilon \to 0$ *and* $R \to \infty$ *to the function*[6]

$$(\ ;\ _0) := \frac{1}{2\pi|\ -\ _0|^2}\ \otimes(\ -\ _0)^{\perp} + \nabla\ (\ -\ _0) \tag{3.3}$$

with

$$(\ ) = -\frac{\mu \log|\ |}{2\pi(\lambda+2\mu)}\ ^{\perp} - \frac{\lambda+\mu}{4\pi(\lambda+2\mu)|\ |^2}\left\{(\ \cdot\ ^{\perp})\ + (\ \cdot\ )\ ^{\perp}\right\}, \tag{3.4}$$

which is a solution in the distributional sense of the system

$$\begin{cases} \mathrm{Curl}\ \ = \delta_{\ _0} \\ \mathrm{Div}\, C[\ (\ )] = 0 \end{cases} \quad \text{in } \mathbb{R}^2.$$

Proof. By Proposition 2.1 and Remark 2.2 the functions $\ _{,\varepsilon,R}$ are given by the solutions of (2.9) in $B_R(\ _0) \setminus B_\varepsilon(\ _0)$ satisfying (3.2). In the isotropic case, these are explicitly known [28]:

$$\ _{,\varepsilon,R}(\ ;\ _0) = \ (\ ;\ _0) + \nabla\ _{,\varepsilon,R}(\ -\ _0), \tag{3.5}$$

where

$$\ _{,\varepsilon,R}(\ ) = \frac{(\lambda+\mu)|\ |^2}{2\pi(\lambda+2\mu)(\varepsilon^2+R^2)}\left\{-\ ^{\perp} - \frac{\lambda+3\mu}{2(\lambda+\mu)|\ |^2}\left((\ \cdot\ ^{\perp})\ + (\ \cdot\ )\ ^{\perp}\right)\right\}$$
$$+ \frac{(\lambda+\mu)\,\varepsilon^2 R^2}{2\pi(\lambda+2\mu)(\varepsilon^2+R^2)|\ |^4}\left\{(\ \cdot\ ^{\perp})\ + (\ \cdot\ )\ ^{\perp}\right\}.$$

A straightforward calculation shows that $\ _{,\varepsilon,R}$ satisfies the constraint (3.2) and the Euler equations (2.10). Uniform convergence to $\ $ is immediate.

It is easy to see that $\frac{1}{2\pi|\ -\ _0|^2}\ \otimes(\ -\ _0)^{\perp}$ satisfies

$$\mathrm{Curl}\ \ = \delta_{\ _0} \tag{3.6}$$

[6]Given a vector $\boldsymbol{v}$, we denote by $\boldsymbol{v}^{\perp}$ the vector perpendicular to $\boldsymbol{v}$ obtained by rotating $\boldsymbol{v}$ counterclockwise by $\pi/2$.

in the sense of distributions, and it is clear that all other solutions have the form $\frac{1}{2\pi|\ \ -\ \ _0|^2} \ \otimes (\ \ -\ \ _0)^\perp + \nabla\ \ ,$ a vector field in $W^{1,1}_{\mathrm{loc}}(\mathbb{R}^2;\mathbb{R}^2)$. A straightforward calculation shows that choosing as in (3.4) we obtain that also satisfies

$$\operatorname{Div} C[\ \ (\ \ )] = 0, \tag{3.7}$$

and the proof is complete. ∎

Remark 3.2.

(i) The field may be regarded as the deformation induced by a dislocation with Burgers vector in the whole plane. By introducing polar coordinates (ϱ, ϑ) centered at $_0$, with associated basis $(\ _\varrho,\ _\vartheta)$, we may write

$$= \frac{1}{2\pi\varrho} \ \otimes\ \ _\vartheta + \nabla \tag{3.8}$$

with

$$= -\frac{\mu\log\varrho}{2\pi(\lambda+2\mu)}\ \ ^\perp - \frac{\lambda+\mu}{4\pi(\lambda+2\mu)}\left\{(\ \cdot\ _\vartheta)\ _\varrho + (\ \cdot\ _\varrho)\ _\vartheta\right\}. \tag{3.9}$$

The complete expression for in polar coordinates is

$$\begin{aligned} = \frac{1}{2\pi\varrho(\lambda+2\mu)} [&\mu(\ \cdot\ _\vartheta)\ _\varrho\otimes\ _\varrho + (2\lambda+3\mu)(\ \cdot\ _\varrho)\ _\varrho\otimes\ _\vartheta \\ &-\mu(\ \cdot\ _\varrho)\ _\vartheta\otimes\ _\varrho + \mu(\ \cdot\ _\vartheta)\ _\vartheta\otimes\ _\vartheta], \end{aligned}$$

and the corresponding stress tensor is

$$= \frac{\mu(\lambda+\mu)}{\pi\varrho(\lambda+2\mu)}\{(\ \cdot\ _\vartheta)\ _\varrho\otimes\ _\varrho + (\ \cdot\ _\varrho)(\ _\varrho\otimes\ _\vartheta + \ _\vartheta\otimes\ _\varrho) + (\ \cdot\ _\vartheta)\ _\vartheta\otimes\ _\vartheta\}.$$

Note that is homogeneous of degree -1 in ϱ so that we may write

$$(\varrho,\vartheta;\ _0) = \frac{1}{\varrho}\ \ (\vartheta), \tag{3.10}$$

where is independent of ϱ and $_0$.

(ii) In what follows we shall use extensively the family of tensor fields

$$_{,\varepsilon}(\ ;\ _0) := \ \ (\ ;\ _0) + \nabla\ \ _{,\varepsilon}(\ \ -\ \ _0) \tag{3.11}$$

with

$$_{,\varepsilon}(\ \ ) = \lim_{R\to\infty}\ \ _{,\varepsilon,R}(\ \ ) = \frac{(\lambda+\mu)\,\varepsilon^2}{2\pi(\lambda+2\mu)|\ \ |^4}\left\{(\ \cdot\ ^\perp)\ \ + (\ \cdot\ \ )\ ^\perp\right\}, \tag{3.12}$$

which have the property that $\operatorname{Div} C[\ \ (\ \ _{,\varepsilon})] = 0$ on $\mathbb{R}^2 \setminus B_\varepsilon(\ _0)$, and $C[\ \ (\ \ _{,\varepsilon})]\ \ = 0$ on $\partial B_\varepsilon(\ _0)$. Notice also that $_{,\varepsilon} \to 0$ uniformly on compacta in $\mathbb{R}^2 \setminus \{\ _0\}$.

4. Existence for systems of dislocations in a bounded domain. In this section we study the asymptotic behavior as $\varepsilon \to 0^+$ of the solutions of the minimization problem

$$\min_{\boldsymbol{H} \in H(\ _1, \ldots, \ _N; \Omega_\varepsilon)} \int_{\Omega_\varepsilon} W(\ (\ )) \, da,$$

where, we recall,

$$H(\ _1, \ldots, \ _N; \Omega_\varepsilon) = \left\{ \quad \in H(\operatorname{Curl} 0; \Omega_\varepsilon) \, : \, \int_{\partial B_\varepsilon(\ _i)} \quad ds = \ _i, \quad i = 1, \ldots, N \right\},$$

and where $\ _1, \ldots, \ _N$ and $\ _1, \ldots, \ _N$ are given sets of points in Ω and of Burgers vectors, respectively. The main result of this section is the following theorem.

THEOREM 4.1. *Assume that the elasticity tensor C satisfies condition* (2.3). *Then the minimization problem*

$$\min_{\boldsymbol{H} \in H(\ _1, \ldots, \ _N; \Omega_\varepsilon)} \int_{\Omega_\varepsilon} W(\ (\ )) \, da \tag{4.1}$$

admits a unique solution, modulo an infinitesimal rigid-body motion, $\ _\varepsilon$ which converges as $\varepsilon \to 0$, strongly in $L^2_{\mathrm{loc}}(\Omega \setminus \cup_{i=1}^N \{ \ _i\}; \mathbb{R}^{2\times 2})$, to a solution, in the distributional sense, of the system

$$\begin{cases} \operatorname{Curl} \quad = \sum_{i=1}^N \ _i \, \delta_{\ _i} \\ \operatorname{Div} C[\ (\ )] = 0 \end{cases} \qquad \text{in } \Omega. \tag{4.2}$$

The proof of the previous theorem is divided in several lemmas. We begin by recalling that any tensor field $\ \in H(\ _1, \ldots, \ _N; \Omega_\varepsilon)$ can be written as the sum of a given tensor field in $H(\ _1, \ldots, \ _N; \Omega_\varepsilon)$ and the gradient of a vector field. In particular, we may choose

$$= \sum_{i=1}^N \ _{i,\varepsilon} + \nabla \tag{4.3}$$

with $\ \in H^1(\Omega_\varepsilon; \mathbb{R}^2)$ and (cf. (3.5))

$$\ _{i,\varepsilon}(\ ) := \ _{i,\varepsilon}(\ ; \ _i). \tag{4.4}$$

Notice that $\ _{i,\varepsilon}$ satisfies the Euler equations (2.10) on $\mathbb{R}^2 \setminus B_\varepsilon(\ _i)$, i.e.,

$$\begin{cases} \operatorname{Div} C[\ (\ _{i,\varepsilon})] = 0 & \text{in } \mathbb{R}^2 \setminus B_\varepsilon(\ _i), \\ C[\ (\ _{i,\varepsilon})] \quad = \mathbf{0} & \text{on } \partial B_\varepsilon(\ _i). \end{cases}$$

Also, $\int_{\partial B_\varepsilon(\ _i)} \ _{i,\varepsilon} \ ds = \ _i$.

Inserting (4.3) into the energy functional (2.8) and applying the divergence theorem we obtain

$$J_\varepsilon(\ ) = \sum_{i=1}^N J_\varepsilon(\ _{i,\varepsilon}) + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \int_{\Omega_\varepsilon} C[\ (\ _{i,\varepsilon})] \cdot \ _{j,\varepsilon} \, da + I_\varepsilon(\ ) \tag{4.5}$$

with

$$\text{(4.6)}\quad I_\varepsilon(\ ) := \int_{\Omega_\varepsilon} W(\ (\ ))\, da + \sum_{i=1}^{N} \int_{\partial\Omega} \ \cdot\ _{i,\varepsilon}\ \ ds - \sum_{i=1}^{N}\sum_{j\neq i} \int_{\partial B_\varepsilon(\ _i)} \ \cdot\ _{j,\varepsilon}\ \ ds$$

and where $\ _{i,\varepsilon} := C[\ (\ _{i,\varepsilon})]$.

Hence, granted the decomposition (4.5), for ε fixed, the minimization problem (4.1) is equivalent to the problem

$(M\ _{,\varepsilon})$: minimize the functional I_ε over all displacement fields $\ \in H^1(\Omega_\varepsilon;\mathbb{R}^2)$, i.e., find the solutions of

$$\text{(4.7)}\qquad \min_{\ \in H^1(\Omega_\varepsilon;\mathbb{R}^2)} I_\varepsilon(\ ).$$

In view of (4.3), (4.5), and the invariance of the functional J_ε with respect to infinitesimal rigid-body motions, it is clear that to minimize the functional I_ε over all displacement fields $\ \in H^1(\Omega_\varepsilon;\mathbb{R}^2)$ is equivalent to minimize I_ε over all $\ \in H^1(\Omega_\varepsilon;\mathbb{R}^2)$ such that

$$\text{(4.8)}\qquad \int_B \ \ da = \mathbf{0}, \qquad \int_{\Omega_\varepsilon} (\nabla\ \ - (\nabla\ \ )^\top)\, da = 0$$

for a fixed ball $B \subset \Omega_\varepsilon$. Conditions (4.8) guarantee the coerciveness of the functional I_ε and in turn the existence of minimizers. Indeed we have the following lemma.

LEMMA 4.2. *Assume that the elasticity tensor C satisfies condition* (2.3). *Then there exist two positive constants c_1 and c_2 independent of ε such that*

$$\text{(4.9)}\qquad I_\varepsilon(\ ) \geq c_1 \|\ \|^2_{H^1(\Omega_\varepsilon;\mathbb{R}^2)} - c_2 \|\ \|_{H^1(\Omega_\varepsilon;\mathbb{R}^2)}$$

for every $\ _\varepsilon \in H^1(\Omega_\varepsilon;\mathbb{R}^2)$ satisfying the constraint (4.8). *Moreover, for every ε the minimization problem*

$$\min_{\ \in H^1(\Omega_\varepsilon;\mathbb{R}^2)} I_\varepsilon(\ )$$

admits a unique solution $\ _\varepsilon \in H^1(\Omega_\varepsilon;\mathbb{R}^2)$ satisfying (4.8) *and such that*

$$\text{(4.10)}\qquad \|\ _\varepsilon\|_{H^1(\Omega_\varepsilon;\mathbb{R}^2)} \leq M$$

for some positive constant M independent of ε.

Proof. By the positive definiteness of the elasticity tensor C, for $\ \in H^1(\Omega_\varepsilon;\mathbb{R}^2)$,

$$\text{(4.11)}\qquad I_\varepsilon(\ ) \geq K_0 \int_{\Omega_\varepsilon} |\ (\ )|^2\, da - \sum_{i=1}^{N} \sup_{\partial\Omega} |\ _{i,\varepsilon}| \int_{\partial\Omega} |\ |\, ds$$

$$\text{(4.12)}\qquad - \sum_{i=1}^{N}\sum_{j\neq i} \sup_{\partial B_\varepsilon(\ _i)} |\ _{j,\varepsilon}| \int_{\partial B_\varepsilon(\ _i)} |\ |\, ds.$$

By Korn's inequality (see Proposition A.5) there exists a constant c_3, independent of ε, such that

$$\text{(4.13)}\qquad \int_{\Omega_\varepsilon} |\ (\ _\varepsilon)|^2\, da \geq c_3 \|\ _\varepsilon\|^2_{H^1(\Omega_\varepsilon;\mathbb{R}^2)}.$$

Now, by Proposition A.6

$$(4.14) \qquad \int_{\partial\Omega} |\ _{\varepsilon}|\, ds \leq c_4 \|\ _{\varepsilon}\|_{H^1(\Omega_\varepsilon;\mathbb{R}^2)}, \quad \text{and} \quad \int_{\partial B_\varepsilon(\ _i)} |\ _{\varepsilon}|\, ds \leq c_4 \|\ _{\varepsilon}\|_{H^1(\Omega_\varepsilon;\mathbb{R}^2)}$$

with c_4 independent of ε. Moreover,

$$(4.15) \qquad \sup_{\partial B_\varepsilon(\ _i)} |\ _{j,\varepsilon}| \leq c_5, \qquad j \neq i,$$

with c_5 independent of ε.

Combining (4.12), (4.13), (4.14), and (4.15) yields (4.9). In turn, since the functional I_ε is convex and $I_\varepsilon(\mathbf{0}) = 0$ the remaining of the proof follows immediately. $\square$

We now study the asymptotic behavior of the minimizers $\ _\varepsilon$.

Lemma 4.3. *Assume that the elasticity tensor C satisfies condition* (2.3). *Let $\ _\varepsilon \in H^1(\Omega_\varepsilon;\mathbb{R}^2)$ be the unique solution of*

$$\min_{\ \in H^1(\Omega_\varepsilon;\mathbb{R}^2)} I_\varepsilon(\ )$$

satisfying (4.8). *Then as $\varepsilon \to 0$ the sequence $\{\ _\varepsilon\}$ converges strongly in $H^1_{\mathrm{loc}}(\Omega \setminus \cup_{i=1}^N \{\ _i\};\mathbb{R}^2)$ to a solution $\ _0$ of the minimization problem*

$$(4.16) \qquad \min_{\ \in H^1(\Omega;\mathbb{R}^2)} I_0(\ ).$$

Here

$$(4.17) \qquad I_0(\ ) := \int_\Omega W(\ (\ ))\, da + \sum_{i=1}^N \int_{\partial\Omega} \ \cdot\ _i\ \, ds,$$

where $\ _i := C[\ (\ _i)]$ and

$$(4.18) \qquad \ _i(\ ) := \ _i(\ ;\ _i)$$

is the fundamental solution defined in (3.3). *Moreover,*

$$(4.19) \qquad I_\varepsilon(\ _\varepsilon) \to I_0(\ _0).$$

Proof. By Proposition A.7, we can extend $\ _\varepsilon$ to Ω in such a way that

$$\|\ _\varepsilon\|_{H^1(\Omega;\mathbb{R}^2)} \leq cM,$$

where M is the constant given by (4.10). Hence there exists a subsequence of $\{\ _\varepsilon\}$ not relabeled, such that

$$\ _\varepsilon \rightharpoonup\ _0 \qquad \text{in } H^1(\Omega;\mathbb{R}^2)$$

for some $\ _0 \in H^1(\Omega;\mathbb{R}^2)$. By Hölder's inequality,

(4.20)

$$\left| \int_{\partial B_\varepsilon(\ _i)} \ _\varepsilon \cdot\ _{j,\varepsilon}\ \, ds \right|^2 \leq \int_{\partial B_\varepsilon(\ _i)} |\ _\varepsilon|^2 ds \int_{\partial B_\varepsilon(\ _i)} |\ _{j,\varepsilon}|^2 ds \leq \varepsilon c \sup_{B_\varepsilon(\ _i)} |\ _{j,\varepsilon}|^2 M^2,$$

which vanishes as $\varepsilon \to 0$, and where we have used Proposition A.6, (4.10) and the fact that ${}_{j,\varepsilon} \to {}_{j}$ uniformly on $B_\varepsilon(\ {}_i)$. Hence

$$\lim_{\varepsilon\to 0}\int_{\partial B_\varepsilon(\ {}_i)} {}_\varepsilon \cdot {}_{j,\varepsilon}\ ds = 0. \tag{4.21}$$

Fix now $\varepsilon_0 > 0$. For $\varepsilon < \varepsilon_0$, by (4.6),

$$I_\varepsilon(\ {}_\varepsilon) \geq \int_{\Omega_{\varepsilon_0}} W(\ (\ {}_\varepsilon))\, da + \sum_{i=1}^{N}\int_{\partial\Omega} {}_\varepsilon \cdot {}_{i,\varepsilon}\ ds - \sum_{i=1}^{N}\sum_{j\neq i}\int_{\partial B_\varepsilon(\ {}_i)} {}_\varepsilon \cdot {}_{j,\varepsilon}\ ds.$$

Letting $\varepsilon \to 0^+$, by standard lower semicontinuity results and (4.21), we obtain that

$$\liminf_{\varepsilon\to 0^+} I_\varepsilon(\ {}_\varepsilon) \geq \int_{\Omega_{\varepsilon_0}} W(\ (\ {}_0))\, da + \sum_{i=1}^{N}\int_{\partial\Omega} {}_0 \cdot {}_i\ ds.$$

Letting $\varepsilon_0 \to 0^+$ we get

$$\liminf_{\varepsilon\to 0^+} I_\varepsilon(\ {}_\varepsilon) \geq I_0(\ {}_0).$$

On the other hand, since

$$I_\varepsilon(\ {}_\varepsilon) \leq I_\varepsilon(\ {}_0),$$

we also have that

$$\limsup_{\varepsilon\to 0^+} I_\varepsilon(\ {}_\varepsilon) \leq I_0(\ {}_0).$$

Hence

$$\lim_{\varepsilon\to 0^+} I_\varepsilon(\ {}_\varepsilon) = I_0(\ {}_0). \tag{4.22}$$

To prove strong convergence, notice that (4.19) implies that

$$\lim_{\varepsilon\to 0^+}\int_{\Omega_\varepsilon} W(\ (\ {}_\varepsilon))\, da = \int_{\Omega} W(\ (\ {}_0))\, da,$$

from which we conclude that, as in Evans [14],

$$\lim_{\varepsilon\to 0^+}\int_{\Omega_\varepsilon} |\ (\ {}_\varepsilon) - \ (\ )|^2\, da = 0,$$

and strong convergence of ${}_\varepsilon$ in $H^1_{\mathrm{loc}}(\Omega;\mathbb{R}^2)$ follows from Korn's inequality.

Now we claim that ${}_0$ minimizes I_0. Indeed for any $\ \in H^1(\Omega;\mathbb{R}^2)$ we have that

$$I_\varepsilon(\ ) \geq I_\varepsilon(\ {}_\varepsilon),$$

so that letting $\varepsilon \to 0^+$ and using (4.19),

$$I_0(\ ) \geq I_0(\ {}_0).$$

Next we claim that ${}_0$ satisfies

$$\int_B {}_0 da = \mathbf{0}, \qquad \int_\Omega (\nabla {}_0 - (\nabla {}_0)^\top)\, da = 0, \tag{4.23}$$

The first constraint follows immediately from (4.8), since $\{ {}_\varepsilon\}$ converges strongly in $H^1_{\rm loc}(\Omega \setminus \cup_{i=1}^N \{ {}_i\}; \mathbb{R}^2)$ to ${}_0$. To prove the second constraint, let ${}_\varepsilon := \frac{1}{2}(\nabla {}_\varepsilon - (\nabla {}_\varepsilon)^\top)$ and ${}_0 = \frac{1}{2}(\nabla {}_0 - (\nabla {}_0)^\top)$, and notice that ${}_\varepsilon \to {}_0$ strongly in $L^2_{\rm loc}(\Omega \setminus \cup_{i=1}^N \{ {}_i\}; \mathbb{R}^{2\times 2})$. Now, denote by $\tilde{}_\varepsilon$ the extension of ${}_\varepsilon$ to zero on Ω. Then, since $\|\nabla {}_\varepsilon\|_{L^2(\Omega_\varepsilon;\mathbb{R}^{2\times 2})}$ is bounded independently of ε, it follows that the sequence $\|\tilde{}_\varepsilon\|_{L^2(\Omega;\mathbb{R}^{2\times 2})}$ is bounded, so that $\tilde{}_\varepsilon \rightharpoonup \tilde{}_0$ in $L^2(\Omega;\mathbb{R}^{2\times 2})$ for some $\tilde{}_0 \in L^2(\Omega;\mathbb{R}^{2\times 2})$. Hence, also $\tilde{}_\varepsilon \rightharpoonup \tilde{}_0$ weakly in $L^2_{\rm loc}(\Omega \setminus \{ {}_0\}; \mathbb{R}^{2\times 2})$, and $\tilde{}_0 = {}_0$. By weak convergence,

$$0 = \int_{\Omega_\varepsilon} {}_\varepsilon da = \int_\Omega \tilde{}_\varepsilon da \to \int_\Omega {}_0 da,$$

and the claim follows. Since the minimization problem

$$\min_{\in H^1(\Omega;\mathbb{R}^2)} I_0(\ ),$$

admits a unique solution modulo an infinitesimal rigid-body displacement, we conclude that *all* sequences ${}_\varepsilon$ converge strongly to ${}_0$. □

We are now ready to conclude the proof of Theorem 4.1.

Proof of Theorem 4.1. Let ${}_\varepsilon \in H^1(\Omega_\varepsilon;\mathbb{R}^2)$ be the unique solution of

$$\min_{\in H^1(\Omega_\varepsilon;\mathbb{R}^2)} I_\varepsilon(\ )$$

satisfying (4.8). It suffices to define

$${}_\varepsilon := \sum_{i=1}^N {}_{i,\varepsilon} + \nabla {}_\varepsilon.$$

Since, by Proposition 3.1, ${}_{i,\varepsilon} \to {}_i$ uniformly on compact subsets of $\mathbb{R}^2 \setminus \{ {}_i\}$ the proof is concluded. □

5. The renormalized energy. In this section we prove a sharp estimate for the minimum energy

$$\min_{\boldsymbol{H}\in H({}_1,\dots, {}_N;\Omega_\varepsilon)} \int_{\Omega_\varepsilon} W(\ (\ ))\, da,$$

as the core radius $\varepsilon \to 0$, and compute the renormalized energy which, being a function of the defect position only, allows to study the equilibrium configurations of the defects and the force acting on them.

Let Ω a bounded domain with the cone property as before, let $S = \{ {}_1, \dots, {}_N\}$ be a system of dislocations in Ω, and let

$$\bar{R} := \frac{1}{4}\min\{|\ -\ | : \ \neq\ , (\ ,\ ) \in S \times (S \cup \partial\Omega)\}. \tag{5.1}$$

The main result of this section is the following theorem.

THEOREM 5.1. *Assume that the elasticity tensor C satisfies condition* (2.3)*. Let* $_{\varepsilon} \in H(\ _1, \ldots, \ _N; \Omega_\varepsilon)$ *be a solution of*

$$\min_{\boldsymbol{H} \in H(\ _1, \ldots, \ _N; \Omega_\varepsilon)} \int_{\Omega_\varepsilon} W(\ (\ ))\, da$$

for a system of dislocations with Burgers vectors $_i$*. Then*

$$\int_{\Omega_\varepsilon} W(\ (\ _\varepsilon))\, da = \sum_{i=1}^{N} \frac{\mu(\lambda+\mu)}{4\pi(\lambda+2\mu)} |\ _i|^2 \ln \frac{1}{\varepsilon} + F(\ _1, \ldots, \ _N) + c + O(\varepsilon), \tag{5.2}$$

where

$$F(\ _1, \ldots, \ _N) = F_{\text{self}}(\ _1, \ldots, \ _N) + F_{\text{int}}(\ _1, \ldots, \ _N) + F_{\text{elastic}}(\ _1, \ldots, \ _N) \tag{5.3}$$

is the renormalized energy with

(5.4)

$$\begin{cases} F_{\text{self}}(\ _1, \ldots, \ _N) = \displaystyle\sum_{i=1}^{N} \int_{\Omega \setminus B_R(\ _i)} W(\ (\ _i))\, da + \sum_{i=1}^{N} \frac{\mu(\lambda+\mu)}{4\pi(\lambda+2\mu)} |\ _i|^2 \ln R, \\ F_{\text{int}}(\ _1, \ldots, \ _N) = \displaystyle\sum_{i=1}^{N-1} \sum_{j=i+1}^{N} \int_{\Omega} C[\ (\ _i)] \cdot \ (\ _j)\, da, \\ F_{\text{elastic}}(\ _1, \ldots, \ _N) = \displaystyle\int_{\Omega} W(\ (\ _0))\, da + \sum_{i=1}^{N} \int_{\partial\Omega} \ _0 \cdot \ _i \ \ ds, \end{cases}$$

where $_i(\ ) := \ _i(\ ;\ _i)$ *is the fundamental solution defined in* (3.3)*, the function* $_0$ *is defined in Lemma* 4.3*, c is a constant independent of* $_1, \ldots, \ _N$*, and* $0 < R < \bar{R}$ *is arbitrary. Moreover,* F_{self} *is independent of R.*

Proof. Consider the fundamental solution $_i(\ ) := \ _i(\ ;\ _i)$ defined in (3.3): by (3.10) we may write

$$_i(\varrho_i, \vartheta_i) = \frac{1}{\varrho_i} \ _i(\vartheta_i), \tag{5.5}$$

where (ϱ_i, ϑ_i) are polar coordinates centered at $_i$, and $_i(\vartheta_i)$ is independent of ϱ_i and is defined by (3.10), with replaced by $_i$. A straightforward computation using (3.8) and (3.9) yields

$$a_i := \int_0^{2\pi} W(\ (\ _i(\vartheta)))\, d\vartheta = \frac{\mu(\lambda+\mu)}{4\pi(\lambda+2\mu)} |\ _i|^2. \tag{5.6}$$

By (4.5) we can write the minimum energy in the form

$$J_\varepsilon(\ _\varepsilon) = I_\varepsilon(\ _\varepsilon) + \sum_{i=1}^{N} J_\varepsilon(\ _{i,\varepsilon}) + \sum_{i=1}^{N-1} \sum_{j=i+1}^{N} \int_{\Omega_\varepsilon} C[\ (\ _{i,\varepsilon})] \cdot \ _{j,\varepsilon}\, da,. \tag{5.7}$$

where $I_\varepsilon(\ _\varepsilon)$ is the functional defined by (4.6).

Notice first that the representation of the elastic contribution F_{elastic} in $(5.4)_3$ follows immediately from (4.19).

We now compute the self-energy contribution F_{self}: fix $R < \bar{R}$ and write

$$J_\varepsilon(\ _{i,\varepsilon}) = \int_{\Omega_\varepsilon \setminus B_R(\ _i)} W(\ (\ _{i,\varepsilon}))\, da + \int_{C_{\varepsilon,R}(\ _i)} W(\ (\ _{i,\varepsilon}))\, da \tag{5.8}$$

with $C_{\varepsilon,R}(\ _i) = B_R(\ _i) \setminus B_\varepsilon(\ _i)$.

Now, as $\varepsilon \to 0$, by uniform-on-compacta convergence of $\ _{i,\varepsilon}$ on $\mathbb{R}^2 \setminus \{\ _i\}$,

$$\int_{\Omega_\varepsilon \setminus B_R(\ _i)} W(\ (\ _{i,\varepsilon}))\, da \to \int_{\Omega \setminus B_R(\ _i)} W(\ (\ _i))\, da. \tag{5.9}$$

Moreover, writing as in (3.11) $\ _{i,\varepsilon} = \ _i + \nabla\ _\varepsilon$, with $\ _\varepsilon \to 0$ uniformly on compacta in $\mathbb{R}^2 \setminus \{\ _i\}$, we have

$$\begin{aligned}\int_{C_{\varepsilon,R}(\ _i)} W(\ (\ _{i,\varepsilon}))\, da = \int_{C_{\varepsilon,R}(\ _i)} W(\ (\ _i))\, da + \int_{C_{\varepsilon,R}(\ _i)} C[\ (\ _i)] \cdot \nabla\ _\varepsilon\, da \\ + \int_{C_{\varepsilon,R}(\ _i)} W(\ (\ _\varepsilon))\, da,\end{aligned}$$

and, by (5.5), the first integral on the right-hand side of this identity gives

$$\int_{C_{\varepsilon,R}(\ _i)} W(\ (\ _i))\, da = a_i(\ln R - \ln \varepsilon), \tag{5.10}$$

while the second and third integral may be written as

$$\begin{aligned}&\int_{\partial B_R(\ _i)} \ _\varepsilon \cdot C\left[\ (\ _i) + \frac{1}{2}\ (\ _\varepsilon)\right]\ ds - \int_{\partial B_\varepsilon(\ _i)} \ _\varepsilon \cdot C\left[\ (\ _i) + \frac{1}{2}\ (\ _\varepsilon)\right]\ ds \\ &= \int_{\partial B_R(\ _i)} \ _\varepsilon \cdot C\left[\ (\ _i) + \frac{1}{2}\ (\ _\varepsilon)\right]\ ds - \frac{1}{2}\int_{\partial B_\varepsilon(\ _i)} \ _\varepsilon \cdot C[\ (\ _i)]\ ds \end{aligned} \tag{5.11}$$

where we have used the fact that $C[\ (\ _\varepsilon)]\ = -C[\ (\ _i)]\ $ on $\partial B_\varepsilon(\ _i)$, since $C[\ (\ _{i,\varepsilon})]\ = \mathbf{0}$ on $\partial B_\varepsilon(\ _i)$. The first integral on the right-hand side of the above expression vanishes as $\varepsilon \to 0$, while by (3.12) we may write

$$\ _\varepsilon(\varrho_i, \vartheta_i) = \frac{\varepsilon^2}{\varrho_i^2}\ ^-(\vartheta_i),$$

which, in conjunction with (5.5), shows that

$$-\frac{1}{2}\int_{\partial B_\varepsilon(\ _i)} \ _\varepsilon \cdot C[\ (\ _i)]\ ds = -\frac{1}{2}\int_0^{2\pi} \ ^-(\vartheta) \cdot C[\ (\ _i(\vartheta))]\ d\vartheta = c$$

with c a constant independent of $(\ _1, \dots, \ _N)$. To summarize, (5.11) converges, as $\varepsilon \to 0$, to a constant c independent of R and $\ _i$. Note that this is the constant which appears in (5.2).

Notice that F_{self} is independent of R, since, for $R' < \bar{R}$, say, $R' < R$,

$$\begin{aligned}&\int_{\Omega \setminus B_{R'}(\ _i)} W(\ (\ _i))\, da + a_i \ln R' \\ &\quad = \int_{\Omega \setminus B_R(\ _i)} W(\ (\ _i))\, da + \int_{C_{R',R}(\ _i)} W(\ (\ _i))\, da + a_i \ln R'\end{aligned}$$

$$= \int_{\Omega \setminus B_R(\;_i)} W(\;(\;_i))\, da + a_i \ln \frac{R}{R'} + a_i \ln R'$$
$$= \int_{\Omega \setminus B_R(\;_i)} W(\;(\;_i))\, da + a_i \ln R.$$

We finally compute the contribution of the interaction term F_{int} to the renormalized energy and prove that

$$\int_{\Omega_\varepsilon} C[\;(\;_{i,\varepsilon})] \cdot \;(\;_{j,\varepsilon})\, da = \int_\Omega C[\;(\;_i)] \cdot \;(\;_j)\, da + O(\varepsilon). \tag{5.12}$$

To see this, let as before $\;_{i,\varepsilon} = \;_i + \nabla \;_{i,\varepsilon}$ and $\;_{j,\varepsilon} = \;_j + \nabla \;_{j,\varepsilon}$ (cf. (3.11)), so that

$$\int_{\Omega_\varepsilon} C[\;(\;_{i,\varepsilon})] \cdot \;(\;_{j,\varepsilon})\, da = \int_{\Omega_\varepsilon} C[\;(\;_i)] \cdot \;(\;_j)\, da + \int_{\Omega_\varepsilon} C[\;(\;_i)] \cdot \nabla \;_{j,\varepsilon}\, da$$
$$+ \int_{\Omega_\varepsilon} C[\;(\;_j)] \cdot \nabla \;_{i,\varepsilon}\, da + \int_{\Omega_\varepsilon} C[\;(\;_{i,\varepsilon})] \cdot \nabla \;_{j,\varepsilon}\, da.$$

It can be easily proved that

$$\int_{\Omega_\varepsilon} C[\;(\;_i)] \cdot \;(\;_j)\, da \to \int_\Omega C[\;(\;_i)] \cdot \;(\;_j)\, da,$$

while, applying the divergence theorem, the last three integrals become

$$\int_{\partial\Omega} (\;_{j,\varepsilon} \cdot C[\;(\;_i)]\; + \;_{i,\varepsilon} \cdot C[\;(\;_j)]\; + \;_{j,\varepsilon} \cdot C[\;(\;_{i,\varepsilon})]\;)\, da$$
$$-\sum_{k=1}^N \int_{\partial B_\varepsilon(\;_k)} (\;_{j,\varepsilon} \cdot C[\;(\;_i)]\; + \;_{i,\varepsilon} \cdot C[\;(\;_j)]\; + \;_{j,\varepsilon} \cdot C[\;(\;_{i,\varepsilon})]\;)\, da. \tag{5.13}$$

Now, recall that $\;_{i,\varepsilon} \to 0$ uniformly on compacta in $\mathbb{R}^2 \setminus \{\;_i\}$ (see Remark 3.2(ii)), so that the integrals over $\partial\Omega$ and $\partial B_\varepsilon(\;_k)$ with $k \neq i, j$ vanish in the limit as $\varepsilon \to 0$, and (5.13) becomes

$$-\int_{\partial B_\varepsilon(\;_i)} (\;_{j,\varepsilon} \cdot C[\;(\;_i)]\; + \;_{i,\varepsilon} \cdot C[\;(\;_j)]\; + \;_{j,\varepsilon} \cdot C[\;(\;_{i,\varepsilon})]\;)\, da$$
$$-\int_{\partial B_\varepsilon(\;_j)} (\;_{j,\varepsilon} \cdot C[\;(\;_i)]\; + \;_{i,\varepsilon} \cdot C[\;(\;_j)]\; + \;_{j,\varepsilon} \cdot C[\;(\;_{i,\varepsilon})]\;)\, da, \tag{5.14}$$

which tends to 0 as $\varepsilon \to 0$. Consider in fact the first term: then

$$\left| \int_{\partial B_\varepsilon(\;_i)} \;_{j,\varepsilon} \cdot C[\;(\;_i)]\;\, da \right| \leq C \sup_{B_\varepsilon(\;_i)} |\;_{j,\varepsilon}| \int_{\partial B_\varepsilon(\;_i)} |C[\;(\;_i)]\;|\, da$$
$$\leq \sup_{B_\varepsilon(\;_i)} |\;_{j,\varepsilon}| \int_{\partial B_\varepsilon(\;_i)} |\;_i|\, da \to 0$$

by uniform convergence of $\;_{j,\varepsilon}$. Consider now the second term in (5.14): as before, we may write

$$\;_{i,\varepsilon}(\varrho_i, \vartheta_i) = \frac{\varepsilon^2}{\varrho_i^2}\;\bar{\;}_i(\vartheta_i)$$

so that, since $_j$ is continuous at $_i$,

$$\left|\int_{\partial B_\varepsilon(\ _i)} \ _{i,\varepsilon}\cdot C[\ (\ _j)]\ \ ds\right| \le \sup_{B_\varepsilon(\ _i)} |C[\ (\ _j)]| \int_{\partial B_\varepsilon(\ _i)} |\ ^-{}_i|\, ds \to 0$$

as $\varepsilon \to 0$, since $\ ^-{}_i$ is bounded. The remaining terms in (5.14) can be treated analogously, and this completes the proof of (5.2). ◻

PROPOSITION 5.2. *The interaction energy F_{int} in $(5.4)_2$ diverges logarithmically with the relative distance between the defects:*

$$F_{\text{int}}(\ _1,\dots,\ _N) = \sum_{i=1}^{N-1}\sum_{j=i+1}^{N} \frac{\mu(\lambda+\mu)}{\pi(\lambda+2\mu)}\ _i\cdot\ _j \ln\frac{1}{|\ _i-\ _j|} + O(1), \tag{5.15}$$

as $|\ _i - \ _j| \to 0$.

Proof. Recall that $_i \in L^1(\Omega;\mathbb{R}^{2\times 2})$ for each i, and

$$F_{\text{int}}(\ _1,\dots,\ _N) = \sum_{i=1}^{N-1}\sum_{j=i+1}^{N}\int_\Omega C[\ (\ _i)]\cdot\ (\ _j)\, da,$$

let $_i,\ _j \in \Omega$, and γ a line segment parallel to $_j -\ _i$ connecting $_j$ to $\partial\Omega$ (cf. Figure 5.1), so that $\gamma = \{\ \in\Omega :\ =\ _j + s(\ _j -\ _i)\}$, with $s\in[0,\bar{s}]$. Moreover, let $\ = (\frac{\ _j-\ _i}{|\ _j-\ _i|})^\perp$ be the unit vector orthogonal to γ. Consider the tensor field $_j$: while $\Omega\setminus\{\ _j\}$ is not simply connected, $\Omega\setminus\gamma$ is, so that there exists a field $_j$ on $\Omega\setminus\gamma$ such that $_j = \nabla\ _j$, and

$$[\![\ _j]\!] = -\ _j,$$

where $[\![\ _j]\!]$ is the jump of $_j$ across γ, defined by

$$[\![\ _j]\!](\ ) := \lim_{\ \to\ ,\ \cdot\ >0}\ _j(\ ) - \lim_{\ \to\ ,\ \cdot\ <0}\ _j(\ )$$

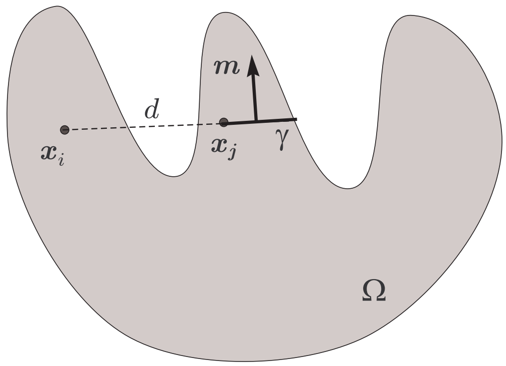

FIG. 5.1. *Connecting cut γ.*

for $\in \gamma$. Applying the divergence theorem to $\Omega\backslash\gamma$, and noting that $\partial(\Omega\backslash\gamma) = \partial\Omega\cup\gamma$, we find

$$\int_{\Omega} C[\ (\ _i)] \cdot \ _j \, da = \int_{\Omega\backslash\gamma} C[\ (\ _i)] \cdot \nabla \ _j \, da$$
$$= \int_{\partial\Omega} \ _j \cdot C[\ (\ _i)] \ \ ds - \int_{\gamma} [\![\ _j]\!] \cdot C[\ (\ _i)] \ \ ds.$$

The first integral in the above expression remains bounded as $_i - \ _j \to \mathbf{0}$, since $_i(\ ) = \ _i(\ ;\ _i) \to \ _i(\ ;\ _j)$ uniformly on $\partial\Omega$ as $_j - \ _j \to \mathbf{0}$. As to the second integral, write $_i = \frac{1}{\varrho_i} \ _i(\vartheta_i)$, and choose $s = \varrho_i - d$, $\vartheta_i = \bar{\vartheta}$ on γ with $d = |\ _j - \ _i|$: then

$$-\int_{\gamma} [\![\ _j]\!] \cdot C[\ (\ _i)] \ \ ds = \int_0^{\bar{s}} \ _j \cdot C[\ (\ _i(\bar{\vartheta}))] \ \ \frac{1}{d+s} \, ds$$
$$= \ _j \cdot C[\ (\ _i(\bar{\vartheta}))] \ \ \left(\ln \frac{1}{d} + \ln(d + \bar{s})\right),$$

which proves (5.15) since by a straightforward computation using (3.8) and (3.9) we have

$$_j \cdot C[\ (\ _i(\bar{\vartheta}))] \ \ = \frac{\mu(\lambda+\mu)}{\pi(\lambda+2\mu)} \ _i \cdot \ _j. \qquad \square$$

6. The force on a dislocation. We prove in this section that the derivative of the renormalized energy with respect to defect position coincides with the resultant of the Eshelby stress

$$= W(\ (\ ))\mathbf{1} - \ ^{\top} C[\ (\ )] \tag{6.1}$$

on the dislocation.[7]

To highlight the dependence of the minimizers on the location of the dislocations, we write

$$_0(\ ;\ _1, \ldots, \ _N)$$

[7]Here $\mathbf{1}$ is the identity tensor.

for a minimizer of I_0 relative to a system of dislocations located at $(\ _1, \dots, \ _N)$ in Ω, and

$$(6.2) \qquad \ _0 = \ _0(\ ; \ _1, \dots, \ _N) := \sum_{i=1}^{N} \ _i(\ ; \ _i) + \nabla \ _0(\ ; \ _1, \dots, \ _N)$$

for the corresponding solution of (4.2) as in Theorem 2.1. Let also $\ \in \mathbb{R}^2$ be a fixed vector and $t \in I \subset \mathbb{R}$ a real parameter.

LEMMA 6.1. *The field* $\ _i(\ ; \ _i)$, $\ _0(\ ; \ _1, \dots, \ _N)$ *and* $\ _0(\ ; \ _1, \dots, \ _N)$ *are smooth with respect to* $\ _i$ *for* $i \in \{1, \dots, N\}$.

In particular,

$$(6.3) \qquad \dot{\ }_i(\ ) := \frac{d}{dt} \ _i(\ ; \ _i + t \ )\Big|_{t=0} = -\nabla (\ _i(\ ; \ _i) \ ) = -\nabla (\ _i(\ ) \ ) .$$

Moreover, if for a fixed $k \in \{1, \dots, N\}$ *we denote by* $\dot{\ }_0$ *and* $\dot{\ }_0$ *the smooth fields such that*

$$\dot{\ }_0(\ ) := \frac{d}{dt} \ _0(\ ; \ _1, \dots, \ _k + t \ , \dots, \ _N)\Big|_{t=0},$$

$$\dot{\ }_0(\ ) := \frac{d}{dt} \ _0(\ ; \ _1, \dots, \ _k + t \ , \dots, \ _N)\Big|_{t=0},$$

then

$$(6.4) \qquad \dot{\ }_0 = \nabla \qquad \text{with} \qquad = \dot{\ }_0 - \ _k \ .$$

Proof. Smoothness of $\ _i$ follows upon recalling that $\ _i(\ ; \ _i)$ is a smooth function of $\ - \ _i$ (cf. (3.3)). This implies that $\ _i(\ ; \ _i + t \ ) = \ _i(\ - t \ ; \ _i) = \ _i(\ - t \ )$, so that

$$\dot{\ }_i(\ ) = -\nabla(\ _i(\ )) \ ,$$

where $\nabla(\ _i)$ is the tensor field defined by the identity $[\nabla(\ _i) \ ] = [\nabla(\ _i \ )]$ for any constant vector $\ \in \mathbb{R}^2$. Since Curl $\ _i = 0$ in $\mathbb{R}^2 \setminus \{ \ _i\}$,

$$\nabla(\ _i) \ = \nabla(\ _i \ ),$$

which yields (6.3).

Now, since $\ _0$ minimizes the functional I_0, and satisfies the corresponding Euler equations, it may be written in the form

$$(6.5) \qquad \ _0(\ ; \ _1, \dots, \ _N) = \int_{\partial\Omega} (\ , \ ) \left(\sum_{i=1}^{N} \ _i(\ ; \ _1, \dots, \ _N) \ (\ ) \right) da \ ,$$

modulo an infinitesimal rigid body motion, where $(\ , \ )$ is the Green's function for the Neumann problem in plane elasticity. Since

$$\sum_{i=1}^{N} \ _i(\ ; \ _1, \dots, \ _N) = \sum_{i=1}^{N} C[\ (\ _i(\ ; \ _i))],$$

the smoothness of $\ _0$ follows from the smoothness of $\ _i$.

Finally, the smoothness of $\ _0$ follows from (6.2), and (6.4) can be directly verified. ∎

LEMMA 6.2. *Let $f = f(\ ,t)$, $g = g(\ ,t)$, $r = r(\ ,t)$ be smooth functions defined on $B_R(\ _0+t\ )$, $\partial B_R(\ _0+t\ )$ and $\Omega \setminus B_R(\ _0+t\ )$ for $t \in I \subset \mathbb{R}$, respectively, with $R > 0$ and $\ $ a constant vector. Then*

$$\frac{d}{dt}\int_{B_R(\ _0+t\ )} f(\ ,t)\,da\bigg|_{t=0} = \int_{B_R(\ _0)} D_t f(\ ,0)\,da$$

$$= \int_{B_R(\ _0)} \partial_t f(\ ,0)\,da + \int_{\partial B_R(\ _0)} f(\ ,0)\ \ \cdot\ \ ds, \tag{6.6}$$

and

$$\frac{d}{dt}\int_{\partial B_R(\ _0+t\ )} g(\ ,t)\,ds\bigg|_{t=0} = \int_{\partial B_R(\ _0)} D_t g(\ ,0)\,ds. \tag{6.7}$$

Moreover,

$$\frac{d}{dt}\int_{\Omega\setminus B_R(\ _0+t\ )} r(\ ,t)\,da\bigg|_{t=0} = \int_{\Omega\setminus B_R(\ _0)} \partial_t r(\ ,0)\,da - \int_{\partial B_R(\ _0)} r(\ ,0)\ \ \cdot\ \ ds, \tag{6.8}$$

where

$$D_t f = \partial_t f + \nabla f \cdot\ \ . \tag{6.9}$$

Proof. The first identity follows upon applying the classical theorem of derivation under the integral

$$\frac{d}{dt}\int_{B_R(\ _0+t\ )} f(\ ,t)\,da = \frac{d}{dt}\int_{B_R(\ _0)} f(\ \ +t\ \ ,t)\,da$$

$$= \int_{B_R(\ _0)} (\partial_t f(\ \ +t\ \ ,t) + \ \ \cdot \nabla f(\ \ +t\ \ ,t))\,da;$$

letting $t = 0$ and using the divergence theorem we obtain (6.6). Relation (6.7) follows from a similar argument. To prove (6.8), denote by $\hat{r}(\ ,t)$ a smooth extension of $r(\ ,t)$ to Ω for all $t \in I$. Then

$$\begin{aligned}
\frac{d}{dt}\int_{\Omega\setminus B_R(\ _0+t\ )} r(\ ,t)\,da &= \frac{d}{dt}\int_{\Omega} \hat{r}(\ ,t)\,da - \frac{d}{dt}\int_{B_R(\ _0+t\ )} \hat{r}(\ ,t)\,da \\
&= \int_{\Omega} \partial_t \hat{r}(\ ,t)\,da - \int_{B_R(\ _0+t\ )} \partial_t \hat{r}(\ ,t)\,da \\
&\quad - \int_{\partial B_R(\ _0+t\ )} \hat{r}(\ ,t)\ \ \cdot\ \ ds \\
&= \int_{\Omega\setminus B_R(\ _0+t\ )} \partial_t \hat{r}(\ ,t)\,da - \int_{\partial B_R(\ _0+t\ )} \hat{r}(\ ,t)\ \ \cdot\ \ ds,
\end{aligned}$$

which proves the assertion. ∎

The next theorem, one of our main results, shows that the derivative of the renormalized energy coincides with the force on a dislocation and thus, as mentioned in the introduction, it may be viewed as the generalization of Eshelby's notion of force on a defect, when bad singularities are associated to the defect itself.

THEOREM 6.3. *Let* $\;_0$ *be defined by* (6.2), *and let* $F = F(\;_1, \ldots, \;_N)$ *be the renormalized energy* (5.3)*: then*

$$\nabla\;_k F = -\int_{\partial B_R(\;_k)} \left\{ W(\;(\;_0))\mathbf{1} - \;_0^\top C[\;(\;_0)] \right\} \; ds \tag{6.10}$$

for $R < \bar{R}$, *where* $\bar{R}$ *is defined in* (5.1).

Proof. The first step is to rewrite the renormalized energy as the sum of two contributions,

$$F(\;_1, \ldots, \;_N) = F_R(\;_1, \ldots, \;_N) + G(\;_1, \ldots, \;_N), \tag{6.11}$$

where we have omitted the constant logarithmic term and

$$F_R(\;_1, \ldots, \;_N) = \int_{\Omega_R} W(\;(\;_0))\, da, \tag{6.12}$$

and

$$\begin{aligned} G(\;_1, \ldots, \;_N) &= \sum_{i=1}^{N} \sum_{h \neq i} \int_{B_R(\;_h)} W(\;(\;_i))\, da + \sum_{h=1}^{N} \sum_{i=1}^{N-1} \sum_{j=i+1}^{N} \int_{B_R(\;_h)} C[\;(\;_i)] \cdot \;_j\, da \\ &\quad + \sum_{h=1}^{N} \int_{B_R(\;_h)} W(\;(\;_0))\, da + \sum_{h=1}^{N} \sum_{i=1}^{N} \int_{\partial B_R(\;_h)} \;_0 \cdot C[\;(\;_i)] \; da. \end{aligned} \tag{6.13}$$

Consider now a variation of the position of the kth dislocation of the form $\;_k \to \;_k + t$ with a fixed vector. Then

$$\begin{aligned} &\frac{d}{dt} F_R(\;_1, \ldots, \;_k + t\;, \ldots, \;_N)\bigg|_{t=0} \\ &= \frac{d}{dt} \int_{\Omega_R \setminus (B_R(\;_1) \cup \cdots \cup B_R(\;_k + t\;) \cup \cdots \cup B_R(\;_N))} W(\;(\;_0(\;;\;_1, \ldots, \;_k + t\;, \ldots, \;_N)))\, da \bigg|_{t=0} \end{aligned}$$

and applying Lemma 6.2 we obtain

$$\int_{\Omega_R} C[\;(\;_0)] \cdot \dot{\;}_0\, da - \int_{\partial B_R(\;_k)} W(\;(\;_0)) \;\cdot\; ds.$$

Recalling now Lemma 6.1, writing $\dot{\;}_0 = \nabla\;$, applying the divergence theorem, and recalling that $C[\;(\;_0)]\; = 0$ on $\partial\Omega$ this becomes

$$\begin{aligned} &\int_{\Omega_R} C[\;(\;_0)] \cdot \nabla\; \; da - \int_{\partial B_R(\;_k)} W(\;(\;_0)) \;\cdot\; ds \\ &\qquad = -\sum_{i=1}^{N} \int_{\partial B_R(\;_i)} \;\cdot C[\;(\;_0)]\; ds - \int_{\partial B_R(\;_k)} W(\;(\;_0)) \;\cdot\; ds, \end{aligned}$$

which in turn equals

$$-\int_{\partial B_R(\ _k)} \cdot (W(\ (\ _0))\mathbf{1} - \ _0^{\top} C[\ (\ _0)])\ \ ds$$
$$-\int_{\partial B_R(\ _k)} (\ +\ \ _0\ ) \cdot C[\ (\ _0)]\ \ ds - \sum_{i\neq k} \int_{\partial B_R(\ _i)} \cdot C[\ (\ _0)]\ \ ds.$$

The first term is the resultant of the Eshelby stress on the kth dislocation, while the second and third term may be written as

$$-\int_{\partial B_R(\ _k)} (\ \dot{}_0 + (\nabla\ _0)\ \ + \sum_{i\neq k}\ _i\ ) \cdot C[\ (\ _0)]\ \ ds$$
$$-\sum_{i\neq k} \int_{\partial B_R(\ _i)} (\ \dot{}_0 - \ _k\ ) \cdot C[\ (\ _0)]\ \ ds \tag{6.14}$$

since $=\ \dot{}_0 - \ _k$ and

$$+\ \ _0\ = \ \dot{}_0 - \ _k\ + \left(\sum_i\ _i + \nabla\ _0\right)\ = \ \dot{}_0 + (\nabla\ _0)\ + \sum_{i\neq k}\ _i\ .$$

We now prove that (6.14) cancels with the derivative of (6.13), i.e.,

$$\frac{d}{dt} G(\ _1, \ldots, \ _k + t\ , \ldots, \ _N)\Big|_{t=0}.$$

In fact, rewriting (6.13) as the sum of the terms

$$\int_{B_R(\ _k)} \left\{ \sum_{i\neq k} W(\ (\ _i)) + \sum_{i<j} C[\ (\ _i)] \cdot \ _j + W(\ (\ _0)) \right\} da$$
$$+\int_{\partial B_R(\ _k)} \sum_i (\ _0 \cdot C[\ (\ _i)]\ \ )\ ds \tag{6.15}$$

and

$$\sum_{h\neq k} \int_{B_R(\ _h)} \left\{ \sum_{i\neq h} W(\ (\ _i)) + \sum_{i<j} C[\ (\ _i)] \cdot \ _j + W(\ (\ _0)) \right\} da$$
$$+\sum_{h\neq k} \int_{\partial B_R(\ _h)} \sum_i (\ _0 \cdot C[\ (\ _i)]\ \ )\ ds \tag{6.16}$$

and computing the derivative of (6.15) with respect to t and using Lemma 6.2, we find

$$\int_{B_R(\ _k)} \left\{ \sum_{i\neq k} C[\ (\ _i)] \cdot D_t\ \ _i + \sum_{i<j} C[\ (\ _i)] \cdot D_t\ \ _j \right.$$
$$\left. + \sum_{i<j} C[\ (\ _j)] \cdot D_t\ \ _i + C[\ (\ _0)] \cdot \nabla(D_t\ \ _0) \right\} da$$
$$+ \int_{\partial B_R(\ _k)} \left\{ \sum_i\ \ _0 \cdot C[\ (D_t\ \ _i)]\ \ + \sum_i D_t\ \ _0 \cdot C[\ (\ _i)]\ \ \right\} ds,$$

where $D_t \; _j := \dot{} _j + \nabla(\; _j)$ and $D_t \; _0 = \dot{}_0 + (\nabla \; _0)$. Since $D_t \; _k = 0$ and $D_t \; _j = \nabla(\; _j) \; = \nabla(\; _j \;)$ for $j \neq k$ (since $\dot{} _j = 0$ for $j \neq k$), using the divergence theorem and noting that $\operatorname{Div} C[\; (D_t \; _i)] = 0$ on $\mathbb{R}^2 \setminus \{ \; _i\}$, we find

$$\int_{\partial B_R(\; _k)} \Bigg\{ D_t \; _0 \cdot C[\; (\; _0)] \; + \sum_{i\neq k} (\; _i \;) \cdot C[\; (\; _0)] + \sum_{i\neq k} (\; _i \;) \cdot C[\; (\; _i)] \; + \sum_{i\neq k}\sum_{j\neq i} (\; _i \;) \cdot C[\; (\; _j)] \; \Bigg\} \, ds,$$

which becomes finally

$$\int_{\partial B_R(\; _k)} (D_t \; _0 + \sum_{i\neq k} \; _i \;) \cdot C[\; (\; _0)] \; ds. \tag{6.17}$$

Consider now the derivative of (6.16) with respect to t: using Lemma 6.2, we find

$$\sum_{h\neq k} \int_{B_R(\; _h)} \Bigg\{ C[\; (\; _k)] \cdot \dot{} _k + \sum_{i\neq k} C[\; (\; _i)] \cdot \dot{} _k + C[\; (\; _0)] \cdot \nabla \dot{}_0 \Bigg\} \, da + \sum_{h\neq k} \int_{\partial B_R(\; _h)} \Bigg\{ \; _0 \cdot C[\; (\dot{} _k)] \; + \sum_i \dot{}_0 \cdot C[\; (\; _i)] \; \Bigg\} \, ds,$$

and using the fact that $\operatorname{Div} C[\; (\dot{} _k)] = 0$ on $\mathbb{R}^2 \setminus \{ \; _k\}$, and $\dot{} _k = -\nabla(\; _k \;)$ we finally obtain

$$\sum_{h\neq k} \int_{\partial B_R(\; _h)} (\dot{}_0 - \; _k \;) \cdot C[\; (\; _0)] \; ds. \tag{6.18}$$

Relation (6.10) follows now upon noting that the sum of (6.14), (6.17), and (6.18) vanishes. ∎

Appendix: Poincaré and Korn inequalities for Ω_ε.

The basic tool to study the compactness of a sequence of minimizers of problem (2.9) is Korn's inequality: we prove here that for a perforated domain such as Ω_ε, under mild regularity assumptions, Korn's and Poincaré's inequalities hold uniformly in ε as $\varepsilon \to 0$. Also, we show that the trace constant for Ω_ε may be chosen independent of ε.

We begin by proving that Poincaré's inequality holds for each domain Ω_ε uniformly in ε, when Ω has the cone property.

Proposition A.1. *Let Ω be a bounded open connected domain in $\mathbb{R}^2$ with the cone property: then, for any $\; \in H^1(\Omega_\varepsilon; \mathbb{R}^2)$,*

$$\int_{\Omega_\varepsilon} | \; - \; _B|^2 \, d \; \leq c \int_{\Omega_\varepsilon} |\nabla \; |^2 \, d \; , \tag{A.1}$$

where

$$_B := \frac{1}{|B|} \int_B \; da, \tag{A.2}$$

B is any fixed ball contained in $\Omega \setminus \{\ _1, \dots, \ _N\}$, and the constant c is independent of ε (but may depend on $\Omega \setminus \{\ _1, \dots, \ _N\}$ and B).

Proof. Fix $R > 2\epsilon$ so small that $B_R(\ _i) \subset \Omega \setminus B$ for any $i = 1, \dots, N$, $B_R(\ _i) \cap B_R(\ _j) = \emptyset$ for $i \neq j$, and decompose Ω_ε as the union of the annuli $C_{\varepsilon, \frac{R}{2}}(\ _i) = B_{\frac{R}{2}}(\ _i) \setminus B_\varepsilon(\ _i)$ and its complement Ω', which is independent of ε. Since Ω' is still connected and has the cone property, by the classical Poincaré's inequality we may find a constant c depending on Ω' and B such that

$$\text{(A.3)} \qquad \int_{\Omega'} |\ \ -\ \ _B|^2\, d\ \ \leq c \int_{\Omega'} |\nabla\ \ |^2\, d\ \ .$$

For each fixed $i = 1, \dots, N$ let (ϱ, ϑ) be polar coordinates centered at $\ _i$: for $\mathcal{L}^1$ almost everywhere $\varepsilon \leq s \leq \varrho < R$ and $\theta \in [0, 2\pi]$ we have

$$\ (s, \vartheta) = \ \ (\varrho, \vartheta) - \int_s^\varrho \frac{\partial\ }{\partial \varrho}(r, \vartheta)\, dr,$$

from which it follows, by Hölder's inequality,

$$|\ \ (s, \vartheta)|^2 \leq 2|\ \ (\varrho, \vartheta)|^2 + 2R \int_s^R \left| \frac{\partial\ }{\partial \varrho}(r, \vartheta) \right|^2 dr.$$

Integrating with respect to ϑ and multiplying by s yields

$$\text{(A.4)} \qquad \int_0^{2\pi} s|\ \ (s, \vartheta)|^2\, d\vartheta \leq 2 \int_0^{2\pi} \varrho|\ \ (\varrho, \vartheta)|^2\, d\vartheta + 2R \int_{C_{\varepsilon, R}(\ _i)} |\nabla\ \ |^2\, da,$$

where we have used the fact that $s \leq \varrho$, r. By integrating first with respect to s in $[\varepsilon, \frac{R}{2}]$ and then to ϱ in $[\frac{R}{2}, R]$ we obtain

$$\int_{C_{\varepsilon, \frac{R}{2}}(\ _i)} |\ \ |^2\, da \leq 2 \int_{C_{\frac{R}{2}, R}(\ _i)} |\ \ |^2\, da + 2R \int_{C_{\varepsilon, R}(\ _i)} |\nabla\ \ |^2\, da.$$

If we now replace $\ $ with $\ \ -\ \ _B$ in the previous inequality we get

$$\int_{C_{\varepsilon, \frac{R}{2}}(\ _i)} |\ \ -\ \ _B|^2\, da \leq 2 \int_{C_{\frac{R}{2}, R}(\ _i)} |\ \ -\ \ _B|^2\, da + 2R \int_{C_{\varepsilon, R}(\ _i)} |\nabla\ \ |^2\, da,$$

which together with (A.3) and the fact that $C_{\frac{R}{2}, R} \subset \Omega'$ concludes the proof. ◻

We now turn to Korn's inequality. First we notice that if Ω has the cone property, then for all $\varepsilon > 0$ Ω_ε has the cone property, and the following version of this inequality holds [9, 17, 24].

Proposition A.2 (Korn's inequality I). *Let $\Omega \subset \mathbb{R}^2$ be an open bounded connected domain with the cone property, and let $\ \ \in H^1(\Omega_\varepsilon; \mathbb{R}^2)$ such that*

$$\text{(A.5)} \qquad \int_{\Omega_\varepsilon} \left(\nabla\ \ - (\nabla\ \ )^\top\right) da = 0;$$

then there exists a constant c_ε such that

$$\text{(A.6)} \qquad \int_{\Omega_\varepsilon} |\nabla\ \ |^2 da \leq c_\varepsilon \int_{\Omega_\varepsilon} |\ \ (\ \ )|^2 da.$$

We continue to denote by c_ε the infimum of all constants satisfying (A.6) and refer to it as Korn's constant for Ω_ε. The following result shows that c_ε is bounded from above independently of ε as $\varepsilon \to 0$.

Proposition A.3. *Let c_ε be Korn's constant for Ω_ε as defined in* (A.6)*: then there exists a constant $c < \infty$, independent of ε (but possibly depending on Ω), such that*

$$c_\varepsilon \leq c \tag{A.7}$$

for all $\varepsilon > 0$.

Proof. Consider first the case $N = 1$, and let $\ _1 = \mathbf{0}$, so that $\Omega_\varepsilon = \Omega \setminus B_\varepsilon(\mathbf{0})$. The proof follows from two results of [9]. The first result states that the minimum value for Korn's constant of the annulus $C_{\varepsilon,R}(\mathbf{0})$ with internal radius ε and external radius R (under the constraint (A.5)) is

$$4\left[1 - \left(\frac{3R^2\varepsilon^2}{R^4 + R^2\varepsilon^2 + \varepsilon^4}\right)\right]^{-1}, \tag{A.8}$$

which tends to Korn's constant for the circle $c = 4$ as $\varepsilon \to 0$. The second result states that if Korn's inequality (A.5)–(A.6) holds for two open bounded domains Ω_1 and Ω_2 such that $|\Omega_1 \cap \Omega_2| > 0$, then it also holds for $\Omega_1 \cup \Omega_2$, and

$$c_{12} \leq c_1 + c_2 + \frac{\min\{|\Omega_1|, |\Omega_2|\}}{|\Omega_1 \cap \Omega_2|}\left(\sqrt{c_1} + \sqrt{c_2}\right)^2 \tag{A.9}$$

with c_{12}, c_1, and c_2 the Korn's constants of $\Omega_1 \cup \Omega_2$, Ω_1, and Ω_2, respectively.

To prove (A.7), choose R such that $2R < d(\mathbf{0}, \partial\Omega)$, let $\Omega_1 = C_{\varepsilon,2R}(\mathbf{0})$ and $\Omega_2 = \Omega_\varepsilon \setminus C_{\varepsilon,R}(\mathbf{0})$, and apply (A.9): since c_2 is independent of ε and, by (A.8), $c_1 \to 4$ as $\varepsilon \to 0$, Korn's constant $c_\varepsilon = c_{12}$ is bounded from above, and the thesis follows for $N = 1$.

When $N > 1$, to obtain the thesis it is sufficient to iterate the above procedure: define

$$\begin{cases} \tilde{\Omega}_0 := \Omega \setminus \left(\cup_{i=1}^N B_R(\ _i)\right) \\ \vdots \\ \tilde{\Omega}_i := \tilde{\Omega}_{i-1} \cup \left(B_{2R}(\ _i) \setminus B_\varepsilon(\ _i)\right), \qquad i = 1, \dots, N-1, \\ \vdots \\ \tilde{\Omega}_N := \Omega_\varepsilon. \end{cases}$$

Applying (A.9) to each $\tilde{\Omega}_i$ we obtain

$$\begin{aligned} \tilde{c}_i &\leq \tilde{c}_{i-1} + \tilde{c}_\varepsilon + \frac{\min\{|\tilde{\Omega}_{i-1}|, |c_{\varepsilon,2R}(\ _i)|\}}{|\tilde{\Omega}_{i-1} \cap c_{\varepsilon,2R}(\ _i)|}\left(\sqrt{\tilde{c}_{i-1}} + \sqrt{\tilde{c}_\varepsilon}\right)^2 \\ &= \tilde{c}_{i-1} + \tilde{c}_\varepsilon + \frac{4R^2 - \varepsilon^2}{3R^2}\left(\sqrt{\tilde{c}_{i-1}} + \sqrt{\tilde{c}_\varepsilon}\right)^2, \end{aligned}$$

where $\tilde{c}_i$ and $\tilde{c}_\varepsilon$ are Korn's constants for $\tilde{\Omega}_i$ and $C_{\varepsilon,2R}(\ _i)$, respectively. Using the relation $(a+b)^2 \leq 2(a^2 + b^2)$, and taking $\varepsilon = 0$, this relation implies

$$\tilde{c}_i \leq \frac{11}{3}(\tilde{c}_{i-1} + \tilde{c}_\varepsilon),$$

which yields in turn

$$\tilde{c}_N \leq \left(\frac{11}{3}\right)^N \tilde{c}_0 + \left(\sum_{i=1}^{N}\left(\frac{11}{3}\right)^i\right)\tilde{c}_\varepsilon.$$

Since $\tilde{c}_\varepsilon$ is given by (A.8) and is bounded from above, and $\tilde{c}_0$ is independent of ε, this relation shows that $c_\varepsilon = \tilde{c}_N$ is also bounded from above as $\varepsilon \to 0$. ∎

Korn's inequality extends trivially to displacement fields which do not satisfy (A.5).

COROLLARY A.4 (Korn's inequality I′). *Let $\Omega \subset \mathbb{R}^2$ be an open bounded connected domain with the cone property, and $\in H^1(\Omega_\varepsilon;\mathbb{R}^2)$: then there exists a constant c, independent of ε, such that*

$$\int_{\Omega_\varepsilon} |\nabla \quad - \quad |^2 da \leq c \int_{\Omega_\varepsilon} | \quad (\quad)|^2 da, \tag{A.10}$$

where

$$= \frac{1}{2}\int_{\Omega_\varepsilon} (\nabla \quad - (\nabla \quad)^\top)\, da. \tag{A.11}$$

Combining (A.1), (A.6), and (A.7), we finally obtain the following basic inequality.

PROPOSITION A.5 (Korn's inequality II). *Let $\in H^1(\Omega_\varepsilon;\mathbb{R}^2)$ such that*

$$\int_{\Omega_\varepsilon} \left(\nabla \quad - (\nabla \quad)^\top\right) da = 0; \tag{A.12}$$

then there exists a constant c, independent of ε, such that

$$\int_{\Omega_\varepsilon} | \quad - \quad _B|^2 da + \int_{\Omega_\varepsilon} |\nabla \quad |^2 da \leq c \int_{\Omega_\varepsilon} | \quad (\quad)|^2 da, \tag{A.13}$$

where

$$_B := \frac{1}{|B|}\int_B \quad da, \tag{A.14}$$

and B is any fixed ball contained in $\Omega \setminus \{ \ _1, \ldots, \ _N\}$.

We now show that the trace constant for Ω_ε may be chosen to be independent of ε.

PROPOSITION A.6. *Let $\in H^1(\Omega_\varepsilon;\mathbb{R}^2)$: then there exists a positive constant c, independent of ε, such that*

$$\int_{\partial\Omega_\varepsilon} | \quad |^2 ds \leq c\left(\int_{\Omega_\varepsilon} | \quad |^2 da + \int_{\Omega_\varepsilon} |\nabla \quad |^2 da\right). \tag{A.15}$$

Proof. Taking $s = \varepsilon$ in (A.4) we have

$$\int_{\partial B_\varepsilon(\ _i)} | \quad |^2 ds \leq 2\int_0^{2\pi} \varrho\, | \quad (\varrho,\vartheta)|^2\, d\vartheta + 2R\int_{C_{\varepsilon,R}(\ _i)} |\nabla \quad |^2\, da.$$

By averaging with respect to ϱ over $[\varepsilon, R]$ we obtain

$$\int_{\partial B_\varepsilon(\ _i)} | \quad |^2 ds \leq \frac{2}{R-\varepsilon}\int_{C_{\varepsilon,R}(\ _i)} | \quad |^2\, da + 2R\int_{C_{\varepsilon,R}(\ _i)} |\nabla \quad |^2\, da.$$

Hence, for ε sufficiently small, there exists a constant c_1 such that

$$\int_{\partial B_\varepsilon(\ _i)} |\ |^2 ds \le c_1 \left(\int_{\Omega_\varepsilon} |\ |^2\, da + \int_{\Omega_\varepsilon} |\nabla\ |^2\, da \right) \tag{A.16}$$

for each $i = 1, \dots, N$. Now, let c_2 be the trace constant for Ω_R, so that

(A.17)
$$\int_{\partial\Omega} |\ |^2 ds \le c_2 \left(\int_{\Omega_R} |\ |^2\, da + \int_{\Omega_R} |\nabla\ |^2\, da \right) \le c_2 \left(\int_{\Omega_\varepsilon} |\ |^2\, da + \int_{\Omega_\varepsilon} |\nabla\ |^2\, da \right).$$

Adding the expressions above we finally obtain the thesis. □

Finally, we show that functions in $H^1(\Omega_\varepsilon;\mathbb{R}^2)$ can be extended to Ω with extension constant independent of ε.

Proposition A.7. *Let* $\ \in H^1(\Omega_\varepsilon;\mathbb{R}^2)$*: then* $\ $ *admits an extension* $\hat{\ } \in H^1(\Omega,\mathbb{R}^2)$ *such that*

$$\|\hat{\ }\|_{H^1(\Omega,\mathbb{R}^2)} \le c \|\ \|_{H^1(\Omega_\varepsilon;\mathbb{R}^2)}, \tag{A.18}$$

where the constant c *is independent of* ε*.*

Proof. First notice that, using a partition of unity, we may assume that $\ \in H^1(\mathbb{R}^2 \setminus B_\varepsilon(\mathbf{0});\mathbb{R}^2)$, and $\ = 0$ outside a compact in $\mathbb{R}^2$. Let

$$\hat{\ }(\ ) = \begin{cases} \ \left(\dfrac{\varepsilon^2}{|\ |^2}\ \right), & \ \in B_\varepsilon(\mathbf{0}), \\ \ (\ ), & \ \in \mathbb{R}^2 \setminus B_\varepsilon(\mathbf{0}), \end{cases}$$

so that $\hat{\ }(\ ) = \ (\ )$ when $|\ | = \varepsilon$. Then

$$\int_{B_\varepsilon(\mathbf{0})} |\hat{\ }(\ )|^2\, da = \int_{B_\varepsilon(\mathbf{0})} \left| \ \left(\frac{\varepsilon^2}{|\ |^2}\ \right)\right|^2 da = \int_{\mathbb{R}^2\setminus B_\varepsilon(\mathbf{0})} \frac{\varepsilon^4}{|\ |^4} |\ (\ )|^2\, da$$
$$\le \int_{\mathbb{R}^2\setminus B_\varepsilon(\mathbf{0})} |\ (\ )|^2\, da,$$

since the modulus of the Jacobian of the transformation $\ \to \varepsilon^2\ /|\ |^2$ is $|J| = \varepsilon^4/|\ |^4$, and $\varepsilon^4/|\ |^4 \le 1$ for $|\ | \ge \epsilon$. Also, notice that

$$\nabla\hat{\ }(\ ) = \nabla\ \left(\frac{\varepsilon^2}{|\ |^2}\ \right)\left[\frac{\varepsilon^2}{|\ |^2}\left(\mathbf{1} - \frac{2}{|\ |^2}\ \otimes\ \right)\right]$$

and

$$\left|\mathbf{1} - \frac{2}{|\ |^2}\ \otimes\ \right|^2 = 1.$$

Hence,

$$\int_{B_\varepsilon(\mathbf{0})} |\nabla\hat{\ }(\ )|^2\, da \le M \int_{B_\varepsilon(\mathbf{0})} \frac{\varepsilon^4}{|\ |^4} \left|\nabla\ \left(\frac{\varepsilon^2}{|\ |^2}\ \right)\right|^2 da$$
$$= M \int_{\mathbb{R}^2\setminus B_\varepsilon(\mathbf{0})} \frac{\varepsilon^4}{|\ |^4} \frac{|\ |^4}{\varepsilon^4} |\nabla\ (\ )|^2\, da$$
$$\le M \int_{\mathbb{R}^2\setminus B_\varepsilon(\mathbf{0})} |\nabla\ (\ )|^2\, da$$

with M a positive constant independent of ε. Since $\hat{} =$ on $\mathbb{R}^2 \setminus B_\varepsilon(\mathbf{0})$, it follows that there exists a constant c independent of ε such that

$$\|\hat{}\|_{H^1(\mathbb{R}^2,\mathbb{R}^2)} \leq c\| \quad \|_{H^1(\mathbb{R}^2\setminus B_\varepsilon(\mathbf{0});\mathbb{R}^2)},$$

which implies the thesis. $\square$

CORRECTIONS TO THE KdV APPROXIMATION FOR WATER WAVES*

J. DOUGLAS WRIGHT†

This article is dedicated to the memory of Dr. Joseph Hammack

Abstract. In order to investigate corrections to the common KdV approximation for surface water waves in a canal, we derive modulation equations for the evolution of long wavelength initial data. We work in Lagrangian coordinates. The equations which govern corrections to the KdV approximation consist of linearized and inhomogeneous KdV equations plus an inhomogeneous wave equation. These equations are explicitly solvable and we prove estimates showing that they do indeed give a significantly better approximation than the KdV equation alone.

Key words. water wave equation, KdV equation, linearized KdV equation, modulation equations, solitary waves, solitons, collisions of solitary waves

1. Introduction.

It is often easier to write down a partial differential equation which models a physical phenomena than it is to study solutions of such an equation. Equations which model the evolution of the surface of a fluid in a canal have been known since at least the 19th century; however, it has only been in recent years that questions of existence and uniqueness for general initial data have been answered (see [35], [36], and [22]). Moreover, numerical simulations of water waves and similarly complex phenomena are frequently time consuming and challenging to implement. Consequently, it can be quite difficult to say much about the behavior of a general solution. Therefore scientists often restrict their attention to limiting cases—for instance, one may assume that solutions are of long wavelength and small amplitude (see Figure 1). Under such a supposition, a *modulation equation* may be (formally) derived. In particular, one hopes that the modulation equation

- is well-posed,
- is either explicitly solvable or easy to solve numerically, and
- captures the essential behavior of the original system.

Remarkably, many seemingly disparate physical phenomena possess modulation equations of the same form. For solutions of long wavelength, Korteweg–de Vries (KdV) equations are often used as modulation equations for a wide variety of nonlinear dispersive systems, including the water wave equation, the Euler–Poisson equations for plasma dynamics, and the Fermi–Pasta–Ulam equation for the interaction of particles in an infinite lattice.

Despite the fact that modulation equations have been in use for over a hundred years—the KdV equation was first proposed as a model for water waves by Boussinesq in 1872 and also by Korteweg and de Vries in 1895—only recently have attempts been made to rigorously connect the behavior of the modulation equations to the original

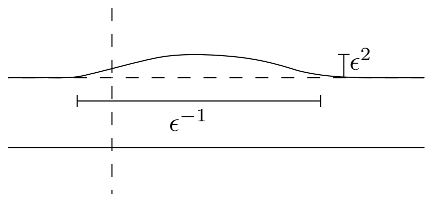

FIG. 1. *The long wave, small amplitude scaling.*

physical problem. In particular, through the work of Craig [10], Kano and Nishida [18], [19], Kalyakin [17], Schneider [27], Ben Youssef and Colin [2], and Schneider and Wayne [28], [29], the validity of KdV equations as a leading order approximation to the evolution of long wavelength water waves and to a number of other dispersive partial differential equations has been established.

In many respects, the KdV equation is an ideal modulation equation; it is simple in form and explicitly solvable via the inverse scattering transform. Nevertheless, both experimentally and numerically one observes deviations from the predictions of the KdV approximation. In this paper we derive a hierarchy of modulation equations which govern corrections to the KdV model and also prove rigorously that these higher order equations do indeed improve the accuracy of the approximation. While the correction is valid in general long wavelength/small amplitude settings, heuristically the model is set up to better approximate interactions between solitary waves—both counterpropagating collisions and unidirectional interactions.

Note that in [33], as a case study, Wayne and Wright examined higher order corrections to the KdV approximation to a Boussinesq equation. As the KdV equation is in some sense a universal approximation for long waves, we expect that the equations for corrections to this approximation will also be universal. Indeed, our results show that the higher order corrections for the water wave equation are nearly identical to those for the Boussinesq equation. Also, since a significant part of the work for the Boussinesq problem consists of showing that the modulation equations have well-behaved solutions over the time scales of interest, this is of use in tackling the water wave problem.

We now describe our results in some detail. The equations of motion for a water wave in an infinitely long canal (commonly called the *water wave equation*) are

$$\begin{gathered} x_{tt}(1+x_\alpha) + y_\alpha(1+y_{tt}) = 0, \\ y_t = K(x,y)x_t, \\ \alpha \in \mathbb{R}, \quad t \geq 0, \quad (x(\alpha,t), y(\alpha,t)) \in \mathbb{R}^2, \end{gathered} \tag{WW}$$

where $K(x,y)$ is a complicated operator (see section 3 for the definition of K) and $(\alpha + x(\alpha,t), y(\alpha,t))$ parameterizes the free surface. According to the KdV approximation results of [28], to the order of the approximation long wavelength solutions of (WW) split up into two pieces, one a right-moving wave train and one a left-moving wave train. Each of these wave trains evolves according to a KdV equation, and *there is no interaction between the left- and right-moving pieces*. That is, for $0 < \epsilon \ll 1$, if we scale amplitudes to be $O(\epsilon^2)$ (i.e., small) and wavelengths to be $O(\epsilon^{-1})$ (i.e., long), then for times of $O(\epsilon^{-3})$, solutions to (WW) satisfy

$$-x_\alpha(\alpha,t) = \epsilon^2 U(\epsilon(\alpha - t), \epsilon^3 t) + \epsilon^2 V(\epsilon(\alpha + t), \epsilon^3 t) + O(\epsilon^4), \tag{1}$$

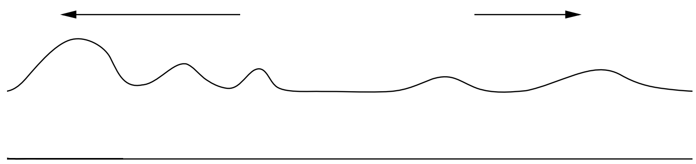

FIG. 2. *Sketch of the right- and left-moving wave trains.*

where U and V satisfy the KdV equations

$$\text{(KdV)} \qquad \begin{aligned} -2\partial_T U &= \frac{1}{3}\partial^3_{\beta_-} U + \frac{3}{2}\partial_{\beta_-}(U^2), \\ 2\partial_T V &= \frac{1}{3}\partial^3_{\beta_+} V + \frac{3}{2}\partial_{\beta_+}(V^2). \end{aligned}$$

See Figure 2. Here, $\beta_\pm = \epsilon(\beta \pm t)$ represent long wavelength moving reference frames and $T = \epsilon^3 t$ is the very long time scale coordinate. For technical reasons (which we discuss later), $-x_\alpha$ is the natural variable to estimate for the water wave equation. To lowest order, $-x_\alpha$ is proportional to the height of the wave. At higher order, this ceases to be true, though for purposes of intuition one can think of $-x_\alpha$ as representing the wave amplitude.

The KdV equation was initially derived from the water wave equation in an attempt to prove the existence of a solitary wave solution for waves in a canal. Famously, the KdV equation admits solitary wave solutions and also multisoliton solutions. (See Figure 3.) Note that the existence of a true solitary wave solution to (WW) was established first by Friedrichs and Hyers in [14] and subsequently by Beale in [1]. Also note that there exist standing wave solutions (also known as Stokes' waves) to (WW) which in many ways are similar to solitary waves, though our methods do not carry over to studying such behavior—see Toland [32] and Constantin and Strauss [8] for an overview of Stokes' waves in the irrotational and rotational problems, respectively.

We will frequently refer to multisoliton solutions as "overtaking wave" collisions. We remind the reader that the only notable first order effect after such a collision is that the waves are phase shifted after the collision.

Given the results in [28], one expects to see similar behavior in solutions systems modeled by KdV equations. Though it is unknown if these soliton-like solutions persist globally, analogous behavior is indeed observed for very long times (see [15]). The most notable deviation between true solutions and the KdV approximation is the size of the phase shift after a collision. In addition, soliton-like solutions to the type of systems we study frequently develop a very small amplitude dispersive wave train behind each soliton, which moves in the same direction; see Figure 4. The KdV approximation does not predict the existence of these dispersive wave trains. As these sorts of discrepancies are observed even in the case where there is only one wave train moving unidirectionally, we believe that they are, loosely, independent of interactions between the left- and right-moving wave trains. They reflect intrinsic differences between the approximation and the original system.

On the other hand, there is evidence that a noticeable interaction takes place between the left- and right-moving waves. One can see from the form of the approximation in (1) that during a head-on collision of waves moving in opposite directions, the KdV approximation predicts that the heights of the waves add linearly. In true head-on collisions in solutions to the water wave equation, however, the height of the

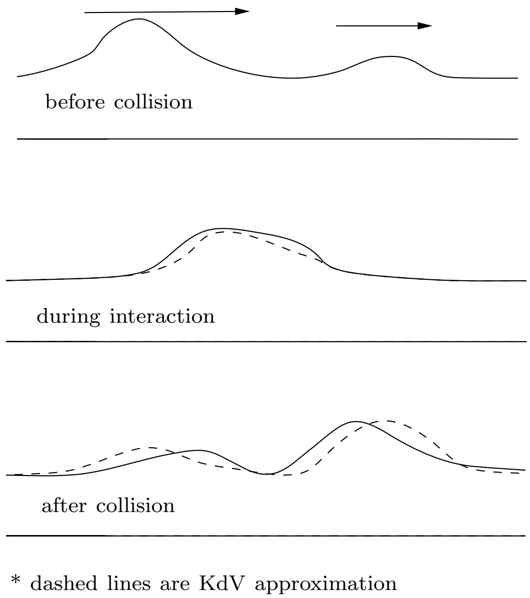

FIG. 3. *Sketch of the overtaking wave interaction.*

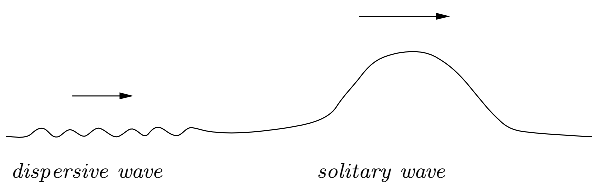

FIG. 4. *Sketch of the dispersive wave.*

waves is slightly different from the sum of the heights of the waves taken separately—it is slightly larger. (See the works of Maxworthy [23], Byatt-Smith [6], [7], Cooker, Weidman, and Bale [9], and Su and Mirie [30], [31].) We sketch this in Figure 5.

Thus we might expect two types of corrections to the KdV approximation:

- corrections due to the fact that, even in the case of a purely right- (or left-) moving wave train, solutions to the water wave equation are not exactly described by solutions to the KdV equation—we will refer to this source of error as *unidirectional error*;
- corrections due the fact that the left- and right-moving wave trains will interact at higher order—we call such errors *counterpropagation error*.

Both of these types of corrections are apparent in our results, and to incorporate these two types of corrections, we add an additional three functions to the KdV wave trains. The first two, F and G, will correct for unidirectional errors. The third, P, will correct for counterpropagation errors. We scale the amplitudes of these three functions so they are $O(\epsilon^4)$, which is the same as the order of the error in using only the KdV equations. F and G will take the same functional form as U and V, as they correct for differences between the approximate and actual wave trains. Therefore we

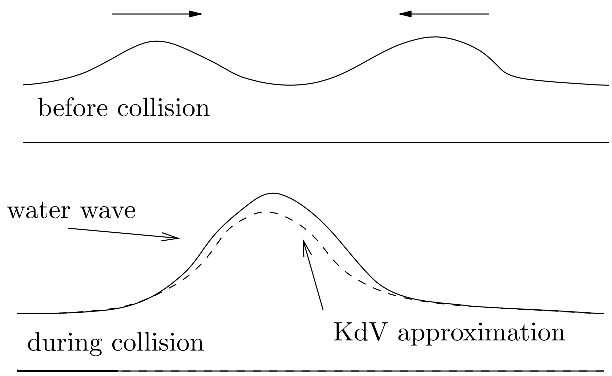

FIG. 5. *Sketch of the head-on collision.*

add

$$\epsilon^4 F(\epsilon(\alpha - t), \epsilon^3 t) + \epsilon^4 G(\epsilon(\alpha + t), \epsilon^3 t)$$

to the first order approximation (1).

We do not expect P to be moving strictly left or right, as it corrects for the interaction between waves moving in opposite directions. Thus its spatial dependence will be on $\beta = \epsilon\alpha$. Suppose that the functions U and V are solitary wave solutions. In the long wavelength variables we are considering, this means that the right- and left-moving wave packets are large only over a length of $O(\epsilon^{-1})$. In addition, the reference frame moves with unit velocity. Thus we expect any interaction of the two waves to last a time of $O(\epsilon^{-1})$. Accordingly, we let P depend on the time variable $\tau = \epsilon t$. That is, we add a correction term of the form

$$\epsilon^4 P(\epsilon\alpha, \epsilon t)$$

to the KdV model.

Through formal means we find that P satisfies an inhomogeneous wave equation

$$\text{(IW)} \qquad \partial_\tau^2 P - \partial_\beta^2 P = 3\partial_\beta^2 \left(U(\beta - \tau, \epsilon^2\tau) V(\beta + \tau, \epsilon^2\tau) \right).$$

Similarly, F and G satisfy a pair of driven, linearized KdV equations

$$\text{(LK)} \qquad \begin{aligned} -2\partial_T F =& \frac{1}{3}\partial_{\beta_-}^3 F + 3\partial_{\beta_-}(UF) + J^-, \\ 2\partial_T G =& \frac{1}{3}\partial_{\beta_+}^3 G + 3\partial_{\beta_+}(VG) + J^+. \end{aligned}$$

Notice that these equations are linearized about the KdV solutions U and V. The inhomogeneous terms J^- and J^+ are made up of a combination of sums and products of U, V, and P. For explicit forms of these driving terms see equations (22). Linearized KdV equations are explicitly solvable, though this is a complicated matter (see [25] and [16]). However, solutions are simple to compute numerically.

One can solve inhomogeneous wave equations explicitly and easily via the method of characteristics. Moreover, we can reduce such systems to a pair of transport equations by the following fact.

FACT 1. *If* $\partial_t f - \partial_x f = 1/2\partial_x h$ *and* $\partial_t g + \partial_x g = -1/2\partial_x h$, *then* $q = f + g$ *satisfies* $\partial_t^2 q - \partial_x^2 q = \partial_x^2 h$.

Thus, we have

$$\begin{aligned} P^-_\tau + P^-_\beta &= -\frac{3}{2}\partial_\beta (U(\beta-\tau,\epsilon^2\tau)V(\beta+\tau,\epsilon^2\tau)), \\ P^+_\tau - P^+_\beta &= \frac{3}{2}\partial_\beta (U(\beta-\tau,\epsilon^2\tau)V(\beta+\tau,\epsilon^2\tau)), \end{aligned} \tag{T}$$

where

$$P(\beta,\tau) = P^+(\beta,\tau) + P^-(\beta,\tau).$$

We remark that the initial data for the modulation equations is determined from initial conditions for the original system in ways described in section 6. Also, this hierarchy of higher order modulation equations is nearly identical to that derived in Wayne and Wright [33] for the Boussinesq equation—the chief difference lying in the specific forms of the inhomogeneous terms $J^\pm$.

To enforce the notion of spatial localization, we will be considering initial data which is of rapid decay, that is, initial data in

$$H^s(m) = \left\{ f(\alpha) | (1+\alpha^2)^{m/2} f(\alpha) \in H^s \right\}.$$

The inner product on $H^s(m)$ is given by

$$(f(\cdot), g(\cdot))_{H^s(m)} = \left((1+\cdot^2)^{m/2} f(\cdot), (1+\cdot^2)^{m/2} g(\cdot) \right)_{H^s},$$

where we use the standard inner product in H^s. In particular, the known soliton solutions of the KdV equations are in such spaces.

That the KdV equations have solutions for all times with this sort of initial data is well known. In particular, we have the following theorem from [28].

THEOREM 1. *Let* $\sigma \geq 4$. *Then for all* $C_I, T_0 > 0$ *there exists* $C_1 > 0$ *such that if* U, V *satisfy* (KdV) *with initial conditions* U_0, V_0 *and*

$$\max\{\|U_0\|_{H^\sigma(4)\cap H^{\sigma+4}(2)\cap H^{\sigma+9}}, \|V_0\|_{H^\sigma(4)\cap H^{\sigma+4}(2)\cap H^{\sigma+9}}\} < C_I, \tag{2}$$

then

$$\sup_{T\in[0,T_0]} \left\{ \|U(\cdot,T)\|_{H^\sigma(4)\cap H^{\sigma+4}(2)\cap H^{\sigma+8}}, \|V(\cdot,T)\|_{H^\sigma(4)\cap H^{\sigma+4}(2)\cap H^{\sigma+8}} \right\} < C_1. \tag{3}$$

On the other hand, it is less clear that solutions of (IW) and (LK) will remain bounded over the very long time scales necessary for the KdV approximation. In [33] we proved the following result which guarantees that the solutions of the modulation equations remain bounded for sufficiently long times.

PROPOSITION 1. *Fix* $T_0 > 0$ *and* $\sigma > 11/2$. *Suppose that* U_0, V_0 *satisfy* (2) *and* U, V, $P^\pm$, F, *and* G *satisfy* (KdV), (T), *and* (LK). *Then there exists a constant* C_2, *independent of* ϵ, *such that the solutions of* (T) *and* (LK) *satisfy the estimates*

$$\sup_{\tau\in[0,T_0\epsilon^{-2}]} \|P^\pm(\cdot,\tau)\|_{H^{\sigma+3}} \leq C_2,$$

$$\sup_{T\in[0,T_0]} \left\{ \|F(\cdot,T)\|_{H^\sigma\cap H^{\sigma-4}(2)}, \|G(\cdot,T)\|_{H^\sigma\cap H^{\sigma-4}(2)} \right\} \leq C_2.$$

Moreover, $P^{\pm}(\beta,\tau) = \varphi^{\pm}(\beta_{\pm}, T)$ *with*

$$\sup_{T\in[0,T_0]} \|\varphi^{\pm}(\cdot,T)\|_{H^{\sigma+3}\cap H^{\sigma-1}(2)} \leq C_2.$$

Finally we note that since $\partial_\tau P = \partial_\beta P^+ - \partial_\beta P^-$ we have $\|\partial_\tau P\|_s \leq \|\partial_\beta P\|_s$.

With this preliminary result in hand we can state our principal results. Denote the sum of the modulation functions, properly scaled, as

$$\begin{aligned} -\psi^d(\alpha,t) &= \epsilon^2 U\left(\epsilon(\alpha-t),\epsilon^3 t\right) + \epsilon^2 V\left(\epsilon(\alpha+t),\epsilon^3 t\right) \\ &\quad + \epsilon^4 F\left(\epsilon(\alpha-t),\epsilon^3 t\right) + \epsilon^4 G\left(\epsilon(\alpha+t),\epsilon^3 t\right) \\ &\quad + \epsilon^4 P(\epsilon\alpha,\epsilon t). \end{aligned} \tag{4}$$

As mentioned earlier, (x,y) are not the natural coordinates to study solutions to (WW). The coordinates we use are $(x_\alpha, y, x_t)^{tr}$. x_α is approximated by ψ^d, and the functions y and x_t are approximated by functions we denote ψ^y and ψ^u, respectively. They are given by

$$\begin{aligned} \psi^y(\alpha,t) &= \epsilon^2 U(\epsilon(\alpha-t),\epsilon^3 t) + \epsilon^2 V(\epsilon(\alpha+t),\epsilon^3 t) \\ &\quad + \epsilon^4 F(\epsilon(\alpha-t),\epsilon^3 t) + \epsilon^4 G(\epsilon(\alpha+t),\epsilon^3 t) + \epsilon^4 P(\epsilon\alpha,\epsilon t) \\ &\quad + \frac{1}{3}\epsilon^4 \partial_{\beta_-}^2 U(\epsilon(\alpha-t),\epsilon^3 t) + \frac{1}{3}\epsilon^4 \partial_{\beta_+}^2 V(\epsilon(\alpha+t),\epsilon^3 t) \\ &\quad + \epsilon^4 \left(U(\epsilon(\alpha-t),\epsilon^3 t) + V(\epsilon(\alpha+t),\epsilon^3 t)\right)^2 \end{aligned} \tag{5}$$

and

$$\begin{aligned} \psi^u(\alpha,t) &= \epsilon^2 U(\epsilon(\alpha-t),\epsilon^3 t) - \epsilon^2 V(\epsilon(\alpha+t),\epsilon^3 t) \\ &\quad + \epsilon^4 F(\epsilon(\alpha-t),\epsilon^3 t) - \epsilon^4 G(\epsilon(\alpha+t),\epsilon^3 t) \\ &\quad + \epsilon^4 \varphi^-(\epsilon(\alpha-t),\epsilon^3 t) - \epsilon^4 \varphi^+(\epsilon(\alpha+t),\epsilon^3 t) \\ &\quad + \frac{1}{6}\epsilon^4 \partial_{\beta_-}^2 U(\epsilon(\alpha-t),\epsilon^3 t) - \frac{1}{6}\epsilon^4 \partial_{\beta_+}^2 V(\epsilon(\alpha+t),\epsilon^3 t) \\ &\quad + \frac{3}{4}\epsilon^4 U^2(\epsilon(\alpha-t),\epsilon^3 t) - \frac{3}{4}\epsilon^4 V^2(\epsilon(\alpha+t),\epsilon^3 t). \end{aligned} \tag{6}$$

We discuss the origin of these equations in section 4.

The approximation will be valid in the space

$$\mathfrak{H}^s = H^s \times H^s \times H^{s-1/2}.$$

Our main result is the following.

THEOREM 2. *Fix* T_0, $C_I > 0$, $s > 4$, $\sigma \geq s+7$. *Suppose that* U, V, P, F, *and* G *satisfy* (KdV), (IW), *and* (LK) *and that* ψ^d, ψ^y, *and* ψ^u *are the combinations of these functions given in* (4), (5), *and* (6). *Then there exist* $\epsilon_0 > 0$ *and* $C_F > 0$ *such that the following is true. If the initial conditions for* (WW) *are of the form* $((x_\alpha(\alpha,0), y(\alpha,0), x_t(\alpha,0))^{tr} = \left(0, \epsilon^2\Theta_y(\epsilon\alpha), \epsilon^2\Theta_u(\epsilon\alpha)\right)^{tr}$ *with*

$$\max_{i=y,z}\left\{\|\Theta_i(\cdot)\|_{H^\sigma(4)\cap H^{\sigma+4}(2)\cap H^{\sigma+9}}\right\} \leq C_I,$$

then for $\epsilon \in (0,\epsilon_0)$ *there is a reparameterization of the free surface such that the unique solution to* (WW) *satisfies*

$$\left\| \begin{pmatrix} x_\alpha(\cdot,t) \\ y(\cdot,t) \\ x_t(\cdot,t) \end{pmatrix} - \begin{pmatrix} \psi^d(\cdot,t) \\ \psi^y(\cdot,t) \\ \psi^u(\cdot,t) \end{pmatrix} \right\|_{\mathfrak{H}^s} \leq C_F \epsilon^{11/2}$$

for $t \in [0, T_0\epsilon^{-3}]$*. The constant* C_F *does not depend on* ϵ*.*

Remark 1. The loss of the one-half power of ϵ in Theorem 2 is caused by the long wave scaling and not a lack of sharpness in the estimates.

Remark 2. It is clear that the form of the initial conditions specified in the hypotheses of this theorem does not agree with that found by setting $t = 0$ in the approximation inequality (unless, of course, $\psi^d \equiv 0$). This is precisely why we mention the need to reparameterize the free surface. We discuss this at length in section 6.

Remark 3. In [28], Schneider and Wayne prove the analogous result for the KdV (i.e., $O(\epsilon^4)$) approximation alone. The methods used here follow largely from their work.

Remark 4. The long time scale on which this theorem holds is natural given the form of the approximation—$t \sim O(\epsilon^{-3})$ corresponds to times T of $O(1)$ in the KdV equation. The methods of the proof rely on a Gronwall-type estimate which imposes this time scale. Moreover, while Proposition 1 shows that the functions F and G remain $O(1)$ for $t \sim O(\epsilon^{-3})$, estimates show that beyond this they are likely to grow very rapidly, ruining any chance for the higher order correction to be valid for longer times. Nonetheless, it is unclear whether or not the approximation of water waves by the KdV solutions alone is valid for even longer times. Numerical experiments done for the KdV approximation to the Euler–Poisson equations by Haragus, Nicholls, and Sattinger in [15] indicate that the approximation is valid for very long times, but little is known analytically.

Less technically, this theorem states that solutions to (WW), in the long wavelength limit, satisfy

$$x_\alpha(\alpha, t) = \psi^d(\alpha, t) + O(\epsilon^6)$$

for times of $O(\epsilon^{-3})$. This is, as expected, a marked improvement over the use of KdV alone.

We note that this is not the first time that linearized KdV equations have been put forward as a means to improve the accuracy of the KdV approximation. Other instances where linearized KdV equations appear include Sachs [26], Haragus, Nicholls, and Sattinger [15], Kodama and Taniuti [21], and Drazin and Johnson [12]. Moreover, there have been numerous models put forward over the years which model water waves in the same scaling regime we are considering. We refer the reader to Kodama [20], Olver [24], Bona, Pritchard, and Scott [5], Craig and Groves [11], Dullin, Gottwald, and Holm [13], and Bona and Chen [4]. Much of the work done in the above papers pertains to analyzing the behavior of the model equations and not to their connection to the original system. A notable exception is the recent work by Bona, Colin, and Lannes [3], wherein they prove the rigorous validity of a large number of Boussinesq-style models. There, they prove that such models are at least as accurate as the KdV approximation alone (though not as accurate as the model described here) and for the same time scales. Their models are designed, in part, to be easy to approximate numerically and are not, in general, explicitly solvable. Our particular combination of linearized KdV equations with an inhomogeneous wave equation appears to be unique and is asymptotically the most accurate model for long wavelength solutions to the water wave equation which has currently been justified rigorously.

The remainder of this paper is organized as follows. First, in section 2, we conduct a preliminary discussion of the water wave equation. Sections 3 and 5 contain a thorough discussion of the operator $K(x, y)$. Then, in section 4 we derive the higher order modulation equations and prove an important estimate. In section 6 we prove

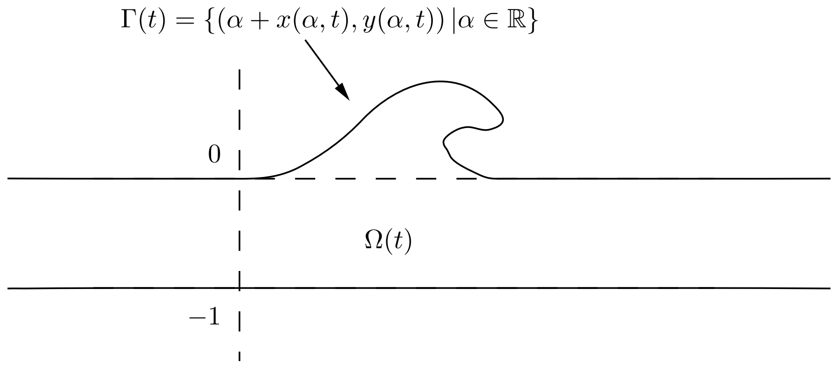

FIG. 6. *The water wave in Lagrangian coordinates.*

the validity of the approximation, i.e., Theorem 2. Finally, section 7 contains the details for a number of proofs.

2. Preliminaries. We begin by discussing the water wave problem in greater detail. Consider an infinitely long canal of unit mean depth in two dimensions (see Figure 6). We denote the region occupied by the fluid at time t as $\Omega(t)$, and the upper surface as $\Gamma(t)$. We parameterize $\Gamma(t)$ by $(\tilde{x}(\alpha,t), y(\alpha,t))$, where $\alpha \in \mathbb{R}$ is the parameter and $\tilde{x}$ and y are the real-valued coordinate functions. It is useful to break $\tilde{x}$ up as follows:

$$\tilde{x}(\alpha,t) = \alpha + x(\alpha,t).$$

We consider fluids which are inviscid and incompressible and flows which are irrotational. Also, we assume that the pressure on the top surface is constant and that the acceleration due to gravity is 1. With these assumptions, the evolution of x and y are given by the equations

$$\begin{aligned} x_{tt}(1+x_\alpha) + y_\alpha(1+y_{tt}) &= 0, \\ y_t &= K(x,y)x_t. \end{aligned} \tag{WW}$$

(See [10].)

The first of these two equations is found from Euler's equations for fluid motion. The operator K in the second line is a transformation which is linear in x_t, but depends nonlinearly on (x,y). That such an operator exists and gives a relationship between x_t and y_t is discussed in sections 3 and 5, along with an analysis of K. Much of the difficulty in answering questions about the water wave equation is related to this operator. If the surface of the water is perfectly flat, i.e., $x = y = 0$, then we have $K(0,0) = K_0$, where K_0 is a linear operator defined by $\widehat{K_0 f}(k) = \widehat{K_0}(k)\widehat{f}(k)$, with $\widehat{K_0}(k) = -i\tanh(k)$. Notice that since tanh is a bounded function, K_0 is bounded from H^s to H^s. K_0 will be appearing frequently.

This formulation of the water wave problem is said to be in *Lagrangian*, or *material*, coordinates. In this point of view we are not in a fixed "lab" frame, but instead we are tracking the position of each "particle" of water separately. That is, $(\alpha + x(\alpha,t), y(\alpha,t))$ gives the location of the particle which was initially at $(\alpha + x(\alpha,0), y(\alpha,0))$. The *laboratory*, or *Eulerian*, point of view is to fix a system of coordinates on the fluid domain and to measure the velocity of the fluid at each point of this fixed reference frame. For our purposes, it is far more convenient to use Lagrangian coordinates; however, experimentalists work with Eulerian coordinates. The coordinate change from one frame to the other is nontrivial and adapting our approximation results to the Eulerian point of view requires some involved computations. We will carry the change of variables out and give formulae for the approximation in terms of Eulerian coordinates in a future publication. The interested reader may also see the author's thesis [34] for this information. We remark that the results of Bona, Colin, and Lannes on the approximation of water waves by Boussinesq models in [3] are proven in Eulerian coordinates, and as such do not contend with this issue.

Since the water wave equation is second order in time for both x and y, one might suppose that four functions are necessary to specify the initial state of the system—$x(\alpha,0)$, $y(\alpha,0)$, $x_t(\alpha,0)$, and $y_t(\alpha,0)$. In fact, in general only three are needed, and for initial data with small amplitudes, only two are needed. The relationship $y_t = K(x,y)x_t$ specifies the value of $y_t(\alpha,0)$ given the other three functions. We can also "do away" with the initial condition for x, provided we are in the small amplitude, long wave limit. If $x(\alpha,0)$ and its first derivative are sufficiently small, then $\alpha + x(\alpha,0)$ will be invertible. This implies that $\Gamma(0)$ will be a graph over the horizontal coordinate. And so, without loss of generality, we can reparameterize the initial conditions so that

$$\Gamma(0) = \{(\alpha, y(\alpha,0))|\alpha \in \mathbb{R}\}.$$

Thus we need only to choose $y(\alpha,0)$ and $x_t(\alpha,0)$. As it turns out, we need to reparameterize the system one more time to prove the approximation theorem, but we will leave this technicality until section 6. The essential point here is that due to the freedom in choosing the initial parameterization, we can eliminate two of our initial conditions.

Even though we can assume that $x(\alpha,0) = 0$ (or, alternately, is small), this coordinate grows linearly in time. (See the linear estimates in Chapter 2 of [28].) As we are concerned with very long time scales, this is a problem. As was shown in [28], one can replace x with the new coordinate $z = K_0 x$, which is well behaved over long times. Rewriting (WW) with this new variable, we have

$$\begin{aligned}
\partial_t z &= K_0 u,\\
\partial_t y &= K(z,y)u,\\
\partial_t u &= -\frac{\partial_\alpha y(1+\partial_t^2 y)}{1+K_0^{-1}\partial_\alpha z}.
\end{aligned} \tag{WW3}$$

We will see that the operator $K(x,y)$ in truth depends not on x but on z, so the abuse of the notation $K(z,y)$ above is in some sense legitimate (see section 3 for further discussion). Furthermore, even though K_0^{-1} is not well defined, as it blows up at frequency $k=0$, the composition

$$L = K_0^{-1}\partial_\alpha$$

is well defined, as its symbol, $-k/\tanh(k)$, has no singularities; L is also invertible. Finally, we notice that the Maclaurin expansion of $\widehat{K_0}(k) = -ik + O(k^3)$. Thus to lowest order $K_0 \sim -\partial_\alpha$, and so $z \sim -x_\alpha$. This is precisely the reason why, in the introduction, we stated that $-x_\alpha$ is a natural coordinate for the water wave equation.

Though we will primarily be working with the three-dimensional system (WW3), we will need to embed this system into a four-dimensional system to prove certain aspects of the validity of the approximation. We introduce the new coordinate $a = u_t$, and (WW3) becomes

$$\text{(WW4)} \qquad \begin{aligned} \partial_t z &= K_0 u, \\ \partial_t y &= K(z,y)u, \\ \partial_t u &= a, \\ \partial_t a &= -\frac{a\partial_\alpha u + \partial_\alpha \partial_t (1+\partial_t^2 y) + \partial_t y \partial_t^3 y}{1 + K_0^{-1}\partial_\alpha z}. \end{aligned}$$

Though things appear to be getting out of hand, we remark that this is as large a system as we will need. Results in [28] prove that solutions to (WW), (WW3), and (WW4) do indeed exist for long times. We will be considering solutions to the four-dimensional system which are in

$$\mathfrak{H}_e^s = H^s \times H^s \times H^{s-1/2} \times H^{s-1}.$$

The main goal of this paper is to prove Theorem 2. To do this, we first prove a similar theorem for solutions to (WW3), from which Theorem 2 will follow. Let

$$\Psi^d(\alpha,t) = \psi^d(\alpha,t) + \epsilon^6 W_3(\epsilon\alpha, \epsilon t). \tag{7}$$

The additional function W_3 will solve an equation we specify later. While we assure the reader that we will be following Chekhov's rule and that this gun which appears in the first act will be fired in the third, interested parties may look ahead to equation (23) in section 4 for more information about W_3. Define the functions

$$\begin{aligned} \Psi^z =& L^{-1}\Psi^d, \\ \Psi^y =& \Psi^z + \epsilon^4 \Delta_1 + \epsilon^6 \Delta_2, \\ \Psi^u =& \partial_\alpha^{-1}\partial_t \Psi^d. \end{aligned}$$

Δ_1 and Δ_2 are combinations of solutions to the modulation equations and are given in (17) and (19) in section 4. We justify the presence of the inverse derivative in Ψ^u by means of example. Ψ^d contains the term U which solves a KdV equation. Thus $\partial_t \Psi^d$ contains the terms from the right-hand side of the KdV equation, all of which are perfect space derivatives. These then are cancelled by the inverse derivative. It is simple to check that this method applies to all terms in Ψ^d.

With these function, we have the following results.

THEOREM 3. *Fix T_0, $C_I > 0$, $s > 4$, $\sigma \geq s + 7$. Let Ψ^d, Ψ^z, Ψ^y, and Ψ^u be as above. Moreover assume that the initial conditions for* (KdV) *satisfy*

$$\max\{\|U_0\|_{H^\sigma(4)\cap H^{\sigma+4}(2)\cap H^{\sigma+9}}, \|V_0\|_{H^\sigma(4)\cap H^{\sigma+4}(2)\cap H^{\sigma+9}}\} < C_I.$$

Then there exist $\epsilon_0 > 0$ and $C_F = C_F(T_0, C_I, s) > 0$ such that if the initial conditions for (WW3) *are of the form*

$$\begin{pmatrix} z(\alpha,0) \\ y(\alpha,0) \\ u(\alpha,0) \end{pmatrix} = \begin{pmatrix} \Psi^z(\alpha,0) \\ \Psi^y(\alpha,0) \\ \Psi^u(\alpha,0) \end{pmatrix} + \epsilon^{11/2}\bar{R}_0(\alpha)$$

with $\|\bar{R}_0\|_{\mathfrak{H}^s} \leq C_I$, then the unique solution of (WW3) *satisfies the estimate*

$$\left\| \begin{pmatrix} z(\cdot,t) \\ y(\cdot,t) \\ u(\cdot,t) \end{pmatrix} - \begin{pmatrix} \Psi^z(\cdot,t) \\ \Psi^y(\cdot,t) \\ \Psi^u(\cdot,t) \end{pmatrix} \right\|_{\mathfrak{H}^s} \leq C_F \epsilon^{11/2}$$

for $t \in [0, T_0\epsilon^{-3}]$. The constant C_F does not depend on ϵ.

3. The operator ( ). Part I: Basics and basic expansions. This is the first of two sections where we discuss the operator $K(x,y)$ which gives the relation between y_t and x_t in the water wave equation. Here we briefly discuss the origin of this operator and report expansions of K found in previous work. We also state some very basic facts about these expansions. In section 5 we quote more complicated results and prove some new technical extensions needed for our purposes.

$K(x,y)$ (or, more precisely $-K(x,y)$) is sometimes called the Hilbert transform for the region $\Omega(t)$. Loosely, given a region Ω in the complex plane, and any function F which is analytic in Ω, the Hilbert transform for Ω, $H(\Omega)$, is a linear operator which relates the real and imaginary parts of F on the boundary of Ω. That is,

$$\mathrm{Im}(F)|_{\partial\Omega} = H(\Omega)\mathrm{Re}(F)|_{\partial\Omega}.$$

For example, if Ω were the lower half-plane, then the Hilbert transform would be the operator H, given by $\widehat{Hf} = i\ \mathrm{sgn}(k)\widehat{f}$. (This particular operator H is also frequently called the Hilbert transform.) The nature of the operator depends greatly on the region being studied. Unsurprisingly, the proof that such an operator exists is connected to the Riemann mapping theorem and to techniques for solving boundary value problems for Laplace's equation in the plane. In this problem, since the region $\Omega(t)$ is completely specified by the coordinate functions x and y, we denote the Hilbert transform by $H(\Omega(t)) = -K(x,y)$.

As we are considering a fluid which is incompressible and a flow which is irrotational, $x_t(\alpha,t) - iy_t(\alpha,t)$ is the value, on the upper boundary $\Gamma(t)$, of an analytic function on $\Omega(t)$, $\omega(\alpha+i\beta) = v^x(\alpha,\beta) - iv^y(\alpha,\beta)$. Here (v^x, v^y) is the velocity field for the fluid in the whole region. Thus, given that $K(x,y)$ exists, we have

$$y_t = K(x,y)x_t.$$

Of course, the boundary of $\Omega(t)$ is not just $\Gamma(t)$, but also includes the bottom of the canal (i.e., where $\beta = -1$). As we do not have fluid flow through the bottom, we have $v^y(\alpha,-1) = 0$.

Under these conditions, $K(x,y)$ has been analyzed extensively by Craig in [10] and Schneider and Wayne in [28]. In particular Craig shows that $K(x,y)$ has the following expansion:

$$K(x,y)u = K_0u + K_1(x,y)u + S_2(x,y)u, \tag{8}$$

where

$$\widehat{K_0u}(k) = -i\tanh(k)\widehat{u}(k),$$

$$K_1(x,y)u = [x,K_0]\partial_\alpha u - (y + K_0(yK_0))\partial_\alpha u,$$

and S_2 is quadratic in (x,y).

First of all we note that K_0 is a bounded operator from H^s to H^s since $\tanh(k)$ is a bounded function. That is,

$$\|K_0u\|_s \leq \|u\|_s.$$

The operator $L = K_0^{-1}\partial_\alpha$, which is well defined as we discussed in section 2, will also be used frequently. L is not a bounded operator on H^s. It effectively takes one derivative. That is,

$$\|Lu\|_s \leq \|u\|_{s+1}. \tag{9}$$

On the other hand, L^{-1} replaces one derivative. That is, since

$$|\tanh(k)/k| \leq (1+k^2)^{-1/2},$$

we know

$$\|L^{-1}u\|_s \leq \|u\|_{s-1}. \tag{10}$$

We will be considering functions which are of long wavelength, that is, functions of the form $f(\alpha) = F(\beta)$ where $\beta = \epsilon\alpha$. We define operators $K_{0,\epsilon}$ and L_ϵ via

$$\begin{aligned} K_{0,\epsilon}F(\beta) &= K_0 f(\alpha), \\ L_\epsilon F(\beta) &= Lf(\alpha). \end{aligned}$$

Taking the Maclaurin series expansion for $\tanh(k)$ shows that formally

$$K_{0,\epsilon} = -\epsilon\partial_\beta - \frac{1}{3}\epsilon^3\partial_\beta^3 - \frac{2}{15}\epsilon^5\partial_\beta^5 + O(\epsilon^7).$$

Similarly L_ϵ and L_ϵ^{-1} have expansions in terms of derivatives

$$\begin{aligned} L_\epsilon &= -1 + \frac{1}{3}\epsilon^2\partial_\beta^2 + \frac{1}{45}\epsilon^4\partial_\beta^4 + O(\epsilon^6), \\ L_\epsilon^{-1} &= -1 - \frac{1}{3}\epsilon^2\partial_\beta^2 - \frac{2}{15}\epsilon^4\partial_\beta^4 + O(\epsilon^6). \end{aligned}$$

We call such expansions of Fourier multiplier operators *long wave approximations*. The rigorous connection between a long wave approximation and the original operator is given in the following lemma, whose simple proof is contained in section 7.

LEMMA 1. *Suppose A and A_n are linear operators defined by $\widehat{Af}(k) = \widehat{A}(k)\widehat{f}(k)$ and $\widehat{A_n f}(k) = \widehat{A_n}(k)\widehat{f}(k)$, where $\widehat{A}(k)$ and $\widehat{A_n}(k)$ are complex-valued functions. Also suppose that $|\widehat{A}(k) - \widehat{A_n}(k)| \leq C|k|^n$ (e.g., $\widehat{A_n}$ is a Taylor polynomial for $\widehat{A}$). Then for $f \in H^{s+n}$ we have*

$$\|Af(\cdot) - A_n f(\cdot)\|_s \leq C\|\partial_\alpha^n f(\cdot)\|_s.$$

Moreover, if $f(\alpha)$ is of long wavelength form—that is, if $f(\alpha) = F(\epsilon\alpha)$, with $F \in H^{s+n}$—then for $0 < \epsilon < 1$ there exists C independent of ϵ such that

$$\|Af(\cdot) - A_n f(\cdot)\|_s \leq C\epsilon^{n-1/2}\|F(\cdot)\|_{s+n}.$$

In [28], Schneider and Wayne show that the operator $K(x,y)$ does not depend on x per se, but rather on $z = K_0 x$. We confuse the notation for the operators intentionally. They showed that $K(z,y)$ has the following expansion:

$$K(z,y)u = K_0 u + K_1(z,y)u + S_2(z,y)u,$$

where

$$K_1(z,y)u = M_1(z)\partial_\alpha u - (y + K_0 y K_0)\partial_\alpha u$$

with

$$\mathfrak{F}[M_1(z)v](k) = -\int \frac{\widehat{K_0}(k) - \widehat{K_0}(l)}{\widehat{K_0}(k-l)}\widehat{z}(k-l)\widehat{v}(l)dl.$$

S_2 is an operator which depends quadratically on z and y. Section 5 contains an analysis of these operators.

By using the hyperbolic trigonometric identity

$$\frac{\tanh(l) - \tanh(k)}{\tanh(l-k)} = 1 - \tanh(k)\tanh(l), \tag{11}$$

we can simplify the expression for K_1 to

$$\begin{aligned} K_1(z,y)u &= M_1(z+y)\partial_\alpha u \\ &= -\left(z + y + K_0(z+y)K_0\right)\partial_\alpha u. \end{aligned} \tag{12}$$

Since we know K_0 is a bounded operator, it is clear that

$$\|M_1(z)v\|_s \le \|zv\|_s. \tag{13}$$

4. The derivation. In this section we will derive the higher order correction to the KdV approximation. For technical reasons, it is most convenient to work with the water wave equation written in the form (WW3). Suppose that one is given the function $\Psi(\alpha,t) = (\Psi^z(\alpha,t), \Psi^y(\alpha,t), \Psi^u(\alpha,t))^{tr}$. The amount that this function fails to satisfy (WW3) is called the *residual* and is given by $\mathrm{Res}[\Psi] = (\mathrm{Res}_z, \mathrm{Res}_y, \mathrm{Res}_u)^{tr}$ with

$$\begin{aligned} \mathrm{Res}_z &= \partial_t \Psi^z - K_0 \Psi^u, \\ \mathrm{Res}_y &= \partial_t \Psi^y - K(\Psi^z, \Psi^y)\Psi^u, \\ \mathrm{Res}_u &= \partial_t \Psi^u + \partial_\alpha \Psi^y \frac{1 + \partial_t^2 \Psi^y}{1 + L\Psi^z}. \end{aligned}$$

For a true solution, notice that $\mathrm{Res}[\Psi]$ is identically zero.

Remark 5. We will also consider the four-dimensional system (WW4). If we let $\Psi^a = \partial_t \Psi^u$, then we have the additional Res function

$$\begin{aligned} \mathrm{Res}_a &= \partial_t \Psi^a + \frac{\Psi^a \partial_\alpha \Psi^u + \partial_\alpha \partial_t (1 + \partial_t^2 \Psi^y) + \partial_t \Psi^y \partial_t^3 \Psi^y}{1 + L\Psi^z} \\ &= \partial_t \mathrm{Res}_u + \frac{\partial_\alpha \Psi^u}{1 + L\Psi^z} \mathrm{Res}_u. \end{aligned}$$

The main goal when deriving modulation equations is to choose a system of equations such that solutions to this system yield a very small residual. This is different from (but connected to) showing that solutions to the modulation equations are close to true solutions for the original problem. This latter issue is precisely that answered by the main results, Theorem 2 and Proposition 3, and is discussed in section 6. Here, we will perform a series of calculations on the residual and derive equations (KdV), (IW), and (LK). In this process we guarantee the smallness of the residual. While several of the steps will initially seem to have little mathematical justification (i.e., they are formal), once the calculation is completed it will be obvious that all steps are valid. For example, we will take

$$\Psi^u = K_0^{-1} \partial_t \Psi^z. \tag{14}$$

With this choice

$$\mathrm{Res}_z = 0,$$

which is small indeed! However, K_0^{-1} is not in general a well-defined operator. Nonetheless, when we eventually select Ψ^z, $K_0^{-1}\partial_t\Psi^z$ will make perfect sense.

We are looking for solutions which are small in amplitude and long in wavelength. Thus we let

$$\begin{aligned}\Psi^z(\alpha,t) &= \epsilon^2 Z(\beta,\tau)\\ &= \epsilon^2 Z_1(\beta,\tau)+\epsilon^4 Z_2(\beta,\tau)+\epsilon^6 Z_3(\beta,\tau).\end{aligned}$$

Recall $\beta=\epsilon\alpha$ and $\tau=\epsilon t$. We require $\mathrm{Res}[\Psi]$ to be $O(\epsilon^{17/2})$. Loosely, we need three powers of ϵ more than the expected error of $O(\epsilon^{11/2})$ to account for the long times $(O(\epsilon^{-3}))$ over which our approximation will be valid. See Schneider and Wayne [28] and Wayne and Wright [33].

Remark 6. More specifically, if we wish to prove Theorem 2 in the space $\mathfrak{H}^s$ we will need

$$\begin{aligned}\|\mathrm{Res}_z\|_s &\le C\epsilon^{17/2},\\ \|\mathrm{Res}_y\|_s &\le C\epsilon^{17/2},\\ \|\mathrm{Res}_u\|_{s-1} &\le C\epsilon^{17/2},\\ \|\mathrm{Res}_a\|_{s-1} &\le C\epsilon^{19/2}\end{aligned}$$

for $0\le t\le T_0\epsilon^{-3}$. Given the definition of Res_a, the final estimate will follow automatically from the estimate on Res_u.

We have already chosen Ψ^u in terms of Ψ^z. We will first use the expression for Res_y to similarly determine Ψ^y in terms of Ψ^z. This is not as simple a matter because while K_0 commutes with ∂_t, the full operator $K(z,y)$ does not.

We have

$$\begin{aligned}\mathrm{Res}_y &= -\partial_t\Psi^y + K_0\Psi^u + M_1(\Psi^z+\Psi^y)\partial_\alpha\Psi^u + S_2(\Psi^y,\Psi^z)\Psi^u\\ &= -\partial_t\Psi^y + \partial_t\Psi^z + M_1(\Psi^z+\Psi^y)K_0^{-1}\partial_\alpha\partial_t\Psi^z + S_2(\Psi^y,\Psi^z)\Psi^u.\end{aligned}$$

Notice that in the above expression we can cancel the linear terms by taking $\Psi^y\sim\Psi^z$. More precisely, we set

$$\Psi^y(\alpha,t)=\epsilon^2 Z(\beta,\tau)+\epsilon^4\Delta_1(\beta,\tau)+\epsilon^6\Delta_2(\beta,\tau)$$

for as yet undetermined functions Δ_i. Thus

$$\begin{aligned}\mathrm{Res}_y &= -\epsilon^5\partial_\tau\Delta_1-\epsilon^7\partial_\tau\Delta_2+M_1(2\epsilon^2 Z)L_\epsilon\epsilon^3\partial_\tau Z\\ &\quad + M_1(\epsilon^4\Delta_1+\epsilon^6\Delta_2)L_\epsilon\epsilon^3\partial_\tau Z + S_2(\Psi^y,\Psi^z)\Psi^u\\ &= -\epsilon^5\partial_\tau\Delta_1-\epsilon^7\partial_\tau\Delta_2-2\epsilon^5 Z L_\epsilon\partial_\tau Z-\epsilon^6 K_{0,\epsilon}\left(2Z\partial_\beta\partial_\tau Z\right)\\ &\quad -\epsilon^7\Delta_1 L_\epsilon\partial_\tau Z-\epsilon^8 K_{0,\epsilon}\left(\Delta_1\partial_\beta\partial_\tau Z\right)+\epsilon^9 M_1(\Delta_2)L_\epsilon\partial_\tau Z\\ &\quad + S_2(\Psi^y,\Psi^z)\Psi^u.\end{aligned}$$

A number of the terms in Res_y are already $O(\epsilon^{17/2})$. By Lemma 1 we have the following estimate on $K_{0,\epsilon}$:

$$\|K_{0,\epsilon}F\|_s \le \epsilon^{1/2}\|F\|_{s+1}. \tag{15}$$

Thus terms containing $K_{0,\epsilon}$ can be considered to be a power of ϵ smaller than they appear (though this costs a derivative). On the other hand, K_0 is bounded so we have

$$\|K_{0,\epsilon}F\|_s \le \epsilon^{-1/2}\|F\|_s. \tag{16}$$

Thus we can use $K_{0,\epsilon}$ either as a bounded functional *or* to gain powers of ϵ, but not both. Notice that L_ϵ does not contribute any additional powers of ϵ in any case. We separate out all the terms that are already sufficiently small into error terms. That is,

$$\begin{aligned}\mathrm{Res}_y =& -\epsilon^5\partial_\tau\Delta_1 - \epsilon^7\partial_\tau\Delta_2 - 2\epsilon^5 Z_1 L_\epsilon\partial_\tau Z_1\\ &- 2\epsilon^7 Z_1 L_\epsilon \partial_\tau Z_2 - 2\epsilon^7 Z_2 L_\epsilon\partial_\tau Z_1\\ &- \epsilon^6 K_{0,\epsilon}\left(2Z_1\partial_\beta\partial_\tau Z_1\right) - \epsilon^7\Delta_1 L_\epsilon\partial_\tau Z_1\\ &+ E^y_{small} + E^y_{S_2}\end{aligned}$$

with

$$\begin{aligned}E^y_{small} =& 2\epsilon^9 Z_3 L_\epsilon\partial_\tau Z + 2\epsilon^9(Z_1+\epsilon^2 Z_2)L_\epsilon\partial_\tau Z_3 + 2\epsilon^9 Z_2 L_\epsilon\partial_\tau Z_2\\ &- \epsilon^8 K_{0,\epsilon}\big((2Z_2+2\epsilon^2 Z_3)\partial_\beta\partial_\tau Z\big) - \epsilon^8 K_{0,\epsilon}\big(2Z_1\partial_\beta\partial_\tau(Z_2+\epsilon^2 Z_3)\big)\\ &- \epsilon^9\Delta_1 L_\epsilon\partial_\tau(Z_2+\epsilon^2 Z_3) - \epsilon^8 K_{0,\epsilon}\left(\Delta_1\partial_\beta\partial_\tau Z\right) + \epsilon^9 M_1(\Delta_2)L_\epsilon\partial_\tau Z\\ E^y_{S_2} =& S_2(\Psi^y,\Psi^z)\Psi^u.\end{aligned}$$

It is clear that E^y_{small} is $O(\epsilon^{17/2})$. That is,

$$\|E^y_{small}\|_s \le C\epsilon^{17/2}.$$

The constant C depends on various norms of the functions Z_i, $\partial_\tau Z_i$, and Δ_i. Specifically, chasing through the various terms in E^y_{small} and applying the estimates in (9), (13), (15), and (16), one can show that C depends on $\|Z_1\|_{s+1}$, $\|Z_2\|_{s+1}$, $\|Z_3\|_s$, $\|\partial_\tau Z_1\|_{s+2}$, $\|\partial_\tau Z_2\|_{s+2}$, $\|\partial_\tau Z_3\|_{s+1}$, $\|\Delta_1\|_{s+1}$, and $\|\Delta_2\|_s$.

The term $E^y_{S_2}$ is also $O(\epsilon^{17/2})$, though this is not as obvious. We prove this in Proposition 3 in section 5. The proof of this relies strongly on the fact that we have taken Ψ^y and Ψ^z such that $\Psi^y - \Psi^z$ is $O(\epsilon^4)$. This causes a cancellation in S_2, which in turn makes this term small.

We now expand L_ϵ and $K_{0,\epsilon}$ in the remaining low order terms in Res_y to find

$$\begin{aligned}\mathrm{Res}_y =& -\epsilon^5\partial_\tau\Delta_1 - \epsilon^7\partial_\tau\Delta_2 + 2\epsilon^5 Z_1\partial_\tau Z_1 + \frac{4}{3}\epsilon^7 Z_1\partial_\tau\partial_\beta^2 Z_1\\ &+ 2\epsilon^7 Z_1\partial_\tau Z_2 + 2\epsilon^7 Z_2\partial_\tau Z_1\\ &+ 2\epsilon^7\partial_\beta Z_1\partial_\beta\partial_\tau Z_1 + \epsilon^7\Delta_1\partial_\tau Z_1\\ &+ E^y_{small} + E^y_{S_2} + E^y_{lwa}\end{aligned}$$

with

$$\begin{aligned}E^y_{lwa} =& -2\epsilon^5 Z_1\left(L_\epsilon + 1 - \frac{1}{3}\epsilon^2\partial_\beta^2\right)\partial_\tau Z_1 - 2\epsilon^7 Z_1(L_\epsilon+1)\partial_\tau Z_2\\ &- 2\epsilon^7 Z_2(L_\epsilon+1)\partial_\tau Z_1 - 2\epsilon^6(K_{0,\epsilon}+\epsilon\partial_\beta)(Z_1\partial_\beta\partial_\tau Z_1)\\ &- \epsilon^7\Delta_1(L_\epsilon+1)\partial_\tau Z_1.\end{aligned}$$

Each term in E^y_{lwa} is $O(\epsilon^{17/2})$ by Lemma 1. That is,

$$\|E^y_{lwa}\| \le C\epsilon^{17/2},$$

where C depends on $\|Z_1\|_{s+3}$,$\|Z_2\|_s$, $\|\partial_\tau Z_1\|_{s+4}$,$\|\partial_\tau Z_2\|_{s+2}$, and $\|\Delta_1\|_s$. (The subscript "lwa" stands for "long wave approximation.")

The only $O(\epsilon^5)$ terms remaining in Res_y are

$$-\epsilon^5 \partial_\tau \Delta_1 + 2\epsilon^5 Z_1 \partial_\tau Z_1$$

which we remove by selecting

$$\Delta_1 = Z_1^2. \tag{17}$$

Therefore

$$\begin{aligned}\mathrm{Res}_y = &- \epsilon^7 \partial_\tau \Delta_2 + \frac{4}{3}\epsilon^7 Z_1 \partial_\tau \partial_\beta^2 Z_1 \\ &+ 2\epsilon^7 Z_1 \partial_\tau Z_2 + 2\epsilon^7 Z_2 \partial_\tau Z_1 \\ &+ 2\epsilon^7 \partial_\beta Z_1 \partial_\beta \partial_\tau Z_1 + \epsilon^7 Z_1^2 \partial_\tau Z_1 \\ &+ E^y_{small} + E^y_{S_2} + E^y_{lwa}.\end{aligned}$$

The remaining $O(\epsilon^7)$ terms in Res_y are all perfect time derivatives with the exception of

$$\frac{4}{3} Z_1 \partial_\tau \partial_\beta^2 Z_1.$$

Notice, however, that

$$\partial_\tau \left(\frac{4}{3} Z_1 \partial_\beta^2 Z_1 - \frac{2}{3} (\partial_\tau Z_1)^2 \right) = \frac{4}{3} Z_1 \partial_\tau \partial_\beta^2 Z_1 + \frac{4}{3} \partial_\tau Z_2 \left(\partial_\beta^2 Z_1 - \partial_\tau^2 Z_1 \right).$$

Given the form of the approximation in (1), it is not unreasonable to suspect that

$$\partial_\beta^2 Z_1 - \partial_\tau^2 Z_1 \sim O(\epsilon^2). \tag{18}$$

We are now in a position to select Δ_2. Taking

$$\Delta_2 = (\partial_\beta Z_1)^2 + 2 Z_1 Z_2 + \frac{1}{3} Z_1^3 + \frac{4}{3} Z_1 \partial_\beta^2 Z_1 - \frac{2}{3} (\partial_\tau Z_1)^2 \tag{19}$$

gives

$$\mathrm{Res}_y = E^y_{small} + E^y_{S_2} + E^y_{lwa} + E^y_{switch},$$

where

$$E^y_{switch} = \frac{4}{3} \epsilon^7 \partial_\tau Z_1 (\partial_\beta^2 Z_1 - \partial_\tau^2 Z_1).$$

Given that our assumption (18) is valid, we have shown, with our choices for Ψ^y and Ψ^u in terms of Ψ^z, that $\mathrm{Res}_y = O(\epsilon^{17/2})$. More specifically, we have shown that if

$$\|\partial_\beta^2 Z_1 - \partial_\tau^2 Z_1\|_s \le C\epsilon^{3/2},$$

then

$$\mathrm{Res}_y \le C\epsilon^{17/2},$$

where the constant depends only on $\|Z_1\|_{s+3}$, $\|Z_2\|_{s+1}$, $\|Z_3\|_s$, $\|\partial_\tau Z_1\|_{s+4}$, $\|\partial_\tau Z_2\|_{s+2}$, and $\|\partial_\tau Z_3\|_{s+1}$.

Now that we have computed Ψ^y and Ψ^u in terms of Ψ^z, we now turn our attention to determining Ψ^z by examining Res_u:

$$\mathrm{Res}_u = K_0^{-1}\partial_t^2\Psi^z + \partial_\alpha\Psi^y\frac{1+\partial_t^2\Psi^y}{1+L\Psi^z}.$$

We expand $(1+L\Psi^z)^{-1}$ by the geometric series to find

$$\mathrm{Res}_u = K_0^{-1}\partial_t^2\Psi^z + \partial_\alpha\Psi^y(1+\partial_t^2\Psi^y)(1-L\Psi^z+(L\Psi^z)^2) + E_1^u,$$

where

$$E_{geo}^u = \partial_\alpha\Psi^y\frac{1+\partial_t^2\Psi^y}{1+L\Psi^z} - \partial_\alpha\Psi^y(1+\partial_t^2\Psi^y)(1-L\Psi^z+(L\Psi^z)^2).$$

Since Ψ^z is "small" this error term can be shown to be $O(\epsilon^{17/2})$. We have the following lemma.

LEMMA 2. *Let $f \in H^{s+1}$, $s > 0$. Take ϵ_0 such that $\epsilon_0^2\|f\|_{L^\infty} \le 1/2$. Then for $0 < \epsilon < \epsilon_0$ we have that the function*

$$g(\epsilon x) = \frac{1}{1+\epsilon^2 f(\epsilon x)} - 1 + \epsilon^2 f(\epsilon x)$$

satisfies $\|g(\epsilon\cdot)\|_s \le C\epsilon^{7/2}$ for C independent of ϵ.

Remark 7. Under the same hypotheses as in Lemma 2, arguments similar to the proof of that lemma show that

- $(1+\epsilon^2 f(\epsilon x))^{-1} \in C^s$ and is bounded there independent of ϵ,
- $(1+\epsilon^2 f(\epsilon x))^{-1} - 1 \in H^s$ and has norm there bounded by $C\epsilon^{3/2}$ for C independent of ϵ, and
- $(1+\epsilon^2 f(\epsilon x))^{-1} - 1 + \epsilon^2 f(\epsilon x) - \epsilon^4 f^2(\epsilon x) \in H^s$ and has norm there bounded by $C\epsilon^{11/2}$ for C independent of ϵ.

Now, after substituting from the definitions of Ψ^y and Ψ^z, we collect all the terms which are smaller than $O(\epsilon^{17/2})$ and find

$$\begin{aligned}\mathrm{Res}_u = {}& \epsilon^4 K_{0,\epsilon}^{-1}\partial_\tau^2(Z_1+\epsilon^2 Z_2+\epsilon^4 Z_3) + \epsilon^3\partial_\beta Z_1 - \epsilon^5\partial_\beta Z_1 L_\epsilon Z_1\\ &+ \epsilon^5\partial_\beta\left(Z_2+Z_1^2\right) + \epsilon^7\partial_\beta Z_1\left(\partial_\beta^2 Z_1 - L_\epsilon Z_2 + (L_\epsilon Z_1)^2\right)\\ &- \epsilon^7\partial_\beta(Z_2+Z_1^2)L_\epsilon Z_1 + \epsilon^7\partial_\beta Z_3\\ &+ \epsilon^7\partial_\beta\left((\partial_\beta Z_1)^2 + 2Z_1Z_2 + \frac{1}{3}Z_1^3\right)\\ &+ \epsilon^7\partial_\beta\left(\frac{4}{3}Z_1\partial_\beta^2 Z_1 - \frac{2}{3}(\partial_\tau Z_1)^2\right)\\ &+ E_{geo}^u + E_{small}^u + E_{switch}^u.\end{aligned}$$

We omit the exact expression for E_{small}^u because it is both lengthy and uninteresting. We have

$$\|E_{small}^u\|_s \le C\epsilon^{17/2}, \tag{20}$$

where the constant C depends on H^{s+1} norms of the functions Z_i and the H^s norms of $\partial_\tau^2 Z_i$. We have also replaced one instance of $\partial_\tau^2 Z_1$ with $\partial_\beta^2 Z_1$ (much as we did earlier); thus

$$E_{switch}^u = \epsilon^7\partial_\beta Z_1\left(\partial_\beta^2 Z_1 - \partial_\tau^2 Z_1\right).$$

We now define new functions W_i by $Z_i = L_\epsilon^{-1} W_i$. This seemingly mysterious (and sudden!) change of variables will seem less so if we remind the reader that at the end of the day we wish to model not z but rather the function x_α. Accordingly, if we approximate x_α by a function

$$\Psi^d = \epsilon^2 W_1 + \epsilon^4 W_2 + \epsilon^6 W_3,$$

then it is logical to take

$$\Psi^z = L^{-1}\Psi^d,$$

and in the long wavelength limit we arrive at these functions W_i.

Therefore we have

$$\begin{aligned}
\mathrm{Res}_u = {} & \epsilon^3 \partial_\beta^{-1}\partial_\tau^2 (W_1 + \epsilon^2 W_2 + \epsilon^4 W_3) + \epsilon^2 K_{0,\epsilon} W_1 - \epsilon^4 W_1 K_{0,\epsilon} W_1 \\
& + \epsilon^4 K_{0,\epsilon} W_2 + \epsilon^5 \partial_\beta (L_\epsilon^{-1} W_1)^2 \\
& + \epsilon^2 K_{0,\epsilon} W_1 \left(\epsilon^3 K_{0,\epsilon} \partial_\beta W_1 - \epsilon^4 W_2 + \epsilon^4 W_1^2\right) \\
& - (\epsilon^6 K_{0,\epsilon} W_2 + \epsilon^7 \partial_\beta (L_\epsilon^{-1} W_1)^2) W_1 + \epsilon^6 K_{0,\epsilon} W_3 \\
& + \epsilon^5 \partial_\beta \left((K_{0,\epsilon} W_1)^2 + 2\epsilon^2 L_\epsilon^{-1} W_1 L_\epsilon^{-1} W_2 + \frac{1}{3}\epsilon^2 (L_\epsilon^{-1} W_1)^3 \right) \\
& + \epsilon^7 \partial_\beta \left(\frac{4}{3} L_\epsilon^{-1} W_1 L_\epsilon^{-1} \partial_\beta^2 W_1 - \frac{2}{3} (L_\epsilon^{-1} \partial_\tau W_1)^2 \right) \\
& + E^u_{geo} + E^u_{small} + E^u_{switch}.
\end{aligned}$$

At this time, the presence of inverse β derivatives may seem problematic. Notice that each such inverse derivative precedes a time derivative. Once we select the functions W_i we will see that there can be an exchange between time and space derivatives, which will justify the instances of ∂_β^{-1}.

Now we replace $K_{0,\epsilon}$ and L_ϵ^{-1} with their long wave approximates and find

$$\begin{aligned}
\mathrm{Res}_u = {} & \epsilon^3 \partial_\beta^{-1}\partial_\tau^2 (W_1 + \epsilon^2 W_2 + \epsilon^4 W_3) \\
& - \epsilon^2 \left(\epsilon\partial_\beta + \frac{1}{3}\epsilon^3 \partial_\beta^3 + \frac{2}{15}\epsilon^5 \partial_\beta^5 \right) W_1 \\
& + \epsilon^4 W_1 \left(\epsilon\partial_\beta + \frac{1}{3}\epsilon^3 \partial_\beta^3 \right) W_1 \\
& - \epsilon^4 \left(\epsilon\partial_\beta + \frac{1}{3}\epsilon^3 \partial_\beta^3 \right) W_2 + \epsilon^5 \partial_\beta (W_1)^2 + \frac{2}{3}\epsilon^7 \partial_\beta (W_1 \partial_\beta^2 W_1) \\
& - \epsilon^7 \partial_\beta W_1 \left(-\partial_\beta^2 W_1 - W_2 + W_1^2 \right) \\
& - \epsilon^7 W_1 (-\partial_\beta W_2 + \partial_\beta (W_1)^2) - \epsilon^7 \partial_\beta W_3 \\
& + \epsilon^7 \partial_\beta \left((\partial_\beta W_1)^2 + 2 W_1 W_2 - \frac{1}{3} W_1^3 \right) \\
& + \epsilon^7 \partial_\beta \left(\frac{4}{3} W_1 \partial_\beta^2 W_1 - \frac{2}{3} (\partial_\tau W_1)^2 \right) \\
& + E^u_{geo} + E^u_{small} + E^u_{switch} + E^u_{lwa}.
\end{aligned}$$

The error made by the long wave approximations is denoted E^u_{lwa}. By Lemma 1 we have

$$\|E^u_{lwa}\|_s \le C\epsilon^{17/2},$$

where C depends on $\|W_1\|_{s+7}$, $\|W_2\|_{s+5}$, $\|W_3\|_{s+3}$, and $\|\partial_\tau W_1\|_{s+2}$.

Now we organize the above as

$$
\begin{aligned}
\mathrm{Res}_y = {} & \epsilon^3 \partial_\beta^{-1}\partial_\tau^2 W_1 - \epsilon^3 \partial_\beta W_1 \\
& - \epsilon^5 \frac{1}{3}\partial_\beta^3 W_1 + \epsilon^5 \frac{3}{2}\partial_\beta (W_1)^2 \\
& + \epsilon^5 \partial_\beta^{-1}\partial_\tau^2 W_2 - \epsilon^5 \partial_\beta W_2 \\
& - \epsilon^7 \frac{1}{3}\partial_\beta^3 W_2 + \epsilon^7 3\partial_\beta (W_1 W_2) \\
& - \frac{2}{15}\epsilon^7 \partial_\beta^5 W_1 + \epsilon^7 \frac{1}{3} W_1 \partial_\beta^3 W_1 \\
& + \epsilon^7 2\partial_\beta (W_1 \partial_\beta^2 W_1) + \epsilon^7 \frac{3}{2}\partial_\beta (\partial_\beta W_1)^2 \\
& - \epsilon^7 \frac{4}{3}\partial_\beta (W_1)^3 - \epsilon^7 \frac{2}{3}\partial_\beta (\partial_\tau W_1)^2 \\
& + \epsilon^7 \partial_\beta^{-1}\partial_\tau^2 W_3 - \epsilon^7 \partial_\beta W_3 \\
& + E^u_{geo} + E^u_{small} + E^u_{switch} + E^u_{lwa}.
\end{aligned}
\tag{21}
$$

The term on the first line of the right-hand side looks formally like an inverse derivative of a wave equation:

$$\partial_\beta^{-1}\partial_\tau^2 W_1 - \partial_\beta W_1 = \partial_\beta^{-1}\left(\partial_\tau^2 W_1 - \partial_\beta^2 W_1\right).$$

We cancel this term (to lowest order) by taking W_1 of the form

$$W_1(\beta,\tau) = -U(\beta-\tau, \epsilon^2\tau) - V(\beta+\tau, \epsilon^2\tau).$$

Recall $\beta_\pm = \beta \pm \tau$ and $T = \epsilon^2 \tau$. The "minus" signs may seem arbitrary, but are included at this stage so that they agree with previous work in the area. Noting that the third line looks very much like the first, we also set

$$W_2(\beta,\tau) = -F(\beta-\tau, \epsilon^2\tau) - G(\beta+\tau, \epsilon^2\tau) - P(\beta,\tau).$$

These choices for W_1 and W_2 are precisely those described heuristically in the introduction.

The first three lines in (21) become

$$
\begin{aligned}
& \epsilon^5 \left(2\partial_T U + \frac{1}{3}\partial_{\beta_-}^3 U + \frac{3}{2}\partial_{\beta_-} U^2\right) \\
& + \epsilon^5 \left(-2\partial_T V + \frac{1}{3}\partial_{\beta_+}^3 V + \frac{3}{2}\partial_{\beta_+} V^2\right) \\
& + \epsilon^5 \left(\partial_\beta^{-1}\left(\partial_\beta^2 P - \partial_\tau^2 P\right) + 3\partial_\beta (UV)\right) \\
& + \epsilon^7 \left(2\partial_T F - 2\partial_T G - \partial_\beta^{-1}\left(\partial_T^2 U + \partial_T^2 V\right)\right) \\
& - \epsilon^9 \partial_\beta^{-1}\left(\partial_T^2 F + \partial_T^2 G\right).
\end{aligned}
$$

We cancel everything multiplied by ϵ^5 by taking

$$
\begin{aligned}
-2\partial_T U &= \frac{1}{3}\partial_{\beta_-}^3 U + \frac{3}{2}\partial_{\beta_-} U^2, \\
2\partial_T V &= \frac{1}{3}\partial_{\beta_+}^3 V + \frac{3}{2}\partial_{\beta_+} V^2, \\
\partial_\tau^2 P - \partial_\beta^2 P &= 3\partial_\beta^2 (UV),
\end{aligned}
$$

which are precisely equations (KdV) and (IW). By Proposition 1 we know that the solutions to these equations are well behaved over the long time scales.

Given that the functions U and V have been chosen to solve (KdV), one computes that

$$\partial_T^2 U = \partial_{\beta_-}\left(\frac{1}{36}\partial_{\beta_-}^5 U + \frac{9}{4}U^2\partial_{\beta_-}U + \frac{1}{2}U\partial_{\beta_-}^3 U + \frac{3}{4}\partial_{\beta_-}U\partial_{\beta_-}^2 U\right),$$
$$\partial_T^2 V = \partial_{\beta_+}\left(\frac{1}{36}\partial_{\beta_+}^5 V + \frac{9}{4}V^2\partial_{\beta_+}V + \frac{1}{2}V\partial_{\beta_+}^3 V + \frac{3}{4}\partial_{\beta_+}V\partial_{\beta_+}^2 V\right).$$

Thus the term $\partial_\beta^{-1}\left(\partial_T^2 U + \partial_T^2 V\right)$ is perfectly well defined. For brevity, we will continue to write these terms with the inverse derivatives instead of in the longer form above.

Moreover, now we can put more precise estimates on E^y_{switch} and E^u_{switch}. In particular, since each time derivative for solutions to KdV equations counts for three space derivatives, we have

$$\|\partial_\beta^2 W_1 - \partial_\tau^2 W_1\|_s \le C\epsilon^{3/2},$$

where C depends on $\|W_1\|_{s+6}$.

Recall from Fact 1 and Proposition 1 that solutions to (IW) can be rewritten as

$$\begin{aligned} P(\beta,\tau) &= P^+(\beta,\tau) + P^-(\beta,\tau) \\ &= \varphi^+(\beta_+,T) + \varphi^-(\beta_-,T). \end{aligned}$$

The functions $\varphi^\pm$ are rapidly decaying. We make this decomposition so that every remaining term in (21)

- will be a unidirectional term which is rapidly decaying;
- will be a product of two such terms which are moving in opposite directions;
- or will include a derivative of W_3.

That is,

$$\begin{aligned} \mathrm{Res}_y = {} & \epsilon^7\left(2\partial_T F + \frac{1}{3}\partial_{\beta_-}^3 F + 3\partial_{\beta_-}(UF) + J^-\right) \\ & + \epsilon^7\left(-2\partial_T G + \frac{1}{3}\partial_{\beta_+}^3 G + 3\partial_{\beta_+}(VG) + J^+\right) \\ & + \epsilon^7\left(\partial_\beta^{-1}\left(\partial_\tau^2 W_3 - \partial_\beta^2 W_3\right) + J^s\right) \\ & - \epsilon^9\partial_\beta^{-1}\left(\partial_T^2 F + \partial_T^2 G\right) \\ & + E^u_{geo} + E^u_{small} + E^u_{switch} + E^u_{lwa} + E^u_{time}, \end{aligned}$$

where

$$
\begin{aligned}
J^- = {} & 3\partial_{\beta_-}(U\varphi^-) + 4U^2\partial_{\beta_-}U + \frac{7}{3}U\partial^3_{\beta_-}U \\
& + \frac{11}{3}\partial_{\beta_-}U\partial^2_{\beta_-}U + \frac{2}{15}\partial^5_{\beta_-}U + \frac{1}{3}\partial^3_{\beta_-}\varphi^- \\
& - \partial^{-1}_{\beta_-}\partial^2_T U, \\
J^+ = {} & 3\partial_{\beta_+}(V\varphi^+) + 4V^2\partial_{\beta_+}V + \frac{7}{3}V\partial^3_{\beta_+}V \\
& + \frac{11}{3}\partial_{\beta_+}V\partial^2_{\beta_+}V + \frac{2}{15}\partial^5_{\beta_+}V + \frac{1}{3}\partial^3_{\beta_+}\varphi^+ \\
& - \partial^{-1}_{\beta_+}\partial^2_T V, \\
J^s = {} & \partial_\beta\left(U\left(3G + 3\varphi^+ + 4V^2 + \frac{7}{3}\partial^2_{\beta_+}V\right)\right) \\
& + \partial_\beta\left(V\left(3F + 3\varphi^- + 4U^2 + \frac{7}{3}\partial^2_{\beta_-}U\right)\right) \\
& + 4\partial_\beta\left(\partial_{\beta_-}U\partial_{\beta_+}V\right),
\end{aligned}
\tag{22}
$$

and

$$
\begin{aligned}
E^u_{time} = {} & \epsilon^9\frac{4}{3}\partial_\beta\left(\left(\partial_{\beta_-}U - \partial_{\beta_+}V\right)\left(\partial_T U + \partial_T V\right)\right) \\
& - \epsilon^{11}\frac{2}{3}\partial_\beta\left(\left(\partial_T U + \partial_T V\right)^2\right).
\end{aligned}
$$

Notice that $J^\pm = J^\pm(\beta_\pm, T)$. E^u_{time} (so called because each term in it contains some sort of time derivative) is clearly $O(\epsilon^{17/2})$. That is,

$$\|E^u_{time}\|_s \le C\epsilon^{17/2}.$$

The constant above depends on $\|U\|_{s+4}$ and $\|V\|_{s+4}$.

The term $\epsilon^9\partial^{-1}_\beta\left(\partial^2_T F + \partial^2_T G\right)$ is not included in E^u_{time} for the following reason. In a moment, when we select the equations F and G solve, a consequence will be that there will be terms in $\partial^2_T F$ and $\partial^2_T G$ which are $O(\epsilon^{-2})$.

By taking

$$
\begin{aligned}
-2\partial_T F &= \frac{1}{3}\partial_{\beta_-}(UF) + \frac{3}{2}\partial^3_{\beta_-}F + J^-, \\
2\partial_T G &= \frac{1}{3}\partial_{\beta_+}(VG) + \frac{3}{2}\partial^3_{\beta_+}G + J^+,
\end{aligned}
$$

we cancel nearly all the terms which are not in the various E^u terms. These are the linearized KdV equations (LK) discussed in the introduction. Proposition 1 guarantees that the solutions are well behaved. We are left with

$$
\begin{aligned}
\mathrm{Res}_y = {} & + \epsilon^7\left(\partial^{-1}_\beta\left(\partial^2_\tau W_3 - \partial^2_\beta W_3\right) + J^s\right) \\
& - \epsilon^9\partial^{-1}_\beta\left(\partial^2_T F + \partial^2_T G\right) \\
& + E^u_{geo} + E^u_{small} + E^u_{switch} + E^u_{lwa} + E^u_{time}.
\end{aligned}
$$

Now we consider the terms in $\partial_\beta^{-1}\left(\partial_T^2 F + \partial_T^2 G\right)$. Notice that

$$\begin{aligned}-\partial_{\beta_-}^{-1}\partial_T^2 F &= \partial_{\beta_-}^{-1}\partial_T\left(\frac{1}{6}\partial_\beta^3 F + \frac{3}{2}\partial_\beta(UF) + \frac{1}{2}J^-\right)\\ &= \frac{1}{6}\partial_{\beta_-}^2\partial_T F + \frac{3}{2}\partial_T(UF) + \frac{1}{2}\partial_{\beta_-}^{-1}\partial_T J^-.\end{aligned}$$

J^- contains the term $3\partial_{\beta_-}(U\varphi^-) + \frac{1}{3}\partial_{\beta_-}^3\varphi^-$. From the definition of φ^- we know that

$$\partial_T\varphi^- = -\epsilon^{-2}\frac{3}{2}\partial_\beta(UV).$$

Thus we have

$$\begin{aligned}\frac{1}{2}\partial_{\beta_-}^{-1}\partial_T\left(3\partial_{\beta_-}(U\varphi^-) + \frac{1}{3}\partial_{\beta_-}^3\varphi^-\right) &= \frac{3}{2}\varphi^-\partial_T U + \frac{3}{2}U\partial_T\varphi^- + \frac{1}{6}\partial_{\beta_-}^2\partial_T\varphi^-\\ &= \frac{3}{2}\varphi^-\partial_T U - \frac{9}{4}\epsilon^{-2}U\partial_\beta(UV) + \frac{1}{4}\epsilon^{-2}\partial_\beta^3(UV).\end{aligned}$$

We treat $\partial_T^2 G$ in the same fashion. Therefore we can write

$$-\epsilon^9\partial_\beta^{-1}\left(\partial_T^2 F + \partial_T^2 G\right) = E_{F,G}^u - \epsilon^7\left(\frac{9}{4}(U+V)\partial_\beta(UV) + \frac{1}{2}\partial_\beta^3(UV)\right).$$

By construction $E_{F,G}^u$ satisfies the estimate

$$\|E_{F,G}^u\|_s \le C\epsilon^{17/2},$$

where C depends on $\|U\|_{s+7}$, $\|V\|_{s+7}$, $\|F\|_{s+5}$, and $\|G\|_{s+5}$.

We have

$$\begin{aligned}\mathrm{Res}_y = \;&\epsilon^7\left(\partial_\beta^{-1}\left(\partial_\tau^2 W_3 - \partial_\beta^2 W_3\right) + J^s\right)\\ &- \epsilon^7\left(\frac{9}{4}(U+V)\partial_\beta(UV) + \frac{1}{2}\partial_\beta^3(UV)\right)\\ &+ E_{geo}^u + E_{small}^u + E_{switch}^u + E_{lwa}^u + E_{time}^u + E_{F,G}^u.\end{aligned}$$

By selecting

$$\partial_\tau^2 W_3 - \partial_\beta^2 W_3 = \partial_\beta\left(\frac{9}{4}(U+V)\partial_\beta(UV) + \frac{1}{2}\partial_\beta^3(UV) - J^s\right) \tag{23}$$

the gun goes off and we cancel all remaining $O(\epsilon^7)$ terms. Thus

$$\mathrm{Res}_y = E_{geo}^u + E_{small}^u + E_{switch}^u + E_{lwa}^u + E_{time}^u + E_{F,G}^u.$$

Each of the E^u is $O(\epsilon^{17/2})$.

Unlike the previous equations (KdV), (IW), and (LK), Proposition 1 does not tell us that the solutions to (23) are controllable. Nonetheless, (23) is an inhomogeneous wave equation where the inhomogeneity consists entirely of terms which are products of left- and right-moving rapidly decaying functions. From Wayne and Wright [33] we have the following lemma.

LEMMA 3. *Suppose*

$$\partial_\tau u \pm \partial_\beta u = l(\beta+\tau, \epsilon^2\tau) r(\beta-\tau, \epsilon^2\tau), \quad u(X,0)=0,$$

with $\|l(\cdot,T)\|_{H^s(2)} \le C$ *and* $\|r(\cdot,T)\|_{H^s(2)} \le C$ *for* $T\in[0,T_0]$; *then*

$$\|u(\beta,\tau)\|_s \le C$$

for all $\tau \in [0, T_0\epsilon^{-2}]$. *The constant* C *is uniform in* ϵ.

Thus W_3 will remain $O(1)$.

Remark 8. If we are in the situation in which Proposition 1 applies, we see that least regular parts in the driving term are $\partial_\beta^2(UG)$ and $\partial_\beta^2(VF)$, which are in $H^{\sigma-6}(2)$. Thus, by this lemma we have that $W_3 \in H^{\sigma-5}$ for all times of interest.

At this time we have derived the modulation equations and shown that the residual is small. The only remaining order of business in this section is to determine how smooth the solutions to our modulation equations need to be in order for $\mathrm{Res}[\Psi]$ to be appropriately regular. This may seem to be a fairly tiresome task, but fortunately the least regular terms in all of the sundry E functions come from only one term—E^u_{small}! This is because E^u_{small} contains many time derivatives.

We need to control Res_a in H^{s-1}. For this we need $\partial_t \mathrm{Res}_u \in H^{s-1}$, which in turn implies that we must have $\partial_t E^u_{small} \in H^{s-1}$. Recalling (20), we see that this will require $\partial_\tau^3 Z_2 \in H^{s-1}$, or rather (since L_ϵ^{-1} saves a derivative) $\partial_\tau^3 W_2 \in H^{s-2}$. For this, we need $\partial_T^3 F$ and $\partial_T^3 G$ in H^{s-2}. Given that F solves (LK) where J^+ contains the terms $\partial_{\beta\_}^5 U$, $\partial_{\beta\_}^3 \varphi^-$, one sees that $\partial_T^3 F$ will include the terms $\partial_{\beta\_}^9 F$, $\partial_{\beta\_}^{11} U$, and $\partial_{\beta\_}^9 \varphi^-$. Thus $\|\partial_T^3 F\|_{s-2}$ is controlled by the H^{s+9} norms of U and V, and the H^{s+7} norms of φ^-, F, and G. The analogous result is true for $\partial_T^3 G$. We also need $\partial_\tau^3 W_3 \in H^{s-2}$. Since W_3 solves (23), we require $W_3 \in H^{s+1}$.

In summary we have the following proposition.

PROPOSITION 2. *Take* Ψ^d *as in* (7), *with* U, V, F, G, P, *and* W_3 *solving their respective equations. Let*

$$\begin{aligned}
\Psi^z &= L^{-1}\Psi^d,\\
\Psi^y &= \Psi^z + \epsilon^4\Delta_1 + \epsilon^6\Delta_2,\\
\Psi^u &= \partial_\alpha^{-1}\partial_t\Psi^d,\\
\Psi^a &= \partial_\alpha^{-1}\partial_t^2\Psi^d,
\end{aligned}$$

with Δ_1 *and* Δ_2 *as in* (17) *and* (19), *and form* $Res[\Psi]$ *as in* (4). *Then*

$$\begin{aligned}
\|Res_z\|_s &\le C\epsilon^{17/2},\\
\|Res_y\|_s &\le C\epsilon^{17/2},\\
\|Res_u\|_{s-1} &\le C\epsilon^{17/2},\\
\|Res_a\|_{s-1} &\le C\epsilon^{19/2},
\end{aligned}$$

where C *is a constant which depends on* $\|U\|_{s+9}$, $\|V\|_{s+9}$, $\|P\|_{s+7}$, $\|F\|_{s+7}$, $\|G\|_{s+7}$, *and* $\|W_3\|_{s+1}$. *The estimate* (6) *holds as long as these quantities remain bounded. The constant* C *does not depend on* ϵ.

In light of Proposition 1 and Remark 8, we see, if we take the initial conditions for U and V to satisfy (2) with $\sigma \ge s+7$, that $\|U\|_{s+9}$, $\|V\|_{s+9}$, $\|P\|_{s+7}$, $\|F\|_{s+7}$, $\|G\|_{s+7}$, and $\|W_3\|_{s+1}$ are all $O(1)$ for $t\in[0,T_0\epsilon^{-3}]$. Thus we move on.

5. The operator ( ). Part II: Estimates and extensions. In this section we will describe a few more estimates related to $K(x,y)$. All such estimates are either smoothing estimates or ones which show that certain terms are small in the long wavelength setting.

First, since $1+\widehat{K_0}^2(k)$ goes to zero exponentially fast as $|k|\to\infty$, the operator $1+K_0^2$ is smoothing. That is, for all $s\geq 0$

$$\|(1+K_0^2)u\|_s \leq C\|u\|_{L^2}.$$

Also, commutators involving K_0 are smoothing. We quote the following lemma from [28].

LEMMA 4. *Let $r\geq 0$, $q>1/2$, and $0\leq p\leq q$. Then there exists a $C>0$ such that*

$$\|[f,K_0]g\|_r \leq C\|f\|_{r+p}\|g\|_{q-p}.$$

Proof. See Lemma 3.12 on page 1498 of [28]. □

Schneider and Wayne show that $K_1(z,y)$ is a smoothing operator.

LEMMA 5. *For $r\geq 0$, $q\geq 1/2$ and $0\leq p\leq q$, there is C such that*

$$\|K_1(z,y)u\|_r \leq C\left(\|z\|_{r+p}+\|y\|_{r+p}\right)\|u\|_{q-p}. \tag{24}$$

Proof. See Corollary 3.13 on page 1499 of [28]. □

If we let $S_1(z,y)=K(z,y)-K_0$, we also have the following estimates from [28].

LEMMA 6. *Fix $s\geq 4$. If the free surface is sufficiently smooth, then for $j=1,2$ we have*

$$\text{(a)}\qquad \|S_j(z,y)u\|_s \leq C\left(\|z\|_s^j+\|y\|_s^j\right)\|u\|_3,$$

that is, S_j is a smoothing operator;

$$\text{(b)}\qquad \|\partial_\alpha(S_j(z,y)u)\|_s \leq C\left(\|z\|_s^j+\|y\|_s^j\right)\|u\|_3,$$

that is, $\partial_\alpha S_j$ is a smoothing operator;

$$\text{(c)}\qquad \|[\partial_t,S_j]u\| \leq C\left(\|z\|_s^j+\|y\|_s^j\right)\|u\|_3,$$

that is, $[\partial_t,S_j]$ is a smoothing operator and this operator can be bounded independently of $\partial_t u$; and

$$\text{(d)}\qquad \|[\partial_t^2,S_j]u\| \leq C\left(\|z\|_s^j+\|y\|_s^j\right)\left(\|u\|_4+\|\partial_t u\|_4\right),$$

that is, $[\partial_t^2,S_j]$ is a smoothing operator and this operator can be bounded independently of $\partial_t^2 u$.

Proof. The proof is in [28]; see Lemmas 3.14 and 3.15 and Corollary 3.16 on pages 1500, 1506, and 1507, respectively. □

We will also need the following propositions concerning the behavior of the remainder terms S_1 and S_2. The first of these says that more or less the remainder S_2 is negligible for the sort of scalings we are considering. That is to say, the term $E^y_{S_2}$ in section 4 is very small.

PROPOSITION 3. *Fix $s>5/2$. Suppose $z=\epsilon^2Z(\epsilon\alpha)$, $y=\epsilon^2Y(\epsilon\alpha)$, and $f=\epsilon^2F(\epsilon\alpha)$, with $Z,Y,F\in H^{s+1}(2)$. Moreover, assume $z-y=\epsilon^4\Delta(\epsilon\alpha)$ with*

$\Delta \in H^{s+1}(2)$. *Then there exists* ϵ_0 *such that for* $\epsilon \in [0, \epsilon_0]$ *there is a constant* C *independent of* ϵ *such that*

$$\|S_2(z, y)f\|_s \leq C\epsilon^{17/2}.$$

The second proposition is a technical version of the mean value theorem as applied to the operator S_1.

PROPOSITION 4. *Suppose* $z(\alpha, t) = \epsilon^2 Z(\epsilon(\alpha \pm t), \epsilon^3 t)$, $y(\alpha, t) = \epsilon^2 Y(\epsilon(\alpha \pm t), \epsilon^3 t)$, $u(\alpha, t) = \epsilon^2 U(\epsilon(\alpha \pm t), \epsilon^3 t)$, *and* $f(\alpha, t) = \epsilon^2 F(\epsilon(\alpha \pm t), \epsilon^3 t)$ *with* $Z, Y, U, F \in H^s(2)$ *for* $t \in [0, T_0\epsilon^{-3}]$. *Also suppose* $R^z(\alpha, t)$, $R^y(\alpha, t)$, *and* $R^u(\alpha, t) \in H^s$ *for the same time interval. Then*

$$\|S_1(z(\cdot) + \epsilon^{11/2}R^z(\cdot), y(\cdot) + \epsilon^{11/2}R^y(\cdot))f(\cdot) - S_1(z(\cdot), y(\cdot))f(\cdot)\|_s \leq C\epsilon^{17/2}$$

for $t \in [0, T_0\epsilon^{-3}]$.

Proof of Proposition 3. First, notice that $x(\alpha) = \int_0^\alpha Lz(a)da = \epsilon X(\epsilon\alpha)$. We know that X is in L^∞ by the following lemma.

LEMMA 7. *Suppose* $f(\alpha) = \epsilon^2 F(\epsilon\alpha)$ *with* $F \in H^s(2)$. *Then for all* α

$$\left|\int_0^\alpha f(a)da\right| \leq C\epsilon\|F\|_{H^s(2)}.$$

Proof. See section 7. □

Let $\Phi(\tilde{x}, y) = (\Phi_1, \Phi_2)$ be the analytic map which takes $\Omega(t)$ to

$$P^- = \{(\xi, \gamma) | \gamma \in [-1, 0]\}.$$

That such a map exists and is analytic is guaranteed by the Riemann mapping theorem. Let

$$h(\alpha) = \Phi_1(\tilde{x}(\alpha), y(\alpha))$$

and $Qf = f \circ h$. From [28], we know that

$$K(x, y)f(\alpha) = Q \circ K_0 \circ Q^{-1} f(\alpha). \tag{25}$$

We can derive a very useful implicit formula for h^{-1} as follows. The function $\Phi^{-1}(\xi, \gamma)$ is analytic on P^-; thus it satisfies the Cauchy–Riemann equations. If we set

$$\Phi^{-1}(\xi, \gamma) = (\xi + u_1(\xi, \gamma)) + i(\gamma - v_1(\xi, \gamma))$$

and notice that Φ^{-1} sends the bottom and top of P^- to the bottom and top of $\Omega(t)$, respectively, we see that we have the following system:

$$\begin{gathered}\partial_\xi u_1 + \partial_\gamma v_1 = 0,\\ \partial_\gamma u_1 - \partial_\xi v_1 = 0,\\ v_1(\xi, -1) = 0, \quad v_1(\xi, 0) = \eta(\xi),\end{gathered}$$

where $\eta(\xi) = y(h^{-1}(\xi))$. One can solve this system with the use of Fourier transforms relatively simply. If one does so, one finds that

$$u_1(\xi, 0) = -\int_0^\xi \eta(\xi_1)d\xi_1 - M\eta(\xi),$$

where M is the pseudodifferential operator given by

$$\widehat{M\eta}(k) = \frac{k\cosh(k) - \sinh(k)}{ik\sinh(k)}\widehat{\eta}(k).$$

Notice that to lowest order, M is $C\partial_\alpha$.

Now, notice that $h^{-1}(\xi) = \tilde{x}^{-1}(u(\xi,0))$ and so we have an implicit equation for h^{-1}:

$$\begin{aligned} h^{-1}(\xi) &= \tilde{x}^{-1}\left(\xi - \int_0^\xi \eta(\xi_1)d\xi_1 - M\eta(\xi)\right) \\ &= \tilde{x}^{-1}\left(\xi - \int_0^\xi y(h^{-1}(\xi_1))d\xi_1 - M(y\circ h^{-1})(\xi)\right). \end{aligned} \tag{26}$$

Remark 9. In [28, p. 1494], Schneider and Wayne make a minor error in calculating this same function. As a result, they claim that the above representation gives an explicit formula for h^{-1}. Our correction here changes nothing about subsequent steps in their proofs.

Since $\tilde{x} = \alpha + \epsilon X(\epsilon\alpha)$, where X is well behaved, we can expect a similar form for $\tilde{x}^{-1}$.

LEMMA 8. *Suppose $f(\alpha) = \alpha + g(\alpha)$ with $\|g\|_{C^2} \le 1/2$. Then*

$$f^{-1}(\xi) = \xi - g(\xi) + g(\xi)g'(\xi) + E,$$

where $E = O(\|g\|^3_{W^{2,\infty}})$. More specifically

$$E \le C\left(\|g'\|^2_{L^\infty}\|g\|_{L^\infty} + \|g\|^2_{L^\infty}\|g''\|_{L^\infty}\right).$$

In particular, notice that if $g(\alpha) = \epsilon G(\epsilon\alpha)$ this means that $E = O(\epsilon^5)$.

Proof. See section 7. ∎

We apply this lemma to $\tilde{x}$ and find that

$$\tilde{x}^{-1}(\xi) = \xi - \epsilon X(\epsilon\xi) + \epsilon^3 X(\epsilon\xi)\partial_\beta X(\epsilon\xi) + O(\epsilon^5).$$

Combining this with (26) we can determine $h^{-1}(\xi)$ (and therefore h) in terms of x and y to any order we wish. To lowest order we see that

$$h^{-1}(\xi) = \xi + O(\epsilon). \tag{27}$$

Therefore now we have

$$\begin{aligned} h^{-1}(\xi) = \xi &- \int_0^\xi y(h^{-1}(\xi_1))d\xi_1 - M(y\circ h^{-1})(\xi) \\ &- \epsilon X\left(\epsilon\left(\xi - \int_0^\xi y(h^{-1}(\xi_1))d\xi_1 - M(y\circ h^{-1})(\xi)\right)\right) \\ &+ O(\epsilon^3) \\ = \xi &- \int_0^\xi \epsilon^2 Y(\epsilon h^{-1}(\xi_1))d\xi_1 - M(\epsilon^2 Y\circ \epsilon h^{-1})(\xi) \\ &- \epsilon X\left(\epsilon\left(\xi - \int_0^\xi \epsilon^2 Y(\epsilon h^{-1}(\xi_1))d\xi_1 - M(\epsilon^2 Y\circ\epsilon h^{-1})(\xi)\right)\right) \\ &+ O(\epsilon^3). \end{aligned}$$

If we insert (27) into the above and expand we have

$$h^{-1}(\xi) = \xi - \epsilon X(\epsilon\xi) - \int_0^\xi \epsilon^2 Y(\epsilon\xi_1))d\xi_1 - \epsilon^2 M(Y(\epsilon\cdot))(\xi) + O(\epsilon^3).$$

One can continue in this manner and determine the next order terms in the expansion of h^{-1}. If we let

$$\epsilon G_1(\epsilon\alpha) = -\epsilon X(\epsilon\alpha) - \int_0^\alpha \epsilon^2 Y(\epsilon\alpha_1))d\alpha_1 - \epsilon^2 M(Y(\epsilon\cdot))(\alpha),$$

the expansion is

$$h^{-1}(\xi) = \xi + \epsilon G_1(\epsilon\xi) + \epsilon^3 B_1(\epsilon\xi) + O(\epsilon^5),$$

where

$$\begin{aligned} B_1(\xi) = &\int_0^\xi \epsilon G_1(\epsilon a)\partial_\beta \epsilon^3 Y(\epsilon a)da \\ &+ M(\epsilon^3 G_1(\epsilon\cdot)\partial_\beta Y(\epsilon\cdot))(\xi) + \epsilon^3 G_1(\epsilon\xi)\partial_\beta X(\epsilon\xi). \end{aligned}$$

Notice that since M is $C\partial_\alpha$ to lowest order, $-\epsilon^2 M(Y(\epsilon\cdot))(\alpha)$ is $O(\epsilon^3)$. Moreover, by hypothesis, we have $\epsilon^2 Z(\epsilon\alpha) - \epsilon^2 Y(\epsilon\alpha) = \epsilon^4\Delta(\epsilon\alpha)$. Thus

$$\begin{aligned} -\epsilon X(\epsilon\alpha) - \int_0^\alpha \epsilon^2 Y(\epsilon a)da &= -\int_0^\alpha \left(\epsilon^2\partial_\beta X(\epsilon a) + \epsilon^2 Y(\epsilon a)\right) da \\ &= -\int_0^\alpha \left(\epsilon^2 L(Z(\epsilon\cdot))(a) + \epsilon^2 Y(\epsilon a)\right) da \\ &= \int_0^\alpha \left(\epsilon^2 Z(\epsilon a) - \epsilon^2 Y(\epsilon a)\right) da + O(\epsilon^3) \\ &= \int_0^\alpha \left(\epsilon^4 \Delta(\epsilon a)\right) da + O(\epsilon^3) \\ &= O(\epsilon^3). \end{aligned}$$

That is, ϵG_1 is really $O(\epsilon^3)$! This cancellation is the crucial step in this proof. Since ϵG_1 appears in each term in B_1, we have shown

$$h^{-1}(\xi) = \xi + \epsilon^3 G(\epsilon\xi) + O(\epsilon^5)$$

with $\epsilon^3 G = \epsilon G_1$. We appeal to Lemma 8 again, and we have

$$h(\alpha) = \alpha - \epsilon^3 G(\epsilon\alpha) + O(\epsilon^5).$$

Now that we have particularly good estimates on h and h^{-1}, we can begin our discussion of K in earnest. For notational simplicity, we will let

$$\begin{aligned} h(\alpha) &= \alpha + g_1(\alpha), \\ h^{-1}(\xi) &= \xi + g_2(\xi). \end{aligned}$$

If we let

$$\tilde{f} = Q^{-1} f,$$

we can make the following formal approximation using Taylor's theorem:

$$\begin{aligned}K(x,y)f(\alpha) &= Q \circ K_0 \tilde{f}(\alpha)\\ &= K_0 \tilde{f}(h(\alpha))\\ &= K_0 \tilde{f}(\alpha + g_1(\alpha))\\ &= K_0 \tilde{f}(\alpha) + g_1(\alpha) K_0 \partial_\alpha \tilde{f}(\alpha) + \text{h.o.t.}\end{aligned}$$

Also by Taylor's theorem,

$$\tilde{f}(\alpha) = f(\alpha) + g_2(\alpha)\partial_\alpha f(\alpha) + \text{h.o.t.}$$

Putting these together we have

$$K(x,y)f(\alpha) = K_0 f(\alpha) + g_1(\alpha) K_0 f'(\alpha) + K_0(g_2 f')(\alpha) + \text{h.o.t.}$$

Thus let

$$\begin{aligned}E_1 f &= K_0 f(\alpha) + g_1(\alpha) K_0 f'(\alpha) + K_0(g_2 f')(\alpha),\\ E_2 f &= K(x,y) f - E_1 f.\end{aligned}$$

We prove Proposition 3 if we can prove

- $\|E_1 f - K_0 f - K_1(x,y) f\|_s \leq C\epsilon^{17/2}$ and
- $\|E_2 f\|_s \leq C\epsilon^{17/2}$.

Let us deal with $E_2 f$ first. We can rewrite $E_2 f$ as

$$E_2 f = E_2^1 f + E_2^2 f + E_2^3 f$$

with

$$\begin{aligned}E_2^1 f &= K(x,y) f - K_0 \tilde{f} - g_1 K_0 \partial_\alpha \tilde{f},\\ E_2^2 f &= K_0 \tilde{f} - K_0 f - K_0(g_2 \partial_\alpha f),\\ E_2^3 f &= g_1 K_0 \partial_\alpha \tilde{f} - g_1 K_0 \partial_\alpha f.\end{aligned}$$

As our approximation for K was determined by an application of Taylor's theorem, we need to prove a lemma which shows that this formal step can be made rigorous, at least for functions in the weighted Sobolev spaces.

Lemma 9. *Suppose $F \in H^s(n)$, $s > 1/2$, $n > 1/2$. Then for all $C_0 > 0$ there exists ϵ_0 such that for $\epsilon \in [0, \epsilon_0]$ there is a constant C independent of ϵ such that*

$$\left(\int_{|\alpha| > C_0 \epsilon^{-3}} |F(\epsilon\alpha)|^2 d\alpha\right)^{1/2} \leq C\epsilon^{2n-3/2}.$$

Moreover, for $1 \leq j \leq s$ we have

$$\left(\int_{|\alpha| > C_0 \epsilon^{-3}} |\partial_\alpha^j F(\epsilon\alpha)|^2 d\alpha\right)^{1/2} \leq C\epsilon^{2n-3/2+j}.$$

Proof. See section 7. ∎

Remark 10. If instead we are considering

$$\left(\int_{|\alpha|>C_0\epsilon^{-3}} |F(\epsilon(\alpha \pm t), \epsilon^3 t)|^2 d\alpha\right)^{1/2}$$

with $F(\cdot, T) \in H^s(n)$ for $T \in [0, T_0]$, we can maintain the same bound as above by taking $C_0 \geq 2T_0$.

We can use the above lemma to prove a version of Taylor's theorem.

LEMMA 10. *Suppose $F \in H^s(2)$, $s > 5/2$, and $g \in L^\infty$. Then*

$$\|F(\epsilon \cdot + \epsilon^2 g(\epsilon\cdot)) - F(\epsilon\cdot)\|_{L^2} \leq C\epsilon^{3/2}.$$

Proof. By Lemma 9 we have

$$\begin{aligned}
&\|F(\epsilon \cdot + \epsilon^2 g(\epsilon\cdot)) - F(\epsilon\cdot)\|^2 \\
&= \int_{|\alpha|\leq\epsilon^{-3}} |F(\epsilon\alpha + \epsilon^2 g(\epsilon\alpha)) - F(\epsilon\alpha)|^2 d\alpha \\
&+ \int_{|\alpha|\geq\epsilon^{-3}} |F(\epsilon\alpha + \epsilon^2 g(\epsilon\alpha)) - F(\epsilon\alpha)|^2 d\alpha \\
&\leq \int_{|\alpha|\leq\epsilon^{-3}} |F(\epsilon\alpha + \epsilon^2 g(\epsilon\alpha)) - F(\epsilon\alpha)|^2 d\alpha + C\epsilon^5.
\end{aligned}$$

Now, we add and subtract $\epsilon^2 g(\epsilon\alpha) F'(\epsilon\alpha)$ in the remaining integral,

$$\begin{aligned}
&\int_{|\alpha|\leq\epsilon^{-3}} |F(\epsilon\alpha + \epsilon^2 g(\epsilon\alpha)) - F(\epsilon\alpha)|^2 d\alpha \\
&\leq \int_{|\alpha|\leq\epsilon^{-3}} |F(\epsilon\alpha + \epsilon^2 g(\epsilon\alpha)) - F(\epsilon\alpha) - \epsilon^2 g(\epsilon\alpha)F'(\epsilon\alpha)|^2 d\alpha \\
&\quad + \int_{|\alpha|\leq\epsilon^{-3}} |\epsilon^2 g(\epsilon\alpha)F'(\epsilon\alpha)|^2 d\alpha \\
&\leq \int_{|\alpha|\leq\epsilon^{-3}} |F(\epsilon\alpha + \epsilon^2 g(\epsilon\alpha)) - F(\epsilon\alpha) - \epsilon^2 g(\epsilon\alpha)F'(\epsilon\alpha)|^2 d\alpha \\
&\quad + \epsilon^3 \|g(\cdot)\|_{L^\infty}^2 \|F'(\cdot)\|_{L^2}^2.
\end{aligned}$$

We naively bound the above integral and apply the mean value theorem. That is,

$$\begin{aligned}
&\int_{|\alpha|\leq\epsilon^{-3}} |F(\epsilon\alpha + \epsilon^2 g(\epsilon\alpha)) - F(\epsilon\alpha) - \epsilon^2 g(\epsilon\alpha)F'(\epsilon\alpha)|^2 d\alpha \\
&\leq C\epsilon^{-3} \sup_{|\alpha|\leq\epsilon^{-3}} |F(\epsilon\alpha + \epsilon^2 g(\epsilon\alpha)) - F(\epsilon\alpha) - \epsilon^2 g(\epsilon\alpha)F'(\epsilon\alpha)|^2 \\
&\leq C\epsilon^{-3} \sup_{|\alpha|\leq\epsilon^{-3}} |\epsilon^4 g^2(\epsilon\alpha) F''(\epsilon\alpha^*)|^2 \\
&\leq C\epsilon^5 \|g\|_{L^\infty}^4 \|F''\|_{L^\infty}^2.
\end{aligned}$$

With this, we have proven the lemma. $\square$

Remark 11. With this general technique we are also able to show that

$$\|\partial_\alpha^j (F(\epsilon \cdot + \epsilon^2 g(\epsilon\cdot)) - F(\epsilon\cdot))\|_{L^2} \leq C\epsilon^{3/2+j},$$

$$\|\partial_\alpha^j \left(F(\epsilon\cdot+\epsilon^2 g(\epsilon\cdot)) - F(\epsilon\cdot) - \epsilon^2 g(\epsilon\cdot)F'(\cdot)\right)\|_{L^2} \le C\epsilon^{7/2+j},$$

$$\|\partial_\alpha^j \left(F(\epsilon\cdot+\epsilon^2 g(\epsilon\cdot))\right) - \partial_\alpha^j \left(F(\epsilon\cdot) + \epsilon^2 g(\epsilon\cdot)F'(\cdot) + 1/2\epsilon^4 g^2(\epsilon\cdot)F''(\epsilon\cdot)\right)\|_{L^2} \le C\epsilon^{11/2+j},$$

and so on.

Now we will be able to control E_2^1. We can control the other functions in precisely the same fashion. Since f is of long wavelength and rapid decay, so is $\tilde{f}$. Thus we can use Lemma 10. In what follows, $\epsilon^3\tilde{F}(\epsilon\alpha) = K_0\tilde{f}(\alpha)$. (The extra ϵ comes from the long wave approximation of K_0.)

$$\begin{aligned}
&\|E_2^1 f(\cdot)\|_s = \|K_0\tilde{f}(\cdot+g_1(\cdot)) - K_0\tilde{f}(\cdot) - g_1(\cdot)K_0\partial_\alpha\tilde{f}(\cdot)\|_s \\
&\le C\epsilon^3\|\tilde{F}(\epsilon\cdot+\epsilon^4 G(\epsilon\cdot)) - \tilde{F}(\epsilon\cdot) - \epsilon^4 G(\epsilon\cdot)\partial_\beta\tilde{F}(\epsilon\cdot)\|_s \\
&\le C\epsilon^{17/2}.
\end{aligned}$$

Now we turn our attention to $E_1 f - K_0 f - K_1(x,y)f$. A routine calculation shows that this is equal to

$$\begin{aligned}
&-\epsilon^3[G(\epsilon\alpha),K_0]\epsilon^3\partial_\beta F(\epsilon\alpha) - K_1(\epsilon X,\epsilon^2 Y)\epsilon^2 F(\epsilon\alpha) \\
&+(g_1+\epsilon^3 G)K_0\epsilon^3\partial_\beta F(\epsilon\alpha) + K_0\left((g_2-\epsilon^3 G)\epsilon^3\partial_\beta F(\epsilon\cdot)\right)(\alpha).
\end{aligned}$$

Now, $g_1+\epsilon^3 G$ and $g_2-\epsilon^3 G$ are $O(\epsilon^5)$, so the second line above can be bounded by $C\epsilon^{17/2}$, if we make use of K_0's long wavelength approximation. Moreover, we claim that the first line is identically zero. Let

$$\begin{aligned}
b(\alpha) &= -\int_0^\alpha \epsilon^2 Y(\epsilon\alpha_1)d\alpha_1 - \epsilon^2 M(Y(\epsilon\cdot))(\alpha) \\
&= -\int_0^\alpha y(\alpha_1)d\alpha_1 - My(\alpha).
\end{aligned}$$

Thus $\epsilon^3 G(\epsilon\alpha) = b(\alpha) - x(\alpha)$. So

$$\epsilon^3[G(\epsilon\alpha),K_0]\epsilon^3\partial_\beta F(\epsilon\alpha) = -[x(\alpha),K_0]\partial_\alpha f(\alpha) + [b(\alpha),K_0]\partial_\alpha f(\alpha).$$

Taking the Fourier transform of the second term we have

$$\begin{aligned}
&\mathfrak{F}\left([b(\alpha),K_0]\partial_\alpha f(\alpha)\right)(k) \\
&= \int\left(\widehat{K_0}(l)-\widehat{K_0}(k)\right)\widehat{b}(l-k)il\widehat{f}(l)dl \\
&= \int\frac{\widehat{K_0}(l)-\widehat{K_0}(k)}{i(l-k)}i(l-k)\widehat{b}(l-k)il\widehat{f}(l)dl \\
&= \int\frac{\widehat{K_0}(l)-\widehat{K_0}(k)}{i(l-k)}\widehat{\partial_\alpha b}(l-k)il\widehat{f}(l)dl.
\end{aligned}$$

Now notice that $\partial_\alpha b = Ly$, so the above becomes

$$\begin{aligned}
&\int\frac{\widehat{K_0}(l)-\widehat{K_0}(k)}{i(l-k)}\widehat{Ly}(l-k)il\widehat{f}(l)dl = \int\frac{\widehat{K_0}(l)-\widehat{K_0}(k)}{\widehat{K_0}(l-k)}\widehat{y}(l-k)il\widehat{f}(l)dl \\
&= \int(1+\widehat{K_0}(k)\widehat{K_0}(l))\widehat{y}(l-k)il\widehat{f}(l)dl \\
&= \mathfrak{F}\left((y+K_0 y K_0)\partial_\alpha f\right)(k),
\end{aligned}$$

where we have used the trigonometric identity (11) from section 4.

That is,

$$\begin{aligned}&\epsilon^3[G(\epsilon\alpha), K_0]\epsilon^3\partial_\beta F(\epsilon\alpha) = -[x(\alpha), K_0]\partial_\alpha f(\alpha) + ((y + K_0 y K_0)\partial_\alpha f)(k)\\ =& - K_1(x, y)f\end{aligned}$$

and so we are done with the proof of Proposition 3. ∎

Proof of Proposition 4. Let h be as in Proposition 3 and h_2 be the analogous function for the configuration $(z_2, y_2) = (z + \epsilon^{11/2}R^z, y + \epsilon^{11/2}R^y)$. We also define the function $\tilde{x}_2 = \alpha + x_2$ by $\partial_\alpha x_2 = Lz_2$. Unlike in the previous lemma, here the time dependence of the functions is important. Thus we determine x and x_2 by integrating in both space and time. That is,

$$\begin{aligned}\tilde{x}(\alpha, t) &= \alpha + \epsilon\chi(\epsilon\alpha, \epsilon t),\\ \tilde{x}_2(\alpha, t) &= \alpha + \epsilon\chi(\epsilon\alpha, \epsilon t) + \epsilon^{5/2}E(t) + \epsilon^{11/2}\rho(\alpha, t)\end{aligned}$$

with

$$\begin{aligned}\epsilon\chi(\epsilon\alpha, \epsilon t) &= \left(\int_0^t u(0, s)\, ds + \int_0^\alpha Lz(w, t)\, dw\right),\\ \epsilon^{5/2}E(t) &= \epsilon^{11/2}\int_0^t R^u(0, s)\, ds,\\ \epsilon^{11/2}\rho &= \int_0^\alpha LR^z(w, t)\, dw.\end{aligned}$$

The functions satisfy the following estimates for all $t \in [0, T_0\epsilon^{-3}]$:

$$\begin{aligned}|\epsilon\chi(\epsilon\alpha, \epsilon t)| &\le C\epsilon,\\ |\epsilon^{5/2}E(t)| &\le C\epsilon^{5/2},\\ |\epsilon^{11/2}\rho(\alpha, t)| &\le C\sqrt{|\alpha|}\|R^z\|_{H^s}.\end{aligned}$$

The first estimate follows from similar estimates in the previous lemma, the second is the naive bound, and the final follows from the following simple fact.

FACT 2. *If $p(\alpha) = \int_0^\alpha r(a)da$, where $r \in L^2$, then*

$$|p(\alpha)| \le \sqrt{|\alpha|}\|r\|_{L^2}.$$

In what follows we will make strong use of the fact that $E(t)$ does not depend on α.

Using the same techniques as were used in proving Lemma 8, one can show that

$$\tilde{x}_2^{-1}(\xi, t) = \tilde{x}^{-1}(\xi, t) - \epsilon^{5/2}E(t) + \epsilon^{11/2}\rho_2(\xi),$$

where $|\rho_2(\alpha)| \le \sqrt{|\alpha|}\|R^z\|_{L^2}$. This sort of estimate carries over to the functions h. That is,

$$\begin{aligned}h_2^{-1}(\xi, t) &= h^{-1}(\xi, t) - \epsilon^{5/2}E(t) + \epsilon^{11/2}\rho_3(\xi, t),\\ h_2(\alpha, t) &= h(\alpha, t) + \epsilon^{5/2}E(t) + \epsilon^{11/2}\rho_4(\alpha, t),\end{aligned}$$

where $|\rho_3(\alpha, t)|, |\rho_4(\alpha, t)| \le \sqrt{|\alpha|}(\|R^z\|_{L^2} + \|R^y\|_{L^2})$ over the long time scale.

Now define $Q_2 f = f \circ h_2$. Therefore

$$\begin{aligned} &S_1(z+\epsilon^{11/2}R^z, y+\epsilon^{11/2})f - S_1(z,y)f \\ &= Q_2 \circ K_0 \circ Q_2^{-1} f - Q \circ K_0 \circ Q^{-1} f \\ &= Q \circ \big(Q^{-1} \circ Q_2 \circ K_0 \circ Q_2^{-1} \circ Q - K_0\big) \circ Q^{-1} f. \end{aligned}$$

Since Q and its inverse are bounded operators from H^s to H^s, we need only prove the estimate for the operator

$$\tilde{Q} \circ K_0 \circ \tilde{Q}^{-1} - K_0,$$

where $\tilde{Q} = Q^{-1} \circ Q_2$. Notice that $\tilde{Q} \circ K_0 \circ \tilde{Q}^{-1}$ is the Hilbert operator K for a domain with the "h" function given by $\tilde{h}(\alpha) = h_2(h^{-1}(\alpha))$. Moreover, from the above calculations for h and h_2 we have

$$h_2(h^{-1}(\alpha)) = \alpha + \epsilon^{5/2}E(t) + \epsilon^{11/2}\rho_5(\alpha,t),$$

with ρ_5 satisfying the same type of estimates as ρ_4.

At this point we can make an appeal to Lemma 3.14 on page 1500 of [28]. In this lemma they prove that $\|S_1(z,y)f\|_s \le C\left(\|z\|_s + \|y\|_s\right)\|f\|_3$. In the course of their proof, they show that if $h(\alpha) = \alpha + g(\alpha)$, then

$$\|Q \circ K_0 \circ Q^{-1} f(\cdot) - K_0 f(\cdot)\|_s \le C\|\partial_\alpha g\|_{s-1}\|\partial_\alpha f\|_2.$$

(See the inequalities in Cases I–IV on pages 1501–1506.) Therefore, if we set $\tilde{g} = \epsilon^{5/2}E(t) + \epsilon^{11/2}\rho_5(\alpha,t)$, we see that taking a spatial derivative leaves us with

$$\partial_\alpha \tilde{g} = O(\epsilon^{11/2}).$$

Thus, if we keep in mind that $f(\alpha,t) = \epsilon^2 F(\epsilon(\alpha \pm t), \epsilon^3 t)$,

$$\begin{aligned} \|\tilde{Q} \circ K_0 \circ \tilde{Q}^{-1} f(\cdot) - K_0 f(\cdot)\|_s &\le C\|\partial_\alpha \tilde{g}\|_{s-1}\|\partial_\alpha f\|_2 \\ &\le C\epsilon^{17/2}. \end{aligned}$$

This completes the proof of Proposition 4. □

6. The error estimates. In this section we prove that the approximation is rigorous. That is we will prove Theorem 2. We will be working with the three- and four-dimensional formulations of the water wave problem (equations (WW3) and (WW4)). From [28], we know that for initial data of the type we are considering, solutions to these equations exist over the long times we are considering. If (z,y,u) is a solution to (WW3), let

$$\begin{aligned} z(\alpha,t) &= \Psi^z(\alpha,t) + \epsilon^{11/2}R^z(\alpha,t), \\ y(\alpha,t) &= \Psi^y(\alpha,t) + \epsilon^{11/2}R^y(\alpha,t), \\ u(\alpha,t) &= \Psi^u(\alpha,t) + \epsilon^{11/2}R^u(\alpha,t), \end{aligned} \tag{28}$$

with the functions Ψ defined as above. We call R^z, R^y, and R^u "error" functions and we denote $\bar{R} = (R^z, R^y, R^u)$. Our goal will be to show that $\bar{R}$ remain $O(1)$ in $\mathfrak{H}^s = H^s \times H^s \times H^{s-1/2}$ over the long time scale. If we can do this, then we will have proven the main theorem. The first step will be to determine the equations which these functions satisfy. Loosely, we want to be able to write for each of the error functions an evolution equation of the form

$$\partial_t R = \text{quasi-linear} + \text{small and smooth}.$$

We will at times go to great lengths to achieve this!

Clearly,

$$\partial_t R^z = K_0 R^u.$$

Finding the equations for R^y and R^u is a bit more complex. First we focus on R^y. Substituting from (28) into $\partial_t y = K(z,y)u$, we have

$$\begin{aligned}
\partial_t R^y &= \epsilon^{-11/2}\left(K(\Psi^z + \epsilon^{11/2}R^z, \Psi^y + \epsilon^{11/2}R^y)(\Psi^u + \epsilon^{11/2}R^u) - \partial_t \Psi^y\right)\\
&= K(\Psi^z + \epsilon^{11/2}R^z, \Psi^y + \epsilon^{11/2}R^y)R^u\\
&\quad + \epsilon^{-11/2}\left(K(\Psi^z + \epsilon^{11/2}R^z, \Psi^y + \epsilon^{11/2}R^y)\Psi^u - \partial_t \Psi^y\right)\\
&= K_0 R^u + M_1(\Psi^z)\partial_\alpha R^u - (\Psi^y + K_0(\Psi^y K_0))\partial_\alpha R^u + N^y,
\end{aligned}$$

where

$$\begin{aligned}
N^y = \epsilon^{-11/2}\mathrm{Res}_y &+ \epsilon^{-11/2}\left(\left(S_1(\Psi^z + \epsilon^{11/2}R^z, \Psi^y + \epsilon^{11/2}R^y) - S_1(\Psi^z, \Psi^y)\right)\Psi^u\right)\\
&+ \left(K(\Psi^z + \epsilon^{11/2}R^z, \Psi^y + \epsilon^{11/2}R^y) - K_0 - K_1(\Psi^z, \Psi^y)\right)R^u.
\end{aligned}$$

We claim that N^y is "small." That is, we have the following lemma.

LEMMA 11. *For all $C_R > 0$, there exists ϵ_0 such that for all $\epsilon \in (0, \epsilon_0)$ and t such that $\sup_{0\le t' \le t} \|\bar{R}(\cdot, t')\|_{\mathfrak{H}^s} \le C_R$ we have*

$$\|N^y\|_s \le C\left(\epsilon^3 + \epsilon^3\|\bar{R}\|_{\mathfrak{H}^s} + \epsilon^{11/2}\|\bar{R}\|^2_{\mathfrak{H}^s}\right).$$

Proof. First we remark that the approximating functions Ψ and their derivatives are all bounded over the long time scales. Thus, we will not be keeping track of the dependence of the norm of N^y on the norms of these functions. By Proposition 2, we know that $\|\epsilon^{-11/2}\mathrm{Res}_y\|_s \le C\epsilon^3$.

We can bound

$$\epsilon^{-11/2}\left(S_1(\Psi^z + \epsilon^{11/2}R^z, \Psi^y + \epsilon^{11/2}R^y) - S_1(\Psi^z, \Psi^y)\right)\Psi^u$$

by Lemma 4.

Finally,

$$\begin{aligned}
&\|(K(\Psi^z + \epsilon^{11/2}R^z, \Psi^y + \epsilon^{11/2}R^y) - K_0 - K_1(\Psi^z, \Psi^y))R^u\|_s\\
&\le C\left(\epsilon^3\|\bar{R}\|_{\mathfrak{H}^s} + \epsilon^{11/2}\|\bar{R}\|^2_{\mathfrak{H}^s}\right)
\end{aligned}$$

by the estimates on K and its expansions which we saw in sections 3 and 5 (in particular Lemmas 5 and 6). ◻

Now we discuss R^u. We know that

$$\partial_t u(1 + Lz) + \partial_\alpha y(1 + \partial_t^2 y) = 0. \tag{29}$$

We would like an evolution-type equation for R^u. Notice that since $\partial_t y = K(z,y)u$, there is a "hidden" $\partial_t u$ in the term $\partial_t^2 y$. Recall that the commutator $[\partial_t, S_1(z,y)]u$ can be bounded independently of $\partial_t u$ (see Lemma 6 in section 5). Therefore, we can rewrite the above as

$$(1 + Lz + \partial_\alpha y K(z,y))\partial_t u + \partial_\alpha y(1 + [\partial_t, S_1(z,y)]u) = 0.$$

Replacing u with its definition in (28) the above becomes

$$\begin{aligned} 0 = &(1 + Lz + \partial_\alpha y K(z,y))\, \partial_t \epsilon^{11/2} R^u \\ &+ (1 + Lz + \partial_\alpha y K(z,y))\, \partial_t \epsilon^2 \Psi^u \\ &+ \partial_\alpha y\, (1 + [\partial_t, S_1(z,y)]\Psi^u) \\ &+ \partial_\alpha y \left([\partial_t, S_1(z,y)]\epsilon^{11/2} R^u \right) \end{aligned}$$

or rather

$$\begin{aligned} 0 = &(1 + Lz + \partial_\alpha y K(z,y))\, \partial_t \epsilon^{11/2} R^u \\ &+ (1 + Lz)\, \partial_t \epsilon^2 \Psi^u \\ &+ \partial_\alpha y\, (1 + \partial_t (K(z,y)\Psi^u)) \\ &+ \partial_\alpha y \left([\partial_t, S_1(z,y)]\epsilon^{11/2} R^u \right). \end{aligned}$$

We rearrange this a bit and break up y and z:

$$\begin{aligned} 0 = &(1 + Lz + \partial_\alpha y K(z,y))\, \partial_t R^u + \partial_\alpha R^y \\ &+ LR^z \partial_t \Psi^u + \partial_\alpha R^y \partial_t (K(z,y)\Psi^u) + \partial_\alpha y [\partial_t, S_1(z,y)] R^u \\ &+ \epsilon^{-11/2} \left((1 + L\Psi^z)\, \partial_t \epsilon^2 \Psi^u + \partial_\alpha \Psi^y\, (1 + \partial_t (K(z,y)\Psi^u)) \right). \end{aligned}$$

The operator

$$A(z,y) = (1 + Lz + \partial_\alpha y K(z,y))$$

is invertible since $K(z,y)$ is a bounded operator on H^s, provided z and y are small (which they are). Moreover, we can approximate A^{-1} via the Neumann series. Thus the above equation can be rewritten as

$$\partial_t R^u = -(1 - \epsilon^2 W_1)\partial_\alpha R^y + N^u,$$

where $N^u = N_1^u + N_2^u$ and

$$\begin{aligned} N_1^u = &- \epsilon^{-11/2} A^{-1} \left((1 + L\Psi^z)\, \partial_t \epsilon^2 \Psi^u + \partial_\alpha \Psi^y\, (1 + \partial_t (K(z,y)\Psi^u)) \right), \\ N_2^u = &- A^{-1} \left(LR^z \partial_t \Psi^u + \partial_\alpha R^y \partial_t (K(z,y)\Psi^u) + \partial_\alpha y [\partial_t, S_1(z,y)] R^u \right) \\ &+ \left(-A^{-1} + (1 - \epsilon^2 W_1) \right) \partial_\alpha R^y. \end{aligned}$$

LEMMA 12. *For all $C_R > 0$, there exists ϵ_0 such that for all $\epsilon \in (0, \epsilon_0)$ and t such that $\sup_{0 \le t' \le t} \|\bar{R}(\cdot, t')\|_{\mathfrak{H}^s} \le C_R$ we have*

$$\|N^u\|_{s-1} \le C \left(\epsilon^3 + \epsilon^3 \|\bar{R}\|_{\mathfrak{H}^s} + \epsilon^{11/2} \|\bar{R}\|_{\mathfrak{H}^s}^2 \right).$$

Proof. First we point out that this estimate is in H^{s-1}. The loss of regularity here is easily seen. Both LR^z and $\partial_\alpha R^y$ explicitly appear in N_2^u, and are not smoothed by any operators. Thus, losing this derivative is unavoidable. In fact, it is easy to see that the above estimates hold for N_2^u by noting that A^{-1}, K, and $[\partial_t, S_1]$ are bounded operators.

Bounding N_1^u is also easily done once we recognize that this term is almost exactly $\epsilon^{-11/2}\mathrm{Res}_u$. We have

$$\begin{aligned}
&\epsilon^{-11/2}A^{-1}\left(\left(1+L\Psi^z\right)\partial_t\epsilon^2\Psi^u+\partial_\alpha\Psi^y\left(1+\partial_t(K(z,y)\Psi^u)\right)\right)\\
&=\epsilon^{-11/2}A^{-1}\left(\left(1+L\Psi^z\right)\partial_t\epsilon^2\Psi^u+\partial_\alpha\Psi^y\left(1+\partial_t(K(\Psi^z,\Psi^y)\Psi^u)\right)\right)+N_3^u\\
&=\epsilon^{-11/2}\left(\partial_t\epsilon^2\Psi^u+\partial_\alpha\Psi^y\frac{1+\partial_t(K(\Psi^z,\Psi^y)\Psi^u)}{1+L\Psi^z}\right)+N_3^u+N_4^u\\
&=\epsilon^{-11/2}\left(\partial_t\epsilon^2\Psi^u+\partial_\alpha\Psi^y\frac{1+\partial_t^2(\Psi^y)}{1+L\Psi^z}\right)+N_3^u+N_4^u+N_5^u\\
&=\epsilon^{-11/2}\mathrm{Res}_u+N_3^u+N_4^u+N_5^u,
\end{aligned}$$

where

$$\begin{aligned}
N_3^u&=\epsilon^{-11/2}A^{-1}\left(\partial_\alpha\Psi^y\partial_t\left(K(z,y)\Psi^u-K(\Psi^z,\Psi^y)\Psi^u\right)\right),\\
N_4^u&=\epsilon^{-11/2}(A^{-1}-(1+L\Psi^z)^{-1})\\
&\quad\times\left(\left(1+L\Psi^z\right)\partial_t\epsilon^2\Psi^u+\partial_\alpha\Psi^y\left(1+\partial_t(K(\Psi^z,\Psi^y)\Psi^u)\right)\right),\\
N_5^u&=\epsilon^{-11/2}\partial_\alpha\Psi^y\frac{\partial_t(\mathrm{Res}_y)}{1+L\Psi^z}.
\end{aligned}$$

We bound N_3^u using mean value theorem arguments entirely analogous to those used when bounding N^y. To bound N_4^y, one observes that

$$\left(1+L\Psi^z\right)\partial_t\epsilon^2\Psi^u+\partial_\alpha\Psi^y\left(1+\partial_t(K(\Psi^z,\Psi^y)\Psi^u)\right)$$

is very nearly Res_u and is thus $O(\epsilon^{17/2})$. N_5^u is clearly small, as it contains $\partial_t\mathrm{Res}_y$. This completes the proof. ∎

We need to make analogous calculations for the four-dimensional system. Let

$$a(\alpha,t)=\epsilon^3\Psi^a(\epsilon\alpha,\epsilon t)+\epsilon^{11/2}R^a(\alpha,t)$$

and $\bar{R}_e=(R^z,R^y,R^u,R^a)$. This extended set of error functions lives in $\mathfrak{H}_e^s=H^s\times H^s\times H^{s-1/2}\times H^{s-1}$.

It is easy to see that

$$\partial_tR^u=R^a$$

but more difficult to determine the evolution of R^a. We begin by taking a time derivative of (29):

$$\partial_t^2u(1+Lz)+\partial_tu\partial_\alpha u+\partial_\alpha\partial_ty(1+\partial_t^2y)+\partial_\alpha y\partial_t^3y=0. \tag{30}$$

Letting

$$\begin{aligned}
I&=\partial_t^2u(1+Lz)+\partial_\alpha y\partial_t^3y,\\
II&=\partial_\alpha\partial_ty(1+\partial_t^2y)+\partial_tu\partial_\alpha u,
\end{aligned}$$

(30) is $I + II = 0$.

Manipulations very similar to those carried out in determing $\partial_t R^u$ show that

$$I = A(z,y)\partial_t \epsilon^{11/2} R^a + \partial_\alpha y[\partial_t^2, S_1(z,y)]\epsilon^{11/2} R^u \\ + (1+Lz)\partial_t \epsilon^3 \Psi^a + \partial_\alpha y \partial_t^2 (K(z,y)\Psi^u).$$

For II, we have

$$\begin{aligned} II &= (1+\partial_t^2 y)\partial_\alpha \partial_t \epsilon^{11/2} R^y + \partial_t u \partial_\alpha \epsilon^{11/2} R^u \\ &\quad + (1+\partial_t^2 y)\partial_\alpha \partial_t \Psi^y + \partial_t u \partial_\alpha \Psi^u \\ &= \epsilon^{11/2}\left((1+\partial_t^2 y)\partial_\alpha (K_0 R^u + K_1(\Psi^z,\Psi^y)R^u + N^y) + \partial_t u \partial_\alpha R^u\right) \\ &\quad + (1+\partial_t^2 y)\partial_\alpha \partial_t \Psi^y + \partial_t u \partial_\alpha \Psi^u \\ &= \epsilon^{11/2}\left((1+\partial_t^2 y - \partial_t u K_0 \cdot)K_0 \partial_\alpha R^u + \partial_\alpha K_1(\Psi^z,\Psi^y)R^u\right) \\ &\quad + (1+\partial_t^2 y)\partial_\alpha \partial_t \Psi^y + \partial_t u \partial_\alpha \Psi^u + \epsilon^{11/2} B_{II}, \end{aligned}$$

where

$$B_{II} = \partial_t u(1+K_0^2)\partial_\alpha R^u + \partial_t^2 y \partial_\alpha (K_1(\Psi^z,\Psi^y)R^u + N^y) + \partial_\alpha N^y.$$

Noting that $\partial_t^2 y = K_0 a + [\partial_t, S_1]u + S_1 a$, we see that B_{II} is smooth in the error functions, and is $O(\epsilon^3)$.

Adding I and II gives

$$\begin{aligned} 0 &= A(z,y)\partial_t R^a + (1+\partial_t^2 y - \partial_t u K_0 \cdot)K_0 \partial_\alpha R^u \\ &\quad + \partial_\alpha K_1(\Psi^z,\Psi^y)R^u + B, \end{aligned} \tag{31}$$

where

$$\begin{aligned} B &= B_{II} + \partial_\alpha y[\partial_t^2, S_1(z,y)]R^u + B_{\text{Res}}, \\ \epsilon^{11/2} B_{\text{Res}} &= (1+Lz)\partial_t \epsilon^3 \Psi^a + \partial_\alpha y \partial_t^2 (K(z,y)\Psi^u) \\ &\quad + (1+\partial_t^2 y)\partial_\alpha \partial_t \Psi^y + \partial_t u \partial_\alpha \Psi^u. \end{aligned}$$

The terms B_{II} and $\partial_\alpha y[\partial_t^2, S_1(z,y)]$ are small and smooth, and we can bound B_{Res} via the residual estimates, much as we did for N_1^u above. That is, we have

$$\|B\|_{s-1} \le C\left(\epsilon^3 + \epsilon^3 \|\bar{R}\|_{\mathfrak{H}_\epsilon^s} + \epsilon^{11/2}\|\bar{R}\|_{\mathfrak{H}_\epsilon^s}^2\right)$$

under the same hypotheses as in the above lemmas.

At this time, it is tempting to simply invert $A(z,y)$. Though we could do this, the inverse of this operator is not smoothing. In particular the presence of the term $\partial_\alpha y K_0$ in A will cause problems. We can eliminate K_0 to highest order by letting $H_0(z,y) = (1 + Lz - \partial_\alpha y K_0)$ act on (31). We have for the first term

$$\begin{aligned} &H_0(z,y)A(z,y)\partial_t R^a \\ &= (1+Lz)^2 \partial_t R^u + (1+Lz)\partial_\alpha y K_0 \partial_t R^a - \partial_\alpha y K_0\left((1+Lz)\partial_t R^a\right) \\ &\quad - \partial_\alpha y K_0\left(\partial_\alpha y K_0 \partial_t R^a\right) + H_0(z,y)(\partial_\alpha y S_1(z,y)\partial_t R^a) \\ &= \left((1+Lz)^2 + (\partial_\alpha y)^2 + H_1(z,y)\cdot\right)\partial_t R^a, \end{aligned}$$

where

$$\begin{aligned} H_1(z,y)\cdot &= \partial_\alpha y \left([Lz, K_0]\cdot - K_0[\partial_\alpha y, K_0]\cdot - (1+K_0^2)\partial_\alpha y \cdot\right) \\ &\quad + H_0(z,y)\left(\partial_\alpha y S_1(z,y)\cdot\right). \end{aligned}$$

Notice that H_1 is made up of smoothing operators and is thus a smoothing operator.

Now, for the second term in (31) we have

$$\begin{aligned} &H_0(z,y)(1+\partial_t^2 y - \partial_t u K_0\cdot)K_0\partial_\alpha R^u \\ &= (1+Lz)(1+\partial_t^2 y)K_0\partial_\alpha R^u - (1+Lz)\partial_t u K_0^2 \partial_\alpha R^u \\ &\quad - \partial_\alpha y K_0\left((1+\partial_t^2 y)K_0\partial_\alpha R^u\right) + \partial_\alpha y K_0 \left(\partial_t u K_0^2 \partial_\alpha R^u\right) \\ &= (1+Lz)(1+\partial_t^2 y)K_0\partial_\alpha R^u \\ &\quad - \partial_\alpha y [K_0, \partial_t^2 y]K_0 \partial_\alpha R^u + \partial_\alpha y K_0\left(\partial_t u K_0^2 \partial_\alpha R^u\right) \\ &\quad + \left(\partial_t u(1+Lz) + \partial_\alpha y(1+\partial_t^2 y)\right)K_0^2\partial_\alpha R^u. \end{aligned}$$

Notice that by comparing the last line of the above with (29), we see that it is identically zero! One more rearrangement of this yields

$$\left((1+Lz)(1+\partial_t^2 y) - \partial_\alpha y \partial_t u\right)K_0\partial_\alpha R^u + B_2,$$

where

$$B_2 = \partial_\alpha y\left(-[K_0, \partial_t^2 y] + [K_0, \partial_t u]K_0 + \partial_t u(1+K_0^2)\right)K_0\partial_\alpha u$$

is a smooth and small function by Lemma 4 in section 5.

If we let

$$\begin{aligned} f &= ((1+Lz)^2 + (\partial_\alpha y)^2)^{-1}, \\ g &= (1+Lz)(1+\partial_t^2 y) - \partial_\alpha y \partial_t u, \end{aligned}$$

then we have transformed (31) into

$$\begin{aligned} 0 &= (1+fH_1(z,y))\partial_t R^a + fgK_0\partial_\alpha R^u \\ &\quad + fH_0(z,y)\left(\partial_\alpha\left(K_1(\Psi^z,\Psi^y)R^u\right)\right) \\ &\quad + f\left(B_2 + H_0(z,y)B\right). \end{aligned}$$

By the Neumann series,

$$(1+fH_1(z,y)\cdot)^{-1} = 1 + \sum_{n=0}^{\infty}(-1)^n f^n H_1^n(z,y)\cdot.$$

Since H_1 is smoothing, this is the identity plus a smoothing piece. Let

$$H_2(z,y)\cdot = \sum_{n=0}^{\infty}(-1)^n f^n H_1^n(z,y)\cdot.$$

Thus,

$$\begin{aligned} 0 &= \partial_t R^a + fgK_0\partial_\alpha R^u \\ &\quad + fH_0(z,y)\left(\partial_\alpha\left(K_1(\Psi^z,\Psi^y)R^u\right)\right) - N_1^a - N_2^a, \end{aligned}$$

where

$$-N_1^a = H_2(z,y)\left(fgK_0\partial_\alpha R^u + fH_0(z,y)\left(\partial_\alpha\left(K_1(\Psi^z,\Psi^y)R^u\right)\right)\right),$$
$$-N_2^a = (1+H_2(z,y))f\left(B_2 + H_0(z,y)B\right).$$

Finally we rewrite the above as

$$\partial_t R^a = -\left(1+K_0a - Lz + N_s^a\right)\partial_\alpha K_0 R^u - \partial_\alpha\left(K_1(\Psi^z,\Psi^y)R^u\right) + N^a$$

with

$$N_s^a = fg - (1+K_0a - Lz),$$
$$N^a = N_1^a + N_2^a + N_3^a,$$
$$N_4^a = -\left(fH_0(z,y)-1\right)\left(\partial_\alpha\left(K_1(\Psi^z,\Psi^y)R^u\right)\right).$$

Notice that $(1+K_0a-Lz)$ is the first order approximation to fg. Thus, using techniques exactly like those we used in proving the bounds on N^y and N^u, we have the following.

LEMMA 13. *For all $C_R>0$, there exists ϵ_0 such that for all $\epsilon\in(0,\epsilon_0)$ and t such that* $\sup_{0\le t'\le t}\|\bar{R}_e(\cdot,t')\|_{\mathfrak{H}_e^s}\le C_R$ *we have*

$$\max\left\{\|N_s^a\|_{s-1},\|N^a\|_{s-1}\right\}\le C\left(\epsilon^3+\epsilon^3\|\bar{R}_e\|_{\mathfrak{H}_e^s}+\epsilon^{11/2}\|\bar{R}_e\|^2_{\mathfrak{H}_e^s}\right).$$

Recapping, we have shown that the three-dimensional system may be rewritten as

$$\begin{aligned}
&\partial_t R^z = K_0R^u,\\
&\partial_t R^y = K_0R^u + M_1(\Psi^z)\partial_\alpha R^u - (\Psi^y + K_0(\epsilon^2\Psi^yK_0))\partial_\alpha R^u + N^y,\\
&\partial_t R^u = -(1-\epsilon^2W_1)\partial_\alpha R^y + N^u,
\end{aligned}\tag{32}$$

and the four-dimensional system as

$$\begin{aligned}
\partial_t R^z &= K_0R^u,\\
\partial_t R^y &= K_0R^u + M_1(\Psi^z)\partial_\alpha R^u\\
&\quad - (\Psi^y + K_0(\epsilon^2\Psi^yK_0))\partial_\alpha R^u + N^y,\\
\partial_t R^u &= R^a,\\
\partial_t R^a &= -\left(1+K_0a-Lz+N_s^a\right)\partial_\alpha K_0R^u\\
&\quad - \partial_\alpha\left(K_1(\Psi^z,\Psi^y)R^u\right) + N^a.
\end{aligned}\tag{33}$$

We remark now that these are only cosmetically different from the equations which determine the evolution of the error for the KdV approximation alone in [28]. See page 1524 for the equations in three dimensions and page 1526 in four dimensions. Their variables

$$(Z_1, X_2, U_1, V_1)$$

correspond to our

$$(z, y, u, a),$$

and their functions

$$(N^2, N^3, N^4, N^5, N^8)$$

are our

$$(N^z, N^y, N^u, N_s^a, N^a).$$

The only difference of note is that their estimates contain a term they call $q(t)$ while ours do not. This term, which is related to the interaction of the left- and right-moving wavetrains, has been removed in this paper by the inclusion of the function W_3 in the approximating functions Ψ. This simplification does not adversely affect the means which they employ to prove that the error functions remain $O(1)$ over the long time scale. Therefore we appeal to their results on pages 1524–1533.

PROPOSITION 5. *For all $T_0 > 0$, $s > 4$, and $C_I > 0$, there exists ϵ_0 such that for all $0 \le \epsilon \le \epsilon_0$, the unique solution $\bar{R}_e$ of* (33)*, with initial conditions such that*

$$\|\bar{R}_e(\cdot, 0)\|_{\mathfrak{H}_e^s} \le C_I,$$

satisfies

$$\sup_{t\in[0,T_0\epsilon^{-3}]} \|\bar{R}_e(\cdot, t)\|_{\mathfrak{H}_e^s} \le C,$$

where C is independent of ϵ.

Implicit in the above proposition is the assumption that the initial conditions for the water wave problem have the form

$$\begin{pmatrix} z(\alpha,0) \\ y(\alpha,0) \\ u(\alpha,0) \end{pmatrix} = \begin{pmatrix} \Psi^z(\alpha,0) \\ \Psi^y(\alpha,0) \\ \Psi^u(\alpha,0) \end{pmatrix} + \epsilon^{11/2}\bar{R}_0(\alpha).$$

Thus we see that this proposition immediately proves Theorem 3.

Now that we have this result, there are a few small steps and one big step needed to prove Theorem 2. The first simple step is to note that the z is not a very physical coordinate and that we would prefer estimates for x_α. Since L is a bounded operator and gives the relationship between both z and x_α and Ψ^z and Ψ^d, we automatically have

$$\sup_{t\in[0,T_0\epsilon^{-3}]} \|x_\alpha(\cdot,t) - \Psi^d(\cdot,t)\|_{H^s} \le C\epsilon^{11/2}.$$

Second, the expressions for Ψ^d, Ψ^y, and Ψ^u contain terms of $O(\epsilon^6)$. These terms were needed to make the residual sufficiently small, but they are unnecessary now. Moreover, the appearance of the operator L^{-1} and inverse derivatives in the definitions of Ψ^y and Ψ^u is not very intuitive. Thus, it is a simple consequence of Lemma 1 and the triangle inequality that

$$\|\Psi^d - \psi^d\|_s \le C\epsilon^{11/2},$$
$$\|\Psi^y - \psi^y\|_s \le C\epsilon^{11/2},$$
$$\|\Psi^u - \psi^u\|_s \le C\epsilon^{11/2},$$

where ψ^d, ψ^y, and ψ^u were given in the introduction in (4), (5), and (6). Therefore we have the following corollary.

COROLLARY 1. *If the initial conditions for* (WW) *are of the form*

$$\begin{pmatrix} x_\alpha(\alpha,0) \\ y(\alpha,0) \\ u(\alpha,0) \end{pmatrix} = \begin{pmatrix} \psi^d(\alpha,0) \\ \psi^y(\alpha,0) \\ \psi^u(\alpha,0) \end{pmatrix} + \epsilon^{11/2}\bar{R}_1(\alpha) \tag{34}$$

with $\|\bar{R}_1\|_{\mathfrak{H}^s} \leq C_I$, *then the solution of* (WW) *satisfies the estimate*

$$\left\| \begin{pmatrix} x_\alpha(\cdot,t) \\ y(\cdot,t) \\ u(\cdot,t) \end{pmatrix} - \begin{pmatrix} \psi^d(\cdot,t) \\ \psi^y(\cdot,t) \\ \psi^u(\cdot,t) \end{pmatrix} \right\|_{\mathfrak{H}^s} \leq C_F \epsilon^{11/2}$$

for $t \in [0, T_0\epsilon^{-3}]$. *The constant* C_F *does not depend on* ϵ.

Finally, we must deal with initial conditions. Recall from the discussion in section 2 that it is typical to specify the initial data for the water wave problem in the long wavelength, small amplitude limit by

$$(\bar{x}_{\bar{\alpha}}(\bar{\alpha},0), \bar{y}(\bar{\alpha},0), \bar{u}(\bar{\alpha},0)) = (0, \epsilon^2\Theta_y(\epsilon\bar{\alpha}), \epsilon^2\Theta_u(\epsilon\bar{\alpha})). \tag{35}$$

However, the above results are applicable if the initial data is of the form seen in (34). We eliminate this discrepancy by altering the initial parameterization of the free surface. What should this change be? Clearly,

$$\bar{\alpha} = \alpha + x(\alpha,0). \tag{36}$$

Now set $U(\beta,0) = U_0(\beta)$, $V(\beta,0) = V_0(\beta)$, $F(\beta,0) = F_0(\beta)$, $G(\beta,0) = G_0(\beta)$, and $P(\beta,0) = 0$, and let

$$\begin{aligned} \bar{\alpha} &= \alpha + \int_0^\alpha \psi^d(a,0)da \\ &= \alpha + \epsilon X_1(\epsilon\alpha) + \epsilon^3 X_2(\epsilon\alpha), \end{aligned}$$

where

$$\begin{aligned} \epsilon X_1(\alpha) &= -\epsilon^2 \int_0^\alpha (U_0(\epsilon a) + V_0(\epsilon a))\, da, \\ \epsilon^3 X_2(\alpha) &= -\epsilon^4 \int_0^\alpha (F_0(\epsilon a) + G_0(\epsilon a))\, da. \end{aligned} \tag{37}$$

With this definition, we clearly have satisfied the first condition in (34). We also want

$$\begin{aligned} \Theta_y(\epsilon\bar{\alpha}) &= \epsilon^2\psi^y(\alpha) + O(\epsilon^{11/2}), \\ \Theta_u(\epsilon\bar{\alpha}) &= \epsilon^2\psi^u(\alpha) + O(\epsilon^{11/2}) \end{aligned}$$

or rather

$$\begin{aligned} \epsilon^2\Theta_y(\epsilon\alpha + \epsilon^2 X_1(\epsilon\alpha) + \epsilon^4 X_2(\epsilon\alpha)) &= \epsilon^2\psi^y(\alpha) + O(\epsilon^{11/2}), \\ \epsilon^2\Theta_u(\epsilon\alpha + \epsilon^2 X_1(\epsilon\alpha) + \epsilon^4 X_2(\epsilon\alpha)) &= \epsilon^2\psi^u(\alpha) + O(\epsilon^{11/2}). \end{aligned}$$

Applying Taylor's theorem we have

$$\begin{aligned}\Theta_y + \epsilon^2 X_1 \Theta_y' &= (U_0+V_0) + \epsilon^2\left(\frac{1}{3}\partial_{\beta_-}^2 U_0 + \frac{1}{3}\partial_{\beta_+}^2 V_0\right)\\ &\quad + \epsilon^2(F_0+G_0) + \epsilon^2(U_0+V_0)^2,\\ \Theta_u + \epsilon^2 X_1 \Theta_u' &= (U_0-V_0) + \epsilon^2\left(\frac{1}{6}\partial_{\beta_-}^2 U_0 - \frac{1}{6}\partial_{\beta_+}^2 V_0\right)\\ &\quad + \epsilon^2(F_0-G_0) + \epsilon^2\left(\frac{3}{4}U_0^2 - \frac{3}{4}V_0^2\right).\end{aligned}$$

We can solve the above by taking

$$\begin{aligned} U_0 &= 1/2(\Theta_y + \Theta_u),\\ V_0 &= 1/2(\Theta_y - \Theta_u)\end{aligned} \tag{38}$$

and

$$\begin{aligned} F_0 &= 1/2(h_y + h_u),\\ G_0 &= 1/2(h_y - h_u),\end{aligned} \tag{39}$$

where

$$\begin{aligned} h_y &= X_1\Theta_y' - \frac{1}{3}\partial_{\beta_-}^2 U_0 - \frac{1}{3}\partial_{\beta_+}^2 V_0 - (U_0+V_0)^2,\\ h_u &= X_1\Theta_u' - \frac{1}{6}\partial_{\beta_-}^2 U_0 + \frac{1}{6}\partial_{\beta_+}^2 V_0 - \frac{3}{4}U_0^2 + \frac{3}{4}V_0^2.\end{aligned}$$

The functions U_0, V_0, F_0, and G_0 are all in $H^s(4)$, and so the use of Taylor's theorem is justified by Lemma 10. Thus we have proven the following lemma.

LEMMA 14. *Given initial conditions for the water wave equation in the form* (35), *define U_0, V_0, F_0, G_0, X_1, and X_2 as in* (38), (39), *and* (37). *Then the reparameterization of the initial profile given by*

$$\bar{\alpha} = \alpha + \epsilon X_1(\epsilon\alpha) + \epsilon X_2(\epsilon\alpha)$$

results in initial conditions given by (34).

Remark 12. Let $\varphi^{\pm}(\beta_{\pm},0) = \varphi_0^{\pm}(\beta_{\pm})$. Then this lemma will still be true if we replace F_0 with φ_0^- and G_0 with φ^+ and set F_0 and G_0 to be identically zero. That is, we have some choice in the way we select the initial conditions for the higher order equations.

Combining this lemma with Corollary 1 we prove Theorem 2. Thus we are done.

7. Assorted proofs.

Proof of Lemma 8. Let $f^{-1}(\xi) = \xi - g_2(\xi)$. Since $f^{-1}(f(\alpha)) = \alpha$ we have

$$\alpha = f(\alpha) - g_2(f(\alpha)),$$

or rather

$$g_2(f(\alpha)) = g(\alpha). \tag{40}$$

Notice that this relation implies $\|g_2\|_{L^\infty} = \|g\|_{L^\infty}$. Taking a derivative, we have

$$g_2'(f(\alpha)) = \frac{g'(\alpha)}{1+g'(\alpha)},$$

which implies that $\|g_2'\|_{L^\infty} \leq C\|g'\|_{L^\infty}$. If we expand the left-hand side of (40) by the mean value theorem, we see

$$g_2(\alpha + g(\alpha)) = g(\alpha),$$
$$g_2(\alpha) + g_2'(\alpha^*)g(\alpha) = g(\alpha).$$

This implies $g_2(\alpha) = g(\alpha) + O(\|g'\|_{L^\infty}\|g\|_{L^\infty})$. Now, (40) can be rewritten and expanded using Taylor's theorem,

$$\begin{aligned} g_2(\xi) &= g(f^{-1}(\xi)) \\ &= g(\xi - g(\xi) + O(\|g'\|_{L^\infty}\|g\|_{L^\infty})) \\ &= g(\xi) + g'(\xi)(-g(\xi) + O(\|g'\|_{L^\infty}\|g\|_{L^\infty})) \\ &\quad + 1/2g''(\xi^*)(-g(\xi) + O(\|g'\|_{L^\infty}\|g\|_{L^\infty}))^2 \\ &= g(\xi) - g(\xi)g'(\xi) - E \end{aligned}$$

which completes the proof. □

Proof of Lemma 9. Since $(1+\beta^2)^{n/2}F(\beta) \in H^s$, by the Sobolev embedding theorem there is a C such that

$$F(\beta) \leq C(1+\beta^2)^{-n/2}.$$

So

$$\begin{aligned} &\int_{|\alpha|>C_0\epsilon^{-3}} |F(\epsilon\alpha)|^2 d\alpha \leq C\int_{|\alpha|>C_0\epsilon^{-3}} |1+(\epsilon\alpha)^2|^{-n} d\alpha \\ &\leq C\int_{|\alpha|>C_0\epsilon^{-3}} |\epsilon\alpha|^{-2n} d\alpha \\ &\leq C\epsilon^{-2n}\int_{|\alpha|>C_0\epsilon^{-3}} |\alpha|^{-2n} d\alpha \\ &\leq C\epsilon^{-2n}(\epsilon^{-3})^{-2n+1} \\ &\leq C\epsilon^{4n-3}. \end{aligned}$$

The higher derivatives are bounded in exactly the same fashion. The extra powers of ϵ come from the long wavelength scaling. □

Proof of Lemma 1. The proof is a straightforward calculation:

$$\begin{aligned} &\|Af(\cdot) - A_nf(\cdot)\|_s^2 \\ &= \int (1+k^2)^s|(\widehat{A}(k) - \widehat{A_n}(k))\widehat{f}(k)|^2 dk \\ &\leq C\int (1+k^2)^s|k^n\widehat{f}(k)|^2 dk \\ &= C\int (1+k^2)^s|\widehat{\partial_x^n f}(k)|^2 dk \\ &= C\|\partial_x^n f(\cdot)\|_s^2. \end{aligned}$$

The proof for long wavelength data follows immediately from this. □

Proof of Lemma 2. The fact that $g(\epsilon x)$ is bounded as such in L^2 follows automatically from the geometric series approximation. That is, since $|\epsilon^2 f(\epsilon x)| \leq 1/2$, we know that

$$|g(\epsilon x)| \leq C|\epsilon^2 f(\epsilon x)|^2.$$

Thus we have

$$\begin{aligned}\|g(\epsilon\cdot)\|_{L^2}^2 &\le C\int \epsilon^4|f(\epsilon x)|^4 dx\\ &\le C\epsilon^4\|f(\cdot)\|_{L^\infty}^2\int f^2(\epsilon x)dx\\ &\le C\epsilon^{7/2}\|f(\cdot)\|_s.\end{aligned}$$

Now consider the L^2 norm of $g'(\epsilon x)$. A direct calculation shows that

$$\frac{d}{dx}g(\epsilon x) = -\epsilon^3 f'(\epsilon x)\left(\frac{1}{(1+\epsilon^2 f(\epsilon x))^2} - 1\right).$$

Taylor's theorem shows that

$$\left|\frac{d}{dx}g(\epsilon x)\right| \le C|\epsilon^3 f'(\epsilon x)||\epsilon^2 f(\epsilon x)|.$$

Therefore, just as before we have that this is bounded by $C\epsilon^{9/2}$ (which is of course bounded by $C\epsilon^{7/2}$).

We could keep on going in this fashion, showing each derivative of g is bounded. This is, however, difficult as finding higher and higher derivatives is a notationally taxing job—see the expression of Faa di Bruno for proof of that!

Instead we take the following approach. Let

$$h(y) = \frac{1}{1+y} - 1 + y.$$

For $y \in [-1/2, 1/2]$, this function is real analytic and there exists another function $\tilde{h}(y)$ (real and analytic on the same interval) such that $h(y) = y\tilde{h}(y)$. Now, define $\tilde{h}_\epsilon(Y) = \tilde{h}(\epsilon^2 y)$. We have that

$$\|\tilde{h}_\epsilon(\cdot)\|_{C^s[-1/2\epsilon^{-2},1/2\epsilon^{-2}]} \le \|\tilde{h}(\cdot)\|_{C^s[-1/2,1/2]}.$$

The point here is that the C^s norm of $\tilde{h}_\epsilon$ can be bounded *independently* of ϵ.

Now notice that $g(X) = \epsilon^2 f(X)\tilde{h}_\epsilon(f(X))$. Since $f \in H^{s+1}$, we know that $f \in C^s$. This implies that $\tilde{h}_\epsilon(f(X)) \in C^s$, with the C^s norm bounded independent of ϵ. Thus we have $f(X)\tilde{h}_\epsilon(f(X)) \in H^s$, with a norm bounded independent of ϵ. With this in hand, we have that $\|g(\cdot)\|_s \le C\epsilon^2$, with $C \ne C(\epsilon)$. Now the derivatives of g can be bounded as follows:

$$\begin{aligned}\left\|\frac{d^n}{dx^n}g(\epsilon\cdot)\right\|_{L^2} &= \epsilon^n\|g^{(n)}(\epsilon\cdot)\|_{L^2}\\ &\le C\epsilon^{n-1/2}\|g(\cdot)\|_s\\ &\le C\epsilon^{n+3/2}.\end{aligned}$$

Provided $n \ge 2$, this term is small enough. Therefore we have shown that the first s derivatives are sufficiently small in L^2, and we have proved the lemma. $\square$

SELF-SIMILAR EXPANDING SOLUTIONS IN A SECTOR FOR A CRYSTALLINE FLOW*

MI-HO GIGA†, YOSHIKAZU GIGA‡, AND HIDEKATA HONTANI§

Abstract. For a given sector a self-similar expanding solution to a crystalline flow is constructed. The solution is shown to be unique. Because of self-similarity the problem is reduced to solve a system of algebraic equations of degree two. The solution is constructed by a method of continuity and obtained by solving associated ordinary differential equations. The self-similar expanding solution is useful to construct a crystalline flow from an arbitrary polygon not necessarily admissible.

Key words. crystalline flow, self-similar expanding solutions, a priori estimate

1. Introduction.

A curvature flow is important to describe motion of phase boundaries in material sciences [13], [22] and also to modify contours in image analysis [18]. A crystalline flow is considered as a discrete version of an anisotropic curvature flow in the plane. It was introduced by Taylor [21] and independently by Angenent and Gurtin [1] almost a decade ago. Let us give a typical example of anisotropic curvature flow equations in $\mathbf{R}^2$:

$$V = -\mathrm{div}\xi(\vec{n}) \quad \text{on } \Gamma_t; \tag{1.1}$$

here V denotes the normal velocity of an evolving curve $\{\Gamma_t\}$ in the direction of unit normal $\vec{n}$ and $\xi = \nabla\gamma$ with the interfacial energy density $\gamma(p)$ which is positively one-homogeneous and convex in $\mathbf{R}^2$; div denotes the surface divergence. If $\gamma(p) = |p|$, then (1.1) is nothing but the curve shortening equation. If γ is piecewise linear, then (1.1) is so singular that it cannot be interpreted as a conventional partial differential equation. This is a typical situation where a crystalline flow arises. To understand (1.1) one restricts $\{\Gamma_t\}$ in a special class of polygonal curves, which is often called "admissible" [21], [1]. The boundary of the Wulff shape

$$W_\gamma = \{x \in \mathbf{R}^2;\ x \cdot m \le \gamma(m) \quad \text{for all} \quad m \in \mathbf{R}^2\}$$

is a typical example of an admissible polygon (crystal). Its weighted curvature $-\mathrm{div}\xi(\vec{n})$ formally equals -1 if $\vec{n}$ is taken outward. Thus if W_γ is a regular polygon centered at the origin, then it is reasonable to say that $\Gamma_t = t^{1/2}\partial W_\gamma$ is a "solution" of (1.1). We say that a polygon Γ is an *admissible crystal* if the orientation of each edge (facet) is one of that in ∂W_γ and the orientations of adjacent facets should be adjacent in ∂W_γ. We say that $\{\Gamma_t\}$ is an *admissible evolving crystal* if Γ_t is an admissible crystal and the motion of all vertices of Γ_t is C^1 in time t. Let $S_j(t)$ denote the jth facet of Γ_t. Then (1.1) is formally of the form

$$V_j(t) = \Lambda_j(t) \quad \text{on } S_j(t) \tag{1.2}$$

with *crystalline curvature*

$$\Lambda_j(t) = \chi_j \Delta(\vec{n}_j)/L_j(t),$$

and $V_j(t)$ denotes the normal velocity of $S_j(t)$ in the direction of $\vec{n}_j$; here $L_j(t)$ denotes the length of $S_j(t)$ and χ_j is the transition number (see section 2). The quantity $\Delta(\vec{n}_j)$ is the length of the facet of ∂W_γ whose orientation equals $\vec{n}_j$. Together with a transport equation (the first displayed formula in section 3) we have a finite system (3.1) of ordinary differential equations (ODEs), which is at least solvable locally in time. The resulting flow $\{\Gamma_t\}$ is often called a crystalline flow.

Our goal in this paper is to construct a self-similar expanding admissible evolving crystal $\{\Gamma_t\}_{t>0}$ satisfying (1.2) (shortly, self-similar expanding solution) such that it tends to the boundary of a sector as time tends to zero. We also prove its uniqueness. (Note that a self-similar expanding solution is not necessarily a dilation of the Wulff shape as numerical calculations in [15], [16] show.) The unique existence of self-similar expanding solutions has been claimed in a pioneering work by Taylor [23, Proposition 2.2(1)]. However, unfortunately the proof is rather sketchy; for example the uniqueness is not proved. It is not at all clear how to complete the proof. In this paper we shall give a complete proof.

There are several reasons such a solution is important. Here is a partial list:

(a) It is useful to construct a solution when initial data is a nonadmissible polygon;

(b) It is useful to construct a self-similar expanding solution to (1.1) for general γ when Γ_t lives in a sector and touches the boundary of the sector with prescribed contact angle.

The first reason (a) is already explained in [23, section 2.2].

Before discussing these reasons we mention relation between crystalline flow and curvature flow with smooth strictly convex interfacial energy density. One comes up with two natural questions.

(i) Is a crystalline flow approximated by a curvature flow with smooth convex γ?

(ii) Is a flow with smooth γ approximated by a crystalline flow with a piecewise linear γ? If so, crystalline flow provides a good numerical algorithm to calculate (1.1).

Fortunately, these problems are affirmatively settled by now; [5], [7], [8], [9] for (i) and [5], [12], [11], [7], [8], [9] for (ii). In [5], [7], [9] general notions of a "solution" to (1.1) based on variational principle or comparison principle are given. Moreover, it is shown that the "solution" in this sense exists for a general initial simple curve not necessarily admissible. Starting from a general polygon is important for a crystalline algorithm (ii). Practically, for a given curve it is easier to approximate it by a polygon rather than by an admissible crystal. However, it is not clear what is a crystalline flow starting from a general polygon although existence of a "solution" is known in an abstract level [5], [6], [9]. It is also numerically calculated in [4] when Γ_t is a graph by a variational inequality.

We now go back to the point (a). Suppose that the initial polygon is nonadmissible and that crystalline curvature of a pair of adjacent facets S_A and S_B equals zero. Assume that between orientations of S_A and S_B there are orientations of ∂W_γ. Then one expects that some new facets (with their missing orientations) are created instantaneously. If one has a self-similar expanding solution (with respect to a point where S_A intersects S_B), then this solution provides newly created facets. (In fact, it is a unique solution in the level set sense [8], [9]. Even if the crystalline curvature of at least one of S_A and S_B is not zero, a self-similar expanding solution represents a leading term of the length of newly created facets. We do not touch these two problems in this paper.) A self-similar expanding solution gives a definite way to create new facets (at least when S_A and S_B do not move), so it is useful to implement numerical algorithm starting with a nonadmissible polygon. We gave such an applications in [15], [16] for multiscale analysis of contour shape to extract its structure.

When the Frank diagram of γ (1-level set of γ) is strictly convex and smooth so that W_γ is smooth and strictly convex, we know that there is a (unique) self-similar expanding solution to (1.1) touching the boundary of a given sector with prescribed angle [17], [3]. Our self-similar expanding solution to (1.2), together with approximation theory [7], [9], provides a self-similar expanding solution (under prescribed contact angle condition) for more general γ whose Frank diagram is not necessarily strictly convex. As in [17], [3] our self-similar solutions represents the large time behavior of general solutions. We shall discuss this topic in a forthcoming paper. Note that our self-similar expanding solution is different from a self-similar shrinking solution studied, for example, in [19], [20].

Let us briefly mention the method of the proof. The uniqueness is proved by a geometric method (section 2)—comparison principle [21], [10]. To construct a self-similar expanding solution it suffices to find a solution of ODEs with $L_j(t) = t^{1/2}/a_j$, $a_j > 0$. The problem is reduced to find a positive a_j's solving a system of algebraic equations of degree two for a_j's. Essentially the same reduction is done by Taylor [23, p. 425]. If the number of missing orientations is small, say one or two, then one can solve it directly. However, solving the algebraic system for a greater number of equations is very tedious. The equation for a_j's is of the form

$$\begin{pmatrix} 1/a_1 \\ \vdots \\ 1/a_n \end{pmatrix} = H \begin{pmatrix} a_1 \\ \vdots \\ a_n \end{pmatrix} \tag{1.3}$$

and $H = (H_{ij})$ is a tridiagonal matrix; see (3.2). In [23, p. 425] a method to solve such a system of algebraic equations is suggested but the proof seems to be too short to achieve the goal. We solve this equation analytically by introducing extra parameter s, so that our algebraic system is decoupled for $s = 0$ to get $a_j = 1/\sqrt{H_{jj}}$ and for $s = 1$ it agrees with (3.2). We differentiate it with respect to s to get ODEs. We solve the ODEs from $s = 0$ to $s = 1$ by establishing a priori estimates. A crucial step is to calculate the determinant of H, in particular to prove its positiveness. An explicit and beautiful formula of $\det H$ is given in Lemma 4.2 up to an explicit constant. It is represented by angles of Wulff shapes. Note that our method provides not only the existence but also a way to calculate numerical values of a_j's by solving the ODEs numerically.

This paper is organized as follows. In section 2 we state our main results and give a proof of uniqueness. In section 3 we derive the ODEs to solve the algebraic equation (3.1). We prove the existence of a solution admitting several estimates for matrices established in section 4, which is the main technical part of this paper.

After this work was completed, we were informed of the work of Campbell [2] who partially solved our problem. In fact, she proved the unique solvability of (1.3) when the Wulff shape is a regular polygon. Her method is a kind of shooting method for a_j. When the Wulff shape is not a regular polygon, it seems that her method does not apply. Moreover, unfortunately her work is only in the form of a master's thesis and is not published. We believe it is very important to publish a complete proof in a full generality of this fundamentally important problem.

2. Main theorems. We start by formulating the problem. Let ∂C be the boundary of a given oriented cone C in $\mathbf{R}^2$ of the form $\partial C = \ell_A \cup \ell_B$, where ℓ_A and ℓ_B are maximal half lines starting from the origin O and are indexed clockwise as in Figure 1. We also call C a sector. In this paper, we assume that $\vec{n}_j = (\cos\theta_j, \sin\theta_j)$ is the outer unit normal of ℓ_j for $j = A, B$ with $|\theta_A - \theta_B| < \pi$. Let n be a nonnegative integer. Let $\Theta = \{\theta_j;\ j = 1, \dots, n\}$ with $\theta_A > \theta_1 > \theta_2 > \cdots > \theta_n > \theta_B$ (resp., $\theta_A < \theta_1 < \theta_2 < \cdots < \theta_n < \theta_B$) if $\theta_A > \theta_B$ (resp., $\theta_A < \theta_B$). We call Θ a *set of admissible angles*. We interpret that Θ is an empty set if $n = 0$.

We call a simple oriented polygonal curve S an *admissible crystal associated with* C if S is of the form $S = \cup_{j=1}^n S_j \ \cup S_A \ \cup S_B$, where S_j is a nontrivial and closed segment with the outer unit normal $\vec{n}_j = (\cos\theta_j, \sin\theta_j)$ for $j \in \{1, \dots, n\} \cup \{A, B\}$ and S_j for $j = A, B$ is a half line contained in ℓ_j. If $n = 0$, we always use the convention that $\cup_{j=1}^n S_j$ is the empty set so that $S = \partial C$. We implicitly assume that segments S_j's are numbered clockwisely. Figure 1 shows examples of C. Figure 2 shows examples of admissible crystals S associated with C.

We say that a family of polygon $\{S(t)\}_{t\in J}$, where J is a time interval, belongs to a *set of orientation-preserving evolving curves* $\mathcal{S}$ if $S(t)$ is an admissible crystal for all $t \in J$ and each corner moves continuously differentiably in time, where J is a time interval. These conditions imply that the orientation of each line (facet) is preserved for $t \in J$.

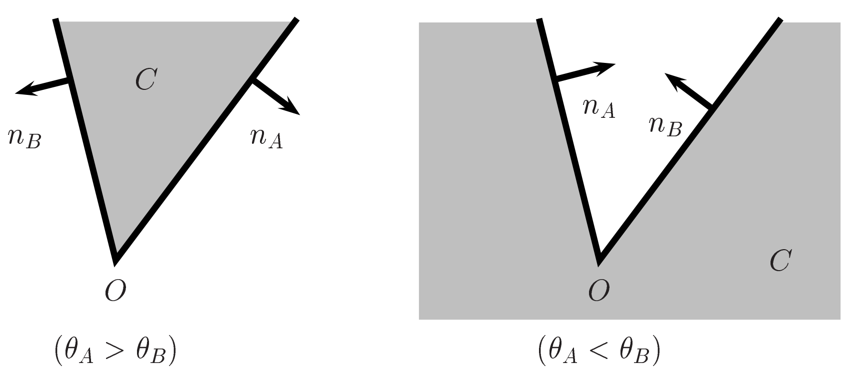

FIG. 1. *Oriented cones C.*

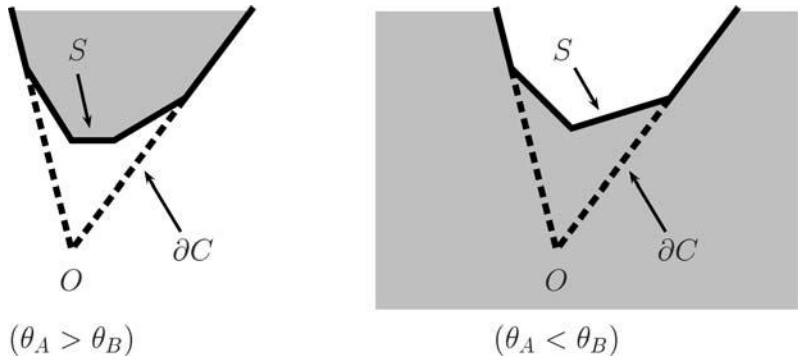

FIG. 2. *Admissible crystals S.*

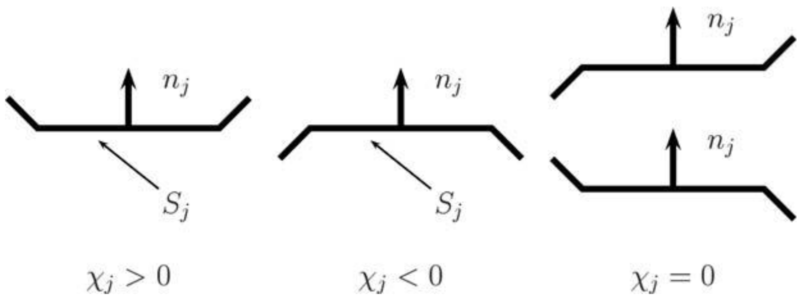

FIG. 3. *Transition number χ_j.*

We recall the notion of crystalline curvature or weighted curvature of $\{S(t)\}_{t\in J} \in S$, where $S(t)$ is of the form

$$S(t) = \bigcup_{j=1}^{n} S_j(t) \cup S_A(t) \cup S_B(t)$$

and $L_j(t)$ is the length of facet $S_j(t)$. Let $\chi_j(t)$ be a transition number defined by

$$\chi_j(t) := \begin{cases} 1 & \text{if } S(t) \text{ is concave around } S_j(t), \\ -1 & \text{if } S(t) \text{ is convex around } S_j(t), \\ 0 & \text{otherwise} \end{cases}$$

(see Figure 3). Let Δ_j be a positive given number. We define these quantities for $j = 1, 2, \ldots, n$. A crystalline curvature $\Lambda_j(t)$ of $S_j(t)$ is defined by

$$\Lambda_j(t) = \frac{\chi_j(t)\Delta_j}{L_j(t)}.$$

We use this formula to define crystalline curvatures Λ_A and Λ_B for S_A and S_B, and observe that $\Lambda_A = \Lambda_B = 0$ no matter how transition number and Δ are taken since the length of S_A and S_B is infinite.

We consider an evolving curve $\{S(t)\}_{t\in J} \in \mathcal{S}$ solving (1.2). In other words, it evolves such that the normal velocity $V_j(t)$ in the direction of $\overrightarrow{n}_j$ of jth facet $S_j(t)$ equals $\Lambda_j(t)$ for $j = 1, \ldots, n, A, B$.

We will now introduce the notion of a self-similar expanding solution.

DEFINITION 2.1. *An orientation-preserving evolving curve $\{S(t)\}_{t>0} \in \mathcal{S}$ is called a* self-similar expanding solution *to* (1.2) *in a sector C if there exists an admissible crystal S_* associated with C such that*

$$S(t) = t^{1/2} S_* = \{t^{1/2}x; x \in S_*\} \quad \textit{for} \quad t > 0; \tag{2.1}$$

$$V_j(t) = \Lambda_j(t) \quad \textit{for} \quad t > 0, \quad j = 1, \dots, n \quad \textit{if} \quad n \geq 1. \tag{2.2}$$

By definition if $n = 0$, then $S_* = \ell_a \cup \ell_b = \partial C$. Thus the only self-similar expanding solution in a sector C must be ∂C.

We note that for a self-similar solution $\{S(t)\}_{t>0}$, the transition number is unique independent of j and t, i.e., $\chi_j(t) = -1$ (resp., 1) if $\theta_A > \theta_B$ (resp., $\theta_A < \theta_B$) for all $j = 1, \dots, n$ and $t > 0$.

Our main results concern the existence and uniqueness of self-similar expanding solutions governed by crystalline curvature in a sector. They are as follows.

THEOREM 2.2 (existence). *Let C be a given oriented cone in $\mathbf{R}^2$. Let $\Theta = \{\theta_j;\ j = 1, \dots, n\}$ (with nonnegative integer n) be a set of admissible angles. Let Δ_j be a positive number for $j = 1, \dots, n$. Then there exists a self-similar expanding solution $\{S(t)\}_{t>0}$ in a sector C.*

THEOREM 2.3 (uniqueness). *Under the same hypotheses of Theorem* 2.2 *there is at most one self-similar expanding solution $\{S(t)\}_{t>0}$ in a sector C.*

We shall prove Theorem 2.2 in section 3 based on key a priori estimates shown in section 4. In the rest of this section we shall prove Theorem 2.3 by geometric argument.

Proof of Theorem 2.3. Let $\{S(t)\}_{t>0}$ and $\{R(t)\}_{t>0}$ be self-similar expanding solutions in a sector C. We may assume that $\theta_A > \theta_B$; i.e., the cone C is convex. We may also assume that $n \geq 1$. Then transition numbers of all facets of $S(t)$ and $R(t)$ are -1. Let $S(t)$ (resp., $R(t)$) be of the form $S(t) = \cup_{j=1}^n S_j(t) \cup S_A(t) \cup S_B(t)$ (resp., $R(t) = \cup_{k=1}^n R_k(t) \cup R_A(t) \cup R_B(t)$). For convenience we introduce an unbounded region $D_S(t) \subset \mathbf{R}^2$ enclosed by $S(t)$ for $t > 0$; let $D_S(t)$ denote the closure of the interior region bounded by curve $S(t)$ (see Figure 4). Let $\tilde{R}(t)$ be of the form $\tilde{R}(t) = \cup_{k=1}^n R_k(t)$.

Suppose that $S \not\equiv R$. We may assume that $\tilde{R}(1) \cap \text{ int } D_S(1) \neq \emptyset$. By this assumption, $t_0 \in (0,1)$ holds for $t_0 := \sup\{t | \tilde{R}(t) \cap \text{ int } D_S(1) = \emptyset\}$. Since $\tilde{R}(0)$ is a singleton and $S(1 - t_0) \neq \partial C$, there exists $\delta > 0$ such that $\tilde{R}(\delta) \cap \text{ int } D_S(t_1) = \emptyset$

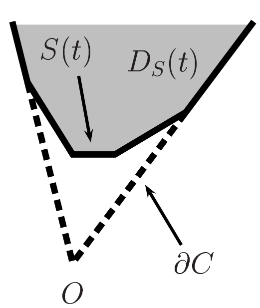

FIG. 4. *Region $D_S(t)$ enclosed by $S(t)$.*

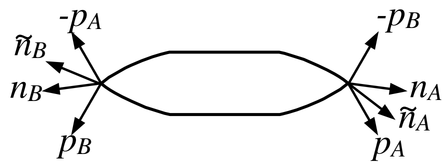

FIG. 5. *Wulff shape W.*

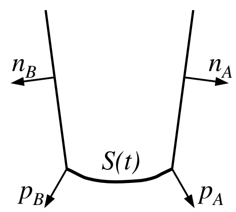

FIG. 6. *Self-similar expanding solution $S(t)$.*

with $t_1 := 1 - t_0$. We fix such δ. Setting $t_2 := \sup\{\tau > 0;\ \tilde{R}(\sigma+\delta) \cap \operatorname{int} D_S(\sigma+t_1) = \emptyset$ for $\sigma \in (0,\tau)\}$, we have $0 < t_2 < t_0$. Since $\tilde{R}(\sigma+\delta)$ touches $D_S(\sigma+t_1)$ first time at $\sigma = t_2$, there exists a facet $R_j(t_2+\delta)$ of $\tilde{R}(t_2+\delta)$ and a facet $S_j(t_2+t_1)$ of $S(t_2+t_1)$ such that the normal of $R_j(t_2+\delta)$ coincides with that of $S_j(t_2+t_1)$, we conclude that $R_j(t_2+\delta) \cap S_j(t_2+t_1) \neq \emptyset$ and that the length of $R_j(t_2+\delta)$ does not equal the length of $S_j(t_2+t_1)$. By geometry, the length of $R_j(t_2+\delta)$ is greater than the length of $S_j(t_2+t_1)$, so that the weighted curvature of $R_j(t_2+\delta)$ is negative and is greater than that of $S_j(t_2+t_1)$ (cf. [21], [10]). So the normal velocity of $R_j(t_2+\delta)$ is negative and is greater than that of $S_j(t_2+t_1)$, which contradicts the definition of t_2. $\square$

Remark. (i) The evolution equation (2.2) can be viewed as a crystalline curvature flow equation (1.1) (or (1.2)) with a suitable polygonal Wulff shape. Indeed, if $\theta_A > \theta_B$ for example, then there exists a convex polygon W such that the set $\mathcal{N}$ of the orientations of all facets in W includes all $\vec{n}_j$'s with $j \in \{1,\ldots,n\}$ and the length of facet with $\vec{n}_j$ equals Δ_j and that $\mathcal{N}$ does not include any $\vec{m} = (\cos\theta, \sin\theta)$ for $\theta \neq \theta_j, \theta \in (\theta_B, \theta_A)$. We may assume that W contains the origin as an interior point. The corresponding interfacial energy density γ is given as a support function: $\gamma(x) = \sup\{x \cdot p; p \in W\}$ for $x \in \mathbf{R}^2$. The case $\theta_A < \theta_B$ can be treated in a similar way.

(ii) If we dilate the Wulff shape so that the length of the jth facet equals $\lambda\Delta_j$, then $\sqrt{\lambda}S(t)$ is the corresponding self-similar expanding solution to (1.2) with Δ_j replaced by $\lambda\Delta_j$, where $S(t)$ is defined by (2.1) with (2.2).

(iii) Here is a numerical example of a profile S_* of the self-similar expanding solutions for given two different sectors with a fixed Wulff shape having many facets so that it looks a smooth curve. See Figures 5, 6, and 7. We use a Newton-type iteration which is closely related to our ODEs (3.4) to find numerical values of a_j's.

3. Existence of self-similar solution of ODE system. We shall show the existence theorem (Theorem 2.2). When $n = 0$, $\{S(t)\}_{t>0}$ with $S(t) = t^{1/2}(\partial C)$ is the desired self-similar expanding solution. In the following we suppose $n \geqq 1$. Let a family of polygon $\{S(t)\}_{t>0}$ belong to $\mathcal{S}$. Then we have a transport equation of

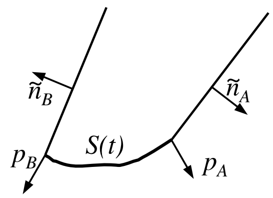

FIG. 7. *Self-similar expanding solution $S(t)$.*

$\{S(t)\}_{t>0}$:

$$\frac{dL_j(t)}{dt} = (\cot\varphi_j + \cot\varphi_{j+1})V_j(t) - \frac{1}{\sin\varphi_j}V_{j-1}(t) - \frac{1}{\sin\varphi_{j+1}}V_{j+1}(t), \quad t>0$$

for $j = 1,\dots,n$, where $\varphi_j := \theta_j - \theta_{j-1}$ for $j = 1,\dots,n+1$. Here we set $\theta_0 := \theta_A, \theta_{n+1} := \theta_B$ so that $V_0 := 0$ and $V_{n+1} := 0$ since $S_A(t)$ and $S_B(t)$ have infinite length. Plugging the governing law $V_j(t) = \Lambda_j(t)$ for $j = 1,\dots,n$, we have an ODE system:

$$\frac{dL_j(t)}{dt} = \frac{1}{2}\left\{\frac{p_j}{L_j(t)} + \frac{q_{j-1}}{L_{j-1}(t)} + \frac{r_{j+1}}{L_{j+1}(t)}\right\}, \quad t>0, \tag{3.1}$$

for $j = 1,\dots,n$, where

$$\begin{aligned} p_j &= 2\chi_j\Delta_j\frac{\sin(\varphi_j+\varphi_{j+1})}{\sin\varphi_j\sin\varphi_{j+1}} && \text{for } j = 1,\dots,n,\\ q_j &= -2\chi_j\Delta_j\frac{1}{\sin\varphi_{j+1}} && \text{for } j = 1,\dots,n-1,\\ r_j &= -2\chi_j\Delta_j\frac{1}{\sin\varphi_j} && \text{for } j = 2,\dots,n, \end{aligned}$$

and $q_0 = 0$ and $r_{n+1} = 0$. Here we used $\cot\varphi_j + \cot\varphi_{j+1} = \frac{\sin(\varphi_j+\varphi_{j+1})}{\sin\varphi_j\sin\varphi_{j+1}}$.

By the assumption on θ_A and θ_B in section 2, we note that $|\sum_{j=1}^{n+1}\varphi_j| = |\theta_A - \theta_B| < \pi$. When C is convex (resp., concave), i.e., $\theta_A > \theta_B$ (resp., $\theta_A < \theta_B$), then $\varphi_j < 0$ (resp., $\varphi_j > 0$) for $j = 1,\dots,n+1$ and $\chi_j < 0$ (resp., $\chi_j > 0$) for $j = 1,\dots,n$. Thus, we have $p_j > 0$ for $j = 1,\dots,n$, $q_j < 0$ for $j = 1,\dots,n-1$, and $r_j < 0$ for $j = 2,\dots,n$.

DEFINITION 3.1. *A family of functions $\{L_j(t)\}_{j=1}^n$ is called a* self-similar solution *of the ODE system* (3.1) *if $L_j(t)$ is of the form $L_j(t) = \alpha_j t^{1/2}$ with positive number α_j satisfying* (3.1) *for $j = 1,\dots,n$.*

Theorem 2.2 is obtained by showing the following proposition.

PROPOSITION 3.2. *Let n be a positive integer. There exists a self-similar solution $\{L_j(t)\}_{j=1}^n$ of the ODE system* (3.1).

When $n = 1$, (3.1) yields an ODE

$$\frac{dL_1(t)}{dt} = \frac{p_1}{2L_1(t)}, \quad t>0.$$

Since $(d/dt)\{L_1(t)^2\} = p_1$, $t>0$, we obtain $L_1(t) = t^{1/2}{p_1}^{1/2}$ for $t>0$, so that Proposition 3.2 holds for $n = 1$.

In the following we assume that $n \geqq 2$. Our strategy to prove Proposition 3.2 is as follows. Substituting $L_j(t) = \alpha_j t^{1/2}$ into (3.1), we have

$$\begin{pmatrix} 1/a_1 \\ 1/a_2 \\ \vdots \\ 1/a_n \end{pmatrix} = H \begin{pmatrix} a_1 \\ a_2 \\ \vdots \\ a_n \end{pmatrix} \tag{3.2}$$

with unknowns $a_j = 1/\alpha_j$, where

$$H = \begin{pmatrix} p_1 & r_2 & & & \\ q_1 & p_2 & r_3 & & \mathbf{0} \\ & \ddots & \ddots & \ddots & \\ & & q_{n-2} & p_{n-1} & r_n \\ & \mathbf{0} & & q_{n-1} & p_n \end{pmatrix}.$$

In particular

$$H = \begin{pmatrix} p_1 & r_2 \\ q_1 & p_2 \end{pmatrix}$$

when $n = 2$. To show the existence of solutions to the system of nonlinear algebraic equations (3.2), we consider the following continuation method sometimes called Davidenko's method. Introducing an extra parameter $s \geq 0$ and the matrix $K(s)$:

$$K(s) = \begin{pmatrix} p_1 & sr_2 & & & \mathbf{0} \\ sq_1 & p_2 & sr_3 & & \\ & \ddots & \ddots & \ddots & \\ & & sq_{n-2} & p_{n-1} & sr_n \\ \mathbf{0} & & & sq_{n-1} & p_n \end{pmatrix},$$

we consider the system of nonlinear algebraic equations

$$\begin{pmatrix} 1/b_1(s) \\ 1/b_2(s) \\ \vdots \\ 1/b_n(s) \end{pmatrix} = K(s) \begin{pmatrix} b_1(s) \\ b_2(s) \\ \vdots \\ b_n(s) \end{pmatrix} \tag{3.3}$$

for $b(s) > 0$. Evidently $b_j(0) = 1/\sqrt{p_j}$, since $K(0)$ is a diagonal matrix. If the solution can be extended up to $s = 1$, then $b_j(1)$ is a solution of (3.2) since $K(1) = H$. Differentiating (3.3) formally with respect to parameter s, we have

$$-\begin{pmatrix} \vdots \\ b_j'(s)/b_j(s)^2 \\ \vdots \end{pmatrix} = K(s) \begin{pmatrix} \vdots \\ b_j'(s) \\ \vdots \end{pmatrix} - J \begin{pmatrix} \vdots \\ b_j(s) \\ \vdots \end{pmatrix}$$

with

$$J = -\begin{pmatrix} 0 & r_2 & & & & \\ q_1 & 0 & r_3 & & \text{\huge 0} & \\ & \ddots & \ddots & \ddots & & \\ & & \ddots & \ddots & \ddots & \\ & \text{\huge 0} & & q_{n-2} & 0 & r_n \\ & & & & q_{n-1} & 0 \end{pmatrix}.$$

Here and thereafter $'$ denotes d/ds, differentiation with respect to s. One can rewrite the above differential equation for b_j in the form

$$Q(s, \vec{b}(s)) \begin{pmatrix} \vdots \\ b_j'(s) \\ \vdots \end{pmatrix} = J \begin{pmatrix} \vdots \\ b_j(s) \\ \vdots \end{pmatrix}, \tag{3.4}$$

i.e.,

$$Q(s, \vec{b}(s))\ \vec{b}'(s) = J\vec{b}(s) \quad \text{with} \quad \vec{b}(s) = {}^{\mathrm{t}}(b_1(s), \ldots, b_n(s)),$$

if we define

$$Q(s, \vec{h}) = K(s) + \mathrm{diag}(1/h_1^2, \ldots, 1/h_n^2) \quad \text{with} \quad \vec{h} = {}^{\mathrm{t}}(h_1, \ldots, h_n).$$

If the inverse matrix of Q exists, (3.4) formally yields

$$\vec{b}'(s) = G(s, \vec{b}(s))\ \vec{b}(s). \tag{3.5}$$

Here we set $G(s, \vec{h}) = Q^{-1}(s, \vec{h})\ J$. We consider the system of ODEs (3.5) for $s > 0$ with initial condition

$$\vec{b}(0) = \vec{h}^*, \qquad \vec{h}^* := {}^{t}(1/\sqrt{p_1}, \ldots, 1/\sqrt{p_n}). \tag{3.6}$$

Local-in-time unique existence of a positive solution $\vec{b}(s)$ of (3.5) and (3.6) is guaranteed, since Q is smooth and det $Q \neq 0$ near $(0, \vec{h}^*)$, so that Q^{-1} is smooth near $(0, \vec{h}^*)$.

As we shall prove in Lemma 3.4, the local solution $\vec{b}(s)$ can be extended uniquely up to $s = 1 + \tau$ with some $\tau > 0$ (obtained in Theorem 4.1). Then $a_j := b_j(1)$ ($j = 1, \ldots, n$) is a solution of (3.2), so that $\{L_j(t)\}_{j=1}^n$, with $L_j(t) = t^{1/2}/b_j(1)$ for $t > 0,\ j = 1, \ldots, n$, is a self-similar solution of (3.1), which implies Proposition 3.2.

To prove the unique solvability up to $s = 1$ we need to prepare a priori estimate. We use the notation $\vec{x} < \vec{y}$ (resp., $\vec{x} \leqq \vec{y}$ for $\vec{x} = {}^{t}(x_1, \ldots, x_n), \vec{y} = {}^{t}(y_1, \ldots, y_n) \in \mathbf{R}^n$ if $x_j < y_j$ (resp., $x_j \leq y_j$) for $j = 1, \ldots, n$.

Lemma 3.3 (a priori estimate). *Let $S_0 > 0$ denote the maximal existence time of a positive solution of the system of ODEs* (3.5) *and* (3.6). *Set $S_1 := \min(S_0, 1 + \tau)$, where τ is a positive number obtained in Theorem* 4.1. *Let $\vec{b}(s)$ be the solution of* (3.5) *and* (3.6).

(I) *The derivative of each component of $\vec{b}(s)$ is positive, i.e., $\vec{b}'(s) > \vec{0}$ for $s \in [0, S_1)$.*

(II) *In particular,* $\vec{b}(s) > \vec{h}^*(> \vec{0})$ *for* $s \in (0, S_1)$.
(III) *There exists a constant* $C_3 > 0$ *independent of* s *such that*

$$0 \leq \{\text{each element of } Q^{-1}(s, \vec{b}(s))\} \leq C_3 \quad \textit{for } s \in [0, S_1).$$

Proof. The main steps of this lemma are proved in the next section, as summarized in Theorem 4.1. Since each element of the matrix J is nonnegative and $\vec{b}(s) > 0$ for $s \in [0, S_1)$, we have $J\vec{b}(s) > \vec{0}$. We now observe that (II) and (III) of Theorem 4.1 imply $\vec{b}'(s) = G(s, \vec{b}(s))\vec{b}(s) > 0$ for $s \in [0, S_1)$. Initial condition (3.6) and (I) yield (II). Theorem 4.1 and (II) implies (III). □

Lemma 3.4 (unique solvability up to $s = 1$). *There exists the unique positive solution* $\vec{b}(s)$ *(i.e.,* $\vec{b}(s) > \vec{0}$*) of the system of ODEs* (3.5) *and* (3.6) *for* $s \in [0, 1 + \tau]$, *where* τ *is a positive number obtained in Theorem* 4.1.

Proof. Let S_0 be the maximal existence time of (3.5) and (3.6), and set $S_1 := \min(S_0, 1 + \tau)$. We note that $G(s, \vec{b}(s))$ is well defined for $s \in [0, S_1)$ by Lemma 3.3. Integrating (3.5), we have

$$\vec{b}(s) - \vec{b}(0) = \int_0^s G(u, \vec{b}(u))\vec{b}(u)du \quad \text{for} \quad s \in [0, S_1),$$

which implies

$$|\vec{b}(s)| \;\leqq\; |\vec{b}(0)| + \int_0^s |G(u, \vec{b}(u))|_{\text{op}}\; |\vec{b}(u)|du \quad \text{for} \quad s \in [0, S_1).$$

Here $|\cdot|$ denotes the Euclidean norm and $|\cdot|_{\text{op}}$ denotes the operator norm from $\mathbf{R}^n$ to $\mathbf{R}^n$. Lemma 3.3 implies that there exist a constant C_1 independent of s such that

$$0 < \; |G(s, \vec{b}(s))|_{\text{op}} \; \leq C_1 \quad \text{for} \quad s \in [0, S_1),$$

since each element of J is nonnegative. So we have

$$|\vec{b}(s)| \;\leqq\; |\vec{b}(0)| + C_1 \int_0^s |\vec{b}(u)|du \quad \text{for} \quad s \in [0, S_1).$$

Gronwall's lemma implies

$$|\vec{b}(s)| \;\leqq\; |\vec{b}(0)| \exp(C_1\; s) \;\leqq\; |\vec{h}^*| \exp(C_1\; S_1) =: C_2 \quad \text{for} \quad s \in [0, S_1).$$

Suppose that $S_0 \leqq 1 + \tau$. Then Lemma 3.3(II) yields

$$1/\sqrt{p_j} \;\leq b_j(s) \;\leq C_2 \quad \text{for} \quad s \in [0, S_0),\; j = 1, \ldots, n. \tag{3.7}$$

Since S_0 is the maximal existence time, by a standard extension theorem for ODEs (e.g., [14, Chapter II, Theorem 3.1]), we have either $\lim_{s \to S_0} b_j(s) = \infty$ or $\lim_{s \to S_0} b_j(s) = 0$ for some $j = 1, \ldots, n$. This evidently contradicts (3.7). Thus we have $S_0 > 1 + \tau$. □

4. A priori estimates for matrices.

Theorem 4.1 (a priori estimates). (I) *There exist some positive constants* C_4 *and* τ *(independent of* s *and* $\vec{h}$*) such that*

$$\det Q(s, \vec{h}) > C_4 \prod_{j=1}^{n} p_j (> 0) \quad \textit{ for all } s \in [0, 1 + \tau] \textit{ and all } \vec{h} \in (\mathbf{R}_+)^n.$$

(II) *The matrix* $Q(s,\vec{h})$ *has its inverse for* $s \in [0,1+\tau]$ *and* $\vec{h} \in (\mathbf{R}_+)^n$. *Each element of* $Q^{-1}(s,\vec{h})$ *is smooth on* $[0,1+\tau] \times (\mathbf{R}_+)^n$.

(III) *Let* $\vec{h}^\sharp \in (\mathbf{R}_+)^n$ *with* $\vec{h}^\sharp > 0$. *There exists a constant* $C_5 > 0$ *(independent of* s *and* $\vec{h}$*) such that* $0 \leqq \{$*each element of* $Q^{-1}(s,\vec{h})\} \leqq C_5$ *for all* $s \in [0,1+\tau]$ *and all* $\vec{h} \in (\mathbf{R}_+)^n$ *with* $\vec{h} \geqq \vec{h}^\sharp$.

Here we use the notation $\mathbf{R}_+ := (0,\infty)$, so that $(\mathbf{R}_+)^n = \overbrace{(0,\infty)\times\cdots\times(0,\infty)}^{n}$. To prove the theorem we shall show the following lemmas. To show positiveness of the determinant of the matrix Q we consider matrix $M^{k\ell}(s)$:

$$M^{k\ell}(s) := \begin{pmatrix} 1 & sr_{k+1}/p_{k+1} & & & & & \\ sq_k/p_k & 1 & sr_{k+2}/p_{k+2} & & & \mathbf{0} & \\ & sq_{k+1}/p_{k+1} & 1 & sr_{k+3}/p_{k+3} & & & \\ & & \ddots & \ddots & \ddots & & \\ & & & \ddots & \ddots & \ddots & \\ & \mathbf{0} & & & sq_{\ell-2}/p_{\ell-2} & 1 & sr_\ell/p_\ell \\ & & & & & sq_{\ell-1}/p_{\ell-1} & 1 \end{pmatrix}$$

for $s \geqq 0$ and $k,\ \ell = 1,\ldots,n$ with $k \leqq \ell$. In particular,

$$M^{kk}(s) = (1) \qquad \text{for}\quad s \geqq 0,\ k = 1,\ldots,n,$$

$$M^{kk+1}(s) = \begin{pmatrix} 1 & sr_{k+1}/p_{k+1} \\ sq_k/p_k & 1 \end{pmatrix} \qquad \text{for}\quad s \geqq 0,\ k = 1,\ldots,n-1.$$

We note that $M^{1n}(s)$ is obtained by dividing each jth column of $K(s)$ by p_j. We set $\tilde{M}^{k\ell} = M^{k\ell}(1)$. Fortunately, $\det\tilde{M}^{k\ell}$ is computable. Note that $\det H = \prod_{j=1}^n p_j \cdot \det\tilde{M}^{1n}$.

LEMMA 4.2. *For* $k,\ell = 1,\ldots,n$ *with* $k \leqq \ell$,

$$\det\tilde{M}^{k\ell} = \frac{\sin\left(\sum_{j=k}^{\ell+1}\varphi_j\right)}{\left(\prod_{j=k}^{\ell}\nu_j\right)\left(\prod_{j=k}^{\ell+1}\sin\varphi_j\right)}, \tag{4.1}$$

where

$$\nu_j := \cot\varphi_{j+1} + \cot\varphi_j \left(= \frac{\sin(\varphi_j+\varphi_{j+1})}{\sin\varphi_j\sin\varphi_{j+1}}\right). \tag{4.2}$$

Proof. The quantities q_j/p_j and r_j/p_j appearing in the matrix $M^{k\ell}(s)$ can be calculated as follows:

$$\frac{q_j}{p_j} = \frac{-1}{\nu_j\sin\varphi_{j+1}}\ ,\quad \frac{r_j}{p_j} = \frac{-1}{\nu_j\sin\varphi_j}.$$

We may assume that $k = 1$ without loss of generality. We shall prove (4.1) by induction. Let m^ℓ denote the right-hand side of (4.1) with $k = 1$.

(i) Using equality (4.2), we have

$$m^1 = \frac{\sin(\varphi_1 + \varphi_2)}{(\cot\varphi_2 + \cot\varphi_1)\sin\varphi_1\sin\varphi_2} = 1 = \det \tilde{M}^{11},$$

which implies (4.1) with $k = 1 = \ell$.

(ii) Next we shall show (4.1) with $k = 1,\ \ell = 2$. We have

$$\det \tilde{M}^{12} = 1 - \frac{-1}{\nu_1 \sin\varphi_2} \cdot \frac{-1}{\nu_2\sin\varphi_2} = \frac{d_2}{\nu_1\nu_2\sin\varphi_1\sin^2\varphi_2\sin\varphi_3} \tag{4.3}$$

with $d_2 = (\nu_1\nu_2\sin^2\varphi_2 - 1)\sin\varphi_1\sin\varphi_3$. Equality (4.2) yields $d_2 = \sin(\varphi_1 + \varphi_2)\sin(\varphi_2+\varphi_3) - \sin\varphi_1\sin\varphi_3$. Using the identity

$$\sin\alpha\sin\beta = -\{\cos(\alpha+\beta) - \cos(\alpha-\beta)\}/2, \tag{4.4}$$

we have

$$d_2 = -\{\cos(\varphi_1 + 2\varphi_2 + \varphi_3) - \cos(\varphi_1+\varphi_3)\}/2.$$

By the identity

$$\cos\alpha - \cos\beta = -2\sin\frac{\alpha+\beta}{2}\sin\frac{\alpha-\beta}{2}, \tag{4.5}$$

we have $d_2 = \sin(\varphi_1+\varphi_2+\varphi_3)\sin\varphi_2$. Substituting this into (4.3), we obtain

$$\det \tilde{M}^{12} = \frac{\sin(\varphi_1+\varphi_2+\varphi_3)}{\nu_1\nu_2\sin\varphi_1\sin\varphi_2\sin\varphi_3} = m^2,$$

which is (4.1) for $k = 1,\ \ell = 2$.

(iii) We assume that $\ell \geqq 3$ and (4.1) holds for $\tilde{M}^{11}, \tilde{M}^{12}, \ldots, \tilde{M}^{1\ \ell-1}$. We have

$$\det \tilde{M}^{1\ell} = \det \tilde{M}^{1\ \ell-1} - \frac{r_\ell}{p_\ell}\frac{q_{\ell-1}}{p_{\ell-1}} \det \tilde{M}^{1\ \ell-2},$$

since

$$\tilde{M}^{1i} = \left(\begin{array}{ccc|c} & & & 0 \\ & \tilde{M}^{1\ i-1} & & \vdots \\ & & & 0 \\ & & & r_i/p_i \\ \hline 0 & \cdots\ 0 & q_{i-1}/p_{i-1} & 1 \end{array}\right) \quad \text{for } i = 2, \ldots, \ell.$$

The assumption of the induction yields

$$\det \tilde{M}^{1\ell} = \frac{\sin\left(\sum_{j=1}^{\ell}\varphi_j\right)}{\left(\prod_{j=1}^{\ell-1}\nu_j\right)\left(\prod_{j=1}^{\ell}\sin\varphi_j\right)} - \frac{-1}{\nu_\ell \sin\varphi_\ell}\cdot\frac{-1}{\nu_{\ell-1}\sin\varphi_\ell}\cdot\frac{\sin\left(\sum_{j=1}^{\ell-1}\varphi_j\right)}{\left(\prod_{j=1}^{\ell-2}\nu_j\right)\left(\prod_{j=1}^{\ell-1}\sin\varphi_j\right)}.$$

An elementary calculation yields

$$\det \tilde{M}^{1\ell} = \frac{d_\ell}{\left(\prod_{j=1}^{\ell}\nu_j\right)\left(\prod_{j=1}^{\ell+1}\sin\varphi_j\right)\sin\varphi_\ell} \tag{4.6}$$

with

$$d_\ell = \sin\left(\sum_{j=1}^{\ell}\varphi_j\right)\sin(\varphi_\ell+\varphi_{\ell+1}) - \sin\left(\sum_{j=1}^{\ell-1}\varphi_j\right)\sin\varphi_{\ell+1}.$$

The identity (4.4) yields

$$d_\ell = \frac{-1}{2}\left\{\cos\left(\sum_{j=1}^{\ell+1}\varphi_j+\varphi_\ell\right) - \cos\left(\sum_{j=1}^{\ell-1}\varphi_j+\varphi_{\ell+1}\right)\right\},$$

and the identity (4.5) yields

$$d_\ell = \sin\left(\sum_{j=1}^{\ell+1}\varphi_j\right)\sin\varphi_\ell.$$

Substituting this into (4.6), we obtain (4.1) for $\det \tilde{M}^{1\ell}$. By induction the proof is now complete. $\square$

LEMMA 4.3. *The identities*

$$\begin{aligned}\frac{d}{ds}\left\{\det M^{k\ell}(s)\right\} = -s\Bigg\{&\sum_{j=k+1}^{\ell-2}\frac{q_j}{p_j}\frac{r_{j+1}}{p_{j+1}}\det M^{k\ j-1}(s)\cdot\det M^{j+2\ \ell}(s)\\ &+\sum_{j=k+2}^{\ell-1}\frac{q_{j-1}}{p_{j-1}}\frac{r_j}{p_j}\det M^{k\ j-2}(s)\cdot\det M^{j+1\ \ell}(s)\\ &+2\frac{q_k}{p_k}\frac{r_{k+1}}{p_{k+1}}\det M^{k+2\ \ell}(s)+2\frac{q_{\ell-1}}{p_{\ell-1}}\frac{r_\ell}{p_\ell}\det M^{k\ \ell-2}(s)\Bigg\}\end{aligned} \tag{4.7}$$

for $s \geqq 0$ and $k,\ell = 1,\dots,n$ with $k+2<\ell$ hold. Moreover,

$$\begin{aligned}&\frac{d}{ds}\left\{\det\ M^{kk}(s)\right\} = 0 && \text{for } s \geqq 0 \text{ and } k=1,\dots,n;\\ &\frac{d}{ds}\left\{\det M^{k\ k+1}(s)\right\} = -2s\frac{q_k}{p_k}\frac{r_{k+1}}{p_{k+1}} && \text{for } s \geqq 0 \text{ and } k=1,\dots,n-1;\\ &\frac{d}{ds}\left\{\det M^{k\ k+2}(s)\right\} = -2s\left(\frac{q_k}{p_k}\frac{r_{k+1}}{p_{k+1}}+\frac{q_{k+1}}{p_{k+1}}\frac{r_{k+2}}{p_{k+2}}\right) && \text{for } s \geqq 0 \text{ and } k=1,\dots,n-2.\end{aligned}$$

Proof. We observe that for $s \geqq 0$ and $k, \ell = 1, \ldots, n$ with $k+2<\ell$,

$$
\begin{aligned}
&\frac{d}{ds}\{\det M^{k\ell}(s)\} \\
&= \sum_{j=k+1}^{\ell-1} \det \left(\begin{array}{c|c|c}

\hline
0 & \\
\vdots & M^{k+2\ \ell}(s) \\
0 &
\end{array}\right) \\
&\quad - s\frac{q_k}{p_k}\ \frac{r_{k+1}}{p_{k+1}} \det M^{k+2\ \ell}(s) - s\frac{r_\ell}{p_\ell}\ \frac{q_{\ell-1}}{p_{\ell-1}} \det M^{k\ \ell-2}(s),
\end{aligned}
$$

which yields (4.7). A direct calculation yields the desired formulas for $k+2 \geq \ell$. ☐

LEMMA 4.4.

(I) *For* $k,\ell = 1,\dots,n$ *with* $k \leqq \ell$, $\det M^{k\ell}(1) = \det \tilde{M}^{k\ell} > 0$.

(II) *There exists* $\tau > 0$ *such that*

$$\frac{d}{ds}\{\det M^{k\ell}(s)\} \leqq 0 \quad \textit{and} \quad \det M^{k\ell}(s) \geqq \det M^{k\ell}(1+\tau) > 0$$

for $s \in [0, 1+\tau]$ *and* $k,\ell = 1,\dots,n$ *with* $k \leqq \ell$.

Proof. (I) For all $j = 1,\dots,n+1$ we see that $\varphi_j < 0$ (resp., $\varphi_j > 0$) if the cone C is convex (resp., concave). Since the original assumption in section 2 yields $|\sum_{j=1}^{n+1} \varphi_j| = |\theta_A - \theta_B| < \pi$, identity (4.1) in Lemma 4.2 implies (I).

(II) First we note that $p_j > 0$ $(j = 1,\dots,n), q_j < 0$ $(j = 1,\dots,n-1)$, and $r_j < 0$ $(j = 2,\dots,n)$. We shall prove by induction.

(i) For $k = 1,\dots,n$, $\det M^{kk}(s) = 1$, so that $(d/ds)\{\det M^{kk}(s)\} = 0$ for $s \in \mathbf{R}$.

(ii) For $k = 1,\dots,n-1$, $(d/ds)\{\det M^{k\ k+1}(s)\} \leqq 0$ for $s \geqq 0$ by Lemma 4.3. By (I) with $\ell = k+1$, there exists $\tau^{k\,k+1} > 0$ such that $\det M^{k\,k+1}(s) > 0$ for $s \in [0, 1+\tau^{k\,k+1}]$.

(iii) For $k = 1,\dots,n-2, (d/ds)\{\det M^{k\ k+2}(s)\} \leq 0$ for $s \geq 0$ by Lemma 4.3. By (I) with $\ell = k+1$, there exists $\tau^{k\,k+2} > 0$ such that det $M^{k\,k+2}(s) > 0$ for $s \in [0, 1+\tau^{k\,k+2}]$.

(iv) Next we consider when $n \geqq 4$. We argue by induction on $\ell - k$. By (i)–(iii) we know (II) holds for $\ell - k \leqq 2$. Let m be $3,4,\dots,n-1$. Assume that (II) holds for $\ell - k \leqq m-1$. We shall prove (II) for $\ell - k = m$. By assumptions of the induction for $k = 1,2,\dots,\ n-(m-1)$, $i = 0,1,\dots,m-1$, there exists $\tau^{k\,k+i} > 0$ such that $\det M^{k\,k+i}(s) > 0$ for $s \in [0, 1+\tau^{k\,k+i}]$. For $k = 1,2,\dots,n-m$, identity (4.7) in Lemma 4.3 with $\ell = k+m$ yields $(d/ds)\{\det M^{k\,k+m}(s)\} \leqq 0$ for $s \in [0, 1+\hat{\tau}^{k\,k+m}]$ with $\hat{\tau}^{k\,k+m} = \min\{\min\{\tau^{kj}; j = k+1, k+2,\dots,k+m-2\}, \min\{\tau^{j\,k+m}; j = k+2, k+3,\dots,k+m-1\}\}$. By (I) with $\ell = k+m$, there exists $\tau^{k\,k+m} > 0$ such that $\det M^{k\,k+m}(s) > 0$ for $s \in [0, 1+\tau^{k\,k+m}]$. ☐

Next we shall show an inequality, which is used in the proof of Theorem 4.1. For $\mu_j > 0$ $(j = 1,\dots,n)$, $\xi_j \in \mathbf{R}$ $(j = 1,\dots,n-1)$, and $\eta_j \in \mathbf{R}$ $(j = 2,\dots,n)$, we set

$$A^{k\ell} := B^{k\ell} + \operatorname{diag}(\mu_k, \mu_{k+1},\dots,\mu_\ell),$$

$$B^{k\ell} := \begin{pmatrix} 1 & \eta_{k+1} & & & & & \mathbf{0} \\ \xi_k & 1 & \eta_{k+2} & & & & \\ & \xi_{k+1} & 1 & \eta_{k+3} & & & \\ & & \ddots & \ddots & \ddots & & \\ & & & \ddots & \ddots & \ddots & \\ & & & \xi_{\ell-3} & 1 & \eta_{\ell-1} & \\ & \mathbf{0} & & & \xi_{\ell-2} & 1 & \eta_\ell \\ & & & & & \xi_{\ell-1} & 1 \end{pmatrix}$$

for $k,\ell = 1,\dots,n$ with $k \leqq \ell$. In particular,

$$B^{kk} := (1) \qquad \text{for } k = 1,\dots,n;$$

$$B^{k\ k+1} := \begin{pmatrix} 1 & \eta_{k+1} \\ \xi_k & 1 \end{pmatrix} \qquad \text{for } k = 1,\dots,n-1 \text{ when } n \geqq 2.$$

LEMMA 4.5. *Let* k *and* ℓ *be* $1,\dots,n$ *with* $k \leqq \ell$. *If* $\det B^{pq} > 0$ *for* $p,q = k,k+1,\dots,\ell$ *with* $p \leqq q$ *then* $\det A^{k\ell} > \det B^{k\ell}$.

Proof. For $k,\ \ell = 1, \ldots, n$ with $k \leq \ell$ we set

$$C^{k\ell}(r) := B^{k\ell} + r\ \mathrm{diag}(\mu_k, \ldots, \mu_\ell) \qquad \text{for } r > 0,$$

which yields $C^{k\ell}(0) = B^{k\ell}$ and $C^{k\ell}(1) = A^{k\ell}$. We shall prove by induction on $\ell - k = 0, 1, 2, \ldots, n-1$. If $0 \leq \ell - k \leq 1$, direct calculation yields $(d/dr)\{\det C^{k\ell}(r)\} > 0$ for $r > 0$, which implies $\det C^{k\ell}(r) > \det B^{k\ell} > 0$ for $r > 0$. We assume that $k, \ell = 1, \ldots, n$ with $k + 2 \leq \ell$. Suppose that $(d/dr)\{\det C^{pq}(r)\} > 0$ for $r > 0$ and for $p, q = k, k+1, \ldots, \ell$ with $p \leq q \leq p + \ell - k - 1$. An elementary calculation yields

$$\begin{aligned}\frac{d}{dr}\det C^{k\ell}(r) &= \mu_k \cdot \det C^{k+1\ \ell}(r) + \det C^{k\ \ell-1}(r) \cdot \mu_\ell \\ &\quad + \sum_{j=k+1}^{\ell-1} \det C^{k\ j-1}(r) \cdot \mu_j \cdot \det C^{j+1\ \ell}(r) \\ &> 0 \qquad\qquad \text{for} \quad r > 0,\end{aligned}$$

since $\det C^{pq}(r) > \det C^{pq}(0) = \det B^{pq} > 0$ for $r > 0$ and for $p, q = k, k+1, \ldots, \ell$ with $p \leq q \leq p + \ell - k - 1$ by the assumption of the induction. Thus we obtain

$$\det A^{k\ell} = \det C^{k\ell}(1) > \det C^{k\ell}(0) = \det B^{k\ell}$$

for $k \leq \ell$. $\square$

Finally, we shall show the identities on a cofactor of tridiagonal matrix, which are used in the proof of Theorem 4.1. For $\lambda_j \in \mathbf{R}$ $(j = 1, \ldots, n)$, $\xi_j \in \mathbf{R}$ $(j = 2, \ldots, n)$, and $\eta_j \in \mathbf{R}$ $(j = 1, \ldots, n-1)$, we set the matrix

$$E^{k\ell} := \begin{pmatrix} \lambda_k & \xi_{k+1} & & & & & & \\ \eta_k & \lambda_{k+1} & \xi_{k+2} & & & \mathbf{0} & & \\ & \eta_{k+1} & \lambda_{k+2} & \xi_{k+3} & & & & \\ & & \ddots & \ddots & \ddots & & & \\ & & & \ddots & \ddots & \ddots & & \\ & & & & \eta_{\ell-3} & \lambda_{\ell-2} & \xi_{\ell-1} & \\ & \mathbf{0} & & & & \eta_{\ell-2} & \lambda_{\ell-1} & \xi_\ell \\ & & & & & & \eta_{\ell-1} & \lambda_\ell \end{pmatrix}$$

for $k, \ell = 1, \ldots, n$ with $k \leqq \ell$. In particular,

$$\begin{aligned} E^{kk} &:= (\lambda_k) && \text{for } k = 1, \ldots, n; \\ E^{kk+1} &:= \begin{pmatrix} \lambda_k & \eta_{k+1} \\ \eta_k & \lambda_{k+1} \end{pmatrix} && \text{for } k = 1, \ldots, n-1 \text{ when } n \geqq 2. \end{aligned}$$

Let D_{pq} be the (p, q) cofactor of the matrix E^{1n} for $p, q = 1, \ldots, n$. The next lemma is obtained by an elementary calculation.

LEMMA 4.6. *For $p, q = 1, \ldots, n$ the following identities hold.*

(I) *When $p < q$,*

$$D_{pq} = (-1)^{p+q} \prod_{j=p}^{q-1} \eta_j \det E^{1\ p-1} \det E^{q+1\ n}.$$

(II) *When* $p > q$,

$$D_{pq} = (-1)^{p+q} \prod_{j=q+1}^{p} \xi_j \det E^{1\ q-1} \det E^{p+1\ n}.$$

(III)

$$D_{pp} = \det E^{1\ p-1} \det E^{p+1\ n}.$$

Here we use the convention $\det E^{10} = 1 = \det E^{n+1\ n}$.

Proof of Theorem 4.1. (I) We set

$$Q^{k\ell}\left(s, \vec{h}^{k\ell}\right) := K^{k\ell}(s) + \operatorname{diag}\left(1/h_k^2, 1/h_{k+1}^2, \ldots, 1/h_\ell^2\right)$$

and

$$K^{k\ell}(s) := \Big(K_{ij}(s)\Big)_{i,j=k,k+1,\ldots,\ell},$$

where $(K_{ij}(s))_{i,j=1,\ldots,n}$ is the matrix $K(s)$ defined in section 3. Note that $Q^{1\,n}$ equals Q defined in section 3. Setting

$$W^{k\ell}\left(s, \vec{h}^{k\ell}\right) := M^{k\ell}(s) + \operatorname{diag}\left(\frac{1}{p_k h_k^2}, \frac{1}{p_{k+1} h_{k+1}^2}, \ldots, \frac{1}{p_\ell h_\ell^2}\right)$$

for $s \geqq 0, \vec{h}^{k\ell} = {}^{\mathrm{t}}(h_k, h_{k+1}, \ldots, h_\ell) \in (\mathbf{R}_+)^{\ell-k+1}$, and $k, \ell = 1, \ldots, n$ with $k \leqq \ell$, we have

$$\det Q^{k\ell}\left(s, \vec{h}^{k\ell}\right) = \det W^{k\ell}\left(s, \vec{h}^{k\ell}\right) \cdot \prod_{j=k}^{\ell} p_j.$$

Lemma 4.4(II) yields that there exists $\tau > 0$ such that $\det M^{pq}(s) \geqq C_{pq}$ for $s \in [0, 1+\tau]$ and $p, q = 1, \ldots, n$ with $p \leqq q$, where $C_{pq} := \det M^{pq}(1+\tau) > 0$. By Lemma 4.5 we have $\det W^{k\ell}(s, \vec{h}^{k\ell}) > \det M^{k\ell}(s)$ for $s \in [0, 1+\tau]$ and $\vec{h}^{k\ell} \in (\mathbf{R}_+)^{\ell-k+1}$. Since $p_j > 0$ $(j = 1, \ldots, n)$,

$$\det Q^{k\ell}\left(s, \vec{h}^{k\ell}\right) > C_{k\ell} \prod_{j=k}^{\ell} p_j \quad (> 0) \tag{4.8}$$

for $s \in [0, 1+\tau]$ and $\vec{h}^{k\ell} \in (\mathbf{R}_+)^{\ell-k+1}$.

(II) Part (II) follows from (I) with $k = 1$ and $\ell = n$ and the definition of Q.

(III) When $n = 1, Q(s, \vec{h})$ is a scalar and equals $\left(p_1 + 1/h_1^2\right)$, so that

$$0 < Q^{-1}(s, \vec{h}) = \left(p_1 + 1/h_1^2\right)^{-1} < 1/p_1.$$

We may assume that $n \geqq 2$. Since $Q(s, \vec{h})$ is invertible for $s \in [0, 1+\tau]$ and $\vec{h} \in (\mathbf{R}_+)^n$ by (I), the (p, q) element of the inverse matrix of $Q(s, \vec{h})$ equals $\Delta_{qp}(s, \vec{h}) / \det Q(s, \vec{h})$ for $p, q = 1, \ldots, n$, where $\Delta_{pq}(s, \vec{h})$ denotes the (p, q) cofactor of $Q(s, \vec{h})$. By Lemma

4.6 we have

$$\Delta_{pq}(s,\vec{h}) = (-1)^{p+q}\left(\prod_{j=p}^{q-1} q_j\right) s^{q-p} \det Q^{1\ p-1}(s,\vec{h}) \det Q^{q+1\ n}(s,\vec{h}) \quad \text{for} \quad p<q;$$

$$\Delta_{pq}(s,\vec{h}) = (-1)^{p+q}\left(\prod_{j=q+1}^{p} r_j\right) s^{p-q} \det Q^{1\ q-1}(s,\vec{h}) \det Q^{p+1\ n}(s,\vec{h}) \quad \text{for} \quad p>q;$$

$$\Delta_{pp}(s,\vec{h}) = \det Q^{1\ p-1}(s,\vec{h}) \det Q^{p+1\ n}(s,\vec{h})$$

for $s \geqq 0$ and $\vec{h} \in (\mathbf{R}_+)^n$. Here we use the convention

$$\det Q^{10}(s,\vec{h}) = 1 = \det Q^{n+1\ n}(s,\vec{h}).$$

Since $q_j < 0$ $(j = 1,\ldots,n-1)$ and $r_j < 0$ $(j = 2,\ldots,n)$, inequality (4.8) yields $\Delta_{pq}(s,\vec{h}) \geqq 0$ for $s \in [0, 1+\tau]$, $\vec{h} \in (\mathbf{R}_+)^n$ and $p,q = 1,\ldots,n$, which implies $\{(p,q)$ element of $Q^{-1}(s,\vec{h})\} = \Delta_{qp}(s,\vec{h})/\det Q(s,\vec{h}) \geqq 0$ by (I). On the other hand, $\Delta_{pq}(s,\vec{h})$ is bounded from the above for $s \in [0,1+\tau]$ and $\vec{h} = (h_1,\ldots,h_n) \in (\mathbf{R}_+)^n$ with $\vec{h} \geq \vec{h}^\sharp$, since $\Delta_{pq}(s,\vec{h})$ is a polynomial of $1/h_1^2,\ldots,1/h_n^2$ and s. Thus (I) yields that there exists $C_5 > 0$ such that $\Delta_{pq}(s,\vec{h})/\det Q(s,\vec{h}) \leqq C_5$ for $s \in [0,1+\tau], \vec{h} \in (\mathbf{R}_+)^n$ with $\vec{h} \geq \vec{h}^\sharp$ and $p,q = 1,\ldots,n$. $\square$

EULERIAN CALCULUS FOR THE CONTRACTION IN THE WASSERSTEIN DISTANCE*

FELIX OTTO† AND MICHAEL WESTDICKENBERG†

Abstract. We consider the porous medium equation on a compact Riemannian manifold and give a new proof of the contraction of its semigroup in the Wasserstein distance. This proof is based on the insight that the porous medium equation does not increase the size of infinitesimal perturbations along gradient flow trajectories and on an Eulerian formulation for the Wasserstein distance using smooth curves. Our approach avoids the existence result for optimal transport maps on Riemannian manifolds.

Key words. porous medium equation, contraction, Wasserstein distance

1. Introduction.

In this paper we consider the porous medium equation

$$\partial_t \rho - \Delta U(\rho) = 0 \tag{1.1}$$

and give an entirely "Eulerian" argument for the contraction of its semigroup in the Wasserstein distance. The argument is guided by the formal gradient flow structure of the porous medium equation proposed in [12].

More precisely, we choose as our state space $\mathcal{M}$ the space of probability measures $\rho(x)\,dx$, endowed with a suitable metric tensor g; see section 2.2. The metric tensor g induces a distance on $(\mathcal{M}, g)$ that coincides with the Wasserstein distance $\mathcal{W}(\rho_0, \rho_1)$. Loosely speaking, this equivalence is a consequence of the Benamou–Brenier Eulerian formulation of the optimal transportation problem defining $\mathcal{W}(\rho_0, \rho_1)$ [4]. Then the porous medium equation is the gradient flow on $(\mathcal{M}, g)$ of the functional

$$E(\rho) = \int e(\rho)\,dx, \tag{1.2}$$

where the "osmotic pressure" $U(\rho)$ is related to the energy density $e(\rho)$ via

$$U(\rho) = \rho e'(\rho) - e(\rho) \quad \text{for } \rho \geqslant 0. \tag{1.3}$$

We notice that U is (strictly) monotone if and only if e is (strictly) convex and that for strictly monotone U, (1.1) is of parabolic type. The contraction property for the porous medium semigroup then follows from the convexity of E on $(\mathcal{M}, g)$. The latter is a reformulation of McCann's displacement convexity [10].

This formal argument has been made rigorous in [12] using the fact that for any two points ρ_0, ρ_1 a shortest curve with respect to $\mathcal{W}$ exists. The existence of these shortest curves relies on Brenier's result [5] on the existence of a one-to-one optimal

transport map $y = \Phi(x)$ between two measures $\rho_0(x)\,dx$ and $\rho_1(y)\,dy$. This can be seen as a Lagrangian approach. It is somewhat delicate since the optimal transport map Φ can be nonsmooth even if the densities ρ_0 and ρ_1 are smooth.

In this paper, we carry out a rigorous Eulerian approach based on the new insight

- that the porous medium equation does not increase the naturally defined action $\mathcal{A}(\rho)$ of *smooth* curves $[0,1] \ni s \mapsto \rho(s) \in \mathcal{M}$ (see Proposition 4.2);
- that the squared Wasserstein distance $\frac{1}{2}\mathcal{W}(\rho_0,\rho_1)^2$ is the infimum of $\mathcal{A}(\rho)$ over smooth curves connecting ρ_0 to ρ_1 (see Proposition 4.3).

Hence we can work in the "class of smooth objects." Alternatively, contraction estimates can also be derived in more elaborate frameworks based on metric space theory. We refer the reader to the recent publications [6, 1] for further information.

Our approach allows us to obtain the contraction property on a compact Riemannian manifold $\mathbb{M}^n$ (instead of $\mathbb{R}^n$) without additional effort. A sufficient condition is that the Ricci curvature of $\mathbb{M}^n$ be nonnegative. This is the well-known Bakry–Emery criterion for the logarithmic Sobolev inequality [3] (which can be refined using Γ_2-calculus [2]). It turns out that contractivity of the semigroup for certain nonlinear evolution equations is in fact equivalent to lower bounds for the Ricci curvature. This has been proved for the heat semigroup in [17] and more generally in [16]. Our Eulerian approach avoids the subtle existence result for optimal transport maps Φ on Riemannian manifolds by McCann [11].

2. Gradient flows. It is instructive to discuss our approach in the language of gradient flows. This heuristics will serve as a guideline for the rigorous argument.

2.1. Abstract framework. Let us quickly recall the mathematical structure required for a gradient flow. One first needs a smooth function $\mathcal{M} \ni \rho \mapsto E(\rho)$ on a differentiable manifold $\mathcal{M}$. The differential $\operatorname{diff} E$ of E is a cotangent vector field:

$$\mathcal{M} \ni \rho \mapsto \operatorname{diff} E_{|\rho} \in T_\rho\mathcal{M}^*.$$

Therefore one also needs a metric tensor g on $\mathcal{M}$, i.e., a scalar product g_ρ on $T_\rho\mathcal{M}$ in every point $\rho \in \mathcal{M}$. This scalar product allows one to identify cotangent with tangent vectors, yielding the gradient vector field $\operatorname{grad} E$. The gradient flow of E on the Riemannian manifold $(\mathcal{M}, g)$ is then given by the dynamical system

$$\frac{d\rho}{dt} = -\operatorname{grad} E_{|\rho}. \tag{2.1}$$

For subsequent use, we shall reformulate (2.1). We recall that the differential $\operatorname{diff} E$ can be inferred from differentiating E along a curve $[0,1] \ni s \mapsto \rho(s) \in \mathcal{M}$:

$$\frac{d}{ds}E\big(\rho(s)\big) = \left\langle \operatorname{diff} E_{|\rho(s)},\, \frac{d\rho}{ds}(s)\right\rangle.$$

Then the gradient $\operatorname{grad} E$ is defined by the requirement that for any tangent vector field $[0,1] \ni s \mapsto \delta\rho(s) \in T_{\rho(s)}\mathcal{M}$ along the above curve we have

$$g_{\rho(s)}\big(\operatorname{grad} E_{|\rho(s)},\, \delta\rho(s)\big) = \big\langle \operatorname{diff} E_{|\rho(s)},\, \delta\rho(s)\big\rangle.$$

Now a trajectory $[0,\infty) \ni t \mapsto \rho(t) \in \mathcal{M}$ of (2.1) is characterized by the fact that for any tangent vector field $[0,\infty) \ni t \mapsto \delta\rho(t) \in T_{\rho(t)}\mathcal{M}$ one has

$$g_{\rho(t)}\left(\frac{d\rho}{dt}(t),\, \delta\rho(t)\right) + \big\langle \operatorname{diff} E_{|\rho(t)},\, \delta\rho(t)\big\rangle = 0 \quad \forall\, t. \tag{2.2}$$

2.2. Heuristics: The porous medium equation as gradient flow. We are interested in the porous medium equation on a compact, connected Riemannian manifold $\mathbb{M}^n$ without boundary. We denote by $\cdot$ the metric tensor on $\mathbb{M}^n$ and by ∇, $\nabla\cdot$, and $\Delta = \nabla\cdot\nabla$ the gradient, divergence, and Laplacian on $\mathbb{M}^n$. Finally, dx denotes the volume form on $\mathbb{M}^n$; without loss of generality we assume $\int_{\mathbb{M}^n} 1\,dx = 1$. The porous medium equation describes the evolution of a nonnegative density $\rho(t,x)$ on $\mathbb{M}^n$. It is given by the nonlinear diffusion equation

$$\partial_t \rho - \Delta U(\rho) = 0. \tag{2.3}$$

The porous medium equation preserves the total mass, and we assume $\int_{\mathbb{M}^n} \rho\,dx = 1$ for definiteness. In view of this, our state space $\mathcal{M}$ is the space of all nonnegative functions $\rho\colon \mathbb{M}^n \to [0,\infty)$ with unit integral:

$$\int_{\mathbb{M}^n} \rho\,dx = 1. \tag{2.4}$$

We also may think of $\mathcal{M}$ as the space of probability measures $\rho(x)\,dx$ on $\mathbb{M}^n$. For convenience we will not distinguish in the following between functions and the measures they induce via the volume element dx defined on $\mathbb{M}^n$.

Following [12], we now introduce the metric tensor g on $\mathcal{M}$. Notice that in view of (2.4) we may think of infinitesimal perturbations $\delta\rho \in T_\rho\mathcal{M}$ of a state $\rho\in\mathcal{M}$ as functions $\delta\rho\colon \mathbb{M}^n \to \mathbb{R}$ with

$$\int_{\mathbb{M}^n} \delta\rho\,dx = 0. \tag{2.5}$$

For given $\rho\in\mathcal{M}$ we define the scalar product g_ρ on $T_\rho\mathcal{M}$ as

$$g_\rho\big(\delta\rho_0,\, \delta\rho_1\big) = \int_{\mathbb{M}^n} \nabla\phi_0\cdot\nabla\phi_1\,\rho\,dx, \tag{2.6}$$

where, up to additive constants, the functions $\phi_i\colon \mathbb{M}^n \to \mathbb{R}$ are defined by

$$\delta\rho_i - \nabla\cdot(\rho\nabla\phi_i) = 0. \tag{2.7}$$

Notice that (2.7) constitutes an elliptic equation with variable coefficient $\rho \geqslant 0$ for ϕ_i; (2.5) is necessary for the existence. If ρ is strictly positive and $\rho, \delta\rho_i$ are smooth, then (2.5) is also sufficient for the existence of a smooth solution ϕ_i. For later use we notice that $g_\rho(\delta\rho_0, \delta\rho_1)$ can be rewritten as

$$g_\rho\big(\delta\rho_0,\, \delta\rho_1\big) = -\int_{\mathbb{M}^n} \delta\rho_0\,\phi_1\,dx. \tag{2.8}$$

The quadratic part of the metric tensor can also be characterized variationally:

$$\tfrac12 g_\rho\big(\delta\rho,\, \delta\rho\big) = \sup_\phi \Big\{ -\int_{\mathbb{M}^n} \tfrac12|\nabla\phi|^2\rho\,dx - \int_{\mathbb{M}^n} \delta\rho\,\phi\,dx \Big\}, \tag{2.9}$$

where the sup is taken over all smooth functions $\phi\colon \mathbb{M}^n \longrightarrow \mathbb{R}$. In view of (2.7), we may think of ϕ_i as the "velocity potential" that generates the infinitesimal change $\delta\rho_i$ of the density ρ.

We now formally argue that (2.3) is indeed the gradient flow of (1.2) on $(\mathcal{M}, g)$, reproducing the argument in [12]. We are given a nonnegative function $\rho = \rho(t,x)$

satisfying (2.4); we fix a time t. Let the function $\delta\rho$ of x be given with (2.5), and let ϕ be related to $\delta\rho$ by (2.7). Then we have, on the one hand, that

$$\begin{aligned} \left\langle \operatorname{diff} E_{|\rho}, \delta\rho \right\rangle &= \int_{\mathbb{M}^n} e'(\rho)\, \delta\rho\, dx \\ &\overset{(2.7)}{=} -\int_{\mathbb{M}^n} e''(\rho)\nabla\rho\cdot\rho\nabla\phi\, dx \\ &\overset{(1.3)}{=} -\int_{\mathbb{M}^n} \nabla U(\rho)\cdot\nabla\phi\, dx \\ &= \int_{\mathbb{M}^n} \Delta U(\rho)\,\phi\, dx. \end{aligned} \tag{2.10}$$

On the other hand, we have according to (2.8)

$$g_\rho\big(\partial_t\rho,\, \delta\rho\big) = -\int_{\mathbb{M}^n} \partial_t\rho\,\phi\, dx.$$

The combination of the last two identities gives, for any $\delta\rho$ satisfying (2.5),

$$g_\rho\big(\partial_t\rho,\, \delta\rho\big) + \left\langle \operatorname{diff} E_{|\rho}, \delta\rho \right\rangle = -\int_{\mathbb{M}^n} \big(\partial_t\rho - \Delta U(\rho)\big)\,\phi\, dx.$$

In view of (2.2), this proves that indeed (2.3) is the gradient flow of (1.2) with respect to the metric tensor (2.6) defined on $\mathcal{M}$.

3. Convexity and contraction. In this section we discuss heuristically how the convexity of E on $(\mathcal{M}, g)$ implies contraction for the gradient flow.

3.1. Abstract framework. Recall that a function E on a Riemannian manifold $(\mathcal{M}, g)$ is convex if its Hessian $\operatorname{Hess} E$ is positive definite in any point $\rho \in \mathcal{M}$, i.e.,

$$g_\rho\Big(\delta\rho,\, \operatorname{Hess} E_{|\rho}\,\delta\rho\Big) \geqslant 0 \quad \forall\ \delta\rho \in T_\rho\mathcal{M} \text{ and } \rho\in\mathcal{M}.$$

In an infinite-dimensional context, it is convenient to have alternative ways of probing convexity. We mention two possibilities:

- The standard way to probe convexity is by geodesics: If $[0,1] \ni s \mapsto \rho(s) \in \mathcal{M}$ is a geodesic, i.e., any curve for which

$$\frac{D}{ds}\frac{d\rho}{ds} = 0,$$

  where $\frac{D}{ds}$ denotes the covariant derivative along $s \mapsto \rho(s)$, then we have

$$\frac{d^2}{ds^2}\, E\big(\rho(s)\big) \geqslant 0.$$

  Indeed, this follows from the chain rule

$$\begin{aligned} \frac{d^2}{ds^2}\, E\big(\rho(s)\big) &= \frac{d}{ds}\, g_\rho\left(\frac{d\rho}{ds},\, \operatorname{grad} E_{|\rho}\right) \\ &= g_\rho\left(\frac{d\rho}{ds},\, \operatorname{Hess} E_{|\rho}\,\frac{d\rho}{ds}\right) + g_\rho\left(\frac{D}{ds}\frac{d\rho}{ds},\, \operatorname{grad} E_{|\rho}\right) \\ &= g_\rho\left(\frac{d\rho}{ds},\, \operatorname{Hess} E_{|\rho}\,\frac{d\rho}{ds}\right). \end{aligned} \tag{3.1}$$

- There is another way to probe convexity of E: For any gradient flow trajectory $[0,\infty) \ni t \mapsto \rho(t) \in \mathcal{M}$, i.e., any curve for which

  $$\frac{d\rho}{dt} = -\operatorname{grad} E_{|\rho},$$

  and any infinitesimal perturbation $[0,\infty) \ni t \mapsto \delta\rho(t) \in T_{\rho(t)}\mathcal{M}$ along this curve for which by the chain rule

  $$\frac{D}{dt}\,\delta\rho = -\operatorname{Hess} E_{|\rho}\,\delta\rho, \tag{3.2}$$

  we have that the size of this perturbation does not increase over time:

  $$\frac{d}{dt}\,\tfrac{1}{2} g_\rho\big(\delta\rho,\,\delta\rho\big) \leqslant 0. \tag{3.3}$$

  Indeed, this follows from

  $$\frac{d}{dt}\,\tfrac{1}{2} g_\rho\big(\delta\rho,\,\delta\rho\big) = g_\rho\left(\delta\rho,\,\frac{D}{dt}\,\delta\rho\right) = -g_\rho\Big(\delta\rho,\,\operatorname{Hess} E_{|\rho}\,\delta\rho\Big). \tag{3.4}$$

The property (3.3) has a finite counterpart: Recall that the distance $\operatorname{dist}(\rho_0,\rho_1)$ between $\rho_0,\rho_1 \in \mathcal{M}$ induced by the metric tensor g is defined by

$$\tfrac{1}{2}\operatorname{dist}(\rho_0,\rho_1)^2 = \inf\left\{\mathcal{A}(\rho)\,\middle|\,[0,1]\ni s\mapsto \rho(s)\in\mathcal{M},\ \left\{\begin{array}{l}\rho(0,\cdot)=\rho_0\\ \rho(1,\cdot)=\rho_1\end{array}\right\}\right\}, \tag{3.5}$$

where $\mathcal{A}(\rho)$ is the natural action of a curve, i.e.,

$$\mathcal{A}(\rho) := \int_0^1 \tfrac{1}{2} g_\rho\left(\frac{d\rho}{ds},\frac{d\rho}{ds}\right) ds. \tag{3.6}$$

We now argue that (3.3) easily yields a global consequence of the convexity of E: The gradient flow of E is a contraction in dist. This means that for any two gradient flow trajectories $[0,\infty) \ni t \mapsto \rho_i(t) \in \mathcal{M}$, $i=0,1$, i.e., any curves with

$$\frac{d\rho_i}{dt} = -\operatorname{grad} E_{|\rho_i},$$

we have

$$\operatorname{dist}(\rho_0,\rho_1) \quad \text{is nonincreasing in } t.$$

Indeed, by translational invariance in time, it is enough to show that

$$\tfrac{1}{2}\operatorname{dist}\big(\rho_0(t),\rho_1(t)\big)^2 \leqslant \tfrac{1}{2}\operatorname{dist}\big(\rho_0(0),\rho_1(0)\big)^2 \quad \forall\, t \geqslant 0. \tag{3.7}$$

According to (3.5), for given $\epsilon > 0$, there exists a curve $[0,1] \ni s \mapsto \bar\rho(s) \in \mathcal{M}$ such that $\bar\rho(s=0) = \rho_0(t=0)$ and $\bar\rho(s=1) = \rho_1(t=0)$, with

$$\tfrac{1}{2}\operatorname{dist}\big(\rho_0(0),\rho_1(0)\big)^2 = \tfrac{1}{2}\operatorname{dist}\big(\bar\rho(0),\bar\rho(1)\big)^2 \geqslant \mathcal{A}(\bar\rho) - \epsilon. \tag{3.8}$$

Now for every $s \in [0,1]$ let $[0,\infty) \ni t \mapsto \rho(s,t) \in \mathcal{M}$ denote the solution of

$$\frac{d\rho(s,\cdot)}{dt} = -\operatorname{grad} E_{|\rho(s,\cdot)}, \tag{3.9}$$

with $\rho(s,0)=\bar\rho(s)$. Notice that then $\rho(0,t)=\rho_0(t)$ and $\rho(1,t)=\rho_1(t)$ so that

$$\tfrac12 \operatorname{dist}\big(\rho_0(t),\rho_1(t)\big)^2 \leqslant \mathcal{A}\big(\rho(\cdot,t)\big). \tag{3.10}$$

Taking the covariant derivative of (3.9) with respect to s yields

$$\frac{D}{\partial t}\frac{\partial\rho}{\partial s}=\frac{D}{\partial s}\frac{\partial\rho}{\partial t}=-\operatorname{Hess}E_{|\rho}\frac{\partial\rho}{\partial s}.$$

Thus we obtain from (3.3) applied to $\delta\rho=\frac{\partial\rho}{\partial s}$

$$\frac{\partial}{\partial t}\,\tfrac12 g_\rho\left(\frac{\partial\rho}{\partial s},\frac{\partial\rho}{\partial s}\right)\leqslant 0.$$

Integration over s yields

$$\frac{d}{dt}\mathcal{A}\big(\rho(\cdot,t)\big)=\int_0^1\frac{\partial}{\partial t}\,\tfrac12 g_\rho\left(\frac{\partial\rho}{\partial s},\frac{\partial\rho}{\partial s}\right)ds\leqslant 0.$$

Integration over t yields

$$\mathcal{A}\big(\rho(\cdot,t)\big)\leqslant\mathcal{A}\big(\rho(\cdot,0)\big).$$

Together with (3.10) and (3.8) we therefore end up with

$$\tfrac12 \operatorname{dist}\big(\rho_0(t),\rho_1(t)\big)^2\leqslant\tfrac12 \operatorname{dist}\big(\rho_0(0),\rho_1(0)\big)^2+\epsilon,$$

and since $\epsilon>0$ was arbitrary, (3.7) is proved.

Remark 3.1 (added in proof). It is possible to give an argument in favor of

$$\frac{\partial}{\partial t}\,\tfrac12 g_\rho\left(\frac{\partial\rho}{\partial s},\frac{\partial\rho}{\partial s}\right)=-g_\rho\left(\frac{\partial\rho}{\partial s},\operatorname{Hess}E_{|\rho}\frac{\partial\rho}{\partial s}\right) \tag{3.11}$$

that avoids using the covariant derivative altogether: Consider first a family of curves $[0,1]\ni s\mapsto\tilde\rho(s,t)\in\mathcal{M}$ for $t\in[0,\infty)$ such that $s\mapsto\tilde\rho(s,0)$ is a geodesic. Then

$$\frac{\partial}{\partial t}\,\tfrac12 g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s},\frac{\partial\tilde\rho}{\partial s}\right)=\frac{\partial}{\partial s}\,g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s},\frac{\partial\tilde\rho}{\partial t}\right)\quad\text{for } t=0. \tag{3.12}$$

Indeed, given any function $[0,1]\ni s\mapsto\alpha(s)\in\mathbb{R}$ with $\alpha(0)=\alpha(1)=0$ let

$$\hat\rho(s,t):=\tilde\rho\big(s,\alpha(s)t\big)\quad\forall\ s,t.$$

Since $\hat\rho(0,t)=\tilde\rho(0,0)$ and $\hat\rho(1,t)=\tilde\rho(1,0)$, the definition of geodesic yields

$$0=\frac{d}{dt}_{|t=0}\int_0^1\tfrac12 g_{\hat\rho}\left(\frac{\partial\hat\rho}{\partial s},\frac{\partial\hat\rho}{\partial s}\right)ds=\int_0^1\frac{\partial}{\partial t}_{|t=0}\tfrac12 g_{\hat\rho}\left(\frac{\partial\hat\rho}{\partial s},\frac{\partial\hat\rho}{\partial s}\right)ds. \tag{3.13}$$

On the other hand, we have $\frac{\partial\hat\rho}{\partial s}(s,t)=\frac{\partial\tilde\rho}{\partial s}(s,\alpha(s)t)+\alpha'(s)t\,\frac{\partial\tilde\rho}{\partial t}(s,\alpha(s)t)$, and therefore

$$\begin{aligned}\left[\tfrac12 g_{\hat\rho}\left(\frac{\partial\hat\rho}{\partial s},\frac{\partial\hat\rho}{\partial s}\right)\right](s,t)&=\left[\tfrac12 g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s},\frac{\partial\tilde\rho}{\partial s}\right)\right]\big(s,\alpha(s)t\big)\\&\quad+\alpha'(s)t\left[g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s},\frac{\partial\tilde\rho}{\partial t}\right)\right]\big(s,\alpha(s)t\big)\\&\quad+\tfrac12\big(\alpha'(s)t\big)^2\left[g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial t},\frac{\partial\tilde\rho}{\partial t}\right)\right]\big(s,\alpha(s)t\big).\end{aligned}$$

Using this identity in (3.13) then gives

$$\begin{aligned} 0 &= \int_0^1 \alpha \,\frac{\partial}{\partial t}_{|t=0} \tfrac{1}{2} g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s}, \frac{\partial\tilde\rho}{\partial s}\right) ds + \int_0^1 \alpha' \, g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s}, \frac{\partial\tilde\rho}{\partial t}\right)_{|t=0} ds \\ &= \int_0^1 \alpha \left\{ \frac{\partial}{\partial t} \,\tfrac{1}{2} g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s}, \frac{\partial\tilde\rho}{\partial s}\right) - \frac{\partial}{\partial s}\, g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s}, \frac{\partial\tilde\rho}{\partial t}\right)\right\}_{|t=0} ds. \end{aligned}$$

This proves (3.12) because α was arbitrary. Consider now the family of gradient flows $\rho = \rho(s,\cdot)$ satisfying (3.9). For any $s_0 \in [0,1]$ there exists a map $\tilde\rho$ such that

$$\left\{ \begin{array}{c} [0,1] \ni s \mapsto \tilde\rho(s,t) \text{ is a geodesic} \\ \tilde\rho(s_0,t) = \rho(s_0,t) \\ \frac{\partial\tilde\rho}{\partial s}(s_0,t) = \frac{\partial\rho}{\partial s}(s_0,t) \end{array} \right\} \quad \forall\, t \in [0,\infty). \tag{3.14}$$

At $s = s_0$ we then find

$$\begin{aligned} \frac{\partial}{\partial t}\,\tfrac{1}{2} g_\rho\left(\frac{\partial\rho}{\partial s}, \frac{\partial\rho}{\partial s}\right) \overset{(3.14)}{=} \frac{\partial}{\partial t}\,\tfrac{1}{2} g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s}, \frac{\partial\tilde\rho}{\partial s}\right) &\overset{(3.12)}{=} \frac{\partial}{\partial s}\, g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s}, \frac{\partial\tilde\rho}{\partial t}\right) \\ &\overset{(3.14)}{=} \frac{\partial}{\partial s}\, g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s}, \frac{\partial\rho}{\partial t}\right) \\ &\overset{(2.2)}{=} \frac{\partial}{\partial s}\left[- \left\langle \operatorname{diff} E_{|\rho}, \frac{\partial\tilde\rho}{\partial s}\right\rangle\right] \\ &\overset{(3.14)}{=} \frac{\partial}{\partial s}\left[- \left\langle \operatorname{diff} E_{|\tilde\rho}, \frac{\partial\tilde\rho}{\partial s}\right\rangle\right] = -\frac{\partial^2}{\partial s^2} E(\tilde\rho). \end{aligned}$$

By definition of the Hessian, we have

$$\frac{\partial^2}{\partial s^2} E(\tilde\rho) = g_{\tilde\rho}\left(\frac{\partial\tilde\rho}{\partial s}, \operatorname{Hess} E_{|\tilde\rho} \frac{\partial\tilde\rho}{\partial s}\right) \overset{(3.14)}{=} g_\rho\left(\frac{\partial\rho}{\partial s}, \operatorname{Hess} E_{|\rho} \frac{\partial\rho}{\partial s}\right),$$

and (3.11) follows.

3.2. Heuristics: Convexity and induced metric. In this section we show heuristically how the abstract framework of the previous section yields a contraction property in the Wasserstein distance for the porous medium equation. This argument will be made rigorous in the remainder of the paper.

We recall the heuristic argument for the convexity of E on $(\mathcal{M}, g)$ for which we probe the convexity along geodesics. Therefore we start by heuristically deriving the equation for geodesics, essentially reproducing [13]. An alternative heuristic derivation can be found in [12]. Notice first that within the abstract framework, the geodesic equation is the Euler–Lagrange equation (i.e., the first variation) of the action functional (3.6). In view of (2.6), our action functional for a curve in $\mathcal{M}$, i.e., for a function $\rho\colon [0,1] \times \mathbb{M}^n \to [0,\infty)$ with $\int_{\mathbb{M}^n} \rho(s,x)\,dx = 1$ for all $s \in [0,1]$, takes the form

$$\mathcal{A}(\rho) = \iint_{[0,1]\times\mathbb{M}^n} \tfrac{1}{2} |\nabla\phi|^2 \,\rho \,dx\,ds, \tag{3.15}$$

where the function $\phi\colon [0,1] \times \mathbb{M}^n \to \mathbb{R}$ is determined by

$$\partial_s \rho - \nabla \cdot (\rho \nabla \phi) = 0 \tag{3.16}$$

and plays the role of the tangent vector field along the curve. Like for the metric tensor itself (cf. (2.9)), the action functional can be written variationally:

$$\begin{aligned}\mathcal{A}(\rho) &= \sup_\phi \bigg\{ -\iint_{[0,1]\times\mathbb{M}^n} \tfrac{1}{2}|\nabla\phi|^2 \,\rho\, dx\, ds - \iint_{[0,1]\times\mathbb{M}^n} \phi\, \partial_s \rho\, dx\, ds \bigg\} \\ &= \sup_\phi \bigg\{ -\iint_{[0,1]\times\mathbb{M}^n} \tfrac{1}{2}|\nabla\phi|^2 \,\rho\, dx\, ds + \iint_{[0,1]\times\mathbb{M}^n} \partial_s\phi\, \rho\, dx\, ds \\ &\qquad + \int_{\mathbb{M}^n} \phi(0,x)\, \rho_0(x)\, dx - \int_{\mathbb{M}^n} \phi(1,x)\, \rho_1(x)\, dx \bigg\},\end{aligned} \tag{3.17}$$

where the sup is taken over all smooth functions $\phi\colon [0,1]\times\mathbb{M}^n \to \mathbb{R}$. Here ρ_0, ρ_1 are the fixed endpoints of the curve; i.e., we have

$$\rho(0,\cdot) = \rho_0 \quad \text{and} \quad \rho(1,\cdot) = \rho_1. \tag{3.18}$$

To obtain the induced distance in $\mathcal{M}$, the expression (3.17) needs to be minimized over all functions $\rho\colon [0,1]\times\mathbb{M}^n \to [0,\infty)$ with $\int_{\mathbb{M}^n} \rho(\cdot,x)\,dx = 1$; see (3.5). In fact, we may think of minimizing (3.17) over all functions $\rho\colon [0,1]\times\mathbb{M}^n \to \mathbb{R}$ because (3.17) is $+\infty$ if (3.16) or (3.18) is violated. Maximizing in ϕ and minimizing in ρ amounts to a saddle-point problem. The first variation in ϕ is given by (3.16) and (3.18). The first variation in ρ is given by the Hamilton–Jacobi equation

$$\partial_s \phi - \tfrac{1}{2}|\nabla\phi|^2 = 0. \tag{3.19}$$

Hence the combination of the transport equation (3.16) and the Hamilton–Jacobi equation (3.19) forms the geodesic equation. Note that the system (3.16) and (3.19) is of hyperbolic nature as a partial differential equation. The velocity $u = -\nabla\phi$ satisfies the "pressureless Euler equation"

$$\frac{D}{ds} u + Du\, u = 0,$$

and thus the flow $\partial_s \Phi = u \circ \Phi$ consists of geodesic trajectories, i.e., $\frac{D}{ds}\frac{\partial}{\partial s}\Phi = 0$. Notice that (3.16) states that $\rho(s,\cdot)$ is the push-forward of $\rho(s=0)$ under $\Phi(s,\cdot)$. This is what we call the Lagrangian approach. Geodesics in the sense of shortest curves were given a rigorous meaning for a Riemannian manifold $\mathbb{M}^n$ in [11].

Having identified the geodesic equation, we can probe the convexity of (1.2) along geodesics. This was first done in the Lagrangian framework in [10] and gave rise to the notion of displacement convexity. We reproduce the heuristic Eulerian argument from [13]. Let $\rho\colon [0,1]\times\mathbb{M}^n \to [0,\infty)$ be a geodesic with tangent field $\phi\colon [0,1]\times\mathbb{M}^n \to \mathbb{R}$; i.e., let (3.16) and (3.19) be satisfied. As in (2.10), we find for the first derivative

$$\frac{dE}{ds} = \int_{\mathbb{M}^n} \Delta U(\rho)\, \phi\, dx = \int_{\mathbb{M}^n} U(\rho)\, \Delta\phi\, dx.$$

For the second derivative, we obtain

$$\begin{aligned}
\frac{d^2E}{ds^2} &= \int_{\mathbb{M}^n} \Big(U'(\rho)\,\partial_s\rho\,\Delta\phi + U(\rho)\,\Delta\partial_s\phi\Big)\,dx \\
&\overset{(3.16)}{\underset{(3.19)}{=}} \int_{\mathbb{M}^n} \Big(U'(\rho)\,\nabla\cdot(\rho\nabla\phi)\,\Delta\phi + U(\rho)\,\Delta\tfrac{1}{2}|\nabla\phi|^2\Big)\,dx \\
&= \int_{\mathbb{M}^n} \Big(\rho U'(\rho)\,(\Delta\phi)^2 + \nabla U(\rho)\cdot\nabla\phi\,\Delta\phi + U(\rho)\,\Delta\tfrac{1}{2}|\nabla\phi|^2\Big)\,dx \\
&= \int_{\mathbb{M}^n} \Big(\rho U'(\rho)\,(\Delta\phi)^2 + U(\rho)\Big(-\nabla\cdot(\nabla\phi\,\Delta\phi) + \Delta\tfrac{1}{2}|\nabla\phi|^2\Big)\Big)\,dx \\
&= \int_{\mathbb{M}^n} \Big(\Big(\rho U'(\rho) - U(\rho)\Big)(\Delta\phi)^2 + U(\rho)\Big(-\nabla\phi\cdot\nabla\Delta\phi + \Delta\tfrac{1}{2}|\nabla\phi|^2\Big)\Big)\,dx.
\end{aligned}$$

We appeal to Bochner's formula (see [14]):

$$-\nabla\phi\cdot\nabla\Delta\phi + \Delta\tfrac{1}{2}|\nabla\phi|^2 = |\mathrm{D}^2\phi|^2 + \nabla\phi\cdot\mathrm{Ric}\,\nabla\phi,$$

where $\mathrm{D}^2\phi$ denotes the Hessian of ϕ, $|A|^2$ stands for the trace of A^tA, and Ric denotes the Ricci curvature of $\mathbb{M}^n$. We thus obtain the formula

$$\frac{d^2E}{ds^2} = \int_{\mathbb{M}^n} \Big(\Big(\rho U'(\rho) - U(\rho)\Big)(\Delta\phi)^2 + U(\rho)\Big(|\mathrm{D}^2\phi|^2 + \nabla\phi\cdot\mathrm{Ric}\,\nabla\phi\Big)\Big)\,dx. \tag{3.20}$$

In view of (3.1), the right-hand side of (3.20) can be understood as the quadratic part of the Hessian of E in the direction of the infinitesimal variation $\delta\rho = \nabla\cdot(\rho\nabla\phi)$. We notice that it is nonnegative for all functions $\rho \geqslant 0$ and ϕ if and only if

$$\rho U'(\rho) \geqslant \big(1 - \tfrac{1}{n}\big)U(\rho) \geqslant 0 \quad \text{and} \quad \mathrm{Ric}(x) \geqslant 0 \quad \forall\ x \in \mathbb{M}^n$$

because $(\Delta\phi)^2 \leqslant n|\mathrm{D}^2\phi|^2$. The convexity of E along geodesics in the Riemannian case $\mathbb{M}^n$ was given a rigorous meaning in [7].

To conclude, it remains only to prove that (3.5) with (3.15) and (3.16) coincides with $\frac{1}{2}\mathcal{W}^2(\rho_0, \rho_1)$. Recall that for $\rho_0, \rho_1 \in \mathrm{Prob}(\mathbb{M}^n)$, $\mathcal{W}^2(\rho_0, \rho_1)$ is defined as

$$\inf\left\{ \iint_{\mathbb{M}^n\times\mathbb{M}^n} d(x,y)^2\,d\pi(x,y) \;\middle|\; \begin{array}{l} \pi \in \mathrm{Prob}(\mathbb{M}^n\times\mathbb{M}^n), \\ \displaystyle\int_{\mathbb{M}^n} d\pi(\cdot,y) = \rho_0, \int_{\mathbb{M}^n} d\pi(x,\cdot) = \rho_1 \end{array} \right\};$$

cf. [18]. Several heuristic arguments are possible here (cf. [12] and [13]). However, the rigorous proof we provide in the next section is no more difficult than a heuristic one; therefore we refer the reader to Proposition 4.3.

4. Rigorous result: Contraction. We recall that $\mathbb{M}^n$ is a compact connected Riemannian manifold without boundary, with geodesic distance d and $\int_{\mathbb{M}^n} 1\,dx = 1$.

Here is our main result.

THEOREM 4.1 (contraction estimate). *Assume that $\rho U'(\rho) \geqslant \big(1 - \frac{1}{n}\big)U(\rho) \geqslant 0$ for all $\rho \geqslant 0$ and that $\mathrm{Ric}(x) \geqslant 0$ for all $x \in \mathbb{M}^n$. For nonnegative initial data $\bar\rho_0, \bar\rho_1$ with $\int_{\mathbb{M}^n} \bar\rho_i\,dx = 1$ consider solutions ρ_i of the porous medium equation*

$$\left.\begin{array}{r} \partial_t\rho_i - \Delta U(\rho_i) = 0 \\ \rho_i(t=0) = \bar\rho_i \end{array}\right\} \quad \textit{for } i = 0, 1.$$

Then the Wasserstein distance of ρ_0 and ρ_1 is nonincreasing in time, i.e.,

$$\frac{d^+}{dt}\mathcal{W}^2(\rho_0,\rho_1) \leqslant 0. \tag{4.1}$$

Remark 4.1. We have seen in section 3.2 that heuristically the convexity of E is equivalent to the conditions on U and Ric required in Theorem 4.1. We have seen in section 3.1 that convexity of E is equivalent to the contractivity of the corresponding gradient flow. Hence we expect that the conditions on U and Ric are also necessary. This has been rigorously proven in [16]. Also in [16], the sufficiency of these conditions has been established using the Lagrangian approach mentioned in section 1 which relies on [11].

The theorem will be a consequence of the following two propositions.

PROPOSITION 4.2. *Assume that $\rho U'(\rho) \geqslant \big(1-\frac{1}{n}\big)U(\rho) \geqslant 0$ for all $\rho \geqslant 0$ and that $\mathrm{Ric}(x) \geqslant 0$ for all $x \in \mathbb{M}^n$. Consider a family of smooth positive solutions of*

$$\partial_t\rho - \Delta U(\rho) = 0, \tag{4.2}$$

depending smoothly on the parameter $s \in [0,1]$. For any (s,t) let ϕ be defined by

$$\partial_s\rho - \nabla\cdot(\rho\nabla\phi) = 0.$$

Then the following holds:

$$\frac{d}{dt}\iint_{[0,1]\times\mathbb{M}^n} |\nabla\phi|^2\rho\,dx\,ds \leqslant 0.$$

Remark 4.2. Proposition 4.2 is guided by the abstract observation of section 3.1: Convexity can be probed by the gradient flow. More precisely, convexity expresses itself by the fact that the action of curves is reduced when the points along the curve are evolved by the gradient flow.

PROPOSITION 4.3. *Consider $\rho_0\,dx, \rho_1\,dx \in \mathrm{Prob}(\mathbb{M}^n)$, where ρ_0,ρ_1 are smooth and positive functions. Then the Wasserstein distance squared $\frac{1}{2}\mathcal{W}^2(\rho_0,\rho_1)$ equals*

$$\inf\left\{\iint_{[0,1]\times\mathbb{M}^n} \tfrac{1}{2}|\nabla\phi|^2\rho\,dx\,ds \;\middle|\; \begin{array}{l}(\rho>0,\phi) \text{ smooth functions on } [0,1]\times\mathbb{M}^n,\\ \partial_s\rho - \nabla\cdot(\rho\nabla\phi) = 0,\ \left\{\begin{array}{l}\rho(0,\cdot)=\rho_0\\ \rho(1,\cdot)=\rho_1\end{array}\right\}\end{array}\right\}. \tag{4.3}$$

Proof of Theorem 4.1. Assume first that the initial data are smooth and positive and that U is linear for $\rho \notin [\alpha, 1/\alpha]$ with $\alpha > 0$ small. Then standard parabolic theory yields that solutions of the porous medium equation for smooth and positive initial data are also smooth and positive. By Proposition 4.3 we can, for any $\varepsilon > 0$, find smooth functions $\big(\bar\rho > 0, \bar\phi\big)$ on $[0,1]\times\mathbb{M}^n$, with

$$\partial_s\bar\rho - \nabla\cdot\big(\bar\rho\nabla\bar\phi\big) = 0,\ \left\{\begin{array}{l}\bar\rho(0,\cdot)=\bar\rho_0\\ \bar\rho(1,\cdot)=\bar\rho_1\end{array}\right\}$$

such that

$$\iint_{[0,1]\times\mathbb{M}^n} \big|\nabla\bar\phi\big|^2\bar\rho\,dx\,ds \leqslant \mathcal{W}^2(\bar\rho_0,\bar\rho_1) + \varepsilon.$$

For any $s \in [0,1]$, let $\bar{\rho}(\cdot, s)$ evolve according to the porous medium equation. This yields a family ρ of solutions depending smoothly on s for which Proposition 4.2 applies. Using again the characterization of Proposition 4.3 then yields

$$\begin{aligned} \mathcal{W}^2\big(\rho_0(t), \rho_1(t)\big) &\leqslant \iint_{[0,1]\times\mathbb{M}^n} |\nabla\phi(t)|^2 \rho(t)\, dx\, ds \\ &\leqslant \iint_{[0,1]\times\mathbb{M}^n} \big|\nabla\bar{\phi}\big|^2 \bar{\rho}\, dx\, ds \leqslant \mathcal{W}^2(\bar{\rho}_0, \bar{\rho}_1) + \varepsilon \quad \forall\, t > 0. \end{aligned} \tag{4.4}$$

Since $\varepsilon > 0$ was arbitrary, we obtain (4.1) in this case.

The general case follows by an approximation argument that we do not discuss in detail here. For general nonnegative initial data one can find sequences of smooth positive functions, converging strongly to the given $\bar{\rho}_0, \bar{\rho}_1$. Then standard theory for the porous medium equation yields that the solutions converge strongly in $L^1(\mathbb{M}^n)$, hence a posteriori also in the Wasserstein distance which metrizes the weak* topology of measures. Therefore the contraction estimate generalizes to this setting. Similarly, one can approximate a given U with $\rho U'(\rho) \geqslant \big(1 - \frac{1}{n}\big) U(\rho) \geqslant 0$ for all $\rho \geqslant 0$ by a sequence of functions that have the same property and are linear for small and large ρ and that converge uniformly. Then standard theory applies and allows one to conclude. We refer the reader to [12], where this program has been carried out in $\mathbb{R}^n$. □

Proof of Proposition 4.2. The following remark is at the core of Proposition 4.2.

LEMMA 4.4. *Consider smooth functions* $\big(\rho > 0, \delta\rho\big)$ *on* $[0,\infty) \times \mathbb{M}^n$ *solving*

$$\left\{ \begin{aligned} &\partial_t \rho \quad\;\; - \Delta U(\rho) &&= 0, \\ &\partial_t(\delta\rho) - \Delta\Big(U'(\rho)\, \delta\rho\Big) &&= 0. \end{aligned} \right. \tag{4.5}$$

For any t let ϕ be defined by

$$\delta\rho - \nabla \cdot \big(\rho \nabla\phi\big) = 0. \tag{4.6}$$

Then we have

$$\begin{aligned} &\frac{d}{dt} \int_{\mathbb{M}^n} \tfrac{1}{2} |\nabla\phi|^2 \rho\, dx \\ &\quad = - \int_{\mathbb{M}^n} \bigg(\Big(\rho U'(\rho) - U(\rho)\Big)(\Delta\phi)^2 + U(\rho)\Big(|\mathrm{D}^2\phi|^2 + \nabla\phi \cdot \mathrm{Ric}\, \nabla\phi\Big)\bigg)\, dx. \end{aligned} \tag{4.7}$$

Remark 4.3. Observe that the second equation in (4.5) describes the evolution of an infinitesimal perturbation $\delta\rho$ of ρ; see (3.2). Notice further that in view of (4.6), the left-hand side of (4.7) measures how the squared norm of $\delta\rho$ changes in time; cf. (3.3). Observe finally that the right-hand side expression of (4.7) coincides with what we expect to be—up to the sign—the Hessian; see (3.20). In this sense the formula (4.7) reproduces (3.4).

Proof. The left-hand side of (4.7) equals, after an integration by parts,

$$\frac{d}{dt} \int_{\mathbb{M}^n} \tfrac{1}{2} |\nabla\phi|^2 \rho\, dx = \int_{\mathbb{M}^n} \Big(- \phi\, \nabla \cdot \big(\rho\, \partial_t \nabla\phi\big) + \tfrac{1}{2} |\nabla\phi|^2\, \partial_t \rho\Big)\, dx. \tag{4.8}$$

We express $-\nabla\cdot(\rho\,\partial_t\nabla\phi)$ in terms of ρ and ϕ. We find by differentiating (4.6)

$$\begin{aligned} &-\nabla\cdot\big(\rho\,\partial_t\nabla\phi\big)\\ &\qquad = \; -\partial_t(\delta\rho)+\nabla\cdot\big(\partial_t\rho\,\nabla\phi\big)\\ &\qquad \overset{(4.5)}{=} -\Delta\Big(U'(\rho)\,\delta\rho\Big)+\nabla\cdot\Big(\Delta U(\rho)\,\nabla\phi\Big)\\ &\qquad \overset{(4.6)}{=} -\Delta\Big(U'(\rho)\,\nabla\cdot(\rho\nabla\phi)\Big)+\nabla\cdot\Big(\Delta U(\rho)\,\nabla\phi\Big)\\ &\qquad = \; -\Delta\Big(\big(\rho U'(\rho)-U(\rho)\big)\,\Delta\phi\Big)-\Delta\nabla\cdot\Big(U(\rho)\,\nabla\phi\Big)+\nabla\cdot\Big(\Delta U(\rho)\,\nabla\phi\Big). \end{aligned}$$

Using this identity and (4.5) in (4.8) gives, after throwing all derivatives onto ϕ,

$$\begin{aligned} &\frac{d}{dt}\int_{\mathbb{M}^n}\tfrac12|\nabla\phi|^2\rho\,dx\\ &\quad = -\int_{\mathbb{M}^n}\bigg(\Big(\rho U'(\rho)-U(\rho)\Big)(\Delta\phi)^2+U(\rho)\Big(-\nabla\Delta\phi\cdot\nabla\phi+\Delta\tfrac12|\nabla\phi|^2\Big)\bigg)\,dx. \end{aligned}$$

Then we use Bochner's formula

$$-\nabla\Delta\phi\cdot\nabla\phi+\Delta\tfrac12|\nabla\phi|^2=|\mathrm{D}^2\phi|^2+\nabla\phi\cdot\mathrm{Ric}\,\nabla\phi$$

(see Proposition 3.3 of [14]) to conclude. ◻

Fix $s\in[0,1]$, and let $\delta\rho=\partial_s\rho(\cdot,s)$. Differentiating (4.2) with respect to s gives

$$\partial_t\big(\partial_s\rho\big)-\Delta\Big(U'(\rho)\,\partial_s\rho\Big)=0.$$

Then Lemma 4.4 applies and yields

$$\begin{aligned} &\frac{d}{dt}\int_{\mathbb{M}^n}\tfrac12|\nabla\phi|^2\rho\,dx\\ &\quad = -\int_{\mathbb{M}^n}\bigg(\Big(\rho U'(\rho)-U(\rho)\Big)(\Delta\phi)^2+U(\rho)\Big(|\mathrm{D}^2\phi|^2+\nabla\phi\cdot\mathrm{Ric}\,\nabla\phi\Big)\bigg)\,dx. \end{aligned}\tag{4.9}$$

Notice that $(\Delta\phi)^2\leqslant n|\mathrm{D}^2\phi|^2$. By the assumption on U, we therefore get

$$\Big(\rho U'(\rho)-U(\rho)\Big)(\Delta\phi)^2+U(\rho)|\mathrm{D}^2\phi|^2\geqslant U(\rho)\Big(-\tfrac1n(\Delta\phi)^2+|\mathrm{D}^2\phi|^2\Big)\geqslant 0.$$

Furthermore, we have $\nabla\phi\cdot\mathrm{Ric}\,\nabla\phi\geqslant 0$. This proves the proposition. ◻

Remark 4.4. The same reasoning also yields convergence rates: In fact, if

$$U(\rho)\;\xi\cdot\mathrm{Ric}(x)\xi\geqslant\lambda\rho|\xi|^2\quad\forall\rho\geqslant 0\text{ and }(x,\xi)\in T\mathbb{M}^n\tag{4.10}$$

for a suitable constant $\lambda\in\mathbb{R}$, then (4.9) gives

$$\frac{d}{dt}\int_{\mathbb{M}^n}\tfrac12|\nabla\phi|^2\rho\,dx=-\int_{\mathbb{M}^n}U(\rho)\Big(\nabla\phi\cdot\mathrm{Ric}\,\nabla\phi\Big)\,dx\leqslant-2\lambda\int_{\mathbb{M}^n}\tfrac12|\nabla\phi|^2\rho\,dx.$$

We obtain exponential decay of $\int_{\mathbb{M}^n}\frac12|\nabla\phi|^2\rho\,dx$ with rate 2λ, thus of $\mathcal{W}^2(\rho_1,\rho_0)$, by (4.4). For the heat equation on the unit sphere, for example, condition (4.10) is satisfied with constant $\lambda=1$.

Proof of Proposition 4.3. We proceed in five steps.

Step 1. We first prove that $\frac{1}{2}\mathcal{W}^2(\rho_0,\rho_1) \leqslant (4.3)$. Therefore assume that (ρ,ϕ) is admissible in (4.3). For abbreviation we introduce the velocity field $u := -\nabla\phi$, such that $\partial_s\rho + \nabla\cdot(\rho u) = 0$, and consider the flow induced by u:

$$\Phi\colon [0,1]\times\mathbb{M}^n \longrightarrow \mathbb{M}^n \quad\text{with}\quad \partial_s\Phi(s,x) = u\big(s,\Phi(s,x)\big),\ \Phi(0,x) = x, \tag{4.11}$$

for all $(s,x)\in[0,1]\times\mathbb{M}^n$. Then the measure $\rho(s,x)\,dx$ is the push-forward of the measure $\rho_0(x)\,dx$ under $\Phi(s,\cdot)$; i.e., we have for all smooth functions ζ on $\mathbb{M}^n$

$$\int_{\mathbb{M}^n}\zeta(x)\rho(s,x)\,dx = \int_{\mathbb{M}^n}\zeta\big(\Phi(s,x)\big)\rho_0(x)\,dx \quad \forall\, s\in[0,1]. \tag{4.12}$$

Moreover, by definition of the geodesic distance d we have

$$d\big(x,\Phi(1,x)\big)^2 \leqslant \int_0^1 |\partial_s\Phi(s,x)|^2\,ds. \tag{4.13}$$

Let π be the nonnegative measure defined by

$$\iint_{\mathbb{M}^n\times\mathbb{M}^n}\zeta(x,y)\,d\pi(x,y) = \int_{\mathbb{M}^n}\zeta\big(x,\Phi(1,x)\big)\rho_0(x)\,dx \tag{4.14}$$

for all smooth functions ζ on $\mathbb{M}^n\times\mathbb{M}^n$. Thanks to (4.12), π is admissible in the definition of the Wasserstein distance $\mathcal{W}^2(\rho_0,\rho_1)$. Furthermore, we have

$$\begin{aligned}
&\iint_{\mathbb{M}^n\times\mathbb{M}^n} d(x,y)^2\,d\pi(x,y)\\
&\overset{(4.14)}{=} \int_{\mathbb{M}^n} d\big(x,\Phi(1,x)\big)^2\rho_0(x)\,dx\\
&\overset{(4.13)}{\leqslant} \int_{\mathbb{M}^n}\left(\int_0^1 |\partial_s\Phi(s,x)|^2\,ds\right)\rho_0(x)\,dx\\
&\overset{(4.11)}{=} \int_0^1\int_{\mathbb{M}^n}\big|u\big(s,\Phi(s,x)\big)\big|^2\rho_0(x)\,dx\,ds\\
&\overset{(4.12)}{=} \int_0^1\int_{\mathbb{M}^n}|u(s,x)|^2\rho(s,x)\,dx\,ds = \iint_{[0,1]\times\mathbb{M}^n}|\nabla\phi|^2\rho\,dx\,ds.
\end{aligned}$$

This proves our claim.

Step 2. Notice that any smooth vector field on $[0,1]\times\mathbb{M}^n$ can be identified with a pair (ρ,m), where ρ is a function on $[0,1]\times\mathbb{M}^n$ and m is an s-dependent vector field on $\mathbb{M}^n$ (such as $m=-\rho\nabla\phi$). We will now show that (4.3) equals

$$\inf\left\{\iint_{[0,1]\times\mathbb{M}^n}\tfrac{1}{2}\rho^{-1}|m|^2\,dx\,ds \;\middle|\; \begin{array}{l}(\rho>0,m)\text{ smooth vector field on }[0,1]\times\mathbb{M}^n,\\ \partial_s\rho+\nabla\cdot m = 0,\ \left\{\begin{array}{l}\rho(0,\cdot)=\rho_0\\ \rho(1,\cdot)=\rho_1\end{array}\right\}\end{array}\right\}. \tag{4.15}$$

That (4.15) does not exceed (4.3) is obvious. To prove the converse consider an admissible pair (ρ,m) in the sense of (4.15). By positivity of ρ we then find, for any $s\in[0,1]$, a smooth function ϕ on $\mathbb{M}^n$ solving the elliptic equation

$$\nabla\cdot\big(m+\rho\nabla\phi\big) = 0 \quad\text{on }\mathbb{M}^n. \tag{4.16}$$

This ϕ depends smoothly on s because (ρ, m) does. Since $\mathbb{M}^n$ has no boundary,

$$\int_{\mathbb{M}^n} \big(m + \rho\nabla\phi\big) \cdot \nabla\phi \, dx = 0.$$

Therefore by Cauchy–Schwarz

$$\begin{aligned}\int_{\mathbb{M}^n} \rho|\nabla\phi|^2 \, dx &\overset{(4.16)}{=} \int_{\mathbb{M}^n} -m \cdot \nabla\phi \, dx \\ &\leqslant \left(\int_{\mathbb{M}^n} \rho^{-1}|m|^2 \, dx\right)^{1/2} \left(\int_{\mathbb{M}^n} \rho|\nabla\phi|^2 \, dx\right)^{1/2},\end{aligned}$$

and thus

$$\int_{\mathbb{M}^n} \tfrac{1}{2}\rho|\nabla\phi|^2 \, dx \leqslant \int_{\mathbb{M}^n} \tfrac{1}{2}\rho^{-1}|m|^2 \, dx.$$

Step 3. Now we generalize the functional (4.15) to a certain class of distributions and prove that then the inf is bounded by the Wasserstein distance for any measures $\rho_0, \rho_1 \in \mathrm{Prob}(\mathbb{M}^n)$. To achieve this, notice first that thanks to the Riemannian metric on $\mathbb{M}^n$, any smooth 1-form ω on $[0,1] \times \mathbb{M}^n$ can be identified with a pair (σ, ξ), where σ is a function on $[0,1] \times \mathbb{M}^n$ and ξ is an s-dependent vector field on $\mathbb{M}^n$, via

$$\big\langle \omega,\ (\rho, m)\big\rangle = \sigma\rho + \xi \cdot m$$

for all (smooth) vector fields (ρ, m). We write

$$\omega = \sigma \, ds + \xi \cdot dx.$$

The space of 1-forms can be topologized as usual in the theory of distributions, but we do not want to go into details and refer the reader to [8, 9] instead. A linear functional on the space of smooth 1-forms is called a current. Any smooth vector field (ρ, m) defined on $[0,1] \times \mathbb{M}^n$ gives rise to a current T via

$$\Big\langle T,\ \sigma \, ds + \xi \cdot dx\Big\rangle := \iint_{[0,1]\times\mathbb{M}^n} \rho\sigma + m \cdot \xi \, dx \, ds. \tag{4.17}$$

But of course not all currents T can be represented in this form.

We consider currents defined on $[0,1] \times \mathbb{M}^n$ that satisfy

$$\Big\langle T,\ \partial_s\zeta \, ds + \nabla\zeta \cdot dx\Big\rangle = \int_{\mathbb{M}^n} \zeta(1,x) \, d\rho_1(x) - \int_{\mathbb{M}^n} \zeta(0,x) \, d\rho_0(x) \tag{4.18}$$

for all test functions ζ for given $\rho_0, \rho_1 \in \mathrm{Prob}(\mathbb{M}^n)$. If now T is of the form (4.17), then (4.18) is just the weak formulation of the continuity equation $\partial_s\rho + \nabla \cdot m = 0$ with initial and final data ρ_0 and ρ_1. Following [4], we can generalize the action

$$\iint_{[0,1]\times\mathbb{M}^n} \tfrac{1}{2}\rho^{-1}|m|^2 \, dx \, ds \tag{4.19}$$

as follows. For any current T with (4.18) we consider

$$\mathcal{A}(T) := \sup\left\{ \Big\langle T,\ \sigma \, ds + \xi \cdot dx\Big\rangle \;\middle|\; \begin{array}{l}(\sigma, \xi) \text{ smooth vector field on } [0,1] \times \mathbb{M}^n \\ \text{with } \sigma + \tfrac{1}{2}|\xi|^2 \leqslant 0\end{array} \right\}. \tag{4.20}$$

We claim that this $\mathcal{A}(T)$ coincides with (4.19) if T is of the form (4.17): Indeed, setting $\xi = \rho^{-1}m$ and $\sigma = -\frac{1}{2}|\xi|^2 = -\frac{1}{2}\rho^{-2}|m|^2$ shows that (4.19) $\leqslant \mathcal{A}(T)$; and

$$\rho\sigma + m\cdot\xi \leqslant -\rho\,\tfrac{1}{2}|\xi|^2 + m\cdot\xi \leqslant \tfrac{1}{2}\rho^{-1}|m|^2$$

for all admissible (σ,ξ) implies that $\mathcal{A}(T) \leqslant$ (4.19).

Step 4. Now we prove that $\frac{1}{2}\mathcal{W}^2(\rho_0,\rho_1)$ is bigger than or equal to

$$\inf\Big\{\mathcal{A}(T)\,\Big|\,T \text{ current on } [0,1]\times\mathbb{M}^n \text{ satisfying (4.18)}\Big\}. \tag{4.21}$$

Consider any transference plan $\pi \in \operatorname{Prob}(\mathbb{M}^n\times\mathbb{M}^n)$ that is admissible in the definition of $\mathcal{W}^2(\rho_0,\rho_1)$, and let $\Phi\colon [0,1]\times\mathbb{M}^n\times\mathbb{M}^n \longrightarrow \mathbb{M}^n$ be defined by

$$[0,1]\ni s\mapsto \Phi(s,x,y)\quad\text{is the shortest geodesic between } x \text{ and } y.$$

Then we have in particular

$$\int_0^1 |\partial_s\Phi(s,x,y)|^2\,ds = d(x,y)^2 \quad\text{and}\quad \left\{\begin{array}{l}\Phi(0,x,y)=x\\ \Phi(1,x,y)=y\end{array}\right\}. \tag{4.22}$$

We define a current T on $[0,1]\times\mathbb{M}^n$ as follows: For all 1-forms $\sigma\,ds + \xi\cdot dx$ let

$$\begin{aligned}&\Big\langle T,\ \sigma\,ds + \xi\cdot dx\Big\rangle\\ &\quad := \iint\int_0^1 \Big\{\sigma\big(s,\Phi(s,x,y)\big) + \xi\big(s,\Phi(s,x,x)\big)\cdot\partial_s\Phi(s,x,y)\Big\}\,ds\,d\pi(x,y).\end{aligned}$$

This current satisfies the admissibility condition (4.18). Indeed, we have

$$\begin{aligned}&\Big\langle T,\ \partial_s\zeta\,ds + \nabla\zeta\cdot dx\Big\rangle\\ &\quad= \iint\int_0^1 \Big\{\partial_s\zeta\big(s,\Phi(s,x,y)\big) + \nabla\zeta\big(s,\Phi(s,x,y)\big)\cdot\partial_s\Phi(s,x,y)\Big\}\,ds\,d\pi(x,y)\\ &\quad= \iint\int_0^1 \frac{d}{ds}\Big\{\zeta\big(s,\Phi(s,x,y)\big)\Big\}\,ds\,d\pi(x,y)\\ &\quad= \iint \zeta\big(1,\Phi(1,x,y)\big)\,d\pi(x,y) - \iint \zeta\big(0,\Phi(0,x,y)\big)\,d\pi(x,y)\\ &\quad\overset{(4.22)}{=} \iint \zeta(1,y)\,d\pi(x,y) - \iint \zeta(0,x)\,d\pi(x,y)\\ &\quad= \int \zeta(1,y)\,d\rho_1(y) - \int \zeta(0,x)\,d\rho_0(x)\end{aligned}$$

for all test functions ζ. Now we argue that $\mathcal{A}(T) \leqslant \iint \frac{1}{2}d(x,y)^2\,d\pi(x,y)$. Indeed, we have for any vector field (σ, ξ) admissible in (4.20) that

$$\begin{aligned}
&\Big\langle T,\ \sigma\, ds + \xi \cdot dx \Big\rangle \\
&\quad = \iint \int_0^1 \Big\{ \sigma\big(s, \Phi(s,x,y)\big) + \xi\big(s, \Phi(s,x,y)\big) \cdot \partial_s \Phi(s,x,y) \Big\}\, ds\, d\pi(x,y) \\
&\quad \leqslant \iint \int_0^1 \Big\{ -\tfrac{1}{2}\big|\xi\big(s, \Phi(s,x,y)\big)\big|^2 + \xi\big(s, \Phi(s,x,y)\big) \cdot \partial_s \Phi(s,x,y) \Big\}\, ds\, d\pi(x,y) \\
&\quad \leqslant \iint \int_0^1 \tfrac{1}{2} |\partial_s \Phi(s,x,y)|^2\, ds\, d\pi(x,y) \\
&\quad \overset{(4.22)}{=} \iint \tfrac{1}{2} d(x,y)^2\, d\pi(x,y).
\end{aligned}$$

Step 5. To conclude the proof of the proposition it is then sufficient to show that the two inf in (4.15) and (4.21) coincide. This will follow from Proposition 5.1 below, which shows that any current T satisfying the admissibility condition (4.18) for smooth and positive data ρ_0, ρ_1 can in fact be approximated by a current T_ε that is representable by a smooth vector field $(\rho_\varepsilon \geqslant 0, m_\varepsilon)$ in such a way that (4.18) still holds with T_ε in place of T and $\limsup_{\varepsilon \to 0} \mathcal{A}(T_\varepsilon) \leqslant \mathcal{A}(T)$.

The only detail that needs to be settled is (strict) positivity of ρ_ε. We argue as follows. Since $\rho_0, \rho_1 > 0$ and $\mathbb{M}^n$ is compact, there exists $0 < \delta < 1$ with $\rho_0, \rho_1 \geqslant \delta$. Recall that by assumption $\int_{\mathbb{M}^n} 1\, dx = 1$. Then we consider

$$\tilde{\rho}_0 := \frac{\rho_0 - \delta}{1 - \delta} \quad \text{and} \quad \tilde{\rho}_1 := \frac{\rho_1 - \delta}{1 - \delta},$$

which are in $\mathrm{Prob}(\mathbb{M}^n)$. Let $\tilde{T}$ be the current constructed in Step 4, based on an admissible transference plan π in the definition of $\mathcal{W}^2(\tilde{\rho}_0, \tilde{\rho}_1)$. As shown there,

$$\mathcal{A}(\tilde{T}) \leqslant \tfrac{1}{2} \mathcal{W}^2(\tilde{\rho}_0, \tilde{\rho}_1). \tag{4.23}$$

We apply Proposition 5.1 to $\tilde{T}$. This gives an approximation $\tilde{T}_\varepsilon$ that satisfies (4.18) and is representable by smooth vector fields $(\tilde{\rho}_\varepsilon \geqslant 0, \tilde{m}_\varepsilon)$, such that

$$\limsup_{\varepsilon \to 0} \mathcal{A}(\tilde{T}_\varepsilon) \leqslant \mathcal{A}(\tilde{T}). \tag{4.24}$$

In view of the remark in Step 3, the admissibility condition (4.18) amounts to

$$\partial_s \tilde{\rho}_\varepsilon + \nabla \cdot \tilde{m}_\varepsilon = 0, \ \left\{ \begin{array}{l} \tilde{\rho}_\varepsilon(0, \cdot) = \tilde{\rho}_0 \\ \tilde{\rho}_\varepsilon(1, \cdot) = \tilde{\rho}_1 \end{array} \right\}.$$

Now notice that $\tilde{\rho}_0$ and $\tilde{\rho}_1$ are constructed in such a way that

$$(\rho_\varepsilon, m_\varepsilon) := \big((1-\delta)\tilde{\rho}_\varepsilon + \delta, (1-\delta)\tilde{m}_\varepsilon \big)$$

is admissible in (4.15) because $\rho_\varepsilon \geqslant \delta > 0$. We have $\rho_\varepsilon^{-1} |m_\varepsilon|^2 \leqslant (1-\delta)\, \tilde{\rho}_\varepsilon^{-1} |\tilde{m}_\varepsilon|^2$, and thus by the remark in Step 3

$$\iint_{[0,1] \times \mathbb{M}^n} \tfrac{1}{2} \rho_\varepsilon^{-1} |m_\varepsilon|^2\, dx\, ds \leqslant (1-\delta) \iint_{[0,1] \times \mathbb{M}^n} \tfrac{1}{2} \tilde{\rho}_\varepsilon^{-1} |\tilde{m}_\varepsilon|^2 = (1-\delta)\, \mathcal{A}(\tilde{T}_\varepsilon). \tag{4.25}$$

In view of (4.23), (4.24), and (4.25) it remains to argue that

$$\mathcal{W}(\tilde{\rho}_0,\tilde{\rho}_1) \leqslant \mathcal{W}(\rho_0,\rho_1) + o(1) \quad \text{as } \delta \to 0.$$

By the triangle inequality for the Wasserstein distance (see Theorem 7.3 of [18]),

$$\mathcal{W}(\tilde{\rho}_0,\tilde{\rho}_1) \leqslant \mathcal{W}(\rho_0,\rho_1) + \mathcal{W}(\rho_0,\tilde{\rho}_0) + \mathcal{W}(\rho_1,\tilde{\rho}_1). \tag{4.26}$$

In order to conclude, it suffices therefore to prove that the last two terms on the right-hand side of (4.26) can be made small by choosing δ appropriately. We consider the transference plan $\pi \in \mathrm{Prob}(\mathbb{M}^n \times \mathbb{M}^n)$ defined by

$$\begin{aligned} &\iint_{\mathbb{M}^n\times\mathbb{M}^n} \zeta(x,y)\,d\pi(x,y) \\ &:= \int_{\mathbb{M}^n} \zeta(x,x)\,\big(\rho_0(x)-\delta\big)\,dx + \tfrac{\delta}{1-\delta} \iint_{\mathbb{M}^n\times\mathbb{M}^n} \zeta(x,y)\,\big(\rho_0(y)-\delta\big)\,dx\,dy \end{aligned} \tag{4.27}$$

for all ζ. This π is admissible in the definition of $\mathcal{W}^2(\rho_0,\tilde{\rho}_0)$ because

$$\begin{aligned} &\iint_{\mathbb{M}^n\times\mathbb{M}^n} \zeta(x)\,d\pi(x,y) \\ &\quad= \int_{\mathbb{M}^n} \zeta(x)\,\big(\rho_0(x)-\delta\big)\,dx + \tfrac{\delta}{1-\delta}\int_{\mathbb{M}^n}\zeta(x)\,dx \int_{\mathbb{M}^n}\big(\rho_0(y)-\delta\big)\,dy \\ &\quad= \int_{\mathbb{M}^n} \zeta(x)\,\rho_0(x)\,dx \end{aligned}$$

and similarly

$$\begin{aligned} &\iint_{\mathbb{M}^n\times\mathbb{M}^n} \zeta(y)\,d\pi(x,y) \\ &\quad= \int_{\mathbb{M}^n} \zeta(y)\,\big(\rho_0(y)-\delta\big)\,dy + \tfrac{\delta}{1-\delta}\int_{\mathbb{M}^n} dx \int_{\mathbb{M}^n}\zeta(y)\,\big(\rho_0(y)-\delta\big)\,dy \\ &\quad= \int_{\mathbb{M}^n} \zeta(y)\,\frac{\rho_0(y)-\delta}{1-\delta}\,dy. \end{aligned}$$

Using $\zeta(x,y) := d(x,y)^2$ in (4.27) then yields

$$\mathcal{W}^2(\rho_0,\tilde{\rho}_0) \leqslant \delta\,\mathrm{diam}(\mathbb{M}^n)^2.$$

The same argument applies to $\mathcal{W}^2(\rho_1,\tilde{\rho}_1)$, thereby finishing the proof. ∎

5. Approximation of currents. In this section we prove the approximation result for currents used in the proof of Proposition 4.3. Notice that the regularization of currents is well understood; see, e.g., [15, 9]. Here we need to adopt the standard arguments somewhat in order to obtain convergence of the action functional (4.20).

PROPOSITION 5.1. *Let $\mathbb{M}^n$ be a compact connected Riemannian manifold without boundary. For given measures $\rho_0,\rho_1 \in \mathrm{Prob}(\mathbb{M}^n)$ consider a current T on $[0,1]\times\mathbb{M}^n$ with $\mathcal{A}(T)<\infty$ which satisfies the admissibility condition*

$$\Big\langle T,\ \partial_s\zeta\,ds + \nabla\zeta\cdot dx \Big\rangle = \int_{\mathbb{M}^n} \zeta(1,x)\,d\rho_1(x) - \int_{\mathbb{M}^n}\zeta(0,x)\,d\rho_0(x) \tag{5.1}$$

for all test functions ζ defined on $[0,1]\times\mathbb{M}^n$. Then we have the following:

(1) *There exists a family of currents* $\{T_\varepsilon\}_{\varepsilon>0}$ *representable in the form*

$$\Big\langle T_\varepsilon,\ \sigma\, ds + \xi \cdot dx \Big\rangle = \iint_{[0,1]\times\mathbb{M}^n} \rho_\varepsilon \sigma + m_\varepsilon \cdot \xi \, dx\, ds \tag{5.2}$$

for suitable vector fields $(\rho_\varepsilon \geqslant 0, m_\varepsilon)$ *which are smooth inside* $(0,1)\times\mathbb{M}^n$*. The admissibility condition* (5.1) *still holds with* T_ε *in place of* T *and*

$$\limsup_{\varepsilon\to 0} \mathcal{A}(T_\varepsilon) \leqslant \mathcal{A}(T).$$

(2) *If* ρ_0 *and* ρ_1 *are smooth functions, we may assume that the fields* $(\rho_\varepsilon, m_\varepsilon)$ *are smooth up to the boundary, and thus* $\rho_\varepsilon(0,\cdot) = \rho_0$ *and* $\rho_\varepsilon(1,\cdot) = \rho_1$*.*

Remark 5.1. Since the action functional $\mathcal{A}(T)$ is lower semicontinuous in the usual weak* topology of currents (see [9]), it even holds that $\lim_{\varepsilon\to 0}\mathcal{A}(T_\varepsilon) = \mathcal{A}(T)$.

Proof. We start with a remark on notation. Because of the action and the admissibility condition, the s- and x-variables have to be treated differently. However, it will often be convenient to lump s- and x-variables together; therefore we will write $\mathbf{x} = (s,x)$, $\quad = (\sigma,\xi)$, and $\mathbf{m} = (\rho, m)$. As a rule, bold symbols always denote $(n+1)$-dimensional objects (vector fields, parameters, operators, sets).

The approximating currents T_ε are obtained by regularization of T. We proceed as usual (see [15, 9]): Since a current is a linear form on 1-forms, we regularize T by duality, i.e., by constructing a linear operator that regularizes 1-forms $\ \cdot d\mathbf{x}$. This must be done in such a way that exact 1-forms $\ \cdot d\mathbf{x} = \boldsymbol{\nabla}\zeta \cdot d\mathbf{x}$ turn into exact 1-forms since, by assumption (5.1), T vanishes on exact 1-forms that are compactly supported in $(0,1)\times\mathbb{M}^n$. Recall that pulling back a 1-form under a smooth map preserves exactness. Therefore we regularize $\ \cdot d\mathbf{x}$ as follows: We construct a family of diffeomorphisms $\{\boldsymbol{\Phi}(\mathbf{z},\cdot)\}_{\mathbf{z}}$ of $\mathbb{R}\times\mathbb{M}^n$, parametrized by $\mathbf{z}\in\mathbb{R}\times\mathbb{R}^n$, and then consider its pull-back $\boldsymbol{\Phi}(\mathbf{z},\cdot)^{\#}(\ \cdot d\mathbf{x})$ and average over $\mathbf{z}$.

In order to preserve the boundary condition (5.1), it is necessary that $\boldsymbol{\Phi}(\mathbf{z},\cdot)$ leaves the complement of $(0,1)\times\mathbb{M}^n$ invariant. On the other hand, in order to achieve the regularizing effect, it is important that $\mathbf{z}\in\mathbb{R}\times\mathbb{R}^n$ "acts transitively" on $(0,1)\times\mathbb{M}^n$. Because of topological reasons, this cannot be achieved globally by a single map $\boldsymbol{\Phi}$ in general. We have to work locally with several maps $\boldsymbol{\Phi}$, each of which is attached to some open set U of a suitable covering of $\mathbb{M}^n$.

More precisely, we consider a finite covering $\{U_i\}_{i=1}^N$ of $\mathbb{M}^n$ subordinate to some atlas, with $U_i\subset\mathbb{M}^n$ homeomorphic to the unit ball $B_1(0)\subset\mathbb{R}^n$ and $\phi_i\colon U_i \longrightarrow \mathbb{R}^n$ the corresponding smooth coordinate map. We may assume that each ϕ_i extends to a neighborhood of U_i and $B_1(0)$. Based on this map, we shall construct an operator $T\mapsto T^{U_i}_{\varepsilon_i}$ for $\varepsilon_i>0$ with the following properties:

(a) The operator $T\mapsto T^{U_i}_{\varepsilon_i}$ regularizes in $(0,1)\times U_i$; i.e., $T^{U_i}_{\varepsilon_i}$ is representable in $(0,1)\times U_i$ by a smooth vector field $(\rho_{\varepsilon_i}\geqslant 0, m_{\varepsilon_i})$ as in (5.2).

(b) The operator $T\mapsto T^{U_i}_{\varepsilon_i}$ does not destroy smoothness; i.e., if T is representable by a smooth vector field in $(0,1)\times V$ with $V\subset\mathbb{M}^n$ open, then also $T^{U_i}_{\varepsilon_i}$ is representable by a smooth vector field in $(0,1)\times V$.

(c) The new current is admissible in the sense that (5.1) still holds with $T^{U_i}_{\varepsilon_i}$ in place of T, and we have upper semicontinuity of the action

$$\limsup_{\varepsilon_i\to 0}\mathcal{A}\big(T^{U_i}_{\varepsilon_i}\big) \leqslant \mathcal{A}(T).$$

Then the composition

$$T \;\mapsto\; T^{U_1}_{\varepsilon_1} \;\mapsto\; \big(T^{U_1}_{\varepsilon_1}\big)^{U_2}_{\varepsilon_2} \;\mapsto\; \cdots \;\mapsto\; \big(\cdots\big(T^{U_1}_{\varepsilon_1}\big)^{U_2}_{\varepsilon_2}\cdots\big)^{U_N}_{\varepsilon_N}$$

yields an approximate current T_ε with all the properties required by the proposition. In particular, we obtain a vector field $(\rho_\varepsilon \geqslant 0, m_\varepsilon)$ that represents T_ε in the sense of (5.2) and is smooth throughout $(0,1)\times\mathbb{M}^n$. It suffices to consider each operator $T \mapsto T^{U_i}_{\varepsilon_i}$ separately and check that (a)–(c) are satisfied. To simplify the notation, we will suppress the index i and do not indicate the dependence on U_i. The idea of regularizing a current defined on a manifold by composing several operators attached to local coordinate maps already appeared in [15].

We proceed in eight steps.

Step 1. As mentioned before, the regularization $T \mapsto T_\varepsilon$ is based on a family of diffeomorphisms $\{\mathbf{\Phi}(\mathbf{z},\cdot)\}_{\mathbf{z}}$ of $\mathbb{R}\times\mathbb{M}^n$, parametrized by $\mathbf{z}\in\mathbb{R}\times\mathbb{R}^n$ and attached to the open set $U\subset\mathbb{M}^n$. We would like these diffeomorphisms to leave the complement of $(0,1)\times U$ invariant, but we cannot impose this since in order to control the action we need that the first component of $\mathbf{\Phi}$ does not depend on x.

We shall use

- a smooth map $\mathbf{\Phi} = (\Phi_0,\Phi)\colon (\mathbb{R}\times\mathbb{R}^n)\times(\mathbb{R}\times\mathbb{M}^n) \longrightarrow \mathbb{R}\times\mathbb{M}^n$ (whose construction is postponed until Step 7) with the following properties:

$$\forall\, \mathbf{z}\in\mathbb{R}\times\mathbb{R}^n \quad \mathbf{\Phi}(\mathbf{z},\cdot) \text{ is a diffeomorphism of } \mathbb{R}\times\mathbb{M}^n \text{ onto } \mathbb{R}\times\mathbb{M}^n, \tag{5.3a}$$

$$\forall\, \mathbf{x}\in\mathbb{R}\times\mathbb{M}^n \quad \mathbf{\Phi}(0,\mathbf{x}) = \mathbf{x}, \tag{5.3b}$$

$$\forall\, \mathbf{x}\in(0,1)\times U \quad \mathbf{\Phi}(\cdot,\mathbf{x}) \text{ is a diffeomorphism of } \mathbb{R}\times\mathbb{R}^n \text{ onto } (0,1)\times U, \tag{5.3c}$$

$$\Phi_0 \text{ does not depend on } x, \tag{5.3d}$$

$$\forall\, (\mathbf{z},\mathbf{x})\in(\mathbb{R}\times\mathbb{R}^n)\times\big((0,1)\times(\mathbb{M}^n - U)\big) \quad \Phi(\mathbf{z},\mathbf{x}) = x, \tag{5.3e}$$

$$\forall\, (\mathbf{z},\mathbf{x})\in(\mathbb{R}\times\mathbb{R}^n)\times\big(\big(\mathbb{R}-(0,1)\big)\times\mathbb{M}^n\big) \quad \mathbf{\Phi}(\mathbf{z},\mathbf{x}) = \mathbf{x}. \tag{5.3f}$$

We shall also need the following maps which exist by (5.3a) and (5.3c):

- the right inverse $\mathbf{\Theta} = (\Theta_0,\Theta)\colon (\mathbb{R}\times\mathbb{R}^n)\times(\mathbb{R}\times\mathbb{M}^n) \longrightarrow \mathbb{R}\times\mathbb{M}^n$ of $\mathbf{\Phi}$ which is characterized by

$$\forall\, (\mathbf{z},\mathbf{x})\in(\mathbb{R}\times\mathbb{R}^n)\times(\mathbb{R}\times\mathbb{M}^n) \quad \mathbf{\Phi}\big(\mathbf{z},\mathbf{\Theta}(\mathbf{z},\mathbf{x})\big) = \mathbf{x}; \tag{5.4}$$

- the left inverse $\mathbf{\Psi} = (\Psi_0,\Psi)\colon \big((0,1)\times U\big)\times\big((0,1)\times U\big) \longrightarrow \mathbb{R}\times\mathbb{R}^n$ of $\mathbf{\Phi}$ which is characterized by

$$\forall\, (\mathbf{x},\mathbf{y})\in\big((0,1)\times U\big)\times\big((0,1)\times U\big) \quad \mathbf{\Phi}\big(\mathbf{\Psi}(\mathbf{y},\mathbf{x}),\mathbf{x}\big) = \mathbf{y}. \tag{5.5}$$

For later reference we collect some properties: Let $D_1\mathbf{\Phi}$ and $D_2\mathbf{\Phi}$ denote the derivatives of $\mathbf{\Phi}$ with respect to the first (resp., second) variable. Then

$$\forall\, (\mathbf{z},\mathbf{x})\in(\mathbb{R}\times\mathbb{R}^n)\times(\mathbb{R}\times\mathbb{M}^n) \quad D_2\mathbf{\Phi}(\mathbf{z},\mathbf{x}) \text{ has full rank}, \tag{5.6}$$

$$\forall\, (\mathbf{z},\mathbf{x})\in(\mathbb{R}\times\mathbb{R}^n)\times\big((0,1)\times U\big) \quad D_1\mathbf{\Phi}(\mathbf{z},\mathbf{x}) \text{ has full rank}, \tag{5.7}$$

as a consequence of (5.3a) and (5.3c). From (5.4) we obtain

$$\begin{gathered} D_{\mathbf{z}}\mathbf{\Theta}(\mathbf{z},\mathbf{x}) = -\Big(D_2\mathbf{\Phi}\big(\mathbf{z},\mathbf{\Theta}(\mathbf{z},\mathbf{x})\big)\Big)^{-1} D_1\mathbf{\Phi}\big(\mathbf{z},\mathbf{\Theta}(\mathbf{z},\mathbf{x})\big), \\ D_{\mathbf{x}}\mathbf{\Theta}(\mathbf{z},\mathbf{x}) = \Big(D_2\mathbf{\Phi}\big(\mathbf{z},\mathbf{\Theta}(\mathbf{z},\mathbf{x})\big)\Big)^{-1}, \end{gathered} \tag{5.8}$$

which together with (5.6) implies that $\mathbf{\Theta}$ is smooth. Similarly, (5.5) yields

$$\begin{aligned} D_{\mathbf{y}}\mathbf{\Psi}(\mathbf{y},\mathbf{x}) &= \Big(D_1\mathbf{\Phi}\big(\mathbf{\Psi}(\mathbf{y},\mathbf{x}),\mathbf{x}\big)\Big)^{-1}, \\ D_{\mathbf{x}}\mathbf{\Psi}(\mathbf{y},\mathbf{x}) &= -\Big(D_1\mathbf{\Phi}\big(\mathbf{\Psi}(\mathbf{y},\mathbf{x}),\mathbf{x}\big)\Big)^{-1} D_2\mathbf{\Phi}\big(\mathbf{\Psi}(\mathbf{y},\mathbf{x}),\mathbf{x}\big), \end{aligned} \tag{5.9}$$

so $\mathbf{\Psi}$ is smooth by (5.7). Moreover, we gather from (5.3b) that

$$D_2\mathbf{\Phi}(\mathbf{z},\cdot) = \mathrm{Id} + \mathcal{O}(|\mathbf{z}|) \quad \text{as } |\mathbf{z}| \to 0. \tag{5.10}$$

Finally, we notice that the properties above entail that

$$\forall\, \mathbf{y} \in (0,1)\times U \qquad \lim_{\substack{\mathbf{x}\in(0,1)\times U \\ \mathbf{x}\to\partial((0,1)\times U)}} |\mathbf{\Psi}(\mathbf{y},\mathbf{x})| = +\infty. \tag{5.11}$$

We argue by contradiction. Indeed, suppose that (5.11) fails. Then there exist a sequence $\{\mathbf{x}_\nu\}_\nu \subset (0,1)\times U$ and $\mathbf{x} \in \partial\big((0,1)\times U\big)$, $\mathbf{z} \in \mathbb{R}\times\mathbb{R}^n$ with

$$\lim_{\nu\to\infty} \mathbf{x}_\nu = \mathbf{x} \quad \text{and} \quad \lim_{\nu\to\infty} \mathbf{\Psi}(\mathbf{y},\mathbf{x}_\nu) = \mathbf{z}.$$

Passing to the limit in (5.5) yields by continuity of $\mathbf{\Phi}$ that

$$\mathbf{\Phi}(\mathbf{z},\mathbf{x}) = \mathbf{y} \;\in\; (0,1)\times U. \tag{5.12}$$

Now recall that $\mathbf{x} \in \partial\big((0,1)\times U\big) = \big((0,1)\times\partial U\big) \cup \big(\{0,1\}\times\bar{U}\big)$. If $\mathbf{x} \in (0,1)\times\partial U$, then (5.12) contradicts (5.3e); if $\mathbf{x} \in \{0,1\}\times\bar{U}$, then (5.12) contradicts (5.3f).

We now introduce our T_ε. We select a smooth nonnegative function k on $\mathbb{R}\times\mathbb{R}^n$ with compact support in $B_1(0)$ and $\iint_{\mathbb{R}\times\mathbb{R}^n} k(\mathbf{z})\,d\mathbf{z} = 1$. For $\varepsilon > 0$, we denote by $k_\varepsilon(\mathbf{z}) = k(\mathbf{z}/\varepsilon)/\varepsilon^{n+1}$ the rescaled kernel. Given a smooth 1-form $\;\cdot\, d\mathbf{x}$ on $\mathbb{R}\times\mathbb{M}^n$ and $\mathbf{z} \in \mathbb{R}\times\mathbb{R}^n$ we consider its pull-back $\mathbf{\Phi}(\mathbf{z},\cdot)^{\#}(\;\cdot\, d\mathbf{x}) =: \;(\mathbf{z},\cdot)\cdot d\mathbf{x}$. Observe that in terms of the vector fields this means

$$\forall\, \mathbf{x} \in \mathbb{R}\times\mathbb{M}^n \qquad (\mathbf{z},\mathbf{x}) = \big(D_{\mathbf{x}}\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)^t \;\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big), \tag{5.13}$$

where A^t denotes the transpose of A with respect to the metric on $\mathbb{R}\times\mathbb{M}^n$. Then we define the smeared out 1-form $\;_\varepsilon \cdot d\mathbf{x}$ by averaging $\;(\mathbf{z},\cdot)\cdot d\mathbf{x}$ over $\mathbf{z}$ with respect to k_ε. On the level of the vector fields this means

$$\forall\, \mathbf{x} \in \mathbb{R}\times\mathbb{M}^n \qquad {}_\varepsilon(\mathbf{x}) = \iint_{\mathbb{R}\times\mathbb{R}^n} \;(\mathbf{z},\mathbf{x})\;\; k_\varepsilon(\mathbf{z})\,d\mathbf{z}. \tag{5.14}$$

Finally, we introduce T_ε by duality; i.e., for all 1-forms $\;\cdot\, d\mathbf{x}$ we put

$$\Big\langle T_\varepsilon, \;\cdot\, d\mathbf{x}\Big\rangle := \Big\langle T, \;_\varepsilon \cdot d\mathbf{x}\Big\rangle. \tag{5.15}$$

Step 2. We first argue that T_ε has a smooth representative in $(0,1)\times U$. In order to see this, we write (5.14) in the form of

$$ {}_{\varepsilon}(\mathbf{x}) = \iint_{(0,1)\times U} K_\varepsilon(\mathbf{y},\mathbf{x}) \quad (\mathbf{y})\, d\mathbf{y} \quad \text{for } \mathbf{x}\in(0,1)\times U. \tag{5.16}$$

Indeed, we shall see that (5.16) holds for the tensor field

$$ K_\varepsilon(\mathbf{y},\mathbf{x}) = \left\{ \begin{array}{ll} \Big(-\big(D_{\mathbf{y}}\mathbf{\Psi}(\mathbf{y},\mathbf{x})\big)^{-1} D_{\mathbf{x}}\mathbf{\Psi}(\mathbf{y},\mathbf{x})\Big)^t & k_\varepsilon\big(\mathbf{\Psi}(\mathbf{y},\mathbf{x})\big) \det D_{\mathbf{y}}\mathbf{\Psi}(\mathbf{y},\mathbf{x}) \\ & \text{for } \mathbf{x}\in(0,1)\times U \\ 0 & \text{otherwise} \end{array} \right\} $$

$$ \forall\ \mathbf{y}\in\big(0,1)\times U. \tag{5.17}$$

Notice that $K_\varepsilon(\mathbf{y},\mathbf{x})$ is an endomorphism from the tangent space $T_{\mathbf{y}}(\mathbb{R}\times\mathbb{M}^n)$ into $T_{\mathbf{x}}(\mathbb{R}\times\mathbb{M}^n)$ and that $K_\varepsilon(\mathbf{y},\mathbf{x})$ is smooth in $(\mathbf{y},\mathbf{x})\in\big((0,1)\times U\big)\times(\mathbb{R}\times\mathbb{M}^n)$. Indeed, if $\mathbf{y}$ varies in a compact subset of $(0,1)\times U$ and $\mathbf{x}\in(0,1)\times U$ is close to $\partial\big((0,1)\times U\big)$, we learn from (5.11) that $k_\varepsilon\big(\mathbf{\Psi}(\mathbf{y},\mathbf{x})\big)=0$ and thus $K_\varepsilon(\mathbf{y},\mathbf{x})=0$, because k_ε has bounded support. We check (5.16): For all $\mathbf{x}\in(0,1)\times U$

$$\begin{aligned}
{}_{\varepsilon}(\mathbf{x}) &\overset{(5.14)}{=} \iint_{\mathbb{R}\times\mathbb{R}^n} \quad (\mathbf{z},\mathbf{x}) \ \ k_\varepsilon(\mathbf{z})\, d\mathbf{z} \\
&\overset{(5.13)}{=} \iint_{\mathbb{R}\times\mathbb{R}^n} \big(D_{\mathbf{x}}\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)^t \ \ \big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big) \ \ k_\varepsilon(\mathbf{z})\, d\mathbf{z} \\
&\overset{(5.5)}{=} \iint_{(0,1)\times U} \Big(D_2\mathbf{\Phi}\big(\mathbf{\Psi}(\mathbf{y},\mathbf{x}),\mathbf{x}\big)\Big)^t \ \ (\mathbf{y}) \ \ k_\varepsilon\big(\mathbf{\Psi}(\mathbf{y},\mathbf{x})\big) \det D_{\mathbf{y}}\mathbf{\Psi}(\mathbf{y},\mathbf{x})\, d\mathbf{y} \\
&\overset{(5.9)}{=} \iint_{(0,1)\times U} \Big(-\big(D_{\mathbf{y}}\mathbf{\Psi}(\mathbf{y},\mathbf{x})\big)^{-1} D_{\mathbf{x}}\mathbf{\Psi}(\mathbf{y},\mathbf{x})\Big)^t \ \ (\mathbf{y}) \ \ k_\varepsilon\big(\mathbf{\Psi}(\mathbf{y},\mathbf{x})\big) \\
&\qquad\qquad \times \det D_{\mathbf{y}}\mathbf{\Psi}(\mathbf{y},\mathbf{x})\, d\mathbf{y} \\
&\overset{(5.17)}{=} \iint_{(0,1)\times U} K_\varepsilon(\mathbf{y},\mathbf{x}) \quad (\mathbf{y})\, d\mathbf{y}.
\end{aligned}$$

We now argue that in $(0,1)\times U$, T_ε is represented by $\mathbf{m}_\varepsilon$ defined through

$$ \mathbf{m}_\varepsilon(\mathbf{y})\cdot \quad := \Big\langle T,\ \big(K_\varepsilon(\mathbf{y},\cdot) \quad \big)\cdot d\mathbf{x}\Big\rangle \quad \text{for } \mathbf{y}\in(0,1)\times U, \quad \in T_{\mathbf{y}}(\mathbb{R}\times\mathbb{M}^n). \tag{5.18}$$

Since $K_\varepsilon(\mathbf{y},\mathbf{x})$ is smooth in $(\mathbf{y},\mathbf{x})\in\big((0,1)\times U\big)\times(\mathbb{R}\times\mathbb{M}^n)$, $\mathbf{m}_\varepsilon$ is smooth in $\mathbf{y}\in(0,1)\times U$. We check that $\mathbf{m}_\varepsilon$ is indeed the representative of T_ε in $(0,1)\times U$. Let be a smooth vector field compactly supported in $(0,1)\times U$: Then

$$\begin{aligned}
\Big\langle T_\varepsilon, \quad \cdot\, d\mathbf{x}\Big\rangle &\overset{(5.15)}{=} \Big\langle T, \quad {}_{\varepsilon}\cdot d\mathbf{x}\Big\rangle \\
&\overset{(5.16)}{=} \iint_{(0,1)\times U} \Big\langle T,\ \big(K_\varepsilon(\mathbf{y},\cdot) \quad (\mathbf{y})\big)\cdot d\mathbf{x}\Big\rangle\, d\mathbf{y} \\
&\overset{(5.18)}{=} \iint_{(0,1)\times U} \mathbf{m}_\varepsilon(\mathbf{y})\cdot \quad (\mathbf{y})\, d\mathbf{y}.
\end{aligned}$$

Step 3. We now prove that the operator $T \mapsto T_\varepsilon$ does not destroy smoothness. More precisely, we shall argue that for $V \subset \mathbb{M}^n$ open

$$\begin{aligned} &T \text{ has a smooth representative in } (0,1) \times V \\ &\quad \Longrightarrow \quad T_\varepsilon \text{ has a smooth representative in } (0,1) \times (U \cup V) \end{aligned} \tag{5.19}$$

and that

$$\begin{aligned} &T \text{ has a smooth representative in a neighborhood of } \{0,1\} \times \mathbb{M}^n \\ &\quad \Longrightarrow \quad T_\varepsilon \text{ has the same property.} \end{aligned} \tag{5.20}$$

To treat both situations simultaneously, we consider a set $\mathbf{V}$ that is relatively open in $[0,1] \times \mathbb{M}^n$ and in which T is represented by a smooth vector field $\mathbf{m}$ in the sense that for all smooth vector fields compactly supported in $\mathbf{V}$:

$$\Big\langle T, \quad \cdot\, d\mathbf{x} \Big\rangle = \iint_{\mathbb{R}\times\mathbb{M}^n} \mathbf{m} \cdot \quad d\mathbf{x}. \tag{5.21}$$

Then we claim that in the set

$$\mathbf{V}_\varepsilon := \bigcap_{\mathbf{z} \in \overline{B_\varepsilon(0)}} \mathbf{\Phi}(\mathbf{z}, \mathbf{V}) \tag{5.22}$$

the regularized current T_ε is represented by

(5.23)

$$\mathbf{m}_\varepsilon(\mathbf{x}) := \left\{ \begin{array}{ll} \displaystyle\iint_{\mathbb{R}\times\mathbb{R}^n} & \big(D_\mathbf{x}\mathbf{\Theta}(\mathbf{z},\mathbf{x})\big)^{-1} \mathbf{m}\big(\mathbf{\Theta}(\mathbf{z},\mathbf{x})\big) \;\; k_\varepsilon(\mathbf{z}) \, \det D_\mathbf{x}\mathbf{\Theta}(\mathbf{z},\mathbf{x}) \, d\mathbf{z} \\ & \qquad \text{for } \mathbf{x} \in \mathbf{V}_\varepsilon \cap \big((0,1) \times \mathbb{M}^n\big) \\ \mathbf{m}(\mathbf{x}) & \qquad \text{for } \mathbf{x} \in \mathbf{V}_\varepsilon \cap \big(\{0,1\} \times \mathbb{M}^n\big) \end{array} \right\}.$$

Notice first that $\mathbf{V}_\varepsilon$ is relatively open in $[0,1] \times \mathbb{M}^n$ since (5.3a) and (5.3f) give

$$\mathbf{V}_\varepsilon = \big([0,1] \times \mathbb{M}^n\big) - \mathbf{\Phi}\Big(\overline{B_\varepsilon(0)},\ \big([0,1] \times \mathbb{M}^n\big) - \mathbf{V}\Big).$$

According to (5.21), (5.22), and (5.4), the vector field $\mathbf{m}_\varepsilon$ is well defined. Moreover, $\mathbf{m}_\varepsilon$ inherits the smoothness of $\mathbf{m}$ separately in both subsets of $\mathbf{V}_\varepsilon$. Hence we only need to check that $\mathbf{m}_\varepsilon$ is regular throughout $\mathbf{V}_\varepsilon$. By smoothness of $\mathbf{\Theta}$ and (5.3f), the function $(s,x) \mapsto \mathbf{\Theta}\big(\mathbf{z},(s,x)\big)$ approaches the identity map as $s \to \{0,1\}$, uniformly in all derivatives and in both $\mathbf{z} \in \overline{B_\varepsilon(0)}$ and $x \in \mathbb{M}^n$. This implies in particular that $D_\mathbf{x}\mathbf{\Theta} \to \mathrm{Id}$ and $\det D_\mathbf{x}\mathbf{\Theta} \to 1$. Since, by assumption, $\mathbf{m}$ is smooth in $\mathbf{V}$, regularity of $\mathbf{m}_\varepsilon$ then follows easily by standard arguments. Therefore the operator $T \mapsto T_\varepsilon$ does not destroy smoothness in the above sense. We now check that $\mathbf{m}_\varepsilon$ is indeed the representative. Let a smooth vector field be given that is compactly supported in $\mathbf{V}_\varepsilon$. Because of (5.22), $(\mathbf{z}, \cdot)$ defined in (5.13) is compactly supported in $\mathbf{V}$ for all

$\mathbf{z} \in \overline{B_\varepsilon(0)}$, and so $\quad_\varepsilon$ is compactly supported in $\mathbf{V}$ by definition (5.14). We obtain

$$
\begin{aligned}
&\Big\langle T_\varepsilon, \quad \cdot\, d\mathbf{x} \Big\rangle \\
&\quad \overset{(5.15)}{=} \Big\langle T, \quad_\varepsilon \cdot d\mathbf{x} \Big\rangle \\
&\quad \overset{(5.21)}{=} \iint_{\mathbb{R}\times\mathbb{M}^n} \mathbf{m} \cdot \quad_\varepsilon \, d\mathbf{x} \\
&\quad \overset{(5.14)}{=} \iint_{\mathbb{R}\times\mathbb{R}^n} \iint_{\mathbb{R}\times\mathbb{M}^n} \mathbf{m}(\mathbf{x}) \cdot \quad (\mathbf{z},\mathbf{x}) \, d\mathbf{x} \;\; k_\varepsilon(\mathbf{z}) \, d\mathbf{z} \\
&\quad \overset{(5.13)}{=} \iint_{\mathbb{R}\times\mathbb{R}^n} \iint_{\mathbb{R}\times\mathbb{M}^n} D_\mathbf{x}\boldsymbol{\Phi}(\mathbf{z},\mathbf{x}) \, \mathbf{m}(\mathbf{x}) \cdot \quad \big(\boldsymbol{\Phi}(\mathbf{z},\mathbf{x})\big) \, d\mathbf{x} \;\; k_\varepsilon(\mathbf{z}) \, d\mathbf{z} \\
&\quad \overset{(5.4)}{=} \iint_{\mathbb{R}\times\mathbb{R}^n} d\mathbf{z} \; k_\varepsilon(\mathbf{z}) \\
&\qquad\qquad \times \iint_{\mathbb{R}\times\mathbb{M}^n} D_\mathbf{x}\boldsymbol{\Phi}\big(\mathbf{z},\boldsymbol{\Theta}(\mathbf{z},\mathbf{y})\big) \, \mathbf{m}\big(\boldsymbol{\Theta}(\mathbf{z},\mathbf{y})\big) \cdot \quad (\mathbf{y}) \;\; \det D_\mathbf{y}\boldsymbol{\Theta}(\mathbf{z},\mathbf{y}) \, d\mathbf{y} \\
&\quad \overset{(5.8)}{=} \iint_{\mathbb{R}\times\mathbb{R}^n} d\mathbf{z} \; k_\varepsilon(\mathbf{z}) \\
&\qquad\qquad \times \iint_{\mathbb{R}\times\mathbb{M}^n} \big(D_\mathbf{y}\boldsymbol{\Theta}(\mathbf{z},\mathbf{y})\big)^{-1} \mathbf{m}\big(\boldsymbol{\Theta}(\mathbf{z},\mathbf{y})\big) \cdot \quad (\mathbf{y}) \;\; \det D_\mathbf{y}\boldsymbol{\Theta}(\mathbf{z},\mathbf{y}) \, d\mathbf{y} \\
&\quad \overset{(5.23)}{=} \iint_{\mathbf{V}_\varepsilon} \mathbf{m}_\varepsilon(\mathbf{y}) \cdot \quad (\mathbf{y}) \, d\mathbf{y}.
\end{aligned}
$$

If now $\mathbf{V} = (0,1) \times V$ with $V \subset \mathbb{M}^n$ open, then (5.3d)–(5.3f) entail

$$
\mathbf{V}_\varepsilon - \big((0,1)\times U\big) = \mathbf{V} - \big((0,1)\times U\big).
$$

In particular, $\mathbf{V}_\varepsilon$ contains an open neighborhood of $\mathbf{V} \cap \big((0,1)\times \partial U\big)$. Therefore T_ε is smooth in $\mathbf{V} \cup \big((0,1)\times U\big)$. This establishes (5.19). Similarly, if $\mathbf{V} = [0,\alpha) \times \mathbb{M}^n$ for some $0 < \alpha < 1$, then $\mathbf{V}_\varepsilon = [0,\alpha') \times \mathbb{M}^n$ for some $0 < \alpha' \leqslant \alpha$ by (5.3d) and (5.3f). Therefore T_ε is smooth up to the boundary $\{0\} \times \mathbb{M}^n$. The same argument applies to $\mathbf{V} = (1-\alpha, 1] \times \mathbb{M}^n$. This establishes (5.20).

Step 4. We now argue that T_ε is admissible if T is, i.e., if

$$
\Big\langle T, \; \boldsymbol{\nabla}\zeta \cdot d\mathbf{x} \Big\rangle = \int_{\mathbb{M}^n} \zeta(1,x) \, d\rho_1(x) - \int_{\mathbb{M}^n} \zeta(0,x) \, d\rho_0(x) \tag{5.24}
$$

for all smooth functions ζ on $\mathbb{R}\times\mathbb{M}^n$. Consider the gradient field $\quad := \boldsymbol{\nabla}\zeta$. We gather from (5.13) and the chain rule that

$$
\quad (\mathbf{z},\mathbf{x}) = \boldsymbol{\nabla}_\mathbf{x} \zeta(\mathbf{z},\mathbf{x}), \quad \text{where} \quad \zeta(\mathbf{z},\mathbf{x}) := \zeta\big(\boldsymbol{\Phi}(\mathbf{z},\mathbf{x})\big).
$$

We thus infer from (5.14) that

$$
\quad_\varepsilon(\mathbf{x}) = \boldsymbol{\nabla}\zeta_\varepsilon(\mathbf{x}), \quad \text{where} \quad \zeta_\varepsilon(\mathbf{x}) := \iint_{\mathbb{R}\times\mathbb{R}^n} \zeta(\mathbf{z},\mathbf{x}) \;\; k_\varepsilon(\mathbf{z}) \, d\mathbf{z}. \tag{5.25}
$$

Then (5.3f) implies that

$$
\forall\, (\mathbf{z},\mathbf{x}) \in (\mathbb{R}\times\mathbb{R}^n) \times \big(\big(\mathbb{R} - (0,1)\big) \times \mathbb{M}^n\big) \quad \left\{ \begin{array}{c} \zeta(\mathbf{z},\mathbf{x}) = \zeta(\mathbf{x}) \\ \text{and thus} \\ \zeta_\varepsilon(\mathbf{x}) = \zeta(\mathbf{x}) \end{array} \right\}. \tag{5.26}
$$

Hence we obtain as desired

$$\begin{aligned}
\Big\langle T_\varepsilon,\ \boldsymbol{\nabla}\zeta\cdot d\mathbf{x}\Big\rangle &\overset{\substack{(5.15)\\(5.25)}}{=} \Big\langle T,\ \boldsymbol{\nabla}\zeta_\varepsilon\cdot d\mathbf{x}\Big\rangle\\
&\overset{(5.24)}{=} \int_{\mathbb{M}^n}\zeta_\varepsilon(1,x)\,d\rho_1(x) - \int_{\mathbb{M}^n}\zeta_\varepsilon(0,x)\,d\rho_0(x)\\
&\overset{(5.26)}{=} \int_{\mathbb{M}^n}\zeta(1,x)\,d\rho_1(x) - \int_{\mathbb{M}^n}\zeta(0,x)\,d\rho_0(x).
\end{aligned}$$

Step 5. Now we address the action estimate. We claim that for small ε

$$\mathcal{A}(T_\varepsilon) \leqslant \big(1+\mathcal{O}(\varepsilon)\big)\,\mathcal{A}(T)+\mathcal{O}(\varepsilon) \tag{5.27}$$

with the modulus $\mathcal{O}(\varepsilon)$ depending only on $\mathbf{\Phi}$. Let $\quad = (\sigma,\xi)$ be an admissible vector field in the definition of $\mathcal{A}$, i.e., for which

$$\sigma+\tfrac{1}{2}|\xi|^2 \leqslant 0. \tag{5.28}$$

Consider $\quad(\mathbf{z},\mathbf{x}) = \big(\sigma(\mathbf{z},\mathbf{x}),\xi(\mathbf{z},\mathbf{x})\big)$ defined in (5.13). We will then show that the modified vector field

$$\begin{gathered}
\Big(\lambda(\mathbf{z})\,\big(\sigma(\mathbf{z},\cdot)-\mu(\mathbf{z})\big),\ \lambda(\mathbf{z})\,\xi(\mathbf{z},\cdot)\Big)\ \text{ is admissible}\\
\text{for suitable constants } \lambda(\mathbf{z}) = 1-\mathcal{O}(|\mathbf{z}|),\ \mu(\mathbf{z}) = O(|\mathbf{z}|).
\end{gathered} \tag{5.29}$$

Indeed, the anisotropy condition (5.3d) on $\mathbf{\Phi} = (\Phi_0,\Phi)$ and (5.13) give

$$\begin{aligned}
\sigma(\mathbf{z},\mathbf{x}) &= \partial_s\Phi_0(\mathbf{z},s)\,\sigma\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)+\partial_s\Phi(\mathbf{z},\mathbf{x})\cdot\xi\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big),\\
\xi(\mathbf{z},\mathbf{x}) &= \big(D_x\Phi(\mathbf{z},\mathbf{x})\big)^t\,\xi\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big).
\end{aligned}$$

Because of (5.10) this yields the estimates

$$\begin{aligned}
\sigma(\mathbf{z},\mathbf{x}) &\leqslant \big(1-\mathcal{O}(|\mathbf{z}|)\big)\,\sigma\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)+\mathcal{O}(|\mathbf{z}|)\,\big|\xi\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)\big|,\\
|\xi(\mathbf{z},\mathbf{x})| &\leqslant \big(1+\mathcal{O}(|\mathbf{z}|)\big)\,\big|\xi\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)\big|.
\end{aligned} \tag{5.30}$$

Using Young's inequality

$$2\lambda(\mathbf{z})\,\big|\xi\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)\big| \leqslant 1+\lambda(\mathbf{z})^2\,\big|\xi\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)\big|^2, \tag{5.31}$$

we notice that the latter implies

$$\begin{aligned}
&\lambda(\mathbf{z})\,\big(\sigma(\mathbf{z},\mathbf{x})-\mu(\mathbf{z})\big)+\tfrac{1}{2}|\lambda(\mathbf{z})\,\xi(\mathbf{z},\mathbf{x})|^2\\
&\quad\overset{(5.30)}{\leqslant} \lambda(\mathbf{z})\,\Big(\big(1-\mathcal{O}(|\mathbf{z}|)\big)\,\sigma\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)+\mathcal{O}(|\mathbf{z}|)\,\big|\xi\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)\big|-\mu(\mathbf{z})\Big)\\
&\qquad\quad + \lambda(\mathbf{z})^2\,\big(1+\mathcal{O}(|\mathbf{z}|)\big)^2\,\tfrac{1}{2}\big|\xi\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)\big|^2\\
&\quad\overset{(5.31)}{\leqslant} \lambda(\mathbf{z})\,\big(1-\mathcal{O}(|\mathbf{z}|)\big)\,\sigma\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)+\lambda(\mathbf{z})^2\,\big(1+\mathcal{O}(|\mathbf{z}|)\big)\,\tfrac{1}{2}\big|\xi\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)\big|^2\\
&\qquad\quad + \mathcal{O}(|\mathbf{z}|)-\lambda(\mathbf{z})\,\mu(\mathbf{z})\\
&\quad\overset{(5.28)}{\leqslant} \lambda(\mathbf{z})\,\Big(-\big(1-\mathcal{O}(|\mathbf{z}|)\big)+\big(1+\mathcal{O}(|\mathbf{z}|)\big)\,\lambda(\mathbf{z})\Big)\,\tfrac{1}{2}\big|\xi\big(\mathbf{\Phi}(\mathbf{z},\mathbf{x})\big)\big|^2\\
&\qquad\quad + \mathcal{O}(|\mathbf{z}|)-\lambda(\mathbf{z})\,\mu(\mathbf{z}),
\end{aligned}$$

which in turn yields (5.29).

Choosing $\zeta(s,x) = s$ in the admissibility condition (5.24) yields

$$\Big\langle T,\ 1\,ds \Big\rangle = 1. \tag{5.32}$$

Thus we have by definition of $\mathcal{A}(T)$

$$\begin{aligned}
&\Big\langle T,\ \sigma(\mathbf{z},\cdot)\,ds + \xi(\mathbf{z},\cdot)\cdot dx \Big\rangle \\
&\quad \overset{(5.29)}{=} \frac{1}{\lambda(\mathbf{z})} \Big\langle T,\ \lambda(\mathbf{z})\big(\sigma(\mathbf{z},\cdot) - \mu(\mathbf{z})\big)\,ds + \lambda(\mathbf{z})\,\xi(\mathbf{z},\cdot)\cdot dx \Big\rangle + \mu(\mathbf{z}) \Big\langle T,\ 1\,ds \Big\rangle \\
&\quad \overset{(5.32)}{\leqslant} \frac{1}{\lambda(\mathbf{z})}\,\mathcal{A}(T) + \mu(\mathbf{z}) \\
&\quad \overset{(5.29)}{=} \big(1 + \mathcal{O}(|\mathbf{z}|)\big)\,\mathcal{A}(T) + \mathcal{O}(|\mathbf{z}|).
\end{aligned} \tag{5.33}$$

We therefore obtain as desired

$$\begin{aligned}
\Big\langle T_\varepsilon,\ \sigma\,ds + \xi\cdot dx \Big\rangle &\overset{(5.15)}{=} \Big\langle T,\ \sigma_\varepsilon\,ds + \xi_\varepsilon\cdot dx \Big\rangle \\
&\overset{(5.14)}{=} \iint_{\mathbb{R}\times\mathbb{R}^n} \Big\langle T,\ \sigma(\mathbf{z},\cdot)\,ds + \xi(\mathbf{z},\cdot)\cdot dx \Big\rangle\ k_\varepsilon(\mathbf{z})\,d\mathbf{z} \\
&\overset{(5.33)}{=} \big(1 + \mathcal{O}(\varepsilon)\big)\mathcal{A}(T) + \mathcal{O}(\varepsilon).
\end{aligned}$$

Since (σ,ξ) was arbitrary with (5.28), this yields (5.27) by definition of $\mathcal{A}(T_\varepsilon)$.

Step 6. Let T_ε have a smooth representative $(\rho_\varepsilon, m_\varepsilon)$ in $(0,1)\times\mathbb{M}^n$ and satisfy $\mathcal{A}(T_\varepsilon) < \infty$. We now argue that $\rho_\varepsilon \geqslant 0$. More precisely, we shall show that

$$\Big\langle T_\varepsilon,\ \zeta\,ds \Big\rangle \geqslant 0 \quad \forall \text{ smooth test function } \zeta \text{ with } \zeta \geqslant 0. \tag{5.34}$$

Indeed, for $n \in \mathbb{N}$ the vector field $\;= (-n\zeta, 0)$ is admissible and yields

$$-n\Big\langle T_\varepsilon,\ \zeta\,ds \Big\rangle = \Big\langle T_\varepsilon,\ \ \cdot d\mathbf{x} \Big\rangle \leqslant \mathcal{A}(T_\varepsilon),$$

which gives (5.34) in the limit $n \to \infty$. By (5.2), this proves that $\rho_\varepsilon \geqslant 0$.

Step 7. It remains to construct the map $\mathbf{\Phi} = (\Phi_0, \Phi)$. This is done in a series of short steps. The starting point is the diffeomorphism $h_0\colon (0,1) \longrightarrow \mathbb{R}$ defined by

$$h_0(s) = \big(s - \tfrac{1}{2}\big)\,\exp\Big(\frac{1}{s(1-s)}\Big).$$

Next we introduce the map $\Phi_0\colon \mathbb{R}\times\mathbb{R} \longrightarrow \mathbb{R}$:

$$\Phi_0(u,s) = \left\{ \begin{array}{ll} h_0^{-1}\big(h_0(s) + u\big) & \text{for } s \in (0,1) \\ s & \text{otherwise} \end{array} \right\}. \tag{5.35}$$

The properties of the exponential function imply that Φ_0 is smooth. In particular, we have by the inverse function theorem that

$$\partial_u \Phi_0(u,s) = \left\{ \begin{array}{ll} \Big(h_0'\big(\Phi_0(u,s)\big)\Big)^{-1} & \text{for } s \in (0,1) \\ 0 & \text{otherwise} \end{array} \right\},$$

$$\partial_s \Phi_0(u,s) = \left\{ \begin{array}{ll} \Big(h_0'\big(\Phi_0(u,s)\big)\Big)^{-1} h_0'(s) & \text{for } s \in (0,1) \\ 1 & \text{otherwise} \end{array} \right\}.$$

The map Φ_0 obviously has the homomorphism property

$$\begin{aligned} \forall\, u, u' \in \mathbb{R},\ s \in \mathbb{R} \quad \Phi_0(u+u', s) &= \Phi_0\big(u, \Phi_0(u', s)\big), \\ \forall\, s \in \mathbb{R} \quad \Phi_0(0, s) &= s. \end{aligned} \tag{5.36}$$

In a similar way, we introduce the diffeomorphism $\tilde{h}\colon B_1(0) \to \mathbb{R}^n$ defined by

$$\tilde{h}(\tilde{x}) = \tilde{x}\, \exp\bigg(\frac{1}{1-|\tilde{x}|^2}\bigg)$$

and the map $\tilde{\Phi}\colon \mathbb{R}^n \times \mathbb{R}^n \longrightarrow \mathbb{R}^n$ through

$$\tilde{\Phi}(z, \tilde{x}) = \left\{ \begin{array}{ll} \tilde{h}^{-1}\big(\tilde{h}(\tilde{x}) + z\big) & \text{for } \tilde{x} \in B_1(0) \\ \tilde{x} & \text{otherwise} \end{array} \right\}. \tag{5.37}$$

Again, the properties of the exponential function imply that $\tilde{\Phi}$ is smooth, and

$$D_z\tilde{\Phi}(z, \tilde{x}) = \left\{ \begin{array}{ll} \Big(D\tilde{h}\big(\tilde{\Phi}(z, \tilde{x})\big)\Big)^{-1} & \text{for } \tilde{x} \in B_1(0) \\ 0 & \text{otherwise} \end{array} \right\},$$

$$D_{\tilde{x}}\tilde{\Phi}(z, \tilde{x}) = \left\{ \begin{array}{ll} \Big(D\tilde{h}\big(\tilde{\Phi}(z, \tilde{x})\big)\Big)^{-1} D\tilde{h}(\tilde{x}) & \text{for } \tilde{x} \in B_1(0) \\ \mathrm{Id} & \text{otherwise} \end{array} \right\}.$$

As for Φ_0 above, the map $\tilde{\Phi}$ has the homomorphism property

$$\begin{aligned} \forall\, z, z' \in \mathbb{R}^n,\ \tilde{x} \in \mathbb{R}^n \quad \tilde{\Phi}(z+z', \tilde{x}) &= \tilde{\Phi}\big(z, \tilde{\Phi}(z', \tilde{x})\big), \\ \forall\, \tilde{x} \in \mathbb{R}^n \quad \tilde{\Phi}(0, \tilde{x}) &= \tilde{x}. \end{aligned} \tag{5.38}$$

Recall that $U \subset \mathbb{M}^n$ is an open subset homeomorphic to the ball $B_1(0) \subset \mathbb{R}^n$, with $\phi\colon U \longrightarrow \mathbb{R}^n$ a coordinate map. We may assume that ϕ extends to some neighborhood of U and $B_1(0)$. Then the composition

$$h(x) := \tilde{h}\big(\phi(x)\big) \quad \forall\, x \in U$$

defines a diffeomorphism $h\colon U \longrightarrow \mathbb{R}^n$. In view of (5.37),

$$\Phi(z, x) = \left\{ \begin{array}{ll} \phi^{-1}\Big(\tilde{\Phi}\big(z, \phi(x)\big)\Big) & \text{for } x \in U \\ x & \text{otherwise} \end{array} \right\}$$

defines a smooth map $\Phi\colon \mathbb{R}^n \times \mathbb{M}^n \longrightarrow \mathbb{M}^n$, and it is immediately clear that the properties (5.37) and (5.38) are conserved; i.e., we have

$$\Phi(z, x) = \left\{ \begin{array}{ll} h^{-1}\big(h(x) + z\big) & \text{for } x \in U \\ x & \text{otherwise} \end{array} \right\} \tag{5.39}$$

and

$$\begin{aligned} \forall\, z, z' \in \mathbb{R}^n,\ x \in \mathbb{M}^n \quad \Phi(z+z', x) &= \Phi\big(z, \Phi(z', x)\big), \\ \forall\, x \in \mathbb{M}^n \quad \Phi(0, x) &= x. \end{aligned} \tag{5.40}$$

Finally, we consider the smooth function $\delta\colon \mathbb{R} \longrightarrow \mathbb{R}$ defined through

$$\delta(s) = \left\{ \begin{array}{ll} \exp\Big(-\dfrac{1}{s(1-s)}\Big) & \text{for } s \in (0,1) \\ 0 & \text{otherwise} \end{array} \right\}. \tag{5.41}$$

We now introduce the smooth map $\mathbf{\Phi}\colon (\mathbb{R}\times\mathbb{R}^n)\times(\mathbb{R}\times\mathbb{M}^n) \longrightarrow (\mathbb{R}\times\mathbb{M}^n)$:

$$\mathbf{\Phi}\big((u,z),(s,x)\big) := \Big(\Phi_0(u,s), \Phi\big(\delta(s)z,x\big)\Big).$$

Let us quickly check that $\mathbf{\Phi}$ has the required properties. We establish the diffeomorphism properties (5.3a) by explicitly giving the right inverse

$$\mathbf{\Theta}\big((u,z),(s,x)\big) = \Big(\Phi_0(-u,s), \Phi\big(-\delta\big(\Phi_0(-u,s)\big)z,x\big)\Big)$$

which defines a smooth map $\mathbf{\Theta}\colon (\mathbb{R}\times\mathbb{R}^n)\times(\mathbb{R}\times\mathbb{M}^n) \longrightarrow (\mathbb{R}\times\mathbb{M}^n)$. Then (5.36) and (5.40) imply (5.4) and (5.3b). The anisotropy property (5.3d) is clear by construction. The first invariance property (5.3e) can be read off from (5.39); the second invariance property (5.3f) follows from (5.35) for the Φ_0-component and from (5.41) combined with (5.40) for the Φ-component. The second diffeomorphism property (5.3c) follows from an explicit formula for the left inverse

$$\mathbf{\Psi}\big((t,y),(s,x)\big) = \left(h_0(t)-h_0(s), \frac{h(y)-h(x)}{\delta(s)}\right)$$

which defines a smooth map $\mathbf{\Psi}\colon \big((0,1)\times U\big)\times\big((0,1)\times U\big) \longrightarrow \mathbb{R}\times\mathbb{R}^n$ (recall that δ is positive on $(0,1)$). The identities (5.35) and (5.39) imply (5.5) as desired.

Step 8. In this last step, we prove that if ρ_0 and ρ_1 are smooth functions and if T is a current defined on $[0,1]\times\mathbb{M}^n$ satisfying the admissibility condition (5.1), then the regularization T_ε of T is representable by a vector field $(\rho_\varepsilon \geqslant 0, m_\varepsilon)$ that is smooth up to the boundary $\{0,1\}\times\mathbb{M}^n$. This can be achieved by first approximating T by an admissible current T_α that is representable by a smooth vector field in $[0,\alpha)\times\mathbb{M}^n$ and $(1-\alpha,1]\times\mathbb{M}^n$ for suitable α and then applying to T_α the regularization procedure described above. Since the operators $T\mapsto T^{U_i}_{\varepsilon_i}$ do not destroy smoothness in stripes around the boundary $\{0,1\}\times\mathbb{M}^n$ (see Step 3), the regularized current $(T_\alpha)_\varepsilon$ can be represented by a vector field that attains the data ρ_0 and ρ_1 smoothly as desired.

We proceed as follows: For $0<\alpha<\frac{1}{2}$ we consider the map

$$\mathbf{\Phi}_\alpha(s,x) := \big(\alpha+(1-2\alpha)s,x\big) \quad \text{for } (s,x)\in[0,1]\times\mathbb{M}^n.$$

Given a smooth 1-form $\cdot\, d\mathbf{x}$, let $\mathbf{\Phi}_\alpha^{\#}(\ \cdot\, d\mathbf{x}) =: {}_\alpha \cdot d\mathbf{x}$ be its pull-back under the map $\mathbf{\Phi}_\alpha$. In terms of the vector field $= (\sigma,\xi)$ this means

$$\forall\, \mathbf{x}\in[0,1]\times\mathbb{M}^n \qquad {}_\alpha(\mathbf{x}) = \big(D_{\mathbf{x}}\mathbf{\Phi}_\alpha(\mathbf{x})\big)^t\ \big(\mathbf{\Phi}_\alpha(\mathbf{x})\big), \tag{5.42}$$

and hence ${}_\alpha = (\sigma_\alpha,\xi_\alpha)$ with

$$\sigma_\alpha(\mathbf{x}) = (1-2\alpha)\,\sigma\big(\mathbf{\Phi}_\alpha(\mathbf{x})\big) \quad \text{and} \quad \xi_\alpha(\mathbf{x}) = \xi\big(\mathbf{\Phi}_\alpha(\mathbf{x})\big). \tag{5.43}$$

We define the approximate current T_α by duality as

$$\begin{aligned} \Big\langle T_\alpha,\ \cdot\, d\mathbf{x}\Big\rangle := \Big\langle T,\ {}_\alpha\cdot d\mathbf{x}\Big\rangle &+ \iint_{[0,\alpha]\times\mathbb{M}^n} \sigma(s,x)\,\rho_0(x)\,dx\,ds \\ &+ \iint_{[1-\alpha,1]\times\mathbb{M}^n} \sigma(s,x)\,\rho_1(x)\,dx\,ds \end{aligned} \tag{5.44}$$

for all smooth 1-forms $\cdot\, d\mathbf{x} = \sigma\, ds + \xi \cdot dx$. This T_α is admissible: If ζ is a smooth function and $:= \boldsymbol{\nabla}\zeta$ the gradient field, then (5.42) implies that

$$ {}_\alpha(\mathbf{x}) = \boldsymbol{\nabla}\zeta_\alpha(\mathbf{x}), \quad \text{where} \quad \zeta_\alpha(\mathbf{x}) := \zeta\big(\boldsymbol{\Phi}_\alpha(\mathbf{x})\big), $$

and therefore

$$ \begin{aligned} \Big\langle T_\alpha,\ \boldsymbol{\nabla}\zeta \cdot d\mathbf{x} \Big\rangle &= \int_{\mathbb{M}^n} \zeta(1-\alpha, x)\, \rho_1(x)\, dx + \iint_{[1-\alpha,1]\times\mathbb{M}^n} \partial_s\zeta(s,x)\, \rho_1(x)\, dx\, ds \\ &\quad - \int_{\mathbb{M}^n} \zeta(\alpha, x)\, \rho_0(x)\, dx + \iint_{[0,\alpha]\times\mathbb{M}^n} \partial_s\zeta(s,x)\, \rho_0(x)\, dx\, ds \\ &= \int_{\mathbb{M}^n} \zeta(1,x)\, \rho_1(x)\, dx - \int_{\mathbb{M}^n} \zeta(0,x)\, \rho_0(x)\, dx. \end{aligned} $$

It follows easily from (5.44) that T_α is represented by the smooth vector field $(\rho_0, 0)$ in the stripe $[0,\alpha)\times\mathbb{M}^n$ and by $(\rho_1, 0)$ in $(1-\alpha, 1]\times\mathbb{M}^n$. Consider the action functional. Notice first that if $= (\sigma, \xi)$ is admissible in the definition of $\mathcal{A}$, then also the modified vector field $(1-2\alpha)\ {}_\alpha$ is admissible since by (5.43)

$$ (1-2\alpha)\sigma_\alpha + \tfrac{1}{2}|(1-2\alpha)\xi_\alpha|^2 = (1-2\alpha)^2\Big(\sigma \circ \boldsymbol{\Phi}_\alpha + \tfrac{1}{2}|\xi \circ \boldsymbol{\Phi}_\alpha|^2\Big) \leqslant 0. $$

The extra integrals in (5.44) do not contribute to $\mathcal{A}(T_\alpha)$ because $\sigma \leqslant -\frac{1}{2}|\xi|^2 \leqslant 0$ and $\rho_0, \rho_1 \geqslant 0$. This yields as above $\mathcal{A}(T_\alpha) \leqslant (1-2\alpha)^{-1}\mathcal{A}(T)$, and thus

$$ \limsup_{\alpha\to 0} \mathcal{A}(T_\alpha) \leqslant \mathcal{A}(T). $$

Now we regularize as before to conclude. $\square$

ZERO-VISCOSITY LIMIT OF THE LINEARIZED COMPRESSIBLE NAVIER-STOKES EQUATIONS WITH HIGHLY OSCILLATORY FORCES IN THE HALF-PLANE*

YA-GUANG WANG† AND ZHOUPING XIN‡

Abstract. We study the asymptotic behavior of the solution to the linearized compressible Navier–Stokes equations with highly oscillatory forces in the half-plane with nonslip boundary conditions for small viscosity. The wavelength of oscillation is assumed to be proportional to the square root of the viscosity. By means of asymptotic analysis, we deduce that the leading profiles of the solution have four terms: the first one is the outflow satisfying the linearized Euler equations, the second one is an oscillatory wave propagated along the characteristic field tangential to the boundary associated with the linearized Euler operator in the half-plane, the third one is a boundary layer satisfying a linearized Prandtl equation, the fourth one represents the oscillation propagated in the boundary layer, and it is described by an initial-boundary value problem for an Poisson–Prandtl coupled system. By using the energy method and mode analysis, we obtain the well-posedness of this Poisson–Prandtl coupled problem, and a rigorous theory on the asymptotic analysis of the zero-viscosity limit. Finally, we have briefly discussed the case that the wavelength of the oscillatoy force is shorter than the square root of the viscosity.

1. Introduction.

Consider the following initial-boundary value problem for the two-dimensional isentropic compressible Navier–Stokes equations with nonslip boundary conditions in $\{t, x_1 > 0, x_2 \in \mathbb{R}\}$:

$$
\begin{cases}
\partial_t \rho + (v \cdot \nabla)\rho + \rho \nabla \cdot v = f(t,x), \\
\rho(\partial_t v + (v \cdot \nabla)v) + \nabla p = \nabla \cdot (2\mu P + \lambda I_2 \nabla \cdot v) + g(t,x), \\
v|_{x_1=0} = 0, \\
(\rho, v)|_{t=0} = (\rho_0, v_0)(x),
\end{cases}
\tag{1.1}
$$

where f and g represent the source and force terms, $P = \frac{1}{2}\{\partial_{x_j} v_i + \partial_{x_i} v_j\}_{i \times j}$ is a 2×2 matrix with $v = (v_1, v_2)^T$, $p = p(\rho)$ is the equation of state, μ and λ denote the coefficient and the second coefficient of viscosity, respectively, with $\mu > 0$ and $\mu' = \mu + \lambda \geq 0$. Corresponding to (1.1), the motion of an inviscid compressible fluid

is governed by the following Euler equations:

$$
\begin{cases}
\partial_t \rho + (v \cdot \nabla)\rho + \rho \nabla \cdot v = f(t,x), \\
\rho(\partial_t v + (v \cdot \nabla) v) + \nabla p = g(t,x), \\
v_1|_{x_1=0} = 0, \\
(\rho, v)|_{t=0} = (\rho_0, v_0)(x).
\end{cases} \tag{1.2}
$$

For simplicity, we assume that μ and μ' are proportional to a parameter, say ϵ^2 with $\epsilon > 0$.

One interesting problem is to study the convergence of the solution of the Navier–Stokes equations (1.1) to that of the Euler equations (1.2) in the limit of small viscosity. It is expected that uniform convergence can take place only away from the physical boundary $\{x_1 = 0\}$ even for smooth solutions of (1.2) due to the disparity of the boundary conditions in (1.1) and (1.2), and a thin region comes out near the boundary $\{x_1 = 0\}$ (the boundary layer) in which values of unknowns change drastically in the process of this limit.

It is a challenging problem to analyze rigorously this boundary layer phenomena displayed by the actual Navier–Stokes solutions. For the problem of incompressible Navier–Stokes equations, Prandtl carried out a formal analysis in his speech [6] at the International Congress of Mathematicians in 1904, and derived a nonlinear degenerate parabolic-elliptic coupled system for the velocity fields in the boundary layer, which is now called the Prandtl system. Under the monotonic assumption on the velocity of the outflow, Oleinik and Samokhin established the local existence of smooth solutions for boundary value problems of the Prandtl system since the 1960's, and their works were surveyed recently in the monography [5]. The existence and uniqueness of global weak solutions to the Prandtl system are recently established by Xin and Zhang [13] and Xin, Zhang, and Zhao [14], respectively. In [7, 8], Sammartino and Caflisch obtained the local existence of analytic solutions to the Prandtl system, and a rigorous theory on the boundary layer in incompressible fluids with analytic data in the frame of the abstract Cauchy–Kowaleskaya theory. Grenier [2, 3] investigated the stability of boundary layer type solutions to the Euler equations and the instability of solutions to the incompressible Navier–Stokes equations. Till now, there existed no general rigorous theory of viscous boundary layer in the case of nonslip boundary conditions; this is reviewed in [1, 11]. The problem of the viscous boundary layer in the case of slip boundary conditions was studied rigorously by Temam and Wang in [10].

To study the theory of the viscous boundary layer for compressible fluids with nonslip boundary conditions, recently, Xin and Yanagisawa [12] obtained a rigorous justification of the Prandtl boundary layer theory for the linearized compressible fluids when the viscosity goes to zero.

The purpose of this paper is to study the asymptotic behavior of solutions to the linearized compressible Navier–Stokes equations on the half-plane with nonslip boundary conditions perturbed by high frequency oscillatory force terms, and to investigate the interaction between the linearized boundary layer and rapidly oscillatory waves.

In the case that the oscillation of the force term is propagated along the tangential characteristic field of the boundary with respect to the linearized Euler operator, see (2.6)–(2.9), and the wavelength is proportional to the square root of the viscosity, we establish a rigorous theory on the boundary layer and its oscillatory behavior. Roughly speaking, it is shown that the leading profiles of the solution to the linearized compressible Navier–Stokes equations can be divided into four terms: the first one is the outflow satisfying the linearized Euler equations, the second one is an oscillatory wave propagated along the characteristic field tangential to the boundary associated with the linearized Euler operator in the half-plane, and its amplitude satisfies a linear degenerate parabolic equation with the second order term coming from the viscous term in the linearized Navier–Stokes equations, the third one is the classical linearized Prandtl boundary layer supported in a thin neighborhood of the boundary, and the fourth one is an oscillatory wave propagated in the boundary layer, this term together with its vorticity with respect to the normal variable and the fast variable satisfy an initial-boundary value problem for an Poisson–Prandtl coupled system. This result shows that the zero-viscosity limit of the solution to the linearized compressible Navier–Stokes equations with highly oscillatory forces satisfies the linearized Euler equations away from the boundary, and the oscillation is propagated in a way of linear geometric optics in free space. The boundary layer is of the Prandtl type as usual, but the novelties are that the oscillation is propagated in the layer, and there is an interaction between the boundary layer and highly oscillatory waves near the boundary; for details see Theorem 2.1.

When the wavelength of the oscillatory force term is shorter than the square root of the viscosity, we observe that both the oscillation in the outflow and in the boundary layer appear only in the high order profiles, and the leading profiles are the same as the case studied in [12] with the force term without oscillation. This phenomenon will be explained in the appendix for the case that the wavelength of the oscillatory force term is the same order as the viscosity. The case that the wavelength of the oscillatory force term is longer than the square root of the viscosity is more complicated and challenging as it may destabilize the boundary layer. We shall study this problem in a forthcoming paper.

The nonlinear interaction between the boundary layer and high frequency oscillating waves for the artificial viscosity problem of a semilinear hyperbolic system was studied by Gues in [4], for which the leading profiles of solutions have three terms: the outflow satisfying the hyperbolic problem, an oscillatory wave propagated in the half space (its amplitude satisfies an initial value problem for a degenerate parabolic equation), and the boundary layer, which satisfies an initial-boundary value problem for a degenerate parabolic equation. Due to the nonlinearity of the system, problems for these three profiles are coupled together. Main differences between this paper and Gues' work [4] are that the profile of the boundary layer in the Navier–Stokes system satisfies the Prandtl system even when the force term without oscillation, and the phase function of oscillation we will study is nonlinear in general, which gives rise to the above fourth profile, describing the oscillation in the boundary layer, while the phase function of the oscillatory waves considered by Gues in [4] is linear and vanishes at the boundary, which implies that the above fourth term does not appear in that case (see Remark 5.1).

Another related work is that of Szepessy in [9], which gave a geometric optics expansion for a linearized viscous shock profile perturbed by a highly oscillatory wave in two space variables.

The remainder of this paper shall be arranged as follows. In section 2, we carry out the formal analysis to derive problems for the leading profiles of the asymptotic expansion of the solution to the linearized Navier–Stokes equations with respect to ϵ, proportional to the square root of the viscosity, and observe that one of leading profiles describes the oscillation propagated in the boundary layer, and this profile together with its vorticity with respect to the normal variable and the oscillatory variable satisfy an initial-boundary value problem for an Poisson–Prandtl coupled system. The derivation of problems for higher order profiles will be given in the appendix. The problem for the Poisson–Prandtl coupled equations is not a classical one. To our knowledge, there is no any literature devoted to this kind of problem, so we shall establish the well-posedness of this problem in section 3. In section 4, we rigorously justify the formal analysis of the zero-viscosity limit for the solution to the linearized Navier–Stokes equations. Finally, in the appendix, we shall also study the problem with the wavelength of the oscillatory force term being the same order as the viscosity.

2. Asymptotic analysis and main results. Corresponding to the problem (1.1) for the compressible Navier–Stokes equations, we consider the following linearized problem at a state $V'=(\rho',v_1',v_2')^T$ with a high frequency oscillatory force term in the half-space $\{t,x_1>0,x_2\in\mathbb{R}\}$:

$$\begin{cases} A_0(V')\partial_t V^\epsilon + A_1(V')\partial_{x_1}V^\epsilon + A_2(V')\partial_{x_2}V^\epsilon = B(\epsilon^2, D\epsilon^2)V^\epsilon + \Phi(t,x;\frac{\varphi(t,x)}{\epsilon}) \\ M^+V^\epsilon = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} V^\epsilon = 0, \qquad \text{on} \quad x_1=0 \\ V^\epsilon|_{t=0} = V_0(x), \end{cases} \tag{2.1}$$

where $V^\epsilon=(\rho^\epsilon,v_1^\epsilon,v_2^\epsilon)^T$, $\Phi(t,x;\theta)$ is periodic in $\theta\in T^1=\mathbb{R}/2\pi Z$,

$$A_0(V')=\begin{pmatrix} 1 & 0 & 0 \\ 0 & \rho' & 0 \\ 0 & 0 & \rho' \end{pmatrix},\ A_1(V')=\begin{pmatrix} v_1' & \rho' & 0 \\ c^2 & \rho' v_1' & 0 \\ 0 & 0 & \rho' v_1' \end{pmatrix},\ A_2(V')=\begin{pmatrix} v_2' & 0 & \rho' \\ 0 & \rho' v_2' & 0 \\ c^2 & 0 & \rho' v_2' \end{pmatrix}$$

with $c=\sqrt{\frac{dp(\rho')}{d\rho}}>0$ being the sound speed at V', and

$$B(\epsilon^2, D\epsilon^2)V^\epsilon = \epsilon^2(B_1\partial^2_{x_1}V^\epsilon + B_2\partial^2_{x_2}V^\epsilon + B_3\partial^2_{x_1x_2}V^\epsilon)$$

with $D\ge 0$ being a constant, and

$$B_1=\begin{pmatrix} 0 & 0 & 0 \\ 0 & 1+D & 0 \\ 0 & 0 & 1 \end{pmatrix},\quad B_2=\begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1+D \end{pmatrix},\quad B_3=\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & D \\ 0 & D & 0 \end{pmatrix},$$

where we have assumed that $\mu=\epsilon^2$ and $\mu'=D\epsilon^2$ in (1.1).

For convenience we shall assume that the background state V' is smooth and bounded. The case of finite order regularity can be handled as well, but much more bookkeeping is needed.

Suppose that

$$v_1'|_{x_1=0}=0. \tag{2.2}$$

For any fixed $(\xi_1,\xi_2)\neq(0,0)$, denote by

$$\tau_1=-(\xi_1 v_1'+\xi_2 v_2'),\quad \tau_{2,3}=-\left(\xi_1 v_1'+\xi_2 v_2' \pm c\sqrt{\xi_1^2+\xi_2^2}\right) \tag{2.3}$$

eigenvalues of the symbol $L(\tau, \xi_1, \xi_2)$ associated with the linearized Euler operator at V',

$$L(\partial_t, \partial_x) = A_0(V')\partial_t + A_1(V')\partial_{x_1} + A_2(V')\partial_{x_2} \tag{2.4}$$

which means that τ_k are roots to the following characteristic equation:

$$\det(\tau A_0(V') + \xi_1 A_1(V') + \xi_2 A_2(V')) = 0.$$

Denote by $\{\vec{r}_k\}_{k=1}^3$ and $\{\vec{l}_k\}_{k=1}^3$ the associated right and left eigenvectors, respectively,

$$\begin{cases} (\tau_k A_0(V') + \xi_1 A_1(V') + \xi_2 A_2(V'))\vec{r}_k = 0 \\ \vec{l}_k(\tau_k A_0(V') + \xi_1 A_1(V') + \xi_2 A_2(V')) = 0 \end{cases} \tag{2.5}$$

with the normalization

$$\vec{l}_j A_0 \vec{r}_k = \delta_{jk} = \begin{cases} 1, & j = k \\ 0, & j \neq k. \end{cases}$$

It follows from (2.2) that the boundary $\{x_1 = 0\}$ is uniformly characteristic with respect to the eigenvalue $\tau_1 = -(\xi_1 v_1' + \xi_2 v_2')$ associated with the linearized Euler operator (2.4).

As in the classical theory of nonlinear geometric optics [4], it is assumed that the oscillation phase $\varphi(t, x)$ in (2.1) satisfies the eikonal equation with respect to τ_1,

$$\partial_t \varphi + v_1' \partial_{x_1} \varphi + v_2' \partial_{x_2} \varphi = 0. \tag{2.6}$$

In this paper, we shall assume

$$\varphi^0(t, x_2) := \varphi(t, 0, x_2) \neq 0. \tag{2.7}$$

Obviously, the assumption $v_1'|_{x_1=0} = 0$ implies

$$\partial_t \varphi^0 + v_2'(0)\partial_{x_2} \varphi^0 = 0 \tag{2.8}$$

with $v_2'(0)$ denoting $v_2'(t, 0, x_2)$.

Moreover, we assume

$$\partial_{x_2} \varphi^0 = \partial_{x_2} \varphi|_{x_1=0} \neq 0 \tag{2.9}$$

at each point of $\{(t, x_2) \in \mathbb{R}^+ \times \mathbb{R}\}$. If $\partial_{x_2} \varphi^0 \equiv 0$, then from (2.8) we have $\partial_t \varphi^0 = 0$ as well, which implies

$$\varphi^0(t, x_2) \equiv \text{const}$$

yielding no oscillation factor in the boundary layer. The problem in the general case of φ, e.g., $\varphi(t, 0, x_2)$ degenerates in a subset of $(t, x_2) \in \mathbb{R}^+ \times \mathbb{R}$ is interesting, and shall be investigated in the future. As we shall see, the case $\varphi(t, 0, x_2) \equiv 0$ is easier to handle.

In the case of (2.6)–(2.9), we take the following ansatz for the solution of (2.1):

$$V^\epsilon(t, x) = V_{in}^\epsilon(t, x) + V_{bd}^\epsilon(t, x), \tag{2.10}$$

where

$$
\begin{cases} V_{in}^{\epsilon}(t,x) = \sum_{j\geq 0} \epsilon^j \left(a_j(t,x) + c_j\left(t,x; \frac{\varphi(t,x)}{\epsilon}\right)\right) \\ V_{bd}^{\epsilon}(t,x) = \sum_{j\geq 0} \epsilon^j \left(b_j\left(t,x_2; \frac{x_1}{\epsilon}\right) + d_j\left(t,x_2; \frac{x_1}{\epsilon}, \frac{\varphi^0(t,x_2)}{\epsilon}\right)\right), \end{cases} \tag{2.11}
$$

where $c_j(t,x;\theta)$ and $d_j(t,x_2;z,\theta)$ are $2\pi-$periodic in θ with mean value vanishing, and $b_j(t,x_2;z)$ and $d_j(t,x_2;z,\theta)$ are rapidly decreasing in z when $z \to +\infty$.

In what follows, we shall always denote by $C_p^k(T_\theta^1)$ the set of kth order smooth functions which are $2\pi-$periodic in $\theta \in T^1$, $S(\mathbb{R}_z^+)$ the set of smooth functions rapidly decreasing in z when $z \to +\infty$, and $a_j^{(k)}$ $(k = 1,2,3)$ the kth component of a_j etc.

Taking the formal expansion as

$$
\begin{aligned} &(A_0(V')\partial_t + A_1(V')\partial_{x_1} + A_2(V')\partial_{x_2})V_{in}^{\epsilon} - B(\epsilon^2, D\epsilon^2)V_{in}^{\epsilon} - \Phi\left(t,x;\tfrac{\varphi(t,x)}{\epsilon}\right) \\ &= \textstyle\sum_{j\geq -1} \epsilon^j \mathcal{F}_j, \end{aligned} \tag{2.12}
$$

in ϵ, we have

$$
\begin{cases} \mathcal{F}_{-1} = \sum_{k=0}^{2} \varphi_{x_k} A_k(V')\partial_\theta c_0, \\ \mathcal{F}_0 = L(\partial_t,\partial_x)(a_0 + c_0) - (\varphi_{x_1}^2 B_1 + \varphi_{x_2}^2 B_2 + \varphi_{x_1}\varphi_{x_2}B_3)\partial_\theta^2 c_0 - \Phi(t,x;\theta) \\ \qquad + \sum_{k=0}^{2} \varphi_{x_k} A_k(V')\partial_\theta c_1, \\ \cdots\cdots \\ \mathcal{F}_j = L(\partial_t,\partial_x)(a_j + c_j) - (\varphi_{x_1}^2 B_1 + \varphi_{x_2}^2 B_2 + \varphi_{x_1}\varphi_{x_2}B_3)\partial_\theta^2 c_j \\ \qquad + \sum_{k=0}^{2} \varphi_{x_k} A_k(V')\partial_\theta c_{j+1} + f_j \end{cases} \tag{2.13}
$$

for each $j \geq 1$, where $\varphi_{x_k} = \partial_{x_k}\varphi$ with $x_0 = t$, and

$$
\begin{aligned} f_j = &-(\varphi_{x_1x_1}B_1 + \varphi_{x_2x_2}B_2 + \varphi_{x_1x_2}B_3)\partial_\theta c_{j-1} - (2\varphi_{x_1}B_1 + \varphi_{x_2}B_3)\partial_{\theta x_1}^2 c_{j-1} \\ &-(2\varphi_{x_2}B_2 + \varphi_{x_1}B_3)\partial_{\theta x_2}^2 c_{j-1} - (B_1\partial_{x_1}^2 + B_2\partial_{x_2}^2 + B_3\partial_{x_1x_2}^2)(a_{j-2} + c_{j-2}) \end{aligned}
$$

with $a_{-1} = c_{-1} = 0$.

Set $z = \frac{x_1}{\epsilon}$. Then

$$
(A_0(V')\partial_t + A_1(V')\partial_{x_1} + A_2(V')\partial_{x_2})V_{bd}^{\epsilon} - B(\epsilon^2, D\epsilon^2)V_{bd}^{\epsilon} = \sum_{j\geq -1} \epsilon^j \mathcal{G}_j \tag{2.14}
$$

implies

$$
\begin{cases} \mathcal{G}_{-1} = (\varphi_t^0 A_0(0) + \varphi_{x_2}^0 A_2(0))\partial_\theta d_0 + A_1(0)\partial_z(b_0 + d_0), \\ \mathcal{G}_0 = L_{bd}(\partial_t,\partial_{x_2})(b_0 + d_0) + z(\varphi_t^0 A_0'(0) + \varphi_{x_2}^0 A_2'(0))\partial_\theta d_0 - B_1\partial_z^2 b_0 \\ \qquad + zA_1'(0)\partial_z(b_0 + d_0) - (B_1\partial_z^2 + (\varphi_{x_2}^0)^2 B_2 \partial_\theta^2 + \varphi_{x_2}^0 B_3 \partial_{z\theta}^2)d_0 \\ \qquad + (\varphi_t^0 A_0(0) + \varphi_{x_2}^0 A_2(0))\partial_\theta d_1 + A_1(0)\partial_z(b_1 + d_1), \\ \cdots\cdots \\ \mathcal{G}_j = L_{bd}(\partial_t,\partial_{x_2})(b_j + d_j) + z(\varphi_t^0 A_0'(0) + \varphi_{x_2}^0 A_2'(0))\partial_\theta d_j - B_1\partial_z^2 b_j \\ \qquad + zA_1'(0)\partial_z(b_j + d_j) - (B_1\partial_z^2 + (\varphi_{x_2}^0)^2 B_2 \partial_\theta^2 + \varphi_{x_2}^0 B_3 \partial_{z\theta}^2)d_j \\ \qquad + (\varphi_t^0 A_0(0) + \varphi_{x_2}^0 A_2(0))\partial_\theta d_{j+1} + A_1(0)\partial_z(b_{j+1} + d_{j+1}) + g_j \end{cases} \tag{2.15}
$$

for any $j \geq 1$, where g_j depends smoothly on $\{b_k, d_k\}_{k \leq j-1}$ and their derivatives up to order two, $A_k(0) = A_k(V')|_{x_1=0}$, $A_k'(0) = \partial_{x_1}(A_k(V'))|_{x_1=0}$, and

$$L_{bd}(\partial_t, \partial_{x_2}) = A_0(0)\partial_t + A_2(0)\partial_{x_2}.$$

From the equations in (2.1) and the assumption that each term (b_j, d_j) in V_{bd}^ϵ is rapidly decreasing in z when $z \to +\infty$, it is natural to set

$$\mathcal{F}_j \equiv 0 \qquad \text{and} \qquad \mathcal{G}_j \equiv 0 \tag{2.16}$$

in (2.12) and (2.14), respectively, for all $j \geq -1$.

The next step is to derive the governing problems for various order of profiles from (2.16) and initial and boundary conditions given in (2.1).

Let $\{\vec{r}_k(\nabla\varphi), \vec{l}_k(\nabla\varphi)\}_{k=1}^3$ be the right and left eigenvectors given in (2.5) associated with $(\xi_1, \xi_2) = (\varphi_{x_1}, \varphi_{x_2})$.

It follows from $\mathcal{F}_{-1} = 0$ that

$$c_0(t, x; \theta) = v_0(t, x; \theta)\vec{r}_1(\nabla\varphi) \tag{2.17}$$

with $v_0(t, x; \theta)$ being a scalar unknown.

Acting upon the mean value operator

$$\mathbf{m}_\theta(u) = \frac{1}{2\pi}\int_0^{2\pi} u(\theta)d\theta$$

on the equation $\mathcal{F}_0 = 0$, we deduce

$$L(\partial_t, \partial_x)a_0 = \mathbf{m}_\theta(\Phi) \tag{2.18}$$

and the difference between (2.18) and $\mathcal{F}_0 = 0$ gives

$$\begin{aligned} &L(\partial_t, \partial_x)c_0 - (\varphi_{x_1}^2 B_1 + \varphi_{x_2}^2 B_2 + \varphi_{x_1}\varphi_{x_2}B_3)\partial_\theta^2 c_0 - \Phi + \mathbf{m}_\theta(\Phi) \\ &\quad = -\sum_{k=0}^{2} \varphi_{x_k} A_k(V')\partial_\theta c_1. \end{aligned} \tag{2.19}$$

Multiplying $\vec{l}_1(\nabla\varphi)$ from the left of (2.19), and using (2.17), one discovers that $v_0(t, x; \theta)$ satisfies the following problem:

$$\begin{cases} [(\vec{l}_1 A_0 \vec{r}_1)\partial_t + (\vec{l}_1 A_1 \vec{r}_1)\partial_{x_1} + (\vec{l}_1 A_2 \vec{r}_1)\partial_{x_2}]v_0 + \vec{l}_1(A_0\partial_t\vec{r}_1 + A_1\partial_{x_1}\vec{r}_1 + A_2\partial_{x_2}\vec{r}_1)v_0 \\ \qquad -\vec{l}_1(\varphi_{x_1}^2 B_1 + \varphi_{x_2}^2 B_2 + \varphi_{x_1}\varphi_{x_2}B_3)\vec{r}_1\partial_\theta^2 v_0 = \vec{l}_1(\Phi - \mathbf{m}_\theta(\Phi)) \\ v_0|_{t=0} = 0. \end{cases} \tag{2.20}$$

Note that the vector field

$$(\vec{l}_1 A_0 \vec{r}_1)\partial_t + (\vec{l}_1 A_1 \vec{r}_1)\partial_{x_1} + (\vec{l}_1 A_2 \vec{r}_1)\partial_{x_2}$$

is tangential to the boundary $\{x_1 = 0\}$, and

$$\vec{l}_1(\varphi_{x_1}^2 B_1 + \varphi_{x_2}^2 B_2 + \varphi_{x_1}\varphi_{x_2}B_3)\vec{r}_1 = \frac{1}{\rho'}(\varphi_{x_1}^2 + \varphi_{x_2}^2) > 0.$$

The problem (2.20) is the one for a linear degenerate parabolic equation, which can be easily solved.

To solve a_0 from (2.18), we need to impose a boundary datum for $a_0^{(2)}$ on $\{x_1 = 0\}$.

It follows from the ansatz (2.10) and (2.11) that the $0(\epsilon^0)-$term of the boundary condition $M^+V^\epsilon|_{x_1=0} = 0$ in (2.1) gives rise to

$$a_0^{(k)}(t,x) + c_0^{(k)}(t,x;\theta) + b_0^{(k)}(t,x_2;z) + d_0^{(k)}(t,x_2;z,\theta^0) = 0 \tag{2.21}$$

on $\{x_1 = 0, z = 0, \theta = \theta^0\}$ for $k \in \{2,3\}$. Since $c_0^{(k)}$ and $d_0^{(k)}$ are $2\pi-$periodic in θ and θ^0, with mean values vanishing, respectively, the condition (2.21) is equivalent to

$$\begin{cases} a_0^{(k)}(t,x) + b_0^{(k)}(t,x_2;z) = 0 \quad \text{on } \{x_1 = z = 0\} \\ c_0^{(k)}(t,x;\theta) + d_0^{(k)}(t,x_2;z,\theta^0) = 0 \quad \text{on } \{x_1 = z = 0, \theta = \theta^0\} \end{cases} \tag{2.22}$$

for $k \in \{2,3\}$.

Thus, we should first study $b_0^{(2)}$ in order to determine the boundary value of $a_0^{(2)}$.

Acting upon the mean value operator $\mathbf{m}_\theta$ on $\mathcal{G}_{-1} = 0$ leads to

$$A_1(0)\partial_z b_0 = 0. \tag{2.23}$$

So, $\mathcal{G}_{-1} = 0$ gives rise to

$$(\varphi_t^0 A_0(0) + \varphi_{x_2}^0 A_2(0))\partial_\theta d_0 + A_1(0)\partial_z d_0 = 0. \tag{2.24}$$

From (2.23), we obtain immediately that

$$\partial_z b_0^{(1)} = \partial_z b_0^{(2)} = 0$$

which implies

$$b_0^{(1)} = b_0^{(2)} \equiv 0 \tag{2.25}$$

by using $b_0 \in S(I\!R_z^+)$.

Thus, it follows from (2.18) and (2.22) that $a_0(t,x)$ satisfies the following problem for the linearized Euler equations:

$$\begin{cases} (A_0(V')\partial_t + A_1(V')\partial_{x_1} + A_2(V')\partial_{x_2})a_0 = \mathbf{m}_\theta(\Phi), \quad t, x_1 > 0, \\ a_0^{(2)}|_{x_1=0} = 0, \\ a_0|_{t=0} = V_0(x). \end{cases} \tag{2.26}$$

To determine $b_0^{(3)}(t,x_2;z)$, by acting upon the mean value operator $\mathbf{m}_\theta$ on $\mathcal{G}_0 = 0$ we deduce that

$$L_{bd}(\partial_t, \partial_{x_2})b_0 + zA_1'(0)\partial_z b_0 + A_1(0)\partial_z b_1 = B_1\partial_z^2 b_0, \tag{2.27}$$

and the difference between (2.27) and $\mathcal{G}_0 = 0$ gives rise to

$$\begin{aligned} &L_{bd}(\partial_t, \partial_{x_2})d_0 + z(\varphi_t^0 A_0'(0) + \varphi_{x_2}^0 A_2'(0))\partial_\theta d_0 + zA_1'(0)\partial_z d_0 \\ &\quad -(B_1\partial_z^2 + (\varphi_{x_2}^0)^2 B_2 \partial_\theta^2 + \varphi_{x_2}^0 B_3 \partial_{z\theta}^2)d_0 \\ &\quad = -(\varphi_t^0 A_0(0) + \varphi_{x_2}^0 A_2(0))\partial_\theta d_1 - A_1(0)\partial_z d_1. \end{aligned} \tag{2.28}$$

From the third component of (2.27), we conclude that $b_0^{(3)}(t,x_2;z)$ satisfies the following problem:

$$\begin{cases} (\partial_t + v_2'(0)\partial_{x_2})b_0^{(3)} + z\dfrac{\partial v_1'(0)}{\partial x_1}\partial_z b_0^{(3)} - \dfrac{1}{\rho'(0)}\partial_z^2 b_0^{(3)} = 0, \quad t,\ z>0, \\ b_0^{(3)}|_{z=0} = -a_0^{(3)}(t,0,x_2), \\ b_0^{(3)}|_{t=0} = 0, \end{cases} \tag{2.29}$$

where $a_0^{(3)}$ is given by (2.26).

The problem (2.29) is the one for a linearized Prandtl equation, which has been solved by Xin and Yanagisawa in [12].

Now, let us derive the problems for $d_0(t,x_2;z,\theta)$ from (2.24) and (2.28).

It follows from $\varphi_t^0 + v_2'(0)\varphi_{x_2}^0 = 0$ that

$$(\varphi_t^0 A_0(0) + \varphi_{x_2}^0 A_2(0))\partial_\theta d + A_1(0)\partial_z d = \begin{pmatrix} \rho'(0)(\varphi_{x_2}^0 \partial_\theta d^{(3)} + \partial_z d^{(2)}) \\ c^2(0)\partial_z d^{(1)} \\ c^2(0)\varphi_{x_2}^0 \partial_\theta d^{(1)} \end{pmatrix}.$$

Thus, (2.24) yields

$$\varphi_{x_2}^0 \partial_\theta d_0^{(3)} + \partial_z d_0^{(2)} = 0 \tag{2.30}$$

and

$$\varphi_{x_2}^0 \partial_\theta d_0^{(1)} = 0, \quad \partial_z d_0^{(1)} = 0$$

which implies

$$d_0^{(1)} \equiv 0. \tag{2.31}$$

To solve $(d_0^{(2)}, d_0^{(3)})$, we define the operator $\mathbb{E}$ by

$$\mathbb{E}\begin{pmatrix} d^{(1)} \\ d^{(2)} \\ d^{(3)} \end{pmatrix} = \begin{pmatrix} \mathbf{m}_\theta d^{(1)} \\ \varphi_{x_2}^0 \partial_\theta d^{(2)} - \partial_z d^{(3)} \end{pmatrix}$$

for any $d = (d^{(1)}, d^{(2)}, d^{(3)})^T \in C^1(\mathbb{R}_z^+ \times T_\theta^1)$. It is easy to know that for any $d(t,x_2;z,\theta) \in C_p^1(T_\theta^1) \cap S(\mathbb{R}_z^+)$ with $\mathbf{m}_\theta(d) = 0$, we have

$$\mathbb{E}((\varphi_t^0 A_0(0) + \varphi_{x_2}^0 A_2(0))\partial_\theta d + A_1(0)\partial_z d) = 0. \tag{2.32}$$

Acting upon the operator $\mathbb{E}$ on (2.28) and using (2.32), one gets

$$\mathbb{E}(\text{left-hand side of (2.28)}) = 0. \tag{2.33}$$

Denote by A and B the second and the third components of the left-hand side of (2.28), respectively. Then, one obtains from (2.30) and (2.31) that

$$\begin{cases} A = \rho'(0)((\partial_t + v_2'(0)\partial_{x_2})d_0^{(2)} + z\dfrac{\partial v_1'(0)}{\partial x_1}\partial_z d_0^{(2)} + z\dfrac{\partial v_2'(0)}{\partial x_1}\varphi_{x_2}^0\partial_\theta d_0^{(2)}) - (\partial_z^2 + (\varphi_{x_2}^0)^2\partial_\theta^2)d_0^{(2)}, \\ B = \rho'(0)((\partial_t + v_2'(0)\partial_{x_2})d_0^{(3)} + z\dfrac{\partial v_1'(0)}{\partial x_1}\partial_z d_0^{(3)} + z\dfrac{\partial v_2'(0)}{\partial x_1}\varphi_{x_2}^0\partial_\theta d_0^{(3)}) - (\partial_z^2 + (\varphi_{x_2}^0)^2\partial_\theta^2)d_0^{(3)}. \end{cases}$$

Now, (2.33) implies that

$$\varphi^0_{x_2}\partial_\theta A - \partial_z B = 0,$$

which can be explicitly written as

$$(2.34)\quad (\partial_t + v_2'(0)\partial_{x_2})\omega_0 + z\left(\frac{\partial v_1'(0)}{\partial x_1}\partial_z + \varphi^0_{x_2}\frac{\partial v_2'(0)}{\partial x_1}\partial_\theta\right)\omega_0 - \frac{1}{\rho'(0)}(\partial_z^2 + (\varphi^0_{x_2})^2\partial_\theta^2)\omega_0 - \left(\frac{\partial v_1'(0)}{\partial x_1}\partial_z + \varphi^0_{x_2}\frac{\partial v_2'(0)}{\partial x_1}\partial_\theta\right)d_0^{(3)} = 0,$$

where $\omega_0(t,x_2;z,\theta) = \varphi^0_{x_2}\partial_\theta d_0^{(2)} - \partial_z d_0^{(3)}$.

Combining (2.30) with (2.34) and using (2.22), one obtains that $d_0^{(3)}$ and ω_0 satisfy the following problem:

$$(2.35)\quad \begin{cases} (\partial_z^2 + (\varphi^0_{x_2})^2\partial_\theta^2)d_0^{(3)} = -\partial_z\omega_0 \\ (\partial_t + v_2'(0)\partial_{x_2})\omega_0 + z\left(\dfrac{\partial v_1'(0)}{\partial x_1}\partial_z + \varphi^0_{x_2}\dfrac{\partial v_2'(0)}{\partial x_1}\partial_\theta\right)\omega_0 \\ \qquad -\dfrac{1}{\rho'(0)}(\partial_z^2 + (\varphi^0_{x_2})^2\partial_\theta^2)\omega_0 - \left(\dfrac{\partial v_1'(0)}{\partial x_1}\partial_z + \varphi^0_{x_2}\dfrac{\partial v_2'(0)}{\partial x_1}\partial_\theta\right)d_0^{(3)} = 0 \\ d_0^{(3)}|_{z=0} = -c_0^{(3)}(t,0,x_2;\theta) \\ (\omega_0 + \partial_z d_0^{(3)})|_{z=0} = -\varphi^0_{x_2}(\partial_\theta c_0^{(2)})(t,0,x_2;\theta) \\ (d_0^{(3)},\omega_0) \in S(\mathbb{R}_z^+) \\ \omega_0|_{t=0} = 0 \end{cases}$$

and $d_0^{(2)}(t,x_2;z,\theta)$ satisfies

$$(2.36)\quad \begin{cases} (\partial_z^2 + (\varphi^0_{x_2})^2\partial_\theta^2)d_0^{(2)} = \varphi^0_{x_2}\partial_\theta\omega_0 \\ d_0^{(2)}|_{z=0} = -c_0^{(2)}(t,0,x_2;\theta) \\ d_0^{(2)} \in S(\mathbb{R}_z^+), \end{cases}$$

where $(c_0^{(2)}, c_0^{(3)})$ are given by (2.17) and (2.20).

The problems for high order terms in the expansion of $V_{in}^\epsilon(t,x) + V_{bd}^\epsilon(t,x)$ can be formulated in a similar way. For completeness, we shall derive these problems in the appendix.

In section 3, we study the well-posedness of the problem (2.35) in detail, and in section 4 we justify rigorously the above formal analysis to conclude the following main result of this paper.

THEOREM 2.1. *Suppose that compatibility conditions for problems* (2.1), (2.29), (2.35), *and* (5.11), (5.13), (5.22) *given later are satisfied. Then, the solution* $V^\epsilon = (\rho^\epsilon, v_1^\epsilon, v_2^\epsilon)$ *of* (2.1) *admits the following asymptotics:*

$$(2.37)\quad V^\epsilon(t,x) = a_0(t,x) + c_0\left(t,x;\frac{\varphi(t,x)}{\epsilon}\right) + b_0\left(t,x_2;\frac{x_1}{\epsilon}\right) + d_0\left(t,x_2;\frac{x_1}{\epsilon},\frac{\varphi^0(t,x_2)}{\epsilon}\right) + O(\epsilon)$$

in $L^\infty([0,T], L^2(\mathbb{R}^2_+))$ for any $T > 0$, where $a_0(t,x)$ satisfies the problem for the linearized Euler equations (2.26)*, $c_0 = v_0(t,x; \frac{\varphi(t,x)}{\epsilon})\vec{r}_1(\nabla\varphi)$ with v_0 satisfying the degenerate parabolic equation* (2.20)*, $(b_0^{(1)}, b_0^{(2)}) = 0$ and $b_0^{(3)}(t,x_2;z)$ satisfies the linearized Prandtl equation* (2.29)*, $d_0^{(1)} = 0$, and $(d_0^{(2)}, d_0^{(3)})(t,x_2;z,\theta)$ together with its vorticity with respect to $(z,\theta)-$variables satisfy the Poisson–Prandtl coupled system* (2.35) *and the Poisson equation* (2.36)*, respectively.*

Remark 2.2. When the wavelength of the force term Φ is shorter than ϵ, i.e., $\Phi = \Phi(t,x; \frac{\varphi(t,x)}{\epsilon^\alpha})$ with $\alpha > 1$, we obtain $c_0 = d_0 \equiv 0$, and (a_0, b_0) are the same as the case studied in [12] with $\Phi \equiv 0$. This phenomenon will be studied for the case $\alpha = 2$ in the appendix.

3. The study of a Poisson–Prandtl coupled system. It is clear from problems (2.35), (2.36), and (5.22), (5.23) given later that in order to determine $(d_j^{(2)}, d_j^{(3)})$ for any $j \geq 0$, we need to study the following initial-boundary value problem for a Poisson–Prandtl coupled system in $\{t, z > 0, x \in \mathbb{R}, \theta \in T^1\}$:

$$\tag{3.1}
\begin{cases}
(\partial_z^2 + a^2\partial_\theta^2)u = f(t,x;z,\theta) - \partial_z w \\
(\partial_t + a_1\partial_x)w + z(a_2\partial_z + a_3\partial_\theta)w - a_4^2(\partial_z^2 + a^2\partial_\theta^2)w - (a_2\partial_z + a_3\partial_\theta)u = g(t,x;z,\theta) \\
u|_{z=0} = b_0(t,x;\theta), \quad u \in S(\mathbb{R}_z^+) \\
(w + \partial_z u)|_{z=0} = b_1(t,x;\theta), \quad (u,w) \in S(\mathbb{R}_z^+) \\
w|_{t=0} = 0
\end{cases}$$

for the unknowns (u,w), where (f,g) are rapidly decreasing in z when $z \to +\infty$, and periodic in $\theta \in T^1 = \mathbb{R}/2\pi Z$ as well as for $(b_0, b_1)(t,x;\theta)$ with mean values vanishing,

$$\mathbf{m}_\theta(f) = \mathbf{m}_\theta(g) = \mathbf{m}_\theta(b_0) = \mathbf{m}_\theta(b_1) = 0,$$

all coefficients in (3.1) are smooth functions of (t,x), with $a(t,x) \geq a_0$, $a_4(t,x) \geq a_0$ for a positive constant a_0.

For simplicity, we assume that (f, g, b_0, b_1) are smooth. To study smooth solutions to (3.1), as usual, one needs to impose compatibility conditions on data.

(1) The zero-th order compatibility condition.

From the initial data $w|_{t=0} = 0$, we have $\partial_z w|_{t=0} = 0$. Thus, from the first and third equations of (3.1), the datum $u_0(x,z,\theta) = u|_{t=0}$ should satisfy the problem

$$\tag{3.2}
\begin{cases}
(\partial_z^2 + a_0^2\partial_\theta^2)u_0 = f(0,x;z,\theta) \\
u_0|_{z=0} = b_0(0,x,\theta), \quad u_0 \in S(\mathbb{R}_z^+),
\end{cases}$$

where $a_0(x) = a(0,x)$.

By using Remark 3.2 given later, the problem (3.2) has a unique solution $u_0(x,z,\theta)$, and can be explicitly given by $f(0,x;z,\theta)$ and $b_0(0,x,\theta)$

From the fourth equation in (3.1), we conclude the zero-th order compatibility condition for (3.1) as follows:

$$\tag{3.3} b_1(0,x;\theta) = \partial_z u_0|_{z=0}.$$

(2) The kth order compatibility condition for any fixed integer $k \geq 1$.

In the discussion of compatibility conditions of (3.1) up to order $k-1$, we first suppose that one has the data $u_l(x,z,\theta) = \partial_t^l u|_{t=0}$ and $w_l(x,z,\theta) = \partial_t^l w|_{t=0}$ for any integer $l \leq k-1$ in terms of (f, g, b_0, b_1). From the second equation in (3.1), we immediately obtain the datum $w_k(x,z,\theta) = \partial_t^k w|_{t=0}$ in terms of $\{u_l, w_l\}_{l \leq k-1}$. By differentiating the first equation of (3.1) k-times with respect to t, and applying Remark 3.2 (given later) to solve the problem

$$\begin{cases} (\partial_z^2 + a_0^2 \partial_\theta^2) u_k = F_k(x,z,\theta) \\ u_k|_{z=0} = (\partial_t^k b_0)(0,x,\theta), \quad u_k \in S(\mathbb{R}_z^+) \end{cases}$$

with $F_k(x,z,\theta) = (\partial_t^k f - \partial_t^k (a^2 \partial_\theta^2 u) + a^2 \partial_\theta^2 \partial_t^k u - \partial_z \partial_t^k w)|_{t=0}$ being given in terms of $\{u_l\}_{l \leq k-1}$ and $\{w_l\}_{l \leq k}$, we can determine the data $u_k(x,z,\theta) = \partial_z^k u|_{t=0}$.

In this way, we get formulae of (u_k, w_k) in terms of (f, g, b_0, b_1). From the boundary condition of (3.1), it follows that the kth order compatibility condition should be

$$(w_k + \partial_z u_k)|_{z=0} = (\partial_t^k b_1)(0, x; \theta) \tag{3.4}$$

which can be explicitly formulated in terms of (f, g, b_0, b_1).

In the remainder of this section, for simplicity, we assume that any order compatibility condition is satisfied for the problem (3.1).

The goal of this section is to study the solvability of the problem (3.1) in the class that u and w are rapidly decreasing when $z \to +\infty$ and periodic in $\theta \in T^1$ with $\mathbf{m}_\theta(u, w) = 0$, which constitutes the main part of the rigorous justification for the formal analysis given in section 2. To this end, first, we derive a functional representation $u = u(w)$ of u in terms of w from the first and the third equations of (3.1), second, by substituting the relation $u = u(w)$ into the second and the fourth equations of (3.1), we solve the unknown $w = w(t, x; z, \theta)$.

3.1. Derivation of the representation = ( ). To deduce the relation $u = u(w)$, we first consider the following boundary value problem:

$$\begin{cases} (\partial_z^2 + a^2 \partial_\theta^2) u = F(t, x; z, \theta) \\ u|_{z=0} = b_0(t, x; \theta), \quad u \in S(\mathbb{R}_z^+), \end{cases} \tag{3.5}$$

where F is rapidly decreasing when $z \to +\infty$, and (b_0, F) are periodic in $\theta \in T^1$ with mean values vanishing.

Obviously, to solve the problem (3.5) is equivalent to studying the following problem:

$$\begin{cases} (\partial_z^2 + a^2 \partial_\theta^2) u = F(t, x; z, \theta) \\ u|_{z=0} = b_0(t, x; \theta), \quad u_z|_{z=0} = u_0(t, x; \theta), \end{cases} \tag{3.6}$$

where u_0, periodic in $\theta \in T^1$ with $\mathbf{m}_\theta(u_0) = 0$, will be determined by $(b_0(t, x; \theta), F(t, x; z, \theta))$ such that the problem (3.6) admits a unique solution $u(t, x; z, \theta) \in C_p^2(T_\theta^1) \cap S(\mathbb{R}_z^+)$ with $\mathbf{m}_\theta(u) = 0$.

Denote by

$$\begin{cases} F(t, x; z, \theta) = \displaystyle\sum_{k \neq 0} F^{(k)}(t, x; z) e^{ik\theta} \\ b_0(t, x; \theta) = \displaystyle\sum_{k \neq 0} b_0^{(k)}(t, x) e^{ik\theta} \end{cases} \tag{3.7}$$

the Fourier expansions of (F, b_0) with respect to $\theta \in T^1$.

LEMMA 3.1. *The necessary and sufficient condition for the solution $u(t,x;z,\theta)$ of (3.6) to be rapidly decreasing when $z \to +\infty$ is*

$$u_0(t,x;\theta) = -\sum_{k=1}^{\infty}\left(kab_0^{(k)} + \int_0^\infty e^{-ka\xi}F^{(k)}(t,x;\xi)d\xi\right)e^{ik\theta} + \sum_{k=-1}^{-\infty}\left(kab_0^{(k)} - \int_0^\infty e^{ka\xi}F^{(k)}(t,x;\xi)d\xi\right)e^{ik\theta}. \tag{3.8}$$

Proof. (1) First, we solve the following problem:

$$\begin{cases} (\partial_z^2 + a^2\partial_\theta^2)w = F(t,x;z,\theta) \\ w|_{z=0} = 0, \quad w_z|_{z=0} = w_0(t,x;\theta). \end{cases} \tag{3.9}$$

We will find $w_0(t,x;\theta)$, periodic in $\theta \in T^1$ with $\mathbf{m}_\theta(w_0) = 0$, such that the solution $w(t,x;z,\theta)$ to (3.9) is rapidly decreasing when $z \to +\infty$.

If we set

$$\begin{cases} w(t,x;z,\theta) = \sum_{k\neq 0} w^{(k)}(t,x;z)e^{ik\theta} \\ w_0(t,x;\theta) = \sum_{k\neq 0} w_0^{(k)}(t,x)e^{ik\theta}, \end{cases} \tag{3.10}$$

then the problem (3.9) is equivalent to the following one for $w^{(k)}(t,x;z)$:

$$\begin{cases} (\partial_z^2 - k^2a^2)w^{(k)} = F^{(k)}(t,x;z) \\ w^{(k)}|_{z=0} = 0, \quad w_z^{(k)}|_{z=0} = w_0^{(k)}(t,x;\theta) \end{cases} \tag{3.11}$$

for any $k \neq 0$.

Obviously, the solution to (3.11) can be expressed as

$$w^{(k)}(t,x;z) = \frac{1}{2ka}\left(w_0^{(k)}(t,x) + \int_0^z e^{-ka\xi}F^{(k)}(t,x;\xi)d\xi\right)e^{kaz} - \frac{1}{2ka}\left(w_0^{(k)}(t,x) + \int_0^z e^{ka\xi}F^{(k)}(t,x;\xi)d\xi\right)e^{-kaz}. \tag{3.12}$$

When $k > 0$, the necessary condition for $w^{(k)} \in S(\mathbb{R}_z^+)$ is

$$\lim_{z\to+\infty}\left(w_0^{(k)}(t,x) + \int_0^z e^{-ka\xi}F^{(k)}(t,x;\xi)d\xi\right) = 0$$

which implies

$$w_0^{(k)}(t,x) = -\int_0^\infty e^{-ka\xi}F^{(k)}(t,x;\xi)d\xi. \tag{3.13}$$

Substituting (3.13) into (3.12) it follows

$$w^{(k)}(t,x;z) = -\frac{1}{2ka}\int_z^\infty e^{ka(z-\xi)}F^{(k)}(t,x;\xi)d\xi + \frac{1}{2ka}\int_0^\infty e^{-ka(z+\xi)}F^{(k)}(t,x;\xi)d\xi - \frac{1}{2ka}\int_0^z e^{ka(\xi-z)}F^{(k)}(t,x;\xi)d\xi. \tag{3.14}$$

Since $F^{(k)} \in S(\mathbb{R}_z^+)$, we deduce

$$\int_0^\infty e^{-ka(z+\xi)} F^{(k)}(t,x;\xi)d\xi \in S(\mathbb{R}_z^+)$$

and

$$\int_z^\infty e^{ka(z-\xi)} F^{(k)}(t,x;\xi)d\xi \in S(\mathbb{R}_z^+).$$

On the other hand, we have

$$\left| z^l \int_0^z e^{ka(\xi-z)} F^{(k)}(t,x;\xi)d\xi \right| \le \sum_{0\le j\le l} \binom{l}{j} \left| \int_0^z (z-\xi)^{l-j}\xi^j e^{-ka(z-\xi)} F^{(k)}(t,x;\xi)d\xi \right|$$

which is bounded for all $l \ge 0$ by using $F^{(k)} \in S(\mathbb{R}_z^+)$. Thus, we also have

$$\int_0^z e^{ka(\xi-z)} F^{(k)}(t,x;\xi)d\xi \in S(\mathbb{R}_z^+).$$

Therefore, the function $w^{(k)}(t,x;z)$ given in (3.14) is rapidly decreasing when $z \to +\infty$.

Similarly, we deduce that when $k < 0$, the necessary and sufficient condition for $w^{(k)}$ given in (3.1) belonging to $S(\mathbb{R}_z^+)$ is

$$w_0^{(k)}(t,x) = -\int_0^\infty e^{ka\xi} F^{(k)}(t,x;\xi)d\xi \tag{3.15}$$

and in this case, the solution to (3.11) can be expressed as

$$\begin{aligned} w^{(k)}(t,x;z) = &\frac{1}{2ka}\int_z^\infty e^{ka(\xi-z)} F^{(k)}(t,x;\xi)d\xi + \frac{1}{2ka}\int_0^z e^{ka(z-\xi)} F^{(k)}(t,x;\xi)d\xi \\ &- \frac{1}{2ka}\int_0^\infty e^{ka(\xi+z)} F^{(k)}(t,x;\xi)d\xi. \end{aligned} \tag{3.16}$$

Combining (3.13), (3.14), and (3.15) with (3.16) shows that

$$\begin{aligned} w(t,x;z,\theta) = &\sum_{k=1}^{\infty} \frac{1}{2ka}\left[\int_0^\infty e^{-ka(z+\xi)} F^{(k)}(t,x;\xi)d\xi - \int_0^z e^{-ka(z-\xi)} F^{(k)}(t,x;\xi)d\xi \right. \\ &\left. - \int_z^\infty e^{ka(z-\xi)} F^{(k)}(t,x;\xi)d\xi\right] e^{ik\theta} + \sum_{k=-1}^{-\infty} \frac{1}{2ka}\left[\int_0^z e^{ka(z-\xi)} F^{(k)}(t,x;\xi)d\xi \right. \\ &\left. - \int_0^\infty e^{ka(z+\xi)} F^{(k)}(t,x;\xi)d\xi + \int_z^\infty e^{-ka(z-\xi)} F^{(k)}(t,x;\xi)d\xi\right] e^{ik\theta} \\ &\in S(\mathbb{R}_z^+) \end{aligned} \tag{3.17}$$

is the unique solution to

$$\begin{cases} (\partial_z^2 + a^2\partial_\theta^2)w = F(t,x;z,\theta) \\ w|_{z=0} = 0 \\ w_z|_{z=0} = -\sum_{k=1}^{\infty}\int_0^\infty e^{k(i\theta-a\xi)} F^{(k)}(t,x;\xi)d\xi - \sum_{k=-1}^{-\infty}\int_0^\infty e^{k(i\theta+a\xi)} F^{(k)}(t,x;\xi)d\xi. \end{cases} \tag{3.18}$$

(2) Let $v = u - w$ with u being the solution to (3.6). Then v solves the following problem:

$$
\begin{cases}
(\partial_z^2 + a^2\partial_\theta^2)v = 0 \\
v|_{z=0} = b_0(t,x;\theta) \\
v_z|_{z=0} = u_0(t,x;\theta) + \sum_{k=1}^{\infty}\int_0^\infty e^{k(i\theta - a\xi)}F^{(k)}(t,x;\xi)d\xi + \sum_{k=-1}^{-\infty}\int_0^\infty e^{k(i\theta + a\xi)}F^{(k)}(t,x;\xi)d\xi.
\end{cases}
\tag{3.19}
$$

Denote by

$$
\begin{cases}
v(t,x;z,\theta) = \sum_{k\neq 0} v^{(k)}(t,x;z)e^{ik\theta}, \\
u_0(t,x;\theta) = \sum_{k\neq 0} u_0^{(k)}(t,x)e^{ik\theta}
\end{cases}
$$

the Fourier expansions of (v, u_0). Then, from (3.19), $v^{(k)}$ satisfies

$$
\begin{cases}
(\partial_z^2 - k^2a^2)v^{(k)} = 0, \\
v^{(k)}|_{z=0} = b_0^{(k)}(t,x), \\
v_z^{(k)}|_{z=0} = \begin{cases} u_0^{(k)}(t,x) + \int_0^\infty e^{-ka\xi}F^{(k)}(t,x;\xi)d\xi, & k \geq 1, \\ u_0^{(k)}(t,x) + \int_0^\infty e^{ka\xi}F^{(k)}(t,x;\xi)d\xi, & k \leq -1. \end{cases}
\end{cases}
\tag{3.20}
$$

It follows that

$$
\begin{aligned}
v^{(k)}(t,x;z) = & \left[\frac{1}{2}b_0^{(k)} + \frac{1}{2ka}\left(u_0^{(k)} + \int_0^{+\infty} e^{-ka\xi}F^{(k)}(t,x;\xi)d\xi\right)\right]e^{kaz} \\
& + \left[\frac{1}{2}b_0^{(k)} - \frac{1}{2ka}\left(u_0^{(k)} + \int_0^{+\infty} e^{-ka\xi}F^{(k)}(t,x;\xi)d\xi\right)\right]e^{-kaz}
\end{aligned}
\tag{3.21}
$$

when $k > 0$, and

$$
\begin{aligned}
v^{(k)}(t,x;z) = & \left[\frac{1}{2}b_0^{(k)} + \frac{1}{2ka}\left(u_0^{(k)} + \int_0^{+\infty} e^{ka\xi}F^{(k)}(t,x;\xi)d\xi\right)\right]e^{kaz} \\
& + \left[\frac{1}{2}b_0^{(k)} - \frac{1}{2ka}\left(u_0^{(k)} + \int_0^{+\infty} e^{ka\xi}F^{(k)}(t,x;\xi)d\xi\right)\right]e^{-kaz}
\end{aligned}
\tag{3.22}
$$

when $k < 0$.

From (3.21) and (3.22), we conclude that one should have the condition (3.8) to guarantee $v^{(k)} \in S(\mathbb{R}_z^+)$, and in this case we have

$$
v(t,x;z,\theta) = \sum_{k=1}^{\infty} b_0^{(k)}(t,x)e^{-k(az - i\theta)} + \sum_{k=-1}^{-\infty} b_0^{(k)}(t,x)e^{k(az + i\theta)}. \qquad \square
\tag{3.23}
$$

Remark 3.2. From (3.17) and (3.23), it immediately follows that the unique solution to the problem (3.5) is given by

(3.24)

$$\begin{aligned} u(t,x;z,\theta) = &\sum_{k=1}^{\infty} b_0^{(k)}(t,x)e^{-k(az-i\theta)} + \sum_{k=-1}^{-\infty} b_0^{(k)}(t,x)e^{k(az+i\theta)} \\ &+\sum_{k=1}^{\infty}\frac{1}{2ka}\bigg[\int_0^{\infty} e^{-ka(z+\xi)}F^{(k)}(t,x;\xi)d\xi - \int_0^{z} e^{-ka(z-\xi)}F^{(k)}(t,x;\xi)d\xi \\ &- \int_z^{\infty} e^{ka(z-\xi)}F^{(k)}(t,x;\xi)d\xi\bigg]e^{ik\theta} + \sum_{k=-1}^{-\infty}\frac{1}{2ka}\bigg[\int_0^{z} e^{ka(z-\xi)}F^{(k)}(t,x;\xi)d\xi \\ &- \int_0^{\infty} e^{ka(z+\xi)}F^{(k)}(t,x;\xi)d\xi + \int_z^{\infty} e^{-ka(z-\xi)}F^{(k)}(t,x;\xi)d\xi\bigg]e^{ik\theta}. \end{aligned}$$

For the problem (3.1), let the Fourier expansion of w be

$$w(t,x;z,\theta) = \sum_{k\neq 0} w^{(k)}(t,x;z)e^{ik\theta}.$$

Using (3.24), we conclude with the following proposition.

PROPOSITION 3.3. *For the problem* (3.1), *the solution u has the following representation in terms of w:*

$$\begin{aligned} u(t,x;z,\theta) = &\sum_{k=1}^{\infty} b_0^{(k)}(t,x)e^{k(i\theta-az)} + \sum_{k=-1}^{-\infty} b_0^{(k)}(t,x)e^{k(i\theta+az)} \\ &+\sum_{k=1}^{\infty}\frac{1}{2}\bigg\{\int_0^{\infty} e^{-ka(z+\xi)}\left(\frac{f^{(k)}(t,x;\xi)}{ka} - w^{(k)}(t,x;\xi)\right)d\xi \\ &- \int_0^{z} e^{-ka(z-\xi)}\left(\frac{f^{(k)}(t,x;\xi)}{ka} + w^{(k)}(t,x;\xi)\right)d\xi \\ &- \int_z^{\infty} e^{ka(z-\xi)}\left(\frac{f^{(k)}(t,x;\xi)}{ka} - w^{(k)}(t,x;\xi)\right)d\xi\bigg\}e^{ik\theta} \\ &- \sum_{k=-1}^{-\infty}\frac{1}{2}\bigg\{\int_0^{\infty} e^{ka(z+\xi)}\left(\frac{f^{(k)}(t,x;\xi)}{ka} + w^{(k)}(t,x;\xi)\right)d\xi \\ &- \int_0^{z} e^{ka(z-\xi)}\left(\frac{f^{(k)}(t,x;\xi)}{ka} + w^{(k)}(t,x;\xi)\right)d\xi \\ &- \int_z^{\infty} e^{-ka(z-\xi)}\left(\frac{f^{(k)}(t,x;\xi)}{ka} + w^{(k)}(t,x;\xi)\right)d\xi\bigg\}e^{ik\theta} \end{aligned} \tag{3.25}$$

and

$$\begin{aligned} \partial_z u|_{z=0} = &\sum_{k=-1}^{-\infty} kab_0^{(k)}(t,x)e^{ki\theta} - \sum_{k=1}^{\infty} kab_0^{(k)}(t,x)e^{ki\theta} \\ &- \sum_{k=1}^{\infty}\int_0^{\infty} e^{k(i\theta-a\xi)}(f^{(k)}(t,x;\xi) - \partial_\xi w^{(k)}(t,x;\xi))d\xi \\ &- \sum_{k=-1}^{-\infty}\int_0^{\infty} e^{k(i\theta+a\xi)}(f^{(k)}(t,x;\xi) - \partial_\xi w^{(k)}(t,x;\xi))d\xi. \end{aligned} \tag{3.26}$$

3.2. The problem of a linear integro-Prandtl equation. It follows from Proposition 3.3 that to solve the problem (3.1), it suffices to use (3.25) and (3.26) to study the following problem for w:

$$\begin{cases} (\partial_t + a_1\partial_x)w + z(a_2\partial_z + a_3\partial_\theta)w - a_4^2(\partial_z^2 + a^2\partial_\theta^2)w - (a_2\partial_z + a_3\partial_\theta)u = g, \\ w|_{z=0} = b_1(t,x;\theta) - \partial_z u(t,x;0,\theta), \quad w \in S(\mathbb{R}_z^+), \\ w|_{t=0} = 0. \end{cases} \tag{3.27}$$

Obviously, in (3.27) both the equation and boundary condition have integral terms coming from those of u. First, let us transform (3.27) into a problem with the boundary condition being a standard Dirichlet form.

The compatibility conditions for the problem (3.27) follow immediately from those for the problem (3.1) given at the beginning of this section.

Denote by

$$\begin{cases} w(t,x;z,\theta) = \sum\limits_{k\neq 0} w^{(k)}(t,x;z)e^{ik\theta}, \\ g(t,x;z,\theta) = \sum\limits_{k\neq 0} g^{(k)}(t,x;z)e^{ik\theta}, \\ b_1(t,x;\theta) = \sum\limits_{k\neq 0} b_1^{(k)}(t,x)e^{ik\theta} \end{cases} \tag{3.28}$$

the Fourier expansions with respect to $\theta \in T^1$.

It follows from (3.27) that $w^{(k)}(t,x;z)$ satisfies the following problem:

$$\begin{cases} (\partial_t + a_1\partial_x)w^{(k)} + z(a_2\partial_z + ika_3)w^{(k)} - a_4^2(\partial_z^2 - k^2a^2)w^{(k)} + a_2 w^{(k)} \\ \qquad + \dfrac{k}{2}(ia_3 - aa_2)\Big[\displaystyle\int_0^{+\infty} e^{-ka(z+\xi)}\Big(w^{(k)}(t,x;\xi) - \frac{f^{(k)}(t,x;\xi)}{ka}\Big)d\xi \\ \qquad + \displaystyle\int_0^z e^{-ka(z-\xi)}\Big(w^{(k)}(t,x;\xi) + \frac{f^{(k)}(t,x;\xi)}{ka}\Big)d\xi\Big] \\ \qquad - \dfrac{k}{2}(aa_2 + ia_3)\displaystyle\int_z^{+\infty} e^{ka(z-\xi)}\Big(w^{(k)}(t,x;\xi) - \frac{f^{(k)}(t,x;\xi)}{ka}\Big)d\xi \\ \qquad\quad = g^{(k)}(t,x;z) - k(aa_2 + ia_3)b_0^{(k)}e^{-kaz} \\ w^{(k)}|_{z=0} = b_1^{(k)} + kab_0^{(k)} + \displaystyle\int_0^{+\infty} e^{-ka\xi}(f^{(k)}(t,x;\xi) - \partial_\xi w^{(k)}(t,x;\xi))d\xi \\ w^{(k)}|_{t=0} = 0, \quad w^{(k)} \in S(\mathbb{R}_z^+) \end{cases} \tag{3.29}$$

for any $k \geq 1$, and

$$
\begin{cases}
(\partial_t + a_1\partial_x)w^{(k)} + z(a_2\partial_z + ika_3)w^{(k)} - a_4^2(\partial_z^2 - k^2a^2)w^{(k)} + a_2 w^{(k)} \\
\quad + \frac{k}{2}(aa_2 + ia_3)\Big[\int_0^{+\infty} e^{ka(z+\xi)}\Big(w^{(k)}(t,x;\xi) + \frac{f^{(k)}(t,x;\xi)}{ka}\Big)d\xi \\
\quad + \int_0^z e^{ka(z-\xi)}\Big(w^{(k)}(t,x;\xi) - \frac{f^{(k)}(t,x;\xi)}{ka}\Big)d\xi\Big] \\
\quad + \frac{k}{2}(aa_2 - ia_3)\int_z^{+\infty} e^{-ka(z-\xi)}\Big(w^{(k)}(t,x;\xi) + \frac{f^{(k)}(t,x;\xi)}{ka}\Big)d\xi \\
\qquad\qquad = g^{(k)}(t,x;z) + k(aa_2 + ia_3)b_0^{(k)}e^{kaz} \\
w^{(k)}|_{z=0} = b_1^{(k)} - kab_0^{(k)} + \int_0^{+\infty} e^{ka\xi}(f^{(k)}(t,x;\xi) - \partial_\xi w^{(k)}(t,x;\xi))d\xi \\
w^{(k)}|_{t=0} = 0, \quad w^{(k)} \in S(\mathbb{R}_z^+)
\end{cases}
\tag{3.30}
$$

for any $k \leq -1$.

The boundary conditions of $w^{(k)}(t,x;z)$ at $\{z = 0\}$ given in (3.29) and (3.30) can be expressed as:

$$
\begin{cases}
\int_0^{+\infty} e^{-ka\xi}(f^{(k)} - kaw^{(k)})(t,x;\xi)d\xi + b_1^{(k)}(t,x) + kab_0^{(k)}(t,x) = 0, \quad k \geq 1, \\
\int_0^{+\infty} e^{ka\xi}(f^{(k)} + kaw^{(k)})(t,x;\xi)d\xi + b_1^{(k)}(t,x) - kab_0^{(k)}(t,x) = 0, \quad k \leq -1.
\end{cases}
\tag{3.31}
$$

In terms of the transformation

$$
Y^{(k)}(t,x;z) = \begin{cases}
\int_z^{+\infty} e^{ka(z-\xi)}w^{(k)}(t,x;\xi)d\xi, \quad k \geq 1 \\
\int_z^{+\infty} e^{ka(\xi-z)}w^{(k)}(t,x;\xi)d\xi, \quad k \leq -1,
\end{cases}
\tag{3.32}
$$

problems (3.29), (3.30), and (3.31) can be reformulated as

$$
\begin{cases}
(\partial_t + a_1\partial_x)Y^{(k)} - a_4^2(\partial_z^2 - k^2a^2)Y^{(k)} + z(a_2\partial_z + ika_3)Y^{(k)} \\
\qquad + ka_5\int_z^{+\infty} e^{ka(z-\xi)}Y^{(k)}(t,x;\xi)d\xi + ka_6\int_0^z e^{ka(\xi-z)}Y^{(k)}(t,x;\xi)d\xi \\
\quad = G^{(k)}(t,x;z) \\
Y^{(k)}|_{z=0} = W_0^{(k)}(t,x), \quad Y^{(k)} \in S(\mathbb{R}_z^+) \\
Y^{(k)}|_{t=0} = 0
\end{cases}
\tag{3.33}
$$

for any $k \geq 1$, and

$$(3.34)\quad \begin{cases} (\partial_t + a_1\partial_x)Y^{(k)} - a_4^2(\partial_z^2 - k^2a^2)Y^{(k)} + z(a_2\partial_z + ika_3)Y^{(k)} \\ \qquad + ka_5\displaystyle\int_z^{+\infty} e^{ka(\xi-z)}Y^{(k)}(t,x;\xi)d\xi + ka_6\int_0^z e^{ka(z-\xi)}Y^{(k)}(t,x;\xi)d\xi \\ \quad = G^{(k)}(t,x;z) \\ Y^{(k)}|_{z=0} = W_0^{(k)}(t,x), \quad Y^{(k)} \in S(\mathbb{R}_z^+) \\ Y^{(k)}|_{t=0} = 0 \end{cases}$$

for any $k \leq -1$, where

$$\begin{cases} G^{(k)} = \displaystyle\int_z^{+\infty} e^{ka(z-\xi)}g^{(k)}(t,x;\xi)d\xi + \frac{aa_2 - ia_3}{4ka^2}\Big(\int_0^{+\infty} e^{-ka(z+\xi)}f^{(k)}(t,x;\xi)d\xi \\ \qquad + \displaystyle\int_z^{+\infty} e^{ka(z-\xi)}f^{(k)}(t,x;\xi)d\xi + \int_0^z e^{ka(\xi-z)}f^{(k)}(t,x;\xi)d\xi\Big) \\ \qquad - \dfrac{aa_2 + ia_3}{2a}\displaystyle\int_z^{\infty}(\xi - z)e^{ka(z-\xi)}f^{(k)}(t,x;\xi)d\xi + \frac{aa_2 - ia_3}{2ka^2}e^{-kaz}b_1^{(k)}(t,x) \\ W_0^{(k)}(t,x) = b_0^{(k)} + \dfrac{1}{ka}b_1^{(k)} + \dfrac{1}{ka}\displaystyle\int_0^{+\infty} e^{-ka\xi}f^{(k)}(t,x;\xi)d\xi \end{cases}$$

for any $k \geq 1$,

$$\begin{cases} G^{(k)} = \displaystyle\int_z^{+\infty} e^{ka(\xi-z)}g^{(k)}(t,x;\xi)d\xi - \frac{aa_2 + ia_3}{4ka^2}\Big(\int_0^{+\infty} e^{ka(z+\xi)}f^{(k)}(t,x;\xi)d\xi \\ \qquad + \displaystyle\int_z^{\infty} e^{ka(\xi-z)}f^{(k)}(t,x;\xi)d\xi + \int_0^z e^{ka(z-\xi)}f^{(k)}(t,x;\xi)d\xi\Big) \\ \qquad - \dfrac{aa_2 - ia_3}{2a}\displaystyle\int_z^{\infty}(\xi - z)e^{ka(\xi-z)}f^{(k)}(t,x;\xi)d\xi - \frac{aa_2 + ia_3}{2ka^2}e^{kaz}b_1^{(k)}(t,x) \\ W_0^{(k)}(t,x) = b_0^{(k)} - \dfrac{1}{ka}b_1^{(k)} - \dfrac{1}{ka}\displaystyle\int_0^{+\infty} e^{ka\xi}f^{(k)}(t,x;\xi)d\xi \end{cases}$$

for any $k \leq -1$, and

$$\begin{cases} a_5 = a_t + a_1a_x + \dfrac{aa_2 + ia_3}{2}, \quad a_6 = -\dfrac{1}{2}(aa_2 + ia_3), \quad k \geq 1, \\ a_5 = -\Big(a_t + a_1a_x + \dfrac{aa_2 - ia_3}{2}\Big), \quad a_6 = \dfrac{1}{2}(aa_2 + ia_3), \quad k \leq -1. \end{cases}$$

The compatibility conditions for problems (3.33) and (3.34) can be easily formulated in a classical way. For example, the zero-th order compatibility condition for (3.33) is

$$W_0^{(k)}(0,x) = 0$$

and the first order one is

$$G^{(k)}(0,x;0) = (\partial_t W_0^{(k)})(0,x).$$

It is not difficult to verify that compatibility conditions for problems (3.33) and (3.34) are implied directly by those for the problem (3.1).

The problem (3.33) shall be solved in the following steps, and (3.34) can be studied similarly.

3.2.1. Step 1: Homogenization of the initial data. Let $\chi(z) \in C_0^\infty(\mathbb{R})$ be an arbitrary smooth function with compact support and $\chi(0) = 1$. Then, the function

$$Y_0^{(k)}(t, x; z) = \chi(z) W_0^{(k)}(t, x)$$

satisfies the initial and boundary conditions given in (3.33) due to the compatibility conditions.

Using the transformation $\tilde{Y}^{(k)} = Y^{(k)} - Y_0^{(k)}$, if necessary, it suffices to study the problem (3.33) for the special case $Y^{(k)}|_{z=0} \equiv 0$, which will be assumed in what follows.

3.2.2. Step 2: Construction of approximation solutions. We construct an approximate solution sequence $\{Y_n^{(k)}\}_{n\geq 1}$ of (3.33) by solving the following problem for each $n \geq 1$:

(3.35)
$$\begin{cases} (\partial_t + a_1\partial_x)Y_n^{(k)} - a_4^2(\partial_z^2 - k^2a^2)Y_n^{(k)} + z(a_2\partial_z + ika_3)Y_n^{(k)} - \dfrac{1}{n}\partial_x^2 Y_n^{(k)} \\ \quad +ka_5 \displaystyle\int_z^{+\infty} e^{ka(z-\xi)} Y_{n-1}^{(k)}(t, x; \xi) d\xi + ka_6 \int_0^z e^{ka(\xi - z)} Y_{n-1}^{(k)}(t, x; \xi) d\xi = G^{(k)}(t, x; z) \\ Y_n^{(k)}|_{z=0} = 0, \quad Y_n^{(k)} \in S(\mathbb{R}_z^+) \\ Y_n^{(k)}|_{t=0} = 0, \end{cases}$$

where $Y_0^{(k)}(t, x, z) \equiv 0$.

It remains to study properties of the sequence $\{Y_n^{(k)}\}_{n\geq 1}$. Most of this part will follow the idea of Xin and Yanagisawa in section 4 of [12] for studying the linearized Prandtl equation.

In what follows, for any $j \in \mathbb{N}$, we shall denote by C_j a constant depending only upon the bounds of derivatives of coefficients appeared in (3.35) up to order j.

3.2.3. Step 3: The boundedness of { ( )} ≥1 in ²− norm. Denote by $\langle z \rangle = (1 + z^2)^{\frac{1}{2}}$, and $\Omega = \mathbb{R}_+^2 = \{(x, z) \in \mathbb{R}^2 |\ z > 0\}$. For any fixed integer $l \in \mathbb{N}$, multiplying (3.35) by $< z >^{2l}\ \overline{Y}_n^{(k)}$, and integrating the resulting equation over Ω, one gets

$$\begin{aligned} &\frac{d}{dt}\int_\Omega \langle z\rangle^{2l} |Y_n^{(k)}|^2 dxdz - \int_\Omega \partial_x a_1 \langle z\rangle^{2l} |Y_n^{(k)}|^2 dxdz \\ &\quad + 2k^2 \int_\Omega a^2 a_4^2 \langle z\rangle^{2l} |Y_n^{(k)}|^2 dxdz + 4l\mathcal{R}\int_\Omega a_4^2 z \langle z\rangle^{2(l-1)} Y_n^{(k)} \partial_z \overline{Y}_n^{(k)} dxdz \\ &\quad + 2\int_\Omega a_4^2 \langle z\rangle^{2l} |\partial_z Y_n^{(k)}|^2 dxdz + \frac{2}{n}\int_\Omega \langle z\rangle^{2l} |\partial_x Y_n^{(k)}|^2 dxdz + 2kA_0 \\ &\quad = 2\mathcal{R}\int_\Omega \langle z\rangle^{2l} G^{(k)} \overline{Y}_n^{(k)} dxdz, \end{aligned} \tag{3.36}$$

where $\mathcal{R}(\cdot)$ denotes the real part of the related functions, and

$$\begin{aligned} A_0 = \mathcal{R}\int_\Omega \langle z\rangle^{2l} \overline{Y}_n^{(k)} \Big(& a_5 \int_z^{+\infty} e^{ka(z-\xi)} Y_{n-1}^{(k)}(t, x; \xi) d\xi \\ & + a_6 \int_0^z e^{ka(\xi - z)} Y_{n-1}^{(k)}(t, x; \xi) d\xi \Big) dxdz. \end{aligned} \tag{3.37}$$

By a simple computation, one deduces

$$
\begin{aligned}
&\int_\Omega \langle z\rangle^{2l} |\overline{Y}_n^{(k)} \int_0^z e^{ka(\xi-z)} Y_{n-1}^{(k)}(t,x;\xi) d\xi| dxdz \\
&\quad \le \frac{1}{2}\int_\Omega \int_0^z \langle z\rangle^{2l} e^{ka(\xi-z)} (|Y_n^{(k)}(t,x;z)|^2 + |Y_{n-1}^{(k)}(t,x;\xi)|^2) d\xi dxdz \\
&\quad \le \frac{c(l,a_0)}{k}\int_\Omega \langle z\rangle^{2l} (|Y_n^{(k)}|^2 + |Y_{n-1}^{(k)}|^2) dxdz,
\end{aligned}
\tag{3.38}
$$

where $c(l,a_0)$ is a constant depending only upon $l\in\mathbb{N}$ and a_0 satisfying $0<a_0\le a(t,x)$.

Similarly, we have

$$
\begin{aligned}
&\int_\Omega \langle z\rangle^{2l} |\overline{Y}_n^{(k)} \int_z^{+\infty} e^{ka(z-\xi)} Y_{n-1}^{(k)}(t,x;\xi) d\xi| dxdz \\
&\quad \le \frac{c(l,a_0)}{k}\int_\Omega \langle z\rangle^{2l} (|Y_n^{(k)}|^2 + |Y_{n-1}^{(k)}|^2) dxdz.
\end{aligned}
\tag{3.39}
$$

Substituting (3.38) and (3.39) into (3.37) shows that

$$
|A_0| \le \frac{C_0}{k}\int_\Omega \langle z\rangle^{2l} (|Y_n^{(k)}|^2 + |Y_{n-1}^{(k)}|^2) dxdz. \tag{3.40}
$$

Combining (3.40) and (3.36), we get

$$
\begin{aligned}
&\frac{d}{dt}\int_\Omega \langle z\rangle^{2l} |Y_n^{(k)}|^2 dxdz + \int_\Omega \langle z\rangle^{2l} (|\partial_z Y_n^{(k)}|^2 + k^2|Y_n^{(k)}|^2) dxdz \\
&\quad \le C_0 \int_\Omega \langle z\rangle^{2l} (|Y_n^{(k)}|^2 + |Y_{n-1}^{(k)}|^2) dxdz + \int_\Omega \langle z\rangle^{2l} |G^{(k)}|^2 dxdz.
\end{aligned}
\tag{3.41}
$$

To study (3.41), first we have to note the following lemma.

LEMMA 3.4. *Given nonnegative functions $f\in C^0[0,\infty)$, $b_n\in C^0[0,\infty)$, $a_n\in C^1[0,\infty)$ satisfying $a_n(0)\le a$ for a constant a for any $n\in\mathbb{N}$, if we have*

$$
a_n'(t) + b_n(t) \le C_0(a_n(t) + a_{n-1}(t)) + f(t) \quad \forall n\ge 1
$$

for a constant $C_0\ge 0$ independent of n, then the estimate

$$
a_n(t) + \int_0^t e^{C_0(t-s)} b_n(s) ds \le a e^{2C_0 t} + \int_0^t e^{2C_0(t-s)} f(s) ds
$$

holds for any $n\in\mathbb{N}$.

This Gronwall type estimate can be obtained by induction on n.

By using Lemma 3.4 in (3.42), we immediately refer to the following lemma.

LEMMA 3.5. *Denote by $\langle z\rangle = (1+z^2)^{\frac{1}{2}}$ and $\Omega = \mathbb{R}_+^2 = \{(x,z)\in\mathbb{R}^2 |\ z>0\}$. For any fixed integer $l\in\mathbb{N}$, there is a constant C_0 depending only upon l and a_0 satisfying $0<a_0\le a(t,x)$, such that the following estimate*

$$
\begin{aligned}
&\max_{0\le t\le T}\int_\Omega \langle z\rangle^{2l} |Y_n^{(k)}|^2 dxdz + \int_0^T\int_\Omega \langle z\rangle^{2l} (|\partial_z Y_n^{(k)}|^2 + k^2|Y_n^{(k)}|^2) dxdzdt \\
&\quad \le \int_0^T\int_\Omega e^{2C_0(T-t)} \langle z\rangle^{2l} |G^{(k)}|^2 dxdzdt
\end{aligned}
\tag{3.42}
$$

holds for any $T\ge 0$ and $n\in\mathbb{N}$.

3.2.4. Step 4: Estimates of spatial tangential derivatives ( ). For any $\alpha \in \mathbb{N}$, set $Y^{(k)}_{n,\alpha} = \partial_x^\alpha Y^{(k)}_n$. From (3.35), we know that $Y^{(k)}_{n,\alpha}$ satisfies the following problem:

(3.43)
$$\begin{cases} (\partial_t + a_1\partial_x)Y^{(k)}_{n,\alpha} - a_4^2(\partial_z^2 - k^2a^2)Y^{(k)}_{n,\alpha} + z(a_2\partial_z + ika_3)Y^{(k)}_{n,\alpha} - \dfrac{1}{n}\partial_x^2 Y^{(k)}_{n,\alpha} \\ \qquad +ka_5\displaystyle\int_z^{+\infty} e^{ka(z-\xi)}Y^{(k)}_{n-1,\alpha}(\cdot,\xi)d\xi + ka_6\int_0^z e^{ka(\xi-z)}Y^{(k)}_{n-1,\alpha}(\cdot,\xi)d\xi + R_\alpha = \partial_x^\alpha G^{(k)} \\ Y^{(k)}_{n,\alpha}|_{z=0} = 0, \quad Y^{(k)}_{n,\alpha} \in S(\mathbb{R}^+_z) \\ Y^{(k)}_{n,\alpha}|_{t=0} = 0, \end{cases}$$

where

$$\begin{aligned} R_\alpha &= [\partial_x^\alpha, a_1\partial_x - a_4^2(\partial_z^2 - k^2a^2) + z(a_2\partial_z + ika_3)]Y^{(k)}_n \\ &\quad + k\sum_{0<j\le\alpha}\binom{\alpha}{j}\Big(\partial_x^j a_5\int_z^{+\infty}\partial_x^{\alpha-j}(e^{ka(z-\xi)}Y^{(k)}_{n-1}(\cdot,\xi))d\xi \\ &\quad + \partial_x^j a_6\int_0^z \partial_x^{\alpha-j}(e^{ka(\xi-z)}Y^{(k)}_{n-1}(\cdot,\xi))d\xi\Big) \\ &\quad + ka_5\int_z^{+\infty}[\partial_x^\alpha, e^{ka(z-\xi)}]Y^{(k)}_{n-1}(t,x;\xi)d\xi + ka_6\int_0^z[\partial_x^\alpha, e^{ka(\xi-z)}]Y^{(k)}_{n-1}(t,x;\xi)d\xi. \end{aligned}$$

Similar to (3.41), by multiplying the equation in (3.43) by $\langle z\rangle^{2l}\overline{Y}^{(k)}_{n,\alpha}$ for any fixed $l \in \mathbb{N}$, and integrating the resulting equation over Ω, we obtain

$$\begin{aligned} &\frac{d}{dt}\int_\Omega \langle z\rangle^{2l}|Y^{(k)}_{n,\alpha}|^2dxdz + \int_\Omega\langle z\rangle^{2l}(|\partial_z Y^{(k)}_{n,\alpha}|^2 + k^2|Y^{(k)}_{n,\alpha}|^2)dxdz \\ &\qquad \le C_0\int_\Omega\langle z\rangle^{2l}(|Y^{(k)}_{n,\alpha}|^2 + |Y^{(k)}_{n-1,\alpha}|^2)dxdz + \int_\Omega < z >^{2l} |\partial_x^\alpha G^{(k)}|^2dxdz \\ &\qquad\quad -2\mathcal{R}\int_\Omega\langle z\rangle^{2l}R_\alpha\overline{Y}^{(k)}_{n,\alpha}dxdz. \end{aligned} \tag{3.44}$$

On the other hand, we have

$$\begin{aligned} &\Big|\int_\Omega\langle z\rangle^{2l}R_\alpha\overline{Y}^{(k)}_{n,\alpha}dxdz\Big| \\ &\quad \le C_0\int_\Omega\langle z\rangle^{2l}|Y^{(k)}_{n,\alpha}|^2dxdz + \epsilon\int_\Omega\langle z\rangle^{2l}(|\partial_z Y^{(k)}_{n,\alpha}|^2 + k^2|Y^{(k)}_{n,\alpha}|^2)dxdz \\ &\qquad + \sum_{0<j\le\alpha}\frac{C_j}{\epsilon}\int_\Omega\langle z\rangle^{2l}(|\partial_z Y^{(k)}_{n,\alpha-j}|^2 + k^2|Y^{(k)}_{n,\alpha-j}|^2 + \langle z\rangle^2|Y^{(k)}_{n,\alpha-j}|^2)dxdz \\ &\qquad + \sum_{0<j\le\alpha}C_j\int_\Omega\langle z\rangle^{2l}(\langle z\rangle^2|\partial_z Y^{(k)}_{n,\alpha-j}|^2 + |Y^{(k)}_{n-1,\alpha-j}|^2)dxdz \end{aligned} \tag{3.45}$$

for any $\epsilon > 0$.

Substituting (3.45) into (3.44), and letting ϵ be small, we obtain

$$\begin{aligned}
&\frac{d}{dt}\int_\Omega \langle z\rangle^{2l}\,|Y_{n,\alpha}^{(k)}|^2 dxdz + \int_\Omega \langle z\rangle^{2l}(|\partial_z Y_{n,\alpha}^{(k)}|^2 + k^2|Y_{n,\alpha}^{(k)}|^2)dxdz \\
&\qquad \le C_0\int_\Omega \langle z\rangle^{2l}(|Y_{n,\alpha}^{(k)}|^2 + |Y_{n-1,\alpha}^{(k)}|^2)dxdz + \int_\Omega \langle z\rangle^{2l}|\partial_x^\alpha G^{(k)}|^2 dxdz \\
&\qquad\quad + \sum_{0<j\le\alpha} C_j\Big(\int_\Omega \langle z\rangle^{2(l+1)}(|\partial_z Y_{n,\alpha-j}^{(k)}|^2 + |Y_{n,\alpha-j}^{(k)}|^2)dxdz \\
&\qquad\quad + \int_\Omega \langle z\rangle^{2l}(|Y_{n-1,\alpha-j}^{(k)}|^2 + k^2|Y_{n,\alpha-j}^{(k)}|^2)dxdz\Big).
\end{aligned}$$

By using Lemma 3.4 and induction on $\alpha\in\mathbb{N}$, Lemma 3.6 follows.

LEMMA 3.6. *For the problem* (3.35), *let* $Y_{n,\alpha}^{(k)} = \partial_x^\alpha Y_n^{(k)}$; *the following estimate*

$$\begin{aligned}
&\max_{0\le t\le T}\int_\Omega \langle z\rangle^{2l}|Y_{n,\alpha}^{(k)}|^2 dxdz + \int_0^T\int_\Omega \langle z\rangle^{2l}(|\partial_z Y_{n,\alpha}^{(k)}|^2 + k^2|Y_{n,\alpha}^{(k)}|^2)dxdzdt \\
&\qquad \le C(T)\sum_{j=0}^{\alpha}\int_0^T\int_\Omega \langle z\rangle^{2(l+\alpha-j)}|\partial_x^j G^{(k)}|^2 dxdzdt
\end{aligned} \tag{3.46}$$

holds for any $\alpha\in\mathbb{N}$.

3.2.5. Step 5: Estimates of derivatives , ( ). For any fixed integer $j\ge 0$, set $V_{n,j}^{(k)} = \partial_t^j Y_n^{(k)}$.

From (3.35) we know that $V_{n,j}^{(k)}$ satisfies the following problem:

(3.47)
$$\begin{cases}
(\partial_t + a_1\partial_x)V_{n,j}^{(k)} - a_4^2(\partial_z^2 - k^2a^2)V_{n,j}^{(k)} + z(a_2\partial_z + ika_3)V_{n,j}^{(k)} - \frac{1}{n}\partial_x^2 V_{n,j}^{(k)} \\
\quad + ka_5\displaystyle\int_z^{+\infty} e^{ka(z-\xi)}V_{n-1,j}^{(k)}(\cdot,\xi)d\xi + ka_6\int_0^z e^{ka(\xi-z)}V_{n-1,j}^{(k)}(\cdot,\xi)d\xi + Q_j = \partial_t^j G^{(k)} \\
V_{n,j}^{(k)}|_{z=0} = 0, \quad V_{n,j}^{(k)}\in S(\mathbb{R}_z^+) \\
V_{n,j}^{(k)}|_{t=0} = V_{n,j,0}^{(k)}(x,z),
\end{cases}$$

where

$$\begin{aligned}
Q_j &= [\partial_t^j, a_1\partial_x - a_4^2(\partial_z^2 - k^2a^2) + z(a_2\partial_z + ika_3)]Y_n^{(k)} \\
&\quad + k\sum_{0<m\le j}\binom{j}{m}\Big(\partial_t^m a_5\int_z^{+\infty}\partial_t^{j-m}(e^{ka(z-\xi)}Y_{n-1}^{(k)}(t,x;\xi))d\xi \\
&\quad + \partial_t^m a_6\int_0^z \partial_t^{j-m}(e^{ka(\xi-z)}Y_{n-1}^{(k)}(t,x;\xi))d\xi\Big) \\
&\quad + ka_5\int_z^{+\infty}[\partial_t^j, e^{ka(z-\xi)}]Y_{n-1}^{(k)}(t,x;\xi)d\xi + ka_6\int_0^z[\partial_t^j, e^{ka(\xi-z)}]Y_{n-1}^{(k)}(t,x;\xi)d\xi
\end{aligned}$$

and

(3.48)
$$\begin{aligned}
V_{n,j,0}^{(k)} &= \partial_t^{j-1}G^{(k)}|_{t=0} - \Big(a_1\partial_x - a_4^2(\partial_z^2 - k^2a^2) + z(a_2\partial_z + ika_3) - \frac{1}{n}\partial_x^2\Big)V_{n,j-1,0}^{(k)} \\
&\quad - ka_5\int_z^{+\infty} e^{ka(z-\xi)}V_{n-1,j-1,0}^{(k)}d\xi - ka_6\int_0^z e^{ka(\xi-z)}V_{n-1,j-1,0}^{(k)}d\xi - Q_{j-1}|_{t=0}
\end{aligned}$$

is defined by induction on j with $V^{(k)}_{n,1,0} = G^{(k)}(0, x, z)$.

Multiplying (3.47) by $\langle z\rangle^{2l}\overline{V}^{(k)}_{n,j}$, and integrating the resulting equation over Ω, one gets

$$\begin{aligned}
&\frac{d}{dt}\int_\Omega \langle z\rangle^{2l}\,|V^{(k)}_{n,j}|^2 dxdz + \int_\Omega \langle z\rangle^{2l}(|\partial_z V^{(k)}_{n,j}|^2 + k^2|V^{(k)}_{n,j}|^2)dxdz\\
&\qquad\le C_0\int_\Omega \langle z\rangle^{2l}(|V^{(k)}_{n,j}|^2 + |V^{(k)}_{n-1,j}|^2)dxdz + \int_\Omega \langle z\rangle^{2l}|\partial_t^j G^{(k)}|^2 dxdz\\
&\qquad\quad -2\mathcal{R}\int_\Omega \langle z\rangle^{2l} Q_j \overline{V}^{(k)}_{n,j} dxdz.
\end{aligned}\tag{3.49}$$

On the other hand, we have

$$\begin{aligned}
&\left|\int_\Omega \langle z\rangle^{2l}\,Q_j\overline{V}^{(k)}_{n,j}dxdz\right|\\
&\qquad\le C_0\int_\Omega \langle z\rangle^{2l}|V^{(k)}_{n,j}|^2 dxdz + \epsilon\int_\Omega \langle z\rangle^{2l}(|\partial_z V^{(k)}_{n,j}|^2 + k^2|V^{(k)}_{n,j}|^2)dxdz\\
&\qquad\quad + \sum_{0<m\le j}\frac{C_m}{\epsilon}\int_\Omega \langle z\rangle^{2l}(|\partial_z V^{(k)}_{n,j-m}|^2 + k^2|V^{(k)}_{n,j-m}|^2\\
&\qquad\quad + \langle z\rangle^2|V^{(k)}_{n,j-m}|^2 + |V^{(k)}_{n-1,j-m}|^2)dxdz\\
&\qquad\quad + \sum_{0<m\le j} C_m\int_\Omega \langle z\rangle^{2l}(\langle z\rangle^2|\partial_z V^{(k)}_{n,j-m}|^2 + |\partial_x V^{(k)}_{n,j-m}|^2)dxdz
\end{aligned}\tag{3.50}$$

for any $\epsilon > 0$.

Substituting (3.50) into (3.49), and letting ϵ be small, we obtain

$$\begin{aligned}
&\frac{d}{dt}\int_\Omega \langle z\rangle^{2l}\,|V^{(k)}_{n,j}|^2 dxdz + \int_\Omega \langle z\rangle^{2l}(|\partial_z V^{(k)}_{n,j}|^2 + k^2|V^{(k)}_{n,j}|^2)dxdz\\
&\quad\le C_0\int_\Omega \langle z\rangle^{2l}(|V^{(k)}_{n,j}|^2 + |V^{(k)}_{n-1,j}|^2)dxdz + \int_\Omega \langle z\rangle^{2l}|\partial_t^j G^{(k)}|^2 dxdz\\
&\qquad + \sum_{0<m\le j} C_m\Big(\int_\Omega \langle z\rangle^{2(l+1)}(|\partial_z V^{(k)}_{n,j-m}|^2 + |V^{(k)}_{n,j-m}|^2)dxdz\\
&\qquad + \int_\Omega \langle z\rangle^{2l}(|V^{(k)}_{n-1,j-m}|^2 + k^2|V^{(k)}_{n,j-m}|^2 + |\partial_x V^{(k)}_{n,j-m}|^2)dxdz\Big).
\end{aligned}\tag{3.51}$$

Thus, to complete the estimate on $V^{(k)}_{n,j}$, we should study $\{\partial_x V^{(k)}_{n,m}\}_{m=1}^{j-1}$ first.

It follows from (3.47) that $\partial_x^p V^{(k)}_{n,j} = \partial_x^p\partial_t^j Y^{(k)}_n$ satisfies the following problem:

$$\begin{cases}
(\partial_t + a_1\partial_x - a_4^2(\partial_z^2 - k^2a^2) + z(a_2\partial_z + ika_3) - \frac{1}{n}\partial_x^2)\partial_x^p V^{(k)}_{n,j}\\
\qquad + ka_5\displaystyle\int_z^{+\infty} e^{ka(z-\xi)}\partial_x^p V^{(k)}_{n-1,j}d\xi + ka_6\int_0^z e^{ka(\xi-z)}\partial_x^p V^{(k)}_{n-1,j}d\xi + Q_{j,p} = \partial_x^p\partial_t^j G^{(k)}\\
\partial_x^p V^{(k)}_{n,j}|_{z=0} = 0, \quad \partial_x^p V^{(k)}_{n,j} \in S(\mathbb{R}_z^+)\\
\partial_x^p V^{(k)}_{n,j}|_{t=0} = \partial_x^p V^{(k)}_{n,j,0}(x,z),
\end{cases}\tag{3.52}$$

where $V^{(k)}_{n,j,0}(x,z)$ is given in (3.48), and

$$Q_{j,p} = \partial_x^p Q_j + [\partial_x^p, a_1\partial_x - a_4^2(\partial_z^2 - k^2a^2) + z(a_2\partial_z + ika_3)]V^{(k)}_{n,j}$$
$$+ k \sum_{0<m\le p} \binom{p}{m} \Big(\partial_x^m a_5 \int_z^{+\infty} \partial_x^{p-m}(e^{ka(z-\xi)}V^{(k)}_{n-1,j}(t,x;\xi))d\xi$$
$$+ \partial_x^m a_6 \int_0^z \partial_x^{p-m}(e^{ka(\xi-z)}V^{(k)}_{n-1,j}(t,x;\xi))d\xi\Big)$$
$$+ ka_5 \int_z^{+\infty} [\partial_x^p, e^{ka(z-\xi)}]V^{(k)}_{n-1,j}(t,x;\xi)d\xi + ka_6 \int_0^z [\partial_x^p, e^{ka(\xi-z)}]V^{(k)}_{n-1,j}(t,x;\xi)d\xi$$

with Q_j being given in (3.47).

Multiplying (3.52) by $< z >^{2l} \partial_x^p \overline{V}^{(k)}_{n,j}$, and integrating the resulting equation over Ω, one gets

$$\frac{d}{dt}\int_\Omega \langle z\rangle^{2l}\,|\partial_x^p V^{(k)}_{n,j}|^2 dxdz + \int_\Omega \langle z\rangle^{2l}(|\partial_z\partial_x^p V^{(k)}_{n,j}|^2 + k^2|\partial_x^p V^{(k)}_{n,j}|^2)dxdz$$
$$\le C_0 \int_\Omega \langle z\rangle^{2l}(|\partial_x^p V^{(k)}_{n,j}|^2 + |\partial_x^p V^{(k)}_{n-1,j}|^2)dxdz \tag{3.53}$$
$$+ \int_\Omega \langle z\rangle^{2l}|\partial_x^p\partial_t^j G^{(k)}|^2 dxdz - 2\mathcal{R}\int_\Omega \langle z\rangle^{2l} Q_{j,p}\partial_x^p \overline{V}^{(k)}_{n,j}dxdz.$$

A direct computation shows

$$\left|\int_\Omega \langle z\rangle^{2l} Q_{j,p}\partial_x^p\overline{V}^{(k)}_{n,j}dxdz\right|$$
$$\le C_0\int_\Omega \langle z\rangle^{2l}|\partial_x^p V^{(k)}_{n,j}|^2 dxdz + \epsilon\int_\Omega \langle z\rangle^{2l}(|\partial_z\partial_x^p V^{(k)}_{n,j}|^2 + k^2|\partial_x^p V^{(k)}_{n,j}|^2)dxdz$$
$$+ \sum_{0<m\le j, q\le p} \frac{C_{q+m}}{\epsilon}\int_\Omega \langle z\rangle^{2(l+1)}(|\partial_z\partial_x^q V^{(k)}_{n,j-m}|^2 + |\partial_x^q V^{(k)}_{n,j-m}|^2)dxdz$$
$$+ k^2 \sum_{0<m\le j, q\le p}\frac{C_{q+m}}{\epsilon}\int_\Omega \langle z\rangle^{2l}|\partial_x^q V^{(k)}_{n,j-m}|^2 dxdz$$
$$+ \sum_{q<p}\frac{C_q}{\epsilon}\int_\Omega \langle z\rangle^{2l}(|\partial_z\partial_x^q V^{(k)}_{n,j}|^2 + k^2|\partial_x^q V^{(k)}_{n,j}|^2)dxdz$$
$$+ \sum_{q<p} C_q \int_\Omega \langle z\rangle^{2l}(\langle z\rangle^2|\partial_z\partial_x^q V^{(k)}_{n,j}|^2 + |\partial_x^q V^{(k)}_{n-1,j}|^2)dxdz$$
$$+ \sum_{1\le q\le p} C_q\int_\Omega \langle z\rangle^{2l}|\partial_x^q V^{(k)}_{n,j}|^2 dxdz + \sum_{0<m\le j} C_m\int_\Omega \langle z\rangle^{2l}|\partial_x^{q+1} V^{(k)}_{n,j-m}|^2 dxdz$$
$$+ \sum_{0<m\le j, q\le p} C_{q+m}\int_\Omega \langle z\rangle^{2l}|\partial_x^q V^{(k)}_{n-1,j-m}|^2 dxdz.$$

Thus, from (3.53) one has

$$\begin{aligned}
&\frac{d}{dt}\int_\Omega \langle z\rangle^{2l}|\partial_x^p V_{n,j}^{(k)}|^2 dxdz + \int_\Omega \langle z\rangle^{2l}(|\partial_z\partial_x^p V_{n,j}^{(k)}|^2 + k^2|\partial_x^p V_{n,j}^{(k)}|^2)dxdz \\
&\quad \le C_0\int_\Omega \langle z\rangle^{2l}(|\partial_x^p V_{n,j}^{(k)}|^2 + |\partial_x^p V_{n-1,j}^{(k)}|^2)dxdz + \int_\Omega \langle z\rangle^{2l}|\partial_x^p\partial_t^j G^{(k)}|^2 dxdz \\
&\qquad + C_{j+p}\left\{\sum_{0<m\le j, q\le p}\left(\int_\Omega \langle z\rangle^{2(l+1)}(|\partial_z\partial_x^q V_{n,j-m}^{(k)}|^2 + |\partial_x^q V_{n,j-m}^{(k)}|^2)dxdz\right.\right. \\
&\qquad \left.\left. + \int_\Omega \langle z\rangle^{2l}(k^2|\partial_x^q V_{n,j-m}^{(k)}|^2 + |\partial_x^q V_{n-1,j-m}^{(k)}|^2)dxdz\right)\right\} \\
&\qquad + C_p\sum_{q<p}\int_\Omega \langle z\rangle^{2l}(\langle z\rangle^2|\partial_z\partial_x^q V_{n,j}^{(k)}|^2 + k^2|\partial_x^q V_{n,j}^{(k)}|^2 + |\partial_x^q V_{n-1,j}^{(k)}|^2)dxdz \\
&\qquad + C_j\sum_{0<m\le j}\int_\Omega \langle z\rangle^{2l}|\partial_x^{q+1}V_{n,j-m}^{(k)}|^2 dxdz.
\end{aligned} \tag{3.54}$$

By using Lemmas 3.4 and 3.5 in (3.51) for the case $j=1$, it follows that $V_{n,1}^{(k)} = \partial_t V_n^{(k)}$ satisfies

$$\begin{aligned}
&\max_{0\le t\le T}\int_\Omega \langle z\rangle^{2l}|V_{n,1}^{(k)}|^2 dxdz + \int_0^T\int_\Omega \langle z\rangle^{2l}(|\partial_z V_{n,1}^{(k)}|^2 + k^2|V_{n,1}^{(k)}|^2)dxdzdt \\
&\qquad \le C(T)\int_0^T\int_\Omega \langle z\rangle^{2l}(|\partial_x G^{(k)}|^2 + |\partial_t G^{(k)}|^2 + |G^{(k)}|^2)dxdzdt.
\end{aligned} \tag{3.55}$$

Using Lemma 3.6 and (3.55) in (3.54) for the case $j=1$ and $p=1$, and using Lemma 3.4, it follows that $\partial_x V_{n,1}^{(k)} = \partial_t\partial_x Y_n^{(k)}$ satisfies

$$\begin{aligned}
&\max_{0\le t\le T}\int_\Omega < z >^{2l} |\partial_x V_{n,1}^{(k)}|^2 dxdz + \int_0^T\int_\Omega \langle z\rangle^{2l}(|\partial_z\partial_x V_{n,1}^{(k)}|^2 + k^2|\partial_x V_{n,1}^{(k)}|^2)dxdzdt \\
&\quad \le C(T)\left(\sum_{j=0}^{2}\int_0^T\int_\Omega \langle z\rangle^{2(l+2-j)}|\partial_x^j G^{(k)}|^2 dxdzdt\right. \\
&\qquad \left. + \sum_{j=0}^{1}\int_0^T\int_\Omega \langle z\rangle^{2(l+1-j)}|\partial_x^j\partial_t G^{(k)}|^2 dxdzdt\right).
\end{aligned} \tag{3.56}$$

Employing (3.56), (3.46), and (3.55) in (3.51) for the case $j=2$, and using Lemma 3.4 we deduce that $V_{n,2}^{(k)} = \partial_t^2 Y_n^{(k)}$ satisfies

$$\begin{aligned}
&\max_{0\le t\le T}\int_\Omega \langle z\rangle^{2l}|V_{n,2}^{(k)}|^2 dxdz + \int_0^T\int_\Omega \langle z\rangle^{2l}(|\partial_z V_{n,2}^{(k)}|^2 + k^2|V_{n,2}^{(k)}|^2)dxdzdt \\
&\quad \le C(T)\left(\int_\Omega \langle z\rangle^{2l}|V_{n,2,0}^{(k)}|^2 dxdz + \sum_{|\alpha|\le 2}\int_0^T\int_\Omega \langle z\rangle^{2(l+2-|\alpha|)}|\partial_{t,x}^\alpha G^{(k)}|^2 dxdzdt\right),
\end{aligned}$$

which implies

$$\begin{aligned}
&\max_{0\le t\le T}\int_\Omega \langle z\rangle^{2l}|V_{n,2}^{(k)}|^2dxdz+\int_0^T\int_\Omega\langle z\rangle^{2l}(|\partial_zV_{n,2}^{(k)}|^2+k^2|V_{n,2}^{(k)}|^2)dxdzdt\\
&\quad\le C\Bigg(\sum_{|\alpha|\le 2}\int_0^T\int_\Omega\langle z\rangle^{2(l+2-|\alpha|)}|\partial_{t,x}^\alpha G^{(k)}|^2dxdzdt\\
&\qquad+k^4\int_0^T\int_\Omega\langle z\rangle^{2l}(|G^{(k)}|^2+|\partial_tG^{(k)}|^2)dxdzdt\\
&\qquad+\sum_{j=1}^2\sum_{i=0}^1\int_0^T\int_\Omega\langle z\rangle^{2(l+2-j)}|\partial_t^i\partial_z^jG^{(k)}|^2dxdzdt\\
&\qquad+\sum_{j=1}^2\int_0^T\int_\Omega\langle z\rangle^{2l}|\partial_t\partial_x^jG^{(k)}|^2dxdzdt\Bigg)
\end{aligned}\tag{3.57}$$

from the formula of $V_{n,2,0}^{(k)}$ given in (3.48), where the positive constant C depends only on T, C_0, and C_2.

By induction on $|\alpha|\in\mathbb{N}$, we obtain the following lemma.

LEMMA 3.7. *Let $Y_n^{(k)}$ be the solution sequence to the problem* (3.35). *Then for any $\alpha\in\mathbb{N}^2$, $\partial_{t,x}^\alpha Y_n^{(k)}$ satisfies the following estimate:*

$$\begin{aligned}
&\max_{0\le t\le T}\int_\Omega\langle z\rangle^{2l}|\partial_{t,x}^\alpha Y_n^{(k)}|^2dxdz+\int_0^T\int_\Omega\langle z\rangle^{2l}(|\partial_z\partial_{t,x}^\alpha Y_n^{(k)}|^2+k^2|\partial_{t,x}^\alpha Y_n^{(k)}|^2)dxdzdt\\
&\le C(T)\Bigg(\sum_{j=2}^{|\alpha|}\sum_{m=0}^{|\alpha|-j}\sum_{\substack{r+i+p\le j-1\\0\le q\le 2i\\0\le h\le 1}}\int_0^T\int_\Omega\langle z\rangle^{2(l+|\alpha|-j-m+2i-q)}k^{4r}|\partial_t^h\partial_z^q\partial_x^{m+2p}G^{(k)}|^2dxdzdt\\
&\qquad+\sum_{|\beta|\le|\alpha|}\int_0^T\int_\Omega\langle z\rangle^{2(l+|\alpha|-|\beta|)}|\partial_{t,x}^\beta G^{(k)}|^2dxdzdt\Bigg).
\end{aligned}\tag{3.58}$$

3.2.6. Step 6: Estimates of normal derivatives , ( ). For any $j\in\mathbb{N}$ and $\alpha=(\alpha_1,\alpha_2)\in\mathbb{N}^2$, set $W_{n,\alpha,j}^{(k)}=\partial_z^j\partial_{t,x}^\alpha Y_n^{(k)}$.

From (3.58) and the obvious identity

$$\partial_z^j\partial_t^{\alpha_1}\partial_x^{\alpha_2}Y_n^{(k)}(t,x,z)=\partial_z^j\partial_t^{\alpha_1}\partial_x^{\alpha_2}Y_n^{(k)}(0,x,z)+\int_0^t\partial_z^j\partial_t^{\alpha_1+1}\partial_x^{\alpha_2}Y_n^{(k)}(s,x,z)ds$$

we get

$$\max_{0\le t\le T}\int_\Omega \langle z\rangle^{2l}|\partial_z\partial_t^{\alpha_1}\partial_x^{\alpha_2}Y_n^{(k)}|^2dxdz \le \int_\Omega \langle z\rangle^{2l}|\partial_z\partial_t^{\alpha_1}\partial_x^{\alpha_2}Y_n^{(k)}(t=0)|^2dxdz \tag{3.59}$$
$$+C(T)\Bigg(\sum_{j=2}^{|\alpha|+1}\sum_{m=0}^{|\alpha|+1-j}\int_\Omega \langle z\rangle^{2(l+|\alpha|+1-j-m)}|\partial_x^m\partial_t^jY_n^{(k)}(t=0)|^2dxdz$$
$$+\sum_{|\beta|\le|\alpha|+1}\int_0^T\int_\Omega \langle z\rangle^{2(l+|\alpha|+1-|\beta|)}|\partial_{t,x}^\beta G^{(k)}|^2dxdzdt\Bigg).$$

From (3.52) it follows that

(3.60)
$$\int_\Omega \langle z\rangle^{2l}\ |\partial_z^2\partial_t^{\alpha_1}\partial_x^{\alpha_2}Y_n^{(k)}|^2dxdz$$
$$\le C_0\Bigg\{\int_\Omega \langle z\rangle^{2(l+1)}(|\partial_z\partial_t^{\alpha_1}\partial_x^{\alpha_2}Y_n^{(k)}|^2+k^2|\partial_t^{\alpha_1}\partial_x^{\alpha_2}Y_n^{(k)}|^2)dxdz$$
$$+\int_\Omega \langle z\rangle^{2l}(|\partial_t^{\alpha_1+1}\partial_x^{\alpha_2}Y_n^{(k)}|^2+|\partial_t^{\alpha_1}\partial_x^{\alpha_2+1}Y_n^{(k)}|^2+|\partial_t^{\alpha_1}\partial_x^{\alpha_2+2}Y_n^{(k)}|^2$$
$$+k^4|\partial_t^{\alpha_1}\partial_x^{\alpha_2}Y_n^{(k)}|^2+|\partial_t^{\alpha_1}\partial_x^{\alpha_2}Y_{n-1}^{(k)}|^2+|\partial_t^{\alpha_1}\partial_x^{\alpha_2}G^{(k)}|^2+Q_{\alpha_1,\alpha_2})dxdz\Bigg\}$$

and

(3.61)
$$\int_\Omega \langle z\rangle^{2l}|Q_{\alpha_1,\alpha_2}|^2dxdz$$
$$\le C\Bigg\{\sum_{j\le\alpha_1-1,m\le\alpha_2}\int_\Omega \langle z\rangle^{2l}(|\partial_z^2\partial_t^j\partial_x^mY_n^{(k)}|^2+k^4|\partial_t^j\partial_x^mY_n^{(k)}|^2+|\partial_t^j\partial_x^mY_{n-1}^{(k)}|^2)dxdz$$
$$+\sum_{j\le\alpha_1-1,m\le\alpha_2}\int_\Omega \langle z\rangle^{2(l+1)}(|\partial_z\partial_t^j\partial_x^mY_n^{(k)}|^2+k^2|\partial_t^j\partial_x^mY_n^{(k)}|^2)dxdz$$
$$+\int_\Omega \langle z\rangle^{2l}(|\partial_t^{\alpha_1}\partial_x^{\alpha_2}Y_n^{(k)}|^2+\sum_{j\le\alpha_1-1}|\partial_t^j\partial_x^{\alpha_2+1}Y_n^{(k)}|^2)dxdz$$
$$+\sum_{m\le\alpha_2-1}\int_\Omega \langle z\rangle^{2l}(|\partial_z^2\partial_t^{\alpha_1}\partial_x^mY_n^{(k)}|^2+k^4|\partial_t^{\alpha_1}\partial_x^mY_n^{(k)}|^2+|\partial_t^{\alpha_1}\partial_x^mY_{n-1}^{(k)}|^2)dxdz$$
$$+\sum_{m\le\alpha_2-1}\int_\Omega \langle z\rangle^{2(l+1)}(|\partial_z\partial_t^{\alpha_1}\partial_x^mY_n^{(k)}|^2+k^2|\partial_t^{\alpha_1}\partial_x^mY_n^{(k)}|^2)dxdz\Bigg\}.$$

Substituting (3.61) into (3.60) yields

$$
\begin{aligned}
&\int_\Omega \langle z\rangle^{2l}\ |\partial_z^2\partial_t^{\alpha_1}\partial_x^{\alpha_2}Y_n^{(k)}|^2dxdz \\
&\qquad \le C\Bigg\{\sum_{\beta\le\alpha}\int_\Omega \langle z\rangle^{2(l+1)}(|\partial_z\partial_{t,x}^\beta Y_n^{(k)}|^2+k^2|\partial_{t,x}^\beta Y_n^{(k)}|^2)dxdz \\
&\qquad\quad +\int_\Omega\langle z\rangle^{2l}\Bigg(\sum_{\beta\le\alpha}(k^4|\partial_{t,x}^\beta Y_n^{(k)}|^2+|\partial_{t,x}^\beta Y_{n-1}^{(k)}|^2)+\sum_{\beta<\alpha}|\partial_z^2\partial_{t,x}^\beta Y_n^{(k)}|^2 \\
&\qquad\quad +\sum_{j\le\alpha_1}|\partial_t^j\partial_x^{\alpha_2+1}Y_n^{(k)}|^2+|\partial_t^{\alpha_1}\partial_x^{\alpha_2+2}Y_n^{(k)}|^2 \\
&\qquad\quad +|\partial_t^{\alpha_1+1}\partial_x^{\alpha_2}Y_n^{(k)}|^2+|\partial_t^{\alpha_1}\partial_x^{\alpha_2}G^{(k)}|^2\Bigg)dxdz\Bigg\},
\end{aligned}
\tag{3.62}
$$

where the notations $\beta\le\alpha$ and $\beta<\alpha$ for $\alpha,\beta\in\mathbb{N}^2$ mean that $\beta_1\le\alpha_1,\beta_2\le\alpha_2$, and $\beta_1\le\alpha_1,\beta_2\le\alpha_2$, $\beta_1+\beta_2<\alpha_1+\alpha_2$, respectively.

By using (3.59) and (3.58) in (3.62), we get

$$
\begin{aligned}
&\max_{0\le t\le T}\int_\Omega\langle z\rangle^{2l}|\partial_z^2\partial_{t,x}^\alpha Y_n^{(k)}|^2dxdz \\
&\qquad \le C\Bigg\{k^4\sum_{\beta\le\alpha}\Bigg(\int_\Omega\langle z\rangle^{2(l+|\alpha|-|\beta|)}|\partial_{t,x}^\beta Y_n^{(k)}(t=0)|^2dxdz \\
&\qquad\qquad +\int_0^T\int_\Omega\langle z\rangle^{2(l+|\alpha|-|\beta|)}|\partial_{t,x}^\beta G^{(k)}|^2dxdzdt\Bigg) \\
&\qquad\quad +\sum_{|\beta|\le|\alpha|+2}\Bigg(\int_\Omega\langle z\rangle^{2(l+|\alpha|+2-|\beta|)}|\partial_{t,x}^\beta Y_n^{(k)}(t=0)|^2dxdz \\
&\qquad\quad +\int_0^T\int_\Omega\langle z\rangle^{2(l+|\alpha|+2-|\beta|)}|\partial_{t,x}^\beta G^{(k)}|^2dxdzdt\Bigg) \\
&\qquad\quad +\sum_{\beta\le\alpha}\int_\Omega\langle z\rangle^{2(l+1)}|\partial_z\partial_{t,x}^\beta Y_n^{(k)}(t=0)|^2dxdz \\
&\qquad\quad +\sum_{\beta<\alpha}\int_0^T\int_\Omega\langle z\rangle^{2l}|\partial_z^2\partial_{t,x}^\beta Y_n^{(k)}|^2dxdzdt\Bigg\}
\end{aligned}
$$

which implies

$$
\begin{aligned}
&\max_{0\le t\le T}\int_\Omega \langle z\rangle^{2l}|\partial_z^2\partial_{t,x}^\alpha Y_n^{(k)}|^2dxdz\\
&\quad\le C(T)\Bigg\{k^4\sum_{\beta\le\alpha}\bigg(\int_\Omega\langle z\rangle^{2(l+|\alpha|-|\beta|)}|\partial_{t,x}^\beta Y_n^{(k)}(t=0)|^2dxdz\\
&\qquad+\int_0^T\int_\Omega\langle z\rangle^{2(l+|\alpha|-|\beta|)}|\partial_{t,x}^\beta G^{(k)}|^2dxdzdt\bigg)\\
&\qquad+\sum_{|\beta|\le|\alpha|+2}\bigg(\int_\Omega\langle z\rangle^{2(l+|\alpha|+2-|\beta|)}|\partial_{t,x}^\beta Y_n^{(k)}(t=0)|^2dxdz\\
&\qquad+\int_0^T\int_\Omega\langle z\rangle^{2(l+|\alpha|+2-|\beta|)}|\partial_{t,x}^\beta G^{(k)}|^2dxdzdt\bigg)\\
&\qquad+\sum_{\beta\le\alpha}\int_\Omega\langle z\rangle^{2(l+1)}|\partial_z\partial_{t,x}^\beta Y_n^{(k)}(t=0)|^2dxdz\Bigg\}.
\end{aligned}\tag{3.63}
$$

Differentiating (3.52) with respect to z and by induction on $j\in\mathbb{N}$, one can obtain the following lemma.

LEMMA 3.8. *The solution $Y_n^{(k)}$ of* (3.35) *satisfies the following estimate:*

$$
\begin{aligned}
&\max_{0\le t\le T}\int_\Omega \langle z\rangle^{2l}|\partial_z^j\partial_{t,x}^\alpha Y_n^{(k)}|^2dxdz\\
&\le C(T)\Bigg\{\sum_{m=0}^{[j/2]}k^{4m}\sum_{|\beta|\le|\alpha|+j-2m}\bigg(\int_\Omega\langle z\rangle^{2(l+|\alpha|+j-2m-|\beta|)}|\partial_{t,x}^\beta Y_n^{(k)}(t=0)|^2dxdz\\
&\quad+\int_0^T\int_\Omega\langle z\rangle^{2(l+|\alpha|+j-2m-|\beta|)}|\partial_{t,x}^\beta G^{(k)}|^2dxdzdt\bigg)\\
&\quad+\sum_{|\beta|\le|\alpha|+j-1-2m}\int_\Omega <z>^{2(l+|\alpha|+j-1-2m-|\beta|)}|\partial_z\partial_{t,x}^\beta Y_n^{(k)}(t=0)|^2dxdz\\
&\quad+\max_{0\le t\le T}\sum_{m=1}^{j-2}\int_\Omega\langle z\rangle^{2(l+j-2-m)}|\partial_z^m\partial_{t,x}^\alpha G^{(k)}|^2dxdzdt\Bigg\}.
\end{aligned}\tag{3.64}
$$

Remark 3.9. From the problem (3.35), it is easy to estimate the first and third terms on the right-hand side of (3.64) by the source term $G^{(k)}$. For example, one can obtain

(3.65)
$$
\begin{aligned}
&\int_\Omega \langle z\rangle^{2(l+|\alpha|+j-2m-|\beta|)}|\partial_{t,x}^\beta Y_n^{(k)}(t=0)|^2 dxdz\\
&\leq C(T)\left(\sum_{\substack{r+i+p\leq\beta_t-1\\ 0\leq q\leq 2i}}\int_\Omega\langle z\rangle^{2(l+|\alpha|+j-2m-|\beta|+2i-q)}k^{4r}|\partial_z^q\partial_x^{\beta_x+2p}G^{(k)}|_{t=0}|^2dxdz\right.\\
&+\sum_{r+i+p\leq\beta_t-1}\int_\Omega\langle z\rangle^{2(l+|\alpha|+j-2m-|\beta|)}k^{4r}|\partial_t^i\partial_x^{\beta_x+2p}G^{(k)}|_{t=0}|^2dxdz\\
&\left.+\sum_{\substack{i+p\leq\beta_t-2\\ 0\leq q\leq 2i}}\int_\Omega\langle z\rangle^{2(l+|\alpha|-j-2m-|\beta|+2i-q)}|\partial_t\partial_z^q\partial_x^{\beta_x+2p}G^{(k)}|_{t=0}|^2dxdz\right)
\end{aligned}
$$

with $\beta=(\beta_t,\beta_x)$.

In summary, we conclude with the following proposition.

PROPOSITION 3.10. *The approximate solution sequence* $\{Y_n^{(k)}\}_{n\geq1}$ *constructed by* (3.35) *is bounded in* $W^{k,\infty}([0,T],H^s(\Omega))$ *for any fixed* $k,s\in\mathbb{N}$*; moreover,* $\{Y_n^{(k)}\}_{n\geq1}$ *satisfies the estimates given in Lemmas* 3.6*,* 3.7*, and* 3.8.

3.2.7. Step 7: Convergence of { ( )} ≥1. As usual, based on the high order norm boundedness estimate (3.64) of $\{Y_n^{(k)}\}_{n\geq1}$, it suffices to consider the convergence of $\{Y_n^{(k)}\}_{n\geq1}$ in the L^2-norm.

Let $W_n^{(k)}=Y_{n+1}^{(k)}-Y_n^{(k)}$. It follows from (3.35) that $W_n^{(k)}$ solves the following problem:

(3.66)
$$
\begin{cases}
(\partial_t+a_1\partial_x)W_n^{(k)}-a_4^2(\partial_z^2-k^2a^2)W_n^{(k)}+z(a_2\partial_z+ika_3)W_n^{(k)}-\dfrac{1}{n+1}\partial_x^2W_n^{(k)}\\
\quad+ka_5\displaystyle\int_z^{+\infty}e^{ka(z-\xi)}W_{n-1}^{(k)}(\cdot,\xi)d\xi+ka_6\int_0^z e^{ka(\xi-z)}W_{n-1}^{(k)}(\cdot,\xi)d\xi=-\dfrac{1}{n(n+1)}\partial_x^2Y_n^{(k)}\\
W_n^{(k)}|_{z=0}=0,\quad W_n^{(k)}\in S(\mathbb{R}_z^+)\\
W_n^{(k)}|_{t=0}=0.
\end{cases}
$$

In a way similar to (3.42), we deduce that for all $n\geq1$,

$$
\begin{aligned}
&\frac{d}{dt}\int_\Omega\langle z\rangle^{2l}|W_n^{(k)}|^2dxdz+\int_\Omega\langle z\rangle^{2l}(|\partial_zW_n^{(k)}|^2+k^2|W_n^{(k)}|^2)dxdz\\
&\qquad\leq C_0\int_\Omega\langle z\rangle^{2l}(|W_n^{(k)}|^2+|W_{n-1}^{(k)}|^2)dxdz+\frac{C_0}{n(n+1)}
\end{aligned}
\tag{3.67}
$$

by using the boundedness of $\{Y_n^{(k)}\}_{n\geq1}$. Applying Lemma 3.4 in (3.67) we achieve the following proposition.

PROPOSITION 3.11. *For any fixed $T > 0$ and $l \in \mathbb{N}$, it holds that*

$$\max_{0 \le t \le T} \int_\Omega \langle z \rangle^{2l} |Y_{n+1}^{(k)} - Y_n^{(k)}|^2 dxdz \longrightarrow 0 \tag{3.68}$$

when n goes to infinite.

By bringing together Propositions 3.10 with 3.11, we deduce the following theorem.

THEOREM 3.12. *Consider problems* (3.33) *and* (3.34)*. Let $T > 0$ be fixed. Suppose that coefficients a and $\{a_j\}_{j=1}^6$ belong to $H^\infty([0,T] \times \mathbb{R}_x)$ with $a(t,x) \ge a_0$ and $a_4(t,x) \ge a_0$ for a constant $a_0 > 0$, $W_0^{(k)} \in H^\infty([0,T] \times \mathbb{R}_x)$ and $G^{(k)} \in H^\infty([0,T] \times \mathbb{R}_x \times \mathbb{R}_z^+)$ satisfying all compatibility conditions, with $z^l G^{(k)} \in H^\infty([0,T] \times \mathbb{R}_x \times \mathbb{R}_z^+)$ for all $l \in \mathbb{N}$. Then there exist unique solutions $\{Y^{(k)}\}_{k \in Z \setminus \{0\}}$ to problems* (3.33) *and* (3.34) *satisfying $< z >^l Y^{(k)} \in H^\infty([0,T] \times \mathbb{R}_x \times \mathbb{R}_z^+)$ for all $l \in \mathbb{N}$.*

Combining Theorem 3.12 with the transformation (3.32) and Proposition 3.3, we obtain the following existence and uniqueness result of solutions (u, w) to the Poisson–Prandtl coupled problem (3.1).

THEOREM 3.13. *Let $T > 0$ be fixed and all coefficients a and $\{a_j\}_{j=1}^4$ be the same as given in Theorem* 3.12*. Assume that $(b_0, b_1) \in C_p^\infty(T^1, H^\infty([0,T] \times \mathbb{R}_x))$ and $(f, g) \in C_p^\infty(T^1, H^\infty([0,T] \times \mathbb{R}_x \times \mathbb{R}_z^+))$, smooth periodic in $\theta \in T^1$ with valued in $H^\infty([0,T] \times \mathbb{R}_x)$ and $H^\infty([0,T] \times \mathbb{R}_x \times \mathbb{R}_z^+)$, respectively, satisfying*

$$\mathbf{m}_\theta(f) = \mathbf{m}_\theta(g) = \mathbf{m}_\theta(b_0) = \mathbf{m}_\theta(b_1) = 0$$

and $(z^l f, z^l g) \in C_p^\infty(T^1, H^\infty([0,T] \times \mathbb{R}_x \times \mathbb{R}_z^+))$ for any $l \in \mathbb{N}$, and, moreover, all compatibility conditions for (3.1) *hold. Then, there exist unique solutions $(u, w) \in C_p^\infty(T^1, H^\infty([0,T] \times \mathbb{R}_x \times \mathbb{R}_z^+))$ to the problem* (3.1) *satisfying $\mathbf{m}_\theta(u) = \mathbf{m}_\theta(w) = 0$ and $(z^l u, z^l w) \in C_p^\infty(T^1, H^\infty([0,T] \times \mathbb{R}_x \times \mathbb{R}_z^+))$ for all $l \in \mathbb{N}$.*

4. Rigorous justification of the zero-viscosity limit. In this section, we shall rigorously justify the formal analysis given in section 2.

First, let us suppose that

(H1) all compatibility conditions for the problem (2.1) are satisfied,

(H2) all compatibility conditions for problems (2.29), (2.35), and (5.11), (5.13), and (5.22) given later are satisfied,

which will be studied in detail at the end of this section. It is easy to see that compatibility conditions for the problem (2.26) follow from those for (2.1) by setting $\epsilon = 0$.

Let V^ϵ be the solution to the problem (2.1). From section 3, we know that one can uniquely determine $(d_0^{(2)}, d_0^{(3)})$ and $\{(d_{j+1}^{(2)}, d_{j+1}^{(3)})\}_{j \ge 0}$ from problems (2.35) and (2.36) and (5.22) and (5.23), respectively. Thus, from sections 2 and 5.1 we obtain each order smooth profile $\{(a_j, c_j, b_j, d_j)\}_{j \ge 0}$ in the formal expansion of the solution

$$V^\epsilon(t,x) \sim \sum_{j \ge 0} \epsilon^j (a_j(t,x) + c_j\left(t, x; \frac{\varphi(t,x)}{\epsilon}\right) + b_j\left(t, x_2; \frac{x_1}{\epsilon}\right) + d_j\left(t, x_2; \frac{x_1}{\epsilon}, \frac{\varphi^0(t,x_2)}{\epsilon}\right). \tag{4.1}$$

Denote by

$$V_J^\epsilon(t,x) = \sum_{j=0}^J \epsilon^j \left(a_j(t,x) + c_j\left(t, x; \frac{\varphi(t,x)}{\epsilon}\right) + b_j\left(t, x_2; \frac{x_1}{\epsilon}\right) + d_j\left(t, x_2; \frac{x_1}{\epsilon}, \frac{\varphi^0(t,x_2)}{\epsilon}\right)\right)$$

the Jth order approximate solution for any fixed $J \in \mathbb{N}$.

From the discussion in sections 2 and 5.1, it is easy to see that $W_J^\epsilon = V^\epsilon - V_J^\epsilon$ satisfies the following problem:

$$
\begin{cases}
A_0(V')\partial_t W_J^\epsilon + A_1(V')\partial_{x_1} W_J^\epsilon + A_2(V')\partial_{x_2} W_J^\epsilon = B(\epsilon^2, D\epsilon^2) W_J^\epsilon + R_J^\epsilon, \\
M^+ W_J^\epsilon = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} W_J^\epsilon = 0, \qquad \text{on} \quad x_1 = 0, \\
W_J^\epsilon|_{t=0} = 0,
\end{cases} \tag{4.2}
$$

where the remainder $R_J^\epsilon(t,x)$ satisfies

$$
\|R_J^\epsilon\|_{L^\infty([0,T],L^2(\mathbb{R}_+^2))} \le C\epsilon^{J-1} \tag{4.3}
$$

for any $T > 0$ and a constant $C > 0$.

By using the classical theory of the linearized Navier–Stokes equations in the problem (4.2), we immediately conclude

$$
\|V^\epsilon - V_J^\epsilon\|_{L^\infty([0,T],L^2(\mathbb{R}_+^2))} \le C_1\epsilon^{J-1} \tag{4.4}
$$

which implies

$$
\|V^\epsilon - V_J^\epsilon\|_{L^\infty([0,T],L^2(\mathbb{R}_+^2))} \le C_2\epsilon^{J+1} \tag{4.5}
$$

for any $J \in \mathbb{N}$ with the constant C_2 depending only upon T and J.

Therefore, we obtain the following theorem.

THEOREM 4.1. *Under the assumptions* (H1) *and* (H2), *the solution* $V^\epsilon = (\rho^\epsilon, v_1^\epsilon, v_2^\epsilon)$ *of* (2.1) *has the following asymptotics:*

$$
\begin{aligned}
V^\epsilon(t,x) = \sum_{j=0}^{J} \epsilon^j \Bigg(& a_j(t,x) + c_j\left(t, x; \frac{\varphi(t,x)}{\epsilon}\right) + b_j\left(t, x_2; \frac{x_1}{\epsilon}\right) \\
& + d_j\left(t, x_2; \frac{x_1}{\epsilon}, \frac{\varphi^0(t,x_2)}{\epsilon}\right)\Bigg) + O(\epsilon^{J+1})
\end{aligned} \tag{4.6}
$$

in $L^\infty([0,T], L^2(\mathbb{R}_+^2))$ *for any fixed* $J \in \mathbb{N}$, *where* $a_j(t,x)$ *satisfy problems* (2.26) *and* (5.11) *for the linearized Euler equations;* $c_j(t,x;\frac{\varphi(t,x)}{\epsilon})$ *are determined from* (2.17) *and* (2.20), *and* (5.3)–(5.5); $(b_j^{(1)}, b_j^{(2)})$ *are given in* (2.25) *and* (5.10); *and* $b_j^{(3)}(t,x_2;z)$ *satisfy problems* (2.29) *and* (5.13) *for the linearized Prandtl equation;* $d_j^{(1)}$ *are given in* (2.31) *and* (5.17); *and* $(d_j^{(2)}, d_j^{(3)})(t,x_2;z,\theta)$ *together with their vorticity with respect to* $(z,\theta)-$*variables satisfy problems* (2.35) *and* (2.36), *and* (5.22) and (5.23) *for the Poisson–Prandtl coupled system.*

Remark 4.2. (1) From (4.6), one immediately concludes Theorem 2.1.

(2) The asymptotic relation (4.6) holds in high order Sobolev spaces with weighted norms due to the high frequency of oscillations in $\{c_j, d_j\}_{j\ge 0}$ and the multiple scales in boundary layers $\{b_j, d_j\}_{j\ge 0}$, e.g., in $L^\infty([0,T], H_\epsilon^s(\mathbb{R}^2))$ with the norm of $H_\epsilon^s(\mathbb{R}^2)$ being defined as

$$
\|u\|_{s,\epsilon} = \left(\sum_{|\alpha|\le s} \epsilon^{2|\alpha|} \|\partial_x^\alpha u\|_{L^2(I\!R_+^2)}^2 \right)^{\frac{1}{2}}.
$$

Finally, for completeness, let us investigate the assumptions (H1) and (H2).

(I) The compatibility condition for the problem of linearized Navier–Stokes equations (2.1) can be formulated in the classical way as follows.

(I1) The zero-th order compatibility condition is

$$V_0^{(2)} = V_0^{(3)} = 0 \qquad \text{on} \quad \{x_1 = 0\}. \tag{4.7}$$

(I2) The jth order compatibility condition ($j \geq 1$).

Set $\Phi^\epsilon(t,x) = \Phi(t,x; \frac{\varphi(t,x)}{\epsilon})$. For any fixed $j \in \mathbb{N}$ with $j \geq 1$, it follows from the equations in (2.1) that

$$\begin{aligned}\partial_t^j V^\epsilon = (A_0(V'))^{-1}\{&B(\epsilon^2, D\epsilon^2)\partial_t^{j-1}V^\epsilon + \partial_t^{j-1}\Phi^\epsilon \\ &-[\partial_t^{j-1}, A_0(V')]\partial_t V^\epsilon - \partial_t^{j-1}(A_1(V')\partial_{x_1}V^\epsilon + A_2(V')\partial_{x_2}V^\epsilon)\}\end{aligned}$$

by induction on j. By using the initial data $V^\epsilon|_{t=0} = V_0(x)$, we know that $V_j^\epsilon(x) = \partial_t^j V^\epsilon|_{t=0}$ is a linear function of $\{\partial_x^\alpha V_0\}_{|\alpha|\leq 2j}$ and $\{\partial_t^k \partial_x^\alpha \Phi^\epsilon(t=0)\}_{k\leq j-1, |\alpha|\leq 2(j-1-k)}$. Then, the jth order compatibility condition for the problem (2.1) is

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} V_j^\epsilon = 0 \qquad \text{on} \quad \{x_1 = 0\}. \tag{4.8}$$

Next, we study the assumption (H1).

($\mathbb{I}$) The compatibility condition for the problem of linearized Prandtl equation (2.29).

($\mathbb{I}$1) The zero-th order compatibility condition is

$$a_0^{(3)} = 0 \qquad \text{on} \quad \{t = x_1 = 0\}, \tag{4.9}$$

which is a simple consequence of the zero-th order compatibility condition (4.7) by noting $a_0|_{t=0} = V_0(x)$ in (2.26).

($\mathbb{I}$2) The jth order compatibility condition ($j \geq 1$).

It follows from the equation and the initial data in (2.29) that

$$\partial_t^j b_0^{(3)}|_{t=0} = 0.$$

So, the jth order compatibility condition for the problem (2.29) is

$$\partial_t^j a_0^{(3)} = 0 \qquad \text{on} \quad \{t = x_1 = 0\}, \tag{4.10}$$

where $a_0^{(3)}(t,x)$ is determined by the problem (2.26).

The compatibility conditions for the problem (5.13) can be obtained in the same ways as those for the problem (2.29) given above.

Both of problems (2.35) and (5.22) are the special cases of the problem (3.1), so their compatibility conditions can be stated in the same way as those for the problem (3.1) given in section 3.

Finally, we note that in general compatibility conditions for problems of profiles, $\{a_j, c_j, b_j, d_j\}_{j\geq 0}$ could not be implied by those for the original linearized Navier–Stokes equations (2.1). The simplest case to guarantee all compatibility conditions given as above valid is that

$$\begin{cases} \partial_t^k \partial_x^\alpha \Phi(t,x;\theta) = 0, & \text{on } \{t = x_1 = 0\} \\ \partial_x^\alpha V_0(x) = 0, & \text{on } \{x_1 = 0\} \end{cases}$$

hold for any $k \in \mathbb{N}$ and $\alpha \in \mathbb{N}^2$.

5. Appendix.

5.1. Problems of high order profiles. In section 2, we derived problems for the leading profiles in the expansion of the solution $V^\epsilon(t,x) = V^\epsilon_{in}(t,x) + V^\epsilon_{bd}(t,x)$ to the problem (2.1). In this subsection, let us briefly derive problems for high order terms in the expansion.

By induction, suppose that $\{a_k(t,x), c_k(t,x;\theta), b_k(t,x_2;z), d_k(t,x_2;z,\theta^0)\}_{k\le j}$ are known already, we want to determine profiles $\{a_{j+1}(t,x), c_{j+1}(t,x;\theta), b_{j+1}(t,x_2;z), d_{j+1}(t,x_2;z,\theta^0)\}$ in the expansion (2.11).

It follows from (2.13) and the fact $\mathbf{m}_\theta(\mathcal{F}_j)=0$ that

$$L(\partial_t,\partial_x)a_j = (B_1\partial^2_{x_1} + B_2\partial^2_{x_2} + B_3\partial^2_{x_1x_2})a_{j-2} \tag{5.1}$$

and the difference between $\mathcal{F}_j = 0$ and (5.1) gives rise to

$$\sum_{k=0}^{2} \varphi_{x_k} A_k(V')\partial_\theta c_{j+1} = \tilde f_j, \tag{5.2}$$

where

$$\begin{aligned}\tilde f_j = {} & (\varphi^2_{x_1}B_1 + \varphi^2_{x_2}B_2 + \varphi_{x_1}\varphi_{x_2}B_3)\partial^2_\theta c_j - L(\partial_t,\partial_x)c_j \\ & + (\varphi_{x_1x_1}B_1 + \varphi_{x_2x_2}B_2 + \varphi_{x_1x_2}B_3)\partial_\theta c_{j-1} \\ & + (2\varphi_{x_1}B_1 + \varphi_{x_2}B_3)\partial^2_{\theta x_1}c_{j-1} + (2\varphi_{x_2}B_2 + \varphi_{x_1}B_3)\partial^2_{\theta x_2}c_{j-1} \\ & + (B_1\partial^2_{x_1} + B_2\partial^2_{x_2} + B_3\partial^2_{x_1x_2})c_{j-2}\end{aligned}$$

satisfies $\mathbf{m}_\theta(\tilde f_j) = 0$.

If we set

$$c_{j+1}(t,x;\theta) = \sum_{k=1}^{3} v^{(k)}_{j+1}(t,x;\theta)\vec r_k(\nabla\varphi), \tag{5.3}$$

then from (5.2) it follows

$$(\varphi_t - \tau_k(\nabla\varphi))\partial_\theta v^{(k)}_{j+1} = (\vec l_k(\nabla\varphi)\cdot \tilde f_j)(t,x;\theta), \quad k=2,3, \tag{5.4}$$

where $\tau_k(\nabla\varphi)$ are defined in (2.3). Due to the assumption (2.6), we obtain that $(v^{(2)}_{j+1}, v^{(3)}_{j+1})$ can be uniquely determined by (5.4) with $\mathbf{m}_\theta(v^{(2)}_{j+1}, v^{(3)}_{j+1}) = 0$.

To solve $v^{(1)}_{j+1}$, acting $\vec l_1(\nabla\varphi)$ from the left on the same equation as (5.2) with j being replaced by $j+1$, and using (5.3), one gets that $v^{(1)}_{j+1}$ satisfies the following problem:

$$\begin{cases} [(\vec l_1 A_0\vec r_1)\partial_t + (\vec l_1 A_1 \vec r_1)\partial_{x_1} + (\vec l_1 A_2\vec r_1)\partial_{x_2}]v^{(1)}_{j+1} + \vec l_1(A_0\partial_t\vec r_1 + A_1\partial_{x_1}\vec r_1 + A_2\partial_{x_2}\vec r_1)v^{(1)}_{j+1} \\ \quad -\vec l_1(\varphi^2_{x_1}B_1 + \varphi^2_{x_2}B_2 + \varphi_{x_1}\varphi_{x_2}B_3)\vec r_1\partial^2_\theta v^{(1)}_{j+1} = h_{j+1} \\ v^{(1)}_{j+1}|_{t=0} = 0, \end{cases} \tag{5.5}$$

which is similar to the problem (2.20), where

$$\begin{aligned} h_{j+1} = \vec l_1[& (\varphi_{x_1x_1}B_1 + \varphi_{x_2x_2}B_2 + \varphi_{x_1x_2}B_3)\partial_\theta c_j + (2\varphi_{x_1}B_1 + \varphi_{x_2}B_3)\partial^2_{\theta x_1}c_j \\ & + (2\varphi_{x_2}B_2 + \varphi_{x_1}B_3)\partial^2_{\theta x_2}c_j + (B_1\partial^2_{x_1} + B_2\partial^2_{x_2} + B_3\partial^2_{x_1x_2})c_{j-1} \\ & - (L(\partial_t,\partial_x) - (\varphi^2_{x_1}B_1 + \varphi^2_{x_2}B_2 + \varphi_{x_1}\varphi_{x_2}B_3)\partial^2_\theta)(v^{(2)}_{j+1}\vec r_2 + v^{(3)}_{j+1}\vec r_3)]. \end{aligned}$$

As in (2.21) and (2.22), the $0(\epsilon^{j+1})-$term of the boundary condition $M^+V^\epsilon|_{x_1=0} = 0$ in (2.1) gives

$$\begin{cases} a_{j+1}^{(k)}(t,x) + b_{j+1}^{(k)}(t,x_2;z) = 0 & \text{on } \{x_1 = z = 0\} \\ c_{j+1}^{(k)}(t,x;\theta) + d_{j+1}^{(k)}(t,x_2;z,\theta^0) = 0 & \text{on } \{x_1 = z = 0, \theta = \theta^0\} \end{cases} \tag{5.6}$$

for $k \in \{2,3\}$.

Thus, to solve a_{j+1} from the same equation as (5.1) with j being replaced by $j+1$, one should study $b_{j+1}^{(2)}$ first in order to determine the boundary value of $a_{j+1}^{(2)}$ on $\{x_1 = 0\}$.

Acting upon the averaging operator $\mathbf{m}_\theta$ on $\mathcal{G}_j = 0$ from (2.15), and using the assumption $\mathbf{m}_\theta(d_k) = 0$ for any $k \geq 0$, we get

$$A_1(0)\partial_z b_{j+1} = \tilde{g}_j(t,x_2;z), \tag{5.7}$$

and the difference between $\mathcal{G}_j = 0$ and (5.7) gives rise to

$$(\varphi_t^0 A_0(0) + \varphi_{x_2}^0 A_2(0))\partial_\theta d_{j+1} + A_1(0)\partial_z d_{j+1} = g_j^\star(t,x_2;z,\theta), \tag{5.8}$$

where

$$\begin{cases} \tilde{g}_j(t,x_2;z) = B_1\partial_z^2 b_j - (A_0(0)\partial_t + A_2(0)\partial_{x_2})b_j - zA_1'(0)\partial_z b_j - \mathbf{m}_\theta(g_j), \\ g_j^\star(t,x_2;z,\theta) = (B_1\partial_z^2 + (\varphi_{x_2}^0)^2 B_2\partial_\theta^2 + \varphi_{x_2}^0 B_3\partial_{z\theta}^2)d_j - (A_0(0)\partial_t + A_2(0)\partial_{x_2})d_j \\ \qquad -z(\varphi_t^0 A_0'(0) + \varphi_{x_2}^0 A_2'(0))\partial_\theta d_j - zA_1'(0)\partial_z d_j - g_j + \mathbf{m}_\theta(g_j). \end{cases}$$

From (5.7), we deduce immediately that $(b_{j+1}^{(1)}, b_{j+1}^{(2)})$ solves the following problem:

$$\begin{cases} \begin{pmatrix} 0 & \rho'(0) \\ c^2(0) & 0 \end{pmatrix} \begin{pmatrix} \partial_z b_{j+1}^{(1)} \\ \partial_z b_{j+1}^{(2)} \end{pmatrix} = \begin{pmatrix} \tilde{g}_j^{(1)} \\ \tilde{g}_j^{(2)} \end{pmatrix} \\ (b_{j+1}^{(1)}, b_{j+1}^{(2)}) \in S(\mathbb{R}_z^+), \end{cases} \tag{5.9}$$

which implies

$$\begin{cases} b_{j+1}^{(1)}(t,x_2;z) = -c^{-2}(0)\int_z^{+\infty} \tilde{g}_j^{(2)}(t,x_2;\xi)d\xi \\ b_{j+1}^{(2)}(t,x_2;z) = -(\rho'(0))^{-1}\int_z^{+\infty} \tilde{g}_j^{(1)}(t,x_2;\xi)d\xi. \end{cases} \tag{5.10}$$

Therefore, from the same equation as (5.1) with j being replaced by $j+1$, we know that $a_{j+1}(t,x)$ solves the following problem:

$$\begin{cases} L(\partial_t,\partial_x)a_{j+1} = (B_1\partial_{x_1}^2 + B_2\partial_{x_2}^2 + B_3\partial_{x_1x_2}^2)a_{j-1}, \\ a_{j+1}^{(2)}|_{x_1=0} = (\rho'(0))^{-1}\int_0^{+\infty} \tilde{g}_j^{(1)}(t,x_2;\xi)d\xi, \\ a_{j+1}|_{t=0} = 0. \end{cases} \tag{5.11}$$

To determine $b_{j+1}^{(3)}(t,x_2;z)$, we act upon the averaging operator $\mathbf{m}_\theta$ on $\mathcal{G}_{j+1} = 0$ with $\mathcal{G}_{j+1}$ being given as in (2.15), and obtain

$$L_{bd}(\partial_t,\partial_{x_2})b_{j+1} + zA_1'(0)\partial_z b_{j+1} - B_1\partial_z^2 b_{j+1} + A_1(0)\partial_z b_{j+2} + \mathbf{m}_\theta(g_{j+1}) = 0. \tag{5.12}$$

The third component of (5.12) shows that $b_{j+1}^{(3)}$ solves the following initial-boundary value problem for the linearized Prandtl equation:

(5.13)
$$\begin{cases} (\partial_t + v_2'(0)\partial_{x_2})b_{j+1}^{(3)} + z\dfrac{\partial v_1'(0)}{\partial x_1}\partial_z b_{j+1}^{(3)} - \dfrac{1}{\rho'(0)}\partial_z^2 b_{j+1}^{(3)} = -\dfrac{c^2(0)}{\rho'(0)}\partial_{x_2} b_{j+1}^{(1)} - \mathbf{m}_\theta(g_{j+1}^{(3)}) \\ b_{j+1}^{(3)}|_{z=0} = -a_{j+1}^{(3)}(t,0,x_2), \quad b_{j+1}^{(3)} \in S(\mathbb{R}_z^+) \\ b_{j+1}^{(3)}|_{t=0} = 0, \end{cases}$$

where $a_{j+1}^{(3)}$ is the third component of a_{j+1} given in (5.11), and $b_{j+1}^{(1)}$ is given already in (5.10).

However, it remains to be determined that $d_{j+1}(t,x_2;z,\theta)$. From (5.8), we get

$$\begin{cases} \varphi_{x_2}^0 \partial_\theta d_{j+1}^{(1)} = \dfrac{1}{c^2(0)} g_j^{\star(3)}, \quad \partial_z d_{j+1}^{(1)} = \dfrac{1}{c^2(0)} g_j^{\star(2)} \\ d_{j+1}^{(1)} \in S(\mathbb{R}_z^+) \end{cases} \tag{5.14}$$

and

$$\partial_z d_{j+1}^{(2)} + \varphi_{x_2}^0 \partial_\theta d_{j+1}^{(3)} = \frac{1}{\rho'(0)} g_j^{\star(1)}. \tag{5.15}$$

By using the fact (2.32) in (5.8), we know

$$\mathbb{E}(g_j^\star) = 0,$$

which implies especially

$$\partial_z g_j^{\star(3)} - \varphi_{x_2}^0 \partial_\theta g_j^{\star(2)} = 0. \tag{5.16}$$

Obviously, (5.16) is the compatibility condition for solving $d_{j+1}^{(1)}$ from (5.14), and

$$d_{j+1}^{(1)} = -c^{-2}(0)\int_z^{+\infty} g_j^{\star(2)}(t,x_2;\xi,\theta)d\xi. \tag{5.17}$$

Acting upon the operator $\mathbb{E}$ on the same equations as in (5.8) with j being replaced by $j+1$, it follows that

$$\mathbb{E}(L_{bd}(\partial_t,\partial_{x_2})d_{j+1} + z(\varphi_t^0 A_0'(0) + \varphi_{x_2}^0 A_2'(0))\partial_\theta d_{j+1} + zA_1'(0)\partial_z d_{j+1}$$

$$-(B_1\partial_z^2 + (\varphi_{x_2}^0)^2 B_2 \partial_\theta^2 + \varphi_{x_2}^0 B_3 \partial_{z\theta}^2)d_{j+1} + g_{j+1} - \mathbf{m}_\theta(g_{j+1})) = 0. \tag{5.18}$$

Denote by $\tilde{A}$ and $\tilde{B}$ the second and third components of the above term on which $\mathbb{E}$

acts. Due to (5.15), they can be expressed as

$$\begin{cases} \tilde{A} = \rho'(0)\left((\partial_t + v_2'(0)\partial_{x_2})d_{j+1}^{(2)} + z\left(\dfrac{\partial v_1'(0)}{\partial x_1}\partial_z + \varphi_{x_2}^0\dfrac{\partial v_2'(0)}{\partial x_1}\partial_\theta\right)d_{j+1}^{(2)}\right) \\ \qquad - (\partial_z^2 + (\varphi_{x_2}^0)^2\partial_\theta^2)d_{j+1}^{(2)} + z\dfrac{\partial c^2(0)}{\partial x_1}\partial_z d_{j+1}^{(1)} + g_{j+1}^{(2)} - \mathbf{m}_\theta(g_{j+1}^{(2)}) - \dfrac{D}{\rho'(0)}\partial_z g_j^{\star(1)} \\ \tilde{B} = \rho'(0)\left((\partial_t + v_2'(0)\partial_{x_2})d_{j+1}^{(3)} + z\left(\dfrac{\partial v_1'(0)}{\partial x_1}\partial_z + \varphi_{x_2}^0\dfrac{\partial v_2'(0)}{\partial x_1}\partial_\theta\right)d_{j+1}^{(3)}\right) \\ \qquad - (\partial_z^2 + (\varphi_{x_2}^0)^2\partial_\theta^2)d_{j+1}^{(3)} + c^2(0)\partial_{x_2}d_{j+1}^{(1)} + z\dfrac{\partial c^2(0)}{\partial x_1}\varphi_{x_2}^0\partial_\theta d_{j+1}^{(1)} + g_{j+1}^{(3)} \\ \qquad - \mathbf{m}_\theta(g_{j+1}^{(3)}) - \frac{D\varphi_{x_2}^0}{\rho'(0)}\partial_\theta g_j^{\star(1)}. \end{cases}$$

We deduce from (5.18) that

$$\omega_{j+1}(t,x_2;z,\theta) = \varphi_{x_2}^0\partial_\theta d_{j+1}^{(2)} - \partial_z d_{j+1}^{(3)} \tag{5.19}$$

satisfies

(5.20)

$$(\partial_t + v_2'(0)\partial_{x_2})\omega_{j+1} + z\left(\frac{\partial v_1'(0)}{\partial x_1}\partial_z + \varphi_{x_2}^0\frac{\partial v_2'(0)}{\partial x_1}\partial_\theta\right)\omega_{j+1} - \frac{1}{\rho'(0)}(\partial_z^2 + (\varphi_{x_2}^0)^2\partial_\theta^2)\omega_{j+1}$$
$$- \left(\frac{\partial v_1'(0)}{\partial x_1}\partial_z + \varphi_{x_2}^0\frac{\partial v_2'(0)}{\partial x_1}\partial_\theta\right)d_{j+1}^{(3)} = R_{j+1},$$

where

(5.21)

$$R_{j+1} = \frac{1}{\rho'(0)}\left[\partial_z g_{j+1}^{(3)} - \mathbf{m}_\theta(\partial_z g_{j+1}^{(3)}) - \varphi_{x_2}^0\partial_\theta g_{j+1}^{(2)} + c^2(0)\partial_{zx_2}^2 d_{j+1}^{(1)} + \frac{\partial c^2(0)}{\partial x_1}\varphi_{x_2}^0\partial_\theta d_{j+1}^{(1)}\right]$$

with $d_{j+1}^{(1)}$ being given in (5.17).

Combining (5.15), (5.19), (5.20), and (5.6) leads to $(d_{j+1}^{(2)}, d_{j+1}^{(3)}, \omega_{j+1})$ satisfying the following problems:

(5.22)

$$\begin{cases} (\partial_z^2 + (\varphi_{x_2}^0)^2\partial_\theta^2)d_{j+1}^{(3)} = \dfrac{\varphi_{x_2}^0}{\rho'(0)}\partial_\theta g_j^{\star(1)} - \partial_z\omega_{j+1} \\ (\partial_t + v_2'(0)\partial_{x_2})\omega_{j+1} + z\left(\dfrac{\partial v_1'(0)}{\partial x_1}\partial_z + \varphi_{x_2}^0\dfrac{\partial v_2'(0)}{\partial x_1}\partial_\theta\right)\omega_{j+1} - \dfrac{1}{\rho'(0)}(\partial_z^2 + (\varphi_{x_2}^0)^2\partial_\theta^2)\omega_{j+1} \\ \quad -\left(\dfrac{\partial v_1'(0)}{\partial x_1}\partial_z + \varphi_{x_2}^0\dfrac{\partial v_2'(0)}{\partial x_1}\partial_\theta\right)d_{j+1}^{(3)} = R_{j+1} \\ d_{j+1}^{(3)}|_{z=0} = -c_{j+1}^{(3)}(t,0,x_2;\theta) \\ (\omega_{j+1} + \partial_z d_{j+1}^{(3)})|_{z=0} = -\varphi_{x_2}^0(\partial_\theta c_{j+1}^{(2)})(t,0,x_2;\theta) \\ (d_{j+1}^{(3)}, \omega_{j+1}) \in S(\mathbb{R}_z^+) \\ \omega_{j+1}|_{t=0} = 0 \end{cases}$$

and

$$\begin{cases} (\partial_z^2 + (\varphi^0_{x_2})^2\partial_\theta^2)d^{(2)}_{j+1} = \varphi^0_{x_2}\partial_\theta\omega_{j+1} + \dfrac{1}{\rho'(0)}\partial_z g_j^{\star(1)}, \\ d^{(2)}_{j+1}|_{z=0} = -c^{(2)}_{j+1}(t,0,x_2;\theta), \\ d^{(2)}_{j+1} \in S(\mathbb{R}^+_z), \end{cases} \tag{5.23}$$

which are similar to problems (2.35) and (2.36).

Remark 5.1. When $\varphi|_{x_1=0} = \varphi^0(t,x_2) \equiv 0$, the terms d_j disappear, similar to Gues [4], the boundary conditions (2.21) and (5.6) become

$$(a_j^{(k)}(t,x) + c_j^{(k)}(t,x;\theta) + b_j^{(k)}(t,x_2;z))|_{x_1=z=\theta=0} = 0$$

for any $j \geq 0, k = 2,3$. In this case, we obtain that $a_0(t,x)$ and $c_0(t,x;\theta)$ satisfy the same problems as (2.26) and (2.17), but for $j \geq 0$, $b_j(t,x_2;z)$ satisfies problems (2.29) and (5.13) with different boundary conditions.

5.2. The case of shorter wavelength. In this subsection, we are going to study the problem (2.1) when the wavelength of the oscillatory force term is shorter than the square root of the viscosity, i.e., $\Phi = \Phi(t,x;\frac{\varphi(t,x)}{\epsilon^\alpha})$ with $\alpha > 1$. It is observed in this case that the leading profiles of the solution V^ϵ are the same as the case without oscillations [12], and the oscillation shall appear only at the high order profiles. To explain the idea, we shall investigate the case that $\alpha = 2$.

Take the following ansatz for the solution of (2.1) with $\Phi = \Phi(t,x;\frac{\varphi(t,x)}{\epsilon^2})$ and $\varphi(t,x)$ being the same as in (2.6):

$$V^\epsilon(t,x) = V^\epsilon_{in}(t,x) + V^\epsilon_{bd}(t,x), \tag{5.24}$$

where the outflow V^ϵ_{in} admits the expansion

$$V^\epsilon_{in}(t,x) = \sum_{j\geq 0}\epsilon^j\left(a_j(t,x) + c_j\left(t,x;\frac{\varphi(t,x)}{\epsilon^2}\right)\right) \tag{5.25}$$

and the flow near the boundary $V^\epsilon_{bd}(t,x)$ will be developed later, where $c_j(t,x;\theta)$ are 2π-periodic in θ with mean value vanishing.

Plugging the expansion (5.25) into

$$L(\partial_t,\partial_x)V^\epsilon_{in} - B(\epsilon^2, D\epsilon^2)V^\epsilon_{in} - \Phi\left(t,x;\frac{\varphi(t,x)}{\epsilon^2}\right) = 0, \tag{5.26}$$

it follows that the vanishing of the $O(\epsilon^{-2})$, $O(\epsilon^{-1})$, and $O(\epsilon^0)-$terms on the left side of (5.26) give rise to

$$\sum_{k=0}^{2}\varphi_{x_k}A_k(V')\partial_\theta c_0 = (\varphi^2_{x_1}B_1 + \varphi^2_{x_2}B_2 + \varphi_{x_1}\varphi_{x_2}B_3)\partial_\theta^2 c_0, \tag{5.27}$$

$$\sum_{k=0}^{2}\varphi_{x_k}A_k(V')\partial_\theta c_1 = (\varphi^2_{x_1}B_1 + \varphi^2_{x_2}B_2 + \varphi_{x_1}\varphi_{x_2}B_3)\partial_\theta^2 c_1, \tag{5.28}$$

and

$$\begin{aligned} L(\partial_t,\partial_x)(a_0+c_0) + \sum_{k=0}^{2}\varphi_{x_k}A_k(V')\partial_\theta c_2 - (\varphi^2_{x_1}B_1 + \varphi^2_{x_2}B_2 + \varphi_{x_1}\varphi_{x_2}B_3)\partial_\theta^2 c_2 \\ - \Phi(t,x,\theta) = 0, \end{aligned} \tag{5.29}$$

respectively.

Using the assumption (2.6) in (5.27), it follows that

$$\begin{cases} \varphi_{x_1}\partial_\theta c_0^{(2)} + \varphi_{x_2}\partial_\theta c_0^{(3)} = 0, \\ c^2\varphi_{x_1}\partial_\theta c_0^{(1)} = ((1+D)\varphi_{x_1}^2 + \varphi_{x_2}^2)\partial_\theta^2 c_0^{(2)} + D\varphi_{x_1}\varphi_{x_2}\partial_\theta^2 c_0^{(3)}, \\ c^2\varphi_{x_2}\partial_\theta c_0^{(1)} = (\varphi_{x_1}^2 + (1+D)\varphi_{x_2}^2)\partial_\theta^2 c_0^{(3)} + D\varphi_{x_1}\varphi_{x_2}\partial_\theta^2 c_0^{(2)}, \end{cases} \tag{5.30}$$

which implies

$$\varphi_{x_2}\partial_\theta^2 c_0^{(2)} - \varphi_{x_1}\partial_\theta^2 c_0^{(3)} = 0. \tag{5.31}$$

Combining (5.31) and the first equation in (5.30) leads to

$$c_0^{(2)} = c_0^{(3)} \equiv 0 \tag{5.32}$$

by using $\mathbf{m}_\theta(c_0) = 0$.

By substituting (5.32) into the last two equations in (5.30), it follows that

$$c_0^{(1)} \equiv 0. \tag{5.33}$$

Similarly, from (5.28) it follows that

$$c_1(t, x, \theta) \equiv 0. \tag{5.34}$$

From (5.29) we obtain

$$L(\partial_t, \partial_x)a_0 = \mathbf{m}_\theta(\Phi) \tag{5.35}$$

and

$$\sum_{k=0}^{2} \varphi_{x_k} A_k(V')\partial_\theta c_2 - (\varphi_{x_1}^2 B_1 + \varphi_{x_2}^2 B_2 + \varphi_{x_1}\varphi_{x_2} B_3)\partial_\theta^2 c_2 = \Phi - \mathbf{m}_\theta(\Phi). \tag{5.36}$$

which implies that $c_2 = (c_2^{(1)}, c_2^{(2)}, c_2^{(3)})^T$ satisfies

$$\begin{cases} \rho'(\varphi_{x_1}\partial_\theta c_2^{(2)} + \varphi_{x_2}\partial_\theta c_2^{(3)}) = \Phi^{(1)} - \mathbf{m}_\theta(\Phi^{(1)}), \\ c^2\varphi_{x_1}\partial_\theta c_2^{(1)} = ((1+D)\varphi_{x_1}^2 + \varphi_{x_2}^2)\partial_\theta^2 c_2^{(2)} + D\varphi_{x_1}\varphi_{x_2}\partial_\theta^2 c_2^{(3)} + \Phi^{(2)} - \mathbf{m}_\theta(\Phi^{(2)}), \\ c^2\varphi_{x_2}\partial_\theta c_2^{(1)} = (\varphi_{x_1}^2 + (1+D)\varphi_{x_2}^2)\partial_\theta^2 c_2^{(3)} + D\varphi_{x_1}\varphi_{x_2}\partial_\theta^2 c_2^{(2)} + \Phi^{(3)} - \mathbf{m}_\theta(\Phi^{(3)}). \end{cases} \tag{5.37}$$

From (5.37), it follows that

$$\begin{cases} \rho'(\varphi_{x_1}\partial_\theta^2 c_2^{(2)} + \varphi_{x_2}\partial_\theta^2 c_2^{(3)}) = \partial_\theta\Phi^{(1)}, \\ (\varphi_{x_1}^2 + \varphi_{x_2}^2)(\varphi_{x_2}\partial_\theta^2 c_2^{(2)} - \varphi_{x_1}\partial_\theta^2 c_2^{(3)}) = \varphi_{x_1}(\Phi^{(3)} - \mathbf{m}_\theta(\Phi^{(3)})), -\varphi_{x_2}(\Phi^{(2)} - \mathbf{m}_\theta(\Phi^{(2)})) \end{cases} \tag{5.38}$$

from which $c_2^{(2)}(t, x; \theta)$ and $c_2^{(3)}(t, x; \theta)$ are determined uniquely. Consequently, $c_2^{(1)}$ can be uniquely determined from the last two equations in (5.36) as well.

To determine $a_0(t,x)$ from the linearized Euler equations (5.35), one needs to have the boundary data on $\{x_1=0\}$, which shall be deduced from the boundary layer profiles given later. Suppose that this is known already, then we have determined the leading profiles of the flow away from the boundary $\{x_1=0\}$. In this way, one can obtain profiles of $V_{in}^\epsilon(t,x)$ up to any fixed order, which satisfy problems similar to those of a_0 and $c_2(t,x,\theta)$. Therefore, the outflow V_{in}^ϵ has the formal expansion

$$V_{in}^\epsilon(t,x)=\sum_{j\geq 0}\epsilon^j a_j(t,x)+\sum_{j\geq 2}\epsilon^j c_j\left(t,x;\frac{\varphi(t,x)}{\epsilon^2}\right). \tag{5.39}$$

The formula (5.39) inspires us to take the following ansatz for the boundary layer part V_{bd}^ϵ to (2.1):

$$V_{bd}^\epsilon(t,x)=\sum_{j\geq 0}\epsilon^j b_j\left(t,x_2;\frac{x_1}{\epsilon}\right)+\sum_{j\geq 2}\epsilon^j d_j\left(t,x_2;\frac{x_1}{\epsilon^2},\frac{\varphi^0(t,x_2)}{\epsilon^2}\right), \tag{5.40}$$

where $d_j(t,x_2;\eta,\theta)$ are $2\pi-$periodic in θ with mean value vanishing, and $b_j(t,x_2;z)$ and $d_j(t,x_2;\eta,\theta)$ are rapidly decreasing in $z=\frac{x_1}{\epsilon}$ and $\eta=\frac{x_1}{\epsilon^2}$, respectively, when $z,\eta\to+\infty$.

Plugging the ansatz (5.40) into

$$L(\partial_t,\partial_x)V_{bd}^\epsilon-B(\epsilon^2,D\epsilon^2)V_{bd}^\epsilon=0$$

and grouping each power of ϵ, it follows from the vanishing of $O(\epsilon^{-1})$ and $O(\epsilon^0)$-terms that

$$A_1(0)\partial_z b_0=0 \tag{5.41}$$

and

$$\begin{cases}(A_0(0)\partial_t+A_2(0)\partial_{x_2}+zA_1'(0)\partial_z)b_0=B_1\partial_z^2 b_0,\\ (\varphi_t^0A_0(0)+\varphi_{x_2}^0A_2(0))\partial_\theta d_2+A_1(0)\partial_\eta d_2=B_1\partial_\eta^2 d_2+(\varphi_{x_2}^0)^2B_2\partial_\theta^2 d_2+\varphi_{x_2}^0B_3\partial_{\eta\theta}^2 d_2.\end{cases} \tag{5.42}$$

From (5.41), we deduce

$$\partial_z b_0^{(1)}=\partial_z b_0^{(2)}=0,$$

which implies

$$b_0^{(1)}=b_0^{(2)}\equiv 0 \tag{5.43}$$

by using $b_0\in\mathcal{S}(\mathbb{R}_z^+)$.

As in (2.22), from the boundary condition in (2.1) we get

$$\begin{cases}a_0^{(k)}(t,x)+b_0^{(k)}(t,x_2;z)=0, & \text{on } \{x_1=z=0\},\\ c_2^{(k)}(t,x;\theta)+d_2^{(k)}(t,x_2;\eta,\theta^0)=0, & \text{on } \{x_1=\eta=0,\theta=\theta^0\}\end{cases} \tag{5.44}$$

for $k\in\{2,3\}$.

Therefore, from (5.35), (5.43), and (5.44) we obtain that $a_0(t,x)$ satisfies the same initial boundary value problem of the linearized Euler equations (2.26) as for the case studied in section 2. From the first equation in (5.42), it also implies that the boundary layer profile $b_0^{(3)}(t,x_2,z)$ satisfies the same problem of the linearized Prandtl equation (2.29) derived in section 2.

From the second equation in (5.42), we deduce that $d_2=(d_2^{(1)},d_2^{(2)},d_2^{(3)})^T$ satisfies

$$\begin{cases} \partial_\eta d_2^{(2)}+\varphi^0_{x_2}\partial_\theta d_2^{(3)}=0,\\ c^2(0)\partial_\eta d_2^{(1)}=(1+D)\partial_\eta^2 d_2^{(2)}+(\varphi^0_{x_2})^2\partial_\theta^2 d_2^{(2)}+D\varphi^0_{x_2}\partial^2_{\eta\theta}d_2^{(3)},\\ c^2(0)\varphi^0_{x_2}\partial_\theta d_2^{(1)}=\partial_\eta^2 d_2^{(3)}+(1+D)(\varphi^0_{x_2})^2\partial_\theta^2 d_2^{(3)}+D\varphi^0_{x_2}\partial^2_{\eta\theta}d_2^{(2)}. \end{cases} \tag{5.45}$$

From (5.45), it is easy to see that $\omega=\varphi^0_{x_2}\partial_\theta d_2^{(2)}-\partial_\eta d_2^{(3)}$ and $d_2^{(3)}$ satisfy the following problem:

$$\begin{cases} [\partial_\eta^2+(\varphi^0_{x_2})^2\partial_\theta^2]\omega=0,\\ [\partial_\eta^2+(\varphi^0_{x_2})^2\partial_\theta^2]d_2^{(3)}=-\partial_\eta\omega,\\ (\omega+\partial_\eta d_2^{(3)})|_{\eta=0}=-\varphi^0_{x_2}\partial_\theta c_2^{(2)}|_{x_1=0},\\ d_2^{(3)}|_{\eta=0}=-c_2^{(3)}|_{x_1=0}, \end{cases} \tag{5.46}$$

where $c_2^{(2)}$ and $c_2^{(3)}$ are given in (5.38).

In an argument even simpler than in section 3, one concludes that the problem (5.46) admits unique smooth solutions $(d_2^{(3)},\omega)\in\mathcal{C}_p^\infty(T^1,H^\infty([0,T]\times\mathbb{R}_{x_2}\times\mathbb{R}_\eta^+))$ rapidly decreasing in η when $\eta\to+\infty$.

Obviously, from the definition of ω and the first equation in (5.45) we know that $d_2^{(2)}(t,x_2;\eta,\theta)$ satisfies the following problem:

$$\begin{cases} [\partial_\eta^2+(\varphi^0_{x_2})^2\partial_\theta^2]d_2^{(2)}=\varphi^0_{x_2}\partial_\theta\omega,\\ d_2^{(2)}|_{\eta=0}=-c_2^{(2)}(t,0,x_2,\theta), \end{cases} \tag{5.47}$$

which is the same as (2.36). Thus, from (5.47) one can uniquely determine $d_2^{(2)}\in\mathcal{C}_p^\infty(T^1,\,H^\infty([0,T]\times\mathbb{R}_{x_2}\times\mathbb{R}_\eta^+))$ rapidly decreasing in η when $\eta\to+\infty$.

Substituting $(d_2^{(2)},d_2^{(3)})$ into the right-hand side of the third equation in (5.45) we can determine $d_2^{(1)}(t,x_2,\eta,\theta)$ by using $\mathbf{m}_\theta(d_2^{(1)})=0$.

Up to now, we have solved all leading profiles of the solution $V^\epsilon(t,x)$ to (2.1) with $\Phi=\Phi(t,x,\frac{\varphi(t,x)}{\epsilon^2})$ both near and away from the boundary. Similar to the discussion given at the last subsection, one can obtain all other high order profiles for this problem.

In a way similar to section 4, we can obtain the following theorem.

THEOREM 5.2. *Under the assumption that all compatibility conditions are satisfied for the problem* (2.1) *with* $\Phi=\Phi(t,x,\frac{\varphi(t,x)}{\epsilon^2})$, *the solution* V^ϵ *of* (2.1) *has the following asymptotics:*

$$V^\epsilon(t,x)=a_0(t,x)+b_0\left(t,x_2;\frac{x_1}{\epsilon}\right)+O(\epsilon)$$

in $L^\infty([0,T]\times\mathbb{R}^2_+)$ *for any* $T>0$, *where* $a_0(t,x)$ *satisfies the problem for the linearized Euler equations* (2.26), $(b_0^{(1)},b_0^{(2)})=0$, *and* $b_0^{(3)}(t,x_2;z)$ *satisfies the linearized Prandtl equation* (2.29).

Acknowledgement. The authors would like to thank the referees for their suggestion for improving the presentation of this work.

PERIODICITY AND UNIQUENESS OF GLOBAL MINIMIZERS OF AN ENERGY FUNCTIONAL CONTAINING A LONG-RANGE INTERACTION*

XINFU CHEN† AND YOSHIHITO OSHITA‡

Abstract. We consider, on an interval of arbitrary length, global minimizers of a class of energy functionals containing a small parameter ε and a long-range interaction. Such functionals arise from models for phase separation in diblock copolymers and from stationary solutions of FitzHugh–Nagumo systems. We show that every global minimizer is periodic with a period of order $\varepsilon^{1/3}$. Also, we identify the number of global minimizers and provide asymptotic expansions for the periods and global minimizers.

Key words. singular perturbation, elliptic systems, transition layer

1. Introduction.

We consider global minimizers of the energy functional

$$\mathbf{E}(u,v,\varepsilon,\ell) := \int_0^\ell \left\{ \tfrac{1}{2}\varepsilon^2 u_x^2 + F(u) + \tfrac{1}{2}v_x^2 + \tfrac{1}{2}\gamma v^2 \right\} dx \tag{1.1}$$

under the constraint

$$-v_{xx} + \gamma v = u - m \quad \text{in} \quad (0,\ell), \qquad v_x(0) = v_x(\ell) = 0. \tag{1.2}$$

Here $\gamma \geqslant 0$ and $m \in (0,1)$ are fixed constants, ε is a small positive parameter, and $\ell > 0$ is arbitrary. The function F is a smooth double-equal-well potential; more precisely,

$$F \in C^3(\mathbb{R}), \quad F(0) = F(1) = 0 < F(s) \quad \forall s \in \mathbb{R} \setminus \{0,1\}, \quad F''(0)F''(1) \neq 0. \tag{1.3}$$

When $\gamma = 0$, the solvability of v in (1.2) requires the average $\bar{u}$ of u be equal to m. In this case, the functional (1.1) was first introduced by Ohta and Kawasaki [20], and later by Bahiana and Oono [3], as a free energy modeling a microphase separation in diblock copolymers. In this model, u and $1-u$ represent the concentrations of two different repulsive monomers that constitute the diblock copolymers. The nonlocal term v represents the long-range interaction of copolymer chains. In numerical simulations, phase separations with fine structures were observed to be in agreement with those from laboratory experiments. In [18], Nishiura and Ohnishi derived and studied a gradient flow of the functional defined on a finite interval. For a detailed physical background on diblock copolymers, see Hamley [10]; other related mathematical treatments can be found in [6, 9, 11, 19, 22, 23, 24].

The Euler–Lagrange equation for a critical point of the functional is

$$\varepsilon^2 u_{xx} = F'(u) + v \quad \text{in} \quad (0, \ell), \quad u_x(0) = u_x(\ell) = 0. \tag{1.4}$$

Any solution to the system (1.2), (1.4) can be regarded as a stationary pattern of the FitzHugh–Nagumo equations; see [7, 8, 12, 16, 17] and the references therein. Recently, one of the authors used the functional (1.1) for $\gamma > 0$ obtaining mesoscopic patterns of the FitzHugh–Nagumo dynamics in higher space dimensions [21].

The functional (1.1) admits many local minimizers [16, 19, 22]; this paper focuses on global minimizers. Recently, Ren and Wei [24] carried out an impressive mathematical analysis on global minimizers of (1.1) with $\ell = 1$ and $\gamma = 0$. Their results are in line with a classical result of Müller [15] on energy functionals of the type

$$\int_0^1 \left\{ \varepsilon^2 w_{xx}^2 + (w_x^2 - 1)^2 + w^2 \right\} dx.$$

Under periodic or homogeneous Dirichlet boundary conditions, Müller proved that global minimizers have periods of order $\varepsilon^{1/3}$ and are in general unique; see also [1]. The above energy can be regarded as a special case of (1.1), after taking $\gamma = 0$, $\ell = 1$, $m = 1/2$, and $F(s) = 2s^2(1-s)^2$, and setting $w = -2v_x$. In this paper we provide a unified framework to analyze the stationary diblock copolymer equation ($\gamma = 0$) and the stationary FitzHugh–Nagumo system ($\gamma > 0$). Besides using many ingenious ideas from Müller [15], Alberti and Müller [1], Nishiura [16], Ohnishi et al. [19], and Ren and Wei [22, 23, 24], we develop new techniques to

(i) treat the case $\gamma > 0$,
(ii) remove technical assumptions on F in [1, 15, 24] (here we only assume (1.3)),
(iii) simplify some of their proofs, and
(iv) provide a (seemingly) more complete result by introducing ℓ as a parameter.

The energy functional (1.1) is designed to have two length scales (e.g., [6, 16, 20, 19, 24]). To see this, let's denote the average of u and v over $(0, \ell)$ by

$$\bar{u} = \frac{1}{\ell} \int_0^\ell u(x) dx, \qquad \bar{v} = \frac{1}{\ell} \int_0^\ell v(x) dx.$$

An integration of the equation for v gives $\gamma \bar{v} = \bar{u} - m$. As $\|v\|_{L^2}^2 = \|v - \bar{v}\|_{L^2}^2 + \|\bar{v}\|_{L^2}^2$, the functional can also be written as

$$\mathbf{E}(u, v, \varepsilon, \ell) = \int_0^\ell \left\{ \tfrac{1}{2}\varepsilon^2 u_x^2 + F(u) + \tfrac{1}{2\gamma}(\bar{u} - m)^2 \right\} dx + \int_0^\ell \left\{ \tfrac{1}{2} v_x^2 + \tfrac{\gamma}{2}(v - \bar{v})^2 \right\} dx. \tag{1.5}$$

We call the first integral the *interfacial energy* and the second integral the *interaction energy*.

For the interfacial energy to be small, u has to stay close to either 0 or 1, whereas its average stays close to m. The transition layer (interface) where u changes from 0 to 1 has to be of ε scale; see Carr, Gurtin, and Slemrod [4], who studied minimizers of the interfacial energy functional in the class $\{u \mid \bar{u} = m\}$. Indeed, near each interface located at z, $u(x) \sim Q(\pm(x - z)/\varepsilon)$, where Q is the profile of the transition being the unique solution to

$$\begin{cases} \ddot{Q}(\xi) = f(Q(\xi)) \quad \forall \xi \in \mathbb{R}, \\ Q(-\infty) = 0, \quad Q(\infty) = 1, \quad \int_{\mathbb{R}} \xi \dot{Q}(\xi)\, d\xi = 0. \end{cases}$$

Here $f(u) \equiv F'(u)$ and the last condition is a normalization to fix the translation invariance. Each layer (interface) contains an interfacial energy about $\sigma\varepsilon$, where $\sigma = \int_0^1 \sqrt{2F(s)}ds$; the fewer the interfaces there are, the smaller the total interfacial energy is. The thickness of each interfacial region is of order ε.

On the other hand, the interaction energy is proportional to the cubic power of the length of phase regions (the sets where $u \sim 0$ or 1): when the distance between two interfaces is l and the equation for v is approximated by $v_{xx} \approx m$ or $m-1$, the interaction energy can be calculated to be about $\frac{1}{6}m^2(1-m)^2l^3$. Hence, the energy density

$$\frac{\text{interfacial energy} + \text{interaction energy}}{\text{length}} \approx \frac{1}{l}\left(\sigma\varepsilon + \frac{m^2(1-m)^2}{6}l^3\right).$$

Consequently, the energy density becomes optimal (the smallest) if $l \sim L_0\varepsilon^{1/3}$, where

$$L_0 := \left(\frac{3\sigma}{m^2(1-m)^2}\right)^{1/3}, \qquad \sigma := \int_0^1 \sqrt{2F(s)}ds. \tag{1.6}$$

Thus, at least formally, energies are minimized under an *interaction scale* of size $\varepsilon^{1/3}$ and an *interfacial scale* of size ε. An arbitrary sample of the material studied would in general exhibit a high oscillating pattern of frequency about $\varepsilon^{-1/3}$ per unit length.

To state our analytical result, we introduce the following:

$$\mathbf{K}_N(\ell) = \{(u,v) \mid u \in H^1(0,\ell), v'' - \gamma v = m - u, v'(0) = v'(\ell) = 0\},$$
$$E(\varepsilon,\ell) = \inf_{(u,v)\in\mathbf{K}_N(\ell)} \mathbf{E}(u,v,\varepsilon,\ell), \qquad \rho(\varepsilon,\ell) = \frac{1}{\ell}E(\varepsilon,\ell).$$

Associated with each $(u,v) \in \mathbf{K}_N(\ell)$, there are two natural companions of the same energy density:

(i) *Reflection* about $x = \ell/2$: $(\tilde{u}(x), \tilde{v}(x)) := (u(\ell - x), v(\ell - x))$.

(ii) *Even-periodic extension*: extend (u,v) first evenly to $[-\ell, 0)$ and then periodically to $\mathbb{R}$.

The reflection $(\tilde{u},\tilde{v})$ can be viewed as an ℓ-spatial translation of the even-periodic extension $(\hat{u},\hat{v})$: for every $x \in (0,\ell)$, $\hat{u}(x+\ell) = \hat{u}(x+\ell-2\ell) = \hat{u}(x-\ell) = u(\ell-x) = \tilde{u}(x)$.

Using the even-periodic extensions as test functions, one immediately derives that

$$\rho(\varepsilon, k\ell) \le \rho(\varepsilon,\ell) \quad \text{ or } \quad \rho(\varepsilon,\ell) \le \rho(\varepsilon,\ell/k) \qquad \forall\, \ell > 0,\ k = 2,3,\dots.$$

Hence, for the uniqueness of global minimizers, it would be better to modulo out the periodicity. For this purpose, we introduce

$$\mathbf{K}_N^+(\ell) = \{(u,v) \in \mathbf{K}_N(\ell) \mid v' \ge 0 \text{ in } (0,\ell)\},$$
$$E^+(\varepsilon,\ell) = \inf_{(u,v)\in\mathbf{K}_N^+(\ell)} \mathbf{E}(u,v,\varepsilon,\ell), \qquad \rho^+(\varepsilon,\ell) = \frac{1}{\ell}E^+(\varepsilon,\ell).$$

In what follows, we always assume that F satisfies (1.3), $m \in (0,1)$ is a fixed constant, and $\gamma = \gamma(\varepsilon) \in [0,\gamma_0]$, where γ_0 is a fixed constant. The following technical result, stated first for easy reference, can be regarded as a lemma.

THEOREM 1. *There exists $\varepsilon_0 > 0$ such that when $\varepsilon \in (0,\varepsilon_0]$, the following holds.*

1. *With* σ *and* L_0 *defined as in* (1.6),

$$\text{(1.7)}\qquad \frac{L_0}{\sigma\varepsilon^{2/3}}\,\rho^+(\varepsilon,\ell) \leqslant \sqrt[3]{5} \qquad \text{if} \quad \frac{1}{\sqrt[3]{3}} \leqslant \frac{\ell}{L_0\varepsilon^{1/3}} \leqslant \frac{2}{\sqrt[3]{3}},$$

$$\text{(1.8)}\qquad \frac{L_0}{\sigma\varepsilon^{2/3}}\,\rho^+(\varepsilon,\ell) \geqslant \sqrt[3]{6} \qquad \text{if} \quad \frac{\ell}{L_0\varepsilon^{1/3}} \geqslant \sqrt[3]{4} \quad \text{or} \quad \frac{\ell}{L_0\varepsilon^{1/3}} \leqslant \frac{1}{4}.$$

2. *For each* $\ell \in [\frac{1}{16}L_0\varepsilon^{1/3}, \sqrt[3]{5}L_0\varepsilon^{1/3}]$, *there is a unique minimizer of* $\mathbf{E}(\cdot,\cdot,\varepsilon,\ell)$ *in* $\mathbf{K}_N^+(\ell)$.
3. *As a function of* ℓ, $E^+(\varepsilon,\ell)$ *is smooth in* $[\frac{1}{16}L_0\varepsilon^{1/3}, \sqrt[3]{5}L_0\varepsilon^{1/3}]$ *and, denoting* $E^+_\ell = \frac{d}{d\ell}E^+$,

$$\begin{aligned} E^+(\varepsilon,\ell) &= \sigma\varepsilon + \tfrac{1}{6}m^2(1-m)^2\ell^3 + O(1)\ell^4,\\ E^+_\ell(\varepsilon,\ell) &= \tfrac{1}{2}m^2(1-m)^2\ell^2 + O(1)\ell^3,\\ E^+_{\ell\ell}(\varepsilon,\ell) &= m^2(1-m)^2\ell + O(1)\ell^2,\\ \ell^2\rho^+_\ell(\varepsilon,\ell) &= \tfrac{1}{3}m^2(1-m)^2\ell^3 - \sigma\varepsilon + O(1)\ell^4,\\ \ell^3\rho^+_{\ell\ell}(\varepsilon,\ell) &= \tfrac{1}{3}m^2(1-m)^2\ell^3 + 2\sigma\varepsilon + O(1)\ell^4. \end{aligned}$$

In particular, both $E^+(\varepsilon,\cdot)$ *and* $\rho^+(\varepsilon,\cdot)$ *are strictly convex in*

$$\left[\frac{1}{16}L_0\varepsilon^{1/3}, \sqrt[3]{5}L_0\varepsilon^{1/3}\right].$$

4. *There is a unique positive constant* $\ell^\varepsilon = L_0\varepsilon^{1/3}[1+O(1)\varepsilon^{1/3}]$ *such that*

$$\rho^+(\varepsilon,\ell) > \rho^+(\varepsilon,\ell^\varepsilon) \qquad \forall \ell \in (0,\ell^\varepsilon)\cup(\ell^\varepsilon,\infty).$$

In addition, for each positive integer n, *there is a unique solution* $\ell_n = \ell_n(\varepsilon)$ *to*

$$\text{(1.9)}\qquad \rho^+\left(\varepsilon, \frac{\ell_n}{n+1}\right) = \rho^+\left(\varepsilon, \frac{\ell_n}{n}\right), \qquad \frac{\ell_n}{n+1} < \ell^\varepsilon < \frac{\ell_n}{n}.$$

Furthermore, uniformly in $n \geq 1$, *the solution has the expansion*

$$\text{(1.10)}\qquad \frac{\ell_n(\varepsilon)}{\ell^\varepsilon} = \left(n+\tfrac{1}{2}\right)\left[\frac{n^2+n}{n^2+n+1/4}\right]^{2/3} + O(1)\varepsilon^{1/3}.$$

In this paper, every $O(1)$ refers to a quantity that is bounded uniformly in ε and in ℓ.

The following is our main result, where $\ell_0(\varepsilon) := \ell_1(\varepsilon)/2$.

Theorem 2 (periodicity and uniqueness of global minimizers). *For every sufficiently small positive* ε *the following holds:*

1. *For every integer* $n \geq 1$ *and* $\ell \in (\ell_{n-1}(\varepsilon), \ell_n(\varepsilon))$, (1.1) *under the constraint* (1.2) *has a global minimizer. It must have a half-period* ℓ/n *and is unique up to a half-period translation.*

2. *If* $\ell = \ell_n$ $(n \geq 1)$, (1.1) *under the constraint* (1.2) *has exactly (modulo a half-period translation) two minimizers; one has a half-period* ℓ/n *and the other a half-period* $\ell/(n+1)$.

In both cases 1 *and* 2, *a global minimizer in a half-period l is the unique global minimizer of $\mathbf{E}(\cdot,\cdot,\varepsilon,l)$ in $\mathbf{K}_N^+(l)$ or its reflection about the quarter-period $x = l/2$.*

Here letting $\hat{u}$ be the even-periodic extension of u, we call $\hat{u}(\cdot - l)$ the half-period translation of u if $\hat{u}$ has the period $2l$.

Remark 1.1. (1) Suppose $\{(u^\ell, v^\ell)\}_{\ell\geq\ell_0(\varepsilon)}$ is a family of global minimizers normalized so that $v^\ell_{xx}(0) \geq 0$. Then their even-periodic extensions satisfy

$$\lim_{\ell\to\infty}(u^\ell, v^\ell) = (u^{\ell^\varepsilon}, v^{\ell^\varepsilon}) = (u^{k\ell^\varepsilon}, v^{k\ell^\varepsilon}) \qquad \forall x \in (-\infty,\infty), k = 2,3,\ldots,$$

$$\lim_{\ell\to\infty}\rho(\varepsilon,\ell) = \rho(\varepsilon,\ell^\varepsilon) = \rho(\varepsilon,k\ell^\varepsilon) \qquad \forall\, k = 2,3,\ldots.$$

These limits follow from the continuous dependence of global minimizers in $\mathbf{K}_N^+(\ell)$ for ℓ near ℓ^ε.

(2) The maximum period of all minimizers (for $\ell \geq \ell^\varepsilon$) is

$$2\ell_1 = \frac{4L_0}{\sqrt[3]{3}}\,\varepsilon^{1/3} + O(1)\varepsilon^{2/3}.$$

Namely, every global minimizer in any length of interval has a fine structure of length scale $\varepsilon^{1/3}$.

(3) Theorem 1 part 3 is indeed the announced Proposition 4.7 in [19], stating that the minimum energy and the corresponding energy density are convex functions of ℓ in a neighborhood of $L_0\varepsilon^{1/3}$.

The paper is organized as follows. In section 2, we use Theorem 1 to prove our main result, Theorem 2. The proof of part 4 of Theorem 1 is also included. In section 3 and section 4, we establish energy upper and lower bounds, respectively; that is, we prove Theorem 1 part 1. The rest of the paper is devoted to the proof of Theorem 1 parts 2 and 3. First we provide certain estimates on energy minimizers in section 5; in particular, we provide rigorously up to $O(\varepsilon\ell)$ order expansions. Then in section 6 we estimate the principal eigenvalue of the linearized operator around any minimizer. We remark that Nishiura [16] has already proven the positivity of the principal eigenvalue. Here we identify its precise value. The estimate shows that minimizers in any $o(\ell^2)$ neighborhood are unique. Since the expansion provided in section 5 for minimizers is unique, we conclude that minimizers, for ℓ close to $L_0\varepsilon^{1/3}$, are unique. The uniqueness of minimizers allows us to differentiate the minimizer with respect to ℓ and to prove the convexity of minimum energy with respect to ℓ, which will be done in the last section.

2. Proof of the main result. In this section, we use Theorem 1 to prove our main result, Theorem 2.

2.1. The idea. The key to the proof is to show that all zeros of v_x of a global minimizer (u,v) are equally spaced, with a distance approximately equal to $L_0\varepsilon^{1/3}$. Once this is done, the rest of the proof follows from a straightforward calculation using the estimates of ρ^+ and the uniqueness of global minimizers in $\mathbf{K}_N^+$ stated in Theorem 1.

To show that the zeros of v_x are equally spaced, we compare the energy $E(\varepsilon,\ell)$ with $H(\varepsilon,P) := \sum_{i=1}^n E^+(\varepsilon,l_i)$, where $P = \{l_1,\ldots,l_n\}$ is an arbitrary partition of ℓ, defined as follows.

Definition 1. *A* partition *P of a positive number ℓ is a collection of finitely many positive numbers $l_1,\ldots,l_n$ satisfying $\sum_{i=1}^n l_i = \ell$. A partition $P = \{l_1,\ldots,l_n\}$ is called an* equal partition *if all $l_1,\ldots,l_n$ are identical, namely, equal to ℓ/n.*

Using a step-by-step modification of partition lengths, we show that if $E(\varepsilon,\ell) \geq H(\varepsilon,P)$, where P is a partition of ℓ, then P must be an equal partition with partition length as "close" to ℓ^ε as possible. The modification involves combining short lengths with, and splitting long lengths into, intermediate ones. The criteria for short, intermediate, and long are the two numbers $\frac{1}{16}L_0\varepsilon^{1/3}$ and $\sqrt[3]{4}L_0\varepsilon^{1/3}$.

To treat minimizers on short intervals, we need the following energy lower bound estimate whose proof will be given later in this section.

LEMMA 2.1. *There exists a positive constant c_1 (depending only on m and F) such that*

$$\rho(\varepsilon,\ell) \geqslant \min\{\, c_1\,,\ \sigma\varepsilon/(2\ell)\,\} \qquad \forall \varepsilon > 0, \ell > 0.$$

2.2. Proof of Theorem 2. Let $\ell \geq \frac{1}{\sqrt[3]{3}}L_0\varepsilon^{1/3}$ be given and consider the minimization of (1.1) under the constraint (1.2).

Step 1. Since each term that appeared in $\mathbf{E}$ defined in (1.1) is nonnegative, one can easily show that in $\mathbf{K}_N(\ell)$, $\mathbf{E}(\cdot,\cdot,\ell,\varepsilon)$ admits at least one global minimizer. In addition, any global minimizer is smooth and satisfies the Euler–Lagrange equation (1.4). Furthermore, applying a classical uniqueness result to an initial value problem of the ode system (1.2), (1.4), one can conclude that if all $v_x, v_{xx}, v_{xxx}, v_{xxxx}$ vanish at the same point, say $y \in [0,\ell]$, then $u_x(y) = u_{xx}(y) = 0$, which implies that $(u_x(x), v_x(x)) \equiv (0,0)$ for all $x \in [0,\ell]$; namely (u,v) is a constant function.

Now let $(u,v) \in \mathbf{K}_N(\ell)$ be an arbitrary global minimizer of $\mathbf{E}(\cdot,\cdot,\ell,\varepsilon)$ in $\mathbf{K}_N(\ell)$; that is, $\mathbf{E}(u,v,\varepsilon,\ell) = E(\varepsilon,\ell)$. Assume that ε is small. We see $\rho(\varepsilon,\ell)$ is small uniformly in $\ell \geq L_0\varepsilon^{1/3}/\sqrt[3]{3}$. Then (u,v) cannot be a constant function, and thus all $v_x, v_{xx}, v_{xxx}, v_{xxxx}$ cannot vanish simultaneously at any point. Hence all roots to $v_x = 0$ are isolated. We denote all the roots to $v' = 0$ in $[0,\ell]$ by $\{x_0, x_1, \ldots, x_n\}$, in increasing order with $x_0 = 0$ and $x_n = \ell$. Set $l_i = x_i - x_{i-1}$. In each interval (x_{i-1}, x_i), $i = 1, \ldots, n$, either $v_x > 0$ or $v_x < 0$. Set $(u_i(y), v_i(y)) = (u(x_{i-1}+y), v(x_{i-1}+y))$ in the former case and set $(u_i(y), v_i(y)) = (u(x_i - y), v(x_i - y))$ in the latter case. Then $(u_i, v_i) \in \mathbf{K}_N^+(l_i)$. Consequently,

$$\int_{x_{i-1}}^{x_i} \left[\tfrac{1}{2}u_x^2 + F(u) + \tfrac{1}{2}v_x^2 + \tfrac{\gamma}{2}v^2\right] dx = \mathbf{E}(u_i, v_i, \varepsilon, l_i) \geq E^+(\varepsilon, l_i).$$

Hence, for the partition $P := \{l_1, \ldots, l_n\}$ of ℓ,

$$H(\varepsilon,P) := \sum_{i=1}^n E^+(\varepsilon, l_i) \leq E(\varepsilon,\ell). \tag{2.1}$$

If each l_i is in the range $[L_0\varepsilon^{1/3}/16, \sqrt[3]{5}L_0\varepsilon^{1/3}]$, we can apply the convexity of E^+ to show that all l_i are the same (Step 5). If not, we show (Steps 2–4) that different partitions with decreased values of H could be found, and that after finitely many steps the partition found has the property that all its partition lengths lie in $[L_0\varepsilon^{1/3}/16, \sqrt[3]{5}L_0\varepsilon^{1/3}]$.

Step 2. We shall show that short partition lengths, if there are any, can combine with some others to form new partitions with smaller H. For this we need the following:

Any partition $\tilde{P} = \{\tilde{l}_1, \ldots, \tilde{l}_{\tilde{n}}\}$ of ℓ satisfying $H(\varepsilon,\tilde{P}) \leqslant E(\varepsilon,\ell)$ admits at least one $\tilde{l}_j$, $j \in \{1, \ldots, \tilde{n}\}$ such that

$$\tfrac{\tilde{l}_j}{(L_0\varepsilon^{1/3})} \in \left[\tfrac{1}{4}, \sqrt[3]{4}\right]. \tag{2.2}$$

Indeed, since $\rho(\varepsilon,\ell) \le \rho(\varepsilon,\ell/k) \le \rho^+(\varepsilon,\ell/k)$ for every integer $k \ge 1$, dividing $H(\varepsilon,\tilde{P}) \le E(\varepsilon,\ell)$ by ℓ gives us

$$\sum_{i=1}^{\tilde{n}} \frac{\tilde{l}_i}{\ell}\, \rho^+(\varepsilon,\tilde{l}_i) \le \rho(\varepsilon,\ell) \le \min_{k\ge 1} \rho^+\left(\varepsilon,\frac{\ell}{k}\right) \le \sqrt[3]{5}\, \frac{\sigma\varepsilon^{2/3}}{L_0}$$

by picking a test k such that $\ell/(kL_0\varepsilon^{1/3}) \in [1/\sqrt[3]{3}, 2/\sqrt[3]{3}]$ and using (1.7). Since $\sum \tilde{l}_i = \ell$, in view of (1.8), we see that there is at least one $j \in \{1,\dots,\tilde{n}\}$ such that (2.2) holds.

Step 3. We now combine, one at a time, the short partition lengths, if there are any, with intermediate ones.

Suppose, for some i, that $l_i/(L_0\varepsilon^{1/3}) \le \frac{1}{16}$. Pick an arbitrary l_j satisfying (2.2). Then $l_i + l_j \le (\frac{1}{16} + \sqrt[3]{4})L_0\varepsilon^{1/3} < \sqrt[3]{5}L_0\varepsilon^{1/3}$. We can calculate, by the mean value theorem,

$$E^+(\varepsilon,l_i) + E^+(\varepsilon,l_j) - E^+(\varepsilon,l_j+l_i) = l_i\left\{\rho^+(\varepsilon,l_i) - \tfrac{d}{d\ell}E^+(\varepsilon,l_j+\theta l_i)\right\}$$

for some $\theta \in (0,1)$. Using Lemma 2.1 we find that $\rho^+(\varepsilon,l_i) \ge \rho(\varepsilon,l_i) \ge 8\sigma\varepsilon^{2/3}/L_0$. On the other hand, using Theorem 1 we have $\frac{d}{d\ell}E^+(\varepsilon,l_j+\theta l_i) \le \frac{1}{2}m^2(1-m)^2(\sqrt[3]{5}L_0\varepsilon^{1/3})^2 = \frac{3\sqrt[3]{25}}{2}\sigma\varepsilon^{2/3}/L_0$, since $L_0^3 = 3\sigma/[m^2(1-m)^2]$. Thus,

$$E^+(\varepsilon,l_i) + E^+(\varepsilon,l_j) > E^+(\varepsilon,l_i+l_j).$$

Now deleting two members l_i and l_j from and adding one new member $l_i + l_j$ to P, we obtain a new partition $\tilde{P}$ satisfying $H(\varepsilon,\tilde{P}) < H(\varepsilon,P) \leqslant E(\varepsilon,\ell)$. Repeating the same process finitely many times, we then obtain a partition $P' = \{l'_1,\dots,l'_{n'}\}$ of ℓ such that $l'_i/(L_0\varepsilon^{1/3}) > \frac{1}{16}$ for all $i = 1,\dots,n'$ and $H(\varepsilon,P') \leqslant H(\varepsilon,P)$, where the strict inequality holds if $P' \ne P$.

Step 4. Here we split longer partition lengths, if there are any, into shorter ones.

Suppose $l'_i/(L_0\varepsilon^{1/3}) \ge \sqrt[3]{4}$ for some i. For each such i, let $k_i > 1$ be an integer such that $l'_i/(k_iL_0\varepsilon^{1/3}) \in [1/\sqrt[3]{3}, 2/\sqrt[3]{3}]$. Then, by (1.7) and (1.8),

$$\begin{aligned} E^+(\varepsilon,l'_i) &= l'_i\rho^+(\varepsilon,l'_i) \ge l'_i\sqrt[3]{6}\sigma\varepsilon^{2/3}/L_0 \ge l'_i\sqrt[3]{\tfrac{6}{5}}\;\rho^+(\varepsilon,l'_i/k_i) \\ &= \sqrt[3]{\tfrac{6}{5}}\sum_{j=1}^{k_i}(l'_i/k_i)\rho^+(\varepsilon,l'_i/k_i) = \sqrt[3]{\tfrac{6}{5}}\sum_{j=1}^{k_i}E^+(\varepsilon,l_i^j), \quad l_i^1 = \cdots = l_i^{k_i} := l'_i/k_i. \end{aligned}$$

Hence, splitting each such l'_i into k_i copies of l'_i/k_i ($k_i = 1$ if $l'_i < \sqrt[3]{4}L_0\varepsilon^{1/3}$) we obtain a new partition $P'' = \cup_{i=1}^{n'}\cup_{j=1}^{k_i}\{l_i^j\}$ of ℓ satisfying, after renaming the entries of P'',

(2.3)
$$H(\varepsilon,P'') \le H(\varepsilon,P'), \qquad P'' = \{l''_1,\dots,l''_{n''}\},\ \tfrac{1}{16} < l''_i/(L_0\varepsilon^{1/3}) < \sqrt[3]{4}\ \ \forall\, i = 1,\dots,n'',$$

where the strict inequality holds if $P'' \ne P'$.

Step 5. Now we can use the convexity of $E^+(\varepsilon,\cdot)$ in $[L_0\varepsilon^{1/3}/16, \sqrt[3]{5}L_0\varepsilon^{1/3}]$ to conclude that

$$E(\varepsilon,\ell) \ge H(\varepsilon,P'') = n''\sum_{i=1}^{n''}\tfrac{1}{n''}E^+(\varepsilon,l''_i) \ge n''E^+\Big(\varepsilon,\Sigma_{i=1}^{n''}\tfrac{l''_i}{n''}\Big) = n''E^+(\varepsilon,\tfrac{\ell}{n''}).$$

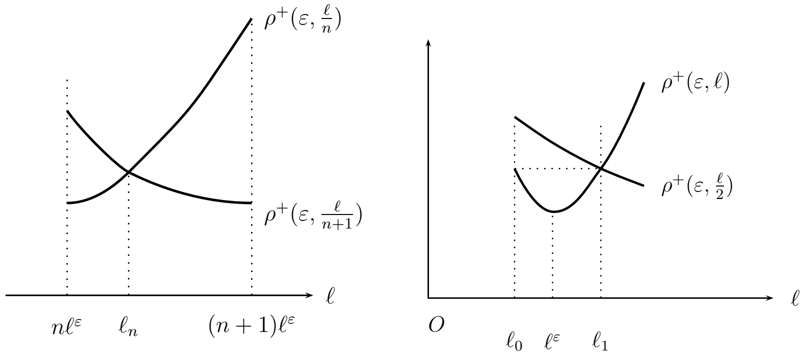

FIG. 1.

Dividing both sides by ℓ we then obtain $\rho^+(\varepsilon, \ell/n'') \leq \rho(\varepsilon, \ell) \leq \min_{k\geq 1} \rho^+(\varepsilon, \ell/k)$. This implies that

$$\rho^+(\varepsilon, \ell/n'') = \rho(\varepsilon, \ell) = \min_{k\geq 1} \rho^+(\varepsilon, \ell/k). \tag{2.4}$$

Since any one of the nontrivial reductions in Steps 3 and 4 gives a strict inequality, we conclude that $P = P' = P''$. In addition, for each i, (u_i, v_i) must be equal to the unique minimizer of $\mathbf{E}$ in $\mathbf{K}_N^+(\ell/n)$. Thus, (u, v) is even with a half-period ℓ/n (the half-period cannot be an integer fraction of ℓ/n since $v' \neq 0$ in $(0, \ell/n)$).

Step 6. It remains to identify n. Let $s \geq 1$ be the unique integer such that $\ell/(s+1) < \ell^\varepsilon \leq \ell/s$. Consider three cases:

(i) $\rho^+(\varepsilon, \ell/(s+1)) > \rho^+(\varepsilon, \ell/s)$,

(ii) $\rho^+(\varepsilon, \ell/(s+1)) < \rho^+(\varepsilon, \ell/s)$,

(iii) $\rho^+(\varepsilon, \ell/(s+1)) = \rho^+(\varepsilon, \ell/s)$.

Here we include Figure 1 to help readers to follow our argument.

In the first case we must have $n = s$. Indeed if $n < s$, then $\ell/n > \ell/s \geq \ell^\varepsilon$. As $\rho^+(\varepsilon, \cdot)$ is strictly increasing in $[\ell^\varepsilon, \sqrt[3]{5}L_0\varepsilon^{1/3}]$, we derive that $\rho^+(\varepsilon, \ell/n) > \rho^+(\varepsilon, \ell/s)$, contradicting (2.4). Similarly, if $n > s$, then $\ell/n \leq \ell/(1+s) < \ell^\varepsilon$. As $\rho^+(\varepsilon, \cdot)$ is strictly decreasing in $(\frac{1}{16}L_0\varepsilon^{1/3}, \ell^\varepsilon)$, $\rho^+(\varepsilon, \ell/n) \geq \rho^+(\varepsilon, \ell/(s+1)) > \rho^+(\varepsilon, \ell/s)$, again contradicting (2.4). Hence, we must have $n = s$.

In case (ii), we can derive in a similar manner that $n = s + 1$.

Finally, in case (iii), we can only have either $n = s$ or $n = s + 1$.

This completes the proof of Theorem 2. $\square$

Remark 2.1. Our proof is simpler than that in [15] and [24] since we do not need any a priori estimation on the distances between any successive zeros of v_x. In [24], great efforts (tens of pages) were devoted to the estimation that $C_1\varepsilon^{1/3} < x_i - x_{i-1} < C_2\varepsilon^{1/3}$, whereas in [15] such estimation was bypassed after imposing more symmetric conditions on the nonlinearity F and on m. Our proof relies on estimates (1.7) and (1.8).

Since the last assertion of Theorem 1 follows from the previous assertion of the same theorem, it is convenient to provide its proof here.

2.3. Proof of Theorem 1 part 4. (a) From the third assertion of Theorem 1, $\rho^+(\varepsilon, \cdot)$ is strictly convex in $[\frac{1}{16}L_0\varepsilon^{1/3}, \sqrt[3]{5}L_0\varepsilon^{1/3}]$ and $\frac{d}{d\ell}\rho^+$ changes sign in the interval. Hence $\rho^+(\varepsilon, \cdot)$ attains a unique strict minimum in $[\frac{1}{16}L_0\varepsilon^{1/3}, \sqrt[3]{5}L_0\varepsilon^{1/3}]$. Denote this minimum by ℓ^ε. Then $\rho^+_\ell(\varepsilon, \ell^\varepsilon) = 0$ so that $\ell^\varepsilon/(L_0\varepsilon^{1/3}) = 1 + O(1)\varepsilon^{1/3}$. In view of (1.7), and (1.8), this minimum is also global.

(b) Now we solve (1.9) for ℓ_n. Writing $\ell_n/n = \mu\ell^\varepsilon$, we need only find $\mu \in (1, 1 + 1/n)$ such that

$$\rho^+\left(\varepsilon, \frac{n}{n+1}\mu\ell^\varepsilon\right) - \rho^+(\varepsilon, \mu\ell^\varepsilon) = 0.$$

Since $\rho^+(\varepsilon, \cdot)$ is strictly increasing in $[\ell^\varepsilon, \sqrt[3]{5}L_0\varepsilon^{1/3}]$ and strictly decreasing in $[L_0\varepsilon^{1/3}/16, \ell^\varepsilon]$, as a function of $\mu \in [1, 1 + 1/n]$, the left-hand side is decreasing and has different signs at $\mu = 1$ and $\mu = 1 + 1/n$. Thus the above equation admits a unique solution $\mu \in (1, 1 + 1/n)$.

It remains to estimate μ. For $\ell \in [L_0\varepsilon^{1/3}/16, \sqrt[3]{5}L_0\varepsilon^{1/3}]$, writing $\rho^+(\varepsilon, \ell)$ as $\rho^+(\ell)$ and using $\rho_\ell(\ell^\varepsilon) = 0$, we obtain

$$\begin{aligned}
\rho^+(\ell) - \rho^+(\ell^\varepsilon) &= \int_{\ell^\varepsilon}^{\ell} \rho^+_s(s)\,ds = \int_{\ell^\varepsilon}^{\ell} (\ell - s)\rho^+_{ss}(s)\,ds \\
&= \int_{\ell^\varepsilon}^{\ell} (\ell - s)\left\{\frac{2\sigma\varepsilon}{s^3} + \frac{m^2(1-m)^2}{3} + O(s)\right\} ds \\
&= \frac{m^2(1-m^2)}{6}(\ell - \ell^\varepsilon)^2\left\{O(\ell) + 1 + \frac{2\ell^\varepsilon}{\ell}\right\} \\
&= \frac{m^2(1-m^2)}{6}\left\{\ell^2 + \frac{2\ell^{\varepsilon 3}}{\ell} - 3\ell^{\varepsilon 2} + O(\ell)(\ell - \ell^\varepsilon)^2\right\}
\end{aligned}$$

by using the expansion for $\rho^+_{\ell\ell}$ in Theorem 1 part 3, the definition of L_0, and expansion $\ell^\varepsilon = [1 + O(\varepsilon^{1/3})]L_0\varepsilon^{1/3}$.

Upon setting $\ell = \mu\ell^\varepsilon$ and $\ell = n\mu\ell^\varepsilon/(n+1)$, respectively, and noting that $\mu \in (1, 1 + 1/n)$ we obtain

$$\mu^2 + \frac{2}{\mu} = \frac{n^2\mu^2}{(n+1)^2} + \frac{2(n+1)}{n\mu} + \frac{O(\ell^\varepsilon)}{n^2}.$$

Therefore,

$$\begin{aligned}
&\mu = \left[\frac{2(n+1)^2}{(2n+1)n}\right]^{1/3}\left[1 + \left(\frac{O(\ell^\varepsilon)}{n}\right)\right], \\
&\frac{\ell_n}{\ell^\varepsilon} = n\mu = \left[\frac{n^2(n+1)^2}{(n+1/2)}\right]^{1/3}\left[1 + \frac{O(\ell^\varepsilon)}{n}\right] = \left(n + \frac{1}{2}\right)\left(\frac{n^2+n}{n^2+n+1/4}\right)^{2/3} + O(\varepsilon^{1/3}).
\end{aligned}$$

This completes the proof of Theorem 1 part 4. $\square$

2.4. Proof of Lemma 2.1. Let δ be a small positive fixed number that is independent of ε and let $(u, v) \in \mathbf{K}_N(\ell)$ be any function. We consider three cases:

(i) There exist x_1 and x_2 in $[0, \ell]$ such that $u(x_1) < \delta$ and $u(x_2) > 1 - \delta$,

(ii) $u \leq 1 - \delta$ in $[0, \ell]$, and

(iii) $u \geq \delta$ in $[0, \ell]$.

In case (i), since δ is small,

$$\mathbf{E}(u,v,\varepsilon,\ell) \geq \int_0^\ell \varepsilon |u_x| \sqrt{2F(u)} dx \geq \varepsilon \int_\delta^{1-\delta} \sqrt{2F(s)} ds \geq \tfrac{1}{2}\sigma\varepsilon.$$

In case (ii) we consider two subcases:

$$\text{(a) } |\{x \mid \delta \leq u \leq 1-\delta\}| \geq \tfrac{1}{2}m\ell; \quad \text{(b) } |\{x \mid \delta \leq u \leq 1-\delta\}| < \tfrac{1}{2}m\ell.$$

In case (a),

$$\mathbf{E}(u,v,\varepsilon,\ell) \geq \int_0^\ell F(u)\, dx \geq \frac{1}{2} m\ell c(\delta), \quad c(\delta) := \min_{\delta < s < 1-\delta} F(s).$$

In case (b), $\ell\bar{u} = \int_0^\ell u \leq \frac{1}{2}(1-\delta)m\ell + \delta\ell \leq \frac{3}{4}m\ell$ since δ is small. Thus, $|\bar{u} - m| \geq \frac{1}{4}m$ and, by (1.5),

$$\mathbf{E}(u,v,\varepsilon,\ell) \geq \frac{1}{2\gamma} \int_0^\ell (\bar{u} - m)^2 \geq \frac{1}{32\gamma} m^2 \ell.$$

Similarly, we can consider case (iii). Hence, combining all the cases we see that

$$1/\ell\, \mathbf{E}(u,v,\varepsilon,\ell) \geq \min\{\sigma\varepsilon/(2\ell), mc(\delta)/2, (1-m)c(\delta)/2, m^2/(32\gamma), (1-m)^2/(32\gamma)\}.$$

Taking $c_1 := \min\{m(1-m)c(\delta)/2, m^2(1-m)^2/(32\gamma)\}$, the assertion of Lemma 2.1 follows. $\square$

3. An energy upper bound. In what follows, we use notation

$$\psi = \mathbf{K}_N^\ell \phi \iff \begin{cases} -\psi'' + \gamma\psi = \phi & \text{in } (0,\ell), \\ \psi'(0) = \psi'(\ell) = 0. \end{cases} \tag{3.1}$$

When $\gamma = 0$, ψ is unique up to an additive constant which does not affect the energy at all.

Lemma 3.1. *For every $\varepsilon > 0$ and $\ell > 0$,*

$$\min_{(u,v)\in\mathbf{K}_N^+(\ell)} \mathbf{E}(u,v,\ell,\varepsilon) < \sigma\varepsilon + \tfrac{1}{6}m^2(1-m)^2\ell^3. \tag{3.2}$$

Consequently, (1.7) *holds for every $\varepsilon > 0$.*

Proof. (a) Test function. With $\mathbf{K}_N^\ell$ defined in (3.1), we choose a test function

$$u(x) = Q\Big(\frac{x-z}{\varepsilon}\Big), \qquad v = \mathbf{K}_N^\ell(u - m),$$

where z is a constant chosen such that the average of u over $(0,\ell)$ is m. Such a z exists and is unique since $\dot{Q} > 0$, $Q(-\infty) = 0$, and $Q(\infty) = 1$. Also, since $-(v_x)_{xx} + \gamma v_x = u_x > 0$, and $v_x(0) = v_x(\ell) = 0$, the maximum principle implies that $v_x > 0$ on $(0,\ell)$. Thus, $(u,v) \in \mathbf{K}_N^+(\ell)$.

(b) Interfacial energy. Using $\dot{Q} = \sqrt{2F(Q)} > 0$, we have $\varepsilon u_x = \sqrt{2F(u)}$ and thus

$$\int_0^\ell \left\{\tfrac{1}{2}\varepsilon^2 u_x^2 + F(u)\right\} dx = \varepsilon \int_0^\ell u_x \sqrt{2F(u)} dx < \varepsilon \int_0^1 \sqrt{2F(s)} ds = \sigma\varepsilon.$$

(c) Interaction energy. We compare the energies of v and $\tilde{v} \equiv \int_0^x \int_0^{x'} [m - u(x'')]dx''dx'$.

Note $\tilde{v}_x = \int_0^x (m - u(x'))dx'$ and $\tilde{v}_{xx} = m - u$. Since the average of u is m, $\tilde{v}_x(\ell) = 0$. Also, as $-\tilde{v}_{xxx} = u_x > 0$, the maximum principle implies that $\tilde{v}_x > 0$ in $(0, \ell)$. Furthermore, $\tilde{v}_x(x) = \int_0^x (m - u(x'))dx' < mx$, $\tilde{v}_x(x) = \int_x^\ell (u(x') - m)dx' < (1 - m)(\ell - x)$. Hence,

$$0 < \tilde{v}_x(x) < \min\{mx, (1 - m)(\ell - x)\} \quad \forall\, x \in (0, \ell).$$

Finally, using $-v_{xx} + \gamma v = u - m = -\tilde{v}_{xx}$ we calculate

$$\begin{aligned} \int_0^\ell (v_x^2 + \gamma v^2)\, dx &= \int_0^\ell v(-v_{xx} + \gamma v)\, dx = \int_0^\ell v(u - m)\, dx \\ &= -\int_0^\ell v\tilde{v}_{xx}\, dx = \int_0^\ell v_x \tilde{v}_x \le \tfrac{1}{2} \int_0^\ell (v_x^2 + \tilde{v}_x^2)\, dx. \end{aligned}$$

Thus

$$\int_0^\ell (v_x^2 + 2\gamma v^2)\, dx \le \int_0^\ell \tilde{v}_x^2 \le \int_0^\ell \Big(\min\{mx, (1 - m)(\ell - x)\}\Big)^2 dx = \tfrac{1}{3} m^2 (1 - m)^2 \ell^3.$$

Combining this with the estimation in (b), the assertion (3.2) thus follows.

(d) Proof of (1.7). Since $m^2(1 - m)^2 = 3\sigma/L_0^3$, (3.2) implies, for every $\varepsilon > 0$ and $\ell = \mu L_0 \varepsilon^{1/3}$ with $\mu \in [1/\sqrt[3]{3}, 2/\sqrt[3]{3}]$, that

$$\rho^+(\varepsilon, \ell) < \frac{\sigma\varepsilon + \sigma\ell^3/(2L_0^3)}{\ell} = \frac{\sigma\varepsilon^{2/3}}{L_0}\Big(\frac{1}{\mu} + \frac{\mu^2}{2}\Big) \le \frac{7\sqrt[3]{3}}{6}\frac{\sigma\varepsilon^{2/3}}{L_0} < \sqrt[3]{5}\frac{\sigma\varepsilon^{2/3}}{L_0}. \qquad \square$$

4. Energy lower bounds. Lemma 2.1 provides an energy lower bound that can be used to prove (1.8) for all $\ell < \frac{1}{4} L_0 \varepsilon^{1/3}$. Here we establish energy lower bounds for all $\ell \ge \frac{1}{16} L_0 \varepsilon^{1/3}$, aimed at (i) completing the proof of (1.8) and (ii) sandwiching tightly the energy with the upper bound (3.2) for $\ell \in [\frac{1}{16} L_0 \varepsilon^{1/3}, \sqrt[3]{5} L_0 \varepsilon^{1/3}]$ so that a leading order expansion of the energy minimizer can be obtained.

4.1. The idea about how to deal with arbitrarily large . When $\ell/\varepsilon^{1/3}$ is bounded uniformly in ε, estimates can be obtained via a limiting process, e.g., the Γ-convergence presented in the next subsection. However, for arbitrarily large ℓ, this process may not work. For this reason, we shall not estimate $\rho^+(\varepsilon, \ell)$ directly for large ℓ. Instead, we estimate $\rho_*(\varepsilon, \ell)$ defined as follows:

$$\begin{gathered} \mathbf{K}^+(\ell) = \{(u, v)|\ u \in H^1(0, \ell), v'' - \gamma v = m - u, v' \ge 0 \ \text{ in } \ (0, \ell)\}, \\ E_*(\varepsilon, \ell) = \inf_{(u,v)\in\mathbf{K}^+(\ell)} \mathbf{E}(u, v, \varepsilon, \ell), \quad \rho_*(\varepsilon, \ell) = \frac{1}{\ell} E_*(\varepsilon, \ell). \end{gathered}$$

There are the relations, for every $\varepsilon > 0$, $\ell > 0$, and positive integer k,

$$\rho^+(\varepsilon, \ell) \ge \rho_*(\varepsilon, \ell) \ge \rho_*(\varepsilon, \ell/k). \tag{4.1}$$

Here the first inequality follows from the fact that the class $\mathbf{K}_N^+(\ell)$ of test functions for ρ^+ is a subset of the class $\mathbf{K}^+(\ell)$ of test functions for ρ_*. For the second inequality, one observes that any portion of a minimizer in $\mathbf{K}^+$ can be extracted to be used as a test function for smaller length intervals; more precisely, for any $(u,v) \in \mathbf{K}^+(\ell)$,

$$\begin{aligned}\frac{\mathbf{E}(u,v,\varepsilon,\ell)}{\ell} &\geq \frac{k}{\ell} \min_{0\leq j\leq k-1} \int_{j\ell/k}^{(j+1)\ell/k} \left\{ \frac{1}{2}u_x^2 + F(u) + \frac{1}{2}v_x^2 + \frac{\gamma}{2}v^2 \right\} dx \geq \frac{k}{\ell} E_* \left(\varepsilon, \frac{\ell}{k} \right) \\ &= \rho_* \left(\varepsilon, \frac{\ell}{k} \right).\end{aligned}$$

Note that (4.1) gives, for each fixed ε,

$$\inf_{\mu\geq 6} \rho^+(\varepsilon, \mu L_0 \varepsilon^{1/3}) \geq \inf_{\mu \geq 6} \rho_*(\varepsilon, \mu L_0 \varepsilon^{1/3}) = \min_{6\leq\mu\leq 12} \rho_*(\varepsilon, \mu L_0 \varepsilon^{1/3}). \tag{4.2}$$

In this manner, the estimate of $\rho^+(\varepsilon,\ell)$ for all $\ell \geq 6L_0\varepsilon^{1/3}$ can be obtained by estimating $\rho_*(\varepsilon, \mu L_0\varepsilon^{1/3})$ for all $\mu \in [6,12]$.

Finally, we remark that for every positive ε and ℓ, the energy functional $\mathbf{E}(\cdot,\cdot,\varepsilon,\ell)$ admits at least one global minimizer in each of the three function classes $\mathbf{K}_N^+(\ell)$, $\mathbf{K}^+(\ell)$, and $\mathbf{K}_N(\ell)$.

4.2. The Γ-convergence. The Γ-convergence was used by Modica [13] to the interfacial energy functional in the class of functions with prescribed average in arbitrary high space dimensions. This technique applies directly to the current situation if we impose

$$\int_0^\infty \sqrt{2F(s)}\, ds = \infty, \qquad \int_{-\infty}^0 \sqrt{2F(s)}\, ds = \infty. \tag{4.3}$$

Since this theory is elegant and the result is clean, we present it here under the above assumption. Though this is a very reasonable assumption, we still want to drop it. This will be done in the next subsection with a direct approach using neither assumption (4.3) nor the Γ-convergence. It is certainly not true that the Γ-convergence theory cannot be used without (4.3).

To set up the Γ-convergence, we use the scaling change

$$x = \ell\, y, \quad \ell = L\,\varepsilon^{1/3}, \quad \varepsilon = \epsilon\ell, \quad u(x) = U(y), \quad v(x) = \ell^2 V(y). \tag{4.4}$$

Then

$$\mathbf{E}(u,v,\varepsilon,\ell) \;=\; \varepsilon\Psi(U,V,\epsilon,L), \tag{4.5}$$

$$\Psi(U,V,\epsilon,L) := \int_0^1 \left\{ \frac{\epsilon}{2}U_y^2 + \frac{1}{\epsilon}F(U) \right\} dy + \frac{L^3}{2}\int_0^1 \left\{ V_y^2 + \gamma L^3 \epsilon V^2 \right\} dy, \tag{4.6}$$

where V satisfies $V_{yy} = m - U + \gamma L^3 \epsilon V$ in $(0,1)$.

Denote by (U^ϵ, V^ϵ) a global minimizer of $\Psi(\cdot,\cdot,\epsilon,L)$ in a space analogous to any one of $\mathbf{K}_N(\ell)$, $\mathbf{K}_N^+(\ell)$, or $\mathbf{K}^+(\ell)$. The energy upper bound (3.2) translates to

$$\Psi(U^\epsilon, V^\epsilon, \epsilon, L) < \sigma + \frac{L^3 m^2(1-m)^2}{6} \qquad \forall \epsilon > 0, L > 0.$$

For fixed $L > 0$, the right-hand side is independent of ϵ, so the $\epsilon \searrow 0$ limit can be studied to derive energy lower bounds. The key here is that the function $\tilde{U}^\varepsilon$ defined by

$$\tilde{U}^\epsilon(y) := \int_0^{U^\epsilon(y)} \sqrt{2F(s)} ds \qquad \forall y \in [0,1]$$

satisfies the estimate

$$\int_0^1 \left|\widetilde{U}^\epsilon_y(y)\right|dy = \int_0^1 \sqrt{2F(U^\epsilon)}\left|U^\epsilon_y\right|dy \leqslant \int_0^1 \left\{\frac{\epsilon}{2}U_y^{\epsilon 2} + \frac{1}{\epsilon}F(U^\varepsilon)\right\}dy < \sigma + \frac{L^3m^2(1-m)^2}{6}.$$

Since (U^ϵ, V^ϵ) are energy minimizers (in the space where at least $V^\epsilon_y \geq 0$), without using assumption (4.3) one can still show that there is at least one point at which U^ϵ takes a value in $[0,1]$. Indeed, if everywhere $U^\epsilon < 0$ or everywhere $U^\epsilon > 1$, then (i) if $L \geq 6L_0$, the interaction energy will be too large to allow (U^ϵ, V^ϵ) to be an energy minimizer (see the calculation later in this section), and (ii) if $L \in (0, 6L_0]$, one derives a similar contradiction after adding $\frac{(\bar{U}^\epsilon - m)^2}{2\epsilon\gamma}$ to the interfacial energy.

Thus, $\{\tilde{U}^\epsilon\}_{0<\epsilon<1}$ is a bounded family in the function space of bounded variations $(BV(0,1))$. Hence, along a subsequence, it converges pointwisely to a limit, say $\tilde{U}^0$, a BV function. In addition, along the sequence,

$$\liminf_{\epsilon\to 0}\int_0^1 \left\{\frac{\epsilon}{2}U_y^{\epsilon 2} + \frac{1}{\epsilon}F(U^\epsilon)\right\}dy \geq \sigma \int_0^1 |D\tilde{U}^0(y)|\,dy.$$

A pointwise convergence of $\tilde{U}^\epsilon$ implies a pointwise convergence of U^ϵ to a limit U^0. Furthermore, as $\int_0^1 F(U^\epsilon(y))dy < O(1)\epsilon$, by Fatou's lemma the limit U^0 satisfies

$$\int_0^1 F(U^0(y))dy = 0, \qquad \tilde{U}^0(y) = \int_0^{U^0(y)} \sqrt{2F(s)}ds \quad \forall\, y \in [0,1].$$

Under assumption (4.3), one infers from the uniform boundedness of $\tilde{U}^\varepsilon$ that $\{U^\epsilon\}$ is also uniformly bounded, and hence along the sequence converges to U^0 in L^2. Thus, almost everywhere, U^0 takes only two values, 0 and 1; that is, for some set $\Omega \subset [0,1]$, $U_0 = \chi_\Omega$ a.e.

The uniform bound on the energy provides a uniform bound on the L^2 norm of $\{V^\epsilon_y\}$ and the L^2 limit, $\lim_{\epsilon\to 0}(\gamma L^3 \epsilon V^\epsilon) = 0$. The uniform L^∞ bound on $\{U^\epsilon\}$ gives a uniform Lipschitz continuity of $\{V^\epsilon_y\}$. Hence, along a subsequence, $V^\epsilon_y \to W$ uniformly for some Lipschitz continuous function W. In conclusion,

$$U^0 = \chi_\Omega, \qquad W_y = m - \chi_\Omega,$$

$$\liminf_{\epsilon\to 0}\Psi(U^\epsilon, V^\epsilon, \epsilon, L) \geqslant \Psi^0(\bar{\Omega}, W, L) := \sigma\int_0^1 |D\chi_\Omega|dy + \frac{L^3}{2}\int_0^1 W^2(y)dy,$$

where $\int_0^1 |D\chi_\Omega|dy$ is the number of boundary points of Ω (after it is defined in a unique way). With a related reverse inequality established (which we omit here), the functional Ψ^0 is then called the Γ-limit of the original functional sequence $\{\Psi(\cdot,\cdot,\epsilon,\cdot)\}_{0<\epsilon<1}$; see [13] for more details.

For a given L, minimizers of Ψ^0 can be calculated explicitly.

1. First, we consider the functional in the class that corresponds to the original $\mathbf{K}^+$. This is the set

$$\mathbf{J}^+ := \{(\Omega, W) \in BV(0,1) \times H^1(0,1) \mid W_y = m - \chi_\Omega, W \geq 0\}.$$

Write $\Omega = \cup_{i=1}^{k_1}[c_i, d_i]$ and $\Omega^c = \cup_{i=1}^{k_0}(a_i, b_i)$, where $d_i < c_{i+1}$ and $b_i < a_{i+1}$. Note that

$$|k_0 - k_1| \le 1, \quad \int_0^1 |D\chi_\Omega| dy = k_0 + k_1 - 1.$$

On $[a_i, b_i]$, we integrate $W_y = m$ over $[a_i, y]$ to obtain $W(y) = W(a_i) + m(y - a_i) \geqslant m(y - a_i)$, so that $\int_{a_i}^{b_i} W^2 dy \ge \frac{1}{3} m^2 (b_i - a_i)^2$.

On $[c_i, d_i]$, we integrate $W_y = m - 1$ over $[y, d_i]$ to obtain $W(y) = W(d_i) + (1 - m)(d_i - y) \geqslant (1 - m)(d_i - y)$, so that $\int_{c_i}^{d_i} W^2 dy \ge \frac{1}{3}(1 - m)^2 (d_i - c_i)^3$. Thus,

$$\begin{aligned}
\int_0^1 W^2 dy &\geqslant \frac{m^2}{3} \sum_{i=1}^{k_0} (b_i - a_i)^3 + \frac{(1-m)^2}{3} \sum_{i=1}^{k_1} (d_i - c_i)^3 \\
&\geqslant \frac{m^2}{3k_0^2} \left(\sum_{i=1}^{k_0} (b_i - a_i) \right)^3 + \frac{(1-m)^2}{3k_1^2} \left(\sum_{i=1}^{k_1} (d_i - c_i) \right)^3 \\
&= \frac{m^2 (1 - |\Omega|)^3}{3k_0^2} + \frac{(1-m)^2 |\Omega|^3}{3k_1^2} \\
&\geqslant \min_{0 \le t \le 1} \left\{ \frac{m^2 t^3}{3k_0^2} + \frac{(1-m)^2 (1-t)^3}{3k_1^2} \right\},
\end{aligned}$$

where in the second inequality we have used $\sum e_i \le (\sum e_i^3)^{1/3} (\sum 1)^{2/3}$. The minimum is attained at $t = (1 - m)k_0/[mk_1 + (1 - m)k_0]$ so that

$$\int_0^1 W^2(y)\, dy \ge \frac{m^2 (1-m)^2}{3[mk_1 + (1-m)k_0]^2}. \tag{4.7}$$

Note that this estimate holds even if $k_0 = 0$ (e.g., $\Omega = [0, 1]$) or $k_1 = 0$ (e.g., $\Omega = \emptyset$). Thus,

$$\Psi^0(\Omega, W, L) \ge \sigma(k_0 + k_1 - 1) + \frac{L^3 m^2 (1-m)^2}{6[mk_1 + (1-m)k_0]^2}.$$

We remark that here the equality can be attained for any given k_0, k_1 satisfying $|k_0 - k_1| \leqslant 1 \leqslant k_1 + k_0$. Indeed, set $t = (1 - m)k_0/[mk_1 + (1 - m)k_0]$ and take (1) $a_1 = 0$ if $k_0 \ge k_1$ and $c_1 = 0$ if $k_0 < k_1$; (2) $b_i = a_i + l_0$, $l_0 := t/k_0$ for all i; (3) $d_i = c_i + l_1$, $l_1 := (1 - t)/k_1$ for all i; (4) $W = m(y - a_i)$ for all $y \in [a_i, b_i]$; and (5) $W(y) = (1 - m)(d_i - y)$ for all $y \in [c_i, d_i]$. Then W is a continuous function since $ml_0 = (1 - m)l_1$. For this particular choice, $(\Omega, W) \in \mathbf{J}^+$ and the above inequality is indeed an equality. Thus, for any $L > 0$,

$$\min_{\mathbf{J}^+} \Psi^0 = \min_{|p-q| \le 1 \le p+q} \left(\sigma(p + q - 1) + \frac{L^3 m^2 (1-m)^2}{6[mp + (1-m)q]^2} \right).$$

2. Next we consider the space that corresponds to the original space $\mathbf{K}_N^+$. This is the space

$$\mathbf{J}_N^+ := \{(\Omega, W) \in \mathbf{J}^+ \mid W(0) = W(1) = 0\}.$$

Suppose $(\Omega, W) \in \mathbf{J}_N^+$. Use the same notation as in the previous case. Note that $W(0) = 0$, $W \ge 0$, and $W_y = m - \chi_\Omega$ imply that $\Omega \subset [b, 1]$ for some $b > 0$. Similarly,

$W(1) = 0$ implies that $[c, 1] \subset \Omega$ for some $c < 1$. Hence, we must have $k_0 = k_1 \geq 1$. Thus, for every $L > 0$,

$$\min_{\mathbf{J}_N^+} \Psi^0 = \min_{k \geq 1} \left(\sigma(2k-1) + \frac{L^3 m^2 (1-m)^2}{6k^2} \right).$$

Remark 4.1. With a little extra work, i.e., constructing test functions for upper bounds, one can indeed prove the following: For every $\mu > 0$,

$$\lim_{\varepsilon \to 0} \frac{L_0}{\sigma \varepsilon^{2/3}} \rho_*(\varepsilon, \mu L_0 \varepsilon^{1/3}) = \min_{|p-q| \leq 1 \leq p+q} \left(\frac{p+q-1}{\mu} + \frac{\mu^2}{2[pm + (1-m)q]^2} \right),$$
$$\lim_{\varepsilon \to 0} \frac{L_0}{\sigma \varepsilon^{2/3}} \rho^+(\varepsilon, \mu L_0 \varepsilon^{1/3}) = \min_{k \geq 1} \left(\frac{2k-1}{\mu} + \frac{\mu^2}{2k^2} \right),$$
$$\lim_{\varepsilon \to 0} \frac{L_0}{\sigma \varepsilon^{2/3}} \rho(\varepsilon, \mu L_0 \varepsilon^{1/3}) = \min_{n \geq 1} \left(\frac{n}{\mu} + \frac{\mu^2}{2n^2} \right).$$

We leave the details to interested readers.

When condition (4.3) is dropped, we face technical difficulties on the convergence of $\{U^\epsilon\}$ and the equation $V^\epsilon_{yy} = m - U^\epsilon + \gamma L^3 \epsilon V^\epsilon$. Though these difficulties could be overcome by establishing a uniform L^∞ bound of $\{U^\epsilon\}$, we prefer to present another approach.

4.3. Assumption (4.3) dropped. Let $\delta \in (0, 1/2)$ be any small positive number. Define

$$\sigma^\delta := \int_\delta^{1-\delta} \sqrt{2F(s)} ds, \qquad A(\delta) = \sup_{0<s<1-\delta} \frac{s}{\sqrt{F(s)}} + \sup_{\delta<s<1} \frac{1-s}{\sqrt{F(s)}}.$$

Since $F''(0) > 0 = F(0) = F'(0)$ and $F''(1) > 0 = F(1) = F'(1)$, $A(\delta)$ is bounded.

LEMMA 4.1. *Assume* (1.3) *only. Suppose $U \in H^1(0,1)$, V satisfies $V_{yy} = m - U + \gamma L^3 \epsilon V$, and $V_y \geq 0$ on $[0,1]$. Then, for every $\delta \in (0, 1/2)$ there exist non-negative integers k_0, k_1, and k such that $k_0 + k_1 \leqslant k+1$, $|k_0 - k_1| \leqslant 1$, and*

$$(k+1)\sigma^\delta \geqslant \int_0^1 \left\{ \frac{\epsilon}{2} U_y^2 + \frac{1}{\epsilon} F(U) \right\} dy > k\sigma^\delta, \tag{4.8}$$

$$\int_0^1 (V_y^2 + \gamma \epsilon L^3 V^2) dy + \frac{1}{4} \gamma L^3 \epsilon + A\sqrt{(k+1)\sigma\epsilon} \geqslant \frac{m^2(1-m)^2}{3[mk_1 + (1-m)k_0]^2}. \tag{4.9}$$

Proof. The idea is to approximate the equation for V by $V_{yy} \geqslant m -$ error in one set Ω_0, and $V_{yy} \leqslant m - 1 +$ error in the other set Ω_1, where the error terms are either positively small or negative. The numbers k_0 and k_1 of disjoint pieces of Ω_0 and Ω_1 are taken as small as possible so that after integration V_y will not be underestimated too much.

We are only interested in the case $U \not\equiv 0$ and $U \not\equiv 1$. Then (4.8) defines a unique nonnegative integer k. Set $y_0 = 0$, $y_{k+1} = 1$. When $k > 0$, define $y_1, \ldots, y_k$ by

$$j\sigma^\delta = \int_0^{y_j} \left\{ \frac{\epsilon}{2} U_y^2 + \frac{1}{\epsilon} F(U) \right\} dy \qquad \forall\, j = 1, \ldots, k.$$

Then for each $j = 0, \dots, k$, either $U \geq \delta$ on $[y_j, y_{j+1}]$ or $U \leq 1-\delta$ on $[y_j, y_{j+1}]$, since

$$\int_\delta^{1-\delta} \sqrt{2F(s)}ds = \sigma^\delta \geqslant \int_{y_j}^{y_{j+1}} |U_y|\sqrt{2F(U)}dy.$$

Now define

$$\Omega_0 = \Big\{[y_j, y_{j+1}] \mid U \leq 1-\delta \text{ on } \ [y_j, y_{j+1}]\Big\} =: \cup_{i=1}^{k_0}[a_i, b_i], \quad \Big(b_i < a_{i+1}\Big),$$
$$\Omega_1 = [0,1] \setminus \Big(\cup_{i=1}^{k_0}(a_i, b_i)\Big) =: \cup_{i=1}^{k_1}[c_i, d_i], \quad \Big(d_i < c_{i+1}\Big).$$

Note that each maximal connected component of Ω_0 or Ω_1 is one interval or a union of several consecutive intervals of $[y_j, y_{j+1}]$ so that $k_0 + k_1 \leq k+1$. Also, maximal connected components of Ω_0 and Ω_1 interlace each other so that $|k_0 - k_1| \leqslant 1$. Furthermore, $U \leq 1-\delta$ on Ω_0 and $U \geqslant \delta$ on Ω_1. Hence,

$$U \leq A(\delta)\sqrt{F(U)} \ \text{ on } \ \Omega_0, \qquad 1 - U \leq A(\delta)\sqrt{F(U)} \ \text{ on } \ \Omega_1.$$

Pick any maximal connected component $[a_i, b_i]$ of Ω_0. Integrating $V_{yy} = m - U + \gamma L^3 \epsilon V$ over $[a_i, y]$, $y \in [a_i, b_i]$ gives

$$V_y(y) = m(y - a_i) + \Bigg\{V_y(a_i) + \int_{a_i}^{y}(\gamma L^3\epsilon V - U)\Bigg\}. \tag{4.10}$$

First squaring both sides and then using $V_y(a_i) \geqslant 0$ and $U \leqslant A(\delta)\sqrt{F(U)}$ we obtain

$$\begin{aligned} V_y^2(y) &\geqslant m^2(y-a_i)^2 + 2m(y-a_i)\left(V_y(a_i) + \int_{a_i}^{y}(\gamma L^3\epsilon V - U)\right) \\ &\geqslant m^2(y-a_i)^2 - 2m(y-a_i)\int_{a_i}^{b_i}\Big\{\gamma L^3\epsilon|V| + A(\delta)\sqrt{F(U)}\Big\}, \end{aligned}$$
$$\int_{a_i}^{b_i} V_y^2 dy \geqslant \frac{m^2}{3}(b_i - a_i)^3 - m\int_{a_i}^{b_i}\Big\{\gamma L^3\epsilon|V| + A\sqrt{F(U)}\Big\}dy.$$

Similarly, for any interval $[c_i, d_i]$ of Ω_1, we integrate the equation for V over $[y, d_i]$ for $y \in [c_i, d_i]$ to obtain $V_y(y) = (1-m)(d_i - y) + V_y(d_i) + \int_y^{d_i}(U - 1 - \gamma L^3\epsilon V)$ and

$$\int_{c_i}^{d_i} V_y^2 dy \geqslant \frac{(1-m)^2}{3}(d_i - c_i)^3 - (1-m)\int_{c_i}^{d_i}\Big\{\gamma L^3\epsilon|V| + A\sqrt{F(U)}\Big\}.$$

Now adding them up we obtain

$$\int_0^1 V_y^2 dy \geq \frac{m^2}{3}\sum_{i=1}^{k_0}(b_i - a_i)^3 + \frac{(1-m)^2}{3}\sum_{i=1}^{k_1}(d_i - c_i)^3 - \int_0^1\Big\{\gamma L^3\epsilon|V| + A\sqrt{F(U)}\Big\}dy.$$

The first two sums can be estimated from below by the right-hand side of (4.7), whereas the integral can be estimated by

$$\int_0^1\Big\{\gamma L^3\epsilon|V| + A\sqrt{F(U)}\Big\}dy \leqslant \tfrac{1}{4}\epsilon\gamma L^3 + \int_0^1 \gamma\epsilon L^3 V^2 + \sqrt{\epsilon}A\sqrt{(k+1)\sigma},$$

since $\int_0^1 \sqrt{F}dy \leq \sqrt{\int_0^1 F dy} \leq \sqrt{(k+1)\sigma\epsilon}$. This completes the proof. $\square$

4.4. Energy lower bounds. Now we are ready to calculate explicitly energy lower bounds. Depending on the size of $\mu := L/L_0$ we consider three cases.

Case I. $\mu = L/L_0 = \ell/[L_0\varepsilon^{1/3}] \in [6, 12]$.

Let (u, v) be a minimizer of $\mathbf{E}(\cdot, \cdot, \varepsilon, \ell)$ in $\mathbf{K}^+(\ell)$ so that $\mathbf{E}(u, v, \varepsilon, \ell) = \rho_*(\varepsilon, \ell)$.

Define (U, V) as in (4.4). Applying Lemma 4.1, we obtain (4.8) and (4.9) for some integers k, k_1, k_0 satisfying $k_0 + k_1 \leqslant k + 1$, $|k_0 - k_1| \leqslant 1$. Translating to (u, v) (recalling $L = \mu L_0$, $m^2(1-m)^2 = 3\sigma/L_0^3$, $\epsilon = \varepsilon^{2/3}/(\mu L_0)$) we obtain

$$\frac{L_0\mathbf{E}(u,v,\varepsilon,\ell)}{\sigma\ell\varepsilon^{2/3}} + \frac{\mu^2 L_0^3}{2\sigma}\left\{A(\delta)\sqrt{\tfrac{(k+1)\sigma}{\mu L_0}}\varepsilon^{1/3} + \frac{\gamma\mu^2 L_0^2\varepsilon^{2/3}}{4}\right\} + \frac{k(\sigma-\sigma^\delta)}{\sigma\mu}$$

$$\geqslant \frac{k}{\mu} + \frac{\mu^2}{2[mk_1 + (1-m)k_0]^2}\ . \tag{4.11}$$

There are two cases to consider: (i) $k \le 5$, (ii) $k \ge 6$.

(i) $k \le 5$. Then $k_0 \le 3$ and $k_1 \le 3$, so that the right-hand side of (4.11) is $\ge \mu^2/18 \ge 2$.

(ii) $k \ge 6$. Then using $\max\{k_0, k_1\} \le \frac{k}{2}+1$ and $a + \frac{1}{2}b \ge \frac{3}{2}(a^2b)^{1/3}$, the right-hand side of (4.11) is no smaller than $\frac{3}{2}l(\frac{k^2}{(k+1/2)^2})^{1/3} \geqslant (\frac{243}{32})^{1/3}$.

Thus, in both cases the right-hand side of (4.11) is $\ge (\frac{243}{32})^{1/3} > \sqrt[3]{7}$. Taking δ small we see that for all sufficiently small positive ε,

$$\frac{L_0}{\sigma\varepsilon^{2/3}}\rho_*(\varepsilon, \mu L_0\varepsilon^{1/3}) > \sqrt[3]{7} \quad \forall \mu \in [6, 12]. \tag{4.12}$$

Case II. $\mu = L/L_0 = \ell/(L_0\varepsilon^{1/3}) \in [\sqrt[3]{4}, 6]$.

Let (u, v) be a minimizer of $\mathbf{E}$ in $\mathbf{K}_N^+(\ell)$. We claim that in (4.11) we can have $k_1 = k_0$ (and $k \ge k_0 + k_1 - 1 = 2k_0 - 1$), at a cost of at most an $O(\epsilon)$ term added.

Suppose $k_0 > k_1$. Then $k_0 = k_1 + 1$. This implies that $b_{k_0} = 1$. Since $V'(1) = 0$, (4.10) with $y = 1$ gives

$$\begin{aligned} 0 &= m(1 - a_{k_0}) + V_y(a_{k_0}) + \int_{a_{k_0}}^1 (\gamma L^3\epsilon V - U) \\ &\geqslant m(1 - a_{k_0}) - \int_{a_{k_0}}^1 \Big\{\gamma L^3\epsilon|V| + A(\delta)\sqrt{F(U)}\Big\}. \end{aligned}$$

After using the Hölder inequality

$$\int_{a_{k_0}}^1 (\gamma L^3\epsilon|V| + A\sqrt{F}) \le \sqrt{(1 - a_{k_0})\int_{a_{k_0}}^1 \{\gamma L^3\epsilon|V| + A\sqrt{F}\}^2},$$

we then obtain

$$m^2(1 - a_{k_0}) \le \int_{a_{k_0}}^1 \Big\{\gamma L^3\epsilon|V| + A\sqrt{F}\Big\}^2 \le 2\epsilon\int_0^1 \Big\{\gamma^2 L^6\epsilon V^2 + \frac{A^2}{\epsilon}F(U)\Big\}\,dy = O(1)\epsilon.$$

Thus, the component $[a_{k_0}, b_{k_0}] = [a_{k_0}, 1]$ has length of size $O(1)\epsilon$. In the estimation in deriving the right-hand side of (4.7), we redo the estimate for the first term by

$$\begin{aligned} \sum_{i=1}^{k_0}(b_i - a_i)^3 &\ge \sum_{i=1}^{k_0-1}(b_i - a_i)^3 \ge \frac{1}{(k_0-1)^2}\left(\sum_{i=1}^{k_0-1}(b_i - a_i)\right)^3 \\ &= \frac{m^2(|\Omega_0| - (1 - a_{k_0}))^3}{3(k_0-1)^2} = \frac{m^2|\Omega_0|^3}{3(k_0-1)^2} + O(1)\epsilon. \end{aligned}$$

Hence, k_0 in (4.11) can be replaced by $k_0 - 1$, with the cost of adding a term of order $O(1)\epsilon = O(1)\varepsilon^{2/3}$. The case $k_1 > k_0$ can be similarly treated.

We remark that we are working on a finite range of $\mu \in [1/2, 12]$, so all k_0 and k_1 cannot be too large, e.g., ≥ 12, since otherwise interfacial energy $k\sigma^\delta\epsilon$ alone will be large enough to eliminate the possibility. Hence, all $O(1)$ may depend on k, but it is irrelevant.

Once we know $k_0 = k_1$, (4.11) can be expressed simply as

$$\frac{L_0}{\sigma\varepsilon^{2/3}}\rho^+(\varepsilon, \mu L_0\varepsilon^{1/3}) + O(1)\varepsilon^{1/3} + O(1)(\sigma - \sigma^\delta) \geq \frac{2k_0 - 1}{\mu} + \frac{\mu^2}{2k_0^2}.$$

If $k_0 = 1$, then the right-hand side is $\geq \frac{1}{\mu} + \frac{\mu^2}{2} \geq \sqrt[3]{\frac{27}{4}}$ since $\mu \geq \sqrt[3]{4}$.

If $k_0 \geq 2$, then by $a + \frac{1}{2}b \geq \frac{3}{2}(a^2b)^{1/3}$, the right-hand side is $\geqslant \frac{3}{2}(1 - 1/k_0)^{2/3} \geq \sqrt[3]{\frac{243}{32}} > \sqrt[3]{7}$.

In any case, the right-hand side is $\geq \sqrt[3]{27/4} > \sqrt[3]{6}$. Thus, for all sufficiently small positive ε,

$$\frac{L_0}{\sigma\varepsilon^{2/3}}\rho^+(\varepsilon, \mu L_0\varepsilon^{1/3}) > \sqrt[3]{6} \qquad \forall\, \mu \in [\sqrt[3]{4}, 6]. \tag{4.13}$$

Proof of (1.8). The estimate for $\mu \leq 1/4$ follows from Lemma 2.1 since we have

$$\frac{L_0}{\sigma\varepsilon^{2/3}}\rho^+(\varepsilon, \ell) \geq \frac{L_0}{\sigma\varepsilon^{2/3}}\rho(\varepsilon, \ell) \geq \min\left\{\frac{c_1 L_0}{\sigma\varepsilon^{2/3}}, \frac{1}{2\mu}\right\},$$

where c_1 is a constant depending only on m and F. The estimate for $\mu \geq \sqrt[3]{4}$ follows from (4.2), (4.12), and (4.13).

Case III. $\mu = L/L_0 = \ell/(L_0\varepsilon^{1/3}) \in [\frac{1}{16}, \sqrt[3]{5}]$.

Let (u, v) be a minimizer of $\mathbf{E}$ in $\mathbf{K}_N^+(\ell)$. The same consideration as above leads to the conclusion that (4.11) holds with $k_0 = k_1$. From the energy upper bound, we conclude that we must have $k = k_0 = k_1 = 1$, and the total energy is $\mathbf{E}(u, v, \varepsilon, \ell) \geq [\sigma\varepsilon + \ell^3 m^2(1 - m)^2/6](1 - o(1))$. As the energy upper bound differs from the energy lower bound by a tiny fraction, the separate lower bound estimates on the interfacial and potential energy in Lemma 4.1 then give us

$$\int_0^\ell \left\{\frac{\varepsilon}{2}u_x^2 + \frac{1}{\varepsilon}F(u) + \frac{1}{2\gamma\varepsilon}(\bar{u} - m)^2\right\} dx = \sigma + o(1), \tag{4.14}$$

$$\frac{1}{\ell^3}\int_0^\ell \left\{v_x^2 + \gamma(v - \bar{v})^2\right\} dx = \frac{1}{3}m^2(1 - m)^2 + o(1). \tag{4.15}$$

Furthermore, after checking the lower bound estimation that leads to the right-hand side of (4.7), we conclude that we must have $b_1 = c_1 = 1 - m + o(1)$. Namely,

$$u = \begin{cases} o(1) & \text{in } [0, (1 - m - o(1))\ell], \\ 1 - o(1) & \text{in } [(1 - m + o(1))\ell, \ell], \end{cases} \tag{4.16}$$

$$v_x = \begin{cases} [m + o(1)]x & \text{in } [0, (1 - m)\ell], \\ -(1 - m + o(1))(x - \ell) & \text{in } [(1 - m)\ell, \ell]. \end{cases} \tag{4.17}$$

5. Certain quantitative estimates for minimizers. To complete the proof of Theorem 1, it remains to show its parts 2 and 3. The rest of this paper is devoted to this task. Hence, in what follows we always assume that

$$0 < \varepsilon \ll 1, \qquad \tfrac{1}{16}\, L_0 \varepsilon^{1/3} \le \ell \le \sqrt[3]{5}\, L_0 \varepsilon^{1/3}. \tag{5.1}$$

Our plan is as follows. First, in this section we provide certain quantitative estimates for energy minimizers in $\mathbf{K}_N^+(\ell)$. In particular, we show that any two minimizers are at most $O(\ell^4)$ apart. In the next section, we study the principal eigenvalue of the linearized operator around any minimizer. We show that the eigenvalue is bigger than $c\ell^2$ for some c independent of ε. As a consequence, energy minimizers are unique. Once we have the uniqueness, we can differentiate the solution with respect to ℓ to calculate the derivatives of E^+ and ρ^+ with respect to ℓ, and show that E^+ and ρ^+ are convex in ℓ in the range specified in (5.1).

5.1. The Euler–Lagrange equation. In what follows, differentiation with respect to x will be denoted by $'$. Also, (u, v) is always a global minimizer of $\mathbf{E}(\cdot,\cdot,\varepsilon,\ell)$ in $\mathbf{K}_N^+(\ell)$ with ℓ in the range specified in (5.1). Since $\mathbf{K}_N^+(\ell)$ is not an open set, that (u, v) satisfies the Euler–Lagrange equation is not obvious.

LEMMA 5.1. *Let (u, v) be a minimizer of $\mathbf{E}$ in $\mathbf{K}_N^+(\ell)$. Then $v' > 0$ in $(0,\ell)$, $v''(0) > 0 > v''(\ell)$, and (u, v) satisfies the Euler–Lagrange system*

$$\begin{cases} \varepsilon^2 u'' = f(u) + v \quad \text{in} \quad (0,\ell),\\ v'' = m + \gamma v - u \quad \text{in} \quad (0,\ell),\\ u'(0) = v'(0) = u'(\ell) = v'(\ell) = 0. \end{cases}$$

Furthermore, for all $\phi \in H^1(0,\ell)$ and $\psi = \mathbf{K}_N^\ell \phi$,

$$\int_0^\ell \left\{ \varepsilon^2 \phi'^2 + f_u(u)\phi^2 + \frac{1}{\gamma}\bar{\phi}^2 + \psi'^2 + \gamma(\psi - \bar{\psi})^2 \right\} dx \ge 0. \tag{5.2}$$

Proof. We shall start from the elementary estimates (4.14)–(4.17).

(a) Note that γv is small since (i) (4.17) gives $v' = O(\ell)$, (ii) $\gamma \bar{v} = \bar{u} - m$ (obtained by integrating $v'' - \gamma v = m - u$), and (iii) the energy upper bound and (1.5) give $m - \bar{u} = O(\sqrt{\varepsilon/\ell})$.

(b) As long as we know that γv is small, we immediately conclude that $v''(0) = m + \gamma v - u = m + o(1)$ and $v''(\ell) = m + \gamma v - u = m - 1 + o(1)$. Together with (4.17), we have $v''(0) > 0 > v''(\ell)$ and $v' > 0$ in $(0,\ell)$. This will allow us to do the standard calculus of variation.

(c) For every $\phi \in H^1(0,\ell)$, consider the test function

$$\tilde{u} = u + t\phi, \quad \tilde{v} = v + t\psi, \quad \psi := \mathbf{K}_N^\ell \phi = \tfrac{1}{\gamma}\bar{\phi} + \mathbf{K}_N^\ell(\phi - \bar{\phi}).$$

Here $\mathbf{K}_N^\ell$ is the operator defined in (3.1). This operator is uniquely defined for $\gamma > 0$. When $\gamma = 0$, it is defined only for functions of zero mean, and ψ is unique up to an additive constant. Hence, here we use $\bar{\phi}/\gamma$ to denote such an additive constant when $\gamma = 0$.

Note that $\|\psi\|_{C^2}$ is bounded and $\psi'(0) = \psi'(\ell) = 0$. Since $v_x > 0$ in $(0, \ell)$ and $v''(0) > 0 > v''(\ell)$, it follows that $(\tilde{u}, \tilde{v}) \in \mathbf{K}_N^+(\ell)$ if $|t|$ is small enough. Hence,

$$0 = \frac{d}{dt}\mathbf{E}(u + t\phi, v + t\psi, \varepsilon, \ell)\Big|_{t=0} = \int_0^\ell \Big\{\varepsilon^2 u'\phi' + f(u)\phi + v'\psi' + \gamma v\psi\Big\}$$
$$= \varepsilon^2 u'\phi\Big|_0^\ell + \int_0^\ell \Big\{-\varepsilon^2 u'' + f(u) + v\Big\}\phi\, dx$$

after integrating by parts and using equation $-\psi'' + \gamma\psi = \phi$. This integral identity implies that u is a weak solution to $\varepsilon^2 u'' = f(u) + v$ in $(0, \ell)$ with the natural boundary condition $u'(0) = u'(\ell) = 0$. Since (u, v) is bounded, (u, v) is a classical solution.

(d) Finally, since (u, v) is a minimizer, $\frac{d^2}{dt^2}\mathbf{E}(u + t\phi, v + t\psi, \varepsilon, \ell)|_{t=0} \geq 0$, which is equivalent to (5.2). □

Once we have the Euler–Lagrange equation, we can estimate the L^∞ bound of v. First of all, from the equation for u we derive that

$$\bar{v} = -\frac{1}{\ell}\int_0^\ell f(u)dx = \frac{1}{\ell}\int_0^\ell O(\sqrt{F(u)})dx$$
$$= O(1)\ell^{-1/2}\left(\int_0^\ell F(u)dx\right)^{1/2} = O(1)\ell^{-1/2}\varepsilon^{1/2} = O(\ell).$$

Here we used the fact that $u \in [-o(1), 1 + o(1)]$ and that

$$\sup_{s\in[-1,2]\setminus\{0,1\}} \frac{|f(s)|}{\sqrt{F(s)}} < \infty.$$

Since $\|v'\|_{L^2}^2 = O(\varepsilon)$, we conclude that $\|v\|_{L^\infty} = O(\ell)$. Improvements will be made later.

5.2. The profile of **.** Note that

$$\frac{d}{dx}\Big(\tfrac{1}{2}\varepsilon^2 u'^2 - F(u) - \tfrac{\gamma}{2}v^2 + vv'' - \tfrac{1}{2}v'^2\Big) = 0. \tag{5.3}$$

After integration we see that $\frac{1}{2}\varepsilon^2 u'^2 = F(u) + o(1)$. Hence, for any fixed small positive δ and ε sufficiently small, $|u'| > 0$ whenever $\delta < u < 1 - \delta$. Since u has only one layer, it follows that $u' > 0$ whenever $\delta < u < 1 - \delta$. In summary, we have the following basic estimate.

LEMMA 5.2. *In* $[0, \ell]$, $v = o(1)$, $\varepsilon u' = \sqrt{2F(u)} + o(1)$, *and there exists a unique* $z = (1 - m + o(1))\ell$ *such that*

$$u(z) = Q(0), \qquad u(x) = Q\Big(\frac{x - z}{\varepsilon}\Big) + o(1) \quad \forall x \in [0, \ell].$$

5.3. A relation between the tails of **and** **.** Away from the interface $x = z$, we expect $f(u) + v = \varepsilon^2 u'' = O(\varepsilon^2)$. Thus, formally $u \sim f^{-1}(-v)$, where f^{-1} represents the inverse of f near 0 or 1. To make this statement more precise, we introduce below functions h_0 and h_1, which will later be shown to be exponentially $O(e^{-c|x-z|/\varepsilon})$ close to $u - Q$.

LEMMA 5.3. *For each* $i = 0$ *and* $i = 1$ *there exists a unique solution* h_i *to*

$$\begin{cases} \varepsilon^2 h_i'' = f(h_i) + v & \text{in } (0, \ell), \\ h_i'(0) = h_i'(\ell) = 0, \ h_i = i + O(v). \end{cases} \tag{5.4}$$

In addition, h_i satisfies the following estimates:

$$f(h_i) + v = O(\varepsilon^2), \quad h_i' = O(\ell), \quad h_i'' = O(1) \qquad \text{on } [0, \ell].$$

Proof. Denote by f_i^{-1} the inverse of f near $i = 0$ or $i = 1$. As $v = o(1)$, $v'(0) = v'(\ell) = 0$, and $v'' = O(1)$, it is easy to show that for some large enough constant M, $f_i^{-1}(-v) \pm M\varepsilon^2$ is a super- or sub-solution. As $f'(0) > 0$ and $f'(1) > 0$, it then follows from a standard elliptic theory that (5.4) admits a unique solution and the solution satisfies $|h_i - f_i^{-1}(-v)| \le M\varepsilon^2$ on $[0, \ell]$. Consequently, $\varepsilon^2 h_i'' = f(h_i) + v = O(\varepsilon^2)$ so that $h_i'' = O(1)$, which implies, as $h_i'(0) = 0$, that $h_i' = O(\ell)$. ◻

LEMMA 5.4. *Let θ, h be defined as*

$$\theta(x) = u(x) - \begin{cases} h_0(x), & x \in (0, z), \\ h_1(x) - 1, & x \in (z, \ell], \end{cases} \qquad h(x) = \begin{cases} h_0(x), & x \in (0, z), \\ h_1(x), & x \in (z, \ell]. \end{cases}$$

Then

$$\text{(5.5)} \qquad \begin{cases} \varepsilon^2 \theta'' - f(\theta) = [O(v) + O(\varepsilon^2)]\theta(1 - \theta) & \text{in } [0, \ell] \setminus \{z\}, \\ \theta'(0) = 0 = \theta'(\ell), \\ \theta(z\pm) = Q(0) + O(v(z)) + O(\varepsilon^2). \end{cases}$$

Proof. The boundary conditions of θ at 0 and ℓ follow from that of u and h_i. The condition at $z\pm$ follows from the fact that $u(z) = Q(0)$ and $h_i = f_i^{-1}(-v) + O(\varepsilon^2) = i + O(v) + O(\varepsilon^2)$.

For $x \in [0, z-]$, $\theta = u - h_0$ and thus $\varepsilon^2\theta'' = \varepsilon^2(u'' - h_0'') = f(\theta + h_0) - f(h_0)$. Note that

$$f(\theta + h_0) - f(h_0) - f(\theta) = \int_0^\theta \int_0^{h_0} f_{uu}(\xi + \eta)\, d\eta\, d\xi = O(1) h_0 \theta.$$

The assertion for $x \in [0, z-]$ thus follows. The case $x \in [z+, \ell]$ is similar. ◻

Note that (5.5) shows that $\theta(x)$ is very close to $Q = Q((x - z)/\varepsilon)$. The following lemma shows that θ is similar to Q.

LEMMA 5.5. *For all $x \in (0, z-] \cup [z+, \ell)$, we have $0 < \theta(x) < 1$, $\theta'(x) > 0$, and*

$$\varepsilon\theta' = [1 + O(v(z)) + O(\varepsilon\ell \ln(\theta - \theta^2))]\sqrt{2(F(\theta) - F(\theta_i))} \quad \forall x \in [0, z-] \cup [z+, \ell],$$
$$\theta(1 - \theta) = O(1) e^{-c|x - z|/\varepsilon} \quad \forall x \in [0, \ell],$$

where $\theta_i = \theta(0)$ if $x < z$, $\theta_i = \theta(\ell)$ if $x > z$, and $c = \frac{1}{2}\min\{\sqrt{f'(0)}, \sqrt{f'(1)}\}$.

Note that the assertion implies that u is exponentially $O(e^{-c|x-z|/\varepsilon})$ close to h, which has expansion $h = f^{-1}(-v) + O(\varepsilon^2)$.

Proof. Since $f'(0) > 0$ and $f'(1) > 0$, it is easy to see from equation $\varepsilon^2\theta'' = f(\theta) + o(1)\theta(1 - \theta)$ that $0 < \theta < 1$ and $\theta' > 0$ in $(0, z-] \cup [z+, \ell)$.

For $x \in [0, z-]$, we have

$$\frac{1}{2}\varepsilon^2\theta'^2 = \int_0^x \Big\{ f(\theta) + [O(v) + O(\varepsilon^2)]\theta \Big\} \theta' = [1 + o(1)][F(\theta) - F(\theta(0))]$$

by the mean value theorem $\int_a^b A(x)B(x)dx = A(\xi)\int_a^b B(x)dx$ (for $B \ge 0$) and the fact that there exist positive constants c_1 and c_2 such that $c_1^2(s^2 - \hat{s}^2) \le 2(F(s) -$

$F(\hat{s})) \le c_2^2(s^2 - \hat{s}^2)$ for all $\hat{s} \in (0, \delta]$ and $s \in (\hat{s}, Q(0) + \delta]$ (for fixed small positive δ). Consequently,

$$c_1\sqrt{\theta^2 - \theta(0)^2} \le \varepsilon\theta' \le c_2\sqrt{\theta^2 - \theta(0)^2}.$$

Dividing both sides by $\sqrt{\theta^2 - \theta(0)^2}$ and integrating over $[x, z]$ then gives

$$c_1(z - x) \le \varepsilon \ln \frac{\theta(z) + \sqrt{\theta^2(z) - \theta^2(0)}}{\theta(x) + \sqrt{\theta^2(x) - \theta^2(0)}} \le c_2(z - x).$$

This gives us

$$z - x = O(\varepsilon \ln \theta), \qquad \theta = O(e^{-c_1(z-x)/\varepsilon}).$$

Using $v(x) = v(z) + \int_z^x v' = v(z) + O(\ell)(x - z) = v(z) + O(\varepsilon\ell \ln \theta)$, we then obtain

$$\begin{aligned}\tfrac{1}{2}\varepsilon^2\theta'^2 &= \int_{\theta(0)}^{\theta(x)} \Big\{ f(\theta) + O(v(z))\theta + O(\varepsilon\ell\theta \ln \theta) \Big\}\, d\theta \\ &= [1 + O(v(z)) + O(\varepsilon\ell \ln \theta)][F(\theta) - F(\theta(0))].\end{aligned}$$

After taking the square root and using $O(\ln \theta) = O(\ln[\theta - \theta^2])$, we obtain the assertion of the lemma for $x \in [0, z-]$. The proof for the case $x \in [z+, \ell]$ is similar and is omitted. ∎

5.4. The value ( ). Usually one writes $u = Q + \phi$ and solves ϕ iteratively from the equation $-\varepsilon^2\phi'' + f_u(Q)\phi = -v + O(\phi^2)$. This equation has a small amplitude solution if and only if the right-hand side is (almost) orthogonal to Q', which renders to a small value of $v(z)$ since $Q' = 1/\varepsilon\dot{Q}((x - z)/\varepsilon)$ is similar to a Delta function; see, e.g., Ren and Wei [24]. In this approach, an accurate enough, say $O(\varepsilon^{1/2})$, a priori estimate on ϕ is needed to control the $O(\phi^2)$ term; also, rigorous higher order expansions are needed for more accurate results, which requires higher order differentiability of F. Here we replace Q by θ and take an approach where the a priori estimate on ϕ is replaced by that of $h \approx f^{-1}(-v)$. The key is to carry out the computation that v is almost orthogonal to $Q' \sim \theta'$.

LEMMA 5.6. *For C_0 defined as in (5.8) below, $v(z) = C_0\varepsilon^2 + O(\varepsilon^2\ell^2)$.*

Proof. For $x \ne z$ we have $\theta' = u' - h'$ and $v = \varepsilon^2 u'' - f(u) = \varepsilon^2 h'' - f(h)$. Hence,

$$\begin{aligned}\int_{[0,\ell]\setminus\{z\}} \theta' v &= \int_{[0,\ell]\setminus\{z\}} \{u'(\varepsilon^2 u'' - f(u)) - h'(\varepsilon^2 h'' - f(h))\} \\ &= [F(h) - F(u)]\Big|_0^\ell + \Big(\tfrac{1}{2}\varepsilon^2 h'^2 - F(h)\Big)\Big|_{z-}^{z+} \\ &= O(\varepsilon^2\ell^2 + v^2(z)),\end{aligned} \tag{5.6}$$

since $1 - \theta(\ell) = O(e^{-c\ell/\varepsilon})$, $\theta(0) = O(e^{-c\ell/\varepsilon})$, $h_i' = O(\ell)$, and $F(h(z\pm)) = O((|v(z)| + \varepsilon^2)^2)$.

On the other hand, integration by parts twice gives

$$\begin{aligned}\int_{[0,\ell]\setminus\{z\}} \theta' v = v(z)\left\{ \theta\Big|_0^{z-} + (\theta - 1)\Big|_{z+}^{\ell} \right\} - v'(z)\left\{ \int_0^z \theta + \int_z^\ell (\theta - 1) \right\} \\ + \int_0^z v'' \int_0^x \theta + \int_z^\ell v'' \int_\ell^x (\theta - 1) + \theta(0)v\Big|_0^z + (\theta(\ell) - 1)v\Big|_z^\ell.\end{aligned} \tag{5.7}$$

First, $\{\theta|_0^{z-} + (\theta-1)|_{z+}^{\ell}\} = 1 + O(v(z)) + O(\varepsilon^2)$. Second,

$$\int_0^z \theta = \varepsilon \int_{\theta(0)}^{\theta(z-)} \frac{\theta}{\varepsilon\theta'} d\theta = \varepsilon \int_{\theta(0)}^{\theta(z-)} \frac{[1 + O(v(z)) + O(\varepsilon\ell \ln(s-s^2))]s}{\sqrt{2F(s) - 2F(\theta(0))}} ds$$
$$= \varepsilon \int_0^{Q(0)} \frac{s}{\sqrt{2F(s)}} ds + O(\varepsilon v(z)) + O(\varepsilon^2 \ell),$$

since $\theta(z-) = Q(0) + O(v(z)) + O(\varepsilon^2)$. After a similar estimate for $\int_z^\ell (1-\theta)$ we derive that

$$\int_0^z \theta(x)dx + \int_z^\ell (\theta(x)-1)dx = \varepsilon \left(\int_0^{Q(0)} \frac{s}{\sqrt{2F(s)}} ds + \int_{Q(0)}^1 \frac{s-1}{\sqrt{2F(s)}} ds \right)$$
$$+ O(\varepsilon v(z)) + O(\varepsilon^2 \ell) = O(\varepsilon v(z)) + O(\varepsilon^2 \ell),$$

since the sum of integrals on the right-hand side equals $\int_{-\infty}^0 Q\, d\xi + \int_0^\infty (Q-1)\, d\xi = \int_{\mathbb{R}} \xi \dot{Q}\, d\xi = 0$.

At this moment, we can compare the two results from (5.6) and (5.7) to conclude that $v(z) = O(\varepsilon^2)$ since for $x \in [0, z-]$, $\int_0^x \theta = O(\varepsilon\theta(x))$ and $\int_0^x \int_0^{\hat{x}} \theta = O(\varepsilon^2\theta(x))$ after using $\varepsilon\theta' = [1 + o(1)]\sqrt{2F(\theta) - 2F(\theta(0))}$ and $dx = d\theta/\theta'$. Consequently, $v = O(\ell^2)$, $u = \theta + O(v) + O(\varepsilon^2) = \theta + O(\ell^2)$, and $v'' = m + \gamma v - u = m - \theta + O(\ell^2)$. It then follows that

$$\int_0^z v'' \int_0^x \theta = \int_0^z (m - \theta + O(\ell^2)) \int_0^x \theta$$
$$= \varepsilon^2 \int_0^{Q(0)} \frac{(m-s)\, ds}{\sqrt{2F(s)}} \int_0^s \frac{\hat{s}}{\sqrt{2F(\hat{s})}} d\hat{s} + O(\varepsilon^2 \ell^2).$$

After a similar calculation for the integral on $[z, \ell]$, we then derive that

$$[1 + O(v(z)) + O(\varepsilon)]v(z) = C_0\varepsilon^2 + O(\varepsilon^2\ell^2),$$

where

$$C_0 = \int_0^{Q(0)} \frac{(s-m)\, ds}{\sqrt{2F(s)}} \int_0^s \frac{\hat{s}}{\sqrt{2F(\hat{s})}} d\hat{s} + \int_{Q(0)}^1 \frac{(s-m)\, ds}{\sqrt{2F(s)}} \int_s^1 \frac{1-\hat{s}}{\sqrt{2F(\hat{s})}} d\hat{s}. \tag{5.8}$$

The assertion of the lemma thus follows. $\square$

5.5. The location of interface. The rough estimate of z originates from integrating the equation $v'' = m - u + \gamma v \approx m - u$ so the boundary conditions of v give $\bar{u} \approx m$. That $u \approx 0$ in $[0, z)$ and $u \approx 1$ in $(z, 1]$ gives the first order estimate $z \approx (1-m)\ell$. Equipped with the better estimate that $u = \theta + h_0$ for $x < z$ and $u = \theta + (h_1 - 1)$ for $x > z$, where $f(h_i) + v = O(\varepsilon^2)$, we can perform such integration in a much more accurate manner. Here we notice that

$$\int_0^z \int_0^x \theta \approx \varepsilon^2 \int_0^{Q(0)} \frac{1}{\sqrt{F(s)}} \int_0^s \frac{\hat{s}}{\sqrt{2F(\hat{s})}} d\hat{s} = O(\varepsilon^2).$$

A similar integral on $[z, \ell]$ can also be estimated.

As $v = O(\ell^2)$, by Taylor's expansion, with

$$A_0 = \gamma + 1/f'(0) \quad \text{and} \quad B_0 = f''(0)/(2[f'(0)]^3),$$

we have

$$\gamma v - h_0 = \gamma v - f_0^{-1}(-v) + O(\varepsilon^2) = A_0 v + B_0 v^2 + O(\ell^6) \quad \forall x \in [0, z].$$

Hence, when $x \in [0, z]$,

$$\begin{aligned} v'(x) &= \int_0^x (m + \gamma v - h_0 - \theta) \\ &= mx + \int_0^x (A_0 v + B_0 v^2) - \int_0^x \theta + O(\ell^7), \\ v(x) &= v(z) + \int_z^x v' \\ &= v(z) + \tfrac{1}{2} m(x^2 - z^2) + A_0 \int_z^x d\hat{x} \int_0^{\hat{x}} v + O(\varepsilon^2 + \ell^6). \end{aligned}$$

This gives $v = \frac{1}{2}m(x^2 - z^2) + O(\ell^4 + \varepsilon^2)$, and thus inserting it into the integral gives

$$v(x) = \frac{m}{2}(x^2 - z^2) + \frac{A_0 m}{24}(x^2 - z^2)(x^2 - 5z^2) + O(\ell^6 + \varepsilon^2).$$

Substituting this back into the equation for v' gives

$$v'(z) = mz - \frac{A_0 m}{3} z^3 + \frac{2A_0^2 m + 2B_0 m^2}{15} z^5 - \int_0^z \theta + O(\varepsilon^2 \ell).$$

In a similar manner, working on $[z, \ell]$ and denoting $A_1 = \gamma + 1/f'(1)$ and $B_1 = f''(1)/(2[f'(1)]^3)$, we can derive

$$\begin{aligned} v'(z) = (1 - m)(\ell - z) &- \frac{A_1(1 - m)}{3}(\ell - z)^3 \\ &+ \frac{2A_1^2(1 - m) - 2B_1(1 - m)^2}{15}(\ell - z)^5 - \int_z^\ell (1 - \theta) + O(\varepsilon^2 \ell). \end{aligned}$$

After equating both expressions and using $\int_0^z \theta + \int_z^\ell (\theta - 1) = O(\varepsilon^2 \ell)$, we obtain

$$\begin{aligned} z = (1 - m)\ell &+ \frac{1}{3}\Big\{ m A_0 z^3 - (1 - m) A_1 (\ell - z)^3 \Big\} \\ &+ \frac{2}{15}\Big\{ [A_1^2(1 - m) - B_1(1 - m)^2](\ell - z)^5 - [A_0^2 m + B_0 m^2] z^5 \Big\} + O(\varepsilon^2 \ell). \end{aligned}$$

This "algebraic" equation can be solved iteratively. We state the result as follows.

LEMMA 5.7. *There exist constants c_1, c_2 that depend only on f, m, and γ such that*

$$z = (1 - m)\ell + c_1 \ell^3 + c_2 \ell^5 + O(\varepsilon^2 \ell).$$

Remark 5.1. Here we implicitly assumed that $f \in C^3$, i.e., $F \in C^4$. If we assumed only $F \in C^3$, namely (1.3), then we simply add an $o(\ell^5)$ error.

Here we keep separate traces of error terms in ε and ℓ. They can be used to consider $\ell \in [\pi\sqrt{\varepsilon}, \sqrt[3]{5} L_0 \varepsilon^{1/3}]$.

5.6. Conclusion. Finally, we provide an estimate for u. Writing $Q = Q((x - z)/\varepsilon)$ and $\dot{Q} = \varepsilon Q' = \sqrt{2F(Q)}$, we have

$$\frac{d\theta}{dQ} = \frac{[1 + O(\varepsilon^2) + O(\varepsilon\ell \ln(\theta - \theta^2))]\sqrt{2F(\theta)}}{\sqrt{2F(Q)}}.$$

This provides a relation between θ and Q by

$$\int_{\theta(z\pm)}^{\theta} \frac{d\theta}{[1 + O(\varepsilon^2) + O(\varepsilon\ell \ln(\theta - \theta^2))]\sqrt{2F(\theta)}} = \int_{Q(0)}^{Q} \frac{dQ}{\sqrt{2F(Q)}}.$$

Since $\theta(z\pm) = Q(0) + O(\varepsilon^2)$, we can integrate the above equation to obtain

$$\theta(x) = Q((x - z)/\varepsilon) + O(\varepsilon\ell), \qquad \varepsilon\theta'(x) = \dot{Q}((x - z)/\varepsilon) + O(\varepsilon\ell).$$

Hence we have the following lemma.

LEMMA 5.8. *For all $x \in [0, \ell]$,*

$$\begin{aligned} v(x) &= O(\varepsilon\ell) + \begin{cases} \frac{m}{2}(x^2 - z^2), & x < z, \\ \frac{(1-m)}{2}[(\ell - z)^2 - (\ell - x)^2], & x > z, \end{cases} \\ u(x) &= O(\varepsilon\ell) + Q\Big(\frac{x - z}{\varepsilon}\Big) - \begin{cases} \frac{v(x)}{f_u(0)}, & x \le z, \\ \frac{v(x)}{f_u(1)}, & x \ge z, \end{cases} \\ \varepsilon u'(x) &= O(\varepsilon\ell) + \dot{Q}\Big(\frac{x - z}{\varepsilon}\Big). \end{aligned}$$

In addition, $u''(0) = O(1)$ and $u''(\ell) = O(1)$.

Here the conclusion for $u''(0)$ follows by $u''(0) = h''(0) + \theta''(0) = O(1) + O(e^{-c\ell/\varepsilon})$. The estimate for $u''(\ell)$ is analogous.

6. An eigenvalue estimate. In this section, we study the linear operator

$$\begin{aligned} \mathcal{L}\phi &:= -\varepsilon^2\phi'' + f_u(u)\phi + \mathbf{K}_N^{\ell}(\phi) \\ &= -\varepsilon^2\phi'' + f_u(u)\phi + \gamma^{-1}\,\bar{\phi} + \mathbf{K}_N^{\ell}(\phi - \bar{\phi}), \end{aligned}$$

where (u, v) is a minimizer in $\mathbf{K}_N^{+}(\ell)$. As mentioned earlier, $\bar{\phi}/\gamma$ is written here to remind the reader that when $\gamma = 0$, we work in the class of functions with zero mean value. The additive constant is indeed a Lagrange multiplier which makes $\mathcal{L}$ map zero mean functions to zero mean functions. More precisely,

$$\frac{\bar{\phi}}{\gamma} := -\int_0^1 f_u(u)\phi dx \quad \text{when } \bar{\phi} = \gamma = 0.$$

Such a convention is always imposed when $\gamma = 0$.

The eigenvalue problem has been studied by Nishiura in [16], who showed that the principal (smallest) eigenvalue λ_1 is positive and small. For the case $\gamma = 0$, Ren and Wei [24] demonstrated that $\lambda_1 > c\varepsilon/\ell$ for some positive constant c. The precise value of λ_1 in the $\gamma = 0$ case was given in [23] assuming that F is symmetric, i.e., $F(s) = F(1 - s)$. Here we present a complete analysis giving the precise value of λ_1. The idea [2, 5] is to construct approximate eigenfunctions.

In what follows $\|\cdot\|$ is the L^2 norm and $(\cdot,\cdot)$ the L^2 inner product. Also, $\|\cdot\|_p$ stands for the L^p norm.

6.1. The approximate eigenvalue pair. Denote by Q_1 the solution to

$$-\ddot{Q}_1 + f_u(Q)Q_1 = \sigma - \dot{Q} \quad \text{in } \mathbb{R}, \quad Q_1 \in L^\infty(\mathbb{R}), \quad \int_{\mathbb{R}} Q_1 \dot{Q} d\xi = 0.$$

It is easy to show that Q_1 exists, is unique, and satisfies

$$\int_{-\infty}^0 \Big|Q_1(\xi) - \frac{\sigma}{f_u(0)}\Big| d\xi + \int_0^\infty \Big|Q_1(\xi) - \frac{\sigma}{f_u(1)}\Big| d\xi < \infty.$$

In what follows, we write

$$Q = Q\Big(\frac{x-z}{\varepsilon}\Big), \quad \dot{Q} = \varepsilon Q', \quad Q_1 = Q_1\Big(\frac{x-z}{\varepsilon}\Big), \quad \bar{Q}_1 = \frac{1}{\ell}\int_0^\ell Q_1 dx.$$

We define

$$\hat{\phi}_1(x) = \frac{\sqrt{\varepsilon}}{\sqrt{\sigma}}\Big(u'(x) - \frac{\alpha}{\ell} Q_1\Big), \qquad \hat{\psi}_1 = \mathbf{K}_N^\ell \hat{\phi}_1, \qquad \hat{\lambda}_1 = \frac{\alpha\varepsilon}{\ell}, \tag{6.1}$$

where

$$\alpha := \frac{u(\ell) - u(0)}{\sigma\gamma + \bar{Q}_1} = \frac{1 + O(\ell^2)}{\sigma[\gamma + (1-m)/f_u(0) + m/f_u(1)]}.$$

We shall show that $(\hat{\lambda}_1, \hat{\phi}_1)$ is a good approximation to the principal eigenpair. Here the coefficient is taken so that

$$\|\hat{\phi}_1\|_1 = O(\sqrt{\varepsilon}), \quad \|\hat{\phi}_1\| = 1 + o(1), \quad \|\hat{\phi}_1\|_\infty = O(1/\sqrt{\varepsilon}).$$

6.2. An estimation of .

LEMMA 6.1. *For $\psi = \mathbf{K}_N^\ell \phi$, there holds*

$$\|\psi - \bar{\psi}\|_\infty \le \sqrt{\ell}\|\psi_x\| \le \ell\|\phi - \bar{\phi}\|_1 \le \ell^{3/2}\|\phi - \bar{\phi}\| \le \ell^2\|\phi - \bar{\phi}\|_\infty.$$

Proof. We need only prove the second inequality. Multiplying the equation for ψ by $\psi - \bar{\psi}$, integrating the resulting equation over $(0, \ell)$, and using integration by parts we obtain

$$\int_0^\ell (\psi_x^2 + \gamma(\psi - \bar{\psi})^2) dx = \int_0^\ell \phi(\psi - \bar{\psi}) = \int_0^\ell (\phi - \bar{\phi})(\psi - \bar{\psi})$$
$$\leqslant \|\psi - \bar{\psi}\|_\infty \|\phi - \bar{\phi}\|_1 \leqslant \sqrt{\ell}\|\psi_x\| \, \|\phi - \bar{\phi}\|_1.$$

The assertion thus follows. $\square$

From the lemma, we see that

$$\int_0^\ell \Big\{\hat{\psi}_1'^2 + \gamma(\hat{\psi}_1 - \bar{\hat{\psi}}_1)^2\Big\} \le \ell\|\hat{\phi}_1 - \bar{\hat{\phi}}_1\|_1^2 = O(\varepsilon\ell).$$

6.3. The approximate equation for the principal eigenvalue. Using $-\varepsilon^2 u''' + f_u(u)u' = -v'$, $\dot{Q} = \varepsilon Q'$, and the definition of α, we can calculate

$$\begin{aligned}\mathcal{L}\hat{\phi}_1 &= \frac{\sqrt{\varepsilon}}{\sqrt{\sigma}}\left(-v' + \frac{\alpha}{\ell}(\varepsilon Q' - \sigma) + \frac{u(\ell) - u(0) - \alpha\bar{Q}_1}{\gamma\ell}\right)\\ &\qquad + \hat{\psi}_1 - \bar{\hat{\psi}}_1 + \frac{\alpha\sqrt{\varepsilon}}{\ell\sqrt{\sigma}}(f_u(Q) - f_u(u))Q_1\\ &= \frac{\alpha\varepsilon\sqrt{\varepsilon}}{\ell\sqrt{\sigma}}Q' + \hat{\psi}_1 - \bar{\hat{\psi}}_1 - \frac{\sqrt{\varepsilon}}{\sqrt{\sigma}}v' + \frac{\alpha\sqrt{\varepsilon}}{\ell\sqrt{\sigma}}(f_u(Q) - f_u(u))Q_1 = \hat{\lambda}_1\hat{\phi}_1 + R,\end{aligned}$$

where

$$\hat{\lambda}_1 := \frac{\alpha\varepsilon}{\ell}, \quad R = \hat{\lambda}_1\frac{\sqrt{\varepsilon}}{\sqrt{\sigma}}\Big(Q' - u' + \frac{\alpha}{\ell}Q_1\Big) - \frac{\sqrt{\varepsilon}}{\sqrt{\sigma}}v' + \hat{\psi}_1 - \bar{\hat{\psi}}_1 + \frac{\alpha\sqrt{\varepsilon}}{\ell\sqrt{\sigma}}(f_u(Q) - f_u(u))Q_1. \tag{6.2}$$

Using $Q' - u' = O(\ell^2/\varepsilon)$, $v' = O(\ell)$, one sees that

$$\|R\|_\infty = O(\ell^{5/2}), \qquad \|R\| = O(\ell^3).$$

LEMMA 6.2. *Let* $(\hat{\phi}_1, \hat{\lambda}_1)$ *be defined as in* (6.1). *Then*

$$\mathcal{L}\hat{\phi}_1 = \hat{\lambda}_1\hat{\phi}_1 + R, \quad \|\hat{\phi}_1\| = 1 + o(1), \quad \|R\| = O(\ell^3). \tag{6.3}$$

6.4. Positivity of second eigenvalue. As in [2, 5], a successful analysis on the sign of the tiny principal eigenvalue relies on the fact that the second eigenvalue, if it exists, is positive, uniformly in ε. This allows one to extract information on the principal eigenvalue from an approximate eigenequation, such as (6.3).

LEMMA 6.3. *There exists a positive constant* ν *that is independent of* ε *such that if* $\phi \perp \hat{\phi}_1$, *then with* $\psi = \mathbf{K}_N^\ell(\phi)$,

$$\begin{aligned}\mathrm{L}(\phi, \phi) &:= \int_0^\ell \Big(\varepsilon^2\phi'^2 + f_u(u)\phi^2 + \gamma^{-1}\bar{\phi}^2 + \psi'^2 + \gamma(\psi - \bar{\psi})^2\Big)\\ &\geq \nu\left\{\varepsilon|\phi(0)|^2 + \varepsilon|\phi(\ell)|^2 + \int_0^\ell (\varepsilon^2\phi'^2 + \phi^2 + \psi'^2 + \psi^2)\right\}.\end{aligned}$$

Proof. (a) One need only show the existence of a positive constant ν_1 such that

$$\int_0^\ell (\varepsilon^2\phi'^2 + f_u(Q)\phi^2)\,dx \geq \nu_1\int_0^\ell \phi^2\,dx. \tag{6.4}$$

The reason is as follows. Suppose this is true. Then, for $a \in (0, 1)$ to be chosen at the end,

$$\begin{aligned}&\int_0^\ell (\varepsilon^2\phi'^2 + f_u(u)\phi^2)\,dx \geqslant \int_0^\ell \Big\{\varepsilon^2\phi'^2 + f_u(Q)\phi^2 - C\|u - Q\|_\infty\phi^2\Big\}\\ &\geqslant (1 - a)\int_0^\ell \Big\{\varepsilon^2\phi'^2 + f_u(Q)\phi^2\Big\} + a\{\varepsilon^2\|\phi'\|^2 - \|f_u(Q)\|_\infty\|\phi\|^2\} - C\|u - Q\|_\infty\|\phi\|^2\\ &\geqslant a\varepsilon^2\|\phi'\|^2 + \Big\{(1 - a)\nu_1 - a\|f_u(Q)\|_\infty - C\|u - Q\|_\infty\Big\}\|\phi\|^2\\ &= a\{\varepsilon^2\|\phi'\|^2 + \|\phi\|^2\}\end{aligned}$$

if we take $a = (\nu_1 - C\|u-Q\|_\infty)/(1+\nu_1+\|f_u(Q)\|_\infty)$. Upon observing that $\varepsilon\|\phi\|_\infty^2 \le C\{\varepsilon^2\|\phi'\|^2 + \|\phi\|^2\}$, one obtains the required estimate.

(b) The proof of (6.4) is quite standard; see, for example, de Mottoni and Schatzman [14] or Chen [5]. It is based on the fact that the operator $\mathcal{L}_0 := -\frac{d^2}{d\xi^2} + f_u(Q(\xi))$ on $\mathbb{R}$ has zero as its principal eigenvalue, with a positive eigenfunction $\dot{Q}(\xi)$. Namely, there exists a positive constant $\lambda_2 > 0$ such that for any $\Phi \perp \dot{Q}$

$$L_0(\Phi,\Phi) := \int_{\mathbb{R}} \Big\{\dot{\Phi}^2 + f_u(Q)\Phi^2\Big\} d\xi \ge \lambda_2 \int_{\mathbb{R}} \Phi^2\, d\xi\ .$$

This inequality can be generalized in two ways.

First, the orthogonal condition $\Phi \perp \dot{Q}$ can be relaxed by the assumption that the angle between Φ and $\dot{Q}$ is larger than $\frac{\pi}{4}$, e.g., $\sqrt{2}|(\Phi,\dot{Q})| \le \|\Phi\|\,\|\dot{Q}\|$. Indeed, decomposing $\Phi = c\dot{Q} + \Phi^\perp$ and using $L_0(\dot{Q},\dot{Q}) = 0$ and $L_0(\Phi^\perp,\dot{Q}) = 0$, one has $L_0(\Phi,\Phi) = L_0(\Phi^\perp,\Phi^\perp) \ge \lambda_2\|\Phi^\perp\|^2 \ge \frac{1}{2}\lambda_2\|\Phi\|^2$.

Second, since $f_u(Q(-\infty)) = f_u(0) > 0$ and $f_u(Q(\infty)) = f_u(1) > 0$, the whole space $\mathbb{R}$ can be replaced by a finite interval large enough. Namely, there exists an $M > 0$ such that for any interval $[a,b]$ that contains $[-M,M]$ and any Φ satisfying $\sqrt{2}|(\Phi,\dot{Q})| \le \|\Phi\|\,\|\dot{Q}\|$ (in the $L^2([a,b])$ metric),

$$\int_a^b \Big\{\dot{\Phi}^2 + f_u(Q)\Phi^2\Big\}\, d\xi \ge \frac{\lambda_2}{3}\int_a^b \Phi^2\, d\xi.$$

Translating it into the current situation via $\xi = (x-z)/\varepsilon$, we obtain (6.4) with $\nu_1 = \lambda_2/3$. Here one observes that $\hat{\phi}_1$ is almost parallel to Q' so that $\phi \perp \hat{\phi}_1$ implies that the angle between Q' and ϕ is larger than $\frac{\pi}{4}$. This completes the proof. ∎

6.5. A boundary value problem. To finish our eigenvalue analysis and, more important, for our later applications, we consider the boundary value problem

$$\mathcal{L}\phi = g \quad \text{in } (0,\ell), \quad \phi'(0) \text{ and } \phi'(\ell) \text{ given.}$$

Suppose there is a solution. We write it as

$$\phi = c\hat{\phi}_1 + \phi_\perp, \qquad \phi_\perp \perp \hat{\phi}_1.$$

Then

$$\begin{aligned}(g,\hat{\phi}_1) &= (\mathcal{L}\phi,\hat{\phi}_1) = (-\varepsilon^2\phi'\hat{\phi}_1 + \varepsilon^2\phi\hat{\phi}_1')\Big|_0^\ell + (\phi,\mathcal{L}\hat{\phi}_1)\\ &= \Big(-\varepsilon^2\phi'\hat{\phi}_1 + \varepsilon^2(c\hat{\phi}_1+\phi_\perp)\hat{\phi}_1'\Big)\Big|_0^\ell + \hat{\lambda}_1 c\|\hat{\phi}_1\|^2 + c(R,\hat{\phi}_1) + (R,\phi_\perp).\end{aligned}$$

Since $\|R\| = O(\ell^3)$, $\hat{\lambda}_1 = \alpha\varepsilon/\ell \sim \ell^2$, and $\hat{\phi}_1' = O(\sqrt{\varepsilon})$ at $x=0$ and ℓ, we see that

$$\hat{\lambda}_1\|\hat{\phi}_1\|^2 c = O(1)\left\{(g,\hat{\phi}_1) + \varepsilon^2\phi'\hat{\phi}_1\Big|_0^\ell\right\} + O(\ell^3)\Big\{\|\phi_\perp\| + \sqrt{\varepsilon}|\phi_\perp(0)| + \sqrt{\varepsilon}|\phi_\perp(\ell)|\Big\}.$$

On the other hand,

$$\begin{aligned}(g,\phi_\perp) &= (\mathcal{L}\phi,\phi_\perp) = -\varepsilon^2\phi'\phi_\perp\Big|_0^\ell + c\varepsilon^2\hat{\phi}_1'\phi_\perp\Big|_0^\ell + \mathrm{L}(\phi_\perp,\phi_\perp) + c(\mathcal{L}\hat{\phi}_1,\phi_\perp)\\ &= -\varepsilon^2\phi'\phi_\perp\Big|_0^\ell + O(\ell^3)c\Big\{\|\phi_\perp\| + \sqrt{\varepsilon}|\phi_\perp(0)| + \sqrt{\varepsilon}|\phi_\perp(\ell)|\Big\} + \mathrm{L}(\phi_\perp,\phi_\perp).\end{aligned}$$

Substituting the estimate for c, we then find that

$$\mathrm{L}(\phi_\perp,\phi_\perp)=O(1)\Big(\|g\|+\varepsilon^{3/2}|\phi'(0)|+\varepsilon^{3/2}|\phi'(\ell)|\Big)\Big(\|\phi_\perp\|+O(\sqrt{\varepsilon})[|\phi_\perp(0)|+|\phi_\perp(\ell)|]\Big).$$

After using Lemma 6.3 for $\mathrm{L}(\phi_\perp,\phi_\perp)$, we conclude that

$$\varepsilon\phi_\perp^2(0)+\varepsilon\phi_\perp^2(\ell)+\int_0^\ell\Big(\varepsilon^2{\phi'_\perp}^2+\phi_\perp^2\Big)=O(1)\Big\{\|g\|^2+\varepsilon^3|\phi'(0)|^2+\varepsilon^3|\phi'(\ell)|^2\Big\},\tag{6.5}$$

$$\hat\lambda_1\|\hat\phi_1\|^2c=O(1)\Big\{(g,\hat\phi_1)+\varepsilon^2\phi'\hat\phi_1\Big|_0^\ell\Big\}+O(\ell^3)\Big\{\|g\|+\varepsilon^{3/2}|\phi'(0)|+\varepsilon^{3/2}|\phi'(\ell)|\Big\}.\tag{6.6}$$

We can summarize our calculation as follows.

Lemma 6.4. *Assume that $\mathcal{L}\phi=g$ in $(0,\ell)$. Write $\phi=c\hat\phi_1+\phi_\perp$, where $\phi_\perp\perp\hat\phi_1$. Then* (6.5) *and* (6.6) *hold.*

We remark that the combined quantity $(g,\hat\phi_1)+\varepsilon^2\phi'\hat\phi_1|_0^\ell$ measures the main contribution of the boundary value problem toward the orthogonal projection of the solution in the principal eigenfunction direction. That is, if this quantity is of order 1, then the solution will be of order $1/\hat\lambda_1>c\ell^{-2}$.

6.6. The principal eigenvalue. We can now complete our eigenvalue analysis.

Lemma 6.5. *The principal (smallest) eigenvalue λ_1 of the self-adjoint operator $\mathcal{L}$ is given by*

$$\lambda_1=\hat\lambda_1+O(\ell^3)=\frac{\varepsilon}{\sigma\ell[\gamma+(1-m)/f_u(0)+m/f_u(1)]}+O(\varepsilon).$$

Proof. Note that

$$\lambda_1=\inf_{\|\phi\|=1}\mathrm{L}(\phi,\phi).$$

Taking $\phi=\hat\phi_1/\|\hat\phi_1\|$ as a test function we see that $\lambda_1\le O(\ell^2)$. From (5.2), we see that $\lambda_1\ge 0$. Thus, $\lambda_1=O(\ell^2)$. Let ϕ_1 be the eigenfunction of unit length, $\mathcal{L}\phi_1=\lambda_1\phi_1$. Write $g=\lambda_1\phi_1$ and $\phi_1=c\hat\phi_1+\phi_\perp$, and apply the previous lemma. Since $\phi_1'(0)=\phi_1'(\ell)=0$ and $\|g\|=|\lambda_1|=O(\ell^2)$, the estimate (6.5) then gives $\|\phi_\perp\|=O(\ell^2)$. This implies that $c^2\|\hat\phi_1\|^2=1-\|\phi_\perp\|^2=1-O(\ell^4)$. The equation $\mathcal{L}\phi_1=\lambda_1\phi_1$ can be written as

$$\mathcal{L}\phi_\perp-\lambda_1\phi_\perp=(\lambda_1-\hat\lambda_1)c\hat\phi_1-cR.$$

Taking the inner product with $\hat\phi_1$ and using $(\mathcal{L}\phi_\perp,\hat\phi_1)=-\varepsilon^2\phi'_\perp\hat\phi_1\big|_0^\ell+\varepsilon^2\phi_\perp\hat\phi_1'\big|_0^\ell+(\phi_\perp,\mathcal{L}\hat\phi_1)=\varepsilon^2O(\varepsilon/\ell)+\varepsilon^2O(\sqrt{\varepsilon\ell})+(\phi_\perp,\hat\lambda_1\hat\phi_1+R)=O(\ell^5)$ (note $\phi'_\perp(0)=-c\hat\phi_1'(0)=O(\sqrt{\varepsilon})$, $\hat\phi_1(0)=O(\sqrt{\varepsilon}/\ell)$, $\phi_\perp(0)=O(\sqrt{\ell})$ by (6.5), etc.), we then obtain the required result. ∎

7. Proof of Theorem 1. Now we complete the proof of Theorem 1 parts 2 and 3.

7.1. Uniqueness of the minimizers. Suppose (u,v) and $(\tilde u,\tilde v)$ are two minimizers in $\mathbf{K}_N^+(\ell)$. Denote their interfaces by z and $\tilde z$. From the estimate in section 5 we see that

$$\phi:=u-\tilde u=O(\ell^4)+O(1)\frac{z-\tilde z}{\varepsilon}=o(1)\ell^2\qquad\text{in } L^\infty((0,\ell)).$$

Note that ϕ satisfies

$$\mathcal{L}\phi = f(u+\phi) - f(u) - f_u(u)\phi = O(\phi^2) = o(\ell^2)\phi.$$

Hence,

$$\lambda_1\|\phi\|^2 \le (\mathcal{L}\phi, \phi) = o(\ell^2)\|\phi\|^2.$$

This implies that $\phi \equiv 0$. Hence, minimizers are unique.

7.2. The first order derivative $^+$**.** Once we know the uniqueness of the minimizer, we can then show that minimizers are smooth in the parameter $\ell \in [L_0\varepsilon^{1/3}/16, L_0\varepsilon^{1/3}\sqrt[3]{5}]$. For simplicity, if possible, we use $(u(x), v(x)) = (u(x,\ell), v(x,\ell))$ to denote the energy minimizer in $\mathbf{K}_N^+(\ell)$. Also, we use (u_ℓ, v_ℓ) to denote the derivative of (u, v) with respect to ℓ. Then (u_ℓ, v_ℓ) satisfies

$$\begin{cases} -\varepsilon^2 u_\ell'' + f_u(u)u_\ell + v_\ell = 0 & \text{in } (0,\ell), \\ -v_\ell'' + \gamma v_\ell = u_\ell & \text{in } (0,\ell), \\ v_\ell'(0) = u_\ell'(0) = 0, \quad u_\ell'(\ell) = -u''(\ell), & v_\ell'(\ell) = -v''(\ell), \end{cases}$$

where the boundary conditions are obtained by differentiating $u'(0,\ell) = v'(0,\ell) = u'(\ell,\ell) = v'(\ell,\ell) = 0$.

First we calculate

$$\begin{aligned} E_\ell^+(\varepsilon,\ell) &= F(u) + \tfrac{\gamma}{2}v^2|^{x=\ell} + \int_0^\ell (\varepsilon^2 u' u_\ell' + f(u)u_\ell + v'v_\ell' + \gamma v v_\ell) \\ &= F(u) + \tfrac{\gamma}{2}v^2 - vv''\Big|^{x=\ell} =: c(\varepsilon,\ell) \end{aligned}$$

after integrating by parts and using the equation for u and v_ℓ. Using (5.3) we find that

$$\begin{aligned} E_\ell^+ = c(\varepsilon,\ell) &= \frac{1}{\ell}\int_0^\ell \left\{-\frac{1}{2}\varepsilon^2 u'^2 + \frac{1}{2}v'^2 + F(u) + \frac{\gamma}{2}v^2 - vv''\right\} \\ &= \frac{E^+(\varepsilon,\ell)}{\ell} + \frac{1}{\ell}\int_0^\ell (v'^2 - \varepsilon^2 u'^2)dx. \end{aligned}$$

Hence, as $E^+(\varepsilon,\ell) = \ell\rho^+(\varepsilon,\ell)$,

$$\ell^2\rho_\ell^+(\varepsilon,\ell) = \ell E_\ell^+ - E^+ = \int_0^\ell (v'^2 - \varepsilon^2 u'^2)dx.$$

Using the estimate on the interaction and interfacial energy, we then see that

$$\ell^2\rho_\ell^+ = \frac{m^2(1-m)^2}{3}\ell^3 - \sigma\varepsilon + O(\ell^4).$$

Here one observes an interesting phenomenon: ρ_ℓ^+ does not depend on the first order derivative of (u,v) with respect to ℓ. That is, it does not need equations involving the derivatives of f.

7.3. The second order derivative $^+$. To calculate the second order derivative, we need to use (u_ℓ, v_ℓ). For this purpose, we make the change of variables

$$v_\ell = \psi(x) + A[v''(0)(x-z) - v'(x)], \qquad u_\ell = \phi(x) + A[\gamma v''(0)(x-z) - u'],$$

where

$$A = \frac{-v''(\ell)}{v''(0) - v''(\ell)} = 1 - m + O(\ell^2).$$

As one shall see in a moment, ϕ and ψ are small. That is, $v_\ell \approx A[v''(0)(x-z) - v'(x)]$. This function is obtained from the observation that $v \approx \frac{1}{2}m(x^2 - z^2)$ for $x < z$ and $v = \frac{1}{2}(1-m)[(\ell - z)^2 - (\ell - x)^2]$ for $x > z \approx (1-m)\ell$, and thus $v_\ell \approx (1-m)[-m(1-m) + (x-z)\chi_{[z,\ell]}]$. We found that a good approximation to this function is $A[v''(0)(x-z) - v'(x)]$.

It is easy to verify that $\psi'(0) = \psi'(\ell) = 0$ and $-\psi'' + \gamma\psi = \phi$; namely, $\psi = \mathbf{K}_N^\ell \phi = \gamma^{-1}\bar{\phi} + \mathbf{K}_N^\ell(\phi - \bar{\phi})$. In addition, ϕ satisfies

$$\begin{gathered}\mathcal{L}\phi = g := Av''(0)(z-x)[1 + \gamma f_u(u)],\\ \phi'(0) = A[u''(0) - \gamma v''(0)] = O(1),\\ \phi'(\ell) = (A-1)u''(\ell) - A\gamma v''(0) = O(1).\end{gathered}$$

Now we can calculate

$$\begin{aligned}\frac{d}{d\ell}\Big(\ell^2 \rho_\ell^+(\varepsilon,\ell)\Big) &= 2\int_0^\ell (v'v'_\ell - \varepsilon^2 u'u'_\ell)dx\\ &= I + 2\int_0^\ell (v'\psi' - \varepsilon^2 u'\phi')dx,\end{aligned}$$

where

$$\begin{aligned}I &= 2A\int_0^\ell \Big\{v'[v''(0) - v''] - \varepsilon^2 u'[\gamma v''(0) - u'']\Big\}\\ &= 2Av''(0)[v(\ell) - v(0)] - 2A\gamma v''(0)\varepsilon^2[u(\ell) - u(0)] = m^2(1-m)^2\ell^2 + O(\ell^4).\end{aligned}$$

To estimate the integral involving ϕ and ψ, we write

$$\phi = c\hat{\phi}_1 + \phi_\perp, \quad \psi = c\hat{\psi}_1 + \psi_\perp, \quad \phi_\perp \perp \hat{\phi}_1.$$

Then, by Lemma 6.4,

$$\begin{aligned}&\int_0^\ell \Big\{\varepsilon^2 {\phi'_\perp}^2 + \phi_\perp^2 + {\psi'_\perp}^2 + \gamma\psi_\perp^2\Big\}\\ &\qquad = O(1)\Big\{\|g\|^2 + \varepsilon^3|\phi'(0)|^2 + \varepsilon^3|\phi'(\ell)|^2\Big\} = O(\ell^3).\end{aligned}$$

Since $\|\varepsilon u'\| + \|v'\| = O(\ell^{3/2})$, it then follows that

$$\int_0^\ell (v'\psi'_\perp - \varepsilon^2 u'\phi'_\perp) = O(\ell^3).$$

Also, by Lemma 6.4,

$$
\begin{aligned}
\hat{\lambda}_1\|\hat{\phi}_1\|^2 c &= O(1)\left\{\int_0^\ell g\hat{\phi}_1 dx + \varepsilon^2\hat{\phi}_1\phi'\Big|_0^\ell\right\} + O(\ell^4)\\
&= O(\ell^4) + O(\sqrt{\varepsilon})\int_0^\ell (x-z)[1+\gamma f_u(u)]\Big\{u' - \frac{\alpha}{\ell}Q_1\Big\}\\
&= O(\sqrt{\varepsilon}\ell) + O(\sqrt{\varepsilon})\left\{\int_0^z (u+\gamma f(u))dx + \int_z^\ell (u-1+\gamma f(u))dx\right\}\\
&= O(\sqrt{\varepsilon}\ell) = O(\ell^{5/2}).
\end{aligned}
$$

Thus, $c = O(\sqrt{\ell})$. Consequently, since $\|v'\|^2 = O(\ell^3)$ and $\|\hat{\psi}_1\|^2 = O(\varepsilon\ell) = O(\ell^4)$,

$$
c\int_0^\ell v'\hat{\psi}_1' dx = O(\sqrt{\ell})\|v'\|\,\|\hat{\psi}_1'\| = O(\ell^4).
$$

Using the definition of $\hat{\phi}_1$,

$$
c\int_0^\ell \varepsilon^2 u'\hat{\phi}_1' = \frac{c\sqrt{\varepsilon}}{\sqrt{\sigma}}\int_0^\ell \varepsilon^2 u'\left(u'' - \frac{\alpha}{\ell}Q_1'\right) = -\frac{c\alpha\sqrt{\varepsilon}}{\ell\sqrt{\sigma}}\int_0^\ell \varepsilon^2 u' Q_1' = O\Big(\frac{c\varepsilon\sqrt{\varepsilon}}{\ell}\Big) = O(\ell^4),
$$

since $\|u'\|^2 = O(1/\varepsilon)$ and $\|Q_1'\|^2 = O(1/\varepsilon)$. Thus,

$$
\frac{d}{d\ell}\Big(\ell^2\rho_\ell^+(\varepsilon,\ell)\Big) = m^2(1-m)^2\ell^2 + O(\ell^3).
$$

From this, assertion 3 of Theorem 1 follows. Here note that the estimates of $E_\ell^+(\varepsilon,\ell)$ and $E_{\ell\ell}^+(\varepsilon,\ell)$ follow from the ones of $\rho_\ell^+(\varepsilon,\ell)$ and $\rho_{\ell\ell}^+(\varepsilon,\ell)$ since $E^+(\varepsilon,\ell) = \ell\rho^+(\varepsilon,\ell)$. This also completes the whole proof of Theorem 1. $\square$

8. A final remark for the case $\in (0 \quad {}^{\varepsilon}]$. To make our result more complete, here we provide a final analysis on minimizers for small ℓ.

First of all, one can follow the analysis in the previous sections to conclude that *for all sufficiently small positive ε, $\rho^+(\varepsilon,\cdot) = \rho(\varepsilon,\cdot)$ is strictly decreasing and convex on $[\sqrt{\varepsilon},\ell^\varepsilon]$. In addition,*

$$
\lim_{\varepsilon\to 0,\ell\in[\sqrt{\varepsilon},2L_0\varepsilon^{1/3}/\sqrt[3]{3}]} \frac{E(\varepsilon,\ell)-\sigma\varepsilon}{\ell^3} = \frac{m^2(1-m)^2}{6}.
$$

We omit the proof here.

For $\ell \in (0,\pi\sqrt{\varepsilon}]$ we provide the following as a complement.

LEMMA 8.1. *For every $\varepsilon > 0$, $\rho(\varepsilon,\cdot)$ is a decreasing function on $(0,\pi\sqrt{\varepsilon}]$. More precisely, for every $\varepsilon > 0$, there exists a number $\hat{l}(\varepsilon) \in (0,\pi\sqrt{\varepsilon}]$ such that*

(i) *when $\ell \in (0,\hat{l}(\varepsilon))$, every global minimizer is a constant function, and thus*

$$
\rho(\varepsilon,\ell) = \rho_0 := \min_{s\in\mathbb{R}}\left\{F(s) + \frac{1}{2\gamma}(s-m)^2\right\} \qquad \forall\ell\in(0,\hat{l}(\varepsilon)];
$$

(ii) *in $[\hat{l}(\varepsilon),\pi\sqrt{\varepsilon}]$, $\rho(\varepsilon,\cdot)$ is a strictly decreasing function.*

Proof. If for every $\ell \in (0,\pi\sqrt{\varepsilon}]$ any minimizer is a constant function, then the assertion holds with $\hat{l}(\varepsilon) = \pi\sqrt{\varepsilon}$. Hence, we consider the case that there are non-constant minimizers for some $\ell \in (0,\pi\sqrt{\varepsilon})$.

Suppose $\ell \in (0, \pi\sqrt{\varepsilon})$ and (u, v) is a global nonconstant minimizer of $\mathbf{E}(\cdot,\cdot,\varepsilon,\ell)$ in $\mathbf{K}_N(\ell)$.

Take any $\ell_1 \in (\ell, \pi\sqrt{\varepsilon}]$. Set $\eta = \ell/\ell_1$. Let $\tilde{v}$ be the solution to

$$-\eta^2 \tilde{v}_{xx} + \gamma \tilde{v} = u - m \quad \text{in} \ \ (0,\ell), \qquad \tilde{v}_x(0) = 0 = \tilde{v}_x(\ell).$$

Define

$$(u_1(y), v_1(y)) = (\, u(\eta y), \tilde{v}(\eta y)) \qquad \forall\, y \in (0, \ell_1).$$

Then one can verify that $(u_1, v_1) \in \mathbf{K}_N(\ell_1)$. We shall show that $\frac{1}{\ell_1}\mathbf{E}(u_1, v_1, \varepsilon, \ell_1) < \rho(\varepsilon, \ell)$.

Note that the interaction energy can be written as

$$\int_0^\ell (v_x^2 + \gamma v^2) = \int_0^\ell v(-v_{xx} + \gamma v) = \int_0^\ell v(u - m).$$

A similar calculation for the interaction energy of v_1 then leads to

$$\rho(\varepsilon,\ell) - \frac{\mathbf{E}(u_1, v_1, \varepsilon, \ell_1)}{\ell_1} = \frac{1}{2\ell}\int_0^\ell \Big\{\varepsilon^2[1-\eta^2]u_x^2 + (u-m)(v-\tilde{v})\Big\}dx.$$

The difference $v - \tilde{v}$ can be estimated as follows:

$$\int_0^\ell \Big\{\eta^2(v_x - \tilde{v}_x)^2 + \gamma(v-\tilde{v})^2\Big\}\,dx = \int_0^\ell (v-\tilde{v})\Big\{(-\eta^2 v_{xx} + \gamma v) - (-\eta^2 \tilde{v}_{xx} + \gamma\tilde{v})\Big\}$$

$$= \int_0^\ell (v-\tilde{v})(1-\eta^2)v_{xx} = (1-\eta^2)\int_0^\ell (\tilde{v}_x - v_x)v_x \le (1-\eta^2)\|v_x - \tilde{v}_x\|\,\|v_x\|.$$

This implies that

$$\|v_x - \tilde{v}_x\| \le \frac{1-\eta^2}{\eta^2}\|v_x\|.$$

To continue, we recall the Sobolev inequality $\|g - \bar{g}\| \le \frac{\ell}{\pi}\|g_x\|$ for every $g \in H^1((0,\ell))$. Hence,

$$\int_0^\ell v_x^2 + \gamma(v-\bar{v})^2 = \int_0^\ell (u-m)(v-\bar{v}) = \int_0^\ell (u-\bar{u})(v-\bar{v}) \le \frac{\ell^2}{\pi^2}\,\|u_x\|\,\|v_x\|.$$

It then follows that $\|v_x\| \le \frac{\ell^2}{\pi^2}\|u_x\|$. Consequently, since the averages of v and $\tilde{v}$ are the same,

$$\int_0^\ell (m-u)(v-\tilde{v}) \ = \int_0^\ell (\bar{u}-u)(v-\tilde{v}) \le \frac{\ell^2}{\pi^2}\|u_x\|\,\|v_x - \tilde{v}_x\| \le \frac{\ell^4(1-\eta^2)}{\pi^4\eta^2}\|u_x\|^2.$$

Thus, recalling $\eta = \ell/\ell_1$,

$$\rho(\varepsilon,\ell) - \frac{\mathbf{E}(u_1, v_1, \varepsilon, \ell_1)}{\ell_1} \ge \frac{1-\eta^2}{2\ell}\left(\varepsilon^2 - \frac{\ell^2\ell_1^2}{\pi^4}\right)\int_0^\ell u_x^2\,dx > 0.$$

This implies that $\rho(\varepsilon,\ell) > \rho(\varepsilon,\ell_1)$. This also implies that any minimizer of $\mathbf{E}(\cdot,\cdot,\varepsilon,\ell_1)$ in $\mathbf{K}_N(\ell_1)$ cannot be a constant function (since if it is, then $\rho = \rho_0$).

Now let $\hat{l}(\varepsilon) = \sup\{\ell \mid \rho(\varepsilon,\ell) = \rho_0\}$. We see that when $\ell \in (0, \hat{l})$, any minimizer has to be a constant. On the other hand, $\rho(\varepsilon,\cdot)$ is strictly decreasing in $(\hat{l}, \pi\sqrt{\varepsilon}]$ (if $\hat{l} < \pi\sqrt{\varepsilon}$). ∎

One observes that the above analysis is for any $\varepsilon \in (0,\infty)$.

Acknowledgment. The authors thank the anonymous referee for giving many references and, more important, providing very useful suggestions on making this paper more readable than its earlier version.

MULTISCALE MODELING FOR THE BIOELECTRIC ACTIVITY OF THE HEART*

MICOL PENNACCHIO†, GIUSEPPE SAVARÉ‡, AND PIERO COLLI FRANZONE‡

Abstract. This paper deals with the mathematical models for the electrical activity of the heart at the micro- and macroscopic levels. By using the tools of the Γ-convergence theory, a rigorous mathematical derivation of the macroscopic model, called "bidomain" and derived directly from the microscopic properties of the tissue, is presented.

Key words. homogenization, Γ-convergence, degenerate evolution equations, reaction-diffusion systems, FitzHugh–Nagumo dynamic, cardiac electric field, bidomain model

DOI. 10.1137/040615249

1. Introduction.

The aim of this work is to study, in the framework of Γ-convergence theory, the asymptotic behavior of a microscopic-level (i.e., cellular level) modeling problem for the bioelectric activity of the heart.

The cardiac tissue is composed of an arrangement of elongated cells physically interconnected by specialized membrane structures of densely packed channels called *gap junctions*; see, e.g., [30, 22]. The *gap junction* channels connect the cytoplasmatic compartments of adjacent cells and allow the intercellular flow of ionic currents. The intercellular communication between cardiac myocytes occurs in an end-to-end orientation and in a side-to-side apposition. At a cellular level the tissue can be viewed as composed of two conducting volumes, the intra- and extracellular spaces, separated by the cellular membrane. The two spaces are considered ohmic conducting media and since the junctional resistance between two adjoining cells is different from the myoplasm of either cell, the intracellular conductivity is space dependent. The microscopic mathematical model consists of a system of two partial differential equations of elliptic type and the unknown functions are the intra- and extracellular electric potentials. These equations are coupled by means of a distinctive evolutive boundary condition in the potential jump at the interface separating the two media, i.e., the cellular membrane.

The problem, written in a nondimensional form, contains a small parameter ε related to the microstructure.

In spite of the discrete cellular structure, it is well known that the cardiac tissue can be represented by a continuous model, called the *bidomain model*, which attempts to describe the averaged electric potentials and current flows inside (intracellular space) and outside (extracellular space) the cardiac cells. Despite the widespread use of the macroscopic bidomain model, its rigorous derivation directly from the microscopic properties of the tissue is still lacking. Formally, the macroscopic equations

can be obtained from the microscopic ones by multiple scale expansion and averaging. For instance, a first formal derivation, based on current balances and expressed by averages of integral identities, was obtained in [28]. By standard multiscale arguments of homogenization the same formal derivation can be found also in the appendix of [16] and in [25, 26].

We investigate the homogenization limit when $\varepsilon \to 0$ under the simplifying assumption that cardiac cells are arranged in a periodic box structure. In this work the micro- and the macroscopic structures of the cardiac tissue are studied by using the tools of the Γ-convergence theory, and a rigorous mathematical derivation of the limit problem at the tissue level (i.e., the bidomain model) is presented.

The microscopic model of the cardiac tissue.

Intra- and extracellular regions. At a microscopic level the cardiac tissue Ω (a bounded Lipschitz open subset of $\mathbb{R}^d$, $d = 3$) is composed of a collection of elongated cardiac cells, connected end-to-end and/or side-to-side by junctions, surrounded by the extracellular fluid. The end-to-end contacts form the fiber structure of the cardiac muscle, whereas the presence of lateral junctions establishes a connection between the elongated fibers.

We can consider the cardiac tissue Ω as composed of two *connected* regions, the *intracellular* (inside the cells) Ω_i^ε, separated from the *extracellular* (fluid outside the cells) Ω_e^ε by a membrane surface Γ^ε; thus $\Omega = \Omega_i^\varepsilon \cup \Omega_e^\varepsilon \cup \Gamma^\varepsilon$, and $\Gamma^\varepsilon = \partial\Omega_i^\varepsilon \cap \partial\Omega_e^\varepsilon$ is the common part of the two boundaries of $\Omega_{i,e}^\varepsilon$. Here $\varepsilon > 0$ is a small dimensionless parameter (whose precise definition in terms of the various physical constants will be discussed in the appendix) which is proportional to the ratio between the *"micro" scale* of the length of the cells and the *"macro" scale* of the length of the cardiac fibers.

The periodic lattice of the cells. Following the standard approach of the homogenization theory, we are assuming that the cells are distributed according to an ideal periodic organization similar to a regular lattice of interconnected cylinders.

If ${}_1, \ldots, {}_d$ is an orthogonal basis of $\mathbb{R}^d$, we denote by

$$E_i, \quad E_e := \mathbb{R}^d \setminus \overline{E}_i \quad \text{with common boundary } \Gamma := \partial E_i \cap \partial E_e,$$

two reference open, *connected, and periodic* subsets of $\mathbb{R}^d$ with Lipschitz boundary, i.e., satisfying

$$E_{i,e} + {}_k = E_{i,e}, \quad k = 1, \ldots, d. \tag{1.1}$$

The elementary periodicity region

$$Y := \left\{ \sum_{k=1}^{d} \alpha_k \, {}_k : 0 \le \alpha_k < 1, \quad k = 1, \ldots, d \right\} \tag{1.2}$$

where its intra- and extracellular parts $Y_{i,e} = Y \cap E_{i,e}$ represents a reference unit volume box containing a single cell Y_i. The main geometrical assumption is that the physical intra- or extracellular regions are the ε-dilation of the reference lattices $E_{i,e}$, defined as

$$\varepsilon E_{i,e} = \big\{ \varepsilon\xi : \xi \in E_{i,e} \big\} \quad \text{with} \quad \varepsilon\Gamma := \big\{ \varepsilon\xi : \xi \in \Gamma \big\}, \tag{1.3}$$

and therefore the decomposition of the physical region Ω occupied by the heart into the intra- and extracellular domains $\Omega_{i,e}^\varepsilon$ (see, e.g., Figure 1.1) can be obtained simply

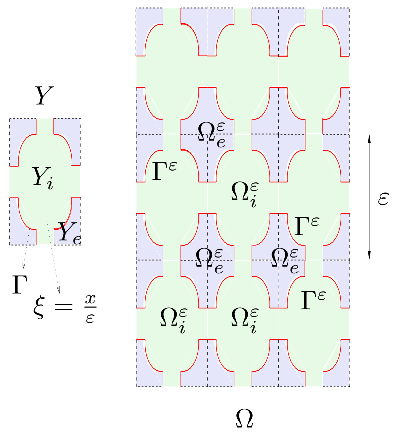

FIG. 1.1. *Right: The ideal periodic geometry in a bidimensional section of the simplified three-dimensional periodic network of interconnected cells. Left: Unit cell in the microscopic variable* $\xi = x/\varepsilon$.

by intersecting Ω with $\varepsilon E_{i,e}$, i.e.,

$$\Omega_i^\varepsilon = \Omega \cap \varepsilon E_i, \quad \Omega_e^\varepsilon = \Omega \cap \varepsilon E_e, \quad \Gamma^\varepsilon = \Omega \cap \left(\partial\Omega_i^\varepsilon \cap \partial\Omega_e^\varepsilon\right) = \Omega \cap \varepsilon\Gamma. \tag{1.4}$$

Unknowns and equations. The electric properties of the tissue are described by the couple,

$$\underline{u}^\varepsilon = (u_i^\varepsilon, u_e^\varepsilon), \quad u_{i,e}^\varepsilon : \Omega_{i,e}^\varepsilon \to \mathbb{R}, \tag{1.5}$$

of *intra- and extracellular potentials,* each one admitting a trace $u_{i,e}^\varepsilon|_{\Gamma^\varepsilon}$ on Γ^ε, whose difference

$$v^\varepsilon := u_i^\varepsilon|_{\Gamma^\varepsilon} - u_e^\varepsilon|_{\Gamma^\varepsilon} : \Gamma^\varepsilon \to \mathbb{R} \tag{1.6}$$

is the *transmembrane potential* (in the following, we will simply write $v^\varepsilon = u_i^\varepsilon - u_e^\varepsilon$ on Γ^ε) and satisfies a *dynamic condition on* Γ^ε involving auxiliary functions

$$w^\varepsilon : \Gamma^\varepsilon \to \mathbb{R}^h, \tag{1.7}$$

the so-called *gating (or recovery) variables.* We denote by $\sigma_{i,e}^\varepsilon$ suitably rescaled symmetric conductivity matrices,

$$\sigma_{i,e}^\varepsilon(x) = \sigma_{i,e}\left(x, \frac{x}{\varepsilon}\right), \tag{1.8}$$

obtained by continuous functions $\sigma_{i,e}(x,\xi) : \Omega \times E_{i,e} \to \mathbb{M}^{d\times d}$ satisfying the usual uniform ellipticity and periodicity conditions

$$\begin{matrix} \sigma|y|^2 \le \sigma_{i,e}(x,\xi)y\cdot y \le \sigma^{-1}|y|^2 \\ \sigma_{i,e}(x,\xi + {}_k) = \sigma_{i,e}(x,\xi) \end{matrix} \quad \forall\,(x,\xi) \in \Omega \times E_{i,e}, \qquad y \in \mathbb{R}^d, \tag{1.9}$$

for a given constant $\sigma > 0$; $\nu_{i,e}^\varepsilon$ are the exterior unit normals to the boundaries of $\Omega_{i,e}^\varepsilon$: observe that $\nu_i^\varepsilon = -\nu_e^\varepsilon$ on Γ^ε.

We can formulate the reaction-diffusion system satisfied by the vector $(u_i^\varepsilon, u_e^\varepsilon, w^\varepsilon)$, with $v^\varepsilon = u_i^\varepsilon - u_e^\varepsilon$ on Γ^ε, in the following way:

$$(P_{1a}^\varepsilon) \qquad -\operatorname{div}\left(\sigma_{i,e}^\varepsilon \nabla u_{i,e}^\varepsilon\right) = 0 \qquad \text{in } \Omega_{i,e}^\varepsilon \times (0,T) \qquad \textit{(quasi-stationary conduction),}$$

$$(P_{1b}^\varepsilon) \qquad \left.\begin{matrix} -\sigma_i^\varepsilon \nabla u_i^\varepsilon \cdot \nu_i^\varepsilon \\ \sigma_e^\varepsilon \nabla u_e^\varepsilon \cdot \nu_e^\varepsilon \end{matrix}\right\} = I_m^\varepsilon \quad \text{on } \Gamma^\varepsilon \times (0,T) \qquad \textit{(continuity equation),}$$

$$(P_2^\varepsilon) \qquad \varepsilon\left(\partial_t v^\varepsilon + I(v^\varepsilon, w^\varepsilon)\right) = I_m^\varepsilon \quad \text{on } \Gamma^\varepsilon \times (0,T) \qquad \textit{(reaction surface condition),}$$

$$(P_3^\varepsilon) \qquad \partial_t w^\varepsilon + r(v^\varepsilon, w^\varepsilon) = 0 \qquad \text{on } \Gamma^\varepsilon \times (0,T) \qquad \textit{(dynamic coupling)}$$

supplemented by the boundary and initial conditions

$$(P_4^\varepsilon) \qquad \sigma_{i,e}^\varepsilon \nabla u_{i,e}^\varepsilon \cdot \nu_{i,e} = 0 \qquad \text{on } (\partial\Omega_{i,e}^\varepsilon \setminus \Gamma^\varepsilon) \times (0,T),$$

$$(P_5^\varepsilon) \qquad v^\varepsilon(\cdot,0) = v_0^\varepsilon \quad \text{on } \Gamma^\varepsilon,$$

$$(P_6^\varepsilon) \qquad w^\varepsilon(\cdot,0) = w_0^\varepsilon \quad \text{on } \Gamma^\varepsilon,$$

where the coupling terms $I(v^\varepsilon, w^\varepsilon)$ (the *membrane ionic current*) and $r(v^\varepsilon, w^\varepsilon)$ depend on the particular model of the ionic flux through the cellular membrane chosen.

Here we are mainly concerning with the so-called *FitzHugh–Nagumo model,* first introduced as a simplified membrane kinetic of the Hodgkin–Huxley equations for the transmission of nervous electric impulses (see, e.g., [13, 20]) that requires only one scalar *recovery variable* w^ε (thus $h = 1$ in (1.7)). Therefore, I and r take the form

$$(P_7^\varepsilon) \qquad I(v^\varepsilon, w^\varepsilon) := F(v^\varepsilon) + \Theta w^\varepsilon, \quad r(v^\varepsilon, w^\varepsilon) := \gamma w^\varepsilon - \eta v^\varepsilon,$$

where Θ, γ, η are nonnegative constants, and

$$(1.10) \qquad F \in C^1(\mathbb{R}) \quad \text{is a cubic-like function with} \quad \inf_{x\in\mathbb{R}} F'(x) > -\infty.$$

If $(u_i^\varepsilon, u_e^\varepsilon, w^\varepsilon)$ is a solution of this system, it is easy to check that $(u_i^\varepsilon + c, u_e^\varepsilon + c, w^\varepsilon)$ is still a solution, where $c = c(t)$ is an arbitrary family of additive time-dependent constants. We avoid the use of quotient spaces by fixing a reference open subdomain

$$(1.11) \qquad \Omega_0 \subset\subset \Omega \quad \text{with} \quad \mathscr{L}^d(\partial\Omega_0) = 0, \quad \mathscr{L}^d(\Omega_0 \cap \Omega_e^\varepsilon) > 0,$$

(here $\mathscr{L}^d$ denotes the usual Lebesgue measure on $\mathbb{R}^d$) and imposing that

$$(P_8^\varepsilon) \qquad \int_{\Omega_e^\varepsilon \cap \Omega_0} u_e^\varepsilon(x)\,dx = 0.$$

We refer to the system $(P_{1a}^\varepsilon, P_{1b}^\varepsilon, \ldots, P_8^\varepsilon)$ as the *(microscopic or cellular) problem* $^{\varepsilon}$.

Well posedness of $^{\varepsilon}$ *and energy estimate.* The well posedness of problem $^{\varepsilon}$ in suitable function spaces has been studied in [16], whose main result we will report in section 4; here we recall only one of the basic a priori estimates, which involves the energy-like functionals

$$\underline{a}^\varepsilon\big(\underline{u}^\varepsilon\big) := \sum_{i,e} \int_{\Omega^\varepsilon_{i,e}} \sigma^\varepsilon_{i,e} \nabla u^\varepsilon_{i,e} \cdot \nabla u^\varepsilon_{i,e}\, dx, \quad \underline{u}^\varepsilon = (u^\varepsilon_i, u^\varepsilon_e), \tag{1.12a}$$

$$b^\varepsilon\big(v^\varepsilon\big) := \varepsilon \int_{\Gamma^\varepsilon} |v^\varepsilon|^2\, d\mathscr{H}^{d-1}, \quad b^\varepsilon\big(w^\varepsilon\big) := \varepsilon \int_{\Gamma^\varepsilon} |w^\varepsilon|^2\, d\mathscr{H}^{d-1}, \tag{1.12b}$$

$$\phi^\varepsilon\big(v^\varepsilon\big) := \varepsilon \int_{\Gamma^\varepsilon} \varphi(v^\varepsilon)\, d\mathscr{H}^{d-1}, \tag{1.12c}$$

$$j^\varepsilon\big(v^\varepsilon\big) := \inf\Big\{\underline{a}^\varepsilon\big(\underline{u}^\varepsilon\big) : u^\varepsilon_{i,e} \in H^1(\Omega^\varepsilon_{i,e}),\ u^\varepsilon_i - u^\varepsilon_e = v^\varepsilon \text{ on } \Gamma^\varepsilon\Big\}, \tag{1.12d}$$

where φ is a positive, convex, primitive function of $x \mapsto F(x) + \lambda_F x$ for a sufficiently big $\lambda_F > -\inf_{x\in\mathbb{R}} F'(x)$ (see (4.1)) and $\mathscr{H}^{d-1}$ denotes the usual $(d-1)$-dimensional Hausdorff measure.

For every $v^\varepsilon_0, w^\varepsilon_0 \in L^2(\Gamma^\varepsilon)$ (the L^2 space with respect to $\mathscr{H}^{d-1}$) with $j(v^\varepsilon_0) < +\infty$, there exists a unique variational solution $u^\varepsilon_{i,e}, w^\varepsilon, v^\varepsilon = u^\varepsilon_i - u^\varepsilon_e$ on Γ^ε, of problem $^\varepsilon$ satisfying the uniform energy bound

$$\sup_{t\in[0,T]} \Big(\underline{a}^\varepsilon\big(\underline{u}^\varepsilon\big) + b^\varepsilon\big(w^\varepsilon\big) + \phi^\varepsilon\big(v^\varepsilon\big)\Big) \le C\Big(j^\varepsilon\big(v^\varepsilon_0\big) + b^\varepsilon\big(w^\varepsilon_0\big) + \phi^\varepsilon\big(v^\varepsilon\big)\Big) \tag{1.13}$$

for a constant $C = C(T, \lambda_F, \eta, \Theta)$ independent of ε.

Convergence to the solution of the macroscopic bidomain model. One possible way to describe the asymptotic behavior of $u^\varepsilon_{i,e}, v^\varepsilon, w^\varepsilon$ as $\varepsilon \downarrow 0$ is to consider local averages. First, we denote by $\beta_{i,e}, \beta$ the asymptotic local ratios (uniform in space) of the intra- and extracellular volumes and of the membrane surface area to the volume occupied by the tissue, i.e.,

$$\begin{aligned} \beta_{i,e} &:= \lim_{\varepsilon\downarrow 0} \frac{\mathscr{L}^d(\Omega^\varepsilon_{i,e} \cap B_\rho(x))}{\mathscr{L}^d(\Omega \cap B_\rho(x))} = \frac{\mathscr{L}^d(Y_{i,e})}{\mathscr{L}^d(Y)} \\ \beta &:= \lim_{\varepsilon\downarrow 0} \frac{\varepsilon\mathscr{H}^{d-1}(\Gamma^\varepsilon \cap B_\rho(x))}{\mathscr{L}^d(\Omega \cap B_\rho(x))} = \frac{\mathscr{H}^{d-1}(\Gamma \cap Y)}{\mathscr{L}^d(Y)} \end{aligned} \qquad \forall\, \rho > 0, \qquad x \in \Omega. \tag{1.14}$$

Taking into account the a priori bound (1.13), we will introduce the following definition (where z^ε represents either the transmembrane potential v^ε or the recovery variable w^ε).

Definition 1.1 (a weak notion of convergence). *Let $u^\varepsilon_{i,e} \in L^1_{loc}(\Omega^\varepsilon_{i,e}), z^\varepsilon \in L^1_{loc}(\Gamma^\varepsilon)$, $\varepsilon > 0$, be given families of functions. We say that $u^\varepsilon_{i,e}$ converges to $u_{i,e} \in L^1_{loc}(\Omega)$ and z^ε converges to $z \in L^1_{loc}(\Omega)$ as $\varepsilon \downarrow 0$ if for every test function $\zeta \in C^0_c(\Omega)$ we have*

$$\lim_{\varepsilon\downarrow 0} \int_{\Omega^\varepsilon_{i,e}} u^\varepsilon_{i,e}(x)\zeta(x)\, dx = \beta_{i,e} \int_\Omega u(x)\zeta(x)\, dx, \tag{1.15}$$

$$\lim_{\varepsilon\downarrow 0} \varepsilon \int_{\Gamma^\varepsilon} z^\varepsilon(x)\zeta(x)\, d\mathscr{H}^{d-1}(x) = \beta \int_\Omega z(x)\zeta(x)\, dx. \tag{1.16}$$

We say that a vector $(u^\varepsilon_i, u^\varepsilon_e, z^\varepsilon) \in L^1_{loc}(\Omega^\varepsilon_i) \times L^1_{loc}(\Omega^\varepsilon_e) \times L^1_{loc}(\Gamma^\varepsilon)$ is converging to $(u_i, u_e, z) \in \big(L^1_{loc}(\Omega)\big)^3$ if each component is converging to the corresponding one according to (1.15) *and* (1.16).

Remark 1.2 (weak* convergence of the associated measures). The above formulae correspond to considering the local weak* convergence in the sense of (signed) measures: to clarify this point, we introduce the reference positive measures

$$\lambda^\varepsilon_{i,e} := \mathscr{L}^d|_{\Omega^\varepsilon_{i,e}}, \quad \lambda^\varepsilon := \varepsilon\mathscr{H}^{d-1}|_{\Gamma^\varepsilon}, \quad \lambda_{i,e} := \beta_{i,e}\mathscr{L}^d|_{\Omega}, \quad \lambda := \beta\mathscr{L}^d|_{\Omega} \tag{1.17}$$

and the Radon measures

$$\tilde u^\varepsilon_{i,e} := u^\varepsilon_{i,e}\cdot\lambda^\varepsilon_{i,e}, \quad \tilde z^\varepsilon := z^\varepsilon\cdot\lambda^\varepsilon \tag{1.18}$$

whose densities are $u^\varepsilon_{i,e}$ and z, respectively. The convergence introduced in Definition 1.1 is then equivalent to asking whether

$$\tilde u^\varepsilon_{i,e} \rightharpoonup^* \tilde u_{i,e} := u_{i,e}\lambda_{i,e}, \quad \tilde z^\varepsilon \rightharpoonup^* \tilde z := z\cdot\lambda \tag{1.19}$$

in the local weak* topology of the space of Radon measures [4, Definition 1.58].

Since the microscopic problem is strictly related to the energy functionals (1.12a), (1.12b), it is natural to introduce the corresponding homogenized ones, which are defined by

$$\underline{a}(\underline{u}) := \sum_{i,e}\int_\Omega M_{i,e}(x)\nabla u_{i,e}(x)\cdot\nabla u_{i,e}(x)\,dx, \quad \underline{u} := (u_i,u_e), \tag{1.20a}$$

$$b(v) := \beta\int_\Omega |v(x)|^2\,dx, \quad b(w) := \beta\int_\Omega |w(x)|^2\,dx, \tag{1.20b}$$

$$\phi(v) := \beta\int_\Omega \varphi(v(x))\,dx, \tag{1.20c}$$

$$j(v) := \inf\Big\{\underline{a}(\underline{u}) : \underline{u} = (u_i,u_e)\in H^1(\Omega)\times H^1(\Omega),\ u_i-u_e = v \text{ in } \Omega\Big\}, \tag{1.20d}$$

where $M_i(x), M_e(x)$ are the symmetric and positive definite matrices obtained by solving the cellular problems for every $y\in\mathbb{R}^d$,

$$\begin{aligned} M_{i,e}(x)\,y\cdot y := \min\Bigg\{&\frac{1}{\mathscr{L}^d(Y)}\int_{Y_{i,e}}\sigma_{i,e}(x,\xi)\big(\nabla u(\xi)+y\big)\cdot\big(\nabla u(\xi)+y\big)\,d\xi : \\ &u\in H^1_{loc}(\mathbb{R}^d),\ u\ Y\text{-periodic}\Bigg\}, \end{aligned} \tag{1.21}$$

and satisfying the usual uniform ellipticity condition for a constant $\mu>0$,

$$\mu|y|^2 \le M_{i,e}(x)y\cdot y \le \mu^{-1}|y|^2 \quad \forall\, y\in\mathbb{R}^d, \qquad x\in\Omega. \tag{1.22}$$

We have now all the elements to state our main result.

THEOREM 1.3 (convergence to the macroscopic problem). *Let us suppose that, as $\varepsilon\downarrow 0$, the initial data $v^\varepsilon_0, w^\varepsilon_0\in L^2(\Gamma^\varepsilon)$ converge to $v_0, w_0\in L^2(\Omega)$ according to* (1.16)*, and the related energies satisfy*

$$\lim_{\varepsilon\downarrow 0} b^\varepsilon(v^\varepsilon_0) = b(v_0), \quad \lim_{\varepsilon\downarrow 0} b^\varepsilon(w^\varepsilon_0) = b(w_0), \quad \limsup_{\varepsilon\downarrow 0}\Big(j^\varepsilon(v^\varepsilon_0)+\phi^\varepsilon(v^\varepsilon_0)\Big) < +\infty. \tag{1.23}$$

Then there exists $\underline{u} = (u_i,u_e)$, $v = u_i-u_e$, w with

$$u_{i,e}, v, w\in C^0(0,T;H^1(\Omega)), \quad \partial_t v,\ \partial_t w\in L^2(0,T;L^2(\Omega)),$$

such that for every time $t \in [0,T]$

$$(u^{\varepsilon}_{i,e}, v^{\varepsilon}, w^{\varepsilon}) \to (u_{i,e}, v, w) \quad \textit{as } \varepsilon \downarrow 0 \textit{ according to Definition } 1.1, \tag{1.24}$$

with

$$\underline{a}^{\varepsilon}(\underline{u}^{\varepsilon}) = j^{\varepsilon}(v^{\varepsilon}) \to \underline{a}(\underline{u}) = j(v), \quad b^{\varepsilon}(v^{\varepsilon}) \to b(v), \quad b^{\varepsilon}(w^{\varepsilon}) \to b(w). \tag{1.25}$$

$\big(u_{i,e}, w\big)$ *with* $v = u_i - u_e$ *is the (unique) variational solution of the* macroscopic reaction-diffusion system

$$(P_1) \qquad \left.\begin{array}{c} \operatorname{div}(M_i \nabla u_i) \\ -\operatorname{div}(M_e \nabla u_e) \end{array}\right\} = I_m \qquad \textit{in } \Omega \times (0,T) \qquad \textit{(continuity equation)},$$

$$(P_2) \qquad \beta\,(\partial_t v + I(v,w)) = I_m \qquad \textit{in } \Omega \times (0,T) \qquad \textit{(reaction-diffusion condition)},$$

$$(P_3) \qquad \partial_t w + r(v,w) = 0 \qquad \textit{in } \Omega \times (0,T), \qquad \textit{(dynamic coupling)}$$

supplemented by the boundary and initial conditions

$$(P_4) \qquad M_{i,e} \nabla u_{i,e} \cdot \nu_{i,e} = 0 \qquad \textit{on } \partial\Omega \times (0,T),$$

$$(P_5) \qquad v(\cdot,0) = v_0 \qquad \textit{in } \Omega,$$

$$(P_6) \qquad w(\cdot,0) = w_0 \qquad \textit{in } \Omega;$$

again, the coupling terms I *and* r *take the same form as* (P^{ε}_7),

$$(P_7) \qquad I(v,w) := F(v) + \Theta w, \quad r(v,w) := \gamma w - \eta v,$$

and a reference value for the potential u_e *is determined by imposing*

$$(P_8) \qquad \int_{\Omega_0} u_e(x)\,dx = 0.$$
