Thus we find the equations of the so-called *bidomain model* (see, e.g., [21, 14, 15, 31, 24]): it describes at a macroscopic level the averaged electric potentials and current flows inside (intracellular space) and outside (extracellular space) the cardiac cells, disregarding the discrete cellular structure and representing the cardiac tissue as the superposition of two interpenetrating and superimposed continua. In this representation Ω, the physical region occupied by the heart, coincides with the intra- and extracellular domains and at every point the two media are connected by a distributed cellular membrane on Ω. The two superposed conducting media are ohmic, i.e., their current densities are given by $\mathbf{j}_{i,e} = -M_{i,e}\nabla u_{i,e}$ with $M_{i,e}$ the conductivity tensors. Thus condition P_1 is the current conservation law

$$\operatorname{div}(\mathbf{j}_i + \mathbf{j}_e) = 0 \qquad \text{and} \qquad -\ \operatorname{div}\mathbf{j}_i = \operatorname{div}\mathbf{j}_e = I_m,$$

where I_m is the current per unit volume crossing the cellular membrane.

Convergence by extensions of the data. One could also consider a different approach to capture the asymptotic behavior of $u^{\varepsilon}_{i,e}, v^{\varepsilon}, w^{\varepsilon}$ by performing a preliminary extension of them to the whole Ω and considering the limit of such extensions in a suitable (ε-independent) function space.

THEOREM 1.4 (weak convergence in H^1_{loc} for extended solutions). *Let us assume that the initial data* $v^{\varepsilon}_0, w^{\varepsilon}_0$ *converge to* v_0, w_0 *according to* (1.15), (1.16) *of Definition* 1.1, *they satisfy the energy condition* (1.23), *and there exist extensions* $\breve{w}^{\varepsilon}_0$ *of* w^{ε}_0

which are bounded in $H^1(\Omega')$*, for every* $\Omega' \subset\subset \Omega$*. Then there exist extensions* $\breve{u}^\varepsilon_{i,e}$*,* $\breve{w}^\varepsilon$ *of the microscopic solutions* $u^\varepsilon_{i,e}, w^\varepsilon$ *of problem* ${}^{\boldsymbol{\varepsilon}}$ *satisfying*

$$\sup_{t\in[0,T],\varepsilon>0} \int_{\Omega'} \Big(|\breve{u}^\varepsilon_{i,e}|^2 + |\breve{w}^\varepsilon|^2 + |\nabla \breve{u}^\varepsilon_{i,e}|^2 + |\nabla \breve{w}^\varepsilon|^2 \Big)\, dx < +\infty \quad \forall\, \Omega' \subset\subset \Omega; \tag{1.26}$$

moreover, for every $\Omega' \subset\subset \Omega$ *and* $t \in [0,T]$*, any family* $\breve{u}^\varepsilon_{i,e}, \breve{w}^\varepsilon$ *of such extensions will satisfy*

$$\breve{u}^\varepsilon_{i,e} \rightharpoonup u_{i,e}, \quad \breve{w}^\varepsilon \rightharpoonup w \quad \textit{weakly in } H^1(\Omega') \quad \textit{as } \varepsilon \downarrow 0, \tag{1.27}$$

where $(u_{i,e}, w)$ *is the solution of the macroscopic problem* .

Remark 1.5. As we will discuss in section 2 the existence of admissible extensions $\breve{u}^\varepsilon_{i,e}, \breve{w}^\varepsilon$ satisfying the uniform bounds (1.26) follows by a general result of Acerbi et al. [1]; they also show that only local a priori bounds like (1.26) are available, due to the particular geometry of this problem: in fact, the boundary of $\Omega^\varepsilon_{i,e}$ could be quite irregular and one cannot find global extension operators which preserve the H^1-norm.

Homogenization and Γ*-convergence of the associated stationary problems.* As we shall discuss in more detail in section 5, the microscopic problems ($P^\varepsilon_{1a}, \dots, P^\varepsilon_8$) can be considered as a sort of (perturbation of) gradient flows of ε-dependent energies with respect to a varying family of degenerate metrics, which are induced by nonnegative quadratic forms with a nontrivial kernel (the forms b^ε of (1.12b)).

The characterization of the asymptotic behavior of the energy functionals, in the framework of Γ-convergence theory, is one of the crucial step of the proof of Theorem 1.3 and it is naturally related to a stationary homogenization problem, which is of independent interest. Here we state the stationary homogenization result in a simplified version, obtained by neglecting the role of the recovery variable w^ε.

We first introduce the family of convex functionals defined on $H^1(\Omega^\varepsilon_i) \times H^1(\Omega^\varepsilon_e)$,

$$\mathscr{F}^\varepsilon(\underline{u}) := \frac{h}{2} b^\varepsilon(v - v^\varepsilon_0) + \frac{1}{2} \underline{a}^\varepsilon(\underline{u}) + \phi^\varepsilon(v), \quad v := u_i - u_e \quad \text{on } \Gamma^\varepsilon, \tag{1.28}$$

with $h \geq 0$ a given constant, $v^\varepsilon_0 \in L^2(\Gamma^\varepsilon)$, $b^\varepsilon, \underline{a}^\varepsilon, \phi^\varepsilon$ defined in (1.12), and the limit functional defined in $\big(H^1(\Omega)\big)^2$

$$\mathscr{F}(\underline{u}) := \frac{h}{2} b(v - v_0) + \frac{1}{2} \underline{a}(\underline{u}) + \phi(v), \quad v := u_i - u_e \quad \text{in } \Omega \tag{1.29}$$

for a given $v_0 \in L^2(\Omega)$ and $b, \underline{a}, \phi$ introduced in (1.20).

THEOREM 1.6 (coercivity and Γ-convergence). *Let us suppose that* $v^\varepsilon_0 \in L^2(\Gamma^\varepsilon)$ *converge to* $v_0 \in L^2(\Omega)$ *as* $\varepsilon \downarrow 0$ *according to* (1.16) *and satisfy*

$$\lim_{\varepsilon\downarrow 0} b^\varepsilon(v^\varepsilon_0) = b(v_0), \qquad \limsup_{\varepsilon\downarrow 0} \Big(j^\varepsilon(v^\varepsilon_0) + \phi^\varepsilon(v^\varepsilon_0) \Big) < +\infty. \tag{1.30}$$

Then the following properties hold:

(a) *Compactness. If* $\underline{u}^\varepsilon = (u^\varepsilon_i, u^\varepsilon_e) \in H^1(\Omega^\varepsilon_i) \times H^1(\Omega^\varepsilon_e)$ *satisfies*

$$\liminf_{\varepsilon\downarrow 0} \mathscr{F}^\varepsilon(\underline{u}^\varepsilon) < +\infty \quad \textit{and} \quad \int_{\Omega^\varepsilon_e \cap \Omega_0} u^\varepsilon_e(x)\, dx = 0 \tag{1.31}$$

then there exists $\underline{u} \in H^1(\Omega) \times H^1(\Omega)$ *satisfying*

$$\int_{\Omega_0} u_e(x)\,dx = 0 \tag{1.32}$$

and a vanishing subsequence ε_n *such that* $\underline{u}^{\varepsilon_n}$ *converges to* u *according to Definition* 1.1 *as* $n \to \infty$.

(b) lim inf *inequality. For every family* $\underline{u}^{\varepsilon_n}$ *converging to* $\underline{u}$ *according to Definition* 1.1,

$$\liminf_{n\to\infty} \mathscr{F}^{\varepsilon_n}(\underline{u}^{\varepsilon_n}) \geq \mathscr{F}(\underline{u}). \tag{1.33}$$

(c) lim sup *inequality. For every* $\underline{u} = (u_i, u_e) \in \big(H^1(\Omega)\big)^2$ *satisfying* (1.32) *there exist* $\underline{u}^\varepsilon \in H^1(\Omega_i^\varepsilon) \times H^1(\Omega_e^\varepsilon)$ *converging to* $\underline{u}$ *as in Definition* 1.1 *with* $v^\varepsilon = u_i^\varepsilon - u_e^\varepsilon$ *converging to* $v = u_i - u_e$ *as in* (1.16) *such that*

$$\int_{\Omega_e^\varepsilon\cap\Omega_0} u_e^\varepsilon(x)\,dx = 0, \qquad \limsup_{\varepsilon\downarrow 0} \mathscr{F}^\varepsilon(\underline{u}^\varepsilon) \leq \mathscr{F}(\underline{u}). \tag{1.34}$$

Whenever a suitable weak (and metrizable) topology is introduced in the spaces of (signed) Radon measures (we postpone the discussion of this point to section 3), the above result shows that $\mathscr{F}$ is the Γ-limit of the coercive family of functionals $\mathscr{F}^\varepsilon$.

Well-known results on Γ-convergence [19, Cor. 2.4] and a standard computation of the first variation of the functionals $\mathscr{F}^\varepsilon, \mathscr{F}$ [16] immediately yield the following.

Corollary 1.7 (homogenization of the stationary problems). *Under the assumptions of Theorem* 1.6, *each functional* $\mathscr{F}^\varepsilon$ *admits a unique minimizer* $\underline{u}^\varepsilon = (u_i^\varepsilon, u_e^\varepsilon) \in H^1(\Omega_i^\varepsilon) \times H^1(\Omega_e^\varepsilon)$ *satisfying* (1.31) *with* $v^\varepsilon = u_i^\varepsilon - u_e^\varepsilon \in H^{1/2}(\Gamma^\varepsilon)$ *and characterized by the system*

$$-\operatorname{div}\big(\sigma_{i,e}^\varepsilon \nabla u_{i,e}^\varepsilon\big) = 0 \qquad \text{in } \Omega_{i,e}^\varepsilon, \tag{1.35a}$$

$$\left.\begin{matrix} -\sigma_i^\varepsilon \nabla u_i^\varepsilon \cdot \nu_i^\varepsilon \\ \sigma_e^\varepsilon \nabla u_e^\varepsilon \cdot \nu_e^\varepsilon \end{matrix}\right\} = I_m^\varepsilon \qquad \text{on } \Gamma^\varepsilon, \tag{1.35b}$$

$$\varepsilon\Big((h+\lambda_F)v^\varepsilon + F(v^\varepsilon)\Big) = I_m^\varepsilon + \varepsilon h v_0^\varepsilon \qquad \text{on } \Gamma^\varepsilon, \tag{1.35c}$$

$$\sigma_{i,e}^\varepsilon \nabla u_{i,e}^\varepsilon \cdot \nu_{i,e} = 0 \qquad \text{on } \partial\Omega_{i,e}^\varepsilon \setminus \Gamma^\varepsilon, \tag{1.35d}$$

$$\int_{\Omega_e^\varepsilon\cap\Omega_0} u_e^\varepsilon(x)\,dx = 0. \tag{1.35e}$$

$(u_{i,e}^\varepsilon, v^\varepsilon)$ *converge to* $(u_{i,e}, v) \in \big(H^1(\Omega)\big)^3$ *as* $\varepsilon \downarrow 0$ *according to Definition* 1.1; $\underline{u} = (u_i, u_e)$ *with* $v = u_i - u_e$ *is the (unique) minimizer of* $\mathscr{F}$ *satisfying* (1.32) *and it is characterized by the system*

$$\left.\begin{matrix} \operatorname{div}(M_i \nabla u_i) \\ -\operatorname{div}(M_e \nabla u_e) \end{matrix}\right\} = I_m \qquad \text{in } \Omega, \tag{1.36a}$$

$$\beta\Big((h+\lambda_F)v + F(v)\Big) = I_m + \beta h v_0 \qquad \text{in } \Omega, \tag{1.36b}$$

$$M_{i,e}\nabla u_{i,e} \cdot \nu_{i,e} = 0 \qquad \text{on } \partial\Omega, \tag{1.36c}$$

$$\int_{\Omega_0} u_e(x)\,dx = 0. \tag{1.36d}$$

Plan of the paper. The paper is divided into two parts: the first part (sections 2 and 3) is devoted to the stationary homogenization result stated in Theorem 1.6 and can be read independently of the remaining sections. The next section contains some preliminary technical results related to the extension problem of functions defined on Γ^ε and $\Omega^\varepsilon_{i,e}$; we also present a natural generalization of the Riemann–Lebesgue lemma and some properties of the notion of convergence introduced in Definition 1.1; finally we discuss some applications to lower semicontinuity and approximation results for integral functionals defined on Γ^ε.

Section 3 will conclude the proof of Theorem 1.6 and its corollary. Here we combine very general results on Γ-convergence of noncoercive functionals [12] (related to elliptic problems with Neumann boundary conditions) with the more recent extension techniques of [1]. Our main contribution is to extend this framework to the homogenization of integral functionals defined on the interface between the two ε-domains.

The second part of the paper is more specifically devoted to the evolutive systems $^\varepsilon$, . The well posedness of their variational formulation and some preliminary accessory results are collected in section 4.

In section 5 we outline and carry out the main steps of the proof of Theorems 1.3 and 1.4. Here we adopt the point of view of the "Minimizing movement" approach to evolution equations suggested by De Giorgi in [18]: we perform an auxiliary "semi-implicit time discretization" of the microscopic reaction-diffusion system, which consists of a recursive family of variational problems depending on the step size $\tau > 0$. The final macroscopic model will thus result in two limit procedures: the first one in the time discretization, as the time step τ goes to 0 keeping ε fixed, and the second in the homogenization process as $\varepsilon \downarrow 0$.

Uniform approximation estimates for the discretized problem (which are strictly related to the *convexity* of the underlying functionals) allow us to "invert" the order of the limits: we can therefore pass first to the limit as $\varepsilon \downarrow 0$ keeping τ fixed, and in this way we obtain a family of *homogenized discrete macroscopic problems*; a final limit as $\tau \downarrow 0$ recovers the continuous form of the macroscopic problem. By this approach, the homogenization of the time-dependent problem $^\varepsilon$ is reduced to the homogenization of a finite sequence of stationary problems of elliptic type, which exhibit (up to lower order perturbation terms) the same structure we studied in section 3.

Applications of Γ-convergence to evolution problems are well known for gradient flows of *convex* (or λ-*convex*) functionals in Hilbert spaces [6]: in that case the uniform convergence of the induced evolution semigroups can be deduced from the Γ-convergence and Mosco-convergence [27, 19] of the underlying functionals.

In our case things are more difficult due to the degeneration of the parabolic structure of our systems (as was discussed in [16]) and to the lack of a "fixed" (i.e., independent of ε) Hilbert space, where the evolution can be settled.

Therefore, a general abstract result for studying the convergence of the present problem seems to be missing. Nevertheless, we tried to develop a general procedure (uniform discretization estimates and Γ-convergence of the discretized variational problems) to attack this kind of λ-convex but "degenerate" evolution problems: even if our arguments could have been presented in a more compact (but maybe more obscure) form, we decided to clarify their structure as much as possible, hoping that a better understanding of the main ideas of this approach could also be helpful for other applications in different contexts.

In section 6 we briefly sketch the rigorous derivation of the error estimates for the semi-implicit discretization of Problems $^\varepsilon$ and : here we adapt to our setting the technique introduced in [29] (but see also [7, 32, 33]) to obtain optimal a priori estimates for gradient flows of convex functionals in Hilbert spaces.

Such estimates could have also been derived by standard perturbation arguments from the general results of [9] for a fully implicit discretization scheme; here we chose a direct approach to have precise control of the various constants involved (which should be *independent of* ε) and to keep the presentation simpler and almost self-contained.

The main advantage of the semi-implicit discretization (instead of an implicit one) lies in the variational structure of the problems, which should be solved at each time step: in fact, they are associated with the minimum of convex functionals.

For the sake of completeness, in the appendix we briefly recall the derivation of the model at the cellular level from well established physical laws and introduce its dimensionless form.

2. Notation, extension results, and related convergence properties.

2.1. Vector notation, function spaces, and bilinear forms. In order to write the micro- and macroscopic problems in a compact form, we introduce a vector notation, which will also be useful for dealing with the evolution systems; thus

$$\underline{u}^{\,\varepsilon}, \underline{u} \quad \text{will denote the vectors } (u_i^\varepsilon, u_e^\varepsilon),\ (u_i, u_e), \tag{2.1}$$

and we will use underlined letters (as $\underline{u}, \underline{\phi}, \underline{\mathcal{V}}, \dots$) for vectors, functions, and spaces involving intraextracellular couples. We set

$$\begin{aligned} &\mathcal{H}^\varepsilon := L^2(\Gamma^\varepsilon), \underline{\mathcal{V}}^\varepsilon := \Big\{ \underline{u} \in H^1(\Omega_i^\varepsilon) \times H^1(\Omega_e^\varepsilon) : v = u_i^\varepsilon - u_e^\varepsilon \in L^2(\Gamma^\varepsilon) \Big\}, \\ &\mathcal{H} := L^2(\Omega),\ \underline{\mathcal{V}} := \ H^1(\Omega) \times H^1(\Omega), \quad \underline{\mathcal{V}}_{loc} := H^1_{loc}(\Omega) \times H^1_{loc}(\Omega), \end{aligned} \tag{2.2}$$

together with their closed subspaces

$$\underline{\mathcal{V}}_0^\varepsilon := \left\{ \underline{u}^\varepsilon \in \underline{\mathcal{V}}^\varepsilon : \int_{\Omega_e^\varepsilon \cap \Omega_0} u_e^\varepsilon(x)\, dx = 0 \right\}, \quad \underline{\mathcal{V}}_0 := \left\{ \underline{u} \in \underline{\mathcal{V}} : \int_{\Omega_0} u_e(x)\, dx = 0 \right\}. \tag{2.3}$$

Remark 2.1. Since $\Omega_{i,e}^\varepsilon$ could have a very irregular boundary, we do not know if the traces $u_{i,e}^\varepsilon|_{\Gamma^\varepsilon}$ of $u_{i,e}^\varepsilon \in H^1(\Omega_{i,e}^\varepsilon)$ belong to $H^{1/2}(\Gamma^\varepsilon) \subset L^2(\Gamma^\varepsilon)$: a priori we only know $u_{i,e}^\varepsilon|_{\Gamma^\varepsilon} \in H^{1/2}_{loc}(\Gamma^\varepsilon) \subset L^2_{loc}(\Gamma^\varepsilon)$. Therefore, the integrability condition on $v = u_i^\varepsilon - u_e^\varepsilon$ on Γ^ε imposed in the definition (2.2) of $\underline{\mathcal{V}}_0^\varepsilon$ is not redundant.

We now introduce some continuous and symmetric bilinear forms on $\underline{\mathcal{V}}^\varepsilon, \mathcal{H}^\varepsilon, \underline{\mathcal{V}}, \mathcal{H}$ which will play a crucial role in the following. Recalling (1.12a,b,c) and (1.20a,b,c), we set

$$\underline{a}^\varepsilon(\underline{u}, \underline{\hat{u}}) := \sum_{i,e} \int_{\Omega_{i,e}^\varepsilon} \sigma_{i,e}^\varepsilon \nabla u_{i,e} \cdot \nabla \hat{u}_{i,e}\, dx \quad \forall\, \underline{u}, \underline{\hat{u}} \in \underline{\mathcal{V}}^\varepsilon, \tag{2.4}$$

$$\underline{a}(\underline{u}, \underline{\hat{u}}) := \sum_{i,e} \int_{\Omega} M_{i,e} \nabla u_{i,e} \cdot \nabla \hat{u}_{i,e}\, dx \quad \forall\, \underline{u}, \underline{\hat{u}} \in \underline{\mathcal{V}}, \tag{2.5}$$

and we introduce the scalar products on $\mathcal{H}^\varepsilon, \mathcal{H}$,

$$\begin{aligned} b^\varepsilon(w, \hat{w}) &:= \varepsilon \int_{\Gamma^\varepsilon} w\, \hat{w}\, d\mathscr{H}^{d-1} \quad \forall\, w, \hat{w} \in \mathcal{H}^\varepsilon, \\ b(w, \hat{w}) &:= \beta \int_{\Omega} w\, \hat{w}\, dx \quad \forall\, w, \hat{w} \in \mathcal{H}. \end{aligned} \tag{2.6}$$

We also set

$$\underline{b}^\varepsilon(\underline{u},\hat{\underline{u}}) := \varepsilon \int_{\Gamma^\varepsilon} (u_i - u_e)(\hat{u}_i - \hat{u}_e)\, d\mathscr{H}^{d-1} = b^\varepsilon(\underline{B}^\varepsilon \underline{u}^\varepsilon, \underline{B}^\varepsilon \hat{\underline{u}}^\varepsilon) \quad \forall\, \underline{u},\hat{\underline{u}} \in \underline{\mathcal{V}}^\varepsilon, \tag{2.7}$$

$$\underline{b}(\underline{u},\hat{\underline{u}}) := \beta \int_{\Omega} (u_i - u_e)(\hat{u}_i - \hat{u}_e)\, dx = b(\underline{B}\underline{u}, \underline{B}\hat{\underline{u}}) \quad \forall\, \underline{u},\hat{\underline{u}} \in \underline{\mathcal{V}}, \tag{2.8}$$

$$\underline{\phi}^\varepsilon(\underline{u}) := \varepsilon \int_{\Gamma^\varepsilon} \varphi(u_i - u_e)\, d\mathscr{H}^{d-1} = \phi^\varepsilon(\underline{B}^\varepsilon \underline{u}) \quad \forall\, \underline{u} \in \underline{\mathcal{V}}^\varepsilon, \tag{2.9}$$

$$\underline{\phi}(\underline{u}) := \beta \int_{\Omega} \varphi(u_i - u_e)\, dx = \phi(\underline{B}\underline{u}) \quad \forall\, \underline{u} \in \underline{\mathcal{V}}, \tag{2.10}$$

where $\underline{B}^\varepsilon, \underline{B}$ are the linear continuous operators

$$\begin{aligned} &\underline{B}^\varepsilon : \underline{\mathcal{V}}^\varepsilon \to \mathcal{H}^\varepsilon, \underline{B}^\varepsilon \underline{u} := u_i|_{\Gamma^\varepsilon} - u_e|_{\Gamma^\varepsilon} \forall\, \underline{u} \in \underline{\mathcal{V}}_0^\varepsilon,\\ &\underline{B} : \underline{\mathcal{V}} \to \mathcal{H}, \quad \underline{B}\underline{u} := u_i - u_e \qquad \forall\, \underline{u} \in \underline{\mathcal{V}}_0. \end{aligned} \tag{2.11}$$

It is easy to check that the bilinear forms $\underline{a}^\varepsilon(\cdot,\cdot) + \underline{b}^\varepsilon(\cdot,\cdot)$ and $\underline{a}(\cdot,\cdot) + \underline{b}(\cdot,\cdot)$ are scalar products on $\underline{\mathcal{V}}_0^\varepsilon$ and $\underline{\mathcal{V}}_0$; they induce on $\underline{\mathcal{V}}_0^\varepsilon$ and $\underline{\mathcal{V}}_0$ the usual topology as closed subspaces of $\underline{\mathcal{V}}^\varepsilon$ and $\underline{\mathcal{V}}$, respectively. As in (1.12a,b,c) and (1.20a,b,c), we adopt the convention of writing the associated quadratic forms as

$$\underline{b}^\varepsilon(\underline{u}) := \underline{b}^\varepsilon(\underline{u},\underline{u}), \quad \underline{a}^\varepsilon(\underline{u}) := \underline{a}^\varepsilon(\underline{u},\underline{u}), \quad \underline{b}(\underline{u}) := \underline{b}(\underline{u},\underline{u}), \quad \underline{a}(\underline{u}) := \underline{a}(\underline{u},\underline{u}). \tag{2.12}$$

2.2. Uniform bounds for extension operators. Let us now discuss some extension results for functions defined in $\Omega^\varepsilon_{i,e}, \Gamma^\varepsilon$, which will be applied to the notion of convergence introduced in Definition 1.1.

DEFINITION 2.2 (extensions). *We say that* $\breve{\underline{u}}^\varepsilon \in \underline{\mathcal{V}}_{loc} = H^1_{loc}(\Omega) \times H^1_{loc}(\Omega)$ *is an* extension *of* $\underline{u}^\varepsilon \in \underline{\mathcal{V}}^\varepsilon$ *if*

$$\breve{u}^\varepsilon_{i,e}|_{\Omega^\varepsilon_{i,e}} = u^\varepsilon_{i,e}. \tag{2.13}$$

Analogously, we say that $\breve{w}^\varepsilon \in H^1_{loc}(\Omega)$ *is an* extension *of* $w^\varepsilon \in H^{1/2}_{loc}(\Gamma^\varepsilon)$ *if*

$$\breve{w}^\varepsilon|_{\Gamma^\varepsilon} = w^\varepsilon \quad \textit{in the sense of traces.} \tag{2.14}$$

One of the technical difficulties in the present setting is to find suitable extension operators $T^\varepsilon_{i,e}$ of functions defined only on $\Omega^\varepsilon_{i,e}$ to the whole Ω which preserve uniform bounds of the L^2 and H^1 norms. Due to the possible irregular behavior of the boundary of $\Omega_{i,e}$, only *local bounds* are available.

The following result proved by Acerbi et al. [1] is almost optimal. The crucial assumption, here is that the sets $E_{i,e}$ are Lipschitz and connected; we denote by $\Omega(\delta)$, $\delta \ge 0$, the open subset of Ω defined by

$$\Omega(\delta) := \big\{x \in \Omega : d(x, \mathbb{R}^d \setminus \Omega) > \delta\big\}. \tag{2.15}$$

THEOREM 2.3 (see [1]). *There exists linear and continuous extension operators* $T^\varepsilon_{i,e} : H^1(\Omega^\varepsilon_{i,e}) \to H^1_{loc}(\Omega)$ *and three constants* $k_0, h_0, h_1 > 0$ *independent of* $\varepsilon > 0$ *and* Ω*, such that for every* $u \in H^1(\Omega^\varepsilon_{i,e})$ *we have*

$$T^\varepsilon_{i,e} u = u \qquad \textit{a.e. in } \Omega^\varepsilon_{i,e}, \tag{2.16}$$

$$\int_{\Omega(\varepsilon k_0)} |T^\varepsilon_{i,e} u|^2\, dx \le h_0 \int_{\Omega^\varepsilon_{i,e}} |u|^2\, dx, \tag{2.17}$$

$$\int_{\Omega(\varepsilon k_0)} |\nabla T^\varepsilon_{i,e} u|^2\, dx \le h_1 \int_{\Omega^\varepsilon_{i,e}} |\nabla u|^2\, dx. \tag{2.18}$$

As usual we set $\underline{T}^\varepsilon := \big(T_i^\varepsilon, T_e^\varepsilon\big) : \underline{\mathcal{V}}^\varepsilon \to \underline{\mathcal{V}}_{loc}$.

Remark 2.4. In general, it is not possible to construct a family of extension operators $T_{i,e}^\varepsilon : H^1(\Omega_{i,e}^\varepsilon) \to H^1(\Omega)$ satisfying (2.16), (2.17), (2.18) with $\Omega(\varepsilon k_0)$ replaced by Ω, since we do not have any control of the behavior of E^ε near $\partial\Omega$. For more details and an explicit counterexample we refer to [1].

2.3. Generalized Riemann–Lebesgue lemma. Let us first recall a well-known version of the Riemann–Lebesgue lemma.

LEMMA 2.5 (generalized Riemann–Lebesgue lemma). *Let A be a bounded open subset of $\mathbb{R}^d$ with $\mathscr{L}^d(\partial A) = 0$ and let $\zeta \in C^0(\overline{A})$. Then*

$$\lim_{\varepsilon\downarrow 0} \int_{A\cap E_{i,e}^\varepsilon} \zeta(x)\,dx = \beta_{i,e} \int_A \zeta(x)\,dx, \tag{2.19}$$

$$\lim_{\varepsilon\downarrow 0} \varepsilon \int_{A\cap\Gamma^\varepsilon} \zeta(x)\,d\mathscr{H}^{d-1}(x) = \beta \int_A \zeta(x)\,dx, \tag{2.20}$$

where the coefficients $\beta_{i,e}, \beta$ are defined in (1.14).

Remark 2.6 (weak* convergence in L^∞). Limit (2.19) shows that the characteristic functions $\chi_{A\cap E_{i,e}^\varepsilon}$ of $A\cap E_{i,e}^\varepsilon$ are converging to $\beta_{i,e}\,\chi_A$ in the sense of distributions as $\varepsilon\downarrow 0$; since they are also uniformly bounded in $L^\infty(\Omega)$, an obvious weak*-compactness argument shows that

$$\chi_{A\cap E_{i,e}^\varepsilon} \rightharpoonup^* \beta_{i,e}\,\chi_A \quad \text{in } L^\infty(\Omega) \quad \text{as } \varepsilon\downarrow 0. \tag{2.21}$$

Remark 2.7 (weak* convergence in the space of measures). Lemma 2.5 also shows that the measures $\lambda_{i,e}^\varepsilon, \lambda^\varepsilon$ defined by (1.17) converge to $\lambda_{i,e}, \lambda$, respectively, as $\varepsilon\downarrow 0$ in the weak* topology of the space of finite Radon measures on Ω.

The next result reinforces Lemma 2.5 and how weak convergence in $H^1_{loc}(\Omega)$ implies the convergence in the sense of Definition 1.1. Since we will deal with functionals depending on the continuous parameter $\varepsilon > 0$ or on the discrete values of a suitable decreasing infinitesimal sequence $\{\varepsilon_n\}_{n\in\mathbb{N}}$, for notational convenience we will treat both cases in the same way by considering a general nonempty set Λ of real numbers such that

$$\Lambda \subset (0, +\infty), \quad \inf\Lambda = 0. \tag{2.22}$$

Expressions like $\lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda}$, $\liminf_{\varepsilon\downarrow 0,\varepsilon\in\Lambda}$, etc., have an obvious meaning as limits for ε going to 0 in Λ. Of course, when Λ contains an open interval $(0,\delta)$, $\delta > 0$, we will use the usual notation $\lim_{\varepsilon\downarrow 0}$.

PROPOSITION 2.8 (weak H^1_{loc}-convergence yields convergence of Definition 1.1). *Let us suppose that z^ε weakly converge to z in $H^1_{loc}(\Omega)$ for $\varepsilon\downarrow 0, \varepsilon\in\Lambda$. Then for every continuous function $\zeta \in C^0_c(\Omega)$ we have*

$$\lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} \int_{\Omega_{i,e}^\varepsilon} z^\varepsilon(x)\zeta(x)\,dx = \beta_{i,e} \int_\Omega z(x)\zeta(x)\,dx, \tag{2.23}$$

$$\lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} \varepsilon \int_{\Gamma^\varepsilon} z^\varepsilon(x)\zeta(x)\,d\mathscr{H}^{d-1}(x) = \beta \int_A z(x)\zeta(x)\,dx. \tag{2.24}$$

In particular $z^\varepsilon|_{\Gamma^\varepsilon}$ and $z^\varepsilon|_{\Omega_{i,e}^\varepsilon}$ converge to z according to Definition 1.1.

Proof. By the Rellich compactness theorem, we know that $z^\varepsilon \to z$ strongly in $L^2_{loc}(\Omega)$ as $\varepsilon\downarrow 0, \varepsilon\in\Lambda$. Equation (2.23) thus follows directly from Remark 2.6 since

$$\chi_{\Omega_{i,e}^\varepsilon} \rightharpoonup^* \beta_{i,e} \quad \text{in } L^\infty(\Omega), \quad \text{and therefore} \quad z^\varepsilon\chi_{\Omega_{i,e}^\varepsilon} \rightharpoonup \beta_{i,e} z \ \text{ weakly in } L^2_{loc}(\Omega).$$

In order to prove (2.24), we first observe that for ε sufficiently small, we can find pluricellular regions (recall (1.2))

$$R^\varepsilon = \bigcup_{m=1}^{M^\varepsilon} \varepsilon\left(Y + \sum_{k=1}^{d} j^\varepsilon_{m,k}\ {}_k\right) \quad \text{for some} \quad {}^{\varepsilon}_{m} = (j^\varepsilon_{m,1}, \cdots, j^\varepsilon_{m,d}) \in \mathbb{Z}^d,$$

and a regular open set A such that

$$\operatorname{supp}\zeta \subset R^\varepsilon \subset A \subset\subset \Omega.$$

Poincaré inequality and a rescaling argument easily yield

$$\varepsilon\mathscr{H}^{d-1}(R^\varepsilon \cap \varepsilon\Gamma) = \beta\mathscr{L}^d(R^\varepsilon), \quad \varepsilon^2\|z\|^2_{L^1(R^\varepsilon\cap\varepsilon\Gamma)} \le \varepsilon\beta\mathscr{L}^d(A)\|z\|^2_{L^2(R^\varepsilon\cap\varepsilon\Gamma)}, \tag{2.25}$$

$$\varepsilon\|z\|^2_{L^2(R^\varepsilon\cap\varepsilon\Gamma)} \le c_1\left(\|z\|^2_{L^2(R^\varepsilon_{i,e})} + \varepsilon^2\|\nabla z\|^2_{L^2(R^\varepsilon_{i,e})}\right). \tag{2.26}$$

Then, if $S := \sup_{x\in\Omega}|\zeta(x)|$, we have

$$\begin{aligned}\left|\varepsilon\int_{\Gamma^\varepsilon}\big(z^\varepsilon(x) - z(x)\big)\zeta(x)\,d\mathscr{H}^{d-1}(x)\right| &\le \varepsilon S\|z^\varepsilon - z\|_{L^1(R^\varepsilon\cap\varepsilon\Gamma)}\\ &\le C\Big(\|z^\varepsilon - z\|_{L^2(A)} + \varepsilon\|\nabla z^\varepsilon - \nabla z\|_{L^2(A)}\Big),\end{aligned} \tag{2.27}$$

where $C := S\sqrt{c_1\beta\mathscr{L}^d(A)}$; since z^ε is bounded in $H^1(A)$ and converges to z in $L^2(A)$, (2.27) vanishes as $\varepsilon\downarrow 0$. Thus we simply have to prove (2.24) for $z^\varepsilon \equiv z$.

Choosing now another arbitrary function $\eta \in H^1(A)\cap C^0(\overline{A})$ and taking into account Lemma 2.5, we get

$$\begin{aligned}&\limsup_{\varepsilon\downarrow 0,\varepsilon\in\Lambda}\left|\varepsilon\int_{\Gamma^\varepsilon} z(x)\zeta(x)\,d\mathscr{H}^{d-1}(x) - \beta\int_\Omega z(x)\zeta(x)\,dx\right|\\ &\qquad\le \limsup_{\varepsilon\downarrow 0,\varepsilon\in\Lambda}\left|\varepsilon\int_{\Gamma^\varepsilon}\big(z(x)-\eta(x)\big)\zeta(x)\,d\mathscr{H}^{d-1}(x)\right| + \left|\beta\int_\Omega\big(z(x)-\eta(x)\big)\zeta(x)\,dx\right|\\ &\qquad\le (1+\beta)Z\Big(\varepsilon\|z-\eta\|_{L^1(R^\varepsilon\cap\varepsilon\Gamma)} + \|z-\eta\|_{L^1(R^\varepsilon)}\Big) \le C'\|z-\eta\|_{H^1(A)}\end{aligned}$$

for a constant C' independent of z and η. Being η arbitrary and A regular, a standard density result yields (2.24). □

COROLLARY 2.9. *Suppose that $w^\varepsilon \in H^{1/2}_{loc}(\Gamma^\varepsilon)$ converge to $w \in L^1_{loc}(\Omega)$ according to Definition* 1.1 *and let $\breve{w}^\varepsilon \in H^1_{loc}(\Omega)$ be an extension of w^ε which is uniformly bounded in $H^1(A)$ for every open subset $A \subset\subset \Omega$. Then $w \in H^1_{loc}(\Omega)$ and $\breve{w}^\varepsilon \rightharpoonup w$ in $H^1_{loc}(\Omega)$.*

Proof. By Proposition 2.8 w is the unique limit point of any weakly convergent subsequence of $\breve{w}^\varepsilon$ in $H^1_{loc}(\Omega)$. □

2.4. Compactness properties. Recall that in (1.11) we introduced an open subset $\Omega_0 \subset\subset \Omega$ which induces closed subspaces of $H^1(\Omega^\varepsilon_e)$ and $H^1(\Omega)$ through the integral conditions (2.3). By Lemma 2.5 with $A := \Omega_0$ and $\zeta \equiv 1$ we have that

$$\lim_{\varepsilon\downarrow 0}\mathscr{L}^d(\Omega_0\cap\varepsilon E_e) = \beta_e\mathscr{L}^d(\Omega_0), \quad \lim_{\varepsilon\downarrow 0}\varepsilon\mathscr{H}^{d-1}(\Omega_0\cap\varepsilon\Gamma) = \beta\mathscr{L}^d(\Omega_0), \tag{2.28}$$

so that we can always assume that

$$\mathscr{L}^d(\Omega_0 \cap \varepsilon E_e) \geq \frac{\beta_e}{2}\mathscr{L}^d(\Omega_0), \quad \varepsilon\mathscr{H}^{d-1}(\Omega_0 \cap \varepsilon\Gamma) \geq \frac{\beta}{2}\mathscr{L}^d(\Omega_0) \quad \forall\, \varepsilon \in \Lambda. \tag{2.29}$$

LEMMA 2.10 (uniform local H^1 bounds and compactness). *Let $\underline{u}^\varepsilon \in \underline{\mathcal{V}}_0^\varepsilon$, $\varepsilon \in \Lambda$, be a family of functions satisfying*

$$\sup_{\varepsilon\in\Lambda}\Big(\underline{a}^\varepsilon(\underline{u}^\varepsilon) + \underline{b}^\varepsilon(\underline{u}^\varepsilon)\Big) = S < +\infty. \tag{2.30}$$

Then for every open subset $A \subset\subset \Omega$ we have

$$\sup_{\varepsilon\in\Lambda}\|\underline{T}^\varepsilon\underline{u}^\varepsilon\|_{H^1(A)} < +\infty. \tag{2.31}$$

In particular, there exists an infinitesimal subsequence $\Lambda' = (\varepsilon_j)_{j\in\mathbb{N}} \subset \Lambda$ and a limit function $\underline{u} \in \underline{\mathcal{V}}_0$ such that

$$\lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda'} \underline{T}^\varepsilon\underline{u}^\varepsilon = \underline{u} \quad \textit{weakly in } \underline{\mathcal{V}}_{loc} = H^1_{loc}(\Omega)\times H^1_{loc}(\Omega). \tag{2.32}$$

Proof. Let $\underline{u}^\varepsilon = (u_i^\varepsilon, u_e^\varepsilon) \in \underline{\mathcal{V}}_0^\varepsilon, \underline{\check{u}}^\varepsilon := \underline{T}^\varepsilon\underline{u}^\varepsilon \in \underline{\mathcal{V}}_{loc}$, and let us choose $\delta > 0$ sufficiently small such that (see (2.15) and, e.g., [34])

$$A \subset \Omega(\delta), \quad \Omega_0 \subset \Omega(2\delta), \quad \Omega(\delta) \text{ is Lipschitz.} \tag{2.33}$$

We can suppose that $(k_0 + \ell)\varepsilon < \delta$; by using the properties (2.16), (2.17), (2.18) of the extension operators $T^\varepsilon_{i,e}$, we get

$$\|\nabla\check{u}^\varepsilon_{i,e}\|^2_{L^2(A)} \leq \|\nabla\check{u}^\varepsilon_{i,e}\|^2_{L^2(\Omega(\delta))} \leq h_1\|\nabla u^\varepsilon_{i,e}\|^2_{L^2(\Omega^\varepsilon_{i,e})} \leq h_1\sigma^{-1}\underline{a}^\varepsilon(\underline{u}^\varepsilon). \tag{2.34}$$

Poincaré inequality yields constants $c^\varepsilon_{i,e}$ (depending on $u^\varepsilon_{i,e}$) and c_P (depending only on Ω) satisfying

$$\|\check{u}^\varepsilon_{i,e} - c^\varepsilon_{i,e}\|_{L^2(\Omega(\delta))} \leq c_P\|\nabla\check{u}^\varepsilon_{i,e}\|_{L^2(\Omega(\delta))}. \tag{2.35}$$

Setting $\Omega^\varepsilon_{0,e} := \Omega_0 \cap \varepsilon E_e$, by the properties of the extension operator we know that

$$\int_{\Omega_0^\varepsilon}\check{u}^\varepsilon_e\,dx = 0, \tag{2.36}$$

so that

$$|c^\varepsilon_e|\,\mathscr{L}^d(\Omega^\varepsilon_{0,e}) \leq \int_{\Omega^\varepsilon_{0,e}}|c^\varepsilon_e - \check{u}^\varepsilon_e|\,dx \leq \mathscr{L}^d(\Omega^\varepsilon_{0,e})^{1/2}\|\check{u}^\varepsilon_e - c^\varepsilon_e\|_{L^2(\Omega^\varepsilon_{0,e})}$$

and therefore by (2.29) we have

$$|c^\varepsilon_e| \leq \Big(\frac{\beta_e}{2}\mathscr{L}^d(\Omega_0)\Big)^{-1/2}\|\check{u}^\varepsilon_e - c^\varepsilon_e\|_{L^2(\Omega(\delta))},$$

which, together with (2.35) and (2.34), shows that c^ε_e is uniformly bounded with respect to ε. In order to get an analogous bound for c^ε_i we will use the estimate

$$\varepsilon\int_{\Gamma^\varepsilon}|u^\varepsilon_i - u^\varepsilon_e|^2\,d\mathscr{H}^{d-1} = \underline{b}^\varepsilon(\underline{u}^\varepsilon) \leq S, \tag{2.37}$$

observing that by (2.33) and (2.26),

$$\begin{aligned}\varepsilon\int_{\Omega_0\cap\varepsilon\Gamma}|u^\varepsilon_{i,e}-c^\varepsilon_{i,e}|^2\,d\mathscr{H}^{d-1}\le& c_1\int_{\Omega(\delta)\cap\varepsilon E_{i,e}}\Big((u^\varepsilon_{i,e}-c^\varepsilon_{i,e})^2+\varepsilon^2\left|\nabla u^\varepsilon_{i,e}\right|^2\Big)\,dx\\ \le& c_1({c_P}^2+\varepsilon^2)\|\nabla\breve{u}^\varepsilon_{i,e}\|^2_{L^2(\Omega(\delta))}\le c_2:=c_1(c_P+\varepsilon^2)h_1\sigma^{-1}S.\end{aligned}$$

Thus we get

$$\begin{aligned}\frac{\beta}{2}\mathscr{L}^d(\Omega_0)|c^\varepsilon_i-c^\varepsilon_e|^2&\le\varepsilon\int_{\Omega_0\cap\varepsilon\Gamma}|c^\varepsilon_i-c^\varepsilon_e|^2\,d\mathscr{H}^{d-1}\\&\le\varepsilon\int_{\Omega_0\cap\varepsilon\Gamma}\left|c^\varepsilon_i-c^\varepsilon_e-(u^\varepsilon_i-u^\varepsilon_e)+(u^\varepsilon_i-u^\varepsilon_e)\right|^2d\mathscr{H}^{d-1}\\&\le3\varepsilon\int_{\Gamma^\varepsilon}|u^\varepsilon_i-u^\varepsilon_e|^2\,d\mathscr{H}^{d-1}+6c_2=3\underline{b}^\varepsilon(\underline{u}^\varepsilon)+6c_2\le3S+6c_2.\end{aligned}$$

It follows that also c^ε_i is uniformly bounded with respect to ε, so that $\breve{u}^\varepsilon_{i,e}$ are bounded in $H^1(A)$.

A standard diagonal argument yields (2.32) for some $\underline{u}\in\underline{\mathcal{V}}$; the fact that $\underline{u}$ belongs to $\underline{\mathcal{V}}_0$, too, follows from Proposition 2.8. ∎

COROLLARY 2.11. *Let us consider $\underline{u}\in L^2_{loc}(\Omega)\times L^2_{loc}(\Omega)$ and let us suppose that $\underline{u}^\varepsilon\in\underline{\mathcal{V}}^\varepsilon_0$, $\varepsilon\in\Lambda$, satisfy*

$$\sup_{\varepsilon\in\Lambda}\Big(\underline{a}^\varepsilon(\underline{u}^\varepsilon)+\underline{b}^\varepsilon(\underline{u}^\varepsilon)\Big)<+\infty. \tag{2.38}$$

Then $\underline{u}\in\underline{\mathcal{V}}_0$ and $\underline{u}^\varepsilon\to\underline{u}$ according to Definition 1.1 *if and only if there exist extensions $\breve{\underline{u}}^\varepsilon\in\underline{\mathcal{V}}_{loc}$ of $\underline{u}^\varepsilon$ such that*

$$\breve{\underline{u}}^\varepsilon\rightharpoonup\underline{u}\quad\textit{weakly in }\underline{\mathcal{V}}_{loc}=H^1_{loc}(\Omega)\times H^1_{loc}(\Omega)\quad\textit{as }\varepsilon\downarrow0,\varepsilon\in\Lambda. \tag{2.39}$$

Moreover, if $\underline{u}^\varepsilon\to\underline{u}$ according to Definition 1.1, *then* every *extension $\breve{\underline{u}}^\varepsilon$ bounded in $\underline{\mathcal{V}}_{loc}$ is weakly convergent to $\underline{u}$ in $\underline{\mathcal{V}}_{loc}$; in particular, we always have*

$$\underline{T}^\varepsilon(\underline{u}^\varepsilon)\rightharpoonup\underline{u}\quad\textit{weakly in }\underline{\mathcal{V}}_{loc}=H^1_{loc}(\Omega)\times H^1_{loc}(\Omega), \tag{2.40}$$

and setting $v^\varepsilon:=\underline{B}^\varepsilon\underline{u}^\varepsilon=u^\varepsilon_i|_{\Gamma^\varepsilon}-u^\varepsilon_e|_{\Gamma^\varepsilon}$ we have

$$v^\varepsilon\to u_i-u_e\quad\textit{according to Definition }1.1. \tag{2.41}$$

Proof. If $\breve{\underline{u}}^\varepsilon$ is an extension of $\underline{u}^\varepsilon$ which is bounded in $\underline{\mathcal{V}}_{loc}$, then any weak limit point $\breve{\underline{u}}$ in $\underline{\mathcal{V}}_{loc}$ should coincide with $\underline{u}$ and belongs to $\underline{\mathcal{V}}_0$ by Proposition 2.8. Lemma 2.10 and (2.38) show that $\underline{T}^\varepsilon$ provides such an extension, so that the equivalence between the two notions of convergence is proved. ∎

Remark 2.12. Observe that for a general family $\underline{u}^\varepsilon\in\underline{\mathcal{V}}^\varepsilon_0$ converging to $\underline{u}$ according to Definition 1.1, such that $v^\varepsilon=\underline{B}^\varepsilon\underline{u}^\varepsilon$ converges to v as $\varepsilon\downarrow0,\varepsilon\in\Lambda$, it may happen that $v\ne u_i-u_e$ in Ω. The above corollary shows that this inconvenience can be avoided if $\underline{u}$ satisfies the equibounded energy condition (2.38).

PROPOSITION 2.13 (compactness for the convergence of Definition 1.1). *For $\varepsilon\in\Lambda$ let $\underline{u}^\varepsilon\in\underline{\mathcal{V}}^\varepsilon_0$ (resp., $w^\varepsilon\in L^2(\Gamma^\varepsilon)$) satisfy* (2.38) *(resp., $\sup_{\varepsilon\in\Lambda}b^\varepsilon(w^\varepsilon)<+\infty$). Then there exists a decreasing vanishing subsequence $\Lambda'=(\varepsilon_j)_{j\in\mathbb{N}}\subset\Lambda$ and an element $\underline{u}\in\underline{\mathcal{V}}_0$ (resp., $w\in\mathcal{H}$) such that $\underline{u}^{\varepsilon_j}$ converges to $\underline{u}$ as $j\to\infty$ according to Definition* 1.1 *(resp., $w^{\varepsilon_j}\to w$).*

Proof. The compactness of $\underline{u}^\varepsilon$ follows directly from Lemma 2.10 and Corollary 2.11. In the case of w^ε we observe that the total variation of the measures $\tilde{w}^\varepsilon$ introduced in (1.18) is easily bounded by

$$|\tilde{w}^\varepsilon|(\Omega) = \varepsilon \int_{\Gamma^\varepsilon} |w^\varepsilon(x)| \, d\mathscr{H}^{d-1}(x) \le C b^\varepsilon(w^\varepsilon)^{1/2}$$

thanks to (2.28). Therefore we can extract a subsequence $\Lambda' = (\varepsilon_j)_{j\in\mathbb{N}}$ and a limiting Radon measure $\tilde{w}$ in Ω such that $\tilde{w}^\varepsilon \rightharpoonup^* \tilde{w}$, i.e.,

$$\lim_{\varepsilon\to 0, \varepsilon\in\Lambda'} \varepsilon \int_{\Gamma^\varepsilon} w^\varepsilon(x)\zeta(x) \, d\mathscr{H}^{d-1}(x) = \int_\Omega \zeta(x) \, d\tilde{w}(x) \quad \forall\, \zeta \in C^0_c(\Omega). \tag{2.42}$$

On the other hand, keeping the same notation of (1.17), we have

$$w^\varepsilon = \frac{d\tilde{w}^\varepsilon}{d\lambda^\varepsilon}, \quad b^\varepsilon(w^\varepsilon) = \int_\Omega \left| \frac{d\tilde{w}^\varepsilon}{d\lambda^\varepsilon}(x)\right|^2 \, d\lambda^\varepsilon(x).$$

Since $\lambda^\varepsilon \rightharpoonup^* \lambda = \beta\mathscr{L}^d$, as shown by Remark 2.7, general lower semicontinuity results on integral functionals defined on measures [4, Thm. 2.34] show that for every convex function $\psi : \mathbb{R} \to [0, +\infty]$ with superlinear growth (in our case $\psi(s) := s^2$)

$$\liminf_{\varepsilon\downarrow 0, \varepsilon\in\Lambda'} \int_\Omega \psi\Big(\frac{d\tilde{w}^\varepsilon}{d\lambda^\varepsilon}(x)\Big) \, d\lambda^\varepsilon(x) < +\infty \quad \Rightarrow \quad \tilde{w} = w\cdot\lambda << \lambda \tag{2.43}$$

and

$$\int_\Omega \psi\big(w(x)\big) \, d\lambda(x) \le \liminf_{\varepsilon\to 0, \varepsilon\in\Lambda'} \int_\Omega \psi\Big(\frac{d\tilde{w}^\varepsilon}{d\lambda^\varepsilon}\Big) \, d\lambda^\varepsilon. \tag{2.44}$$

It follows that $\tilde{w} = \beta w \mathscr{L}^d$ for $w \in \mathcal{H} = L^2(\Omega)$ and (2.42) yields (1.16). □

2.5. Lower semicontinuity and convergence results for integral functionals on Γ^ε. Arguing as in the last part of the proof of Proposition 2.13 and taking into account (2.43) and (2.44), we have the following.

PROPOSITION 2.14 (lower semicontinuity for the convergence of Definition 1.1). *Let $v^\varepsilon \in L^1_{loc}(\Gamma^\varepsilon)$, $\varepsilon \in \Lambda$, converge to $v \in L^1_{loc}(\Omega)$ according to Definition 1.1 and let $\psi : \mathbb{R} \to [0, +\infty]$ be a convex, lower semicontinuous function with superlinear growth. We have*

$$\liminf_{\varepsilon\downarrow 0, \varepsilon\in\Lambda} \varepsilon \int_{\Gamma^\varepsilon} \psi(v^\varepsilon(x)) \, d\mathscr{H}^{d-1}(x) \ge \beta \int_\Omega \psi(v(x)) \, dx. \tag{2.45}$$

When ψ is locally Lipschitz and v^ε are uniformly bounded with uniformly bounded extensions in $H^1_{loc}(\Omega)$, we can prove a convergence result.

LEMMA 2.15. *If $\psi : \mathbb{R} \to \mathbb{R}$ is a locally Lipschitz function and*

$$v^\varepsilon \rightharpoonup v \quad \textit{weakly in } H^1_{loc}(\Omega) \textit{ as } \varepsilon \downarrow 0, \varepsilon \in \Lambda, \quad \sup_{\varepsilon\in\Lambda} \|v^\varepsilon\|_{L^\infty(\Omega)} = S < +\infty,$$

then

$$\lim_{\varepsilon\downarrow 0, \varepsilon\in\Lambda} \varepsilon \int_{\Gamma^\varepsilon} \psi(v^\varepsilon) \, d\mathscr{H}^{d-1} = \beta \int_\Omega \psi(v) \, dx. \tag{2.46}$$

Proof. Up to a possible modification of ψ outside $[-S,S]$, it is not restrictive to assume that ψ is globally Lipschitz; since $\psi(v^\varepsilon) \rightharpoonup \psi(v)$ in $H^1_{loc}(\Omega)$, it is not restrictive to assume that ψ is the identity in (2.46).

If $\zeta \in C^0_c(\Omega)$, Proposition 2.8 yields

$$\begin{aligned}\limsup_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} &\left|\varepsilon\int_{\Gamma^\varepsilon} v\, d\mathscr{H}^{d-1} - \beta\int_\Omega v\,dx\right| \\ &\le \limsup_{\varepsilon\downarrow 0}\varepsilon\int_{\Gamma^\varepsilon}|v^\varepsilon|\,|1-\zeta|\,d\mathscr{H}^{d-1} + \beta\int_\Omega |v|\,|1-\zeta|\,dx \\ &\le S\limsup_{\varepsilon\downarrow 0}\varepsilon\int_{\Gamma^\varepsilon}|1-\zeta|\,d\mathscr{H}^{d-1} + S\beta\int_\Omega|1-\zeta|\,dx \\ &\le 2S\beta\int_\Omega |1-\zeta|\,dx.\end{aligned}$$

Taking the infimum of the last integral with respect to ζ, we conclude the proof. ◻

Combining Proposition 2.14, Lemma 2.15, and the equivalence property stated by (2.41) of Corollary 2.11, we obtain the following.

COROLLARY 2.16. *If $\underline{u}^\varepsilon \in \underline{\mathcal{V}}^\varepsilon_0$, $\varepsilon \in \Lambda$, is a family satisfying the bounded energy condition* (2.30) *and converging to $\underline{u} \in \underline{\mathcal{V}}_0$ according to Definition* 1.1, *then for every convex functional $\psi : \mathbb{R} \to [0,+\infty)$ we have*

$$\liminf_{\varepsilon\downarrow 0,\varepsilon\in\Lambda}\varepsilon\int_{\Gamma^\varepsilon}\psi(u^\varepsilon_i - u^\varepsilon_e)\,d\mathscr{H}^{d-1} \ge \beta\int_\Omega \psi(u_i-u_e)\,dx. \tag{2.47}$$

Moreover, if $\sup_{\varepsilon\in\Lambda}\|u^\varepsilon_i - u^\varepsilon_e\|_{L^\infty(\Gamma^\varepsilon)} < +\infty$, *then*

$$\lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda}\int_{\Gamma^\varepsilon}\psi(u^\varepsilon_i - u^\varepsilon_e)\,d\mathscr{H}^{d-1} = \beta\int_\Omega\psi(u_i-u_e)\,dx. \tag{2.48}$$

We conclude this section with a final auxiliary result.

LEMMA 2.17 (bulk energy approximation). *Let $\psi : \mathbb{R} \to [0,+\infty)$ be a locally Lipschitz function such that $\psi' \ge 0$ in $(a,+\infty)$, $\psi' \le 0$ in $(-\infty,-a)$ for some $a > 0$, and let $\underline{u} \in \underline{\mathcal{V}}_0$ such that*

$$\int_\Omega \psi(u_i-u_e)\,dx < +\infty. \tag{2.49}$$

There exists a sequence $(\underline{u}_k)_{k\in\mathbb{N}} \subset \underline{\mathcal{V}}_0$ such that

$$\begin{gathered} u_{i,k} - u_{e,k} \in L^\infty(\Omega), \quad \lim_{k\uparrow\infty}\underline{u}_k \to \underline{u} \quad \textit{strongly in } \underline{\mathcal{V}}_0, \\ \lim_{k\uparrow\infty}\int_\Omega \psi(u_{i,k}-u_{e,k})\,dx = \int_\Omega\psi(u_i-u_e)\,dx. \end{gathered} \tag{2.50}$$

Proof. Recalling that $v := u_i - u_e$, we set

$$v_k := (v\wedge k)\vee(-k), \quad s = (u_i+u_e)/2, \quad \gamma_k := \frac{1}{\mathscr{L}^d(\Omega_0)}\int_{\Omega_0}\big(s(x) - v_k(x)/2\big)\,dx$$

and

$$u_{i,k} := s - \gamma_k + v_k/2, \quad u_{e,k} := s - \gamma_k - v_k/2.$$

By construction, $\underline{u}_k \in \underline{\mathcal{V}}_0$ and

$$u_{i,k} - u_{e,k} = v_k \in L^\infty(\Omega), \quad \lim_{k\uparrow\infty} v_k = v \quad \text{strongly in } H^1(\Omega).$$

In particular,

$$\lim_{k\uparrow\infty} \gamma_k = \frac{1}{\mathscr{L}^d(\Omega_0)} \int_{\Omega_0} \big(s(x) - v(x)/2\big)\, dx = \frac{1}{\mathscr{L}^d(\Omega_0)} \int_{\Omega_0} u_e(x)\, dx = 0,$$

so that

$$\underline{u}_k \to \underline{u} \quad \text{strongly in } \underline{\mathcal{V}}_0 \quad \text{as } k \uparrow \infty.$$

Finally, since $k \mapsto \psi(v_k(x))$ is (definitively) nondecreasing and converges pointwise to $\psi(v(x))$, Levi's theorem yields

$$\lim_{k\uparrow+\infty} \int_\Omega \psi(v_k(x))\, dx = \int_\Omega \psi(v(x))\, dx. \qquad \square$$

3. Γ-convergence results.

3.1. Γ-convergence. For the reader's convenience, we include hereafter a few definitions and theorems used in what follows [17, 19].

DEFINITION 3.1 (Γ-convergence). *Let (X, d) be a metric space and $\mathscr{F}^\varepsilon$, $\mathscr{F}$, $\varepsilon \in \Lambda$, be functionals from X into $[-\infty, +\infty]$. We say that $(\mathscr{F}^\varepsilon)_{\varepsilon\in\Lambda}$ $\Gamma(X)$-converges to $\mathscr{F}$ as $\varepsilon \downarrow 0, \varepsilon \in \Lambda$, i.e.,*

$$\mathscr{F} = \Gamma(X)\text{-}\lim_{\varepsilon\downarrow 0, \varepsilon\in\Lambda} \mathscr{F}^\varepsilon,$$

if for every $x \in X$ the following conditions are fulfilled:

$$\forall\, x^\varepsilon \in X: \quad \lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} x^\varepsilon = x \quad \Rightarrow \quad \liminf_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} \mathscr{F}^\varepsilon(x^\varepsilon) \geq \mathscr{F}(x), \tag{3.1}$$

$$\exists \hat{x}^\varepsilon \in X: \quad \lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} \hat{x}^\varepsilon = x, \quad \limsup_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} \mathscr{F}^\varepsilon(\hat{x}^\varepsilon) \leq \mathscr{F}(x). \tag{3.2}$$

Remark 3.2. Notice that by (3.1) the "lim sup" in (3.2) is in fact a limit. We will sometimes use a slight variant of this property, when $\mathscr{F}^\varepsilon, \mathscr{F}$ admit the decomposition $\mathscr{F}^\varepsilon = \mathscr{F}_1^\varepsilon + \mathscr{F}_2^\varepsilon$, $\mathscr{F} = \mathscr{F}_1 + \mathscr{F}_2$, and $\mathscr{F}_1^\varepsilon, \mathscr{F}_2^\varepsilon$ satisfy condition (3.1) with respect to $\mathscr{F}_1, \mathscr{F}_2$. In this case, every "optimal" family $\hat{x}^\varepsilon$ for $\mathscr{F}^\varepsilon$ satisfies

$$\hat{x}^\varepsilon \to x, \ \limsup_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} \mathscr{F}^\varepsilon(\hat{x}^\varepsilon) \leq \mathscr{F}(x) \quad \Rightarrow \quad \lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} \mathscr{F}_j^\varepsilon(\hat{x}^\varepsilon) = \mathscr{F}_j(x), \qquad j = 1, 2. \tag{3.3}$$

THEOREM 3.3 (see [19, Cor. 2.4]). *Let (X, d) be a metric space, $\mathscr{F}^\varepsilon, \mathscr{F}$, $\varepsilon \in \Lambda$, be functionals from X into $(-\infty, +\infty]$ such that $\mathscr{F} = \Gamma(X)\text{-}\lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} \mathscr{F}^\varepsilon$, and let $x^\varepsilon \in X$ be a minimizer for $\mathscr{F}^\varepsilon$, i.e.,*

$$\mathscr{F}^\varepsilon(x^\varepsilon) = \min\left\{\mathscr{F}^\varepsilon(x) \,:\, x \in X\right\}.$$

If the family $(x^\varepsilon)_{\varepsilon\in\Lambda}$ is relatively compact *in X and x^0 is the* unique minimizer *for $\mathscr{F}$, then*

$$\lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} x^\varepsilon = x^0, \quad \lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} \mathscr{F}^\varepsilon(x^\varepsilon) = \mathscr{F}(x^0). \tag{3.4}$$

The following useful criterion [11, p. 97] allows us to check (3.2) on a smaller $\mathscr{F}$-dense subset $D \subset X$.

PROPOSITION 3.4 (a density argument for Γ-$\limsup$). *Let $X, \mathscr{F}^\varepsilon, \mathscr{F}$ as in Definition* 3.1 *and let $D \subset X$ satisfy*

$$\forall\, x \in X \quad \exists x^\varepsilon \in D : \quad \lim_{\varepsilon \downarrow 0, \varepsilon \in \Lambda} x^\varepsilon = x, \quad \lim_{\varepsilon \downarrow 0, \varepsilon \in \Lambda} \mathscr{F}(x^\varepsilon) = \mathscr{F}(x). \tag{3.5}$$

If

$$\forall\, x \in D, \quad \exists x^\varepsilon \in X : \quad \lim_{\varepsilon \downarrow 0, \varepsilon \in \Lambda} x^\varepsilon = x, \quad \limsup_{\varepsilon \downarrow 0, \varepsilon \in \Lambda} \mathscr{F}_\varepsilon(x^\varepsilon) \le \mathscr{F}(x), \tag{3.6}$$

then the Γ-$\limsup$ *condition* (3.2) *for* Γ*-convergence is satisfied.*

Combining the results of Braides ([10]; see also [12, Thm. 14.8]) and of Acerbi et al. [1] we obtain the following homogenization result for noncoercive integral functionals.

THEOREM 3.5. *Let us consider the family of integral functionals in $L^2_{loc}(\Omega)$,*

$$a^\varepsilon_{i,e}(u) := \begin{cases} \displaystyle\int_{\Omega^\varepsilon_{i,e}} \sigma^\varepsilon_{i,e}(x)\nabla u(x)\cdot\nabla u(x)\,dx & \text{if } u \in L^2_{loc}(\Omega), u|_{\Omega_{i,e}} \in H^1(\Omega_{i,e}),\\ +\infty & \text{otherwise,}\end{cases} \tag{3.7}$$

where $\sigma^\varepsilon_{i,e}$ were introduced in (1.8) *and* (1.9)*, and let us define*

$$a_{i,e}(u) := \begin{cases} \displaystyle\int_\Omega M_{i,e}(x)\nabla u(x)\cdot\nabla u(x)\,dx & \text{if } u \in H^1(\Omega),\\ +\infty & \text{if } u \in L^2_{loc}(\Omega)\setminus H^1(\Omega)\end{cases} \tag{3.8}$$

with $M_{i,e}$ defined as in (1.21)*. Then we have*

$$a_{i,e}(u) = \Gamma(L^2_{loc}(\Omega))\text{-}\lim_{\varepsilon\downarrow 0} a^\varepsilon_{i,e}(u) = \Gamma(L^\infty(\Omega))\text{-}\lim_{\varepsilon\downarrow 0} a^\varepsilon_{i,e}(u). \tag{3.9}$$

3.2. Γ-convergence of $\mathscr{F}^\varepsilon$ and proof of Theorem 1.6. In this section we want to prove Theorem 1.6. The natural topology for this variational approach should be the one introduced by Definition 1.1. Therefore, in order to apply the Γ-convergence technique, we have to imbed the domain of the functionals $\mathscr{F}^\varepsilon, \mathscr{F}$ in a fixed underlying metric space, whose converging sequences with equibounded energy coincide with those characterized by Definition 1.1.

To this aim, we consider the space of finite signed Radon measures on Ω [4, Section 1.57],

$$\mathcal{M} := \mathcal{M}(\Omega) = \big(C_c(\Omega)\big)' = \big(C_0(\Omega)\big)', \tag{3.10}$$

endowed with the dual norm

$$\|\mu\|_{\mathcal{M}} := |\mu|(\Omega) \tag{3.11}$$

and the (weaker) continuous distance

$$\begin{aligned} d(\mu,\nu) := \sup\Big\{ \int_\Omega \zeta(x)\,d(\mu-\nu)(x) : \zeta \in C_c(\Omega)\cap \mathrm{Lip}(\Omega),\\ \sup_{x\in\Omega}|\zeta(x)| \le 1, \quad \mathrm{Lip}(\zeta,\Omega)\le 1\Big\}, \end{aligned} \tag{3.12}$$

where $\mathrm{Lip}(\Omega)$ (resp., $\mathrm{Lip}(\zeta, \Omega)$) is the space of the Lipschitz real functions defined in Ω (resp., the Lipschitz constant of ζ).

Since $C_0(\Omega)$ is a separable Banach space, the dual unit ball of $\mathcal{M}$ is weakly* compact and separable, so that the distance d induces the weak* topology of $\mathcal{M}$ on each norm-bounded subset of $\mathcal{M}$; in particular, $(\mathcal{M}, d)$ is a separable metric space and norm-bounded sequences are relatively compact with respect to the weaker topology induced by the distance d.

We then identify vectors $\underline{u}^\varepsilon = (u_i^\varepsilon, u_e^\varepsilon) \in \underline{\mathcal{V}}_0^\varepsilon, \underline{u} = (u_i, u_e) \in \underline{\mathcal{V}}_0$ with measures $\tilde{\underline{u}}^\varepsilon = (\tilde{u}_i^\varepsilon, \tilde{u}_e^\varepsilon), \tilde{\underline{u}} = (\tilde{u}_i, \tilde{u}_e) \in \mathcal{M}^2$ as in (1.18) and (1.19), denoting by $\underline{\mathsf{m}}^\varepsilon : \underline{\mathcal{V}}_0^\varepsilon \to \mathcal{M}^2$, $\underline{\mathsf{m}} : \underline{\mathcal{V}}_0 \to \mathcal{M}^2$ the corresponding maps.

This operator allows us to extend all the functionals on $\underline{\mathcal{V}}_0^\varepsilon$ to $\mathcal{M}^2$; e.g., in the case of $\mathscr{F}^\varepsilon$ we set

$$\tilde{\mathscr{F}}^\varepsilon(\tilde{\underline{u}}) := \begin{cases} \mathscr{F}^\varepsilon(\underline{u}) & \text{if } \tilde{\underline{u}} = \mathsf{m}^\varepsilon(\underline{u}), \quad \text{in } \mathcal{M}^2, \\ +\infty & \text{otherwise.} \end{cases} \tag{3.13}$$

We can thus consider coercivity and Γ-convergence of $\tilde{\mathscr{F}}^\varepsilon$ in $\mathcal{M}^2$ as $\varepsilon \downarrow 0$ which are in fact equivalent to statements (a), (b), (c) of Theorem 1.6. We split the proof of these properties in three steps. Recall that by (1.30) we can assume that $v_0^\varepsilon = \underline{B}^\varepsilon \underline{u}_0^\varepsilon$ with

$$\limsup_{\varepsilon \downarrow 0} \Big(\underline{a}^\varepsilon(\underline{u}_0^\varepsilon) + \underline{b}^\varepsilon(\underline{u}_0^\varepsilon) \Big) < +\infty, \tag{3.14}$$

v_0^ε converges to v_0 according to Definition 1.1, and $b^\varepsilon(v_0^\varepsilon) \to b(v_0)$; the functional $\mathscr{F}^\varepsilon$ takes the form

$$\mathscr{F}^\varepsilon(\underline{u}^\varepsilon) := \frac{h}{2} b^\varepsilon(v^\varepsilon - v_0^\varepsilon) + \frac{1}{2} \underline{a}^\varepsilon(\underline{u}^\varepsilon) + \phi^\varepsilon(v^\varepsilon), \quad v^\varepsilon := \underline{B}^\varepsilon \underline{u}^\varepsilon. \tag{3.15}$$

(a) *Compactness.* It follows directly from Proposition 2.13, thanks to (1.31).

(b) lim inf *inequality.* Suppose that $\underline{u}^\varepsilon \in \underline{\mathcal{V}}_0^\varepsilon$, $\varepsilon \in \Lambda$, converges to $\underline{u} \in \underline{\mathcal{V}}_0$ as $\varepsilon \downarrow 0, \varepsilon \in \Lambda$ according to Definition 1.1 and satisfies

$$\limsup_{\varepsilon \downarrow 0, \varepsilon \in \Lambda} \Big(\underline{a}^\varepsilon(\underline{u}^\varepsilon) + \underline{b}^\varepsilon(\underline{u}^\varepsilon) \Big) < +\infty. \tag{3.16}$$

Corollary 2.11 and Theorem 3.5 yield

$$\liminf_{\varepsilon \downarrow 0, \varepsilon \in \Lambda} \underline{a}^\varepsilon(\underline{u}^\varepsilon) \geq \underline{a}(\underline{u}), \tag{3.17}$$

whereas (2.47) of Corollary 2.16 and (3.14) show that

$$\liminf_{\varepsilon \downarrow 0, \varepsilon \in \Lambda} b^\varepsilon(v^\varepsilon - v_0^\varepsilon) \geq b(\underline{u} - \underline{u}_0), \quad \liminf_{\varepsilon \downarrow 0, \varepsilon \in \Lambda} \phi^\varepsilon(v^\varepsilon) \geq \phi(v), \qquad v := \underline{B}\underline{u}. \tag{3.18}$$

(c) lim sup *inequality.* We introduce the set

$$D := \Big\{ \underline{u} = (u_i, u_e) \in \underline{\mathcal{V}}_0 : \underline{B}\underline{u} = v = u_i - u_e \in L^\infty(\Omega) \Big\},$$

which satisfies the density condition (3.5) thanks to Lemma 2.17. By Proposition 3.4 it is then sufficient to prove the lim sup inequality for $\underline{u} \in D$.

By Theorem 3.5 we find a uniformly bounded family $\breve{\underline{u}}^\varepsilon = (\breve{u}_i^\varepsilon, \breve{u}_e^\varepsilon)$ converging to $\underline{u}$ in $L^\infty(\Omega) \times L^\infty(\Omega)$, whose restriction $\underline{u}^\varepsilon$ to $\Omega_i^\varepsilon \times \Omega_e^\varepsilon$ belongs to $\underline{\mathcal{V}}_0^\varepsilon$ (we can add a vanishing constant to $\breve{u}_e^\varepsilon$ as in Lemma 2.17) such that

$$\lim_{\varepsilon\downarrow 0} \underline{a}^\varepsilon(\underline{u}^\varepsilon) = \underline{a}(\underline{u}).$$

The boundedness and the regularity of Ω show that $\underline{b}^\varepsilon(\underline{u}^\varepsilon)$ is bounded so that (3.16) holds. Therefore, a simple application of (2.48) of Corollary 2.16 yields

$$\lim_{\varepsilon\downarrow 0} b^\varepsilon(v^\varepsilon) = b(v), \quad \lim_{\varepsilon\downarrow 0} \phi^\varepsilon(v^\varepsilon) = \phi(v), \qquad v^\varepsilon := \underline{B}^\varepsilon \underline{u}^\varepsilon, \quad v = \underline{B}\underline{u}. \tag{3.19}$$

In order to conclude the proof we have to pass to the limit in the term $b^\varepsilon(v^\varepsilon - v_0^\varepsilon)$. We invoke the next lemma.

LEMMA 3.6. *For every couple $v_0^\varepsilon, v^\varepsilon \in \mathcal{H}^\varepsilon$ converging to v_0, v as in Definition* 1.1, *we have*

$$\left.\begin{aligned} \lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} b^\varepsilon(v_0^\varepsilon) = b(v_0) \\ \limsup_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} b^\varepsilon(v^\varepsilon) = S < +\infty \end{aligned}\right\} \quad \Rightarrow \quad \lim_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} b^\varepsilon(v_0^\varepsilon, v^\varepsilon) = b(v_0, v). \tag{3.20}$$

Proof. Let us recall that

$$\liminf_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} b^\varepsilon(z^\varepsilon) \ge b(z) \tag{3.21}$$

for every family $z^\varepsilon \in \mathcal{H}^\varepsilon$ converging to z according to Definition 1.1. For every positive scalar $\rho > 0$ we have

$$2b^\varepsilon(v_0^\varepsilon, v^\varepsilon) = 2b^\varepsilon(\rho^{-1}v_0^\varepsilon, \rho v^\varepsilon) = b^\varepsilon(\rho^{-1}v_0^\varepsilon + \rho v^\varepsilon) - \rho^{-2}b^\varepsilon(v_0^\varepsilon) - \rho^2 b^\varepsilon(v^\varepsilon).$$

Taking the inferior limit as $\varepsilon \downarrow 0, \varepsilon \in \Lambda$ we get

$$\begin{aligned} \liminf_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} 2b^\varepsilon(v_0^\varepsilon, v^\varepsilon) &\ge b(\rho^{-1}v_0 + \rho v) - \rho^{-2}b(v_0) - \rho^2 S \\ &= 2b(v_0, v) + \rho^2\Big(b(v) - S\Big). \end{aligned}$$

Since $\rho > 0$ is arbitrary, we obtain

$$\liminf_{\varepsilon\downarrow 0,\varepsilon\in\Lambda} b^\varepsilon(v_0^\varepsilon, v^\varepsilon) \ge b(v_0, v);$$

inverting sign to v_0^ε we prove the lemma. ∎

As a corollary, we also obtain the following accessory result.

COROLLARY 3.7. *Let $v^\varepsilon \in \mathcal{H}^\varepsilon$ converge to $v \in \mathcal{H}$ according to Definition* 1.1 *and let us suppose that*

$$\lim_{\varepsilon\downarrow 0} b^\varepsilon(v^\varepsilon) = b(v), \quad \limsup_{\varepsilon\downarrow 0} j^\varepsilon(v^\varepsilon) < +\infty. \tag{3.22}$$

If $\underline{u}^\varepsilon = (u_i^\varepsilon, u_e^\varepsilon)$ is the unique solution of the minimum problem

$$\min\Big\{\underline{a}^\varepsilon(\underline{u}) : \underline{u} \in \underline{\mathcal{V}}_0^\varepsilon, \underline{B}^\varepsilon\underline{u} = v^\varepsilon\Big\}, \tag{3.23}$$

then $\underline{u}^\varepsilon \to \underline{u}$ as $\varepsilon \downarrow 0$ according to Definition 1.1 *and*

$$\underline{a}^\varepsilon(\underline{u}^\varepsilon) = j^\varepsilon(v^\varepsilon) \to \underline{a}(\underline{u}) = j(v), \tag{3.24}$$

with $\underline{u}$ being the unique solution of

$$\min\Big\{\underline{a}(\underline{u}) : \underline{u} \in \underline{\mathcal{V}}_0, \underline{B}\underline{u} = v\Big\}. \tag{3.25}$$

4. Variational formulation of the evolution problems. In this section we collect some basic notation and preliminary results on the variational formulation and the related well posedness of the micro- and macroscopic problems as discussed in [16].

4.1. Nonlinear terms and convex primitives. Recalling (1.10), from now on we set

$$\lambda_F := 1 + \Big(\inf_{x\in\mathbb{R}} F'(x)\Big)^{-}, \quad f(x) := F(x) + \lambda_F\, x, \tag{4.1}$$

$$\varphi(x) := \int_0^x f(\rho)\, d\rho = \frac{1}{2}\lambda_F x^2 + \int_0^x F(\rho)\, d\rho. \tag{4.2}$$

Observe that f is a strictly increasing C^1 function with $f' \geq 1$, so that φ is a strictly convex function with (at least) quadratic growth, thus satisfying

$$\varphi(x) \geq \varphi(0) = 0, \quad \varphi(x) \geq \frac{1}{2}|x|^2 \quad \forall\, x \in \mathbb{R}. \tag{4.3}$$

The conjugate function $\varphi^* : \mathbb{R} \to \mathbb{R}$ defined by

$$\varphi^*(y) = \sup_{x\in\mathbb{R}} \Big(yx - \varphi(x)\Big) \tag{4.4}$$

is still a strictly convex function which satisfies

$$\varphi^*(y) \geq \varphi^*(0) = 0 \quad \forall\, y \in \mathbb{R}, \quad \lim_{|y|\to\infty} \frac{\varphi^*(y)}{|y|} = +\infty, \tag{4.5}$$

$$xy \leq \varphi(x) + \varphi^*(y), \quad xf(x) = \varphi(x) + \varphi^*(f(x)) \quad \forall\, x, y \in \mathbb{R}. \tag{4.6}$$

In particular, we have

$$|f(x)| \leq \varphi^*(f(x)) + \sup_{|z|\leq 1} \varphi(z) \quad \forall\, x \in \mathbb{R} \tag{4.7}$$

and the "subdifferential inequality"

$$y = f(x) \quad \Leftrightarrow \quad y(z - x) \leq \varphi(z) - \varphi(x) \quad \forall\, z \in \mathbb{R}. \tag{4.8}$$

4.2. Vector notation for the complete system. Besides the couples $\underline{u}^\varepsilon = (u_i^\varepsilon, u_e^\varepsilon)$, $\underline{u} = (u_i, u_e)$, the micro- and macroscopic evolution problems involve a third "recovery" variable, w^ε, w. Thus the electric state of the heart will be determined by the three-component vectors

$$^{\varepsilon} := (\underline{u}^\varepsilon, w^\varepsilon), \qquad := (\underline{u}, w). \tag{4.9}$$

As a general rule, boldface letters (as , , $\boldsymbol{\mathcal{V}}, \dots$) will occur when the three-component vectors that determine the electric state of our systems are involved.

We will adopt the usual convention to identify functions $u = u(x,t)$ defined in the space-time cylinders $A \times (0,T)$ (A being some open subset of $\mathbb{R}^d$ endowed with the Lebesgue measure $\mathscr{L}^d$ or some Lipschitz hypersurface endowed with the $(d-1)$-dimensional Hausdorff measure $\mathscr{H}^{d-1}$) with the time-dependent function $u(\cdot,t)$ taking its values in suitable function subspaces of $L^1_{loc}(A)$ (we do not indicate explicitly the dependence on the underlying measure $\mathscr{L}^d$ or $\mathscr{H}^{d-1}$). Vector functions will therefore take their values in suitable product vector spaces, which we are now introducing.

As we said before in section 2.1, the electric potentials $\underline{u}^\varepsilon$ (resp., $\underline{u}$) will take their values in $\underline{\mathcal{V}}_0^\varepsilon$ (resp., $\underline{\mathcal{V}}_0$), whereas the recovery variables w^ε (resp., w) are valued into $\mathcal{H}^\varepsilon$ (resp., $\mathcal{H}$). Therefore, we will also introduce the following product spaces for the vector functions $\ ^\varepsilon, \ $:

$$\boldsymbol{\mathcal{V}}^\varepsilon := \underline{\mathcal{V}}^\varepsilon \times \mathcal{H}^\varepsilon, \quad \boldsymbol{\mathcal{V}}_0^\varepsilon := \underline{\mathcal{V}}_0^\varepsilon \times \mathcal{H}^\varepsilon, \quad \boldsymbol{\mathcal{V}} := \underline{\mathcal{V}} \times \mathcal{H}, \quad \boldsymbol{\mathcal{V}}_0 := \underline{\mathcal{V}}_0 \times \mathcal{H}. \tag{4.10}$$

4.3. The variational formulation of the microscopic problem and its well posedness. As shown in [16], the variational formulation of Problem $\ ^{\boldsymbol{\varepsilon}}$ can be easily obtained by performing the following steps:

1. Choose test functions $\hat{\ } = (\hat{u}_i, \hat{u}_e, \hat{w}) \in \boldsymbol{\mathcal{V}}_0^\varepsilon$;
2. multiply (P_{1a}^ε) by $\hat{u}_{i,e}$, integrate by parts using (P_{1b}^ε) and (P_4^ε), and sum up taking (P_2^ε) into account;
3. take the b^ε-scalar product in $\mathcal{H}^\varepsilon$ of (P_3^ε) with $\hat{w}$;
4. sum up the results of the previous two steps.

In order to write the variational formulation in a compact form, we introduce the bilinear forms which are defined for every $\ , \hat{\ } \in \boldsymbol{\mathcal{V}}^\varepsilon = \underline{\mathcal{V}}^\varepsilon \times \mathcal{H}^\varepsilon$,

$$\ ^\varepsilon(\ , \hat{\ }) := \underline{b}^\varepsilon(\underline{u}, \hat{\underline{u}}) + b^\varepsilon(w, \hat{w}), \qquad \ ^\varepsilon(\ , \hat{\ }) := \underline{a}^\varepsilon(\underline{u}, \hat{\underline{u}}) + \gamma b^\varepsilon(w, \hat{w}), \tag{4.11}$$

$$\ ^\varepsilon(\ , \hat{\ }) := \lambda_F \underline{b}^\varepsilon(\underline{u}, \hat{\underline{u}}) - \Theta b^\varepsilon(w, \underline{B}^\varepsilon \hat{\underline{u}}) + \eta b^\varepsilon(\underline{B}^\varepsilon \underline{u}, \hat{w}), \tag{4.12}$$

together with the related quadratic forms

$$\ ^\varepsilon(\ ) := \ ^\varepsilon(\ , \ ), \qquad \ ^\varepsilon(\ ) := \ ^\varepsilon(\ , \ ), \tag{4.13}$$

the functionals

$$\ ^\varepsilon(\ ) := \varepsilon \int_{\Gamma^\varepsilon} \varphi(u_i - u_e)\, d\mathscr{H}^{d-1}, \qquad \ ^\varepsilon(\ ) := \varepsilon \int_{\Gamma^\varepsilon} \varphi^*(f(u_i - u_e))\, d\mathscr{H}^{d-1}, \tag{4.14}$$

and the nonlinear form

$$\mathcal{F}^\varepsilon(\ , \hat{\ }) = \varepsilon \int_{\Gamma^\varepsilon} f(u_i - u_e)(\hat{u}_i - \hat{u}_e)\, d\mathscr{H}^{d-1} = \varepsilon \int_{\Gamma^\varepsilon} f(v)\hat{v}\, d\mathscr{H}^{d-1}, \tag{4.15}$$

which is well defined by (4.6) if $\ ^\varepsilon(\ ), \ ^\varepsilon(\hat{\ }) < +\infty$. Viewing $u_i^\varepsilon, u_e^\varepsilon, w^\varepsilon$ as time-dependent functions with values in a "space-dependent" functional space, as we discussed in section 4.2, we see that Problem $\ ^{\boldsymbol{\varepsilon}}$ can be solved by looking for the solution $\ ^\varepsilon : (0,T) \to \boldsymbol{\mathcal{V}}_0^\varepsilon$ of the abstract variational equation,

$$\begin{cases} \dfrac{d}{dt}\ ^\varepsilon(\ ^\varepsilon, \hat{\ }) + \ ^\varepsilon(\ ^\varepsilon, \hat{\ }) + \mathcal{F}^\varepsilon(\ ^\varepsilon, \hat{\ }) = \ ^\varepsilon(\ ^\varepsilon, \hat{\ }), \\ \qquad\qquad\qquad\qquad \ ^\varepsilon(\ ^\varepsilon(0), \hat{\ }) = \ ^\varepsilon(\ _0^\varepsilon, \hat{\ }), \end{cases} \tag{4.16}$$

for any $\hat{\ } \in \boldsymbol{\mathcal{V}}_0^\varepsilon$ with $\ ^\varepsilon(\hat{\ }) < +\infty$. Here the initial datum $\ _0^\varepsilon := (u_{0,i}^\varepsilon, u_{0,e}^\varepsilon, w_0^\varepsilon)$ satisfies

$$\ _0^\varepsilon \in \boldsymbol{\mathcal{V}}_0^\varepsilon, \qquad \ ^\varepsilon(\ _0^\varepsilon) < +\infty, \tag{4.17}$$

and it is related to v_0^ε by

$$\underline{B}^\varepsilon \underline{u}_0^\varepsilon = v_0^\varepsilon, \quad \underline{a}^\varepsilon(\underline{u}_0^\varepsilon) = j^\varepsilon(v_0^\varepsilon) = \min\left\{\underline{a}^\varepsilon(\hat{\underline{u}}^\varepsilon) : \underline{B}^\varepsilon \hat{\underline{u}}^\varepsilon = v_0^\varepsilon\right\}. \tag{4.18}$$

The following theorem provides an existence result for the microscopic problem; see [16] for more details.

THEOREM 4.1. *Let us assume that* $\ {}_0^\varepsilon$ *satisfies* (4.17) *and* (4.18)*. Then, there exists a unique solution of the variational formulation* (4.16) *of Problem* $\ ^{\boldsymbol{\varepsilon}}$*,*

$$\ ^\varepsilon = (u_i^\varepsilon, u_e^\varepsilon, w^\varepsilon) \in C^0\big([0,T]; \boldsymbol{\mathcal{V}}_0^\varepsilon\big), \quad v^\varepsilon := \underline{B}^\varepsilon \underline{u}^\varepsilon,$$

with

$$\partial_t\big(\underline{B}^\varepsilon \underline{u}^\varepsilon\big) = \partial_t v^\varepsilon, \qquad \partial_t w^\varepsilon \in L^2(0,T;\mathcal{H}^\varepsilon), \tag{4.19}$$

$$\sup_{t\in(0,T)} \ ^\varepsilon(\ ^\varepsilon) = \sup_{t\in(0,T)} \varepsilon \int_{\Gamma^\varepsilon} \varphi(v^\varepsilon)\, d\mathscr{H}^{d-1} < +\infty, \tag{4.20}$$

$$\int_0^T \ ^\varepsilon(\ ^\varepsilon)\, dt = \varepsilon \int_0^T \int_{\Gamma^\varepsilon} \varphi^*(f(v^\varepsilon))\, d\mathscr{H}^{d-1}\, dt < +\infty. \tag{4.21}$$

Moreover, the solution $\ ^\varepsilon$ *satisfies the a priori estimates*

$$\left.\begin{aligned} &\sup_{t\in[0,T]} \Big(\ ^\varepsilon(\ ^\varepsilon) + \ ^\varepsilon(\ ^\varepsilon) + \ ^\varepsilon(\ ^\varepsilon)\Big) \\ &\int_0^T \Big(b^\varepsilon(\partial_t v^\varepsilon) + b^\varepsilon(\partial_t w^\varepsilon)\Big)\, dt \end{aligned}\right\} \le C\Big(\ ^\varepsilon(\ {}_0^\varepsilon) + \ ^\varepsilon(\ {}_0^\varepsilon) + \ ^\varepsilon(\ {}_0^\varepsilon)\Big) \tag{4.22}$$

for a constant C independent of ε and of the initial datum*; finally, at each time* $t \in [0,T]$, $\underline{u}^\varepsilon(t)$ *is the unique solution of the minimum problem*

$$\underline{B}^\varepsilon \underline{u}^\varepsilon(t) = v^\varepsilon(t), \quad \underline{a}^\varepsilon(\underline{u}^\varepsilon(t)) = j^\varepsilon(v^\varepsilon(t)) = \min\Big\{\underline{a}^\varepsilon(\hat{\underline{u}}^\varepsilon) : \underline{B}^\varepsilon \hat{\underline{u}}^\varepsilon = v^\varepsilon(t)\Big\}. \tag{4.23}$$

Theorem 4.1 and (4.22) rely on two a priori estimates which are interesting by themselves: we will briefly present their formal derivation after a short discussion on the abstract structure of the system (4.16). As we will see in the next section, the main interest of this approach is that the macroscopic problem can be formulated in the same way.

4.4. The variational formulation of the macroscopic problem and its well posedness. The derivation of the variational formulation of this problem is completely analogous to the previous one; as before, we introduce the bilinear forms on $\boldsymbol{\mathcal{V}} \supset \boldsymbol{\mathcal{V}}_0$,

$$(\ ,\hat{\ }) := \underline{b}(\underline{u},\hat{\underline{u}}) + b(w,\hat{w}), \qquad (\ ,\hat{\ }) := \underline{a}(\underline{u},\hat{\underline{u}}) + \gamma b(w,\hat{w}), \tag{4.24}$$

$$(\ ,\hat{\ }) := \lambda_F \underline{b}(\underline{u},\hat{\underline{u}}) - \Theta b(w,\underline{B}\hat{\underline{u}}) + \eta b(\underline{B}\underline{u},\hat{w}), \tag{4.25}$$

together with the related quadratic forms

$$(\ ) := (\ ,\ ), \quad \underline{b}(\ ) := \underline{b}(\ ,\ ), \tag{4.26}$$

the functionals

$$(\ ) := \beta \int_\Omega \varphi(u_i - u_e)\, dx, \qquad (\ ) := \beta \int_\Omega \varphi^*(f(u_i - u_e))\, dx, \tag{4.27}$$

and the nonlinear form

$$\mathcal{F}(\ ,\hat{\ }) = \beta \int_\Omega f(u_i - u_e)(\hat{u}_i - \hat{u}_e)\, dx = \beta \int_\Omega f(v)\hat{v}\, dx, \tag{4.28}$$

which is well defined by (4.6) if $(\ ),\ (\hat{\ }) < +\infty$. The solution $: (0,T) \to \boldsymbol{\mathcal{V}}_0$ of the macroscopic problem thus satisfies the variational evolution equation,

$$\begin{cases} \dfrac{d}{dt}\ (\ ,\hat{\ }) + (\ ,\hat{\ }) + \mathcal{F}(\ ,\hat{\ }) = (\ ,\hat{\ }), \\ \qquad\qquad (\ (0),\hat{\ }) = (\ _0,\hat{\ }), \end{cases} \tag{4.29}$$

for any $\hat{\ } \in \boldsymbol{\mathcal{V}}_0$ with $(\hat{\ }) < +\infty$. Again the initial datum $_0 := (u_{0,i}, u_{0,e}, w_0)$ satisfies

$$_0 \in \boldsymbol{\mathcal{V}}_0, \qquad (\ _0) < +\infty, \tag{4.30}$$

and it is related to v_0 by

$$\underline{B}\underline{u}_0 = v_0, \quad \underline{a}(\underline{u}_0) = j(v_0) = \min\Big\{\underline{a}(\hat{\underline{u}}) : \underline{B}\hat{\underline{u}} = v_0\Big\}. \tag{4.31}$$

THEOREM 4.2. *Let us assume that* $_0$ *satisfies* (4.30), (4.31)*. Then, there exists a unique solution of the variational formulation of Problem* ,

$$= (u_i, u_e, w) \in C^0\big([0,T];\boldsymbol{\mathcal{V}}_0\big), \quad v = \underline{B}\underline{u},$$

with

$$\partial_t\big(\underline{B}\underline{u}\big) = \partial_t v, \qquad \partial_t w \in L^2(0,T;\mathcal{H}), \tag{4.32}$$

$$\sup_{t\in(0,T)}\ (\ ) = \sup_{t\in(0,T)} \int_\Omega \varphi(v)\,dx < +\infty, \tag{4.33}$$

$$\int_0^T (\ )\,dt = \int_0^T\int_\Omega \varphi^*\big(f(v)\big)\,dx\,dt < +\infty. \tag{4.34}$$

Moreover, the solution satisfies the a priori estimates

$$\left.\begin{aligned} &\sup_{t\in[0,T]}\Big(\ (\ ) + (\ ) + (\ )\Big) \\ &\int_0^T \Big(b(\partial_t w) + b(\partial_t v)\Big)\,dt \end{aligned}\right\} \le C\Big(\ (\ _0) + (\ _0) + (\ _0)\Big) \tag{4.35}$$

for a constant C *independent of the initial datum; at each time* $t \in [0,T]$, $\underline{u}(t)$ *is the unique solution of the minimum problem*

$$\underline{B}\underline{u}(t) = v(t), \quad \underline{a}(\underline{u}(t)) = j(v(t)) = \min\Big\{\underline{a}(\hat{\underline{u}}) : \underline{B}\hat{\underline{u}} = v(t)\Big\}. \tag{4.36}$$

4.5. Structural properties and a priori estimates. Now, we point out some distinctive properties of $^\varepsilon,\ ^\varepsilon, \mathcal{F}^\varepsilon$, and $^\varepsilon$ (see [16]): they are also valid for the macroscopic model, which corresponds to $\varepsilon = 0$.

Notation 4.3. In order to avoid tedious repetitions, whenever it is possible we will systematically include the case $\varepsilon = 0$ in our statements simply by making the obvious identifications

$$\underline{u}^0 := \underline{u},\ w^0 := w,\ v^0 := v,\ \ ^0 := \ ,\ \underline{a}^0 := \underline{a},\ b^0 := b,\ \underline{\mathcal{V}}^0 := \underline{\mathcal{V}}, \ldots. \tag{4.37}$$

It can be verified that $^\varepsilon,\ ^\varepsilon,\ \mathcal{F}^\varepsilon$, and $^\varepsilon$ satisfy (see [16]):

(A) $^\varepsilon$ is continuous and *symmetric*; the associated quadratic form (still denoted by $^\varepsilon$) is *nonnegative* but its kernel has infinite dimension, so that (4.16) is a *degenerate evolution equation.*

(B) $\ ^{\varepsilon}$ is a continuous, symmetric, and nonnegative bilinear form, too.

(C) The sum of the quadratic forms $\ ^{\varepsilon} + \ ^{\varepsilon}$ is coercive in $\boldsymbol{\mathcal{V}}_0^{\varepsilon}$, thus providing an equivalent scalar product.

(D) The bilinear form $\ ^{\varepsilon}$ satisfies

$$\exists\, G \geq 0: \quad |\ ^{\varepsilon}(\ ,\hat{\ })|^2 \leq G^2\ ^{\varepsilon}(\ )\ ^{\varepsilon}(\hat{\ }) \quad \forall\ ,\hat{\ } \in \boldsymbol{\mathcal{V}}_0^{\varepsilon}, \tag{4.38}$$

where G is *independent of* ε; in the present case we can choose $G = \lambda_F + \Theta + \eta$.

(E) The nonlinear form $\mathcal{F}$ satisfies the subdifferential inequalities

$$\mathcal{F}^{\varepsilon}(\ ,\ ) = \ ^{\varepsilon}(\ ) + \ ^{\varepsilon}(\ ) \quad \forall \ \in \boldsymbol{\mathcal{V}}_0^{\varepsilon}, \tag{4.39}$$

$$\mathcal{F}^{\varepsilon}(\ ,\hat{\ } - \ ) + \ ^{\varepsilon}(\ ) \leq \ ^{\varepsilon}(\hat{\ }) \quad \forall\ ,\hat{\ } \in \boldsymbol{\mathcal{V}}_0^{\varepsilon} \tag{4.40}$$

for the

$$\text{convex and lower semicontinuous functional } \ ^{\varepsilon}, \quad \text{with } \ ^{\varepsilon}(\ ) \geq \ ^{\varepsilon}(\ ) \quad \forall \ \in \boldsymbol{\mathcal{V}}_0^{\varepsilon}. \tag{4.41}$$

Remark 4.4 (regularity of F). Concerning the nonlinearity of the problems, we note that the regularity assumptions on F can be relaxed, so $F : \mathbb{R} \to \mathbb{R}$ can be a continuous function such that $F(0) = 0$ and

$$\exists\, \lambda_F \geq 0: \quad (F(x) - F(y))(x-y) + (\lambda_F - 1)|x-y|^2 \geq 0 \quad \forall\, x, y \in \mathbb{R}. \tag{4.42}$$

Now we briefly show a formal derivation of the basic a priori estimates for the macroscopic problem (for the microscopic one, one can simply add the superscript ε to each occurrence of $\ ,\ ,\mathcal{F},\ ,\ ,\ ,\dots$); we assume that $\ \in H^1(0,T;\boldsymbol{\mathcal{V}}_0)$ and f has a linear growth, so that $\mathcal{F}$ is a continuous form. The computations below can be made rigorous, e.g., by passing to the limit in the analogous stability estimates for a suitably discretized or regularized system, and will be studied in section 6.

Recalling that

$$\frac{d}{dt}\ (\ (t),\hat{\ }) = \ (\ '(t),\hat{\ }), \quad \frac{1}{2}\frac{d}{dt}\ (\ (t)) = \ (\ '(t),\ ) \quad \forall\, \hat{\ } \in \boldsymbol{\mathcal{V}}_0,$$

choosing $\hat{\ } := \ (t)$ in (4.29) we get

$$\frac{1}{2}\frac{d}{dt}\ (\ (t)) + \ (\ (t)) + \mathcal{F}(\ (t),\ (t)) = \ (\ (t),\ (t)) \leq G\ (\ (t)), \tag{4.43}$$

so that a simple application of the Gronwall lemma and the relation

$$\mathcal{F}(\ ,\ ) = \ (\ ) + \ (\ ) \tag{4.44}$$

yields

$$\max\left[\sup_{t\in[0,T]}\ (\ (t)), \int_0^T \Big(\ (\ ) + \ (\ ) + \ (\ )\Big)\, dt\right] \leq e^{2GT}\ (\ _0). \tag{4.45}$$

Choosing now $\hat{\ } := \ '$ and observing that

$$\frac{d}{dt}\ (\ (t)) = \mathcal{F}(\ (t),\ '(t)), \quad \frac{1}{2}\frac{d}{dt}\ (\ (t)) = \ (\ (t),\ '(t)),$$

the previous estimate and the Cauchy inequality yield

$$
\begin{aligned}
(4.46)\qquad & (\ '(t)) + \frac{d}{dt}\Big(\frac{1}{2}\ (\ (t)) + \ (\ (t))\Big) = \ (\ (t),\ '(t)) \\
& \leq G\ (\ (t))^{1/2}\ (\ '(t))^{1/2} \leq \frac{1}{2}\ (\ '(t)) + \frac{G^2}{2} e^{2Gt}\ (\ _0).
\end{aligned}
$$

Integrating in time we get

$$
(4.47)\qquad \left.\begin{matrix} \sup\limits_{t\in[0,T]} \left(\frac{1}{2}\ (\ ) + \ (\ )\right) \\ \frac{1}{2}\int_0^T\ (\ ')\,dt \end{matrix}\right\} \leq \frac{1}{2}\ (\ _0) + \ (\ _0) + \frac{G}{4} e^{2GT}\ (\ _0).
$$

Combining (4.45) with (4.47) we obtain (4.35) with $C = \max\big(2, (\frac{G}{2}+1)e^{2GT}\big)$.

5. Proof of Theorems 1.3 and 1.4.

5.1. Outline. As we said in the introduction, our approach (inspired by the so-called "minimizing movement" method introduced by De Giorgi [18, 3, 5]) combines general approximation results, yielding uniform error estimates for a semi-implicit Euler time discretization of evolution equations such as (4.16) and (4.29), with homogenization results for the discretized problems.

More precisely, we begin in section 5.2 by considering the approximation of $^{\varepsilon}$ and in the time interval $[0,T]$ by the semi-implicit Euler method of time step $\tau = T/N > 0$: thus we will consider a uniform partition $\mathcal{P}_\tau$ of the time interval $[0,T]$ into N subintervals

$$
(5.1)\qquad \mathcal{P}_\tau := \{0 = t_0 < t_1 < \cdots < t_{N-1} < t_N = T\}, \quad t_n := n\tau,
$$

and we will replace the continuous problems by a sequence of discrete microscopic and macroscopic problems $^{\varepsilon,}$, ^{0,} , $n = 1, \ldots, N$, whose solutions $^{\varepsilon,\tau}_{n}$, $^{0,\tau}_{n}$ provide an approximation of $^{\varepsilon}(t)$, (t) for t in the time interval $(t_{n-1}, t_n]$.

Denoting by $^{\varepsilon,\tau}$, $^{0,\tau}$ the piecewise linear interpolant on $\mathcal{P}_\tau$ of the values $^{\varepsilon,\tau}_{n}$, $^{0,\tau}_{n}$, general error estimates for variational evolution problems with the structure discussed in section 4.5 show that the error (measured in the natural energy norms) between the continuous solution $^{\varepsilon}$ of $^{\varepsilon}$ (resp., of) and the discrete solution $^{\varepsilon,\tau}$ (resp., $^{0,\tau}$) vanishes as $\tau \downarrow 0$ *uniformly with respect to* ε. We will devote section 6 to proving these estimates.

Since the nonsymmetric parts $^{\varepsilon}$, are discretized "explicitly" it turns out (see section 5.3) that each step of the discretization scheme (the problems $^{\varepsilon,}$ and ^{0,}) involves the minimization of suitable functionals $\Phi^{\varepsilon,\tau}_n, \Phi^{0,\tau}_n$, which depend only on ε, τ and on the discrete solutions $^{\varepsilon,\tau}_{n-1}$, $^{0,\tau}_{n-1}$ at the previous node of the partition $\mathcal{P}_\tau$; therefore $^{\varepsilon,\tau}_{n}$ and $^{0,\tau}_{n}$ are the unique minima of $\Phi^{\varepsilon,\tau}_n$ and $\Phi^{0,\tau}_n$, respectively.

By adapting the Γ-convergence results of section 3, we shall see (Theorem 5.2) that each discrete value $^{\varepsilon,\tau}_{n}$ converges, as $\varepsilon \downarrow 0$ to $^{0,\tau}_{n}$, whenever τ is fixed. Since for each $\tau > 0$ the discrete interpolant $^{\varepsilon,\tau}$ is determined only by a *finite* number of vectors $^{\varepsilon,\tau}_{n}$, it follows that the discrete solution $^{\varepsilon,\tau}$ converges to the homogenized one $^{0,\tau}$ in the time interval $[0,T]$ as $\varepsilon \downarrow 0$.

Combining this result with the above uniform error estimate between $^{\varepsilon}$, and $^{\varepsilon,\tau}$, $^{0,\tau}$, we will conclude also that the continuous solution $^{\varepsilon}$ converges to at each time $t \in [0,T]$.

Thus, by introducing the auxiliary problems $^{\boldsymbol{\varepsilon},}$, $^{\mathbf{0},}$, the homogenization of time-dependent evolution equations is reduced to the homogenization of a family of functionals depending on the parameters τ, n, which can be tackled by Γ-convergence arguments.

Let us reproduce the above argument in the following scheme:

$$
\begin{array}{ccc}
{}^{\varepsilon} := \begin{cases} \text{Continuous solution of} \\ \text{the evolution problem } \boldsymbol{P}^{\boldsymbol{\varepsilon}} \end{cases} & \underset{\substack{\textit{uniform error} \\ \textit{estimates}}}{\longleftrightarrow} & {}^{\varepsilon,\tau} := \begin{cases} \text{Discrete solution of the} \\ \text{variational problem } \boldsymbol{P}^{\boldsymbol{\varepsilon},\boldsymbol{\tau}} \end{cases} \\
 & & \downarrow \ \Gamma\textit{-convergence} \\
:= \begin{cases} \text{Continuous solution of} \\ \text{the evolution problem } \boldsymbol{P} \end{cases} & \underset{\substack{\textit{uniform error} \\ \textit{estimates}}}{\longleftrightarrow} & {}^{0,\tau} := \begin{cases} \text{Discrete solution of the} \\ \text{variational problem } \boldsymbol{P}^{\mathbf{0},\boldsymbol{\tau}} \end{cases}
\end{array}
$$

Let us now consider in more detail each step of the proof.

5.2. Time discretization. We look for a suitable approximation $\{\ {}^{\varepsilon,\tau}_{n}\}_{n=0}^{N} \subset \boldsymbol{\mathcal{V}}_0^{\varepsilon}$ of the values of $\ ^{\varepsilon}$ on the grid $\mathcal{P}_\tau$ (5.1), which solves the following discrete problem $^{\boldsymbol{\varepsilon},}$:

$$
(\ \boldsymbol{\varepsilon},\ ) \qquad \begin{cases} \text{Given } \ {}^{\varepsilon,\tau}_{0} := \ {}^{\varepsilon}_{0} \quad \text{find } \ {}^{\varepsilon,\tau}_{1}, \ldots, \ {}^{\varepsilon,\tau}_{N} \in \boldsymbol{\mathcal{V}}_0^{\varepsilon} \text{ which recursively solve} \\ {}^{\varepsilon}\left(\dfrac{\ {}^{\varepsilon,\tau}_{n} - \ {}^{\varepsilon,\tau}_{n-1}}{\tau}, \ \hat{}\ \right) + \ {}^{\varepsilon}(\ {}^{\varepsilon,\tau}_{n}, \ \hat{}\ ) + \mathcal{F}^{\varepsilon}(\ {}^{\varepsilon,\tau}_{n}, \ \hat{}\ ) = \ {}^{\varepsilon}(\ {}^{\varepsilon,\tau}_{n-1}, \ \hat{}\ ) \\ \qquad\qquad \text{for every choice of } \ \hat{}\ \in D(\ ) \subset \boldsymbol{\mathcal{V}}_0^{\varepsilon}. \end{cases}
$$

In fact, due to the convexity of and to the coercivity of the quadratic form $\ ^{\varepsilon} + \ ^{\varepsilon}$ on $\boldsymbol{\mathcal{V}}_0^{\varepsilon}$, it is easy to check that each step of ($\boldsymbol{\varepsilon},$) is equivalent to the minimum problem

$$
(\ \boldsymbol{\varepsilon},\ ) \quad \text{find } \ {}^{\varepsilon,\tau}_{n} \in \boldsymbol{\mathcal{V}}_0^{\varepsilon} \text{ which attains the minimum } \quad \min\left\{\Phi_n^{\varepsilon,\tau}(\ ) : \ \in \boldsymbol{\mathcal{V}}_0^{\varepsilon}\right\},
$$

where

$$
\Phi_n^{\varepsilon,\tau}(\ ) := \frac{1}{2\tau}\ {}^{\varepsilon}(\ - \ {}^{\varepsilon,\tau}_{n-1}) + \ {}^{\varepsilon}(\ ) + \ {}^{\varepsilon}(\ ) - \ {}^{\varepsilon}(\ {}^{\varepsilon,\tau}_{n-1}, \ ). \tag{5.2}
$$

We can proceed in a completely analogous way for the macroscopic problem, simply by setting $\varepsilon := 0$ and recalling Notation 4.3. The corresponding discrete solutions $\ ^{\varepsilon,\tau}(t)$ and $\ ^{0,\tau}(t)$ are the piecewise linear interpolants of $\{\ {}^{\varepsilon,\tau}_{n}\}_{n=0}^{N}$ and $\{\ {}^{0,\tau}_{n}\}_{n=0}^{N}$ on the grid $\mathcal{P}_\tau$, i.e.,

$$
\ {}^{\varepsilon,\tau}(t) := (n - t/\tau)\ {}^{\varepsilon,\tau}_{n-1} + (t/\tau - (n-1))\ {}^{\varepsilon,\tau}_{n} \quad \text{if } t \in ((n-1)\tau, n\tau]. \tag{5.3}
$$

The next theorem shows that the discrete solutions of the above schemes converge uniformly to the solutions of $\ ^{\boldsymbol{\varepsilon}}$ and in the intrinsic energy norms induced by the bilinear forms $\ ^{\varepsilon}$, $\ ^{\varepsilon}$. We denote by $\mathsf{E}^{\varepsilon}, \mathsf{E} = \mathsf{E}^0$ (recall Notation 4.3) the (squared) errors

$$
\mathsf{E}^{\varepsilon} = \max_{t \in (0,T)} \ {}^{\varepsilon}(\ {}^{\varepsilon}(t) - \ {}^{\varepsilon,\tau}(t)) + \int_0^T \ {}^{\varepsilon}(\ {}^{\varepsilon}(t) - \ {}^{\varepsilon,\tau}(t))\, dt. \tag{5.4}
$$

THEOREM 5.1 (uniform error estimates). *There exists a constant* $C = C(G, T)$ independent of ε *such that*

$$\mathsf{E}^\varepsilon \le C\tau\Big({}^{\varepsilon}({}^{\varepsilon}_{0}) + {}^{\varepsilon}({}^{\varepsilon}_{0}) + {}^{\varepsilon}({}^{\varepsilon}_{0})\Big). \tag{5.5}$$

The proof of Theorem 5.1 is presented in section 6: it is the extension to a semi-implicit discretization scheme of the arguments developed in [9]; in order to give a self-contained simpler proof, we decided to follow the general scheme introduced by [29] for the derivation of optimal a priori and a posteriori error estimates for evolution variational problems.

5.3. Discrete problems and the role of Γ-convergence. Let us now consider the convergence as $\varepsilon \downarrow 0$ of the solutions ${}^{\varepsilon,\tau}_{n}$ of the discrete problem ${}^{\varepsilon,}$. The following crucial result provides the main induction step.

THEOREM 5.2 (convergence of the discrete approximations). *Let us suppose that the vector* ${}^{\varepsilon,\tau}_{n-1} = (U^{\varepsilon,\tau}_n, W^{\varepsilon,\tau}_n) \in \boldsymbol{\mathcal{V}}^\varepsilon_0$ *converges to* ${}^{0,\tau}_{n-1}$ *according to Definition* 1.1 *as* $\varepsilon \downarrow 0$*, with*

$$\lim_{\varepsilon\downarrow 0} {}^{\varepsilon}({}^{\varepsilon,\tau}_{n-1}) = ({}^{0,\tau}_{n-1}), \quad \limsup_{\varepsilon\downarrow 0} {}^{\varepsilon}({}^{\varepsilon,\tau}_{n-1}) + {}^{\varepsilon}({}^{\varepsilon,\tau}_{n-1}) < +\infty, \tag{5.6}$$

and let us define the functional $\Phi^{\varepsilon,\tau}_n, \Phi^{0,\tau}_n$ *as in* (5.2). *Then the unique minimum* ${}^{\varepsilon,\tau}_{n} \in \boldsymbol{\mathcal{V}}^\varepsilon_0$ *of* $\Phi^{\varepsilon,\tau}_n$ *converges to the unique minimum* ${}^{0,\tau}_{n}$ *of* $\Phi^{0,\tau}_n$ *as* $\varepsilon \downarrow 0$ *according to Definition* 1.1 *and*

$$\lim_{\varepsilon\downarrow 0} {}^{\varepsilon}({}^{\varepsilon,\tau}_{n}) = ({}^{0,\tau}_{n}), \quad \lim_{\varepsilon\downarrow 0} {}^{\varepsilon}({}^{\varepsilon,\tau}_{n}) = ({}^{0,\tau}_{n}), \quad \lim_{\varepsilon\downarrow 0} {}^{\varepsilon}({}^{\varepsilon,\tau}_{n}) = ({}^{0,\tau}_{n}). \tag{5.7}$$

COROLLARY 5.3 (convergence of the discrete solutions). *Let us suppose that the assumption* (1.23) *of Theorem* 1.3 *on the initial data* $(v^\varepsilon_0, w^\varepsilon_0)$ *and* (v_0, w_0) *holds and that* ${}^{\varepsilon}_{0} \in \boldsymbol{\mathcal{V}}^\varepsilon_0$ *is chosen as in* (4.18). *Then each vector* ${}^{\varepsilon,\tau}_{n}$, $n = 1, \ldots, N$, *of the discrete solution* ${}^{\varepsilon,\tau}$ *converges to the corresponding one* ${}^{0,\tau}_{n}$ *of the discrete solution* ${}^{0,\tau}$ *as* $\varepsilon \downarrow 0$ *according to Definition* 1.1.

Thanks to Theorem 3.3, we will deduce Theorem 5.2 from a corresponding coercivity and Γ-convergence result for the functionals $\Phi^{\varepsilon,\tau}_n$. Observe that (5.7) is a consequence of the convergence of the energies $\Phi^{\varepsilon,\tau}_n({}^{\varepsilon,\tau}_{n}) \to \Phi^{0,\tau}_n({}^{0,\tau}_{n})$ given by (3.4) and Remark 3.2, thanks to the separate lower semicontinuity property (3.17).

As in section 3.2 we identify vectors ${}^{\varepsilon} = (u^\varepsilon_i, u^\varepsilon_e, w^\varepsilon) \in \boldsymbol{\mathcal{V}}^\varepsilon_0$, $\;= (u_i, u_e, w) \in \boldsymbol{\mathcal{V}}_0$ with measures $\tilde{\ }^{\varepsilon} = (\tilde u^\varepsilon_i, \tilde u^\varepsilon_e, \tilde u^\varepsilon)$, $\tilde{\ } = (\tilde u_i, \tilde u_e, \tilde u) \in \mathcal{M}^3$ through (1.18) and (1.19), denoting by $\mathsf{m}^\varepsilon : \boldsymbol{\mathcal{V}}^\varepsilon_0 \to \mathcal{M}^3$, $\mathsf{m} : \boldsymbol{\mathcal{V}}_0 \to \mathcal{M}^3$ the corresponding maps. We also extend all the functionals on $\boldsymbol{\mathcal{V}}^\varepsilon_0$ to $\mathcal{M}^3$ as we did in (3.13). We can thus consider the Γ-limit of $\tilde\Phi^{\varepsilon,\tau}_n$ in $\mathcal{M}^3$ as $\varepsilon \downarrow 0$, keeping τ fixed.

THEOREM 5.4 (Γ-convergence). *Let us fix* $\tau > 0$ *and let us suppose that the vectors* ${}^{\varepsilon,\tau}_{n-1} \in \boldsymbol{\mathcal{V}}^\varepsilon_0$ *satisfy the same assumption as in Theorem* 5.2. *If a family* $\tilde{\ }^{\varepsilon} = \mathsf{m}^\varepsilon({}^{\varepsilon})$, ${}^{\varepsilon} \in \boldsymbol{\mathcal{V}}^\varepsilon_0$ *for* $\varepsilon \in \Lambda$*, satisfies*

$$\limsup_{\varepsilon\downarrow 0, \varepsilon\in\Lambda} \tilde\Phi^{\varepsilon,\tau}_n(\tilde{\ }^{\varepsilon}) = \limsup_{\varepsilon\downarrow 0, \varepsilon\in\Lambda} \Phi^{\varepsilon,\tau}_n({}^{\varepsilon}) < +\infty, \tag{5.8}$$

then $\tilde{\ }^{\varepsilon}$ *is relatively compact in* $\mathcal{M}^3$*; it converges to* $\tilde{\ }$ *in* $\mathcal{M}^3$ *if and only if* $\tilde{\ } = \mathsf{m}(\ )$ *for some* $\;\in \boldsymbol{\mathcal{V}}_0$ *and* ${}^{\varepsilon}$ *converges to* $\;$ *according to Definition* 1.1.

The functionals $\tilde{\Phi}_n^{\varepsilon,\tau}$, extensions of (5.2), *satisfy*

$$\Gamma(\mathcal{M}^3)\text{-}\lim_{\varepsilon\downarrow 0}\tilde{\Phi}_n^{\varepsilon,\tau} = \tilde{\Phi}_n^{0,\tau}. \tag{5.9}$$

The proof of Theorem 5.4 is completely analogous to that of Theorem 1.6: if we write

$${}^{\varepsilon,\tau}_{n-1} = (\underline{U}^{\varepsilon,\tau}_{n-1}, W^{\varepsilon,\tau}_{n-1}), \qquad {}^{\varepsilon} = (\underline{U}^{\varepsilon}, W^{\varepsilon}), \quad \underline{U}^{\varepsilon} \in \underline{\mathcal{V}}^{\varepsilon}_0,\ W \in \mathcal{H}^{\varepsilon},$$

we choose $h := \tau^{-1}$ and the term v_0^ε of (1.28) as $\underline{B}^\varepsilon \underline{U}^{\varepsilon,\tau}_{n-1}$, then

$$\Phi_n^{\varepsilon,\tau}(\ {}^{\varepsilon}) = \mathscr{F}^\varepsilon(\underline{U}^\varepsilon) + \ {}^{\varepsilon,\tau}_{n}(\ {}^{\varepsilon}), \tag{5.10}$$

where

$$\begin{aligned} {}^{\varepsilon,\tau}_{n}(\ {}^{\varepsilon}) := {}& \frac{1}{2\tau} b^\varepsilon(W^\varepsilon - W^{\varepsilon,\tau}_{n-1}) + \frac{\gamma}{2} b^\varepsilon(W^\varepsilon) \\ & - \lambda \underline{b}^\varepsilon(\underline{U}^{\varepsilon,\tau}_{n-1}, \underline{U}^\varepsilon) + \Theta b^\varepsilon(W^{\varepsilon,\tau}_{n-1}, \underline{B}^\varepsilon \underline{U}^\varepsilon), -\eta b^\varepsilon(\underline{B}^\varepsilon \underline{U}^{\varepsilon,\tau}_{n-1}, W^\varepsilon). \end{aligned} \tag{5.11}$$

Thus the asymptotic behavior of $\Phi_n^{\varepsilon,\tau}$ can be easily deduced from Theorem 1.6 and Lemma 3.6.

Remark 5.5. Usually, when one considers gradient flows of convex functionals $\mathscr{F}^\varepsilon$ in a *fixed* Hilbert space, their asymptotic behavior is determined by the Γ-convergence and Mosco-convergence of Lyapunov functionals $\mathscr{F}^\varepsilon$ (see, e.g., [6]), and it is not necessary to take into account the dependence of τ.

Here also the underlying Hilbert spaces are changing in a singular way with respect to ε and the major novelty is the explicit presence of the mesh size τ in the minimizing functionals $\Phi_n^{\varepsilon,\tau}$, which reflects the metric of the functional spaces governing the gradient flows. In the present case, this metric is related to the quadratic forms ${}^{\varepsilon}$: therefore it is degenerate and it depends on ε.

5.4. Conclusion of the proof of Theorems 1.3 and 1.4. By Corollary 3.7, the a priori estimates (4.22) and (4.23), and the variational characterizations (4.23), (4.36), we simply have to show that $v^\varepsilon := \underline{B}^\varepsilon \underline{u}^\varepsilon$ and w^ε are converging to $v := \underline{B}\underline{u}$ and w for every $t \in [0,T]$ according to Definition 1.1.

Let us consider the case of v^ε, the argument for w^ε being completely analogous. We set $V^{\varepsilon,\tau}(t) := \underline{B}^\varepsilon \underline{U}^{\varepsilon,\tau}(t)$, $\varepsilon \ge 0$: for every $\zeta \in C^0_c(\Omega)$ and every $t \in [0,T]$ (which will not be indicated explicitly) we have

$$\begin{aligned} \varepsilon \int_{\Gamma^\varepsilon} v^\varepsilon \zeta \, d\mathscr{H}^{d-1} - \beta \int_\Omega v\zeta \, dx = {}& \varepsilon \int_{\Gamma^\varepsilon} \big(v^\varepsilon - V^{\varepsilon,\tau}\big)\zeta \, d\mathscr{H}^{d-1} - \beta \int_\Omega \big(v - V^{0,\tau}\big)\zeta \, dx \\ & + \varepsilon \int_{\Gamma^\varepsilon} V^{\varepsilon,\tau}\zeta \, d\mathscr{H}^{d-1} - \beta \int_\Omega V^{0,\tau}\zeta \, dx \end{aligned}$$

so that, if $Z := \sup_\Omega |\zeta|$ and $S^2 \ge \varepsilon \mathscr{H}^{d-1}(\Gamma^\varepsilon) + \beta \mathscr{L}^d(\Omega)$,

$$\begin{aligned} \left| \varepsilon \int_{\Gamma^\varepsilon} v^\varepsilon \zeta \, d\mathscr{H}^{d-1} - \beta \int_\Omega v\zeta \, dx \right| \le {}& SZ b^\varepsilon\big(v^\varepsilon - V^{\varepsilon,\tau}\big)^{1/2} + SZ b\big(v - V^{0,\tau}\big)^{1/2} \\ & + \left| \varepsilon \int_{\Gamma^\varepsilon} V^{\varepsilon,\tau}\zeta \, d\mathscr{H}^{d-1} - \beta \int_\Omega V^{0,\tau}\zeta \, dx \right| \le C\tau^{1/2} + r_\varepsilon, \end{aligned}$$

where we applied the uniform estimates of Theorem 5.1 and the bounds on the initial data. Passing now to the limit as $\varepsilon \downarrow 0$ keeping τ fixed, we get

$$\limsup_{\varepsilon\downarrow 0} r_\varepsilon = \limsup_{\varepsilon\downarrow 0} \left| \varepsilon \int_{\Gamma^\varepsilon} v^\varepsilon \zeta \, d\mathscr{H}^{d-1} - \beta \int_\Omega v\zeta \, dx \right| \leq C\tau^{1/2}$$

thanks to Corollary 5.3. Finally letting $\tau \downarrow 0$ we get the desired convergence.

The corresponding property for the energy $b^\varepsilon(v^\varepsilon)$ follows by the same argument.

Let us eventually consider Theorem 1.4: if we show the existence of a suitable extension satisfying the uniform bound (1.26), then the thesis follows immediately from Theorem 1.3 and Corollary 2.11. Thanks to the a priori estimates (4.22) and Lemma 2.10, the choice $\breve{u}^\varepsilon_{i,e} := T^\varepsilon_{i,e} u^\varepsilon_{i,e}$ will surely satisfy (1.26); therefore we should find an analogous extension for w^ε. Recalling that w^ε satisfies on Γ^ε the ordinary differential equation

$$\partial_t w^\varepsilon + \gamma w^\varepsilon = \eta v^\varepsilon,$$

so that

$$w^\varepsilon(x,t) = w^\varepsilon_0 e^{-\gamma t} + \eta \int_0^t e^{-\gamma(t-s)} v^\varepsilon(x,s)\, ds \quad \forall\, x \in \Gamma^\varepsilon,\ t \in [0,T],$$

we can use the same formula to extend w^ε to Ω starting from the initial datum $\breve{w}^\varepsilon_0 \in H^1_{loc}(\Omega)$. Therefore, we set $\breve{v}^\varepsilon(x,s) := \breve{u}^\varepsilon_i - \breve{u}^\varepsilon_e \in H^1_{loc}(\Omega)$ and correspondingly

$$\breve{w}^\varepsilon(x,t) = \breve{w}^\varepsilon_0 e^{-\gamma t} + \eta \int_0^t e^{-\gamma(t-s)} \breve{v}^\varepsilon(x,s)\, ds \quad \forall\, x \in \Omega,\ t \in [0,T], \tag{5.12}$$

and it is easy to see by differentiating under the integral sign that (1.26) is satisfied.

6. Uniform error estimates. In this section we prove Theorem 5.1; since all the estimates will depend only on the structural assumptions of section 4.5 and will therefore be independent of ε, for the sake of simplicity we will not indicate the explicit dependence on ε.

Thus, $\{\ {}^{\tau}_{n}\}_{n=0}^{N}$ is a discrete solution of the variational algorithm introduced in section 5.2. We already denoted by $\ {}^{\tau}$ the piecewise linear interpolant of the discrete values, which can be expressed in the form

$$\ {}^{\tau}(t) := (1-\ell(t))U^\tau_{n-1} + \ell(t) U^\tau_n \quad \text{if } t \in ((n-1)\tau, n\tau], \tag{6.1}$$

where ℓ is the piecewise linear (but discontinuous) function associated with the mesh $\mathcal{P}_\tau$ by

$$\ell(t) := \frac{t}{\tau} - (n-1) \quad \text{if } t \in ((n-1)\tau, n\tau].$$

The piecewise constant interpolant $\bar{\ }^{\tau}$ is defined by

$$\bar{\ }^{\tau}(t) := \ {}^{\tau}_{n} \quad \text{if } t \in ((n-1)\tau, n\tau]. \tag{6.2}$$

The basic quantity which will control our estimates is

$$\mathscr{E}(\ ) := \frac{1}{2}\ (\ ) + \ (\ ) \geq \ (\ ). \tag{6.3}$$

We split the proof into several steps, denoting by C different constants which solely depend on G and T.

Discrete variational inequality. The discrete solution solves

$$\text{(6.4)}\qquad \left(\frac{{}^{\tau}_{n} - \ {}^{\tau}_{n-1}}{\tau},\ {}^{\tau}_{n} - \quad \right) + \frac{1}{2}\ (\ {}^{\tau}_{n} - \quad) + \mathscr{E}(\ {}^{\tau}_{n})$$
$$\le \mathscr{E}(\quad) + \ (\ {}^{\tau}_{n-1},\ {}^{\tau}_{n} - \quad) \quad \forall \quad \in D(\phi).$$

This property follows from the well-known (see, e.g., [8]) variational characterization of the minima for a functional, such as Φ^{τ}_{n}, which is the sum of a quadratic continuous form (involving , ,) and a convex functional (in this case).

Stability estimates. There exists a constant $C = C(G,T)$ such that

$$\text{(6.5)}\qquad \sum_{n=1}^{N} \tau\ \left(\frac{{}^{\tau}_{n} - \ {}^{\tau}_{n-1}}{\tau}\right) + \ (\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1}) + \sup_{n=0,\dots,N} \mathscr{E}(\ {}^{\tau}_{n}) \le C\mathscr{E}(\ {}_{0}).$$

We use a "discrete" version of the arguments of the formal a priori estimate of section 4.5. We choose $:= 0$ in (6.4); recalling the identity $2\ (x-y,x) = \ (x) - \ (y) + \ (x-y)$ and multiplying by 2τ we obtain

$$\text{(6.6)}\qquad \begin{aligned} & b(\ {}^{\tau}_{n}) + \ (\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1}) + 2\tau\ (\ {}^{\tau}_{n}) + 2\tau\phi(\ {}^{\tau}_{n}) \\ &\quad \le b(\ {}^{\tau}_{n-1}) + 2\tau\ (\ {}^{\tau}_{n-1},\ {}^{\tau}_{n}) \\ &\quad = b(\ {}^{\tau}_{n-1}) + 2\tau\Big(\ (\ {}^{\tau}_{n-1},\ {}^{\tau}_{n-1}) + \ (\ {}^{\tau}_{n-1},\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1})\Big) \\ &\quad \le b(\ {}^{\tau}_{n-1}) + 2\tau G^2(1+\tau)\ (\ {}^{\tau}_{n-1}) + \ (\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1}). \end{aligned}$$

A simple application of the discrete Gronwall lemma yields

$$\text{(6.7)}\qquad \sup_{0\le m\le N} b(\ {}^{\tau}_{m}) \le C_0\ (\ {}_{0}) \quad \text{for } C_0 := e^{2G^2(1+\tau)T}.$$

Choosing $:= \ {}^{\tau}_{n-1}$ in (6.4) and summing up for $n = 1$ to $m \le N$ we get

$$\text{(6.8)}\qquad \begin{aligned} & \sum_{n=1}^{m}\Big(\tau^{-1}\ \Big(\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1}) + \frac{1}{2}\ (\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1})\Big) + \mathscr{E}(\ {}^{\tau}_{m}) \\ &\quad \le \mathscr{E}(\ {}_{0}) + \sum_{n=1}^{m}\ (\ {}^{\tau}_{n-1},\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1}) \\ &\quad \le \mathscr{E}(\ {}_{0}) + G\sum_{n=1}^{m}\Big(\ (\ {}^{\tau}_{n-1})\ (\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1})\Big)^{1/2} \\ &\quad \le \mathscr{E}(\ {}_{0}) + \frac{G^2\tau}{2}\sum_{n=1}^{m}\ (\ {}^{\tau}_{n-1}) + \frac{\tau^{-1}}{2}\sum_{n=1}^{m}\ (\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1}) \end{aligned}$$

so that choosing $m = N$ we get

$$\sum_{n=1}^{N}\Big(\tau^{-1}\ \Big(\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1}) + \ (\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1})\Big) \le 2\mathscr{E}(\ {}_{0}) + C_0 G^2 T\ (\ {}_{0}),$$
$$\sup_{1\le m\le N} \mathscr{E}(\ {}^{\tau}_{m}) \le \mathscr{E}(\ {}_{0}) + \frac{1}{2}C_0 G^2 T\ (\ {}_{0}).$$

A continuous version of the discrete variational inequalities. The piecewise linear interpolant $\ ^{\tau}$ satisfies

$$
\begin{aligned}
&\left(\frac{d}{dt}\ ^{\tau}(t),\ \ ^{\tau}(t)-\ \ \right)+\frac{1}{2}\ \ (\ ^{-\tau}(t)-\ \ )+\mathscr{E}(\ ^{\tau}(t))\\
&\quad\le \mathscr{E}(\ \ )+\ (\ ^{\tau}(t)-\tau\ell(t)\frac{d}{dt}\ ^{\tau}(t),\ \ ^{\tau}(t)-\ \ )+\mathcal{R}^{\tau}(t),
\end{aligned}
\tag{6.9}
$$

where

$$
\mathcal{R}^{\tau}(t):=(1-\ell)\Big(\mathscr{E}(\ ^{\tau}_{n-1})-\mathscr{E}(\ ^{\tau}_{n})+\ (\ ^{\tau}_{n-1},\ \ ^{\tau}_{n}-\ \ ^{\tau}_{n-1})\Big),
$$

and

$$
\int_0^T\left(\ \left(\frac{d}{dt}\ ^{\tau}(t)\right)+\tau^{-1}\ \ (\ ^{\tau}(t)-\ ^{-\tau}(t))\right)dt\le C\mathscr{E}(\ _0).
\tag{6.10}
$$

We check (6.9) simply by writing the discrete value of all the terms for $t\in(t_{n-1},t_n)$, recalling that

$$
\frac{d}{dt}\ ^{\tau}(t)=\frac{\ ^{\tau}_{n}-\ \ ^{\tau}_{n-1}}{\tau}\quad\text{for } t\in(t_{n-1},t_n).
\tag{6.11}
$$

Thus we have

$$
\begin{aligned}
\left(\frac{d}{dt}\ ^{\tau},\ \ ^{\tau}-\ \ \right)&=\left(\frac{\ ^{\tau}_{n}-\ \ ^{\tau}_{n-1}}{\tau},(1-\ell)\ \ ^{\tau}_{n-1}+\ell\ \ ^{\tau}_{n}-\ \ \right)\\
&=\left(\frac{\ ^{\tau}_{n}-\ \ ^{\tau}_{n-1}}{\tau},\ \ ^{\tau}_{n}-\ \ \right)-(1-\ell)\tau^{-1}\ \ (\ ^{\tau}_{n}-\ \ ^{\tau}_{n-1})
\end{aligned}
\tag{6.12}
$$

$$
\begin{aligned}
\mathscr{E}(\ ^{\tau})&=\mathscr{E}((1-\ell)\ \ ^{\tau}_{n-1}+\ell\ \ ^{\tau}_{n})\le(1-\ell)\mathscr{E}(\ ^{\tau}_{n-1})+\ell\mathscr{E}(\ ^{\tau}_{n})\\
&=\mathscr{E}(\ ^{\tau}_{n})+(1-\ell)\Big(\mathscr{E}(\ ^{\tau}_{n-1})-\mathscr{E}(\ ^{\tau}_{n})\Big)
\end{aligned}
\tag{6.13}
$$

$$
\begin{aligned}
&\left(\ \ ^{\tau}-\tau\ell\frac{d}{dt}\ ^{\tau},\ \ ^{\tau}-\ \ \right)\\
&\quad=\ ((1-\ell)\ \ ^{\tau}_{n-1}+\ell\ \ ^{\tau}_{n}-\ell(\ ^{\tau}_{n}-\ \ ^{\tau}_{n-1}),(1-\ell)\ \ ^{\tau}_{n-1}+\ell\ \ ^{\tau}_{n}-\ \ )\\
&\quad=\ (\ ^{\tau}_{n-1},\ \ ^{\tau}_{n}-\ \ )-(1-\ell)\ (\ ^{\tau}_{n-1},\ \ ^{\tau}_{n}-\ \ ^{\tau}_{n-1}).
\end{aligned}
\tag{6.14}
$$

Equation (6.10) follows directly from (6.5) by (6.11) and

$$
\ ^{-\tau}(t)-\ \ ^{\tau}(t)=(1-\ell)\big(\ ^{\tau}_{n}-\ \ ^{\tau}_{n-1}\big)\quad\text{for } t\in(t_{n-1},t_n).
\tag{6.15}
$$

An estimate for the remainder term.

$$
\int_0^T\left|\mathcal{R}^{\tau}(t)\right|dt\le C_1\mathscr{E}(\ _0)\tau.
\tag{6.16}
$$

First of all, since $\ ^{\tau}_{n}$ minimizes Φ^{τ}_{n}, we easily have

$$
\mathscr{E}(\ ^{\tau}_{n})-\ (\ ^{\tau}_{n-1},\ \ ^{\tau}_{n})\le\mathscr{E}(\ ^{\tau}_{n-1})-\ (\ ^{\tau}_{n-1},\ \ ^{\tau}_{n-1})
$$

so that $\mathcal{R}^{\tau}(t)\ge 0$. Moreover

$$
\begin{aligned}
\int_0^T\mathcal{R}^{\tau}(t)\,dt&=\frac{1}{2}\tau\sum_{n=1}^{N}\Big(\mathscr{E}(\ ^{\tau}_{n-1})-\mathscr{E}(\ ^{\tau}_{n})+\ (\ ^{\tau}_{n-1},\ \ ^{\tau}_{n}-\ \ ^{\tau}_{n-1})\Big)\\
&=\frac{1}{2}\tau\Big(\mathscr{E}(\ _0)+\mathscr{E}(\ _0)+C_0G^2T\ (\ _0)\Big)\le C_1\tau\mathscr{E}(\ _0),
\end{aligned}
$$

where we used, as in (6.8),

$$\sum_{n=1}^{N} \ (\ {}^{\tau}_{n-1},\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1}) \leq \frac{G^2\tau}{2}\sum_{n=1}^{N} \ (\ {}^{\tau}_{n-1}) + \frac{\tau^{-1}}{2}\sum_{n=1}^{N} \ (\ {}^{\tau}_{n} - \ {}^{\tau}_{n-1})$$
$$\leq \frac{C_0G^2T}{2} \ (\ _0) + \mathscr{E}(\ _0) + \frac{C_0G^2T}{2} \ (\ _0).$$

A Gronwall-type estimate for the error. If $\ ^{\eta}$, $\eta > 0$, is the discrete solution associated with the partition $\mathcal{P}_\eta$, we have

$$\sup_{t\in[0,T]} \ (\ ^{\tau}(t) - \ ^{\eta}(t)) + \int_0^T \ (\ ^{\tau}(t) - \ ^{\eta}(t)) \leq C(\tau+\eta)\mathscr{E}(\ _0). \tag{6.17}$$

Let ℓ^τ, ℓ^η be the interpolating functions corresponding to $\mathcal{P}_\tau, \mathcal{P}_\eta$. Choosing $\ :=\ ^{\eta}(t)$ in (6.9) and $\ :=\ ^{\tau}(t)$ in the analogous inequality written for $\ ^{\eta}$, we obtain

$$\frac{d}{dt} \ (\ ^{\tau} - \ ^{\eta}) + \ (\ ^{-\tau} - \ ^{\eta}) + \ (\ ^{\eta} - \ ^{-\tau})$$
$$\leq 2\ (\ ^{\tau} - \ ^{\eta},\ ^{\tau} - \ ^{\eta}) - 2\left(\tau\ell^\tau\frac{d}{dt}\ ^{\tau} - \eta\ell^\eta\frac{d}{dt}\ ^{\eta},\ ^{\tau} - \ ^{\eta}\right) + \mathcal{R}^\tau + \mathcal{R}^\eta$$
$$\leq 3G\ (\ ^{\tau} - \ ^{\eta}) + 2G\tau^2\ \left(\frac{d}{dt}\ ^{\tau}\right) + 2G\eta^2\ \left(\frac{d}{dt}\ ^{\eta}\right) + \mathcal{R}^\tau + \mathcal{R}^\eta.$$

A direct application of the Gronwall lemma, (6.16), and (6.10) yields

$$\sup_{t\in[0,T]} (U^\tau(t) - \ ^{\eta}(t)) \leq \left(\int_0^T 2G\tau^2\ \left(\frac{d}{dt}\ ^{\tau}\right) + 2G\tau^2\ \left(\frac{d}{dt}\ ^{\eta}\right)\right.$$
$$\left. + \mathcal{R}^\tau + \mathcal{R}^\eta\, dt\right)e^{3GT}$$
$$\leq C\tau\mathscr{E}(\ _0).$$

An analogous argument and (6.10) provide the integral bound for $\ (\ ^{\tau} - \ ^{-\tau})$.

If now we pass to the limit as $\eta \downarrow 0$ we obtain the estimates of (5.5).

Appendix. The derivation of the scaled problem $\ ^{\varepsilon}$. For completeness, in this appendix, we present the scaling used to obtain problem $\ ^{\varepsilon}$.

The basic equations modeling the electrical activity of the heart at the cellular level can be obtained as follows. Cardiac tissue consists of interconnected cells surrounded by extracellular fluid. Let Ω_i^ε, Ω_e^ε be the intra- and extracellular ohmic conductive media, Γ^ε be the excitable membrane that separates Ω_i^ε and Ω_e^ε, and let $\nu_i^\varepsilon, \nu_e^\varepsilon$ denote the unit exterior normals to the boundary of Ω_i^ε and Ω_e^ε, respectively, satisfying $\nu_i^\varepsilon = -\nu_e^\varepsilon$ on Γ^ε. The electric behavior of the tissue is described by the intra- and extracellular potentials u_i^ε and u_e^ε and by their driven current densities $\mathbf{j}_{i,e}^\varepsilon = -\Sigma_{i,e}\nabla u_{i,e}^\varepsilon$. Due to the current conservation law, the normal current flux through the membrane Γ^ε is continuous $\nu_i^\varepsilon\cdot\mathbf{j}_i^\varepsilon = \nu_e^\varepsilon\cdot\mathbf{j}_e^\varepsilon$; hence we have

$$\Sigma_i\nabla u_i^\varepsilon\cdot\nu_i^\varepsilon + \Sigma_e\nabla u_e^\varepsilon\cdot\nu_e^\varepsilon = 0 \quad \text{on } \Gamma^\varepsilon\times(0,T),$$

where $\Sigma_{i,e}$ are the cellular conductivity matrices in the intra- and extracellular media.

Since the only active source elements lie on the membrane Γ^ε, each flux equals the membrane current per unit area J_m, i.e.,

$$J_m = \begin{cases} -\Sigma_i \nabla u_i^\varepsilon \cdot \nu_i^\varepsilon \\ \Sigma_e \nabla u_e^\varepsilon \cdot \nu_e^\varepsilon \end{cases} \quad \text{on } \Gamma^\varepsilon \times (0,T). \tag{A.1}$$

The membrane current per unit area J_m consists of a capacitive term and an ionic term (see [23]):

$$J_m := \mathsf{C}_m \partial_t v^\varepsilon + I(v^\varepsilon, w^\varepsilon) \quad \text{on } \Gamma^\varepsilon, \tag{A.2}$$

with C_m the surface capacitance of the membrane.

Moreover, disregarding the presence of applied current terms, we have that currents are conserved in Ω_i^ε and Ω_e^ε; then the intra- and extracellular potentials are solutions of

$$-\operatorname{div}(\Sigma_i \nabla u_i^\varepsilon) = 0 \quad \text{in } \Omega_i^\varepsilon \times (0,T) \qquad -\operatorname{div}(\Sigma_e \nabla u_e^\varepsilon) = 0 \quad \text{in } \Omega_e^\varepsilon \times (0,T) \tag{A.3}$$

with Neumann boundary conditions for u_i^ε, u_e^ε on the remaining part of the boundaries $\Gamma_{i,e}^\varepsilon = \partial\Omega_{i,e}^\varepsilon \setminus \Gamma^\varepsilon$.

We now want to rewrite problem (A.1)–(A.3) in a nondimensional form. To this end we note that we can consider two characteristic length scales: the microscopic scale, related to a typical dimension d_c of the cells (e.g., the cell diameter 15–20 μm or the length of the cell 100 μm), and the macroscopic one determined by a suitable length constant of the tissue denoted by L. The cellular conductivity matrices Σ_i and Σ_e are symmetric positive definite matrices; let $\bar\lambda = \bar\lambda_i + \bar\lambda_e$ with $\bar\lambda_i$, $\bar\lambda_e$ be the average eigenvalues on a cell element and let us consider

$$\sigma_{i,e} = \Sigma_{i,e}/\bar\lambda.$$

Here we assume that $v^\varepsilon = 0$, $w^\varepsilon = 0$ is the equilibrium point for problem (A.1)–(A.3); then we can define the macroscopic space scale along fibers L as

$$\mathsf{L} = \sqrt{\mathsf{d}_c \mathsf{R}_m \bar\lambda} \quad \text{with} \quad \mathsf{R}_m^{-1} = \partial_v I(0,0).$$

Now, we can convert the cellular problem into a nondimensional form by scaling space and time with the macroscopic units of length $\mathsf{L} = \mathsf{d}_c/\varepsilon$ and with respect to the membrane constant $\mathsf{T} = \mathsf{R}_m\ \mathsf{C}_m$; i.e., we perform the space and time scaling

$$\widehat{\ } = \ /\mathsf{L}, \quad \widehat{t} = t/\mathsf{T}.$$

The dimensionless parameter ε is then a small parameter whose order of magnitude is the ratio of the two macro- and microscopic space scales, i.e.,

$$\varepsilon = d_c/\mathsf{L}.$$

We take $\widehat{\ }$ to be the variable of the macroscale behavior and

$$\xi := \widehat{\ }/\varepsilon$$

to be the microscopic space variable measured in a unit cell. For simplicity, in what follows, we omit the hats $\widehat{\ }$ on the dimensionless variables.

Cardiac tissue exhibits a number of significant inhomogeneities, in particular, those related to cell-to-cell communications. The conductivity tensors are considered dependent on both the slow and the fast variables, i.e., $\sigma_{i,e}(x, \frac{x}{\varepsilon})$. The latter dependence of the intracellular conductivity represents an attempt to include the effects of the gap junctions.

We then define the rescaled symmetric conductivity matrices

$$\sigma^{\varepsilon}_{i,e}(x) = \sigma_{i,e}\left(x, \frac{x}{\varepsilon}\right)$$

obtained by the continuous functions $\sigma_{i,e}(x,\xi) : \Omega \times E_{i,e} \to \mathbb{M}^{d\times d}$ satisfying

$$\text{(A.4)} \qquad \begin{array}{c} 0 < \sigma|y|^2 \le \sigma_{i,e}(x,\xi)y\cdot y \le \sigma^{-1}|y^2| \\ \sigma_{i,e}(x,\xi + \ _k) = \sigma_{i,e}(x,\xi) \end{array} \quad \forall\,(x,\xi)\in\Omega\times E_{i,e}, \qquad y \in \mathbb{R}^d.$$

Finally, rescaling (A.1)–(A.3) in the intra- and extracellular potentials we obtain

$$\begin{aligned} -\operatorname{div}\left(\sigma^{\varepsilon}_{i,e}\nabla u^{\varepsilon}_{i,e}\right) &= 0 \quad \text{in } \Omega^{\varepsilon}_{i,e}\times(0,T),\\ -\sigma^{\varepsilon}_i\nabla u^{\varepsilon}_i\cdot\nu^{\varepsilon}_i &= \varepsilon\left(\partial_t v + I(v^{\varepsilon},w^{\varepsilon})\right) \quad \text{on } \Gamma^{\varepsilon}\times(0,T)\\ \sigma^{\varepsilon}_e\nabla u^{\varepsilon}_e\cdot\nu^{\varepsilon}_e &= \varepsilon\left(\partial_t v + I(v^{\varepsilon},w^{\varepsilon})\right) \quad \text{on } \Gamma^{\varepsilon}\times(0,T), \end{aligned}$$

that is, problem $\ ^{\varepsilon}$.

A homogenization process for different mathematical models, describing the response of biological tissues to electromagnetic fields and based on a completely different scaling, can be found in [2].

LAGRANGIAN SOLUTIONS OF SEMIGEOSTROPHIC EQUATIONS IN PHYSICAL SPACE*

MICHAEL CULLEN† AND MIKHAIL FELDMAN‡

Abstract. The semigeostrophic equations are a simple model of large-scale atmosphere/ocean flows. Previous work by J.-D. Benamou and Y. Brenier, M. Cullen and W. Gangbo, and M. Cullen and H. Maroofi proves that the semigeostrophic equations can be solved in the cases, respectively, of 3-dimensional (3-d) incompressible flow between rigid boundaries, vertically averaged 3-d incompressible flow with a free surface, and fully compressible flow. However, all these results prove only the existence of weak solutions in "dual" variables, where the dual variables result from a change of variables introduced by Hoskins. This makes it difficult to relate the solutions to the full Euler or Navier–Stokes equations, or to those of other simple atmosphere/ocean models. We therefore seek to extend these results to prove existence of a solution in physical variables. We do this using the Lagrangian form of the equations in physical space. The proof is based on the recent results of L. Ambrosio on transport equations and ODE for BV vector fields.

Key words. semigeostrophic equations, Lagrangian solutions, transport equations, BV vector fields

DOI. 10.1137/040615444

1. Introduction. The semigeostrophic equations are a simple model of large-scale atmosphere/ocean flows, where "large-scale" is defined to mean that the flow is rotation-dominated [4]. They are also accurate in the case where one horizontal scale becomes small, allowing them to describe weather fronts and jet streams. Previous work by Benamou and Brenier [2], Cullen and Gangbo [5], and Cullen and Maroofi [6] proves that the semigeostrophic equations can be solved in the cases, respectively, of 3-dimensional (3-d) incompressible flow between rigid boundaries, vertically averaged 3-d incompressible flow with a free surface, and fully compressible flow. However, all these results only prove the existence of weak solutions in "dual" variables, where the dual variables result from the change of variables introduced by [11]. This makes it difficult to relate the solutions to the full Euler or Navier–Stokes equations, or to those of other simple atmosphere/ocean models. We therefore seek to extend the results of [2] and [5] to prove existence of a solution in physical variables. We do this using the Lagrangian form of the equations in physical space. The proof is based on the recent results of L. Ambrosio [1] on transport equations and ODE for BV vector fields. It is not clear whether it is possible to prove existence of a weak solution to the Eulerian form of the equations.

The transport theory of [1] gives uniqueness. However, the analysis of [2], [5], and [6] does not give uniqueness, because of the dependence of the transport velocity on the transported quantity. This question remains open.

The remaining part of the paper is organized as follows: in section 2 we consider a 3-d incompressible semigeostrophic system in a domain with rigid boundary, and in section 3 we consider the semigeostrophic shallow water model.

2. Lagrangian solutions of 3-d incompressible semigeostrophic system in a domain with rigid boundary in physical space.

2.1. Background. Let $\Omega \subset \mathbf{R}^3$ be an open bounded set. We study the following semigeostrophic system:

$$
\begin{aligned}
&D_t(v_1^g, v_2^g) + (\partial_1 p, \partial_2 p) = (u_2, -u_1), \quad (v_1^g, v_2^g) = (-\partial_2 p, \partial_1 p),\\
&D_t \rho = 0, \quad \operatorname{div} u = 0, \quad \partial_3 p + \rho = 0,\\
&D_t = \partial_t + u \cdot \nabla, \quad \nabla = (\partial_{x_1}, \partial_{x_2}, \partial_{x_3}),
\end{aligned}
\tag{2.1}
$$

where $u = (u_1, u_2, u_3)$ is the velocity, p is the pressure, and ρ is the density. All these quantities are functions of $(t, x) \in (0, T) \times \Omega$. The initial and boundary data are

$$
\begin{aligned}
&u \cdot \nu = 0 \quad \text{on } [0, T) \times \partial\Omega,\\
&p(0, x) = p_0(x) \quad \text{in } \Omega,
\end{aligned}
\tag{2.2}
$$

ν is the outward normal to $\partial\Omega$, and $p_0(x)$ is a given function.

Introducing the function

$$P(t, x) = p(t, x) + \frac{1}{2}(x_1^2 + x_2^2),$$

we rewrite (2.1) as the following system of equations for P, $u = (u_1, u_2, u_3)$ depending on $(t, x) \in (0, T) \times \Omega$:

$$
\begin{aligned}
&D_t X = J(X - x),\\
&\operatorname{div} u = 0,\\
&X = \nabla P,\\
&u \cdot \nu = 0 \quad \text{on } [0, T) \times \partial\Omega,\\
&P(0, x) = P_0(x) \quad \text{in } \Omega,
\end{aligned}
\tag{2.3}
$$

where $P_0(x) = p_0(x) + \frac{1}{2}(x_1^2 + x_2^2)$. Here

$$J = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Note that a solution of (2.3) determines a solution of the original system (2.1), (2.2). Indeed, given a solution (P, u) of (2.3), we have $X = \nabla P$, we set the function u in (2.1) to be equal to the function u in (2.3), and

$$
\begin{aligned}
&p(t, x) = P(t, x) - \frac{1}{2}(x_1^2 + x_2^2),\\
&\rho(t, x) = -\partial_3 p(t, x).
\end{aligned}
$$

Then (2.1), (2.2) holds, in particular the equation $D_t \rho = 0$ follows from the equation $D_t X_3 = 0$ of (2.3). The form (2.3) is more convenient than the original system because it allows the system to be stated in the Lagrangian sense.

The solutions of [2] and [5] were obtained by interchanging dependent and independent variables in (2.3) to give a set of equations in the dual coordinates (t, X), where $X = (X_1, X_2, X_3)$. We now regard x as a function of (t, X) which is shown in [2] to be given by defining

$$P^*(t,X) = \sup_{x\in\Omega}(x \cdot X - P(t,x)) \quad \text{for } (t,X) \in [0,T) \times \mathbf{R}^3 \tag{2.4}$$

and setting $x = \nabla P^*(t, X)$. The semigeostrophic system then takes the form

$$\partial_t \alpha + \nabla \cdot (U\alpha) = 0 \quad \text{in } [0,T) \times \mathbf{R}^3, \tag{2.5}$$

$$\nabla P(t,\cdot)\#\chi_\Omega = \alpha(t,\cdot) \quad \text{for any } t \in [0,T); \tag{2.6}$$

$$U(t,X) = J(X - \nabla P^*(t,X)), \tag{2.7}$$

$$\alpha(0,X) = \alpha_0(X) \quad \text{for a.e. } X \in \mathbf{R}^3. \tag{2.8}$$

The initial data $\alpha_0(X)$ are chosen by applying (2.6) with $P(0,\cdot) = P_0(x)$. Here (2.6) means that the map $\nabla P(t,\cdot)$ pushes χ_Ω forward to $\alpha(t,\cdot)$; see Definition A.1 in Appendix A.

The proofs in [2] and [5] depended on the use of the convexity principle introduced by Cullen and Purser [7], which requires that the function $P(t,\cdot)$ is convex. Shutts and Cullen [13] relate this condition to a physical stability condition required for the semigeostrophic approximation to be appropriate. Equation (2.4) shows that $P^*(t,\cdot)$ also has to be convex, as the Legendre–Fenchel transform of P.

In this paper we are interested in the solution of the problem in the original ("physical") coordinates, i.e., in the solution of problem (2.3). The unknown functions in this problem are the (modified) pressure P and the velocity u. The Eulerian form of the first equation of (2.3) is

$$\partial_t X + u \cdot \nabla X = J(X - x). \tag{2.9}$$

Using $\operatorname{div} u = 0$, this expression can be written in the divergence form, which yields the following definition of a weak (Eulerian) solution of (2.3).

Definition 2.1. *Let $u : [0,T) \times \Omega \to \mathbf{R}^3$ and $P : [0,T) \times \Omega \to \mathbf{R}^1$ satisfy $u \in L^1([0,T) \times \Omega, \mathbf{R}^3)$, $\nabla P \in L^\infty([0,T) \times \Omega) \cap C([0,T); L^1(\Omega))$; and $P(t,\cdot)$ is convex in Ω for every $t \in [0,\infty)$. The pair (u,P) is a weak Eulerian solution of* (2.3) *if*

$$\begin{aligned}\int_{(0,T)\times\Omega} &\{\nabla P(t,x) \cdot [\partial_t \phi(t,x) + (u(t,x)\cdot\nabla)\phi(t,x)] \\ &+ J[\nabla P(t,x) - x]\cdot\phi(t,x)\}dtdx + \int_\Omega \nabla P_0(x)\cdot\phi(0,x)dx = 0\end{aligned} \tag{2.10}$$

for any $\phi \in C^1_c([0,T) \times \Omega; \mathbf{R}^3)$, and

$$\int_{[0,T)\times\Omega} u(t,x)\cdot\nabla\psi(t,x)dtdx = 0 \tag{2.11}$$

for any $\psi \in C^1_c([0,T) \times \overline{\Omega})$.

Remark 2.2. Equality (2.11) is a weak form of the equation $\operatorname{div} u = 0$ in $(0,T)\times\Omega$ with the boundary condition $u_\nu = 0$ on $(0,T) \times \partial\Omega$ in (2.3).

In order to obtain a solution (u,P), we can find P and $x(t,X) = \nabla P^*$ by solving the problem (2.5)–(2.8) in the dual coordinates, using the results of [2], [5]. Thus the problem is to find u such that (2.10), (2.11) hold. Since u in physical coordinates is by definition equal to $D_t x(t,X)$, (2.7) and (2.4) yield the following expression for u in terms of P and P^*:

$$u(t,x) = \partial_t \nabla P^*(t,X) + U\cdot\nabla(\nabla P^*(t,X)) \\ = \partial_t\nabla P^*(t,\nabla P(t,x)) + D^2P^*(t,\nabla P(t,x))[J(\nabla P(t,x)-x)]. \tag{2.12}$$

Formally, if (P,α) satisfy (2.5)–(2.8), P^* is defined by (2.4), and u is defined by (2.12), then (P,u) satisfy (2.3). However, because of the low regularity of $P(t,x)$ obtained as a weak solution of the problem (2.5)–(2.8), it is not clear how to make these calculations rigorous. There is a further difficulty. The product terms $u_i\partial_j P$ that appear in (2.10) are not well defined given that $\nabla P\in L^\infty$ and that u defined by (2.12) is a measure, which is all the regularity of P currently available.

In this paper we circumvent these difficulties by defining Lagrangian solutions of the problem (2.3). We prove existence of such Lagrangian solutions for initial data P_0 satisfying some mild strict convexity conditions. The proof is based on the recent results of L. Ambrosio [1] on transport equations and ODE for BV vector fields.

In the conclusion of this introduction, we show that the time-stepping procedure and estimates of [5] can be applied to the model considered in [2] to improve some estimates of [2]. This is required to allow the solutions in the dual variables to be transferred to real space.

Let $q>1$. Denote by $C([0,T);L^q_w(\mathbf{R}^3))$ the set of all measurable functions $v(t,x)$ on $[0,T)\times\mathbf{R}^3$, such that $v_t(\cdot)=v(t,\cdot)\in L^q(\mathbf{R}^3)$ for any $t\in[0,T)$, and for any $\{t_k\}_{k=1}^\infty, t^*\in[0,T)$ satisfying $\lim_{k\to\infty}t_k=t_*$ there holds $v_{t_k}\rightharpoonup v_{t^*}$ weakly in $L^q(\mathbf{R}^3)$ (weakly-* if $q=\infty$).

THEOREM 2.3 (see [2], [5]). *Let $\Omega\subset\mathbf{R}^3$ be an open bounded set and $\overline{\Omega}\subset B$, where B is an open ball $B(0,S)$. Let $P_0(x)$ be a convex bounded function in B satisfying*

$$\alpha_0 := DP_0\#\chi_\Omega \in L^q(\mathbf{R}^3) \tag{2.13}$$

for some $q>1$. Then for any $T>0$ there exist functions $\alpha(t,X), P(t,X)$ on $[0,T)\times\mathbf{R}^3$ such that

i. *α, P satisfy*

$$\alpha\in L^\infty([0,T);L^q(\mathbf{R}^3))\cap C([0,T);L^q_w(\mathbf{R}^3)),$$
$$P\in L^\infty([0,T);W^{1,\infty}(\Omega))\cap C([0,T);W^{1,r}(\Omega)),$$

where r is any number in $[1,\infty)$;

ii. *let $R_0=S(1+T)$, then*

$$\operatorname{supp}(\alpha(t,\cdot))\subset B(0,R_0) \quad \textit{for all } t\in[0,T); \tag{2.14}$$

iii. *$P(t,\cdot)$ is convex in Ω;*

iv. *P^* defined by (2.4) satisfies*

$$P^*(t,\cdot) \textit{ is convex in } \mathbf{R}^3 \textit{ for any } t\in[0,T),$$
$$P^*\in L^\infty_{loc}([0,T)\times\mathbf{R}^3),$$
$$\nabla P^*\in L^\infty([0,T)\times\mathbf{R}^3;\mathbf{R}^3)\cap C([0,T);L^r(B(0,R);\mathbf{R}^3))$$

for any $R>0$ and any $r\in[1,\infty)$. Moreover,

$$\|\nabla P^*(t,\cdot)\|_{L^\infty(\mathbf{R}^3)}\le S \quad \textit{for every } t\in[0,T); \tag{2.15}$$

v. (α, P, P^*) *satisfy* (2.5)–(2.8)*, where the evolution equation* (2.5) *and the initial condition* (2.8) *are understood in the weak sense: for any* $\phi \in C_c^1([0,T)\times \mathbf{R}^3)$

$$\begin{aligned}\int_{(0,T)\times\mathbf{R}^3}&[\partial_t\phi(t,X)+U(t,X)\cdot\nabla\phi(t,X)]\alpha(t,X)dtdX\\ &+\int_{\mathbf{R}^3}\alpha_0(X)\phi(0,X)dX=0.\end{aligned}\tag{2.16}$$

Proof. We sketch the proof.

Since P_0 is convex and bounded in B, then

$$\|\nabla P_0\|_{L^\infty(\Omega)} \le C(B,\Omega,\|P_0\|_{L^\infty(B)}).\tag{2.17}$$

Thus α_0 defined by (2.13) has compact support.

As in [2], [5], we construct solutions using a time-stepping procedure. Fix $x^* \in \Omega$. Let $h > 0$ be small, chosen so that T/h is an integer. Let $\eta_h(\cdot) = \frac{1}{h^3}\eta(\frac{\cdot}{h})$ be a standard mollifier. Define

$$\alpha_h^0 = (\alpha_0) * \eta_h,$$

and then inductively define the following quantities for $k = 0, 1, \ldots, T/h$.

Suppose $\alpha_h^k \in L^q(\mathbf{R}^3)$, with compact support, is defined. Then let P_h^k be the unique convex function satisfying

$$\nabla P_h^k \# \chi_\Omega = \alpha_h^k, \qquad P_h^k(x^*) = P_0(x^*).$$

Existence and uniqueness of such P_h^k follows from Brenier [3].

$$\begin{aligned}&(P_h^k)^*(X) = \sup_{x\in\Omega}(x\cdot X - P_h^k(x)) \quad \text{for } X \in \mathbf{R}^3,\\ &Q_h^k = \eta_h * (P_h^k)^*,\\ &U_h^k(X) = J\left[X - \nabla Q_h^k(X)\right].\end{aligned}\tag{2.18}$$

Since $\Omega \subset B(0,S)$, it follows that

$$\|\nabla(P_h^k)^*,\ \nabla Q_h^k\|_{L^\infty(\mathbf{R}^3)} \le S.\tag{2.19}$$

From (2.18), (2.19)

$$\|(P_h^k)^* - Q_h^k\|_{L^\infty(\mathbf{R}^3)} \le hS.$$

To define α_h^{k+1} we solve

$$\frac{\partial\alpha_h}{\partial t} + \operatorname{div}(\alpha_h U_h^k) = 0 \qquad \text{in } \mathbf{R}^3\times[kh,(k+1)h],\tag{2.20}$$

$$\alpha_h(kh,X) = \alpha_h^k(X),\tag{2.21}$$

and set

$$\alpha_h^{k+1}(X) = \alpha_h((k+1)h,X).\tag{2.22}$$

Similar to [5, Lemma 4.1] we show that $\alpha_h \in L^\infty([kh,(k+1)h], L^q(\mathbf{R}^3))$ and that

$$\|\alpha_h(t,\cdot)\|_{L^q(\mathbf{R}^3)} = \|\alpha_0\|_{L^q(\mathbf{R}^3)} \qquad \text{for every } t \in [kh,(k+1)h],\tag{2.23}$$

$$\operatorname{supp}(\alpha_h(t,\cdot)) \subset B(0,S(1+(k+1)h)) \qquad \text{for every } t \in [kh,(k+1)h],\tag{2.24}$$

$$W_1(\alpha_h(t_1,\cdot),\alpha_h(t_2,\cdot)) \le C(T)|t_1-t_2| \qquad \text{for all } t_1,t_2 \in [kh,(k+1)h],\tag{2.25}$$

where q is from (2.13), and $W_1(\alpha_h(t_1,\cdot),\alpha_h(t_2,\cdot))$ is the 1-Wasserstein distance between $\alpha_h(t_1,\cdot)$ and $\alpha_h(t_2,\cdot)$ (see, e.g., [5, Appendix A] for the definition of W_1).

We repeat this procedure for $k = 1,\dots,T/h$. In particular, we thus define a function

$$\alpha_h \in L^\infty([0,T],L^q(\mathbf{R}^3)). \tag{2.26}$$

For every $t \in (0,T)$ define $P_h(t,\cdot)$ to be the unique convex function satisfying

$$\nabla P_h(t,\cdot)\#\chi_\Omega = \alpha_h(t,\cdot), \qquad P_h(t,x^*) = P_0(x^*),$$

and then define $Q_h(t,\cdot)$, $U_h(t,\cdot)$ by using the $P_h(t,\cdot)$ in (2.18) instead of P_h^k.

We also define functions $\overline{P}_h$ on $[0,T]\times\Omega$ and $\overline{\alpha}_h$, $\overline{Q}_h$, $\overline{U}_h$ on $[0,T]\times\mathbf{R}^3$ by setting them equal to $P_h^k,\alpha_h^k,Q_h^k,U_h^k$, respectively, on the time interval $t\in[kh,(k+1)h)$.

We note the following fact.

Lemma 2.4 (see [3]). *Let $p \geq 1$. Let $\Omega\subset\mathbf{R}^n$ be an open bounded set, $x^*\in\Omega$, $a\in\mathbf{R}$. Let $\rho_j,\rho\in L^p(\mathbf{R}^n)$ for $j=1,\dots$ be such that $\rho_j\rightharpoonup\rho$ weakly in $L^p(\mathbf{R}^n)$ and $\operatorname{supp}(\rho_j,\rho)\subset B(0,R)$. Let ϕ_j, ϕ be the convex functions on $\mathbf{R}^n$ satisfying $\nabla\phi_j\#\chi_\Omega = \rho_j$, $\nabla\phi\#\chi_\Omega=\rho$, $\phi(x^*),\phi_j(x^*)=a$ for $j=1,\dots$. Then $\phi_j\to\phi$ in $W^{1,r}(\Omega)$ for any $r\in[1,\infty)$.*

From (2.23)–(2.25), repeating the argument of [5, pp. 263–268], with the use of Lemma 2.4 we obtain a sequence $h_j\to 0+$ and a function $\alpha\in L^q([0,T]\times\mathbf{R}^3)$, where q is from (2.13), such that

$$\operatorname{supp}(\alpha_{h_j}(t,\cdot))\subset B(0,S(1+T)) \quad \text{for each } t\in[0,T],\ \ j=1,2,\dots, \tag{2.27}$$

$$\alpha_{h_j}\rightharpoonup\alpha \quad \text{weakly in } L^q([0,T]\times\mathbf{R}^3), \tag{2.28}$$

$$\alpha_{h_j}(t,\cdot)\rightharpoonup\alpha(t,\cdot) \quad \text{weakly in } L^q(\mathbf{R}^3) \quad \text{for each } t\in[0,T], \tag{2.29}$$

and such that, denoting by $P(t,\cdot)$, for every $t\in(0,T)$, the unique convex function satisfying

$$\nabla P(t,\cdot)\#\chi_\Omega = \alpha(t,\cdot), \qquad P(t,x^*) = P_0(x^*),$$

and denoting by $P^*(t,\cdot)$ the convex dual of $P(t,\cdot)$ defined by (2.4), we have

$$\overline{P}^*_{h_j}(t,\cdot)\to P^*(t,\cdot) \quad \text{in } C(\overline{B(0,R)}) \quad \text{for each } R>0,\ t\in[0,T], \tag{2.30}$$

$$\overline{Q}_{h_j}(t,\cdot)\to P^*(t,\cdot) \quad \text{in } C(\overline{B(0,R)}) \quad \text{for each } R>0,\ t\in[0,T], \tag{2.31}$$

$$\alpha_{h_j}\overline{U}_{h_j}\rightharpoonup\alpha J(id-\nabla P^*) \quad \text{weakly in } L^q([0,T]\times\mathbf{R}^3;\mathbf{R}^3). \tag{2.32}$$

Then the proof of Theorem 2.3 is completed as in [5, pp. 268–269]. □

2.2. Statement of results. In this paper we study the system in the "physical" space (t,x) and define its weak Lagrangian solutions. In order to do that, we first rewrite system (2.3) in terms of F,P, where $F:[0,T]\times\Omega\to\Omega$ is the (formal) Lagrangian flow corresponding to the full wind velocity $u=(u_1,u_2,u_3)$, and then we define the corresponding weak solution F,P. This gives the following.

Definition 2.5. *Let $\Omega\subset\mathbf{R}^3$ be an open bounded set, and let $T>0$. Let $P_0(x)\in W^{1,\infty}(\Omega))$ be convex. Let $r\in[1,\infty)$. Let $P:[0,T)\times\Omega\to\mathbf{R}^1$ satisfy*

$$P\in L^\infty([0,T);W^{1,\infty}(\Omega))\cap C([0,T);W^{1,r}(\Omega)), \tag{2.33}$$

$$P(t,\cdot) \quad \textit{is convex in } \ \Omega \ \textit{ for each } \ t\in[0,T). \tag{2.34}$$

Let $F : [0,T) \times \Omega \to \Omega$ be a Borel map satisfying

$$F \in C([0,T); L^r(\Omega; \mathbf{R}^3)). \tag{2.35}$$

Then the pair (P, F) is called a weak Lagrangian solution of (2.3) in $[0,T) \times \Omega$ if (P, F) has the following properties:

i. *$F(0,x) = x$, $P(0,x) = P_0(x)$ for a.e. $x \in \Omega$.*
ii. *For any $t > 0$ the mapping $F_t = F(t,\cdot) : \Omega \to \Omega$ is Lebesgue measure preserving, in the sense that $F_t \# \chi_\Omega = \chi_\Omega$.*
iii. *There exists a Borel map $F^* : [0,T) \times \Omega \to \Omega$ such that for every $t \in (0,T)$ the map $F_t^* = F^*(t,\cdot) : \Omega \to \Omega$ is Lebesgue measure preserving: $F_t^* \# \chi_\Omega = \chi_\Omega$ and satisfies $F_t^* \circ F_t(x) = x$, and $F_t \circ F_t^*(x) = x$ for a.e. $x \in \Omega$.*
iv. *The function*

$$Z(t,x) = \nabla P(t, F_t(x)) \tag{2.36}$$

is a weak solution of

$$\begin{aligned} &\partial_t Z(t,x) = J[Z(t,x) - F(t,x)] \qquad \text{in } [0,T) \times \Omega, \\ &Z(0,x) = \nabla P_0(x) \qquad \text{in } \Omega \end{aligned} \tag{2.37}$$

in the following sense: for any $\varphi \in C_c^1([0,T) \times \Omega; \mathbf{R}^3)$

$$\begin{aligned} \int_{(0,T)\times\Omega} &[Z(t,x) \cdot \partial_t \varphi(t,x) + J(Z(t,x) - F(t,x)) \cdot \varphi(t,x)] dt dx \\ &+ \int_\Omega \nabla P_0(x) \cdot \varphi(0,x) dx = 0. \end{aligned} \tag{2.38}$$

Remark 2.6. We comment on Definition 2.5:

- Continuity in time of P, F, considered as maps on $[0,T)$ with values in $W^{1,r}(\Omega)$ and $L^r(\Omega)$, respectively, required in (2.33), (2.35), combined with initial conditions in Definition 2.5(i), imply that

$$\lim_{t\to 0+} \|F_t - Id\|_{L^r(\Omega)} = 0, \qquad \lim_{t \to 0+} \|P_t - P_0\|_{W^{1,r}(\Omega)} = 0, \tag{2.39}$$

  where $Id : \Omega \to \Omega$ is the identity mapping. Furthermore, the continuity property of F in (2.35) can be interpreted as "generic continuity" of particle paths in physical space.
- The property Definition 2.5(ii) of the flow F is the Lagrangian form of the equation $\operatorname{div} u = 0$ in $(0,T) \times \Omega$ with the boundary condition $u_\nu = 0$ on $(0,T) \times \partial\Omega$ in (2.3).
- (2.38) is a weak Lagrangian form of the first equation of (2.3) with an initial condition for P.

Remark 2.7 (semigroup property). The weak Lagrangian solution in Definition 2.5 satisfies the following semigroup property. For every $t_1, t_2 \geq 0$ define $F_{(t_1,t_2)} = F_{t_1} \circ F_{t_2}^*$, where F_t^* is defined as in Definition 2.5(iii). Then for any $t_1, t_2, t_3 \geq 0$

$$F_{(t_1,t_2)} \circ F_{(t_2,t_3)} = F_{(t_1,t_3)} \qquad \text{for a.e. } x \in \Omega. \tag{2.40}$$

This follows from the property $F_t^* \circ F_t(x) = x$ for a.e. $x \in \Omega$ in Definition 2.5(iii), and from $\mathcal{L}^3$-measure-preserving properties of maps F_t, F_t^*. Indeed, it follows that

$$F_{t_1} \circ F_{t_3}^*(x) = F_{t_1} \circ F_{t_2}^* \circ F_{t_2} \circ F_{t_3}^*(x) = F_{t_1} \circ F_{t_2}^* \circ F_{t_2} \circ F_{t_3}^* \circ F_{t_3} \circ F_{t_3}^*(x)$$

for a.e. $x \in \Omega$, which is (2.40).

To justify Definition 2.5 we now show that a weak Lagrangian solution (F, P) with the additional regularity property $\partial_t F \in L^\infty([0,T) \times \Omega)$ determines a weak Eulerian solution of (2.3), and that a smooth Lagrangian solution determines a classical solution of (2.3).

Lemma 2.8 (consistency of weak Lagrangian solutions). *Let $\Omega \subset \mathbf{R}^3$ be an open bounded set, and let $T > 0$. Let (F, P) be a weak Lagrangian solution of* (2.3) *in* $[0,T) \times \Omega$.

i. *If $\partial_t F \in L^\infty([0,T) \times \Omega; \mathbf{R}^3)$, then the function*

$$u(t,x) := (\partial_t F)(t, F_t^*(x)) \tag{2.41}$$

satisfies $u \in L^\infty([0,T) \times \Omega; \mathbf{R}^3)$, and (u, P) is a weak Eulerian solution of (2.3) *in* $[0,T) \times \Omega$ *in the sense of Definition* 2.1*;*

ii. *If $(F, F^*, P) \in C^2([0,T] \times \overline{\Omega})$, then the function* (2.41) *satisfies $u \in C^1([0,T] \times \overline{\Omega}; \mathbf{R}^3)$, and (u, P) is a classical solution of* (2.3) *in* $[0,T) \times \Omega$.

Proof. We first prove (i). Since F^* is a Borel map, and $\partial_t F \in L^\infty([0,T) \times \Omega)$, the right-hand side of (2.41) is a bounded measurable function, and thus $u \in L^\infty([0,T) \times \Omega)$. It remains to prove that (P, u) is a weak Eulerian solution. We prove first that (2.11) holds. Let $\psi \in C_c^1([0,T) \times \overline{\Omega})$. Fix $t \in (0,T)$. Since $F_t \# \chi_\Omega = \chi_\Omega$, then

$$\int_\Omega (\partial_t \psi)(t, F_t(x)) dx = \int_\Omega \partial_t \psi(t,x) dx.$$

Integrating with respect to t and using $\partial_t F \in L^\infty([0,T) \times \Omega)$, we get

$$\int_{[0,T)\times\Omega} \{\partial_t[\psi(t, F_t(x))] - \partial_t F_t(x) \cdot (\nabla\psi)(t, F_t(x))\} dt dx = \int_{[0,T)\times\Omega} \partial_t \psi(t,x) dt dx.$$

Using $\psi(T, \cdot) \equiv 0$ and (2.39), we get

$$\int_{[0,T]\times\Omega} \partial_t F_t(x) \cdot (\nabla\psi)(t, F_t(x)) dt dx = 0.$$

Making the change of variables $y = F_t(x)$ and using properties (ii) and (iii) of Definition 2.5, we get

$$\int_{[0,T]\times\Omega} (\partial_t F_t)(F_t^* y) \cdot \nabla\psi(t,y) dt dy = 0.$$

Since (2.41) defines u, then (2.11) follows.

Now we prove (2.10). From properties P and F in Definition 2.5 it follows that $Z(t,x)$ defined by (2.36) satisfies $Z \in L^\infty([0,T] \times \overline{\Omega})$. Then, since Ω is a bounded set and $F_t \# \chi_\Omega = \chi_\Omega$ for all $t \in [0,T)$, (A.2) of Corollary A.3 allows us to make the change of variables $y = F_t(x)$ in the first integral of (2.38). Then $x = F_t^*(y)$ for a.e. $(t,x) \in [0,T) \times \Omega$ by (iii) in Definition 2.5, and from (2.38) we get for any $\varphi \in C_c^1([0,T) \times \Omega)$

$$\begin{aligned}\int_{(0,T)\times\Omega} [\nabla P(t,y) \cdot (\partial_t \varphi)(t, F_t^*(y)) + J(\nabla P(t,y) - y)\varphi(t, F_t^*(y))] dt dy \\ + \int_\Omega \nabla P_0(x) \varphi(0,x) dx = 0.\end{aligned} \tag{2.42}$$

Next we show that (2.42) holds for all $\varphi \in L^\infty([0,T)\times\Omega)$ satisfying $\partial_t\varphi \in L^\infty([0,T)\times\Omega)$ and $\mathrm{supp}(\varphi)\subset[0,T-\varepsilon]\times\overline{\Omega}$ for some $\varepsilon>0$. Indeed, for such φ we construct an approximating sequence $\varphi_j \in C^1_c([0,T)\times\Omega)$ as follows. Extend φ to $[0,\infty)\times\Omega$ by defining $\varphi(t,\cdot)\equiv 0$ for $t\ge T$, and further extend φ to $(-\infty,\infty)\times\Omega$ by defining $\varphi(t,x)=\varphi(-t,x)$ for $t<0$, $x\in\Omega$. Let $h>0$ and $\Omega_h=\{x\in\Omega \mid \mathrm{dist}(x,\partial\Omega)>h\}$. Now $\varphi\chi_{\Omega_h}$ is defined on $\mathbf{R}^1\times\mathbf{R}^3$. Let $\eta_h(t,x)=\frac{1}{h^4}\eta(\frac{|(t,x)|}{h})$, where $\eta(\cdot)$ is a standard mollifier. Let $j>\frac{1}{\varepsilon}$ be integer. Then functions $\varphi_j=(\varphi\chi_{\Omega_{4h}})*\eta_h$ with $h=\frac{1}{j}<\varepsilon$ satisfy $\varphi_j\in C^1_c([0,T)\times\Omega)$ with $\|\varphi_j,\partial_t\varphi_j\|_{L^\infty([0,T)\times\Omega)}\le C$, where C does not depend on j, and $(\varphi_j,\partial_t\varphi_j)\to(\varphi,\partial_t\varphi)$ a.e. on $[0,T)\times\Omega$ as $j\to\infty$. Since $F^*_t\#\chi_\Omega=\chi_\Omega$ for all t, it follows that $(\varphi_j,\partial_t\varphi_j)(t,F^*_t(y))\to(\varphi,\partial_t\varphi)(t,F^*_t(y))$ for a.e. $(t,y)\in[0,T)\times\Omega$. With this, since Ω is bounded, $\nabla P\in L^\infty([0,T)\times\Omega)$, and (2.42) holds for each φ_j; the bounded convergence theorem implies (2.42) for φ.

Let $\varphi(t,x)=\eta(t,F_t(x))$, where $\eta\in C^1_c([0,T)\times\Omega)$. Then $\varphi\in L^\infty([0,T)\times\Omega)$, and $\mathrm{supp}(\varphi)\subset[0,T-\varepsilon]\times\overline{\Omega}$ since $\mathrm{supp}(\eta)\subset[0,T-\varepsilon]\times\overline{\Omega}$ for some $\varepsilon>0$. Moreover, since $\partial_tF\in L^\infty([0,T)\times\Omega)$, it follows that $\partial_t\varphi\in L^\infty([0,T)\times\Omega)$ with

$$\partial_t\varphi(t,x)=(\partial_t\eta)(t,F_t(x))+\sum_{i=1}^{3}\partial_tF^j_t(x)(\partial_{x_j}\eta)(t,F_t(x)) \qquad \text{a.e. in} \quad [0,T)\times\Omega,$$

where we used notation $F(t,x)=(F^1,F^2,F^3)(t,x)$.

Thus (2.42) holds for φ. By properties (ii) and (iii) in Definition 2.5

$$\varphi(t,F^*_t(y))=\eta(t,y), \qquad \partial_t\varphi(t,F^*_t(y))=\partial_t\eta(t,y)+[(\partial_tF)(t,F^*_t(y))]\cdot\nabla\eta(t,y)$$

for a.e. $(t,y)\in[0,T)\times\Omega$. Thus, inserting $\varphi(t,x)=\eta(t,F_t(x))$ into (2.42), we obtain for every $\eta\in C^1_c([0,T)\times\Omega)$

$$\int_{(0,T)\times\Omega}[\nabla P(t,y)\cdot(\partial_t\eta(t,y)+[(\partial_tF)(t,F^*_t(y))]\cdot\nabla\eta(t,y))$$
$$+J(\nabla P(t,y)-y)\eta(t,y)]dtdy+\int_\Omega\nabla P_0(x)\eta(0,F_0(x))dx=0.$$

Using property (i) in Definition 2.5 and (2.41), and changing notations y to x and η to φ, we obtain (2.10). Assertion (i) of Lemma 2.8 is proved.

Now assertion (ii) follows directly from (i). ◻

Our main result is the following.

THEOREM 2.9. *Let $\Omega\subset\mathbf{R}^3$ be an open bounded set and $\overline{\Omega}\subset B$ where B is an open ball $B(0,S)$. Let $P_0(x)$ be a convex bounded function in B. Assume that P_0 satisfies*

$$DP_0\#\chi_\Omega\in L^q(\mathbf{R}^3) \tag{2.43}$$

for some $q>1$. Then for any $T>0$ there exists a weak Lagrangian solution (P,F) of (2.3) *in $[0,T)\times\Omega$, where* (2.33), (2.35) *are satisfied for any $r\in[1,\infty)$. Moreover, the function $Z(t,x)$ defined by* (2.36) *satisfies $Z(\cdot,x)\in W^{1,\infty}([0,T);\mathbf{R}^3)$ for a.e. $x\in\Omega$, and* (2.37) *is satisfied, in addition to the weak form* (2.38)*, in the following sense:*

$$\begin{aligned}&\partial_tZ(t,x)=J(Z(t,x)-F(t,x)) \qquad \textit{for } \mathcal{L}^4\textit{-a.e. in } (t,x)\in(0,T)\times\Omega,\\ &Z(0,x)=\nabla P_0(x) \qquad \textit{for } \mathcal{L}^3\textit{-a.e. in } x\in\Omega.\end{aligned} \tag{2.44}$$

Remark 2.10. The condition (2.43) is equivalent to

$$\det D^2P^*_0\in L^q(\nabla P_0(\Omega)),$$

where P_0^* is the Legendre–Fenchel transform of P_0, i.e., $P_0^*(X) = \sup_{x\in\Omega}[x\cdot X - P_0(x)]$ for $X \in \mathbf{R}^3$. The condition (2.43) is a certain strict convexity condition for P_0. In particular, if P_0 is uniformly strictly convex in B, in the sense that there exists $\varepsilon > 0$ such that $P_0(x) - \varepsilon|x|^2$ is a convex function in B, then $\det D^2 P_0^* \in L^\infty(\nabla P_0(\Omega))$, and $\nabla P_0(\Omega)$ is a bounded set by (2.17). Thus (2.43) is satisfied.

We prove Theorem 2.9 in sections 2.3 and 2.4.

2.3. Lagrangian flow in the dual space. Let Ω, T, P_0 be as in Theorem 2.9.

Let $\alpha_0 = \nabla P_0 \# \chi_\Omega$. By Theorem 2.3, there exists a solution (α, P, P^*) of the problem (2.5)–(2.7) with initial data α_0 satisfying all assertions of Theorem 2.3.

Note that the vector field U defined by (2.7) is divergence free. Thus the evolution equation (2.5) and its weak form (2.16) can be seen as the transport equation

$$\partial_t \alpha + U \cdot \nabla \alpha = 0. \tag{2.45}$$

Since $\nabla P^* \in L^\infty([0,T) \times \mathbf{R}^3))$, and $P_t^*(\cdot)$ is convex in $\mathbf{R}^3$ for all $t \in [0,T)$, it follows from (2.7) that

$$U \in L^\infty_{loc}([0,T) \times \mathbf{R}^3) \text{ and } U \in L^\infty([0,T); BV(B(0,R))) \quad \text{for all } R > 0.$$

By (2.14) α has compact support in $[0,T] \times \mathbf{R}^3$. Thus we can modify U away from $B(0,R_1)$, where large R_1 will be chosen below so that, in particular, $\text{supp}(\alpha) \subset [0,T] \times \overline{B(0,R_1)}$ and the modified function $\tilde{U}$ satisfies

$$\begin{aligned} &\tilde{U} \in L^\infty([0,T) \times \mathbf{R}^3), \qquad \tilde{U} \in L^\infty([0,T); BV(B(0,R))) \quad \text{for all } R > 0; \\ &\operatorname{div} \tilde{U}(t,\cdot) = 0 \quad \text{in } \mathbf{R}^3 \quad \text{for all } t \in [0,T). \end{aligned} \tag{2.46}$$

To construct $\tilde{U}$ satisfying (2.46), we choose $\zeta \in C^\infty(\mathbf{R}^1)$ such that

$$\zeta \equiv 1 \quad \text{on } \{|s| < R_1\}, \quad \zeta \equiv 0 \quad \text{on } \{|s| > R_1 + 1\}, \quad 0 \le \zeta \le 1 \text{ on } \mathbf{R}^1, \tag{2.47}$$

and define, for $X \in \mathbf{R}^3$,

$$H(X) = (\zeta(|X_1|)X_1, \zeta(|X_2|)X_2, \zeta(|X_3|)X_3). \tag{2.48}$$

Define $\tilde{U}$ by

$$\tilde{U}(t,X) = J\,[H(X) - \nabla P^*(t,X)]. \tag{2.49}$$

Then $\tilde{U}$ satisfies (2.46), and from (2.47)–(2.48), (2.15)

$$U = \tilde{U} \quad \text{in } B(0,R_1), \tag{2.50}$$

$$\|U(t,\cdot)\|_{L^\infty(\mathbf{R}^3)} \le S + R_1 + 1 \quad \text{for all } t \in [0,T). \tag{2.51}$$

Now the theory developed by Ambrosio [1] applies to (2.45) with U replaced by $\tilde{U}$.

LEMMA 2.11. *Let $\tilde{U}$ be defined by* (2.47)–(2.49). *There exists a unique locally bounded Borel measurable map $\Phi : [0,T) \times \mathbf{R}^3 \to \mathbf{R}^3$ satisfying*

i. $\Phi(\cdot, X) \in W^{1,\infty}([0,T); \mathbf{R}^3)$ *for a.e.* $X \in \mathbf{R}^3$*;*
ii. $\Phi(0,X) = X$ *for* $\mathcal{L}^3$*-a.e.* $X \in \mathbf{R}^3$*;*
iii. *for a.e.* $(t,X) \in \mathbf{R}^3 \times (0,T)$

$$\partial_t \Phi(t,X) = \tilde{U}(t, \Phi(t,X)); \tag{2.52}$$

iv. $\Phi(t,\cdot) : \mathbf{R}^3 \to \mathbf{R}^3$ *is a* $\mathcal{L}^3$*-measure-preserving map for every* $t \in [0,T)$.

Proof. Since $\tilde{U}$ satisfies (2.46), by [1, section 6] there exists a unique regular flow relative to $\tilde{U}$. This flow determines a locally bounded Borel measurable map $\Phi : [0,T) \times \mathbf{R}^3 \to \mathbf{R}^3$ satisfying (i)–(iii) and the following property.

Let $\tilde{U}_\varepsilon : [0,T) \times \mathbf{R}^3 \to \mathbf{R}^3$ be a family of approximations to $\tilde{U}$ satisfying the following:

$$\begin{aligned}
&\tilde{U}_\varepsilon \in C([0,T) \times \mathbf{R}^3; \mathbf{R}^3), \qquad \sup_\varepsilon \|\tilde{U}_\varepsilon\|_{L^\infty([0,T)\times\mathbf{R}^3;\mathbf{R}^3)} < \infty,\\
&\tilde{U}_\varepsilon \to \tilde{U} \quad \text{in } \ L^1_{loc}((0,T) \times \mathbf{R}^3; \mathbf{R}^3),\\
&\|\nabla \tilde{U}_\varepsilon\|_{L^\infty([0,T)\times B_R;\mathbf{R}^3)} \le C(\varepsilon, R) < \infty \quad \text{for any } \ \varepsilon, R > 0,\\
&\operatorname{div} \tilde{U}_\varepsilon = 0.
\end{aligned} \tag{2.53}$$

Let $\Phi_\varepsilon(t,X)$ be the unique solution in $[0,T]$ of the ODE $\frac{d}{dt}\Phi_\varepsilon(t,X) = \tilde{U}(t, \Phi_\varepsilon(t,X))$ with the initial condition $\Phi_\varepsilon(0,X) = X$. Then

$$\lim_{\varepsilon\to 0} \int_{B_R} \sup_{t\in[0,T]} |\Phi(t,X) - \Phi_\varepsilon(t,X)|\, dX = 0 \quad \text{for any } \ R > 0. \tag{2.54}$$

Note that a family $\tilde{U}_\varepsilon$ satisfying the conditions stated above exists. Indeed, let $\eta_\varepsilon : \mathbf{R}^3 \times \mathbf{R}^1 \to \mathbf{R}^1$ be a family of mollifiers. Extend $P^*(t,X)$ to the time interval $(-\infty,\infty)$ by setting $P^*(t,X) = P^*(0,X)$ for $t < 0$ and $P^*(t,X) = P^*(T,X)$ for $t > 0$, and let

$$\tilde{U}_\varepsilon(t,X) = J\left[H(X) - (\nabla P^* * \eta_\varepsilon)(t,X)\right],$$

where the convolution is with respect to (t,X)-variables. Then all properties in (2.53) are satisfied.

Also, since $\tilde{U}_\varepsilon$ is smooth and $\operatorname{div} \tilde{U}_\varepsilon = 0$, it follows that each $\Phi_\varepsilon(t,\cdot)$ is a measure-preserving diffeomorphism. Thus (2.54) implies (iv).

Conversely, a map Φ satisfying (i)–(iv) determines a regular Lagrangian flow relative to $\tilde{U}$. This implies uniqueness of Φ by Theorem 6.4 of [1]. ∎

LEMMA 2.12. *Let* $\tilde{U}$ *be defined by* (2.47)–(2.49)*, and let* Φ *be the map defined in Lemma* 2.11. *Then we have the following conditions:*

i. *If* R_1 *in the definition of* $\tilde{U}$ *is chosen sufficiently large depending only on* Ω*,* T *and* $\|\nabla P_0\|_{L^\infty(\Omega)}$*, then*

$$\Phi(t,X) \subset B(0,R_1) \quad \text{for a.e. } \ (t,X) \in [0,T) \times \nabla P_0(\Omega). \tag{2.55}$$

In particular,

$$\partial_t \Phi(t,X) = U(t, \Phi(t,X)) \quad \text{for a.e. } \ (t,X) \in [0,T) \times \nabla P_0(\Omega). \tag{2.56}$$

ii. *There exists a Borel map* $\Phi^* : [0,T) \times \mathbf{R}^3 \to \mathbf{R}^3$ *such that for every* $t \in (0,T)$ *the map* $\Phi_t^* : \mathbf{R}^3 \to \mathbf{R}^3$ *is* $\mathcal{L}^3$*-measure preserving, and such that* $\Phi_t^* \circ \Phi_t(x) = x$ *and* $\Phi_t \circ \Phi_t^*(x) = x$ *for a.e.* $x \in \mathbf{R}^3$.

Proof. We prove (i). For the family $\tilde{U}_\varepsilon$ satisfying (2.53) constructed in the proof of Lemma 2.11, we have for $0 < \varepsilon < 1/2$, using (2.15),

$$|\tilde{U}_\varepsilon(t,X)| \le |X| + 1 + S. \tag{2.57}$$

Thus

$$\frac{1}{2}\frac{d}{dt}|\Phi_\varepsilon(t,X)|^2 = \tilde{U}(t, \Phi_\varepsilon(t,X)) \cdot \Phi_\varepsilon(t,X) \le \frac{3}{2}|\Phi_\varepsilon(t,X)|^2 + \frac{1}{2}(1+S)^2.$$

Thus, by the Gronwall inequality,

$$|\Phi_\varepsilon(t,X)| \le e^{3T/2}\left(|X|^2+(1+S)^2T^2\right)^{\frac{1}{2}} \qquad \text{for all } (t,X)\in[0,T]\times\mathbf{R}^3. \tag{2.58}$$

The same is true for $|\Phi(t,X)|$ for a.e. $(t,X)\in[0,T]\times\mathbf{R}^3$. Now choosing

$$R_1 = 2e^{3T/2}\left(\|\nabla P_0\|^2_{L^\infty(\Omega)}+(1+S)^2T^2\right)^{1/2}+1, \tag{2.59}$$

we obtain (2.55), which implies (2.56).

It remains to prove (ii). This is in fact a general property of regular Lagrangian flows constructed by Ambrosio [1, section 6]. It can be seen as follows. For $t_1,t_2\in[0,T]$ with $t_1\ge t_2$ and $x\in\mathbf{R}^3$, denote by $\hat{\Phi}(t_1,t_2,x)$ the regular Lagrangian flow relative to $\tilde{U}$ and starting at time t_1; i.e., $\hat{\Phi}(t_1,\cdot,\cdot)$ satisfies properties (i), (iii), (iv) of Lemma 2.11 on time interval $[t_1,T]$ and $\hat{\Phi}(t_1,t_1,X)=X$ for $\mathcal{L}^3$-a.e. $X\in\mathbf{R}^3$. In the case $t_2\le t_1$, $\hat{\Phi}(t_1,t_2,x)$ denotes the regular flow Lagrangian flow relative to $\tilde{U}$ backwards in time; i.e., $\hat{\Phi}(t_1,\cdot,\cdot)$ satisfies properties (i), (iii), (iv) of Lemma 2.11 on time interval $[0,t_1]$ and $\hat{\Phi}(t_1,t_1,X)=X$ for $\mathcal{L}^3$-a.e. $X\in\mathbf{R}^3$. Repeating the argument of Remark 6.7 of [1], we see that the following semigroup property holds: for every $t_1,t_2,t_3\in[0,T]$

$$\hat{\Phi}(t_1,t_2,\hat{\Phi}(t_2,t_3,x))=\hat{\Phi}(t_1,t_3,x) \qquad \text{for a.e. } x\in\mathbf{R}^n.$$

Also, from the proof of Theorem 6.6 of [1], one can see that if $\tilde{U}_\varepsilon$ is a family of approximations to $\tilde{U}$ satisfying (2.53), and if $\hat{\Phi}^\varepsilon(t_1,t_2,x)$ is the regular Lagrangian flow of $\tilde{U}_\varepsilon$ starting at time t_1, then $\hat{\Phi}^\varepsilon$ converges to $\hat{\Phi}$ in $L^1_{loc}([0,T]\times[0,T]\times\mathbf{R}^3)$. Thus, possibly after a modification on a negligible set, $\hat{\Phi}$ is a Borel map since it is an a.e. limit of continuous maps. Since $\Phi=\hat{\Phi}(0,\cdot,\cdot)$, the map $\Phi^*(t,x)=\hat{\Phi}(t,0,x)$ satisfies all properties asserted in (ii). $\square$

Now we prove the following property of transport equations.

LEMMA 2.13. *Let* $\tilde{U}\in L^\infty((0,T)\times\mathbf{R}^3)$ *with* $\tilde{U}(t,\cdot)\in BV_{loc}(\mathbf{R}^3)$ *and* $\operatorname{div}\tilde{U}(t,\cdot)=0$ *in* $\mathbf{R}^3$ *in the sense of distributions for every* $t\in(0,T)$. *Let a locally bounded Borel measurable map* $\Phi:\mathbf{R}^3\times[0,T)\to\mathbf{R}^3$ *satisfy properties* (i)–(iv) *of Lemma* 2.11. *Let* $q\in(1,\infty]$, $v_0\in L^q(\mathbf{R}^3)$, *and* $\operatorname{supp}(v_0)\subset B(0,R)$. *Let* $v(t,x):=(\Phi_t\#v_0)(x)$. *Then*

$$v\in L^\infty((0,T);L^q(\mathbf{R}^3))\cap C([0,T];L^q_w(\mathbf{R}^3)), \quad \textit{supp}\ v\subset B(0,R_T)\times[0,T],$$

where $R_T=R+T\|\tilde{U}\|_{L^\infty}$, *and* v *is a weak solution of*

$$\partial_t v+\operatorname{div}(v\tilde{U})=0 \tag{2.60}$$

on $(0,T)\times\mathbf{R}^3$, *with initial data* $v_{|t=0}=v_0$, *in the sense that for any* $\varphi\in C^1_c([0,T)\times\mathbf{R}^3)$

$$\int_{[0,T)\times\mathbf{R}^3} v\left(\partial_t\varphi+\tilde{U}\cdot\nabla\varphi\right)dtdx+\int_{\mathbf{R}^3}v_0(x)\varphi(0,x)dx=0.$$

Proof. Let p be such that $\frac{1}{p}+\frac{1}{q}=1$ (where $p=1$ if $q=\infty$). Fix $t\in[0,T)$. From the definition of v and using that Φ_t is $\mathcal{L}^3$-measure preserving and locally bounded, we get for all $\varphi\in C_c(\mathbf{R}^3)$

$$\begin{aligned}\int_{\mathbf{R}^3}\varphi(x)v_t(x)dx &= \int_{\mathbf{R}^3}\varphi(\Phi_t(x))v_0(x)dx \le \|v_0\|_{L^q}\left[\int_{\mathbf{R}^3}\left|\varphi(\Phi_t(x))\right|^p dx\right]^{\frac{1}{p}}\\ &= \|v_0\|_{L^q}\left[\int_{\mathbf{R}^3}|\varphi(x)|^p dx\right]^{\frac{1}{p}} = \|v_0\|_{L^q}\|\varphi\|_{L^p}.\end{aligned}$$

Thus $v_t \in L^q(\mathbf{R}^3)$ with $\|v_t\|_{L^q} \le \|v_0\|_{L^q}$ for any t.

Also, weak continuity of v with respect to t also follows: if $\{t_k\}_{k=1}^\infty, t_* \in [0,T)$, and $\lim_{k\to\infty} t_k = t_*$, then we get for every $\varphi \in C_c(\mathbf{R}^3)$ using (i), (iv) of Lemma 2.11 and the dominated convergence theorem

$$\int_{\mathbf{R}^3} v_{t_k}(x)\varphi(x)dx = \int_{\mathbf{R}^3} v_0(x)\varphi(\Phi_{t_k}(x))dx \to \int_{\mathbf{R}^3} v_0(x)\varphi(\Phi_{t_*}(x))dx = \int_{\mathbf{R}^3} v_{t_*}(x)\varphi(x)dx.$$

The bounds on the support of v_t follow from $|\Phi_t(X)| \le |X| + T\|\tilde U\|_{L^\infty}$, which can be obtained by approximating $\tilde U$ by smooth vector fields as in the proof of Lemmas 2.11 and 2.12.

Now we prove that v is a weak solution of (2.60) with initial data $v_{|t=0} = v_0$. Let $\varphi \in C_c^\infty(\mathbf{R}^3 \times [0,T))$. Then using the definition $v_t = \Phi_t \# v_0$ of v, the properties of Φ stated in (i)–(iv) of Lemma 2.11, we get

$$\begin{aligned}
\int_{\mathbf{R}^3\times[0,T)} v\partial_t\varphi dtdx &= \int_{\mathbf{R}^3\times[0,T)} v_0(x)(\partial_t\varphi)(t,\Phi_t(x))dtdx \\
&= \int_{\mathbf{R}^3} v_0(x)\int_0^T \frac{d}{dt}\left[\varphi(t,\Phi_t(x))\right]dtdx \\
&\quad - \int_{\mathbf{R}^3\times[0,T)} v_0(x)\nabla\varphi(t,\Phi_t(x))\cdot\partial_t\Phi_t(x)dtdx \\
&= -\int_{\mathbf{R}^3} v_0(x)\varphi(0,x)dx - \int_{\mathbf{R}^3\times[0,T)} v_0(x)\nabla\varphi(t,\Phi_t(x))\cdot\tilde U(t,\Phi_t(x))dx \\
&= -\int_{\mathbf{R}^3} v_0(x)\varphi(0,x)dx - \int_{\mathbf{R}^3\times[0,T)} v_t(x)\nabla\varphi(t,x)\cdot\tilde U(t,x)dx.
\end{aligned}$$

Lemma 2.13 is proved. ∎

Now we prove that the solution (α, P) of (2.5)–(2.8) satisfies the property that α is a Lagrangian solution of the transport equation (2.5), in the sense of (2.61).

PROPOSITION 2.14. *Let Ω, T, q, P_0 be as in Theorem* 2.3. *Let (α, P) be the weak solution of* (2.5)–(2.8) *constructed in Theorem* 2.3. *Let $\tilde U$ be defined by* (2.47)–(2.49), *and let Φ be the regular Lagrangian flow of $\tilde U$ defined in Lemma* 2.11. *If R_1 in the definition of $\tilde U$ is chosen sufficiently large depending only on Ω, T, and $\|\nabla P_0\|_{L^\infty(\Omega)}$, then for every $t \in [0,T]$*

$$\alpha_t = \Phi_t \# \alpha_0. \tag{2.61}$$

Moreover, for every $t \in [0,T]$

$$\alpha_t(x) = \alpha_0(\Phi_t^*(x)) \quad \textit{for a.e. } x \in \mathbf{R}^3, \tag{2.62}$$

where the map Φ_t^* is defined in Lemma 2.12(ii).

Proof. We choose R_1 to be defined by (2.59). Then, in particular, $R_1 \ge R_0 + 1$ where $R_0 = S(1+T)$ is the number in (2.14).

We use notations introduced in the proof of Theorem 2.3, and for h, k considered there define

$$\tilde U_h^k(X) = J\left[H(X) - \nabla Q_h^k(X)\right], \tag{2.63}$$

where Q_h^k is defined by (2.18), and $H(X)$ is defined by (2.47)–(2.48) with R_1 given by (2.59). Define functions $\tilde U_h$ on $[0,T]\times\Omega$ by setting them equal to $\tilde U_h^k$ on the time interval $t \in [kh, (k+1)h)$. Then, from (2.19) and (2.47)–(2.48), we have $\tilde{U}_h \in L^\infty((0,T) \times \mathbf{R}^3)$ with

$$\|\tilde{U}_h(t,\cdot)\|_{L^\infty(\mathbf{R}^3)} \le S + R_1 + 1 \quad \text{for all } t \in [0,T),\ h \in (0,1). \tag{2.64}$$

Let $h_j \to 0$ be a sequence for which (2.27)–(2.32) hold. From (2.31), using convexity of $Q_{h_j}(t,\cdot)$ we conclude that

$$\nabla \overline{Q}_{h_j}(t,\cdot) \to \nabla P^*(t,\cdot) \quad \text{a.e. in } \mathbf{R}^3 \quad \text{for each } t \in [0,T),$$

and from this, noting that $U_{h_j}(X,t) = J[H(X) - \nabla \overline{Q}_{h_j}(X,t)]$ on $[0,T) \times \mathbf{R}^3$, we get

$$\tilde{U}_{h_j}(t,\cdot) \to \tilde{U}(t,\cdot) \quad \text{a.e. in } \mathbf{R}^3 \quad \text{for each } t \in [0,T), \tag{2.65}$$

where $\tilde{U}$ is defined by (2.47)–(2.49). By (2.64), (2.65) and the dominated convergence theorem

$$\tilde{U}_{h_j} \to \tilde{U} \quad \text{in } L^r([0,T) \times B(0,R); \mathbf{R}^3) \quad \text{for all } \ R > 0,\ r \in [1,\infty). \tag{2.66}$$

Our choice $R_1 \ge R_0 + 1$ implies that $\overline{U}_h(t,X) = \tilde{U}_h(t,X)$ in $[0,T) \times B(0,R_0+1)$. Then from (2.24) it follows that α_h satisfy (2.20) with U_h^k replaced by $\tilde{U}_h^k$. Thus each α_h is a weak solution of

$$\begin{aligned} &\frac{\partial \alpha_h}{\partial t} + \operatorname{div}(\alpha_h \tilde{U}_h) = 0 \qquad \text{in } \ \mathbf{R}^3 \times (0,T), \\ &\alpha_h(0,X) = \alpha_h^0(X). \end{aligned} \tag{2.67}$$

For each $h \in (0,1)$, from (2.19), (2.47)–(2.48), and (2.63)

$$\|\nabla \tilde{U}_h\|_{L^\infty((0,T)\times\mathbf{R}^3)} \le C\left(\frac{S}{h} + 1\right), \tag{2.68}$$

where C depends only on functions η, ζ. Also, from its definition, $\tilde{U}_h$ is a divergence-free vector field. Then there exists a unique Lagrangian flow $\Phi_h : \mathbf{R}^3 \times \mathbf{R}^1 \to \mathbf{R}^3$ induced by $\tilde{U}_h$, and for each t the map $(\Phi_h)_t : \mathbf{R}^3 \to \mathbf{R}^3$ is $\mathcal{L}^3$ measure-preserving (see, e.g., [8, Theorem III.2]). From this, for the sequence $\{h_j\}$ considered above, using also the properties (2.64), (2.68) of $\tilde{U}_{h_j}$, the properties (2.46) of $\tilde{U}$, and the convergence in (2.66), we can apply [1, Theorem 6.5] to conclude that for each $t \in [0,T]$

$$(\Phi_{h_j})_t \to \Phi_t \quad \text{in } L^1_{loc}(\mathbf{R}^3) \quad \text{as } j \to \infty. \tag{2.69}$$

Let $q > 1$ be as in (2.13). Then $\|\alpha_h^0\|_{L^q(\mathbf{R}^3)} \le \|\alpha_0\|_{L^q(\mathbf{R}^3)}$. From Lemma 2.13, it follows that the function $v(t,\cdot) = (\Phi_h)_t \# \alpha_h^0$ satisfies $v \in L^\infty([0,T], L^q(\mathbf{R}^3))$ and v is a weak solution of (2.67). Since $\tilde{U}_h \in L^\infty((0,T), W^{1,\infty}(\mathbf{R}^3))$ by (2.64) and (2.68)), it follows that (2.67) has at most one weak solution in $v \in L^\infty([0,T], L^q(\mathbf{R}^3))$; see, e.g., [8, Theorem II.2]. Using (2.26), we conclude that

$$\alpha_h(t,\cdot) = (\Phi_h)_t \# \alpha_h^0. \tag{2.70}$$

From (2.70) and (2.27), we get for any $t > 0$, $j = 1, \dots$ and any $\varphi \in C_c(\mathbf{R}^3)$

$$\int_{\mathbf{R}^3} \varphi(\Phi_{h_j}(t,X)) \alpha_{h_j}^0(X) dX = \int_{\mathbf{R}^3} \varphi(y) \alpha_{h_j}(t,y) dy.$$

Passing to the limit $j \to \infty$ in the last equality, by using (2.69), the fact that $\alpha^0_{h_j} \to \alpha_0$ in $L^q(\mathbf{R}^3)$, the dominated convergence theorem in the left-hand side, and (2.29) in the right-hand side we obtain

$$\int_{\mathbf{R}^3} \varphi(\Phi(t,X))\alpha_0(X)dX = \int_{\mathbf{R}^3} \varphi(y)\alpha(t,y)dy \tag{2.71}$$

for any $\varphi \in C_c(\mathbf{R}^3)$. This implies (2.61).

Since Φ_t is a measure-preserving map, we use Lemma 2.12(ii) to conclude that the left-hand side of (2.71) is equal to $\int_{\mathbf{R}^3} \varphi(y)\alpha_0(\Phi_t^*(y))dy$, and now (2.71) implies (2.62). ∎

2.4. Lagrangian flow in the physical space. Throughout this section we assume that Ω, T, P_0, α, P, U, $\tilde{U}$, Φ are as in Proposition 2.14. Moreover, we fix R_1 in the definition of $\tilde{U}$ sufficiently large so that the conclusions of Proposition 2.14 hold.

Below we use the following notation: for a function $g(t,x)$ we denote $g_t(x) := g(t,x)$.

We intend to define a Lagrangian flow in the physical space $F : [0,T) \times \Omega \to \Omega$ by defining $F_t : \Omega \to \Omega$ for $t \in [0,T)$ by

$$F_t := \nabla P_t^* \circ \Phi_t \circ \nabla P_0, \tag{2.72}$$

where P_t^* is the convex dual of P_t, and $\Phi_t : \mathbf{R}^3 \to \mathbf{R}^3$ is the Lagrangian flow in the dual space constructed in Lemma 2.11. For that, we need to prove first the following.

LEMMA 2.15. *The right-hand side of* (2.72) *is defined $\mathcal{L}^4$-a.e. in* $[0,T) \times \Omega$. *Moreover, for any $t \in [0,T)$ the right-hand side of* (2.72) *is defined $\mathcal{L}^3$-a.e. in Ω. The map $F : [0,T) \times \Omega \to \Omega$ defined by* (2.72) *is Borel.*

Proof. Since P_0 is a bounded convex function on B, then ∇P_0 exists on $\Omega \setminus N_0^1$, where N_0^1 is a Borel subset of Ω with $\mathcal{L}^3(N_0^1) = 0$. Also, since P^* is a bounded Borel function on $[0,T] \times \mathbf{R}^3$ and for every t the function $P^*(t,\cdot)$ is convex in $\mathbf{R}^3$, then ∇P^* exists on $([0,T] \times \mathbf{R}^3) \setminus N^2$, where N^2 is a Borel subset of $[0,T] \times \mathbf{R}^3$ with $\mathcal{L}^4(N^2) = 0$; moreover, denoting $N_t^2 := N^2 \cap (\{t\} \times \mathbf{R}^3)$, we have $\mathcal{L}^3(N_t^2) = 0$ for every $t \in [0,T]$.

Then the right-hand side of (2.72) is defined for all

$$(t,x) \in ([0,T] \times \Omega) \setminus (([0,T] \times N_0^1) \cup M),$$
$$\text{where } \; M = \left\{(s,y) \in [0,T] \times (\Omega \setminus N_0^1) \mid (s, \Phi(s, \nabla P_0(y))) \in N^2\right\}.$$

From its definition, M is a Borel set.

It remains to prove that $\mathcal{L}^4(M) = 0$ and $\mathcal{L}^3(M_t) = 0$ for every $t \in [0,T]$, where $M_t := M \cap (\{t\} \times \mathbf{R}^3)$. By Fubini's theorem, it is sufficient to prove that $\mathcal{L}^3(M_t) = 0$ for every $t \in [0,T]$.

Fix $t \in [0,T)$. Then, since $\Phi_t : \mathbf{R}^3 \to \mathbf{R}^3$ is $\mathcal{L}^3$-measure preserving, we have $\mathcal{L}^3\left(\Phi_t^{-1}(N_t^2)\right) = 0$, and using that $\nabla P_0 \# \chi_\Omega = \alpha_0$ and thus $\nabla P_0 \# \chi_{\Omega \setminus N_0^1} = \alpha_0$, we compute

$$|M_t| = \left|\left\{x \in \Omega \setminus N_0^1 \mid \nabla P_0(x) \in \Phi_t^{-1}(N_t^2)\right\}\right| = \int_{\Phi_t^{-1}(N_t^2)} \alpha_0(z)dz = 0$$

since $\alpha_0 \in L^1_{loc}(\mathbf{R}^3)$.

Thus we can define $F : [0,T) \times \Omega \to \Omega$ by (2.72). Then by Lemma 2.11, F is a Borel mapping. ∎

It remains to prove that if F is defined by (2.72), then (F, P) is a weak Lagrangian solution in the sense of Definition 2.5.

We first show that the initial condition for the flow is satisfied.

PROPOSITION 2.16. *$F(0, x) = x$ for a.e. $x \in \Omega$.*

Proof. By (2.72), $F_0(x) = \nabla P_0^* \circ \Phi_0 \circ \nabla P_0(x)$ for all $x \in \Omega \setminus N_0$, where N_0 is a Borel set with $\mathcal{L}^3[N_0] = 0$.

From convexity of P_0 in B and (2.4), there exist Borel sets $N_1 \subset \Omega$, $N_2 \subset \mathbf{R}^3$ with $\mathcal{L}^3(N_1) = \mathcal{L}^3(N_2) = 0$ such that P_0 (resp. P_0^*) is differentiable on $\Omega \setminus N_1$ (resp. $\mathbf{R}^3 \setminus N_2$). Moreover, if $x \in \Omega \setminus [N_1 \cup (\nabla P_0)^{-1}(N_2)]$, then $\nabla P_0^* \circ \nabla P_0(x) = x$.

By Lemma 2.11(ii), $\Phi_0(x) = x$ in $\mathbf{R}^3 \setminus N_3$, where N_3 is a Borel set with $\mathcal{L}^3[N_3] = 0$.

Thus $F_0(x) = x$ for all $x \in \Omega \setminus [N_0 \cup N_1 \cup (\nabla P_0)^{-1}(N_2 \cup N_3)]$. In order to complete the proof of the proposition, we need to show that $\mathcal{L}^3[(\nabla P_0)^{-1}(N_2 \cup N_3) \cap \Omega] = 0$.

Denote $\mu = \alpha_0 dx$ in $\mathbf{R}^3$. Since $\alpha_0 \in L^q(\mathbf{R}^3)$, then $\mu[N_2 \cup N_3] = 0$, and since $\nabla P_0 \# \chi_\Omega = \alpha_0$, we get $\mathcal{L}^3[(\nabla P_0)^{-1}(N_2 \cup N_3) \cap \Omega] = \mu[N_2 \cup N_3] = 0$. ∎

The next step is to prove that the property stated in Definition 2.5(ii) is satisfied.

PROPOSITION 2.17. *For every $t > 0$ the map $F_t : \Omega \to \Omega$ is $\mathcal{L}^3$-measure preserving.*

Proof. In order to complete the proof, we need to justify the following calculation: for any $\varphi \in C(\mathbf{R}^3)$,

$$\int_\Omega \varphi(F_t(x))dx = \int_\Omega \varphi \circ \nabla P_t^* \circ \Phi_t \circ \nabla P_0(x)dx \tag{2.73}$$

$$= \int_{\mathbf{R}^3} \varphi \circ \nabla P_t^* \circ \Phi_t(y)\alpha_0(y)dy \tag{2.74}$$

$$= \int_{\mathbf{R}^3} \varphi \circ \nabla P_t^*(z)\alpha_t(z)dz \tag{2.75}$$

$$= \int_\Omega \varphi(x)dx. \tag{2.76}$$

Then the proposition follows from Lemma A.2.

Now we prove these equalities.

Equality (2.73) follows from the definition of F_t.

Since $\nabla P_0 \# \chi_\Omega = \alpha_0$ and $\alpha_0 \in L^q(\mathbf{R}^3)$ with compact support, Corollary A.3 implies

$$\int_\Omega \psi(\nabla P_0(x))dx = \int_{\mathbf{R}^3} \psi(y)\alpha_0(y)dy \qquad \text{for all} \quad \psi \in L^\infty(\mathbf{R}^3).$$

Choosing $\psi = \varphi \circ \nabla P_t^* \circ \Phi_t \in L^\infty(\mathbf{R}^3)$, we conclude that the right-hand side of (2.73) is equal to (2.74).

Equality of expressions (2.75) and (2.74) follows from (2.61) and Corollary A.3, since $\varphi \circ \nabla P_t^* \in L^\infty(\mathbf{R}^3)$ and $\alpha_0 \in L^q(\mathbf{R}^3)$ with compact support.

Equality of expressions (2.75) and (2.76) follows from $\nabla P_t^* \# \alpha_t = \chi_\Omega$. ∎

Now we prove that (2.35) holds for all $r \in [1, \infty)$.

PROPOSITION 2.18. *For any $t_0 \in [0, T)$, any $r \in [1, \infty)$ and*

$$\lim_{t \to t_0,\, t \in [0,T)} \int_\Omega |F_t(x) - F_{t_0}(x)|^r dx = 0.$$

Proof. By Lemma 2.15, for any $t \in [0,T)$ (2.72) holds $\mathcal{L}^3$-a.e. in Ω. Also, $\nabla P_0 \# \chi_\Omega = \alpha_0$. Thus we get for any $t, t_0 \in [0,T)$

$$\begin{aligned}\int_\Omega |F_t(x) - F_{t_0}(x)|^r dx &= \int_\Omega |\nabla P_t^* \circ \Phi_t \circ \nabla P_0(x) - \nabla P_{t_0}^* \circ \Phi_{t_0} \circ \nabla P_0(x)|^r dx \\ &= \int_{\mathbf{R}^3} |\nabla P_t^* \circ \Phi_t(y) - \nabla P_{t_0}^* \circ \Phi_{t_0}(y)|^r \alpha_0(y) dy \\ &\le C \int_{\mathbf{R}^3} |\nabla P_t^* \circ \Phi_t(y) - \nabla P_{t_0}^* \circ \Phi_t(y)|^r \alpha_0(y) dy \\ &\quad + C \int_{\mathbf{R}^3} |\nabla P_{t_0}^* \circ \Phi_t(y) - \nabla P_{t_0}^* \circ \Phi_{t_0}(y)|^r \alpha_0(y) dy \\ &=: C(I_1 + I_2).\end{aligned}$$

We show first that $I_1 \to 0$ as $t \to t_0$. Note that $\|\alpha_t\|_{L^q(\mathbf{R}^3)} = \|\alpha_0\|_{L^q(\mathbf{R}^3)}$ for $t \in (0,T)$; this follows from (2.62) since Φ_t^* is a $\mathcal{L}^3$-measure-preserving map. Now we use (2.61) to estimate

$$\begin{aligned} I_1 &= \int_{\mathbf{R}^3} |\nabla P_t^* \circ \Phi_t(y) - \nabla P_{t_0}^* \circ \Phi_t(y)|^r \alpha_0(y) dy \\ &= \int_{\mathbf{R}^3} |\nabla P_t^*(y) - \nabla P_{t_0}^*(y)|^r \alpha_t(y) dy \\ &\le \|\nabla P_t^* - \nabla P_{t_0}^*\|_{rq'}^r \|\alpha_t\|_q \\ &= \|\nabla P_t^* - \nabla P_{t_0}^*\|_{rq'}^r \|\alpha_0\|_q \to 0 \quad \text{as } t \to t_0 \end{aligned}$$

by Theorem 2.3.

Now we show that $I_2 \to 0$ as $t \to t_0$. Since $\nabla P_t^*(y) \in B$ for a.e. y for each t, and $\alpha_0 \in L^1(\mathbf{R}^3)$ (since α_0 is in L^q and has compact support), then by the dominated convergence theorem it remains to prove that, for every t_0,

$$\nabla P_{t_0}^* \circ \Phi_t(y) - \nabla P_{t_0}^* \circ \Phi_{t_0}(y) \to 0 \quad \text{as } t \to t_0 \tag{2.77}$$

for a.e. $y \in \mathbf{R}^3$. First we note that, since Φ_t is measure preserving, then it follows from Lemma 2.11(i) that

$$\Phi_t(y) \to \Phi_{t_0}(y) \text{ as } t \to t_0 \text{ in } [0,T] \text{ for a.e. } y \in \mathbf{R}^3.$$

If y is such a point, and if in addition $\Phi_{t_0}(y)$ is a point of continuity for $\nabla P_{t_0}^*$, then convergence in (2.77) holds at y. As $P_{t_0}^*$ is convex, $\nabla P_{t_0}^*$ is differentiable a.e. Since Φ_{t_0} is measure preserving, it follows that $\Phi_{t_0}(y)$ is a point of continuity for $\nabla P_{t_0}^*$ for a.e. y. Thus (2.77) holds for a.e. $y \in \mathbf{R}^3$. The proposition is proved. ∎

It remains to show that properties (iii) and (iv) in Definition 2.5 are satisfied. The first step is the following.

LEMMA 2.19. *$\nabla P_t \circ F_t(x) = \Phi_t \circ \nabla P_0(x)$ for a.e. $(t,x) \in (0,T) \times \Omega$.*

Proof. To prove the lemma, we need to justify the formal computation

$$\nabla P_t \circ F_t = \nabla P_t \circ \nabla P_t^* \circ \Phi_t \circ \nabla P_0 = \Phi_t \circ \nabla P_0,$$

since $\nabla P_t \circ \nabla P_t^*$ is the identity on the support of α_t.

Now we make this argument rigorous.

Since $P(t,x)$ is a bounded Borel function in $[0,T] \times B$ and $P(t,\cdot)$ is a convex function in B for every $t \in [0,T]$, then ∇P exists in $([0,T] \times \Omega) \setminus N^1$, where N^1 is a

Borel subset of $[0,T]\times\Omega$ with $\mathcal{L}^4(N^1)=0$; moreover, denoting $N^1_t := N^1\cap(\{t\}\times\mathbf{R}^3)$, we have $\mathcal{L}^3(N^1_t)=0$ for every $t\in[0,T]$.

Then $F^{-1}(N^1)$ is a Borel subset of $[0,T]\times\Omega$ satisfying

$$\mathcal{L}^4(F^{-1}(N^1))=0.$$

Indeed, it is enough to show that $\mathcal{L}^3(F_t^{-1}(N^1_t))=0$ for every $t\in[0,T]$, and this follows from $\mathcal{L}^3(N^1_t)=0$ and Proposition 2.17.

Now we can conclude, using Lemma 2.15, that

$$Z_t(x)=\nabla P_t\circ\nabla P_t^*\circ\Phi_t\circ\nabla P_0(x)\quad\text{ for }(t,x)\in([0,T]\times\Omega)\setminus\tilde{N},\quad\text{ where }\mathcal{L}^4(\tilde{N})=0.$$

Let $\tilde{M}=\{(t,x)\in[0,T]\times\mathbf{R}^3\mid\nabla P(\nabla P^*(t,x),t)\neq x\}$, where we include (t,x) such that either $\nabla P^*(t,x)$ or $\nabla P(\nabla P^*(t,x),t)$ do not exist. Then $\tilde{M}$ is a Borel set.

The proof of the lemma will be completed if we show that

$$\mathcal{L}^4\left[\{(t,x)\in([0,T]\times\Omega)\setminus\tilde{N}\ \mid\ (\Phi_t\circ\nabla P_0(x),t)\in\tilde{M}\}\right]=0. \tag{2.78}$$

Since $\nabla P_t\#\chi_\Omega=\alpha_t$ and $\nabla P_t^*\#\alpha_t=\chi_\Omega$, it follows that for any t

$$\nabla P_t\circ\nabla P_t^*(x)=x\quad\text{ for }\alpha_t\text{-a.e. }\ x\in\mathbf{R}^3.$$

Then, denoting $\tilde{M}_t=\tilde{M}\cap(\mathbf{R}^3\times\{t\})$, we have

$$\int_{\tilde{M}_t}\alpha_t(x)dx=0\quad\text{ for any }t\in[0,T].$$

Thus for any $t\in[0,T]$ we get, using that $\mathcal{L}^3(\tilde{N}_t)=0$ and thus $\nabla P_0\#\chi_{\Omega\setminus\tilde{N}_t}=\alpha_0$, and also using Lemma 2.11(iv), Lemma 2.12(ii), and (2.62), the following:

$$\begin{aligned}\mathcal{L}^3\left[\{x\in\Omega\setminus\tilde{N}_t\ \mid\ \Phi_t\circ\nabla P_0(x)\in\tilde{M}_t\}\right]&=\mathcal{L}^3\left[\{x\in\Omega\setminus\tilde{N}_t\ \mid\ \nabla P_0(x)\in\Phi_t^*(\tilde{M}_t)\}\right]\\&=\int_{\Phi_t^*(\tilde{M}_t)}\alpha_0(x)dx=\int_{\tilde{M}_t}\alpha_0(\Phi_t^*(x))dx\\&=\int_{\tilde{M}_t}\alpha_t(x)dx=0.\end{aligned}$$

Now (2.78) follows from Fubini's theorem. The lemma is proved. □

Now we show existence of the map F^* from Definition 2.5(iii).

PROPOSITION 2.20. *The map F satisfies property* (iii) *in Definition* 2.5.

Proof. Similar to Lemma 2.15, we can show that for every $t\in[0,T]$ the expression $\nabla P_0^*\circ\Phi_t^*\circ\nabla P_t(x)$ is defined for a.e. $x\in\Omega$, and that the map $F_t^*:\Omega\to\Omega$ defined by $F_t^*=\nabla P_0^*\circ\Phi_t^*\circ\nabla P_t$ is Borel.

Since F_t is measure preserving, then $F_t^*\circ F_t(x)=\nabla P_0^*\circ\Phi_t^*\circ\nabla P_t\circ F_t(x)$ for a.e. $x\in\Omega$. Using Lemma 2.19, get $F_t^*\circ F_t(x)=\nabla P_0^*\circ\Phi_t^*\circ\Phi_t\circ\nabla P_0(x)$ a.e. in Ω. Since $\Phi_t^*\circ\Phi_t(y)=y$ for a.e. y and thus for α_0-a.e. $y\in\mathbf{R}^3$, and $\nabla P_0\#1_{|\Omega}=\alpha_0$, then $\Phi_t^*\circ\Phi_t\circ\nabla P_0(x)=\nabla P_0(x)$ for a.e. $x\in\Omega$. Thus $F_t^*\circ F_t(x)=\nabla P_0^*\circ\nabla P_0(x)=x$ for a.e. $x\in\Omega$.

By a similar argument, $F_t\circ F_t^*(x)=x$ for a.e. $x\in\Omega$. □

Finally we show property (iv) of Definition 2.5.

PROPOSITION 2.21. *Equality* (2.38) *holds for any* $\phi \in C_c^1((0,T)\times\Omega, \mathbf{R}^3)$. *Moreover, possibly after modifying* $Z(t,x)$ *on a negligible subset of* $(0,T)\times\Omega$, *we have* $Z(\cdot,x) \in W^{1,\infty}([0,T);\mathbf{R}^3)$ *for a.e.* $x\in\Omega$, *and* (2.44) *holds.*

Proof. From the definition of the Lagrangian flow Φ, i.e., properties (i)–(iii) of Lemma 2.11, for a.e. $X \in \mathbf{R}^3$ and every $t\in[0,T)$

$$\Phi(t,X) = X + \int_0^t \tilde{U}(s,\Phi_s(X))ds.$$

Thus the above equality holds for all $X\in\mathbf{R}^3\backslash N$, where $|N|=0$. Since $\nabla P_0 \# \chi_\Omega = \alpha_0$ and $\alpha_0 \in L^q(\mathbf{R}^3)$, it follows that $\left|(\nabla P_0)^{-1}(N)\cap\Omega\right| = \int_N \alpha_0(z)dz = 0$. Thus for a.e. $x\in\Omega$ and every $t\in[0,T)$

$$\Phi(t,\nabla P_0(x)) = \nabla P_0(x) + \int_0^t U(s,\Phi_s(\nabla P_0(x)))ds, \tag{2.79}$$

where we replaced $\tilde{U}(s,\Phi_s(\nabla P_0(x)))$ by $U(s,\Phi_s(\nabla P_0(x)))$ based on (2.55), (2.56). Multiplying the last equality by $\partial_t\eta(t,x)$, where $\eta\in C_c^1([0,T)\times\mathbf{R}^3)$, and integrating we get

$$\begin{aligned}\int_{[0,T)\times\Omega}\partial_t\eta(t,x)\Phi(t,\nabla P_0(x))dtdx &= \int_{[0,T)\times\Omega}\partial_t\eta(t,x)\nabla P_0(x)dtdx\\ &\quad+\int_{[0,T)\times\Omega}\partial_t\eta(t,x)\int_0^t U(s,\Phi_s(\nabla P_0(x)))dsdtdx.\end{aligned}$$

Note that $\eta(T,x)\equiv 0$. In the right-hand side, we perform the integration with respect to t in the first integral, and integrate by parts with respect to t in the second integral, to get

$$\begin{aligned}\int_{[0,T)\times\Omega}\partial_t\eta(t,x)\Phi(t,\nabla P_0(x))dtdx &= -\int_\Omega \eta(0,x)\nabla P_0(x)dx\\ &\quad-\int_{[0,T)\times\Omega}\eta(t,x)U(t,\Phi_t(\nabla P_0(x)))dtdx.\end{aligned}\tag{2.80}$$

Now we compute using (2.7), (2.72), and Lemma 2.19

$$U(t,\Phi_t(\nabla P_0(x))) = J[\Phi_t(\nabla P_0(x)) - \nabla P_t^*(\Phi_t(\nabla P_0(x)))] = J[Z(t,x)-F(t,x)]$$

for a.e. (t,x). Substituting this into the right-hand side of (2.80) and using Lemma 2.19 to replace $\Phi(t,\nabla P_0(x))$ by $Z(t,x)$ in the left-hand side of (2.80), we obtain (2.38).

Finally, $Z(\cdot,x)\in W^{1,\infty}([0,T);\mathbf{R}^3)$ for a.e. $x\in\Omega$ (possibly after modifying $Z(t,x)$ on a negligible subset of $(0,T)\times\Omega$) follows from Lemmas 2.19 and 2.11(i). Then (2.79) and Lemma 2.19 imply (2.44). ∎

Now the properties of P in Theorem 2.3, and the properties of (F,P) proved in Propositions 2.16, 2.17, 2.18, 2.20, and 2.21 imply Theorem 2.9.

3. Lagrangian solutions of 2-dimensional semigeostrophic shallow water equations in physical space.

3.1. Model formulation and background. In this section we extend the approach of the previous section to the model considered by Cullen and Gangbo in [5]. They study a shallow water approximation to the following free boundary problem for the system (2.1) in an evolving region $\mathcal{D}(t)$: the free boundary condition is

$$u \cdot \nu = \text{normal speed of the boundary} \quad \text{on } \partial\left[\cup_{t\in[0,T)}\{t\}\times\mathcal{D}(t)\right], \tag{3.1}$$

and the initial conditions are

$$\begin{aligned} &\mathcal{D}(0) = \mathcal{D}_0, \\ &p(0,x) = p_0(x) \quad \text{in } \Omega, \end{aligned} \tag{3.2}$$

where $\mathcal{D}_0, p_0(x)$ are a given set and function, respectively. In [5], problem (2.1), (3.1), (3.2) is considered in the following shallow water approximation.

The fluid is contained within a region Ω of (x_1, x_2)-plane but the height $h(t, x_1, x_2)$ above the reference level is unknown and can evolve in time:

$$\mathcal{D}(t) = \{(x_1, x_2, x_3) \in \mathbf{R}^3 \quad | \quad (x_1, x_2) \in \Omega, \quad 0 \le x_3 \le h(t, x_1, x_2)\}. \tag{3.3}$$

The pressure on the top boundary of the fluid is a given constant p_0, and

$$p(t, x_1, x_2, x_3) = [h(t, x_1, x_2) - x_3] + p_0. \tag{3.4}$$

The horizontal components of velocity are independent of x_3.

Then the problem (2.1), (3.1), (3.2) in an evolving 3-d domain can be rewritten as a problem in the 2-d domain Ω, for the unknown height function $h(t,x)$ defined on $[0,T)\times\Omega$, and horizontal components of velocity $v = (v_1, v_2)$. As noted by [5], it is possible for h to become zero on part of Ω. We set $v = 0$ in such regions. Then the problem (2.1), (3.1), (3.2) in the shallow water approximation (3.3)–(3.4) can be written as the following problem for $h(t,x)$ and $v = (v_1, v_2)$ defined on $[0,T)\times\Omega$ and $v = (v_1, v_2)$ defined in Ω:

$$D_t X = J(X - x) \qquad \text{in } [0,T)\times\Omega, \tag{3.5}$$

$$\partial_t h + \operatorname{div}(hv) = 0 \qquad \text{in } [0,T)\times\Omega, \tag{3.6}$$

$$X = \nabla P, \quad \text{where } P(t, x_1, x_2) = h(t, x_1, x_2) + \frac{1}{2}(x_1^2 + x_2^2), \tag{3.7}$$

$$D_t = \partial_t + v\cdot\nabla, \quad \nabla = (\partial_{x_1}, \partial_{x_2}), \tag{3.8}$$

$$v \cdot \nu = 0 \quad \text{on } [0,T)\times\partial\Omega, \tag{3.9}$$

$$h(0,x) = h_0(x) \quad \text{in } \Omega. \tag{3.10}$$

Here $J \equiv J_2 = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$. Note that (3.6) corresponds to the condition (3.1) on the surface $\{(x_1, x_2, x_3) \mid h(x_1, x_2) > 0,\ x_3 = h(x_1, x_2)\}$, which is the top of the fluid.

The Cullen–Purser stability condition implies that the function $x \to P(t,x)$ is convex in Ω for any t, where $P(t,x)$ is defined in (3.7). Thus the initial height function $h_0(x)$ must satisfy

$$h_0 + \frac{1}{2}|x|^2 \text{ is convex in } \Omega.$$

Cullen and Gangbo in [5] rewrite the system (3.5)–(3.10) in dual variables (t, X):

$$\partial_t \alpha + \nabla\cdot(U\alpha) = 0 \quad \text{in } [0,T)\times\mathbf{R}^2, \tag{3.11}$$

$$\nabla P_t \# h_t = \alpha_t \quad \text{for any } t \in [0,T), \tag{3.12}$$

$$U(t,X) = J_2(X - \nabla P^*(t,X)) \quad \text{in } [0,T) \times \mathbf{R}^2, \tag{3.13}$$

$$P^*(t,X) = \sup_{x \in \Omega}(x \cdot X - P(t,x)) \quad \text{for } (t,X) \in [0,T) \times \mathbf{R}^2, \tag{3.14}$$

$$\alpha_0(X) \quad \text{is prescribed on } \mathbf{R}^2. \tag{3.15}$$

Cullen and Gangbo in [5] prove existence of a weak solution of system (3.11)–(3.15). The precise statement of their result is Theorem 2.3 with the following changes: $\mathbf{R}^3$ replaced by $\mathbf{R}^2$; $DP_0\#\chi_\Omega$ replaced by $DP_0\#h_0$ in (2.13); and (2.5)–(2.8) replaced by (3.11)–(3.15) in the assertion Theorem 2.3(v), where $h(t,x) = P(t,x) - \frac{1}{2}|x|^2$.

In this section we study the shallow water semigeostrophic model (3.5)–(3.10) in physical space. The unknown functions in this problem are the (modified) pressure P and the velocity v. The Eulerian formulation of weak solutions is obtained from the following argument. The Eulerian form of (3.5) is

$$\partial_t X + v \cdot \nabla X = J(X - x). \tag{3.16}$$

Multiplying (3.16) by h and adding (3.5) multiplied by X, we get

$$\partial_t(hX) + \sum_{j=1}^{2} \partial_{x_j}(hv_j X) = hJ(X - x).$$

Thus we have the following.

Definition 3.1. *Let $v : [0,T) \times \Omega \to \mathbf{R}^2$ and $P : [0,T) \times \Omega \to \mathbf{R}^1$ satisfy $v \in L^1([0,T) \times \Omega, \mathbf{R}^2)$, $\nabla P \in L^\infty([0,T) \times \Omega) \cap C([0,T); L^1(\Omega))$, and $P(t,\cdot)$ is convex in Ω for every $t \in [0,\infty)$. Let $h(t,x) = P(t,x) - \frac{1}{2}|x|^2$. The pair (v,P) is a weak Eulerian solution of* (3.5)–(3.10) *if*

$$\begin{aligned} &\int_{(0,T)\times\Omega} \{\nabla P(t,x) \cdot [\partial_t \phi(t,x) + (v(t,x) \cdot \nabla)\phi(t,x)] \\ &\qquad + J[\nabla P(t,x) - x] \cdot \phi(t,x)\} h(t,x)\,dt\,dx \\ &\qquad + \int_\Omega [\nabla h_0(x) + x] \cdot \phi(0,x) h_0(x)\,dx = 0 \end{aligned} \tag{3.17}$$

for any $\phi \in C_c^1([0,T) \times \Omega; \mathbf{R}^2)$ and

$$\int_{[0,T)\times\Omega} [\partial_t \psi(t,x) + v(t,x) \cdot \nabla \psi(t,x)] h\,dt\,dx + \int_\Omega \psi(0,x) h_0(x)\,dx = 0 \tag{3.18}$$

for any $\psi \in C_c^1([0,T) \times \overline{\Omega})$.

Remark 3.2.

- Equality (3.17) is a weak form of (3.5). In the second integral in the left-hand side of (3.17), we used the fact that $P_0(x) = h_0(x) + \frac{1}{2}|x|^2$.
- Equality (3.18) is a weak form of (3.6) with the boundary condition (3.9) and initial condition (3.10).

Remark 3.3. Equality (3.17) of Definition 3.1 essentially requires the evolution equation (3.5) to hold only in the fluid region $\mathcal{D} = \{(t,x) \in [0,T) \times \Omega \mid h(t,x) > 0\}$. This is natural since, physically, the evolution is defined only in $\mathcal{D}$.

As in the case of the incompressible model (2.3), we can find P by solving the problem (3.11)–(3.15) in the dual coordinates, and v then is expressed by (2.12), but regularity of this solution is not sufficient to show that such v, P satisfy (3.5) in the Eulerian sense. Thus we define a Lagrangian solution.

3.2. Lagrangian solutions for shallow water model in physical space. Similar to section 2.2, we rewrite (3.5)–(3.10) in terms of (F, P), where $F : [0, T] \times \Omega \to \Omega$ is a (formal) Lagrangian flow corresponding to the full wind velocity $v = (v_1, v_2)$, and then we define the corresponding weak solution F, P. The difference is now that the vector field v is not divergence-free, but instead the transport equation $\partial_t h + \mathrm{div}\,(hv) = 0$ holds. Since F is a Lagrangian flow of v, solutions h of this transport equation satisfy $F_t \# h_0 = h_t$ for any $t \in (0, T)$. This property in the present replaces the Lebesgue-measure-preserving property of F in section 2.2.

Then we come to the following.

Definition 3.4. *Let $\Omega \subset \mathbf{R}^2$ be an open set, and let $T > 0$. Let $P_0(x)$ be a convex bounded function in Ω such that $h_0(x) = P_0(x) - \frac{1}{2}|x|^2 \geq 0$ in Ω. Let $r \in [1, \infty)$. Let $P : [0, T) \times \Omega \to \mathbf{R}^1$ satisfy*

$$P \in L^\infty([0, T); W^{1,\infty}(\Omega)) \cap C([0, T); W^{1,r}(\Omega)), \tag{3.19}$$

$$P(t, \cdot) \text{ is convex in } \Omega \text{ for each } t \in [0, T). \tag{3.20}$$

Let $h(t, x) = P(t, x) - \frac{1}{2}|x|^2$. Let $F : [0, T) \times \Omega \to \Omega$ be a Borel map satisfying

$$F \in C([0, T); L^r(\Omega, h_0 dx)). \tag{3.21}$$

Then the pair (P, F) is called a weak Lagrangian solution of (3.5)–(3.10) *in* $[0, T) \times \Omega$ *if (P, F) has the following properties:*

i. *$F(0, x) = x$ for $h_0\mathcal{L}^2$-a.e. $x \in \Omega$, and $P(0, x) = P_0(x)$ for a.e. $x \in \Omega$.*

ii. *For any $t \in [0, T]$ the mapping $F_t = F(t, \cdot) : \Omega \to \Omega$ satisfies $F_t \# h_0 = h_t$.*

iii. *There exists a Borel map $F^* : [0, T) \times \Omega \to \Omega$ such that for every $t \in (0, T)$ the map $F^*_t = F^*(t, \cdot) : \Omega \to \Omega$ satisfies $F^*_t \# h_t = h_0$, $F^*_t \circ F_t(x) = x$ for $h_0\mathcal{L}^2$-a.e. $x \in \Omega$, and $F_t \circ F^*_t(x) = x$ for $h_t\mathcal{L}^2$-a.e. $x \in \Omega$.*

iv. *The function*

$$Z(t, x) = \nabla P(t, F(t, x)) \tag{3.22}$$

is a weak solution of

$$\begin{aligned} &\partial_t Z(t, x) = J[Z(t, x) - F(t, x)] \qquad \text{on supp } h_0 \text{ in } (0, T) \times \Omega, \\ &Z(0, x) = \nabla P_0(x) \qquad \text{on supp } h_0 \text{ in } \Omega \end{aligned} \tag{3.23}$$

in the following sense: for any $\phi \in C^1_c([0, T) \times \Omega; \mathbf{R}^2)$

$$\begin{aligned} \int_{(0,T)\times\Omega} &[Z(t, x) \cdot \partial_t \phi(t, x) \\ &+ J(Z(t, x) - F(t, x))\phi(t, x)] h_0(x) dt dx \\ &+ \int_\Omega \nabla P_0(x) \cdot \phi(0, x) h_0(x) dx = 0. \end{aligned} \tag{3.24}$$

Remark 3.5. Remark 2.6, with obvious modifications, applies to the present case. In particular, continuity in time of P, F in (3.19), (3.21), combined with initial conditions in Definition 3.4(i), imply that

$$\begin{aligned} &\lim_{t\to 0+} \int_\Omega |F_t(x) - x|^r h_0(x) dx = 0, \\ &\lim_{t\to 0+} \|P_t - P_0\|_{W^{1,r}(\Omega)} = 0, \qquad \lim_{t\to 0+} \|h_t - h_0\|_{W^{1,r}(\Omega)} = 0, \end{aligned} \tag{3.25}$$

where $r \in [1, \infty)$ is from (3.19), (3.21).

Remark 3.6 (semigroup property). Similar to Remark 2.7, weak Lagrangian solution in Definition 3.4 satisfies the semigroup property: for any $t_1, t_2, t_3 \geq 0$ (2.40) holds for $h_{t_3}dx$ a.e. $x \in \Omega$, where $F_{(t_i,t_j)} = F_{t_i} \circ F^*_{t_j}$. The proof is based on properties of F_t, F^*_t in Definition 3.4(ii) and (iii), and the argument is similar to the one in Remark 2.7.

Remark 3.7. In Definition 3.4 we essentially consider the flow mapping F_t and its inverse F^*_t only in the fluid region $\mathcal{D} = \{(t,x) \in [0,T) \times \Omega \mid h(t,x) > 0\}$. That is, for any $t \in [0,T)$, Definition 3.4 does not contain any conditions for the map F_t away from $\mathcal{D}(0) = \{x \in \Omega \mid h_0(x) > 0\}$ or for the map F^*_t away from $\mathcal{D}(t) = \{x \in \Omega \mid h_t(x) > 0\}$. This is natural since, physically, the evolution is defined only in $\mathcal{D}$. A similar feature of weak Eulerian solutions is discussed in Remark 3.3. In particular, we can define F and F^* arbitrarily outside the domains $[0,T) \times \mathcal{D}_0$ and $\mathcal{D}$, respectively. Note also that the set $\Omega \setminus \mathcal{D}(t)$ is $h_t\mathcal{L}^2$-negligible for each t; thus Definition 3.4 determines the maps F_t and F^*_t almost everywhere with respect to the measures $h_0\mathcal{L}^2$ and $h_t\mathcal{L}^2$, respectively.

We now justify Definition 3.4 by showing that a smooth Lagrangian solution (F,P) with additional regularity property $\partial_t F \in L^\infty([0,T) \times \Omega)$ determines a weak Eulerian solution of (3.5)–(3.10).

LEMMA 3.8 (consistency of weak solutions for shallow water model). *Let $\Omega \subset \mathbf{R}^2$ be an open bounded set and $T > 0$. Let (F,P) be a weak Lagrangian solution of* (3.5)–(3.10) *in $[0,T) \times \Omega$ satisfying $\partial_t F \in L^\infty([0,T) \times \Omega; \mathbf{R}^2)$. Then the function*

$$v(t,x) := \frac{\partial F}{\partial t}(t, F^*_t(x)) \quad \text{for} \quad (t,x) \in [0,T) \times \Omega \tag{3.26}$$

satisfies $v \in L^\infty([0,T) \times \Omega; \mathbf{R}^2)$, and (v,P) is a weak Eulerian solution of (3.5)–(3.10) *in the sense of Definition* 3.1.

Proof. The proof is similar to the proof of Lemma 2.8(i). Thus we only sketch the argument and emphasize the structural differences between the models (2.3) and (3.5)–(3.10).

We show (3.18). Fix $t \in [0,T)$. Since $F_t \# h_0 = h_t$, then for each $\psi \in C^1_c([0,T) \times \overline{\Omega})$

$$\int_\Omega (\partial_t \psi)(t, F_t(x)) h_0(x) dx = \int_\Omega \partial_t \psi(t,x) h(t,x) dx.$$

Integrating with respect to t and using $\partial_t F \in L^\infty([0,T) \times \Omega)$, we get

$$\begin{aligned} &\int_{[0,T)\times\Omega} \{\partial_t[\psi(t, F_t(x))h_0(x)] - \partial_t F_t(x) \cdot (\nabla\psi)(t, F_t(x))h_0(x)\} \, dtdx \\ &\quad = \int_{[0,T)\times\Omega} \partial_t \psi(t,x) h(t,x) dtdx. \end{aligned}$$

Since $\psi(T,x) \equiv 0$ and $F(0,x) = x$ for all $x \in \Omega$ and using that $h \in C([0,T); W^{1,r}(\Omega))$ by (3.25), we get

$$\begin{aligned} &-\int_\Omega \partial_t \psi(0,x) h_0(x) dx - \int_{[0,T]\times\Omega} \partial_t F(t,x) \cdot (\nabla\psi)(t, F_t(x)) h_0(x) dtdx \\ &\quad = \int_{[0,T)\times\Omega} \partial_t \psi(t,x) h(t,x) dtdx. \end{aligned}$$

Now, changing variables $y = F_t(x)$ in the second integral in the left-hand side using $F_t\#h_0 = h_t$, we rewrite this integral as $\int_{[0,T]\times\Omega}(\partial_t F)(t, F_t^*(x)) \cdot \nabla\psi(t,x)h(t,x)dtdx$. Recalling the definition (3.26) of v, we get (3.18).

To show (3.17), we change variables $y = F_t(x)$ in (3.24), and using $F_t\#h_0 = h_t$ get

$$\begin{aligned}\int_{(0,T)\times\Omega}[\nabla P(t,y)\cdot\partial_t\phi(t,F_t^*(y)) \quad &+ \quad J(\nabla P(t,y)-y)\phi(t,F_t^*(y))]h(t,y)dtdy\\ &+ \textstyle\int_\Omega \nabla P_0(x)\cdot\phi(0,x)h_0(x)dx = 0,\end{aligned}$$

for all $\phi \in C_c^1([0,T)\times\Omega;\mathbf{R}^2)$. Now, similar to the proof of Lemma 2.8(i), we show that this equality holds for all ϕ of the form $\varphi(t,x) = \eta(t, F_t(x))$, where $\eta \in C_c^1([0,T)\times\Omega)$, and this, with use of the property in Definition 3.4(iii), implies (3.17). ∎

The main result of this section is the following.

THEOREM 3.9. *Let $\Omega \subset \mathbf{R}^2$ be an open bounded set and $\overline{\Omega} \subset B$, where B is an open ball $B(0,S)$. Let $h_0(x) \geq 0$ be such that $P_0(x) = h_0(x) + \frac{1}{2}|x|^2$ is a convex bounded function in B and that*

$$DP_0\#h_0 \in L^q(\nabla P_0(\Omega)) \text{ for some } q > 1. \tag{3.27}$$

Then for any $T > 0$ there exists a weak Lagrangian solution (P,F) of (3.5)–(3.10) *in $[0,T)\times\Omega$, where the properties stated in* (3.19) *are satisfied for any $r \in [1,\infty)$. Moreover, the function $Z(t,x)$ defined by* (3.22) *satisfies $Z(\cdot,x) \in W^{1,\infty}([0,T);\mathbf{R}^2)$ for $h_0\mathcal{L}^2$-a.e. $x \in \Omega$, and* (3.23) *is satisfied, in addition to the weak form* (3.24)*, in the following sense:*

$$\begin{aligned}&\partial_t Z(t,x) = J(Z(t,x) - F(t,x)) \qquad \text{for } h_0\mathcal{L}^2\times\mathcal{L}^1\text{-a.e. in } (t,x)\in,\\ &Z(0,x) = \nabla P_0(x) \qquad \text{for } h_0\mathcal{L}^2\text{-a.e. in } x\in\Omega.\end{aligned} \tag{3.28}$$

The proof of this theorem follows closely the proof of Theorem 2.9. Indeed, since in the present case we have $U \in BV(\mathbf{R}^2)$ and $\operatorname{div} U(t,\cdot) = 0$ in the sense of distributions by (3.13), we can repeat the argument of section 2.3 to define Lagrangian flow $\Phi_t : \mathbf{R}^2 \to \mathbf{R}^2$ in the dual space, with the same properties as Φ_t in section 2.3. Then we define $F_t : \Omega \to \Omega$ by (2.72) and repeat the argument of section 2.4 with some obvious changes which come from the fact that the property $\nabla P_t\#\chi_\Omega = \alpha_t$ is now replaced by $\nabla P_t\#h_t = \alpha_t$.

Appendix A. Some properties of measure-preserving maps.

DEFINITION A.1. *Let $\Psi : \mathbf{R}^m \to \mathbf{R}^n$ be a Borel map.*

i. *Let μ, ν be Radon measures on $\mathbf{R}^m$ and $\mathbf{R}^n$, respectively. The map Ψ pushes μ forward to ν, denoted $\Psi\#\mu = \nu$, if $\mu[\Psi^{-1}(A)] = \nu[A]$ for all Borel $A \subset \mathbf{R}^m$.*

ii. *Let $f \in L^1(\mathbf{R}^m)$ and $g \in L^1(\mathbf{R}^n)$. The map Ψ pushes f forward to g, denoted $\Psi\#f = g$, if Ψ pushes the measure $f\mathcal{L}^m$ forward to $g\mathcal{L}^n$.*

LEMMA A.2. *Let $\Psi : \mathbf{R}^m \to \mathbf{R}^n$ be a Borel map. Let μ, ν be Radon measures on $\mathbf{R}^m$ and $\mathbf{R}^n$, respectively. Then $\nu = \Psi\#\mu$ if and only if*

$$\int_{\mathbf{R}^m}\phi(\Psi(x))d\mu(x) = \int_{\mathbf{R}^n}\phi(y)d\nu(y)$$

for all ν-integrable functions ϕ on $\mathbf{R}^n$.

Proof. Since every ν-measurable function ϕ on $\mathbf{R}^n$ can be represented as

$$f = \sum_{k=1}^\infty \frac{1}{k}\chi_{A_k}$$

for some ν-measurable sets A_k in $\mathbf{R}^n$ [9, sect. 1.1.2, Thm. 7], and since μ and ν are Radon measures, Lemma A.2 follows directly from Definition A.1. $\square$

COROLLARY A.3. *Let Ψ, μ, ν be as in Lemma* A.2. *Assume also that $\nu = g\mathcal{L}^n$, where $g \in L^1(\mathbf{R}^n)$. If $\nu = \Psi\#\mu$, then*

$$\int_{\mathbf{R}^m} \phi(\Psi(x))d\mu(x) = \int_{\mathbf{R}^n} \phi(y)g(y)dy \qquad \textit{for all} \quad \phi \in L^\infty(\mathbf{R}^n). \tag{A.1}$$

In particular, if $f \in L^1(\mathbf{R}^m)$, $g \in L^1(\mathbf{R}^n)$, and $\Psi\#f = g$, then

$$\int_{\mathbf{R}^m} \phi(\Psi(x))f(x)dx = \int_{\mathbf{R}^n} \phi(y)g(y)dy \qquad \textit{for all} \quad \phi \in L^\infty(\mathbf{R}^n). \tag{A.2}$$

Proof. If $\nu = g\mathcal{L}^n$, where $g \in L^1(\mathbf{R}^n)$, then every $\phi \in L^\infty(\mathbf{R}^n)$ is ν-integrable. Now we apply Lemma A.2 to get (A.1). Finally, (A.2) follows from (A.1). $\square$

Note added in proof. After this paper was accepted for publication, we were informed by Helena Nussenzveig Lopes that, by combining the techniques of this paper with the ones of Lopes Filho and Nussenzveig Lopes [12], the results of Theorems 2.9 and 3.9 can be extended to the case $q = 1$.

NEAR-PERIODIC LOCAL MINIMIZERS OF SINGULARLY PERTURBED FUNCTIONALS WITH NONLOCAL TERM*

NIKO TZOUKMANIS†

Abstract. We consider singular perturbed functionals with a nonlocal term which are a one-dimensional model for an austenite/twinned martensite interface. The parameter range is chosen in a way that a limit functional can be derived. By examining the limit problem, we show the existence of highly oscillating, near-periodic minimizers of the original functionals which are close to periodic sawtooth functions.

Key words. nonlocal variational problems, Γ-convergence, singular perturbations, solid-solid phase transitions

AMS subject classifications. 49K40, 74N15, 74G65

DOI. 10.1137/04061708X

1. Introduction.

Mathematical models for phase transitions often lead to variational problems involving nonlocal terms. Examples are given by phase separation in two-phase fluids (cf. [2], [3]) and the formation of diblock copolymer (cf. [20], [19], [21], [22], [23]). Nonlocal terms also appear in models for microstructure in solid-to-solid phase transitions.

In martensitic transformations, the phenomenon of twinning can occur. Hereby, a homogeneous phase called austenite is separated from a family of thin lamellae called twinned martensite. A nonlinear theory based on energy minimization has been established by Ball and James (cf. [5], [6]). In [12], Kohn and Müller have introduced a two-dimensional nonlocal model for an austenite/twinned martensite interface and discussed mathematical properties in [13]. Restriction of the model to the common boundary of the phases delivers a one-dimensional problem (cf. [4]), which is given by the functionals

$$J^\varepsilon(u) = \int_{-1}^{1} \varepsilon^2 (u'')^2 + W(u')dy + \sigma \|u\|^2_{H^{1/2}} \tag{1.1}$$

with parameters $\varepsilon > 0$ and $\sigma > 0$, where

$$u \in H^{2,0}_{per}(-1,1) = H^2(-1,1) \cap \{u(-1) = u(1), u'(-1) = u'(1)\} \cap \left\{ \int_{-1}^{1} u = 0 \right\}.$$

Hereby, W is a smooth double-well potential with $W(v) \geq 0$ and $W(v) = 0$ if and only if $v = -1$ or $v = 1$. We assume that W has at least quadratic growth at infinity; i.e., there exist $k > 0$, $v_0 > 0$ with $W(v) \geq k|v|^2$ for every $v \geq v_0$. The $H^{1/2}$-norm is given by

$$\|u\|^2_{H^{1/2}} = 2\pi \sum_{k=-\infty}^{\infty} |k||u_k|^2 = \int_{-1}^{1}\int_{-1}^{1} g(x-y)(u(x)-u(y))^2 dxdy,$$

*Received by the editors October 14, 2004; accepted for publication (in revised form) June 27, 2005; published electronically January 10, 2006. This article provides an overview of the author's doctoral thesis [24].

where u_k are the Fourier coefficients of u, and $g(t) = \frac{\pi}{4(1-\cos(\pi t))}$ (cf. [4], [13]). The W-term is the elastic energy in the martensite, while $\|u\|^2_{H^{1/2}}$, which is a nonlocal term, is derived from the energy in the austenite in the two-dimensional model by restriction to the interface. The variable u models the deformation of the material at the interface. The second-order singular perturbation term describes the surface energy and mathematically has the meaning of selecting certain "regular" minimizing sequences for the unperturbed functional J^0. It is easy to see that J^0 has no minimizer in $H^1(-1,1)$ and that any sequence of functions (u_n) with $u_n' = \pm 1$ on $(-1,1)$ and $u_n \to 0$ is a minimizing sequence. The perturbed functionals, however, do have minimizers due to convexity in the highest derivative (cf. [7, Chapter 3, Theorem 4.1]) and one is interested in the asymptotic behavior of the minimizers for $\varepsilon \to 0$.

Functionals similar to (1.1) have been studied in the literature but with a simpler right-hand term. In the parameter range $\sigma \sim 1$, and with $\|\cdot\|^2_{H^{1/2}}$ replaced by $\|\cdot\|^2_{L^2}$, Müller has shown in [18] that for small ε, the minimizers u_ε of J^ε are periodic with period $P^\varepsilon \sim \varepsilon^{1/3}$ and that intervals where $u_\varepsilon' \approx 1$ and $u_\varepsilon' \approx -1$ are separated by transition layers of size $\sim \varepsilon$ where u_ε' switches between these two values. In [4], where a new rescaling technique involving the Young measure on micropatterns has been introduced to characterize the minimizers of this problem, it has been conjectured that a similar result holds for the problem with the $H^{1/2}$-norm. More precisely, it is expected that the minimizers of (1.1) are close to periodic functions with period $P^\varepsilon \sim \varepsilon^{1/2}$ if ε is sufficiently small. However, the characterization of global minimizers turns out to be very difficult due to the nonlocal structure of $\|u\|^2_{H^{1/2}}$.

In this work, we examine a simpler but general nonlocal term whose kernel g is bounded and has no singularities but possesses the same symmetry and periodicity properties as the function g defined above. Following Ren and Wei (cf. [21]), we consider the parameter range $\sigma = \varepsilon$ rather than $\sigma = 1$. Physically, this has an interpretation related to the size of the sample (see [23]). Mathematically, it has the advantage that we can easily derive a limit functional via the Modica–Mortola theorem. Otherwise, the rescaling method introduced by Alberti and Müller [4] becomes necessary. The aim is to show a result similar to [21]. In that work, Ren and Wei have identified near-periodic local minimizers of functionals which in the special case where $m = 0$ (the parameter m being the average of u) can be written in the form (1.1) with $\sigma = \varepsilon$ but with $\|\cdot\|_{H^{1/2}}$ replaced by $\|\cdot\|_{L^2}$. We consider

$$I^\varepsilon(u) = \int_{-1}^{1} \varepsilon(u'')^2 + \frac{1}{\varepsilon}W(u')dy + E(u) \tag{1.2}$$

for $\varepsilon > 0$, where $u \in H^{2,0}_{per}(-1,1)$ and

$$E(u) = \int_{-1}^{1}\int_{-1}^{1} g(x-y)(u(x)-u(y))^2 dxdy$$

with a kernel $g : \mathbb{R} \to \mathbb{R}$ that satisfies the following conditions:

(g_1) $g(x+2) = g(x)$ for every $x \in \mathbb{R}$.
(g_2) $g(x) = g(-x)$ for every $x \in \mathbb{R}$.
(g_3) $0 < g_0 \le g(x) \le g_1$ for every $x \in \mathbb{R}$.
(g_4) $g\big|_{[0,1]} \in C^3[0,1]$.
(g_5) $g'(1) = 0$.

In particular, g is Lipschitz continuous on $\mathbb{R}$. For examples, see Figure 1.1. W is a potential as described above, the most common example being given by $W(v) = (v^2-1)^2$. The main result of the paper is the following.

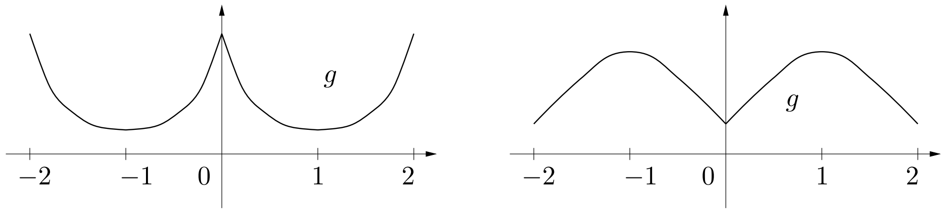

FIG. 1.1. *Examples of the kernel g.*

THEOREM 1.1. *For $\varepsilon > 0$, let I^ε be as defined by (1.2). Then there exists $N_0 \in \mathbb{N}$ such that for every even $N \geq N_0$, we find $\varepsilon_0 > 0$ and $\delta > 0$ satisfying the following condition:*

For every $\varepsilon \in (0, \varepsilon_0)$, there is a local minimizer $u_\varepsilon \in H^{2,0}_{per}(-1,1)$ of I^ε with respect to the $H^1(-1,1)$-norm such that

$$I^\varepsilon(u_\varepsilon) \leq I^\varepsilon(u) \quad \textit{for every} \quad u \in H^{2,0}_{per}(-1,1) \quad \textit{with} \quad \|u - \bar{u}_N\|_{H^1(-1,1)} < \delta$$

and

$$\lim_{\varepsilon \to 0} \|u_\varepsilon - \bar{u}_N\|_{H^1(-1,1)} = 0,$$

where $\bar{u}_N$ is a sawtooth function with N equidistant corners. More precisely, $\bar{u}_N$ is the unique function in $H^1(-1,1)$ satisfying $\int_{-1}^1 \bar{u}_N(x)dx = 0$ and

$$\bar{u}_N'(x) = (-1)^{i-1} \quad \textit{for} \quad x \in \left(-1 + \frac{2}{N}(i-1), -1 + \frac{2}{N}i\right), \quad i = 1, \ldots, N.$$

Remarks.

(a) The theorem states that if $\varepsilon > 0$ is chosen sufficiently small, the functionals I^ε have strongly oscillating local minimizers close to a sawtooth function with equidistant corners (see Figure 1.2). Near the corners of $\bar{u}_N$, the local minimizers u_ε have transition layers where u_ε' switches between -1 and 1 (see Figure 1.3).

(b) Since we consider periodic functions, only the case where N is even makes sense.

(c) To some extent, this theorem generalizes Theorem 1.1 in [21], since the functionals considered there can, in the case where $m = 0$, be written in the form (1.2) with $g = 1$. However, Ren and Wei found necessary conditions for critical points and thus identified local minimizers with an arbitrary number N

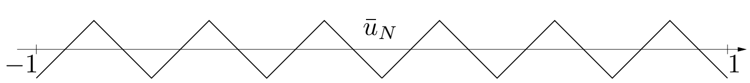

FIG. 1.2. *The function $\bar{u}_N$ for $N = 12$.*

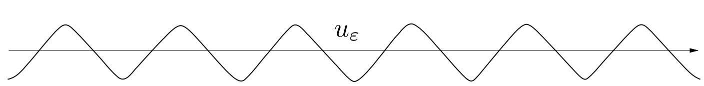

FIG. 1.3. *Near-periodic local minimizer u_ε resembling $\bar{u}_N$.*

of transition layers, which we cannot do here due to the very general nonlocal term E in (1.2). One has to let $N \to \infty$ to gain information, so that we are only able to characterize local minimizers with a sufficiently large number of oscillations.

Unfortunately, it was not possible to include all steps of the proof in this paper, since some of them are very long and technical. The complete proof is found in [24], which we cite whenever it is necessary. In this paper, we often make use of generic constants C whose value may change during estimations. Also, we sometimes make use of the 2-periodicity of functions and identify them with their periodical extensions to $\mathbb{R}$, so the integration domain may change from $(-1,1)$ to $(0,2)$, for example. $a \vee b$ denotes the maximum of two real numbers a and b, while $a \wedge b$ is their minimum. $C_0^\infty(a,b)$ is the space of C^∞-functions with compact support in (a,b). For a set $I \subset \mathbb{R}$, χ_I denotes the characteristic function of I.

2. The Γ-limit of $\;^{\varepsilon}$. The Γ-limit of the functionals I^ε is easily obtained via the Modica–Mortola theorem, which is found in [15], [16], [17] in its original form, while Alberti [1] gives an alternative proof. Although we consider periodic functions and use the L^2-topology rather than L^1, the proof can be easily transferred to the functionals I^ε, and only minor modifications are required (for details, see [24, Chapter 3], where Alberti's proof is transferred to this case). For a general theory on Γ-convergence, we refer the reader to [8]. We define the Hilbert space

$$Y = H^{1,0}_{per}(-1,1) = \left\{ u \in H^1(-1,1) \,|\, u(-1) = u(1),\ \int_{-1}^1 u(x)dx = 0 \right\},$$

equipped with the usual H^1-norm. We define the set of sawtooth functions with slope -1 and 1 only by

$$\mathcal{S}(-1,1) = \{u : [-1,1] \to \mathbb{R} \,|\, u' \in BV((-1,1),\{-1,1\})\} \tag{2.1}$$

and the set of periodic sawtooth functions with average zero by

$$\mathcal{S}^0_{per}(-1,1) = \left\{ u \in \mathcal{S}(-1,1) \,|\, u(-1) = u(1),\ \int_{-1}^1 u(x)dx = 0 \right\}. \tag{2.2}$$

We extend the functionals I^ε to Y by

$$I^\varepsilon(u) = \begin{cases} \displaystyle\int_{-1}^1 \varepsilon(u'')^2 + \frac{1}{\varepsilon}W(u')dx + E(u) & \text{for } u \in H^{2,0}_{per}(-1,1), \\ +\infty & \text{for } u \in Y \setminus H^{2,0}_{per}(-1,1) \end{cases} \tag{2.3}$$

and define $I : Y \to [0,\infty]$ by

$$I(u) = \begin{cases} A_0\#(Su' \cap [-1,1)) + E(u) & \text{for } u \in \mathcal{S}^0_{per}(-1,1), \\ +\infty & \text{for } u \in Y \setminus \mathcal{S}^0_{per}(-1,1), \end{cases} \tag{2.4}$$

where

$$A_0 = 2\int_{-1}^1 \sqrt{W(v)}dv$$

and the term $\#(Su' \cap [-1,1))$ counts the corners of u (i.e., the discontinuity points of u') on $[-1,1)$, which means that if the periodic extension of u has a corner at -1 (and thus at 1), this corner is counted once. The Modica–Mortola theorem yields that the integral in (2.3) Γ-converges to the counting term in (2.4). Since the nonlocal energy E is L^2-continuous (see Lemma 4.2 in [24]), this implies (cf. [8] or Proposition 2.11 (iv) in [4]) the following theorem.

THEOREM 2.1.

(i) *Let* $(u_\varepsilon)_{\varepsilon>0} \subset H^{2,0}_{per}(-1,1)$, $u \in Y$, *such that* $\|u_\varepsilon - u\|_{H^1(-1,1)} \to 0$ *for* $\varepsilon \to 0$. *Then*

$$I(u) \leq \liminf_{\varepsilon\to 0} I^\varepsilon(u_\varepsilon).$$

(ii) *For every* $u \in \mathcal{S}^0_{per}(-1,1)$, *we find a sequence* $(u_\varepsilon)_{\varepsilon>0} \subset H^{2,0}_{per}(-1,1)$ *such that* $\|u_\varepsilon - u\|_{H^1(-1,1)} \to 0$ *for* $\varepsilon \to 0$ *and*

$$\limsup_{\varepsilon\to 0} I^\varepsilon(u_\varepsilon) \leq I(u).$$

In particular, $I^\varepsilon \xrightarrow{\Gamma} I$ *in* Y.

The connection between local minimizers of singularly perturbed functionals and those of the Γ-limit has been studied by De Giorgi (cf. section 3 in [10]), Kohn and Sternberg (cf. Theorem 4.1 in [14]), and Ren and Wei (cf. Proposition 2.3 in [21]). However, these results assume that the Γ-limit I has an isolated local minimizer u, which cannot hold in this case due to the translation invariance of I. By considering orbits of functions rather than the functions themselves, one can transfer the proof of Proposition 2.3 in [21] to this case to obtain the theorem below (for details see [24, Chapter 4]). For $u \in Y$, we also denote by u the periodic extension of u to $\mathbb{R}$. Then, obviously, $u \in H^1_{loc}(\mathbb{R})$. For $\tau \in \mathbb{R}$, we define the τ-translation $T_\tau u : \mathbb{R} \to \mathbb{R}$ by

$$T_\tau u(x) = u(x-\tau) \quad \text{for every} \quad x \in \mathbb{R},$$

and the orbit of u is defined as the set

$$\mathcal{O}(u) = \{T_\tau u \,|\, \tau \in \mathbb{R}\}$$

of all translations of u. Then the following holds.

THEOREM 2.2. *Let* $\bar{u} \in \mathcal{S}^0_{per}(-1,1)$. *Assume that there exists a* $\delta > 0$ *such that for every* $u \in \mathcal{S}^0_{per}(-1,1)$ *with* $\|u - \bar{u}\|_{H^1(-1,1)} < \delta$ *and* $u \notin \mathcal{O}(\bar{u})$ *we have*

$$I(u) > I(\bar{u}).$$

Then there exists $\varepsilon_0 > 0$ *such that for every* $\varepsilon \in (0, \varepsilon_0)$ *we find* $u_\varepsilon \in H^{2,0}_{per}(-1,1)$ *with* $\|u_\varepsilon - \bar{u}\|_{H^1(-1,1)} < \frac{\delta}{2}$ *and*

$$I^\varepsilon(u_\varepsilon) \leq I^\varepsilon(u) \quad \textit{for every} \quad u \in H^{2,0}_{per}(-1,1) \quad \textit{satisfying} \quad \|u - \bar{u}\|_{H^1(-1,1)} < \frac{\delta}{2}.$$

Furthermore,

$$\lim_{\varepsilon\to 0} \|u_\varepsilon - \bar{u}\|_{H^1(-1,1)} = 0.$$

In particular, for every $\varepsilon \in (0, \varepsilon_0)$, u_ε *is an* H^1*-local minimizer of* I^ε *in* $H^{2,0}_{per}(-1,1)$.

Thus, Theorem 1.1 follows if we can show that for large N, the regular sawtooth function $\bar{u}_N$ is a strict local minimizer of I on $\mathcal{S}^0_{per}(-1,1)$ "up to translation" in the sense of the condition in Theorem 2.2. Since I is a sum of a counting term and the nonlocal energy E, it is sufficient to identify $\bar{u}_N$ (N large) as a strict H^1-local minimizer of E (up to translation) in the set of all $u \in \mathcal{S}^0_{per}(-1,1)$ with N corners on $[-1,1)$, since—roughly speaking—a sufficiently small H^1-ball around $\bar{u}_N$ can only contain such sawtooth functions which have at least N corners. A larger number of corners, however, would increase I by an integer, so that functions with more than N corners need not be considered.

3. Perturbation of periodic sawtooth functions. In order to show that for large N the sawtooth function $\bar{u}_N$ with N equidistant corners is a local minimizer of the nonlocal energy E on the set of all $u \in \mathcal{S}^0_{per}(-1,1)$ with $\#(Su' \cap [-1,1)) = N$, we consider all possible perturbations of $\bar{u}_N$ in this set. The periodicity will be dropped for the moment, and we consider E as a functional on $\mathcal{S}(-1,1)$. The corners of $\bar{u}_N$ are given by

$$t_i = -1 + \frac{2}{N}i \quad \text{for} \quad i = 0, \dots, N, \tag{3.1}$$

and we have

$$\bar{u}_N'(x) = (-1)^{i-1} \quad \text{for} \quad x \in (t_{i-1}, t_i)$$

for $i = 1, \dots, N$. Let $r = (r_1, \dots, r_{N-1}) \in \mathbb{R}^{N-1}$ be an arbitrary vector, and set $r_0 = r_N = 0$. For $\delta \in (-\delta_0, \delta_0)$, we define the shifted corners by

$$t_i^{(\delta)} = t_i + r_i\delta \quad \text{for} \quad i = 0, \dots, N, \tag{3.2}$$

where $\delta_0 > 0$ is chosen such that for every $\delta \in (-\delta_0, \delta_0)$, the monotonicity

$$-1 = t_0^{(\delta)} < t_1^{(\delta)} < \cdots < t_{N-1}^{(\delta)} < t_N^{(\delta)} = 1 \tag{3.3}$$

still holds. For every $\delta \in (-\delta_0, \delta_0)$, we define $u_\delta \in \mathcal{S}(-1,1)$ as the unique function satisfying

$$\begin{cases} u_\delta(-1) = \bar{u}_N(-1) = -\frac{1}{N}, \\ u_\delta'(x) = (-1)^{i-1} \quad \text{for} \quad x \in (t_{i-1}^{(\delta)}, t_i^{(\delta)}), \quad i = 1, \dots, N \end{cases} \tag{3.4}$$

(see Figure 3.1).

We define the function $F_r : (-\delta_0, \delta_0) \to \mathbb{R}$ by

$$F_r(\delta) = E(u_\delta) \tag{3.5}$$

for every $\delta \in (-\delta_0, \delta_0)$. Clearly, we have $u_0 = \bar{u}_N$, and thus $F_r(0) = E(\bar{u}_N)$.

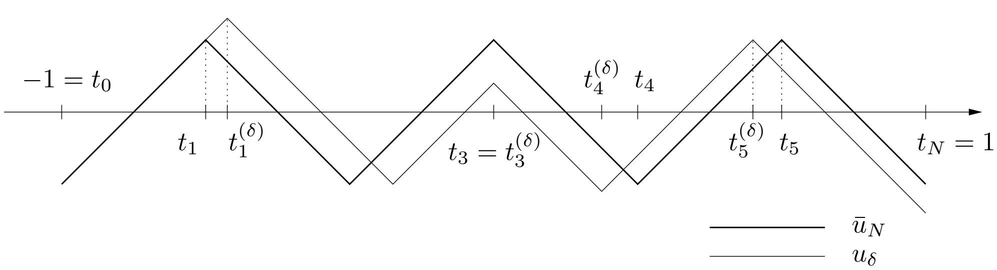

FIG. 3.1. *Example of a perturbation u_δ of $\bar{u}_N$ with $r_3 = 0$; case $N = 6$.*

Remarks.

(i) Since the corner at -1 is fixed, this definition does not cover all possible perturbations of $\bar{u}_N$ but indeed all relevant ones, which is due to the translation invariance of I.

(ii) To avoid ugly notation, we drop the dependence of u_δ on r.

(iii) The zero average condition $\int u = 0$ can be ignored due to the invariance of the functionals under the addition of constants.

We introduce a bilinear form by

$$(u, v)_g = \int_{-1}^{1} \int_{-1}^{1} g(x-y)(u(x)-u(y))(v(x)-v(y))dxdy. \tag{3.6}$$

Since we want to show that $\bar{u}_N$ is a local minimizer of E in the sense described above, we have to consider derivatives of F_r. To compute F_r', we need the following technical lemma.

LEMMA 3.1. *With the above definitions, let $\delta \in (-\delta_0, \delta_0)$. Then for a.e. $x \in (-1, 1)$, we have*

$$\begin{aligned} &\lim_{\varepsilon \to 0} \frac{1}{\varepsilon}(u_{\delta+\varepsilon}(x) - u_\delta(x)) = 2 \sum_{i=1}^{N} \sum_{j=1}^{i-1} (-1)^{j-1} r_j \chi_{(t_{i-1}^{(\delta)}, t_i^{(\delta)})}(x), \\ &\lim_{\varepsilon \to 0} (u_{\delta+\varepsilon}(x) - u_\delta(x)) = 0. \end{aligned} \tag{3.7}$$

Furthermore, $|u_\delta(x)|$, $|u_{\delta+\varepsilon}(x)|$, $|\frac{1}{\varepsilon}(u_{\delta+\varepsilon}(x) - u_\delta(x))| \le C$ with C independent of δ, ε, x (but dependent on r).

Proof. For fixed $\delta \in (-\delta_0, \delta_0)$, choose $\varepsilon_0 > 0$ such that $(\delta - \varepsilon_0, \delta + \varepsilon_0) \subset (-\delta_0, \delta_0)$ and $t_{i-1}^{(\delta+\varepsilon)} \vee t_{i-1}^{(\delta)} < t_i^{(\delta+\varepsilon)} \wedge t_i^{(\delta)}$ for every $\varepsilon \in (-\varepsilon_0, \varepsilon_0)$ and $i \in \{1, \dots, N\}$. Then, according to (3.4), we have

$$(u_{\delta+\varepsilon}' - u_\delta')(x) = 0 \ \text{ for } \ x \in (t_{i-1}^{(\delta)}, t_i^{(\delta)}) \cap (t_{i-1}^{(\delta+\varepsilon)}, t_i^{(\delta+\varepsilon)}) = (t_{i-1}^{(\delta+\varepsilon)} \vee t_{i-1}^{(\delta)}, t_i^{(\delta+\varepsilon)} \wedge t_i^{(\delta)})$$

for $i = 1, \dots, N$. Thus, up to a finite subset of $[-1, 1]$, $(u_{\delta+\varepsilon}' - u_\delta')(x) \neq 0$ can only hold if $x \in (t_i^{(\delta+\varepsilon)} \wedge t_i^{(\delta)}, t_i^{(\delta+\varepsilon)} \vee t_i^{(\delta)})$ for an $i \in \{1, \dots, N-1\}$. Consider a fixed $x \in (t_{i-1}^{(\delta)}, t_i^{(\delta)})$, $i \in \{1, \dots, N\}$. Then $x \in (t_{i-1}^{(\delta+\varepsilon)} \vee t_{i-1}^{(\delta)}, t_i^{(\delta+\varepsilon)} \wedge t_i^{(\delta)})$ for small $\varepsilon \in (-\varepsilon_0, \varepsilon_0)$ since $t_j^{(\delta+\varepsilon)} \to t_j^{(\delta)}$ for $\varepsilon \to 0$. Thus, using $u_\delta(-1) = u_{\delta+\varepsilon}(-1)$ we obtain

$$u_{\delta+\varepsilon}(x) - u_\delta(x) = \int_{-1}^{x} (u_{\delta+\varepsilon}' - u_\delta')(\xi) d\xi = \sum_{j=1}^{i-1} \int_{t_j^{(\delta+\varepsilon)} \wedge t_j^{(\delta)}}^{t_j^{(\delta+\varepsilon)} \vee t_j^{(\delta)}} (u_{\delta+\varepsilon}' - u_\delta')(\xi) d\xi \tag{3.8}$$

for $x \in (t_{i-1}^{(\delta)}, t_i^{(\delta)})$ if ε is sufficiently small. Let $j \in \{1, \dots, N\}$. If $r_j \varepsilon > 0$, we have $t_j^{(\delta+\varepsilon)} > t_j^{(\delta)}$, so that by (3.4) and (3.2), we get

$$\int_{t_j^{(\delta+\varepsilon)} \wedge t_j^{(\delta)}}^{t_j^{(\delta+\varepsilon)} \vee t_j^{(\delta)}} (u_{\delta+\varepsilon}' - u_\delta')(\xi) d\xi = \int_{t_j^{(\delta)}}^{t_j^{(\delta+\varepsilon)}} (u_{\delta+\varepsilon}' - u_\delta')(\xi) d\xi = 2(-1)^{j-1} r_j \varepsilon$$

for ε sufficiently small since $(t_j^{(\delta)}, t_j^{(\delta+\varepsilon)}) \subset (t_j^{(\delta)}, t_{j+1}^{(\delta)}) \cap (t_{j-1}^{(\delta+\varepsilon)}, t_j^{(\delta+\varepsilon)})$. If $r_j \varepsilon < 0$, we analogously show the same formula, which obviously also holds if $r_j \varepsilon = 0$. Setting this into (3.8), we obtain

$$u_{\delta+\varepsilon}(x) - u_\delta(x) = 2\varepsilon \sum_{j=1}^{i-1} (-1)^{j-1} r_j \quad \text{for} \quad x \in (t_{i-1}^{(\delta)}, t_i^{(\delta)}), \quad i = 1, \dots, N,$$

if ε is small, and thus

$$u_{\delta+\varepsilon} - u_\delta = 2\varepsilon \sum_{i=1}^{N} \sum_{j=1}^{i-1} (-1)^{j-1} r_j \chi_{(t_{i-1}^{(\delta)}, t_i^{(\delta)})}$$

for a.e. $x \in (-1, 1)$ if ε is sufficiently small, which implies (3.7), while the other conditions are obvious. ∎

THEOREM 3.2. *For arbitrary* $r = (r_1, \ldots, r_{N-1}) \in \mathbb{R}^{N-1}$*, choose* $\delta_0 > 0$ *as above. Then the function* $F_r : (-\delta_0, \delta_0) \to \mathbb{R}$ *as defined in* (3.5) *is differentiable, and for every* $\delta \in (-\delta_0, \delta_0)$*, we have*

$$F_r'(\delta) = 4 \sum_{i=1}^{N} \alpha_i h_r^{(i)}(\delta), \tag{3.9}$$

where $\alpha_i \in \mathbb{R}$*,* $h_r^{(i)} : (-\delta_0, \delta_0) \to \mathbb{R}$ *are given by*

$$\alpha_i = \sum_{j=1}^{i-1} (-1)^{j-1} r_j, \quad h_r^{(i)}(\delta) = \left(\chi_{(t_{i-1}^{(\delta)}, t_i^{(\delta)})}, u_\delta \right)_g \tag{3.10}$$

for $i = 1, \ldots, N$.

Proof. Let $\delta \in (-\delta_0, \delta_0)$, $\varepsilon_0 > 0$ such that $(\delta - \varepsilon_0, \delta + \varepsilon_0) \subset (-\delta_0, \delta_0)$. Then for every $\varepsilon \in (-\varepsilon_0, \varepsilon_0)$

$$F_r(\delta+\varepsilon) - F_r(\delta) = (u_{\delta+\varepsilon}, u_{\delta+\varepsilon})_g - (u_\delta, u_\delta)_g = (u_{\delta+\varepsilon} - u_\delta, u_{\delta+\varepsilon} + u_\delta)_g. \tag{3.11}$$

Hence

$$\frac{1}{\varepsilon}(F_r(\delta+\varepsilon) - F_r(\delta)) = \left(\frac{1}{\varepsilon} \left(u_{\delta+\varepsilon} - u_\delta \right), u_{\delta+\varepsilon} + u_\delta \right)_g,$$

which due to Lemma 3.1 and Lebesgue's convergence theorem yields

$$\lim_{\varepsilon \to 0} \frac{1}{\varepsilon}(F_r(\delta+\varepsilon) - F_r(\delta)) = 4 \sum_{i=1}^{N} \sum_{j=1}^{i-1} (-1)^{j-1} r_j \left(\chi_{(t_{i-1}^{(\delta)}, t_i^{(\delta)})}, u_\delta \right)_g,$$

i.e.,

$$F_r'(\delta) = \lim_{\varepsilon \to 0} \frac{1}{\varepsilon}(F_r(\delta+\varepsilon) - F_r(\delta)) = 4 \sum_{i=1}^{N} \alpha_i h_r^{(i)}(\delta),$$

with $\alpha_i \in \mathbb{R}$, $h_r^{(i)} : (-\delta_0, \delta_0) \to \mathbb{R}$, $i = 1, \ldots, N$, as given in (3.10), which completes the proof of Theorem 3.2. ∎

As for the second derivative, we have the following result, the proof of which is extremely technical, so that we refer the reader to Theorem 5.3 in [24], where a detailed proof can be found.

THEOREM 3.3. *For arbitrary* $r = (r_1, \ldots, r_{N-1}) \in \mathbb{R}^{N-1}$*, choose* $\delta_0 > 0$ *as above. Then the function* $F_r : (-\delta_0, \delta_0) \to \mathbb{R}$ *as defined in* (3.5) *satisfies* $F_r \in C^2(-\delta_0, \delta_0)$*,* *and for every $\delta \in (-\delta_0, \delta_0)$, we have*

$$
\begin{aligned}
F_r''(\delta) &= 8\sum_{i=1}^N \sum_{k=1}^N \alpha_i\alpha_k \left(\chi_{(t_{k-1}^{(\delta)}, t_k^{(\delta)})}, \chi_{(t_{i-1}^{(\delta)}, t_i^{(\delta)})}\right)_g \\
&\quad + 8\sum_{i=1}^N \alpha_i r_i \int_{-1}^1 g(t_i^{(\delta)} - y)(u_\delta(t_i^{(\delta)}) - u_\delta(y))dy \\
&\quad - 8\sum_{i=1}^N \alpha_i r_{i-1} \int_{-1}^1 g(t_{i-1}^{(\delta)} - y)(u_\delta(t_{i-1}^{(\delta)}) - u_\delta(y))dy,
\end{aligned} \tag{3.12}
$$

with α_i, $i = 1, \ldots, N$, defined as in (3.10).

4. Criticality. From Theorem 3.2, we conclude that $\bar{u}_N$ is critical for the nonlocal energy in the following sense.

THEOREM 4.1. *Let $(r_1, \ldots, r_{N-1}) \in \mathbb{R}^{N-1}$, and choose $\delta_0 > 0$ as above. For every $\delta \in (-\delta_0, \delta_0)$, let u_δ be as defined by* (3.4). *Then*

$$F_r'(0) = 0. \tag{4.1}$$

Proof. Theorem 3.2 and (3.2) yield

$$F_r'(0) = 4\sum_{i=1}^N \alpha_i(\chi_{(t_{i-1}, t_i)}, \bar{u}_N)_g,$$

with $\alpha_1, \ldots, \alpha_N$ as defined in (3.10). We aim to show that

$$(\chi_{(t_{i-1}, t_i)}, \bar{u}_N)_g = 0$$

for $i = 1, \ldots, N$, which yields (4.1). The symmetry of g implies that the function $\varphi(x, y) = g(x - y)(\bar{u}_N(x) - \bar{u}_N(y))$ satisfies $\varphi(y, x) = -\varphi(x, y)$, so that

$$\int_{t_{i-1}}^{t_i} \int_{t_{i-1}}^{t_i} g(x - y)(\bar{u}_N(x) - \bar{u}_N(y))dxdy = 0.$$

Thus, using the symmetry and the 2-periodicity of g,

$$
\begin{aligned}
(\chi_{(t_{i-1}, t_i)}, \bar{u}_N)_g &= \int_{-1}^1 \int_{-1}^1 g(x - y)(\chi_{(t_{i-1}, t_i)}(x) - \chi_{(t_{i-1}, t_i)}(y))(\bar{u}_N(x) - \bar{u}_N(y))dxdy \\
&= 2\int_{-1}^{t_{i-1}} \int_{t_{i-1}}^{t_i} g(x - y)(\bar{u}_N(x) - \bar{u}_N(y))dxdy \\
&\quad + 2\int_{t_i}^1 \int_{t_{i-1}}^{t_i} g(x - y)(\bar{u}_N(x) - \bar{u}_N(y))dxdy \\
&= 2\int_{-1}^1 \int_{t_{i-1}}^{t_i} g(x - y)(\bar{u}_N(x) - \bar{u}_N(y))dxdy \\
&= 2\int_{t_{i-1}}^{t_i} \bar{u}_N(x)dx \int_{-1}^1 g(y)dy - 2\int_{t_{i-1}}^{t_i} \int_{-1}^1 g(y - x)\bar{u}_N(y)dydx \\
&= -2\int_{t_{i-1}}^{t_i} \int_{-1}^1 g(y - x)\bar{u}_N(y)dydx,
\end{aligned}
$$

since $\int_{t_{i-1}}^{t_i} \bar{u}_N(x)dx = 0$, which is easy to see. We claim that

$$x \mapsto \int_{-1}^{1} g(y-x)\bar{u}_N(y)dy$$

is antisymmetric on (t_{i-1}, t_i), which implies $(\chi_{(t_{i-1},t_i)}, \bar{u}_N)_g = 0$. To show this, we set $x_1 = t_{i-1} + \beta$, $x_2 = t_i - \beta$ with $\beta \in [0, \frac{t_{i-1}+t_i}{2}]$. The 2-periodicity of $\bar{u}_N$ and g and the antisymmetry of $\bar{u}_N$ with respect to the center of each interval $[t_{i-1}, t_i]$ yield

$$\begin{aligned}\int_{-1}^{1} g(y-x_1)\bar{u}_N(y)dy &= \int_{-1}^{1} g(y)\bar{u}_N(y+x_1)dy = \int_{-1}^{1} g(y)\bar{u}_N(y+t_{i-1}+\beta)dy \\ &= -\int_{-1}^{1} g(y)\bar{u}_N(t_i-\beta-y)dy = -\int_{-1}^{1} g(y)\bar{u}_N(x_2-y)dy \\ &= -\int_{-1}^{1} g(y)\bar{u}_N(x_2+y)dy = -\int_{-1}^{1} g(y-x_2)\bar{u}_N(y)dy,\end{aligned}$$

which implies the antisymmetry. $\square$

It is obvious that the perturbation u_δ of $\bar{u}_N$ as defined in (3.4) is not necessarily periodic (see Figure 3.1). However, to show the local minimizing property for an equidistant sawtooth function, we have to treat the periodicity as a constraint which is given as follows.

LEMMA 4.2. *Let $\delta \in (-\delta_0, \delta_0) \setminus \{0\}$, where $\delta_0 > 0$ is chosen as above. Then u_δ as given by* (3.4) *is periodic (i.e., $u_\delta(-1) = u_\delta(-1)$) if and only if*

$$\sum_{i=1}^{N-1} (-1)^{i-1} r_i = 0, \tag{4.2}$$

which in terms of (3.10) *is equivalent to $\alpha_N = 0$.*

Proof. Periodicity holds if and only if $u_\delta(1) = u_\delta(-1) = -\frac{1}{N}$, i.e.,

$$\begin{aligned}0 &= \int_{-1}^{1} u'_\delta(\xi)d\xi = \sum_{i=1}^{N} \int_{t_{i-1}^{(\delta)}}^{t_i^{(\delta)}} (-1)^{i-1} d\xi = \sum_{i=1}^{N} (-1)^{i-1} \left(t_i - t_{i-1} + (r_i - r_{i-1})\delta\right) \\ &= \sum_{i=1}^{N} (-1)^{i-1} \left(\frac{2}{N} + (r_i - r_{i-1})\delta\right) = \delta \sum_{i=1}^{N} (-1)^{i-1}(r_i - r_{i-1}) = 2\delta \sum_{i=1}^{N-1} (-1)^{i-1} r_i,\end{aligned}$$

where we used the fact that N is even and $r_0 = r_N = 0$. Since $\delta \neq 0$, the condition now follows. $\square$

Application of Theorem 3.3 leads to the following property on the second variation. Since the proof is a very technical but straightforward computation, we refer the reader to Theorem 6.4 in [24].

THEOREM 4.3. *For $N \in \mathbb{N}$ even, let $\bar{u}_N \in \mathcal{S}^0_{per}(-1,1)$ as defined in Theorem* 1.1. *Let $(r_1, \ldots, r_{N-1}) \in \mathbb{R}^{N-1}$ such that the periodicity condition* (4.2) *holds, and choose $\delta_0 > 0$ as before. Let $F_r : (-\delta_0, \delta_0) \to \mathbb{R}$ as given in* (3.5). *Let $\alpha = (\alpha_1, \ldots, \alpha_N)^t \in \mathbb{R}^N$ as defined in* (3.10) *(in particular, $\alpha_1 = \alpha_N = 0$). Then $F_r \in C^2(-\delta_0, \delta_0)$ with*

$$\frac{1}{8} F''_r(0) = \frac{2}{N} \alpha^t A_N \alpha,$$

where $A_N = (a_{|i-j|}^{(N)})_{i,j=1,\dots,N} \in \mathbb{R}^{N \times N}$ *is a symmetric circulant matrix, i.e.,* $a_k^{(N)} = a_{N-k}^{(N)}$ *for* $k = 1, \dots, N-1$. *The coefficients are given by*

$$
\begin{aligned}
a_0^{(N)} &= b_0^{(N)} + c_0^{(N)} + d_0^{(N)} \\
a_1^{(N)} = a_{N-1}^{(N)} &= b_1^{(N)} + c_1^{(N)} + d_1^{(N)} = \tfrac{1}{2}(b_0^{(N)} - d_0^{(N)}) + c_1^{(N)} \\
a_k^{(N)} &= c_k^{(N)} \quad \text{for} \quad k = 2, \dots, N-2,
\end{aligned} \tag{4.3}
$$

where

$$
\begin{aligned}
b_0^{(N)} &= \int_{-1}^{1} g(y)dy, \quad b_1^{(N)} = \frac{1}{2} b_0^{(N)}, \\
d_0^{(N)} &= N(-1)^{\frac{N}{2}+1} \int_{-1}^{1} g(y)\bar{u}_N(y)dy, \quad d_1^{(N)} = -\frac{1}{2} d_0^{(N)},
\end{aligned} \tag{4.4}
$$

and

$$
c_k^{(N)} = -N \int_0^{\frac{2}{N}} \int_{\frac{2}{N}k}^{\frac{2}{N}(k+1)} g(x-y)dydx \tag{4.5}
$$

for $k = 0, \dots, N-1$. *The circulant matrix* $C_N = (c_{|i-j|}^{(N)})_{i,j=1,\dots,N}$ *can alternatively be defined as* $C_N = (c_{ij}^{(N)})_{i,j=1,\dots,N} \in \mathbb{R}^{N \times N}$ *with*

$$
c_{ij}^{(N)} = -N \int_{\frac{2}{N}(i-1)}^{\frac{2}{N}i} \int_{\frac{2}{N}(j-1)}^{\frac{2}{N}j} g(x-y)dydx \tag{4.6}
$$

for $i, j = 1, \dots, N$.

5. Eigenvalues of $_N$**.** Theorem 4.3 shows that the positivity of the second variation is connected to a definiteness condition for the matrix A_N. Since the matrix is circulant, its eigenvalues and eigenvectors can be written down explicitly. Using Theorem 3.2.2 in [9] (or see Chapter 3 in [11]), the eigenvalues are

$$
\lambda_t^{(N)} = a_0^{(N)} + (-1)^t a_{\frac{N}{2}}^{(N)} + 2 \sum_{k=1}^{\frac{N}{2}-1} a_k^{(N)} \cos\left[\frac{2\pi kt}{N}\right] \quad \text{for} \quad t = 0, \dots, \frac{N}{2} \tag{5.1}
$$

with coefficients given in Theorem 4.3, where $\lambda_1^{(N)}, \dots, \lambda_{\frac{N}{2}-1}^{(N)}$ are double eigenvalues. For every $t \in \{0, \dots, \frac{N}{2}\}$, an eigenvector corresponding to $\lambda_t^{(N)}$ is given by

$$
\begin{aligned}
v_t &= (v_t^{(0)}, \dots, v_t^{(N-1)}) \in \mathbb{R}^N, \\
v_t^{(k)} &= \cos\left[\frac{2\pi kt}{N}\right], \quad k = 0, \dots, N-1.
\end{aligned} \tag{5.2}
$$

A long but straightforward calculation (see [24, proof of Theorem 7.3]) yields the following.

THEOREM 5.1. *For every even number* $N \in \mathbb{N}$, *we have*

$$
\lambda_0^{(N)} = \lambda_{\frac{N}{2}}^{(N)} = 0. \tag{5.3}
$$

Using this property and the fact that in view of (5.2), the associated eigenvectors are given by $v_0 = (1, \dots, 1)$ and $v_{\frac{N}{2}} = (1, -1, \dots, 1, -1)$, it is easy to show that if the double eigenvalues $\lambda_t^{(N)}$, $t = 1, \dots, \frac{N}{2} - 1$, are positive, then the quadratic form associated with A_N is positive definite on the $(N-2)$-dimensional subspace

$$X_N = \{\alpha = (\alpha_1, \dots, \alpha_N) \in \mathbb{R}^N \mid \alpha_1 = \alpha_N = 0\}$$

(see Theorem 7.4 in [24]). Thus, if we can show that $\lambda_t^{(N)} > 0$ for $t = 1, \dots, \frac{N}{2} - 1$, it follows from Theorem 4.3 that $F_r''(0) > 0$ for every $r \in \mathbb{R}^{N-1}$ satisfying (4.2), since this periodicity condition is equivalent to $\alpha_N = 0$ (note that $\alpha_1 = 0$ is always the case). Another very technical approach (see Chapter 8 in [24]) shows that the condition $F_r''(0) > 0$ for every r satisfying (4.2) indeed implies that $\bar{u}_N$ is an H^1-local minimizer of E on the set

$$\{u \in \mathcal{S}^0_{per}(-1,1) | \#(Su' \cap [-1,1)) = N\},$$

so that $\bar{u}_N$ is an H^1-local minimizer of I on $\mathcal{S}^0_{per}(-1,1)$, which together with Theorem 2.2 yields Theorem 1.1. The most important idea in the proof of this correlation is to rewrite the nonlocal energy E—viewed as a functional $E : \mathcal{S}(-1,1) \to \mathbb{R}$—as a function of the corners $t_1, \dots, t_N$ of sawtooth functions and to apply Ljusternik's sufficient condition for local minima under equality constraints (see [25, Theorem 43.D]). In this case, the constraint is given by a periodicity condition similar to (4.2).

6. Asymptotic behavior of eigenvalues. In view of the remarks in the previous section, our aim is to show that the existence of near-periodic local minimizers of I^ε for small $\varepsilon > 0$ is reduced to the positivity of the eigenvalues $\lambda_1^{(N)}, \dots, \lambda_{\frac{N}{2}-1}^{(N)}$ of A_N for large N. A first step is to assume the existence of arbitrarily large even numbers N for which at least one of these eigenvalues is nonpositive. We obtain the following "critical index" property.

THEOREM 6.1. *For every even number $N \in \mathbb{N}$, let $\lambda_t^{(N)}$, $t = 0, \dots, \frac{N}{2}$, be the eigenvalues of A_N as given in* (5.1). *Assume there is a sequence of even numbers $(N_n)_{n\in\mathbb{N}} \subset \mathbb{N}$ with $N_n \nearrow \infty$ for $n \to \infty$ and a sequence $(t_n)_{n\in\mathbb{N}} \subset \mathbb{N}$ with $t_n \in \{1, \dots, \frac{N_n}{2} - 1\}$ for every $n \in \mathbb{N}$ such that*

$$\limsup_{n\to\infty} \lambda_{t_n}^{(N_n)} \le 0.$$

Then we find a subsequence of $(N_n)_{n\in\mathbb{N}}$ (not relabelled) such that

$$\lim_{n\to\infty} \lambda_{t_n}^{(N_n)} = 0, \quad \lim_{n\to\infty} \frac{t_n}{N_n} = \frac{1}{2}.$$

The proof needs some preparations. First, we will compare A_N to a different circulant symmetric matrix $\bar{A}_N = (\bar{a}_{|i-j|}^{(N)})_{i,j=1,\dots,N} \in \mathbb{R}^{N\times N}$ with coefficients

$$\begin{array}{lcl} \bar{a}_0^{(N)} & = & b_0^{(N)} + c_0^{(N)}, \\ \bar{a}_1^{(N)} = \bar{a}_{N-1}^{(N)} & = & b_1^{(N)} + c_1^{(N)} = \frac{1}{2} b_0^{(N)} + c_1^{(N)}, \\ \bar{a}_k^{(N)} & = & c_k^{(N)} \quad \text{for} \quad k = 2, \dots, N-2, \end{array} \tag{6.1}$$

where the coefficients $c_i^{(N)}$ and $b_i^{(N)}$ are defined as in Theorem 4.3. Thus, $\bar{A}_N$ is the matrix that results from A_N by removing the $d_i^{(N)}$-terms. As remarked in the previous chapter, the eigenvalues are given explicitly by

$$\bar{\lambda}_t^{(N)} = \bar{a}_0^{(N)} + (-1)^t \bar{a}_{\frac{N}{2}}^{(N)} + 2 \sum_{k=1}^{\frac{N}{2}-1} \bar{a}_k^{(N)} \cos\left[\frac{2\pi kt}{N}\right] \quad \text{for} \quad t = 0, \ldots, \frac{N}{2} \tag{6.2}$$

for $t = 0, \ldots, \frac{N}{2}$ with corresponding eigenvectors $v_t = (v_t^{(0)}, \ldots, v_t^{(N-1)}) \in \mathbb{R}^N$, where

$$v_t^{(k)} = \cos\left[\frac{2\pi kt}{N}\right], \quad k = 0, \ldots, N-1. \tag{6.3}$$

For large N, the eigenvalues of $\bar{A}_N$ are close to those of A_N.

LEMMA 6.2. *There exists a constant $C > 0$, dependent only on g, such that for every even $N \in \mathbb{N}$, we have*

$$|\lambda_t^{(N)} - \bar{\lambda}_t^{(N)}| \leq \frac{C}{N} \tag{6.4}$$

for $t = 0, \ldots, \frac{N}{2}$.

Proof. From (5.1), (6.2), (6.1), and the definition of A_N in Theorem 4.3 we conclude that

$$\begin{aligned} \lambda_t^{(N)} - \bar{\lambda}_t^{(N)} &= d_0^{(N)} + 2d_1^{(N)} \cos\left[\frac{2\pi t}{N}\right] = d_0^{(N)}\left[1 - \cos\left[\frac{2\pi t}{N}\right]\right] \\ &= N(-1)^{\frac{N}{2}+1} \int_{-1}^{1} g(y)\bar{u}_N(y)dy \left[1 - \cos\left[\frac{2\pi t}{N}\right]\right]. \end{aligned}$$

Since $\int_{t_{i-1}}^{t_i} \bar{u}_N(y)dy = 0$ for $i = 1, \ldots, N$ and $|\bar{u}_N| \leq \frac{1}{N}$ by definition of $\bar{u}_N$, we obtain

$$\begin{aligned} |\lambda_t^{(N)} - \bar{\lambda}_t^{(N)}| &\leq 2N \left|\int_{-1}^{1} g(y)\bar{u}_N(y)dy\right| = 2N \left|\sum_{i=1}^{N} \int_{t_{i-1}}^{t_i} g(y)\bar{u}_N(y)dy\right| \\ &= 2N \left|\sum_{i=1}^{N} \int_{t_{i-1}}^{t_i} (g(y) - g(t_{i-1}))\bar{u}_N(y)dy\right| \leq 2 \sum_{i=1}^{N} \int_{t_{i-1}}^{t_i} |g(y) - g(t_{i-1})|dy \\ &\leq C \sum_{i=1}^{N} \int_{t_{i-1}}^{t_i} |y - t_{i-1}|dy \leq C \sum_{i=1}^{N} (t_i - t_{i-1})^2 \leq \frac{C}{N}, \end{aligned}$$

where we used the Lipschitz continuity of g and $t_i - t_{i-1} = \frac{2}{N}$ (cf. (3.1)). ∎

We also need the boundedness of the eigenvalues.

LEMMA 6.3. *There is a constant $C > 0$, dependent only on g, such that for every even $N \in \mathbb{N}$, we have*

$$|\lambda_t^{(N)}|, |\bar{\lambda}_t^{(N)}| \leq C \tag{6.5}$$

for $t = 0, \ldots, \frac{N}{2}$.

Proof. By Lemma 6.2, we only have to show the estimate for $\bar{\lambda}_t^{(N)}$. Let $\bar{\lambda}_t^{(N)}$, $t \in \{0, \ldots, \frac{N}{2}\}$, be an eigenvalue of $\bar{A}_N$ and $\alpha = (\alpha_1, \ldots, \alpha_N) \in \mathbb{R}^N$ a corresponding normed eigenvector of A_N (i.e., $\|\alpha\| = 1$) and set $\alpha_{N+1} = \alpha_1$. Then, by definition of $\bar{A}_N$ (cf. (6.1)) and the characterization of the matrix C_N in Theorem 4.3,

$$\bar{\lambda}_t^{(N)} = \bar{\lambda}_t^{(N)} \alpha^t \alpha = \alpha^t \bar{A}_N \alpha = b_0^{(N)} \sum_{i=1}^{N} (\alpha_i^2 + \alpha_i \alpha_{i+1}) + \sum_{i=1}^{N} \sum_{j=1}^{N} \alpha_i \alpha_j c_{ij}^{(N)}.$$

From (4.6) and the boundedness of g, we deduce $|c_{ij}^{(N)}| \le \frac{C}{N}$ for every $i, j = 1, \ldots, N$, and we conclude, using the Cauchy–Schwarz inequality, $\alpha_{N+1} = \alpha_1$, and $\|\alpha\| = 1$, that

$$|\bar{\lambda}_t^{(N)}| \le b_0^{(N)} \sum_{i=1}^N (\alpha_i^2 + |\alpha_i \alpha_{i+1}|) + \sum_{i=1}^N \sum_{j=1}^N |\alpha_i \alpha_j c_{ij}^{(N)}| \le 2b_0^{(N)} \sum_{i=1}^N \alpha_i^2 + \frac{C}{N} \left(\sum_{i=1}^N |\alpha_i| \right)^2$$
$$\le 2b_0^{(N)} + \frac{C}{N} \left(\sum_{i=1}^N |\alpha_i|^2 \right) \left(\sum_{i=1}^N 1^2 \right) \le 2b_0^{(N)} + C \le C,$$

and the proof of the lemma is complete. ∎

Finally, we need the following property, which is easy to show (cf. [24, Lemma 9.3]).

LEMMA 6.4. *Let $\mathcal{B} : L^2(0,2) \times L^2(0,2) \to \mathbb{R}$, given by*

$$\mathcal{B}(\psi, \varphi) = 2 \int_{-1}^1 g(y) dy \int_0^2 \psi(x)\varphi(x) dx - 2 \int_0^2 \int_0^2 g(x-y)\psi(x)\varphi(y) dy dx. \tag{6.6}$$

Then $\mathcal{B}$ is a continuous, symmetric bilinear form.

We can now show Theorem 6.1.

Sketch of the proof of Theorem 6.1. Let $(N_n)_{n\in\mathbb{N}} \subset \mathbb{N}$ with $N_n \nearrow \infty$ for $n \to \infty$, $(t_n)_{n\in\mathbb{N}} \subset \mathbb{N}$ as described. Due to Lemma 6.3, we may choose a subsequence (not relabelled) with $\lim_{n\to\infty} \lambda_{t_n}^{(N_n)} = \lambda \le 0$. For the eigenvalues $\bar{\lambda}_t^{(N)}$ of $\bar{A}_N$ (cf. (6.2)), Lemma 6.2 then yields

$$\lim_{n\to\infty} \bar{\lambda}_{t_n}^{(N_n)} = \lambda \le 0. \tag{6.7}$$

For every $n \in \mathbb{N}$, the vector $v_n = (v_n^{(0)}, \ldots, v_n^{(N_n-1)}) \in \mathbb{R}^{N_n}$ with

$$v_n^{(k)} = \sqrt{\frac{2}{N_n}} \cos\left[\frac{2\pi k t_n}{N_n}\right] \quad \text{for} \quad k = 0, \ldots, N_n - 1 \tag{6.8}$$

is an eigenvector of $\bar{A}_{N_n}$ corresponding to the eigenvalue $\bar{\lambda}_{t_n}^{(N_n)}$ (cf. (6.3)). We define a sequence of step functions $(\varphi_n)_{n\in\mathbb{N}} \subset L^2(0,2)$ by

$$\varphi_n = \sum_{k=0}^{N_n-1} \cos\left[\frac{2\pi k t_n}{N_n}\right] \chi_{\left(\frac{2}{N_n}k, \frac{2}{N_n}(k+1)\right)} = \sqrt{\frac{N_n}{2}} \sum_{k=0}^{N_n-1} v_n^{(k)} \chi_{\left(\frac{2}{N_n}k, \frac{2}{N_n}(k+1)\right)}.$$

Obviously, $|\varphi_n| \le 1$, so that $\|\varphi_n\|_{L^2(0,2)} \le \sqrt{2}$ for every $n \in \mathbb{N}$; hence we can choose a subsequence (not relabelled) weakly converging to a function $\varphi \in L^2(0,2)$, i.e.,

$$\varphi_n \underset{n\to\infty}{\rightharpoonup} \varphi \quad \text{in} \quad L^2(0,2). \tag{6.9}$$

Furthermore, since $\frac{t_n}{N_n} \notin \mathbb{Z}$, we can apply Euler's formula to obtain

$$\int_0^2 \varphi_n(x) dx = \sum_{k=0}^{N_n-1} \int_{\frac{2}{N_n}k}^{\frac{2}{N_n}(k+1)} \varphi_n(x) dx = \frac{2}{N_n} \sum_{k=0}^{N_n-1} \cos\left[\frac{2\pi k t_n}{N_n}\right] = 0 \tag{6.10}$$

for every $n \in \mathbb{N}$. Now, take an arbitrary $\psi \in C_0^\infty(0,2)$ and set

$$\psi_n = \sum_{k=0}^{N_n-1} \psi\left(\frac{2}{N_n}k\right) \chi_{\left(\frac{2}{N_n}k, \frac{2}{N_n}(k+1)\right)}$$

for every $n \in \mathbb{N}$. Then

$$\psi_n \underset{n\to\infty}{\longrightarrow} \psi \text{ in } L^2(0,2). \tag{6.11}$$

For every $n \in \mathbb{N}$, we define $w_n = (w_n^{(0)}, \dots, w_n^{(N_n-1)}) \in \mathbb{R}^{N_n}$ by

$$w_n^{(k)} = \sqrt{\frac{2}{N_n}}\,\psi\left(\frac{2}{N_n}k\right)$$

for $k = 0, \dots, N_n - 1$, and together with (6.8) we get

$$w_n^t v_n = \int_0^2 \psi_n(x)\varphi_n(x)dx, \tag{6.12}$$

and if φ_n and ψ_n also denote the periodic extensions of φ_n, ψ_n on $\mathbb{R}$, a careful calculation that makes use of $v_n^{(0)} = \sqrt{\frac{2}{N_n}}$ and $w_n^{(0)} = 0$ yields

$$\sum_{i=1}^{N_n-1} w_n^{(i-1)}v_n^{(i)} + w_n^{(N_n-1)}v_n^{(0)} = \int_0^2 \psi_n(x)\varphi_n\left(x + \frac{2}{N_n}\right)dx,$$
$$\sum_{i=1}^{N_n-1} w_n^{(i)}v_n^{(i-1)} + w_n^{(0)}v_n^{(N_n-1)} = \int_0^2 \psi_n(x)\varphi_n\left(x - \frac{2}{N_n}\right)dx.$$

Recalling (6.1) and the definitions in Theorem 4.3, a further computation leads to

$$\begin{aligned} w_n^t \bar{A}_{N_n} v_n &= \int_{-1}^1 g(y)dy \int_0^2 \psi_n(x)\left[\varphi_n(x) + \frac{1}{2}\varphi_n\left(x + \frac{2}{N_n}\right) + \frac{1}{2}\varphi_n\left(x - \frac{2}{N_n}\right)\right]dx \\ &\quad - 2\int_0^2\int_0^2 g(x-y)\psi_n(x)\varphi_n(y)dydx \\ &=: \mathcal{B}_n(\psi_n, \varphi_n). \end{aligned}$$

Since v_n is an eigenvector of $\bar{A}_{N_n}$ corresponding to the eigenvalue $\bar{\lambda}_{t_n}^{(N_n)}$, we derive from (6.12)

$$\bar{\lambda}_{t_n}^{(N_n)} \int_0^2 \psi_n(x)\varphi_n(x)dx = \bar{\lambda}_{t_n}^{(N_n)} w_n^t v_n = w_n^t \bar{A}_{N_n} v_n = \mathcal{B}_n(\psi_n, \varphi_n). \tag{6.13}$$

By straightforward methods, we obtain, using (6.9), (6.11), and the boundedness of g,

$$\lim_{n\to\infty} \mathcal{B}_n(\psi_n, \varphi_n) = \mathcal{B}(\psi, \varphi), \tag{6.14}$$

where $\mathcal{B} : L^2(0,2) \times L^2(0,2) \to \mathbb{R}$ is the symmetric, continuous bilinear form given by (6.6). Furthermore, we deduce from (6.9), (6.11), and $\bar{\lambda}_{t_n}^{(N_n)} \to \lambda$ that

$$\lim_{n\to\infty} \bar{\lambda}_{t_n}^{(N_n)} \int_0^2 \psi_n(x)\varphi_n(x)dx = \lambda(\psi, \varphi)_{L^2(0,2)},$$

which by (6.14) and (6.13) implies

$$\mathcal{B}(\psi, \varphi) = \lambda(\psi, \varphi)_{L^2(0,2)}. \tag{6.15}$$

Since $\psi \in C_0^\infty(0,2)$ was chosen arbitrarily, (6.15) holds for every $\psi \in C_0^\infty(0,2)$. Since $C_0^\infty(0,2)$ is dense in $L^2(0,2)$ and because of the $L^2(0,2)$-continuity of both sides, (6.15) holds for every $\psi \in L^2(0,2)$. Choosing $\psi = \varphi$ we obtain, using the 2-periodicity of g on $\mathbb{R}$ and the symmetry of g,

$$\begin{aligned}\lambda\|\varphi\|^2_{L^2(0,2)} = \mathcal{B}(\varphi,\varphi) &= 2\int_{-1}^1 g(y)dy \int_0^2 \varphi(x)^2 dx - 2\int_0^2\int_0^2 g(x-y)\varphi(x)\varphi(y)dydx \\ &= \int_0^2\int_0^2 g(x-y)(\varphi(x)-\varphi(y))^2 dydx.\end{aligned}$$

Equations (6.10) and (6.9) immediately imply $\int_0^2 \varphi(x)dx = 0$, so that due to (6.7) and the positivity of g (i.e., $g \geq g_0 > 0$ on $\mathbb{R}$; see the conditions on g in the introduction), we get

$$0 \geq \lambda\|\varphi\|^2_{L^2(0,2)} \geq g_0 \int_0^2\int_0^2 (\varphi(x)-\varphi(y))^2 dydx = 4g_0\|\varphi\|^2_{L^2(0,2)},$$

which, since $g_0 > 0$, can only hold if $\varphi = 0$, and due to (6.9), this implies

$$\varphi_n \xrightarrow[n\to\infty]{} 0 \quad \text{in} \quad L^2(0,2). \tag{6.16}$$

Recalling (6.2) and the definitions in Theorem 4.3, we obtain

$$\begin{aligned}\bar{\lambda}_{t_n}^{(N_n)} &= b_0^{(N_n)} + 2b_1^{(N_n)}\cos\left[\frac{2\pi t_n}{N_n}\right] + c_0^{(N_n)} + (-1)^{t_n} c_{\frac{N_n}{2}}^{(N_n)} + 2\sum_{k=1}^{\frac{N_n}{2}-1} c_k^{(N_n)}\cos\left[\frac{2\pi k t_n}{N_n}\right] \\ &= b_0^{(N_n)}\left(1+\cos\left[\frac{2\pi t_n}{N_n}\right]\right) + \sum_{k=0}^{\frac{N_n}{2}-1} c_k^{(N_n)}\cos\left[\frac{2\pi k t_n}{N_n}\right] + \sum_{k=1}^{\frac{N_n}{2}} c_k^{(N_n)}\cos\left[\frac{2\pi t_n}{N_n}\right].\end{aligned}$$

Setting

$$\tilde{c}_k^{(N_n)} = -2\int_{\frac{2}{N_n}k}^{\frac{2}{N_n}(k+1)} g(y)dy \quad \text{for} \quad k = 0,\dots,\frac{N_n}{2},$$

one can show that $|\tilde{c}_k^{(N_n)} - c_k^{(N_n)}| \leq \frac{C}{N_n^2}$. Thus, if we define

$$\mu_{t_n}^{(N_n)} = b_0^{(N_n)}\left(1+\cos\left[\frac{2\pi t_n}{N_n}\right]\right) + \sum_{k=0}^{\frac{N_n}{2}-1} \tilde{c}_k^{(N_n)}\cos\left[\frac{2\pi k t_n}{N_n}\right] + \sum_{k=1}^{\frac{N_n}{2}} \tilde{c}_k^{(N_n)}\cos\left[\frac{2\pi k t_n}{N_n}\right],$$

we observe that $|\mu_{t_n}^{(N_n)} - \bar{\lambda}_{t_n}^{(N_n)}| \leq \frac{C}{N_n}$; hence by Lemma 6.2

$$\lambda_{t_n}^{(N_n)} \geq \bar{\lambda}_{t_n}^{(N_n)} - \frac{C}{N_n} \geq \mu_{t_n}^{(N_n)} - \frac{C}{N_n}.$$

A simple calculation yields

$$\begin{aligned}\sum_{k=0}^{\frac{N_n}{2}-1} \tilde{c}_k^{(N_n)}\cos\left[\frac{2\pi k t_n}{N_n}\right] &= -2\int_0^1 g(y)\varphi_n(y)dy, \\ \sum_{k=1}^{\frac{N_n}{2}} \tilde{c}_k^{(N_n)}\cos\left[\frac{2\pi k t_n}{N_n}\right] &= -2\int_{\frac{2}{N_n}}^{1+\frac{2}{N_n}} g(y)\varphi_n(y)dy = -2\int_0^1 g(y)\varphi_n(y)dy + O\left(\frac{1}{N_n}\right),\end{aligned}$$

so that

$$\lambda_{t_n}^{(N_n)} \geq \mu_{t_n}^{(N_n)} - \frac{C}{N_n} = \int_0^2 g(y)dy \left(1 + \cos\left[\frac{2\pi t_n}{N_n}\right]\right) - 4\int_0^1 g(y)\varphi_n(y)dy - \frac{C}{N_n},$$

and due to (6.16), taking the limit for $n \to \infty$ yields

$$\begin{aligned} 0 \geq \lambda &\geq \int_0^2 g(y)dy \cdot \limsup_{n\to\infty} \left(1 + \cos\left[\frac{2\pi t_n}{N_n}\right]\right) \\ &\geq \int_0^2 g(y)dy \cdot \liminf_{n\to\infty} \left(1 + \cos\left[\frac{2\pi t_n}{N_n}\right]\right) \geq 0, \end{aligned}$$

which implies $\lambda = 0$. Furthermore, since $\int_{-1}^1 g(y)dy > 0$, we deduce that

$$\lim_{n\to\infty} \left(1 + \cos\left[\frac{2\pi t_n}{N_n}\right]\right) = 0,$$

which due to $\frac{2\pi t_n}{N_n} \in [0, \pi]$ implies that $\lim_{n\to\infty} \frac{t_n}{N_n} = \frac{1}{2}$, and thus the proof is complete. ∎

From Theorem 6.1 we easily conclude the following property.

COROLLARY 6.5. *For every even number $N \in \mathbb{N}$, let $\lambda_t^{(N)}$, $t = 0, \ldots, \frac{N}{2}$, be the eigenvalues of A_N as given in* (5.1). *Then for every $\delta > 0$, we find $\nu_0 > 0$ and $N_0 \in \mathbb{N}$ such that for every even number $N \geq N_0$, the following holds true:*

$$\lambda_t^{(N)} \geq \nu_0 \quad \textit{for every} \quad t \in \left\{1, \ldots, \frac{N}{2} - 1\right\} \quad \textit{satisfying} \quad \frac{t}{N} \leq \frac{1}{2} - \delta. \tag{6.17}$$

7. Estimation of the eigenvalues. In order to show the positivity of the eigenvalues $\lambda_t^{(N)}$ for $t = 1, \ldots, \frac{N}{2} - 1$ and N large, due to Corollary 6.5 we only have to consider the indices t with $\frac{t}{N} \geq \frac{1}{2} - \delta$, where δ is sufficiently small. We can do so by introducing the parameter

$$\delta = \delta_{t,N} = 1 - \frac{2t}{N} \tag{7.1}$$

and then estimating $\lambda_t^{(N)}$ in terms of $\frac{1}{N}$ and δ. Recall the eigenvalues of A_N given by (5.1) with coefficients as given in Theorem 4.3. While in the proof of the "index property" (Theorem 6.1) we could omit the $d_i^{(N)}$-terms (which was done by replacing A_N with $\bar{A}_N$), since they disappear in the limit $N \to \infty$ when $\frac{t}{N}$ is not close to $\frac{1}{2}$, they play an essential role in the case considered in this section. Unfortunately, since the calculations are extremely long and very technical, we can only mention the results here and have to refer the reader to [24] for details. First, a calculation yields

$$\begin{aligned} \lambda_t^{(N)} = &\int_{-1}^1 g(y)dy \left(1 + \cos\left[\frac{2\pi t}{N}\right]\right) + \left(c_0^{(N)} + (-1)^t c_{\frac{N}{2}}^{(N)} + 2\sum_{k=1}^{\frac{N}{2}-1} c_k^{(N)} \cos\left[\frac{2\pi k t}{N}\right]\right) \\ &+ 2N \sum_{k=0}^{\frac{N}{2}-1} (-1)^k \int_0^{\frac{1}{N}} x \left[g\left(\frac{2k+1}{N} - x\right) - g\left(\frac{2k+1}{N} + x\right)\right] dx \left(1 - \cos\left[\frac{2\pi t}{N}\right]\right). \end{aligned} \tag{7.2}$$

The middle part can be written in the form

$$c_0^{(N)} + (-1)^t c_{\frac{N}{2}}^{(N)} + 2\sum_{k=1}^{\frac{N}{2}-1} c_k^{(N)} \cos\left[\frac{2\pi kt}{N}\right] = T_{t,N}^{(1)} + T_{t,N}^{(2)},$$

where

$$T_{t,N}^{(1)} = \sum_{k=0}^{\frac{N}{2}-1} c_k^{(N)} \left(\cos\left[\frac{2\pi kt}{N}\right] + \cos\left[\frac{2\pi(k+1)t}{N}\right]\right), \tag{7.3}$$

$$T_{t,N}^{(2)} = \sum_{k=0}^{\frac{N}{2}-1} (c_{k+1}^{(N)} - c_k^{(N)}) \cos\left[\frac{2\pi(k+1)t}{N}\right]. \tag{7.4}$$

Then (cf. [24, Lemma 10.2 and remarks at the end of Chapter 10]) we have the following.

LEMMA 7.1. *Let $N \in \mathbb{N}$ be an even number, $t \in \{1, \ldots, \frac{N}{2} - 1\}$, δ as given by* (7.1). *Then*

$$|T_{t,N}^{(1)}| \le C\left(\delta^3 + \frac{\delta^2}{N} + \frac{\delta}{N^2}\right).$$

Idea of the proof. The first step is to observe that

$$\begin{aligned}\cos\left[\frac{2\pi kt}{N}\right] + \cos\left[\frac{2\pi(k+1)t}{N}\right] &= (-1)^{k+1}(\cos((k+1)\pi\delta) - \cos(k\pi\delta)) \\ &= (-1)^k \pi\delta \sin(k\pi\delta) + \frac{1}{2}(-1)^k \pi^2\delta^2 \cos(\xi_{k,N})\end{aligned}$$

and to show that

$$\begin{aligned}T_{t,N}^{(1)} &\approx \pi\delta \sum_{k=0}^{\frac{N}{2}-1} (-1)^k c_k^{(N)} \sin(k\pi\delta) = \pi\delta \sum_{\substack{k=0 \\ k \text{ even}}}^{\frac{N}{2}-1} (c_k^{(N)} \sin(k\pi\delta) - c_{k+1}^{(N)} \sin((k+1)\pi\delta)) \\ &= \pi\delta \sum_{\substack{k=0 \\ k \text{ even}}}^{\frac{N}{2}-1} (c_k^{(N)} - c_{k+1}^{(N)}) \sin(k\pi\delta) + \pi\delta \sum_{\substack{k=0 \\ k \text{ even}}}^{\frac{N}{2}-1} c_{k+1}^{(N)} (\sin(k\pi\delta) - \sin((k+1)\pi\delta)).\end{aligned}$$

As for the left-hand term, we have

$$\begin{aligned}c_k^{(N)} - c_{k+1}^{(N)} &= N\int_0^{\frac{2}{N}} \int_{\frac{2}{N}k}^{\frac{2}{N}(k+1)} \left[g\left(x - y + \frac{2}{N}\right) - g(x-y)\right] dxdy \\ &\approx 2\int_0^{\frac{2}{N}} \int_{\frac{2}{N}k}^{\frac{2}{N}(k+1)} g'(x-y)dxdy \\ &= 2\int_0^{\frac{2}{N}} \left[g\left(\frac{2}{N}(k+1) - y\right) - g\left(\frac{2}{N}k - y\right)\right] dy \\ &\approx \frac{4}{N}\int_0^{\frac{2}{N}} g'\left(\frac{2}{N}k - y\right) dy,\end{aligned} \tag{7.5}$$

from which one can conclude that

$$\pi\delta \sum_{\substack{k=2 \\ k\ even}}^{\frac{N}{2}-2} (c_k^{(N)} - c_{k+1}^{(N)}) \sin(k\pi\delta) \approx 4\pi\frac{\delta}{N} \sum_{\substack{k=2 \\ k\ even}}^{\frac{N}{2}-2} \sin(k\pi\delta) \int_{\frac{2}{N}(k-1)}^{\frac{2}{N}k} g'(y)dy,$$

$$\approx 4\pi\frac{\delta}{N} \sum_{\substack{k=2 \\ k\ even}}^{\frac{N}{2}-2} \int_{\frac{2}{N}(k-1)}^{\frac{2}{N}k} g'(y)\sin\left(\frac{N}{2}\pi\delta y\right) dy \approx 2\pi\frac{\delta}{N}\int_0^1 g'(y)\sin\left(\frac{N}{2}\pi\delta y\right) dy.$$

With similar techniques, the right-hand term in (7.5) can be approximated by a Fourier integral for g as

$$\pi\delta \sum_{\substack{k=0 \\ k\ even}}^{\frac{N}{2}-1} c_{k+1}^{(N)}(\sin(k\pi\delta) - \sin((k+1)\pi\delta)) \approx \pi^2\delta^2 \int_0^1 g(x)\cos\left(\frac{N}{2}\pi\delta x\right) dx,$$

and by partial integration both integrals sum up to zero.

Although the estimation of $T_{t,N}^{(2)}$ is done similarly, one has to be even more careful. So far, one could "delete" terms where a Taylor representation is not possible due to nondifferentiability of g in 0. In the above sketch, this was done by leaving out the index $k = 0$ in the sum over even indices. This is not possible here, and one obtains border terms.

LEMMA 7.2. *Let $N \in \mathbb{N}$ be even, δ as given by* (7.1)*. Then*

$$T_{t,N}^{(2)} = \frac{4}{3N^2}g'(0) + O\left(\frac{\delta^2}{N}\right) + O\left(\frac{\delta}{N^2}\right) + O\left(\frac{1}{N^3}\right).$$

As for the rear part of (7.2), one can show the following.

LEMMA 7.3. *Let $N \in \mathbb{N}$ be a multiple of* 4 *(i.e., $\frac{N}{2}$ is even), $t \in \{1, \dots, \frac{N}{2} - 1\}$, δ as given by* (7.1)*. Then*

$$2N \sum_{k=0}^{\frac{N}{2}-1} (-1)^k \int_0^{\frac{1}{N}} x \left[g\left(\frac{2k+1}{N} - x\right) - g\left(\frac{2k+1}{N} + x\right)\right] dx \left(1 - \cos(\frac{2\pi t}{N})\right)$$
$$= -\frac{4}{3N^2}g'(0) + O\left(\frac{\delta}{N^2}\right) + O\left(\frac{1}{N^3}\right).$$

Thus, (7.2) yields

$$\lambda_t^{(N)} = \int_{-1}^1 g(y)dy\left(1 + \cos\left[\frac{2\pi t}{N}\right]\right) + O\left(\delta^3\right) + O\left(\frac{\delta^2}{N}\right) + O\left(\frac{\delta}{N^2}\right) + O\left(\frac{1}{N^3}\right),$$

and using $\delta \geq \frac{2}{N}$ (cf. (7.1)), one obtains

$$\int_{-1}^1 g(y)dy\left(1 + \cos\left[\frac{2\pi t}{N}\right]\right) \geq C\delta^2 \geq C\left(\delta^2 + \frac{1}{N^2}\right),$$

so that the first term is the dominant one, which implies $\lambda_t^{(N)} > 0$ for $t = 1, \dots, \frac{N}{2} - 1$ if N is large and δ is small, the latter being equivalent to $\frac{t}{N} \geq \frac{1}{2} - \delta$. Thus, if δ is small enough, application of Corollary 6.5 yields positivity of all eigenvalues $\lambda_t^{(N)}$, $t = 1, \dots, \frac{N}{2} - 1$, if N is large.

Acknowledgments. I would like to thank Prof. Dr. Hansjörg Kielhöfer for constant support and good advice during the years I had been working on my thesis. My gratitude goes to Prof. Dr. Stefan Müller for inviting me to the Max-Planck-Institute for Mathematics in the Sciences twice, for pointing me to this subject, and for several stimulating discussions. I want to thank Prof. Dr. Timothy Healey for inviting me to the Department of Theoretical Applied Mechanics at Cornell University, where I was able to present first results and to exchange ideas. I am also indebted to Prof. Dr. Stanislaus Maier-Paape for inviting me to the RWTH Aachen and for inspiring discussions.

A BLOW-UP CRITERION FOR THE NONHOMOGENEOUS INCOMPRESSIBLE NAVIER–STOKES EQUATIONS*

HYUNSEOK KIM†

Abstract. Let (ρ, u) be a strong or smooth solution of the nonhomogeneous incompressible Navier–Stokes equations in $(0, T^*) \times \Omega$, where T^* is a finite positive time and Ω is a bounded domain in $\mathbf{R}^3$ with smooth boundary or the whole space $\mathbf{R}^3$. We show that if (ρ, u) blows up at T^*, then $\int_0^{T^*} |u(t)|^s_{L^r_w(\Omega)}\, dt = \infty$ for any (r, s) with $\frac{2}{s} + \frac{3}{r} = 1$ and $3 < r \leq \infty$. As immediate applications, we obtain a regularity theorem and a global existence theorem for strong solutions.

Key words. blow-up criterion, nonhomogeneous incompressible Navier–Stokes equations

AMS subject classifications. 35Q30, 76D05

DOI. 10.1137/S0036141004442197

1. Introduction.

The motion of a nonhomogeneous incompressible viscous fluid in a domain Ω of $\mathbf{R}^3$ is governed by the *Navier–Stokes equations*

$$(\rho u)_t + \operatorname{div}(\rho u \otimes u) - \Delta u + \nabla p = \rho f, \tag{1.1}$$

$$\rho_t + \operatorname{div}(\rho u) = 0 \quad \text{in} \quad (0, \infty) \times \Omega, \tag{1.2}$$

$$\operatorname{div} u = 0 \tag{1.3}$$

and the initial and boundary conditions

$$\begin{aligned} &(\rho,\, \rho u)|_{t=0} = (\rho_0,\, \rho_0 u_0) \quad \text{in} \quad \Omega, \qquad u = 0 \quad \text{on} \quad (0, T) \times \partial\Omega, \\ &\rho(t, x) \to 0, \quad u(t, x) \to 0 \quad \text{as} \quad |x| \to \infty, \quad (t, x) \in (0, T) \times \Omega. \end{aligned} \tag{1.4}$$

Here we denote by ρ, u, and p the unknown density, velocity, and pressure fields of the fluid, respectively. f is a given external force driving the motion. Ω is either a bounded domain in $\mathbf{R}^3$ with smooth boundary or the whole space $\mathbf{R}^3$. Throughout this paper, we adopt the following simplified notation for standard homogeneous and inhomogeneous Sobolev spaces:

$$\begin{aligned} &L^r = L^r(\Omega), \quad D^{k,r} = \{v \in L^1_{loc}(\Omega) : |v|_{D^{k,r}} < \infty\}; \\ &H^{k,r} = L^r \cap D^{k,r}, \quad D^k = D^{k,2}, \quad H^k = H^{k,2}; \\ &D^1_0 = \{v \in L^6 : |v|_{D^1_0} < \infty \ \text{and} \ v = 0 \ \text{on} \ \partial\Omega\}; \\ &H^1_0 = L^2 \cap D^1_{0,}, \quad D^1_{0,\sigma} = \{v \in D^1_0 : \operatorname{div} v = 0 \text{ in } \Omega\}; \\ &|v|_{D^{k,r}} = |\nabla^k v|_{L^r} \quad \text{and} \quad |v|_{D^1_0} = |v|_{D^1_{0,\sigma}} = |\nabla v|_{L^2}. \end{aligned}$$

Note that the space D^1_0 is the completion of $C^\infty_c(\Omega)$ in D^1, and thus there holds the following Sobolev inequality:

$$|v|_{L^6} \leq \frac{2}{\sqrt{3}} |v|_{D^1_0} \qquad \text{for all } v \in D^1_0. \tag{1.5}$$

For a proof of (1.5), see sections II.5 and II.6 in the book by Galdi [11].

The global existence of weak solutions has been established by Antontsev and Kazhikov [1], Fernandez-Cara and Guillen [10], Kazhikov [13], Lions [21], and Simon [26, 27]. From these results (see [21] in particular), it follows that for any data (ρ_0, u_0, f) with the regularity

$$0 \le \rho_0 \in L^{\frac{3}{2}} \cap L^\infty, \quad u_0 \in L^6, \quad \text{and} \quad f \in L^2(0,\infty; L^2),$$

there exists at least one weak solution (ρ, u) to the initial boundary value problem (1.1)–(1.4) satisfying the regularity

$$\rho \in L^\infty(0,\infty; L^{\frac{3}{2}} \cap L^\infty), \quad \sqrt{\rho} u \in L^\infty(0,\infty; L^2), \quad \text{and} \quad u \in L^2(0,\infty; D^1_{0,\sigma}) \tag{1.6}$$

as well as the natural energy inequality. Then an associated pressure p is determined as a distribution in $(0,\infty) \times \Omega$.

But the global existence of strong or smooth solutions is still an open problem and only local existence results have been obtained for sufficiently regular data satisfying some compatibility conditions. For details, we refer to the papers by Choe and the author [6], Kim [15], Ladyzhenskaya and Solonnikov [19], Okamoto [22], Padula [23], and Salvi [24]. In particular, it is shown in [6] (see also [7]) that if the data ρ_0, u_0, and f satisfy

$$\begin{gathered} 0 \le \rho_0 \in L^{\frac{3}{2}} \cap H^2, \quad u_0 \in D^1_{0,\sigma} \cap D^2, \quad -\Delta u_0 + \nabla p_0 = \rho_0^{\frac{1}{2}} g, \\ f \in L^2(0,\infty; H^1), \quad \text{and} \quad f_t \in L^2(0,\infty; L^2) \end{gathered} \tag{1.7}$$

for some $(p_0, g) \in D^1 \times L^2$, then there exist a positive time T and a unique strong solution (ρ, u) to the problem (1.1)–(1.4) such that

$$\begin{gathered} \rho \in C([0,T]; L^{\frac{3}{2}} \cap H^2), \quad u \in C([0,T]; D^1_{0,\sigma} \cap D^2) \cap L^2(0,T; D^3), \\ u_t \in L^2(0,T; D^1_{0,\sigma}), \quad \text{and} \quad \sqrt{\rho} u_t \in L^\infty(0,T; L^2). \end{gathered} \tag{1.8}$$

Moreover, the existence of a pressure p in $C([0,T]; D^1) \cap L^2(0,T; D^2)$ can be deduced from (1.1)–(1.3). See [5] for a detailed argument.

Let (ρ, u) be a global weak solution to the problem (1.1)–(1.4) with the data (ρ_0, u_0, f) satisfying condition (1.7). Then from the above local existence result and weak-strong uniqueness results in [6] and [21], we conclude that the solution (ρ, u) satisfies the regularity (1.8) for some positive time T. One fundamental problem in mathematical fluid mechanics is to determine whether or not (ρ, u) satisfies (1.8) for all time T. As an equivalent formulation, we may ask the following.

Fundamental question 1.1. Does the solution (ρ, u) blow up at some finite time T^*? Such a time T^*, if it exists, is called the finite *blow-up time* of the solution (ρ, u) in the class H^2.

In spite of great efforts since the pioneering works by Leray [20] in 1930s, there have been no definite answers to the fundamental question even for the case of the *homogenous Navier–Stokes equations* with only some blow-up criteria available. The first criterion is due to Leray [20] who proved, among other things, that if T^* is the finite blow-up time of a strong solution u to the Cauchy problem for the homogeneous Navier–Stokes equations, then for each r with $3 < r \le \infty$, there exists a constant $C = C(r) > 0$ such that

$$|u(t)|_{L^r} \ge C(T^* - t)^{-\frac{1}{2}(1-\frac{3}{r})} \qquad \text{for all near } t < T^*. \tag{1.9}$$

This estimate near the blow-up time was extended by Giga [12] to the case of bounded domains. An immediate consequence of (1.9) is the following well-known blow-up criterion in terms of the so-called Serrin class (see [9, 25, 29]):

$$\int_0^{T^*} |u(t)|_{L^r}^s \, dt = \infty \quad \text{for any } (r,s) \text{ with } \frac{2}{s} + \frac{3}{r} = 1, \qquad 3 < r \le \infty. \tag{1.10}$$

By virtue of Sobolev inequality (1.5), we deduce from (1.10) that

$$\int_0^{T^*} |\nabla u(t)|_{L^2}^4 \, dt = \infty. \tag{1.11}$$

Further generalizations of (1.10) and (1.11) have been obtained by Beirao da Veiga [2], Berselli [3], Chae and Choe [4], and Kozono and Taniuchi [17].

The major purpose of this paper is to prove the blow-up criterion (1.10) for strong solutions of the nonhomogeneous Navier–Stokes equations (1.1)–(1.3). In fact, we establish a more general result. To state our main result precisely, we first introduce the notion of the blow-up time of solutions in the class H^{2m} with $m \ge 1$. Let (ρ, u) be a strong solution to the initial boundary value problem (1.1)–(1.4) with the regularity

$$\begin{aligned} &\rho \in C([0,T]; L^{\frac{3}{2}} \cap H^{2m}), \quad u \in C([0,T]; D^1_{0,\sigma} \cap D^{2m}) \cap L^2(0,T; D^{2m+1}), \\ &\partial_t^j u \in C([0,T]; D^1_{0,\sigma} \cap D^{2m-2j}) \cap L^2(0,T; D^{2m-2j+1}) \quad \text{for} \quad 1 \le j < m, \\ &\quad \partial_t^m u \in L^2(0,T; D^1_{0,\sigma}), \qquad \text{and} \qquad \sqrt{\rho}\, \partial_t^m u \in L^\infty(0,T; L^2) \end{aligned} \tag{1.12}$$

for any $T < T^*$, where T^* is a finite positive time. Then we can define

$$\begin{aligned} \Phi_m(T) = {} & 1 + \sup_{0 \le t \le T} \left(|\nabla \rho(t)|_{H^{2m-1}} + |u(t)|_{D_0^1 \cap D^{2m}} \right) + \int_0^T |u(t)|_{D^{2m+1}}^2 \, dt \\ & + \sup_{1 \le j < m} \left(\sup_{0 \le t \le T} |\partial_t^j u(t)|_{D_0^1 \cap D^{2m-2j}} + \int_0^T |\partial_t^j u(t)|_{D^{2m-2j+1}}^2 \, dt \right) \\ & + \operatorname*{ess\,sup}_{0 \le t \le T} |\sqrt{\rho}\, \partial_t^m u(t)|_{L^2} + \int_0^T |\partial_t^m u(t)|_{D_0^1}^2 \, dt \end{aligned} \tag{1.13}$$

for any $T < T^*$. Hereafter we use the obvious notation

$$|\cdot|_{X \cap Y} = |\cdot|_X + |\cdot|_Y \quad \text{for (semi-)normed spaces } X,\, Y.$$

Definition 1.2. A finite positive number T^* is called the finite *blow-up time* of the solution (ρ, u) in the class H^{2m}, provided that

$$\Phi_m(T) < \infty \quad \text{for} \quad 0 < T < T^* \quad \text{and} \quad \lim_{T \to T^*} \Phi_m(T) = \infty.$$

We are now ready to state the main result of this paper.

Theorem 1.3. *For a given integer $m \ge 1$, we assume that*

$$\partial_t^m f \in L^2(0,\infty; L^2) \quad \textit{and} \quad \partial_t^j f \in L^2(0,\infty; H^{2m-2j-1}) \quad \textit{for} \quad 0 \le j < m.$$

Let (ρ, u) be a strong solution of the nonhomogeneous Navier–Stokes equations (1.1)–(1.3) *satisfying the regularity* (1.12) *for any $T < T^*$. If T^* is the finite blow-up time of (ρ, u) in the class H^{2m}, then we have*

$$\int_0^{T^*} |u(t)|_{L_w^r}^s \, dt = \infty \quad \textit{for any } (r,s) \textit{ with } \frac{2}{s} + \frac{3}{r} = 1, \qquad 3 < r \le \infty. \tag{1.14}$$

Here L^r_w denotes the weak L^r-space, that is, the space consisting of all vector fields $v \in L^1_{loc}(\Omega)$ such that $|v|_{L^r_w} = \sup_{\alpha>0} \alpha \left|\{x \in \Omega : |v(x)| > \alpha\}\right|^{\frac{1}{r}} < \infty$ for $3 < r < \infty$ and $|v|_{L^\infty_w} = |v|_{L^\infty} < \infty$. In the case when $3 < r < \infty$, L^r is a proper subspace of L^r_w ($|x|^{-3/r} \in L^r_w(\mathbf{R}^3)$ for instance) and so Theorem 1.3 is in fact a generalization of the blow-up criterion (1.10) due to Leray and Giga even for the homogeneous Navier–Stokes equations.

Theorem 1.3 is proved in the next two sections. In section 2, we provide a proof of the theorem for the very special case $m = 1$. Our method of the proof is quite well known in the case of the homogeneous Navier–Stokes equations and was also applied in an earlier paper [6] by Choe and the author to the nonhomogeneous case: combining classical regularity results on the Stokes equations with Hölder and Sobolev inequalities, we show that $\Phi_1(T)$ is bounded in a double exponential way by $\int_0^T |u(t)|^s_{L^r_w}\, dt$ for any T less than the blow-up time T^*. But the use of weak Lebesgue spaces in space variables makes it more difficult to estimate the nonlinear convection term. To overcome this technical difficulty, we utilize some basic theory of the Lorenz spaces developed in [18] and [30]. See the derivations of (2.6) and (2.7) for details. Concerning the proof for the general case $m \geq 2$, the basic idea is also to show that $\Phi_m(T)$ is bounded in some specific way by $\int_0^T |u(t)|^s_{L^r_w}\, dt$ for any $T < T^*$. Such an approach is more or less standard in the case of the homogeneous Navier–Stokes equations, but its extension to the nonhomogeneous case is not straightforward and indeed much complicated due to the evolution of the density. A detailed argument is provided in section 3.

Some corollaries of Theorem 1.3 can be deduced from a local existence result on strong solutions in the class H^{2m}. For instance, as an immediate consequence of Theorem 1.3, the local existence result in the class H^2, and the weak-strong uniqueness result, we obtain the following regularity result whose obvious proof may be omitted.

Corollary 1.4. *Let* (ρ, u) *be a global weak solution to the initial boundary value problem* (1.1)–(1.4) *with the data satisfying condition* (1.7). *If there exists a finite positive time* T_* *such that*

$$u \in L^s(0, T_*; L^r_w) \quad \text{for some } (r, s) \text{ with } \frac{2}{s} + \frac{3}{r} = 1, \qquad 3 < r \leq \infty, \tag{1.15}$$

then the solution (ρ, u) *satisfies regularity* (1.8) *for some* $T > T_*$.

A similar result was obtained by Choe and the author [6] assuming, however, a stronger condition on u, that is, $u \in L^4(0, T_*; D^1_0)$. By virtue of Corollary 1.4, we may conclude that the class (which we call a *weak Serrin class*) in (1.15) is a regularity class for weak solutions of the nonhomogeneous Navier–Stokes equations, which was already proved by Sohr [28] for the homogeneous case. See also a local version of Sohr's result in [14]. Moreover, thanks to a recent result by Dubois [8], the weak Serrin class is a uniqueness class for the homogeneous Navier–Stokes equations. It is also noticed that the same results can be easily derived from regularity and uniqueness results due to Kozono by adapting the arguments in the remarks of Theorem 3 in [16].

Theorem 1.3 and its proof can be used to obtain a global existence result on solutions in the class H^2 under some smallness condition on u_0 and f (but not on ρ_0).

Theorem 1.5. *For each* $K > 1$*, there exists a small constant* $\varepsilon > 0$*, depending only on* K *and the domain* Ω*, with the following property: if the data* ρ_0*,* u_0*, and* f *satisfy*

$$|\rho_0|_{L^{\frac{3}{2}} \cap L^\infty} \leq K, \quad |u_0|_{D^1_0} \leq \varepsilon, \quad \text{and} \quad \int_0^\infty |f(t)|^2_{L^2}\, dt \leq \varepsilon^2 \tag{1.16}$$

in addition to condition (1.7)*, then there exists a unique global strong solution* (ρ, u) *to problem* (1.1)–(1.4) *satisfying regularity* (1.8) *for any* $T < \infty$*.*

A rather simple proof of Theorem 1.5 is provided in section 4. Finally, we recall that in the case when ρ_0 is bounded away from zero and Ω is a bounded domain in $\mathbf{R}^3$ with smooth boundary, Salvi [24] proved the local existence of strong solutions in the class H^{2m} for every $m \geq 1$. Hence adapting the proofs of Corollary 1.4 and Theorem 1.5, we can also prove analogous regularity and global existence results on strong solutions in every class H^{2m} provided that $\Omega \subset\subset \mathbf{R}^3$ and $\rho_0 > 0$ on $\overline{\Omega}$.

2. Proof of Theorem 1.3 with $\;\;= 1$. In this section, we prove Theorem 1.3 for the special case $m = 1$. Let t_0 be a fixed time with $0 < t_0 < T^*$ and let us denote

$$\Phi_0(T) = \int_0^T |u(t)|_{L^r_w}^s \, dt \quad \text{for} \quad t_0 \leq T < T^*,$$

where (r, s) is any pair satisfying condition (1.14). To prove Theorem 1.3, we have only to show that

$$\Phi_1(T) \leq C \exp\left(C \exp\left(C\Phi_0(T)\right)\right) \quad \text{for} \quad t_0 \leq T < T^*. \tag{2.1}$$

Throughout this paper, we denote by C a generic positive constant depending only on r, m, $\Phi_m(t_0)$, T^*, Ω, $|\rho(0)|_{L^{\frac{3}{2}} \cap L^\infty}$, $|u(0)|_{L^6}$, and the norm of f, but independent of T in particular. To begin with, we recall from (1.6) that

$$\sup_{0 \leq t \leq T} \left(|\rho(t)|_{L^{\frac{3}{2}} \cap L^\infty} + |\sqrt{\rho} u(t)|_{L^2} \right) + \int_0^T |u(t)|_{D_0^1}^2 \, dt \leq C \tag{2.2}$$

for $t_0 \leq T < T^*$.

2.1. Estimates for $\int_0^T |\sqrt{\;\;}\;\;_t(\;\;)|_{L^2}^2$ and $\sup_{0 \leq t \leq T} |\;\;(\;\;)|_{D_0^1}$. Next, we will show that

$$\int_0^T \left(|\sqrt{\rho} u_t(t)|_{L^2}^2 + |u(t)|_{D_0^1 \cap D^2}^2 \right) dt + \sup_{0 \leq t \leq T} |u(t)|_{D_0^1}^2 \leq C \exp\left(C\Phi_0(T)\right) \tag{2.3}$$

for $t_0 \leq T < T^*$. To show this, we multiply the momentum equation (1.1) by u_t and integrate over Ω. Then using (1.2) and (1.3), we easily derive

$$\int \rho |u_t|^2 \, dx + \frac{1}{2} \frac{d}{dt} \int |\nabla u|^2 \, dx = \int \rho \left(f - u \cdot \nabla u \right) \cdot u_t \, dx$$

and

$$\int \rho |u_t|^2 \, dx + \frac{d}{dt} \int |\nabla u|^2 \, dx \leq 2 \int \rho |f|^2 \, dx + 2 \int \rho |u \cdot \nabla u|^2 \, dx. \tag{2.4}$$

On the other hand, since (u, p) is a solution of the stationary Stokes equations

$$-\Delta u + \nabla p = F \quad \text{and} \quad \operatorname{div} u = 0 \quad \text{in} \quad \Omega,$$

where $F = \rho(f - u \cdot \nabla u - u_t)$, it follows from the classical regularity theory that

$$\begin{aligned} |\nabla u|_{H^1} &\leq C \left(|F|_{L^2} + |\nabla u|_{L^2} \right) \\ &\leq C \left(|f|_{L^2} + |\sqrt{\rho} u_t|_{L^2} + |u \cdot \nabla u|_{L^2} + |\nabla u|_{L^2} \right). \end{aligned} \tag{2.5}$$

To estimate the right-hand sides of (2.4) and (2.5), we first observe that

$$|u\cdot\nabla u|_{L^2} = |u\cdot\nabla u|_{L^{2,2}} \le C|u|_{L^r_w}|\nabla u|_{L^{\frac{2r}{r-2},2}}, \tag{2.6}$$

which follows from Hölder inequality in the Lorenz spaces. See Proposition 2.1 in [18]. Next, we will show that

$$|\nabla u|_{L^{\frac{2r}{r-2},2}} \le C|\nabla u|_{L^2}^{1-\frac{3}{r}}|\nabla u|_{H^1}^{\frac{3}{r}}. \tag{2.7}$$

If $r=\infty$, then (2.7) is obvious. Assuming that $3<r<\infty$, we choose r_1 and r_2 such that $3<r_1<r<r_2<\infty$ and $\frac{2}{r}=\frac{1}{r_1}+\frac{1}{r_2}$. Then in view of Hölder and Sobolev inequalities, we have

$$|\nabla u|_{L^{\frac{2r_i}{r_i-2}}} \le |\nabla u|_{L^2}^{1-\frac{3}{r_i}}|\nabla u|_{L^6}^{\frac{3}{r_i}} \le |\nabla u|_{L^2}^{1-\frac{3}{r_i}}\left(C|\nabla u|_{H^1}\right)^{\frac{3}{r_i}}$$

for each $i=1,2$. Since $L^{\frac{2r}{r-2},2}$ is a real interpolation space of $L^{\frac{2r_2}{r_2-2}}$ and $L^{\frac{2r_1}{r_1-2}}$, more precisely, $L^{\frac{2r}{r-2},2}=(L^{\frac{2r_2}{r_2-2}},L^{\frac{2r_1}{r_1-2}})_{\frac12,2}$, it thus follows that

$$\begin{aligned}|\nabla u|_{L^{\frac{2r}{r-2},2}} &\le C|\nabla u|^{\frac12}_{L^{\frac{2r_2}{r_2-2}}}|\nabla u|^{\frac12}_{L^{\frac{2r_1}{r_1-2}}}\\ &\le C\left(|\nabla u|_{L^2}^{1-\frac{3}{r_2}}\left(C|\nabla u|_{H^1}\right)^{\frac{3}{r_2}}\right)^{\frac12}\left(|\nabla u|_{L^2}^{1-\frac{3}{r_1}}\left(C|\nabla u|_{H^1}\right)^{\frac{3}{r_1}}\right)^{\frac12},\end{aligned}$$

which proves (2.7). For some facts on the real interpolation theory and Lorenz spaces used above, we refer to sections 1.3.3 and 1.18.6 in Triebel's book [30].

The estimates (2.6) and (2.7) yield

$$|u\cdot\nabla u|_{L^2} \le C|u|_{L^r_w}|\nabla u|_{L^2}^{\frac{2}{s}}|\nabla u|_{H^1}^{\frac{3}{r}} \le \eta^{-\frac{3s}{2r}}C|u|_{L^r_w}^{\frac{s}{2}}|\nabla u|_{L^2}+\eta|\nabla u|_{H^1}$$

for any small number $\eta\in(0,1)$. Substituting this into (2.5), we obtain

$$|\nabla u|_{H^1} \le C\left(|f|_{L^2}+|\sqrt{\rho}u_t|_{L^2}+|u|_{L^r_w}^{\frac{s}{2}}|\nabla u|_{L^2}+|\nabla u|_{L^2}\right), \tag{2.8}$$

and thus

$$|u\cdot\nabla u|_{L^2} \le \eta^{-\frac{3s}{2r}}C\left(|u|_{L^r_w}^{\frac{s}{2}}+1\right)|\nabla u|_{L^2}+C|f|_{L^2}+\eta|\sqrt{\rho}u_t|_{L^2}.$$

Therefore, substituting this estimate into (2.4) and choosing a sufficiently small $\eta>0$, we conclude that

$$\frac12|\sqrt{\rho}u_t(t)|_{L^2}^2+\frac{d}{dt}|\nabla u(t)|_{L^2}^2 \le C|f(t)|_{L^2}^2+C\left(|u(t)|_{L^r_w}^s+1\right)|\nabla u(t)|_{L^2}^2 \tag{2.9}$$

for $t_0\le t<T^*$. In view of Gronwall's inequality, we have

$$\int_0^T|\sqrt{\rho}u_t(t)|_{L^2}^2\,dt+\sup_{0\le t\le T}|\nabla u(t)|_{L^2}^2 \le C\exp\left(C\Phi_0(T)\right)$$

for any T with $t_0\le T<T^*$. Combining this and (2.8), we obtain the desired estimate (2.3).

2.2. Estimates for $\operatorname{ess\,sup}_{0\le t\le T}|\sqrt{\rho}u_t(\cdot)|^2_{L^2}$ and $\int_0^T|\nabla u_t(\cdot)|^2_{D_0^1}$. To derive these estimates, we differentiate the momentum equation (1.1) with respect to time t and obtain

$$\rho u_{tt}+\rho u\cdot\nabla u_t-\Delta u_t+\nabla p_t=\rho_t(f-u_t-u\cdot\nabla u)+\rho(f_t-u_t\cdot\nabla u).$$

Then multiplying this by u_t, integrating over Ω, and using (1.2) and (1.3), we have

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int\rho|u_t|^2\,dx+\int|\nabla u_t|^2\,dx\\&\qquad=\int(\rho_t(f-u_t-u\cdot\nabla u)+\rho(f_t-u_t\cdot\nabla u))\cdot u_t\,dx.\end{aligned}\tag{2.10}$$

Note that since $\rho\in C([0,T];L^{\frac{3}{2}}\cap L^\infty)$, $\rho_t\in C([0,T];L^{\frac{3}{2}})$, and $u_t\in L^2(0,T;D_0^1)$ for any $T<T^*$, the right-hand side of (2.10) is well defined for almost all $t\in(0,T^*)$. Hence using finite differences in time, we can easily show that the identity (2.10) holds for almost all $t\in(0,T^*)$.

In view of the continuity equation (1.2) again, we deduce from (2.10) that

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int\rho|u_t|^2\,dx+\int|\nabla u_t|^2\,dx\\&\quad\le\int 2\rho|u||u_t||\nabla u_t|+\rho|u||u_t||\nabla u|^2+\rho|u|^2|u_t||\nabla^2u|\\&\qquad+\rho|u|^2|\nabla u||\nabla u_t|+\rho|u_t|^2|\nabla u|+\rho|u||u_t||\nabla f|\\&\qquad+\rho|u||f||\nabla u_t|+\rho|f_t||u_t|\ dx\equiv\sum_{j=1}^{8}I_j.\end{aligned}\tag{2.11}$$

Following the arguments in [6], we can estimate each term I_j:

$$\begin{aligned}I_1,\,I_5&\le C|\rho|^{\frac{1}{2}}_{L^\infty}|\nabla u|_{L^2}|\sqrt{\rho}u_t|_{L^3}|\nabla u_t|_{L^2}\le C|\rho|^{\frac{3}{4}}_{L^\infty}|\nabla u|_{L^2}|\sqrt{\rho}u_t|^{\frac{1}{2}}_{L^2}|\nabla u_t|^{\frac{3}{2}}_{L^2}\\&\le C|\nabla u|^4_{L^2}|\sqrt{\rho}u_t|^2_{L^2}+\frac{1}{16}|\nabla u_t|^2_{L^2},\end{aligned}$$

$$I_2,\,I_3,\,I_4\le C|\rho|_{L^\infty}|\nabla u|^2_{L^2}|\nabla u_t|_{L^2}|\nabla u|_{H^1}\le C|\nabla u|^4_{L^2}|\nabla u|^2_{H^1}+\frac{1}{16}|\nabla u_t|^2_{L^2},$$

$$I_6,\,I_7\le C|\rho|_{L^6}|\nabla u|_{L^2}|f|_{H^1}|\nabla u_t|_{L^2}\le C|\nabla u|^2_{L^2}|f|^2_{H^1}+\frac{1}{16}|\nabla u_t|^2_{L^2},$$

and finally

$$I_8\le C|\rho|_{L^3}|f_t|_{L^2}|\nabla u_t|_{L^2}\le C|f_t|^2_{L^2}+\frac{1}{16}|\nabla u_t|^2_{L^2}.$$

Substitution of these estimates into (2.11) yields

$$\begin{aligned}&\frac{d}{dt}|\sqrt{\rho}u_t|^2_{L^2}+|\nabla u_t|^2_{L^2}\\&\qquad\le C|\nabla u|^4_{L^2}\left(|\sqrt{\rho}u_t|^2_{L^2}+|\nabla u|^2_{H^1}+|f|^2_{H^1}\right)+C\left(|f|^2_{H^1}+|f_t|^2_{L^2}\right).\end{aligned}$$

Therefore, by virtue of estimate (2.3), we conclude that

$$\operatorname*{ess\,sup}_{0\le t\le T}|\sqrt{\rho}u_t(t)|_{L^2}^2+\int_0^T|\nabla u_t(t)|_{L^2}^2\,dt\le C\exp\left(C\Phi_0(T)\right) \tag{2.12}$$

for $t_0\le T<T^*$. On the other hand, using the regularity theory of the Stokes equations again, we have

$$\begin{aligned}|\nabla u|_{H^1}&\le C\left(|f|_{L^2}+|\sqrt{\rho}u_t|_{L^2}+|u\cdot\nabla u|_{L^2}+|\nabla u|_{L^2}\right)\\&\le C\left(|f|_{L^2}+|\sqrt{\rho}u_t|_{L^2}+|\nabla u|_{L^2}^{\frac{3}{2}}|\nabla u|_{H^1}^{\frac{1}{2}}+|\nabla u|_{L^2}\right)\end{aligned}$$

and

$$\begin{aligned}|\nabla u|_{H^{1,6}}&\le C\left(|u_t|_{L^6}+|u\cdot\nabla u|_{L^6}+|f|_{L^6}+|\nabla u|_{L^6}\right)\\&\le C\left(|\nabla u_t|_{L^2}+|\nabla u|_{H^1}^2+|f|_{H^1}+|\nabla u|_{H^1}\right).\end{aligned}$$

Hence it follows immediately from (2.3) and (2.12) that

$$\sup_{0\le t\le T}|u(t)|_{D_0^1\cap D^2}^2+\int_0^T|\nabla u(t)|_{H^{1,6}}^2\,dt\le C\exp\left(C\Phi_0(T)\right) \tag{2.13}$$

for $t_0\le T<T^*$.

2.3. Estimates for $\sup_{0\le t\le T}|\nabla\ (\ )|_{H^1}$ and $\int_0^T|\ (\ )|_{D^3}^2$. To derive these, we first observe that each ρ_{x_j} $(j=1,2,3)$ satisfies

$$\left(\rho_{x_j}\right)_t+u\cdot\nabla\rho_{x_j}=-u_{x_j}\cdot\nabla\rho.$$

Then multiplying this by ρ_{x_j}, integrating over Ω, and summing up, we obtain

$$\frac{d}{dt}\int|\nabla\rho|^2\,dx\le C\int|\nabla u||\nabla\rho|^2\,dx\le C|\nabla u|_{L^\infty}|\nabla\rho|_{L^2}^2.$$

A similar argument shows that

$$\begin{aligned}\frac{d}{dt}\int|\nabla^2\rho|^2\,dx&\le C\int\left(|\nabla u||\nabla^2\rho|^2+|\nabla^2u||\nabla\rho||\nabla^2\rho|\right)dx\\&\le C|\nabla u|_{L^\infty}|\nabla^2\rho|_{L^2}^2+|\nabla^2u|_{L^6}|\nabla\rho|_{L^3}|\nabla^2\rho|_{L^2}.\end{aligned}$$

Hence using Sobolev embedding results and then Gronwall's inequality, we derive the well-known estimate

$$\begin{aligned}|\nabla\rho(t)|_{H^1}&\le C\exp\left(C\int_0^t|\nabla u(\tau)|_{H^{1,6}}\,d\tau\right)\\&\le C\exp\left(\int_0^t\left(C|\nabla u(\tau)|_{H^{1,6}}^2+1\right)\,d\tau\right).\end{aligned}$$

Therefore by virtue of (2.13), we conclude that

$$\sup_{0\le t\le T}|\nabla\rho(t)|_{H^1}\le C\exp\left(C\exp\left(C\Phi_0(T)\right)\right) \tag{2.14}$$

for $t_0 \leq T < T^*$. Finally, observing from the regularity theory on the Stokes equations that

$$\begin{aligned} |u|_{D^3} &\leq C\left(|\rho u_t|_{H^1} + |\rho u \cdot \nabla u|_{H^1} + |\rho f|_{H^1}\right) \\ &\leq C\left(|\nabla\rho|_{L^3} + 1\right)\left(|\nabla u_t|_{L^2} + |\nabla u|_{H^1}^2 + |f|_{H^1}\right), \end{aligned}$$

we easily deduce from (2.3), (2.12), (2.13), and (2.14) that

$$\int_0^T |u(t)|_{D^3}^2\,dt \leq C\exp\left(C\exp\left(C\Phi_0(T)\right)\right) \tag{2.15}$$

for $t_0 \leq T < T^*$. This completes the proof of (2.1) and thus the proof of Theorem 1.3 with $m = 1$.

3. Proof of Theorem 1.3 with $\geq$ 2. Assume that $m \geq 2$. Then to prove Theorem 1.3, it suffices to show that the following estimate holds for each k, $0 \leq k < m$:

$$\Phi_{k+1}(T) \leq C\exp\left(C\exp\left(C\Phi_k(T)^{10m}\right)\right) \quad \text{for} \quad t_0 \leq T < T^*. \tag{3.1}$$

The case $k = 0$ was already proved in section 2 and so it remains to prove (3.1) for the case $1 \leq k < m$.

Let k be a fixed integer with $1 \leq k < m$. From (1.13), we recall that

$$\begin{aligned} \Phi_k(T) &= 1 + \sup_{0\leq j<k}\left(\sup_{0\leq t\leq T}|\partial_t^j u(t)|_{D_0^1\cap D^{2k-2j}} + \int_0^T |\partial_t^j u(t)|_{D^{2k-2j+1}}^2\,dt\right) \\ &\quad + \sup_{0\leq t\leq T}|\nabla\rho(t)|_{H^{2k-1}} + \operatorname{ess}\sup_{0\leq t\leq T}|\sqrt{\rho}\,\partial_t^k u(t)|_{L^2} + \int_0^T |\partial_t^k u(t)|_{D_0^1}^2\,dt \end{aligned} \tag{3.2}$$

for any $T < T^*$.

3.1. Estimates for $^{j}_{t}($ $\cdot\,\nabla$ $)$, $^{j+1}_{t}$, and $^{j}_{t}($ $)$ with $0 \leq$ $\leq$. To estimate nonlinear terms, we will make repeated use of the following simple lemma whose proof is omitted.

LEMMA 3.1. *If $g \in D_0^1 \cap D^j$, $h \in H^i$, $0 \leq i \leq j$, and $j \geq 2$, then*

$$gh \in H^i \qquad \text{and} \qquad |gh|_{H^i} \leq C|g|_{D_0^1\cap D^j}|h|_{H^i}$$

for some constant $C > 0$ depending only on j and Ω.

Using this lemma together with the fact that

$$\partial_t^j(u\cdot\nabla u) = \sum_{i=0}^{j}\frac{j!}{i!(j-i)!}\partial_t^i u\cdot\nabla\partial_t^{j-i}u,$$

we can estimate $\partial_t^j(u\cdot\nabla u)$ as follows: for $0 \leq j < k$,

$$\begin{aligned} |\partial_t^j(u\cdot\nabla u)|_{H^{2k-2j-1}} &\leq C\sum_{i=0}^{j}|\partial_t^i u\cdot\nabla\partial_t^{j-i}u|_{H^{2k-2j-1}} \\ &\leq C\sum_{i=0}^{j}|\partial_t^i u|_{D_0^1\cap D^{2k-2j}}|\nabla\partial_t^{j-i}u|_{H^{2k-2j-1}} \\ &\leq C\sum_{i=0}^{j}|\partial_t^i u|_{D_0^1\cap D^{2k-2i}}|\partial_t^{j-i}u|_{D_0^1\cap D^{2k-2(j-i)}} \end{aligned}$$

and

$$\begin{aligned}
|\partial_t^k(u\cdot\nabla u)|_{L^2} &\le C\sum_{i=0}^{k-1}|\partial_t^i u\cdot\nabla\partial_t^{k-i}u|_{L^2}+|\partial_t^k u\cdot\nabla u|_{L^2}\\
&\le C\sum_{i=0}^{k-1}|\partial_t^i u|_{D_0^1\cap D^2}|\nabla\partial_t^{k-i}u|_{L^2}+|\partial_t^k u|_{D_0^1}|\nabla u|_{H^1}\\
&\le C\sum_{i=0}^{k-1}|\partial_t^i u|_{D_0^1\cap D^{2k-2i}}|\partial_t^{k-i}u|_{D_0^1}+|\partial_t^k u|_{D_0^1}|u|_{D_0^1\cap D^2}.
\end{aligned}$$

Hence it follows from (3.2) that

$$\sup_{0\le j<k}\sup_{0\le t\le T}|\partial_t^j(u\cdot\nabla u)(t)|_{H^{2k-2j-1}}+\int_0^T|\partial_t^k(u\cdot\nabla u)(t)|_{L^2}^2\,dt\le C\Phi_k(T)^4 \tag{3.3}$$

for $t_0\le T<T^*$. Applying Lemma 3.1 to the continuity equation

$$\rho_t=-\mathrm{div}(\rho u)=-u\cdot\nabla\rho, \tag{3.4}$$

we also deduce that

$$\sup_{0\le t\le T}|\rho_t(t)|_{H^{2k-1}}\le C\Phi_k(T)^2\quad\text{for}\quad t_0\le T<T^*. \tag{3.5}$$

Using (3.4) and (3.5), we can show that

$$\sup_{1\le j<k}\sup_{0\le t\le T}|\partial_t^{j+1}\rho(t)|_{H^{2k-2j}}+\int_0^T|\partial_t^{k+1}\rho(t)|_{L^2}^2\,dt\le C\Phi_k(T)^{2k+4} \tag{3.6}$$

for $t_0\le T<T^*$. A simple inductive proof of (3.6) may be based on the observation that for $1\le j<k$,

$$\begin{aligned}
|\partial_t^{j+1}\rho|_{H^{2k-2j}} &= |-\partial_t^j(u\cdot\nabla\rho)|_{H^{2k-2j}}\\
&\le C\sum_{i=0}^{j}|\partial_t^{j-i}u\cdot\nabla\partial_t^i\rho|_{H^{2k-2j}}\\
&\le C\sum_{i=0}^{j}|\partial_t^{j-i}u|_{D_0^1\cap D^{2k-2j}}|\nabla\partial_t^i\rho|_{H^{2k-2j}}\\
&\le C\sum_{i=0}^{j}|\partial_t^{j-i}u|_{D_0^1\cap D^{2k-2(j-i)}}|\partial_t^i\rho|_{H^{2k-2(i-1)}}
\end{aligned}$$

and

$$|\partial_t^{k+1}\rho|_{L^2}\le C\sum_{i=0}^{k}|\partial_t^{k-i}u\cdot\nabla\partial_t^i\rho|_{L^2}\le C\sum_{i=0}^{k}|\partial_t^{k-i}u|_{D_0^1}|\partial_t^i\rho|_{H^2}.$$

Moreover, it follows easily from (3.6) that

$$\sup_{0\le j<k}\sup_{0\le t\le T}|\partial_t^j(\rho u)(t)|_{H^{2k-2j}}+\int_0^T|\partial_t^k(\rho u)(t)|_{H^1}^2\,dt\le C\Phi_k(T)^{4k+10} \tag{3.7}$$

for $t_0 \le T < T^*$. Finally, recalling that

$$\partial_t^{k+1} f \in L^2(0,\infty; L^2) \quad \text{and} \quad \partial_t^j f \in L^2(0,\infty; H^{2k-2j+1}) \quad \text{for} \quad 0 \le j \le k,$$

we deduce from standard embedding results that

$$\partial_t^j f \in C([0,\infty); H^{2k-2j}) \quad \text{for} \quad 0 \le j \le k.$$

3.2. Estimates for $\int_0^T |\sqrt{\ }\ {}^{k+1}_{t}\ (\ )|^2_{L^2}$ and $\sup_{0\le t\le T} |\ {}^{k}_{t}\ (\ )|_{D_0^1}$. From the momentum equation (1.1), we derive

$$\rho \left(\partial_t^k u\right)_t - \Delta \partial_t^k u + \nabla \partial_t^k p = \partial_t^k(\rho f - \rho u \cdot \nabla u) + \left(\rho \partial_t^k u_t - \partial_t^k(\rho u_t)\right).$$

Hence multiplying this by $\partial_t^{k+1} u$ and integrating over Ω, we have

$$\begin{aligned} &\int \rho |\partial_t^{k+1} u|^2 \, dx + \frac{1}{2} \frac{d}{dt} \int |\nabla \partial_t^k u|^2 \, dx \\ &\quad = \int \left(\partial_t^k(\rho f - \rho u \cdot \nabla u) + \left(\rho \partial_t^k u_t - \partial_t^k(\rho u_t)\right)\right) \cdot \partial_t^{k+1} u \, dx \\ &\quad = I_{0,1} + \sum_{j=1}^{k} \frac{k!}{j!(k-j)!} \left(I_{j,1} + I_{j,2}\right), \end{aligned} \tag{3.8}$$

where

$$I_{j,1} = \int \partial_t^j \rho \, \partial_t^{k-j}(f - u \cdot \nabla u) \cdot \partial_t^{k+1} u \, dx, \quad I_{j,2} = -\int \partial_t^j \rho \, \partial_t^{k-j} u_t \cdot \partial_t^{k+1} u \, dx.$$

We easily estimate $I_{0,1}$ as follows:

$$\begin{aligned} I_{0,1} &\le |\rho|_{L^\infty}^{\frac{1}{2}} \left(|\partial_t^k f|_{L^2} + |\partial_t^k (u \cdot \nabla u)|_{L^2}\right) |\sqrt{\rho} \partial_t^{k+1} u|_{L^2} \\ &\le C \left(|\partial_t^k f|_{L^2}^2 + |\partial_t^k (u \cdot \nabla u)|_{L^2}^2\right) + \frac{1}{2} |\sqrt{\rho} \partial_t^{k+1} u|_{L^2}^2. \end{aligned}$$

To estimate $I_{j,1}$ for $1 \le j \le k$, we rewrite it as

$$\begin{aligned} I_{j,1} = &\frac{d}{dt} \int \partial_t^j \rho \, \partial_t^{k-j}(f - u \cdot \nabla u) \cdot \partial_t^k u \, dx - \int \partial_t^{j+1} \rho \, \partial_t^{k-j}(f - u \cdot \nabla u) \cdot \partial_t^k u \, dx \\ &- \int \partial_t^j \rho \, \partial_t^{k-j+1}(f - u \cdot \nabla u) \cdot \partial_t^k u \, dx \end{aligned}$$

and observe that

$$\begin{aligned} &- \int \partial_t^{j+1} \rho \, \partial_t^{k-j}(f - u \cdot \nabla u) \cdot \partial_t^k u \, dx \\ &\quad \le C \left(|\partial_t^{k-j} f|_{H^1}^2 + |\partial_t^{k-j}(u \cdot \nabla u)|_{H^1}^2\right) |\partial_t^{j+1} \rho|_{L^2}^2 + |\nabla \partial_t^k u|_{L^2}^2 \end{aligned}$$

and

$$\begin{aligned} &- \int \partial_t^j \rho \, \partial_t^{k-j+1}(f - u \cdot \nabla u) \cdot \partial_t^k u \, dx \\ &\quad \le C |\partial_t^j \rho|_{H^1}^2 \left(|\partial_t^{k-j+1} f|_{L^2}^2 + |\partial_t^{k-j+1}(u \cdot \nabla u)|_{L^2}^2\right) + |\nabla \partial_t^k u|_{L^2}^2. \end{aligned}$$

Using the continuity equation (1.2), we can also estimate $I_{j,2}$ as follows:

$$\begin{aligned} I_{1,2} &= -\int \rho_t \left(\frac{1}{2}|\partial_t^k u|^2\right)_t dx = -\frac{d}{dt}\int \rho_t \frac{1}{2}|\partial_t^k u|^2\,dx + \int \partial_t^2\rho \frac{1}{2}|\partial_t^k u|^2\,dx \\ &= -\frac{d}{dt}\int \rho u\cdot\nabla\left(\frac{1}{2}|\partial_t^k u|^2\right)dx + \int \partial_t(\rho u)\cdot\nabla\left(\frac{1}{2}|\partial_t^k u|^2\right)dx \\ &\leq -\frac{d}{dt}\int (\rho u\cdot\nabla\partial_t^k u)\cdot\partial_t^k u\,dx + C|\partial_t(\rho u)|_{H^1}|\nabla\partial_t^k u|_{L^2}^2 \end{aligned}$$

and similarly

$$\begin{aligned} I_{j,2} &= -\frac{d}{dt}\int \partial_t^j\rho\,\partial_t^{k-j}u_t\cdot\partial_t^k u\,dx + \int\left(\partial_t^{j+1}\rho\,\partial_t^{k-j}u_t + \partial_t^j\rho\,\partial_t^{k-j+1}u_t\right)\cdot\partial_t^k u\,dx \\ &\leq -\frac{d}{dt}\int \partial_t^{j-1}(\rho u)\cdot\nabla\left(\partial_t^{k-j+1}u\cdot\partial_t^k u\right)dx \\ &\quad + C\left(|\partial_t^j(\rho u)|_{H^1}|\nabla\partial_t^{k-j+1}u|_{L^2} + |\partial_t^{j-1}(\rho u)|_{H^1}|\nabla\partial_t^{k-j+2}u|_{L^2}\right)|\nabla\partial_t^k u|_{L^2} \end{aligned}$$

for $2\leq j\leq k$. Substituting all the estimates into (3.8), we have

$$\begin{aligned} &\frac{1}{2}\int \rho|\partial_t^{k+1}u|^2\,dx + \frac{1}{2}\frac{d}{dt}\int|\nabla\partial_t^k u|^2\,dx \\ &\quad\leq \frac{d}{dt}\int\left(\sum_{j=1}^k \frac{k!}{j!(k-j)!}\partial_t^j\rho\partial_t^{k-j}(f-u\cdot\nabla u)\cdot\partial_t^k u - (\rho u\cdot\nabla\partial_t^k u)\cdot\partial_t^k u\right)dx \\ &\quad\quad -\frac{d}{dt}\int\sum_{j=2}^k\frac{k!}{j!(k-j)!}\partial_t^{j-1}(\rho u)\cdot\nabla\left(\partial_t^{k-j+1}u\cdot\partial_t^k u\right)dx \\ &\quad\quad + C\sum_{j=1}^{k-1}\left(|\partial_t^j(\rho u)|_{H^1}^2 + |\partial_t^{j+1}\rho|_{H^1}^2\right)\left(|\partial_t^{k-j}f|_{H^1}^2 + |\partial_t^{k-j}(u\cdot\nabla u)|_{H^1}^2 + |\partial_t^{k-j+1}u|_{D_0^1}^2\right) \\ &\quad\quad + C|\partial_t^{k+1}\rho|_{L^2}^2\left(|f|_{H^1}^2 + |u|_{D_0^1\cap D^2}^2\right) + C\left(1+|\partial_t\rho|_{H^1}^2\right)\left(|\partial_t^k f|_{L^2}^2 + |\partial_t^k(u\cdot\nabla u)|_{L^2}^2\right) \\ &\quad\quad + C|\partial_t^k(\rho u)|_{H^1}^2 + C\left(1+|\partial_t(\rho u)|_{H^1}^2 + |\nabla\partial_t u|_{L^2}^2\right)|\nabla\partial_t^k u|_{L^2}^2. \end{aligned}$$

Hence, integrating this in time over (t_0,T) and using (3.3), (3.5), (3.6), and (3.7) together with the estimates

$$\begin{aligned} &\int |\partial_t^j\rho||\partial_t^{k-j}(f-u\cdot\nabla u)||\partial_t^k u|\,dx \\ &\quad\leq \eta^{-1}|\partial_t^j\rho|_{H^1}^2|\partial_t^{k-j}(f-u\cdot\nabla u)|_{L^2}^2 + \eta|\nabla\partial_t^k u|_{L^2}, \end{aligned}$$

$$\int\rho|u||\nabla\partial_t^k u||\partial_t^k u|\,dx \leq \eta^{-3}C|\rho|_{L^\infty}^3|\nabla u|_{L^2}^4|\sqrt{\rho}\partial_t^k u|_{L^2}^2 + \eta|\nabla\partial_t^k u|_{L^2}^2$$

and

$$\begin{aligned} &\int|\partial_t^{j-1}(\rho u)|\left(|\nabla\partial_t^{k-j+1}u||\partial_t^k u| + |\partial_t^{k-j+1}u||\nabla\partial_t^k u|\right)dx \\ &\quad\leq \eta^{-1}C|\partial_t^{j-1}(\rho u)|_{H^1}^2|\nabla\partial_t^{k-j+1}u|_{L^2}^2 + \eta|\nabla\partial_t^k u|_{L^2}, \end{aligned}$$

where η is any small positive number, we deduce that

$$\begin{aligned}&\int_{t_0}^{T} |\sqrt{\rho}\partial_t^{k+1}u(t)|_{L^2}^2\,dt + |\nabla\partial_t^k u(T)|_{L^2}^2\\ &\qquad\le C\Phi_k(T)^{20m} + C\int_{t_0}^{T}\left(1+|\partial_t(\rho u)(t)|_{H^1}^2 + |u_t(t)|_{D_0^1}^2\right)|\nabla\partial_t^k u(t)|_{L^2}^2\,dt\end{aligned}$$

for $t_0 \le T < T^*$. Note that

$$\int_{t_0}^{T}\left(1+|\partial_t(\rho u)(t)|_{H^1}^2 + |u_t(t)|_{D_0^1}^2\right)dt \le C\Phi_k(T)^{10m}.$$

Therefore, in view of Gronwall's inequality, we conclude that

$$\int_0^T |\sqrt{\rho}\partial_t^{k+1}u(t)|_{L^2}^2\,dt + \sup_{0\le t\le T}|\partial_t^k u(t)|_{D_0^1}^2 \le C\exp\left(C\Phi_k(T)^{10m}\right) \tag{3.9}$$

for any T with $t_0 \le T < T^*$.

3.3. Estimates for $\operatorname{ess\,sup}_{0\le t\le T}|\sqrt{\ }\ {}_t^{k+1}\ (\ )|_{L^2}$ and $\int_0^T|\ {}_t^{k+1}\ (\ )|_{D_0^1}^2$.
From the momentum equation (1.1), it follows that

$$\begin{aligned}&\rho\left(\partial_t^{k+1}u\right)_t + \rho u\cdot\nabla\partial_t^{k+1}u - \Delta\partial_t^{k+1}u + \nabla\partial_t^{k+1}p\\ &\quad= \partial_t^{k+1}(\rho f) + \left(\rho\partial_t^{k+1}u_t - \partial_t^{k+1}(\rho u_t)\right) + \left(\rho u\cdot\nabla\partial_t^{k+1}u - \partial_t^{k+1}(\rho u\cdot\nabla u)\right).\end{aligned}$$

Multiplying this by $\partial_t^{k+1}u$ and integrating over Ω, we have

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int\rho|\partial_t^{k+1}u|^2\,dx + \int|\nabla\partial_t^{k+1}u|^2\,dx\\ &\quad= \int\partial_t^{k+1}(\rho f)\cdot\partial_t^{k+1}u\,dx + \int\left(\rho\partial_t^{k+1}u_t - \partial_t^{k+1}(\rho u_t)\right)\cdot\partial_t^{k+1}u\,dx\\ &\qquad+\int\left(\rho u\cdot\nabla\partial_t^{k+1}u - \partial_t^{k+1}(\rho u\cdot\nabla u)\right)\cdot\partial_t^{k+1}u\,dx.\end{aligned}\tag{3.10}$$

This identity can be derived rigorously by using a standard finite difference method because if $0 < T < T^*$, then $\partial_t^m\rho \in L^2(0,T;L^{\frac{3}{2}}\cap L^2)$ and $\partial_t^j\rho \in C([0,T];L^{\frac{3}{2}}\cap L^\infty)$ for $0 \le j < m$. The first term of the right-hand side in (3.10) is bounded by

$$\begin{aligned}&C\sum_{j=0}^{k}\int|\partial_t^j\rho||\partial_t^{k-j+1}f||\partial_t^{k+1}u|\,dx + \int|\partial_t^{k+1}\rho||f||\partial_t^{k+1}u|\,dx\\ &\qquad\le C\sum_{j=0}^{k}|\partial_t^j\rho|_{H^1}^2|\partial_t^{k-j+1}f|_{L^2}^2 + C|\partial_t^{k+1}\rho|_{L^2}^2|f|_{H^1}^2 + \frac{1}{6}|\nabla\partial_t^{k+1}u|_{L^2}^2.\end{aligned}$$

In view of the continuity equation (1.2), we can rewrite the second term as

$$\begin{aligned}&-\sum_{j=1}^{k+1}\frac{(k+1)!}{j!(k-j+1)!}\int\partial_t^j\rho\,\partial_t^{k-j+1}u_t\cdot\partial_t^{k+1}u\,dx\\ &\qquad= -\sum_{j=1}^{k+1}\frac{(k+1)!}{j!(k-j+1)!}\int\partial_t^{j-1}(\rho u)\cdot\nabla\left(\partial_t^{k-j+2}u\cdot\partial_t^{k+1}u\right)dx,\end{aligned}$$

which is bounded by

$$C|\rho|_{L^\infty}|u|^2_{D_0^1\cap D^2}|\sqrt{\rho}\partial_t^{k+1}u|^2_{L^2}+C\sum_{j=1}^{k}|\partial_t^j(\rho u)|^2_{H^1}|\partial_t^{k-j+1}u|^2_{D_0^1}+\frac{1}{6}|\nabla\partial_t^{k+1}u|^2_{L^2}.$$

Finally, the last term is bounded by

$$\begin{aligned}
C\sum_{j=1}^{k}\int|\partial_t^j(\rho u)||\nabla\partial_t^{k-j+1}u||\partial_t^{k+1}u|\,dx+\int|\partial_t^{k+1}(\rho u)||\nabla u||\partial_t^{k+1}u|\,dx&\\
\le C\sum_{j=1}^{k}\left(|\partial_t^j(\rho u)|^2_{H^1}+|\partial_t^j\rho|^2_{H^1}|u|^2_{D_0^1\cap D^2}\right)|\partial_t^{k-j+1}u|^2_{D_0^1}+C|\partial_t^{k+1}\rho|^2_{L^2}|u|^4_{D_0^1\cap D^2}&\\
+C|\rho|_{L^\infty}|u|^2_{D_0^1\cap D^2}|\sqrt{\rho}\partial_t^{k+1}u|^2_{L^2}+\frac{1}{6}|\nabla\partial_t^{k+1}u|^2_{L^2}.&
\end{aligned}$$

Hence substituting these estimates into (3.10), we have

$$\begin{aligned}
&\frac{d}{dt}\int\rho|\partial_t^{k+1}u|^2\,dx+\int|\nabla\partial_t^{k+1}u|^2\,dx\\
&\quad\le C\left(1+|u|^2_{D_0^1\cap D^2}\right)|\sqrt{\rho}\partial_t^{k+1}u|^2_{L^2}+C\sum_{j=0}^{k}|\partial_t^j\rho|^2_{H^1}|\partial_t^{k-j+1}f|^2_{L^2}+C|\partial_t^{k+1}\rho|^2_{L^2}|f|^2_{H^1}\\
&\qquad+C\sum_{j=1}^{k}\left(|\partial_t^j(\rho u)|^2_{H^1}+|\partial_t^j\rho|^2_{H^1}|u|^2_{D_0^1\cap D^2}\right)|\partial_t^{k-j+1}u|^2_{D_0^1}+C|\partial_t^{k+1}\rho|^2_{L^2}|u|^4_{D_0^1\cap D^2}.
\end{aligned}$$

Therefore, by virtue of (3.5), (3.6), (3.7), and (3.9), we conclude that

$$\text{(3.11)}\quad \operatorname*{ess\,sup}_{0\le t\le T}|\sqrt{\rho}\,\partial_t^{k+1}u(t)|_{L^2}+\int_0^T|\partial_t^{k+1}u(t)|^2_{D_0^1}\,dt\le C\exp\left(C\Phi_k(T)^{10m}\right)$$

for any T with $t_0\le T<T^*$.

3.4. Estimates for $\sup_{0\le t\le T}|\ {}^{j}_{t}\ (\ )|_{D_0^1\cap D^{2k-2j+2}}$ with $0\le\ \ \le\ $. To derive these estimates, we observe that

$$\text{(3.12)}\quad \partial_t^j u\in C([0,T^*);D^1_{0,\sigma})\quad\text{and}\quad -\Delta\partial_t^j u+\nabla\partial_t^j p=\partial_t^j(\rho f-\rho u\cdot\nabla u-\rho u_t)$$

for each $j\le k$. From (3.5), (3.6), (3.9), and (3.11), it follows easily that

$$\operatorname*{ess\,sup}_{0\le t\le T}\left(|\partial_t^k(\rho u\cdot\nabla u)(t)|_{L^2}+|\partial_t^k(\rho u_t)(t)|_{L^2}\right)\le C\exp\left(C\Phi_k(T)^{10m}\right)$$

for $t_0\le T<T^*$. Hence applying the regularity theory of the Stokes equations to (3.12) with $j=k$, we obtain

$$\sup_{0\le t\le T}|\partial_t^k u(t)|_{D_0^1\cap D^2}\le C\exp\left(C\Phi_k(T)^{10m}\right)\quad\text{for } t_0\le T<T^*.$$

It also follows from the Stokes regularity theory that for $0\le j<k$,

$$\text{(3.13)}\qquad |\partial_t^j u|_{D_0^1\cap D^{2k-2j+2}}\le C|\partial_t^j(\rho f-\rho u\cdot\nabla u-\rho u_t)|_{H^{2k-2j}}+C|\partial_t^j u|_{D_0^1}.$$

Using the estimates in section 3.1, we can estimate the first term of the right-hand side in (3.13) as follows:

$$\begin{aligned} &C|\partial_t^j(\rho f - \rho u\cdot\nabla u - \rho u_t)(t) + \rho\partial_t^j(u\cdot\nabla u + u_t)(t)|_{H^{2k-2j}} \\ &\quad\le C|\rho\partial_t^j f(t)|_{H^{2k-2j}} + C\sum_{i=1}^{j}|\partial_t^i\rho\partial_t^{j-i}(f - u\cdot\nabla u - u_t)(t)|_{H^{2k-2j}} \\ &\quad\le C\exp\left(C\Phi_k(T)^{10m}\right), \end{aligned}$$

$$\begin{aligned} &C|\rho\partial_t^j(u\cdot\nabla u)(t)|_{H^{2k-2j}} \\ &\quad\le C\sum_{i=1}^{j}|\rho\partial_t^i u\cdot\nabla\partial_t^{j-i}u(t)|_{H^{2k-2j}} + C|\rho u\cdot\nabla\partial_t^j u(t)|_{H^{2k-2j}} \\ &\quad\le C\exp\left(C\Phi_k(T)^{10m}\right) + C|\rho(t)|_{H^{2k}}|u(t)|_{D_0^1\cap D^{2k}}|\partial_t^j u(t)|_{D_0^1\cap D^{2k-2j+1}} \\ &\quad\le C\exp\left(C\Phi_k(T)^{10m}\right) + \frac{1}{2}|\partial_t^j u(t)|_{D_0^1\cap D^{2k-2j+2}} \end{aligned}$$

and

$$C|\rho\partial_t^j u_t(t)|_{H^{2k-2j}} \le C|\rho(t)|_{H^{2k}}|\partial_t^{j+1}u(t)|_{D_0^1\cap D^{2k-2j}}.$$

Substituting these into (3.13), we deduce that

$$|\partial_t^j u(t)|_{D_0^1\cap D^{2k-2j+2}} \le C\exp\left(C\Phi_k(T)^{10m}\right)\left(1 + |\partial_t^{j+1}u(t)|_{D_0^1\cap D^{2k-2j}}\right).$$

Therefore, by a backward induction on j, we conclude that

$$\sup_{0\le j<k+1}\sup_{0\le t\le T}|\partial_t^j u(t)|_{D_0^1\cap D^{2k-2j+2}} \le C\exp\left(C\Phi_k(T)^{10m}\right). \tag{3.14}$$

3.5. Estimates for $\sup_{0\le t\le T}|\nabla\ (\ )|_{H^{2k+1}}$ and $\int_0^T|\ {}_t^j\ (\ )|^2_{D^{2k-2j+3}}$ with $\le$. Let α be a multi-index with $1\le|\alpha|\le 2k+2$. Then taking the differential operator D^α to the continuity equation (1.2), we have

$$(D^\alpha\rho)_t + u\cdot\nabla(D^\alpha\rho) = u\cdot\nabla(D^\alpha\rho) - D^\alpha(u\cdot\nabla\rho).$$

Multiplying this by $D^\alpha\rho$ and integrating over Ω, we obtain

$$\frac{d}{dt}\int|D^\alpha\rho|^2\,dx \le C\int|u\cdot\nabla(D^\alpha\rho) - D^\alpha(u\cdot\nabla\rho)||D^\alpha\rho|\,dx. \tag{3.15}$$

But since

$$|u\cdot\nabla(D^\alpha\rho) - D^\alpha(u\cdot\nabla\rho)| \le C\sum_{l=1}^{|\alpha|}\left|\nabla^{|\alpha|+1-l}u\right|\left|\nabla^l\rho\right|,$$

Hölder and Sobolev inequalities yield

$$\begin{aligned} |u\cdot\nabla(D^\alpha\rho) - D^\alpha(u\cdot\nabla\rho)|_{L^2} &\le C\left(|\nabla u|_{H^{2k+1}}|\nabla\rho|_{H^{2k+1}} + |\nabla u|_{L^\infty}|\nabla\rho|_{H^{2k+1}}\right) \\ &\le C|\nabla u|_{H^{2k+1}}|\nabla\rho|_{H^{2k+1}}. \end{aligned}$$

Hence from (3.15), we derive the standard estimate

$$\frac{d}{dt}|\nabla\rho|^2_{H^{2k+1}} \le C|u|_{D_0^1\cap D^{2k+2}}|\nabla\rho|^2_{H^{2k+1}},$$

which implies then that

$$\sup_{0\le t\le T}|\nabla\rho(t)|_{H^{2k+1}} \le |\nabla\rho_0|_{H^{2k+1}}\exp\left(C\int_0^T |u(t)|_{D_0^1\cap D^{2k+2}}\,dt\right).$$

Therefore, by virtue of (3.14), we conclude that

$$\sup_{0\le t\le T}|\nabla\rho(t)|_{H^{2k+1}} \le C\exp\left(C\exp\left(C\Phi_k(T)^{10m}\right)\right)$$

for any T with $t_0 \le T < T^*$. Finally, applying the Stokes regularity theory to (3.12) for each j and arguing by induction on $k-j$, we easily show that

$$\sup_{0\le j<k+1}\int_0^T |\partial_t^j u(t)|^2_{D^{2k-2j+3}}\,dt \le C\exp\left(C\exp\left(C\Phi_k(T)^{10m}\right)\right)$$

for any T with $t_0 \le T < T^*$. This completes the proof of (3.1) and so we have completed the proof of Theorem 1.3.

4. Proof of Theorem 1.5. Let (ρ,u) be a strong solution satisfying the regularity (1.8) for some $T>0$. Assume that $|\rho_0|_{L^{\frac32}\cap L^\infty} \le K$ for some constant $K>1$. Then it follows easily from (1.2) and (1.3) that

$$|\rho(t)|_{L^{\frac32}\cap L^\infty} = |\rho_0|_{L^{\frac32}\cap L^\infty} \le K \quad \text{for} \quad 0\le t\le T.$$

Moreover, from the energy equality

$$\frac12\frac{d}{dt}\int\rho|u|^2\,dx + \int|\nabla u|^2\,dx = \int\rho f\cdot u\,dx,$$

we derive

$$|\sqrt{\rho}u(t)|^2_{L^2} + \int_0^t |\nabla u(\tau)|^2_{L^2}\,d\tau \le |\sqrt{\rho}_0u_0|^2_{L^2} + C\int_0^t |\rho(\tau)|^2_{L^3}|f(\tau)|^2_{L^2}\,d\tau,$$

and thus

$$\int_0^T |\nabla u(\tau)|^2\,d\tau \le C_K\left(|\nabla u_0|^2_{L^2} + \int_0^\infty |f(\tau)|^2_{L^2}\,d\tau\right). \tag{4.1}$$

Throughout the proof, we denote by $C_K>1$ a generic constant dependent only on K and Ω but independent of time T. On the other hand, from the estimate (2.9) with $(r,s)=(6,4)$, it follows that

$$|\nabla u(t)|^2_{L^2} \le |\nabla u_0|^2_{L^2} + C_K\int_0^t |f(\tau)|^2_{L^2}\,d\tau + C_K\int_0^t \left(|u(\tau)|^4_{L^6_w}+1\right)|\nabla u(\tau)|^2_{L^2}\,d\tau$$

for $0\le t\le T$. Hence by virtue of the estimate (4.1) and Sobolev inequality (1.5), we have

$$|\nabla u(t)|^2_{L^2} \le C_K\left(\sup_{0<\tau<t}|\nabla u(\tau)|^4_{L^2}+1\right)\left(|\nabla u_0|^2_{L^2} + \int_0^\infty |f(\tau)|^2_{L^2}\,d\tau\right) \tag{4.2}$$

for $0 < t \le T$. Let us choose a positive constant ε such that

$$0 < \varepsilon < 1 \qquad \text{and} \qquad 6C_K\varepsilon^2 < 1.$$

We now prove the global existence of a strong solution under the assumption that $|\nabla u_0|_{L^2} \le \varepsilon$ and $\int_0^\infty |f(\tau)|_{L^2}^2\, d\tau \le \varepsilon^2$. The local existence of a unique solution (ρ, u) was already proved in [6] (see also [7]). To prove the global existence, we argue by contradiction. Assume that (ρ, u) blows up at some finite time T^*, $0 < T^* < \infty$. Then since (ρ, u) satisfies the regularity (1.8) for any $T < T^*$, it follows from (4.2) that

$$|\nabla u(t)|_{L^2}^2 \le \frac{1}{3}\left(\sup_{0<\tau<t} |\nabla u(\tau)|_{L^2}^4 + 1\right) \quad \text{for} \quad 0 < t < T^*. \tag{4.3}$$

Note that $|\nabla u_0|_{L^2}^2 < 1$ and $u \in C([0,T^*); D_0^1)$. Hence from (4.3), we easily deduce that $|\nabla u(t)|_{L^2}^2 < 1$ for any $0 \le t < T^*$. Therefore, in view of Sobolev embedding again, we conclude that

$$\int_0^{T^*} |u(t)|_{L^6_w}^4\, dt \le C \int_0^{T^*} |\nabla u(t)|_{L^2}^4\, dt < \infty,$$

which contradicts Theorem 1.3. This completes the proof of Theorem 1.5.

Acknowledgments. The author would like to express his deep gratitude to Professor Hideo Kozono for very helpful discussion on the weak spaces. The author is also grateful to the referees for several valuable comments on the paper.

HOMOGENIZATION OF QUASICONVEX INTEGRALS VIA THE PERIODIC UNFOLDING METHOD*

DOINA CIORANESCU†, ALAIN DAMLAMIAN‡, AND RICCARDO DE ARCANGELIS§

Abstract. The homogenization problem in the general case of quasiconvex integral energies with polynomial growth, defined on vector-valued configurations, was studied by the Γ-convergence methods in [A. Braides, *Rend. Accad. Naz. Sci.* XL *Mem. Mat.* (5), 9 (1985), pp. 313–321] and [S. Müller, *Arch. Rational Mech. Anal.*, 99 (1987), pp. 189–212]. This paper presents a new proof by means of the periodic unfolding method introduced in [D. Cioranescu, A. Damlamian, and G. Griso, *C. R. Math. Acad. Sci. Paris*, 335 (2002), pp. 99–104]. It is an elementary proof since it reduces the homogenization process to a weak convergence problem in an L^p-type space.

Key words. homogenization, quasiqconvexity, periodic unfolding method

AMS subject classifications. 49J45, 35B27, 74Q05

DOI. 10.1137/040620898

Introduction. The homogenization of periodic structures was carried out in the last 30 years for various kinds of problems involving differential equations and systems, as well as integral energies. Starting from the basic works [DGS], [BLP], [MT], several methods and techniques were developed to approach the analytic study of the asymptotic behavior of such structures, thus generating a great range of results in different settings and a wide bibliography; cf., for example, the volumes [At], [BP], [BD], [CDA], [CD], [DM], [JKO], [SP]. In particular, various kinds of problems concerning both scalar-valued and vector-valued configurations were considered also for convex and nonconvex energies. Among the various tools, we recall the two-scale method introduced in [N] (and used in [A]) and the "dilation" operation introduced in [ADH] (to study the homogenization of periodic media with double porosity).

The periodic unfolding method, proposed for the study of the homogenization of multiscale periodic problems in [CDG] combines the dilation technique with ideas from finite elements approximations. This approach reduces two-scale convergence to a mere weak convergence in an appropriate space.

The present paper is part of a series of ongoing work concerning the applications of the periodic unfolding method to homogenization. The first part in the series, [CDDA], considers the periodic homogenization of nonlinear integrals with convex densities and polynomial growth. It recovers the well-known homogenization results already established in [M1] and [CS], and various types of limit formulas, via weak convergence in a space of type L^p.

Here, we study the homogenization problem in the general case of quasiconvex integral energies defined on vector-valued configurations. For such energies, the homogenization result was originally obtained, under p-growth assumptions, by sophisticated Γ-convergence arguments (see [B] and [Mu]). Since then, many attempts at simplifying the proofs (for example, by using two-scale convergence) seem not to have borne fruit. Using the unfolding method, we propose a direct approach which, again, reduces to weak convergence in L^p spaces.

Homogenization processes for integral functionals defined on vector-valued configurations are particularly interesting in applications, since they describe various physical situations in nonlinear elasticity. For example, the study of the overall behavior of cellular elastic materials with very fine structure can be developed in the framework of the homogenization of the corresponding stored energy functionals, defined on the set of the admissible deformations and whose densities are quasiconvex. Indeed, as the structure of the material becomes finer and finer, it behaves more and more like a limit material, whose energy is just the one produced by the homogenization process.

Let m and n be positive integers. We denote by Y the unit reference cell $]0,1[^n$ and by $\mathcal{A}_0$ the class of all bounded open subsets of $\mathbb{R}^n$ with Lipschitz boundary.

Let f be a Carathéodory energy density, i.e., a function satisfying

$$\text{(0.1)}\qquad \begin{cases} f\colon (y,z)\in\mathbb{R}^n\times\mathbb{R}^{nm}\mapsto f(y,z)\in[0,+\infty[, \\ f(\cdot,z) \text{ Lebesgue measurable and } Y\text{-periodic for every } z\in\mathbb{R}^{nm}, \\ f(y,\cdot) \text{ continuous for a.e. } x\in\mathbb{R}^n. \end{cases}$$

Assume furthermore that

$$\text{(0.2)}\qquad f(y,\cdot) \text{ is quasiconvex for a.e. } y\in\mathbb{R}^n$$

(cf. section 1.2 below for the definition of quasiconvexity).

For $p\in[1,+\infty[$, $M>0$, and a Y-periodic $a\in L^1(Y)$, we consider the following growth conditions:

$$\text{(0.3)}\qquad f(y,z)\le a(y)+M|z|^p \quad \text{for a.e. } y\in\mathbb{R}^n \text{ and every } z\in\mathbb{R}^{nm},$$

$$\text{(0.4)}\qquad |z|^p\le f(y,z) \quad \text{for a.e. } y\in\mathbb{R}^n \text{ and every } z\in\mathbb{R}^{nm},$$

the first of which is slightly more general that the corresponding ones in [B] and [Mu].

Our purpose, for each $\Omega\in\mathcal{A}_0$ and every $\{\varepsilon_h\}\subseteq\,]0,+\infty[$ converging to 0, is to find the limit, as h goes to infinity, of the sequence of functionals

$$u\in W^{1,p}(\Omega;\mathbb{R}^m)\mapsto \int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u\Big)\,\mathrm{d}x.$$

We start in section 1 by recalling the result of Castaing on the existence of measurable selections of measurable multivalued functions (Theorem 1.1), together with some basic facts concerning the periodic unfolding method (Theorem 1.7), as well as an essential approximation result (Lemma 1.8) due to De Giorgi.

The convergence results are established in section 2. As in [B] and [Mu], we first prove that the limit below exists for every $z\in\mathbb{R}^{nm}$, thus defining the homogenized energy density f_{hom},

$$\text{(0.5)}\quad f_{\mathrm{hom}}\colon z\in\mathbb{R}^{nm}\mapsto \lim_{t\to+\infty}\frac{1}{t^n}\inf\Big\{\int_{tY} f(y,z+\nabla v)\,\mathrm{d}y : v\in W_0^{1,p}(tY;\mathbb{R}^m)\Big\}.$$

Then, in Theorem 2.5 we show that for every $\Omega \in \mathcal{A}_0$ and $u \in W^{1,p}(\Omega;\mathbb{R}^m)$,

$$\begin{aligned}
&\inf\left\{\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x : \{u_h\}\subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ u_h\to u \text{ in } L^p(\Omega;\mathbb{R}^m)\right\}\\
&\quad=\inf\left\{\limsup_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x :\right.\\
&\qquad\qquad\left.\{u_h\}\subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ u_h\to u \text{ in } L^p(\Omega;\mathbb{R}^m)\right\}\\
&\quad=\int_\Omega f_{\mathrm{hom}}(\nabla u)\,\mathrm{d}x.
\end{aligned}$$

Finally, Lemma 1.8 allows to complete the proof of Theorem 2.5, in the sense that for every Ω in $\mathcal{A}_0$ and u in $W^{1,p}(\Omega;\mathbb{R}^m)$,

$$\begin{aligned}
&\inf\left\{\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x : \{u_h\}\subseteq u+W_0^{1,p}(\Omega;\mathbb{R}^m),\ u_h\to u \text{ in } L^p(\Omega;\mathbb{R}^m)\right\}\\
&\quad=\inf\left\{\limsup_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x :\right.\\
&\qquad\qquad\left.\{u_h\}\subseteq u+W_0^{1,p}(\Omega;\mathbb{R}^m),\ u_h\to u \text{ in } L^p(\Omega;\mathbb{R}^m)\right\}\\
&\quad=\int_\Omega f_{\mathrm{hom}}(\nabla u)\,\mathrm{d}x.
\end{aligned}$$

In the convex case, i.e., when the condition

$$f(x,\cdot) \text{ is convex for a.e. } x\in\mathbb{R}^n \tag{0.6}$$

replaces hypothesis (0.2), the proof becomes even simpler. The result is stated in Theorem 3.1.

1. Preliminary results. For every $\Omega \in \mathcal{A}_0$, we denote by $\mathcal{L}(\Omega)$ the σ-algebra of the Lebesgue measurable subsets of Ω, and, for every $S \in \mathcal{L}(\Omega)$, by $|S|$ the n-dimensional Lebesgue measure of S.

By $\mathcal{L}(\Omega)\times\mathcal{L}(Y)$ we denote the product σ-algebra of $\mathcal{L}(\Omega)$ and $\mathcal{L}(Y)$. We recall that (cf., for example, Theorems III.11.17 and III.2.22 in [DS]), if $\Omega\in\mathcal{A}_0$ and $U \in L^1(\Omega;L^1(Y))$, then there exists an $\mathcal{L}(\Omega)\times\mathcal{L}(Y)$-measurable function $\widetilde{U}\colon\Omega\times Y\to\mathbb{R}$, uniquely determined up to a subset in $\mathcal{L}(\Omega)\times\mathcal{L}(Y)$ of zero measure, such that $\widetilde{U}(x,\cdot)=U(x)$ for a.e. $x\in\Omega$. Moreover, if $p\in[1,+\infty[$ and $U\in L^p(\Omega;L^p(Y))$, then $\widetilde{U}\in L^p(\Omega\times Y)$, and $\|\widetilde{U}\|_{L^p(\Omega\times Y)}=\|U\|_{L^p(\Omega;L^p(Y))}$. Consequently, we will not distinguish between U and $\widetilde{U}$ but rather denote them by U. With this convention in mind, $C_0^\infty(\Omega\times Y)$ turns out to be dense in $L^p(\Omega;L^p(Y))$, $L^p(\Omega\times Y)$, and in $L^p(Y;L^p(\Omega))$ with the respective norms.

In what follows, C will be used to denote various constants depending only upon n, m, p, and M.

1.1. Castaing's theorem on measurable selections. Let Ω, X be sets, and let Γ be a multifunction from Ω to X. A function $\sigma\colon\Omega\to X$ is said to be a selection of Γ if $\sigma(x)\in\Gamma(x)$ for every $x\in\Omega$. The measurable selection result below is proved in Theorem III.6 and Proposition III.11 in [CV].

THEOREM 1.1. *Let X be a separable metric space, $(\Omega, \mathcal{M})$ a measurable space, and Γ a multifunction from Ω to X. Assume that for every $x \in \Omega$, $\Gamma(x)$ is nonempty and complete in X. Assume, moreover, that for every closed subset F of X, $\{x \in \Omega : \Gamma(x) \cap F \neq \emptyset\}$ belongs to $\mathcal{M}$. Then Γ admits an $\mathcal{M}$-measurable selection.*

1.2. Quasiconvexity.

DEFINITION 1.2. *A continuous function $g\colon \mathbb{R}^{nm} \to [0, +\infty[$ is said to be quasiconvex whenever*

$$g(z) \leq \frac{1}{|A|} \int_A g(z + \nabla\varphi(x))\,\mathrm{d}x$$

for every $A \in \mathcal{A}_0$ and every $(z, \varphi) \in \mathbb{R}^{nm} \times C_0^1(A; \mathbb{R}^m)$.

Jensen's inequality implies that a convex function is also quasiconvex. It is also well known that if $n = 1$ or $m = 1$, quasiconvexity reduces to convexity. Moreover, it is easy to verify that g is quasiconvex if the above inequality holds for some $A \in \mathcal{A}_0$ and for all $(z, \varphi) \in \mathbb{R}^{nm} \times C_0^1(A; \mathbb{R}^m)$.

The following lower semicontinuity result for convex Carathéodory functions is well known (a direct consequence of Fatou's lemma).

PROPOSITION 1.3. *Let f satisfy* (0.1) *and* (0.6). *Let $p \in [1, +\infty[$ and $\Omega \in \mathcal{A}_0$. Then, the functional*

$$w \in L^p(\Omega; \mathbb{R}^{nm}) \mapsto \int_\Omega f(x, w(x))\,\mathrm{d}x$$

is sequentially weakly $L^p(\Omega; \mathbb{R}^{nm})$-lower semicontinuous.

In the quasiconvex case, it turns out that a similar result holds (cf., for example, [Mo], [Ba], [D], [Bu], [AF], [M2]).

PROPOSITION 1.4. *Assume that f satisfies* (0.1), (0.2), *and* (0.3) *for some $p \in [1, +\infty[$. Then, for every $\Omega \in \mathcal{A}_0$ the functional*

$$w \in W^{1,p}(\Omega; \mathbb{R}^m) \mapsto \int_\Omega f(x, \nabla w(x))\,\mathrm{d}x$$

is sequentially weakly $W^{1,p}(\Omega; \mathbb{R}^m)$-lower semicontinuous.

Let f be as in (0.1). Consider the following local Lipschitz condition for $p \in [1, +\infty[$, $C \geq 0$ and a Y-periodic $a \in L^1(Y)$:

$$\begin{aligned} &|f(x, z_1) - f(x, z_2)| \leq C(a(x)^{1-\frac{1}{p}} + |z_1|^{p-1} + |z_2|^{p-1})|z_1 - z_2| \\ &\qquad \text{for a.e. } x \in \mathbb{R}^n \text{ and every } z_1, z_2 \in \mathbb{R}^{nm}. \end{aligned} \tag{1.1}$$

The result below is well known (cf., for example, [Mo], [F]).

PROPOSITION 1.5. *Assume that f satisfies* (0.1), (0.2), *and* (0.3) *for some $p \in [1, +\infty[$ and $a \in L^1(Y)$. Then,* (1.1) *holds for some constant $C \geq 0$.*

1.3. The unfolding operator and its main properties. For every z in $\mathbb{R}^n$ we denote by $[z]$ the vector whose coordinates are the integer parts of the corresponding coordinates of z.

DEFINITION 1.6. *Let $\Omega \in \mathcal{A}_0$. For $\varepsilon > 0$, the unfolding operator $\mathcal{T}_\varepsilon\colon L^1(\Omega) \to L^1(\mathbb{R}^n \times Y)$ is defined as follows:*

$$\mathcal{T}_\varepsilon(v)(x, y) = \widetilde{v}\Big(\varepsilon\Big[\frac{x}{\varepsilon}\Big] + \varepsilon y\Big)$$

for every $v \in L^1(\Omega)$ and a.e. $(x,y) \in \mathbb{R}^n \times Y$, where $\widetilde{v}$ is the extension of v by zero outside Ω.

Let $\Omega \in \mathcal{A}_0$. For every $\varepsilon > 0$ we set

$$\Omega_\varepsilon \doteq \bigcup \{\varepsilon(\xi + \overline{Y}) : \xi \in \mathbb{Z}^n,\ \varepsilon(\xi + \overline{Y}) \cap \overline{\Omega} \neq \emptyset\}.$$

Then one has (cf. [CDG])

$$\int_{\Omega_\varepsilon \times Y} \mathcal{T}_\varepsilon(v)(x,y)\,\mathrm{d}x\,\mathrm{d}y = \int_\Omega v(x)\,\mathrm{d}x \quad \text{for every } \varepsilon > 0 \text{ and for every } v \text{ in } L^1(\Omega). \tag{1.2}$$

Furthermore

$$\mathcal{T}_\varepsilon(v) \to \widetilde{v} \text{ in } L^p(\mathbb{R}^n \times Y) \text{ as } \varepsilon \to 0 \quad \text{for every } p \in [1,+\infty[\text{ and } v \in L^p(\Omega). \tag{1.3}$$

If d is a positive integer, $w = (w_1, \ldots, w_d)$ belongs to $L^1(\Omega;\mathbb{R}^d)$, and $\varepsilon > 0$, we set

$$\mathcal{T}_\varepsilon(w) = (\mathcal{T}_\varepsilon(w_1), \ldots, \mathcal{T}_\varepsilon(w_d)).$$

Concerning the unfolding operator, the main result is the following (cf. Theorem 1 in [CDG]).

THEOREM 1.7. *Let $\Omega \in \mathcal{A}_0$, $p \in]1,+\infty[$, and let $\{\varepsilon_h\}$ be a sequence of positive numbers converging to 0. Let $\{v_h\}$ be a sequence converging weakly in $W^{1,p}(\Omega)$ to some v. Then, there exist a subsequence $\{h_k\}$ and $V \in L^p(\Omega; W^{1,p}_{\mathrm{per}}(Y))$ such that, as $k \to +\infty$,*

$$\mathcal{T}_{\varepsilon_{h_k}}(\nabla v_{h_k}) \to \nabla v + \nabla_y V \ \textit{weakly in } L^p(\Omega \times Y;\mathbb{R}^n).$$

1.4. A result of De Giorgi. We recall De Giorgi's argument allowing us to fix boundary values when computing Γ-limits (see [DG] for the scalar case and [F] for an extension to the vector-valued case).

LEMMA 1.8. *Assume that f satisfies* (0.1), (0.3), *and* (0.4) *for some $p \in [1,+\infty[$. Let $\{\nu_h\} \subseteq]0,+\infty[$ be increasing and diverging. Then, for every $\Omega \in \mathcal{A}_0$, and every $u \in W^{1,p}(\Omega;\mathbb{R}^m)$,*

$$\begin{aligned}
&\inf\left\{ \liminf_{h\to+\infty} \int_\Omega f(\nu_h x, \nabla u_h)\,\mathrm{d}x : \{u_h\} \subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ u_h \to u \ \textit{in } L^p(\Omega;\mathbb{R}^m) \right\} \\
&\quad = \inf\Bigg\{ \liminf_{h\to+\infty} \int_\Omega f(\nu_h x, \nabla u_h)\,\mathrm{d}x : \\
&\qquad\qquad \{u_h\} \subseteq u + W^{1,p}_0(\Omega;\mathbb{R}^m),\ u_h \to u \ \textit{in } L^p(\Omega;\mathbb{R}^m) \Bigg\}.
\end{aligned}$$

2. The homogenization result. Let f satisfy hypothesis (0.1), and let p be in $[1,+\infty[$. For every $t > 0$, set

$$\begin{aligned}
f_t \colon z \in \mathbb{R}^{nm} &\mapsto \frac{1}{t^n} \inf\left\{ \int_{tY} f(y, z + \nabla v)\,\mathrm{d}y : v \in W^{1,p}_0(tY;\mathbb{R}^m) \right\} \\
&= \inf\left\{ \int_Y f(ty, z + \nabla v)\,\mathrm{d}y : v \in W^{1,p}_0(Y;\mathbb{R}^m) \right\}.
\end{aligned} \tag{2.1}$$

For every $t > 0$, the function f_t is upper semicontinuous as the infimum of a family of continuous functions. If, in addition, hypothesis (0.3) holds, then clearly

$$f_t(z) \le \int_Y a(ty)\,\mathrm{d}y + M|z|^p \quad \text{for every } t > 0 \text{ and every } z \in \mathbb{R}^{nm}. \tag{2.2}$$

LEMMA 2.1. *Assume that f satisfies (0.1) and that $f(\cdot, z) \in L^1(Y)$ for every $z \in \mathbb{R}^{nm}$. For every $t > 0$, let f_t be defined by (2.1). Then, for every z in $\mathbb{R}^{nm}$, the limit $\lim_{t\to+\infty} f_t(z)$ exists and*

$$\lim_{t\to+\infty} f_t(z) = \inf_{h\in\mathbb{N}} f_h(z).$$

Proof. Fix z in $\mathbb{R}^{nm}$. By the periodicity of $f(\cdot, z)$, one has

$$f_{k\nu}(z) \le f_\nu(z) \quad \text{for every } \nu, k \in \mathbb{N}. \tag{2.3}$$

Let s, $t \in]0, +\infty[$ with $s < t$. The periodicity of $f(\cdot, z)$ implies that

$$\begin{aligned} f_s(z) &\ge \frac{t^n}{s^n}\left(f_t(z) - \frac{1}{t^n}\int_{tY\setminus sY} f(y,z)\,\mathrm{d}y\right) \\ &\ge f_t(z) - \frac{1}{t^n}\int_{([t]+1)Y\setminus[s]Y} f(y,z)\,\mathrm{d}y \\ &= f_t(z) - \frac{([t]+1)^n - [s]^n}{t^n}\int_Y f(y,z)\,\mathrm{d}y. \end{aligned} \tag{2.4}$$

Combining (2.4) and (2.3), we get

$$\begin{aligned} f_t(z) &\le f_{[\frac{t}{[s]}][s]}(z) + \frac{([t]+1)^n - [\frac{t}{[s]}]^n[s]^n}{t^n}\int_Y f(y,z)\,\mathrm{d}y \\ &\le f_{[s]}(z) + \frac{([t]+1)^n - [\frac{t}{[s]}]^n[s]^n}{t^n}\int_Y f(y,z)\,\mathrm{d}y. \end{aligned} \tag{2.5}$$

Hence, applying again (2.4),

$$f_t(z) \le f_{s-1}(z) + \left(\frac{([s]+1)^n - [s-1]^n}{[s]^n} + \frac{([t]+1)^n - [\frac{t}{[s]}]^n[s]^n}{t^n}\right)\int_Y f(y,z)\,\mathrm{d}y. \tag{2.6}$$

By the summability assumption on $f(\cdot, z)$, letting first t and then s go to infinity in (2.6), we conclude that $\limsup_{t\to+\infty} f_t(z) \le \liminf_{s\to+\infty} f_s(z)$, namely, that the limit $\lim_{t\to+\infty} f_t(z)$ exists.

Now choose $h \in \mathbb{N}$ and $t \in]h, +\infty[$. Then (2.5), together with (2.3), implies

$$\begin{aligned} f_t(z) &\le f_{[\frac{t}{h}]h}(z) + \frac{([t]+1)^n - [\frac{t}{h}]^n h^n}{t^n}\int_Y f(y,z)\,\mathrm{d}y \\ &\le f_h(z) + \frac{([t]+1)^n - [\frac{t}{h}]^n h^n}{t^n}\int_Y f(y,z)\,\mathrm{d}y. \end{aligned}$$

Letting t go to infinity, we obtain

$$\limsup_{t\to+\infty} f_t(z) \le f_h(z)$$

for every $h \in \mathbb{N}$. This inequality completes the proof of the lemma. $\square$

LEMMA 2.2. *Assume that f satisfies* (0.1), (0.2), (0.3), *and* (0.4) *for some $p \in]1,+\infty[$. For every $t > 0$, let f_t be defined in* (2.1). *Then, for every Ω in $\mathcal{A}_0$, $t > 0$, and every u in $W^{1,p}(\Omega;\mathbb{R}^m)$, the following inequality holds:*

$$\int_\Omega f_t(\nabla u)\,\mathrm{d}x$$
$$= \frac{1}{t^n}\inf\left\{\int_{\Omega\times tY} f(y,\nabla u(x)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V \in L^p(\Omega;W_0^{1,p}(tY;\mathbb{R}^m))\right\}.$$

Proof. Let Ω, t, u be as above. Fix V in $W_0^{1,p}(tY;\mathbb{R}^m)$. Obviously, for a.e. $x \in \Omega$,

$$\begin{aligned}\frac{1}{t^n}\int_{tY} &f(y,\nabla u(x)+\nabla_y V(x,y))\,\mathrm{d}y\\ &\geq \frac{1}{t^n}\inf\left\{\int_{tY} f(y,\nabla u(x)+\nabla v(y))\,\mathrm{d}y : v \in W_0^{1,p}(tY;\mathbb{R}^m)\right\}\\ &= f_t(\nabla u(x)),\end{aligned}$$

from which follows

$$\begin{aligned}\frac{1}{t^n}\inf&\left\{\int_{\Omega\times tY} f(y,\nabla u(x)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V \in L^p(\Omega;W_0^{1,p}(tY;\mathbb{R}^m))\right\}\\ &\geq \int_\Omega f_t(\nabla u(x))\,\mathrm{d}x.\end{aligned}$$

The reverse inequality is obvious if $\int_\Omega f_t(\nabla u(x))\,\mathrm{d}x = +\infty$. If $\int_\Omega f_t(\nabla u(x))\,\mathrm{d}x$ is finite, we make use of Castaing's selection theorem applied to the metric space $X = W_0^{1,p}(tY;\mathbb{R}^m)$.

Let Γ be the multifunction defined by

$$\Gamma\colon z \in \mathbb{R}^{nm} \mapsto \left\{v \in W_0^{1,p}(tY;\mathbb{R}^m) : \frac{1}{t^n}\int_{tY} f(y,z+\nabla v(y))\,\mathrm{d}y = f_t(z)\right\}.$$

By (0.4) and Proposition 1.4 applied to tY, the infimum defining $f_t(z)$ is achieved for every $z \in \mathbb{R}^{nm}$. So, $\Gamma(z)$ is nonempty and weakly closed, and hence strongly closed. We claim that Γ has a $\mathcal{B}(\mathbb{R}^{nm})$-measurable selection (where $\mathcal{B}(\mathbb{R}^{nm})$ denotes the σ-algebra of the Borel subsets of $\mathbb{R}^{nm}$). By Theorem 1.1, it is enough to show that for every strongly closed subset F of $W_0^{1,p}(tY;\mathbb{R}^m)$, one has

$$\Gamma^-(F) \doteq \{\zeta \in \mathbb{R}^{nm} : \Gamma(\zeta)\cap F \neq \emptyset\} \in \mathcal{B}(\mathbb{R}^{nm}).$$

We first assume that F is a closed ball in $W_0^{1,p}(tY;\mathbb{R}^m)$ and prove that $\Gamma^-(F)$ is closed. Let $\{z_h\} \subseteq \Gamma^-(F)$, $z \in \mathbb{R}^{nm}$, with $z_h \to z$. For every $h \in \mathbb{N}$, let $v_h \in \Gamma(z_h)\cap F$. Then, $\{v_h\}$ turns out to be bounded in $W_0^{1,p}(tY;\mathbb{R}^m)$. In fact, (0.4), the upper semicontinuity of f_t, (0.3), and (2.2) imply that

$$\begin{aligned}\limsup_{h\to+\infty}\frac{1}{t^n}\int_{tY}|z_h+\nabla v_h(y)|^p\,\mathrm{d}y &\leq \limsup_{h\to+\infty}\frac{1}{t^n}\int_{tY} f(y,z_h+\nabla v_h(y))\,\mathrm{d}y\\ &= \limsup_{h\to+\infty} f_t(z_h) \leq f_t(z) < +\infty.\end{aligned}$$

Therefore, there is a subsequence $\{v_{h_k}\}$ of $\{v_h\}$, and some v_∞ in F such that $v_{h_k} \rightharpoonup v_\infty$ in $W_0^{1,p}(tY;\mathbb{R}^m)$. Then, Proposition 1.4 (applied to tY) and the upper semicontinuity of f_t imply

$$f_t(z) \leq \frac{1}{t^n} \int_{tY} f(y, z + \nabla v_\infty(y))\,\mathrm{d}y \leq \liminf_{k\to+\infty} \frac{1}{t^n} \int_{tY} f(y, z_{h_k} + \nabla v_{h_k}(y))\,\mathrm{d}y$$
$$\leq \limsup_{k\to+\infty} f_t(z_{h_k}) \leq f_t(z)$$

so that $v_\infty \in \Gamma(z) \cap F$ and $z \in \Gamma^-(F)$.

By using the separability of $W_0^{1,p}(tY;\mathbb{R}^m)$, every strongly closed subset F of $W_0^{1,p}(tY;\mathbb{R}^m)$ can be written as a countable intersection of countable unions of balls. Consequently, $\Gamma^-(F)$ is itself a countable intersection of countable unions of closed sets, and hence $\Gamma^-(F) \in \mathcal{B}(\mathbb{R}^{nm})$. By Theorem 1.1, Γ admits a $\mathcal{B}(\mathbb{R}^{nm})$-measurable selection σ.

For a.e. $x \in \Omega$, set $U(x) = \sigma(\nabla u(x))$. Then, U is $\mathcal{L}(\Omega)$-measurable with values in $W_0^{1,p}(tY;\mathbb{R}^m)$. Moreover, for a.e. $x \in \Omega$,

$$f_t(\nabla u(x)) = \frac{1}{t^n} \int_{tY} f(y, \nabla u(x) + \nabla_y U(x)(y))\,\mathrm{d}y.$$

Since $f_t(\nabla u)$ is summable, the previous equality, together with (0.4), implies that $\nabla_y U \in L^p(\Omega\times tY;\mathbb{R}^{nm})$. Thus, by the Poincaré inequality, U is in $L^p(\Omega; W_0^{1,p}(tY;\mathbb{R}^m))$. Consequently,

$$\begin{aligned}
&\int_\Omega f_t(\nabla u(x))\,\mathrm{d}x \\
&\quad= \frac{1}{t^n} \int_{\Omega\times tY} f(y, \nabla u(x) + \nabla_y U(x)(y))\,\mathrm{d}x\,\mathrm{d}y \\
&\quad\geq \frac{1}{t^n} \inf\left\{ \int_{\Omega\times tY} f(y, \nabla u(x) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V \in L^p(\Omega; W_0^{1,p}(tY;\mathbb{R}^m)) \right\},
\end{aligned}$$

and this completes the proof of the lemma. ∎

PROPOSITION 2.3. *Assume that f satisfies* (0.1), (0.2), (0.3), *and* (0.4) *for some $p \in\,]1, +\infty[$. Let f_{hom} be defined by* (0.5). *Then, for every $\Omega \in \mathcal{A}_0$ and $u \in W^{1,p}(\Omega;\mathbb{R}^m)$, the limit below exists, and*

$$\begin{aligned}
&\lim_{t\to+\infty} \frac{1}{t^n} \inf\left\{ \int_{\Omega\times tY} f(y, \nabla u(x) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V \in L^p(\Omega; W_0^{1,p}(tY;\mathbb{R}^m)) \right\} \\
&\qquad= \int_\Omega f_{\mathrm{hom}}(\nabla u(x))\,\mathrm{d}x.
\end{aligned}$$

Proof. The conclusion follows from Lemma 2.2, Lemma 2.1, (2.2), and the Lebesgue dominated convergence theorem. ∎

Remark 2.4. Under the assumptions of Proposition 2.3, note the various formulations for the limit energy, the latter deriving from Lemma 2.1:

$$\begin{aligned}
&\int_\Omega f_{\mathrm{hom}}(\nabla u)\,\mathrm{d}x \\
&\quad= \lim_{t\to+\infty} \frac{1}{t^n} \inf\left\{ \int_{\Omega\times tY} f(y, \nabla u(x) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V \in L^p(\Omega; W_0^{1,p}(tY;\mathbb{R}^m)) \right\} \\
&\quad= \lim_{t\to+\infty} \inf\left\{ \int_{\Omega\times Y} f(ty, \nabla u(x) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V \in L^p(\Omega; W_0^{1,p}(Y;\mathbb{R}^m)) \right\} \\
&\quad= \inf_{h\in\mathbb{N}} \inf\left\{ \int_{\Omega\times Y} f(hy, \nabla u(x) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V \in L^p(\Omega; W_0^{1,p}(Y;\mathbb{R}^m)) \right\}.
\end{aligned}$$

We now state the main homogenization result for nonlinear energy integral functionals.

THEOREM 2.5. *Let f satisfy* (0.1) *and* (0.2). *Let $p \in]1, +\infty[$, and assume that* (0.3) *and* (0.4) *hold. Let f_{hom} be defined by* (0.5). *Then, for every $\{\varepsilon_h\} \subseteq]0, +\infty[$ converging to* 0, *Ω in $\mathcal{A}_0$, and u in $W^{1,p}(\Omega; \mathbb{R}^m)$,*

$$\begin{aligned}
&\int_\Omega f_{\mathrm{hom}}(\nabla u)\,\mathrm{d}x \\
&\quad = \inf\left\{\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h}, \nabla u_h\Big)\,\mathrm{d}x : \{u_h\} \subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ u_h \to u \ in\ L^p(\Omega;\mathbb{R}^m)\right\} \\
&\quad = \inf\left\{\limsup_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h}, \nabla u_h\Big)\,\mathrm{d}x : \{u_h\} \subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ u_h \to u \ in\ L^p(\Omega;\mathbb{R}^m)\right\} \\
&\quad = \inf\left\{\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h}, \nabla u_h\Big)\,\mathrm{d}x : \right. \\
&\qquad\qquad \left. \{u_h\} \subseteq u + W^{1,p}_0(\Omega;\mathbb{R}^m),\ u_h \to u \ in\ L^p(\Omega;\mathbb{R}^m)\right\} \\
&\quad = \inf\left\{\limsup_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h}, \nabla u_h\Big)\,\mathrm{d}x : \right. \\
&\qquad\qquad \left. \{u_h\} \subseteq u + W^{1,p}_0(\Omega;\mathbb{R}^m),\ u_h \to u \ in\ L^p(\Omega;\mathbb{R}^m)\right\}.
\end{aligned}$$

The proof uses the following lemmas and will be given at the end of this section.

LEMMA 2.6. *Assume that f satisfies* (0.1) *and* (0.3) *for some $p \in]1, +\infty[$. Let $\{\varepsilon_h\} \subseteq]0, +\infty[$ converge to* 0, *Ω in $\mathcal{A}_0$, and u in $W^{1,p}(\Omega; \mathbb{R}^m)$. Then*

$$\begin{aligned}
&\inf\left\{\limsup_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h}, \nabla u_h\Big)\,\mathrm{d}x : \{u_h\} \subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ u_h \to u \ in\ L^p(\Omega;\mathbb{R}^m)\right\} \\
&\quad \le \inf_{k\in\mathbb{N}} \frac{1}{k^n} \inf\left\{\int_{\Omega\times kY} f(y, \nabla u(x) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V \in L^p(\Omega; W^{1,p}_{\mathrm{per}}(kY;\mathbb{R}^m))\right\}.
\end{aligned}$$

Proof. Let $k \in \mathbb{N}$, and let $U \in C^1(\mathbb{R}^n \times \mathbb{R}^n; \mathbb{R}^m)$ with $U(x,\cdot)$ kY-periodic for every $x \in \Omega$. For every $h \in \mathbb{N}$ and $x \in \Omega$, set $u_h(x) = u(x) + \varepsilon_h U(x, \frac{x}{\varepsilon_h})$. Clearly, $\nabla u_h(x) = \nabla u(x) + \varepsilon_h \nabla_x U(x, \frac{x}{\varepsilon_h}) + \nabla_y U(x, \frac{x}{\varepsilon_h})$ for every $h \in \mathbb{N}$ and $x \in \Omega$.

Using the unfolding operator, (1.2), and the periodicity properties of f and U, one has

$$\begin{aligned}
\int_\Omega f\Big(\frac{x}{\varepsilon_h}, \nabla u_h\Big)\,\mathrm{d}x &= \int_{\Omega_{k\varepsilon_h}\times Y} \mathcal{T}_{k\varepsilon_h}\Big(f\Big(\frac{\cdot}{\varepsilon_h}, \nabla u_h(\cdot)\Big)\Big)(x,y)\,\mathrm{d}x\,\mathrm{d}y \\
&= \int_{\Omega_{k\varepsilon_h}\times Y} f\Big(\frac{1}{\varepsilon_h}\Big(k\varepsilon_h\Big[\frac{x}{k\varepsilon_h}\Big] + k\varepsilon_h y\Big), \mathcal{T}_{k\varepsilon_h}(\nabla u_h)(x,y)\Big)\,\mathrm{d}x\,\mathrm{d}y \\
&= \int_{\Omega_{k\varepsilon_h}\times Y} f\Big(ky, \mathcal{T}_{k\varepsilon_h}(\nabla u)(x,y) + \varepsilon_h \nabla_x U\Big(k\varepsilon_h\Big[\frac{x}{k\varepsilon_h}\Big] + k\varepsilon_h y, k\Big[\frac{x}{k\varepsilon_h}\Big] + ky\Big) \\
&\qquad + \nabla_y U\Big(k\varepsilon_h\Big[\frac{x}{k\varepsilon_h}\Big] + k\varepsilon_h y, k\Big[\frac{x}{k\varepsilon_h}\Big] + ky\Big)\Big)\,\mathrm{d}x\,\mathrm{d}y \\
&= \int_{\Omega_{k\varepsilon_h}\times Y} f\Big(ky, \mathcal{T}_{k\varepsilon_h}(\nabla u)(x,y) + \varepsilon_h \nabla_x U\Big(k\varepsilon_h\Big[\frac{x}{k\varepsilon_h}\Big] + k\varepsilon_h y, ky\Big) \\
&\qquad + \nabla_y U\Big(k\varepsilon_h\Big[\frac{x}{k\varepsilon_h}\Big] + k\varepsilon_h y, ky\Big)\Big)\,\mathrm{d}x\,\mathrm{d}y.
\end{aligned}$$

Since $\{u_h\}$ converges uniformly to u in Ω, we have

$$\begin{aligned}\inf\Big\{ \limsup_{h\to+\infty} \int_\Omega f\Big(\frac{x}{\varepsilon_h}, \nabla u_h\Big)\,\mathrm{d}x : \{v_h\} \subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ v_h \to u \text{ in } L^p(\Omega;\mathbb{R}^m)\Big\}\\ \le \limsup_{h\to+\infty} \int_{\Omega_{k\varepsilon_h}\times Y} f\Big(ky, \mathcal{T}_{k\varepsilon_h}(\nabla u)(x,y) + \varepsilon_h \nabla_x U\Big(k\varepsilon_h\Big[\frac{x}{k\varepsilon_h}\Big] + k\varepsilon_h y, ky\Big)\\ + \nabla_y U\Big(k\varepsilon_h\Big[\frac{x}{k\varepsilon_h}\Big] + k\varepsilon_h y, ky\Big)\Big)\,\mathrm{d}x\,\mathrm{d}y.\end{aligned}$$

On the other hand, by the continuity properties $\nabla_x U$ and $\nabla_y U$, one has

$$\varepsilon_h \nabla_x U\Big(k\varepsilon_h\Big[\frac{\cdot}{k\varepsilon_h}\Big] + k\varepsilon_h\cdot,\cdot\Big) \to 0,\ \nabla_y U\Big(k\varepsilon_h\Big[\frac{\cdot}{k\varepsilon_h}\Big] + k\varepsilon_h\cdot,\cdot\Big) \to \nabla_y U \text{ uniformly in } \Omega.$$

By (1.3), $\mathcal{T}_{k\varepsilon_h}(\nabla u) \to \widetilde{\nabla u}$ in $L^p(\mathbb{R}^n\times Y;\mathbb{R}^{nm})$. Then, since $|\partial\Omega| = 0$, using (0.3) we conclude that

$$\begin{aligned}\lim_{h\to+\infty} \int_{\Omega_{k\varepsilon_h}\times Y} f\Big(ky, \mathcal{T}_{k\varepsilon_h}(\nabla u)(x,y) + \varepsilon_h \nabla_x U\Big(k\varepsilon_h\Big[\frac{x}{k\varepsilon_h}\Big] + k\varepsilon_h y, ky\Big)\\ + \nabla_y U\Big(k\varepsilon_h\Big[\frac{x}{k\varepsilon_h}\Big] + k\varepsilon_h y, ky\Big)\Big)\,\mathrm{d}x\,\mathrm{d}y\\ = \int_{\Omega\times Y} f(ky, \nabla u(x) + \nabla_y U(x,ky))\,\mathrm{d}x\,\mathrm{d}y\\ = \frac{1}{k^n}\int_{\Omega\times kY} f(y, \nabla u(x) + \nabla_y U(x,y))\,\mathrm{d}x\,\mathrm{d}y.\end{aligned}$$

By the above inequalities we get

$$\begin{aligned}\inf\Big\{ \limsup_{h\to+\infty} \int_\Omega f\Big(\frac{x}{\varepsilon_h}, \nabla u_h\Big)\,\mathrm{d}x :\\ \{v_h\} \subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ v_h \to u \text{ in } L^p(\Omega;\mathbb{R}^m)\Big\}\\ \le \frac{1}{k^n}\int_{\Omega\times kY} f(y, \nabla u(x) + \nabla_y U(x,y))\,\mathrm{d}x\,\mathrm{d}y\end{aligned} \tag{2.7}$$

for every $U \in C^1(\mathbb{R}^n\times\mathbb{R}^n;\mathbb{R}^m)$ with $U(x,\cdot)$ kY-periodic for every $x\in\Omega$.

By virtue of (0.1) and (0.3), we observe that the right-hand side of (2.7) is continuous with respect to $U \in L^p(\Omega; W^{1,p}_{\mathrm{per}}(kY;\mathbb{R}^m))$ and that the set of functions U in $C^1(\mathbb{R}^n\times\mathbb{R}^n;\mathbb{R}^m)$ with $U(x,\cdot)$ kY-periodic for every $x\in\Omega$ is dense in $L^p(\Omega; W^{1,p}_{\mathrm{per}}(kY;\mathbb{R}^m))$. Consequently, (2.7) holds for every $U \in L^p(\Omega; W^{1,p}_{\mathrm{per}}(kY;\mathbb{R}^m))$ as well. Taking first the infimum as U varies in $L^p(\Omega; W^{1,p}_{\mathrm{per}}(kY;\mathbb{R}^m))$, and then the infimum on k, completes the proof. ∎

Remark 2.7. Since, for every integer k, the space $W^{1,p}_0(kY;\mathbb{R}^m)$ is a subspace of $W^{1,p}_{\mathrm{per}}(kY;\mathbb{R}^m)$, Lemma 2.6 holds with the V in $L^p(\Omega; W^{1,p}_0(kY;\mathbb{R}^m))$.

LEMMA 2.8. *Assume that f satisfies* (0.1), (0.3), (0.4), *and* (1.1) *for some $p \in [1,+\infty[$. Let $\{\varepsilon_h\} \subseteq]0,+\infty[$ converge to 0, Ω in $\mathcal{A}_0$, and u in $W^{1,p}(\Omega;\mathbb{R}^m)$. Then*

$$\inf\Big\{\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u+\nabla u_h\Big)\,\mathrm{d}x : \{u_h\}\subseteq W_0^{1,p}(\Omega;\mathbb{R}^m),\ u_h\to 0 \text{ in } L^p(\Omega;\mathbb{R}^m)\Big\}$$

$$\geq \sup_{\nu\in\mathbb{N}}\inf\Big\{\liminf_{h\to+\infty}\int_\Omega f(\nu hx,\nabla u+\nabla v_h)\,\mathrm{d}x : \{v_h\}\subseteq W_0^{1,p}(\Omega;\mathbb{R}^m),\ v_h\to 0 \text{ in } L^p(\Omega;\mathbb{R}^m)\Big\}.$$

Proof. Let $\{u_h\}\subseteq W_0^{1,p}(\Omega;\mathbb{R}^m)$ be such that $u_h\to 0$ in $L^p(\Omega;\mathbb{R}^m)$. Clearly, we can assume

$$\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u+\nabla u_h\Big)\,\mathrm{d}x<+\infty.$$

Let Ω' in $\mathcal{A}_0$ satisfy $\overline{\Omega}\subseteq\Omega'$. For every $h\in\mathbb{N}$, we still denote u_h the zero extension of u_h from Ω to Ω'. We also select an extension of u to Ω' in $W^{1,p}(\Omega';\mathbb{R}^m)$ which, for simplicity, is denoted u. Then, clearly

$$\begin{aligned}&\int_{\Omega'} f\Big(\frac{x}{\varepsilon_h},\nabla u+\nabla u_h\Big)\,\mathrm{d}x\\ &\quad\leq\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u+\nabla u_h\Big)\,\mathrm{d}x+\int_{\Omega'\setminus\Omega}\Big(a\Big(\frac{x}{\varepsilon_h}\Big)+M|\nabla u(x)|^p\Big)\,\mathrm{d}x\\ &\quad\text{for every } h\in\mathbb{N}.\end{aligned}\tag{2.8}$$

Let $\{h_j\}\subseteq\mathbb{N}$ be such that $\{[\frac{1}{\nu\varepsilon_{h_j}}]\}$ is strictly increasing, and

$$\lim_{j\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_{h_j}},\nabla u+\nabla u_{h_j}\Big)\,\mathrm{d}x=\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u+\nabla u_h\Big)\,\mathrm{d}x.\tag{2.9}$$

Then (0.4) provides that $\sup_{j\in\mathbb{N}}\int_\Omega|\nabla u_{h_j}|^p\,\mathrm{d}x<+\infty$.

Now, let ν be a positive integer. For every $j\in\mathbb{N}$, set $\theta_j=\nu\varepsilon_{h_j}[\frac{1}{\nu\varepsilon_{h_j}}]$, and observe that $\theta_j\to 1^-$ as j goes to $+\infty$. For every $j\in\mathbb{N}$, define $v_j\doteq\frac{1}{\theta_j}u_{h_j}(\theta_j\cdot)$. Clearly, v_j has support in $\frac{1}{\theta_j}\overline{\Omega}$, which is included in Ω' for large values of j, so it is in $W_0^{1,p}(\Omega';\mathbb{R}^m)$ for the same values of j. From its definition, it is straightforward that $\{v_j\}$ goes to zero in $L^p(\Omega;\mathbb{R}^m)$ because $\{u_h\}$ does. Moreover,

$$\sup_{j\in\mathbb{N}}\int_{\Omega'}|\nabla v_j|^p\,\mathrm{d}x<+\infty.\tag{2.10}$$

By performing the change of variable $x=\theta_jx'$, for j large enough, we get successively

$$\begin{aligned}\int_{\Omega'} f\Big(\frac{x}{\varepsilon_{h_j}},\nabla u+\nabla u_{h_j}\Big)\,\mathrm{d}x&=\theta_j^n\int_{\theta_j^{-1}\Omega'} f\Big(\frac{\theta_jx'}{\varepsilon_{h_j}},(\nabla_xu+\nabla_xu_{h_j})(\theta_jx')\Big)\,\mathrm{d}x'\\ &=\theta_j^n\int_{\theta_j^{-1}\Omega'} f\Big(\frac{\theta_jx'}{\varepsilon_{h_j}},\nabla_xu(\theta_jx')+\nabla_{x'}v_j(x')\Big)\,\mathrm{d}x'\\ &\geq\theta_j^n\int_\Omega f\Big(\frac{\theta_jx'}{\varepsilon_{h_j}},\nabla_xu(\theta_jx')+\nabla_{x'}v_j(x')\Big)\,\mathrm{d}x'.\end{aligned}$$

Consequently, using (1.1) and Hölder's inequality,

$$\begin{aligned}
&\int_{\Omega'} f\Big(\frac{x}{\varepsilon_{h_j}}, \nabla u + \nabla u_{h_j}\Big)\,\mathrm{d}x \\
&\quad\geq \theta_j^n \int_\Omega f\Big(\frac{\theta_j x'}{\varepsilon_{h_j}}, \nabla_x u(x') + \nabla_{x'} v_j(x')\Big)\,\mathrm{d}x' \\
&\quad - \theta_j^n C\bigg\{\bigg(\int_\Omega a\Big(\frac{\theta_j x'}{\varepsilon_{h_j}}\Big)\,\mathrm{d}x'\bigg)^{1-\frac{1}{p}} + \bigg(\int_\Omega |\nabla_x u(\theta_j x')|^p\,\mathrm{d}x'\bigg)^{1-\frac{1}{p}} \\
&\qquad + \bigg(\int_\Omega |\nabla_x u(x')|^p\,\mathrm{d}x'\bigg)^{1-\frac{1}{p}} + \bigg(\int_\Omega |\nabla_{x'} v_j(x')|^p\,\mathrm{d}x'\bigg)^{1-\frac{1}{p}}\bigg\} \\
&\qquad \times \bigg(\int_\Omega |\nabla_x u(\theta_j x') - \nabla_x u(x')|^p\,\mathrm{d}x'\bigg)^{\frac{1}{p}} \quad \text{for } j \text{ large enough.}
\end{aligned} \tag{2.11}$$

Now, for every $j \in \mathbb{N}$, set $n_j = [\frac{1}{\nu\varepsilon_{h_j}}]$. Since $\frac{\theta_j}{\varepsilon_{h_j}} = \nu[\frac{1}{\nu\varepsilon_{h_j}}] = \nu n_j$, going to the limit in (2.11), exploiting the periodicity of a and (2.10), gives

$$\begin{aligned}
\liminf_{j\to+\infty} \int_\Omega f(\nu n_j x, \nabla u + \nabla v_j)\,\mathrm{d}x &= \liminf_{j\to+\infty} \theta_j^n \int_\Omega f\Big(\frac{\theta_j x}{\varepsilon_{h_j}}, \nabla u + \nabla v_j\Big)\,\mathrm{d}x \\
&\leq \lim_{j\to+\infty} \int_{\Omega'} f\Big(\frac{x}{\varepsilon_{h_j}}, \nabla u + \nabla u_{h_j}\Big)\,\mathrm{d}x,
\end{aligned} \tag{2.12}$$

where we used the fact that $\int_\Omega |\nabla_x u(\theta_j x') - \nabla_x u(x')|^p\,\mathrm{d}x'$ converges to 0 by the continuity as $\theta_j \to 1$ of the scaling operator in L^p.

Combining (2.12), (2.8), and (2.9), and using the periodicity of the function a, yields

$$\begin{aligned}
&\liminf_{j\to+\infty} \int_\Omega f(\nu n_j x, \nabla u + \nabla v_j)\,\mathrm{d}x \\
&\quad \leq \liminf_{h\to+\infty} \int_\Omega f\Big(\frac{x}{\varepsilon_h}, \nabla u + \nabla u_h\Big)\,\mathrm{d}x \\
&\qquad + |\Omega' \setminus \Omega| \int_Y a(y)\,\mathrm{d}y + M \int_{\Omega'\setminus\Omega} |\nabla u(x)|^p\,\mathrm{d}x.
\end{aligned} \tag{2.13}$$

Recall that $\{n_j\}$ is strictly increasing. Thus, for every $h \in \mathbb{N}$ we define $\{w_h\}$ as

$$w_h = \begin{cases} v_j & \text{if } h = n_j \text{ for some } j \in \mathbb{N}, \\ 0 & \text{otherwise.} \end{cases}$$

Observe that $\{w_h\} \subseteq W^{1,p}(\Omega;\mathbb{R}^m)$, and that $w_h \to 0$ in $L^p(\Omega;\mathbb{R}^m)$. Then, since $|\partial\Omega| = 0$ and $\{n_j\} \subseteq \mathbb{N}$, once Ω' shrinks to $\overline{\Omega}$, by (2.13) we conclude that

$$\begin{aligned}
&\inf\bigg\{\liminf_{h\to+\infty} \int_\Omega f(\nu h x, \nabla u + \nabla v_h)\,\mathrm{d}x : \{v_h\} \subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ v_h \to 0 \text{ in } L^p(\Omega;\mathbb{R}^m)\bigg\} \\
&\quad \leq \liminf_{h\to+\infty} \int_\Omega f(\nu h x, \nabla u + \nabla w_h)\,\mathrm{d}x \leq \liminf_{j\to+\infty} \int_\Omega f(\nu n_j x, \nabla u + \nabla v_j)\,\mathrm{d}x \\
&\quad \leq \liminf_{h\to+\infty} \int_\Omega f\Big(\frac{x}{\varepsilon_h}, \nabla u + \nabla u_h\Big)\,\mathrm{d}x.
\end{aligned}$$

The desired conclusion follows by using Lemma 1.8 and taking the supremum for ν in $\mathbb{N}$. ◻

LEMMA 2.9. *Assume that f satisfies* (0.1), (0.3), (0.4), *and* (1.1) *for some $p \in [1, +\infty[$. Let $\{\varepsilon_h\} \subseteq]0, +\infty[$ converge to 0, Ω in $\mathcal{A}_0$, and u in $W^{1,p}(\Omega; \mathbb{R}^m)$. Then*

$$\begin{aligned}
&\inf\left\{\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h}, \nabla u + \nabla u_h\Big)\,\mathrm{d}x : \{u_h\} \subseteq W_0^{1,p}(\Omega;\mathbb{R}^m),\ u_h \to 0 \textit{ in } L^p(\Omega;\mathbb{R}^m)\right\}\\
&\quad \geq \liminf_{h\to+\infty}\ \inf\left\{\int_{\Omega\times Y} f(hy, \nabla u(x) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V \in L^p(\Omega; W_0^{1,p}(Y;\mathbb{R}^m))\right\}.
\end{aligned}$$

Proof. Since Ω has Lipschitz boundary, u can be extended as an element of $W^{1,p}(\mathbb{R}^n;\mathbb{R}^m)$ without changing notation.

To prove the lemma, we estimate from below the right-hand side of the inequality in Lemma 2.8.

Let $\nu \in \mathbb{N}$, and let $\{v_h\} \subseteq W_0^{1,p}(\Omega;\mathbb{R}^m)$ be such that $v_h \to 0$ in $L^p(\Omega;\mathbb{R}^m)$. As before, each v_h can be considered as extended by zero outside of Ω. For every $j \in \mathbb{Z}^n$, set $Y_{\nu,j} = \frac{1}{\nu}(j + Y)$ and let $J_\nu = \{j \in \mathbb{Z}^n : \overline{Y_{\nu,j}} \cap \overline{\Omega} \neq \emptyset\}$. Then

$$\begin{aligned}
&\sum_{j\in J_\nu}\liminf_{h\to+\infty}\int_{Y_{\nu,j}} f(\nu h x, \nabla u + \nabla v_h)\,\mathrm{d}x\\
&\leq \liminf_{h\to+\infty}\int_\Omega f(\nu h x, \nabla u + \nabla v_h)\,\mathrm{d}x + |\Omega_{1/\nu}\setminus\Omega|\int_Y a\,\mathrm{d}y + M\int_{\Omega_{1/\nu}\setminus\Omega}|\nabla u|^p\,\mathrm{d}x.
\end{aligned} \tag{2.14}$$

For every $j \in J_\nu$, we apply Lemma 1.8 to $Y_{\nu,j}$, and get $\{w_{\nu,j,h}\} \subseteq W_0^{1,p}(Y_{\nu,j};\mathbb{R}^m)$ such that $w_{\nu,j,h} \to 0$ in $L^p(Y_{\nu,j};\mathbb{R}^m)$, and

$$\liminf_{h\to+\infty}\int_{Y_{\nu,j}} f(\nu h x, \nabla u + \nabla w_{\nu,j,h})\,\mathrm{d}x \leq \liminf_{h\to+\infty}\int_{Y_{\nu,j}} f(\nu h x, \nabla u + \nabla v_h)\,\mathrm{d}x. \tag{2.15}$$

For every $j \in J_\nu$ and $h \in \mathbb{N}$, using the unfolding operator $\mathcal{T}_{1/\nu}$ on $Y_{\nu,j}$, together with the same arguments as in Lemma 2.6, gives

$$\begin{aligned}
&\int_{Y_{\nu,j}} f(\nu h x, \nabla u + \nabla w_{\nu,j,h})\,\mathrm{d}x\\
&\qquad \geq \int_{Y_{\nu,j}\times Y} f(hy, \mathcal{T}_{1/\nu}(\nabla u)(x,y) + \mathcal{T}_{1/\nu}(\nabla w_{\nu,j,h})(x,y))\,\mathrm{d}x\,\mathrm{d}y.
\end{aligned}$$

Observe now that for every $h \in \mathbb{N}$ and $j \in J_\nu$,

$$\mathcal{T}_{1/\nu}(\nabla w_{\nu,j,h}) = \nu\nabla_y\mathcal{T}_{1/\nu}(w_{\nu,j,h}).$$

When x varies almost everywhere in some $Y_{\nu,j}$, the function $\mathcal{T}_{1/\nu}(w_{\nu,j,h})(x,\cdot)$ belongs to $W_0^{1,p}(Y;\mathbb{R}^m)$, which implies $\mathcal{T}_{1/\nu}(w_{\nu,j,h}) \in L^p(Y_{\nu,j}; W_0^{1,p}(Y;\mathbb{R}^m))$. Consequently,

$$\begin{aligned}
&\int_{Y_{\nu,j}} f(\nu h x, \nabla u + \nabla w_{\nu,j,h})\,\mathrm{d}x\\
&\qquad \geq \inf\bigg\{\int_{Y_{\nu,j}\times Y} f(hy, \mathcal{T}_{1/\nu}(\nabla u)(x,y) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y :\\
&\qquad\qquad V \in L^p(Y_{\nu,j}; W_0^{1,p}(Y;\mathbb{R}^m))\bigg\}.
\end{aligned}$$

Since the sets $\{Y_{\nu,j}\}_{j\in J_\nu}$ are pairwise disjoint and $\Omega \subseteq \Omega_{1/\nu} = \cup_{j\in J_\nu} Y_{\nu,j}$ up to a null set, it is easy to verify that for every $h \in \mathbb{N}$

$$\begin{aligned}
&\sum_{j\in J_\nu} \inf\bigg\{\int_{Y_{\nu,j}\times Y} f(hy, \mathcal{T}_{1/\nu}(\nabla u)(x,y) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : \\
&\qquad V \in L^p(Y_{\nu,j}; W_0^{1,p}(Y;\mathbb{R}^m))\bigg\} \\
&\quad = \inf\bigg\{\int_{\Omega_{1/\nu}\times Y} f(hy, \mathcal{T}_{1/\nu}(\nabla u)(x,y) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : \\
&\qquad V \in L^p(\Omega; W_0^{1,p}(Y;\mathbb{R}^m))\bigg\} \\
&\quad \geq \inf\bigg\{\int_{\Omega\times Y} f(hy, \mathcal{T}_{1/\nu}(\nabla u)(x,y) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : \\
&\qquad V \in L^p(\Omega; W_0^{1,p}(Y;\mathbb{R}^m))\bigg\}.
\end{aligned}$$

Then (2.15), (2.15), and Proposition 2.3 provide

$$\begin{aligned}
&\liminf_{h\to+\infty} \int_\Omega f(\nu hx, \nabla u + \nabla v_h)\,\mathrm{d}x + |\Omega_{1/\nu} \setminus \Omega| \int_Y a\,\mathrm{d}y + M \int_{\Omega_{1/\nu}\setminus\Omega} |\nabla u|^p\,\mathrm{d}x \\
&\quad \geq \sum_{j\in J_\nu} \liminf_{h\to+\infty} \inf\bigg\{\int_{Y_{\nu,j}\times Y} f(hy, \mathcal{T}_{1/\nu}(\nabla u)(x,y) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : \\
&\qquad V \in L^p(Y_{\nu,j}; W_0^{1,p}(Y;\mathbb{R}^m))\bigg\} \\
&\quad = \lim_{h\to+\infty} \sum_{j\in J_\nu} \inf\bigg\{\int_{Y_{\nu,j}\times Y} f(hy, \mathcal{T}_{1/\nu}(\nabla u)(x,y) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : \\
&\qquad V \in L^p(Y_{\nu,j}; W_0^{1,p}(Y;\mathbb{R}^m))\bigg\} \\
&\quad \geq \lim_{h\to+\infty} \inf\bigg\{\int_{\Omega\times Y} f(hy, \mathcal{T}_{1/\nu}(\nabla u)(x,y) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : \\
&\qquad V \in L^p(\Omega; W_0^{1,p}(Y;\mathbb{R}^m))\bigg\}.
\end{aligned}$$

As ν goes to $+\infty$, $|\Omega_{1/\nu} \setminus \Omega| \to 0$. Therefore, to complete the proof, we just need to verify that

$$\begin{aligned}
&\liminf_{\nu\to+\infty} \lim_{h\to+\infty} \inf\bigg\{\int_{\Omega\times Y} f(hy, \mathcal{T}_{1/\nu}(\nabla u(x)) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : \\
&\qquad V \in L^p(\Omega; W_0^{1,p}(Y;\mathbb{R}^m))\bigg\} \\
&\quad \geq \liminf_{h\to+\infty} \inf\bigg\{\int_{\Omega\times Y} f(hy, \nabla u(x) + \nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : \\
&\qquad V \in L^p(\Omega; W_0^{1,p}(Y;\mathbb{R}^m))\bigg\}.
\end{aligned} \tag{2.16}$$

To do this, we first recall that, by (1.3), $\{\mathcal{T}_{1/\nu}(\nabla u)\}$ converges to ∇u in $L^p(\Omega\times Y;\mathbb{R}^{mn})$ as ν goes to $+\infty$. For ν and h in $\mathbb{N}$, using (0.3), (0.4), and the boundedness of $\{\int_Y a(hy)\,\mathrm{d}y\}$, it is straightforward to find a $K(u)\in\,]0,+\infty[$, not depending on ν and h, such that

$$\begin{aligned}&\inf\Big\{\int_{\Omega\times Y} f(hy,\mathcal{T}_{1/\nu}(\nabla u)(x,y)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y:\\&\qquad V\in L^p(\Omega;W_0^{1,p}(Y;\mathbb{R}^m))\Big\}\\&\quad=\inf\Big\{\int_{\Omega\times Y} f(hy,\mathcal{T}_{1/\nu}(\nabla u)(x,y)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y:\\&\qquad V\in L^p(\Omega;W_0^{1,p}(Y;\mathbb{R}^m)),\ \|\mathcal{T}_{1/\nu}(\nabla u)+\nabla_y V\|_{L^p(\Omega\times Y;\mathbb{R}^m)}\le K(u)\Big\}.\end{aligned}\tag{2.17}$$

If $V\in L^p(\Omega;W_0^{1,p}(Y;\mathbb{R}^m))$ satisfies $\|\mathcal{T}_{1/\nu}(\nabla u)+\nabla_y V\|_{L^p(\Omega\times Y;\mathbb{R}^m)}\le K(u)$, using (1.1) and Hölder's inequality, we have

$$\begin{aligned}&\int_{\Omega\times Y} f(hy,\mathcal{T}_{1/\nu}(\nabla u)(x,y)+\nabla_y V(x,y))\,\mathrm{d}x\\&\quad\ge\int_{\Omega\times Y} f(hy,\nabla u(x)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y\\&\qquad-C\bigg\{\Big(|\Omega|\int_Y a(hy)\,\mathrm{d}y\Big)^{1-\frac{1}{p}}+\|\mathcal{T}_{1/\nu}(\nabla u)+\nabla_y V\|^{p-1}_{L^p(\Omega\times Y;\mathbb{R}^m)}\\&\qquad\quad+\|\nabla u+\nabla_y V\|^{p-1}_{L^p(\Omega\times Y;\mathbb{R}^m)}\bigg\}\|\mathcal{T}_{1/\nu}(\nabla u)-\nabla u\|_{L^p(\Omega\times Y;\mathbb{R}^m)}\\&\quad\ge\int_{\Omega\times Y} f(hy,\nabla u(x)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y-C\bigg\{\Big(|\Omega|\int_Y a(hy)\,\mathrm{d}y\Big)^{1-\frac{1}{p}}+K(u)^{p-1}\\&\qquad+(\|\nabla u-\mathcal{T}_{1/\nu}(\nabla u)\|_{L^p(\Omega\times Y;\mathbb{R}^m)}+K(u))^{p-1}\bigg\}\|\mathcal{T}_{1/\nu}(\nabla u)-\nabla u\|_{L^p(\Omega\times Y;\mathbb{R}^m)}.\end{aligned}$$

This, together with (2.17), implies for every ν, h in $\mathbb{N}$ that

$$\begin{aligned}&\inf\Big\{\int_{\Omega\times Y} f(hy,\mathcal{T}_{1/\nu}(\nabla u)(x,y)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y:\\&\qquad V\in L^p(\Omega;W_0^{1,p}(Y;\mathbb{R}^m))\Big\}\\&\quad\ge\inf\Big\{\int_{\Omega\times Y} f(hy,\nabla u(x)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y:\\&\qquad V\in L^p(\Omega;W_0^{1,p}(Y;\mathbb{R}^m))\Big\}\\&\qquad-C\bigg\{\Big(|\Omega|\int_Y a(hy)\,\mathrm{d}y\Big)^{1-\frac{1}{p}}+K(u)^{p-1}\\&\qquad\quad+\|\nabla u-\mathcal{T}_{1/\nu}(\nabla u)\|^{p-1}_{L^p(\Omega\times Y;\mathbb{R}^m)}\bigg\}\|\mathcal{T}_{1/\nu}(\nabla u)-\nabla u\|_{L^p(\Omega\times Y;\mathbb{R}^m)}.\end{aligned}\tag{2.18}$$

From the boundedness of $\{\int_Y a(hy)\,\mathrm{d}y\}$, and the convergence of $\{\mathcal{T}_{1/\nu}(\nabla u)\}$ to ∇u in $L^p(\Omega\times Y;\mathbb{R}^{mn})$, (2.18) implies equality (2.16) by letting h and ν successively go to $+\infty$. ∎

Proof of Theorem 2.5. First, (1.1) follows by Proposition 1.5. Then the theorem is a direct consequence of Lemma 2.6, Remark 2.7, Lemma 2.9, Lemma 1.8, and Proposition 2.3. ∎

3. The convex case. Let $W^{1,p}_{\mathrm{per}}(Y;\mathbb{R}^m)$ denote the Banach space of Y-periodic functions in $W^{1,p}_{\mathrm{loc}}(\mathbb{R}^n;\mathbb{R}^m)$ endowed with the $W^{1,p}(Y;\mathbb{R}^m)$-norm.

Consider the case where hypothesis (0.2) is replaced by (0.6). We show below how the proof of the homogenization result in simplified by the periodic unfolding method.

In the convex case, the homogenized density is classically defined as

$$f_{\#}\colon z\in\mathbb{R}^{nm}\mapsto \inf\left\{\int_Y f(y,z+\nabla v)\,\mathrm{d}y : v\in W^{1,p}_{\mathrm{per}}(Y;\mathbb{R}^m)\right\}. \tag{3.1}$$

THEOREM 3.1. *Let f satisfy* (0.1) *and* (0.6). *Let $p\in\,]1,+\infty[$, and assume that* (0.3) *and* (0.4) *hold. Let $f_{\#}$ be defined by* (3.1). *Then, for every $\{\varepsilon_h\}\subseteq\,]0,+\infty[$ converging to* 0, *Ω in $\mathcal{A}_0$, and u in $W^{1,p}(\Omega;\mathbb{R}^m)$,*

$$\begin{aligned}
&\int_\Omega f_{\#}(\nabla u)\,\mathrm{d}x\\
&\quad=\inf\left\{\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x : \{u_h\}\subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ u_h\to u \textit{ in } L^p(\Omega;\mathbb{R}^m)\right\}\\
&\quad=\inf\left\{\limsup_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x : \{u_h\}\subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ u_h\to u \textit{ in } L^p(\Omega;\mathbb{R}^m)\right\}\\
&\quad=\inf\Bigg\{\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x :\\
&\qquad\qquad \{u_h\}\subseteq u+W^{1,p}_0(\Omega;\mathbb{R}^m),\ u_h\to u \textit{ in } L^p(\Omega;\mathbb{R}^m)\Bigg\}\\
&\quad=\inf\Bigg\{\limsup_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x :\\
&\qquad\qquad \{u_h\}\subseteq u+W^{1,p}_0(\Omega;\mathbb{R}^m),\ u_h\to u \textit{ in } L^p(\Omega;\mathbb{R}^m)\Bigg\}.
\end{aligned}$$

Proof. First of all, we recall that (0.6) trivially implies (0.2) so that, by Proposition 1.5, (1.1) holds.

Let $\{\varepsilon_h\}$, Ω, and u be as above. We claim that

$$\begin{aligned}
&\inf\Bigg\{\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x :\\
&\qquad \{u_h\}\subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ u_h\rightharpoonup u \text{ in } W^{1,p}(\Omega;\mathbb{R}^m)\Bigg\}\\
&\qquad\quad\geq \inf\left\{\int_{\Omega\times Y} f(y,\nabla u(x)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V\in L^p(\Omega;W^{1,p}_{\mathrm{per}}(Y;\mathbb{R}^m))\right\}.
\end{aligned} \tag{3.2}$$

Indeed, let $\{u_h\}\subseteq W^{1,p}(\Omega;\mathbb{R}^m)$ weakly converge to u in $W^{1,p}(\Omega;\mathbb{R}^m)$, and assume for simplicity that $\lim_{h\to+\infty}\int_\Omega f(\frac{x}{\varepsilon_h},\nabla u_h)\,\mathrm{d}x$ exists and is finite. Then, Theorem 1.7

implies that there exist a strictly increasing sequence of integers $\{h_k\}$ and some U in $L^p(\Omega; W^{1,p}_{\mathrm{per}}(Y;\mathbb{R}^m))$ with

$$\mathcal{T}_{\varepsilon_{h_k}}(\nabla u_{h_k}) \rightharpoonup \nabla u + \nabla_y U \text{ in } L^p(\Omega\times Y;\mathbb{R}^{nm}). \tag{3.3}$$

By (1.2) and the periodicity properties of f, for every h in $\mathbb{N}$, we have

$$\begin{aligned}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x &\geq \int_{\Omega\times Y} f\Big(\frac{1}{\varepsilon_h}\Big(\varepsilon_h\Big[\frac{x}{\varepsilon_h}\Big]+\varepsilon_h y\Big),\mathcal{T}_{\varepsilon_h}(\nabla u_h)(x,y)\Big)\,\mathrm{d}x\,\mathrm{d}y\\ &= \int_{\Omega\times Y} f(y,\mathcal{T}_{\varepsilon_h}(\nabla u_h)(x,y))\,\mathrm{d}x\,\mathrm{d}y.\end{aligned}$$

Hence, using (3.3), (0.6), and Proposition 1.3 applied to $\Omega\times Y$, we conclude that

$$\begin{aligned}\lim_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x &= \lim_{k\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_{h_k}},\nabla u_{h_k}\Big)\,\mathrm{d}x\\ &\geq \int_{\Omega\times Y} f(y,\nabla u(x)+\nabla_y U(x,y))\,\mathrm{d}x\,\mathrm{d}y\\ &\geq \inf\Big\{\int_{\Omega\times Y} f(y,\nabla u(x)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V\in L^p(\Omega;W^{1,p}_{\mathrm{per}}(Y;\mathbb{R}^m))\Big\},\end{aligned}$$

from which (3.2) follows.

By (3.2), (0.4), and Rellich's theorem, it then follows that

$$\begin{aligned}&\inf\Big\{\liminf_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x :\\ &\qquad \{u_h\}\subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ u_h\to u \text{ in } L^p(\Omega;\mathbb{R}^m)\Big\}\\ &\quad\geq \inf\Big\{\int_{\Omega\times Y} f(y,\nabla u(x)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V\in L^p(\Omega;W^{1,p}_{\mathrm{per}}(Y;\mathbb{R}^m))\Big\}.\end{aligned}\tag{3.4}$$

On the other hand, Lemma 2.6 yields

$$\begin{aligned}&\inf\Big\{\limsup_{h\to+\infty}\int_\Omega f\Big(\frac{x}{\varepsilon_h},\nabla u_h\Big)\,\mathrm{d}x :\\ &\qquad \{u_h\}\subseteq W^{1,p}(\Omega;\mathbb{R}^m),\ u_h\to u \text{ in } L^p(\Omega;\mathbb{R}^m)\Big\}\\ &\quad\leq \inf\Big\{\int_{\Omega\times Y} f(y,\nabla u(x)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V\in L^p(\Omega;W^{1,p}_{\mathrm{per}}(Y;\mathbb{R}^m))\Big\}.\end{aligned}\tag{3.5}$$

Eventually, we observe that the very same proof of Lemma 2.2 for $t=1$, with $W^{1,p}_0(Y;\mathbb{R}^m)$ replaced by $W^{1,p}_{\mathrm{per}}(Y;\mathbb{R}^m)$, and f_1 by $f_\#$, provides

$$\begin{aligned}&\inf\Big\{\int_{\Omega\times Y} f(y,\nabla u(x)+\nabla_y V(x,y))\,\mathrm{d}x\,\mathrm{d}y : V\in L^p(\Omega;W^{1,p}_{\mathrm{per}}(Y;\mathbb{R}^m))\Big\}\\ &\quad= \int_\Omega f_\#(\nabla u)\,\mathrm{d}x.\end{aligned}\tag{3.6}$$

Consequently, (3.4), (3.5), (3.6), and Lemma 1.8 prove the theorem. $\square$

YOUNG MEASURES ASSOCIATED WITH HOMOGENIZATION*

PABLO PEDREGAL†

Abstract. We address the issue of determining the Young measure associated with the sequence of gradients of the solutions to a highly oscillatory boundary value problem as in a homogenization setting. After proving a general result, we focus on the standard periodic case providing explicit formulae for the situation of a first-order laminate.

Key words. homogenization, Γ-convergence, Young measure

DOI. 10.1137/040614578

1. Introduction.

In [10], a treatment was given by which Γ-convergence [4] can be understood and examined, in some situations, by means of Young measures. See also [6], [7]. Here we would like to provide some hint not only about Γ-limits of functionals in typical cases and their minimizers, but also about the full Young measure associated with minimizers of a sequence of functionals. From this perspective, this work can be considered as a second part of [10].

To be more precise we will focus on a typical situation in homogenization. Suppose that the sequence $\{u_j\}$ is the sequence of solutions for

$$\text{div}\,[A_j(x)\nabla u_j(x)] = 0 \text{ in } \Omega, \quad u_j = u_0 \text{ on } \partial\Omega, \tag{1.1}$$

where $u_0 \in H^1(\Omega)$, Ω is a regular bounded domain, and we have the uniform bounds

$$0 < a \leq A_j(x) \leq b.$$

We have considered the homogeneous case for simplicity. Any source right-hand-side term can similarly be examined. Suppose that for a given relevant quantity ϕ we know that $\{\phi(\nabla u_j)\}$ weakly converges in $L^1(\Omega)$. How can we determine the limit

$$\lim_{j\to\infty}\int_\Omega \phi\left(\nabla u_j(x)\right)\,dx,$$

or, more generally,

$$\lim_{j\to\infty}\int_\Omega \xi(x)\phi\left(\nabla u_j(x)\right)\,dx, \tag{1.2}$$

for an arbitrary, measurable, uniformly bounded function $\xi(x)$ and continuous ϕ? This is the issue of the identification of arbitrary macroscopic quantities (see [5]).

We know too well that when the density ϕ is linear the answer is given by the solution of the corresponding homogenized equation. What can be said for a general nonlinear quantity if the sequence of gradients $\{\nabla u_j\}$ does not converge strongly in

$H^1(\Omega)$, which is the case of interest? This issue is nothing more than determining the Young measure corresponding to the sequence of gradients $\{\nabla u_j\}$ [3], [8], [11], [12]. Whenever $\psi(x,\lambda)$ is a Carathéodory integrand (measurable in x and continuous in λ), the Young measure associated with $\{\nabla u_j\}$ furnishes a representation of all limits of $\{\psi(x,\nabla u_j)\}$ whenever this sequence is weakly convergent in $L^1(\Omega)$, namely,

$$\lim_{j\to\infty}\int_\Omega \psi(x,\nabla u_j(x))\,dx = \int_\Omega\int_{\mathbf{R}^N}\psi(x,\lambda)\,d\nu_x(\lambda)\,dx$$

if $\nu=\{\nu_x\}_{x\in\Omega}$ is the Young measure generated by $\{\nabla u_j\}$.

In the one-dimensional situation, for some simple examples the functions u_j can even be computed explicitly (see [9]) so that, in particular, we can determine the associated Young measure. Having a sequence of functions is much more than having its underlying Young measure. The whole point is to determine and understand the limits (1.2) without calculating explicitly the solutions. Obviously, this is always the case in higher dimensions. Specifically, we will see the role played by the homogenized equation in determining such families of probability measures.

Since we will describe our results from the horizon of Γ-convergence and convergence of functionals, an additional comparison with variational problems may be of help. When we face a nonconvex variational problem such as

$$\text{minimize in } u: \quad \int_\Omega W(\nabla u(x))\,dx$$

subject to $u\in W^{1,p}(\Omega)$, $u-u_0\in W_0^{1,p}(\Omega)$, we need to examine relaxation at two different levels. At first we examine the convexified problem

$$\text{minimize in } u: \quad \int_\Omega CW(\nabla u(x))\,dx,$$

where CW designates the (quasi-)convexification of W under appropriate technical assumptions. This new problem admits minimizers which are the weak limits of minimizing sequences of the initial nonconvex problem. At the second relaxation level we explore the generalized variational problem in terms of Young measures,

$$\text{minimize in } \nu=\{\nu_x\}_{x\in\Omega}: \quad \int_\Omega\int_{\mathbf{M}} W(X)\,d\nu_x(X)\,dx,$$

where the admissible families of probability measures ν need to verify some main structural assumptions [8], [11] so that this new variational problem is truly a different way of looking at the same underlying variational principle. The optimal solutions of this generalized problem are the Young measures associated with the gradients of minimizing sequences of the initial problem, and their first moments are the minimizers of the first level of relaxation. Indeed, the identification of an optimal Young measure starts by determining its first moment (mean field) as the solution of this first level of relaxation or of the corresponding homogenized equation. Once we have this mean field, by looking at the second level of relaxation and, based on the knowledge of the first moment, we try to identify the optimal underlying Young measure, the "fluctuations" around the mean field.

We would like to follow this same strategy in the context of homogenization, where solutions of homogenized equations provide first moments of associated Young measures. As indicated, this would be like a first level of relaxation. The second step would require the full Young measure which somehow needs to be recovered from its first moment. In fact, the identification of the Young measure is somehow encoded in the process of computing the integrand for the convexified functional or for the Γ-limit, so that it typically involves a careful re-examination of how this integrand was computed or defined.

Despite our strategy described above, a more general and abstract treatment may be possible in which relevant Young measures are sought directly without any reference to its first moment or knowledge of it. See [2]. Our ideas are obviously very closely connected and motivated by homogenization techniques. In particular, we would like to refer to [1] and [6].

In the context of Γ-convergence, and without being precise at this stage, if I_j Γ-converges to I and u is a given field, we say that $\nu = \{\nu_x\}_{x\in\Omega}$ is an optimal Young measure associated with u if there is a sequence $\{u_j\}$ generating ν such that $I_j(u_j) \to I(u)$. When u is a minimizer for I, ν will be the Young measure corresponding to a sequence of minimizers for I_j and, hence, it provides macroscopic quantities.

Although more general results are possible, our main contribution here focuses on the standard periodic homogenization setting

$$A_j(x) = A(jx), \quad 0 < a \le A(y) \le b, \ y \in Q, \quad A \text{ is } Q\text{-periodic},$$

where Q is the unit cube in $\mathbf{R}^2$. We restrict our attention to the two-dimensional situation. Here Q replaces the domain Ω above as we concentrate on a periodic situation. For a given, Q-periodic $u_0 \in H^1(Q)$, let $u_j \in H^1(Q)$ be the unique, Q-periodic, weak solution of (1.1). Let

$$\xi : \mathbf{R}^2 \times \mathbf{R}^2 \to \mathbf{R}, \quad \xi(\lambda, \rho),$$

Q-periodic in the λ-variable, be the unique, Q-periodic, weak solution in $H^1(Q)$ of the cell problem for fixed ρ,

$$\operatorname{div}_\lambda \left[A(\lambda)\left(\rho + \nabla_\lambda \xi(\lambda, \rho)\right)\right] = 0. \tag{1.3}$$

THEOREM 1.1. *Let $\nu = \{\nu_x\}_{x\in\Omega}$ be the Young measure associated with $\{\nabla u_j\}$. Then for any continuous ϕ we have*

$$\langle \phi, \nu_x \rangle = \int_Q \phi\left(\nabla u(x) + \nabla_\lambda \xi(\lambda, \nabla u(x))\right) d\lambda,$$

where u is the solution of the homogenized equation

$$\operatorname{div}\left[\frac{\partial \psi}{\partial \rho}\left(\nabla u(x)\right)\right] = 0 \text{ in } Q, \quad u = u_0 \text{ on } \partial Q,$$
$$\psi(\rho) = \int_Q \frac{A(\lambda)}{2} \left|\rho + \nabla_\lambda \xi(\lambda, \rho)\right|^2 d\lambda.$$

Notice that because of (1.3) and the periodicity of $\xi(\lambda, \rho)$, we also have

$$\frac{\partial \psi}{\partial \rho}(\rho) = \int_Q A(\lambda)(\rho + \nabla_\lambda \xi(\lambda, \rho))\, d\lambda.$$

When $\{\psi(x, \nabla u_j(x))\}$ converges weakly in $L^1(\Omega)$, Theorem 1.1 implies

$$\lim_{j\to\infty} \int_Q \psi(x, \nabla u_j(x))\, dx = \int_Q \int_Q \psi\left(x, \nabla u(x) + \nabla_\lambda \xi(\lambda, \nabla u(x))\right) d\lambda\, dx.$$

Theorem 1.1 is a direct consequence of results proved in sections 2 and 3, namely, the main result, Theorem 2.2, and Corollary 3.2.

More explicit formulae can be given for more specific examples. For a typical first-order laminate, where we take

$$A(y) = \chi(y \cdot n)a + (1 - \chi(y \cdot n))b, \quad 0 < a < b, \ |n| = 1,$$

χ being the characteristic function of $(0, t)$ in $(0, 1)$ extended by periodicity and n the unit normal to the layers, we have

$$\psi(\rho) = (ta + (1-t)b) |\rho|^2 - \frac{(b-a)^2 t(1-t)}{(1-t)a + tb} (\rho \cdot n)^2$$

and

$$\lim_{j\to\infty} \int_Q \phi(\nabla u_j(x))\, dx = \int_Q \left[t\phi\left(F(\nabla u(x))\right) + (1-t)\phi\left(G(\nabla u(x))\right)\right] dx,$$

where u is the solution of the homogenized equation

$$\operatorname{div} \left[\frac{\partial \psi}{\partial \rho}(\nabla u(x))\right] = 0 \text{ in } Q, \quad u = u_0 \text{ on } \partial Q,$$

and $F(\rho)$, $G(\rho)$ are the linear mappings with matrices

$$\mathbf{1} + \frac{(1-t)(b-a)}{(1-t)a + tb} n \otimes n, \quad \mathbf{1} - \frac{t(b-a)}{(1-t)a + tb} n \otimes n,$$

respectively, where $\mathbf{1}$ is the identity matrix.

Corollary 1.2. *For any Carathéodory integrand $\psi(x, \lambda)$ such that $\{\psi(x, \nabla u_j(x))\}$ weakly converges in $L^1(Q)$, we have*

$$\begin{aligned}
&\lim_{j\to\infty} \int_Q \psi(x, \nabla u_j(x))\, dx \\
&= \int_\Omega t\psi\left(x, \left(\mathbf{1} + \frac{(1-t)(b-a)}{(1-t)a + tb} n \otimes n\right) \nabla u(x)\right) \\
&\qquad + (1-t)\psi\left(x, \left(\mathbf{1} - \frac{t(b-a)}{(1-t)a + tb} n \otimes n\right) \nabla u(x)\right) dx.
\end{aligned}$$

As an even more specific example, if $\{|\nabla u_j|^2\}$ weakly converges in $L^1(Q)$, we should have

$$\lim_{j\to\infty} \int_Q |\nabla u_j(x)|^2\, dx = \int_Q \left(|\nabla u(x)|^2 + \frac{t(1-t)(b-a)^2}{((1-t)a + tb)^2} (\nabla u(x) \cdot n)^2\right) dx,$$

where u is the solution of the corresponding homogenized equation. Similar formulae are valid for higher moments.

In section 2, as a preliminary step we treat the nongradient case, while in section 3 we concentrate on the gradient case. An equivalent analysis for situations more general than the typical periodic case investigated here is possible, for instance for the almost periodic case. This, however, would depend on a preliminary study analogous to the one in [10] for more general situations.

2. Case without derivatives. Let us first consider the case without derivatives as a preliminary step. It can serve as a training ground for the main ideas we will have to implement later for the case with gradients,

$$I_j(v) = \int_\Omega W(A_j(x), v(x))\, dx,$$

where the assumptions on

$$W(\lambda, \rho) : \mathbf{R}^m \times \mathbf{R}^d \to \mathbf{R}$$

and the sequence $\{A_j\}$ are as follows:

1. $\{A_j\}$ is a weakly convergent sequence in $L^q(\Omega)$ for some $q > 1$;
2. W is uniformly coercive in ρ for all j with an exponent $p > 1$ and is uniformly bounded from above by the same power so that

$$c\,(|\rho|^p - 1) \leq W(A_j(x), \rho) \leq C\,(|\rho|^p + 1)$$

   for some $C \geq c > 0$, all j, and a.e. $x \in \Omega$. Under this hypothesis, every sequence $\{u_j\}$ such that $\{I_j(u_j)\}$ is bounded from above will be bounded in $L^p(\Omega)$ and thus, possibly for a subsequence, it will converge weakly to some $u \in L^p(\Omega)$.
3. W is uniformly continuous in λ as indicated earlier,

$$|W(\lambda_1, \rho) - W(\lambda_2, \rho)| \leq w(|\lambda_1 - \lambda_2|)\, |\rho|^p\,,$$

   where w is continuous and $w(0) = 0$.
4. W is strictly convex in ρ for every fixed λ. This assumption can be dispensed with as we will see in the proof of the theorem below, but we will retain it for simplicity.

Let $u \in L^p(\Omega)$ be given, and let $\sigma = \{\sigma_x\}_{x\in\Omega}$ be the Young measure generated by the sequence $\{A_j\}$.

DEFINITION 2.1. *A family of probability measures $\nu = \{\nu_x\}_{x\in\Omega}$ is an optimal Young measure associated with $u \in L^p(\Omega)$ if it is the Young measure associated with a sequence of functions $\{u_j\}$ such that the limit*

$$\lim_{j\to\infty} \int_\Omega W(A_j(x), u_j(x))\, dx$$

is precisely the value of the Γ-limit at u taken with respect to the weak topology in $L^p(\Omega)$.

Our main task consists of determining an optimal Young measure associated with any given $u \in L^p(\Omega)$.

THEOREM 2.2. *There exists a map*

$$\varphi_0 : \Omega \times \mathbf{R}^m \times \mathbf{R}^d \to \mathbf{R}^d$$

such that the family of measures supported in $\mathbf{R}^d$ and determined by

$$\langle \phi, \nu_x \rangle = \int_{\mathbf{R}^m} \phi\left(\varphi_0(x, \lambda, u(x))\right)\, d\sigma_x(\lambda)$$

for any continuous ϕ is an optimal Young measure associated with u.

Proof. The proof is nothing more than a careful analysis of how the Γ-limit of $\{I_j\}$ was obtained in [10] through Young measures. We recall here some of those main ideas for the convenience of the readers.

In the nongradient case, the integrand ψ for the Γ-limit is given by

$$\psi(x,\rho) = \min_{\varphi} \left\{ \int_{\mathbf{R}^m} CW(\lambda, \varphi(\lambda))\, d\sigma_x(\lambda) : \rho = \int_{\mathbf{R}^m} \varphi(\lambda)\, d\sigma_x(\lambda) \right\}.$$

CW stands for the convexification with respect to λ of W. Let us pretend we do not have the hypothesis of convexity on W. Since, under our assumptions, there are optimal solutions for this optimization problem, let us put $\varphi_0(x,\lambda,\rho)$ for one such optimal solution so that

$$\begin{aligned} \rho &= \int_{\mathbf{R}^m} \varphi_0(x,\lambda,\rho)\, d\sigma_x(\lambda), \\ \psi(x,\rho) &= \int_{\mathbf{R}^m} CW(\lambda, \varphi_0(x,\lambda,\rho))\, d\sigma_x(\lambda). \end{aligned} \tag{2.1}$$

Further, by convexity arguments, find a family of probability measures $\mu^{(0)} = \{\mu^{(0)}_{\lambda,x}\}$ such that

$$\begin{aligned} \varphi_0(x,\lambda,u(x)) &= \int_{\mathbf{R}^d} \rho\, d\mu^{(0)}_{\lambda,x}(\rho), \\ CW\left(\lambda, \varphi_0(x,\lambda,u(x))\right) &= \int_{\mathbf{R}^d} W(\lambda,\rho)\, d\mu^{(0)}_{\lambda,x}(\rho). \end{aligned} \tag{2.2}$$

Write

$$\Lambda = \{\Lambda_x\}_{x\in\Omega}, \quad \Lambda_x = \mu^{(0)}_{\lambda,x}(\rho) \otimes \sigma_x(\lambda).$$

Then [10] Λ is the joint Young measure generated by $\{(A_j, u_j)\}$ for some sequence $\{u_j\}$ so that

$$\lim_{j\to\infty} \int_\Omega W(A_j(x), u_j(x))\, dx = \int_\Omega \psi(x, u(x))\, dx.$$

The main idea now consists of projecting Λ_x onto the ρ-variable to obtain the Young measure $\nu = \{\nu_x\}_{x\in\Omega}$ corresponding to $\{u_j\}$,

$$\Lambda_x = \pi_{\rho,x}(\lambda) \otimes \nu_x(\rho),$$

for a certain family of probability measures $\pi_{\rho,x}$. Notice how Λ_x, for a.e. $x \in \Omega$, is a probability measure in the product space $\mathbf{R}^m \times \mathbf{R}^d$ that has been obtained and defined through the optimality property written in (2.1) and (2.2). Its projection onto $\mathbf{R}^m$ is $\sigma = \{\sigma_x\}_{x\in\Omega}$ which is the Young measure associated with $\{A_j\}$. Then, we are decomposing such probability measure Λ_x projecting onto the other component $\mathbf{R}^d$ to obtain a family $\nu = \{\nu_x\}_{x\in\Omega}$, which, due to that optimality property coming from $\mu^{(0)}_{\lambda,x}$ (see [10]), turns out to be an optimal Young measure associated with u. As indicated, this is the main idea of this paper and it completes the analysis in [10].

Indeed, by (2.1) and (2.2), we have

$$\begin{aligned}\psi(x,u(x)) &= \int_{\mathbf{R}^m} CW(x,\varphi_0(x,\lambda,u(x)))\,d\sigma_x(\lambda)\\ &= \int_{\mathbf{R}^m}\int_{\mathbf{R}^d} W(\lambda,\rho)\,d\mu^{(0)}_{\lambda,x}(\rho)\,d\sigma_x(\lambda)\\ &= \int_{\mathbf{R}^d}\int_{\mathbf{R}^m} W(\lambda,\rho)\,d\pi_{\rho,x}(\lambda)\,d\nu_x(\rho).\end{aligned}$$

Consequently,

$$\int_\Omega \psi(x,u(x))\,dx = \int_\Omega\int_{\mathbf{R}^d\times\mathbf{R}^m} W(\lambda,\rho)\,d\Lambda_x(\lambda,\rho)\,dx = \lim_{j\to\infty}\int_\Omega W(A_j(x),u_j(x))\,dx.$$

For any continuous ϕ

$$\langle\phi,\nu_x\rangle = \int_{\mathbf{R}^d\times\mathbf{R}^m}\phi(\rho)\,d\mu^{(0)}_{\lambda,x}(\rho)\,d\sigma_x(\lambda).$$

But notice that the strict convexity of W with respect to ρ implies that in fact

$$\mu^{(0)}_{\lambda,x}(\rho) = \delta_{\varphi_0(x,\lambda,u(x))}$$

and therefore

$$\langle\phi,\nu_x\rangle = \int_{\mathbf{R}^m}\phi\left(\varphi_0(x,\lambda,u(x))\right)\,d\sigma_x(\lambda).$$

This is the statement of the theorem. ∎

What is interesting is that this map φ_0 can be explicitly computed in some standard cases.

Take first for $0<a<b$, $p>1$, and $0<t<1$

$$\sigma_x = t\delta_a + (1-t)\delta_b, \quad W(\lambda,\rho) = \lambda\,|\rho|^p\,.$$

As it was shown in [10], the integrand for the Γ-limit is obtained from the mathematical programming problem

$$\psi(\rho) = \min_\varphi\left\{tW(a,\varphi(a)) + (1-t)W(b,\varphi(b)) : \rho = t\varphi(a) + (1-t)\varphi(b)\right\},$$

where if we set $F=\varphi(a)$, $G=\varphi(b)$, and we put $F(\rho)$ and $G(\rho)$ for the optimal choices for F and G so that

$$\psi(\rho) = tW(a,F(\rho)) + (1-t)W(b,G(\rho)), \quad \rho = tF(\rho) + (1-t)G(\rho),$$

then the optimal Young measure associated with a given $u\in L^p(\Omega)$ comes from the projection of

$$t\delta_{F(u(x))}\otimes\delta_a + (1-t)\delta_{G(u(x))}\otimes\delta_b$$

onto the first variable, i.e.,

$$t\delta_{F(u(x))} + (1-t)\delta_{G(u(x))}.$$

Explicit expressions for $F(\rho)$ and $G(\rho)$ are found in an elementary way.

Consider as a second example a sequence $\{A_j\}$ whose Young measure is

$$d\lambda|_{[1,2]}$$

independent of $x \in \Omega$. Then the integrand $\psi(\rho)$ is found through the minimum

$$\psi(\rho) = \min_{\varphi} \left\{ \int_1^2 W(\lambda, \varphi(\lambda))\, d\lambda : \rho = \int_1^2 \varphi(\lambda)\, d\lambda \right\}.$$

The optimal solution of this zero-order variational problem should be a solution of

$$\frac{\partial W}{\partial \rho}(\lambda, \varphi(\lambda)) = \gamma$$

if W is strictly convex with respect to ρ, where γ is a multiplier determined so that the integral constraint is fulfilled. As an explicit example take

$$W(\lambda, \rho) = \frac{1}{2(\lambda - 1)(2 - \lambda)} |\rho|^2 .$$

Then it is elementary to check that the optimal mapping φ_0 is given by

$$\varphi_0(\lambda, \rho) = \rho\, 6(\lambda - 1)(2 - \lambda),$$

and then the optimal Young measure associated with $u \in L^2(\Omega)$ is given by

$$\nu = \{\nu_x\}_{x \in \Omega}, \quad \langle \phi, \nu_x \rangle = \int_1^2 \phi\left(6(\lambda - 1)(2 - \lambda)\, u(x)\right) d\lambda.$$

We see that this time the projection is not one-to-one since φ_0 itself is not one-to-one. There is some overlapping effect on the oscillations from the viewpoint of the u variable.

3. Gradient case. We now consider the sequence of functionals

$$I_j(v) = \int_\Omega W(A_j(x), \nabla v(x))\, dx,$$

where W and the sequence $\{A_j\}$ are as in section 2. The difficulties attached to the same analysis have been emphasized in [10]. To be able to provide a complete analysis of the gradient situation, we need to add an important structural assumption on the sequence $\{A_j\}$. This is the AGP (average gradient property) which, in plain words, amounts to the fact that "averages of gradients over level sets of a_j are gradients themselves." See [10] for a much more precise formulation. Here we would like to show a general result similar to Theorem 2.2 for the gradient case based on this main assumption, and then apply it to the typical situation of periodic homogenization. The abstract theorem is formally the same as in the nongradient case. The difference is hidden in the much stronger AGP condition. In the case of periodic homogenization, under our technical assumptions, the AGP requirement has been seen to be fulfilled in [10] so that we do not need to bother here about it. To avoid unnecessary repetition, we refer our readers to this work for a complete discussion.

THEOREM 3.1. *Under the general assumptions on $\{A_j\}$ and W indicated in the preceding section and the AGP condition on the sequence $\{A_j\}$, there exists a map*

$$\varphi_0 : \Omega \times \mathbf{R}^m \times \mathbf{R}^d \to \mathbf{R}^d$$

such that the family of measures supported in $\mathbf{R}^d$ *and determined by*

$$\langle \phi, \nu_x \rangle = \int_{\mathbf{R}^m} \phi\left(\varphi_0(x, \lambda, \nabla u(x))\right) \, d\sigma_x(\lambda),$$

for any continuous ϕ, *is an optimal Young measure associated with* u.

The proof of this result is exactly the same as the proof of Theorem 2.2. The precise place where the gradient constraint enters is the definition of the integrand for the Γ-limit which again is

$$\psi(x, \rho) = \min_{\varphi} \left\{ \int_{\mathbf{R}^m} CW(\lambda, \varphi(\lambda)) \, d\sigma_x(\lambda) : \rho = \int_{\mathbf{R}^m} \varphi(\lambda) \, d\sigma_x(\lambda) \right\}.$$

In the gradient case, this is so because of the AGP condition assumed on the sequence $\{a_j\}$ (Lemma 9 in [10]). In the nongradient case, there is no need for this structural assumption, as there is "no gradient constraint."

We next focus on the periodic homogenization situation, where

$$A_j(x) = A(jx)$$

and A is Q-periodic. Recall that Q is the unit cube in $\mathbf{R}^2$. A direct corollary for this situation follows.

COROLLARY 3.2. *There exists a mapping*

$$\xi : \mathbf{R}^2 \times \mathbf{R}^2 \to \mathbf{R}, \quad \xi(\lambda, \rho)$$

Q*-periodic in the first variable* λ *such that an optimal Young measure associated with any given* $u \in W^{1,p}(\Omega)$ *is given by*

$$\nu = \{\nu_x\}_{x \in \Omega}, \quad \langle \phi, \nu_x \rangle = \int_Q \phi\left(\nabla u(x) + \nabla_\lambda \xi(\lambda, \nabla u(x))\right) \, d\lambda$$

for any continuous ϕ.

This mapping ξ is given as the solution of the typical cell problem in homogenization

$$\int_Q W\left(\lambda, \rho + \nabla_\lambda \xi(\lambda, \rho)\right) \, d\lambda = \min_{\zeta} \int_Q W\left(\lambda, \rho + \nabla_\lambda \zeta(\lambda, \rho)\right) \, d\lambda.$$

In the typical quadratic case, where we put

$$W(\lambda, \rho) = \frac{A(\lambda)}{2} |\rho|^2,$$

the integrand for the Γ-limit is given by

$$\psi(\rho) = \int_Q \frac{A(\lambda)}{2} |\rho + \nabla_\lambda \xi(\lambda, \rho)|^2 \, d\lambda.$$

In this way, if $u_j \in H^1(Q)$ is the solution of

$$\operatorname{div} [A(jx) \nabla u_j(x)] = 0 \text{ in } Q, \quad u = u_0 \text{ on } \partial Q,$$

then for any continuous ϕ for which $\{\phi(\nabla u_j)\}$ weakly converges in $L^1(Q)$, we have

$$\lim_{j \to \infty} \int_Q \phi(\nabla u_j(x)) \, dx = \int_Q \int_Q \phi\left(\nabla u(x) + \nabla_\lambda \xi(\lambda, \nabla u(x))\right) \, d\lambda \, dx,$$

where u is the solution of the homogenized equation

$$\operatorname{div}\left[\frac{\partial\psi}{\partial\rho}(\nabla u(x))\right] = 0 \text{ in } Q, \quad u = u_0 \text{ on } \partial Q.$$

In the case of a single, first-order laminate, more explicit calculations can be performed. Indeed if we put

$$A(x) = \chi(x\cdot n)a + (1-\chi(x\cdot n))\,b, \qquad 0<a<b, \quad |n|=1,$$

where χ is the characteristic function of the interval $(0,t)$ over $(0,1)$ extended by periodicity and the unit vector n indicates the normal direction to the layers, then the optimal mapping $\nabla_\lambda\xi(\lambda,\rho)$ can be computed explicitly. This calculation can be found in [10], namely,

$$\psi(\rho) = \min_{F,G\in\mathbf{R}^2}\left\{t\frac{a}{2}\,|F|^2 + (1-t)\frac{b}{2}\,|G|^2 : \rho = tF + (1-t)G, (F-G)\cdot Tn = 0\right\}.$$

T is the counterclockwise, $\pi/2$ rotation in the plane. Then

$$\psi(\rho) = (ta + (1-t)b)\,|\rho|^2 - \frac{(b-a)^2 t(1-t)}{(1-t)a + tb}\,(\rho\cdot n)^2$$

and the optimal pair $F(\rho)$ and $G(\rho)$ furnishing this value can also be written explicitly (see the introduction). Then if

$$\operatorname{div}\,[A(jx)\nabla u_j(x)] = 0 \text{ in } Q, \quad u_j = u_0 \text{ on } \partial Q,$$

and if for any given continuous ϕ we have that $\{\phi(\nabla u_j)\}$ converges in $L^1(Q)$, we have

$$\lim_{j\to\infty}\int_Q \phi(\nabla u_j(x))\,dx = \int_Q \left[t\phi\left(F(\nabla u(x))\right) + (1-t)\phi\left(G(\nabla u(x))\right)\right]dx,$$

where u is the solution of the homogenized equation

$$\operatorname{div}\left[\frac{\partial\psi}{\partial\rho}(\nabla u(x))\right] = 0 \text{ in } Q, \quad u = u_0 \text{ on } \partial Q.$$

More general examples can also be treated.

Acknowledgments. The author would like to express his gratitude to several referees for their valuable comments in improving the original manuscript.

EXISTENCE OF EIGENVALUES OF A LINEAR OPERATOR PENCIL IN A CURVED WAVEGUIDE—LOCALIZED SHELF WAVES ON A CURVED COAST*

E. R. JOHNSON†, MICHAEL LEVITIN‡, AND LEONID PARNOVSKI†

Abstract. The question of the existence of nonpropagating, trapped continental shelf waves (CSWs) along curved coasts reduces mathematically to a spectral problem for a self-adjoint operator pencil in a curved strip. Using methods developed for the waveguide trapped mode problem, we show that such CSWs exist for a wide class of coast curvature and depth profiles.

Key words. continental shelf waves, curved coasts, trapped modes, essential spectrum, operator pencil

1. Introduction. Measurements of velocity fields along the coasts of oceans throughout the world show that much of the fluid energy is contained in motions with periods of a few days or longer. The comparison of measurements at different places along the same coast shows that in general these low-frequency disturbances propagate along coasts with shallow water to the right in the northern hemisphere and to the left in the southern hemisphere. These waves have come to be known as continental shelf waves (CSWs). The purpose of the present paper is to demonstrate, using the most straightforward model possible, the possibility of nonpropagating, trapped CSWs along curved coasts. The existence of such nonpropagating modes would be significant as they would tend to be forced by atmospheric weather systems, which have similar periods of a few days, similar horizontal extent, and a reasonably broad spectrum in space and time. Areas where such modes were trapped would thus appear to be likely to show higher than normal energy in the low-frequency horizontal velocity field.

The simplest models for CSWs take the coastal oceans to be inviscid and of constant density. Both these assumptions might be expected to fail in various regions such as when strong currents pass sharp capes or when the coastal flow is strongly stratified. However, for small-amplitude CSWs in quiescent flow along smooth coasts, viscous separation is negligible. Similarly most disturbance energy is concentrated in the modes with the least vertical structure, which are well described by the constant density model [LBMy]. The governing equations are then simply the rotating incompressible Euler equations. Further, coastal flows are shallow in the sense that the ratio of depth to typical horizontal scale is small. Expanding the rotating incompressible Euler equations in powers of this ratio and retaining only the leading order terms

gives the rotating shallow water equations [Pe]:

$$\frac{\partial \mathbf{u}}{\partial t} + \mathbf{u} \cdot \mathbf{grad}\,\mathbf{u} - 2\Omega\mathbf{k} \times \mathbf{u} = -g\,\mathbf{grad}\,\widetilde{H}, \tag{1.1}$$

$$\frac{\partial \widetilde{H}}{\partial t} + \mathbf{div}[(\widetilde{H} + H)\mathbf{u}] = 0. \tag{1.2}$$

Here **div** and **grad** are taken with respect to horizontal coordinates (x, y) in a frame fixed to the rotating Earth, $\mathbf{k}$ is a vertical unit vector, $\mathbf{u}(x, y, t)$ is the horizontal velocity (with components $\mathbf{u} = (u, v)$), Ω is the (locally constant) vertical component of the Earth's rotation, g is the gravitational acceleration, $\widetilde{H}(x, y, t)$ is the vertical displacement of the free surface, and $H(x, y)$ is the local undisturbed fluid depth.

System (1.1), (1.2) admits waves of two types, denoted Class 1 and Class 2 by [La]. Class 1 waves are fast high-frequency waves, the rotation-modified form of the usual free surface water waves, although here present only as long, nondispersive waves with speeds of order $\sqrt{gH}$. Class 2 waves are slower, low-frequency waves that vanish in the absence of depth change or in the absence of rotation. It is the Class 2 waves that give CSWs. They have little signature in the vertical height field $\widetilde{H}(x, y, t)$ and are observed through their associated horizontal velocity fields [Ha]. The Class 1 waves can be removed from (1.1), (1.2) by considering the "rigid-lid" limit, where the external Rossby radius $\sqrt{gH}/2\Omega$ (which gives the relaxation distance of the free surface) is large compared to the horizontal scale of the motion. This is perhaps the most accurate of the approximations noted here, causing the time-dependent term to vanish from (1.2) and the right side of (1.1) to become a simple pressure gradient.

For small amplitude waves the nonlinear terms in (1.1), (1.2) are negligible, and cross-differentiating gives

$$\frac{\partial \zeta}{\partial t} + 2\Omega\,\mathbf{div}\,\mathbf{u} = 0, \tag{1.3}$$

$$\mathbf{div}(H\mathbf{u}) = 0, \tag{1.4}$$

where $\zeta = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}$ is the vertical component of relative vorticity. Equation (1.4) is satisfied by introducing the volume flux streamfunction defined through

$$Hu = -\frac{\partial \psi}{\partial y}, \qquad Hv = \frac{\partial \psi}{\partial x}, \tag{1.5}$$

allowing (1.3) to be written as the single equation

$$\mathbf{div}\left(\frac{1}{H}\,\mathbf{grad}\,\frac{\partial \psi}{\partial t}\right) + 2\Omega\mathbf{k} \cdot \mathbf{grad}\,\psi \times \mathbf{grad}\left(\frac{1}{H}\right) = 0. \tag{1.6}$$

Equation (1.6) is generally described as the topographic Rossby wave equation or the equation for barotropic CSWs. Many solutions have been presented for straight coasts, where the coast lies along $y = 0$ (say) and the depth H is a function of y alone (described as rectilinear topography here) [LBMy]. These have shown excellent agreement with observations of CSWs, as in [Ha]. There has been far less discussion of nonrectilinear geometries, where either the coast or the depth profile or both are not functions of a single coordinate. Yet interesting results appear. The papers [StHu1], [StHu2] present extensive numerical integrations of a low-order spectral model of a rectangular lake with idealized topography. For their chosen depth profiles normal modes can be divided into two types: *basin-wide modes* which extend throughout the lake and localized *bay modes*. These bay modes correspond to the high-frequency modes found in a finite-element model of Lake Lugarno by [Tr] and observed by [StHuSaTrZa]. The papers [Jo2], [StJo1], [StJo2] give a variational formulation and describe simplified quasi-analytical models that admit localized trapped bay modes. However the geometry changes in these models are large, with the sloping lower boundary terminating abruptly where it strikes a coastal wall. Further [Jo1] notes that (1.6) is invariant under conformal mappings and so any geometry that can be mapped conformally to a rectilinear shelf cannot support trapped modes. The question thus arises as to whether it is only for the most extreme topographic changes that shelf waves can be trapped or whether trapping can occur on smoothly varying shelves. The purpose of this paper is to provide the answer: trapped modes can exist on smoothly curving coasts.

The geometry considered here is that of a shelf of finite width lying along an impermeable coast. Thus sufficiently far from the coast the undisturbed fluid depth becomes the constant depth of the open ocean. It is shown in [Jo3] that at the shelf-ocean boundary of finite-width rectilinear shelves the tangential velocity component u vanishes for waves sufficiently long compared to the shelf width. The wavelength of long propagating disturbances is proportional to their frequency which is in turn proportional to the slope of the shelf. Thus it appears that for sufficiently weakly sloping shelves the tangential velocity component, i.e., the normal derivative of the streamfunction, at the shelf-ocean boundary can be made arbitrarily small. Here this will be taken as also giving a close approximation to the boundary condition at the shelf-ocean boundary when this boundary is no longer straight. The unapproximated boundary condition is that the streamfunction and its normal derivative are continuous across the boundary where they match to the decaying solution of Laplace's equation (to which (1.6) reduces in regions of constant depth). This gives a linear integral condition along the boundary. The unapproximated problem will not be pursued further here. The boundary condition at the coast is simply one of impermeability and thus on both rectilinear and curving coasts is simply that the streamfunction vanishes. Now consider flows of the form

$$\psi(x,y,t) = \mathrm{Re}\{\Phi(x,y)\exp(-2\mathrm{i}\omega\Omega\mathrm{t})\}, \tag{1.7}$$

so $\Phi(x,y)$ gives the spatial structure of the flow and ω its nondimensional frequency. Then Φ satisfies

$$\frac{1}{H}\,\Delta\,\Phi + \mathbf{grad}\left(\frac{1}{H}\right)\cdot\mathbf{grad}\,\Phi + \frac{i}{\omega}\mathbf{k}\cdot\left(\mathbf{grad}\,\Phi\times\mathbf{grad}\left(\frac{1}{H}\right)\right) = 0, \tag{1.8}$$

$$\Phi = 0 \text{ at the coast}, \tag{1.9}$$

$$\hat{\mathbf{n}}\cdot\mathbf{grad}\,\Phi = 0 \text{ at the shelf-ocean boundary}, \tag{1.10}$$

where vector $\hat{\mathbf{n}}$ is normal to the shelf-ocean boundary.

Mathematically, we are going to study the existence of trapped modes (i.e., the eigenvalues either embedded into the essential spectrum or lying in the gap of the essential spectrum) for the problem (1.8)–(1.10) in a curved strip. Similar problems for the Laplace operator have been extensively studied in the literature—either in a curved strip, in a straight strip with an obstacle, or in a strip with compactly perturbed boundary. In the case of Laplacians with Dirichlet boundary conditions these problems are usually called "quantum waveguides"; the Neumann case is usually referred to as "acoustic waveguides." The important result concerning quantum waveguides was established in [ExSe], [DuEx]: in the curved waveguides there always exists a trapped mode. Later this result was extended to more general settings; in particular, in [DiKr] (see also [KrKr]) it was shown that in the case of mixed boundary conditions (i.e., Dirichlet conditions on one side of the strip and Neumann conditions on the other side) trapped modes exist if the strip is curved "in the direction of the Dirichlet boundary."

The case of acoustic waveguides is more complicated because any eventual eigenvalues are embedded into the essential spectrum and are, therefore, highly unstable. Therefore, it is believed that in general the existence of trapped modes in this case is due to some sort of the symmetry of the problem (see [EvLeVa], [DaPa], [AsPaVa]).

In the present paper we use an approach similar to the one used in [DuEx] and [EvLeVa]; however, we have to modify this approach substantially due to the fact that we are working with a spectral problem for an operator pencil rather than that for an ordinary operator.

The rest of the paper is organized in the following way. In section 2, we discuss the rigorous mathematical statement of the problem; in section 3, we study the essential spectrum; and in section 4, we state and prove the main result on the existence of a discrete spectrum (Theorem 4.1). In particular we show that a trapped mode always exists if all of the following conditions are satisfied: (a) the depth profile H does not depend upon the longitudinal coordinate and is monotone increasing and logarithmically concave in the direction perpendicular to the coast; (b) the channel is curved in the direction of the Dirichlet boundary; (c) the curvature is sufficiently small.

Similar results can be obtained in a straight strip if the depth profile H depends nontrivially upon the longitudinal coordinate; we however do not discuss this problem here.

2. Mathematical statement of the problem.

2.1. Geometry. The original geometry is a straight planar strip of width δ:

$$G_0 = \{(x, y) : x \in \mathbb{R},\ y \in (0, \delta)\}.$$

Deformed geometry G is assumed to be a curved planar strip of constant width δ. To describe it precisely, we introduce the curve $\Gamma = \{(x = X(\xi),\, y = Y(\xi))\}$, $\xi \in \mathbb{R}$, where ξ is a natural arc-length parameter, i.e., $X'(\xi)^2 + Y'(\xi)^2 \equiv 1$. By

$$\gamma(\xi) = X''(\xi)Y'(\xi) - X'(\xi)Y''(\xi) \tag{2.1}$$

we denote a (signed) curvature of Γ (see Figure 1 and Remark 2.2). Note that $|\gamma(\xi)|^2 = X''(\xi)^2 + Y''(\xi)^2$.

We additionally assume

$$\operatorname{supp} \gamma \Subset [-R, R] \qquad \text{for some } R > 0, \tag{2.2}$$

and set

$$\kappa^+ = \sup_{\xi \in [-R,R]} \gamma(\xi), \qquad \kappa^- = -\inf_{\xi \in [-R,R]} \gamma(\xi). \tag{2.3}$$

We shall assume throughout the paper the smoothness condition

$$\gamma \in C^\infty(\mathbb{R}), \tag{2.4}$$

which can be obviously softened.

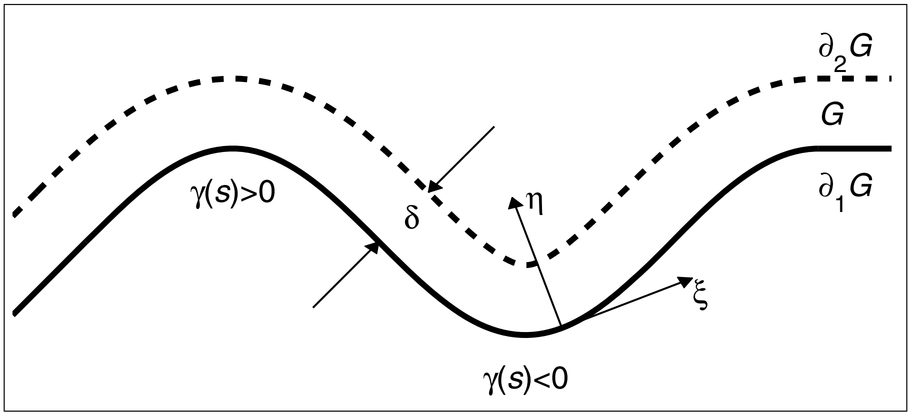

FIG. 1. *Domain G and curvilinear coordinates ξ, η. The solid line denotes the boundary $\partial_1 G$ with the Dirichlet boundary condition, and the dotted line denotes the boundary $\partial_2 G$ with the Neumann boundary condition.*

Now we can introduce, in a neighborhood of Γ, the curvilinear coordinates (ξ, η) as

$$x = X(\xi) - \eta Y'(\xi), \qquad y = Y(\xi) + \eta X'(\xi), \tag{2.5}$$

(where η is a distance from a point (x, y) to Γ) and describe the *deformed strip* G in these coordinates as

$$G = G_\gamma = \{(\xi, \eta) : \ \xi \in \mathbb{R}, \ \eta \in (0, \delta)\}. \tag{2.6}$$

REMARK 2.1. *As sets of points, $G_\gamma \equiv G_0$ for any γ, but the metrics are different, see below. We shall often omit the index γ if the metric is obvious from the context.*

REMARK 2.2. *Often one chooses the opposite sign in the definition of the signed curvature γ in* (2.1). *Our choice, though not canonical, is made to match the one in* [ExSe].

To avoid local self-intersections, we must restrict the width of the strip by natural conditions

$$\kappa^{\pm} \le A\delta^{-1}, \qquad A = \text{const} \in [0, 1). \tag{2.7}$$

We shall also assume throughout, without stating it explicitly, that G does not self-intersect globally, i.e., the mapping $(\xi, \eta) \mapsto (x, y)$ given by (2.5) is an injection on G.

Finally, it is an easy computation to show that the Euclidean metric in the curvilinear coordinates has a form $dx^2 + dy^2 = g d\xi^2 + d\eta^2$, where

$$g(\xi, \eta) = (1 + \eta\gamma(\xi))^2.$$

Later on, we shall widely use the notation

$$p(\xi, \eta) = (g(\xi, \eta))^{1/2} = 1 + \eta\gamma(\xi). \tag{2.8}$$

Note that in all the volume integrals,

$$\mathrm{d}G_\gamma = p(\xi, \eta)\, \mathrm{d}\xi\, \mathrm{d}\eta = (1 + \eta\gamma(\xi))\, \mathrm{d}\xi\, \mathrm{d}\eta = p(\xi, \eta)\, \mathrm{d}G_0.$$

2.2. Governing equations. For a given positive continuously differentiable function $H(\xi,\eta)$ (describing a depth profile), we are looking for a function $\Phi(\xi,\eta)$ satisfying (1.8) with spectral parameter ω.

By substituting

$$\beta(\xi,\eta) := \ln H(\xi,\eta), \tag{2.9}$$

and using explicit expressions for differential operators in curvilinear coordinates, we can rewrite (1.8) as

$$\begin{aligned}\omega\left(-\frac{1}{p^2}\frac{\partial^2\Phi}{\partial\xi^2}-\frac{\partial^2\Phi}{\partial\eta^2}+\left(\frac{1}{p^3}\frac{\partial p}{\partial\xi}+\frac{1}{p^2}\frac{\partial\beta}{\partial\xi}\right)\frac{\partial\Phi}{\partial\xi}+\left(\frac{\partial\beta}{\partial\eta}-\frac{1}{p}\frac{\partial p}{\partial\eta}\right)\frac{\partial\Phi}{\partial\eta}\right)\\ =\frac{i}{p}\left(\frac{\partial\beta}{\partial\xi}\frac{\partial\Phi}{\partial\eta}-\frac{\partial\beta}{\partial\eta}\frac{\partial\Phi}{\partial\xi}\right).\end{aligned} \tag{2.10}$$

Remark 2.3. *When deducing* (2.10)*, we have cancelled, on both sides, a common positive factor* $h(\xi,\eta) := \frac{1}{H(\xi,\eta)} = \mathrm{e}^{-\beta(\xi,\eta)}$*. However, we have to use this factor when considering corresponding variational equations, in order to keep the resulting forms symmetric. This leads to a special choice of weighted Hilbert spaces below.*

Further on, we consider only the case of a longitudinally uniform monotone depth profile,

$$\beta(\xi,\eta) \equiv \beta(\eta), \qquad \beta'(\eta) > 0, \tag{2.11}$$

in which case (2.10) simplifies to

$$\begin{aligned}\omega\left(-\frac{1}{p^2}\frac{\partial^2\Phi}{\partial\xi^2}-\frac{\partial^2\Phi}{\partial\eta^2}+\frac{1}{p^3}\frac{\partial p}{\partial\xi}\frac{\partial\Phi}{\partial\xi}+\left(\beta'-\frac{1}{p}\frac{\partial p}{\partial\eta}\right)\frac{\partial\Phi}{\partial\eta}\right)\\ =-\frac{i}{p}\beta'\frac{\partial\Phi}{\partial\xi},\end{aligned} \tag{2.12}$$

with $\beta' = \frac{\mathrm{d}\beta}{\mathrm{d}\eta}$.

2.3. Boundary conditions. Let $\partial_1 G = \{(\xi,0) : \xi\in\mathbb{R}\}$ and $\partial_2 G = \{(\xi,\delta) : \xi\in\mathbb{R}\}$ denote the lower and the upper boundary of the strip G, respectively. Boundary conditions (1.9), (1.10) then become

$$\Phi|_{\partial_1 G} = \left.\frac{\partial\Phi}{\partial\eta}\right|_{\partial_2 G} = 0. \tag{2.13}$$

Remark 2.4. *If the flow is confined to a channel, then the Dirichlet boundary condition* (1.9) *applies on both channel walls. This leads to a mathematically different problem which we do not consider in this paper.*

2.4. Function spaces and rigorous operator statement. We want to discuss the function spaces in which everything acts. Let us denote by $L_2(G;h)$ the Hilbert space of functions $\phi : G\to\mathbb{C}$ which are square-integrable on G with the weight $h(\eta)\equiv\frac{1}{H}=\exp(-\beta(\eta))$:

$$\|\phi\|^2_{L_2(G;h)} = \int_G |\phi(\xi,\eta)|^2\,h(\eta)\,\mathrm{d}G = \int_{\mathbb{R}}\int_0^\delta |\phi(\xi,\eta)|^2\,h(\eta)p(\xi,\eta)\,\mathrm{d}\eta\,\mathrm{d}\xi < \infty.$$

The corresponding inner product will be denoted $\langle\cdot,\cdot\rangle_{L_2(G;h)}$. Similarly we can define the space $L_2(F;h)$ for an arbitrary open subset F of G.

Let us formally introduce the operators

$$\mathcal{L}_\gamma : \Phi \mapsto -\frac{1}{p^2}\frac{\partial^2\Phi}{\partial\xi^2} - \frac{\partial^2\Phi}{\partial\eta^2} + \frac{1}{p^3}\frac{\partial p}{\partial\xi}\frac{\partial\Phi}{\partial\xi} + \left(\beta' - \frac{1}{p}\frac{\partial p}{\partial\eta}\right)\frac{\partial\Phi}{\partial\eta}$$

and

$$\mathcal{M}_\gamma : \Phi \mapsto -\frac{i}{p}\beta'\frac{\partial\Phi}{\partial\xi}.$$

(The dependence on γ is of course via p; see (2.8).) Then (2.12) can be formally rewritten as

$$\omega\mathcal{L}_\gamma\Phi = \mathcal{M}_\gamma\Phi, \tag{2.14}$$

or via an *operator pencil*

$$\mathcal{A}_\gamma \equiv \mathcal{A}_\gamma(\omega) = \omega\mathcal{L}_\gamma - \mathcal{M}_\gamma \tag{2.15}$$

as

$$\mathcal{A}_\gamma(\omega)\Phi = 0. \tag{2.16}$$

The *domain* of the pencil $\mathcal{A}_\gamma$ in the L_2-sense is naturally defined as

$$\mathrm{Dom}(\mathcal{A}_\gamma) = \{\Phi \in H^2(G),\ \Phi \text{ satisfies } (2.13)\}, \tag{2.17}$$

where H^2 denotes a standard Sobolev space.

On the domain (2.17), $\mathcal{M}_\gamma$ is symmetric, and $\mathcal{L}_\gamma$ is symmetric and positive in the sense of the scalar product $\langle\cdot,\cdot\rangle_{L_2(G;h)}$, with

$$\langle\mathcal{L}_\gamma\Phi,\Phi\rangle_{L_2(G;h)} = \int_{\mathbb{R}}\int_0^\delta \left(\frac{1}{p}\left|\frac{\partial\Phi}{\partial\xi}\right|^2 + p\left|\frac{\partial\Phi}{\partial\eta}\right|^2\right)\mathrm{e}^{-\beta}\,\mathrm{d}\eta\,\mathrm{d}\xi.$$

Later on, we shall use a *weak* (or *variational*) form of (2.16), and shall require some other function spaces described below. Let $F \subseteq G$, and suppose its boundary is decomposed into two disjoint parts: $\partial F = \partial_1 F \sqcup \partial_2 F$. We introduce the space

$$\begin{aligned}\widetilde{C}_0^\infty(F;\partial_1 F) = \{\phi \in C^\infty(F) : \overline{\operatorname{supp}\phi} \cap \partial_1 F = \emptyset,\\ \text{and there exists } r > 0 \text{ such that } \phi(\xi,\eta) = 0 \text{ for } (\xi,\eta)\in F,\ |\xi| \ge r\}\end{aligned}$$

consisting of smooth functions with compact support vanishing near $\partial_1 F$.

By $\widetilde{H}_0^1(F;\partial_1 F;h)$ we denote the closure of $\widetilde{C}_0^\infty(F;\partial_1 F)$ with respect to the scalar product

$$\langle\phi,\psi\rangle_{\widetilde{H}_0^1(F,\partial_1 F;h)} = \langle\phi,\psi\rangle_{L_2(F;h)} + \langle\mathbf{grad}\,\phi,\mathbf{grad}\,\psi\rangle_{L_2(F;h)}.$$

In what follows we shall study the operators $\mathcal{L}_\gamma$, $\mathcal{M}_\gamma$ and the pencil $\mathcal{A}_\gamma$ from a variational point of view. The details are given in the next section; here we note only that from now we understand the expression $\langle\mathcal{L}_\gamma\Psi,\Psi\rangle_{L_2(G_\gamma,h)}$ as the quadratic form for the operator $\mathcal{L}_\gamma$, with the quadratic form domain $\widetilde{H}_0^1(G;\partial_1 G;h)$.

The main purpose of this paper is to study the *spectral properties* of the operator pencil $\mathcal{A}_\gamma$. We recall the following definitions.

A number $\omega \in \mathbb{C}$ is said to belong to the *spectrum* of $\mathcal{A}_\gamma$ (denoted $\operatorname{spec}(\mathcal{A}_\gamma)$) if $\mathcal{A}_\gamma(\omega)$ is not invertible.

It is easily seen that in our case the spectrum of $\mathcal{A}_\gamma$ is real.

We say that $\omega \in \mathbb{R}$ belongs to the *essential spectrum* of the operator pencil $\mathcal{A}_\gamma$ (denoted $\omega \in \operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_\gamma)$) if for this ω the operator $\mathcal{A}_\gamma(\omega)$ is non-Fredholm.

We say that $\omega \in \mathbb{C}$ belongs to the *point spectrum* of the operator pencil $\mathcal{A}_\gamma$ (denoted $\omega \in \operatorname{spec}_{\mathrm{pt}}(\mathcal{A}_\gamma)$), or, in other words, say that ω is an *eigenvalue*, if for this ω there exists a nontrivial solution $\Psi \in \operatorname{Dom}(\mathcal{A}_\gamma)$ of the problem $\mathcal{A}_\gamma(\omega)\Psi = 0$.

It is known that the essential spectrum is a closed subset of $\mathbb{R}$, and that any point of the spectrum outside the essential spectrum is an isolated eigenvalue of finite multiplicity. The set of all such points is called the *discrete spectrum*, and will be denoted $\operatorname{spec}_{\mathrm{dis}}(\mathcal{A}_\gamma)$. There may, however, exist the points of the spectrum which belong to both the essential spectrum and the point spectrum.

Our main result (Theorem 4.1 below) establishes some conditions on the curvature γ of the waveguide which guarantee the existence of eigenvalues of $\mathcal{A}_\gamma$.

It is more convenient to deal with problems of this type variationally, and we start the next section with an abstract variational scheme suitable for self-adjoint pencils with nonempty essential spectrum.

3. Essential spectrum.

3.1. Variational principle for the essential spectrum.

DEFINITION 3.1. *We set, for $j \in \mathbb{N}$,*

$$\mu_{\gamma,j} = \sup_{\substack{U \subset \widetilde{H}_0^1(G;\partial_1 G;h) \\ \dim U = j}} \inf_{\Psi \in U,\, \Psi \neq 0} \frac{\langle \mathcal{M}_\gamma \Psi, \Psi\rangle_{L_2(G_\gamma,h)}}{\langle \mathcal{L}_\gamma \Psi, \Psi\rangle_{L_2(G_\gamma,h)}}. \tag{3.1}$$

As $\langle \mathcal{L}_\gamma \Psi, \Psi\rangle_{L_2(G_\gamma,h)}$ is positive, the right-hand side of (3.1) is well defined, though the numbers $\mu_{\gamma,j}$ may a priori be finite or infinite.

Obviously, for any fixed curvature profile γ the numbers $\mu_{\gamma,j}$ form a nonincreasing sequence:

$$\mu_{\gamma,1} \geq \mu_{\gamma,2} \geq \cdots \geq \mu_{\gamma,j} \geq \mu_{\gamma,j+1} \geq \cdots .$$

DEFINITION 3.2. *Denote*

$$\underline{\mu}_\gamma = \lim_{j\to\infty} \mu_{\gamma,j}. \tag{3.2}$$

For general self-adjoint operator pencils the analogue of (3.2) may be finite or equal to $\pm\infty$; as we shall see below, in our case $\underline{\mu}_\gamma$ is finite.

The following result is a modification, to the case of an abstract self-adjoint linear pencil, of the general variational principle for a self-adjoint operator with an essential spectrum; see [Da, Prop. 4.5.2].

PROPOSITION 3.3. *Either*

(i) $\underline{\mu}_\gamma > -\infty$, *and then* $\sup \operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_\gamma) = \underline{\mu}_\gamma$,

or

(ii) $\underline{\mu}_\gamma = -\infty$, *and then* $\operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_\gamma) = \emptyset$.

Moreover, if $\mu_{\gamma,j} > \underline{\mu}_\gamma$, *then* $\mu_{\gamma,j} \in \operatorname{spec}_{\mathrm{dis}}(\mathcal{A}_\gamma)$.

Proposition 3.3 ensures that we can use the variational principle (3.1) in order to find the eigenvalues of the pencil $\mathcal{A}_\gamma$ lying *above* the supremum $\underline{\mu}_\gamma$ of the essential spectrum.

3.2. Essential spectrum for the straight strip. The spectral analysis in the case of a straight strip ($\gamma \equiv 0$) is rather straightforward as the problem admits in this case the separation of variables.

Let us seek the solutions of (2.12), (2.13) in the case of a straight strip ($\gamma \equiv 0$, and so $p \equiv 1$) in the form

$$\Phi(\xi, \eta) = \phi(\eta) \exp(i\alpha\xi); \tag{3.3}$$

it is sufficient to consider only real values of α.

After separation of variables, (2.12), (2.13) are written, for each α, as a one-dimensional transversal spectral problem

$$\omega(-\phi'' + \beta'\phi' + \alpha^2\phi) = \alpha\beta'\phi, \qquad \phi(0) = \phi'(\delta) = 0. \tag{3.4}$$

Alternatively, introduce operators

$$\mathfrak{l}_\alpha : \phi \mapsto -\phi'' + \beta'\phi' + \alpha^2\phi, \qquad \mathfrak{m}_\alpha : \phi \mapsto \alpha\beta'\phi,$$

and a pencil

$$\mathfrak{a}_\alpha(\omega) = \omega\mathfrak{l}_\alpha - \mathfrak{m}_\alpha,$$

(again understood in an $L_2((0,\delta); h)$ sense with the domain defined similarly to (2.17)), and consider a one-dimensional operator pencil spectral problem $\mathfrak{a}_\alpha(\omega)\phi = 0$.

For a fixed value of α, the one-dimensional linear operator pencil (3.4) has the essential spectrum $\{0\}$ and a discrete spectrum $\operatorname{spec}(\mathfrak{a}_\alpha)$; note that

$$\operatorname{spec}(\mathfrak{a}_{-\alpha}) = -\operatorname{spec}(\mathfrak{a}_\alpha). \tag{3.5}$$

Denote, for $\alpha > 0$, the top of the spectrum of this transversal problem by $\omega_\alpha = \sup \operatorname{spec}(\mathfrak{a}_\alpha)$.

Lemma 3.4. *Let $\alpha > 0$. Then, under condition* (2.11)*,*

(i) $\operatorname{spec}(\mathfrak{a}_\alpha) \subset [0, +\infty)$*;*
(ii) $0 < \omega_\alpha < +\infty$*;*
(iii) $\omega_\alpha \to +0$ *as* $\alpha \to \infty$.

Proof. By the variational principle analogous to Proposition 3.3(i),

$$\omega_\alpha = \sup_{\substack{\phi \in \widetilde{H}_0^1((0,\delta),0,h) \\ \phi \neq 0}} J_\alpha(\phi),$$

where we set

$$J_\alpha(\phi) = \frac{\langle \mathfrak{m}_\alpha\phi, \phi\rangle_{L_2((0,\delta),h)}}{\langle \mathfrak{l}_\alpha\phi, \phi\rangle_{L_2((0,\delta),h)}} = \frac{\displaystyle\int_0^\delta \alpha\beta'(\eta)\phi(\eta)^2 h(\eta)\,\mathrm{d}\eta}{\displaystyle\int_0^\delta (-\phi''(\eta) + \beta'(\eta)\phi'(\eta) + \alpha^2\phi(\eta))\phi(\eta)h(\eta)\,\mathrm{d}\eta}. \tag{3.6}$$

After integrating by parts using $h(\eta) = \mathrm{e}^{-\beta(\eta)}$ and inverting the quotient, we get

$$J_\alpha(\phi) = \left(\alpha J^{(1)}(\phi) + \frac{1}{\alpha} J^{(2)}(\phi)\right)^{-1}, \tag{3.7}$$

where we denote

$$J^{(1)}(\phi) = \frac{\displaystyle\int_0^\delta \mathrm{e}^{-\beta(\eta)}|\phi(\eta)|^2\,\mathrm{d}\eta}{\displaystyle\int_0^\delta \beta'(\eta)\mathrm{e}^{-\beta(\eta)}|\phi(\eta)|^2\,\mathrm{d}\eta}$$

and

$$J^{(2)}(\phi) = \frac{\displaystyle\int_0^\delta \mathrm{e}^{-\beta(\eta)}|\phi'(\eta)|^2\,\mathrm{d}\eta}{\displaystyle\int_0^\delta \beta'(\eta)\mathrm{e}^{-\beta(\eta)}|\phi(\eta)|^2\,\mathrm{d}\eta}.$$

The statements (ii) and (iii) of the lemma now follow immediately from the estimates

$$J^{(1)}(\phi) \ge \frac{\inf\limits_{\eta\in(0,\delta)} \mathrm{e}^{-\beta(\eta)}}{\sup\limits_{\eta\in(0,\delta)} (\beta'(\eta)\mathrm{e}^{-\beta(\eta)})}$$

and

$$J^{(2)}(\phi) \ge \frac{\pi^2}{4\delta^2}\,\frac{\inf\limits_{\eta\in(0,\delta)} \mathrm{e}^{-\beta(\eta)}}{\sup\limits_{\eta\in(0,\delta)} (\beta'(\eta)\mathrm{e}^{-\beta(\eta)})},$$

where the latter inequality uses the variational principle and the fact that the principal eigenvalue of the mixed Dirichlet–Neumann spectral problem for the operator $-\frac{\mathrm{d}^2}{\mathrm{d}\eta^2}$ on the interval $(0,\delta)$ is equal to $\frac{\pi^2}{4\delta^2}$. The statement (i) follows from the positivity of the right-hand side of (3.7). ∎

We are now able to find the essential spectrum of the problem in a straight strip.

Lemma 3.5. *Assume that conditions* (2.11) *hold. Then*

$$\mathrm{spec}_{\mathrm{ess}}(\mathcal{A}_0) = [-\Omega_*, \Omega_*], \tag{3.8}$$

where

$$\Omega_* = \sup_{\phi\in\widetilde{H}_0^1((0,\delta),0,h)} \frac{\displaystyle\frac{1}{2}\int_0^\delta \beta'(\eta)\mathrm{e}^{-\beta(\eta)}|\phi(\eta)|^2\,\mathrm{d}\eta}{\sqrt{\displaystyle\int_0^\delta \mathrm{e}^{-\beta(\eta)}|\phi'(\eta)|^2\,\mathrm{d}\eta\cdot\int_0^\delta \mathrm{e}^{-\beta(\eta)}|\phi(\eta)|^2\,\mathrm{d}\eta}} > 0. \tag{3.9}$$

Proof. It is standard that

$$\mathrm{spec}_{\mathrm{ess}}(\mathcal{A}_0) = \overline{\bigcup_{\alpha\in\mathbb{R}} \mathrm{spec}(\mathfrak{a}_\alpha)}.$$

Thus, by Lemma 3.4, and with account of the antisymmetry of the spectrum of $\mathfrak{a}_\alpha$ with respect to α and its positivity for $\alpha>0$, we have

$$\sup\mathrm{spec}_{\mathrm{ess}}(\mathcal{A}_0) = \sup_{\alpha>0}\omega_\alpha = \sup_{\alpha>0}\ \sup_{\phi\in\widetilde{H}_0^1((0,\delta),0,h)} J_\alpha(\phi).$$

By maximizing first with respect to α, we obtain, from (3.7),

$$J_\alpha(\phi) \le J_{\alpha_*(\phi)}(\phi)$$

with the maximizer

$$\alpha_*(\phi) = \sqrt{\frac{J^{(2)}(\phi)}{J^{(1)}(\phi)}}.$$

Maximizing now with respect to ϕ gives $\sup \operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_0) = \Omega_*$, with Ω_* given by (3.9). Finally, we note that ω_α depends continuously on $\alpha > 0$. Since $\omega_\alpha \to +0$ as $\alpha \to +\infty$ by Lemma 3.4(iii), ω_α thus takes all the values in $(0, \Omega_*]$. Therefore, the closed interval $[0, \Omega_*]$ lies in $\operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_0)$. By symmetry (3.5), we also have $[-\Omega_*, 0] \subset \operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_0)$, which finishes the proof. $\square$

3.3. Essential spectrum for a curved strip. It is now a standard procedure to show that under our conditions the essential spectrum of the problem in a curved strip coincides with the essential spectrum of the problem in a straight strip given by Lemma 3.5. Namely, we have the following.

LEMMA 3.6. *Let us assume conditions* (2.2), (2.4), *and* (2.11) *hold. Then*

$$\operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_\gamma) = \operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_0) = [-\Omega_*, \Omega_*]$$

with Ω_* *given by* (3.9).

The proof is based on the fact that any solution of the problem (2.12), (2.13) with $\gamma \not\equiv 0$ (and thus $p \not\equiv 1$) should coincide in

$$G \cap \{|\xi| > R > \max(|\inf \operatorname{supp} \gamma|, |\sup \operatorname{supp} \gamma|)\}$$

with a solution of the same problem for $\gamma \equiv 0$. An analogous result has been proved in a number of similar situations elsewhere (see, e.g., [ExSe], [EvLeVa], [DaPa], [KrTA]), so we omit the details of the proof. We briefly note that the inclusion $\operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_\gamma) \subseteq \operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_0)$ is proved using the separation of variables as above and a construction of appropriate Weyl's sequences, and in order to prove the inclusion $\operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_\gamma) \supseteq \operatorname{spec}_{\mathrm{ess}}(\mathcal{A}_0)$ one can use the Dirichlet–Neumann bracketing and the discreteness of the spectrum of the problem (2.12), (2.13) considered in $G \cap \{|\xi| < R\}$ with additional Dirichlet or Neumann boundary conditions imposed on the "cuts" $\{\xi = \pm R\}$.

4. Main result. Our main result consists in stating some sufficient conditions on the depth profile $\beta(\eta)$ and the curvature profile $\gamma(\xi)$ which guarantee the existence of an eigenvalue of the pencil $\mathcal{A}_\gamma$ lying outside the essential spectrum.

THEOREM 4.1. *Assume, as before, that condition* (2.11) *holds. Assume additionally that*

$$\beta''(\eta) < 0 \qquad \textit{for } \eta \in (0, \delta). \tag{4.1}$$

Then there exists a constant $C_\beta > 0$, *which depends only on the depth profile* β, *such that* $\operatorname{spec}_{\mathrm{dis}}(\mathcal{A}_\gamma) \neq \emptyset$ *whenever* γ *satisfies conditions* (2.2), (2.4), *and*

$$\int \gamma(\xi)\, \mathrm{d}\xi > C_\beta \int \gamma(\xi)^2\, \mathrm{d}\xi. \tag{4.2}$$

We give an explicit expression for C_β below; see (4.15).

An integral sufficient condition (4.2) may be replaced by a pointwise, although more restrictive, condition.

COROLLARY 4.2. *Assume that conditions* (2.11) *and* (4.1) *hold. Then there exists a constant* $c_{\beta,R} = \frac{C_\beta}{2R}$ *which depends only on the depth profile* β *and a given* $R > 0$ *such that* $\operatorname{spec}_{\mathrm{dis}}(\mathcal{A}_\gamma) \neq \emptyset$ *whenever* $\gamma \not\equiv 0$ *satisfies conditions* (2.2), (2.4), *and*

$$0 \le \gamma(\xi) < c_{\beta,R} \qquad \text{for } |\xi| \le R. \tag{4.3}$$

We prove Theorem 4.1 using a number of simple lemmas, the central of which is the following.

LEMMA 4.3. *Suppose there exists a function* $\widetilde{\Psi} \in \widetilde{H}_0^1(G_\gamma, h)$ *such that*

$$\frac{\langle \mathcal{M}_\gamma \widetilde{\Psi}, \widetilde{\Psi}\rangle_{L_2(G_\gamma,h)}}{\langle \mathcal{L}_\gamma \widetilde{\Psi}, \widetilde{\Psi}\rangle_{L_2(G_\gamma,h)}} > \Omega_*. \tag{4.4}$$

Then there exists $\omega > \Omega_*$ *which belongs to* $\operatorname{spec}_{\mathrm{dis}}(\mathcal{A}_\gamma)$.

Lemma 4.3 is just a restatement of the variational principle of Proposition 3.3. The main difficulty in its application is of course the choice of an appropriate test function $\widetilde{\Psi}$. However such choice becomes much easier if we use the following modification of this lemma which allows us to consider test functions which are not necessarily square-integrable on G_γ.

Denote, for brevity, $G_\gamma^r = G_\gamma \cap \{|\xi| < r\}$.

LEMMA 4.4. *Suppose there exist a function* Ψ *and a constant* D *such that, for any* $r > R$, *we have* $\Psi \in \widetilde{H}_0^1(G_\gamma^r, h)$ *and*

$$\langle \mathcal{M}_\gamma \Psi, \Psi\rangle_{L_2(G_\gamma^r,h)} - \Omega_* \langle \mathcal{L}_\gamma \Psi, \Psi\rangle_{L_2(G_\gamma^r,h)} \ge D > 0. \tag{4.5}$$

Then there exists $\omega > \Omega_*$ *which belongs to* $\operatorname{spec}_{\mathrm{dis}}(\mathcal{A}_\gamma)$.

The proof of Lemma 4.4 uses the construction of an appropriate cutoff function $\chi(\xi)$ such that $\widetilde{\Psi} = \chi\Psi$ satisfies the conditions of Lemma 4.3; cf. [DaPa, Prop. 1].

We now proceed as follows.

Let $\phi_*(\eta)$ be a maximizer in (3.9), and set

$$\Psi(\xi,\eta) = \phi_*(\eta) \mathrm{e}^{i\alpha_\bullet \xi},$$

where

$$\alpha_\bullet = \alpha_*(\phi_*) = \sqrt{\frac{J^{(2)}(\phi_*)}{J^{(1)}(\phi_*)}}. \tag{4.6}$$

It is important to note that Ψ is in fact an "eigenfunction" of the essential spectrum of $\mathcal{A}_\gamma$ corresponding to its highest positive point Ω_* and that ϕ_* is an eigenfunction of (3.4) with $\alpha = \alpha_\bullet$ (i.e., of the pencil $\mathfrak{a}_{\alpha_\bullet}$) again corresponding to the eigenvalue Ω_*, and so

$$\phi_*'' = \beta'\phi_*' + (\alpha_\bullet^2 - \Lambda_*\alpha_\bullet\beta')\phi_*, \qquad \phi_*(0) = \phi_*'(\delta) = 0 \tag{4.7}$$

with $\Lambda_* := \frac{1}{\Omega_*}$ (cf. (3.4)).

For future use, we summarize the relations obtained so far:

$$\begin{aligned}
\mathcal{L}_0\Psi &= (-\phi_*''(\eta) + \beta'(\eta)\phi_*'(\eta) + \alpha_\bullet\phi_*(\eta))\,\mathrm{e}^{i\alpha_\bullet\xi} = (\mathfrak{l}_{\alpha_\bullet}\phi_*)\,\mathrm{e}^{i\alpha_\bullet\xi},\\
\mathcal{M}_0\Psi &= \alpha_\bullet\beta'(\eta)\phi_*(\eta)\,\mathrm{e}^{i\alpha_\bullet\xi} = (\mathfrak{m}_{\alpha_\bullet}\phi_*)\,\mathrm{e}^{i\alpha_\bullet\xi},\\
\mathcal{L}_\gamma\Psi &= \Bigg(-\phi_*''(\eta) + \left(\beta'(\eta) - \frac{1}{p(\xi,\eta)}\,\frac{\partial p(\xi,\eta)}{\partial\eta}\right)\phi_*'(\eta)\\
&\qquad + \left(\frac{i\alpha_\bullet}{p(\xi,\eta)^3}\,\frac{\partial p(\xi,\eta)}{\partial\xi} + \frac{\alpha_\bullet^2}{p(\xi,\eta)^2}\right)\phi_*(\eta)\Bigg)\,\mathrm{e}^{i\alpha_\bullet\xi},\\
\mathcal{M}_\gamma\Psi &= \frac{\alpha_\bullet}{p(\xi,\eta)}\beta'(\eta)\phi_*(\eta)\,\mathrm{e}^{i\alpha_\bullet\xi},\\
p(\xi,\eta) &= 1 + \gamma(\xi)\eta
\end{aligned}$$

(with $'$ denoting differentiation with respect to η).

It is important to note that for any $r > 0$,

$$\frac{\langle\mathcal{M}_0\Psi,\Psi\rangle_{L_2(G_0^r,h)}}{\langle\mathcal{L}_0\Psi,\Psi\rangle_{L_2(G_0^r,h)}} = \frac{\langle\mathfrak{m}_{\alpha_\bullet}\phi_*,\phi_*\rangle_{L_2((0,\delta),h)}}{\langle\mathfrak{l}_{\alpha_\bullet}\phi_*,\phi_*\rangle_{L_2((0,\delta),h)}} = \Omega_* > 0$$

and, as explicit formulae above show,

$$\begin{aligned}
\langle\mathcal{M}_\gamma\Psi,\Psi\rangle_{L_2(G_\gamma^r,h)} &= \langle\mathcal{M}_0\Psi,\Psi\rangle_{L_2(G_0^r,h)} = \alpha_\bullet\int_{-r}^{r}\int_0^\delta \beta'(\eta)\mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2\,\mathrm{d}\eta\,\mathrm{d}\xi\\
&= 2r\alpha_\bullet\int_0^\delta \beta'(\eta)\mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2\,\mathrm{d}\eta > 0.
\end{aligned} \tag{4.8}$$

We want to show that under conditions of Theorem 4.1 and with the choice of Ψ as above, inequality (4.5) holds for any $r > R$.

In view of (4.8), it is enough to show that

$$D_\gamma := \langle\mathcal{L}_\gamma\Psi,\Psi\rangle_{L_2(G_\gamma^r,h)} - \langle\mathcal{L}_0\Psi,\Psi\rangle_{L_2(G_0^r,h)}$$

is *negative* for $r > R$.

Explicit substitution gives, after taking into account the formula

$$\int \frac{1}{p(\xi,\eta)^2}\,\frac{\partial p(\xi,\eta)}{\partial\xi}\,\mathrm{d}\xi = 0$$

(due to (2.2), with account of (2.8)), the following expression:

$$D_\gamma = \int_{-r}^{r}\int_0^\delta \gamma(\xi)\eta\mathrm{e}^{-\beta(\eta)}|\phi_*'(\eta)|^2\,\mathrm{d}\eta\,\mathrm{d}\xi - \int_{-r}^{r}\int_0^\delta \alpha_\bullet^2\frac{\eta\gamma(\xi)}{1+\eta\gamma(\xi)}\mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2\,\mathrm{d}\eta\,\mathrm{d}\xi.$$

This, in turn, can be rewritten, using the obvious identity

$$\frac{\eta\gamma(\xi)}{1+\eta\gamma(\xi)} = \eta\gamma(\xi) - \frac{\eta^2\gamma(\xi)^2}{1+\eta\gamma(\xi)},$$

as

$$\begin{aligned}
D_\gamma &= \int_{-r}^{r}\gamma(\xi)\int_0^\delta \eta\mathrm{e}^{-\beta(\eta)}\left(|\phi_*'(\eta)|^2 - \alpha_\bullet^2|\phi_*(\eta)|^2\right)\mathrm{d}\eta\,\mathrm{d}\xi\\
&\quad + \alpha_\bullet^2\int_{-r}^{r}\int_0^\delta \frac{\eta^2\gamma(\xi)^2}{1+\eta\gamma(\xi)}\mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2\,\mathrm{d}\eta\,\mathrm{d}\xi.
\end{aligned} \tag{4.9}$$

We shall deal with the two terms in (4.9) separately.

The first one is more difficult. As (4.6) yields explicitly

$$\alpha_\bullet^2 = \frac{\displaystyle\int_0^\delta \mathrm{e}^{-\beta(\eta)}|\phi_*'(\eta)|^2\,\mathrm{d}\eta}{\displaystyle\int_0^\delta \mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2\,\mathrm{d}\eta},$$

we get

$$\begin{aligned}
I_1 &:= \int_0^\delta \eta\mathrm{e}^{-\beta(\eta)}\left(|\phi_*'(\eta)|^2 - \alpha_\bullet^2|\phi_*(\eta)|^2\right)\mathrm{d}\eta \\
&= \frac{1}{\displaystyle\int_0^\delta \mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2\,\mathrm{d}\eta} \times \left(\int_0^\delta \eta\mathrm{e}^{-\beta(\eta)}|\phi_*'(\eta)|^2\,\mathrm{d}\eta \cdot \int_0^\delta \mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2\,\mathrm{d}\eta\right. \\
&\qquad\left. - \int_0^\delta \mathrm{e}^{-\beta(\eta)}|\phi_*'(\eta)|^2\,\mathrm{d}\eta \cdot \int_0^\delta \eta\mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2\,\mathrm{d}\eta\right).
\end{aligned} \tag{4.10}$$

We want to show that the term in brackets is negative under some reasonable assumptions.

Lemma 4.5. *Assume that the conditions of Theorem* 4.1 *hold. Then* $I_1 < 0$.

The proof of Lemma 4.5 uses the following simple fact.[1]

Lemma 4.6. *Let* $(a,b) \subset (0,+\infty)$ *be a finite interval, and let a function* $g : (a,b) \to \mathbb{R}$ *be nonincreasing. Then*

$$\left(\int_a^b xg(x)f(x)\,\mathrm{d}x\right)\cdot\left(\int_a^b f(x)\,\mathrm{d}x\right) - \left(\int_a^b g(x)f(x)\,\mathrm{d}x\right)\cdot\left(\int_a^b xf(x)\,\mathrm{d}x\right) \le 0$$

for any nonnegative function $f : (a,b) \to \mathbb{R}$.

Proof of Lemma 4.6. We have

$$\begin{aligned}
&\left(\int_a^b xg(x)f(x)\,\mathrm{d}x\right)\cdot\left(\int_a^b f(x)\,\mathrm{d}x\right) - \left(\int_a^b g(x)f(x)\,\mathrm{d}x\right)\cdot\left(\int_a^b xf(x)\,\mathrm{d}x\right) \\
&\quad = \int_a^b\int_a^b xg(x)f(x)f(y)\,\mathrm{d}x\,\mathrm{d}y - \int_a^b\int_a^b g(x)f(x)yf(y)\,\mathrm{d}x\,\mathrm{d}y \\
&\quad = \int_a^b\int_a^y (x-y)f(x)f(y)g(x)\,\mathrm{d}x\,\mathrm{d}y + \int_a^b\int_y^b (x-y)f(x)f(y)g(x)\,\mathrm{d}x\,\mathrm{d}y.
\end{aligned}$$

Interchanging the variables x and y in the last integral, we obtain that the whole expression is equal to

$$\int_a^b\int_a^y \underbrace{(x-y)}_{\text{nonpositive}}\ \underbrace{f(x)f(y)(g(x)-g(y))}_{\text{nonnegative}}\,\mathrm{d}x\,\mathrm{d}y$$

and is therefore nonpositive. ∎

[1]We are grateful to Daniel Elton for a useful suggestion that helped to prove this lemma.

We can now proceed with evaluating I_1.

Proof of Lemma 4.5. We act by doing a lot of integrations by parts. We shall also use (4.7).

We have (all integrals are over $[0,\delta]$ and with respect to η)

$$\begin{aligned}\int \eta \mathrm{e}^{-\beta}|\phi_*'|^2 &= -\int \phi_* \cdot (\eta \mathrm{e}^{-\beta}\phi_*')' \\ &= -\int \phi_* \cdot (\mathrm{e}^{-\beta}\phi_*' - \beta'\eta\mathrm{e}^{-\beta}\phi_*' + \eta\mathrm{e}^{-\beta}\phi_*'') \\ &= -\int \phi_* \cdot (\mathrm{e}^{-\beta}\phi_*' + (\alpha_\bullet^2 - \Lambda_*\alpha_\bullet\beta')\mathrm{e}^{-\beta}\eta\phi_*).\end{aligned}$$

Further,

$$-\int (\phi_*\mathrm{e}^{-\beta})\phi_*' = \left(\int \left(\phi_*'\mathrm{e}^{-\beta} - \beta'\phi_*\mathrm{e}^{-\beta}\right)\phi_*\right) - \mathrm{e}^{-\beta(\delta)}\phi_*^2(\delta),$$

thus producing

$$\begin{aligned}\int \eta\mathrm{e}^{-\beta}|\phi_*'|^2 &= -\frac{1}{2}\int \beta'\phi_*^2\mathrm{e}^{-\beta} \underbrace{-\frac{1}{2}\mathrm{e}^{-\beta(\delta)}\phi_*^2(\delta)}_{\text{negative constant}} \\ &\quad - \alpha_\bullet^2\int \eta\mathrm{e}^{-\beta}|\phi_*|^2 + \Lambda_*\alpha_\bullet\int \eta\beta'\mathrm{e}^{-\beta}|\phi_*|^2.\end{aligned} \tag{4.11}$$

Also,

$$\begin{aligned}\int \mathrm{e}^{-\beta}|\phi_*'|^2 &= -\int \mathrm{e}^{-\beta}\phi_*(-\beta'\phi_*' + \phi_*'') \\ &= -\int \mathrm{e}^{-\beta}\phi_*\left(-\beta'\phi_*' + \beta'\phi_*' + \alpha_\bullet^2\phi_* - \Lambda_*\alpha_\bullet\beta'\phi_*\right) \\ &= -\int \mathrm{e}^{-\beta}\phi_*^2\,(\alpha_\bullet^2 - \Lambda_*\alpha_\bullet\beta').\end{aligned} \tag{4.12}$$

Substituting (4.11) and (4.12) into (4.10), and simplifying, we get

(4.13)

$$\begin{aligned}I_1 \cdot \underbrace{\int \mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2}_{\text{positive integral}} &= \int \eta\mathrm{e}^{-\beta}|\phi_*'|^2 \cdot \int \mathrm{e}^{-\beta}|\phi_*|^2 - \int \mathrm{e}^{-\beta}|\phi_*'|^2 \cdot \int \eta\mathrm{e}^{-\beta}|\phi_*|^2 \\ &= \left(\underbrace{\left(-\frac{1}{2}\int \beta'\mathrm{e}^{-\beta}|\phi_*|^2\right)}_{\text{negative as } \beta'>0} + \underbrace{\left(-\frac{1}{2}\mathrm{e}^{-\beta(\delta)}\phi_*^2(\delta)\right)}_{\text{negative constant}}\right)\int \mathrm{e}^{-\beta}|\phi_*|^2 \\ &\quad + \underbrace{(\Lambda_*\alpha_\bullet)}_{\text{+ve constant}} \times \underbrace{\left(\int \eta\beta'\mathrm{e}^{-\beta}|\phi_*|^2 \cdot \int \mathrm{e}^{-\beta}|\phi_*|^2 - \int \beta'\mathrm{e}^{-\beta}|\phi_*|^2 \cdot \int \eta\mathrm{e}^{-\beta}|\phi_*|^2\right)}_{\text{nonpositive by Lemma 4.6 with } g=\beta',\ f=\mathrm{e}^{-\beta}|\phi_*|^2 \text{ as } g'=\beta''\le 0}.\end{aligned}$$

Thus $I_1 < 0$. $\square$

Let us now return to (4.9) and deal with the second term in the right-hand side. We have, with account of (2.3) and (2.7),

$$\frac{\eta^2\gamma(\xi)^2}{1+\eta\gamma(\xi)} \le \begin{cases} \eta^2\gamma(\xi)^2 & \text{if } \gamma(\xi)\ge 0,\\ \dfrac{1}{1-A}\eta^2\gamma(\xi)^2 & \text{if } \gamma(\xi)<0 \end{cases} \le \max\left\{1, \frac{1}{1-A}\right\}\eta^2\gamma(\xi)^2,$$

and so

$$\alpha_\bullet^2\int_{-r}^{r}\int_0^\delta \frac{\eta^2\gamma(\xi)^2}{1+\eta\gamma(\xi)}\mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2\,\mathrm{d}\eta\,\mathrm{d}\xi \le I_2\int_{-r}^{r}\gamma(\xi)^2\,\mathrm{d}\xi,$$

where

$$I_2 := \max\left\{1, \frac{1}{1-A}\right\}\alpha_\bullet^2\int_0^\delta \eta^2\mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2\,\mathrm{d}\eta \ge 0. \tag{4.14}$$

Thus, as $\gamma(\xi)$ vanishes for $|\xi|>R$, we have

$$D_\gamma = I_1\int\gamma(\xi)\,\mathrm{d}\xi + I_2\int\gamma(\xi)^2\,\mathrm{d}\xi = (-I_1)\left(C_\beta\int\gamma(\xi)^2\,\mathrm{d}\xi - \int\gamma(\xi)\,\mathrm{d}\xi\right),$$

where

$$C_\beta = \frac{I_2}{-I_1} = \frac{\max\left\{1, \dfrac{1}{1-A}\right\}\alpha_\bullet^2\displaystyle\int_0^\delta \eta^2\mathrm{e}^{-\beta(\eta)}|\phi_*(\eta)|^2\,\mathrm{d}\eta}{\displaystyle\int_0^\delta \eta\mathrm{e}^{-\beta(\eta)}\left(|\phi_*'(\eta)|^2-\alpha_\bullet^2|\phi_*(\eta)|^2\right)\mathrm{d}\eta} \tag{4.15}$$

is a positive constant.

As soon as (4.2) holds, D_γ is negative, and so (4.5) holds. This proves Theorem 4.1.

Finally, it is sufficient to note that (4.3) implies $\int\gamma(\xi)^2\,\mathrm{d}\xi < 2Rc_{\beta,R}\int\gamma(\xi)\,\mathrm{d}\xi$, which proves Corollary 4.2.

5. Conclusions. It has been shown that a trapped mode is possible in the model presented here. To increase confidence that such modes exist on real coasts further work is clearly required to demonstrate that this mode is not an artifact of the modelling assumptions. However these assumptions are the usual ones for the simple theory of CSWs and extensions to include stratification and more realistic boundary conditions have not in general contradicted them [LBMy]. The result here suggests that it would be of interest to compare low-frequency velocity records in the neighborhood of capes with those on nearby straight coasts to determine whether there is indeed enhanced energy at the cape. Both the above endeavors are being pursued.

GLOBAL BIFURCATION THEORY OF DEEP-WATER WAVES WITH VORTICITY*

VERA MIKYOUNG HUR†

Abstract. The classical deep-water wave problem is to find a periodic traveling wave with a free surface of infinite depth. The main result is the construction of a global connected set of rotational solutions for a general class of vorticities. Each nontrivial solution on the continuum has a wave profile symmetric around the crests and monotone between crest and trough.

The problem is formulated as a nonlinear elliptic boundary value problem in an unbounded domain with a parameter. The analysis is based on generalized degree theory and the global theory of bifurcation. The unboundedness of the domain renders consideration of approximate problems with stronger compactness properties.

Key words. water waves, vorticity, nonlinear elliptic, Leray–Schauder degree, bifurcation

1. Introduction.

The classical deep-water wave problem is to find a periodic traveling wave with a free surface of infinite depth. A two-dimensional incompressible inviscid fluid, at rest at great depths, occupies the domain bounded by a free surface, where the pressure balances out with the constant atmospheric pressure. The main result is to construct a global connected set of nontrivial solutions to the full Euler equations for positive monotone vorticities. The methods involved are the global theory of bifurcation which has its foundation in topological degree theory, maximum principles and the Schauder theory for nonlinear second-order elliptic partial differential equations.

Irrotational solutions to the deep-water wave problem are referred to as *Stokes waves*, for which existence theory has been studied in a number of works. The first rigorous mathematical treatment is the construction, following Levi-Civita [26] and Nekrasov [30], of small-amplitude waves by a series expansion method. The global theory of existence began with Krasovskii [24] who used a degree-theoretic argument to obtain finite-amplitude waves. Subsequently, with the invention by Rabinowitz [33] of abstract global bifurcation theory, Keady and Norbury [22] inferred that these solutions form a global connected set. Amick [3], Amick, Fraenkel, and Toland [4], and McLeod [29] refined this result further to prove that this continuum contains in its closure Stokes waves of extreme form with stagnation at their crests. A survey on the existence theory for Stokes waves is to be found in [39].

The existence theory for *rotational* waves is, on the other hand, much less complete. Gerstner [14, 6] found an explicit formula for a family of trochoidal deep-water waves for a particular nonzero vorticity early in 1802. However, an extensive existence theory for a general class of vorticities appeared much later in the work of Dubreil-Jacotin [12], who constructed small-amplitude waves by a series expansion method. This result was later improved by Goyon [16] and Zeidler [42]. Recently, Constantin

and Strauss [9, 10] employed generalized degree theory [18, 23] as adapted for nonlinear elliptic boundary value problems and global bifurcation theory [33] to obtain a global connected set of rotational waves of finite depth. The purpose of the present work is to obtain an analogous result for the case of infinite depth. An important difference from [10] lies in the lack of compact embedding properties of Ascoli type due to the unboundedness of the physical domain. Under the additional restriction that the vorticity distribution is positive and monotone, the set of nontrivial solutions acquires the desired compactness with the exploitation of maximum principles.

At the beginning of section 3.1, the unknown fluid region is conveniently mapped onto a fixed semi-infinite strip in the plane by exchanging the roles of the stream function and the vertical coordinate. The depth below the free surface is regarded as a solution to a quasi-linear elliptic partial differential equation with a nonlinear oblique boundary condition. The problem is successively formulated as an operator equation of the form $F(\lambda, w) = 0$; λ is a real parameter and the "nontrivial perturbation" w from the trivial shear current belongs to the Banach space, denoted by X, of $C^{3+\alpha}$ Hölder continuous functions which vanish asymptotically at the infinite bottom. The equation is singular in the sense that the operator is not Fredholm, and thus topological degree theory/global bifurcation theory may not be applied directly. This difficulty is overcome by studying a sequence of approximate problems $F^\epsilon(\lambda, w) = 0$ for $\epsilon > 0$, where F^ϵ is a nonlinear Fredholm operator.

Section 4 gives a detailed global bifurcation analysis for the approximate problems. The first step is to linearize F^ϵ around the trivial solution and to find a sequence of bifurcation points through each of which a local curve of nontrivial solutions emanates. This is an application of the local bifurcation theorem due to Crandall and Rabinowitz [11]. Next, several properties of F^ϵ including the properness and the Fredholm property of the linearized operator are established. The generalized degree theory developed in [18, 23] and the global bifurcation theorem [33] apply at once, and after further detailed analysis based on the maximum principle and its sharp form at corner points [35], a global continuum of nontrivial solutions is obtained to each approximate problem.

The central part of this work is section 5.1 on the existence theory for the singular problem. We employ the development by Rabinowitz of the global theory of bifurcation to conclude that the continuum of the nontrivial solutions to $F(\lambda, w) = 0$ either is unbounded in $\mathbb{R} \times X$ or intersects the boundary of the admissible set where the boundary value problem becomes degenerate. An important observation here is that the positiveness and monotonicity of the vorticity enable us to obtain the uniform decay of solutions at infinity and hence the compactness of the solution set. In the following subsection, with the use of the regularity estimates for quasi-linear elliptic partial differential equations, the alternative that the size of w increases unboundedly in the $C^{3+\alpha}$ norm along the continuum reduces to the unboundedness of either w or its first-order derivatives in the maximum norm.

Finally, section 5.3 is the examination of the remaining alternatives to prove that our global continuum contains a sequence of nontrivial solutions to the deep-water wave problem such that along a sequence on the continuum either the relative flow speed at the wave troughs becomes arbitrarily large or the relative flow speed somewhere on the free surface becomes arbitrarily close to zero (stagnation). In the case of irrotational flows, the existence of a limiting wave with stagnation at its crests, where the wave profile has sharp cusps with the containing angle of $2\pi/3$, was conjectured by Stokes [37] and proved by Amick, Fraenkel, and Toland [4].

2. Formulation and the main result.

2.1. The deep-water wave problem in physical variables. The gravity water wave problem concerns the motion of an incompressible inviscid fluid with a free surface acted on only by gravity. Consider a two-dimensional flow which at time t occupies the region in the (x, y)-plane bounded by a free surface $y = \eta(t; x)$. In the fluid region $\{(x, y) : y < \eta(t; x)\}$, the velocity field $(u(t; x, y), v(t; x, y))$ and the pressure $P(t; x, y)$ satisfy the following Euler equations:

$$\begin{aligned} u_t + uu_x + vu_y &= -P_x, \\ v_t + uv_x + vv_y &= -P_y - g, \\ u_x + v_y &= 0. \end{aligned}$$

Here g denotes the gravitational constant of acceleration. The flow is supposed to be rotational and characterized by the vorticity $\omega = v_x - u_y$.

The dynamic and kinematic boundary conditions hold on the free surface $y = \eta(t; x)$:

$$P = P_0 \quad \text{and} \quad v = \eta_t + u\eta_x,$$

where P_0 is the constant atmospheric pressure. The boundary condition at the infinite bottom

$$(u, v) \to (0, 0) \quad \text{as } y \to -\infty \text{ uniformly for } x \in \mathbb{R}$$

expresses the fact [19] that the fluid at great depths is practically at rest. Our bottom boundary condition precludes wave trains on water of infinite depth, numerically calculated in [36, 40], which exhibit a nonphysical asymptotic behavior at the infinite bottom.

The steady water wave problem is then to find solutions for which the wave profile, the velocity, and the pressure have space-time dependence $(x - ct, y)$, where $c > 0$ is the speed of wave propagation. In the frame of reference moving with speed c, the velocity field $(u(x, y), v(x, y))$ and the pressure $P(x, y)$ of the steady flow satisfy

$$(u - c)u_x + vu_y = -P_x, \tag{2.1}$$

$$(u - c)v_x + vv_y = -P_y - g, \tag{2.2}$$

$$u_x + v_y = 0 \tag{2.3}$$

in the stationary region $\{(x, y) : y < \eta(x)\}$. The boundary conditions are

$$P = P_0 \quad \text{and} \quad v = (u - c)\eta_x \qquad \text{on } y = \eta(x), \tag{2.4}$$

$$(u, v) \to (-c, 0) \quad \text{as } y \to -\infty \text{ uniformly for } x \in \mathbb{R}. \tag{2.5}$$

Equations (2.1)–(2.5) are supplemented with the following periodicity and symmetry conditions:

$$\begin{aligned} \eta(-x) = \ \eta(x) \quad &= \eta(x + L), \\ u(-x, y) = u(x, y) &= u(x + L, y), \\ -v(-x, y) = v(x, y) &= v(x + L, y), \end{aligned} \tag{2.6}$$

where $L > 0$ is the wavelength.

Our objective here is to find nontrivial solutions to (2.1)–(2.6) for a general class of vorticities. If the flow is *irrotational*, i.e., $\omega \equiv 0$, the solutions are referred to as *Stokes waves*, for which existence theory has been studied in a number of works. A survey on the existence theory for Stokes waves is to be found in [39].

In this setting, L and c are considered as parameters whose values form part of the solution. The wavelength L of the deep-water wave problem is independent of other physical parameters, and hence is taken to be 2π for simplicity in what follows.

Two distinct features of problem (2.1)–(2.6) are that the free surface is *not* known a priori and that the physical domain is *unbounded*.

2.2. The vorticity-stream formulation. We define the (relative) *stream function* $\psi(x,y)$ by

$$\psi_x = -v, \qquad \psi_y = u - c. \tag{2.7}$$

This reduces (2.1)–(2.6) to a stationary elliptic boundary value problem.

The Poisson equation

$$-\Delta\psi = v_x - u_y = \omega$$

follows from (2.7). Note that ψ is 2π periodic in the x-variable. Indeed, $\int_0^{2\pi} v(s,y)ds$ is independent of y and therefore is zero by (2.5). The kinematic boundary condition allows us to normalize ψ so that $\psi = 0$ on the free surface. The boundary condition at the infinite bottom becomes $\nabla\psi(x,y) = (\psi_x, \psi_y) \to (0, -c)$ as $y \to -\infty$ uniformly for x.

The vorticity equation $(u-c)\omega_x + v\omega_y = 0$, compared to (2.7), states that ω is a function of ψ at least locally away from a stagnation point, a point where $u = c$ and $v = 0$. Under the restriction that the vorticity is nonnegative and nonincreasing with the depth, i.e., $\omega(x,y) \geq 0$ and $\omega_y(x,y) \geq 0$, one can show that $u - c < 0$ everywhere in the fluid; see Lemma 2.1. Experimental evidence [28] indicates that for wave patterns which are not near the spilling or breaking state, the speed of wave propagation is in general considerably larger than the horizontal velocity of any water particle.

We shall show later in section 3.1 that $u - c < 0$ guarantees that

$$-\Delta\psi = \gamma(\psi)$$

for some function γ throughout the fluid. The *vorticity function* γ measures the strength of the vorticity.

Assumptions on γ. For some $\alpha \in (0,1)$ a constant, $\gamma \in C^{1+\alpha}([0,\infty))$ is nonincreasing along with depth, $\gamma'(s) \leq 0$ for $s \in [0,\infty)$, and $\gamma(s) \in O(s^{-2-2l})$ as $s \to \infty$ for some $l > 0$.

Our assumptions imply that the vorticity is nonnegative, $\gamma(s) \geq 0$ for $s \in [0,\infty)$, and that ω vanishes in the limit as $y \to -\infty$.

Let us define

$$\Gamma(p) = \int_p^0 \gamma(-s)ds \tag{2.8}$$

and

$$\Gamma_\infty = \int_{-\infty}^0 \gamma(-s)ds.$$

From the equations of motion follows Bernoulli's law, which states that the quantity

$$E = \tfrac{1}{2}(\psi_x^2 + \psi_y^2) + gy + P + \Gamma(-\psi)$$

is constant throughout the fluid. The sum of the first four terms in the expression of E is the total mechanical energy of the flow; $\frac{1}{2}(\psi_x^2 + \psi_y^2)$ is the kinetic energy, gy is the gravitational potential energy, and P is the energy of fluid pressures. In view of Bernoulli's law, the dynamic boundary condition takes the form that

$$Q = \psi_x^2(x, \eta(x)) + \psi_y^2(x, \eta(x)) + 2g\eta(x)$$

is independent of x. The quantity $\frac{1}{2}Q$, i.e., E evaluated at the free surface, is called the *hydraulic head*. We remark that E and Q may vary along continua of solutions.

In summary, there results the following formulation of the deep-water wave problem, equivalent to (2.1)–(2.6). Let

$$\mathcal{D}_\eta = \{(x, y) : x \in \mathbb{R},\ \ y < \eta(x)\} \quad \text{and} \quad \mathcal{S}_\eta = \{(x, \eta(x)) : x \in \mathbb{R}\}.$$

For a parameter $c > 0$, there exist $\eta(x)$ and $\psi(x, y)$ such that η is even and 2π periodic, ψ is even and 2π periodic in the x-variable, and

$$-\Delta\psi = \gamma(\psi) \quad \text{in } \mathcal{D}_\eta, \tag{2.9a}$$

$$\psi = 0 \quad \text{on } \mathcal{S}_\eta, \qquad \psi > 0 \quad \text{in } \mathcal{D}_\eta, \tag{2.9b}$$

$$|\nabla\psi(x, \eta(x))|^2 + 2g\eta(x) = Q \quad \text{for } x \in \mathbb{R}, \tag{2.9c}$$

$$\nabla\psi(x, y) \to (0, -c) \quad \text{as } y \to -\infty \text{ uniformly for } x \in \mathbb{R}. \tag{2.9d}$$

We locate the origin of Cartesian coordinates at one of the wave crests (where η attains its maximum over one period), i.e., $\eta(0) = 0$. With this convention, $Q = (c - u(0, 0))^2 > 0$ is the square of the relative flow speed at the crest.

Under the assumptions on the vorticity, the exponential decay estimates of solutions follow as applications of the maximum principle.

LEMMA 2.1. *Assume that $\omega(x, y) \geq 0$ and $\omega_y(x, y) \geq 0$. Let $\eta(x)$ and $\psi(x, y)$ be a solution pair of* (2.9) *corresponding to the solution triple $(u - c, v, \eta)$ of* (2.1)–(2.6) *via the definition* (2.7).

(a) *$\psi_y = u - c < 0$ on $\overline{\mathcal{D}}_\eta$. Therefore, $\omega = \gamma(\psi)$ throughout the fluid region for some function γ. Note that γ satisfies the assumptions described above.*

(b) *Assume further that $\psi_x(x, \eta(x)) > 0$ for $x \in (-\pi, 0)$. Then $\psi_x(x, y) > 0$ on $\{(x, y) \in \overline{\mathcal{D}}_\eta : x \in (-\pi, 0)\}$, and $\psi_x(x, y)$ and $\psi_{xx}(0, y)$ decay exponentially as $y \to -\infty$ uniformly for x. More precisely,*

$$|\psi_x(x, y)| < Ae^y \qquad \text{on } (-\pi, \pi) \times (-\infty, \eta(\pm\pi)), \tag{2.10}$$

$$|\psi_{xx}(0, y)| < Be^y \qquad \text{for } y \in (-\infty, \eta(\pm\pi)), \tag{2.11}$$

where $A, B > 0$ depend only on $\eta(\pm\pi)$.

Remark 2.2. Assertion (a) justifies the existence of the vorticity function γ and supports a detailed global bifurcation analysis; see sections 3 and 4, respectively. Assertion (b) is important for compactness reasons later in Lemmas 4.6 and 5.1.

An easy consequence of the monotonicity of ψ_x and ψ_y is that the wave profile decreases monotonically from crest to trough. Constantin and Escher [7] proved that the symmetry of the wave profile is not a hypothesis but rather a conclusion when the wave profile is monotone between crest and trough and the vorticity is positive and decreases with depth.

Proof. (a) Since $\psi = 0$ on $\mathcal{S}_\eta$ and $\psi \to \infty$ as $y \to -\infty$, the subharmonic function ψ is positive in $\mathcal{D}_\eta$. It therefore attains its minimum on $\mathcal{S}_\eta$, and by the Hopf boundary point lemma $\psi_y < 0$ on $\mathcal{S}_\eta$.

Note that

$$\Delta\psi_y + \omega_y(x, y) = 0$$

and that ψ_y tends to $-c < 0$ as $y \to -\infty$. The maximum principle then implies that $\psi_y < 0$ on $\overline{\mathcal{D}}_\eta$.

(b) Note that

$$\Delta\psi_x + \gamma'(\psi)\psi_x = 0$$

and that $\psi_x \to 0$ as $y \to -\infty$ uniformly for x. Since $\psi_x(x, \eta(x)) > 0$ for $x \in (-\pi, 0)$, by the maximum principle, $\psi_x(x, y) > 0$ for $(x, y) \in \overline{\mathcal{D}}_\eta$ and $x \in (-\pi, 0)$.

For the second assertion, let

$$D = (-\pi, \pi) \times (-\infty, \eta(\pm\pi)) \quad \text{and} \quad D^- = \{(x, y) \in D : x \in (-\pi, 0)\}.$$

For $A > 0$ we define a C^2-function on D^- by

$$W(x, y) = \psi_x(x, y) - Ae^y \sin x.$$

Choose A sufficiently large so that $W(x, y) < 0$ on $(0, \pi) \times \{\eta(\pm\pi)\}$. Such an A depends only on $\eta(\pm\pi)$; see [7]. A simple calculation yields

$$\Delta W + \gamma'(\psi)W = -A\gamma'(\psi)e^y \sin x \geq 0 \quad \text{in } D^-.$$

By oddness and periodicity of ψ_x, we infer that $W(-\pi, y) = 0 = W(0, y)$ for $y \leq \eta(-\pi)$. Since $W(x, y) \to 0$ as $y \to -\infty$ uniformly for x, the maximum principle ensures $W(x, y) < 0$ in D^-. A similar consideration leads to an analogous inequality on $D \cap \{x \in (0, \pi)\}$, and (2.10) follows at once.

Finally, from the classical gradient estimate [15, page 37] for Poisson's equation, it follows that

$$\begin{aligned} |\psi_{xx}(0, y)| &\leq \frac{2}{\pi} \sup_D |\psi_x(x, y)| + \frac{\pi}{2} \sup_D |\gamma'(\psi)||\psi_x(x, y)| \\ &\leq Be^y \end{aligned}$$

for $y < \eta(\pm\pi) - \pi$, where $B > 0$ depends only on $\eta(\pm\pi)$. This proves (2.11). $\square$

2.3. The main result. For a positive integer k and a constant $\alpha \in (0, 1)$, a domain $D \subset \mathbb{R}^2$ is called a $C^{k+\alpha}$ domain if each point on its boundary ∂D has a neighborhood in which ∂D is the graph of a $C^{k+\alpha}$ function. Given a $C^{k+\alpha}$ domain $D \subset \mathbb{R}^2$ (not necessarily bounded), we define

$$C^{k+\alpha}_{per}(\overline{D}) = \{\, w \in C^{k+\alpha}(\overline{D}) : w \text{ is even and } 2\pi \text{ periodic in the } x\text{-variable} \,\}, \tag{2.12}$$

where $C^{k+\alpha}(\overline{D})$ is a Hölder space with the norm as in [2, Chapter II]:

$$\|w\|_{C^{k+\alpha}(\overline{D})} = \sum_{|\beta|=0}^{k} \max_{\overline{D}} |\partial^\beta w(x, y)| + \sup_{|\beta|=k} \sup_{\substack{(x,y)\neq(\tilde{x},\tilde{y}) \\ \overline{D}}} \frac{|\partial^\beta w(x, y) - \partial^\beta w(\tilde{x}, \tilde{y})|}{\sqrt{(x - \tilde{x})^2 + (y - \tilde{y})^2}^{\,\alpha}}.$$

This notation is extended in an obvious way to the case when $\alpha = 0$ and to functions of a single variable.

Our main result is the following theorem on the existence of nontrivial deep-water waves with vorticity.

THEOREM 2.3 (main theorem). *Suppose that the vorticity function $\gamma \in C^{1+\alpha}([0,\infty))$ for some $\alpha \in (0,1)$ satisfies $\gamma'(s) \leq 0$ for $s \in [0,\infty)$ and $\gamma \in O(s^{-2-2l})$ as $s \to \infty$ for some $l > 0$. Suppose furthermore that*

$$\Gamma_\infty = \int_{-\infty}^{0} \gamma(-s)ds < \frac{1}{2} \min \left(\left(\frac{g}{2}\right)^{2/3}, \left(\frac{g}{2}\right)^2 \right). \tag{2.13}$$

Consider the deep-water wave problem (2.1)–(2.6). There exists a connected set $\mathcal{C}$ of solution triples $(u-c, v, \eta)$ in the space $C^{2+\alpha}_{per}(\overline{\mathcal{D}}_\eta) \times C^{2+\alpha}_{per}(\overline{\mathcal{D}}_\eta) \times C^{3+\alpha}_{per}(\mathbb{R})$ such that

(i) *the continuum $\mathcal{C}$ contains a trivial shear flow with $v \equiv 0$ (under the flat surface $\eta \equiv 0$); and*

(ii) *there is a sequence of solution triples $\{(u_j - c_j, v_j, \eta_j)\} \subset \mathcal{C}$, for which*

$$\text{either} \quad \lim_{j\to\infty} (c_j - u_j(\pm\pi, \eta_j(\pm\pi))) = \infty \quad \text{or} \quad \lim_{j\to\infty} \min_{\mathcal{S}_{\eta_j}} (c_j - u_j) = 0.$$

Each nontrivial solution triple $(u-c, v, \eta) \in \mathcal{C}$ enjoys the following properties:

(iii) *η has a single maximum (crest) and a single minimum (trough) per wavelength; we say the crest occurs at $x = 0$;*

(iv) *the wave profile decreases monotonically from crest to trough, i.e., $\eta'(x) < 0$ for $x \in (0,\pi)$;*

(v) *the relative horizontal velocity is negative, $u - c < 0$, throughout the fluid; and*

(vi) *a water particle located at (x,y) with $x \in (0,\pi)$ has positive vertical velocity $v > 0$.*

In addition, if $\gamma(0)$ is sufficiently small, (ii) *can be replaced by*

(ii′) *there is a sequence of solution triples $\{(u_j - c_j, v_j, \eta_j)\} \subset \mathcal{C}$, for which*

$$\text{either} \quad \lim_{j\to\infty} (c_j - u_j(\pm\pi, \eta_j(\pm\pi))) = \infty \quad \text{or} \quad \lim_{j\to\infty} (c_j - u_j(0,0)) = 0.$$

The smallness condition (2.13) guarantees the local bifurcation of approximate problems; see Lemma 4.1.

Theorem 2.3 presents two alternatives in (ii). When the first alternative holds, either the speed of wave propagation or the wave amplitude becomes unboundedly large; see Remark 5.9. The second alternative means that the continuum contains waves with horizontal particle velocity somewhere on the free surface arbitrarily close to the speed of wave propagation. In other words, there is a region of almost stagnant fluid on the free surface, a region which is carried along by the traveling wave.

If $\gamma(0)$ is small enough so that the relative flow speed $c-u$ is nondecreasing from crest to trough (and it hence attains its minimum on the surface at the crest), then the crest is the point of almost stagnation. A precise condition is given in (5.23).

Our conclusion, in the case of zero vorticity, partly recovers the well-known result for Stokes waves [39] that the connected continuum contains a limiting wave with stagnation at the wave crests.

3. Reformulation: Reduction to an operator equation. We now turn to establishing the existence of solutions to (2.1)–(2.6). On account of the unknown surface, we use the coordinate transformation devised by Dubreil-Jacotin [12] to reformulate the problem as a boundary value problem in a fixed domain.

3.1. Change of independent variables. We begin by the observation that ψ is constant on the free surface and decreases along with y as a function of y; i.e., the y-coordinate is a single-valued function of ψ for each fixed x. This suggests the introduction of new independent variables

$$q = x \quad \text{and} \quad p = -\psi(x, y),$$

which map the fluid region of one period $\{(x, y) \in \mathcal{D}_\eta : x \in (-\pi, \pi)\}$ to a fixed semi-infinite strip $(-\pi, \pi) \times (-\infty, 0)$ in the (q, p)-plane, the free surface $\{(x, \eta(x)) : x \in (-\pi, \pi)\}$ to $(-\pi, \pi) \times \{0\}$. Let

$$R = \{(q, p) : -\pi < q < \pi,\, p < 0\} \quad \text{and} \quad T = \{(q, 0) : -\pi < q < \pi\}.$$

The depth function $h(q, p) = y - Q/2g$ replaces the dependent variables. An explicit calculation shows that

$$h_q = \frac{v}{u - c}, \qquad h_p = \frac{1}{c - u}. \tag{3.1}$$

From $u - c < 0$ throughout the fluid it follows that ω is a single-valued function of p. Indeed,

$$\partial_q \omega = \left(\partial_x + \frac{h_q}{h_p}\partial_p\right)\omega = \left(\partial_x - \frac{v}{c - u}\partial_y\right)\omega = 0.$$

We say $\omega = \gamma(-p)$.

The vorticity-stream formulation (2.9) is accordingly reformulated as an elliptic boundary value problem in a fixed domain:

$$(1 + h_q^2)h_{pp} - 2h_p h_q h_{pq} + h_p^2 h_{qq} = -\gamma(-p)h_p^3 \qquad \text{in } R, \tag{3.2a}$$

$$1 + 2ghh_p^2 + h_q^2 = 0 \qquad \text{on } T, \tag{3.2b}$$

$$\nabla h = (h_q, h_p) \to (0, \tfrac{1}{c}) \quad \text{as } p \to -\infty \qquad \text{uniformly for } q, \tag{3.2c}$$

with h even and 2π periodic in the q-variable.

The above formulation is equivalent to (2.1)–(2.6), as is presented in the next lemma.

LEMMA 3.1. *Suppose that $h \in C^{3+\alpha}_{per}(\overline{R})$ is a solution of* (3.2). *There corresponds to h a solution triple $(u - c, v, \eta)$ of* (2.1)–(2.6) *in the space $C^{2+\alpha}_{per}(\overline{\mathcal{D}}_\eta) \times C^{2+\alpha}_{per}(\overline{\mathcal{D}}_\eta) \times C^{3+\alpha}_{per}(\mathbb{R})$.*

The subscript "*per*" for a domain in the (q, p)-plane refers to evenness and periodicity in the q-variable.

Proof. The proof is similar to that of [10, Lemma 2.1], and therefore we will not carry out every detail. First, it is observed from the partial differential equation (3.2a) that $\gamma \in C^{1+\alpha}([0, \infty))$.

Suppose for the moment that $h \in C^2_{per}(\overline{R})$ is a solution of (3.2). We define $C^1_{per}(\overline{R})$ functions

$$F(q, p) = \frac{1}{h_p(q, p)}, \qquad G(q, p) = -\frac{h_q(q, p)}{h_p(q, p)}. \tag{3.3}$$

The wave profile is given by $\eta(x) = h(x, 0) + Q/2g$ for $x \in [-\pi, \pi]$ and is extended to the entire real line as an even and 2π periodic function. Clearly, $\eta \in C^2_{per}(\mathbb{R})$.

In order to recover the relative stream function ψ, we consider the ordinary differential equation

$$\begin{cases} \frac{d}{dy}\psi(x,y) = -F(x, -\psi(x,y)), \\ \psi(x, \eta(x)) = 0, \end{cases} \tag{3.4}$$

where $x \in [-\pi, \pi]$ is fixed. Since F is of C^1, from the standard theory of ordinary differential equations it follows that there exists a unique local solution $\psi(x, y)$ to (3.4). Furthermore, the solution exists for all $(-\infty, \eta(x)]$. Indeed, $F \geq \delta > 0$ for some δ over $\overline{R}$, and thus $F(q, p)$ defines a nondegenerate complete vector field on $p \in (-\infty, 0)$. Clearly, $\psi \in C^2_{per}(\overline{\mathcal{D}}_\eta)$.

It is straightforward to show that $\eta(x)$ and $\psi(x, y)$ constructed above are solutions to (2.9), completely analogous to the finite-depth case. One can repeat the calculation in [10, Lemma 2.1] to show that $\psi_x(x, y) = -G(x, -\psi(x, y))$. The boundary condition at infinity

$$\nabla\psi(x,y) \to (0, -c) \quad \text{as } y \to -\infty \text{ uniformly for } x \in \mathbb{R}$$

is fulfilled by (3.2c) and (3.3).

The relative velocity components are successively defined by

$$u(x,y) - c = -F(x, -\psi(x,y)), \qquad v(x,y) = G(x, -\psi(x,y)),$$

which are in $C^2_{per}(\overline{\mathcal{D}}_\eta)$ and solve (2.1)–(2.6). Finally, if h is $C^{3+\alpha}_{per}(\overline{R})$ for $\alpha \in (0, 1)$, then, by construction, $(u - c, v, \eta)$ belongs to the function space $C^{2+\alpha}_{per}(\overline{\mathcal{D}}_\eta) \times C^{2+\alpha}_{per}(\overline{\mathcal{D}}_\eta) \times C^{3+\alpha}_{per}(\mathbb{R})$. $\square$

As in section 2, let

$$\Gamma(p) = \int_p^0 \gamma(-s)ds, \qquad \Gamma_\infty = \int_{-\infty}^0 \gamma(-s)ds.$$

LEMMA 3.2 (trivial flows). *For each $\lambda \in (2\Gamma_\infty, \infty)$ the system* (3.2) *has a solution*

$$H(p) = H(p; \lambda) = \int_0^p \frac{ds}{\sqrt{\lambda - 2\Gamma(s)}} - \frac{\lambda}{2g}, \tag{3.5}$$

which corresponds to a parallel shear flow in the horizontal direction under the flat surface $\eta \equiv 0$.

Proof. These solutions do not depend on q, and thus (3.2a) reduces to $H'' = -\gamma(-p)(H')^3$. Here and elsewhere the prime denotes differentiation with respect to p. Solutions to this ordinary differential equation are

$$H'(p) = (\lambda - 2\Gamma(p))^{-1/2},$$

which are defined for $\lambda > 2\Gamma_\infty$. The formula (3.5) then follows from the boundary condition on top, $1 + 2gH(0)(H'(0))^2 = 0$.

The boundary condition at infinity, $H'(p) \to \frac{1}{c}$ as $p \to -\infty$, relates the bifurcation parameter λ with the wave speed c:

$$\lambda = c^2 + 2\Gamma_\infty. \qquad \square$$

Note 3.3. Let us denote

$$a(\lambda) = a(p;\lambda) = \sqrt{\lambda - 2\Gamma(p)}.$$

The derivatives of H can be expressed in terms of a:

$$H'(p) = a^{-1}(p;\lambda), \qquad H''(p) = -\gamma(-p)a^{-3}(p;\lambda).$$

Note that $a(\lambda)$ is bounded for each $\lambda > 2\Gamma_\infty$.

In order to establish the existence of nontrivial solutions to (3.2) via bifurcation theory, we need to formulate the problem as an abstract operator equation $F(\lambda, w) = 0$, where w belongs to a Banach space. However, a set of functions with the condition (3.2c) at infinity does not form a linear space. For this reason, we introduce the "nontrivial perturbation" $w(q,p)$ of the depth function $h(q,p)$ from that of a trivial flow $H(p)$ defined as

$$h(q,p) = H(p) + w(q,p). \tag{3.6}$$

Problem (2.1)–(2.6) is ultimately formulated as follows:

$$\begin{aligned}(1+w_q^2)w_{pp} - 2(a^{-1}(\lambda)+w_p)w_q w_{pq} + (a^{-1}(\lambda)+w_p)^2 w_{qq}&\\ + \gamma(-p)(a^{-1}(\lambda)+w_p)^3 - \gamma(-p)a^{-3}(\lambda)(1+w_q^2) = 0 &\qquad \text{in } R,\end{aligned} \tag{3.7a}$$

$$1 + (2gw-\lambda)(\lambda^{-1/2}+w_p)^2 + w_q^2 = 0 \qquad \text{on } T. \tag{3.7b}$$

Here w is required to be even and 2π periodic in the q-variable. The principal point is that ∇w vanishes asymptotically:

$$\nabla w = (w_q, w_p) \to 0 \quad \text{as } p \to -\infty \text{ uniformly for } q. \tag{3.7c}$$

3.2. The operator equation and its approximation. We introduce the function spaces. Let

$$\begin{aligned} X &= \{\, w \in C^{3+\alpha}_{per}(\overline{R}) : \partial^\beta w \in o(1) \text{ as } p \to -\infty,\ |\beta| \le 3 \text{ uniformly for } q \,\},\\ Y_1 &= \{\, w \in C^{1+\alpha}_{per}(\overline{R}) : \partial^\beta w \in o(1) \text{ as } p \to -\infty,\ |\beta| \le 1 \text{ uniformly for } q \,\},\end{aligned}$$

and $Y_2 = C^{2+\alpha}_{per}(T)$. Let $Y = Y_1 \times Y_2$ with the product topology. We equip X and Y with the Hölder norms (thus rendering them Banach spaces):

$$\begin{aligned} \|\cdot\|_X &:= \|\cdot\|_{C^{3+\alpha}(\overline{R})}\,,\\ \|\cdot\|_Y &:= \|\cdot\|_{Y_1} + \|\cdot\|_{Y_2}\,,\end{aligned}$$

where $\|\cdot\|_{Y_1} = \|\cdot\|_{C^{1+\alpha}(\overline{R})}$ and $\|\cdot\|_{Y_2} = \|\cdot\|_{C^{2+\alpha}(T)}$. Here the Hölder norms of functions on the unbounded domain $\overline{R}$ take supremum values over the entire domain (see [2, Chapter II]):

$$\|w\|_{C^{k+\alpha}(\overline{R})} = \sum_{|\beta|=0}^{k} \max_{\overline{R}} |\partial^\beta w(q,p)| + \sup_{|\beta|=k}\ \sup_{\substack{(q,p)\neq(\tilde q,\tilde p)\\ \overline{R}}} \frac{|\partial^\beta w(q,p) - \partial^\beta w(\tilde q,\tilde p)|}{\sqrt{(q-\tilde q)^2 + (p-\tilde p)^2}^{\,\alpha}}.$$

Let $Z = C^0_{per}(\overline{R})$ have the usual maximum norm $\|\cdot\|_Z = \|\cdot\|_{C^0(\overline{R})}$.

A nonlinear differential operator

$$F(\lambda, w) = (F_1(\lambda, w), F_2(\lambda, w)) : \mathbb{R} \times X \to Y$$

is defined by

$$\begin{aligned} F_1(\lambda, w) = {}& (1 + w_q^2)w_{pp} - 2(a^{-1}(\lambda) + w_p)w_q w_{pq} + (a^{-1}(\lambda) + w_p)^2 w_{qq} \\ & + \gamma(-p)(a^{-1}(\lambda) + w_p)^3 - \gamma(-p)a^{-3}(\lambda)(1 + w_q^2), \end{aligned} \tag{3.8}$$

$$F_2(\lambda, w) = 1 + (2gw - \lambda)(\lambda^{-1/2} + w_p)^2 + w_q^2\big|_T. \tag{3.9}$$

The operator form of the deep-water wave problem is then to find a nontrivial solution $(\lambda, w) \in \mathbb{R} \times X$ to

$$F(\lambda, w) = 0. \tag{3.10}$$

The existence theory "in the large" for the finite-depth case [9, 10] follows as an application to F of generalized degree theory [18, 23] and abstract global bifurcation theory [33]. For the infinite-depth case, however, the presence of the continuous spectrum due to the unboundedness of the physical domain renders this application much less than routine.

Denoted by $F_w(\lambda, w)$ is the Fréchet derivative of F in its second argument at $(\lambda, w) \in \mathbb{R} \times X$. A straightforward calculation yields

$$F_w(\lambda, w) = (A(\lambda, w), B(\lambda, w)),$$

where

$$\begin{aligned} A(\lambda, w)[\phi] = {}& (1 + w_q^2)\phi_{pp} - 2(a^{-1}(\lambda) + w_p)w_q\phi_{pq} + (a^{-1}(\lambda) + w_p)^2\phi_{qq} \\ & + \left(-2w_q w_{pq} + 2(a^{-1}(\lambda) + w_p)w_{qq} + 3\gamma(-p)(a^{-1}(\lambda) + w_p)^2\right)\phi_p \\ & + \left(2w_q w_{pp} - 2(a^{-1}(\lambda) + w_p)w_{pq} - 2\gamma(-p)a^{-3}(\lambda)w_q\right)\phi_q, \\ B(\lambda, w)[\phi] = {}& 2(2gw - \lambda)(\lambda^{-1/2} + w_p)\phi_p + 2w_q\phi_q + 2g(\lambda^{-1/2} + w_p)^2\phi\big|_T \end{aligned}$$

for $\phi \in X$.

The linear operator $(A(\lambda, w), B(\lambda, w))$ defines the "limiting" operator

$$\begin{cases} A_\infty(\lambda)[\phi] = \phi_{pp} + (\lambda - 2\Gamma_\infty)^{-1}\phi_{qq}, \\ B_\infty(\lambda)[\phi] = -2\lambda^{1/2}\phi_p + 2g\lambda^{-1}\phi\big|_T \end{cases}$$

for $\phi \in X$, which is obtained by substituting each coefficient function by its limit as $p \to -\infty$. Unfortunately, this operator is *not* semi-Fredholm as its spectrum consists of only the continuous spectrum $(-\infty, 0]$. In particular, $F_w(\lambda, w) : X \to Y$ is *not* a Fredholm operator of index zero, and thus topological degree theory may not be directly applied.

This difficulty can be overcome by studying a sequence of approximate problems:

$$F^\epsilon(\lambda, w) := \left(F_1(\lambda, w) - \epsilon(a^{-1}(\lambda) + w_p)^3 w, F_2(\lambda, w)\right) = 0, \tag{3.11}$$

where $\epsilon > 0$. The properness of F^ϵ and the Fredholm property of its linearization will follow from the fact that the limiting problem

$$\left(A_\infty(\lambda) - \epsilon(\lambda - 2\Gamma_\infty)^{-3/2}I, B_\infty(\lambda)\right)[\phi] = 0$$

admits only the zero solution; see Lemmas 4.4 and 4.6.

Remark 3.4. Construction of a topological degree for general nonlinear elliptic operators has been studied in a number of works (see [18, 23, 41] and the references therein) under the condition that the nonlinear elliptic operator is proper and the linearization is a Fredholm operator of index zero. The Fredholm property of a linear elliptic operator in an unbounded domain is related to the uniform decay of the solutions at infinity. Indeed, a linear elliptic operator in an unbounded domain is semi-Fredholm if and only if the limiting problem does not have nonzero solutions (see [41, Theorem 2.15]).

A simple calculation yields that

$$F^\epsilon_w(\lambda, w) = (A^\epsilon(\lambda, w), B(\lambda, w)),$$

where

$$\begin{aligned} A(\lambda,w)[\phi] &= (1+w_q^2)\phi_{pp} - 2(a^{-1}(\lambda)+w_p)w_q\phi_{pq} + (a^{-1}(\lambda)+w_p)^2\phi_{qq} \\ &\quad + \big(-2w_q w_{pq} + 2(a^{-1}(\lambda)+w_p)w_{qq} \\ &\qquad + 3\gamma(-p)(a^{-1}(\lambda)+w_p)^2 + 3\epsilon(a^{-1}(\lambda)+w_p)^2 w\big)\phi_p \\ &\quad + \left(2w_q w_{pp} - 2(a^{-1}(\lambda)+w_p)w_{pq} - 2\gamma(-p)a^{-3}(\lambda)w_q\right)\phi_q \\ &\quad - \epsilon(a^{-1}(\lambda)+w_p)^3\phi, \end{aligned} \tag{3.12}$$

$$B(\lambda,w)[\phi] = 2(2gw-\lambda)(\lambda^{-1/2}+w_p)\phi_p + 2w_q\phi_q + 2g(\lambda^{-1/2}+w_p)^2\phi\big|_T \tag{3.13}$$

for $\phi \in X$. Similarly,

$$F^\epsilon_\lambda(\lambda, w) = (F_{1\lambda}(\lambda, w), F_{2\lambda}(\lambda, w)),$$

where

$$\begin{aligned} F_{1\lambda}(\lambda,w)[\mu] &= \mu a^{-3}(\lambda)\big(w_q w_{pq} - (a^{-1}(\lambda)+w_p)w_{qq} \\ &\qquad - \tfrac{3}{2}\gamma(-p)(a^{-1}(\lambda)+w_p) \\ &\qquad + \tfrac{3}{2}\gamma(-p)a^{-2}(\lambda)(1+w_q^2) - 3\epsilon(a^{-1}(\lambda)+w_p)^2 w\big), \\ F_{2\lambda}(\lambda,w)[\mu] &= -\mu(\lambda^{-1/2}+w_p)\left(\lambda^{-1/2}+w_p+(2gw-\lambda)\lambda^{3/2}\right)\big|_T. \end{aligned}$$

Since F^ϵ_w and F^ϵ_λ are both continuous, $F^\epsilon : \mathbb{R}\times X \to Y$ is continuously differentiable. Indeed, the smoothness of γ ensures that F^ϵ is at least twice continuously Fréchet differentiable.

4. Existence theory for approximate problems. Our goal in this section is to construct for each ϵ a global connected set of nontrivial solutions to (3.11) via generalized degree theory and abstract global bifurcation theory.

4.1. The linearized approximate problem. The linearization of F^ϵ about the trivial solution $(\lambda, 0)$ is $F^\epsilon_w(\lambda, 0) = (A^\epsilon(\lambda, 0), B(\lambda, 0))$, where

$$\begin{aligned} A^\epsilon(\lambda,0)[\phi] &= \phi_{pp} + a^{-2}(\lambda)\phi_{qq} + 3\gamma(-p)a^{-2}(\lambda)\phi_p - \epsilon a^{-3}(\lambda)\phi \\ &= a^{-3}(\lambda)(a^3(\lambda)\phi_p)_p + a^{-2}(\lambda)\phi_{qq} - \epsilon a^{-3}(\lambda)\phi, \\ B(\lambda,0)[\phi] &= -2\lambda^{1/2}\phi_p + 2g\lambda^{-1}\phi\big|_T \end{aligned}$$

for $\phi \in X$. A necessary condition for bifurcation at a trivial solution $(\lambda, 0)$ is that

$$F^\epsilon_w(\lambda, 0) : X \to Y \text{ is not injective;}$$

equivalently, the following problem of self-adjoint form

$$(a^3(\lambda)\phi_p)_p + (a(\lambda)\phi_q)_q - \epsilon\phi = 0 \quad \text{in } R, \tag{4.1a}$$

$$\lambda^{3/2}\phi_p = g\phi \qquad \text{on } T \tag{4.1b}$$

admits a nontrivial solution in X.

LEMMA 4.1. *Suppose that $\gamma \in C^{1+\alpha}([0,\infty))$ for $\alpha \in (0,1)$ satisfies the smallness condition* (2.13).

(a) *For each $0 \le \epsilon < \epsilon_0$ and $0 < \epsilon_0 \le g$ fixed, there exist $\lambda^\epsilon \in (2\Gamma_\infty, g + 2\Gamma_\infty]$ and a nontrivial solution $\phi^\epsilon \in X$ to* (4.1).

(b) *For a sequence $\epsilon_j \to 0$ as $j \to \infty$, $\{\lambda^{\epsilon_j}\}$ converges to $\lambda^0 \in (2\Gamma_\infty, g+2\Gamma_\infty]$ as $j \to \infty$.*

Proof. (a) For each $0 \le \epsilon < \epsilon_0$ we will look for a solution of the form $\phi^\epsilon(q,p) = \Phi^\epsilon(p)\cos kq$ with $k \ge 0$ an integer; Φ^ϵ will solve the ordinary differential equation $-(a^3(\lambda)\Phi')' + \epsilon\Phi = -k^2 a(\lambda)\Phi$.

Let us define for $\lambda \in (2\Gamma_\infty, \infty)$ an ordinary differential operator $L^\epsilon v = -(a^3(\lambda)v')' + \epsilon v$. We consider the (singular) Sturm–Liouville problem

$$\begin{cases} L^\epsilon v = \mu(\lambda)a(\lambda)v & \text{for } p \in (-\infty, 0), \\ \lambda^{3/2}v'(0) = gv(0), \\ v, v' \to 0 & \text{as } p \to -\infty. \end{cases} \tag{4.2}$$

It is known that L^ϵ with the boundary conditions above has the essential spectrum $[\epsilon(\lambda - 2\Gamma_\infty)^3, \infty)$. We define for $0 \le \epsilon < \epsilon_0$

$$\begin{aligned} R^\epsilon(\lambda) &= R^\epsilon(v;\lambda) \\ &= \frac{-gv^2(0) + \int_{-\infty}^0 a^3(\lambda)(v')^2dp + \epsilon\int_{-\infty}^0 v^2dp}{\int_{-\infty}^0 a(\lambda)v^2dp} \end{aligned} \tag{4.3}$$

and

$$\Lambda^\epsilon(\lambda) = \inf\{\, R^\epsilon(v;\lambda) : v \in H^1((-\infty,0)) \text{ and } v \not\equiv 0\,\}. \tag{4.4}$$

A straightforward calculation shows that $R^\epsilon(\lambda)$ is bounded from below for each λ. More precisely, $R^\epsilon(\lambda) > -g^2(\lambda - 2\Gamma_\infty)^{-2}$. The Rayleigh principle then asserts that the complementary interval $(-\infty, \epsilon)$ contains a generalized eigenvalue μ (such that $L^\epsilon v = \mu a(\lambda)v$ for some $v \not\equiv 0$) if and only if $\Lambda^\epsilon(\lambda) < 0$. Furthermore, such $\Lambda^\epsilon(\lambda)$ is a simple eigenvalue.

Our aim is to find a λ^ϵ such that $\Lambda^\epsilon(\lambda^\epsilon) = -k^2$. There may be multiple solutions, for instance, corresponding to different values of k. Rather, here we restrict ourselves to finding one for $k = 1$. Note that Λ^ϵ is a C^1-function of λ.

First, for $\lambda \in [g + 2\Gamma_\infty, \infty)$ the inequality

$$\begin{aligned} \int_{-\infty}^0 \big(a(\lambda)v^2 + a^3(\lambda)(v')^2 + \epsilon v^2\big)dp &\ge \sqrt{g}\int_{-\infty}^0 \big(v^2 + g(v')^2\big)dp \\ &\ge 2g\int_{-\infty}^0 vv'dp = gv^2(0) \end{aligned}$$

holds for every $v \in H^1((-\infty,0))$. This in turn implies $R^\epsilon(\lambda) \geq -1$, and therefore $\Lambda^\epsilon(\lambda) \geq -1$. Next, provided that (2.13) holds, one can show that

$$\begin{aligned}\Lambda^\epsilon(2\Gamma_\infty) &\leq R^\epsilon(e^p;2\Gamma_\infty)\\ &= \frac{-g+\int_{-\infty}^0 a^3(2\Gamma_\infty)e^{2p}\,dp+\epsilon\int_{-\infty}^0 e^{2p}\,dp}{\int_{-\infty}^0 a(2\Gamma_\infty)e^{2p}\,dp}\\ &< \frac{-g+\frac{1}{2}\int_{-\infty}^0\sqrt{2\Gamma_\infty-2\Gamma(p)}\,dp+\frac{\epsilon}{2}}{\int_{-\infty}^0 e^{2p}\sqrt{2\Gamma_\infty-2\Gamma(p)}\,dp} < -1.\end{aligned}$$

By continuity, there exists $\lambda^\epsilon \in (2\Gamma_\infty, g+2\Gamma_\infty]$ such that $\Lambda^\epsilon(\lambda^\epsilon) = -1$.

Now we consider an eigenfunction $\Phi^\epsilon \in H^1((-\infty,0))$ to (4.2) with $\lambda = \lambda^\epsilon$ (and $k=1$). It follows from standard regularity theory that Φ^ϵ is indeed smooth. Note that $\sqrt{\lambda^\epsilon - 2\Gamma_\infty} \leq a(\lambda^\epsilon) \leq \sqrt{\lambda^\epsilon}$. The comparison theorem for second-order ordinary differential equations [8, Chapter 8] then asserts that $\Phi^\epsilon > 0$ and decays exponentially:

$$|\Phi^\epsilon(p)| \leq A\exp\bigl(p(\lambda-2\Gamma_\infty)^{-1/2}\bigr)$$

for some constant $A>0$. Therefore, $\phi^\epsilon = \Phi^\epsilon(p)\cos q$ is in X.

(b) Since $\{\lambda^\epsilon\}$ forms a bounded sequence in $\mathbb{R}$, there are a sequence $\epsilon_j \to 0$ as $j\to\infty$ and a subsequence $\{\lambda^{\epsilon_j}\}$ which converges to λ^0 in $\mathbb{R}$ as $j\to\infty$. By continuity, $\Lambda^0(\lambda^0) = -1$.

Since $R^0(\lambda) \geq -1$ for $\lambda \in [g+2\Gamma_\infty,\infty)$, it must hold that $\lambda^0 \leq g+2\Gamma_\infty$. On the other hand, $\lambda^0 > 2\Gamma_\infty$ since

$$\Lambda^0(2\Gamma_\infty) \leq R^0(e^p;2\Gamma_\infty) < R^\epsilon(e^p;2\Gamma_\infty) < -1.$$

Therefore, $\lambda^0 \in (2\Gamma_\infty, g+2\Gamma_\infty]$. This completes the proof. ∎

It follows as an application of local bifurcation theorem from a simple eigenvalue due to Crandall and Rabinowitz [11] that for each $0<\epsilon<\epsilon_0$ there emanates from $(\lambda^\epsilon,0)$ a local curve in $\mathbb{R}\times X$ of solutions to (3.11). The detailed analysis is carried out in Appendix A.

PROPOSITION 4.2 (local bifurcation for approximate problems). *For each $0<\epsilon<\epsilon_0$, there exist $s_0>0$ and a C^1-curve $\mathcal{C}^\epsilon_{loc}$ in $\mathbb{R}\times X$ of the form $(\lambda(s),w(s))$ such that each $(\lambda(s),w(s))$ for $|s|<s_0$ is a solution to (3.11) with $(\lambda(0),w(0)) = (\lambda^\epsilon,0)$.*

Recorded in the next lemma is the Fredholm property of $F^\epsilon_w(\lambda^\epsilon,0)$, which is a special case of Lemma 4.4.

LEMMA 4.3 (Fredholm property at the bifurcation point). *For each $0<\epsilon<\epsilon_0$, the linear operator $F^\epsilon_w(\lambda^\epsilon,0) = (A^\epsilon(\lambda^\epsilon,0),B(\lambda^\epsilon,0)) : X\to Y$ is a Fredholm operator of index zero.*

Proof. Let us denote the limiting operator of $(A^\epsilon(\lambda^\epsilon,0),B(\lambda^\epsilon,0))$ of constant coefficients by

$$\begin{aligned}A_0[\phi] &= \phi_{pp} + (\lambda^\epsilon-2\Gamma_\infty)^{-1}\phi_{qq} - \epsilon(\lambda^\epsilon-2\Gamma_\infty)^{-3/2}\phi,\\ B_0[\phi] &= B(\lambda^\epsilon,0) = -2(\lambda^\epsilon)^{1/2}\phi_p + 2g(\lambda^\epsilon)^{-1}\phi\big|_T\end{aligned}$$

for $\phi\in X$. Consider the one-parameter family of linear operators

$$(A_t,B_t) : X\to Y \qquad \text{for } t\in[0,1],$$

where

$$A_t = (1-t)A_0 + tA^\epsilon(\lambda^\epsilon, 0),$$
$$B_t = B(\lambda^\epsilon, 0).$$

Below we prove that (A_t, B_t) is semi-Fredholm for all $t \in [0,1]$; i.e., (A_t, B_t) has a closed range and finite-dimensional kernel. On the other hand, $(A_0, B_0) : X \to Y$ is bijective (see [25, Chapter 3], for instance). In particular, it is a Fredholm operator of index zero. Therefore, by the homotopy invariance of Fredholm index [21, Chapter 4, Theorems 2.23 and 5.17], $(A_1, B_1) = (A^\epsilon(\lambda^\epsilon, 0), B(\lambda^\epsilon, 0))$ is also a Fredholm operator of index zero.

Note that (A_t, B_t) satisfies the complementing condition on the interval $[0,1]$. Indeed, A_t is uniformly elliptic for each $t \in [0,1]$, whose coefficients are bounded in $C^{2+\alpha}(\overline{R})$; $B(\lambda^\epsilon, 0)$ is uniformly oblique. Therefore, for each $t \in [0,1]$ the following Schauder estimate [2, Theorem 7.3] holds:

$$\|\phi\|_X \leq C(\|A_t[\phi]\|_{Y_1} + \|B_t[\phi]\|_{Y_2} + \|\phi\|_Z) \tag{4.5}$$

for all $\phi \in X$, where $C > 0$ is independent of ϕ. We remark that the Schauder estimate (4.5) is valid even in an unbounded domain. However, the compact embedding property of Ascoli type is not available. In particular, Z is not compactly embedded in X. (The semi-Fredholm property of an elliptic operator in a bounded domain is a direct consequence of the Schauder estimate (4.5) and the compact embedding properties of Hölder spaces; see [32], for instance.)

In order to obtain the semi-Fredholm property of (A_t, B_t), we need to show that (A_t, B_t) is proper. In general, for linear operators these two concepts are equivalent; see [34, 41]. For $t \in [0,1]$ fixed, consider the equation

$$(A_t, B_t)[w_j] = f_j,$$

where $\{w_j\}$ is a bounded sequence in X and $\{f_j\}$ converges to f, say, in Y. There exists a function $w \in X$ such that $w_j \to w$ in $C^3_{per}(R')$ and $(A_t, B_t)[w] = f$ for any compact subset R' of $\overline{R}$.

We claim that $w_j \to w$ in $C^0_{per}(\overline{R})$. Suppose this convergence does not take place. Accordingly, we may choose a sequence $\{(q_j, p_j)\} \subset \overline{R}$ with $p_j \to -\infty$ such that

$$|w_j(q_j, p_j) - w(q_j, p_j)| \geq c > 0,$$

where $c > 0$ is fixed. Consider the functions $v_j(q,p) = w_j(q, p+p_j) - w(q, p+p_j)$, the operators (A_t, B_t) with the coefficient function $a(p; \lambda^\epsilon)$ shifted by p_j, and the shifted domains $\{(q,p) \in R : p + p_j < 0\}$. Passing to the limit we find a nontrivial limiting function $v_0 \in C^0(\overline{R})$ which is a solution to the limiting problem

$$(A_0, B_0)[v_0] = 0.$$

This contradicts the unique solvability of (A_0, B_0) and proves the claim.

From the convergence of $w_j \to w$ in $C^0_{per}(\overline{R})$, the Schauder estimate (4.5), and the convergence $f_j \to f$ in Y, it follows that $\{w_j\}$ is a Cauchy sequence in X. That is, (A_t, B_t) is proper. Subsequently, (A_t, B_t) is semi-Fredholm for each $t \in [0,1]$. This completes the proof. $\square$

4.2. Preliminary results for degree theory. In order to define a topological degree for F^ϵ we need some properties to establish including the properness and the Fredholm property of the linearized operator.

In the following discussion, we define for $\delta > 0$ the open set

$$\mathcal{O}_\delta = \Big\{ (\lambda, w) \in \mathbb{R} \times X \text{ which satisfies} \\ \lambda > 2\Gamma_\infty + \delta,\ a^{-1}(\lambda) + w_p > \delta \text{ in } R,\ w < \frac{2\lambda - \delta}{4g} \text{ on } T \Big\}. \tag{4.6}$$

Throughout this subsection ϵ and δ are fixed positive constants.

Let us recall that $F^\epsilon : \mathcal{O}_\delta \to Y$ is of class C^2 and that its Fréchet derivative in its second argument is of the form

$$F^\epsilon_w(\lambda, w) = (A^\epsilon(\lambda, w), B(\lambda, w)) \in Y_1 \times Y_2,$$

where

$$\begin{aligned} A^\epsilon(\lambda, w)[\phi] &= (1 + w_q^2)\phi_{pp} - 2(a^{-1}(\lambda) + w_p)w_q\phi_{pq} + (a^{-1}(\lambda) + w_p)^2\phi_{qq} \\ &\quad + \big(-2w_q w_{pq} + 2(a^{-1}(\lambda) + w_p)w_{qq} \\ &\qquad + 3\gamma(-p)(a^{-1}(\lambda) + w_p)^2 + 3\epsilon(a^{-1}(\lambda) + w_p)^2 w\big)\phi_p \\ &\quad + \big(2w_q w_{pp} - 2(a^{-1}(\lambda) + w_p)w_{pq} - 2\gamma(-p)a^{-3}(\lambda)w_q\big)\phi_q \\ &\quad - \epsilon(a^{-1}(\lambda) + w_p)^3\phi, \end{aligned} \tag{4.7}$$

$$B(\lambda, w)[\phi] = 2(2gw - \lambda)(\lambda^{-1/2} + w_p)\phi_p + 2w_q\phi_q + 2g(\lambda^{-1/2} + w_p)^2\phi\big|_T \tag{4.8}$$

for $\phi \in X$. The principal parts of operators $A^\epsilon(\lambda, w)$ and $B(\lambda, w)$ are denoted by

$$\tilde{A}(\lambda, w)[\phi] = (1 + w_q^2)\phi_{pp} - 2(a^{-1}(\lambda) + w_p)w_q\phi_{pq} + (a^{-1}(\lambda) + w_p)^2\phi_{qq}, \tag{4.9}$$

$$\tilde{B}(\lambda, w)[\phi] = 2(2gw - \lambda)(\lambda^{-1/2} + w_p)\phi_p + 2w_q\phi_q\big|_T, \tag{4.10}$$

respectively. Note that for each $(\lambda, w) \in \mathcal{O}_\delta$ the differential operator $A^\epsilon(\lambda, w)$ is uniformly elliptic with coefficients bounded in $C^{2+\alpha}(\overline{R})$; the coefficients of the principal part satisfy

$$(1 + w_q^2)\xi_1^2 - 2(a^{-1}(\lambda) + w_p)w_q\xi_1\xi_2 + (a^{-1}(\lambda) + w_p)^2\xi_2^2 \geq 4\delta^2(\xi_1^2 + \xi_2^2)$$

for all $(\xi_1, \xi_2) \in \mathbb{R}^2$. Also note that for each $(\lambda, w) \in \mathcal{O}_\delta$ the boundary operator $B(\lambda, w)$ is uniformly oblique in the sense that it is bounded away from being tangential; the coefficient of ϕ_p is nonzero and

$$|2(2gw - \lambda)(\lambda^{-1/2} + w_p)| > \delta^2 > 0 \qquad \text{on } T.$$

Therefore, $F^\epsilon_w(\lambda, w)$ satisfies the complementing condition for each $(\lambda, w) \in \mathcal{O}_\delta$ and the following Schauder estimate [2] holds:

$$\|\phi\|_X \leq C(\|A^\epsilon(\lambda, w)[\phi]\|_{Y_1} + \|B(\lambda, w)[\phi]\|_{Y_2} + \|\phi\|_Z) \tag{4.11}$$

for all $\phi \in X$, where $C > 0$ is independent of ϕ.

An important observation is that the limiting problem

$$\big(A_\infty(\lambda) - \epsilon(\lambda - 2\Gamma_\infty)^{-3/2}I, B_\infty(\lambda)\big)[\phi] = 0$$

admits only the zero solution.

Our first preliminary result is the Fredholm property of $F^\epsilon_w(\lambda, w)$.

LEMMA 4.4 (Fredholm property). *For each* $(\lambda, w) \in \mathcal{O}_\delta$ *the linear operator* $F^\epsilon_w(\lambda, w) = (A^\epsilon(\lambda, w), B(\lambda, w)) : X \to Y$ *is a Fredholm operator of index zero.*

Proof. The argument in the proof of Lemma 4.3 shows that $F^\epsilon_w(\lambda, w)$ is semi-Fredholm. This involves the Schauder estimate (4.11) and the fact that the limiting problem

$$\big(A_\infty(\lambda) - \epsilon(\lambda - 2\Gamma_\infty)^{-3/2} I, B_\infty(\lambda)\big)[\phi] = 0$$

has only the zero solution.

On the other hand, the result of Lemma 4.3 is that $F^\epsilon_w(\lambda^\epsilon, 0)$ is a Fredholm operator of index zero. Since $\mathcal{O}_\delta$ is connected, the assertion then follows from the continuity of the Fredholm index [21, Chapter 4, Theorem 5.17]. $\square$

For our next preliminary result, we need several notations to define. The domain of the operator $A^\epsilon(\lambda, w)$ is defined by

$$D(A^\epsilon(\lambda, w)) = \{\, w \in X : B(\lambda, w) = 0 \,\}. \tag{4.12}$$

Note that $A^\epsilon(\lambda, w)$ restricted to $D(A^\epsilon(\lambda, w))$ is closed in Y_1. The spectrum of $A^\epsilon(\lambda, w)$ is defined by

$$\begin{aligned} \sigma(\lambda, w) = \{\, \mu \in \mathbb{C} \text{ such that} \\ (A^\epsilon - \mu I) : D(A^\epsilon(\lambda, w)) \to Y_1 \text{ is not an isomorphism} \,\}. \end{aligned} \tag{4.13}$$

Here A^ϵ, $D(A^\epsilon(\lambda, w))$, and Y_1 are complexified in the natural way.

LEMMA 4.5 (spectral properties). *For* $M > 0$ *and* $(\lambda, w) \in \mathcal{O}_\delta$ *with* $|\lambda| + \|w\|_X \leq M$, *there exist positive constants* s, C_1, C_2 *such that*

$$C_1 \|\phi\|_X \leq |\mu|^{\alpha/2} \|(A^\epsilon(\lambda, w) - \mu I)[\phi]\|_{Y_1} + |\mu|^{(\alpha+1)/2} \|B(\lambda, w)[\phi]\|_{Y_2} \tag{4.14}$$

for all $\phi \in X$ *and for all* $\mu \in \mathbb{C}$ *satisfying* $|\arg(\mu)| \leq \pi/2 + s$ *and* $|\mu| \geq C_2$.

In addition,

(a) $\sigma(\lambda, w)$ *possesses only finitely many eigenvalues in the sector* $|\arg(\mu)| \leq \pi/2 + s$, *each of which has a finite multiplicity; and*

(b) *the boundary operator* $B(\lambda, w) : X \to Y_2$ *is surjective.*

Proof. The proof uses the method due to Agmon [1]. See [18, Proposition 4.4] for one in a Hölder-space setting.

We introduce the differential operator $A^\epsilon(\lambda, w) + e^{i\theta} \frac{\partial^2}{\partial t^2}$ on the cylinder $\Omega := R \times (-\infty, \infty)$, where $\theta = \arg(\mu)$. Note that the operator is elliptic if $|\theta| \leq \pi/2 + s$ for small $s > 0$. The boundary condition on $\partial\Omega = \partial R \times (-\infty, \infty)$ is given by $B(\lambda, w) = 0$.

It is known that $\big(A^\epsilon(\lambda, w) + e^{i\theta} \frac{\partial^2}{\partial t^2}, B(\lambda, w)\big)$ satisfies the complementing condition. Accordingly, one may write down the Schauder estimate: there are $s, C_1 > 0$ such that

$$\begin{aligned} C_1 \|e(t)\phi\|_{C^{3+\alpha}(\overline{\Omega}_1)} \leq\ & \|\zeta(t) e(t) (A^\epsilon - \mu I)[\phi]\|_{C^{1+\alpha}(\overline{\Omega}_2)} \\ & + \|\zeta(t) e(t) B[\phi]\|_{C^{2+\alpha}(\partial\Omega_1)} \\ & + |\mu|^{1/2} \|\zeta_1(t) e(t) \phi\|_{C^0(\overline{\Omega}_2)} \end{aligned} \tag{4.15}$$

for all $\phi \in X$ and for all $\mu \in \mathbb{C}$ with $|arg(\mu)| \leq \pi/2 + s$. Here $\overline{\Omega}_r = \overline{R} \times [-r, r]$, $\partial\Omega_r = \partial\Omega \times [-r, r]$ for some $r > 0$, and $e(t) = \exp(i|\mu|^{1/2} t)$; ζ, ζ_1 are smooth functions with support on the interval $[-2, 2]$ and $\zeta, \zeta_1 \equiv 1$ on $[-1, 1]$.

An explicit calculation shows that

$$\|\zeta_1(t)e(t)\phi\|_{C^0(\Omega_2)} \leq C_3|\mu|^{\alpha/2}\|\phi\|_{Y_1}$$

for $|\mu| > C_2$, where $C_2, C_3 > 0$ are independent of ϕ. Analogous estimates are valid for other terms on the right side of (4.15); see [18, Proposition 4.4] for the details. These estimates together with (4.15) yield the spectral estimate (4.14).

Our task now is to verify (a) and (b). The argument in the proof of Lemma 4.4 indicates that $(A^\epsilon - \mu I, B)$ is a Fredholm operator of index zero for all $\mu \in \mathbb{C}$ with $|arg(\mu)| \leq \pi/2 + s$. On the other hand, the estimate (4.14) dictates that for any $|\mu| > C_2$ the operator $A^\epsilon - \mu I$ restricted to $D(A^\epsilon(\lambda, w))$ has trivial kernel. Assertion (a) then follows from known properties of Fredholm operators [20]. In particular, $(A^\epsilon - \mu I, B) : X \to Y_1 \times Y_2$ is bijective for $\mu > C_2$, which proves (b). ∎

Our last preliminary result is the properness of F^ϵ.

LEMMA 4.6 (properness). *The nonlinear elliptic operator F^ϵ is (locally) proper on $\overline{\mathcal{O}}_\delta$; i.e, $(F^\epsilon)^{-1}(K) \cap \overline{D}$ is compact for each bounded set $D \subset \overline{\mathcal{O}}_\delta$ and compact set $K \subset Y$.*

Proof. Let $\{(\lambda_j, w_j)\} \subset D \subset \overline{\mathcal{O}_\delta}$ be a bounded sequence and let $\{(y_{1j}, y_{2j})\} \subset K \subset Y$ converge to (y_1, y_2) in $Y_1 \times Y_2$ satisfying

$$F^\epsilon(\lambda_j, w_j) = (y_{1j}, y_{2j}) \qquad \text{for } j = 1, 2, \dots.$$

Our goal is to find a subsequence of $\{(\lambda_j, w_j)\}$ which converges in $\mathbb{R} \times X$. For the sake of simplicity, we may assume that $\lambda_j \to \lambda$ in $\mathbb{R}$ for some $\lambda \in \mathbb{R}$ and that $w_j \to w$ in $C^3_{per}(R')$ for some $w \in X$ for any compact subset R' of $\overline{R}$. By continuity, $F^\epsilon(\lambda, w) = (y_1, y_2)$.

It is convenient to decompose F^ϵ as

$$\begin{aligned} F^\epsilon_1(\lambda, w) &= \tilde{A}(\lambda, w)[w] + f_1(\lambda, w) - \epsilon a^{-3}(\lambda) w, \\ F_2(\lambda, w) &= \tilde{B}(\lambda, w)[w] + f_2(\lambda, w). \end{aligned} \tag{4.16}$$

Here $\tilde{A}(\lambda, w)$ and $\tilde{B}(\lambda, w)$ are defined in (4.9) and (4.10); $f_1(\lambda, w)$ is a quartic polynomial expression of w, w_q and w_p, and $f_2(\lambda, w) = \lambda^{-1/2}(2gw - \lambda)(\lambda^{-1/2} + w_p)$.

We claim that $w_j \to w$ in $C^0_{per}(\overline{R})$. Otherwise, there would be a sequence $\{(q_j, p_j)\} \subset \overline{R}$ with $p_j \to -\infty$ such that

$$|w_j(q_j, p_j) - w(q_j, p_j)| \geq c > 0.$$

As is done in Lemma 4.3, consider the shifted domains $\{(q, p) \in R : p < p_j\}$, the operator $(\tilde{A}(\lambda_j, \tilde{w}_j, \tilde{a}) - \epsilon\tilde{a}^{-3}(\lambda_j)I, \tilde{B}(\lambda_j, \tilde{w}_j, \tilde{a}))$ with coefficients shifted by p_j, i.e., $\tilde{w}_j(q, p) = w_j(q, p + p_j)$ and $\tilde{a}(p; \lambda) = a(p + p_j; \lambda)$, and the functions $v_j(q, p) = w_j(q, p + p_j) - w(q, p + p_j)$. Passing to subsequences we conclude that there exist a limiting domain $R_\infty = R$, a limiting operator $(A_\infty - \epsilon(\lambda - 2\Gamma_\infty)^{-3/2}I, B_\infty)$, and a nonzero limiting function $v_\infty \in C^0(\overline{R})$ such that

$$\big(A_\infty - \epsilon(\lambda - 2\Gamma_\infty)^{-3/2}I, B_\infty\big)[v_\infty] = 0.$$

However, the limiting problem has only the zero solution. This proves by contradiction the uniform convergence of $\{w_j\}$ to w.

Since $\{w_j\}$ is uniformly bounded in X, an interpolation inequality (see [15, Lemma 6.32] and [25, Theorem 3.2.1]) asserts that $w_j \to w$ in $C^{k'+\alpha'}(\overline{R})$ for $k' + \alpha' < 3 + \alpha$. Indeed, for any $s > 0$ there exists a constant $C = C(s) > 0$ such that

$$\|w_j - w_k\|_{C^{k'+\alpha'}(\overline{R})} \leq s\|w_j - w_k\|_{C^{3+\alpha}(\overline{R})} + C\|w_j - w_k\|_{C^0(\overline{R})}. \tag{4.17}$$

Next, in order to obtain the convergence in $C^{3+\alpha}(\overline{R})$, Schauder theory is employed. Since $\{(\lambda_j, w_j)\} \subset \overline{\mathcal{O}}_\delta$ is bounded, the uniform Schauder estimates [2] yield

$$\|\phi\|_X \leq C(\|\tilde{A}(\lambda_j, w_j)[\phi]\|_{Y_1} + \|\tilde{B}(\lambda_j, w_j)[\phi]\|_{Y_2} + \|\phi\|_Z)$$

for all $\phi \in X$, where $C > 0$ is independent of ϕ and the index j. In particular,

$$\|w_j - w_k\|_X \leq C(\|\tilde{A}(\lambda_j, w_j)[w_j - w_k]\|_{Y_1} + \|\tilde{B}(\lambda_j, w_j)[w_j - w_k]\|_{Y_2} + \|w_j - w_k\|_Z). \tag{4.18}$$

Already shown is that the last term on the right side of the inequality approaches zero as $j, k \to \infty$. By virtue of the decomposition (4.16), the first two terms on the right side of (4.18) may be written as

$$\begin{aligned}\tilde{A}(\lambda_j, w_j)[w_j - w_k] &= y_{1j} - y_{1k} - \big(\tilde{A}(\lambda_j, w_j) - \tilde{A}(\lambda_k, w_k)\big)w_k \\ &\quad - \big(f_1(\lambda_j, w_j) - f_1(\lambda_k, w_k)\big) \\ &\quad + \epsilon a^{-3}{}_{(\lambda_j)}(w_j - w_k) + \epsilon\big(a^{-3}{}_{(\lambda_j)} - a^{-3}{}_{(\lambda_k)}\big)w_k, \\ \tilde{B}(\lambda_j, w_j)[w_j - w_k] &= y_{2j} - y_{2k} - \big(\tilde{B}(\lambda_j, w_j) - \tilde{B}(\lambda_k, w_k)\big)w_k \\ &\quad - \big(f_2(\lambda_j, w_j) - f_2(\lambda_k, w_k)\big).\end{aligned}$$

Since $\{w_j\} \subset X$ is bounded, by the interpolation inequality (4.17) it follows that the coefficients of the quasi-linear operator $\tilde{A}(\lambda_j, w_j)$ are equicontinuous in j, and thus

$$\|(\tilde{A}(\lambda_j, w_j)[w_k] - \tilde{A}(\lambda_k, w_k))[w_k]\|_{Y_1} \to 0 \qquad \text{as } j, k \to \infty.$$

The convergence

$$\|f_1(\lambda_j, w_j) - f_1(\lambda_k, w_k)\|_{Y_1} \to 0 \qquad \text{as } j, k \to \infty$$

uses the fact that f is a quartic polynomial expression for w and w_p, w_q. These together with the convergence of $\{y_{1j}\}$ in Y_1 yield that

$$\|\tilde{A}(\lambda_j, w_j)[w_j - w_k]\|_{Y_1} \to 0 \qquad \text{as } j, k \to \infty.$$

On the other hand, the standard Schauder estimates and the embedding properties for Hölder spaces in a bounded domain confirm

$$\|\tilde{B}(\lambda_j, w_j)[w_j - w_k]\|_{Y_2} \to 0 \qquad \text{as } j, k \to \infty.$$

Therefore, $w_j \to w$ in $C^{3+\alpha}(\overline{R})$. The assertion then follows since X is a closed subspace of $C^{3+\alpha}(\overline{R})$. ∎

We are now in a position to define a degree for $F^\epsilon(\lambda, w)$. Summarized in Appendix B is the general development in [18, 23], which takes into account the nonlinear boundary operator.

4.3. Global theory of bifurcation for approximate problems. Now the presentation is the existence in the large of nontrivial solutions to (3.11) via global results of abstract bifurcation theory, which uses the generalized degree theory developed in the previous subsection and Appendix B.

For each $\delta > 0$ and $0 < \epsilon < \epsilon_0$, let $\mathcal{S}_\delta^\epsilon$ be the closure in $\mathbb{R} \times X$ of the set of all nontrivial solution pairs $(\lambda, w) \in \mathcal{O}_\delta$ to (3.11), where $\mathcal{O}_\delta$ is defined in (4.6), and let

$\mathcal{C}_\delta^\epsilon \subset \mathbb{R} \times X$ be the connected component of $\mathcal{S}_\delta^\epsilon$ which contains the bifurcation point $(\lambda^\epsilon, 0)$ determined in Lemma 4.1. The local curve of solutions $\mathcal{C}_{loc}^\epsilon$ constructed in Proposition 4.2 is contained in $\mathcal{C}_\delta^\epsilon$ for the parameter $s_0 > 0$ of the curve sufficiently small.

The following global bifurcation result is immediate.

THEOREM 4.7. *For any $\delta > 0$ and $0 < \epsilon < \epsilon_0$, at least one of the following holds:*

(i) *$\mathcal{C}_\delta^\epsilon$ is unbounded in $\mathbb{R} \times X$;*

(ii) *$\mathcal{C}_\delta^\epsilon$ contains another trivial solution pair $(\lambda, 0)$ with $\lambda \neq \lambda^\epsilon$;*

(iii) *$\mathcal{C}_\delta^\epsilon$ meets $\partial\mathcal{O}_\delta$.*

Proof. The proof is almost identical to that of [33, Theorem 1.3] except that we now use the generalized degree defined in [18, 23] (see Appendix B) in place of the Leray–Schauder degree. We assume on the contrary that $\mathcal{C}_\delta^\epsilon$ is not characterized by any of (i), (ii), or (iii), and we argue by contradiction. ∎

The remainder of this subsection is devoted to extending and refining the result of Theorem 4.7.

First, the exploitation of symmetry rules out the second alternative from Theorem 4.7. In order to state our result more precisely, we define the nodal sets

$$R^+ = (0, \pi) \times (-\infty, 0), \qquad T^+ = (0, \pi) \times \{0\},$$
$$\partial R_l^+ = \{(0, p) : p \in (-\infty, 0)\}, \qquad \partial R_r^+ = \{(\pi, p) : p \in (-\infty, 0)\}.$$

It follows as an application of the maximum principle and its sharp form at the corner points [35] that any nontrivial solution $w \in \mathcal{C}_\delta^\epsilon$ to (3.11) possesses the following nodal pattern:

$$w_q < 0 \quad \text{in } R^+ \cup T^+, \tag{4.19}$$
$$w_{qq} < 0 \quad \text{on } \partial R_l^+, \qquad w_{qq} > 0 \quad \text{on } \partial R_r^+, \tag{4.20}$$
$$\text{either} \quad w_{qq}(0,0) < 0 \quad \text{or} \quad w_{qqp}(0,0) > 0, \tag{4.21}$$
$$\text{either} \quad w_{qq}(\pi,0) > 0 \quad \text{or} \quad w_{qqp}(\pi,0) < 0. \tag{4.22}$$

In other words, inequalities (4.19)–(4.22) hold along the entire continuum $\mathcal{C}_\delta^\epsilon \setminus (\lambda^\epsilon, 0)$. The proof is given in Appendix C. Let us define the open set

$$\mathcal{N} = \{\, w \in X : w \text{ satisfies (4.19)–(4.22)}\}. \tag{4.23}$$

By evenness and periodicity of $w \in X$, we infer that $w_q = 0$ on $\partial R_l^+ \cup \partial R_r^+$.

LEMMA 4.8. *If a trivial solution $(\lambda, 0)$ belongs to the continuum $\mathcal{C}_\delta^\epsilon$, then $\lambda = \lambda^\epsilon$.*

Proof. Suppose there is a sequence of nontrivial solution pairs $\{(\lambda_j, w_j)\} \subset \mathcal{C}_\delta^\epsilon$ to (3.11) which converges to $(\lambda, 0)$ in $\mathbb{R} \times X$. We consider a sequence of functions $v_j = \partial_q w_j / \|\partial_q w_j\|_{C^{2+\alpha}(\overline{R})}$, each of which solves

$$(A^\epsilon(\lambda_j, w_j), B(\lambda_j, w_j))[v_j] = 0.$$

The difference $v_j - v_k$ with $j, k \geq 1$ in turn solves the following linear boundary value problem:

$$A^\epsilon(\lambda_j, w_j)[v_j - v_k] = \big(A^\epsilon(\lambda_k, w_k) - A^\epsilon(\lambda_j, w_j)\big)[v_k] \qquad \text{in } R,$$
$$B(\lambda_j, w_j)[v_j - v_k] = \big(B(\lambda_k, w_k) \ - B(\lambda_j, w_j)\big)[v_k] \qquad \text{on } T.$$

The Schauder estimates [2] yield

$$\|v_j - v_k\|_{C^{2+\alpha}(\overline{R})} \le C\big(\|A^\epsilon(\lambda_j, w_j)[v_j - v_k]\|_{C^\alpha(\overline{R})} + \|B(\lambda_j, w_j)[v_j - v_k]\|_{C^{1+\alpha}(T)} + \|v_j - v_k\|_{C^0(\overline{R})}\big), \tag{4.24}$$

where $C > 0$ is independent of index j, k. As is done in Lemma 4.6, we show that

$$\begin{aligned}\|\big(A^\epsilon(\lambda_k, w_k) - A^\epsilon(\lambda_j, w_j)\big)[v_k]\|_{C^\alpha(\overline{R})} &\to 0,\\ \|\big(B(\lambda_k, w_k) - B(\lambda_j, w_j)\big)[v_k]\|_{C^{1+\alpha}(T)} &\to 0,\end{aligned}$$

as $j, k \to \infty$. This utilizes the facts that $\{(\lambda_j, w_j)\}$ converges in $\mathbb{R} \times X$ and that $\{v_j\}$ is bounded in $C^{2+\alpha}(\overline{R})$. The last term on the right side of (4.24) approaches zero as $j, k \to \infty$ since the limiting problem of $(A^\epsilon(\lambda_j, w_j), B(\lambda_j, w_j))$ does not have nontrivial solutions, completely analogous to the argument in the proof of Lemma 4.3 or Lemma 4.6. Therefore, $\{v_j\}$ converges to v, say, in $C^{2+\alpha}(\overline{R})$.

Note that $\partial^\beta v \in o(1)$ as $p \to -\infty$ uniformly for q for all multi-indices $|\beta| \le 2$ and $\|v\|_{C^{2+\alpha}(\overline{R})} = 1$. Since each v_j is 2π periodic in the q-variable and of mean zero over one period, $v = \partial_q \phi$ for some function ϕ which is 2π periodic in the q-variable. By continuity,

$$F^\epsilon_w(\lambda, 0)[\partial_q \phi] = 0, \tag{4.25}$$

$\partial_q \phi \le 0$ on R^+, and $\partial_q \phi = 0$ on $\partial R^+_l \cup \partial R^+_r$. Furthermore, since $\partial_q \phi$ satisfies (4.25) and $\partial_q \phi \not\equiv 0$ in R^+, the maximum principle ensures that $\partial_q \phi < 0$ in R^+.

We now write $\partial_q \phi$ as a sine series

$$\partial_q \phi(q, p) = \sum_{k=0}^\infty \phi_k(p) \sin kq,$$

whence (4.25) is written as

$$\begin{aligned}\sum_{k=0}^\infty \big((a^3(\lambda)\phi_k')' - \epsilon\phi_k - k^2 a(\lambda)\phi_k\big) \sin kq = 0 \qquad &\text{in } R^+,\\ \sum_{k=0}^\infty \big(-2\sqrt{\lambda}\phi_k'(0) + 2g/\lambda \phi_k(0)\big) \sin kq = 0.&\end{aligned}$$

Here $\partial_q \phi$ is subject to the vanishing condition $\partial_q \phi_k \to 0$ as $p \to -\infty$. In particular, ϕ_1 solves the boundary value problem

$$\begin{aligned}(a^3(\lambda)\phi_1')' - \epsilon\phi_1 = a(\lambda)\phi_1 \quad &\text{for } p \in (-\infty, 0),\\ \lambda^{3/2}\phi_1'(0) = g\phi_1(0),&\\ \phi_1(p) \to 0 \qquad\qquad &\text{as } p \to -\infty.\end{aligned}$$

In view of the definitions (4.3) and (4.4) it follows that $\Lambda^\epsilon(\lambda) \le R^\epsilon(\phi_1; \lambda) = -1$. Suppose $\Lambda^\epsilon(\lambda) < -1$; the minimizer Φ would be an eigenfunction corresponding to the simple eigenvalue $\Lambda^\epsilon(\lambda)$ (such that $R^\epsilon(\Phi; \lambda) = \Lambda^\epsilon(\lambda) = \inf R^\epsilon(\lambda)$), and hence Φ does not vanish on $p \in (-\infty, 0)$. On the other hand,

$$\phi_1(p) = \frac{2}{\pi} \int_0^\pi \phi_q(q, p) \sin q \, dq < 0 \qquad \text{for all } p \in (-\infty, 0). \tag{4.26}$$

This contradicts the orthogonality

$$\int_{-\infty}^{0} a(\lambda)\Phi^{\epsilon}(p)\phi_1(p)dp = 0.$$

Therefore, $\Lambda^{\epsilon}(\lambda) = -1$, and $\lambda = \lambda^{\epsilon}$ follows from the monotonicity of Λ (see [10, Lemma 3.4]). $\square$

We summarize our results from Theorem 4.7 and Lemma 4.8.

THEOREM 4.9. *For $\delta > 0$ and $0 < \epsilon < \epsilon_0$, the global continuum $\mathcal{C}_\delta^\epsilon$ either is unbounded in $\mathbb{R} \times X$ or intersects $\partial\mathcal{O}_\delta$. Each nontrivial solution lying on $\mathcal{C}_\delta^\epsilon$ has the nodal configuration* (4.19)–(4.22)*, i.e., $\mathcal{C}_\delta^\epsilon \setminus (\lambda^\epsilon, 0) \subset \mathbb{R} \times \mathcal{N}$.*

The following theorem describes global bifurcation in terms of open sets in $\mathcal{O}_\delta$, which was first developed in [33] and stated explicitly in [5].

THEOREM 4.10 (see [5, Theorem A6]). *Suppose $S \subset \mathcal{O}_\delta$ is a closed set with $(\lambda, 0) \in S$ such that every bounded subset of S is relatively compact in $\mathbb{R} \times X$. Let C be the maximal connected subset of S which contains $(\lambda, 0)$. Then C either is unbounded in $\mathbb{R} \times X$ or meets $\partial\mathcal{O}_\delta$ if and only if $\partial U \cap S \neq \emptyset$ for every bounded open set U with $(\lambda, 0) \in U$ and $\overline{U} \subset \mathcal{O}_\delta$.*

Proof. The proof is almost identical to that of [5, Theorem A6]. We choose an open set U as described above. If C is unbounded, then $(\lambda, 0) \in U \cap C \neq \emptyset$ and $(\overline{\mathcal{O}}_\delta \setminus \overline{U}) \cap C \neq \emptyset$. Since C is connected, $\partial U \cap C \neq \emptyset$, and thus $\partial U \cap S \neq \emptyset$. Similarly, if C intersects $\partial\mathcal{O}_\delta$, then $(\lambda, 0) \in U \cap C \neq \emptyset$ and $(\overline{\mathcal{O}}_\delta \setminus \overline{U}) \cap C \neq \emptyset$. Therefore, $\partial U \cap S \neq \emptyset$.

Conversely, we assume that C is bounded and does not intersect $\partial\mathcal{O}_\delta$, yet $\partial U \cap S \neq \emptyset$ for every bounded open set U with $(\lambda, 0) \in U$ and $\overline{U} \subset \mathcal{O}_\delta$. We choose $R > 0$ large enough that $C \subset B(R)$, where $B(R) = \{(\lambda, w) : |\lambda| + \|w\|_X < R\}$. Let us denote by M a compact metric space $\overline{B(R)} \cap S$; $E = C$ and $F = \{(\lambda, w) \in S : |\lambda| + \|w\|_X = 2R\}$ are nonempty disjoint compact subsets of M. Then Whyburn's lemma [33, Lemma 1.2] applies, and there exist disjoint compact subsets M_1 and M_2 such that $M_1 \cup M_2 = M$, $E \subset M_1$, and $F \subset M_2$. Let

$$U = \{(\lambda, w) : |\lambda - \lambda'| + \|w - w'\|_X < \delta/2 \text{ for } (\lambda', w') \in M_1\},$$

where $\delta = \min(\operatorname{dist}(M_1, M_2), \operatorname{dist}(M_1, \partial B(2R)))$. By assumption, we can find a $(\lambda, w) \in \partial U \cap S$. However, this contradicts that $\operatorname{dist}((\lambda, w), M_1) \leq \delta/2$ and $\operatorname{dist}(M_1, M_2) \geq \delta$. This completes the proof. $\square$

COROLLARY 4.11. *Let U be a bounded open set in $\mathcal{O}_\delta$ such that $(\lambda^0, 0) \in U$ and $\overline{U} \subset \mathcal{O}_\delta$. Then for ϵ sufficiently small,*

$$\partial U \cap \mathcal{C}_\delta^\epsilon \neq \emptyset.$$

Proof. This result is an immediate application of Theorems 4.9 and 4.10. The result of Lemma 4.6 says that any bounded subset of $\mathcal{S}_\delta^\epsilon$ is relatively compact in $\mathbb{R} \times X$. By Lemma 4.1(b), $(\lambda^\epsilon, 0) \in U$ for sufficiently small ϵ. $\square$

5. Existence theory for deep-water waves.

5.1. Global theory of existence for the singular problem. In this subsection, we demonstrate the existence of a global connected set in $\mathbb{R} \times X$ of nontrivial solutions to the original singular problem (3.10).

Let $\mathcal{S}_\delta$ be the closure in $\mathbb{R} \times X$ of the set

$$\{ (\lambda, w) \in \mathcal{O}_\delta : F(\lambda, w) = 0, \ \ w \not\equiv 0, \ \ w \in \mathcal{N} \} \cup \{(\lambda^0, 0)\},$$

the set of nontrivial solutions to (3.10) with the nodal properties (4.19)–(4.22).

LEMMA 5.1. *A bounded subset of $\mathcal{S}_\delta$ is relatively compact in $\mathbb{R} \times X$.*

Proof. Let $\{(\lambda_j, w_j)\} \subset \mathcal{S}_\delta$ be a bounded sequence in $\mathbb{R} \times X$. Then $\{\lambda_j\}$ has a convergent subsequence in $\mathbb{R}$; we say $\lambda_j \to \lambda$ in $\mathbb{R}$. Our goal is to show that $\{w_j\}$ has a convergent subsequence in X.

As is indicated in the proof of Lemma 4.6, an important step is to obtain the convergence in the $C^0_{per}(\overline{R})$-norm. To accomplish this, it is convenient to express w_j as

$$w_j(q,p) = \int_0^q \partial_q w_j(s,p)ds + w_j(0,p). \tag{5.1}$$

Note that $\{\partial_q w_j(q,p)\}$ and $\{w_j(0,p)\}$ are bounded sequences in $C^{2+\alpha}_{per}(\overline{R})$ and $C^{3+\alpha}_{per}((-\infty, 0])$, respectively.

Our task is to prove that $\partial_q w_j$ decays exponentially as $p \to -\infty$ uniformly for q and the index j. The transformations in section 2.2 and section 3.1 assign to each (λ_j, w_j) a solution pair of $\eta_j(x)$ and $\psi_j(x,y)$ of the vorticity-stream formulation (2.9). With this prescription, $w_j \in \mathcal{N}$ means that $\partial_x \psi_j$ is odd and 2π periodic in the x-variable, and that $\partial_x \psi_j(x,y) > 0$ for $x \in (-\pi, 0)$. Lemma 2.1 applies, and $\partial_x \psi_j(x,y)$ acquires the exponential decay property (2.10). A straightforward change of variables back into (q,p)-variables via definitions (2.7) and (3.6) and the change of variables (3.1) yields the corresponding pointwise exponential decay of $\partial_q w_j$:

$$|\partial_q w_j(q,p)| \le \delta A \exp(p/\sqrt{\lambda_j}) \qquad \text{in } \{(q,p) \in \overline{R},\ \ p < p_0\}, \tag{5.2}$$

where $A > 0$ and $p_0 < 0$ are independent of j. Indeed,

$$\begin{aligned} y = H(p) + w(q,p) &= \int_0^p \frac{ds}{\sqrt{\lambda - 2\Gamma(s)}} - \frac{\lambda}{2g} + w(q,p) \\ &\le \frac{p}{\sqrt{\lambda}} + |w(q,p)|. \end{aligned} \tag{5.3}$$

We remark that the choice of A indeed depends only on $\sup_j |w_j(\pm\pi, 0)|$, which is bounded a priori once a bounded sequence $\{w_j\}$ is chosen.

We proceed similarly on the estimate (2.11) to obtain an analogous exponential decay property of $w_j(0,p)$:

$$|\partial_q^2 w_j(0,p)| \le B \exp(p/\sqrt{\lambda_j}) \qquad \text{on } p \in (-\infty, p_0), \tag{5.4}$$

where $B > 0$ is independent of the index j. When restricted on $q = 0$, oddness of w_j reduces (3.7a) to

$$\begin{aligned} &\partial_p^2 w_j + (a^{-1}(\lambda) + \partial_p w_j)\partial_q^2 w_j \\ &\qquad + \gamma(-p)(a^{-1}(\lambda) + \partial_p w_j)^3 - \gamma(-p)a^{-3}(\lambda) = 0. \end{aligned} \tag{5.5}$$

Since $\gamma \in O(s^{-2-2l})$ as $s \to \infty$ for $l > 0$, it follows from the exponential decay (5.4) and from (5.5) that $w_j(0,p)$ decays as $p \to -\infty$ uniformly for j.

Having now established the uniform decay of $\partial_q w_j(q,p)$ and $w_j(0,p)$, we employ an argument of Ascoli type to conclude that both $\{\partial_q w_j(q,p)\}$ and $\{w_j(0,p)\}$ have subsequences which converge uniformly in the C^0-norm. These uniform convergences together with the expression (5.1) ensure that $\{w_j\}$ has a convergent subsequence in the C^0-norm; we say $w_j \to w$ in $C^0_{per}(\overline{R})$ for some $w \in X$.

The remainder of the proof is nearly identical to that of Lemma 4.6, and we only outline the various stages of the proof.

Since $\{w_j\}$ is bounded in X, an interpolation inequality (see (4.17) in Lemma 4.6 and [25, Theorem 3.2.1]) asserts that $w_j \to w$ in $C^3_{per}(\overline{R})$.

As is done in (4.16) in the proof of Lemma 4.6, we decompose F as

$$F_1(\lambda, w) = \tilde{A}(\lambda, w)[w] + f_1(\lambda, w),$$
$$F_2(\lambda, w) = \tilde{B}(\lambda, w)[w] + f_2(\lambda, w).$$

Here $\tilde{A}(\lambda, w)$, $\tilde{B}(\lambda, w)$, and f_2 are same as in the proof of Lemma 4.6; f_1 is a cubic polynomial expression of w_p and w_q. An estimate of Schauder type [2]

$$\|w_j - w_k\|_X \le C(\|\tilde{A}(\lambda_j, w_j)[w_j - w_k]\|_{Y_1} + \|\tilde{B}(\lambda_j, w_j)[w_j - w_k]\|_{Y_2} + \|w_j - w_k\|_Z)$$

holds, where $C > 0$ is independent of w_j. From the interpolation inequality (4.17) and the above decomposition follows

$$\|\tilde{A}(\lambda_j, w_j)[w_j - w_k]\|_{Y_1} \to 0,$$
$$\|\tilde{B}(\lambda_j, w_j)[w_j - w_k]\|_{Y_2} \to 0$$

as $j, k \to \infty$. The Schauder estimate then asserts $w_j \to w$ in X. This completes the proof. □

The global result of the existence of the deep-water waves is now immediate and is described in the next theorem.

THEOREM 5.2. *Let $\mathcal{C}'_\delta$ denote the maximal connected subset of $\mathcal{S}_\delta$ which contains* $(\lambda^0, 0)$.

(i) *The continuum $\mathcal{C}'_\delta$ either is unbounded in $\mathbb{R} \times X$ or intersects $\partial\mathcal{O}_\delta$.*

(ii) *Each nontrivial solution lying on $\mathcal{C}'_\delta$ has precisely the nodal properties* (4.19)–(4.22).

Proof. (i) By virtue of Theorem 4.10, it suffices to show that if U is a bounded open set with $(\lambda^0, 0) \in U$ and $\overline{U} \subset \mathcal{O}_\delta$, then $\partial U \cap \mathcal{S}_\delta \neq \emptyset$. Let U be such an open set. The result of Corollary 4.11 is that there are sequences $\epsilon_j \to 0$ as $j \to \infty$ and $\{(\lambda_j, w_j)\} \subset \mathcal{O}_\delta$ such that

$$(\lambda_j, w_j) \in \partial U \cap \mathcal{C}^{\epsilon_j}_\delta.$$

In other words, $\{(\lambda_j, w_j)\} \subset \mathcal{O}_\delta$ is a bounded sequence in $\mathbb{R} \times X$ and

$$F(\lambda_j, w_j) = \epsilon_j (a^{-1}(\lambda_j) + \partial_p w_j)^3 w_j. \tag{5.6}$$

It will follow by the methods in the proof of Lemma 5.1 that $\{(\lambda_j, w_j)\}$ has a subsequence which converges in $\mathbb{R} \times X$ to an element in $\partial U \cap \mathcal{S}_\delta$. For the rest of the proof it is assumed that $\lambda_j \to \lambda$ in $\mathbb{R}$ as $j \to \infty$.

As in done in the previous lemma, to each solution (λ_j, w_j) of (5.6) we associate a pair of functions $\eta_j(x)$ and $\psi_j(x, y)$ via the definitions (2.9) and (3.6) and the change of variables (3.1). It immediately follows that $\eta_j(x)$ and $\psi_j(x, y)$ are even and 2π periodic in the x-variable. From the nodal property $\partial_q w_j(q, p) < 0$ for $q \in (-\pi, 0)$, we infer that $\partial_x \psi_j(x, y) < 0$ for $(x, y) \in$ and $x \in (-\pi, 0)$.

It is straightforward to see that $\partial_x \psi_j$ satisfies the following Poisson equation in $\overline{\mathcal{D}}_{\eta_j}$:

$$-\Delta \partial_x \psi_j + \epsilon H'(-\psi_j) \partial_x \psi_j = \gamma'(\psi_j) \partial_x \psi_j.$$

Note that $H'(-\psi_j) > 0$ and $\gamma'(\psi_j) \leq 0$. One exercises the argument of the maximum principle type employed in the proof of Lemma 2.1 to conclude that $\partial_x \psi_j(x,y)$ decays exponentially uniformly for x:

$$|\partial_x \psi_j(x,y)| < Ae^y \qquad \text{on } (-\pi,\pi) \times (-\infty, \eta_j(\pm\pi)),$$

where $A > 0$ depends only on $\sup_j |\eta_j(\pm\pi)|$. In particular, A is independent of ϵ. An exponential decay property of $\partial_x^2 \psi_j(0,y)$, analogous to (2.11), is valid on $(-\infty, \eta_j(\pm\pi))$.

Henceforth, the exponential decay estimates for $\partial_q w_j(q,p)$ and $\partial_q^2 w_j(0,p)$ follow with the prescribed change of variables back into (q,p)-variables:

$$\begin{aligned}
|\partial_q w_j(q,p)| \leq& A_1 \exp(p/\sqrt{\lambda_j}) \qquad \text{in } \{(q,p) \in \overline{R},\ \ p < p_0\},\\
|\partial_q^2 w_j(0,p)| \leq& B_1 \exp(p/\sqrt{\lambda_j}) \qquad \text{on } p \in (-\infty, p_0),
\end{aligned}$$

where p_0 depends only on $\sup_j |w_j(\pm\pi, 0)|$. In particular, p_0 is independent of ϵ and the index j. As is done in the previous lemma, one can show that $w_j(0,p)$ decays as $p \to -\infty$ uniformly for the index j. Since $\{\partial_q w_j(q,p)\}$ and $\{w_j(0,p)\}$ are bounded in the Hölder norms, an argument of Ascoli type yields that both $\{\partial_q w_j(q,p)\}$ and $\{w_j(0,p)\}$ have subsequences which converge in the C^0-norm. We will denote the convergent subsequence by $\{w_j\}$. From the expression (5.1) follows $w_j \to w$ in $C^0_{per}(\overline{R})$ for some $w \in X$.

The remainder of the proof is nearly identical to those of Lemmas 4.6 and 5.1. Since $\{w_j\}$ is bounded in X, an interpolation inequality (4.17) (see [25, Theorem 3.2.1], for instance) asserts that $w_j \to w$ in $C^3_{per}(\overline{R})$.

We employ Schauder theory [2] to obtain the inequality

$$\begin{aligned}
\|w_j - w_k\|_X \leq C(&\|\tilde{A}(\lambda_j, w_j)[w_j - w_k]\|_{Y_1}\\
&+ \|\tilde{B}(\lambda_j, w_j)[w_j - w_k]\|_{Y_2} + \|w_j - w_k\|_Z),
\end{aligned}$$

where $C > 0$ is independent of the index j and k. With the decomposition (4.16),

$$\begin{aligned}
\tilde{A}(\lambda_j, w_j)[w_j - w_k] =& \epsilon_j a^{-3}(\lambda_j)(w_j - w_k) + w_k(\epsilon_j a^{-3}(\lambda_j) - \epsilon_k a^{-3}(\lambda_k))\\
&- \big(\tilde{A}(\lambda_j, w_j) - \tilde{A}(\lambda_k, w_k)\big)w_k - \big(f_1(\lambda_j, w_j) - f_1(\lambda_k, w_k)\big),\\
\tilde{B}(\lambda_j, w_j)[w_j - w_k] =& -\big(\tilde{B}(\lambda_j, w_j) - \tilde{B}(\lambda_k, w_k)\big)w_k\\
&- \big(f_2(\lambda_j, w_j) - f_2(\lambda_k, w_k)\big).
\end{aligned}$$

An interpolation inequality (4.17) and the above observation imply

$$\|\tilde{A}(\lambda_j, w_j)[w_j - w_k]\|_{Y_1} \to 0 \qquad \text{as } j,k \to \infty,$$

completely analogous to that in the proof of Lemma 4.6. Evidently,

$$\|\epsilon_j a^{-3}(\lambda_j)(w_j - w_k) + w_k(\epsilon_j a^{-3}(\lambda_j) - \epsilon_k a^{-3}(\lambda_k))\|_{Y_1} \to 0 \qquad \text{as } j,k \to \infty.$$

The above Schauder estimate together with the elliptic estimate on the bounded domain T yields

$$\|\tilde{B}(\lambda_j, w_j)[w_j - w_k]\|_{Y_2} \to 0 \qquad \text{as } j,k \to \infty,$$

whence it follows that $w_j \to w$ in X.

(ii) The proof is nearly identical to that of Lemma C.3 in Appendix C. Suppose the contrary. Since $\mathcal{C}'_\delta \subset \mathcal{S}_\delta$ is connected, there must be a nontrivial solution $(\lambda, w) \in \mathcal{C}'_\delta$ with $w_q \not\equiv 0$ such that at least one of the nodal properties (4.19)–(4.22) would fail with (λ, w). We argue by contradiction using the maximum principle, the Hopf boundary lemma, and its sharp form at corner points due to Serrin [35] (see Lemma C.2). □

Remark 5.3. In case $\mathcal{C}'_\delta$ is unbounded in $\mathbb{R} \times X$, there is a sequence of solution pairs $\{(\lambda_j, w_j)\} \subset \mathcal{C}'_\delta$ such that either

(1) $\lim_{j\to\infty} \lambda_j = \infty$ or

(2) $\lim_{j\to\infty} \|w_j\|_X = \infty$.

If the other alternative that $\mathcal{C}'_\delta$ intersects $\partial\mathcal{O}_\delta$ holds, there is a solution pair $(\lambda, w) \in \mathcal{C}'_\delta$ such that one of the following holds:

(3) $\lambda = 2\Gamma_\infty + \delta$,

(4) $a^{-1}(\lambda) + w_p = \delta$ somewhere in $\overline{R}$,

(5) $w = \frac{2\lambda-\delta}{4g}$ somewhere on T.

5.2. Uniform regularity. The purpose of this subsection is to obtain bounds for the higher derivatives of w in terms of w and w_p uniformly along the continuum $\mathcal{C}'_\delta$.

THEOREM 5.4. *For each* $\delta > 0$, $\sup_{w\in\mathcal{C}'_\delta} \sup_{\overline{R}}(|w| + |w_p|) < \infty$ *implies*

$$\sup_{w\in\mathcal{C}'_\delta} \sup_{\overline{R}} \|w\|_X < \infty.$$

Proof. First, to demonstrate a uniform bound for w_q we consider the following linear elliptic boundary value problem:

$$\begin{aligned} A(\lambda, w)[w_q] = \tilde{A}(\lambda, w)[w_q] \\ &+ \big(-2w_q w_{pq} + 3\gamma(-p)(a^{-1}(\lambda) + w_p)^2\big) w_{qp} \\ &+ \big(2w_q w_{pp} - 2\gamma(-p)a^{-3}(\lambda) w_q\big) w_{qq} = 0, \end{aligned} \tag{5.7}$$

$$B(\lambda, w)[w_q] = \tilde{B}(\lambda, w)[w_q] + 2g(\lambda^{-1/2} + w_p)^2 w_q\big|_T = 0. \tag{5.8}$$

Here the principal parts $\tilde{A}(\lambda, w)$ and $\tilde{B}(\lambda, w)$ are defined in (4.9). We assume the solutions take the form $w(q,p) = k(q,p) - sqe^p$, where $s > 0$ is a constant. Substituting this into (5.7) results in the equation

$$\begin{aligned} &\tilde{A}(\lambda, k - sqe^p)[k_q] \\ &\quad - 2k_q k_{pq}^2 + 3\gamma(-p)(a^{-1}(\lambda) + k_p)^2 k_{qp} + 2k_q k_{pp} k_{qq} - 2\gamma(-p)a^{-3}(\lambda) k_q k_{qq} \\ &\quad - se^p\big((1 + k_q)^2 - 4k_q k_{pq} - 2k_{pq}^2 + 2k_{pp}k_{qq} - 2qk_q k_{qq} - 2\gamma(-p)k_{qq} \\ &\qquad + 3\gamma(-p)(a^{-1}(\lambda) + k_p)^2 + 6q\gamma(-p)(a^{-1}(\lambda) + k_p)k_{qp}\big) + O(s^2) = 0. \end{aligned} \tag{5.9}$$

Suppose k_q had an interior maximum in $\overline{R}$. At such a point the following would hold:

$$\begin{cases} k_{qp} = k_{qq} = 0, \\ k_{qpp}, k_{qqq} \le 0 \quad \text{and} \quad k_{qpp}k_{qqq} \ge k_{qpq}^2, \end{cases}$$

whence (5.9) would become

$$\tilde{A}(\lambda, k - sqe^p)[k_p] - se^p\big((1 + k_q^2) + 3\gamma(-p)(a^{-1}(\lambda) + k_p)^2\big) + O(s^2) = 0.$$

Since $(1+k_q^2)+3\gamma(-p)(a^{-1}(\lambda)+k_p)^2 > 1$, (5.9) is further reduced to the elliptic inequality $\tilde{A}(\lambda, k-sqe^p)[k_q] > 0$ for $s>0$ sufficiently small. Then, by the maximum principle, $k_q = w_q + se^p$ cannot have an interior maximum along $\mathcal{C}'_\delta$.

Note that $k_q \to 0$ as $p \to -\infty$. On the other hand, the nonlinear boundary condition (3.2b),

$$1 + (2gw-\lambda)(1/\sqrt{\lambda} + w_p^2) + (k_q - s)^2 = 0,$$

dictates that k_q on T is bounded by w and w_p.

Since w and w_p are uniformly bounded along $\mathcal{C}'_\delta$, the maximum of k_q and also the maximum of w_q are uniformly bounded along $\mathcal{C}'_\delta$. One repeats the same consideration with $w(q,p) = k(q,p) + sqe^p$ to conclude that the minimum of w_q along $\mathcal{C}'_\delta$ is bounded by w and w_p. Therefore, $\sup_{w\in\mathcal{C}'_\delta} \sup_{\overline{R}} |w_q|$ is finite.

Next, in order to obtain bounds for the second derivatives, we proceed with the a priori estimates of Schauder type due to Lieberman and Trudinger [27] for nonlinear elliptic partial differential equations with a nonlinear oblique boundary condition.

We consider a quasi-linear boundary value problem of the form

$$\begin{cases} F_1(\nabla w)[w] = \displaystyle\sum_{i,j=1}^{2} a^{ij}(\nabla w)\partial_{ij} w + f_1(\nabla w) = 0 & \text{in } R, \\ F_2(w, \nabla w) = 0 & \text{on } T. \end{cases} \tag{5.10}$$

Here $a^{ij}, f_1 \in C^2(\mathbb{R}^2)$, $F_2 \in C^2(\mathbb{R}\times\mathbb{R}^2)$; $\nabla w = (w_q, w_p)$ denotes the gradient of w.

Theorem 5.5. *Let $w \in C^2_{per}(\overline{R})$ be a solution to (5.10) such that $\partial^\beta w \in o(1)$ as $p \to -\infty$ for all multi-indices $|\beta| \le 2$. Suppose that $|w| + |\nabla w| \le K$ in $\overline{R}$ for some constant $K>0$ and that there exist $\delta, M > 0$ such that the following conditions hold for all $(z,r) \in \mathbb{R}\times\mathbb{R}^2$ with $|z|+|r| \le K$:*

$$\sum_{i,j=1}^{2} a^{ij}\xi_i\xi_j \ge \delta(\xi_1^2 + \xi_2^2) \qquad \textit{for all } (\xi_1,\xi_2) \in \mathbb{R}^2, \tag{5.11}$$

$$|a^{ij}|, |a^{ij}_r|, |f_r| \le \delta M, \tag{5.12}$$

$$\chi := F_{2r}\cdot(0,-1) > 0 \qquad \textit{on } T\times\mathbb{R}, \tag{5.13}$$

$$|F_2|, |F_{2z}|, |F_{2r}|, |F_{2zz}|, |F_{2zr}|, |F_{2rr}| \le \chi M. \tag{5.14}$$

Then for $\alpha' \in (0,1)$ and $C = C(K,M) > 0$ constants, $w \in C^{2+\alpha'}(\overline{R})$ and

$$\|w\|_{C^{2+\alpha'}(\overline{R})} \le C.$$

The assertion for any compact subset of $\overline{R}$ follows as a direct consequence of [27, Theorem 1.1]. Then we employ the treatment in [2, Theorem 6.3] and an interpolation theorem to obtain estimates valid on the entire domain $\overline{R}$.

In order to adapt Theorem 5.5 to the present setting, we take

$$\begin{aligned} \sum_{i,j=1}^{2} a^{ij}(r)\partial_{ij} &= (1+r_1^2)\partial_p^2 - 2(a^{-1}(\lambda)+r_2)r_1\partial_p\partial_q + (a^{-1}(\lambda)+r_2^2)\partial_q^2, \\ f_1(r) &= \gamma(-p)(a^{-1}+r_2)^3 - \gamma(-p)a^{-3}(\lambda)(1+r_1^2), \\ F_2(z,r) &= 1 + (2gz-\lambda)(\lambda^{-1/2}+r_2)^2 + r_1^2, \end{aligned}$$

where $z \in \mathbb{R}$ and $r = (r_1, r_2) \in \mathbb{R}^2$. Conditions (5.11) and (5.13) are fulfilled evidently; F_1 is uniformly elliptic and F_2 is uniformly oblique. In particular, there exists $s > 0$ such that

$$\chi = F_{2r} \cdot (0, -1) = 2(\lambda - 2gz)(\lambda^{-1/2} + r_2)\big|_T \geq s > 0,$$

since by (3.7b) we have

$$(\lambda - 2gw)(\lambda^{-1/2} + w_p) = \frac{1 + w_q^2}{\lambda^{-1/2} + |w_p|} \geq \frac{1}{(2\Gamma_\infty + \delta)^{-1/2} + \sup_{\overline{R}} |w_p|}$$

and the right side of the inequality is bounded along $\mathcal{C}'_\delta$. It is straightforward to verify the structure conditions (5.12) and (5.14). By virtue of Theorem 5.5 we then conclude that $\|w\|_{C^{2+\alpha'}(\overline{R})}$ for some $\alpha' \in (0,1)$ is uniformly bounded by $\sup_{\mathcal{C}'_\delta} \sup_{\overline{R}}(|w| + |w_p|)$ along the entire continuum $\mathcal{C}'_\delta$.

Our final task is to gain bounds for the higher derivatives. To do so, it is convenient to write (5.7) and (5.8) in the form

$$\begin{cases} \tilde{A}(\lambda, w)[w_q] = f_1(w_p, w_q, w_{pp}, w_{pq}, w_{qq}) & \text{in } R, \\ \tilde{B}(\lambda, w)[w_q] = -2g(\lambda^{-1/2} + w_p)^2 w_q & \text{on } T. \end{cases}$$

Note that $\tilde{A}(\lambda, w)$ is a uniformly elliptic differential operator whose coefficients are bounded in $C^{1+\alpha}(\overline{R})$ and that $\tilde{B}(\lambda, w)$ is a uniformly oblique boundary operator with bounded coefficients in $C^{1+\alpha}(T)$. Note as well that $f_1 \in C^{\alpha'}(\overline{R})$, where α' is as in the previous step. Accordingly, the (standard) Schauder estimate [2]

$$\begin{aligned} \|w_q\|_{C^{2+\alpha'}(\overline{R})} &\leq C\left(\|f_1\|_{C^{\alpha'}(\overline{R})} + \|2g(\lambda^{-1/2} + w_p)^2 w_q\|_{C^{1+\alpha'}(T)} + \|w_q\|_{C^0(\overline{R})}\right) \\ &\leq \tilde{C}(\|w\|_{C^{2+\alpha'}(\overline{R})}) \end{aligned}$$

holds, where $\tilde{C}$ depends on $\|w\|_{C^{2+\alpha'}(\overline{R})}$. That is to say, w_q earns a uniform $C^{2+\alpha'}(\overline{R})$ bound along $\mathcal{C}'_\delta$.

It remains to prove a uniform $C^{2+\alpha'}(\overline{R})$ estimate for w_p along $\mathcal{C}'_\delta$. We use the differential equation (3.7a) to express w_{pp} in terms of other derivatives of w of order less than or equal to 2, each of which is bounded along $\mathcal{C}'_\delta$ in the $C^{2+\alpha'}(\overline{R})$-norm. Thus, $\|w\|_{C^{3+\alpha'}(\overline{R})}$ remains uniformly bounded along $\mathcal{C}'_\delta$. In particular, $\|w\|_{C^{2+\alpha}(\overline{R})}$ is bounded along $\mathcal{C}'_\delta$. The assertion of Theorem 5.4 then follows by repeating the same argument as in the previous step with $\alpha' = \alpha$. □

5.3. Proof of the main result (Theorem 2.3). Throughout this subsection, $(u - c, v, \eta)$ represents the solution triple of the deep-water problem (2.1)–(2.6) corresponding to the solution pair (λ, w) of (3.10) via the transform in section 3.1.

The following observations are useful.

LEMMA 5.6 (speed at crest). *The relative flow speed at the crest of any nontrivial flow is bounded:*

$$(c - u(0,0))^2 = Q < \lambda. \tag{5.15}$$

Proof. Any nontrivial solution w belongs to $\mathcal{N}$, and thus it enjoys the nodal properties, $w_q = 0$ and $w_{qq} < 0$ on $q = 0$. Subsequently, $h_q = 0$ and $h_{qq} < 0$ on $q = 0$. Under the circumstances, (3.2a) reduces to the inequality $h_{pp} > -\gamma(-p)h_p^3$. Further,

$$-\left(\frac{1}{h_p^2(0,p)}\right)_p > -2\gamma(-p) \qquad \text{for } p \in (-\infty, 0).$$

Integration over $p \in (-\infty, 0)$ then yields $c^2 - (c - u(0,0))^2 > -2\Gamma_\infty$, from which (5.15) follows. $\square$

The same calculation carried out on $q = \pm\pi$ leads to an analogous bound for the relative flow speed at the trough:

$$(c - u(\pm\pi, \eta(\pm\pi)))^2 > \lambda. \tag{5.16}$$

The following properties of nontrivial solutions are direct consequences of (5.15) and (5.16):

$$w(0,0) = \ h(0,0) - \ H(0) = \frac{\lambda - Q}{2g} > 0, \tag{5.17}$$

$$w(\pm\pi, 0) = h(\pm\pi, 0) - \ H(0) = \frac{\lambda - (c - u(\pi, \eta(\pi)))^2}{2g} < 0. \tag{5.18}$$

Lemma 5.7 (pressure estimate). *The pressure satisfies the inequality*

$$P + gy - \Gamma(-\psi) \geq P_0 + g\eta(\pm\pi). \tag{5.19}$$

Proof. Let $s > 0$ and define a function on $\mathcal{D}_\eta$ by

$$M^s(x,y) = \tfrac{1}{2}(\psi_x^2 + \psi_y^2) + sy - E + P_0 = (s-g)y - P - \Gamma(-\psi) + P_0. \tag{5.20}$$

Note that

$$\Delta M^s + 2\gamma'(\psi) M^s = \psi_{xx}^2 + 2\psi_{xy}^2 + \psi_{yy}^2 + 2(sy - E + P_0)\gamma'(\psi) \geq 0.$$

The inequality utilizes the fact that $\gamma'(\psi) \leq 0$ and that $E - P_0 = \frac{1}{2}(c - u(0,0))^2 > 0$. The weak maximum principle asserts that M^s in $\overline{\mathcal{D}}_\eta$ attains its maximum on the free surface or at the infinite bottom. On the other hand,

$$\begin{aligned} M_y^s &= \psi_x\psi_{xy} + \psi_y\psi_{yy} + s \\ &= \psi_x\psi_{xy} - \psi_y\psi_{xx} - \psi_y\gamma(\psi) + s > 0 \end{aligned}$$

as $y \to -\infty$, since $\psi_x, \psi_{xx} \to 0$ and $\gamma(\psi) \to 0$ as $y \to -\infty$ uniformly for x while ψ_y is bounded. Therefore, M^s attains its maximum on the surface, and

$$(s-g)y - P - \Gamma(-\psi) + P_0 \leq (s-g)\eta(\pm\pi)$$

for each $s > 0$. Inequality (5.19) then follows as the limit $s \to 0$. $\square$

By the same token, the function

$$M(x,y) := \tfrac{1}{2}(\psi_x^2 + \psi_y^2) + gy - E + P_0 = -P - \Gamma(-\psi) + P_0$$

attains its maximum on the free surface. By the Hopf boundary point lemma,

$$e(x) := (-\eta_x, 1) \cdot (M_x, M_y)\big|_{\mathcal{S}_\eta} > 0 \qquad \text{for } x \in [0, \pi]. \tag{5.21}$$

On the other hand, since M is constantly zero on the surface,

$$(1, \eta_x) \cdot (M_x, M_y)\big|_{\mathcal{S}_\eta} = 0 \qquad \text{for } x \in [0, \pi], \tag{5.22}$$

and hence

$$M_x\big|_{\mathcal{S}_\eta} = -\frac{e(x)}{1+\eta_x^2}\eta_x \ge 0 \qquad \text{for } x \in [0,\pi].$$

Therefore, for $x \in [0,\pi]$

$$\begin{aligned}\frac{d}{dx}\left(\psi_y^2(x,\eta(x))\right) &= 2\psi_y\psi_{xy} + 2\psi_y\psi_{yy}\eta_x = 2\psi_y\psi_{xy} - 2\psi_x\psi_{yy} \\ &= 2\psi_y\psi_{xy} + 2\psi_x(\psi_{xx}+\gamma(0)) \\ &= -2\eta_x\left(\frac{e(x)}{1+\eta_x^2} - \gamma(0)(c-u)\big|_{\mathcal{S}_\eta}\right) \ge 0,\end{aligned}$$

provided that

$$\gamma(0) \le \min_{x\in[0,\pi]}\left(\frac{e(x)}{1+\eta_x^2(x)}\cdot\frac{1}{c-u(x,\eta(x))}\right). \tag{5.23}$$

Since $\psi_y(x,\eta(x))<0$, this says that $\psi_y(x,y)$ is nondecreasing for $x\in[0,\pi]$.

This is summarized in the following lemma.

LEMMA 5.8. *If $\gamma(0)$ satisfies* (5.23), *then the relative flow speed $c-u(x,\eta(x))$ is nondecreasing from crest to trough:*

$$c-u(x,\eta(x)) \ge c-u(0,0) > 0 \qquad \textit{for } x\in[0,\pi]. \tag{5.24}$$

Proof of Theorem 2.3. For any $\delta>0$, due to Theorem 5.2, Remark 5.3, and Theorem 5.4, at least one of the following holds:

(1) there exists a sequence $\{(\lambda_j,w_j)\}\subset\mathcal{C}'_\delta$ such that $\lim_{j\to\infty}\lambda_j=\infty$;
(2) there exists a sequence $\{(\lambda_j,w_j)\}\subset\mathcal{C}'_\delta$ such that $\sup_{\overline{R}}|w_j|\to\infty$;
(3) there exists a sequence $\{(\lambda_j,w_j)\}\subset\mathcal{C}'_\delta$ such that $\sup_{\overline{R}}|\partial_p w_j|\to\infty$;
(4) there exists a solution pair $(\lambda,w)\in\mathcal{C}'_\delta$ such that $\lambda=2\Gamma_\infty+\delta$;
(5) there exists a solution pair $(\lambda,w)\in\mathcal{C}'_\delta$ such that $a^{-1}(\lambda)+w_p=\delta$ at some point in $\overline{R}$;
(6) there exists a solution pair $(\lambda,w)\in\mathcal{C}'_\delta$ such that $w=\frac{2\lambda-\delta}{4g}$ at some point on T.

Our task is to give an interpretation of each alternative (1) through (6) in terms of the relative flow speed $c-u$ to prove assertion (ii) in Theorem 2.3. We note that

$$a^{-1}(\lambda)+w_p = h_p = \frac{1}{c-u}. \tag{5.25}$$

Alternative (1). From (5.16) it follows that $\lim_{j\to\infty}(c_j-u_j(\pm\pi,\eta_j(\pm\pi)))=\infty$.

Alternative (2). The nodal configuration says that $\partial_q w_j<0$ on R^+ whereas oddness of $\partial_q w_j$ requires that $w_q>0$ on R with $q\in(-\pi,0)$. That is, w is increasing where $q\in(-\pi,0)$ and decreasing where $q\in(0,\pi)$, and thus w attains its maximum on $q=0$ and its minimum on $q=\pm\pi$. Therefore, in the case of Alternative (2) either $\sup_p w_j(0,p)\uparrow\infty$ or $\inf_p w_j(\pm\pi,p)\downarrow-\infty$ must hold.

Suppose $\sup_p w_j(0,p)\uparrow\infty$. The nodal properties, $\partial_q w_j=0$ and $\partial_q^2 w_j<0$ on $q=0$, reduce (3.7a) to the inequality

$$\partial_p^2 w_j + \gamma(-p)\left((\partial_p w_j + \tfrac{3}{2}a^{-1}(\lambda_j))^2 + \tfrac{3}{4}a^{-2}(\lambda_j)\right)\partial_p w_j > 0 \qquad \text{on } q=0.$$

Since $w_j(0,0) > 0$ and $w_j(0,p)$ tends to zero as $p \to -\infty$, the maximum principle implies that $\sup_p w_j(0,p) = w_j(0,0)$. From (5.17) it follows $\lambda_j \uparrow \infty$, and in turn it follows $\lim_{j\to\infty}(c_j - u_j(\pm\pi, \eta_j(\pm\pi))) = \infty$, as is done previously for Alternative (1).

A similar consideration on $q = \pm\pi$ implies that $w(\pm\pi, p)$ on $p \in (-\infty, 0)$ attains a negative minimum at $p = 0$. Therefore, in case $\inf_p w_j(\pm\pi, p) \downarrow -\infty$, (5.18) implies that $\lim_{j\to\infty}(c_j - u_j(\pm\pi, \eta_j(\pm\pi))) = \infty$.

Alternative (3). Since $\delta < a^{-1}(\lambda) + w_p < \delta^{-1/2} + w_p$ for $(\lambda, w) \in \mathcal{O}_\delta$, i.e., w_p is bounded from below by $\delta - \delta^{-1/2}$, it must hold $\sup_{\overline{R}} \partial_p w_j \uparrow \infty$ under the circumstance. Then, by (5.25), $\sup_{\overline{R}} \partial_p h_j \uparrow \infty$ holds, and consequently $\inf_{\overline{\mathcal{D}}_{\eta_j}}(c_j - u_j) \downarrow 0$.

Alternative (4). To each $\delta_j \downarrow 0$ we associate $(\lambda_j, w_j) \in \mathcal{C}'_{\delta_j}$ such that $\lambda_j = 2\Gamma_\infty + \delta_j$. We may assume that $\sup_R \partial_p w_j$ is bounded; otherwise, $\inf_{\overline{\mathcal{D}}_{\eta_j}}(c_j - u_j) \downarrow 0$ must hold by the previous treatment for Alternative (3).

For a sequence $p_j \to -\infty$ with $2\Gamma_\infty - 2\Gamma(p_j) = \delta_j$, we have

$$\partial_p h_j(0,p) = a^{-1}(\lambda_j) + \partial_p w_j(0,p) > (2\delta_j)^{-1/2} - \sup_R \partial_p w_j(0,p) \uparrow \infty.$$

Therefore, by (5.25) $\inf_{\overline{\mathcal{D}}_{\eta_j}}(c_j - u_j) \downarrow 0$.

Alternative (5). Choose sequences $\delta_j \downarrow 0$ and $(\lambda_j, w_j) \in \mathcal{C}'_{\delta_j}$ such that $a^{-1}(\lambda_j) + \partial_p w_j = \delta_j$. By (5.25) it follows that $\sup_{\overline{\mathcal{D}}_{\eta_j}}(c_j - u_j) \uparrow \infty$.

Alternative (6). For a sequence $\delta_j \downarrow 0$ there exists a sequence $(\lambda_j, w_j) \in \mathcal{C}'_{\delta_j}$ such that $\lambda_j - 2gw_j = \frac{1}{2}\delta_j$ somewhere on T. The nonlinear boundary condition on top (3.2b) then yields

$$\frac{1}{\partial_p h_j^2} \le \frac{1 + \partial_q h_j^2}{\partial_p h_j^2} = \frac{\delta_j}{2} \downarrow 0,$$

whence $\inf_{\overline{\mathcal{D}}_{\eta_j}}(c_j - u_j) \downarrow 0$.

Let $\mathcal{C}' = \cup_{\delta>0}\mathcal{C}'_\delta$. By construction, $\mathcal{C}'_\delta \subset \mathcal{C}'_{\delta'}$ if $\delta > \delta'$. At this stage, the conclusion is that there is a sequence of solution triples $\{(u_j - c_j, v_j, \eta_j)\} \subset \mathcal{C}$ in the space $C^{2+\alpha}(\overline{\mathcal{D}}_\eta) \times C^{2+\alpha}(\overline{\mathcal{D}}_\eta) \times C^{3+\alpha}(\mathbb{R})$ such that

$$\text{either} \quad \sup_{\overline{\mathcal{D}}_{\eta_j}}(c_j - u_j) \uparrow \infty \quad \text{or} \quad \inf_{\overline{\mathcal{D}}_{\eta_j}}(c_j - u_j) \downarrow 0.$$

The remainder of the proof consists of studying the above two alternatives further.

First, let the first alternative $\sup_{\overline{\mathcal{D}}_{\eta_j}}(c_j - u_j) \uparrow \infty$ hold. We recall that

$$E = \tfrac{1}{2}\left((c-u)^2 + v^2\right) + gy + P + \Gamma(-\psi).$$

Evaluated at the trough $(\pm\pi, \eta(\pm\pi))$, it reduces to

$$E = \tfrac{1}{2}\left(c - u(\pm\pi, \eta(\pm\pi))\right)^2 + g\eta(\pm\pi) + P_0.$$

Subtracting the above two expressions for E, we arrive at

$$\begin{aligned}\tfrac{1}{2}(c-u)^2 &\le \tfrac{1}{2}\left(c - u(\pm\pi, \eta(\pm\pi))\right)^2 + g\eta(\pi) + P_0 - P - gy + \Gamma(-\psi) \\ &\le \tfrac{1}{2}\left(c - u(\pm\pi, \eta(\pm\pi))\right)^2.\end{aligned}$$

The last inequality uses Lemma 5.7. Therefore, if the first alternative $\sup_{\overline{\mathcal{D}}_{\eta_j}}(c_j - u_j) \uparrow \infty$ holds, $\lim_{j\to\infty}(c_j - u_j(\pm\pi, \eta_j(\pm\pi))) = \infty$ must hold.

Next, we assume the second alternative $\inf_{\overline{\mathcal{D}}_{\eta_j}}(c_j - u_j) \downarrow 0$ holds. We may choose a sequence $\{s_j\}$ and a sequence of solution triples $\{(u_j - c_j, v_j, \eta_j)\} \subset \mathcal{C}$ such that $s_j \downarrow 0$ and $c_j - u_j(x_j, y_j) = s_j$ at some point (x_j, y_j) in $\overline{\mathcal{D}}_{\eta_j}$; $\{y_j\}$ is assumed to be bounded from below as $u_j(x,y) \to 0$ as $y \to -\infty$ uniformly for x.

Differentiating the Poisson equation $-\Delta\psi = \gamma(\psi)$ leads to $\Delta(u-c)+\gamma'(\psi)(u-c) = 0$ in $\mathcal{D}_\eta$. Recall that $\psi_y = u - c$. Let us introduce a sequence of functions,

$$W_j(x,y) = u_j(x,y) - c_j + s_j e^{\beta(y-y_j)} \qquad \text{for } (x,y) \in \overline{\mathcal{D}}_{\eta_j}, \tag{5.26}$$

where $\beta > 0$ is a constant such that $\beta^2 + \gamma'(s) \geq 0$ for all $s \in [0,\infty)$. Note that

$$\Delta W_j + \gamma'(\psi) W_j = s_j(\beta^2 + \gamma'(\psi)) e^{\beta(y-y_j)} \geq 0 \qquad \text{in } \overline{\mathcal{D}}_{\eta_j}$$

and that $W_j(x_j, y_j) = 0$.

Since $\gamma'(\psi) \leq 0$, the weak maximum principle ensures that W_j in $\overline{\mathcal{D}}_{\eta_j}$ attains its maximum either on the surface or at the infinite bottom. On the other hand,

$$W_j \to -c_j < 0 \qquad \text{as } y \to -\infty.$$

Therefore, W_j in $\overline{\mathcal{D}}_{\eta_j}$ attains its maximum on the free surface $y = \eta_j(x)$. In particular, there is a sequence of points $\{(\xi_j, \eta_j(\xi_j)) : \xi_j \in [0,\pi]\}$ such that

$$u_j(\xi_j, \eta_j(\xi_j)) - c_j + s_j e^{\beta(\eta_j(\xi_j) - y_j)} \geq 0,$$

whence

$$0 \leq c_j - u_j(\xi_j, \eta_j(\xi_j)) \leq s_j e^{\beta(\eta_j(\xi_j) - y_j)}.$$

Since $\eta_j(\xi_j) \leq \eta_j(0) = 0$ and $\{y_j\}$ is bounded from below, we conclude that

$$\lim_{j\to\infty} (c_j - u_j(\xi_j, \eta_j(\xi_j))) = 0.$$

This proves (ii) of Theorem 2.3.

Furthermore, if $\gamma(0)$ satisfies (5.23), then, by Lemma 5.8, W_j in $\overline{\mathcal{D}}_{\eta_j}$ attains its maximum at the crest $(0,0)$, and therefore

$$\lim_{j\to\infty} (c_j - u_j(0,0)) = 0.$$

This completes the proof. $\square$

Remark 5.9. When the first alternative $\lim_{j\to\infty}(c_j - u_j(\pm\pi, \eta_j(\pm\pi))) = \infty$ holds, either the speed of wave propagation or the wave amplitude becomes unboundedly large. Indeed, as is done previously in the proof,

$$E = \tfrac{1}{2}(c - u(0,0))^2 = \tfrac{1}{2}(c - u(\pm\pi, \eta(\pm\pi)))^2 + g\eta(\pm\pi) + P_0,$$

from which it follows that

$$\begin{aligned}(c - u(\pm\pi, \eta_j(\pm\pi)))^2 &= (c - u(0,0))^2 + 2g|\eta(\pm\pi)| \\ &< \lambda + 2g|\eta(\pm\pi)|.\end{aligned}$$

Therefore, when the left side approaches infinity as $j \to \infty$,

$$\text{either} \quad \lim_{j\to\infty} c_j = \infty \quad \text{or} \quad \lim_{j\to\infty} |\eta_j(\pm\pi)| = \infty$$

holds.

Appendix A. Proof of Proposition 4.2 (local bifurcation). This section is devoted to the detailed analysis of local bifurcation for the regular approximate problem (3.11). We begin by invoking the theorem of local bifurcation from a simple eigenvalue due to Crandall and Rabinowitz.

THEOREM A.1 (see [11, Theorem 1] and [10, Theorem 3.6]). *Suppose that X and Y are Banach spaces and $I \subset \mathbb{R}$ is an open interval of λ^*. Also suppose that $F : I \times X \to Y$ is of class C^2 and satisfies*

(i) $F(\lambda, 0) = 0$ *for all* $\lambda \in I$*;*

(ii) $F_w(\lambda^*, 0)$ *is a Fredholm operator of index zero;*

(iii) $\ker F_w(\lambda^*, 0)$ *is one-dimensional and generated by* ϕ^**; and*

(iv) $F_{w\lambda}(\lambda^*, 0)[\phi^*] \notin \mathrm{range} F_w(\lambda^*, 0)$.

Then $(\lambda^*, 0)$ is a local bifurcation point. More precisely, there exists $s_0 > 0$ and a local curve of solutions

$$\{ (\lambda, w) = (\lambda(s), w(s)),\ |s| < s_0 : F(\lambda(s), w(s)) = 0 \}$$

in $\mathbb{R} \times X$ such that $(\lambda(0), w(0)) = (\lambda^*, 0)$. Furthermore, any solution near $(\lambda^*, 0)$ is of the form

$$w(s) = s\phi^* + o(s) \qquad \text{for} \quad |s| < s_0.$$

The curve of solutions is unique in the sense that there is an open neighborhood $U \subset I \times X$ of $(\lambda^*, 0)$ such that

$$\{ (\lambda, w) \in U : F(\lambda, w) = 0,\ w \not\equiv 0 \} = \{ (\lambda(s), w(s)) : 0 < |s| < s_0 \}.$$

Our task is to verify conditions (i) through (iv) for the setting in section 4.1. From the definition of F^ϵ in (3.11) follows that $F^\epsilon(\lambda, 0) = 0$ for $\lambda \in (2\Gamma_\infty, \infty)$. The Fredholm property of $F^\epsilon_w(\lambda^\epsilon, 0)$ is proved in Lemma 4.3.

LEMMA A.2 (null space). *The null space of $F^\epsilon_w(\lambda^\epsilon, 0)$ is one-dimensional and generated by ϕ^ϵ. Here ϕ^ϵ is an eigenfunction of (4.1) with $\lambda = \lambda^\epsilon$.*

Proof. As is established in Lemma 4.1, $\phi^\epsilon(q, p) = \Phi^\epsilon(p) \cos q$ belongs to $\ker F^\epsilon_w(\lambda^\epsilon, 0)$. Conversely, let $\phi \in X$ be in $\ker F^\epsilon_w(\lambda^\epsilon, 0)$. Such a function ϕ is even and 2π periodic in the q-variable, and hence it can be written as

$$\phi(q, p) = \sum_{k=0}^{\infty} \phi_k(p) \cos kq.$$

Each ϕ_k solves the ordinary differential equation

$$(a^3(\lambda^\epsilon)\phi_k')' - \epsilon\phi_k = k^2 a(\lambda^\epsilon)\phi_k \qquad \text{for } p \in (-\infty, 0),$$

with the boundary conditions

$$\begin{aligned} (\lambda^\epsilon)^{3/2}\phi_k'(0) &= g\phi_k(0), \\ \phi_k, \phi_k' \to 0 \qquad &\text{as } \ p \to -\infty. \end{aligned}$$

In case $k = 1$, it follows from Lemma 4.1 that ϕ_1 is a constant multiple of Φ^ϵ. For $k \geq 2$, any nontrivial solution ϕ_k would satisfy

$$\begin{aligned} R(\phi_k; \lambda^\epsilon) &= \frac{-g\phi_k^2(0) + \int_{-\infty}^0 a^3(\lambda^\epsilon)(\phi_k')^2 + \epsilon \int_{-\infty}^0 \phi_k^2\, dp}{\int_{-\infty}^0 a(\lambda^\epsilon)\phi_k^2\, dp} \\ &= -k^2 < -1. \end{aligned}$$

This contradicts (4.4), the characterization of λ^ϵ. Therefore, $\phi_k \equiv 0$ for $k \geq 2$. Consider a solution ϕ_0 of $k = 0$. From the comparison theorem for ordinary differential equations follows that any nontrivial solution ϕ_0 vanishes nowhere. This, however, contradicts the orthogonality,

$$\int_{-\infty}^{0} a(\lambda^\epsilon)\Phi^\epsilon(p)\phi_0(p)dp = 0,$$

which proves the assertion. ∎

Proof of Proposition 4.2. It remains to verify (iv) of Theorem A.1. We first claim that if $(f_1, f_2) \in Y$ belongs to the range of $F_w^\epsilon(\lambda^\epsilon, 0)$, then the orthogonality condition

$$\int_R f_1 \cdot a^3(\lambda^\epsilon)\phi^\epsilon dqdp + \frac{1}{2}\int_T f_2 \cdot \lambda^\epsilon \phi^\epsilon dq = 0 \tag{A.1}$$

holds. We remark that for any $f_1 \in Y_1$ the first integral converges since ϕ^ϵ decays exponentially as $p \to -\infty$ uniformly for q and $a(\lambda^\epsilon)$ is bounded.

To prove the claim, let $f_1 = A(\lambda^\epsilon, 0)v$ and $f_2 = B(\lambda^\epsilon, 0)v$ for some $v \in X$, i.e.,

$$\begin{aligned} f_1 &= a^{-3}(\lambda^\epsilon)(a^3(\lambda^\epsilon)v_p)_p + (a(\lambda^\epsilon)v_q)_q - \epsilon a^{-3}(\lambda^\epsilon)v, \\ f_2 &= (2g/\lambda^\epsilon)v - 2\sqrt{\lambda^\epsilon}v_p\big|_T. \end{aligned}$$

An integration by parts shows that

$$\begin{aligned} \iint_R f_1 \cdot a^3(\lambda^\epsilon)\phi^\epsilon\, dqdp &= \iint_R [(a^3(\lambda^\epsilon)v_p)_p + (a(\lambda^\epsilon)v_q)_q - \epsilon v]\phi^\epsilon\, dqdp \\ &= \iint_R [(a^3(\lambda^\epsilon)\phi^\epsilon_p)_p + (a(\lambda^\epsilon)\phi^\epsilon_q)_q - \epsilon\phi^\epsilon]v\, dqdp \\ &\quad + \int_T (a^3(\lambda^\epsilon)v_p\phi^\epsilon - a^3(\lambda^\epsilon)v\phi^\epsilon_p)\, dq \\ &= -\frac{1}{2}\int_T f_2 \cdot \lambda^\epsilon\phi^\epsilon\, dp. \end{aligned}$$

The last equality uses that ϕ^ϵ solves (4.1) with $\lambda = \lambda^\epsilon$. This proves the claim.

An explicit calculation yields

$$\begin{aligned} F^\epsilon_{w\lambda}(\lambda^\epsilon, 0)[\phi^\epsilon] = \big(&-a^{-4}(\lambda^\epsilon)\phi^\epsilon_{qq} - 3\gamma(-p)\, a^{-4}(\lambda^\epsilon)\phi^\epsilon_p + \frac{3}{2}\epsilon a^{-5}(\lambda^\epsilon)\phi^\epsilon, \\ &-2g(\lambda^\epsilon)^{-2}\phi^\epsilon - (\lambda^\epsilon)^{-1/2}\phi^\epsilon_p\big|_T\big). \end{aligned}$$

We shall show that (A.1) fails with $(f_1, f_2) = F^\epsilon_{w\lambda}(\lambda^\epsilon, 0)[\phi^\epsilon]$:

$$\begin{aligned} &\iint_R \left(-a^{-4}(\lambda^\epsilon)\phi^\epsilon_{qq} - 3\gamma(-p)a^{-4}(\lambda^\epsilon)\phi^\epsilon_p + \frac{3}{2}\epsilon a^{-5}(\lambda^\epsilon)\phi^\epsilon\right) \cdot a^3(\lambda^\epsilon)\phi^\epsilon\, dqdp \\ &\quad + \frac{1}{2}\int_T \left(2g(\lambda^\epsilon)^{-2}\phi^\epsilon - (\lambda^\epsilon)^{-1/2}\phi^\epsilon_p\right) \cdot \lambda^\epsilon\phi^\epsilon\, dq \\ &= -\iint_R a^{-1}(\lambda^\epsilon)\phi^\epsilon\phi^\epsilon_{qq}\, dqdp - 3\iint_R \gamma(-p)a^{-1}(\lambda^\epsilon)\phi^\epsilon\phi^\epsilon_p\, dqdp \\ &\quad - \frac{3}{2}\epsilon\iint_R a^{-2}(\lambda^\epsilon)(\phi^\epsilon)^2\, dqdp \\ &\quad + \frac{1}{2}\int_T \left(-2g(\lambda^\epsilon)^{-1}(\phi^\epsilon)^2 - \sqrt{\lambda^\epsilon}\phi^\epsilon\phi^\epsilon_p\right)\, dq \end{aligned}$$

$$
\begin{aligned}
&= \iint_R a^{-1}(\lambda^\epsilon)(\phi^\epsilon)^2\,dqdp - 3\iint_R \gamma(-p)a^{-1}(\lambda^\epsilon)\phi^\epsilon\phi^\epsilon_p\,dqdp\\
&\quad - \frac{3}{2}\epsilon\iint_R a^{-2}(\lambda^\epsilon)(\phi^\epsilon)^2\,dqdp - \frac{3}{2}\int_T g(\lambda^\epsilon)^{-1}(\phi^\epsilon)^2\,dq\\
&= -\frac{1}{2}\iint_R a^{-1}(\lambda^\epsilon)(\phi^\epsilon)^2\,dqdp - \frac{3}{2}\iint_R a(\lambda^\epsilon)(\phi^\epsilon_p)^2\,dqdp < 0.
\end{aligned}
$$

The last equality uses (4.1) with $\lambda = \lambda^\epsilon$ and $a'(p;\lambda^\epsilon) = \gamma(-p)a^{-1}(p;\lambda^\epsilon)$:

$$
\begin{aligned}
&\iint_R \gamma(-p)a^{-1}(\lambda^\epsilon)\phi^\epsilon\phi^\epsilon_p\,dqdp\\
&\qquad = \frac{1}{2}\iint_R a^{-1}(\lambda^\epsilon)(\phi^\epsilon)^2\,dqdp + \frac{1}{2}\iint_R a(\lambda^\epsilon)(\phi^\epsilon_p)^2\,dqdp\\
&\qquad\qquad + \frac{1}{2}\epsilon\iint_R a^{-2}(\lambda^\epsilon)(ep)^2\,dqdp - \frac{1}{2}\int_T g(\lambda^\epsilon)^{-1}(\phi^\epsilon)^2\,dq.
\end{aligned}
$$

Therefore, $F^\epsilon_{w\lambda}(\lambda^\epsilon,0)[\phi^\epsilon] \notin \mathrm{range} F^\epsilon_w(\lambda^\epsilon,0)$.

We deduce from Theorem A.1 the existence of a local bifurcation curve $(\lambda(s),w(s)) \in \mathcal{C}^\epsilon_{loc}$ in $\mathbb{R}\times X$ such that $(\lambda(0),w(0)) = (\lambda^\epsilon,0)$ and $F^\epsilon(\lambda(s),w(s)) = 0$. ◻

Appendix B. Generalized degree theory. This section is the summary of the general development in [18, 23] to define a generalized degree for a large class of mappings which includes $F^\epsilon(\lambda,\cdot)$ defined in (3.11). Let X, Y_1, and Y_2 be real Banach spaces, with X continuously embedded in Y_1. The Banach space $Y = Y_1\times Y_2$ is equipped with the product topology. Let $\mathcal{W}$ be a bounded open set of X and $F : \overline{\mathcal{W}} \to Y$ be of $C^2(\mathcal{W},Y)\cap C^0(\overline{\mathcal{W}},Y)$. The mapping F is supposed to be proper, i.e., $F^{-1}(K)\cap\overline{\mathcal{W}}$ is compact in X for any $K\subset Y$ compact. The linearized operator $F_w(w) = (A(w),B(w))$ is *admissible* in the following sense:

(L1) F_w is a Fredholm operator of index zero;
(L2) $B : X\to Y_2$ is surjective;
(L3) for each $w\in\mathcal{W}$ there exist $C_1, C_2 > 0$ such that

$$C_1\|\phi\|_X \le \mu^{\alpha/2}\|(A(w)-\mu I)\phi\|_{Y_1} + \mu^{(\alpha+1)/2}\|B(w)\phi\|_{Y_2}$$

for all $\phi\in X$ and for all $\mu\ge C_2$; and
(L4) there exists an open neighborhood N of the ray $\{\mu\in\mathbb{R},\,\mu\ge 0\}$ in the complex plane such that $\sigma(A)\cap N$ consists of finitely many eigenvalues, each of finite algebraic multiplicity; the spectrum $\sigma(A)$ is defined in (4.13).

Consider the equation

$$F(w) = y \quad \text{for } y\notin F(\partial\mathcal{W}).$$

We assume for now that y is a regular value, i.e., $F_w(w) = (A(w),B(w))$ is surjective for all $w\in F^{-1}(y)\cap\mathcal{W}$. It is in turn bijective by the Fredholm property. Then (L3) and (L4) ensure that $A(w)$ has only finitely many positive real eigenvalues, $\nu(w)$ say, counted by algebraic multiplicity. By properness, the inverse image $F^{-1}(y)\cap\mathcal{W}$ is compact and thereby a finite set. Accordingly, we define the *degree* of F with respect to y by

$$\deg(F,\mathcal{W},y) = \sum_{w\in F^{-1}(y)\cap\mathcal{W}} (-1)^{\nu(w)}. \tag{B.1}$$

Set $\deg(F,\mathcal{W},y) = 0$ if $F^{-1}(y)\cap\mathcal{W} = \emptyset$.

Suppose that $y \notin F(\partial\mathcal{W})$ is not a regular value. For this we employ the Sard–Smale–Quinn theorem which asserts that the set of regular values of F is dense in Y. We may choose a nearby regular value $\tilde{y}$ of F with $\|\tilde{y} - y\|_Y \le \inf_{\hat{y}\in F(\partial\mathcal{W})} \|\hat{y} - y\|_Y$ and define

$$\deg(F, \mathcal{W}, y) = \deg(F, \mathcal{W}, \tilde{y}), \tag{B.2}$$

where the right side is well defined.

An important property of degree is the following generalized homotopy invariance valid on noncylindrical domains. Let $\mathcal{U} \subset [0,1] \times \mathcal{W}$ be open and

$$\mathcal{U}_t = \{w \in \mathcal{W} : (t, w) \in \mathcal{U}\}, \qquad \partial\mathcal{U}_t = \{w \in \mathcal{W} : (t, w) \in \partial\mathcal{U}\}.$$

By an *admissible homotopy* we mean a proper map $H : \overline{\mathcal{U}} \to Y$ of class C^2 such that $H(t, \cdot) : \mathcal{U}_t \to Y$ is admissible in the sense of (L1)–(L4) above for each $t \in [0,1]$.

Proposition B.1 (generalized homotopy invariance). *The degree defined by* (B.1) *and* (B.2) *is invariant under admissible homotopies, i.e.,*

$$\deg(H(0,\cdot), \mathcal{U}_0, y) = \deg(H(1,\cdot), \mathcal{U}_1, y)$$

provided $y \notin H(t, \partial\mathcal{U}_t)$ *for all* $t \in [0,1]$.

The proof is standard. See [18, Appendix] for one in the present setting.

Appendix C. Preservation of nodal structure. Here we demonstrate that the continuum obtained in Theorem 4.7 globally preserves the nodal configuration which it inherits from the eigenfunction of the linearized problem at the local bifurcation point. Accordingly, the second alternative in Theorem 4.7 is eliminated.

As is done in section 4.2, let

$$R^+ = (0, \pi) \times (-\infty, 0), \qquad T^+ = (0, \pi) \times \{0\},$$
$$\partial R^+_l = \{(0, p) : p \in (-\infty, 0)\}, \qquad \partial R^+_r = \{(\pi, p) : p \in (-\infty, 0)\}.$$

Our goal is to show that any nontrivial solution to (3.11) in $\mathcal{C}^\epsilon_\delta$ possesses the following nodal pattern:

$$w_q < 0 \quad \text{in } R^+ \cup T^+, \tag{C.1}$$
$$w_{qq} < 0 \quad \text{on } \partial R^+_l, \qquad w_{qq} > 0 \quad \text{on } \partial R^+_r, \tag{C.2}$$
$$\text{either} \quad w_{qq}(0,0) < 0 \quad \text{or} \quad w_{qqp}(0,0) > 0, \tag{C.3}$$
$$\text{either} \quad w_{qq}(\pi,0) > 0 \quad \text{or} \quad w_{qqp}(\pi,0) < 0. \tag{C.4}$$

Inequalities (C.1)–(C.4) define the open set $\mathcal{N}$; see (4.23). By evenness and periodicity of $w \in X$, we infer that $w_q = 0$ on $\partial R^+_l \cup \partial R^+_r$.

Lemma C.1. $\mathcal{C}^\epsilon_{loc} \cap (\mathbb{R} \times \mathcal{N}) \neq \emptyset$*; i.e.,* (C.1)–(C.4) *hold along the local curve* $\mathcal{C}^\epsilon_{loc} \setminus (\lambda^\epsilon, 0)$ *of bifurcation in a small neighborhood of* $(\lambda^\epsilon, 0)$ *in* $\mathbb{R} \times X$.

Proof. We begin with the observation that an eigenfunction $\phi^\epsilon(q,p) = \Phi^\epsilon(p)\cos q$ of (4.1) at $(\lambda^\epsilon, 0)$ belongs to $\mathcal{N}$. This uses the fact that

$$\Phi^\epsilon(p) > 0 \quad \text{for } p \in (-\infty, 0] \qquad \text{and} \qquad (\Phi^\epsilon)'(0) > 0. \tag{C.5}$$

The alternatives (C.3) and (C.4) hold since $\phi^\epsilon_{qqp}(0,0) < 0$ and $\phi^\epsilon_{qq}(\pi,0) > 0$.

By virtue of Proposition 4.2, any solution of (3.11) contained in $\mathbb{R}\times X$ near $(\lambda^\epsilon, 0)$ is of the form

$$w(q,p) = s\Phi^\epsilon(p)\cos q + o(s) \quad \text{in } C^{3+\alpha}(\overline{R})$$

for $s > 0$ sufficiently small. By restricting it to $\overline{R}^+$ and differentiating, we arrive at

$$\begin{aligned} w_q(q,p) &= -s\Phi^\epsilon(p)\sin q &&+ o(s) \quad \text{in } C^{2+\alpha}(R^+ \cup T^+), \\ w_{qq}(0,p) &= -s\Phi^\epsilon(p) &&+ o(s) \quad \text{in } C^{1+\alpha}(\partial R_l^+), \\ w_{qq}(\pi,p) &= \ \ s\Phi^\epsilon(p) &&+ o(s) \quad \text{in } C^{1+\alpha}(\partial R_r^+), \\ w_{qqp}(q,p) &= -s(\Phi^\epsilon)'(p)\cos q &&+ o(s) \quad \text{in } C^{\alpha}(\overline{R}^+). \end{aligned} \tag{C.6}$$

Choose $s_1 > 0$ small enough, and (C.1), (C.2) follow for $w(s)$ with $0 < |s| < s_1$.

Next, at the left corner point $(0,0)$, oddness of w_q leads to

$$w_q(0,0) = w_{qp}(0,0) = w_{qqq}(0,0) = w_{qpp}(0,0) = 0.$$

Accordingly, we may write down Taylor expansions in the neighborhood $\overline{R}^+ \cap B_{1/k}((0,0))$ of w_q and w_{qq} as

$$\begin{aligned} w_q(q,p) &= w_{qq}(0,0)q + w_{qqp}(0,0)qp + O(k^{-3}), \\ w_{qq}(q,p) &= w_{qq}(0,0) \ \ + w_{qqp}(0,0)p \ \ + O(k^{-2}), \end{aligned} \tag{C.7}$$

respectively. Here $B_r(Q)$ denotes the open ball in the (q,p)-plane of radius r centered at Q. Analogous expansions are valid at the right corner point $(\pi, 0)$,

$$\begin{aligned} w_q(q,p) &= w_{qq}(\pi,0)(q-\pi) + w_{qqp}(\pi,0)(q-\pi)p + O(k^{-3}), \\ w_{qq}(q,p) &= w_{qq}(\pi,0) \qquad\quad + w_{qqp}(\pi,0)p \qquad\quad + O(k^{-2}), \end{aligned}$$

in $\overline{R}^+ \cap B_{1/k}((\pi,0))$. From (C.5) and (C.6) it follows that

$$\begin{aligned} w_{qq}(0,0) &\le -\tfrac{s}{2}\Phi^\epsilon(0) < 0, \quad & w_{qqp}(0,0) &\le -\tfrac{s}{2}(\Phi^\epsilon)'(0) < 0, \\ w_{qq}(\pi,0) &\ge \ \ \tfrac{s}{2}\Phi^\epsilon(0) > 0, \quad & w_{qqp}(\pi,0) &\ge \ \ \tfrac{s}{2}(\Phi^\epsilon)'(0) > 0 \end{aligned} \tag{C.8}$$

for $s > 0$ sufficiently small.

In view of (C.7) and (C.8), we deduce that for large $k_2 > 0$ an integer and $0 < s_2 < s_1$ sufficiently small, (C.1)–(C.3) hold for $w(s)$ with $0 < s < s_2$, w restricted to $B_{1/k_2}((0,0))$. We proceed similarly at the right corner point $(\pi, 0)$ to conclude that (C.1), (C.2), and (C.4) hold for $w(s)$ restricted to $B_{1/k_3}((\pi,0))$, with $0 < s_3 < s_1$, for a large integer $k_3 \ge 0$ and $0 < s_3 < s_1$ small enough. Finally, the assertion follows if we take $s = \min(s_2, s_3)$ and consider $\overline{R}^+ = R^+ \cup T^+ \cup \partial R_l^+ \cup \partial R_r^+ \cup \overline{B}_{1/k_2}((0,0)) \cup \overline{B}_{1/k_3}((\pi,0))$. ∎

For our next result, we appeal to the following sharp form of the maximum principle.

Lemma C.2. *Let R^+ be the open semi-infinite strip $(0,\pi)\times(-\infty,0)$ and let w be a C^2-subsolution of the uniformly elliptic differential operator*

$$L = a_{11}(q,p)\partial_q^2 + 2a_{12}(q,p)\partial_p\partial_q + a_{22}(q,p)\partial_p^2 + b_1(q,p)\partial_q + b_2(q,p)\partial_p$$

in R^+. We assume that the coefficients a_{ij}, b_i $(i, j = 1, 2)$ are continuous and uniformly bounded on $\overline{R}^+$. Suppose $w \geq 0$ in $\overline{R}^+$ and $w \to 0$ as $p \to -\infty$ uniformly for q.

(a) *$w > 0$ in R^+ unless $u \equiv 0$.*

(b) *We further assume that there is a constant $k > 0$ such that*

$$|a_{12}(q,p)| \leq k \min(q, \pi - q) \tag{C.9}$$

for all $(q,p) \in \overline{R}^+$. If $w = 0$ at some corner point Q of $\overline{R}^+$, then

$$\text{either} \quad \frac{\partial w}{\partial \vec{s}}(Q) > 0 \quad \text{or} \quad \frac{\partial^2 w}{\partial \vec{s}^2}(Q) > 0 \tag{C.10}$$

unless $w \equiv 0$. Here $\vec{s}$ is any direction vector at Q which enters R^+ nontangentially.

Assertion (a) follows from the Phragmén-Lindelöf theorem [14] and the weak maximum principle. Assertion (b) is the edge point lemma due to Serrin [35, Lemma 2].

LEMMA C.3. *The nodal properties* (C.1)–(C.4) *hold along the entire continuum $\mathcal{C}^\epsilon_\delta \setminus (\lambda^\epsilon, 0)$ unless $(\lambda, 0) \in \mathcal{C}^\epsilon_\delta$ with $\lambda \neq \lambda^\epsilon$.*

Proof. Assume the contrary. Then by the previous lemma and the connectedness of $\mathcal{C}^\epsilon_\delta$, there must be a nontrivial solution $(\hat{\lambda}, \hat{w}) \in \mathcal{C}^\epsilon_\delta$ which belongs to the boundary of $\mathbb{R} \times \mathcal{N}$. That is, $\hat{w}_q \not\equiv 0$, $\hat{w}_q \leq 0$ on $\overline{R}^+$, and at least one of the following conditions holds:

(1) $\hat{w}_q = 0$ at some point $(\hat{q}, 0) \in T^+$;

(2) $\hat{w}_q = 0$ and $\hat{w}_{qq} = 0$ at some point $(\hat{q}, \hat{p}) \in \overline{R}^+ \setminus ((0,0) \cup (\pi, 0))$;

(3) $\hat{w}_{qq} = 0$ and $\hat{w}_{qqp} = 0$ at some corner point.

Observe that $\hat{w}_q$ solves the linear partial differential equation in R^+

$$\begin{aligned} A(\hat{\lambda}, \hat{w})[\hat{w}_q] &= \tilde{A}(\hat{\lambda}, \hat{w})[\hat{w}_q] \\ &\quad + [-2\hat{w}_q \hat{w}_{pq} + 3\gamma(-p)(a^{-1}(\hat{\lambda}) + \hat{w}_p)^2]\hat{w}_{qp} \\ &\quad + [2\hat{w}_q \hat{w}_{pp} - 2\gamma(-p) a^{-3}(\hat{\lambda}) \hat{w}_q]\hat{w}_{qq} = 0 \end{aligned} \tag{C.11}$$

with the boundary condition

$$\begin{aligned} B(\hat{\lambda}, \hat{w})[\hat{w}_q] &= 2(2g\hat{w} - \hat{\lambda})(\hat{\lambda}^{-1/2} + \hat{w}_p)\hat{w}_{qp} \\ &\quad + 2\hat{w}_q \hat{w}_{qq} + 2g(\hat{\lambda}^{-1/2} + \hat{w}_p)^2 \hat{w}_q\big|_T = 0. \end{aligned} \tag{C.12}$$

Since $(\hat{\lambda}, \hat{w}) \in \mathcal{C}^\epsilon_\delta \subset \mathcal{O}_\delta$, $A(\hat{\lambda}, \hat{w})$ is uniformly elliptic and its coefficients are bounded and continuous in $\overline{R}^+$. By continuity, $\hat{w}_q \leq 0$ in $\overline{R}^+$. The bluntness condition (C.9) is fulfilled since $w_q = 0$ on $\partial R^+_l \cup \partial R^+_r$.

We first suppose $\hat{w}_q(\hat{q}, 0) = 0$ for some $(\hat{q}, 0) \in T^+$. At such a point the boundary condition becomes

$$2(2g\hat{w} - \hat{\lambda})(\hat{\lambda}^{-1/2} + \hat{w}_p)\hat{w}_{qp} = 0.$$

The Hopf boundary lemma requires $\hat{w}_{qp}(\hat{q}, 0) > 0$. Since $\hat{\lambda}^{-1/2} + \hat{w}_p \geq \delta > 0$ for $(\hat{\lambda}, \hat{w}) \in \mathcal{O}_\delta$, it must hold $2g\hat{w} - \hat{\lambda} = 0$. This contradicts the boundary condition on top (3.2b) since

$$1 \leq 1 + \hat{w}_q^2 = 1 + \hat{w}_q^2 + (2g\hat{w} - \hat{\lambda})(\hat{\lambda}^{-1/2} + \hat{w}_p)^2 = 0 \qquad \text{at } (\hat{q}, 0).$$

Therefore, (C.1) holds for $\hat{w}_q$.

Next, provided that $\hat{w}_q \leq 0$ in $\overline{R}^+$, we employ Lemma C.2(a) and the Hopf boundary lemma to conclude that condition (2) implies that $\hat{w}_q \equiv 0$.

Finally, suppose that condition (3) holds at $(0,0)$. By oddness of w_q, we infer that

$$w_q(0,0) = w_{pq}(0,0) = w_{qqq}(0,0) = w_{qpp}(0,0) = 0.$$

Hence,

$$\frac{\partial w_q}{\partial \vec{s}}(0,0) = 0 \quad \text{and} \quad \frac{\partial^2 w_q}{\partial \vec{s}^2}(0,0) = 0$$

for any direction $\vec{s}$ which enters R^+ nontangentially. This contradicts Lemma C.2(b). The same consideration at $(\pi, 0)$ excludes possibility (3). This completes the proof. ∎

At this stage, we have shown that (C.1)–(C.4) hold along the entire continuum $\mathcal{C}_\delta^\epsilon$ except in the case $(\lambda, 0) \in \mathcal{C}_\delta^\epsilon$ with $\lambda \neq \lambda^\epsilon$. Lemma 4.8 rules out this possibility and proves the preservation of the nodal configuration globally along the continuum.

Acknowledgment. This work was done as part of the author's doctoral dissertation. The author would like to thank her advisor, Walter Strauss, for his excellent guidance and for reading many drafts of this work.

ASYMPTOTIC STABILITY IN A NEUTRAL DELAY DIFFERENTIAL SYSTEM WITH VARIABLE DELAYS*

WU-HUA CHEN†, XIAOMEI LU†, ZHI-HONG GUAN‡, AND WEI XING ZHENG§

Abstract. By applying M-matrix theory and some new analysis techniques, we have succeeded in establishing the asymptotic stability of the zero solution of the "pure-delay type" neutral system with variable delays. The criteria obtained in this paper extend and improve the existing ones.

Key words. neutral delay system, pure-delay type, asymptotic stability, M-matrix

AMS subject classifications. 34K20, 34K60

DOI. 10.1137/S0036141004441167

1. Introduction. In this paper, we will be concerned with establishing new results for asymptotic stability of the trivial solution of the perturbed nonlinear neutral systems of the form

$$\begin{aligned} \frac{d}{dt}\left(x_i(t) - p_i(t)x_i(t-q_i)\right) = &-b_i(t)x_i(t-\tau_i(t)) \\ &+ f_i\left(t, x_1(t-\tau_{i1}(t)), \dots, x_n(t-\tau_{in}(t))\right), \\ &\qquad i = 1, 2, \dots, n, \end{aligned} \tag{1.1}$$

where $q_i > 0$ is a constant, $p_i(t),\ b_i(t) \geq 0,\ \tau_i(t) \geq 0$, and $\tau_{ij}(t) \geq 0$ are continuous on $R_+ = [0, +\infty)$, $i, j = 1, 2, \dots, n$, and $|p_i(t)| \leq p_i$, $\tau_i(t) \leq \tau_i$, $\tau_{ij}(t) \leq \tau_{ij}$. For each $i \in \{1, 2, \dots, n\}$, we assume that $f_i : R_+ \times R^n \to R$ is a continuous function and there exists a nonnegative matrix $D = (d_{ij})_{n\times n}$ such that

$$|f_i(t, x_1, x_2, \dots, x_n)| \leq b_i(t)\sum_{j=1}^{n} d_{ij}|x_j|,\ i = 1, 2, \dots, n. \tag{1.2}$$

When $p_i(t) = 0,\ \tau_i(t) = 0$, and $b_i(t) \equiv b_i$, $i = 1, 2, \dots, n$, (1.1) reduces to

$$\dot{x}_i(t) = -b_i x_i(t) + f_i\left(t, x_1(t-\tau_{i1}(t)), \dots, x_n(t-\tau_{in}(t))\right),\ i = 1, 2, \dots, n. \tag{1.3}$$

Equation (1.1) is usually used to model the delayed neural networks and has many important applications. The interested reader can refer to [1] and [2] and the references therein. A typical result for asymptotic stability of system (1.1) is that if

$$|f_i(t, x_1, x_2, \dots, x_n)| \leq \sum_{j=1}^{n} |a_{ij}||x_j|,\ i = 1, 2, \dots, n, \tag{1.4}$$

and $\mathrm{diag}\{b_1, b_2, \ldots,\ b_n\} - |A|$ is a nonsingular M-matrix, where $|A| = (|a_{ij}|)_{n\times n}$, then the trivial solution of system (1.4) is globally asymptotically stable; see, for example, [17] .

When $\tau_i(t) \neq 0,\ i = 1, \ldots, n$, system (1.1) is referred to as a "pure-delay type" system [3], [4], [5] which has many important applications, such as in congestion control for the internet [15] and in delay feedback control for chaotic systems [16]. For pure-delay type systems, the stability problem becomes much harder since there is no linear nondelayed term that dominates the others. In [14], Györi considered the stability problem for a special case of system (1.1):

$$\dot{x}_i(t) = -b_i x_i(t-\tau_i) + f_i\left(t, x_1(t-\tau_{i1}), \ldots, x_n(t-\tau_{in})\right),\ i = 1, 2, \ldots, n. \tag{1.5}$$

He established the following result.

THEOREM 1.1. *If condition* (1.4) *is satisfied,* $b_i\tau_i < 1/\mathrm{e},\ i = 1, 2, \ldots, n,$ *and*

$$\mathrm{diag}\{b_1, b_2, \ldots,\ b_n\} - |A| \tag{1.6}$$

is a nonsingular M-matrix, then the trivial solution of system (1.5) *is globally asymptotically stable for all constant delays* τ_{ij}.

The main techniques used in [14] are based on the asymptotic representation of the solutions of linear differential equations with constant coefficients and constant delays, so the method in [14] seems to be useless for system (1.1) with variable delays and variable coefficient.

When $n = 1$, (1.1) reduces to the scalar neutral delay differential equation

$$\frac{d}{dt}\left(x(t) - p(t)x(t-q)\right) = -b(t)x(t-\tau(t)) + a(t)x(t-r(t)), \tag{1.7}$$

where $p(t),\ b(t),\ a(t),\ \tau(t),\ r(t)$ are continuous on $[0, +\infty)$, and $b(t) \geq 0$, $0 \leq \tau(t) \leq \tau$, $0 \leq r(t) \leq r$, q is a positive constant.

It is shown in Yu [10] that if

$$\int_t^{t+\tau} b(s)ds < \frac{3}{2} - 2p(2-p), \quad \int_0^{+\infty} b(s)ds = +\infty,$$

then the zero solution of (1.7) with $a(t) = 0$ is asymptotically stable. This is the first 3/2 stability result in the literature for neutral differential equations. In [19], Bartha investigated the stability properties of neutral differential equations with state-dependent delay. Recently, Wang and Liao [13] studied the global attractivity of the zero solution of (1.7) under the assumptions of $\tau(t) = \tau$ and $r(t) = r$. By making the change of variable

$$z(t) = x(t) - p(t)x(t-q) - \int_{t+r-\tau}^{t} a(s)ds, \tag{1.8}$$

Wang and Liao transformed (1.7) with $\tau(t) = \tau$ and $r(t) = r$ into the following neutral differential equation with distributed delay:

$$\dot{z}(t) = -\bar{b}(t)x(t-\tau),$$

where $\bar{b}(t) = b(t) - a(t+r-\tau)$. Then applying the modified techniques used in [10], they derived the following theorem.

THEOREM 1.2. *Consider* (1.7) *with* $\tau(t) = \tau$ *and* $r(t) = r$. *Set* $\eta = \sup_{t\geq 0}\int_t^{t+\tau} b(s)ds$. *Assume that there exists a constant* $p \geq 0$ *such that*

$$|p(t)| + \int_{t-(\tau-r)}^{t} \operatorname{sign}(\tau - r)|a(s)|ds \leq p, \tag{1.9}$$

and

$$p < \frac{1}{4},\ \eta < \frac{3}{2} - 2p\,, \tag{1.10}$$

or

$$\frac{1}{4} \leq p < \frac{1}{2},\ \eta < \sqrt{2(1-2p)}\,. \tag{1.11}$$

If

$$\bar{b}(t) \geq 0,\ \int_0^{+\infty} \bar{b}(t)dt = +\infty,$$

then every solution of (1.7) *tends to zero as* $t \to +\infty$.

The techniques in [13] are based on the variable change (1.8), so the method in [13] is not applicable to (1.7) with variable delays. Moreover, the result in [13] depends on the delay of the perturbation (see condition (1.9)) and cannot guarantee the zero solution of (1.7) to be asymptotically stable.

Recently, So, Tang, and Zou [11] studied the global attractivity for the following linear differential system with constant delays:

$$\dot{x}_i(t) = -b_i x(t - \tau_i) + \sum_{j=1}^{n} a_{ij} x_j(t - \tau_{ij}),\ i = 1, 2, \ldots, n. \tag{1.12}$$

By using M-matrix theory and some inequality techniques, So, Tang, and Zou [11] proved the following theorem.

THEOREM 1.3. *Let* $\hat{A} = (\hat{a}_{ij})$ *be defined by*

$$\hat{a}_{ij} = \frac{1 + 1/9 b_i\tau_i(3 + 2b_i\tau_i)}{1 - 1/9 b_i\tau_i(3 + 2b_i\tau_i)}|a_{ij}|,\ i, j = 1, \ldots, n.$$

If $b_i\tau_i < 3/2,\ i = 1, \ldots, n,$ *and*

$$\operatorname{diag}\{b_1, \ldots, b_n\} - \hat{A} \tag{1.13}$$

is a nonsingular M-matrix, then every solution of (1.12) *tends to zero as* $t \to \infty$.

The techniques in [11] may be applicable to studying the global attractivity for system (1.1); however, they cannot be used to investigate the asymptotic stability for nonlinear system (1.1) with variable delays. Therefore, the stability problem for system (1.1) has not been fully investigated. In this paper, we will consider the following question: When all subsystems of (1.1),

$$\frac{d}{dt}\left(x_i(t) - p_i(t)x_i(t - q_i)\right) = -b_i(t)x_i(t - \tau_i(t)),\ i = 1, 2, \ldots, n,$$

are asymptotically stable, what conditions should be given on the perturbation terms $f_i(t, x_1(t - \tau_{i1}(t)), \ldots, x_n(t - \tau_{in}(t))),\ i = 1, 2, \ldots, n,$ such that the trivial solution of perturbed system (1.1) is globally asymptotically stable for all bounded variable delays $\tau_{ij}(t)$?

Before moving on, we need to introduce some notation and definitions.

For vector $x = (x_1, x_2, \dots, x_n)^T \in R^n$, $|x|$ denotes a vector norm defined by $|x| = \max_{1\le i\le n}\{|x_i|\}$. Let $h = \max_{1\le i,j\le n}\{q_i, \tau_i, \tau_{ij}\}$. $C = C([-h,\ 0],\ R^n)$ denotes the space of bounded, continuous functions $\phi:\ [-h,\ 0] \to R^n$ with norm $\|\phi\| = \sup_{s\in[-h,\ 0]}|\phi(s)|$. If $y \in C([-h,\ \alpha),\ R^n)$ with $\alpha > 0$ and $t \in [0,\ \alpha)$, then $y_t \in C$ is defined by $y_t(s) = y(t+s)$, $s \in [-h,\ 0]$. For $t_0 \ge 0$, $\phi \in C$, vector function $x \in C([-h,\ \alpha),\ R^n)$ with $\alpha > 0$ is called a solution of system (1.1) on $[0,\ \alpha)$ through (t_0, ϕ), denoted by $x(t, t_0, \phi)$ if $x_{t_0} = \phi$ and x satisfies (1.1) on $[0,\ \alpha)$.

DEFINITION 1.1. *The zero solution of system* (1.1) *is said to be stable if for any* $\epsilon > 0$ *there exists* $\delta(t_0, \epsilon) > 0$ *such that* $t \ge t_0 \ge 0$ *and* $\phi \in C$ *with* $\|\phi\| < \delta$ *implies* $|x(t, t_0, \phi)| < \epsilon$. *It is uniformly stable if the above* δ *is independent of* t_0.

DEFINITION 1.2. *The zero solution of system* (1.1) *is said to be globally asymptotically stable if it is stable and for any* $t_0 \ge 0$ *and for any* $\phi \in C$, $|x(t, t_0, \phi)| \to 0$ *as* $t \to \infty$.

Set $\eta_i = \sup_{t\ge 0}\int_t^{t+\tau_i} b_i(s)ds$. *Associated with matrix* $D = (d_{ij})_{n\times n}$, *we define the new matrix* $\tilde{D} = (\tilde{d}_{ij})_{n\times n}$ *by* $\tilde{d}_{ij} = d_{ij}/c_i$ *for* $i,\ j = 1, 2, \dots, n$, *where*

$$c_i = \begin{cases} \dfrac{2 - \eta_i^2 - 4p_i}{2 + \eta_i^2} & \text{if } \ \eta_i < 1\,, \\ \dfrac{3/2 - 2p_i - \eta_i}{1/2 + \eta_i} & \text{if } \ \eta_i \ge 1\,. \end{cases}$$

LEMMA 1.1. *If*

$$p_i < \frac{1}{4},\ \eta_i < \frac{3}{2} - 2p_i,\ i = 1, 2, \dots, n, \tag{1.14}$$

or

$$\frac{1}{4} \le p_i < \frac{1}{2},\ \eta_i < \sqrt{2(1-2p_i)},\ i = 1, 2, \dots, n, \tag{1.15}$$

then $0 < c_i < 1 - 2p_i$ *for* $i = 1, 2, \dots, n$.

Proof. For each $i \in \{1, 2, \dots, n\}$, we have $3/2 - 2p_i \ge \sqrt{2(1-2p_i)}$. So if condition (1.15) holds, then we have $c_i > 0$. Now we consider the case that condition (1.14) holds. If $\eta_i \ge 1$, it is obvious that $c_i > 0$. If $\eta_i < 1$, since $p_i < \frac{1}{4}$, so $2 - \eta_i^2 - 4p_i > 1 - \eta_i^2 > 0$. Thus, $c_i > 0$. The proof for $c_i < 1 - 2p_i$ is direct; we omit it. □

Now we can state our main result.

THEOREM 1.4. *Assume that* (1.2) *is satisfied, and* (1.14) *or* (1.15) *holds. If* $I - \tilde{D}$ *is a nonsingular* M*-matrix,* I *is an* $n \times n$ *identity matrix, and*

$$\int_0^{+\infty} b_i(t)dt = +\infty,\ i = 1, 2, \dots, n, \tag{1.16}$$

then the zero solution of (1.1) *is globally asymptotically stable.*

Applying Theorem 1.3 to system (1.12) yields the following result.

COROLLARY 1.1. *Consider system* (1.12). *Let* $\bar{A} = (\bar{a}_{ij})$ *be defined by* $\bar{a}_{ij} = \mu_i|a_{ij}|$, $i, j = 1, 2, \dots, n$, *where*

$$\mu_i = \begin{cases} \dfrac{2 + (b_i\tau_i)^2}{2 - (b_i\tau_i)^2} & \text{if } \ b_i\tau_i < 1, \\ \dfrac{1 + 2b_i\tau_i}{3 - 2b_i\tau_i} & \text{if } \ b_i\tau_i \ge 1. \end{cases}$$

If $b_i\tau_i < 3/2,\ i = 1, \dots, n,$ *and*

$$\operatorname{diag}\{b_1,\ b_2, \dots,\ b_n\} - \bar{A} \tag{1.17}$$

is a nonsingular M-matrix, then the trivial solution of system (1.12) *is globally asymptotically stable.*

Remark 1.1. It is easy to check that $\hat{a}_{ij} \geq \bar{a}_{ij}$ for $i, j = 1, 2, \dots, n$. So the condition (1.13) in Theorem 1.3 is improved by the condition (1.17) in Corollary 1.1. Moreover, the conditions in Corollary 1.1 can guarantee the trivial solution of (1.5) to be globally asymptotically stable, which cannot be achieved by using the method proposed by So, Tang, and Zou in [11]. Therefore, the results obtained in this paper extend and improve the ones in [11].

Remark 1.2. Corollary 1.1 is not an extension of Theorem 1.1, since the condition (1.17) in Corollary 1.1 is stronger than the condition (1.6) in Theorem 1.1. This suggests that there is room for improving condition (1.17).

Applying Theorem 1.4 to (1.7), we get the following corollary.

Corollary 1.2. *Assume that there exists a constant* $p \geq 0$ *such that*

$$|p(t)| \leq p. \tag{1.18}$$

Set

$$\eta = \sup_{t\geq 0} \int_t^{t+\tau} b(s)ds, \quad c = \begin{cases} \dfrac{2-\eta^2-4p}{2+\eta^2} & \text{if } \ \eta < 1\,, \\ \dfrac{3/2-2p-\eta}{1/2+\eta} & \text{if } \ \eta \geq 1\,. \end{cases}$$

If condition (1.10) *or* (1.11) *is satisfied,* $\int_0^{+\infty} b(t)dt = +\infty$*, and there exists a constant* $\delta,\ 0 \leq \delta < c$*, such that* $|a(t)| \leq \delta b(t)$*, then the zero solution of* (1.7) *is globally asymptotically stable.*

Remark 1.3. Comparing Corollary 1.2 with Theorem 1.2 obtained in [13], condition (1.9) in Theorem 1.2 is improved by (1.18). Moreover, our result is independent of the delay r. When $\delta = 0$, we will get the 3/2 asymptotic stability result for neutral differential delay equations. Therefore, Corollary 1.2 extends the 3/2 asymptotic stability results obtained in [6], [7], [8], [9], [10] to the perturbed equations. However, as pointed out in Corollary 1.1, the upper bound c of δ in Corollary 1.2 may not be the best possible. A special example is given in section 3 which shows that the best possible upper bound of δ may be 1.

2. Proof of Theorem 1.4. First we introduce some notation. Since $I - \tilde{D}$ is a nonsingular M-matrix, there exist positive constants $r_1,\ r_2, \dots,\ r_n$, such that

$$-r_i + \sum_{j=1}^n r_j \tilde{d}_{ij} < 0.$$

By the definition of $\tilde{d}_{ij}$, we get

$$-r_i + 1/c_i \sum_{j=1}^n r_j d_{ij} < 0. \tag{2.1}$$

In what follows, we set $\bar{d} = \max_{1\leq i\leq n}\{1 + \sum_{j=1}^n d_{ij} r_j / r_i\}$, $q = \min_{1\leq i\leq n}\{q_i\}$, $\bar{r} = \max_{1\leq i\leq n}\{r_i\}$, $\underline{r} = \min_{1\leq i\leq n}\{r_i\}$.

LEMMA 2.1. *Consider* (1.1) *and assume that condition* (1.2) *is satisfied for* $\eta_i < +\infty$ *for* $i \in \{1, 2, \dots, n\}$. *Set* $\eta = \sum_{j=1}^{n} \eta_j$. *For* $\phi \in C$, *let* $x(t) = x(t, t_0, \phi)$, *and* $v(t) = \max_{1\le i\le n} \{\|x_{it}\|/r_i\}$ *for* $t \ge t_0$. *Then*

$$v(t) \le \left[\max_{1\le i\le n} \{1 + 2p_i\}\right]^m \exp\left(m\bar{d}\eta\right) v(t_0), \quad t \in [t_0+(m-1)q,\ t_0+mq], \quad m = 1, 2, \dots.$$

Proof. For $t \in [t_0,\ t_0 + q]$, integrating (1.1) on $[t_0,\ t]$, we get

$$\begin{aligned} x_i(t) = x_i(t, t_0, \phi) &= x_i(t_0) + p_i(t)x_i(t - q_i) - p_i(t_0)x_i(t_0 - q_i) \\ &\quad + \int_{t_0}^{t} (-b_i(s)x_i(s - \tau_i(s)) + f_i(s, x_{i1}(s - \tau_{i1}(s)), \dots, x_{in}(s - \tau_{in}(s))))\, ds \end{aligned}$$

for $i = 1, \dots, n$. So, by (1.2), for $i = 1, \dots, n$, $t \in [t_0,\ t_0 + q]$,

$$\begin{aligned} |x_i(t)| &\le (1 + 2p_i)\|x_{it_0}\| + \int_{t_0}^{t} b_i(s) \left[\|x_{is}\| + \sum_{j=1}^{n} d_{ij}\|x_{js}\|\right] ds \\ &= (1 + 2p_i)r_i\|x_{it_0}\|/r_i + \int_{t_0}^{t} b_i(s) \left[r_i\left(\|x_{is}\|/r_i\right) + \sum_{j=1}^{n} d_{ij}r_j\left(\|x_{js}\|/r_j\right)\right] ds \\ &\le (1 + 2p_i)r_i v(t_0) + \int_{t_0}^{t} b_i(s) \left[r_i + \sum_{j=1}^{n} d_{ij}r_j\right] v(s)ds. \end{aligned}$$

It follows that for $i = 1, \dots, n$, $t \in [t_0,\ t_0 + q]$,

$$\|x_{it}\|/r_i \le (1 + 2p_i)v(t_0) + \int_{t_0}^{t} b_i(s) \left[1 + \sum_{j=1}^{n} d_{ij}r_j/r_i\right] v(s)ds.$$

Hence, for $t \in [t_0,\ t_0 + q]$,

$$v(t) \le \max_{1\le i\le n} \{1 + 2p_i\}\, v(t_0) + \int_{t_0}^{t} \sum_{j=1}^{n} b_j(s)\bar{d}v(s)ds.$$

By Gronwall's inequality, for $t \in [t_0,\ t_0 + q]$,

$$v(t) \le \max_{1\le i\le n} \{1 + 2p_i\} \exp\left(\bar{d}\sum_{j=1}^{n}\int_{t_0}^{t} b_j(s)ds\right) v(t_0) \le \max_{1\le i\le n} \{1 + 2p_i\} \exp\left(\bar{d}\eta\right) v(t_0).$$

Then, using the induction method, for any $m \ge 1$, we get

$$v(t) \le \left[\max_{1\le i\le n} \{1 + 2p_i\}\right]^m \exp\left(m\bar{d}\eta\right) v(t_0), \quad t \in [t_0 + (m - 1)q,\ t_0 + mq]. \qquad \square$$

LEMMA 2.2. *Under the conditions of Theorem* 1.4, *the zero solution of* (1.1) *is uniformly stable.*

Proof. Let $y_i(t) = x_i(t) - p_i(t)x_i(t - q_i)$, $z(t) = \max_{1\le i\le n}\{|x_i(t)|/r_i\}$. Choose positive integer l such that $lq \ge 2h$. For given $\epsilon > 0$, let

$$\delta = \frac{\underline{r}}{\bar{r}}\frac{1-\bar{p}}{1+\bar{p}}\left[\max_{1\le i\le n}\{1+2p_i\}\right]^{-l}\exp\left(-\bar{d}l\eta\right)\epsilon.$$

From Lemma 2.1, for $\|\phi\| < \delta$,

$$\begin{aligned} z(t) &\le v(t) \le \left[\max_{1\le i\le n}\{1+2p_i\}\right]^{l}\exp\left(\bar{d}l\eta\right)v(t_0) \\ &\le \left[\max_{1\le i\le n}\{1+2p_i\}\right]^{l}\exp\left(\bar{d}l\eta\right)\|\phi\|/\underline{r} \\ &< \frac{1-\bar{p}}{1+\bar{p}}\bar{\epsilon},\quad t\in[t_0,\ t_0+lq], \end{aligned} \tag{2.2}$$

where $\bar{\epsilon} = \epsilon/\bar{r}$.

Now we use the techniques in [12] and [13] to prove that

$$|z(t)| < \bar{\epsilon}\ \text{ for }\ t > t_0 + lq. \tag{2.3}$$

If this is true, then by (2.2), we get

$$|x(t)| \le \bar{r}z(t) < \epsilon\ \text{ for } t > t_0,$$

which implies that the zero solution of (1.1) is uniformly stable. Suppose that (2.3) is not true; then there exists $t^* > t_0 + lq$ such that

$$z(t) < \bar{\epsilon} \text{ for } t\in[t_0,\ t^*] \text{ and }\ z(t^*) = \bar{\epsilon}.$$

Then there exists some $k \in \{1, 2, \ldots, n\}$ such that $z(t^*) = |x_k(t^*)|/r_k$. Without loss of generality, we may assume that $x_k(t^*) > 0$; then $x_k(t^*) = r_k\bar{\epsilon}$, and

$$|x_i(t)| \le r_i z(t) < r_i\bar{\epsilon} \text{ for } t\in[t_0,\ t^*],\ i = 1, 2, \ldots, n. \tag{2.4}$$

It follows that

$$y_k(t^*) = x_k(t^*) - p_k(t^*)x_k(t^* - q_k) > (1 - p_k)r_k\bar{\epsilon}. \tag{2.5}$$

On the other hand, by (2.2) and (2.4), for $t \in [t_0,\ t_0 + lq]$,

$$\begin{aligned} |y_k(t)| &= |x_k(t) - p_k(t)x_k(t - q_k)| \\ &< (1 + p_k)r_k\bar{\epsilon}(1 - \bar{p})/(1 + \bar{p}) \le (1 - p_k)r_k\bar{\epsilon}. \end{aligned} \tag{2.6}$$

Combining (2.5) and (2.6) yields that there exists $\xi \in (t_0 + lq,\ t^*]$ such that

$$\dot{y}_k(\xi) \ge 0,\quad \text{and}\quad y_k(\xi) = \max_{s\in[t_0,\ t^*]} y_k(s) > (1 - p_k)r_k\bar{\epsilon}. \tag{2.7}$$

Set $u(t) = y_k(t) - p_k r_k\bar{\epsilon}$; then for $t \in [t_0, t^*]$,

$$r_k\bar{\epsilon} \ge x_k(t) = y_k(t) + p_k(t)x_k(t - q_k) \ge y_k(t) - p_k r_k\bar{\epsilon} = u(t). \tag{2.8}$$

So,

$$\begin{aligned} \dot{u}(t) &= \dot{y}_k(t) < b_k(t)(-x_k(t - \tau_k(t)) + c_k r_k\bar{\epsilon}) \\ &\le b_k(t)(-u(t - \tau_k(t)) + c_k r_k\bar{\epsilon}). \end{aligned} \tag{2.9}$$

In particular,

$$\dot{u}(\xi) < b_k(\xi)(-u(\xi - \tau_k(\xi)) + c_k r_k \bar{\epsilon}). \tag{2.10}$$

If we can prove that

$$u(t) > c_k r_k \bar{\epsilon} \text{ for } t \in [\xi - \tau_k,\ \xi], \tag{2.11}$$

then by (2.10), we will get $\dot{u}(\xi) < 0$, which contradicts $\dot{u}(\xi) = \dot{y}_k(\xi) \geq 0$, so the proof will be complete. In what follows, we will prove (2.11). Suppose the contrary. Since $u(\xi) = y_k(\xi) - p_k r_k \bar{\epsilon} > (1 - 2p_k) r_k \bar{\epsilon} > c_k r_k \bar{\epsilon}$ by Lemma 1.1 and (2.7), there exists $t_1 \in [\xi - \tau_k,\ \xi)$ such that

$$u(t_1) = c_k r_k \bar{\epsilon} \text{ and } \ u(t) > c_k r_k \bar{\epsilon} \text{ for } t \in (t_1,\ \xi]. \tag{2.12}$$

We assert that

$$\dot{u}(t) < (1 + c_k) b_k(t) \int_{t-\tau_k}^{t_1} b_k(s) ds r_k \bar{\epsilon},\ \ t \in [t_1 - \tau_k, \xi]. \tag{2.13}$$

In fact, if $t - \tau_k(t) > t_1$ for some $t \in [t_1 - \tau_k, \xi]$, then $\dot{u}(t) < 0$ by (2.9) and (2.12), which yields (2.13). On the other hand, by (2.8) and (2.9), we have

$$\dot{u}(t) < (1 + c_k) b_k(t) r_k \bar{\epsilon},\ \ t \in [t_1 - \tau_k, \xi]. \tag{2.14}$$

If $t - \tau_k(t) < t_1$ for some $t \in [t_1 - \tau_k, \xi]$, integrating the above inequality from $t - \tau_k(t)$ to t_1, we have

$$c_k r_k \bar{\epsilon} - u(t - \tau_k(t)) = u(t_1) - u(t - \tau_k(t)) = \int_{t-\tau_k(t)}^{t_1} \dot{u}(s) ds < (1 + c_k) \int_{t-\tau_k}^{t_1} b_k(s) ds r_k \bar{\epsilon}.$$

Substituting the above inequality into (2.9), we get (2.13).

Combining (2.13) and (2.14), we have

$$\begin{aligned}
\dot{u}(t) &< (1 + c_k) b_k(t) \min \left\{ 1,\ \int_{t-\tau_k}^{t_1} b_k(s) ds \right\} r_k \bar{\epsilon} \\
&= (1 + c_k) b_k(t) \min \left\{ 1,\ \int_{t-\tau_k}^{t} b_k(s) ds - \int_{t_1}^{t} b_k(s) ds \right\} r_k \bar{\epsilon} \\
&\leq (1 + c_k) b_k(t) \min \left\{ 1,\ \eta_k - \int_{t_1}^{t} b_k(s) ds \right\} r_k \bar{\epsilon}.
\end{aligned}$$

For $t \in [t_1,\ \xi]$, integrating the above inequality on the two side from t_1 to ξ, we get

$$(1 - 2p_k - c_k) r_k \bar{\epsilon} < u(\xi) - u(t_1) < (1 + c_k) I_k r_k \bar{\epsilon}. \tag{2.15}$$

Let $I_k = \int_{t_1}^{\xi} b_k(t) \min\{1,\ \eta_k - \int_{t_1}^{t} b_k(s) ds\} dt$. Now we give an estimation of I_k. There are two possible cases.

Case 1. $\int_{t_1}^{\xi} b_k(t) dt \geq 1$. In this case, choose $t_2 \in (t_1,\ \xi)$ such that $\int_{t_2}^{\xi} b_k(t) dt = 1$.

$$\begin{aligned}
I_k &\leq \int_{t_1}^{t_2} b_k(t) dt + \int_{t_2}^{\xi} b_k(t) \left[\eta_k - \int_{t_1}^{t} b_k(s) ds \right] dt \\
&\leq \int_{t_1}^{t_2} b_k(t) dt + \eta_k \int_{t_2}^{\xi} b_k(t) dt - \frac{1}{2} \int_{t_2}^{\xi} b_k(t) dt \left[\int_{t_2}^{\xi} b_k(t) dt \right. \\
&\qquad \left. + 2 \int_{t_1}^{t_2} b_k(t) dt \right] \\
&= \eta_k - \frac{1}{2}.
\end{aligned} \tag{2.16}$$

Case 2. $\int_{t_1}^{\xi} b_k(t)dt < 1$.

$$\begin{aligned} I_k &\le \eta_k \int_{t_1}^{\xi} b_k(t)dt - \int_{t_1}^{\xi} b_k(t) \int_{t_1}^{t} b_k(s)dsdt \\ &= \eta_k \int_{t_1}^{\xi} b_k(t)dt - \frac{1}{2}\left[\int_{t_1}^{\xi} b_k(t)dt\right]^2 . \end{aligned}$$

Note that $\int_{t_1}^{\xi} b_k(t)dt \le \eta_k$ and the function $-1/2\,x^2 + \eta_k x$ is increasing on $x \in [0, \eta_k]$. Therefore, if $\eta_k \ge 1$, then $I_k \le \eta_k - \frac{1}{2}$. If $\eta_k < 1$, then $I_k \le \frac{1}{2}{\eta_k}^2$.

Since $\frac{1}{2}{\eta_k}^2 \ge \eta_k - \frac{1}{2}$, combining Cases 1 and 2 yields

$$I_k \le \begin{cases} \frac{1}{2}\eta_k^2 & \text{if } \eta_k < 1\,, \\ \eta_k - \frac{1}{2} & \text{if } \eta_k \ge 1\,. \end{cases}$$

Substituting the above inequality into (2.15), we get

$$c_k > \begin{cases} \dfrac{2 - 4p_k - \eta_k^2}{2 + \eta_k^2} & \text{if } \eta_k < 1, \\ \dfrac{3/2 - 2p_k - \eta_k}{\eta_k + 1/2} & \text{if } \eta_k \ge 1, \end{cases}$$

which contradicts the definition of $c_i,\ i = 1, 2, \dots, n$. The proof is complete. $\square$

Proof of Theorem 1.4. In view of Lemma 2.2, the zero solution is uniformly stable. Moreover, from the proof of Lemma 2.2, every solution $x(t)$ of (1.1) is bounded. Now we prove that

$$\lim_{t\to\infty} x(t) = 0. \tag{2.17}$$

Set $\gamma = \max_{1\le i\le n} t\{\sum_{j=1}^{n} d_{ij} r_j/(c_i r_i)\}$. Then by (2.1), $0 < \gamma < 1$. Set $\beta_i = \limsup_{t\to\infty}|x_i(t)|$, then $0 \le \beta_i < \infty$. We assume that $\beta_k/r_k = \max_{1\le i\le n}\{\beta_i/r_i\}$ for some $k \in \{1, 2, \dots, n\}$. If $\beta_k = 0$, then (2.17) holds. If $\beta_k > 0$, choose

$$\bar\sigma_k = \begin{cases} (1-\gamma)\frac{1-2p_k-\frac{1}{2}\eta_k^2}{1+\gamma\left(1-2p_k-\frac{1}{2}\eta_k^2\right)\bar r/\underline{r}+\frac{1}{2}\eta_k^2\bar r/\underline{r}}\beta_k & \text{if } \ \eta_k < 1, \\ (1-\gamma)\frac{3/2-2p_k-\eta_k}{1+\gamma(3/2-2p_k-\eta_k)\bar r/\underline{r}+(\eta_k-1/2)\bar r/\underline{r}}\beta_k & \text{if } \ \eta_k \ge 1. \end{cases}$$

It is easy to see that $0 < \bar\sigma_k < \beta_k$. Moreover, for any $0 < \sigma_k < \min\{\bar\sigma_k,\ (1 - 2p_k - \gamma c_k)\beta_k/\left(1 + \gamma c_k \bar r/\underline{r}\right)\}$, there exists $T > t_0 + 2h$, such that

$$|x_i(t)| < \beta_i + \sigma_k \text{ for } t \ge T, \quad i = 1, \dots, n.$$

Let $y_k(t) = x_k(t) - p_k(t)x_k(t - q_k)$. We distinguish the two cases.

Case A. *$\dot y_k(t)$ is eventually sign-definite.* By the boundedness of $y_k(t)$, the limit $\mu_k = \lim_{t\to+\infty} y_k(t)$ exists. We may assume that $\limsup_{t\to+\infty} x_k(t) = \beta_k$. Then,

$$\beta_k = \limsup_{t\to+\infty} x_k(t) \le \limsup_{t\to+\infty} y_k(t) + p_k \limsup_{t\to+\infty} |x_k(t - q_k)| = \mu_k + p_k\beta_k.$$

So $\mu_k \ge (1 - p_k)\,\beta_k$. Set $\alpha_k = \liminf_{t\to+\infty} x_k(t)$. Then

$$\alpha_k = \liminf_{t\to+\infty} x_k(t) \ge \liminf_{t\to+\infty} y_k(t) - p_k \limsup_{t\to+\infty} |x_k(t - q_k)| = \mu_k - p_k\beta_k \ge (1 - 2p_k)\,\beta_k.$$

Thus, there exists $T_1 \geq T$ such that

$$(1-2p_k)\,\beta_k - \sigma_k < x_k(t) < \beta_k + \sigma_k,\ \ t \geq T_1 + h.$$

By (1.1) and (2.1), for $t \geq T_1 + h$,

$$\begin{aligned}
\dot{y}_k(t) &\leq -b_k(t)x_k(t-\tau_k(t)) + b_k(t)\sum_{j=1}^{n} d_{kj}|x_j(t-\tau_{kj}(t))| \\
&< -b_k(t)\left((1-2p_k)\,\beta_k - \sigma_k\right) + b_k(t)\sum_{j=1}^{n} d_{kj}\left(\beta_j + \sigma_k\right) \\
&= -b_k(t)\left((1-2p_k)\,\beta_k - \sigma_k\right) + b_k(t)\sum_{j=1}^{n} d_{kj}r_j\left(\beta_j/r_j + \sigma_k/r_j\right) \\
&\leq -b_k(t)\left((1-2p_k)\,\beta_k - \sigma_k\right) + b_k(t)\sum_{j=1}^{n} d_{kj}r_j\left(\beta_k/r_k + \sigma_k/\underline{r}\right) \\
&\leq -b_k(t)\left((1-2p_k)\,\beta_k - \sigma_k\right) + \gamma b_k(t)c_k r_k\left(\beta_k/r_k + \sigma_k/\underline{r}\right) \\
&= -b_k(t)\left\{(1-2p_k-\gamma c_k)\,\beta_k - \sigma_k\left[1+\gamma c_k\bar{r}/\underline{r}\right]\right\}.
\end{aligned}$$

By using (1.16) and the definition of σ_k, the above inequality implies that $y_k(t) \to -\infty$. This is a contradiction. So, $\beta_k = 0$.

Case B. *$\dot{y}_k(t)$ is oscillatory.* Noticing that

$$\limsup_{t\to\infty}|y_k(t)| \geq \limsup_{t\to\infty}|x_k(t)| - p_k\limsup_{t\to\infty}|x_k(t-q_k)| \geq (1-p_k)\beta_k,$$

there exists an increasing sequence $\{t_{km}\}$ such that $t_{km} \to \infty$ as $m \to \infty$, $\dot{y}_k(t_{km}) \geq 0$, and

$$|y_k(t_{km})| > (1-p_k)(\beta_k - \sigma_k).$$

Without loss of generality, we assume $t_{km} > T + h$ and $y_k(t_{km}) > 0$. Set $u(t) = y_k(t) - p_k(\beta_k + \sigma_k)$; then $\dot{u}(t_{km}) = \dot{y}_k(t_{km}) \geq 0$ and

$$\begin{aligned}
\beta_k + \sigma_k \ &\geq\ x_k(t) = y_k(t) + p_k(t)x_k(t-q_k) \\
&>\ y_k(t) - p_k(\beta_k+\sigma_k) = u(t),\ \ t \geq T+h.
\end{aligned} \tag{2.18}$$

Moreover, By (1.1), (2.1), and the above inequality,

$$\begin{aligned}
\dot{u}(t) \ &=\ \dot{y}_k(t) < -b_k(t)x_k(t-\tau_k(t)) + \gamma b_k(t)c_k\left(\beta_k + \sigma_k\bar{r}/\underline{r}\right) \\
&<\ -b_k(t)u(t-\tau_k(t)) + \gamma b_k(t)c_k\left(\beta_k + \sigma_k\bar{r}/\underline{r}\right).
\end{aligned} \tag{2.19}$$

In particular,

$$\begin{aligned}
0 \leq \dot{u}(t_{km}) = \dot{y}_k(t_{km}) \ &<\ -b_k(t_{km})u(t_{km} - \tau_k(t_{km})) \\
&\quad +\gamma b_k(t_{km})c_k\left(\beta_k + \ \sigma_k\bar{r}/\underline{r}\right).
\end{aligned} \tag{2.20}$$

If we can prove that

$$u(t) > \gamma c_k(\beta_k + \sigma_k\bar{r}/\underline{r}) \text{ for } t \in [t_{km} - \tau_k,\ t_{km}], \tag{2.21}$$

then by (2.20), we will obtain a contradiction, so we can deduce $\beta_k = 0$ and the proof is complete. Now under the assumption of $\beta_k > 0$, we prove that (2.21) holds. Note that by the definition of σ_k,

$$u(t_{km}) = y_k(t_{km}) + p_k(t_{km})x_k(t_{km} - q_k) > (1 - 2p_k)\beta_k - \sigma_k > \gamma c_k(\beta_k + \sigma_k\bar{r}/\underline{r}).$$

So, if (2.21) is not true, then there exists $t^1_{km} \in [t_{km} - \tau_k,\ t_{km})$, such that

$$u\left(t^1_{km}\right) = \gamma c_k(\beta_k + \sigma_k\bar{r}/\underline{r}) \text{ and } u(t) > \gamma c_k\left(\beta_k + \sigma_k\bar{r}/\underline{r}\right) \tag{2.22}$$

for $t \in \left(t^1_{km},\ t_{km}\right]$. We assert that

$$\dot{u}(t) < (1 + \gamma c_k)b_k(t)\int_{t-\tau_k}^{t^1_{km}} b_k(s)ds(\beta_k + \sigma_k\bar{r}/\underline{r}),\ t \in [t^1_{km} - \tau_k, t_{km}]. \tag{2.23}$$

In fact, by (2.18) and (2.19), we have

$$\dot{u}(t) < b_k(t)(1 + \gamma c_k)(\beta_k + \sigma_k\bar{r}/\underline{r}),\ t \in [t^1_{km} - \tau_k, t_{km}]. \tag{2.24}$$

If $t-\tau_k(t) \le t^1_{km}$ for some $t \in [t^1_{km}, t_{km}]$, integrating the above inequality from $t-\tau_k(t)$ to t^1_{km}, we get

$$\begin{aligned}\gamma c_k(\beta_k + \sigma_k\bar{r}/\underline{r}) - u(t - \tau_k(t)) &= u(t^1_{km}) - u(t - \tau_k(t))\\ &< (1 + \gamma c_k)\int_{t-\tau_k}^{t^1_{km}} b_k(s)ds(\beta_k + \sigma_k\bar{r}/\underline{r}).\end{aligned}$$

Substituting the above inequality into the second inequality in (2.19), we get (2.23). If $t - \tau_k(t) > t^1_{km}$ for some $t \in [t^1_{km}, t_{km}]$, then by (2.23) and the second inequality of (2.19), we get (2.23).

Combining (2.23) and (2.24) yields

$$\dot{u}(t) < (1 + \gamma c_k)b_k(t)\min\left\{1,\ \int_{t-\tau_k}^{t^1_{km}} b_k(s)ds\right\}\left(\beta_k + \sigma_k\bar{r}/\underline{r}\right).$$

Integrating this inequality from t^1_{km} to t_{km}, we get

$$\begin{aligned}&(1 - \gamma c_k - 2p_k)\beta_k - \sigma_k\left(1 + \gamma c_k\right)\bar{r}/\underline{r} < u(t_{km}) - u\left(t^1_{km}\right)\\ <\ &(1 + \gamma c_k)I_{km}\left(\beta_k + \sigma_k\bar{r}/\underline{r}\right),\end{aligned} \tag{2.25}$$

where $I_{km} = \int_{t^1_{km}}^{t_{km}} b_k(t)\min\{1,\ \int_{t-\tau_k}^{t^1_{km}} b_k(s)ds\}dt$.

Using the same technique as in the proof of Lemma 2.2, we have

$$I_{km} \le \begin{cases} 1/2\eta_k^2 & \text{if } \eta_k < 1\,,\\ \eta_k - 1/2 & \text{if } \eta_k \ge 1\,.\end{cases}$$

Therefore, by (2.25), we have

$$\sigma_k > \bar{\sigma}_k\,,$$

which is impossible since $\sigma_k < \bar{\sigma}_k$. Therefore, $\beta_k = 0$; that is, (2.17) holds, and so the proof is complete. $\square$

3. A special example.

Example 3.1. Consider the delay differential equation

$$\dot{x}(t) = -b(t)(x(t-1) - \delta x(t-1/2)), \tag{3.1}$$

where $\delta > 0$ and $b(t)$ is defined by

$$b(t) = \begin{cases} 48(t-3i)(3i+1/2-t) & \text{for } 3i \le t \le 3i+1/2, \\ \beta(t-3i-1/2)(3i+1-t) & \text{for } 3i+1/2 \le t \le 3i+1, \\ 48(t-3i-1)(3i+3/2-t) & \text{for } 3i+1 \le t \le 3i+3/2, \\ 0 & \text{for } 3i+3/2 \le t \le 3(i+1), \end{cases}$$

where $\beta > 0$ is a constant.

The example is a perturbed version of Example 3.1 in [18]. It is easy to see that $\eta = \sup_{t\ge 0} \int_t^{t+1} b(s)ds = 1 + \beta/48$. By Corollary 1.2, if $\beta < 24$ and $\delta < c$, then the zero solution of (3.1) is asymptotically stable.

But by elementary calculations, we have, for $i = 1, 2, \ldots,$

$$x(t) = x\left(3i - 3/2\right)\left\{1 - 48(1-\delta)\left[\frac{1}{4}(t-3i)^2 - \frac{1}{3}(t-3i)^3\right]\right\} \text{ for } t \in [3i, 3i+1/2],$$

$$\begin{aligned} x(t) = x\left(3i - 3/2\right)\Bigg\{&\delta - \frac{\beta}{4}(1-\delta)\left(t - 3i - \frac{1}{2}\right)^2 + \frac{\beta}{3}(1-\delta)\left(t-3i-\frac{1}{2}\right)^3 \\ &-\frac{3}{2}\beta\delta(1-\delta)\left(t-3i-\frac{1}{2}\right)^4 + 4\beta\delta(1-\delta)\left(t-3i-\frac{1}{2}\right)^5 \\ &-\frac{8}{3}\beta\delta(1-\delta)\left(t-3i-\frac{1}{2}\right)^6\Bigg\} \text{ for } t \in [3i+1/2, 3i+1], \end{aligned}$$

$$\begin{aligned} x(t) = x\left(3i - 3/2\right)\Bigg\{&\delta - \frac{\beta}{96}(\delta+2)(1-\delta) - (1-\delta)(t-3i-1)^2[12 - 16(t-3i-1)] \\ &+(1-\delta)(48-\beta\delta)(t-3i-1)^4\left[\frac{3}{2} - 4(t-3i-1) + \frac{8}{3}(t-3i-1)^2\right] \\ &-48\beta\delta^2(1-\delta)(t-3i-1)^6\left[\frac{1}{8} - \frac{1}{2}(t-3i-1) + \frac{8}{3}(t-3i-1)^2\right]\Bigg\} \\ &\text{for } t \in [3i+1, 3i+3/2], \end{aligned}$$

$$x(t) = x\left(3i-3/2\right)g(\delta) \text{ for } t \in [3i+3/2, 3i+3],$$

where $g(\delta) = -1 + 2\delta - \frac{\beta}{96}(\delta+2)(1-\delta) + \frac{1}{96}(1-\delta)(48-\beta\delta) - \frac{\beta}{288}\delta^2(1-\delta)$. By induction, we have $x(3i-3/2) = x(3/2)g^{i-1}(\delta)$ for $i \ge 1$. So there exists a constant $M_0 > 0$ such that $|x(t)| \le M_0|x(3/2)||g(\delta)|^{i-1}$ for $t \in [3i, 3i+3]$ and $i \ge 1$. Note that $\dot{g}(\lambda) = \frac{\beta}{96}\delta^2 + \frac{5\beta}{144}\delta + \frac{3}{2} > 0$ for $\delta \in [0,1)$, so $-\frac{\beta}{48} - \frac{1}{2} \le g(\delta) < 1$ for $\delta \in [0,1)$. Therefore, the necessary and sufficient conditions for asymptotic stability of the zero solution of (3.1) are $\beta < 24$ and $\delta < 1$. This means that condition $\delta < c$ in Corollary 1.2 is a sufficient condition (not a necessary condition) for the zero solution of (1.7) to be asymptotically stable.

Remark 3.1. When $\delta = 0$, this example (see [18]) also shows that the upper bound 3/2 for the stability result in [7] is the best possible when the coefficient is a continuous function (the case when the coefficient is a piecewise continuous function was proved in [7]). However, how to find the sharp condition for the stability of the perturbed system remains an open question.

GLOBAL BRANCHES OF TRAVELLING-WAVES TO A GROSS–PITAEVSKII–SCHRÖDINGER SYSTEM IN ONE DIMENSION*

MIHAI MARIŞ†

Abstract. We are interested in the existence of travelling-wave solutions to a system which modelizes the motion of an uncharged impurity in a Bose condensate. We prove that in space dimension one, there exist travelling-waves moving with velocity c if and only if c is less than the sound velocity at infinity. In this case we investigate the structure of the set of travelling-waves and we show that it contains global subcontinua in appropriate Sobolev spaces.

Key words. Gross–Pitaevskii system, travelling-waves, global bifurcation

1. Introduction.

This paper is devoted to the study of a special kind of solutions of a system describing the motion of an uncharged impurity in a Bose condensate. In dimensionless variables, the system reads

$$\left\{\begin{aligned} 2i\frac{\partial\psi}{\partial t} &= -\Delta\psi + \tfrac{1}{\varepsilon^2}(|\psi|^2 + \tfrac{1}{\varepsilon^2}|\varphi|^2 - 1)\psi, \\ 2i\delta\frac{\partial\varphi}{\partial t} &= -\Delta\varphi + \tfrac{1}{\varepsilon^2}(q^2|\psi|^2 - \varepsilon^2 k^2)\varphi. \end{aligned}\right. \tag{1.1}$$

Here ψ and φ are the wavefunctions for bosons, respectively for the impurity, $\delta = \frac{\mu}{M}$, where μ is the mass of impurity, M is the boson mass (δ is supposed to be small), $q^2 = \frac{l}{2d}$, l is the boson-impurity scattering length and d the boson diameter, k is a dimensionless measure for the single-particle impurity energy, and ε is a dimensionless constant ($\varepsilon = (\frac{a\mu}{lM})^{\frac{1}{5}}$, where a is the "healing length"; in applications, $\varepsilon \cong 0.2$). Assuming that we are in a frame in which the condensate is at rest at infinity, the solutions must satisfy the "boundary conditions"

$$|\psi| \longrightarrow 1, \quad \varphi \longrightarrow 0 \quad \text{as } |x| \longrightarrow \infty. \tag{1.2}$$

This system (originally introduced by Clark and Gross) was studied by Grant and Roberts [5]. Using formal asymptotic expansions and numerical experiments, they computed the effective radius and the induced mass of the uncharged impurity.

We consider here the system (1.1) in a one dimensional space and we look for solitary waves, that is, for solutions of the form

$$\psi(x,t) = \tilde{\psi}(x - ct), \quad \varphi(x,t) = \tilde{\varphi}(x - ct). \tag{1.3}$$

This kind of solution corresponds to the case where the only disturbance present in the condensate is that caused by the uniform motion of the impurity with velocity c.

In view of the boundary conditions, we seek solutions of the form

$$\tilde{\psi}(x) = (1+\tilde{r}(x))e^{i\psi_0(x)}, \quad \tilde{\varphi}(x) = \tilde{u}(x)e^{i\varphi_0(x)}, \tag{1.4}$$

with $\tilde{r}(x) \longrightarrow 0$, $\tilde{u}(x) \longrightarrow 0$ as $|x| \longrightarrow \infty$. By an easy computation we find that the real functions ψ_0, φ_0, $\tilde{r}$, $\tilde{u}$ must satisfy

$$\psi_0' = c\left(1 - \frac{1}{(1+\tilde{r})^2}\right), \tag{1.5}$$

$$\varphi_0' = c\delta, \tag{1.6}$$

$$\tilde{r}'' = c^2\left(\frac{1}{(1+\tilde{r})^3} - (1+\tilde{r})\right) + \frac{1}{\varepsilon^2}\left((1+\tilde{r})^3 - (1+\tilde{r}) + \frac{1}{\varepsilon^2}(1+\tilde{r})\tilde{u}^2\right), \tag{1.7}$$

$$\tilde{u}'' = \left(\frac{q^2}{\varepsilon^2}(1+\tilde{r})^2 - c^2\delta^2 - k^2\right)\tilde{u}. \tag{1.8}$$

From (1.6) we see that necessarily $\varphi_0(x) = c\delta x + C$. Note that the system is invariant under the transform $(\psi,\varphi) \longmapsto (e^{i\alpha}\psi, e^{i\beta}\varphi)$, so the integration constants in (1.5) and (1.6) are not important. Thus all we have to do is to solve the system (1.7)–(1.8). Thereafter it will be easy to find the corresponding phases from (1.5)–(1.6), and (1.4) will give a solitary-wave solution of (1.1).

After the scale change $\tilde{u}(x) = \frac{1}{\varepsilon}u(\frac{x}{\varepsilon})$, $\tilde{r}(x) = r(\frac{x}{\varepsilon})$, we find that the functions r and u satisfy

$$r'' = (1+r)^3 - (1+r) - c^2\varepsilon^2\left(1 + r - \frac{1}{(1+r)^3}\right) + (1+r)u^2, \tag{1.9}$$

$$u'' = (q^2(1+r)^2 - \lambda)u, \tag{1.10}$$

where

$$\lambda = \varepsilon^2(c^2\delta^2 + k^2). \tag{1.11}$$

The equation $r'' = (1+r)^3 - (1+r) - \frac{v^2}{4}(1 + r - \frac{1}{(1+r)^3}) + (1+r)U$, where U is a positive Borel measure, was studied in [7]. In the case $U \equiv 0$, it has been shown that this equation has only the trivial solution $r \equiv 0$ if $|v| \geq \sqrt{2}$; for $0 < |v| < \sqrt{2}$, it also admits the solution

$$r_v(x) = -1 + \sqrt{\frac{v^2}{2} + \left(1 - \frac{v^2}{2}\right)\tanh^2\left(\frac{\sqrt{2-v^2}}{2}x\right)}. \tag{1.12}$$

Moreover, any other nontrivial solution is of the form $r_v(\cdot - x_0)$ for some $x_0 \in \mathbf{R}$. Equation (1.10) is linear in u; more precisely, u must be an eigenvector of the linear operator $-\frac{d^2}{dx^2} + q^2(1+r)^2$ corresponding to the eigenvalue $\lambda = \varepsilon^2(c^2\delta^2 + k^2)$.

It is now clear that except for translations, the only solutions of (1.9)–(1.10) of the form $(r,0)$ are $(0,0)$ and $(r_{2c\varepsilon}, 0)$ (the latter exists only for $|c\varepsilon| < \frac{1}{\sqrt{2}}$). We call these solutions the *trivial solutions* of (1.9)–(1.10). We will prove that there exist nontrivial solutions of (1.9)–(1.10) in a neighborhood of $(r_{2c\varepsilon}, 0)$ (for suitable values of the parameter λ) and we will study the global structure of the set of nontrivial solutions.

It has been shown (see, e.g., [7] and references therein) that by using the Madelung transform $\psi = \sqrt{\rho}e^{i\psi_0}$, the first equation in (1.1) can be put into a hydrodynamical form (i.e., it is equivalent to a system of Euler equations for a compressible inviscid fluid of density ρ and velocity $\nabla\psi_0$). In this context, $\frac{1}{\varepsilon\sqrt{2}}$ represents the sound velocity at infinity. It will be proved at the beginning of section 3 that (1.1) does not possess nonconstant travelling-waves moving with velocity $|c| \geq \frac{1}{\varepsilon\sqrt{2}}$. Hence we will assume throughout that $|c| < \frac{1}{\varepsilon\sqrt{2}}$.

Observe that the system (1.9)–(1.10) has a good variational formulation: its solutions are critical points of the "energy" functional. Indeed, since $1 + \tilde{r} = |\tilde{\psi}| \geq 0$, it is clear that we must have $\tilde{r} \geq -1$. Therefore we will look for solutions r of (1.9) with $r > -1$. Let $V = \{r \in H^1(\mathbf{R}) \mid \inf_{x\in\mathbf{R}} r(x) > -1\}$. It is obvious that V is open in $H^1(\mathbf{R})$ because $H^1(\mathbf{R}) \subset C_b^0(\mathbf{R})$ by the Sobolev embedding. A pair $(r,u) \in V \times H^1(\mathbf{R})$ satisfy (1.9)–(1.10) if and only if (r,u) is a critical point of the C^∞ functional $E : V \times H^1(\mathbf{R}) \longrightarrow \mathbf{R}$,

$$
\begin{aligned}
E(r,u) \quad = \quad & \int_{\mathbf{R}} |r'|^2 dx + \frac{1}{2}\int_{\mathbf{R}} \Big((1+r)^2 - 1\Big)^2 \left(1 - \frac{2c^2\varepsilon^2}{(1+r)^2}\right) dx \\
& + \int_{\mathbf{R}} u^2(1+r)^2 dx + \frac{1}{q^2}\int_{\mathbf{R}} |u'|^2 dx - \frac{\lambda}{q^2}\int_{\mathbf{R}} u^2 dx.
\end{aligned}
\tag{1.13}
$$

However, $E(r,\cdot)$ is quadratic in u for any fixed r and it would be very difficult to find critical points of E by using a classical topological argument.

In this paper we use bifurcation theory to show the existence of nontrivial solitary waves for the system (1.1). Note that this system (or, equivalently, (1.9)–(1.10)) is invariant by translations. To avoid the degeneracy of the linearized system due to this invariance, we work on symmetric function spaces. Consequently, the travelling-waves that we obtain will also present a symmetry. To be more precise, we will use the spaces

$$\mathbf{H} = H^2_{rad}(\mathbf{R}) = \{u \in H^2(\mathbf{R}) \mid u(x) = u(-x) \ \ \forall x \in \mathbf{R}\} \quad \text{and}$$

$$\mathbf{L} = L^2_{rad}(\mathbf{R}) = \{u \in L^2(\mathbf{R}) \mid u(x) = u(-x) \ \text{ a.e. } \ x \in \mathbf{R}\}.$$

Clearly $\mathbf{H}\cap V$ is an open set of $\mathbf{H}$. We define $S : (\mathbf{H}\cap V)\times\mathbf{H} \longrightarrow \mathbf{L}$, $T : \mathbf{R}\times\mathbf{H}\times\mathbf{H} \longrightarrow \mathbf{L}$,

$$S(r,u) = -r'' + (1+r)^3 - (1+r) - c^2\varepsilon^2\left(1 + r - \frac{1}{(1+r)^3}\right) + (1+r)u^2, \tag{1.14}$$

$$T(\lambda,r,u) = -u'' + (q^2(1+r)^2 - \lambda)u. \tag{1.15}$$

It is obvious that S and T are well defined and of class C^∞ (recall that $\mathbf{H} \subset C_b^1(\mathbf{R})$ and $\mathbf{H}$ is an algebra). Clearly r and u satisfy the system (1.9)–(1.10) if and only if $S(r,u) = 0$ and $T(\lambda,r,u) = 0$.

In the next section, we will study the structure of the set of nontrivial solutions in a neighborhood of the trivial ones. It follows easily from the implicit function theorem that there are no nontrivial solutions of (1.9)–(1.10) in a neighborhood of $(\lambda,0,0)$ for $\lambda < q^2$ (see the proof of Theorem 3.8). It is well known that we may have nontrivial solutions arbitrarily close to $(\lambda, r_{2c\varepsilon}, 0)$ if and only if the differential $d_{(r,u)}(S,T)(\lambda, r_{2c\varepsilon}, 0)$ is not invertible. For $\lambda < q^2$, we will see that $d_{(r,u)}(S,T)(\lambda, r_{2c\varepsilon}, 0)$ is not invertible if and only if λ is an eigenvalue of the particular Schrödinger operator given by (1.10). In this case we show that all the nontrivial solutions in a neighborhood of $(\lambda, r_{2c\varepsilon}, 0)$ form a smooth curve in $\mathbf{R} \times \mathbf{H} \times \mathbf{H}$.

It is natural to ask how long such a branch of solutions exists. Recently, there were obtained general global bifurcation results for C^1 Fredholm mappings of index 0 which apply to a broad class of elliptic equations in $\mathbf{R}^N$ (see, e.g., [9], [10]). Using the ideas and techniques developed in [11] it can be proved that for any fixed $\lambda < q^2$, the mapping $(S, T(\lambda, \cdot, \cdot)) : (\mathbf{H} \cap V) \times \mathbf{H} \longrightarrow \mathbf{L} \times \mathbf{L}$ is Fredholm of index 0. By a general global bifurcation theorem (a variant of Theorem 6.1 in [9]), one can prove that either the branch of nontrivial solutions of (1.9)–(1.10) starting from a bifurcation point $(\lambda, r_{2c\varepsilon}, 0)$ is noncompact in $\mathbf{R} \times \mathbf{H} \times \mathbf{H}$ or it meets $[q^2, \infty) \times \mathbf{H} \times \mathbf{H}$ (note that $[q^2, \infty)$ is the essential spectrum of the linear Schrödinger operator appearing in (1.10)).

To obtain further information (such as unboundedness) about the branches of nontrivial solutions, a key ingredient would be the properness of the operator (S,T), at least on closed bounded sets. Unfortunately, it is easy to see that the operator (S,T) is not proper on closed bounded sets. Indeed, it suffices to take $r_n = r_{2c\varepsilon}(\cdot - n) + r_{2c\varepsilon}(\cdot + n)$ and to observe that $(S,T)(\lambda, r_n, 0) \longrightarrow (0,0)$ as $n \longrightarrow \infty$; the sequence (r_n) is bounded in $\mathbf{H}$ but has no convergent subsequence.

In order to obtain a more precise description of the branches of nontrivial solutions and to avoid troubles due to the lack of properness, we choose a different approach: we reformulate the problem and we work on a weighted Sobolev space (which is a subspace of $\mathbf{H}$). In section 3, we use a variant of the global bifurcation theorem of Rabinowitz [12] to obtain global branches of solutions of (1.9)–(1.10) in that space. Note that the use of a slowly increasing weight (for example, $(1+x^2)^s$ for $s > 0$) is sufficient to eliminate the lack of properness and to obtain global branches of travelling-waves. It is worth noting that for $\lambda < q^2$, any nontrivial travelling-wave which is in $\mathbf{H}$ also belongs to the weighted space which is used (i.e., there is no loss of solutions). We show that there exists exactly one branch of nontrivial solutions bifurcating from the curve $(\lambda, r_{2c\varepsilon}, 0)$ if $q \leq \frac{1}{\sqrt{2 \ln 2}}$. The number of these branches is increasing with q and tends to infinity as $q \longrightarrow \infty$. We will prove that any of these branches is either unbounded (in the weighted space) or λ tends to q^2 along it. On the other hand, we prove that there are no nontrivial solutions of (1.9)–(1.10) for $\lambda > q^2$.

2. Local curves of solutions. In order to prove a local existence result of nontrivial solitary waves for the system (1.1), we have to study the properties of the linear operator $A = -\frac{d^2}{dx^2} + q^2(1 + r_{2c\varepsilon})^2$, which can be written as $A = -\frac{d^2}{dx^2} + q^2 r_{2c\varepsilon}(2 + r_{2c\varepsilon}) + q^2$. Since $-1 < r_{2c\varepsilon}(x) < 0$ for any $x \in \mathbf{R}$, the function $r_{2c\varepsilon}(2 + r_{2c\varepsilon})$ is everywhere negative (and even). Actually, in a slightly more general framework, we will study the operator $L = -\frac{d^2}{dx^2} + V(x)$ for a negative potential V, the properties of A being then deduced from those of L by a shift. For any $\lambda \leq 0$, we also consider the Cauchy problem

$$(2.1) \qquad \begin{cases} -u''(x) + V(x)u(x) = \lambda u(x), \\ u(0) = 1, \quad u'(0) = 0. \end{cases}$$

If V is continuous and even (i.e., $V(x) = V(-x)$), it is clear that problem (2.1) has a unique *global* solution which is also even. We denote by u_λ this solution and by $n(\lambda)$ the number of zeroes of u_λ in $(0, \infty)$.

Proposition 2.1. *Let $V \in L^2 \cap L^\infty(\mathbf{R}^N)$, $V \not\equiv 0$ be continuous, less than or equal to zero, even, and satisfy $\lim_{x \longrightarrow \pm\infty} V(x) = 0$. The operator $L = -\frac{d^2}{dx^2} + V(x) : \mathbf{H} \longrightarrow \mathbf{L}$ is self-adjoint and has the following properties:*

(i) $\sigma_{ess}(L) = [0, \infty)$.

(ii) *L has at least one negative eigenvalue.*

(iii) *Any eigenvalue of L is simple.*

(iv) *For any $\lambda < 0$ and $\varepsilon > 0$, there exists $C > 0$ such that*

$$|u_\lambda^{(m)}(x)| \le Ce^{\sqrt{-\lambda+\varepsilon}|x|}, \qquad m = 0, 1, 2. \tag{2.2}$$

If $\lambda < 0$ is an eigenvalue and $0 < \varepsilon < -\lambda$, there exist $C_1, C_2, M > 0$ such that

$$C_1 e^{-\sqrt{-\lambda+\varepsilon}|x|} \le |u_\lambda^{(m)}(x)| \le C_2 e^{-\sqrt{-\lambda-\varepsilon}|x|} \qquad \text{on} \qquad [M, \infty), \qquad m = 0, 1, 2. \tag{2.3}$$

(v) *For any $\lambda \le 0$, the number of eigenvalues of L in $(-\infty, \lambda)$ is exactly $n(\lambda)$, the number of zeroes of u_λ in $(0, \infty)$.*

(vi) *If $\int_0^\infty x|V(x)|dx < \infty$, then L has at most $1 + \int_0^\infty x|V(x)|dx$ negative eigenvalues.*

Proof. (i) The operator $-\frac{d^2}{dx^2} + V(x)$ on $L^2(\mathbf{R})$ (with domain $H^2(\mathbf{R})$) is self-adjoint, so it is easy to see that L is self-adjoint. Multiplication by V is a relatively compact perturbation of $-\Delta$ and it follows from a classical theorem of Weyl that $\sigma_{ess}(L) = \sigma_{ess}(-\Delta) = [0, \infty)$.

(ii) It suffices to show that there exists $u \in \mathbf{H}$ such that $\langle Lu, u\rangle_{\mathbf{L}} < 0$ and it will follow from the min-max principle (see [13, Theorem XIII.1, p. 76]) that L has negative eigenvalues. Consider an even function $u \in C_0^\infty$ such that $u \equiv 1$ on $[-1, 1]$ and u is nonincreasing on $[0, \infty)$. Let $u_n(x) = u(\frac{x}{n})$. Then

$$\langle Lu_n, u_n\rangle_{\mathbf{L}} = \frac{1}{n}\int_{\mathbf{R}} |u'(x)|^2 dx + \int_{\mathbf{R}} \left|u\left(\frac{x}{n}\right)\right|^2 V(x)dx \longrightarrow \int_{\mathbf{R}} V(x)dx < 0$$

as $n \longrightarrow \infty$, and thus $\langle Lu_n, u_n\rangle_{\mathbf{L}} < 0$ for n sufficiently large.

(iii) Clearly, λ is an eigenvalue of L if and only if $u_\lambda \in \mathbf{H}$. If this is the case, it is obvious that $\mathrm{Ker}(L - \lambda) = Span\{u_\lambda\}$. Since L is self-adjoint, we have $\mathrm{Ker}(L - \lambda) \cap \mathrm{Im}(L - \lambda) = \{0\}$, so for any $n \in \mathbf{N}^*$ we have $\mathrm{Ker}(L - \lambda)^n = \mathrm{Ker}(L - \lambda) = Span\{u_\lambda\}$; that is, λ is a simple eigenvalue.

(iv) By (2.1), u_λ and u_λ' cannot vanish simultaneously, so u_λ must change sign any time it vanishes and u_λ has only isolated zeroes. There exists $d > 0$ such that $V(x) - \lambda > -\frac{\lambda}{2} > 0$ on $[d, \infty)$ because $V(x) \longrightarrow 0$ as $x \longrightarrow \infty$. Two situations may occur:

1. There exists $x_0 > d$ such that $u_\lambda(x_0)$ and $u_\lambda'(x_0)$ have the same sign, say, are positive. Then $u_\lambda'' = (V(x) - \lambda)u_\lambda$, and thus u_λ'' will remain positive after x_0 as long as $u_\lambda > 0$, which implies that u_λ' is increasing, hence it remains positive as long as $u_\lambda > 0$. Consequently, u_λ is increasing after x_0 as long as it remains positive, which implies that u_λ is positive and increasing on $[x_0, \infty)$. Since $u_\lambda'(x) \ge u_\lambda'(x_0) > 0$ for any $x > x_0$, we have necessarily $\lim_{x\to\infty} u_\lambda(x) = \infty$. By (2.1) we find that $\lim_{x\to\infty} u_\lambda''(x) = \infty$, so we have also $\lim_{x\to\infty} u_\lambda'(x) = \infty$. Let $f(x) = (u_\lambda'(x))^2$ and $g(x) = u_\lambda^2(x)$. Clearly, $f(x) \longrightarrow \infty$, $g(x) \longrightarrow \infty$ as $x \longrightarrow \infty$ and

$$\frac{f'(x)}{g'(x)} = \frac{u_\lambda''(x)}{u_\lambda(x)} = V(x) - \lambda \longrightarrow -\lambda \qquad \text{as } x \longrightarrow \infty.$$

L'Hôpital's rule implies that $\lim_{x\to\infty} \frac{f(x)}{g(x)} = -\lambda$, which gives $\lim_{x\to\infty} \frac{u_\lambda'(x)}{u_\lambda(x)} = \sqrt{-\lambda}$. Thus, for any $\epsilon > 0$ there exists $x_\epsilon > 0$ such that

$$\sqrt{-\lambda-\epsilon} < \frac{u_\lambda'(x)}{u_\lambda(x)} < \sqrt{-\lambda+\epsilon} \qquad \text{on } [x_\epsilon, \infty). \tag{2.4}$$

Integrating (2.4) from x_ϵ to x we get, for any $x > x_\epsilon$,

$$\sqrt{-\lambda-\epsilon}(x-x_\epsilon) < \ln u_\lambda(x) - \ln u_\lambda(x_\epsilon) < \sqrt{-\lambda+\epsilon}(x-x_\epsilon),$$

that is,

$$u_\lambda(x_\epsilon)e^{\sqrt{-\lambda-\epsilon}(x-x_\epsilon)} < u_\lambda(x) < u_\lambda(x_\epsilon)e^{\sqrt{-\lambda+\epsilon}(x-x_\epsilon)} \qquad \text{for any } x > x_\epsilon. \tag{2.5}$$

Note that the above situation always occurs if u_λ has a zero in (d,∞). Indeed, if $u_\lambda(x_0) = 0$, then necessarily $u_\lambda(x)$ and $u_\lambda'(x)$ have opposite signs for $x < x_0$ and x close to x_0 (because if u_λ and u_λ' have the same sign at some $x_1 \in (d, x_0)$, we have just seen that u_λ cannot vanish after x_1). But u_λ changes sign at x_0 and $u_\lambda'(x_0) \neq 0$, hence u_λ and u_λ' have the same sign just after x_0.

2. The functions u_λ and u_λ' have opposite signs in (d,∞). Replacing u_λ by $-u_\lambda$ if necessary, we may suppose that $u_\lambda > 0$ and $u_\lambda' < 0$ in (d,∞) (observe that u_λ' cannot vanish because it also changes sign at any zero and we would be in case 1). So u_λ is decreasing and positive on (d,∞). Let $l = \lim_{x\to\infty} u_\lambda(x)$. Clearly, $l \geq 0$. If $l > 0$, then $u_\lambda''(x) \longrightarrow -\lambda l > 0$ as $x \longrightarrow \infty$ by (2.1), which implies $u_\lambda'(x) \longrightarrow \infty$ as $x \longrightarrow \infty$, a contradiction. Thus necessarily $l = 0$. Also, u_λ' is increasing on (d,∞) (because $u_\lambda''(x) = (V(x)-\lambda)u_\lambda(x) > 0$) and negative, so it also has a limit at infinity. Since u_λ converges (to zero) at infinity, we must have $\lim_{x\to\infty} u_\lambda'(x) = 0$. Now we may apply l'Hôpital's rule to get

$$\lim_{x\to\infty} \frac{(u_\lambda'(x))^2}{u_\lambda^2(x)} = \lim_{x\to\infty} \frac{u_\lambda''(x)}{u_\lambda(x)} = \lim_{x\to\infty} (V(x)-\lambda) = -\lambda.$$

Thus $\frac{u_\lambda'(x)}{u_\lambda(x)} \longrightarrow -\sqrt{-\lambda}$ as $x \longrightarrow \infty$ because u_λ and u_λ' have opposite signs at infinity. Given $\epsilon > 0$, there exists $M > d$ such that

$$-\sqrt{-\lambda+\epsilon} < \frac{u_\lambda'(x)}{u_\lambda(x)} < -\sqrt{-\lambda-\epsilon} \qquad \text{on } [M,\infty). \tag{2.6}$$

Integrating (2.6) on $[M,x]$ we obtain, as in case 1,

$$u_\lambda(M)e^{-\sqrt{-\lambda+\epsilon}(x-M)} < u_\lambda(x) < u_\lambda(M)e^{-\sqrt{-\lambda-\epsilon}(x-M)} \qquad \text{for any } x > M. \tag{2.7}$$

Finally, (2.2) and (2.3) follow from (2.5), respectively (2.7), and the fact that $\lim_{x\to\infty} \frac{u_\lambda''(x)}{u_\lambda(x)} = -\lambda$, $\lim_{x\to\infty} \frac{u_\lambda'(x)}{u_\lambda(x)} = \pm\sqrt{-\lambda}$. It is obvious that λ is an eigenvalue of L if and only if $u_\lambda \in \mathbf{H}$, i.e., if and only if we are in case 2. Therefore assertion (iv) is proved.

Note also that u_λ has only a finite number of zeroes. Indeed, it follows from the above arguments that u_λ has at most one zero in (d,∞) and we know that any zero is isolated, and thus there are only finitely many zeroes in $[0,d]$.

The proofs of (v) and (vi) are rather classical and are similar to the proofs of Theorems XIII.8 and XIII.9, pp. 90–94 in [13]. The bound on the number of eigenvalues given by (vi) is due to Bargmann (see [13] and references therein). $\square$

COROLLARY 2.2. *The linear operator* $A = -\frac{d^2}{dx^2} + q^2(1 + r_{2c\varepsilon})^2$ *(considered on* $\mathbf{L}$ *with domain* $D(A) = \mathbf{H}$*) is self-adjoint and has the following properties:*

(i) $A \geq 2c^2\varepsilon^2 q^2$ *and* $\sigma_{ess}(A) = [q^2, \infty)$.

(ii) *A has at least one eigenvalue in* $[2c^2\varepsilon^2 q^2, q^2)$.

(iii) *Any eigenvalue of A is simple. If* $\mu < q^2$ *is an eigenvalue and* u_μ *is a corresponding eigenvector, then for any* $\epsilon > 0$*, there exist* $C_1, C_2, M > 0$ *such that*

$$C_1 e^{-\sqrt{q^2-\mu+\epsilon}|x|} \leq |u_\mu^{(m)}(x)| \leq C_2 e^{-\sqrt{q^2-\mu-\epsilon}|x|} \qquad \text{if } |x| \geq M, \quad m = 0, 1, 2. \tag{2.8}$$

(iv) *Let* N_q *be the number of eigenvalues of A in* $[2c^2\varepsilon^2 q^2, q^2)$*. We have* $N_q < 1 + (2\ln 2)q^2$*. In particular, if* $q \leq \frac{1}{\sqrt{2\ln 2}}$*, then A has exactly one eigenvalue less than* q^2.

(v) *We have* $N_q \longrightarrow \infty$ *as* $q \longrightarrow \infty$.

It can be proved that there exist $c_1, c_2, q_0 > 0$ such that $c_1 q \leq N_q \leq c_2 q$ for any $q \geq q_0$, but we will not make use of this result in what follows.

Proof. Recall that $r_{2c\varepsilon}$ is given by (1.12). We have $A = -\frac{d^2}{dx^2} + q^2 V(x) + q^2$, where the function V given by $V(x) = (1+r_{2c\varepsilon}(x))^2 - 1 = (1-2c^2\varepsilon^2)(-1+\tanh^2(\sqrt{\frac{1-2c^2\varepsilon^2}{2}}x))$ is even, negative, tends exponentially to zero as $x \longrightarrow \pm\infty$, and $\inf_{x\in\mathbf{R}} V(x) = 2c^2\varepsilon^2 - 1$. Obviously, μ is an eigenvalue of A if and only if $\mu - q^2$ is an eigenvalue of $-\frac{d^2}{dx^2} + q^2 V(x)$, so (i), (ii), and (iii) follow at once from Proposition 2.1.

An easy computation gives

$$\begin{aligned} \int_0^\infty x|V(x)|dx &= (1 - 2c^2\varepsilon^2)\int_0^\infty x\left(1 - \tanh^2\left(\sqrt{\frac{1-2c^2\varepsilon^2}{2}}x\right)\right)dx \\ &= 2\int_0^\infty y(1-\tanh^2 y)dy = 2\int_0^\infty y(\tanh y - 1)' dy = 2\ln 2. \end{aligned}$$

Now (iv) is a direct consequence of Proposition 2.1(vi).

(v) Fix $n \in \mathbf{N}$, $n \geq 1$ and take n symmetric functions $\varphi_1, \ldots, \varphi_n \in C_0^\infty(\mathbf{R})$, $\varphi_i \not\equiv 0$ such that $\text{supp}(\varphi_i) \cap \text{supp}(\varphi_j) = \emptyset$ if $i \neq j$. Clearly,

$$\langle A\varphi_i, \varphi_i\rangle_{\mathbf{L}} - q^2\langle \varphi_i, \varphi_i\rangle_{\mathbf{L}} = \int_{\mathbf{R}} |\nabla\varphi_i|^2 dx + q^2\int_{\mathbf{R}} V(x)|\varphi_i(x)|^2 dx \longrightarrow -\infty \quad \text{ as } q \longrightarrow \infty.$$

Hence, there exists $q_0 > 0$ such that for any $q \geq q_0$ and any $i = 1, \ldots, n$ we have $\langle A\varphi_i, \varphi_i\rangle_{\mathbf{L}} - q^2\langle \varphi_i, \varphi_i\rangle_{\mathbf{L}} < 0$. Since the φ_i's have disjoint supports, we get

$$\begin{aligned} &\left\langle A\left(\sum_{i=1}^n \alpha_i\varphi_i\right), \sum_{i=1}^n \alpha_i\varphi_i\right\rangle_{\mathbf{L}} - q^2\left\|\sum_{i=1}^n \alpha_i\varphi_i\right\|_{\mathbf{L}}^2 \\ &= \sum_{i=1}^n |\alpha_i|^2\left(\int_{\mathbf{R}} |\nabla\varphi_i|^2 dx + q^2\int_{\mathbf{R}} V(x)|\varphi_i(x)|^2 dx\right) < 0. \end{aligned}$$

Therefore we have found an n-dimensional subspace of $\mathbf{H}$, $V_n = Span\{\varphi_1, \ldots, \varphi_n\}$, such that $\langle Au, u\rangle_{\mathbf{L}} - q^2||u||_{\mathbf{L}} < 0$ for any $u \in V_n$ and any $q \geq q_0$. By the min-max principle (see, e.g., [13, Theorem XIII.1, p. 76]) it follows that for $q \geq q_0$, A has at least n eigenvalues less than q^2; that is, $N_q \geq n$ if $q \geq q_0$. This proves (v). ∎

We have the following result concerning the existence of nontrivial solitary waves.

THEOREM 2.3. *Let $\lambda_* < q^2$ be an eigenvalue of A and let u_* be a corresponding eigenvector. There exists $\eta > 0$ and C^∞ functions*

$$s \longmapsto (\lambda(s), r(s), u(s)) \in \mathbf{R} \times \mathbf{H} \times (u_*^\perp \cap \mathbf{H})$$

defined on $(-\eta, \eta)$ such that $\lambda(0) = \lambda_*$, $r(0) = 0$, $u(0) = 0$, and

$$S(r_{2c\varepsilon} + sr(s), s(u_* + u(s))) = 0, \quad T(\lambda(s), r_{2c\varepsilon} + sr(s), s(u_* + u(s))) = 0.$$

Moreover, there exists a neighborhood U of $(\lambda_*, r_{2c\varepsilon}, 0)$ in $\mathbf{R} \times \mathbf{H} \times \mathbf{H}$ such that any solution of $S(r,u) = 0$, $T(\lambda, r, u) = 0$ in U is either of the form $(\lambda(s), r_{2c\varepsilon} + sr(s), s(u_* + u(s)))$ or of the form $(\lambda, r_{2c\varepsilon}, 0)$.

That is, $r = r_{2c\varepsilon} + sr(s)$, $u = s(u_* + u(s))$ are nontrivial solutions of (1.9)–(1.10) for $\lambda = \lambda(s)$.

Let $g_{2c\varepsilon} : (-1, \infty) \longrightarrow \mathbf{R}$, $g_{2c\varepsilon}(x) = (1+x)^3 - (1+x) - c^2\varepsilon^2(1 + x - \frac{1}{(1+x)^3})$. Then $S(r,u)$ can be written as $S(r,u) = -r'' + g_{2c\varepsilon}(r) + (1+r)u^2$. It is easily seen that $d_r S(r_{2c\varepsilon}, 0) = -\frac{d^2}{dx^2} + g'_{2c\varepsilon}(r_{2c\varepsilon})$.

For the proof of Theorem 2.3, we need the following lemmas.

LEMMA 2.4. *The linear operator $J := -\frac{d^2}{dx^2} + g'_{2c\varepsilon}(r_{2c\varepsilon}) : \mathbf{H} \longrightarrow \mathbf{L}$ has the following properties:*

(i) *J is self-adjoint, invertible, and has the essential spectrum $\sigma_{ess}(J) = [2 - 4c^2\varepsilon^2, \infty)$.*

(ii) *J has exactly one negative eigenvalue and any eigenvalue of J is simple.*

Proof. (i) The linear operator $B = -\frac{d^2}{dx^2} + g'_{2c\varepsilon}(r_{2c\varepsilon})$ with domain $D(B) = H^2(\mathbf{R})$ is self-adjoint in $L^2(\mathbf{R})$. We claim that $\mathrm{Ker}(B) = Span\{\frac{d}{dx} r_{2c\varepsilon}\}$. Indeed, we have

$$\frac{d^2}{dx^2} r_{2c\varepsilon} = g_{2c\varepsilon}(r_{2c\varepsilon}). \tag{2.9}$$

Thus $r''_{2c\varepsilon} \in C^1(\mathbf{R})$. Differentiating (2.9) with respect to x we get $\frac{d}{dx} r_{2c\varepsilon} \in \mathrm{Ker}(B)$.

Conversely, let $h \in \mathrm{Ker}(B)$. Then $h'' = g'_{2c\varepsilon}(r_{2c\varepsilon})h$, so that

$$(h' r'_{2c\varepsilon})' = h'' r'_{2c\varepsilon} + h' r''_{2c\varepsilon} = h g'_{2c\varepsilon}(r_{2c\varepsilon}) r'_{2c\varepsilon} + h' g_{2c\varepsilon}(r_{2c\varepsilon}) = (h g_{2c\varepsilon}(r_{2c\varepsilon}))'.$$

Hence $h' r'_{2c\varepsilon} = h g_{2c\varepsilon}(r_{2c\varepsilon}) + C$ on $\mathbf{R}$. Taking the limits as $|x| \longrightarrow \infty$, we get $C = 0$, so $h' r'_{2c\varepsilon} = h g_{2c\varepsilon}(r_{2c\varepsilon}) = h r''_{2c\varepsilon}$. Since $r'_{2c\varepsilon} \neq 0$ on $(-\infty, 0)$ and on $(0, \infty)$, on each of these intervals we have $(\frac{h}{r'_{2c\varepsilon}})' = \frac{h' r'_{2c\varepsilon} - h r''_{2c\varepsilon}}{(r'_{2c\varepsilon})^2} = 0$. Thus there exist constants C_1, C_2 such that $h(x) = C_1 r'_{2c\varepsilon}(x)$ on $(-\infty, 0)$ and $h(x) = C_2 r'_{2c\varepsilon}(x)$ on $(0, \infty)$. Consequently, $h'(x) = C_1 r''_{2c\varepsilon}(x) = C_1 g(r_{2c\varepsilon}(x))$ on $(-\infty, 0)$ and $h'(x) = C_2 r''_{2c\varepsilon}(x) = C_2 g_{2c\varepsilon}(r_{2c\varepsilon}(x))$ on $(0, \infty)$. But h' is continuous because $h \in H^2(\mathbf{R})$ and therefore $C_1 = C_2$, which proves our claim.

Since $r'_{2c\varepsilon} \notin \mathbf{H}$, it is clear that the restriction of B to $\mathbf{H}$ is one-to-one from $\mathbf{H}$ into $\mathbf{L}$. It remains to prove that $B\mathbf{H} = \mathbf{L}$. It is well known that $\mathrm{Im}(B) = \mathrm{Ker}(B)^\perp = (r'_{2c\varepsilon})^\perp$ since B is self-adjoint. We have $\mathbf{L} \subset \mathrm{Im}(B)$ because $r'_{2c\varepsilon}$ is an odd function. Let $f \in \mathbf{L}$. Clearly there exists $r \in H^2(\mathbf{R})$ such that $Br = f$. Let $\tilde{r}(x) = r(-x)$. It is easy to see that $B\tilde{r} = f$, hence there exists C such that $r - \tilde{r} = C r'_{2c\varepsilon}$. Then $r - \frac{1}{2} C r'_{2c\varepsilon} = \frac{1}{2}(r + \tilde{r}) \in \mathbf{H}$ and $B(r - \frac{1}{2} C r'_{2c\varepsilon}) = f$.

Now it is clear that J, which is the restriction of B to $\mathbf{H}$, is self-adjoint in $\mathbf{L}$ and invertible. The function $g'_{2c\varepsilon}(r_{2c\varepsilon})$ tends (exponentially) to $g'_{2c\varepsilon}(0) = 2 - 4c^2\varepsilon^2$ as $x \longrightarrow \infty$. It follows from Weyl's theorem that $\sigma_{ess}(J) = \sigma_{ess}(B) = [2 - 4c^2\varepsilon^2, \infty)$. This completes the proof of (i).

(ii) It follows from Proposition 2.1(iii) and (v) that any eigenvalue of J is simple and the number of negative eigenvalues of J is exactly the number of zeroes of u in $(0,\infty)$, where u is the solution of the Cauchy problem

$$\left\{ \begin{array}{l} -u'' + g'_{2c\varepsilon}(r_{2c\varepsilon})u = 0 \quad \text{ in } [0,\infty), \\ u(0) = 1, \quad u'(0) = 0. \end{array} \right. \tag{2.10}$$

We use the following simplified version of the well-known Sturm oscillation lemma (this is also a particular case of Lemma 5 in [8]).

STURM OSCILLATION LEMMA. *Let Y and Z be nontrivial solutions of the differential equation*

$$-\varphi'' + h(x)\varphi = 0$$

on some interval (μ,ν), where h is continuous on (μ,ν). If Y and Z are linearly independent and $Y(\mu) = Y(\nu) = 0$, then Z has at least one zero in (μ,ν).

From this lemma it follows at once that J has at most one negative eigenvalue. Indeed, suppose that J has at least two negative eigenvalues. Then the solution u of (2.10) has at least two zeroes in $(0,\infty)$, say $x_1 < x_2$. But the function $r'_{2c\varepsilon}$ also satisfies the differential equation in (2.10), and obviously u and $r'_{2c\varepsilon}$ are linearly independent (because $r'_{2c\varepsilon}(0) = 0$). Using Sturm's oscillation lemma, we infer that $r'_{2c\varepsilon}$ must have a zero on (x_1,x_2), which is absurd because $r'_{2c\varepsilon}(x) > 0$ on $(0,\infty)$.

Now let us prove that J has (at least) one negative eigenvalue. We argue again by contradiction and we suppose that J has no negative eigenvalues. Then the solution u of (2.10) has no zeroes in $[0,\infty)$, consequently $u(x) > 0$ for any $x \in [0,\infty)$. Since $g'_{2c\varepsilon}(r_{2c\varepsilon}(x)) \longrightarrow 2 - 4c^2\varepsilon^2 > 0$ as $x \longrightarrow \infty$, repeating the argument used in the proof of Proposition 2.1(iv) we infer that either $u(x) \longrightarrow \infty$ or $u(x) \longrightarrow 0$ as $x \longrightarrow \infty$. In the latter case we have also

$$|u^{(m)}(x)| \le Ce^{-\sqrt{2-4c^2\varepsilon^2-\delta}|x|}, \qquad m = 0,1,2,$$

for some constant $C > 0$, $\delta \in (0, 2 - 4c^2\varepsilon^2)$, and x sufficiently large. Consequently, $u \in \mathbf{H}$ and 0 is an eigenvalue of J. But this is excluded by (i). Therefore we must have $u(x) \longrightarrow \infty$ as $x \longrightarrow \infty$.

Since $u(0) = 1$, we have $u > 0$ in a neighborhood of 0. Note that $g'_{2c\varepsilon}(r_{2c\varepsilon}(0)) = (5 + \frac{3}{2c^2\varepsilon^2})(c^2\varepsilon^2 - \frac{1}{2}) < 0$, hence $g'_{2c\varepsilon}(r_{2c\varepsilon}) < 0$ near 0. From (2.10) we get $u''(x) < 0$ for $x > 0$ and x close to 0. We have $u'(0) = 0$, so there exists $\delta > 0$ such that $u'(x) < 0$ on $(0,\delta]$. We may choose δ so small that $u(\delta) > 0$ and $r''_{2c\varepsilon}(\delta) > 0$ (note that $r''_{2c\varepsilon}(0) = g_{2c\varepsilon}(r_{2c\varepsilon}(0)) = \frac{(1-2c^2\varepsilon^2)^2}{2\sqrt{2}c\varepsilon} > 0$). Let $\beta = \frac{u(\delta)}{r'_{2c\varepsilon}(\delta)} > 0$ and let $h(x) = \beta r'_{2c\varepsilon}(x) - u(x)$. Clearly, h is a solution of the differential equation in (2.10) and $h(\delta) = 0$, $h'(\delta) = \beta r''_{2c\varepsilon}(\delta) - u'(\delta) > 0$. Hence $h(x) > 0$ for $x > \delta$ and x close to δ. On the other hand, we have $\lim_{x\longrightarrow\infty} h(x) = -\infty$, so there exists $\eta > \delta$ such that $h(\eta) = 0$. Since both $r'_{2c\varepsilon}$ and h satisfy the differential equation in (2.10), by the Sturm oscillation lemma we infer that $r'_{2c\varepsilon}$ must have a zero in (δ,η), which is absurd. This finishes the proof of Lemma 2.4. □

LEMMA 2.5. *We have the following:*

(i) $\operatorname{Ker}(T(\lambda_*, r_{2c\varepsilon}, \cdot)) = Span(u_*)$.

(ii) $\operatorname{Im}(T(\lambda_*, r_{2c\varepsilon}, \cdot)) = u_*^{\perp} \cap \mathbf{L}$.

The proof is obvious.

Proof of Theorem 2.3. Let $\tilde{V} = \{r \in \mathbf{H} \mid \sup_{x\in\mathbf{R}} |r(x)| < 1\}$ and $I = (-\sqrt{2}c\varepsilon, \sqrt{2}c\varepsilon)$. Clearly $\tilde{V}$ is open in $\mathbf{H}$. We define $F : I \times \mathbf{R} \times \tilde{V} \times (\mathbf{H} \cap u_*^\perp) \longrightarrow \mathbf{L} \times \mathbf{L}$ by

$$F(s,\lambda,r,u) = \begin{cases} \begin{pmatrix} \frac{1}{s} S(r_{2c\varepsilon} + sr, s(u_* + u)) \\ \\ \frac{1}{s} T(\lambda, r_{2c\varepsilon} + sr, s(u_* + u)) \end{pmatrix} & \text{if } s \neq 0, \\ \\ \begin{pmatrix} d_r S(r_{2c\varepsilon}, 0).r \\ T(\lambda, r_{2c\varepsilon}, u_* + u) \end{pmatrix} & \text{if } s = 0. \end{cases}$$

It is easily seen that F is C^∞ because

$$F_1(s,\lambda,r,u) = \tfrac{1}{s}\left(S(r_{2c\varepsilon} + sr, s(u_* + u)) - S(r_{2c\varepsilon}, 0)\right)$$

$$= \tfrac{1}{s}\int_0^1 \frac{d}{dt} S(r_{2c\varepsilon} + tsr, ts(u_* + u))dt$$

$$= \tfrac{1}{s}\int_0^1 d_r S(r_{2c\varepsilon} + tsr, ts(u_* + u)).sr + d_u S(r_{2c\varepsilon} + tsr, ts(u_* + u)).s(u_* + u)dt$$

$$= \int_0^1 d_r S(r_{2c\varepsilon} + tsr, ts(u_* + u)).r + d_u S(r_{2c\varepsilon} + tsr, ts(u_* + u)).(u_* + u)dt$$

and $F_2(s,\lambda,r,u) = T(\lambda, r_{2c\varepsilon} + sr, u_* + u)$.

It is also clear that $F(0,\lambda_*,0,0) = \binom{0}{0}$ and

$$d_{(\lambda,r,u)}F(0,\lambda_*,0,0)(\tilde{\lambda},\tilde{r},\tilde{u}) = \begin{pmatrix} 0 \\ -\tilde{\lambda}u_* \end{pmatrix} + \begin{pmatrix} d_r S(r_{2c\varepsilon},0).\tilde{r} \\ 0 \end{pmatrix} + \begin{pmatrix} 0 \\ T(\lambda_*, r_{2c\varepsilon}, \tilde{u}) \end{pmatrix}.$$

In view of Lemmas 2.4 and 2.5, $d_{(\lambda,r,u)}F(0,\lambda_*,0,0)$ is invertible. By the implicit function theorem, there exist $\eta > 0$ and C^∞ functions defined on $(-\eta,\eta)$,

$$s \longmapsto (\lambda(s), r(s), u(s)) \in \mathbf{R} \times \mathbf{H} \times (\mathbf{H} \cap u_*^\perp),$$

such that $\lambda(0) = \lambda_*$, $r(0) = 0$, $u(0) = 0$, and $F(s,\lambda(s),u(s),r(s)) = (0,0)$. It is obvious that for $s \neq 0$, $(\lambda(s), (r_{2c\varepsilon} + sr(s), s(u_0 + u(s))))$ satisfy the system (1.9)–(1.10). Finally, the uniqueness part in Theorem 2.3 is proved exactly in the same way as in the bifurcation from a simple eigenvalue theorem (see [4]). ∎

Remark 2.6. Let $\lambda(s)$, $r(s)$, $u(s)$ be given by Theorem 2.3. We have $\dot{\lambda}(0) = 0$, $\dot{u}(0) = 0$, and

$$\ddot{\lambda}(0) = -\frac{4q^2}{||u_*||^2_{\mathbf{L}}}\langle(1 + r_{2c\varepsilon})u_*^2, J^{-1}((1 + r_{2c\varepsilon})u_*^2)\rangle_{\mathbf{L}}, \tag{2.11}$$

where the dots denote derivatives with respect to s and J is the operator in Lemma 2.4.

To see this, we differentiate with respect to s the equation $T(\lambda(s), r_{2c\varepsilon} + sr(s), u_* + u(s)) = 0$ and then take $s = 0$ to obtain

$$-\frac{d^2}{dx^2}\dot{u}(0) + [q^2(1 + r_{2c\varepsilon})^2 - \lambda_*]\dot{u}(0) - \dot{\lambda}(0)u_* = 0, \tag{2.12}$$

that is, $(A-\lambda_*)\dot{u}(0)-\dot{\lambda}(0)u_*=0$. But $\mathrm{Im}(A-\lambda_*)$ and $\mathrm{Ker}(A-\lambda_*)=Span\{u_*\}$ are orthogonal (because A is self-adjoint), and thus (2.12) implies that $\dot{\lambda}(0)=0$ and $\dot{u}(0)=0$.

We differentiate twice with respect to s the equation $T(\lambda(s), r_{2c\varepsilon}+sr(s), u_*+u(s))=0$, then we take $s=0$ to get

$$(A-\lambda_*)\ddot{u}(0)+4q^2(1+r_{2c\varepsilon})\dot{r}(0)u_*-\ddot{\lambda}(0)u_*=0. \tag{2.13}$$

Substracting the equation $-r''_{2c\varepsilon}+g_{2c\varepsilon}(r_{2c\varepsilon})=0$ from the equation $S(r_{2c\varepsilon}+sr(s), s(u_*+u(s)))=0$ and then dividing by s we get

(2.14)
$$-\frac{d^2}{dx^2}r(s)+\int_0^1 g'_{2c\varepsilon}(r_{2c\varepsilon}+tsr(s))\,dt\cdot r(s)+s(1+r_{2c\varepsilon}+sr(s))(u_*+u(s))^2=0.$$

We differentiate (2.14) with respect to s, then we take $s=0$ to obtain

$$-\frac{d^2}{dx^2}\dot{r}(0)+g'_{2c\varepsilon}(r_{2c\varepsilon})\dot{r}(0)+(1+r_{2c\varepsilon})u_*^2=0;$$

that is, $J\dot{r}(0)+(1+r_{2c\varepsilon})u_*^2=0$, which can still be written as

$$\dot{r}(0)=-J^{-1}((1+r_{2c\varepsilon})u_*^2). \tag{2.15}$$

Taking the scalar product of (2.13) with u_* we find $\ddot{\lambda}(0)||u_*||^2_{\mathbf{L}}=4q^2\langle(1+r_{2c\varepsilon})u_*^2, \dot{r}(0)\rangle_{\mathbf{L}}$. We replace $\dot{r}(0)$ from (2.15) in the last equality to obtain (2.11).

3. Global branches of solutions. Our purpose is to obtain information about the global structure of the set of nontrivial solutions of (1.9)–(1.10). We give a nonexistence result first.

PROPOSITION 3.1. (i) *The system* (1.9)–(1.10) *does not admit solutions* $(\lambda, r, u)\in\mathbf{R}\times V\times H^1(\mathbf{R})$ *with* $(r,u)\neq(0,0)$ *if* $c\geq\frac{1}{\varepsilon\sqrt{2}}$.

(ii) *Suppose that* $c<\frac{1}{\varepsilon\sqrt{2}}$ *and let* $(\lambda, r, u)\in\mathbf{R}\times V\times H^1(\mathbf{R})$ *be a nontrivial solution of the system* (1.9)–(1.10). *Then* $2c^2\varepsilon^2q^2<\lambda\leq q^2$ *and* $-1+\sqrt{2}c\varepsilon<r(x)\leq 0$ *for any* $x\in\mathbf{R}$.

Proof. Let $(\lambda, r, u)\in\mathbf{R}\times V\times H^1(\mathbf{R})$ be a solution of (1.9)–(1.10). Since $H^1(\mathbf{R})\subset C_b(\mathbf{R})$, (1.9)–(1.10) imply that r'' and u'' are continuous; hence $r, u\in C^2(\mathbf{R})$.

If $u\equiv 0$ and $c\geq\frac{1}{\varepsilon\sqrt{2}}$, the only solution of (1.9) which tends to zero at $\pm\infty$ is $r\equiv 0$ (this was proved in [7], but can be easily deduced from the arguments below). From now on we suppose that $u\not\equiv 0$. Multiplying (1.10) by u and integrating we find

$$\int_{\mathbf{R}}|u'|^2dx+q^2\int_{\mathbf{R}}(1+r)^2|u|^2dx=\lambda\int_{\mathbf{R}}|u|^2dx. \tag{3.1}$$

Since $u\not\equiv 0$, we have necessarily $\lambda>0$. Let $G_{2c\varepsilon}(s)=\int_0^s g_{2c\varepsilon}(\tau)d\tau=\frac{1}{4}((1+s)^2-1)^2(1-\frac{2c^2\varepsilon^2}{(1+s)^2})$. Multiplying (1.9) by r' gives

$$-\frac{1}{2}[(r')^2]'+[G_{2c\varepsilon}(r)]'+\frac{1}{2}[(1+r)^2]'u^2=0, \tag{3.2}$$

and multiplying (1.10) by u' leads to

$$-\frac{1}{2}[(u')^2]'+\frac{1}{2}q^2(1+r)^2(u^2)'-\frac{\lambda}{2}(u^2)'=0. \tag{3.3}$$

From (3.2) and (3.3) we get

$$-\frac{1}{2}[(r')^2]' - \frac{1}{2q^2}[(u')^2]' + [G_{2c\varepsilon}(r)]' + \frac{1}{2}[(1+r)^2u^2]' - \frac{\lambda}{2q^2}(u^2)' = 0. \tag{3.4}$$

Integrating (3.4) from $-\infty$ to x and taking into account that $r(x) \longrightarrow 0$, $r'(x) \longrightarrow 0$, $u(x) \longrightarrow 0$, and $u'(x) \longrightarrow 0$ as $x \longrightarrow \pm\infty$, we obtain

(3.5)
$$|r'|^2(x) + \frac{1}{q^2}|u'|^2(x) + \left(\frac{\lambda}{q^2} - (1+r(x))^2\right)u^2(x) = 2G_{2c\varepsilon}(r(x)) \qquad \text{for any } x \in \mathbf{R}.$$

Suppose that there exists $x_0 \in \mathbf{R}$ such that $r(x_0) < \min(-1 + \frac{\sqrt{\lambda}}{q}, -1 + \sqrt{2}c\varepsilon)$. Then $\frac{\lambda}{q^2} - (1 + r(x_0))^2 > 0$ and the left-hand side of (3.5) is positive at x_0 (because $u(x_0) = u'(x_0) = 0$ and (1.10) would imply $u \equiv 0$) while $G_{2c\varepsilon}(r(x_0)) < 0$, a contradiction. Thus $r(x) \geq \min(-1 + \frac{\sqrt{\lambda}}{q}, -1 + \sqrt{2}c\varepsilon)$ for any $x \in \mathbf{R}$.

Suppose that $\lambda \leq 2c^2\varepsilon^2q^2$ (that is, $\frac{\sqrt{\lambda}}{q} \leq \sqrt{2}c\varepsilon$). Then we have $(1 + r(x))^2 \geq \frac{\lambda}{q^2}$ for any $x \in \mathbf{R}$ and (3.1) gives

$$\int_{\mathbf{R}} |u'|^2 dx + q^2 \int_{\mathbf{R}} \left((1+r)^2 - \frac{\lambda}{q^2}\right) u^2 dx = 0,$$

which implies $u \equiv 0$, again a contradiction. Therefore we have $\lambda > 2c^2\varepsilon^2q^2$ and $r(x) \geq -1 + \sqrt{2}c\varepsilon$ for any $x \in \mathbf{R}$. This is impossible if $\sqrt{2}c\varepsilon > 1$ because $r(x) \longrightarrow 0$ as $x \longrightarrow \pm\infty$.

Hence we cannot have solutions other than $(\lambda, 0, 0)$ if $\sqrt{2}c\varepsilon > 1$. From now on we suppose that $\sqrt{2}c\varepsilon \leq 1$. In this case we have $r \leq 0$ on $\mathbf{R}$ by the maximum principle. Indeed, the function $g_{2c\varepsilon}$ is strictly increasing and positive on $(0, \infty)$. Suppose that r achieves a positive maximum at x_0. Then $r''(x_0) \leq 0$. On the other hand, from (1.9) we infer that $r''(x_0) = g_{2c\varepsilon}(r(x_0)) + (1 + r(x_0))u^2(x_0) > 0$, which is absurd.

If $\sqrt{2}c\varepsilon = 1$ we have seen that $0 \geq r(x) \geq -1 + \sqrt{2}c\varepsilon = 0$; hence $r \equiv 0$. Then (1.10) becomes $u'' = (q^2 - \lambda)u$; together with the boundary condition $u(x) \longrightarrow 0$ as $x \longrightarrow \pm\infty$, this gives $u \equiv 0$. Thus (i) is proved.

From now on we suppose throughout that $2c^2\varepsilon^2 < 1$. Clearly, if $r(x_0) = -1+\sqrt{2}c\varepsilon$ for some $x_0 \in \mathbf{R}$, then (3.5) would imply $u(x_0) = u'(x_0) = 0$ (because $\lambda > 2c^2\varepsilon^2q^2$), hence $u \equiv 0$ by (1.10), which is impossible. Hence $0 \geq r(x) > -1 + \sqrt{2}c\varepsilon$ for any $x \in \mathbf{R}$.

It remains only to show that we cannot have nontrivial solutions with $\lambda > q^2$. Suppose that (λ, r, u) is such a solution. First, observe that r cannot vanish because (3.5) would give a contradiction. We prove that r decays sufficiently fast at infinity. Take $0 < \epsilon < \frac{\lambda}{q^2} - 1$. There exists $M_\epsilon > 0$ such that $(1 + r(x))^2 \leq 1 + \epsilon$ on $[M_\epsilon, \infty)$ (because $r(x) \longrightarrow 0$ as $x \longrightarrow \infty$). Using (3.5), we have on $[M_\epsilon, \infty)$

$$0 \leq \left(\frac{\lambda}{q^2} - 1 - \epsilon\right) u^2(x) \leq 2G_{2c\varepsilon}(r(x)),$$

hence $0 \leq (\frac{\lambda}{q^2} - 1 - \epsilon)\frac{u^2(x)}{|r(x)|} \leq 2\frac{|G_{2c\varepsilon}(r(x))|}{|r(x)|}$. Passing to the limit as $x \longrightarrow \infty$ we obtain $\lim_{x\to\infty} \frac{u^2(x)}{r(x)} = 0$. Dividing (1.9) by r we get

$$\frac{r''(x)}{r(x)} = \frac{g_{2c\varepsilon}(r(x))}{r(x)} + (1 + r(x))\frac{u^2(x)}{r(x)} \longrightarrow g'_{2c\varepsilon}(0) > 0 \qquad \text{as } x \longrightarrow \infty. \tag{3.6}$$

Since r'' must have at least one zero between two zeroes of r', (3.6) shows that r' has no zeroes in some neighborhood of infinity. In that neighborhood we have

$$\frac{(|r'(x)|^2)'}{(r^2(x))'} = \frac{r''(x)}{r(x)} \longrightarrow g'_{2c\varepsilon}(0) > 0 \qquad \text{as } x \longrightarrow \infty.$$

Since $r(x) \longrightarrow 0$ and $r'(x) \longrightarrow 0$ at infinity, we may apply l'Hôpital's rule to get $\lim_{x\to\infty}(\frac{r'(x)}{r(x)})^2 = g'_{2c\varepsilon}(0)$. We know that r and r' have constant signs in a neighborhood of infinity and that they cannot have the same sign because r tends to 0 at infinity, so necessarily $\lim_{x\to\infty}\frac{r'(x)}{r(x)} = -\sqrt{g'_{2c\varepsilon}(0)}$. The argument, already used in the proof of Proposition 2.1, shows that for any $\epsilon > 0$, there exists $C_\epsilon > 0$ such that

$$|r(x)| \le C_\epsilon e^{-\sqrt{g'_{2c\varepsilon}(0)-\epsilon}\, x} \qquad \text{for any } x \in [0,\infty).$$

Of course a similar estimate is valid on $(-\infty, 0]$. In particular, r^2+2r is a continuous, bounded function on $\mathbf{R}$ and $\lim_{x\to\pm\infty}|x|(r^2(x)+2r(x)) = 0$. Moreover, multiplication by r^2+2r is a bounded operator on $L^2(\mathbf{R})$; hence it is also bounded with respect to $-\frac{d^2}{dx^2}$ with relative bound zero. Consequently, by the Kato–Agmon–Simon theorem (see, e.g., [13, Theorem XIII.58, p. 226]), the operator $-\frac{d^2}{dx^2} + q^2(r^2+2r)$ (with domain $H^2(\mathbf{R})$ and range $L^2(\mathbf{R})$) cannot have eigenvalues embedded in the continuous spectrum $(0,\infty)$. This means exactly that the operator $-\frac{d^2}{dx^2} + q^2(1+r)^2$ has no eigenvalues in (q^2,∞) and contradicts the existence of a nontrivial solution (λ, r, u) with $\lambda > q^2$. $\square$

We will use the following variant of the global bifurcation theorem of Rabinowitz.

PROPOSITION 3.2. *Let E be a real Banach space and $\Omega \subset \mathbf{R}\times E$ an open set. Suppose that $G : \Omega \longrightarrow E$ is compact on closed, bounded subsets $\omega \subset \Omega$ such that $dist(\omega, \partial\Omega) > 0$ and is of the form $G(a,u) = L(a,u)+H(a,u)$, where L and H satisfy the following assumptions:*

(a) *$L(a,\cdot)$ is linear, compact for any fixed a and $(a,u) \longmapsto L(a,u)$ is continuous and compact on closed, bounded subsets $\omega \subset \Omega$ such that $dist(\omega, \partial\Omega) > 0$.*

(b) *For any closed, bounded subset $\omega \subset \Omega$ such that $dist(\omega, \partial\Omega) > 0$, there exists a function h_ω such that $h_\omega(s) \longrightarrow 0$ as $s \longrightarrow 0$ and*

$$||H(a,u)|| \le ||u||h_\omega(||u||) \qquad \textit{for any } (a,u) \in \omega.$$

(c) *There exists a_0 and $\epsilon > 0$ such that*
- *$(a_0, 0) \in \Omega$,*
- *for any $a \in [a_0-\epsilon, a_0+\epsilon] \setminus \{a_0\}$ we have $\mathrm{Ker}(Id - L(a,\cdot)) = \{0\}$,*
- *if $a_1 \in [a_0-\epsilon, a_0)$ and $a_2 \in (a_0, a_0+\epsilon]$, then*
$$ind(Id - L(a_1,\cdot), 0) \ne ind(Id - L(a_2,\cdot), 0).$$

Let

$$\mathcal{S} = \{(a,u) \in \Omega \mid u \ne 0 \textit{ and } u = G(a,u)\}$$

be the set of nontrivial solutions of the equation $u = G(a,u)$. Then $\mathcal{S}\cup\{(a_0,0)\}$ possesses a maximal subcontinuum (i.e., a maximal closed connected subset) $\mathcal{C}_{a_0}$ which contains $(a_0,0)$ and has at least one of the following properties:

(i) *$\mathcal{C}_{a_0}$ is unbounded.*

(ii) *$dist(\mathcal{C}_{a_0}, \partial\Omega) = 0$.*

(iii) *$\mathcal{C}_{a_0}$ meets $(a_1, 0)$, where $a_1 \ne a_0$ and $\mathrm{Ker}(Id - L(a_1,\cdot)) \ne \{0\}$.*

From the first assertion in (c) it follows that the index $ind(Id - L(a,\cdot),0) = deg(Id - L(a,\cdot), B(0,\rho), 0)$ is well defined for any $a \in [a_0 - \epsilon, a_0 + \epsilon] \setminus \{a_0\}$. By (a) and the homotopy invariance of the Leray–Schauder degree, it is a continuous function of a. Thus we have necessarily $\mathrm{Ker}(Id - L(a_0,\cdot)) \neq \{0\}$ (since otherwise $ind(Id - L(a_0,\cdot),0)$ would be defined and $ind(Id - L(a,\cdot)\ 0)$ would be constant for $a \in [a_0 - \epsilon, a_0 + \epsilon]$, contradicting the last assertion in (c)).

The proof of Proposition 3.2 is similar to that of Theorem 1.3, p. 490 in [12] (see also Corollary 1.12 in [12]).

Next, we give a reformulation of problem (1.9)–(1.10) suitable for the use of Proposition 3.2.

Equation (1.9) can be written as $-r'' + g_{2c\varepsilon}(r) + (1+r)u^2 = 0$, where $g_{2c\varepsilon}(x) = (1+x)^3 - (1+x) - c^2\varepsilon^2(1 + x - \frac{1}{(1+x)^3})$. We will seek solutions of the form $r(x) = r_{2c\varepsilon}(x) + w(x)$. Taking into account that $r_{2c\varepsilon}$ satisfies $-r''_{2c\varepsilon} + g_{2c\varepsilon}(r_{2c\varepsilon}) = 0$, (1.9) becomes

$$-w'' + g_{2c\varepsilon}(r_{2c\varepsilon} + w) - g_{2c\varepsilon}(r_{2c\varepsilon}) + (1 + r_{2c\varepsilon} + w)u^2 = 0. \tag{3.7}$$

Note that $g'_{2c\varepsilon}(0) = 2 - 4c^2\varepsilon^2 > 0$, thus the linear operator $-\frac{d^2}{dx^2} + g'_{2c\varepsilon}(0)$ (with domain $\mathbf{H}$ and range $\mathbf{L}$) is invertible, and thus (3.7) is equivalent to

(3.8)
$$\begin{aligned} w = &-\Big(-\tfrac{d^2}{dx^2} + g'_{2c\varepsilon}(0)\Big)^{-1}[g_{2c\varepsilon}(r_{2c\varepsilon} + w) - g_{2c\varepsilon}(r_{2c\varepsilon}) - g'_{2c\varepsilon}(r_{2c\varepsilon})w + (1 + r_{2c\varepsilon} + w)u^2] \\ &-\Big(-\tfrac{d^2}{dx^2} + g'_{2c\varepsilon}(0)\Big)^{-1}[(g'_{2c\varepsilon}(r_{2c\varepsilon}) - g'_{2c\varepsilon}(0))w]. \end{aligned}$$

In the same way, (1.10) can be written as

$$-u'' + (q^2 - \lambda)u = q^2(1 - (1 + r_{2c\varepsilon} + w)^2)u.$$

For $\lambda < q^2$, the linear operator $-\frac{d^2}{dx^2} + q^2 - \lambda$ is invertible and (1.10) becomes

$$\begin{aligned} u = &-q^2\left(-\frac{d^2}{dx^2} + q^2 - \lambda\right)^{-1}[(r^2_{2c\varepsilon} + 2r_{2c\varepsilon})u] \\ &-q^2\left(-\frac{d^2}{dx^2} + q^2 - \lambda\right)^{-1}[(w^2 + 2wr_{2c\varepsilon} + 2w)u]. \end{aligned} \tag{3.9}$$

We denote

$$\begin{aligned} H_1(w,u) &= \left(-\frac{d^2}{dx^2} + g'_{2c\varepsilon}(0)\right)^{-1}[g_{2c\varepsilon}(r_{2c\varepsilon} + w) - g_{2c\varepsilon}(r_{2c\varepsilon}) - g'_{2c\varepsilon}(r_{2c\varepsilon})w \\ &\qquad + (1 + r_{2c\varepsilon} + w)u^2], \\ H_2(\lambda, w, u) &= q^2\left(-\frac{d^2}{dx^2} + q^2 - \lambda\right)^{-1}[(w^2 + 2wr_{2c\varepsilon} + 2w)u], \\ A_\lambda(u) = A(\lambda, u) &= q^2\left(-\frac{d^2}{dx^2} + q^2 - \lambda\right)^{-1}[(r^2_{2c\varepsilon} + 2r_{2c\varepsilon})u], \\ B(w) &= \left(-\frac{d^2}{dx^2} + g'_{2c\varepsilon}(0)\right)^{-1}[(g'_{2c\varepsilon}(r_{2c\varepsilon}) - g'_{2c\varepsilon}(0))w]. \end{aligned}$$

It is easy to see that $A_\lambda,\ B : \mathbf{L} \longrightarrow \mathbf{H}$ are linear and continuous. Denote $V_{2c\varepsilon} = \{r \in \mathbf{H} \mid r + r_{2c\varepsilon} \in V\}$. It is obvious that $V_{2c\varepsilon}$ is open in $\mathbf{H}$. Since $\mathbf{H} \subset C_b^1(\mathbf{R})$ and $\mathbf{H}$ is an algebra, H_1 and H_2 are well defined and continuous from $V_{2c\varepsilon} \times \mathbf{H}$ and $(-\infty, q^2) \times \mathbf{H} \times \mathbf{H}$, respectively, to $\mathbf{H}$.

If $\lambda < q^2$, then (λ, r, u) satisfies the system (1.9)–(1.10) if and only if (λ, w, u) (where $w = r - r_{2c\varepsilon}$) satisfies the system (3.8)–(3.9), which is equivalent to

$$\begin{pmatrix} w \\ u \end{pmatrix} = -\begin{pmatrix} B & 0 \\ 0 & A_\lambda \end{pmatrix}\begin{pmatrix} w \\ u \end{pmatrix} - \begin{pmatrix} H_1(w,u) \\ H_2(\lambda, w, u) \end{pmatrix}. \tag{3.10}$$

We have already shown in the introduction that we cannot expect to have properness for problem (1.9)–(1.10). The counterexample that we have seen is essentially due to the invariance by translations of the system and to the fact that we have localized solutions. Of course passing from (1.9)–(1.10) to (3.10) should not prevent the same problems from appearing. To overcome this difficulty, we shall work on some weighted Sobolev space. As a "weight," we take a function $W : \mathbf{R} \longrightarrow \mathbf{R}$ which satisfies the following properties:

(W1) W is continuous and even, i.e., $W(x) = W(-x)$;

(W2) $W \geq 1$ and $\lim\limits_{x\to\infty} W(x) = \infty$;

(W3) There exists $C_W > 0$ such that $W(a+b) \leq C_W(W(a) + W(b))$.

It follows easily from (W1) and (W3) that there exist $K, s > 0$ such that $W(x) \leq K|x|^s$ for $|x| \geq 1$. Indeed, from (W3) we infer that for all $a \in \mathbf{R}$, $W(2^n a) \leq (2C_W)^n W(a)$. If $x \in [2^{n-1}, 2^n]$ and $M = \max_{x\in[0,1]} W(x)$, then

$$\begin{aligned} W(x) &\leq (2C_W)^n W\left(\frac{x}{2^n}\right) \leq 2C_W M(2C_W)^{n-1} \\ &= 2C_W M 2^{(n-1)(1+\log_2 C_W)} \leq 2C_W M x^{1+\log_2 C_W}. \end{aligned}$$

In particular, we get

$$e^{-a|\cdot|}W(\cdot) \in L^1 \cap L^\infty(\mathbf{R}) \quad \forall a > 0. \tag{W4}$$

For a function W satisfying (W1)–(W3) we consider the spaces

$$\mathbf{L}_W = \{\varphi \in \mathbf{L} \mid W\varphi \in \mathbf{L}\},$$

$$\mathbf{H}_W = \{\varphi \in \mathbf{H} \mid W\varphi, W\varphi', W\varphi'' \in \mathbf{L}\},$$

endowed with the norms $||\varphi||_{\mathbf{L}_W} = ||W\varphi||_{L^2}$, respectively $||\varphi||^2_{\mathbf{H}_W} = ||W\varphi||^2_{L^2} + ||W\varphi'||^2_{L^2} + ||W\varphi''||^2_{L^2}$. Equipped with these norms, $\mathbf{L}_W$ and $\mathbf{H}_W$ are Hilbert spaces. It is clear that $||\varphi||_{L^2} \leq ||\varphi||_{\mathbf{L}_W}$, $||\varphi||_{H^2} \leq ||\varphi||_{\mathbf{H}_W}$, and $\mathbf{L}_W$ (respectively, $\mathbf{H}_W$) is a dense subspace of $\mathbf{L}$ (respectively, of $\mathbf{H}$).

LEMMA 3.3. *The embedding $\mathbf{H}_W \subset C_b^1(\mathbf{R})$ is compact.*

Proof. It is clear that the embeddings $\mathbf{H}_W \subset H^2(\mathbf{R}) \subset C_b^1(\mathbf{R})$ are continuous. To prove compactness, consider an arbitrary sequence $u_n \rightharpoonup 0$ in $\mathbf{H}_W$ and let us show that $u_n \longrightarrow 0$ in $C_b^1(\mathbf{R})$. Fix $\epsilon > 0$. Let $K = \sup_n ||u_n||_{\mathbf{H}_W}$. There exists $M > 0$ such that $W(x) \geq \frac{K}{\epsilon}$ if $|x| \geq M$. It follows that $||u_n||_{H^2((-\infty,M)\cup(M,\infty))} \leq \epsilon$. By the Sobolev embedding theorem, we have $||u_n||_{L^\infty((-\infty,M]\cup[M,\infty))} + ||u_n'||_{L^\infty((-\infty,M]\cup[M,\infty))} \le C_S\epsilon$. On the other hand $u_{n|[-M,M]} \rightharpoonup 0$ in $H^2(-M,M)$. Since the embedding $H^2(-M,M) \subset C^1([-M,M])$ is compact, it follows that $u_n \longrightarrow 0$ in $C^1([-M,M])$, so $||u_n||_{L^\infty([-M,M])} + ||u_n'||_{L^\infty([-M,M])} \le \epsilon$ if n is sufficiently big. Thus $||u_n||_{L^\infty(\mathbf{R})} + ||u_n'||_{L^\infty(\mathbf{R})} \le (C_S+1)\epsilon$ for n sufficiently big. As ϵ was arbitrary, we infer that $u_n \longrightarrow 0$ in $C_b^1(\mathbf{R})$ and the lemma is proved. □

Lemma 3.4. *Let W satisfy* (W1)–(W3). *For any $a>0$, the operator $-\frac{d^2}{dx^2}+a : \mathbf{H}_W \longrightarrow \mathbf{L}_W$ is bounded and invertible. Moreover, the norm of $(-\frac{d^2}{dx^2}+a)^{-1}$ is uniformly bounded in $\mathcal{L}(\mathbf{L}_W,\mathbf{H}_W)$ when the parameter a remains in a compact subinterval of* $(0,\infty)$.

Proof. It is clear that

$$\left\|\left(-\frac{d^2}{dx^2}+a\right)v\right\|_{\mathbf{L}_W} = ||-v''+av||_{\mathbf{L}_W} \le C||v||_{\mathbf{H}_W},$$

and thus the operator is bounded. Since $-\frac{d^2}{dx^2}+a : \mathbf{H} \longrightarrow \mathbf{L}$ is bounded and invertible, it is clear that the restriction of $-\frac{d^2}{dx^2}+a$ to $\mathbf{H}_W$ is one-to-one and for any $f \in \mathbf{L}_W \subset \mathbf{L}$ there exists a unique $v \in \mathbf{H}$ such that $(-\frac{d^2}{dx^2}+a)v = f$. It remains only to prove that $v \in \mathbf{H}_W$ and $||v||_{\mathbf{H}_W} \le ||f||_{\mathbf{L}_W}$. Using the Fourier transform we get $(\xi^2+a)\widehat{v}(\xi) = \widehat{f}(\xi)$ or, equivalently, $\widehat{v}(\xi) = \frac{1}{\xi^2+a}\widehat{f}(\xi)$. Since $\mathcal{F}(e^{-\sqrt{a}|\cdot|})(\xi) = \frac{2\sqrt{a}}{\xi^2+a}$, we infer that

$$v = \frac{1}{2\sqrt{a}}(e^{-\sqrt{a}|\cdot|}) * f. \tag{3.11}$$

From (3.11) we get

$$\begin{aligned}|v(x)W(x)| &= \frac{1}{2\sqrt{a}}W(x)\left|\int_{\mathbf{R}} e^{-\sqrt{a}|x-y|}f(y)dy\right| \\ &\le \frac{C_W}{2\sqrt{a}}\int_{\mathbf{R}} W(x-y)e^{-\sqrt{a}|x-y|}|f(y)| + e^{-\sqrt{a}|x-y|}W(y)|f(y)|dy \\ &\le C_1(a)[((We^{-\sqrt{a}|\cdot|}) * |f|)(x) + (e^{-\sqrt{a}|\cdot|}) * (|f|W)(x)],\end{aligned}$$

that is, $|vW| \le C_1(a)[(We^{-\sqrt{a}|\cdot|}) * |f| + e^{-\sqrt{a}|\cdot|} * (|f|W)]$. But

$$||(We^{-\sqrt{a}|\cdot|}) * |f|\,||_{L^2} \le ||We^{-\sqrt{a}|\cdot|}||_{L^1}||f||_{L^2} \le ||We^{-\sqrt{a}|\cdot|}||_{L^1}||f||_{\mathbf{L}_W}$$

and

$$||e^{-\sqrt{a}|\cdot|} * (|f|W)||_{L^2} \le ||e^{-\sqrt{a}|\cdot|}||_{L^1}||Wf||_{L^2},$$

and thus we obtain from (3.11) that

$$||v||_{\mathbf{L}_W} \le C_2(a)||f||_{\mathbf{L}_W}, \tag{3.12}$$

where $C_2(a)$ remains bounded if $a \in [d,e]$, $0<d<e<\infty$.

In the same way, we have $\widehat{v'}(\xi) = i\xi\widehat{v}(\xi) = \frac{i\xi}{\xi^2+a}\widehat{f}(\xi)$; hence $v'(x) = -\frac{1}{2}\zeta_a * f(x)$, where $\zeta_a(x) = \mathrm{sgn}(x)e^{-\sqrt{a}|x|}$. Repeating the above argument we find

$$||v'W||_{L^2} \le C_3(a)||f||_{\mathbf{L}_W}, \tag{3.13}$$

where $C_3(a)$ remains bounded if a is in a compact interval of $(0,\infty)$.

Finally, using the equation satisfied by v we get $v'' = -f + av$; hence

$$||v''W||_{L^2} \le ||f||_{\mathbf{L}_W} + a||v||_{\mathbf{L}_W} \le (1 + aC_2(a))||f||_{\mathbf{L}_W}. \tag{3.14}$$

Lemma 3.4 follows from (3.12), (3.13), and (3.14). □

Note that the operator $-\frac{d^2}{dx^2} + a : \mathbf{H}_W \longrightarrow \mathbf{L}_W$ is not invertible if the weight W increases too fast at infinity. Indeed, if $f \in C_0^\infty(\mathbf{R})$ and $f \ge 0$, it is easily seen (e.g., from (3.11)) that the solution v of $-v'' + av = f$ behaves like $e^{-\sqrt{a}|\cdot|}$ at $\pm\infty$. If we take $W(x) = e^{b|x|}$ and $a < b^2$, then v does not belong to $\mathbf{H}_W$, and thus $-\frac{d^2}{dx^2} + a : \mathbf{H}_W \longrightarrow \mathbf{L}_W$ is not surjective.

The next lemma shows that we do not lose solutions if we work in $\mathbf{H}_W$ instead of $\mathbf{H}$.

Lemma 3.5. *Let (λ, r, u) be a solution of* (1.9)–(1.10) *with $r \in \mathbf{H}$, $u \in \mathbf{H}$, and $\lambda < q^2$. Then r and u belong to $\mathbf{H}_W$.*

Proof. We have already seen in Proposition 3.1 that $-1+\sqrt{2}c\varepsilon < r \le 0$. Applying Proposition 2.1(iv) (see also Corollary 2.2(iii)) for $V(x) = q^2(r^2(x) + 2r(x))$, we infer that for any $\epsilon > 0$, u, u', and u'' decay at $\pm\infty$ faster than $e^{-\sqrt{q^2-\lambda-\epsilon}|x|}$; hence $u \in \mathbf{H}_W$.

Since $g'_{2c\varepsilon}(0) > 0$ and $r(x) \longrightarrow 0$ as $|x| \longrightarrow \infty$, there exists $M > 0$ such that $r(x)g_{2c\varepsilon}(r(x)) \ge \frac{1}{2}g'_{2c\varepsilon}(0)r^2(x)$ if $|x| > M$.

Consider a symmetric function $\chi \in C_0^\infty(\mathbf{R})$ such that $\chi \equiv 1$ on $[-1,1]$, χ is nonincreasing on $[0,\infty)$, and $\operatorname{supp}(\chi) \subset [-2,2]$. We multiply (1.9) by $xr(x)\chi(\frac{x}{n})$ and integrate on $[0,\infty)$. Integrating by parts, we get

$$\begin{aligned}
&\int_0^\infty |r'|^2(x)x\chi\left(\frac{x}{n}\right)dx - \frac{1}{2}r^2(0) - \frac{1}{2}\int_0^\infty r^2(x)\left(\frac{2}{n}\chi'\left(\frac{x}{n}\right) + \frac{x}{n^2}\chi''\left(\frac{x}{n}\right)\right)dx\\
&+\int_0^M g_{2c\varepsilon}(r(x))r(x)x\chi\left(\frac{x}{n}\right)dx + \int_M^\infty g_{2c\varepsilon}(r(x))r(x)x\chi\left(\frac{x}{n}\right)dx\\
&+\int_0^\infty (1+r(x))u^2(x)r(x)x\chi\left(\frac{x}{n}\right)dx = 0.
\end{aligned} \tag{3.15}$$

By the monotone convergence theorem, the first integral in (3.15) tends to $\int_0^\infty |r'(x)|^2 xdx$ as $n \longrightarrow \infty$, while the fourth integral tends to $\int_M^\infty g_{2c\varepsilon}(r(x))r(x)xdx$. The other three integrals converge as $n \longrightarrow \infty$ by Lebesgue's theorem on dominated convergence. Letting $n \longrightarrow \infty$ in (3.15) we obtain

$$\begin{aligned}
&\int_0^\infty |r'|^2(x)xdx - \frac{1}{2}r^2(0) + \int_0^M g_{2c\varepsilon}(r(x))r(x)xdx\\
&+\int_M^\infty g_{2c\varepsilon}(r(x))r(x)xdx + \int_0^\infty r(x)(1+r(x))xu^2(x)dx = 0.
\end{aligned} \tag{3.16}$$

Since the second and the last integral in (3.16) are finite (because u decays exponentially at $\pm\infty$), we infer that $\int_0^\infty |r'|^2(x)xdx < \infty$ and $\int_M^\infty g_{2c\varepsilon}(r(x))r(x)xdx < \infty$. Consequently, $|x|^{\frac{1}{2}}r'(x)$ and $|x|^{\frac{1}{2}}r(x)$ belong to $L^2(\mathbf{R})$.

We have $g_{2c\varepsilon}(s) = g'_{2c\varepsilon}(0)s + h(s)s^2$, where h is continuous on $(-1,\infty)$; hence $h(r(x))$ is bounded. Equation (1.9) can be written as

$$-r'' + g'_{2c\varepsilon}(0)r = -(1+r)u^2 - h(r)r^2, \tag{3.17}$$

which gives, as in the proof of Lemma 3.4,

$$r = -\frac{1}{2\sqrt{g'_{2c\varepsilon}(0)}} e^{-\sqrt{g'_{2c\varepsilon}(0)}|\cdot|} * ((1+r)u^2 + h(r)r^2). \tag{3.18}$$

Suppose that $|x|^\alpha r(x) \in L^2(\mathbf{R})$ for some $\alpha > 0$. Since $|x|^\beta u(x) \in L^p(\mathbf{R})$ for any $\beta > 0$ and $1 \le p \le \infty$ we have

$$\begin{aligned} |x|^{2\alpha}|r(x)| \le C[(| \cdot |^{2\alpha} e^{-\sqrt{g'_{2c\varepsilon}(0)}|\cdot|}) * ((1+r)u^2 + h(r)r^2)(x) \\ + e^{-\sqrt{g'_{2c\varepsilon}(0)}|\cdot|} * ((1+r)u^2 | \cdot |^{2\alpha} + h(r)(| \cdot |^\alpha r)^2)](x), \end{aligned} \tag{3.19}$$

and we infer that $| \cdot |^{2\alpha} r \in L^p(\mathbf{R})$ for $1 \le p \le \infty$.

We have already proved that $|x|^{\frac{1}{2}} r(x) \in L^2(\mathbf{R})$, so it follows easily by induction that $|x|^\sigma r(x) \in L^p(\mathbf{R})$ for any $\sigma > 0$ and $1 \le p \le \infty$. Since $W(x) \le K|x|^s$ for some $K, s > 0$, we infer that $(1+r)u^2 + h(r)r^2 \in \mathbf{L}_W$. Now it follows from (3.17) and Lemma 3.4 that $r \in \mathbf{H}_W$, and Lemma 3.5 is proved. □

Now we turn our attention to the operators A, B, H_1, and H_2 appearing in (3.10).

LEMMA 3.6. *We have the following:*

(i) *For any* $\lambda \in (-\infty, q^2)$, $A_\lambda : \mathbf{H}_W \longrightarrow \mathbf{H}_W$ *is linear, compact and the mapping* $(\lambda, u) \longmapsto A_\lambda(u)$ *is continuous from* $(-\infty, q^2) \times \mathbf{H}_W$ *to* $\mathbf{H}_W$ *and compact on closed bounded subsets of* $[d, e] \times \mathbf{H}_W$ *for* $-\infty < d < e < q^2$.

(ii) *The linear operator* $B : \mathbf{H}_W \longrightarrow \mathbf{H}_W$ *is compact.*

(iii) $H_1 : ((V - r_{2c\varepsilon}) \cap \mathbf{H}_W) \times \mathbf{H}_W \longrightarrow \mathbf{H}_W$ *is continuous, compact on closed bounded subsets* ω_1 *of* $((V - r_{2c\varepsilon}) \cap \mathbf{H}_W) \times \mathbf{H}_W$ *such that* $dist(\omega_1, (\mathbf{H}_W \setminus (V - r_{2c\varepsilon})) \times \mathbf{H}_W) > 0$ *and*

$$||H_1(w, u)||_{\mathbf{H}_W} \le C_{\omega_1}(||w||^2_{\mathbf{H}_W} + ||u||^2_{\mathbf{H}_W}). \tag{3.20}$$

(iv) $H_2 : (-\infty, q^2) \times \mathbf{H}_W \times \mathbf{H}_W \longrightarrow \mathbf{H}_W$ *is continuous, compact on closed bounded subsets of* $[d, e] \times \mathbf{H}_W \times \mathbf{H}_W$ *for* $-\infty < d < e < q^2$ *and*

$$||H_2(\lambda, w, u)||_{\mathbf{H}_W} \le C_{d,e}(||w||^2_{\mathbf{H}_W} + ||w||^4_{\mathbf{H}_W} + ||u||^2_{\mathbf{H}_W}) \qquad \text{for any } \lambda \in [d, e]. \tag{3.21}$$

Proof. It is easy to see that $u_n \rightharpoonup u_*$ in $\mathbf{H}_W$ and $v_n \rightharpoonup v_*$ in $\mathbf{H}_W$ imply that $u_n v_n \longrightarrow u_* v_*$ in $\mathbf{L}_W$. Indeed, (u_n) and (v_n) are bounded in $\mathbf{H}_W$, and by Lemma 3.3 we have

$$||u_n v_n - u_* v_*||_{\mathbf{L}_W} \le ||v_n - v_*||_{L^\infty} ||u_n||_{\mathbf{L}_W} + ||u_n - u_*||_{L^\infty} ||v_*||_{\mathbf{L}_W} \longrightarrow 0 \quad \text{as } n \longrightarrow \infty. \tag{3.22}$$

(i) It is now clear that $u \longmapsto (r^2_{2c\varepsilon} + 2r^2_{2c\varepsilon})u$ is a linear compact mapping from $\mathbf{H}_W$ to $\mathbf{L}_W$, and we get (i) by using Lemma 3.4 and the resolvent formula

$$\begin{aligned} &\Big(-\frac{d^2}{dx^2} + q^2 - \lambda_1\Big)^{-1} - \Big(-\frac{d^2}{dx^2} + q^2 - \lambda_2\Big)^{-1} \\ &\quad = (\lambda_1 - \lambda_2)\Big(-\frac{d^2}{dx^2} + q^2 - \lambda_1\Big)^{-1}\Big(-\frac{d^2}{dx^2} + q^2 - \lambda_2\Big)^{-1}. \end{aligned}$$

(ii) This is obvious.

(iii) Let ω_1 be as in Lemma 3.6. We claim that there exists $\eta > 0$ such that for any $(w,u) \in \omega_1$ we have $\inf_{x\in\mathbf{R}}(w(x)+r_{2c\varepsilon}(x)) \geq -1+\eta$. We argue by contradiction and suppose that there exists a sequence $(w_n,u_n) \in \omega_1$ such that $a_n := \inf_{x\in\mathbf{R}}(w_n(x) + r_{2c\varepsilon}(x)) = (w_n + r_{2c\varepsilon})(x_n)$ tends to -1. The sequence (w_n) is bounded in $\mathbf{H}_W$; hence we may assume (passing to a subsequence if necessary) that $w_n \rightharpoonup w_*$ in $\mathbf{H}_W$. By Lemma 3.3, $w_n + r_{2c\varepsilon} \longrightarrow w_* + r_{2c\varepsilon}$ in $C^1_b(\mathbf{R})$. Since $w_*(x) + r_{2c\varepsilon}(x) \longrightarrow 0$ as $x \longrightarrow \infty$, the sequence (x_n) is bounded, say, $x_n \in [-M,M]$. Take $\chi \in C_0^\infty(\mathbf{R})$ such that $\mathrm{supp}(\chi) \subset [-M-1,M+1]$ and $\chi \equiv 1$ on $[-M,M]$. Then $\inf_{x\in\mathbf{R}}(w_n(x)+r_{2c\varepsilon}(x)-(a_n+1)\chi(x)) = w_n(x_n)+r_{2c\varepsilon}(x_n)-(a_n+1)\chi(x_n) = -1$, so that $w_n+r_{2c\varepsilon}-(a_n+1)\chi \notin V$ and

$$dist(w_n, \mathbf{H}_W \setminus (V - r_{2c\varepsilon})) \leq dist(w_n, w_n - (a_n+1)\chi) = |1+a_n|\ ||\chi||_{\mathbf{H}_W} \longrightarrow 0$$

as $n \longrightarrow \infty$, contradicting the fact that $(w_n,u_n) \in \omega_1$. This proves the claim.

For a given $w \in V - r_{2c\varepsilon}$, we have

$$\begin{aligned}
&(g_{2c\varepsilon}(r_{2c\varepsilon}+w) - g_{2c\varepsilon}(r_{2c\varepsilon}) - g'_{2c\varepsilon}(r_{2c\varepsilon})w)(x)\\
&\quad = \int_0^1 g'_{2c\varepsilon}(r_{2c\varepsilon}+tw)w(x)dt - g'_{2c\varepsilon}(r_{2c\varepsilon})w(x)\\
&\quad = w^2(x)\int_0^1\int_0^1 g''_{2c\varepsilon}(r_{2c\varepsilon}+tsw)(x)ds\ t\ dt = w^2(x)h_1(w)(x),
\end{aligned}$$

where $h_1(w)(x) = \int_0^1\int_0^1 g''_{2c\varepsilon}(r_{2c\varepsilon}+tsw)(x)ds\ t\ dt$.

To prove (iii) it suffices to show that for any sequence $(w_n,u_n) \in \omega_1$ such that $w_n \rightharpoonup w_*$ and $u_n \rightharpoonup u_*$ in $\mathbf{H}_W$, we have $H_1(w_n,u_n) \longrightarrow H_1(w_*,u_*)$ in $\mathbf{H}_W$. In view of Lemma 3.4, it suffices to show that

(3.23)
$$h_1(w_n)w_n^2 + (1+r_{2c\varepsilon}+w_n)u_n^2 \longrightarrow h_1(w_*)w_*^2 + (1+r_{2c\varepsilon}+w_*)u_*^2 \qquad \text{in } \mathbf{L}_W.$$

The sequence (w_n) being bounded in $\mathbf{H}_W$, there exists $K > 0$ such that $-1 + \min(\eta, \sqrt{2}c\varepsilon) \leq r_{2c\varepsilon}(x) + stw_n(x) \leq K$ for any $x \in \mathbf{R}$, $n \in \mathbf{N}$, and $s, t \in [0,1]$. Since $g''_{2c\varepsilon}$ is uniformly continuous on $[-1+\min(\eta,\sqrt{2}c\varepsilon), K]$, it is standard to prove that $h_1(w_n) \longrightarrow h_1(w_*)$ in $L^\infty(\mathbf{R})$, and then (3.23) follows from (3.22). Finally, using Lemma 3.4 we have for any $(w,u) \in \omega_1$

$$||H_1(w,u)||_{\mathbf{H}_W} \leq C||h_1(w)w^2 + (1+r_{2c\varepsilon}+w)u^2||_{\mathbf{L}_W} \leq C_{\omega_1}(||w||^2_{\mathbf{H}_W} + ||u||^2_{\mathbf{H}_W}).$$

(iv) From the preceding arguments it is easy to see that the mapping $(w,u) \longmapsto (w^2 + 2wr_{2c\varepsilon} + 2w)u$ is continuous from $\mathbf{H}_W \times \mathbf{H}_W$ to $\mathbf{L}_W$ and the image of any bounded set in $\mathbf{H}_W \times \mathbf{H}_W$ is precompact in $\mathbf{L}_W$, so (iv) follows from Lemma 3.4 and the resolvent formula above. The estimate (3.21) is straightforward. ∎

LEMMA 3.7. *For any $\lambda < q^2$ we have the following:*

(i) $\mathrm{Ker}(Id_{\mathbf{H}_W} + A_\lambda) \neq \{0\}$ *if and only if λ is an eigenvalue of the operator $A = -\frac{d^2}{dx^2} + q^2(1+r_{2c\varepsilon})^2$. In this case we have $\mathrm{Ker}(Id_{\mathbf{H}_W} + A_\lambda)^n = Span\{u_\lambda\}$ for any $n \in \mathbf{N}^*$.*

(ii) *If λ is not an eigenvalue of A, then $ind(Id_{\mathbf{H}_W} + A_\lambda, 0) = (-1)^{n(\lambda)}$ (where $n(\lambda)$ is the number of eigenvalues of A less than λ).*

Proof. (i) It is easy to see that $u \in \mathbf{L}$ and $u + A_\lambda u = 0$ is equivalent to $u \in \mathbf{H}$ and $Au = \lambda u$. Recall that if $\lambda < q^2$ is an eigenvalue of A in $\mathbf{L}$, then the corresponding eigenvector u_λ is in $\mathbf{H}_W$ by Corollary 2.2(iii). Consequently, we have $\mathrm{Ker}(Id_{\mathbf{H}_W} + A_\lambda) = \mathrm{Ker}(Id_{\mathbf{L}} + A_\lambda) = \mathrm{Ker}(\lambda Id_{\mathbf{H}} - A) = Span\{u_\lambda\}$.

To prove (i), it suffices to show that $u_\lambda \notin \mathrm{Im}(Id_{\mathbf{L}} + A_\lambda)$. Suppose by contradiction that there exists $v \in \mathbf{L}$ such that $v + A_\lambda v = u_\lambda$. This is equivalent to $v \in \mathbf{H}$ and $Av - \lambda v = -u''_\lambda + (q^2-\lambda)u_\lambda$, that is, $-u''_\lambda + (q^2-\lambda)u_\lambda \in \mathrm{Im}(A-\lambda)$. Since $A-\lambda$ is self-adjoint on $\mathbf{L}$, $-u''_\lambda + (q^2-\lambda)u_\lambda$ must be orthogonal (in $\mathbf{L}$) to $\mathrm{Ker}(A-\lambda) = Span\{u_\lambda\}$, which gives $\int_{\mathbf{R}} |u'_\lambda|^2 dx + (q^2-\lambda)\int_{\mathbf{R}} |u_\lambda|^2 dx = 0$, a contradiction.

(ii) A well-known result of Leray and Schauder asserts that if K is a compact operator on a real Banach space X and 1 is not an eigenvalue of K, then

$$ind(Id - K, 0) = (-1)^\beta,$$

where β is the sum of all the (algebraic) multiplicities of eigenvalues of K greater than 1 (see, e.g., [6, Theorem 4.6, p. 133]).

Thus, for a given λ which is not an eigenvalue of A, we are interested in the eigenvalues $\mu > 1$ of $-A_\lambda$. Clearly, $-A_\lambda u = \mu u$ is equivalent to

$$q^2\left(-\frac{d^2}{dx^2} + q^2 - \lambda\right)^{-1}((r_{2c\varepsilon}^2 + 2r_{2c\varepsilon})u) + \mu u = 0,$$

that is,

$$-u'' + q^2(1+r_{2c\varepsilon})^2 u + q^2\left(1 - \frac{1}{\mu}\right)[1-(1+r_{2c\varepsilon})^2]u = \lambda u.$$

In other words, $\mu > 1$ is an eigenvalue of $-A_\lambda$ if and only if λ is an eigenvalue of the operator

$$\begin{aligned} M_\mu &= -\frac{d^2}{dx^2} + q^2(1+r_{2c\varepsilon})^2 + q^2\left(1-\frac{1}{\mu}\right)[1-(1+r_{2c\varepsilon})^2] \\ &= A + q^2\left(1-\frac{1}{\mu}\right)[1-(1+r_{2c\varepsilon})^2]. \end{aligned}$$

Note that $M_\mu \geq A$ for any $\mu \geq 1$ and $\sigma_{ess}(M_\mu) = [q^2, \infty)$ by Weyl's theorem. By Proposition 2.1(iv), $\lambda \in (-\infty, q^2)$ is an eigenvalue of M_μ considered as an operator on $\mathbf{L}_W$ if and only if λ is an eigenvalue of M_μ considered as an operator on $\mathbf{L}$. We will work on $\mathbf{L}$ because on this space M_μ is self-adjoint.

If $\lambda < q^2$ is not an eigenvalue of A, we will prove that there are exactly $n(\lambda)$ values $\mu \in (1,\infty)$ such that λ is an eigenvalue of M_μ.

For $\mu \in [1,\infty)$, we define

$$\alpha_n(\mu) = \sup_{\varphi_1,\dots,\varphi_{n-1}\in\mathbf{H}} \inf_{\psi\in\{\varphi_1,\dots,\varphi_{n-1}\}^\perp} \frac{\langle M_\mu\psi,\psi\rangle_{\mathbf{L}}}{||\psi||^2_{\mathbf{L}}}. \tag{3.24}$$

By the min-max principle ([13, Theorem XIII.1, p. 76]), either $\alpha_n(\mu)$ is the nth eigenvalue of M_μ (counted with multiplicity) or $\alpha_n(\mu) = q^2$. By Proposition 2.1(iii), the eigenvalues of M_μ are simple, thus we have $\alpha_p(\mu) < \alpha_n(\mu)$ if $p < n$ and $\alpha_p(\mu) < q^2$.

It is obvious that the functions $\mu \longmapsto \alpha_n(\mu)$ are increasing on $[1,\infty)$ because $M_{\mu_1} \leq M_{\mu_2}$ if $1 \leq \mu_1 < \mu_2$. In fact, α_n is strictly increasing on $\{\mu \in [1,\infty) \mid \alpha_n(\mu) < q^2\}$. To see this, consider $\mu_1 < \mu_2$ such that $\alpha_n(\mu_2) < q^2$. Then $\alpha_1(\mu_2), \dots, \alpha_n(\mu_2)$ are eigenvalues of M_{μ_2}. Let $u_1, \dots, u_n \in \mathbf{H}$ be corresponding eigenvectors with $||u_i||_{\mathbf{L}} = 1$.

Clearly, $u_1, \dots, u_n$ are mutually orthogonal in $\mathbf{L}$ and it is easily seen from the definition of M_μ that $\langle M_{\mu_1} u_i, u_i \rangle_{\mathbf{L}} < \langle M_{\mu_2} u_i, u_i \rangle_{\mathbf{L}} = \alpha_i(\mu_2)$, $i = 1, \dots, n$. Note that the quantity $N(u) = (\int_{\mathbf{R}} [1 - (1 + r_{2c\varepsilon})^2] |u|^2 dx)^{\frac{1}{2}}$ is a norm on $\mathbf{L}$. Since $Span\{u_1, \dots, u_n\}$ is finite dimensional, there exists $N_1 > 0$ such that $N(u) \geq N_1 ||u||_{\mathbf{L}}$ for any $u \in Span\{u_1, \dots, u_n\}$. Therefore

(3.25)
$$\begin{aligned}
&\left\langle M_{\mu_1} \left(\sum_{i=1}^{n} a_i u_i \right), \left(\sum_{i=1}^{n} a_i u_i \right) \right\rangle_{\mathbf{L}} \\
&= \left\langle M_{\mu_2} \left(\sum_{i=1}^{n} a_i u_i \right), \left(\sum_{i=1}^{n} a_i u_i \right) \right\rangle_{\mathbf{L}} - \left\langle (M_{\mu_2} - M_{\mu_1}) \left(\sum_{i=1}^{n} a_i u_i \right), \left(\sum_{i=1}^{n} a_i u_i \right) \right\rangle_{\mathbf{L}} \\
&= \sum_{i=1}^{n} \alpha_i(\mu_2) |a_i|^2 - q^2 \left(\frac{1}{\mu_1} - \frac{1}{\mu_2} \right) \int_{\mathbf{R}} [1 - (1 + r_{2c\varepsilon})^2] \left| \sum_{i=1}^{n} a_i u_i \right|^2 dx \\
&\leq \alpha_n(\mu_2) \left\| \sum_{i=1}^{n} a_i u_i \right\|_{\mathbf{L}}^2 - q^2 \left(\frac{1}{\mu_1} - \frac{1}{\mu_2} \right) N_1^2 \left\| \sum_{i=1}^{n} a_i u_i \right\|_{\mathbf{L}}^2 .
\end{aligned}$$

Thus for any u in the n-dimensional subspace $Span\{u_1, \dots, u_n\}$ we have

$$\langle M_{\mu_1} u, u \rangle_{\mathbf{L}} \leq \left(\alpha_n(\mu_2) - q^2 \left(\frac{1}{\mu_1} - \frac{1}{\mu_2} \right) N_1^2 \right) ||u||_{\mathbf{L}}^2 .$$

By the min-max principle it follows that $\alpha_n(\mu_1) \leq \alpha_n(\mu_2) - q^2 (\frac{1}{\mu_1} - \frac{1}{\mu_2}) N_1^2$.

A standard argument shows that each α_n is continuous. Indeed, suppose by contradiction that $\mu_* \in (1, \infty)$ is a discontinuity point. Then necessarily $l_1 := \sup_{\mu < \mu_*} \alpha_n(\mu) < \inf_{\mu > \mu_*} \alpha_n(\mu) := l_2$. Take $0 < \epsilon < \frac{l_2 - l_1}{4}$ and $\mu_1 < \mu_*$, $\mu_2 > \mu_*$ such that $q^2 (\frac{1}{\mu_1} - \frac{1}{\mu_2}) < \epsilon$. Since $\alpha_n(\mu_2) > l_2 - \epsilon$, there exist $\varphi_1, \dots, \varphi_{n-1} \in \mathbf{H}$ such that $\langle M_{\mu_2} \psi, \psi \rangle_{\mathbf{L}} > l_2 - \epsilon$ for any $\psi \in \{\varphi_1, \dots, \varphi_{n-1}\}^\perp$ with $||\psi||_{\mathbf{L}} = 1$. We have

$$\begin{aligned}
&\langle M_{\mu_2} \psi, \psi \rangle_{\mathbf{L}} - \langle M_{\mu_1} \psi, \psi \rangle_{\mathbf{L}} \\
&= q^2 \left(\frac{1}{\mu_1} - \frac{1}{\mu_2} \right) \int_{\mathbf{R}} [1 - (1 + r_{2c\varepsilon})^2] |\psi|^2 dx \leq q^2 \left(\frac{1}{\mu_1} - \frac{1}{\mu_2} \right) ||\psi||_{\mathbf{L}}^2 < \epsilon;
\end{aligned}$$

thus $\langle M_{\mu_1} \psi, \psi \rangle_{\mathbf{L}} > l_2 - 2\epsilon$ for any $\psi \in \{\varphi_1, \dots, \varphi_{n-1}\}^\perp$ with $||\psi||_{\mathbf{L}} = 1$. Therefore $\alpha_n(\mu_1) > l_2 - 2\epsilon$, which is a contradiction.

We also have for any $u \in \mathbf{H}$

$$\langle M_\mu u, u \rangle_{\mathbf{L}} = ||u'||_{L^2}^2 + q^2 ||u||_{\mathbf{L}}^2 - \frac{q^2}{\mu} \int_{\mathbf{R}} [1 - (1 + r_{2c\varepsilon})^2] |u|^2 dx \geq q^2 ||u||_{\mathbf{L}}^2 - \frac{C}{\mu} ||u||_{\mathbf{L}}^2 ;$$

hence $\alpha_1(\mu) \geq q^2 - \frac{C}{\mu} \longrightarrow q^2$ as $\mu \longrightarrow \infty$. Consequently, $\alpha_n(\mu) \longrightarrow q^2$ as $\mu \longrightarrow \infty$ for any $n \geq 1$.

Note that $\lambda < q^2$ is an eigenvalue of M_μ if and only if $\lambda = \alpha_n(\mu)$ for some $n \in \mathbf{N}^*$. We know that there are exactly $n(\lambda)$ eigenvalues of A less than λ, say, $\lambda_1 < \lambda_2 < \dots < \lambda_{n(\lambda)} < \lambda$. We have $\alpha_i(1) = \lambda_i$ because $M_1 = A$, and the functions α_i are strictly increasing (until they reach the value q^2, if this happens) and continuous, and they tend to q^2 at infinity. We infer that for each $i \in \{1, \dots, n(\lambda)\}$, there exists exactly one value μ_i such that $\alpha_i(\mu_i) = \lambda$. Moreover, $\mu_1 > \mu_2 > \cdots > \mu_{n(\lambda)} > 1$. For any $n > n(\lambda)$, we have $\alpha_n(1) > \lambda$, hence $\alpha_n(\mu) > \lambda$ for $\mu \in (0, \infty)$ because α_n is increasing.

Thus we have shown that the operator $-A_\lambda$ has exactly $n(\lambda)$ eigenvalues greater than 1, $\mu_1 > \mu_2 > \cdots > \mu_{n(\lambda)}$. Moreover, $\mathrm{Ker}(\mu_i + A_\lambda) = \mathrm{Ker}(M_{\mu_i} - \lambda)$. We know by Proposition 2.1(iii) that $\mathrm{Ker}(M_{\mu_i} - \lambda)$ is one dimensional. If this kernel is spanned by a function v_i, then $v_i \notin \mathrm{Im}(\mu_i + A_\lambda)$. Indeed, $\mu_i u + A_\lambda u = v_i$ would imply $(M_{\mu_i} - \lambda)u = \frac{1}{\mu_i}(-v_i'' + (q^2 - \lambda)v_i)$. Since M is self-adjoint, $-v_i'' + (q^2 - \lambda)v_i$ would be orthogonal to $\mathrm{Ker}(M_{\mu_i} - \lambda) = Span\{v_i\}$, which gives a contradiction. Consequently, we have $\mathrm{Ker}(\mu_i + A_\lambda)^n = Span\{v_i\}$ for any $n \in \mathbf{N}^*$; that is, μ_i is a simple eigenvalue of $-A_\lambda$.

As a consequence, we have $ind(Id_{\mathbf{H}_W} + A_\lambda, 0) = (-1)^{n(\lambda)}$ and Lemma 3.7 is proved. □

We are now in position to state the main result of this paper.

THEOREM 3.8. *Let $\mathcal{S}$ be the set of nontrivial solutions of the system* (1.9)–(1.10) *in $\mathbf{R} \times (\mathbf{H} \cap V) \times \mathbf{H}$. For any eigenvalue $\lambda_m < q^2$ of $A = -\frac{d^2}{dx^2} + (1 + r_{2c\varepsilon})^2$, the set $\mathcal{S} \cup \{(\lambda_m, r_{2c\varepsilon}, 0)\}$ contains a maximal closed connected subset $\mathcal{C}_m$ in $(-\infty, q^2) \times \mathbf{H}_W \times \mathbf{H}_W$ such that $\mathcal{C}_m \cap \mathcal{C}_p = \emptyset$ if $m \neq p$ and $\mathcal{C}_m$ satisfies at least one of the two following properties:*

(i) *$\mathcal{C}_m$ is unbounded in $\mathbf{R} \times \mathbf{H}_W \times \mathbf{H}_W$.*

(ii) *There exists a sequence $(\lambda_n, r_n, u_n) \in \mathcal{C}_m$ such that $\lambda_n \longrightarrow q^2$ as $n \longrightarrow \infty$.*

Proof. We have already seen that $(\lambda, r, u) \in (-\infty, q^2) \times (\mathbf{H} \cap V) \times \mathbf{H}$ is a nontrivial solution of (1.9)–(1.10) if and only if $(\lambda, r - r_{2c\varepsilon}, u)$ belongs to $(-\infty, q^2) \times (\mathbf{H}_W \cap (V - r_{2c\varepsilon})) \times \mathbf{H}_W$ and satisfies the system (3.8)–(3.9) (or, equivalently, (3.10)).

Let $E = \mathbf{H}_W \times \mathbf{H}_W$, $\Omega = (-\infty, q^2) \times (\mathbf{H}_W \cap (V - r_{2c\varepsilon})) \times \mathbf{H}_W$, $L_\lambda = \begin{pmatrix} -B & 0 \\ 0 & -A_\lambda \end{pmatrix}$, and $H(\lambda, w, u) = \begin{pmatrix} -H_1(w,u) \\ -H_2(\lambda,w,u) \end{pmatrix}$. Let $G(\lambda, w, u) = L_\lambda(w, u) + H(\lambda, w, u)$. It is obvious that on Ω, (3.10) is equivalent to the equation $(w, u) = G(\lambda, w, u)$. It follows easily from Lemma 3.6 that L and H satisfy assumptions (a) and (b) in Proposition 3.2.

We claim that $Id_{\mathbf{H}_W} + B : \mathbf{H}_W \longrightarrow \mathbf{H}_W$ is invertible. Indeed, $(Id_{\mathbf{H}_W} + B)u = v$ is equivalent to $-u'' + g_{2c\varepsilon}'(r_{2c\varepsilon})u = (-\frac{d^2}{dx^2} + g_{2c\varepsilon}'(0))v$. By Lemma 2.4, there exists a unique $u \in \mathbf{H}$ satisfying this equation. We have

$$-u'' + g_{2c\varepsilon}'(0)u = \left(-\frac{d^2}{dx^2} + g_{2c\varepsilon}'(0)\right)v + (g_{2c\varepsilon}'(0) - g_{2c\varepsilon}'(r_{2c\varepsilon}))u \in \mathbf{L}_W$$

(recall that $v \in \mathbf{H}_W$ and $g_{2c\varepsilon}'(0) - g_{2c\varepsilon}'(r_{2c\varepsilon})$ decays exponentially at infinity). Using Lemma 3.4, we infer that $u \in \mathbf{H}_W$.

For $\lambda < q^2$, it is clear that $Id_{\mathbf{H}_W \times \mathbf{H}_W} - L_\lambda$ is not invertible if and only if $Id_{\mathbf{H}_W} + A_\lambda$ is not invertible, i.e., if and only if λ is an eigenvalue of A. Let $\lambda_1 < \lambda_2 < \cdots < \lambda_{N_q} < q^2$ be the eigenvalues of A below q^2. If λ is not an eigenvalue of A, we infer using Lemma 3.7 that $i(\lambda) := ind(Id_{\mathbf{H}_W \times \mathbf{H}_W} - L_\lambda, 0) = ind(Id_{\mathbf{H}_W} + A_\lambda, 0) \cdot ind(Id_{\mathbf{H}_W} + B, 0) = (-1)^{n(\lambda)} ind(Id_{\mathbf{H}_W} + B, 0)$ is constant on each of the intervals $(-\infty, \lambda_1), (\lambda_i, \lambda_{i+1}), (\lambda_{N_q}, q^2)$ and changes sign at each λ_i. Consequently, L_λ also satisfies assumption (c) in Proposition 3.2 at any point $(\lambda_i, 0, 0)$. Let $\tilde{\mathcal{S}}_0 = \{(\lambda, w, u) \in \Omega \mid (w, u) \neq (0, 0)$ and (λ, w, u) satisfies (3.10)$\}$ and let $\tilde{\mathcal{S}} = \tilde{\mathcal{S}}_0 \setminus \{(\lambda, -r_{2c\varepsilon}, 0) \mid \lambda \in (-\infty, q^2)\}$. Note that the solutions $(\lambda, -r_{2c\varepsilon}, 0)$ of (3.10) correspond to the solutions $(\lambda, 0, 0)$ of (1.9)–(1.10) and $\mathcal{S} \cap ((-\infty, q^2) \times (V \cap \mathbf{H}_W) \times \mathbf{H}_W) = \tilde{\mathcal{S}} + (0, r_{2c\varepsilon}, 0)$. We may apply Proposition 3.2 to infer that for any $1 \leq m \leq N_q$, there exists a maximal closed connected subset $\mathcal{D}_m$ (in Ω) of $\tilde{\mathcal{S}}_0 \cup \{(\lambda_m, 0, 0)\}$ which contains $(\lambda_m, 0, 0)$ and satisfies at least one of the following properties:

1. $\mathcal{D}_m$ is unbounded.
2. There exists a sequence $(\lambda_n, w_n, u_n) \in \mathcal{D}_m$ such that $\lambda_n \longrightarrow q^2$ as $n \longrightarrow \infty$.
3. There exists a sequence $(\lambda_n, w_n, u_n) \in \mathcal{D}_m$ such that $dist(w_n, \partial((V - r_{2c\varepsilon}) \cap \mathbf{H}_W)) \longrightarrow 0$, that is, $\inf_{x\in\mathbf{R}}(w_n(x) + r_{2c\varepsilon}(x)) \longrightarrow -1$ as $n \longrightarrow \infty$.
4. The closure in Ω of $\mathcal{D}_m$ contains a point $(\lambda_i, 0, 0)$ with $i \neq m$.

Let us show first that $\mathcal{D}_m$ cannot meet $\{(\lambda, -r_{2c\varepsilon}, 0) \mid \lambda \in (-\infty, q^2)\}$. A straightforward computation gives $d_{(w,u)}(Id_E - G)(\lambda, -r_{2c\varepsilon}, 0) = Id_E$ for any $\lambda < q^2$. By the implicit function theorem, there exists a neighborhood N_λ of $(\lambda, -r_{2c\varepsilon}, 0)$ in $\mathbf{R} \times E$ such that the only solutions of the equation $(w, u) = G(\lambda, w, u)$ in N_λ are $(\mu, -r_{2c\varepsilon}, 0)$. Hence $\cup_\lambda N_\lambda$ is a neighborhood of $\{(\lambda, -r_{2c\varepsilon}, 0) \mid \lambda < q^2\}$ in Ω which contains no other solutions of (3.10). Consequently, we have $\mathcal{D}_m \subset \tilde{\mathcal{S}}$.

By Proposition 3.1, for any $(\lambda, w, u) \in \tilde{\mathcal{S}}_0$ we have $\inf_{x\in\mathbf{R}}(w(x) + r_{2c\varepsilon}(x)) > -1 + \sqrt{2}c\varepsilon$; hence $\mathcal{D}_m$ cannot satisfy property 3.

We will also eliminate the alternative 4. Observe that if $(\lambda, r, u) \in (-\infty, q^2) \times \mathbf{H} \times \mathbf{H}$ is a nontrivial solution of (1.9)–(1.10), then, in particular, u is an eigenvector of the linear operator $-\frac{d^2}{dx^2} + q^2(1 + r)^2$ corresponding to the eigenvalue λ. It is easily checked that this operator is a compact perturbation of $-\frac{d^2}{dx^2} + q^2$, so it has the essential spectrum $[q^2, \infty)$. Since $\lambda < q^2$, the operator $-\frac{d^2}{dx^2} + q^2(1 + r)^2$ has only a finite number of eigenvalues less than λ, say p. We define $z(\lambda, r, u) = p$. By Proposition 2.1(v), we know that u has exactly p zeroes in $(0, \infty)$. We also define $z(\lambda_i, r_{2c\varepsilon}, 0) = i - 1$. We have the following lemma.

LEMMA 3.9. *The function z is continuous on* $(\mathcal{S} \cup \{(\lambda_i, r_{2c\varepsilon}, 0) \mid i = 1, \ldots, N_q\}) \cap ((-\infty, q^2) \times \mathbf{H} \times \mathbf{H})$.

Assume for the moment that Lemma 3.9 holds. Obviously, the function z is also continuous for the $\mathbf{R} \times E$ topology. Since z takes values in $\mathbf{N}$, it must be constant on each connected component of $(\mathcal{S} \cup \{(\lambda_i, r_{2c\varepsilon}, 0) \mid i = 1, \ldots, N_q\}) \cap ((-\infty, q^2) \times \mathbf{H} \times \mathbf{H}) = (\tilde{\mathcal{S}} + (0, r_{2c\varepsilon}, 0)) \cup \{(\lambda_i, r_{2c\varepsilon}, 0) \mid i = 1, \ldots, N_q\}$. In particular, it is constant on $\mathcal{D}_m + (0, r_{2c\varepsilon}, 0)$ and we find $z(\mathcal{D}_m + (0, r_{2c\varepsilon}, 0)) = z(\lambda_m, r_{2c\varepsilon}, 0) = m - 1$. We have also $z(\mathcal{D}_i + (0, r_{2c\varepsilon}, 0)) = i - 1$; hence $\mathcal{D}_m$ and $\mathcal{D}_i$ are disjoint if $i \neq m$ (in fact, we see that the closures of $\mathcal{D}_m$ and $\mathcal{D}_i$ in $(-\infty, q^2) \times \mathbf{H} \times \mathbf{H}$ are disjoint if $i \neq m$). Thus $\mathcal{D}_m$ cannot satisfy alternative 4 above; hence it necessarily satisfies one of alternatives 1 or 2. Let $\mathcal{C}_m = \mathcal{D}_m + (0, r_{2c\varepsilon}, 0)$. It is now clear that $\mathcal{C}_m$ satisfies (i) or (ii) in Theorem 3.8. $\square$

Proof of Lemma 3.9. Let $(\lambda, r, u), (\nu_n, r_n, u_n) \in (\mathcal{S} \cup \{(\lambda_i, r_{2c\varepsilon}, 0) \mid i = 1, \ldots, N_q\}) \cap ((-\infty, q^2) \times \mathbf{H} \times \mathbf{H})$ be such that $z(\lambda, r, u) = p$ and $(\nu_n, r_n, u_n) \longrightarrow (\lambda, r, u)$ as $n \longrightarrow \infty$. Let $\mu_1 < \mu_2 < \cdots < \mu_{p+1} = \lambda$ be the eigenvalues of the operator $B = -\frac{d^2}{dx^2} + q^2(1 + r)^2$ in $\mathbf{L}$ and let $u_1^*, \ldots, u_{p+1}^* = u$ be corresponding eigenvectors. Denote $B_n = -\frac{d^2}{dx^2} + q^2(1 + r_n)^2$.

We prove that $z(\nu_n, r_n, u_n) \geq p$ if n is sufficiently big. There is nothing to do if $p = 0$. Suppose that $p \geq 1$. Take $0 < \epsilon < \frac{\mu_{p+1} - \mu_p}{4}$ and let n_0 be sufficiently big, so that $||(r_n - r)(2 + r_n + r)||_{L^\infty} < \frac{\epsilon}{q^2}$ and $\lambda - \epsilon < \nu_n < \lambda + \epsilon$ for any $n \geq n_0$. For $n \geq n_0$ and $v \in Span\{u_1^*, \ldots u_p^*\}$ we have

$$\langle B_n v, v\rangle_{\mathbf{L}} = \langle Bv, v\rangle_{\mathbf{L}} + \langle (B_n - B)v, v\rangle_{\mathbf{L}}$$
$$\leq \mu_p ||v||_{\mathbf{L}}^2 + q^2 \int_{\mathbf{R}} (r_n - r)(2 + r_n + r)|v|^2 dx \leq (\mu_p + \epsilon)||v||_{\mathbf{L}}^2 < (\nu_n - \epsilon)||v||_{\mathbf{L}}^2.$$

By the min-max principle, B_n has at least p eigenvalues less than or equal to $\nu_n - \epsilon$, and thus $z(\nu_n, r_n, u_n) \geq p$.

Let $\mu_{p+2} = \sup_{\varphi_1,\ldots,\varphi_{p+1}\in\mathbf{H}} \inf_{\psi\in\{\varphi_1,\ldots,\varphi_{p+1}\}^\perp} \frac{\langle B\psi,\psi\rangle_\mathbf{L}}{||\psi||^2_\mathbf{L}}$. Since $\lambda = \mu_{p+1} < q^2$ and λ is a simple eigenvalue of B by Proposition 2.1(iii), we know by the min-max principle that either $\mu_{p+2} = q^2$ or μ_{p+2} is an eigenvalue of B and $\mu_{p+2} > \mu_{p+1}$. Let $\epsilon \in (0, \frac{\mu_{p+2}-\mu_{p+1}}{4})$. Take n_0 as above and $\varphi_1, \ldots, \varphi_{p+1} \in \mathbf{H}$ such that $\inf_{\psi\in\{\varphi_1,\ldots,\varphi_{p+1}\}^\perp} \frac{\langle B\psi,\psi\rangle_\mathbf{L}}{||\psi||^2_\mathbf{L}} \geq \mu_{p+2} - \epsilon$. For any $\psi \in \{\varphi_1, \ldots, \varphi_{p+1}\}^\perp$, $\psi \neq 0$ we have

$$\langle B_n\psi,\psi\rangle_\mathbf{L} = \langle B\psi,\psi\rangle_\mathbf{L} + \langle(B_n - B)\psi,\psi\rangle_\mathbf{L} \geq (\mu_{p+2} - \epsilon)||\psi||^2_\mathbf{L} - \epsilon||\psi||^2_\mathbf{L} \geq (\nu_n + \epsilon)||\psi||^2_\mathbf{L}.$$

It follows from the min-max principle that for $n \geq n_0$, either B_n has at most $p+1$ eigenvalues or the $(p+2)$th eigenvalue is greater than $\nu_n + \epsilon$. Since ν_n is an eigenvalue of B_n, there are at most p eigenvalues of B_n less than ν_n, hence $z(\nu_n, r_n, u_n) \leq p$ for any $n \geq n_0$. This finishes the proof of Lemma 3.9 and that of Theorem 3.8. ◻

We were not able to eliminate either of the alternatives in Theorem 3.8.

Up to now, we have proved the existence of branches of nontrivial *symmetric* solutions (λ, r, u) to the system (1.9)–(1.10). For any such solution, $(\tilde\psi, \tilde\varphi)$ is a travelling-wave of (1.1) for $\varepsilon^2(c^2\delta^2 + k^2) = \lambda$ and satisfies the boundary condition (1.2), where $\tilde\varphi(x) = \frac{1}{\varepsilon}u(\frac{x}{\varepsilon})e^{ic\delta x}$ and $\tilde\psi(x) = (1 + r(\frac{x}{\varepsilon}))e^{i\psi_0(x)}$ (with $\psi_0(x) = c\int_0^x [1 - \frac{1}{(1+r(\frac{s}{\varepsilon}))^2}]ds = c\varepsilon\int_0^{\frac{x}{\varepsilon}} \frac{2r(\tau)+r^2(\tau)}{(1+r(\tau))^2}d\tau$). Note also that $\tilde\psi(-x) = \overline{\tilde\psi(x)}$, $\tilde\varphi(-x) = \overline{\tilde\varphi(x)}$, $|\tilde\psi| > \sqrt{2}c\varepsilon$ by Proposition 2.1, and the phase ψ_0 of $\tilde\psi$ remains bounded because r decays at infinity faster than $|x|^\beta$ for any $\beta > 0$ (see the end of the proof of Lemma 3.5). Since $2c^2\varepsilon^2q^2 < \lambda \leq q^2$, we have bounds on the single-particle impurity energy: $c^2(2q^2 - \delta^2) < k^2 \leq \frac{q^2}{\varepsilon^2} - c^2\delta^2$.

Remark 3.10. It follows from Corollary 2.2(iv)–(v) that there is exactly one branch of travelling-waves bifurcating from the trivial solutions if $q \leq \frac{1}{\sqrt{2\ln 2}}$. The number of these branches is the same as the number of eigenvalues of A, so it tends to infinity as $q \longrightarrow \infty$.

It is natural to ask how the branches $\mathcal{C}_m$ given by Theorem 3.8 behave in $\mathbf{R}\times\mathbf{H}\times\mathbf{H}$. The topology of $\mathbf{H}_W$ being stronger than that of $\mathbf{H}$, any of the sets $\mathcal{C}_m$ is also connected in $\mathbf{R}\times\mathbf{H}\times\mathbf{H}$. Roughly speaking, either $\mathcal{C}_m$ approaches $\{q^2\}\times(\mathbf{H}\cap V)\times\mathbf{H}$, or $\mathcal{C}_m$ is unbounded in $\mathbf{R}\times\mathbf{H}\times\mathbf{H}$, or it remains bounded in $\mathbf{R}\times\mathbf{H}\times\mathbf{H}$ but the norm in $\mathbf{R}\times\mathbf{H}_W\times\mathbf{H}_W$ tends to infinity along $\mathcal{C}_m$, i.e., "there is some mass moving to infinity."

Remark 3.11. The importance of Theorem 2.3 is that it gives a precise description of $\mathcal{C}_m$ in a neighborhood of $(\lambda_m, r_{2c\varepsilon}, 0)$ in $\mathbf{R}\times\mathbf{H}\times\mathbf{H}$. Let $\mathcal{C}_m^+$ (respectively $\mathcal{C}_m^-$) be the maximal subcontinuum in $\mathbf{R}\times\mathbf{H}_W\times\mathbf{H}_W$ of $\mathcal{C}_m\setminus\{(\lambda(s), r_{2c\varepsilon}+sr(s), s(u_m+u(s))) \mid s \in (-\eta, 0)\}$, (respectively of $\mathcal{C}_m\setminus\{(\lambda(s), r_{2c\varepsilon}+sr(s), s(u_m+u(s))) \mid s \in (0, \eta)\}$), where the curve $s \longmapsto (\lambda(s), r(s), u(s))$ is given by Theorem 2.3. It can be proved by using a variant of a classical result of Rabinowitz (Theorem 1.40, p. 500 in [12]) that each of $\mathcal{C}_m^+$ and $\mathcal{C}_m^-$ satisfies (i) or (ii) in Theorem 3.8.

Remark 3.12. It is not hard to prove that in dimension $N = 1$, 2, or 3 the Cauchy problem for the system (1.1) is globally well posed in $(1+H^1(\mathbf{R}^N))\times H^1(\mathbf{R}^N)$. However, the dynamics associated to (1.1) and the asymptotic behavior of solutions are not yet understood.

Remark 3.13. The existence of solitary waves for (1.1) in dimension greater than 1 is an open problem. Even the existence of "trivial" solitary waves (i.e., solutions of the form $(\psi(x_1 - ct, x_2, \ldots, x_N), 0)$ is a difficult problem. Note that if $\varphi \equiv 0$, the system (1.1) reduces to the Gross–Pitaevskii equation

$$2i\frac{\partial\psi}{\partial t} = -\Delta\psi + (|\psi|^2 - 1)\psi, \quad |\psi| \longrightarrow 1 \text{ as } |x| \longrightarrow \infty.$$

The existence of travelling-waves moving with small speed for this equation was proved, for instance, in [2] (in dimension $N = 2$) and in [1], [3] (in dimension $N \geq 3$).

Acknowledgments. I am indebted to Professor Jean-Claude Saut, who brought the subject to my attention, for interesting and stimulating discussions. I am also very grateful to Professor Louis Jeanjean for constant help and encouragement and to Professor Patrick J. Rabier for useful remarks.

-DIMENSIONAL ELLIPTIC INVARIANT TORI FOR THE PLANAR (+ 1)-BODY PROBLEM*

LUCA BIASCO†, LUIGI CHIERCHIA†, AND ENRICO VALDINOCI‡

Abstract. For any $N \geq 2$ we prove the existence of quasi-periodic orbits lying on N-dimensional invariant elliptic tori for the planetary planar $(N+1)$-body problem. For small planetary masses, such orbits are close to the limiting solutions given by the N planets revolving around the sun on planar circles. The eigenvalues of the linearized secular dynamics are also computed asymptotically. The proof is based on an appropriate averaging and KAM theory which overcomes the difficulties caused by the intrinsic degeneracies of the model. For concreteness, we focus on a caricature of the outer solar system.

Key words. N-body problem, nearly integrable Hamiltonian systems, lower-dimensional elliptic tori

1. Introduction and results.

1.1. Quasi-periodic motions in the many-body problem. The existence of stable trajectories of the many-body problem viewed as a model for the solar system has been the subject of researches of many distinguished scientists both in the past and in recent years; see, for example, the theoretical work of Poincaré [Poi1905], Arnold [A63], Herman [H95], and the numerical investigations of Laskar [L96]. Only recently, a complete proof, based on [H95], of the existence of quasi-periodic motions (corresponding to maximal invariant tori of dimension $3N-1$) for the $(N+1)$-body problem for arbitrary N has been produced in [F04]. We recall that the main difficulties that one encounters in the application of general tools (such as averaging and KAM theory) to particular cases of interest in celestial mechanics, are related to the strong degeneracies of the analytical models.

The scope of this paper is to show the existence of quasi-periodic orbits lying on N-dimensional invariant elliptic tori for the planar $(N+1)$-body problem. The main difference from [H95] and [F04], besides the dimension of the constructed tori, relies on the explicit evaluations of the eigenvalues of the linearized secular dynamics (which allow us to apply more standard KAM methods).

Though the method exposed here is quite general, for concreteness we will focus our attention on a caricature of the outer solar system. More precisely, our model will be given by a Sun and N planets with relatively small masses (say, of order ε). All these $(N+1)$ bodies are considered as point masses in mutual gravitational interaction. Two planets (such as Jupiter and Saturn in the real world) will be assumed to have mass considerably bigger than the other planets. The bodies lie in a given plane and we assume that the initial configuration is far from collisions. We

also assume, mimicking the case of the outer solar system, that the two big planets have an orbit which is internal with respect to the orbits of the small planets. We will establish, for a large set of semiaxes, the existence of quasi-periodic orbits with small eccentricities filling up N-dimensional invariant elliptic tori. Such orbits can be seen as continuations of "limiting" circular trajectories of the system obtained by neglecting the mutual interactions among the planets. A more precise statement is given in Theorem 1.1 below.

The above "outer model," which roughly mimics some traits of physically relevant cases, has also the nice feature of providing particularly simple expressions in the related perturbing functions, as we will see in section 3 below. We stress, however, that many other situations (such as one large planet plus $N-1$ small planets; "inner" or "mixed" models, etc.) may be easily dealt with using the techniques and results presented in this paper.

The proof of our result is based on techniques developed in [BCV03] and on the explicit computation of the eigenvalues of the quadratic part of the so-called principal part of the perturbation for the planar many-body problem.

The first result on quasi-periodic orbits of interest in celestial mechanics goes back to [A63], where quasi-periodic orbits lying on 4-dimensional tori are shown to exist for the planar three-body problem (the general case was discussed there, but no complete proof was given). Related results were given in [JM66], which found linearly unstable quasi-periodic orbits lying on 2-dimensional tori for the nonplanar three-body problem. More recently, [LR95] and [R95] and [BCV03] proved the existence of quasi-periodic orbits for the nonplanar three-body problem, lying on 4-dimensional and linearly stable 2-dimensional tori, respectively. Two-dimensional invariant tori for the planar three-body problem have been found in [F02]. Periodic orbits of the nonplanar three-body problem winding around invariant tori have been constructed in [BBV04]. Finally, the existence of a positive measure set of initial data giving rise to maximal invariant tori for the planetary $(N+1)$-body problem has been established in [F04].

The paper is organized as follows. In section 1.2, we give a more precise statement of our main result. In section 2 we write down the $(N+1)$-body problem Hamiltonian in Delaunay–Poincaré variables. In section 3 (which, in a sense, is the crucial part of the paper) we discuss degeneracies. In section 4 we give the proof of the main result. The scheme of proof is similar to the one presented in [BCV03] (see also [BBV04]) in the three-body case and it is based on a "general" averaging theorem and on KAM theory for lower-dimensional tori (see [P96], [BCV03], [BBV04]). For completeness, we include a classical (but not easy to find) description of analytical properties of the Delaunay–Poincaré variables (see section 2 and Appendix A); in Appendix B we collect some simple linear algebra lemmata that are used in the arguments given in section 3.

1.2. Statement of results. We denote the $N+1$ massive points ("bodies") by $P_0, \dots, P_N$ and let $m_0, \dots, m_N$ be their masses interacting through gravity (with constant of gravitation 1). Fix $m_0 > 0$ and assume that

$$m_i = \varepsilon \mu_i, \qquad i = 1, \dots, N, \qquad 0 < \varepsilon < 1. \tag{1.1}$$

Here, ε is regarded as a small parameter and μ_i is of order 1 in ε. The point P_0 represents the "Sun" and the points P_i, $i = 1, \dots, N$, the "planets." We assume that all the bodies lie on a fixed plane, that will be identified with $\mathbf{R}^2$. The phase space of this dynamical system—the planetary, planar $(N+1)$-body system—has dimension $4N$ (after reduction by the symmetries of translations).

We will state the result in terms of orbital elements of the "osculating ellipses" of the two-body problems associated to (P_0, P_j). Let $u^{(0)}$ and $u^{(j)}$ denote the coordinates of P_0 and P_j (at a given time) and let $\dot{u}^{(0)}$ and $\dot{u}^{(j)}$ denote the corresponding velocities. By definition, the "osculating ellipse" is the ellipse described by the solution of the two-body problem (P_0, P_j) with initial data given by $(u^{(0)}, u^{(j)}, \dot{u}^{(0)}, \dot{u}^{(j)})$. Of course, such ellipses describe the motions of the full $(N+1)$-body problem only approximately; nevertheless, they provide a nice set of coordinates allowing, for example, to describe the true motions in terms of the eccentricities e_j and the major semiaxes a_j of the osculating ellipses. For further details and pictures of the orbital elements, we refer the reader to [Ch88] and [BCV03].

In this paper we consider a planetary (planar) model with planets evolving from phase points corresponding to well-separated nearly circular ellipses ($e_i \ll 1$); here "well-separated" means that

$$0 < a_i < \theta\, a_{i+1}, \qquad 1 \le i \le N-1. \tag{1.2}$$

for a suitable constant $0 < \theta < 1$. For concreteness, we shall focus on a caricature of the outer solar system; i.e., we will assume that, for some $m_0 < \bar{\mu}_i < 4m_0$,

$$\begin{aligned} &\mu_i = \bar{\mu}_i && \text{for} \quad i = 1, 2, \\ &\mu_i = \delta\bar{\mu}_i && \text{for} \quad i = 3, \dots, N, \qquad 0 < \delta < 1. \end{aligned} \tag{1.3}$$

In this setting, P_1 and P_2 imitate (in a very rough way, of course) the physical[1] features of the giant planets Jupiter and Saturn, while P_3 and P_4 represent Uranus and Neptune.[2]

A rough description of our main result is given in the following theorem; a more precise and quantitative version is given in Theorem 4.2 below.

THEOREM 1.1. *Consider a planar, planetary $(N+1)$-body system satisfying (if $N \ge 3$)* (1.1) *and* (1.3). *Let $A \subset \mathbf{R}^N$ be a compact set of semiaxes where* (1.2) *holds for a suitable $0 < \theta < 1$. Then, there exists $\delta^\star > 0$ and for any $0 < \delta < \delta^\star$ there exists $\varepsilon^\star > 0$ so that the following holds. For any $0 < \varepsilon < \varepsilon^\star$, the planetary, planar $(N+1)$-body system possesses a family of N-dimensional elliptic invariant Diophantine quasi-periodic tori; such family is parametrized by the osculating major semiaxes varying in a subset of A of density*[3] $1 - C_1\varepsilon^{c_1}$. *These motions correspond to orbits with osculating eccentricities bounded by $C_2\varepsilon^{c_2}$ and the variation in time of the osculating major semiaxes of these orbits is bounded by $C_3\varepsilon^{c_3}$.*

We have the following few comments.

- The numbers $\delta^\star$ and θ can be easily computed in the course of the proof and are not "very small"; in fact θ is a "universal" constant while $\delta^\star$ depends only on N and A. On the other hand, $\varepsilon^\star$, which depends on N, A, and δ, is related to a KAM smallness condition and rough estimates lead, as is well known, to ridiculously small quantities (for somewhat more serious KAM estimates, we refer the reader to [CC03]). Finally, the positive constants C_i's depend on N, A, and δ, while the c_i's depend only on N (and could also be easily calculated; see (4.43)).
- The assumptions (1.2) and (1.3) in the theorem are used to check *explicitly* suitable "nondegeneracy" conditions. However, giving explicit constants and

[1] A mathematical motivation for considering *two* dominant planets is given in Remark 3.2(iii).

[2] The Jupiter/Saturn mass ratio is approximately 3.34, while the Neptune/Uranus mass ratio is about 1.18 (to have it all, the Jupiter/Uranus mass ratio is ~ 21.78).

[3] Here and in what follows, the "density" is intended with respect to Lebesgue measure.

estimates, one can show that the thesis of the theorem holds, essentially, with no hypotheses on the semiaxes a_j and the rescaled masses μ_j (provided $a_i \neq a_j > 0$ and $\mu_j > 0$); a rigorous argument, based on analytic continuation of the eigenvalues, could be given along the lines discussed in [F04].

- The invariant tori found in Theorem 1.1 are *lower-dimensional elliptic tori* meaning that the dimension of the tori is strictly smaller than (in fact, half of) the dimension of the Lagrangian (maximal) tori, which have dimension $2N$. "Elliptic" means that the tori are linearly stable. It is not difficult to show that such elliptic tori are surrounded by a set of positive measure of maximal tori.
- The proof given below is based on a well-known elliptic KAM theorem, which works under "nondegeneracy" (or Melnikov) conditions. To check these conditions one has to study the eigenvalues of the "secular" (or averaged) quadratic part of the Newtonian many-body interaction, which will be denoted $\overline{\mathcal{H}}_{1,2}$; "quadratic" here refers to the symplectic Cartesian variables measuring the eccentricity and the orientation of the osculating ellipses. The diagonalization of $\overline{\mathcal{H}}_{1,2}$ is trivial (under the only assumption that $a_i \neq a_j$), while conditions (1.2) and (1.3) will be used to check that the associated eigenvalues are nonzero, simple, and distinct so that Melnikov conditions are satisfied. The proof is noninductive on N.

2. Poincaré Hamiltonian setting. The results described in this section are classical (even if not easy to find) and go back to Delaunay and Poincaré; the reader not familiar with Delaunay and Poincaré variables will find a self-contained exposition in Appendix A.

Consider $N+1$ bodies $P_0, \dots, P_N$, in a fixed (ecliptic) plane, of masses $m_0, \dots, m_N$ interacting through gravity (with constant of gravitation 1). We assume that the mass of P_0 (the "star") is much larger than the mass of the other bodies (the "planets"); i.e., we assume (1.1). In heliocentric planar (suitably rescaled) variables, the dynamics of the planar $(N+1)$-body problem is governed (as explained in Appendix A) by the Hamiltonian

$$\mathcal{H}^{(N)}(X,x) := \mathcal{H}_0^{(N)}(X,x) + \varepsilon \mathcal{H}_1^{(N)}(X,x), \tag{2.1}$$

where $X := (X^{(1)}, \dots, X^{(N)}) \in \mathbf{R}^{2N}$ and $x := (x^{(1)}, \dots, x^{(N)}) \in \mathbf{R}^{2N}$ are conjugated Cartesian symplectic variables and

$$\begin{aligned} \mathcal{H}_0^{(N)} &:= \sum_{i=1}^{N} \left(\frac{1}{2\mathrm{m_i}} |X^{(i)}|^2 - \frac{\mathrm{m}_i \mathrm{M}_i}{|x^{(i)}|} \right), \\ \mathcal{H}_1^{(N)} &:= \sum_{1 \le i < j \le N} \left(X^{(i)} \cdot X^{(j)} - \frac{\mu_i \mu_j}{m_0^2} \, \frac{1}{|x^{(i)} - x^{(j)}|} \right); \end{aligned} \tag{2.2}$$

here we have introduced the dimensionless masses[4]

$$\mathrm{M}_i := 1 + \varepsilon \frac{\mu_i}{m_0}, \qquad \mathrm{m}_i := \frac{\mu_i}{m_0 + \varepsilon \mu_i} = \frac{\mu_i}{m_0} \, \frac{1}{\mathrm{M}_i}. \tag{2.3}$$

The Hamiltonian $\mathcal{H}_0^{(N)}$ is simply the sum of N uncoupled planar Kepler problems (formed by the star and the ith planet). Being interested in phase region where

[4]Beware not to confuse the dimensionless masses m_i with the real masses m_i introduced at the beginning of section 1.2.

the uncoupled Kepler problem describes nearly circular orbits, we introduce *planar Poincaré variables*, the construction of which is based on the classical 4-dimensional symplectic map (2.8) below. Let

$$F_1(t) := \left(1-\frac{t}{4}\right)^{\frac{1}{2}}, \qquad F_2(t) := \frac{1}{2}\left(1-\frac{t}{4}\right)^{-1}, \qquad \left(|t|<\frac{1}{4}\right); \tag{2.4}$$

let $G_0(s,t) = t + st + \cdots$ be the function analytic in a neighborhood of $(0,0)$ implicitly defined by

$$G_0(0,0) = 0, \qquad G_0 = s\sin G_0 + t\cos G_0; \tag{2.5}$$

define the following four functions of three variables $(\hat\eta, \hat\xi, \lambda)$ real-analytic in a neighborhood of the set $\{(\hat\eta,\hat\xi) = (0,0)\} \times \mathbf{T}$:

$$\begin{aligned}
G(\hat\eta,\hat\xi,\lambda) &:= G_0\Big((\hat\eta\cos\lambda - \hat\xi\sin\lambda)\ F_1(t),\ (\hat\xi\cos\lambda - \hat\eta\sin\lambda)\ F_1(t)\Big),\\
\mathcal{E}_{\mathrm{s}}(\hat\eta,\hat\xi,\lambda) &:= \Big(\hat\xi\cos(\lambda+G) + \hat\eta\sin(\lambda+G)\Big)\ F_1(t),\\
\mathcal{C}(\hat\eta,\hat\xi,\lambda) &:= \cos(\lambda+\mathcal{E}_{\mathrm{s}}) - \hat\eta\ F_1(t) - \hat\xi\,\mathcal{E}_{\mathrm{s}}\ F_1(t)\,F_2(t),\\
\mathcal{S}(\hat\eta,\hat\xi,\lambda) &:= \sin(\lambda+\mathcal{E}_{\mathrm{s}}) + \hat\xi\ F_1(t) - \hat\eta\,\mathcal{E}_{\mathrm{s}}\ F_1(t)\,F_2(t),
\end{aligned} \tag{2.6}$$

where t is short for $t = \hat\eta^2 + \hat\xi^2$, G is short for $G(\hat\eta,\hat\xi,\lambda)$, and $\mathcal{E}_{\mathrm{s}}$ is short for $\mathcal{E}_{\mathrm{s}}(\hat\eta,\hat\xi,\lambda)$.

LEMMA 2.1 (planar Poincaré variables). *Fix $\varepsilon, \mu, m_0 > 0$ and let*

$$\begin{aligned}
&\mathrm{M} := 1 + \varepsilon\frac{\mu}{m_0}, \qquad \mathrm{m} := \frac{\mu}{m_0}\ \frac{1}{\mathrm{M}}, \qquad \overline{\mathrm{m}} := \frac{\mu}{m_0}\ \frac{1}{\sqrt{\mathrm{M}}},\\
&\sigma := \left(\frac{\mu}{m_0}\right)^3\frac{1}{\mathrm{M}}, \qquad a = a(\Lambda;\mu,\varepsilon) := \frac{\Lambda^2}{\overline{\mathrm{m}}^2}.
\end{aligned} \tag{2.7}$$

Then, for any $\Lambda_+ > \Lambda_- > 0$, there exists a ball B around the origin in $\mathbf{R}^2$ such that the 4-dimensional map

$$\Psi_{\mathrm{P}} : (\Lambda,\lambda,\eta,\xi) \in D := (\Lambda_-,\Lambda_+)\times\mathbf{T}\times B \to (X,x) \in \mathbf{R}^4,$$

where

$$\begin{aligned}
x_1 &= x_1(\Lambda,\lambda,\eta,\xi;\mu,\varepsilon) := a(\Lambda;\mu,\varepsilon)\ \mathcal{C}\left(\frac{\eta}{\sqrt\Lambda},\frac{\xi}{\sqrt\Lambda},\lambda\right),\\
x_2 &= x_2(\Lambda,\lambda,\eta,\xi;\mu,\varepsilon) := a(\Lambda;\mu,\varepsilon)\ \mathcal{S}\left(\frac{\eta}{\sqrt\Lambda},\frac{\xi}{\sqrt\Lambda},\lambda\right),\\
X &= X(\Lambda,\lambda,\eta,\xi;\mu,\varepsilon) := \frac{\overline{\mathrm{m}}^4}{\Lambda^3}\frac{\partial x}{\partial\lambda}(\Lambda,\lambda,\eta,\xi;\mu,\varepsilon) = \frac{\overline{\mathrm{m}}}{a(\Lambda;\mu,\varepsilon)^{3/2}}\ \frac{\partial x}{\partial\lambda},
\end{aligned} \tag{2.8}$$

is real-analytic in D and symplectic:

$$d\Lambda\wedge d\lambda + d\eta\wedge d\xi = dX_1\wedge dx_1 + dX_2\wedge dx_2.$$

Furthermore, if $\mathcal{H}_0^{(1)}$ denotes the two-body Hamiltonian

$$\mathcal{H}_0^{(1)}(X,x) := \frac{1}{2\mathrm{m}}|X|^2 - \frac{\mathrm{mM}}{|x|},$$

then, on the phase region of negative energies $(\mathcal{H}_0^{(1)})^{-1}(-\frac{\sigma}{2\Lambda_-^2}, -\frac{\sigma}{2\Lambda_+^2})$*, one has*

$$\mathcal{H}_0^{(1)} \circ \Psi_{\mathrm{P}} = -\frac{\sigma}{2\Lambda^2};$$

in the planar coordinates $x \in \mathbf{R}^2$ *the corresponding motion describes an ellipse of major semiaxis* $a = a(\Lambda; \mu, \varepsilon)$ *and eccentricity*

$$e = \sqrt{\frac{\eta^2+\xi^2}{\Lambda}}\ F_1\left(\frac{\eta^2+\xi^2}{\Lambda}\right) = \sqrt{\frac{\eta^2+\xi^2}{\Lambda}\ \left(1 - \frac{\eta^2+\xi^2}{4\Lambda}\right)}. \tag{2.9}$$

The proof of this lemma can be found in Appendix A. Note that

$$\mathcal{C}(0,0,\lambda) = \cos\lambda, \qquad \mathcal{S}(0,0,\lambda) = \sin\lambda, \tag{2.10}$$

so that the $(a,\lambda) \to x$ transformation is, for $\eta = \xi = 0$, just polar coordinates. Let, now, $\Psi_{\mathrm{P}}^{(N)}$ be the $4N$-dimensional map, parametrized by $(\mu_1, \ldots, \mu_N, \varepsilon)$, defined by

$$\Psi_{\mathrm{P}}^{(N)} : \Big((\Lambda_1, \lambda_1, \eta_1, \xi_1), \ldots, (\Lambda_N, \lambda_N, \eta_N, \xi_N)\Big) \in \Big((0,\infty) \times \mathbf{T} \times \mathbf{R}^2\Big)^N \to (X, x) \tag{2.11}$$

with

$$(X, x) = \Big((X^{(1)}, \ldots, X^{(N)}), (x^{(1)}, \ldots, x^{(N)})\Big),$$
$$(X^{(i)}, x^{(i)}) = \Psi_{\mathrm{P}}(\Lambda_i, \lambda_i, \eta_i, \xi_i; \mu_i, \varepsilon). \tag{2.12}$$

Then, $\Psi_{\mathrm{P}}^{(N)}$ is symplectic and

$$\mathcal{H}_0^{(N)} \circ \Psi_{\mathrm{P}}^{(N)} = -\frac{1}{2}\sum_{i=1}^N \frac{\sigma_i}{\Lambda_i^2} =: \mathcal{H}_0(\Lambda), \qquad \sigma_i := \left(\frac{\mu_i}{m_0}\right)^3 \frac{1}{\mathrm{M}_i}. \tag{2.13}$$

In such Poincaré variables the full planar $(N+1)$-body Hamiltonian $\mathcal{H}^{(N)}$ becomes

$$\mathcal{H}(\Lambda, \lambda, \eta, \xi) = \mathcal{H}_0(\Lambda) + \varepsilon\mathcal{H}_1(\Lambda, \lambda, \eta, \xi), \qquad \mathcal{H}_1 := \mathcal{H}_1^{(N)} \circ \Psi_{\mathrm{P}}^{(N)} =: \mathcal{H}_1^{\mathrm{compl}} + \mathcal{H}_1^{\mathrm{princ}}, \tag{2.14}$$

where the so-called "complementary part" $\mathcal{H}_1^{\mathrm{compl}}$ and the "principal part" $\mathcal{H}_1^{\mathrm{princ}}$ of the perturbation are, respectively, the functions

$$\sum_{1 \le i < j \le N} X^{(i)} \cdot\ X^{(j)} \qquad \text{and} \qquad \sum_{1 \le i < j \le N} \frac{\mu_i \mu_j}{m_0^2} \frac{1}{|x^{(i)} - x^{(j)}|} \tag{2.15}$$

expressed in Poincaré variables:[5]

$$X^{(i)} = X(\Lambda_i, \lambda_i, \eta_i, \xi_i; \mu_i, \varepsilon) \qquad \text{and} \qquad x^{(i)} = x(\Lambda_i, \lambda_i, \eta_i, \xi_i; \mu_i, \varepsilon).$$

[5] $X = (X_1, X_2)$ and $x = (x_1, x_2)$ denote here the functions defined in (2.8).

Notice that, since $X^{(i)} = (\overline{\mathrm{m}}_i^4/\Lambda_i^3)\partial_{\lambda_i} x^{(i)}$ the λ-average of $\mathcal{H}_1^{\mathrm{compl}}$ vanishes. Moreover, as it is well known, the λ-average of $\mathcal{H}_1$ is an even function of (η, ξ); see, also, Appendix A. Hence, we may split the perturbation function as

$$\mathcal{H}_1 = \overline{\mathcal{H}}_1 + \widetilde{\mathcal{H}}_1 \tag{2.16}$$

with

$$\overline{\mathcal{H}}_1(\Lambda, \eta, \xi) := \int_{\mathbf{T}^N} \mathcal{H}_1 \frac{d\lambda}{(2\pi)^N}, \qquad \int_{\mathbf{T}^N} \widetilde{\mathcal{H}}_1 \, d\lambda = 0. \tag{2.17}$$

Furthermore, $\overline{\mathcal{H}}_1$ may be written as

$$\overline{\mathcal{H}}_1(\Lambda, \eta, \xi) = \overline{\mathcal{H}}_{1,0}(\Lambda) + \overline{\mathcal{H}}_{1,2}(\Lambda, \eta, \xi) + \overline{\mathcal{H}}_{1,*}(\Lambda, \eta, \xi), \tag{2.18}$$

where $\overline{\mathcal{H}}_{1,0} := \overline{\mathcal{H}}_1(\Lambda, 0, 0)$, $\overline{\mathcal{H}}_{1,2}$ is the (η, ξ)-quadratic part of $\overline{\mathcal{H}}_1$ while $\overline{\mathcal{H}}_{1,*}$ is the "remainder of order four":

$$|\overline{\mathcal{H}}_{1,*}(\Lambda, \eta, \xi)| \le \mathrm{const}\, |(\eta, \xi)|^4.$$

3. The averaged quadratic potential $\overline{\mathcal{H}}_{1,2}$. In this section we analyze the function $\overline{\mathcal{H}}_{1,2}$ (i.e., the (η, ξ)-quadratic part of the λ-average of the perturbation) defined in (2.18), which may be written as

$$\overline{\mathcal{H}}_{1,2} = \frac{1}{2} \sum_{1 \le i,j \le N} Q_{ij} \begin{pmatrix} \eta_j \\ \xi_j \end{pmatrix} \cdot \begin{pmatrix} \eta_i \\ \xi_i \end{pmatrix}, \tag{3.1}$$

where Q_{ij} are (2×2) matrices defined as

$$Q_{ij} := \left. \begin{pmatrix} \partial^2_{\eta_i, \eta_j} \overline{\mathcal{H}}_{1,2} & \partial^2_{\eta_i, \xi_j} \overline{\mathcal{H}}_{1,2} \\ \partial^2_{\xi_i, \eta_j} \overline{\mathcal{H}}_{1,2} & \partial^2_{\xi_i, \xi_j} \overline{\mathcal{H}}_{1,2} \end{pmatrix} \right|_{(\Lambda, 0, 0)}.$$

The aim of this section is to prove that there exists a symplectic linear change of variables $(p, q) \to (\eta, \xi)$ putting the quadratic part (3.1) in the normal form

$$\frac{1}{2} \sum_{i=1}^N \bar{\Omega}_i (p_i^2 + q_i^2); \tag{3.2}$$

see Remark 3.1(i). A crucial fact, in order to apply KAM theory, consists in proving that such $\bar{\Omega}_i$'s are nondegenerate[6] in the sense that they are nonvanishing and distinct. Such nondegeneracy is proved in Proposition 3.2 in which we manage to compute explicitly the asymptotics of the $\bar{\Omega}_i$'s.

In view of the definition of the Poincaré variables, we look at the rescaled variables $(\hat{\eta}, \hat{\xi})$ rather than (η, ξ). Therefore, we define

$$\bar{f}_{ij}(\Lambda, \hat{\eta}, \hat{\xi}) := \frac{1}{(2\pi)^N} \int_{\mathbf{T}^N} \frac{d\lambda}{|x^{(i)}(\Lambda_i, \lambda_i, \sqrt{\Lambda_i}\hat{\eta}_i, \sqrt{\Lambda_i}\hat{\xi}_i; \mu_i, \varepsilon) - x^{(j)}(\Lambda_j, \lambda_j \sqrt{\Lambda_j}\hat{\eta}_j, \sqrt{\Lambda_j}\hat{\xi}_j; \mu_j, \varepsilon)|}. \tag{3.3}$$

[6]See the "Melnikov condition" (4.33).

Thus, letting[7]

$$a_i := a(\Lambda_i;\mu_i,\varepsilon), \qquad\qquad c_{ij} := \frac{1}{m_0}\left(\frac{\mathrm{M}_i\mathrm{M}_j}{a_ia_j}\right)^{1/4},$$

$$A_{ij} := \begin{pmatrix} \partial^2_{\hat\eta_i\hat\eta_j}\bar f_{ij} & \partial^2_{\hat\eta_i\hat\xi_j}\bar f_{ij} \\ \partial^2_{\hat\xi_i\hat\eta_j}\bar f_{ij} & \partial^2_{\hat\xi_i\hat\xi_j}\bar f_{ij}\end{pmatrix}\Bigg|_{\hat\eta=\hat\xi=0}, \quad B_{ij} := \begin{pmatrix} \partial^2_{\hat\eta_j\hat\eta_j}\bar f_{ij} & \partial^2_{\hat\eta_j\hat\xi_j}\bar f_{ij} \\ \partial^2_{\hat\xi_j\hat\eta_j}\bar f_{ij} & \partial^2_{\hat\xi_j\hat\xi_j}\bar f_{ij}\end{pmatrix}\Bigg|_{\hat\eta=\hat\xi=0}, \tag{3.4}$$

we find

$$Q_{ij} = \begin{cases} \sqrt{\mu_i\mu_j}\,c_{ij}\;A_{ij} & \text{if } i\neq j,\\ \displaystyle\sum_{k\neq j}\sqrt{\mu_k\mu_j}\,c_{kj}\;B_{kj} & \text{if } i=j.\end{cases}$$

It is a remarkable fact that, *for the planar planetary* $(N+1)$*-body problem the matrices* A_{ij} *and* B_{ij} *are proportional to the* (2×2) *identity matrix* $\mathbf{1}_2 = \left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$ and have simple integral representation. In fact, define, for $a\neq b$,

$$\mathcal{J}(a,b) := \frac{1}{2\pi}\int_0^{2\pi}\frac{-17ab\cos t + 8(a^2+b^2)\cos(2t) + ab\cos(3t)}{(a^2+b^2-2ab\cos t)^{5/2}}\,dt,$$

$$\mathcal{I}(a,b) := \frac{1}{2\pi}\int_0^{2\pi}\frac{-7ab + 4(a^2+b^2)\cos t - ab\cos(2t)}{(a^2+b^2-2ab\cos t)^{5/2}}\,dt,$$

and denote, for $a_i\neq a_j$,

$$\alpha_{ij} := \frac{a_ia_j}{8}\mathcal{J}(a_i,a_j), \qquad \beta_{ij} := \frac{a_ia_j}{4}\mathcal{I}(a_i,a_j). \tag{3.5}$$

Then, the following "algebraic" result holds.

PROPOSITION 3.1. *Assume* $a_i\neq a_j$ *for* $i\neq j$. *Then* $A_{ij} = \alpha_{ij}\mathbf{1}_2$ *and* $B_{ij} = \beta_{ij}\mathbf{1}_2$.

Remark 3.1. (i) An immediate corollary of this result is that, in the collisionless domain $\{a_i\neq a_j\}$, $\overline{\mathcal{H}}_{1,2}$ has the simple form

$$\overline{\mathcal{H}}_{1,2} = \frac12\Big(M\eta\cdot\eta + M\xi\cdot\xi\Big), \tag{3.6}$$

M being the real, symmetric $(N\times N)$ matrix with entries

$$M_{ij} = \begin{cases} \sqrt{\mu_i\mu_j}\,c_{ij}\;\alpha_{ij} & \text{if } i\neq j,\\ \displaystyle\sum_{k\neq j}\sqrt{\mu_k\mu_j}\,c_{kj}\;\beta_{kj} & \text{if } i=j.\end{cases} \tag{3.7}$$

The Hamiltonian (3.6) can be immediately put in symplectic normal form: if U is the real orthogonal matrix ($U^T = U^{-1}$) which diagonalizes M ($U^TMU = \mathrm{diag}\,(\bar\Omega_1,\dots,\bar\Omega_N)$), then the map $p = U^T\eta$, $q = U^T\xi$ is symplectic and, in such variables, the new Hamiltonian takes the form (3.2).

(ii) The functions $\mathcal{J}$ and $\mathcal{I}$ (which admit simple representations in terms of Gauss hypergeometric functions) are symmetric ($\mathcal{J}(a,b) = \mathcal{J}(b,a)$ and $\mathcal{I}(a,b) = \mathcal{I}(b,a)$) and satisfy

$$\mathcal{J}(a,b) = b^{-3}\mathcal{J}(a/b,1), \qquad \mathcal{I}(a,b) = b^{-3}\mathcal{I}(a/b,1), \qquad a<b.$$

[7]Recall (2.7) and (2.3).

The functions of one real variable $s \in (-1,1) \to \mathcal{J}(s,1)$ and $s \in (-1,1) \to \mathcal{I}(s,1)$ are, respectively, even and odd in s, and satisfy, for small s, the following asymptotics:

$$\mathcal{J}(s,1) = -\frac{15}{8}s^2 - \frac{105}{8}s^4 + O(s^6), \qquad \mathcal{I}(s,1) = 3s + \frac{45}{8}s^3 + O(s^5). \tag{3.8}$$

(iii) Proposition 3.1 is a suitable version of a well-known result which can be found, e.g., in [Poi1905]; see also [LR95].

(iv) The asymptotics of the α_{ij}'s and β_{ij}'s may be also computed in terms of the Laplace coefficients (see, e.g., [LR95]); for our purposes it is simpler to derive the needed asymptotics directly from the integral representations given before (3.5).

Proof of Proposition 3.1. The computations we are going to perform are algebraic in character and it is therefore enough to consider real variables. Fix $i \neq j$ and define

$$\mathcal{R}_{ij}(\Lambda,\lambda,\hat\eta,\hat\xi) := \left| x^{(i)}(\Lambda_i,\lambda_i,\sqrt{\Lambda_i}\hat\eta_i,\sqrt{\Lambda_i}\hat\xi_i;\mu_i,\varepsilon) - x^{(j)}(\Lambda_j,\lambda_j\sqrt{\Lambda_j}\hat\eta_j,\sqrt{\Lambda_j}\hat\xi_j;\mu_j,\varepsilon)\right|^2, \tag{3.9}$$

so that (recall (3.3))

$$\bar f_{ij}(\Lambda,\hat\eta,\hat\xi) = \frac{1}{(2\pi)^N}\int_{\mathbf{T}^N}\frac{d\lambda}{\sqrt{\mathcal{R}_{ij}}}. \tag{3.10}$$

By (2.8) we find

$$\mathcal{R}_{ij} = a_i^2\chi_i^2 + a_j^2\chi_j^2 - 2a_ia_j\Big(\mathcal{C}_i\mathcal{C}_j - \mathcal{S}_i\mathcal{S}_j\Big), \tag{3.11}$$

where $\mathcal{C}_k$, $\mathcal{S}_k$, and χ_k are short for, respectively,

$$\mathcal{C}_k = \mathcal{C}(\hat\eta_k,\hat\xi_k,\lambda_k), \quad \mathcal{S}_k = \mathcal{S}(\hat\eta_k,\hat\xi_k,\lambda_k), \quad \text{and} \quad \chi_k = \sqrt{\mathcal{C}_k^2 + \mathcal{S}_k^2}.$$

The proof will consist in computing explicitly λ-averages of quantities of the form

$$\rho_{\zeta_i,\zeta_j}(\lambda_i,\lambda_j) := \partial^2_{\zeta_i\zeta_j}\frac{1}{\sqrt{\mathcal{R}_{ij}}}\Bigg|_{\hat\eta=\hat\xi=0} = \frac{3(\partial_{\zeta_i}\mathcal{R}_{ij})(\partial_{\zeta_j}\mathcal{R}_{ij}) - 2\mathcal{R}_{ij}(\partial_{\zeta_i\zeta_j}\mathcal{R}_{ij})}{4\mathcal{R}_{ij}^{5/2}}\Bigg|_{\hat\eta=\hat\xi=0}, \tag{3.12}$$

where ζ_k denotes either of the variables $\hat\eta_k$ or $\hat\xi_k$. Thus, what we need to do is to compute suitable orders in the variables $(\hat\eta_k,\hat\xi_k)$ of the function $\mathcal{R}_{ij}$. For this purpose the following lemma will be useful.

LEMMA 3.1. *Define the following elementary functions:*

$$\begin{aligned}
C_+(\lambda) &:= 1+\cos^2\lambda \;=\; \frac{3+\cos(2\lambda)}{2},\\
C_-(\lambda) &:= 1+\sin^2\lambda \;=\; \frac{3-\cos(2\lambda)}{2},\\
S_0(\lambda) &:= \cos\lambda\sin\lambda \;=\; \frac{1}{2}\sin(2\lambda),\\
\bar\chi(x,y,\lambda) &:= 1-2y\cos\lambda+2x\sin\lambda,\\
S(x,y,\lambda) &:= \sin\lambda + xC_+(\lambda) + yS_0(\lambda),\\
C(x,y,\lambda) &:= \cos\lambda - yC_-(\lambda) - xS_0(\lambda),
\end{aligned}$$

and denote by $O_p(z_1,\dots,z_n)$ *a function of the variables* $(z_1,\dots,z_n)$ *(depending possibly on other variables) analytic in a neighborhood of* $(0,\dots,0)$ *and starting with a homogeneous polynomial of degree p in* $(z_1,\dots,z_n)$. *Then,*

$$\begin{aligned}
&\chi_k^2 = \mathcal{C}(\hat\eta_k,\hat\xi_k,\lambda_k)^2+\mathcal{S}(\hat\eta_k,\hat\xi_k,\lambda_k)^2=\bar\chi(\hat\eta_k,\hat\xi_k,\lambda_k)+O_2(\hat\eta_k,\hat\xi_k),\\
&\mathcal{C}_k=\mathcal{C}(\hat\eta_k,\hat\xi_k,\lambda_k)=C(\hat\xi_k,\hat\eta_k,\lambda_k)+O_2(\hat\eta_k,\hat\xi_k),\\
&\mathcal{S}_k=\mathcal{S}(\hat\eta_k,\hat\xi_k,\lambda_k)=S(\hat\xi_k,\hat\eta_k,\lambda_k)+O_2(\hat\eta_k,\hat\xi_k).
\end{aligned}\tag{3.13}$$

The proof of this lemma follows at once from the explicit expressions for $\mathcal{C}$ and $\mathcal{S}$ given in Lemma 2.1 and is left to the reader.

We consider first the matrices A_{ij} (which allow to compute Q_{ij} for $i\neq j$) and then we turn to the matrices B_{ij} (which allow to compute Q_{jj}).

Computation of the matrices A_{ij}. First, observe that the two derivatives involved in the definition of A_{ij} are *always* mixed in the variables with indexes i and j. Thus, we can neglect the terms of third order in $(\hat\eta_i,\hat\xi_i,\hat\eta_j,\hat\xi_j)$ and the terms of *second order* of the type $O_2(\hat\eta_i,\hat\xi_i)$ and $O_2(\hat\eta_j,\hat\xi_j)$.

By Lemma 3.1, the function $\mathcal{R}_{ij}$ in (3.11) has the form

$$\begin{aligned}
\mathcal{R}_{ij}&=a_i^2(1-2\hat\eta_i\cos\lambda_i+2\hat\xi_i\sin\lambda_i)+a_j^2(1-2\hat\eta_j\cos\lambda_j+2\hat\xi_j\sin\lambda_j)\\
&\quad-2a_ia_j\Big[(\cos\lambda_i-\hat\xi_iS_0(\lambda_i)-\hat\eta_iC_-(\lambda_i))(\cos\lambda_j-\hat\xi_jS_0(\lambda_j)-\hat\eta_jC_-(\lambda_j))\\
&\quad+(\sin\lambda_i+\hat\xi_iC_+(\lambda_i)+\hat\eta_iS_0(\lambda_i))(\sin\lambda_j+\hat\xi_jC_+(\lambda_j)+\hat\eta_jS_0(\lambda_j))\Big]\\
&\quad+O_2(\hat\eta_i,\hat\xi_i)+O_2(\hat\eta_j,\hat\xi_j)+O_3(\hat\eta_i,\hat\xi_i,\hat\eta_j,\hat\xi_j).
\end{aligned}\tag{3.14}$$

Therefore, letting $(\cdot)|_0$ be short for $(\cdot)|_{\hat\eta_i=\hat\xi_i=\hat\eta_j=\hat\xi_j=0}$, one finds

$$\begin{aligned}
\mathcal{R}_{ij}\big|_0&=a_i^2+a_j^2-2a_ia_j\cos(\lambda_i-\lambda_j),\\
\partial_{\hat\eta_i}\mathcal{R}_{ij}\big|_0&=-2a_i^2\cos\lambda_i-2a_ia_j[-C_-(\lambda_i)\cos\lambda_j+S_0(\lambda_i)\sin\lambda_j],\\
\partial_{\hat\eta_j}\mathcal{R}_{ij}\big|_0&=-2a_j^2\cos\lambda_j-2a_ia_j[-C_-(\lambda_j)\cos\lambda_i+S_0(\lambda_j)\sin\lambda_i],\\
\partial_{\hat\xi_i}\mathcal{R}_{ij}\big|_0&=2a_i^2\sin\lambda_i-2a_ia_j[C_+(\lambda_i)\sin\lambda_j-S_0(\lambda_i)\cos\lambda_j],\\
\partial_{\hat\xi_j}\mathcal{R}_{ij}\big|_0&=2a_j^2\sin\lambda_j-2a_ia_j[C_+(\lambda_j)\sin\lambda_i-S_0(\lambda_j)\cos\lambda_i],\\
\partial^2_{\hat\eta_i\hat\eta_j}\mathcal{R}_{ij}\big|_0&=-2a_ia_j[C_-(\lambda_i)C_-(\lambda_j)+S_0(\lambda_i)S_0(\lambda_j)],\\
\partial^2_{\hat\xi_i\hat\xi_j}\mathcal{R}_{ij}\big|_0&=-2a_ia_j[C_+(\lambda_i)C_+(\lambda_j)+S_0(\lambda_i)S_0(\lambda_j)],\\
\partial^2_{\hat\eta_i\hat\xi_j}\mathcal{R}_{ij}\big|_0&=-2a_ia_j[C_-(\lambda_i)S_0(\lambda_j)+S_0(\lambda_i)C_+(\lambda_j)],\\
\partial^2_{\hat\xi_i\hat\eta_j}\mathcal{R}_{ij}\big|_0&=-2a_ia_j[S_0(\lambda_i)C_-(\lambda_j)+C_+(\lambda_i)S_0(\lambda_j)].
\end{aligned}\tag{3.15}$$

In particular, $\mathcal{R}_{ij}$ and $\partial_{\hat\eta_i}\mathcal{R}_{ij}$ are even in $(\lambda_i,\lambda_j)\in\mathbf{T}^2$, while $\partial_{\hat\xi_j}\mathcal{R}_{ij}$ and $\partial^2_{\hat\eta_i\hat\xi_j}\mathcal{R}_{ij}$ are odd. Thus, recalling the definition of $\rho_{\zeta_i,\zeta_j}(\lambda_i,\lambda_j)$ in (3.12), we find that $\rho_{\hat\eta_i,\hat\xi_j}(\lambda_i,\lambda_j)$ is odd in (λ_i,λ_j) and it has therefore zero average. For the same reasons, also $\rho_{\hat\xi_i,\hat\eta_j}(\lambda_i,\lambda_j)$ has zero average. Hence, the off-diagonal terms of A_{ij} are zero. We now compute the diagonal terms of A_{ij}. We begin with $\rho_{\hat\eta_i,\hat\eta_j}(\lambda_i,\lambda_j)$. By (3.12) and the list in (3.15), we find

$$\rho_{\hat\eta_i,\hat\eta_j}(\lambda_i,\lambda_j) := \partial^2_{\hat\eta_i\hat\eta_j}\frac{1}{\sqrt{\mathcal{R}_{ij}}}\bigg|_0 = \frac{\rho_1(\lambda_i,\lambda_j)}{\rho_2(\lambda_i,\lambda_j)} \tag{3.16}$$

with

(3.17)

$$\begin{aligned}\rho_1(\lambda_i,\lambda_j) := a_ia_j\cdot\Big[&-24a_i^2\cos(2\lambda_i)-24a_j^2\cos(2\lambda_j)+8(a_i^2+a_j^2)\cos(2(\lambda_i-\lambda_j))\\ &-3a_ia_j\cos(\lambda_i-3\lambda_j)-17a_ia_j\cos(\lambda_i-\lambda_j)\\ &+a_ia_j\cos(3(\lambda_i-\lambda_j))-3a_ia_j\cos(3\lambda_i-\lambda_j)\\ &+54a_ia_j\cos(\lambda_i+\lambda_j)\Big],\\ \rho_2(\lambda_i,\lambda_j) := 8\Big(&a_i^2+a_j^2-2a_ia_j\cos(\lambda_i-\lambda_j)\Big)^{5/2}.\end{aligned}$$

Thus, changing the variable of integration, one finds

$$\begin{aligned}&\frac{1}{(2\pi)^2}\int_{\mathbf{T}^2}\partial^2_{\hat\eta_i\hat\eta_j}\frac{1}{\sqrt{\mathcal{R}_{ij}}}\bigg|_0 d\lambda_i\,d\lambda_j\\ &\qquad=\frac{1}{2\pi}\int_{\mathbf{T}}a_ia_i\cdot\frac{-17a_ia_j\cos t+8(a_i^2+a_j^2)\cos(2t)+a_ia_j\cos(3t)}{8(a_i^2+a_j^2-2a_ia_j\cos t)^{5/2}}\,dt\\ &\qquad=\frac{a_ia_j}{8}\,\mathcal{J}(a_i,a_j)=:\alpha_{ij}.\end{aligned}$$

The case $\rho_{\hat\xi_i,\hat\xi_j}(\lambda_i,\lambda_j)$ is very similar (and will yield the same result). In place of (3.16) one finds

$$\rho_{\hat\xi_i,\hat\xi_j}(\lambda_i,\lambda_j) := \partial^2_{\hat\xi_i\hat\xi_j}\frac{1}{\sqrt{\mathcal{R}_{ij}}}\bigg|_0 = \frac{\rho_3(\lambda_i,\lambda_j)}{\rho_2(\lambda_i,\lambda_j)} \tag{3.18}$$

with

$$\begin{aligned}\rho_3(\lambda_i,\lambda_j) := a_ia_j\cdot\Big[&24a_i^2\cos(2\lambda_i)+24a_j^2\cos(2\lambda_j)+8(a_i^2+a_j^2)\cos(2(\lambda_i-\lambda_j))\\ &+3a_ia_j\cos(\lambda_i-3\lambda_j)-17a_ia_j\cos(\lambda_i-\lambda_j)\\ &+a_ia_j\cos(3(\lambda_i-\lambda_j))+3a_ia_j\cos(3\lambda_i-\lambda_j)\\ &-54a_ia_j\cos(\lambda_i+\lambda_j)\Big].\end{aligned} \tag{3.19}$$

Integrating, one finds again

$$\frac{1}{(2\pi)^2}\int_{\mathbf{T}^2}\partial^2_{\hat\xi_i\hat\xi_j}\frac{1}{\sqrt{\mathcal{R}_{ij}}}\bigg|_0 d\lambda_i\,d\lambda_j=\alpha_{ij}.$$

This proves Proposition 3.1 in the case of Q_{ij}, with $i\neq j$.

Computation of the matrices B_{ij}. Observe that the derivatives involved in the definition of B_{ij} are two derivatives with the same index j. We can, therefore, neglect the third order terms and set $\hat\eta_i=\hat\xi_i=0$.

Recalling (2.10) we see that $\chi_i|_{\hat\eta_i=\hat\xi_i=0}=1$ and

$$\mathcal{R}_{ij}\Big|_{\hat\eta_i=\hat\xi_i=0}=a_i^2+a_j^2\chi_j^2-2a_ia_j\chi_j\left((\cos\lambda_i)\,\frac{\mathcal{C}_j}{\chi_j}-(\sin\lambda_i)\,\frac{\mathcal{S}_j}{\chi_j}\right). \tag{3.20}$$

Defining $\varphi_j=\varphi_j(\Lambda_j,\lambda_j,\hat\eta_j,\hat\xi_j)$ through the relations[8]

$$\cos\varphi_j=\frac{\mathcal{C}_j}{\chi_j},\qquad \sin\varphi_j=\frac{\mathcal{S}_j}{\chi_j}, \tag{3.21}$$

we find

$$\mathcal{R}_{ij}\Big|_{\hat\eta_i=\hat\xi_i=0}=a_i^2+a_j^2\chi_j^2-2a_ia_j\chi_j\cos(\varphi_j-\lambda_i). \tag{3.22}$$

Denote by $\langle\, f\,\rangle_{\theta,\tau}$ the average of a function f over the angles θ and τ. Integrating *first* with respect to λ_i and changing variable of integration ($t=\lambda_i-\varphi_j$), one gets

$$\left\langle\,\frac{1}{\sqrt{\mathcal{R}_{ij}}}\Big|_{\hat\eta_i=\hat\xi_i=0}\right\rangle_{\lambda_i,\lambda_j}=\left\langle\,\frac{1}{\sqrt{\tilde{\mathcal{R}}_{ij}}}\,\right\rangle_{t,\lambda_j} \tag{3.23}$$

with

$$\tilde{\mathcal{R}}_{ij}:=a_i^2+a_j^2\chi_j^2-2a_ia_j\chi_j\cos t. \tag{3.24}$$

At this point, the argument is completely analogous to that used above. First, we observe that

$$\left\langle\,\partial^2_{\zeta_h\zeta_k}\frac{1}{\sqrt{\mathcal{R}_{ij}}}\Big|_0\right\rangle_{\lambda_i,\lambda_j}=\left\langle\,\frac{3(\partial_{\zeta_h}\tilde{\mathcal{R}}_{ij})(\partial_{\zeta_k}\tilde{\mathcal{R}}_{ij})-2\tilde{\mathcal{R}}_{ij}(\partial^2_{\zeta_h\zeta_k}\tilde{\mathcal{R}}_{ij})}{4\tilde{\mathcal{R}}_{ij}^{5/2}}\Big|_0\right\rangle_{t,\lambda_j}, \tag{3.25}$$

where ζ_ℓ denotes here any of the variables $\hat\eta_j,\hat\xi_j$. From Lemma 3.1 it follows that $\tilde{\mathcal{R}}_{ij}$ can be written as

$$\tilde{\mathcal{R}}_{ij}=f(t)+g(t)(h_1-h_2)+a_j^2h_1^2+O_3(\hat\eta_j,\hat\xi_j)$$

with

$$f(t):=a_i^2+a_j^2-2a_ia_j\cos t,\qquad g(t):=-2a_j^2+2a_ia_j\cos t,$$
$$h_1:=\hat\eta_j\cos\lambda_j-\hat\xi_j\sin\lambda_j,\qquad h_2:=\hat\xi_j^2\cos^2\lambda_j+\hat\eta_j^2\sin^2\lambda_j+\hat\eta_j\hat\xi_j\sin(2\lambda_j).$$

Thus, since h_1 is of order one in $(\hat\eta_j,\hat\xi_j)$ and h_2 is of order two in $(\hat\eta_j,\hat\xi_j)$,

$$\begin{aligned}
\tilde{\mathcal{R}}_{ij}\Big|_0&=f(t),\\
\partial_{\eta_j}\tilde{\mathcal{R}}_{ij}\Big|_0&=g(t)\,\cos\lambda_j,\\
\partial_{\hat\xi_j}\tilde{\mathcal{R}}_{ij}\Big|_0&=-g(t)\,\sin\lambda_j,\\
\partial^2_{\hat\eta_j\hat\eta_j}\tilde{\mathcal{R}}_{ij}\Big|_0&=-2g(t)\,\sin^2\lambda_j+2a_j^2\cos^2\lambda_j,\\
\partial^2_{\hat\eta_j\hat\xi_j}\tilde{\mathcal{R}}_{ij}\Big|_0&=-(g(t)+a_j)^2\,\sin(2\lambda_j),\\
\partial^2_{\hat\xi_j\hat\xi_j}\tilde{\mathcal{R}}_{ij}\Big|_0&=-2g(t)\,\cos^2\lambda_j+2a_j^2\sin^2\lambda_j.
\end{aligned}$$

[8]Physically, φ_j coincides with v_j+g_j where v_j and g_j are, respectively, the true anomaly and the argument of the perihelion of the osculating ellipse associated to the star and the jth planet; compare to Appendix A.

Therefore, using (3.25), one finds

$$\left\langle \partial^2_{\hat\eta_j\hat\xi_j} \frac{1}{\sqrt{\tilde{\mathcal{R}}_{ij}}}\bigg|_0 \right\rangle_{\lambda_i,\lambda_j} = \left\langle \frac{-\left(\frac{3}{2}g^2+2(a_j^2-g)f\right)\sin(2\lambda_j)}{4f^{5/2}}\bigg|_0 \right\rangle_{t,\lambda_j} = 0$$

(since the integrand is odd in λ_j), showing that also B_{ij} is a diagonal matrix. To compute the diagonal elements we calculate

$$\partial^2_{\hat\eta_j\hat\eta_j}\frac{1}{\sqrt{\tilde{\mathcal{R}}_{ij}}}\bigg|_0 = \frac{\tilde\rho_1(\lambda_j,t)}{\tilde\rho_2(\lambda_j,t)} \qquad \text{and} \qquad \partial^2_{\hat\xi_j\hat\xi_j}\frac{1}{\sqrt{\tilde{\mathcal{R}}_{ij}}}\bigg|_0 = \frac{\tilde\rho_3(\lambda_j,t)}{\tilde\rho_2(\lambda_j,t)} \tag{3.26}$$

with

$$\begin{aligned}
\tilde\rho_1 &= -7\,a_i^2\,a_j^2 + (9\,a_i^2\,a_j^2 + 8\,{a_j}^4)\,\cos(2\,\lambda_j) + \frac{7}{2}\,a_i^2\,a_j^2\,\cos(2\,\lambda_j - 2\,t)\\
&\quad - (2\,{a_i}^3\,a_j + 10\,a_i\,{a_j}^3)\,\cos(2\,\lambda_j - t) + 4({a_i}^3\,a_j + a_i\,{a_j}^3)\,\cos(t)\\
&\quad - a_i^2\,a_j^2\,\cos(2\,t) - (2\,{a_i}^3\,a_j + 10\,a_i\,{a_j}^3)\,\cos(2\,\lambda_j + t) + \frac{7}{2}\,a_i^2\,a_j^2\,\cos(2\,\lambda_j + 2\,t);\\
\tilde\rho_2 &= 4(a_i^2 + a_j^2 - 2a_ia_j\cos t)^{5/2};\\
\tilde\rho_3 &= -7\,a_i^2\,a_j^2 - (9\,a_i^2\,a_j^2 + 8\,{a_j}^4)\,\cos(2\,\lambda_j) - \frac{7}{2}\,a_i^2\,a_j^2\,\cos(2\,\lambda_j - 2\,t)\\
&\quad + (2\,{a_i}^3\,a_j + 10\,a_i\,{a_j}^3)\,\cos(2\,\lambda_j - t) + 4({a_i}^3\,a_j + a_i\,{a_j}^3)\,\cos(t)\\
&\quad - a_i^2\,a_j^2\,\cos(2\,t) + (2\,{a_i}^3\,a_j + 10\,a_i\,{a_j}^3)\,\cos(2\,\lambda_j + t) - \frac{7}{2}\,a_i^2\,a_j^2\,\cos(2\,\lambda_j + 2\,t);
\end{aligned}$$

taking the λ_j-average, one finds immediately

$$\left\langle \partial^2_{\hat\eta_j\hat\eta_j}\frac{1}{\sqrt{\tilde{\mathcal{R}}_{ij}}}\bigg|_0\right\rangle_{\lambda_i,\lambda_j} = \left\langle \partial^2_{\hat\xi_j\hat\xi_j}\frac{1}{\sqrt{\tilde{\mathcal{R}}_{ij}}}\bigg|_0\right\rangle_{\lambda_i,\lambda_j} = \frac{a_ia_j}{4}\mathcal{I}(a_i,a_j) =: \beta_{ij}. \qquad \square$$

The next result shows that, for δ and ε small, generically the eigenvalues of M in (3.6)–(3.7) are nonvanishing, simple, and distinct. We formulate the result regarding the semiaxis a_j as *independent variables*. Recall the definitions of α_{ij} and β_{ij} in (3.5) and let (if $N \geq 3$)

$$\beta_j := \sum_{k=1,2} \frac{\sqrt{\bar\mu_k\bar\mu_j}}{m_0}\,\frac{1}{\sqrt[4]{a_ka_j}}\,\beta_{kj}, \qquad j \geq 3. \tag{3.27}$$

PROPOSITION 3.2. *Assume that a_j and $\bar\mu_j$ verify*[9]

$$\alpha_{12} \neq 0 \quad \text{and} \quad \beta_{12} \neq \pm\alpha_{12}, \qquad \beta_i \neq 0 \quad \text{and} \quad \beta_i \neq \beta_j \quad \text{for} \quad i \neq j. \tag{3.28}$$

Then, there exist $0 < \delta^\star < 1$ and $0 < \varepsilon_0 < 1$ such that for all $0 < \delta < \delta^\star$ and $0 \leq \varepsilon < \varepsilon_0$ the eigenvalues $\{\bar\Omega_1, \dots, \bar\Omega_N\}$ of the matrix M are nonvanishing, simple,

[9]Clearly, if $N = 2$, the statements regarding the β_j and the eigenvalues $\bar\Omega_j$ for $j \geq 3$ have to be omitted.

and distinct. Furthermore the following asymptotics hold:[10]

$$\bar\Omega_1 = \frac{\sqrt{\bar\mu_1\bar\mu_2}}{m_0}\ \frac{\beta_{12}+\alpha_{12}}{\sqrt[4]{a_1 a_2}}\ + O(\sqrt{\delta},\varepsilon),$$

$$\bar\Omega_2 = \frac{\sqrt{\bar\mu_1\bar\mu_2}}{m_0}\ \frac{\beta_{12}-\alpha_{12}}{\sqrt[4]{a_1 a_2}}\ + O(\sqrt{\delta},\varepsilon),$$

$$\bar\Omega_j = \sqrt{\delta}\,\beta_j\ +\ \sqrt{\delta}\ O(\sqrt{\delta},\varepsilon),\qquad 3\le j\le N. \tag{3.29}$$

As mentioned above (see Remark 3.1(iv)) the asymptotic of the α_{ij}'s and β_{ij}'s may be evaluated in terms of the Laplace coefficients (see, e.g., [L91]). For completeness we give a detailed proof.

Proof. First of all, from the definition of c_{ij} (see (3.4) and (2.3)) it follows that

$$c_{ij} = \frac{1}{m_0}\ \frac{1}{\sqrt[4]{a_i a_j}} + O(\varepsilon). \tag{3.30}$$

Thus, by definition of M, by definition of β_j and α_{ij}, and by the hypothesis on the masses μ_i (see (1.3)) we find the following asymptotics:

$$\begin{aligned}
&\begin{pmatrix} M_{11} & M_{12}\\ M_{21} & M_{22}\end{pmatrix} = M^\star + O(\sqrt{\delta},\varepsilon), && \text{where}\quad M^\star := \frac{\sqrt{\bar\mu_1\bar\mu_2}}{m_0\sqrt[4]{a_1a_2}}\begin{pmatrix}\beta_{12} & \alpha_{12}\\ \alpha_{12} & \beta_{12}\end{pmatrix},\\
&M_{jj} = \sqrt{\delta}\beta_j + O(\delta,\varepsilon) && \text{for } j\ge 3,\\
&M_{ij} = O(\sqrt{\delta}) && \text{for } i=1,2 \text{ and } j\ge 3, \text{ or } j=1,2 \text{ and } i\ge 3,\\
&M_{ij} = O(\delta) && \text{for } i,j\ge 3 \text{ with } i\ne j.
\end{aligned}$$

Therefore[11]

$$M = \begin{pmatrix} M^\star + O(\sqrt{\delta},\varepsilon) & O(\sqrt{\delta})\\ O(\sqrt{\delta}) & \sqrt{\delta}M_\star + O(\delta,\varepsilon)\end{pmatrix},$$

where

$$M_\star := \operatorname{diag}(\beta_3,\dots,\beta_N) \in \mathrm{Mat}((N-2)\times(N-2)).$$

The eigenvalues of $M^\star$ are

$$\frac{\sqrt{\bar\mu_1\bar\mu_2}}{m_0\sqrt[4]{a_1a_2}}\ (\beta_{12}+\alpha_{12})\qquad\text{and}\qquad \frac{\sqrt{\bar\mu_1\bar\mu_2}}{m_0\sqrt[4]{a_1a_2}}\ (\beta_{12}-\alpha_{12}),$$

which, by the first two requirements in (3.28), are nonzero, simple, and distinct. The matrix $M_\star$ is diagonal and its eigenvalues β_j are also nonzero, simple, and distinct by (3.28). The claim now follows by elementary linear algebra (compare, e.g., Lemma B.2 in Appendix B). $\square$

[10] We use the standard notation $a = O(\varepsilon) \iff \exists$ a constant $c>0$ (independent of ε) and $0<\varepsilon_0<1$ s.t. $|a|\le c|\varepsilon|$ for all $|\varepsilon|\le\varepsilon_0$; $O(\sigma,\varepsilon) = O(\sigma)+O(\varepsilon)$.

[11] The $O(\sqrt{\delta})$ in the upper right part of M is a $(2\times(N-2))$ matrix while the $O(\sqrt{\delta})$ in the lower left part of M is an $((N-2)\times 2)$ matrix.

Remark 3.2. (i) The hypotheses (3.28) of Proposition 3.2 are easily checked, for example, if a_j verifies (1.2) for a suitable $\theta > 0$. In fact the asymptotics for $\mathcal{J}(s,1)$ and $\mathcal{I}(s,1)$ (see (3.8)) yield immediately

$$
\begin{aligned}
\alpha_{12} &= -\frac{15}{64}\,\frac{1}{a_2}\,\Big(\frac{a_1}{a_2}\Big)^3\ \Big[1+O\Big(\Big(\frac{a_1}{a_2}\Big)^2\Big)\Big],\\
\beta_{12} &= \frac{3}{4}\,\frac{1}{a_2}\,\Big(\frac{a_1}{a_2}\Big)^2\ \Big[1+O\Big(\Big(\frac{a_1}{a_2}\Big)^2\Big)\Big],\\
\beta_j &= \frac{3}{4}\,\frac{\sqrt{\bar\mu_j\bar\mu_2}}{m_0}\ \frac{1}{a_j^{3/2}}\ \Big(\frac{a_2}{a_j}\Big)^{7/4}\ \Big[1+O\Big(\Big(\frac{a_1}{a_2}\Big)^{7/4}\Big)+O\Big(\Big(\frac{a_2}{a_j}\Big)^2\Big)\Big], \qquad j\ge 3,\\
\beta_{12}\pm\alpha_{12} &= \frac{3}{4}\,\frac{1}{a_2}\,\Big(\frac{a_1}{a_2}\Big)^2\ \Big[1\mp\frac{5}{16}\,\frac{a_1}{a_2}+O\Big(\Big(\frac{a_1}{a_2}\Big)^2\Big)\Big],\\
\beta_j-\beta_i &= \frac{3}{4}\,\frac{\sqrt{\bar\mu_j\bar\mu_2}}{m_0}\ \frac{1}{a_j^{3/2}}\ \Big(\frac{a_2}{a_j}\Big)^{7/4}\\
&\qquad\times\Big[1+O\Big(\Big(\frac{a_1}{a_2}\Big)^{7/4}\Big)+O\Big(\Big(\frac{a_2}{a_j}\Big)^2\Big)+O\Big(\Big(\frac{a_i}{a_j}\Big)^{13/4}\Big)\Big], \qquad i>j\ge 3.
\end{aligned}
$$

Thus, if θ is small enough and if (1.2) holds, one sees that

$$
\begin{aligned}
&\alpha_{12} < 0,\\
&\beta_{12}\pm\alpha_{12} > 0,\\
&\beta_j > 0 \qquad \forall\ j\ge 3,\\
&\beta_j-\beta_i > 0 \qquad \forall\ i>j\ge 3,
\end{aligned}
$$

and the hypotheses (3.28) are verified as claimed.

(ii) The $O(\cdot)$'s appearing in (3.29) (and in the proof of Proposition 3.2) depend on the a_j's (and on[12] m_0). Thus, the order in fixing the various parameters is important. One way of proceeding is as follows. First determine θ as explained in the previous point (i). Then, let $\bar a_i$, $1\le i\le N$, be positive numbers such that (1.2) holds, i.e., $\bar a_i/\bar a_{i+1} < \theta$ for any $1\le i\le N-1$; (the $\bar a_i$ may be physically interpreted as observed mean major semiaxis). Now, consider a compact order-one neighborhood $A\subset\{0<a_1<\cdots<a_N\}$ of $(\bar a_1,\dots,\bar a_N)$ for which (1.2) continues to be valid (such neighborhood exists simply by continuity). Finally, fix $\delta^\star$ and ε_0 so that Proposition 3.2 holds: such numbers will depend only on $\bar a_j$'s and the (order-one) size of the chosen neighborhood A.

(iii) In the case of only *one* dominant planet (i.e., $\mu_1=\bar\mu_1=O(1)$, $\mu_i=O(\delta)$ for $i\ge 2$), the first two asymptotics in (3.29) do not give any information: in particular we cannot assure that $\bar\Omega_1$ and $\bar\Omega_2$ are different from zero. On the other hand, one could also consider the case of three or more dominant planets and the choice of focusing on *two* dominant planets has been made for simplicity.

4. Existence of -dimensional elliptic invariant tori. In this section we prove the existence of N-dimensional elliptic invariant tori for the $(N+1)$-body problem Hamiltonian $\mathcal{H}$ in (2.14) for any $N\ge 2$.

Let $m_0<\bar\mu_j<4m_0$, let θ, A, $\delta^\star$, and ε_0 be as in Remark 3.2(ii), and fix $0<\delta<\delta^\star$, which henceforth will be kept fixed. In the rest of the paper only ε is

[12]Recall that $m_0<\bar\mu_j<4m_0$; compare with the line before (1.3).

regarded as a free parameter: at the moment, ε is assumed not to exceed ε_0 but later will be required to satisfy stronger smallness conditions. The semimajor axis map

$$\vec{a} : \Lambda = (\Lambda_1, \ldots, \Lambda_N) \mapsto \big(a(\Lambda_1; \mu_1, \varepsilon), \ldots, a(\Lambda_N; \mu_N, \varepsilon)\big) \tag{4.1}$$

is a real-analytic diffeomorphism and we define

$$\mathfrak{I} = \vec{a}^{\,-1}(A),$$

then the Hamiltonian $\mathcal{H}$ is real-analytic (and bounded) on the domain $\mathfrak{I} \times \mathbf{T}^N \times B_R^{2N}$ for a suitable $R > 0$ (here B_r^n denotes the n-ball of radius r and center $0 \in \mathbf{R}^n$).

By Proposition 3.1, the quadratic part $\overline{\mathcal{H}}_{1,2}$ of the averaged Newtonian interaction $\mathcal{H}_1$ has the simple form (3.6), M being the symmetric matrix defined in (3.7). As already pointed out in Remark 3.1, the matrix M can be diagonalized with eigenvalues, which, thanks to our assumptions and to Proposition 3.2, have the form in (3.29) and, therefore, satisfy

$$\inf_{\mathfrak{I}} |\bar{\Omega}_j| > \bar{c}, \qquad \inf_{\mathfrak{I}} \left|\bar{\Omega}_i - \bar{\Omega}_j\right| > \bar{c} \tag{4.2}$$

for any $i \neq j = 1, \ldots, N$ and for a suitable positive constant $\bar{c}$ independent of ε. If $U := U(\Lambda)$ is the symmetric matrix which diagonalizes M, $U^T M U = \operatorname{diag}(\bar{\Omega}_1, \ldots, \bar{\Omega}_N)$, then the map

$$\Xi : (I, \varphi, p, q) \mapsto (\Lambda, \lambda, \eta, \xi), \qquad \text{where} \qquad \begin{cases} p = U^T \eta, \qquad q = U^T \xi, \\ I = \Lambda, \\ \varphi = \lambda + \displaystyle\sum_{h,k,\ell} (\partial_\Lambda U_{k\ell}) U_{h\ell}\, \eta_k\, \xi_\ell, \end{cases} \tag{4.3}$$

is symplectic (and real-analytic) and

$$\overline{\mathcal{H}}_{1,2} \circ \Xi = \frac{1}{2} \sum_{i=1}^N \bar{\Omega}_i(I)(p_i^2 + q_i^2). \tag{4.4}$$

Thus, the $(N+1)$-body problem Hamiltonian $\mathcal{H}$ in (2.14), in the case we are considering, can be written as

$$\mathcal{H} \circ \Xi(I, \varphi, p, q; \varepsilon) = h(I) + f(I, \varphi, p, q; \varepsilon) \tag{4.5}$$

with

$$h := \mathcal{H}_0, \qquad f := \varepsilon f_1(I, p, q; \varepsilon) + \varepsilon f_2(I, \varphi, p, q; \varepsilon),$$

$$f_1 := f_{1,0}(I) + \frac{1}{2} \sum_{i=1}^N \bar{\Omega}_i(I)(p_i^2 + q_i^2) + \tilde{f}_1(I, p, q; \varepsilon),$$

$$f_{1,0} := \overline{\mathcal{H}}_{1,0}, \qquad \tilde{f}_1 := \overline{\mathcal{H}}_{1,*} \circ \Xi, \qquad f_2 := \widetilde{\mathcal{H}}_1 \circ \Xi.$$

Here h is uniformly strictly concave,

$$|\tilde{f}_1| \leq \text{const}\, |(p, q)|^4, \qquad \text{and} \qquad \int_{\mathbf{T}^N} f_2 \, d\varphi = 0.$$

The construction of elliptic invariant tori for the Hamiltonian (4.5) is based on four steps, which we proceed to describe.

4.1. Averaging. Fix $\tau > N-1 \geq 1$ and pick two numbers b_1, b_2 such that

$$0 < b_1 < \frac{1}{2}, \qquad 0 < b_2 < \Big(\frac{1}{2} - b_1\Big)\frac{1}{\tau+1}. \tag{4.6}$$

Since the integrable Hamitlonian h depends only on the action I, the conjugated variable φ is a "fast" angle and, in "first approximation," the $(h+f)$-motions are governed by the averaged Hamiltonian $h+\varepsilon f_1$, which possesses an elliptic equilibrium at $p = q = 0$. As we, now, proceed to describe, one may remove the φ-dependence of the perturbation function f up to high order in ε by using averaging theory; for detailed information on averaging theory in similar situations, see Proposition A.1 of [BCV03] or Proposition 7.1 of [BBV04].

Denote by D^n_R the complex n-ball of center zero and radius $R > 0$ and, for any $V \subset \mathbf{R}^N$, denote by V_R the complex neighborhood of radius $R > 0$ of the set V given by $V_R := \cup_{x\in V} D_R(x)$. Next, define the set $\hat{\mathfrak{I}}$ as the following "Diophantine subset" of $\mathfrak{I}$:

$$\hat{\mathfrak{I}} := \left\{ I \in \mathfrak{I} \,:\, |\partial_I h(I)\cdot k| \geq \frac{\bar\gamma}{|k|^\tau}\ \forall k \in \mathbf{Z}^N \setminus \{0\} \right\} \quad \text{with} \quad \bar\gamma := \text{const}\ \varepsilon^{b_1}. \tag{4.7}$$

Notice that (as it is standard to prove)

$$\text{meas}\left(\mathfrak{I} \setminus \hat{\mathfrak{I}}\right) \leq \text{const}\,\bar\gamma = \text{const}\,\varepsilon^{b_1}. \tag{4.8}$$

The Hamiltonian $h+f$ in (4.5) is real-analytic on the complex domain

$$\mathfrak{D}_{\mathrm{r},s,\rho} := \hat{\mathfrak{I}}_{\mathrm{r}} \times \mathbf{T}^N_s \times D^{2N}_\rho \subset \mathbf{C}^{4N}, \tag{4.9}$$

with

$$\mathrm{r} := \text{const}\,\sqrt{\varepsilon}, \qquad s := \text{const}, \qquad \rho := \text{const}\,\varepsilon^{b_2}. \tag{4.10}$$

The definition of $\hat{\mathfrak{I}}$ is motivated by the necessity to have an estimate on small divisors. In fact, let $I \in \hat{\mathfrak{I}}_{\mathrm{r}}$ (and ε small enough) and let $I_0 \in \hat{\mathfrak{I}}$ be a point at distance less than r from I. Then, for any $k \in \mathbf{Z}^N\backslash\{0\}$ such that $|k| \leq K := \text{const}\,\varepsilon^{-b_2}$, by the second relation in (4.6), by (4.7), and by Cauchy estimates, one finds

$$\begin{aligned}|\partial_I h(I)\cdot k| &\geq |\partial_I h(I_0)\cdot k| - |\partial_I h(I_0) - \partial_I h(I)|\ |k| \\ &\geq \frac{\bar\gamma}{K^\tau} - \max|\partial^2_I h|\ r\ K \\ &\geq \frac{\bar\gamma}{2K^\tau} =: \alpha = \text{ const}\,\varepsilon^{b_1+\tau b_2}, \qquad \Big(0 < |k| \leq K := \text{const}\,\varepsilon^{-b_2}\Big).\end{aligned} \tag{4.11}$$

In order to apply averaging theory (see, e.g., [N77]) so as to remove the ε-dependence up to order $\exp(-\,\text{const}\,K)$, one has to verify the following "smallness condition" (compare condition (A.2), p. 110 in [BCV03])

$$\|f\|_{\mathrm{r},s,\rho} \leq \text{const}\,\frac{\alpha\min\{\mathrm{r}s, \rho^2\}}{K},$$

where the norm $\|\cdot\|_{\mathrm{r},s,\rho}$ is defined as the standard "sup-Fourier norm"

$$\|f\|_{\mathrm{r},s,\rho} := \sum_{k\in\mathbf{Z}^N} \Big(\sup_{(I,p,q)\in\hat{\mathfrak{I}}_{\mathrm{r}}\times D^{2N}_\rho} |f_k(I,p,q)| \Big) e^{|k|s}, \tag{4.12}$$

($f_k(I,p,q)$ denoting Fourier coefficients of the multiperiodic, real-analytic function $\varphi \mapsto f(I,\varphi,p,q)$). Such condition, in view of (4.6), can be achieved by taking ε small enough since, by (4.11) and (4.10), one has

$$\|f\|_{\mathrm{r},s,\rho} = O(\varepsilon) \qquad \text{and} \qquad \frac{\alpha \min\{\mathrm{r}s, \rho^2\}}{K} = O(\varepsilon^{b_1+(\tau+1)b_2+1/2}).$$

Hence, there exists a close-to-identity (real-analytic) symplectic change of variables $(I',\varphi',p',q') \mapsto (I,\varphi,p,q)$ verifying (compare formulae (2.16) and (A.7) of [BCV03])

$$|I'-I| \le \text{ const}\,\varepsilon^{\frac{1}{2}+b_2} \qquad \text{and} \qquad |p'-p|, |q'-q| \le \text{const}\,\sqrt{\varepsilon}, \tag{4.13}$$

and such that the Hamiltonian expressed in the new symplectic variables becomes

$$h(I') + \hat{g}(I',p',q') + \hat{f}(I',\varphi',p',q'), \qquad \hat{g} := \varepsilon f_1(I',p',q') + \varepsilon \hat{f}_1(I',p',q') \tag{4.14}$$

with $\hat{f}_1$ and $\hat{f}$ real-analytic on the complex domain $\mathfrak{D}_{\mathrm{r}/2,s/6,\rho/2}$ and satisfying

$$\begin{aligned} &\|\hat{f}_1\|_{\mathrm{r}/2,s/6,\rho/2} \le \frac{\varepsilon}{\alpha \mathrm{r}} = \text{ const}\,\varepsilon^{b_2+b_3} \quad \text{with} \quad b_3 := \frac{1}{2} - b_1 - (\tau+1)b_2 > 0, \\ &\|\hat{f}\|_{\mathrm{r}/2,s/6,\rho/2} \le \text{ const}\,e^{-\text{ const}\,K} \ll \text{ const}\,\varepsilon^3. \end{aligned} \tag{4.15}$$

4.2. New elliptic equilibrium. Due to the (small) term $\hat{f}_1$ in (4.14), zero is no longer an elliptic equilibrium for the "averaged" (i.e., φ-independent) Hamiltonian $h+\hat{g}$. Using the implicit function theorem, we can find a new elliptic equilibrium for $h+\hat{g}$, which is $\varepsilon^{b_2+b_3}$ close to zero. Hence we construct a real-analytic symplectic transformation

$$(J',\psi',v',u') \mapsto (I',\varphi',p',q') \quad \text{with} \quad I' = J' \quad \text{and } \varepsilon^{b_2+b_3}\text{-close-to-the-identity}, \tag{4.16}$$

such that in the new symplectic variables (J',ψ',v',u') the Hamiltonian takes the form

$$h(J') + \tilde{g}(J',v',u') + \tilde{f}(J',\psi',v',u')$$

with $\tilde{g}$ having $v'=u'=0$ as elliptic equilibrium; the functions $\tilde{g}$ and $\tilde{f}$ are real-analytic on a slightly smaller complex domain, say $\mathfrak{D}_{\mathrm{r}/7,s/7,\rho/7}$, where they satisfy bounds similar to those in (4.15). Furthermore, for $j=1,\dots,N$, the eigenvalues $\tilde{\Omega}_j(J')$ of the symplectic quadratic part of $\tilde{g}$ are purely imaginary and $\varepsilon^{1+b_2+b_3}$-close to $\varepsilon\bar{\Omega}_j(J')$.

4.3. Symplectic diagonalization of the quadratic term. Using a well-known result on the symplectic diagonalization of quadratic Hamiltonians, we can find a real-analytic, symplectic transformation

$$(\tilde{J},\tilde{\psi},\tilde{v},\tilde{u}) \mapsto (J',\psi',v',u') \quad \text{with} \quad J' = \tilde{J} \quad \text{and } \varepsilon^{b_2+b_3}\text{-close-to-the-identity}, \tag{4.17}$$

such that the quadratic part of $\tilde{g}$ becomes, simply, $\sum_{i=1}^N \tilde{\Omega}_i(\tilde{J})\,(\tilde{u}_j^2 + \tilde{v}_j^2)$. Whence, the new Hamiltonian becomes (compare formula (2.22) of [BCV03])

$$\widetilde{\mathcal{H}} := h_0(\tilde{J}) + \sum_{i=1}^N \tilde{\Omega}_i(\tilde{J})\,(\tilde{u}_i^2 + \tilde{v}_i^2) + \tilde{g}_0(\tilde{J},\tilde{v},\tilde{u}) + \tilde{f}_0(\tilde{J},\tilde{\psi},\tilde{v},\tilde{u}), \tag{4.18}$$

where

$$h_0(\tilde{J}) := h(\tilde{J}) + \varepsilon \tilde{g}(\tilde{J}, 0, 0), \tag{4.19}$$

$\tilde{g}_0$, $\tilde{f}_0$, $\tilde{\Omega}_j$ are real-analytic, and

(4.20)

$$|\tilde{g}_0(\tilde{J}, \tilde{v}, \tilde{u})| \leq \text{ const } \varepsilon\, |(\tilde{v}, \tilde{u})|^3, \qquad |\tilde{\Omega}| \leq \text{ const}\, \varepsilon, \qquad \|\tilde{f}\|_{\mathrm{r}/8, s/8, \rho/8} \leq \text{ const}\, \varepsilon^3.$$

Finally, because of (4.2),

$$\inf |\tilde{\Omega}_i| \geq \text{ const } \varepsilon > 0, \qquad \inf |\tilde{\Omega}_2 - \tilde{\Omega}_1| \geq \text{ const } \varepsilon > 0. \tag{4.21}$$

4.4. Applying KAM theory. We rewrite now the Hamiltonian $\widetilde{\mathcal{H}}$ in (4.18) in a form suitable for applying (elliptic) KAM theory. Introducing translated variables $y := \tilde{J} - \mathfrak{p}$ and complex variables $z, \bar{z}$, we define

$$H = \widetilde{\mathcal{H}}\Big(\mathfrak{p} + y, \psi, \frac{z + l\bar{z}}{\sqrt{2}}, \frac{z - \bar{z}}{\mathrm{i}\sqrt{2}}\Big), \tag{4.22}$$

here $\mathfrak{p}$ is regarded as a parameter and the symplectic form is $\sum_{j=1}^N dy_j \wedge d\psi_j + \mathrm{i} \sum_{j=1}^N dz_j \wedge d\bar{z}_j$ with $\mathrm{i} := \sqrt{-1}$. The Hamiltonian H is then seen to have the form

$$H = \mathcal{N} + P$$

with

$$\mathcal{N} = e + \omega \cdot y + \sum_{j=1}^N \Omega_j z_j \bar{z}_j, \qquad e := h_0(\mathfrak{p}), \quad \omega := \partial_{\tilde{J}} h_0(\mathfrak{p}), \quad \Omega := \tilde{\Omega}(\mathfrak{p}), \tag{4.23}$$

and P a perturbation, which can naturally be split into four terms:

$$P = \sum_{1 \leq k \leq 4} P_k$$

with

$$\begin{aligned}
P_1 &= h_0(\mathfrak{p} + y) - h_0(\mathfrak{p}) - \partial_{\tilde{J}} h_0(\mathfrak{p}) \cdot y \sim y^2, \\
P_2 &= \sum_{j=1}^n \Big(\tilde{\Omega}_j(\mathfrak{p} + y) - \tilde{\Omega}_j(\mathfrak{p})\Big)\, z_j \bar{z}_j \sim y|z||\bar{z}|, \\
P_3 &= \tilde{g}_0\Big(\mathfrak{p} + y, \frac{z + \bar{z}}{\sqrt{2}}, \frac{z - \bar{z}}{\mathrm{i}\sqrt{2}}\Big) \sim \varepsilon(|z| + |\bar{z}|)^3, \qquad (\text{by } \ (4.20)), \\
P_4 &= \tilde{f}_0\Big(\mathfrak{p} + y, \psi, \frac{z + \bar{z}}{\sqrt{2}}, \frac{z - \bar{z}}{\mathrm{i}\sqrt{2}}\Big) = O(\varepsilon^3).
\end{aligned} \tag{4.24}$$

The parameter $\mathfrak{p}$ runs over the Diophantine set $\hat{\mathfrak{J}}$ defined in (4.7). Notice that the integrable Hamiltonian $\mathcal{N}$ affords, for any given value of the parameter $\mathfrak{p}$, the N-*dimensional elliptic torus*

$$\{y = 0\} \times \mathbf{T}^N \times \{z = \bar{z} = 0\}, \tag{4.25}$$

which is invariant for the Hamiltonian flow generated by $\mathcal{N}$, the flow being, simply, the Diophantine translation $x \mapsto x + \omega t$, with ω as in (4.23).

Since $\det \partial^2_{\bar{J}} h_0 \neq 0$, we can use the frequencies ω as parameters rather than the actions $\mathfrak{p}$. We, therefore, set

$$\mathcal{O} := \partial_{\bar{J}} h_0(\hat{\mathfrak{I}}) = \left\{ \omega = \partial_{\bar{J}} h_0(\mathfrak{p}) \ : \ \mathfrak{p} \in \hat{\mathfrak{I}} \right\}. \tag{4.26}$$

Notice that, by (4.7), we have

$$\operatorname{meas}\Big(\partial_{\bar{J}} h_0(\mathfrak{I}) \setminus \mathcal{O} \Big) \leq \text{const } \varepsilon^{b_1}. \tag{4.27}$$

Now, if we put $\mathfrak{p} = \mathfrak{p}(\omega) := (\partial_{\bar{J}} h_0)^{-1}(\omega)$ in (4.22), we can rewrite the $(N+1)$-body Hamiltonian in the form

$$H(y, \psi, z, \overline{z}; \omega) := \mathcal{N}(y, z, \bar{z}; \omega) + P(y, \psi, z, \bar{z}; \omega), \tag{4.28}$$

where

(4.29)

$$\mathcal{N}(y, z, \overline{z}; \omega) := e(\omega) + \omega \cdot y + \sum_{j=1}^{N} \Omega_j(\omega) z_j \bar{z}_j, \qquad e(\omega) := h_0(\mathfrak{p}(\omega)), \qquad \Omega(\omega) := \widetilde{\Omega}(\mathfrak{p}(\omega)),$$

and the perturbation $P(y, \psi, z, \bar{z}; \omega)$ is obtained by replacing $\mathfrak{p}$ with $\mathfrak{p}(\omega)$ in (4.24). Recalling (4.10), the Hamiltonian H in (4.28) is real-analytic in

$$(y, \psi, z, \bar{z}; \omega) \in \mathfrak{D}_{\mathfrak{r}^2, \mathfrak{s}, \mathfrak{r}, \mathfrak{d}} := D^N_{\mathfrak{r}^2} \times \mathbf{T}^N_{\mathfrak{s}} \times D^{2N}_{\mathfrak{r}} \times \mathcal{O}^N_{\mathfrak{d}} \tag{4.30}$$

with

$$\mathfrak{r} := \text{const } , \varepsilon^{3/4}, \qquad \mathfrak{s} := \text{const}, \qquad \mathfrak{d} := \text{const} \sqrt{\varepsilon}. \tag{4.31}$$

We recall, now, a well-known KAM result concerning the persistence of lower-dimensional elliptic tori for nearly integrable Hamiltonian systems (see [M65], [E88], [K88]). The version we present here is, essentially, a reformulation of Pöschel's theorem in [P89] (compare, also, with Theorem 5.1 of [BBV04]).

THEOREM 4.1. *Let H have the form in* (4.28), (4.29) *and let it be real-analytic on a domain $\mathfrak{D}_{\mathfrak{r}^2, \mathfrak{s}, \mathfrak{r}, \mathfrak{d}}$ of the form* (4.30) *for some $\mathfrak{r}$, $\mathfrak{s}$, and $\mathfrak{d}$ positive. Assume that*

$$\sup_{\omega \in \mathcal{O}_{\mathfrak{d}}} |\partial_\omega \Omega(\omega)| \leq \frac{1}{4} \tag{4.32}$$

and that the nonresonance (or Melnikov) condition

$$|\Omega(\omega) \cdot k| \geq \gamma_0 \qquad \forall\ 1 \leq |k| \leq 2,\ k \in \mathbf{Z}^N, \forall\ \omega \in \mathcal{O}, \tag{4.33}$$

is satisfied for some $\gamma_0 > 0$. Then, if $\mathfrak{d} \geq \gamma_0$ and P is sufficiently small, i.e.,

$$\|P\|_{\mathfrak{r}, \mathfrak{s}, \mathfrak{d}} := \sup_{\omega \in \mathcal{O}_{\mathfrak{d}}} \|P(\,\cdot; \omega)\|_{\mathfrak{r}^2, \mathfrak{s}, \mathfrak{r}} \leq \text{const}\, \gamma_0\, \mathfrak{r}^2, \tag{4.34}$$

then there exist a normal form $\mathcal{N}_* := e_*(\omega) + \omega \cdot y_* + \Omega_*(\omega) z_* \bar{z}_*$, a Cantor set $\mathcal{O}(\gamma_0) \subset \mathcal{O}$ with

$$\operatorname{meas}\big(\mathcal{O} \setminus \mathcal{O}(\gamma_0)\big) \leq \text{const}\, \gamma_0, \tag{4.35}$$

and a transformation

$$\mathcal{F} :\ D^N_{\mathfrak{r}^2/4} \times \mathbf{T}^N_{\mathfrak{s}/2} \times D^{2N}_{\mathfrak{r}/2} \times \mathcal{O}(\gamma_0) \longrightarrow D^N_{\mathfrak{r}^2} \times \mathbf{T}^N_{\mathfrak{s}} \times D^{2N}_{\mathfrak{r}} \times \mathcal{O}_{\mathfrak{d}}$$
$$(y_*, \psi_*, z_*, \bar{z}_*; \omega) \longmapsto (y, \psi, z, \bar{z}; \omega)$$

real-analytic and symplectic for each ω and Whitney smooth in ω, such that

$$H \circ \mathcal{F} = \mathcal{N}_* + R_* \qquad \text{with} \quad \partial^j_{y_*} \partial^h_{z_*} \partial^k_{\bar{z}_*} R_* = 0 \quad \text{if} \quad 2|j| + |h+k| \le 2. \tag{4.36}$$

In particular, for each $\omega \in \mathcal{O}(\gamma_0)$, the torus $\{y_* = 0\} \times \mathbf{T}^N \times \{z_* = \bar{z}_* = 0\}$ is an N-dimensional, linearly elliptic, invariant torus run by the flow $\psi_* \to \psi_* + \omega t$. Finally

$$|y_* - y|, \quad \mathfrak{r}|z_* - z|, \quad \mathfrak{r}|\bar{z}_* - \bar{z}| \le \text{ const } \frac{\|P\|_{\mathfrak{r},\mathfrak{s},\mathfrak{d}}}{\gamma_0}. \tag{4.37}$$

In this section we have shown that the many-body Hamiltonian (2.14) (under the hypotheses spelled out at the beginning of the section) has indeed the form assumed in the KAM theorem (Theorem 4.1). Furthermore, by (4.21), the elliptic frequencies Ω_i verify the Melnikov conditions (4.33) with

$$\gamma_0 = \text{const } \varepsilon, \tag{4.38}$$

and, by (4.24) and (4.31), the perturbation P verifies, for small ε, the KAM condition (4.34), since

$$\|P\|_{\mathfrak{r},\mathfrak{s},\mathfrak{d}} = O(\mathfrak{r}^4 + \varepsilon\mathfrak{r}^3 + \varepsilon^3) = O(\varepsilon^3) \le \text{const}\, \gamma_0\, \mathfrak{r}^2 = O(\varepsilon^{5/2}). \tag{4.39}$$

Thus, the existence of the desired quasi-periodic orbits follows at once from Theorem 4.1. We may summarize the final result as follows.

THEOREM 4.2. *Let $N \ge 2$ and let $\mathcal{H}$ be the $(N+1)$-body problem Hamiltonian in Poincaré variables defined in* (2.14). *Let $m_0 < \bar{\mu}_j < 4m_0$, let θ, A, $\delta^\star$, and ε_0 be as in Remark* 3.2*(ii). Fix $0 < \delta < \delta^\star$ and let $\mathfrak{I} = \vec{a}^{-1}(A)$ where $\vec{a}$ is the semimajor axis map defined in* (4.1). *Let $\tau > N - 1$ and pick b_1, b_2 as in* (4.6). *Finally, let $0 < \varepsilon^\star < \varepsilon_0$ be such that* (4.39) *holds for any $\varepsilon \le \varepsilon^\star$ and such that all conditions on ε required for constructing the symplectic transformations introduced in sections* 4.1–4.3 *are satisfied for $\varepsilon < \varepsilon^\star$. Then, for any $\varepsilon < \varepsilon^\star$, there exist a Cantor set $\mathfrak{I}_* \subset \mathfrak{I}$, with*

$$\text{meas}\,(\mathfrak{I} \setminus \mathfrak{I}_*) \le \text{const}\, \varepsilon^{b_1}, \tag{4.40}$$

and a Lipschitz continuous family of tori embedding

$$\phi\ :\ (\vartheta, \mathfrak{p}) \in \mathbf{T}^N \times \mathfrak{I}_* \mapsto \Big(\Lambda(\vartheta; \mathfrak{p}),\ \lambda(\vartheta; \mathfrak{p}),\ \eta(\vartheta; \mathfrak{p}),\ \xi(\vartheta; \mathfrak{p}) \Big) \in \mathfrak{I} \times \mathbf{T}^N \times B^{2N}_{\rho_*}$$

with $\rho_* := \text{const}\, \varepsilon^{b_2}$ such that, for any $\mathfrak{p} \in \mathfrak{I}_*$, $\phi(\mathbf{T}^N; \mathfrak{p})$ is a real-analytic elliptic $\mathcal{H}$-invariant torus, on which the $\mathcal{H}$-flow is analytically conjugated to the linear flow $\vartheta \to \vartheta + \omega_* t$, ω_* being (γ, τ)-diophantine with $\gamma = O(\varepsilon^{b_1})$. Furthermore, the following bounds hold uniformly on $\mathbf{T}^N \times \mathfrak{I}_*$:

$$|\Lambda(\vartheta; \mathfrak{p}) - \mathfrak{p}| \le \text{const}\, \varepsilon^{\frac{1}{2} + b_2}, \tag{4.41}$$

$$|\eta(\vartheta; \mathfrak{p})| + |\xi(\vartheta; \mathfrak{p})| \le \text{const}\, \varepsilon^{b_2}. \tag{4.42}$$

Theorem 1.1 follows, now, by taking (recall the definitions of b_k in (4.6))

$$c_1 := b_1, \qquad c_2 := b_2, \qquad c_3 := b_2 + \frac{1}{2}. \tag{4.43}$$

In particular the statements on the density of the set of the osculating major semiaxes, on the bound on the osculating eccentricities and on the variation of the osculating major semiaxes, follows from (4.40), (2.9), (4.42), (2.7), and (4.41).

Appendix A. Poincaré variables for the planar (+ 1)-body problem. We briefly recall in this appendix the classical derivation of the Poincaré variables for the planar N-body problem,[13] showing, in particular, the validity of Lemma 2.1, which is proven in subsections A.1 and A.2; subsections A.3 and A.4 are included for completeness.

A.1. Canonical variables for the two-body problem. Consider two bodies P_0, P_1 of masses $\mathfrak{m}_0$, $\mathfrak{m}_1$ and position $u^{(0)}$, $u^{(1)} \in \mathbf{R}^2$ (with respect to an inertial frame). We assume that P_0 and P_1 interact through gravity, with gravitational constant 1. By Newton's laws, the equations of motion for such two-body problem are

$$\ddot{u}^{(0)} = \mathfrak{m}_1 \frac{(u^{(1)} - u^{(0)})}{|u^{(1)} - u^{(0)}|^3},$$
$$\ddot{u}^{(1)} = \mathfrak{m}_0 \frac{(u^{(0)} - u^{(1)})}{|u^{(0)} - u^{(1)}|^3}.$$

Let

$$\mathfrak{M} := \mathfrak{m}_0 + \mathfrak{m}_1, \quad \mathfrak{m} := \frac{\mathfrak{m}_0 \mathfrak{m}_1}{\mathfrak{M}}, \quad x := u^{(1)} - u^{(0)}, \quad X := \mathfrak{m}\dot{x}. \tag{A.1}$$

Then, the above equations of motion become

$$\ddot{x} = \frac{\mathfrak{M}x}{|x|^3},$$

and the motion of the two bodies is governed by the Hamiltonian

$$\mathcal{K}(X,x) = \frac{1}{2\mathfrak{m}}|X|^2 - \frac{\mathfrak{m}\mathfrak{M}}{|x|}, \tag{A.2}$$

with $(X,x) \in \mathbf{R}^2 \times \mathbf{R}^2$ conjugate variables; i.e., the equations of motion are $\dot{x} = \partial_X \mathcal{K}$, $\dot{X} = -\partial_x \mathcal{K}$.

As well known, such system is integrable and for $\mathcal{K} < 0$ the orbits are ellipses. More precisely, one has the following proposition.

Proposition A.1. *Fix $\Lambda_- > 0 > \mathcal{K}_0$ and let $\Lambda_+ := \left(\frac{\mathfrak{m}^3\mathfrak{M}^2}{-2\mathcal{K}_0}\right)^{\frac{1}{2}} > \Lambda_-$. Then, there exist $\hat{\rho} > 0$ and a real-analytic symplectic transformation*

$$\Psi_{\mathrm{DP}} : \Big((\Lambda,\eta),(\lambda,\xi)\Big) \in \Big([\Lambda_-,\Lambda_+] \times [-\hat{\rho},\hat{\rho}]\Big) \times \Big(\mathbf{T} \times [-\hat{\rho},\hat{\rho}]\Big) \mapsto (X,x) \in \Big\{|x| \geq \frac{\hat{\rho}^2}{\mathfrak{m}^2\mathfrak{M}}\Big\},$$

casting (A.2) *into the integrable Hamiltonian* $(-\mathfrak{m}^3\mathfrak{M}^2)/(2\Lambda^2)$.

[13]For a review of the Poincaré variables in the nonplanar case, see, for instance, [Ch88] and [BCV03].

This classical proposition is a planar version of the classical one, due to Poincaré (see [Poi1905, Chapter III]) and the variables $(\Lambda, \eta, \lambda, \xi)$ are, usually, called (planar) Poincaré variables. The proof of Proposition A.1 is particularly interesting from the physical point of view and rests upon the introduction of three different (famous) changes of variables, which we, now, proceed to describe briefly.

Let ℓ and g denote, respectively, the mean anomaly and the argument of the perihelion.

Step 1. The system is set in *"symplectic" polar variables*; namely, we consider the symplectic map $\Psi_{\rm spc} : ((R,\Phi),(r,\varphi)) \mapsto (X,x)$ (where $r>0$ and $\varphi \in \mathbf{T}$) given by

$$\Psi_{\rm spc} : \begin{cases} x_1 = r\ \cos\varphi, \\ x_2 = r\ \sin\varphi, \end{cases} \qquad X = \begin{pmatrix} \cos\varphi & -\dfrac{\sin\varphi}{r} \\ \sin\varphi & \dfrac{\cos\varphi}{r} \end{pmatrix} \begin{pmatrix} R \\ \Phi \end{pmatrix} \tag{A.3}$$

and consider the new Hamiltonian $\mathcal{K}_{\rm spc} := \mathcal{K} \circ \Psi_{\rm spc}$.

Step 2. There is a symplectic map $\Psi_{\rm D} : ((L,G),(\ell,g)) \mapsto ((R,\Phi),(r,\varphi))$ that integrates the system: $\Psi_{\rm D}$ is obtained via the generating function

$$S(L,G,r,\varphi) = \int \sqrt{-\frac{\mathfrak{m}^4\mathfrak{M}^2}{L^2} + \frac{2\mathfrak{m}^2\mathfrak{M}}{r} - \frac{G^2}{r^2}}\ dr\ +\ G\,\varphi. \tag{A.4}$$

The variables $((L,G),(\ell,g))$ are known as (planar) *Delaunay variables*. In such variables, the new Hamiltonian becomes

$$\mathcal{K}_{\rm D} := \mathcal{K}_{\rm spc} \circ \Psi_{\rm D} = -\frac{\mathfrak{m}^3\mathfrak{M}^2}{2L^2}.$$

Also, if C is the angular momentum of the planet and a is the major semiaxis, by construction, one has that

$$G = |C| \qquad \text{and} \qquad L = \mathfrak{m}\sqrt{\mathfrak{M}a}.$$

Step 3. We need now to remove singularities, which appear for small eccentricity. To this aim, we first introduce (planar) *Poincaré action-angle variables* by means of the linear symplectic transformation

$$\Psi_{\rm P_{aa}} : \Big((\Lambda,H),(\lambda,h)\Big) \mapsto \Big((L,G),(\ell,g)\Big)$$

given by

$$\Psi_{\rm P_{aa}} : \quad \begin{cases} \Lambda = L, \quad H = L - G, \\ \lambda = \ell + g, \quad h = -g. \end{cases} \tag{A.5}$$

Then, we let $\Psi_{\rm P} : ((\Lambda,\eta),(\lambda,\xi)) \mapsto ((\Lambda,H),(\lambda,h))$ be the symplectic map defined by

$$\sqrt{2H}\ \cos h = \eta, \qquad \sqrt{2H}\ \sin h = \xi. \tag{A.6}$$

As Poincaré showed (see [Poi1905], [Ch88], [BCV03]), the symplectic map

$$\Psi_{\rm DP} : \Big((\Lambda,\eta),(\lambda,\xi)\Big) \mapsto (X,x)$$

with

$$\Psi_{\rm DP} := \Psi_{\rm spc} \circ \Psi_{\rm D} \circ \Psi_{\rm P_{aa}} \circ \Psi_{\rm P} \tag{A.7}$$

is real-analytic in a (complex) neighborhood of

$$\Lambda \in [\Lambda_-, \Lambda_+], \qquad |\eta|, |\xi| \le \text{const}\sqrt{\Lambda_-}, \qquad \lambda \in \mathbf{T}.$$

Also, the two-body Hamiltonian, in Poincaré variables, is $\mathcal{K} \circ \Psi = -\frac{\mathfrak{m}^3\mathfrak{M}^2}{2\Lambda^2}$.

Remark A.1. (i) If we denote $(X, x) = \Phi_{\rm DP}((\Lambda, \eta, {\rm p}), (\lambda, \xi, {\rm q}))$, then

$$X = \frac{\mathfrak{m}^4\mathfrak{M}^2}{\Lambda^3}\frac{\partial x}{\partial \lambda}. \tag{A.8}$$

Indeed, from the Hamilton equations one sees that: $\dot\lambda = \partial_\Lambda(-\frac{\mathfrak{m}^3\mathfrak{M}^2}{2\Lambda^2}) = \frac{\mathfrak{m}^3\mathfrak{M}^2}{\Lambda^3}$, and $\dot\Lambda = \dot\xi = \dot\eta = \dot{\rm p} = \dot{\rm q} = 0$. Thus, by the chain rule, $X = \mathfrak{m}\dot x = \mathfrak{m}(\partial_\lambda x)\,\dot\lambda = \frac{\mathfrak{m}^4\mathfrak{M}^2}{\Lambda^3}\frac{\partial x}{\partial\lambda}$, proving (A.8).

(ii) We collect some useful relations among the above-introduced quantities. Let, as usual, e denote the eccentricity of the Keplerian ellipse and let a denote the major semiaxis. Then, by construction, one sees that

$$\Lambda = \mathfrak{m}\sqrt{\mathfrak{M}a}, \qquad \sqrt{\xi^2+\eta^2} = \sqrt{\Lambda}\, e\,(1+O(e^2)). \tag{A.9}$$

Also, if C is the angular momentum of the system, one infers that

$$|C| = \Lambda\sqrt{1-e^2} = \Lambda(1+O(e^2)). \tag{A.10}$$

(iii) A proof of the analyticity of Poincaré variables will also follow by directly inspecting the formulae given in Lemma 2.1, which is proved in the coming section.

A.2. Orbital elements. We now sketch a way to explicitly represent some quantities in terms of Poincaré variables. This will also lead to the proof of Lemma 2.1. Let u and v denote the eccentric anomaly and the true anomaly, respectively. By geometric considerations,

$$u = \ell + e\sin u \tag{A.11}$$

and[14]

$$\cos v = \frac{\cos u - e}{1 - e\cos u}, \tag{A.12}$$

where

$$\ell = \lambda + h. \tag{A.13}$$

Also, by (A.6),

$$H = \frac{\eta^2+\xi^2}{2}. \tag{A.14}$$

An explicit expression taking into account H, the eccentricity, and the major semiaxis is given by

$$H = \Lambda\,(1-\sqrt{1-e^2}) = \Lambda\,\frac{e^2}{2}(1+O(e^2)), \tag{A.15}$$

$$e(H,\Lambda) = \sqrt{\frac{H}{\Lambda}\left(2-\frac{H}{\Lambda}\right)}. \tag{A.16}$$

[14]Such relations are classical and we refer the reader to [Ch88] and [BCV03] for a geometric interpretation of these anomalies.

In light of (A.12),

$$\sin v = \frac{\sqrt{1-e^2}\sin u}{1-e\cos u}. \tag{A.17}$$

By means of (A.11), we have

$$u - \ell = e\,\sin(u-\ell+\ell) = e\,\cos\ell\,\sin(u-\ell) + e\,\sin\ell\,\cos(u-\ell).$$

Thus, in the notation of Lemma 2.1, if G_0 is implicitly defined by

$$G_0(x,y) = x\sin G_0(x,y) + y\cos G_0(x,y),$$

with $G_0(0,0)=0$, we have that G_0 is real-analytic, $G_0(x,y) = y + xy + O_3(x,y)$ and

$$u - \ell = G_0(e\cos\ell, e\sin\ell). \tag{A.18}$$

Therefore, we deduce from (A.18) and (A.13) that

$$u = \lambda + h + G_0(e\cos h\cos\lambda - e\sin h\sin\lambda,\ e\sin h\cos\lambda + e\cos h\sin\lambda). \tag{A.19}$$

Moreover, denoting

$$\hat\eta = \eta/\sqrt{\Lambda}, \qquad \hat\xi = \xi/\sqrt{\Lambda}, \tag{A.20}$$

we deduce from (A.6) and (A.16) that

$$e\sin h = \sqrt{\frac{2H}{\Lambda}}\cdot\sqrt{1-\frac{H}{2\Lambda}}\sin h = \hat\xi\,F_1(\hat\eta^2+\hat\xi^2), \tag{A.21}$$

where $F_1(t) = \sqrt{1-(t/4)}$ is real-analytic for $|t|<4$ (and agrees with the one introduced in Lemma 2.1). Analogously,

$$e\cos h = \hat\eta\,F_1(\hat\eta^2+\hat\xi^2). \tag{A.22}$$

Therefore, substituting (A.21) and (A.22) in (A.19), we can write G_0 as an analytic expression of $(\hat\eta,\hat\xi,\lambda)$: more formally, there exists a real-analytic $(\hat\eta,\hat\xi,\lambda)\mapsto G(\hat\eta,\hat\xi,\lambda)$ (which agrees with the one introduced in (2.6) by (A.21) and (A.22)), so that

$$G_0(e\cos h\cos\lambda - e\sin h\sin\lambda,\ e\sin h\cos\lambda - e\cos h\sin\lambda) = G(\hat\eta,\hat\xi,\lambda).$$

Hence, from (A.19),

$$\begin{aligned} e\cos u &= e\cos h\cos(\lambda+G) - e\sin h\sin(\lambda+G),\\ e\sin u &= e\sin h\cos(\lambda+G) + e\cos h\sin(\lambda+G) \end{aligned} \tag{A.23}$$

with $G = G(\hat\eta,\hat\xi,\lambda)$. Notice also that, from the formulae in (A.16) and (A.14),

$$\frac{1-\sqrt{1-e^2}}{e^2} = F_2(\hat\eta^2+\hat\xi^2)$$

for a suitable real-analytic function F_2 (actually, $F_2(t) = \frac12(1-\frac t4)^{-1}$, which agrees with the notation in Lemma 2.1). Thus, if we set $\varphi = \lambda + v - \ell = v - h$, recalling also

(A.12) and (A.17), we have

$$\begin{aligned}\sin\varphi &= \sin v\cos h - \cos v \sin h\\ &= \frac{1}{1-e\cos u}[\sqrt{1-e^2}\sin u\cos h - \cos u \sin h + e\sin h]\\ &= \frac{1}{1-e\cos u}[\sin(u-h) + e\sin h - F_2\cdot(e\sin u)\cdot(e\cos h)]\\ &= \frac{1}{1-e\cos u}[\sin(\lambda + e\sin u) + e\sin h - F_2\cdot(e\sin u)\cdot(e\cos h)] \qquad \text{(A.24)}\end{aligned}$$

for $F_2 = F_2(\hat\eta^2 + \hat\xi^2)$ and analogously

$$\cos\varphi = \frac{1}{1-e\cos u}[\cos(\lambda + e\sin u) - e\cos h - F_2\cdot(e\sin u)\cdot(e\sin h)]. \qquad \text{(A.25)}$$

Hence, from (A.21), (A.22), (A.23), (A.24), and (A.25), it follows that $\sin\varphi$ and $\cos\varphi$ are real-analytic functions in $\lambda, \hat\eta, \hat\xi$, for $\lambda \in \mathbf{T}$ and small $\hat\xi, \hat\eta$. In particular, if $\mathcal{C}$, $\mathcal{S}$, and $\mathcal{E}_{\mathrm{s}}$ are as defined in Lemma 2.1, we deduce from (A.23), (A.21), and (A.22) that

$$e\sin u = \mathcal{E}_{\mathrm{s}}, \qquad \text{(A.26)}$$

and then from (A.25) and (A.24) that

$$(1-e\cos u)\cos\varphi = \mathcal{C} \qquad \text{and} \qquad (1-e\cos u)\sin\varphi = \mathcal{S}. \qquad \text{(A.27)}$$

Finally, by geometric considerations, we have

$$r = a(1-e\cos u), \qquad \text{(A.28)}$$

where r is the distance between the planet and the sun. Thus, the formulae in Lemma 2.1 follow at once by (A.26), (A.27), (A.3), and (A.8).

A.3. Hamiltonian setting for the planar many-body problem. Consider $(N+1)$ bodies $P_0, \dots, P_N$ of masses $m_0, \dots, m_N$, all lying in the same plane, interacting through gravity (with constant of gravitation 1). Denote by $u^{(i)}$ the position of P_i in a given inertial frame of $\mathbf{R}^2$, with origin in the center of mass of the system. By Newton's laws, we have that

$$\ddot u^{(i)} = \sum_{0\le j\ne i\le N} \frac{m_j(u^{(j)} - u^{(i)})}{|u^{(j)} - u^{(i)}|^3}. \qquad \text{(A.29)}$$

Thus, if $U^{(i)} := m_i \dot u^{(i)}$ denotes the momentum of P_i, we see that the equations of motion (A.29) come from the Hamiltonian

$$\sum_{i=0}^{N} \frac{1}{2m_i}|U^{(i)}|^2 - \sum_{0\le i<j\le N} \frac{m_i m_j}{|u^{(i)} - u^{(j)}|},$$

where $U = (U^{(0)}, \dots, U^{(N)}) \in \mathbf{R}^{2(N+1)}$ and $u = (u^{(0)}, \dots, u^{(N)}) \in \mathbf{R}^{2(N+1)}$ are conjugate symplectic variables.

We now consider P_0 as the "sun" and introduce canonical heliocentric variables via the linear symplectic transformation

$$\begin{aligned}&u^{(0)} = r^{(0)}, \quad u^{(i)} = r^{(0)} + r^{(i)},\\ &U^{(0)} = R^{(0)} - R^{(1)} - \cdots - R^{(N)}, \quad U^{(i)} = R^{(i)}, \qquad \text{for} \quad i = 1, \dots, N. \qquad \text{(A.30)}\end{aligned}$$

Notice that, by our choice of coordinates, $R^{(0)} = 0$. Thus, the planar many-body problem is governed by the $(2N)$-degree-of-freedom Hamiltonian

$$\sum_{i=1}^{N}\left(\frac{m_0+m_i}{2m_0m_i}|R^{(i)}|^2 - \frac{m_0m_i}{|r^{(i)}|}\right) + \sum_{1\le i<j\le N}^{N}\left(\frac{R^{(i)}\cdot R^{(j)}}{m_0} - \frac{m_im_j}{|r^{(i)}-r^{(j)}|}\right).$$

If $m_i = \varepsilon\mu_i$ for $i = 1,\dots,N$, i.e., if the "planets" are very much smaller than the "sun," the momenta $R^{(i)}$ are of order ε. Therefore, it is convenient to introduce the following rescaled symplectic variables:

$$X^{(i)} = \frac{R^{(i)}}{\varepsilon m_0^{5/3}}, \qquad x^{(i)} = \frac{r^{(i)}}{m_0^{2/3}}, \qquad i = 1,\dots,N. \tag{A.31}$$

In such variables, after a time scale of factor $\varepsilon m_0^{7/3}$ we obtain the Hamiltonian in (2.1). Notice that, in that setting, the Hamiltonian $\mathcal{H}_0^{(N)}$ corresponds to the sum of N integrable Hamiltonians of the form (A.2), with $\mathfrak{m}$ and $\mathfrak{M}$ replaced by $\mathrm{m_i}$ and $\mathrm{M_i}$, respectively.

A.4. A parity property. We recall here the well-known fact that the λ-average of $\mathcal{H}_1$ (as in (2.14)) is even in (η,ξ). The proof of this will be accomplished by a 180-degree rotation of the perihelia.

Proposition A.2. *Let*

$$f_1(\Lambda,\eta,\xi) := \frac{1}{\varepsilon}\int_{\mathbf{T}^2}\mathcal{H}_1(\Lambda,\eta,\lambda,\xi)\ d\lambda.$$

Then, $f_1(\Lambda,-\eta,-\xi) = f_1(\Lambda,\eta,\xi)$.

The rescaling by $\frac{1}{\varepsilon}$ is made so that f_1 is a (real-analytic) uniformly bounded (by an order-one constant) function.

Proof. The eccentricity e_i, the semiaxis a_i, and the mean anomaly ℓ_i of the osculating ellipse of P_i are invariant under the map $(\Lambda_i,\lambda_i,H_i,h_i)\mapsto(\Lambda_i,\lambda_i-\pi,H_i,h_i+\pi)$, while the argument of the perihelion g_i changes of π. Let us denote $\vec{\pi} := (\pi,\dots,\pi)\in\mathbf{R}^N$. In light of the consideration above we have that the map

$$(\Lambda,\lambda,H,h)\mapsto(\Lambda,\lambda-\vec{\pi},H,h+\vec{\pi}) \tag{A.32}$$

leaves $|r^{(i)}-r^{(j)}|$ invariant, for any $i,j = 1,\dots,N$. The map in (A.32) corresponds to

$$(\Lambda,\lambda,\xi,\eta)\mapsto(\Lambda,\lambda-\pi,-\xi,-\eta),$$

usually referred to as "space inversion." ∎

Appendix B. Simple eigenvalue perturbations.

Lemma B.1. *Let* $M^\star\in\mathrm{Mat}(m\times m)$, $M_\star\in\mathrm{Mat}(k\times k)$, *and* $M^\sharp\in\mathrm{Mat}(m\times k)$. *Then,*

$$\det\begin{pmatrix} M^\star & M^\sharp \\ \mathbf{0}_{k\times m} & M_\star\end{pmatrix} = \det(M^\star)\det(M_\star).$$

Proof. The proof is obvious. ∎

LEMMA B.2. *Let* $M^\star \in \mathrm{Mat}(m\times m)$, $M_\star \in \mathrm{Mat}(k\times k)$, $M^\sharp \in \mathrm{Mat}(m\times k)$, *and* $M_\sharp \in \mathrm{Mat}(k\times m)$. *Let*

$$M_\epsilon := \begin{pmatrix} M^\star + O(\epsilon) & \epsilon M^\sharp + O(\epsilon^2) \\ \\ \epsilon M_\sharp + O(\epsilon^2) & \epsilon M_\star + O(\epsilon^2) \end{pmatrix}.$$

Then

- *if* $\bar\lambda \neq 0$ *is a simple eigenvalue of* $M^\star$, *then there exists* $\bar\lambda_\epsilon = \bar\lambda + O(\epsilon)$ *which is an eigenvalue of* M_ϵ, *provided* $|\epsilon|$ *is suitably small;*
- *if* $\tilde\lambda$ *is a simple eigenvalue of* $M_\star$ *and* $\det(M^\star)\neq 0$, *then there exists* $\tilde\lambda_\epsilon = \tilde\lambda + O(\epsilon)$ *so that* $\epsilon\tilde\lambda_\epsilon$ *is an eigenvalue of* M_ϵ, *provided* $|\epsilon|$ *is suitably small.*

Proof. For the first claim, apply the implicit function theorem to

$$\mathcal{F}_1(t,\epsilon) := \det(M_\epsilon - t\mathbf{1}_{(m+k)}),$$

noticing that $\mathcal{F}_1(t,0) = (-1)^k t^k \det(M^\star - t\mathbf{1}_m)$. For the second claim, apply the implicit function theorem to

$$\mathcal{F}_2(t,\epsilon) := \det \begin{pmatrix} M^\star - \epsilon t\mathbf{1}_m & M^\sharp \\ \epsilon M_\sharp & M_\star - t\mathbf{1}_k \end{pmatrix},$$

noticing that $\epsilon^k \mathcal{F}_2(t,\epsilon) = \det(M_\epsilon - \epsilon t\mathbf{1}_{(m+k)})$ and that, by Lemma B.1, $\mathcal{F}_2(t,0) = \det(M^\star)\det(M_\star - t\mathbf{1}_k)$. □

QUASIMINIMAL PARTITIONS WITH PRESCRIBED MEASURE*

SÉVERINE RIGOT†

Abstract. We prove that, in a fairly general context, quasiminimal partitions with prescribed measure enjoy quantitative rectifiability properties with universal bounds. Namely, we show that the set of interfaces of a quasiminimal partition is uniformly rectifiable with bounds that depend only on the structural data of the problem.

Key words. partitions, Ahlfors-regular sets, uniform rectifiability

AMS subject classifications. 49Q20, 49N60, 28A75

DOI. 10.1137/S003614100443960X

1. Introduction.

This paper is devoted to the study of quantitative and uniform rectifiability properties for quasiminimal partitioning hypersurfaces between regions in $\mathbb{R}^n$ of prescribed n dimensional measure. Usually one says that a partition is minimal if admissible deformations of it cannot decrease its energy. For quasiminimal partitions one allows the energy to decrease but only in a controlled way. Energies we shall consider here will be surface-like energies of interface type.

There is a wide class of variational problems involving a competition between surface- and volume-like energies where quasiminimality conditions appear naturally. There are also many situations where such a variational problem turns out to be related to a partitioning problem. For instance the various regions delimitated by a quasiminimal partitioning hypersurface seem to provide a model for equilibrium configurations of a system of immiscible and incompressible fluids subject to external forces of volume type (for example the gravity). Roughly speaking the term in the energy corresponding to these external forces is, mostly for homogeneity reasons, negligible compared to the surface-like energy, which reflects the effects of the surface tension between the different fluids. Then, when a configuration has minimal total energy among all other possible configurations, the surface-like energy turns out to enjoy on its own some suitable quasiminimality condition.

A major work in the study of minimal partitions is due to Almgren [1]. He proved existence and regularity of partitioning hypersurfaces between regions of given measure, hypersurfaces which minimize an appropriate surface-like energy with so-called partitioning regular weights assigned to the various interfaces. This work has been the main source for the present paper, the goal being to give (nontrivial) improvements of some of the results in [1] about the regularity theory of minimal partitions (we will not consider here questions of existence).

First we consider more general energies since it seems that relevant physical situations do not fit Almgren's setting (compare in particular (H1), (H2), and (H3) with the hypotheses in [1, section VI.1], see also [8], [11]). We shall however go back to Almgren's setting in section 6. Next we relax the minimality into a quasiminimality condition which reflects more closely the presence of external forces of volume type.

This will actually not be a serious issue here and can be handled without too much pain.

More significantly we prove some uniform and universal versions of properties that appeared more or less explicitly, and in weaker form, in [1]. The properties we have in mind, namely Ahlfors-regularity and condition B (see section 3 for precise definitions), or the weaker forms exploited in [1], constitute some of the main steps in the proof of the regularity results of $C^{1,\alpha}$ type obtained in [1] (this actually turns out to be more generally the case in many other geometric variational problems). Another major motivation for the study of Ahlfors-regularity and condition B comes from the fact that they imply the uniform rectifiability of the set of interfaces. We use here the terminology of David and Semmes who have developed an extensive theory of uniformly rectifiable sets. Uniform rectifiability is a quantitative and uniform version of the classical notion of rectifiability, but it is much stronger because it comes with uniform bounds (see [5] and the references therein). Note that due to the generality adopted here—we assume only some Lipschitz regularity and nondegeneracy of the defining integrands of the energy—one cannot hope to have much more in the way of smoothness than uniform rectifiability, just for reasons of bi-Lipschitz invariance.

Finally we stress that, besides these quantitative rectifiability properties, the main goal of this paper is to prove them with universal bounds. This roughly means that we want to prove that these properties hold for any quasiminimal partition with prescribed measure with quantifiers which depend only on the structural data of the problem (the dimension, the prescribed measure, the way the quasiminimality is formulated, bounds on the defining integrands of the energy) but not on the particular partition under study (see section 3 for precise statements). In particular one of the main steps in our proof is to show that quasiminimal partitions with prescribed measure actually satisfy an apparently stronger condition where there is no volume constraint anymore on the various components of admissible deformations, this new condition being formulated in a way that depends only on the structural data of the problem (see Theorem 3.6). This is one of the main points which improves what was proved in [1] where the same kind of condition without volume constraint was obtained but in a way that depends strongly on the specific geometry of the partition under study (see especially the comment around typical examples of (F, ε, δ) minimal sets on page vii in [1]).

The main issue when studying quasiminimal partitions with prescribed measure is indeed to handle properly the volume constraint and Theorem 3.6 follows actually from the construction of suitable deformations which modify the measure of each component of the partition by a prescribed amount given in advance. As just pointed out an additional difficulty here comes from the fact that we also need to keep a universal control in these constructions just because of the uniform constants we are seeking in the formulation of Ahlfors-regularity and condition B. This will be done through a uniform version of Almgren's original deformations, see Theorem 4.1 (compare with Theorem 4.2 which comes from [1]).

The same kind of results have been previously proved in [10] in a similar context and for the simpler case of quasiminimal crystals, that is, for partitions composed by simply one set and its complement, but with a completely different method.

The paper is organized as follows. In section 2 we recall basic facts about the theory of sets with finite perimeter and define various classes of partitions and of energies. We state the main results of this paper in section 3. Theorem 3.6 which says that any quasiminimal partition with a volume constraint is locally quasiminimal in a suitable universal way is proved in section 4. In particular the key argument of the proof, the above-mentioned construction of suitable deformations, is given there by Theorem 4.1. We prove the Ahlfors-regularity and condition B for locally quasiminimal partitions in section 5. In section 6 we restrict the study to energies with so-called partitioning regular interface coefficients as in [1] and prove refined properties.

2. Preliminaries. Throughout this paper we work in $\mathbb{R}^n$, $n \geq 2$, equipped with its euclidean structure. For $x \in \mathbb{R}^n$ and $t > 0$, we denote by $B(x,t)$ the open ball with center x and radius t. For any set $G \subset \mathbb{R}^n$ we denote by $\mathbb{1}_G$ its characteristic function. If G is measurable, then $|G|$ stands for its Lebesgue measure. Finally we denote by $\mathcal{H}^{n-1}$ the $(n-1)$ dimensional Hausdorff measure.

We first recall some results about the theory of sets with finite perimeter that will be relevant for our purposes. For more details we refer the reader, for instance, to [2], [7], or [12]. If $G \subset \mathbb{R}^n$ is a measurable set and $\Omega \subset \mathbb{R}^n$ is open, the perimeter of G in Ω, denoted by $P(G,\Omega)$, is defined by

$$P(G,\Omega) = \sup\left\{\int_\Omega \mathbb{1}_G \,\operatorname{div}\phi\, dx;\ \phi \in C_0^1(\Omega,\mathbb{R}^n),\ \|\phi\|_\infty \leq 1\right\}.$$

We say that a measurable set G has finite perimeter if $P(G,\mathbb{R}^n) < +\infty$ and we then simply write $P(G) = P(G,\mathbb{R}^n)$.

If G has finite perimeter, then one knows that the set function $\Omega \mapsto P(G,\Omega)$ defined above is the restriction to the open subsets of $\mathbb{R}^n$ of a finite Borel measure, called the perimeter of G and still denoted by $P(G,.)$. Equivalently it follows from Riesz' representation theorem that a measurable set G has finite perimeter if and only if the distributional gradient of its characteristic function $\nabla\mathbb{1}_{\mathrm{G}}$ can be represented by a vector-valued measure. Then it turns out that the total variation $|\nabla\mathbb{1}_{\mathrm{G}}|$ of this measure coincides with $P(G,.)$.

The reduced boundary $\partial_* G$ of a set G with finite perimeter is defined as the set of points $x \in \mathbb{R}^n$ such that

$$\int_{B(x,r)} |\nabla\mathbb{1}_{\mathrm{G}}| > 0 \quad \text{for all } r > 0,$$

the limit

$$\nu_G(x) = \lim_{r\to 0}\left(\int_{B(x,r)} \nabla\mathbb{1}_{\mathrm{G}}\right) / \int_{B(x,r)} |\nabla\mathbb{1}_{\mathrm{G}}|$$

exists, and $\|\nu_G(x)\| = 1$. It follows from the theorem of Besicovitch on differentiation of measures that $\nu_G(x)$ exists and $\|\nu_G(x)\| = 1$ for $|\nabla\mathbb{1}_{\mathrm{G}}|$-a.e. $x \in \mathbb{R}^n$. Moreover, it is well known that the perimeter $P(G,.)$ coincides with $\mathcal{H}^{n-1}_{|\partial_* G}(.)$.

For any measurable set G and $t > 0$, we set

$$G(t) = \left\{x \in \mathbb{R}^n;\ \lim_{r\to 0}\frac{|G \cap B(x,r)|}{|B(x,r)|} = t\right\},$$

and define the essential boundary $\partial^* G$ of G as the set of points where the volume density of G is neither 0 nor 1, $\partial^* G = \mathbb{R}^n \setminus (G(0) \cup G(1))$. It is also well known that if G has finite perimeter, then

$$\partial_* G \subset G(1/2) \subset \partial^* G \quad \text{and} \quad \mathcal{H}^{n-1}(\mathbb{R}^n \setminus (G(0) \cup G(1) \cup \partial_* G)) = 0. \tag{2.1}$$

Note that it follows in particular that $P(G,.)$ coincides with $\mathcal{H}^{n-1}_{|\partial^* G}$. Note also that we always have $\partial^* G \subset \partial G$ where ∂G is the topological boundary of G.

We turn now to the definition of a partition we shall work with. We fix once and for all an integer $N \in \mathbb{N}^*$.

DEFINITION 2.1 (partition). *We say that a family $A = (A_0, \dots, A_N)$ of measurable sets is a partition if*

$$\begin{gathered} A_i \text{ is a set with finite perimeter for all } i \in \{0, \dots, N\}, \\ |A_i \cap A_j| = 0 \text{ when } i \neq j, \\ |\mathbb{R}^n \setminus \cup_{i=0}^N A_i| = 0. \end{gathered}$$

We denote by $\mathcal{P}$ the set of all partitions.

DEFINITION 2.2 (partition with prescribed measure). *Let $a = (a_1, \dots, a_N)$, $a_i > 0$, be fixed. We say that a partition $A \in \mathcal{P}$ has measure a if $|A_i| = a_i$ for all $i \in \{1, \dots, N\}$. We denote by $\mathcal{P}_a$ the set of all partitions with measure a.*

We will be mostly interested here in the regularity properties of the set of interfaces of some partitions. This set is precisely defined as follows.

DEFINITION 2.3 (set of interfaces). *For any $A \in \mathcal{P}$, we define the set S of its interfaces by $S = \cup_{i=0}^N \partial^* A_i$.*

Note that $\partial^* A_i = \cup_{j \neq i} \partial^* A_i \cap \partial^* A_j$ for all $i \in \{0, \dots, N\}$. Note also that the interfaces $S_{ij} = \partial^* A_i \cap \partial^* A_j$, $i \neq j$, are essentially pairwise disjoint in the sense that

$$\mathcal{H}^{n-1}(S_{ij} \cap S_{lk}) = 0$$

whenever $i \neq j$, $l \neq k$, and at least three of the indexes are distinct.

The symmetric difference $A \triangle A'$ between two partitions A and $A' \in \mathcal{P}$ is defined by

$$A \triangle A' = \cup_{i=0}^N A_i \triangle A'_i,$$

where $A_i \triangle A'_i = (A_i \setminus A'_i) \cup (A'_i \setminus A_i)$ denotes the usual symmetric difference between sets. We set

$$|A \triangle A'| = \max_{i \geq 0} |A_i \triangle A'_i|,$$

and $\operatorname{diam}(A \triangle A') = \max_{i \geq 0} \operatorname{diam}(A_i \triangle A'_i)$. We say that A and A' are equivalent if $|A \triangle A'| = 0$. Note that two equivalent partitions have the same set of interfaces.

DEFINITION 2.4 (reduced partition). *We say that $A \in \mathcal{P}$ is a reduced partition if each component A_i of A coincides with the set of its Lebesgue points, that is, $A_i = A_i(1)$ for all $i \in \{0, \dots, N\}$.*

For any given partition A there exists a unique reduced equivalent partition. It is obtained from A replacing each one of its components by the set of their Lebesgue points. Note that if $A \in \mathcal{P}$ is reduced, then $A_i \cap A_j = \emptyset$ for $i \neq j$, $A_i \cap S = \emptyset$ for all $i \in \{0, \dots, N\}$, and $\mathbb{R}^n = (\cup_{i=0}^N A_i) \cup S$.

We now define the energy of a partition. We denote by S^{n-1} the unit sphere in $\mathbb{R}^n$. Given a family of Borel functions $F_{ij} : \mathbb{R}^n \times S^{n-1} \to \mathbb{R}^+$, $i, j \in \{0, \dots, N\}$, $i \neq j$, we define the associated energy E as

$$E(A, U) = \sum_{\substack{i,j \\ i \neq j}} \int_{\partial^* A_i \cap \partial^* A_j} \mathbb{1}_U(x) F_{ij}(x, \nu_{A_i}(x)) \, d\mathcal{H}^{n-1}$$

for any $A \in \mathcal{P}$ and any measurable set $U \subset \mathbb{R}^n$. When $U = \mathbb{R}^n$ we simply write $E(A)$. Note that this definition is consistent because ν_{A_i} is well defined $\mathcal{H}^{n-1}$-a.e. on $\partial^* A_i$ with $\|\nu_{A_i}(x)\| = 1$ for $\mathcal{H}^{n-1}$-a.e. $x \in \partial^* A_i$. Note also that two equivalent partitions have the same energy.

Let $\underline{F} > 0$ and $\overline{F} > 0$ be two fixed positive constants with $\underline{F} \leq \overline{F}$. Given a map $F : \mathbb{R}^n \times S^{n-1} \to \mathbb{R}^+$ we consider the following conditions:

$$\text{(H1)} \qquad \sup_{\mathbb{R}^n \times S^{n-1}} F \leq \overline{F},$$

$$\text{(H2)} \qquad \underline{F} \leq \inf_{\mathbb{R}^n \times S^{n-1}} F,$$

$$\text{(H3)} \qquad F \text{ is } \overline{F}\text{-Lipschitz on } \mathbb{R}^n \times S^{n-1}, \text{ that is,}$$

$$|F(x,u) - F(y,v)| \leq \overline{F} \max(\|x-y\|, \|u-v\|) \quad \text{for all } x, y \in \mathbb{R}^n, \text{ for all } u, v \in S^{n-1}.$$

Then we denote by $\mathcal{E}_0(\underline{F}, \overline{F})$ the class of all those energies that are defined with respect to some family of integrands (F_{ij}) where each F_{ij} satisfies (H1) and (H2), and by $\mathcal{E}(\underline{F}, \overline{F})$ the class of all energies for which each associated defining integrand F_{ij} satisfies (H1), (H2), and (H3). Finally we denote by $\mathcal{E}(\overline{F})$ the class of all energies for which each defining integrand F_{ij} satisfies (H1) and (H3).

When $F_{ij}(x, \nu) = \|\nu\|$ the corresponding energy is simply the sum of the perimeters of the different components. With a slight abuse of terminology and notation we will call it the perimeter of the partition and denote it by P, that is,

$$P(A, U) = \sum_{i=0}^{N} \sum_{\substack{j=0 \\ j \neq i}}^{N} \mathcal{H}^{n-1}(\partial^* A_i \cap \partial^* A_j \cap U) = \sum_{i=0}^{N} P(A_i, U)$$

for all $A \in \mathcal{P}$ and measurable set $U \subset \mathbb{R}^n$. Note that $\mathcal{H}^{n-1}$-a.e. point in S belongs to exactly one interface $\partial^* A_i \cap \partial^* A_j$ for some $i \neq j$ and thus

$$P(A, U) = 2\, \mathcal{H}^{n-1}(S \cap U). \tag{2.2}$$

Finally note that, whenever $E \in \mathcal{E}_0(\underline{F}, \overline{F})$, we have

$$\underline{F}\, P(A, U) \leq E(A, U) \leq \overline{F}\, P(A, U). \tag{2.3}$$

To conclude these preliminaries we fix some more conventions. In general nonindexed letters, typically the letter C, will denote positive constants whose precise value can change at each occurrence (unless otherwise stated). On the other hand, indexed letters (C_0, C_n, $\eta_0, \dots$) should denote constants whose value remains the same throughout a same paragraph (but whose signification and value may change from one paragraph to another, unless otherwise stated). Finally when specifying $C = C(n, N, \dots)$ we mean that the value of C can be chosen depending only on the fixed data inside the parentheses.

3. Quasiminimality conditions and main results. We fix an energy E as defined in section 2. We also fix $\underline{F} > 0$ and $\overline{F} > 0$ with $\underline{F} \leq \overline{F}$ in view of further assumptions we shall make on the energy. We first define quasiminimal partitions with prescribed measure.

DEFINITION 3.1. *Let $g : [0, +\infty) \to [0, +\infty)$ be such that $\lim_{t \to 0} t^{(1-n)/n} g(t) = 0$ and some $a = (a_1, \dots, a_N)$, $a_i > 0$, be fixed. We say that a partition $A \in \mathcal{P}$ is (g, a)-quasiminimal (with respect to E) if $A \in \mathcal{P}_a$ and*

$$E(A) \leq E(A') + g(|A' \triangle A|) \tag{3.1}$$

for all $A' \in \mathcal{P}_a$ such that $A' \triangle A \subset\subset \mathbb{R}^n$.

Note that in this definition admissible perturbations must preserve the measure of the partition. Note also that (3.1) gives significant information only when $|A'\triangle A|$ is small. In that case the way the energy can be decreased is controlled by $g(|A'\triangle A|)$ and hence negligible compared to $|A'\triangle A|^{(n-1)/n}$. Roughly speaking this turns out to be essentially equivalent to requiring the variation of the energy to be negligible compared to the initial energy.

Before stating the main results of this paper we need some more definitions.

Definition 3.2 (Ahlfors-regularity). *We say that a closed subset Σ of $\mathbb{R}^n$ is Ahlfors-regular if there exist some constants $c > 0$ and $C > 0$, called Ahlfors-regularity constants, such that*

$$c\, r^{n-1} \leq \mathcal{H}^{n-1}(\Sigma \cap B(x,r)) \leq C\, r^{n-1}$$

for all $x \in \Sigma$ and $r \leq 1$.

This is a uniform and scale-invariant version of the property of having upper and lower densities with respect to $\mathcal{H}^{n-1}$ that are positive and finite.

Definition 3.3 (condition B). *We say that a subset Σ of $\mathbb{R}^n$ satisfies condition B if there exists a constant $C > 0$, called condition B constant, such that, for each ball B centered on Σ with radius $r \leq 1$, one can find two balls contained in B, with radius $C\, r$, and which are contained in two distinct connected components of $\mathbb{R}^n \setminus \Sigma$.*

This topological condition is a quantitative, uniform, and scale-invariant way of saying that Σ separates well the different connected components of its complement. Sets that are Ahlfors-regular and satisfy condition B have strong rectifiability properties. Namely, they contain "big pieces of Lipschitz graphs" and thus are uniformly rectifiable (see [3] for the original proof or [4] and [6] for simpler proofs). The aim of this paper not being to speak about the theory of uniform rectifiability, we will not enter the details and refer the reader to [5] and the references therein for more information.

We can now state the main result of this paper about quasiminimal partitions with prescribed measure.

Theorem 3.4. *Assume that $E \in \mathcal{E}(\underline{F}, \overline{F})$. Let $g : [0,+\infty) \to [0,+\infty)$ be non-decreasing and such that $\lim_{t\to 0} t^{(1-n)/n} g(t) = 0$ and let $a = (a_1, \ldots, a_N)$, $a_i > 0$, be fixed. Let A be a (g,a)-quasiminimal partition with respect to E and let S denote its set of interfaces. Then S is a closed Ahlfors-regular set which satisfies condition B. Moreover, the Ahlfors-regularity and condition B constants can be taken depending only on n, N, $\underline{F}$, $\overline{F}$, g, and a.*

As already stressed in the introduction, besides the Ahlfors-regularity and condition B on their own, the main point in this result is that one can find universal Ahlfors-regularity and condition B constants, which do not depend on the specific quasiminimal partition A.

We now wish to explain the main lines of the proof. Let us first introduce another notion of quasiminimality where admissible perturbations are not required to be volume preserving anymore, but a little bit localized instead (this constraint will actually not be a serious issue here).

Definition 3.5 (locally quasiminimal partitions). *Let $g : [0,+\infty) \to [0,+\infty)$ be such that $\lim_{t\to 0} t^{(1-n)/n} g(t) = 0$ and let $\delta > 0$ be fixed. We say that a partition $A \in \mathcal{P}$ is (g,δ)-quasiminimal (with respect to E) if A satisfies (3.1) for all $A' \in \mathcal{P}$ such that $\operatorname{diam}(A'\triangle A) < \delta$.*

In a first step we want to get rid of the volume constraint, proving that quasiminimal partitions with prescribed measure are locally quasiminimal in an appropriate and universal way.

THEOREM 3.6. *Assume that $E \in \mathcal{E}(\underline{F}, \overline{F})$. Let $g : [0, +\infty) \to [0, +\infty)$ be nondecreasing and such that $\lim_{t\to 0} t^{(1-n)/n} g(t) = 0$ and let $a = (a_1, \ldots, a_N)$, $a_i > 0$, be fixed. Then there exist $\tilde{g} : [0, +\infty) \to [0, +\infty)$ such that $\lim_{t\to 0} t^{(1-n)/n} \tilde{g}(t) = 0$ and $\delta > 0$ such that any (g, a)-quasiminimal partition with respect to E is $(\tilde{g}, \delta)$-quasiminimal with respect to E. In particular $\tilde{g}$ and δ can be chosen depending only on n, N, $\underline{F}$, $\overline{F}$, g, and a.*

We shall prove this theorem in section 4. Let us mention that the assumption on g to be nondecreasing is here mostly for technical convenience. As already stressed, Theorem 3.6 is, at least from a technical point of view, the most delicate point here, essentially because, in view of the last part of Theorem 3.4, we need to find $\tilde{g}$ and δ universal. The proof of Theorem 3.6 relies on the construction of suitable deformations of a partition which modify the measure of each component of a prescribed amount given in advance. This will be done in Theorem 4.1 which is actually the crucial step in the proof.

Next, with Theorem 3.6 in hand, we only need to worry about locally quasiminimal partitions and we shall prove in section 5 the Ahlfors-regularity and condition B in that context (see Theorem 5.1). Arguments are based on comparison arguments that one can now easily implement because there is no volume constraint anymore. Let us also mention that we will actually get more information. First note that if A and A' are two equivalent partitions and if A is quasiminimal, then A' is quasiminimal as well and both partitions have the same set of interfaces. In particular one can always assume with no loss of generality that the quasiminimal partition is reduced (remember the remarks around Definition 2.4). Then it is possible to prove that each component is open and that one can replace essential boundaries with topological boundaries in the definition of the set of interfaces.

THEOREM 3.7. *Assume that $E \in \mathcal{E}_0(\underline{F}, \overline{F})$. Let $g : [0, +\infty) \to [0, +\infty)$ be such that $\lim_{t\to 0} t^{(1-n)/n} g(t) = 0$ and let $\delta > 0$ be fixed. Let A be a reduced (g, δ)-quasiminimal partition with respect to E and let S denote its set of interfaces. Then each component A_i, $i \in \{0, \ldots, N\}$, of A is open and $S = \cup_{i=0}^{N} \partial A_i$. Moreover each component with finite Lebesgue measure is bounded.*

Note that we do not say in Theorem 3.7 that each boundary ∂A_i satisfies the regularity properties, the Ahlfors-regularity and condition B, on its own and neither that $\partial^* A_i$ and ∂A_i coincide. This is actually not true in general. However it turns out, as we shall show in section 6, that this is the case when one imposes more conditions on the defining integrands F_{ij} of the energy. These conditions correspond to those taken in [1]. We refer the reader to section 6 for more details and precise statements; see, in particular, Theorem 6.1.

4. Quasiminimal partitions with a volume constraint are locally quasiminimal. This section is devoted to the proof of Theorem 3.6. We first construct in section 4.1 suitable families of deformations of a partition that allow to modify the measure of each component by some prescribed amount given in advance. The proof of Theorem 3.6 itself will be done in section 4.2.

4.1. Measure-prescribed deformations. We first define what we mean by suitable families of deformations. Let $\overline{F} > 0$ be fixed. Let $A \in \mathcal{P}$ be a partition, $\Omega \subset \mathbb{R}^n$ be open, $\varepsilon > 0$ and $C > 0$ be fixed. We say that a map $\psi : (-\varepsilon, \varepsilon)^N \times \mathbb{R}^n \to \mathbb{R}^n$

belongs to $\mathcal{D}_\Omega(A,\varepsilon,C)$ if for all $v=(v_1,\dots,v_N)\in(-\varepsilon,\varepsilon)^N$ we have

$$\psi(v,.) \text{ is a } C^1 \text{ diffeomorphism}, \quad \psi(0,.)=\mathrm{Id}, \tag{4.1}$$

$$\mathcal{O}(\psi(v,.)) \subset\subset \Omega, \tag{4.2}$$

where $\mathcal{O}(f)$ is defined for $f:\mathbb{R}^n\to\mathbb{R}^n$ by $\mathcal{O}(f)=\{x\in\mathbb{R}^n;\ f(x)\neq x\}$,

$$|\psi(v,A_i)|-|A_i|=v_i, \tag{4.3}$$

$$|\psi(v,A_i)\triangle A_i| \le C\,P(A_i,\Omega)\,|v|, \tag{4.4}$$

for all $i\in\{1,\dots,N\}$, with $|v|=\max|v_i|$, and finally

$$E(\psi(v,A),\psi(v,U)) \le E(A,U)+C\,P(A,U)\,|v| \tag{4.5}$$

for all energy $E\in\mathcal{E}(\overline{F})$ and all measurable set $U\subset\mathbb{R}^n$.

In other words one can view an element ψ in $\mathcal{D}_\Omega(A,\varepsilon,C)$ as a family $\psi(v,.)$ of deformations of the partition A. The main point is that for any given $v\in(-\varepsilon,\varepsilon)^N$, one can use $\psi(v,.)$ to add, or remove, depending on the sign of v_i, exactly the prescribed amount of mass v_i to the component A_i (see (4.3)). At the same time (4.4) and (4.5) give a control of order $|v|$ on the measure of the symmetric difference between $\psi(v,A)$ and A and on the induced variation of the energy. This will fit exactly our needs for the estimation of each term in the quasiminimality condition.

For technical reasons we will actually need to use two such families of deformations, each one acting far away from the other. Let $\delta>0$ be fixed. We say that (ψ_1,ψ_2) belongs to $\mathcal{CD}_\Omega(A,\varepsilon,\delta,C)$ if $\psi_j\in\mathcal{D}_\Omega(A,\varepsilon,C)$ for $j=1,2$ and

$$\mathrm{dist}(\mathcal{O}(\psi_1(v,.)),\mathcal{O}(\psi_2(v,.)))\ge\delta$$

for all $v\in(-\varepsilon,\varepsilon)^N$. When $\Omega=\mathbb{R}^n$ we just write $\mathcal{D}(A,\varepsilon,C)$ and $\mathcal{CD}(A,\varepsilon,\delta,C)$.

We are now ready to state the main result about the existence of such families of deformations. Let $\underline{a}>0$, $\overline{a}>0$, $\overline{P}>0$ be fixed with $\underline{a}\le\overline{a}$. We denote by $\mathcal{P}_{\underline{a},\overline{a},\overline{P}}$ the set of all partitions $A=(A_0,\dots,A_N)\in\mathcal{P}$ such that

$$\underline{a}\le\min_{i\ge1}|A_i|\le\max_{i\ge1}|A_i|\le\overline{a} \qquad \text{and} \qquad P(A)\le\overline{P}.$$

Theorem 4.1. *There exist three constants $\varepsilon_0>0$, $\delta_0>0$, and $C_0>0$, depending only on n, N, $\overline{F}$, $\underline{a}$, $\overline{a}$, and $\overline{P}$, such that, for any $A\in\mathcal{P}_{\underline{a},\overline{a},\overline{P}}$, we have $\mathcal{CD}(A,\varepsilon_0,\delta_0,C_0)\neq\emptyset$.*

It has been proved in [1] that for a fixed $A\in\mathcal{P}$ we have $\mathcal{CD}(A,\varepsilon,\delta,C)\neq\emptyset$ for suitable parameters $\varepsilon=\varepsilon(A)$, $\delta=\delta(A)$, and $C=C(A)$ which depend strongly on the specific geometry of A. As already explained in the introduction this does not fit our needs. However it also follows from [1] that $\mathcal{CD}(A',\varepsilon,\delta,C)\neq\emptyset$ with the same parameters ε, δ, and C as for A, as soon as A' is close enough to A in measure. This will be used in the proof of Theorem 4.1. More precisely, one has the following result.

Theorem 4.2 (see [1]). *Let $A\in\mathcal{P}$ and $\Omega\subset\mathbb{R}^n$ be open. Assume that $|A_i\cap\Omega|>0$ for all $i\in\{0,\dots,N\}$. Then there exist $\varepsilon>0$, $\delta>0$, $C>0$, and $\eta>0$ such that, if $A'\in\mathcal{P}$ is such that $|A\triangle A'|\le\eta$, then $\mathcal{CD}_\Omega(A',\varepsilon,\delta,C)\neq\emptyset$. Moreover if $\Omega=\cup_{l=1}^s\Omega_l$ where Ω_l is open and $\Omega_l\cap\Omega_r=\emptyset$ for $l\neq r$, one can construct $(\psi_1,\psi_2)\in\mathcal{CD}_\Omega(A',\varepsilon,\delta,C)$ in such a way that*

$$\{x\in\Omega_l\,;\ \psi_j(v,x)\neq x\}\cup\psi_j(v,\{x\in\Omega_l\,;\ \psi_j(v,x)\neq x\})\subset\subset\Omega_l$$

for all $l\in\{1,\dots,s\}$, $j\in\{1,2\}$, and $v\in(-\varepsilon,\varepsilon)^N$.

This theorem is essentially given by Proposition VI.12 in [1]. We add here the requirement (4.4) about the measure of the symmetric difference between the initial partition and the deformed one. This condition never appears in [1] because Almgren deals with minimal partitions and does not need to handle the extra term given by the function g in the quasiminimality condition. Next we want to control the variation of the energy for all energies in the class $\mathcal{E}(\overline{F})$ (see (4.5)) which is a priori quite larger than the class of energies considered in [1]. Finally we also add, mainly for technical reasons, the localization in Ω and each Ω_l. It turns actually out that one can easily check that the deformations constructed in [1] satisfy these properties (or at least only minor technical modifications of them). We now turn to the proof of Theorem 4.1.

Proof of Theorem 4.1. We argue by contradiction and assume that one can find a sequence A_ν of partitions in $\mathcal{P}_{\underline{a},\overline{a},\overline{P}}$ such that $\mathcal{CD}(A_\nu,\nu^{-1},\nu^{-1},\nu)=\emptyset$ for all $\nu\in\mathbb{N}^*$. We would like to find some limit, say A, to the sequence A_ν and then apply Theorem 4.2 to get a contradiction. For notational convenience, let us denote in this proof the different components of the partition A_ν by $A_\nu(i)$, $i\in\{0,\dots,N\}$, (and similarly for any other partition we shall introduce). In other words we need to know that each sequence $A_\nu(i)$ converges to some set $A(i)$ in L^1. This is not true in general because the sets $A_\nu(i)$ are not a priori uniformly bounded as subsets of $\mathbb{R}^n$ and classical embedding theorems only ensure convergence in L^1_{loc}. For that reason we first construct from A_ν a uniformly bounded sequence A'_ν for which we will have the required convergence. We must also do the construction in such a way to be able to go back to the original sequence A_ν when applying Theorem 4.2. Some of the arguments in what follows are similar in spirit to arguments used in [1], but for different purposes though.

Step 1. One can find $C_1=C_1(n,\underline{a},\overline{P})>0$ and for all $\nu\in\mathbb{N}^*$ and $i\in\{1,\dots,N\}$ a point $p_\nu(i)\in\mathbb{R}^n$ such that

$$|A_\nu(i)\cap B(p_\nu(i),1)|\ge C_1,$$

see for instance [9, Lemma 4.1]. This essentially comes from the fact that a set with positive and finite Lebesgue measure and finite perimeter cannot spread out too much and must meet in a substantial way (which depends only on a lower bound for its Lebesgue measure and an upper bound for its perimeter) at least one ball with unit radius. Next we fix some $R=R(n,N,\underline{a},\overline{a},\overline{P})\ge 4$ large enough so that

$$|B(0,R/2)|-N\overline{a}\ge C_1.$$

Step 2. Up to a subsequence one can always assume that

$$\lim_{\nu\to+\infty}\|p_\nu(i)-p_\nu(j)\|$$

exists in $\mathbb{R}^+\cup\{+\infty\}$ for all $i,j\in\{1,\dots,N\}$. Let $\Lambda_1,\dots,\Lambda_s$ be a partitioning of $\{1,\dots,N\}$ so that $k,l\in\Lambda_r$ if and only if there exist $k_1=k,\dots,k_t=l$ in $\{1,\dots,N\}$ such that

$$\lim_{\nu\to+\infty}\|p_\nu(k_j)-p_\nu(k_{j+1})\|\le 2\,R$$

for $j=1,\dots,t-1$. We also assume, passing to a subsequence if necessary, that for all $r\in\{1,\dots,s\}$ and $k,l\in\Lambda_r$,

$$\lim_{\nu\to+\infty}p_\nu(k)-p_\nu(l)$$

exists. Finally for each $r\in\{1,\dots,s\}$, we fix an index $k_r\in\Lambda_r$.

Step 3. For each $\nu \in \mathbb{N}^*$ and $r \in \{1, \dots, s\}$, we set

$$B_{\nu,r} = \cup_{k\in\Lambda_r} B(p_\nu(k), R).$$

Note that if $l, r \in \{1, \dots, s\}$ with $l \neq r$ we have

$$\lim_{\nu\to+\infty} \|p_\nu(i) - p_\nu(j)\| > 2\,R$$

for all $i \in \Lambda_l$ and $j \in \Lambda_r$, hence $B_{\nu,l} \cap B_{\nu,r} = \emptyset$ if ν is large enough. For each $r \in \{1, \dots, s\}$ and $i \in \{1, \dots, N\}$, we set

$$A_{\nu,r}(i) = A_\nu(i) \cap B_{\nu,r}.$$

Step 4. Let $C_2 = C_2(N) \geq 2$ be a constant chosen large enough so that, for all ν large enough, we have

$$\|p_\nu(j) - p_\nu(k_r)\| \leq C_2 R/2$$

for all $r \in \{1, \dots, s\}$ and $j \in \Lambda_r$. Then we have

$$B_{\nu,r} \subset B(p_\nu(k_r), C_2 R).$$

For each $\nu \in \mathbb{N}^*$, $r \in \{1, \dots, s\}$, and $i \in \{1, \dots, N\}$, we set

$$A'_{\nu,r}(i) = \tau_{\nu,r}(A_{\nu,r}(i)),$$

where $\tau_{\nu,r}$ is the translation defined by $\tau_{\nu,r}(x) = x - p_\nu(k_r) + (0, \dots, 0, 2\,C_2 R\, r)$. We have for all ν large enough,

$$A'_{\nu,r}(i) \subset \tau_{\nu,r}(B_{\nu,r}) \subset B(r),$$

where $B(r) = B((0, \dots, 0, 2\,C_2 R\, r), C_2 R)$. Note that for $l, r \in \{1, \dots, s\}$, $l \neq r$, we have $B(l) \cap B(r) = \emptyset$. Finally for $i \in \{1, \dots, N\}$, we set

$$A'_\nu(i) = \cup_{r=1}^{s} A'_{\nu,r}(i)$$

and

$$\begin{aligned} A'_\nu(0) &= \mathbb{R}^n \setminus \cup_{i=1}^{N} A'_\nu(i), \\ A'_\nu &= (A'_\nu(0), \dots, A'_\nu(N)). \end{aligned}$$

Step 5. By construction we have, for some constant $C_3 = C_3(n, N, \underline{a}, \overline{a}, \overline{P}) > 0$ and all ν large enough,

$$A'_\nu(i) \subset B(0, C_3)$$

for each $i \in \{1, \dots, N\}$. Moreover, recalling that $A_\nu \in \mathcal{A}$, we have for ν large enough,

$$\begin{aligned} P(A'_\nu(i)) &\leq \sum_{r=1}^{s} P(A'_{\nu,r}(i)) = \sum_{r=1}^{s} P(A_{\nu,r}(i)) \\ &\leq \sum_{r=1}^{s} P(A_\nu(i), B_{\nu,r}) + P(B_{\nu,r}) \\ &\leq P(A_\nu(i)) + \sum_{j=1}^{N} P(B(p_\nu(j), R)) \leq C \end{aligned}$$

for some suitable $C = C(n, N, \underline{a}, \overline{a}, \overline{P}) > 0$. Hence we have uniformly bounded sequences of sets with uniformly bounded perimeter and thus, passing to a subsequence, one can assume that for each $i \in \{1, \ldots, N\}$ the set $A'_\nu(i)$ converges in L^1 to some set $A(i)$ with finite perimeter (in the sense of convergence of the corresponding characteristic functions, see for instance [7, Theorem 1.19]). Note that it follows that the sequence $A'_\nu(0)$ converges to $A(0)$ in L^1 where

$$A(0) = \mathbb{R}^n \setminus \cup_{i=1}^N A(i).$$

Let us set

$$A = (A(0), \ldots, A(N)) \in \mathcal{P}.$$

Step 6. For each $r \in \{1, \ldots, s\}$ and $j \in \Lambda_r$, we set

$$p_j = \lim_{\nu \to +\infty} \tau_{\nu,r}(p_\nu(j)),$$

(this limit is well defined because of Step 2) and

$$\begin{aligned} \Omega_r &= \cup_{j \in \Lambda_r} B(p_j, R/2), \\ \Omega &= \cup_{r=1}^s \Omega_r. \end{aligned}$$

By construction we have $\Omega_l \cap \Omega_r = \emptyset$ whenever $l \neq r$ and we also have that the partitions A'_ν and $\tau_{\nu,r}(A_\nu)$ coincide on the open set Ω_r provided ν is large enough, that is,

$$A'_\nu(i) \cap \Omega_r = \tau_{\nu,r}(A_\nu(i)) \cap \Omega_r \tag{4.6}$$

for all $r \in \{1, \ldots, s\}$ and all $i \in \{1, \ldots, N\}$. Indeed for each $r \in \{1, \ldots, s\}$ and $j \in \Lambda_r$ set $q_\nu(j) = \tau_{\nu,r}^{-1}(p_j)$. We have $q_\nu(j) - p_\nu(j) = p_j - \tau_{\nu,r}(p_\nu(j))$ and it follows that, if ν is large enough,

$$B(p_\nu(j), R/4) \subset B(q_\nu(j), R/2) \subset B(p_\nu(j), R).$$

(The left inclusion will be used later in Step 7.) In particular we get for all ν large enough and all $r \in \{1, \ldots, s\}$,

$$\begin{aligned} \Omega_r &= \tau_{\nu,r}(\cup_{j \in \Lambda_r} B(q_\nu(j), R/2)) \\ &\subset \tau_{\nu,r}(\cup_{j \in \Lambda_r} B(p_\nu(j), R)) \\ &= \tau_{\nu,r}(B_{\nu,r}) \subset B(r). \end{aligned}$$

Since $B(l) \cap B(r) = \emptyset$ whenever $l \neq r$, it follows that the sets Ω_r are pairwise disjoint. Next (4.6) follows automatically from the previous inclusions and the construction of $A'_\nu(i)$ in Step 4 and that of $A_{\nu,r}(i)$ in Step 3.

Step 7. We have

$$|A(i) \cap \Omega| > 0$$

for all $i \in \{0, \ldots, N\}$. Indeed if $i \in \{1, \ldots, N\}$ and $r \in \{1, \ldots, s\}$ are such that $i \in \Lambda_r$, then

$$\begin{aligned} |A'_\nu(i) \cap \Omega| &\geq |A'_{\nu,r}(i) \cap B(p_i, R/2)| \\ &= |A_{\nu,r}(i) \cap B(q_\nu(i), R/2)| \\ &\geq |A_\nu(i) \cap B(p_\nu(i), R/4)| \geq C_1 > 0 \end{aligned}$$

for all ν large enough, by choice of C_1 in Step 1 and remembering that $R \geq 4$. Passing to the limit when ν goes to infinity, we get the conclusion for $i \in \{1,\dots,N\}$. Finally, if ν is large enough, we have by construction $|A'_\nu(i) \cap \Omega| \leq |A_\nu(i)| \leq \overline{a}$ for all $i \in \{1,\dots,N\}$ hence $|A(i) \cap \Omega| \leq \overline{a}$ if $i \neq 0$. Then, for any $j \in \{1,\dots,N\}$, we get

$$\begin{aligned}|A(0) \cap \Omega| &\geq |A(0) \cap B(p_j, R/2)|\\ &\geq |B(p_j, R/2)| - |\cup_{i=1}^N A(i)|\\ &\geq |B(p_j, R/2)| - N\overline{a} \geq C_1 > 0\end{aligned}$$

by choice of R in Step 1.

Step 8. It follows from Step 7 that one can apply Theorem 4.2 to the partition A and the open set Ω and find corresponding ε, δ, C, and $\eta > 0$. Then, if ν is large enough, we have $|A'_\nu \triangle A| \leq \eta$ so that one can find $(\psi^1_\nu, \psi^2_\nu) \in \mathcal{CD}_\Omega(A'_\nu, \varepsilon, \delta, C)$ with

$$\{x \in \Omega_r;\ \psi^j_\nu(v,x) \neq x\} \cup \psi^j_\nu(v, \{x \in \Omega_r;\ \psi^j_\nu(v,x) \neq x\}) \subset\subset \Omega_r$$

for $j \in \{1,2\}$, all $r \in \{1,\dots,s\}$, and $v \in (-\varepsilon,\varepsilon)^N$. We set

$$\varphi^j_\nu(v,x) = (\tau^{-1}_{\nu,r} \circ \psi^j_\nu(v,.) \circ \tau_{\nu,r})(x)$$

if $x \in \tau^{-1}_{\nu,r}(\Omega_r)$ and

$$\varphi^j_\nu(v,x) = x$$

otherwise. Remember that, if ν is large enough, $\tau^{-1}_{\nu,r}(\Omega_r) \subset B_{\nu,r}$ and $B_{\nu,r} \cap B_{\nu,l} = \emptyset$ for $l \neq r$ (see Step 3). Hence $\tau^{-1}_{\nu,r}(\Omega_r) \cap \tau^{-1}_{\nu,l}(\Omega_l) = \emptyset$ and $\varphi^j_\nu(v,.)$ is well defined.

Next we clearly have, at least if ν is large enough,

$$\{x \in \tau^{-1}_{\nu,r}(\Omega_r);\ \varphi^j_\nu(v,x) \neq x\} \cup \varphi^j_\nu(v, \{x \in \tau^{-1}_{\nu,r}(\Omega_r);\ \varphi^j_\nu(v,x) \neq x\}) \subset\subset \tau^{-1}_{\nu,r}(\Omega_r)$$

and

$$\mathcal{O}(\varphi^j_\nu(v,.)) \subset\subset \cup_{r=1}^s \tau^{-1}_{\nu,r}(\Omega_r).$$

Since each $\psi^j_\nu(v,.)$ is a C^1 diffeomorphism, it follows in particular that $\varphi^j_\nu(v,.)$ is a C^1 diffeomorphism for $j \in \{1,2\}$ and each $v \in (-\varepsilon,\varepsilon)^N$.

To compute the variation of the measure and of the energy of A_ν under φ^j_ν, we clearly need to worry only about what happens inside the pairwise disjoint open sets $\tau^{-1}_{\nu,r}(\Omega_r)$. Recalling that the partitions $\tau_{\nu,r}(A_\nu)$ and A'_ν coincide on Ω_r (see (4.6)), we have

$$\begin{aligned}|\varphi^j_\nu(v, A_\nu(i))| - |A_\nu(i)| &= \sum_{r=1}^s |\varphi^j_\nu(v, A_\nu(i) \cap \tau^{-1}_{\nu,r}(\Omega_r))| - |A_\nu(i) \cap \tau^{-1}_{\nu,r}(\Omega_r)|\\ &= \sum_{r=1}^s |\psi^j_\nu(v, A'_\nu(i) \cap \Omega_r)| - |A'_\nu(i) \cap \Omega_r|\\ &= |\psi^j_\nu(v, A'_\nu(i))| - |A'_\nu(i)| = v_i\end{aligned}$$

for all ν large enough and $i \in \{1,\dots,N\}$ according to the property (4.3) of the map $\psi^j_\nu \in \mathcal{D}_\Omega(A'_\nu, \varepsilon, C)$. Similarly, using (4.4) for ψ^j_ν, we have for all ν large enough and $i \in \{1,\dots,N\}$,

$$\begin{aligned}|\varphi^j_\nu(v, A_\nu(i)) \triangle A_\nu(i)| &= |\psi^j_\nu(v, A'_\nu(i)) \triangle A'_\nu(i)|\\ &\leq CP(A'_\nu(i), \Omega)|v| \leq CP(A_\nu(i))|v|.\end{aligned}$$

The last inequality follows from the invariance of the perimeter under translations together with (4.6). Indeed we have for all ν large enough,

$$\begin{aligned} P(A'_\nu(i),\Omega) &= \sum_{r=1}^{s} P(A'_\nu(i),\Omega_r) = \sum_{r=1}^{s} P(\tau_{\nu,r}(A_\nu(i)),\Omega_r) \\ &= \sum_{r=1}^{s} P(A_\nu(i),\tau_{\nu,r}^{-1}(\Omega_r)) \le P(A_\nu(i)). \end{aligned}$$

Next we consider an energy $E \in \mathcal{E}(\overline{F})$ defined with respect to some family (F_{ij}). Note that

$$E(\tau(\tilde{A}),\tau(U)) = E_\tau(\tilde{A},U)$$

for any partition $\tilde{A} \in \mathcal{P}$, any measurable set $U \subset \mathbb{R}^n$, and any translation $\tau : \mathbb{R}^n \to \mathbb{R}^n$ where $E_\tau \in \mathcal{E}(\overline{F})$ is defined with respect to the family $((x,y) \mapsto F_{ij}(\tau(x),y))$. It follows that if U is a measurable set, then, for ν large enough,

$$\begin{aligned} &E(\varphi^j_\nu(v,A_\nu),\varphi^j_\nu(v,U)) - E(A_\nu,U) \\ &\quad = \sum_{r=1}^{s} E(\tau_{\nu,r}^{-1} \circ \psi^j_\nu(v,A'_\nu),\tau_{\nu,r}^{-1}(\Omega_r) \cap \varphi^j_\nu(v,U)) - E(\tau_{\nu,r}^{-1}(A'_\nu),\tau_{\nu,r}^{-1}(\Omega_r) \cap U) \\ &\quad = \sum_{r=1}^{s} E_{\tau_{\nu,r}^{-1}}(\psi^j_\nu(v,A'_\nu),\Omega_r \cap \psi^j_\nu(v,\tau_{\nu,r}(U))) - E_{\tau_{\nu,r}^{-1}}(A'_\nu,\Omega_r \cap \tau_{\nu,r}(U)). \end{aligned}$$

Since $E_{\tau_{\nu,r}^{-1}} \in \mathcal{E}(\overline{F})$ and $\psi^j_\nu(v,\Omega_r \cap \tau_{\nu,r}(U)) = \Omega_r \cap \psi^j_\nu(v,\tau_{\nu,r}(U))$ for all ν large enough and all $r \in \{1,\dots,s\}$, it follows from the property (4.5) of ψ^j_ν that

$$\begin{aligned} &E_{\tau_{\nu,r}^{-1}}(\psi^j_\nu(v,A'_\nu),\Omega_r \cap \psi^j_\nu(v,\tau_{\nu,r}(U))) - E_{\tau_{\nu,r}^{-1}}(A'_\nu,\Omega_r \cap \tau_{\nu,r}(U)) \\ &\qquad \le C\,P(A'_\nu,\Omega_r \cap \tau_{\nu,r}(U))\,|v| = C\,P(A_\nu,\tau_{\nu,r}^{-1}(\Omega_r) \cap U)\,|v| \end{aligned}$$

and thus

$$E(\varphi^j_\nu(v,A_\nu),\varphi^j_\nu(v,U)) - E(A_\nu,U) \le C\,P(A_\nu,U)\,|v|$$

for all ν large enough.

Finally by construction it is clear that one can find $\delta' > 0$, may be smaller than δ but still strictly positive and not depending on ν, such that

$$\operatorname{dist}(\mathcal{O}(\varphi^1_\nu(v,.)),\mathcal{O}(\varphi^2_\nu(v,.))) \ge \delta'.$$

Hence taking ν large enough and so that $\nu \ge \max(\varepsilon^{-1},\delta'^{-1},C)$ we have just proved that

$$(\varphi^1_\nu,\varphi^2_\nu) \in \mathcal{CD}(A_\nu,\nu^{-1},\nu^{-1},\nu)$$

which gives the required contradiction and concludes the proof. □

Although we will not need this refinement here one can note that, with essentially the same proof modulo only minor technical modifications, one can get a localized version of Theorem 4.1 similar to that given in Theorem 4.2. More precisely, assume that $\Omega \subset \mathbb{R}^n$ is open and, for simplicity, bounded and that $\Omega = \cup_{l=1}^{s}\Omega_l$ with the sets

Ω_l open and pairwise disjoint. Let $\mathcal{P}_{\underline{a},\overline{P},\Omega}$ denote the class of all partitions $A \in \mathcal{P}$ such that

$$\underline{a} \leq \min_{i=0,\ldots,N} |A_i \cap \Omega| \quad \text{and} \quad P(A,\Omega) \leq \overline{P}$$

for some $\underline{a} > 0$ and $\overline{P} > 0$. Then one can find $\varepsilon_0 > 0$, $\delta_0 > 0$, and $C_0 > 0$, depending only on n, N, $\overline{F}$, $\underline{a}$, and $\overline{P}$, such that for all $A \in \mathcal{P}_{\underline{a},\overline{P},\Omega}$ one can find $(\psi_1,\psi_2) \in \mathcal{CD}_\Omega(A,\varepsilon_0,\delta_0,C_0)$ such that

$$\{x \in \Omega_l\,;\ \psi_j(v,x) \neq x\} \cup \psi_j(v,\{x \in \Omega_l\,;\ \psi_j(v,x) \neq x\}) \subset\subset \Omega_l$$

for all $l \in \{1,\ldots,s\}$, $j \in \{1,2\}$, and $v \in (-\varepsilon_0,\varepsilon_0)^N$.

4.2. Proof of Theorem 3.6. We now prove Theorem 3.6. We let $0 < \underline{F} \leq \overline{F} < +\infty$, $E \in \mathcal{E}(\underline{F},\overline{F})$, $g : [0,+\infty) \to [0,+\infty)$, $a = (a_1,\ldots,a_N)$ be as in the statement and $A \in \mathcal{P}_a$ be a (g,a)-quasiminimal partition with respect to E. Recall that we want to find some suitable $\tilde{g} : [0,+\infty) \to [0,+\infty)$ such that $\lim_{t\to 0} t^{(1-n)/n}\tilde{g}(t) = 0$ and $\delta > 0$ both universal and such that A is a $(\tilde{g},\delta)$-quasiminimal partition with respect to E. Throughout this subsection, when saying that some object is universal, we mean more precisely that it can be chosen depending only on n, N, $\underline{F}$, $\overline{F}$, g, and a.

Set $\underline{a} = \min_{i\geq 1} a_i$ and $\overline{a} = \max_{i\geq 1} a_i$. Next we claim that one can find $\overline{P} > 0$ universal such that $P(A) \leq \overline{P}$. To see this, setting $B_t = B(0,t)$ for all $t > 0$, we choose $R > 0$ large enough so that

$$P(A_i,\mathbb{R}^n \setminus B_R) \leq 1$$

for all $i \in \{0,\ldots,N\}$ and so that one can find N open balls $B_1,\ldots,B_N$ with $B_i \subset\subset B_R$, $|B_i| = a_i$ and $B_i \cap B_j = \emptyset$ for $i \neq j$. By the coarea formula and Tchebytchev's inequality, we have

$$|\{t \in (R,R+1);\ \mathcal{H}^{n-1}(A_i \cap \partial B_t) > C\,\overline{a}\}|_1 \leq \frac{|A_i \cap (B_{R+1} \setminus B_R)|}{C\,\overline{a}} \leq C^{-1},$$

where $|.|_1$ denotes the one dimensional Lebesgue measure. Then, choosing C large enough, depending only on N, and recalling that

$$P(A_i \setminus B_t) = P(A_i,\mathbb{R}^n \setminus \overline{B}_t) + \mathcal{H}^{n-1}(A_i \cap \partial B_t)$$

for a.e. $t > 0$ (see for instance [7, Remark 2.14]), one can find $t \in (R,R+1)$ such that this last equality holds and

$$\mathcal{H}^{n-1}(A_i \cap \partial B_t) \leq C\,\overline{a}$$

for all $i \in \{1,\ldots,N\}$. We set

$$A_i' = (A_i \setminus B_t) \cup B_i'$$

for $i \in \{1,\ldots,N\}$, where $B_i' \subset B_i$ is a ball with $|B_i'| = |A_i \cap B_t|$, and

$$A_0' = \mathbb{R}^n \setminus \cup_{i=1}^N A_i'.$$

We have $A' = (A_0',\ldots,A_N') \in \mathcal{P}_a$ and $A' \triangle A \subset\subset \mathbb{R}^n$. Next, for all $i \in \{1,\ldots,N\}$, we have

$$\begin{aligned} P(A_i') &= P(B_i') + P(A_i \setminus B_t) \\ &\leq C\,\overline{a}^{\frac{n-1}{n}} + P(A_i,\mathbb{R}^n \setminus \overline{B}_t) + \mathcal{H}^{n-1}(A_i \cap \partial B_t) \\ &\leq C\,\overline{a}^{\frac{n-1}{n}} + P(A_i,\mathbb{R}^n \setminus B_R) + C\,\overline{a} \leq C \end{aligned}$$

for some universal constants $C > 0$. When $i = 0$, we have

$$P(A'_0) = P(\mathbb{R}^n \setminus \cup_{i=1}^N A'_i) \leq \sum_{i=1}^n P(A'_i).$$

Then it follows from (2.3) that

$$E(A') \leq \overline{F}\, P(A') \leq C$$

for some suitable universal constant $C > 0$. On the other hand, for $i \in \{1, \ldots, N\}$, we have $|A'_i \triangle A_i| \leq 2\,\overline{a}$ and $A'_0 \triangle A_0 \subset \cup_{i=1}^N A'_i \triangle A_i$, hence $g(|A' \triangle A|) \leq g(2\,N\,\overline{a})$ since g is nondecreasing. Then it follows from (2.3) together with the (g, a)-quasiminimality (3.1) of A that

$$P(A) \leq \underline{F}^{-1}\, E(A) \leq \underline{F}^{-1}\, (E(A') + g(|A' \triangle A|)) \leq \overline{P}$$

for some suitable universal constant $\overline{P} > 0$ as claimed.

Thus we have $A \in \mathcal{P}_{\underline{a},\overline{a},\overline{P}}$ as in section 4.1 and Theorem 4.1 gives some $\varepsilon_0 > 0$, $\delta_0 > 0$, and $C_0 > 0$ universal such that $\mathcal{CD}(A, \varepsilon_0, \delta_0, C_0) \neq \emptyset$. Let $(\psi_1, \psi_2) \in \mathcal{CD}(A, \varepsilon_0, \delta_0, C_0)$ and let us fix $\delta > 0$ universal and small enough so that

$$|B_\delta| < \varepsilon_0 \quad \text{and} \quad 4\delta < \delta_0.$$

Now let $A' \in \mathcal{P}$ be such that $\operatorname{diam}(A' \triangle A) < \delta$ (A' has here nothing to do with the partition constructed a few lines above). To prove the theorem we need to compare the energy of A' with that of A. We first use the suitable deformations given by ψ_1 (or ψ_2) to construct from A' a partition $A'' \in \mathcal{P}_a$. Then we will use the (g, a)-quasiminimality of A to get a comparison between the energies.

For $i \in \{1, \ldots, N\}$ we set $v_i = |A_i| - |A'_i|$. Since $\operatorname{diam}(A' \triangle A) < \delta$ then $A' \triangle A \subset\subset B$ for some ball B with radius δ and thus

$$|v_i| = ||A_i \setminus A'_i| - |A'_i \setminus A_i|| \leq |A'_i \triangle A_i| \leq |B|,$$

that is, $v = (v_1, \ldots, v_N) \in (-\varepsilon_0, \varepsilon_0)^N$ by choice of δ. Next let us assume that

$$2B \cap \mathcal{O}(\psi_1(v, .)) = \emptyset,$$

where $2B$ denotes the ball concentric to B with radius 2δ. Otherwise, since

$$\operatorname{dist}(\mathcal{O}(\psi_1(v, .)), \mathcal{O}(\psi_2(v, .))) \geq \delta_0$$

and $4\delta < \delta_0$, we would have $2B \cap \mathcal{O}(\psi_2(v, .)) = \emptyset$ and would simply use ψ_2 instead of ψ_1 in what follows. Then we set

$$A''_i = (A'_i \cap B) \cup (\psi_1(v, A_i) \cap \mathbb{R}^n \setminus B)$$

and $A'' = (A''_0, \ldots, A''_N)$. Since A'_i coincides with A_i on a neighborhood of $\mathbb{R}^n \setminus B$ and $\psi_1(v, A_i)$ with A_i on B (note that since $\psi_1(v, .)$ is a C^1 diffeomorphism, we have $\psi_1(v, \mathcal{O}(\psi_1(v, .))) = \mathcal{O}(\psi_1(v, .))$) it follows from the property (4.3) of $\psi_1 \in \mathcal{D}(A, \varepsilon_0, C_0)$ that, for all $i \in \{1, \ldots, N\}$,

$$\begin{aligned} |A''_i| &= |A'_i \cap B| + |\psi_1(v, A_i) \cap \mathbb{R}^n \setminus B| \\ &= |A'_i| + |\psi_1(v, A_i)| - |A_i| \\ &= |A'_i| + v_i = |A_i| \end{aligned}$$

hence $A'' \in \mathcal{P}_a$. For the same reasons we have

$$E(A', \mathbb{R}^n \setminus B) = E(A, \mathbb{R}^n \setminus B),$$
$$E(\psi_1(v, A), B) = E(A, B).$$

Next A'' coincides with A' on B and with $\psi_1(v, A)$ on a neighborhood of $\mathbb{R}^n \setminus B$, hence

$$\begin{aligned} E(A'') &= E(A', B) + E(\psi_1(v, A), \mathbb{R}^n \setminus B) \\ &= E(A') + E(\psi_1(v, A)) - E(A) \\ &\leq E(A') + C_0\, P(A)\, |v| \\ &\leq E(A') + C_0\, \overline{P}\, |A' \triangle A| \end{aligned}$$

according to (4.5). Finally we have

$$A'' \triangle A = (A' \triangle A) \cup (\psi_1(v, A) \triangle A)$$

and thus, since, thanks to (4.4),

$$|\psi_1(v, A_i) \triangle A_i| \leq C_0\, P(A_i)\, |v| \leq C_0\, P(A_i)\, |A' \triangle A|$$

for all $i \in \{1, \ldots, N\}$ and $|\psi_1(v, A_0) \triangle A_0| \leq |\cup_{i=1}^N \psi_1(v, A_i) \triangle A_i|$, we get

$$|A'' \triangle A| \leq (2\, C_0\, \overline{P} + 1)\, |A' \triangle A|.$$

To conclude we use the (g, a)-quasiminimality of A to compare $E(A)$ and $E(A'')$,

$$\begin{aligned} E(A) &\leq E(A'') + g(|A'' \triangle A|) \\ &\leq E(A') + C_0\, \overline{P}\, |A' \triangle A| + g((2\, C_0\, \overline{P} + 1)\, |A' \triangle A|) \end{aligned}$$

because g is nondecreasing. Then setting $\tilde{g}(t) = C_0\, \overline{P}\, t + g((2\, C_0\, \overline{P} + 1)\, t)$ we have just proved that A is $(\tilde{g}, \delta)$-quasiminimal and this concludes the proof.

5. Ahlfors-regularity and condition B. This section is devoted to the study of locally quasiminimal partitions. Namely, we fix some $0 < \underline{F} \leq \overline{F} < +\infty$, $E \in \mathcal{E}_0(\underline{F}, \overline{F})$, $g : [0, +\infty) \to [0, +\infty)$ such that $\lim_{t \to 0} t^{(1-n)/n} g(t) = 0$ and $\delta > 0$ and we prove the following theorem, Theorem 5.1, together with Theorem 3.7.

THEOREM 5.1. *Let A be a (g, δ)-quasiminimal partition with respect to E and let S denote its set of interfaces. Then S is a closed Ahlfors-regular set with Ahlfors-regularity constants that can be chosen depending only on n, $\underline{F}$, $\overline{F}$, g, and δ, and S satisfies condition B with a condition B constant that can be chosen depending only on n, $\underline{F}$, $\overline{F}$, g, δ, and N.*

We shall actually get slightly refined properties, see especially Lemma 5.7 (see also section 6 for a particular case). For simplicity, and with no loss of generality, we assume that $\delta < 1$. We also assume that A is a reduced (g, δ)-quasiminimal partition (remember that the assumption on A to be reduced is not restrictive, see the comments before Theorem 3.7). We begin with the upper bound in the Ahlfors-regularity.

LEMMA 5.2. *There exist a constant $C_0 = C_0(n, \underline{F}, \overline{F}) > 0$ and a radius $r_0 = r_0(n, g, \delta) \leq 1$ such that, for all $x \in \mathbb{R}^n$ and $r \leq r_0$, we have*

$$\mathcal{H}^{n-1}(S \cap B(x, r)) \leq C_0\, r^{n-1}.$$

Proof. The proof is based on a simple comparison argument. We take $x \in \mathbb{R}^n$, $r > 0$ and set

$$\begin{aligned} A'_0 &= A_0 \cup B(x,r), \\ A'_i &= A_i \backslash B(x,r) \end{aligned}$$

for $i \in \{1, \ldots, N\}$. Then $A' = (A'_0, \ldots, A'_N) \in \mathcal{P}$ and, since $A' \triangle A \subset B(x,r)$, we have $\operatorname{diam}(A' \triangle A) < \delta$ provided $r < \delta/2$. Moreover $|A' \triangle A| \leq |B(x,r)|$ hence, if r is small enough, depending only on n and g, we get from the behavior of g near 0 that

$$g(|A' \triangle A|) \leq r^{n-1}.$$

On the other hand, A' and A coincide on the open set $\mathbb{R}^n \setminus \overline{B}(x,r)$ hence they have the same energy there and it follows from the (g,δ)-quasiminimality of A that

$$E(A, \overline{B}(x,r)) \leq E(A', \overline{B}(x,r)) + g(|A' \triangle A|) \leq E(A', \overline{B}(x,r)) + r^{n-1}.$$

We have

$$\begin{aligned} E(A, \overline{B}(x,r)) &\geq \sum_{i=0}^{N} \sum_{\substack{j=0 \\ j \neq i}}^{N} \int_{\partial^* A_i \cap \partial^* A_j} \mathbb{1}_{B(x,r)}(y) F_{ij}(y, \nu_{A_i}(y)) \; d\mathcal{H}^{n-1} \\ &\geq \underline{F} \sum_{i=0}^{N} \sum_{\substack{j=0 \\ j \neq i}}^{N} \mathcal{H}^{n-1}(\partial^* A_i \cap \partial^* A_j \cap B(x,r)) \\ &= 2\, \underline{F}\, \mathcal{H}^{n-1}(S \cap B(x,r)), \end{aligned}$$

where the last equality follows from (2.2). On the other hand, we clearly have $E(A', B(x,r)) = 0$. Next, any point y in $\partial B(x,r)$ is a point of lower density at least $1/2$ for A'_0 because $B(x,r) \subset A'_0$. Then, since $\partial_* A'_i \subset A'_i(1/2)$, such points $y \in \partial B(x,r)$ can only belong to at most a single set $\partial_* A'_i$ with $i \neq 0$. It follows that

$$\mathcal{H}^{n-1}(\partial^* A'_i \cap \partial^* A'_j \cap \partial B(x,r)) = 0$$

whenever i, $j \in \{1, \ldots, N\}$, $i \neq j$, and hence

$$\begin{aligned} &E(A', \partial B(x,r)) \\ &\quad = \sum_{i=1}^{N} \int_{\partial^* A'_0 \cap \partial^* A'_i} \mathbb{1}_{\partial B(x,r)}(y) (F_{0i}(y, \nu_{A'_0}(y)) + F_{i0}(y, \nu_{A'_i}(y)))\, d\mathcal{H}^{n-1} \\ &\quad \leq 2\, \overline{F} \sum_{i=1}^{N} \mathcal{H}^{n-1}(\partial^* A'_0 \cap \partial^* A'_i \cap \partial B(x,r)) \\ &\quad = 2\, \overline{F}\, \mathcal{H}^{n-1}(\partial^* A'_0 \cap \partial B(x,r)) \leq C\, r^{n-1} \end{aligned}$$

(remember the comments after Definition 2.3 for the equality on the last line). Then we get

$$\begin{aligned} \mathcal{H}^{n-1}(S \cap B(x,r)) &\leq (2\, \underline{F})^{-1}\, E(A, \overline{B}(x,r)) \\ &\leq (2\, \underline{F})^{-1}\, (E(A', \partial B(x,r)) + r^{n-1}) \leq C_0\, r^{n-1} \end{aligned}$$

for some $C_0 = C_0(n, \underline{F}, \overline{F}) > 0$ as wanted. $\square$

Analogues of the next lemma are quite standard in the regularity theory of (quasi-)minimal sets and is technically one of our main steps. It says that if the proportion of some component inside a ball is large enough, then this component contains one half the ball.

LEMMA 5.3. *There exists* $\eta_0 = \eta_0(n, \underline{F}, \overline{F}, g) > 0$ *such that, for all* $i \in \{0, \dots, N\}$, $x \in \mathbb{R}^n$, *and* $r \le \delta/2$, *if* $|B(x,r) \backslash A_i| \le \eta_0\, r^n$, *then* $B(x, r/2) \subset A_i$.

Proof. Since A is a reduced partition, and hence $A_i = A_i(1)$, it is sufficient to show that $|B(x,r/2)\backslash A_i| = 0$ when $i \in \{0, \dots, N\}$, $x \in \mathbb{R}^n$, and $r \le \delta/2$ are fixed as in the statement. For $t > 0$, we set $m(t) = |B(x,t)\backslash A_i|$ and assume that $m(r) \le \eta_0\, r^n$ for some $\eta_0 > 0$ to be fixed small later. Arguing by contradiction, we also assume that $m(r/2) > 0$. Using a similar comparison argument as in the proof of Lemma 5.2, we set for $t \in (r/2, r)$,

$$A'_i = A_i \cup B(x,t),$$

and, for $j \neq i$,

$$A'_j = A_j \backslash B(x,t).$$

Then $A' = (A'_0, \dots, A'_N) \in \mathcal{P}$ and, since $A' \triangle A \subset B(x,t)$, we have $\operatorname{diam}(A' \triangle A) < \delta$. Since A' and A coincide on the open set $\mathbb{R}^n \setminus \overline{B}(x,t)$, they have the same energy there and we get from the (g,δ)-quasiminimality of A that

$$E(A, \overline{B}(x,t)) \le E(A', \overline{B}(x,t)) + g(|A' \triangle A|).$$

We have

$$\begin{aligned} E(A, \overline{B}(x,t)) &\ge \sum_{\substack{j=0 \\ j\neq i}}^{N} \int_{\partial^* A_i \cap \partial^* A_j} \mathbb{1}_{B(x,t)}(y) F_{ij}(y, \nu_{A_i}(y))\, d\mathcal{H}^{n-1} \\ &\ge \underline{F} \sum_{\substack{j=0 \\ j\neq i}}^{N} \mathcal{H}^{n-1}(\partial^* A_i \cap \partial^* A_j \cap B(x,t)) \\ &= \underline{F}\, \mathcal{H}^{n-1}(\partial^* A_i \cap B(x,t)) \\ &\ge C\ \min(|B(x,t) \setminus A_i|, |A_i \cap B(x,t)|)^{\frac{n-1}{n}} = C\, m(t)^{\frac{n-1}{n}}, \end{aligned}$$

where the equality follows from the comments after Definition 2.3 and the last inequality from the relative isoperimetric inequality for balls, provided η_0 is small enough, how small depending only on n. On the other hand, $E(A', B(x,t)) = 0$ and, arguing as in Lemma 5.2 (see the estimation of $E(A', \partial B(x,r))$ there), we have

$$E(A', \partial B(x,t)) \le 2\, \overline{F}\, \mathcal{H}^{n-1}(\partial^* A'_i \cap \partial B(x,t)) = 2\, \overline{F}\, P(A_i \cup B(x,t), \partial B(x,t)).$$

Combining these inequalities we get

$$C\, m(t)^{\frac{n-1}{n}} \le P(A_i \cup B(x,t), \partial B(x,t)) + g(|A' \triangle A|) \tag{5.1}$$

for some suitable constant $C = C(n, \underline{F}, \overline{F}) > 0$. We have

$$|A' \triangle A| = m(t) \le \eta_0\, r^n \le \eta_0$$

thus, if η_0 is small enough,

$$g(|A'\triangle A|) \leq \frac{C\, m(t)^{\frac{n-1}{n}}}{2},$$

where C is the constant that shows up in (5.1). Then, recalling that

$$P(A_i \cup B(x,t), \partial B(x,t)) = m'(t)$$

for a.e. $t > 0$ (this follows for instance from [7, Remark 2.14] and the coarea formula), it follows that

$$m(t)^{\frac{n-1}{n}} \leq C\, P(A_i \cup B(x,t), \partial B(x,t)) \leq C\, m'(t)$$

for a.e. $t \in (r/2, r)$ and for some suitable constant $C = C(n, \underline{F}, \overline{F}) > 0$. Finally, since by assumption $m(t) > 0$ for all $t \geq r/2$, we can rewrite this inequality in the following way:

$$C \leq m(t)^{\frac{1-n}{n}}\, m'(t),$$

and, integrating over $(r/2, r)$, we get

$$r \leq C\,(m(r)^{\frac{1}{n}} - m(r/2)^{\frac{1}{n}}) \leq C\, m(r)^{\frac{1}{n}} \leq C\, \eta_0^{\frac{1}{n}}\, r$$

for some $C = C(n, \underline{F}, \overline{F}) > 0$. This is impossible if η_0 is small enough and gives the contradiction. □

We draw in the following lemma some easy consequences of Lemma 5.3 which help to clarify the picture and give the first part of Theorem 3.7.

Lemma 5.4. *For all $i \in \{0, \dots, N\}$, A_i is open and $S = \cup_{i=0}^N \partial A_i$.*

Proof. Let $i \in \{0, \dots, N\}$ be fixed and $x \in A_i$. Since A is reduced, x is point of density 1 for A_i hence $|B(x,r)\backslash A_i| \leq \eta_0\, r^n$ for all r small enough where η_0 is given by Lemma 5.3. Then according to that lemma we have $B(x, r/2) \subset A_i$ hence A_i is open. Next we always have $S \subset \cup_{i=0}^N \partial A_i$. On the other hand, if $x \in \partial A_i$ for some $i \in \{0, \dots, N\}$, then $x \notin \cup_{j=0}^N A_j$ because these sets are open and pairwise disjoint, and hence $x \in S$ as required (remember what follows Definition 2.4). □

We now prove the lower bound in the Ahlfors-regularity.

Lemma 5.5. *There exists $c_0 = c_0(n, \underline{F}, \overline{F}, g) > 0$ such that, for all $x \in S$ and $r \leq \delta/2$, we have*

$$\mathcal{H}^{n-1}(S \cap B(x,r)) \geq c_0\, r^{n-1}.$$

Proof. Let $c_0 > 0$ be a constant that will be fixed small later, depending only on n, $\underline{F}$, $\overline{F}$, and g, and assume by contradiction that one can find $x \in S$ and $r \leq \delta/2$ such that

$$\mathcal{H}^{n-1}(S \cap B(x,r)) < c_0\, r^{n-1}.$$

First one can find $i \in \{0, \dots, N\}$ such that

$$|A_i \cap B(x,r)| > |B(x,r)|/2.$$

Otherwise the relative isoperimetric inequality for balls would give

$$\begin{aligned} |A_i \cap B(x,r)|^{\frac{n-1}{n}} &= \min(|A_i \cap B(x,r)|, |B(x,r) \setminus A_i|)^{\frac{n-1}{n}} \\ &\leq C\, \mathcal{H}^{n-1}(\partial^* A_i \cap B(x,r)) \end{aligned}$$

for all $i \in \{0, \ldots, N\}$. Using (2.2) we would get

$$\begin{aligned}\sum_{i=0}^{N} |A_i \cap B(x,r)|^{\frac{n-1}{n}} &\leq C \sum_{i=0}^{N} \mathcal{H}^{n-1}(\partial^* A_i \cap B(x,r)) \\ &\leq C\, \mathcal{H}^{n-1}(S \cap B(x,r)) \leq C\, c_0\, r^{n-1}.\end{aligned}$$

On the other hand, since $|A_i \cap B(x,r)| \leq |B(x,r)|/2$ for all $i \in \{0, \ldots, N\}$, we have

$$\sum_{i=0}^{N} |A_i \cap B(x,r)|^{\frac{n-1}{n}} \geq 2^{\frac{1}{n}}\, |B(x,r)|^{-\frac{1}{n}} \sum_{i=0}^{N} |A_i \cap B(x,r)| = 2^{\frac{1}{n}}\, |B(x,r)|^{\frac{n-1}{n}}.$$

Hence we would have

$$|B(x,r)|^{\frac{n-1}{n}} \leq C\, c_0\, r^{n-1}$$

for some dimensional constant $C > 0$ but this is impossible if c_0 is small enough. Thus let us fix $i \in \{0, \ldots, N\}$ such that $|A_i \cap B(x,r)| > |B(x,r)|/2$. Then once again by the relative isoperimetric inequality for balls we have

$$\begin{aligned}|B(x,r) \backslash A_i| &\leq C\, \mathcal{H}^{n-1}(\partial^* A_i \cap B(x,r))^{\frac{n}{n-1}} \\ &\leq C\, \mathcal{H}^{n-1}(S \cap B(x,r))^{\frac{n}{n-1}} \\ &\leq C\, c_0^{\frac{n}{n-1}}\, r^n,\end{aligned}$$

and Lemma 5.3 implies that $B(x, r/2) \subset A_i$ provided $c_0 = c_0(n, \underline{F}, \overline{F}, g)$ is small enough. In particular $x \in A_i$. But A is a reduced partition and thus $S \cap A_i = \emptyset$ which gives the required contradiction. $\square$

Corollary 5.6. *The set of interfaces S is a closed Ahlfors-regular set with regularity constants that can be chosen depending only on n, $\underline{F}$, $\overline{F}$, g, and δ.*

Proof. First, according to Lemma 5.4, S is the finite union of the topological boundaries ∂A_i and hence is closed. Next Lemmas 5.2 and 5.5 give the required inequalities

$$c_0\, r^{n-1} \leq \mathcal{H}^{n-1}(S \cap B(x,r)) \leq C_0\, r^{n-1}$$

for all $x \in S$ and $r \leq r_1 = \min(\delta/2, r_0)$. If $r \in [r_1, 1]$ we obviously have

$$(c_0\, r_1^{n-1})\, r^{n-1} \leq c_0\, r_1^{n-1} \leq \mathcal{H}^{n-1}(S \cap B(x, r_1)) \leq \mathcal{H}^{n-1}(S \cap B(x,r)).$$

Finally the upper inequality in the Ahlfors-regularity for $r \in [r_1, 1]$ follows from a standard covering argument that we include here for the sake of completeness. Let us consider a maximal family $\mathcal{A}$ of points in $S \cap B(x,r)$ at mutual distance greater than or equal to r_1. The balls $B(y, r_1/2)$, $y \in \mathcal{A}$, are pairwise disjoint and contained in $B(x, 2r)$, hence,

$$\begin{aligned}\text{card } \mathcal{A} &\leq C \sum_{y \in \mathcal{A}} |B(y, r_1/2)| = C\, |\cup_{y \in \mathcal{A}} B(y, r_1/2)| \\ &\leq C\, |B(x, 2r)| \leq C\, r^n \leq C\, r^{n-1}\end{aligned}$$

for some suitable constants $C > 0$. Since $S \cap B(x,r) \subset \cup_{y \in \mathcal{A}} B(y, r_1)$, it follows that

$$\begin{aligned}\mathcal{H}^{n-1}(S \cap B(x,r)) &\leq \sum_{y \in \mathcal{A}} \mathcal{H}^{n-1}(S \cap B(y, r_1)) \\ &\leq C\, (\text{card } \mathcal{A})\, r_1^{n-1} \leq C\, r^{n-1}\end{aligned}$$

for some suitable constant $C = C(n, \underline{F}, \overline{F}, g, \delta) > 0$. $\square$

We prove in the next lemma a slightly refined version of condition B.

LEMMA 5.7. *There exists a constant* $C_1 = C_1(n, N, \underline{F}, \overline{F}, g, \delta) > 0$ *such that, for all* $x \in S$ *and* $r \leq 1$*, there exist* i*,* $j \in \{0, \dots, N\}$*,* $i \neq j$*, and two balls* B_i *and* B_j *with radius* $C_1\, r$ *such that* $B_i \subset A_i \cap B(x, r)$ *and* $B_j \subset A_j \cap B(x, r)$*.*

Proof. Let $x \in S$ and $r \leq 1$ be fixed. The set S is Ahlfors-regular according to Corollary 5.6 hence Lemma 5.8, to be proved below, applied with $B = B(x, r/2)$ gives us a point $y \in B(x, r/2)$ such that $B(y, \gamma\, r) \cap S = \emptyset$ for some $\gamma = \gamma(n, \underline{F}, \overline{F}, g, \delta) \leq 1/4$. Recalling that $\mathbb{R}^n = (\cup_{i=0}^{N} A_i) \cup S$ because A is reduced and that S is, according to Lemma 5.4, the union of the topological boundaries of the open and disjoint sets A_i, it follows automatically that one can find $i \in \{0, \dots, N\}$ such that $B(y, \gamma\, r) \subset A_i$. Note that $B(y, \gamma\, r) \subset B(x, r)$.

Next, since $x \in S$ and $A_i \cap S = \emptyset$, we have $|B(x, r/2) \setminus A_i| \geq C\, r^n$ for some constant $C = C(n, \underline{F}, \overline{F}, g, \delta) > 0$, because otherwise Lemma 5.3 would give $x \in A_i$. Let us choose $j \in \{0, \dots, N\} \setminus \{i\}$ such that

$$|B(x, r/2) \cap A_j| = \max_{l \in \{0, \dots, N\} \setminus \{i\}} |B(x, r/2) \cap A_l|.$$

Then we have

$$\begin{aligned} |B(x, r/2) \cap A_j| &\geq N^{-1} \sum_{\substack{l=0 \\ l \neq i}}^{N} |B(x, r/2) \cap A_l| \\ &= N^{-1}\, |B(x, r/2) \setminus A_i| \geq \beta\, r^n \end{aligned}$$

for some $\beta = \beta(n, N, \underline{F}, \overline{F}, g, \delta) > 0$. Then, using once again Lemma 5.8 with now $B = B(x, r/2) \cap A_j$, one can find $\gamma' = \gamma'(n, N, \underline{F}, \overline{F}, g, \delta) \leq 1/4$ and $y' \in B(x, r/2) \cap A_j$ such that $B(y', \gamma'\, r) \subset B(x, r)$ does not meet S. In particular $B(y', \gamma'\, r)$ does not meet ∂A_j hence $B(y', \gamma'\, r) \subset A_j \cap B(x, r)$. Finally $B_i = B(y, C_1\, r)$ and $B_j = B(y', C_1\, r)$ with $C_1 = \min(\gamma, \gamma')$ give the conclusion. ∎

LEMMA 5.8. *Let* $\Sigma \subset \mathbb{R}^n$ *be an Ahlfors-regular set, let* $x \in \Sigma$*,* $r \leq 1$ *be fixed, and let* $B \subset B(x, r/2)$ *be such that* $|B| \geq \beta\, r^n$ *for some* $\beta > 0$*. Then there exist* $\gamma \leq 1/4$*, depending only on* n*,* β *and the Ahlfors-regularity constants for* Σ*, and* $y \in B$ *such that* $B(y, \gamma\, r) \cap \Sigma = \emptyset$*.*

Proof. We argue by contradiction and assume that for any $y \in B$ one can find $z_y \in B(y, \gamma\, r) \cap \Sigma$ with $\gamma \leq 1/4$ to be fixed small later. Then let us consider a maximal family $\mathcal{A}$ of points in B at mutual distance greater than or equal to $4\, \gamma\, r$. We have $B \subset \cup_{y \in \mathcal{A}} B(y, 4\, \gamma\, r)$, hence,

$$\beta\, r^n \leq |B| \leq \sum_{y \in \mathcal{A}} |B(y, 4\, \gamma\, r)| \leq C\, (\text{card } \mathcal{A})\, \gamma^n\, r^n,$$

and thus card $\mathcal{A} \geq C\, \gamma^{-n}$ for some constant $C = C(n, \beta) > 0$. Since the balls $B(y, 2\, \gamma\, r)$, $y \in \mathcal{A}$, are pairwise disjoint and $B(z_y, \gamma\, r) \subset B(y, 2\, \gamma\, r) \subset B(x, r)$, we get from the Ahlfors-regularity of Σ that

$$\begin{aligned} C\, r^{n-1} &\geq \mathcal{H}^{n-1}(\Sigma \cap B(x, r)) \\ &\geq \sum_{y \in \mathcal{A}} \mathcal{H}^{n-1}(\Sigma \cap B(y, 2\, \gamma\, r)) \\ &\geq \sum_{y \in \mathcal{A}} \mathcal{H}^{n-1}(\Sigma \cap B(z_y, \gamma\, r)) \\ &\geq C'\, (\text{card } \mathcal{A})\, \gamma^{n-1}\, r^{n-1} \geq C'\, \gamma^{-1}\, r^{n-1} \end{aligned}$$

which is impossible if γ is small enough, depending only on n, β, and the Ahlfors-regularity constants for Σ. $\square$

Let us now conclude. The Ahlfors-regularity of S is given by Corollary 5.6. Next it is not hard to see that Lemma 5.7 implies condition B stated in Definition 3.3. Indeed the fact that the balls B_i and B_j given by Lemma 5.7 are contained in two distinct connected components of $\mathbb{R}^n \setminus S$ follows from the fact that A_i and A_j are open and disjoint and, for instance, that $\partial A_i \subset S$. Note that we do not know in general whether the components of the partition are connected or not. Hence Lemma 5.7 is slightly stronger than condition B because it says not only that the two balls B_i and B_j are contained in two distinct connected components of $\mathbb{R}^n \setminus S$, but moreover in two distinct components of the partition.

The first part of Theorem 3.7 is given by Lemma 5.4 and it remains to prove that any component with finite Lebesgue measure is bounded. This follows from the Ahlfors-regularity and a covering argument. Let A_i be such that $|A_i| < +\infty$ and let $\mathcal{A}$ be a maximal family of points in ∂A_i at mutual distance greater than or equal to 1. The balls $B(x, 1/2)$, $x \in \mathcal{A}$, are pairwise disjoint and since $\partial A_i \subset S$ and S is Ahlfors-regular, we have

$$\begin{aligned}\operatorname{card} \mathcal{A} &\leq C \sum_{x\in\mathcal{A}} \mathcal{H}^{n-1}(S \cap B(x,1/2)) \\ &\leq C\, \mathcal{H}^{n-1}(S \cap \cup_{x\in\mathcal{A}} B(x,1/2)) \leq C\, \mathcal{H}^{n-1}(S).\end{aligned}$$

According to (2.2) we have $2\,\mathcal{H}^{n-1}(S) = P(A) < +\infty$ hence $\operatorname{card} \mathcal{A} < +\infty$. Since $\partial A_i \subset \cup_{x\in\mathcal{A}} B(x,1)$ and A_i has finite Lebesgue measure, it follows that $\operatorname{diam}(A_i) = \operatorname{diam}(\partial A_i) < +\infty$. Hence A_i is bounded as claimed.

6. Partitioning regular interface coefficients. We consider in this section a particular class of energies similar to that considered in [1] and prove refined properties for quasiminimal partitions. Namely, we show that in that case each topological boundary ∂A_i of some component of a reduced quasiminimal partition A is Ahlfors-regular and satisfies condition B (and even a slightly stronger condition, see Lemma 6.5) on its own. This is quite stronger than the general Theorem 5.1 which concerns only the set of interfaces.

First we need some definitions. Following [1, Chapter VI] we say that the coefficients σ_{ij}, $i,j \in \{0,\dots,N\}$, $i \neq j$, are partitioning regular if $\sigma_{ij} > 0$ and $\sigma_{ij} = \sigma_{ji}$ for all $i,j \in \{0,\dots,N\}$, $i \neq j$, and if, for all $i \in \{0,\dots,N\}$ and $b = (b_0,\dots,b_N) \in (\mathbb{R}^+)^{N+1}$ such that $b_l > 0$ for some $l \neq i$, one can find $j \in \{0,\dots,N\}$, $j \neq i$, such that

$$b_j\, \sigma_{ij} > \sum_{k\neq i,j} b_k\, (\sigma_{jk} - \sigma_{ik}).$$

Then we set

$$\sigma = \inf_i \left(\inf \left(\sup_{j,\, j\neq i} \left(b_j\, \sigma_{ij} - \sum_{k\neq i,j} b_k\, (\sigma_{jk} - \sigma_{ik}) \right) ;\, b \in (\mathbb{R}^+)^{N+1},\, b_i = 0,\, |b| = 1 \right) \right).$$

We have $\sigma > 0$. Next we say that a Borel map $F : \mathbb{R}^n \times S^{n-1} \to \mathbb{R}^+$ is admissible if F is even in its second variable, $F(x,\nu) = F(x,-\nu)$ for all $x \in \mathbb{R}^n$, $\nu \in S^{n-1}$, and if

$$F^- \leq F(x,\nu) \leq F^+$$

for all $x \in \mathbb{R}^n$, $\nu \in S^{n-1}$, and for some constants F^- and F^+ with $0 < F^- \leq F^+ < +\infty$. Then we say that E is an energy with partitioning regular interface coefficients if E is defined with respect to a family (F_{ij}) with $F_{ij} = \sigma_{ij}\, F$ for some partitioning regular coefficients σ_{ij} and some admissible function F. Heuristically the main point here is that the partitioning regularity of the coefficients σ_{ij} guarantees that it can always be advantageous in terms of minimizing the energy $E(A)$ to remove some component A_i and add it to some other component A_j for some judiciously chosen j (see, e.g., the argument in Lemma 6.2). Note that $E \in \mathcal{E}_0(\underline{\sigma} F^-, \overline{\sigma} F^+)$ with $\underline{\sigma} = \min_{i,j} \sigma_{ij}$ and $\overline{\sigma} = \max_{i,j} \sigma_{ij}$. Note also that for all $A \in \mathcal{P}$ and $U \subset \mathbb{R}^n$ measurable, we have

$$E(A, U) = \sum_{\substack{i,j \\ i \neq j}} \sigma_{ij} E_{ij}(A, U),$$

where

$$E_{ij}(A, U) = \int_{\partial^* A_i \cap \partial^* A_j} \mathbb{1}_U(x)\, F(x, \nu_{A_i}(x))\, d\mathcal{H}^{n-1}.$$

Since $\nu_{A_i}(x) = -\nu_{A_j}(x)$ for $\mathcal{H}^{n-1}$-a.e. $x \in \partial^* A_i \cap \partial^* A_j$ and all $i \neq j$, we also have $E_{ij}(A, U) = E_{ji}(A, U)$.

The main result reads now as follows.

THEOREM 6.1. *Let E be an energy with partitioning regular interface coefficients, let $g : [0, +\infty) \to [0, +\infty)$ be such that $\lim_{t \to 0} t^{(1-n)/n} g(t) = 0$, and let $\delta > 0$ be fixed. Let A be a reduced (g, δ)-quasiminimal partition with respect to E. Then, for all $i \in \{0, \dots, N\}$, we have $\partial^* A_i = \partial A_i$ and ∂A_i is an Ahlfors-regular set which satisfies condition B. Moreover, the Ahlfors-regularity and condition B constants can be chosen depending only on n, F^-, F^+, $\underline{\sigma}$, $\overline{\sigma}$, σ, g, δ, and N.*

Of course, assuming moreover that F satisfies (H3) and combining Theorem 6.1 with Theorem 3.6, one gets similar results for quasiminimal partitions with prescribed measure.

We fix for the rest of this section an energy E with partitioning regular interface coefficients, a function $g : [0, +\infty) \to [0, +\infty)$ such that $\lim_{t \to 0} t^{(1-n)/n} g(t) = 0$, some $\delta < 1$, and a reduced (g, δ)-quasiminimal partition A with respect to E. The main tool in the proof of Theorem 6.1 is the following analogue of Lemma 5.3 when the proportion of some component A_i inside a ball is assumed to be small. Then we prove that one half the ball is entirely contained in the interior of the complement of A_i.

LEMMA 6.2. *There exists $\eta_1 = \eta_1(n, F^-, F^+, \sigma, \overline{\sigma}, g, N) > 0$ such that for all $i \in \{0, \dots, N\}$, $x \in \mathbb{R}^n$, and $r \leq \delta/2$, if $|B(x, r) \cap A_i| \leq \eta_1 r^n$, then $B(x, r/2) \subset \mathbb{R}^n \setminus \overline{A}_i$.*

Proof. Since A is a reduced quasiminimal partition, we know from Lemma 5.4 that A_i is open hence it will be sufficient to prove that $|B(x, r/2) \cap A_i| = 0$. Thus let $i \in \{0, \dots, N\}$, $x \in \mathbb{R}^n$, and $r \leq \delta/2$ be such that $|B(x, r) \cap A_i| \leq \eta_1 r^n$ for some $\eta_1 > 0$ to be fixed small later and let us set $m(t) = |B(x, t) \cap A_i|$ for all $t > 0$. Arguing by contradiction we assume that $m(r/2) > 0$. For $t > 0$, we set $b_k = E_{ik}(A, B(x, t))$ when $k \neq i$ and $b_i = 0$, and, using the partitioning regularity of the coefficients, we choose $j \in \{0, \dots, N\}$, $j \neq i$, such that

$$b_j\, \sigma_{ij} - \sum_{k \neq i, j} b_k\, (\sigma_{jk} - \sigma_{ik}) \geq \sigma\, |b|.$$

Then we define $A' \in \mathcal{P}$ setting $A'_i = A_i \setminus B(x, t)$, $A'_j = A_j \cup (A_i \cap B(x, t))$, and $A'_k = A_k$ for $k \neq i, j$. The partitions A and A' coincide on the open set $\mathbb{R}^n \setminus \overline{B}(x, t)$

and hence have the same energy there. Inside $B(x,t)$ we have $\partial^* A'_i \cap B(x,t) = \emptyset$. On the other hand, we have $\partial^* A'_j \cap B(x,t) \subset (\partial^* A_j \cup \partial^* A_i) \cap B(x,t)$ with $\nu_{A'_j} = \nu_{A_j}$ $\mathcal{H}^{n-1}$-a.e. on $\partial^* A'_j \cap \partial^* A_j \cap B(x,t)$, $\nu_{A'_j} = \nu_{A_i}$ $\mathcal{H}^{n-1}$-a.e. on $\partial^* A'_j \cap \partial^* A_i \cap B(x,t)$. Obviously $\partial^* A'_k = \partial^* A_k$ for all $k \neq i,j$. It follows that for $k \neq i,j$,

$$\begin{aligned}
E_{jk}(A', B(x,t)) &= \int_{\partial^* A'_j \cap \partial^* A_k} \mathbb{1}_{B(x,t)}(y)\, F(y, \nu_{A'_j}(y))\, d\mathcal{H}^{n-1} \\
&\leq \int_{\partial^* A_j \cap \partial^* A_k} \mathbb{1}_{B(x,t)}(y)\, F(y, \nu_{A_j}(y))\, d\mathcal{H}^{n-1} \\
&\quad + \int_{\partial^* A_i \cap \partial^* A_k} \mathbb{1}_{B(x,t)}(y)\, F(y, \nu_{A_i}(y))\, d\mathcal{H}^{n-1} \\
&= E_{jk}(A, B(x,t)) + E_{ik}(A, B(x,t)),
\end{aligned}$$

and hence

$$\begin{aligned}
E(A', B(x,t)) \leq & \sum_{\substack{k,l \neq i,j \\ k \neq l}} \sigma_{kl}\, E_{kl}(A, B(x,t)) \\
& + 2 \sum_{k \neq i,j} \sigma_{jk}\, E_{jk}(A, B(x,t)) + 2 \sum_{k \neq i,j} \sigma_{jk}\, E_{ik}(A, B(x,t)) \\
\leq & \sum_{\substack{k,l \neq i,j \\ k \neq l}} \sigma_{kl}\, E_{kl}(A, B(x,t)) \\
& + 2 \sum_{k \neq i,j} \sigma_{jk}\, E_{jk}(A, B(x,t)) + 2 \sum_{k \neq i,j} \sigma_{ik}\, E_{ik}(A, B(x,t)) \\
& + 2\, \sigma_{ij}\, E_{ij}(A, B(x,t)) + 2 \sum_{k \neq i,j} b_k\, (\sigma_{jk} - \sigma_{ik}) - 2\, b_j\, \sigma_{ij} \\
\leq & E(A, B(x,t)) - 2\, \sigma\, |b|.
\end{aligned}$$

Next let us estimate $E(A', \partial B(x,t))$. We have $\partial^* A'_j \subset \partial^* A_j \cup \partial^* (A_i \cap B(x,t))$ with $\nu_{A'_j} = \nu_{A_j}$ $\mathcal{H}^{n-1}$-a.e. on $\partial^* A'_j \cap \partial^* A_j$, hence,

$$\begin{aligned}
\sum_{k \neq i,j} \sigma_{jk} E_{jk}(A', \partial B(x,t)) \leq & \sum_{k \neq i,j} \sigma_{jk} E_{jk}(A, \partial B(x,t)) \\
& + F^+\, \overline{\sigma} \sum_{k \neq i,j} \mathcal{H}^{n-1}(\partial^* A_k \cap \partial^* (A_i \cap B(x,t)) \cap \partial B(x,t)),
\end{aligned}$$

and

$$\begin{aligned}
\sigma_{ij} E_{ij}(A', \partial B(x,t)) \leq & F^+\, \overline{\sigma}\, (\mathcal{H}^{n-1}(\partial^* A_j \cap \partial^* (A_i \setminus B(x,t)) \cap \partial B(x,t)) \\
& + \mathcal{H}^{n-1}(\partial^* (A_i \cap B(x,t)) \cap \partial^* (A_i \setminus B(x,t)) \cap \partial B(x,t))).
\end{aligned}$$

Similarly we have

$$\sum_{k \neq i,j} \sigma_{ik} E_{ik}(A', \partial B(x,t)) \leq F^+\, \overline{\sigma} \sum_{k \neq i,j} \mathcal{H}^{n-1}(\partial^* A_k \cap \partial^* (A_i \setminus B(x,t)) \cap \partial B(x,t))).$$

It follows that

$$\begin{aligned} E(A', \partial B(x,t)) \leq & \sum_{\substack{k,l \neq i,j \\ k \neq l}} \sigma_{kl}\, E_{kl}(A, \partial B(x,t)) + 2 \sum_{k \neq i,j} \sigma_{jk}\, E_{jk}(A, \partial B(x,t)) \\ & + 2\, F^+\, \overline{\sigma} \sum_{k \neq i,j} \mathcal{H}^{n-1}(\partial^* A_k \cap \partial^*(A_i \cap B(x,t)) \cap \partial B(x,t)) \\ & + 2\, F^+\, \overline{\sigma} \sum_{k \neq i} \mathcal{H}^{n-1}(\partial^* A_k \cap \partial^*(A_i \setminus B(x,t)) \cap \partial B(x,t)) \\ & + 2\, F^+\, \overline{\sigma}\, \mathcal{H}^{n-1}(\partial^*(A_i \cap B(x,t)) \cap \partial^*(A_i \setminus B(x,t)) \cap \partial B(x,t)). \end{aligned}$$

Since $\mathcal{H}^{n-1}$-a.e. point belongs to at most two of the sets $\partial^* A_k$ (see what follows Definition 2.3), we get

$$\begin{aligned} E(A', \partial B(x,t)) \leq & \; E(A, \partial B(x,t)) \\ & + F^+\, \overline{\sigma}\, (4\, P(A_i \cap B(x,t), \partial B(x,t)) + 6\, P(A_i \setminus B(x,t), \partial B(x,t))) \end{aligned}$$

and thus

$$E(A', \partial B(x,t)) \leq E(A, \partial B(x,t)) + 10\, F^+\, \overline{\sigma}\, m'(t)$$

for a.e. $t > 0$. Then we get from the (g, δ)-quasiminimality of A that

$$2\, \sigma\, |b| \leq 10\, F^+\, \overline{\sigma}\, m'(t) + g(|A' \triangle A|).$$

On other hand, we have

$$\begin{aligned} |b| = \max_k |b_k| & \geq N^{-1} \sum_{k \neq i} E_{ik}(A, B(x,t)) \\ & \geq N^{-1}\, F^- \sum_{k \neq i} \mathcal{H}^{n-1}(\partial^* A_k \cap \partial^* A_i \cap B(x,t)) \\ & = N^{-1}\, F^-\, P(A_i, B(x,t)) \geq C\, m(t)^{\frac{n-1}{n}} \end{aligned}$$

for some constant $C = C(n, F^-, N) > 0$ provided η_1 is small enough. We also have $|A' \triangle A| = m(t) \leq \eta_1\, r^n \leq \eta_1$ hence, if η_1 is small enough,

$$g(|A' \triangle A|) \leq C\, \sigma\, m(t)^{\frac{n-1}{n}},$$

where C is the same constant as above. It follows that

$$m(t)^{\frac{n-1}{n}} \leq C\, m'(t)$$

for a.e. $t \in (r/2, r)$ and for some suitable constant $C = C(n, F^-, F^+, \sigma, \overline{\sigma}, N) > 0$. Then, dividing both sides by $m(t)^{(n-1)/n}$ which does not vanish for $t \geq r/2$ and integrating on $t \in (r/2, r)$, we get

$$r \leq C\, (m(r)^{\frac{1}{n}} - m(r/2)^{\frac{1}{n}}) \leq C\, m(r)^{\frac{1}{n}} \leq C\, \eta_1^{\frac{1}{n}}\, r.$$

This is impossible if η_1 is small enough and concludes the proof. $\square$

Let $\eta_2 = \min(\eta_0, \eta_1)$ where η_0 and η_1 are given by Lemmas 5.3 and 6.2, respectively. For all $i \in \{0, \ldots, N\}$, we set

$$\partial_i = \{x \in \mathbb{R}^n \, ; \, \min(|A_i \cap B(x,r)|, |B(x,r) \setminus A_i|) > \eta_2 \, r^n \text{ for all } r \leq \delta/2\}. \tag{6.1}$$

The first part of Theorem 6.1 is given by the following lemma.

LEMMA 6.3. *For all $i \in \{0, \ldots, N\}$, we have $\partial_i = \partial^* A_i = \partial A_i$.*

Proof. First since A_i and $\mathbb{R}^n \setminus \overline{A}_i$ are open (see Lemma 5.4) we have $\partial_i \cap (A_i \cup \mathbb{R}^n \setminus \overline{A}_i) = \emptyset$. Then it follows from Lemmas 5.3 and 6.2 that $\mathbb{R}^n$ is the disjoint union of the three sets A_i, $\mathbb{R}^n \setminus \overline{A}_i$, and ∂_i and we get in particular that $\partial_i = \overline{A}_i \setminus A_i = \partial A_i$. On the other hand, we have $A_i = A_i(1)$ by definition of a reduced partition hence, to prove that $\partial_i = \partial^* A_i$, we only need to check that $\mathbb{R}^n \setminus \overline{A}_i = A_i(0)$. One always has $\mathbb{R}^n \setminus \overline{A}_i \subset A_i(0)$. Conversely if $x \in A_i(0)$, then $\min(|A_i \cap B(x,r)|, |B(x,r) \setminus A_i|) = |B(x,r) \cap A_i| \leq \eta_2 \, r^n$ for all r small enough, hence $x \in \mathbb{R}^n \setminus \overline{A}_i$ according to Lemma 6.2. □

Next we prove the Ahlfors-regularity of ∂A_i. As a convention for the rest of this section, we say that a constant is universal if its value can be chosen depending only on n, F^-, F^+, $\underline{\sigma}$, $\overline{\sigma}$, σ, g, δ, and N.

LEMMA 6.4. *For all $i \in \{0, \ldots, N\}$, ∂A_i is an Ahlfors-regular set with Ahlfors-regularity constants that can be chosen universal.*

Proof. Let $x \in \partial A_i$ and $r \leq 1$ be fixed. Since $\partial A_i \subset S$ by Lemma 5.4 and S is Ahlfors-regular with universal regularity constants (see Corollary 5.6), we have

$$\mathcal{H}^{n-1}(\partial A_i \cap B(x,r)) \leq \mathcal{H}^{n-1}(S \cap B(x,r)) \leq C \, r^{n-1}$$

for some universal constant $C > 0$. On the other hand, the relative isoperimetric inequality for balls together with Lemma 6.3 and (6.1) gives

$$\eta_2^{\frac{n-1}{n}} \, r^{n-1} < \min(|A_i \cap B(x,r)|, |B(x,r) \setminus A_i|)^{\frac{n-1}{n}} \leq C \, \mathcal{H}^{n-1}(\partial A_i \cap B(x,r))$$

provided $r \leq \delta/2$. Finally the lower inequality in the Ahlfors-regularity for all radii $r \leq 1$ follows easily, with a slightly different constant (depending on δ). □

LEMMA 6.5. *There exists a universal constant $C_2 > 0$ such that for all $i \in \{0, \ldots, N\}$, $x \in \partial A_i$, and $r \leq 1$, one can find a ball B_i with radius $C_2 \, r$ such that $B_i \subset A_i \cap B(x,r)$.*

Proof. Let $i \in \{0, \ldots, N\}$, $x \in \partial A_i$, and $r \leq 1$ be fixed and set $B = A_i \cap B(x, r/2)$. It follows from Lemma 6.3 and (6.1) that $|B| \geq \beta \, r^n$ for some universal $\beta > 0$ and from Lemma 6.4 that ∂A_i is Ahlfors-regular with universal regularity constants. Hence one can apply Lemma 5.8 to find a universal constant $C_2 \leq 1/4$ and a point $y \in A_i \cap B(x, r/2)$ such that $B(y, C_2 \, r) \cap \partial A_i = \emptyset$. This implies automatically that $B(y, C_2 \, r) \subset A_i$ and since $B(y, C_2 \, r) \subset B(x,r)$ this gives the required conclusion. □

This implies easily that ∂A_i satisfies condition B. Indeed combining Lemma 6.5 with Lemma 5.7 we get the existence of a universal constant $C_3 > 0$ such that for all $i \in \{0, \ldots, N\}$, $x \in \partial A_i$, and $r \leq 1$, one can find two balls B and B' with radius $C_3 \, r$ and such that $B \subset A_i \cap B(x,r)$ and $B' \subset A_j \cap B(x,r)$ for some $j \neq i$. In particular we have $B' \subset \mathbb{R}^n \setminus \overline{A}_i$ hence B and B' are contained in two distinct connected components of $\mathbb{R}^n \setminus \partial A_i$. This concludes the proof of Theorem 6.1.

LANDAU–DE GENNES MODEL OF LIQUID CRYSTALS WITH SMALL GINZBURG–LANDAU PARAMETER*

XING-BIN PAN†

Abstract. Liquid crystals may exhibit two types of behaviors, in comparison with two types of superconductors. We wish to explore type-I behavior of liquid crystals by using the Landau–de Gennes model with small Ginzburg–Landau parameter κ. In this paper, for small κ, we give an estimate on the critical wave number Q_{c_3}, at which a liquid crystal undergoes a phase transition from a nematic state to a smectic state. We show that, if κ is small, a smectic phase can nucleate only from a special class of nematic states, which depends on the geometry of the domain occupied by the liquid crystal. If the wave number is further lowered, the liquid crystal is in a uniform smectic state, which resembles the perfect superconducting state of type-I superconductors.

Key words. liquid crystal, phase transition, Landau–de Gennes model, critical wave number

1. Introduction.

As predicted by P. G. de Gennes in [dG], smectic liquid crystals can exhibit either type-I or type-II behavior, in comparison with two types of superconductivity. Both behavior types have been reported; see [dGP, p. 512]. Type I superconductivity has been successfully described by the minimizers of the Ginzburg–Landau functional with small Ginzburg–Landau parameter [GL], and it is natural to expect that the minimizers of the Landau–de Gennes model of liquid crystals with small Ginzburg–Landau parameter exhibit type-I behavior. In this paper, continuing our study in [P1],[1] we shall examine this expectation.

According to de Gennes's theory [dG, dGP], the state of a liquid crystal can be described (at least for a temperature close to the transition point) by a complex-valued function Ψ called *order parameter*, a real vector field of unit length $\mathbf{n}$ called *director field*, and a real number q called *wave number*, which depends on the material and temperature. $\Psi = 0$ for a nematic phase, and $\Psi \neq 0$ for a smectic phase. $(\Psi, \mathbf{n})$ is a minimizer of the Landau–de Gennes energy (see [dGP, C, BCLP]):

$$\mathcal{L}[\Psi, \mathbf{n}] = \int_\Omega \big\{ c|\nabla_{q\mathbf{n}}\Psi|^2 + \mathcal{F}_A(|\Psi|) + \mathcal{F}_N(\mathbf{n}, \nabla\mathbf{n}) \big\} dx,$$

where Ω is the region occupied by the liquid crystal, c is a real constant, $\nabla_{q\mathbf{n}}\Psi = \nabla\Psi - iq\mathbf{n}\Psi$ with $i = \sqrt{-1}$, $\mathcal{F}_A(|\Psi|)$ and $\mathcal{F}_N(\mathbf{n}, \nabla\mathbf{n})$ denote the smectic energy density and the nematic Oseen–Frank energy density, respectively;

$$\mathcal{F}_A(|\Psi|) = r|\Psi|^2 + \frac{u}{2}|\Psi|^4,$$

[1]Our investigation in [P1] was motivated by Lin [L] and Aviles and Giga [AG] on the phase transitions of liquid crystals, and by Calderer [C] and Bauman et al. [BCLP] on the Landau–de Gennes model.

where $u > 0$, $r < 0$, and $r \sim \alpha(T - T_0)$ as temperature T approaches a critical temperature T_0; see [dGP, p. 508]. In the case without external electromagnetic fields, the Oseen–Frank energy density is given by

$$\begin{aligned}\mathcal{F}_N(\mathbf{n}, \nabla\mathbf{n}) = \mathcal{K}_1|\mathrm{div}\ \mathbf{n}|^2 + \mathcal{K}_2|\mathbf{n}\cdot \mathrm{curl}\ \mathbf{n} + \tau|^2 + \mathcal{K}_3|\mathbf{n}\wedge \mathrm{curl}\ \mathbf{n}|^2 \\ + (\mathcal{K}_2 + \mathcal{K}_4)[\mathrm{tr}(\nabla\mathbf{n})^2 - (\mathrm{div}\ \mathbf{n})^2],\end{aligned}$$

where $\mathcal{K}_j$, $j = 1, 2, 3, 4$, called elastic coefficients, are material constants, among them $\mathcal{K}_1$, $\mathcal{K}_2$, and $\mathcal{K}_3$ are positive; τ is a real number referring to the chiral pitch in some liquid crystal materials. As explained in [P1], we shall drop the last term in the Oseen–Frank energy density, and assume $\mathcal{K}_3 = \mathcal{K}_2$. After making the rescaling

$$\Psi = \sqrt{\frac{|r|}{u}}\psi, \quad \kappa = \sqrt{\frac{|r|}{c}}, \quad K_j = \frac{u}{c|r|}\mathcal{K}_j, \quad j = 1, 2,$$

and replacing $\mathcal{L}$ by $\frac{u}{c|r|}\mathcal{L}$, we are led to the following functional:[2]

$$\mathcal{G}[\psi, \mathbf{n}] = \int_\Omega \Big\{|\nabla_{q\mathbf{n}}\psi|^2 + \frac{\kappa^2}{2}(1 - |\psi|^2)^2 + K_1|\mathrm{div}\ \mathbf{n}|^2 + K_2|\mathrm{curl}\ \mathbf{n} + \tau\mathbf{n}|^2\Big\}dx. \tag{1.1}$$

As mentioned in [P1], we believe that the simplified energy functional (1.1) catches the main feature and most difficulties of the Landau–de Gennes model with the full Oseen–Frank energy. Note that in [dGP] the quantity $\xi = \sqrt{\frac{c}{|r|}}$ is called the *order parameter coherence length*. Hence

$$\kappa = \frac{1}{\xi}.$$

We prefer keeping the notation κ in our model instead of ξ, as κ corresponds to the Ginzburg–Landau parameter in the Ginzburg–Landau model of superconductivity (when taking the penetration length as unit of length). For convenience, let us call κ in (1.1) the *Ginzburg–Landau parameter* for liquid crystals.[3] From the analogy between liquid crystals and superconductivity, we expect that liquid crystals exhibit type-I behavior when the Ginzburg–Landau parameter κ is small.

As explained in [P1], the natural space for variational problems of (1.1) is

$$W^{1,2}(\Omega, \mathbb{C}) \times V(\Omega, \mathbb{S}^2),$$

where[4]

$$\begin{aligned}V(\Omega, \mathbb{R}^3) &= \big\{\mathbf{u} \in L^2(\Omega, \mathbb{R}^3) : \ \ \mathrm{div}\ \mathbf{u} \in L^2(\Omega), \ \ \mathrm{curl}\ \mathbf{u} \in L^2(\Omega, \mathbb{R}^3)\big\}, \\ V(\Omega, \mathbb{S}^2) &= \big\{\mathbf{n} \in V(\Omega, \mathbb{R}^3) : \ \ |\mathbf{n}(x)| = 1 \quad \text{a.e. in } \Omega\big\}.\end{aligned}$$

$V(\Omega, \mathbb{R}^3)$ is a Hilbert space with the inner product and norm defined by

$$\begin{aligned}(\mathbf{u}, \mathbf{v})_V &= \int_\Omega \{\mathrm{div}\ \mathbf{u}\ \mathrm{div}\ \mathbf{v} + \mathrm{curl}\ \mathbf{u}\cdot \mathrm{curl}\ \mathbf{v} + \mathbf{u}\cdot\mathbf{v}\}dx, \\ \|\mathbf{u}\|_V &= \Big\{\|\mathrm{div}\ \mathbf{u}\|^2_{L^2(\Omega)} + \|\mathrm{curl}\ \mathbf{u}\|^2_{L^2(\Omega)} + \|\mathbf{u}\|^2_{L^2(\Omega)}\Big\}^{1/2}.\end{aligned}$$

[2]In [P1] we used the functional $\mathcal{E}[\psi, \mathbf{n}] = \mathcal{G}[\psi, \mathbf{n}] - \frac{\kappa^2}{2}|\Omega|$, which is zero on the trivial critical points.

[3]In physical literature on liquid crystals, the letter κ has been used also for other ratios. For instance, Renn and Lubensky [RL] defined the twist Ginzburg parameter $\kappa_2 = \frac{\lambda_2}{\xi}$.

[4]The space $V(\Omega, \mathbb{R}^3)$ was denoted by $H(\mathrm{curl}, \mathrm{div}, \Omega)$ in Dautray and Lions [DL].

Here and throughout, unless specified otherwise, $\|\cdot\|_{L^2(\Omega)}$ denotes both the usual L^2 norm for scalar functions and the L^2 norm for vector fields. Throughout this paper we assume that

$$\Omega \text{ is a bounded, simply connected domain in } \mathbb{R}^3 \text{ with smooth boundary.} \tag{1.2}$$

We concern the global minimizers of $\mathcal{G}$ in $W^{1,2}(\Omega,\mathbb{C})\times V(\Omega,\mathbb{S}^2)$, without prescribing boundary data of the director fields. Let

$$C(K_1,K_2,\kappa,\tau,q)=\inf_{(\psi,\mathbf{n})\in W^{1,2}(\Omega,\mathbb{C})\times V(\Omega,\mathbb{S}^2)}\mathcal{G}[\psi,\mathbf{n}]. \tag{1.3}$$

Note that if $(\psi,\mathbf{n})$ is a minimizer of $\mathcal{G}$ with wave number q, then $(\psi,-\mathbf{n})$, $(-\psi,\mathbf{n})$, and $(\bar\psi,\mathbf{n})$ are minimizers of $\mathcal{G}$ with wave number $-q$. Therefore in the following we shall always assume $q\ge 0$. The functional $\mathcal{G}$ has many trivial minimizers $(0,\mathbf{n})$ with $\mathbf{n}\in\mathcal{C}(\tau)$, where

$$\mathcal{C}(\tau)=\{\mathbf{n}\in V(\Omega,\mathbb{S}^2):\ \text{div } \mathbf{n}=0,\ \text{curl } \mathbf{n}+\tau\mathbf{n}=\mathbf{0} \text{ in } \Omega\}. \tag{1.4}$$

The trivial minimizers correspond to the nematic state. The classification of vector fields in $\mathcal{C}(\tau)$ has been proved in [BCLP].

It is useful to find the regime of parameters that the global minimizers are nontrivial. In [P1], motivated by the analogy between liquid crystals and superconductivity (see [dG, dGP]), we introduced the *critical wave number* Q_{c_3}, which is a critical number for q such that if $|q|<Q_{c_3}$, then there exist nontrivial minimizers:

$$Q_{c_3}(K_1,K_2,\kappa,\tau)=\inf\{q>0:\ \mathcal{G} \text{ has only trivial minimizers}\}. \tag{1.5}$$

In [P1] we also gave estimates of Q_{c_3} and investigated the behavior of nontrivial minimizers for large K_1, K_2. As we are now concerned with the type-I behavior of liquid crystals, we shall estimate the value of Q_{c_3} when the Ginzburg–Landau parameter κ is small, with K_1, K_2 fixed; and we shall examine the behavior of the minimizers when the wave number q is less than Q_{c_3}.

To state the main results of this paper, let us define, for a vector field $\mathbf{u}\in V(\Omega,\mathbb{R}^3)$,[5]

$$\omega(\mathbf{u})\equiv\omega(\mathbf{u},\Omega)=\inf_{\phi\in W^{1,2}(\Omega)}\fint_\Omega|\nabla\phi-\mathbf{u}|^2dx, \tag{1.6}$$

where $\fint_\Omega\phi dx=\frac{1}{|\Omega|}\int_\Omega\phi dx$, and $|\Omega|$ is the volume of Ω. It is easy to show that $\omega(\mathbf{u})$ is achieved by the unique (real-valued) solution $\zeta_{\mathbf{u}}$ of the equation

$$\begin{cases}\Delta\zeta_{\mathbf{u}}=\text{div } \mathbf{u} & \text{in } \Omega,\\ \dfrac{\partial\zeta_{\mathbf{u}}}{\partial\nu}=\gamma_\nu\mathbf{u} & \text{on } \partial\Omega,\\ \displaystyle\int_\Omega\zeta_{\mathbf{u}}\,dx=0,\end{cases} \tag{1.7}$$

[5]In the case $\mathbf{u}=\mathbf{F_h}$, where $\mathbf{h}$ is a unit vector, and $\mathbf{F_h}$ is a vector field satisfying curl $\mathbf{F_h}=\mathbf{h}$ and div $\mathbf{F_h}=0$ in Ω, the number $\omega(\mathbf{F_h})$ was denoted by $\omega(\mathbf{h})$ in [P2], and was denoted by $\lambda(\mathbf{h})$ in [P1].

where $\gamma_\nu \mathbf{u}$ is the trace of $\mathbf{u}$ on $\partial\Omega$, and $\gamma_\nu \mathbf{u}$ is the restriction of $\mathbf{u}\cdot\nu$ to $\partial\Omega$ if $\mathbf{u}$ is smooth. Up to an additive constant, the minimizer is unique. We shall call $\zeta_{\mathbf{u}}$ the minimizer of $\omega(\mathbf{u})$. Let

$$
\begin{aligned}
&\omega_*(\tau) = \inf_{\mathbf{n}\in\mathcal{C}(\tau)} \omega(\mathbf{n}),\\
&\mathcal{C}_*(\tau) = \{\mathbf{n}\in\mathcal{C}(\tau):\ \omega(\mathbf{n}) = \omega_*(\tau)\}.
\end{aligned}
\tag{1.8}
$$

We can show that $0<\omega_*(\tau)<1$ (see (2.2) in section 2). Note that $\omega(-\mathbf{n}) = \omega(\mathbf{n})$. So if $\mathbf{n}\in\mathcal{C}_*(\tau)$, then $-\mathbf{n}\in\mathcal{C}_*(\tau)$.

THEOREM 1.1. *Assume condition* (1.2)*, and fix the positive constants K_1, K_2, and τ. For small $\kappa>0$ we have*

$$
Q_{c_3}(K_1,K_2,\kappa,\tau) = \frac{\kappa}{\sqrt{\omega_*(\tau)}} + o(\kappa). \tag{1.9}
$$

Let $q = a_\kappa\kappa$ with $0<a_\kappa\kappa<Q_{c_3}(K_1,K_2,\kappa,\tau)$ and $\lim_{\kappa\to 0} a_\kappa = a_0$, where $0<a_0\le \frac{1}{\sqrt{\omega_*(\tau)}}$. Then

$$
C(K_1,K_2,\kappa,\tau,a_\kappa\kappa) = a_0^2\omega_*(\tau)\Big[1-\frac{1}{2}a_0^2\omega_*(\tau)\Big]|\Omega|\kappa^2 + o(\kappa^2); \tag{1.10}
$$

and for any sequence $\kappa\to 0$, there exist a subsequence $\kappa_j\to 0$ and $\mathbf{n}_0\in\mathcal{C}_*(\tau)$, such that the minimizers $(\psi_{\kappa_j},\mathbf{n}_{\kappa_j})$ of the functional $\mathcal{G}$ have expansions

$$
\begin{aligned}
\psi_{\kappa_j} &= c_{\kappa_j}\big[1 + i a_{\kappa_j}\kappa_j(\zeta_{\mathbf{n}_0} + \phi_{\kappa_j})\big],\\
\mathbf{n}_{\kappa_j} &= \mathbf{n}_0 + \kappa_j \mathbf{v}_{\kappa_j},
\end{aligned}
\tag{1.11}
$$

where $\zeta_{\mathbf{n}_0}$ is the minimizer of $\omega(\mathbf{n}_0)$, c_{κ_j} is a complex number, $\phi_{\kappa_j}\in W^{1,2}(\Omega,\mathbb{C})$, $\mathbf{v}_{\kappa_j}\in V(\Omega,\mathbb{R}^3)$, and as $\kappa_j\to 0$,

$$
\begin{aligned}
&|c_{\kappa_j}| \to [1-a_0^2\omega_*(\tau)]^{1/2},\\
&\|\phi_{\kappa_j}\|_{W^{1,2}(\Omega,\mathbb{C})}\to 0,\\
&\|\mathrm{div}\mathbf{v}_{\kappa_j}\|_{L^2(\Omega)}\to 0,\\
&\|\mathrm{curl}\mathbf{v}_{\kappa_j} + \tau\mathbf{v}_{\kappa_j}\|_{L^2(\Omega)}\to 0.
\end{aligned}
\tag{1.12}
$$

Remark. (1) When $0<a_0<\frac{1}{\sqrt{\omega_*(\tau)}}$, the expansion (1.11) shows that the minimizers have the approximation

$$
|\psi_{\kappa_j}| \sim [1-a_0^2\omega_*(\tau)]^{1/2}, \qquad \mathbf{n}_{\kappa_j}\sim\mathbf{n}_0 \quad \text{as } \kappa_j\to 0.
$$

So we may say that the liquid crystal is in a *uniform smectic state* when κ is small, which resembles the perfect superconducting state of type-I superconductors under an applied magnetic field below the critical field H_c.

(2) From (1.11) we also see that, when the wave number q decreases from Q_{c_3}, a smectic phase nucleates from a nematic state $(0,\mathbf{n}_0)$, where $\mathbf{n}_0\in\mathcal{C}_*(\tau)$. Let

$$
\begin{aligned}
\mathcal{N}(\tau) &= \{(0,\mathbf{n}):\ \mathbf{n}\in\mathcal{C}(\tau)\},\\
\mathcal{N}_*(\tau) &= \{(0,\mathbf{n}):\ \mathbf{n}\in\mathcal{C}_*(\tau)\}.
\end{aligned}
$$

Every element in $\mathcal{N}(\tau)$ represents a nematic state; however, only the nematic states in $\mathcal{N}_*(\tau)$ allow a smectic state to nucleate. Note that the structure of $\mathcal{N}_*(\tau)$ reflects the geometry of the domain Ω.

Theorem 1.1 indicates some similarity between smectic liquid crystals with small Ginzburg–Landau parameter κ and type-I superconductors. In fact, the estimate (1.9) for Q_{c_3} is similar to the estimate of the critical field H_c for type I superconductors obtained in [P2, Theorem 1]; and the expansion (1.11) resembles the expansions of minimizers for type-I superconductivity; see [P2, Theorem 2]. However, there is an important difference between liquid crystals and superconductors. For liquid crystals we require the director field to satisfy the pointwise unit length constraint

$$|\mathbf{n}(x)| = 1 \quad \text{on } \Omega. \tag{1.13}$$

The constraint (1.13) is one of the sources of complications, especially for analysis of high order terms in (1.11). Another source of complications is that the functional $\mathcal{I}$ is not coercive in the orthogonal complement of the kernel, where $\mathcal{I}$ is defined by the last two terms in $\mathcal{G}$:

$$\mathcal{I}[\mathbf{v}] = \int_\Omega \{K_1|\text{div } \mathbf{v}|^2 + K_2|\text{curl } \mathbf{v} + \tau\mathbf{v}|\}dx. \tag{1.14}$$

The kernel $X(\tau)$ of $\mathcal{I}$ consists of all solutions of the following equations in $V(\Omega, \mathbb{R}^3)$:

$$\text{div } \mathbf{u} = 0, \qquad \text{curl } \mathbf{u} + \tau\mathbf{u} = \mathbf{0} \quad \text{ in } \Omega. \tag{1.15}$$

Obviously $X(\tau)$ is a closed subspace of $V(\Omega, \mathbb{R}^3)$, and $\mathcal{C}(\tau) = X(\tau) \cap V(\Omega, \mathbb{S}^2)$. With respect to the inner product $(\cdot, \cdot)_V$, the space $V(\Omega, \mathbb{R}^3)$ has orthogonal decomposition

$$V(\Omega, \mathbb{R}^3) = X(\tau) \oplus X_V^\perp(\tau).$$

Unfortunately, $\mathcal{I}$ is not coercive on $X_V^\perp(\tau)$, and a sequence satisfying $\mathcal{I}[\mathbf{u}_j] \to 0$ may exhibit boundary concentrations. Fortunately we are able to classify vector fields that satisfy (1.15) coupled with a pointwise constraint (Lemma 3.1), and obtain an orthogonality property (Proposition 3.3). These results will be useful in sections 4 and 5.

The outline of this paper is as follows. Section 2 contains some preliminary results that will be needed in later sections. In section 3 we classify the solutions of (1.15) coupled with a pointwise constraint. In section 4 we prove the estimate of Q_{c_3} for small κ, and provide an energy upper bound that is better than (1.10). In section 5 we investigate the behavior of nontrivial minimizers as $\kappa \to 0$.

We would like to mention that the mathematical theory of phase transitions of liquid crystals has been studied extensively by many mathematicians, among others we mention Hardt, Kinderlehrer, and Lin [HKL], Hardt and Kinderlehrer [HK], Brezis [B], Lin [L], and Aviles and Giga [AG]. Following the work by P. G. de Gennes [dG], the investigation on liquid crystals based on the Landau–de Gennes theory has been successfully conducted by many physicists, and the similarity between superconductivity and liquid crystals has been explored; see, for instance, Chen and Lubensky [ChL], Lubensky and Renn [LR], and Renn and Lubensky [RL]. The mathematical theory of the Landau–de Gennes model has been investigated by Calderer [C] and Bauman et al. [BCLP].

2. Preliminaries.

Given a vector field $\mathbf{u} \in V(\Omega, \mathbb{R}^3)$, let $\omega(\mathbf{u})$ and $\omega_*(\tau)$ be the numbers defined in (1.6) and (1.8), respectively, and let $\zeta_{\mathbf{u}}$ be the minimizer of $\omega(\mathbf{u})$.

LEMMA 2.1. *For any $\tau > 0$ and $\mathbf{n} \in \mathcal{C}(\tau)$ we have*

$$0 < \omega(\mathbf{n}) < 1. \tag{2.1}$$

In particular,

$$0 < \omega_*(\tau) < 1. \tag{2.2}$$

Proof. Using (1.7) we have, for any smooth function ϕ,

$$\int_\Omega (\nabla\zeta_{\mathbf{u}} - \mathbf{u}) \cdot \nabla\phi dx = 0. \tag{2.3}$$

Note that $\mathbf{u}$ has canonical decomposition

$$\mathbf{u} = \mathbf{v}_{\mathbf{u}} + \nabla\zeta_{\mathbf{u}}, \tag{2.4}$$

where $\mathbf{v}_{\mathbf{u}}$ satisfies

$$\begin{cases} \operatorname{div} \mathbf{v}_{\mathbf{u}} = 0, \quad \operatorname{curl} \mathbf{v}_{\mathbf{u}} = \operatorname{curl} \mathbf{u} & \text{in } \Omega, \\ \gamma_\nu \mathbf{v}_{\mathbf{u}} = 0 & \text{on } \partial\Omega. \end{cases}$$

Using (2.3) we find

$$\int_\Omega |\mathbf{u}|^2 dx = \int_\Omega |\mathbf{v}_{\mathbf{u}}|^2 dx + \int_\Omega |\nabla\zeta_{\mathbf{u}}|^2 dx.$$

Hence

$$\omega(\mathbf{u}) = -\!\!\!\!\!\!\int_\Omega |\mathbf{v}_{\mathbf{u}}|^2 dx = -\!\!\!\!\!\!\int_\Omega (|\mathbf{u}|^2 - |\nabla\zeta_{\mathbf{u}}|^2) dx.$$

In particular, for a unit vector field $\mathbf{n} \in V(\Omega, \mathbb{S}^2)$ we have $0 \le \omega(\mathbf{n}) \le 1$. If $\mathbf{n}$ has canonical decomposition $\mathbf{n} = \mathbf{v}_{\mathbf{n}} + \nabla\zeta_{\mathbf{n}}$, then

$$-\!\!\!\!\!\!\int_\Omega |\nabla\zeta_{\mathbf{n}}|^2 dx = -\!\!\!\!\!\!\int_\Omega (|\mathbf{n}|^2 - |\mathbf{v}_{\mathbf{n}}|^2) dx = 1 - \omega(\mathbf{n}). \tag{2.5}$$

Moreover, $\omega(\mathbf{n}) = 0$ if and only if $\mathbf{n} = \nabla\zeta_{\mathbf{n}}$; and $\omega(\mathbf{n}) = 1$ if and only if $\zeta_{\mathbf{n}} = 0$.

Now we assume $\mathbf{n} \in \mathcal{C}(\tau)$. Since $\operatorname{curl} \mathbf{n} = -\tau\mathbf{n} \ne \mathbf{0}$, we see that $\mathbf{n} \not\equiv \nabla\zeta_{\mathbf{n}}$. So $\omega(\mathbf{n}) > 0$. It has been proved in [BCLP] that every $\mathbf{n} \in \mathcal{C}(\tau)$ has the form

$$\begin{gathered} \mathbf{n} = Q\mathbf{N}_\tau(Q^t x), \\ \text{where} \quad \mathbf{N}_\tau = (\cos(\tau x_3), \sin(\tau x_3), 0)^\top, \quad Q \in SO(3). \end{gathered} \tag{2.6}$$

Here and thereafter, for a row vector $\mathbf{w}$, $\mathbf{w}^\top$ denotes the corresponding column vector. Note that $\zeta_{\mathbf{n}}$ depends on Q through $\mathbf{n}$. Let $\zeta_{\tau,Q}$ be the solution of

$$\begin{cases} \Delta\zeta_{\tau,Q} = 0 & \text{in } Q^t\Omega, \\ \dfrac{\partial\zeta_{\tau,Q}}{\partial\nu} = \mathbf{N}_\tau \cdot \nu & \text{on } \partial(Q^t\Omega), \\ \displaystyle\int_{Q^t\Omega} \zeta_{\tau,Q}\, dx = 0. \end{cases}$$

Then

$$\zeta_{\mathbf{n}}(x) = \zeta_{\tau,Q}(Q^t x).$$

From (2.6) we see that, for any bounded domain Ω with smooth boundary,

$$\mathbf{N}_\tau \cdot \nu \not\equiv 0 \quad \text{on } \partial(Q^t\Omega).$$

Hence $\zeta_{\tau,Q} \not\equiv 0$. Thus, $\omega(\mathbf{n}) < 1$. So (2.1) is true. Note that $\omega_*(\tau)$ is achieved by some $\mathbf{n}_0$ in $\mathcal{C}_*(\tau)$. So (2.2) is true. □

From the above discussion we see that

$$\omega(\mathbf{n}, \Omega) = \fint_\Omega |\nabla\zeta_{\mathbf{n}} - \mathbf{n}|^2 dx = \fint_{Q^t\Omega} |\nabla\zeta_{\tau,Q} - \mathbf{N}_\tau|^2 dx = \omega(\mathbf{N}_\tau, Q^t\Omega).$$

Therefore

$$\begin{aligned}\omega_*(\tau) &= \inf_{Q\in SO(3)} \fint_{Q^t\Omega} |\nabla\zeta_{\tau,Q} - \mathbf{N}_\tau|^2 dx \\ &= \inf_{Q\in SO(3)} \inf_{\phi\in W^{1,2}(Q^t\Omega)} \fint_{Q^t\Omega} |\nabla\phi - \mathbf{N}_\tau|^2 dx.\end{aligned}$$

Next we consider an eigenvalue problem. Given a vector field $\mathbf{u} \in V(\Omega, \mathbb{R}^3)$, let $\mu(\varepsilon\mathbf{u})$ be the lowest eigenvalue of the equation

$$\begin{cases} -\nabla^2_{\varepsilon\mathbf{u}}\phi = \mu\phi & \text{in } \Omega, \\ (\nabla_{\varepsilon\mathbf{u}}\phi)\cdot\nu = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.7}$$

Lemma 2.2. *For any $\mathbf{n} \in V(\Omega, \mathbb{S}^2)$ we have, as $\varepsilon \to 0$,*

$$\varepsilon^2\omega(\mathbf{n}) + O(\varepsilon^3) \le \mu(\varepsilon\mathbf{n}) \le \omega(\mathbf{n})\varepsilon^2 + \frac{1-\omega(\mathbf{n})}{|\Omega|}\|\zeta_{\mathbf{n}}\|^2_{L^2(\Omega)}\varepsilon^4 + O(\varepsilon^6). \tag{2.8}$$

Proof. The lower bound can be proved as in [P2, Lemma 2.1]. To prove the upper bound, let $\phi = 1 + i\varepsilon\zeta_{\mathbf{n}}$. Then

$$\int_\Omega |\nabla_{\varepsilon\mathbf{n}}\phi|^2 dx = \varepsilon^2 \int_\Omega \{|\nabla\zeta_{\mathbf{n}} - \mathbf{n}|^2 + \varepsilon^2|\zeta_{\mathbf{n}}\mathbf{n}|^2\} dx = \varepsilon^2|\Omega|\omega(\mathbf{n}) + \varepsilon^4\|\zeta_{\mathbf{n}}\|^2_{L^2(\Omega)}.$$

Here we have used the fact $|\mathbf{n}(x)| \equiv 1$. Then we use the inequality

$$\mu(\varepsilon\mathbf{n}) \le \frac{\int_\Omega |\nabla_{\varepsilon\mathbf{n}}\phi|^2 dx}{\int_\Omega |\phi|^2 dx}$$

to get the upper bound in (2.8). □

It has been proved in [P1] (see the proof of Lemma 3.2 there) that, for a simply connected domain, a sequence bounded in $V(\Omega, \mathbb{R}^3)$ is bounded in $W^{1,2}_{\mathrm{loc}}(\Omega, \mathbb{R}^3)$. The proof given in [P1] is based on the canonical decomposition of vector fields. This conclusion is true for general bounded domains, and we include it here for our convenience.

Lemma 2.3. *Let Ω be a bounded and smooth domain in $\mathbb{R}^3$. For any subdomain $D_1 \Subset D_2 \subseteq \Omega$, there exists a constant $C(D_1, D_2)$ such that for any $\mathbf{u} \in V(\Omega, \mathbb{R}^3)$ we have*

$$\|\mathbf{u}\|_{W^{1,2}(D_1,\mathbb{R}^3)} \le C(D_1, D_2)\left\{\|\mathrm{div}\mathbf{u}\|_{L^2(D_2)} + \|\mathrm{curl}\mathbf{u}\|_{L^2(D_2)} + \|\mathbf{u}\|_{L^2(D_2)}\right\}.$$

In particular, every bounded sequence in $V(\Omega, \mathbb{R}^3)$ is bounded in $W^{1,2}_{loc}(\Omega, \mathbb{R}^3)$.

The proof of Lemma 2.3 will be given in Appendix A.

3. Solutions of the equation curl $\mathbf{u}$ + $\quad\mathbf{u} = \mathbf{0}$ under a pointwise constraint. Assume condition (1.2) and let $\tau > 0$. For a given $\mathbf{n}_0 \in \mathcal{C}(\tau)$, we shall classify all the solutions in $V(\Omega, \mathbb{R}^3)$ to (1.15) coupled with a pointwise orthogonality constraint $\mathbf{n}_0 \cdot \mathbf{u} = 0$, that is,

$$\mathbf{u} \in V(\Omega, \mathbb{R}^3), \quad \text{div}\, \mathbf{u} = 0, \quad \text{curl}\, \mathbf{u} + \tau \mathbf{u} = \mathbf{0}, \quad \mathbf{n}_0 \cdot \mathbf{u} = 0 \quad \text{in } \Omega. \tag{3.1}$$

LEMMA 3.1. *Let $\mathbf{n}_0 = Q\mathbf{N}_\tau(Q^t x)$ with $Q \in SO(3)$. The solutions of* (3.1) *are given by*

$$\mathbf{u}(x) = a\mathbf{U}_1 + b\mathbf{U}_2 + c\mathbf{U}_3,$$

where a, b, c are arbitrary real numbers,

$$\mathbf{U}_j(x) = Q\mathbf{V}_j(Q^t x), \tag{3.2}$$

and

$$\begin{aligned} \mathbf{V}_1 &= \big(\tau y_1 \sin(\tau y_3), -\tau y_1 \cos(\tau y_3), \cos(\tau y_3)\big)^\top, \\ \mathbf{V}_2 &= \big(\tau y_2 \sin(\tau y_3), -\tau y_2 \cos(\tau y_3), \sin(\tau y_3)\big)^\top, \\ \mathbf{V}_3 &= \big(\tau \sin(\tau y_3), -\tau \cos(\tau y_3), 0\big)^\top. \end{aligned} \tag{3.3}$$

Proof. We prove only the conclusion in the case where $\tau = 1$ and

$$\mathbf{n}_0 = \mathbf{N}_1 = (\cos x_3, \sin x_3, 0)^\top.$$

The conclusion for the general case is obtained by rotation and rescaling. From (3.1) we see that $\mathbf{u}$ is a solution of

$$\Delta \mathbf{u} + \mathbf{u} = \mathbf{0}, \tag{3.4}$$

and hence $\mathbf{u}$ is smooth in the interior of Ω. Let us take a small cube located in the interior of Ω and restrict ourselves to the cube. From the pointwise orthogonality constraint $\mathbf{u} \cdot \mathbf{N}_1 = 0$ we have

$$u_1 \cos x_3 + u_2 \sin x_3 = 0. \tag{3.5}$$

Hence $u_2 = -u_1 \cot x_3$ and

$$\partial_{x_3} u_2 = -\cot x_3 \partial_{x_3} u_1 + \frac{u_1}{\sin^2 x_3}. \tag{3.6}$$

Applying the Laplacian operator to (3.5) and using (3.4) we find

$$\begin{aligned} 0 &= \Delta(u_1 \cos x_3 + u_2 \sin x_3) \\ &= \cos x_3 \Delta u_1 + \sin x_3 \Delta u_2 - 2 \sin x_3 \partial_{x_3} u_1 + 2 \cos x_3 \partial_{x_3} u_2 - u_1 \cos x_3 - u_2 \sin x_3 \\ &= -2 \sin x_3 \partial_{x_3} u_1 + 2 \cos x_3 \partial_{x_3} u_2. \end{aligned}$$

So

$$\partial_{x_3} u_2 = \tan x_3 \partial_{x_3} u_1.$$

Combining this with (3.6) we find

$$\frac{\partial_{x_3} u_1}{u_1} = \cot x_3.$$

So there exists a function $f(x_1, x_2)$ such that

$$u_1 = f(x_1, x_2) \sin x_3, \qquad u_2 = -f(x_1, x_2) \cos x_3.$$

Now we use the condition div $\mathbf{u} = 0$ to find

$$\partial_{x_1} f(x_1, x_2) \sin x_3 - \partial_{x_2} f(x_1, x_2) \cos x_3 + \partial_{x_3} u_3 = 0.$$

Hence we can write

$$u_3 = \partial_{x_1} f(x_1, x_2) \cos x_3 + \partial_{x_2} f(x_1, x_2) \sin x_3 + g(x_1, x_2).$$

In order to determine f and g, we check each component of the equation curl $\mathbf{u}+\mathbf{u} = \mathbf{0}$ to find

$$\begin{aligned}
&f_{x_1x_2}(x_1, x_2) \cos x_3 + f_{x_2x_2}(x_1, x_2) \sin x_3 + g_{x_2}(x_1, x_2) = 0,\\
&f_{x_1x_1}(x_1, x_2) \cos x_3 + f_{x_1x_2}(x_1, x_2) \sin x_3 + g_{x_1}(x_1, x_2) = 0,\\
&g(x_1, x_2) = 0.
\end{aligned}$$

So ∇f is a constant vector, and $f(x_1, x_2) = ax_1 + bx_2 + c$. Hence on the cube we have

$$\begin{aligned}
u_1 &= (ax_1 + bx_2 + c) \sin x_3,\\
u_2 &= -(ax_1 + bx_2 + c) \cos x_3,\\
u_3 &= a \cos x_3 + b \sin x_3.
\end{aligned} \tag{3.7}$$

Since Ω is connected, (3.7) must be true everywhere on Ω.

On the other hand, computation shows that for any constants a, b, c, the vector field $\mathbf{u}$ defined by (3.7) satisfies the conditions

$$\text{div } \mathbf{u} = 0, \qquad \text{curl } \mathbf{u} + \mathbf{u} = \mathbf{0}, \qquad \mathbf{u} \cdot \mathbf{N}_1 = 0. \qquad \square$$

Notation. For $\mathbf{n}_0 \in \mathcal{C}(\tau)$ and $\tau > 0$, $\mathcal{U}(\tau, \mathbf{n}_0)$ denotes the set of all solutions of (3.1).

It follows from Lemma 3.1 that $\mathcal{U}(\tau, \mathbf{n}_0)$ is a linear space of dimension 3. Note that $\mathcal{U}(\tau, \mathbf{n}_0) = \mathcal{U}(\tau, -\mathbf{n}_0)$.

In addition to (3.7), if we further request that $\mathbf{u}$ satisfies the unit length condition $|\mathbf{u}(x)| = 1$ on Ω, then

$$\mathbf{u} = \pm(\sin x_3, -\cos x_3, 0)^\top.$$

Thus we get the following corollary.

COROLLARY 3.2. *Given $\mathbf{n}_0 \in \mathcal{C}(\tau)$, the set $\mathcal{U}(\tau, \mathbf{n}_0) \cap V(\Omega, \mathbb{S}^2)$ contains exactly two elements.*

The following result is useful in sections 4 and 5.

PROPOSITION 3.3. *Let $\mathbf{n}_0 \in \mathcal{C}_*(\tau)$ and $\mathbf{u}_0 \in \mathcal{U}(\tau, \mathbf{n}_0)$. We have*

$$\int_\Omega \mathbf{u}_0 \cdot \nabla \zeta_{\mathbf{n}_0} dx = 0, \tag{3.8}$$

where $\zeta_{\mathbf{n}_0}$ *is the solution of* (1.7) *associated with* $\mathbf{n}_0$.

Proof. We give the proof for $\tau = 1$.

Step 1. Let us introduce some notation. For a 3×3 nonsingular matrix $Q = (q_{ij})$ we assign a vector $\mathbf{q} = (q_{11}, q_{12}, \dots, q_{33})^\top \in \mathbb{R}^9$. Let

$$\mathcal{A} = \big\{\mathbf{q} = (q_{11}, q_{12}, \dots, q_{33})^\top \in \mathbb{R}^9 :\ \det(q_{ij}) > 0\big\},$$
$$\mathcal{Q} = \big\{\mathbf{q} = (q_{11}, q_{12}, \dots, q_{33})^\top \in \mathbb{R}^9 :\ (q_{ij}) \in SO(3)\big\}.$$

Then $\mathcal{A}$ is an open set in $\mathbb{R}^9$. Let

$$\mathbf{n}(x,\mathbf{q}) = Q\mathbf{N}_1(Q^t x), \qquad \zeta(x,\mathbf{q}) = \zeta_{\mathbf{n}(x,\mathbf{q})}.$$

Thus

$$n(x,\mathbf{q})_k = q_{k1}\cos y_3 + q_{k2}\sin y_3, \text{where } y_j = \sum_{i=1}^{3} q_{ij}x_i, \quad j = 1,2,3;$$

and $\zeta(x,\mathbf{q})$ is the unique solution of the equation

$$\begin{cases} \Delta\zeta = 0 & \text{in } \Omega,\\ \dfrac{\partial\zeta}{\partial\nu} = Q\mathbf{N}_1(Q^t x)\cdot\nu & \text{on } \partial\Omega,\\ \displaystyle\int_\Omega \zeta\, dx = 0. \end{cases}$$

If Ω is a bounded domain with $C^{3+\alpha}$ boundary, then the solution of the equation is $C^{3+\alpha}$ in x; see [GT, Theorem 6.3] (also see [ADN, LM]). We can show that ζ is C^2 in the parameter q_{ij} for $\mathbf{q} = (q_{11}, \dots, q_{33})^\top \in \mathcal{A}$, and $\frac{\partial^2\zeta}{\partial q_{ij}\partial q_{lm}}$ is C^2 in x. Of course if $q \in \mathcal{Q}$, then $\mathbf{n} \equiv \mathbf{n}(x,\mathbf{q}) \in \mathcal{C}(\tau)$ and $\zeta(x,\mathbf{q}) = \zeta_{\mathbf{n}}$. Let us define a function on $\mathcal{A}$ by

$$F(\mathbf{q}) = \frac{1}{2}\int_\Omega |\nabla\zeta(x,\mathbf{q}) - \mathbf{n}(x,\mathbf{q})|^2 dx.$$

Then $F(\mathbf{q})$ is a C^2 function in $\mathcal{A}$.

Step 2. Assume $\mathbf{n}_0 = (n_1^0, n_2^0, n_3^0)^\top \in \mathcal{C}_*(1)$, and $\mathbf{n}_0 = Q_0\mathbf{N}_1(Q_0^t x)$, where $Q_0 = (q_{ij}^0)$. Then $\mathbf{q}_0 = (q_{11}^0, \dots, q_{33}^0)$ is a minimizer of the following problem:

$$\text{Minimize } F(\mathbf{q}) \text{ subjected to the conditions } g_k(\mathbf{q}) = 0,\ k = 1, \dots, 6,$$

where

$$g_1(\mathbf{q}) = \sum_{j=1}^{3} q_{j1}^2 - 1, \qquad g_2(\mathbf{q}) = \sum_{j=1}^{3} q_{j2}^2 - 1,$$
$$g_3(\mathbf{q}) = \sum_{j=1}^{3} q_{j3}^2 - 1, \qquad g_4(\mathbf{q}) = \sum_{j=1}^{3} q_{j1}q_{j2},$$
$$g_5(\mathbf{q}) = \sum_{j=1}^{3} q_{j1}q_{j3}, \qquad g_6(\mathbf{q}) = \sum_{j=1}^{3} q_{j2}q_{j3}.$$

Thus $\mathbf{q}_0$ is a solution of the Euler–Lagrange equations

$$\frac{\partial F}{\partial q_{ij}}(\mathbf{q}_0)=\sum_{k=1}^{6}\lambda_k\frac{\partial g_k}{\partial q_{ij}}(\mathbf{q}_0),\qquad i,j=1,2,3,$$

where λ_k's are constants that may depend on $\mathbf{q}_0$. We compute

$$\frac{\partial F}{\partial q_{ij}}(\mathbf{q}_0)=\int_\Omega(\nabla\zeta_{\mathbf{n}_0}-\mathbf{n}_0)\cdot\Big(\nabla\frac{\partial\zeta}{\partial q_{ij}}(x,\mathbf{q}_0)-\frac{\partial\mathbf{n}}{\partial q_{ij}}(x,\mathbf{q}_0)\Big)dx.$$

Applying (2.3) for

$$\mathbf{u}=\mathbf{n}_0,\qquad \phi=\frac{\partial\zeta}{\partial q_{ij}}(x,\mathbf{q}_0),$$

we find

$$\frac{\partial F}{\partial q_{ij}}(\mathbf{q}_0)=-\int_\Omega(\nabla\zeta_{\mathbf{n}_0}-\mathbf{n}_0)\cdot\frac{\partial\mathbf{n}}{\partial q_{ij}}(x,\mathbf{q}_0)dx.$$

We compute

$$\begin{aligned}&\frac{\partial n_k}{\partial q_{i1}}(x,\mathbf{q}_0)=\delta_{ik}\cos y_3,\\&\frac{\partial n_k}{\partial q_{i2}}(x,\mathbf{q}_0)=\delta_{ik}\sin y_3,\\&\frac{\partial n_k}{\partial q_{i3}}(x,\mathbf{q}_0)=-x_i(q^0_{k1}\sin y_3-q^0_{k2}\cos y_3),\end{aligned}$$

where $y_3=q^0_{13}x_1+q^0_{23}x_2+q^0_{33}x_3$. Thus the Euler–Lagrange equations can be written as

$$\begin{aligned}&-\int_\Omega\left(\frac{\partial\zeta_{\mathbf{n}_0}}{\partial x_i}-n^0_i\right)\cos y_3dx=2\lambda_1q^0_{i1}+\lambda_4q^0_{i2}+\lambda_5q^0_{i3},\\&-\int_\Omega\left(\frac{\partial\zeta_{\mathbf{n}_0}}{\partial x_i}-n^0_i\right)\sin y_3dx=2\lambda_2q^0_{i2}+\lambda_4q^0_{i1}+\lambda_6q^0_{i3},\\&\sum_{k=1}^{3}\int_\Omega\left(\frac{\partial\zeta_{\mathbf{n}_0}}{\partial x_k}-n^0_k\right)\left(q^0_{k1}\sin y_3-q^0_{k2}\cos y_3\right)x_idx=2\lambda_3q^0_{i3}+\lambda_5q^0_{i1}+\lambda_6q^0_{i2}.\end{aligned}\tag{3.9}$$

If we multiply the first equation of (3.9) by q^0_{i3} and take sum over i, we get

$$-\sum_{i=1}^{3}q^0_{i3}\int_\Omega\left(\frac{\partial\zeta_{\mathbf{n}_0}}{\partial x_i}-n^0_i\right)\cos y_3dx=\lambda_5.$$

The left side of the above equality is equal to

$$-\int_\Omega(\nabla\zeta_{\mathbf{n}_0}-\mathbf{n}_0)\nabla\sin y_3dx,$$

which is zero by (2.3) (letting $\mathbf{u}=\mathbf{n}_0$). Thus $\lambda_5=0$. Similarly, we multiply the second equality in (3.9) by q^0_{i3} and take sum over i to get

$$\lambda_6=-\sum_{i=1}^{3}q^0_{i3}\int_\Omega\left(\frac{\partial\zeta_{\mathbf{n}_0}}{\partial x_i}-n^0_i\right)\sin y_3dx=\int_\Omega(\nabla\zeta_{\mathbf{n}_0}-\mathbf{n}_0)\nabla\cos y_3dx=0.$$

So we can write (3.9) as

$$
\begin{aligned}
&-\int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_i} - n_i^0\right)\cos y_3 dx = 2\lambda_1 q_{i1}^0 + \lambda_4 q_{i2}^0,\\
&-\int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_i} - \mathbf{n}_i^0\right)\sin y_3 dx = 2\lambda_2 q_{i2}^0 + \lambda_4 q_{i1}^0,\\
&\sum_{k=1}^3 \int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_k} - n_k^0\right)(q_{k1}^0 \sin y_3 - q_{k2}^0\cos y_3) x_i dx = 2\lambda_3 q_{i3}^0.
\end{aligned}
\tag{3.10}
$$

Step 3. Let $\mathbf{u}_0 \in \mathcal{U}(1, \mathbf{n}_0)$. From Lemma 3.1,

$$
\mathbf{u}_0 = \sum_{j=1}^3 c_j \mathbf{U}_j,
$$

where

$$
\begin{aligned}
\mathbf{U}_j &= (U_{j1}, U_{j2}, U_{j3})^\top,\\
U_{1k} &= y_1(q_{k1}^0 \sin y_3 - q_{k2}^0 \cos y_3) + q_{k3}^0 \cos y_3,\\
U_{2k} &= y_2(q_{k1}^0 \sin y_3 - q_{k2}^0 \cos y_3) + q_{k3}^0 \sin y_3,\\
U_{3k} &= q_{k1}^0 \sin y_3 - q_{k2}^0 \cos y_3.
\end{aligned}
$$

Recall that $y_j = \sum_{i=1}^3 q_{ij}^0 x_i$ and $\mathbf{U}_j \cdot \mathbf{n}_0 = 0$. We use (3.10) to compute

$$
\begin{aligned}
-\int_\Omega \nabla\zeta_{\mathbf{n}_0} \cdot \mathbf{U}_1 dx &= -\int_\Omega (\nabla\zeta_{\mathbf{n}_0} - \mathbf{n}_0)\cdot \mathbf{U}_1 dx\\
&= -\sum_{k=1}^3 \int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_k} - n_k^0\right)[y_1(q_{k1}^0 \sin y_3 - q_{k2}^0 \cos y_3) + q_{k3}^0 \cos y_3] dx\\
&= -\sum_{i,k=1}^3 \int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_i} - n_i^0\right) q_{i1}^0 x_i (q_{k1}^0 \sin y_3 - q_{k2}^0 \cos y_3) dx\\
&\quad -\sum_{k=1}^3 q_{k3}^0 \int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_k} - n_k^0\right)\cos y_3 dx\\
&= -\sum_{i=1}^3 2q_{i1}^0 \lambda_3 q_{i3}^0 + \sum_{k=1}^3 q_{k3}^0 (2\lambda_1 q_{k1}^0 + \lambda_4 q_{k2}^0)\\
&= 0;
\end{aligned}
$$

$$
\begin{aligned}
-\int_\Omega \nabla\zeta_{\mathbf{n}_0} \cdot \mathbf{U}_2 dx &= -\int_\Omega (\nabla\zeta_{\mathbf{n}_0} - \mathbf{n}_0)\cdot \mathbf{U}_2 dx\\
&= -\sum_{k=1}^3 \int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_k} - n_k^0\right)[y_2(q_{k1}^0 \sin y_3 - q_{k2}^0 \cos y_3) + q_{k3}^0 \sin y_3] dx\\
&= -\sum_{i,k=1}^3 \int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_i} - n_i^0\right) q_{i2}^0 x_i (q_{k1}^0 \sin y_3 - q_{k2}^0 \cos y_3) dx\\
&\quad -\sum_{k=1}^3 q_{k3}^0 \int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_k} - n_k^0\right)\sin y_3 dx
\end{aligned}
$$

$$= -\sum_{i=1}^{3} 2q_{i2}^0\lambda_3 q_{i3}^0 + \sum_{k=1}^{3} q_{k3}^0(2\lambda_2 q_{k2}^0 + \lambda_4 q_{k1}^0)$$
$$= 0;$$

$$\begin{aligned}
-\int_\Omega \nabla\zeta_{\mathbf{n}_0}\cdot \mathbf{U}_3 dx &= -\int_\Omega (\nabla\zeta_{\mathbf{n}_0} - \mathbf{n}_0)\cdot \mathbf{U}_3 dx \\
&= -\sum_{i=1}^{3}\int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_i} - n_i^0\right)(q_{i1}^0\sin y_3 - q_{i2}^0\cos y_3)dx \\
&= -\sum_{i=1}^{2} q_{i1}^0\int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_i} - n_i^0\right)\sin y_3 dx \\
&\quad + \sum_{i=1}^{2} q_{i2}^0\int_\Omega \left(\frac{\partial \zeta_{\mathbf{n}_0}}{\partial x_i} - n_i^0\right)\cos y_3 dx \\
&= \sum_{i=1}^{3} q_{i1}^0(2\lambda_2 q_{i2}^0 + \lambda_4 q_{i1}^0) - \sum_{i=1}^{3} q_{i2}^0(2\lambda_1 q_{i1}^0 + \lambda_4 q_{i2}^0) \\
&= \lambda_4 - \lambda_4 = 0.
\end{aligned}$$

Thus, (3.8) is true. $\square$

4. Estimates of $\mathbf{{}_{c_3}}$ and energy upper bound for small . In this section we shall give an estimate of Q_{c_3} for small κ and establish an energy upper bound. For simplicity of notation, we write $\kappa = \varepsilon$. Throughout this section we assume that

(4.1) $\qquad K_1$, K_2, and τ are fixed positive constants, and $\kappa = \varepsilon > 0$ is small.

We write the functional $\mathcal{G}$ as

$$\mathcal{G}_\varepsilon[\psi, \mathbf{n}] = \int_\Omega \left\{ |\nabla_{q\mathbf{n}}\psi|^2 + \frac{\varepsilon^2}{2}(1-|\psi|^2)^2 + K_1|\text{div } \mathbf{n}|^2 + K_2|\text{curl } \mathbf{n} + \tau\mathbf{n}|^2 \right\} dx.$$

Then

$$C(K_1, K_2, \varepsilon, \tau, q) = \inf_{(\psi,\mathbf{n})\in W^{1,2}(\Omega,\mathbb{C})\times V(\Omega,\mathbb{S}^2)} \mathcal{G}_\varepsilon[\psi, \mathbf{n}].$$

The existence of minimizers has been proved in [P1].

THEOREM 4.1. *Assume that conditions* (1.2) *and* (4.1) *hold. We have, as* $\varepsilon \to 0$,

$$\frac{\varepsilon}{\sqrt{\omega_*(\tau)}} - L\varepsilon^3 \le Q_{c_3}(K_1, K_2, \varepsilon, \tau) = \frac{\varepsilon}{\sqrt{\omega_*(\tau)}} + o(\varepsilon), \tag{4.2}$$

where $\omega_*(\tau)$ *was defined in* (1.8), *and* $L > 0$ *depends only on* Ω *and* τ.

Proof. Step 1. Choose $\mathbf{n}_0 \in \mathcal{C}_*(\tau)$ such that

$$\|\zeta_{\mathbf{n}_0}\|_{L^2(\Omega)} = \min_{\mathbf{n}\in\mathcal{C}_*(\tau)} \|\zeta_{\mathbf{n}}\|_{L^2(\Omega)}.$$

Let

$$L_* = \frac{1-\omega_*(\tau)}{2\omega_*(\tau)^{5/2}|\Omega|}\|\zeta_{\mathbf{n}_0}\|^2_{L^2(\Omega)}.$$

Then L_* depends only on Ω and τ. Fix any positive number $L > L_*$. We show that there exists $\varepsilon_0 > 0$ depending only on Ω, τ, and L such that

$$Q_{c_3}(K_1, K_2, \varepsilon, \tau) \geq \frac{\varepsilon}{\sqrt{\omega_*(\tau)}} - L\varepsilon^3 \quad \text{for all } 0 < \varepsilon \leq \varepsilon_0. \tag{4.3}$$

Let us choose a number a_ε satisfying

$$0 < a_\varepsilon < \frac{1}{\sqrt{\omega_*(\tau)}} - L\varepsilon^2. \tag{4.4}$$

For the vector field $\mathbf{n}_0$ chosen above, we have $\omega(\mathbf{n}_0) = \omega_*(\tau)$, and from Lemma 2.2,

$$\begin{aligned}
\mu(a_\varepsilon \varepsilon \mathbf{n}_0) &\leq \omega_*(\tau) a_\varepsilon^2 \varepsilon^2 + \frac{1 - \omega_*(\tau)}{|\Omega|} \|\zeta_{\mathbf{n}_0}\|^2_{L^2(\Omega)} a_\varepsilon^4 \varepsilon^4 + O(\varepsilon^6) \\
&\leq \varepsilon^2 - \left[2L\sqrt{\omega_*(\tau)} - \frac{1 - \omega_*(\tau)}{\omega_*(\tau)^2 |\Omega|} \|\zeta_{\mathbf{n}_0}\|^2_{L^2(\Omega)} \right] \varepsilon^4 + O(\varepsilon^6) \\
&= \varepsilon^2 - 2(L - L_*)\sqrt{\omega_*(\tau)}\varepsilon^4 + O(\varepsilon^6).
\end{aligned}$$

So

$$\varepsilon^2 - \mu(a_\varepsilon \varepsilon \mathbf{n}_0) \geq 2(L - L_*)\sqrt{\omega_*(\tau)}\varepsilon^4 + O(\varepsilon^6) \quad \text{for all small } \varepsilon.$$

Let ϕ_0 be the eigenfunction of (2.7) for $\mathbf{u} = \mathbf{n}_0$ associated with the lowest eigenvalue $\mu(a\varepsilon \mathbf{n}_0)$. For $q = a_\varepsilon \varepsilon$ we take $\psi = t\phi_0$ and $\mathbf{n} = \mathbf{n}_0$ as test functions for $\mathcal{G}_\varepsilon$ and find that, for sufficiently small $t > 0$,

$$\begin{aligned}
\mathcal{G}_\varepsilon[t\phi_0, \mathbf{n}_0] &= \frac{\varepsilon^2|\Omega|}{2} - t^2 \int_\Omega \left\{ (\varepsilon^2 - \mu(a_\varepsilon \varepsilon \mathbf{n}_0))|\phi_0|^2 - \frac{t^2}{2}|\phi_0|^4 \right\} dx \\
&< \frac{\varepsilon^2|\Omega|}{2}.
\end{aligned}$$

Thus the minimizers are nontrivial, and hence $Q_{c_3}(K_1, K_2, \varepsilon, \tau) \geq a_\varepsilon \varepsilon$ for all small ε. So (4.3) is true.

Step 2. Now we prove an upper bound

$$\limsup_{\varepsilon \to 0} \frac{1}{\varepsilon} Q_{c_3}(K_1, K_2, \varepsilon, \tau) \leq \frac{1}{\sqrt{\omega_*(\tau)}}.$$

Let us choose a_ε such that

$$0 < a_\varepsilon < \frac{1}{\varepsilon} Q_{c_3}(K_1, K_2, \varepsilon, \tau).$$

We may assume $a_\varepsilon \to a_0 > 0$ as $\varepsilon \to 0$. Then $\mathcal{G}_\varepsilon$ has a nontrivial minimizer $(\psi_\varepsilon, \mathbf{n}_\varepsilon)$ for $q = a_\varepsilon \varepsilon$. Recall that $(0, \mathbf{N}_\tau)$ is a trivial critical point of $\mathcal{G}_\varepsilon$, and

$$\mathcal{G}_\varepsilon[0, \mathbf{N}_\tau] = \frac{\varepsilon^2|\Omega|}{2}.$$

Thus

$$\begin{aligned}
&\int_\Omega \left\{ |\nabla_{a_\varepsilon \varepsilon \mathbf{n}_\varepsilon} \psi_\varepsilon|^2 + \frac{\varepsilon^2}{2}(1 - |\psi_\varepsilon|^2)^2 + K_1|\text{div } \mathbf{n}_\varepsilon|^2 + K_2|\text{curl } \mathbf{n}_\varepsilon + \tau \mathbf{n}_\varepsilon|^2 \right\} dx \\
&\quad < \frac{\varepsilon^2|\Omega|}{2}.
\end{aligned} \tag{4.5}$$

Since $|\mathbf{n}_\varepsilon| = 1$, from (4.5) we see that $\{\mathbf{n}_\varepsilon\}$ is bounded in $V(\Omega, \mathbb{R}^3)$. Using Lemma 2.3, we find that there exist a subsequence, still denoted by $\mathbf{n}_\varepsilon$, and a vector field $\mathbf{n}_0 \in V(\Omega, \mathbb{R}^3)$ such that, as $\varepsilon \to 0$,

$$\begin{aligned}\mathbf{n}_\varepsilon \to \mathbf{n}_0 \quad & \text{weakly in } L^p(\Omega, \mathbb{R}^3) \text{ for all } 1 \le p < \infty, \text{ weakly in } W^{1,2}_{\mathrm{loc}}(\Omega, \mathbb{R}^3), \\ & \text{and strongly in } L^4_{\mathrm{loc}}(\Omega, \mathbb{R}^3).\end{aligned}$$

Then $|\mathbf{n}_0(x)| = 1$ a.e. in Ω. Since $|\mathbf{n}_\varepsilon| = |\mathbf{n}_0| = 1$, we see that

$$\mathbf{n}_\varepsilon \to \mathbf{n}_0 \quad \text{strongly in } L^p(\Omega, \mathbb{R}^3) \text{ for all } 1 \le p < \infty.$$

Using (4.5) again we see that $\operatorname{div} \mathbf{n}_0 = 0$ and $\operatorname{curl} \mathbf{n}_0 + \tau \mathbf{n}_0 = \mathbf{0}$ a.e. in Ω. Thus $\mathbf{n}_0 \in \mathcal{C}(\tau)$.

Let $\mathbf{w}_\varepsilon = \mathbf{n}_\varepsilon - \mathbf{n}_0$. Then

$$\mathbf{w}_\varepsilon \to \mathbf{0} \quad \text{strongly in } L^p(\Omega, \mathbb{R}^3) \text{ as } \varepsilon \to 0, \text{ for all } 1 \le p < \infty.$$

Using (4.5) we have

$$\begin{aligned}\mathcal{G}_\varepsilon[\psi_\varepsilon, \mathbf{n}_\varepsilon] = \int_\Omega \Big\{ & |\nabla_{a_\varepsilon \varepsilon(\mathbf{n}_0 + \mathbf{w}_\varepsilon)} \psi_\varepsilon|^2 + \frac{\varepsilon^2}{2}(|\psi_\varepsilon|^2 - 1)^2 \\ & + K_1 |\operatorname{div} \mathbf{w}_\varepsilon|^2 + K_2 |\operatorname{curl} \mathbf{w}_\varepsilon + \tau \mathbf{w}_\varepsilon|^2 \Big\} dx \\ < {} & \frac{\varepsilon^2 |\Omega|}{2}.\end{aligned}$$

In particular,

$$\int_\Omega \left\{ |\nabla_{a_\varepsilon \varepsilon(\mathbf{n}_0 + \mathbf{w}_\varepsilon)} \psi_\varepsilon|^2 - \varepsilon^2 |\psi_\varepsilon|^2 \right\} dx < 0.$$

So the lowest eigenvalue of $-\nabla^2_{a_\varepsilon \varepsilon(\mathbf{n}_0 + \mathbf{w}_\varepsilon)}$ (see (2.7)) is less than ε^2:

$$\mu\big(a_\varepsilon \varepsilon(\mathbf{n}_0 + \mathbf{w}_\varepsilon)\big) < \varepsilon^2.$$

Let ϕ^ε be the associated eigenfunction such that $\|\phi^\varepsilon\|_{L^2(\Omega)} = 1$. Then

$$\|\nabla_{a_\varepsilon \varepsilon(\mathbf{n}_0 + \mathbf{w}_\varepsilon)} \phi^\varepsilon\|^2_{L^2(\Omega)} = \mu\big(a_\varepsilon \varepsilon(\mathbf{n}_0 + \mathbf{w}_\varepsilon)\big) \|\phi^\varepsilon\|^2_{L^2(\Omega)} < \varepsilon^2 \|\phi^\varepsilon\|^2_{L^2(\Omega)}.$$

Using the Sobolev imbedding theorem and Kato's inequality, we have

$$\begin{aligned}\|\phi^\varepsilon\|_{L^4(\Omega)} & \le C(\Omega) \left\{ \|\nabla|\phi^\varepsilon|\|_{L^2(\Omega)} + \|\phi^\varepsilon\|_{L^2(\Omega)} \right\} \\ & \le C(\Omega) \left\{ \|\nabla_{a_\varepsilon \varepsilon(\mathbf{n}_0 + \mathbf{w}_\varepsilon)} \phi^\varepsilon\|_{L^2(\Omega)} + \|\phi^\varepsilon\|_{L^2(\Omega)} \right\} \\ & < C(\Omega)(1 + \varepsilon) \|\phi^\varepsilon\|_{L^2(\Omega)}.\end{aligned} \tag{4.6}$$

So

$$\begin{aligned}
&\varepsilon^2 \int_\Omega |\phi^\varepsilon|^2 dx > \mu\big(a_\varepsilon\varepsilon(\mathbf{n}_0+\mathbf{w}_\varepsilon)\big) \int_\Omega |\phi^\varepsilon|^2 dx \\
&= \int_\Omega |\nabla_{a_\varepsilon\varepsilon(\mathbf{n}_0+\mathbf{w}_\varepsilon)}\phi_\varepsilon|^2 dx \\
&= \int_\Omega \left\{|\nabla_{a_\varepsilon\varepsilon\mathbf{n}_0}\phi^\varepsilon|^2 - 2a_\varepsilon\varepsilon\mathbf{w}_\varepsilon\Im[\bar\phi^\varepsilon\nabla_{a_\varepsilon\varepsilon(\mathbf{n}_0+\mathbf{w}_\varepsilon)}\phi^\varepsilon] - a_\varepsilon^2\varepsilon^2|\mathbf{w}_\varepsilon\phi^\varepsilon|^2\right\} dx \\
&\geq \int_\Omega |\nabla_{a_\varepsilon\varepsilon\mathbf{n}_0}\phi^\varepsilon|^2 dx - 2a_\varepsilon\varepsilon\|\mathbf{w}_\varepsilon\|_{L^4(\Omega)}\|\phi^\varepsilon\|_{L^4(\Omega)}\|\nabla_{a_\varepsilon\varepsilon(\mathbf{n}_0+\mathbf{w}_\varepsilon)}\phi^\varepsilon\|_{L^2(\Omega)} \\
&\qquad - a_\varepsilon^2\varepsilon^2\|\mathbf{w}_\varepsilon\|^2_{L^4(\Omega)}\|\phi^\varepsilon\|^2_{L^4(\Omega)} \\
&\geq \int_\Omega |\nabla_{a_\varepsilon\varepsilon\mathbf{n}_0}\phi^\varepsilon|^2 dx - Ca_\varepsilon\varepsilon^2\|\mathbf{w}_\varepsilon\|_{L^4(\Omega)}\|\phi^\varepsilon\|^2_{L^2(\Omega)} - Ca_\varepsilon^2\varepsilon^2\|\mathbf{w}_\varepsilon\|^2_{L^4(\Omega)}\|\phi^\varepsilon\|^2_{L^2(\Omega)},
\end{aligned}$$

where we have used (4.6). As $\varepsilon \to 0$, $a_\varepsilon \to a_0$, and $\mathbf{w}_\varepsilon \to \mathbf{0}$ in $L^4(\Omega, \mathbb{R}^3)$, so

$$\begin{aligned}
\omega(\mathbf{n}_0)a_0^2\varepsilon^2 + o(\varepsilon^2) \leq \mu(a_\varepsilon\varepsilon\mathbf{n}_0) &\leq \frac{\int_\Omega |\nabla_{a_\varepsilon\varepsilon\mathbf{n}_0}\phi^\varepsilon|^2 dx}{\|\phi^\varepsilon\|^2_{L^2(\Omega)}} \\
&\leq \varepsilon^2 + Ca_\varepsilon\varepsilon^2\|\mathbf{w}_\varepsilon\|_{L^4(\Omega)} + Ca_\varepsilon^2\varepsilon^2\|\mathbf{w}_\varepsilon\|^2_{L^4(\Omega)} \\
&= \varepsilon^2(1+o(1)).
\end{aligned}$$

So $\omega(\mathbf{n}_0)a_0^2 \leq 1$; that is,

$$0 < a_0 \leq \frac{1}{\sqrt{\omega(\mathbf{n}_0)}} \leq \frac{1}{\sqrt{\omega_*(\tau)}}.$$

Thus, the upper bound is true. ∎

Next we look for an energy upper bound of the minimizers. For a vector field $\mathbf{n}_0 \in \mathcal{C}_*(\tau)$ and $a > 0$, we define a function of t by

$$f_{a,\mathbf{n}_0}(t) = a^2\omega(\mathbf{n}_0)t^2 + \frac{1}{2}(1-t^2)^2. \tag{4.7}$$

Obviously,

$$\min_{t\geq 0} f_{a,\mathbf{n}_0}(t) = \begin{cases} \frac{1}{2} & \text{if } a \geq \frac{1}{\sqrt{\omega(\mathbf{n}_0)}}, \\ a^2\omega(\mathbf{n}_0)[1-\frac{1}{2}a^2\omega(\mathbf{n}_0)] & \text{if } 0 < a < \frac{1}{\sqrt{\omega(\mathbf{n}_0)}}, \end{cases}$$

and the minimum is attained at

$$t = \sqrt{[1-a^2\omega(\mathbf{n}_0)]_+};$$

here we use the notation $a_+ = \max\{a, 0\}$. Let

$$d_0(\varepsilon) = a_\varepsilon^2\omega_*(\tau)\left[1 - \frac{1}{2}a_\varepsilon^2\omega_*(\tau)\right]|\Omega|. \tag{4.8}$$

THEOREM 4.2. *Assume the conditions* (1.2) *and* (4.1). *For small* $\kappa = \varepsilon > 0$ *and* $q = a_\varepsilon\varepsilon$, *where* a_ε *satisfies* (4.4), *we have*

$$C(K_1, K_2, \varepsilon, \tau, a_\varepsilon\varepsilon) \leq d_0(\varepsilon)\varepsilon^2 - d(\varepsilon)\varepsilon^4 + o(\varepsilon^4), \tag{4.9}$$

where $d_0(\varepsilon)$ is given in (4.8), *and there exists a constant $c > 0$ independent of ε such that $-c \le d(\varepsilon) < +\infty$.*

The proof of (4.9) is lengthy and will be divided into several steps. Note that (4.9) is a rough estimate, and better upper bounds can be obtained; see the discussions below.

Step 1. *A general computation.* To begin with, we consider test functions in the form

$$\psi^\varepsilon = c^\varepsilon[1 + i\varepsilon a_\varepsilon(\zeta + \varepsilon\rho\varphi^\varepsilon)], \qquad \mathbf{n}^\varepsilon = \mathbf{n}_0 + \varepsilon\rho\mathbf{u}^\varepsilon, \tag{4.10}$$

where $\mathbf{n}_0 \in \mathcal{C}(\tau)$, $\mathbf{u}^\varepsilon \in V(\Omega, \mathbb{R}^3)$, such that

$$|\mathbf{n}_0(x) + \varepsilon\rho\mathbf{u}^\varepsilon(x)| = 1 \qquad \text{for a.e. } x \in \Omega, \tag{4.11}$$

c^ε is a real number, and ρ is a positive number. ζ and φ^ε are complex-valued functions such that

$$\int_\Omega \zeta dx = 0, \qquad \int_\Omega \varphi^\varepsilon dx = 0. \tag{4.12}$$

ρ and ζ may depend on ε. Let us define a set $V(\mathbf{n}_0, b)$ by

$$V(\mathbf{n}_0, b) = \left\{ \mathbf{u} \in V(\Omega, \mathbb{R}^3) : \ \mathbf{u}(x) \cdot \mathbf{n}_0(x) = -\frac{b}{2}|\mathbf{u}(x)|^2 \quad \text{a.e. in } \Omega \right\}.$$

From (4.11), $\mathbf{u}^\varepsilon \in V(\mathbf{n}_0, \varepsilon\rho)$. We compute

$$\begin{aligned}
|\nabla_{a_\varepsilon\varepsilon\mathbf{n}^\varepsilon}\psi^\varepsilon|^2 &= \varepsilon^2 a_\varepsilon^2 |c^\varepsilon|^2 |\nabla\zeta - \mathbf{n}_0 + \varepsilon\rho(\nabla\varphi^\varepsilon - \mathbf{u}^\varepsilon) - i\varepsilon a_\varepsilon(\zeta + \varepsilon\rho\varphi^\varepsilon)\mathbf{n}^\varepsilon|^2 \\
&= \varepsilon^2 a_\varepsilon^2 |c^\varepsilon|^2 \Big\{ |\nabla\zeta - \mathbf{n}_0|^2 + 2\varepsilon\rho\Re[(\nabla\zeta - \mathbf{n}_0)\cdot(\nabla\bar{\varphi}^\varepsilon - \mathbf{u}^\varepsilon)] + \varepsilon^2\rho^2|\nabla\varphi^\varepsilon - \mathbf{u}^\varepsilon|^2 \\
&\qquad - 2\varepsilon a_\varepsilon \Im[\bar{\zeta}\mathbf{n}_0 \cdot (\nabla\zeta - \mathbf{n}_0)] \\
&\qquad - 2\varepsilon^2\rho a_\varepsilon \Im[\bar{\zeta}\mathbf{n}_0 \cdot (\nabla\varphi^\varepsilon - \mathbf{u}^\varepsilon) + (\nabla\zeta - \mathbf{n}_0)\cdot(\bar{\zeta}\mathbf{u}^\varepsilon + \bar{\varphi}^\varepsilon\mathbf{n}_0)] \\
&\qquad - 2\varepsilon^3\rho^2 a_\varepsilon \Im[(\nabla\varphi^\varepsilon - \mathbf{u}^\varepsilon)\cdot(\bar{\zeta}\mathbf{u}^\varepsilon + \bar{\varphi}^\varepsilon\mathbf{n}^\varepsilon) + \bar{\varphi}^\varepsilon\mathbf{u}^\varepsilon\cdot(\nabla\zeta - \mathbf{n}_0)] \\
&\qquad + \varepsilon^2 a_\varepsilon^2 |\zeta + \varepsilon\rho\varphi^\varepsilon|^2 \Big\},
\end{aligned}$$

$$\begin{aligned}
(1 - |\psi^\varepsilon|^2)^2 &= \Big[1 - |c^\varepsilon|^2 + 2\varepsilon a_\varepsilon |c^\varepsilon|^2 \Im(\zeta + \varepsilon\rho\varphi^\varepsilon) - \varepsilon^2 a_\varepsilon^2 |c^\varepsilon|^2 |\zeta + \varepsilon\rho\varphi^\varepsilon|^2 \Big]^2 \\
&= (1 - |c^\varepsilon|^2)^2 + 4\varepsilon a_\varepsilon |c^\varepsilon|^2 (1 - |c^\varepsilon|^2)\Im(\zeta + \varepsilon\rho\varphi^\varepsilon) \\
&\quad - 2\varepsilon^2 a_\varepsilon^2 |c^\varepsilon|^2 (1 - |c^\varepsilon|^2)|\zeta + \varepsilon\rho\varphi^\varepsilon|^2 \\
&\quad + \varepsilon^2 a_\varepsilon^2 |c^\varepsilon|^4 \Big[2\Im(\zeta + \varepsilon\rho\varphi^\varepsilon) - \varepsilon a_\varepsilon |\zeta + \varepsilon\rho\varphi^\varepsilon|^2 \Big]^2.
\end{aligned}$$

Since $\mathcal{I}[\mathbf{n}_0] = 0$, we have

$$\mathcal{I}[\mathbf{n}_0 + \varepsilon\rho\mathbf{u}^\varepsilon] = \varepsilon^2\rho^2\mathcal{I}[\mathbf{u}^\varepsilon].$$

So

(4.13)

$$
\begin{aligned}
&\varepsilon^{-2}\mathcal{G}_\varepsilon[\psi^\varepsilon, \mathbf{n}^\varepsilon] \\
&= \int_\Omega \left\{ a_\varepsilon^2 |c^\varepsilon|^2 |\nabla\zeta - \mathbf{n}_0|^2 + \frac{1}{2}(1-|c^\varepsilon|^2)^2 \right\} dx \\
&+ \rho^2 \mathcal{I}[\mathbf{u}^\varepsilon] \\
&+ 2\varepsilon\rho a_\varepsilon^2 |c^\varepsilon|^2 \Re \int_\Omega (\nabla\zeta - \mathbf{n}_0)\cdot(\nabla\bar{\varphi}^\varepsilon - \mathbf{u}^\varepsilon) dx \\
&+ 2\varepsilon a_\varepsilon |c^\varepsilon|^2 \Im \int_\Omega \big\{ (1-|c^\varepsilon|^2)\zeta - a_\varepsilon^2 \bar{\zeta}\mathbf{n}_0 \cdot (\nabla\zeta - \mathbf{n}_0) \big\} dx \\
&+ \varepsilon^2\rho^2 a_\varepsilon^2 |c^\varepsilon|^2 \int_\Omega |\nabla\varphi^\varepsilon - \mathbf{u}^\varepsilon|^2 dx \\
&+ 2\varepsilon^2\rho a_\varepsilon |c^\varepsilon|^2 \Im \int_\Omega \big\{ (1-|c^\varepsilon|^2)\varphi^\varepsilon - a_\varepsilon^2 [\bar{\zeta}\mathbf{n}_0 \cdot (\nabla\varphi^\varepsilon - \mathbf{u}^\varepsilon) + (\nabla\zeta - \mathbf{n}_0)\cdot(\bar{\zeta}\mathbf{u}^\varepsilon + \bar{\varphi}^\varepsilon \mathbf{n}_0)] \big\} dx \\
&+ \varepsilon^2 a_\varepsilon^2 |c^\varepsilon|^2 (a_\varepsilon^2 - 1 + |c^\varepsilon|^2) \int_\Omega |\zeta + \varepsilon\rho\varphi^\varepsilon|^2 dx \\
&- 2\varepsilon^3\rho^2 a_\varepsilon^3 |c^\varepsilon|^2 \Im \int_\Omega \{ (\nabla\varphi^\varepsilon - \mathbf{u}^\varepsilon)\cdot(\bar{\zeta}\mathbf{u}^\varepsilon + \bar{\varphi}^\varepsilon \mathbf{n}^\varepsilon) + \bar{\varphi}^\varepsilon \mathbf{u}^\varepsilon \cdot (\nabla\zeta - \mathbf{n}_0) \} dx \\
&+ \frac{1}{2}\varepsilon^2 a_\varepsilon^2 |c^\varepsilon|^4 \int_\Omega \big[2\Im(\zeta + \varepsilon\rho\varphi^\varepsilon) - \varepsilon a_\varepsilon |\zeta + \varepsilon\rho\varphi^\varepsilon|^2 \big]^2 dx.
\end{aligned}
$$

Checking the first line in the right-hand side of (4.13), we choose

$$
\mathbf{n}_0 \in \mathcal{C}_*(\tau), \qquad \zeta = \zeta_{\mathbf{n}_0}, \qquad c^\varepsilon = \sqrt{1 - a_\varepsilon^2 \omega_*(\tau)}, \tag{4.14}
$$

where $\zeta_{\mathbf{n}_0}$ is determined by (1.7) for $\mathbf{n}_0$. Then the first line in the right-hand side of (4.13) becomes

$$
a_\varepsilon^2 (1 - a_\varepsilon^2 \omega_*(\tau))\omega_*(\tau)|\Omega| + \frac{1}{2}(a_\varepsilon^2 \omega_*(\tau))^2 |\Omega| = d_0(\varepsilon).
$$

Applying (2.3) for $\mathbf{u} = \mathbf{n}_0$ we have

$$
\int_\Omega (\nabla\zeta_{\mathbf{n}_0} - \mathbf{n}_0)\cdot \nabla\bar{\varphi}^\varepsilon dx = 0.
$$

So the third line in the right-hand side of (4.13) becomes

$$
-2\varepsilon\rho a_\varepsilon^2 |c^\varepsilon|^2 \int_\Omega (\nabla\zeta_{\mathbf{n}_0} - \mathbf{n}_0)\cdot \mathbf{u}^\varepsilon \, dx.
$$

Since $\zeta_{\mathbf{n}_0}$ is real-valued, the fourth line in the right-hand side of (4.13) vanishes. From (4.12), the sixth line in the right-hand side of (4.13) becomes

$$
-2\varepsilon^2\rho a_\varepsilon^3 |c^\varepsilon|^2 \Im \int_\Omega \mathbf{n}_0 \cdot (\zeta_{\mathbf{n}_0}\nabla\varphi^\varepsilon + \bar{\varphi}^\varepsilon \nabla\zeta_{\mathbf{n}_0}) dx.
$$

Let us define a functional $T_{\varepsilon,\rho}$ by

$$
T_{\varepsilon,\rho}[\mathbf{u}] = \rho^2 \mathcal{I}[\mathbf{u}] - 2\varepsilon\rho a_\varepsilon^2 |c^\varepsilon|^2 \int_\Omega (\nabla\zeta_{\mathbf{n}_0} - \mathbf{n}_0)\cdot \mathbf{u}\, dx. \tag{4.15}
$$

Then we can rewrite (4.13) as follows:

(4.16)
$$\begin{aligned}
&\varepsilon^{-2}\mathcal{G}_\varepsilon[\psi^\varepsilon,\mathbf{n}^\varepsilon]-d_0(\varepsilon)-T_{\varepsilon,\rho}[\mathbf{u}^\varepsilon]\\
&=\varepsilon^2\rho^2a_\varepsilon^2|c^\varepsilon|^2\int_\Omega|\nabla\varphi^\varepsilon-\mathbf{u}^\varepsilon|^2dx\\
&\quad-2\varepsilon^2\rho a_\varepsilon^3|c^\varepsilon|^2\Im\int_\Omega\mathbf{n}_0\cdot(\zeta_{\mathbf{n}_0}\nabla\varphi^\varepsilon+\bar\varphi^\varepsilon\nabla\zeta_{\mathbf{n}_0})dx\\
&\quad+\varepsilon^2a_\varepsilon^2|c^\varepsilon|^2(a_\varepsilon^2-1+|c^\varepsilon|^2)\int_\Omega|\zeta_{\mathbf{n}_0}+\varepsilon\rho\varphi^\varepsilon|^2dx\\
&\quad-2\varepsilon^3\rho^2a_\varepsilon^3|c^\varepsilon|^2\Im\int_\Omega\big\{\zeta_{\mathbf{n}_0}\mathbf{u}^\varepsilon\cdot\nabla\varphi^\varepsilon+\bar\varphi^\varepsilon\big[\mathbf{u}^\varepsilon\cdot(\nabla\zeta_{\mathbf{n}_0}-\mathbf{n}_0)+\mathbf{n}^\varepsilon\cdot(\nabla\varphi^\varepsilon-\mathbf{u}^\varepsilon)\big]\big\}dx\\
&\quad+\frac{1}{2}\varepsilon^4a_\varepsilon^2|c^\varepsilon|^4\int_\Omega\big[2\rho\Im(\varphi^\varepsilon)-a_\varepsilon|\zeta_{\mathbf{n}_0}+\varepsilon\rho\varphi^\varepsilon|^2\big]^2dx.
\end{aligned}$$

Step 2. *A variational problem in* $W(\mathbf{n}_0)$. Equation (4.16) suggests that $\mathbf{u}^\varepsilon$ and ρ should be chosen to minimize $T_{\varepsilon,\rho}$ asymptotically; namely,

$$T_{\varepsilon,\rho}[\mathbf{u}^\varepsilon]=T_v(\varepsilon)+o(1)\quad\text{as }\varepsilon\to0,$$

where

$$T_v(\varepsilon)=\inf_{0<\rho<+\infty}\ \inf_{\mathbf{u}\in V(\mathbf{n}_0,\varepsilon\rho)}T_{\varepsilon,\rho}[\mathbf{u}]. \tag{4.17}$$

In order to get an upper bound estimate of $T_v(\varepsilon)$, one may first look at the following variational problem, which can be derived as a formal limit of (4.17):

$$\begin{aligned}
t_v(\varepsilon,\rho)&=\inf_{\mathbf{u}\in V(\mathbf{n}_0)}T_{\varepsilon,\rho}[\mathbf{u}],\\
t_v(\varepsilon)&=\inf_{0<\rho<+\infty}t_v(\varepsilon,\rho),
\end{aligned}\tag{4.18}$$

where

$$V(\mathbf{n}_0)=\{\mathbf{u}\in V(\Omega,\mathbb{R}^3):\ \mathbf{u}(x)\cdot\mathbf{n}_0(x)=0\quad\text{a.e. in }\Omega\}.$$

We may try to use the minimizing sequence of (4.18) to construct test functions for $T_v(\varepsilon)$. However, to avoid technical complexity, instead of working on $V(\mathbf{n}_0)$, we consider the variational problem in a subset of the Sobolev space $W^{1,2}(\Omega,\mathbb{R}^3)$:

$$W(\mathbf{n}_0)=\{\mathbf{u}\in W^{1,2}(\Omega,\mathbb{R}^3):\ \mathbf{u}(x)\cdot\mathbf{n}_0(x)=0\quad\text{a.e. in }\Omega\}.$$

Define

$$\begin{aligned}
t_w(\varepsilon,\rho)&=\inf_{\mathbf{u}\in W(\mathbf{n}_0)}T_{\varepsilon,\rho}[\mathbf{u}],\\
t_w(\varepsilon)&=\inf_{0<\rho<+\infty}t_w(\varepsilon,\rho).
\end{aligned}\tag{4.19}$$

On $W(\mathbf{n}_0)$ we can write

$$T_{\varepsilon,\rho}[\mathbf{u}]=\rho^2\mathcal{I}[\mathbf{u}]-2\varepsilon\rho a_\varepsilon^2|c^\varepsilon|^2\int_\Omega\nabla\zeta_{\mathbf{n}_0}\cdot\mathbf{u}dx.$$

As a subspace of $W^{1,2}(\Omega,\mathbb{R}^3)$, the set $W(\mathbf{n}_0)$ has a decomposition

$$W(\mathbf{n}_0) = \mathcal{U}(\tau,\mathbf{n}_0) \oplus \mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0),$$

where $\mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0)$ is the orthogonal complement of $\mathcal{U}(\tau,\mathbf{n}_0)$ in $W(\mathbf{n}_0)$. Since $\mathbf{n}_0 \in \mathcal{C}_*(\tau)$, using Proposition 3.3 we see that

$$T_{\varepsilon,\rho}[\mathbf{u}] = 0 \quad \text{for all } \mathbf{u} \in \mathcal{U}(\tau,\mathbf{n}_0).$$

Thus

$$t_w(\varepsilon,\rho) = \inf_{\mathbf{u}\in\mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0)} T_{\varepsilon,\rho}[\mathbf{u}].$$

It is interesting that the variational problem (4.19) is linked to the following number:

$$\mu_w(\mathbf{n}_0) = \sup_{\mathbf{v}\in W(\mathbf{n}_0),\ \mathcal{I}[\mathbf{v}]>0} \frac{\int_\Omega \nabla\zeta_{\mathbf{n}_0}\cdot\mathbf{v}dx}{\sqrt{\mathcal{I}[\mathbf{v}]}}. \tag{4.20}$$

The advantage of choosing $W(\mathbf{n}_0)$ as the admissible set is that we know $C^1(\bar\Omega,\mathbb{R}^3)$ is dense in $W(\mathbf{n}_0)$. Since $\mathcal{I}[\mathbf{v}] \neq 0$ for nonzero elements $\mathbf{v} \in \mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0)$, and using the homogeneity of the ratio, we have

$$\begin{aligned}\mu_w(\mathbf{n}_0) &= \sup\left\{\frac{\int_\Omega \nabla\zeta_{\mathbf{n}_0}\cdot\mathbf{v}dx}{\sqrt{\mathcal{I}[\mathbf{v}]}} :\ \mathbf{v}\in\mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0)\cap C^1(\bar\Omega,\mathbb{R}^3)\right\}\\ &= \sup\left\{\frac{\int_\Omega \nabla\zeta_{\mathbf{n}_0}\cdot\mathbf{v}dx}{\sqrt{\mathcal{I}[\mathbf{v}]}} :\ \mathbf{v}\in\mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0)\cap C^1(\bar\Omega,\mathbb{R}^3),\ \|\mathbf{v}\|_{C^1(\bar\Omega,\mathbb{R}^3)}=1\right\}.\end{aligned}$$

Note that, if $\{\mathbf{v}_j\} \subset W(\mathbf{n}_0)$ is a maximizing sequence of $\mu_w(\mathbf{n}_0)$, then for any $\mathbf{u}_j \in \mathcal{U}(\tau,\mathbf{n}_0)$, $\{\mathbf{u}_j+\mathbf{v}_j\}$ is also a maximizing sequence of $\mu_w(\mathbf{n}_0)$ in $W(\mathbf{n}_0)$.

LEMMA 4.3. *Let $\tau>0$ and $\mathbf{n}_0\in\mathcal{C}_*(\tau)$.*

(1) $0<\mu_w(\mathbf{n}_0)\le+\infty$.

(2) *Assume $\mu_w(\mathbf{n}_0)<+\infty$. If $\mu_w(\mathbf{n}_0)$ is achieved, we can choose $\rho^\varepsilon>0$, $\rho^\varepsilon = O(\varepsilon)$ as $\varepsilon\to0$, such that*

$$t_w(\varepsilon) = t_w(\varepsilon,\rho^\varepsilon) = -\varepsilon^2 a_\varepsilon^4|c^\varepsilon|^4\mu_w(\mathbf{n}_0)^2. \tag{4.21}$$

If $\mu_w(\mathbf{n}_0)$ is not achieved, we can choose $\rho^\varepsilon>0$, $\rho^\varepsilon \ll \varepsilon|\log\varepsilon|$ as $\varepsilon\to0$, such that

$$-\varepsilon^2 a_\varepsilon^4|c^\varepsilon|^4\mu_w(\mathbf{n}_0)^2 \le t_w(\varepsilon) \le t_w(\varepsilon,\rho^\varepsilon) = -\varepsilon^2 a_\varepsilon^4|c^\varepsilon|^4\mu_w(\mathbf{n}_0)^2 + o(\varepsilon^2). \tag{4.22}$$

(3) *Assume $\mu_w(\mathbf{n}_0)=+\infty$. Then $t_w(\varepsilon)=-\infty$ for any $\varepsilon>0$.*

Proof of (1). Suppose $\mu_w(\mathbf{n}_0)=0$. Then we use Proposition 3.3 to conclude that

$$\int_\Omega \nabla\zeta_{\mathbf{n}_0}\cdot\mathbf{u}dx = 0 \qquad \text{for all } \mathbf{u}\in W(\mathbf{n}_0). \tag{4.23}$$

Let us choose

$$\mathbf{v}_0 = \nabla\zeta_{\mathbf{n}_0} - (\mathbf{n}_0\cdot\nabla\zeta_{\mathbf{n}_0})\mathbf{n}_0.$$

Then $\mathbf{v}_0 \in W(\mathbf{n}_0)$, and

$$\int_\Omega \nabla\zeta_{\mathbf{n}_0} \cdot \mathbf{v}_0 dx = \int_\Omega \{|\nabla\zeta_{\mathbf{n}_0}|^2 - (\mathbf{n}_0 \cdot \nabla\zeta_{\mathbf{n}_0})^2\} dx.$$

From (4.23), the right side of the above equality is zero. From this and the fact $|\mathbf{n}_0 \cdot \nabla\zeta_{\mathbf{n}_0}| \le |\nabla\zeta_{\mathbf{n}_0}|$, we must have

$$\nabla\zeta_{\mathbf{n}_0} = g\mathbf{n}_0 \quad \text{on } \Omega,$$

where $g = \mathbf{n}_0 \cdot \nabla\zeta_{\mathbf{n}_0}$. Applying the operator curl to the above equality we get

$$\mathbf{0} = \text{curl } (\nabla\zeta_{\mathbf{n}_0}) = \text{curl } (g\mathbf{n}_0) = g\text{curl } \mathbf{n}_0 + \nabla g \times \mathbf{n}_0 = -\tau g\mathbf{n}_0 + \nabla g \times \mathbf{n}_0.$$

So $\tau g\mathbf{n}_0 = \nabla g \times \mathbf{n}_0$, and hence $g = \frac{1}{\tau}\mathbf{n}_0 \cdot (\nabla g \times \mathbf{n}_0) = 0$. Thus $\nabla\zeta_{\mathbf{n}_0} = g\mathbf{n}_0 = \mathbf{0}$, which is a contradiction.

Proof of (2). Assume $\mu_w(\mathbf{n}_0) < +\infty$. For any $\rho > 0$, if $\mathbf{u} \in \mathcal{U}(\tau, \mathbf{n}_0)$, then $T_{\varepsilon,\rho}[\mathbf{u}] = 0$. Now if $\mathbf{u} \in W(\mathbf{n}_0) \setminus \mathcal{U}(\tau, \mathbf{n}_0)$, then

$$\begin{aligned} T_{\varepsilon,\rho}[\mathbf{u}] &= \rho^2\mathcal{I}[\mathbf{u}] - 2a_\varepsilon^2|c^\varepsilon|^2\varepsilon\rho\int_\Omega \nabla\zeta_{\mathbf{n}_0} \cdot \mathbf{u} dx \\ &= \left[\rho\sqrt{\mathcal{I}[\mathbf{u}]} - a_\varepsilon^2|c^\varepsilon|^2\varepsilon\frac{\int_\Omega \nabla\zeta_{\mathbf{n}_0} \cdot \mathbf{u} dx}{\sqrt{\mathcal{I}[\mathbf{u}]}}\right]^2 - \varepsilon^2 a_\varepsilon^4|c^\varepsilon|^4\left[\frac{\int_\Omega \nabla\zeta_{\mathbf{n}_0} \cdot \mathbf{u} dx}{\sqrt{\mathcal{I}[\mathbf{u}]}}\right]^2 \\ &\ge -\varepsilon^2 a_\varepsilon^4|c^\varepsilon|^4\mu_w(\mathbf{n}_0)^2. \end{aligned}$$

Hence

$$t_w(\varepsilon) \ge -\varepsilon^2 a_\varepsilon^4|c^\varepsilon|^4\mu_w(\mathbf{n}_0)^2.$$

Case 1. $\mu_w(\mathbf{n}_0)$ is achieved. We fix a maximizer $\mathbf{v}_0$ of $\mu_w(\mathbf{n}_0)$ with $\|\mathbf{v}_0\|_{C^1(\bar\Omega,\mathbb{R}^3)} = 1$, and let

$$\rho^\varepsilon = \frac{\varepsilon a_\varepsilon^2|c^\varepsilon|^2\mu_w(\mathbf{n}_0)}{\mathcal{I}[\mathbf{v}_0]}.$$

We have

$$T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}_0] = -a_\varepsilon^4|c^\varepsilon|^4\mu_w(\mathbf{n}_0)^2.$$

From the choice of a_ε and c^ε, we have $\rho^\varepsilon = O(\varepsilon)$ as $\varepsilon \to 0$.

Case 2. $\mu_w(\mathbf{n}_0)$ is not achieved. We can show that, if $\mu_w(\mathbf{n}_0)$ is not achieved, then the following conclusions are true:

(i) if $\{\mathbf{v}_j\} \subset W(\mathbf{n}_0)$ is a maximizing sequence of $\mu_w(\mathbf{n}_0)$ and if it is bounded in $W^{1,2}(\Omega, \mathbb{R}^3)$, then

$$\mathcal{I}[\mathbf{v}_j] \to 0 \quad \text{as } j \to \infty;$$

(ii) if in addition $\{\mathbf{v}_j\} \subset \mathcal{U}_w^\perp(\tau, \mathbf{n}_0)$, then

$$\mathbf{v}_j \to \mathbf{0} \quad \text{weakly in } W^{1,2}(\Omega, \mathbb{R}^3) \text{ as } j \to \infty.$$

To prove (i) and (ii), let $\{\mathbf{v}_j\} \subset W(\mathbf{n}_0)$ be a maximizing sequence of $\mu_w(\mathbf{n}_0)$ that is bounded in $W^{1,2}(\Omega, \mathbb{R}^3)$. We pass to a subsequence and assume that $\mathbf{v}_j \to \mathbf{v}_0$ weakly in $W^{1,2}(\Omega,\mathbb{R}^3)$. Since $\mu_w(\mathbf{n}_0)$ is not achieved, we have $\mathcal{I}[\mathbf{v}_0]=0$, because otherwise $\mathbf{v}_0$ achieves $\mu_w(\mathbf{n}_0)$. Hence $\mathcal{I}[\mathbf{v}_j]\to 0$. Now if $\{\mathbf{v}_j\}\subset\mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0)$, then $\mathbf{v}_0\in\mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0)$. Since $\mathcal{I}[\mathbf{v}_0]=0$, we have $\mathbf{v}_0\in\mathcal{U}(\tau,\mathbf{n}_0)$. So $\mathbf{v}_0\in\mathcal{U}(\tau,\mathbf{n}_0)\cap\mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0)=\{\mathbf{0}\}$, and $\mathbf{v}_j\to\mathbf{0}$ weakly in $W^{1,2}(\Omega,\mathbb{R}^3)$ as $j\to\infty$.

To finish the proof of (2) of Lemma 4.3 in Case 2, note that we may choose a maximizing sequence in $\mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0)$ that approaches $\mathbf{0}$ weakly as slowly as possible. So let us choose a maximizing sequence $\{\mathbf{v}^\varepsilon\}\subset\mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0)$ such that $\|\mathbf{v}^\varepsilon\|_{C^1(\bar\Omega,\mathbb{R}^3)}=1$, and

$$\mathcal{I}[\mathbf{v}^\varepsilon]\gg\frac{1}{|\log\varepsilon|}\quad\text{as }\varepsilon\to 0.$$

Let

$$\rho^\varepsilon=\frac{\varepsilon a_\varepsilon^2|c^\varepsilon|^2\mu_w(\mathbf{n}_0)}{\mathcal{I}[\mathbf{v}^\varepsilon]}.$$

Then $\rho^\varepsilon\ll\varepsilon|\log\varepsilon|$ as $\varepsilon\to 0$, and

$$T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon]=-\varepsilon^2a_\varepsilon^4|c^\varepsilon|^4\left[\frac{\int_\Omega\nabla\zeta_{\mathbf{n}_0}\cdot\mathbf{v}^\varepsilon dx}{\sqrt{\mathcal{I}[\mathbf{v}^\varepsilon]}}\right]^2=-\varepsilon^2a_\varepsilon^4|c^\varepsilon|^4\mu_w(\mathbf{n}_0)^2+o(\varepsilon^2).$$

Hence (2) of Lemma 4.3 is true.

Proof of (3). Assume $\mu_w(\mathbf{n}_0)=+\infty$. Choose $\mathbf{v}_j\in\mathcal{U}_w^{\perp}(\tau,\mathbf{n}_0)$ such that $\|\mathbf{v}_j\|_{C^1(\bar\Omega,\mathbb{R}^3)}$ $=1$ and

$$\frac{\int_\Omega\nabla\zeta_{\mathbf{n}_0}\cdot\mathbf{v}_j dx}{\sqrt{\mathcal{I}[\mathbf{v}_j]}}\equiv M_j\to+\infty\quad\text{as }j\to\infty.$$

Fix $\varepsilon>0$ and let

$$\rho_j=\frac{\varepsilon a_\varepsilon^2|c^\varepsilon|^2M_j}{\mathcal{I}[\mathbf{v}_j]}.$$

Then

$$t_v(\varepsilon)\le t_v(\varepsilon,\rho_j)\le T_{\varepsilon,\rho_j}[\mathbf{v}_j]=-\varepsilon^2a_\varepsilon^4|c^\varepsilon|^4M_j^2\to-\infty\quad\text{as }j\to\infty.\qquad\square$$

Note that, when $\mu_w(\mathbf{n}_0)<+\infty$, the estimate on ρ^ε given in Lemma 4.3 (conclusion (2)) is not optimal. In fact, we do not exclude the existence of a sequence $\tilde\rho^\varepsilon$ such that $t_w(\varepsilon)=t_w(\varepsilon,\tilde\rho^\varepsilon)$ holds but $\tilde\rho^\varepsilon\not\to 0$ as $\varepsilon\to 0$.

Step 3. *Upper bound of* $T_v(\varepsilon)$. Now we can prove an upper bound estimate of $T_v(\varepsilon)$ using Lemma 4.3. Let us write

$$W(\mathbf{n}_0,b)=\left\{\mathbf{u}\in W^{1,2}(\Omega,\mathbb{R}^3):\ \mathbf{u}(x)\cdot\mathbf{n}_0(x)=-\frac{b}{2}|\mathbf{u}(x)|^2\text{ a.e. in }\Omega\right\},$$
$$W_1(\mathbf{n}_0,\mathbf{v}^\varepsilon,b)=\left\{\mathbf{w}\in W^{1,2}(\Omega,\mathbb{R}^3):\ \mathbf{w}(x)\cdot\mathbf{n}_0(x)=-\frac{1}{2}|\mathbf{v}^\varepsilon(x)+b\mathbf{w}(x)|^2\text{ on }\Omega\right\}.$$

Note that $\mathbf{v}^\varepsilon+\varepsilon\rho^\varepsilon\mathbf{w}\in W(\mathbf{n}_0,\varepsilon\rho^\varepsilon)$ if and only if $\mathbf{w}\in W_1(\mathbf{n}_0,\mathbf{v}^\varepsilon,\varepsilon\rho^\varepsilon)$.

Lemma 4.4. *Let $\tau > 0$ and $\mathbf{n}_0 \in \mathcal{C}_*(\tau)$. Assume $\mu_w(\mathbf{n}_0) < +\infty$. There exist $\rho^\varepsilon > 0$, $\mathbf{v}^\varepsilon \in W(\mathbf{n}_0) \cap C^1(\bar\Omega, \mathbb{R}^3)$, and $\mathbf{w}^\varepsilon \in W^{1,2}(\Omega, \mathbb{R}^3)$ such that*

$$\begin{aligned} &\mathbf{v}^\varepsilon + \varepsilon\rho^\varepsilon \mathbf{w}^\varepsilon \in W(\mathbf{n}_0, \varepsilon\rho^\varepsilon), \\ &\rho^\varepsilon \ll \varepsilon|\log\varepsilon|, \\ &\|\mathbf{v}^\varepsilon\|_{C^1(\bar\Omega,\mathbb{R}^3)} = 1, \\ &\|\mathbf{w}^\varepsilon\|_{W^{1,2}(\Omega,\mathbb{R}^3)} \le C; \end{aligned} \tag{4.24}$$

and as $\varepsilon \to 0$,

$$T_v(\varepsilon) \le T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon + \varepsilon\rho^\varepsilon\mathbf{w}^\varepsilon] = -\varepsilon^2 a_\varepsilon^4 |c^\varepsilon|^4 \mu_w(\mathbf{n}_0)^2 + o(\varepsilon^2). \tag{4.25}$$

Moreover, if $\mu_w(\mathbf{n}_0)$ is achieved, then we can choose ρ^ε such that $\rho^\varepsilon = O(\varepsilon)$ as $\varepsilon \to 0$.

Proof. From the proof of Lemma 4.3 (conclusion (2)) we see that for any $\varepsilon > 0$ there exist $\rho^\varepsilon > 0$ and $\mathbf{v}^\varepsilon \in W(\mathbf{n}_0) \cap C^1(\bar\Omega, \mathbb{R}^3)$ such that, as $\varepsilon \to 0$,

$$\begin{aligned} &\|\mathbf{v}^\varepsilon\|_{C^1(\bar\Omega,\mathbb{R}^3)} = 1, \\ &0 < \rho^\varepsilon \ll \varepsilon|\log\varepsilon|, \\ &\mathcal{I}[\mathbf{v}^\varepsilon] \gg \frac{1}{|\log\varepsilon|}, \\ &T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon] = t_w(\varepsilon) + o(\varepsilon^2) = -\varepsilon^2 a_\varepsilon^4 |c^\varepsilon|^4 \mu_w(\mathbf{n}_0)^2 + o(\varepsilon^2). \end{aligned} \tag{4.26}$$

Moreover, if $\mu_w(\mathbf{n}_0)$ is achieved, then ρ^ε can be chosen such that $\rho^\varepsilon = O(\varepsilon)$. We have

$$\begin{aligned} T_v(\varepsilon) &\le \inf_{\mathbf{u}\in V(\mathbf{n}_0,\varepsilon\rho^\varepsilon)} T_{\varepsilon,\rho^\varepsilon}[\mathbf{u}] \le \inf_{\mathbf{u}\in W(\mathbf{n}_0,\varepsilon\rho^\varepsilon)} T_{\varepsilon,\rho^\varepsilon}[\mathbf{u}] \\ &\le \inf_{\mathbf{w}\in W_1(\mathbf{n}_0,\mathbf{v}^\varepsilon,\varepsilon\rho^\varepsilon)} T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon + \varepsilon\rho^\varepsilon\mathbf{w}]. \end{aligned}$$

Let

$$\begin{aligned} &\mathbf{w}^\varepsilon(x) = -f^\varepsilon(x)\mathbf{n}_0(x), \\ &\text{where} \quad f^\varepsilon(x) = \frac{|\mathbf{v}^\varepsilon(x)|^2}{1 + \sqrt{1 - (\varepsilon\rho^\varepsilon)^2|\mathbf{v}^\varepsilon(x)|^2}}. \end{aligned} \tag{4.27}$$

It is direct to verify that $\mathbf{w}^\varepsilon \in W_1(\mathbf{n}_0, \mathbf{v}^\varepsilon, \varepsilon\rho^\varepsilon)$. Moreover, since $\|\mathbf{v}^\varepsilon\|_{C^1(\bar\Omega,\mathbb{R}^3)} = 1$, we can show that there exists a constant C such that for all small ε,

$$\|\mathbf{w}^\varepsilon\|_{W^{1,2}(\Omega,\mathbb{R}^3)} \le C. \tag{4.28}$$

Now we choose $\mathbf{v}^\varepsilon + \varepsilon\rho^\varepsilon\mathbf{w}^\varepsilon$ as a test function for $T_v(\varepsilon)$. We use (4.28) to compute

$$\begin{aligned} &T_v(\varepsilon) \le T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon + \varepsilon\rho^\varepsilon\mathbf{w}^\varepsilon] \\ &= T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon] + \varepsilon(\rho^\varepsilon)^3 \int_\Omega \{K_1 \text{div } \mathbf{v}^\varepsilon \text{div } \mathbf{w}^\varepsilon + K_2(\text{curl } \mathbf{v}^\varepsilon + \tau\mathbf{v}^\varepsilon) \cdot (\text{curl } \mathbf{w}^\varepsilon + \tau\mathbf{w}^\varepsilon)\} dx \\ &\quad + \varepsilon^2(\rho^\varepsilon)^4 \mathcal{I}[\mathbf{w}^\varepsilon] - 2\varepsilon^2(\rho^\varepsilon)^2 a_\varepsilon^2 |c^\varepsilon|^2 \int_\Omega (\nabla\zeta_{\mathbf{n}_0} - \mathbf{n}_0) \cdot \mathbf{w}^\varepsilon dx \\ &= T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon] + O\left(\varepsilon(\rho^\varepsilon)^3 \|\mathbf{v}^\varepsilon\|_{W^{1,2}(\Omega,\mathbb{R}^3)} \|\mathbf{w}^\varepsilon\|_{W^{1,2}(\Omega,\mathbb{R}^3)}\right) + O\big(\varepsilon^2(\rho^\varepsilon)^4 \|\mathbf{w}^\varepsilon\|^2_{W^{1,2}(\Omega,\mathbb{R}^3)}\big) \\ &\quad + O\left(\varepsilon^2(\rho^\varepsilon)^2 \|\mathbf{w}^\varepsilon\|_{W^{1,2}(\Omega,\mathbb{R}^3)}\right) \\ &= T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon] + O\left(\varepsilon(\rho^\varepsilon)^3\right) + O\left(\varepsilon^2(\rho^\varepsilon)^4\right) + O\left(\varepsilon^2(\rho^\varepsilon)^2\right) \\ &= T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon] + O\left(\varepsilon^4|\log\varepsilon|^3\right) \\ &= T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon] + o(\varepsilon^3). \end{aligned}$$

Inequality (4.25) follows from this and the last line in (4.26). $\square$

LEMMA 4.5. *Let $\tau > 0$ and $\mathbf{n}_0 \in \mathcal{C}_*(\tau)$. Assume that $\mu_w(\mathbf{n}_0) = +\infty$. Let δ_ε satisfy for any ε*

$$\varepsilon^2 \ll \delta_\varepsilon \le \delta_0,$$

where $0 < \delta_0 < 1$ is independent of ε. There exist $\rho^\varepsilon > 0$, $\mathbf{v}^\varepsilon \in W(\mathbf{n}_0) \cap C^1(\bar{\Omega}, \mathbb{R}^3)$, and $\mathbf{w}^\varepsilon \in W^{1,2}(\Omega, \mathbb{R}^3)$ such that

$$\begin{aligned} &\mathbf{v}^\varepsilon + \varepsilon\rho^\varepsilon \mathbf{w}^\varepsilon \in W(\mathbf{n}_0, \varepsilon\rho^\varepsilon),\\ &\rho_\varepsilon \le \frac{\delta_\varepsilon}{\varepsilon},\\ &\|\mathbf{v}^\varepsilon\|_{C^1(\bar{\Omega},\mathbb{R}^3)} = 1,\\ &\|\mathbf{w}^\varepsilon\|_{W^{1,2}(\Omega,\mathbb{R}^3)} \le C; \end{aligned} \tag{4.29}$$

and as $\varepsilon \to 0$,

$$T_v(\varepsilon) \le T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon + \varepsilon\rho^\varepsilon\mathbf{w}^\varepsilon] = -\varepsilon^2 a_\varepsilon^4 |c^\varepsilon|^4 L^\varepsilon + O\left(\frac{\delta_\varepsilon^3}{\varepsilon^2}\right), \tag{4.30}$$

where $L^\varepsilon \to +\infty$.

Proof. Let

$$W_\varepsilon(\mathbf{n}_0) = \left\{ \mathbf{v} \in \mathcal{U}_w^\perp(\tau, \mathbf{n}_0) \cap C^1(\bar{\Omega}, \mathbb{R}^3) : \ \frac{\int_\Omega \nabla\zeta_{\mathbf{n}_0} \cdot \mathbf{v}\,dx}{\mathcal{I}[\mathbf{v}]^{3/2}} \le \frac{\delta_\varepsilon}{a_\varepsilon^2 |c^\varepsilon|^2 \varepsilon^2} \right\},$$

and define

$$\mu_\varepsilon(\mathbf{n}_0) = \sup_{\mathbf{v} \in W_\varepsilon(\mathbf{n}_0)} \frac{\int_\Omega \nabla\zeta_{\mathbf{n}_0} \cdot \mathbf{v}\,dx}{\sqrt{\mathcal{I}[\mathbf{v}]}}. \tag{4.31}$$

We have

$$\mu_\varepsilon(\mathbf{n}_0) = \sup \left\{ \frac{\int_\Omega \nabla\zeta_{\mathbf{n}_0} \cdot \mathbf{v}\,dx}{\sqrt{\mathcal{I}[\mathbf{v}]}} : \ \mathbf{v} \in W_\varepsilon(\mathbf{n}_0), \ \|\mathbf{v}\|_{C^1(\bar{\Omega},\mathbb{R}^3)} = 1 \right\}.$$

We claim that, if $\mu_w(\mathbf{n}_0) = +\infty$, then

$$\lim_{\varepsilon \to 0} \mu_\varepsilon(\mathbf{n}_0) = +\infty. \tag{4.32}$$

To prove (4.32), let v_j and M_j be given in the proof of Lemma 4.3 (conclusion (3)). Note that, as $\varepsilon \to 0$, a_ε and $|c^\varepsilon|$ remain bounded, and $\delta_\varepsilon/\varepsilon^2 \to +\infty$. Let us choose $j(\varepsilon)$ such that $j(\varepsilon_2) \ge j(\varepsilon_1)$ if $0 < \varepsilon_2 < \varepsilon_1$, and

$$\frac{M_{j(\varepsilon)}}{\mathcal{I}[\mathbf{v}_{j(\varepsilon)}]} \le \frac{\delta_\varepsilon}{a_\varepsilon^2 |c^\varepsilon|^2 \varepsilon^2}.$$

Then $\mathbf{v}_{j(\varepsilon)} \in W_\varepsilon(\mathbf{n}_0)$. Hence

$$\mu_\varepsilon(\mathbf{n}_0) \ge \frac{\int_\Omega \nabla\zeta_{\mathbf{n}_0} \cdot \mathbf{v}_{j(\varepsilon)}\,dx}{\sqrt{\mathcal{I}[\mathbf{v}_{j(\varepsilon)}]}} = M_{j(\varepsilon)} \to +\infty \quad \text{as } \varepsilon \to 0.$$

So (4.32) is true.

Now we choose $\mathbf{v}^\varepsilon \in W_\varepsilon(\mathbf{n}_0) \cap C^1(\bar{\Omega}, \mathbb{R}^3)$ such that $\|\mathbf{v}^\varepsilon\|_{C^1(\bar{\Omega},\mathbb{R}^3)} = 1$ and

$$\frac{\int_\Omega \nabla\zeta_{\mathbf{n}_0} \cdot \mathbf{v}^\varepsilon dx}{\sqrt{\mathcal{I}[\mathbf{v}^\varepsilon]}} = \mu_\varepsilon(\mathbf{n}_0) + o\left(\frac{\varepsilon^2}{\mu_\varepsilon(\mathbf{n}_0)}\right).$$

Let

$$\rho^\varepsilon = \frac{\varepsilon a_\varepsilon^2 |c^\varepsilon|^2 \mu_\varepsilon(\mathbf{n}_0)}{\mathcal{I}[\mathbf{v}^\varepsilon]}.$$

Then $\varepsilon\rho^\varepsilon \le \delta_\varepsilon$, and

$$T_{\varepsilon,\rho_\varepsilon}[\mathbf{v}^\varepsilon] = -\varepsilon^2 a_\varepsilon^4 |c^\varepsilon|^4 \mu_\varepsilon(\mathbf{n}_0)^2 + o(\varepsilon^4).$$

For these $\mathbf{v}^\varepsilon$ and ρ^ε we define $\mathbf{w}^\varepsilon$ by (4.27). Then $\mathbf{w}^\varepsilon \in W_1(\mathbf{n}_0, \mathbf{v}^\varepsilon, \varepsilon\rho^\varepsilon)$ and satisfies (4.28). By computation as in the proof of Lemma 4.4 we have

$$T_v(\varepsilon) \le T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon + \varepsilon\rho^\varepsilon \mathbf{w}^\varepsilon] = T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon] + O(\varepsilon(\rho^\varepsilon)^3) + O(\varepsilon^2(\rho^\varepsilon)^4) + O(\varepsilon^2(\rho^\varepsilon)^2).$$

Since $\rho^\varepsilon \le \delta_\varepsilon/\varepsilon$ and $\delta_\varepsilon \gg \varepsilon^2$, the error terms in the above inequality can be controlled by

$$O(\delta_\varepsilon^2) + O\left(\frac{\delta_\varepsilon^3}{\varepsilon^2}\right) = O\left(\frac{\delta_\varepsilon^3}{\varepsilon^2}\right).$$

Estimate (4.30) follows from this and the last line in (4.29) if we set $L^\varepsilon = \mu_\varepsilon(\mathbf{n}_0)^2$. $\square$

Note that, in Lemma 4.5 we do not have control on the growth rate of L^ε, but we have control on ρ^ε by $\rho^\varepsilon \ll \delta_\varepsilon/\varepsilon$, which is needed in order to get (4.28). In order to make (4.30) useful, we choose δ_ε such that

$$\varepsilon^2 \ll \delta_\varepsilon \ll \varepsilon^2|\log\varepsilon|.$$

Hence $\rho^\varepsilon \ll \varepsilon|\log\varepsilon|$.

Now we return to the construction of the test functions for $\mathcal{G}_\varepsilon$. Let

$$\mu_*(\tau) = \sup_{\mathbf{n}_0 \in \mathcal{C}_*(\tau)} \mu_w(\mathbf{n}_0). \tag{4.33}$$

Step 4. *Constructing test functions for $\mathcal{G}_\varepsilon$ when $\mu_*(\tau) < +\infty$.* When $\mu_w(\mathbf{n}_0) < +\infty$, from Lemma 4.4, we can choose $\mathbf{v}^\varepsilon$, $\mathbf{w}^\varepsilon$, and ρ^ε satisfying (4.24) such that (4.25) holds. In particular, $\rho^\varepsilon \ll \varepsilon|\log\varepsilon|$. Moreover, $\rho^\varepsilon = O(\varepsilon)$ if $\mu_w(\mathbf{n}_0)$ is achieved. We set

$$\mathbf{u}^\varepsilon = \mathbf{v}^\varepsilon + \varepsilon\rho^\varepsilon \mathbf{w}^\varepsilon, \qquad \rho = \rho^\varepsilon, \qquad \varphi^\varepsilon = \varphi_1^\varepsilon + \frac{ia_\varepsilon}{\rho^\varepsilon} f^\varepsilon, \tag{4.34}$$

where φ_1^ε and f_ε are real-valued functions bounded in $W^{1,2}(\Omega)$ as $\varepsilon \to 0$, and

$$\int_\Omega \varphi_1^\varepsilon dx = 0, \qquad \int_\Omega f^\varepsilon dx = 0.$$

From (4.16) we have

(4.35)

$$
\begin{aligned}
&\varepsilon^{-2}\mathcal{G}_\varepsilon[\psi^\varepsilon, \mathbf{n}^\varepsilon] - d_0(\varepsilon) - T_{\varepsilon,\rho^\varepsilon}[\mathbf{u}^\varepsilon] \\
&= \varepsilon^2 a_\varepsilon^4 |c^\varepsilon|^2 \int_\Omega \{|\nabla f^\varepsilon|^2 - 2\mathbf{n}_0 \cdot (\zeta_{\mathbf{n}_0}\nabla f^\varepsilon - f^\varepsilon \nabla\zeta_{\mathbf{n}_0})\}dx \\
&\quad + \varepsilon^2 a_\varepsilon^2 |c^\varepsilon|^2 (a_\varepsilon^2 - 1 + |c^\varepsilon|^2) \int_\Omega \{|\zeta_{\mathbf{n}_0} + \varepsilon\rho^\varepsilon \varphi_1^\varepsilon|^2 + \varepsilon^2 a_\varepsilon^2 |f^\varepsilon|^2\}dx \\
&\quad + (\varepsilon\rho^\varepsilon)^2 a_\varepsilon^2 |c^\varepsilon|^2 \int_\Omega |\nabla\varphi_1^\varepsilon - \mathbf{u}^\varepsilon|^2 dx \\
&\quad - 2\varepsilon^3\rho^\varepsilon a_\varepsilon^4 |c^\varepsilon|^2 \int_\Omega \{\nabla f^\varepsilon \cdot (\zeta_{\mathbf{n}_0}\mathbf{u}^\varepsilon + \varphi_1^\varepsilon \mathbf{n}^\varepsilon) - f^\varepsilon[\mathbf{u}^\varepsilon(\nabla\zeta_{\mathbf{n}_0} - \mathbf{n}_0) + \mathbf{n}^\varepsilon(\nabla\varphi_1^\varepsilon - \mathbf{u}^\varepsilon)]\}dx \\
&\quad + \frac{1}{2}\varepsilon^4 a_\varepsilon^4 |c^\varepsilon|^4 \int_\Omega [2f^\varepsilon - |\zeta_{\mathbf{n}_0} + \varepsilon\rho^\varepsilon\varphi_1^\varepsilon|^2 - \varepsilon^2 a_\varepsilon^2 |f^\varepsilon|^2]^2 dx \\
&= -\varepsilon^2 a_\varepsilon^2 |c^\varepsilon|^2 (1 - |c^\varepsilon|^2) \int_\Omega |\zeta_{\mathbf{n}_0}|^2 dx \\
&\quad + \varepsilon^2 a_\varepsilon^4 |c^\varepsilon|^2 \int_\Omega \{|\nabla f^\varepsilon - \zeta_{\mathbf{n}_0}\mathbf{n}_0|^2 + 2(\mathbf{n}_0 \cdot \nabla\zeta_{\mathbf{n}_0}) f^\varepsilon\}dx \\
&\quad + (\varepsilon\rho^\varepsilon)^2 a_\varepsilon^2 |c^\varepsilon|^2 \int_\Omega |\nabla\varphi_1^\varepsilon - \mathbf{u}^\varepsilon|^2 dx \\
&\quad + O(\varepsilon^3\rho^\varepsilon) + O(\varepsilon^4),
\end{aligned}
$$

where we have used the fact that $\mathbf{v}^\varepsilon$ and $\mathbf{w}^\varepsilon$ are bounded in $W^{1,2}(\Omega, \mathbb{R}^3)$, φ_1^ε and f^ε are bounded in $W^{1,2}(\Omega)$, and $\rho^\varepsilon \ll \varepsilon|\log\varepsilon|$. Write

$$F_{\mathbf{n}_0}[f] = \int_\Omega \{|\nabla f - \zeta_{\mathbf{n}_0}\mathbf{n}_0|^2 + 2(\mathbf{n}_0 \cdot \nabla\zeta_{\mathbf{n}_0}) f\}dx.$$

Checking the right side of (4.35), we choose f^ε to be the minimizer of the variational problem

$$\min \left\{ F_{\mathbf{n}_0}[f] : \ f \in W^{1,2}(\Omega), \ \int_\Omega f dx = 0 \right\}. \tag{4.36}$$

It is easy to verify that (4.36) has a unique minimizer, which is denoted by $f_{\mathbf{n}_0}$; and for any $g \in W^{1,2}(\Omega)$ satisfying $\int_\Omega g dx = 0$ we have

$$\int_\Omega \{(\nabla f_{\mathbf{n}_0} - \zeta_{\mathbf{n}_0}\mathbf{n}_0) \cdot \nabla g + (\mathbf{n}_0 \cdot \nabla\zeta_{\mathbf{n}_0}) g\}dx = 0. \tag{4.37}$$

Thus $f_{\mathbf{n}_0}$ is the solution of the following equation:

$$\begin{cases} \Delta f_{\mathbf{n}_0} = 2\mathbf{n}_0 \cdot \nabla\zeta_{\mathbf{n}_0} - l(\mathbf{n}_0) & \text{in } \Omega, \\ \dfrac{\partial f_{\mathbf{n}_0}}{\partial\nu} = \zeta_{\mathbf{n}_0}\mathbf{n}_0 \cdot \nu & \text{on } \partial\Omega, \\ \displaystyle\int_\Omega f_{\mathbf{n}_0} dx = 0, \end{cases} \tag{4.38}$$

where

$$l(\mathbf{n}_0) = \fint_\Omega |\nabla\zeta_{\mathbf{n}_0}|^2 dx = \fint_\Omega \mathbf{n}_0 \cdot \nabla\zeta_{\mathbf{n}_0} dx.$$

Using (4.37) with $g = f_{\mathbf{n}_0}$ we find

$$F_{n_0}[f_{\mathbf{n}_0}] = \int_\Omega \{|\nabla f_{\mathbf{n}_0} - \zeta_{\mathbf{n}_0}\mathbf{n}_0|^2 - 2(\nabla f_{\mathbf{n}_0} - \zeta_{\mathbf{n}_0}\mathbf{n}_0)\cdot\nabla f_{\mathbf{n}_0}\}dx = \int_\Omega (|\zeta_{\mathbf{n}_0}|^2 - |\nabla f_{\mathbf{n}_0}|^2)dx. \tag{4.39}$$

From the above discussion and (4.10), (4.14), and (4.34), the test functions for $\mathcal{G}_\varepsilon$ are chosen to be

$$\begin{aligned} &\psi^\varepsilon = c^\varepsilon\{1 + i\varepsilon a_\varepsilon\zeta_{\mathbf{n}_0} - \varepsilon^2 a_\varepsilon^2 f_{\mathbf{n}_0} + i\varepsilon^2\rho^\varepsilon a_\varepsilon \varphi_1^\varepsilon\},\\ &\mathbf{n}^\varepsilon = \mathbf{n}_0 + \varepsilon\rho^\varepsilon\mathbf{u}^\varepsilon,\\ &\text{where}\quad \mathbf{n}_0\in\mathcal{C}_*(\tau),\quad \mathbf{u}^\varepsilon = \mathbf{v}^\varepsilon + \varepsilon\rho^\varepsilon\mathbf{w}^\varepsilon,\quad \varphi_1^\varepsilon = \zeta_{\mathbf{u}^\varepsilon}, \end{aligned} \tag{4.40}$$

where $\zeta_{\mathbf{u}^\varepsilon}$ is the solution of (1.7) for $\mathbf{u} = \mathbf{u}^\varepsilon$. Now we explain how φ_1^ε is chosen.

Case 1. ρ^ε satisfies

$$\varepsilon \ll \rho^\varepsilon \ll \varepsilon|\log\varepsilon| \quad \text{as } \varepsilon\to 0. \tag{4.41}$$

Checking the term of order $O((\varepsilon\rho^\varepsilon)^2)$ in the right-hand side of (4.35), we naturally choose $\varphi_1^\varepsilon = \zeta_{\mathbf{u}^\varepsilon}$. Then from (4.35) and (4.39) we find

$$\begin{aligned} &\varepsilon^{-2}\mathcal{G}_\varepsilon[\psi^\varepsilon,\mathbf{n}^\varepsilon] - d_0(\varepsilon) - T_{\varepsilon,\rho^\varepsilon}[\mathbf{u}^\varepsilon]\\ &= -\varepsilon^2 a_\varepsilon^2|c^\varepsilon|^2(1-|c^\varepsilon|^2)\int_\Omega|\zeta_{\mathbf{n}_0}|^2dx + \varepsilon^2 a_\varepsilon^4|c^\varepsilon|^2\int_\Omega(|\zeta_{\mathbf{n}_0}|^2 - |\nabla f_{\mathbf{n}_0}|^2)dx\\ &\quad + (\varepsilon\rho^\varepsilon)^2 a_\varepsilon^2|c^\varepsilon|^2\omega(\mathbf{u}^\varepsilon)|\Omega| + O(\varepsilon^3\rho^\varepsilon)\\ &= \varepsilon^2 a_\varepsilon^2|c^\varepsilon|^2\left\{(a_\varepsilon^2 - 1 + |c^\varepsilon|^2)\|\zeta_{\mathbf{n}_0}\|^2_{L^2(\Omega)} - a_\varepsilon^2\|\nabla f_{\mathbf{n}_0}\|^2_{L^2(\Omega)}\right\}\\ &\quad + (\varepsilon\rho^\varepsilon)^2 a_\varepsilon^2|c^\varepsilon|^2\omega(\mathbf{u}^\varepsilon)|\Omega| + O(\varepsilon^3\rho^\varepsilon) + O(\varepsilon^4). \end{aligned}$$

From (4.14), (4.25), and (4.40) we have, under the condition (4.41),

$$\begin{aligned} &\varepsilon^{-2}\mathcal{G}_\varepsilon[\psi^\varepsilon,\mathbf{n}^\varepsilon]\\ &= d_0(\varepsilon) + T_{\varepsilon,\rho^\varepsilon}[\mathbf{u}^\varepsilon] + \varepsilon^2 a_\varepsilon^2|c^\varepsilon|^2\left\{(a_\varepsilon^2 - 1 + |c^\varepsilon|^2)\|\zeta_{\mathbf{n}_0}\|^2_{L^2(\Omega)} - a_\varepsilon^2\|\nabla f_{\mathbf{n}_0}\|^2_{L^2(\Omega)}\right\}\\ &\quad + (\varepsilon\rho^\varepsilon)^2 a_\varepsilon^2|c^\varepsilon|^2\omega(\mathbf{u}^\varepsilon)|\Omega| + O(\varepsilon^3\rho^\varepsilon)\\ &= d_0(\varepsilon) - \varepsilon^2[a_\varepsilon^4(1 - a_\varepsilon^2\omega_*(\tau))^2\mu_w(\mathbf{n}_0)^2 + d_1(\varepsilon,\mathbf{n}_0)] + o(\varepsilon^2), \end{aligned}$$

where

$$d_1(\varepsilon,\mathbf{n}_0) = a_\varepsilon^4(1 - a_\varepsilon^2\omega_*(\tau))\left\{\|\nabla f_{\mathbf{n}_0}\|^2_{L^2(\Omega)} - (1-\omega_*(\tau))\|\zeta_{\mathbf{n}_0}\|^2_{L^2(\Omega)}\right\}. \tag{4.42}$$

Thus, under the condition (4.41) we have

$$\mathcal{G}_\varepsilon[\psi^\varepsilon,\mathbf{n}^\varepsilon] = d_0(\varepsilon)\varepsilon^2 - d_1(\varepsilon)\varepsilon^4 + o(\varepsilon^4). \tag{4.43}$$

Case 2. $\rho^\varepsilon = O(\varepsilon)$. In this case, (4.43) remains valid if we also choose $\varphi_1^\varepsilon = \zeta_{\mathbf{u}^\varepsilon}$. However, we mention that, if we wish to get a better estimate in the higher order terms, we may compute all the terms of order $O(\varepsilon^4)$ in the right-hand side of (4.35) to determine a better choice of φ_1^ε.

Summarizing the above discussions we have the following proposition.

Proposition 4.6. *Assume $\mu_*(\tau) < +\infty$. We have the energy upper bound estimate*

$$C(K_1, K_2, \varepsilon, \tau, a_\varepsilon\varepsilon) \le d_0(\varepsilon)\varepsilon^2 - \varepsilon^4[a_\varepsilon^4(1 - a_\varepsilon^2\omega_*(\tau))^2\mu_*(\tau)^2 + d_1(\varepsilon)] + o(\varepsilon^4), \tag{4.44}$$

where

$$d_1(\varepsilon) = \inf_{\mathbf{n}_0 \in \mathcal{C}_*(\tau)} d_1(\varepsilon, \mathbf{n}_0). \tag{4.45}$$

Step 5. *Constructing test functions for $\mathcal{G}_\varepsilon$ when $\mu_*(\tau) = +\infty$.* When $\mu_w(\mathbf{n}_0) = +\infty$, we use Lemma 4.5 for $\delta_\varepsilon = \varepsilon^2|\log\varepsilon|$ to find $\mathbf{v}^\varepsilon$, $\mathbf{w}^\varepsilon$, and ρ^ε satisfying (4.29) such that (4.30) holds, that is,

$$T_{\varepsilon,\rho^\varepsilon}[\mathbf{v}^\varepsilon + \varepsilon\rho^\varepsilon\mathbf{w}^\varepsilon] = -\varepsilon^2 a_\varepsilon^4|c^\varepsilon|^4 L^\varepsilon + O(\varepsilon^4|\log\varepsilon|^3),$$

where $L^\varepsilon \to +\infty$. Then we define the test functions ψ^ε and $\mathbf{n}^\varepsilon$ by (4.40) with $\varphi_1^\varepsilon = \zeta_{\mathbf{u}^\varepsilon}$. Similar to the computations in Step 5, we have

$$\begin{aligned}
&\varepsilon^{-2}\mathcal{G}_\varepsilon[\psi^\varepsilon, \mathbf{n}^\varepsilon] \\
&= d_0(\varepsilon) + T_{\varepsilon,\rho^\varepsilon}[\mathbf{u}^\varepsilon] + \varepsilon^2 a_\varepsilon^2|c^\varepsilon|^2\left\{(a_\varepsilon^2 - 1 + |c^\varepsilon|^2)\|\zeta_{\mathbf{n}_0}\|^2_{L^2(\Omega)} - a_\varepsilon^2\|\nabla f_{\mathbf{n}_0}\|^2_{L^2(\Omega)}\right\} \\
&\quad + (\varepsilon\rho^\varepsilon)^2 a_\varepsilon^2|c^\varepsilon|^2\omega(\mathbf{u}^\varepsilon)|\Omega| + O(\varepsilon^3\rho^\varepsilon) \\
&\le d_0(\varepsilon) - \varepsilon^2 L^\varepsilon a_\varepsilon^4(1 - a_\varepsilon^2\omega_*(\tau))^2 - \varepsilon^2 d_1(\varepsilon, \mathbf{n}_0) + o(\varepsilon^2).
\end{aligned}$$

So we have the following proposition.

Proposition 4.7. *Assume $\mu_*(\tau) = +\infty$. Then we have the energy upper bound estimate*

$$C(K_1, K_2, \varepsilon, \tau, a_\varepsilon\varepsilon) \le d_0(\varepsilon)\varepsilon^2 - \varepsilon^4 L^\varepsilon a_\varepsilon^4(1 - a_\varepsilon^2\omega_*(\tau))^2 - \varepsilon^4 d_{1,\infty}(\varepsilon) + o(\varepsilon^4), \tag{4.46}$$

where

$$d_{1,\infty}(\varepsilon) = \inf_{\mathbf{n}_0 \in \mathcal{C}_*(\tau),\ \mu_w(\mathbf{n}_0) = +\infty} d_1(\varepsilon, \mathbf{n}_0). \tag{4.47}$$

Proof of Theorem 4.2. The proof follows from Propositions 4.6 and 4.7. ∎

5. Asymptotics of minimizers for small . In this section we investigate the behavior of the minimizers for small κ. We always assume the condition (1.2), and let ε denote κ. In the following we write the minimizers of $\mathcal{G}$ by $(\psi_\varepsilon, \mathbf{n}_\varepsilon)$. Note that they depend also on the wave number q.

Theorem 5.1. *Assume* (1.2) *and* (4.1) *hold. For small $\varepsilon > 0$, let $q = a_\varepsilon\varepsilon$, where*

$$\begin{gathered}
0 < a_\varepsilon < \frac{1}{\varepsilon}Q_{c_3}(K_1, K_2, \varepsilon, \tau), \\
\lim_{\varepsilon \to 0^+} a_\varepsilon = a_0 \le \frac{1}{\sqrt{\omega_*(\tau)}}.
\end{gathered} \tag{5.1}$$

We have the following:

(1) $C(K_1, K_2, \varepsilon, \tau, a_\varepsilon\varepsilon) = m(a_0)\varepsilon^2 + o(\varepsilon^2)$, *where*

$$m(a_0) = \begin{cases} \frac{1}{2}|\Omega| & \text{if } a_0 = \frac{1}{\sqrt{\omega_*(\tau)}}, \\ a_0^2\omega_*(\tau)[1 - \frac{1}{2}a_0^2\omega_*(\tau)]|\Omega| & \text{if } 0 < a_0 < \frac{1}{\sqrt{\omega_*(\tau)}}. \end{cases}$$

(2) *Let* $(\psi_\varepsilon, \mathbf{n}_\varepsilon)$ *be the minimizers of* $\mathcal{G}$ *for* $q = a_\varepsilon \varepsilon$. *Then there exist a subsequence and* $\mathbf{n}_0 \in \mathcal{C}_*(\tau)$ *such that*

$$\mathbf{n}_\varepsilon \to \mathbf{n}_0 \text{ weakly in } W^{1,2}_{loc}(\Omega, \mathbb{R}^3) \text{ and strongly in } L^p(\Omega, \mathbb{R}^3) \text{ for all } 1 \le p < \infty. \tag{5.2}$$

Moreover, the following expansions hold:

$$\begin{aligned} \psi_\varepsilon &= c_\varepsilon[1 + i a_\varepsilon \varepsilon(\zeta_{\mathbf{n}_0} + \varepsilon \rho_\varepsilon \varphi_\varepsilon)], \\ \mathbf{n}_\varepsilon &= \mathbf{n}_0 + \varepsilon \rho_\varepsilon \mathbf{u}_\varepsilon, \end{aligned} \tag{5.3}$$

where, as $\varepsilon \to 0$,

(i) $\rho_\varepsilon \ge 0$ *and* $\varepsilon \rho_\varepsilon \to 0$;

(ii) $\|\mathbf{u}_\varepsilon\|_{L^2(\Omega)} = 1$ *and* $\rho_\varepsilon^2 \mathcal{I}[\mathbf{u}_\varepsilon] \to 0$;

(iii) $\int_\Omega \varphi_\varepsilon dx = 0$ *and* $\varepsilon \rho_\varepsilon \varphi_\varepsilon \to 0$ *strongly in* $W^{1,2}(\Omega, \mathbb{C})$;

(iv) c_ε *is a complex number and*

$$|c_\varepsilon| \to \sqrt{[1 - a_0^2 \omega_*(\tau)]_+}. \tag{5.4}$$

Proof. The upper bound of energy follows from Theorem 4.2. Now we prove the lower bound. Let $q = a_\varepsilon \varepsilon$, where a_ε satisfies (5.1). From (4.9) we find

$$\begin{aligned} &\int_\Omega \Big\{ |\nabla_{a_\varepsilon \varepsilon \mathbf{n}_\varepsilon} \psi_\varepsilon|^2 + \frac{\varepsilon^2}{2}(1 - |\psi_\varepsilon|^2)^2 + K_1 |\text{div } \mathbf{n}_\varepsilon|^2 + K_2 |\text{curl } \mathbf{n}_\varepsilon + \tau \mathbf{n}_\varepsilon|^2 \Big\} dx \\ &\le d_0(\varepsilon)\varepsilon^2 + O(\varepsilon^4). \end{aligned} \tag{5.5}$$

As in the proof of Theorem 4.1 (Step 2) we can show that there exists a subsequence, still denoted by $(\psi_\varepsilon, \mathbf{n}_\varepsilon)$, such that (5.2) holds, where $\mathbf{n}_0 \in \mathcal{C}(\tau)$. From (5.5),

$$\int_\Omega |\nabla_{a_\varepsilon \varepsilon \mathbf{n}_\varepsilon} \psi_\varepsilon|^2 dx = O(\varepsilon^2).$$

Since $|\psi_\varepsilon(x)| \le 1$, we have

$$\|\nabla \psi_\varepsilon\|_{L^2(\Omega)} \le \|\nabla_{a_\varepsilon \varepsilon \mathbf{n}_\varepsilon} \psi_\varepsilon\|_{L^2(\Omega)} + a_\varepsilon \varepsilon \|\mathbf{n}_\varepsilon \psi_\varepsilon\|_{L^2(\Omega)} = O(\varepsilon)$$

and

$$\psi_\varepsilon \to c_0 \quad \text{strongly in } W^{1,2}(\Omega, \mathbb{C}) \text{ as } \varepsilon \to 0,$$

where c_0 is a constant. Let

$$c_\varepsilon = \fint_\Omega \psi_\varepsilon dx.$$

Then $c_\varepsilon \to c_0$ as $\varepsilon \to 0$.

CLAIM 1. $c_\varepsilon \ne 0$ *for all small* ε.

Suppose Claim 1 were not true. Passing to a subsequence if necessary, we have $c_\varepsilon = 0$ for all small ε. Then $\psi_\varepsilon \to 0$ in $W^{1,2}(\Omega, \mathbb{C})$ as $\varepsilon \to 0$. We write

$$\psi_\varepsilon = \varepsilon b_\varepsilon \phi_\varepsilon,$$

where $\int_\Omega \phi_\varepsilon dx = 0$, and $\|\phi_\varepsilon\|_{L^2(\Omega)} = 1$, $b_\varepsilon > 0$, and $\varepsilon b_\varepsilon \to 0$. Thus

$$\|\nabla \phi_\varepsilon\|^2_{L^2(\Omega)} \ge \mu_1 \|\phi_\varepsilon\|^2_{L^2(\Omega)} = \mu_1,$$

where

$$\mu_1 = \inf\left\{\|\nabla\phi\|^2_{L^2(\Omega)} :\ \phi \in W^{1,2}(\Omega),\ \|\phi\|_{L^2(\Omega)} = 1,\ \int_\Omega \phi dx = 0\right\}.$$

We have

$$\begin{aligned}
\varepsilon^{-2}\mathcal{G}_\varepsilon[\psi_\varepsilon, \mathbf{n}_\varepsilon] &\geq \frac{1}{\varepsilon^2}\int_\Omega \left\{|\nabla_{a_\varepsilon\varepsilon\mathbf{n}_\varepsilon}\psi_\varepsilon|^2 + \frac{1}{2}(1-\varepsilon^2 b_\varepsilon^2|\phi_\varepsilon|^2)^2\right\} dx \\
&= \frac{|\Omega|}{2} + b_\varepsilon^2 \int_\Omega |\nabla_{a_\varepsilon\varepsilon\mathbf{n}_\varepsilon}\phi_\varepsilon|^2 dx + O(\varepsilon^2 b_\varepsilon^2) \\
&= \frac{|\Omega|}{2} + b_\varepsilon^2 \left\{\int_\Omega |\nabla\phi_\varepsilon|^2 dx + O(\varepsilon)\right\} \\
&\geq \frac{|\Omega|}{2} + b_\varepsilon^2(\mu_1 + O(\varepsilon)) \\
&> \frac{|\Omega|}{2},
\end{aligned}$$

which contradicts the obvious upper bound $\mathcal{G}_\varepsilon[\psi_\varepsilon, \mathbf{n}_\varepsilon] < \frac{|\Omega|}{2}$. Thus Claim 1 is true.

Now we write

$$\psi_\varepsilon = c_\varepsilon(1 + ia_\varepsilon\varepsilon\phi_\varepsilon), \qquad \mathbf{n}_\varepsilon = \mathbf{n}_0 + \varepsilon\rho_\varepsilon\mathbf{u}_\varepsilon,$$

where $\int_\Omega \phi_\varepsilon dx = 0$ and $\|\mathbf{u}_\varepsilon\|_{L^2(\Omega)} = 1$. Since $c_\varepsilon \to c_0$, $\varepsilon\phi_\varepsilon \to 0$ in $W^{1,2}(\Omega, \mathbb{C})$, and $\mathbf{n}_\varepsilon \to \mathbf{n}_0$ in $L^4(\Omega, \mathbb{R}^3)$ as $\varepsilon \to 0$, we find

(5.6)

$$\begin{aligned}
\varepsilon^{-2}\mathcal{G}_\varepsilon[\psi_\varepsilon, \mathbf{n}_\varepsilon] = \int_\Omega \Bigg\{ & a_\varepsilon^2|c_\varepsilon|^2|\nabla\phi_\varepsilon - \mathbf{n}_\varepsilon - ia_\varepsilon\varepsilon\phi_\varepsilon\mathbf{n}_\varepsilon|^2 + \frac{1}{2}(1-|c_\varepsilon|^2|1+ia_\varepsilon\varepsilon\phi_\varepsilon|^2)^2 \\
&+ \rho_\varepsilon^2 K_1|\mathrm{div}\ \mathbf{u}_\varepsilon|^2 + \rho_\varepsilon^2 K_2|\mathrm{curl}\ \mathbf{u}_\varepsilon + \tau\mathbf{u}_\varepsilon|^2\Bigg\} dx \\
= \int_\Omega & \left\{a_0^2|c_\varepsilon|^2|\nabla\phi_\varepsilon - \mathbf{n}_0|^2 + \frac{1}{2}(1-|c_\varepsilon|^2)^2\right\} dx + \rho_\varepsilon^2\mathcal{I}[\mathbf{u}_\varepsilon] + o(1).
\end{aligned}$$

Let $f_{a_0,\mathbf{n}_0}(t)$ be the function defined in (4.7). From (2.1), (5.5), and (5.6), we have

$$\begin{aligned}
d_0(\varepsilon) - \rho_\varepsilon^2\mathcal{I}[\mathbf{u}_\varepsilon] + O(\varepsilon^2) &\geq \int_\Omega \left\{a_0^2|c_\varepsilon|^2|\nabla\phi_\varepsilon - \mathbf{n}_0|^2 + \frac{1}{2}(1-|c_\varepsilon|^2)^2\right\} dx + o(1) \\
&\geq \left\{a_0^2|c_\varepsilon|^2\omega(\mathbf{n}_0) + \frac{1}{2}(1-|c_\varepsilon|^2)^2\right\}|\Omega| + o(1) \\
&= \left\{a_0^2|c_0|^2\omega(\mathbf{n}_0) + \frac{1}{2}(1-|c_0|^2)^2\right\}|\Omega| + o(1) \\
&= f_{a_0,\mathbf{n}_0}(|c_0|)|\Omega| + o(1) \\
&\geq |\Omega| \min_{\mathbf{n}\in\mathcal{C}(\tau)} \min_{c\geq 0} f_{a_0,\mathbf{n}}(c) + o(1) \\
&= m(a_0) + o(1).
\end{aligned}$$

Note that $d_0(\varepsilon) = m_0(a_0) + o(1)$. Thus

$$
\begin{aligned}
&f_{a_0,\mathbf{n}_0}(|c_0|) = \frac{m(a_0)}{|\Omega|} = \min_{c\geq 0} f_{a_0,\mathbf{n}_0}(c) = f_{a_0,\mathbf{n}_0}\Big(\sqrt{[1-a_0^2\omega(\mathbf{n}_0)]_+}\Big),\\
&\omega(\mathbf{n}_0) = \omega_*(\tau),\\
&\lim_{\varepsilon\to 0}|c_\varepsilon| = |c_0| = \sqrt{[1-a_0^2\omega(\mathbf{n}_0)]_+},\\
&⨍_\Omega |\nabla\phi_\varepsilon - \mathbf{n}_0|^2 dx = \omega(\mathbf{n}_0) + o(1);
\end{aligned}
\tag{5.7}
$$

and

$$
\begin{aligned}
&\mathcal{G}_\varepsilon[\psi_\varepsilon, \mathbf{n}_\varepsilon] = m(a_0)\varepsilon^2 + o(\varepsilon^2),\\
&\rho_\varepsilon^2 \mathcal{I}[\mathbf{u}_\varepsilon] = o(1).
\end{aligned}
$$

From the last equality in (5.7) we find that, as $\varepsilon \to 0$,

$$\nabla\phi_\varepsilon = \nabla\zeta_{\mathbf{n}_0} + o(1) \quad \text{in } L^2(\Omega).$$

Since $\int_\Omega \phi_\varepsilon dx = 0$, we have

$$\phi_\varepsilon = \zeta_{\mathbf{n}_0} + o(1) \quad \text{in } W^{1,2}(\Omega).$$

Summarizing the above discussions, we get the conclusions of Theorem 5.1. ☐

Proof of Theorem 1.1. The proof follows from Theorems 4.1 and 5.1.

Appendix A. Proof of Lemma 2.3. We follow the idea of Evans in the proof of the div-curl lemma; see [E, p. 54]. Without loss of generality we assume $D_2 = \Omega$ and $\mathbf{u} \in V(\Omega, \mathbb{R}^3) \cap C^2(\bar\Omega, \mathbb{R}^3)$. Let D denote D_1. Let $\mathbf{w}$ be the solution of

$$\Delta\mathbf{w} = \mathbf{u} \quad \text{in } \Omega, \quad \mathbf{w} = \mathbf{0} \quad \text{on } \partial\Omega. \tag{A.1}$$

There exists a constant $C_1(\Omega)$ such that

$$\|\mathbf{w}\|_{W^{2,2}(\Omega,\mathbb{R}^3)} \leq C_1(\Omega)\|\mathbf{u}\|_{L^2(\Omega)}.$$

Let $\xi = \text{div } \mathbf{w}$ and $\mathbf{v} = \mathbf{u} - \nabla\xi = \Delta\mathbf{w} - \nabla\text{div } \mathbf{w} = -\text{curl }^2\mathbf{w}$. Then

$$\mathbf{u} = \mathbf{v} + \nabla\xi.$$

From (A.1), we have

$$\Delta(\text{curl } \mathbf{w}) = \text{curl } \mathbf{u} \quad \text{in } \Omega.$$

Applying the interior elliptic estimate we have

$$
\begin{aligned}
\|\text{curl } \mathbf{w}\|_{W^{2,2}(D,\mathbb{R}^3)} &\leq C_2(D,\Omega)\{\|\text{curl } \mathbf{w}\|_{W^{1,2}(\Omega,\mathbb{R}^3)} + \|\text{curl } \mathbf{u}\|_{L^2(\Omega)}\}\\
&\leq C_2(D,\Omega)\{\|\mathbf{w}\|_{W^{2,2}(\Omega,\mathbb{R}^3)} + \|\text{curl } \mathbf{u}\|_{L^2(\Omega)}\}\\
&\leq C_3(D,\Omega)\{\|\mathbf{u}\|_{L^2(\Omega)} + \|\text{curl } \mathbf{u}\|_{L^2(\Omega)}\}.
\end{aligned}
$$

Thus

$$
\begin{aligned}
\|\mathbf{v}\|_{W^{1,2}(D,\mathbb{R}^3)} = \|\text{curl}^2\mathbf{w}\|_{W^{1,2}(D,\mathbb{R}^3)} &\leq C_4\|\text{curl } \mathbf{w}\|_{W^{2,2}(D,\mathbb{R}^3)}\\
&\leq C_5(D,\Omega)\{\|\mathbf{u}\|_{L^2(\Omega)} + \|\text{curl } \mathbf{u}\|_{L^2(\Omega)}\}.
\end{aligned}
$$

Using (A.1) again, we have

$$\Delta(\text{div } \mathbf{w}) = \text{div } \mathbf{u} \quad \text{in } \Omega.$$

Applying the interior elliptic estimate again, we have

$$\begin{aligned}\|\text{div } \mathbf{w}\|_{W^{2,2}(D)} &\le C_6(D,\Omega)\{\|\text{div } \mathbf{w}\|_{W^{1,2}(\Omega)} + \|\text{div } \mathbf{u}\|_{L^2(\Omega)}\} \\ &\le C_7(D,\Omega)\{\|\mathbf{w}\|_{W^{2,2}(\Omega,\mathbb{R}^3)} + \|\text{div } \mathbf{u}\|_{L^2(\Omega)}\} \\ &\le C_8(D,\Omega)\{\|\mathbf{u}\|_{L^2(\Omega)} + \|\text{curl } \mathbf{u}\|_{L^2(\Omega)}\}.\end{aligned}$$

Hence

$$\begin{aligned}\|\nabla\xi\|_{W^{1,2}(D)} = \|\nabla(\text{div } \mathbf{w})\|_{W^{1,2}(D)} &\le \|\text{div } \mathbf{w}\|_{W^{2,2}(D)} \\ &\le C_8(D,\Omega)\{\|\mathbf{u}\|_{L^2(\Omega)} + \|\text{curl } \mathbf{u}\|_{L^2(\Omega)}\}.\end{aligned}$$

Now we have

$$\begin{aligned}\|\mathbf{u}\|_{W^{1,2}(D,\mathbb{R}^3)} &\le \|\mathbf{v}\|_{W^{1,2}(D,\mathbb{R}^3)} + \|\nabla\xi\|_{W^{1,2}(D)} \\ &\le C_9(D,\Omega)\{\|\mathbf{u}\|_{L^2(\Omega)} + \|\text{div } \mathbf{u}\|_{L^2(\Omega)} + \|\text{curl } \mathbf{u}\|_{L^2(\Omega)}\}. \qquad \square\end{aligned}$$

ON THE REGULARITY CONDITIONS FOR THE DISSIPATIVE QUASI-GEOSTROPHIC EQUATIONS*

DONGHO CHAE†

Abstract. We obtain regularity conditions for solutions of the dissipative quasi-geostrophic equation. The first one imposes on the integrability of the magnitude of the temperature gradient, and corresponds to the Serrin type of condition in the theory of Navier–Stokes equations. The other one incorporates the direction of normals to the level curves and the magnitude of the temperature gradient simultaneously. For the proof of the second result, in particular, we use geometric properties of the nonlinear term as well as the estimates using the Triebel–Lizorkin type of norms.

Key words. quasi-geostrophic equations, regularity conditions, Triebel–Lizorkin spaces

1. Introduction.

We are concerned with the regularity of the quasi-geostrophic equation with a dissipation term:

$$\frac{\partial\theta}{\partial t} + (v\cdot\nabla)\theta = -\kappa\Lambda^\alpha\theta, \tag{1.1}$$

$$v(x,t) = -\nabla^\perp(-\Delta)^{-\frac{1}{2}}\theta = -\int_{\mathbb{R}^2}\frac{\nabla^\perp\theta(x+y,t)}{|y|}dy, \tag{1.2}$$

$$\theta(x,0)=\theta_0(x), \tag{1.3}$$

where $\theta(x,t)$ is a scalar function representing temperature, $v(x,t)$ is the velocity field of the fluid, $\kappa\geq 0$ is the diffusion constant, $\Lambda^\alpha=(-\Delta)^{\frac{\alpha}{2}}$, and $\nabla^\perp=(-\partial_{x_2},\partial_{x_1})$. See, e.g., [5, 3, 10] for the instructive discussions and the physical and mathematical motivations of the study of (1.1)–(1.3), in particular of the inviscid case ($\kappa=0$). For $\alpha>1$ the global regularity of the solution of (1.1)–(1.3) is well known (see [6]). On the other hand, for $0\leq\alpha\leq 1$, the question of global regularity/finite time singularity is still a challenging open problem (see, e.g., [2, 4, 7, 8, 9, 15, 16, 17] for related studies). In particular, the critical dissipation case ($\alpha=1$) has similar features to the three-dimensional (3D) Navier–Stokes equations, and could be considered as its model problem. In order to see the similarities to the 3D Navier–Stokes equations (with fractional powers of Laplacian) more apparently we apply the operation $\nabla^\perp$ to (1.1) to obtain

$$\frac{\partial\nabla^\perp\theta}{\partial t} + (v\cdot\nabla)\nabla^\perp\theta = (\nabla^\perp\theta\cdot\nabla)v - \kappa\Lambda^\alpha\nabla^\perp\theta. \tag{1.4}$$

Then, we observe that $\nabla^\perp\theta$ has the role of vorticity, and (1.2) corresponds to the Biot–Savart law for the 3D Navier–Stokes equations. In this note we are concerned with the sufficient conditions to guarantee regularity of solutions of the quasi-geostrophic equations, which have been studied by many authors for the case of the 3D Navier–Stokes equations since Prodi [11] and Serrin [12]. To the author's knowledge the only regularity condition available in the literature for (1.1)–(1.3) is the following one obtained by Constantin, Majda, and Tabak [5] (except its refinement in [1]):

$$\limsup_{t\nearrow T}\|\theta(t)\|_{H^m}<\infty \quad \text{if and only if} \quad \int_0^T\|\nabla^\perp\theta(t)\|_{L^\infty}dt<\infty, \tag{1.5}$$

where $m>2$, which holds for solutions of both viscous and inviscid ($\kappa=0$) equations. Our first theorem generalizes this as follows.

THEOREM 1.1. *Let $\theta(x,t)$ be a solution of the quasi-geostrophic equation* (1.1)–(1.3) *with $\alpha\in(0,1]$, $\kappa>0$, and its derivative $\nabla^\perp\theta$ satisfies*

$$\nabla^\perp\theta\in L^r(0,T;L^p(\mathbb{R}^2)) \quad \textit{for some } p,r \textit{ with} \quad \frac{2}{p}+\frac{\alpha}{r}\le\alpha,\quad \frac{2}{\alpha}<p<\infty; \tag{1.6}$$

then there is no singularity up to T.

Remark 1.1. We observe that $p=\infty$, $r=1$ corresponds to (1.5) for any $\alpha\in(0,1]$.

Remark 1.2. We note that the system (1.1)–(1.2) has symmetry under the scaling transform

$$\theta(x,t)\to\theta^\lambda(x,t)=\lambda^{\alpha-1}\theta(\lambda x,\lambda^\alpha t).$$

Under this scaling transform we have the invariance of the norms,

$$\|\nabla^\perp\theta\|_{L^r(0,T;L^p(\mathbb{R}^2))}=\|\nabla^\perp\theta^\lambda\|_{L^r(0,\lambda^\alpha T;L^p(\mathbb{R}^2))} \quad \text{if} \quad \frac{2}{p}+\frac{\alpha}{r}=\alpha.$$

In this sense the condition (1.6) is optimal.

For the statement of our next theorem we introduce a function space. Given $0<\alpha<1$, $1\le p\le\infty$, $1\le q\le\infty$, the function space $\dot{\mathcal{F}}^s_{p,q}$ is defined by the seminorm

$$\|f\|_{\dot{\mathcal{F}}^s_{p,q}}=\begin{cases}\left\|\left(\int_{\mathbb{R}^n}\frac{|f(x+y)-f(x)|^q}{|y|^{n+sq}}dy\right)^{\frac{1}{q}}\right\|_{L^p(\mathbb{R}^n,dx)} & \text{if } 1\le p\le\infty,\ 1\le q<\infty,\\ \left\|ess\sup_{|y|\neq0}\frac{|f(x+y)-f(x)|}{|y|^s}\right\|_{L^p(\mathbb{R}^n,dx)} & \text{if } 1\le p\le\infty,\ q=\infty.\end{cases}$$

Observe that, in particular, $\dot{\mathcal{F}}^s_{\infty,\infty}\cong C^s$, the usual Hölder seminormed space. In order to compare this space with other more classical function spaces let us introduce the Banach space $\mathcal{F}^s_{p,q}$ by defining its norm,

$$\|f\|_{\mathcal{F}^s_{p,q}}=\|f\|_{L^p}+\|f\|_{\dot{\mathcal{F}}^s_{p,q}}.$$

We note that for $0<s<1$, $2\le p<\infty$, and $q=2$, $\mathcal{F}^s_{p,2}\cong L^p_s(\mathbb{R}^n)=(1-\Delta)^{-\frac{s}{2}}L^p(\mathbb{R}^n)$, the fractional order Sobolev space (or the Bessel potential space); see [13, p. 163]. On the other hand, if $\frac{n}{\min\{p,q\}} < s < 1$, $n < p < \infty$, and $n < q \le \infty$, then $\mathcal{F}^s_{p,q}$ coincides with the usual Triebel–Lizorkin space $F^s_{p,q}$ (see [14, p. 101]). The following is our second main theorem.

THEOREM 1.2. *Let $\theta(x,t)$ be a solution of the dissipative quasi-geostrophic equation* (1.1)–(1.3) *with $\kappa > 0$. Let $\xi(x,t)$ be its direction field, $\xi(x,t) = \nabla^\perp\theta(x)/|\nabla^\perp\theta(x)|$ defined for $\nabla^\perp\theta(x,t) \neq 0$. Suppose there exist $s \in (0,1)$, $q \in (\frac{2}{2-s}, \infty]$, $p_1 \in (1,\infty]$, $p_2 \in (1, \frac{2}{s})$ satisfying $\frac{s}{2} < \frac{1}{p_1} + \frac{1}{p_2} < \frac{s+\alpha}{2}$, and $r_1, r_2 \in [1,\infty]$ such that the following hold:*

$$\xi(x,t) \in L^{r_1}(0,T;\dot{\mathcal{F}}^s_{p_1,q}) \quad \textit{and} \quad \nabla^\perp\theta(x,t) \in L^{r_2}(0,T;L^{p_2}(\mathbb{R}^2))$$

$$\textit{with} \qquad \frac{2}{p_1} + \frac{2}{p_2} + \frac{\alpha}{r_1} + \frac{\alpha}{r_2} \le \alpha + s. \tag{1.7}$$

Then, the solution $\theta(x,t)$ is regular up to T.

Remark 1.3. The condition (1.7) describes quantitatively that by assuming regularity of the direction field $\xi(x,t)$ we can have regularity of solution with assumption of lower integrability of $|\nabla^\perp\theta(x,t)|$ than required by Theorem 1.1.

2. Proof of the main theorems.

Proof of Theorem 1.1. We plan to show that our integrability condition for $\nabla^\perp\theta$ in Theorem 1.1 implies

$$\int_0^T \|\nabla^\perp\theta(t)\|_{L^\infty} dt < \infty, \tag{2.1}$$

thus guaranteeing the desired regularity until T by (1.5). We take $L^2(\mathbb{R}^2)$ inner product of (1.4) with $\Delta\nabla^\perp\theta$ and integrate it by parts to obtain

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|\Lambda^2\theta(t)\|^2_{L^2} + \kappa\|\Lambda^{2+\frac{\alpha}{2}}\theta\|^2_{L^2} &= \int_{\mathbb{R}^2}(v\cdot\nabla)\nabla^\perp\theta\cdot\Delta\nabla^\perp\theta dx\\ &\quad - \int_{\mathbb{R}^2}(\nabla^\perp\theta\cdot\nabla)v\cdot\Delta\nabla^\perp\theta dx = I + J.\end{aligned} \tag{2.2}$$

Integrating by parts, we have

$$\begin{aligned} I &= -\int_{\mathbb{R}^2}\nabla[(v\cdot\nabla)\nabla^\perp\theta]\cdot\nabla\nabla^\perp\theta dx\\ &= -\int_{\mathbb{R}^2}(\nabla v)(\nabla\nabla^\perp\theta)\cdot\nabla\nabla^\perp\theta dx - \int_{\mathbb{R}^2}(v\cdot\nabla)\nabla\nabla^\perp\theta\cdot\nabla\nabla^\perp\theta dx\\ &= I_1 + I_2.\end{aligned}$$

Integrating by parts again, and using the fact that $\operatorname{div} v = 0$, we derive

$$I_2 = -\frac{1}{2}\int_{\mathbb{R}^2}(v\cdot\nabla)|\nabla\nabla^\perp\theta|^2 dx = \frac{1}{2}\int_{\mathbb{R}^2}(\operatorname{div} v)|\nabla\nabla^\perp\theta|^2 dx = 0. \tag{2.3}$$

In the case $\frac{4}{\alpha} \le p < \infty$ we estimate

$$\begin{aligned} I_1 &\le \int_{\mathbb{R}^2}|\nabla v||\nabla\nabla^\perp\theta|^2 dx\\ &\le \|\nabla\nabla^\perp\theta\|_{L^2}\|\nabla v\|_{L^p}\|\nabla\nabla^\perp\theta\|_{L^{\frac{2p}{p-2}}} \quad \text{(Hölder's inequality)}\end{aligned}$$

$$
\begin{aligned}
&\leq C\|\nabla\nabla^\perp\theta\|_{L^2}\|\nabla v\|_{L^p}\|\nabla\nabla^\perp\theta\|_{L^2}^{1-\frac{4}{\alpha p}}\\
&\quad\times\|\Lambda^{\frac{\alpha}{2}}\nabla\nabla^\perp\theta\|_{L^2}^{\frac{4}{\alpha p}} \quad \text{(Gagliardo–Nirenberg's inequality)}\\
&\leq C\|\Lambda^2\theta\|_{L^2}^{2-\frac{4}{\alpha}}\|\nabla^\perp\theta\|_{L^p}\|\Lambda^{2+\frac{\alpha}{2}}\theta\|_{L^2}^{\frac{4}{\alpha}} \quad \text{(Calderon–Zygmund's inequality)}\\
&\leq \frac{\kappa}{4}\|\Lambda^{2+\frac{\alpha}{2}}\theta\|_{L^2}^2 + C\|\nabla^\perp\theta\|_{L^p}^{\frac{\alpha p}{\alpha p-2}}\|\Lambda^2\theta\|_{L^2}^2 \quad \text{(Young's inequality)}, \qquad (2.4)
\end{aligned}
$$

while in the case $\frac{2}{\alpha} < p < \frac{4}{\alpha}$, we estimate

$$
\begin{aligned}
I_1 &\leq \|\nabla\nabla^\perp\theta\|_{L^{\frac{4}{2-\alpha}}}\|\nabla v\|_{L^p}\|\nabla\nabla^\perp\theta\|_{L^{\frac{4p}{2p-4+\alpha p}}} \quad \text{(Hölder's inequality)}\\
&\leq C\|\Lambda^{\frac{\alpha}{2}}\nabla\nabla^\perp\theta\|_{L^2}\|\nabla v\|_{L^p}\|\nabla\nabla^\perp\theta\|_{L^2}^{2-\frac{4}{\alpha p}}\|\Lambda^{\frac{\alpha}{2}}\nabla\nabla^\perp\theta\|_{L^2}^{\frac{4}{\alpha p}-1}\\
&\quad \text{(Sobolev's and Gagliardo–Nirenberg's inequalities)}\\
&\leq C\|\Lambda^2\theta\|_{L^2}^{2-\frac{4}{\alpha}}\|\nabla^\perp\theta\|_{L^p}\|\Lambda^{2+\frac{\alpha}{2}}\theta\|_{L^2}^{\frac{4}{\alpha}} \quad \text{(Calderon–Zygmund's inequality)}\\
&\leq \frac{\kappa}{4}\|\Lambda^{2+\frac{\alpha}{2}}\theta\|_{L^2}^2 + C\|\nabla^\perp\theta\|_{L^p}^{\frac{\alpha p}{\alpha p-2}}\|\Lambda^2\theta\|_{L^2}^2 \quad \text{(Young's inequality)}. \qquad (2.5)
\end{aligned}
$$

In order to estimate J we first integrate by parts:

$$
\begin{aligned}
J &= \int_{\mathbb{R}^2} \nabla[(\nabla^\perp\theta\cdot\nabla)v]\cdot\nabla\nabla^\perp\theta dx\\
&= \int_{\mathbb{R}^2} \nabla\nabla^\perp\theta\cdot\nabla v\cdot\nabla\nabla^\perp\theta dx + \int_{\mathbb{R}^2}(\nabla^\perp\theta\cdot\nabla)\nabla v\cdot\nabla\nabla^\perp\theta dx.
\end{aligned}
$$

Since $\|\nabla\nabla v\|_{L^q} \leq C\|\nabla\nabla^\perp\theta\|_{L^q}$, $1<q<\infty$, due to the Calderon–Zygmund inequality, we observe that the estimate of J is the same as the estimate of I_1, and we have

$$
J \leq \frac{\kappa}{4}\|\Lambda^{2+\frac{\alpha}{2}}\theta\|_{L^2}^2 + C\|\nabla^\perp\theta\|_{L^p}^{\frac{\alpha p}{\alpha p-2}}\|\Lambda^2\theta\|_{L^2}^2. \tag{2.6}
$$

Combining the estimates (2.3)–(2.6) and absorbing the diffusion term into the left-hand side, we obtain

$$
\frac{d}{dt}\|\Lambda^2\theta\|_{L^2}^2 + \kappa\|\Lambda^{2+\frac{\alpha}{2}}\theta\|_{L^2}^2 \leq C\|\nabla^\perp\theta\|_{L^p}^{\frac{\alpha p}{\alpha p-2}}\|\Lambda^2\theta\|_{L^2}^2. \tag{2.7}
$$

By Gronwall's lemma,

$$
\|\Lambda^2\theta(t)\|_{L^2} \leq \|\Lambda^2\theta_0\|_{L^2}\exp\left[C\int_0^T \|\nabla^\perp\theta(t)\|_{L^p}^{\frac{\alpha p}{\alpha p-2}}dt\right] \quad \forall t\in[0,T].
$$

Hence, $\|\Lambda^2\theta(t)\|_{L^2} \in L^\infty(0,T)$. Integrating (2.7) over $[0,T]$, we have

$$
\begin{aligned}
&\|\Lambda^2\theta(t)\|_{L^2}^2 + \kappa\int_0^T \|\Lambda^{2+\frac{\alpha}{2}}\theta(t)\|_{L^2}^2 dt\\
&\qquad \leq C\int_0^T \|\nabla^\perp\theta(t)\|_{L^p}^{\frac{\alpha p}{\alpha p-2}}dt \sup_{0\leq t\leq T}\|\Lambda^2\theta(t)\|_{L^2}^2 + \|\Lambda^2\theta_0\|_{L^2}^2,
\end{aligned}
$$

which implies $\int_0^T \|\Lambda^{2+\frac{\alpha}{2}}\theta(t)\|_{L^2}^2 dt < \infty$. Applying the Gagliardo–Nirenberg inequality,

$$
\|\nabla f\|_{L^\infty} \leq C\|f\|_{L^2}^{\frac{\alpha}{4+\alpha}}\|\Lambda^{2+\frac{\alpha}{2}}f\|_{L^2}^{\frac{4}{4+\alpha}},
$$

in $\mathbb{R}^2$, we have

$$\int_0^T \|\nabla\theta(t)\|_{L^\infty} dt \le C \int_0^T \|\theta(t)\|_{L^2}^{\frac{\alpha}{4+\alpha}} \|\Lambda^{2+\frac{\alpha}{2}}\theta(t)\|_{L^2}^{\frac{4}{4+\alpha}} dt$$
$$\le C\|\theta_0\|_{L^2}^{\frac{\alpha}{4+\alpha}} T^{\frac{2+\alpha}{4+\alpha}} \left(\int_0^T \|\Lambda^{2+\frac{\alpha}{2}}\theta\|_{L^2}^2 dt\right)^{\frac{2}{4+\alpha}} < \infty.$$

Hence, (2.1) is proved. ◻

Proof of Theorem 1.2. Let p be an integer of the form $p = 2^m$, where m is a positive integer, and satisfy

$$\frac{2}{\alpha} \le p < \infty. \tag{2.8}$$

Taking $L^2(\mathbb{R}^2)$ inner product of (1.4) with $\nabla^\perp\theta(x,t)|\nabla^\perp\theta(x,t)|^{p-2}$ and substituting v from (1.2) into it, we have after integration by parts

$$\begin{aligned}
&\frac{1}{p}\frac{d}{dt}\|\nabla^\perp\theta(t)\|_{L^p}^p + \kappa \int_{\mathbb{R}^2} (\Lambda^\alpha \nabla^\perp\theta)\cdot\nabla^\perp\theta|\nabla^\perp\theta|^{p-2}dx\\
&= \int_{\mathbb{R}^2} (\nabla^\perp\theta\cdot\nabla)v\cdot\nabla^\perp\theta|\nabla^\perp\theta|^{p-2}dx\\
&= \int_{\mathbb{R}^2}\int_{\mathbb{R}^2} [\nabla\theta(x,t)\cdot\hat{y}][\nabla^\perp\theta(x+y,t)\cdot\nabla\theta(x,t)]\frac{dy}{|y|^2}|\nabla^\perp\theta(x,t)|^{p-2}dx\\
&:= I,
\end{aligned}\tag{2.9}$$

where the integral with respect to y in the right-hand side is in the sense of principal value. We start estimating the dissipation term

$$\begin{aligned}
\kappa \int_{\mathbb{R}^2} (\nabla^\perp\theta\cdot\nabla)v\cdot\nabla^\perp\theta|\nabla^\perp\theta|^{p-2}dx &\ge \frac{\kappa}{p}\int_{\mathbb{R}^2} \left|\Lambda^{\frac{\alpha}{2}}|\nabla^\perp\theta|^{\frac{p}{2}}\right|^2 dx\\
&\ge \frac{\kappa C_\alpha}{p}\left(\int_{\mathbb{R}^2} |\nabla^\perp\theta|^{\frac{2p}{2-\alpha}}dx\right)^{\frac{2-a}{2}} = \frac{\kappa C_\alpha}{p}\|\nabla^\perp\theta\|_{L^{\frac{2p}{2-\alpha}}}^p,
\end{aligned}\tag{2.10}$$

where we used Lemma 2.4 of [8] for the estimate of the fractional derivative in the first inequality, and the Sobolev imbedding, $L^2_{\frac{\alpha}{2}}(\mathbb{R}^2) \hookrightarrow L^{\frac{4}{2-\alpha}}(\mathbb{R}^2)$, in the second inequality. Next, we estimate I as follows:

$$\begin{aligned}
I &= \int_{\mathbb{R}^2}\int_{\mathbb{R}^2} (\xi^\perp(x,t)\cdot\hat{y})[\xi(x+y,t)\cdot\xi^\perp(x,t)]|\nabla^\perp\theta(x+y,t)|\frac{dy}{|y|^2}|\nabla^\perp\theta(x,t)|^p dx\\
&= \int_{\mathbb{R}^2}\int_{\mathbb{R}^2} (\xi^\perp(x,t)\cdot\hat{y})[\xi(x+y,t)-\xi(x,t)]\cdot\xi^\perp(x,t)|\nabla^\perp\theta(x+y,t)|\frac{dy}{|y|^2}|\nabla^\perp\theta(x,t)|^p dx\\
&\le \int_{\mathbb{R}^2}\int_{\mathbb{R}^2} |\xi(x+y,t)-\xi(x,t)||\nabla^\perp\theta(x+y,t)|\frac{dy}{|y|^2}|\nabla^\perp\theta(x,t)|^p dx\\
&\le \int_{\mathbb{R}^2}\left(\int_{\mathbb{R}^2}\frac{|\xi(x+y,t)-\xi(x,t)|^q}{|y|^{2+sq}}dy\right)^{\frac{1}{q}}\left(\int_{\mathbb{R}^2}\frac{|\nabla^\perp\theta(x+y,t)|^{q'}}{|y|^{2-sq'}}dy\right)^{\frac{1}{q'}}|\nabla^\perp\theta|^p dx\\
&\le \|\xi\|_{\dot{\mathcal{F}}^s_{p_1,q}}\left\|\{I_{\alpha q'}(|\nabla^\perp\theta|^{q'})\}^{\frac{1}{q'}}\right\|_{L^{\tilde{p}_2}}\|\nabla^\perp\theta\|_{L^{p_3}}^p,
\end{aligned}\tag{2.11}$$

where we used the fact that $\xi(x,t)\cdot\xi^\perp(x,t)=0$ in the second equality, and Hölder's inequality in the second and the third inequalities with the exponents satisfying

$$\frac{1}{p_1}+\frac{1}{\tilde p_2}+\frac{p}{p_3}=1,\qquad \frac{1}{q}+\frac{1}{q'}=1, \tag{2.12}$$

and $I_\sigma(\cdot)$, $0<\sigma<2$, is the operator defined by the Riesz potential as follows:

$$I_\sigma(f)(x)=\gamma(\sigma)\int_{\mathbb{R}^2}\frac{f(x+y)}{|y|^{2-\sigma}}dy,\quad \gamma(\sigma)=2^\sigma\pi\frac{\Gamma(\frac{\sigma}{2})}{\Gamma(\frac{2-\sigma}{2})}.$$

From the well-defined property of the Riesz operator we have the restriction $0<sq'<2$, which gives us $q\in(\frac{2}{2-s},\infty]$ due to the second equation of (2.12). Using the Hardy–Littlewood–Sobolev inequality [13], we estimate

$$\begin{aligned}\left\|\{I_{sq'}(|\nabla^\perp\theta|^{q'})\}^{\frac{1}{q'}}\right\|_{L^{p_2}}&=\|I_{sq'}(|\nabla^\perp\theta|^{q'})\|^{\frac{1}{q'}}_{L^{\frac{\tilde p_2}{q'}}}\\&\le C\||\nabla^\perp\theta|^{q'}\|^{\frac{1}{q'}}_{L^r}=C\|\nabla^\perp\theta\|_{L^{rq'}}=C\|\nabla^\perp\theta\|_{L^{\frac{2\tilde p_2}{2+s\tilde p_2}}},\end{aligned}\tag{2.13}$$

where we used the relation $\frac{1}{r}=\frac{q'}{\tilde p_2}+\frac{sq'}{2}$, and hence $rq'=\frac{2\tilde p_2}{2+s\tilde p_2}$. On the other hand, using the L^p interpolation inequality, we estimate

$$\begin{aligned}\|\nabla^\perp\theta\|^p_{L^{p_3}}&\le\|\nabla^\perp\theta\|^{p(1+\frac{2p}{\alpha p_3}-\frac{2}{\alpha})}_{L^p}\|\nabla^\perp\theta\|^{p(\frac{2}{\alpha}-\frac{2p}{\alpha p_3})}_{L^{\frac{2p}{2-\alpha}}}\\&=\|\nabla^\perp\theta\|^{p-\frac{2p}{\alpha p_1}-\frac{2p}{\alpha\tilde p_2}}_{L^p}\|\nabla^\perp\theta\|^{\frac{2p}{\alpha p_1}+\frac{2p}{\alpha\tilde p_2}}_{L^{\frac{2p}{2-\alpha}}}.\end{aligned}\tag{2.14}$$

Note that use of the interpolation inequality in (2.14) requires that $p<p_3<\frac{2p}{2-\alpha}$, which, in turn, gives us the condition

$$0<\frac{1}{p_1}+\frac{1}{\tilde p_2}<\frac{\alpha}{2}\tag{2.15}$$

due to the first equation of (2.12). Combining (2.11) with (2.13) and (2.14), we derive

$$\begin{aligned}I&\le C\|\xi\|_{\dot{\mathcal{F}}^s_{p_1,q}}\|\nabla^\perp\theta\|_{L^{\frac{2\tilde p_2}{2+s\tilde p_2}}}\|\nabla^\perp\theta\|^{p-\frac{2p}{\alpha p_1}-\frac{2p}{\alpha\tilde p_2}}_{L^p}\|\nabla^\perp\theta\|^{\frac{2p}{\alpha p_1}+\frac{2p}{\alpha\tilde p_2}}_{L^{\frac{2p}{2-\alpha}}}\\&\le C\left(\|\xi\|_{\dot{\mathcal{F}}^s_{p_1,q}}\|\nabla^\perp\theta\|_{L^{\frac{2\tilde p_2}{2+s\tilde p_2}}}\right)^{\frac{\alpha p_1\tilde p_2}{\alpha p_1\tilde p_2-2p_1-2\tilde p_2}}\|\nabla^\perp\theta\|^p_{L^p}+\frac{\kappa C_\alpha}{2}\|\nabla^\perp\theta\|^p_{L^{\frac{2p}{2-\alpha}}},\end{aligned}\tag{2.16}$$

where we used Young's inequality, $ab\le\frac{a^u}{u}+\frac{b^{u'}}{u'}$, with

$$a=\|\xi\|_{\dot{\mathcal{F}}^s_{p_1,q}}\|\nabla^\perp\theta\|_{L^{\frac{2\tilde p_2}{2+s\tilde p_2}}}\|\nabla^\perp\theta\|^{p-\frac{2p}{\alpha p_1}-\frac{2p}{\alpha\tilde p_2}}_{L^p},\quad b=\|\nabla^\perp\theta\|^{\frac{2p}{\alpha p_1}+\frac{2p}{\alpha\tilde p_2}}_{L^{\frac{2p}{2-\alpha}}},$$

and

$$u=\frac{\alpha p_1\tilde p_2}{2(p_1+\tilde p_2)},\quad u'=\frac{\alpha p_1\tilde p_2}{\alpha p_1\tilde p_2-2(p_1+\tilde p_2)}.$$

Setting $\frac{2\tilde p_2}{2+s\tilde p_2}=p_2$, we have $\tilde p_2=\frac{2p_2}{2-sp_2}$. We observe here that there is the restriction $p_2<\frac{2}{s}$ due to positiveness of $\tilde p_2$. Substituting this value of $\tilde p$ into (2.16), we obtain

$$I\le C\|\xi\|^Q_{\dot{\mathcal{F}}^s_{p_1,q}}\|\nabla^\perp\theta\|^Q_{L^{p_2}}\|\nabla^\perp\theta\|^p_{L^p}+\frac{\kappa C_\alpha}{2}\|\nabla^\perp\theta\|^p_{L^{\frac{2p}{2-\alpha}}},\tag{2.17}$$

where we set

$$Q = \frac{\alpha p_1 p_2}{(\alpha + s)p_1 p_2 - 2p_1 - 2p_2}.$$

We note that the restriction (2.15) becomes

$$\frac{s}{2} < \frac{1}{p_1} + \frac{1}{p_2} < \frac{s}{2} + \frac{\alpha}{2} \tag{2.18}$$

in terms of p_1, p_2. We substitute the estimate (2.17) into (2.9), and combine this with (2.10). Then, after absorbing $\frac{\kappa C_\alpha}{2}\|\nabla^\perp\theta\|^p_{L^{\frac{2p}{2-\alpha}}}$ to the left-hand side, we obtain

$$\begin{aligned} &\frac{d}{dt}\|\nabla^\perp\theta(t)\|^p_{L^p} + \frac{\kappa C_\alpha}{2}\|\nabla^\perp\theta(t)\|^p_{L^{\frac{2p}{2-\alpha}}} \\ &\quad \le C\|\xi(t)\|^Q_{\dot{\mathcal{F}}^s_{p_1,q}}\|\nabla^\perp\theta(t)\|^Q_{L^{p_2}}\|\nabla^\perp\theta(t)\|^p_{L^p}. \end{aligned} \tag{2.19}$$

Now the inequality condition (1.7) becomes

$$\frac{1}{r_1} + \frac{1}{r_2} \le \frac{1}{Q}$$

in terms of Q. Thanks to the Gronwall lemma and Hölder's inequality we estimate

$$\begin{aligned} &\|\nabla^\perp\theta(t)\|_{L^p} \le \|\nabla^\perp\theta_0\|_{L^p}\exp\left[C\int_0^T \|\xi(t)\|^Q_{\dot{\mathcal{F}}^s_{p_1,q}}\|\nabla^\perp\theta(t)\|^Q_{L^{p_2}}\,dt\right] \\ &\le \|\nabla^\perp\theta_0\|_{L^p}\exp\left[C\left(\int_0^T \|\xi(t)\|^{r_1}_{\dot{\mathcal{F}}^s_{p_1,q}}\,dt\right)^{\frac{Q}{r_1}}\left(\int_0^T \|\nabla^\perp\theta(t)\|^{r_2}_{L^{p_p}}\,dt\right)^{\frac{Q}{r_2}} T^{\left(1-\frac{Q}{r_1}-\frac{Q}{r_2}\right)}\right] \end{aligned} \tag{2.20}$$

for all $t \in [0,T]$. Hence, $\nabla^\perp\theta \in L^\infty(0,T;L^p(\mathbb{R}^2))$. Integrating (2.19) over $[0,T]$ we have

$$\begin{aligned} &\|\nabla^\perp\theta(t)\|^p_{L^p} + \frac{\kappa C_\alpha}{2}\|\nabla^\perp\theta\|^p_{L^{\frac{2p}{2-\alpha}}} \\ &\quad \le C\int_0^T \|\xi(t)\|^Q_{\dot{\mathcal{F}}^s_{p_1,q}}\|\nabla^\perp\theta(t)\|^Q_{L^{p_2}}\,dt \sup_{0\le t\le T}\|\nabla^\perp\theta(t)\|^p_{L^p} + \|\nabla^\perp\theta_0\|^p_{L^p} < \infty \end{aligned}$$

for all $t \in [0,T]$, and

$$\int_0^T \|\nabla^\perp\theta\|^p_{L^{\frac{2p}{2-\alpha}}}\,dt < \infty.$$

Since $\nabla^\perp\theta \in L^p(0,T;L^{\frac{2p}{2-\alpha}}(\mathbb{R}^2))$, and our choice of p in (2.8) implies

$$2\cdot\frac{(2-\alpha)}{2p} + \frac{\alpha}{p} \le \alpha,$$

the solution $\theta(x,t)$ is regular on $[0,T]$ by applying Theorem 1.1. $\square$

GLOBAL SOLUTIONS TO THE GRADIENT FLOW EQUATION OF A NONCONVEX FUNCTIONAL*

G. BELLETTINI†, M. NOVAGA‡, AND E. PAOLINI§

Abstract. We study the L^2-gradient flow of the nonconvex functional $F_\phi(u) := \frac{1}{2}\int_{(0,1)} \phi(u_x)\,dx$, where $\phi(\xi) := \min(\xi^2, 1)$. We show the existence of a global in time possibly discontinuous solution u starting from a mixed-type initial datum u_0, i.e., when u_0 is a piecewise smooth function having derivative taking values both in the region where $\phi'' > 0$ and where $\phi'' = 0$. We show that, in general, the region where the derivative of u takes values where $\phi'' = 0$ progressively disappears while the region where ϕ'' is positive grows. We show this behavior with some numerical experiments.

1. Introduction.

Let $\phi : \mathbb{R} \to [0, +\infty)$ be the nonconvex continuous function defined as

$$\phi(\xi) := \begin{cases} \xi^2 & \text{if } |\xi| \le 1, \\ 1 & \text{otherwise.} \end{cases} \tag{1.1}$$

In this paper we study the L^2-gradient flow of the nonconvex functional

$$F_\phi(u) := \frac{1}{2}\int_{(0,1)} \phi(u_x)\,dx, \qquad u \in BV(0,1), \tag{1.2}$$

where u_x stands for the absolutely continuous part of the distributional derivative of u. Note that $\phi^{**} \equiv 0$, where ϕ^{**} is the convex envelope of ϕ; hence the L^2-lower semicontinuous envelope of F_ϕ is identically zero. Note also that if the initial datum u_0 is smooth and such that $u_{0x}([0,1]) \subset (-1,1)$, it is reasonable to look for a solution of the gradient flow of F_ϕ which coincides with the usual solution of the heat equation starting from u_0. In particular, such a solution cannot coincide with the standing solution $u(x,t) \equiv u_0(x)$ obtained as the gradient flow of the lower semicontinuous envelope of F_ϕ.

The solution $u(x,t)$ of the formal gradient flow of F_ϕ should satisfy the following evolution equation:

$$\begin{cases} u_t = u_{xx}, & \text{where } |u_x| < 1, \\ u_t = 0, & \text{where } |u_x| > 1, \\ u(0) = u_0, \end{cases} \tag{1.3}$$

but the behavior of the interface $\{|u_x| = 1\}$ is not apparent.

While existence and regularity theories for solutions of gradient flow equations originated by convex energies is well established (see, for instance, [12], [31], [4], [2]), very little is known for nonconvex evolution problems. The main difficulty is due to the fact that nonconvexity of the energy density leads in general to ill-posed (i.e., backward-parabolic) problems and, as a consequence, to instabilities in the evolution. The lack of forward parabolicity of the equation shows that even the local in time existence of a solution (in some reasonable class of functions) is not straightforward, as well as uniqueness and regularity. We refer the reader to [30] and to the papers [26], [27], [32], [29], [23], [24], [5], [6] for some results in this direction and for possible regularization techniques. We point out that variational models involving (1.2) have been used in [11] in the context of image segmentation; see also [14]. See also the papers [28], [20], where other backward-forward parabolic equations, such as the Perona–Malik equation corresponding to the choice $\phi_{PM}(\xi) := \log(1+\xi^2)$, have been used to reconstruct a digital image; see [34], [33], [13], [17], [18], [7], [8], [9].

Among nonconvex energy densities, the function ϕ in (1.1) is maybe the simplest one (despite the fact that it is not of class $\mathcal{C}^1$, there are no points in $\mathbb{R} \setminus \{\pm 1\}$ where ϕ'' is negative), and this motivates our choice of studying the gradient flow of the associated functional F_ϕ.

The aim of the present paper is to prove the existence of a reasonable notion of (discontinuous) *global* solution u to the gradient flow of F_ϕ starting from u_0; we stress that u_0 will be allowed to be of mixed type, i.e., to have points where u_{0x} belongs to the locally convex region $(-1,1)$ of ϕ *and* points where u_{0x} belongs to the region $\mathbb{R} \setminus [-1,1]$. We show that, in general, the interface $\{|u_x| = 1\}$ has a velocity, and that the region where u_x takes values in $(-1,1)$ has the tendency to grow at the expenses of the remaining region, with a well determined speed. Thus we are in the presence of a free boundary problem and, in general,

(a) our solution does not coincide with the standing solution $u(x,t) \equiv u_0(x)$;

(b) our solution does not coincide with the solution of (1.3) obtained by keeping the interface $\{|u_x| = 1\}$ fixed and by imposing the condition

$$\lim_{y \to x,\, y \in \{|u_x(\cdot,t)|<1\}} u_x(y,t) = 0 \qquad \text{for } x \in \{|u_x(\cdot,t)| = 1\}, \tag{1.4}$$

i.e., zero Neumann boundary conditions from the side of $\{|u_x| < 1\}$;

(c) these behaviors appear in numerical experiments; see section 7.

Observe that the lack of forward parabolicity precludes, as far as we know, a direct way to construct global solutions based on the comparison principle, such as viscosity solutions [15] or minimal barriers [10]. Moreover, global solutions obtained by using the usual minimization methods (such as the implicit Euler scheme; see [16]) coincide with the solution $u(x,t) \equiv u_0(x)$; this is due to the fact that, in the minimization procedure, the functional F_ϕ can be equivalently replaced with its lower semicontinuous envelope.

In the present paper we restrict the analysis to periodic boundary conditions, even if the same technique can be adapted to different situations such as Neumann or Dirichlet boundary conditions. We base our approach on the study of the system of ODEs obtained as the gradient flow of the restriction $F_{\phi_{|V_N}}$ of F_ϕ to V_N, the space of continuous piecewise affine functions on a uniformly distributed grid of $[0,1]$ of size $1/N$. The function $F_{\phi_{|V_N}}$ turns out to be Lipschitz continuous; nevertheless, it is possible to give a precise notion to the equation $\dot{u} = -\nabla(F_{\phi_{|V_N}})(u)$. After solving the resulting system of ODEs, we pass to the limit as the discretization step goes to zero ($N \to +\infty$), and we identify the limit problem. This sort of regularization is particularly handleable (as a consequence of the special features of ϕ in (1.1)) since the interior of the region $\{|u_x| > 1\}$ has zero velocity, so that we can focus the attention only at the free boundary $\{|u_x| = 1\}$. This is a remarkable simplification, for instance in comparison with the Perona–Malik equation where the quick formation of microstructures in the region where $|u_x| > 1$ seems to be present.

The plan of the paper is the following. In section 2 we state the main result (Theorem 2.4). We look for a solution in the class of ϕ-admissible functions in the sense of Definition 2.1. Several comments clarify both the definition and the theorem (see, in particular, Remark 2.3 concerning condition (4) of Definition 2.1). In section 3 we motivate from a variational point of view the evolution law. In section 4 we discretize the problem and introduce the discretized operator A_u; see Definition 4.4. The rigorous analysis of the discretized scheme is performed in section 5; in particular, in Theorem 5.4 we prove the basic estimates and comparisons necessary to pass to the limit as $N \to +\infty$. In section 6 we prove Theorem 2.4. In Remark 6.16 we discuss in which sense our solution could provide a solution to the gradient flow of the Mumford–Shah functional in one dimension. In section 7 we implement our scheme and show that the numerical experiments are in agreement with Theorem 2.4. In particular, we show that the free boundary $\{|u_x(\cdot)| = 1\}$ has, in general, nonzero speed.

We conclude this introduction by observing that the analysis of the gradient flow of (1.2) could be considered as a first step toward the understanding of the behavior of the Perona–Malik equation.

2. Statement of the main results. We now state the main results of the paper (Theorem 2.4). To this purpose we need some preparation. $BV(0,1)$ stands for the space of functions with bounded variation in $(0,1)$. If $u \in BV(0,1)$ and $x \in (0,1)$, $u(x_-)$ (resp., $u(x_+)$) is the left (resp., right) limit of u at x. We always identify the function u with its representative defined pointwise everywhere as the mean value of u; i.e., $u(x) = (u(x_+)+u(x_-))/2$ for any $x \in (0,1)$. We set $u(0) := u(0_+)$ $u(1) := u(1_-)$. We denote by J_u the jump set of u.

We recall that the distributional derivative of $u \in BV(0,1)$ is represented by a measure Du, with finite total variation in $(0,1)$ (which we denote by $\|Du\|$), and that it splits into the sum of an absolutely continuous part (which we denote by u_x or by u') and a singular part. We refer the reader to [3] for the main properties of BV functions. If $u : [0,T) \to \mathbb{R}$, we indicate by $\frac{d}{dt^+}u$ the right derivative of u; i.e., $\frac{d}{dt^+}u(t) := \lim_{h\to 0^+} \frac{u(t+h)-u(t)}{h}$ for any $t \in [0,T)$, provided the limit is finite.

If u depends on $(x,t) \in (0,1) \times (0,T)$, we write $u(t)(\cdot) = u(\cdot,t) = u(t)$.

Given $B \subseteq \mathbb{R}$ we denote by $\overline{B}$ (resp., $\mathrm{int}(B)$, ∂B, $\#(B)$, $|B|$) the closure (resp., the interior part, the topological boundary, the number of elements, the Lebesgue measure) of B. We denote by $d_{\mathcal{H}}(\cdot,\cdot)$ the Hausdorff distance between sets.

Our analysis is restricted to a subset of $BV(0,1)$ given by the *ϕ-admissible* functions, according to the following definition.

Definition 2.1. *Let $u \in BV(0,1)$ with $u(0) = u(1)$. We say that u is ϕ-*admissible*, and we write $u \in \mathcal{A}_\phi(0,1)$, if there exist a natural number $m \geq 0$ and real numbers $0 < a_1 \leq b_1 < \cdots < a_m \leq b_m < 1$ such that, setting*

$$\sigma_B^\phi(u) := \bigcup_{j=1}^m [a_j, b_j] \subset (0,1), \qquad \sigma_G^\phi(u) := [0,1] \setminus \sigma_B^\phi(u), \tag{2.1}$$

we have

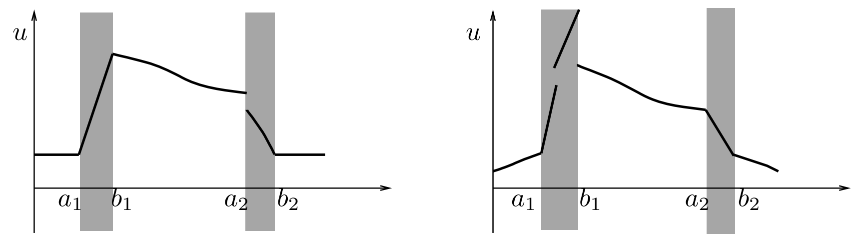

FIG. 2.1. *The gray rectangles correspond to the closed intervals of $\sigma_B^\phi(u)$. The function on the left is ϕ-admissible. The function on the right is not ϕ-admissible, because it is not monotone on the* closed *interval* $[a_1, b_1]$.

(1) $|u(x) - u(y)| \leq |x - y|$ *whenever* $[x, y] \subset \sigma_G^\phi(u)$*;*
(2) *if* $a_j = b_j$ *for some* $j \in \{1, \dots, m\}$*, then* $a_j \in J_u$*;*
(3) *if* $j \in \{1, \dots, m\}$ *and* $a_j < b_j$*, then* $|u(x) - u(y)| > |x - y|$ *whenever* $x, y \in [a_j, b_j]$*,* $x \neq y$*;*
(4) *if* $j \in \{1, \dots, m\}$ *and* $a_j < b_j$*, then* u *is monotone on* $[a_j, b_j]$*.*

Remark 2.2. Let us clarify Definition 2.1.

(a) Note that $\sigma_G^\phi(u) \neq \emptyset$ for any $u \in \mathcal{A}_\phi(0,1)$. We adopt the convention that there are no points a_i, b_j if $m = 0$; in this case, $\sigma_B^\phi(u) = \emptyset$, $\sigma_G^\phi(u) = (0,1)$ and u is one-Lipschitz in the whole of $(0,1)$. The assumptions $a_1 > 0$ and $b_m < 1$ are not restrictive, since we can always assume (up to a translation) that a one-periodic function $u \in \mathcal{C}^1(\mathbb{R})$ is such that $|u_x(0)| < 1$. Due to our periodicity assumption, the point $\{0\}$ is identified with $\{1\}$ and can be considered as belonging to the interior of $\sigma_G^\phi(u)$.
(b) In each interval I of $\sigma_G^\phi(u)$ we have that u is one-Lipschitz; hence, at almost every $x \in I$ we have that $u_x(x)$ belongs (unless $|u_x(x)| = 1$) to the set where ϕ is twice differentiable and $\phi'' > 0$, i.e., $u_x(x) \in (-1, 1)$.
(c) In each interval I of $\sigma_B^\phi(u)$ we have that

$$Du(A) \geq |A| \quad \forall\ A \subseteq I \qquad \text{or} \qquad Du(A) \leq -|A| \quad \forall\ A \subseteq I,$$

with the strict inequalities when $|A| > 0$, where A is any Borel subset of I.
(d) The class $\mathcal{A}_\phi(0,1)$ is L^2-dense in $BV(0,1)$.

The following remark shows some analogy with the entropy condition in hyperbolic conservation laws.

Remark 2.3. Condition (4) in Definition 2.1 is required on the *closed* intervals $[a_j, b_j]$. Hence, since $u(x) = (u(x_+) + u(x_-))/2$ for any $x \in (0,1)$, if u is discontinuous at some a_j and u is nondecreasing on $[a_j, b_j]$ (resp., u is nonincreasing on $[a_j, b_j]$), then $u(a_j) \leq u(a_{j_+})$ (resp., $u(a_j) \geq u(a_{j_+})$). Similarly, it happens if u is discontinuous at some b_j; see Figure 2.1. Condition (4) is fulfilled at each time by the solution that we are going to construct in Theorem 2.4 and arises naturally as a consequence of the approximation procedure through spatial discretizations. Ultimately, it can be considered as a consequence of the fact that, once a region in $\sigma_G^\phi(u_N(t))$ appears for the discretized solutions $u_N(t)$ considered in Theorem 5.4 below, it must persist (and possibly increase) with time.

Let us denote by $AC^2([0, +\infty); L^2(0,1))$ the space of absolutely continuous functions u from $[0, +\infty)$ to $L^2(0,1)$ such that $u_t \in L^2((0, +\infty) \times (0,1))$; see, for instance, [2]. Let $V_N \subset H^1(0,1)$ be the N-dimensional vector space of one-periodic continuous functions on $\mathbb{R}$ which are affine on every interval of the form $[i/N, (i+1)/N]$ with

$i = 0, \dots, N-1$. It is clear that $V_N \subset \mathcal{A}_\phi(0,1)$ and that each function in V_N is N-Lipschitz.

Let us denote by A_u the differential of $F_{\phi|V_N}$ at $u \in V_N$; the linear operator A_u is a discrete Laplace operator with zero blocks corresponding to the region $\sigma_B^\phi(u)$ and zero Neumann boundary conditions on the boundaries; see Remark 4.3 and Definition 4.4 below.

THEOREM 2.4. *Let $u_0 \in \mathcal{A}_\phi(0,1)$, and write*

$$\sigma_B^\phi(u_0) = \bigcup_{j=1}^m [a_j^0, b_j^0].$$

Then there exist a sequence of initial data $(u_0^N) \subset V_N$, a sequence (u^N) of functions taking $[0,+\infty)$ in V_N, and a function $u : (0,1) \times [0,+\infty) \to \mathbb{R}$ with the following properties:

(i) *There exist numbers $0 < a_1^{0N} \le b_1^{0N} < \cdots < a_m^{0N} \le b_m^{0N} < 1$ such that*

$$\sigma_B^\phi(u_0^N) = \bigcup_{j=1}^m [a_j^{0N}, b_j^{0N}], \tag{2.2}$$

and

$$\begin{aligned}
&\lim_{N\to+\infty} \|u_0^N - u_0\|_{L^2} = 0,\\
&\lim_{N\to+\infty} \left(\|u_0^N\|_{BV(0,1)} - \|u_0\|_{BV(0,1)}\right) = 0,\\
&\lim_{N\to+\infty} \Big(d_{\mathcal{H}}(\sigma_G^\phi(u_0^N), \sigma_G^\phi(u_0)) + d_{\mathcal{H}}(\sigma_B^\phi(u_0^N), \sigma_B^\phi(u_0))\Big) = 0,\\
&\lim_{N\to+\infty} F_\phi(u_0^N) = F_\phi(u_0).
\end{aligned} \tag{2.3}$$

(ii) *$u^N : [0,+\infty) \to V_N$ is continuous and right-differentiable, and satisfies*

$$\begin{cases} \dfrac{d}{dt^+} u^N(t) = A_{u^N(t)} u^N(t), & t \in [0,+\infty),\\ u^N(0) = u_0^N. \end{cases} \tag{2.4}$$

(iii) *$u^N, u \in L^\infty((0,+\infty); BV(0,1)) \cap AC^2([0,+\infty); L^2(0,1))$, and $u^N \rightharpoonup u$ weakly in $H^1_{\mathrm{loc}}((0,+\infty); L^2(0,1))$ and weakly* in $L^\infty((0,+\infty); BV(0,1))$ as $N \to +\infty$.*

(iv) *$u(t) \in \mathcal{A}_\phi(0,1)$ for any $t \in [0,+\infty)$.*

(v) *For any $j \in \{1,\dots,m\}$ there exist $T_j \in (0,+\infty]$ and functions $a_j, b_j : [0,T_j) \to (0,1)$ such that*

(v1) *$a_j(0) = a_j^0$, a_j is continuous and nondecreasing;*

(v2) *$b_j(0) = b_j^0$, b_j is continuous and nonincreasing;*

(v3) *$a_j \le b_j$ on $[0,T_j)$, and $\lim_{t\to T_{j\_}} a_j(t) = \lim_{t\to T_{j\_}} b_j(t)$;*

(v4) *$\overline{\bigcup_{j=1}^m (a_j(t), b_j(t))} \subseteq \sigma_B^\phi(u(t)) \subseteq \bigcup_{j=1}^m [a_j(t), b_j(t)]$ for any $t \in [0,+\infty)$, where we have set $(a_j(t), b_j(t)) = [a_j(t), b_j(t)] := \emptyset$ if $t \ge T_j$.*

(vi) *$u_{xx} \in L^2(\Gamma_u)$, where $\Gamma_u := \bigcup_{t\in(0,+\infty)} (\sigma_G^\phi(u(t)) \times \{t\})$, and u is a solution of*

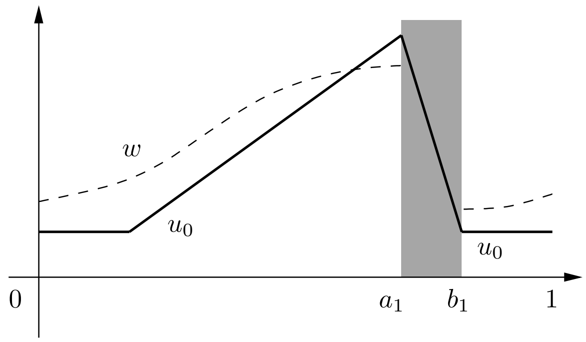

FIG. 2.2. *Remark* 2.6(b). *We construct a function w starting from u_0, such that $w \equiv u_0$ in (a_1, b_1) and that evolves according to the heat equation in $(0, a_1) \cup (b_1, 1)$ with zero Neumann boundary conditions in a_1, b_1 (dashed curve). Recall that we have periodic boundary conditions. Note that $J_{w(t)} = \{a_1, b_1\}$ for $t > 0$, and that $w(t) \notin \mathcal{A}_\phi(0,1)$ for any $t > 0$, since (4) of Definition* 2.1 *is violated at a_1, b_1.*

$$
(2.5)\quad
\begin{cases}
u_t = u_{xx}, & x \in \sigma_G^\phi(u(t)),\ t \in (0,+\infty),\\
u_t = 0, & x \in \mathrm{int}(\sigma_B^\phi(u(t))),\ t \in (0,+\infty),\\
\displaystyle\lim_{y \to x,\, y \in \sigma_G^\phi(u(t))} u_x(y,t) = 0, & x \in \partial\sigma_G^\phi(u(t)) \setminus \{0,1\},\ t \in (0,+\infty),\\
u(x,0) = u_0(x), & x \in (0,1),\\
u(0,t) = u(1,t),\ u_x(0,t) = u_x(1,t), & t \in (0,+\infty).
\end{cases}
$$

(vii) *For any $t \in (0,+\infty)$ we have*
$\sup_{\sigma_G^\phi(u(t))} |u_x(\cdot,t)| < 1$;
$\sup_{[0,1]} u(\cdot,t) \le \sup_{[0,1]} u_0$;
$\inf_{[0,1]} u(\cdot,t) \ge \inf_{[0,1]} u_0$;
$\|Du(\cdot,t)\| \le \|Du_0\|$.

The proof of Theorem 2.4 is achieved in sections 5 and 6. In particular, (i) is given by Lemma 6.1, (ii) is given by Theorem 5.4, (iii) is the content of Remark 6.5, (iv) is given by Lemma 6.12, (v) is given by Lemma 6.8, Remark 6.6, and Lemma 6.12, and (vi) is the content of Theorem 6.14. Finally, the first inequality in (vii) follows from (vi) and the maximum principle applied to u_x, while the last three inequalities in (vii) are consequences of (c) and (d) of Theorem 5.4.

Remark 2.5.

(a) In general a function u and intervals (a_j, b_j) satisfying (v) and (vi) of Theorem 2.4 are not unique: it is easy to construct a solution w of (2.5) satisfying also the requirement

$$
(2.6)\qquad \sigma_B^\phi(w(t)) = \sigma_B^\phi(u_0) \qquad \forall\, t \in (0,+\infty),
$$

and the function w in general cannot coincide with u. Indeed, $w(t) = u(t)$ for all times t for which $w(t) \in \mathcal{A}_\phi(0,1)$, but the property $w(t) \in \mathcal{A}_\phi(0,1)$ for all $t \in (0,+\infty)$ is in general violated; see Figure 2.2. In fact, condition (4) in Definition 2.1 cannot be satisfied for all times by w (cf. Remark 2.3), unless $\sigma_G^\phi(w(\cdot))$ is allowed to expand, in contrast with (2.6).

(b) If we do not require the functions a_j, b_j to be monotone (nondecreasing and

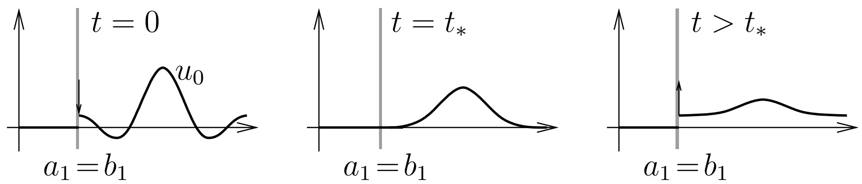

FIG. 2.3. *The "bouncing" solution discussed in Example* 1.

nonincreasing, respectively), several different solutions could be constructed; see Figure 2.4(b).

One can ask whether a function u and intervals (a_j, b_j) satisfying (iv), (v), and (vi) of Theorem 2.4 are unique. This is not the case, as shown by the following example related, in spirit, to the so-called fattening phenomenon in mean curvature flow (see [22] for similar behaviors concerning the evolution of the Mumford–Shah functional in one dimension).

Example 1. Let us construct an initial datum $u_0 \in \mathcal{A}_\phi(0,1)$ as follows:

u_0 has only one jump point $a_1 = b_1 = 1/2$;
$u_0 = 0$ in $(0, 1/2)$;
u_0 is a smooth function in $(1/2, 1)$ with the following property: $|u_{0x}| < 1$ and, if we flow $u_{0|(1/2,1)}$ by the heat equation with zero Neumann boundary conditions in $\{1/2, 1\}$, then there is a first time $t_* > 0$ for which the solution, evaluated at the point $1/2$, touches the horizontal axis with *zero vertical velocity* and then, for t immediately after t_*, becomes *positive* at $1/2$; see Figure 2.3.

Then we can exhibit two functions u_1, u_2, which coincide for $t \in [0, t_*]$ but differ for $t \in (t_*, +\infty)$, and both satisfy (iv), (v), and (vi) of Theorem 2.4. The function u_1 is defined as follows: $u_1 = 0$ in $(0, 1/2) \times [0, +\infty)$; u_1 equals, in $(1/2, 1) \times [0, t_*)$, the solution of the heat equation with zero Neumann boundary conditions in $\{1/2, 1\}$; u_1 equals, in $(0,1) \times [t_*, +\infty)$, the solution of the heat equation with zero Neumann boundary conditions in $\{0, 1\}$ starting from $u_1(t_{*-})$. Namely, immediately after the time t_* when the two graphs of the solution on the left and on the right of $1/2$ join, the evolution continues with one graph only, and the jump disappears.

The function u_2 is defined as follows: $u_2 = 0$ in $(0, 1/2) \times [0, +\infty)$; u_2 equals, in $(1/2, 1) \times [0, +\infty)$, the solution of the heat equation with zero Neumann boundary conditions in $\{1/2, 1\}$. That is, the function u_2 "bounces" at $1/2$ at time t_*, the evolutions in $(0, 1/2)$ and in $(1/2, 1)$ do not "see" each other, and $1/2$ becomes again a jump point of $u_2(t)$ for t immediately larger than t_*.

Remark 2.6.

(a) As a consequence of (v) of Theorem 2.4, the set-valued map $t \in [0, +\infty) \to \sigma_G^\phi(u(t)) \subseteq (0, 1)$ is nondecreasing up to a finite number of points (at most m), and the number of connected components with nonempty interior of $\sigma_B^\phi(u(\cdot))$ is nonincreasing. Itmay happen that at some time $\bar{t}_j \in (0, T_j)$ the interval $[a_j(\bar{t}_j), b_j(\bar{t}_j)]$ is reduced to a point not belonging to $J_{u(\bar{t}_j)}$ (recall conclusion (iv) of Theorem 2.4 and Definition 2.1(2)) but belonging to $J_{u(t)}$ for some $t \in (\bar{t}_j, T_j)$ (as it happens for the function u_2 in Example 1). At time T_j at least one of the intervals in $\sigma_B^\phi(u(\cdot))$ disappears (provided $T_j < +\infty$).

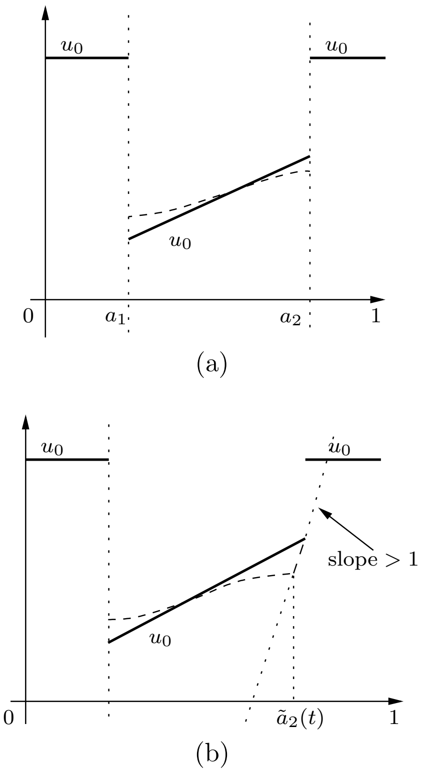

FIG. 2.4. *Remark* 2.5(b). *For the function u_0 we have $a_1^0 = b_1^0$ and $a_2^0 = b_2^0$. In* (a) *is displayed the solution u of Theorem* 2.4 *starting from u_0 for which $a_1(t) = b_1(t) \equiv a_1^0$, $a_2(t) = b_2(t) \equiv a_2^0$, u evolves according to the heat equation in $[a_1(t), a_2(t)]$ with zero Neumann boundary conditions (dashed curve), and $u(t) \equiv u_0$ in $[0,1] \setminus [a_1(t), a_2(t)]$. In* (b) *we construct a function w with $w(t) \in \mathcal{A}_\phi(0,1)$, such that w evolves according to the heat equation in $[a_1^0, \tilde{a}_2(t)]$ with zero Neumann boundary conditions, and $\tilde{a}_2(t)$ is decreasing in time, in such a way that the corresponding point $w(\tilde{a}_2(t), t)$ slides on a line with slope greater than one; hence the function w does not satisfy condition* (v1) *of Theorem* 2.4.

(b) A weak formulation of (2.5) is given by

$$\int_{(0,1)\times(0,+\infty)} u\,\psi_t\,dx\,dt - \int_{\mathrm{int}(\Gamma_u)} u_x\psi_x\,dx\,dt = 0 \tag{2.7}$$

for any $\psi \in \mathcal{C}_c^1([0,1]\times[0,+\infty))$.

(c) Solutions verifying conditions (iv), (v), and (vi) of Theorem 2.4 do not satisfy the comparison principle, in the sense that it is easy to find solutions u_1, u_2 such that $u_1(\cdot,0) \le u_2(\cdot,0)$ on $(0,1)$, but $u_1(\bar{x},\bar{t}) > u_2(\bar{x},\bar{t})$ for some $(\bar{x},\bar{t}) \in (0,1)\times(0,+\infty)$; see Figure 2.5.

Remark 2.7.

(a) Under sufficient regularity on u we can predict the speed of the free boundary $\partial\sigma_G^\phi(u(\cdot))$. For instance, assume that a_j is of class $\mathcal{C}^1$ in a neighborhood U of $\bar{t} \in (0, T_j)$ and that $a_j'(\bar{t}) \neq 0$. Assume in addition that $u(\cdot,\cdot)$ is twice differentiable in $\bigcup_{t\in U} \sigma_G^\phi(u(t)) \times \{t\}$ up to the boundary. Then from the equality

$$u(a_j(t), t) = u_0(a_j(t))$$

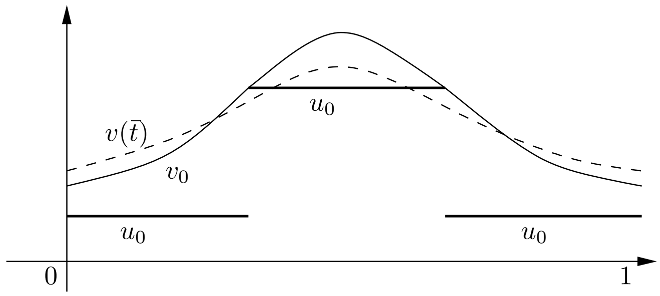

FIG. 2.5. *Remark* 2.6(c). *In general the solution* u *of Theorem* 2.4 *cannot satisfy the comparison principle. Indeed, let* u_0 *and* v_0 *be as in the figure,* $u_0 \le v_0$*, where we assume that the function* v_0 *is one-Lipschitz, so that* $\sigma_G^\phi(v_0) = (0,1)$*. Moreover,* $u(t) \equiv u_0$ *for any* $t \in (0,+\infty)$*. On the other hand, the solution* v *starting from* v_0 *given by Theorem* 2.4 *is the usual solution of the heat equation in* $(0,1)$ *with zero Neumann boundary conditions. Hence, at some time* $\bar t > 0$ *and at some* $\bar x \in (0,1)$ *it happens that* $v(\bar x, \bar t) < u(\bar x, \bar t)$*.*

valid in the neighborhood of $\bar t$ it follows, using the third equality in (2.5), that

$$u_t(a_j(t)_-, t) = \frac{d}{dt} u(a_j(t), t) = u_{0x}(a_j(t)_+) a_j'(t). \tag{2.8}$$

Hence, using the first equation in (2.5), we get

$$a_j'(\bar t) = \frac{u_{xx}(a_j(\bar t)_-, \bar t)}{u_{0x}(a_j(\bar t)_+)}. \tag{2.9}$$

Similarly, under the corresponding regularity assumptions and provided $b_j'(\bar t) \neq 0$, we get

$$b_j'(\bar t) = \frac{u_{xx}(b_j(\bar t)_+, \bar t)}{u_{0x}(b_j(\bar t)_-)}. \tag{2.10}$$

(b) We expect that if $u_0 \in \mathcal{C}^{1,1}(\sigma_G^\phi(u_0))$ and $\lim_{y\to x,\, y\in\sigma_G^\phi(u_0)} u_{0x}(y) = 0$ for any $x \in \partial\sigma_G^\phi(u_0)$, then

$$\|u_{xx}\|_{L^\infty(\sigma_G^\phi(u(t)))} \le \|u_{0xx}\|_{L^\infty(\sigma_G^\phi(u_0))}, \qquad t \ge 0. \tag{2.11}$$

Indeed, assuming we can differentiate a_j, b_j in $(0, T_j)$ and $u(\cdot, t)$ in $\sigma_G^\phi(u(t))$ up to the boundary, arguing as in (a) we get

$$\frac{u_{xx}(a_j(t)_-, t) a_j'(t)}{u_{0x}(a_j(t)_+)} \ge 0, \qquad \frac{u_{xx}(b_k(t)_+, t) b_k'(t)}{u_{0x}(b_k(t)_-)} \ge 0 \tag{2.12}$$

for any $t \ge 0$. Differentiating the equalities $u_x(a_j(t)_-, t) = u_x(b_k(t)_+, t) = 0$

with respect to t and using (2.12), we then get

$$\begin{aligned} &\frac{u_{xxx}(a_j(t)_-,t)}{u_{0x}(a_j(t)_+)} = -\frac{u_{xx}(a_j(t)_-,t)a_j'(t)}{u_{0x}(a_j(t)_+)} \le 0, \\ &u_{xxx}(a_j(t)_-,t) = 0 \quad \text{if} \quad \frac{u_{xx}(a_j(t)_-,t)}{u_{0x}(a_j(t)_+)} < 0, \\ &\frac{u_{xxx}(b_k(t)_+,t)}{u_{0x}(b_k(t)_-)} = -\frac{u_{xx}(b_k(t)_+,t)b_k'(t)}{u_{0x}(b_k(t)_-)} \le 0, \\ &u_{xxx}(b_k(t)_+,t) = 0 \quad \text{if} \quad \frac{u_{xx}(b_k(t)_+,t)}{u_{0x}(b_k(t)_-)} > 0. \end{aligned} \tag{2.13}$$

Letting $v := u_{xx}$ and differentiating (2.5) twice with respect to x, we obtain

$$\begin{cases} v_t = v_{xx}, & x \in \sigma_G^\phi(u(t)),\ t \in (0,+\infty), \\ v_t = 0, & x \in \operatorname{int}(\sigma_B^\phi(u(t))),\ t \in (0,+\infty), \\ v(x,0) = u_{0xx}(x), & x \in (0,1), \end{cases} \tag{2.14}$$

with the boundary conditions on $\partial\sigma_G^\phi(u(t))$ given by (2.13). Note that, from the third equality in (2.5), for any $t \ge 0$ it follows that

$$\int_{\sigma_G^\phi(u(t))} v(x,t)\,dx = 0 \Longrightarrow \max_{\sigma_G^\phi(u(t))} v(\cdot,t) \ge 0, \qquad \min_{\sigma_G^\phi(u(t))} v(\cdot,t) \le 0.$$

The boundary conditions (2.13) then imply that $v(\cdot,t)$ assumes its maximum and minimum in the interior of $\sigma_G^\phi(u(t))$; hence (2.11) follows from (2.14) by the maximum principle.

Let us observe that from (2.8) and (2.11) it follows that

$$\|a_j'\|_{L^\infty(0,T_j)} \le \|u_{0xx}\|_{L^\infty(\sigma_G^\phi(u_0))}, \qquad \|b_j'\|_{L^\infty(0,T_j)} \le \|u_{0xx}\|_{L^\infty(\sigma_G^\phi(u_0))}.$$

In particular, we also expect that the functions a_j and b_j are Lipschitz continuous on $[0,T_j)$.

Remark 2.8. It is clear that Theorem 2.4 holds also for the function

$$\overline{\phi}(\xi) := \min(1, \phi_{PM}(\xi)) = \min(1, \log(1+\xi^2)).$$

In the present paper, solutions u to the gradient flow of $F_{\overline{\phi}}$ are intended as those functions satisfying (iv), (v), and (vi) (with $u_t = u_{xx}$ replaced by $u_t = (\overline{\phi}'(u_x))_x$) of Theorem 2.4. These solutions could be compared with some notion of weak solutions of the gradient flow of $F_{\phi_{PM}}$; see [29]. We can observe that u is not a BV-distributional solution of the Perona–Malik equation in the sense of [29, Definition 1]; see (2.7). However, u turns out to be a Young-varifold solution of the Perona–Malik equation; see [19], [21]. We also observe that if $a = b \in (0,1)$ is a jump point of $u(t)$ and if u is sufficiently smooth in a neighborhood of a (see Remark 2.7), then as a consequence of (2.9), (2.10), we have that $a'(t) = 0$. This is consistent with [29, formula (3)], in connection with the notion of generalized solution. Finally, observe that $a'(t) = 0$ is also a consequence of the $AC_2([0,+\infty); L^2(0,1))$ regularity of u.

3. First variation. In this section we want to identify the L^2-gradient of the functional F_ϕ in (1.2) on a suitable dense subspace X of $L^2(0,1)$; see Definition 3.3. We begin by computing the first variation of F_ϕ along functions $\psi \in \mathrm{Lip}(0,1)$.

PROPOSITION 3.1. *Let $u \in \mathcal{A}_\phi(0,1)$ be such that $\sigma_B^\phi(u) = \bigcup_{j=1}^m [a_j, b_j]$, $a_j < b_j$ for any $j = 1, \dots, m$,*

$$u \in H^2(\sigma_G^\phi(u)) \qquad \text{and} \qquad \sup_{\sigma_G^\phi(u)} |u_x| < 1.$$

Then for any $\psi \in \mathrm{Lip}(0,1)$ with $\psi(0) = \psi(1)$ we have

$$\begin{aligned} \frac{d}{d\lambda} F_\phi(u+\lambda\psi)_{|\lambda=0} &= \int_{\sigma_G^\phi(u)} u_x \psi_x \, dx \\ &= -\int_{\sigma_G^\phi(u)} u_{xx} \psi \, dx \\ &\quad + \sum_{j=1}^m \big(u_x(a_{j-})\psi(a_j) - u_x(b_{j+})\psi(b_j) \big). \end{aligned} \tag{3.1}$$

Proof. Since $\sup_{\sigma_G^\phi(u)} |u_x| < 1$ and $\psi \in \mathrm{Lip}(0,1)$, we have $\sigma_G^\phi(u+\lambda\psi) = \sigma_G^\phi(u)$ for $|\lambda|$ small enough. In addition, $\sigma_B^\phi(u+\lambda\psi) = \sigma_B^\phi(u)$ for $|\lambda|$ small enough. For such λ we have

$$\begin{aligned} F_\phi(u+\lambda\psi) &= \frac{1}{2}\int_{\sigma_B^\phi(u+\lambda\psi)} 1 \, dx + \frac{1}{2}\int_{\sigma_G^\phi(u+\lambda\psi)} (u_x + \lambda\psi_x)^2 \, dx \\ &= \frac{|\sigma_B^\phi(u)|}{2} + \frac{1}{2}\int_{\sigma_G^\phi(u)} (u_x + \lambda\psi_x)^2 \, dx \\ &= \frac{|\sigma_B^\phi(u)|}{2} + \frac{1}{2}\int_{\sigma_G^\phi(u)} (u_x)^2 \, dx + \lambda \int_{\sigma_G^\phi(u)} u_x \psi_x \, dx + O(\lambda^2). \end{aligned}$$

Then (3.1) follows with an integration by parts, using the assumptions $u \in H^2(\sigma_G^\phi(u))$ and $\psi(0) = \psi(1)$. ◻

Remark 3.2. Observe that the variations $u \to u + \lambda\psi$, as in Proposition 3.1, cannot increase the number of singular points of $u \in \mathcal{A}_\phi(0,1)$.

If u is as in Proposition 3.1 it follows that

$$\begin{aligned} &\inf_{\substack{\psi \in \mathrm{Lip}(0,1),\, \psi(0)=\psi(1) \\ \|\psi\|_{L^2} \le 1}} \frac{d}{d\lambda} F_\phi(u+\lambda\psi)_{|\lambda=0} \\ &= \begin{cases} -\|u_{xx}\|_{L^2(\sigma_G^\phi(u))} & \text{if } u_x(a_{j-}) = u_x(b_{j+}) = 0, \quad 1 \le j \le m, \\ -\infty & \text{otherwise.} \end{cases} \end{aligned} \tag{3.2}$$

DEFINITION 3.3. *We denote by X the dense subset of $L^2(0,1)$ consisting of the functions u as in Proposition* 3.1 *and satisfying $u_x(a_{j-}) = u_x(b_{j+}) = 0$ for any $1 \le j \le m$.*

Once we fix $u \in X$, the right-hand side of (3.1), if considered as a function of ψ, is a linear functional defined on the Lipschitz functions ψ in $(0,1)$ with $\psi(0) = \psi(1)$ (which form a dense subset of $L^2(0,1)$), which is continuous with respect to the

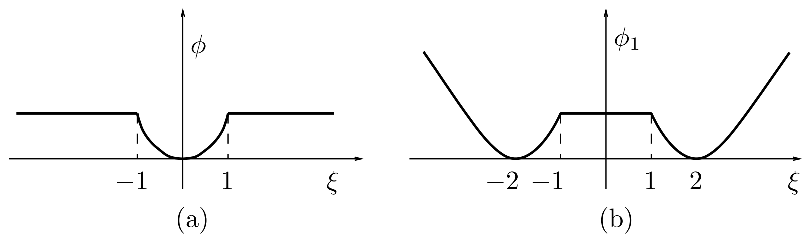

FIG. 3.1. (a) *the function ϕ considered in the present paper;* (b) *the function ϕ_1 of Remark* 3.6.

$L^2(0,1)$-norm. Therefore it can be extended on the whole of $L^2(0,1)$, thus providing a well-defined unique left-hand side of (3.1) for any $\psi \in L^2(0,1)$, and

$$\inf_{\substack{\psi\in\mathrm{Lip}(0,1),\,\psi(0)=\psi(1)\\ \|\psi\|_{L^2}\le 1}} \frac{d}{d\lambda}F_\phi(u+\lambda\psi)_{|\lambda=0} = \inf_{\substack{\psi\in L^2(0,1)\\ \|\psi\|_{L^2}\le 1}} \frac{d}{d\lambda}F_\phi(u+\lambda\psi)_{|\lambda=0}. \tag{3.3}$$

The infimum in (3.3) is attained at $\tilde\psi \in L^2(0,1)$, where

$$\tilde\psi = \begin{cases} 0 & \text{on } \sigma_B^\phi(u),\\ \|u_{xx}\|^{-1}_{L^2(\sigma_G^\phi(u))} u_{xx} & \text{on } \sigma_G^\phi(u). \end{cases}$$

It follows that the L^2-gradient flow of F_ϕ starting from $u_0 \in X$ is given by the free boundary problem (2.5).

As already observed in the introduction, in general, solutions to problem (2.5) are not unique, since the motion of the free boundary $\partial\sigma_G^\phi(u)$ is not prescribed. However, among all ϕ-admissible solutions we can look for those which most decrease the energy F_ϕ. This is expressed by the following proposition, which follows by a direct computation and recalling that $\phi \equiv 1/2$ on $\sigma_B^\phi(u)$.

PROPOSITION 3.4. *Let u be a solution of* (2.5) *satisfying* (iv) *of Theorem* 2.4. *Then for almost every $t \in (0,+\infty)$ we have*

$$\frac{d}{dt}F_\phi(u(t)) = -\frac{1}{2}\frac{d}{dt}|\sigma_G^\phi(u(t))| - \int_{\sigma_G^\phi(u(t))} |u_{xx}(x,t)|^2\,dx. \tag{3.4}$$

Remark 3.5. Proposition 3.4 implies that in order to most decrease the energy F_ϕ, the region $\sigma_G^\phi(u)$ should expand as fast as possible, compatibly with the ϕ-admissibility of u.

Remark 3.6. Our results can be extended to other integrands. Let us consider, for example, the potential in Figure 3.1(b), i.e.,

$$\phi_1(\xi) := \begin{cases} |\xi-2|^2 & \text{if } \xi \ge 1,\\ |\xi+2|^2 & \text{if } \xi \le -1,\\ 1 & \text{otherwise,} \end{cases} \tag{3.5}$$

which is related to the ones considered in [26], [1], [36], [35]. Then Definition 2.1 still makes sense, provided that we define $\sigma_B^{\phi_1}(u)$ as the finite union of closed intervals where $|u(x)-u(y)| < |x-y|$, and $\sigma_G^{\phi_1}(u) = [0,1] \setminus \sigma_B^{\phi_1}(u)$ as the finite union of intervals where either $u(x)-u(y) \ge x-y$ or $u(x)-u(y) \le -(x-y)$. Let us denote by

$\sigma^{\phi_1}_{G,+}(u)$ (resp., $\sigma^{\phi_1}_{G,-}(u)$) the subset of $\sigma^{\phi_1}_G(u)$ where u is increasing (resp., decreasing). The first variation of F_{ϕ_1} can be computed as in Proposition 3.1, and the evolution equation corresponding to (2.5) reads as

$$
\begin{cases}
u_t = u_{xx}, & x \in \sigma^{\phi_1}_G(u(t)),\ t \in (0,+\infty),\\
u_t = 0, & x \in \mathrm{int}(\sigma^{\phi_1}_B(u(t))),\ t \in (0,+\infty),\\
\displaystyle\lim_{y\to x,\, y\in\sigma^{\phi_1}_{G,\pm}(u(t))} u_x(y,t) = \pm 2, & x \in \partial\sigma^{\phi_1}_{G,\pm}(u(t)) \setminus \{0,1\},\ t \in (0,+\infty),\\
u(x,0) = u_0(x), & x \in (0,1),\\
u(0,t) = u(1,t),\ u_x(0,t) = u_x(1,t), & t \in (0,+\infty).
\end{cases}
\tag{3.6}
$$

Since equality (3.4) still holds, also in this case the region $\sigma^{\phi_1}_G(u(\cdot))$ expands as fast as possible, compatibly with (3.6). We finally observe that the analogue of Theorem 2.4 is not expected to hold in this case; cf. Remark 7.1.

Remark 3.7. Let us consider a continuous function $\phi_2 : \mathbb{R} \to [0,+\infty)$ of the form $\phi_2(\xi) = \xi^2$ for $|\xi| \in [0,1]$, and $\phi_2(\xi) = \alpha\xi + \beta$ for $|\xi| \in [1,+\infty)$, where $\alpha + \beta = 1$ and $\alpha \geq 0$. The computations leading to (3.2) can be repeated for the functional F_{ϕ_2} and give the following result:

$$
\begin{aligned}
&\inf_{\substack{\psi\in\mathrm{Lip}(0,1),\,\psi(0)=\psi(1)\\ \|\psi\|_{L^2}\leq 1}} \frac{d}{d\lambda} F_{\phi_2}(u+\lambda\psi)_{|\lambda=0}\\
&= \begin{cases}
-\|u_{xx}\|_{L^2(\sigma^{\phi_2}_G(u))} & \text{if } |u_x(a_{j-})| = |u_x(b_{j+})| = \alpha/2, \quad 1 \leq j \leq m,\\
-\infty & \text{otherwise,}
\end{cases}
\end{aligned}
\tag{3.7}
$$

where the interior Neumann boundary condition, for example in a_j, is equal to $\alpha/2$ (resp., $-\alpha/2$) if u_0 is increasing (resp., decreasing) in $[a_j, b_j]$.

In particular, the resulting PDE arising from (3.7) is different from (2.5) (since the conditions on the free boundary are different) unless $\alpha = 0$, i.e., $\phi_2 = \phi$.

4. Discretization. In this section we define the spatial discretization used to approximate problem (2.5). In particular, in Definition 4.4 we introduce the discretized operator A_v.

Let $N \in \mathbb{N}$ and $i \in \{1,\ldots,N\}$. To simplify notation, we set $i+1 = 1$ and $[i,i+1] = [0,1]$ when $i = N$, and $i-1 = N$ and $[i-1,i] = [0,1]$ when $i = 1$.

For any $i = 1,\ldots,N$ we define the *hat* function $h^i \in H^1(0,1)$ as

$$
h^i(x) := \begin{cases}
Nx - (i-1) & \text{if } Nx \in [i-1,i],\\
i+1-Nx & \text{if } Nx \in [i,i+1],\\
0 & \text{otherwise.}
\end{cases}
$$

We denote by V_N the N-dimensional vector subspace of $H^1(0,1)$ generated by $h^1,\ldots,h^N$. Each function $v \in V_N$ is Lipschitz and is the restriction to $[0,1]$ of an affine continuous periodic function defined on $\mathbb{R}$.

For any $i = 1,\ldots,N$ we define the *flat* function $k^i \in L^2(0,1)$ as

$$
k^i(x) := \begin{cases}
1 & \text{if } Nx \in (i-1,i],\\
0 & \text{otherwise.}
\end{cases}
$$

We denote by W_N the N-dimensional vector subspace of $L^2(0,1)$ generated by $k^1,\dots,k^N$. W_N is the space of all piecewise constant functions on the grid.

The spaces $\bigcup_N V_N$ and $\bigcup_N W_N$ are dense in $BV(0,1)$ with respect to the weak*-topology.

Given $v \in V_N$ (resp., $w \in W_N$) we denote with $v_1,\dots,v_N$ the coordinates of v with respect to the basis $\{h^1,\dots,h^N\}$ (resp., $\{k^1,\dots,k^N\}$), i.e.,

$$v = \sum_{i=1}^N v_i h^i, \qquad v_i = v(i/N),$$

$$w = \sum_{i=1}^N w_i k^i, \qquad w_i = w\left(\frac{i-\frac{1}{2}}{N}\right).$$

We recall that

$$\int_{(0,1)} u\,dx = \frac{1}{N}\sum_{i=1}^N u_i, \qquad u \in V_N \cup W_N.$$

We define the scalar product $\langle\cdot,\cdot\rangle$ on V_N and on W_N as

$$\langle v,\overline{v}\rangle = \frac{1}{N}\sum_{i=1}^N v_i\overline{v}_i, \quad \langle w,\overline{w}\rangle = \frac{1}{N}\sum_{i=1}^N w_i\overline{w}_i, \qquad v,\overline{v}\in V_N,\ w,\overline{w}\in W_N.$$

Recall that

$$\langle w,\overline{w}\rangle = \int_{(0,1)} w\overline{w}\,dx = \frac{1}{N}\sum_{i=1}^N w_i\overline{w}_i, \qquad w,\overline{w}\in W_N.$$

Given $v \in V_N$ we define

$$\begin{aligned}
\|v\|_{L^\infty} &:= \max\{|v_i| \colon i = 1,\dots,N\},\\
\|v\|_{L^2} &:= \langle v,v\rangle^{\frac{1}{2}},\\
\|\nabla v\|_{L^1} &:= \sum_{i=1}^N |v_{i+1}-v_i| = \int_{(0,1)} |v_x|\,dx.
\end{aligned}$$

Definition 4.1. *We define the linear map $D^+\colon V_N \to W_N$ as the restriction of the weak derivative taking $H^1(0,1)$ in $L^2(0,1)$. In coordinates,*

$$(D^+v)_i = N(v_{i+1}-v_i), \qquad i \in \{1,\dots,N\}.$$

We let $D^-\colon W_N \to V_N$ be the adjoint operator of $-D^+$.

The operator D^- satisfies $\langle D^-w, v\rangle = -\langle w, D^+v\rangle$ for all $v \in V_N$ and $w \in W_N$. In coordinates,

$$(D^-w)_i = N(w_i - w_{i-1}), \qquad i \in \{1,\dots,N\}.$$

Definition 4.2. *Given $v \in V_N$ we define $\Psi_v \in W_N$ in coordinates by*

$$(\Psi_v)_i = \begin{cases} 1 & \text{if } |(D^+v)_i| \le 1,\\ 0 & \text{otherwise,}\end{cases} \qquad i \in \{1,\dots,N\}.$$

If v is ϕ-admissible, the function $\Psi_v\colon (0,1) \to \mathbb{R}$ is the characteristic function of the set $\sigma_G^\phi(v)$.

Note that the restriction of F_ϕ to V_N reads as follows: given $v \in V_N$,

$$
\begin{aligned}
F_\phi(v) &= \frac{1}{2N} \sum_{i=1}^{N} \min\big(((D^+v)_i)^2, 1\big) \\
&= \frac{1}{2}\langle \Psi_v D^+v, D^+v\rangle + \frac{1}{2}\int_{(0,1)} (1-\Psi_v)\,dx,
\end{aligned}
\tag{4.1}
$$

where

$$
\langle \Psi_v D^+v, D^+v\rangle = \sum_{i=1}^{N} (\Psi_v)_i (D^+v)_i (D^+v)_i.
$$

Remark 4.3. The function $F_{\phi|V_N}$ is Lipschitz in V_N and is of class $\mathcal{C}^\infty$ out of the polyhedral hypersurface $H := \bigcup_{i=1}^N H_i$, where $H_i := \{v \in V_N : |(D^+v)_i| = 1\}$. Assume that $v \in V_N \setminus H$. Then, for any $\overline{v} \in V_N$, we have

$$
\lim_{\lambda\to 0} \frac{\Psi_{v+\lambda\overline{v}} - \Psi_v}{\lambda} = 0 \in V_N.
$$

Therefore, using also (4.1), we get

$$
\begin{aligned}
\lim_{\lambda\to 0} \frac{F_\phi(v+\lambda\overline{v}) - F_\phi(v)}{\lambda} &= \frac{1}{2}\langle \Psi_v D^+\overline{v}, D^+v\rangle + \frac{1}{2}\langle \Psi_v D^+v, D^+\overline{v}\rangle \\
&= -\big\langle D^-\big(\Psi_v D^+v\big), \overline{v}\big\rangle.
\end{aligned}
\tag{4.2}
$$

More generally, for $v \in V_N$ there exists the limit

$$
\begin{aligned}
&\lim_{\lambda\to 0^+} \frac{F_\phi(v+\lambda\overline{v}) - F_\phi(v)}{\lambda} \\
&= \sum_{i\colon |(D^+v)_i|<1} (D^+v)_i(D^+\overline{v})_i + \sum_{i\colon |(D^+v)_i|=1} \min\big(\big((D^+v)_i(D^+\overline{v})_i\big), 0\big) \\
&= -\big\langle D^-\big(\Psi_v D^+v\big), \overline{v}\big\rangle - \sum_{i\colon |(D^+v)_i|=1} \max\big(\big((D^+v)_i(D^+\overline{v})_i\big), 0\big) \\
&\le -\big\langle D^-\big(\Psi_v D^+v\big), \overline{v}\big\rangle.
\end{aligned}
\tag{4.3}
$$

Note that both the limits in (4.2) and (4.3) attain their minimum on $\{v \in V_N : \|v\|_{L^2} = 1\}$ at

$$
\overline{v} = \frac{D^-\big(\Psi_v D^+v\big)}{\big\|D^-\big(\Psi_v D^+v\big)\big\|_{L^2}}.
$$

We are now in a position to define the discretized operator.

Definition 4.4. *Given any $v \in V_N$ we define the linear operator $A_v\colon V_N \to V_N$ as follows: for any $\overline{v} \in V_N$ we let*

$$
A_v\overline{v} := D^-\big(\Psi_v D^+\overline{v}\big).
$$

In coordinates, we have

$$(A_v\overline{v})_i = \frac{(\Psi_v)_i[\overline{v}_{i+1} - \overline{v}_i] - (\Psi_v)_{i-1}[\overline{v}_i - \overline{v}_{i-1}]}{1/N^2}.$$

Remark 4.5. By Remark 4.3, if $v \in V_N \setminus H$, then $A_v = -\nabla(F_{\phi_{|V_N}})(v)$, where ∇ indicates the gradient of the function $F_{\phi_{|V_N}}$ defined in the finite-dimensional space V_N. Note also that the equality holds in the last line of (4.3) if we take $v \in V_N$ and $\overline{v} = A_v v$.

Remark 4.6. If $v, \overline{v} \in V_N$ are such that $\Psi_v = \Psi_{\overline{v}}$, then $A_v = A_{\overline{v}}$.

5. Discretized evolution. Maximum principles. The aim of this section is to prove Theorem 5.4, which is a key step in the proof of Theorem 2.4. We begin with some elementary lemmata.

LEMMA 5.1. *Let $u_1, \dots, u_n$ be real continuous right-differentiable functions in an interval $[0, t_1)$. Define $M(t) := \max_{i=1,\dots,n} u(t)_i$. Then $M(t)$ is continuous and right-differentiable in $[0, t_1)$ and*

$$\frac{d}{dt^+}M(t) = \max_{i=1,\dots,n}\left\{\frac{d}{dt^+}u(t)_i \colon u(t)_i = M(t)\right\}, \qquad t \in [0, t_1).$$

Proof. It is enough to prove the lemma when $n = 2$. Set $f := u_1$, $g := u_2$, and let $t \in [0, t_1)$. If $f(t) \neq g(t)$, the claim is trivial since $M(t)$ equals one of the two functions in a neighborhood of t. Suppose $f(t) = g(t) = M(t)$. If $\frac{d}{dt^+}f(t) > \frac{d}{dt^+}g(t)$, then for all $h > 0$ sufficiently small $M(t+h) = f(t+h)$; hence $\frac{d}{dt^+}M(t) = \frac{d}{dt^+}f(t)$. If $\frac{d}{dt^+}f(t) = \frac{d}{dt^+}g(t)$, then $M(t+h) - M(t)$ belongs to $[f(t+h) - f(t),\ g(t+h) - g(t)]$ if $f(t+h) \leq g(t+h)$ or to $[g(t+h) - g(t),\ f(t+h) - f(t)]$ if $f(t+h) \geq g(t+h)$. Hence $\frac{d}{dt^+}M(t) = \frac{d}{dt^+}f(t) = \frac{d}{dt^+}g(t)$. $\square$

LEMMA 5.2. *Let u be a real continuous right-differentiable function in an interval $[0, t_1)$. If $\frac{d}{dt^+}u \leq 0$ on $[0, t_1)$, then u is nonincreasing.*

Proof. See, for instance, [25, p. 298]. $\square$

LEMMA 5.3. *Let u be a real continuous right-differentiable function in an interval $[0, t_1)$, and let $g = |u|$. Then g is right-differentiable on $[0, t_1)$ and*

$$\frac{d}{dt^+}g(t) = \begin{cases} (\operatorname{sign} u(t))\frac{d}{dt^+}u(t) & \text{if } u(t) \neq 0, \\ |\frac{d}{dt^+}u(t)| & \text{if } u(t) = 0, \end{cases} \qquad t \in [0, t_1).$$

Proof. If $u(t) \neq 0$, the assertion is trivial, since g is right-differentiable at t. Suppose $u(t) = 0$. Given $h > 0$ we have $\frac{g(t+h)-g(t)}{h} = |\frac{u(t+h)}{h}|$. Being u right-differentiable at t we find that $\frac{d}{dt^+}g(t) = |\frac{d}{dt^+}u(t)|$. $\square$

THEOREM 5.4. *Let $N \in \mathbb{N}$ and $u_0 \in V_N$. Then there exists a unique function u_N such that*

(a) *$u_N : [0, +\infty) \to V_N$ is continuous and right-differentiable, and satisfies*

$$(5.1) \qquad \begin{cases} \frac{d}{dt^+}u_N(t) = A_{u_N(t)}u_N(t), \qquad t \in [0, +\infty), \\ u_N(0) = u_0. \end{cases}$$

In addition, u_N satisfies the following properties:

(b) *The set-valued map* $t \in [0,+\infty) \to \{\Psi_{u_N(t)} = 1\} \subseteq (0,1)$ *is nondecreasing, and the set-valued map* $t \in [0,+\infty) \to \#\partial\{\Psi_{u_N(t)} = 1\}$ *is nonincreasing. Moreover, for any* $t \geq 0$ *there exists* $\varepsilon > 0$ *such that* $\Psi_{u_N(\tau)}$ *is constant for any* $\tau \in [t, t+\varepsilon]$*. In particular,* $\frac{d}{dt^+}\Psi_{u_N(t)} = 0$ *for any* $t \geq 0$*.*

(c) *The function* $t \in [0,+\infty) \mapsto \sup_{x\in(0,1)} u_N(x,t)$ *is nonincreasing, and the function* $t \in [0,+\infty) \mapsto \inf_{x\in(0,1)} u_N(x,t)$ *is nondecreasing.*

(d) *The function* $t \in [0,+\infty) \mapsto \|\nabla u_N(t)\|_{L^1}$ *is nonincreasing.*

(e) *The function* $t \in [0,+\infty) \mapsto F_\phi(u_N(t))$ *is continuous and right-differentiable, and*

$$\frac{d}{dt^+} F_\phi(u_N(t)) = -\left\| \frac{d}{dt^+} u_N(t) \right\|_{L^2}^2 \leq 0. \tag{5.2}$$

(f) *There exist* $M \in \mathbb{N}$*,* $M \leq N$*, and positive times* $t_1, \dots, t_M$ *such that* u_N *is analytic on each interval of* $(0,+\infty)\setminus\{t_1,\dots,t_M\}$*, and* $\{t_1,\dots,t_M\}$ *coincides with the jump set of the function* $t \in [0,+\infty) \to \Psi_{u_N(t)}$*.*

Proof. Let $t_0 := 0$, and consider the function $u : [t_0,+\infty) \to V_N$,

$$u(t) = u_0 \exp((t - t_0)A_{u_0}), \qquad t \geq t_0, \tag{5.3}$$

i.e., the solution of

$$\begin{cases} \frac{d}{dt^+} u(t) = A_{u_0}\, u(t), & t \in (t_0, +\infty), \\ u(t_0) = u_0, \end{cases}$$

where we view the operator A_{u_0} as an $(N \times N)$-matrix.

For any $t \geq t_0$ let

$$\begin{aligned} \widetilde{M}(t) &:= \max\left(0, \max_{i=1,\dots,N} \{(D^+u(t))_i \colon (\Psi_{u_0})_i = 1\}\right), \\ \widetilde{m}(t) &:= \min\left(0, \min_{i=1,\dots,N} \{(D^+u(t))_i \colon (\Psi_{u_0})_i = 1\}\right). \end{aligned}$$

Observe that

$$-1 \leq \widetilde{m}(t_0) \leq \widetilde{M}(t_0) \leq 1. \tag{5.4}$$

In addition, the maps $t \in [t_0,+\infty) \to (D^+u(t))_i$ are continuously differentiable for any $i \in \{1,\dots,N\}$; hence, by Lemma 5.1, $\widetilde{M}(t)$ and $\widetilde{m}(t)$ are right-differentiable for any $t \geq t_0$.

Claim 1. For any $t \geq t_0$ we have

$$\frac{d}{dt^+}\widetilde{M}(t) \leq 0, \qquad \frac{d}{dt^+}\widetilde{m}(t) \geq 0. \tag{5.5}$$

Since D^+ is a linear operator, for all $t \geq t_0$ we have

$$\frac{d}{dt^+} D^+u(t) = D^+ \frac{d}{dt^+} u(t) = D^+ A_{u_0} u(t) = D^+ D^- \left(\Psi_{u_0} D^+ u(t)\right).$$

Therefore, if $i \in \{1, \dots, N\}$ is such that $(D^+u(t))_i = \widetilde{M}(t)$, we have

$$
\begin{aligned}
\frac{d}{dt^+}(D^+u)_i &= N\left[(D^-(\Psi_{u_0}D^+u))_{i+1} - (D^-(\Psi_{u_0}D^+u))_i\right] \\
&= N^2\left[(\Psi_{u_0})_{i+1}(D^+u)_{i+1} - (\Psi_{u_0})_i(D^+u)_i\right] \\
&\quad - N^2\left[(\Psi_{u_0})_i(D^+u)_i - (\Psi_{u_0})_{i-1}(D^+u)_{i-1}\right] \\
&= N^2\left[(\Psi_{u_0})_{i+1}(D^+u)_{i+1} - \widetilde{M}(t)\right. \\
&\quad \left. + (\Psi_{u_0})_{i-1}(D^+u)_{i-1} - \widetilde{M}(t)\right],
\end{aligned}
\tag{5.6}
$$

where both sides are evaluated at $t \geq t_0$. Since $(\Psi_{u_0}D^+u)_j \leq \widetilde{M}(t)$ for all $j \in \{1, \dots, N\}$, from the previous equation we obtain $\frac{d}{dt^+}(D^+u(t))_i \leq 0$ for all $i \in \{1, \dots, N\}$ such that $(\Psi_{u_0})_i = 1$ and $(D^+u(t))_i = \widetilde{M}(t)$. As a consequence we get

$$
0 \geq \max_{i=1,\dots,N}\left\{\frac{d}{dt^+}\left(D^+u(t)\right)_i : (\Psi_{u_0})_i = 1,\ (D^+u(t))_i = \widetilde{M}(t)\right\} = \frac{d}{dt^+}\widetilde{M}(t),
$$

where the last equality follows from Lemma 5.1. In a similar way we can prove that if $i \in \{1, \dots, N\}$ is such that $(\Psi_{u_0})_i = 1$ and $(D^+u(t))_i = \widetilde{m}(t)$, we have $\frac{d}{dt^+}(D^+u(t))_i \geq 0$; hence $\frac{d}{dt^+}\widetilde{m}(t) \geq 0$. This concludes the proof of Claim 1.

Claim 1 and Lemma 5.2 imply that $t \to \widetilde{M}(t)$ is nonincreasing and that $t \to \widetilde{m}(t)$ is nondecreasing. Recalling (5.4) we conclude that $-1 \leq \widetilde{m}(t) \leq \widetilde{M}(t) \leq 1$ for any $t \geq t_0$. Hence

$$
\Psi_{u(t)} = 1 \quad \text{at those nodes where} \quad \Psi_{u_0} = 1.
$$

It follows that the set-valued map $t \in [t_0, +\infty) \to \{|D^+u(t)| \leq 1\} = \sigma_G^\phi(u(t)) \subseteq (0,1)$ is nondecreasing.

Let us define

$$
t_1 := \sup\{t \geq t_0 \colon A_{u(s)} = A_{u_0} \quad \forall\, s \in [t_0, t)\}. \tag{5.7}
$$

We want to show that $t_1 > t_0$.

For all $i \in \{1, \dots, N\}$ such that $|(D^+u_0)_i| \leq 1$ we have $|(D^+u(t))_i| \leq 1$ for all $t \geq t_0$. In addition, $t \to D^+u(t)$ being a continuous function, if $|(D^+u_0)_i| > 1$, then there exists $\varepsilon > 0$ independent of i such that $|(D^+u(t))_i| > 1$ for any $t \in [t_0, t_0 + \varepsilon)$. Hence $\Psi_{u(t)} = \Psi_{u_0}$ for any $t \in [t_0, t_0 + \varepsilon]$. From Remark 4.6 it follows that $A_{u(t)} = A_{u_0}$ for any $t \in [t_0, t_0 + \varepsilon)$, which gives $t_1 \geq t_0 + \varepsilon > t_0$.

We have proven that the function $u(t)$ in (5.3) satisfies (5.1) for $t \in [t_0, t_1)$. We have also proven that either $t_1 = +\infty$ or $\Psi_{u(t_1)} \geq \Psi_{u(t_0)}$ and $(\Psi_{u(t_1)})_i > \Psi_{u(t_0)}$ for some $i \in \{1, \dots, N\}$.

If $t_1 < +\infty$, repeating the previous construction with t_1 in place of t_0 and $u(t_1)$ in place of u_0, we find a time $t_2 > t_1$ and a solution u of (5.1) defined in $[t_1, t_2)$ which satisfies (5.1). Repeating this argument, we can construct an increasing sequence (t_k) of times. Since at step k the number of nodes where $\Psi_{u(t)} = 1$ is nondecreasing, we can only have a finite number $M \leq N$ of steps, and in the last step we find that $t_M = +\infty$. Gluing together the solutions defined in the intervals $[t_k, t_{k+1})$ we find a function u_N defined for all $t \geq 0$ such that (a), (b), and (f) hold.

Let us prove (c), (d), and (e). Write for notational simplicity u in place of u_N. Let $t \in [0, +\infty)$. We say that $i \in \{1, \dots, N\}$ is a relative maximum (resp., minimum) for $u(t)$ if

$$
u(t)_i \geq \max\{u(t)_{i-1}, u(t)_{i+1}\} \qquad (\text{resp., } u(t)_i \leq \min\{u(t)_{i-1}, u(t)_{i+1}\}).
$$

Claim 2. Let $t \in [0, +\infty)$. If i is a relative maximum (resp., minimum) for $u(t)$, then $\frac{d}{dt^+} u(t)_i \le 0$ (resp., ≥ 0).

By (5.1),

$$
\begin{aligned}
\frac{d}{dt^+} u(t)_i &= N\Big[(\Psi_{u(t)})_i (D^+ u(t))_i - (\Psi_{u(t)})_{i-1} (D^+ u(t))_{i-1}\Big] \\
&= N^2\Big[(\Psi_{u(t)})_i (u(t)_{i+1} - u(t)_i) - (\Psi_{u(t)})_{i-1} (u(t)_i - u(t)_{i-1})\Big].
\end{aligned} \tag{5.8}
$$

Hence, if i is a relative maximum, we have $\frac{d}{dt^+} u(t)_i \le 0$ since $u(t)_{i+1} - u(t)_i \le 0$ and $u(t)_i - u(t)_{i-1} \ge 0$. Similarly, we can reason when i is a relative minimum, and Claim 2 follows.

Assertion (c) then follows from Claim 2.

Consider now the function

$$
S_i(t) := \begin{cases} \operatorname{sign}(u(t)_{i+1} - u(t)_i) & \text{if } u(t)_{i+1} \ne u(t)_i, \\ |\frac{d}{dt^+}(u(t)_{i+1} - u(t)_i| & \text{if } u(t)_{i+1} = u(t)_i. \end{cases}
$$

By Lemma 5.3 we have

$$
\begin{aligned}
\frac{d}{dt^+} \|\nabla u(t)\|_{L^1} &= \sum_{i=1}^N \frac{d}{dt^+} |u(t)_{i+1} - u(t)_i| = \sum_{i=1}^N S_i(t) \left(\frac{d}{dt^+} u(t)_{i+1} - \frac{d}{dt^+} u(t)_i \right) \\
&= \sum_{i=1}^N (S_{i-1}(t) - S_i(t)) \frac{d}{dt^+} u(t)_i.
\end{aligned}
$$

In order to prove that $\frac{d}{dt^+} \|\nabla u(t)\|_{L^1} \le 0$, it is enough to show that

$$
(S_{i-1}(t) - S_i(t)) \frac{d}{dt^+} u(t)_i \le 0 \qquad \forall\, i \in \{1, \dots, N\}. \tag{5.9}
$$

We divide the proof into four cases. We write for simplicity u in place of $u(t)$ and S in place of $S(t)$.

Case 1: the point i is simultaneously a relative maximum and a relative minimum, i.e., $u_{i-1} = u_i = u_{i+1}$. From (5.8) we deduce that $\frac{d}{dt^+} u_i = 0$, and (5.9) is satisfied.

Case 2: the point i is a relative maximum but not a relative minimum. Then either $u_i > u_{i-1}$ or $u_i > u_{i+1}$. So either $S_{i-1} = 1$ or $S_i = -1$, and in both cases $S_{i-1} - S_i \ge 0$. With $(D^+ u)_i \le 0$ and $(D^+ u)_{i-1} \ge 0$, from (5.8) we find that $\frac{d}{dt^+} u \le 0$, and (5.9) follows.

Case 3: the point i is a relative minimum but not a relative maximum. Then either $S_{i-1} = -1$ or $S_i = 1$, while $\frac{d}{dt^+} u \ge 0$.

Case 4: the point i is neither a relative maximum nor a relative minimum. Then either $u_{i-1} < u_i < u_{i+1}$ or $u_{i-1} > u_i > u_{i+1}$. In both cases we have $S_{i-1} = S_i$, and hence (5.9) holds.

Then (d) follows from Claim 1 and Lemma 5.2.

Let us now prove (e). Recalling that $\frac{d}{dt^+} \Psi_u = 0$ and using the expression of $F_\phi(u)$ as

$$
F_\phi(u) = \frac{1}{2} \int_{(0,1)} [\Psi_u (D^+ u)^2 + (1 - \Psi_u)]\, dx, \tag{5.10}
$$

we have

$$\begin{aligned}\frac{d}{dt^+}F_\phi(u) &= \frac{1}{2}\int_{(0,1)}\Psi_u\frac{d}{dt^+}(D^+u)^2\,dx = \int_{(0,1)}\Psi_u D^+u\frac{d}{dt^+}D^+u\,dx\\ &= \left\langle D^+\frac{d}{dt^+}u, \Psi_u D^+u\right\rangle = -\left\langle \frac{d}{dt^+}u, D^-\left(\Psi_u D^+u\right)\right\rangle\\ &= -\left\langle \frac{d}{dt^+}u, A_u u\right\rangle = -\int_{(0,1)}\left(\frac{d}{dt^+}u\right)^2 dx = -\left\|\frac{d}{dt^+}u\right\|_{L^2}^2 \le 0,\end{aligned}$$

which proves (5.2).

For all $t \geq 0$ for which $\Psi_{u(\cdot)}$ is continuous at t, the continuity of $F_\phi(u(\cdot))$ at t is a consequence of (5.10). On the other hand, if $(\Psi_{u(\cdot)})_i$ has a discontinuity at $\bar{t} \geq 0$, we know that there exists $\sigma > 0$ such that $(\Psi_u)_i = 0$ in $(\bar{t} - \sigma, \bar{t})$ and $(\Psi_u)_i = 1$ in $[\bar{t}, \bar{t} + \sigma)$. This implies that $|(D^+u)_i| > 1$ in $(\bar{t} - \sigma, \bar{t})$ and $|(D^+u)_i| \leq 1$ in $[\bar{t}, \bar{t} + \sigma)$. Since $(D^+u(\cdot))_i$ is continuous, we deduce that $(D^+u(\bar{t}))_i^2 = 1$. As a result,

$$\lim_{t \to \bar{t}^\pm} \Psi_{u(t)}(D^+u(t))^2 + (1 - \Psi_{u(t)}) = 1.$$

This implies the continuity of the map $t \mapsto F_\phi(u(t))$ at $\bar{t}$.

To conclude the proof of the theorem, we need to show that the function u_N is unique. The proof is divided into two steps.

Step 1. Let $\underline{u}_N : [0, +\infty) \to V_N$ be a continuous right-differentiable function satisfying (5.1). Assume, in addition, that for any $t \geq 0$ there exists $\varepsilon > 0$ such that $\Psi_{\underline{u}_N(\tau)}$ is constant for any $\tau \in [t, t+\varepsilon]$. Then $\underline{u}_N = u_N$.

Let $\varepsilon > 0$ be such that $\Psi_{\underline{u}_N}$ is constant on $[0, \varepsilon]$. It follows that $\underline{u}_N = u_N$ in $[0, \varepsilon]$, since the solution of (5.1), in $[0, \varepsilon]$, is uniquely given by (5.3). Without loss of generality, we can assume that

$$\varepsilon < t_1, \tag{5.11}$$

where t_1 is defined in (5.7) and is the first time for which Ψ_{u_N} is discontinuous. Recall that, by definition, $\{\Psi_{u_N(\varepsilon)} = 0\} = \{|D^+u_N(\varepsilon)| > 1\}$.

We claim that

$$\{\Psi_{u_N(\varepsilon)} = 1\} = \{|D^+u_N(\varepsilon)| < 1\}. \tag{5.12}$$

Indeed, denote by $I_j = (j/N, (j+1)/N)$ the generic interval of the grid and by $\sigma_j(t)$ the slope of $u_N(t)$ in I_j. A closer look at the last term in (5.6) reveals that for any $t \in [0, t_1)$, if

$$\widetilde{M}(t) = (D^+u(t))_i = 1, \text{ and either } \sigma_{i-1}(t) \neq 1 \text{ or } \sigma_{i+1}(t) \neq 1, \tag{5.13}$$

then

$$\frac{d}{dt^+}(D^+u(t))_i < 0, \tag{5.14}$$

where we recall that u stands for u_N. Similarly, if

$$\widetilde{m}(t) = (D^+u(t))_i = -1, \text{ and either } \sigma_{i-1}(t) \neq -1 \text{ or } \sigma_{i+1}(t) \neq -1, \tag{5.15}$$

then

$$\frac{d}{dt^+}(D^+u(t))_i > 0. \tag{5.16}$$

Observe that from (5.13), (5.14), (5.15), and (5.16), we already deduce that if $|\sigma_i(t)| = 1$ and if either $|\sigma_{i-1}(t)| \neq 1$ or $|\sigma_{i+1}(t)| \neq 1$, then $|\sigma_i(t+\tau)| < 1$ for any $\tau > 0$ small enough. What remains is the most delicate case; namely, we have to consider those intervals I_i of the grid where $|\sigma_i(t)| = 1$ and also $|\sigma_{i-1}(t)| = |\sigma_{i+1}(t)| = 1$. The following observation again follows from the expression on the right-hand side of (5.6). For any $t \in [0, t_1)$, if

$$\widetilde{M}(t) = (D^+u(t))_i = 1, \text{ and } \sigma_{i-1}(t) = 1 = \sigma_{i+1}(t), \tag{5.17}$$

then

$$\frac{d}{dt^+}(D^+u(t))_i = 0. \tag{5.18}$$

Similarly, if

$$\widetilde{m}(t) = (D^+u(t))_i = -1, \text{ and } \sigma_{i-1}(t) = -1 = \sigma_{i+1}(t), \tag{5.19}$$

then

$$\frac{d}{dt^+}(D^+u(t))_i = 0. \tag{5.20}$$

Hence (5.18) and (5.20) do not allow us to conclude that if $|\sigma_i(t)| = 1$ and if $|\sigma_{i-1}(t)| = 1 = |\sigma_{i+1}(t)|$, then $|\sigma_i(t+\tau)| < 1$ for any $\tau > 0$ small enough. However, such an inequality is valid and can be proved as follows. Let us denote by C the connected component of $\{\Psi_{u(t)} = 1\}$ containing I_i and by I_{i^-} (resp., I_{i^+}) the extremal left (resp., right) interval of the grid belonging to C (note that thanks to the boundary conditions, 0 is not a boundary point of I_{i^-} and 1 is not a boundary point of I_{i^+}). By (5.14) and (5.16) it follows that $|\sigma_{I_{i^-}}(t+\tau)| < 1$ and $|\sigma_{I_{i^+}}(t+\tau)| < 1$ for any $\tau > 0$. Using the previous arguments, we deduce that $|\sigma_{I_{i^-+1}}(t+\tau)| < 1$ and $|\sigma_{I_{i^+-1}}(t+\tau)| < 1$ for any $\tau > 0$ small enough. After a finite number of iterations, we deduce that $|\sigma_i(t+\tau)| < 1$ for any $\tau > 0$ small enough. This concludes the proof of the claim.

We can now repeat the reasoning taking ε as initial time, and we conclude that $\underline{u}_N = u_N$ in $[0, t_1]$. Iterating the argument for any $i = 1, \ldots, M$ we obtain that $\underline{u}_N = u_N$ in $[0, +\infty)$.

Step 2. Let $\underline{u}_N : [0, +\infty) \to V_N$ be a continuous right-differentiable function satisfying (5.1). Then for any $t \geq 0$ there exists $\varepsilon > 0$ such that $\Psi_{\underline{u}_N(\tau)}$ is constant for any $\tau \in [t, t+\varepsilon]$.

Let us consider an interval I_i where the slope $\underline{\sigma}_i(t)$ of $\underline{u}_N(t)$ satisfies $|\underline{\sigma}_i(t)| = 1$. Arguing as in Step 1, independently of the values of $|\underline{\sigma}_{i-1}(t)|$ and $|\underline{\sigma}_{i+1}(t)|$, we deduce that $|\underline{\sigma}_i(t+\tau)| < 1$ for any $\tau > 0$ sufficiently small. This implies that $\Psi_{\underline{u}_N(t)}$ is right continuous and proves Step 2.

Steps 1 and 2 conclude the proof of uniqueness, and hence the proof of the theorem. $\square$

Remark 5.5. We have already observed in the introduction that the right-hand side of the ODE's system $\dot{u} = -\nabla(F_{\phi_{|V_N}})$ (see (5.1)) is only a bounded function, since $F_{\phi_{|V_N}}$ is Lipschitz. Nevertheless, due to the special form of F_ϕ the solution in the sense of Theorem 5.4 is unique. This is not the case if we change the notion of solution to (5.1), for instance if we consider solutions to the system (5.1) only for almost all times. This is shown in the following example, which is related to the nonuniqueness example (Example 1 of section 2) and also shows another interesting phenomenon: the solution considered in Theorem 5.4 does not depend continuously on the initial datum.

Example 2. Assume that the initial datum $u_0 = u_{0N} \in V_N$ (with N even, in such a way that $1/2$ is a point of the mesh) is as follows:

$u_0 = 0$ in $(0, 1/2)$;

u_0 is increasing in $(1/2, 1/2 + 1/N)$ with slope exactly 1;

u_0 is piecewise linear, with slopes (in modulus) strictly less than 1 in $(1/2 + 1/N, 1)$.

Note that such an initial datum can be obtained from the discretization of solutions considered in the nonuniqueness example (Example 1 of section 2) at a time slightly smaller than t_* (and converging to t_* as $N \to +\infty$). The (unique) solution u_N of Theorem 5.4 is such that the linear part in the interval $(1/2, 1/2 + 1/N)$ for small positive times decreases its slope to a value less than 1. This solution, in the limit $N \to +\infty$, produces the solution $u_1(\cdot + t_*)$ of Example 1 of section 2.

Given $\varepsilon \in (0, 1)$ let us consider the functions $u_0^{\varepsilon\pm} = u_{0N}^{\varepsilon\pm} \in V_N$ defined as follows: $u_0^{\varepsilon\pm} := u_0$ in $(0, 1/2)$, $u_0^{\varepsilon\pm} := u_0 \pm \frac{\varepsilon}{N}$ in $(1/2 + 1/N, 1)$, and $u_0^{\varepsilon\pm}$ is increasing in $(1/2, 1/2 + 1/N)$ with slope $1 \pm \varepsilon$. Then, if $u_N^{\varepsilon\pm}$ denotes the solution of Theorem 5.4 having $u_0^{\varepsilon\pm}$ as initial datum, we have

$$\lim_{\varepsilon \to 0^+} u_N^{\varepsilon -} = u_N,$$

while

$$\lim_{\varepsilon \to 0^+} u_N^{\varepsilon +} = \widetilde{u}_N,$$

where $\widetilde{u}_N \in V_N$ satisfies (a) of Theorem 5.4 for any $t > 0$ but *not* for $t = 0$, and

$$\lim_{N \to +\infty} \widetilde{u}_N(\cdot) = u_2(\cdot + t_*),$$

where u_2 is as in Example 1 of section 2. Hence the solution u_N of Theorem 5.4 is not continuous with respect to initial data. We can summarize the above discussion, coupled with the remarks of section 2, with the following conclusion: solutions to (iv), (v), and (vi) of Theorem 2.4 are not unique thanks to Example 1 of section 2 (which, however, we believe to be nongeneric). On the other hand, solutions of Theorem 5.4 are unique; however, they do not depend in a continuous way on the initial data. It is such an instability at the discrete level (i.e., for fixed N) which seems to produce nonuniqueness in the limit $N \to +\infty$.

6. Convergence of the approximating schemes. In this section we prove Theorem 2.4. We begin with the following elementary lemma.

LEMMA 6.1. *Let* $u_0 \in \mathcal{A}_\phi(0, 1)$. *Then there exists a sequence* $(u_0^N) \subset V_N$ *of functions satisfying assertion* (i) *of Theorem* 2.4.

Proof. Define $u_0^N \in V_N$ as $(u_0^N)_i := u_0(i/N)$. Then $\|u_0^N\|_{BV(0,1)} \le \|u_0\|_{BV(0,1)}$ for any $N \in \mathbb{N}$, (u_0^N) converges to u_0 weakly* in $BV(0, 1)$ and strongly in $L^2(0, 1)$, and $\lim_{N \to +\infty} \|u_0^N\|_{BV(0,1)} = \|u_0\|_{BV(0,1)}$. Note that for any $x \in [0, 1]$ such that $\mathrm{dist}(x, \sigma_B^\phi(u_0)) > 1/N$ (resp., $\mathrm{dist}(x, \sigma_G^\phi(u_0)) > 1/N$), then $x \in \sigma_G^\phi(u_0^N)$ (resp., $x \in$

$\sigma_B^\phi(u_0^N))$. It follows that $\lim_{N\to+\infty} d_{\mathcal{H}}(\sigma_G^\phi(u_0^N), \sigma_G^\phi(u_0)) = 0$. Since any isolated point in $\sigma_B^\phi(u)$ belongs to $\sigma_B^\phi(u_0^N)$ for N large enough, we also have $d_{\mathcal{H}}(\sigma_B^\phi(u_0^N), \sigma_B^\phi(u_0)) \to 0$ as $N \to +\infty$.

Now let $K \subset \sigma_G^\phi(u_0)$ be an interval with $\overline{K} \subset (0,1)$. Then $\|u_0^N\|_{L^2(K)} \leq \|u_0\|_{L^2(K_N)}$, where $K_N := \{x \in \mathbb{R} : \operatorname{dist}(x,K) < 1/N\}$ and N is large enough in such a way that $K_N \subset (0,1)$. Hence $\|u_0^N\|_{L^2(K)} \leq \|u_0\|_{L^2(K)} + \frac{2}{N}$, (u_0^N) weakly converges to u_0 in $H^1(K)$, and $\|u_0^N{}_x\|_{L^2(K)}$ converges to $\|u_{0x}\|_{L^2(K)}$. Therefore $\lim_{N\to+\infty} F_\phi(u_0^N) = F_\phi(u_0)$, and this concludes the proof. ∎

By construction, $u_0^N \in V_N \subset \mathcal{A}_\phi(0,1)$; moreover, we can assume that if N is large enough, the number of connected components of $\sigma_B^\phi(u_0^N)$ equals m, the number of connected components of $\sigma_B^\phi(u_0)$, and we can uniquely write $\sigma_B^\phi(u_0^N)$ as in (2.2).

DEFINITION 6.2. *Let $u_0 \in \mathcal{A}_\phi(0,1)$, and let (u_0^N) be as in Lemma* 6.1. *We denote by $u^N\colon [0,+\infty) \to V_N$ the solution of*

$$\begin{cases} \dfrac{d}{dt^+}u(t) = A_{u(t)}u(t), & t \in (0,+\infty), \\ u^N(0) = u_0^N \end{cases} \tag{6.1}$$

given by Theorem 5.4 *(with u_0 in* (5.1) *replaced by u_0^N).*

Note that all assertions in Theorem 2.4(ii) are satisfied.

Remark 6.3.

(a) For any $j \in \{1,\dots,m\}$ we define

$$T_j^N := \sup\left\{t \geq 0\colon \sigma_B^\phi(u^N(t)) \cap [a_j^N(0), b_j^N(0)] \neq \emptyset\right\} > 0,$$
$$[a_j^N(t), b_j^N(t)] := \sigma_B^\phi(u^N(t)) \cap [a_j^N(0), b_j^N(0)], \qquad t \in [0, T_j^N).$$

Then $a_j^N(0) = a_j^0$, $b_j^N(0) = b_j^0$, and

$$\sigma_B^\phi(u^N(t)) = \bigcup_{j=1}^m [a_j^N(t), b_j^N(t)], \qquad t \in [0,+\infty),$$

where we have set

$$[a_j^N(t), b_j^N(t)] := \emptyset \qquad \text{if } t \geq T_j^N.$$

(b) The map $t \in [0,T_j^N) \mapsto a_j^N(t)$ is continuous and nondecreasing, and the map $t \in [0,T_j^N) \mapsto b_j^N(t)$ is continuous and nonincreasing.

(c) Since $u^N(\cdot,t) = u_0^N(\cdot)$ on $\sigma_B^\phi(u^N(t))$, for any $j \in \{1,\dots,m\}$ we have that either $u_0^N{}_x(x,t) > 1$ for a.e. $x \in [a_j^N(t), b_j^N(t)]$ or $u_0^N{}_x(x,t) < -1$ for a.e. $x \in [a_j^N(t), b_j^N(t)]$.

LEMMA 6.4. *There exists a constant $C > 0$ depending only on u_0 such that*

$$\sup_{t>0}\sup_{N\in\mathbb{N}} F_\phi(u^N(t)) \leq C,$$
$$\sup_{N\in\mathbb{N}} \left\|\frac{d}{dt^+}u^N\right\|_{L^2((0,+\infty);L^2(0,1))} \leq C,$$
$$\sup_{N\in\mathbb{N}} \|u^N\|_{L^\infty((0,+\infty);BV(0,1))} \leq C.$$

Proof. The first two inequalities follow from (2.3) and (5.2). The last one follows from Theorem 5.4 (c) and (d) and (2.3). ∎

Remark 6.5. Thanks to Lemma 6.4 (and extracting if necessary a not relabelled subsequence) the sequence (u^N) converges weakly in $H^1_{\mathrm{loc}}((0,+\infty);L^2(0,1))$ and weakly* in $L^\infty((0,+\infty);BV(0,1))$ to a function u as $N\to+\infty$, and this gives assertion (iii) of Theorem 2.4. In particular, for almost every $x\in(0,1)$ the function $t\in[0,+\infty)\to u(x,t)$ is continuous, and $u^N(x,\cdot)\to u(x,\cdot)$ uniformly on $[0,+\infty)$. As a consequence the function $u(\cdot,t)$ is well defined for all $t\in[0,+\infty)$ and $\|Du(\cdot,t)\|\le\|Du_0\|$. It also follows that $u^N(t)\to u(t)$ weakly* in $BV(0,1)$ for almost every $t\ge 0$.

Remark 6.6. Possibly extracting a further subsequence, we can assume that for any $j\in\{1,\dots,m\}$, $T_j^N\to T_j$ as $N\to+\infty$ for some $T_j\in[0,+\infty]$. If $T_j>0$, since the functions $a_j^N(\cdot)$ (resp., $b_j^N(\cdot)$) are nondecreasing (resp., nonincreasing), there exist nondecreasing functions $a_j:[0,T_j)\to[0,1]$ (resp., nonincreasing functions $b_j:[0,T_j)\to[0,1]$) such that $a_j^N\to a_j$ (resp., $b_j^N\to b_j$) weakly* in $BV(0,T_j-\varepsilon)$ as $N\to+\infty$ for all $\varepsilon>0$ small enough. Since $a_j^N(t)<b_j^N(t)$ for all $t\in[0,T_j^N)$, passing to the limit we obtain that $a_j(t)\le b_j(t)$ for all $t\in[0,T_j)$. Recall that $a_j(0)=a_j^0$ and $b_j(0)=b_j^0$ for any $j\in\{1,\dots,m\}$.

In the following, set $\mathcal{J}(0):=\{1,\dots,m\}$.

DEFINITION 6.7. *For any $t\in[0,+\infty)$ we define*

$$
\begin{aligned}
\mathcal{J}(t) &:= \{j\in\{1,\dots,m\}: t<T_j\},\\
B(t) &:= \bigcup_{j\in\mathcal{J}(t)}[a_j(t),b_j(t)],\\
G(t) &:= [0,1]\setminus B(t),\\
\widetilde{B}(t) &:= \bigcup_{j\in\mathcal{J}(t):\,a_j(t)<b_j(t)}[a_j(t),b_j(t)]\cup\bigcup_{j\in\mathcal{J}(t):\,a_j(t)=b_j(t)\in J_{u(t)}}\{a_j(t)\},\\
\widetilde{G}(t) &:= [0,1]\setminus\widetilde{B}(t).
\end{aligned}
$$

Note that

$$
\overline{\mathrm{int}(B(t))}\subseteq\widetilde{B}(t)\subseteq B(t). \tag{6.2}
$$

LEMMA 6.8. *For any $j\in\{1,\dots,m\}$ we have $T_j>0$, and the functions a_j and b_j are continuous on $[0,T_j)$.*

Proof. Assume by contradiction that there exists $j\in\{1,\dots,m\}$ such that $T_j=0$. Then $[a_j^0,b_j^0]\in\sigma_G^\phi(u(s))$ for any $s>0$. Hence $u(s)$ is one-Lipschitz in $[a_j^0,b_j^0]$ for any $s>0$.

Case 1. Assume that $a_j^0<b_j^0$. Using the triangular property and $u(0)=u_0$, for any $x,x'\in[a_j^0,b_j^0]$, $x\neq x'$, we have

$$
\begin{aligned}
|u(x,s)-u(x,0)|+|u(x',s)-u(x',0)| &\ge |u_0(x)-u_0(x')|-|u(x,s)-u(x',s)|\\
&\ge |u_0(x)-u_0(x')|-|x-x'|>0.
\end{aligned}
$$

This means that $s\mapsto u(x,s)$ has a discontinuity at $s=0$ for a.e. $x\in[a_j^0,b_j^0]$, and this is in contradiction with $u\in AC^2([0,+\infty);L^2(0,1))$.

Case 2. Assume that $a_j^0=b_j^0$. Let $L:=u_0(a^0_{j+})$ and $l:=u_0(a^0_{j-})$. We can assume $l<L$. Let $\delta:=\min(\frac{(L-l)}{4},a_1^0,(1-b_m^0),\min_{j=1,\dots,m-1}(a_{j+1}^0-b_j^0))>0$, and define $x^{\pm} := a_j^0 \pm \delta$. Note that $u(s)$ is one-Lipschitz in (x^-, x^+) for any $s > 0$. For any $x, x' \in (x^-, x^+)$, $x \neq x'$, we have

$$\begin{aligned}|u(x,s) - u(x,0)| + |u(x',s) - u(x',0)| &\geq |u_0(x) - u_0(x')| - |x - x'| \\ &\geq |u_0(a_{j\,-}^0) - u_0(a_{j\,+}^0)| - |u_0(x) - u_0(a_{j\,-}^0)| \\ &\quad - |u_0(x') - u_0(a_{j\,+}^0)| - |x - x'| \\ &\geq L - l - 4\delta > 0.\end{aligned}$$

As above, this is in contradiction with $u \in AC^2([0, +\infty); L^2(0, 1))$.

Let us now prove that a_j and b_j are continuous. Assume by contradiction that a_j has a discontinuity at $t = \bar{t} \in [0, T_j)$. Since a_j is nondecreasing, $\bar{t}$ is a jump point of a_j. If $\bar{t} = 0$, we can argue in analogy to Case 1. Assume $\bar{t} > 0$, and let $x^- := \lim_{t \to \bar{t}^-} a_j(t) < x^+ := \lim_{t \to \bar{t}^+} a_j(t)$. Since $u^N(\cdot, t)$ coincides with $u_0^N(\cdot)$ in $\sigma_B^\phi(u^N(t))$, it follows that $u(\cdot, t)$ coincides with $u_0(\cdot)$ in each connected component of $\mathrm{int}(B(t))$. In particular, the function $u(t)$ coincides with u_0 in (x^-, x^+) for all $t \in [0, \bar{t})$. We then obtain

$$|u(x,t) - u(x',t)| = |u_0(x) - u_0(x')| > |x - x'| \qquad \forall\ x, x' \in (x^-, x^+).$$

On the other hand, $u(s)$ is one-Lipschitz in (x^-, x^+) for any $s > \bar{t}$. It follows that, for any $x, x' \in (x^-, x^+)$,

$$|u(x,t) - u(x,s)| + |u(x',t) - u(x',s)| \geq |u_0(x) - u_0(x')| - |x - x'| > 0,$$

which contradicts $u \in AC^2([0, +\infty); L^2(0, 1))$. This proves the continuity of a_j. The continuity of b_j follows using a similar argument. ∎

Remark 6.9. Whenever $T_j < +\infty$, arguing as in Lemma 6.8 with $\bar{t} = T_j$, we get $\lim_{t \to T_j^-} a_j(t) = \lim_{t \to T_j^-} b_j(t)$.

Remark 6.10.

(a) Since $u^N(\cdot, t)$ is one-Lipschitz in each connected component of $\sigma_G^\phi(u^N(t))$, it follows that $u(\cdot, t)$ is one-Lipschitz in each connected component of $\widetilde{G}(t)$.

(b) The function $u(\cdot, t)$ coincides with $u_0(\cdot)$ in each connected component of $\mathrm{int}(B(t))$.

Remark 6.11. As a consequence of Lemma 6.8 the sequence (a_j^N) (resp., (b_j^N)) converges to a_j (resp., to b_j) uniformly in $[0, T_j - \varepsilon)$ as $N \to +\infty$ for any $\varepsilon > 0$ small enough. In particular, for any connected component I of $B(t)$ there exists a connected component I_N of $\sigma_B^\phi(u^N(t))$ such that

$$\lim_{N \to +\infty} d_{\mathcal{H}}(I_N, I) = 0.$$

LEMMA 6.12. *The function $u(t)$ is ϕ-admissible for any $t \geq 0$ and*

$$\overline{\mathrm{int}(B(t))} \subseteq \sigma_B^\phi(u(t)) \subseteq B(t) \qquad \forall\ t \in [0, +\infty). \tag{6.3}$$

Proof. Recalling Remark 6.5, let us fix $t \geq 0$ such that $u^N(t) \to u(t)$ weakly* in $BV(0, 1)$. From Remark 6.10(a) it follows that $u(t)$ is one-Lipschitz in each connected component of $\widetilde{G}(t)$; hence

$$\widetilde{G}(t) \subseteq \sigma_G^\phi(u(t)).$$

Moreover, from Remarks 6.3(c) and 6.11 it follows that the assertion in Remark 2.2(c) holds with u replaced by $u(t)$ for any connected component I of $\widetilde{B}(t)$ and any Borel set $A \subseteq I$. Indeed, if A is compactly contained in I, then $Du^N(A) = Du_0^N(A)$ for $N \in \mathbb{N}$ large enough, and by construction (see Lemma 6.1) in the first case $|A| < \lim_{N\to+\infty} Du_0^N(A) = Du(A)$ or in the second case $-|A| > \lim_{N\to+\infty} Du_0^N(A) = Du(A)$. If A is a boundary point of I, then (using Remarks 6.11 and 6.10(a)) in the first case $0 \le \lim_{N\to+\infty} Du^N(A) = Du(A)$ or in the second case $0 \le \lim_{N\to+\infty} Du^N(A) = Du(A)$. To obtain the desired inequalities when A is a generic Borel set in I, it is enough to write $A = (A \cap \operatorname{int}(I)) \cup (A \cap \partial I)$, to approximate $A \cap \operatorname{int}(I)$ with a sequence of subsets of A compactly contained in I, and to use the previous arguments. It follows that

$$\widetilde{B}(t) \subseteq \sigma_B^\phi(u(t)).$$

In particular, for almost every $t \ge 0$, $u(t)$ is ϕ-admissible, $\sigma_B^\phi(u(t)) = \widetilde{B}(t)$, and (6.3) follows from (6.2).

Assume now that $t \ge 0$ is generic, and pick a sequence $(t_n) \subset (0, +\infty)$ converging to t as $n \to +\infty$ such that $u(t_n) \in \mathcal{A}_\phi(0,1)$ and for which (6.3) holds with t_n in place of t. Since $u \in AC^2([0,+\infty); L^2(0,1))$ and $u(t) \in BV(0,1)$, we have $u(t_n) \to u(t)$ weakly* in $BV(0,1)$ as $n \to +\infty$. It is then enough to repeat the previous arguments, and the assertion follows. ◻

Remark 6.13.

(a) We have $\lim_{N\to+\infty} d_{\mathcal{H}}(\Gamma_{u^N}, \Gamma_u) = 0$, where $\Gamma_{u^N} := \bigcup_{t\in(0,+\infty)} (\sigma_G^\phi(u^N(t)) \times \{t\})$. In particular, by Lemma 6.8, for all $t \in [0, +\infty)$ we have

$$\begin{aligned} &\lim_{N\to+\infty} d_{\mathcal{H}}\big(\sigma_G^\phi(u^N(t)), \sigma_G^\phi(u(t))\big) = 0, \\ &\lim_{N\to+\infty} d_{\mathcal{H}}\big(\operatorname{int}(\sigma_B^\phi(u^N(t))), \operatorname{int}(\sigma_B^\phi(u(t)))\big) = 0. \end{aligned} \tag{6.4}$$

(b) Since $u^N \rightharpoonup u$ weakly* in $L^\infty([0,+\infty); BV(0,1))$ and $u^N \equiv u_0^N$ in $[0,1] \times [0,+\infty) \setminus \overline{\Gamma_{u^N}}$ by Remark 6.3(c), we have $u \equiv u_0$ in $[0,1] \times [0,+\infty) \setminus \overline{\Gamma_u}$.

THEOREM 6.14. *The function u satisfies $u_{xx} \in L^2(\Gamma_u)$ and is a solution of*

$$\begin{cases} u_t = u_{xx}, & x \in \sigma_G^\phi(u(t)),\ t \in (0,+\infty), \\ u_t = 0, & x \in \operatorname{int}(\sigma_B^\phi(u(t))),\ t \in (0,+\infty), \\ \displaystyle\lim_{y\to x,\, y\in\sigma_G^\phi(u(t))} u_x(y,t) = 0, & x \in \partial\sigma_G^\phi(u(t)) \setminus \{0,1\},\ t \in (0,+\infty), \\ u(x,0) = u_0(x), & x \in (0,1), \\ u(0,t) = u(1,t),\ u_x(0,t) = u_x(1,t), & t \in (0,+\infty). \end{cases} \tag{6.5}$$

Proof. Let $\psi \in \mathcal{C}_c^1([0,+\infty) \times [0,1])$, and let $\psi^N : [0,+\infty) \to V_N$, $\psi^N \in \operatorname{Lip}_c([0,+\infty) \times [0,1])$, be such that $\psi^N(t) \to \psi(t)$ in $H^1(0,1)$ for any $t \ge 0$. We have

$$
\begin{aligned}
\mathrm{I}_N(t) := \int_{\sigma_G^\phi(u^N(t))} u_x^N(t)\psi_x^N(t)\,dx &= \sum_{i:\,(\Psi_{u^N(t)})_i=1} \frac{D^+u_i^N(t)\,D^+\psi_i^N(t)}{N} \\
&= -\int_{(0,1)} D^-(\Psi_{u^N(t)}D^+u^N(t))\psi^N(t)\,dx \\
&= -\int_{(0,1)} A_{u^N(t)}u^N(t)\psi^N(t)\,dx \\
&= -\int_{(0,1)} \frac{d}{dt^+}u^N(t)\psi^N(t)\,dx =: \mathrm{II}_N(t).
\end{aligned} \tag{6.6}
$$

From (6.4) (which is valid for any $t \geq 0$ thanks to Lemma 6.8) and from the weak $H^1_{\mathrm{loc}}(\mathrm{int}(\Gamma_u))$-convergence of (u^N) to u, using (6.3) it follows that

$$
\lim_{N\to+\infty} \mathrm{I}_N(t) = \int_{\sigma_G^\phi(u(t))} u_x(t)\psi_x(t)\,dx \qquad \text{for a.e. } t \geq 0. \tag{6.7}
$$

On the other hand, $\frac{d}{dt^+}u^N \rightharpoonup \frac{d}{dt^+}u$ in $L^2((0,1)\times(0,+\infty))$ as $N \to +\infty$; hence

$$
\lim_{N\to+\infty} \mathrm{II}_N(t) = \int_{(0,1)} \frac{d}{dt^+}u(t)\psi(t)\,dx \qquad \text{for a.e. } t \geq 0. \tag{6.8}
$$

Recalling also Remark 6.13(b), equalities (6.7), (6.8) coupled with (6.6) imply that u solves the problem

$$
\begin{cases}
u_t = u_{xx} & \text{in } \mathrm{int}(\Gamma_u),\\
u_t = 0 & \text{in } [0,1]\times[0,+\infty)\setminus\overline{\Gamma_u},\\
u(0) = u_0 & \text{in } [0,1]\times\{0\}.
\end{cases} \tag{6.9}
$$

In particular, we have $u \in \mathcal{C}^\infty(\mathrm{int}(\Gamma_u))$. Moreover, since $u_t \in L^2((0,1)\times(0,+\infty))$, we also get $u_{xx} \in L^2(\Gamma_u)$. It then follows that there exists the limit

$$
\lim_{x\to\bar{x},\, x\in\sigma_G^\phi(u(t))} u_x(x,t) = 0 \qquad \text{for a.e. } t \geq 0,\ \bar{x} \in \partial\sigma_G^\phi(u(t)); \tag{6.10}
$$

i.e., $u|_{\mathrm{int}(\Gamma_u)}$ satisfies zero Neumann boundary conditions on $\partial\Gamma_u$. Problem (6.9), together with the boundary condition (6.10), is equivalent to problem (6.5).

The periodic boundary conditions are a consequence of u being ϕ-admissible. ◻

Remark 6.15. The same results of Theorem 2.4 hold if we replace in the definition (1.1) of ϕ the function ξ^2 with a function $f \in \mathcal{C}^\infty(\mathbb{R})$ which satisfies $f(0) = 0$, $f(1) = 1$, $f(\xi) = f(-\xi)$, and $f''(\xi) > 0$ for all $\xi \in (-1,1)$. It is clear that the equation $u_t = u_{xx}$ in (2.5) is replaced by $u_t = \frac{1}{2}f''(u_x)u_{xx}$.

Remark 6.16. Let $N \in \mathbb{N}$, and set $\phi^N(\xi) := \min(\xi^2, N)$ for any $\xi \in \mathbb{R}$. Define the functional $F_{\phi^N,N} : L^1(0,1) \to [0,+\infty]$ as

$$
F_{\phi^N,N}(v) := \frac{1}{2N}\sum_{i=1}^N \min\left(((D^+v)_i)^2, N\right), \qquad v \in V_N
$$

(and extended to $+\infty$ elsewhere). In [14] it is proved that the sequence $(F_{\phi^N,N})$ Γ-converges, as $N \to +\infty$, to the Mumford–Shah functional. Let $\overline{u} \in BV(0,1)$, with

$\overline{u}(0) = \overline{u}(1)$, having a finite set $\overline{x}_1, \ldots, \overline{x}_n$ of jump points in $(0,1)$, and of class $\mathcal{C}^1(\overline{I})$, for any interval $I \subset (0,1) \setminus \{\overline{x}_1, \ldots, \overline{x}_n\}$. Then $\overline{u}$ is ϕ^N-admissible for N large enough; i.e., $\overline{u}$ satisfies Definition 2.1, where (1) is replaced by $|\overline{u}(x) - \overline{u}(y)| \leq \sqrt{N}|x-y|$ whenever $[x,y] \subset \sigma_G^{\phi^N}(\overline{u})$, and where the inequality involving u in (3) is replaced by $|\overline{u}(x) - \overline{u}(y)| > \sqrt{N}|x-y|$. Let us consider the solutions ω^N to the rescaled gradient flow system of ODEs

$$\begin{cases} \omega_t^N = -N\nabla(F_{\phi^N, N|V_N})(\omega^N), \\ \omega^N(0) = \overline{u}^N, \end{cases} \tag{6.11}$$

$\overline{u}^N$ as in Lemma 6.1. Reasoning as in Theorem 2.4 we get that, as $N \to +\infty$, the sequence (ω^N) converges, up to a subsequence, to a function ω which satisfies the heat equation with zero Neumann interior conditions on each interval of $(0,1) \setminus \{\overline{x}_1, \ldots, \overline{x}_n\}$ (except in $\{0,1\}$), has periodic conditions in $\{0,1\}$, and keeps the points $\overline{x}_1, \ldots, \overline{x}_n$ fixed in time ($\overline{x}_j$ may disappear at time $\overline{t}_j < +\infty$ if $\lim_{x \to \overline{x}_{j_-}} \omega(x, \overline{t}_j) = \lim_{x \to \overline{x}_{j_+}} \omega(x, \overline{t}_j)$). Therefore ω can be considered as a reasonable global solution to the gradient flow of the Mumford–Shah functional in one dimension starting from $\overline{u}$ (compare [22], [20]).

7. Numerical simulations. In this section we show a numerical simulation which confirms the behaviors predicted by Theorem 2.4. Let $u_0 \in \mathcal{A}_\phi(0,1)$ be the upper graph in Figure 7.2; see also Figure 7.1. We have

$$\sigma_B^\phi(u_0) = [a_1^0, b_1^0] \cup [a_2^0, b_2^0] \cup [a_3^0, b_3^0],$$

where $a_1^0 = 0.05$, $b_1^0 = 0.2$, $a_2^0 = b_2^0 = 0.6$, $a_3^0 = 0.9$, and $b_3^0 = 0.99$. Note that $J_{u_0} = \{a_2^0, a_3^0\}$.

The sequence of graphs displayed in Figures 7.1 and 7.2 presents the solution u starting from u_0 at subsequent times. The computation solves the discrete evolution presented in section 5 with space discretization $\Delta x = 1/N$ with $N = 500$. The algorithm used is a forward Euler scheme with time step $\Delta t = (\Delta x)^2/10$. Let us list the main features of the computed evolution u, all of which are in accordance with Theorem 2.4.

(1) We have $a_1(t) \equiv a_1^0$ for all $t > 0$, and on the interval $(0, a_1(t))$ the solution u evolves according to the heat equation with zero Neumann boundary condition at $a_1(t)$. In addition,

$$a_1(t) \in J_{u(t)} \qquad \forall\ t > 0.$$

Since $a_1^0 \notin J_{u_0}$, $a_1(t)$ "instantly" becomes a discontinuity point of the solution; see also Figure 7.1.

(2) The function $t \to b_1(t)$ is decreasing for positive times. The interval $[a_1(t), b_1(t)]$ is gradually eroded, from the right, by the interval $[b_1(t), a_2(t)]$, where the solution evolves according to the heat equation, with zero Neumann boundary conditions.

(3) There exists $T_2 > 0$ such that $a_2(t) \equiv a_2^0$ and $a_2^0 \in J_{u(t)}$ for $t \in [0, T_2)$, and then a_2^0 becomes a continuity point of $u(t)$ for $t \geq T_2$. In the region $[b_2^0, a_3(t)]$, for all times $t \in (0, T_2)$, the solution evolves according to the heat equation with zero Neumann boundary conditions at b_2^0 and $a_3(t)$. Note that

$$\sigma_B^\phi(u(t)) = [a_1(t), b_1(t)] \cup [a_3(t), b_3(t)], \qquad t \geq T_2,$$

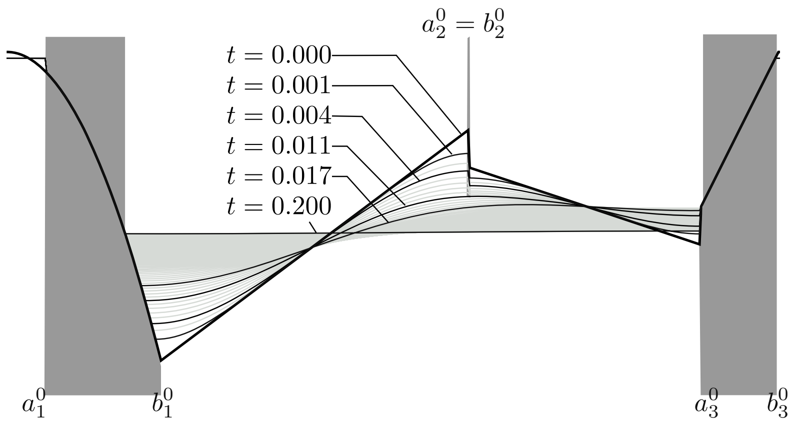

FIG. 7.1. *A simulation of the discretized evolution. The function is plotted in black for some relevant time values. The initial datum u_0 is plotted thick. The gray regions represent the intervals $[a_j(t), b_j(t)]$.*

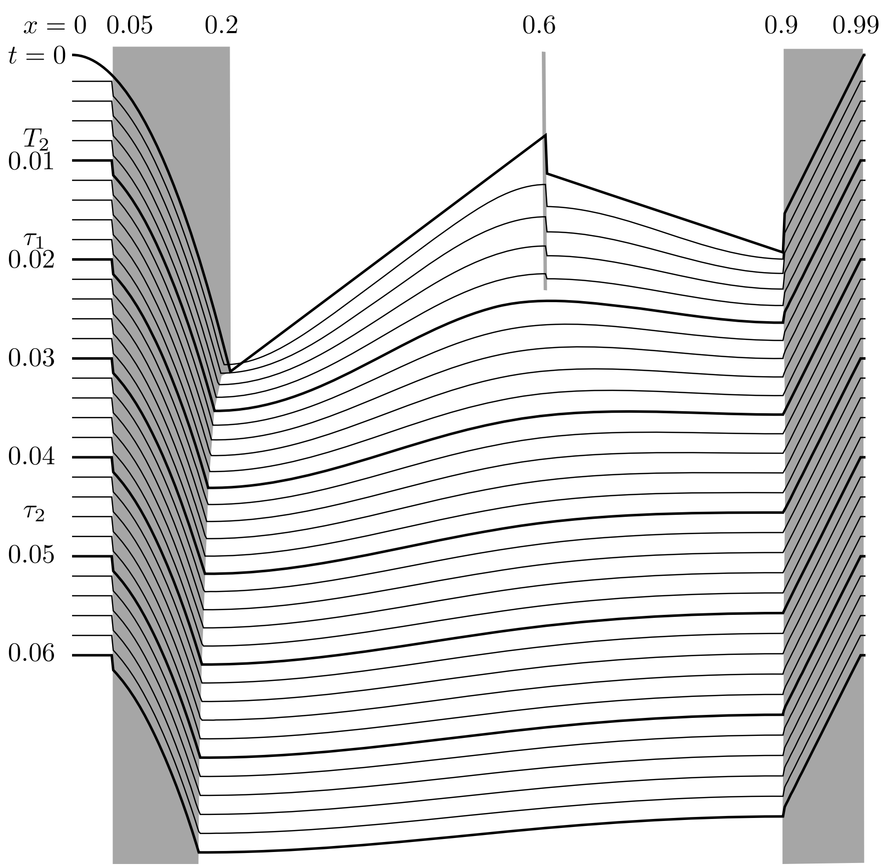

FIG. 7.2. *A vertical translation has been added to the evolution to distinguish the functions.*

and u evolves accordingly to the heat equation in the interval $(b_1(t), a_3(t))$ with zero Neumann boundary conditions.

(4) There exist two positive times $0 < \tau_1 < \tau_2$ such that $a_3(t) \equiv a_3^0 \in J_{u(t)}$ for $t \in [0, \tau_1)$, the point $a_3(t)$ becomes a continuity point of u for $t \in [\tau_1, \tau_2]$, and the function $t \to a_3(t)$ is strictly increasing in that interval, $a_3(t) \equiv a_3(\tau_2) \in J_{u(t)}$ for all $t > \tau_2$. The function $t \to b_3(t)$ is strictly decreasing.

(5) On the interval $(b_3(t), 1)$ the solution u evolves according to the heat equation with zero Neumann boundary conditions for all $t > 0$.

Remark 7.1. We conclude the paper by observing that, for energy densities different from (1.1), in particular for the function ϕ_1 considered in Figure 3.1 (the nonconvex region of which is bounded), the discrete approximation scheme discussed in sections 5 and 6, which keeps *fixed in time* the nodes of the mesh in $(0, 1)$, could converge to functions $\widetilde{u}$ which are not solutions to (3.6). In particular, the functions $\widetilde{u}$ might not satisfy the condition $\widetilde{u}_t = 0$ in $\mathrm{int}(\sigma_B^{\phi_1}(\widetilde{u}(t)))$; see also the comments in [21, p. 590]. This behavior of $\widetilde{u}$, which is related to the interactions of the nonconvex region of ϕ_1 with the numerical scheme with fixed nodes, deserves further investigation.

DYNAMICS OF A STAGE-STRUCTURED POPULATION MODEL ON AN ISOLATED FINITE LATTICE*

Y. KYRYCHKO†, S. A. GOURLEY†, AND M. V. BARTUCCELLI†

Abstract. In this paper we derive a stage-structured model for a single species on a finite one-dimensional lattice. There is no migration into or from the lattice. The resulting system of equations, to be solved for the total adult population on each patch, is a system of delay equations involving the maturation delay for the species, and the delay term is nonlocal involving the population on all patches. We prove that the model has a positivity preserving property. The main theorems of the paper are comparison principles for the cases when the birth function is increasing and when the birth function is a nonmonotone function. Using these theorems we prove results on the global stability of a positive equilibrium.

1. Background.

There has recently been some interest in the study of stage-structured population models on lattices. The following model, which is of particular relevance to the present paper, was derived and studied by Weng, Huang, and Wu [8]:

$$\begin{aligned}\frac{dw_j(t)}{dt} &= \frac{\mu}{2\pi}\sum_{k=-\infty}^{\infty}\mathcal{B}_\alpha(j-k)b(w_k(t-r)) + D_m\left[w_{j+1}(t)+w_{j-1}(t)-2w_j(t)\right]\\ &\quad - d_m w_j(t), \qquad t>0, \qquad j\in\mathbf{Z},\end{aligned}\tag{1.1}$$

where $j \in \mathbf{Z} := \{0, \pm 1, \pm 2, \dots\}$ are the integer nodes of an infinite one-dimensional lattice. The r-dependent parameters μ and α are given by

$$\mu = \exp\left(-\int_0^r d(a)\,da\right), \qquad \alpha = \int_0^r D(a)\,da\tag{1.2}$$

with $d(a)$, $D(a)$, and r defined below, and the function $\mathcal{B}_\alpha(l)$ in (1.1), which we shall sometimes refer to as the *kernel*, is given by

$$\mathcal{B}_\alpha(l) = 2e^{-2\alpha}\int_0^\pi \cos(l\omega)e^{2\alpha\cos\omega}\,d\omega.\tag{1.3}$$

In their paper, Weng, Huang, and Wu [8] actually used the symbol β for their kernel. However, it is important that their kernel should not be confused with the corresponding kernel for a finite lattice (which we are calling β in this paper); thus we shall refer to the infinite lattice kernel of Weng, Huang, and Wu as $\mathcal{B}$.

In (1.1) the parameter r measures the time from birth until reaching maturity and $w_j(t)$ denotes the total number of adults (i.e., the total number of age at least r) in the jth patch. The function $b(\cdot)$, which always satisfies $b(0) = 0$, is the birth function

†Department of Mathematics and Statistics, University of Surrey, Guildford, Surrey GU2 7XH, U.K. (s.gourley@surrey.ac.uk).

and the constants D_m and d_m are, respectively, the diffusion coefficient and death rate for the mature population.

In (1.2), the functions $D(a)$ and $d(a)$ are the diffusion coefficient and death rate for the immature population. For the immature population these rates can depend on age a, but for the mature population the diffusion coefficient and death rate must be independent of age and they are taken as D_m and d_m.

Weng, Huang, and Wu [8] derived their model from the following von Foerster type of equation:

$$\frac{\partial u_j}{\partial t} + \frac{\partial u_j}{\partial a} = D(a)\left[u_{j+1}(t,a) + u_{j-1}(t,a) - 2u_j(t,a)\right] - d(a)u_j(t,a) \tag{1.4}$$

with $D(a) = D_m$ and $d(a) = d_m$ for $a \geq r$. Equation (1.4) incorporates a discrete representation of diffusion. Von Foerster equations for the case of continuous space have been considered also, in which case the Laplacian operator can be used to model Fickian diffusion (see [4]). In (1.4), $u_j(t,a)$ is the density of age a at time t in the jth patch. Furthermore

$$w_j(t) = \int_r^\infty u_j(t,a)\,da.$$

In [8] the interest is mainly in the existence of travelling front solutions connecting two distinct equilibria. The highly nontrivial matter of the stability of these fronts is also investigated. Gourley and Wu [3] continued the study in [8] by providing conditions under which the population will go extinct, and conditions for the existence of periodic travelling waves.

The aim of the present paper is to derive and study an equation analogous to (1.1) for the case when the lattice is finite, with the nodes being given by $j = 1, 2, \ldots, N$. As we shall see, the model changes in two main respects. The first is that the discrete representation of diffusion will only be $w_{j+1}(t)+w_{j-1}(t)-2w_j(t)$ at "interior" points of the lattice (i.e., the nodes $j = 2, 3, \ldots, N-1$) with a different expression for the nodes $j = 1$ and $j = N$. We shall use the expression appropriate for an isolated lattice which individuals cannot escape from or enter into; this is the analogy of the homogeneous Neumann problem (i.e., no flux at boundaries) in the case of continuous space. The second and more complicated difference between the model of the present paper and (1.1) is that the term with the time delay assumes a rather different appearance. The function $\mathcal{B}_\alpha(l)$ given by (1.3) is completely inappropriate for the case of a finite lattice. Additionally, as we shall see, in the case of a finite lattice the time delay term no longer assumes a "convolution" structure (i.e., depending on the lattice index through the variables $j-k$ and k with summation over k). This convolution formulation cannot allow for interactions with the endpoints of a finite lattice and therefore is strictly for infinite lattices only.

The derivation in [8] relies heavily on the fact that their lattice was infinite (their derivation utilizes a discrete Fourier transform technique). For a finite lattice a different model derivation is required and this will be the subject of the next section.

A model on a finite lattice similar to the one we propose in this paper was considered in Smith and Thieme [7]. Their model has n patches each of which offers a different quality of life (the per capita reproduction rates, mortality rates, and maturation delays can vary from patch to patch). Additionally their model permits individuals to migrate from any one patch directly to any other. Their model assumes the form

$$\left(\frac{\partial}{\partial t}+\frac{\partial}{\partial a}\right)u_j(t,a)=\sum_{k=1}^{n}\gamma_{jk}u_k(t,a)-\left(\sum_{k=1}^{n}\gamma_{kj}+\mu_j\right)u_j(t,a)$$

with birth law

$$u_j(t,0)=g_j\left(\int_{\tau_j}^{\infty}u_j(t,a)\,da\right),$$

where each g_j is a bounded function. In some respects this model is more general than the one we propose in this paper, particularly with regard to the migration terms (γ_{jk} is the per capita migration rate from node k to node j). Their key assumption on the migration terms is that the matrix (γ_{jk}) be irreducible. Our model in this paper considers migration only on a nearest neighbor basis, but we study our model in somewhat more detail.

Our approach is to start with an age-structured model (the "original problem") given by system (2.1) below, and derive from it a delay differential equation system (the "reduced problem") for $w_j(t)$, the total mature population at the jth patch. As we shall discover, the reduced system (system (2.10) below) is valid only after a transient period of length r. For $0<t<r$ the variable $w_j(t)$ is governed by some different nonautonomous equations that involve the initial data $\mathbf{u}_0(a)$ for the original problem (2.1). We shall not be concerned in this paper with these other nonautonomous equations but will effectively neglect the transient phase and study the reduced problem independently (i.e., we study system (2.10) below for $t>0$, subject to (2.11)). However, there are delicate issues regarding initial data and positivity which will be discussed later in this paper and which are treated in more detail in Bocharov and Hadeler [2] for problems without diffusion. For example, only certain initial data for the reduced problem with delay are related to the original problem. Also, while positive solutions of the original problem lead to positive solutions of the reduced problem, the cone of positive solutions of the reduced problem is larger in general, since we study the reduced problem for arbitrary nonnegative initial data, and not just those initial data that are related to the original problem. These issues will be discussed further as they arise.

2. Finite lattice: Model derivation. Let $u_j(t,a)$ denote the density of the population of the species at the jth patch at time $t\geq 0$ and age $a\geq 0$. Let $D(a)$ and $d(a)$ denote the diffusion and death rates of the population at age a. Assume that the patches are located at the integer nodes $j=1,2,\ldots,N$ of a one-dimensional lattice and that spatial diffusion occurs only at the nearest neighborhood and is proportional to the difference of the densities of the population at adjacent patches. These assumptions lead to the model

$$\left(\frac{\partial}{\partial t}+\frac{\partial}{\partial a}\right)\mathbf{u}(t,a)=D(a)A\mathbf{u}(t,a)-d(a)\mathbf{u}(t,a) \tag{2.1}$$

for $t>0$, where

$$\mathbf{u}(t,a)=(u_1(t,a),\ldots,u_N(t,a))^T$$

and

$$A = \begin{pmatrix} -1 & 1 & 0 & \cdots & 0 & 0 & 0 \\ 1 & -2 & 1 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & -2 & 1 \\ 0 & 0 & 0 & \cdots & 0 & 1 & -1 \end{pmatrix}, \tag{2.2}$$

subject to

$$u_j(t,0) = b(w_j(t)), \tag{2.3}$$

where $w_j(t)$ is the total mature population at the jth patch, given by

$$w_j(t) = \int_r^\infty u_j(t,a)\,da \tag{2.4}$$

and $b(\cdot)$ is the birth function, which satisfies $b(0) = 0$. Furthermore, it is natural to assume that

$$u_j(t,\infty) = 0, \qquad t \geq 0, \qquad j = 1, \dots, N.$$

The initial data for (2.1) has the form

$$\mathbf{u}(0,a) = \mathbf{u}_0(a), \qquad 0 \leq a < \infty \tag{2.5}$$

with $\mathbf{u}_0(a)$ prescribed.

Note that, at the node $j = 1$, the diffusion term is $D(a)(u_2 - u_1)$ with a similar expression for the other "end" node $j = N$. In this way the model (2.1) has been set up so as to be the discrete analogue of what is commonly called the homogeneous Neumann problem in the continuous case, in which no-flux boundary conditions are applied. For the heat equation $u_t = \Delta u$ on a finite domain Ω with homogeneous Neumann boundary conditions $\partial u/\partial n = 0$ on $\partial\Omega$, it is well known that $\int_\Omega u(t,x)\,dx$ is constant. An analogous result holds for (2.1) in the case when there are no births or deaths (i.e., $b(\cdot) = d(\cdot) = 0$). Indeed, in this case,

$$\begin{aligned} \underbrace{\frac{d}{dt}\sum_{j=1}^N \int_0^\infty u_j(t,a)\,da}_{\text{total population}} &= \sum_{j=1}^N \int_0^\infty \frac{\partial u_j(t,a)}{\partial t}\,da = -\sum_{j=1}^N \int_0^\infty \frac{\partial u_j(t,a)}{\partial a}\,da \\ &+ \sum_{j=2}^{N-1} \int_0^\infty D(a)(u_{j-1}(t,a) - 2u_j(t,a) + u_{j+1}(t,a))\,da \\ &+ \int_0^\infty D(a)(-u_1(t,a) + u_2(t,a))\,da + \int_0^\infty D(a)(u_{N-1}(t,a) - u_N(t,a))\,da \\ &= -\sum_{j=1}^N (\underbrace{u_j(t,\infty)}_{=0} - \underbrace{b(w_j(t))}_{=0 \text{ if no births}}) = 0. \end{aligned}$$

Our intention is to derive from (2.1), (2.3) a system of equations satisfied by the total matured population $w_j(t)$, $j = 1, 2, \dots, N$. Before doing so, let us introduce the function $\beta(t,k,j)$ defined by

$$\beta(t,k,j) = \frac{1}{N} + \frac{2}{N}\sum_{l=1}^{N} e^{-4\sin^2\left(\frac{l\pi}{2N}\right)t}\cos\left[(2j-1)\frac{l\pi}{2N}\right]\cos\left[(2k-1)\frac{l\pi}{2N}\right]. \tag{2.6}$$

We will prove the following result which is useful for later calculations.

PROPOSITION 2.1. *The function $\beta(t,k,j)$ defined by* (2.6) *has the following properties:*

(i) *it satisfies*

$$\frac{d}{dt}\begin{pmatrix}\beta(t,k,1)\\ \vdots\\ \beta(t,k,N)\end{pmatrix} = \begin{pmatrix} -1 & 1 & 0 & \cdots & 0 & 0 & 0\\ 1 & -2 & 1 & \cdots & 0 & 0 & 0\\ \vdots & \vdots & \vdots & & \vdots & \vdots & \vdots\\ 0 & 0 & 0 & \cdots & 1 & -2 & 1\\ 0 & 0 & 0 & \cdots & 0 & 1 & -1\end{pmatrix}\begin{pmatrix}\beta(t,k,1)\\ \vdots\\ \beta(t,k,N)\end{pmatrix}, \tag{2.7}$$

(ii) *$\beta(0,k,j)$ is the Kronecker delta:*

$$\beta(0,k,j) = \begin{cases} 1 & \text{if } j = k,\\ 0 & \text{if } j \neq k;\end{cases} \tag{2.8}$$

(iii) *$\sum_{k=1}^{N}\beta(t,k,j) = 1$ for each $j = 1,2,\ldots,N$ and all $t \geq 0$;*
(iv) *$\beta(t,k,j) > 0$ for all $t > 0$ and all $1 \leq k,j \leq N$.*

Proof. Property (i) is straightforward. Property (ii) is fairly easily seen. Indeed,

$$\begin{aligned}\beta(0,k,k) &= \frac{1}{N} + \frac{2}{N}\sum_{l=1}^{N}\cos^2(2k-1)\frac{l\pi}{2N} = \frac{1}{N} + \frac{1}{N}\sum_{l=1}^{N}\left(1+\cos(2k-1)\frac{l\pi}{N}\right)\\ &= \frac{1}{N} + 1 + \frac{1}{N}\mathrm{Re}\left(\sum_{l=1}^{N} e^{i(2k-1)\frac{l\pi}{N}}\right)\\ &= \frac{1}{N} + 1 + \frac{2}{N}\mathrm{Re}\left(\frac{e^{i(2k-1)\frac{\pi}{N}}}{1-e^{i(2k-1)\frac{\pi}{N}}}\right)\\ &= 1\end{aligned}$$

after some algebra. Similarly, $\beta(0,k,j) = 0$ for $j \neq k$.

To show statement (iii) it is clearly sufficient to prove that

$$\sum_{k=1}^{N}\cos(2k-1)\frac{l\pi}{2N} = 0$$

and this is easily shown.

Finally we prove (iv), that $\beta(t,k,j) > 0$ for all $t > 0$. We have already noted that the function $\beta(t,k,j)$ defined by (2.6) satisfies the system of differential equations (2.7) with the initial condition (2.8). Here, j is thought of as the spatial coordinate and $k \in \{1,2,\ldots,N\}$ as fixed. Certain theorems in the theory of matrices (Berman and Plemmons [1]) are useful here. The matrix $\beta(t) = [\beta(t,k,j)]_{N\times N}$ is the solution of the linear system $\dot{\beta} = A\beta$, where A is the matrix defined by (2.2), subject to $\beta(0) = I$. Thus

$$\beta(t) = e^{At} = e^{-3t}e^{(3I+A)t} = e^{-3t}\sum_{i=0}^{\infty}\frac{t^i(3I+A)^i}{i!}.$$

It is easily checked that $3I + A$ is a positive and irreducible matrix. Therefore, it follows [1] that $(3I + A)^i$ is a strictly positive matrix for all $i \geq N + 1$. Therefore, for any $t > 0$ the infinite sum above furnishes a matrix all of whose elements are strictly positive. Therefore, $\beta(t, k, j) > 0$ for all $t > 0$. The proof of Proposition 2.1 is complete. $\square$

We will now prove the following theorem.

THEOREM 2.2. *Assume that the diffusion and death rates of the mature population are age-independent, i.e.,*

$$D(a) = D_m, \qquad d(a) = d_m \quad \textit{for } a \in [r, \infty),$$

where $D_m > 0$ and $d_m > 0$ are constants. Let the function $\beta(t, k, j)$ be defined by (2.6) *and let*

$$\mu = e^{-\int_0^r d(z)\,dz}, \qquad \alpha = \int_0^r D(z)\,dz. \tag{2.9}$$

Then for $t \geq r$ the total matured population $w_j(t)$ defined by (2.4) *satisfies*

$$\frac{d}{dt}\begin{pmatrix} w_1(t) \\ w_2(t) \\ \vdots \\ w_{N-1}(t) \\ w_N(t) \end{pmatrix} = \mu \sum_{k=1}^{N} b(w_k(t-r)) \begin{pmatrix} \beta(\alpha, k, 1) \\ \beta(\alpha, k, 2) \\ \vdots \\ \beta(\alpha, k, N-1) \\ \beta(\alpha, k, N) \end{pmatrix}$$

$$+D_m \begin{pmatrix} -1 & 1 & 0 & \cdots & 0 & 0 & 0 \\ 1 & -2 & 1 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & -2 & 1 \\ 0 & 0 & 0 & \cdots & 0 & 1 & -1 \end{pmatrix} \begin{pmatrix} w_1(t) \\ w_2(t) \\ \vdots \\ w_{N-1}(t) \\ w_N(t) \end{pmatrix} - d_m \begin{pmatrix} w_1(t) \\ w_2(t) \\ \vdots \\ w_{N-1}(t) \\ w_N(t) \end{pmatrix}. \tag{2.10}$$

Remark 1. For $0 < t < r$ the variable $w_j(t)$ does not obey system (2.10) but is governed instead by some different (nonautonomous) equations that still contain information about the initial data of the system (2.1). This issue is discussed in detail in Bocharov and Hadeler [2] for systems without diffusion. However, in this paper we shall concentrate on the problem consisting of system (2.10) for $t > 0$, subject to the initial conditions

$$w_j(s) = w_j^0(s) \geq 0, \qquad j = 1, 2, \ldots, N, \qquad s \in [-r, 0] \tag{2.11}$$

with $w_j^0(s)$ prescribed.

Remark 2. Related to the above point, is the issue of initial data. If we solve (2.10) for $t > 0$ an important question arises: does an arbitrary nonnegative initial function $w_j^0(s)$, $s \in [-r, 0]$, necessarily result, in any sense, from an initial datum $\mathbf{u}_0(a)$ for system (2.1)? The answer is, not necessarily. Given an initial datum $\mathbf{u}_0(a)$ for system (2.1), one should first evolve the variable $w_j(t)$ until time r according to the nonautonomous equations which govern $w_j(t)$ for $0 < t < r$, and then evolve $w_j(t)$ for $t > r$ according to (2.10) with initial time r, using as initial data the values of $w_j(t)$, $t \in [0, r]$, found by solving the nonautonomous equations. Those functions $w_j(t)$, $t \in [0, r]$, which arise in this way are, once translated r units back in time, those functions which are admissible in (2.11) as initial data for system (2.10) with initial time 0. For a class of systems without diffusion, Bocharov and Hadeler [2] characterize completely those initial data for their delay equation starting at time r, which result from a positive initial datum of their analogy to our system (2.1). In this paper we shall not develop this issue further but will consider (2.10) for $t > 0$ subject only to (2.11) (i.e., as though the system had not been derived from a structured population model).

Proof of Theorem 2.2. Letting

$$\mathbf{w}(t) = (w_1(t), \ldots, w_N(t))^T,$$

we have

$$\frac{d\mathbf{w}(t)}{dt} = \int_r^\infty \frac{\partial}{\partial t}\mathbf{u}(t,a)\,da = \int_r^\infty \left[-\frac{\partial}{\partial a}\mathbf{u}(t,a) + D(a)A\mathbf{u}(t,a) - d(a)\mathbf{u}(t,a)\right] da. \tag{2.12}$$

We obtain from (2.1) and (2.12) that

$$\frac{d\mathbf{w}(t)}{dt} = \mathbf{u}(t,r) + D_m A\mathbf{w}(t) - d_m\mathbf{w}(t) \qquad \text{for } t > 0. \tag{2.13}$$

In order to have a complete system for $w_j(t)$ we need to calculate $u_j(t,r)$, $j = 1, 2, \ldots, N$. For fixed $s \geq 0$ let $\mathbf{V}^s(t) = (V_1^s(t), \ldots, V_N^s(t))^T$, where

$$V_j^s(t) = u_j(t, t-s) \quad \text{for } s \leq t \leq s + r. \tag{2.14}$$

Since only the mature population can reproduce, we have

$$V_j^s(s) = u_j(s, 0) = b(w_j(s)), \tag{2.15}$$

where $b : \mathbb{R}_+ \to \mathbb{R}_+$ is the birth function. From (2.1), we have

$$\frac{d}{dt}\mathbf{V}^s(t) = \left(\frac{\partial}{\partial t} + \frac{\partial}{\partial a}\right)\mathbf{u}(t,a)\bigg|_{a=t-s} = D(t-s)A\mathbf{V}^s(t) - d(t-s)\mathbf{V}^s(t). \tag{2.16}$$

We want to solve (2.16) subject to (2.15). First, let

$$V_j^s(t) = \tilde{V}_j^s(t) e^{-\int_0^{t-s} d(z)\,dz}$$

and $\tilde{\mathbf{V}}^s(t) = (\tilde{V}_1^s(t), \ldots, \tilde{V}_N^s(t))^T$; then system (2.16) becomes

$$\frac{d}{dt}\tilde{\mathbf{V}}^s(t) = D(t-s)A\tilde{\mathbf{V}}^s(t).$$

Making a further transformation of time t as

$$\tilde{t} = \int_0^{t-s} D(z)\,dz$$

so that $d\tilde{t}/dt = D(t-s)$, we obtain

$$\frac{d}{d\tilde{t}}\tilde{\mathbf{V}}^s(\tilde{t}) = A\tilde{\mathbf{V}}^s(\tilde{t}) \tag{2.17}$$

which has to be solved subject to the initial condition (2.15) in the form

$$\tilde{V}_j^s(0) = b(w_j(s)), \quad j = 1, 2, \ldots, N. \tag{2.18}$$

We look for a solution of (2.17) in the form

$$\tilde{V}_j^s(\tilde{t}) = \sum_{k=1}^{N} c_k \beta(\tilde{t}, k, j),$$

where the function $\beta(t, k, j)$ is defined in (2.6) and c_k are unknown constants to be found using the initial condition (2.18). That is, with $\tilde{t} = 0$ one gets

$$\tilde{V}_j^s(0) = \sum_{k=1}^{N} c_k \beta(0, k, j) = c_j,$$

by (ii) of Proposition 2.1. Consequently,

$$c_j = b(w_j(s)),$$

and the solution of the system (2.17) is given as follows:

$$\tilde{V}_j^s(\tilde{t}) = \sum_{k=1}^{N} b(w_k(s)) \beta(\tilde{t}, k, j),$$

or, in terms of t,

$$\tilde{V}_j^s(t) = \sum_{k=1}^{N} b(w_k(s)) \beta\left(\int_0^{t-s} D(z)dz, k, j\right).$$

Hence,

$$u_j(t, t-s) = V_j^s(t) = e^{-\int_0^{t-s} d(z)dz} \sum_{k=1}^{N} b(w_k(s)) \beta\left(\int_0^{t-s} D(z)dz, k, j\right).$$

Recalling that $s \geq 0$ we deduce that, for $t \geq r$,

$$u_j(t, r) = \mu \sum_{k=1}^{N} b(w_k(t-r)) \beta(\alpha, k, j), \tag{2.19}$$

where $b(w_k(t))$ is the birth function introduced above, and μ and α are given by (2.9). Thus, the system for w_j has the form (2.10) for $t \geq r$.

3. Positivity of solutions. In the previous sections we derived the reduced model for $w_j(t)$ and proved various properties of $\beta(t, k, j)$. Using the fact that $\beta(t, k, j) > 0$ for all $t > 0$ we shall now prove a positivity-preserving property for system (2.10).

The result which we shall prove in this section is for the system consisting of the differential equations (2.10) for $t > 0$, supplemented by the initial data (2.11). As noted previously, the reduced system (2.10) is actually only valid for $t \geq r$. For $0 < t < r$ another nonautonomous system applies and governs $w_j(t)$. Thus there is a subtle relationship between the original problem (2.1) and the reduced problem (2.10) as regards positivity. This issue is discussed in detail in [2] for systems without diffusion, and the issues concerning positivity are basically the same for systems with and without diffusion.

First, we consider the initial value problem

$$\frac{d\mathbf{v}(t)}{dt} = DA\mathbf{v}(t) - d\mathbf{v}(t) + \mathbf{h}(t), \tag{3.1}$$

where $\mathbf{v}(t) = (v_1(t), \ldots, v_N(t))^T$ and $\mathbf{h}(t) = (h_1(t), \ldots, h_N(t))^T$, subject to

$$v_j(0) = c_j,\ c_j \in \mathbb{R},\ j = 1, \ldots, N.$$

From the definition of $\beta(t, k, j)$ it is easy to check that the solution to this problem is

$$v_j(t) = e^{-dt}\sum_{k=1}^{N}\beta(Dt, k, j)c_k + \sum_{k=1}^{N}\int_0^t e^{-d(t-s)}\beta(D(t-s), k, j)h_k(s)\,ds,\ j = 1, \ldots, N. \tag{3.2}$$

Therefore if $c_j \geq 0$ and $h_j(t) \geq 0$ for all $t \geq 0$ and $j = 1, \ldots, N$, then, since $\beta(t, k, j) \geq 0$, we have $v_j(t) \geq 0$ for all $j = 1, \ldots, N$ and $t \geq 0$. We shall now prove that the solutions of (2.10) enjoy positivity-preserving properties analogous to results that can be proved using the strong maximum principle in the case of continuous space.

THEOREM 3.1. *Let $b(0) = 0$ and $b(w) > 0$ when $w > 0$, and let $\{w_j\}$ be the solution of system* (2.10), *$t > 0$, corresponding to the initial data $w_j(s) = w_j^0(s)$, $s \in [-r, 0]$. If $w_j^0(s) \geq 0$ for all $j = 1, \ldots, N$ and $s \in [-r, 0]$, then $w_j(t) \geq 0$ for all $j = 1, \ldots, N$ and $t \geq 0$.*

Also, if $w_j^0(s) \not\equiv 0$ on $(s, j) \in [-r, 0] \times \{1, 2, \ldots, N\}$, then $w_j(t) > 0$ for all $j = 1, \ldots, N$ and $t \geq r$.

Proof. We first prove the nonnegativity property $w_j(t) \geq 0$. This is achieved in steps; we first prove the result for $t \in [0, r]$. Applying (3.2) to system (2.10) with

$$h_j(t) = \mu\sum_{k=1}^{N}\beta(\alpha, k, j)b(w_k(t-r))$$

gives, for $t \in [0, r]$,

$$\begin{aligned} w_j(t) = {} & e^{-d_m t}\sum_{k=1}^{N}\beta(D_m t, k, j)w_k(0) \\ & + \mu\sum_{k=1}^{N}\int_0^t e^{-d_m(t-s)}\beta(D_m(t-s), k, j)\sum_{l=1}^{N}\beta(\alpha, l, k)b(w_l(s-r))\,ds. \end{aligned} \tag{3.3}$$

Now $t \in [0, r]$ so the right-hand side of the above expression refers only to the initial data for $w_j(t)$, which is nonnegative by hypothesis. Since β is nonnegative also, we conclude that $w_j(t) \geq 0$ for $t \in [0, r]$. On the interval $t \in [r, 2r]$ an expression analogous to (3.3) can easily be found, referring in its right-hand side to $w_j(\cdot)$ only at times between 0 and r, on which interval we have just shown nonnegativity. Therefore, $w_j(t) \geq 0$ for $t \in [r, 2r]$. This argument can be continued indefinitely, and so we have shown $w_j(t) \geq 0$ for all $t \geq 0$.

We now prove the second part of the theorem: strict positivity of $w_j(t)$ for all $t \geq r$, provided the initial data is not identically zero. From (3.3) we can infer that

$$w_j(r) > 0 \qquad \text{for all } j = 1, \ldots, N.$$

Indeed, if we had $w_j(r) = 0$, then, since $\beta(t, k, j) > 0$ for $t > 0$ and since $b(\cdot)$ is positive definite, it would follow that $w_j(s) \equiv 0$ on $(s, j) \in [-r, 0] \times \{1, 2, \ldots, N\}$, contrary to hypothesis. For $t \geq r$ an expression for $w_j(t)$ similar to (3.3) can be found, and from this expression we can infer that, for $t \geq r$,

$$w_j(t) \geq e^{-d_m(t-r)} \sum_{k=1}^{N} \beta(D_m(t-r), k, j) w_k(r) > 0$$

for all $j = 1, \ldots, N$. The proof of the theorem is complete. $\square$

4. Comparison principle: Monotone birth functions. In this section we shall prove a comparison theorem for system (2.10) for the case when the birth function is increasing, and we shall use it to prove that in this case if a positive uniform equilibrium solution exists, then it is globally stable. Theorem 4.1 below can also be established using results in Chapter 5 of Smith [6] (indeed, for increasing birth functions system (2.10) satisfies the quasimonotone condition on page 78 of [6], and (2.10) constitutes a cooperative and irreducible system of functional differential equations). However, we will include a self-contained proof of our Theorem 4.1 here because, as will become clear later, a detailed understanding of the monotone case throws much light on how one can approach the case of a nonmonotone birth function which we do later in Theorem 5.1.

THEOREM 4.1. *Let the birth function $b(w)$ be increasing and differentiable for all $w \geq 0$ and let $\beta(t, k, j)$ be given by (2.6). Let $\bar{\mathbf{w}}(t) = (\bar{w}_1(t), \ldots, \bar{w}_N(t))^T$ and $\hat{\mathbf{w}}(t) = (\hat{w}_1(t), \ldots, \hat{w}_N(t))^T$ be such that*

$$\frac{d\bar{\mathbf{w}}(t)}{dt} - D_m A \bar{\mathbf{w}}(t) + d_m \bar{\mathbf{w}}(t) - \mu \sum_{k=1}^{N} b(\bar{w}_k(t-r)) \begin{pmatrix} \beta(\alpha, k, 1) \\ \beta(\alpha, k, 2) \\ \vdots \\ \beta(\alpha, k, N-1) \\ \beta(\alpha, k, N) \end{pmatrix}$$

$$\geq \frac{d\hat{\mathbf{w}}(t)}{dt} - D_m A \hat{\mathbf{w}}(t) + d_m \hat{\mathbf{w}}(t) - \mu \sum_{k=1}^{N} b(\hat{w}_k(t-r)) \begin{pmatrix} \beta(\alpha, k, 1) \\ \beta(\alpha, k, 2) \\ \vdots \\ \beta(\alpha, k, N-1) \\ \beta(\alpha, k, N) \end{pmatrix} \tag{4.1}$$

for $t > 0$ and

$$\bar{w}_j(s) \geq \hat{w}_j(s), \qquad j = 1, \ldots, N, \qquad s \in [-r, 0].$$

Then $\bar{w}_j(t) \geq \hat{w}_j(t)$ for all $t > 0$ and $j = 1, \ldots, N$.

Proof. Let $\mathbf{W}(t)$ be the vector with components $W_j(t) := \bar{w}_j(t) - \hat{w}_j(t)$. Then (4.1) can be rewritten as

$$\frac{d\mathbf{W}(t)}{dt} - D_m A\mathbf{W}(t) + d_m\mathbf{W}(t) - \mu\sum_{k=1}^{N}[b(\bar{w}_k(t-r)) - b(\hat{w}_k(t-r))]\begin{pmatrix}\beta(\alpha,k,1)\\ \beta(\alpha,k,2)\\ \vdots\\ \beta(\alpha,k,N-1)\\ \beta(\alpha,k,N)\end{pmatrix} \geq 0.$$

Applying the mean value theorem to the last term in the left-hand side of the above inequality we obtain

$$\frac{d\mathbf{W}(t)}{dt} - D_m A\mathbf{W}(t) + d_m\mathbf{W}(t) - \mu\sum_{k=1}^{N} b'(\theta_k(t-r))W_k(t-r)\begin{pmatrix}\beta(\alpha,k,1)\\ \beta(\alpha,k,2)\\ \vdots\\ \beta(\alpha,k,N-1)\\ \beta(\alpha,k,N)\end{pmatrix} \geq 0, \tag{4.2}$$

where $\theta_k(t)$ is between $\bar{w}_k(t)$ and $\hat{w}_k(t)$, $k = 1, \ldots, N$. By hypothesis $\bar{w}_j(s) \geq \hat{w}_j(s)$ for $s \in [-r, 0]$, so $W_j(s) \geq 0$ for $s \in [-r, 0]$. To prove the theorem we need to show that $W_j(t) \geq 0$ for all $t > 0$, and as a first step we shall prove this fact for $t \in (0, r]$. For $t \in (0, r]$,

$$f_j(t) := \mu\sum_{k=1}^{N} b'(\theta_k(t-r))W_k(t-r)\beta(\alpha,k,j) \geq 0.$$

Inequality (4.2) becomes

$$\frac{d\mathbf{W}(t)}{dt} - D_m A\mathbf{W}(t) + d_m\mathbf{W}(t) \geq \mathbf{f}(t), \tag{4.3}$$

where $\mathbf{f}(t) = (f_1(t), \ldots, f_N(t))^T$. We claim that $W_j(t) \geq 0$ for all $j = 1, \ldots, N$ and $t \in [0, r]$. Suppose this is false, i.e., that $W_j(t)$ goes negative. Then $W_j(t)$ must attain a negative minimum on the set $(t, j) \in [0, r] \times \{1, 2, \ldots, N\}$. Let this happen at time t^* and at the node j^*. Since $W_j(0) \geq 0$ we must have $t^* > 0$, but it is possible that $t^* = r$. In any case,

$$\frac{dW_{j^*}(t^*)}{dt} \leq 0,$$

and, of course, $W_{j^*}(t^*) < 0$. Also, if j^* is an "interior" node, then

$$W_{j^*-1}(t^*) - 2W_{j^*}(t^*) + W_{j^*+1}(t^*) \geq 0$$

while if $j^* = 1$, then $-W_1(t^*) + W_2(t^*) \geq 0$ and similarly if $j^* = N$. Extracting the j^*th component of (4.3) and evaluating it at time t^* gives

$$\underbrace{\frac{dW_{j^*}(t^*)}{dt} - (j^*\text{th component of } D_m \text{ term})}_{\leq 0} + \underbrace{d_m W_{j^*}(t^*)}_{<0} \geq \underbrace{f_{j^*}(t^*)}_{\geq 0}$$

which is a contradiction. Thus $W_j(t) \geq 0$ for all $j = 1, \ldots, N$ and $t \in [0, r]$. Repeating this argument establishes that $W_j(t) \geq 0$ for $t \in [r, 2r]$ and the argument can be continued to include all positive times. The proof of the theorem is complete. ◻

4.1. Convergence to equilibrium. In this section we will prove that if the birth function $b(w)$ is increasing and is such that there exists a uniform equilibrium solution w^* (independent of both j and t) to system (2.10) and is biologically realistic, then solutions of (2.10) approach the equilibrium w^*. Note first that a uniform equilibrium state w^* must necessarily satisfy

$$\mu b(w^*) = d_m w^*. \tag{4.4}$$

We will prove the following theorem.

THEOREM 4.2. *In system* (2.10) *let the birth function* $b(w)$ *satisfy* $b(0) = 0$ *and be an increasing differentiable function for all* $w \geq 0$. *Assume there exists* $w^* > 0$ *such that* $\mu b(w) > d_m w$ *when* $0 < w < w^*$ *and* $\mu b(w) < d_m w$ *when* $w > w^*$. *Assume further that, in* (2.11), $w_j^0(s) \not\equiv 0$ *on* $(s, j) \in [-r, 0] \times \{1, 2, \ldots, N\}$. *Then the solution* $w_j(t)$ *of* (2.10) *for* $t > 0$, *subject to* (2.11), *satisfies* $w_j(t) \to w^*$ *as* $t \to \infty$, *for each* $j = 1, 2, \ldots, N$.

Proof. To prove this theorem we shall use Theorem 4.1. More specifically, we shall show using Theorem 4.1 that the solution $w_j(t)$ of (2.10) subject to (2.11) can be bounded above and below by solutions of (2.10) that are functions of t only.

Indeed, if we denote by $w(t)$ any solution of the scalar equation

$$\frac{dw(t)}{dt} = \mu b(w(t - r)) - d_m w(t), \tag{4.5}$$

then the function

$$(w_1(t), w_2(t), \ldots, w_N(t)) := (w(t), w(t), \ldots, w(t))$$

satisfies (2.10). Two applications of Theorem 4.1 are required. In the first, we choose $\hat{w}_j(t)$ to be the solution $w_j(t)$ of (2.10) subject to (2.11) and $\bar{w}_j(t) = \bar{w}(t)$ for each j, where $\bar{w}(t)$ satisfies

$$\begin{aligned} &\frac{d\bar{w}(t)}{dt} = \mu b(\bar{w}(t - r)) - d_m \bar{w}(t), \\ &\bar{w}(s) = \max\{w_j^0(s),\ j = 1, 2, \ldots, N\} \quad \text{for } s \in [-r, 0]. \end{aligned} \tag{4.6}$$

Then Theorem 4.1 yields

$$w_j(t) \leq \bar{w}(t), \qquad t > 0, \qquad j = 1, 2, \ldots, N.$$

For the second application of Theorem 4.1 the most obvious choices are to take $\bar{w}_j(t)$ as the solution $w_j(t)$ of (2.10) subject to (2.11) and, for each j, $\hat{w}_j(t) = \hat{w}(t)$ where $\hat{w}(t)$ satisfies

$$\begin{aligned} &\frac{d\hat{w}(t)}{dt} = \mu b(\hat{w}(t - r)) - d_m \hat{w}(t), \\ &\hat{w}(s) = \min\{w_j^0(s),\ j = 1, 2, \ldots, N\} \quad \text{for } s \in [-r, 0] \end{aligned} \tag{4.7}$$

so that

$$w_j(t) \geq \hat{w}(t), \qquad t > 0, \qquad j = 1, 2, \ldots, N,$$

but this presents a possible problem in that $\hat{w}(s)$ could be zero on all of $s \in [-r, 0]$ without violating the assumption $w_j^0(s) \not\equiv 0$ on $(s, j) \in [-r, 0] \times \{1, 2, \ldots, N\}$ (e.g., if $w_j^0(s)$ were zero for all s on one particular node) in which case $\hat{w}(t)$ would be zero for all $t > 0$, which is not helpful for us. The way round this difficulty is to remember that we showed earlier (Theorem 3.1) that $w_j(t) > 0$ for all $t \geq r$. Consider the initial value problem starting at time $t = 2r$ and consisting of equation (2.10) for $t > 2r$, with initial data taken to be the solution $w_j(t)$, $t \in [r, 2r]$, of the original problem. The solution of this new initial value problem for $t > 2r$ is clearly the same as the solution $w_j(t)$ of the original problem, but the new problem has strictly positive initial data. This means that, without loss of generality, the minimum in (4.7) can be assumed to be strictly positive for all $s \in [-r, 0]$.

To complete the proof of Theorem 4.2 it therefore suffices to prove that every solution of the scalar ODE (4.5) such that $w(s) > 0$ for all $s \in [-r, 0]$ will satisfy $w(t) \to w^*$, if the hypotheses on the parameters and the function $b(w)$ are satisfied. This follows immediately from Theorem 9.1 on page 159 of the book by Kuang [9]. Therefore, the proof of Theorem 4.2 is complete. $\square$

5. Nonmonotone birth functions. Of considerable interest to ecologists, is the case of a birth function $b(w)$ which is increasing up to a certain value of w and decreasing thereafter (for example, a function qualitatively resembling $b(w) = Pwe^{-Aw}$). Such birth functions are important in modelling certain insect populations in which the birth rate is observed to be roughly proportional to the number of adults if the number of adults is small, but effectively zero if the number of adults is large, since competition for resources then becomes so intense that the adults require all their resources for their own maintenance. The aims of this section are to establish a comparison principle that works for very general birth functions, and then to use the comparison principle to prove convergence theorems in the case when the birth function qualitatively resembles $b(w) = Pwe^{-Aw}$.

THEOREM 5.1. *Let the birth function $b(w)$ be a differentiable function for all $w \geq 0$ and satisfy $b(0) = 0$, $b(w) > 0$ when $w > 0$. Let $\hat{w}$ and $\bar{w}$ be a pair of sub- and supersolutions for* (2.10), (2.11)*, i.e., a pair of functions satisfying*

(i) *$\hat{w}_j(t) \leq \bar{w}_j(t)$ for all $t \in [-r, \infty)$, $j = 1, 2, \ldots, N$;*

(ii) *letting $\bar{\mathbf{w}}(t) = (\bar{w}_1(t), \ldots, \bar{w}_N(t))^T$ and $\hat{\mathbf{w}}(t) = (\hat{w}_1(t), \ldots, \hat{w}_N(t))^T$ for $t > 0$ and $j = 1, 2, \ldots, N$,*

$$\frac{d\hat{\mathbf{w}}(t)}{dt} \leq D_m A\hat{\mathbf{w}}(t) - d_m\hat{\mathbf{w}}(t) + \mu \sum_{k=1}^{N} b(\varphi_k(t-r)) \begin{pmatrix} \beta(\alpha, k, 1) \\ \beta(\alpha, k, 2) \\ \vdots \\ \beta(\alpha, k, N-1) \\ \beta(\alpha, k, N) \end{pmatrix}, \tag{5.1}$$

and

$$\frac{d\bar{\mathbf{w}}(t)}{dt} \geq D_m A\bar{\mathbf{w}}(t) - d_m\bar{\mathbf{w}}(t) + \mu \sum_{k=1}^{N} b(\varphi_k(t-r)) \begin{pmatrix} \beta(\alpha, k, 1) \\ \beta(\alpha, k, 2) \\ \vdots \\ \beta(\alpha, k, N-1) \\ \beta(\alpha, k, N) \end{pmatrix} \tag{5.2}$$

for all functions $\varphi_j(t)$ *such that* $\hat{w}_j(t) \le \varphi_j(t) \le \bar{w}_j(t)$, $t \in [-r, \infty)$, $j = 1, 2, \ldots, N$;

(iii) $\hat{w}_j(s) \le w_j^0(s) \le \bar{w}_j(s)$, $s \in [-r, 0]$, $j = 1, 2, \ldots, N$, *where* $w_j^0(s)$ *is the initial data for* (2.10).

Then the solution $w_j(t)$ *of* (2.10), (2.11) *satisfies*

$$\hat{w}_j(t) \le w_j(t) \le \bar{w}_j(t) \quad \textit{for all } t > 0,\ j = 1, 2, \ldots, N.$$

Proof. Using (2.10), inequality (5.1) can be rewritten as

$$\frac{d\hat{\mathbf{w}}(t)}{dt} - D_m A\hat{\mathbf{w}}(t) + d_m\hat{\mathbf{w}}(t) - \mu\sum_{k=1}^{N} b(\varphi_k(t-r))\begin{pmatrix}\beta(\alpha,k,1)\\ \beta(\alpha,k,2)\\ \vdots\\ \beta(\alpha,k,N-1)\\ \beta(\alpha,k,N)\end{pmatrix}$$

$$\le \frac{d\mathbf{w}(t)}{dt} - D_m A\mathbf{w}(t) + d_m\mathbf{w}(t) - \mu\sum_{k=1}^{N} b(w_k(t-r))\begin{pmatrix}\beta(\alpha,k,1)\\ \beta(\alpha,k,2)\\ \vdots\\ \beta(\alpha,k,N-1)\\ \beta(\alpha,k,N)\end{pmatrix}. \tag{5.3}$$

Define $W_j(t) = w_j(t) - \hat{w}_j(t)$ and $\mathbf{W}(t)$ to be the vector with components $W_j(t)$. Then (5.3) becomes

$$\begin{aligned}\frac{d\mathbf{W}(t)}{dt} &- D_m A\mathbf{W}(t) + d_m\mathbf{W}(t) - \mu\sum_{k=1}^{N}[b(w_k(t-r))\\ &- b(\varphi_k(t-r))]\begin{pmatrix}\beta(\alpha,k,1)\\ \beta(\alpha,k,2)\\ \vdots\\ \beta(\alpha,k,N-1)\\ \beta(\alpha,k,N)\end{pmatrix} \ge 0\end{aligned} \tag{5.4}$$

and by hypothesis this holds for all $\varphi_j(t)$ such that $\hat{w}_j(t) \le \varphi_j(t) \le \bar{w}_j(t)$, $t \in [-r, \infty)$, $j = 1, 2, \ldots, N$.

We need to prove that $W_j(t) \ge 0$ for all $t > 0$ and all j, and we shall first prove this conclusion for $t \in (0, r]$. In inequality (5.4), for each j choose $\varphi_j(t)$ to be any function between $\hat{w}_j(t)$ and $\bar{w}_j(t)$, $t \in [-r, \infty)$, which is such that $\varphi_j(s) = w_j^0(s)$ when $s \in [-r, 0]$. From this choice for $\varphi_j(t)$ we infer that, for $t \in (0, r]$ only, the last term in the left-hand side of inequality (5.4) is zero, so that the inequality holds for $t \in (0, r]$ with just the first three terms in the left-hand side. The proof that $W_j(t) \ge 0$ for $t \in (0, r]$ then proceeds the same way as in the proof of Theorem 4.1 because our inequality is the same as (4.3) in the case when the functions $f_i(t)$ of the latter are zero.

Proving that $w_j(t) \le \bar{w}_j(t)$ for $t \in (0, r]$ and all j is similar. Thus

$$\hat{w}_j(t) \le w_j(t) \le \bar{w}_j(t) \quad \text{for } t \in (0, r],\ j = 1, 2, \ldots, N. \tag{5.5}$$

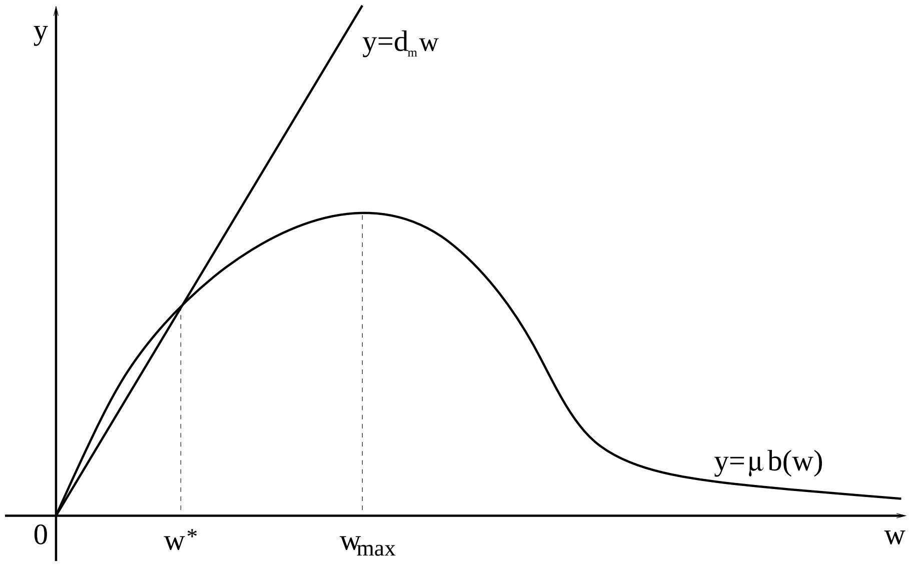

FIG. 1. *Graphical depiction of the situation in which Theorem* 5.2 *holds. In particular, the equilibrium* w^* *has to satisfy* $0 < w^* < w_{\max}$.

Proving that $W_j(t) = w_j(t) - \hat{w}_j(t) \geq 0$ for $t \in (r, 2r]$ is similar. Inequality (5.4) still holds for all $t > 0$ and in particular for $t \in (r, 2r]$. This time, we choose $\varphi_j(t)$ to be any function between $\hat{w}_j(t)$ and $\bar{w}_j(t)$, $t \in [-r, \infty)$, which is such that $\varphi_j(t) = w_j(t)$ when $t \in [0, r]$. This choice furnishes for us inequality (5.4), on $t \in (r, 2r]$ only, but without the term involving summation. We thus conclude that $W_j(t) \geq 0$ for $t \in (r, 2r]$ and it is clear how to continue the proof. $\square$

Remark. A comparison theorem similar to Theorem 5.1 was proved for the case of continuous space by Redlinger [5].

5.1. Convergence to equilibrium when * $_{\max}$. We will use Theorem 5.1 to establish, essentially, that if $b(w)$ qualitatively resembles Pwe^{-Aw} and if a nonzero equilibrium of (2.10) exists, is unique, and is in the interval of w for which $b(w)$ is increasing, then the equilibrium is globally stable as a solution of (2.10).

THEOREM 5.2. *In system* (2.10) *let the birth function* $b(w)$ *satisfy* $b(0) = 0$ *and* $b(w) > 0$ *when* $w > 0$. *Also, let* $b(w)$ *be increasing for* $0 < w < w_{\max}$, *with* $b'(w_{\max}) = 0$, *and decreasing for* $w > w_{\max}$. *Assume further that there exists* $w^* > 0$ *such that* $\mu b(w) > d_m w$ *when* $0 < w < w^*$ *and* $\mu b(w) < d_m w$ *when* $w > w^*$, *and assume that* $w^* < w_{\max}$.

Then, if $w_j^0(s) \not\equiv 0$ *on* $(s, j) \in [-r, 0] \times \{1, 2, \ldots, N\}$, *the solution* $w_j(t)$ *of* (2.10) *for* $t > 0$, *subject to* (2.11), *satisfies* $w_j(t) \to w^*$ *as* $t \to \infty$, *for each* $j = 1, 2, \ldots, N$.

Remark. The situation we have in mind is shown in Figure 1.

Proof of Theorem 5.2. Let $\hat{w}_j(t) = 0$ and $\bar{w}_j(t) = v(t)$ for each $j = 1, 2, \ldots, N$, where $v(t)$ is the solution of

$$\frac{dv(t)}{dt} = \mu b(w_{\max}) - d_m v(t),$$

$$v(s) = \max\{w_j^0(s),\ j = 1, 2, \ldots, N\}, \qquad s \in [-r, 0].$$

It is easily seen that $\hat{w}_j(t)$ and $\bar{w}_j(t)$ are a pair of sub- and supersolutions. Thus, by Theorem 5.1,

$$0 \le w_j(t) \le v(t) \qquad \text{for all } t > 0,\ \ j = 1, \dots, N.$$

Thus

$$\limsup_{t\to\infty} \max_{j\in\{1,2,\dots,N\}} w_j(t) \le \lim_{t\to\infty} v(t) = \frac{\mu b(w_{\max})}{d_m}.$$

Under the hypotheses it can be shown that

$$w^* < \frac{\mu b(w_{\max})}{d_m} < w_{\max}.$$

Choose $\epsilon > 0$ sufficiently small such that

$$\frac{\mu b(w_{\max})}{d_m} + \epsilon < w_{\max}.$$

There exists a time $T > 0$ such that, for all $t > T$ and all j,

$$w_j(t) \le \frac{\mu b(w_{\max})}{d_m} + \epsilon < w_{\max}.$$

Then as soon as t exceeds $T + r$ there is effectively no record, as far as system (2.10) is concerned, of the solution $w_j(t)$ ever having taken values outside the interval $[0, w_{\max}]$. From this point on the analysis proceeds as if the birth function were increasing for all w, and therefore it follows from Theorem 4.2 that the solution converges to w^*. The proof is complete. ◻

5.2. Convergence to equilibrium when * $_{\max}$. This section will show that if $w^* > w_{\max}$, then solutions of (2.10), (2.11) will still converge to w^* if additional conditions hold. These additional conditions will hold if w^* is not too much larger than $w_{\max}$.

THEOREM 5.3. *In system* (2.10) *let the birth function $b(w)$ satisfy $b(0) = 0$ and $b(w) > 0$ when $w > 0$. Also, let $b(w)$ be increasing for $0 < w < w_{\max}$, with $b'(w_{\max}) = 0$, and decreasing for $w > w_{\max}$. Assume further that there exists $w^* > 0$ such that $\mu b(w) > d_m w$ when $0 < w < w^*$ and $\mu b(w) < d_m w$ when $w > w^*$. Assume that $w^* > w_{\max}$ and that*

$$\frac{1}{d_m}\mu b\left(\frac{\mu b(w_{\max})}{d_m}\right) > w_{\max}. \tag{5.6}$$

Furthermore, we assume that

$$(d_m + \bar{f})r < 1, \tag{5.7}$$

where

$$\bar{f} = \mu \max\{|b'(w)|,\ \ w \in [\underline{w}, \overline{w}]\}$$

with $\overline{w} = (\mu/d_m)b(w_{\max})$ and $\underline{w} = b^{-1}(b(w^*))|_{[0,w_{\max}]}$. Assume further that

$$\frac{\mu}{d_m} b'(w^*) > -1. \tag{5.8}$$

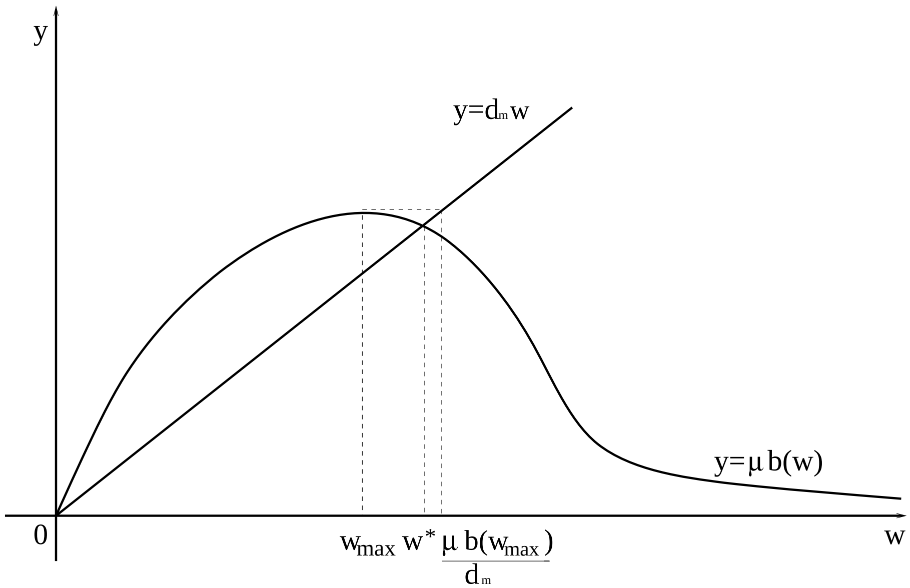

FIG. 2. *Graphical depiction of the situation in which Theorem* 5.3 *holds. In particular, the equilibrium w^* has to satisfy $w^* > w_{\max}$.*

Then, if $w_j^0(s) \not\equiv 0$ on $(s, j) \in [-r, 0] \times \{1, 2, \ldots, N\}$, the solution $w_j(t)$ of (2.10) *for $t > 0$, subject to* (2.11) *satisfies $w_j(t) \to w^*$ as $t \to \infty$, for each $j = 1, 2, \ldots, N$.*

Remarks. It is natural to question whether these hypotheses can be satisfied. The graph shown in Figure 2 shows that they can, and also suggests that the hypotheses are likely to be satisfied only when w^* is not too much greater than $w_{\max}$.

The notation $b^{-1}(b(w^*))|_{[0,w_{\max}]}$ requires some explaining. Under the assumptions on $b(w)$, $b^{-1}(w)$ will, if defined, have in general two values. Thus $b^{-1}(b(w^*))$ is either w^* or a value in $[0, w_{\max}]$ and $b^{-1}(b(w^*))|_{[0,w_{\max}]}$ means the latter value.

Proof of Theorem 5.3. Let us define

$$\begin{aligned} w^0_{\max} &= \max\{w^*, \max\{w_j^0(s),\ j = 1, 2, \ldots, N,\ \ s \in [-r, 0]\}\}, \\ w^0_{\min} &= \min\{w^*, \min\{w_j^0(s),\ j = 1, 2, \ldots, N,\ \ s \in [-r, 0]\}\}. \end{aligned}$$

We can assume without loss of generality that $w^0_{\min} > 0$ (this can be justified similarly to the proof of Theorem 4.2).

The proof begins with the observation that $(\hat{w}_j(t), \bar{w}_j(t)) = (0, V_1(t))$ is a sub/supersolution pair for (2.10), (2.11), where $V_1(t)$ satisfies

$$\frac{dV_1(t)}{dt} = \mu b(w_{\max}) - d_m V_1(t),$$

$$V_1(s) = w^0_{\max},\ s \in [-r, 0].$$

Therefore,

$$\limsup_{t\to\infty} \max_{j\in\{1,2,\ldots,N\}} w_j(t) \le \lim_{t\to\infty} V_1(t) = \frac{\mu b(w_{\max})}{d_m}.$$

Next it is easy to see that (v_1, V_1) is a sub/supersolution pair, where V_1 is the above function and v_1 satisfies

$$\frac{dv_1}{dt} = \mu \min\{b(v_1(t-r)), b(V_1(t-r))\} - d_m v_1(t), \tag{5.9}$$
$$v_1(s) = w^0_{\min},\ s \in [-r, 0].$$

Inequality (5.7) assures us that the solution of

$$\frac{dv}{dt} = \mu b(v(t-r)) - d_m v(t)$$

with positive initial data satisfies $\lim_{t\to\infty} v(t) = w^*$. This follows from Theorem 9.5 in Kuang (see [9, page 165]). On the other hand, any solution of

$$\frac{dv}{dt} = \mu b(V_1(t-r)) - d_m v(t)$$

satisfies

$$\lim_{t\to\infty} v(t) = \frac{\mu}{d_m} b\left(\frac{\mu b(w_{\max})}{d_m}\right).$$

Therefore the solution $v_1(t)$ of (5.9) tends, as $t \to \infty$, to either w^* or $\frac{\mu}{d_m} b(\frac{\mu b(w_{\max})}{d_m})$ and so our proof proceeds by considering two cases.

Case 1. $\lim_{t\to\infty} v_1(t) = w^*$. In this case we obtain immediately that

$$\liminf_{t\to\infty} \min_{j\in\{1,2,\dots,N\}} w_j(t) \geq w^*.$$

It can be shown similarly that

$$\limsup_{t\to\infty} \max_{j\in\{1,2,\dots,N\}} w_j(t) \leq w^*,$$

completing the proof of the theorem for Case 1.

Case 2. $\lim_{t\to\infty} v_1(t) = \frac{\mu}{d_m} b(\frac{\mu b(w_{\max})}{d_m})$. What we initially get in this case is

$$\liminf_{t\to\infty} \min_{j\in\{1,2,\dots,N\}} w_j(t) \geq \frac{\mu}{d_m} b\left(\frac{\mu b(w_{\max})}{d_m}\right),$$

which, by (5.6), strictly exceeds $w_{\max}$. Therefore, for t sufficiently large, $w_j(t) > w_{\max}$. Since the problem has finite delay, this further means that for t sufficiently large there is no history of $w_j(t)$ ever having assumed values below $w_{\max}$, so that for the remainder of the proof $b(w)$ can be treated as decreasing in w. In fact we may shift the origin of time such as to assume, without loss of generality, that $w^0_{\min} > w_{\max}$. With this fact in mind, our proof now proceeds by successive refinement of pairs of sub/supersolutions.

In general, for each $n = 2, 3, \dots$, let (v_n, V_n) be defined by

$$\frac{dv_n}{dt} = \mu b(V_{n-1}(t-r)) - d_m v_n, \tag{5.10}$$
$$\frac{dV_n}{dt} = \mu b(v_{n-1}(t-r)) - d_m V_n$$

with the initial conditions $V_n(s) = w^0_{\max},\ s \in [-r, 0]$, and $v_n(s) = w^0_{\min},\ s \in [-r, 0]$. We will show that (v_n, V_n) is a sub/supersolution pair for each $n = 2, 3, \ldots$. According to Theorem 5.1, what we need to show is that

$$b(V_{n-1}(t-r)) \le \sum_{k=1}^{N} b(\varphi_k(t-r))\beta(\alpha, k, j)$$

whenever $\varphi_j(t)$ is such that $v_n(t) \le \varphi_j(t) \le V_n(t)$ for $j = 1, 2, \ldots, N$ and $t \in [-r, \infty)$. Since we are now working in an interval of w in which $b(w)$ is decreasing, it is enough to establish that

$$b(V_{n-1}(t-r)) \le \sum_{k=1}^{N} b(V_n(t-r))\beta(\alpha, k, j) = b(V_n(t-r))$$

and the latter is true if $V_n(t) \le V_{n-1}(t)$ for each $n = 2, 3, \ldots$. Similarly, we need to show that $v_n(t) \ge v_{n-1}(t)$ for each n. In fact, we shall show by induction that

$$v_1(t) \le \cdots \le v_{n-1}(t) \le v_n(t) < w^* < V_n(t) \le V_{n-1}(t) \le \cdots \le V_1(t). \tag{5.11}$$

To achieve this we assume (5.11) and prove that

$$w^* < V_{n+1}(t) \le V_n(t) \tag{5.12}$$

and

$$w^* > v_{n+1}(t) \ge v_n(t). \tag{5.13}$$

We will prove only (5.12). Now

$$\begin{aligned}\frac{dV_{n+1}(t)}{dt} &= \mu b(v_n(t-r)) - d_m V_{n+1}(t)\\ &\le \mu b(v_{n-1}(t-r)) - d_m V_{n+1}(t).\end{aligned}$$

Therefore

$$\frac{dV_{n+1}(t)}{dt} + d_m V_{n+1}(t) \le \frac{dV_n(t)}{dt} + d_m V_n(t),$$

or, equivalently,

$$\frac{d}{dt}(V_{n+1} - V_n)(t) + d_m(V_{n+1} - V_n)(t) \le 0.$$

Therefore

$$V_{n+1}(t) - V_n(t) \le \underbrace{(V_{n+1}(0) - V_n(0))}_{=0} e^{-d_m t}$$

and so

$$V_{n+1}(t) \le V_n(t).$$

Also

$$\begin{aligned}\frac{dV_{n+1}(t)}{dt} &= \mu b(v_n(t-r)) - d_m V_{n+1}(t)\\ &\ge \mu b(w^*) - d_m V_{n+1}(t)\\ &= d_m(w^* - V_{n+1})\end{aligned}$$

so that

$$\frac{d}{dt}(V_{n+1} - w^*) \geq -d_m(V_{n+1} - w^*).$$

Therefore,

$$V_{n+1}(t) - w^* \geq \underbrace{(V_{n+1}(0) - w^*)}_{\geq 0} e^{-d_m t} \geq 0$$

and so

$$V_{n+1}(t) \geq w^*$$

which establishes (5.12).

Denote $V_n^* = \lim_{t\to\infty} V_n(t)$ and $v_n^* = \lim_{t\to\infty} v_n(t)$. That these limits exist follows from (5.10) and an inductive argument. We know $v_1(t)$ and $V_1(t)$ approach limits as $t \to \infty$. There are theories of asymptotically autonomous differential equations which allow us to let $t \to \infty$ in system (5.10), with $n = 2$, giving an autonomous system of differential equations from which it becomes clear that $v_2(t)$ and $V_2(t)$ approach limits as $t \to \infty$. The argument can be continued and we thus conclude the existence of the limits as $t \to \infty$ for each n. From (5.10) these limits satisfy

$$\begin{aligned} \mu b(V_{n-1}^*) &= d_m v_n^*, \\ \mu b(v_{n-1}^*) &= d_m V_n^*. \end{aligned} \tag{5.14}$$

We define $V^* = \lim_{n\to\infty} V_n^*$ and $v^* = \lim_{n\to\infty} v_n^*$; then (5.14) reduces to a limiting system

$$\begin{aligned} \mu b(V^*) &= d_m v^*, \\ \mu b(v^*) &= d_m V^*. \end{aligned} \tag{5.15}$$

These equations imply that $V^* = v^* = w^*$ (condition (5.8) assures us that they have no other solutions). Therefore, $\lim_{t\to\infty} w_j(t) = w^*$ and the proof of the theorem is complete. ∎

6. Discussion. The main results in this paper are, first, the derivation of the model (2.10) itself, which is nontrivial and substantially different from the case of an infinite lattice considered previously in [8]. Second, the positivity-preservation properties of solutions which turn out to be analogous to results that can be proved using the strong maximum principle in the case of continuous space. Third, the comparison principle of section 4 for the case of increasing birth functions. Fourth, the use of this comparison principle to prove that the positive equilibrium of system (2.10), if feasible, is globally asymptotically stable for increasing birth functions. Fifth, in section 5, the comparison principle for the case of nonmonotone birth functions is proved. With the help of this principle we have shown that the nontrivial equilibrium is globally asymptotically stable if it is in the interval of w for which the birth function $b(w)$ is increasing, and that it can remain globally stable if it is larger, but not too much larger, than the value of w at which $b(w)$ attains its maximum, assuming additionally the delay is not too large.

Acknowledgment. We would like to thank the referees for their very valuable comments.

NEW LYAPUNOV FUNCTIONALS OF THE VLASOV–POISSON SYSTEM*

MYEONGJU CHAE† AND SEUNG-YEAL HA‡

Abstract. We present new Lyapunov functionals and L^1-stability for the Vlasov–Poisson system with a self-consistent electrostatic force in a small initial data case. Lyapunov functionals measure possible future crossings of projected particle trajectories in the physical space, and they are nonincreasing along smooth solutions when the initial datum is smooth and decays fast enough at infinity in the phase space. For sufficiently large physical dimensions, we also show that smooth solutions are uniformly L^1-stable.

Key words. Vlasov–Poisson system, Lyapunov functional, L^1-stability

1. Introduction.

Consider a collisionless plasma consisting of M distinct species under the effect of an electromagnetic field. The issue can be understood by the Vlasov–Maxwell system. When the speed of light is taken to be infinity and a magnetic field is ignored, the Vlasov–Poisson system with a self-consistent electrostatic field is addressed. Suppose there are M species of particles with mass m_α, charge q_α, and density in the phase space $f_\alpha(x, v, t)$ for $\alpha = 1, \dots, M$. Here $(x, v) \in \mathbb{R}^N \times \mathbb{R}^N$ denotes position and velocity, respectively. The self-consistent electric field is denoted by $E = -\nabla_x \phi$ and the total charge density ρ is

$$\rho(x,t) = \sum_{\alpha=1}^{M} q_\alpha \int_{\mathbb{R}^N} f_\alpha(x,v,t)\, dv.$$

In this case, the Vlasov–Poisson system reads

$$\begin{cases} \partial_t f_\alpha + v \cdot \nabla_x f_\alpha + \dfrac{q_\alpha}{m_\alpha} \nabla_x \phi \cdot \nabla_v f_\alpha = 0 \quad \text{in} \quad \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}_+, \\ -\Delta_x \phi = N(N-2)\omega_N \rho, \end{cases} \tag{1.1}$$

with the prescribed initial datum

$$f_\alpha(x,v,0) = f_{\alpha,0}(x,v) \quad \text{in} \quad \mathbb{R}^N \times \mathbb{R}^N, \tag{1.2}$$

where ω_N is the volume of the unit ball in $\mathbb{R}^N$.

The Vlasov–Poisson system has many applications in the modeling of an electron gun, plasma sheath, and galaxies as a large ensemble of stars in plasma physics and astrophysics, respectively. The global existence of a smooth solution in one space variable has been proved by Iordanskii [25] and that of two space variables by Ukai

and Okabe [36]. On the other hand, for the three-dimensional case, Batt [3] and Horst [21, 22, 23] established the global existence for spherical and cylindrically symmetric data, respectively. For general but small data, Bardos and Degond [2] obtained global existence, and finally Pfaffelmoser [30] proved the global existence of a smooth solution with large data, and simpler proofs were provided by Schaeffer [33] and Lions and Perthame [27]. For other issues such as weak solutions, relativistic effects, stability, and dispersion estimates, we refer the reader to [1, 4, 12, 23, 28, 29, 31, 34, 35, 38, 40].

The aim of this paper is twofold. First, we present Lyapunov functionals for the repulsive Vlasov–Poisson system when the dimension of the physical space $N \neq 2$. These functionals measure the future collisions between charged particles, although the Vlasov–Poisson system does not register them. As in the Boltzmann equation [19, 20], these functionals might be useful to establish L^1-scattering-type results for the Vlasov–Poisson–Boltzmann equation near vacuum [18]. Second, we study the L^1-stability of smooth C^2-solutions to (1.1) using Gronwall-type estimates when the dimension of the physical space is sufficiently large, and the initial data are smooth and decay fast enough in the phase space. Throughout this paper, we denote by C a universal positive constant independent of time t.

The above two main results of this paper are subject to the following estimates on the time-decay of the electric field and the velocity variation of the density function f_α (see section 2).

(E1) The electric field $E(x,t)$ decays, and it is integrable in t:

$$\int_0^\infty \|E(t)\|_{L^\infty(\mathbb{R}^N_x)}\, dt < \infty.$$

(E2) For fixed $(x,t) \in \mathbb{R}^N \times \mathbb{R}_+$ and $\alpha \in \{1,\dots,M\}$,

$$\Big\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha(t)|\, dv \Big\|_{L^\infty(\mathbb{R}^N_x)} \le \frac{C}{(1+t)^{N-1}},$$
$$\Big\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha(t)|\, dv \Big\|_{L^1(\mathbb{R}^N_x)} \le C(1+t).$$

Based on the time-integrable decay of the electric field E, we first construct an interaction potential $\mathcal{D}(f_\alpha)$ which is nonincreasing along smooth solutions to (1.1) with $N \ge 3$, and which satisfies a Lyapunov estimate: for $\alpha \in \{1,\dots,M\}$,

$$\mathcal{D}(f_\alpha(t)) + \int_0^t \Lambda(f_\alpha(s))\, ds = \mathcal{D}(f_{\alpha,0}), \qquad t \ge 0,$$

where $\Lambda(f_\alpha(s)) \ge 0$ is an interaction production functional

$$\Lambda(f_\alpha(t)) := \iiint_{\mathbb{R}^N\times\mathbb{R}^N\times\mathbb{R}^N} f_\alpha(x,v,t) f_\alpha(x,v_*,t)\, dv_*\, dv\, dx.$$

The above functional measures the possible crossings of the projected particle trajectories in the physical space, and hence it can be regarded as a kinetic counterpart of Glimm's interaction potential [17] in hyperbolic conservation laws in one-space dimension. Due to the strong dispersive effect of the free transport part, the crossings of projected trajectories in the physical space will tend to be nonincreasing in time t. In fact, in the absence of external forces, such interaction potentials have been constructed for the full Boltzmann equation in [6, 19, 20] based on the free transport equation $\partial_t f + v \cdot \nabla_x f = 0$ with small initial data. Unlike the Boltzmann equation, where the interaction potential is constructed based on the free transport part, the external force term $\nabla_x \phi \cdot \nabla_v f_\alpha$ produces error terms which cannot be controlled by the interaction production functional $\Lambda(f_\alpha(t))$. We overcome this difficulty by devising a new functional capturing the nonlinear feature of the system, and by essentially using time-integrable decay of the electric field; thus small initial data are assumed.

Second, we establish the uniform L^1-stability for (1.1) with $N \geq 4$:

$$\sup_{0 \leq t < \infty} \|f(t) - \bar{f}(t)\|_{L^1} \leq G \|f_0 - \bar{f}_0\|_{L^1}, \tag{1.3}$$

where G is a positive constant independent of t, and a simplified notation for L^1-norm is used:

$$\|f(t) - \bar{f}(t)\|_{L^1} := \sum_{\alpha=1}^{M} \|f_\alpha(\cdot, \cdot, t) - \bar{f}_\alpha(\cdot, \cdot, t)\|_{L^1(\mathbb{R}^N \times \mathbb{R}^N)}.$$

Unlike the Boltzmann equation [19, 20], the nonlinear functional approach incorporating the Lyapunov functional $\mathcal{D}(f_\alpha)$ cannot be applied to L^1-stability estimates for (1.1). By direct calculation, $|f_\alpha - \bar{f}_\alpha|$ satisfies

$$\partial_t |f_\alpha - \bar{f}_\alpha| + v \cdot \nabla_x |f_\alpha - \bar{f}_\alpha| + E(f) \cdot \nabla_v |f_\alpha - \bar{f}_\alpha| \leq |E(\bar{f}) - E(f)| |\nabla_v \bar{f}_\alpha|, \tag{1.4}$$

which yields

$$\frac{d}{dt} \|f_\alpha(t) - \bar{f}_\alpha(t)\|_{L^1} \leq \iint_{\mathbb{R}^N \times \mathbb{R}^N} |E(\bar{f}) - E(f)| |\nabla_v \bar{f}_\alpha| \, dv \, dx. \tag{1.5}$$

In contrast, the time-derivative of $\mathcal{D}(|f_\alpha - \bar{f}_\alpha|)$ based on the left-hand sides of (1.1) and (1.4) yields good decay terms:

$$-\iiint_{\mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}^N} |f_\alpha - \bar{f}_\alpha|(x, v, t) f_\alpha(x, v_*, t) \, dv_* \, dv \, dx;$$

however, these terms cannot control the right-hand side of (1.5). In fact these good terms can be used to control the error terms due to the difference $Q(f, f) - Q(\bar{f}, \bar{f})$ in the L^1-stability estimates of the Vlasov–Poisson–Boltzmann system (see [19, 20] for the related issue of the Boltzmann equation); hence instead of using the nonlinear functional approach for (1.3), we employ Gronwall-type estimates incorporating (E2) in Theorem 1.2 (see section 4):

$$\|f(t) - \bar{f}(t)\|_{L^1} \leq \|f_0 - \bar{f}_0\|_{L^1} + C \int_0^t (1 + s)^{-(N-2)} \|f(s) - \bar{f}(s)\|_{L^1} \, ds.$$

Since

$$\int_0^t (1 + s)^{-(N-2)} < C \quad \text{for} \quad N \geq 4,$$

we can establish the uniform L^1-stability (1.3) for the physical space dimension $N \geq 4$.

The main hypotheses (H) employed in this paper are as follows:

(H1) The initial data $f_{\alpha,0}$ $(\alpha = 1, \ldots, M)$ are twice continuously differentiable:

$$f_{\alpha,0} \in C^2(\mathbb{R}^N \times \mathbb{R}^N).$$

(H2) The initial data are small and decay at infinity in the phase space:

$$\max_{\alpha=1}^{M} \sum_{0\le i,j\le 2} \sup_{x,v} (1+|x|^2)^{\frac{\mu_1}{2}}(1+|v|^2)^{\frac{\mu_2}{2}} |\nabla_x^i \nabla_v^j f_{\alpha,0}(x,v)| \le \varepsilon_0,$$

where $\mu_1 > N+2$, $\mu_2 > N+1$, and $0 < \varepsilon_0 \ll 1$.

Our first main result shows that the system (1.1) with $N \ge 3$ admits an interaction potential.

THEOREM 1.1. *Suppose the main hypotheses* (H) *with* $N \ge 3$ *hold, and let* f_α $(1 \le \alpha \le M)$ *be a smooth solution to* (1.1) *corresponding to the initial datum* $f_{\alpha,0}$. *Then there exists an interaction potential* $\mathcal{D}(f_\alpha)$ *satisfying a Lyapunov estimate:*

$$\mathcal{D}(f_\alpha(t)) + \int_0^t \Lambda(f_\alpha(s))\, ds = \mathcal{D}(f_{\alpha,0}), \quad t \ge 0.$$

REMARK 1.1. (1) *Following the arguments in* [2]*, the global existence of smooth* C^2*-solutions satisfying the main estimates* (E1)–(E2) *can be shown.*

(2) *For* $N = 1$*, we can construct a similar Lyapunov functional under the monotonicity assumption of the electric field (see section* 3.1*).*

Our second main theorem is concerned with the uniform L^1-stability.

THEOREM 1.2. *Suppose the main hypotheses* (H) *with* $N \ge 4$ *hold, and let* f_α *and* $\bar{f}_\alpha$ *be smooth solutions to* (1.1) *corresponding to the initial data* $f_{\alpha,0}$ *and* $\bar{f}_{\alpha,0}$, *respectively. Then smooth solutions are uniformly* L^1*-stable with respect to the initial data:*

$$\sup_{0\le t<\infty} \|f(t) - \bar{f}(t)\|_{L^1} \le G\|f_0 - \bar{f}_0\|_{L^1},$$

where G *is a positive constant independent of time* t.

The rest of this paper is organized as follows. In section 2, we review basic a priori estimates for the Vlasov–Poisson system, and in section 3 we construct kinetic Glimm-type interaction potentials for the one-dimensional (1D) and multidimensional cases, respectively. In section 4, we study the uniform L^1-stability estimate. Finally, in the appendix, we briefly discuss an interaction potential for the relativistic Vlasov–Maxwell system with small data.

2. Preliminaries. We briefly review dispersion estimates for the local charge density, the electric force, and the velocity variation of the density function, and we study the strict separation property of backward particle trajectories. The details can be found in [2, 7].

2.1. Time-decay estimate of the electric field. In this part, we review the dispersion estimates studied in [2]. Consider C^2-initial data for the system (1.1) satisfying

$$\max_{\alpha=1}^{M} \sum_{0\le i,j\le 2} \sup_{x,v} (1+|x|^2)^{\frac{\mu_1}{2}}(1+|v|^2)^{\frac{\mu_2}{2}} |\nabla_x^i \nabla_v^j f_{\alpha,0}(x,v)| \le \varepsilon_0,$$

where $\mu_1 > N+2$, $\mu_2 > N+1$, and $0 < \varepsilon_0 \ll 1$.

Let $h \in C(\mathbb{R}_+; (L^1 \cap W^{1,\infty})(\mathbb{R}^N))$ be given, and define a Newtonian potential $\mathcal{P}$ by the representation formula

$$\mathcal{P}(h)(x,t) := \int_{\mathbb{R}^N} \frac{h(y,t)}{|x-y|^{N-2}}\, dy. \tag{2.1}$$

The following lemmas can be found in [2] for $N = 3$, and their proofs are exactly the same as those for $N > 3$; hence we omit its proof.

LEMMA 2.1. *Suppose that a function* $h(\cdot, t) \in (L^1 \cap W^{1,\infty})(\mathbb{R}^N)$ *for all* $t \in \mathbb{R}^+$. *Then we have*

(1) $\|\mathcal{P}(h)(t)\|_{L^\infty} \le C(N)\|h(t)\|_{L^1}^{\frac{2}{N}}\|h(t)\|_{L^\infty}^{\frac{N-2}{N}}$.

(2) $\|\nabla_x\mathcal{P}(h)(t)\|_{L^\infty} \le C(N)\|h(t)\|_{L^1}^{\frac{1}{N}}\|h(t)\|_{L^\infty}^{\frac{N-1}{N}}$.

(3) $\|\nabla_x^2\mathcal{P}(h)(t)\|_{L^\infty} \le C(N,\kappa)\|h(t)\|_{L^1}^{\frac{\kappa}{\kappa+N}}\|h(t)\|_{L^\infty}^{\frac{N(1-\kappa)}{N+\kappa}}\|\nabla_x h(t)\|_{L^\infty}^{\frac{N\kappa}{N+\kappa}}$ *for* $\kappa \in (0, 1)$.

A direct modification of the proof given in [2] for $N = 3$ and Lemma 2.1 give the global existence of smooth C^2-solutions under the main hypotheses (H).

THEOREM 2.2 (see [2]). *Suppose the main hypotheses* (H) *hold. Then the Vlasov–Poisson system* (1.1) *has a unique global in time solution such that* $f_\alpha \in C^1(\mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}_+)$ *satisfies the following uniform estimate:*

$$\|f(t)\|_{L^\infty(\mathbb{R}^N\times\mathbb{R}^N)} \le \varepsilon_0, \quad \|f(t)\|_{L^1(\mathbb{R}^N\times\mathbb{R}^N)} \le C\varepsilon_0,$$
$$\Big\| \int f(t)\, dv \Big\|_{L^\infty(\mathbb{R}^N_x)} \le \frac{C\varepsilon_0}{(1+t)^N}.$$

Moreover, we have for any $\kappa \in (0, 1)$,

$$\max_{1\le k\le 2} \|\nabla_x^k E(\cdot, t)\|_{L^\infty} \le \frac{C\varepsilon_0}{(1+t)^{\frac{N^2}{N+\kappa}}}.$$

REMARK 2.1. *The time-decay rate* $\frac{N^2}{N+\kappa}$ *has a lower bound which is strictly greater than* 2 (*see* [2]).

$$e(N,\kappa) := \frac{N^2}{N+\kappa} \ge \frac{N^2}{N+1} > 2 \quad \textit{for} \;\; N \ge 3. \tag{2.2}$$

The decay estimates of the electric field and the initial data yield the following estimate. The detailed proof for $N = 3$ can be found in [2], and it can be directly applied for the general case $N \ge 4$.

LEMMA 2.3 (see [2]). *Suppose the main hypotheses* (H) *hold, and let* f *be the smooth solution to* (1.1). *Then we have*

$$\Big\| \int_{\mathbb{R}^N} |\nabla_v f(t)|\, dv \Big\|_{L^\infty(\mathbb{R}^N_x)} \le \frac{C\varepsilon_0}{(1+t)^{N-1}} \quad \textit{and} \quad \Big\| \int_{\mathbb{R}^N} |\nabla_v f(t)|\, dv \Big\|_{L^1(\mathbb{R}^N_x)} \le C\varepsilon_0(1+t).$$

The above estimate will be used in the L^1-stability analysis in section 4.

2.2. Particle trajectories. In this part, we study the "*strict separation property*" of particle trajectories when an external force decays sufficiently fast in time t. Consider a Vlasov equation with a sufficiently smooth electric field E:

$$\partial_t f + v \cdot \nabla_x f + E \cdot \nabla_v f = 0. \tag{2.3}$$

We define a particle trajectory as the characteristic curve related to (2.3), i.e., for a fixed point $(x, v) \in \mathbb{R}^N \times \mathbb{R}^N$ at time t, the particle trajectory $[X(s; t, x, v), V(s; t, x, v)]$ passing through (x, v) at time t is defined as the unique solution of the ODE system:

$$\frac{d}{ds}X(s; t, x, v) = V(s; t, x, v) \quad \text{and} \quad \frac{d}{ds}V(s; t, x, v) = E(X(s; t, x, v), s) \tag{2.4}$$

with an initial datum

$$X(t;t,x,v) = x \quad \text{and} \quad V(t;t,x,v) = v.$$

We integrate (2.4) along the particle trajectory to see that Liouville's principle holds:

$$f(x,v,t) = f_0(X(0;t,x,v), V(0;t,x,v)), \qquad t \geq 0;$$

therefore, the L^p-norm of f is conserved for every p, $1 \leq p \leq \infty$,

$$\|f(t)\|_{L^p} = \|f_0\|_{L^p}, \quad t \geq 0,$$

since the mapping $(x,v) \to (X,V)$ is measure preserving.

Note that in the absence of an external field ($F \equiv 0$), the particle trajectory is simply a straight line:

$$X(s;t,x,v) = x - v(t-s) \quad \text{and} \quad V(s;t,x,v) = v.$$

Hence particle trajectories with different initial velocities are well separated in the sense that

$$|X(s;t,x,v) - X(s;t,x,w)| = (t-s)|v-w|.$$

While external forces such as an electromagnetic force act on particles, trajectories are no longer straight lines; they, nevertheless, behave almost like straight lines as long as the external force is sufficiently small and decays fast enough in time. The following lemma shows this strict separation property of particle trajectories.

LEMMA 2.4 (see [7]). *Suppose the main hypotheses* (H) *in section* 1 *hold and* $N \geq 3$. *Then particle trajectories are strictly separated: for fixed* x, v, t, *there exists a positive constant* C_1 *independent of* t *and* s *such that*

$$\frac{1}{C_1}|t-s||v-w| \leq |X(s;t,x,v) - X(s;t,x,w)| \leq C_1|t-s||v-w|, \qquad 0 \leq s \leq t.$$

Proof. Let x, v, w, and t be given, and for the simplicity of notation set

$$\begin{aligned} &X_1(s) := X(s;t,x,v), \quad V_1(s) := V(s;t,x,v) \quad \text{and} \\ &X_2(s) := X(s;t,x,w), \quad V_2(s) := V(s;t,x,w). \end{aligned}$$

Then it follows from (2.4) that

$$X_1(s) = x - \int_s^t V_1(\tau)\,d\tau \quad \text{and} \quad X_2(s) = x - \int_s^t V_2(\tau)\,d\tau.$$

We use the above two equations to find

$$\begin{aligned} X_1(s) - X_2(s) &= -\int_s^t (V_1(\tau) - V_2(\tau))\,d\tau \\ &= \int_s^t \left[\int_\tau^t (\partial_\theta V_1(\theta) - \partial_\theta V_2(\theta))\,d\theta - (v-w)\right] d\tau \\ &= \int_s^t \int_\tau^t (E(X_1(\theta),\theta) - E(X_2(\theta),\theta))d\theta\,d\tau - (v-w)(t-s). \end{aligned} \tag{2.5}$$

We set

$$A(s) := |X_1(s) - X_2(s) + (t-s)(v-w)|.$$

Then (2.5) implies

$$\begin{aligned}
A(s) &\le \int_s^t \int_\tau^t \|\nabla_x E(\cdot,\theta)\|_{L^\infty} |X_2(\theta) - X_1(\theta)|\, d\theta\, d\tau \\
&\le \int_s^t \int_\tau^t \|\nabla_x E(\cdot,\theta)\|_{L^\infty} (|X_2(\theta) - X_1(\theta) + (t-\theta)(v-w)| + (t-\theta)|v-w|)\, d\theta\, d\tau \\
&\le \mathcal{O}(\varepsilon_0) \int_s^t \int_\tau^t \left(\frac{A(\theta)}{(1+\theta)^{e(N,\kappa)}} + \frac{(t-\theta)|v-w|}{(1+\theta)^{e(N,\kappa)}} \right) d\theta\, d\tau \\
&\le \mathcal{O}(\varepsilon_0) \int_s^t \int_s^\theta \left(\frac{A(\theta)}{(1+\theta)^{e(N,\kappa)}} + \frac{t-\theta}{(1+\theta)^{e(N,\kappa)}} |v-w| \right) d\tau\, d\theta \\
&\le \mathcal{O}(\varepsilon_0) \int_s^t \left(\frac{(\theta-s)A(\theta)}{(1+\theta)^{e(N,\kappa)}} + \frac{(t-\theta)(\theta-s)}{(1+\theta)^{e(N,\kappa)}} |v-w| \right) d\theta \\
&\le \mathcal{O}(\varepsilon_0) \left(\int_s^t \frac{A(\theta) d\theta}{(1+\theta)^{e(N,\kappa)-1}} + (t-s)|v-w| \right),
\end{aligned}$$

where we used Theorem 2.2 and

$$e(N,\kappa) > 2, \quad \theta - s \le \theta + 1, \quad \text{and} \quad \int_s^t \frac{(t-\theta)(\theta-s)}{(1+\theta)^{e(N,\kappa)}}\, d\theta \le \mathcal{O}(1)|t-s|.$$

Since

$$\exp\left(\int_0^\infty \frac{d\theta}{(1+\theta)^{e(N,\kappa)-1}} \right) = \mathcal{O}(1),$$

Gronwall's inequality implies

$$A(s) \le \mathcal{O}(\varepsilon_0)(t-s)|v-w|.$$

By a triangle inequality, we have

$$(1 - \mathcal{O}(\varepsilon_0))(t-s)|v-w| \le |X_1(s) - X_2(s)| \le (1 + \mathcal{O}(\varepsilon_0))(t-s)|v-w|.$$

Since $\varepsilon_0 \ll 1$, we obtain the desired result. ∎

LEMMA 2.5 (see [18]). *Suppose the main hypotheses* (H) *holds. For any fixed* (x, v, t)*, let* $[X(s), V(s)]$ *be the particle trajectory passing through the point* (x, v) *at time* t*. Then we have*

$$|V(s_1) - V(s_2)| \le \mathcal{O}(\varepsilon_0) \quad \textit{and} \quad ||V(s_1)|^2 - |V(s_2)|^2| \le \mathcal{O}(\varepsilon_0), \quad 0 \le s_1, s_2 \le \infty.$$

3. Interaction potentials. In this part, we present an interaction potential measuring possible future crossings of projected particle trajectories in the physical space. For the one-space-dimensional case $N = 1$, we consider a plasma consisting of a single species with a positive charge $q = 1$; hence the electric field

$$\partial_x E(x,t) = \int_{\mathbb{R}} f(x,v,t)\, dv \ge 0$$

is monotonic increasing in the space. In contrast, for the multidimensional case $N \ge 3$, we consider a plasma with M species. In the multispecies case, we crucially use the time-integrable decay of electric force.

3.1. 1D Vlasov–Poisson system. Consider the planar motion of single species particles with a positive charge confined inside the self-consistent potential field $E := \partial_x \phi$ as in [37, 39]:

$$\partial_t f + v\partial_x f + E\partial_v f = 0 \quad \text{and} \quad \partial_x E = \int_{\mathbb{R}} f dv. \tag{3.1}$$

Note that the electric field $E(\cdot, t)$ is nondecreasing in x. In what follows, we consider smooth solutions to (3.1); hence particle trajectories $[X(s; x, v, t), V(s; x, v, t)]$ associated with a divergence-free vector field (v, E) do not cross in the phase space. However, their projected trajectories onto the physical space can cross each other, which explains the occurrence of singularities such as shocks in the corresponding macroscopic Euler–Poisson system. For a repulsive external force, particles tend to repel each other; so it is feasible to expect that the number of future crossings of projected trajectories will be nonincreasing in time. In the following, we measure this dispersive phenomenon via an interaction potential. Throughout the paper, we suppress t-dependence in f, i.e.,

$$f(x, v) := f(x, v, t).$$

3.1.1. Construction of an interaction potential. Note that $f(x, v)f(y, v_*)$ satisfies the Vlasov equation on the two-point particle phase space $\mathbb{R}^4$:

(3.2)
$$\begin{aligned}\partial_t(f(x, v)f(y, v_*)) &+ \nabla_{(x,y)} \cdot (vf(x, v)f(y, v_*), \quad v_* f(x, v)f(y, v_*)) \\ &+ \nabla_{(v,v_*)} \cdot (E(x, t)f(x, v)f(y, v_*), E(y, t)f(x, v)f(y, v_*)) = 0.\end{aligned}$$

Define an interaction potential $\mathcal{D}_1(f)$ and its production $\Lambda_1(f)$ as follows:

$$\mathcal{D}_1(f(t)) := \underbrace{\iiiint}_{x<y, v>v_*} f(x, v)f(y, v_*)\, dv_*\, dv\, dy\, dx, \tag{3.3}$$

$$\begin{aligned}\Lambda_1(f(t)) := &\iiint_{\mathbb{R}^3} |v - v_*| f(x, v)f(x, v_*)\, dv_*\, dv\, dx \\ &+ \iiint_{\mathbb{R}^3} |E(y, t) - E(x, t)| f(x, v)f(y, v)\, dv\, dy\, dx.\end{aligned}$$

For each $t \in (0, \infty)$, $\mathcal{D}_1(f(t))$ is a priori bounded by the square of the total mass:

$$\mathcal{D}_1(f(t)) \le \|f_0\|_{L^1}^2.$$

3.1.2. Time-decay estimate. In this part, we study the time-decay of the interaction potential.

PROPOSITION 3.1. *Let f be a smooth C^1-solution with an initial datum f_0 with a finite mass, and f decays at infinity in the phase space. Then the functional $\mathcal{D}_1(f)$ satisfies a time-decay estimate*

$$\mathcal{D}_1(f(t)) + \frac{1}{2}\int_0^t \Lambda_1(f(s))\, ds = \mathcal{D}_1(f_0), \quad t \ge 0.$$

Proof. It follows from (3.2) that

$$\begin{aligned}\partial_t[f(x, v)f(y, v_*)] = &-\nabla_{(x,y)} \cdot [vf(x, v)f(y, v_*), v_* f(x, v)f(y, v_*)] \\ &-\nabla_{(v,v_*)} \cdot [E(x, t)f(x, v)f(y, v_*), E(y, t)f(x, v)f(y, v_*)].\end{aligned} \tag{3.4}$$

We integrate (3.4) and use the Fubini theorem to get

$$\begin{aligned}\frac{d}{dt}\mathcal{D}_1(f(t)) &= -\iiiint_{v>v_*,x<y} \nabla_{(x,y)} \cdot [vf(x,v)f(y,v_*), v_*f(x,v)f(y,v_*)]\, dv_*\, dv\, dy\, dx \\ &\quad - \iiiint_{x<y,v>v_*} \nabla_{(v,v_*)} \cdot [E(x,t)f(x,v)f(y,v_*), E(y,t)f(x,v)f(y,v_*)]\, dv_*\, dv\, dy\, dx \\ &= \mathcal{I}_1 + \mathcal{I}_2.\end{aligned}$$

We first estimate $\mathcal{I}_1$. The Fubini and Green theorems yield

$$\begin{aligned}\mathcal{I}_1 &= -\iiiint_{v>v_*,x<y} [\partial_x(vf(x,v)f(y,v_*)) + \partial_y(v_*f(x,v)f(y,v_*))]\, dy\, dx\, dv\, dv_* \\ &= -\iint_{v>v_*} \int_{\mathbb{R}} |v-v_*| f(x,v)f(x,v_*)\, dx\, dv_*\, dv \\ &= -\frac{1}{2}\iiint_{\mathbb{R}^3} |v-v_*| f(x,v)f(y,v_*)\, dv_*\, dv\, dx.\end{aligned}$$

Similarly, we have

$$\mathcal{I}_2 = -\frac{1}{2}\iiint_{\mathbb{R}^3} |E(y,t)-E(x,t)| f(x,v)f(y,v)\, dv\, dy\, dx,$$

where we used the fact that the electric field $E(\cdot,t)$ is nonincreasing: for each t,

$$E(x,t) \le E(y,t) \quad \text{if} \quad x \le y.$$

We finally combine the above two estimates:

$$\frac{d\mathcal{D}_1(f(t))}{dt} + \frac{1}{2}\Lambda_1(f(t)) = 0.$$

This implies

$$\mathcal{D}_1(f(t)) + \frac{1}{2}\int_0^t \Lambda_1(f(s))\, ds = \mathcal{D}_1(f_0). \qquad \square$$

REMARK 3.1. *The above lemma holds for the general* 1D *Vlasov equation with a smooth monotone increasing force field* $F(\cdot,t)$*:*

$$\partial_t f + v\partial_x f + F\partial_v f = 0 \quad \text{and} \quad \partial_x F \ge 0.$$

3.2. Multidimensional Vlasov–Poisson system. In this part, we consider the multidimensional Vlasov–Poisson system with $N \ge 3$. Compared to the 1D case in the previous section, we consider a collisionless plasma consisting of M distinct species. The main difficulty in the multidimensional case is that it is not easy to identify the region of two-point particle phase spaces where interactions occur. Hence we need to devise a more sophisticated functional which takes into account all possible interaction pairs. For this, we will see that the time-integrability of the electric field does play a key role in the following analysis.

3.2.1. Construction of an interaction functional. Let $t \geq 0$ be given, and let (x, v) be the phase space position of a given test particle at time $s = 0$. We denote $[\hat{X}(s), \hat{V}(s)]$ by the trajectory of a test particle,

$$\hat{X}(0) = x \quad \text{ and } \quad \hat{V}(0) = v,$$

and set its terminal velocity v_∞ by

$$v_\infty(x, v) \equiv v + \int_0^\infty E(\hat{X}(s), s)\, ds.$$

Then $v_\infty(x, v)$ is well defined, since the electric field E has an integrable time-decay.

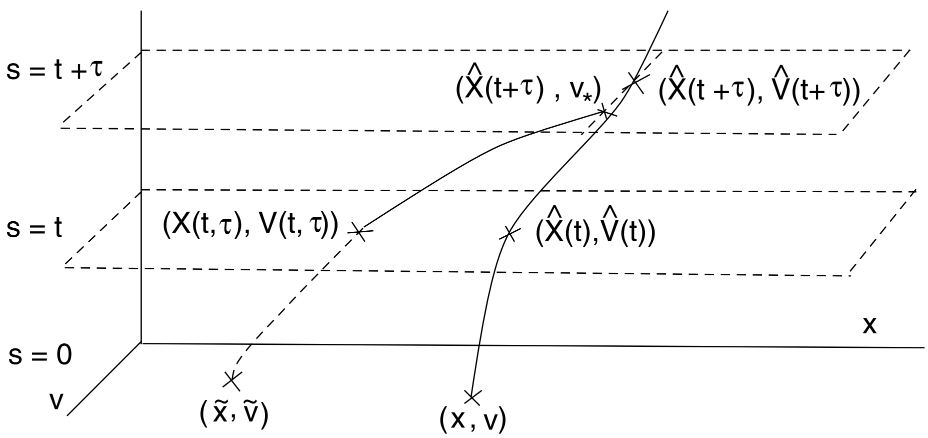

FIG. 3.1. *Schematic diagram of $X(t, \tau)$ and $V(t, \tau)$ in the phase space.*

Let $t, \tau \geq 0$ be given, and for $v_* \notin \{\hat{V}(t + \tau), v_\infty(x, v)\}$, we set (see Figure 3.1)

$$\begin{aligned} X(t, \tau) &:= X(t; t + \tau, \hat{X}(t + \tau), v_*), \quad V(t, \tau) := V(t; t + \tau, \hat{X}(t + \tau), v_*), \\ \tilde{x} &:= X(0; t + \tau, \hat{X}(t + \tau), v_*), \quad \tilde{v} := V(0; t + \tau, \hat{X}(t + \tau), v_*). \end{aligned} \tag{3.5}$$

The invariance of f_α along the trajectory gives

$$f_\alpha(X(t, \tau), V(t, \tau), t) = f_{\alpha,0}(\tilde{x}, \tilde{v}),$$

and we have

$$\begin{aligned} X(t, \tau) &= \hat{X}(t + \tau) - \tau v_* \\ &\quad + \int_t^{t+\tau} \int_{\theta_2}^{t+\tau} E(X(\theta_1; t + \tau, \hat{X}(t + \tau), v_*), \theta_1)\, d\theta_1\, d\theta_2, \end{aligned} \tag{3.6}$$

$$V(t, \tau) = v_* - \int_t^{t+\tau} E(X(\theta_1; t + \tau, \hat{X}(t + \tau), v_*), \theta_1)\, d\theta_1. \tag{3.7}$$

Define an interaction potential and its production functional: for $\alpha \in \{1, \dots, M\}$,

$$\begin{aligned}\mathcal{D}(f_\alpha(t)) &:= \iint_{\mathbb{R}^N\times\mathbb{R}^N} f_\alpha(\hat{X}(t), \hat{V}(t), t) \\ &\qquad \times \left[\int_0^\infty \int_{\mathbb{R}^N} f_\alpha(X(t,\tau), V(t,\tau), t) dv_* d\tau\right] dv\, dx, \\ \Lambda(f_\alpha(t)) &:= \iiint_{\mathbb{R}^N\times\mathbb{R}^N\times\mathbb{R}^N} f_\alpha(x,v,t) f_\alpha(x,v_*,t)\, dv_*\, dv\, dx.\end{aligned} \tag{3.8}$$

Here we used the simplified notation

$$\hat{X}(t) := X(t;0,x,v), \quad \hat{V}(t) := V(t;0,x,v).$$

In order to show that $\mathcal{D}(f_\alpha(t))$ is well defined, i.e., bounded for each t, we need to estimate the quantity inside the bracket of (3.8). For notational simplicity, we denote it by $I_{f_\alpha}(x,v,t)$:

$$I_{f_\alpha}(x,v,t) := \int_0^\infty \int_{\mathbb{R}^3} f_\alpha(X(t,\tau), V(t,\tau), t)\, dv_*\, d\tau.$$

LEMMA 3.2. *Suppose the main hypotheses* (H) *in section* 1 *hold. Then* $I_{f_\alpha}(x,v,t)$ *is finite for a.e.* (x,v,t)*. Moreover, we have the following estimate: for any fixed* $x \in \mathbb{R}^N$,

$$\max_{\alpha=1}^{M} \sup_{v,t} I_{f_\alpha}(x,v,t) \le \mathcal{O}(\varepsilon_0)(|x|+1)^2.$$

Proof. Let $(x,v,t) \in \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}_+$ be given. Since f_α is invariant along the trajectory, it is easy to see that $I_{f_\alpha}(x,v,t)$ is nonincreasing with respect to t; hence it suffices to estimate $I_{f_\alpha}(x,v,0)$. Let $\alpha \in \{1, \dots, M\}$ be fixed and let A be a positive number to be chosen later. We decompose $I_{f_\alpha}(x,v,0)$ into three parts,

$$\begin{aligned}I_{f_\alpha}(x,v,0) \;&=\; \int_0^{A+1} \int_{\mathbb{R}^3} f_{\alpha,0}(X(0,\tau), V(0,\tau))\, dv_*\, d\tau \\ &\quad+ \int_{A+1}^\infty \int_{|v_*-\hat{V}(\tau)|\le \frac{1}{\sqrt{\tau}}} f_{\alpha,0}(X(0,\tau), V(0,\tau))\, dv_*\, d\tau \\ &\quad+ \int_{A+1}^\infty \int_{|v_*-\hat{V}(\tau)|> \frac{1}{\sqrt{\tau}}} f_{\alpha,0}(X(0,\tau), V(0,\tau))\, dv_*\, d\tau \\ &:= I^1_{f_\alpha}(x,v,0) + I^2_{f_\alpha}(x,v,0) + I^3_{f_\alpha}(x,v,0),\end{aligned}$$

where we used the simplified notation (3.5) with $t=0$:

$$X(0,\tau) := X(0;\tau,\hat{X}(\tau),v_*), \quad V(0,\tau) := V(0;\tau,\hat{X}(\tau),v_*).$$

Case 1: $I^1_{f_\alpha}(x,v,0)$. By (H2) and Lemma 2.5,

$$\begin{aligned}I^1_{f_\alpha}(x,v,0) &\le \varepsilon_0 \int_0^{A+1} \int_{\mathbb{R}^N} \frac{1}{(1+|X(0,\tau)|^2)^{\frac{\mu_1}{2}} (1+|V(0,\tau)|^2)^{\frac{\mu_2}{2}}}\, dv_*\, d\tau \\ &\le \varepsilon_0 \int_0^{A+1} \int_{\mathbb{R}^N} \frac{1}{(1+|X(0,\tau)|^2)^{\frac{\mu_1}{2}} (1+|v_*|^2+\mathcal{O}(\varepsilon_0))^{\frac{\mu_2}{2}}}\, dv_*\, d\tau \\ &\le \mathcal{O}(\varepsilon_0)(A+1),\end{aligned}$$

where we used Lemma 2.5 to get

$$\int_{\mathbb{R}^N} \frac{1}{(1+|V(0,\tau)|^2)^{\frac{\mu_2}{2}}}\, dv_* = \int_{\mathbb{R}^N} \frac{1}{(1+|v_*|^2+\mathcal{O}(\varepsilon_0))^{\frac{\mu_2}{2}}}\, dv_* = \mathcal{O}(1). \tag{3.9}$$

Case 2: $I^2_{f_\alpha}(x,v,0)$. Similarly to Case 1, we have

$$\begin{aligned} I^2_{f_\alpha}(x,v,0) &\le \varepsilon_0 \int_{A+1}^{\infty} \int_{|v_*-\hat{V}(\tau)|\le \frac{1}{\sqrt{\tau}}} \frac{1}{(1+|X(0,\tau)|^2)^{\frac{\mu_1}{2}}(1+|V(0,\tau)|^2)^{\frac{\mu_2}{2}}}\, dv_*\, d\tau \\ &\le \mathcal{O}(\varepsilon_0) \int_{A+1}^{\infty} \tau^{-\frac{N}{2}}\, d\tau \\ &= \mathcal{O}(\varepsilon_0)(A+1)^{-\frac{N-2}{2}}. \end{aligned}$$

Case 3: $I^3_{f_\alpha}(x,v,0)$. For v_* satisfying $|v_*-\hat{V}(\tau)| > \frac{1}{\sqrt{\tau}}$, we have

$$|X(0,\tau)-x| \ge \frac{\sqrt{\tau}}{C_1} \quad \text{by Lemma 2.4.}$$

This yields

$$|X(0,\tau)| \ge \frac{\sqrt{\tau}}{C_1} - |x| \ge 0 \quad \text{for } \tau \ge C_1^2|x|^2.$$

We now set

$$A := C_1^2|x|^2.$$

$$\begin{aligned} I^3_{f_\alpha}(x,v,0) &\le \varepsilon_0 \int_{C_1^2|x|^2+1}^{\infty} \int_{|v_*-\hat{V}(\tau)|> \frac{1}{\sqrt{\tau}}} \frac{1}{(1+(\sqrt{\tau}/C_1-|x|)^2)^{\frac{\mu_1}{2}}(1+|V(0,\tau)|^2)^{\frac{\mu_2}{2}}}\, dv_*\, d\tau \\ &\le \mathcal{O}(\varepsilon_0) \int_{C_1^2|x|^2+1}^{\infty} \frac{1}{(1+\sqrt{\tau}/C_1-|x|)^{\mu_1}} \int_{\mathbb{R}^N} \frac{1}{(1+|V(0,\tau)|^2)^{\frac{\mu_1}{2}}}\, dv_*\, d\tau \\ &\le \mathcal{O}(\varepsilon_0) \int_{C_1^2|x|^2+1}^{\infty} \frac{1}{(1+\sqrt{\tau}/C_1-|x|)^{\mu_1}}\, d\tau \qquad \text{by (3.9).} \end{aligned} \tag{3.10}$$

In (3.10), we have

$$\begin{aligned} \int_{C_1^2|x|^2+1}^{\infty} \frac{1}{(1+\sqrt{\tau}/C_1-|x|)^{\mu_1}}\, d\tau &\le 2C_1^2 \int_0^{\infty} \frac{\xi+|x|}{(1+\xi)^{\mu_1}}\, d\xi, \qquad \text{where } \xi := \sqrt{\tau}/C_1-|x| \\ &= \mathcal{O}(1)(1+|x|). \end{aligned}$$

Finally we combine all cases to see

$$I_{f_\alpha}(x,v,0) \le \mathcal{O}(\varepsilon_0)\Big(|x|^2 + (|x|^2+1)^{-\frac{(N-2)}{2}} + |x| + 1\Big) = \mathcal{O}(\varepsilon_0)(|x|+1)^2. \qquad \square$$

REMARK 3.2. *The above lemma implies a priori boundedness of* $\mathcal{D}(f_\alpha)$*:*

$$\mathcal{D}(f_\alpha(t)) \le \mathcal{O}(\varepsilon_0^2) \qquad \textit{for} \quad t \ge 0.$$

3.2.2. Time-decay estimate. In this part we study the time-evolution of the functional $\mathcal{D}(f_\alpha)$ along smooth solutions to (1.1). We first estimate the difference between ∂_t and ∂_τ derivatives of $X(t,\tau)$ and $V(t,\tau)$, respectively.

LEMMA 3.3. *For any fixed $(x,v,t) \in \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}_+$ and α, let $[X(t,\tau), V(t,\tau)]$ be given by* (3.6) *and* (3.7). *Then we have*

$$\partial_t X(t,\tau) - \partial_\tau X(t,\tau) = V(t,\tau) \quad \text{and} \quad \partial_t V(t,\tau) - \partial_\tau V(t,\tau) = E(X(t,\tau),t).$$

Proof. Recall that

$$X(t,\tau) = \hat{X}(t+\tau) - \tau v_* + \int_t^{t+\tau} \int_{\theta_2}^{t+\tau} E(X(\theta_1; t+\tau, \hat{X}(t+\tau), v_*), \theta_1)\, d\theta_1\, d\theta_2.$$

We take ∂_t and ∂_τ to the above identity to get

- $$\partial_t X(t,\tau) = \hat{V}(t+\tau) + \tau E(\hat{X}(t+\tau), t+\tau) - \int_t^{t+\tau} E(X(\theta_1; t+\tau, \hat{X}(t+\tau), v_*), \theta_1)\, d\theta_1, \\ + \int_t^{t+\tau} \int_{\theta_2}^{t+\tau} \partial_t (E(X(\theta_1; t+\tau, \hat{X}(t+\tau), v_*), \theta_1))\, d\theta_1\, d\theta_2,$$
- $$\begin{aligned} \partial_\tau X(t,\tau) &= \hat{V}(t+\tau) - v_* + \tau E(\hat{X}(t+\tau), t+\tau) \\ &\quad + \int_t^{t+\tau} \int_{\theta_2}^{t+\tau} \partial_\tau (E(X(\theta_1; t+\tau, \hat{X}(t+\tau), v_*), \theta_1))\, d\theta_1\, d\theta_2 \\ &= \hat{V}(t+\tau) - \left(V(t,\tau) + \int_t^{t+\tau} E(X(\theta_1; t+\tau, \hat{X}(t+\tau), v_*), \theta_1)\, d\theta_1 \right) \\ &\quad + \tau E(\hat{X}(t+\tau), t+\tau) + \int_t^{t+\tau} \int_{\theta_2}^{t+\tau} \partial_\tau (E(X(\theta_1; t+\tau, \hat{X}(t+\tau), v_*), \theta_1)) d\theta_1 d\theta_2. \end{aligned}$$

Note that

$$\partial_t (E(X(\theta_1; t+\tau, \hat{X}(t+\tau), v_*), \theta_1)) = \partial_\tau (E(X(\theta_1; t+\tau, \hat{X}(t+\tau), v_*), \theta_1))$$

to get

$$\partial_t X(t,\tau) - V(t,\tau) = \partial_\tau X(t,\tau).$$

Again we use the relation

$$V(t,\tau) = v_* - \int_t^{t+\tau} E(X(\theta_1; t+\tau, \hat{X}(t+\tau), v_*), \theta_1)\, d\theta_1$$

to find

- $$\begin{aligned} \partial_t V(t,\tau) &= E(X(t,\tau),t) - E(\hat{X}(t+\tau), t+\tau) \\ &\quad - \int_t^{t+\tau} \partial_t (E(X(\theta_1; t+\tau, \hat{X}(t+\tau), v_*), \theta_1))\, d\theta_1, \end{aligned}$$
- $$\begin{aligned} \partial_\tau V(t,\tau) &= -E(\hat{X}(t+\tau), t+\tau) \\ &\quad - \int_t^{t+\tau} \partial_t (E(X(\theta_1; t+\tau, \hat{X}(t+\tau), v_*), \theta_1))\, d\theta_1. \end{aligned}$$

The above relations yield

$$\partial_t V(t,\tau) = \partial_\tau V(t,\tau) + E(X(t,\tau),t). \qquad \square$$

LEMMA 3.4. *For any* $(x,v,t) \in \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}_+$ *and* $\alpha \in \{1,\dots,M\}$, *let* $[\hat{X}(t),\hat{V}(t)]$ *be the trajectory of a test particle. Then we have*

$$\begin{aligned}&\partial_t(f_\alpha(\hat{X}(t),\hat{V}(t),t)f_\alpha(X(t,\tau),V(t,\tau),t))\\ &= \partial_\tau(f_\alpha(\hat{X}(t),\hat{V}(t),t)f_\alpha(X(t,\tau),V(t,\tau),t)).\end{aligned}$$

Proof. By direct calculation, we have

$$\begin{aligned}&\partial_t(f_\alpha(\hat{X}(t),\hat{V}(t),t)f_\alpha(X(t,\tau),V(t,\tau),t))\\
&\quad= f_\alpha(\hat{X}(t),\hat{V}(t),t)(\partial_t f_\alpha + \nabla_y f_\alpha \cdot \partial_t X(t,\tau) + \nabla_{v_*} f_\alpha \cdot \partial_t V(t,\tau))\\
&\quad= f_\alpha(\hat{X}(t),\hat{V}(t),t)[\partial_t f_\alpha + \nabla_y f_\alpha \cdot (V(t,\tau) + \partial_t X(t,\tau) - V(t,\tau))\\
&\qquad+\nabla_{v_*} f_\alpha \cdot (E(X(t,\tau),t) + \partial_t V(t,\tau) - E(X(t,\tau),t))]\\
&\quad= f_\alpha(\hat{X}(t),\hat{V}(t),t)[\nabla_y f_\alpha \cdot \partial_\tau X(t,\tau) + \nabla_{v_*} f_\alpha \cdot \partial_\tau V(t,\tau)]\\
&\quad= f_\alpha(\hat{X}(t),\hat{V}(t),t)\partial_\tau(f_\alpha(X(t,\tau),V(t,\tau),t))\\
&\quad= \partial_\tau(f_\alpha(\hat{X}(t),\hat{V}(t),t)f_\alpha(X(t,\tau),V(t,\tau),t)),\end{aligned}$$

where $\nabla_y f_\alpha$ and $\nabla_{v_*} f_\alpha$ are evaluated at $(X(t,\tau),V(t,\tau),t)$, and we used

$$\frac{d}{dt} f_\alpha(\hat{X}(t),\hat{V}(t),t) = 0. \qquad \square$$

Finally, the above lemma yields the time-decay of $\mathcal{D}(f_\alpha(t))$ as follows.

Proof of Theorem 1.1. Let $t \geq 0$ be given. Then by definition of $\mathcal{D}(f_\alpha)$

$$\begin{aligned}\frac{d}{dt}\mathcal{D}(f_\alpha(t)) &= \iint_{\mathbb{R}^N\times\mathbb{R}^N}\int_0^\infty\int_{\mathbb{R}^N} \partial_t(f_\alpha(\hat{X}(t),\hat{V}(t),t)f_\alpha(X(t,\tau),V(t,\tau),t))\,dv_*\,d\tau\,dv\,dx\\
&= \iint_{\mathbb{R}^N\times\mathbb{R}^N}\int_0^\infty\int_{\mathbb{R}^N} \partial_\tau(f_\alpha(\hat{X}(t),\hat{V}(t),t)f_\alpha(X(t,\tau),V(t,\tau),t))\,dv_*\,d\tau\,dv\,dx\\
&= \iint_{\mathbb{R}^N\times\mathbb{R}^N}\int_0^\infty \partial_\tau\left(\int_{\mathbb{R}^N} f_\alpha(\hat{X}(t),\hat{V}(t),t)f_\alpha(X(t,\tau),V(t,\tau),t)\,dv_*\right)d\tau\,dv\,dx\\
&= \iint_{\mathbb{R}^N\times\mathbb{R}^N} f_\alpha(\hat{X}(t),\hat{V}(t),t)\left(\lim_{\tau\to\infty}\int_{\mathbb{R}^N} f_\alpha(X(t,\tau),V(t,\tau),t)\,dv_*\right)dv\,dx\\
&\quad- \iiint_{\mathbb{R}^N\times\mathbb{R}^N\times\mathbb{R}^N} f_\alpha(\hat{X}(t),\hat{V}(t),t)f_\alpha(\hat{X}(t),v_*,t)\,dv_*\,dv\,dx\\
&= J_1 + J_2.\end{aligned}$$

Case 1: (J_2). We use the Liouville property $dxdv = d\hat{X}(t)\,d\hat{V}(t)$ to get

$$J_2 = -\iiint_{\mathbb{R}^N\times\mathbb{R}^N\times\mathbb{R}^N} f_\alpha(x,v,t)f_\alpha(x,v_*,t)\,dv_*\,dv\,dx.$$

Case 2: (J_1). We split the integral J_1 into two parts:

$$J_1 = \iint_{\mathbb{R}^N\times\mathbb{R}^N} f_\alpha(\hat{X}(t),\hat{V}(t),t)\left(\lim_{\tau\to\infty}\int_{\mathbb{R}^N} f_\alpha(X(t,\tau),V(t,\tau),t)\,dv_*\right)dv\,dx$$
$$= \iint_{\mathbb{R}^N\times\mathbb{R}^N} f_\alpha(\hat{X}(t),\hat{V}(t),t)\lim_{\tau\to\infty}\left(\int_{|v_*-\hat{V}(t+\tau)|\le\frac{1}{\sqrt{\tau}}} f_\alpha(X(t,\tau),V(t,\tau),t)\,dv_* + \int_{|v_*-\hat{V}(t+\tau)|>\frac{1}{\sqrt{\tau}}} f_\alpha(X(t,\tau),V(t,\tau),t)\,dv_*\right)dv\,dx.$$

We claim

$$\lim_{\tau\to\infty}\left(\int_{|v_*-\hat{V}(t+\tau)|\le\frac{1}{\sqrt{\tau}}} f_\alpha(X(t,\tau),V(t,\tau),t)\,dv_* + \int_{|v_*-\hat{V}(t+\tau)|>\frac{1}{\sqrt{\tau}}} f_\alpha(X(t,\tau),V(t,\tau),t)\,dv_*\right) = 0.$$

Proof of claim. We repeat the argument used in the proof of Lemma 3.2. Let τ_0 be a positive number to be chosen later and consider $\tau\ge\max\{\tau_0, C_1^2|x|^2\}$. For v_* such that $|v_*-\hat{V}(t+\tau)|\le\frac{1}{\sqrt{\tau}}$, we use the fact

$$f_\alpha(X(t,\tau),V(t,\tau),t) = f_{\alpha,0}(\tilde{x},\tilde{v}) \le \frac{\varepsilon_0}{(1+|\tilde{x}|^2)^{\frac{\mu_1}{2}}(1+|\tilde{v}|^2)^{\frac{\mu_2}{2}}}$$

to get

$$\int_{|v_*-\hat{V}(t+\tau)|\le\frac{1}{\sqrt{\tau}}} f_\alpha(X(t,\tau),V(t,\tau),t)\,dv_* = \int_{|v_*-\hat{V}(t+\tau)|\le\frac{1}{\sqrt{\tau}}} f_{\alpha,0}(\tilde{x},\tilde{v})\,dv_* \le \mathcal{O}(\varepsilon_0)\tau^{-\frac{N}{2}}. \tag{3.11}$$

On the other hand, for v_* such that $|v_*-\hat{V}(t+\tau)|\ge\frac{1}{\sqrt{\tau}}$, we use Lemma 2.4 to find

$$\frac{\sqrt{\tau}}{C_1}\le\frac{t+\tau}{C_1}|v_*-\hat{V}(t+\tau)|\le|x-\tilde{x}|,$$

from which we have

$$1+|\tilde{x}|^2\ge 1+(|x-\tilde{x}|-|x|)^2\ge 1+\left(\frac{\sqrt{\tau}}{C_1}-|x|\right)^2 \quad\text{since}\quad |x|\le\frac{\sqrt{\tau}}{C_1}.$$

Hence if

$$\sqrt{\tau}\ge\frac{2C_1|x|+C_1^2+\sqrt{4C_1^3|x|+C_1^4}}{2} := \sqrt{\tau_0(x)},$$

we have

$$\left(\frac{\sqrt{\tau}}{C_1}-|x|\right)^2\ge\sqrt{\tau} \quad\text{or}\quad \frac{1}{(1+(\sqrt{\tau}/C_1-|x|)^2)^{\frac{\mu_1}{2}}}\le\frac{1}{(1+\sqrt{\tau})^{\frac{\mu_1}{2}}}. \tag{3.12}$$

Then the second integral in the claim can be estimated as follows: for $\tau \geq \tau_0(x)$,

$$
\begin{aligned}
(3.13)\quad &\int_{|v_*-\hat{V}(t+\tau)|>\frac{1}{\sqrt{\tau}}} f_\alpha(X(t,\tau),V(t,\tau),t)\,dv_* \\
&= \int_{|v_*-\hat{V}(t+\tau)|>\frac{1}{\sqrt{\tau}}} f_{\alpha,0}(\tilde{x},\tilde{v})\,dv_* \\
&\leq \varepsilon_0 \int_{|v_*-\hat{V}(t+\tau)|>\frac{1}{\sqrt{\tau}}} \frac{1}{(1+|\tilde{x}|^2)^{\frac{\mu_1}{2}}(1+|\tilde{v}|^2)^{\frac{\mu_2}{2}}}\,dv_* \\
&\leq \mathcal{O}(\varepsilon_0) \int_{|v_*-\hat{V}(t+\tau)|>\frac{1}{\sqrt{\tau}}} \frac{1}{(1+(\sqrt{\tau}/C_1-|x|)^2)^{\frac{\mu_1}{2}}(1+|v_*|^2+\mathcal{O}(\varepsilon_0))^{\frac{\mu_2}{2}}}\,dv_* \\
&\leq \frac{\mathcal{O}(\varepsilon_0)}{(1+\sqrt{\tau})^{\frac{\mu_1}{2}}} \int_{\mathbb{R}^N} \frac{1}{(1+|v_*|^2+\mathcal{O}(\varepsilon_0))^{\frac{\mu_2}{2}}}\,dv_* \quad \text{by (3.12)} \\
&= \frac{\mathcal{O}(\varepsilon_0)}{(1+\sqrt{\tau})^{\frac{\mu_1}{2}}}.
\end{aligned}
$$

We combine (3.11) and (3.13) to get

$$
\begin{aligned}
\lim_{\tau\to\infty} \Bigg(&\int_{|v_*-\hat{V}(t+\tau)|\leq\frac{1}{\sqrt{\tau}}} f_\alpha(X(t,\tau),V(t,\tau),t)\,dv_* \\
&+ \int_{|v_*-\hat{V}(t+\tau)|>\frac{1}{\sqrt{\tau}}} f_\alpha(X(t,\tau),V(t,\tau),t)\,dv_* \Bigg) = \lim_{\tau\to\infty}\left(\tau^{-\frac{N}{2}}+\tau^{-\frac{\mu_1}{4}}\right) = 0,
\end{aligned}
$$

which yields

$$J_1 = 0.$$

Finally we combine Cases 1 and 2 to conclude

$$\frac{d}{dt}\mathcal{D}(f_\alpha(t)) = -\Lambda(f_\alpha(t)).$$

REMARK 3.3. *The functional $\mathcal{D}(f_\alpha(t))$ is also a Lyapunov functional for the relativistic Vlasov–Maxwell system for sufficiently small and smooth decaying solutions given in* [7] *(see the appendix).*

4. Uniform ^{1}-stability. In this section, we study uniform L^1-stability for smooth solutions to (1.1). Unlike the case of the Boltzmann equation in [6, 19, 20], the nonlinear functional approach based on the interaction potential $\mathcal{D}(f_\alpha)$ seems very difficult to apply to the Vlasov–Poisson system. For large physical dimensions $N \geq 4$, instead, the direct L^1-stability estimate based on the Gronwall-type inequality can be used; we first need to estimate an integral

$$K_\alpha(x,t) := \int_{\mathbb{R}^N} \frac{1}{|x-y|^{N-1}} \left(\int_{\mathbb{R}^N} |\nabla_v f_\alpha|(y,v,t)\,dv \right) dy.$$

LEMMA 4.1. *Suppose the main hypothesis* (H) *in section 1 holds, and $N \geq 4$. Let f and $\bar{f}$ be two smooth solutions corresponding to the initial data f_0 and $\bar{f}_0$, respectively. Then we have*

$$\sum_{\alpha=1}^{M} \|K_\alpha(\cdot,t)\|_{L^\infty(\mathbb{R}^N_x)} \leq CM(1+t)^{-(N-2)}.$$

Proof. Let $\alpha \in \{1, \dots, M\}$ be given and recall Lemma 2.3:

$$\left\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha(x,v,t)|\, dv \right\|_{L^\infty(\mathbb{R}^N_x)} \le \mathcal{O}(1)(1+t)^{-(N-1)}, \tag{4.1}$$

$$\left\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha(x,v,t)|\, dv \right\|_{L^1(\mathbb{R}^N_x)} \le \mathcal{O}(1)(1+t). \tag{4.2}$$

Let r be a positive constant to be determined later. Then we split $K_\alpha(x,t)$ into two parts:

$$\begin{aligned} K_\alpha(x,t) &= \int_{|y-x|\le r} \frac{1}{|x-y|^{N-1}} \left(\int_{\mathbb{R}^N} |\nabla_v f_\alpha(y,v,t)|\, dv \right) dy \\ &\quad + \int_{|y-x|>r} \frac{1}{|x-y|^{N-1}} \left(\int_{\mathbb{R}^N} |\nabla_v f_\alpha(y,v,t)|\, dv \right) dy \\ &\le d(N) r \left\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha(x,v,t)|\, dv \right\|_{L^\infty(\mathbb{R}^N_x)} \\ &\quad + \left\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha(x,v,t)|\, dv \right\|_{L^1(\mathbb{R}^N_x)} \frac{1}{r^{N-1}}, \end{aligned} \tag{4.3}$$

where $d(N)$ is a positive constant depending only on N. In order to minimize the right-hand side of (4.3), we choose r such that

$$\left\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha|\, dv \right\|_{L^\infty(\mathbb{R}^N_x)} d(N) r = \left\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha|\, dv \right\|_{L^1(\mathbb{R}^N_x)} \frac{1}{r^{N-1}},$$

i.e.,

$$r = \left(\frac{\left\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha|\, dv \right\|_{L^1(\mathbb{R}^N_x)}}{\left\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha|\, dv \right\|_{L^\infty(\mathbb{R}^N_x)} d(N)} \right)^{\frac{1}{N}}.$$

Hence for such r, we have

$$\begin{aligned} K_\alpha(x,t) &\le 2 d(N)^{\frac{N-1}{N}} \left\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha|\, dv \right\|^{1-\frac{1}{N}}_{L^\infty(\mathbb{R}^N_x)} \left\| \int_{\mathbb{R}^N} |\nabla_v f_\alpha|\, dv \right\|^{\frac{1}{N}}_{L^1(\mathbb{R}^N_x)} \\ &\le \mathcal{O}(1)(1+t)^{-(N-2)}. \end{aligned}$$

We take a supremum over x and add all α to get the desired result. ∎

REMARK 4.1. *Note that* $\sum_{\alpha=1}^M \|K_\alpha(\cdot,t)\|_{L^\infty(\mathbb{R}^N_x)}$ *is integrable in* t *for* $N \ge 4$.

Based on the above estimate, we obtain the uniform L^1-stability estimate.

Proof of Theorem 1.2. Let f_α and $\bar f_\alpha$ be smooth solutions of (1.1) corresponding to the initial data $f_{\alpha,0}$ and $\bar f_{\alpha,0}$, respectively:

$$\partial_t f_\alpha + v \cdot \nabla_x f_\alpha + E(f) \cdot \nabla_v f_\alpha = 0, \tag{4.4}$$

$$\partial_t \bar f_\alpha + v \cdot \nabla_x \bar f_\alpha + E(\bar f) \cdot \nabla_v \bar f_\alpha = 0. \tag{4.5}$$

We subtract (4.5) from (4.4) to get

$$\partial_t (f_\alpha - \bar f_\alpha) + v \cdot \nabla_x (f_\alpha - \bar f_\alpha) + E(f) \cdot \nabla_v (f_\alpha - \bar f_\alpha) = (E(\bar f) - E(f)) \cdot \nabla_v \bar f_\alpha. \tag{4.6}$$

Let $(x, v, t) \in \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}_+$ be fixed and let $(X(s), V(s))$ be the trajectories of particles for f_α passing through the point (x, v) at time t, i.e.,

$$X(t) = x \quad \text{and} \quad V(t) = v.$$

We integrate (4.6) along the trajectory $(X(s), V(s))$ to get

$$\begin{aligned}(f_\alpha - \bar{f}_\alpha)(x, v, t) &= (f_{\alpha,0} - \bar{f}_{\alpha,0})(X(0), V(0)) \\ &\quad + \int_0^t (E(\bar{f}) - E(f))(X(s), s) \cdot \nabla_v \bar{f}_\alpha(X(s), V(s), s)\, ds.\end{aligned} \tag{4.7}$$

If we take an absolute for (4.7) and integrate it over the whole phase space, then we obtain

(4.8)

$$\begin{aligned}&\|f_\alpha(t) - \bar{f}_\alpha(t)\|_{L^1} \le \|f_{\alpha,0} - \bar{f}_{\alpha,0}\|_{L^1} \\ &\quad + \int_0^t \iint_{\mathbb{R}^N \times \mathbb{R}^N} |(E(\bar{f}) - E(f))(X(s), s)||\nabla_v \bar{f}_\alpha(X(s), V(s), s)|\, dv\, dx\, ds \\ &\quad \le \|f_{\alpha,0} - \bar{f}_{\alpha,0}\|_{L^1} + C\int_0^t \int_{\mathbb{R}^N} |\rho(y, s) - \bar{\rho}(y, s)| \\ &\qquad \times \Big[\int_{\mathbb{R}^N} \frac{dX(s)}{|X(s) - y|^{N-1}} \Big(\int_{\mathbb{R}^N} |\nabla_v \bar{f}_\alpha(X(s), V(s), t) dV(s) \Big) \Big] dy\, ds \le \|f_{\alpha,0} - \bar{f}_{\alpha,0}\|_{L^1} \\ &\qquad + C\int_0^t \iint_{\mathbb{R}^N \times \mathbb{R}^N} K_\alpha(y, s) \Big(\sum_{\alpha=1}^M |f_\alpha(y, v_*, s) - \bar{f}_\alpha(y, v_*, s)| \Big) dv_*\, dy\, ds \\ &\quad = \|f_{\alpha,0} - \bar{f}_{\alpha,0}\|_{L^1} + C\int_0^t \|K_\alpha(\cdot, s)\|_{L^\infty} \sum_{\alpha=1}^M \|f_\alpha(s) - \bar{f}_\alpha(s)\|_{L^1} ds,\end{aligned}$$

where Lemma 4.1 and the Liouville principle $dx\, dv = dX(s)dV(s)$ were employed to get

$$\begin{aligned}&\iint_{\mathbb{R}^N \times \mathbb{R}^N} \frac{1}{|X(s) - y|^{N-1}} |\nabla_v \bar{f}_\alpha(X(s), V(s), t)|\, dX(s)\, dV(s) \\ &\quad = \iint_{\mathbb{R}^N \times \mathbb{R}^N} \frac{1}{|x - y|^{N-1}} |\nabla_v \bar{f}_\alpha(x, v, t)|\, dx\, dv.\end{aligned}$$

We now add (4.8) over all α to get

$$\begin{aligned}\|f(t) - \bar{f}(t)\|_{L^1} &\le \|f_0 - \bar{f}_0\|_{L^1} + C\int_0^t \Big(\sum_{\alpha=1}^M \|K_\alpha(\cdot, s)\|_{L^\infty} \Big) \|f(s) - \bar{f}(s)\|_{L^1} ds \\ &\le \|f_0 - \bar{f}_0\|_{L^1} + CM\int_0^t (1+s)^{-(N-2)} \|f(s) - \bar{f}(s)\|_{L^1} ds.\end{aligned}$$

Hence Gronwall's inequality yields

$$\begin{aligned}\|f(t) - \bar{f}(t)\|_{L^1} &\le \|f_0 - \bar{f}_0\|_{L^1} \exp\Big(CM\int_0^t (1+s)^{-(N-2)} ds \Big) \\ &= G\|f_0 - \bar{f}_0\|_{L^1},\end{aligned} \tag{4.9}$$

where

$$G := \exp\left(CM\int_0^\infty (1+s)^{-(N-2)}ds\right) < \infty \quad \text{for} \quad N \geq 4.$$

Appendix. Relativistic Vlasov–Maxwell system. In this appendix we briefly discuss the interaction potential $\mathcal{D}(f)$ for the relativistic Vlasov–Maxwell system. For details on the global existence, we refer the reader to [5, 8, 9, 10, 11, 13, 14, 15, 16, 26]. Since the number of species is irrelevant in the following analysis, without loss of generality, we assume that a plasma consists of single species, i.e., $M = 1$; moreover, we also assume the phase space is $\mathbb{R}^3 \times \mathbb{R}^3$.

Consider a plasma consisting of ions confined to the whole phase space $\mathbb{R}^3 \times \mathbb{R}^3$ under the self-consistent electromagnetic force. We denote a one-point particle distribution function by f, and the electric field and magnetic field are denoted by E and B, respectively. The total charge ρ and the current j are defined as

$$\rho = 4\pi\int_{\mathbb{R}^3} f dv \quad \text{and} \quad j = 4\pi\int_{\mathbb{R}^3} \hat{v} f dv,$$

where the relativistic velocity is

$$\hat{v} = \frac{v}{\sqrt{1+|v|^2}}$$

if the speed of light c and the particle mass are taken to be 1. In this case, the relativistic Vlasov–Maxwell system reads

$$\text{(A.1)} \qquad \begin{cases} \partial_t f + \hat{v}\cdot\nabla_x f + (E + \hat{v}\times B)\cdot\nabla_v f = 0 \quad \text{in } \mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}_+, \\ \partial_t E = \nabla\times B - j, \quad \nabla\cdot E = \rho, \\ \partial_t B = -\nabla\times E, \quad \nabla\cdot B = 0, \end{cases}$$

subject to the initial data

$$f(x,v,0) = f_0(x,v) \quad \text{and} \quad (E,B)(x,0) = (E_0,B_0)(x) \quad (x,v)\in\mathbb{R}^3\times\mathbb{R}^3$$

satisfying constraint conditions

$$\nabla\cdot E_0 = \rho_0 \quad \text{and} \quad \nabla\cdot B_0 = 0.$$

The smooth global solution is known to exist under the small data assumption.

THEOREM A.1 (see [7, 16]). *Let f_0 be a nonnegative C^1 function with supports in $|x| \leq k, |v| \leq k$ and let E_0, B_0 be C^2 functions with supports in $|x| \leq k$. If the initial data satisfy the smallness assumption*

$$\|f_0\|_{C^1} + \|E\|_{C^2} + \|B\|_{C^2} \leq \varepsilon_0 \ll 1,$$

then there exists a unique C^1-global solution: for $(x,t)\in\mathbb{R}^3\times\mathbb{R}_+$,

$$\text{(A.2)} \quad f(t,x,v) = 0 \text{ for } |v| \geq \beta \quad \text{and} \quad |E(t,x)| + |B(t,x)| \leq \frac{\varepsilon_0}{(1+t)(t-|x|+2k)}.$$

REMARK A.1. *The compact support assumption $|v| \leq k$ on the initial data can be relaxed to include the Gaussian-type initial data* [32].

In what follows, we consider smooth solutions. For a given point $(x,v) \in \mathbb{R}^3 \times \mathbb{R}^3$, the particle path $[\bar{X}(s), \bar{V}(s)]$ is defined as the solution of the following ODE system:

$$\frac{d\bar{X}(s)}{ds} = \hat{\bar{V}}(s) \quad \text{and} \quad \frac{d\bar{V}(s)}{ds} = E(\bar{X}(s), s) + \hat{\bar{V}} \times B, \tag{A.3}$$

with the initial data

$$\bar{X}(0) = x \quad \text{and} \quad \bar{V}(0) = v,$$

where

$$\hat{\bar{V}} = \frac{\bar{V}}{\sqrt{1 + |\bar{V}|^2}}.$$

Since $\nabla_{(X,V)} \cdot (\hat{V}, E + \hat{V} \times B) = 0$, the mapping $(x,v) \longrightarrow (\bar{X}(s), \bar{V}(s))$ is measure preserving. As in section 3.2 we define $[X(t,\tau), V(t,\tau)]$ by

$$\begin{aligned} X(t,\tau) &:= X(t; t+\tau, \bar{X}(t+\tau), v_*) \quad \text{and} \\ V(t,\tau) &:= V(t; t+\tau, \bar{X}(t+\tau), v_*), \end{aligned}$$

from which we have

$$X(t,\tau) := \bar{X}(t+\tau) - \int_t^{t+\tau} \hat{V}(\theta; t+\tau, \bar{X}(t+\tau), v_*)\, d\theta, \tag{A.4}$$

$$\begin{aligned} V(t,\tau) := v_* - \int_t^{t+\tau} & E(X(\theta; t+\tau, \bar{X}(t+\tau), v_*), \theta) \\ &+ \hat{V}(\theta; t+\tau, \bar{X}(t+\tau), v_*) \times B(X(\theta; t+\tau, \bar{X}(t+\tau), v_*), \theta)\, d\theta. \end{aligned} \tag{A.5}$$

The following lemma can easily be computed.

LEMMA A.2. *Let $[X(t,\tau), V(t,\tau)]$ be the curve parameterized by τ and given by* (A.4) *and* (A.5). *Then the following estimates hold:*

(1) $\partial_t X(t,\tau) - \partial_\tau X(t,\tau) = \hat{V}(t,\tau)$,

(2) $\partial_t V(t,\tau) - \partial_\tau V(t,\tau) = E(X(t,\tau), t) + \hat{V}(t,\tau) \times B(X(t,\tau), t)$.

We also define $\mathcal{D}(f(t))$ and $\Lambda(f(t))$ by

$$\mathcal{D}(f(t)) := \iint_{\mathbb{R}^3 \times \mathbb{R}^3} f(\bar{X}(t), \bar{V}(t), t) \left(\int_0^\infty \int_{\mathbb{R}^3} f(X(t,\tau), V(t,\tau), t)\, d\tau\, dv_* \right) dv\, dx,$$

$$\Lambda(f(t)) := \iiint_{\mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3} f(x,v,t) f(x, v_*, t)\, dv_*\, dv\, dx.$$

Below we state two lemmas whose proofs can be found in [7].

LEMMA A.3. *If $0 \le s \le t$ and $f(t,x,v) \neq 0$, then*

$$s - |X(s; t, x, v)| + 2k \ge (k+s)(2 + 2P^2(t))^{-1},$$

where the function $P(t)$ is bounded by a constant β.

LEMMA A.4. *If ε_0 is sufficiently small, there is a constant $c > 0$ such that*

$$|X(0;t,x,v) - X(0;t,x,w)| \geq ct|v-w|.$$

For us to follow the steps in section 3.2, it is enough to prove Lemma 2.5 for the relativistic Vlasov–Maxwell system or to verify directly (3.9):

$$\int_{\mathbb{R}^3} \frac{1}{(1+|V(0,\tau)|^2)^{\frac{\mu_2}{2}}}\,dv_* = \mathcal{O}(1).$$

Below for the simplicity of notation, we denote $X(s;\tau,\bar{X}(\tau),v_*)$, $V(s;\tau,\bar{X}(\tau),v_*)$ by $X(s,\tau), V(s,\tau)$, respectively. Note that $X(s,\tau), V(s,\tau)$ here are not the same as $X(s,\tau), V(s,\tau)$ defined in (3.5). It follows from (A.2) and Lemma A.3 that

$$\begin{aligned}
&\left|\int_0^\tau E(X(s,\tau),\theta) + \hat{V}(s,\tau)\times B(X(s,\tau),\theta)\,d\theta\right| \\
&\quad\leq \varepsilon_0 \int_0^\tau \frac{1}{(s+1)(s-|X(s,\tau)|+2k)}\,ds \\
&\quad\leq \varepsilon_0 \int_0^\tau \frac{2+2P^2(s)}{(s+1)(k+s)}\,ds \\
&\quad\leq \bar{C}_1\varepsilon_0 \qquad \text{for some positive constant} \quad \bar{C}_1
\end{aligned} \tag{A.6}$$

and that

$$\begin{aligned}
&\int_{\mathbb{R}^3} \frac{1}{(1+|V(0,\tau)|^2)^{\frac{\mu_2}{2}}}\,dv_* \\
&\quad= \int_{\mathbb{R}^3} \frac{1}{\left(1+\left|v_* - \int_0^\tau E(X(s,\tau),s)+\hat{V}(s,\tau)\times B(X(s,\tau),s)ds\right|^2\right)^{\frac{\mu_2}{2}}}\,dv_* \\
&\quad\leq \int_{|v_*|\leq 2\bar{C}_1\varepsilon_0} \frac{1}{\left(1+\left||v_*| - |\int_0^\tau E(X(s,\tau),s)-\hat{V}(s,\tau)\times B(X(s,\tau),s)ds|\right|^2\right)^{\frac{\mu_2}{2}}}\,dv_* \\
&\qquad+ \int_{|v_*|\geq 2\bar{C}_1\varepsilon_0} \frac{1}{\left(1+\left||v_*| - |\int_0^\tau E(X(s,\tau),s)-\hat{V}(s,\tau)\times B(X(s,\tau),s)ds|\right|^2\right)^{\frac{\mu_2}{2}}}\,dv_* \\
&\quad\leq \mathcal{O}(\varepsilon_0) + \int_{|v_*|\geq 2\bar{C}_1\varepsilon_0} \frac{1}{(1+\frac{1}{2}|v_*|^2)^{\frac{\mu_2}{2}}}\,dv_* \\
&\quad\leq \mathcal{O}(1).
\end{aligned}$$

We obtain the time decay estimates of the interaction potential.

PROPOSITION A.5. *Let f be a smooth solution to* (A.1). *Then if ε_0 is sufficiently small, $\mathcal{D}(f)$ satisfies*

$$\frac{d\mathcal{D}(f(t))}{dt} + \Lambda(f(t)) = 0.$$

Acknowledgment. The second author thanks Prof. Tai-Ping Liu for his hospitality and support.

COARSENING RATES IN OFF-CRITICAL MIXTURES*

SERGIO CONTI†, BARBARA NIETHAMMER‡, AND FELIX OTTO§

Abstract. We study coarsening of a binary mixture within the Mullins–Sekerka evolution in the regime where one phase has small volume fraction $\phi \ll 1$. Heuristic arguments suggest that the energy density, which represents the inverse of a typical length scale, decreases as $\phi t^{-1/3}$ as $t \to \infty$. We prove rigorously a corresponding weak lower bound. Moreover, we establish a stronger result for the two-dimensional case, where we find a lower bound of the form $\phi(\ln \phi^{-1})^{1/3} t^{-1/3}$. Our approach follows closely the analysis in [R. V. Kohn and F. Otto, *Comm. Math. Phys.*, 229 (2002), pp. 375–395], which exploits the relation between two suitable length scales. Our main contribution is an isoperimetric inequality in the two-dimensional case.

Key words. Mullins–Sekerka evolution, coarsening rates, isoperimetric inequalities

1. Introduction. The Mullins–Sekerka model describes the late stage coarsening in the phase separation of a binary mixture. In this model the interface between two phases is characterized by the boundary $\partial\Omega$ of a region $\Omega \subset Q \subset \mathbb{R}^n$, where Ω denotes the region covered by one phase. The Mullins–Sekerka model is based on the assumption that the diffusion field, given by the negative gradient $-\nabla u$ of the chemical potential u, is in quasi-stationary equilibrium given the phase distribution and satisfies the Gibbs–Thomson condition of local equilibrium on the interface. That is, u satisfies

$$-\Delta u = 0 \qquad \text{in } Q\backslash\partial\Omega, \tag{1.1}$$

$$u = \kappa \qquad \text{on } \partial\Omega, \tag{1.2}$$

where κ denotes the mean curvature of the interface and is defined to be positive if Ω is a ball. Then the normal velocity v of the interface is given by the jump of the normal component of the diffusion field across the interface, that is,

$$v = [\nabla u \cdot \vec{n}] := \lim_{\substack{x \in Q\backslash\overline{\Omega} \\ x \to \partial\Omega}} \nabla u(x) \cdot \vec{n} - \lim_{\substack{x \in \Omega \\ x \to \partial\Omega}} \nabla u(x) \cdot \vec{n} \qquad \text{on } \partial\Omega, \tag{1.3}$$

where $\vec{n}$ denotes the outer normal to Ω. With periodic or Neumann boundary conditions the evolution (1.1)–(1.3) reduces the total surface area and keeps the volume fraction covered by each phase constant. In the following we consider a periodic setting with period cell $Q = [0, l)^n$, where l is the system size. This is not a significant restriction, since our results will be independent of the size l.

Equations (1.1)–(1.3) do not in general possess a global smooth solution since the geometry might become singular—for example, when two previously separated regions touch or when pinching occurs. We assume in the following that we are in a situation where a piecewise smooth solution of the Mullins–Sekerka problem exists and for which the evolution of $\partial\Omega$ is continuous for all times. For typical scenarios in the regime of small volume fraction this assumption is satisfied. In this regime the new phase nucleates in the form of many small well-separated regions which quickly become approximately radially symmetric. If such a configuration is taken as initial data for the Mullins–Sekerka evolution, then there exists a global solution in the described sense [1, 2]. The different regions compete for surface area such that the smaller ones shrink and disappear while the larger ones grow.

We are interested in the coarsening rate within the Mullins–Sekerka evolution in the regime of small volume fraction, i.e., $\phi := |\Omega \cap Q|/|Q| \ll 1$. Here and in the following we denote by $|\omega| := \mathcal{L}^n(\omega)$ the n-dimensional Lebesgue measure of a set $\omega \subset \mathbb{R}^n$. The coarsening rate is described by the growth rate of a typical length scale $L = L(t)$. Since the Mullins–Sekerka evolution is scale invariant with respect to a rescaling $x \mapsto \lambda x, t \mapsto \lambda^3 t$, the only possible universal growth law is $L(t) \sim t^{1/3}$. This growth law has been rigorously established in the form of a weak upper bound in [7] for the Cahn–Hilliard equation in the case of equal volume fractions, that is, $\phi \sim \frac{1}{2}$.

How do we expect that this growth law depends on the volume fraction ϕ? To that aim consider as a natural inverse length scale the energy density

$$E = \text{ interfacial area per unit volume } = \frac{\mathcal{H}^{n-1}(\partial\Omega \cap Q)}{|Q|}. \tag{1.4}$$

If now, for example, the configuration consists of N approximately spherical domains of mean radius $\overline{R}(t)$, we expect

$$E(t) \sim \frac{1}{|Q|} N \overline{R}^{n-1}(t) \sim \phi \frac{1}{\overline{R}(t)}. \tag{1.5}$$

A prediction of the scaling of $\overline{R}(t)$ goes back to the classical theory by Lifshitz and Slyozov [9] and Wagner [12] (see also [10] for more details on the two-dimensional case). To that aim consider again a collection of approximately spherical regions with radius R and total volume fraction ϕ, which are well separated by a typical distance of order $d \sim \frac{R}{\phi^{1/n}}$. Due to the clear separation of length scales, the potential u should approximately be close to a slowly varying field $\bar{u}$ away from the particles. Hence, due to (1.1) and (1.2) we expect that close to a particle with center x_0 the potential is well approximated by

$$u \sim \begin{cases} (1 - R\bar{u}) \frac{R^{n-3}}{|x-x_0|^{n-2}}, & n \geq 3, \\ \left(\frac{1}{R} - \bar{u}\right) \frac{\ln \frac{d}{|x-x_0|}}{\ln\left(\frac{d}{R}\right)}, & n = 2. \end{cases}$$

Plugging the preceding formula into (1.3) gives

$$\dot{R}(t) \sim \begin{cases} \frac{n-2}{R^2(t)}(R\bar{u} - 1), & n \geq 3, \\ \frac{1}{\ln\left(\frac{d}{R}\right)} \frac{1}{R^2(t)}(R\bar{u} - 1), & n = 2. \end{cases} \tag{1.6}$$

Thus, the growth rate of a particle is, to leading order, independent of ϕ for $n \geq 3$ and depends only on $\ln\left(\frac{d}{R}\right) \sim \ln \phi^{-1}$ for $n = 2$. In particular we also find $R^2 \dot{R} \sim 1$

and $R^2\dot{R} \sim \frac{1}{\ln(\frac{d}{R})}$, respectively, such that the mean radius should follow the growth law

$$\overline{R}(t) \sim \begin{cases} t^{1/3}, & n \geq 3, \\ \frac{1}{(\ln \phi^{-1})^{1/3}} t^{1/3}, & n = 2. \end{cases} \tag{1.7}$$

This implies, together with (1.5), that

$$E(t) \sim \begin{cases} \phi t^{-1/3}, & n \geq 3, \\ \phi(\ln \phi^{-1})^{1/3} t^{-1/3}, & n = 2. \end{cases} \tag{1.8}$$

Our goal in this article is to support these heuristics by rigorously establishing a corresponding weak lower bound in the spirit of [7]. This approach has also been successfully applied to other cases, such as phase separation in multicomponent systems or epitaxial growth [8], mean-field models for coarsening [3], temperature-dependent phase field models [4], and coarsening of droplet configurations [11]. The approach is based on exploiting the relation of two suitably chosen global length scales. The first has already been introduced and is given by the inverse of the energy density E. In the following we use the notation from geometric measure theory and denote the perimeter of Ω with respect to Q by $\int_Q |\nabla\chi|$, where χ denotes here and in the following the characteristic function of the set Ω. It is well known (cf., e.g., [6]) that if $\partial\Omega$ is smooth, which we assume here for all but finitely many times, then the perimeter equals the surface area. Thus, the energy can also be written as $E = \fint_Q |\nabla\chi|$, where here and in the following $\fint_Q := \frac{1}{|Q|}\int_Q$.

The second length scale is, as in [7], a suitable negative norm of the characteristic function of Ω. We define

$$L := \left(\fint_Q |\nabla^{-1}(\chi - \phi)|^2 \, dx \right)^{1/2}, \tag{1.9}$$

where $\|\nabla^{-1}u\|_{L^2} = \|u\|_{H^{-1}}$ denotes the H^{-1}-norm for Q-periodic functions with mean value zero.

This choice of length scale is motivated by the interpretation of the Mullins–Sekerka evolution as a gradient flow on a Riemannian manifold. In fact, it is the gradient flow of the surface energy with respect to the scalar product given by the H^{-1}-norm in the bulk. In principle a natural choice for L would be the induced distance on the manifold between the phase configuration and the uniform reference state ϕ. However, we cannot easily compute this distance in the present setting due to the nonconvex constraint that χ takes only two integer values. Nevertheless one would expect that this distance is close to the distance within the Cahn–Hilliard model which is just given by (1.9). In fact, the main result formulated in the following theorem can with similar arguments also be established within the Cahn–Hilliard framework.

THEOREM 1.1. *Let E_0 and L_0 be the initial energy density and initial length, respectively, and let $\phi \ll 1$. Then we have for $T \gg \phi^{-3/2}L_0^3$ that*

$$\fint_0^T E^2(t)\,dt \gtrsim \begin{cases} \phi^2\, T^{-2/3}, & n \geq 3, \\ \phi^2\left(\ln\phi^{-1}\right)^{2/3} T^{-2/3}, & n = 2. \end{cases}$$

Here and in the following we use the notation $A \lesssim B$ or $A \gtrsim B$ if there is a constant C such that $A \leq CB$ or $A \geq CB$, respectively. The constants will be independent of ϕ but may depend on the space dimension n. Such a dependence we sometimes indicate with $C = C(n)$.

The proof of Theorem 1.1 is based exactly as in [7] on three ingredients. The first is an interpolation (or isoperimetric) inequality which relates E and L and is independent of the dynamics of the evolution.

LEMMA 1.2. *We have*

$$EL \gtrsim \begin{cases} \phi^{3/2}, & n \geq 3, \\ \phi^{3/2}\big(\ln \phi^{-1}\big)^{1/2}, & n = 2. \end{cases}$$

The proof of Lemma 1.2—in particular for the case $n = 2$—is the main contribution of this article. We provide it in the next section.

The second ingredient in the analysis of [7] is a diffusion inequality which relates the rate of change of the length L to the rate of change of the energy density.

LEMMA 1.3. *For almost all $t \in (0, T)$ we have*

$$|\dot{L}(t)|^2 \leq -\dot{E}(t).$$

Proof. We denote by u the potential of the normal velocity v of $\partial\Omega$ and by w the potential for $\chi - \phi$, that is,

$$-\Delta u = v \, d\mathcal{H}^{n-1} \lfloor \partial\Omega \qquad \text{and} \qquad -\Delta w = \chi - \phi \qquad \text{in } \mathcal{D}'(Q),$$

with periodic boundary conditions. Here $d\mathcal{H}^{n-1}\lfloor\partial\Omega$ denotes the Hausdorff measure restricted onto $\partial\Omega$.

We assume that for all but a finite number of times the solution of the Mullins–Sekerka equation is smooth, and for those times we have the relation $\partial_t w = u$. By definition $L^2(t) = \fint_Q |\nabla w|^2 \, dx$ and we find

$$\begin{aligned} L(t)\dot{L}(t) &= \fint_Q \nabla w \cdot \nabla u \, dx \\ &\leq \Big(\fint_Q |\nabla u|^2 \, dx\Big)^{1/2} \Big(\fint_Q |\nabla w|^2 \, dx\Big)^{1/2} \\ &= \Big(\fint_Q |\nabla u|^2 \, dx\Big)^{1/2} L(t). \end{aligned}$$

Hence, dividing by $L(t)$, integrating by parts, and using (1.1)–(1.3), it follows that

$$|\dot{L}(t)|^2 \leq \fint_Q |\nabla u|^2 \, dx = \frac{1}{|Q|} \int_{\partial\Omega \cap Q} v\kappa \, d\mathcal{H}^{n-1} = -\dot{E}\,.$$

The last equality follows from the well-known fact that the mean curvature is the variation of the surface area with respect to kinematically admissible normal velocities of the surface (cf., e.g., [6, Chap. 10]). ∎

The final ingredient of Theorem 1.1 is an ODE lemma which we can take directly from [7].

To that aim we consider the rescaled quantities

$$\begin{aligned} \hat{E} &= \begin{cases} \phi^{(1-n)/n} E, & n \geq 3, \\ \phi^{-1/2}\big(\ln \phi^{-1}\big)^{-1/2} E, & n = 2, \end{cases} \\ \hat{L} &= \phi^{-(n+2)/2n} L, \\ \hat{t} &= \begin{cases} \phi^{-3/n} t, & n \geq 3, \\ \phi^{-3/2}\big(\ln \phi^{-1}\big)^{1/2} t, & n = 2, \end{cases} \end{aligned} \tag{1.10}$$

and obtain

$$\hat{E}\hat{L} \gtrsim 1 \qquad \text{and} \qquad |\dot{\hat{L}}|^2 \leq -\dot{\hat{E}}. \tag{1.11}$$

In order to arrive at (1.11) one has some freedom in the choice of factors in (1.10). The present choice is just the natural one in the sense that for typical configurations the new quantities are of order one in ϕ.

The ODE lemma (see [7, Lemma 3]) now yields for $\hat{T} \gg (\hat{L}_0)^3$

$$⨍_0^{\hat{T}} (\hat{E}(\hat{t}))^2 \, d\hat{t} \gtrsim \hat{T}^{-2/3},$$

which in view of (1.10) implies the estimate in Theorem 1.1.

2. Proof of the interpolation inequality. Let χ denote the characteristic function of the set Ω. We claim that for $\phi \leq \frac{1}{2}$ the following interpolation inequality is true:

$$⨍_Q (\chi - \phi)^2 \, dx \lesssim \Big(⨍_Q |\nabla \chi| \, dx \Big)^{2/3} \Big(⨍_Q |\nabla^{-1}(\chi - \phi)|^2 \, dx \Big)^{1/3}. \tag{2.1}$$

To see that, define $(\chi - \phi)_\varepsilon := (\chi - \phi) * \eta_\varepsilon$ and $\chi_\varepsilon := \chi * \eta_\varepsilon$, where η_ε is a standard sequence of mollifiers. We have

$$⨍_Q |\nabla \chi_\varepsilon|^2 \, dx \lesssim \frac{1}{\varepsilon^2} ⨍_Q |\chi - \phi|^2 \, dx \,,$$

such that by duality

$$⨍_Q |(\chi - \phi)_\varepsilon|^2 \, dx \lesssim \frac{1}{\varepsilon^2} ⨍_Q |\nabla^{-1}(\chi - \phi)_\varepsilon|^2 \, dx \leq \frac{1}{\varepsilon^2} ⨍_Q |\nabla^{-1}(\chi - \phi)|^2 \, dx \,. \tag{2.2}$$

Hence, using $|\chi|, |\chi_\varepsilon| \leq 1$, we find

$$\begin{aligned} ⨍_Q (\chi - \phi)^2 \, dx &\leq 2 ⨍_Q |\chi - \chi_\varepsilon|^2 + 2 ⨍_Q |(\chi - \phi)_\varepsilon|^2 \, dx \\ &\overset{(2.2)}{\lesssim} ⨍_Q |\chi - \chi_\varepsilon| + \frac{1}{\varepsilon^2} ⨍_Q |\nabla^{-1}(\chi - \phi)|^2 \, dx \\ &\lesssim \varepsilon ⨍_Q |\nabla \chi| + \frac{1}{\varepsilon^2} ⨍_Q |\nabla^{-1}(\chi - \phi)|^2 \, dx. \end{aligned}$$

The preceding inequality is optimal for

$$\varepsilon = \left(\frac{⨍_Q |\nabla^{-1}(\chi - \phi)|^2 \, dx}{⨍_Q |\nabla \chi|} \right)^{1/3},$$

which proves (2.1). Since

$$⨍_Q (\chi - \phi)^2 \, dx \geq \frac{1}{2} ⨍_Q \chi^2 \, dx = \frac{1}{2} ⨍_Q \chi \, dx = \frac{1}{2}\phi,$$

inequality (2.1) implies Lemma 1.2 for the case $n \geq 3$.

In the case $n = 2$ we can even do better. We claim that

$$\fint_Q \chi^2\,dx \lesssim \frac{1}{\left(\ln\phi^{-1}\right)^{1/3}}\left(\fint_Q |\nabla\chi|\,dx\right)^{2/3}\left(\fint_Q |\nabla^{-1}(\chi-\phi)|^2\,dx\right)^{1/3} \quad \text{if } n = 2. \tag{2.3}$$

We recall that by the definition of the dual norm we have for all $\zeta \in H^1_{per}(Q)$, that is, the space of H^1 functions with periodic boundary conditions, that

$$\fint_Q |\nabla^{-1}(\chi-\phi)|^2\,dx \ge \frac{\left(\fint_Q (\chi-\phi)\zeta\,dx\right)^2}{\fint_Q |\nabla\zeta|^2\,dx}. \tag{2.4}$$

We are going to construct a periodic test function $\zeta \ge 0$ which satisfies the following properties:

$$\fint_Q \chi\zeta\,dx \ge \frac{1}{2}\fint_Q \chi\,dx, \tag{2.5}$$

$$\fint_Q \zeta\,dx \ll 1\,, \tag{2.6}$$

$$\fint_Q |\nabla\zeta|^2\,dx \lesssim \frac{\phi}{\mathcal{R}^2\ln\phi^{-1}}, \tag{2.7}$$

where

$$\mathcal{R} := \frac{\phi}{\fint_Q |\nabla\chi|}. \tag{2.8}$$

Then (2.5) and (2.6) imply

$$\fint_Q (\chi-\phi)\zeta\,dx \ge \frac{1}{4}\fint_Q \chi\,dx = \frac{1}{4}\fint_Q \chi^2\,dx,$$

and using (2.4) and (2.7) we find

$$\left(\fint_Q \chi^2\,dx\right)^2 \lesssim \left(\fint_Q (\chi-\phi)\zeta\,dx\right)^2 \le \frac{\left(\fint_Q |\nabla\chi|\right)^2}{\phi\ln\phi^{-1}}\fint_Q |\nabla^{-1}(\chi-\phi)|^2\,dx,$$

which, recalling $\fint_Q \chi^2 = \phi$, proves (2.3).

Hence it remains to construct a test function ζ with the properties (2.5)–(2.7). Fundamental for the construction is the following geometric lemma which says that for given Ω we can construct another set $\Omega_{\mathcal{R}}$ which covers a substantial part of Ω and behaves like a union of balls with radius larger than $\mathcal{R}$.

LEMMA 2.1. *Let $\Omega \subset \mathbb{R}^n$ be a given Q-periodic set and χ its characteristic function, and let $\mathcal{R}$ be such that*

$$\mathcal{R}\int_Q |\nabla\chi| \le |\Omega\cap Q|.$$

Then there exists a Q-periodic set $\Omega_{\mathcal{R}} \subset \mathbb{R}^n$ such that

$$|\Omega\cap\Omega_{\mathcal{R}}\cap Q| \ge \frac{1}{2}|\Omega\cap Q|$$

and, for all $r > 0$,

$$|\Omega_{\mathcal{R}}^r \cap Q| \le C|\Omega \cap Q| \left(1 + \left(\frac{r}{\mathcal{R}}\right)^n\right),$$

where $\Omega_{\mathcal{R}}^r = \{x \,|\, \mathrm{dist}(x, \Omega_{\mathcal{R}}) \le r\}$ *and* C *is a constant which depends only on* n.

We postpone the proof of the lemma, choose $\mathcal{R}$ as in (2.8), and define

$$\zeta(x) := \psi(r(x)),$$

where $r(x) := \mathrm{dist}(x, \Omega_{\mathcal{R}})$ and

$$\psi(r) = \begin{cases} 0, & r \ge d, \\ \frac{\ln \frac{d}{r}}{\ln \frac{d}{\mathcal{R}}}, & r \in (\mathcal{R}, d), \\ 1, & r \le \mathcal{R} \end{cases}$$

with $d = \frac{\mathcal{R}}{\phi^{1/2}} \gg \mathcal{R}$. This choice of test function is motivated by the simplest case, when $\Omega = B_{\mathcal{R}}(0)$ and $B_d(0) \subset Q$, whence $\zeta(x) := \ln \frac{d}{|x|} / \ln \frac{d}{\mathcal{R}}$ fulfills (2.5)–(2.7). (Here and in the following we use the notation $B_r(x)$ to denote a ball with radius r and center x.)

The fact that $|\nabla r(x)| = 1$ for almost all x and Theorem 2, Ch.3.4.3 and Proposition 2, Ch. 3.4.4 of [5] imply

$$\begin{aligned}
\int_Q |\nabla \zeta|^2 \, dx &= \int_Q |\psi'(r(x))|^2 |\nabla r(x)|^2 \, dx \\
&= \int_0^\infty |\psi'(s)|^2 \mathcal{H}^{n-1}(\{x \in Q \,|\, r(x) = s\}) \, ds \\
&= \int_{\mathcal{R}}^d |\psi'(s)|^2 \mathcal{H}^{n-1}(\{x \in Q \,|\, r(x) = s\}) \, ds \\
&\le - \int_{\mathcal{R}}^d \frac{d}{ds} |\psi'(s)|^2 |\{x \in Q \,|\, r(x) < s\}| \, ds \\
&\quad + |\psi'(d)|^2 |\{x \in Q \,|\, r(x) < d\}| \,.
\end{aligned}$$

Lemma 2.1 for $n = 2$ gives $|\{x \in Q \,|\, r(x) < s\}| \le C|\Omega \cap Q| \left(\frac{s}{\mathcal{R}}\right)^2$, and a straightforward computation yields

$$\begin{aligned}
\fint_Q |\nabla \zeta|^2 \, dx &\lesssim \int_{\mathcal{R}}^d \frac{\phi}{s^3 |\ln \frac{d}{\mathcal{R}}|^2} \left(\frac{s}{\mathcal{R}}\right)^2 ds \; + \; \frac{\phi}{|d \ln \frac{d}{\mathcal{R}}|^2} \left(\frac{d}{\mathcal{R}}\right)^2 \\
&\lesssim \frac{\phi}{\mathcal{R}^2 |\ln \frac{d}{\mathcal{R}}|},
\end{aligned}$$

which establishes (2.7).

Furthermore, an analogous computation yields

$$\begin{aligned}
\int_Q \zeta \, dx &= \int_{\mathcal{R}}^d \psi(s) \mathcal{H}^{n-1}(\{x \in Q \,|\, r(x) = s\}) \, ds + |\Omega_{\mathcal{R}}^{\mathcal{R}} \cap Q| \\
&= - \int_{\mathcal{R}}^d \psi'(s) |\{x \in Q \,|\, r(x) < s\}| \, ds + \psi(s) |\{x \in Q \,|\, r(x) < s\}| \Big|_{\mathcal{R}}^d + |\Omega_{\mathcal{R}}^{\mathcal{R}} \cap Q| \,.
\end{aligned} \tag{2.9}$$

Since $\psi(d) = 0$ and $\psi(\mathcal{R}) = 1$ the last two terms cancel. Lemma 2.1 and the choice of d imply

$$\fint_Q \zeta\, dx \lesssim \frac{1}{\ln \frac{d}{\mathcal{R}}} \int_{\mathcal{R}}^d \frac{\phi s}{\mathcal{R}^2}\, ds \lesssim \frac{d^2}{\mathcal{R}^2 \ln \frac{d}{\mathcal{R}}} \phi = \frac{1}{\ln \phi^{-1/2}} \ll 1,$$

so that the desired property (2.6) follows.

Proof of Lemma 2.1. We first observe that it suffices to prove the statement for $|Q \cap \Omega| \le \frac{1}{2}|Q|$; otherwise one can take $\Omega_{\mathcal{R}} = Q$. Next, it is convenient to redefine $\mathcal{R}$ such that

$$\mathcal{R} \int_Q |\nabla \chi| \le \frac{1}{4} |\Omega \cap Q|. \tag{2.10}$$

We notice that the isoperimetric inequality in particular implies that

$$\mathcal{R} \le \frac{1}{4} |\Omega \cap Q|^{1/n} \le \frac{1}{4} |Q|^{1/n}. \tag{2.11}$$

We set

$$\Omega_{\mathcal{R}} := \left\{ x \,|\, |\Omega \cap B_{\mathcal{R}}(x)| > \frac{1}{2} |B_{\mathcal{R}}(x)| \right\} \tag{2.12}$$

and claim that

$$|\Omega \cap \Omega_{\mathcal{R}} \cap Q| \ge \frac{1}{2} |\Omega \cap Q|. \tag{2.13}$$

We first notice that

$$\Omega_{\mathcal{R}} = \left\{ x \,|\, \chi_{\mathcal{R}}(x) > \frac{1}{2} \right\}, \qquad \text{where} \qquad \chi_{\mathcal{R}}(x) := \frac{|\Omega \cap B_{\mathcal{R}}(x)|}{|B_{\mathcal{R}}(x)|},$$

and $\chi_{\mathcal{R}}$ can be considered as a convolution of the characteristic function χ of Ω.

Furthermore we have

$$\chi - \chi_{\mathcal{R}} \ge 1 - \frac{1}{2} = \frac{1}{2} \qquad \text{on } \Omega \backslash \Omega_{\mathcal{R}},$$

so that

$$\begin{aligned} |(\Omega \backslash \Omega_{\mathcal{R}}) \cap Q| &\le 2 \int_Q |\chi - \chi_{\mathcal{R}}|\, dx \\ &\le 2 \sup_{|h| \le \mathcal{R}} \int_Q |\chi(x) - \chi(x+h)|\, dx \\ &\le 2\mathcal{R} \int_Q |\nabla \chi| \\ &\le \frac{1}{2} |\Omega \cap Q|, \end{aligned}$$

where the last inequality follows from (2.10). Thus

$$|\Omega \cap \Omega_{\mathcal{R}} \cap Q| = |\Omega \cap Q| - |(\Omega \backslash \Omega_{\mathcal{R}}) \cap Q| \ge \frac{1}{2} |\Omega \cap Q|,$$

which establishes (2.13).

Next we claim that there exists a set $A \subset \Omega_{\mathcal{R}} \cap Q$ of points such that

$$\#A \leq C\frac{|\Omega \cap Q|}{|B_{\mathcal{R}}|} \qquad \text{and} \qquad \Omega_{\mathcal{R}} \cap Q \subset \bigcup_{x\in A} B_{2\mathcal{R}}(x), \tag{2.14}$$

where $\#A$ denotes the cardinality of the set A. To that aim let $A \subset \Omega_{\mathcal{R}} \cap Q$ be a maximal family such that

$$\{B_{\mathcal{R}}(x)\}_{x\in A} \quad \text{are disjoint.} \tag{2.15}$$

We claim that

$$\Omega_{\mathcal{R}} \cap Q \subset \bigcup_{x\in A} B_{2\mathcal{R}}(x) \cap Q. \tag{2.16}$$

Indeed, assume that (2.16) were wrong. Then there exists $y \in \Omega_{\mathcal{R}} \cap Q$ such that for all $x \in A$ we have $y \notin B_{2\mathcal{R}}(x)$; that is, for all $x \in A$ we find $B_{\mathcal{R}}(y) \cap B_{\mathcal{R}}(x) = \emptyset$. This contradicts the maximality of A.

We now have, because of $A \subset \Omega_{\mathcal{R}} \cap Q$,

$$\begin{aligned} \#A|B_{\mathcal{R}}| \quad &= \quad \sum_{x\in A} |B_{\mathcal{R}}(x)| \\ &\overset{(2.12)}{<} \quad 2\sum_{x\in A} |\Omega \cap B_{\mathcal{R}}(x)| \\ &\overset{(2.15),(2.11)}{\leq} \quad C(n)|\Omega \cap Q|. \end{aligned}$$

Finally we claim

$$|\Omega_{\mathcal{R}}^r \cap Q| \leq C(n)|\Omega \cap Q|\Big(2 + \frac{r}{\mathcal{R}}\Big)^n. \tag{2.17}$$

In view of (2.16) we have the inclusion $\Omega_{\mathcal{R}} \cap Q \subset \bigcup_{x\in A} B_{2\mathcal{R}}(x) \cap Q$, which implies $\Omega_{\mathcal{R}}^r \subset \bigcup_{x\in A} B_{2\mathcal{R}+r}(x) \cap Q$. Thus

$$\begin{aligned} |\Omega_{\mathcal{R}}^r \cap Q| \quad &\leq \quad \sum_{x\in A} |B_{2\mathcal{R}+r}(x) \cap Q| \\ &\overset{(2.14)}{\leq} \quad C\frac{|\Omega \cap Q|}{|B_{\mathcal{R}}|}|B_{2\mathcal{R}+r}| \\ &= \quad C|\Omega \cap Q|\Big(\frac{2\mathcal{R}+r}{\mathcal{R}}\Big)^n, \end{aligned}$$

which proves (2.17) and thus completes the proof of Lemma 2.1. ∎

UNIQUENESS OF WEAK SOLUTIONS OF THE NAVIER–STOKES EQUATIONS OF MULTIDIMENSIONAL, COMPRESSIBLE FLOW*

DAVID HOFF†

Abstract. We prove uniqueness and continuous dependence on initial data of weak solutions of the Navier–Stokes equations of compressible flow in two and three space dimensions. The solutions we consider may display codimension-one discontinuities in density, pressure, and velocity gradient, and consequently are the generic singular solutions of this system. The key point of the analysis is that solutions with minimal regularity are best compared in a Lagrangean framework; that is, we compare the instantaneous states of corresponding fluid particles in two different solutions rather than the states of different fluid particles instantaneously occupying the same point of space-time. Estimates for H^{-1} differences in densities and L^2 differences in velocities are obtained by duality from bounds for the corresponding adjoint system.

Key words. uniqueness, continuous dependence, Navier–Stokes equations, compressible flow

1. Introduction.

We prove uniqueness and continuous dependence on initial data of weak solutions of the Navier–Stokes equations of compressible flow

$$
\begin{cases} \rho_t + \mathrm{div}(\rho u) = 0, \\ (\rho u^j)_t + \mathrm{div}(\rho u^j u) + P(\rho)_{x_j} = \mu \Delta u^j + \lambda \mathrm{div} u_{x_j} + \rho f^j \end{cases} \tag{1.1}
$$

for $x \in \mathbb{R}^n$, $n = 2, 3$, and $t > 0$, and with initial data

$$
(\rho, u)|_{t=0} = (\rho_0, u_0). \tag{1.2}
$$

Here ρ and $u = (u^1, \dots, u^n)$ are the unknown functions of x and t representing density and velocity, $P = P(\rho)$ is the pressure, f is a given external force, $\mu > 0$ and $\lambda \geq 0$ are viscosity constants, and div and Δ are the usual spatial divergence and Laplace operators.

We compare solutions with only minimal regularity, including the generic singular solutions of the Navier–Stokes system—solutions with codimension-one discontinuities in density, pressure, and velocity gradient (see Hoff [6]). Our result extends that of Danchin [1], which applies to solutions in certain Besov spaces of continuous functions. Danchin makes a direct comparison by subtracting the equations satisfied by different solutions and controlling the linearization errors by the assumed regularity. This regularity is absent for solutions in the class considered here, however, and a different approach is required.

One could hope to prove uniqueness and continuous dependence for solutions in the largest class for which existence is known, that is, solutions with finite energies and nonnegative densities (see Feireisl [3] and Feireisl, Novotny, and Petzeltova [4], for example). Such a result may be unattainable, however, and may be in fact be

false: it is known that certain anomalies can arise in solutions of (1.1) when densities are zero on nonnegligible sets, and there are examples of nonphysical solutions. To be more specific, we say that a solution (ρ, u) is *locally momentum conserving* if, whenever E and V are bounded open sets in $\mathbb{R}^n$ with $\bar{E} \subset V$ and with $\rho = 0$ a.e. in $(V - E) \times [t_1, t_2]$, then the change in the momentum of the fluid in E from time t_1 to time t_2 should be the impulse $\int_{t_1}^{t_2} \int_E \rho f \, dxdt$ applied by the external force to the fluid in E. Weak solutions violating this condition do in fact exist, one such solution being constructed in Hoff and Serre [8]: initial data (ρ_0, u_0) is given corresponding to two fluids initially separated by a vacuum; it is shown that, if ρ_0 is replaced by $\rho_0 + \delta$, then the limit as $\delta \to 0$ of the corresponding perturbed solutions exists and is a weak solution in the entire physical space but fails to be locally momentum conserving. It is also shown that there is a different, locally momentum conserving solution corresponding to the same initial data, but this solution is defined only on the support of the density and cannot be extended as a weak solution to the entire space. We also point out that it appears likely, although it is not presently known, that even if the initial density is strictly positive, large energies can cause spontaneous cavitation. (This cannot occur in one space dimension, however, but the argument, given in Hoff and Smoller [9], depends upon restoring forces which scale unfavorably with dimension.) It therefore remains an interesting open problem to select physical solutions from the most general class of known weak solutions with large energies and possible vacuum states and to establish their uniqueness and continuous dependence on initial data. In the present paper we avoid these issues and difficulties by assuming that at least one of the solutions being compared has strictly positive density.

Our regularity assumptions are listed below in (1.4)–(1.14). These have been made as weak as the analysis will allow and consequently are somewhat technical. We discuss these assumptions in some detail below following the statement of the theorem, giving at the very end of this section six somewhat stronger *sufficient* conditions under which our result applies. Five of these are fairly mild a priori conditions on the system parameters P, μ, and λ and on the forces and initial data, and are easily checked.

The sixth condition is an a posteriori condition imposed on solutions rather than on data, and therefore deserves special comment. A key point of our analysis is that weak solutions are best compared in a Lagrangean framework: it is more natural to compare the instantaneous states of corresponding fluid particles in different solutions rather than the states of different fluid particles which are instantaneously at the same point of space-time. Consequently, the function which maps the position x of a fluid particle in one solution to the position of the corresponding particle in the other solution at a given time plays a special role in the analysis. Our proof requires that this function be Lipschitz continuous with respect to x, a condition which follows from the assumption that velocity gradients are in the space $L^1((0,T); L^\infty(\mathbb{R}^n))$; this is the sixth condition. Now, a large class of weak solutions is constructed in Hoff [6] that satisfy this regularity condition and that at the same time exhibit the generic singularities described above. However, a simple characterization of singular data for which there exist corresponding solutions satisfying this sixth condition has been elusive. The difficulty is essentially equivalent to the classical fact that Calderon–Zygmund operators map L^p into L^p for $p \in (1, \infty)$ but not for $p = 1$ or ∞. We shall discuss this point in greater detail below.

We compare two weak solutions (ρ, u, f) and $(\overline{\rho}, \overline{u}, \overline{f})$ defined on $\mathbb{R}^n \times (0,T)$ and obtain bounds for

$$\left(\int_0^T \int_{\mathbb{R}^n} |u - \overline{u}|^2 dxdt \right)^{1/2} + \sup_{0 \le t \le T} \|(\rho - \overline{\rho})(\cdot, t)\|_{H^{-1}(\mathbb{R}^n)}$$

in terms of $\|\rho_0-\overline{\rho}_0\|_{L^2}$, $\|\rho_0 u_0-\overline{\rho}_0\overline{u}\|_{L^2}$, and $\left(\int_0^T\int|f-\overline{f}|^2dxdt\right)^{1/2}$. Now, a cursory examination of the second equation in (1.1) suggests that L^2 differences in u are driven by H^{-1} differences in $P(\rho)$, whereas H^{-1} bounds for differences in ρ, not $P(\rho)$, are natural in this theory. These are the same when P is linear or more generally when the divided difference $(\rho-\overline{\rho})^{-1}[P(\rho)-P(\overline{\rho})]$ is somewhat regular. Our theorem will therefore apply either when P is the pressure $P=K\rho$ of an ideal isothermal fluid, or for more general pressures when somewhat greater regularity conditions are imposed on solutions; see (1.16) below and the corresponding discussion following (3.13).

Before describing our result in more detail, we introduce some standard notation. First, the usual convective derivative $\frac{d}{dt}$ of a given function $w:\mathbb{R}^n\times(0,T)\to\mathbb{R}$ with respect to a velocity field u is given by $\frac{dw}{dt}=\dot{w}=w_t+u\cdot\nabla w$, where ∇w is the spatial gradient of w, and for $w:\mathbb{R}^n\times(0,T)\to\mathbb{R}^n$, $\frac{dw}{dt}=\dot{w}=w_t+\nabla wu$, where ∇w is the $n\times n$ matrix of partial derivatives of w. We apply this notation to rewrite the momentum equation in (1.1): subtracting u^j times the first equation in (1.1) from the second, we obtain

$$\rho\dot{u}^j+P(\rho)_{x_j}=\mu\Delta u^j+\lambda\,\mathrm{div}\,u_{x_j}+\rho f^j,$$

and adding and subtracting terms, that

$$\begin{aligned}\rho\dot{u}^j&=[(\mu+\lambda)\mathrm{div}\,u-P(\rho)+P(\widetilde{\rho})]_{x_j}+\mu(u^j_{x_k}-u^k_{x_j})_{x_k}+\rho f^j\\&\equiv F_{x_j}+\mu\omega^{j,k}_{x_k}+\rho f^j\end{aligned}\tag{1.3}$$

(summation over repeated indices is understood, and $\widetilde{\rho}$ is a constant, positive reference density). Here ω is the vorticity matrix, which together with the scalar quantity F plays an important role in the existence theory: F and ω are more regular than are ∇u and ρ in general, and (1.3) gives a representation of the internal surface forces acting in the fluid as the sum of a divergence-free field and the gradient of a scalar field. As we shall see, F and ω play an important role in the uniqueness theory as well.

We now give a precise formulation of our results. Let $\widetilde{\rho}$ be a fixed, positive, constant reference density as above and let $\widetilde{P}=P(\widetilde{\rho})$. The solutions we consider will be weak solutions in the following sense.

Definition. *A weak solution on $\mathbb{R}^n\times[0,T]$ of the system (1.1)–(1.2) is a triple (ρ,u,f) satisfying the following:*

(1.4) *$\rho-\widetilde{\rho}$ is a bounded map from $[0,T]$ into $L^1_{loc}(\mathbb{R}^n)\cap H^{-1}(\mathbb{R}^n)$ and $\rho\ge 0$ a.e.;*

(1.5)
$\rho_0u_0\in L^2(\mathbb{R}^n)$; ρu, $P-\widetilde{P}$, ∇u, $\rho f\in L^2(\mathbb{R}^n\times(0,T))$; $\rho|u|^2\in L^1(\mathbb{R}^n\times(0,T))$;

(1.6) *For $0\le t_1\le t_2\le T$ and for test functions φ which are Lipschitz on $\mathbb{R}^n\times[t_1,t_2]$ and for which $\mathrm{supp}\,\varphi(\cdot,t)\subset K$, $t_1\le t\le t_2$, where K is compact,*

$$\int_{\mathbb{R}^n}\rho\varphi dx\Big|_{t_1}^{t_2}=\int_{t_1}^{t_2}\int_{\mathbb{R}^n}(\rho\varphi_t+\rho u\cdot\nabla\varphi)dxdt$$

(it is understood here that $\rho(\cdot,0)=\rho_0$);

(1.7) The weak form of the momentum equation

$$-\int_{\mathbb{R}^n}\rho_0 u_0\cdot\psi(\cdot,0)dx=\int_0^T\int_{\mathbb{R}^n}[\rho u\cdot(\psi_t+\nabla\psi u)+(P(\rho)-\widetilde{P})\mathrm{div}\,\psi \\ -\mu\nabla u^j\cdot\nabla\psi^j-\lambda(\mathrm{div}\,u)(\mathrm{div}\,\psi)+\rho f\cdot\psi]dxdt$$

holds for test functions ψ which are locally Lipschitz on $\mathbb{R}^n\times[0,T]$ and for which $\psi,\psi_t,\nabla\psi\in L^2(\mathbb{R}^n\times(0,T))$, $\nabla\psi\in L^\infty(\mathbb{R}^n\times(0,T))$, and $\psi(\cdot,T)=0$.

The two solutions (ρ,u,f) and $(\overline{\rho},\overline{u},\overline{f})$ we compare will also be assumed to satisfy

(1.8) $$u,\overline{u}\in C(\mathbb{R}^n\times(0,T])\cap L^1((0,T);W^{1,\infty}(\mathbb{R}^n))\cap L^\infty_{loc}((0,T];L^\infty(\mathbb{R}^n))$$

and

(1.9) $$\rho-\widetilde{\rho},\ \overline{\rho}-\widetilde{\rho},\ u,\ \overline{u},\ f,\overline{f}\in L^2(\mathbb{R}^n\times(0,T)).$$

One of the solutions (ρ,u,f) will have to satisfy

(1.10) $$\rho,\rho^{-1}\in L^\infty(\mathbb{R}^n\times(0,T))$$

and

(1.11) $$\int_0^T\int_{\mathbb{R}^n}|u|^r dxdt<\infty$$

for some $r>n$, and the other solution $(\overline{\rho},\overline{u},\overline{f})$ will have to satisfy

(1.12)
$$\int_0^T\left[\|\overline{u}(0,t)\|^2_{L^\infty}+t\|\nabla\overline{u}(\cdot,t)\|^2_{L^\infty}+t\|\nabla\overline{F},\nabla\overline{\omega}\|^2_{L^2}+(t\|\nabla\overline{F},\nabla\overline{\omega}\|^2_{L^4})^a\right]dt<\infty,$$

where $\bar{F}$ and $\bar{\omega}$ are as in (1.3), the gradients are with respect to x, and $a=2/3$ for $n=2$ and $a=4/5$ for $n=3$; and

(1.13) $$\overline{f}\in L^1((0,T);L^{2q}(\mathbb{R}^n))$$

for some $q\in[1,\infty]$. Finally, we shall assume that

(1.14) $$\rho_0-\overline{\rho}_0\in(L^2\cap L^{2p})(\mathbb{R}^n),$$

where p is the Hölder conjugate of q.

We now state our main result.

Theorem. *Given $P=K\rho$, M, T, and $r>n$, where n is 2 or 3, there is a constant C depending on K, M, T, and r such that if (ρ,u,f) and $(\overline{\rho},\overline{u},\overline{f})$ are weak solutions of* (1.1) *satisfying* (1.4)–(1.9)*, with (ρ,u,f) satisfying* (1.10) *and* (1.11) *and $(\overline{\rho},\overline{u},\overline{f})$ satisfying* (1.12) *and* (1.13)*, if* (1.14) *holds, and if all norms occurring in these conditions are bounded by M, then*

(1.15)
$$\left(\int_0^T\int_{\mathbb{R}^n}|u-\overline{u}|^2dxdt\right)^{1/2}+\sup_{0\le t\le T}\|(\rho-\overline{\rho})(\cdot,t)\|_{H^{-1}(\mathbb{R}^n)} \\ \le C\left[\|\rho_0-\overline{\rho}_0\|_{L^2\cap L^{2p}}+\|\rho_0u_0-\overline{\rho}_0\overline{u}_0\|_{L^2}+\left(\int_0^T\int_{\mathbb{R}^n}|f-\overline{f}\circ S|^2dxdt\right)^{1/2}\right]$$

(the notation $\overline{f}\circ S$ *is explained below in* (1.18)*). If* $\int_0^T t\|\nabla\overline{f}(\cdot,t)\|_{L^\infty}dt \le M$*, then* $\overline{f}\circ S$ *may be replaced by* $\overline{f}$ *in* (1.15)*. Also, these same results hold with no restriction on the pressure function* P *provided that*

$$\sup_{0\le t\le T}\left\|\nabla\left(\frac{P(\rho(\cdot,t))-P(\overline{\rho}(\cdot,t))}{\rho(\cdot,t)-\overline{\rho}(\cdot,t)}\right)\right\|_{L^\alpha}<\infty, \tag{1.16}$$

where $\alpha>2$ *when* $n=2$ *and* $\alpha=3$ *when* $n=3$*; in this case the constant* C *depends additionally on* α *and on the above* sup.

The key point of the analysis, and the major premise of this paper, is that solutions with minimal regularity are best compared in a Lagrangean framework, as mentioned earlier. Now, in one space dimension, the initial position of a fluid particle and the cumulative mass are equivalent Lagrangean coordinates, and the corresponding Lagrangean formulation of the system (1.1) consists of simple equations in divergence form for which a straightforward weak interpretation is possible. In several space variables, however, the only Lagrangean coordinate is the initial position, and the system (1.1), written in Lagrangean coordinates, is neither simple nor in divergence form, making a weak interpretation problematic. We deal with this difficulty as follows. First, by imposing the condition (1.8), we ensure the existence of particle trajectories $X(y,t,s)$ satisfying

$$\begin{cases}\dfrac{\partial X}{\partial t}(y,t,s)=u(X(y,t,s),t),\\ X(y,s,s)=y,\end{cases} \tag{1.17}$$

and similarly for $\overline{X}$. $X(y,t,s)$ is therefore the position at time t of the fluid particle whose position at time s is y. In particular, the fluid particle in (ρ,u,f) at (x,t) was at $X(x,0,t)$ initially and so corresponds to the particle in $(\overline{\rho},\overline{u},\overline{f})$ which at time t is at the point

$$\overline{X}(X(x,0,t),t,0)\equiv S(x,t) \tag{1.18}$$

(this is the S appearing in (1.15)). The "Lagrangean" comparison therefore consists of an estimate for $u-\overline{u}\circ S$, where we abuse notation slightly and abbreviate $\overline{u}(S(x,t),t)=(\overline{u}\circ S)(x,t)$. The advantages of the Lagrangean formulation may be understood briefly as follows. First, from its definition, $S(X(y,t,0),t)=\overline{X}(y,t,0)$, and thus $S_t+\nabla Su=\overline{u}\circ S$. It then follows easily that if $w=\overline{u}\circ S$,

$$(\overline{u}_t+\nabla\overline{u}\,\overline{u})\circ S=w_t+\nabla wu,$$

a result which could have been predicted from the meaning of convective differentiation. Given the form of the momentum equation, the comparison of u with $w=\overline{u}\circ S$ now appears quite natural and proceeds in the usual way: bounds for $u-\overline{u}\circ S$ are obtained by duality from estimates for solutions of the adjoint of the weak equation satisfied by $u-\overline{u}\circ S$. A bound for the Eulerian difference $u-\overline{u}$ can then be derived via the regularity assumption in (1.12) for $\|\nabla\overline{u}\|_{L^\infty}$ (which is required elsewhere in the analysis) and the simple fact that

$$\int|x-S(x,t)|^2dx\le Ct\int_0^t\int|u-\overline{u}\circ S|^2dxdt.$$

The convenience of the Lagrangean framework comes at a price, however: we require at several points in the analysis a bound for $\sup_t\|\nabla S(\cdot,t)\|_{L^\infty}$. This bound follows from corresponding bounds for $\nabla X(\cdot, 0, t)$ and $\nabla \overline{X}(\cdot, t, 0)$, and these in turn are consequences of the hypothesis in (1.8) that $u, \overline{u} \in L^1((0,T); W^{1,\infty}(\mathbb{R}^n))$, about which more below.

We now discuss the existence of solutions satisfying the conditions listed in (1.4)–(1.12). First we recall the results of Hoff [7], which apply to flows both in half-spaces and in the whole space: under somewhat technical but fairly mild restrictions on P, μ, λ, and f, which we refer to as conditions (H), the system (1.1)–(1.2) has a global weak solution (ρ, u) provided that

$$\begin{cases} 0 \le \rho_0 \text{ a.e.}, \quad \rho_0 \in L^\infty, \\ \displaystyle\int \left[\rho_0 |u_0|^q + \varphi(\rho_0 |u_0|^2 + (\rho_0 - \tilde{\rho})^2)\right] dx < \infty \\ \displaystyle\int [\rho_0 |u_0|^2 + (\rho_0 - \widetilde{\rho})^2] dx \ll 1, \end{cases} \tag{1.19}$$

where $q > 6$ and $\varphi = 1$ for $n = 3$ and $q > 2$ and $\varphi = (1 + |x|^2)^\beta, \beta > 0$, for $n = 2$. The solution is shown to satisfy all the conditions in (1.4)–(1.9) as well as the energy estimates

$$\begin{aligned} &\sup_{0 \le t \le T} \int \left[\rho |u|^2 + t|\nabla u|^2 + t^n \rho |\dot{u}|^2\right] dx \\ &\qquad + \int_0^T \int \left[|\nabla u|^2 + t|(\rho u^j)_t + \operatorname{div}(\rho u^j u)|^2 + t^n |\nabla \dot{u}|\right]^2 dx dt \\ &\quad \le C(T), \end{aligned}$$

with the exception of the condition in (1.8) that $u \in L^1((0,T); W^{1,\infty}(\mathbb{R}^n))$. Moreover, if $\inf \rho_0 > 0$, then $\rho \ge C^{-1} > 0$ a.e., and as a consequence, the conditions (1.10) and (1.11) hold. To summarize, *the results of* [7] *guarantee the existence of a solution* (ρ, u, f) *satisfying all the conditions* (1.4)–(1.11)*, with the exception of the requirement in* (1.8) *that* $u \in L^1((0,T); W^{1,\infty}(\mathbb{R}^n))$*, provided only that the system conditions* (H) *hold, that* (ρ_0, u_0) *satisfies* (1.19)*, and that* $\inf \rho_0 > 0$.

Next, by applying the interpolation techniques of [6], we can show that if $\inf \overline{\rho}_0 > 0$ and $\overline{u}_0 \in H^s(\mathbb{R}^n)$ for some $s \in [0,1]$, then the improved energy estimates

$$\begin{aligned} &\sup_{0 \le t \le T} \int \left[\overline{\rho} |\overline{u}|^2 + (\overline{\rho} - \tilde{\rho})^2 + t^{1-s} |\nabla \overline{u}|^2 + t^\sigma |\dot{\overline{u}}|^2\right] dx \\ &\qquad + \int_0^T \int \left[|\nabla \overline{u}|^2 + t^{1-s} |\dot{\overline{u}}|^2 + t^\sigma |\nabla \dot{\overline{u}}|^2\right] dx dt \\ &\quad \le C(T) \end{aligned} \tag{1.20}$$

hold, where

$$\sigma = \begin{cases} 2 - s, & n = 2, \\ \max\{2 - s, 3 - 3s\}, & n = 3. \end{cases} \tag{1.21}$$

It then follows that the bounds in (1.12) hold if $s > 0$ when $n = 2$ and $s > 1/2$ when $n = 3$. For example, when $n = 2$ we can apply the fact that $\nabla \overline{F} = \operatorname{div}(\overline{\rho}\, \dot{\overline{u}} - \overline{\rho} \overline{f})$ (see (1.3)) together with standard elliptic theory and Sobolev estimates to obtain that, modulo constants depending on $\overline{f}$,

$$\int_0^T t^{2/3}\|\nabla\overline{F}(\cdot,t)\|_{L^4}^{4/3}dt \le C\int_0^T t^{2/3}\left(\int|\dot{\overline{u}}|^2dx\right)^{1/3}\left(\int|\nabla\dot{\overline{u}}|^2dx\right)^{1/2}dt$$
$$\le C\left(\int_0^T t^{2s-1}dt\right)^{1/3}\left(\int_0^T\int t^{1-s}|\dot{\overline{u}}|^2dxdt\right)^{1/3}\left(\int_0^T\int t^{2-s}|\nabla\dot{\overline{u}}|^2dxdt\right)^{1/3},$$

which is finite if $s > 0$. A similar result holds for $n = 3$ if $s > 1/2$. To summarize, *the results of* [6] *and* [7] *guarantee the existence of a solution* $(\overline{\rho},\overline{u})$ *satisfying all the conditions* (1.4)–(1.9) *and* (1.12)–(1.13)*, with the exception of the condition in* (1.8) *that* $u \in L^1((0,T);W^{1,\infty}(\mathbb{R}^n))$*, provided that the system conditions* (H) *hold, that* $(\overline{\rho}_0,\overline{u}_0)$ *satisfies* (1.19)*, and that* $\inf\overline{\rho}_0 > 0$ *and* $\overline{u}_0 \in H^s(\mathbb{R}^n)$*, where* $s > 0$ *for* $n = 2$ *and* $s > 1/2$ *for* $n = 3$. Recall that functions in H^s may be discontinuous across hypersurfaces of $\mathbb{R}^n$ for $s < 1/2$ but not for $s > 1/2$. The above restrictions on $\overline{u}_0$ therefore allow locally Riemann-like initial data in $\mathbb{R}^2$, but codimension-one singularities only in ρ_0 in $\mathbb{R}^3$.

The assumption in (1.8) that ∇u, $\nabla\overline{u} \in L^1((0,T);L^\infty(\mathbb{R}^n))$ is the most restrictive condition on the list. In order to examine it in more detail we decompose the velocity field u by splitting off its most singular part: recalling the definitions in (1.3) of F and ω, we write

$$\begin{aligned}\Delta u^j &= u^j_{x_kx_k} = u^k_{x_kx_j} + (u^j_{x_k} - u^k_{x_j})_{x_k}\\ &= \left[(\mu+\lambda)^{-1}F_{x_j} + \omega^{j,k}_{x_k}\right] + (\mu+\lambda)^{-1}(P-\widetilde{P})_{x_j}\\ &\equiv \Delta u^j_{F,\omega} + \Delta u^j_P,\end{aligned}\tag{1.22}$$

so that $u = u_{F,\omega} + u_P$. We can easily show that $\int_0^T\|\nabla u_{F,\omega}(\cdot,t)\|_{L^\infty}dt < \infty$ if (1.20) holds for the same values of s as above, which again is a consequence of the assumptions (1.19), $\inf\rho_0 > 0$, and $u_0 \in H^s$. To see this, we apply standard elliptic theory in the definitions (1.22) and (1.3) of $u_{F,\omega}$ and F, ignoring the contribution of ω, which turns out to be the same as that of F, and of f, which is a lower-order term, to obtain that, in $\mathbb{R}^3$, for some $\gamma > 3$ and some $\varepsilon > 0$ determined by γ,

$$\|\nabla u_{F,\omega}(\cdot,t)\|_{L^\infty} \le C\|D_x^2u_{F,\omega}(\cdot,t)\|_{L^\gamma} \le C\|\nabla F(\cdot,t)\|_{L^\gamma}$$
$$\le C\|\dot{u}(\cdot,t)\|_{L^\gamma} \le C\|\dot{u}(\cdot,t)\|_{L^2}^{(1-\varepsilon)/2}\|\nabla\dot{u}(\cdot,t)\|_{L^2}^{(1+\varepsilon)/2},$$

so that

$$\int_0^T\|\nabla u_{F,\omega}(\cdot,t)\|_{L^\infty}dt \le C\int_0^T t^\beta\left(t^{1-s}\int|\dot{u}|^2dx\right)^{(1-\varepsilon)/4}\left(t^\sigma\int|\nabla\dot{u}|^2dx\right)^{(1+\varepsilon)/4}dt$$
$$\le C\left(\int_0^T t^{2\beta}dt\right)^{1/2}$$

by (1.20), where $4\beta = (s-1)(1-\varepsilon) - \sigma$. The above integral is therefore finite if $2\beta > -1$ for some $\varepsilon > 0$ and hence some $\gamma > 3$, and this holds if $s > 1/2$. A similar result holds for $n = 2$ with $s > 0$. Thus for the solution constructed in [7], $\int_0^T\|\nabla u_{F,\omega}(\cdot,t)\|_{L^\infty}dt$ is finite if (1.16) holds, $\inf\rho_0 > 0$, and $u_0 \in H^s$, where $s > 1/2$ for $n = 3$ and $s > 0$ for $n = 2$.

There remains the condition that $\int_0^T \|\nabla u_P(\cdot,t)\|_{L^\infty} dt < \infty$, that is, that

$$\int_0^T \|\nabla \Gamma_{x_j} * (P(\rho(\cdot,t)) - \widetilde{P})\|_{L^\infty} dt < \infty,$$

where Γ is the fundamental solution of the Laplace operator on $\mathbb{R}^n$. Now, it is a standard result of Calderon–Zygmund theory that $\nabla\Gamma_{x_j}*$ is a bounded linear transformation from L^p to L^p for $p \in (1,\infty)$ but not for $p = 1$ or ∞ (see [5, pp. 230–235], for example). It is also true that if $P(\rho(\cdot,t)) \in L^\infty$, then $u_P^j(\cdot,t) = (\mu+\lambda)^{-1}\Gamma_{x_j}*(P(\rho(\cdot,t))-\widetilde{P})$ is log-Lipschitz, if not Lipschitz. This is sufficient to guarantee the existence and uniqueness of the particle trajectories $X(y,t,s)$ in (1.17). It does not ensure, however, that X is Lipschitz with respect to y, and this is essential for our analysis. Of course, we could obtain that $\nabla u_P(\cdot,t) \in L^\infty$ by imposing the condition that $P(\rho(\cdot,t)) \in C^\alpha$, but this would exclude solutions with codimension-one singularities and is altogether too strong. On the other hand, a large class of solutions is constructed in Hoff [6] in which densities are *piecewise* C^α and, as a consequence, $\nabla u_P(\cdot,t) \in L^\infty$. The results of the present paper therefore do apply to this class, which includes solutions with Riemann-like initial data.

We make one final observation concerning (1.8) for the isothermal case $P = K\rho$, namely that for the solutions constructed in Hoff [6, 7], the condition $\nabla u_P(\cdot,t) \in L^\infty$ can be shown to hold if in addition to (1.19) it is assumed that $\inf \rho_0 > 0$ and there is a constant C such that

$$\left| \int \rho_0(x)\varphi(x)dx \right| \leq C\|\varphi\|_{L^1_w} \tag{1.23}$$

for integrable functions φ. Here $\|\varphi\|_{L^1_w}$ is the weak-L^1 norm of φ, which is the smallest number $M \geq 0$ such that $k|\{x : |\varphi(x)| \geq k\}| \leq M$ for all $k > 0$. L^1_w contains L^1 but is not a Banach space, and $\|\cdot\|_{L^1_w}$ is not a norm. However, $A \equiv \Gamma_{x_j x_k}* : L^1 \to L^1_w$ is "bounded," and the adjoint of the mass equation in (1.1) is easily seen to preserve the class L^1_w. That is, if φ is the solution of the initial-value problem

$$\begin{cases} \varphi_t + \nabla\varphi \cdot u = 0, \\ \varphi(x,\bar{t}) = \Phi(x), \end{cases}$$

then as a simple consequence of the conservation of mass, $\|\varphi(\cdot,t)\|_{L^1_w} \leq C\|\Phi\|_{L^1_w}$ for a constant C determined by the assumed pointwise bounds on ρ. Taking $\psi \in L^1$ and $\Phi = A\psi \in L^1_w$, we then obtain that

$$\begin{aligned} \left| \int (A\rho)(x,\bar{t})\psi(x)dx \right| &= \left| \int \rho(x,\bar{t})\Phi(x)dx \right| \\ &= \left| \int \rho_0(x)\varphi(x,0)dx \right| \leq C\|\varphi(\cdot,0)\|_{L^1_w} \\ &\leq C\|\Phi\|_{L^1_w} \leq C\|\psi\|_{L^1} \end{aligned}$$

by (1.23), so that $\|(A\rho)(\cdot,t)\|_{L^\infty} \leq C$, as required. While fairly simple and appealing, this argument is apparently of little practical importance because of the extreme difficulty in verifying the condition (1.23).

We summarize the above considerations as follows: solutions (ρ,u) and $(\overline{\rho},\overline{u})$ satisfying all the conditions (1.4)–(1.14) are known to exist under the following hypotheses:

- The conditions (H) described in [7] on the system parameters P, f, $\overline{f}$, μ, and λ hold;
- Both (ρ_0, u_0) and $(\overline{\rho}_0, \overline{u}_0)$ satisfy (1.19);
- $\inf \rho_0 > 0$ and $\inf \overline{\rho}_0 > 0$;
- The initial densities and forces satisfy (1.13) and (1.14);
- $u_0, \overline{u}_0 \in H^s(\mathbb{R}^n)$ where $s > 0$ for $n = 2$ and $s > 1/2$ for $n = 3$;
- $\nabla u_P, \nabla \overline{u}_P \in L^1([0,T]; L^\infty(\mathbb{R}^n))$, where u_P and $\overline{u}_P$ are as defined in (1.22).

The first five of these conditions may be verified a priori and, again, the last is known to hold for the large class of solutions exhibiting codimension-one singularities constructed in Hoff [6].

There is now a large and growing literature on various mathematical aspects of the Navier–Stokes equations of compressible fluid flow. See the books of Feireisl [2] and Lions [10] for general discussions and more complete bibliographies relating to the existence of weak solutions, including for the nonbarotropic case in which temperature appears and an energy balance equation is appended to (1.1). See also Xin [11] for a result concerning the blowup of smooth solutions of (1.1) when the initial density has compact support.

2. Lagrangean structure. In this section we discuss properties of the particle trajectories $X(y,t,s)$ required for the proof of the theorem. We shall make repeated use both in this section and in the next of Rademacher's theorem and some of its consequences (see Ziemer [12, pp. 49–53]): a Lipschitz function has a differential almost everwhere; the composition of a function in $W^{1,p}$ with a bi-Lipschitz map is again in $W^{1,p}$, and the chain rule holds; and the usual change of variables formula holds for integrable functions composed with univalent Lipschitz mappings.

LEMMA 2.1. *Let u satisfy* (1.8). *Then there is a unique function $X \in C(\mathbb{R}^n \times [0,T]^2)$ satisfying*

$$\begin{cases} \dfrac{\partial X}{\partial t}(y,t,s) = u(X(y,t,s),t) \\ X(y,s,s) = y. \end{cases} \tag{2.1}$$

$X(\cdot,t,s)$ is Lipschitz on $\mathbb{R}^n$ for $(t,s) \in [0,T]^2$, and there is a constant C such that

$$\left\| \frac{\partial X}{\partial y}(\cdot,t,s) \right\|_{L^\infty} \le C, \qquad (t,s) \in [0,T]^2.$$

Also, given $\tau > 0$ there is a constant $C = C(\tau)$ such that

$$\left| \frac{\partial X}{\partial t}(y,t,s) \right| \le C(\tau)$$

for all $(y,s) \in \mathbb{R}^n \times [0,T]$ and almost all $t \in [\tau,T]$, and

$$\left| \frac{\partial X}{\partial s}(y,t,s) \right| \le C(\tau)$$

for all $(y,t) \in \mathbb{R}^n \times [0,T]$ and almost all $s \in [\tau,T]$.

Proof. The proof is elementary and thus is omitted. We do note, however, the importance of the assumption that $u \in L^1((0,T); W^{1,\infty})$ in the derivation of the first bound above:

$$\begin{aligned} \frac{1}{2}\frac{\partial}{\partial t}\left|\nabla_y X(y,t,s)\right|^2 &= \nabla_y X(y,t,s) \cdot \nabla_y u(X(y,t,s),t) \\ &\le \|\nabla u(\cdot,t)\|_{L^\infty} \left|\nabla_y X(y,t,s)\right|^2. \qquad \square \end{aligned}$$

In the following lemma we compute the Jacobian determinant of $X(\cdot, t, s)$.

LEMMA 2.2. *Let u be as in (1.8) and ρ as in (1.4). Assume that ρu is locally integrable on $\mathbb{R}^n \times [0,T]$ and that the weak form (1.6) of the mass equation holds. If E_{t_0} is a bounded measurable set in $\mathbb{R}^n$ and if $E_t = \{X(y,t,t_0) : y \in E_{t_0}\}$, then*

$$\int_{E_t} \rho(x,t)dx = \int_{E_{t_0}} \rho(y,t_0)dy. \tag{2.2}$$

Also,

$$\rho(X(\cdot,t,t_0),t)\,|\det \nabla_y X(\cdot,t,t_0)| = \rho(\cdot,t_0) \tag{2.3}$$

a.e. on $\mathbb{R}^n$.

Proof. The conservation of mass (2.2) is proved by applying (1.6) to the solution $\varphi^{\eta,\delta}$ of the adjoint system

$$\begin{cases} \varphi_t^{\eta,\delta} + \nabla\varphi^{\eta,\delta}\cdot u^\delta = 0, \\ \varphi^{\eta,\delta}(\cdot,t_0) = \chi^\eta_{E_{t_0}}, \end{cases}$$

where u^δ and $\chi^\eta_{E_{t_0}}$ are smooth approximations to u and to the characteristic function of E_{t_0}, and then letting first δ, then η tend to zero. The bound $\|\nabla\varphi^{\eta,\delta}\|_{L^\infty} \le C(\eta)$, which follows from the condition $\int_0^T \|\nabla u(\cdot,t)\|_{L^\infty}dt < \infty$ as in the proof of Lemma 2.1, ensures that the approximation errors disappear in the limit. This proves (2.2). Then as a consequence,

$$\begin{aligned} \int_{E_{t_0}} \rho(y,t_0)dy &= \int_{E_t} \rho(x,t)dx \\ &= \int_{E_{t_0}} \rho(X(y,t,t_0),t)\,|\det \nabla_y X(y,t,t_0)|\,dy. \end{aligned}$$

This holds for all bounded measureable sets E_{t_0}; the integrands therefore agree a.e. $\square$

In the following lemma we list properties of the mapping S defined in (1.18) that are required for the proof of the theorem.

LEMMA 2.3. *Let both (ρ,u) and $(\overline{\rho},\overline{u})$ satisfy the hypotheses of Lemmas 2.1 and 2.2, let X and $\overline{X}$ be as in Lemma 2.1, and define*

$$\begin{cases} S(x,t) = \overline{X}(X(x,0,t),t,0), \\ S^{-1}(x,t) = X(\overline{X}(x,0,t),t,0). \end{cases} \tag{2.4}$$

Then

(a) *$S^{\pm1}$ is continuous on $\mathbb{R}^n \times [0,T]$ and Lipschitz continuous on $\mathbb{R}^n \times [\tau,T]$ for all $\tau > 0$, and there is a constant C such that*

$$\|\nabla S^{\pm1}(\cdot,t)\|_{L^\infty} \le C, \qquad t \in [0,T];$$

(b) *$(S_t + \nabla S u)(x,t) = \overline{u}(S(x,t),t)$ a.e. in $\mathbb{R}^n \times (0,T)$;*

(c) *$\overline{\rho}(S(x,t),t)\rho_0(X(x,0,t)) \det \nabla S(x,t) = \rho(x,t)\overline{\rho}_0(X(x,0,t))$ a.e. in $\mathbb{R}^n \times (0,T)$;*

(d) *if u, $\overline{u} \in L^2(\mathbb{R}^n \times (0,T))$, then*

$$\int |x - S(x,t)|^2 dx \le Ct\int_0^t \int |u(x,s) - \overline{u}(S(x,s),s)|^2 dxds,$$

$$\int |x - S^{-1}(x,t)|^2 dx \le Ct\int_0^t \int |u(S^{-1}(x,s),s) - \overline{u}(x,s)|^2 dxds.$$

The constants C in (a) *and* (d) *depend on upper bounds for u and $\overline{u}$ in $L^1((0,T);W^{1,\infty}(\mathbb{R}^n))$.*

Proof. (a) and (b) follow directly from Lemmas 2.1 and 2.2. To prove (c) we differentiate the relation $S(X(y,t,0),t) = \overline{X}(y,t,0)$ to obtain

$$\det\nabla S(X(y,t,0),t)\det\nabla_y X(y,t,0) = \det\nabla_y \bar{X}(y,t,0)$$

a.e. Multiplying by $\rho(X(y,t,0),t)\bar{\rho}(\bar{X}(y,t,0),t)$ and applying (2.3) with $t_0 = 0$, we then get

$$\bar{\rho}(\bar{X}(y,t,0),t)\rho_0(y)\det\nabla S(X(y,t,0),t) = \rho(X(y,t,0))\bar{\rho}_0(y)\,.$$

We then set $x = X(y,t,0)$ so that $y = X(x,0,t)$ and $S(x,t) = \bar{X}(y,t,0)$ to obtain (c). To prove (d) we compute

$$\begin{aligned}
\int |x - S(x,t)|^2 dx &\le C\int |X(y,t,0) - \overline{X}(y,t,0)|^2 dy \\
&= C\int \left|\int_0^t [u(X(y,s,0),s) - \overline{u}(\overline{X}(y,s,0),s)]ds\right|^2 dy \\
&\le Ct\int_0^t \int |u(x,s) - \overline{u}(S(x,s),s)|^2 dxds.
\end{aligned}$$

Notice that the Jacobian determinants occurring in the above changes of variables are bounded by (a). The proof for S^{-1} is similar. □

3. Proof of the theorem. We now fix two solutions (ρ,u,f) and $(\overline{\rho},\overline{u},\overline{f})$ as described in the theorem of section 1 and define the mappings X, $\overline{X}$, and S as in (2.1) and (2.4). We shall make frequent use of the conclusions of Lemma 2.3 and the properties of Lipschitz mappings described at the beginning of section 2.

We begin by deriving the weak form of the equation satisfied by $u - \overline{u}\circ S$, where again we abuse notation slightly and write $\overline{u}(S(x,t),t) = (\overline{u}\circ S)(x,t)$. Let $\psi : \mathbb{R}^n \times [0,T] \to \mathbb{R}^n$ be a test function satisfying the conditions in (1.7) and which additionally is in $(H^2\cap C^2)(\mathbb{R}^n\times[0,T])$. Then

$$\begin{aligned}
&-\int_{\mathbb{R}^n} \rho_0(x)u_0(x)\cdot\psi(x,0)dx \\
&\qquad = \int_0^T\int_{\mathbb{R}^n}\Big[\rho u\cdot(\psi_t + \nabla\psi u) + (P(\rho) - \widetilde{P})\operatorname{div}\psi \\
&\qquad\qquad - \mu\nabla u^j\cdot\nabla\psi^j - \lambda\operatorname{div}u\operatorname{div}\psi + \rho f\cdot\psi\Big]dxdt.
\end{aligned}\tag{3.1}$$

Now let $\overline{\psi} \equiv \psi\circ S^{-1}$ and note that $\overline{\psi}$ also satisfies the conditions in (1.7). Thus

$$\begin{aligned}
&-\int_{\mathbb{R}^n} \overline{\rho}_0(x)\overline{u}_0(x)\cdot\overline{\psi}(x,0)dx \\
&\qquad = \int_0^T\int_{\mathbb{R}^n}\Big[\overline{\rho u}\cdot(\overline{\psi}_t + \nabla\overline{\psi}\,\overline{u}) + (P(\overline{\rho}) - \widetilde{P})\operatorname{div}\overline{\psi} \\
&\qquad\qquad - \mu\nabla\overline{u}^j\cdot\nabla\overline{\psi}^j - \lambda\operatorname{div}\overline{u}\operatorname{div}\overline{\psi} + \overline{\rho}\overline{f}\cdot\overline{\psi}\Big]dxdt.
\end{aligned}$$

We make the change of variables $x = S(y,t)$ in the first and last terms on the right here, noting that, by Lemma 2.3,

$$(\overline{\psi}_t + \nabla\overline{\psi}\,\overline{u}) \circ S = \psi_t + \nabla\psi u$$

and

$$(\overline{\rho} \circ S)|\det \nabla S| = A_0\rho,$$

where

$$A_0(x,t) = \overline{\rho}_0(X(x,0,t))/\rho_0(X(x,0,t)) \tag{3.2}$$

(recall that ρ_0 is strictly positive by (1.10)). The result is that

$$\begin{aligned}
&-\int_{\mathbb{R}^n} \overline{\rho}_0(x)\overline{u}_0(x)\cdot\overline{\psi}(x,0)dx \\
&= \int_0^T\int_{\mathbb{R}^n}\Big[A_0\rho(\overline{u}\circ S)\cdot(\psi_t+\nabla\psi u) + (P(\overline{\rho})-\widetilde{P})\mathrm{div}\overline{\psi} \\
&\qquad -\mu\nabla\overline{u}^j\cdot\nabla\overline{\psi}^j - \lambda\,\mathrm{div}\,\overline{u}\,\mathrm{div}\,\overline{\psi} + A_0\rho(\overline{f}\circ S)\cdot\psi\Big]\,dxdt.
\end{aligned} \tag{3.3}$$

Next we subtract (3.3) from (3.1), letting

$$z = u - \overline{u}\circ S$$

and noting that $\overline{\psi}(\cdot,0) = \psi(\cdot,0)$:

$$\begin{aligned}
&\int_{\mathbb{R}^n}(\overline{\rho}_0\overline{u}_0 - \rho_0 u_0)\cdot\psi(\cdot,0)dx \\
&= \int_0^T\int_{\mathbb{R}^n}\big[\rho z\cdot(\psi_t+\nabla\psi u) + (1-A_0)\rho(\overline{u}\circ S)(\psi_t+\nabla\psi u) \\
&\qquad + (P(\rho)-\widetilde{P})\mathrm{div}\,\psi - (P(\overline{\rho})-\widetilde{P})\mathrm{div}\,\overline{\psi} \\
&\qquad - \mu(\nabla u^j\cdot\nabla\psi^j - \nabla\overline{u}^j\cdot\nabla\overline{\psi}^j) \\
&\qquad - \lambda(\mathrm{div}\,u\,\mathrm{div}\,\psi - \mathrm{div}\,\overline{u}\,\mathrm{div}\,\overline{\psi}) \\
&\qquad + \rho(f-\overline{f}\circ S)\cdot\psi + (1-A_0)\rho(\overline{f}\circ S)\cdot\psi\big]\,dxdt.
\end{aligned} \tag{3.4}$$

We rewrite three of the terms on the right here as follows (recall the definitions of $\overline{F}$ and $\overline{\omega}$ in (1.3)):

$$\begin{aligned}
&\iint\Big[(\widetilde{P}-P(\overline{\rho}))\mathrm{div}\overline{\psi} + \mu\nabla\overline{u}^j\cdot\nabla\overline{\psi}^j + \lambda\,\mathrm{div}\,\overline{u}\,\mathrm{div}\,\overline{\psi}\Big] \\
&\quad = \iint\Big[((\mu+\lambda)\mathrm{div}\,\overline{u} - P(\overline{\rho}) + \widetilde{P})\mathrm{div}\,\overline{\psi} + \mu(\overline{u}^j_{x_k} - \overline{u}^k_{x_j})\overline{\psi}^j_{x_k}\Big] \\
&\quad = -\iint(\nabla\overline{F}\cdot\overline{\psi} + \mu\,\overline{\omega}^{j,k}_{x_k}\overline{\psi}^j) \\
&\quad = -\iint(\nabla\overline{F}\cdot\psi + \mu\,\overline{\omega}^{j,k}_{x_k}\psi^j) + E_1 \\
&\quad = \iint\Big[(\widetilde{P}-P(\overline{\rho}))\mathrm{div}\,\psi + \mu\nabla\overline{u}^j\cdot\nabla\psi^j + \lambda\,\mathrm{div}\,\overline{u}\,\mathrm{div}\,\psi\Big] + E_1,
\end{aligned}$$

where

$$E_1 = \int_0^T \int \left[\nabla \overline{F} \cdot (\psi - \psi \circ S^{-1}) + \mu \overline{\omega}^{j,k}_{x_k} (\psi^j - \psi^j \circ S^{-1})\right] dxdt. \tag{3.5}$$

Defining E_2 by

$$E_2 = \iint \left[\rho(f - \overline{f} \circ S) \cdot \psi + (1 - A_0)\rho(\overline{f} \circ S) \cdot \psi\right],$$

we then have from (3.4) that

$$\begin{aligned}
&\int_{\mathbb{R}^n} (\overline{\rho}_0 \overline{u}_0 - \rho_0 u_0) \cdot \psi(\cdot, 0) dx \\
&= \int_0^T \int_{\mathbb{R}^n} [\rho z \cdot (\psi_t + \nabla \psi u) + (1 - A_0)\rho(\overline{u} \circ S)(\psi_t + \nabla \psi u) \\
&\qquad + (P(\rho) - P(\overline{\rho}))\mathrm{div}\, \psi \\
&\qquad - \mu(\nabla u^j - \nabla \overline{u}^j) \cdot \nabla \psi^j - \lambda(\mathrm{div}\, u - \mathrm{div}\, \overline{u})\mathrm{div}\, \psi\big] \, dxdt \\
&\quad + E_1 + E_2.
\end{aligned} \tag{3.6}$$

We write

$$\begin{aligned}
&\iint \rho z \cdot [(\psi_t + \nabla \psi u) - \mu(\nabla u^j - \nabla \overline{u}^j) \cdot \nabla \psi^j - \lambda(\mathrm{div}\, u - \mathrm{div}\, \overline{u})\mathrm{div}\, \psi] \\
&= \iint z \cdot [\rho(\psi_t + \nabla \psi u) + \mu \Delta \psi + \lambda \nabla \mathrm{div} \psi] + E_3 ,
\end{aligned}$$

where

$$E_3 = \iint (\overline{u} \circ S - \overline{u}) \cdot (\mu \Delta \psi + \lambda \nabla \mathrm{div}\, \psi).$$

We then have from (3.6) that

$$\begin{aligned}
&\int_{\mathbb{R}^n} (\overline{\rho}_0 \overline{u}_0 - \rho_0 u_0) \cdot \psi(\cdot, 0) dx \\
&= \int_0^T \int_{\mathbb{R}^n} z \cdot [\rho(\psi_t + \nabla \psi u) + \mu \Delta \psi + \lambda \nabla \mathrm{div}\, \psi] \, dxdt \\
&\quad + \int_0^T \int_{\mathbb{R}^n} [(1 - A_0)\rho(\overline{u} \circ S)(\psi_t + \nabla \psi u) + (P(\rho) - P(\overline{\rho}))\mathrm{div}\, \psi] \, dxdt \\
&\quad + E_1 + E_2 + E_3.
\end{aligned} \tag{3.7}$$

Now extend ρ and u to be constant in t outside $[0, T]$, let ρ^δ and u^δ be corresponding smooth approximations obtained by mollifying in both x and t, and let $\psi^\delta : \mathbb{R}^n \times [0, T] \to \mathbb{R}^n$ be the solution of the adjoint system

$$\begin{cases} \rho^\delta(\psi^\delta_t + \nabla \psi^\delta u^\delta) + \mu \Delta \psi^\delta + \lambda \nabla \mathrm{div}\, \psi^\delta = G, \\ \psi^\delta(\cdot, T) = 0 \end{cases} \tag{3.8}$$

for a given $G \in H^\infty(\mathbb{R}^n \times [0, T])$. The existence of the solution ψ^δ is a straightforward exercise; bounds for various of its norms are given in the following lemma.

LEMMA 3.1. *There is a constant C as described in the theorem of section 1 and independent of δ and G such that the solution ψ^δ of (3.8) satisfies*

$$\sup_{0\le t\le T}\int_{\mathbb{R}^n}[|\psi^\delta(x,t)|^2+|\nabla\psi^\delta(x,t)|^2]dx+\int_0^T\int_{\mathbb{R}^n}\left[|\psi_t^\delta+\nabla\psi^\delta u^\delta|^2+|D_x^2\psi^\delta|^2\right]dxdt \le C\int_0^T\int_{\mathbb{R}^n}|G|^2dxdt, \tag{3.9}$$

and there is a constant $C=C(G)$ depending on higher derivatives of G but independent of δ, such that

$$\sup_{0\le t\le T}\|\nabla\psi^\delta(\cdot,t)\|_{L^\infty}+\int_0^T\int_{\mathbb{R}^n}|\psi^\delta|^r dxdt\le C(G), \tag{3.10}$$

where r is as in (1.11).

The proof, which is elementary, is deferred to the end of this section.

We now take $\psi=\psi^\delta$ in (3.7) to obtain finally that

$$\begin{aligned}&\int_{\mathbb{R}^n}(\overline{\rho}_0\overline{u}_0-\rho_0u_0)\cdot\psi^\delta(\cdot,0)dx\\ &=\int_0^T\int_{\mathbb{R}^n}z\cdot G\,dxdt+E_1+E_2+E_3+E_4+E_5+E_6\,,\end{aligned} \tag{3.11}$$

where

$$\begin{aligned}E_4&=\iint z\cdot\left[(\rho-\rho^\delta)\psi_t^\delta+\nabla\psi^\delta(\rho u-\rho^\delta u^\delta)\right],\\ E_5&=\iint(1-A_0)\rho(\overline{u}\circ S)\cdot(\psi_t^\delta+\nabla\psi^\delta u),\end{aligned}$$

and

$$E_6=\iint(P(\rho)-P(\overline{\rho}))\operatorname{div}\psi^\delta.$$

We now apply the bounds of Lemma 3.1 to estimate each of the terms $E_1,\dots,E_6$ and the term on the left-hand side of (3.11), and then take the limit as $\delta\to0$. First, it is easy to see that $E_4\to0$ as $\delta\to0$ and that the term on the left-hand side of (3.11) is bounded by

$$\|\rho_0u_0-\overline{\rho}_0\overline{u}_0\|_{L^2}\left(\iint|G|^2\right)^{1/2}.$$

Next we note that, from the definition (3.2) of A_0,

$$\sup_{0\le t\le T}\|1-A_0(\cdot,t)\|_{L^{2p}}\le C\|\rho_0-\overline{\rho}_0\|_{L^{2p}}, \tag{3.12}$$

so that, if q is the Hölder conjugate of p as in (1.13)–(1.14), then the force terms E_2

are bounded by

$$
\begin{aligned}
&C\Bigg[\left(\iint |f-\overline{f}\circ S|^2\right)^{1/2}\left(\iint |\psi^\delta|^2\right)^{1/2} \\
&\qquad + \sup_t \|\rho_0-\overline{\rho}_0\|_{L^{2p}} \sup_t \left(\int |\psi^\delta|^2 dx\right)^{1/2} \int_0^T \|\overline{f}(\cdot,t)\|_{L^{2q}} dt\Bigg] \\
&\quad \le C\left[\left(\iint |f-\overline{f}\circ S|^2\right)^{1/2} + \|\rho_0-\overline{\rho}_0\|_{L^{2p}}\right]\left(\iint |G|^2\right)^{1/2}
\end{aligned}
$$

by (3.9).

Next we bound the term E_1, disregarding the contribution of $\overline{\omega}$, which is essentially identical to that of $\overline{F}$. The argument requires that we subdivide time intervals into smaller subintervals. Thus let J be a large positive integer and for $t \in [0,T]$ define $t_j = jt/J$, $j = 0,\ldots,J$. Then

$$
\begin{aligned}
|E_1| &\le \int_0^T \int_{\mathbb{R}^n} |\nabla\overline{F}(x,t)|\,|\psi^\delta(x,t) - \psi^\delta(S^{-1}(x,t),t)|dxdt \\
&\le \sum_j \int_0^T \int_{\mathbb{R}^n} |\nabla\overline{F}(x,t)|\,|\psi^\delta(S^{-1}(x,t_{j+1}),t) - \psi^\delta(S^{-1}(x,t_j),t)|dxdt \\
&\le \sum_j \int_0^T \|\nabla\overline{F}(\cdot,t)\|_{L^4} \|S^{-1}(\cdot,t_{j+1}) - S^{-1}(\cdot,t_j)\|_{L^2} \\
&\qquad \times \left(\int_0^1 \int_{\mathbb{R}^n} |\nabla\psi^\delta(\theta S^{-1}(x,t_{j+1}) + (1-\theta)S^{-1}(x,t_j),t)|^4 dxd\theta\right)^{1/4} dt.
\end{aligned}
$$

Now, the mapping $x \mapsto S^{-1}(x,t_j)$ is bi-Lipschitz on $\mathbb{R}^n$, so that the inner double integral here is bounded by

$$
C\int_0^1 \int_{\mathbb{R}^n} |\nabla\psi^\delta(x+\theta T(x),t)|^4 dxd\theta,
$$

where $T(x) = S^{-1}(S(x,t_j),t_{j+1}) - x$. It is easy to check from the definitions (2.4) and the condition (1.8) that $\|\nabla T\|_{L^\infty}$ is arbitrarily small if t_{j+1} is sufficiently close to t_j, i.e., if J is sufficiently large. The mapping $x \mapsto x + \theta T(x)$ is then one-to-one (and bi-Lipschitz) on $\mathbb{R}^n$, so that the change of variables $y = x + \theta T(x)$ is valid. The inner double integral above is thus bounded by $C\int |\nabla\psi^\delta(x,t)|^4 dx$, and therefore

$$
|E_1| \le C\left(\iint |z|^2 dxdt\right)^{1/2} \int_0^T t^{1/2} \|\nabla\overline{F}(\cdot,t)\|_{L^4} \|\nabla\psi^\delta(\cdot,t)\|_{L^4} dt
$$

by Lemma 2.3(d). Finally we apply the standard Sobolev embedding $H^1(\mathbb{R}^3) \to$

$L^4(\mathbb{R}^3)$ for $n = 3$ to obtain

$$
\begin{aligned}
|E_1| &\leq C \left(\iint |z|^2 dxdt \right)^{1/2} \int_0^T t^{1/2} \|\nabla \overline{F}(\cdot,t)\|_{L^4} \left(\int |\nabla \psi^\delta|^2 dx \right)^{1/8} \left(\int |D_x^2 \psi^\delta|^2 \right)^{3/8} dt \\
&\leq C \left(\iint |z|^2 dxdt \right)^{1/2} \left(\iint |G|^2 dxdt \right)^{1/8} \left(\int t^{4/5} \|\nabla \overline{F}(\cdot,t)\|_{L^4}^{8/5} dt \right)^{5/8} \\
&\qquad \times \left(\iint |D_x^2 \psi^\delta|^2 dxdt \right)^{3/8} \\
&\leq \left(\iint |z|^2 dxdt \right)^{1/2} \left(\iint |G|^2 dxdt \right)^{1/2} \left(\int_0^T \beta(t) dt \right)^{5/8},
\end{aligned}
$$

where $\beta(t) = Ct^{4/5} \|\nabla \overline{F}(\cdot,t)\|_{L^4}^{8/5}$, which is in $L^1((0,T))$ by the hypothesis (1.12). A similar bound holds for $n = 2$. More generally, we can define $E_1(t_1,t_2)$ to be the integral in (3.5), but with $[0,T]$ replaced by $[t_1,t_2] \subseteq [0,T]$. It is then clear from the above analysis that

$$
|E_1(t_1,t_2)| \leq \left(\int_0^{t_2} \int |z|^2 dxdt \right)^{1/2} \left(\int_0^{t_2} \int |G|^2 dxdt \right)^{1/2} \left(\int_{t_1}^{t_2} \beta(t) dt \right)^s \tag{3.13}
$$

for the same β and s, where β is determined solely by the properties of (ρ, u, f) and $(\overline{\rho}, \overline{u}, \overline{f})$ and s is determined by n. In particular, C, β, and s are independent of G, t_1, and t_2.

The term E_3 is bounded in almost the same way as E_1 (the hypothesis on the second term in (1.12) is required here), and the bound for E_5 is trivial. For E_6 we first define the divided difference

$$
a(x,t) = \int_0^1 P'(\rho(x,t) + \theta(\overline{\rho}(x,t) - \rho(x,t))) d\theta
$$

as in (1.16). Then for $\varphi \in \mathcal{D}(\mathbb{R}^n)$ and at a fixed time t,

$$
\begin{aligned}
\left| \int_{\mathbb{R}^n} [P(\rho) - P(\overline{\rho})] \varphi dx \right| &= \left| \int_{\mathbb{R}^n} a(\rho - \overline{\rho}) \varphi dx \right| \\
&\leq \|(\rho - \overline{\rho})(\cdot,t)\|_{H^{-1}} \|a\varphi\|_{H^1} \\
&\leq C \|(\rho - \overline{\rho})(\cdot,t)\|_{H^{-1}} \left(\|\varphi\|_{H^1} + \|\varphi \nabla a\|_{L^2} \right).
\end{aligned}
$$

Now, for an ideal isothermal fluid, $P(\rho) = K\rho$, a is constant, and $\nabla a = 0$. For more general P we apply the hypothesis (1.16) for the case $n = 3$ that $\nabla a \in L^3$ and the embedding $H^1 \to L^6$ to obtain

$$
\|\varphi \nabla a\|_{L^2} \leq \|\varphi\|_{L^6} \|\nabla a\|_{L^3} \leq C \|\nabla \varphi\|_{L^2} \leq C \|\varphi\|_{H^1}.
$$

A similar result holds for $n = 2$. It follows that

$$
\|(P(\rho) - P(\overline{\rho}))(\cdot,t)\|_{H^{-1}} \leq C \|(\rho - \overline{\rho})(\cdot,t)\|_{H^{-1}}
$$

when either $P(\rho) = K\rho$ or for more general P when (1.16) holds. Thus in either case,

$$
\begin{aligned}
|E_6| &\leq \int_0^T \|P(\rho) - P(\overline{\rho})\|_{H^{-1}} \|\operatorname{div} \psi^\delta\|_{H^1} dt \\
&\leq CT^{1/2} \sup_{0 \leq t \leq T} \|(\rho - \overline{\rho})(\cdot,t)\|_{H^{-1}} \left(\iint |G|^2 dxdt \right)^{1/2}
\end{aligned} \tag{3.14}
$$

by Lemma 3.1. In order to complete the bound for E_6 we therefore need to obtain a bound for $\|\rho-\overline{\rho}\|_{H^{-1}}$. Again let $\varphi\in\mathcal{D}(\mathbb{R}^n)$ so that at a fixed time,

$$\begin{aligned}\left|\int(\rho-\overline{\rho})\varphi dx\right| &= \left|\int\left[\rho\varphi-(\overline{\rho}\circ S)(\varphi\circ S)|\det\nabla S|\right]dx\right|\\ &= \left|\int\rho(\varphi-A_0(\varphi\circ S))dx\right|\\ &\le \int\rho|\varphi-\varphi\circ S|dx+\int\rho|\varphi\circ S|\,|1-A_0|dx\end{aligned}$$

by Lemma 2.3(c) and the definition (3.2). An argument similar to that given above in the bound for E_1 shows that the first term on the right here is bounded by

$$Ct^{1/2}\left(\iint|z|^2dxdt\right)^{1/2}\left(\int|\nabla\varphi|^2dx\right)^{1/2},$$

and the second term is clearly bounded by $C\|\rho_0-\overline{\rho}_0\|_{L^2}\|\varphi\|_{L^2}$, by (3.12). We thus obtain that

$$\sup_{0\le t\le T}\|(\rho-\overline{\rho})(\cdot,t)\|_{H^{-1}}\le C\left[\|\rho_0-\overline{\rho}_0\|_{L^2}+T^{1/2}\left(\iint|z|^2dxdt\right)^{1/2}\right], \tag{3.15}$$

and, substituting into (3.14), that

$$|E_6|\le CT^{1/2}\left[\|\rho_0-\overline{\rho}_0\|_{L^2}+\left(\iint|z|^2dxdt\right)^{1/2}\right]\left(\iint|G|^2dxdt\right)^{1/2}.$$

Combining all the above bounds, we conclude from (3.11) that

$$\left|\int_0^T\int z\cdot Gdxdt\right|\le C\left[M_0\left(\int_0^T\int|G|^2dxdt\right)^{1/2}+E_1(0,T)\right], \tag{3.16}$$

where

$$\begin{aligned}M_0 &= \|\rho_0-\overline{\rho}_0\|_{L^2\cap L^{2p}}+\|\rho_0u_0-\overline{\rho}_0\overline{u}_0\|_{L^2}\\ &\quad+\left(\int_0^T\int|f-\overline{f}\circ S|^2dxdt\right)^{1/2}+T^{1/2}\left(\int_0^T\int|z|^2dxdt\right)^{1/2},\end{aligned}$$

E_1 is as in (3.13), and C is now fixed.

We note that (3.16) holds with T replaced by any time $\tau\le T$ with the same constant C, and we recall that β and s in (3.13) are fixed and are independent of G. To complete the bound for z we therefore choose a time $\tau>0$ so that $\left(\int_{t_1}^{t_2}\beta\right)^s\le 1/(2C)$ when $0\le t_2-t_1\le\tau$. Then applying (3.16) with T replaced by τ and bounding $E_1(0,\tau)$ as in (3.13), we obtain that

$$\left(\int_0^\tau\int|z|^2dxdt\right)^{1/2}\le 2CM_0$$

and as a consequence that

$$|E_1(0,\tau)| \le M_0 \left(\int_0^\tau \int |G|^2 dx dt \right)^{1/2}$$

for any G, again by (3.13). We now apply (3.16) with T replaced by 2τ:

$$\begin{aligned}
\left| \int_0^{2\tau} \int z \cdot G dx dt \right| &\le CM_0 \left(\int_0^{2\tau} \int |G|^2 dx dt \right)^{1/2} + C[E_1(0,\tau) + E_1(\tau, 2\tau)] \\
&\le 2CM_0 \left(\int_0^{2\tau} \int |G|^2 dx dt \right)^{1/2} \\
&\quad + C \left(\int_0^{2\tau} \int |z|^2 dx dt \right)^{1/2} \left(\int_0^{2\tau} \int |G|^2 dx dt \right)^{1/2} \cdot (2C)^{-1}
\end{aligned}$$

by (3.13), so that

$$\left(\int_0^{2\tau} \int |z|^2 dx dt \right)^{1/2} \le 4CM_0.$$

Since $\tau > 0$ is fixed, we can exhaust $[0,T]$ in a finite number of such steps to obtain that $\left(\int_0^T \int |z|^2 \right)^{1/2} \le CM_0$ for a new constant C. The term $T^{1/2} \left(\int_0^T \int |z|^2 \right)^{1/2}$ can then be eliminated from the definition of M_0 by a Gronwall-type argument. This together with (3.15) then proves the required bound (1.15), but with $u - \overline{u}$ replaced by $z = u - \overline{u} \circ S$. However, by Lemma 2.3(d) and the assumed bound for the second term in (1.12),

$$\begin{aligned}
\iint |\overline{u} - \overline{u} \circ S|^2 dx dt &\le \int \|\nabla \overline{u}(\cdot,t)\|_{L^\infty}^2 \int |x - S(x,t)|^2 dx dt \\
&\le C \left(\int t \|\nabla \overline{u}(\cdot,t)\|_{L^\infty}^2 dt \right) \left(\iint |z|^2 dx dt \right) \\
&\le C \iint |z|^2 dx dt,
\end{aligned}$$

which has just been shown to satisfy the bound in (1.15). This completes the proof of the theorem. $\square$

Proof of Lemma 3.1. We omit the superscripts. Multiplying the differential equation in (3.8) by ψ^j and adding the equation $\frac{1}{2}|\psi|^2(\rho_t + \operatorname{div}(\rho u)) = 0$, we obtain

$$\left(\tfrac{1}{2}\rho|\psi|^2 \right)_t + \operatorname{div}\left(\tfrac{1}{2}\rho|\psi|^2 u \right) + \psi \cdot (\mu \Delta \psi + \lambda \nabla \operatorname{div} \psi) = \psi \cdot G,$$

from which it follows easily that

$$\sup_{0 \le t \le T} \int |\psi(x,t)|^2 dx + \int_0^T \int_{\mathbb{R}^n} |\nabla \psi|^2 dx dt \le C \int_0^T \int_{\mathbb{R}^n} |G|^2 dx dt,$$

since $C^{-1} \le \rho \le C$. Next, writing $\dot{\psi} = \psi_t + \nabla \psi u$, we obtain from (3.8) that

$$\rho |\dot{\psi}|^2 + \left(\tfrac{1}{2}\mu |\Delta \psi|^2 + \tfrac{1}{2}\lambda (\operatorname{div} \psi)^2 \right) + \{\dots\}_x \le \psi \cdot G + C|\nabla \psi|^2 |\nabla u|,$$

so that

$$\sup_{0\le t\le T}\int|\nabla\psi(x,t)|^2dx+\int_0^T\int|\dot\psi|^2dxdt\le C\int_0^T\int|G|^2dxdt \tag{3.17}$$

since $\nabla u\in L^1((0,T);L^\infty(\mathbb{R}^n))$ by (1.8). It then follows from (3.8) that

$$\iint|\mu\Delta\psi+\lambda\operatorname{div}\psi|^2dxdt\le C\iint|G|^2dxdt$$

and therefore that

$$\iint|D_x^2\psi|^2dxdt\le C\iint|G|^2dxdt$$

because the operator $\mu\Delta+\lambda\nabla\mathrm{div}$ is elliptic. This proves (3.9). The a priori bound required for the proof of (3.10) is similar but slightly more technical: we take the convective derivative in (3.8) then multiply by $\operatorname{sgn}(\dot{\psi^j})|\dot{\psi^j}|^{s-1}$, where $s>n$, to obtain a bound for $\sup_t\int|\dot\psi|^sdx$. This gives a bound for $\sup_t\int|D_x^2\psi|^sdx$, as above, hence a bound for $\sup_t\|\nabla\psi(\cdot,t)\|_{L^\infty}$. $\square$

A NONLINEAR FOURTH-ORDER PARABOLIC EQUATION WITH NONHOMOGENEOUS BOUNDARY CONDITIONS*

MARIA PIA GUALDANI†, ANSGAR JÜNGEL†, AND GIUSEPPE TOSCANI‡

Abstract. A nonlinear fourth-order parabolic equation with nonhomogeneous Dirichlet–Neumann boundary conditions in one space dimension is analyzed. This equation appears, for instance, in quantum semiconductor modeling. The existence and uniqueness of strictly positive classical solutions to the stationary problem are shown. Furthermore, the existence of global nonnegative weak solutions to the transient problem is proved. The proof is based on an exponential transformation of variables and new "entropy" estimates. Moreover, it is proved by the entropy–entropy production method that the transient solution converges exponentially fast to its steady state in the L^1 norm as time goes to infinity, under the condition that the logarithm of the steady state is concave. Numerical examples show that this condition seems to be purely technical.

Key words. fourth-order parabolic equation, fourth-order elliptic equation, existence and uniqueness of nonnegative solutions, entropy–entropy production method, exponential decay in time

1. Introduction.

In recent years, the nonlinear fourth-order parabolic equation

$$u_t + (u(\log u)_{xx})_{xx} = 0, \quad u(\cdot, 0) = u_I \geq 0 \quad \text{in } \Omega,\ t > 0, \tag{1.1}$$

in a bounded interval $\Omega = (0, 1)$ with periodic or Dirichlet–Neumann boundary conditions or in the whole space $\Omega = \mathbb{R}$, has attracted the interest of many mathematicians since it possesses some interesting mathematical properties. For instance, the solutions are nonnegative, there are several Lyapunov functionals, and related logarithmic Sobolev inequalities can be derived [4, 10].

Equation (1.1) was first derived in the context of fluctuations of a stationary nonequilibrium interface [9]. It also appears as an approximation of the so-called quantum drift-diffusion model for semiconductors [1], which can be derived by a quantum moment method from a Wigner-BGK (Bhatnagar–Gross–Krook) equation [8]. More precisely, the quantum drift-diffusion model for the electron density u and the electron current density J reads as

$$u_t - J_x = 0, \quad J = -\frac{\varepsilon^2}{2} u \left(\frac{(\sqrt{u})_{xx}}{\sqrt{u}} \right)_x + T u_x + uE,$$

where ε is the scaled Planck constant, T the temperature, and $E = E(x, t)$ the electric field. Then (1.1) follows from this equation for $\varepsilon = 1$, zero temperature, and zero electric field since $u((\sqrt{u})_{xx}/\sqrt{u})_x = 2(u(\log u)_{xx})_x$.

The first analytical result for (1.1) has been presented in [4]; more precisely, the existence of local-in-time positive classical solutions with periodic boundary conditions has been proved. This result has been generalized to global nonnegative weak solutions in [10]. The existence of global weak periodic solutions in several space dimensions has been proved very recently employing Wasserstein space techniques [12].

In quantum semiconductor modeling, Dirichlet–Neumann boundary conditions of the type

$$u(0,t) = u(1,t) = 1, \quad u_x(0,t) = u_x(1,t) = 0, \quad t > 0, \tag{1.2}$$

have been employed to model resonant tunneling diodes in $\Omega = (0,1)$ [14]. Here, the function $u(x,t)$ signifies the (nonnegative) electron density in the semiconductor device. The existence of global weak solutions to (1.1)–(1.2) has been proved in [13].

The boundary conditions (1.2) simplify the analysis considerably. Indeed, one of the main ideas of the existence proof is to employ an exponential transformation of variables, $u = e^y$. In the new variable y, the boundary conditions are homogeneous. Thus, using, for instance, the test function y in the weak formulation of (1.1), no integrals with boundary data appear.

The boundary conditions (1.2) follow from physical considerations like the charge neutrality at the boundary contacts, i.e., $u - C = 0$ at $x = 0, 1$, where $C = C(x)$ models fixed background charges. Numerical results show that the Neumann boundary conditions for the density u should be nonhomogeneous for ultrasmall semiconductor devices (see section 4 in [16]). Moreover, when the values of the doping profile $C(x)$ are different at the contacts, the Dirichlet boundary conditions satisfy $u(0,t) \neq u(1,t)$. Therefore, we wish to study the more general *nonhomogeneous* boundary conditions

$$u(0,t) = u_0, \quad u(1,t) = u_1, \quad u_x(0,t) = w_0, \quad u_x(1,t) = w_1, \quad t > 0, \tag{1.3}$$

where u_0, $u_1 > 0$ and w_0, $w_1 \in \mathbb{R}$. The treatment of the nonhomogeneities is also interesting from a mathematical point of view. Indeed, almost all results for (1.1) (and for related fourth-order equations like the thin-film model [3]) are shown only for periodic or no-flux boundary conditions or for whole-space problems, in order to avoid integrals with boundary data. In this paper, we show how to deal with nonhomogeneous boundary conditions for (1.1).

More precisely, we show (i) the existence and uniqueness of a classical positive solution u_∞ to the stationary problem corresponding to (1.1), (ii) the existence of global nonnegative weak solutions $u(\cdot,t)$ to the transient problem (1.1), (1.3), and (iii) the exponential convergence of $u(\cdot,t)$ to its steady state u_∞ as $t \to \infty$ in the L^1 norm, under the assumption that the boundary data is such that $\log u_\infty$ is concave. The long-time behavior is illustrated by numerical experiments. Notice that this is the first result of the *stationary* problem corresponding to (1.1) in the literature (if (1.2) or periodic boundary conditions are assumed, the steady state is constant). We also remark that the Wasserstein techniques of [12] cannot be applied to (1.1), (1.3) since this technique relies on the conservation of the L^1 norm which is not the case here.

The long-time behavior of solutions to (1.1) has been studied for periodic boundary conditions [5, 10] and for the boundary conditions (1.2) [15]. In particular, it could be shown that the solutions converge exponentially fast to their (constant) steady states. The decay rate has been numerically computed in [6]. No results are available up to now for the case of the nonhomogeneous boundary conditions (1.3).

Our first main result is the existence and uniqueness of stationary solutions needed in the existence proof for the transient problem.

THEOREM 1.1. *Let u_0, $u_1 > 0$ and w_0, $w_1 \in \mathbb{R}$. Then there exists a unique classical solution $u \in C^\infty([0,1])$ to*

$$(u(\log u)_{xx})_{xx} = 0 \quad \text{in } (0,1), \quad u(0) = u_0,\ u(1) = u_1, \\ u_x(0) = w_0,\ u_x(1) = w_1, \tag{1.4}$$

satisfying $u(x) \geq m > 0$ for all $x \in [0,1]$, and the constant $m > 0$ depends only on the boundary data.

The existence proof is based on a fixed-point argument and appropriate a priori estimates, using the structure of the equation and the one-dimensionality heavily. More precisely, we perform the exponential transformation $u = e^y$ and write the equation in (1.4) as $y_{xx} = (ax+b)e^{-y}$ for some a, $b \in \mathbb{R}$. The key point is to derive uniform bounds on a and b. This implies a uniform H^1 bound for y and, in view of the one-dimensionality, a uniform L^∞ bound for $y = \log u$, hence showing the positivity of u. For the uniqueness we employ a monotonicity property of the operator $\sqrt{u} \mapsto -(u(\log u)_{xx})_{xx}/(2\sqrt{u})$ for suitable functions u (the monotonicity property was first observed in [13]).

The second main result is the existence of solutions to the transient problem. For simplicity, we consider time-independent boundary data only.

THEOREM 1.2. *Let u_0, $u_1 > 0$ and w_0, $w_1 \in \mathbb{R}$. Let $u_I(x) \geq 0$ be integrable such that $\int_0^1 (u_I - \log u_I)dx < \infty$. Then there exists a weak solution u to* (1.1), (1.3) *satisfying $u(x,t) \geq 0$ in $(0,1) \times (0,\infty)$ and*

$$u \in L^{5/2}_{\text{loc}}(0,\infty; W^{1,1}(0,1)) \cap W^{1,10/9}_{\text{loc}}(0,\infty; H^{-2}(0,1)),\ \log u \in L^2_{\text{loc}}(0,\infty; H^2(0,1)).$$

For the proof of this theorem we semidiscretize (1.1) in time and solve at each time step a nonlinear elliptic problem. The main difficulty is to obtain uniform estimates. The idea of [13] is to derive these estimates from a special Lyapunov functional,

$$E_1(t) = \int_0^1 \left(\frac{u}{u_\infty} - \log \frac{u}{u_\infty} \right) dx,$$

which is also called an "entropy" functional. Indeed, a formal computation (made precise in section 3) shows that

$$\frac{dE_1}{dt} + \int_0^1 (\log u)^2_{xx} dx = \int_0^1 u(\log u)_{xx} \left(\frac{1}{u_\infty} \right)_{xx} dx, \tag{1.5}$$

implying that E_1 is nonincreasing if $(1/u_\infty)_{xx} = 0$, which is the case in [13] where $u_\infty = \text{const}$ holds. However, in the general case $(1/u_\infty)_{xx} \neq 0$, the right-hand side of (1.5) still needs to be estimated.

The key idea is to employ the *new* "entropy"

$$E_2(t) = \int_0^1 (\sqrt{u} - \sqrt{u_\infty})^2 dx.$$

A formal computation yields

$$\frac{dE_2}{dt} + 2\int_0^1 \left(\sqrt[4]{\frac{u_\infty}{u}} (\sqrt{u})_{xx} - \sqrt[4]{\frac{u}{u_\infty}} (\sqrt{u_\infty})_{xx} \right)^2 dx = 0. \tag{1.6}$$

With this estimate the right-hand side of (1.5) can be treated. Indeed, the above entropy production integral allows us to find the bound

$$\int_0^1 \left(\sqrt{u}(\log u)_{xx}^2 + (\sqrt[8]{u})_x^4\right) dx \le c \tag{1.7}$$

for some constant $c > 0$ depending only on the boundary data; see Lemma 3.2 for details. (Here and in the following, the notation $(f(u))_x^4$ means $[(f(u))_x]^4$.) Then, using Young's inequality, the right-hand side of (1.5) is bounded from above by

$$\int_0^1 \sqrt{u}(\log u)_{xx}^2 dx + \|1/u_\infty^2\|_{W^{2,\infty}(0,1)} \int_0^1 u^{3/2} dx,$$

which is bounded in view of (1.7). We stress the fact that this idea is new in the literature.

The above estimates are only valid if u is nonnegative. However, no maximum principle is generally available for fourth-order equations. We prove the nonnegativity property by employing the same idea as in the stationary case: after introducing an exponential variable $u = e^y$, we obtain a uniform H^2 bound by (1.5) and (1.7) and hence an L^∞ bound for $y = \log u$, which shows that u is positive. Letting the parameter of the time discretization tend to zero, we conclude the nonnegativity of u.

We notice that, interestingly, the new entropy E_2 is connected with the monotonicity property of $\sqrt{u} \mapsto -(u(\log u)_{xx})_{xx}/(2\sqrt{u})$ since the proof of this property also relies on the estimate (1.6) (see Lemma 2.3 in [13] and (2.7) below).

The physical (relative) entropy

$$E_3(t) = \int_0^1 \left(u \log \frac{u}{u_\infty} - u + u_\infty\right) dx$$

is still another Lyapunov functional. It is used in the proof of the long-time behavior of solutions, which is our final main result.

THEOREM 1.3. *Let the assumptions of Theorem* 1.2 *hold and let* $\int_0^1 u_I(\log u_I - 1)dx < \infty$. *Let* u *be the solution to* (1.1), (1.3) *constructed in Theorem* 1.2 *and let* u_∞ *be the unique solution to* (1.4). *We assume that the boundary data is such that* $\log u_\infty$ *is concave. Then there exist constants* $c, \lambda > 0$ *depending only on the boundary and initial data such that for all* $t > 0$,

$$\|u(\cdot, t) - u_\infty\|_{L^1(0,1)} \le ce^{-\lambda t}.$$

In order to prove this result, we take formally the time derivative of the relative entropy E_3. It can be shown (see section 4 for details) that the assumption $(\log u_\infty)_{xx} \le 0$ allows us to derive

$$\frac{dE_3}{dt} + P \le 0,$$

where $P \ge 0$ denotes the entropy production term involving second derivatives of u. This term can be estimated similarly as in [15] in terms of the entropy yielding

$$\frac{dE_3}{dt} + 2\lambda E_3 \le 0$$

for some $\lambda > 0$. Gronwall's inequality implies the exponential convergence in terms of the relative entropy. A Csiszar–Kullback-type inequality then gives the assertion. The assumption on the concavity of $\log u_\infty$ can be slightly relaxed (see Remark 4.4).

The paper is organized as follows. Section 2 is devoted to the proof of Theorem 1.1. Then the existence of transient solutions (Theorem 1.2) is shown in section 3. Theorem 1.3 is proved in section 4, and finally in section 5, some numerical results are presented.

2. Existence and uniqueness of stationary solutions. In this section we will prove Theorem 1.1. First, we perform the transformation of variables $y = \log u$ and consider the problem

$$(e^y y_{xx})_{xx} = 0 \quad \text{in } (0,1), \quad y(0) = y_0,\ y(1) = y_1,\ y_x(0) = \alpha,\ y_x(1) = \beta, \tag{2.1}$$

where $y_0 = \log u_0$, $y_1 = \log u_1$, $\alpha = w_0/u_0$, and $\beta = w_1/u_1$. Clearly, any classical solution of (2.1) is a positive classical solution of (1.4). We show first some a priori estimates for the solution of (2.1).

LEMMA 2.1. *Let y be a classical solution to* (2.1). *Then*

$$y(x) \le M := \max\{y_0, y_1\} + |\alpha| + |\beta|. \tag{2.2}$$

Proof. First we observe that there exist constants a, $b \in \mathbb{R}$ such that y solves the equation $y_{xx} = (ax+b)e^{-y}$. This implies that y_{xx} can change its sign at most once. In the following we consider several cases for the sign of $y_{xx}(0)$ and $y_{xx}(1)$.

First case. Let $y_{xx}(0) \ge 0$ and $y_{xx}(1) \ge 0$. Since y_{xx} can change the sign at most once it follows that $y_{xx} \ge 0$ in $(0,1)$. We conclude that $y(x) \le \max\{y_0, y_1\}$ for all $x \in [0,1]$.

Second case. Let $y_{xx}(0) \ge 0$ and $y_{xx}(1) < 0$. There exists $x_1 \in [0,1)$ such that $y_{xx}(x_1) = 0$. Therefore, $ax + b \ge 0$ for all $x \in [0, x_1]$ and $ax + b \le 0$ for all $x \in [x_1, 1]$. A Taylor expansion gives for all $x \in [x_1, 1]$

$$\begin{aligned} y(x) &= y(1) + y_x(1)(x-1) + \int_x^1 (s-x) y_{xx}(s)\,ds \\ &= y_1 + \beta(x-1) + \int_x^1 (s-x)(as+b)e^{-y(s)}ds \le \max\{y_0, y_1\} + |\beta|. \end{aligned}$$

We claim that $y(x) \le \max\{y_0, y_1\} + |\beta|$ holds for all $x \in [0, x_1]$. For this, let $x_2 \in [0, x_1]$ be such that $y(x_2) = \max\{y(x) : x \in [0, x_1]\}$. Suppose that $y(x_2) > \max\{y_0, y_1\} + |\beta|$. Then $x_2 \in (0, x_1)$ and, since $y(x)$ reaches a maximum at the interior point x_2, $y_{xx}(x_2) \le 0$. Since $x_2 \in (0, x_1)$, we have $y_{xx}(x_2) = (ax_2 + b)e^{-y(x_2)} \ge 0$. This shows that $y_{xx}(x_2) = 0$. But then $y_{xx}(x_2) = (ax_2 + b)e^{-y(x_2)}$ implies that $ax_2 + b = 0$. Since also $ax_1 + b = 0$, it follows that $a = b = 0$ and thus $y_{xx}(x) = 0$ for all $x \in [0,1]$; this is a contradiction to $y_{xx}(1) < 1$. Hence, $y(x) \le \max\{y_0, y_1\} + |\beta|$ for all $x \in [0,1]$.

Third case. Let $y_{xx}(0) < 0$ and $y_{xx}(1) \ge 0$. By similar arguments as in the second case, it can be shown that $y(x) \le \max\{y_0, y_1\} + |\alpha|$ for all $x \in [0,1]$.

Fourth case. Let $y_{xx}(0) < 0$ and $y_{xx}(1) < 0$. This implies that $ax + b < 0$ for all $x \in [0,1]$ and, by a Taylor expansion,

$$y(x) = y_0 + \alpha x + \int_0^x (x-s)(as+b)e^{-y(s)}ds \le y_0 + |\alpha|, \quad x \in [0,1].$$

The lemma is proved. ∎

LEMMA 2.2. *Let y be a classical solution to* (2.1). *Then there exists a constant $K > 0$ depending only on y_0, y_1, α, and β such that*

$$\|y\|_{H^2(0,1)} \le K.$$

Proof. There exist constants a, $b \in \mathbb{R}$ such that y solves the equation

$$y_{xx} = (ax+b)e^{-y} \quad \text{in } (0,1), \tag{2.3}$$

and $b = e^{y_0} y_{xx}(0)$, $a = e^{y_1} y_{xx}(1) - e^{y_0} y_{xx}(0)$. In order to obtain a uniform estimate for y_{xx} we first have to find uniform estimates for a and b. For this, we multiply (2.3) by y_x^2 and integrate over $(0,1)$:

$$\int_0^1 (ax+b)e^{-y} y_x^2 dx = \int_0^1 y_{xx} y_x^2 dx = \frac{1}{3}\int_0^1 (y_x^3)_x dx = \frac{1}{3}(\beta^3 - \alpha^3).$$

Next we multiply (2.3) by y_{xx}, integrate over $(0,1)$, integrate by parts, and use the above equality:

$$\begin{aligned}\int_0^1 y_{xx}^2 dx &= \int_0^1 (ax+b)e^{-y} y_{xx} dx \\ &= \int_0^1 (ax+b)e^{-y} y_x^2 dx - a\int_0^1 e^{-y} y_x dx + [(ax+b)e^{-y(x)} y_x(x)]_0^1 \\ &= \frac{1}{3}(\beta^3 - \alpha^3) + a(e^{-y_1} - e^{-y_0}) + (a+b)e^{-y_1}\beta - be^{-y_0}\alpha.\end{aligned}$$

By Young's inequality this becomes

$$\int_0^1 y_{xx}^2 dx \le C + \frac{1}{60}e^{-2M} a^2 + \frac{1}{12}e^{-2M} b^2, \tag{2.4}$$

where $C := (\beta^3 - \alpha^3)/3 + 15e^{2M}((1+\beta)e^{-y_1} - e^{-y_0})^2 + 3e^{2M}(\beta e^{-y_1} - \alpha e^{-y_0})^2$. Taking the square of (2.3) and integrating over $(0,1)$ yields, by Lemma 2.1,

$$\begin{aligned}\int_0^1 y_{xx}^2 dx &= \int_0^1 (ax+b)^2 e^{-2y} dx \ge e^{-2M}\int_0^1 (ax+b)^2 dx \\ &= \frac{1}{3}e^{-2M}(a^2 + 3ab + 3b^2) \ge \frac{1}{3}e^{-2M}\left(\frac{a^2}{10} + \frac{b^2}{2}\right),\end{aligned} \tag{2.5}$$

where we have used the Young inequality $3ab \ge -9a^2/10 - 5b^2/2$. Putting together (2.4) and (2.5), we obtain

$$\frac{a^2}{10} + \frac{b^2}{2} \le 3e^{2M}\int_0^1 y_{xx}^2 dx \le 3e^{2M} C + \frac{a^2}{20} + \frac{b^2}{4}. \tag{2.6}$$

Therefore, a and b are bounded by a constant which depends only on y_0, y_1, α, and β. By (2.4) this gives a uniform estimate for $\|y_{xx}\|_{L^2(0,1)}$ and, employing Poincaré's inequality, also for $\|y\|_{H^2(0,1)}$. ◻

Proof of Theorem 1.1. We wish to employ the Leray–Schauder fixed-point theorem. For this let $\sigma \in [0,1]$ and $z \in H^1(0,1)$ and let $y \in H^2(0,1)$ be the unique solution of

$$(e^z y_{xx})_{xx} = 0 \quad \text{in } (0,1), \quad y(0) = \sigma y_0,\ y(1) = \sigma y_1,\ y_x(0) = \sigma\alpha,\ y_x(1) = \sigma\beta.$$

This defines a fixed-point operator $S : H^1(0,1) \times [0,1] \to H^1(0,1)$, $S(z,\sigma) = y$. Clearly, $S(z,0) = 0$ for all z. Moreover, by standard arguments, S is continuous and compact, since the embedding $H^2(0,1) \hookrightarrow H^1(0,1)$ is compact. It remains to show that there exists a constant $K > 0$ such that for all $\sigma \in [0,1]$ and for any fixed point y of $S(\cdot,\sigma)$, the estimate $\|y\|_{H^1(0,1)} \le K$ holds. Lemma 2.2 settles the case $\sigma = 1$. For $\sigma < 1$, a similar proof as in Lemma 2.2 shows the existence of a constant $K > 0$ such that $\|y\|_{H^2(0,1)} \le K$ holds. By the Leray–Schauder theorem, this proves the existence of a solution $y \in H^2(0,1)$ to (2.1).

Actually, the solution y is a classical solution. Indeed, y satisfies $y_{xx} = (ax + b)e^{-y} \in H^2(0,1)$ for some a, $b \in \mathbb{R}$, and hence, $y \in H^4(0,1)$. By bootstrapping, $y \in H^n(0,1)$ for all $n \in \mathbb{N}$ and y is a classical solution.

In order to prove the uniqueness of solutions, we extend an idea of [13]. Let u_1 and u_2 be two positive classical solutions to (1.4). We multiply (1.4) for u_1 by $1 - \sqrt{u_2/u_1}$ and (1.4) for u_2 by $\sqrt{u_1/u_2} - 1$, integrate, and take the difference. This yields, by integrating by parts,

$$
\begin{aligned}
(2.7)\quad 0 &= \int_0^1 \Big[(u_1(\log u_1)_{xx})_{xx}(1 - \sqrt{u_2/u_1}) - (u_2(\log u_2)_{xx})_{xx}(\sqrt{u_1/u_2} - 1)\Big]\,dx \\
&= 2\int_0^1 \Big[(\sqrt{u_1})_{xxxx} - \frac{1}{\sqrt{u_1}}(\sqrt{u_1})_{xx}^2 - (\sqrt{u_2})_{xxxx} \\
&\qquad\qquad + \frac{1}{\sqrt{u_2}}(\sqrt{u_2})_{xx}^2\Big](\sqrt{u_1} - \sqrt{u_2})dx \\
&= 2\int_0^1 \Big[((\sqrt{u_1})_{xx} - (\sqrt{u_2})_{xx})(\sqrt{u_1} - \sqrt{u_2})_{xx} \\
&\quad - (\sqrt{u_1})_{xx}^2\left(1 - \sqrt{\tfrac{u_2}{u_1}}\right) + (\sqrt{u_2})_{xx}^2\left(\sqrt{\tfrac{u_1}{u_2}} - 1\right)\Big]dx \\
&= 2\int_0^1 \left(\sqrt[4]{\frac{u_2}{u_1}}(\sqrt{u_1})_{xx} - \sqrt[4]{\frac{u_1}{u_2}}(\sqrt{u_2})_{xx}\right)^2.
\end{aligned}
$$

Therefore,

$$0 = \sqrt[4]{\frac{u_2}{u_1}}(\sqrt{u_1})_{xx} - \sqrt[4]{\frac{u_1}{u_2}}(\sqrt{u_2})_{xx} \quad \text{in } (0,1).$$

Writing $u_1 = e^{y_1}$ and $u_2 = e^{y_2}$, this identity is equal to

$$
\begin{aligned}
0 &= e^{(y_2-y_1)/4}(e^{y_1/2})_{xx} - e^{(y_1-y_2)/4}(e^{y_2/2})_{xx} \\
&= \frac{1}{2}e^{(y_2+y_1)/4}\left(y_{1,xx} + \frac{1}{2}y_{1,x}^2\right) - \frac{1}{2}e^{(y_1+y_2)/4}\left(y_{2,xx} + \frac{1}{2}y_{2,x}^2\right),
\end{aligned}
$$

and hence

$$(2.8)\qquad y_{1,xx} - y_{2,xx} = -\frac{1}{2}(y_{1,x}^2 - y_{2,x}^2) \quad \text{in } (0,1).$$

We integrate this equation over $(0, x_0)$, use the boundary condition $y_{1x}(0) = y_{2x}(0)$, and take the supremum,

$$\|(y_1 - y_2)_x\|_{L^\infty(0,x_0)} \le \int_0^{x_0} |(y_1 + y_2)_x| \cdot |(y_1 - y_2)_x| dx \le x_0 L \|(y_1 - y_2)_x\|_{L^\infty(0,x_0)},$$

where $L = \|y_{1,x}\|_{L^\infty(0,1)} + \|y_{2,x}\|_{L^\infty(0,1)}$. Choosing $x_0 = 1/2L$ gives $(y_1 - y_2)_x = 0$ and hence $y_1 - y_2 = 0$ in $[0, x_0]$. In particular, $(y_1 - y_2)_x(x_0) = 0$. Therefore, integrating (2.8) over $(x_0, 2x_0)$ we obtain by the same arguments that $y_1 - y_2 = 0$ in $[x_0, 2x_0]$.

After a finite number of steps we achieve $y_1 - y_2 = 0$ in $[0,1]$. This proves the uniqueness of solutions. ∎

Remark 2.3. Equation (2.3) with $y(0) = y(1)$ and $y_x(0) = -y_x(1) \le 0$ is formally related to a combustion problem. Indeed, the boundary conditions imply that y is symmetric around $x = \frac{1}{2}$ and that $y(x) \le y(0) = y_0$ holds for any $x \in [0,1]$. The symmetry implies further $a = e^{y_0}(y_{xx}(1) - y_{xx}(0)) = 0$ and moreover, $b = e^{y_0} y_{xx}(0) \ge 0$. Thus we can write (2.3) as $y_{xx} = be^{-y}$ or, introducing $z(x) = -y(x)$,

$$z_{xx} + be^z = 0 \quad \text{in } (0,1), \quad z(0) = z(1) = -y_0.$$

This is the solid fuel ignition model of [2]. It is well known that there exists $b^* > 0$ such that this problem has exactly two solutions if $b \in (0, b^*)$, it has exactly one solution if $b = b^*$, and it has no solution if $b > b^*$ [2, 11]. This relation provides a better bound for b (for the above special boundary conditions) than the estimate (2.6). Indeed, $a = 0$ and b is uniformly bounded by a number $b^* > 0$ *independently* of the boundary conditions (and depending only on the domain $(0,1)$).

3. Existence of transient solutions. In order to prove Theorem 1.2 we again perform the exponential change of unknowns and we semidiscretize (1.1) in time. For this, we divide the time interval $(0,T]$ for some $T > 0$ into N subintervals $(t_{k-1}, t_k]$, with $k = 1, \ldots, N$, where $0 = t_0 < \cdots < t_N = T$. Define $\tau_k = t_k - t_{k-1} > 0$ and $\tau = \max\{\tau_k : k = 1, \ldots, N\}$. We assume that $\tau \to 0$ as $N \to \infty$.

Let $u_\infty > 0$ be the unique classical solution to (1.4) and set $y_\infty = \log u_\infty$. We perform the transformation $z = \log(u/u_\infty)$ and $z_0 = \log(u_I/u_\infty)$. For given $k \in \{1, \ldots, N\}$ and z_{k-1} we first solve the semidiscrete problem

$$\frac{e^{y_\infty}}{\tau_k}(e^{z_k} - e^{z_{k-1}}) = -\left(e^{z_k + y_\infty}(z_k + y_\infty)_{xx}\right)_{xx}, \quad z_k \in H_0^2(0,1). \tag{3.1}$$

Proposition 3.1. *For each $k = 1, \ldots, N$, there exists a unique weak solution $z_k \in H_0^2(0,1)$ to* (3.1).

For the proof of this proposition we first show some a priori estimates.

Lemma 3.2. *Let $z_k \in H_0^2(0,1)$ be a weak solution to* (3.1). *Then there exists a constant $c > 0$ depending only on T, u_I, and u_∞ such that*

$$\|e^{z_k/2}\|_{L^2(0,1)} \le c, \tag{3.2}$$

$$\sum_{i=1}^N \tau_i \int_0^1 e^{z_i/2}\left((z_i + y_\infty)_{xx}^2 + (z_i + y_\infty)_x^4\right) \le c, \tag{3.3}$$

$$\sum_{i=1}^N \tau_i \|e^{z_i}\|_{L^\infty(0,1)} \le c. \tag{3.4}$$

Proof. Similarly as in the uniqueness proof of Theorem 1.1 we use the test functions $1 - e^{-z_k/2} \in H_0^2(0,1)$ in the weak formulation of the semidiscretized equation (3.1) and $e^{z_k/2} - 1 \in H_0^2(0,1)$ in the weak formulation of the stationary equation (1.4) and take the sum of the corresponding equations:

$$\begin{aligned} \frac{1}{\tau_k}\int_0^1 e^{y_\infty}(e^{z_k} - e^{z_{k-1}})(1 - e^{-z_k/2})dx &= \int_0^1 e^{z_k + y_\infty}(z_k + y_\infty)_{xx}(e^{-z_k/2})_{xx}dx \\ &\quad + \int_0^1 e^{y_\infty} y_{\infty,xx}(e^{z_k/2})_{xx}dx. \end{aligned} \tag{3.5}$$

The right-hand side is equal to the first integral in (2.7) with $u_1 = e^{z_k+y_\infty}$ and $u_2 = e^{y_\infty}$. Therefore, the right-hand side is equal to the expression

$$-2\int_0^1 \left(e^{-z_k/4}(e^{(z_k+y_\infty)/2})_{xx} - e^{z_k/4}(e^{y_\infty/2})_{xx}\right)^2 dx.$$

For the left-hand side of (3.5) we write

$$\begin{aligned}
&\frac{1}{\tau_k}\int_0^1 e^{y_\infty}(e^{z_k} - e^{z_{k-1}})(1-e^{-z_k/2})dx \\
&= \frac{1}{\tau_k}\int_0^1 e^{y_\infty}((e^{z_k/2}-1)^2 - (e^{z_{k-1}/2}-1)^2)dx + \frac{1}{\tau_k}\int_0^1 e^{y_\infty}(e^{z_k/4} - e^{z_{k-1}/2-z_k/4})^2 dx \\
&\geq \frac{1}{\tau_k}\int_0^1 e^{y_\infty}\left((e^{z_k/2}-1)^2 - (e^{z_{k-1}/2}-1)^2\right)dx.
\end{aligned}$$

Therefore, we conclude from (3.5), for all $k = 1, \ldots, N$,

$$\begin{aligned}
&\frac{1}{\tau_k}\int_0^1 e^{y_\infty}(e^{z_k/2}-1)^2 dx + 2\int_0^1 \left(e^{-z_k/4}(e^{(z_k+y_\infty)/2})_{xx} - e^{z_k/4}(e^{y_\infty/2})_{xx}\right)^2 dx \\
&\qquad \leq \frac{1}{\tau_k}\int_0^1 e^{y_\infty}(e^{z_{k-1}/2}-1)^2 dx. \qquad (3.6)
\end{aligned}$$

This yields

$$\int_0^1 e^{y_\infty}(e^{z_k/2}-1)^2 dx \leq \int_0^1 e^{y_\infty}(e^{z_0/2}-1)^2 dx = \int_0^1 (\sqrt{u_I} - \sqrt{u_\infty})^2 dx < \infty \qquad (3.7)$$

and thus (3.2). Moreover, after summing up (3.6),

$$2\sum_{i=1}^k \tau_i \int_0^1 \left(e^{-z_i/4}(e^{(z_i+y_\infty)/2})_{xx} - e^{z_i/4}(e^{y_\infty/2})_{xx}\right)^2 dx \leq \int_0^1 e^{y_\infty}(e^{z_0/2}-1)^2 dx.$$

Young's inequality gives

$$4\sum_{i=1}^k \tau_i \int_0^1 e^{-z_i/2}\left(e^{(z_i+y_\infty)/2}\right)_{xx}^2 dx \leq c + c\sum_{i=1}^k \tau_i \int_0^1 e^{z_i/2} dx,$$

where here and in the following, $c > 0$ denotes a generic constant depending only on T, u_I, and u_∞. In view of (3.7), the right-hand side is uniformly bounded. Hence

$$\begin{aligned}
&\sum_{i=1}^k \tau_i \int_0^1 e^{-(z_i+y_\infty)/2}\left(e^{(z_i+y_\infty)/2}\right)_{xx}^2 dx \\
&\leq \|e^{y_\infty/2}\|_{L^\infty(0,1)} \sum_{i=1}^k \tau_i \int_0^1 e^{-z_i/2}\left(e^{(z_i+y_\infty)/2}\right)_{xx}^2 dx \leq c.
\end{aligned}$$

Now the assertion (3.3) follows since, by integration by parts,

$$\int_0^1 e^{u/2}u_x^2 u_{xx} dx = -\frac{1}{6}\int_0^1 e^{u/2}u_x^4 + \frac{1}{3}(e^{u(1)/2}u_x(1)^3 - e^{u(0)/2}u_x(0)^3)$$

for all $u \in H^2(0,1)$, and hence,

$$\begin{aligned}
&\int_0^1 e^{-(z_i+y_\infty)/2}\left(e^{(z_i+y_\infty)/2}\right)_{xx}^2 dx \\
&= \frac{1}{4}\int_0^1 e^{(z_i+y_\infty)/2}\left((z_i+y_\infty)_{xx}^2 + \frac{1}{4}(z_i+y_\infty)_x^4 + (z_i+y_\infty)_{xx}(z_i+y_\infty)_x^2\right)dx \\
&= \frac{1}{4}\int_0^1 e^{(z_i+y_\infty)/2}\left((z_i+y_\infty)_{xx}^2 + \frac{1}{12}(z_i+y_\infty)_x^4\right)dx + \frac{1}{12}(e^{y_1/2}\beta^3 - e^{y_0/2}\alpha^3).
\end{aligned}$$

Finally, (3.4) is a consequence of (3.3) and the Poincaré–Sobolev inequality since

$$\int_0^1 e^{z_i/2}(z_i)_x^4 dx = 8^4\int_0^1 (e^{z_i/8})_x^4 \geq c\|e^{z_i/8}\|_{L^\infty(0,1)}^4.$$

This shows the lemma. ∎

LEMMA 3.3. *Let $z_k \in H_0^2(0,1)$ be a weak solution to* (3.1). *Then there exists a constant $c > 0$ depending only on T, u_I, and u_∞ such that*

$$\int_0^1 (e^{z_k} - z_k)dx + \sum_{i=1}^k \tau_i \int_0^1 (z_i + y_\infty)_{xx}^2 dx \leq c. \tag{3.8}$$

Proof. We choose the test function $e^{-y_\infty}(1-e^{-z_k}) \in H_0^2(0,1)$ in the weak formulation of (3.1). Then, by Young's inequality,

$$\begin{aligned}
&\int_0^1 (e^{z_k} - e^{z_{k-1}})(1-e^{-z_k})dx \\
&= -\tau_k\int_0^1 e^{z_k}(z_k+y_\infty)_{xx}(y_{\infty,x}^2 - y_{\infty,xx})dx - \tau_k\int_0^1 (z_k+y_\infty)_{xx}^2 dx \\
&\quad + \tau_k\int_0^1 (z_k+y_\infty)_x^2(z_k+y_\infty)_{xx}dx \\
&\leq \tau_k\int_0^1 e^{z_k/2}(z_k+y_\infty)_{xx}^2 dx + \tau_k\int_0^1 e^{3z_k/2}(y_{\infty,x}^2 - y_{\infty,xx})^2 dx \\
&\quad - \tau_k\int_0^1 (z_k+y_\infty)_{xx}^2 dx + \frac{\tau_k}{3}(\beta^3-\alpha^3).
\end{aligned}$$

In view of (3.3) and (3.4), the right-hand side is uniformly bounded. The left-hand side can be estimated by

$$\int_0^1 (e^{z_k} - e^{z_{k-1}})(1-e^{-z_k})dx \geq \int_0^1 (e^{z_k}-z_k)dx - \int_0^1 (e^{z_{k-1}} - z_{k-1})dx,$$

which is a consequence of the elementary inequality $e^x - 1 \geq x$ for all $x \in \mathbb{R}$. Thus, (3.8) is proved. ∎

Proof of Proposition 3.1. The existence of a solution to (3.1) is shown by the Leray–Schauder fixed-point theorem. For this, let $k \in \{1,\ldots,N\}$ and z_{k-1} be given. Furthermore, let $w \in H^1(0,1)$ and $\sigma \in [0,1]$, and define the linear forms

$$\begin{aligned}
a(z,\phi) &= \int_0^1 e^{w+y_\infty} z_{xx}\phi_{xx}dx, \\
F(\phi) &= -\frac{1}{\tau_k}\int_0^1 e^{y_\infty}(e^w - e^{z_{k-1}})\phi dx - \int_0^1 e^{w+y_\infty}y_{\infty,xx}\phi_{xx}dx,
\end{aligned}$$

where $\phi \in H_0^2(0,1)$. Consider the linear problem

$$a(z,\phi) = \sigma F(\phi) \quad \text{for all } \phi \in H_0^2(0,1).$$

By the Lax–Milgram lemma, there exists a unique solution $z \in H_0^2(0,1)$ to this problem. This defines the fixed-point operator $S : H^1(0,1)\times[0,1] \to H^1(0,1)$, $S(w,\sigma) = z$. It is not difficult to show that S is continuous and compact, since the embedding $H_0^2(0,1) \hookrightarrow H^1(0,1)$ is compact. Moreover, $S(w,0) = 0$ for all $w \in H^1(0,1)$. It remains to prove that any fixed point of S satisfies a uniform bound in $H^1(0,1)$. In fact, Lemma 3.3 shows that any fixed point $z \in H_0^2(0,1)$ is uniformly bounded if $\sigma = 1$. The estimate for $\sigma < 1$ is similar (and, in fact, independent of σ). This provides the wanted bound in $H^1(0,1)$, and the Leray–Schauder theorem can be applied to yield the existence of a solution to (3.1). ◻

For the proof of Theorem 1.2 we need some more uniform estimates. Let $z^{(N)}$ be defined by $z^{(N)}(x,t) = z_k(x)$ if $t \in (t_{k-1},t_k]$, $x \in (0,1)$.

Lemma 3.4. *The following estimates hold:*

$$\|z^{(N)}\|_{L^\infty(0,T;L^1(0,1))} + \|z^{(N)}\|_{L^2(0,T;H^2(0,1))} \le c, \tag{3.9}$$

$$\|z^{(N)}\|_{L^{5/2}(0,T;W^{1,\infty}(0,1))} + \|e^{z^{(N)}}\|_{L^{5/2}(0,T;W^{1,1}(0,1))} \le c, \tag{3.10}$$

where $c > 0$ depends only on u_I and the boundary data.

Proof. The inequality $e^x - x \ge |x|$ for all $x \in \mathbb{R}$ and the estimate (3.8) imply that $z^{(N)}$ is uniformly bounded in $L^\infty(0,T;L^1(0,1))$ which, together with (3.8), shows (3.9). Then, using the Poincaré and Gagliardo–Nirenberg inequalities, we obtain from (3.8)

$$\begin{aligned}\|z^{(N)}\|_{L^{5/2}(0,T;W^{1,\infty}(0,1))} &\le c\|z_x^{(N)}\|_{L^{5/2}(0,T;L^\infty(0,1))} \\ &\le c\|z^{(N)}\|^{1/5}_{L^\infty(0,T;L^1(0,1))}\|z^{(N)}\|^{4/5}_{L^2(0,T;H^2(0,1))} \le c.\end{aligned}$$

This estimate, (3.2), and the first bound in (3.9) imply (3.10) since

$$\begin{aligned}\|e^{z^{(N)}}\|_{L^{5/2}(0,T;W^{1,1}(0,1))} &\le c\left(\|e^{z^{(N)}}\|_{L^{5/2}(0,T;L^1(0,1))} + \|(e^{z^{(N)}})_x\|_{L^{5/2}(0,T;L^1(0,1))}\right) \\ &\le c\|e^{z^{(N)}}\|_{L^{5/2}(0,T;L^1(0,1))} \\ &\quad + c\|e^{z^{(N)}}\|_{L^\infty(0,T;L^1(0,1))}\|z_x^{(N)}\|_{L^{5/2}(0,T;L^\infty(0,1))} \\ &\le c.\end{aligned}$$

The lemma is proved. ◻

We also need an estimate for the discrete time derivative. For this, introduce the shift operator $(\sigma_N(z^{(N)}))(\cdot,t) = z_{k-1}$ for $t \in (t_{k-1},t_k]$.

Lemma 3.5. *The following estimate holds:*

$$\|e^{z^{(N)}} - e^{\sigma_N(z^{(N)})}\|_{L^{10/9}(0,T;H^{-2}(0,1))} \le c\tau, \tag{3.11}$$

where $c > 0$ depends only on u_I and u_∞.

Proof. From (3.1) and Hölder's inequality we obtain

$$\begin{aligned}\frac{1}{\tau_k}\|e^{z^{(N)}} - e^{\sigma_N(z^{(N)})}\|_{L^{10/9}(0,T;H^{-2}(0,1))} &\le \|e^{z^{(N)}+y_\infty}(z^{(N)}+y_\infty)_{xx}\|_{L^{10/9}(0,T;L^2(0,1))} \\ &\le \|e^{z^{(N)}+y_\infty}\|_{L^{5/2}(0,T;L^\infty(0,1))}\|(z^{(N)}+y_\infty)_{xx}\|_{L^2(0,T;L^2(0,1))}\end{aligned}$$

and the right-hand side is uniformly bounded by (3.9) and (3.10) since $W^{1,1}(0,1) \hookrightarrow L^\infty(0,1)$. $\square$

Proof of Theorem 1.2. For any $N \in \mathbb{N}$, there exists a solution $z^{(N)} \in L^2(0,T; H_0^2(0,1))$ to the sequence of recursive equations (3.1) satisfying $z^{(N)}(\cdot,0) = z_0$. The uniform bounds (3.10) and (3.11) and the compact embedding $W^{1,1}(0,1) \hookrightarrow L^1(0,1)$ allow us to apply Theorem 5 of [17] (Aubin's lemma) yielding the existence of a subsequence of $e^{z^{(N)}}$ (not relabeled) such that $e^{z^{(N)}} \to \rho$ strongly in $L^1(0,T;L^1(0,1))$ and hence also in $L^1(0,T;H^{-2}(0,1))$. The above results give, using (3.2) and $L^1(0,1) \hookrightarrow H^{-2}(0,1)$,

$$\begin{aligned}
\|e^{z^{(N)}} - \rho\|^2_{L^2(0,T;H^{-2}(0,1))} &\le \|e^{z^{(N)}} - \rho\|_{L^\infty(0,T;H^{-2}(0,1))}\|e^{z^{(N)}} - \rho\|_{L^1(0,T;H^{-2}(0,1))} \\
&\le c\left(\|e^{z^{(N)}}\|_{L^\infty(0,T;L^1(0,1))} + \|\rho\|_{L^\infty(0,T;L^1(0,1))}\right) \\
&\quad \times \|e^{z^{(N)}} - \rho\|_{L^1(0,T;H^{-2}(0,1))} \\
&\le c\|e^{z^{(N)}} - \rho\|_{L^1(0,T;H^{-2}(0,1))} \to 0 \quad \text{as } N \to \infty. \qquad (3.12)
\end{aligned}$$

Moreover, the estimate (3.9) provides the existence of a subsequence, also denoted by $z^{(N)}$, such that

$$z^{(N)} \rightharpoonup z \quad \text{weakly in } L^2(0,T;H^2(0,1)) \text{ as } N \to \infty. \qquad (3.13)$$

We claim now that $e^z = \rho$. For this, let w be a smooth function. Letting $N \to \infty$ in

$$0 \le \int_0^T \langle e^{z^{(N)}} - e^w, z^{(N)} - w\rangle_{H^{-2},H_0^2} dt$$

and using the convergence results (3.12) and (3.13) yield

$$0 \le \int_0^T \int_0^1 (\rho - e^w)(w - z)dxdt.$$

The strict monotonicity of $x \mapsto e^x$ then implies that $e^z = \rho$.

Thus, $e^{z^{(N)}} \to e^z$ strongly in $L^1(0,T;L^1(0,1))$ and (maybe for a subsequence) a.e. The uniform bound (3.10) implies that (after extracting a subsequence) $e^{z^{(N)}} \rightharpoonup e^z$ weakly* in $L^{5/2}(0,T;L^\infty(0,1))$ since $W^{1,1}(0,1) \hookrightarrow L^\infty(0,1)$. Therefore, we conclude via Lebesgue's convergence theorem that

$$e^{z^{(N)}} \to e^z \quad \text{strongly in } L^2(0,T;L^2(0,1)). \qquad (3.14)$$

Finally, the uniform estimate (3.11) gives for a subsequence

$$\frac{1}{\tau}(e^{z^{(N)}} - e^{\sigma_N(z^{(N)})}) \rightharpoonup (e^z)_t \quad \text{weakly in } L^{10/9}(0,T;H^{-2}(0,1)). \qquad (3.15)$$

The convergence results (3.13)–(3.15) allow us to pass to the limit $N \to \infty$ in the weak formulation of (3.1) to obtain a weak solution $z \in L^2(0,T;H_0^2(0,1))$ to

$$e^{y_\infty}(e^z)_t = -(e^{z+y_\infty}(z + y_\infty)_{xx})_{xx} \quad \text{in } (0,1),\ t > 0,$$

such that $z(\cdot,0) = z_0 = \log(u_I/u_\infty)$ in the sense of $H^{-2}(0,1)$. Transforming back to the variable $u = e^{z+y_\infty}$ gives the assertion. $\square$

4. Long-time behavior of the solutions. This section is devoted to the proof of Theorem 1.3. The proof is based on the entropy–entropy production method. For this we need the following lemma for lower and upper estimates for the entropy

$$E_3 = \int_0^1 e^{y_\infty}(e^z(z-1)+1)dx.$$

LEMMA 4.1. *Let z, $y_\infty \in L^\infty(0,1)$. Then*

$$c_1\left(\int_0^1 e^{y_\infty}|e^z-1|dx\right)^2 \le E_3 \le c_2\|e^{z/2}-1\|^2_{L^\infty(0,1)}, \tag{4.1}$$

where c_1, $c_2 > 0$ depend on $\|e^{y_\infty}\|_{L^\infty(0,1)}$ and $\|e^z\|_{L^1(0,1)}$.

The lower bound for E_3 is a Csiszar–Kullback-type inequality. A similar version of this lemma is shown in [15].

Proof. The upper bound is proved by expanding the function $f(x) = x^2(\log x^2 - 1) + 1$ around $x = 1$,

$$\begin{aligned} f(e^{z/2}) &= f(1) + f'(1)(e^{z/2}-1) + \frac{1}{2}f''(\theta)(e^{z/2}-1)^2 \\ &= 2(\log\theta+1)(e^{z/2}-1)^2 \le 2(e^{z/2}+1)(e^{z/2}-1)^2, \end{aligned}$$

where θ lies between $e^{z/2}$ and 1, and using the inequality $\log\theta \le \theta - 1 \le \max\{e^{z/2}, 1\} - 1 \le e^{z/2}$. Then

$$E_3 \le 2\int_0^1 e^{y_\infty}(e^{z/2}+1)(e^{z/2}-1)^2dx \le 2\|e^{y_\infty}\|_{L^\infty(0,1)}(\|e^z\|^{1/2}_{L^1(0,1)}+1)\|e^{z/2}-1\|^2_{L^\infty(0,1)},$$

and we set $c_2 = 2\|e^{y_\infty}\|_{L^\infty(0,1)}(\|e^z\|^{1/2}_{L^1(0,1)} + 1)$.

For the lower bound we observe that a Taylor expansion of $f(x) = x(\log x - 1) + 1$ around $x = 1$ yields

$$e^{2y_\infty}(e^z(z-1)+1) = \frac{e^{2y_\infty}}{2\theta}(e^z-1)^2,$$

and $\theta = \theta(z)$ lies between e^z and 1. Then, by the Cauchy–Schwarz inequality,

$$\begin{aligned} \int_0^1 e^{y_\infty}|e^z-1|dx &\le \int_{\{z<0\}} e^{y_\infty}(1-e^z)dx + \int_{\{z>0\}} e^{y_\infty}(e^z-1)dx \\ &\le \int_{\{z<0\}} e^{y_\infty}\frac{1-e^z}{\theta(z)^{1/2}}dx + \int_{\{z>0\}} e^{y_\infty}\frac{e^z-1}{\theta(z)^{1/2}}\theta(z)^{1/2}dx \\ &\le \operatorname{meas}\{z<0\}^{1/2}\left(\int_{\{z<0\}} e^{2y_\infty}\frac{(1-e^z)^2}{\theta(z)}dx\right)^{1/2} \\ &\quad + \left(\int_{\{z>0\}} e^{2y_\infty}\frac{(e^z-1)^2}{\theta(z)}dx\right)^{1/2}\left(\int_{\{z>0\}}\theta(z)dx\right)^{1/2} \\ &\le (1+\|e^z\|^{1/2}_{L^1(0,1)})\left(\int_0^1 e^{2y_\infty}\frac{(e^z-1)^2}{\theta(z)}dx\right)^{1/2} \\ &\le \sqrt{2}\|e^{y_\infty}\|^{1/2}_{L^\infty(0,1)}(1+\|e^z\|^{1/2}_{L^1(0,1)})E_3^{1/2}, \end{aligned}$$

and the assertion follows with $c_1^{-1} = 2\|e^{y_\infty}\|_{L^\infty(0,1)}(1+\|e^z\|_{L^1(0,1)}^{1/2})^2$. $\square$

Proof of Theorem 1.3. The idea is to differentiate the entropy E_3 of the introduction with respect to time and to use the differential equation (1.1). Since we do not have enough regularity for the solution u to (1.1), we need to regularize. We set as in the proof of Theorem 1.2 $u_\infty = e^{y_\infty}$, where u_∞ is the unique solution to (1.4). There exist numbers a, $b \in \mathbb{R}$ such that $e^{y_\infty} y_{\infty,xx} = ax + b \le 0$ for all $x \in (0,1)$ since $y_\infty = \log u_\infty$ is assumed to be concave. This implies that $y_\infty \ge \min\{y_\infty(0), y_\infty(1)\}$ and hence $e^{y_\infty} \ge \min\{u_0, u_1\}$ in $(0,1)$. Furthermore, let $z_k \in H_0^2(0,1)$ be a solution to (3.1) for given z_{k-1}. We assume for simplicity that $\tau = \tau_k$ for all $k \in \mathbb{N}$.

Using z_k as a test function in the weak formulation of (3.1), we obtain, after integrating by parts,

$$\begin{aligned}
&\frac{1}{\tau}\int_0^1 e^{y_\infty}(e^{z_k} - e^{z_{k-1}})z_k dx = -\int_0^1 e^{z_k + y_\infty}(z_k + y_\infty)_{xx} z_{k,xx} dx \\
&= -\int_0^1 e^{z_k+y_\infty} z_{k,xx}^2 dx - \int_0^1 e^{z_k} z_{k,xx}(ax+b)dx \\
&= -\int_0^1 e^{z_k+y_\infty} z_{k,xx}^2 dx + \int_0^1 e^{z_k} z_{k,x}^2 (ax+b)dx + a\int_0^1 e^{z_k} z_{k,x} dx \\
&\le -\min\{u_0,u_1\}\int_0^1 e^{z_k} z_{k,xx}^2 dx,
\end{aligned} \tag{4.2}$$

since $ax + b \le 0$ in $(0,1)$ and $e^{z_k(x)} = 1$ for $x = 0,1$. The left-hand side is estimated from below by employing the elementary inequality $e^x \ge x + 1$ for all $x \in \mathbb{R}$:

$$\begin{aligned}
&\frac{1}{\tau}\int_0^1 e^{y_\infty}(e^{z_k} - e^{z_{k-1}})z_k dx \\
&= \frac{1}{\tau}\int_0^1 e^{z_k+y_\infty}(z_k - 1)dx - \frac{1}{\tau}\int_0^1 e^{z_{k-1}+y_\infty}(z_{k-1}-1)dx \\
&\quad + \frac{1}{\tau}\int_0^1 e^{z_{k-1}+y_\infty}(e^{z_k - z_{k-1}} + z_{k-1} - z_k - 1)dx \\
&\ge \frac{1}{\tau}\int_0^1 e^{z_k+y_\infty}(z_k - 1)dx - \frac{1}{\tau}\int_0^1 e^{z_{k-1}+y_\infty}(z_{k-1}-1)dx.
\end{aligned} \tag{4.3}$$

This shows that the sequence $E^{(k)} = \int_0^1 e^{y_\infty}(e^{z_k}(z_k - 1) + 1)dx$ is nonincreasing and bounded from below by $E^{(0)} = \int_0^1 (u_I(\log(u_I/u_\infty) - 1) + 1)dx$, which is finite.

We relate the entropy production term on the right-hand side of (4.2) to the entropy itself. We first claim that

$$\int_0^1 e^{z_k} z_{k,xx}^2 dx \ge 4\int_0^1 (e^{z_k/2})_{xx}^2 dx. \tag{4.4}$$

To see this we set $u = e^{z_k}$ and observe that an integration by parts yields

$$\int_0^1 \frac{u_{xx}u_x^2}{u^2}dx = \frac{2}{3}\int_0^1 \frac{u_x^4}{u^3}dx.$$

Then

$$\int_0^1 e^{z_k} z_{k,xx}^2 dx = \int_0^1 \left(\frac{u_{xx}^2}{u} - \frac{1}{3}\frac{u_x^4}{u^3} \right) dx \geq \int_0^1 \left(\frac{u_{xx}^2}{u} - \frac{5}{12}\frac{u_x^4}{u^3} \right) dx \tag{4.5}$$
$$= 4\int_0^1 (\sqrt{u})_{xx}^2 dx = 4\int_0^1 (e^{z_k/2})_{xx}^2 dx.$$

We need the Poincaré inequalities

$$\|u\|_{L^2(0,1)} \leq \frac{1}{\pi}\|u_x\|_{L^2(0,1)}, \quad \|u\|_{L^\infty(0,1)} \leq \|u_x\|_{L^2(0,1)}$$

for all $u \in H_0^1(0,1)$. Therefore, using Lemma 4.1, we infer

$$\int_0^1 e^{z_k} z_{k,xx}^2 dx \geq 4\pi^2 \int_0^1 (e^{z_k/2} - 1)_x^2 dx \geq 4\pi^2 \|e^{z_k/2} - 1\|_{L^\infty(0,1)}^2 \geq \frac{4\pi^2}{c_2} E^{(k)}. \tag{4.6}$$

Setting $\gamma = 4\pi^2 \min\{u_0, u_1\}/c_2$, we obtain from (4.2) the difference inequality

$$E^{(k)} \leq E^{(k-1)} - \gamma\tau E^{(k)},$$

from which

$$E^{(k)} \leq (1+\gamma\tau)^{-1} E^{(k-1)} \leq (1+\gamma\tau)^{-k} E^{(0)} \leq (1+\gamma\tau)^{-t/\tau} E^{(0)} \tag{4.7}$$

follows. The parameter γ depends on $\|e^{z_k}\|_{L^1(0,1)}$ through c_2. However, since $e^{z^{(N)}}$ is uniformly bounded in $L^\infty(0,T;L^1(0,1))$ in view of Lemma 3.3, γ is bounded uniformly in k. We have shown in the proof of Theorem 1.2 that $e^{z_k} \to e^z$ a.e. Then the uniform boundedness of e^{z_k} and z_k and Lebesgue's dominated convergence theorem imply that

$$E^{(k)} \to E_3(t) = \int_0^1 e^{y_\infty}(e^{z(\cdot,t)}(z(\cdot,t)-1)+1)dx.$$

Hence, after letting $\tau \to 0$, we conclude from (4.7) that $E_3(t) \leq E_3(0)e^{-\gamma t}$. The first inequality in (4.1) gives the assertion with $\lambda = \gamma/2$. $\square$

Remark 4.2. The decay rate λ is not optimal. For instance, we neglected the term $\int_0^1 u_x^4/12u^3 dx$ in (4.5) and the constants in (4.1) are not the best ones. For optimal constants in logarithmic Sobolev inequalities related to (1.1) with periodic boundary conditions, we refer the reader to [10].

Remark 4.3. It is not easy to find conditions on the boundary data for which $\log u_\infty$ is concave. An example is $u_0 = u_1$ and $w_0 = -w_1 \geq 0$. Indeed, if $y = \log u_\infty$, we have $y(0) = y(1)$ and $y_x(0) = -y_x(1) \geq 0$ and therefore, y is symmetric around $x = \frac{1}{2}$. Thus (see Remark 2.3) $a = e^{y_0}(y_{xx}(1) - y_{xx}(0)) = 0$ and $b = e^{y_0}y_{xx}(0) \leq 0$. This implies $(\log u_\infty)_{xx} = y_{xx} = be^{-y} \leq 0$ in $(0,1)$.

Remark 4.4. The assumption on the concavity of $\log u_\infty$ can be slightly relaxed. Indeed, we claim that the assertion of Theorem 1.3 also holds if $((\log u_\infty)_{xx})^+$ is small enough in the sense

$$4\,\frac{\max\{u_\infty(x) : 0 \leq x \leq 1\}}{\min\{u_\infty(x) : 0 \leq x \leq 1\}} \int_0^1 ((\log u_\infty)_{xx})^+ \, dx \leq 1 - \delta \tag{4.8}$$

for some $\delta > 0$, where $(x)^+ = \max\{0, x\}$. We prove this result by deriving a bound on the second integral in (4.2) in terms of the first one, employing the weighted Poincaré inequality [7, Thm. 1.4]

$$\int_0^1 u_x^2 \mu(x) dx \leq K \int_0^1 u_{xx}^2 dx$$

for all $u \in H^2(0,1)$ satisfying $u(0) = u(1)$ (which implies that $\int_0^1 u_x dx = 0$). The function μ is assumed to be nonnegative and measurable. The best constant $K > 0$ is not explicit but can be bounded by $K \leq 4 \int_0^1 \mu(x) dx$ [7, Rem. 1.10.4]. We choose $\mu(x) = (ax+b)^+ = (u_\infty (\log u_\infty)_{xx})^+$. Then the weighted Poincaré inequality and (4.4) give

$$\begin{aligned} \int_0^1 e^{z_k + y_\infty} z_{k,xx}^2 dx &\geq 4m \int_0^1 (e^{z_k/2})_{xx}^2 dx \geq \frac{4m}{K} \int_0^1 (e^{z_k/2})_x^2 \mu(x) dx \\ &= \frac{m}{K} \int_0^1 (ax+b)^+ e^{z_k} z_{k,x}^2 dx, \end{aligned}$$

where $m = \min\{u_\infty(x) : 0 \leq x \leq 1\}$. Inserting this inequality into (4.2) and using (4.3), we obtain

$$\begin{aligned} \frac{1}{\tau}\left(E^{(k)} - E^{(k-1)}\right) &\leq -\int_0^1 e^{z_k + y_\infty} z_{k,xx}^2 dx + \int_0^1 (ax+b)^+ e^{z_k} z_{k,x}^2 dx \\ &\leq \left(\frac{K}{m} - 1\right) \int_0^1 e^{z_k + y_\infty} z_{k,xx}^2 dx. \end{aligned}$$

Assumption (4.8) shows that $K/m \leq 1 - \delta$ and hence, by (4.6),

$$\frac{1}{\tau}\left(E^{(k)} - E^{(k-1)}\right) \leq -\delta \int_0^1 e^{z_k + y_\infty} z_{k,xx}^2 dx \leq -\frac{4\pi^2 \delta m}{c_2} E^{(k)}.$$

Now proceed as in the proof of Theorem 1.3. The convergence rate in the L^1 norm is given by $\lambda = 2\pi^2 \delta m / c_2$.

5. Numerical examples. In this section we show by numerical examples that the assumption of concavity of $\log u_\infty$ (or the assumption (4.8)), where u_∞ is the solution to (1.4), seems to be only technical. Equation (1.1) is solved numerically in the formulation

$$u_t = -u_{xxxx} + \left(\frac{u_x^2}{u}\right)_{xx} \quad \text{in } (0,1). \tag{5.1}$$

We use a uniform grid $(x_i, t_j) = (\triangle x \cdot i, \triangle t \cdot j)$ with spatial mesh size $\triangle x = 10^{-3}$ and time step $\triangle t = 10^{-6}$. With the approximation u_{ij} of $u(x_i, t_j)$, the fully implicit discretization reads as

$$\frac{1}{\triangle t}(u_{ij} - u_{i,j-1}) = -D^+ D^- D^+ D^- u_{ij} + D^+ D^- \left(\frac{(D^+ u_{ij})^2}{u_{ij}}\right),$$

where D^+ and D^- are the forward and backward difference operators on the spatial mesh (see [13]). The nonlinear equations are solved on each time level by Newton's method where the initial guess is chosen to be the solution of the previous time level.

For the first example we use the boundary conditions

$$u(0,t) = u_0, \quad u(1,t) = u_1, \tag{5.2}$$

$$u_x(0,t) = w_0 = 2\sqrt{u_0}(\sqrt{u_1} - \sqrt{u_0}), \quad u_x(1,t) = w_1 = 2\sqrt{u_1}(\sqrt{u_1} - \sqrt{u_0}), \tag{5.3}$$

with $u_0 \le u_1$. The advantage of these conditions is that the stationary problem (1.4) has the exact solution

$$u_\infty(x) = \left((\sqrt{u_1} - \sqrt{u_0})x + \sqrt{u_0}\right)^2, \quad x \in (0,1).$$

We choose the initial condition $u_I(x) = e^{-x}\sin(3\pi x) + 3x + 1$ and the boundary values $u_0 = 1$ and $u_1 = 4$. The numerical solution at various times is displayed in Figure 5.1. The discrete solution seems to converge to the exact solution u_∞ as $t \to \infty$. Figure 5.2 shows the exponential decay of the relative entropy

$$E_3(t) = \int_0^1 u(\cdot,t)((\log(u(\cdot,t)/u_\infty) - 1) + u_\infty)dx$$

and of the L^1 deviation $\|u(\cdot,t) - u_\infty\|_{L^1(0,1)}$. As predicted by the proof of Theorem 1.3, the decay rate of the L^1 deviation is half of the rate of the relative entropy. Notice that the function $\log u_\infty$ is concave; i.e., the assumptions of Theorem 1.3 are satisfied.

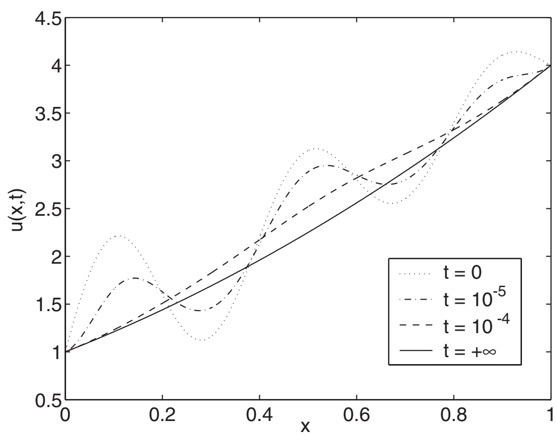

FIG. 5.1. *Numerical solution to* (5.1)–(5.3) *with* $u_0 = 1$, $u_1 = 4$, $w_0 = 2$, *and* $w_1 = 4$ *at various times.*

In the second example we show by a numerical example that the solution to (1.1) decays exponentially fast even if the function $\log u_\infty$ is convex. For this we choose the boundary conditions $u_0 = 1.5$, $u_1 = 0.8$, $w_0 = -4.6127$, and $w_1 = 2.0618$. The stationary solution u_∞ is computed numerically from the equation

$$u_\infty(\log u_\infty)_{xx} = ax + b, \quad x \in (0,1),$$

where $a = 1$ and $b = 3$. Then, $\log u_\infty$ is strictly convex in $(0,1)$ and the assumption (4.8) is not satisfied. We choose the initial function $u_I(x) = -e^{-x}\sin(2\pi x) - \frac{7}{10}x + \frac{3}{2}$. Figure 5.3 shows the discrete solution for various times. In this case, the relative entropy and the L^1 deviation are also exponentially decaying (Figure 5.4) although the condition of Theorem 1.3 is not satisfied. This suggests that the concavity hypothesis is purely technical.

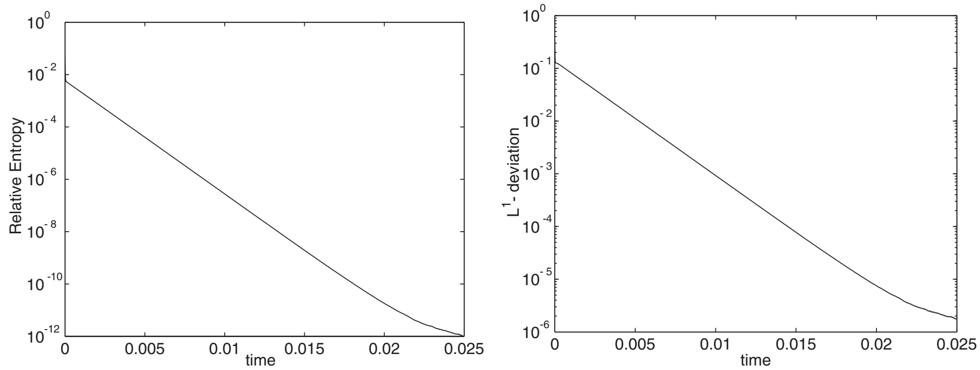

FIG. 5.2. *Logarithmic plot of the relative entropy* $E_3(t)$ *(left) and the* L^1 *deviation* $\|u(\cdot,t) - u_\infty\|_{L^1(0,1)}$ *(right) for the solution to* (5.1)–(5.3) *with* $u_0 = 1$, $u_1 = 4$.

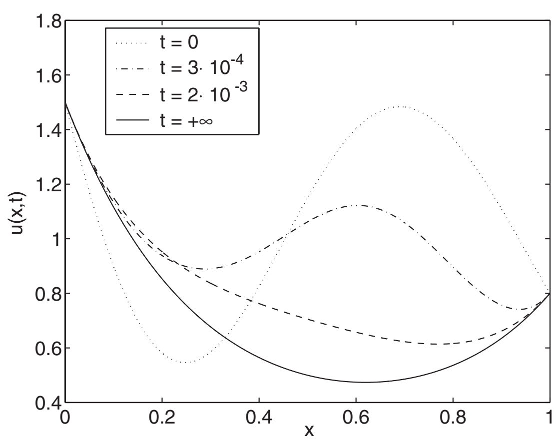

FIG. 5.3. *Numerical solution to* (5.1), (1.3) *with* $u_0 = 1.5$, $u_1 = 0.8$, $w_0 = -4.6127$, *and* $w_1 = 2.0618$ *at various times.*

ON THE EXISTENCE AND UNIQUENESS OF WEAK SOLUTIONS FOR A VORTICITY SEEDING MODEL*

LUIGI C. BERSELLI† AND MARCO ROMITO‡

Abstract. In this paper we study the Navier–Stokes equations with a Navier-type boundary condition that has been proposed as an alternative to common near wall models. The boundary condition we study, involving a linear relation between the tangential part of the velocity and the tangential part of the Cauchy stress-vector, is related to the vorticity seeding model introduced in the computational approach to turbulent flows. The presence of a pointwise nonvanishing normal flux may be considered as a tool to avoid the use of phenomenological near wall models in the boundary layer region. Furthermore, the analysis of the problem is suggested by recent advances in the study of large eddy simulation.

In the two-dimensional case, by using rather elementary tools, we prove existence and uniqueness of weak solutions. The asymptotic behavior of the solution, with respect to the averaging radius δ, is also studied. In particular, we prove convergence of the solutions toward the corresponding solutions of the Navier–Stokes equations with the usual no-slip boundary conditions, as the small parameter δ goes to zero.

Key words. Navier–Stokes equations, boundary models for turbulent flows, existence, uniqueness, LES models

1. Introduction.

In this paper we consider the Navier–Stokes equations and in particular the role of boundary conditions in the simulation of boundary effects in turbulent flows. We consider the Navier–Stokes equations (in nondimensional form) for viscous incompressible fluids in a bounded smooth domain $\Omega \subset \mathbb{R}^n$, $n = 2, 3$:

$$\begin{cases} \partial_t u - \dfrac{2}{Re}\nabla\cdot\mathbb{D}(u) + (u\cdot\nabla)u + \nabla p = 0 \quad \text{in } \Omega\times(0,T), \\ \nabla\cdot u = 0 \quad \text{in } \Omega\times(0,T). \end{cases} \tag{1.1}$$

We recall that $u = (u_1, \ldots, u_n)$ is the unknown velocity field, p is the hydrostatic pressure, $Re > 0$ is the Reynolds number, and $\mathbb{D}(u)$ is the deformation tensor, i.e., the symmetric part of the matrix of derivatives of u,

$$\mathbb{D}(u) = \frac{1}{2}\left(\frac{\partial u_i}{\partial x_k} + \frac{\partial u_k}{\partial x_i}\right),$$

and the Navier–Stokes equations are generally equipped with the *no-slip* boundary conditions on $\Gamma = \partial\Omega$,

$$u = 0 \quad \text{on } \Gamma\times(0,T). \tag{1.2}$$

To introduce the problem that we shall study, we recall that while at a free surface it is natural to require continuity of the stress-tensor ($\mathbb{I}$ being the identity)

$$\mathbb{T}(u,p) = -p\,\mathbb{I} + \frac{2}{Re}\mathbb{D}(u),$$

the conditions at a solid wall are very challenging. The no-slip condition (1.2) has been justified by Stokes [37] since the contrary assumption "... *implies an infinitely greater resistance to the sliding of one portion of fluid past another than to the sliding of fluid over a solid*."

It is well known that there are situations in which the boundary condition (1.2) may not be valid. For instance, in Serrin [35, sect. 64] it is pointed out that in high altitude aerodynamics, or, more generally, when moderate pressure and low surface stresses are involved, the adherence condition is no longer true; see also the review in Truesdell [38]. In this respect several authors proposed various *slip* (generally nonlinear) conditions, modeling precise physical situations; see, for instance, Serrin [35], Beavers and Joseph [4], and Kreĭn and Laptev [23].

From the historical point of view, the slip (with friction) boundary condition proposed by Navier [30] was

$$u \cdot \underline{\mathrm{n}} = 0 \quad \text{and} \quad \beta\, u_\tau + \underline{\mathcal{T}}(u,p) = 0, \quad \beta > 0, \quad \text{on } \Gamma \times (0,T), \tag{1.3}$$

where $\underline{\mathrm{n}}$ denotes the unit normal vector to Γ, $u_\tau = u-(u\cdot\underline{\mathrm{n}})\underline{\mathrm{n}}$, while $\underline{\mathcal{T}}(u,p) = \underline{t}(u,p) - (\underline{t}(u,p)\cdot\underline{\mathrm{n}})\,\underline{\mathrm{n}}$ denotes the tangential part of the *Cauchy stress vector* $\underline{t}$ defined by

$$\underline{t}(u,p) = \underline{\mathrm{n}} \cdot \mathbb{T}(u,p) = \sum_{k=1}^{n} \mathbb{T}_{ik}(u,p)\underline{\mathrm{n}}_k.$$

Maxwell [27] analyzed the two types of boundary conditions (condition (1.3) proposed by Navier and condition (1.2) proposed by Stokes), observing that the same conditions may be derived within the kinetic theory of gases and that the parameter β should depend on the Reynolds number Re and on the mean free-path λ, satisfying the pair of consistency conditions

$$\begin{aligned} &\beta \to \infty \quad \text{as } \lambda \to 0 \text{ for } Re \text{ fixed},\\ &\beta \to 0 \quad \text{as } Re \to \infty \text{ for } \lambda \text{ fixed}. \end{aligned}$$

With the above asymptotics it possible to recover in both cases the correct no-slip boundary condition for viscous fluids and the no-penetration condition for ideal fluids. A study of the numerical problems related to the implementation of (1.3) can be found in John [20].

Recently, Fujita [12] performed the analysis with the "slip or leak with friction" boundary conditions. These conditions are of particular interest in the study of polymers, blood flow, and flow through filters. The boundary conditions studied in [12], with the techniques of variational inequalities, turn out to be particular cases of the nonlinear boundary condition proposed in [35, p. 240] and they are very strictly related to both the Navier and the no-slip boundary conditions. See also Consiglieri [9] for similar problems.

For laminar flows the Navier boundary condition (1.3) also appears in the presence of rough boundaries; see Jäger and Mikelić [18, 19] and Achdou, Pironneau, and Valentin [1]. In the modeling of turbulent flows it appears (with several variants, see

Sagaut [34]) in connection with conventional turbulence models and recently also in large eddy simulation (LES) models (see Layton [24]), as we shall introduce in the next section.

Among other nonstandard boundary conditions we recall those studied by Begue et al. [5] and the "do-nothing" Neumann conditions, very appealing for numerical studies, implemented in Heywood, Rannacher, and Turek [16].

1.1. Near wall models and turbulent flows. Our interest in nonstandard boundary conditions comes essentially from the study of turbulent flows. First, we recall that in the boundary layer theory several log-law and power-law boundaries with asymptotics are introduced, together with the fictitious boundaries, in order to model turbulent flows within a small region near the boundary. Roughly speaking, appropriate nonlinear boundary conditions are imposed on an artificial boundary that lies inside the computational domain. The boundary conditions may simulate (at least in a computational approach) the behavior of the boundary layer, and they are modeled to take into account the peculiar behavior of a fluid near the boundaries. In this respect we recall that Maxwell [27] observed " … *it is almost certain that the stratum of gas next to a solid body is in a very different state from the rest of the gas."*

Our main motivation comes from the mathematical theory of LES. In fact, the purpose of LES is to model the evolution of large coherent structures (eddies); this is done by studying the equations satisfied by a filtered velocity. Generally, the filtered velocity $\overline{u}$ is defined through a convolution

$$\overline{u}(x,t) = g_\delta(x) * u(x,t)$$

with a rapidly decreasing smoothing kernel g_δ of width δ; in several cases of practical interest g_δ is a Gaussian, i.e.,

$$g_\delta(x) = \left(\frac{\gamma}{\pi}\right)^{3/2} \frac{1}{\delta^3}\, \mathrm{e}^{-\frac{\gamma|x|^2}{\delta^2}}.$$

By definition, the value of $\overline{u}$ at a point x_0 on the boundary Γ will depend on the behavior of u in a neighborhood of width δ near that point; even if u is extended to zero for each $x \notin \overline{\Omega}$, it is clear that in general $\overline{u}(x_0) \neq 0$.

As pointed out in Galdi and Layton [15] the physical intuition may suggest that large coherent structures touching a wall do not penetrate, but instead slide along the wall and lose their energy. The boundary condition of Navier may be revisited by linking the microscale λ of the kinetic theory of gases with the radius δ of the averaging filter.

Many near wall models have been tested in the computational approach; see Sagaut [34] and Piomelli and Balaras [33]. The results are not uniformly successful, and a positive application is very often based on a fine tuning of parameters. This is why new models require at least a positive background from the physical hypotheses and a coherent mathematical analysis. In particular, a successful application of the Navier slip-with-friction boundary condition (1.3) is prevented by two main facts: (1) the presence of recirculation regions and (2) the presence of fast time-fluctuating quantities.

The first problem is motivated by the fact that in recirculation regions the local Reynolds number is very different from the main stream, and it is natural to expect that β should depend (possibly in a nonlinear way) on a local Reynolds number related to the local slip speed, i.e.,

$$\beta = \beta(\delta,\, |u_\tau|).$$

Preliminary analysis has been performed by John, Layton, and Sahin [21] and Dunca et al. [11], and an appropriate power-law choice of β seems promising to improve the estimation of reattachment points.

The limitation of Navier law (1.3) in a boundary layer theory is that it can well describe time-averaged flow profiles, while the information coming from fluctuating quantities in the wall-normal direction can play an important role in triggering separation and detachment. To try to overcome this limitation, very recently Layton [24] recognized a particular class of boundary conditions, leading to conditions similar "in spirit" to the so-called *vorticity seeding methods*. In fact, a Navier slip-with-friction boundary condition implies the generation of vorticity at the boundary, proportional to the tangential velocity. More precisely, in the case of a two-dimensional domain Ω, for each smooth function v such that $v \cdot \underline{\mathrm{n}} = 0$ on the boundary, it holds that

$$\underline{\mathrm{n}} \cdot \mathbb{D}(v) \cdot \underline{\tau} - \frac{1}{2}\operatorname{curl} v + k(v \cdot \underline{\tau}) = 0 \qquad \text{on } \Gamma,$$

where $\operatorname{curl} v = \partial v_1/\partial x_2 - \partial v_2/\partial x_1$, and $\underline{\tau}$ denotes the unit tangent vector, while k is the curvature of Γ.

In particular, in [24] the following boundary condition is proposed to simulate the boundary effects

$$u \cdot \underline{\mathrm{n}} = \delta^2 g(x,t) \qquad \text{and} \qquad \frac{L}{\delta Re} u_\tau + \underline{\mathcal{T}}(u,p) = 0, \tag{1.4}$$

where g is a *highly oscillating* function in the time variable (hopefully a random variable in numerical tests), while it may be very smooth in the space variables and should satisfy the natural compatibility condition

$$\int_\Gamma g(x,t)\, d\sigma = 0 \qquad \forall\, t \in (0,T), \tag{1.5}$$

which is required by the normal trace of a divergence-free vector field.

This way of reasoning is also similar to the introduction of stochastic fluctuations to simulate the microscale effects. A comprehensive introduction to stochastic partial differential equations in fluid mechanics and the statistical approach can be found in Monin and Yaglom [28], and one main mathematical paradigm is that an additional nonsmooth term on the right-hand side may naturally take into account the effect of the fast fluctuating quantities. This leads us to study the system

$$\partial_t u - \frac{2}{Re}\nabla \cdot \mathbb{D}(u) + (u \cdot \nabla)u + \nabla p = f + \frac{\partial g}{\partial t},$$

where g is a function that does not have a proper time derivative, but is just continuous or with other weak properties. For the above problems the study of an appropriate notion of solution, together with the corresponding statistical properties, started in Bensoussan and Temam [7] and Višik and Fursikov [39].

1.2. Setting of the problem. In what follows we shall restrict our discussion to the two-dimensional case, since the nonlinear character of the equations imposes some restriction; see Remark 2.5. Furthermore, we fix the values of both L and the Reynolds number to 2, due to the fact that we will not deal with the singular limit $Re \to \infty$. (Regarding this limit see also the recent works of Clopeau, Mikelić, and Robert [8], Lopes Filho, Nussenzveig Lopes, and Planas [26], Mucha [29], and Kelliher [22].) In our case we shall study the following boundary-initial value problem:

$$
\begin{cases}
\partial_t u - \nabla \cdot \mathbb{D}(u) + (u \cdot \nabla)u + \nabla p = f & \text{in } \Omega \times (0,T), \\
\nabla \cdot u = 0 & \text{in } \Omega \times (0,T), \\
u \cdot \underline{\mathrm{n}} = \delta^\alpha g(x,t) & \text{on } \Gamma \times (0,T), \\
u \cdot \underline{\tau} + \delta\, \underline{\mathrm{n}} \cdot \mathbb{D}(u) \cdot \underline{\tau} = 0 & \text{on } \Gamma \times (0,T), \\
u(x,0) = u_0(x) & \text{in } \Omega.
\end{cases}
\tag{1.6}
$$

Remark 1.1. The above problem with $\alpha = 2$ describes the experiment in [4], where δ represents the characteristic pore size and the system is laminar. The error estimate we derive is consistent with the first step in the homogenization procedure employed by Jäger and Mikelić [17] to obtain the law of Beavers and Joseph.

Note that a similar problem, but involving the Smagorinsky–Ladyženskaya turbulence model together with a nonlinear dependence of β on u, has been studied, for instance, by Parés [32], but in that reference the normal datum g is not allowed to depend on the time variable. In what follows our main interest will be to find weak hypotheses on $g(x,t)$ with respect to the time variable (without any essential restriction on the space regularity) that allow us to prove existence of weak solutions to the Navier–Stokes equations; see Theorem 1.2. In particular, in our analysis we will focus on two main points: (1) to show the existence of weak solutions in the sense of Leray and Hopf (since we do not want to deal with any weaker concept of solution) and (2) to use only elementary tools of functional analysis.

In other words, we want to consider solutions in a very standard sense and we also want to interact with applied people interested in this problem, while still keeping all the mathematical rigor needed to deal with the problem and a certain sharpness of the results. In the case of nonhomogeneous no-slip conditions, several results of existence and uniqueness of other classes of solutions can be found in Amann [3].

Our intent to have a nonvanishing normal datum can be heuristically understood also with the following argument: Suppose that (for simplicity in two dimensions) we have a fictitious boundary Γ_1 and we want to impose a condition on it in order to resolve numerically the equation in a smaller domain $\Omega_1 \subset \Omega$ that rules out the boundary layer (see Figure 1 below).

We have to require, by the incompressibility of the flow, that

$$
\int_{\{ABCD\}} \nabla \cdot u \, dx = \int_{\partial\{ABCD\}} u \cdot \underline{\mathrm{n}} \, d\sigma = 0
$$

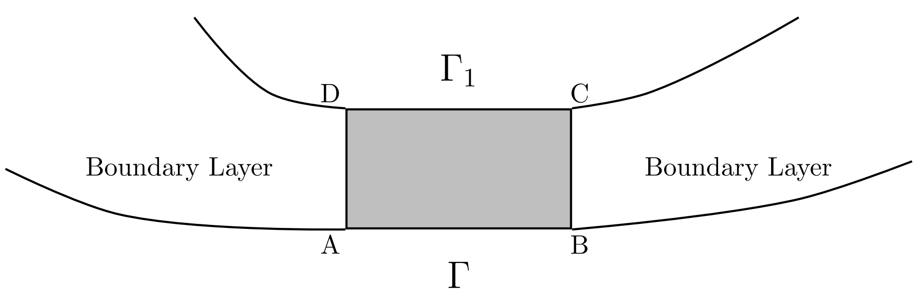

FIG. 1. *The fictitious boundary.*

for each (also curvilinear or infinitesimal) "rectangle" $\{ABCD\}$ touching the boundary Γ as in the figure. Since the behavior of the flow is not known, in general we have

$$\int_{\{CD\}} u \cdot \underline{\mathrm{n}}\, ds = -\left[\int_{\{BC\}} u \cdot \underline{\mathrm{n}}\, ds + \int_{\{DA\}} u \cdot \underline{\mathrm{n}}\, ds\right] \neq 0,$$

while the line integral over the segment $\{AB\}$ vanishes, since on the "true boundary" Γ both the Navier and no-slip conditions impose that $u \cdot \underline{\mathrm{n}} = 0$.

This may justify the introduction of a nonvanishing normal flux, also with very low regularity properties, namely, the same shared by the trace of a turbulent flow in the boundary layer region.

1.3. Main results. In this section we briefly enunciate the results we shall prove, together with their precise and rigorous statement.

In what follows Ω will denote a bounded, connected, open set in $\mathbb{R}^2$, locally situated on one side of its boundary Γ, a manifold of (at least) class $C^{1,1}$ (Lipschitz-continuous first derivatives). The existence of the unit outward normal $\underline{\mathrm{n}}$ derives by results proved in Nečas [31].

The first result we shall prove is an existence and uniqueness theorem for weak solutions of the Navier–Stokes system (1.6), with boundary conditions (1.4).

THEOREM 1.2. *Assume $g \in H^{\frac{1}{2}+\varepsilon}(0,T;H^{\frac{1}{2}}(\Gamma))$, for some $\varepsilon > 0$ satisfying the compatibility condition* (1.5)*; $f \in L^2((0,T)\times\Omega)$; and $u_0 \in L^2(\Omega)$, with $\nabla \cdot u_0 = 0$. Then there exists a unique weak solution*

$$u \in L^\infty(0,T;L^2(\Omega)) \cap L^2(0,T;H^1(\Omega)),$$

of problem (1.6)*.*

Next, we want to study the behavior of the solution to problem (1.6) as the small parameter δ converges to zero. (Other convergence results, under similar assumptions, have been also proved in [22].) In view of the considerations of the previous section, one can expect that, as the boundary layer becomes thinner and thinner, the solutions will look more and more like the classical solutions corresponding to the *no-slip* boundary condition. Indeed, this is the case, as shown by Theorem 1.3.

Let u_δ be the solution of (1.6) (we emphasize the dependence on δ in this framework) and let v be the solution to the Navier–Stokes equations with the same initial value and no-slip boundary conditions. (To be more precise, the vector field v is the solution to system (3.2).) As we shall see in section 3,

$$u_\delta = v + \mathcal{O}(\delta^{\frac{1}{3}}),$$

so that the "no-slip solution" represents the average behavior, once one neglects the effect at the boundary. The term $u_\delta - v$ can be seen as the "fluctuation term," which takes into account the nontrivial dynamics at the boundary.

THEOREM 1.3. *Assume $u_0 \in H^1(\Omega)$, with $\nabla \cdot u_0 = 0$, $g \in H^{\frac{1}{2}+\varepsilon}(0,T;H^{\frac{1}{2}}(\Gamma))$ satisfying the compatibility condition* (1.5)*, and $f \in L^2((0,T)\times\Omega)$. Then*

$$\sup_{0\le t\le T} \|u_\delta - v\|^2 + \int_0^T \left(\|\mathbb{D}(u_\delta - v)\|^2 + \frac{1}{\delta}\|(u_\delta - v)\cdot \underline{\tau}\|_\Gamma^2\right) dt = \mathcal{O}(\delta^{\frac{2}{3}}).$$

In particular, u_δ converges to v in $L^\infty(0,T;L^2(\Omega))$ and $L^2(0,T;H^1(\Omega))$.

2. A result of existence and uniqueness of weak solutions. In this section we prove Theorem 1.2. For the sake of simplicity, we consider the normal datum as

$$u \cdot \underline{\mathrm{n}} = g(x, t);$$

i.e., we drop the dependence on δ, since it is not relevant in view of the existence and uniqueness result we are going to show. In the last section we shall see how to deal with a right-hand side that scales by a power of δ.

Let us consider the evolution problem

$$\begin{cases} \partial_t u - \nabla \cdot \mathbb{D}(u) + (u \cdot \nabla)\, u + \nabla p = f & \text{in } \Omega \times (0, T), \\ \nabla \cdot u = 0 & \text{in } \Omega \times (0, T), \\ u \cdot \underline{\mathrm{n}} = g(x, t) & \text{on } \Gamma \times (0, T), \\ \delta\, \underline{\mathrm{n}} \cdot \mathbb{D}(u) \cdot \underline{\tau} + u \cdot \underline{\tau} = 0 & \text{on } \Gamma \times (0, T), \\ u(x, 0) = u_0(x) & \text{in } \Omega, \end{cases} \tag{2.1}$$

with $f \in L^2((0, T) \times \Omega)$ and $\nabla \cdot f = 0$, just to avoid technicalities, and with g not very smooth, say

$$g \in H^{1/2+\epsilon}(0, T; H^{1/2}(\Gamma)), \tag{2.2}$$

satisfying the compatibility condition (1.5).

2.1. Function spaces. We use the classical Lebesgue spaces and in particular, we will work exclusively in the Hilbert framework and thus use the space L^2. For simplicity we do not distinguish between space of scalar, vector, or either tensor valued functions, and the symbol $\|\,.\,\|$ will denote the norm in $L^2(\Omega)$. The norm in $L^2(\Gamma)$ will be denoted by $\|\,.\,\|_\Gamma$.

In what follows we shall use the customary Sobolev spaces, for which we refer to Adams [2], and the notion of "trace" over the boundary Γ of Ω. Mainly we shall use the space $H^1(\Omega)$ with norm denoted by $\|\,.\,\|_{H^1}$ and its trace space $H^{1/2}(\Gamma)$, with norm $\|\,.\,\|_{H^{\frac{1}{2}}(\Gamma)}$.

In addition, we define the spaces

$$H = \{\, u \in L^2(\Omega) \,|\, \nabla \cdot u = 0,\ u \cdot \underline{\mathrm{n}} = 0 \text{ on } \Gamma \,\},$$

and

$$V = \{\, u \in H^1(\Omega) \,|\, \nabla \cdot u = 0,\ u \cdot \underline{\mathrm{n}} = 0 \text{ on } \Gamma \,\},$$

and we endow V with the norm $\|u\|_V = \|\nabla u\|$. Moreover, we define the space of tangential vector fields as

$$H^1_\tau = \{\, u \in H^1(\Omega) \,|\, u \cdot \underline{\mathrm{n}} = 0 \text{ on } \Gamma \,\}.$$

2.1.1. Fractional derivative. In order to properly define the spaces we shall use, we also need to define fractional derivatives. The fractional derivative may be defined through singular integrals

$$D^\alpha_t U(x, t) = \frac{d}{dt} \int_0^t \frac{U(s, x)}{(t - s)^\alpha}\, ds \qquad \text{for } 0 \le \alpha < 1,$$

but for our purposes it is better to deal with a definition via the Fourier transform.

Given $\phi(x,t)$, defined for $t \in [0,T]$, with values in the Hilbert space $(\mathbb{X}, \|\,.\,\|_{\mathbb{X}})$ and integrable (in the Bochner sense), we define

$$\widetilde{\phi}(t,x) = \begin{cases} \phi(t,x) & \text{for } t \in [0,T], \\ 0 & \text{elsewhere,} \end{cases} \tag{2.3}$$

and its Fourier transform (with respect to the time variable) is

$$\widehat{\phi}(x,\xi) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} \widetilde{\phi}(x,t)\, \mathsf{e}^{-\mathtt{i}t\xi}\, dt,$$

so that we can define the fractional Sobolev spaces of functions having α-order derivative in L^2:

$$H^{\alpha}(\mathbb{R};\mathbb{X}) := \left\{ f \in L^2(\mathbb{R};\mathbb{X}) : \int_{\mathbb{R}} |\xi|^{2\alpha} \|\widehat{f}(\xi)\|^2_{\mathbb{X}}\, d\xi < \infty \right\}.$$

2.2. The linear stationary problem. The first step in solving (2.1) is to consider the linear stationary problem

$$\begin{cases} -\nabla \cdot \mathbb{D}(G) + \nabla \Pi = 0 & \text{in } \Omega \times (0,T), \\ \nabla \cdot G = 0 & \text{in } \Omega \times (0,T), \\ G \cdot \underline{\mathrm{n}} = g(x,t) & \text{on } \Gamma \times (0,T), \\ \delta\, \underline{\mathrm{n}} \cdot \mathbb{D}(G) \cdot \underline{\tau} + G \cdot \underline{\tau} = 0 & \text{on } \Gamma \times (0,T), \end{cases} \tag{2.4}$$

where the time variable is now just a parameter.

THEOREM 2.1. *Let the following be given: $g \in H^{1/2+\epsilon}(0,T;H^{1/2}(\Gamma))$, satisfying the compatibility condition* (1.5). *Then, there exists a unique G solution of* (2.4) *such that*

$$G(x,t) \in H^{1/2+\epsilon}(0,T;H^1(\Omega)). \tag{2.5}$$

Moreover, there is a constant C_0, depending only on Ω, such that

$$\|\nabla G\| + \|\Pi\| \leq C_0(1+\delta^{-\frac{1}{2}})\|g\|_{H^{\frac{1}{2}}(\Gamma)}. \tag{2.6}$$

Proof. See Solonnikov and Ščadilov [36] and Beirão da Veiga [6]. In fact, for each t it is possible to solve a linear stationary Stokes problem (with the appropriate boundary conditions) that has a unique solution belonging to $H^1(\Omega)$. The regularity in the time variable is inherited by the function G.

We give a formal (but completely justified) argument for the estimate (2.6), following the approach to the existence in L^2-spaces introduced in Beirão da Veiga [6] to find appropriate estimates on G. We consider the bilinear form

$$B(u,\phi) = \int_{\Omega} \mathbb{D}(u)\mathbb{D}(\phi)\, dx,$$

and the functions (G,Π) that solve (2.4) must satisfy

$$B(G,\phi) - \int_{\Omega} \Pi\, \nabla \cdot \phi\, dx + \frac{1}{\delta} \int_{\Gamma} G \cdot \phi\, d\sigma = 0 \qquad \forall\, \phi \in H^1_{\tau}.$$

In order to deal with the inhomogeneous problem, we introduce a vector field G_1 such that

$$\begin{cases} \nabla \cdot G_1 = 0 & \text{in } \Omega, \\ G_1 \cdot \underline{\mathrm{n}} = g & \text{on } \Gamma, \\ \|G_1\|_{H^1} \leq C\|g\|_{H^{\frac{1}{2}}(\Gamma)}. \end{cases}$$

The construction of such a vector field is rather standard and can be found, for instance, in Galdi [14].

By defining $G = G_1 + G_2$, the function G_2 must satisfy

$$B(G_2, \phi) - \int_\Omega \Pi\, \nabla \cdot \phi\, dx + \frac{1}{\delta}\int_\Gamma G_2 \cdot \phi\, d\sigma = -B(G_1, \phi) - \frac{1}{\delta}\int_\Gamma G_1 \cdot \phi\, d\sigma$$

for each ϕ tangential to the boundary. If $\phi = G_2$, we get (since $G_2 \cdot \underline{\mathrm{n}} = 0$ and $\nabla \cdot G_2 = 0$)

$$\|\nabla G_2\|^2 + \frac{1}{\delta}\|G_2\|_\Gamma^2 \leq \|\nabla G_2\|\, \|\nabla G_1\| + \frac{1}{\delta}\|G_1\|_\Gamma \|G_2\|_\Gamma$$

and, consequently,

$$\frac{1}{2}\|\nabla G_2\|^2 + \frac{1}{2\delta}\|G_2\|_\Gamma^2 \leq \frac{1}{2}\|\nabla G_1\|^2 + \frac{1}{2\delta}\|G_1\|_\Gamma^2.$$

This finally implies that

$$\|\nabla G_2\|^2 \leq C\left(1 + \frac{1}{\delta}\right)\|g\|^2_{H^{\frac{1}{2}}(\Gamma)},$$

where the constant C depends on Ω but is independent of δ. The estimate on the pressure can be obtained by approximation, by studying a slightly different equation; see [6] for details. □

Indeed, notice that, for our aims, it is enough to have

$$G(x,t) \in H^{1/2+\epsilon}(0,T; L^2(\Omega)) \cap L^2(0,T; H^1(\Omega)), \tag{2.7}$$

but currently we do not know the minimal assumption on g in order to have the above regularity. Regarding the usual no-slip boundary conditions, see the result proved by Fursikov, Gunzburger, and Hou [13].

2.3. The linear evolution problem. The next step for the analysis of the nonlinear evolution problem (2.1) is the following linear evolution problem:

$$\begin{cases} \partial_t z - \nabla \cdot \mathbb{D}(z) + \nabla q = 0 & \text{in } \Omega \times (0,T), \\ \nabla \cdot z = 0 & \text{in } \Omega \times (0,T), \\ z \cdot \underline{\mathrm{n}} = g & \text{on } \Gamma \times (0,T), \\ \delta\, \underline{\mathrm{n}} \cdot \mathbb{D}(z) \cdot \underline{\tau} + z \cdot \underline{\tau} = 0 & \text{on } \Gamma \times (0,T), \\ z(x,0) = G(x,0) & \text{in } \Omega. \end{cases} \tag{2.8}$$

We shall treat the nonlinear problem as a perturbation of such a linear system. Let us introduce the new unknowns

$$Z(x,t) = z(x,t) - G(x,t) \quad \text{and} \quad Q(x,t) = q(x,t) - \Pi(x,t)$$

so that we are reduced to a homogeneous problem for the new unknowns (Z, Q):

$$
\begin{cases}
\partial_t Z - \nabla \cdot \mathbb{D}(Z) + \nabla Q = -\partial_t G & \text{in } \Omega \times (0,T), \\
\nabla \cdot Z = 0 & \text{in } \Omega \times (0,T), \\
Z \cdot \underline{\mathrm{n}} = 0 & \text{on } \Gamma \times (0,T), \\
\delta\, \underline{\mathrm{n}} \cdot \mathbb{D}(Z) \cdot \underline{\tau} + Z \cdot \underline{\tau} = 0 & \text{on } \Gamma \times (0,T), \\
Z(x,0) = 0 & \text{in } \Omega.
\end{cases} \tag{2.9}
$$

The above problem is not completely standard, since the right-hand side does not satisfy the usual properties. For instance, one can note that $\partial_t G$ does not belong to the domain of the Stokes operator, since $\partial_t G \cdot \underline{\mathrm{n}} \neq 0$. This is the main difficulty: The low regularity of this term can be treated in a more standard way, while the above fact is responsible for a different approach.

THEOREM 2.2. *Assume that* (G, Π) *is a solution to system* (2.4), *with* G *satisfying the regularity property* (2.7). *Then there exists a unique solution* (z, q) *(where* q *is unique up to an additive function not depending on the space variable) to system* (2.8) *such that*

$$
z \in L^\infty(0,T; L^2(\Omega)) \cap L^2(0,T; H^1(\Omega)) \cap H^{\frac{1}{2}-\varepsilon}(0,T; L^2(\Omega)). \tag{2.10}
$$

Moreover,

$$
\begin{aligned}
\sup_{0 \le t \le T} \|z(t)\|^2 + \int_0^T \left(\|\mathbb{D}(z)(t)\|^2 + \frac{1}{\delta} \|z(t) \cdot \underline{\tau}\|_\Gamma^2 \right) dt + \|z\|^2_{H^{\frac{1}{2}-\varepsilon}(0,T;L^2(\Omega))} \\
\le C \left(\|G\|^2_{H^{\frac{1}{2}+\varepsilon}(0,T;L^2(\Omega))} + \int_0^T \|\mathbb{D}(G)\|^2 \, dt \right).
\end{aligned} \tag{2.11}
$$

Proof. By virtue of Theorem 2.1, it is enough to prove the same claim of this theorem on the solution (Z, Q) of problem (2.9). Since we just know that $\partial_t G \in H^{-\frac{1}{2}+\varepsilon}(0,T; L^2(\Omega))$, we introduce a sequence $G^N \in H^1(\mathbb{R}; L^2(\Omega))$ of approximate functions such that

(a) $G^N|_{[0,T]} \longrightarrow G$ in $H^{\frac{1}{2}+\varepsilon}(0,T; L^2(\Omega))$ as $N \to \infty$,

(b) $\|\partial_t G^N\|_{L^2(0,T;L^2(\Omega))} = N$.

The way to do this extension is rather standard: First, we can define $\overline{G} : \mathbb{R} \to L^2(\Omega)$ with an extension by reflection. Then, we consider a sequence ρ_N of mollifiers and the function G_N will be the restriction on $[0,T]$ of the function $\rho_N * \overline{G}$.

The proof is based on the Faedo–Galerkin procedure. By Clopeau, Mikelić, and Robert [8] (but also the recent abstract results in [6]), we know that there exists a basis $\{\phi_n\}_{n \in \mathbb{N}}$ of functions in $H^3(\Omega)$ of the space V (and also of H), such that

$$
\delta\, \underline{\mathrm{n}} \cdot \mathbb{D}(\phi_n) \cdot \underline{\tau} + \phi_n \cdot \underline{\tau} = 0.
$$

Now, let $Z_n^N(t,x) = \sum_{k=1}^n \zeta_{n,k}^N(t) \phi_k(x)$ be the solution of the following (finite-dimensional) linear system of ordinary differential equations (ODEs):

$$
\begin{cases}
\dfrac{d}{dt} \displaystyle\int_\Omega Z_n^N \cdot \phi_k + \int_\Omega \mathbb{D}(Z_n^N) \cdot \mathbb{D}(\phi_k) + \frac{1}{\delta} \int_\Gamma (Z_n^N \cdot \underline{\tau})\, (\phi_k \cdot \underline{\tau})\, d\sigma = -\frac{d}{dt} \int_\Omega G^N \cdot \phi_k, \\
\displaystyle\int_\Omega Z_n^N(x,0) \cdot \phi_k \, dx = 0
\end{cases}
$$

for $t \in (0,T)$ and $k = 1,\dots,n$. Notice that the divergence-free constraint and the boundary conditions on Z_n^N are automatically verified. By using a standard argument it is easy to prove that such a system of ODEs has a unique solution $Z_n^N \in L^\infty(0,T;L^2(\Omega)) \cap L^2(0,T;H^1(\Omega))$. Indeed, by multiplying each equation by the corresponding term $\zeta_{n,k}^N$, summing over k, and integrating by parts over Ω, one easily obtains the following estimate:

$$\sup_{0\le t\le T}\|Z_n^N(t)\|^2 + \int_0^T\left(\|\mathbb{D}(Z_n^N)\|^2 + \frac{1}{\delta}\int_0^T\|Z_n^N\|_\Gamma^2\right)dt \le C\|G^N\|^2_{H^1(0,T;L^2(\Omega))},$$

with a constant C, depending only on Ω. Unfortunately, such an estimate, beside being uniform in n, is not uniform in N due to property (b) of the approximate sequence $\{G^N\}_{N\in\mathbb{N}}$. Hence, we need other a priori estimates on the solutions Z_n^N of the finite-dimensional problem. We continue working on the Z_n^N, since such functions are smooth enough for all computations that will be performed.

We again multiply the equations by the terms $\zeta_{n,k}^N$, sum over k, and integrate by parts, but now we estimate the right-hand side in the following way:

(2.12)
$$\begin{aligned}\sup_{0\le t\le T}\|Z_n^N(t)\|^2 + \int_0^T\left(\|\mathbb{D}(Z_n^N)\|^2 + \frac{1}{\delta}\|Z_n^N\|_\Gamma^2\right)dt &\le \left|\int_0^T\int_\Omega \partial_t G^n\cdot Z_n^N\right| dx\,dt\\ &\le \|\partial_t G^N\|_{H^{-\frac12+\varepsilon}(0,T;L^2(\Omega))}\|Z_n^N\|_{H^{\frac12-\varepsilon}(0,T;L^2(\Omega))}\\ &\le \|G^N\|_{H^{\frac12+\varepsilon}(0,T;L^2(\Omega))}\|Z_n^N\|_{H^{\frac12-\varepsilon}(0,T;L^2(\Omega))},\end{aligned}$$

so that we need only show a uniform estimate (with respect to both n and N) of Z_n^N in the space $H^{\frac12-\varepsilon}(0,T;L^2(\Omega))$. We shall use the Fourier transform characterization of the norm of fractional Sobolev spaces (see Adams [2]) to get such an estimate. Each $\widetilde{Z}_n^N$ (such functions have been defined in (2.3)) is a solution of the following equation:

$$\begin{aligned}&\frac{d}{dt}\int_\Omega \widetilde{Z}_n^N\cdot\phi_k + \int_\Omega \mathbb{D}(\widetilde{Z}_n^N)\cdot\mathbb{D}(\phi_k) + \frac{1}{\delta}\int_\Gamma \widetilde{Z}_n^N\cdot\phi_k\,d\sigma\\ &\quad= -\frac{d}{dt}\int_\Omega \widetilde{G}^N\cdot\phi_k + \delta(t)\int_\Omega G^N(0)\cdot\phi_k - \delta(t-T)\int_\Omega (Z_n^N(T)+G^N(T))\cdot\phi_k\end{aligned}$$

for each $k = 1,\dots,n$, in the sense of distributions with respect to the time variable. Here $\delta(\cdot)$ is the usual Dirac's *delta function*. In the frequency Fourier variable ξ, the above equation reads as follows:

$$\begin{aligned}&-\mathtt{i}\xi\int_\Omega \widehat{Z}_n^N\cdot\phi_k + \int_\Omega \mathbb{D}(\widehat{Z}_n^N)\cdot\mathbb{D}(\phi_k) + \frac{1}{\delta}\int_\Gamma \widehat{Z}_n^N\cdot\phi_k\,d\sigma\\ &\qquad= \mathtt{i}\xi\int_\Omega \widehat{G}^N\cdot\phi_k + \int_\Omega G^N(0)\cdot\phi_k - \mathtt{e}^{-\mathtt{i}\xi T}\int_\Omega (Z_n^N(T)+G^N(T))\cdot\phi_k;\end{aligned}$$

see, for instance, Lions [25], where this tool is used to prove estimates on the fractional derivative of the solution. Note that in [25], and in all works involving fractional derivatives for the Navier–Stokes equations, the starting point is the existence of a weak solution, on which it is possible to prove additional estimates. In our case the existence of a weak solution derives from the fractional derivative estimates and at present it does not seem possible to prove the usual existence results.

Consequently, we get

$$-\,\mathtt{i}\xi\|\widehat{Z}_n^N(\xi)\|^2+\|\mathbb{D}(\widehat{Z}_n^N)(\xi)\|^2+\frac{1}{\delta}\|\widehat{Z}_n^N(\xi)\|_\Gamma^2$$
$$=\mathtt{i}\xi\int_\Omega \widehat{G}^N\cdot\overline{\widehat{Z}_n^N}+\int_\Omega G^N(0)\cdot\overline{\widehat{Z}_n^N}-\mathtt{e}^{-\mathtt{i}\xi T}\int_\Omega (Z_n^N(T)+G^N(T))\cdot\overline{\widehat{Z}_n^N}.$$

Take the imaginary part and multiply both sides of the previous formula by $|\xi|^{2\alpha-1}$, with $\alpha<\frac{1}{2}$ so that, by using Young's inequality, one gets

$$|\xi|^{2\alpha}\|\widehat{Z}_n^N(\xi)\|^2\le C|\xi|^{2\alpha}\|\widehat{G}^N\|^2+C|\xi|^{2\alpha-2}(\|G^N(T)\|+\|Z_n^N(T)\|+\|G^N(0)\|)^2.$$

In order to estimate the integral $\int_{\mathbb{R}}|\xi|^{2\alpha}\|\widehat{Z}_n^N(\xi)\|^2\,d\xi$, we split it into two parts: by the above estimate,

$$\int_{|\xi|>1}|\xi|^{2\alpha}\|\widehat{Z}_n^N(\xi)\|^2$$
$$\le C\int_{\mathbb{R}}|\xi|^{2\alpha}\|\widehat{G}^N\|^2+C(\|G^N(T)\|+\|Z_n^N(T)\|+\|G^N(0)\|)^2\int_{|\xi|>1}|\xi|^{2\alpha-2};$$

the first term on the right-hand side is controlled by $C\|G^N\|^2_{H^{\frac{1}{2}+\varepsilon}(0,T;L^2(\Omega))}$, while

$$\|Z_n^N(T)\|^2\le C\|G^N\|_{H^{\frac{1}{2}+\varepsilon}(0,T;L^2(\Omega))}\|Z_n^N\|_{H^{\frac{1}{2}-\varepsilon}(0,T;L^2(\Omega))},$$

by virtue of (2.12); $\|G^N(0)\|$ is bounded by $\|G(0)\|$; and finally, by using the Morrey inequality (see Adams [2]), which implies $H^{1/2+\varepsilon}(0,T)\subset C([0,T])$, we get

$$\|G^N(T)\|\le\|G^N\|_{H^{\frac{1}{2}+\varepsilon}(0,T;L^2(\Omega))}.$$

The second part is estimated as follows, by using Parseval's theorem, Poincaré's inequality, and estimate (2.12):

$$\begin{aligned}\int_{|\xi|\le 1}|\xi|^{2\alpha}\|\widehat{Z}_n^N\|^2\,d\xi&\le\int_{\mathbb{R}}\|\widehat{Z}_n^N\|^2\,d\xi=\int_0^T\|Z_n^N(t)\|^2\,dt\\&\le C\int_0^T\|\mathbb{D}(Z_n^N)\|^2dt\\&\le C\|G^N\|_{H^{\frac{1}{2}+\varepsilon}(0,T;L^2(\Omega))}\|Z_n^N\|_{H^{\frac{1}{2}-\varepsilon}(0,T;L^2(\Omega))}.\end{aligned}$$

In conclusion, by collecting all of the above estimates we finally get that, for each $\varepsilon\in(0,\frac{1}{2})$, there exists a constant C, depending only on Ω and ε, such that

$$\|Z_n^N\|_{H^{\frac{1}{2}-\varepsilon}(0,T;L^2(\Omega))}\le C\|G^N\|_{H^{\frac{1}{2}+\varepsilon}(0,T;L^2(\Omega))},\tag{2.13}$$

which, together with (2.12), shows that Z_n^N is bounded, uniformly in n and N, in the spaces $H^{\frac{1}{2}-\varepsilon}(0,T;L^2(\Omega))$, $L^\infty(0,T;L^2(\Omega))$ and $L^2(0,T;H^1(\Omega))$.

Hence, it is possible to extract a (diagonal) subsequence converging weakly in $L^2(0,T;H^1(\Omega))$, weakly-$*$ in $L^\infty(0,T;L^2(\Omega))$, and strongly in $L^2((0,T)\times\Omega)$ to the unique solution Z of problem (2.9). Indeed, $Z\in H^{\frac{1}{2}-\varepsilon}(0,T;L^2(\Omega))$, that is, the topological dual space of $H^{-\frac{1}{2}+\varepsilon}(0,T;L^2(\Omega))$, the space to which $\partial_t G$ belongs. Furthermore, by passing to the limit and using the semicontinuity of the norms, it follows that Z satisfies the claim stated at the beginning of this proof. ◻

Remark 2.3. The assumption $g \in H^{\frac{1}{2}+\varepsilon}(0,T;H^{\frac{1}{2}}(\Gamma))$, which in turn gives $G \in H^{\frac{1}{2}+\varepsilon}(0,T;H^1(\Omega))$, seems to be rather technical for the presence of ϵ. If $g \in H^{\frac{1}{2}}(0,+\infty;H^{\frac{1}{2}}(\Gamma))$, it follows that $G \in H^{\frac{1}{2}}(0,+\infty;H^1(\Omega))$ and Theorem 2.2 holds accordingly.

Indeed, the main point is estimate (2.12), in which the right-hand side becomes $\|G^N\|_{H^{\frac{1}{2}}}\|Z_n^N\|_{H^{\frac{1}{2}}}$ and, following the lines of the proof presented above, the estimate on the Fourier transform gives that Z_n^N is bounded, uniformly in n and N, in $H^{\frac{1}{2}}(0,+\infty;L^2(\Omega))$. Notice that in the *critical* case $H^{\frac{1}{2}}$, we work on the whole time interval $[0,+\infty)$ to avoid the boundary terms $\|G^N(0)\|$ and $\|G^N(T)\|$, which cannot be estimated by using the Morrey inequality.

We also note that this small relaxation on the assumptions on G requires us to add the hypothesis $G \in L^\infty(0,T;L^2(\Omega))$. Otherwise the function z will not itself belong to $L^\infty(0,T;L^2(\Omega))$ and this fact is crucial to proving the corresponding bound for weak solutions to the full nonlinear Navier–Stokes problem.

2.4. The nonlinear problem. In this section we finally prove Theorem 1.2. Again, we make use of an auxiliary problem; namely, we introduce the new variables

$$U = u - z \qquad \text{and} \qquad P = p - q,$$

where (z,q) is the solution to the linear evolution problem (2.8), and the pair (U,P) solves the following problem:

$$\begin{cases} \partial_t U - \nabla\cdot\mathbb{D}(U) + [(U+z)\cdot\nabla](U+z) + \nabla P = f & \text{in } \Omega\times(0,T),\\ \nabla\cdot U = 0 & \text{in } \Omega\times(0,T),\\ U\cdot\underline{\mathrm{n}} = 0 & \text{on } \Gamma\times(0,T),\\ \delta\,\underline{\mathrm{n}}\cdot\mathbb{D}(U)\cdot\underline{\tau} + U\cdot\underline{\tau} = 0 & \text{on } \Gamma\times(0,T),\\ U(x,0) = u_0(x) - G(x,0) & \text{in } \Omega. \end{cases} \tag{2.14}$$

By virtue of Theorem 2.2, the existence Theorem 1.2 for the nonlinear problem is a straightforward consequence of the following proposition.

PROPOSITION 2.4. *Assume that* (G,Π) *is a solution to system* (2.4), *with* $G \in H^{\frac{1}{2}+\varepsilon}(0,T;L^2(\Omega)) \cap L^2(0,T;H^1(\Omega))$. *Then, there exists a unique*

$$U \in L^\infty(0,T;L^2(\Omega)) \cap L^2(0,T;H^1(\Omega)) \tag{2.15}$$

solution to problem (2.14). *Moreover, the following estimate holds true:*

$$\begin{aligned} \sup_{0\le s\le t}\|U(s)\|^2 + \int_0^t \left(\|\mathbb{D}(U)\|^2 + \frac{1}{\delta}\|U\|_\Gamma^2\right) ds \\ \le \|u_0 - G(\cdot,0)\|^2 \mathrm{e}^{A(t)} + C\int_0^t (\|f\|^2 + \|\nabla z(s)\|^2\|z(s)\|)\mathrm{e}^{A(t)-A(s)}\, ds, \end{aligned} \tag{2.16}$$

where

$$A(t) = Ct + C\left(1 + \|z\|^2_{L^\infty(0,T;L^2(\Omega))}\right)\int_0^t \|\nabla z\|^2\, ds$$

and C *is a constant depending only on* Ω.

Proof. The proof is rather standard and proceeds via a Faedo–Galerkin approximation, as in the proof of Theorem 2.2. We show only an a priori estimate, whose computations are formal but completely meaningful at the level of the Faedo–Galerkin approximate functions. Multiply (2.14) by U and integrate by parts to get

$$\frac{1}{2}\frac{d}{dt}\|U\|^2+\|\mathbb{D}(U)\|^2+\frac{1}{\delta}\|U\|_\Gamma^2=\int_\Omega U\cdot[(U+z)\cdot\nabla](U+z)+\int_\Omega f\cdot U.$$

The estimate of the integral involving f is straightforward, since it is bounded by $\|f\|^2+\|U\|^2$. We estimate the nonlinear term in the right-hand side by using the Gagliardo–Nirenberg inequality

$$\|u\|_{L^4}\leq C\|u\|^{1/2}\|\nabla u\|^{1/2}\qquad\forall\, u\in H^1(\Omega). \tag{2.17}$$

Note that such an inequality is a little bit more general than the so-called *Ladyžhenskaya inequality*, since here the functions are not vanishing on the boundary of Ω and the constant C depends on Ω.

We first observe that since $\nabla\cdot U=0$ and $U\cdot\underline{\mathrm{n}}=0$, then

$$\int_\Omega U\cdot(U\cdot\nabla)U=0\qquad\text{and}\qquad\int_\Omega U\cdot(U\cdot\nabla)z=-\int_\Omega z\cdot(U\cdot\nabla)U,$$

so that, by using repeatedly the Gagliardo–Nirenberg inequality given above, Hölder's inequality, and Young's inequality, we get

$$\begin{aligned}\left|\int_\Omega U\cdot[(U+z)\cdot\nabla](U+z)\right| &\leq 2\|U\|_{L^4}\|z\|_{L^4}\|\nabla U\|+\|U\|_{L^4}\|z\|_{L^4}\|\nabla z\|\\ &\leq\frac{1}{2}\|\nabla U\|^2+C\|z\|_{L^4}^4\|U\|^2+C\|z\|_{L^4}^{\frac{4}{3}}\|\nabla z\|^{\frac{4}{3}}\|U\|^{\frac{2}{3}}\\ &\leq\frac{1}{2}\|\nabla U\|^2+C\|z\|^2\|\nabla z\|^2\|U\|^2+C\|z\|^{\frac{2}{3}}\|\nabla z\|^2\|U\|^{\frac{2}{3}}\\ &\leq\frac{1}{2}\|\nabla U\|^2+C(1+\|z\|^2)\|\nabla z\|^2\|U\|^2+C\|\nabla z\|^2\|z\|.\end{aligned}$$

Since, by Theorem 2.2, $z\in L^\infty(0,T;L^2(\Omega))\cap L^2(0,T;H^1(\Omega))$, both terms $(1+\|z\|^2)\|\nabla z\|^2$ and $\|\nabla z\|^2\|z\|$ are integrable in time, and, by Gronwall's lemma, we can deduce that U is bounded in $L^\infty(0,T;L^2(\Omega))$ and $L^2(0,T;H^1(\Omega))$. Moreover, formula (2.16) also follows.

Finally, uniqueness of the solution follows from similar arguments. Indeed, if $\widetilde{U}$ is the difference between two solutions U_1 and U_2, one easily gets

$$\frac{1}{2}\frac{d}{dt}\|\widetilde{U}\|^2\leq(\|U_2\|_{L^4}^4+\|z\|_{L^4}^4+\|\nabla z\|^2)\|\widetilde{U}\|^2$$

and, since $\widetilde{U}(0)=0$, from Gronwall's lemma it follows that $\widetilde{U}\equiv 0$. ☐

Remark 2.5. In the proof of the result of this section we used in a fundamental way estimate (2.17). In the three-dimensional case this inequality is no longer true. Instead, it holds that

$$\|u\|_{L^4}\leq C\|u\|^{1/4}\|\nabla u\|^{3/4}\qquad\forall\, u\in H^1(\Omega),$$

which can be used to prove just local existence of weak solutions. The global result proved in the two-dimensional case depends in an essential manner on the stronger estimate, and this is the critical difference between the two cases.

3. The proof of Theorem 1.3. In this section we study the limit of the solution of the vorticity seeding model as $\delta \to 0$. We prove the convergence of the solutions of (3.1) to the solutions of the nonstationary Navier–Stokes system with the no-slip boundary condition (3.2). This supports the idea of using a nonstandard boundary condition on the new boundary $\Gamma_1 \subset \Omega$, such that the region between Γ and Γ_1 is very narrow. When the width of this region (presumably the boundary layer) shrinks to zero, then the solution of the Navier–Stokes equations with the usual no-slip boundary condition is recovered.

3.1. Comparison of solutions with different boundary data. Let the following be given: $g \in H^{\frac{1}{2}+\varepsilon}(0,T;H^{\frac{1}{2}}(\Gamma))$, satisfying the compatibility condition (1.5); $f \in L^2((0,T)\times\Omega)$; and $u_0 \in H^1(\Omega)$, with $\nabla\cdot u_0 = 0$. Without loss of generality, we can assume that $u_0 \equiv 0$. Denote by G_δ the solution of the linear stationary problem (2.4), with boundary condition $G_\delta \cdot \underline{\mathrm{n}} = \delta\, g$. Consider the solution (u_δ, p_δ) to the system

$$
\begin{cases}
\partial_t u_\delta - \nabla\cdot\mathbb{D}(u_\delta) + u_\delta\cdot\nabla u_\delta + \nabla p_\delta = f & \text{in } \Omega\times(0,T),\\
\nabla\cdot u_\delta = 0 & \text{in } \Omega\times(0,T),\\
u_\delta\cdot\underline{\mathrm{n}} = \delta\, g(x,t) & \text{on } \Gamma\times(0,T),\\
\delta\,\underline{\mathrm{n}}\cdot\mathbb{D}(u_\delta)\cdot\underline{\tau} + u_\delta\cdot\underline{\tau} = 0 & \text{on } \Gamma\times(0,T),\\
u_\delta(x,0) = u_0(x) + G(x,0) & \text{in } \Omega.
\end{cases}
\tag{3.1}
$$

We want to show the convergence of the vector valued function u_δ to the solution v of the Navier–Stokes equations with zero Dirichlet data:

$$
\begin{cases}
\partial_t v - \nabla\cdot\mathbb{D}(v) + v\cdot\nabla v + \nabla\pi = f & \text{in } \Omega\times(0,T),\\
\nabla\cdot v = 0 & \text{in } \Omega\times(0,T),\\
v = 0 & \text{on } \Gamma\times(0,T),\\
v(x,0) = u_0 & \text{in } \Omega.
\end{cases}
\tag{3.2}
$$

To this end, we also introduce the solution z_δ to the linear evolution problem (2.8), with boundary condition $z_\delta\cdot\underline{\mathrm{n}} = \delta\, g$, and we set

$$
U_\delta = u_\delta - z_\delta \qquad \text{and} \qquad w_\delta = u_\delta - z_\delta - v.
$$

The function w_δ satisfies the following "homogeneous" system

$$
\begin{cases}
\partial_t w_\delta - \nabla\cdot\mathbb{D}(w_\delta) + R(w_\delta, z_\delta, v, U_\delta) + \nabla r = 0 & \text{in } \Omega\times(0,T),\\
\nabla\cdot w_\delta = 0 & \text{in } \Omega\times(0,T),\\
w_\delta\cdot\underline{\mathrm{n}} = 0 & \text{on } \Gamma\times(0,T),\\
\delta\,\underline{\mathrm{n}}\cdot\mathbb{D}(w_\delta)\cdot\underline{\tau} + w_\delta\cdot\underline{\tau} = -\delta\,\underline{\mathrm{n}}\cdot\mathbb{D}(v)\cdot\underline{\tau} & \text{on } \Gamma\times(0,T),\\
w_\delta(x,0) = 0 & \text{in } \Omega,
\end{cases}
\tag{3.3}
$$

where

$$
R(w_\delta, z_\delta, v, U_\delta) = (U_\delta\cdot\nabla)w_\delta + (w_\delta\cdot\nabla)v + (U_\delta\cdot\nabla)z_\delta + (z_\delta\cdot\nabla)U_\delta + (z_\delta\cdot\nabla)z_\delta.
$$

We multiply the first equation in (3.3) by w_δ and integrate by parts to get

$$
\frac{1}{2}\frac{d}{dt}\|w_\delta\|^2 + \|\mathbb{D}(w_\delta)\|^2 + \frac{1}{\delta}\|w_\delta\|_\Gamma^2 = -\int_\Gamma (\underline{\mathrm{n}}\cdot\mathbb{D}(v)\cdot\underline{\tau})(w_\delta\cdot\underline{\tau})\,d\sigma - \int_\Omega w_\delta\cdot R(w_\delta, z_\delta, v, U_\delta)\,dx.
$$

The boundary integral in the right-hand side may be increased in the following way.

$$\left|\int_\Gamma (\underline{\mathrm{n}} \cdot \mathbb{D}(v) \cdot \underline{\tau})(w_\delta \cdot \underline{\tau})\, d\sigma\right| \le \frac{\delta}{2}\|v\|^2_{H^2} + \frac{1}{2\delta}\|w_\delta\|^2_\Gamma. \tag{3.4}$$

Then we analyze the second integral. By integration by parts over Ω (note that $U_\delta \cdot \underline{\mathrm{n}} = 0$ on Γ) and by using Hölder's inequality, the Gagliardo–Nirenberg inequality, and Young's inequality, we obtain

$$\begin{aligned}
&\left|\int_\Omega w_\delta \cdot R(w_\delta, z_\delta, v, U_\delta)\, dx\right| \\
&\le \frac{1}{2}\|\mathbb{D}(w_\delta)\|^2 + C\big[\|\nabla v\|^2 + \|\nabla U_\delta\|^{\frac{2}{3}}\|\nabla z_\delta\|^{\frac{4}{3}} + \|\nabla U_\delta\|^{\frac{4}{3}}\|\nabla z_\delta\|^{\frac{2}{3}} + \|\nabla z_\delta\|^2\big]\|w_\delta\|^2 \\
&\quad + C\big[\|\nabla U_\delta\|^{\frac{2}{3}}\|\nabla z_\delta\|^{\frac{4}{3}}\|U_\delta\| + \|\nabla U_\delta\|^{\frac{4}{3}}\|\nabla z_\delta\|^{\frac{2}{3}}\|z_\delta\| + \|\nabla z_\delta\|^2\|z_\delta\|\big].
\end{aligned}$$

Indeed, for example,

$$\begin{aligned}
\left|\int_\Omega w_\delta \cdot (z_\delta \cdot \nabla) U_\delta\right| &\le \|w_\delta\|_{L^4}\|z_\delta\|_{L^4}\|\nabla U\| \\
&\le C\|w_\delta\|^{\frac{1}{2}}\|\mathbb{D}(w_\delta)\|^{\frac{1}{2}}\|z_\delta\|^{\frac{1}{2}}\|\mathbb{D}(z_\delta)\|^{\frac{1}{2}}\|\nabla U_\delta\| \\
&\le \frac{1}{8}\|\mathbb{D}(w_\delta)\|^2 + C\|\nabla U_\delta\|^{\frac{4}{3}}\|\nabla z_\delta\|^{\frac{2}{3}}\|w_\delta\|^{\frac{2}{3}}\|z_\delta\|^{\frac{2}{3}} \\
&\le \frac{1}{8}\|\mathbb{D}(w_\delta)\|^2 + C\|\nabla U_\delta\|^{\frac{4}{3}}\|\nabla z_\delta\|^{\frac{2}{3}}(\|w_\delta\|^2 + \|z_\delta\|).
\end{aligned}$$

For simplicity we set

$$\begin{aligned}
\psi(t) &:= C\big[\|\nabla U_\delta\|^{\frac{2}{3}}\|\nabla z_\delta\|^{\frac{4}{3}}\|U_\delta\| + \|\nabla U_\delta\|^{\frac{4}{3}}\|\nabla z_\delta\|^{\frac{2}{3}}\|z_\delta\| + \|\nabla z_\delta\|^2\|z_\delta\|\big], \\
\phi(t) &:= \big[\|\nabla v\|^2 + \|\nabla U_\delta\|^{\frac{2}{3}}\|\nabla z_\delta\|^{\frac{4}{3}} + \|\nabla U_\delta\|^{\frac{4}{3}}\|\nabla z_\delta\|^{\frac{2}{3}} + \|\nabla z_\delta\|^2\big], \\
\chi(t) &:= \|v\|^2_{H^2},
\end{aligned}$$

so that, by collecting all of the estimates we obtained before, we end up with the following differential inequality:

$$\frac{d}{dt}\|w_\delta\|^2 + \|\mathbb{D}(w_\delta)\|^2 + \frac{1}{\delta}\|w_\delta\|^2_\Gamma \le \delta\chi(t) + \psi(t) + \phi(t)\|w_\delta\|^2. \tag{3.5}$$

3.1.1. Estimate of and in terms of . First, we note that the functions ψ and ϕ belong to $L^1(0,T)$, by virtue of the regularity properties (2.10) and (2.15) of z_δ and U_δ, respectively. The function $\chi(t)$ belongs to $L^1(0,T)$ as well, since

$$\|v\|_{L^2(0,T;H^2)} \le C\big[\|v(x,0)\|_{H^1} + \|f\|_{L^2((0,T)\times\Omega)}\big];$$

see, for instance, Constantin and Foiaş [10]. And also at this point is crucial to consider the two-dimensional problem, since such an estimate is available just for small times in the three-dimensional case.

It is important now to sharply check the correct behavior of the functions $\phi(t)$ and $\psi(t)$ in terms of δ. Before going further, we collect in the following lemma the results of section 2 that we shall need.

LEMMA 3.1. *Under the assumptions of Theorem* 1.3*, the following estimates hold:*

(i) $\sup_{0\le t\le T}\|z_\delta\|^2+\int_0^T\|\mathbb{D}(z_\delta)\|^2\,dt\le C_1\delta\|g\|^2_{H^{\frac12+\varepsilon}(0,T;H^{\frac12}(\Gamma))}$,

(ii) $\sup_{0\le t\le T}\|U_\delta\|^2+\int_0^T\Big(\|\mathbb{D}(U_\delta)\|^2+\frac{1}{\delta}\|U_\delta\|^2_\Gamma\Big)\,dt\le C_2$,

for all $0<\delta\le 1$*, where the constant* C_1 *depends only on* Ω*, while the constant* C_2 *depends only on* Ω*,* T*,* $\|f\|_{L^2}$*, and* $\|g\|_{H^{\frac12+\varepsilon}}$*.*

Proof. Property (i) is a consequence of (2.11). Indeed, by (2.6) and Poincaré's inequality,

$$\|G_\delta\|\le C\|\mathbb{D}(G_\delta)\|\le C\sqrt{\delta}\|g\|,$$

so that $\|G_\delta\|_{H^{\frac12+\varepsilon}(0,T;L^2(\Omega))}\le C\sqrt{\delta}\|g\|_{H^{\frac12+\varepsilon}(0,T;L^2(\Omega))}$.

Again, from (2.6),

$$\int_0^T\|\mathbb{D}(G_\delta)\|^2\,dt\le C\delta\|g\|^2_{H^{\frac12+\varepsilon}(0,T;L^2(\Omega))},$$

and in conclusion (i) holds true.

As it concerns (ii), we have that, by Poincaré's inequality, (2.6), and Sobolev embeddings,

$$\|G_\delta(\cdot,0)\|\le C\|\mathbb{D}(G_\delta)(\cdot,0)\|\le C\sqrt{\delta}\|g(\cdot,0)\|\le C\sqrt{\delta}\|g\|_{H^{\frac12+\varepsilon}(0,T;L^2)}.$$

Moreover, since $\delta\le 1$ and from the above estimates it follows that

$$A(t)\le A(T)\le CT+C\Big(1+\|g\|^4_{H^{\frac12+\varepsilon}(0,T;L^2(\Gamma))}\Big),$$

that is, $A(t)$ is uniformly bounded by a constant independent of δ, and that

$$\begin{aligned}\int_0^t(\|f\|^2+\|\nabla z_\delta\|^2\|z_\delta\|)\,\mathsf{e}^{A(t)-A(s)}\,ds&\le\mathsf{e}^{A(T)}\left(\int_0^T\|f\|^2+\|z_\delta\|_{L^\infty(0,T;L^2)}\|\mathbb{D}(z_\delta)\|^2\right)\\&\le\Big(\|f\|^2_{L^2((0,T)\times\Omega)}+C\|g\|^3_{H^{\frac12+\varepsilon}(0,T;L^2(\Gamma))}\Big)\mathsf{e}^{A(T)}\end{aligned}$$

as well, so that, by (2.16), (ii) also follows. ∎

The first consequence of the above lemma is that

$$\int_0^t\phi(s)\,ds\le\int_0^T\|\nabla v\|^2\,dt+C(\Omega,T,f,g),\qquad 0\le t\le T,$$

with a bound uniform in δ, for δ small. Moreover, for $t\in[0,T]$

$$\begin{aligned}\int_0^t\psi(s)\,ds&\le C\left(\int_0^T\|\nabla U_\delta\|^2\right)^{\frac13}\left(\int_0^T\|\nabla z_\delta\|^2\right)^{\frac23}\|U_\delta\|_{L^\infty(0,T;L^2)}\\&\quad+C\left(\int_0^T\|\nabla U_\delta\|^2\right)^{\frac23}\left(\int_0^T\|\nabla z_\delta\|^2\right)^{\frac13}\|z_\delta\|_{L^\infty(L^2)}\\&\quad+C\|z_\delta\|_{L^\infty(L^2)}\int_0^T\|\nabla z_\delta\|^2\\&\le C(\delta^{\frac23}+\delta^{\frac56}+\delta^{\frac32})\\&\le C\delta^{\frac23},\end{aligned}$$

so that, by (3.5) and Gronwall's inequality, it follows that

$$\begin{aligned}\sup_{0\le t\le T}\|w_\delta\|^2+\int_0^T\left(\|\mathbb{D}(w_\delta)\|^2+\frac{1}{\delta}\|w_\delta\|_\Gamma^2\right)dt &\le \int_0^T[\delta\chi(s)+\psi(s)]\mathrm{e}^{\int_s^T\phi(r)\,dr}\,ds\\ &\le \mathrm{e}^{\int_0^T\phi(s)\,ds}\int_0^T[\delta\chi(s)+\psi(s)]\,ds\\ &\le C\delta^{\frac{2}{3}}\end{aligned}$$

and finally

$$\sup_{0\le t\le T}\|w_\delta\|^2+\int_0^T\left(\|\mathbb{D}(w_\delta)\|^2+\frac{1}{\delta}\|w_\delta\|_\Gamma^2\right)dt=\mathcal{O}(\delta^{\frac{2}{3}}).$$

Since the corresponding norms of z_δ are of order $\delta^{\frac{1}{2}}$, by the previous lemma, we finally deduce that $u_\delta-v$ is of the order $\delta^{\frac{1}{3}}$, and Theorem 1.3 is proved.

Remark 3.2. The tangential trace of the function w_δ converges a little better, since from the above estimate we can deduce

$$\|w_\delta\|_{L^2(\Gamma\times(0,T))}=\mathcal{O}(\delta^{5/6}).$$

Remark 3.3. The above proof shows that there is a crucial loss in the estimates due to: (1) the boundary effect in the estimate (2.6) and (2) the nonlinearity (recall the contribution of U_δ in the estimate of $\psi(t)$). We observe that the original model was supplemented by the boundary condition

$$u\cdot\underline{\mathrm{n}}=\delta^2 g,$$

but we used in fact $u\cdot\underline{\mathrm{n}}=\delta\, g$. By running through the proof of Theorem 1.3 one gets, using the boundary condition

$$u\cdot\underline{\mathrm{n}}=\delta^\alpha g,$$

that $z_\delta=\mathcal{O}(\delta^{\alpha-\frac{1}{2}})$, so that $\int_0^T\psi(t)\,dt=\mathcal{O}(\delta^{\frac{4}{3}(\alpha-\frac{1}{2})})$ and finally $w_\delta=\mathcal{O}(\delta^{\frac{2}{3}(\alpha-\frac{1}{2})})$. In particular, for $\alpha=2$, which is the value corresponding to models in [4, 24], the behavior of z_δ matches the loss in the estimates due to the boundary term (3.4); see section 1.2. Hence, for larger values of α, the convergence remains slow, because of this term. Supposedly, the loss in the convergence rate caused by this term is an intrinsic feature of the problem, while those losses caused by the nonlinearity may have technical reasons.

ON THE GEOMETRY OF OPTIMAL WINDOWS, WITH SPECIAL FOCUS ON THE SQUARE*

ALMUT BURCHARD† AND JOCHEN DENZLER‡

Abstract. For the Laplace operator with mixed (Dirichlet and Neumann) boundary conditions, the dependence of the principal eigenvalue on the placement of the Dirichlet part is investigated. An optimal window is a Dirichlet part of the boundary that minimizes the principal eigenvalue among all competitors of the same area.

In the special case of a square, we provide both numerical evidence and rigorous partial results for the conjecture that optimal windows in a square are segments centered at either a corner or the midpoint of a side. In particular, we prove that the principal eigenvalue decreases as a window is shifted from a side-centered position towards the corner. An optimal window contained in two sides of the square is connected and contains a corner in its interior. Optimal windows whose length does not exceed the length of one side break the symmetry of the square.

We also construct a star-shaped domain whose optimal window(s) must be disconnected. Finally we give, for general domains in $\mathbb{R}^d$, continuity results for the eigenvalue as a function of the window, and examples of discontinuity when crucial hypotheses are violated. We also give a variation formula that relates the eigenvalue to the singularities of the eigenfunction (stress intensity coefficient) near the boundary of the window.

Methods are based on the variational problem and include rearrangement, Dirichlet–Neumann bracketing, capacity estimates, and deformation under a flow.

Key words. optimal eigenvalue, Laplace operator, mixed boundary conditions, shape optimization, capacity, singular coefficient, rearrangement

1. Introduction.

1.1. Overview over the results. Consider the first eigenvalue of the Laplace operator in a fixed domain $\Omega \subset \mathbb{R}^d$ (say, bounded Lipschitz)

$$-\Delta u = \lambda u \,, \quad u \geq 0 \quad \text{in } \Omega \tag{1.1}$$

with Dirichlet boundary conditions on some subset $D \subset \Omega$ and Neumann on the complement of D, i.e.,

$$u|_D = 0, \quad \partial_\nu u|_{\partial\Omega\setminus D} = 0. \tag{1.2}$$

Technical questions of how these boundary conditions should be interpreted will be discussed below. We will call $\lambda = \lambda(D)$ the principal eigenvalue of the Laplacian under the *window boundary conditions on D*. The problem of optimal windows asks for minimization of this eigenvalue for prescribed surface area of the window.

As explained in [8], one may think of Ω as representing a room with perfectly heat-conducting windows at D and insulating walls along $\partial\Omega \setminus D$. The principal eigenvalue $\lambda(D)$ gives the rate of exponential decay of any initial temperature distribution due

to heat diffusion through the window as time becomes large, while the corresponding eigenfunction gives the asymptotic temperature profile. An optimal window minimizes long-term heat loss among all windows of a given size.

It has been shown in [9] that such optimal windows exist and that in the case of a ball of any dimension the optimal window is a spherical cap of the appropriate area. Similar results have been obtained independently by Cox and Uhlig [6], who treat windows as a singular limiting case of Robin boundary conditions.

Here we are concerned with the question of what can be said about the geometry of optimal windows when Ω is not a ball. We suspect that an optimal window in a convex domain Ω should be connected, have some basic regularity properties, and lie in a region of $\partial\Omega$ with large mean curvature. This is certainly not the case for more general domains, as we show by constructing an example of a star-shaped domain with a disconnected optimal window. Heuristic evidence concerning the location of optimal windows has been discussed in [8], and is also corroborated by results of Harrell, Kröger, and Kurata [13] on a different, but related, problem.

As a model case for a convex domain, we study a square: The determination of the shape of optimal windows is already nontrivial in this case. Here we conjecture that the optimal window is a segment, centered either at the midpoint of a side or at a corner depending on the prescribed boundary measure (length), and that there are no other optimal windows, up to sets of measure zero. This conjecture is supported by a number of rigorous partial results as well as numerical evidence (see Figure 2.1). In particular, we prove that the eigenvalue decreases as a short segment is moved from a side-centered position to a position adjacent to a corner and that this monotonicity extends at least for some distance as the window is moved around the corner. We show the first part of this result by means of a Dirichlet–Neumann bracketing argument (section 3.1). The second part is proved by means of an Euler–Lagrange-type variational formula, which we derive for any domain of sufficient regularity in arbitrary dimension (section 6).

Furthermore, we show that some segment containing a corner in its interior is optimal among all windows lying on only two sides of the square (adjacent or not). The proof relies on discrete rearrangement arguments that are specific to the square (with some obvious, but maybe not too interesting, generalization to a cube or hypercube).

Numerical evidence shows that for segments whose length exceeds the sidelength by a certain small amount, up to slightly more than two sidelengths, the corner-centered position ceases to be optimal, with the side-centered position being better (section 2). This can be understood heuristically in terms of the fact that optimal windows prefer to use corners, as was already discussed in terms of a model problem in [8]. However, sacrificing connectedness to distribute the window evenly around the corners is not advantageous and results in windows inferior to either the side-centered segment or the corner-centered segment (section 3.3). For windows up to one sidelength, we can prove this analytically, for larger ones numerically. On the other hand, our analytic results prove that the (nonoptimal) window with four congruent corner-centered components is still better than any other window that has the full symmetry of the square.

Our study of the square also serves as a building block for an example of a star-shaped domain where any optimal window is disconnected (section 4). A related example was discussed heuristically in Figure 3 of [8].

The variation formula mentioned above is derived in section 6 for windows in general domains of any dimension. Its upshot is that the rate of change of the eigenvalue as a function of the window is determined by certain singular coefficients of the eigenfunction that show up at each interface of window and wall on the boundary. In a neighborhood of such interface points, the eigenfunction (albeit in $W^{1,2}$) cannot be expected to be $W^{2,2}$.

In special geometries the singularities have been studied by Grisvard (e.g., [12]). In the situation of a simple interface of a wall and a window segment on a side of the square, the typically expected singular behavior of the eigenfunction is like $c\,\mathrm{Im}\sqrt{z}$ in a neighborhood of 0, where the number c is the singular coefficient. We give a simple lower estimate for this coefficient, based on a maximum principle, to ensure that it does not vanish. In contrast, in a corner of the square, the singular coefficient vanishes. These two facts make it possible for the eigenvalue to be lowered by moving a segment a bit around the corner. For segments up to one sidelength, a better control of the singular coefficients appearing in the variational formula (which depend on global properties of the eigenfunction) should extend this monotonicity all the way until a minimum is achieved when the segment is centered at a corner, but a proof of this extended monotonicity has eluded us so far.

Contributions from geometric singularities (corners, ridges, conical points) have been studied by many authors, and in vast generality, e.g., Maz'ya and Plamenevskii [21]. Surveys are [16] and [23]. We are using only the very simplest case here.

The continuous dependence of the eigenvalue under shifts of the window and other reasonable modifications of its geometry is an intuitively plausible but nontrivial result of relevance. For deformations of windows that can be achieved by the flow of a vector field, our Euler–Lagrange argument proves even differentiability. However, in the absence of good a priori information on the window geometry, such flow type modifications are rather weak; this is why we include some continuity results for other modifications, in general Lipschitz domains (section 5). In this context, it is crucial to consider, in addition to the formulation of the eigenvalue problem (EVP) adopted in [9], [8], a more sophisticated definition that takes into account fine properties of eigenfunctions. It is easy to see that the results in [9], [8] carry over. We will argue this point specifically for the existence of optimal windows in section 1.3. Both definitions coincide for *optimal* windows, as well as for windows of sufficient regularity, in particular for open windows.

1.2. Basic facts, context, and notation; variational formulation. Let us introduce some notation. The symbol Ω will generally denote a bounded Lipschitz domain in $\mathbb{R}^d$, and the window D will be a measurable subset of $\partial\Omega$. As surface measure on $\partial\Omega$, we use $d-1$-dimensional Hausdorff measure, denoted here by σ. A point in $\overline{D} \cap \overline{\partial\Omega \setminus D}$ will be called an *interface point*.

The Laplacian with the window boundary conditions (1.2) will be denoted by Δ_D. The word "eigenvalue" without adjective or ordinal will always denote the *lowest* eigenvalue, which is simple. This eigenvalue will be denoted by $\lambda(D)$.

Define the *optimal eigenvalue* for windows of a given surface measure by

$$\lambda_*(\ell) \;=\; \inf\{\lambda(D) \;\mid\; D \subset \partial\Omega,\ \sigma(D) \;=\; \ell\}\,. \tag{1.3}$$

A set $D \subset \partial\Omega$ will be called an *optimal window* if $\lambda(D) = \lambda_*(\sigma(D))$, that is, if

$$\lambda(D) \;=\; \inf\{\lambda(D') \;\mid\; D' \subset \partial\Omega,\ \sigma(D') \;=\; \sigma(D)\}\,. \tag{1.4}$$

The eigenvalue $\lambda(D)$ in (1.1) and (1.3) can be defined by the Courant–Hilbert variational problem (CHVP)

$$\lambda(D) = \min\left\{\int_\Omega |\nabla u|^2\,dx \;\middle|\; u \in W^{1,2}(\Omega),\ \int_\Omega u^2\,dx = 1,\ u|_D = 0\right\}. \tag{1.5}$$

In [8] and [9], the restriction $u|_D$ of a function $u \in W^{1,2}(\Omega)$ was to be understood as the *trace* in $L^2(\partial\Omega)$. By general Sobolev space theory ([1, Theorem 5.4] or [10, section 4.3, Theorem 1]), the trace of a $W^{1,2}$-function is guaranteed to be an $L^2(\partial\Omega)$ function. Note that the condition $u|_D = 0$, in the L^2-sense, allows the boundary condition to be violated on a set of $d-1$-dimensional measure zero. We refer to this definition of λ as the *coarse* formulation of the eigenvalue problem (1.1) and the CHVP (1.5).

The Neumann boundary conditions on $\partial\Omega \setminus D$ in (1.1) arise as natural boundary conditions for the variational problem in (1.5). The minimizing function u is a normalized eigenfunction corresponding to $\lambda(D)$ and can be chosen to be nonnegative. It agrees a.e. with an analytic function in the interior of Ω, but is not guaranteed to be continuous up to the boundary $\partial\Omega$, unless some assumptions are made on the geometry of D.

Clearly, the principal eigenvalue $\lambda_1(D)$ increases under inclusion of windows,

$$D_1 \subset D_2 \implies \lambda(D_1) \subset \lambda(D_2),$$

since the minimizing function in the CHVP for $\lambda(D_1)$ is an admissible test function for $\lambda(D_2)$.

1.3. Fine variational formulation. As mentioned above, there is another meaningful definition of the boundary conditions (1.2) and the corresponding variational problem (1.5). Since $W^{1,2}$-functions can actually be determined *quasi-everywhere*, that is, up to a set of zero *capacity*, one can insist that the Dirichlet boundary conditions in (1.1) and in the CHVP (1.5) hold up to a set of zero capacity. Since every set of capacity zero has $d-1$-dimensional measure zero, but not vice versa, this is a stronger condition. It corresponds to choosing a smaller domain for the quadratic form associated with Δ_D. We will refer to this definition of $\lambda(D)$ as the *fine* formulation of (1.1) or (1.5). When necessary, we distinguish the two definitions by superscripts, writing $\lambda^c(D)$ and $\lambda^f(D)$ for the coarse and fine eigenvalues, respectively. In general,

$$\lambda^f(D) \;\geq\; \lambda^c(D), \tag{1.6}$$

and it is easy to construct examples where the inequality is strict: any (fractal) window with Hausdorff dimension between $d-2$ and $d-1$ has measure 0 and nonvanishing capacity [10, section 4.7.2],[19, section 2.1.7], hence coarse eigenvalue 0, but positive fine eigenvalue. The notion of sets of capacity 0 is well defined even in two dimensions, where capacity can only be defined subject to some arbitrary choice. Such subtleties can also be avoided by replacing the window D in $\Omega \subset \mathbb{R}^2$ with the equivalent window $D \times [0,1]$ in $\Omega \times]0,1[\subset \mathbb{R}^3$.

In order to relate coarse and fine eigenvalues more precisely, we represent an element u of a Sobolev space by a function defined everywhere, which will be called the preferred representative. For any given Lipschitz domain Ω and any neighborhood V of $\overline{\Omega}$, there is a linear bounded operator $\mathcal{E} : W^{1,2}(\Omega) \to \mathring{W}^{1,2}(V) \hookrightarrow W^{1,2}(\mathbb{R}^d)$ that extends Sobolev functions in Ω to the entire space as outlined in [10, section 4.4], i.e., $\mathcal{E}u|_\Omega = u$. Then we choose the *preferred representative* as

$$\tilde{u}(x) \;:=\; \limsup_{r\to 0} ⨍_{B_r(x)} \mathcal{E}u(y)\,dy \qquad \text{for} \qquad x \in \overline{\Omega}. \tag{1.7}$$

The lim sup is in fact a limit, except on a set of zero capacity, and $\tilde{u}$ is quasi-continuous (as defined in [19, section 2.17]).

The extension operator $\mathcal{E}$ is not unique but depends on a choice of locally flattening coordinate charts, and we make such a choice once and for all for each given Ω. The preferred representative on $\overline{\Omega}$ depends on the extension operator, but any two choices will only differ on a set of capacity zero. See [19, Theorem 2.55 with following remark] or [10, section 4.8, Theorem 1]. The restriction of $\tilde{u}$ to $\partial\Omega$ represents the trace of u.

THEOREM 1.1. *For the CHVP* (1.5) *in the fine formulation, there exists a minimizer which is uniquely determined quasi-everywhere up to choice of a sign.*

Proof. This is a slight modification of the classical argument for the existence of a minimizer for (1.5) in the (coarse) Sobolev sense. Let u_j be a minimizing sequence of quasi-continuous functions (in $W^{1,2}(\mathbb{R}^d)$, by extension) satisfying the boundary conditions in the fine sense. Extracting a subsequence (again denoted by u_j), we may assume weak convergence in $W^{1,2}(\Omega)$, strong convergence in $L^2(\Omega)$, and (by compactness of the trace map) strong convergence in $L^2(\partial\Omega)$, to a limit function u_*. We have to show that u_* inherits the fine boundary conditions from $\{u_j\}$. To this end, we replace the sequence $\{u_j\}$ by a sequence $\{\bar{u}_j\}$ of convex combinations that converges *strongly* in $W^{1,2}$, according to Mazur's theorem (see, e.g., [18, section 2.13]). The normalized sequence $\hat{u}_j := \bar{u}_j/\|\bar{u}_j\|_{L^2(\Omega)}$ still converges strongly in $W^{1,2}(\Omega)$ because $\|\bar{u}_j\|_{L^2(\Omega)} \to 1$. The $\hat{u}_j$ inherit the fine boundary conditions from u_j and therefore form a sequence of legitimate competitors in the CHVP.

Now by convexity we obtain

$$\int |\nabla u_*|^2 = \lim \int |\nabla \hat{u}_j|^2 = \lim \int |\nabla \bar{u}_j|^2 \leq \lim \int |\nabla u_j|^2 = \inf \int |\nabla u|^2.$$

We must show that u_* inherits the fine boundary conditions from the $\hat{u}_j$. This follows from the arguments in section 2.1.3 of [19], which we sketch briefly, for the sake of being self-contained:

(1) If a sequence of C_0^∞ functions v_j (with uniformly bounded support) converges strongly in $W^{1,2}(\Omega)$ to some u_*, then it holds for some subsequence (again called v_j):

$$\forall \varepsilon > 0\ \exists V_\varepsilon \text{ open}: \operatorname{cap}(V_\varepsilon) < \varepsilon,\ \|v_j - u_*\|_{C^0(\overline{\Omega}\setminus V_\varepsilon)} \to 0$$

(2) Every $W^{1,2}(\Omega)$ function u can be approximated in $W^{1,2}(\Omega)$ norm by C_0^∞ functions v_k (with uniformly bounded support), such that

$$\forall \varepsilon > 0\ \exists W_\varepsilon \text{ open}: \operatorname{cap}(W_\varepsilon) < \varepsilon,\ \|v_k - u\|_{C^0(\overline{\Omega}\setminus W_\varepsilon)} \to 0.$$

(The existence of a quasi-continuous representative is actually a consequence of this.)

Now there are open sets V_j with $\operatorname{cap}(V_j) < 2^{-j}$ such that $\hat{u}_j$ is continuous on $\overline{\Omega} \setminus V_j$ and vanishes on $D \setminus V_j$, and there are smooth approximants $\hat{v}_j$ such that $\|\hat{v}_j - \hat{u}_j\|_{W^{1,2}(\Omega)} < 2^{-j}$ and $\|\hat{v}_j - \hat{u}_j\|_{C^0(\overline{\Omega}\setminus V_j \setminus W_j)} < 2^{-j}$ for appropriate open sets W_j with $\operatorname{cap}(W_j) < 2^{-j}$. Therefore, for every j_0, the sequence $\hat{v}_j$ converges uniformly to u_* outside the set $\overline{V}_{j_0} := \bigcup_{j \geq j_0}(V_j \cup W_j)$, whose capacity is at most 2^{2-j_0}. Hence u_* vanishes on $D \setminus \overline{V}_{j_0}$, for every j_0.

Uniqueness and positivity follow from the strong maximum principle as in the classical argument. ∎

The coarse and fine formulations of *optimal* windows and their eigenfunctions essentially agree.

PROPOSITION 1.2. *Let $\lambda_*^c(\ell)$ and $\lambda_*^f(\ell)$ be optimal eigenvalues for windows of size ℓ, as defined by* (1.3) *in the coarse and fine sense, respectively. Then*

$$\lambda_*^f(\ell) \;=\; \lambda_*^c(\ell), \qquad (0 \leq \ell \leq \lambda_{\mathrm{Dir}}). \tag{1.8}$$

Furthermore, D is an optimal window with respect to the coarse definition if and only if it differs by a set of $d-1$-dimensional measure zero from an optimal window for the fine formulation.

Proof. Clearly, from (1.6) we have

$$\lambda_*^f(\ell) \geq \lambda_*^c(\ell).$$

To see the converse inequality, take an optimal window D for the coarse formulation, i.e., $\lambda^c(D) = \lambda_*^c(\ell)$, and let u^c be a minimizer of the corresponding CHVP (1.5). Let $\tilde{u}^c$ be the preferred representative of u^c, as defined above, and set

$$D' := \{x \in \partial\Omega \mid \tilde{u}^c(x) = 0\}.$$

We refer to this procedure as *refining* the window D. By definition, $\sigma(D') \geq \ell$ and $\lambda^c(D') = \lambda_*(\ell)$. Since $\tilde{u}^c|_{D'}$ vanishes identically, it is an admissible candidate for the CHVP (1.5) for $\lambda^f(D')$. It follows that

$$\lambda_*^f(\ell) \;\leq\; \lambda^f(D') = \lambda^c(D) = \lambda_*^c(\ell). \qquad \square$$

Note that we always have $\lambda^f(D') \leq \lambda^c(D)$ since $\tilde{u}^c$ vanishes on D'. Whenever $\lambda^f(D) > \lambda^c(D)$ occurs, this is due to $D \setminus D'$ having positive capacity, which makes $\tilde{u}^c$ ineligible for the fine CHVP. Whenever de Giorgi's continuity argument applies at each point of D, i.e., when u^c has a representative that is continuous on $\Omega \cup D$, then $\tilde{u}^c$ is admissible for the fine CHVP and thus $\lambda^f(D) = \lambda^c(D)$. This holds in particular if D is open, notwithstanding possible discontinuities of u^c at interface points. A de Giorgi argument can also be used to show continuity of u^c, provided the window has positive density at every interface point $p \in \overline{D} \cap \overline{\partial\Omega \setminus D}$. We suspect that eigenfunctions for optimal windows should be continuous up to the boundary, but this is an unresolved question.

2. Numerical results for the square. We have used the MATLAB pdetool to calculate, by means of finite elements, the lowest eigenvalue for various window configurations. The calculation was done with a sequence of at least three subsequent mesh refinements so that numerical convergence within the precision of the graphics could be checked by inspection. In the accompanying Figure 2.1, we show the eigenvalue as a function of the length of the window, for five different simple geometric configurations.

As outlined in section 1.1, we conjecture that the configurations giving the lowest eigenvalue in Figure 2.1 (namely either a side-centered or a corner-centered segment, depending on the length) are in fact the optimal configurations. As a rule of thumb, the better of the two choices of symmetric and connected windows is the one that contains more corners. Exceptions to this rule occur near integer multiples of a sidelength.

Figure 2.1 also displays a feature of the first variation formula: When the interface points are in the corner (which implies vanishing of the singular coefficients), the derivative of the eigenvalue vanishes. These are just the explicitly calculable cases marked in the figure. Our numerics do not resolve the modulus of continuity at length 0. However, for each of the curves printed, it can be seen analytically that $c_1/\ln(1/\delta) \leq \lambda(\delta) \leq c_2/\ln(1/\delta)$ (with δ the total length of the window): The lower bound follows from Theorem 5 in [8] (slightly modified for two dimensions, as pointed out there); the upper bound is an immediate consequence of our capacity estimate in Proposition 5.2 and its proof. Sharp asymptotics for a different, but closely related, problem can be found in Chapter 9 of [20].

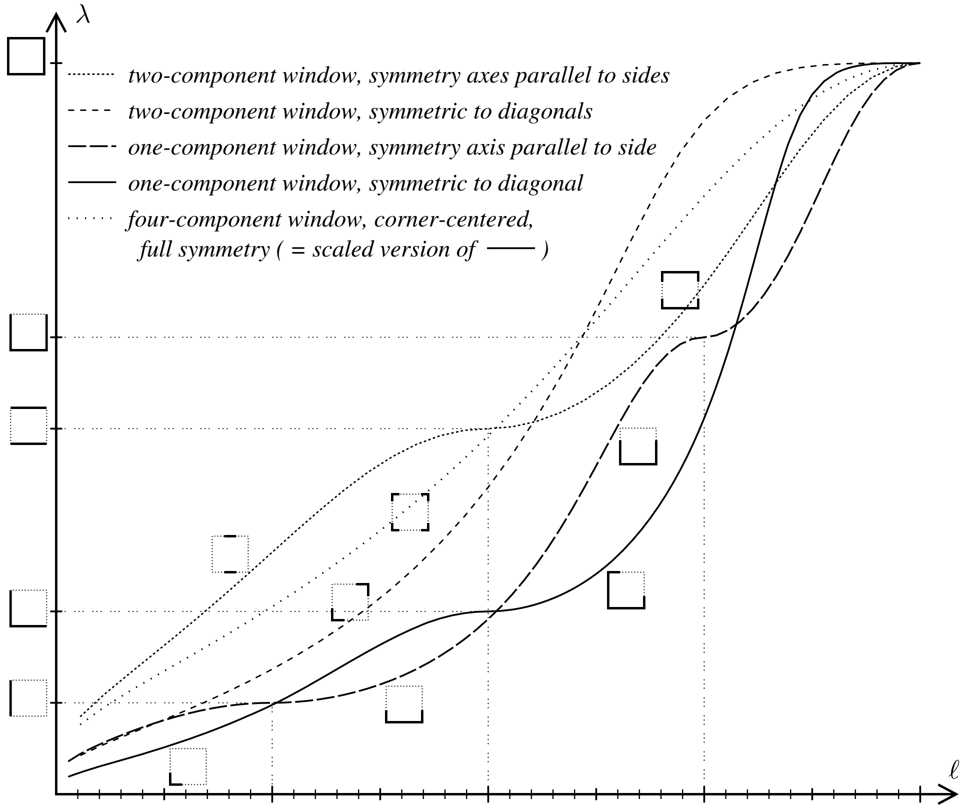

Fig. 2.1. *Five sections through the space of windows, each parametrized by length. The horizontal axis measures the length, in units of the perimeter of the square, the vertical axis gives the eigenvalue relative to the full Dirichlet eigenvalue. The labels mark those window configurations that can be calculated explicitly by separation of variables. In these pictograms, bold lines denote Dirichlet BCs.*

We next study the dependence of the eigenvalue on the position of the window. We cannot expect the eigenvalue to depend monotonically on the shift parameter for all lengths, because the side-centered and the corner-centered configuration yield the same eigenvalue for three particular lengths, close to 1.02, 2.04, 3.15 sidelengths, as seen in Figure 2.1. In Figure 2.2, we shift windows of a given length from a side-centered to a corner-centered position. However, we observe in each case that local minima only occur in symmetric positions, supporting our conjecture.

The derivative of the eigenvalue with respect to the shift parameter is proportional to the difference of the squares of the singular coefficients at the endpoints of the segment (section 6). In the symmetric configurations, this derivative vanishes by symmetry. When both endpoints lie in a corner, where the singular coefficients vanish, the derivative appears to vanish to a higher order, indicating further cancellations. This can be plausibly observed for lengths 1 and 3 in the side-centered configuration, and for length 2 in the corner-centered configuration.

Figure 2.3 shows the effect of tearing apart a connected window into two pieces. Note the competition between corner positions and connectedness as geometric features favoring low eigenvalues.

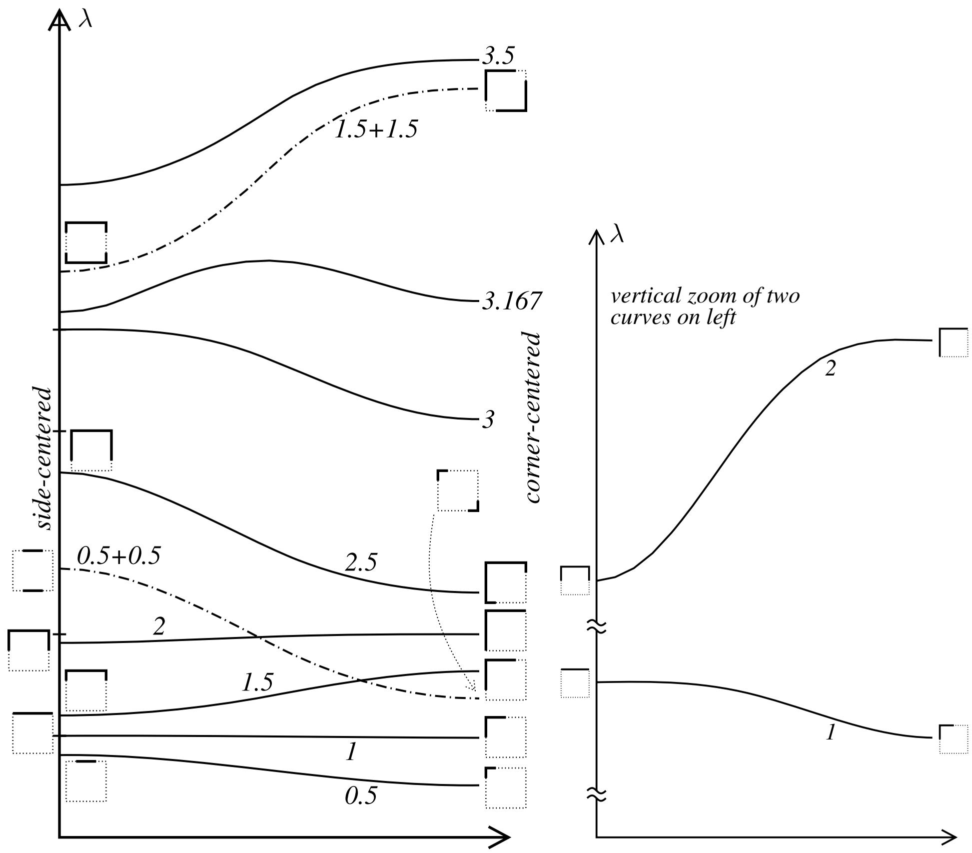

Fig. 2.2. *The eigenvalue for connected windows of nine different lengths and two-component windows of two different lengths, as a function of a shift parameter. The horizontal axis indicates the distance to a side-centered position.*

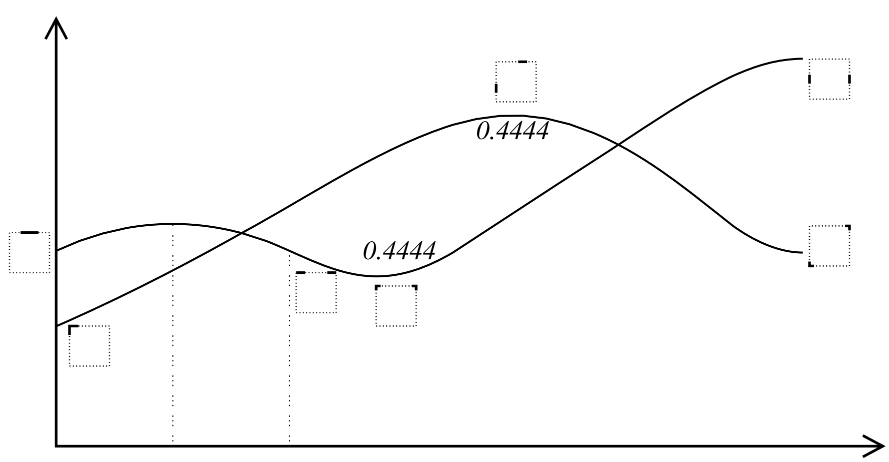

Fig. 2.3. *Examples of competition between connectedness and corner position for small windows. Dotted lines: The first hump for the side-centered window is actually axially symmetric, due to the argument used in section* 3.1.

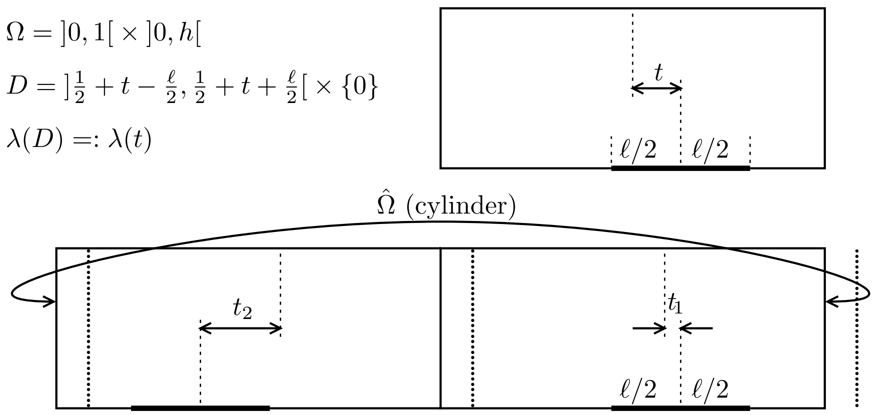

FIG. 3.1. *Shifting windows in a rectangle after doubling it to obtain a cylinder.*

3. Rigorous results for the square. In this section, we collect some inequalities and monotonicity results that are specific to the square.

3.1. Monotonicity of shifting (rectangle). For the geometric situation, see the top of Figure 3.1.

THEOREM 3.1. *Let Ω be a rectangle. The principal eigenvalue of a connected window D that is contained entirely in one side of $\partial\Omega$ is a continuous, strictly decreasing function of the distance of D from the side-centered position.*

Proof. By scaling, rotating, and translating, we may assume that $\Omega =]0,1[\times]0,h[$, and that the window is contained in the bottom side of the rectangle; see Figure 3.1. For $0 < \ell < 1$ and $|t| \le (1-\ell)/2$, let $D(t) =]\frac{1}{2}+t-\frac{\ell}{2}, \frac{1}{2}+t+\frac{\ell}{2}[\times \{0\}$ be the window of length ℓ that has been shifted by t from the side-centered position, and denote the corresponding eigenvalue by $\lambda(t)$. By symmetry, λ is an even function of t. Continuity of $\lambda(t)$ follows most easily from Proposition 5.2. To prove the last assertion, we will show that

$$\lambda\big(\tfrac{1}{2}(t_1+t_2)\big) \; > \; \min\{\lambda(t_1), \lambda(t_2)\} \tag{3.1}$$

holds for any pair $t_1 < t_2$. Setting $t_1 = -t$, $t_2 = t$ in (3.1) and using that $\lambda(-t) = \lambda(t)$ shows that λ takes its global maximum at $t = 0$. Setting $t_{1/2} = t \mp \varepsilon$ in (3.1) shows that $\lambda(t)$ cannot assume a local minimum on the open interval $]0,(1-\ell)/2[$. We conclude that $\lambda(t)$ is strictly decreasing on $[0,(1-\ell)/2]$, as claimed.

In order to prove claim (3.1), we combine a doubling trick with a special case of Dirichlet–Neumann bracketing (see [22, section XIII.15]). Fix $t_1 \le t_2$ with $|t_1|, |t_2| \le (1-\ell)/2$, set $t = (t_1+t_2)/2$, and let u be the positive normalized eigenfunction for the rectangle $\Omega =]0,1[\times]0,h[$ with the window $D(t)$.

Consider the CHVP on the cylinder $\hat{\Omega} = (\mathbb{R}/2\mathbb{Z}) \times]0,h[$, with window $\hat{D}(t) = D(t) \cup (-D(t))$, which is obtained by gluing a copy of Ω with window $D(t)$ to its mirror image along the vertical edges. Since the minimizing function $\hat{u}$ is automatically symmetric by simplicity of the principal eigenvalue in a connected domain, it follows that this CHVP on $\hat{\Omega}$ with window $\hat{D}(t)$ is equivalent to the CHVP on Ω with window $D(t)$. In particular,

$$\hat{u}(x,y) \;=\; \frac{1}{\sqrt{2}} u(|x|,y), \quad (-1 \le x \le 1,\; 0 \le y \le h),$$

and the corresponding principal eigenvalue coincides with $\lambda(t)$.

On the other hand, with the understanding that x coordinates are interpreted modulo 2, the cylinder $\hat{\Omega}$ contains the disjoint union of the rectangles $\Omega_1 =](t_2 - t_1)/2, 1 + (t_2 - t_1)/2[\times]0, h[$ and $\Omega_2 =]-1 + (t_2 - t_1)/2, (t_2 - t_1)/2[\times]0, h[$, which are copies of Ω with windows $D(t_1)$ and $D(t_2)$, respectively. By restricting $\hat{u}$ to $\Omega_1 \cup \Omega_2$ we obtain a test function for $\Omega_1 \cup \Omega_2$ with window $D(t_1) \cup D(t_2)$. Since the principal eigenvalue for a disjoint union of domains is the smaller of the two eigenvalues, it follows that

$$\lambda(t) \geq \min\{\lambda(t_1), \lambda(t_2)\}.$$

The functions $u_1 = \hat{u}|_{\Omega_1}$ and $u_2 = \hat{u}|_{\Omega_2}$ cannot be eigenfunctions for $\lambda(t_1)$ and $\lambda(t_2)$, because the gradient of $\hat{u}$ vanishes at those boundary points of Ω_1 or Ω_2 that were corners of Ω, in violation of the Hopf boundary point lemma for u_1 and u_2. This completes the proof of (3.1). $\square$

The doubling argument used in the proof shows that two connected window segments of length ℓ each, placed symmetrically with distance $2s$ from the center of a rectangle of sidelength 2, yield the same eigenvalue as two such windows placed symmetrically with distance $2(1 - \ell - s)$ apart. This can be observed in the curve for the side-centered configurations in Figure 2.3.

3.2. Optimality among windows on one or two sides. The monotonicity argument in the previous subsection implies in particular that among all connected windows contained in *one* side of a rectangle, the one touching a corner produces the minimal eigenvalue. We next consider windows contained in two sides of a square.

THEOREM 3.2. *Among all windows that lie on only two sides of the square (adjacent or not), the optimal window is connected and contains a corner of the square in its interior.*

The proof is based on rearrangement techniques, which have been widely used for geometric inequalities (see [15], [18] for a general reference). Here we will use two rearrangements adapted to the square: the increasing rearrangement and polarization.

For a nonnegative measurable function u on a rectangle, we define the *increasing rearrangement in the x-direction*, $\mathcal{R}u$, by replacing the restriction of u to each line $y = const$ with the unique nondecreasing left-continuous function which is equimeasurable with $u(\cdot, y)$; see Figure 3.2. By Fubini's theorem, $\mathcal{R}u$ is equimeasurable with u.

LEMMA 3.3. *Let u be a nonnegative $W^{1,2}$-function on a rectangle $\Omega =]0,1[\times]0,h[$, and let $\mathcal{R}u$ be its increasing rearrangement in the x-direction. If the trace of u vanishes σ-a.e. on a window*

$$D = \Big(\{0\} \times D_l\Big) \cup \Big(\{1\} \times D_r\Big) \cup \Big(D_b \times \{0\}\Big) \cup \Big(D_t \times \{h\}\Big),$$

then $\mathcal{R}u$ vanishes σ-a.e. on the window $\mathcal{R}D$ defined by

$$(\mathcal{R}D)_l = D_l \cup D_r, \quad (\mathcal{R}D)_r = \emptyset, \quad (\mathcal{R}D)_b =]0, \sigma(D_b)[, \quad (\mathcal{R}D)_t =]0, \sigma(D_t)[. \tag{3.2}$$

In general,

$$\sigma(D) \geq \sigma(\mathcal{R}D),$$

with equality certainly when $D_r = \emptyset$. The corresponding principal eigenvalues satisfy

$$\lambda(D) \geq \lambda(\mathcal{R}D),$$

with equality only when $\mathcal{R}D$ agrees σ-a.e. with either D or its mirror image.

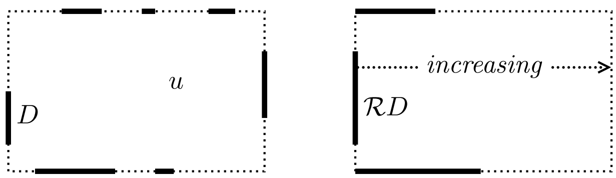

FIG. 3.2. *The effect of the symmetric increasing rearrangement on a window with components on all four sides of a rectangle.*

Proof. If u is continuous up to the boundary of the rectangle and vanishes on D, then its rearrangement $\mathcal{R}u$ is also continuous and vanishes on the window $\mathcal{R}D$. To see that the trace of $\mathcal{R}u$ vanishes on $\mathcal{R}D$ for any nonnegative function u in $W^{1,2}$ vanishing on D, we note that the increasing rearrangement is closely related with Steiner symmetrization. In fact, if we extend both u and $\mathcal{R}u$ by reflection across the line $x = 1$ to functions $\hat{u}$ and $\hat{\mathcal{R}}u$ on the doubled rectangle $\hat{\Omega} =]0, 2[\times]0, h[$, then $\hat{\mathcal{R}}u$ is just the Steiner symmetrization of $\hat{u}$. Since Steiner symmetrization is continuous on $W^{1,2}$ according to [4], $\mathcal{R}$ is continuous as well, and the first claim follows by a density argument.

For the second claim we use that $\mathcal{R}$ preserves the L^2-norm but reduces the norm of the gradient. In particular, $\mathcal{R}$ can only decrease the Rayleigh quotient. Choosing u to be the principal eigenfunction of the CHVP corresponding to the window D, we see that

$$\lambda(D) = \frac{\int |\nabla u|^2 \, dx}{\int |u|^2 \, dx} \geq \frac{\int |\nabla \mathcal{R}u|^2 \, dx}{\int |\mathcal{R}u|^2 \, dx} \geq \lambda(\mathcal{R}D). \tag{3.3}$$

By analyticity, the partial derivative $\partial_x u$ vanishes only on a set of zero measure. It follows from a theorem of Brothers and Ziemer [3] that the rearrangement inequality in (3.3) is strict unless u is already either increasing or decreasing in x on each line $y = const.$ ∎

The second rearrangement exploits the symmetry of the square under reflections at the diagonals. Let $\Omega =]0, 1[\times]0, 1[$ be the unit square, and let $\tau(x, y) = (y, x)$ denote the reflection at the diagonal joining the lower left with the upper right-hand corner. For any function u on Ω, the *polarization* $\mathcal{P}u$ of u with respect τ is given by

$$\mathcal{P}u(x, y) \;=\; \begin{cases} \max\{u(x, y), u(\tau(x, y))\} & \text{if } y \geq x, \\ \min\{u(x, y), u(\tau(x, y))\} & \text{if } y \leq x. \end{cases}$$

For a comprehensive account of polarization we refer to [2]. We have the following lemma.

LEMMA 3.4. *Let u be a nonnegative $W^{1,2}$-function on the unit square $\Omega =\,]0, 1[\times]0, 1[$, and let $\mathcal{P}u$ be its polarization, as defined above. If (the trace of) u vanishes σ-a.e. on a window*

$$D \;=\; \Big(\{0\} \times D_l\Big) \cup \Big(\{1\} \times D_r\Big) \cup \Big(D_b \times \{0\}\Big) \cup \Big(D_t \times \{1\}\Big),$$

then $\mathcal{P}u$ vanishes σ-a.e. on the window $\mathcal{P}D$ with

$$(\mathcal{P}D)_l = D_l \cap D_b, \quad (\mathcal{P}D)_r = D_r \cup D_t, \quad (\mathcal{P}D)_b = D_l \cup D_b, \quad (\mathcal{P}D)_t = D_r \cap D_t.$$

In general,

$$\sigma(D) = \sigma(\mathcal{P}D),$$

and the principal eigenvalues satisfy

$$\lambda(D) \geq \lambda(\mathcal{P}D),$$

with equality only if $\mathcal{P}D$ agrees σ-a.e. with either D or $\tau(D)$.

Proof. The form of $\mathcal{P}D$ is immediate from the definition of $\mathcal{P}$. To see the second claim, choose u to be the principal eigenfunction corresponding to the window D. Since $\mathcal{P}u$ is equimeasurable with u and $|\nabla \mathcal{P}u|$ is equimeasurable with $|\nabla u|$ by definition of the polarization, we have

$$\lambda(D) = \frac{\int |\nabla u|^2\, dx}{\int |u|^2\, dx} = \frac{\int |\nabla \mathcal{P}u|^2\, dx}{\int |\mathcal{P}u|^2\, dx} \geq \lambda(\mathcal{P}D).$$

Unless $\mathcal{P}u$ agrees with either u or $u \circ \tau$, it cannot be real analytic, and hence is not the eigenfunction corresponding to $\lambda(\mathcal{P}D)$. We conclude that then the last inequality is strict. ∎

Proof of Theorem 3.2. Within the class of windows contained in two sides of the square, there clearly exists an optimal one. By Lemma 3.4, a window consisting of two nonempty parts contained in two opposite sides of the square cannot be optimal, since it can be improved by polarization.

If D is contained in two adjacent sides (say, left and bottom) of the square, Lemma 3.3 implies that replacing D with $\mathcal{R}D$ strictly reduces the principal eigenvalue, unless the bottom part of the window is connected and contains a corner. Note that in this case, $\mathcal{R}D$ has the same length as D. Repeating this argument for the vertical direction, we see that also the part of D on the left-hand side must be connected and contain the lower left corner.

It remains to show that a corner must lie in the *interior* of the window. If the length of D happens to equal the length of one side of the square, we refer to the numerical result, which shows that the corner-centered position improves over the one-side position. Otherwise, we refer to Corollary 6.3 below to show that moving the segment a short distance around the corner improves the eigenvalue. ∎

3.3. Nonoptimality of $\mathbb{Z}_2 \times \mathbb{Z}_2$-symmetric windows. We have the following theorem.

THEOREM 3.5. *In a rectangle, any window of sufficiently small length that has the full symmetry group of a rectangle is not optimal. In particular, a symmetric window whose length does not exceed the length of one side is not optimal in a square.*

As mentioned before, numerical results for the square indicate that the length restriction is not needed.

Proof. In self-explanatory pictogram notation, we reason that

(3.4) $\lambda\Bigg($  $\Bigg) = \lambda\Bigg($  $\Bigg) = 4\lambda\Bigg($  $\Bigg) \geq 4\lambda\Bigg($  $\Bigg)$,

exploiting symmetry, scaling, and the rearrangement of Lemma 3.3 in turn. The last inequality is strict unless the window consists of four L-shaped windows in the corners to begin with, showing that an optimal window having full symmetry must be of that form. In (3.4), we have gained a factor 4, but lost half of the window length. We now double the window using Lemma 6.1.

Assume that the rectangle has the form $\Omega =]0, a[\times]0, b[$ and the L-shaped window (called D_L) has lengths $q_x a$ and $q_y b$ on the horizontal and vertical parts, respectively.

An admissible test function for the CHVP for an L-shaped window with sidelengths $2q_xa$ and $2q_yb$ is given by $u\circ\psi$, where $\psi(x,y)=(h(x),k(y))$ with h,k piecewise linear such that $h(0)=k(0)=0$, $h(a)=a$, $k(b)=b$, and $h(2q_xa)=q_xa$, $k(2q_yb)=q_yb$. It is easy to see that $\psi:\Omega\to\Omega$ is bi-Lipschitz. The largest value for the spectral radius of $(D\psi)(D\psi)^T/\det D\psi$ is $2(1-q)/(1-2q)$ with $q=\max\{q_x,q_y\}$, and the largest value for $\det D\psi$ is $(1-q_x)/(1-2q_x)\times(1-q_y)/(1-2q_y)$. By Lemma 6.1, the window $\psi^{-1}(D_L)$ is an improvement over the original window, whenever $2(1-q)^3/(1-2q)^3\le 4$, which happens for $q<0.17$ and translates to a smallness condition on the window size, depending on the sidelengths of the rectangle.

In the square $]0,1[\times]0,1[$, an optimal window which is symmetric under reflections at the vertical and horizontal axes must be symmetric under reflection in the diagonals as well, since otherwise a better window is obtained by polarization; this gives $q_x=q_y=:q$. We can now get a better quantitative estimate in (3.4) for the square. Define a bi-Lipschitz map by setting

$$\psi:(x,y)\mapsto\begin{cases}\left(x,1-\frac{1-q}{1-2q}(1-y)\right) & \text{if } y\ge 1-(1-2q)(1-x) \qquad \text{(I)},\\ \left(x,\frac{1}{2}(x+y)\right) & \text{if } x\le y\le 1-(1-2q)(1-x) \quad \text{(II)}\end{cases}$$

above the diagonal, and an analogous formula below the diagonal. The spectral radius of $(D\psi)(D\psi)^T/\det D\psi$ is $(1-q)/(1-2q)$ in domain (I) and $\frac{1}{2}(3+\sqrt{5})$ in (II). The Jacobian $\det D\psi$ is largest in (I), namely $(1-q)/(1-2q)$. Lemma 6.1 implies that the window can be doubled with a factor ≤ 4 in the eigenvalue, provided $\sigma(D)=4q\le 4(5-\sqrt{5})/(13-\sqrt{5})\approx 1.027$. ∎

COROLLARY 3.6. *The result of Theorem* 3.5 *holds, for sufficiently small windows in a rectangle* $]-a,a[\times]-b,b[$, *under the weaker assumption that either* (a) *there is equal window area in each of the four quadrants, or* (b) *the window is symmetric under the* $180°$ *rotation* $(x,y)\mapsto(-x,-y)$.

Proof. For (a), the first step in (3.4) can be replaced with an inequality, where that quarter is selected that contributes the smallest Rayleigh quotient. For (b), note that the symmetry is inherited by the eigenfunction, and we have $u(0,y)=u(0,-y)$. Thus we can define $\hat u\in W^{1,2}$ by $\hat u(x,y)=u(x,y)$ for $x\le 0$ and $\hat u(x,y)=u(x,-y)$ for $x\ge 0$. $\hat u$ represents another window $\hat D$ with the same area as D, has the same Rayleigh quotient, and is not the optimizer yet, unless $\hat D=D$; this reduces the corollary to the theorem again. ∎

4. A star-shaped domain with disconnected optimal window. Here we prove the properties of the following example.

Example 4.1. There exists a star-shaped Lipschitz domain Ω in $\mathbb{R}^2$ and a length ℓ such that a connected window of length ℓ in Ω cannot be optimal.

Proof. In a one-parameter family of domains Ω_ε, we calculate an upper bound for the eigenvalue of a certain window D_2 with two components. Then we establish a larger lower bound for the eigenvalue of any connected window D. These estimates, based on Dirichlet–Neumann bracketing, work for sufficiently small ε, and can be made quantitative.

Ω_ε is the union of a "torso" rectangle T_ε and a pair of "handles" H_ε, $-H_\varepsilon$:

$$T_\varepsilon:=\,]-1,1[\times]-1-\varepsilon,1+\varepsilon[,\quad H_\varepsilon:=[1,9-\varepsilon[\times]-\varepsilon,\varepsilon[. \tag{4.1}$$

See the top left part of Figure 4.1. We choose $D_2:=(\partial\Omega_\varepsilon)\setminus\overline{T}_\varepsilon$, with $\sigma(D_2)=32$. The remaining boundary $W:=(\partial\Omega_\varepsilon)\setminus D_2$ has measure $\sigma(W)=8$.

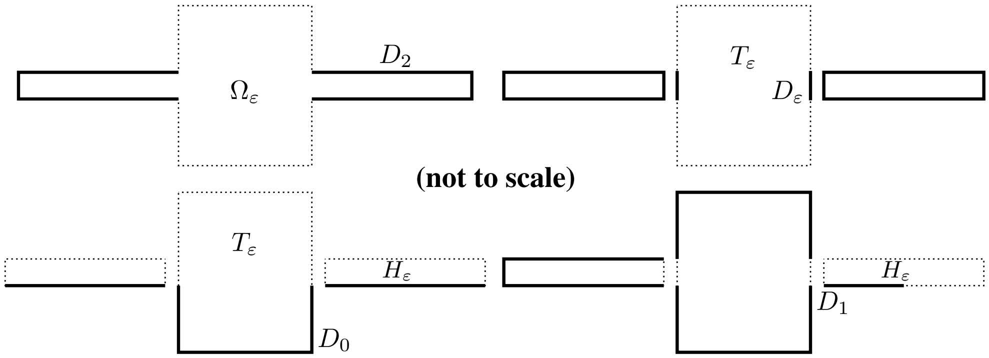

FIG. 4.1. *Top left: A star-shaped Lipschitz domain whose optimal window(s) of a certain length ℓ cannot be connected. Top right: Upper bound for eigenvalue of disconnected window. Bottom: Lower bounds for connected windows.*

For comparison, disconnect the handles from the torso by means of extra Dirichlet boundary $D_\varepsilon = \{\pm 1\} \times [-\varepsilon, \varepsilon]$, as in the top right of Figure 4.1. With fewer competitors in the CHVP (1.5), we get an upper bound. In self-explanatory notation, we conclude

$$\lambda(\Omega_\varepsilon, D_2) < \min\Big\{\lambda_{\mathrm{Dir}}(H_\varepsilon), \lambda(T_\varepsilon, D_\varepsilon)\Big\} = \lambda(T_\varepsilon, D_\varepsilon).$$

By testing the EVP for T_ε with $\sin\frac{\pi}{2}(|y|-\varepsilon)_+$, one can see that the evaluation of the minimum is valid for all $\varepsilon \leq 1$.

For any connected window D of length 32, it can easily be seen that, except for reflection symmetry, either $D \supset D_0$ or $D \supset D_1$, where

$$\begin{aligned} D_0 &= \{(x, y) \in \partial\Omega_\varepsilon \mid y \leq -\varepsilon\}, \\ D_1 &= \{(x, y) \in \partial\Omega_\varepsilon \mid x \leq 1\} \cup [1, 5] \times \{-\varepsilon\}. \end{aligned}$$

To get lower bounds for $\lambda(\Omega_\varepsilon, D_0)$ and $\lambda(\Omega_\varepsilon, D_1)$, disconnect the handles from the torso by means of extra Neumann boundary $\{\pm 1\} \times [-\varepsilon, \varepsilon]$. With slight abuse of notation, we write $\lambda(T_\varepsilon, D_i)$ for $\lambda(T_\varepsilon, D_i \cap \partial T_\varepsilon)$, and similarly for H_ε. We have either

$$\lambda(\Omega_\varepsilon, D) > \min\Big\{\lambda(H_\varepsilon, D_0), \lambda(T_\varepsilon, D_0)\Big\} = \lambda(T_\varepsilon, D_0) > (\tfrac{\pi}{4+4\varepsilon})^2 \tag{4.2}$$

or

$$\lambda(\Omega_\varepsilon, D) > \min\Big\{\lambda(H_\varepsilon, D_1), \lambda(T_\varepsilon, D_1)\Big\} = \lambda(H_\varepsilon, D_1). \tag{4.3}$$

The evaluation of the minimum in (4.2), for any ε, relies on a test function that vanishes for $y \leq -\varepsilon$. The evaluation of the minimum in (4.3) is valid for all $\varepsilon < \frac{3}{2}$, since then, using comparison functions $\cos(\pi y/(2+2\varepsilon))$ and $\sin\pi(x-5)_+/2(4-\varepsilon)$,

$$\lambda(T_\varepsilon, D_1) > (\pi/(2+2\varepsilon))^2 \geq (\pi/(2(4-\varepsilon)))^2 > \lambda(H_\varepsilon, D_1).$$

For $\varepsilon < \frac{2}{3}$, we can also conclude that

$$\lambda(H_\varepsilon, D_1) < (\pi/(8-2\varepsilon))^2 < (\pi/(4+4\varepsilon))^2 < \lambda(T_\varepsilon, D_0).$$

It therefore only remains to prove the middle inequality in

$$\lambda(\Omega_\varepsilon, D) > \lambda(H_\varepsilon, D_1) > \lambda(T_\varepsilon, D_\varepsilon) > \lambda(\Omega_\varepsilon, D_2).$$

But as $\varepsilon \to 0$, one has $\lambda(T_\varepsilon, D_\varepsilon) \to 0$, whereas $\lambda(H_\varepsilon, D_1) \to (\pi/8)^2$. This plausible singular domain limit can be proved in a straightforward way by writing the quadratic form $\int_{H_\varepsilon}(u_x^2 + u_y^2)\, dx\, dy$ as a quadratic form $\int(\varepsilon\chi(\xi)^{-1}u_\xi^2 + \varepsilon^{-1}\chi(\xi)u_\eta^2)\, d\xi\, d\eta$ on L^2 with measure $\varepsilon\chi(\xi)d\xi\, d\eta$ in a fixed reference domain $]0,8[\times]-1,1[$. Here $\chi(\xi) = 1$ for $\xi < 4$, and $\chi(\xi) = 1 - \varepsilon/4$ for $\xi > 4$. If we carry out the limit $\varepsilon \to 0$ in the CHVP with the appropriate eigenfunctions, we have the uniform upper bound $(\pi/(8-2\varepsilon))^2$ for the eigenvalue, as mentioned before. This controls the $W^{1,2}$ norm in the fixed domain, and actually enforces $u_\eta \to 0$. The limiting function will indeed not depend on the η coordinate and solve the 1-dimensional eigenvalue problem $-u_{\xi\xi} = \lambda u$ on $[4,8] \ni \xi$, with $u(4) = 0$, $u_\xi(8) = 0$. ∎

5. Some continuity results. In this section, we study how the eigenvalue changes if a window of a particular size is added at a particular location. The basic philosophy is that windows can be added more cheaply at locations where the eigenfunction was already small before the addition. In the second subsection, we discuss related continuity properties of the corresponding eigenfunctions.

5.1. Continuity of eigenvalues. Our first result is an estimate for the increase of the principal eigenvalue if a set of small capacity is added to a given window.

LEMMA 5.1. *Let $D_2 \supset D_1$ and let u_1 be the normalized eigenfunction for D_1. Let G be a domain containing $D_2 \setminus D_1$; in case the dimension $d = 2$, assume additionally that G is bounded. Then*

$$\lambda(D_2) - \lambda(D_1) \le \frac{\lambda(D_1)\,\mathrm{vol}\,(G\cap\Omega) + \mathrm{cap}(D_2 \setminus D_1, G)}{1 - (\sup_{G\cap\Omega} u_1)^2\,\mathrm{vol}\,(G\cap\Omega)} \big(\sup_{G\cap\Omega} u_1\big)^2, \tag{5.1}$$

where cap *is the capacity defined in* [19, section 2.2.1], *namely*

$$\mathrm{cap}(D_2 \setminus D_1, G) := \inf\left\{ \int_G |\nabla v|^2 \;\middle|\; v = 1 \text{ in a nbhd of } D_2 \setminus D_1\,;\ v \in C_0^\infty(G) \right\}.$$

Proof. Let $M := \sup_{G\cap\Omega} u_1$. As explained in [9] near equation (3.2), it follows from de Giorgi's argument (see formula (5.12) in Chapter 2 of Ladyzhenskaya and Ural'tseva [17]) that $\sup_\Omega u_1$ is finite, and can even be chosen to depend only on Ω, not on D_1. To obtain a test function for the CHVP which determines $\lambda(D_2)$, we modify u_1 in G: In $\overline{G}\cap\Omega$, let $u_2 := \min\{u_1, M(1-v)\}$, where v is one of the functions that approximate the capacity of $D_2 \setminus D_1$; outside (if any), let $u_2 = u_1$. Since $u_2 = u_1$ on $\Omega\cap\partial G$, this does not introduce discontinuities, and u_2 is an admissible test function for $\lambda(D_2)$.

Clearly

$$\int_\Omega u_2^2(x) \ge \int_{\Omega\setminus G} u_1^2 \ge 1 - M^2\,\mathrm{vol}\,(G\cap\Omega)$$

and

$$\int_\Omega |\nabla u_2|^2 \le \int_\Omega |\nabla u_1|^2 + M^2 \int_G |\nabla v|^2 \to \int_\Omega |\nabla u_1|^2 + M^2\,\mathrm{cap}(D_2 \setminus D_1, G)$$

as v runs through a minimizing sequence for the capacity functional. We conclude (5.1) immediately. ∎

In applications of the lemma, G should be a small neighborhood of $D_2 \setminus D_1$, so that in the numerator on the right-hand side of (5.1), the capacity term dominates the volume term. It can be used to establish continuity of the eigenvalue under deformations of sufficiently regular windows. The following simplified estimate suffices to show the continuous dependence of the eigenvalue on the length and position of a segment in a square.

PROPOSITION 5.2. *For a given bounded Lipschitz domain $\Omega \subset \mathbb{R}^d$, there exists a nonnegative continuous function η with $\eta(0) = 0$ so that for any pair of windows $D_1 \subset D_2 \subset \partial\Omega$,*

$$\lambda(D_2) \;\leq\; \lambda(D_1) + \eta\left(\operatorname{diam}(D_2 \setminus D_1)\right),$$

where the η is a continuous function with $\eta(0) = 0$ which depends only on Ω but not on D_1 and D_2. The result applies to the coarse as well as to the fine definition of the eigenvalue.

Proof. We assume $D_2 \setminus D_1 \subset B_\delta(x_0)$ where $\delta := \operatorname{diam}(D_2 \setminus D_1)$ and use the Green's function as a legitimate limiting case for v in the capacity functional; namely, for dimension $d = 2$, let $G = B_R(x_0)$ and $1 - v := \ln_+(|x - x_0|/\delta)/\ln(R/\delta)$, with, say, $R = \sqrt{\delta}$ when $\delta < 1$. For $d \geq 3$, we can take $G = B_R(x_0)$ with $R := \delta^{(d-2)/d}$ and let $1 - v := (\delta^{-(d-2)} - |x - x_0|^{-(d-2)})_+/(\delta^{-(d-2)} - R^{-(d-2)})$. For simplicity, we can take $M := \sup_\Omega u_1$ as an upper bound for $\sup_{G\cap\Omega} u_1$ and obtain the claim with

$$\eta(\delta) := \begin{cases} \pi M^2 \dfrac{\delta\lambda_{\mathrm{Dir}} + 2/\ln(\delta^{-1/2})}{1 - \pi M^2 \delta} & \text{for } d = 2, \\ \dfrac{(d-1)^2 \omega_d M^2 \delta^{d-2}}{1 - \omega_d M^2 \delta^{d-2}} & \text{for } d > 2, \end{cases} \tag{5.2}$$

where ω_d is the volume of the unit ball. $\square$

It should be noted that the modulus of continuity of the eigenvalue cannot be expressed in terms of $\sigma(D_2 \setminus D_1)$ alone. This is due to the fact [8, Theorem 8] that for any ε there exists a window of measure $< \varepsilon$ with eigenvalue $> \lambda_{\mathrm{Dir}} - \varepsilon$. This observation also implies, in view of the a priori estimate for $\|u\|_\infty$ and Hölder's inequality, that an estimate in terms of $\|u_1\|_p$ is not possible for any $p < \infty$.

THEOREM 5.3. *The optimal eigenvalue λ_* depends continuously on the prescribed boundary measure of the window.*

Proof. We will prove that in dimensions $d > 2$, the function $\ell \mapsto \lambda_*(\ell)$ is Hölder continuous with exponent $(d-2)/(d-1)$, for $\ell < \sigma(\partial\Omega)$. In $d = 2$ dimensions, we will obtain a logarithmic estimate for the modulus of continuity.

Fix $\ell_1 < \sigma(\partial\Omega)$ and let D_1 be an optimal window with $\sigma(D_1) = \ell_1$. It follows from Proposition 5.2 that

$$\lambda\big(D_1 \cup (B_\delta(x_0) \cap \partial\Omega)\big) - \lambda(D_1) < \eta(\delta)$$

for any choice of $x_0 \in \partial\Omega$ and $\delta > 0$. We want to choose x_0 in such a way that $\sigma((B_\delta(x_0) \cap \partial\Omega) \setminus D_1)$ is bounded away from zero. To do this, we use Fubini's theorem to estimate

$$\begin{aligned} \fint_{\partial\Omega} \sigma((B_\delta(x) \cap \partial\Omega) \setminus D_1) d\sigma(x) &= \frac{1}{\sigma(\partial\Omega)} \int_{\partial\Omega} \int_{\partial\Omega\setminus D_1} \mathbf{1}_{|x-y|<\delta}\, d\sigma(y) d\sigma(x) \\ &= \frac{1}{\sigma(\partial\Omega)} \int_{\partial\Omega\setminus D_1} \sigma(B_\delta(y))\, d\sigma(y) \\ &\geq \frac{\sigma(\partial\Omega) - \sigma(D_1)}{\sigma(\partial\Omega)} \inf_{y\in\partial\Omega} \sigma(B_\delta(y)). \end{aligned}$$

Since Ω is a bounded Lipschitz domain, there exists a constant c, depending only on Ω, such that $\sigma(B_\delta(x_0)) \geq c\delta^{d-1}$. We conclude that for any value of δ there exists a point $x_0 \in \partial\Omega$ such that

$$\sigma\big(B_\delta(x_0) \setminus D_1\big) \geq \left(1 - \frac{\ell_1}{\sigma(\partial\Omega)}\right) c\delta^{d-1}.$$

For $\ell_2 > \ell_1$, set

$$\delta = \left(\frac{\ell_2 - \ell_1}{c(1 - \ell_1/\sigma(\partial\Omega))}\right)^{1/(d-1)},$$

and let $D_2 = D_1 \cup (B_\delta(x_0) \cap \partial\Omega)$. Since $\sigma(D_2) \geq \ell_2$, it follows that

$$\lambda_*(\ell_2) - \lambda_*(\ell_1) \leq \lambda(D_2) - \lambda(D_1) \leq \eta(\delta).$$

The claim now follows from the expression for η given in Proposition 5.2. ◻

The punchline of Theorem 5.3 is that we get a uniform modulus of continuity without extra regularity assumptions on the boundary. For smoother $\partial\Omega$, stronger results could be obtained using the tools of section 6. We conjecture (but have not pursued) that the window D_2 in Example 4.1 is actually optimal, and that the modulus of continuity at that length in Example 4.1 is precisely $O(\delta^{2/3})$. This intuition is based on the $r^{1/3}$ singularity of the eigenfunction at the re-entrant corner, the role of singularities revealed in section 6, and the estimate from Lemma 5.1. A Lipschitz estimate for $\ell \mapsto \lambda_*(\ell)$ should not be expected without further assumptions on $\partial\Omega$, but smoothness (a.e.) of $\partial\Omega$ will improve upon Theorem 5.3.

The following simple lemma estimates the change of the eigenvalue under increase of a window solely in terms of the eigenfunction.

Lemma 5.4. *Let $\Omega \subset \mathbb{R}^d$, and consider two windows $D_1 \subset D_2 \subset \partial\Omega$. Let u_1 be the normalized eigenfunction corresponding to $\lambda(D_1)$. Then*

$$\lambda(D_2) - \lambda(D_1) \leq \lambda(D_1)\frac{\sqrt{\operatorname{vol}(\Omega)}\,\sup_{D_2\setminus D_1} u_1}{1 - \sqrt{\operatorname{vol}(\Omega)}\,\sup_{D_2\setminus D_1} u_1}. \tag{5.3}$$

Proof. Let $\varepsilon := \sup_{D_2\setminus D_1} u_1$. Then $v_\varepsilon = (u_1 - \varepsilon)_+$ is an admissible test function for both the CHVPs defining $\lambda(D_2)$ and $\lambda(D_1)$. We compute

$$\|\nabla v_\varepsilon\|_2^2 = \int \nabla u_1 \cdot \nabla(u_1 - \varepsilon)_+ = \lambda(D_1)\int u_1(u_1 - \varepsilon)_+, \tag{5.4}$$

where we have used the weak form $\int \nabla u \nabla\varphi = \lambda \int u\varphi$ of the eigenvalue equation $\Delta u = -\lambda u$, with $\varphi := v_\varepsilon$. It follows that

$$\begin{aligned}
\lambda(D_2) - \lambda(D_1) &\leq \frac{\int |\nabla v_\varepsilon|^2}{\int v_\varepsilon^2} - \lambda(D_1)\\
&\leq \lambda(D_1)\frac{\int \varepsilon(u_1 - \varepsilon)_+}{\int (u_1 - \varepsilon)_+^2}\\
&\leq \lambda(D_1)\frac{\varepsilon}{\|(u_1 - \varepsilon)_+\|_2}\left(\operatorname{vol}(\Omega)\right)^{1/2}.
\end{aligned}$$

The triangle inequality $\|(u_1 - \varepsilon)_+\|_2 \ \geq\ 1 - \varepsilon\left(\operatorname{vol}(\Omega)\right)^{1/2}$ now yields the claim. ◻

For a given window $D \subset \partial\Omega$, denote by

$$D_\delta := \Big(\bigcup_{x\in D} B_\delta(x)\Big) \cap \partial\Omega \quad (\delta > 0), \quad D_0 := D \tag{5.5}$$

the relative δ-neighborhood of D in $\partial\Omega$. Continuity of the eigenfunction up to the boundary is sufficient for continuity of the eigenvalue function $\delta \mapsto \lambda(D_\delta)$.

THEOREM 5.5. *Let u be an eigenfunction for window boundary conditions on D, and assume that the preferred representative $\tilde u$ vanishes everywhere on D.*

(a) *If $\tilde u$ is upper semicontinuous on $\overline{\Omega}$, then $\lambda(\cdot)$ is outer regular at D in the sense that for every $\varepsilon > 0$ there exists a relatively open subset $U \subset \partial\Omega$ containing D, with the property that*

$$\lambda(U) \le \lambda(D) + \varepsilon.$$

(b) *If u is continuous up to the boundary of Ω, then the map $\delta \mapsto \lambda(D_\delta)$ is right continuous at $\delta = 0$.*

We will show below (Theorem 5.7) that the hypothesis of part (a) is satisfied for $C^{1,\alpha}$ domains in $\mathbb{R}^2$, and at flat pieces of the boundary in any dimension. We conjecture that upper semicontinuity may hold at least for smooth domains in any dimension.

Concerning part (b), continuity up to the boundary can be shown for the eigenfunction by a careful analysis of de Giorgi's argument, under the assumption that the window D has positive Lebesgue density at every interface point $x_0 \in \overline{D} \cap \overline{\partial\Omega \setminus D}$. We conjecture, but cannot prove, that eigenfunctions for optimal windows are continuous up to the boundary. Below, we show by an example that continuity of the eigenfunction is not necessary for continuity of $\delta \mapsto \lambda(D_\delta)$.

Proof of Theorem 5.5. If the preferred representative $\tilde u$ is upper semicontinuous on the closure of Ω, then the set

$$U = \{x \in \partial\Omega \ \mid \ u(x) < \eta\}$$

is a (relatively) open set containing D. By Lemma 5.4, we have that

$$\lambda(D) \le \lambda(U) \le \frac{\lambda(D)}{1 - \eta\mu(\Omega)^{1/2}} < \lambda(D) + \varepsilon$$

if $\eta = \eta(\varepsilon)$ is chosen sufficiently small (e.g., $\eta := \varepsilon(\lambda_{\mathrm{Dir}}(\Omega)\,\mathrm{vol}\,(\Omega))^{-1}$). This proves outer regularity. If $\tilde u$ is continuous, then D is compact, and hence there exists a $\delta > 0$ so that $D_\delta \subset U$, which proves the second claim. $\square$

Note that assuming that $\tilde u$ vanishes everywhere on D amounts to replacing D with its refinement and selecting the fine eigenvalue. Since coarse and fine eigenvalues agree for the open windows D_δ, continuity of λ^c certainly fails at any window D for which $\lambda^c(D) < \lambda^f(D)$. Cantor sets of zero measure but positive capacity provide examples of such windows.

However, $\delta \mapsto \lambda^f(D_\delta)$ cannot be continuous in general either. For an open-dense window D of small measure, we clearly have $\lambda(D_\delta) = \lambda_{\mathrm{Dir}}$ for all $\delta > 0$. However, we claim that $\lambda_D < \lambda_{\mathrm{Dir}}$. To see this, note that u_D cannot agree with u_{Dir}, since eigenfunctions do not take on"extra" Dirichlet boundary conditions, as was shown near Figure 1 in [9]. Since u_{Dir} is an admissible candidate for the CHVP for λ_D, it follows from the uniqueness of the minimizer that $\lambda_{\mathrm{Dir}} > \lambda_D$. This also provides an example of a window whose eigenfunction is discontinuous on a set of large measure on the boundary.

Example 5.6. There exists an open window D with discontinuous eigenfunction, such that still $\delta \mapsto \lambda(D_\delta)$ is right continuous.

Proof. In a planar domain, parametrize a portion of the boundary by arclength and refer to segments on the boundary as intervals in this parameter. We will construct two decreasing sequences $x_n \searrow 0$ and $\delta_n \searrow 0$ and let $I_n :=]x_n - \delta_n, x_n + \delta_n[$. The sequences x_n and δ_n will be specified later. The window will be $D := \bigcup_{n=1}^\infty I_n$, and we will also define $D_N := \bigcup_{n=1}^N I_n$, with the eigenvalues and normalized eigenfunctions λ, λ_N, u, u_N, respectively. If N is the first index such that $x_N < \delta$, then

$$D_\delta \setminus D \subset]-\delta, \delta[\cup \bigcup_{n=1}^{N} [x_n + \delta_n, x_n + \delta_n + \delta[\cup \bigcup_{n=1}^{N-1}]x_n - \delta_n - \delta, x_n - \delta_n].$$

It follows from Proposition 5.2 that $\lambda(D_\delta) - \lambda(D) < (2N+1)\eta(\delta) < (2N+1)\eta(x_{N-1})$. Choosing the sequence (x_n) such that $(2N+1)\eta(x_{N-1}) \to 0$ as $N \to \infty$ ensures the right continuity of $\delta \mapsto \lambda(D_\delta)$.

With (x_n) thus fixed, we introduce the compact set $K := \{0\} \cup \{y_n \mid n \in \mathbb{N}\}$, where $y_n = (x_n + x_{n+1})/2$ and construct the sequence (δ_n) inductively. Let $\delta_1 = (x_1 - y_1)/2$.

Since D_1 has positive Lebesgue density at all interface points, it follows from de Giorgi's argument that the corresponding eigenfunction u_1 is Hölder continuous up to the boundary. Let $a := \inf_K u_1 > 0$ and define $a_n := (1/2 + 1/2^n)a$. We will choose δ_N in such a way that $\inf_K u_N \geq a_N$. Assume $\delta_1, \ldots, \delta_{N-1}$ have been constructed. The interval I_N, and thus D_N and u_N, will depend on the choice of δ_N. But as $\delta_N \to 0$, the local de Giorgi estimates near K remain uniform, because the L^∞ estimate for u_N does not depend on the window and the interface stays away from K. Then $u_N^{(\delta_N)}$ converges weakly in $W^{1,2}(\Omega)$, strongly in $L^2(\Omega)$, and strongly in $L^2(\partial\Omega)$ by the usual compactness arguments. It also converges strongly in $W^{1,2}(\Omega)$ to u_{N-1} since $\lambda_N^{(\delta_N)} \to \lambda_{N-1}$; the convergence is uniform in a neighborhood of K by the equicontinuity obtained from de Giorgi. Since $u_{N-1} \geq a_{N-1}$ on the compact set K, we can achieve $u_N \geq a_{N-1} - \varepsilon$ for any $\varepsilon > 0$ by making δ_N small; in particular we can achieve $u_N \geq a_N$.

It is now easy to show that u is discontinuous at 0. Indeed, as $N \to \infty$, $u_N \to u$ in the Sobolev spaces mentioned above. Again, the convergence is uniform in a neighborhood of each single y_n. Therefore, $u(y_n) \geq a/2$ for each n, whereas $u(x_n) = 0$. Hence u is discontinuous at 0. □

We finally refer to Lemma 6.1, which gives continuity estimates under distortion of a window by means of a bi-Lipschitz homeomorphism. Due to the similarity of proofs, we conveyed it to section 6.

5.2. On upper semicontinuity of eigenfunctions. Here, we will prove semicontinuity of eigenfunctions as a consequence of a subharmonicity argument.

THEOREM 5.7. *If $\Omega \subset \mathbb{R}^2$ has a $C^{1,\alpha}$ boundary, then for any measurable window $D \subset \partial\Omega$, the eigenfunction u has an upper semicontinuous preferred representative $\tilde{u}$. If $\Omega \subset \mathbb{R}^d$ with $d > 2$, then $\tilde{u}$ is upper semicontinuous at any boundary point where the boundary is locally part of a hyperplane.*

Proof. Let u be the solution of the CHVP (1.5) for D, the eigenvalue being $\lambda(D)$. Fix $x_0 \in \partial\Omega$. We will show that if the $\partial\Omega$ coincides with a hyperplane in some neighborhood of x_0, then the limit

$$\tilde{u}(x) := \lim_{r \to 0} \fint_{B_r(x) \cap \Omega} u(y)\, dy \tag{5.6}$$

exists for all points in this neighborhood and defines an upper semicontinuous function. This limit agrees with the preferred representative defined in (1.7). In the special case of two dimensions, the conclusion holds assuming only that $\partial\Omega$ is of regularity $C^{1,\alpha}$ near x_0. We note that in the interior of Ω, u is always smooth.

The basic idea is as follows: When the boundary is locally part of a hyperplane, extend u by *even* reflection, regardless of the type of boundary conditions. The nonnegative function u, thus extended, has only such discontinuities as are possible for a subharmonic distribution, and this fact is shown by means of the test function $(u - t\varphi)_+$ in the CHVP, where φ is smooth nonnegative. Subharmonicity implies upper semicontinuity according to Theorem 9.3 in [18]. For curved boundary in 2D, the Riemann mapping theorem locally provides an analogue of the reflection.

Consider first the case where there exists a neighborhood V of x_0 such that $\partial\Omega \cap V$ is contained in a hyperplane. We may assume that the hyperplane is given by $x_d = 0$, that Ω lies above the hyperplane, and that V is symmetric under the reflection $(x', x_d) \mapsto (x', -x_d)$. Let φ be a smooth nonnegative function with support in V. Since $(u - t\varphi)_+$ is a legitimate candidate for the CHVP when $t \geq 0$, we have

$$\frac{A(t)}{B(t)} \geq \frac{A(0)}{B(0)}, \tag{5.7}$$

where

$$A(t) := \int_\Omega |\nabla(u - t\varphi)_+|^2, \quad B(t) := \int_\Omega |(u - t\varphi)_+|^2.$$

We calculate from the weak Euler equations

$$\begin{aligned} A(t) &= \int_\Omega \nabla(u - t\varphi)_+ \nabla u - t \int_\Omega \nabla(u - t\varphi)_+ \nabla\varphi \\ &= \lambda \int_\Omega (u - t\varphi)_+ u - t \int_{u > t\varphi} \nabla u \nabla\varphi + t^2 \int_{u > t\varphi} |\nabla\varphi|^2, \end{aligned} \tag{5.8}$$

and expand

$$B(t) = \int_\Omega u\,(u - t\varphi)_+ - t \int_\Omega \varphi\,(u - t\varphi)_+. \tag{5.9}$$

Inserting (5.8) and (5.9) into (5.7) and using that $A(0) = \lambda$ and $B(0) = 1$, we obtain the following for $t > 0$:

$$\begin{aligned} 0 &\leq t^{-1}(A(t)B(0) - A(0)B(t)) \\ &= \int_{u > t\varphi} \Big[-\nabla u \nabla\varphi + \lambda u\varphi \Big] + t \int_{u > t\varphi} \Big[|\nabla\varphi|^2 - \lambda\varphi^2 \Big]. \end{aligned}$$

Since all integrals over sets $u > t\varphi$ converge to integrals over Ω by Lebesgue's dominated convergence theorem, we obtain for $t \to 0+$ that

$$0 \leq \int_{V \cap \Omega} \Big[-\nabla u \nabla\varphi + \lambda u\varphi \Big]. \tag{5.10}$$

We now extend u by even reflection $u(x', -x_d) := u(x', x_d)$ and use (5.10) for the likewise reflected test function φ. Adding the reflected and the original (5.10), we obtain

$$0 \leq \int_V \Big[-\nabla u \nabla\varphi + \lambda u\varphi \Big] = \int_V \Big[u\Delta\varphi + \lambda u\varphi \Big], \tag{5.11}$$

where we have used that φ is C^2 and supported in V.

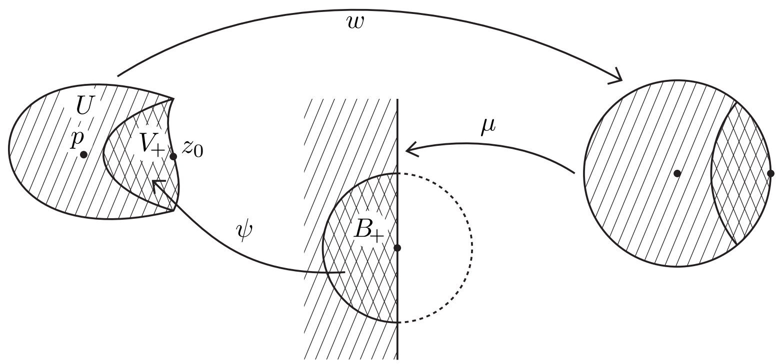

FIG. 5.1. *The Riemann mappings used in the proof of Theorem* 5.7.

We have shown that $\Delta u + \lambda u$ is nonnegative in the sense of distributions. If $v := u + \frac{M\lambda}{2d}|x|^2$, where $M := \|u\|_\infty < \infty$, then $\Delta v \geq 0$ in the sense of distributions. By [18, Theorem 9.3], v is subharmonic; that is,

$$v(x) \;\leq\; \fint_{B_r} v \tag{5.12}$$

for almost every $x \in V$, provided $B_r(x) \subset V$. Furthermore, the preferred representative $\tilde{v}$ of v is upper semicontinuous and satisfies the subharmonicity condition (5.12) for all x and r so that $B_r(x) \subset V$. Since $\tilde{u}$ differs from $\tilde{v}$ by a continuous function, it is upper semicontinuous as well. This settles the case where $\partial\Omega \cap V$ is contained in a hyperplane, in some neighborhood of x_0.

In the case where $\Omega \subset \mathbb{R}^2$ we use complex notation. Let V be a neighborhood of $z_0 \in \partial\Omega$ such that $\partial\Omega \cap V$ is of class $C^{1,\alpha}$, and let V_+ be the intersection of V with Ω. Replacing V by a subset, we may assume that there exists a conformal map ψ from a semidisc B_+ to V_+ such that the diameter of the semidisc maps onto $V \cap \partial\Omega$. The function $\bar{u} = u \circ \psi$ on the semidisc satisfies $\Delta\bar{u} = |\psi'|^2\,(\Delta u) \circ \psi$. Our argument will rely on the boundedness of $|\psi'|$ (shown below). By reflection, we can extend $\bar{u}$ into the full disc B. The extended function $\bar{u}$ is still in $W^{1,2}(B_+)$ since $\psi' \in L^\infty$; as before, the extended function remains in $W^{1,2}(B)$. From (5.10), we conclude, using the conformal invariance of the Dirichlet integral, that

$$0 \leq \int_{B_+} \left[-\nabla(u \circ \psi)\nabla(\varphi \circ \psi) + \lambda|\psi'|^2(u \circ \psi)(\varphi \circ \psi)\right]$$

for all $0 \leq \varphi \in W^{1,2}(V_+)$ that vanish on $\Omega \cap \partial V_+$, particularly for all $\varphi := \bar{\varphi} \circ \psi^{-1}$ with $\bar{\varphi} \in C_0^2(B)$. As with (5.11), we can now conclude that $v := \bar{u} + M\lambda 2d \sup|\psi'|^2$ is subharmonic and finish the argument as before.

We still need to explain why $|\psi'|$ remains bounded near $\partial\Omega$; this is where the $C^{1,\alpha}$ regularity of the boundary enters. Refer to Figure 5.1. Choose U to be the intersection of a neighborhood of $z_0 \in \partial\Omega$ with Ω such that U is simply connected. Choose a point $p \in U$. The Green's function of U can be obtained in the form $\ln|z-p| + \xi(z)$ with ξ harmonic subject to boundary values $-\ln|z-p|$. Near z_0, this harmonic function ξ is $C^{1,\alpha}$ up to the boundary, because the boundary has this regularity there. This result follows from the Schauder estimates given in [11], namely their Theorem 5.1 in connection with Lemma 2.1. If η is a conjugate harmonic to ξ

(namely $\eta_y = \xi_x$, $\eta_x = -\xi_y$), then $w : z \mapsto (z-p)\exp[\xi(z)+i\eta(z)]$ is a conformal map of U onto a disc. (For more details, see [5, section I.7].) The mapping w inherits the $C^{1,\alpha}$ regularity from ξ. With a conformal mapping μ from the disc onto a half plane, we select an appropriate semidisc B_+ from this half plane and let $\psi := (\mu \circ w)^{-1}|_{B_+}$ with $V_+ := \psi(B_+) \subset U$. ∎

It is worth noting that a C^1 boundary is not sufficient for the bounded derivatives of a Riemann map, as can be seen from the map $w(z) = z \ln z$ and its inverse, which map neighborhoods of 0 in the half planes $\operatorname{Re} z > 0$ or $\operatorname{Re} w > 0$, respectively, onto domains bounded by C^1 curves.

6. First variation, and the role of singular coefficients in optimality. In this section, we study how the principal eigenvalue of the Laplacian with window boundary conditions changes under deformations of the window. The first lemma contains some estimates for distortions by bi-Lipschitz maps.

LEMMA 6.1. *Let $\psi : \overline{\Omega}_1 \to \overline{\Omega}_2$ be a bi-Lipschitz map. Then for any window D in $\overline{\Omega}_2$, it holds that*

$$\lambda(\psi^{-1}(D)) \leq \lambda(D) \sup_{\Omega_1} \rho\Big((D\psi)(D\psi)^T(\det D\psi)^{-1}\Big) \sup_{\Omega_1}(\det D\psi),$$

where ρ denotes the spectral radius. In terms of the distortion ratios

$$a(x) := \limsup_{y\to x} \frac{|\psi(y)-\psi(x)|}{|y-x|}, \quad b(x) := 1/\liminf_{y\to x} \frac{|\psi(y)-\psi(x)|}{|y-x|},$$

we have the simpler (but weaker) estimates

$$\frac{\lambda(\psi^{-1}(D))}{\lambda(D)} \leq \sup(ab^{d-1})\sup(a^{d-1}/b) \leq (\sup a)^{d+1}(\sup b)^{d-1}.$$

Proof. For any two differentiable functions h_1, h_2 on Ω and any diffeomorphism ψ, we have the transformation formulas

$$\int_\Omega h_1(y)\, h_2(y)\, dy = \int_{\psi^{-1}(\Omega)} (h_1\circ\psi)(x)\, (h_2\circ\psi)(x)\, \det D\psi(x)\, dx \tag{6.1}$$

and

$$\int_\Omega \nabla h_1(y)\cdot\nabla h_2(y)\, dy = \int_{\psi^{-1}(\Omega)} \nabla_x(h_1\circ\psi)(x)^T M(x)\nabla_x(h_2\circ\psi)(x)\, dx, \tag{6.2}$$

where the matrix M is given by

$$M(x) = D\psi(x)^{-1}\, D\psi(x)^{-T}\, \det D\psi(x). \tag{6.3}$$

Let u be the nonnegative normalized eigenfunction for window $D \subset \partial\Omega$, and take $u\circ\psi$ as a test function in the CHVP for $\psi^{-1}(D)$. The first claim follows from (6.1)–(6.3) by setting $h_1 = h_2 = u$ and using that the smallest eigenvalue of $M(x)$ is the reciprocal of the spectral radius of $M(x)^{-1}$. The distortion ratio estimates follow for $\psi \in C^1$ from $\rho(D\psi(x)^T D\psi(x)) \leq a(x)^2$ and $a(x)^2/b(x)^{2(d-1)} \leq \det(D\psi(x)^T D\psi(x)) \leq a(x)^{2(d-1)}/b(x)^2$, as calculated in an eigenbasis of this symmetric matrix. Both estimates extend to bi-Lipschitz maps by approximation. ∎

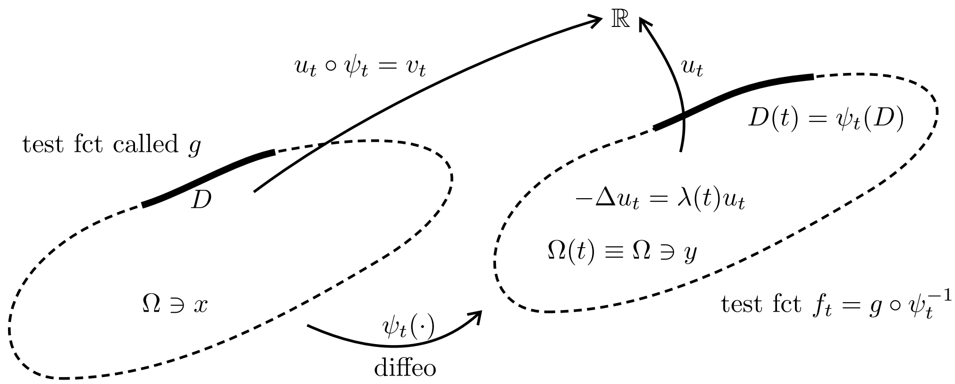

FIG. 6.1. *The mappings in the proof of Theorem* 6.2.

Our main result in this section describes the change of the principal eigenvalue under a diffeomorphism generated by a flow.

THEOREM 6.2. *Let Ω be a Lipschitz domain in $\mathbb{R}^d$, D a window, u its normalized eigenfunction, and X a vector field of regularity $C^1(\overline{\Omega})$ that is "parallel" to the boundary in the sense that Ω is the union of an increasing sequence of smoothly bounded subdomains Ω_δ, with $\delta \searrow 0$, such that X is tangential on $\partial\Omega_\delta$ for δ sufficiently small.*

Let ψ_t be the flow of X. Consider the dependence of the first eigenvalue λ as D changes under the flow. Then it holds that

$$\frac{d}{dt}\lambda(\psi_t(D))\Big|_{t=0} = -2 \lim_{\delta\to 0} \int_{\partial\Omega_\delta} \partial_\nu u \, L_X u, \tag{6.4}$$

where $L_X u$ denotes the directional derivative of u in direction X.

Remark. The assumptions guarantee that X is tangential to the boundary of Ω at smooth boundary points and X may need to vanish in boundary points where the boundary is not C^1.

Proof. Let $\psi_t : x \mapsto \psi_t(x) = y$, and $\Omega \to \Omega$ be the bi-Lipschitz homeomorphism arising from the vector field X, i.e., $\frac{d}{dt}\psi_t(x)|_{t=0} = X(\psi_t(x))$, $\psi_0(x) = x$. Refer to Figure 6.1. Since $X \in C^1$, ψ is a C^1-diffeomorphism in the interior of Ω and satisfies a Lipschitz estimate up to the boundary.

Let $u_t(\cdot)$ and $\lambda(t)$ be the eigenfunctions and eigenvalue for $D(t) := \psi_t(D)$, and let g be a test function on Ω whose trace vanishes on D. The variation of geometry will be expressed as a variation of the operator by referring all windows back to the coordinates x.

We will denote the pullback of the eigenfunction u_t to Ω with window boundary conditions on D as $u_t \circ \psi_t =: v_t$. Similarly $f_t := g \circ \psi_t^{-1}$, the pushforward of the test function g. The weak eigenvalue equation for $u_t(\cdot)$ is

$$\int_{\Omega(t)} \nabla_y u_t(y) \cdot \nabla_y f_t(y)\, dy = \lambda(t) \int_{\Omega(t)} u_t(y) f_t(y)\, dy,$$

where, in our case, $\Omega(t) \equiv \Omega$, g vanishes on D, and f_t vanishes on $D(t)$.

We now use (6.1)–(6.3) with $\psi = \psi_t$, $h_1 = u_t$, $h_2 = f_t$ and expand to first order in t. From $\frac{d}{dt}\psi_t(x) = X(\psi_t(x))$, $\psi_0(x) = x$, we obtain

$$\begin{aligned}
\psi_t(x) &= x + tX(x) + o(t) \\
D\psi_t(x)^j{}_i &= \delta_i^j + t\frac{\partial X^j}{\partial x^i} + o(t) \\
\left(D\psi_t(x)^{-1}\right)^j{}_i &= \delta_i^j - t\frac{\partial X^j}{\partial x^i} + o(t) \\
\det D\psi_t(x) &= 1 + t \operatorname{div} X + o(t).
\end{aligned}$$

The estimates for the remainder terms are uniform in $x \in \Omega$. Inserting the first and last estimate into (6.1) with $\psi = \psi_t$, $h_1 = u_t$, $h_2 = f_t$ yields

$$u_t f_t \, dy = \left(v_t g(1 + t \operatorname{div} X) + o(t)\right) dx,$$

where the $o(t)$ term represents an L^1 function. Similarly, we obtain from (6.2)

$$\begin{aligned}
\nabla_y u_t(y) \cdot \nabla_y f_t(y)\, dy = \Bigg\{ &\nabla_x v_t(x) \cdot \nabla_x g(x) \\
&+ t\left((\operatorname{div} X)\nabla_x v_t \cdot \nabla_x g - \left(\frac{\partial g}{\partial x^i}\frac{\partial v_t}{\partial x^j} + \frac{\partial v_t}{\partial x^i}\frac{\partial g}{\partial x^j}\right)\frac{\partial X^j}{\partial x^i}\right) + o(t)\Bigg\}\, dx,
\end{aligned}$$

where the $o(t)$ term again represents an L^1 function. We have used the Einstein summation convention to express the sum over i and j.

If we truncate the bilinear forms by dropping the $o(t)$ terms, it is immediate that the eigenvalue will only change by $o(t)$. Since the truncated operators depend analytically on the perturbation parameter t, we may use results from Chapter VII of Kato [14] to estimate the eigenvalue up to errors of order $o(t)$. Kato's Theorem VII.4.2 and his discussion in Chapter VII §6, sections 2–5 ascertain, via spectral projections and for any finite set of isolated eigenvalues, that the perturbation theory works as in finite-dimensional spaces. In particular, a simple eigenvalue and its corresponding eigenfunction of the truncated operators depend analytically on t. We may therefore write down expansions $v_t = v_0 + tv_1 + O(t^2)$ of the eigenfunction for the truncated problem, and $\lambda(t) = \lambda_0 + t\lambda_1 + o(t)$ of the eigenvalue (for the truncated as well as for the full problem), and compare like powers of t.

Order t^0 yields

$$\int_\Omega \nabla v_0 \cdot \nabla g \, dx = \lambda_0 \int_\Omega v_0 g \, dx,$$

which is just the weak Euler equation for v_0. Order t^1 yields

$$\begin{aligned}
\lambda_1 \int & v_0 g \, dx + \lambda_0 \int \{v_1 g + (\operatorname{div} X) v_0 g\}\, dx \\
&= \int \left\{ \nabla v_1 \cdot \nabla g + (\operatorname{div} X)\nabla v_0 \cdot \nabla g - \frac{\partial X^j}{\partial x^i}\left(\frac{\partial g}{\partial x^i}\frac{\partial v_0}{\partial x^j} + \frac{\partial v_0}{\partial x^i}\frac{\partial g}{\partial x^j}\right)\right\} dx.
\end{aligned}$$

These equations are valid for integration over any subdomain of Ω. We will integrate over Ω_δ, where Ω_δ runs through an increasing sequence of smoothly bounded domains compactly contained in Ω such that X is tangent to the boundary of Ω_δ. We write

$$\int\!\!\!\!\!\!\bullet := \int_{\Omega_\delta} \quad \text{and} \quad \oint := \int_{\partial\Omega_\delta}$$

for volume and surface integrals, respectively. Using $g = v_0$ as a test function, we obtain in first order

$$\lambda_1 \oint v_0^2 = \oint (\nabla v_1 \cdot \nabla v_0 - \lambda_0 v_0 v_1) + \oint \left\{ (\operatorname{div} X)\big(|\nabla v_0|^2 - \lambda_0 v_0^2\big) - 2\frac{\partial X^j}{\partial x^i}\frac{\partial v_0}{\partial x^i}\frac{\partial v_0}{\partial x^j} \right\}.$$

Since v_1 lies in $W^{1,2}(\Omega)$ and satisfies window boundary conditions for D, it is a valid test function in the Euler–Lagrange equation for v_0, and we conclude that the first integral vanishes as $\delta \to 0$. For the second integral, we use the identity

$$\begin{aligned}\frac{\partial X^j}{\partial x^i}\frac{\partial v_0}{\partial x^i}\frac{\partial v_0}{\partial x^j} &= \frac{\partial}{\partial x^i}\left(\frac{\partial v_0}{\partial x^i} L_X v_0\right) - X^j \frac{\partial}{\partial x^i}\left(\frac{\partial v_0}{\partial x^i}\frac{\partial v_0}{\partial x^j}\right) \\ &= \operatorname{div}(L_X v_0\, \nabla v_0) + \frac{1}{2} L_X(\lambda_0 v_0^2 - |\nabla v_0|^2)\end{aligned}$$

and Gauss' divergence theorem to compute

$$\begin{aligned}\oint &\left\{ (\operatorname{div} X)\big(|\nabla v_0|^2 - \lambda_0 v_0^2\big) - 2\frac{\partial X^j}{\partial x^i}\frac{\partial v_0}{\partial x^i}\frac{\partial v_0}{\partial x^j} \right\} \\ &\qquad = \oint \operatorname{div}\Big(\big(|\nabla v_0|^2 - \lambda_0 v_0^2\big) X\Big) - 2\operatorname{div}(\nabla v_0\, L_X v_0) \\ &\qquad = \oint (|\nabla v_0|^2 - \lambda_0 v_0^2)\, X \cdot \nu - 2\partial_\nu v_0\, L_X v_0.\end{aligned}$$

The first term under the integral vanishes since X is tangential to the boundary of Ω_δ by assumption, and the claim follows as $\delta \to 0$. ◻

We note that, at least formally, the integrand on the right-hand side of (6.4) vanishes on both the Dirichlet and the Neumann parts of the boundary of Ω. The evaluation of the limit of the integral as $\delta \to 0$ is far from trivial in higher dimensions, but reasonably straightforward in two dimensions with nice window geometry. It amounts to the evaluation of certain singular coefficients at interface points between the Neumann and Dirichlet parts of $\partial\Omega$. It has been shown that in polygonal domains, in the neighborhood of a corner, solutions of elliptic boundary problems lie locally in the direct sum of $W^{2,2}$ with a singular space, and in two dimensions, this singular space is one-dimensional. See, eg., Grisvard [12], in particular his Theorem 2.4.3. Indeed, functions in the singular space behave like the explicit harmonic functions $\operatorname{Re}(cz^\alpha)$ with α appropriate for the boundary conditions. In this context, it is understood that an interface point between Dirichlet and Neumann data is a corner even if (in particular if!) the geometric boundary is smooth there. As noted, corners that can be made to disappear by means of the reflection principle (like the geometric corners of a rectangle) do not have a singular space. The singular coefficients (also called stress intensity coefficients) must be calculated (numerically) in practical situations. They depend on global information. For a wider background concerning singular contributions, see [7], [12], [16], [21], [23], and much other work by these authors and references given there.

In particular, the variational equation gives rise to the following corollary.

COROLLARY 6.3. *Consider a segment on the boundary of a rectangle, such that one endpoint of the segment is a corner of the rectangle, whereas the other endpoint is a point that is not a corner. Such a segment is not an optimal window, but can be improved infinitesimally by shifting in the direction that brings the corner point inside the window*

Proof. In self-explanatory notation, we refer to the windows as intervals; let $[a,b]$ be an interval with corner point b and noncorner point a. We will show that (with some positive constants m, M)

$$\lambda([a+\varepsilon,b+\varepsilon]) \le \lambda([a+\varepsilon,b]) + M\varepsilon^2 \qquad \text{and} \qquad \lambda([a+\varepsilon,b]) \le \lambda([a,b]) - m\varepsilon\,.$$

From this the claim is immediate.

The first estimate (local near b) follows from Lemma 5.1, with G a ball of radius 2ε centered at the corner b. The eigenfunction is smooth near b, because reflection in the Neumann boundary removes the singularity: $|u| = O(\varepsilon)$ in G, and the estimate is uniform with respect to small changes at the other end a. The capacity term is bounded as $\varepsilon \to 0$, based on a radial test function $\ln_+(|x-b_1|/\varepsilon)/\ln 2$ as in the proof of Proposition 5.2.

The second estimate (local near a) follows from an evaluation of the singular boundary integral $\int_{\partial\Omega} L_X u \partial_\nu u$. In the particular case of an interface point on a straight line, the local behavior of a solution u is $u = c\sqrt{r}\sin(\varphi/2) + v$ with $v \in W^{2,2}$.

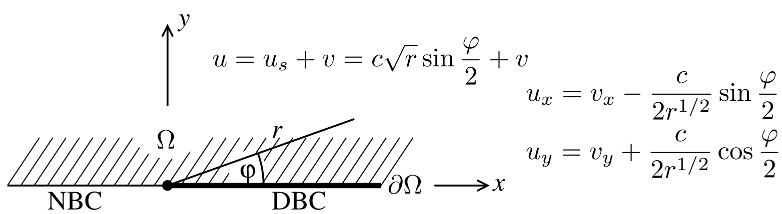

FIG. 6.2. *Coordinates near an interface point.*

To evaluate the singular boundary integral in terms of the singular coefficient, define coordinates as in Figure 6.2, with the boundary point a located at $(0,0)$. Let us assume that the C^1 vector field X is given by $f(x,y)\partial_x$ with the coefficient at the interface $f(0,0) = 1$. It can easily be seen that the regular function v does not contribute to the integral, nor do the mixed terms. We have

$$-2\int_{-t}^{t} L_X u\,\partial_\nu u\,dx = 2\int_{-t}^{t} \frac{\partial u_s}{\partial x}\,\frac{\partial u_s}{\partial y}\,dx = -\frac{c^2}{4}\int_{-t}^{t} \frac{y}{x^2+y^2}\,dx = -\frac{c^2}{2}\arctan\frac{t}{y},$$

and this converges to $-\frac{c^2\pi}{4}$ as $y \to 0+$.

Finally, we estimate the singular coefficient. Choose r so small that $B_r(0)$ intersects $\partial\Omega$ in a straight line as in Figure 6.2, with one radius (N_r) being Neumann boundary and one radius (D_r) Dirichlet boundary; let $S_r := (\partial B_r(0)) \cap \Omega$, and count φ from the Dirichlet to the Neumann boundary. Let

$$-\Delta h = 0 \text{ in } B_r(0)\cap\Omega, \quad \partial_\nu h = 0 \text{ on } N_r,\ h = 0 \text{ on } D_r,\ h = u \text{ on } S_r,$$
$$-\Delta v = \lambda u \text{ in } B_r(0)\cap\Omega, \quad \partial_\nu v = 0 \text{ on } N_r,\ v = 0 \text{ on } D_r,\ v = 0 \text{ on } S_r.$$

Then $u = v + h$ with $v \ge 0$. Evaluation on the boundary implies that the singular coefficient of u is at least as large as the singular coefficient of h. Explicit calculation of the singular coefficient of h by means of Fourier analysis gives exactly

$$c \ge \frac{2}{\pi r^{1/2}}\int_0^\pi u(re^{i\varphi})\,\sin\frac{\varphi}{2}\,d\varphi > 0. \qquad \square$$

The above estimate of the singular coefficient is closely related to formula (2.3) in Dauge, Lubuma, and Nicaise [7], which actually gives the exact coefficient (in terms of u). However, their formula is not designed to show nonvanishing (which relies on using the maximum principle), but is instead built on Fredholm properties. (The distinction that their formula is for a Dirichlet–Dirichlet corner, not a Dirichlet–Neumann corner, is a minor issue.)

Our argument shows that shortening a window infinitesimally at the interface decreases the eigenvalue by an amount proportional to the square of the singular coefficient at the end of the window. Moving a window amounts to shortening it at one end and lengthening it at the other end. To decrease the eigenvalue, the window should be moved in the direction of the smaller singular coefficient (i.e., towards the corner of the square if it is already close to a corner). If the window consists of several intervals, nonlocal changes that lengthen one component at the expense of the other can also be studied in terms of the singular coefficients. Conversely, singular coefficients can be determined graphically from the slopes in Figure 2.1, for the geometric configurations depicted there.

As an immediate consequence of the role of singular coefficients, a window consisting of any number of equidistant and congruent arcs on the boundary of a circle is a critical point for the first eigenvalue. Since these arcs can now be moved independently, these are critical points of arbitrarily large index. The optimal window in a circle is known to be a single arc [9].

Limitations of our result should also be observed. The variations induced by the flow of vector fields correspond to the "weak," C^1-small variations (as opposed to "strong," C^0-small variations) that are exploited in the Euler–Lagrange equations of the classical calculus of variations. It is doubtful how significant a role such variations can play if it comes to show, say, that a certain open-dense set of small measure is *not* an optimal window.

We have not established an analogue of the fundamental lemma of the calculus of variations that would permit elimination of the vector field X. In the absence of a priori regularity for optimal windows, such an attempt seems extremely difficult. There is, however, some hope to get nontrivial boundary regularity for the optimal eigenfunction by selecting vector fields constructed from the eigenfunction in some appropriate way. We plan a further investigation of this issue.

In spite of these limitations, Theorem 6.2 does give some insight into the question of optimal windows, and in particular into the variation of windows with a given a priori regularity.

Acknowledgments. The second author would like to thank Steve Cox for a quick introduction to the MATLAB pdetool that boosted the experimental work, V.G. Maz'ya for an inspiring chat in Darmstadt, and U. Mertins for sharing some of his numerics on the problem, each several years ago.

ON THE DIFFERENTIAL EQUATION $u_{xxxx} + u_{yyyy} = f$ FOR AN ANISOTROPIC STIFF MATERIAL*

B. KAWOHL† AND G. SWEERS‡

Abstract. We study the differential operator $L = \frac{\partial^4}{\partial x^4} + \frac{\partial^4}{\partial y^4}$ and investigate positivity preserving properties in the sense that $f \geq 0$ implies that solutions u of $Lu - \lambda u = f$ are nonnegative. Since the operator is of fourth order we have no maximum principle at our disposal. The operator models the deformation of an anisotropic stiff material like a wire fabric, and it has to be complemented by appropriate boundary conditions. Our operator was introduced by Jacob II Bernoulli as the operator that supposedly models the vibrations of an elastic plate. This model was later revised by Kirchhoff, because the operator and its solutions were anisotropic. Modern materials, however, are often anisotropic, and therefore the old model of Bernoulli deserves an updated investigation. It turns out that even our apparently simple model problem contains some hard analytical challenges.

Key words. orthotropic plate, anisotropic operator, vibrations, spectrum, fourth order elliptic, clamped and hinged boundary condition, positivity of the operator, Green's function, Kirchhoff plate

1. Introduction.

Small vertical deformations u of an elastic membrane are usually described by a second order differential equation $-\Delta u = f$ with f denoting the load, whereas the deformation of a plate is commonly modeled by a fourth order equation $\Delta^2 u = f$. Suppose that the membrane is replaced by a piece of material or cloth that is woven out of elastic strings. Then the material properties change drastically, and in [4] such a problem was studied for second order differential operators. If a plate is replaced by a stiff woven material [17] (running in Cartesian directions), its deformation energy can be described by

$$\int_\Omega \left(u_{xx}^2 + u_{yy}^2\right)\ dx\,dy \tag{1}$$

rather than by the functional for the elastic plate [40]

$$\int_\Omega \left((\Delta u)^2 - (1-\sigma)\left(u_{xx}u_{yy} - u_{xy}^2\right)\right) dx\,dy. \tag{2}$$

For the energy that corresponds to the reinforcement or wire fabric that is embedded in, for example, concrete, a linear combination of (1) and (2) is appropriate.

In contrast to the plate equation, that is, the Euler equation for (2) which contains the operator $\Delta^2 u = u_{xxxx} + 2u_{xxyy} + u_{yyyy}$, the linearized differential equation for a stiff fabric consisting of perpendicular fibers does not contain mixed terms when these fibers run parallel to the x- and y-axes. Indeed, if the torsional stiffness can

be neglected, the energy stored in the grid under a vertical load f is supposed to be given by

$$E(u) = \int_\Omega \left\{ \frac{1}{2} \left(u_{xx}^2 + u_{yy}^2 \right) - fu \right\} dx\, dy.$$

The corresponding Euler equation is $u_{xxxx} + u_{yyyy} = f$. This equation has to be complemented by suitable boundary conditions, and in the present paper we shall study the problem on a planar domain Ω:

- as a general grid that is hinged at the boundary

$$\begin{cases} u_{xxxx} + u_{yyyy} = f & \text{in } \Omega, \\ u = n_1^2\, u_{xx} + n_2^2\, u_{yy} = 0 & \text{on } \partial\Omega, \end{cases} \tag{3}$$

  where $n = n(x,y)$ is the exterior normal at $(x,y) \in \partial\Omega$;
- or as a general grid that is *clamped* at the boundary

$$\begin{cases} u_{xxxx} + u_{yyyy} = f & \text{in } \Omega, \\ u = \frac{\partial}{\partial n} u = 0 & \text{on } \partial\Omega. \end{cases} \tag{4}$$

When we checked the literature for this type of equation, we found a remarkable hint in the chapter on the history of plate theory in Szabó's book [37, p. 409]. Jacob II Bernoulli, inspired by Chladni's experiments on vibrating plates, had attempted to model their behavior by our differential equation in [5], but this was later dismissed for isotropic plates and replaced by Kirchhoff's theory [24]. However, there is more to it. According to [30], Bernoulli had also studied and absorbed Euler's idea that an elastic membrane should be modeled as a fabric of one-dimensional orthogonal elastic strings, and he tried to carry this idea over to modeling a plate as a fabric of one-dimensional beams. Thus he arrived at

$$\frac{\partial^4 z}{\partial x^4} + \frac{\partial^4 z}{\partial y^4} = \frac{z}{c^4}$$

as *"the fundamental equation of the entire theory"* of plate vibrations. In those days church bells were intended as applications for the theory. Both operators, the isotropic plate operator Δ^2 and the anisotropic

$$L = \frac{\partial^4}{\partial x^4} + \frac{\partial^4}{\partial y^4}, \tag{5}$$

retain a certain degree of isotropy. They are special cases of

$$\tilde{L} = \frac{\partial^4}{\partial x^4} + P \frac{\partial^4}{\partial x^2 \partial y^2} + Q \frac{\partial^4}{\partial y^4} \tag{6}$$

with $P \geq 0$ and $Q > 0$ denoting material constants. Notice that $\tilde{L}$ is always invariant under reflections across Cartesian axes, but not always under rotations. Plates whose deformation is described by such operators are called *orthotropic*; see, e.g., [29], [31]. By scaling y and not scaling x one can always force Q to be 1. Realistic values for P and Q in the case of plywood material (birch with bakelite glue) can be found in [25, p. 92], [26, p. 269], or [31]. It is not unrealistic to expect Q to be of order 1–10 and $P \in [0, 1)$. Modern (composite) materials like GLARE (see http://www.lr.tudelft.nl/highlights/glare.asp), a composite of layers of fiberglass and aluminum that is also called "plymetal," can be expected to satisfy similar orthotropic equations. Orthotropic plate equations like $\tilde{L}u = f$ have been rigorously derived by homogenization methods as the right macroscopic model for grid structures as the thickness of the structure and the size of its cells go to zero. To be precise, in [3, p. 130] and using our notation, the limit equation has coefficients $Q = 1$ and $P = 4/(1+\nu)$, where ν denotes the Poisson ratio of the original (solid and unhomogenized) plate material. For $\nu = -1/3$ one gets $P = 6$, as in (19) below. We take the differential equation for granted here and do not address issues of homogenization as in [3].

Section 2 is devoted to proving existence and uniqueness questions, and section 3 to regularity of solutions to these boundary value problems. Regularity near corners of Ω is delicate, and its discussion will be limited to some special cases. Moreover, we address the subject of representations of solutions by series or by means of a Green function at the end of section 3.

In section 4 we study the spectrum of the operator L on rectangular domains and for hinged and clamped boundary conditions. Since the operator is separable, on special domains like rectangles all of its eigenfunctions can be represented in terms of products of one-dimensional eigenfunctions. We learned this from Courant and Hilbert (see [10, Chapter II, Par. 1.6]), who did it for operators of second order. Therefore the one-dimensional cases will always be treated before the rectangular domains. We present all eigenvalues and eigenfunctions for a number of examples and compare spectra for different (parallel or diagonal) alignments of our anisotropic grid.

Section 5 is dedicated to positivity questions. Suppose that the load f on a beam (or grid) is pointing downwards. Does this imply that the deformation u has the same sign everywhere in Ω? The answer is in general negative, unless the geometry of the domain is special or unless the beam (or grid) is embedded in an elastic ambient medium that exerts a restoring force proportional to the deformation. So the modified question is for which (presumably negative) values of λ one can show that $f \geq 0$ implies positivity of the solution to

$$u_{xxxx} + u_{yyyy} = \lambda u + f \qquad \text{in } \Omega,$$

which satisfies the boundary conditions under consideration. This question turns out to be technically most challenging, and its answer is given using different tricks for different alignments or boundary conditions.

For the reader's convenience we finish with a summary in section 6 and an appendix.

2. Existence and uniqueness for hinged and clamped grids. Let $\Omega \subset \mathbb{R}^n$ be a bounded simply connected set. Then the variational problem

$$\text{(7)} \qquad \text{Minimize:} \quad E(v) = \int_\Omega \left(\frac{1}{2} \sum_{i=1}^{n} v_{x_i x_i}^2 - f\, v \right) dx \quad \text{on } W_0^{1,2}(\Omega) \cap W^{2,2}(\Omega)$$

has a unique solution. To see this directly we follow the ideas of [16] and first show that $E(v)$ is coercive on $W^{2,2}(\Omega)$. Obviously $2u_{xx}u_{yy} \leq u_{xx}^2 + u_{yy}^2$, so that

$$E(v) \geq c(n) \int_\Omega (\Delta v)^2 \, dx - \int_\Omega f\, v \, dx.$$

If we denote Δv by g, then a well-known a priori estimate for solutions of Dirichlet problems for second order elliptic differential equations on bounded domains (see, e.g., [14, p. 317]) implies that

$$||D^2 v||_{L^2(\Omega)} \leq C||\Delta v||_{L^2(\Omega)},$$

so that all second derivatives of v are in $L^2(\Omega)$. This and a Poincaré-type inequality show the coerciveness of E on $W_0^{1,2}(\Omega) \cap W^{2,2}(\Omega)$. Now the existence and uniqueness of a solution follow from the direct method in the calculus of variations and from the strict convexity of the functional E. The solution satisfies the Euler equation $\sum_{i=1}^n u_{x_i x_i x_i x_i} = f$ in Ω. To derive the boundary conditions, we note that a weak solution satisfies

$$\int_\Omega \left(\sum_{i=1}^n u_{x_i x_i} \varphi_{x_i x_i} - f\,\varphi \right) dx = 0, \tag{8}$$

and after two integrations by parts we obtain

$$0 = \int_\Omega \left(-\sum_{i=1}^n u_{x_i x_i x_i} \varphi_{x_i} - f\,\varphi \right) dx + \int_{\partial\Omega} \sum_{i=1}^n u_{x_i x_i} \varphi_{x_i} \nu_i \; d\sigma \tag{9}$$

$$= 0 + \int_{\partial\Omega} \sum_{i=1}^n u_{x_i x_i} \varphi_{x_i} \nu_i \; d\sigma - \int_{\partial\Omega} \sum_{i=1}^n u_{x_i x_i x_i} \; \varphi \; \nu_i \; d\sigma \tag{10}$$

$$= \int_{\partial\Omega} \left(\sum_{i=1}^n u_{x_i x_i} \nu_i^2 \right) \frac{\partial \varphi}{\partial \nu} \; d\sigma. \tag{11}$$

Notice that the last integral in (10) vanishes because φ vanishes on the boundary. Therefore the first boundary integral in (10) must vanish too. The vanishing of φ on $\partial\Omega$ implies in particular that the bracket in (11) must vanish on $\partial\Omega$. Thus we have formally derived (3) in the plane case. See also [32].

If the grid or stiff fabric is clamped, we consider the variational problem

$$\text{Minimize:} \quad E(v) = \int_\Omega \left(\frac{1}{2} \sum_{i=1}^n v_{x_i x_i}^2 - f\,v \right) dx \quad \text{on } W_0^{2,2}(\Omega) \tag{12}$$

and observe that the same existence proof works for this problem, too. The solution satisfies

$$\begin{cases} \sum_{i=1}^n u_{x_i x_i x_i x_i} = f & \text{in } \Omega, \\ \qquad u = \frac{\partial u}{\partial \nu} = 0 & \text{on } \partial\Omega. \end{cases} \tag{13}$$

We have the following existence and uniqueness results.

THEOREM 2.1. *Let $\Omega \subset \mathbb{R}^n$ be a bounded domain with piecewise smooth boundary, and suppose that $f \in L^2(\Omega)$. Then problems* (7) *and* (12) *have a unique minimizer. Moreover, the corresponding boundary value problems, which in the case $n = 2$ are given by* (3) *and* (4), *have a unique weak solution.*

Remark 2.1. As usual, a weak solution for (3) is a function u in $W_0^{2,2}(\Omega)$ that satisfies (8) for all $\varphi \in W_0^{2,2}(\Omega)$. A weak solution of (4) is a function u in $W^{2,2}(\Omega) \cap W_0^{1,2}(\Omega)$, satisfying (8) for all $\varphi \in W^{2,2}(\Omega) \cap W_0^{1,2}(\Omega)$.

The existence was shown above by variational methods, and the uniqueness of the weak solution follows from the strict convexity of the underlying functional E. Notice that the second order boundary condition holds only in the sense of distributions. To see that it holds pointwise in every smooth point of the boundary, we need to know more about its regularity.

3. Regularity. One may use the standard regularity theory for elliptic operators whenever the elliptic system is of an appropriate type and if the boundary is sufficiently smooth. First we will show that our systems are regular elliptic.

3.1. Regular elliptic. The symbol, that is $L = \mathcal{L}(\frac{\partial}{\partial x}, \frac{\partial}{\partial y})$, of our fourth order operator can be decomposed as follows:

$$\mathcal{L}(\xi_1, \xi_2) := \xi_1^4 + \xi_2^4 = \left(\xi_1^2 + \sqrt{2}\xi_1\xi_2 + \xi_2^2\right)\left(\xi_1^2 - \sqrt{2}\xi_1\xi_2 + \xi_2^2\right). \tag{14}$$

Hence L can be written as the composition of two second order elliptic operators. Notice, however, that the boundary value problem (4) cannot be split into a system of two second order equations with separated boundary conditions. In fact, even for the boundary value problem (3) this seems to be out of reach. The boundary operators have the following symbols:

- for (3): $\mathcal{B}_1(\xi) = 1$ and $\mathcal{B}_2(\xi) = n_1(x)^2\xi_1^2 + n_2(x)^2\xi_2^2$;
- for (4): $\mathcal{B}_1(\xi) = 1$ and $\mathcal{B}_2(\xi) = n_1(x)\xi_1 + n_2(x)\xi_2$.

A necessary condition for obtaining the full classical regularity results is that the corresponding boundary value problem should be regular elliptic in the sense of [27], and this is indeed the case.

LEMMA 3.1. *Problems* (3) *and* (4) *are regular elliptic.*

Proof. The differential operator is regular elliptic of order $2k$ if there is $c > 0$ such that $\mathcal{L}(\xi) \geq c\,|\xi|^{2k}$ for $\xi \in \mathbb{R}^2$. To show that the operator and boundary conditions constitute a regular elliptic problem in the sense of [27], one has to consider the factorization of $\tau \mapsto \mathcal{L}(\xi + \tau\eta)$. One finds that the roots of this polynomial are

$$\tau_k = -\frac{\xi_1 + (-1)^{\frac{2k-1}{4}}\,\xi_2}{\eta_1 + (-1)^{\frac{2k-1}{4}}\,\eta_2} \qquad \text{with } k \in \{1, 2, 3, 4\}.$$

We use $(-1)^\alpha = \cos\pi\alpha + \boldsymbol{i}\sin\pi\alpha$. Depending on ξ and η, which should be taken independently, there are two roots, τ_I and τ_{II}, which have positive imaginary part. We find $\mathcal{L}(\xi + \tau\eta) = a^+(\xi, \eta; \tau)a^-(\xi, \eta; \tau)$ with

$$a^+(\xi, \eta; \tau) = \sqrt{\eta_1^4 + \eta_2^4}\,(\tau - \tau_I)\,(\tau - \tau_{II}),$$
$$a^-(\xi, \eta; \tau) = \sqrt{\eta_1^4 + \eta_2^4}\,(\tau - \bar{\tau}_I)\,(\tau - \bar{\tau}_{II}).$$

Since the imaginary parts of τ_I and τ_{II} have the same sign the first order term in $a^+(\xi, \eta; \tau)$ has a coefficient with a strictly negative imaginary part; indeed,

$$(\tau - \tau_I)\,(\tau - \tau_{II}) = \tau^2 - (\tau_I + \tau_{II})\,\tau - \tau_I\tau_{II}.$$

The condition for regularity that has to be verified is that, for ξ a tangential direction and η a normal direction, the polynomials $\tau \mapsto \mathcal{B}_1(\xi + \tau\eta)$ and $\tau \mapsto \mathcal{B}_2(\xi + \tau\eta)$ are independent modulo $\tau \mapsto a^+(\xi, \eta; \tau)$. Therefore we set $\eta = (n_1, n_2)$ and $\xi = (-n_2, n_1)$.

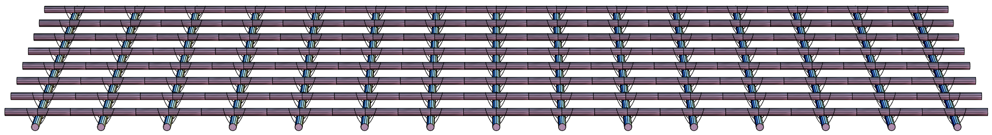

FIG. 1. *A rectangular wire fabric with fibers in Cartesian directions.*

For (3), $\mathcal{B}_1(\xi + \tau\eta) = 1$ and

$$\begin{aligned}\mathcal{B}_2(\xi + \tau\eta) &= n_1^2(-n_2 + n_1\tau)^2 + n_2^2(n_1 + n_2\tau)^2 \\ &= 2n_1^2n_2^2 + (n_2^2 - n_1^2)n_1n_2\tau + \left(n_1^4 + n_2^4\right)\tau^2.\end{aligned}$$

This is a polynomial with only real coefficients. Since $a^+(\xi, \eta; \tau)$ contains a real second order term and an imaginary first order term, both polynomials are linearly independent.

For (4), $\mathcal{B}_1(\xi + \tau\eta) = 1$ and $\mathcal{B}_2(\xi + \tau\eta) = 1 + \tau$. These are clearly independent modulo any second order polynomial. $\square$

3.2. Regularity for smooth domains. Near the smooth boundary part the standard regularity results, e.g., from [27, Ch. 2], may be used, since both the clamped and the hinged problems are regular elliptic. Only the corners need more attention. But to fix the facts let us summarize the regularity results in a theorem.

THEOREM 3.2. *Let $\Omega \subset \mathbb{R}^2$ be a bounded domain with piecewise smooth boundary, and let $\Omega' \subset \Omega$ be a subset such that $\overline{\Omega'}$ contains only the smooth boundary points of $\partial\Omega$. If $f \in W^{k,2}(\Omega)$ and $k \in \{0, 1, 2, \dots\}$, then the weak solutions of* (3) *and* (4) *are of class $W^{k+4}(\Omega')$. In particular, for $f \in L^2(\Omega)$ the derivatives $u_{x_ix_i}$ are in $W^{3/2,2}(\partial\Omega \cap \partial\Omega')$, so that the boundary condition in* (3) *holds pointwise a.e. on $\partial\Omega$.*

3.3. Regularity near corners. It remains to discuss the regularity near singular points of the boundary, and this will be done for some special but typical situations. First we will give an explanation for a simple case.

3.3.1. The hinged rectangular grid with aligned fibers. Let $R = (0, a) \times (0, b)$ be the rectangle. It will be relatively easy to study the regularity of the *hinged grid* near a corner, say $(0, 0)$, when the grid is *aligned with the rectangle* as in Figure 1.

Reflection. The first approach is through a reflection argument. As an example we will consider the hinged rectangular grid with horizontally and vertically aligned fibers.

Note that the differential operator and boundary conditions all satisfy

$$\mathcal{L}\left(\pm\frac{\partial}{\partial x}, \frac{\partial}{\partial y}\right) = \mathcal{L}\left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}\right) \quad \text{and} \quad \mathcal{B}\left(\pm\frac{\partial}{\partial x}, \frac{\partial}{\partial y}\right) = \mathcal{B}\left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}\right).$$

Instead of considering

$$\left\{\begin{aligned} u_{xxxx} + u_{yyyy} &= f && \text{in } R, \\ u = u_{xx} &= 0 && \text{on } \{0, a\} \times [0, b], \\ u = u_{yy} &= 0 && \text{on } [0, a] \times \{0, b\}, \end{aligned}\right. \tag{15}$$

we extend f to $\tilde{f}$ on $(-a, a) \times (0, b)$ by

$$\tilde{f}(x, y) = \operatorname{sign}(x)\ f(|x|, y)$$

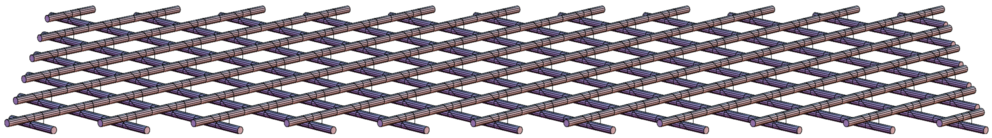

Fig. 2. *Rectangular grid with diagonal fabric.*

and consider

$$(16)\qquad \begin{cases} \tilde{u}_{xxxx} + \tilde{u}_{yyyy} = \tilde{f} & \text{in } \tilde{R} = (-a,a)\times(0,b)\,, \\ \tilde{u} = \tilde{u}_{xx} = 0 & \text{on } \{-a,a\}\times[0,b]\,, \\ \tilde{u} = \tilde{u}_{yy} = 0 & \text{on } [-a,a]\times\{0,b\}\,. \end{cases}$$

If $f \in L^p(R)$, then $\tilde{f} \in L^p(\tilde{R})$, and by the result above there is unique solution $\tilde{u} \in W^{2,p}(\tilde{R})$ and $\tilde{u} \in W^{4,p}(\tilde{R}\backslash N)$ with N some neighborhood of the four corners of $\tilde{R}$; $(0,0)$ has become a regular boundary point. Since the solution $\tilde{u}$ is unique one finds that $\tilde{u}(x,y) = -\tilde{u}(-x,y)$ and hence $\tilde{u}(0,y) = \tilde{u}_{xx}(0,y) = 0$. In other words, $u := \tilde{u}_{|R}$ is the solution of (15) which is in $W^{4,p}(R \cap B_\varepsilon(0))$. Since we may do so for every corner of R we find that $u \in W^{4,p}(R)$.

Separation of eigenfunctions. A second approach can be used if there is a complete orthonormal system of eigenfunctions of the form $\{\varphi_i(x)\psi_j(y); i,j \in \mathbb{N}\}$. For example, for the problem (15) the set $\{\Phi_{ij}; i,j \in \mathbb{N}^+\}$ with

$$\Phi_{i,j}(x,y) = \frac{2}{\sqrt{ab}} \sin\left(i\frac{\pi}{a}x\right) \sin\left(j\frac{\pi}{b}y\right)$$

is a complete orthonormal set of eigenfunctions. Writing $f_{ij} = \langle \Phi_{i,j}, f\rangle$, the solution u is given by

$$u(x,y) = \sum_{i,j=1}^{\infty} \frac{f_{ij}}{\left(i\frac{\pi}{a}\right)^4 + \left(j\frac{\pi}{b}\right)^4} \Phi_{i,j}.$$

Using Parseval's identity, a straightforward computation shows that

$$\left\| \left(\frac{\partial}{\partial x}\right)^k \left(\frac{\partial}{\partial y}\right)^\ell u \right\|^2_{L^2(R)} = \sum_{i,j=1}^{\infty} \frac{\left(i\frac{\pi}{a}\right)^{2k} \left(j\frac{\pi}{b}\right)^{2\ell}}{\left(\left(i\frac{\pi}{a}\right)^4 + \left(j\frac{\pi}{b}\right)^4\right)^2} (f_{ij})^2\,,$$

which is bounded if $f \in L^2(R)$ and $k,l \in \mathbb{N}$ with $k+l \le 4$. Thus $u \in W^{4,2}(R)$.

3.3.2. The hinged rectangular grid with diagonal fibers. Now suppose that the grid runs *diagonally* into the horizontal and vertical axes, as in Figure 2, and that $\hat{x} := \frac{1}{2}\sqrt{2}\,(x+y)$ and $\hat{y} = \frac{1}{2}\sqrt{2}\,(y-x)$. Then a straightforward calculation shows that

$$(17)\qquad u_{xxxx} + u_{yyyy} = \frac{1}{2} u_{\hat{x}\hat{x}\hat{x}\hat{x}} + \frac{6}{2} u_{\hat{x}\hat{x}\hat{y}\hat{y}} + t\frac{1}{2} u_{\hat{y}\hat{y}\hat{y}\hat{y}} = f$$

while the boundary condition from (10) becomes

$$(18)\qquad u_{xx} + u_{yy} = \Delta u = 0 = u_{\hat{x}\hat{x}} + u_{\hat{y}\hat{y}}$$

because $(\nu_1)^2 = (\nu_2)^2 = 1/2$ on the sides of the rectangle and because the Laplacian is invariant under rotations. Since also $u = 0$ on the boundary, this implies $u_{\hat{x}\hat{x}} = 0 = u_{\hat{y}\hat{y}}$. Therefore after an obvious change of notation the deformation u of the *hinged diagonal* grid satisfies again a regular elliptic boundary value problem, namely,

$$\left\{ \begin{aligned} u_{xxxx} + 6u_{xxyy} + u_{yyyy} &= 2f && \text{in } R = (0,a) \times (0,b)\,, \\ u = u_{xx} &= 0 && \text{on } \{0,a\} \times [0,b]\,, \\ u = u_{yy} &= 0 && \text{on } [0,a] \times \{0,b\}\,. \end{aligned} \right. \tag{19}$$

Also for this boundary value problem we find that $\mathcal{L}(\pm\frac{\partial}{\partial x}, \frac{\partial}{\partial y}) = \mathcal{L}(\frac{\partial}{\partial x}, \frac{\partial}{\partial y})$ and $\mathcal{B}(\pm\frac{\partial}{\partial x}, \frac{\partial}{\partial y}) = \mathcal{B}(\frac{\partial}{\partial x}, \frac{\partial}{\partial y})$, and hence we may use the odd reflection argument of (16) to find $u \in W^{4,2}(R)$ that satisfies the boundary conditions for $x = 0$.

Incidentally, the transformed elliptic operator has a symbol that can again be factorized as

$$2\hat{\mathcal{L}}(\xi_1, \xi_2) := \xi_1^4 + 6\xi_1^2\xi_2^2 + \xi_2^4 = \left(\xi_1^2 + \left(3 - 2\sqrt{2}\right)\xi_2^2\right)\left(\xi_1^2 + \left(3 + 2\sqrt{2}\right)\xi_2^2\right). \tag{20}$$

The fact that (19) constitutes a regular elliptic boundary value problem does not need to be checked again, since this property is invariant under changes of the coordinate system. Moreover, the boundary conditions fit nicely with this factorization, and we find a system of two well-posed second order problems:

$$\left\{ \begin{aligned} u_{xx} + \left(3 - 2\sqrt{2}\right) u_{yy} &= v && \text{in } R, \\ u &= 0 && \text{on } \partial R, \\ v_{xx} + \left(3 + 2\sqrt{2}\right) v_{yy} &= 2f && \text{in } R, \\ v &= 0 && \text{on } \partial R. \end{aligned} \right. \tag{21}$$

Using the result of Kadlec [22] for second order operators on convex domains, one finds that $f \in L^2(R)$ implies $v \in W^{2,2}(R) \cap W_0^{1,2}(R)$. Since v satisfies the boundary conditions of u (!), we find not only that $u \in W^{2,2}(R) \cap W_0^{1,2}(R)$ but even that $u \in W^{4,2}(R) \cap W_0^{1,2}(R)$.

We remark that some boundary value problems with different boundary conditions along each side can be treated by a reflection argument. In fact, the same reflection argument works for the aligned rectangular grid if it is clamped on the horizontal parts of the boundary and hinged on the vertical part. To be specific, for $f \in L^2(\Omega)$ the unique solution u of

$$\left\{ \begin{aligned} u_{xxxx} + u_{yyyy} &= f && \text{in } R, \\ u = u_{xx} &= 0 && \text{on } \{0,a\} \times [0,b]\,, \\ u = u_y &= 0 && \text{on } [0,a] \times \{0,b\} \end{aligned} \right. \tag{22}$$

is in $W^{4,2}(R)$.

3.3.3. The clamped rectangular grid with aligned fibers. The regularity of the *clamped* grid near a corner does not follow from such a simple reflection argument, because u_{xx} does in general not vanish on $(0, y)$ with $y \in (0, b)$. However, provided the grid is *aligned* with the rectangle as in Figure 1, we may proceed by "separation of eigenfunctions." To complete this argument we need to borrow some results of subsection 4.2.3 and more specifically Lemmas 4.3 and 4.4.

The set $\{\Phi_{ij}\}$ of eigenfunctions in (34) is a complete orthonormal system in $L^2(\Omega)$. Then, as above for the hinged rectangular grid, the solution of (4) can be represented by

$$u(x,y) = \sum_{i,j=1}^{\infty} \frac{\alpha_{ij}}{\Gamma_{ij}} \Phi_{ij}(x,y),$$

where α_{ij} are the Fourier coefficients from the representation of f with $\sum_{i,j} \alpha_{ij}^2$ being finite by Parseval's identity. The eigenvalues Γ_{ij} are defined by $\Gamma_{ij} = a^{-4}\lambda_i + b^{-4}\lambda_j$, and we find that

$$\frac{\partial^{n+m}}{\partial x^n \partial y^m} u(x,y) = \sum_{i,j=1}^{\infty} \frac{a^{-n}\lambda_i^{n/4} b^{-m}\lambda_j^{m/4}}{a^{-4}\lambda_i + b^{-4}\lambda_j} \alpha_{ij}\Phi_{ij}(x,y),$$

which is bounded when $n+m \le 4$. This shows that $u \in W^{4,2}(R)$ even in this case of a *clamped rectangular grid* aligned with R. From Theorem 2.1 we were allowed to conclude only that $u \in W^{2,2}(R)$.

3.3.4. The clamped rectangular grid with diagonal fibers. How to obtain the regularity of u for a *clamped–hinged* or *clamped–clamped* diagonal grid near a corner is a nontrivial problem and will not be discussed here.

One conceivable way to represent a solution would be using a Green function $g^{0,\xi}(\cdot) = F(\cdot - \xi) + h(\xi, \cdot)$. This can in principle be obtained by adding a solution h of $Lh(\xi,\cdot) = 0$ in R, $h(\xi,\cdot) + F(\cdot - \xi) = 0 = B_2 h(\xi,\cdot) + B_2 F(\cdot - \xi)$ on ∂R to a fundamental solution $F(\cdot - \xi)$, i.e., to a distributional solution of $LF(\cdot - \xi) = \delta_0(\cdot)$. Clearly F is not unique, but just for the record let us quote a fundamental solution F (for L as in (22)) from [39] or [29]:

(23)
$$F(x,y) = -\frac{1}{16\pi\sqrt{2}} \left[(x^2+y^2)\log(x^4+y^4) + 2\sqrt{2}xy \log\left(\frac{x^2+y^2+\sqrt{2}xy}{x^2+y^2-\sqrt{2}xy}\right) + 2\sqrt{2}\left(x^2 \arctan\frac{x^2}{y^2} + y^2 \arctan\frac{y^2}{x^2}\right)\right].$$

An explicit calculation of the Green function even on a quarter plane seems to be beyond reach.

4. Eigenfunctions and eigenvalues.

4.1. Eigenfunctions for a hinged rectangular grid. The eigenfunctions for the *hinged beam*

$$\begin{cases} \varphi_{xxxx} = \lambda\varphi & \text{in } (0,1), \\ \varphi = \varphi_{xx} = 0 & \text{in } \{0,1\} \end{cases} \tag{24}$$

are obviously given by $\phi_i(x) = \sqrt{2}\sin(i\pi x)$, and the eigenvalues are $\lambda_i = i^4\pi^4$.

If a *hinged grid* is rectangular and *aligned with the Cartesian coordinates*, then a calculation shows that the eigenfunctions and eigenvalues of

$$\begin{cases} \Phi_{xxxx} + \Phi_{yyyy} = \Lambda\Phi & \text{in } R, \\ \Phi = \Phi_{xx} = 0 & \text{on } \{0,a\} \times [0,b], \\ \Phi = \Phi_{yy} = 0 & \text{on } [0,a] \times \{0,b\} \end{cases} \tag{25}$$

are given by

$$\Phi_{ij}(x,y) = \frac{2}{\sqrt{ab}} \sin\left(\frac{i\pi x}{a}\right) \sin\left(\frac{j\pi y}{b}\right) \quad \text{and} \quad \Lambda_{ij} = \frac{i^4\pi^4}{a^4} + \frac{j^4\pi^4}{b^4}\ . \tag{26}$$

For $i = j = 1$ one finds the following result.

LEMMA 4.1. *The first eigenfunction for* (25)*, the hinged rectangular grid with aligned fibers, is of fixed sign.*

Even if the *hinged grid* is *diagonally aligned*, we can determine the eigenfunctions and eigenvalues of

$$\begin{cases} \frac{1}{2}\Phi_{xxxx} + 3\Phi_{xxyy} + \frac{1}{2}\Phi_{yyyy} = \tilde{\Lambda}\Phi & \text{in } R, \\ \Phi = \Phi_{xx} = 0 & \text{on } \{0,a\} \times [0,b], \\ \Phi = \Phi_{yy} = 0 & \text{on } [0,a] \times \{0,b\} \end{cases} \tag{27}$$

by a separation of variables. In fact, the eigenfunctions are still given by

$$\Phi_{ij}(x,y) = \frac{2}{\sqrt{ab}} \sin\left(\frac{i\pi x}{a}\right) \sin\left(\frac{j\pi y}{b}\right),$$

but now the eigenvalues are given by

$$2\tilde{\Lambda}_{ij} = \pi^4 \left(\frac{i^4}{a^4} + \frac{6i^2j^2}{a^2b^2} + \frac{j^4}{b^4}\right). \tag{28}$$

We may conclude as before, with the following claim.

LEMMA 4.2. *The first eigenfunction for* (27)*, the hinged rectangular grid with diagonal fibers, is of fixed sign.*

Notice that

$$\tfrac{1}{2}\Lambda_{ij} \le \tilde{\Lambda}_{ij} \le 2\Lambda_{ij}, \tag{29}$$

$$\tilde{\Lambda}_{ij} = \frac{\pi^4}{2}\left(\frac{i^4}{a^4} + \frac{6i^2j^2}{a^2b^2} + \frac{j^4}{b^4}\right) \quad \text{and} \quad \Lambda_{ij} = \pi^4\left(\frac{i^4}{a^4} + \frac{j^4}{b^4}\right).$$

Notice also that the first eigenfunction is of fixed sign.

4.2. Eigenfunctions for clamped problems.

4.2.1. Eigenfunctions for the clamped beam. The set of all normalized eigenfunctions for

$$\begin{cases} \varphi'''' = \lambda\varphi & \text{in } (0,1), \\ \varphi(0) = \varphi'(0) = 0 = \varphi(1) = \varphi'(1) \end{cases} \tag{30}$$

forms a complete orthonormal system in $L^2(0,1)$.

LEMMA 4.3. *These eigenfunctions and eigenvalues are*

$$\varphi_i(x) = \beta_i \cosh\nu_i \left(\frac{\cosh(\nu_i x) - \cos(\nu_i x)}{\cosh\nu_i - \cos\nu_i} - \frac{\sinh(\nu_i x) - \sin(\nu_i x)}{\sinh\nu_i - \sin\nu_i}\right) \quad \textit{and} \quad \lambda_i = \nu_i^4,$$

with $i = 1, 2, \ldots,$ *where* ν_i *is the ith positive zero of* $\cos\nu - \frac{1}{\cosh\nu} = 0$ *and* β_i *is the normalization factor such that* $\int_0^1 \varphi_i(x)^2\, dx = 1$.

Note that the first eigenfunction is of fixed sign.

The statement of this lemma is shown by a lengthy but straightforward calculation.

TABLE 1
Comparison of the of the eigenvalues λ_i and the approximation in Lemma 4.4.

λ_i :	500.56390	3803.5370	14617.630	39943.799	89135.406	173881.31	308208.45
$\left(i-\frac{1}{2}\right)^4\pi^4$:	493.13352	3805.0426	14617.451	39943.815	89135.406	173881.31	308208.45

LEMMA 4.4. *The sequences ν_i and β_i as above have the following asymptotics:*
- $\lim_{i\to\infty} i\pi - \nu_i = \frac{1}{2}\pi$ *and hence* $\lambda_i \approx (i-1/2)^4\,\pi^4$;
- $\lim_{i\to\infty} \beta_i = 1$.

Proof. For obvious reasons two subsequent zeroes ν_i and ν_{i+1} of $\cos\nu - \frac{1}{\cosh\nu} = 0$ are in the interval $((i-\frac{1}{2})\pi, (i+\frac{1}{2})\pi)$ and close to its boundaries. Since $\frac{1}{\cosh\nu_i} \le 2e^{-\nu_i}$ and $|\sin x| > \frac{1}{2}$ in a sufficiently small neighborhood of $(i-\frac{1}{2})\pi$ we have

$$|\nu_i - (i-\tfrac{1}{2})\pi| < 4\ e^{\pi/2}\ e^{-i\pi}.$$

This proves the first statement, as Table 1 illustrates.

Let us now turn to the second statement. With the help of Mathematica one sees that

$$\beta_i = \frac{-Z_i(\cosh\nu_i)^2}{4\,\nu_i\ (\cos\nu_i - \cosh\nu_i)^2\ (\sin\nu_i - \sinh\nu_i)^2}$$

with

$$\begin{aligned} Z_i = \quad & 2\,\nu_i\ \cos 2\,\nu_i + 4\ \cosh\nu_i\ \sin\nu_i - \sin 2\,\nu_i - \cosh 2\,\nu_i\ (2\,\nu_i + \sin 2\,\nu_i) \\ & -\ 4\ \cos\nu_i\ \sinh\nu_i + 8\,\nu_i\ \sin\nu_i\ \sinh\nu_i + \sinh 2\,\nu_i + \cos 2\,\nu_i\ \sinh 2\,\nu_i. \end{aligned}$$

Now the second statement follows by a straightforward computation. □

4.2.2. Comparing eigenvalues of clamped plates and grids. In [33] Philippin, following ideas of Hersch [20], obtained estimates for the eigenvalues of a clamped plate through these for clamped rectangular and diagonal grids. Let us state a special result in this direction that compares the first eigenvalues of a clamped grid,

$$\left\{ \begin{array}{rl} \Phi_{xxxx} + \Phi_{yyyy} = \Gamma\Phi & \text{in } \Omega, \\ \Phi = |\nabla\Phi| = 0 & \text{on } \partial\Omega, \end{array} \right. \tag{31}$$

with those of the clamped plate,

$$\left\{ \begin{array}{rl} \Delta^2\Phi = \Upsilon\Phi & \text{in } \Omega, \\ \Phi = |\nabla\Phi| = 0 & \text{on } \partial\Omega. \end{array} \right. \tag{32}$$

LEMMA 4.5. *Let $\Omega \subset \mathbb{R}^2$ be a bounded domain with a $C^{0,1}$-boundary. Let Γ_1 and Υ_1 be the first eigenvalues of* (31), *respectively* (32). *Then it holds that* $\frac{1}{2}\Upsilon_1 \le \Gamma_1 \le \Upsilon_1$.

For approximations of the lowest eigenvalues for the clamped aligned square grid and the clamped square plate, see Tables 2 and 3.

Proof. The result follows from the definition of the eigenvalue by Rayleigh's quotient and some energy estimates. For the first inequality one uses

$$\frac{1}{4}\int_\Omega (\Delta u)^2 dx\,dy = \frac{1}{4}\int_\Omega \left(u_{xx}^2 + 2u_{xx}u_{yy} + u_{yy}^2\right) dx\,dy \le \frac{1}{2}\int_\Omega \left(u_{xx}^2 + u_{yy}^2\right) dx\,dy.$$

TABLE 2

Numerical eigenvalues Λ_{ij}, with $i, j \le 5$, of a clamped square grid of length 1 that is aligned with Cartesian coordinates (without repeating the multiple ones like $\Lambda_{1,2} = \Lambda_{2,1}$).

Γ_{ij} :	1001.13	4304.10	15118.2	40444.4	89636.0
		7607.07	18421.2	43747.3	92938.9
			29235.3	54561.	103753.
				79887.	129079.
					178271.

TABLE 3

Numerical eigenvalues for a clamped square plate of length 1*. We used the values found in* [15, p. 79] *and scaled these.*

Υ_{ij} :	1294.93	5386.63
		11710.3

For the second one proceeds via an integration by parts that shows, due to the clamped boundary conditions,

$$\begin{aligned} \int_\Omega u_{xx} u_{yy}\, dx\, dy &= \int_{\partial\Omega} (u_x u_{yy} n_1 - u_x u_{xy} n_2)\, d\sigma + \int_\Omega u_{xy}^2\, dx\, dy \\ &= \int_\Omega u_{xy}^2\, dx\, dy \ge 0, \end{aligned}$$

and hence

$$\frac{1}{2} \int_\Omega \left(u_{xx}^2 + u_{yy}^2\right) dx\, dy \le \frac{1}{2} \int_\Omega \left(u_{xx}^2 + 2u_{xy}^2 + u_{yy}^2\right) dx\, dy = \frac{1}{2} \int_\Omega (\Delta u)^2\, dx\, dy.$$

This completes the proof. $\square$

4.2.3. Eigenfunctions for the clamped rectangular grid. A complete orthonormal system of eigenfunctions and eigenvalues for the grid *aligned with the Cartesian coordinates*

$$\left\{ \begin{array}{ll} \Phi_{xxxx} + \Phi_{yyyy} = \Gamma\Phi & \text{in } R, \\ \Phi = |\nabla\Phi| = 0 & \text{on } \partial R \end{array} \right. \tag{33}$$

with $R = (0, a) \times (0, b)$ is given in terms of the one-dimensional eigenfunctions and eigenvalues φ_j and λ_j from Lemma 4.3 by

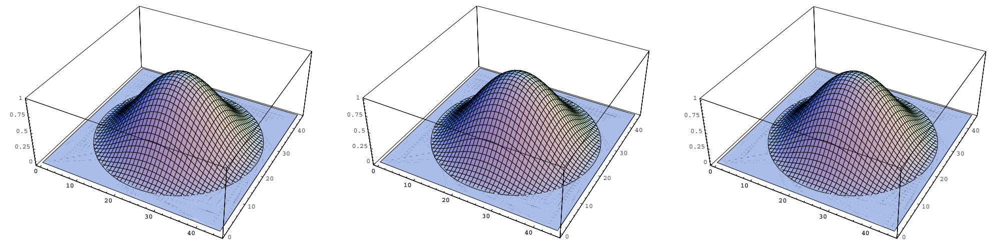
$$\Phi_{ij}(x, y) = \frac{1}{\sqrt{ab}} \varphi_i \left(\frac{x}{a}\right) \varphi_j \left(\frac{y}{b}\right) \quad \text{and} \quad \Gamma_{ij} = a^{-4}\lambda_i + b^{-4}\lambda_j. \tag{34}$$

LEMMA 4.6. *The first eigenfunction for* (33)*, the clamped rectangular grid with aligned fibers, is of fixed sign.*

This is in marked contrast to the biharmonic operator, whose first eigenfunction under Dirichlet conditions on a rectangle is known to change sign infinitely often (see [8]), and positivity of the ground state for our anisotropic operator cannot be expected for a general domain.

An explicit determination of all eigenfunctions and eigenvalues for the *diagonally aligned clamped grid*, however,

$$\left\{ \begin{array}{ll} \frac{1}{2}\Phi_{xxxx} + 3\Phi_{xxyy} + \frac{1}{2}\Phi_{yyyy} = \tilde{\Gamma}\Phi & \text{in } R, \\ \Phi = \Phi_x = 0 & \text{on } \{0, a\} \times [0, b], \\ \Phi = \Phi_y = 0 & \text{on } [0, a] \times \{0, b\}, \end{array} \right. \tag{35}$$



$L_1 = \frac{\partial^4}{\partial x^4} + \frac{\partial^4}{\partial y^4}$ $L_2 = \frac{1}{2}\frac{\partial^4}{\partial x^4} + 3\frac{\partial^4}{\partial x^2 \partial y^2} + \frac{1}{2}\frac{\partial^4}{\partial y^4}$ $L_3 = \Delta^2$

FIG. 3. *Numerical approximations of the first "clamped" eigenfunctions on a disk for L_i, $i = 1, 2, 3$. One sees hardly any difference. We remark that the eigenfunctions for the first and the second operator differ "analytically" just by a 45° rotation. The finite difference scheme, however, is different since in each case the discrete version of the corresponding operator L_i has been used.*

seems to be a nontrivial problem. From Lemma 4.5 we can find an estimate, namely $\Gamma_1 \le 2\tilde{\Gamma}_1$, by using $\Gamma_1 \le \Upsilon_1$ and $\frac{1}{2}\Upsilon_1 \le \tilde{\Gamma}_1$, and similarly $\tilde{\Gamma}_1 \le 2\Gamma_1$. This is consistent with inequality (29) for hinged grids. Note that the estimate $\frac{1}{2}\tilde{\Gamma}_1 \le \Gamma_1 \le 2\tilde{\Gamma}_1$ even holds on general domains.

Remark 4.1. We do not know if the first eigenfunction for (35), the clamped rectangular grid with diagonal fibers, is of fixed sign. Some evidence against a fixed sign follows from Coffman's result in [8].

4.2.4. Eigenfunctions for the clamped circular grid. For a clamped circular plate there are radially symmetric eigenfunctions, and these can be expressed in terms of the (modified) Bessel functions J_0 and I_0. Since Boggio [2] gave an explicit formula for the Dirichlet biharmonic on a circular disk Jentzsch's theorem implies that the first eigenfunction is positive (of fixed sign) and unique and hence radially symmetric. Although a numerical approximation shows that the first eigenfunction of the clamped grid looks similar to the one for the clamped plate (see Figure 3), this eigenfunction is not radially symmetric.

LEMMA 4.7. *Let D denote the unit disk. There is no radial eigenfunction for*

$$\begin{cases} \Phi_{xxxx} + \Phi_{yyyy} = \Gamma\Phi & \textit{in } D, \\ \Phi = |\nabla\Phi| = 0 & \textit{on } \partial D. \end{cases} \tag{36}$$

Remark 4.2. Of course, since the differential equation $u_{xxxx} + u_{yyyy} = \lambda u$ is not rotation invariant, this result should not come as a surprise. A nasty consequence, however, is that the first eigenfunction does not seem to have an "easy" explicit representation. We do not even have analytical proof that this eigenfunction has a fixed sign or that it is unique.

Remark 4.3. The first eigenvalue $\lambda_{cp,1} \approx 104.363$ for the circular clamped plate may be found in [1]. The first one for the clamped grid is approximately 75% of this value.

Proof of Lemma 4.7. Suppose that Φ is a radial eigenfunction. Then we can rotate this eigenfunction by $\pi/4$ and it is still an eigenfunction. However, the rotated Φ now satisfies (see (19))

$$\begin{cases} \frac{1}{2}\Phi_{xxxx} + 3\Phi_{xxyy} + \frac{1}{2}\Phi_{yyyy} = \Gamma\Phi & \text{in } D, \\ \Phi = |\nabla\Phi| = 0 & \text{on } \partial D. \end{cases} \tag{37}$$

Consequently we can add (36) to (37) to arrive at $\frac{3}{2}\Phi_{xxxx}+3\Phi_{xxyy}+\frac{3}{2}\Phi_{yyyy}=2\Gamma\Phi$ or

$$\left\{\begin{array}{ll} \Delta^2\ \Phi=\frac{4}{3}\Gamma\Phi & \text{in } D,\\ \Phi=|\nabla\Phi|=0 & \text{on } \partial D. \end{array}\right. \tag{38}$$

But then Φ must be a radial eigenfunction of the plate equation, an unlikely coincidence. To show that this cannot be the case suppose that $\Phi(r)$ is such a radial function. Then

$$\Phi_{xx}=\Phi''\frac{x^2}{r^2}+\Phi'\frac{y^2}{r^3}\quad\text{and}\quad\Phi_{xx}=\Phi''\frac{y^2}{r^2}+\Phi'\frac{x^2}{r^3}$$

and

$$\begin{aligned}&\Phi_{xxxx}+\Phi_{yyyy}\\ &=\Phi''''\frac{r^4-2x^2y^2}{r^4}+\Phi'''\frac{12x^2y^2}{r^5}+\Phi''\frac{3r^4-30x^2y^2}{r^6}+\Phi'\frac{-3r^4+30x^2y^2}{r^7}=\Gamma\Phi\ ,\end{aligned}$$

or equivalently

$$2x^2y^2\left(-\Phi''''+6r^{-1}\Phi'''-15r^{-2}\Phi''+15r^{-3}\Phi'\right)=r^4\Gamma\Phi-r^4\Phi''''-3r^2\Phi''+3r\Phi'.$$

But this implies that either x^2y^2 is a function of r or both sides are identical zero. Thus we have to show that this second case cannot occur. Suppose that both sides are identical zero. The solutions of

$$-\Phi''''+6r^{-1}\Phi'''-15r^{-2}\Phi''+15r^{-3}\Phi'=0$$

that satisfy the boundary conditions are the functions $(ar^2+b)(1-r^2)^2$. No nonzero a and b will make the right-hand side identically zero, a contradiction. $\square$

5. Positivity questions. From the Krein–Rutman theorem one knows that for a regular elliptic problem strong positivity of the solution operator implies that the first eigenfunction has multiplicity one and, moreover, is of fixed sign. If the solution operator has an integral kernel, one may even use a much earlier result of Jentzsch [21]. Let us be more precise and consider

$$\left\{\begin{array}{ll} Lu=\lambda u+f & \text{in } \Omega,\\ Bu=0 & \text{on } \partial\Omega. \end{array}\right. \tag{39}$$

If the solution operator $(L-\lambda)_B^{-1}:X\mapsto X$ for (39) in the Banach lattice X is compact, positive, and irreducible for some λ_0, then there exists an eigenvalue $\lambda_1\in(\lambda_0,\infty)$ with a positive eigenfunction. For a precise statement, see [6]. Moreover, for all $\lambda\in[\lambda_0,\lambda_1)$ and $f\in X$ one finds that there is a solution $u_\lambda\in X$ and

$$f>0\quad\text{implies}\quad u_\lambda>0.$$

5.1. Known results for plates. Let us recall some of the known positivity preserving results for plates.

For the *hinged plate*

$$\left\{\begin{array}{ll} \Delta^2 u=\lambda u+f & \text{in } \Omega,\\ u=\Delta u=0 & \text{on } \partial\Omega; \end{array}\right. \tag{40}$$

this question was studied in [23] on a general bounded domain Ω. The problem is positivity preserving if $\lambda \in [-\lambda_c(\Omega), \lambda_1(\Omega)^2)$. Here λ_c is a critical number which is bounded above by $\lambda_1(\Omega)\lambda_2(\Omega)$, and $\lambda_i(\Omega)$ are the eigenvalues of the Laplacian operator under Dirichlet conditions. If Ω is a rectangle R with sides a and $b < a$, one can easily calculate $\lambda_1(R) = \pi^2(a^2 + b^2)$ and $\lambda_2(R) = \pi^2(a^2 + 4b^2)$, so that (40) with $\Omega = R$ is positivity preserving for

$$-\pi^4(a^2 + b^2)(a^2 + 4b^2) \leq -\lambda_c(R) \leq \lambda < \pi^4(a^2 + b^2)^2. \tag{41}$$

The *clamped plate*

$$\begin{cases} \Delta^2 u = \lambda u + f & \text{in } \Omega, \\ u = |\nabla u| = 0 & \text{on } \partial\Omega \end{cases} \tag{42}$$

is a more delicate problem. In general (42) is not positivity preserving for $\lambda = 0$; see [13] or [36]. The boundary value problem in (42) is positivity preserving only in the case of the following special domains Ω:

- If Ω is a ball or a disk, Boggio's explicit formula for the solution operator with $\lambda = 0$ implies positivity.
- For small perturbations of the disk, positivity has been shown in [19].
- For Ω some limaçons positivity can be found in [11].
- For a combination of the above results with Möbius transformations, see [12].

5.2. Positivity under hinged boundary conditions.

5.2.1. Hinged beam. For the *hinged beam*

$$\begin{cases} u_{xxxx} = \lambda u + f & \text{in } (0,1), \\ u = u_{xx} = 0 & \text{in } \{0,1\}, \end{cases} \tag{43}$$

the boundary value problem (43) is positivity preserving, provided that (see [23])

$$-950.884 \approx \lambda_c \leq \lambda < \pi^4 \approx 97.409. \tag{44}$$

Here the lower bound λ_c equals $4(\kappa_0)^4$, where κ_0 is the first positive zero of $\tan(x) + \tanh(x)$.

The Green function of the hinged beam. For the sake of completeness we list some facts about the Green function of the hinged beam problem (43). We set $\nu = \sqrt[4]{\lambda}$ and $\mu = \sqrt[4]{-\frac{1}{4}\lambda}$,

$$\phi(\lambda; x) = \begin{cases} \frac{\sinh \nu x - \sin \nu x}{\nu^3} & \text{if } \lambda > 0, \\ \frac{1}{3}x^3 & \text{if } \lambda = 0, \\ \frac{\cosh(\mu x)\sin \mu x - \cos(\mu x)\sinh \mu x}{2\mu^3} & \text{if } \lambda < 0, \end{cases}$$

$$\psi(\lambda; x) = \begin{cases} \frac{\sinh \nu x + \sin \nu x}{2\nu} & \text{if } \lambda > 0, \\ x & \text{if } \lambda = 0, \\ \frac{\cosh(\mu x)\sin \mu x + \cos(\mu x)\sinh \mu x}{2\mu} & \text{if } \lambda < 0. \end{cases}$$

TABLE 4
These values for the coefficients in (45) were obtained using Mathematica.

	$0<\lambda\neq\lambda_i$ set $\nu=\sqrt[4]{\lambda}$	$\lambda=0$	$\lambda<0$ set $\mu=\sqrt[4]{-\frac{1}{4}\lambda}$
α_λ	$\frac{\nu^3}{8}\left(\frac{1}{\sin\nu}-\frac{1}{\sinh\nu}\right)\ \frac{\nu}{2\sin\nu}$	0	$\mu^3\frac{\cos\mu\sinh\mu-\cosh\mu\sin\mu}{\cosh 2\mu-\cos 2\mu}$
β_λ	$-\frac{\nu}{4}\left(\frac{1}{\sin\nu}+\frac{1}{\sinh\nu}\right)$	$-\frac{1}{2}$	$-\mu\frac{\sinh\mu\cos\mu+\cosh\mu\sin\mu}{\cosh 2\mu-\cos 2\mu}$
γ_λ	$-\frac{1}{2\nu}\ \left(\frac{1}{\sin\nu}-\frac{1}{\sinh\nu}\right)$	$\frac{1}{6}$	$\frac{\cosh\mu\sin\mu-\cos\mu\sinh\mu}{\mu(\cosh 2\mu-\cos 2\mu)}$

Now $g_\lambda(x,y)$ can be represented as follows:

(45)
$$g_\lambda(x,y)=\begin{cases}\begin{array}{l}\alpha_\lambda\ \phi(\lambda;x)\,\phi(\lambda;1-y)+\beta_\lambda\ \psi(\lambda;x)\,\phi(\lambda;1-y)\\ +\ \beta_\lambda\ \phi(\lambda;x)\,\phi'(\lambda;1-y)+\gamma_\lambda\ \psi(\lambda;x)\,\psi(\lambda;1-y)\end{array} & \text{if } 0\le x\le y\le 1,\\ \begin{array}{l}\alpha_\lambda\ \phi(\lambda;y)\,\phi(\lambda;1-x)+\beta_\lambda\ \psi(\lambda;y)\,\phi(\lambda;1-x)\\ +\ \beta_\lambda\ \phi(\lambda;y)\,\psi(\lambda;1-x)+\gamma_\lambda\ \psi(\lambda;y)\,\psi(\lambda;1-x)\end{array} & \text{if } 0\le y<x\le 1,\end{cases}$$

and the constants α_λ, β_λ, and γ_λ are suitably chosen in order to accommodate the boundary values in 1 and the continuity requirements of g_λ. Some tedious calculations lead to the coefficients in Table 4.

For $\lambda\ge 0$ formula (45) can be simplified to

$$(46)\qquad \begin{array}{ll} g_\lambda(x,y)=\frac{\sin(x\,\nu)\,\sin(\nu(1-y))}{2\,\nu^3\sin\nu}-\frac{\sinh(x\,\nu)\,\sinh(\nu(1-y))}{2\,\nu^3\sinh\nu} & \text{if } 0\le x\le y\le 1,\\ g_0(x,y)=\frac{1}{6}x\,(1-y)-\frac{1}{6}x\,(1-y)^3-\frac{1}{6}x^3\,(1-y) & \text{if } 0\le x\le y\le 1.\end{array}$$

5.2.2. Hinged rectangular grid with aligned fibers. In this section it will be convenient to use (x_1,x_2) instead of (x,y). An investigation of positivity preserving properties for the *hinged rectangular grid* that is *aligned with the Cartesian axes* seems to be difficult. The eigenfunctions are

$$\Phi_{ij}\,(x_1,x_2)=\frac{1}{\sqrt{ab}}\varphi_i\left(a^{-1}x_1\right)\varphi_j\left(b^{-1}x_2\right)$$

with $\varphi_i\,(t)=\sqrt{2}\sin(i\pi t)$. Recall that the first eigenfunction is of fixed sign and has multiplicity one. Using these eigenfunctions and the Green function g_λ from (45) or (46), the solution of

$$(47)\qquad \left\{\begin{array}{ll}\left(\frac{\partial^4}{\partial x_1^4}+\frac{\partial^4}{\partial x_2^4}\right)u=\lambda u+f & \text{in } R,\\ u=\Delta u=0 & \text{on } \partial R,\end{array}\right.$$

can be written as

$$\begin{aligned}u(x)&=\sum_{i,j=1}^{\infty}\frac{1}{a^{-4}\lambda_i+b^{-4}\lambda_j-\lambda}\left\langle\Phi_{ij},f\right\rangle\Phi_{ij}(x)\\ &=\frac{1}{\sqrt{ab}}\sum_{j=1}^{\infty}\ \left\langle\varphi_j\left(\frac{\circ}{b}\right),\int_{s=0}^{a}g_{b^{-4}\lambda_j-\lambda}\,(x_1,s)\,f\,(s,\circ)\,ds\right\rangle_{(0,b)}\varphi_j\left(\frac{x_2}{b}\right).\end{aligned}$$

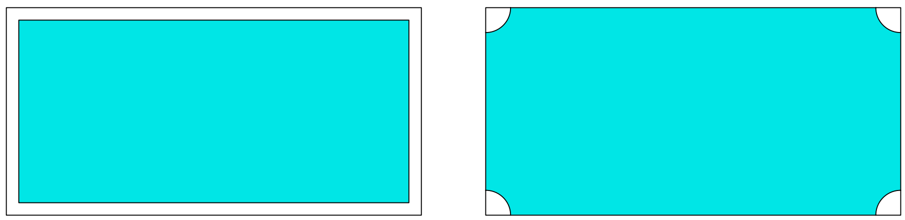


FIG. 4. *The sets* R_ε *and* $R \setminus (C + B^\varepsilon)$ *from Lemma* 5.1.

An inspection of the series representation above suggests that for nonnegative and nontrivial f, for $\lambda < \Lambda_{11}$ and λ close to Λ_{11} the coefficient in front of Φ_{11} becomes very large and positive. This suggests that the first term in the series determines the sign of u. But estimating the remainder of the series in terms of $\Phi_{1,1}$ turns out to be a hard technical problem.

In order to verify that problem (47) is positivity preserving at least for λ in some interval $[\Lambda_{11} - \gamma, \Lambda_{11})$ it suffices to show that the solution of (47) with $f = \delta_y$ is positive for every $y \in R$, where δ_y is the delta function at y.

Since the first eigenfunction is strictly positive in the interior we may prove the following result, in which we use this notation for a domain Ω:

- the ε-interior: $A_\varepsilon = \{x \in A; d(x, \partial\Omega) > \varepsilon\}$,
- the ε-neighborhood: $A + B^\varepsilon = \{x \in \Omega; d(x, \partial A) < \varepsilon\}$.

LEMMA 5.1. *Let* u^λ *be the solution of* (47)*. For every* $\varepsilon > 0$ *there is a positive* $\gamma > 0$ *such that for* $\lambda \in [\Lambda_{11} - \gamma, \Lambda_{11})$ *and* $f \geq 0$ *the following two statements hold (here* C *denotes the set of corner points):*

- *if* support $f \in R_\varepsilon$, *then* $u^\lambda(x) \geq 0$ *for all* $x \in R \setminus (C + B^\varepsilon)$,
- *if* support $f \in R \setminus (C + B^\varepsilon)$, *then* $u^\lambda(x) \geq 0$ *for all* $x \in R_\varepsilon$.

See Figure 4.

Proof. It is sufficient to show such a result for $f = \delta_y$, the delta function, with $y \in R_\varepsilon$. Formally we have

$$\delta_y(\cdot) = \sum_{i,j=1}^{\infty} \Phi_{ij}(y)\, \Phi_{ij}(\cdot),$$

but since $\delta_y \notin L^2(R)$ this series does not converge. The distributional solution $u^{y,\lambda}$ of (47) with $f = \delta_y$, that is,

$$u^{y,\lambda}(\cdot) = \sum_{i,j=1}^{\infty} \frac{\Phi_{ij}(y)}{\Lambda_{ij} - \lambda} \Phi_{ij}(\cdot), \tag{48}$$

lies in $L^2(R)$ since its coefficients are in ℓ_2 :

$$\sum_{i,j=1}^{\infty} \left(\frac{\Phi_{ij}(y)}{\Lambda_{ij} - \lambda} \right)^2 \leq \sum_{i,j=1}^{\infty} \left(\frac{1}{\pi^4 \left(\frac{i^4}{a^4} + \frac{j^4}{b^4} \right) - \lambda} \right)^2 < \infty.$$

We even find for $\alpha + \beta < 3$ that

$$\left\{ i^\alpha j^\beta \frac{\Phi_{ij}(y)}{\Lambda_{ij} - \lambda} \right\} \in \ell_2,$$

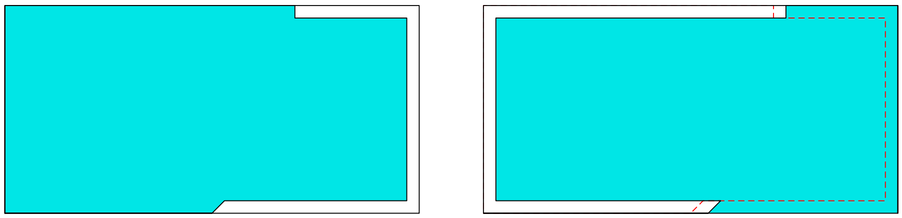

FIG. 5. *The sets* supp$f$ *and* $R_\varepsilon \cup (R \setminus (\text{supp} f + B_\varepsilon))$ *from Lemma* 5.2.

and hence $u^{y,\lambda} \in W^{3-t,2}(R)$ for all $t > 0$.

We split $u^{y,\lambda} = u_1^{y,\lambda} + u_2^{y,\lambda}$, where

$$u_1^{y,\lambda}(\cdot) = \frac{\Phi_{11}(y)}{\Lambda_{11} - \lambda} \Phi_{11}(\cdot).$$

By our assumption we have

$$|\Phi_{ij}(y)| \le \frac{c}{\varepsilon} \Phi_{11}(y) \qquad \text{and} \qquad |\Phi_{ij}(x)| \le c \max(i,j)\, \Phi_{11}(x).$$

This implies that we find

$$\begin{aligned} \left| u_2^{y,\lambda}(x) \right| &\le \sum_{\substack{i,j=1 \\ (i,j) \neq (1,1)}}^{\infty} \left| \frac{\Phi_{ij}(y)}{\Lambda_{ij} - \lambda} \Phi_{ij}(x) \right| \\ &\le \frac{c^3}{\varepsilon^2} \Phi_{11}(x)\, \Phi_{11}(y) \sum_{\substack{i,j=1 \\ (i,j) \neq (1,1)}}^{\infty} \frac{\max(i,j)}{\pi^4 \left(\frac{i^4}{a^4} + \frac{j^4}{b^4} \right) - \lambda}. \end{aligned}$$

Since Λ_{12} and Λ_{21} are greater than Λ_{11}, a straightforward computation shows that the last sum is bounded uniformly with respect to $\lambda < \Lambda_{11}$ by a constant $\gamma = C(a,b)\, \varepsilon^{-2}$. For $\lambda \in [\Lambda_{11} - \gamma, \Lambda_{11})$ we find

$$\left| u_2^{y,\lambda}(x) \right| \le \gamma \Phi_{11}(x)\, \Phi_{11}(y) \le u_1^{y,\lambda}(x)$$

and hence that $u^{y,\lambda}(x) > 0$. □

LEMMA 5.2. *For every $\varepsilon > 0$ there is a $\gamma > 0$ such that if $\lambda \in [\Lambda_{11} - \gamma, \Lambda_{11})$ and $f \ge 0$, then the solution of* (47) *satisfies $u^\lambda(x) \ge 0$ for all $x \in R_\varepsilon \cup (R \setminus (\text{supp} f + B_\varepsilon))$; see Figure* 5.

Proof. If supp$f \in R_\varepsilon$, then the previous lemma yields that $u^\lambda(x) \ge 0$ except near the corners C. By Proposition A.1 in the appendix and using duality, we find that $\left\| u_2^\lambda \right\|_{W^{28,2}(C + B_{\varepsilon/2})} \le c(\varepsilon) \|f\|_{W^{-4,2}(\Omega)}$. Let us denote by $d_h(x)$ and $d_v(x)$ the distance of $x \in R$ to the horizontal and vertical parts of its boundary, and by $\langle v, f \rangle$ the $L^2(R)$ product, when applicable. Then one continues with the imbedding of $W_0^{4,2}(\Omega)$ in $C^2(\bar{\Omega}) \cap C_0^1(\bar{\Omega})$, through

$$\begin{aligned} \|f\|_{W^{-4,2}(\Omega)} &= \sup \left\{ \langle v, f \rangle ; v \in W_0^{4,2}(\Omega) \text{ with } \|v\|_{W^{4,2}(\Omega)} \le 1 \right\} \\ &\le c \sup \left\{ \langle v, f \rangle ; v \in C^2(\bar{\Omega}) \cap C_0^1(\bar{\Omega}) \text{ with } \|v\|_{C^2(\bar{\Omega})} \le 1 \right\} \\ &\le c \sup \left\{ \langle v, f \rangle ; |v(x)| \le d_h(x) d_v(x) | \right\} \\ &\le c' \langle \Phi_{11}, f \rangle. \end{aligned}$$

The last inequality is due to the fact that Φ_{11} can be bounded above and below by multiples of $d_h(x)d_v(x)$.

Similarly, again with an imbedding, we find for the function $u_2^\lambda \in C^2(\bar{\Omega}) \cap C_0^1(\bar{\Omega})$ and for $x \in C + B_{\varepsilon/2}$ that

$$\begin{aligned} u_2^\lambda(x) &\leq c_1 \left\| u_2^\lambda \right\|_{C^2(C+B_{\varepsilon/2})} \Phi_{11}(x) \leq c_2 \left\| u_2^\lambda \right\|_{W^{28,2}\left(C+B_{\varepsilon/2}\right)} \Phi_{11}(x) \\ &\leq c(\varepsilon) \left\| f \right\|_{W^{-3,2}(\Omega)} \Phi_{11}(x) \leq c'(\varepsilon) \left\langle \Phi_{11}, f \right\rangle \Phi_{11}(x). \end{aligned}$$

Since $u_1^\lambda(x) = (\Lambda_{11} - \lambda)^{-1} \langle \Phi_{11}, f \rangle \Phi_{11}(x)$ we find $u^\lambda(x) > 0$ near the corners for $\Lambda_{11} - \lambda$ chosen sufficiently small. A similar proof can be followed for the remaining claim. $\square$

Let us summarize our results in terms of positivity for the Green function $u^{y,\lambda}$ from (48) belonging to the *hinged rectangular grid*.

COROLLARY 5.3. *For every $\varepsilon > 0$ there is a $\gamma(\varepsilon) > 0$ such that $u^{y,\lambda}(x) \geq 0$ for all $x \in R$, all $y \in R_{2\varepsilon}$, and all $\lambda \in [\Lambda_{11} - \gamma(\varepsilon), \Lambda_{11})$.*

Proof. We approximate $\delta_y(\cdot)$ in $\mathcal{D}'(\Omega)$ by a sequence of smooth f_n with support in $B_\varepsilon(y)$, and note that the corresponding solutions $u_n^{y,\lambda}(x)$ of (47) are nonnegative for all $x \in R$ and all $y \in R_{2\varepsilon}$ due to Lemma 5.2. Then we send $n \to \infty$. Since f_n converges in $W^{-1,2}(R)$, the sequence u_n converges pointwise. $\square$

Notice that when sending ε to zero it is conceivable (although it seems unlikely) that $\gamma(\varepsilon) \to 0$. In that case, as $\varepsilon_n \to 0$ there exist sequences $\lambda_n < \Lambda_{11}$ with $\lambda_n \to \Lambda_{11}$, $y_n \in R \setminus R_{2\varepsilon_n}$ with $y_n \to y_0 \in \partial R$, and $x_n \to x_0 \in R$ such that

$$z_n := u^{y_n,\lambda_n}(x_n) < 0 \quad \text{ for all } n \in \mathbb{N}.$$

At present we are unable to derive a contradiction from this.

We will end this section by a another nonuniform positivity result near Λ_{11} by using the fact that the projection on the first eigenfunction will dominate near Λ_{11}. We proceed as for the nonuniform version of the antimaximum principle in [7] to obtain the following nonuniform result.

PROPOSITION 5.4. *For all $f \in L^2(R)$ with $f \geq 0$ there exists $\lambda_f < \Lambda_{11}$ such that for $\lambda \in [\lambda_f, \Lambda_{11})$ the solution u_λ of (47) satisfies $u_\lambda \geq 0$.*

Proof. We will adjust the arguments in [7] for the present situation. Let $\mathcal{L}$: $W^{4,2}(R) \cap W_0^{2,2}(R) \to L^2(R)$ be the operator that corresponds to (47). Fix P_0 to be the projection on the first eigenfunction, that is, $P_0 f = \langle \Phi_{11}, f \rangle_R \ \Phi_{11}$, and set $\tilde{\Lambda} \in (\Lambda_{11}, \min(\Lambda_{12}, \Lambda_{21}))$. Then, using our regularity result for (47) as in [7], we find that there exists a constant C such that for all $\lambda \in \left[0, \tilde{\Lambda}\right]$ the following holds:

$$\left\| (\mathcal{L} - \lambda)^{-1} (I - P_0) f \right\|_{W^{4,2}(R)} \leq C \left\| f \right\|_{L^2(R)}.$$

Since the domain R satisfies a uniform interior cone condition we find by [18, Theorem 7.26] that $W^{4,2}(R)$ is imbedded in $C^{2,\alpha}(\bar{\Omega})$ for any $\alpha \in (0,1)$. Since

$$(\mathcal{L} - \lambda)^{-1} (I - P_0) f \in W_0^{2,2}(\Omega)$$

we find that $u \in C_0(\bar{\Omega})$ and hence that

$$\left\| \frac{(\mathcal{L} - \lambda)^{-1} (I - P_0) f}{\Phi_{11}} \right\|_\infty \leq C' \left\| (\mathcal{L} - \lambda)^{-1} (I - P_0) f \right\|_{W^{4,2}(R)}.$$

FIG. 6. *Top to bottom: a hinged plate, a hinged grid with rectangular fibers, and a hinged grid with diagonal fibers. The arrow denotes the location of the pointed force, and the red (dark) part represents the part of the grid with a negative deviation.*

The solution u_λ of (47) can be written as

$$\begin{aligned} u_\lambda(x) &= \frac{\langle \Phi_{11}, f\rangle_R}{\Lambda_{11} - \lambda}\Phi_{11}(x) + \left((\mathcal{L} - \lambda)^{-1} (I - P_0) f \right)(x) \\ &\geq \left(\frac{\langle \Phi_{11}, f\rangle_R}{\Lambda_{11} - \lambda} - C'' \|f\|_{L^2(R)} \right) \Phi_{11}(x), \end{aligned}$$

which is positive for $0 \leq \Lambda_{11} - \lambda$ sufficiently small. □

5.2.3. Hinged rectangular grid with diagonal fibers. The positivity question is much simpler to decide if the grid runs diagonally. For the *diagonally hinged grid on the rectangle* R as in (17)–(20),

$$\text{(49)} \qquad \begin{cases} \frac{1}{2}u_{xxxx} + 3u_{xxyy} + \frac{1}{2}u_{yyyy} = \lambda u + f & \text{in } R, \\ u = u_{xx} = 0 & \text{on } \{0,a\} \times [0,b], \\ u = u_{yy} = 0 & \text{on } [0,a] \times \{0,b\}, \end{cases}$$

one may decouple the fourth order equation (19) (or (49) with $\lambda = 0$) into a system of two second order equations by using (20).

Since the boundary conditions decouple nicely with the two second order operators, one may use the substitution $v := -u_{xx} - (3 + 2\sqrt{2})u_{yy}$ and two iterations of the standard maximum principle for second order differential operators to find that (49) is positivity preserving for $\lambda = 0$.

Going back to the fourth order problem, one has a strongly positive and compact solution operator that maps $f \in C(\overline{\Omega})$ to $u \in C(\overline{\Omega})$. From the Krein–Rutman theorem one finds that there exists a first eigenvalue, and this eigenvalue corresponds to an eigenfunction of fixed sign. But then one can show the following as in [35].

PROPOSITION 5.5. *For* $\lambda \in \left[0, \pi^4 \left(\frac{1}{2}a^{-4} + 3a^{-2}b^{-2} + \frac{1}{2}b^{-4}\right)\right)$ *the problem* (49) *is positivity preserving.*

The upper bound for λ is the first eigenvalue Γ_{11} given in (28).

5.2.4. Numerical comparison for hinged rectangles. For the hinged rectangular plate and grids we obtained the numerical result shown in Figure 6 by a finite difference method.

5.3. Positivity under clamped boundary conditions.

Table 5
These values for the coefficients in (52) *were obtained using Mathematica.*

	$0<\lambda\neq\lambda_i$ set $\nu=\sqrt[4]{\lambda}$	$\lambda=0$	$\lambda<0$ set $\mu=\sqrt[4]{-\frac{1}{4}\lambda}$
α_λ	$\frac{\nu^3(\sinh\nu+\sin\nu)}{4-4\cosh\nu\cos\nu}$	3	$\frac{2\mu^3(\cos\mu\sinh\mu+\cosh\mu\sin\mu)}{\cosh 2\mu+\cos 2\mu-2}$
β_λ	$\frac{\nu^2(\cos\nu-\cosh\nu)}{4-4\cosh\nu\cos\nu}$	$-\frac{3}{2}$	$\frac{-2\mu^2\sinh\mu\sin\mu}{\cosh 2\mu+\cos 2\mu-2}$
γ_λ	$\frac{\nu(\sinh\nu-\sin\nu)}{4-4\cosh\nu\cos\nu}$	$\frac{1}{2}$	$\frac{\mu(\cosh\mu\sin\mu-\cos\mu\sinh\mu)}{\cosh 2\mu+\cos 2\mu-2}$

5.3.1. Clamped beam. What can be said about positivity preservation for the *clamped beam* (50)?

$$\left\{\begin{array}{ll} u_{xxxx}=\lambda u+f & \text{in } (0,1), \\ u=u_x=0 & \text{in } \{0,1\}. \end{array}\right. \tag{50}$$

This requires more effort. If λ is not an eigenvalue, there exists a Green function g_λ for the clamped beam problem (50) such that the solution can be represented as

$$u(x)=\int_0^1 g_\lambda(x,y)f(y)\,dy.$$

Let us define

$$\phi(\lambda;x)=\left\{\begin{array}{ll} \nu^{-3}\left(\sinh(\nu x)-\sin(\nu x)\right) & \text{if } \lambda>0, \\ \frac{1}{3}x^3 & \text{if } \lambda=0, \\ \frac{1}{2}\mu^{-3}\left(\cosh(\mu x)\sin(\mu x)-\sinh(\mu x)\cos(\mu x)\right) & \text{if } \lambda<0, \end{array}\right. \tag{51}$$

where $\nu=\sqrt[4]{\lambda}$ and $\mu=\sqrt[4]{-\frac{1}{4}\lambda}$. The functions $\phi(\lambda;\cdot)$ and $\frac{\partial}{\partial x}\phi(\lambda;\cdot)$ are two linearly independent solutions of the differential equation and the boundary conditions of (50) in the left end point 0. By the definition of the Green function it follows that

(52)
$$g_\lambda(x,y)=\left\{\begin{array}{ll} \begin{array}{l}\alpha_\lambda\ \phi(\lambda;x)\,\phi(\lambda;1-y)+\beta_\lambda\ \phi'(\lambda;x)\,\phi(\lambda;1-y)\\ +\ \beta_\lambda\ \phi(\lambda;x)\,\phi'(\lambda;1-y)+\gamma_\lambda\ \phi'(\lambda;x)\,\phi'(\lambda;1-y)\end{array} & \text{if } 0\le x\le y\le 1, \\ \begin{array}{l}\alpha_\lambda\ \phi(\lambda;y)\,\phi(\lambda;1-x)+\beta_\lambda\ \phi'(\lambda;y)\,\phi(\lambda;1-x)\\ +\ \beta_\lambda\ \phi(\lambda;y)\,\phi'(\lambda;1-x)+\gamma_\lambda\ \phi'(\lambda;y)\,\phi'(\lambda;1-x)\end{array} & \text{if } 0\le y<x\le 1, \end{array}\right.$$

with appropriate constants to accommodate the boundary values in 1 and the continuity requirements of g_λ. Some tedious calculations lead to the coefficients given in Table 5.

For $\lambda=0$ formula (52) can be simplified to

$$g_0(x,y)=\left\{\begin{array}{ll} \frac{1}{2}x^2(1-y)^2\left(y-x+\frac{2}{3}x(1-y)\right) & \text{if } 0\le x\le y\le 1, \\ \frac{1}{2}y^2(1-x)^2\left(x-y+\frac{2}{3}y(1-x)\right) & \text{if } 0\le y<x\le 1. \end{array}\right.$$

Problem (50) is positivity preserving if and only if the Green function is positive, and for g_0 this is now easily seen to be the case. Instead of directly computing for which λ the Green function g_λ is in fact positive, one may proceed through the results of Schröder in [34]. The Green function changes sign for some λ if and only if this λ is an eigenvalue of either (30) or of

$$\left\{ \begin{array}{c} \varphi'''' = \lambda\varphi \text{ in } (0,1)\,, \\ \varphi(0) = \varphi'(0) = \varphi'''(0) = 0 = \varphi(1). \end{array} \right. \tag{53}$$

The "first" solution of (53) is $g_\lambda(x,1)$ with $\lambda_c = -4\nu_0^4$, where ν_0 is the first positive zero of $\tanh\nu = \tan\nu$.

LEMMA 5.6. *Problem* (50) *is positivity preserving if and only if* $\lambda \in [\lambda_c, \lambda_1)$, *where*

- λ_1 *is the first eigenvalue of* (30)*, that is, the fourth power of the first positive solution of*

$$\cos\lambda = \frac{1}{\cosh\lambda},$$

- λ_c *is the "first" eigenvalue of* (53)*, that is, the first negative solution of*

$$\tan\sqrt[4]{-\frac{1}{4}\lambda} = \tanh\sqrt[4]{-\frac{1}{4}\lambda}. \tag{54}$$

The numerical approximations are $\lambda_1 \approx 4.7300$ and $\lambda_c \approx -950.884$. Notice that this is the same λ_c as in (44) for problem (43).

Proof. The arguments are similar to the ones in [23] and reflect the ideas from [34].

Direct inspection shows that g_0 is strictly positive. To study the case of positive λ, notice that (50) can be rewritten as $(I - \lambda L^{-1})u = f$, where $Lu = u_{xxxx}$, so that by a Neumann series argument $u = \sum_{k=1}^{\infty}(\lambda L^{-1})^k f$ converges and is positive for all $\lambda \in [0, \lambda_1)$. For $\lambda = \lambda_1$ no solution exists when $f = \varphi_1$. For $\lambda > \lambda_1$ and $f = \varphi_1$ the solution is $u = (\lambda_1 - \lambda)^{-1}\varphi_1$, and this is negative.

For $\lambda < 0$ one finds from (52)–(51) and the coefficients in Table 4 that $\lambda \mapsto g_\lambda(x,y)$ is continuous for $\lambda \le 0$ in almost every sense. Let $\lambda_c < 0$ be the first number after which positivity fails. Suppose that for a fixed $y \in (0,1)$ the value of $g_{\lambda_c}(x,y)$ is nonnegative but equals 0 for some $x_y \in (0,1)$. And suppose w.l.o.g. that $x_y \le y$. Then $g_{\lambda_c}(x_y,y) = \frac{\partial}{\partial x} g_{\lambda_c}(x_y,y) = \frac{\partial}{\partial x} g_{\lambda_c}(0,y) = \frac{\partial}{\partial x} g_{\lambda_c}(0,y) = 0$ and we have found an eigenfunction scaled to $[0, x_y]$, a contradiction. Hence $x_y = 0$. Using the symmetry $g_\lambda(x,y) = g_\lambda(y,x)$, we may assume that y is at the boundary, say $y = 1$. We may repeat the argument above for $\tilde{g}_{\lambda_c}$ defined by $\tilde{g}_\lambda(x) = \lim_{y\uparrow 1}(1-y)^{-2} g_\lambda(x,y)$, which is a nontrivial function. Again if $\tilde{g}(x_1) = 0$ for some $x_1 \in (0,1)$, we find an eigenfunction by scaling on $[0, x_1]$. Since $\tilde{g}'(1) < 0 = \tilde{g}(1)$ it remains that $x_1 = 0$. One finds that $\tilde{g}$ is an eigenfunction of (53). The first eigenfunction of that eigenvalue problem is

$$\psi_1(x) = \cosh(\mu x)\sin(\mu x) - \sinh(\mu x)\cos(\mu x)$$

with μ the first positive root of $\cosh\mu\sin\mu = \sinh\mu\cos\mu$ and $\lambda_c = 4\mu^2$. This can be rephrased to (54). For $\lambda < \lambda_c$ one finds that $\tilde{g}_\lambda$ is sign changing, implying that for y near 1 the function $x \mapsto g_\lambda(x,y)$ is sign changing. $\square$

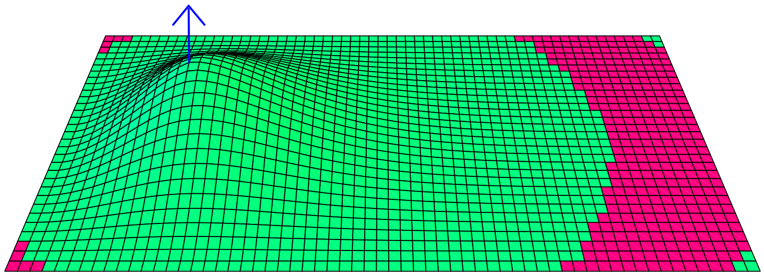

FIG. 7. *Numerical simulation of a clamped rectangularly aligned grid;* (55) *with* $\mu = 0$ *and a point source* f.

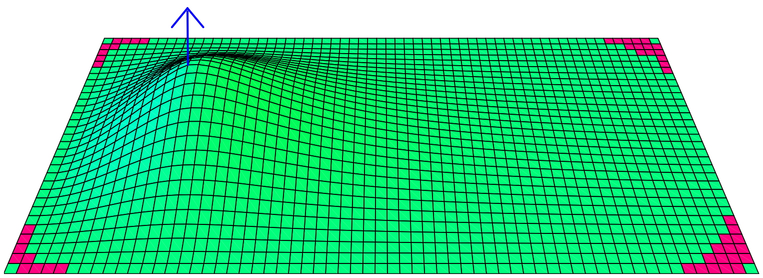

FIG. 8. *Numerical simulation of a clamped diagonally aligned grid.*

5.3.2. Clamped rectangular grid with aligned fibers. In this section we investigate the problem

$$\left\{ \begin{array}{ll} u_{xxxx} + u_{yyyy} = \lambda u + f & \text{in } R, \\ u = |\nabla u| = 0 & \text{on } \partial R. \end{array} \right. \tag{55}$$

Numerical calculations suggest that for $\lambda = 0$ a point load $f = \delta_y(\cdot)$ can lead to a sign changing solution; see Figure 7, in which the sign of u is color coded. This behavior is also known and recorded in [9] for isotropic rectangular plates, whose deformation solves $\Delta^2 u = f$ instead.

However, since the first eigenfunction is positive, by using the eigenfunction expansion one finds the following solution formula for (55):

$$u(x, y) = \sum_{i,j=1}^{\infty} \frac{1}{\Lambda_{ij} - \lambda} \langle \Phi_{ij}, f \rangle_R \; \Phi_{ij}(x, y).$$

As for the hinged plate one might hope that for λ near Λ_{11} the projection on the first eigenfunction will dominate the sign. But to find such a result we would need a C^4 estimate near corner points, which, unfortunately, we do not have at our disposal.

5.3.3. Clamped diagonal grid. Since we do not know if the first eigenfunction is of fixed sign for this grid we can only give some numerical evidence. With the same point source and domain as in rectangularly aligned grid from Figure 7, the area where the solutions change sign seems to be much smaller for the diagonally aligned grid; see Figure 8.

5.3.4. Numerical comparison for clamped rectangles. Duffin's famous counterexample in [13] for the conjecture of Boggio and Hadamard (the clamped plate problem on convex domains is positivity preserving) uses a long thin rectan-

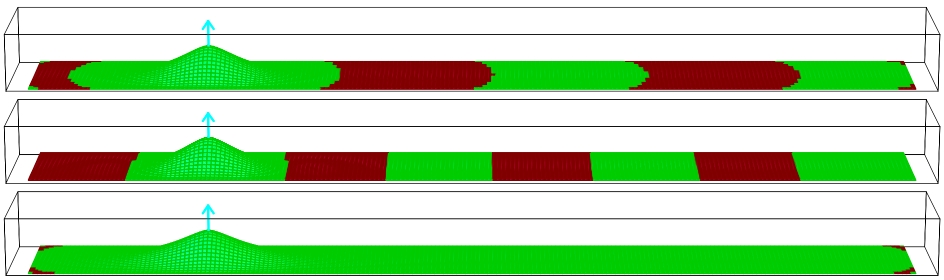

FIG. 9. *Top to bottom: a clamped plate, a clamped grid with rectangular fibers, and a clamped grid with diagonal fibers. The arrow denotes the location of the pointed force and the red (dark) part represents the part of the grid with a negative deviation.*

TABLE 6
Overview for rectangular plates and grids.

		Positive eigenfunction	Positivity preserving
Hinged	Plate	$\Phi_1 > 0$	for $\lambda \in [0, \Lambda_1)$
	Grid aligned with sides	$\Phi_1 > 0$	conditionally near Λ_1
	Grid with diagonal fibers	$\Phi_1 > 0$	for $\lambda \in [0, \Lambda_1)$
Clamped	Plate	Φ_1 changes sign	no
	Grid aligned with sides	$\Phi_1 > 0$	conditionally near Λ_1
	Grid with diagonal fibers	?	?

gle. In Figure 9 we present numerical results for long clamped rectangular plates and grids. Rather surprisingly, the numerical result for a long thin rectangle with a diagonal fabric hardly shows any sign change.

The numerical illustrations have been obtained using a finite difference method.

6. Summary for rectangular grids. We set out to study positivity for rectangular grids with aligned and with diagonal fibers. An overview of the results we obtained for those problems can be found in Table 6. For the sake of comparison we include the known results for the rectangular plate.

Numerics for the clamped plate with diagonal fabric suggest that the first question mark in the table above should be answered affirmatively; the second question mark might have a positive answer for λ near Λ_1. Of course "near Λ_1" always means in a left neighborhood of Λ_1.

Appendix. Nonlocal smoothness. The standard regularity statement for $2m$-th order elliptic problems is usually a statement of the form that $f \in W^{k,p}(\Omega)$ implies $u \in W^{k+2m,p}(\Omega)$ or $f \in C^{k,\gamma}(\bar{\Omega})$ implies $u \in C^{k+2m,\gamma}(\bar{\Omega})$. Such a maximal regularity result is optimal. However, for a function $f \in L^p(\Omega)$ which has its support in $\Omega' \subset \Omega$ one may show that the corresponding solution is smooth outside of Ω'. Although this result is well known, we are not aware of any reference. So allow us to formulate a corresponding statement.

Consider a regular elliptic problem with L of order $2m$ and Ω a domain in $\mathbb{R}^n$:

$$\begin{cases} Lu = f & \text{in } \Omega, \\ B_i u = 0 & \text{on } \partial\Omega \quad \text{for } i = 0, \ldots, m. \end{cases} \tag{56}$$

PROPOSITION A.1. *Let Ω_1, Ω_2 be two disjoint subdomains of Ω having a positive distance r, that is, $r := \inf\{|x-y|\,; x \in \Omega_1, y \in \Omega_2\} > 0$. Suppose that there exists $c > 0$ such that for all $k \in \{0,\dots,\kappa\}$ and all $f \in W^{k,2}(\Omega)$ there is a solution $u \in W^{2m+k,2}(\Omega)$ of (56) with*

$$\|u\|_{W^{2m+k,2}(\Omega)} \le c\,\|f\|_{W^{k,2}(\Omega)}\,; \tag{57}$$

then there exists $C(c,\kappa,r)$ such that for all $f \in L_2(\Omega)$ with support$f$ $\subset \Omega_1$ *the following holds true:*

$$\|u\|_{W^{2m+\kappa,2}(\Omega_2)} \le C(c,\kappa,r)\,\|f\|_{L_2(\Omega_1)}\,. \tag{58}$$

Proof. We will prove this by induction. For $k = 0$ the estimate (58) follows from (57) and the fact that supp $f \subset \Omega_1$. Next we do the induction from k to $k+1$ and suppose that $\|u\|_{W^{2m+k,2}(\Omega_2)} \le C(c,k,r)\,\|f\|_{L_2(\Omega_1)}$ for some $k \ge 0$. One may construct a cut-off function χ such that for some $c_1 \in \mathbb{R}^+$

1. $\chi \in C^\infty(\bar\Omega)$ with $\chi_{|\Omega_1} = 0$ and $\chi_{|\Omega_2} = 1$;
2. $\bar\Omega_2 \Subset \text{support}\chi \Subset \bar\Omega\backslash\Omega_1$;
3. $\|\chi\|_{C^i(\bar\Omega)} \le c_1 r^{-i}$ for $i \in \{0,\dots,k\}$.

Note that $L(\chi u) = \chi L u + \text{l.o.t.} = 0 + \text{l.o.t.}$ and that χu satisfies the boundary conditions from (56). Since the right-hand-side l.o.t. lies in $W^{k+1,2}(\Omega)$ we find $\chi u \in W^{2m+k+1,2}(\Omega)$. Moreover,

$$\begin{aligned} &\|u\|_{W^{2m+k+1,2}(\Omega_2)} \le \|\chi u\|_{W^{2m+k+1,2}(\Omega)} \le c_1\,\|l.o.t.\|_{W^{k+1,2}(\Omega)} \\ &= c_1\,\|l.o.t.\|_{W^{k+1,2}(\text{support}\chi)} \le c(r)\ \|u\|_{W^{2m+k,2}(\tilde\Omega_2)} \le C'(c,k,r/2)\,\|f\|_{L_2(\Omega_1)}\,. \end{aligned}$$

Here $\tilde\Omega_2$ can be chosen so that $d(\Omega_1,\tilde{\Omega_2}) < r/(2k)$. ∎

QUASI-NEUTRAL LIMIT OF THE DRIFT DIFFUSION MODELS FOR SEMICONDUCTORS: THE CASE OF GENERAL SIGN-CHANGING DOPING PROFILE*

SHU WANG†, ZHOUPING XIN‡, AND PETER A. MARKOWICH§

Abstract. In this paper the vanishing Debye length limit (space charge neutral limit) of bipolar time-dependent drift-diffusion models for semiconductors with p-n junctions (i.e., with a fixed bipolar background charge) is studied in one space dimension. For general sign-changing doping profiles, the quasi-neutral limit (zero-Debye-length limit) is justified rigorously in the spatial mean square norm uniformly in time. One main ingredient of our analysis is the construction of a more accurate approximate solution, which takes into account the effects of initial and boundary layers, by using multiple scaling matched asymptotic analysis. Another key point of the proof is the establishment of the structural stability of this approximate solution by an elaborate energy method which yields the uniform estimates with respect to the scaled Debye length.

Key words. quasi-neutral limit, drift-diffusion equations, multiple scaling asymptotic expansions, singular perturbation, classical energy methods, λ-weighted Liapunov-type functional

1. Introduction.

The scaled one-dimensional isothermal drift-diffusion model for semiconductors reads

$$n_t^\lambda = (n_x^\lambda - n^\lambda \Phi_x^\lambda)_x, \quad 0 < x < 1, \quad t > 0, \tag{1}$$

$$p_t^\lambda = (p_x^\lambda + p^\lambda \Phi_x^\lambda)_x, \quad 0 < x < 1, \quad t > 0, \tag{2}$$

$$\lambda^2 \Phi_{xx}^\lambda = n^\lambda - p^\lambda - D, \quad 0 < x < 1, \quad t > 0, \tag{3}$$

$$n_x^\lambda - n^\lambda \Phi_x^\lambda = p_x^\lambda + p^\lambda \Phi_x^\lambda = \Phi_x^\lambda = 0, \quad x = 0, 1, \quad t > 0, \tag{4}$$

$$n^\lambda(x, 0) = n_0^\lambda(x), \quad p^\lambda(x, 0) = p_0^\lambda(x), \quad 0 \le x \le 1. \tag{5}$$

The variables $n^\lambda, p^\lambda, \Phi^\lambda$ are the electron density, the hole density, and the electric potential, respectively. The constant λ is the scaled Debye length of the semiconductor device under consideration. $D = D(x)$ is the given function of space and models the doping profile (i.e., the preconcentration of electrons and holes). Because of the occurrence of p-n junctions in realistic semiconductor devices, the doping profile $D(x)$ typically changes its sign.

In this paper, we assume that $D(x)$ is a smooth function.

Note that for the sake of simplicity we take insulating boundary conditions modeled by outward electric field and current density components, namely (4).

A necessary solvability condition for the Poisson equation (3) subject to the Neumann boundary condition for the field in $(4)_3$ is global space charge neutrality

$$\int_0^1 (n^\lambda - p^\lambda - D)dx = 0.$$

Since the total numbers of electrons and holes are conserved, it is sufficient to require the following corresponding condition for the initial data:

$$\int_0^1 (n_0^\lambda - p_0^\lambda - D)dx = 0. \tag{6}$$

Usually semiconductor physics are concerned with large-scale structures with respect to the Debye length λ (λ takes small values, typically $\lambda^2 \approx 10^{-7}$). For such scales, the semiconductor is almost electrically neutral, i.e., there is no space charge separation or electric field. This is the so-called quasi-neutrality assumption of semiconductors or plasma physics, which was applied by Shockley [31] in the first theoretical studies of semiconductor devices in 1949, but was also applied in other contexts such as the modeling of plasmas [32] and ionic membranes [29]. Under the assumption of space charge neutrality, i.e., $\lambda = 0$, we formally arrive at the following quasi-neutral drift-diffusion model:

$$n_t = (n_x + n\mathcal{E})_x, \tag{7}$$

$$p_t = (p_x - p\mathcal{E})_x, \tag{8}$$

$$\begin{aligned} 0 &= n - p - D, \\ \mathcal{E} &= -\Phi_x. \end{aligned} \tag{9}$$

This formal limit was obtained by Roosbroeck [28] in 1950. For further formal asymptotic analysis, see [25, 27, 20, 33].

Generally speaking, it should be expected at least formally that $(n^\lambda, p^\lambda, -\Phi_x^\lambda) \to (n, p, \mathcal{E})$ as $\lambda \to 0$ in the interior of the interval $[0,1]$, while it cannot be expected a priori that all boundary and initial value conditions are maintained for the limit problem because of the singular perturbation character of the problem (the Poisson equation becomes an algebraic equation in the limit). However, by the conservation form of the continuity equations the property of zero fluxes through the boundary will prevail in the limit

$$n_x + n\mathcal{E} = 0, \qquad p_x - p\mathcal{E} = 0, \quad x = 0, 1, \quad t > 0, \tag{10}$$

while the boundary condition for the electric field E^λ does not.

Similarly, we can expect a priori that quasi-neutral drift-diffusion models (7)–(9) are supplemented by the initial data

$$n(x,0) = n_0(x), \quad p(x,0) = p_0(x) \tag{11}$$

satisfying locally initial time space charge neutrality

$$n_0 - p_0 - D = 0. \tag{12}$$

The aim of this paper is to justify rigorously the above formal limit for $O(1)$-time and sufficiently smooth solutions.

It is important to mention that the quasi-neutral limit is a well-known challenging and physically very complex modeling problem for (bipolar) fluid dynamic models and for kinetic models of semiconductors and plasmas. In both cases there exist only partial results. In particular, for time-dependent transport models, the limit $\lambda \to 0$ has been performed for the Vlasov–Poisson system by Brenier [2], Grenier [12, 13], and Masmoudi [21]; for the Schrödinger–Poisson system by Puel [26] and Jüngel and Wang [16]; for the drift-diffusion-Poisson system by Gasser et al. [10, 11], Jüngel and Peng [15], and Schmeiser and Wang [30] under much more restrictive assumptions on the doping profile that is used in this paper (no sign changes of D are allowed); and for the Euler–Poisson system by Cordier and Grenier [5, 6], Cordier et al. [4], and Wang [35]. However, as already mentioned, all these results are restricted to *the special cases of doping profiles*, i.e., *either assuming that $D(x)$ is constant zero or assuming that $D(x)$ does not change its sign*. But p-n junctions are of great importance both in modern electronic applications and in understanding semiconductor devices since the p-n junction theory serves as the foundation of the physics of semiconductor devices (see Sze [34]). For physically interesting doping profiles with p-n junctions, i.e., for the case where the doping profile can change its sign, there is no rigorous result available for time-dependent semiconductor models for either fluid dynamic models or for kinetic models up to now. Therefore, it is natural to study the quasi-neutral limit on the level of the drift-diffusion-Poisson models first. For stationary drift-diffusion-Poisson models, rigorous convergence results for p-n junction devices with contacts can be found in Markowich [19], and recent extensions were done by Caffarelli et al. [3] and Dolbeault, Markowich, and Unterreiter [7].

In this paper we consider the quasi-neutral limit of the time-dependent drift-diffusion model (1)–(6) for semiconductors with p-n junctions in the general case of physically relevant sign-changing doping profiles.

Our main result can be summarized as follows: The convergence of the drift diffusion models (1)–(5) to (7)–(11) is rigorously proved for general sign-changing and smooth doping profiles in one-space dimension case on time intervals, on which a smooth nonvacuum solution of the reduced problem (7)–(11) exists (the precise statement will be given in section 2).

We mention that one of the main difficulties in dealing with quasi-neutral limits is the oscillatory behavior of the electric field. Usually it is difficult to obtain uniform estimates on the electric field with respect to the Debye length λ due to a possible vacuum set of the density, in particular, the occurrence of the depletion region.

In this paper, we overcome this difficulty by the following strategy. First, we introduce a new transformation (see (13) in section 2) that changes the original problem, (1)–(5), into an equivalent one, (14)–(17), where the dissipation for the electric field becomes apparent. Second, we construct carefully a better uniformly valid approximation solution to (14)–(17) by using a method of matched asymptotic analysis. Finally, we show the asymptotic structural stability of the resulting approximate solution by energy methods based on studies on a weighted entropy and entropy dissipation. This approach is strongly motivated by the analysis of boundary layers in the fluid-dynamic limit of a nonlinear Boltzmann equation by Liu and Xin in [18] and viscous boundary layers by Xin in [36]. This ansatz deviates from the solutions to (7)–(11) slightly in a region away from the parabolic boundaries, since it changes more rapidly in the electronic field in the parabolic boundaries (boundary layers and initial layers). It is this kind of structure of the ansatz that governs the main oscillatory feature of the electric field and plays a key role in our analysis. Due to the special structure of the quasi-neutral drift-diffusion model (7)–(11), and the more or less explicit forms of the boundary layer functions and initial layer functions, the asymptotic ansatz can be estimated rather easily. Thus, the quasi-neutral limit problem is reduced to show the structural stability of such an ansatz. To achieve this goal, our basic idea in the whole analysis in this paper is that the more accurate approximate solutions make it easier to obtain their structural stability for the following reasons.

First, though the linearized system around the approximate solutions is complictaed and involves many scales due to the presence of boundary and initial layers, the detailed forms of the layer structure in the ansatz and the explicit form of the dissipation for the electric field make it possible to derive the uniform energy estimates for the linearized operator. Furthermore, the ansatz is constructed in such a way so that the deviation from the ansatz, the error, satisfies the so-called "error" system (see (104)–(105)) which is only weakly nonlinear with source terms suitably small in appropriate norms. Since the detailed estimates, given in section 4, are very lengthy and involved, we would like to outline some main ingredients here. Note that although the "error" system is very complicated due to the layer structure of the ansatz and the complexity of the problem involved, it is in fact a coupled nonlinear parabolic system with nonhomogeneous source terms, and the major part of its linearized operator has an extra dissipative term for the electric field due to the uniform positivity of the total interior density $\mathcal{Z}^0$, which yields the uniform energy estimates of the electric field with respect to the Debye length λ if one just deals with only the linearized system of the error system. Moreover, according to the structure of the ansatz, we can decompose the inhomogeneous source term of the error system into the inner part, the boundary layer part, the initial layer part, and the mixed boundary and initial layer part, which has a uniform decay rate with respect to λ in a weighted Sobolev's norm. Hence an extra power of λ can be created in the energy bound, as is the main purpose of the approximate solution constructed in this paper. Because there is no maximal principle for the error system (104)–(105), the classical energy method is employed to establish the uniform energy estimates with respect to the Debye length λ in Sobolev's space. However, due to the complexity of the "error" equations, it is not easy to obtain the uniformly a priori energy bound with respect to the Debye length λ or the decay rate (a power of λ) if one just uses only the standard energy estimate techniques. So one needs some new techniques for establishing the uniformly a priori estimate in order to derive the energy bound. One basic point of our approach here is to derive high order spatial energy estimates by combining the basic L^2-estimates of $(z_R^\lambda, E_R^\lambda)$ (see below) and the L^2-estimates of the time derivatives of $(z_R^\lambda, E_R^\lambda)$ to avoid meeting the strong singularity caused by the boundary layer function appearing in the ansatz. Hence the inhomogeneous source terms can be controlled by further using the decay rate of the boundary layer and initial layer functions. Another technique involved here is to control strong nonlinear oscillation, caused by the nonlinearity of the error system, by a combination of the entropy and the entropy dissipation, which is the reason why one can establish the uniform energy bound. Namely, one controls the deviation of the solution to (14)–(17) from the ansatz by introducing the following two λ-weighted Liapunov-type functionals:

$$\Gamma^\lambda(t) = \int_0^1 \big(|z_R^\lambda|^2 + |z_{R,x}^\lambda|^2 + |z_{R,t}^\lambda|^2 + \lambda^2(|E_R^\lambda|^2 + |E_{R,x}^\lambda|^2 + |E_{R,t}^\lambda|^2) + |E_R^\lambda|^2\big)dx$$

and

$$G^\lambda(t) = \int_0^1 \big(|z_{R,x}^\lambda|^2 + |z_{R,xt}^\lambda|^2 + |E_R^\lambda|^2 + |E_{R,t}^\lambda|^2 + \lambda^2(|E_{R,x}^\lambda|^2 + |E_{R,xt}^\lambda|^2)\big)dx,$$

where $z_R^\lambda = n_R^\lambda + p_R^\lambda$, $E_R^\lambda = -\Phi_{R,x}^\lambda$, and $(n_R^\lambda, p_R^\lambda, \Phi_R^\lambda)^T$ denotes the difference between the solution to (14)–(17) from the ansatz (see section 2 for details). Notice that, physically, $\Gamma^\lambda(t)$ is called the entropy while $G^\lambda(t)$ is called the entropy dissipation because it is an entropy derived from the dissipation term of the error system (14)–(17). By a careful energy method, we are able to prove the entropy production integration inequality

$$\begin{aligned}
&\Gamma^\lambda(t) + \int_0^t G^\lambda(s)ds \\
&\leq M\Gamma^\lambda(t=0) + M\int_0^t (\Gamma^\lambda(s) + (\Gamma^\lambda(s))^\iota)ds \\
&\quad + M\int_0^t \Gamma^\lambda(s)G^\lambda(s)ds + M\lambda^q, \quad t \geq 0,
\end{aligned}$$

for some $\iota > 1$, $q > 0$, and $M > 0$, independent of λ, which implies the desired convergence result of this paper.

Finally, we also mention that for drift-diffusion models there are many results on existence, uniqueness, large time asymptotic behavior, stability of stationary states, regularity of weak solutions, etc. For example, see [1, 8, 9, 14, 20, 22, 23, 24].

The plan of this paper is as follows. In section 2 we reformulate our problem and state the main results of this paper; furthermore, the existence and regularity of solutions to the quasi-neutral drift-diffusion models are discussed. In section 3 we give the approximate solutions by a method of matched asymptotic analysis and study the properties of initial and boundary layer function. Finally, section 4 is devoted to the energy estimates for the main theorems of this paper.

2. Reformulation of the equations and main results. Introduce the new variables (z^λ, E^λ) by the following transformation:

$$E^\lambda = -\Phi_x^\lambda, \quad n^\lambda = \frac{z^\lambda + D - \lambda^2 E_x^\lambda}{2}, \quad p^\lambda = \frac{z^\lambda - D + \lambda^2 E_x^\lambda}{2} \quad (z^\lambda = n^\lambda + p^\lambda). \tag{13}$$

Adding (1) and (2) and using (3); taking ∂_t of (3) and replacing n_t, p_t of the resulting equation by (1), (2) and then integrating over $[0, x]$ with respect to x; and using the boundary condition (4) and the transformation (13), we can reduce the initial boundary value problem (1)–(6) to the following equivalent system for (z^λ, E^λ):

$$z_t^\lambda = (z_x^\lambda + DE^\lambda)_x - \lambda^2(E^\lambda E_x^\lambda)_x, \quad 0 \leq x \leq 1, \quad t > 0, \tag{14}$$

$$\lambda^2(E_t^\lambda - E_{xx}^\lambda) = -(D_x + z^\lambda E^\lambda), \quad 0 \leq x \leq 1, \quad t > 0, \tag{15}$$

$$z_x^\lambda = E^\lambda = 0, \quad x = 0, 1, \quad t > 0, \tag{16}$$

$$z^\lambda(x, 0) = z_0^\lambda(x), \quad E^\lambda(x, 0) = E_0^\lambda(x), \quad 0 \leq x \leq 1. \tag{17}$$

Note that the equivalence between system (1)–(6) and system (14)–(17) is easily verified for classical solutions by using the transformation (13). Thus, we have the following proposition.

PROPOSITION 1 (existence and uniqueness). *Assume that* $(z_0^\lambda, E_0^\lambda) \in (C^2)^2$ *satisfies the compatibility conditions*

$$z_{0,x}^\lambda = E_0^\lambda = 0, \quad -\lambda^2 E_{0,xx}^\lambda = -D_x \text{ at } x = 0, 1. \tag{18}$$

Then system (14)–(17) *has a unique, global, and classical solution* $(z^\lambda, E^\lambda) \in C^{2,1}([0,1] \times [0, \infty))$.

Remark 1. The existence in Proposition 1 is obtained by the known existence results for (1)–(6) (see, for example, [24, 9]) and by the transformation (13), while uniqueness in Proposition 1 can be proved easily for H^1-solutions of (14)–(17).

Let us assume that the initial datum $(z_0^\lambda, E_0^\lambda)$ is taken to guarantee that boundary-initial consistency for the initial boundary value problem (14)–(17) for $\lambda > 0$ holds. In particular, the compatibility condition (18) is assumed and the initial datum $(z_0^\lambda, E_0^\lambda)$ is assumed to have an expansion of the form

$$
\begin{aligned}
(z_0^\lambda, E_0^\lambda)^T = \Bigg(& z_0^0(x) + \lambda\left(f(x)z_+^1\left(\frac{x}{\lambda}\right) + g(x)z_-^1\left(\frac{1-x}{\lambda}\right)\right) + \lambda z_{0R}^\lambda(x), \\
& E_0^0(x) + f(x)E_+^0\left(\frac{x}{\lambda}\right) + g(x)E_-^0\left(\frac{1-x}{\lambda}\right) + \lambda E_{0R}^\lambda(x)\Bigg)^T .
\end{aligned}
\tag{19}
$$

To justify the rigorous quasi-neutral assumptions, we make the following ansatz for the approximate solution:

$$
\begin{aligned}
(z^\lambda, E^\lambda)_{app}^T = \Bigg(& \mathcal{Z}^0(x,t) + \sum_{i=0}^{2} \lambda^i \big(f(x)z_+^i(\xi,t) + g(x)z_-^i(\eta,t) + z_I^i(x,s)\big), \\
& \mathcal{E}^0(x,t) + f(x)E_+^0(\xi,t) + g(x)E_-^0(\eta,t) + E_I^0(x,s)\Bigg)^T ,
\end{aligned}
\tag{20}
$$

where the inner function $(\mathcal{Z}^0, \mathcal{E}^0)^T$ is independent of λ; $z_+^i, E_+^0, z_-^i, E_-^0$, $i = 0, 1, 2$, are the left boundary layer functions near $x = 0$ and the right boundary layer functions near $x = 1$, respectively; and z_I^i, $i = 0, 1, 2, E_I^0$, are the initial time layer functions near $t = 0$. The cut-off functions $f(x)$ and $g(x)$ are smooth C^2 functions satisfying $f(0) = g(1) = 1$ and $f(1) = f'(1) = f''(1) = f'(0) = f''(0) = g(0) = g'(0) = g''(0) = g'(1) = g''(1) = 0$. Here we set

$$
\xi = \frac{x}{\lambda}, \quad \eta = \frac{1-x}{\lambda}, \quad s = \frac{t}{\lambda^2},
$$

which corresponds physically to the dielectric relaxation time scale, and $(\cdot,\cdot)^T$ represents transposition. We will discuss in detail the construction of the inner, boundary layer, and initial layer functions in the next section; however, we summarize the results here.

First, the inner function $(\mathcal{Z}^0, \mathcal{E}^0)^T$ is determined as a solution of the following initial boundary value problems for the transformed quasi-neutral drift/diffusion equations:

$$\mathcal{Z}_t^0 = (\mathcal{Z}_x^0 + D\mathcal{E}^0)_x, \quad 0 < x < 1, \quad t > 0, \tag{21}$$

$$0 = -(D_x + \mathcal{Z}^0\mathcal{E}^0), \quad 0 < x < 1, \quad t > 0, \tag{22}$$

$$(\mathcal{Z}_x^0 + D\mathcal{E}^0)(0, 1; t) = 0, \quad t > 0, \tag{23}$$

$$\mathcal{Z}^0(x, 0) = z_0^0(x), \quad 0 \le x \le 1. \tag{24}$$

The existence of the above inner problem is guaranteed by the following proposition.

PROPOSITION 2. *Assume that $D \in C^{2(l+1)+1}$ and that $z_0^0 \in C^{2(l+1)}$ for some integer $l \ge 0$. Also assume that $z_0^0 \ge \delta_0 > 0$ satisfy the compatibility condition of order l for (21)–(24). Then there exist a $T_0 \in (0, +\infty]$ and a unique classical* *solution* $(\mathcal{Z}^0, \mathcal{E}^0)$*, well defined on* $[0,1] \times [0,T_0]$*, of* (21)–(24) *satisfying* $\mathcal{Z}^0, \mathcal{E}^0 \in C^{2(l+1),l+1}([0,1] \times [0,T_0])$ *and* $\mathcal{Z}^0(x,t) \geq \delta_1 > 0$ *on* $[0,1] \times [0,T_0]$ *for some positive constant* δ_1*. In particular, if* $D \in C^\infty([0,1])$ *and* $z_0^0 \in C^\infty([0,1])$ *satisfying the compatibility condition of any order, then* $\mathcal{Z}^0, \mathcal{E}^0 \in C^\infty([0,1] \times [0,T_0])$*.*

Moreover, if δ_0 *is suitably large, then* $T_0 = \infty$*.*

Proof of Proposition 2. The proof is elementary. For completeness, we outline it here. First, it follows from (80) that $\mathcal{E}^0(x,t) = -\frac{D_x}{\mathcal{Z}^0(x,t)}$. Then the problem (79)–(82) is reduced to the following system:

$$\mathcal{Z}_t^0 = \left(\mathcal{Z}_x^0 - \frac{DD_x}{\mathcal{Z}^0}\right)_x, \quad 0 < x < 1, \quad t > 0, \tag{25}$$

$$\left(\mathcal{Z}_x^0 - \frac{DD_x}{\mathcal{Z}^0}\right)(0,1;t) = 0, \quad t > 0, \tag{26}$$

$$\mathcal{Z}^0(x,0) = z_0^0(x), \quad 0 \leq x \leq 1. \tag{27}$$

For $z_0^0 \geq \delta_0 > 0$, the standard parabolic theory yields the desired local existence of classical positive solution $\mathcal{Z}^0$. This concludes the first part of Proposition 2.

To prove the global existence of large classical solutions for large initial data, one introduces the transformation

$$(\mathcal{Z}^0)^2 - D^2 = w. \tag{28}$$

Then it follows from the system (25)–(27) that w satisfies

$$w_t = w_{xx} - \frac{w_x^2 + 2DD_x w_x}{2(w + D^2)}, \quad 0 < x < 1, \quad t > 0, \tag{29}$$

$$w_x(0,1,t) = 0, \quad t > 0, \tag{30}$$

$$w(x,0) = w_0(x) = (z_0^0)^2 - D^2. \tag{31}$$

If $\delta_0 \geq \sqrt{D^2 + \delta_2}$ for some $\delta_2 > 0$, then $w_0 \geq \delta_2 > 0$.

By the standard parabolic theory [17], we know that there exists a unique, classical, and global solution w for (29)–(31) satisfying $0 < \delta_2 \leq w \in C^{2(l+1),l+1}([0,1] \times [0,T])$ for any $T > 0$. By transformation (28), we conclude the second part of Proposition 2. The proof of Proposition 2 is complete. ∎

Remark 2. By the transformation

$$n(x,t) = \frac{\mathcal{Z}^0(x,t) + D(x)}{2}, \quad p(x,t) = \frac{\mathcal{Z}^0(x,t) - D(x)}{2}, \quad \mathcal{E}(x,t) = \mathcal{E}^0(x,t)$$

it is easy to verify that the system (7)–(12) and the system (21)–(24) are equivalent. Thus, by Proposition 2, one obtains the existence of the classical nonvacuum solution of the quasi-neutral drift-diffusion system (7)–(12). The uniform positivity of $z_0^0(x)$, together with (12), excludes singularities of the solution of the quasi-neutral drift-diffusion system (7)–(12). Indeed, if $z_0^0(x) = D(x)$, then (21)–(24) has a stationary solution

$$\mathcal{Z}^0(x,t) = D(x), \quad \mathcal{E}^0 = -(lnD(x))_x.$$

In this case, the electric field $\mathcal{E}^0$ has a singularity in the vacuum set of the density $\mathcal{Z}^0$. In the present paper, the case of singular solutions of the quasi-neutral drift-diffusion models is thus not allowed due to our assumption that $z_0^0 \geq \delta_0 > 0$. But the singular solution case is interesting and will be investigated in the future.

Remark 3. Proposition 2 cannot hold true in the unipolar case. In fact, in the unipolar case we must have $z_0^0(x) = D(x)$ or $z_0^0(x) = -D(x)$ due to the local quasi-neutrality assumption (12) of the initial data, and hence we have no uniform positivity of $z_0^0(x)$ if the doping profile $D(x)$ changes sign. This comes back to the above vacuum singular solution case.

Next, the boundary layer functions z_B^i, E_B^0, $B = +/-$, $i = 0, 1, 2$, are governed by the following boundary value problems for the elliptic equations:

$$-E^0_{+,\xi\xi} = J^0_+, \quad -E^0_{-,\eta\eta} = J^0_-, \quad 0 < \xi, \quad \eta < \infty, \quad t > 0, \tag{32}$$

$$E^0_+(\xi = 0, t) = -\mathcal{E}^0(x = 0, t), \quad E^0_-(\eta = 0, t) = -\mathcal{E}^0(x = 1, t), \quad t > 0, \tag{33}$$

$$E^0_+(\xi \to \infty, t) = E^0_-(\eta \to \infty, t) = 0, \quad t > 0, \tag{34}$$

and

$$z^0_+ = z^0_- = z^2_+ = z^2_+ = 0, \quad 0 < \xi, \quad \eta < \infty, \quad t > 0, \tag{35}$$

$$z^1_{+,\xi} + D(0)E^0_+ = 0, \quad 0 < \xi, \quad \eta < \infty, \quad t > 0, \tag{36}$$

$$-z^1_{-,\eta} + D(1)E^0_- = 0, \quad 0 < \xi, \quad \eta < \infty, \quad t > 0, \tag{37}$$

$$z^0_+(\xi \to \infty, t) = z^0_-(\eta \to \infty, t) = 0, \quad t > 0, \tag{38}$$

where

$$J^0_+ = -\mathcal{Z}^0(0, t)E^0_+, \quad J^0_- = -\mathcal{Z}^0(1, t)E^0_-. \tag{39}$$

Finally, the initial layer functions z_I^i, $i = 0, 1, 2, E_I^0$, are given by the following equations (initial value problems):

$$E^0_{I,s} = J^0_I, \quad s > 0, \quad 0 < x < 1, \tag{40}$$

$$E^0_I(x, 0) = E^0_0(x) - \mathcal{E}^0(x, 0), \quad 0 < x < 1, \tag{41}$$

and

$$z^0_I = z^1_I = 0, \quad 0 < x < 1, \quad s > 0, \tag{42}$$

$$z^2_{I,s} = (DE^0_I)_x, \quad 0 < x < 1, \quad s > 0, \tag{43}$$

$$z^2_I(x, 0) = 0, \quad 0 < x < 1, \tag{44}$$

where

$$J^0_I = -\mathcal{Z}^0(x, 0)E^0_I. \tag{45}$$

It follows from the special structures of the boundary layer problem (32)–(38) and the initial layer problem (40)–(44) that the existence of solutions of these equations is immediate. We will solve these equations explicitly in section 3.

Define the error term $(z_R^\lambda, E_R^\lambda)^T$ of the approximation solution (20) to (14)–(17) with the initial datum

$$\begin{aligned}
&(z_0^\lambda, E_0^\lambda)^T \\
&\quad = \left(z_0^0(x) + \lambda\left(f(x)z^1_+\left(\frac{x}{\lambda}, 0\right) + g(x)z^1_-\left(\frac{1-x}{\lambda}, 0\right)\right) + \lambda z^\lambda_{0R}(x),\right. \\
&\qquad \left. E_0^0(x) + f(x)E^0_+ = \left(\frac{x}{\lambda}, 0\right) + g(x)E^0_-\left(\frac{1-x}{\lambda}, 0\right) + \lambda E^\lambda_{0R}(x)\right)^T
\end{aligned} \tag{46}$$

by

$$(z_R^\lambda(x,t), E_R^\lambda(x,t))^T = (z^\lambda, E^\lambda)^T - (z^\lambda, E^\lambda)^T_{app}. \tag{47}$$

THEOREM 3. *Let $l \geq 1$ and all assumptions of Proposition 2 hold. Assume also that the initial datum $(z_0^\lambda, E_0^\lambda)$ satisfies (46) with $E_0^0 \in C^{2(l+1)}([0,1])$,*

$$E_0^0(x)|_{x=0,1} = -\frac{D_x(x)}{z_0^0(x)}|_{x=0,1} (= \mathcal{E}^0(x = 0, 1, \quad t = 0)), \tag{48}$$

and

$$\|z_{0R}^\lambda(x)\|_{H^1} \leq M\sqrt{\lambda}, \quad \|\partial_x^2 z_{0R}^\lambda(x)\|_{L_x^2} \leq M\lambda^{-\frac{1}{2}}, \tag{49}$$

$$\|\partial_x^j E_{0R}^\lambda(x)\|_{L_x^2} \leq M\lambda^{\frac{1}{2}-j}, \quad j = 0, 1, 2. \tag{50}$$

Then, for any $T \in (0, T_0)$, where T_0 is given by Proposition 2, there exist positive constants M and $\lambda_0, \lambda_0 \ll 1$ such that, for any $\lambda \in (0, \lambda_0]$,

$$\sup_{0\leq t\leq T} \left(\|(z_R^\lambda, E_R^\lambda, z_{R,x}^\lambda, z_{R,t}^\lambda)\|_{L_x^2} + \lambda\|(E_R^\lambda, E_{R,x}^\lambda, E_{R,t}^\lambda)\|_{L_x^2} \right) \leq M\sqrt{\lambda^{1-\delta}} \tag{51}$$

for any δ with $0 < \delta < 1$.

In particular, if $(z_0^\lambda, E_0^\lambda)$ satisfies (46) with $(z_{0R}^\lambda, E_{0R}^\lambda) = (0, 0)$, then

$$\sup_{0\leq t\leq T} \|(z^\lambda - \mathcal{Z}^0)(\cdot, t)\|_{L_x^\infty} \leq M\sqrt{\lambda^{1-\delta}}.$$

Remark 4. The compatibility assumption (48) in Theorem 3 is important in our analysis. It guarantees that one can take the "well-prepared" initial datum (46) instead of the general initial datum (19), and hence the ansatz (20) is appropriate in this case while, generally speaking, its breakdown will introduce an extra layer $W_{IB}(x, \xi, \eta, s)$ of mixing of fast time and fast space scales. The main strategy involved here can be applied to this case too. This will be done in the future.

It should also be noted that assumptions (49) and (50) are just technical ones. In general, $(z_{0R}^\lambda, E_{0R}^\lambda)^T$ in (19) can be written as

$$(z_{0R}^\lambda, E_{0R}^\lambda)^T = (z_0^1(x), E_0^1(x))^T + (\tilde{z}_{0R}^\lambda, \tilde{E}_{0R}^\lambda)^T, \tag{52}$$

where

$$(\tilde{z}_{0R}^\lambda, \tilde{E}_{0R}^\lambda)^T = \lambda O(1). \tag{53}$$

Here $O(1)$ is a smooth bounded function in $x, \frac{x}{\lambda}, \frac{1-x}{\lambda}$, so that the general assumptions on the initial data become

$$\|(z_{0R}^\lambda - z_0^1)(x)\|_{H^1} \leq M\sqrt{\lambda}, \quad \|\partial_x^2(z_{0R}^\lambda - z_0^1)(x)\|_{L_x^2} \leq M\lambda^{-\frac{1}{2}}, \tag{54}$$

$$\|\partial_x^j(E_{0R}^\lambda - E_0^1)(x)\|_{L_x^2} \leq M\lambda^{\frac{1}{2}-j}, \quad j = 0, 1, 2. \tag{55}$$

In this case, it turns out that an additional correction term $\lambda(z_0^1, E_0^1)$, and hence an extra initial layer term $(\lambda^3 z_I^3, \lambda E_I^1)$, caused by z_0^1, will appear in the solution. Thus, we have more general results as follows.

THEOREM 4. *Under the assumptions of Theorem 3, with assumptions (49) and (50) replaced by (54) and (55) with $(z_0^1, E_0^1) \in C^3$, we have that, for any*

$T \in (0, T_0)$, where T_0 is given by Proposition 2, there exist positive constants M and $\lambda_0, \lambda_0 \ll 1$ such that, for any $\lambda \in (0, \lambda_0]$,

$$\sup_{0\le t\le T}\left(\|(\tilde z_R^\lambda, \tilde E_R^\lambda, \tilde z_{R,x}^\lambda, \tilde z_{R,t}^\lambda)\|_{L^2_x} + \lambda\|(\tilde E_R^\lambda, \tilde E_{R,x}^\lambda, \tilde E_{R,t}^\lambda)\|_{L^2_x}\right) \le M\sqrt{\lambda^{1-\delta}} \tag{56}$$

for any $\delta \in (0,1)$, where

$$\begin{aligned}(\tilde z_R^\lambda(x,t), \tilde E_R^\lambda(x,t))^T &= (z_R^\lambda(x,t), E_R^\lambda(x,t))^T - (\lambda z_0^1 + \lambda^3 z_I^3, \lambda(E_0^1 + E_I^1))^T\\ &= (z^\lambda, E^\lambda)^T - (z^\lambda, E^\lambda)^T_{app} - (\lambda z_0^1 + \lambda^3 z_I^3, \lambda(E_0^1 + E_I^1))^T.\end{aligned}$$

The initial layer functions z_I^3 and E_I^1 solve the following problems (initial value problems):

$$E^1_{I,s} = -\mathcal{Z}^0(x,0)E_I^1 - z_0^1(x)E_I^0, \quad s>0, \quad 0<x<1, \tag{57}$$

$$E_I^1(x,0) = 0, \quad 0<x<1, \tag{58}$$

and

$$z^3_{I,s} = (DE_I^1)_x, \quad 0<x<1, \quad s>0, \tag{59}$$

$$z_I^3(x,0) = 0, \quad 0<x<1. \tag{60}$$

Remark 5. It follows from Theorems 3 and 4 above that the approximation of vanishing space charge holds in the interior part of the parabolic domain, but it cannot be valid uniformly up to the boundary in the case where the doping profile changes its sign.

Remark 6. Note that our smoothness assumption on the doping profile D excludes so-called abrupt p-n junctions, where the doping profile has a jump discontinuity. An additional layer thus has to be introduced locally at abrupt junctions. This will be studied further in the future.

Remark 7. It should be noted that in Theorems 3 and 4 the quasi-neutral limits justified rigorously only in spatial L^2-norm. In order to justify this limit in supernorm, a more accurate ansatz than (20) has to be constructed by using higher order corrections. This is left for the future.

3. Approximate solutions and matched asymptotic analysis. In this section we derive the limit equation and the forms of the boundary layers and of the initial time layers by the multiple scaling asymptotic expansion of a singular perturbation with respect to the scaled Debye length.

Let us look for $W^\lambda = (z^\lambda, E^\lambda)^T$ of the form

$$W^\lambda = \sum_{i=0}^N \lambda^i W^i\left(x, \frac{x}{\lambda}, \frac{1-x}{\lambda}, t, \frac{t}{\lambda^2}\right) + W_R^\lambda(x,t),$$

where λ and λ^2 are the lengths of the boundary layer and of the initial time layer, respectively, and

$$W^i = W^i_{Inn}(x,t) + W^i_B(x,\xi,\eta,t) + W^i_I(x,s)$$

is the sum of an interior term W^i_{Inn}, the boundary layer term W^i_B near $x=0$ and $x=1$, and the initial time layer term W^i_I near $t=0$. Here we set $\xi = \frac{x}{\lambda}$, $\eta = \frac{1-x}{\lambda}$, $s = \frac{t}{\lambda^2}$, and $W = (z,E)^T$.

For simplicity of presentation, we will carry out the constructions of boundary layers $W_B^i = W_+^i(\xi, t)$ only near the left boundary, $x = 0$; the parts at $x = 1$ can be done similarly. Thus, we enforce

$$\lim_{\xi\to\infty} W_B(\xi, t) = 0. \tag{61}$$

In this section, without explicitly writing out the scaled variables, the functions marked by Inn, B, I, BI, and R are ones with respect to (x,t), (ξ,t), (x,s), (x,ξ,t,s), and (x,t). In the following we denote (z_{Inn}, E_{Inn}) by $(\mathcal{Z}, \mathcal{E})$.

Our primary interests lie in the rigorous justification of the quasi-neutral assumptions. Thus, we will ignore the higher corrections to the drift-diffusion equations. Hence, we impose the following decomposition for the solution (z^λ, E^λ) of (14)–(17):

$$\begin{aligned}(z^\lambda, E^\lambda)^T = \big(&\mathcal{Z}^0 + z_B^0 + z_I^0 + \lambda(z_B^1 + z_I^1) + \lambda^2(z_B^2 + z_I^2) + z_R^\lambda(x,t),\\ &\mathcal{E}^0 + E_B^0 + E_I^0 + E_R^\lambda(x,t)\big)^T.\end{aligned} \tag{62}$$

Thus, we obtain an approximation of the solution (z^λ, E^λ) of (14)–(17). The expansion (62) will satisfy the differential equations (14)–(15), the boundary condition (16), and the initial condition (17) for arbitrary "well-prepared" initial data $(z_0^\lambda, E_0^\lambda)$ satisfying (46).

Inserting (62) into (14) and (15), by direct computations one gets

$$\begin{aligned}\mathcal{Z}_t^0 &+ \sum_{i=0}^{2}\lambda^i z_{B,t}^i + \frac{1}{\lambda^2} z_{I,s}^0 + \frac{1}{\lambda} z_{I,s}^1 + z_{I,s}^2 + z_{R,t}^\lambda\\ &= \Big[(z_{R,x}^\lambda + DE_R^\lambda)_x + (\mathcal{Z}_x^0 + D\mathcal{E}^0)_x\\ &\quad + \frac{1}{\lambda}\left(\frac{1}{\lambda} z_{B,\xi}^0 + (z_{B,\xi}^1 + D(0)E_B^0) + \lambda z_{B,\xi}^2 + (D(\lambda\xi) - D(0))E_B^0\right)_\xi\\ &\quad + \sum_{i=0}^{2}\lambda^i z_{I,xx}^i + (DE_I^0)_x\Big] - \lambda^2\Big[K_{Inn}^0 + \tilde{K}_B + K_I^\lambda + \tilde{K}_{IB}^\lambda + \tilde{F}_R^\lambda\Big]_x\end{aligned} \tag{63}$$

and

$$\begin{aligned}&\lambda^2(\mathcal{E}_t^0 - \mathcal{E}_{xx}^0) + \big(E_{I,s}^0 - \lambda^2 E_{I,xx}^0\big) + \big(\lambda^2 E_{B,t}^0 - E_{B\xi\xi}^0\big) + \lambda^2(E_{R,t}^\lambda - E_{R,xx}^\lambda)\\ &\quad = J_{Inn}^0 + (\tilde{J}_B^0 + \tilde{J}_{BR}^0) + (J_I^0 + J_{IR}^0) + \tilde{J}_{BI}^0 + \sum_{i=1}^{2}\lambda^i\big(\tilde{J}_B^i + J_I^i + \tilde{J}_{BI}^i\big) + \tilde{G}_R^\lambda,\end{aligned} \tag{64}$$

where K_{Inn}^0, $\tilde{K}_B^i$, K_I^λ, $\tilde{K}_{IB}^\lambda$, and $\tilde{F}_R^\lambda$ are defined by

$$\begin{aligned}K_{Inn}^0 &= \mathcal{E}^0\mathcal{E}_x^0,\\ \tilde{K}_B^\lambda &= (\mathcal{E}^0(0,t) + E_B^0)E_{B,\xi}^0 + E_B^0\mathcal{E}_x^0(0,t)\\ &\quad + (\mathcal{E}^0(\lambda\xi,t) - \mathcal{E}^0(0,t))E_{B,\xi}^0 + E_B^0(\mathcal{E}_x^0(\lambda\xi,t) - \mathcal{E}_x^0(0,t)),\\ K_I^\lambda &= \big(\mathcal{E}^0(x,\lambda^2 s)E_{I,x}^0 + E_I^0(E_{Inn,x}^0(x,\lambda^2 s) + E_{I,x}^0)\big),\\ \tilde{K}_{IB}^\lambda &= E_B^0 E_{I,x}^0 + E_I^0\frac{1}{\lambda}E_{B,\xi}^0,\\ \tilde{F}_R^\lambda &= (\mathcal{E}^0 + E_B^0 + E_I^0)E_{R,x}^\lambda + E_R^\lambda\left(\mathcal{E}_x^0 + E_{B,\xi}^0\frac{1}{\lambda} + E_{I,x}^0\right) + E_{R,x}^\lambda,\end{aligned}$$

and $J^0_{Inn}, \tilde{J}^0_B, \tilde{J}^0_{BR}, J^0_I, J^0_{IR}, \tilde{J}^0_{BI}, \tilde{J}^i_B, J^i_I, \tilde{J}^i_{BI}$, $i = 1, 2$, and $\tilde{G}^\lambda_R$ are defined by the following:

$$
\begin{aligned}
J^0_{Inn} &= -(D_x + \mathcal{Z}^0\mathcal{E}^0),\\
\tilde{J}^0_B &= -(\mathcal{Z}^0(0,t)E^0_B + z^0_B(\mathcal{E}^0(0,t) + E^0_B)),\\
\tilde{J}^0_{BR} &= -\big((\mathcal{Z}^0 - \mathcal{Z}^0(0,t))E^0_B + z^0_B(\mathcal{E} - \mathcal{E}^0(0,t))\big),\\
J^0_I &= -\big(\mathcal{Z}^0(x,0)E^0_I + z^0_I(\mathcal{E}^0(x,0) + E^0_I)\big),\\
J^0_{IR} &= -\big((\mathcal{Z}^0 - \mathcal{Z}^0(x,0))E^0_I + z^0_I(\mathcal{E}^0 - \mathcal{E}^0(x,0))\big),\\
\tilde{J}^0_{BI} &= -(z^0_B E^0_I + z^0_I E^0_B),\\
\tilde{J}^i_B &= -z^i_B(\mathcal{E}^0 + E^0_B), \quad i = 1, 2,\\
J^i_I &= -z^i_I(\mathcal{E}^0 + E^0_I), \quad i = 1, 2,\\
\tilde{J}^i_{BI} &= -z^i_B E^0_I + z^i_I E^0_B, \quad i = 1, 2,
\end{aligned}
$$

and

$$
G^\lambda_R = -\left((\mathcal{E}^0 + E^0_B + E^0_I)z^\lambda_R + \left(\mathcal{Z}^0 + z^0_B + z^0_I + \sum_{i=1}^{2}\lambda^i(z^i_B + z^i_I)\right)E^\lambda_R\right) - z^\lambda_R E^\lambda_R.
$$

Similarly, inserting (62) into the boundary condition (16) yields an expansion at the boundary $x = 0$. Since the boundary expansion is expected to correct the boundary conditions of inner solutions to quasi-neutral drift-diffusion equations well, according to the expansion at the boundary $x = 0$ we may impose the following boundary conditions:

$$z^0_{B,\xi}(\xi = 0; t) = 0, \tag{65}$$

$$z^1_{B,\xi}(\xi = 0; t) = -\mathcal{Z}^0_x(x = 0; t), \tag{66}$$

$$z^2_{B,\xi}(\xi = 0; t) = 0, \tag{67}$$

$$E^0_B(\xi = 0; t) = -\mathcal{E}^0(x = 0; t). \tag{68}$$

Now we start to derive the equations of the inner solution $(\mathcal{Z}^0, \mathcal{E}^0)$ of the various orders of boundary layer and initial time layer functions in the above expansion (62) by comparing coefficients of $O(\lambda^k)$ of (63) and (64). At the leading order λ^{-2} of (63), one gets

$$z^0_{I,s}(x, s) = 0. \tag{69}$$

For z^0_I we take the initial data

$$z^0_I(x, 0) = 0. \tag{70}$$

The only solution of (69) and (70) is given as

$$z^0_I(x, s) = 0, \quad x \in [0, 1], \quad s \geq 0. \tag{71}$$

Similarly

$$z^0_{B,\xi\xi} = 0. \tag{72}$$

We also expect the decay condition at the infinity for z_B^0 such that

$$z_B^0(\xi, t) \to 0 \text{ as } \xi \to \infty. \tag{73}$$

The only solution of (65), (72), and (73) is given as

$$z_B^0(\xi, t) = 0, \quad \xi \geq 0, \quad t \geq 0, \tag{74}$$

which partially explains that the Neumann boundary condition of the density does not produce the boundary layer at the leading order.

At the order λ^{-1} of (63), one gets

$$z_{I,s}^1(x, s) = 0, \text{ hence } z_I^1 = 0, \quad x \in [0, 1], \quad s \geq 0, \tag{75}$$

since $z_I^1(x, 0) = 0$.

One also has from the order λ^{-1} of (63) that

$$z_{B,\xi\xi}^1 + D(0)E_{B,\xi}^0 = 0. \tag{76}$$

As before, we impose the decay condition at the infinity such that

$$z_B^1(\xi, t) \to 0, \quad E_B^0(\xi, t) \to 0 \quad \text{as } \xi \to \infty. \tag{77}$$

It follows from (76) and (77) that

$$z_{B,\xi}^1 + D(0)E_B^0 = 0. \tag{78}$$

Next, we determine the limit equations, which form a system satisfied by the first-order term $(\mathcal{Z}^0, \mathcal{E}^0)$ in the above expansion. At the order of λ^0 of (63) and (64), one gets

$$\mathcal{Z}_t^0 = (\mathcal{Z}_x^0 + D\mathcal{E}^0)_x, \quad 0 < x < 1, \quad t > 0, \tag{79}$$

$$0 = -(D_x + \mathcal{Z}^0\mathcal{E}^0), \quad 0 < x < 1, \quad t > 0. \tag{80}$$

This is nothing but the well-known quasi-neutral drift-diffusion model, which can be formally obtained by setting λ equal to zero in (14)–(15), too. In the context of semiconductor device physics, problems (79)–(80) are referred to as "space charge approximation."

Notice that (80) is an algebraic equation. If $\mathcal{Z}^0(x, t) \geq C_0 > 0$, then

$$\mathcal{E}^0(x, t) = -\frac{D_x(x)}{\mathcal{Z}^0(x, t)}.$$

Generally speaking, $\mathcal{E}^0(x, t)|_{x=0,1} \neq 0$, but $E^\lambda(x, t)|_{x=0,1} = 0$. Therefore, $\mathcal{E}^0(x, t)$ has to be supplemented by a boundary layer term there. Similarly, owing to the arbitrariness of the initial data $E_0^\lambda(x)$, there is an initial layer. Furthermore, it should be clear that the boundary and initial layers are caused by the electric field.

Now we supplement the limit equations (79)–(80) by the appropriate boundary conditions. According to conditions (66) and (68) and equation (78), one gets

$$\mathcal{Z}_x^0(x = 0, t) = -z_{B,\xi}^1(\xi = 0, t) = D(0)E_B^0(\xi = 0) = -D(0)\mathcal{E}^0(x = 0, t), \qquad t \geq 0,$$

i.e.,

$$\mathcal{Z}_x^0 + D(0)\mathcal{E}^0 = 0, \quad x = 0, \quad t \geq 0. \tag{81}$$

For the initial data of $\mathcal{Z}^0(x, t)$, we can take this as

$$\mathcal{Z}^0(x, 0) = z_0^0(x) \geq \delta > 0, \quad 0 \leq x \leq 1. \tag{82}$$

Here $z_0^0(x)$ is given by (19).

Finally, one also gets from the order λ^0 of (63) and (64) that

$$E^0_{I,s}(x,s) = J^0_I(x,s), \quad 0 \le x \le 1, \quad s \ge 0, \tag{83}$$

$$z^2_{I,s}(x,s) = (D(x)E^0_I)_x, \quad 0 \le x \le 1, \quad s \ge 0, \tag{84}$$

and

$$-E^0_{B,\xi\xi}(\xi,t) = \tilde{J}^0_B(\xi,t), \quad \xi > 0, \quad t > 0, \tag{85}$$

$$z^2_{B,\xi\xi} = 0, \quad \xi > 0, \quad t > 0. \tag{86}$$

The initial data of E^0_I can be taken as

$$E^0_I(x,0) = E^0_0(x) - \mathcal{E}^0(x,0), \quad 0 \le x \le 1. \tag{87}$$

The only solution to (83) and (87) can be given explicitly by

$$E^0_I(x,s) = (E^0_0(x) - \mathcal{E}^0(x,0)) \exp(-z^0_0(x)s). \tag{88}$$

The initial data of z^2_I are

$$z^2_I(x,0) = 0, \quad 0 \le x \le 1. \tag{89}$$

The unique solution of (84) and (89) can be given, using (88), by

$$\begin{aligned} z^2_I(x,s) &= \int_0^s (D(x)E^0_I)_x ds \\ &= b(x) + (b_0(x) + b_1(x)s) \exp\{-z^0_0(x)s\}, \quad 0 \le x \le 1, \quad s \ge 0, \end{aligned} \tag{90}$$

where $b(x)$, $b_0(x)$, and $b_1(x)$ depend only upon $D(x)$ and (z^0_0, E^0_0) and satisfy $b_0(x) = -b(x) \neq 0$.

For E^0_B, we impose the decay condition at infinity as

$$E^0_B(\xi,t) = 0 \text{ as } \xi \to \infty, \tag{91}$$

and we also take the boundary condition at $\xi = 0$ as

$$E^0_B(\xi = 0,t) = -\mathcal{E}^0(x = 0,t), \quad t > 0. \tag{92}$$

The unique solution of (85), (91), and (92) can be given by

$$E^0_B(\xi,t) = -\mathcal{E}^0(0,t) \exp(-\sqrt{\mathcal{Z}^0(0,t)}\xi). \tag{93}$$

For z^2_B, the decay condition at infinity is

$$z^2_B(\xi,t) = 0 \text{ as } \xi \to \infty. \tag{94}$$

Then the only solution of (86), (67), and (94) is given by

$$z^2_B(\xi,t) = 0, \quad \xi > 0, \quad t > 0. \tag{95}$$

Similarly, we can construct the boundary layer functions near $x = 1$ and hence deduce the similar boundary conditions of the inner solutions at $x = 1$.

We end this section by summarizing some properties of the boundary layers and the initial time layer and discussing their decay rate, which will be useful for the energy estimates in the next section.

Using (93), one gets from (78) and (77) that

$$\begin{aligned} z_B^1(\xi,t) &= -D(0)\mathcal{E}^0(0,t)\int_\xi^\infty e^{-\sqrt{\mathcal{Z}^0(0,t)}y}dy \\ &= -\frac{D(0)\mathcal{E}^0(0,t)}{\sqrt{\mathcal{Z}^0(0,t)}}e^{-\sqrt{\mathcal{Z}^0(0,t)}\xi}. \end{aligned} \tag{96}$$

Thus, we obtained exact formulae of all initial layer functions and the left boundary layer functions. In particular, we can determine the values of $z_B^1(\xi)$ and $E_B^0(\xi)$, depending only upon $D(0)$, $z_0^0(0)$, and $\mathcal{E}^0(0,0) = E_0^0(0)$, which are given by

$$\begin{aligned} z_B^1(\xi) &= z_B^1(x,0) \\ &= -\frac{D(0)E_0^0(0)}{\sqrt{z_0^0(0)}}e^{-\sqrt{z_0^0(0)}\xi}, \quad \xi > 0, \end{aligned} \tag{97}$$

$$E_B^0(\xi) = E_B^0(x,0) = -E_0^0(0)e^{-\sqrt{z_0^0(0)}\xi}, \quad \xi > 0. \tag{98}$$

Similarly, the right boundary layer functions at $x = 1$, denoted by $z_-^i(\eta,t)$, $i = 0,1,2, E_-^0(\eta,t)$, satisfy similar equations and have exactly the same properties as the left boundary layer functions $z_B^i(\xi,t)$, $i = 0,1,2, E_B^0(\xi,t)$ at $x = 0$, denoted by $z_+^i(\xi,t)$, $i = 0,1,2, E_+^0(\xi,t)$. We omit this.

Thus, we have the following properties of the boundary layer and initial layer functions.

LEMMA 5. (i) $z_+^0 = z_-^0 = z_+^2 = z_-^2 = z_I^0 = z_I^1 = 0$.

(ii) *Assume that the inner solution $(\mathcal{Z}^0,\mathcal{E}^0)$ is C^∞. Then,*

(a) *for any $T > 0$, there exists a positive constant M independent of λ such that*

$$\|\partial_t^{k_1}(\xi^{k_2}\partial_\xi^{k_3}(z_+^1,E_+^0),\eta^{k_4}\partial_\eta^{k_5}(z_-^1,E_-^0))\|_{L^\infty_{(x,t)}([0,1]\times[0,T])} \le M \tag{99}$$

and

$$\|\partial_t^{k_1}(\xi^{k_2}\partial_\xi^{k_3}(z_+^1,E_+^0),\eta^{k_4}\partial_\eta^{k_5}(z_-^1,E_-^0))\|_{L_t^\infty([0,T];L_x^2([0,1]))} \le M\lambda^{\frac{1}{2}} \tag{100}$$

for any nonnegative integer k_j, $j = 0,\dots,5$;

(b) *for any $T > 0$, there exists a positive constant M independent of λ such that*

$$\|\partial_x^{k_6}(z_I^2,s^{k_7}(\partial_s^{k_8}z_I^2,\partial_s^{k_9}E_I^0))\|_{L^\infty_{(x,t)}([0,1]\times[0,T])} \le M \tag{101}$$

and

$$\|\partial_x^{k_{10}}s^{k_{11}}(\partial_s^{k_{12}}z_I^2,\partial_s^{k_{13}}E_I^0)\|_{L_t^2([0,T];L_x^\infty([0,1]))} \le M\lambda \tag{102}$$

for any nonnegative integer k_j, $j = 6,7,9,10,11,13$, and any positive integers k_8,k_{12}.

4. Energy estimates. In this section we investigate the asymptotic behavior of the solution to the problem (14)–(17) as $\lambda \to 0$ and prove our main theorems, Theorems 3 and 4. From now on, we may assume $0 < \lambda \le 1$.

4.1. The proof of Theorem 3. In this subsection we prove Theorem 3 by a careful energy method based on the approximate solutions constructed in the previous section.

Let $\mathcal{Z}^0, \mathcal{E}^0, E_+^0, E_-^0, E_I^0, z_+^1, z_-^1, z_I^2$ be the functions constructed in the previous sections.

Let us assume

$$
\begin{aligned}
&(z^\lambda(x,0), E^\lambda(x,0))^T \\
&\quad = \left(z_0^0(x) + \lambda \left(f(x) z_+^1 \left(\frac{x}{\lambda}, 0\right) + g(x) z_-^1 \left(\frac{1-x}{\lambda}, 0\right)\right) + \lambda z_{0R}^\lambda(x), \right. \\
&\qquad \left. E_0^0(x) + f(x) E_+^0 \left(\frac{x}{\lambda}, 0\right) + g(x) E_-^0 \left(\frac{1-x}{\lambda}, 0\right) + \lambda E_{0R}^\lambda(x) \right)^T,
\end{aligned}
$$

where $f(x)$ and $g(x)$ are two smooth C^2 cut-off functions satisfying $f(0) = g(1) = 1$ and $f(1) = f'(1) = f''(1) = f'(0) = f''(0) = g(0) = g'(0) = g''(0) = g'(1) = g''(1) = 0$, and $(z_{0R}^\lambda, E_{0R}^\lambda)$ satisfies assumptions (49) and (50). In this case, one gets

$$
(z_R^\lambda, E_R^\lambda)^T(x,0) = \lambda (z_{0R}^\lambda(x), E_{0R}^\lambda(x))^T.
$$

Replacing $(z^\lambda, E^\lambda)^T$ by

$$
\begin{aligned}
(z^\lambda, E^\lambda)^T = &\Big(\mathcal{Z}^0 + \lambda (f(x) z_+^1 + g(x) z_-^1) + \lambda^2 z_I^2 + z_R^\lambda(x,t), \\
&\quad \mathcal{E}^0 + f(x) E_+^0 + g(x) E_-^0 + E_I^0 + E_R^\lambda(x,t) \Big)^T
\end{aligned} \tag{103}
$$

in the system (14)–(15) and using the equations of the inner solutions, the boundary layers, and the initial layers, one gets

$$
z_{R,t}^\lambda = H_x^\lambda + f^\lambda, \quad 0 < x < 1, \quad t > 0, \tag{104}
$$

$$
\lambda^2 (E_{R,t}^\lambda - E_{R,xx}^\lambda) + \mathcal{Z}^0 E_R^\lambda = g^\lambda, \quad 0 < x < 1, \quad t > 0, \tag{105}
$$

where

$$
\begin{aligned}
&H^\lambda = z_{R,x}^\lambda + D E_R^\lambda + H_{Inn} + H_B^\lambda + H_I^\lambda + H_{IB}^\lambda + H_R^\lambda, \\
&f^\lambda = -\lambda^1 (f(x) z_{+,t}^1 + g(x) z_{-,t}^1), \quad g^\lambda = G_{Inn} + G_B^\lambda + G_I^\lambda + G_{IB}^\lambda + G_R^\lambda,
\end{aligned}
$$

and H_{Inn} (G_{Inn}), H_B^λ (G_B^λ), H_I^λ (G_I^λ), H_{IB}^λ (G_{IB}^λ), H_R^λ (G_R^λ) represent the inner part, the boundary layer part, the initial layer part, the mixed boundary and initial layer part, and the error parts involving nonlinearities, respectively, and are defined by the following:

$$
H_{Inn}(x,t) = -\lambda^2 \mathcal{E}^0 \mathcal{E}_x^0,
$$

$$
\begin{aligned}
H_B^\lambda(x,t,\xi,\eta) = &\big((D(x) - D(0)) f(x) E_+^0 + (D(x) - D(1)) g(x) E_-^0 \big) \\
&+ \lambda \Big(f'(x) z_+^1 + g'(x) z_-^1 - \mathcal{E}^0 (f(x) E_{+,\xi}^0 - g(x) E_{-,\eta}^0) \\
&\qquad + (f(x) E_+^0 + g(x) E_-^0)(f(x) E_{+,\xi}^0 - g(x) E_{-,\eta}^0) \Big) \\
&+ \lambda^2 \Big(-\mathcal{E}^0 (f'(x) E_+^0 + g'(x) E_-^0) \\
&\qquad - (f(x) E_+^0 + g(x) E_-^0)(\mathcal{E}_x^0 + f'(x) E_+^0 + g'(x) E_-^0) \Big) \\
= &\Big((D(x) - D(0)) f(x) E_+^i + (D(x) - D(1)) g(x) E_-^i \Big) + \lambda \{\cdots\}_{HB}^R.
\end{aligned}
$$

Note that $\{\cdots\}_{HB}^{R}$ is the sum of the boundary layer functions z_+^1, z_-^1, E_+^0, E_-^0, $E_{+,\xi}^0$, $E_{-,\eta}^0$, $E_+^0E_+^0$, $E_-^0E_-^0$, $E_+^0E_-^0$, $E_+^0E_{+,\xi}^0$, $E_-^0E_{-,\eta}^0$, $E_+^0E_{-,\eta}^0$, and $E_-^0E_{+,\xi}^0$ with the coefficients consisting of $D(x)$, $f(x)$, $g(x)$, $\mathcal{E}^0$, $f'(x)$, $g'(x)$, and $\mathcal{E}_x^0$, and that $\{\cdots\}_{HB}^{R}$ does not depend upon the fast dielectric relaxation time scale. Hence, by (99) and (100), we easily obtain that there exists a constant M, independent of λ, such that

$$\|\{\cdots\}_{HB}^{R}(t)\|_{L_x^2}^2 + \int_0^t \|\partial_t\{\cdots\}_{HB}^{R}(t)\|_{L_x^2}^2 dt \le M\lambda, \tag{106}$$

$$\begin{aligned} H_I^\lambda(x,s) &= \lambda^2 z_{I,x}^2 - \lambda^2\big(\mathcal{E}^0E_I^0 + E_I^0(\mathcal{E}_x^0 + E_{I,x}^0)\big),\\ H_{IB}^\lambda(x,\xi,\eta,t,s) &= -\lambda\Big(E_I^0(f(x)E_{+,\xi}^0 - g(x)E_{-,\eta}^0)\Big)\\ &\quad -\lambda^2\Big(E_I^0(f'(x)E_+^0 + g'(x)E_-^0) + (f(x)E_+^0 + g(x)E_-^0)E_{I,x}^0\Big), \end{aligned}$$

$$\begin{aligned} H_R^\lambda &= -\lambda E_R^\lambda(f(x)E_{+,\xi}^0 - g(x)E_{-,\eta}^0)\\ &\quad -\lambda^2\Big((\mathcal{E}^0 + f(x)E_+^0 + g(x)E_-^0)E_{R,x}^\lambda + (\mathcal{E}_x^0 + f'(x)E_+^0 + g'(x)E_-^0)E_R^\lambda\Big)\\ &\quad -\lambda^2\big(E_I^0E_{R,x}^\lambda + E_{I,x}^0E_R^\lambda\big) - \lambda^2E_R^\lambda E_{R,x}^\lambda, \end{aligned}$$

$$G_{Inn}(x,t) = -\lambda^2\big(\mathcal{E}_t^0 - \mathcal{E}_{xx}^0\big),$$

$$\begin{aligned} G_B^\lambda(x,\xi,\eta,t) &= \Big(-f(x)(\mathcal{Z}^0(x,t) - \mathcal{Z}^0(0,t))E_+^0 - g(x)(\mathcal{Z}^0(x,t) - \mathcal{Z}^0(1,t))E_-^0\Big)\\ &\quad +\lambda\{\cdots\}_{GB}^{R}. \end{aligned}$$

Here $\{\cdots\}_{GB}^{R}$ is the sum of the boundary layer functions $z_{+,t}^1$, $z_{-,t}^1$, E_+^0, E_-^0, $E_{+,\xi}^0$, $E_{-,\eta}^0$, $z_+^1E_+^0$, $z_-^1E_-^0$, $z_+^1E_-^0$, and $z_-^1E_+^0$ with the coefficients consisting of $f(x)$, $g(x)$, $\mathcal{E}^0$, $f'(x)$, $g'(x)$, $f''(x)$, $g''(x)$, and $\mathcal{Z}^0$. Like $\{\cdots\}_{HB}^{R}$, $\{\cdots\}_{GB}^{R}$ does not depend upon the fast dielectric relaxation time scale, and hence it easily follows from (99) and (100) that there exists a constant M, independent of λ, such that

$$\|\{\cdots\}_{GB}^{R}(t)\|_{L_x^2}^2 + \int_0^t \|\partial_t\{\cdots\}_{GB}^{R}(t)\|_{L_x^2}^2 dt \le M\lambda, \tag{107}$$

$$\begin{aligned} G_I^\lambda &= (\mathcal{Z}^0 - \mathcal{Z}^0(x,0))E_I^0 + \lambda^2E_{I,xx}^0 + \lambda^2z_I^2(\mathcal{E}^0 + E_I^0),\\ G_{IB}^\lambda &= -\lambda(f(x)z_+^1 + g(x)z_-^1)E_I^0 - \lambda^2z_I^2(f(x)E_+^0 + g(x)E_-^0),\\ G_R^\lambda &= -(\mathcal{E}^0 + f(x)E_+^0 + g(x)E_-^0 + E_I^0)z_R^\lambda\\ &\quad -\lambda(f(x)z_+^1 + g(x)z_-^1)E_R^\lambda - \lambda^2z_I^2E_R^\lambda - z_R^\lambda E_R^\lambda. \end{aligned}$$

We now derive the boundary conditions for the error functions.

First, the assumption

$$E_0^0(x=0,1) = -\frac{D_x(x=0,1)}{z_0^0(x=0,1)} = \mathcal{E}^0(x=0,1;t=0),$$

together with the initial layer function (88), gives

$$E_I^0(x=0,1;t)=0, \quad t>0. \tag{108}$$

Then it follows from (17), (68), and (108) that

$$E_R^\lambda(x=0,1;t)=0, \quad t>0. \tag{109}$$

Next we claim that

$$H^\lambda(x=0,1;t)=0, \quad t>0. \tag{110}$$

In fact, we can rewrite $H^\lambda(x,t)$ as

$$\begin{aligned} H^\lambda &= z_{R,x}^\lambda + DE_R^\lambda + H_{Inn} + H_B^\lambda + H_I^\lambda + H_{IB}^\lambda + H_R^\lambda \\ &= z_{R,x}^\lambda + \lambda(f'(x)z_+^1 + g'(x)z_-^1) + \lambda^2 z_{I,x}^2 + f(x)(D(x)-D(0))E_+^0 \\ &\quad + g(x)(D(x)-D(1))E_-^0 + DE_R^\lambda - \lambda^2 E^\lambda E_x^\lambda. \end{aligned} \tag{111}$$

Then, by the definitions of cut-off functions $f(x)$ and $g(x)$, the boundary condition $E^\lambda(x=0,1;t)=0$, and (109), one gets from (111) that

$$H^\lambda(x=0,1;t)=(z_{R,x}^\lambda + \lambda^2 z_I^2)|_{x=0,1}. \tag{112}$$

Also, replacing z^λ by (103) in the boundary condition $z_x^\lambda(x=0,1;t)=0$ and using

$$z_{+,\xi}^1(\xi=0;t) = -\mathcal{Z}_x^0(x=0;t), \quad z_{-,\eta}^1(\eta=0;t)=\mathcal{Z}_x^0(x=1;t), \quad t>0,$$

one gets

$$(z_{R,x}^\lambda + \lambda^2 z_I^2)|_{x=0,1}=0,$$

which, together with (112), gives (110).

Now we start the energy estimates. In the following, we use c_i, δ_i, ϵ, and $M(\epsilon)$ or M to denote the constants which are independent of λ and may differ from one line to another.

First we derive the basic energy estimates on $(z_R^\lambda, E_R^\lambda)$.

LEMMA 6. *Under the assumptions of Theorem 3, we have*

$$\begin{aligned} &\|z_R^\lambda(t)\|_{L_x^2}^2 + \lambda^2\|E_R^\lambda(t)\|_{L_x^2}^2 + \int_0^t \|(z_{R,x}^\lambda, E_R^\lambda)\|_{L_x^2}^2 dt + \lambda^2 \int_0^t \|E_{R,x}^\lambda\|_{L_x^2}^2 dt \\ &\quad \le \|z_R^\lambda(x,0)\|_{L_x^2}^2 + \lambda^2 \|E_R^\lambda(x,0)\|_{L_x^2}^2 \\ &\qquad + M\int_0^t \|z_R^\lambda\|_{L_x^2}^2 dt + M\lambda^4 \int_0^t \|(E_R^\lambda, E_{R,x}^\lambda)\|_{L_x^2}^2 \|E_{R,x}^\lambda\|_{L_x^2}^2 dt \\ &\qquad + M\int_0^t \|(z_R^\lambda, z_{R,x}^\lambda)\|_{L_x^2}^2 \|E_R^\lambda\|_{L_x^2}^2 dt + M\lambda. \end{aligned} \tag{113}$$

Proof of Lemma 6. Multiplying (104) by z_R^λ and integrating the resulting equation over $[0,1]$ with respect to x, by (110) and integrations by parts one gets

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\|z_R^\lambda\|_{L_x^2}^2 &= -\int_0^1 H^\lambda z_{R,x}^\lambda dx + \int_0^1 f^\lambda z_R^\lambda dx \\ &= -\int_0^1 (z_{R,x}^\lambda + DE_R^\lambda) z_{R,x}^\lambda dx + \int_0^1 f^\lambda z_R^\lambda dx \\ &\quad - \int_0^1 (H_{Inn} + H_B^\lambda + H_I^\lambda + H_{IB}^\lambda + H_R^\lambda) z_{R,x}^\lambda dx. \end{aligned} \tag{114}$$

Now we estimate each term in the right-hand side of (114).

First, by the Cauchy–Schwarz inequality and the properties of the boundary layers, one gets

$$-\int_0^1 (z^\lambda_{R,x} + DE^\lambda_R) z^\lambda_{R,x} dx \le -\frac{1}{2}\|z^\lambda_{R,x}\|^2_{L^2_x} + M(\epsilon)\|E^\lambda_R\|^2_{L^2_x} \tag{115}$$

and

$$\int_0^1 f^\lambda z^\lambda_R dx \le M\|z^\lambda_R\|^2_{L^2_x} + M\|f^\lambda\|^2_{L^2_x} dx \le M\|z^\lambda_R\|^2_{L^2_x} + M\lambda^3. \tag{116}$$

Here we used $\|(z^1_{+,t}, z^1_{-,t})\|^2_{L^2_x} \le M\lambda$ due to (100).

Then, using the regularity of inner solutions, the properties (99) and (100) of boundary layer functions, the properties (101) and (102) of initial layer functions, and the definitions of H_{Inn}, H^λ_B, H^λ_I, and H^λ_{IB}, one easily gets

$$\|H_{Inn}\|^2_{L^2_x} + \|H^\lambda_B\|^2_{L^2_x} + \|H^\lambda_I\|^2_{L^2_x} + \|H^\lambda_{IB}\|^2_{L^2_x} \le M\lambda.$$

This, combined with the Cauchy–Schwarz inequality, yields

$$\begin{aligned} &-\int_0^1 (H_{Inn} + H^\lambda_B + H^\lambda_I + H^\lambda_{IB}) z^\lambda_{R,x} dx \\ &\le \epsilon\|z^\lambda_{R,x}\|^2_{L^2_x} + M(\epsilon)(\|H_{Inn}\|^2_{L^2_x} + \|H^\lambda_B\|^2_{L^2_x} + \|H^\lambda_I\|^2_{L^2_x} + \|H^\lambda_{IB}\|^2_{L^2_x}) \\ &\le \epsilon\|z^\lambda_{R,x}\|^2_{L^2_x} + M\lambda. \end{aligned} \tag{117}$$

Finally, for the nonlinear term, using $\mathcal{E}^0, \mathcal{E}^0_x \in C^0([0,1]\times[0,T])$, (99), and (101), one gets, with the aid of the Cauchy–Schwarz inequality and Sobolev's lemma, that

$$\begin{aligned} &\int_0^1 H^\lambda_R z^\lambda_{R,x} dx \\ &\quad \le \epsilon\|z^\lambda_{R,x}\|^2_{L^2_x} + M(\epsilon)\|H^\lambda_R\|^2_{L^2_x} \\ &\quad \le \epsilon\|z^\lambda_{R,x}\|^2_{L^2_x} + M\lambda^2\|E^\lambda_R\|^2_{L^2_x} + M\lambda^4\|E^\lambda_{R,x}\|^2_{L^2_x} + M\lambda^4\int_0^1 |E^\lambda_R E^\lambda_{R,x}|^2 dx \\ &\quad \le \epsilon\|z^\lambda_{R,x}\|^2_{L^2_x} + M\lambda^2\|E^\lambda_R\|^2_{L^2_x} + M\lambda^4\|E^\lambda_{R,x}\|^2_{L^2_x} \\ &\qquad + M\lambda^4\|(E^\lambda_R, E^\lambda_{R,x})\|^2_{L^2_x}\|E^\lambda_{R,x}\|^2_{L^2_x}. \end{aligned} \tag{118}$$

Thus, combining (114) with (115)–(118) and taking ϵ small enough, one gets

$$\begin{aligned} \frac{d}{dt}\|z^\lambda_R\|^2_{L^2_x} + c_1\|z^\lambda_{R,x}\|^2_{L^2_x} &\le M\|(z^\lambda_R, E^\lambda_R)\|^2_{L^2_x} + M\lambda^4\|E^\lambda_{R,x}\|^2_{L^2_x} \\ &\quad + M\lambda^4(\|(E^\lambda_R, E^\lambda_{R,x})\|^2_{L^2_x}\|E^\lambda_{R,x}\|^2_{L^2_x} + M\lambda. \end{aligned} \tag{119}$$

Integrating (119) with respect to t over $[0,t]$, one gets

$$\begin{aligned} &\|z^\lambda_R(t)\|^2_{L^2_x} + c_1\int_0^t \|z^\lambda_{R,x}\|^2_{L^2_x} dt \\ &\quad \le \|z^\lambda_R(x,0)\|^2_{L^2_x} + M\int_0^t \|(z^\lambda_R, E^\lambda_R)\|^2_{L^2_x} dt + M\lambda^4\int_0^t \|E^\lambda_{R,x}\|^2_{L^2_x} dt \\ &\qquad + M\lambda^4\int_0^t \|(E^\lambda_R, E^\lambda_{R,x})\|^2_{L^2_x}\|E^\lambda_{R,x}\|^2_{L^2_x} dt + M\lambda. \end{aligned} \tag{120}$$

Multiplying (105) by E_R^λ and integrating the resulting equation over $[0,1]$ with respect to x, by (109) and integrations by parts one gets

$$\frac{\lambda^2}{2}\frac{d}{dt}\|E_R^\lambda\|_{L_x^2}^2 + \lambda^2\|E_{R,x}^\lambda\|_{L_x^2}^2 + \int_0^1 \mathcal{Z}^0|E_R^\lambda|^2dx = \int_0^1 g^\lambda E_R^\lambda dx. \tag{121}$$

By the Cauchy–Schwarz inequality, we have

$$\int_0^1 g^\lambda E_R^\lambda dx \le \epsilon\|E_R^\lambda\|_{L_x^2}^2 + M(\epsilon)\|g^\lambda\|_{L_x^2}^2.$$

On one hand, noting that

$$\begin{aligned}
&\int_0^1 \left|(\mathcal{Z}^0(x,t) - \mathcal{Z}^0(x,0))E_I^0\left(x, \frac{t}{\lambda^2}\right)\right|^2 dx\\
&= \int_0^1 \left|\int_0^1 \partial_t\mathcal{Z}^0(x,t\theta)d\theta t \cdot E_I^0\left(x, \frac{t}{\lambda^2}\right)\right|^2 dx\\
&\le M\sup_{s\ge 0}\left(\max_{0\le x\le 1}|sE_I^0(x,s)|^2\right)\lambda^4\\
&\le M\lambda^4,
\end{aligned}$$

and using $\mathcal{Z}^0, \mathcal{E}^0 \in C^{2,1}([0,1]\times[0,T])$, (99), (100), (101), and (102), and the definitions of G_{Inn}, G_B^λ, G_I^λ, and G_{IB}^λ, we have

$$\int_0^1 (|G_{Inn}|^2 + |G_B^\lambda|^2 + |G_I^\lambda|^2 + |G_{IB}^\lambda|^2)dx \le M\lambda.$$

On the other hand, as in (118), with the aid of Sobolev's lemma we have that

$$\|G_R^\lambda\|_{L_x^2}^2 \le M\|z_R^\lambda\|_{L_x^2}^2 + M\lambda^2\|E_R^\lambda\|_{L_x^2}^2 + M\|(z_R^\lambda, z_{R,x}^\lambda)\|_{L_x^2}^2\|E_R^\lambda\|_{L_x^2}^2.$$

Thus

$$\int_0^1 g^\lambda E_R^\lambda dx \le \epsilon\|E_R^\lambda\|_{L_x^2}^2 + M\|z_R^\lambda\|_{L_x^2}^2 + M\lambda^2\|E_R^\lambda\|_{L_x^2}^2 + M\|(z_R^\lambda, z_{R,x}^\lambda)\|_{L_x^2}^2\|E_R^\lambda\|_{L_x^2}^2 + M\lambda. \tag{122}$$

Then, combining (121) with (122), using the positivity of $\mathcal{Z}^0$, taking ϵ small enough, and then restricting λ to be small enough, one gets

$$\begin{aligned}
&\lambda^2\frac{d}{dt}\|E_R^\lambda\|_{L_x^2}^2 + \lambda^2\|E_{R,x}^\lambda\|_{L_x^2}^2 + c_2\|E_R^\lambda\|_{L_x^2}^2\\
&\quad\le M\|z_R^\lambda\|_{L_x^2}^2 + M\|(z_R^\lambda, z_{R,x}^\lambda)\|_{L_x^2}^2\|E_R^\lambda\|_{L_x^2}^2 + M\lambda.
\end{aligned} \tag{123}$$

Integrating (123) with respect to t, one gets

$$\begin{aligned}
&\lambda^2\|E_R^\lambda(t)\|_{L_x^2}^2 + \lambda^2\int_0^t \|E_{R,x}^\lambda\|_{L_x^2}^2 dt + c_2\int_0^t \|E_R^\lambda\|_{L_x^2}^2 dt\\
&\quad\le \lambda^2\|E_R^\lambda(x,0)\|_{L_x^2}^2 + M\int_0^t \|z_R^\lambda\|_{L_x^2}^2 dt\\
&\qquad + M\int_0^t \|(z_R^\lambda, z_{R,x}^\lambda)\|_{L_x^2}^2\|E_R^\lambda\|_{L_x^2}^2 dt + M\lambda.
\end{aligned} \tag{124}$$

The desired estimate (113) follows from (120) and (124). This completes the proof of Lemma 6. ∎

Next we show the estimates of the time derivatives $\partial_t(z_R^\lambda, E_R^\lambda)$ of $(z_R^\lambda, E_R^\lambda)$.

LEMMA 7. *Under the assumptions of Theorem 3, we have*

(125)

$$\begin{aligned}
&\|z_{R,t}^\lambda(t)\|_{L_x^2}^2 + \lambda^2\|E_{R,t}^\lambda(t)\|_{L_x^2}^2 + \int_0^t \|(z_{R,xt}^\lambda, E_{R,t}^\lambda)\|_{L_x^2}^2 dt + \lambda^2\int_0^t \|E_{R,xt}^\lambda\|_{L_x^2}^2 dt\\
&\le M(\|z_{R,t}^\lambda(x,0)\|_{L_x^2}^2 + \lambda^2\|E_{R,t}^\lambda(x,0)\|_{L_x^2}^2)\\
&+ M\int_0^t \|(E_R^\lambda, z_R^\lambda, z_{R,t}^\lambda)\|_{L_x^2}^2 dt + M\lambda^2\int_0^t \|E_{R,t}^\lambda\|_{L_x^2}^2 dt + M\lambda^4\int_0^t \|(E_{R,x}^\lambda, E_{R,xt}^\lambda)\|_{L_x^2}^2 dt\\
&+ M\lambda^4\int_0^t \big(\|(E_{R,t}^\lambda, E_{R,xt}^\lambda)\|_{L_x^2}^2\|E_{R,x}\|_{L_x^2}^2 + \|E_R^\lambda\|_{L_x^2}^2\|E_{R,xt}^\lambda\|_{L_x^2}^2\big)dt\\
&+ M\int_0^t \big(\|(z_{R,t}^\lambda, z_{R,xt}^\lambda)\|_{L_x^2}^2\|E_R^\lambda\|_{L_x^2}^2 + \|(z_R^\lambda, z_{R,x}^\lambda)\|_{L_x^2}^2\|E_{R,t}^\lambda\|_{L_x^2}^2\big)dt + M\lambda.
\end{aligned}$$

Proof of Lemma 7. Differentiating (104) with respect to t, multiplying the resulting equations by $z_{R,t}^\lambda$, then integrating it over $[0,1]\times[0,t]$ and noting that H_t^λ also satisfies the same boundary condition as in (110), one gets by integration by parts that

$$\begin{aligned}
\|z_{R,t}^\lambda(t)\|_{L_x^2}^2 = \|z_{R,t}^\lambda(x,0)\|_{L_x^2}^2 &+ \int_0^t\int_0^1 f_t^\lambda z_{R,t}^\lambda dxdt - \int_0^t\int_0^1 (z_{R,xt}^\lambda + DE_{R,t}^\lambda)z_{R,xt}^\lambda dxdt\\
&- \int_0^t\int_0^1 H_{Inn,t} z_{R,xt}^\lambda dxdt - \int_0^t\int_0^1 H_{B,t}^\lambda z_{R,xt}^\lambda dxdt - \int_0^t\int_0^1 H_{I,t}^\lambda z_{R,xt}^\lambda dxdt\\
&- \int_0^t\int_0^1 H_{IB,t}^\lambda z_{R,xt}^\lambda dxdt - \int_0^t\int_0^1 H_{R,t}^\lambda z_{R,xt}^\lambda dxdt.
\end{aligned}\tag{126}$$

One needs to estimate the terms on the right in the above carefully.

First, it follows from the Cauchy–Schwarz inequality that

$$\int_0^t\int_0^1 (z_{R,xt}^\lambda + DE_{R,t}^\lambda)z_{R,xt}^\lambda dxdt \le -\frac{1}{2}\int_0^t \|z_{R,xt}^\lambda\|_{L_x^2}^2 dt + M\int_0^t \|E_{R,t}^\lambda\|_{L_x^2}^2 dt \tag{127}$$

and

$$\int_0^t\int_0^1 f_t^\lambda z_{R,t}^\lambda dxdt \le \epsilon\int_0^t \|z_{R,t}^\lambda\|_{L_x^2}^2 dt + M(\epsilon)\lambda^3, \tag{128}$$

since f^λ does not depend upon the fast time scale. Here we also used $\mathcal{Z}_{tt}^0, \mathcal{E}_{tt}^0 \in C^0([0,1]\times[0,T])$.

Similarly, since H_{Inn} and H_B^λ do not depend upon the fast time scale, $H_{Inn,t}$ and $H_{B,t}^\lambda$ have the same structures as H_{Inn} and $H_{B,t}$, respectively. Hence, using (106) one obtains in a similar way as for (117) that

$$\int_0^t\int_0^1 H_{Inn,t} z_{R,xt}^\lambda dxdt \le \epsilon\int_0^t \|z_{R,xt}^\lambda\|_{L_x^2}^2 dt + M\lambda^4 \tag{129}$$

and

$$\int_0^t\int_0^1 H_{B,t}^\lambda z_{R,xt}^\lambda dxdt \le \epsilon\int_0^t \|z_{R,xt}^\lambda\|_{L_x^2}^2 dt + M\lambda. \tag{130}$$

Here we used the regularity of the inner solutions $\mathcal{E}^0$, $\mathcal{E}^0_x$, $\mathcal{E}^0_t$, $\mathcal{E}^0_{xt}$, $\mathcal{Z}^0$, $\mathcal{Z}^0_x$, $\mathcal{Z}^0_t$, $\mathcal{Z}^0_{xt} \in C^0([0,1]\times[0,T])$.

Owing to the strong singularity of time derivatives of the initial layers, we must estimate the integrals involving initial layers carefully.

First, by the Cauchy–Schwarz inequality, we have

$$\int_0^t \int_0^1 H^\lambda_{I,t} z^\lambda_{R,xt} dxdt \le \epsilon \int_0^t \|z^\lambda_{R,xt}\|^2_{L^2_x} dt + M(\epsilon) \int_0^t \int_0^1 |H^\lambda_{I,t}|^2 dxdt.$$

But, by (101) and (102), one gets

$$\begin{aligned}
&\int_0^t \int_0^1 |H^\lambda_{I,t}|^2 dxdt \\
&\quad = \int_0^t \int_0^1 |z^2_{I,xs} - \lambda^2\big(\mathcal{E}^0_t(x,t)E^0_{I,x} + E^0_I \mathcal{E}^0_{xt}(x,t)\big) \\
&\qquad - \big(\mathcal{E}^0(x,t)E^0_{I,xs} + E^0_{I,s}(\mathcal{E}^0_x(x,t) + E^0_{I,x}) + E^0_I E^0_{I,xs}\big)|^2 dxdt \\
&\quad \le M \int_0^t \int_0^1 \Big(|z^2_{I,xs}|^2 + |E^0_{I,x}|^2 + |E^0_I|^2 + |E^0_{I,xs}|^2 + |E^0_{I,s}|^2\Big) dxdt \\
&\quad \le M\lambda^2.
\end{aligned}$$

Hence

$$\int_0^t \int_0^1 H^\lambda_{I,t} z^\lambda_{R,xt} dxdt \le \epsilon \int_0^t \|z^\lambda_{R,xt}\|^2_{L^2_x} + M\lambda^2. \tag{131}$$

Then, using the definition of H^λ_{IB}, we have

$$\begin{aligned}
&\int_0^t \int_0^1 H^\lambda_{IB,t} z^\lambda_{R,tx} dxdt \\
&\quad = \int_0^t \int_0^1 -\lambda\Big(E^0_I(f(x)E^0_{+,\xi} - g(x)E^0_{-,\eta})\Big)_t z^\lambda_{R,tx} dxdt \\
&\qquad + \int_0^t \int_0^1 \lambda^2 \partial_t \Big(\cdots\Big)^R_{HIB} z^\lambda_{R,xt} dxdt,
\end{aligned} \tag{132}$$

where $(\cdots)^R_{HIB}$ represents the remaining higher order term $O(\lambda^2)$ of H^λ_{IB}. By (101) and (102), one easily gets

$$\int_0^t \int_0^1 |\lambda^2 \partial_t \Big(\cdots\Big)^R_{HIB}|^2 dxdt \le M\lambda^3,$$

which leads to

$$\begin{aligned}
&\int_0^t \int_0^1 \lambda^2 \partial_t \Big(\cdots\Big)^R_{HIB} z^\lambda_{R,tx} dxdt \\
&\quad \le \epsilon \int_0^t \|z^\lambda_{R,xt}\|^2_{L^2_x} dt + M(\epsilon) \int_0^t \int_0^1 |\lambda^2 \partial_t \Big(\cdots\Big)^R_{HIB}|^2 dxdt \\
&\quad \le \epsilon \int_0^t \|z^\lambda_{R,xt}\|^2_{L^2_x} dt + M\lambda^3.
\end{aligned} \tag{133}$$

It remains to control the first term on the right-hand side of (132). Note that this singular integration is caused by the interactions between the boundary layer and the initial layer. So, to control it, we must use twofold integrals in the time and space directions to cancel the oscillation of the electric field. Indeed, it can be treated as follows:

$$
\begin{aligned}
&-\int_0^t\int_0^1 \lambda\Big(E_I^0(f(x)E^0_{+,\xi}-g(x)E^0_{-,\eta})\Big)_t z^\lambda_{R,tx}dxdt\\
&\quad= -\frac{1}{\lambda}\int_0^t\int_0^1 \Big(E^0_{I,s}(f(x)E^0_{+,\xi}-g(x)E^0_{-,\eta})\Big) z^\lambda_{R,tx}dxdt\\
&\qquad-\int_0^t\int_0^1 \lambda\Big(E_I^0(f(x)E^0_{+,\xi t}-g(x)E^0_{-,\eta t})\Big) z^\lambda_{R,tx}dxdt\\
&\quad\le \epsilon\int_0^t \|z^\lambda_{R,xt}\|^2_{L^2_x}dt+\frac{1}{\lambda^2}\int_0^t\int_0^1 |E^0_{I,s}(f(x)E^0_{+,\xi}-g(x)E^0_{-,\eta})|^2dxdt+M\lambda^5\\
&\quad\le \epsilon\int_0^t \|z^\lambda_{R,xt}\|^2_{L^2_x}dt+M\lambda, \qquad (134)
\end{aligned}
$$

where we have used

$$
\begin{aligned}
&\frac{1}{\lambda^2}\int_0^t\int_0^1 |E^0_{I,s}(f(x)E^0_{+,\xi}+g(x)E^0_{-,\eta})|^2dxdt\\
&\quad\le \frac{M}{\lambda^2}\int_0^t\int_0^1 |E^0_{I,s}|^2(|E^0_{+,\xi}|^2+|E^0_{-,\eta}|^2)dxdt\\
&\quad\le \frac{M}{\lambda^2}\int_0^t \max_{0\le x\le 1}|E^0_{I,s}|^2dt\Big(\int_0^1\max_{0\le t\le T}|E^0_{+,\xi}|^2dx+\int_0^1\max_{0\le t\le T}|E^0_{+,\xi}|^2dx\Big)\\
&\quad\le M\lambda.
\end{aligned}
$$

Combining (132) with (133) and (134), one gets

$$
\int_0^t\int_0^1 H^\lambda_{IB,t}z^\lambda_{R,xt}dxdt\le\int_0^t\|z^\lambda_{R,xt}\|^2_{L^2_x}dt+M\lambda. \qquad (135)
$$

Finally, we estimate the last integral on the right-hand side of (126). We split it into five parts:

$$
\int_0^t\int_0^1 H^\lambda_{R,t}z^\lambda_{R,xt}dxdt = I_1+I_2+I_3+I_4+I_5, \qquad (136)
$$

where

$$
\begin{aligned}
I_1=-\lambda\int_0^t\int_0^1\Big\{&\big(f(x)E^0_{+,\xi}-g(x)E^0_{-,\eta}\big)E^\lambda_{R,t}\\
&+\big(f(x)E^0_{+,\xi t}-g(x)E^0_{-,\eta t}\big)E^\lambda_R\Big\}z^\lambda_{R,xt}dxdt,
\end{aligned}
$$

$$
\begin{aligned}
I_2=-\lambda^2\int_0^t\int_0^1&\Big\{\big(\mathcal{E}^0+f(x)E^0_++g(x)E^0_-\big)E^\lambda_{R,xt}\\
&+\big(\mathcal{E}^0_t+f(x)E^0_{+,t}+g(x)E^0_{-,t}\big)E^\lambda_{R,x}+\big(\mathcal{E}^0_x+f'(x)E^0_++g'(x)E^0_-\big)E^\lambda_{R,t}\\
&+\big(\mathcal{E}^0_{xt}+f'(x)E^0_{+,t}+g'(x)E^0_{-,t}\big)E^\lambda_R\Big\}z^\lambda_{R,xt}dxdt,
\end{aligned}
$$

$$I_3 = -\lambda^2 \int_0^t \int_0^1 (E_I^0 E_{R,xt}^\lambda + E_{I,x}^0 E_{R,t}^\lambda) z_{R,xt}^\lambda dxdt,$$

$$I_4 = -\lambda^2 \int_0^t \int_0^1 (E_{R,t}^\lambda E_{R,x}^\lambda + E_R^\lambda E_{R,xt}^\lambda) z_{R,xt}^\lambda dxdt,$$

$$I_5 = -\int_0^t \int_0^1 (E_{I,s}^0 E_{R,x}^\lambda + E_{I,xs}^0 E_R^\lambda) z_{R,xt}^\lambda dxdt.$$

Noting that there are an λ factor in the first term I_1 of (136) and an λ^2 factor in the second and third terms I_2, I_3 of (136), by the Cauchy–Schwarz inequality, (99), (101), and the fact that $\mathcal{E}^0, \mathcal{E}_x^0, \mathcal{E}_t^0, \mathcal{E}_{xt}^0 \in C^0([0,1]\times[0,T])$, we have

$$I_1 \le \epsilon \int_0^t \|z_{R,xt}^\lambda\|_{L_x^2}^2 dt + M(\epsilon)\lambda^2 \int_0^t \|(E_R^\lambda, E_{R,t}^\lambda)\|_{L_x^2}^2 dt, \tag{137}$$

$$I_2 \le \epsilon \int_0^t \|z_{R,xt}^\lambda\|_{L_x^2}^2 dt + M(\epsilon)\lambda^4 \int_0^t \|(E_R^\lambda, E_{R,x}^\lambda, E_{R,t}^\lambda, E_{R,xt}^\lambda)\|_{L_x^2}^2 dt, \tag{138}$$

and

$$I_3 \le \epsilon \int_0^t \|z_{R,xt}^\lambda\|_{L_x^2}^2 dt + M(\epsilon)\lambda^4 \int_0^t \|(E_{R,t}^\lambda, E_{R,xt}^\lambda)\|_{L_x^2}^2 dt. \tag{139}$$

For the nonlinear term I_4 of (136), one gets by Sobolev's lemma that

$$\begin{aligned} I_4 &\le \epsilon \int_0^t \|z_{R,xt}^\lambda\|_{L_x^2}^2 + M(\epsilon)\lambda^4 \int_0^t \int_0^1 (|E_{R,t}^\lambda E_{R,x}^\lambda|^2 + |E_R^\lambda E_{R,xt}^\lambda|^2) dxdt \\ &\le \epsilon \int_0^t \|z_{R,xt}^\lambda\|_{L_x^2}^2 + M\lambda^4 \int_0^t (\|E_{R,t}^\lambda\|_{L_x^\infty}^2 \|E_{R,x}^\lambda\|_{L_x^2}^2 + \|E_R^\lambda\|_{L_x^\infty}^2 \|E_{R,xt}^\lambda\|_{L_x^2}^2) dt \\ &\le \epsilon \int_0^t \|z_{R,xt}^\lambda\|_{L_x^2}^2 \\ &\quad + M\lambda^4 \int_0^t \big(\|(E_{R,t}^\lambda, E_{R,xt}^\lambda)\|_{L_x^2}^2 \|E_{R,x}^\lambda\|_{L_x^2}^2 + \|E_R^\lambda\|_{L_x^2}^2 \|E_{R,xt}^\lambda\|_{L_x^2}^2) dt. \end{aligned} \tag{140}$$

It remains to estimate I_5. This is more difficult due to the lack of the uniform L^2 estimate of $E_{R,x}^\lambda$. This will be achieved by using the uniform boundedness on $\|s(E_{I,s}^0, E_{I,xs}^0)\|_{L_{(x,t)}^\infty([0,1]\times[0,T])}$ and employing Hardy–Littlewood's inequality. In fact, by the Cauchy–Schwarz inequality, one gets

(141)

$$\begin{aligned} I_5 &\le \epsilon \int_0^t \|z_{R,xt}^\lambda\|_{L_x^2}^2 dt + M(\epsilon) \int_0^t \int_0^1 |E_{I,s}^0 E_{R,x}^\lambda + E_{I,xs}^0 E_R^\lambda|^2 dxdt \\ &= \epsilon \int_0^t \|z_{R,xt}^\lambda\|_{L_x^2}^2 dt + M(\epsilon) \int_0^t \int_0^1 \Bigg| t\Bigg(E_{I,s}^0 \frac{E_{R,x}^\lambda - E_{R,x}^\lambda(x,0)}{t} \\ &\qquad + E_{I,xs}^0 \frac{E_R^\lambda - E_R^\lambda(x,0)}{t} \Bigg) + \big(E_{I,s}^0 E_{R,x}^\lambda(x,0) + E_{I,xs}^0 E_R^\lambda(x,0)\big) \Bigg|^2 dxdt \end{aligned}$$

$$
\begin{aligned}
&= \epsilon \int_0^t \|z^\lambda_{R,xt}\|^2_{L^2_x} dt + M(\epsilon) \int_0^t \int_0^1 \Bigg| \lambda^2 s \Bigg(E^0_{I,s} \frac{E^\lambda_{R,x} - E^\lambda_{R,x}(x,0)}{t} \\
&\quad + E^0_{I,xs} \frac{E^\lambda_R - E^\lambda_R(x,0)}{t} \Bigg) + (E^0_{I,s} E^\lambda_{R,x}(x,0) + E^0_{I,xs} E^\lambda_R(x,0)) \Bigg|^2 dxdt \\
&\le \epsilon \int_0^t \|z^\lambda_{R,xt}\|^2_{L^2_x} dt \\
&\quad + M\lambda^4 \max_{0\le s\le\infty} \max_{0\le x\le 1} (s|E^0_{I,s}| + s|E^0_{I,xs}|)^2 \int_0^1 \int_0^t \Bigg(\Big|\frac{E^\lambda_{R,x} - E^\lambda_{R,x}(x,0)}{t}\Big|^2 \\
&\quad + \Big|\frac{E^\lambda_R - E^\lambda_R(x,0)}{t}\Big|^2 \Bigg) dtdx + M \int_0^t \int_0^1 (|E^0_{I,s} E^\lambda_{R,x}(x,0)|^2 + |E^0_{I,xs} E^\lambda_R(x,0)|^2) dxdt \\
&\le \epsilon \int_0^t \|z^\lambda_{R,xt}\|^2_{L^2_x} dt + M\lambda^4 \int_0^1 \left(\int_0^t |E^\lambda_{R,xt}|^2 dt + \int_0^t |E^\lambda_{R,t}|^2 dt \right) dx + M\lambda \\
&\le \epsilon \int_0^t \|z^\lambda_{R,xt}\|^2_{L^2_x} dt + M\lambda^4 \int_0^t \|(E^\lambda_{R,xt}, E^\lambda_{R,t})\|^2_{L^2_x} dt + M\lambda.
\end{aligned}
$$

Here we have used

$$
\begin{aligned}
&\int_0^t \int_0^1 (|E^0_{I,s} E^\lambda_{R,x}(x,0)|^2 + |E^0_{I,xs} E^\lambda_R(x,0)|^2) dxdt \\
&\qquad \le M\lambda^2 \left(\|E^\lambda_{0R,x}\|^2_{L^\infty_x} \int_0^t \int_0^1 |E^0_{I,s}|^2 dxdt + \|E^\lambda_{0R}\|^2_{L^\infty_x} \int_0^t \int_0^1 |E^0_{I,xs}|^2 dxdt \right) \\
&\qquad \le M\lambda^4 ((M\lambda^{\frac{1}{2}-2})^2 + (M\lambda^{\frac{1}{2}-1})^2) \\
&\qquad \le M\lambda,
\end{aligned}
$$

due to Sobolev's lemma; (102) and the assumption (50);

$$
\begin{aligned}
&\max_{0\le s\le\infty} \max_{0\le x\le 1} (s|E^0_{I,s}| + s|E^0_{I,xs}|) \\
&\qquad = \max_{0\le t\le T} \max_{0\le x\le 1} \left(\frac{t}{\lambda^2} \left(|E^0_{I,s}\left(x, \frac{t}{\lambda^2}\right)| + |E^0_{I,xs}\left(x, \frac{t}{\lambda^2}\right)| \right) \right) \\
&\qquad \le M \max_{0\le t\le T} \left(\left(\frac{t}{\lambda^2} \right) e^{-\delta \frac{t}{\lambda^2}} \right) \\
&\qquad \le M;
\end{aligned}
$$

and the fact that $(E^\lambda_R - E^\lambda_R(x,0))(x,0) = 0$ and hence $(E^\lambda_{R,x} - E^\lambda_{R,x}(x,0))(x,0) = 0$. We have also applied Hardy–Littlewood's inequality to control $\int_0^t |\frac{E^\lambda_{R,x} - E^\lambda_{R,x}(x,0)}{t}|^2 dt$ and $\int_0^t |\frac{E^\lambda_R - E^\lambda_R(x,0)}{t}|^2 dt$ by $\int_0^t |E^\lambda_{R,xt}|^2 dt$ and $\int_0^t |E^\lambda_{R,t}|^2 dt$, respectively.

Combining (136) with (137)–(142), one gets

$$
\begin{aligned}
&\int_0^t \int_0^1 H^\lambda_{R,t} z^\lambda_{R,xt} dxdt \\
&\quad \le \epsilon \int_0^t \|z^\lambda_{R,xt}\|^2_{L^2_x} dt + M\lambda^2 \int_0^t \|(E^\lambda_R, E^\lambda_{R,t})\|^2_{L^2_x} dt + M\lambda^4 \int_0^t \|(E^\lambda_{R,x}, E^\lambda_{R,xt})\|^2_{L^2_x} dt \\
&\quad + M\lambda^4 \int_0^t \left(\|(E^\lambda_{R,t}, E^\lambda_{R,xt})\|^2_{L^2_x} \|E^\lambda_{R,x}\|^2_{L^2_x} + \|E^\lambda_R\|^2_{L^2_x} \|E^\lambda_{R,xt}\|^2_{L^2_x} \right) dt + M\lambda^2.
\end{aligned} \tag{142}
$$

Therefore, putting (126) and estimates (127), (128), (129), (130), (131), (135), and (142) together and taking ϵ small enough, one shows that

$$\begin{aligned}&\|z^\lambda_{R,t}(t)\|^2_{L^2_x}+c_3\int_0^t\|z^\lambda_{R,xt}\|^2_{L^2_x}dt\\&\quad\le\|z^\lambda_{R,t}(x,0)\|^2_{L^2_x}+M\int_0^t\|(z^\lambda_{R,t},E^\lambda_{R,t})\|^2_{L^2_x}dt\\&\quad\quad+M\lambda^2\int_0^t\|E^\lambda_R\|^2_{L^2_x}dt+M\lambda^4\int_0^t\|(E^\lambda_{R,x},E^\lambda_{R,xt})\|^2_{L^2_x}dt\\&\quad\quad+M\lambda^4\int_0^t\big(\|(E^\lambda_{R,t},E^\lambda_{R,xt})\|^2_{L^2_x}\|E_{R,x}\|^2_{L^2_x}+\|E^\lambda_R\|^2_{L^2_x}\|E^\lambda_{R,xt}\|^2_{L^2_x}\big)dt+M\lambda.\end{aligned}\tag{143}$$

Note that $E^\lambda_{R,t}$ also satisfies the same boundary condition as in (109). Thus, differentiating (104) with respect to t, multiplying the resulting equations by $z^\lambda_{R,t}$, and then integrating it over $[0,1]\times[0,t]$, one gets by integrations by parts that

$$\begin{aligned}&\frac{\lambda^2}{2}\|E^\lambda_{R,t}(t)\|^2_{L^2_x}+\lambda^2\int_0^t\|E^\lambda_{R,xt}\|^2_{L^2_x}dt+\int_0^t\int_0^1\mathcal{Z}^0|E^\lambda_{R,t}|^2dxdt\\&\quad=\frac{\lambda^2}{2}\|E^\lambda_{R,t}(x,0)\|^2_{L^2_x}-\int_0^t\int_0^1\mathcal{Z}^0_tE^\lambda_RE^\lambda_{R,t}dxdt+\int_0^t\int_0^1g^\lambda_tE^\lambda_{R,t}dxdt.\end{aligned}\tag{144}$$

First, by the Cauchy–Schwarz inequality, one gets

$$-\int_0^t\int_0^1\mathcal{Z}^0_tE^\lambda_RE^\lambda_{R,t}dxdt\le\epsilon\int_0^t\|E^\lambda_{R,t}\|^2_{L^2_x}dt+M(\epsilon)\int_0^t\|E^\lambda_R\|^2_{L^2_x}dt\tag{145}$$

and

$$\begin{aligned}&\int_0^t\int_0^1g^\lambda_tE^\lambda_{R,t}dxdt\\&\quad\le\epsilon\int_0^t\|E^\lambda_{R,t}\|^2_{L^2_x}dt+M(\epsilon)\int_0^t\|g^\lambda\|^2_{L^2_x}dt\\&\quad\le\epsilon\int_0^t\|E^\lambda_{R,t}\|^2_{L^2_x}dt+M\Bigg(\int_0^t\int_0^1|G_{Inn,t}|^2dxdt+\int_0^t\int_0^1|G^\lambda_{B,t}|^2dxdt\\&\quad\quad+\int_0^t\int_0^1|G^\lambda_{I,t}|^2dxdt+\int_0^t\int_0^1|G^\lambda_{IB,t}|^2dxdt+\int_0^t\int_0^1|G^\lambda_{R,t}|^2dxdt\Bigg).\end{aligned}\tag{146}$$

Now we treat each term on the right-hand side of (146).

Using the structures of the inner solutions $\mathcal{E}^0_{tt}$, $\mathcal{E}^0_{xxt}\in C^0([0,1]\times[0,T])$, one can get

$$\int_0^t\int_0^1|G_{Inn,t}|^2dxdt\le M\lambda^4.\tag{147}$$

Since $G^\lambda_{B,t}$ has the same structure as G^λ_B, one can estimate the third term of (146) by (107) as

$$\int_0^t\int_0^1|G^\lambda_{B,t}|^2dxdt\le M\lambda.\tag{148}$$

Using the definition of G_I^λ, we have

$$\begin{aligned}
&\int_0^t\int_0^1 |G^\lambda_{I,t}|^2 dxdt\\
&\quad\le \int_0^t\int_0^1 |E^0_{I,xxs}|^2 dxdt + J_{IR}\\
&\quad\le M\lambda^2 + J_{IR}, \qquad (149)
\end{aligned}$$

where

$$\begin{aligned}
J_{IR} = &\int_0^t\int_0^1 |z^2_{I,s}(\mathcal{E}^0+E^0_I) + z^2_I E^0_{I,s}|^2 dxdt + \int_0^t\int_0^1 \big(|\lambda^2 z^2_I \mathcal{E}^0_t|^2 + |\mathcal{Z}^0_t E^0_I|^2\big)dxdt\\
&+\int_0^t\int_0^1 |\lambda^{-2}(\mathcal{Z}^0-\mathcal{Z}^0(x,0))E^0_{I,s}|^2 dxdt.
\end{aligned}$$

Using $\|z^2_I\|_{L^\infty_{x,t}} \le M$ and $\|(z^2_{I,s}, E^0_I, E^0_{I,s})\|_{L^2_t(L^\infty_x)} \le M\lambda$, one gets

$$J_{IR} \le M\lambda^2 + \int_0^t\int_0^1 |\lambda^{-2}(\mathcal{Z}^0-\mathcal{Z}^0(x,0))E^0_{I,s}|^2 dxdt. \qquad (150)$$

To estimate the remaining singular term on the right-hand side of (150), we will use the higher regularity of $\mathcal{Z}^0_t$. It will follow from the mean value theorem and (102) that

$$\begin{aligned}
&\int_0^t\int_0^1 |\lambda^{-2}(\mathcal{Z}^0-\mathcal{Z}^0(x,0))E^0_{I,s}|^2 dxdt\\
&\quad= \int_0^t\int_0^1 \Big|\int_0^1 \mathcal{Z}^0_t(x,t\theta)d\theta \frac{t}{\lambda^2} E^0_{I,s}\left(x,\frac{t}{\lambda^2}\right)\Big|^2 dxdt\\
&\quad\le M\int_0^t\int_0^1 \Big(\frac{t}{\lambda^2}\Big)^2 \Big|E^0_{I,s}\left(x,\frac{t}{\lambda^2}\right)\Big|^2 dxdt\\
&\quad\le M\lambda^2. \qquad (151)
\end{aligned}$$

Thus,

$$J_{IR} \le M\lambda^2. \qquad (152)$$

Therefore,

$$\int_0^t\int_0^1 |G^\lambda_{I,t}|^2 dxdt \le M\lambda^2. \qquad (153)$$

The fifth term of (146) can be treated as in (132) so that

$$\begin{aligned}
&\int_0^t\int_0^1 |G^\lambda_{IB,t}|^2 dxdt\\
&\quad= \int_0^t\int_0^1 \Big|\lambda\Big(\big(f(x)z^1_+ + g(x)z^1_-\big)E^0_I\Big)_t + \lambda^2\partial_t\Big(\cdots\Big)^R_{GIB}\Big|^2 dxdt\\
&\quad\le \frac{M}{\lambda^2}\int_0^t\int_0^1 (|z^1_+E^0_{I,s}|^2 + |z^1_-E^0_{I,s}|^2)dxdt + M\lambda^2\\
&\quad\le M\lambda. \qquad (154)
\end{aligned}$$

To estimate the sixth term of (146), we split it into four parts:

$$\int_0^t \int_0^1 G^\lambda_{R,t} E^\lambda_{R,t} dxdt = I_6 + I_7 + I_8 + I_9, \tag{155}$$

where

$$\begin{aligned} I_6 = -\int_0^t \int_0^1 \big\{ &(\mathcal{E}^0_t + f(x)E^0_{+,t} + g(x)E^0_{-,t}) z^\lambda_R \\ &+ (\mathcal{E}^0 + f(x)E^0_+ + g(x)E^0_- + E^0_I) z^\lambda_{R,t} \\ &+ (\mathcal{Z}^0_t + \lambda(f(x)z^1_{+,t} + g(x)z^1_{-,t})) E^\lambda_R \big\} E^\lambda_{R,t} dxdt, \end{aligned}$$

$$I_7 = -\int_0^t \int_0^1 (\mathcal{Z}^0 + \lambda(f(x)z^1_+ + g(x)z^1_-) + \lambda^2 z^2_I) E^\lambda_{R,t} E^\lambda_{R,t} dxdt,$$

$$I_8 = -\int_0^t \int_0^1 (z^\lambda_{R,t} E^\lambda_R + z^\lambda_R E^\lambda_{R,t}) E^\lambda_{R,t} dxdt,$$

and

$$I_9 = -\frac{1}{\lambda^2} \int_0^t \int_0^1 (E^0_{I,s} z^\lambda_R + \lambda^2 z^2_{I,s} E^\lambda_R) E^\lambda_{R,t} dxdt.$$

First I_6, I_7, and I_8 are treated as in (137)–(140) so that

$$I_6 + I_7 \le \epsilon \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt + M \int_0^t \|(z^\lambda_R, z^\lambda_{R,t}, E^\lambda_R)\|^2_{L^2_x} dt + M\lambda^2 \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt \tag{156}$$

and

$$\begin{aligned} I_8 &\le \epsilon \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt + M(\epsilon) \int_0^t \int_0^1 (|z^\lambda_{R,t} E^\lambda_R|^2 + |z^\lambda_R E^\lambda_{R,t}|^2) dxdt \\ &\le \epsilon \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt + M(\epsilon) \int_0^t (\|z^\lambda_{R,t}\|^2_{L^\infty} \|E^\lambda_R\|^2_{L^2_x} + \|z^\lambda_R\|^2_{L^\infty_x} \|E^\lambda_{R,t}\|^2_{L^2_x}) dt \\ &\le \epsilon \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt \\ &\quad + M \int_0^t \big(\|(z^\lambda_{R,t}, z^\lambda_{R,xt})\|^2_{L^2_x} \|E^\lambda_R\|^2_{L^2_x} + \|(z^\lambda_R, z^\lambda_{R,x})\|^2_{L^2_x} \|E^\lambda_{R,t}\|^2_{L^2_x} \big) dt. \end{aligned} \tag{157}$$

Now we treat the most singular term I_9 by employing the Hardy–Littlewood inequality.

$$\begin{aligned} I_9 &= -\frac{1}{\lambda^2} \int_0^t \int_0^1 (E^0_{I,s} z^\lambda_R + \lambda^2 z^2_{I,s} E^\lambda_R) E^\lambda_{R,t} dxdt \\ &= -\frac{1}{\lambda^2} \int_0^t \int_0^1 t \left(E^0_{I,s} \frac{z^\lambda_R - z^\lambda_R(x,0)}{t} + \lambda^2 z^2_{I,s} \frac{E^\lambda_R - E^\lambda_R(x,0)}{t} \right) E^\lambda_{R,t} dxdt \\ &\quad - \frac{1}{\lambda^2} \int_0^t \int_0^1 (E^0_{I,s} z^\lambda_R(x,0) + \lambda^2 z^2_{I,s} E^\lambda_R(x,0)) E^\lambda_{R,t} dxdt \end{aligned} \tag{158}$$

$$
\begin{aligned}
&\leq \int_0^t \int_0^1 \Bigg(\|sE^0_{I,s}\|_{L^\infty_{(x,t)}} \Big|\frac{z^\lambda_R - z^\lambda_R(x,0)}{t}\Big| |E^\lambda_{R,t}| \\
&\quad + \lambda^2 \|sz^2_{I,s}\|_{L^\infty_{(x,t)}} \Big|\frac{E^\lambda_R - E^\lambda_R(x,0)}{t}\Big| |E^\lambda_{R,t}| \Bigg) dxdt \\
&\quad + \frac{1}{\lambda^2} \int_0^t \int_0^1 |(E^0_{I,s} z^\lambda_R(x,0) + \lambda^2 z^2_{I,s} E^\lambda_R(x,0)) E^\lambda_{R,t}| dxdt \\
&\leq M \int_0^1 \Big\|\frac{z^\lambda_R - z^\lambda_R(x,0)}{t}\Big\|_{L^2_t} \|E^\lambda_{R,t}\|_{L^2_t} dx + M\lambda^2 \int_0^1 \Big\|\frac{E^\lambda_R - E^\lambda_R(x,0)}{t}\Big\|_{L^2_t} \|E^\lambda_{R,t}\|_{L^2_t} dx \\
&\quad + \frac{\epsilon}{2} \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt + \frac{M}{\lambda^4} \int_0^t \int_0^1 |E^0_{I,s} z^\lambda_R(x,0)|^2 dxdt + M \int_0^t \int_0^1 |z^2_{I,s} E^\lambda_R(x,0)|^2 dxdt \\
&\leq \frac{\epsilon}{2} \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt + M \int_0^1 \|z^\lambda_{R,t}\|_{L^2_t} \|E^\lambda_{R,t}\|_{L^2_t} dx + M\lambda^2 \int_0^1 \|E^\lambda_{R,t}\|_{L^2_t} \|E^\lambda_{R,t}\|_{L^2_t} dx \\
&\quad + \frac{M}{\lambda^4} \|z^\lambda_R(x,0)\|^2_{L^\infty_x} \int_0^t \int_0^1 |E^0_{I,s}|^2 dxdt + M \|E^\lambda_R(x,0)\|^2_{L^\infty_x} \int_0^t \int_0^1 |z^2_{I,s}|^2 dxdt \\
&\leq (\epsilon + M\lambda^2) \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt + M(\epsilon) \int_0^t \|z^\lambda_{R,t}\|^2_{L^2_x} dt + M\lambda.
\end{aligned}
$$

Here we used the fact that $\|z^\lambda_R(x,0)\|_{L^\infty_x} = \lambda \|z^\lambda_{0R}\|_{L^\infty_x} \leq M\lambda^{\frac{3}{2}}$ and $\|E^\lambda_R(x,0)\|_{L^\infty_x} = \lambda \|E^\lambda_{0R}\|_{L^\infty_x} \leq M$.

Hence, combining (155) with (156)–(158), one gets

$$
\begin{aligned}
&\int_0^t \int_0^1 G^\lambda_{R,t} E^\lambda_{R,t} dxdt \\
&\quad \leq (\epsilon + M\lambda^2) \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt + M \int_0^t \|(z^\lambda_R, z^\lambda_{R,t}, E^\lambda_R)\|^2_{L^2_x} dt \\
&\qquad + M \int_0^t \big(\|(z^\lambda_{R,t}, z^\lambda_{R,xt})\|^2_{L^2_x} \|E^\lambda_R\|^2_{L^2_x} + \|(z^\lambda_R, z^\lambda_{R,x})\|^2_{L^2_x} \|E^\lambda_{R,t}\|^2_{L^2_x} \big) dt.
\end{aligned} \tag{159}
$$

Thus, putting (146), (147), (148), (153), (154), and (159) together and taking ϵ small enough shows

$$
\begin{aligned}
&\int_0^t \int_0^1 g^\lambda_t E^\lambda_{R,t} dxdt \\
&\quad \leq (\epsilon + M\lambda^2) \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt + M \int_0^t \|(z^\lambda_R, z^\lambda_{R,t}, E^\lambda_R)\|^2_{L^2_x} dt \\
&\qquad + M \int_0^t \big(\|(z^\lambda_{R,t}, z^\lambda_{R,xt})\|^2_{L^2_x} \|E^\lambda_R\|^2_{L^2_x} + \|(z^\lambda_R, z^\lambda_{R,x})\|^2_{L^2_x} \|E^\lambda_{R,t}\|^2_{L^2_x} \big) dt + M\lambda.
\end{aligned} \tag{160}
$$

Therefore, for ϵ small enough, (144), together with (145) and (160), gives

$$
\begin{aligned}
&\lambda^2 \|E^\lambda_{R,t}(t)\|^2_{L^2_x} + \lambda^2 \int_0^t \|E^\lambda_{R,xt}\|^2_{L^2_x} dt + c_4 \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt \\
&\quad \leq M\lambda^2 \|E^\lambda_{R,t}(x,0)\|^2_{L^2_x} + M\lambda^2 \int_0^t \|E^\lambda_{R,t}\|^2_{L^2_x} dt + M \int_0^t \|(z^\lambda_R, E^\lambda_R, z^\lambda_{R,t})\|^2_{L^2_x} dt \\
&\qquad + M \int_0^t \Big(\|(z^\lambda_{R,t}, z^\lambda_{R,xt})\|^2_{L^2_x} \|E^\lambda_R\|^2_{L^2_x} + \|(z^\lambda_R, z^\lambda_{R,x})\|^2_{L^2_x} \|E^\lambda_{R,t}\|^2_{L^2_x} \Big) dt + M\lambda.
\end{aligned} \tag{161}
$$

The desired estimate (126) follows from (143) and (161). This completes the proof of Lemma 7. ∎

Finally, we use the basic estimates and the time derivative estimates of $(z_R^\lambda, E_R^\lambda)$ to obtain these estimates of the space derivatives $\partial_x(z_R^\lambda, E_R^\lambda)$ of $(z_R^\lambda, E_R^\lambda)$.

LEMMA 8. *Under the assumptions of Theorem* 3*, we have*

$$\begin{aligned}
&\|(z_{R,x}^\lambda, E_R^\lambda)\|_{L_x^2}^2 + \lambda^2\|E_{R,x}^\lambda\|_{L_x^2}^2 \\
&\quad\le M\|(z_R^\lambda, z_{R,t}^\lambda)\|_{L_x^2}^2 + M\lambda^2\|(E_R^\lambda, E_{R,t}^\lambda)\|_{L_x^2}^2 + M\lambda^4\|E_{R,x}^\lambda\|_{L_x^2}^2 \\
&\qquad + M\lambda^4\|(E_R^\lambda, E_{R,x}^\lambda)\|_{L_x^2}^2\|E_{R,x}^\lambda\|_{L_x^2}^2 + M\|(z_R^\lambda, z_{R,x}^\lambda)\|_{L_x^2}^2\|E_R^\lambda\|_{L_x^2}^2 + M\lambda.
\end{aligned}\tag{162}$$

Proof of Lemma 8. It follows from (119) and the Cauchy–Schwarz inequality that

$$\begin{aligned}
c_1\|z_{R,x}^\lambda\|_{L_x^2}^2 &\le -\frac{d}{dt}\|z_R^\lambda\|_{L_x^2}^2 + M\|(z_R^\lambda, E_R^\lambda)\|_{L_x^2}^2 + M\lambda^4\|E_{R,x}^\lambda\|_{L_x^2}^2 \\
&\quad + M\lambda^4(\|(E_R^\lambda, E_{R,x}^\lambda)\|_{L_x^2}^2\|E_{R,x}^\lambda\|_{L_x^2}^2 + M\lambda \\
&\le M\|(z_R^\lambda, z_{R,t}^\lambda, E_R^\lambda)\|_{L_x^2}^2 + M\lambda^4\|E_{R,x}^\lambda\|_{L_x^2}^2 \\
&\quad + M\lambda^4\|(E_R^\lambda, E_{R,x}^\lambda)\|_{L_x^2}^2\|E_{R,x}^\lambda\|_{L_x^2}^2 + M\lambda.
\end{aligned}\tag{163}$$

Similarly, it follows from (123) and the Cauchy–Schwarz inequality that

$$\begin{aligned}
&\lambda^2\|E_{R,x}^\lambda\|_{L_x^2}^2 + c_2\|E_R^\lambda\|_{L_x^2}^2 \\
&\quad\le -\lambda^2\frac{d}{dt}\|E_R^\lambda\|_{L_x^2}^2 + M\|z_R^\lambda\|_{L_x^2}^2 + M\|(z_R^\lambda, z_{R,x}^\lambda)\|_{L_x^2}^2\|E_R^\lambda\|_{L_x^2}^2 + M\lambda \\
&\quad\le M\lambda^2\|(E_R^\lambda, E_{R,t}^\lambda)\|_{L_x^2}^2 + M\|z_R^\lambda\|_{L_x^2}^2 + M\|(z_R^\lambda, z_{R,x}^\lambda)\|_{L_x^2}^2\|E_R^\lambda\|_{L_x^2}^2 + M\lambda.
\end{aligned}\tag{164}$$

The desired estimate (162) follows from (163) and (164). This completes the proof of Lemma 8. ∎

The end of the proof of Theorem 3. Introduce the following λ-weighted functional for the remainder terms

$$\Gamma^\lambda(t) = \|(z_R^\lambda, z_{R,x}^\lambda, z_{R,t}^\lambda)\|_{L_x^2}^2 + \lambda^2\|(E_R^\lambda, E_{R,x}^\lambda, E_{R,t}^\lambda)\|_{L_x^2}^2 + \|E_R^\lambda\|_{L_x^2}^2.\tag{165}$$

Then it follows from $(113)+(126)+\delta(162)$ that, by taking δ small enough and then λ small enough, and hence absorbing $\delta\big(M\|(z_R^\lambda, z_{R,t}^\lambda)\|_{L_x^2}^2 + M\lambda^2\|(E_R^\lambda, E_{R,t}^\lambda)\|_{L_x^2}^2\big)$ and $M\delta\lambda^4\|E_{R,x}^\lambda\|_{L_x^2}^2 + M\lambda^4\int_0^t\|E_{R,xt}^\lambda\|_{L_x^2}^2dt$ of the right-hand side of $(113)+(126)+\delta(162)$ by $\|(z_R^\lambda, z_{R,t}^\lambda)\|_{L_x^2}^2 + \lambda^2\|(E_R^\lambda, E_{R,t}^\lambda)\|_{L_x^2}^2$ and $\delta\lambda^2\|E_{R,x}^\lambda\|_{L_x^2}^2 + \lambda^2\int_0^t\|E_{R,xt}^\lambda\|_{L_x^2}^2dt$ of the left-hand side of $(113)+(126)+\delta(162)$, and then using the definition of $\Gamma^\lambda(t)$,

$$\begin{aligned}
&\Gamma^\lambda(t) + \int_0^t\|(z_{R,x}^\lambda, z_{R,xt}^\lambda, E_R^\lambda, E_{R,t}^\lambda)\|_{L_x^2}^2dt + \lambda^2\int_0^t\|(E_{R,x}^\lambda, E_{R,xt}^\lambda)\|_{L_x^2}^2dt \\
&\quad\le M\Gamma^\lambda(t=0) + M\int_0^t(\Gamma^\lambda(t) + (\Gamma^\lambda(t))^2)dt + M\lambda^2\int_0^t\Gamma^\lambda(t)\|E_{R,xt}^\lambda\|_{L_x^2}^2dt \\
&\qquad + M\int_0^t\Gamma^\lambda(t)\|(z_{R,xt}^\lambda, E_{R,t}^\lambda)\|_{L_x^2}^2dt + M\lambda + M(\Gamma^\lambda(t))^2.
\end{aligned}\tag{166}$$

We claim that, for any $T \in [0, T_{\max})$, $T_{\max} \le \infty$, there exists an $\lambda_0 \ll 1$ such that, for any $\lambda \le \lambda_0$, if $\Gamma^\lambda(t=0) \le \tilde{M}\lambda^{\min\{\alpha,1\}}$ for some $\alpha > 0$, then

$$\Gamma^\lambda(t) \le \tilde{M}\lambda^{\min\{\alpha,1\}-\delta}\tag{167}$$

holds for any $\delta \in (0, \min\{\alpha, 1\})$ and $0 \le t \le T$.

Otherwise, there exists $T \in [0, T_{\max})$, $T_{\max} \leq \infty$, for any $\lambda_0 \ll 1$ such that, for some $\lambda \leq \lambda_0$,

$$\Gamma^\lambda(t_0^\lambda) > \tilde{M}\lambda^{\min\{\alpha,1\}-\delta}$$

holds for some $\delta \in (0, \min\{\alpha, 1\})$ and for some $0 < t_0^\lambda \leq T$.

Denote the first root of $\Gamma^\lambda(t) = \tilde{M}\lambda^{\min\{\alpha,1\}-\delta}$ in $[0, t_0^\lambda]$ by t_1^λ. Then we have

$$\Gamma^\lambda(t) \leq \tilde{M}\lambda^{\min\{\alpha,1\}-\delta}, \quad 0 < t \leq t_1^\lambda \leq t_0^\lambda \leq T, \quad \Gamma^\lambda(t_1^\lambda) = \tilde{M}\lambda^{\min\{\alpha,1\}-\delta}. \tag{168}$$

Using (166) and (168), one gets

$$\begin{aligned}
\Gamma^\lambda(t) &+ \int_0^t \|(z_{R,x}^\lambda, z_{R,xt}^\lambda, E_R^\lambda, E_{R,t}^\lambda)\|_{L_x^2}^2 dt + \lambda^2 \int_0^t \|(E_{R,x}^\lambda, E_{R,xt}^\lambda)\|_{L_x^2}^2 dt \\
&\leq M\tilde{M}\lambda^{\min\{\alpha,1\}} \\
&\quad + M\int_0^t (\Gamma^\lambda(t) + \tilde{M}\lambda^{\min\{\alpha,1\}-\delta}\Gamma^\lambda(t))dt + M\lambda^2 \int_0^t \tilde{M}\lambda^{\min\{\alpha,1\}-\delta}\|E_{R,xt}^\lambda\|_{L_x^2}^2 dt \\
&\quad + M\int_0^t \tilde{M}\lambda^{\min\{\alpha,1\}-\delta}\|(z_{R,xt}^\lambda, E_{R,t}^\lambda)\|_{L_x^2}^2 dt + M\lambda + M\tilde{M}\lambda^{\min\{\alpha,1\}-\delta}\Gamma^\lambda(t) \\
&\leq M\tilde{M}\lambda^{\min\{\alpha,1\}} + 2M\int_0^t \Gamma^\lambda(t)dt + \frac{\lambda^2}{2}\int_0^t \|E_{R,xt}^\lambda\|_{L_x^2}^2 dt \\
&\quad + \frac{1}{2}\int_0^t (\|z_{R,xt}^\lambda\|_{L_x^2}^2 + \|E_{R,t}^\lambda\|_{L_x^2}^2)dt + M\lambda + \frac{1}{2}\Gamma^\lambda(t),
\end{aligned} \tag{169}$$

since $\lambda \leq \lambda_0 \ll 1$ and λ_0 can be chosen to satisfy that

$$\tilde{M}\lambda_0^{\min\{\alpha,1\}-\delta} \leq 1, M\tilde{M}\lambda_0^{\min\{\alpha,1\}-\delta} \leq \frac{1}{2}.$$

Hence, it follows from (169) that

$$\Gamma^\lambda(t) \leq 2M\tilde{M}\lambda^{\min\{\alpha,1\}} + 4M\int_0^t \Gamma^\lambda(t)dt + 2M\lambda.$$

Gronwall's lemma gives

$$\begin{aligned}
\Gamma^\lambda(t) &\leq (4Me^{4MT}T + 1)\max\{2M\tilde{M}, 2M\}\lambda^{\min\{\alpha,1\}} \\
&\leq (4Me^{4MT}T + 1)\max\{2M\tilde{M}, 2M\}\lambda^\delta\lambda^{\min\{\alpha,1\}-\delta} \\
&\leq \frac{\tilde{M}}{2}\lambda^{\min\{\alpha,1\}-\delta},
\end{aligned}$$

which contradicts (168). This proves our claim (167).

What remains is to prove that there exist a positive constant $\tilde{M}$ and $\alpha > 0$ such that

$$\Gamma^\lambda(t = 0) \leq \tilde{M}\lambda^\alpha. \tag{170}$$

In fact, it follows from the assumptions (49) and (50) on the initial data and (165) that

$$\Gamma^\lambda(t = 0) = \|z_{R,t}^\lambda(x, 0)\|_{L_x^2}^2 + \lambda^2\|E_{R,t}^\lambda(x, 0)\|_{L_x^2}^2 + M\lambda. \tag{171}$$

First, note that (104) implies

$$\|z^\lambda_{R,t}(x,0)\|_{L^2_x} \le \lambda\|\partial_x^2 z^\lambda_{0R}\|_{L^2_x} + \lambda\|\partial_x(DE^\lambda_{0R})\|_{L^2_x} + \|(H_{Inn,x}, H^\lambda_{B,x}, H^\lambda_{I,x}, H^\lambda_{IB,x}, H^\lambda_{R,x})(t=0)\|_{L^2_x} + M\|f^\lambda(t=0)\|_{L^2_x}.$$

The assumptions (49) and (50) lead to

$$\lambda\|\partial_x^2 z^\lambda_{0R}\|_{L^2_x} + \lambda\|\partial_x(DE^\lambda_{0R})\|_{L^2_x} \le M\sqrt{\lambda},$$

while the definitions of H_{Inn}, H^λ_B, H^λ_I, H^λ_{IB}, and f^λ yield that

$$\|(H_{Inn,x}, H^\lambda_{I,x}, H^\lambda_{IB,x})(t=0)\|_{L^2_x} \le M\sqrt{\lambda},$$

$$\|f^\lambda(t=0)\|_{L^2_x} \le M\lambda^{\frac{3}{2}},$$

and

$$\begin{aligned}
&\|H^\lambda_{B,x}(t=0)\|_{L^2_x}\\
&\quad\le M\sqrt{\lambda} + \left\|\left((D(x)-D(0))\frac{1}{\lambda}f(x)E^0_{+,\xi} + (D(x)-D(1))\frac{1}{\lambda}g(x)E^0_{-,\eta}\right)(t=0)\right\|_{L^2_x}\\
&\quad= M\sqrt{\lambda} + \left\|\left(\int_0^1 D_x(\theta x)d\theta\frac{x}{\lambda}f(x)E^0_{+,\xi}\right.\right.\\
&\qquad\qquad \left.\left. - \int_0^1 D_x(1-\theta(1-x))d\theta(x)\frac{1-x}{\lambda}g(x)E^0_{-,\eta}\right)(t=0)\right\|_{L^2_x}\\
&\quad\le M\sqrt{\lambda}.
\end{aligned}$$

Here we have used the mean value theorem and the estimates $\|(\xi E^0_{+,\xi}, \eta E^0_{+,\eta})(t=0)\|_{L^2_x} \le M\sqrt{\lambda}$.

In addition, the definition of $H^\lambda_R(t=0)$ and assumption (50) imply that

$$\begin{aligned}
\|H^\lambda_{R,x}\|_{L^2_x} &\le M\lambda^2\|\lambda\partial_x^2 E^\lambda_{0R}(x)\|_{L^2_x} + M\lambda\|\lambda\partial_x E^\lambda_{0R}\|_{L^2_x} + M\|\lambda E^\lambda_{0R}(x)\|_{L^2_x}\\
&\quad + \lambda^2\|(\lambda^2 E^\lambda_{0R}(x)\partial_x^2 E^\lambda_{0R}(x), (\lambda\partial_x E^\lambda_{0R}(x))^2)\|_{L^2_x}\\
&\le M\lambda^{\frac{3}{2}}.
\end{aligned}$$

Hence,

$$\|z^\lambda_{R,t}(x,0)\|_{L^2_x} \le M\sqrt{\lambda}. \tag{172}$$

Next, (105) implies that

$$\|\lambda E^\lambda_{R,t}(x,0)\|_{L^2_x} \le \lambda^2\|\partial_x^2 E^\lambda_{0R}(x)\|_{L^2_x} + \|z^0_0(x)E^\lambda_{0R}(x)\|_{L^2_x} + \left\|\frac{1}{\lambda}(G_{Inn}, G^\lambda_B, G^\lambda_I, G^\lambda_{IB}, G^\lambda_R)(t=0)\right\|_{L^2_x}.$$

Note that the only singular term is

$$I_{10} = \|\frac{1}{\lambda}\big(-f(x)(\mathcal{Z}^0(x,t)-\mathcal{Z}^0(0,t))E^0_+ - g(x)(\mathcal{Z}^0(x,t)-\mathcal{Z}^0(1,t))E^0_-\big)(t=0)\|_{L^2_x},$$

while the other terms are easily controlled by $M\sqrt{\lambda}$. By the mean value theorem, one gets

$$\begin{aligned}
I_{10} &\le M \left\| \frac{1}{\lambda}(\mathcal{Z}^0(x,t) - \mathcal{Z}^0(0,t))E_+^0(t=0) \right\|_{L_x^2} \\
&\quad + M \left\| \frac{1}{\lambda}(\mathcal{Z}^0(x,t) - \mathcal{Z}^0(1,t))E_-^0(t=0) \right\|_{L_x^2} \\
&= M \left\| \frac{x}{\lambda} \int_0^1 \mathcal{Z}_x^0(\theta x, 0) d\theta E_+^0(t=0) \right\|_{L_x^2} \\
&\quad + M \left\| \frac{1-x}{\lambda} \int_0^1 \mathcal{Z}_x^0(1-\theta(1-x), 0) d\theta E_-^0(t=0) \right\|_{L_x^2} \\
&\le M \|(\xi E_+^0, \eta E_-^0)(t=0)\|_{L_x^2}^2 \\
&\le M\sqrt{\lambda}.
\end{aligned}$$

This gives

$$\|\lambda E_{R,t}^\lambda(x,0)\|_{L_x^2} \le M\sqrt{\lambda}. \tag{173}$$

Notice that here we have used the assumptions

$$\|\partial_x^2 E_{0R}^\lambda(x)\|_{L_x^2} \le M\lambda^{\frac{1}{2}-2}, \quad \|E_{0R}^\lambda(x)\|_{L_x^2} \le M\sqrt{\lambda}.$$

Thus, (171), together with (172) and (173), gives the desired result (170) with $\alpha = 1$.

By (167) with $\alpha = 1$, one gets (51). This completes the proof of Theorem 3. ◻

4.2. The proof of Theorem 4. In this subsection we prove Theorem 4 by pointing out some necessary modifications of the proof of Theorem 3. We want to proceed as in the proof of Theorem 3.

Now we assume that (54) and (55) hold. In this case, we must consider the effect of the nonzero limit (z_0^1, E_0^1) of the error terms $(z_{0R}^\lambda, E_{0R}^\lambda)$ of the initial data (46). In fact, $z_0^1(x)$ produces the extra initial layer functions (z_I^3, E_I^1), given by the solution to (57)–(60). Since (57)–(60) can be solved exactly, it is easy to see that (z_I^3, E_I^1) has exactly the same properties as (z_I^2, E_I^0). Hence we choose the ansatz as

$$\begin{aligned}
(\tilde{z}^\lambda, \tilde{E}^\lambda)_{app}^T = \Big(&\mathcal{Z}^0 + \lambda(f(x)z_+^1 + g(x)z_-^1) + \lambda z_0^1(x) + \lambda^2 z_I^2 + \lambda^3 z_I^3, \\
&\mathcal{E}^0 + f(x)E_+^0 + g(x)E_-^0 + E_I^0 + \lambda(E_0^1(x) + E_I^1)\Big)^T.
\end{aligned}$$

Set

$$\big(\tilde{z}_R^\lambda(x,t), \tilde{E}_R^\lambda(x,t)\big)^T = (z^\lambda, E^\lambda)^T - \big(\tilde{z}^\lambda, \tilde{E}^\lambda\big)_{app}^T. \tag{174}$$

Then

$$\begin{aligned}
\big(\tilde{z}_R^\lambda(x,t), \tilde{E}_R^\lambda(x,t)\big)^T(x,0) &= \lambda(z_{0R}^\lambda - z_0^1, E_{0R}^\lambda - E_0^1)^T \\
&= \lambda(\tilde{z}_{0R}^\lambda, \tilde{E}_{0R}^\lambda).
\end{aligned}$$

By assumptions (54) and (55), one gets that $(\tilde{z}^\lambda_{0R}, \tilde{E}^\lambda_{0R})$ satisfies assumptions (54) and (55). It remains to establish the energy estimates for the error function

$$\big(\tilde{z}^\lambda_R(x,t), \tilde{E}^\lambda_R(x,t)\big)^T.$$

First, replacing $(z^\lambda, E^\lambda)^T$ with

$$(z^\lambda, E^\lambda)^T = \big(\tilde{z}^\lambda, \tilde{E}^\lambda\big)^T_{app} + \big(\tilde{z}^\lambda_R(x,t), \tilde{E}^\lambda_R(x,t)\big)^T$$

in the system (14)–(15), we obtain (104) and (105) with $(z^\lambda_R, E^\lambda_R)$ replaced by $(\tilde{z}^\lambda_R(x,t), \tilde{E}^\lambda_R(x,t))^T$ and H, G replaced by $\tilde{H}, \tilde{G}$, where $\tilde{H}^\lambda_B = H^\lambda_B$, $\tilde{G}^\lambda_B = G^\lambda_B$, and $\tilde{H}_{Inn}$ $(\tilde{G}_{Inn})$, $\tilde{H}^\lambda_I$ $(\tilde{G}^\lambda_I)$, $\tilde{H}^\lambda_{IB}$ $(\tilde{G}^\lambda_{IB})$, $\tilde{H}^\lambda_R$ $(\tilde{G}^\lambda_R)$ are defined by the following:

$$\tilde{H}_{Inn}(x,t) = \lambda(z^1_{0x}(x) + D(x)E^1_0(x)) - \lambda^2\mathcal{E}^0\mathcal{E}^0_x - \lambda^3\mathcal{E}^0E^1_0(x),$$

$$\begin{aligned}
\tilde{H}^\lambda_I(x,s) &= \lambda^2 z^2_{I,x} + \lambda^3 z^3_{I,x}\\
&\quad -\lambda^2\big(\mathcal{E}^0(E^0_{I,x} + \lambda E^1_{I,x}) + (E^0_I + \lambda E^1_I)(\mathcal{E}^0_x + E^0_{I,x} + \lambda(E^1_{0x} + E^1_{I,x}))\big),\\
\tilde{H}^\lambda_{IB}(x,\xi,\eta,t,s) &= -\lambda\Big((E^0_I + \lambda E^1_I)(f(x)E^0_{+,\xi} - g(x)E^0_{-,\eta})\Big)\\
&\quad -\lambda^2\Big((E^0_I + \lambda E^1_I)(f'(x)E^0_+ + g'(x)E^0_-)\\
&\qquad + (f(x)E^0_+ + g(x)E^0_-)(E^0_{I,x} + \lambda E^1_{I,x})\Big),
\end{aligned}$$

$$\begin{aligned}
\tilde{H}^\lambda_R &= -\lambda\tilde{E}^\lambda_R(f(x)E^0_{+,\xi} - g(x)E^0_{-,\eta})\\
&\quad -\lambda^2\Big(((\mathcal{E}^0 + \lambda E^1_0) + f(x)E^0_+ + g(x)E^0_-)\tilde{E}^\lambda_{R,x}\\
&\qquad + ((\mathcal{E}^0_x + \lambda E^1_{0x}) + f'(x)E^0_+ + g'(x)E^0_-)\tilde{E}^\lambda_R\Big)\\
&\quad -\lambda^2\big((E^0_I + \lambda E^1_I)\tilde{E}^\lambda_{R,x} + (E^0_{I,x} + \lambda E^1_{I,x})\tilde{E}^\lambda_R\big) - \lambda^2\tilde{E}^\lambda_R\tilde{E}^\lambda_{R,x},
\end{aligned}$$

$$\tilde{G}_{Inn}(x,t) = -\lambda^2\big(\mathcal{E}^0_t - \mathcal{E}^0_{xx} - \lambda E^1_{0xx}\big) - \lambda(\mathcal{Z}^0E^1_0 + z^1_0\mathcal{E}^0) - \lambda^2 z^1_0E^1_0,$$

$$\begin{aligned}
\tilde{G}^\lambda_I &= -(\mathcal{Z}^0 - \mathcal{Z}^0(x,0))(E^0_I + \lambda E^1_I) + \lambda^2E^0_{I,xx} + \lambda^3E^1_{I,xx} - \lambda^2 z^1_0E^1_I\\
&\quad -\lambda^2(z^2_I + \lambda z^3_I)(\mathcal{E}^0 + \lambda E^1_0 + E^0_I + \lambda E^1_I),\\
\tilde{G}^\lambda_{IB} &= -\lambda(f(x)z^1_+ + g(x)z^1_-)(E^0_I + \lambda E^1_I) - \lambda^2(z^2_I + \lambda z^3_I)(f(x)E^0_+ + g(x)E^0_-),\\
\tilde{G}^\lambda_R &= -(\mathcal{E}^0 + \lambda E^1_0 + f(x)E^0_+ + g(x)E^0_- + E^0_I + \lambda E^1_I)\tilde{z}^\lambda_R\\
&\quad -\lambda(f(x)z^1_+ + g(x)z^1_- + z^1_0)\tilde{E}^\lambda_R - \lambda^2(z^2_I + \lambda z^3_I)\tilde{E}^\lambda_R - \tilde{z}^\lambda_R\tilde{E}^\lambda_R.
\end{aligned}$$

Next, we point out the difference at the boundary between $(\tilde{z}^\lambda_R, \tilde{E}^\lambda_R)$ and $(z^\lambda_R, E^\lambda_R)$. At present, $\tilde{E}^\lambda_R$ satisfies the nonhomogeneous boundary condition

$$(\tilde{E}^\lambda_R + \lambda E^1_0)(x=0,1;t) = 0, \quad t>0. \tag{175}$$

In fact, since $E^0_I(x=0,1;t)=0$, it follows from the system (57)–(58) that

$$E^0_I(x=0,1;t) = 0, \quad t>0, \tag{176}$$

which gives with (57) and (58) that

$$E_I^1(x=0,1;t)=0, \quad t>0. \tag{177}$$

Combining (174), the boundary condition (16), (68), (176), and (177), one gets (175).

But $\tilde{H}^\lambda$ still satisfies the homogeneous boundary condition

$$\tilde{H}^\lambda(x=0,1;t)=0, \quad t>0.$$

Thus

$$\tilde{H}_t^\lambda(x=0,1;t)=\tilde{E}_{R,t}^\lambda(x=0,1;t)=0, \quad t>0,$$

due to the fact that $E_0^1=E_0^1(x)$ does not depend upon time t.

Finally, notice that $\tilde{H}(\tilde{G})$ is the sum of $H(G)$ and the extra higher order $O(\lambda)$, and hence it has the very similar structure as $H(G)$, and that the only term to be affected by nonhomogeneous boundary condition (175) is $-\lambda^2\int_0^1 \tilde{E}_{R,xx}^\lambda \tilde{E}_R^\lambda dx$, which can be dealt with as follows:

$$\begin{aligned}
-\lambda^2 &\int_0^1 \tilde{E}_{R,xx}^\lambda \tilde{E}_R^\lambda dx \\
&= -\lambda^2\int_0^1 \tilde{E}_{R,xx}^\lambda(\tilde{E}_R^\lambda+\lambda E_0^1)dx+\lambda^3\int_0^1 \tilde{E}_{R,xx}^\lambda E_0^1 dx \\
&= \lambda^2\int_0^1 |\tilde{E}_{R,x}^\lambda|^2dx+\lambda^3\int_0^1 \tilde{E}_{R,x}^\lambda E_{0x}^1 dx+\lambda\int_0^1(\lambda^2\tilde{E}_{R,t}^\lambda+\mathcal{Z}^0\tilde{E}_R^\lambda-g^\lambda)E_0^1dx \\
&\geq \frac{\lambda^2}{2}\int_0^1 |\tilde{E}_{R,x}^\lambda|^2dx-M\lambda-M\lambda^5\int_0^1|\tilde{E}_{R,t}^\lambda|^2dx-\lambda\int_0^1(|\tilde{E}_R^\lambda|^2+|g^\lambda|^2)dx \\
&\geq \frac{\lambda^2}{2}\int_0^1 |\tilde{E}_{R,x}^\lambda|^2dx-M\lambda^5\int_0^1|\tilde{E}_{R,t}^\lambda|^2dx-\lambda\int_0^1|\tilde{E}_R^\lambda|^2dx-M\lambda.
\end{aligned}$$

Here we had used (105). Thus, we can proceed with the energy method as in the previous proof of Theorem 3. The proof of Theorem 4 is complete. □

ON THE STOLZ–ADAMS DECONVOLUTION MODEL FOR THE LARGE-EDDY SIMULATION OF TURBULENT FLOWS*

A. DUNCA† AND Y. EPSHTEYN†

Abstract. We consider a family of large-eddy simulation (LES) models with an arbitrarily high consistency error $O(\delta^{2N+2})$ for $N = 1, 2, 3, \dots$ that are based on the van Cittert deconvolution procedure. This family of models has been proposed and tested for LES with success by Adams and Stolz in a series of papers, e.g., [*Deconvolution methods for subgrid-scale approximation in large-eddy simulation*, in Modern Simulation Strategies for Turbulent Flow, R. T. Edwards, Philadelphia, 2001, pp. 21–41], [*Phys. Fluids*, 11 (1999), pp. 1699–1701]. We show that these models have an interesting and quite strong stability property. Using this property we prove an energy equality, existence, uniqueness, and regularity of strong solutions and give a rigorous bound on the modeling error $\|\overline{\mathbf{u}} - \mathbf{w}\|$, where $\mathbf{w}$ is the model's solution and $\overline{\mathbf{u}}$ is the true flow averages.

Key words. large-eddy simulation, scale similarity models, deconvolution, approximate deconvolution models

1. Introduction.

We consider the problem of modeling the motion of large structures in a turbulent fluid. This involves the interaction of many complex decisions made in the simulation. To isolate some effects, we study herein the correctness of the approximate deconvolution modeling (ADM) approach to closure pioneered by Adams and Stolz; see, e.g., [1], [9].

The pointwise velocity and pressure, $\mathbf{u}, p$, in an incompressible viscous flow satisfy the Navier–Stokes equations

$$\begin{aligned} \mathbf{u}_t + \nabla \cdot (\mathbf{u}\mathbf{u}^T) - \nu\Delta\mathbf{u} + \nabla p &= \mathbf{f}, \\ \nabla \cdot \mathbf{u} &= 0, \\ \mathbf{u}(\mathbf{x}, 0) &= \mathbf{u}_0(\mathbf{x}). \end{aligned} \tag{1}$$

We study (1) subject to periodic boundary conditions (with zero mean)

$$\mathbf{u}(x + Le, t) = \mathbf{u}(x, t) \tag{2}$$

for $x \in \mathbb{R}^3, 0 < t \leq T$.

Periodic boundary conditions separate the hard problem of closure for the interior equations from another hard problem of wall laws and near wall models in turbulence.

Let an overbar denote a local spacial averaging associated with a length scale δ which commutes with differentiation. Averaging the Navier–Stokes equations gives the nonclosed equations for $\overline{\mathbf{u}}, \overline{p}$,

$$\begin{aligned} \overline{\mathbf{u}}_t + \nabla \cdot (\overline{\mathbf{u}\mathbf{u}^T}) - \nu\Delta\overline{\mathbf{u}} + \nabla\overline{p} &= \overline{\mathbf{f}}, \\ \nabla \cdot \overline{\mathbf{u}} &= 0. \end{aligned} \tag{3}$$

†Department of Mathematics, University of Pittsburgh, Pittsburgh, PA 15260 (ardst21@math.pitt.edu, yee1@pitt.edu).

Let the averaging operation $\mathbf{u} \to \overline{\mathbf{u}}$ be denoted formally by G so $\overline{\mathbf{u}} = \mathrm{G}\mathbf{u}$. In the most interesting cases G is not invertible. Nevertheless, the closure problem (of replacing $\overline{\mathbf{u}\mathbf{u}^T}$ by a tensor depending only on $\overline{\mathbf{u}}$) is solved once the approximate deconvolution problem (of approximating the action of G^{-1}) is solved.

The van Cittert approximation to G^{-1} can be developed in various ways (see [2] and section 2 for a precise definition of it). The simplest is to find an approximation to $\mathbf{u}$ by extrapolating from the resolved scales of $\overline{\mathbf{u}}$ to those of $\mathbf{u}$. The first three examples are

$$
\begin{aligned}
&\mathbf{u} \approx \mathrm{G}_0\overline{\mathbf{u}} := \overline{\mathbf{u}} && \text{(constant extrapolation in } \delta\text{)},\\
&\mathbf{u} \approx \mathrm{G}_1\overline{\mathbf{u}} := \overline{\mathbf{u}} - \overline{\overline{\mathbf{u}}} && \text{(linear extrapolation in } \delta\text{)},\\
&\mathbf{u} \approx \mathrm{G}_2\overline{\mathbf{u}} := 3\overline{\mathbf{u}} - 3\overline{\overline{\mathbf{u}}} + \overline{\overline{\overline{\mathbf{u}}}} && \text{(quadratic extrapolation in } \delta\text{)}.
\end{aligned}
\tag{4}
$$

Let $\mathrm{G}_N\overline{\mathbf{u}}$ denote the analogous Nth degree accurate approximate inverse (section 2). Calling $(\mathbf{w}, q)$ the approximations that result when this is used in (3) to treat the closure problem, we are inevitably led to the fundamentally important question of how well the solution $\mathbf{w}$ of the resulting model,

$$
\begin{aligned}
\mathbf{w}_t + \nabla \cdot (\overline{\mathrm{G}_N\mathbf{w}(\mathrm{G}_N\mathbf{w})^T}) - \nu\Delta\mathbf{w} + \nabla\overline{q} &= \overline{\mathbf{f}},\\
\nabla \cdot \mathbf{w} &= 0,
\end{aligned}
\tag{5}
$$

matches the behavior of the true flow averages $\overline{\mathbf{u}}$. This question has obvious theoretical and experimental components. We consider herein the theoretical parts of the question for the whole family of models. Our analysis is based on a delicate skew symmetry property that the model's nonlinear interaction terms have when the averaging operator is the differential filter $\varphi \to \overline{\varphi}$ (as studied by Germano [4]). Here for given $\varphi \in L^2(Q)$, $\overline{\varphi}$ is defined to be the unique periodic solution of

$$
-\delta^2\Delta\overline{\varphi} + \overline{\varphi} = \varphi \tag{6}
$$

in Q, where Q denotes the d-dimensional cube of size $L > 0, Q = (0, L)^d$.

Our analysis is for periodic boundary conditions. We believe that many of the results presented in this work can be extended to nonperiodic boundary conditions with further research. Indeed, the basic model (5) does not increase the order of the differential operator, so the model makes perfect sense coupled with any of the well-posed boundary conditions used for the Navier–Stokes equations.

REMARK 1.1. *The model* (5) *using* G_0 *was considered recently in* [6] *and* [7]*. On the other hand, practical calculations of Adams and Stolz in* [1] *and* [9] *have stressed the superiority of models of order* 4, 5 *and higher in practical tests.*

Herein we show that a single, unified mathematical theory is possible for the entire family of models building on the analysis in [6] *and* [7].

2. Deconvolution models. It has been pointed out by Germano (presented well in [5]) that with the differential filter $\overline{\varphi} := (-\delta^2\Delta + \mathrm{I})^{-1}\varphi$ it seems that no deconvolution is necessary; one can write exactly $\varphi := (-\delta^2\Delta + \mathrm{I})\overline{\varphi}$.

This leads to the exact model for $\overline{\mathbf{u}}$ given by

$$
\overline{\mathbf{u}}_t + \nabla \cdot (\overline{(-\delta^2\Delta + \mathrm{I})\overline{\mathbf{u}}[(-\delta^2\Delta + \mathrm{I})\overline{\mathbf{u}}]^T}) - \nu\Delta\overline{\mathbf{u}} + \nabla\overline{p} = \overline{\mathbf{f}} \tag{7}
$$

subject to the periodic boundary conditions. One criticism with using the exact deconvolution model (7) to predict $\overline{\mathbf{u}}$ is that going from the Navier–Stokes equations to (7), no information is lost.

Thus there is no reason to believe that (7) can be approximated with fewer degrees of freedom than the Navier–Stokes equation itself. Another difficulty with (7) is that any model that increases the order of the differential equation must be supplied with extra boundary conditions. Thus for nonperiodic problems, models such as (7) shift the essential difficulty from interior closure to the harder problem of specifying as boundary conditions the higher derivatives of turbulent velocities at walls. Thus approximate deconvolution which will lose information is necessary. The van Cittert method of approximate deconvolution (see [2]) constructs a family G_N of inverses to G as follows: writing $\mathrm{G} = \mathrm{I} - (\mathrm{I} - \mathrm{G})$, a formal inverse to G can be written as the nonconvergent power series,

$$\mathrm{G}^{-1} = \sum_{n=0}^{\infty} (\mathrm{I} - \mathrm{G})^n.$$

Truncating this series gives

$$\mathrm{G}_N = \sum_{n=0}^{N} (\mathrm{I} - \mathrm{G})^n. \tag{8}$$

The first three approximations are given in (4).

LEMMA 2.1. *The operator* $\mathrm{G}_N : L^2(Q) \to L^2(Q)$ *is compact, self-adjoint, and positive.*

Proof. The operator $\mathrm{G} : L^2(Q) \to L^2(Q)$ is compact and self-adjoint. Multiplying (6) by $\overline{\varphi}$ and integrating over Q gives

$$\delta^2 \|\nabla \overline{\varphi}\|^2 + \|\overline{\varphi}\|^2 = (\varphi, \overline{\varphi}) \leq \frac{1}{2}\|\varphi\|^2 + \frac{1}{2}\|\overline{\varphi}\|^2.$$

It follows that G is positive and $\|\mathrm{G}\| \leq 1$. Let $h_N(x) = \sum_{k=0}^{N} (1-x)^k$. By the definition of G_N,

$$\mathrm{G}_N = h_N(\mathrm{G})$$

and, consequently, G_N is also a compact self-adjoint operator. Because h_N is positive on $[0, 1]$, which contains the spectrum of G, it also follows that G_N is positive. ∎

REMARK 2.1. *The operators* $\{\mathrm{G}_N\}_N$ *satisfy the following recursion:*

$$(\mathrm{I} - \delta^2 \Delta)\mathrm{G}_N \mathbf{u} = -\delta^2 \Delta \mathrm{G}_{N-1} \mathbf{u} + (\mathrm{I} - \delta^2 \Delta)\mathbf{u}. \tag{9}$$

The following lemma, which is a consequence of the identity

$$G_N G = I - (I - G)^{N+1},$$

was proved in [10].

LEMMA 2.2. *For smooth* $\mathbf{u}$ *the approximate deconvolution* (8) *has the consistency error* $O(\delta^{2N+2})$,

$$\mathbf{u} - \mathrm{G}_N \overline{\mathbf{u}} = (-1)^{N+1} \delta^{2N+2} \Delta^{N+1} G^{N+1} \overline{\mathbf{u}}, \tag{10}$$

locally in Q *and also*

$$\|\mathbf{u} - \mathrm{G}_N \overline{\mathbf{u}}\| \leq \delta^{2N+2} \|\overline{\mathbf{u}}\|_{H^{2N+2}(Q)}.$$

Lemma 2.2 shows that $\mathrm{G}_N\overline{\mathbf{u}}$ gives an approximation to $\mathbf{u}$ to the accuracy $O(\delta^{2N+2})$ in the smooth flow regions. Thus it is justified to use it for the closure approximation

$$\nabla \cdot \overline{(\mathbf{u}\mathbf{u}^T)} \approx \nabla \cdot \overline{(\mathrm{G}_N\overline{\mathbf{u}}(\mathrm{G}_N\overline{\mathbf{u}})^T)} + O(\delta^{2N+2}).$$

If μ denotes the usual subfilter scale stress tensor $\mu(\mathbf{u},\mathbf{u}) := \overline{\mathbf{u}\mathbf{u}^T} - \bar{\mathbf{u}}\bar{\mathbf{u}}^T$, then the closure approximation is equivalent to the closure model

$$\mu(\mathbf{u},\mathbf{u}) \approx \mu_N(\overline{\mathbf{u}},\overline{\mathbf{u}}) := \overline{\mathrm{G}_N\overline{\mathbf{u}}(\mathrm{G}_N\overline{\mathbf{u}})^T} - \bar{\mathbf{u}}\bar{\mathbf{u}}^T. \tag{11}$$

The true subgrid stress tensor $\mu(\mathbf{u},\mathbf{u})$ is both reversible and Galilean invariant (Sagaut [8]). Thus many feel that appropriate closure models should at least, to leading order effects, share these two properties. We next show that the model (11) is both reversible and Galilean invariant.

LEMMA 2.3. *For each $N = 0, 1, 2, \ldots$ the closure model* (11) *is reversible and Galilean invariant.*

Proof. Reversibility is immediate. Galilean invariance also follows easily once it is noted that $\overline{\mathrm{U}\mathbf{w}^T} = \mathrm{U}\overline{\mathbf{w}}^T$ so $\mathrm{G}_N(\mathrm{U}\overline{\mathbf{u}}^T = \mathrm{U}\mathrm{G}_N(\overline{\mathbf{u}})^T$. Using these and other analogous properties gives

$$\begin{aligned}
\nabla \cdot \mu(\overline{\mathbf{u}} + \mathrm{U}, \overline{\mathbf{u}} + \mathrm{U}) &= \nabla \cdot [\overline{\mathrm{G}_N(\overline{\mathbf{u}})\mathrm{G}_N(\overline{\mathbf{u}})^T} + \mathrm{U}\overline{\mathrm{G}_N(\overline{\mathbf{u}})}^T \\
&\quad + \overline{\mathrm{G}_N(\overline{\mathbf{u}})}\mathrm{U}^T + \overline{\mathrm{U}\mathrm{U}^T} - (\overline{\mathbf{u}} + \mathrm{U})(\overline{\mathbf{u}} + \mathrm{U})^T] \\
&= \nabla \cdot [\overline{\mathrm{G}_N(\overline{\mathbf{u}})\mathrm{G}_N(\overline{\mathbf{u}})^T} - \bar{\mathbf{u}}\bar{\mathbf{u}}^T] + \nabla \cdot \overline{\mathrm{G}_N(\overline{\mathbf{u}})}\mathrm{U} \\
&\quad + \mathrm{U}\nabla \cdot (\overline{\mathrm{G}_N(\overline{\mathbf{u}})} - \nabla \cdot (\overline{\mathbf{u}})\mathrm{U} - \mathrm{U}\nabla \cdot (\overline{\mathbf{u}}) \\
&= \nabla \cdot [\overline{\mathrm{G}_N(\overline{\mathbf{u}})\mathrm{G}_N(\overline{\mathbf{u}})^T} - \bar{\mathbf{u}}\bar{\mathbf{u}}^T] = \nabla \cdot \mu_N(\overline{\mathbf{u}},\overline{\mathbf{u}}),
\end{aligned}$$

since $\nabla \cdot \overline{\mathbf{u}} = \nabla \cdot \mathrm{G}_N(\overline{\mathbf{u}}) = \nabla \cdot \overline{\mathrm{G}_N(\overline{\mathbf{u}})} = 0$ and $\overline{\mathrm{U}\mathrm{U}^T} = \mathrm{U}\mathrm{U}^T$. ∎

3. Variational spaces. Q denotes a d-dimensional cube of size $L > 0$,

$$Q = (0, L)^d.$$

Let

$$H^m(Q) = \{\mathbf{u} \in H^m_{loc}(\mathbb{R}^n) | \mathbf{u} \text{ periodic with period } Q\}$$

and

$$\overline{H}^m(Q) = \left\{\mathbf{u} \in H^m(Q) | \int_Q \mathbf{u}\,\mathrm{d}x = 0\right\}.$$

For the variational formulation of the scale similarity model with periodic boundary conditions, we consider the spaces of divergence-free functions

$$V = \{\mathbf{u} \in H^1(Q), \nabla \cdot \mathbf{u} = 0 \text{ in } \mathbb{R}^d\}$$

and

$$H = \{\mathbf{u} \in L^2(Q), \nabla \cdot \mathbf{u} = 0 \text{ in } \mathbb{R}^d\}$$

as in Temam [12].

$D(Q)$ is defined as

$$D(Q) = \{\psi \in C^\infty(\mathbb{R}^d) | \psi \text{ is periodic with period } Q\}$$

and

$$D(Q_T) = \{\psi \in C^\infty([0,T) \times \mathbb{R}^d) | \text{ for } t \in [0,T), \psi(\cdot,t) \text{ is periodic with period } Q \text{ and } \psi \text{ has compact support in variable } t \in [0,T)\}.$$

The space of vector valued functions $\mathbb{D}(Q)$ is defined as

$$\mathbb{D}(Q) = D(Q)^d. \tag{12}$$

The other spaces $\mathbb{D}(Q_T), \mathbb{H}, \overline{\mathbb{H}}^p(Q)$, and $\mathbb{V}, \mathbb{L}^2(Q)$ are defined accordingly.

REMARK 3.1. *Because the inclusion $\overline{H}^2(Q) \to H$ is compact, the inverse of the Laplacian operator $(-\Delta)^{-1} : H \to \overline{H}^2(Q) \subset H$ is a bounded, self-adjoint, and compact operator. This implies that there exists an orthonormal basis $(\mathbf{w}_j)_{j\in\mathbb{N}}$ of H consisting of eigenfunctions of the Laplacian operator.*

4. The models and the existence of weak solutions.

DEFINITION 4.1. *The strong form of the Stolz–Adams model that we analyze is as follows: Find $(\mathbf{w}, q)$ such that*

$$\begin{aligned} &\mathbf{w} \in (\overline{H}^2(Q) \cap H)^d && \text{for a.e. } t \in [0.T], \\ &\mathbf{w} \in (H^1(0,T))^d && \text{for a.e. } \mathbf{x} \in \overline{Q}, \\ &q \in H^1(Q) \cap L^2_0(Q) && \text{if } t \in (0,T] \end{aligned} \tag{13}$$

and

$$\begin{aligned} \mathbf{w}_t - \nu\Delta\mathbf{w} + \nabla \cdot (\overline{(\mathrm{G}_N\mathbf{w})(\mathrm{G}_N\mathbf{w})^T}) + \nabla\overline{q} &= \overline{\mathbf{f}} && \text{in } (0,T) \times Q, \\ \nabla \cdot \mathbf{w} &= 0 && \text{in } (0,T] \times Q, \\ \mathbf{w}|_{t=0} &= \overline{\mathbf{u}_0} && \text{in } Q, \\ \int_Q q \, \mathrm{d}x &= 0 && \text{in } (0,T]. \end{aligned} \tag{14}$$

DEFINITION 4.2. *Let $\mathbf{f} \in L^2(0,T;\mathbb{V}')$ and $\mathbf{w}_0 \in \overline{\mathbb{H}}^2(Q)$. A measurable function $\mathbf{w} : [0,T] \times Q \to \mathbb{R}^d$ is a weak solution of* (14) *if*

$$\mathbf{w} \in L^2(0,T,\overline{\mathbb{H}}^1(Q)) \cap L^\infty(0,T;\mathbb{H}) \tag{15}$$

and

$$\begin{aligned} &\int_0^\infty \left[\left(\mathbf{w}, \frac{\partial\varphi}{\partial t} \right) - \nu(\nabla\mathbf{w}, \nabla\phi) - (\nabla \cdot (\overline{(\mathrm{G}_N\mathbf{w})(\mathrm{G}_N\mathbf{w})^T}), \varphi) \right] \mathrm{d}t \\ &\quad = -\int_0^\infty (\mathbf{f}, \varphi) \, \mathrm{d}t - (\mathbf{w}_0, \varphi(0)) \end{aligned} \tag{16}$$

for all $\varphi \in \mathbb{D}(Q)$.

The following lemma gives an energy inequality satisfied by the strong solutions of the Stolz–Adams models. We mention here that the same argument is used to derive an energy inequality for the approximate solutions in the proof of existence of weak solutions to the Stolz–Adams models.

LEMMA 4.1. *If* $\mathbf{w}$ *is a strong solution of* (14) *as in Definition* 4.1, *then* $\mathbf{w}$ *satisfies the following energy inequality:*

$$\begin{aligned}\tag{17} &\frac{1}{2}(\|\mathbf{w}(t)\|^2+\delta^2\|\nabla\mathbf{w}(t)\|^2)+\frac{\nu}{2}\int_0^t\|\nabla\mathbf{w}(s)\|^2+\delta^2\|\Delta\mathbf{w}(s)\|^2\,\mathrm{d}s\\ &\quad\le K\left(\int_0^T\|\mathbf{f}(s)\|^2_{V'}\mathrm{d}s+\|\mathbf{w}_0\|^2+\delta^2\|\nabla\mathbf{w}_0\|^2\right)\end{aligned}$$

for all $t\in[0,T]$ *with* $K=\max\{\frac{2\|\mathrm{G}_N\|^2_{L^2(Q)}}{\nu},\frac{1}{2}\delta^2,\frac{1}{2},\frac{\delta^2}{2}\|\mathrm{G}_{N-1}\|_{L^2(Q)}\}$.

Proof. We multiply (14) by the test function $\varphi=(-\delta^2\Delta+\mathrm{I})\mathrm{G}_N\mathbf{w}$ and integrate on Q. Because the weak form of the nonlinear term will vanish,

$$\tag{18} (\nabla\cdot\overline{((\mathrm{G}_N\mathbf{w})(\mathrm{G}_N\mathbf{w})^T)},(-\delta^2\Delta+\mathrm{I})\mathrm{G}_N\mathbf{w})$$

$$\tag{19} =(\nabla\cdot((\mathrm{G}_N\mathbf{w})(\mathrm{G}_N\mathbf{w})^T),\overline{(-\delta^2\Delta+\mathrm{I})\mathrm{G}_N\mathbf{w}})=(\nabla\cdot((\mathrm{G}_N\mathbf{w})(\mathrm{G}_N\mathbf{w})^T),\mathrm{G}_N\mathbf{w})=0,$$

we obtain the following energy equality:

$$\tag{20} \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}(\mathbf{w},(-\delta^2\Delta+\mathrm{I})\mathrm{G}_N\mathbf{w})+\nu(\Delta\mathbf{w},(-\delta^2\Delta+\mathrm{I})\mathrm{G}_N\mathbf{w})=(\overline{\mathbf{f}},(-\delta^2\Delta+\mathrm{I})\mathrm{G}_N\mathbf{w}).$$

In the above equality all terms $(-\delta^2\Delta+\mathrm{I})\mathrm{G}_N\mathbf{w}$ are replaced using Remark 2.1, leading to

$$\begin{aligned}&\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}(\mathbf{w},(-\delta^2\Delta+\mathrm{I})\mathbf{w})+\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}(\mathbf{w},-\delta^2\Delta\mathrm{G}_{N-1}\mathbf{w})-\nu(\Delta\mathbf{w},(-\delta^2\Delta+\mathrm{I})\mathbf{w})\\ &\quad+\nu\delta^2(\Delta\mathbf{w},\delta^2\Delta\mathrm{G}_{N-1}\mathbf{w})=(\mathbf{f},\mathrm{G}_N\mathbf{w}).\end{aligned}$$

Using integration by parts and the commutation property of the operator G_{N-1} with differentiation gives

$$\begin{aligned}&\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|\mathbf{w}\|^2+\frac{1}{2}\delta^2\frac{\mathrm{d}}{\mathrm{d}t}\|\nabla\mathbf{w}\|^2+\frac{\delta^2}{2}\frac{\mathrm{d}}{\mathrm{d}t}(\nabla\mathbf{w},\mathrm{G}_{N-1}\nabla\mathbf{w})\\ &\quad+\nu\|\nabla\mathbf{w}\|^2+\nu\delta^2\|\Delta\mathbf{w}\|+\nu\delta^4(\Delta\mathbf{w},\mathrm{G}_{N-1}\Delta\mathbf{w})=(\mathbf{f},\mathrm{G}_N\mathbf{w}).\end{aligned}\tag{21}$$

We then integrate on $[0,t]$ and obtain

$$\begin{aligned}&\frac{1}{2}\|\mathbf{w}(t)\|^2+\frac{1}{2}\delta^2\|\nabla\mathbf{w}(t)\|^2+\frac{\delta^2}{2}(\nabla\mathbf{w}(t),\mathrm{G}_{N-1}\nabla\mathbf{w}(t))+\nu\int_0^t\|\nabla\mathbf{w}(s)\|^2\,\mathrm{d}s\\ &\quad+\nu\delta^2\int_0^t\|\Delta\mathbf{w}(s)\|^2\,\mathrm{d}s+\nu\delta^4\int_0^t(\Delta\mathbf{w}(s),\mathrm{G}_{N-1}\Delta\mathbf{w}(s))\,\mathrm{d}s\\ &=\int_0^t(\mathbf{f}(\mathbf{s}),\mathrm{G}_N\mathbf{w}(s))\,\mathrm{d}s+\frac{1}{2}\|\mathbf{w}_0\|^2+\frac{1}{2}\delta^2\|\nabla\mathbf{w}_0\|^2+\frac{\delta^2}{2}(\nabla\mathbf{w}_0,\mathrm{G}_{N-1}\nabla\mathbf{w}_0).\end{aligned}$$

We use the positivity of the operators $(\mathrm{G}_N)_N$ in the above inequality to get

$$\begin{aligned}\tag{22} &\frac{1}{2}\|\mathbf{w}(t)\|^2+\frac{1}{2}\delta^2\|\nabla\mathbf{w}(t)\|^2+\nu\int_0^t\|\nabla\mathbf{w}(s)\|^2\,\mathrm{d}s+\nu\delta^2\int_0^t\|\Delta\mathbf{w}(s)\|^2\,\mathrm{d}s\\ &\quad\le\int_0^t(\mathbf{f}(\mathbf{s}),\mathrm{G}_N\mathbf{w}(s))\,\mathrm{d}s+\frac{1}{2}\delta^2\|\mathbf{w}_0\|^2+\frac{1}{2}\|\nabla\mathbf{w}_0\|^2+\frac{\delta^2}{2}(\nabla\mathbf{w}_0,\mathrm{G}_{N-1}\nabla\mathbf{w}_0).\end{aligned}$$

An application of Cauchy's inequality on the first term on the right-hand side above gives

$$\begin{aligned}\int_0^t (\mathbf{f}(\mathbf{s}), \mathrm{G}_N \mathbf{w}(s))\,\mathrm{d}s &\leq \int_0^t \|\mathbf{f}(s)\|_{V'} \|\mathrm{G}_N\|_{L^2(Q)} \|\nabla \mathbf{w}(s)\|_{L^2(Q)}\,\mathrm{d}s \\ &\leq \frac{2\|\mathrm{G}_N\|^2_{L^2(Q)}}{\nu} \int_0^t \|\mathbf{f}(\mathbf{s})\|^2_{V'}\,\mathrm{d}s + \frac{\nu}{2}\int_0^T \|\nabla \mathbf{w}(s)\|^2_{L^2(Q)}\,\mathrm{d}s.\end{aligned}$$

We use this inequality in (22) to obtain

$$\begin{aligned}&\frac{1}{2}\|\mathbf{w}(t)\|^2 + \frac{1}{2}\delta^2\|\nabla \mathbf{w}(t)\|^2 + \nu\delta^2 \int_0^t \|\Delta \mathbf{w}(s)\|^2\,\mathrm{d}s \\ &\quad + \frac{\nu}{2}\int_0^t \|\nabla \mathbf{w}(s)\|^2\,\mathrm{d}s \leq \frac{2\|\mathrm{G}_N\|^2_{L^2(Q)}}{\nu}\int_0^t \|\mathbf{f}(\mathbf{s})\|^2_{V'}\,\mathrm{d}s \\ &\quad + \frac{1}{2}\delta^2\|\mathbf{w}_0\|^2 + \frac{1}{2}\|\nabla \mathbf{w}_0\|^2 + \frac{\delta^2}{2}\|\mathrm{G}_{N-1}\|_{L^2}\|\nabla \mathbf{w}_0\|^2_{L^2}. \qquad \square\end{aligned}$$

REMARK 4.1. *The turbulence model based on the approximate deconvolution procedure introduced by Stolz and Adams in* [9] *and tested by Stolz, Adams, and Kleizer in* [10] *and* [11] *contains a relaxation term added to the right-hand side of the first equation in* (14) *to drain energy near cutoff length scale. This term takes the form*

$$-\chi_\omega(I - G_N G)\mathbf{w}, \tag{23}$$

where $\chi_\omega > 0$ is a function of space and time. If χ_ω is smooth and bounded in space and time, the addition of the relaxation term (23) *does not change the mathematical results proved in this paper. For this model one can derive an energy estimate like Lemma* 4.1 *by treating the weak form of the relaxation term in the following way:*

$$\begin{aligned}&(-\chi_\omega(I - G_N G)\mathbf{w}, (-\delta^2\Delta + I)G_N\mathbf{w}) \\ &= (-\chi_\omega(I - G_N G)\mathbf{w}, G_N\mathbf{w}) + (\chi_\omega(I - G_N G)\mathbf{w}, \delta^2 G_N \Delta\mathbf{w}) \\ &\leq C(\varepsilon, \|\chi_\omega\|_\infty, N, \delta, \nu, \|G\|)\|\mathbf{w}\|^2 + \varepsilon\|\Delta\mathbf{w}\|^2\end{aligned}$$

for given $\varepsilon > 0$

One can then pick $\varepsilon = \frac{\nu\delta^2}{4}$, which results in the cancellation of the term $\frac{\nu\delta^2}{4}\|\Delta\mathbf{w}\|$ on the right-hand side (see (21)*) and apply the Gronwall lemma to get an energy inequality similar to* (17)*.*

Based on this energy inequality all other results proved here for the Stolz–Adams model without the relaxation term can be extended to the case where the relaxation term is incorporated into the equations.

For less regular functions $\chi_\omega > 0$ the same results cannot be proved with the same arguments; this case requires further investigation.

PROPOSITION 4.1. *Let $T > 0$. Then for $\mathbf{w}_0 \in \overline{\mathbb{H}}^2(Q) \cap \mathbb{H}$ and $\mathbf{f} \in L^2(0, T; \mathbb{V}')$, there exists a weak solution $\mathbf{w}$ of* (14) *in the sense of Definition* 4.2*. This solution $\mathbf{w}$ belongs to the space $L^2(0, T, \overline{\mathbb{H}}^2(Q)) \cap L^\infty(0, T; \mathbb{V})$; it is L^2-weakly continuous and satisfies the following energy inequality:*

$$\begin{aligned}&\frac{1}{2}(\|\mathbf{w}(t)\|^2 + \delta^2\|\nabla \mathbf{w}(t)\|^2) + \delta^2\nu\int_0^t \|\Delta\mathbf{w}(s)\|^2\,\mathrm{d}s \\ &\quad \leq K\bigg(\int_0^t \|\mathbf{f}(\mathbf{s})\|^2_{V'}\,\mathrm{d}s + \|\mathbf{w}_0\|^2 + \|\nabla \mathbf{w}_0\|^2\bigg)\end{aligned} \tag{24}$$

for all $t \in [0,T]$ *with* $K = \max\{\frac{2\|G_N\|^2_{L^2(Q)}}{\nu}, \frac{1}{2}\delta^2, \frac{1}{2}, \frac{\delta^2}{2}\|G_{N-1}\|_{L^2(Q)}\}$.

Proof. The proof uses the Faedo–Galerkin method. We will use Galdi [3] as a reference and only point out the differences between the proof of existence of the weak solution of the Navier–Stokes equations and the proof of existence for our models. We pick an orthonormal basis $\{\psi_j\}_j \in \mathbb{D}(Q)$ of $\mathbb{H}$ consisting of eigenfunctions of the Laplacian operator as in Remark (3.1). Let

$$\mathbf{w}_k(x,t) = \sum_{r=1}^{k} \eta_{kr}(t)\psi_r(x) \tag{25}$$

for $k \in \mathbb{N}$ be the solution of the following ODE system:

$$\left(\frac{\partial \mathbf{w}_k}{\partial t}, \psi_r\right) + \nu(\nabla \mathbf{w}_k, \nabla \psi_r) + (\nabla \cdot \overline{(G_N \mathbf{w}_k)(G_N \mathbf{w}_k)^T}, \psi_r) = (\mathbf{f}, \psi_r) \tag{26}$$

for all $r = 1, \ldots, k$ with the initial condition

$$(\mathbf{w}_k(0), \psi_r) = (\mathbf{w}_0, \psi_r)$$

for all $r = 1, \ldots, k$. It follows that the coefficients η_{kr} satisfy the following ODE system:

$$\frac{\mathrm{d}\eta_{kr}}{\mathrm{d}t} + \sum_{i=1}^{k} a_{ir}\eta_{ki} + \sum_{i,j=1}^{k} a_{ijr}\eta_{ki}\eta_{kj} = f_r \tag{27}$$

for all $r = 1, \ldots, k$ with the initial condition

$$\eta_{kr}(0) = C_{0r} \quad \text{for all } r = 1, \ldots, k,$$

where $a_{ir} = \nu(\nabla\psi_i, \nabla\psi_r), a_{ijr} = (\nabla \cdot \overline{((G_N\psi_i)(G_N\psi_j)^T)}, \psi_r), f_r = (\mathbf{f}, \psi_r)$, and $C_{0r} = (bw_0, \psi_r)$.

The function f_r belongs to $L^2[0,T)$ for any r, and consequently (27) has a unique solution near 0,

$$\eta_{kr} \in W^{1,2}(0, T_k),$$

where $T_k \leq T$. Because $\mathbf{w}_0 \in \overline{\mathbb{H}}^2(Q) \cap \mathbb{H}$ there exists $\mathbf{u}_0 \in \mathbb{H}$ such that $\overline{\mathbf{u}}_0 = \mathbf{w}_0$. For the ODE defined above we have $(\mathbf{w}_{k0}, \psi_r) = (\mathbf{w}_0, \psi_r)$ for all $r = 1, \ldots, k$. This gives

$$(\mathbf{w}_{k0}, \psi_r) = (\overline{\mathbf{u}}_0, \psi_r) \tag{28}$$

for all $r = 1, \ldots, k$. But $\mathbf{w}_{k,0} \in G_k = \mathrm{span}\{\psi_j\}_{j=1,\ldots,k}$ and G_k is an invariant subspace of the Laplacian operator. Consequently, we can replace ψ_r in formula (28) with $(I - \delta^2\Delta)\mathbf{w}_{k,0}$ to get

$$(\mathbf{w}_{k0}, (I - \delta^2\Delta)w_{k,0}) = (\overline{\mathbf{u}}_0, (I - \delta^2\Delta)\mathbf{w}_{k,0}) = (\mathbf{u}_0, \mathbf{w}_{k,0}). \tag{29}$$

Integrating by parts the first term above and using Cauchy's inequality in the second, we get

$$\|\mathbf{w}_{k0}\|^2 + \delta^2\|\nabla \mathbf{w}_{k0}\|^2 = (\mathbf{u}_0, \mathbf{w}_{k,0}) \leq \frac{1}{2}(\|\mathbf{u}_0\|^2 + \|\mathbf{w}_{k0}\|^2), \tag{30}$$

which gives the following estimate:

$$\frac{1}{2}\|\mathbf{w}_{k0}\|^2 + \delta^2 \|\nabla \mathbf{w}_{k0}\|^2 \le \frac{1}{2}\|\mathbf{u}_0\|^2 . \tag{31}$$

We want to prove that we can pick $T_k = T$. In (26) we replace ψ_r with $(\mathrm{I} - \delta^2\Delta)\mathrm{G}_N\mathbf{w}_k$. We can do this since $(\mathrm{I}-\delta^2\Delta)\mathrm{G}_N\mathbf{w}_k(t) \in \mathrm{G}_k = \mathrm{span}\{\psi_j\}_{j=1,\ldots,k}$ for any $t \in [0,T)$. In the same way in which the energy inequality (17) for strong solutions was derived, we obtain

$$\frac{1}{2}(\|\mathbf{w}_k(t)\|^2 + \delta^2\|\nabla\mathbf{w}_k(t)\|^2) + \delta^2\nu\int_0^t \|\Delta\mathbf{w}_k(s)\|^2\,\mathrm{d}s + \frac{\nu}{2}\int_0^t \|\Delta\mathbf{w}_k(s)\|^2\,\mathrm{d}s \le M, \tag{32}$$

where

$$M := K\left(\int_0^t \|\mathbf{f}(\mathbf{s})\|_{V'}^2\,\mathrm{d}s + \|\mathbf{w}_{k0}\|^2 + \delta^2\|\nabla\mathbf{w}_{k0}\|^2\right) \tag{33}$$

with $K = \max\{\frac{2\|\mathrm{G}_N\|^2_{L^2(Q)}}{\nu}, \frac{1}{2}\delta^2, \frac{1}{2}, \frac{\delta^2}{2}\|\mathrm{G}_{N-1}\|_{L^2(Q)}\}$.

M does not depend on t and using (31) M also does not depend on k. Due to orthonormality of the family $\{\psi_j\}_j$ in H we get that a priori the coefficients η_{kr} satisfy

$$|\eta_{kr}|^2 \le 2M^{\frac{1}{2}}$$

for any $t \in [0,T), r = 1,\ldots,k$, and $k \in \mathbb{N}$. This implies that for any k there exists a global solution (that is, on $[0,T)$)

$$\eta_{kr} \in W^{1,2}[0,T),$$

$r = 1,\ldots,k$, of the ODE system (26).

In the same way as in Galdi [3] one can show, using estimate (32), that there exists a subsequence of $\mathbf{w}_k$ (which is redenoted by $\mathbf{w}_k$) which converges weakly in V uniformly in t to a function $\mathbf{w} \in L^\infty(0,T,\mathbb{V})$. From estimate (32) we infer that the sequence $\mathbf{w}_k$ is bounded in $L^2(0,T,\overline{\mathbb{H}}^2(Q))$; consequently, it contains a subsequence (which is redenoted by $\mathbf{w}_k$) which is weakly convergent to a function $\mathbf{w}' \in L^2(0,T,\overline{\mathbb{H}}^2(Q))$. One can show, taking limits of $\mathbf{w}_k$ in the space $L^2(0,T,\mathbb{L}^2(Q))$, that $\mathbf{w} = \mathbf{w}'$. It follows that $\mathbf{w} \in (\overline{\mathbb{H}}^2(Q) \cap \mathbb{H})^d$.

We can show that $\mathbf{w}$ satisfies the variational equality (16) in the same way as in Galdi [3] taking the limits of $\mathbf{w}_k$ in equality (26). In the case of Stolz–Adams models, when taking limits, the nonlinear term is handled in the following way: one needs to show that for a given eigenfunction ψ_r,

$$\int_0^t (\overline{\mathrm{G}_N\mathbf{w}_k \cdot \nabla\mathrm{G}_N\mathbf{w}_k}, (\mathrm{I}-\delta^2\Delta)^{-1}\psi_r) - (\overline{\mathrm{G}_N\mathbf{w}\cdot\nabla\mathrm{G}_N\mathbf{w}}, (\mathrm{I}-\delta^2\Delta)^{-1}\psi_r)\,\mathrm{d}s \to 0.$$

However,

$$\begin{aligned}&\left|\int_0^t (\overline{\mathrm{G}_N\mathbf{w}_k \cdot \nabla\mathrm{G}_N\mathbf{w}_k}, (\mathrm{I}-\delta^2\Delta)^{-1}\psi_r) - (\overline{\mathrm{G}_N\mathbf{w}\cdot\nabla\mathrm{G}_N\mathbf{w}}, (\mathrm{I}-\delta^2\Delta)^{-1}\psi_r)\,\mathrm{d}s\right|\\ &\quad = \left|\int_0^t (\mathrm{G}_N\mathbf{w}_k\cdot\nabla\mathrm{G}_N\mathbf{w}_k, \psi_r) - (\mathrm{G}_N\mathbf{w}\cdot\nabla\mathrm{G}_N\mathbf{w}, \psi_r)\,\mathrm{d}s\right|\end{aligned}$$

$$\begin{aligned}&\le \left|\int_0^t (\mathrm{G}_N(\mathbf{w}_k-\mathbf{w})\cdot\nabla \mathrm{G}_N\mathbf{w}_k,\psi_r)\,\mathrm{d}s\right| + \left|\int_0^t (\mathrm{G}_N\mathbf{w}\cdot\nabla \mathrm{G}_N(\mathbf{w}_k-\mathbf{w}),\psi_r)\,\mathrm{d}s\right|\\
&\le \|\mathrm{G}_N\|^2_{L^2(Q)}\|\mathbf{w}_k-\mathbf{w}\|_{L^2(0,T,L^2)}\|\psi_r\|_\infty\|\nabla\mathbf{w}_k\|_{L^2(0,T,L^2)}\\
&\quad+\left|\int_0^t (\mathrm{G}_N\mathbf{w}\cdot \mathrm{G}_N(\nabla(\mathbf{w}_k-\mathbf{w})),\psi_r)\,\mathrm{d}s\right|.\end{aligned}$$

The first term on the right-hand side above converges to 0 since $\mathbf{w}_k \to \mathbf{w}$ in $L^2(0,T,\mathbb{L}^2(Q))$, and the second converges to 0 because $\nabla\mathbf{w}_k \to \nabla\mathbf{w}$ weakly in $L^2(0,T,\mathbb{L}^2(Q))$ and the operator G_N is self-adjoint. The energy inequality (24) is obtained in the same way as in the case of the Navier–Stokes equations taking limits in (32). ∎

LEMMA 4.2. *The weak solution* $\mathbf{w}$ *that was constructed in the previous theorem is also a strong solution of* (14).

Proof. This follows directly from definition (16), the regularity proven for the solution, and an integration by parts. ∎

LEMMA 4.3. *The weak solution* $\mathbf{w}$ *of* (14) *constructed in Proposition* 4.1 *is the unique weak solution of* (14).

Proof. This is a consequence of the regularity of $\mathbf{w}$. The proof is the same as in the case of the Navier–Stokes equations. ∎

5. An a priori estimate of the modeling error. Our goal here is to give an a priori estimate of the modeling error $\|\overline{\mathbf{u}}-\mathbf{w}\|$. In this direction there are several fundamental problems. First, in three dimensions there is no proof of uniqueness of weak solutions $\mathbf{u}$ of the Navier–Stokes equations. Thus for $\mathbf{u}$ a general weak solution of the Navier–Stokes equations, the best result attainable in the usual norms with the present technique seems to be the following.

PROPOSITION 5.1. *Let* $\mathbf{w}=\mathbf{w}(\delta)$ *be the unique strong solution of the model* (14). *Then there is a subsequence* $\delta_j\to 0$ *as* $j\to\infty$ *and a weak solution* $\mathbf{u}$ *of the Navier–Stokes equations such that* $\mathbf{w}(\delta_j)\to\mathbf{u}$ *in* $L^\infty(0,T,\mathbb{L}^2(Q))\cap L^2(0,T,\mathbb{H}^1(Q))$.

Proof. This proof follows that of Theorem 3.1 of Layton and Lewandowski [6]. ∎

The second question concerns the right norm. Obviously if we are restricting our attention to general weak solutions, the right norm must be a very weak norm for which the modeling residual $\left\|\mathbf{u}\mathbf{u}^T-\mathrm{G}_N\overline{\mathbf{u}}(\mathrm{G}_N\overline{\mathbf{u}})^T\right\|$ is not only well defined but also vanishes as $\delta\to 0$. The answer to this question is still unknown; see, e.g., Layton and Lewandowski [6] for first steps. The third question concerns extracting a rate of convergence for $\|\overline{\mathbf{u}}-\mathbf{w}\|$ which gives some insight into the model's accuracy on the laminar regions. This problem is much simpler. It reduces to proving the highest possible rate of convergence for $\|\overline{\mathbf{u}}-\mathbf{w}\|\to 0$ for very smooth solution $\mathbf{u}$.

In the remainder of this subsection we give the answer: the modeling error is a priori $O(\delta^{2N+2})$ for smooth $\mathbf{u}$.

PROPOSITION 5.2. *Assume* $\mathbf{u}$ *is a weak solution of the Navier–Stokes equations and* $\nabla\mathbf{u}\in L^4(0,T,\mathbb{L}^2(Q))$. *For* $\mathbf{w}\in L^2(0,T,\overline{\mathbb{H}}^2(Q))\cap L^\infty(0,T;\mathbb{V})$ *a weak solution of* (14) *and* $\tau := \mathbf{u}\mathbf{u}^T-\mathrm{G}_N\overline{\mathbf{u}}(\mathrm{G}_N\overline{\mathbf{u}})^T$ *there exists a positive constant* $P=P(\nu,N,\|\nabla\mathbf{u}\|_{L^4(0,T,\mathbb{L}^2)})\ge 0$ *such that*

(34)
$$\|\overline{\mathbf{u}}-\mathbf{w}\|^2_{L^\infty(0,T,\mathbb{L}^2)}+\|\nabla(\overline{\mathbf{u}}-\mathbf{w})\|^2_{L^2(0,T,\mathbb{L}^2)}\le P(\nu,N,\|\nabla\mathbf{u}\|_{L^4(0,T,\mathbb{L}^2)})\,\|\tau\|^2_{L^2(0,T,\mathbb{L}^2)}\,.$$

Proof. To begin we derive an equation for $\phi := \overline{\mathbf{u}} - \mathbf{w}$. First we note that $\mathbf{w}$ is a unique strong solution of the model and under stated regularity assumptions on $\mathbf{u}, \mathbf{u}$ is a unique strong solution of the Navier–Stokes equations; see [12, Remark 3.3]. Thus there are no subtleties in the derivation of the error equation. Equality (3) can be rewritten as

$$\begin{aligned} \overline{\mathbf{u}}_t + \nabla \cdot (\overline{\mathrm{G}_N \overline{\mathbf{u}} \mathrm{G}_N \overline{\mathbf{u}}^T}) - \nu \Delta \overline{\mathbf{u}} + \nabla \overline{p} &= \overline{\mathbf{f}} + \nabla \cdot (\overline{\mathrm{G}_N \overline{\mathbf{u}} \mathrm{G}_N \overline{\mathbf{u}}^T - \mathbf{u}\mathbf{u}^T}), \\ \nabla \cdot \overline{\mathbf{u}} &= 0. \end{aligned} \tag{35}$$

Subtraction gives the equation for $\varphi := \overline{\mathbf{u}} - \mathbf{w}$,

$$\begin{aligned} \overline{\varphi}_t + \nabla \cdot \overline{(\mathrm{G}_N \overline{\mathbf{u}} \mathrm{G}_N \overline{\mathbf{u}}^T - \mathrm{G}_N \mathbf{w} \mathrm{G}_N \mathbf{w}^T)} - \nu \Delta \varphi + \nabla \overline{(p-q)} &= -\nabla \cdot \overline{\tau} && \text{in } (0,T) \times \mathbb{R}^d, \\ \nabla \cdot \varphi &= 0 && \text{in } (0,T] \times \mathbb{R}^d, \\ \varphi|_{t=0} &= 0 && \text{in } \mathbb{R}^d, \\ \int_Q p - q \,\mathrm{d}x &= 0 && \text{in } (0,T]. \end{aligned} \tag{36}$$

We multiply the first equation in (36) by $(\mathrm{I} - \delta^2 \Delta)^{-1} \mathrm{G}_N \varphi$ and then integrate on Q. Following exactly the same computations as in Lemma 4.1 gives

$$\begin{aligned} &\frac{1}{2} \frac{\mathrm{d}}{\mathrm{d}t} \|\varphi\|^2 + \frac{1}{2} \delta^2 \frac{\mathrm{d}}{\mathrm{d}t} \|\nabla \varphi\|^2 + \frac{\delta^2}{2} \frac{\mathrm{d}}{\mathrm{d}t} (\nabla \varphi, \mathrm{G}_{N-1} \nabla \varphi) + \nu \|\nabla \varphi\|^2 + \nu \delta^2 \|\Delta \varphi\| \\ &\quad + \nu \delta^4 (\Delta \phi, \mathrm{G}_{N-1} \Delta \varphi) = -(\nabla \cdot \tau, \mathrm{G}_N \varphi) + b(\mathrm{G}_N \varphi, \mathrm{G}_N \overline{\mathbf{u}}, \mathrm{G}_N \varphi), \end{aligned} \tag{37}$$

where b is the standard trilinear form

$$b(\mathbf{u}, \mathbf{v}, \mathbf{w}) = ((\mathbf{u} \cdot \nabla) \mathbf{v}, \mathbf{w}).$$

The first term on the right-hand side is bounded as follows:

$$|(\nabla \cdot \tau, \mathrm{G}_N \varphi)| = |(\tau, \mathrm{G}_N \nabla \varphi)| \leq \|\tau\| \, \|\mathrm{G}_N\|_{L^2} \|\nabla \varphi\| \leq \frac{2 \|\mathrm{G}_N\|_{L^2}^2}{\nu} \|\tau\|^2 + \frac{1}{2} \nu \|\nabla \varphi\|^2.$$

To bound the second term we use Young's inequality

$$ab \leq \epsilon a^4 + \frac{3}{4} (4\epsilon)^{-\frac{1}{3}} b^{\frac{4}{3}},$$

together with the standard estimate for the trilinear form

$$|b(\mathrm{G}_N \varphi, \mathrm{G}_N \overline{\mathbf{u}}, \mathrm{G}_N \varphi)| \leq C(Q) \|\nabla \overline{\mathbf{u}}\| \, \|\varphi\|^{\frac{1}{2}} \|\nabla \varphi\|^{\frac{3}{2}},$$

to obtain that for any $\epsilon > 0$,

$$|b(\mathrm{G}_N \varphi, \mathrm{G}_N \overline{\mathbf{u}}, \mathrm{G}_N \varphi)| \leq \epsilon \|\mathrm{G}_N\|^2 \|\nabla \varphi\|^2 + \frac{3}{4} (4\epsilon)^{-\frac{1}{3}} \|\mathrm{G}_N \nabla \overline{\mathbf{u}}\|^4 \|\mathrm{G}_N \varphi\|^2.$$

Plugging $\epsilon = \frac{\nu}{2\|\mathrm{G}_N\|^2}$ into the above inequality, we get that

$$|b(\mathrm{G}_N \varphi, \mathrm{G}_N \overline{\mathbf{u}}, \mathrm{G}_N \varphi)| \leq \frac{\nu}{2} \|\nabla \varphi\|^2 + \frac{3}{4} \left(\frac{2\nu}{\|\mathrm{G}_N\|^2} \right)^{-\frac{1}{3}} \|\mathrm{G}_N\|^4 \|\nabla \overline{\mathbf{u}}\|^4 \|\varphi\|^2.$$

Using the last two inequalities in (37) gives

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|\varphi\|^2 + \frac{1}{2}\delta^2\frac{\mathrm{d}}{\mathrm{d}t}\|\nabla\varphi\|^2 + \frac{\delta^2}{2}\frac{\mathrm{d}}{\mathrm{d}t}(\nabla\varphi, \mathrm{G}_{N-1}\nabla\varphi) + \nu\delta^2\|\Delta\varphi\|$$
$$+\nu\delta^4(\Delta\phi, \mathrm{G}_{N-1}\Delta\varphi) \le \frac{2\|\mathrm{G}_N\|^2_{L^2}}{\nu}\|\tau\|^2 + \frac{3}{4}(2\nu)^{-\frac{1}{3}}\|\mathrm{G}_N\|^{\frac{10}{3}}\|\nabla\overline{\mathbf{u}}\|^4\|\mathbf{w}\|^2.$$

Gronwall's inequality and positivity of the operators $(\mathrm{G}_N)_N$ give

$$\|\varphi\|^2 \le \int_0^t \exp\left(-2\int_s^t \frac{3}{4}(2\nu)^{-\frac{1}{3}}\|\mathrm{G}_N\|^{\frac{10}{3}}\|\nabla\overline{\mathbf{u}}\|^4\,\mathrm{d}s'\right)\frac{2\|\mathrm{G}_N\|^2_{L^2}}{\nu}\|\tau\|^2_{L^2}\,\mathrm{d}s.$$

For fixed N we have that

$$\|\mathrm{G}_N\| \le 1 + (1+\|\mathrm{G}\|) + (1+\|\mathrm{G}\|)^2 + \cdots + (1+\|\mathrm{G}\|)^N,$$

and since for every δ, $\|\mathrm{G}\| \le 1$ it follows that

$$\|\mathrm{G}_N\| \le 2^{N+1} - 1$$

uniformly in δ. Under the assumption that $\nabla\mathbf{u} \in L^4(0,T,L^2)$ we infer the existence of a constant $M = M(\nu, N, \|\nabla\mathbf{u}\|_{L^4(0,T,L^2)})$ such that

$$\|\varphi\|^2_{L^\infty(0,T,L^2)} \le M\big(\nu, N, \|\nabla\mathbf{u}\|_{L^4(0,T,L^2)}\big)\int_0^T \|\tau\|^2_{0,T,L^2}. \tag{38}$$

To estimate $\|\nabla\varphi\|^2_{L^2(0,T,L^2)}$ we integrate (37) from 0 to t and, using inequality (38), we obtain

$$\|\nabla\phi\|^2_{L^2(0,T,L^2)} \le R(\nu, N, \|\nabla\mathbf{u}\|_{L^4(0,T,L^2)})\int_0^T \|\tau\|^2_{0,T,L^2}$$

for positive constant $R = R(\nu, N, \|\nabla\mathbf{u}\|_{L^4(0,T,L^2)})$. Consequently, there exists a constant $P = P(\nu, N, \|\nabla\mathbf{u}\|_{L^4(0,T,L^2)})$ such that

$$\|\varphi\|^2_{L^\infty(0,T,L^2)} + \|\nabla\phi\|^2_{L^2(L^2)} \le P(\nu, N, \|\nabla\mathbf{u}\|_{L^4(0,T,L^2)})\|\tau\|^2_{L^2(0,T,L^2)}. \tag{39}$$

PROPOSITION 5.3. *Under the conditions of the previous theorem, if* $\mathbf{u} \in \mathbb{H}^{N+1}(Q)$, *there exists* $P = P(\nu, N, \mathbf{u}) \ge 0$ *such that*

$$\|\overline{\mathbf{u}} - \mathbf{w}\|^2_{L^\infty(0,T,L^2)} + \|\nabla(\overline{\mathbf{u}} - \mathbf{w})\|^2_{L^2(0,T,L^2)} \le P(\nu, N, \mathbf{u})\delta^{2N+2}. \tag{40}$$

Proof. An application of Lemma 2.2 gives

$$\|\tau\|^2_{L^2(0,T,L^2)} \le C(\mathbf{u})\delta^{2N+2};$$

(40) will then follow from (39). ∎

6. Conclusions. The Stolz–Adams deconvolution models analyzed herein are shown to have very good mathematical properties, better than any other large-eddy simulation model for turbulent flows that is currently used.

There exists a weak solution of these models; that solution is unique, and further it is shown that it belongs to higher order Sobolev spaces and that it is also the strong solution of the models.

We proved that the Stolz–Adams models give a good description of the local spatial averages of fluid velocities, the modeling error converges to 0, and the rate of convergence is also derived.

This paper provides the mathematical foundations of the Stolz–Adams models, giving guidance for practical computations with these models.

LATTICE POINTS ON CIRCLES AND DISCRETE VELOCITY MODELS FOR THE BOLTZMANN EQUATION*

LAURA FAINSILBER†, PÄR KURLBERG‡, AND BERNT WENNBERG†

Abstract. The construction of discrete velocity models or numerical methods for the Boltzmann equation, may lead to the necessity of computing the collision operator as a sum over lattice points. The collision operator involves an integral over a sphere, which corresponds to the conservation of energy and momentum. In dimension two there are difficulties even in proving the convergence of such an approximation since many circles contain very few lattice points, and some circles contain many badly distributed lattice points. However, by showing that lattice points on most circles are equidistributed we find that the collision operator can indeed be approximated as a sum over lattice points in the two-dimensional case. The proof uses a weak form of the Halberstam–Richert inequality for multiplicative functions (a proof is given in the paper), and estimates for the angular distribution of Gaussian primes. For higher dimensions, this result has already been obtained by Palczewski, Schneider, and Bobylev [*SIAM J. Numer. Anal.*, 34 (1997), pp. 1865–1883].

Key words. Boltzmann equation, discrete velocity model, multiplicative functions, distribution of Gaussian primes

1. Introduction.

The phase space density f of a dilute gas evolves according to the Boltzmann equation. In the physically relevant case, the gas would be confined to a subset $\Omega \subset \mathbb{R}^3$, and then $f(x,v,t){:}\Omega\times\mathbb{R}^3\times\mathbb{R}^+ \to \mathbb{R}^+$, where x denotes a position in space, $v \in \mathbb{R}^3$ is a velocity, and t denotes the time. From a mathematical point of view, it is equally natural to consider the Boltzmann equation in any spatial dimension, and in some cases because of symmetries of Ω, it is also relevant to consider $\Omega \subset \mathbb{R}^{d_1}$ and $v \in \mathbb{R}^{d_2}$ with $d_1 < d_2$.

By a dilute gas we mean one where the particles interact with each other essentially only by *pairwise* interactions. Moreover, the Boltzmann equation assumes that the particles are so small compared to other distances, that they can be considered to be points.

Under these hypotheses, one can formally derive the Boltzmann equation (see [7])

$$\partial_t f(x,v,t) + v\cdot\nabla_x f(x,v,t) = Q(f,f)(x,v,t). \tag{1}$$

The left-hand side describes the evolution of the density by free transport, and the right-hand side describes the impact of collisions. Per definition, a collision is a pairwise interaction that takes place instantaneously and at one single point in space.

Hence x and t appear only as parameters in $Q(f,f)$, and we can write

$$Q(f,f)(v) = \int_{\mathbb{R}^d}\int_{S^{d-1}} \left(f(v')f(v'_*) - f(v)f(v_*)\right) q(|w|,\cos\theta)\, dS(u)dv_*, \tag{2}$$

where the velocities "before and after a collision" are related by

$$\begin{aligned} v' &= \tfrac{1}{2}(v+v_*) + |w|\,u \\ v'_* &= \tfrac{1}{2}(v+v_*) - |w|\,u, \end{aligned} \tag{3}$$

with $w = (v_* - v)/2$, and with $\cos\theta = \frac{u\cdot w}{|w|}$; dv_* is the Lebesgue measure in $\mathbb{R}^d$, and $dS(u)$ is the surface measure on S^{d-1}. Note that the pair of velocities before a collision, v and v_*, and the pair of velocities after the collision, v' and v'_*, are the endpoints of a diameter on the sphere which has its center at $\frac{v+v_*}{2}$ and diameter $|v_* - v|$. This is exactly the condition needed in order that the collisions preserve the momentum and energy of the pair of particles. For $d = 2$, the sphere becomes a circle, and this motivates the title of the paper.

In a discrete velocity model (DVM), the velocities are concentrated on a (usually finite) set of points $v_j \in \mathbb{R}^d$ in the velocity space:

$$f(x,v,t) = \sum_j f_j(x,t)\delta_{v=v_j}.$$

The Boltzmann equation (1) is then changed into a nonlinear system of conservation laws,

$$\partial_t f_j + v_j \cdot \nabla_x f_j = \sum_{k,k',j'} \Gamma_{j,k}^{j',k'}\left(f_{j'}f_{k'} - f_j f_k\right), \tag{4}$$

where the constants $\Gamma_{j,k}^{j',k'} \geq 0$ must be chosen so that (4) makes sense from a physical point of view. In particular, we require that (v_j, v_k) and $(v_{j'}, v_{k'})$ define two diameters on the same sphere, just as for the usual Boltzmann equation.

The first example of a discrete velocity model is that of Carleman [5], which has two velocities in $\mathbb{R}$. Many other models have been proposed, and there is vast literature on how to construct and analyze physically realistic models (i.e., that satisfy the right conservation laws and an entropy principle); see, e.g., [4, 24, 25].

In this paper we are not mainly concerned with the question of whether the model we study is correct in this sense (this has actually been demonstrated in [4]), and so we defer our discussion on this matter to the last section of the paper.

Besides offering many interesting mathematical challenges (for example, there is no general theory of global existence of solutions to systems like (4)), the DVMs are also candidates for the numerical approximation of the real Boltzmann equation (1). This leads naturally to the following question, which is the subject matter of the paper.

Suppose that we choose the discrete set of velocities to be $h\mathbb{Z}^d$, i.e., the integer lattice in $\mathbb{R}^d$, scaled by a factor h, and that we take

$$f^h(v) = \sum_{\xi\in\mathbb{Z}^d} f_{\xi,h}\delta_{v=h\xi},$$

so that $f^h \to f$, in some suitable sense, where $f \in L^1(\mathbb{R}^d)$. Is it then true that $Q(f^h, f^h)(v) \to Q(f,f)(v)$ for all $v \in h\mathbb{Z}^d$ when $h \to 0$? (This property, which is called *consistency*, together with *stability* are the main ingredients when proving that a numerical method converges.) The answer is yes. This was proven by Palczewski, Schneider, and Bobylev [3] for dimensions $d \geq 3$ (see also [2]). In this paper, we prove that it is also true for $d = 2$, and hence for all relevant cases.

Results of this kind are interesting, because, together with the corresponding existence results [21], they provide examples that are relevant to previous results of Desvillettes and Mischler [8], who proved that solutions to families of DVMs can converge to DiPerna–Lions' solutions to (1) if certain conditions are satisfied.

Our result should not, however, be considered as relevant for numerical analysis, because the rate of convergence is so slow that a numerical method based on the theory presented here would hardly ever become useful.

The family of models considered here can be seen as coming from a rather straightforward discretization of the collision integral (2). This integral should be interpreted as an average over the $(2d-1)$-dimensional manifold defined by

$$\mathcal{M}_v = \big\{(v_*, v', v'_*) \in \mathbb{R}^{3d} \text{ such that } v' + v'_* - v_* = v \\ |v'|^2 + |v'_*|^2 - |v_*|^2 = |v|^2\big\}, \tag{5}$$

and (2) is an iterated integral over this manifold. For a fixed v, we write $w = (v_* - v)/2$, and then (3) becomes

$$v' = v + w + |w|u$$
$$v'_* = v + w - |w|u,$$

and also $v_* = v + 2w$. We then write

$$g_v(w, u) = (f(v')f(v'_*) - f(v)f(v_*))\, q(|w|, \cos\theta), \tag{6}$$

and so (after changing variables in the integral),

$$Q(f,f)(v) = 2^d \int_{\mathbb{R}^d} \left(\int_{S^{d-1}} g_v(w, u)\, dS(u) \right) dw.$$

If g is sufficiently regular (continuous), and decays sufficiently rapidly for large w, then the Riemann sum for the outer integral converges:

$$(2h)^d \sum_{\zeta \in \mathbb{Z}^d} \int_{S^{d-1}} g_v(h\zeta, u)\, dS(u) \longrightarrow 2^d \int_{\mathbb{R}^d} \left(\int_{S^{d-1}} g_v(w, u)\, dS(u) \right) dw \tag{7}$$

when $h \to 0$. In order to construct a consistent DVM, it is then sufficient to evaluate the inner integral in terms of the values of g on the lattice points $h\mathbb{Z}^d$, in such a way that the result converges to $\int_{S^{d-1}} g(w, u)\, dS(u)$. While with the formula (3), the collision integral should be taken over all $u \in S^{d-1}$, we have here only access to those u for which v' and v'_* belong to $h\mathbb{Z}^d$. But this is automatically achieved if $\zeta \in \mathbb{Z}^d$, and if $u = \zeta'/|\zeta'|$, where $\zeta' \in \mathbb{Z}^d$ and $|\zeta'| = |\zeta|$; then for all $v \in h\mathbb{Z}^d$,

$$v + h\zeta \pm h|\zeta|u \in h\mathbb{Z}^d.$$

However, note that with this construction, the center of the sphere is restricted to lie on a lattice point, so it excludes cases like $v = (0, 0)$, $v_* = (h, h)$.

Giving all points on the sphere equal weight, one arrives at the expression

$$\frac{1}{r_d(|\zeta|^2)} \sum_{\substack{\zeta' \in \mathbb{Z}^d \\ |\zeta'|=|\zeta|}} \left(f(v')f(v'_*) - f(v)f(v_*)\right) q(|h\zeta|, \cos\theta), \tag{8}$$

for approximating the inner integral in (7). The function $r_d(n)$ denotes the number of points with integer coordinates on a sphere in $\mathbb{R}^d$ with center at the origin and radius $\sqrt{n}$, i.e., the number of integer solutions to $x_1^2 + \cdots + x_d^2 = n$.

We write, for all $v \in h\mathbb{Z}^d$,

$$Q^h(f,f)(v) = (2h)^d \sum_{\zeta \in \mathbb{Z}^d} \frac{1}{r_d(|\zeta|^2)} \sum_{\substack{\zeta' \in \mathbb{Z}^d \\ |\zeta'|=|\zeta|}} \left(f(v')f(v'_*) - f(v)f(v_*)\right) q(|h\zeta|, \cos\theta). \tag{9}$$

In the two-dimensional case, all the terms in the sum are 2π-periodic functions of θ, and assuming sufficient regularity, they can be expressed as a convergent Fourier series. It is then natural to introduce the exponential sum

$$S(n,k) = \sum_{u \in \mathbb{Z}^2 : |u|^2 = n} e^{ik\theta_u}, \tag{10}$$

where θ_u is defined by $u = |u| \cdot (\sin\theta_u, \cos\theta_u)$. We will see in section 4 that to prove that (8) converges to the angular integral in (7), it is enough to prove that for $k \neq 0$, there is sufficient cancellation in the exponential sums $S(n,k)$ on average. Similar exponential sums are relevant for any dimension, and the work of Bobylev et al. [2] and Palczewski et al. [3] also involves such estimates.

Here the needed estimate is given as Proposition 6 in section 3. Then in section 4 we put the estimates together to a proof of the main result.

THEOREM 1. *Consider the Boltzmann equation in two dimensions. Assume that f and q are so smooth that the function $g_v(w,u)$ defined in* (6) *is a C^2-function. Then for all $v \in h\mathbb{Z}^2$*

$$\left|Q(f,f)(v) - Q^h(f,f)(v)\right| \to 0$$

when $h \to 0$.

Section 5, finally, contains a discussion of spurious invariants and of numerical cost. We also illustrate the distribution of points such that the circles passing through them contain many lattice points.

A more general construction of discrete velocity models on scaled integer lattices $h\mathbb{Z}^2$ consists of finding sets of integer points on the manifold $\mathcal{M}$ defined in (5). In this way, mass and energy conservation are automatically satisfied, but one also needs to verify that these are the *only* conserved quantities. Finally, in order that the models converge to the continuous model when $h \to 0$, it is necessary that the integer points are more or less uniformly distributed on $\mathcal{M}$.

The models studied here are constructed by discretizing, one at a time, the iterated integrals (2). An alternative way of writing this integral was introduced by Carleman [5]. Using that $v' - v$ and $v'_* - v$ are orthogonal, one can write (here we specialize to $d = 3$)

$$Q(f,f)(v) = \int_{\mathbb{R}^3} \int_{E_{v,v'}} \left(f(v')f(v'_*) - f(v)f(v_*)\right) q(w, \cos\theta) \frac{1}{|v - v'|^2}\, dE(v'_*)\, dv',$$

where $E_{v,v'}$ is the plane that contains v and is orthogonal to $v'-v$, and where $dE(v'_*)$ is the Euclidean measure on this plane. Panferov and Heintz [17] have analyzed a DVM based on this iterated integral, and proved that the method is consistent with the continuous model. This is somehow easier, because on a given plane, one can find all integer points by solving linear Diophantine equations. However, the density of points depends strongly on $v'-v$, and so it is far from trivial to prove the consistency. Again, the two-dimensional situation is more difficult, and has not yet been studied.

Yet another approach was introduced by Rogier and Schneider [23], who used the theory of Farey series to discretize the angular variable in the collision integral. Some recent, related results on DVMs can be found in [1].

2. Number theoretic background.

2.1. Points on spheres; Asymptotics. To prove that (8) converges to the correct limit when $h \to 0$, one has to study the set

$$\{\zeta/|\zeta| : \zeta \in \mathbb{Z}^d, |\zeta|^2 = n\}$$

and show that the points of this set are sufficiently well distributed on S^{d-1} when n is large; it is here that the number theoretical issues enter the game. Indeed, we can view the set of points with integer coordinates on a sphere of squared radius n centered at the origin,

$$\{(x_1, \dots x_d) \in \mathbb{Z}^d, \sum_{i=1}^{d} x_i^2 = n\},$$

as the solution set for a quadratic form, and use the theory of integral quadratic forms to get estimates on the number of points (see, for instance, [13]). The expected number of points with integer coordinates on a sphere clearly depends on the dimension d. The naive approach to find the order of magnitude for a given dimension is to use the volume of a ball, divided by the number of spheres contained in the ball. The volume of a ball of radius $\sqrt{n}$ grows as $n^{d/2}$ while the number of spheres is n. For $d = 2$, this leads us to expect a constant number of lattice points on circles, for $d = 3$, a growth proportional to $\sqrt{n}$, etc. However, for small d this approach is misleading; the growth is quite irregular and depends on the divisor structure of n. For $d = 2$, we will see below that only values of n of the form $n = 2^s q^2 p_1^{\alpha_1} \dots p_r^{\alpha_r}$, where q is a product of primes of the form $4k+3$ and the p_i's are primes of the form $4k+1$ (see below), yield circles with lattice points, and thus most circles have no points at all. In fact, Landau proved in 1908 that the number of circles with at least one lattice point, of integer squared radius smaller than x, grows as $Cx/\sqrt{\log x}$. Moreover, there are also infinite families of circles with very few lattice points; radii that are a power of 2 yield 4 points for instance, and radii that are the square root of a prime of the form $p = 4k+1$ yield exactly 8 points. On the other hand, the number of lattice points on a circle is not bounded; for instance, a circle with $n = p_1 \dots p_r$ as above, where all the p_i are distinct from each other, has $4 \cdot 2^r$ points.

In dimension 3, all values of n not of the form $n = 4^s(8k+7)$ yield spheres containing points with integer coordinates. This still leaves a fairly large number of spheres having no points, but for our purposes this does not really matter, as such spheres do not appear in the summation formulas (there is no relevant value for ζ). Among the spheres with lattice points, multiplying the radius by a power of 2 does not increase the number of points, but if we correct for this fact, the ratio between the number of points and the naive estimate is bounded, up to constants only depending on ϵ, from above by n^ϵ, and below by $n^{-\epsilon}$ for all $\epsilon > 0$ (see [13, Chap. 4] for exact formulas involving class numbers or L-series.)

The higher-dimensional cases behave in a somewhat more regular fashion. Lagrange proved that every positive integer can be written as the sum of four squares, and thus for dimension $d \geq 4$, every sphere whose squared radius is an integer has lattice points. For $d = 4$, the number of points still oscillates rather wildly (e.g., spheres with radius a power of 2 only have 24 points) but for greater dimensions, the naive estimate gives the correct asymptotic growth of the number of points.

Getting circles (or spheres) with "sufficiently many" lattice points, however, is not quite enough for our purposes: we also require that the lattice points be sufficiently uniformly distributed when projected on the unit sphere. In dimensions 3 and higher, this follows from estimates on Fourier coefficients of modular forms. The case $d \geq 4$, with some restrictions on the set of numbers in which n tends to infinity when $d = 4$, is due to Pommerenke [22]. For $d = 3$, Duke [10] and Golubeva–Fomenko [14] used Iwaniec's [18] estimates on Fourier coefficients of half integral weight forms to obtain uniform distribution. Unfortunately, these techniques do not apply in dimension 2. Moreover, there are circles with a large number of lattice points that are poorly distributed.

Theorem 2 (see Cilleruelo [6]). *For any $\epsilon > 0$ and for any integer k, there exists a circle $x^2 + y^2 = n$ with more than k lattice points such that all the lattice points are on the arcs $\sqrt{n}e^{(\pi/2)(t+\theta)i}$ with $|\theta| < \epsilon$, $t \in \{0, 1, 2, 3\}$.*

On the other hand, we may use some other techniques from analytic number theory to show that lattice points on circles are equidistributed *on average*, and this is good enough for our purpose.

2.2. From points on circles to Gaussian integers. In the plane, we can view lattice points on a circle of radius $\sqrt{n}$, centered at the origin, as complex numbers with integer real and imaginary parts, and squared modulus n. It might seem as a trivial restatement, but doing so allows us to use use some techniques from algebraic number theory. The *Gaussian integers*, i.e., the set

$$\mathbb{Z}[i] = \{x + iy \in \mathbb{C}, (x, y) \in \mathbb{Z}^2\}$$

is the ring of integers of the field $\mathbb{Q}(i)$. It shares an important property with the ordinary integers, namely, unique factorization,[1] i.e., just as every integer in $\mathbb{Z}$ factors into prime numbers, and the factorization is unique up to ordering the primes and multiplying by -1, Gaussian integers factor into Gaussian primes, uniquely up to ordering and multiplication by $-1, i, -i$ (these and 1 are the units, i.e., the elements having a multiplicative inverse in $\mathbb{Z}[i]$). For a more thorough introduction to primes in quadratic number fields, see, for instance, [16, Chap. XV].

The Gaussian primes (i.e., the elements of $\mathbb{Z}[i]$ that cannot be written as a product of Gaussian integers with smaller modulus) are of three types:

- The prime numbers $q \in \mathbb{Z}$ such that $q \equiv 3 \mod 4$ remain prime in $\mathbb{Z}[i]$ (e.g., $3, 7, 11, 19, \ldots$).
- For prime numbers $p \in \mathbb{Z}$ such that $p \equiv 1 \mod 4$, there exists $x, y \in \mathbb{Z}$ such that $p = x^2 + y^2$. Hence p factors in $\mathbb{Z}[i]$ as a product of two Gaussian primes

  $$p = (x + iy)(x - iy).$$

  For example, 5 factors into $(2 + i)(2 - i)$ in $\mathbb{Z}[i]$.

[1] This is rather unusual; the ring of integers in most number fields will not have this property.

- Last (and least!), $1+i$ is prime. (Note that $(1+i)(1-i)=2$ and that $1-i=-i(1+i)$ is merely "another form of the same prime," just as 3 and -3 represent the same prime.)

If n is the sum of two squares, then it can be factored in $\mathbb{Z}[i]$:

$$n = X^2 + Y^2 = (X+iY)(X-iY).$$

If $z = x+iy$ is a prime factor of $X+iY$, then $\bar{z} = x-iy$ must be a prime factor of $X-iY$. It follows that prime factors $q \equiv 3 \mod 4$ of n must appear in even powers. In addition, multiplying n by an even power of a prime q that is congruent with 3 mod 4 changes neither the number of solutions to $n = X^2+Y^2$ nor the distribution of arguments of the solutions.

Suppose now that n contains a factor p^α, where $p \equiv 1 \mod 4$. The number p can be factored in $\mathbb{Z}[i]$ as $(x+iy)(x-iy)$, and hence the multiplicity of $x+iy$ as a factor of n is α, and the same is true for $x-iy$. It follows that the multiplicity of $x+iy$ in $X+iY$ can be any integer j, with $0 \le j \le \alpha$, and the multiplicity of $x-iy$ is then $\alpha - j$.

The same calculation can be done for powers of 2; however, the solutions given by different choices of j in that case differ by a multiplication by a power of i, and so the power of 2 does not influence the number of solutions.

All solutions to $n = X^2+Y^2$ can now be expressed as $X+iY = \sqrt{n}\exp(i\theta)$, where all possible values of the argument θ can be computed as sums of terms deriving from the different factors of n in the following way:

1. $X+iY$ can be multiplied by any unit, i.e., by ± 1 or $\pm i$. This gives a term $k\pi/2$ in the argument, $k = 0,1,2,3$.
2. If the multiplicity of 2 in n is odd, then the argument must contain $\pi/4$, the argument of $1+i$; the number of solutions does not change.
3. For each prime factor $p \equiv 1 \mod 4$ in n, let α_p be the multiplicity of p in n, let $p = x_p^2 + y_p^2$, and set $\theta_p = \arg(x_p + iy_p)$. For a particular choice of j, $0 \le j \le \alpha_p$, the argument added to $X+iY$ is $j\theta_p - (\alpha_p - j)\theta_p = (2j-\alpha_p)\theta_p$.

Since the choices of k and of the different $j's$ are independent the number of different solutions is $4\prod_{p\equiv 1 \bmod 4}(\alpha_p+1)$.

2.3. Results on the distribution of primes and on the angular distribution of points. We will need the results that follow.

Theorem 3 (Merten's theorem, see [16, Chap. 22.8]).

$$\prod_{\substack{p \le x \\ p \text{ prime}}} (1-1/p) \sim e^{-\gamma}/\log x,$$

where $\gamma \simeq 0.57$ is Euler's constant.

As for the angular distribution of Gaussian primes, a result by Kubilyus gives that the angles $\{\theta_p\}_{p\equiv 1 \mod 4}$ are equidistributed in $[0,\pi/4]$ as shown in the following theorem.

Theorem 4 (Kubilyus [20]). *The number of Gaussian primes ω in the sector $0 \le \alpha \le \arg(\omega) \le \beta \le 2\pi$, $|\omega|^2 \le u$ is equal to*

$$\frac{2}{\pi}(\beta-\alpha)\int_2^u \frac{dv}{\log v} + O\left(u\exp(-b\sqrt{\log u})\right),$$

where b is an absolute positive constant.

From Kubilyus' theorem, it is straightforward to deduce (see [11, p. 92]) the following corollary.

COROLLARY 5. *If* $k \in 4\mathbb{N}$ *and* $\log k \le b\sqrt{\log x}$, *then*

$$\sum_{\substack{p \le x \\ p \equiv 1 \mod 4}} \frac{|\cos(k\theta_p)|}{p} \le \frac{1}{\pi} \log\log x + (1 - 2/\pi) \log\log k + O(1).$$

3. Equidistribution of lattice points on circles. What is needed for the proof of consistency of the discrete velocity model are estimates on the equidistribution of lattice points on circles, and the aim of this section is to show that lattice points on circles are equidistributed *on average*.

Let $r(m) = r_2(m)$ be the number of integer solutions to $x^2 + y^2 = m$. We recall the definition of $S(m,k)$:

$$S(m,k) = \sum_{|w'|^2 = m} e^{ik\theta_{w'}}.$$

PROPOSITION 6. *If* $4 \nmid k$, *then* $|S(m,k)| = 0$. *If* $4|k$ *and* $k \neq 0$, *there exist* C *and* $b > 0$ *such that*

$$\log\left(\frac{1}{X}\sum_{m \le X} |S(m,k)|\right) \le C - (1 - 2/\pi)\log\left(\frac{\log X}{(\log|k|)^2}\right)$$

for X *sufficiently large and* $\log|k| \le b\sqrt{\log X}$.

Remark. The mean discrepancy of the distribution of angles of Gaussian integers was studied by Kátai and Környei in [19], and by Erdős and Hall in [11]. Our method is similar to theirs, except that they bound

$$\frac{1}{X/\sqrt{\log X}} \sum_{m \le X} \frac{|S(m,k)|}{r(m)}$$

instead of

$$\frac{1}{X}\sum_{m \le X} |S(m,k)|.$$

The proof is based on the observation that $|S(m,k)|/4$ is a *multiplicative* function, i.e., a function $f : \mathbb{N} \to \mathbb{C}$ such that $f(mn) = f(m)f(n)$ for all m, n such that $(m,n) = 1$. It turns out that the mean value of a multiplicative function, under fairly general circumstances, can be bounded in terms of an exponential of a sum over primes. To make the paper more self-contained, we include a weak form of the *Halberstam–Richert inequality* (cf. [15]).

THEOREM 7. *Let* f *be a nonnegative multiplicative function such that*

$$\sum_{n \le x} f(n) = O(x), \tag{11}$$

and $f(p^k) = O(k)$ *for all primes* p *and* $k \ge 1$. *Then there exists* $C > 0$ *such that*

$$\frac{1}{X}\sum_{m \le X} f(m) \le C \cdot \exp\left(\sum_{p \le X} \frac{f(p) - 1}{p}\right) + O\left(\frac{1}{\log X}\right)$$

for all sufficiently large X.

Proof. Following Wirsing [26], let

$$F(t) = \sum_{n \le t} f(n).$$

Then

$$\int_1^X \frac{F(t)}{t}\,dt = F(X)\log X + O(1) - \sum_{n \le X} f(n)\log n.$$

On the other hand, by assumption, we have $F(t) = O(t)$, thus

$$\int_1^X \frac{F(t)}{t}\,dt = O(X),$$

and hence

$$F(X)\log X \le O(1) + X + \sum_{n \le X} f(n)\log n.$$

Using $\log n = \sum_{d|n} \Lambda(d)$, where Λ is the von Mangoldt function,[2] we have

$$\begin{aligned}\sum_{n \le X} f(n)\log n &= \sum_{n \le X} f(n) \sum_{d|n} \Lambda(d) = \sum_{d \le X} \Lambda(d) \sum_{m \le X/d} f(dm) \\ &= \sum_{d \le X} \Lambda(d) \sum_{\substack{m \le X/d, \\ (m,d)=1}} f(dm) + \sum_{d \le X} \Lambda(d) \sum_{\substack{m \le X/d, \\ (m,d)>1}} f(dm). \qquad (12)\end{aligned}$$

Now, since $\Lambda(d) = 0$ unless d is a prime power, we have

$$\begin{aligned}\sum_{d \le X} \Lambda(d) \sum_{\substack{m \le X/d, \\ (m,d)>1}} f(dm) &= \sum_{\substack{p^{k+l} \le X \\ k,l \ge 1}} \log(p) \sum_{\substack{m \le X/p^{k+l} \\ (p,m)=1}} f(p^{k+l}m) \qquad (13) \\ &= \sum_{\substack{p^{k+l} \le X \\ k,l \ge 1}} \log(p) f(p^{k+l}) \sum_{\substack{m \le X/p^{k+l} \\ (p,m)=1}} f(m).\end{aligned}$$

By the assumptions on f,

$$f(p^{k+l}) \sum_{\substack{m \le X/p^{k+l} \\ (p,m)=1}} f(m) \le O(k+l) \sum_{m \le X/p^{k+l}} f(m) = O\left((k+l)\frac{X}{p^{k+l}}\right),$$

and thus the second term in (12) is

$$= O\left(\sum_{\substack{p^n \le X \\ n \ge 2}} \log(p) n^2 \frac{X}{p^n}\right) = O(X),$$

[2] That is, $\Lambda(d) = \log p$ if $d = p^k$ and $k \ge 1$; otherwise $\Lambda(d) = 0$.

since

$$\sum_p \sum_{n\geq 2} \log(p) n^2 p^{-n} \leq \sum_p \frac{\log(p)}{p^2} \sum_{m\geq 0} (2+m)^2 2^{-m} < \infty.$$

As for the first term in (12), we have (recall that f is multiplicative and nonnegative)

$$\begin{aligned} \sum_{d\leq X} \Lambda(d) \sum_{\substack{m\leq X/d,\\ (m,d)=1}} f(dm) &= \sum_{d\leq X} \Lambda(d) f(d) \sum_{\substack{m\leq X/d,\\ (m,d)=1}} f(m) \\ &\leq \sum_{m\leq X} f(m) \sum_{d\leq X/m} \Lambda(d) f(d). \end{aligned}$$

Now,

$$\sum_{d\leq X/m} \Lambda(d) f(d) = \sum_{\substack{p^k\leq X/m\\ k\geq 1}} \log(p) f(p^k) \leq \sum_{\substack{p^k\leq X/m\\ k\geq 1}} \log(p) O(k) = O(X/m)$$

since

$$\sum_{p\leq X/m} \log(p) = O(X/m)$$

by the prime number theorem, and

$$\sum_{\substack{p^k\leq X/m\\ k\geq 2}} k\log(p) = O\left((X/m)^{1/2}\log^3(X/m)\right) = O(X/m).$$

Thus,

$$\sum_{m\leq X} f(m) \sum_{d\leq X/m} \Lambda(d) f(d) = O\left(\sum_{m\leq X} f(m)\frac{X}{m}\right).$$

But since f is nonnegative and multiplicative, we have

$$\begin{aligned} \sum_{m\leq X} \frac{f(m)}{m} &\leq \prod_{p\leq X} \left(1 + f(p)/p + f(p^2)/p^2 + \dots\right) \\ &\leq \prod_{p\leq X} \left((1+f(p)/p)\cdot\left(1 + f(p^2)/p^2 + f(p^3)/p^3 + \dots\right)\right), \end{aligned}$$

and since

$$\sum_{p\leq X} \left(f(p^2)/p^2 + f(p^3)/p^3 + \dots\right) \leq \sum_p \sum_{k\geq 2} \frac{O(k)}{p^k} < \infty,$$

we find that

$$\sum_{m\leq X} \frac{f(m)}{m} = O\left(\prod_{p\leq X} (1+f(p)/p)\right).$$

Thus,

$$F(X)\log X = O\left(X + X\cdot\prod_{p\le X}(1+f(p)/p)\right),$$

and hence

$$\frac{F(X)}{X} = O\left(\frac{1}{\log X} + \frac{\prod_{p\le X}(1+f(p)/p)}{\log X}\right).$$

Now, by Merten's theorem, we have

$$\prod_{p\le X}(1-1/p) \sim \frac{e^{-\gamma}}{\log X},$$

and thus

$$\begin{aligned}\frac{F(X)}{X} &= O\left(\frac{1}{\log X} + \prod_{p\le X}\left(1+\frac{f(p)-1}{p}-\frac{f(p)}{p^2}\right)\right)\\ &= O\left(\frac{1}{\log X} + \exp\left(\sum_{p\le X}\frac{f(p)-1}{p}\right)\right). \qquad \square\end{aligned}$$

Proof of Proposition 6. To see that $|S(m,k)/4|$ is a multiplicative function, it is enough to recall the factorization of m into Gaussian primes. Namely, if $p_1^{\alpha_1},\dots,p_J^{\alpha_J}$ are all prime factors of m with $p\equiv 1 \mod 4$,

$$S(m,k) = \sum_{\ell=0}^{3} i^{k\ell}\sum_{j_1=1}^{\alpha_1}\cdots\sum_{j_J=1}^{\alpha_J} e^{ik(\theta_0+(\alpha_1-2j_1)\theta_{p_1}+\cdots+(\alpha_J-2j_J)\theta_{p_J})}.$$

Here θ_0 is a multiple of $\pi/4$ which comes from powers of 2 in m, and the θ_{p_j} can be computed from the Gaussian factorization as described in section 2.2. Also, because $\sum_{\ell=0}^{3} i^{k\ell} = 4$ if $4\,|\,k$ and zero otherwise,

$$\frac{|S(m,k)|}{4} = \left|\sum_{j_1=1}^{\alpha_1}\cdots\sum_{j_J=1}^{\alpha_J} e^{ik((\alpha_1-2j_1)\theta_{p_1}+\ldots+(\alpha_J-2j_J)\theta_{p_J})}\right|,$$

and this sum clearly factors, each factor containing a sum of terms corresponding to one of the prime factors p. Hence

$$f_k(m) = \frac{|S(m,k)|}{4}$$

is a nonnegative multiplicative function, as stated. In addition it satisfies $f_k(m) \le r(m)/4$ for all m. Thus, since

$$\sum_{n\le T} r(n) = |\{x,y\in\mathbb{Z} : x^2+y^2\le T\}| \sim \pi\left(\sqrt{T}\right)^2 = \pi T,$$

we have

$$\sum_{n\le T} f_k(n) = O(T).$$

Moreover, if $p \equiv 3 \mod 4$, then

$$f_k(p^l) = \begin{cases} 1 \text{ if } l \text{ is even,} \\ 0 \text{ if } l \text{ is odd,} \end{cases} \tag{14}$$

and if $p \equiv 1 \mod 4$, then

$$f_k(p^l) = \left| \sum_{j=0}^{l} e^{ik(l-2j)\theta_p} \right|, \tag{15}$$

and thus $f_k(p^l) \le l+1$ for all primes p and $l \ge 1$. The assumptions in Theorem 7 are thus satisfied, and we obtain

$$\frac{1}{X}\sum_{m\le X} |S(m,k)| = \frac{4}{X}\sum_{m\le X} f_k(m) \le C\exp\left(\sum_{p\le X}\frac{f_k(p)-1}{p}\right) + O\left(\frac{1}{\log X}\right).$$

Now, by (14) and (15), we have

$$f_k(p) = \begin{cases} 2|\cos(k\theta_p)| & \text{if } p \equiv 1 \mod 4, \\ 0 & \text{if } p \equiv 3 \mod 4. \end{cases}$$

Hence

$$\sum_{p\le X}\frac{f_k(p)-1}{p} = \sum_{\substack{p\le X\\ p\equiv 1 \mod 4}} \frac{2|\cos(k\theta_p)|}{p} - \sum_{p\le X}\frac{1}{p}.$$

By Corollary 5,

$$\sum_{\substack{p\le X\\ p\equiv 1 \mod 4}} \frac{2|\cos(k\theta_p)|}{p} \le \frac{2}{\pi}\log\log X + 2(1-2/\pi)\log\log k + O(1)$$

if $\log k \le b\sqrt{\log X}$. By Merten's theorem,

$$\sum_{p\le X}\frac{1}{p} = \log\log X + O(1),$$

and thus

$$\sum_{p\le X}\frac{f_k(p)-1}{p} \le (2/\pi - 1)\log\log x + 2(1-2/\pi)\log\log k + O(1). \qquad \square$$

4. Proof of Theorem 1. Here we carry out the steps of the proof as indicated in the introduction. First recall that the collision operator can be written

$$Q(f,f)(v) = 4\int_{\mathbb{R}^2}\left(\int_{-\pi}^{\pi} g_v(w,\theta)\,d\theta\right)dw, \tag{16}$$

where, if we identify $u\in S^1$ with $\theta\in[-\pi,\pi[$,

$$g_v(w,\theta) = q(|w|,\cos(\theta))\left(f(v')f(v'_*)-f(v)f(v_*)\right),$$

and

$$\begin{aligned} v' &= v+w+R_\theta w,\\ v'_* &= v+w-R_\theta w; \end{aligned}$$

as before, $w=(v_*-v)/2$, and R_θ denotes a rotation by an angle θ. Writing the Boltzmann equation for two-dimensional velocities, we have of course already stepped away from the physically realistic case. Disregarding this, a common assumption on q is that

$$q(|w|,\cos(\theta)) = q_1(|w|)q_2(\theta),$$

where $q_1(|w|)\sim|w|^\alpha$ for some $\alpha\in[0,1]$, and where $q_2(\theta)\sim|\theta|^{-\gamma}$ for some $\gamma\in]1,3[$. This corresponds to a molecular interaction by hard inverse power law forces. With the stronger assumption that q_1 is smooth and strictly positive, it is possible to prove that there is a smooth solution $f(v,t)$ to the Boltzmann equation (see [9]), and then this also gives some regularity to $g(w,\theta)$, in spite of the singularity of q_2.

However, much work on the Boltzmann equation has been done with the hypothesis that q is bounded or continuous with respect to θ. With that assumption, the solution $f(v,t)$ keeps exactly the regularity of the initial data.

Because of this, it is appropriate to assume whatever regularity of the solutions that is needed for the computations. With the aim of making the calculations easy, Theorem 1 has been written with unnecessarily strong hypotheses.

To simplify notation a little, let

$$G_v(w) = \int_{-\pi}^{\pi} g_v(w,\theta)\,d\theta,$$

in the continuous case, and for the discrete case (where we assume, of course, that $v\in h\mathbb{Z}^2$)

$$G_v^h(h\zeta) = \frac{1}{r(|\zeta|^2)}\sum_{\substack{\zeta'\in\mathbb{Z}^d\\|\zeta'|=|\zeta|}} g_v(h\zeta,\theta),$$

where θ is the angle between ζ' and ζ. As before, $r(|\zeta|^2)$ denotes the number of integer points on a sphere with radius $|\zeta|$.

Let

$$Z_{h,R} = \{z\in\mathbb{Z}^2 \text{ such that } |z|\le R/h\} \tag{17}$$

for some $R > 0$ (this is the most natural example, but other choices might be more efficient). We want to prove that

$$Q(f,f)(v) - (2h)^2 \sum_{\zeta \in Z_{h,R}} G_v^h(h\zeta) \to 0 \tag{18}$$

when $h \to 0$, and also make as precise a statement as possible about the rate of convergence, and thus give a more explicit version of Theorem 1.

THEOREM 8. *Suppose that $g_v(w,\theta)$ in* (16) *satisfies:*

(1) *$g_v(w,\theta)$ is a C^1-function w.r.t. w,*

(2) *$g_v(w,\theta)$ is a C^2-function w.r.t. θ, and*

(3) $\|g_v(\cdot,\theta)(1+|\cdot|^2)\|_{L^1(dw)} \le C$.

(This holds, e.g., if the function f and the cross section q are C^2.) For given $R > 0$ and $h > 0$, let $Z_{h,R}$ be as in (17)*. Then given $\varepsilon > 0$ there are reals $R > 0$ and $h > 0$ such that*

$$\left| Q(f,f)(v) - (2h)^2 \sum_{\zeta \in Z_{h,R}} G_v^h(h\zeta) \right| \le \varepsilon.$$

Proof. We still consider $Q(f,f)$ as an iterated integral, and write (for $v \in h\mathbb{Z}^2$)

$$\begin{aligned} Q(f,f)(v) - (2h)^2 \sum_{\zeta \in Z_{h,R}} G_v^h(h\zeta) &= \int_{\mathbb{R}^2} G_v(w)\,dw - (2h)^2 \sum_{\zeta \in Z_{h,R}} G_v(h\zeta) \\ &\quad + (2h)^2 \sum_{\zeta \in Z_{h,R}} \left(G_v(h\zeta) - G_v^h(h\zeta) \right). \end{aligned} \tag{19}$$

From the third part of the hypothesis on g (which is implied by a decay of $f(v)$ for large velocities), it follows that for all $R > 0$,

$$\int_{|w| \ge R} G_v(w)\,dw \le \frac{C_1}{R^2}. \tag{20}$$

Continuity of $G_v(w)$ would be enough to conclude that

$$\left| \int_{|w| < R} G_v(w)\,dw - (2h)^2 \sum_{\zeta \in Z_{h,R}} G_v(h\zeta) \right| \to 0$$

when $h \to 0$. The hypothesis on $g_v(w,\theta)$ implies that actually $G_v(\cdot) \in C^1$, and there is a constant C_2 such that the difference is smaller than

$$C_2 R^2 h = C \max_{w,j} |\partial_{w_j} G_v(w)|\, R^2 h. \tag{21}$$

Next we turn to the difference $G_v(h\zeta) - G_v^h(h\zeta)$, i.e.,

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} g_v(h\zeta,\theta)\,d\theta - \frac{1}{r(|\zeta|^2)} \sum_{\substack{\zeta' \in \mathbb{Z}^2 \\ |\zeta'| = |\zeta|}} g_v(h\zeta,\theta), \tag{22}$$

(recall that in the second term, θ is the angle between ζ' and ζ). We first write the periodic function $g_v(h\zeta,\theta)$ as a Fourier series,

$$g_v(h\zeta,\theta) = \sum_{k\in\mathbb{Z}} \hat{g}_v(\zeta,k)e^{ik\theta},$$

where

$$\hat{g}_v(\zeta,k) = \frac{1}{2\pi}\int_{-\pi}^{\pi} g_v(h\zeta,\theta)e^{-ik\theta}\,d\theta.$$

The assumptions on g imply the existence of a constant C_3 so that

$$|\hat{g}_v(\zeta,k)| \le \frac{C_3}{1+k^2}. \tag{23}$$

Then (22) becomes

$$\hat{g}_v(\zeta,0) - \frac{1}{r(|\zeta|^2)}\sum_{\substack{\zeta'\in\mathbb{Z}^2\\|\zeta'|=|\zeta|}} \hat{g}_v(\zeta,0) + \frac{1}{r(|\zeta|^2)}\sum_{\substack{\zeta'\in\mathbb{Z}^2\\|\zeta'|=|\zeta|}}\sum_{k\neq 0}\hat{g}_v(\zeta,k)e^{ik\theta},$$

where the first terms cancel out, and only last sum remains. We next split that sum into a part with $|k|\le M$, and a remainder, which can be made small by choosing M large, if g is sufficiently smooth with respect to θ. Using (23),

$$\left|\frac{1}{r(|\zeta|^2)}\sum_{\substack{\zeta'\in\mathbb{Z}^2\\|\zeta'|=|\zeta|}}\sum_{|k|\ge M}\hat{g}_v(\zeta,k)e^{ik\theta}\right| \le 2\frac{C_3}{M}.$$

To find the contribution of this term to (19), we multiply by $(2h)^2$ and sum over $\zeta\in Z_{h,R}$ to find a bound of the form

$$\frac{R^2C_4}{M}. \tag{24}$$

For the remaining part, using (23) again, we find a bound of the form

$$\left|\sum_{0<|k|<M}\frac{C_3}{1+k^2}\frac{1}{r(|\zeta|^2)}\sum_{\substack{\zeta'\in\mathbb{Z}^2\\|\zeta'|=|\zeta|}} e^{ik\theta}\right| \le \max_{0<|k|<M}\left|\frac{S(|\zeta|^2,k)}{r(|\zeta|^2)}\right|\cdot\sum_{0<|k|<M}\frac{C_3}{1+k^2}. \tag{25}$$

Adding the error terms (20), (21), (24) and (25) gives

$$\begin{aligned}&|Q(f,f)(v)-Q^h(f^h,f^h)(v)|\\ &\le \frac{C_1}{R^2}+C_2R^2h+\frac{R^2C_4}{M}+C_3(2h)^2\max_{0<|k|<M}\sum_{\zeta\in Z_{h,R}}\left|\frac{S(|\zeta|^2,k)}{r(|\zeta|^2)}\right|.\end{aligned} \tag{26}$$

In the sum on the right-hand side,

$$\sum_{\zeta\in Z_{h,R}}\left|\frac{S(|\zeta|^2,k)}{r(|\zeta|^2)}\right| = \sum_{n<(R/h)^2}\left|S(n,k)\right|,$$

and this can be estimated by using Proposition 6 with $X = (R/h)^2$. To do this, we must require that

$$R/h > \exp\left(\log(M)^2/b\right) \tag{27}$$

for some positive constant b. Then there is a constant C_5 such that

$$\sum_{n<(R/h)^2} \left|S(n,k)\right| \le C_5 \left(\frac{R}{h}\right)^2 \exp\left(-\left(1-\frac{2}{\pi}\right)\frac{\log\left((R/h)^2\right)}{(\log M)^2}\right).$$

The last term in (26) will always be the dominating one, and at this point, it does not give much to try to optimize the choices of R, M and h. Hence to achieve an error of magnitude ε we

1. Take $R = \sqrt{4C_1/\varepsilon}$,
2. Observe that we must have $h < \varepsilon/(4R^2C_2) = \varepsilon^2/(4C_1C_2)$, and
3. Choose $M = 4R^2C_4/\varepsilon = 64C_1C_4/\varepsilon^2$.

With these choices of R and M, the last term can then be bounded by

$$4C_3C_5\frac{4C_1}{\varepsilon}\exp\left(-\left(1-\frac{2}{\pi}\right)\log\frac{\log(4C_1/(\varepsilon h^2))}{\left(\log(64C_1C_4/\varepsilon^2)\right)^2}\right), \tag{28}$$

which converges to zero when $h \to 0$, and so there is an h so small that also the last term in (26) is smaller than $\varepsilon/4$. We see that in order to achieve an error of magnitude ε, one must take h very small:

$$h = o\left(\exp\left(-2\left(\log\varepsilon\right)^2\varepsilon^{-2/(1-\frac{2}{\pi})}\right)\right)$$

(note that (27) is then satisfied). $\square$

5. Some remarks. From a numerical point of view, the discretization discussed above would be far too costly. It is most common to express the rate of convergence by giving an estimate of the error as a function of h, which in our case is the lattice parameter. The proof of Theorem 8 gives an estimate of h needed to achieve an error of the order ε, and this corresponds to a rate of convergence of the order $(\log(1/h))^p$, where $p < (1-2/\pi)/2$. This can then be used to give an estimation of the computational cost. A discrete velocity model with N velocities would at least correspond to a computational cost of $O(N)$ per time step, because one needs to compute a value for each velocity. When the collision term is computed by the sum (18), the cost is $O(N^2)$ times some logarithmic factor of N (which comes from the summation over the points on the circles). Because $N \sim h^{-2}$, we can conclude that $N >> \exp(\varepsilon^{-c})$ for some positive constant c. It seems clear that this kind of DVM will rarely be useful for numerical computations.

However, disregarding the computational cost, there is also another interesting issue with this kind of discrete velocity model, namely, the possibility of spurious invariants. By a collision invariant, we mean a function $\Psi(v)$ that satisfies

$$\begin{gathered}\forall(j,k,j',k') \text{ such that } \Gamma_{j,k}^{j',k'} > 0,\\ \Psi(v_j)+\Psi(v_k) = \Psi(v_{j'})+\Psi(v_{k'}).\end{gathered} \tag{29}$$

The only invariants should be those corresponding to the conservation of mass, momentum and energy, i.e.,

$$\Psi(v) = 1, \quad \Psi(v) = b\cdot v \ \ (b\in\mathbb{R}^2), \quad \text{and } \Psi(v) = |v|^2.$$

All other functions satisfying (29) are called spurious invariants.

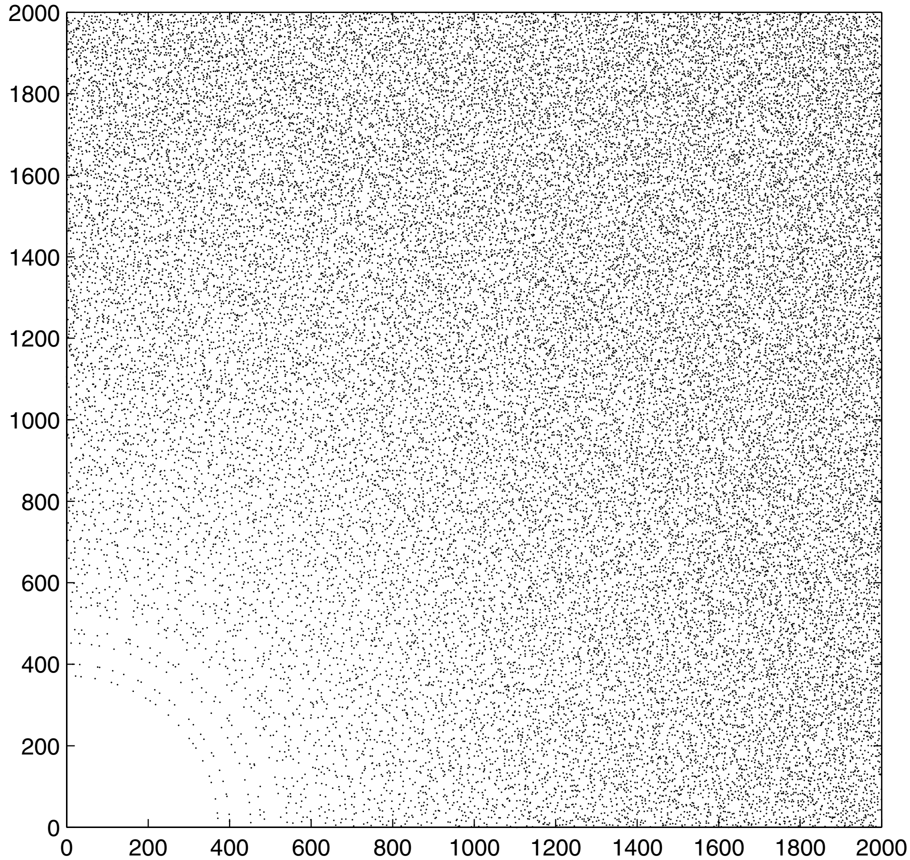

FIG. 1. *Lattice points such that circles through these points contain at least* 72 *lattice points.*

It is interesting to note that the present planar lattice model does not admit any spurious invariants, at least under some very modest requirements on the differential cross section (29). The proof, which can be found in [4], is constructive and basically works in the following way: Starting from a model which is known to possess the correct invariants, one adds one point at a time in such a way that the correct invariants are maintained. The planar lattice models that we study in this paper can thus be obtained by adding points to the Broadwell model, which consists of the velocities $(\pm 1, 0)$, $(0, \pm 1)$, extended with the point $(0, 0)$.

Another question one might ask is whether it is always essential to avoid spurious invariants. When considering whole families of models, one can at least imagine two different definitions of a spurious invariant. Taking into account the scaling of the lattice with respect to the total number of velocity points, N, the definition of a collision invariant would be

$$\begin{aligned}&\forall (j,k,j',k') \text{ such that } \Gamma_{j,k}^{j',k'} > 0,\\ &\Psi(h_N v_j) + \Psi(h_N v_k) = \Psi(h_N v_{j'}) + \Psi(h_N v_{k'}),\end{aligned} \tag{30}$$

where h_N is the lattice parameter corresponding to a given model with N velocities. A "strong invariant" would then be a function Ψ that satisfies (30), for all N sufficiently

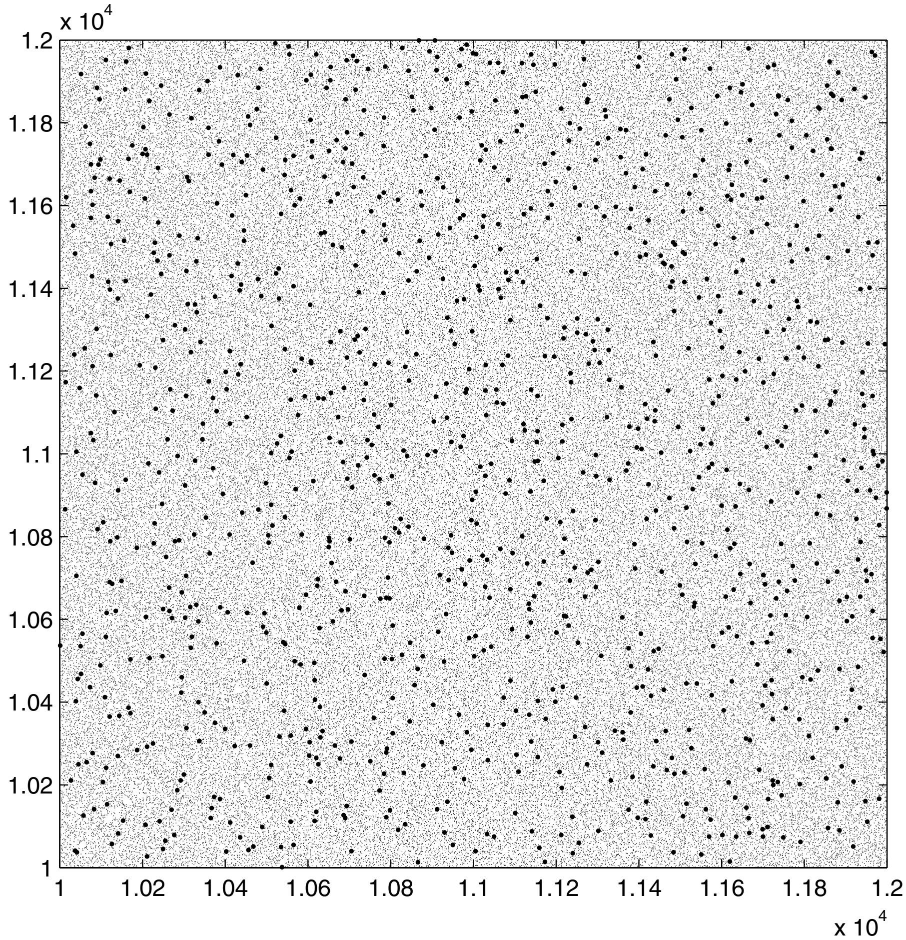

FIG. 2. *Lattice points such that circles through these points contain at least* 72 *lattice points (small dots), or at least* 192 *points (large dots).*

large, or for a large set of $N \in \mathbb{Z}$. However, besides the desired ones, such functions cannot exist in our case, because that would contradict the strong convergence result, namely, Theorem 8.

Although the estimated rate of convergence indicates that the computational cost would be prohibitive for a model with many velocities, it is still possible to carry out simulations. In a companion paper [12], a numerical calculation on a 400×400 grid is reported. This calculation could not have been done with a reasonable computational effort if all terms in (9) had been included. To reduce the number of terms, we chose to only include those ζ for which $r_2(|\zeta|^2)$ is larger than an (arbitrary) threshold. To justify this, one should check that the remaining points are well distributed, and one should verify that there are no spurious invariants in the reduced model.

Proposition 6, which gives an effective estimate on the equidistribution of points, is indirect, and it is interesting to see how the points $\zeta \in \mathbb{Z}^2$ ζ are distributed. We consider $\{\zeta = (\zeta_1, \zeta_2) \in \mathbb{Z}^2 \text{ such that } \zeta_1, \zeta_2 \geq 0, \;\; |\zeta| < 20000\}$. This is an extremely large set of points, which corresponds to a huge number of velocities (the $O(N^2)$ factor would in this case be of the order 10^{17}, which is, of course, absurd).

Among the circles with radii $|\zeta|$ in this set, the largest number of points on one circle is 384. In Figure 1, we show all points $\zeta = (\zeta_1, \zeta_2)$ with $0 < \zeta_i < 2000$ such that the circle passing through ζ has more than 72 points. There are 36163 points in this set. This is a small fraction of the total number of integer points, but they are seemingly well distributed, except near the origin.

Figure 2 shows points in the range $10000 \leq \zeta_i \leq 12000$. Here the small dots denote points on circles having at least 72 points, and the larger dots denote points on circles with at least 192 points (there are 141562 and 1120 points, respectively, in these sets).

As for the question of spurious invariants in this restricted model, this can be checked by an algorithm based on the Bobylev–Cercignani [4] construction. We refer to [12] for a more detailed description of this, but it is interesting to note that if admissibility of the model (i.e., the absence of spurious invariants) is all that one is interested in, then it is in many cases sufficient to use only points lying on circles with just one radius $|\zeta|$. This could be chosen to be a radius giving many points on the corresponding circle, and thus a good approximation of the angular integral. However, the integral over $\mathbb{R}^2$ would be poorly approximated.

Acknowledgment. We would like to thank A. Bobylev, J. Brzezinski, A. Heintz, and Z. Rudnick for useful discussions.

MASS CONCENTRATION PHENOMENON FOR THE QUINTIC NONLINEAR SCHRÖDINGER EQUATION IN ONE DIMENSION*

NIKOLAOS TZIRAKIS†

Abstract. We consider the L^2-critical quintic focusing nonlinear Schrödinger equation (NLS) on $\mathbf{R}$. It is well known that H^1 solutions of the aforementioned equation blow up in finite time. In higher dimensions, for H^1 spherically symmetric blow-up solutions of the L^2-critical focusing NLS, there is a minimal amount of concentration of the L^2-norm (the mass of the ground state) at the origin. In this paper we prove the existence of a similar phenomenon for the one-dimensional case and rougher initial data, ($u_0 \in H^s,\ s < 1$), without any additional assumption.

Key words. nonlinear Schrödinger equation, blow-up, mass concentration

AMS subject classification. 35Q55

DOI. 10.1137/050626284

1. Introduction.

This paper continues the investigation of the quintic nonlinear Schrödinger equation (NLS) in one dimension that we started in [27]:

$$\begin{aligned} &iu_t + u_{xx} \pm |u|^4 u = 0, \\ &u(x,0) = u_0(x) \in H^s(\mathbf{R}), t \in \mathbf{R}. \end{aligned} \tag{1}$$

The (+) sign in front of the nonlinearity corresponds to the focusing NLS while the (−) sign corresponds to the defocusing NLS. The Cauchy problem for (1) is known to be locally well-posed in $H^s(\mathbf{R})$ for $s > 0$ (see [4]). A local result also exists for $s = 0$, but the time of existence depends on the profile of the data as well as the norm. NLS is an infinite-dimensional Hamiltonian system with energy space H^1. It also has a scaling property. Thus $u(x,t)$ is a solution of (1) with initial data u_0 if and only if

$$u^\lambda(x,t) = \frac{1}{\lambda^{1/2}} u\left(\frac{x}{\lambda}, \frac{t}{\lambda^2}\right)$$

is a solution to the same equation with initial data $u_0(\frac{x}{\lambda})$. In [27] we extend the local existence theorem for the defocusing NLS for all times. We do so by iterating the local result in the appropriate norms. To iterate the local result by standard limiting arguments we just need an a priori bound for our solutions in H^s. This bound comes from the next theorem that we proved in [27].

THEOREM 1. *Let u be a global H^1 solution to* (1) *with the* (−) *sign. Then for any $T > 0$ and $s > 4/9$ we have that*

$$\sup_{0 \le t \le T} \|u(t)\|_{H^s} \lesssim C_{(\|u_0\|_{H^s}, T)},$$

where the right-hand side does not depend on the H^1-norm of u.

Remark 1. Note that in the focusing case (where in front of the nonlinearity we have the (+) instead of the (−) sign) we can also proved global well-posedness for $4/9 < s \leq 1/2$, but with the crucial assumption that $\|u_0\|_{L^2} < \|Q\|_{L^2}$, where Q is the unique positive solution (up to translations) of

$$Q_{xx} - Q + |Q|^4 Q = 0.$$

In [29], Q was solved explicitly as $Q(x) = \frac{3^{\frac{1}{4}}}{\sqrt{\cosh(2x)}}$ and then $\|Q\|_{L^2}^2 = \frac{\sqrt{3}\pi}{2}$. In the same paper the author also proved a result that we will use below, namely that $C = \|Q\|_{L^2}^{-4}$ is the best constant in the Gagliardo–Nirenberg inequality

$$\frac{1}{6}\|u\|_{L^6}^6 \leq \frac{C}{2}\|\nabla u\|_{L^2}^2 \|u\|_{L^2}^4.$$

We used the "I-method" that was recently introduced by Colliander et al. [5, 7, 8, 9]. This method allows us to define a modification of the energy functional that is "almost conserved"; that is, its time derivative decays with respect to a very large parameter. Since an implementation of this method also gives the main result of this paper, the details of the method are delayed until the next section. As we mentioned above for the focusing case, the solutions blow up in H^1, in finite time. An elementary proof of the existence of blow-up solutions has been known since the 1960s, but is based on energy constraints and is not constructive (see [26]). In particular, no qualitative information of any type is obtained for the blow-up dynamics. A lower estimate for the blow-up solutions in H^1 is given by Theorem 2 using the scaling and the local existence theorem (see [3]).

THEOREM 2. *Let $[0, T^\star)$ be the maximal interval of existence of the following Cauchy problem:*

$$\begin{aligned} &iu_t + u_{xx} + |u|^4 u = 0, \\ &u(x,0) = u_0(x) \in H^1(\mathbf{R}), t \in \mathbf{R}. \end{aligned} \tag{2}$$

If $u_0 \in H^1$ is such that $T^\star < \infty$, then there exists a C such that

$$\|u_x\|_{L^2} \geq \frac{C}{(T^\star - t)^{\frac{1}{2}}}$$

for $0 \leq t < T^\star$. This bound is often called the scaling bound. It is also fairly easy to show that $\|u(t)\|_{L^p}$ blows up for $p > 2$. In particular we have

$$\|u\|_{L^p} \geq \frac{C}{(T^\star - t)^{\frac{1}{4} - \frac{1}{2p}}}$$

for $p > 2$.

Because it is related to the scaling symmetry of the problem, the above lower bound has long been conjectured to be optimal. But in 1988, Landman, et al. [14] suggested that the correct and stable blow-up speed is a slight correction to the scaling bound:

$$\|u_x\|_{L^2} \sim \sqrt{\frac{\log|\log|T^\star - t||}{T^\star - t}}.$$

In this framework Perelman [24] has constructed a family of blow-up solutions for which

$$\left(\frac{\log|\log|T^\star - t||}{T^\star - t}\right)^{-\frac{1}{4}} \|u(t)\|_{L^\infty} \to c > 0$$

as $t \to T^\star$, which is very close to but different from the scaling bound. Moreover, for initial data in some special class, Merle and Raphael [18, 19] recently showed that for t close to $T^\star$, there is a universal constant $C^\star$ such that

$$\|u_x\|_{L^2} \le C^\star \sqrt{\frac{\log|\log|T^\star - t||}{T^\star - t}},$$

as suggested by the numerics in [14]. Finally it is worth noting that an easy application of the pseudoconformal transformation yields interesting information on the blow-up solutions. In particular we can show that some solutions blow up twice as fast as the scaling bound. For details see [2] and [28]. The above results show in particular that at least two different blow-up estimates are actually achieved.

Another property of the blow-up solutions in the critical case is the phenomenon of mass concentration [3, 26]. For H^1 solutions, there is a concentration of a finite amount of mass in a neighborhood of the focus of width slightly larger than $(T^\star - t)^{1/2}$. For radial initial data in dimension $d \ge 2$ there is a precise lower bound on the amount of concentrated mass in terms of the mass of the ground state Q (see [20]). More precisely we have the following.

Let $d \ge 2$ and let $\gamma : (0, \infty) \to (0, \infty)$ be any function such that $\gamma(s) \to \infty$ and $s^{1/2}\gamma(s) \to 0$ as $s \downarrow 0$. Finally, let $u_0 \in H^1(\mathbf{R^d})$ be radial symmetric. Then if $u(x,t)$ is the maximal solution of the equivalent of (2) in higher dimensions and $T^\star < \infty$, we have

$$\liminf_{t \uparrow T^\star} \|u(t)\|_{L^2_{\{|x| < |T^\star - t|^{1/2}\gamma(T^\star - t)\}}} \ge \|Q\|_{L^2},$$

where Q is the ground state solution of the elliptic equation $Q_{xx} - Q + |Q|^{\frac{4}{d}} Q = 0$.

In the nonradial case and in dimension $d = 1$ this was generalized by Nawa [22] using concentration compactness techniques [15, 16]. In addition to the scaling properties of the NLS, the main ingredients in the proof that H^1 blow-up solutions concentrate at least the mass of the ground state are

(i) the conservation of mass

$$\|u(t)\|_{L^2} = \|u_0\|_{L^2}$$

and the energy

$$E(u)(t) = E(u_0),$$

where

$$E(u) = \frac{1}{2}\int |u_x(t)|^2 dx - \frac{1}{6}\int |u(t)|^6 dx,$$

(ii) a precise Galiardo–Nirenberg inequality which implies that nonzero H^1 functions of nonpositive energy have at least ground state mass.

The purpose of this paper is to investigate the mass concentration phenomenon in H^s, for $s<1$, where the conservation of energy cannot be used. Using the *I-method* we show that solutions of (2) with a finite maximal (forward) existence interval are expected to concentrate at least the L^2-mass of the ground state in H^s for $s<1$. More precisely we have the following theorem.

THEOREM 3. *Suppose $H^s \ni u_0 \longmapsto u(t)$ with $s>0$ solves (2) on the maximal interval of existence $[0,T^\star)$ with $T^\star<\infty$. Then for any $1>s>\frac{10}{11}$ there exists a positive function $\gamma(x)\uparrow\infty$ arbitrarily slowly as $x\downarrow 0$ and a real function $z(t)$ such that*

$$\limsup_{t\uparrow T^\star} \|u(t)\|_{L^2_{\{|x-z(t)|<(T^\star-t)^{\frac{s}{2}}\gamma(T^\star-t)\}}} \geq \|Q\|_{L^2}.$$

Remark 2. In a recent preprint, Colliander, et al. [11] considered the two-dimensional (2D) focusing critical NLS and proved a similar theorem with the additional assumption of radial symmetry. The radial symmetry assumption is needed in order to pass from weak to strong convergence since the general embedding $H^1(\mathbf{R^d})\hookrightarrow L^2(\mathbf{R^d})$ is not compact. But as the four authors noted in [11], one can utilize the concentration compactness method of Lions [15, 16] and prove the analogous theorem in two dimensions. The one-dimensional case that we are dealing with has some similar features but also significant differences. First, in the one dimensional case, the radial assumption does not play a role. More precisely, in one dimension, radial symmetry is not enough for a bounded sequence in H^1 to have a strongly convergent subsequence in L^p for $2<p<\infty$, although the latter is true if we further assume that the sequence in question is a nonincreasing function of $|x|$ for every $n\geq 0$. (For the above discussion the reader can also consult [25]). So we have to prove Theorem 3 by implementing techniques different from those used in [11]. Second, the nonlinearity has a fifth power, and thus the correction terms in the "modified energy" have larger growth. We take advantage of the fact that at each step we work on $[0,\delta]$ and prove a stronger proposition about the decay of the "modified energy" and thus somehow balance the additional correction terms with the greater decay that we prove. Finally, the crucial Lemma 3 that we use in one dimension is true only if the frequencies of the two solutions are separated. In higher dimensions the analogous lemma holds in general [1], although we avoid this difficulty in one dimension by analyzing further the correction terms of the "modified energy"; see Proposition 5.

Remark 3. As we mentioned before, to prove the theorem we use a combination of the concentration compactness and the I-method. Since the energy is infinite for initial data in H^s we define a "modified energy," $E(Iu)$, which is finite, where $I: H^s\to H^1$ is a multiplier operator defined below. The crucial step is to prove that the modified total energy grows more slowly than the modified kinetic energy

$$\frac{1}{2}\int |Iu_x(t)|^2dx.$$

These two steps are shown in Propositions 5 and 3, respectively. Note that Proposition 5 relies on the local theory that we shall establish in Proposition 1.

Remark 4. Let $p(s)$ be a number that depends on s and for the range of s in Theorem 3, $(10/11<s<1)$, it is $p(s)<2$. The statement that the modified total energy grows more slowly than the modified kinetic energy is reflected exactly on $p(s)<2$ and is proven in Proposition 3 below. Note also that our concentration width $(T^\star - t)^{\frac{s}{2}}$ is larger than $(T^\star - t)^{\frac{1}{2}}$ with which ground state mass concentration is conjectured to occur.

Two quick by-products of the above theorem follow. The first is the conjecture that tiny L^2 mass concentration cannot occur when $u_0 \in L^2$, a question that was asked in [21]. See also the relevant result of Bourgain [1]. The second is the following lemma which, as we mention on the first page, is basically a result of the work in [27].

LEMMA 1. *If* $u_0 \in H^s$, $s > \frac{10}{11}$, *and* $\|u_0\|_{L^2} < \|Q\|_{L^2}$, *then the initial value problem* (2) *is globally well-posed.*

We end this section by introducing some useful notation. In what follows we use $A \lesssim B$ to denote an estimate of the form $A \leq CB$ for some constant C. If there exist constants C and D such that $DB \leq A \leq CB$, we say that $A \sim B$, and $A \ll B$ to denote an estimate of the form $A \leq cB$ for small constant $c > 0$. In addition, $\langle a \rangle := 1 + |a|$ and $a\pm := a \pm \epsilon$.

2. Linear and bilinear estimates. Before we state the linear and bilinear estimates that we will use throughout this paper, we recall some basic facts about the $X^{s,b}$ spaces. For an equation of the form

$$iu_t - \phi(-i\nabla)u = 0, \tag{3}$$

where ϕ is a measurable function, let $X^{s,b}$ be the completion of $\mathbb{S}(\mathbb{R}^{d+1})$ with respect to

$$\|u\|_{X^{s,b}} = \|\langle\xi\rangle^s \langle\tau + \phi(\xi)\rangle^b \hat{u}(\xi,\tau)\|_{L^2_\xi L^2_\tau}.$$

From the above definition it is clear that the dual space of $X^{s,b}_{\tau=\phi(\xi)}$ is $X^{-s,-b}_{\tau=-\phi(-\xi)}$. Furthermore for a given interval I, we define

$$\|f\|_{X^{s,b}(I)} = \inf_{\tilde{f}_{|I}=f} \|\tilde{f}\|_{X^{s,b}}.$$

In our case, the interval of existence of the local solutions will be $[0,\delta]$ and we write $X^{s,b}_\delta = X^{s,b}_{[0,\delta]}$. Since conjugate solutions will not play any role in our arguments from now on, we omit any reference to the difference between u and $\bar{u}$. We know that if u is a solution of (3) with $u(0) = f$ and if ψ is a cut-off function in C_0^∞ with support of $\psi \subset (-2,2)$, $\psi = 1$ on $[0,1]$, $\psi(-t) = \psi(t)$, $\psi(t) \geq 0$, $\psi_\delta(t) = \psi(\frac{t}{\delta})$, then if $0 < \delta \leq 1$, we have that for $b \geq 0$

$$\|\psi_1 u\|_{X^{s,b}} \leq C\|f\|_{H^s}. \tag{4}$$

In addition, if ν is a solution of

$$i\nu_t - \phi(-i\nabla)\nu = F$$

with $\nu(0) = 0$, then for $b' + 1 \geq b \geq 0 \geq b' > -\frac{1}{2}$,

$$\|\psi_\delta \nu\|_{X^{s,b}} \leq C\delta^{1+b'-b}\|F\|_{X^{s,b'}}. \tag{5}$$

The proofs of (4) and (5) can be found in [12]. The Strichartz estimates for the Schrödinger equation on $\mathbb{R}^d$ state that for $q, r \geq 2$ such that $(d,q) \neq (2,2)$ and $0 \leq \frac{2}{q} = d(\frac{1}{2} - \frac{1}{r}) < 1$, we have that

$$\|e^{it\Delta}u_0\|_{L^q_t L^r_x} \lesssim \|u_0\|_{L^2(\mathbb{R}^d)}. \tag{6}$$

In particular, in one dimension we have

$$\|e^{it\partial_x^2}u_0\|_{L_t^6L_x^6} \lesssim \|u_0\|_{L^2(\mathbb{R})}$$

and

$$\|e^{it\partial_x^2}u_0\|_{L_t^\infty L_x^2} \lesssim \|u_0\|_{L^2(\mathbb{R})},$$

which by a standard argument gives

$$\|u\|_{L_t^6L_x^6} \lesssim \|u\|_{X_\delta^{0,1/2+}} \tag{7}$$

and

$$\|u\|_{L_t^\infty L_x^2} \lesssim \|u\|_{X_\delta^{0,1/2+}}. \tag{8}$$

By the Sobolev embedding theorem in one dimension, (8) implies that

$$\|u\|_{L_t^\infty L_x^\infty} \lesssim \|u\|_{X_\delta^{1/2+,1/2+}}. \tag{9}$$

Also by interpolation between (7) and the trivial estimate

$$\|u\|_{L_t^2L_x^2} = \|u\|_{X_\delta^{0,0}}, \tag{10}$$

we get

$$\|u\|_{L_t^pL_x^p} \lesssim \|u\|_{X_\delta^{0,(1/2+)\cdot(3/2-3/p)}} \tag{11}$$

for any $2 \leq p \leq 6$.

The dual version of (6) gives

$$\|u\|_{X_\delta^{0,-1/2-}} \lesssim \|u\|_{L_t^{q'}L_x^{r'}}, \tag{12}$$

where r' and q' are the conjugate exponents of r and q, respectively. Interpolation with the trivial estimate

$$\|u\|_{X_\delta^{0,0}} = \|u\|_{L_t^2L_x^2} \tag{13}$$

gives that

$$\|u\|_{X_\delta^{0,-1/2+}} \lesssim \|u\|_{L_t^{q'+}L_x^{r'+}} \tag{14}$$

and also that

$$\|u\|_{X_\delta^{1,-1/2+}} \lesssim \|u\|_{L_t^{q'+}W_x^{1,r'+}} \tag{15}$$

for any $\frac{2}{q}+\frac{1}{r}=\frac{1}{2}$.

As we state in the introduction, we prove that the modified energy grows more slowly than the modified kinetic energy in Proposition 3. We can take advantage of the fact that we work on a small interval $[0,\delta]$ and improve the decay of the "modified energy." To do so we state the following lemma, which we can find in [12] and [23].

LEMMA 2. *If $1/2 > b > b' \geq 0$ and $s \in \mathbf{R}$, then the following embedding is true:*

$$\|f\|_{X_\delta^{s,b'}} \lesssim \delta^{b-b'} \|f\|_{X_\delta^{s,b}}.$$

The second lemma that we state in this section is an improved bilinear Strichartz-type estimate. It is due to Bourgain [1]. As we mentioned before, a general analogue of Lemma 3 holds for $d \geq 2$; see, for example, [10].

LEMMA 3. *Let u and v be any two Schwartz functions whose support of Fourier transform is in $|\xi| \sim M$ and $|\xi| \ll M$, respectively, and let $M \gg 1$. Then*

$$\|(D_x^{\frac{1}{2}} u)v\|_{L_t^2 L_x^2} = \|(D_x^{\frac{1}{2}} \bar{u})v\|_{L_t^2 L_x^2} \lesssim \|u\|_{X^{0,1/2+}} \|v\|_{X^{0,1/2+}}.$$

3. The I-method and the proof of Theorem 3. As we mentioned above, the basic step toward Theorem 3 is the fact that the "modified total energy" decays more slowly than the "modified kinetic energy." To prove the last statement we iterate the local solutions for the new modified system

$$\begin{aligned} &iIu_t + Iu_{xx} + I(|u|^4 u) = 0, \\ &Iu(x,0) = Iu_0(x) \in H^1(\mathbf{R}), t \in \mathbf{R}. \end{aligned} \tag{16}$$

Thus let us define the I-operator. We introduce as in [5, 8] a radial C^∞, monotone multiplier, taking values in [0,1], where

$$m(\xi) := \begin{cases} 1 & \text{if } |\xi| < N, \\ \left(\frac{|\xi|}{N}\right)^{s-1} & \text{if } |\xi| > 2N, \end{cases}$$

and we define $I : H^s \to H^1$ by $\widehat{Iu}(\xi) = m(\xi)\hat{u}(\xi)$. The operator I is smoothing of order $1-s$, and we have that

$$\|u\|_{X_\delta^{s_0,b_0}} \lesssim \|Iu\|_{X_\delta^{s_0+1-s,b_0}} \lesssim N^{1-s} \|u\|_{X_\delta^{s_0,b_0}} \tag{17}$$

for any $s_0, b_0 \in \mathbf{R}$.

Remark 5. It is shown in [6] that if

$$\|uv\|_{X^{s,b-1}} \lesssim \|u\|_{X^{s,b}} \|v\|_{X^{s,b}},$$

then

$$\|I(uv)\|_{X^{1,b-1}} \lesssim \|Iu\|_{X^{1,b}} \|Iv\|_{X^{1,b}},$$

where the constants in the above inequality are independent of N. From now on we use this fact and refer to it as the "interpolation lemma." For details see [8].

PROPOSITION 1. *Let $s > 10/11$ and consider the equation*

$$iIu_t + (Iu)_{xx} + I(|u|^4 u) = 0 \tag{18}$$

with initial data $Iu(x,0) = Iu_0$. Then there exists a

$$\delta \sim (\|Iu_0\|_{H^1})^{-4-\epsilon}$$

such that for all times in $[0,\delta]$, the above problem is locally well-posed and

$$\|Iu\|_{X_\delta^{1,1/2+}} \lesssim \|Iu_0\|_{H^1}.$$

Proof. By Duhamel's formula (18) is equivalent to

$$Iu(t) = \psi_1(t)e^{it\partial_x^2}(Iu_0) + i\psi_\delta(t)\int_0^t e^{i(t-s)\partial_x^2} I(|u|^4u)(s)ds.$$

By (4) and (5) and the fact that $\delta \leq 1$ we have

$$\|Iu\|_{X_\delta^{1,1/2+}} \lesssim \|Iu_0\|_{H^1} + \|I(|u|^4u)\|_{X_\delta^{1,-1/2+}}.$$

Now recall the dual Strichartz estimate (15)

$$\|u\|_{X_\delta^{1,-1/2+}} \lesssim \|u\|_{L_t^{q'+}W_x^{1,r'+}},$$

where $\frac{2}{q} = \frac{1}{2} - \frac{1}{r}$. Thus for $r' = 2-$ we have

$$\|I(|u|^4u)\|_{X_\delta^{1,-1/2+}} \lesssim \|I(|u|^4u)\|_{L_t^{1+\epsilon}H_x^1} \lesssim \delta^{1-\epsilon}\|I(|u|^4u)\|_{L_t^\infty H_x^1}.$$

Since for $s > 1/2$, H^s is a Banach algebra, we have that

$$\||u|^4u\|_{H_x^s} \lesssim \|u\|_{H_x^s}^5,$$

which by the interpolation lemma quickly translates to

$$\|I(|u|^4u)\|_{H_x^1} \lesssim \|Iu\|_{H_x^1}^5.$$

But then

$$\|Iu\|_{X_\delta^{1,1/2+}} \lesssim \|Iu_0\|_{H^1} + \delta^{1-\epsilon}\|Iu\|_{L_t^\infty H_x^1}^5 \lesssim \|Iu_0\|_{H^1} + \delta^{1-\epsilon}\|Iu\|_{X_\delta{}^{1,1/2+}}^5,$$

and by standard iteration arguments (see [13]), we have that the system is locally well-posed for

$$\delta^{1-\epsilon}\|Iu_0\|_{H^1}^4 < \frac{1}{2}. \qquad \square$$

We also need an analogue of Theorem 2 for the I-system (16). Let ∇^s denote the operator which on the Fourier side is given by $\widehat{\nabla^s u}(\xi) = |\xi|^s\hat{u}(\xi)$. It then follows by the definition of the Japanese bracket that on the Fourier side the $\langle\nabla\rangle$u is given by $(1+|\xi|)\hat{u}(\xi)$.

Proposition 2. *If $H^s \ni u_0 \longmapsto u(t)$ with $s > 10/11$ solves* (2) *for all t close enough to $T^\star$ in the maximal finite interval of existence* $[0, T^\star)$, *then*

$$\|I\langle\nabla\rangle u(t)\|_{L^2} \geq C(T^\star - t)^{-\frac{s}{2}}.$$

Proof. Since we know that

$$\|I\langle\nabla\rangle u(t)\|_{L^2} \geq \|u(t)\|_{H^s},$$

it suffices to show that

$$\|\nabla^s u(t)\|_{L^2} \geq C(T^\star - t)^{-\frac{s}{2}}.$$

We assume that $\|\nabla^s u(t)\|_{L^2} > 1$ since otherwise we can change variables to put the time origin near $T^\star$. Now fix $t \in [0, T^\star)$ and consider

$$v^t(\tau, x) = \lambda^{-1/2} u\left(t + \frac{\tau}{\lambda^2}, \frac{x}{\lambda}\right),$$

where $\lambda = \|\nabla^s u(t)\|_{L^2}^{\frac{1}{s}}$. By scaling, invariance $v^t(\tau, x)$ is a solution to (2). Moreover, an easy calculation shows that

$$\|v^t(0, x)\|_{L^2} = \|u_0\|_{L^2}$$

and that

$$\|\nabla^s v^t(0, x)\|_{L^2} = \lambda^{-s}\|u(t, x)\|_{\dot{H}^s} = 1.$$

Thus $\|v^t(t, x)\|_{H^s} < C$, and by the local theory, this means that there exists a $\tau_0 > 0$, independent of t, such that $v^t(t, x)$ is defined on $[0, \tau_0]$ and therefore

$$t + \frac{\tau_0}{\|\nabla^s u(t)\|_{L^2}^{\frac{2}{s}}} \leq T^\star \Longrightarrow \|\nabla^s u(t)\|_{L^2} \geq C(T^\star - t)^{-\frac{s}{2}}. \qquad \square$$

The last step for the proof of Theorem 3 is the following proposition, which for the moment we assume and prove later.

PROPOSITION 3. *For $s > \frac{10}{11}$ there exists $p(s) < 2$ such that the following hold true:*

If $H^s \ni u_0 \longmapsto u(t)$ solves (2) on $[0, T^\star)$, then for all $T < T^\star$ there exists $N = N(T)$ such that

$$|E[I_{N(T)} u(T)]| \leq C_0 \Lambda(T)^{p(s)}$$

with $C_0 = C_0(s, T^\star, \|u_0\|_{H^s})$, and $\Lambda(T)$ is given in terms of $N(T)$ by $N(T) = C(\Lambda(T))^{\frac{p(s)}{2(1-s)}}$.

We prove Theorem 3 by using the concentration compactness method that was developed by Lions in [15, 16]. We will need a series of lemmas. The proofs of the first two lemmas are easy and can be found on pages 21 and 24, respectively, of [3].

LEMMA 4. *Let $u \in L^2$ and let the concentration function be defined by*

$$\rho(u, t) = \sup_{y \in \mathbf{R}} \int_{\{|x-y|<t\}} |u(x)|^2 dx$$

for $t > 0$. Then ρ is a nondecreasing function of t, and there exists $y(u, t) \in \mathbf{R}$ such that

$$\rho(u, t) = \int_{\{|x-y(u,t)|<t\}} |u(x)|^2 dx.$$

Moreover, if $u \in L^r(\mathbb{R})$ for some $r > 2$, then for all $s, t > 0$ and $C = C(r)$ we have

$$|\rho(u, t) - \rho(u, s)| \leq C\|u\|_{L^r}^2 |t - s|^{\frac{r-2}{r}}.$$

LEMMA 5. *There exists a constant K such that for all $u \in H^1$, all $t > 0$, and ρ defined above we have*

$$\int |u|^6 \leq K\rho(u, t)^2 \left(\int |\nabla u|^2 + t^{-2} \int |u|^2\right).$$

LEMMA 6. *Let* $(u_n)_{n\geq 0} \subset H^1$ *be such that*

$$\|u_n\|_{L^2} \leq a < \infty,$$

$$\sup_{n\geq 0} \|\nabla u_n\|_{L^2} < \infty,$$

and let $\rho(u_n, t)$ *be defined as before. Set*

$$\mu = \lim_{t\to\infty} \liminf_{n\to\infty} \rho(u_n, t).$$

Then there exist a subsequence $(u_{n_k})_{n_k\geq 0}$*, a nondecreasing function* $\gamma(t)$*, and a sequence* $t_k \to \infty$ *with the following properties:*

(i) $\rho(u_{n_k}, .) \to \gamma(.) \in [0, a]$ *as* $k \to \infty$ *uniformly on bounded sets of* $[0, \infty)$.

(ii) $\mu = \lim_{t\to\infty} \gamma(t) = \lim_{k\to\infty} \rho(u_{n_k}, t_k) = \lim_{k\to\infty} \rho(u_{n_k}, t_k/2)$.

Proof. Since

$$\mu = \lim_{t\to\infty} \liminf_{n\to\infty} \rho(u_n, t),$$

there exists a $t_k \to \infty$ such that

$$\mu = \lim_{k\to\infty} \rho(u_{n_k}, t_k) \tag{19}$$

and thus one part of (ii) is evident. To prove the first part note that

$$\rho(u_n, t) \leq \|u_n\|_{L^2} \leq a < \infty.$$

In addition since $H^1(\mathbb{R}) \hookrightarrow L^r(\mathbb{R})$ for some r, by the last property of the previous lemma $\rho(u_n, \cdot)$ is Hölder continuous. Therefore (i) follows from Ascoli's theorem (after renaming the sequence n_k). Notice that property (19) is still true after passing to a subsequence. For the rest of (ii) by (19) and the fact that $\rho(u_n, \cdot)$ is nondecreasing we deduce that

$$\limsup_{k\to\infty} \rho\left(u_{n_k}, \frac{t_k}{2}\right) \leq \limsup_{k\to\infty} \rho(u_{n_k}, t_k) = \mu. \tag{20}$$

Next for every $t > 0$ we have

$$\liminf_{k\to\infty} \rho\left(u_{n_k}, t\right) \geq \liminf_{n\to\infty} \rho(u_n, t),$$

Now by letting $t \to \infty$ and using part (i) of the lemma and the definition of μ we get that

$$\lim_{t\to\infty} \gamma(t) \geq \mu. \tag{21}$$

Finally, given $t > 0$ we have $\frac{t_k}{2} > t$ for k large, so that

$$\rho\left(u_{n_k}, \frac{t_k}{2}\right) \geq \rho(u_{n_k}, t),$$

and by letting $k \to \infty$ by part (i) we get

$$\liminf_{k\to\infty} \rho\left(u_{n_k}, \frac{t_k}{2}\right) \geq \mu. \tag{22}$$

By (20) and (22) we have that

$$\mu = \lim_{k\to\infty} \rho(u_{n_k}, t_k/2).$$

Similarly

$$\rho\left(u_{n_k}, \frac{t_k}{2}\right) \geq \rho(u_{n_k}, t) \Rightarrow \sup \rho\left(u_{n_k}, \frac{t_k}{2}\right) \geq \rho(u_{n_k}, t),$$

and by taking $k \to \infty$ and using (20) we get

$$\mu \geq \lim_{t\to\infty} \gamma(t). \qquad \square \tag{23}$$

LEMMA 7. *Let $(u_n)_{n\geq 0} \subset H^1$ be such that*

$$\|u_n\|_{L^2} \leq a < \infty,$$

$$\lim_{n\to\infty} \|u_n\|_{L^2}^2 = b > 0,$$

and

$$\sup_{n\geq 0} \|\nabla u_n\|_{L^2} < \infty.$$

Then there exists a subsequence $(u_{n_k})_{k\geq 0}$ which satisfies the following.

There exist $(q_k)_{k\geq 0}, (w_k)_{k\geq 0} \subset H^1(\mathbb{R})$ such that

$$\operatorname{supp} q_k \cap \operatorname{supp} w_k = \emptyset, \tag{24}$$

$$|q_k| + |w_k| \leq |u_{n_k}|, \tag{25}$$

$$\|q_k\|_{H^1} + \|w_k\|_{H^1} \leq C\|u_{n_k}\|_{H^1}, \tag{26}$$

$$\lim_{k\to\infty} \|q_k\|_{L^2}^2 = \mu, \qquad \lim_{k\to\infty} \|w_k\|_{L^2}^2 = b - \mu, \tag{27}$$

$$\liminf_{k\to\infty} \left\{ \int |\nabla u_{n_k}|^2 - \int |\nabla q_k|^2 - \int |\nabla w_k|^2 \right\} \geq 0, \tag{28}$$

$$\lim_{k\to\infty} \left| \int |u_{n_k}|^p - \int |q_k|^p - \int |w_k|^p \right| = 0 \tag{29}$$

for all $2 \leq p < \infty$.

Proof. We use the sequences $(u_{n_k})_{k\geq 0}$ and $(t_k)_{k\geq 0}$ constructed in the previous lemma. We fix $\theta, \phi \in C^\infty([0,\infty))$ such that $0 \leq \theta, \phi \leq 1$ and

$$\theta(t) = 1 \text{ for } 0 \leq t \leq \frac{1}{2}, \quad \theta(t) = 0 \text{ for } t \geq \frac{3}{4},$$

$$\phi(t) = 0 \text{ for } 0 \leq t \leq \frac{3}{4}, \quad \phi(t) = 1 \text{ for } t \geq 1,$$

and we set

$$q_k = \theta_k u_{n_k}, \quad w_k = \phi_k u_{n_k},$$

where

$$\theta_k = \theta\left(\frac{|x - y(u_{n_k}, \frac{t_k}{2})|}{t_k}\right), \quad \phi_k = \phi\left(\frac{|x - y(u_{n_k}, \frac{t_k}{2})|}{t_k}\right).$$

Now (24), (25), and (26) are immediate. To prove (27) we estimate

$$\rho\left(u_{n_k}, \frac{t_k}{2}\right) = \int_{|x-y(u_{n_k},\frac{t_k}{2})|\leq \frac{t_k}{2}} |u_{n_k}|^2 \leq \int |q_k|^2 \leq \int_{|x-y(u_{n_k},\frac{t_k}{2})|\leq t_k} |u_{n_k}|^2$$

$$\leq \int_{|x-y(u_{n_k},t_k)|\leq t_k} |u_{n_k}|^2 \leq \rho(u_{n_k}, t_k).$$

Applying the second part of Lemma 6 we immediately get

$$\lim_{k\to\infty} \|q_k\|_{L^2}^2 = \mu. \tag{30}$$

We now set $z_k = u_{n_k} - q_k - w_k$. Note that in particular $|z_k| \leq |u_{n_k}|$. We have

$$\begin{aligned}\int |z_k|^2 &\leq \int_{\frac{t_k}{2}\leq|x-y(u_{n_k},\frac{t_k}{2})|\leq t_k} |u_{n_k}|^2 \\ &= \int_{|x-y(u_{n_k},\frac{t_k}{2})|\leq t_k} |u_{n_k}|^2 - \int_{|x-y(u_{n_k},\frac{t_k}{2})|\leq \frac{t_k}{2}} |u_{n_k}|^2 \\ &\leq \int_{|x-y(u_{n_k},t_k)|\leq t_k} |u_{n_k}|^2 - \int_{|x-y(u_{n_k},\frac{t_k}{2})|\leq \frac{t_k}{2}} |u_{n_k}|^2 = \rho(u_{n_k}, t_k) - \rho\left(u_{n_k}, \frac{t_k}{2}\right)\end{aligned}$$

and again by Lemma 6 we have

$$\lim_{k\to\infty} \|z_k\|_{L^2}^2 = 0. \tag{31}$$

By the Cauchy–Schwartz inequality and the above we have that

$$\lim_{k\to\infty} \int u_{n_k} \bar{z}_k = 0.$$

But now by (24), (30), (31), and some trivial algebra we get after integration that

$$\lim_{k\to\infty} \|w_k\|_{L^2}^2 = b - \mu$$

and (27) follows. Also note that z_k is bounded in H^1 and converges to 0 in L^2, and by the Gagliardo–Nirenberg inequality, in L^p for any $2 \leq p < \infty$. Moreover, one can easily verify that

$$\left||u_{n_k}|^p - |q_k|^p - |w_k|^p\right| \leq C|u_{n_k}|^{p-1}|z_k|$$

and by Cauchy–Schwartz since z_k tends to 0 in L^p, (29) follows. Finally, (28) follows easily from the initial assumptions, the Cauchy–Schwartz inequality and the easy calculation

$$|\nabla u_{n_k}|^2 - |\nabla q_k|^2 - |\nabla w_k|^2 = |\nabla u_{n_k}|^2(1-\theta_k^2-\phi_k^2) - |u_{n_k}|^2(|\nabla\theta_k|^2+|\nabla\phi_k|^2)$$

$$-Re(\bar{u}_{n_k}\nabla u_{n_k})\cdot\nabla(\theta_k^2+\phi_k^2) \geq -\frac{C}{t_k^2}|u_{n_k}|^2 - \frac{C}{t_k}|u_{n_k}|\ |\nabla u_{n_k}|. \qquad \square$$

Proof of Theorem 3. Define the blowup parameters:

$$\lambda(t) = \|u(t)\|_{H^s}, \quad \Lambda(t) = \sup_{0\leq\tau\leq t}\lambda(\tau),$$
$$\sigma(t) = \|I_N\langle\nabla\rangle u(t)\|_{L^2}, \quad \Sigma(t) = \sup_{0\leq\tau\leq t}\sigma(\tau).$$

Let $\{t_n\}_{n=1}^{\infty}$ be a sequence such that $t_n \uparrow T^\star$ and for each t_n we have

$$\|u(t_n)\|_{H^s} = \Lambda(t_n)$$

and with $u(t_n) = u_n$ we define

$$I_N u_n = I_{N(t_n)}u(t_n).$$

We rescale these as follows:

$$v_n(x) = \frac{1}{\sqrt{\sigma_n}} I_N u_n\left(\frac{x}{\sigma_n}\right),$$

where

$$\sigma_n = \|I_N\langle\nabla\rangle u_n\|_{L^2} = \sigma(t_n).$$

Note that for these sequences (let us call them maximizing) we have that

$$\Lambda(t_n) \leq \sigma_n,$$

where $\sigma_n \to \infty$ as $n \to \infty$. It is important to note that we are in the blow-up regime and thus

$$\|u_0\|_{L^2} \geq \|Q\|_{L^2}.$$

Moreover, the L^2 part of v_n is bounded uniformly in n. This is because

$$\|v_n\|_{L^2} = \|I_N u_n\|_{L^2} \leq \|u_n\|_{L^2} = \|u(t_n)\|_{L^2} = \|u_0\|_{L^2}.$$

Thus in the limit as $n \to \infty$ we have

$$\lim_{n\to\infty}\|\nabla v_n\|_{L^2} = 1.$$

Also, since $N(t_n)$ goes to infinity as $n \to \infty$,

$$\lim_{n\to\infty}\|v_n\|_{L^2} = \lim_{n\to\infty}\|I_N u_n\|_{L^2} = \lim_{n\to\infty}\|u(t_n)\|_{L^2} = \|u_0\|_{L^2} \geq \|Q\|_{L^2}.$$

In addition, by Proposition 3 we have that

$$|E(v_n)| = \frac{1}{\sigma_n^2}|E(I_N u_n)| \leq C\sigma_n^{-2}\Lambda^{p(s)}(t_n) \leq C\Lambda^{p(s)-2}(t_n)$$

and thus

$$\lim_{n\to\infty} E(v_n) = 0$$

since $p(s) < 2$. This allows another way to prove that

$$\lim_{n\to\infty} \|v_n\|_{L^2} \geq \|Q\|_{L^2}$$

since by the optimality of the Gagliardo–Nirenberg inequality we have

$$E(v_n) \geq \frac{1}{2}\left(1 - \frac{\|v_n\|_{L^2}^4}{\|Q\|_{L^2}^4}\right)\|\nabla v_n\|_{L^2}^2$$

and in the limit as $n \to \infty$ we get

$$\lim_{n\to\infty} \|v_n\|_{L^2} \geq \|Q\|_{L^2}.$$

We collect the three important relations that we have:

$$\lim_{n\to\infty} \|v_n\|_{L^2} = \|u_0\|_{L^2} \geq \|Q\|_{L^2}, \tag{32}$$

$$\lim_{n\to\infty} \|\nabla v_n\|_{L^2} = 1, \tag{33}$$

$$\lim_{n\to\infty} E(v_n) = 0. \tag{34}$$

With the help of (32), (33), and (34) we will conclude the following claim.

Claim 1.

$$\mu(\{v_n\}_{n\geq 0}) \geq \|Q\|_{L^2}^2.$$

First assuming the claim and revisiting the statement of the theorem, it is enough to prove that for any $\epsilon > 0$ we have

$$\lim_{n\to\infty} \|u(t_n)\|_{L^2_{\{|x-z_n|<(T^\star-t_n)^{\frac{s}{2}}\gamma(T^\star-t_n)\}}} \geq \|Q\|_{L^2} - \epsilon.$$

Note that since $N(t_n)$ goes to ∞ we have

$$\lim_{n\to\infty} \|u(t_n)\|_{L^2} = \lim_{n\to\infty} \|I_{N(t_n)}u(t_n)\|_{L^2}.$$

Now given $\epsilon > 0$, the relation

$$\mu(\{v_n\}_{n\geq 0}) \geq \|Q\|_{L^2}^2$$

by Lemma 6 implies that there exists a $T \in \mathbf{R}$ such that

$$\rho(v_n, T) \geq \|Q\|_{L^2}^2 - \epsilon$$

for large n. Note that ρ is a nondecreasing function of t and it is crucial to find a fixed T such that $\rho(v_n, T) \geq \|Q\|_{L^2}^2 - \epsilon$ holds for any large n, for the given ϵ. That this T is independent of all the n's after some n large, up to a subsequence, is guaranteed by the two parts of Lemma 6. Thus the same T works for all large n.

Now setting $y_n = y(v_n, T)$ defined by Lemma 4, we have that

$$\liminf_{n\to\infty} \|v(t_n)\|_{L^2_{\{|x-y_n|<T\}}} \geq \|Q\|^2_{L^2} - \epsilon$$

and up to a subsequence

$$\lim_{n\to\infty} \|v(t_n)\|_{L^2_{\{|x-y_n|<T\}}} \geq \|Q\|^2_{L^2} - \epsilon. \tag{35}$$

But

$$\lim_{n\to\infty} \|v(t_n)\|_{L^2_{\{|x-y_n|<T\}}} = \lim_{n\to\infty} \left\| \frac{1}{\sqrt{\sigma_n}} I_N u_n \left(\frac{x}{\sigma_n}\right) \right\|_{L^2_{\{|x-y_n|<T\}}}$$

$$= \lim_{n\to\infty} \|I_n u_n(x)\|_{L^2_{\{|x-\frac{y_n}{\sigma_n}|<\frac{T}{\sigma_n}\}}} = \lim_{n\to\infty} \|u_n(x)\|_{L^2_{\{|x-\frac{y_n}{\sigma_n}|<\frac{T}{\sigma_n}\}}} = \lim_{n\to\infty} \|u_n(x)\|_{L^2_{\{|x-z_n|<\frac{T}{\sigma_n}\}}},$$

where $z_n = \frac{y_n}{\sigma_n}$. Moreover, note that $\frac{T}{\sigma_n} \to 0$ and that σ_n goes to infinity at least as fast as $(T^\star - t)^{-\frac{s}{2}}$. Thus there exists a function $\gamma(x) \uparrow \infty$ as $x \downarrow 0$ such that

$$\begin{aligned}\lim_{n\to\infty} \|u(t_n)\|_{L^2_{\{|x-z_n|<(T^\star-t_n)^{\frac{s}{2}}\gamma(T^\star-t_n)\}}} &\geq \lim_{n\to\infty} \|u_n(x)\|_{L^2_{\{|x-z_n|<\frac{T}{\sigma_n}\}}} \\ &= \lim_{n\to\infty} \|v(t_n)\|_{L^2_{\{|x-y_n|<T\}}} \geq \|Q\|^2_{L^2} - \epsilon\end{aligned}$$

by equation (35), and the proof is complete. □

Proof of Claim 1. We prove the claim by contradiction. We claim that there exists $\delta > 0$ with the following property. If $(v_n)_{n\geq 0} \in H^1$ is such that

$$\lim_{n\to\infty} \|v_n\|^2_{L^2} = \|u_0\|^2_{L^2}, \tag{36}$$

$$0 < \liminf_{n\to\infty} \|\nabla v_n\|_{L^2} \leq \limsup_{n\to\infty} \|\nabla v_n\|_{L^2} < \infty, \tag{37}$$

$$\limsup_{n\to\infty} E(v_n) \leq 0, \tag{38}$$

and

$$\mu(\{v_n\}_{n\geq 0}) < \|Q\|^2_{L^2}, \tag{39}$$

then there exists a sequence $(\tilde{v}_n)_{n\geq 0} \in H^1$ satisfying (37), (38), and (39) and such that

$$\lim_{n\to\infty} \|\tilde{v}_n\|^2_{L^2} = \|u_0\|^2_{L^2} - \beta$$

for some $\beta > \delta$. Clearly the sequence v_n of Theorem 3 satisfies (36), (37), and (38). But then by Galiardo–Nirenberg and (37), (38), and (39) we have that

$$\mu(\{v_n\}_{n\geq 0}) < \|u_0\|^2_{L^2} - \delta.$$

If we apply the above procedure k times, we get $\mu(\{v_n\}_{n\geq 0}) < \|u_0\|^2_{L^2} - k\delta$, which for large k is absurd. Thus it suffices to prove the claim. We apply Lemmas 6 and 7 to the sequence $(v_n)_{n\geq 0}$ and we consider the corresponding sequences $(q_n)_{n\geq 0}$ and $(w_n)_{n\geq 0}$. We set

$$\delta = \left(\frac{3}{K}\right)^{\frac{1}{2}} > 0,$$

where K is given in Lemma 5. We first show that

$$\mu(\{v_n\}_{n\geq 0}) \geq \delta.$$

By Lemma 5 and the definition of δ we have that

$$E(v_{n_k}) \geq \frac{1}{2}\left(1-\left(\frac{\rho(v_{n_k},t_k)}{\delta}\right)^2\right)\int |\nabla v_{n_k}|^2 - \frac{K}{6t_k^2}\rho(v_{n_k},t_k)^2.$$

Now if we assume by contradiction that $\mu < \delta$, then we obtain by letting $k \to \infty$, applying the second part of Lemma 6, and using (37) that up to a subsequence

$$\limsup_{n\to\infty} E(v_n) \geq \frac{1}{2}\left(1-\left(\frac{\mu}{\delta}\right)^2\right)\liminf_{n\to\infty}\int |\nabla v_n|^2 > 0,$$

which is absurd. Now since by (25) we know that $|w_k| \leq |v_{n_k}|$, we have by the second part of Lemma 6 and (39)

$$\mu((w_k)_{k\geq 0}) \leq \mu < \|Q\|_{L^2}^2.$$

This proves that $(w_k)_{k\geq 0}$ satisfies (39). Also by (27), (39), and the Gagliardo–Nirenberg inequality we know that there exists a $\sigma > 0$ such that for k large

$$E(q_k) \geq \sigma \|\nabla q_k\|_{L^2}^2. \tag{40}$$

On the other hand, by (28) and (29) we have that

$$\liminf_{k\to\infty}\{E(v_{n_k}) - E(q_k) - E(w_k)\} \geq 0 \tag{41}$$

and thus

$$\limsup_{k\to\infty} E(w_k) \leq 0.$$

This proves that $(w_k)_{k\geq 0}$ satisfies (38). By (26) and (37) we easily get that

$$\|\nabla w_k\|_{L^2} \leq C\|v_{n_k}\|_{H^1} < \infty.$$

Finally we show the last property (37), namely, that

$$\liminf_{k\to\infty} \|\nabla w_k\|_{L^2} > 0.$$

We argue again by contradiction and assume that there exists a sequence which we still denote by $(w_k)_{k\geq 0}$ such that $\lim_{k\to\infty} \|\nabla w_k\|_{L^2} = 0$. But then it trivially follows that $E(w_k) \to 0$ as $k \to \infty$ and thus by (38), (40), and (41) we get that

$$\lim_{k\to\infty} \|\nabla q_k\|_{L^2} = 0.$$

But then by (29) and the fact that $\|w_k\|_{L^6}, \|q_k\|_{L^6} \to 0$ we deduce that $\lim_{k\to\infty} \|v_{n_k}\|_{L^6} = 0$ and thus

$$\limsup_{k\to\infty} E(v_{n_k}) > 0,$$

which contradicts (38). Now setting

$$\tilde{v}_k = \frac{\sqrt{\|u_0\|_{L^2}^2 - \mu}}{\|w_k\|_{L^2}} w_k,$$

we see that with the help of (27) the sequence $(\tilde{v}_n)_{n\geq 0}$ satisfies (37), (38), and (39) and that

$$\lim_{k\to\infty} \|\tilde{v}_k\|_{L^2}^2 = \|u_0\|_{L^2}^2 - \mu \leq \|u_0\|_{L^2}^2 - \delta,$$

and we are done. ∎

Remark 6. In dimensions $n \geq 2$ with the additional assumption of radial symmetry on the initial data, the solution of the equivalent L^2-critical Schrödinger equation satisfies the conclusion of Theorem 3 with $z(t) \equiv 0$.

We define the "modified energy" for the system (16) as

$$E(Iu)(t) = \frac{1}{2}\int |Iu_x(t)|^2 dx - \frac{1}{6}\int |Iu(t)|^6 dx.$$

This "energy" functional is not conserved, but we can show that its time derivative decays with respect to a large parameter N. The next proposition quantifies the increament of this functional on $[0,\delta]$.

PROPOSITION 4. *Let u be an H^1 solution of* (2). *Then*

$$\begin{aligned} E(Iu)(\delta) - E(Iu)(0) &= Im\left(\int_0^\delta \int I\bar{u}_{xx}\left(I(|u|^4u) - Iu|Iu|^4\right) dxdt\right) \\ &\quad + Im\left(\int_0^\delta \int I(|u|^4u)\left(I(|u|^4u) - Iu|Iu|^4\right) dxdt\right). \end{aligned}$$

Proof. The derivative of the "modified energy" is

$$\begin{aligned} \frac{dE}{dt}(Iu) &= Im\left(\int I\bar{u}_{xx}\left(I(|u|^4u) - Iu|Iu|^4\right) dx\right) \\ &\quad + Im\left(\int I(|u|^4u)\left(I(|u|^4u) - Iu|Iu|^4\right) dx\right). \end{aligned}$$

But then Proposition 4 follows immediately by applying the fundamental theorem of calculus. ∎

By the previous formal identity we can deduce the desired decay of the "modified energy."

PROPOSITION 5. *For any Schwartz function u we have that*

$$E(Iu)(\delta) - E(Iu)(0) \lesssim \delta^{\frac{1}{4}-} N^{-\frac{3}{2}+} \|Iu\|_{X_\delta^{1,1/2+}}^6 + \delta^{\frac{1}{2}-} N^{-2+} \|Iu\|_{X_\delta^{1,1/2+}}^{10}.$$

Proof. First we establish

$$\left|\int_0^\delta \int I\bar{u}_{xx}\left(I(|u|^4u) - Iu|Iu|^4\right) dxdt\right| \lesssim \delta^{\frac{1}{4}-} N^{-\frac{3}{2}+} \|Iu\|_{X_\delta^{1,1/2+}}^6$$

or, by Plancherel's theorem, that

$$\left|\int_0^\delta \int_{\Gamma_6} \frac{\xi_1^2}{\langle \xi_1 \rangle} \left(\frac{m(\xi_2 + \cdots + \xi_6) - m(\xi_2) \cdots m(\xi_6)}{m(\xi_2) \cdots m(\xi_6)} \right) \hat{u}(\xi_1, t) \cdots \hat{\bar{u}}(\xi_6, t) d\xi dt \right|$$

$$\lesssim \delta^{1/4-} N^{-\frac{3}{2}+} \|u\|^5_{X^{1,1/2+}} \|u_1\|_{X^{0,1/2+}}, \tag{42}$$

where Γ_6 denotes the hyperplane $\xi_1 + \xi_2 + \cdots + \xi_6 = 0$, and u_1 is the function that corresponds on the Fourier side to the frequency ξ_1.

Remark 7.

1. Let us denote $N_i \sim |\xi_i|$ and $N_{max} \sim |\xi|_{max}$, $N_{med} \sim |\xi|_{med}$, where $|\xi|_{max}$, $|\xi|_{med}$ are the largest and second largest of the $|\xi_i|$. If all $|\xi_i| \ll N$, then the big parenthesis above is zero and there is nothing to prove. Thus since the ξ_i are related by $\xi_1 + \xi_2 + \cdots + \xi_6 = 0$, we have that $|\xi|_{max} \sim |\xi|_{med} \gtrsim N$. We also write m_i for $m(\xi_i)$ and m_{ij} for $m(\xi_i + \xi_j)$.
2. Our strategy from now on is to break all the functions into a sum of dyadic constituents ψ_j, each with frequency support $\langle \xi \rangle \sim 2^j, j = 0, \cdots$. Then we pull the absolute value of the symbols out of the integral, estimating it pointwise. After bounding the multiplier, the remaining integrals involving the pieces ψ_j are estimated by reversing Plancherel's formula and using duality, Hölder's inequality, and the Strichartz estimates. We can sum over all the frequency pieces ψ_j as long as we always keep a factor $N_{max}^{-\epsilon}$ inside the summation.
3. Since in all of the estimates that we establish from now on, the right-hand side is in terms of the $X^{s,b}$ norms and the $X^{s,b}$ spaces depend only on the absolute value of the Fourier transform, we can assume without loss of generality that the Fourier transform of all the functions in the estimates are real and positive.
4. Note also that $\frac{N_1^2}{\langle N_1 \rangle} \leq N_1$.

Since, as we mentioned before, our analyses do not rely upon the complex conjugate structure of the left-hand side, there is a symmetry under the interchange of the indices and thus we can assume that

$$N_2 \geq N_3 \geq \cdots \geq N_6.$$

Case 1. Let $N \gg N_2$. Then

$$\frac{m(\xi_2 + \cdots + \xi_6) - m(\xi_2) \cdots m(\xi_6)}{m(\xi_2) \cdots m(\xi_6)} = 0$$

and there is nothing to prove.

Case 2. $N_2 \gtrsim N \gg N_3 \geq \cdots \geq N_6$. This forces $N_1 \sim N_2$ on Γ_6. But then by the mean value theorem we have

$$\left|\frac{m(\xi_2 + \cdots + \xi_6) - m(\xi_2) \cdots m(\xi_6)}{m(\xi_2) \cdots m(\xi_6)}\right| = \left|\frac{m(\xi_2) - m(\xi_1)}{m(\xi_2)}\right|$$

$$\lesssim \left|\frac{\nabla m(\xi_2) \cdot (\xi_3 + \cdots + \xi_6)}{m(\xi_2)}\right| \lesssim \frac{N_3}{N_2}.$$

Now by undoing Plancherel's theorem, using the Cauchy–Schwartz inequality, applying the Strichartz estimates, and using Lemmas 2 and 3, we have that the left-hand side of (42) is

$$\lesssim \frac{N_1 N_3}{N_2 N_1^{1/2}} \|(D^{1/2}u_1)u_3\|_{L_t^2 L_x^2} \|u_2 u_4 u_5 u_6\|_{L_t^2 L_x^2}$$

$$\lesssim \frac{N_3}{N_1^{1/2}} \|u_1\|_{X_\delta^{0,1/2+}} \|u_3\|_{X_\delta^{0,1/2+}} \prod_{j=4}^{6} \|u_j\|_{L_t^\infty L_x^\infty} \|u_2\|_{L_t^2 L_x^2}$$

$$\lesssim \delta^{1/2-} \frac{N_3}{N_1^{1/2}} \prod_{j=1}^{3} \|u_j\|_{X_\delta^{0,1/2+}} \prod_{j=4}^{6} \|u_j\|_{X_\delta^{1/2,1/2+}},$$

where in the last inequality we also used (9) in its dyadic form. Comparing with (42) we see that it is enough to have

$$\delta^{1/2-} \frac{N_3 (N_4 N_5 N_6)^{1/2}}{N_1^{1/2}} \lesssim \delta^{1/4-} N^{-\frac{3}{2}+} N_{max}^{-\epsilon} N_2 \cdots N_6,$$

which is true. Note that in the process we summed the Littlewood–Paley pieces, using the factor $N_{max}^{-\epsilon}$.

Case 3. $N_2 \geq N_3 \gtrsim N$. In this case we use the crude estimate

$$|1 - \frac{m_1}{m_2 \cdots m_6}| \lesssim \frac{m_1}{m_2 \cdots m_6}.$$

Since it is impossible to have $N_1 \gg N_{med} = N_2$, we can divide this case into two subcases.

(a) $N_1 \sim N_2 \geq N_3 \gtrsim N$. Now we start by comparing the different frequencies in order to be able to apply Lemma 3. Note that $m_1 \sim m_2$.

(i) Suppose first that $N_2 \gg N_3$. Without loss of generality we can assume that $N_4 \leq N$. This is because in the case that one of the N_4, N_5, N_5 is $\gtrsim N$, the estimate is even easier and the decay is greater. For the suspicious reader who might object to the previous argument because of the presence of $m_4 m_5 m_6$ in the denominator, we comment that for $N_j \gtrsim N$ we have that

$$\frac{1}{m_j N_j^{1/2}} \lesssim \frac{1}{N^{1/2}}$$

and indeed we can get a better decay. From now on we will use this heuristic without any comment. Thus we can apply Cauchy–Schwartz and Lemma 3, and the left-hand side of (42) is

$$\lesssim \frac{N_1}{m_3 N_1^{1/2}} \|(D^{1/2}u_1)u_3\|_{L_t^2 L_x^2} \|u_2\|_{L_t^2 L_x^2} \cdot \prod_{j=4}^{6} \|u_j\|_{L_t^\infty L_x^\infty}$$

$$\lesssim \delta^{1/2-} \frac{N_1 N_3^{1/2}}{m_3 N_3^{1/2} N_1^{1/2}} \prod_{j=1}^{3} \|u_j\|_{X_\delta^{0,1/2+}} \cdot \prod_{j=4}^{6} \|u_j\|_{X_\delta^{1/2,1/2+}}$$

$$\lesssim \delta^{1/2-} \frac{N_1 N_3^{1/2}}{N^{1/2} N_1^{1/2}} \prod_{j=1}^{3} \|u_j\|_{X_\delta^{0,1/2+}} \cdot \prod_{j=4}^{6} \|u_j\|_{X_\delta^{1/2,1/2+}}.$$

Comparing with (42) we see that it is enough to have

$$\delta^{1/2-}\frac{N_1 N_3^{1/2}}{N^{1/2}N_1^{1/2}} \lesssim \delta^{1/4-}N^{-\frac{3}{2}+}N_{max}^{-\epsilon}(N_4\cdots N_6)^{1/2}N_2N_3,$$

which is true.

(ii) Now assume that $N_2 \sim N_3$ and by the comment in case (i) the worst case is when $N_5, N_6 \leq N$ which we assume without loss of generality. In this case we compare N_3 with N_4. In case that $N_3 \sim N_4$, the estimate is easy since

$$\frac{N_1 m_1}{m_2\cdots m_6} \lesssim \frac{N_1 N_3^{1/2}}{m_3 m_4 N_3^{1/2}} \lesssim \frac{N_1 N_3^{1/2}}{N^{1/2}}$$

and thus the left-hand side of (42) is

$$\lesssim \frac{N_1 N_3^{1/2}}{N^{1/2}}\prod_{j=1}^{4}\|u_j\|_{L_t^4L_x^4}\cdot\|u_5\|_{L_t^\infty L_x^\infty}\|u_6\|_{L_t^\infty L_x^\infty}$$

$$\lesssim \delta^{1/2-}\frac{N_1 N_3^{1/2}}{N^{1/2}}\prod_{j=1}^{4}\|u_j\|_{X_\delta^{0,1/2+}}\cdot\|u_5\|_{X_\delta^{1/2,1/2+}}\|u_6\|_{X_\delta^{1/2,1/2+}}.$$

Comparing with (42) it is enough to have

$$\delta^{1/2-}\frac{N_1 N_3^{1/2}(N_5N_6)^{1/2}}{N^{1/2}} \lesssim \delta^{1/4-}N^{-\frac{3}{2}+}N_{max}^{-\epsilon}N_2\cdots N_6,$$

which is true. If $N_3 \gg N_4$ again without loss of generality we assume that $N_4 \leq N$ and we apply Lemma 3. Moreover,

$$\left|\frac{N_1 m_1}{m_2\cdots m_6}\right| \lesssim \frac{N_1 N_3^{1/2}}{m_3 N_3^{1/2}} \lesssim \frac{N_1 N_3^{1/2}}{N^{1/2}}$$

and thus the left-hand side of (42) is

$$\lesssim \frac{N_1 N_3^{1/2}}{N^{1/2}N_1^{1/2}}\|(D^{1/2}u_1)u_4\|_{L_t^2L_x^2}\|u_2u_3\|_{L_t^2L_x^2}\|u_5\|_{L_t^\infty L_x^\infty}\|u_6\|_{L_t^\infty L_x^\infty}$$

$$\lesssim \frac{N_1 N_3^{1/2}}{N^{1/2}N_1^{1/2}}\|u_1\|_{X_\delta^{0,1/2+}}\|u_4\|_{X_\delta^{0,1/2+}}\|u_2\|_{L_t^6L_x^6}\|u_3\|_{L_t^3L_x^3}\|u_5\|_{X_\delta^{1/2,1/2+}}\|u_6\|_{X_\delta^{1/2,1/2+}}$$

$$\lesssim \delta^{1/4-}\frac{N_1 N_3^{1/2}}{N^{1/2}N_1^{1/2}}\prod_{j=1}^{4}\|u_j\|_{X_\delta^{0,1/2+}}\|u_5\|_{X_\delta^{1/2,1/2+}}\|u_6\|_{X_\delta^{1/2,1/2+}},$$

where we used Lemmas 2 and 3 and (7), (9), and (11). Comparing with (42) it is enough to have

$$\delta^{1/4-}\frac{N_1 N_3^{1/2}(N_5N_6)^{1/2}}{N^{1/2}N_1^{1/2}} \lesssim \delta^{1/4-}N^{-\frac{3}{2}+}N_{max}^{-\epsilon}N_2\cdots N_6,$$

which is true.

(b) $N_2 \sim N_3 \gtrsim N$ and $N_2 \gg N_1$. Since N_1 is in the numerator on the left-hand side of (42), this case is easier than the previous and similar analysis gives the same (or ever better) bounds as in (a). The details are omitted.

To conclude the proof of Proposition 5 it remains to show that

$$\left|\int_0^\delta \int I(|u|^4 u)\left(I(|u|^4 u) - Iu|Iu|^4\right) dxdt\right| \lesssim \delta^{\frac{1}{2}-} N^{-2+} \|Iu\|^{10}_{X^{1,1/2+}_\delta}.$$

By Plancherel's theorem,

$$\left|\int_0^\delta \int_{\Gamma_{10}} m_{12345}\{m_{678910} - m_6 \cdots m_{10}\}\hat{u}(\xi_1,t)\cdots\hat{\bar{u}}(\xi_{10},t)d\xi dt\right| \lesssim \delta^{\frac{1}{2}} N^{-2+}\|Iu\|^{10}_{X^{1,1/2+}_\delta}. \tag{43}$$

As we noted before, if $N_{max} \ll N$, the multiplier is zero so we assume that

$$N_{max} \sim N_{med} \gtrsim N.$$

In addition since $m(\xi) \leq 1$, we have that

$$|m_{12345}\{m_{678910} - m_6 \cdots m_{10}\}| \lesssim C.$$

Finally the last pointwise estimate that we use is

$$\frac{1}{m_{max} N_{max}} \lesssim N^{-1},$$

which follows easily since $N_{max} \gtrsim N$. The left-hand side of (43) is

$$\begin{aligned}
&\lesssim \int_0^\delta \int_{\Gamma_{10}} \prod_{j=1}^{10} \hat{u}(\xi_j,t)d\xi dt \lesssim \int_0^\delta \int_{\Gamma_{10}} \frac{m_{max}N_{max}\hat{u}_{max} \cdot m_{med}N_{med}\hat{u}_{med}}{m_{max}N_{max}m_{med}N_{med}} \cdot \\
&\qquad\qquad \prod_{j \neq j_{max}, j_{med}} \hat{u}(\xi_j,t)d\xi dt \\
&\qquad \lesssim N^{-2+}N^{-\epsilon}_{max} \int_0^\delta \int_{\Gamma_{10}} \widehat{DIu_{max}} \cdot \widehat{DIu_{med}} \prod_{j \neq j_{max}, j_{med}} \hat{u}(\xi_j,t)d\xi dt.
\end{aligned}$$

Now reversing Plancherel's theorem and using the estimates

$$\|u\|_{L^6_t L^6_x} \lesssim \|u\|_{X^{0,1/2+}_\delta},$$

$$\|u\|_{L^3_t L^3_x} \lesssim \delta^{1/4-}\|u\|_{X^{0,1/2+}_\delta},$$

$$\|u\|_{X^{0,1/2+}_\delta} \lesssim \|Iu\|_{X^{1,1/2+}_\delta},$$

$$\|u\|_{X^{1/2,1/2+}_\delta} \lesssim \|Iu\|_{X^{1,1/2+}_\delta},$$

we get that the left-hand side of (43) is

$$\lesssim N^{-2+}N^{-\epsilon}_{max}\|JIu_{max}\|_{L^6_t L^6_x} \cdot \|JIu_{med}\|_{L^6_t L^6_x}\|u\|^2_{L^3_t L^3_x}\|u\|^6_{L^\infty_t L^\infty_x}$$

$$\lesssim \delta^{1/2-} N^{-2+} N_{max}^{-\epsilon} \|JIu\|^2_{X_\delta^{0,1/2}} \|u\|^2_{X_\delta^{0,1/2}} \|u\|^6_{X_\delta^{1/2,1/2}} \lesssim \delta^{\frac{1}{2}-} N^{-2+} \|Iu\|^{10}_{X_\delta^{1,1/2+}},$$

where in the process we sum the different Littlewood–Paley pieces, taking advantage of the factor $N_{max}^{-\epsilon}$. ∎

Now we are finally ready to prove Proposition 3.

Proof. When $s = 1$ we can choose $N(T) = +\infty$ and thus $I_{N(T)} = 1$ and the proposition is true with $p(s) = 0$ since the energy is conserved and the kinetic energy blows up as time approaches $T^\star$. Therefore we can fix $10/11 < s < 1$ and take T near $T^\star$. Now let $N = N(T)$ to be chosen later in the argument. Recall that $\delta \sim (\Sigma(T))^{-4-\epsilon}$ gives the time of the local well-posedness. Thus if we divide the interval $[0, T]$ into $\frac{T}{\delta}$-subintervals of size $\sim \delta$, the local well-posedness result uniformly applies. Moreover for any t in this subinterval we have that

$$\|I\langle\nabla\rangle u(t)\|_{L^2} = \sigma(t) \leq \Sigma(T).$$

The next step is to iterate the almost conservation of the energy. It is apparent that after $\frac{T}{\delta}$ steps the growth of the modified energy is

$$\begin{aligned} E(Iu(T)) &\lesssim E(Iu(0)) + \frac{T^\star}{\delta}\{\delta^{\frac{1}{4}-} N^{-\frac{3}{2}+}\Sigma(T)^6 + \delta^{\frac{1}{2}-} N^{-2+}\Sigma(T)^{10}\} \\ &\leq N^{2(1-s)}\lambda(0) + \frac{T^\star}{\delta}\{\delta^{\frac{1}{4}-} N^{-\frac{3}{2}+}\Sigma(T)^6 + \delta^{\frac{1}{2}-} N^{-2+}\Sigma(T)^{10}\} \\ &\lesssim N^{2(1-s)} + \{\delta^{-\frac{3}{4}-} N^{-\frac{3}{2}+}\Sigma(T)^6 + \delta^{-\frac{1}{2}-} N^{-2+}\Sigma(T)^{10}\} \\ &\lesssim N^{2(1-s)} + N^{-\frac{3}{2}+}\Sigma(T)^{9+} + N^{-2+}\Sigma(T)^{12+}, \end{aligned}$$

where in the third inequality we dismiss the irrelevant constants. Now if we switch from $\Sigma(T)$ to $\Lambda(T)$ we have

$$E(Iu(T)) \lesssim N^{2(1-s)} + N^{-\frac{3}{2}+} N^{9(1-s)+}\Lambda(T)^{9+} + N^{-2+} N^{12(1-s)+}\Lambda(T)^{12+}.$$

We know choose $N = N(T)$ so that

$$N^{2(1-s)} \sim N^{-2+} N^{12(1-s)+}\Lambda(T)^{12+},$$
$$N(T) \sim \Lambda(T)^{\frac{12}{10s-8}+}.$$

This establishes Proposition 3 with

$$p(s) = \frac{2\cdot 12(1-s)}{10s-8} < 2$$

which is true for $s > 10/11$. We emphasize that for $1 > s > 10/11$ the second term in the conservation of the modified energy formula produces a smaller correction. ∎

Acknowledgment. I would like to thank Jim Colliander for introducing me to this problem. I am also grateful to him for the beautiful discussions that we had while I was preparing the manuscript.

FREE BOUNDARY PROBLEMS FOR NONLINEAR WAVE SYSTEMS: MACH STEMS FOR INTERACTING SHOCKS*

SUNČICA ČANIĆ†, BARBARA LEE KEYFITZ‡, AND EUN HEUI KIM§

Abstract. We study a family of two-dimensional Riemann problems for compressible flow modeled by the nonlinear wave system. The initial constant states are separated by two jump discontinuities, $x = \pm\kappa_a y$, which develop into two interacting shock waves. We consider shock angles in a range where regular reflection is not possible. The solution is symmetric about the y-axis and on each side of the y-axis consists of an incident shock, a reflected compression wave, and a Mach stem. This has a clear analogy with the problem of shock reflection by a ramp. It is well known that no triple point structure exists in which incident, reflected, and Mach stem shocks meet at a point. In this paper, we model the reflected wave by a continuous function with a singularity in the derivative. This fails to be a weak solution across the sonic line. We show that a solution to the free boundary problem for the Mach stem exists, and we conjecture that the global solution can be completed by the construction of a reflected shock, by a similar free boundary technique.

The point of our paper is the capability to deal analytically with a Mach stem by solving a free boundary problem. The difficulties associated with the analysis of solutions containing Mach stems include (1) loss of obliqueness in the derivative boundary condition corresponding to the jump conditions across the Mach stem, and (2) loss of ellipticity at the formation point of the Mach stem.

We use barrier functions to show that for sufficiently large values of κ_a the subsonic solution is continuous up to the sonic line at the Mach stem.

Key words. two-dimensional conservation laws, degenerate elliptic equations, free boundary problems, self-similar solutions, Riemann problems

1. Introduction.

This paper marks another step in our program to solve two-dimensional Riemann problems for hyperbolic conservation laws. Our first results involved a method [6] for solving the free boundary problems which arise in the study of small time-independent perturbations of steady transonic shocks in the small disturbance equation. We extended this technique to analyze quasi-steady transonic shocks that are not necessarily small perturbations of known solutions by focusing on weak shock reflection by a wedge, modeled by the unsteady transonic small disturbance (UTSD) equation. We solved this problem in two stages: first, a case corresponding to strong regular reflection in which the free boundary involved a strictly elliptic subsonic state [3] and, second, the case of weak regular reflection, in which proving existence of the free boundary was complicated by the failure of strict ellipticity in the downstream state [4]. The use of a simplified equation was necessary, as

our construction relied in an essential way on reducing the self-similar system to a second-order equation with particular structure which changed type from hyperbolic to elliptic across the sonic line. In [3, 4] we obtained an existence result in only a finite neighborhood of the shock reflection point.

More recently, we have outlined a program for extending our results to a larger class of equations, choosing for a model the nonlinear wave system [5]. This system is a slightly more realistic simplification of the compressible Euler equations of gas dynamics and hence is a better test case for the program. It offers the advantage of being linearly well-posed in space and time (which the UTSD equation is not) and of having a nonlinear acoustic-wave dependence similar to the gas dynamics equations. It also has the convenient feature, just as the UTSD equations have, of reducing to a second-order quasi-linear self-similar equation which, at the sonic line, changes type from hyperbolic to elliptic. It has the additional feature, a more realistic prototype for gas dynamics, of being coupled to a transport equation, so that the change of type takes one from a hyperbolic to a mixed type system. The feature that makes the system more tractable than gas dynamics is that the coupling is very weak: it comes into play only at the point of reconstructing the solution in primitive variables.

As indicated in [5], a number of obstacles must be overcome before a theory for the general Riemann solution, even for this simplified model, can be given. The present result looks at a prototype for a Mach stem. We consider a problem characterized by symmetry and otherwise simplified data. Our eventual goal is to cover all situations which arise with general sectorially constant data. The innovations in this paper are twofold:

1. We are able handle the entire Mach stem without cutoff functions.
2. We overcome the technical difficulty posed by the fact that at the foot of a Mach stem the static boundary condition on the free boundary is no longer a uniformly oblique derivative condition.

We prove existence of a solution in a case where the equation is sonic at the formation point of the Mach stem. However, the correct modeling of the shock interaction is limited to the Mach stem and interaction point itself; we have not attempted to construct the reflected shock. Rather, we have replaced the reflected shock by a weak shock at the sonic boundary, which does not give a weak solution in the neighborhood of the sonic line. Although we have not completely solved the problem, we feel that our result is a significant advance and that this approach will help in solving the full problem. We explain this in section 5.

The analysis applies to the nonlinear wave system (NLWS), a reduction of the inviscid system for compressible isentropic gas dynamics, obtained by neglecting the inertial terms. The system is

$$\begin{aligned} \rho_t + m_x + n_y &= 0, \\ m_t + p(\rho)_x &= 0, \\ n_t + p(\rho)_y &= 0. \end{aligned} \tag{1.1}$$

We consider (1.1) with sectorially constant Riemann data consisting of two states separated by discontinuities at $x = \pm\kappa_a y$ for $y \geq 0$ and with the states chosen so that the one-dimensional Riemann problems at each discontinuity are solved by upward-moving shocks and linear waves only. These determine the solution in the far field. One expects to see a shock interaction consisting either of regular reflection or of Mach reflection, depending on whether the angle between the incident shocks is small or large (see [16]). The scenario we study here for Mach reflection places the formation

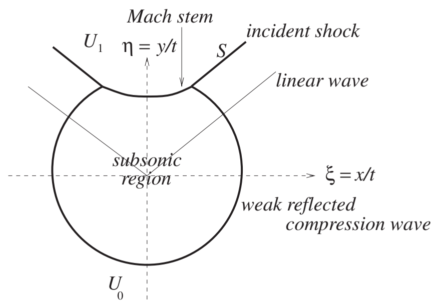

FIG. 1.1. *Sketch of global solution structure.*

point of the Mach stem exactly at the sonic circle, and hence, since this system does not admit triple points, the reflected wave has strength zero at this formation point. This scenario thus requires that the angle between the incident shocks be large enough that the shocks intersect the sonic circle before their extensions intersect each other. Numerical simulations in [17] suggest that such a formation does indeed occur and suggest, further, that the reflected shock is weak.

In this paper, we match a piecewise constant solution outside the sonic circle with a solution of the self-similar equation inside the sonic circle, demanding continuity at the circle. See Figure 1.1 for a sketch of such a solution. Our main result is the existence of a solution to the subsonic problem. The composite function is not a weak solution across the sonic circle. This leaves open the question of what is the actual solution; it differs from the construction here and from the simulations. One possibility is that the reflected wave is a weak, nearly circular shock, which has strength zero at the formation point. Based on the successful construction of the Mach stem in this paper, it may be possible to solve the complete problem by finding this reflected shock as the solution of another free boundary problem. Another possibility is a cascade of supersonic patches, as reported by Tesdall and Hunter for the UTSD equation [25]. We leave this for a future paper.

The techniques we use in this paper to prove global existence of a solution rely on an application of the Schauder fixed point theorem, developed in [6, 3, 4]. A similar approach was used by Chen and Feldman to prove stability of steady transonic shocks for the full potential equation [8, 9]. Chen and Feldman use the potential formulation of the equation to obtain a second-order operator. Both approaches prove existence of a fixed point which solves the underlying free boundary problem. The main difference lies in the compactness arguments used. Owing to the presence of the gradient of the potential in the principal coefficient of the full potential operator, the mapping in [8, 9] is not compact, but it is shown to operate on a compact space. Steady transonic shock perturbation analyses, both in [6] and in [8, 9], examine small perturbations of a uniform solution. A perturbation analysis of steady transonic shocks is also given by Chen, Geng, and Li in [12]. Using partial hodograph transformations which map the free boundary (shock) into a fixed boundary, combined with classical elliptic techniques, [12] obtains stability results for perturbations of conical shocks attached to the tip of a perturbed cone. Chen has used this same partial hodograph technique in a quasisteady problem [11] and has also found an analytical solution for a linearized problem corresponding to quasisteady regular reflection in the gas dynamics equations, [10].

The compressible Euler equations cannot, in general, be written in potential form and self-similar reduction of the compressible Euler equations (see [5, 24, 26]) leads to a system related in structure to the model studied in the present paper. In this connection, we mention also recent work by Zheng on diverging shocks in the pressure gradient system, a type of nonlinear wave system, [27].

In section 2, we derive the second-order operator and derivative boundary condition at the shock for the nonlinear wave system, (1.1); give the technical statement of our result, Theorem 2.3; set up the mapping to find the free boundary; and establish some preliminary estimates. In section 3, using a regularized differential operator, with $\varepsilon\Delta$ added, we prove the existence of a fixed point corresponding to the free boundary for the uniformly elliptic problem. The main point here is to deal with loss of obliqueness in the derivative boundary condition. In section 4, we proceed to the limit $\varepsilon \to 0$. The novelty here is that a uniform upper barrier at the intersection of the Mach stem with the sonic line cannot be found by standard barrier estimates. In section 5, we explain the significance of the result in providing a first step in the construction of Mach stems and other configurations where oblique derivative boundary conditions can become degenerate and where shocks cross the sonic line.

2. Background on the nonlinear wave system. Our point of departure is the compressible Euler system for isentropic flow in two space dimensions,

$$\begin{aligned} \rho_t + (u\rho)_x + (v\rho)_y &= 0, \\ (u\rho)_t + (u^2\rho + p)_x + (uv\rho)_y &= 0, \\ (v\rho)_t + (uv\rho)_x + (v^2\rho + p)_y &= 0, \end{aligned} \tag{2.1}$$

where ρ, u, and v are the density and the components of velocity, respectively, and $p = p(\rho)$ is the pressure. While we have in mind a power-law relation $p(\rho) = A\rho^\gamma$, where $\gamma > 1$ is the ratio of specific heats, all that we require in this paper is $p' > 0$ and $p'' > 0$. We recall that the local speed of sound is c and that $c^2 = dp/d\rho$. The nonlinear wave system is a reduction of (2.1) obtained by neglecting the quadratic terms in u and v. (We do not know if any physical situation is represented by this assumption. However, it underlies the scaling for Stokes flow and was used by Pironneau [23] in a case study of the shallow-water equations, which are modeled by (2.1) with $\gamma = 2$.) In the resulting nonlinear wave system, (1.1), we work with the conserved momentum variables $(m, n) = (\rho u, \rho v)$. The NLWS (1.1) can be written as a second-order nonlinear wave equation for the density and a transport equation for the specific vorticity $\omega = n_x - m_y$:

$$\begin{aligned} \rho_{tt} &= \nabla(c^2(\rho)\nabla\rho), \\ \omega_t &= 0. \end{aligned} \tag{2.2}$$

Since ω is stationary in this simplification of (2.1), then in any regions where the initial data satisfy the irrotationality condition $n_x = m_y$, the solutions, classical or weak, satisfy the same condition.

Introducing self-similar coordinates $\xi = x/t, \eta = y/t$, we can write the system (1.1) as

$$-\xi\rho_\xi - \eta\rho_\eta + m_\xi + n_\eta = 0, \tag{2.3}$$

$$-\xi m_\xi - \eta m_\eta + c^2(\rho)\rho_\xi = 0, \tag{2.4}$$

$$-\xi n_\xi - \eta n_\eta + c^2(\rho)\rho_\eta = 0. \tag{2.5}$$

In self-similar coordinates the nonlinear wave equation in (2.2), with its principal part in divergence form, is

$$Q(\rho) \equiv \big((c^2 - \xi^2)\rho_\xi - \xi\eta\rho_\eta\big)_\xi + \big((c^2 - \eta^2)\rho_\eta - \xi\eta\rho_\xi\big)_\eta + \xi\rho_\xi + \eta\rho_\eta = 0. \tag{2.6}$$

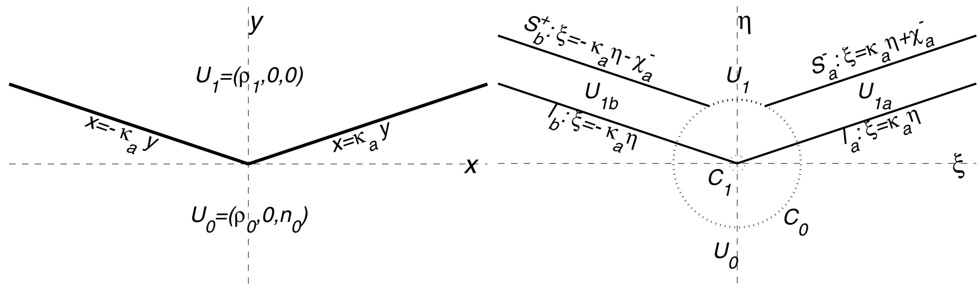

FIG. 2.1. *Riemann data and far-field solution.*

The equation is hyperbolic when $c^2(\rho) < \xi^2 + \eta^2$, elliptic when $c^2(\rho) > \xi^2 + \eta^2$, and degenerate on the sonic circle $c^2(\rho) = \xi^2 + \eta^2$.

It is because we can formulate the problem in terms of ρ that we can apply our fixed point method to this equation.

2.1. Setting up the problem. We consider two-dimensional Riemann data which are constant in sectors. Specifically, in this paper we look at data which correspond to two symmetric converging shocks. This may alternatively be regarded as the reflection of an oblique shock at a vertical wall. The data are constant in two sectors bounded by $\{x = \pm\kappa_a y, y \geq 0\}$ and symmetric with respect to $x = 0$, as shown in Figure 2.1. Let U denote the vector of conserved quantities, $U = (\rho, m, n)$. The Riemann data are

$$U(x, y, 0) = \begin{cases} U_1 \equiv (\rho_1, 0, 0), & -\kappa_a y < x < \kappa_a y, \quad y > 0, \\ U_0 \equiv (\rho_0, 0, n_0) & \text{otherwise.} \end{cases} \tag{2.7}$$

To obtain converging shocks in the far field, we choose $\rho_0 > \rho_1$ and determine n_0, depending on ρ_1, ρ_0, and κ_a, so that the one-dimensional wave between U_0 and U_1 at angle κ_a consists of a backward shock, S_a^-, and a linear wave, l_a, with a state U_{1a} between them:

$$S_a^- : \{\xi = \kappa_a \eta + \chi_a^-\}, \quad l_a : \{\xi = \kappa_a \eta\}, \quad U_{1a} = (\rho_0, m_{1a}, n_{1a}). \tag{2.8}$$

Using the formula (6.1) in [5] these values are

$$\begin{aligned} \chi_a^- &= -\sqrt{1+\kappa_a^2}\sqrt{\frac{p(\rho_0) - p(\rho_1)}{\rho_0 - \rho_1}}; \\ m_{1a} &= -\sqrt{\frac{(p(\rho_0) - p(\rho_1))(\rho_0 - \rho_1)}{1+\kappa_a^2}}; \quad n_{1a} = -\kappa_a m_{1a}; \\ n_0 &= \frac{1}{\kappa_a}\sqrt{(1+\kappa_a^2)(p(\rho_0) - p(\rho_1))(\rho_0 - \rho_1)}. \end{aligned} \tag{2.9}$$

By symmetry, the resolution of the discontinuity at $x = -\kappa_a y$ is

$$S_b^+ : \{\xi = -\kappa_a \eta - \chi_a^-\}, \quad l_b : \{\xi = -\kappa_a \eta\}, \quad U_{1b} = (\rho_0, -m_{1a}, n_{1a}).$$

For the Riemann data (2.7), the sonic circle is important:

$$C_0 \equiv \{(\xi, \eta) : \xi^2 + \eta^2 = c_0^2 \equiv c^2(\rho_0)\}. \tag{2.10}$$

We also define $C_1 \equiv \{(\xi, \eta); \xi^2 + \eta^2 = c_1^2 \equiv c^2(\rho_1)\}$.

Several types of shock interaction seem possible in this model, depending on the relative positions of the incident shock and the sonic circle. They are described in more detail in [17]. For small κ_a, the shocks intersect at a point $\Xi_c \equiv (0, \eta_c) = S_b^+ \cap S_a^- = (0, -\chi_a^-/\kappa_a)$ on the η axis, and two symmetric downward-moving shocks leave Ξ_c. For values of κ_a less than a critical value κ_R which depends on ρ_0 and ρ_1 one expects two solutions of this form, corresponding to "weak" and "strong" regular reflection. For $\kappa_a > \kappa_R$, no solutions of this form exist. On the other hand, for κ_a greater than a value κ_A (with $\kappa_A > \kappa_R$), one finds that $\eta_c < c_0$, so Ξ_c is inside the sonic circle C_0, and the farfield shocks intersect C_0 before reaching the symmetry axis. In this case, it is appealing to believe that a solution like that shown in Figure 1.1 is possible: the subsonic flow interacts with the shocks, which bend to form a single discontinuity; and the flow is continuous at C_0 below the shock. This phenomenon can be thought of as a perturbation of the uniform case $\kappa_a = \infty$.

In this paper, we prove the existence of a solution to the subsonic problem which contains a Mach stem and is continuous up to the sonic line, for sufficiently large values of κ_a; that is, $\kappa_a > \kappa_* > \kappa_A$. In the remainder of the paper, we assume $\kappa_a > \kappa_A$. The paper [17] gives a more detailed discussion of the regions. There, we also give scenarios (without proof) for solutions in the intermediate range of κ where neither regular reflection nor a solution with a weak reflected wave exists.

2.2. The shock evolution equation. At a shock, the Rankine–Hugoniot jump conditions are satisfied across the line of discontinuity. A key element of our solution method has been to rewrite the equations as a problem for a single variable—in this case, ρ. With this goal, we reformulate the Rankine–Hugoniot conditions to obtain two equations: an evolution equation for the shock curve—that is, a relation between the slope of the curve, $\eta' = d\eta/d\xi$, and the variable ρ which appears in (2.6)—and an oblique derivative boundary condition for ρ—that is, an equation linear in the gradient of ρ with coefficients depending on (ξ, η), ρ, and η'. The second equation then becomes a boundary condition for the differential equation (2.6), and we play these two conditions against each other to obtain a mapping on approximate shock positions.

We proceed to derive the jump conditions and formulate the shock evolution equation using the Rankine–Hugoniot conditions.

Writing $U \equiv (\rho, m, n)$ and $\Xi = (\xi, \eta)$, system (2.3)–(2.5) can be put in conservation form:

$$\partial_\xi F(U, \Xi) + \partial_\eta G(U, \xi) = -2U \tag{2.11}$$

with

$$F \equiv \begin{pmatrix} m - \xi\rho \\ p(\rho) - \xi m \\ -\xi n \end{pmatrix} \quad \text{and} \quad G \equiv \begin{pmatrix} n - \eta\rho \\ -\eta m \\ p(\rho) - \eta n \end{pmatrix}.$$

Inside the sonic circle $C_0 = \{\xi^2 + \eta^2 = c^2(\rho_0)\}$, the incident shock need no longer be rectilinear. The state ahead of the shock, U_1, is constant, but the state on the other side, U, is subsonic and is not uniform. The Rankine–Hugoniot conditions along the line of discontinuity $\eta = \eta(\xi)$ are, from (2.11),

$$\frac{d\eta}{d\xi} = \frac{-\eta[\rho] + [n]}{-\xi[\rho] + [m]}, \tag{2.12}$$

$$\frac{d\eta}{d\xi} = \frac{-\eta[m]}{[p] - \xi[m]}, \tag{2.13}$$

$$\frac{d\eta}{d\xi} = \frac{[p] - \eta[n]}{-\xi[n]}, \tag{2.14}$$

where $[f] = f - f_1$ denotes a jump in the state f across the shock $\eta(\xi)$. There are three families of discontinuities; two are genuinely nonlinear, and one is linear (see [5]). For nonlinear waves, $[\rho] \neq 0$. Solving for $[m]$ in (2.13) and for $[n]$ in (2.14) yields

$$[m] = \frac{-[p]\eta'}{-\eta'\xi + \eta}, \quad [n] = \frac{[p]}{-\eta'\xi + \eta}. \tag{2.15}$$

A simple consequence of (2.15) is

$$[m] = -\eta'[n]. \tag{2.16}$$

Using (2.16) in (2.13) we obtain

$$\eta = \frac{[p] - \xi[m]}{[n]}, \tag{2.17}$$

while equating the right sides of (2.12) and (2.13) and using (2.17) gives a relation

$$[p][\rho] = [m]^2 + [n]^2 \tag{2.18}$$

valid for states across a shock.

Using equations (2.15) in (2.12) we get an equation for η' involving only the state variable ρ:

$$([p] - \xi^2[\rho])(\eta')^2 + 2\xi\eta[\rho]\eta' + [p] - \eta^2[\rho] = 0. \tag{2.19}$$

To streamline the discussion, we define a function

$$s(a, b) \equiv \sqrt{\frac{(p(a) - p(b))}{(a - b)}}; \tag{2.20}$$

s is the speed of a one-dimensional shock between states with densities a and b.

PROPOSITION 2.1. *If p is a convex function of ρ, then s^2 is an increasing function of a for fixed b; $s(b, b) \equiv \lim_{a\to b} s(a, b) = c(b)$; and $s(a, b) < c(a)$ for $a > b$.*

Proof. We have

$$\frac{d}{da}s^2 = \frac{p'(a)}{a - b} - \frac{p(a) - p(b)}{(a - b)^2} = \frac{p'(a)(a - b) - (p(a) - p(b))}{(a - b)^2}.$$

Expanding $p(b) = p(a) + p'(a)(b - a) + p''(\beta)(b - a)^2/2$ for some $\beta \in (a, b)$, we obtain $ds^2/da = p''(\beta)/2 > 0$ if p is convex. As $a \to b$, $s^2 \to p'(b) = c^2(b)$ and if $a > b$,

$$c^2(a) - s^2(a, b) = \frac{p'(a)(a - b) - (p(a) - p(b))}{a - b} > 0. \qquad \square$$

For fixed b, we can write

$$a = s_b^{-1}(\eta) \quad \text{when} \quad s(a,b) = \eta. \tag{2.21}$$

Now, solving (2.19) for η' in terms of ρ and writing s^2 for $[p]/[\rho]$ yields

$$\frac{d\eta}{d\xi} = \frac{-\xi\eta \pm \sqrt{s^2(\xi^2+\eta^2-s^2)}}{s^2-\xi^2}. \tag{2.22}$$

Since the subsonic region is symmetric with respect to $\xi = 0$, we solve the problem in the half of the domain in the right half-plane, $\xi \geq 0$, and impose a zero Neumann boundary condition on $\xi = 0$. We may now specify the plus sign in (2.22) for the shock curve Σ in the first quadrant, as we anticipate (and will prove) that the shock slope is nonnegative. This gives the shock evolution equation

$$\frac{d\eta}{d\xi} = \frac{-\xi\eta + \sqrt{s^2(\xi^2+\eta^2-s^2)}}{s^2-\xi^2} = \frac{\eta^2-s^2}{\xi\eta + \sqrt{s^2(\xi^2+\eta^2-s^2)}}. \tag{2.23}$$

The second expression is equivalent to the first, and so both are well defined provided

$$s^2 \leq \xi^2 + \eta^2. \tag{2.24}$$

We will establish this condition in Proposition 2.5. We define $\Xi_s \equiv (0, \eta_s) \equiv (0, \eta(0))$, the point at the foot of the shock, and observe that we want $\eta'(0) = \sqrt{\eta^2 - s^2}/s$ to equal zero, by symmetry, and so $\eta^2 = s^2$ at Ξ_s. Thus we require

$$\eta_s = \eta(0) = s(\rho, \rho_1) = \sqrt{\frac{p(\rho) - p(\rho_1)}{\rho - \rho_1}}. \tag{2.25}$$

This can be interpreted as a condition which determines $\rho(\Xi_s)$ in the subsonic region at the base of the shock (the symmetry boundary).

We also define $\Xi_0 \equiv (\xi_0, \eta_0) = S_a^- \cap C_0$, the point where the incident shock S_a^- and the sonic circle C_0 meet. Using (2.8) for S_a^- and (2.10) for C_0 we determine Ξ_0:

$$\xi_0 = \frac{\kappa_a\sqrt{c_0^2 - s_0^2} - s_0}{\sqrt{1+\kappa_a^2}}, \quad \eta_0 = \frac{\kappa_a s_0 + \sqrt{c_0^2 - s_0^2}}{\sqrt{1+\kappa_a^2}}, \tag{2.26}$$

where $s_0^2 = (p(\rho_0) - p(\rho_1))/(\rho_0 - \rho_1)$. The initial condition for the shock position is $\eta(\xi_0) = \eta_0$.

2.3. The oblique derivative boundary condition. We next use the Rankine–Hugoniot conditions to formulate a boundary condition along the shock $\Sigma = \{(\xi, \eta(\xi))\}$.

Since vorticity is confined to the lines of discontinuity of the Riemann data (see (2.2) and [5]), and these lie below the shock (see Figure 2.1), the vorticity is zero along the shock:

$$m_\eta - n_\xi = 0. \tag{2.27}$$

Using this equation and (2.3)–(2.5), we express all the partial derivatives of m and n in terms of the derivatives of ρ:

$$n_\xi = m_\eta = \frac{1}{\xi^2+\eta^2}\Big(\eta(c^2-\xi^2)\rho_\xi + \xi(c^2-\eta^2)\rho_\eta\Big), \tag{2.28}$$

$$m_\xi = \frac{1}{\xi^2+\eta^2}\Big(\xi(c^2+\eta^2)\rho_\xi - \eta(c^2-\eta^2)\rho_\eta\Big), \tag{2.29}$$

$$n_\eta = \frac{1}{\xi^2+\eta^2}\Big(\xi(-c^2+\xi^2)\rho_\xi + \eta(c^2+\xi^2)\rho_\eta\Big). \tag{2.30}$$

Differentiating (2.18) along Σ ($' = d/d\xi = \partial_\xi + \eta'\partial_\eta$) we get

$$\begin{aligned}(c^2(\rho)[\rho] + [p])(\rho_\xi + \eta'\rho_\eta) &= 2[m]m' + 2[n]n' \\ &= 2[n](-\eta' m' + n') = 2[n](-\eta' m_\xi + (1-(\eta')^2)m_\eta + \eta' n_\eta),\end{aligned}$$

where $[m] = -\eta'[n]$ (equation (2.16)) is used in the second equality and $m_\eta = n_\xi$ (equation (2.27)) in the last equality. We simplify the last expression, replacing derivatives Dm and Dn by $D\rho$ using (2.28), (2.29), (2.30), and

$$[n] = \frac{[p]}{-\eta'\xi + \eta} \tag{2.31}$$

from (2.15), and finally we get

$$\beta \cdot \nabla\rho \equiv \beta_1\rho_\xi + \beta_2\rho_\eta = 0, \tag{2.32}$$

where β is a function of Ξ, ρ, and η' with components

$$\begin{aligned}\beta_1 = {} & (\xi^2+\eta^2)(-\eta'\xi+\eta)(c^2(\rho)+s^2(\rho,\rho_1)) \\ & - 2s^2\left\{-\eta'\xi(c^2+\eta^2) + (1-(\eta')^2)\eta(c^2-\xi^2) + \eta'\xi(-c^2+\xi^2)\right\}\end{aligned} \tag{2.33}$$

and

$$\begin{aligned}\beta_2 = {} & \eta'(\xi^2+\eta^2)(-\eta'\xi+\eta)(c^2(\rho)+s^2(\rho,\rho_1)) \\ & - 2s^2\left\{\eta'\eta(c^2-\eta^2) + (1-(\eta')^2)\xi(c^2-\eta^2) + \eta'\eta(c^2+\xi^2)\right\}.\end{aligned} \tag{2.34}$$

We now examine the obliqueness condition by comparing β with the inward normal to Ω at Σ, $\nu = (\eta', -1)$. It turns out that the operator $\beta\cdot\nabla$ in (2.32) is oblique at all points on the shock except the symmetry point. In fact, obliqueness holds along any monotonic curve which satisfies the shock equation (2.23) at (ξ_0, η_0), that is, $\eta(\xi_0) = \eta_0$ and $\eta'(\xi_0) = 1/\kappa_a$, and for any subsonic function ρ. We prove the following result.

PROPOSITION 2.2. *Let $\Sigma = \{(\xi, \eta(\xi))\}$ be any curve which has positive slope on $(0, \xi_0]$, lies inside the sonic circle C_0, and at $\xi = \xi_0$ satisfies (2.23) and $\eta = \eta_0$; let ν be its inward normal. Then for any function $\rho(\xi,\eta)$ with $c^2(\rho) > \xi^2 + \eta^2$, we have $\beta\cdot\nu > 0$ on Σ for $\xi \in (0, \xi_0]$.*

Proof. We calculate

$$\begin{aligned}\beta\cdot\nu &= \beta_1\eta' - \beta_2 \\ &= -2s^2\left\{-(\eta')^2\xi(c^2+\eta^2) + \eta'(1-(\eta')^2)\eta(c^2-\xi^2) + (\eta')^2\xi(-c^2+\xi^2)\right. \\ &\qquad \left. -\eta'\eta(c^2-\eta^2) - (1-(\eta')^2)\xi(c^2-\eta^2) - \eta'\eta(c^2+\xi^2)\right\} \\ &= 2s^2(\eta'\eta+\xi)\left\{(c^2-\xi^2)(\eta')^2 + 2\xi\eta\eta' + c^2 - \eta^2\right\}.\end{aligned}$$

Now $s^2 = [p]/[\rho] \neq 0$, since $c^2(\rho) > \xi^2+\eta^2 > c^2(\rho_1)$. Also, if $\eta' > 0$ and $\xi > 0$ we have $\eta'\eta + \xi > 0$; so to get obliqueness we need only verify that

$$(c^2-\xi^2)(\eta')^2 + 2\xi\eta\eta' + c^2 - \eta^2 > 0. \tag{2.35}$$

We first note that (2.35) holds at $\xi = \xi_0$, since $c^2(\rho_0) > s^2(\rho_0,\rho_1)$ and $(s^2-\xi^2)(\eta')^2 + 2\xi\eta\eta' + s^2 - \eta^2 = 0$ (equation (2.19)) holds at (ξ_0, η_0).

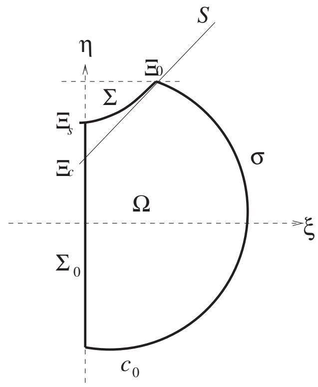

Fig. 2.2. *Sketch of the domain.*

Now, the left-hand side of (2.35) is a quadratic polynomial, $P(\eta')$, where $P(Y) = (c^2-\xi^2)Y^2 + 2\eta\xi Y + (c^2-\eta^2)$, with coefficients depending smoothly on ξ, η, and ρ. For any (ξ,η,ρ) with $\xi^2+\eta^2 < c^2(\rho)$, $P(Y)$ has a fixed sign for all Y since $\mathrm{disc}(P) = c^2\big(\xi^2+\eta^2-c^2(\rho)\big) < 0$. Thus, P has a fixed sign inside C_0. Since $P(\eta') > 0$ at (ξ_0,η_0), then $P > 0$ on $\{(\xi,\eta(\xi)) \mid \xi \in [0,\xi_0]\}$.

Thus obliqueness holds for $\xi > 0$. However, obliqueness fails at $\xi = 0$, where the factor $\eta'\eta + \xi$ vanishes because we impose the condition $\eta' = 0$. ∎

2.4. The free boundary problem. We can now give a technical statement of the main result in this paper. The subsonic domain is bounded by the part of the circle $\xi^2+\eta^2 = c^2(\rho_0)$ which lies below the shock and by the a priori unknown curved transonic shock itself. Taking advantage of the symmetry, we solve the problem in the right half of this domain, which we will call Ω in the remainder of the paper. We define σ to be the closed segment of C_0 bounding Ω and Σ_0 to be the relatively open segment of the η axis which forms the symmetry boundary. See Figure 2.2. The use of a half-domain results in a technical issue at the bottom corner, where Σ_0 meets σ, which is easily dealt with by standard continuity arguments. In addition, the fact that the upper boundary Σ is free means that Σ_0 is also not defined a priori. This matter of nomenclature we shall also ignore in the interest of simplicity.

We define Q to be the governing second-order quasi-linear operator in the domain Ω, given in (2.6) (repeated indices are summed):

$$\begin{aligned} Q\rho &= \big((c^2(\rho)-\xi^2)\rho_\xi - \xi\eta\rho_\eta\big)_\xi + \big((c^2(\rho)-\eta^2)\rho_\eta - \xi\eta\rho_\xi\big)_\eta + \xi\rho_\xi + \eta\rho_\eta \\ &\equiv D_i(a_{ij}(\Xi,\rho)D_j\rho) + b_i(\Xi)D_i\rho = 0. \end{aligned} \tag{2.36}$$

In principle, we should modify Q so that it is elliptic in Ω for any value of ρ. However, in Proposition 2.4, we immediately obtain a priori bounds which enable us to use the original operator. We denote by M the quasi-linear oblique derivative boundary operator on $\Sigma = \{(\xi,\eta(\xi)) \mid \xi \in (0,\xi_0)\}$:

$$M\rho \equiv \beta(\Xi,\rho,\eta')\cdot\nabla\rho = 0. \tag{2.37}$$

Here β is the vectorfield defined by (2.33) and (2.34). The second condition on the free boundary is the shock evolution equation (2.23) for Σ:

$$\frac{d\eta}{d\xi} = f(\Xi,\rho) \equiv \frac{-\xi\eta + \sqrt{s^2(\xi^2+\eta^2-s^2)}}{s^2-\xi^2} \quad \text{with} \quad \eta(\xi_0) = \eta_0. \tag{2.38}$$

Here $s = s(\rho(\xi, \eta(\xi)), \rho_1)$ is the function given by (2.20). On the fixed segments of the boundary, Σ_0 and σ, we impose Neumann and Dirichlet conditions, respectively:

$$\rho_\xi = 0 \quad \text{on} \quad \Sigma_0 \subset \{\xi = 0\}; \quad \rho = \rho_0 \quad \text{on} \quad \sigma \subset \{\xi^2 + \eta^2 = c^2(\rho_0)\}. \tag{2.39}$$

At the Dirichlet boundary, the equation is degenerate elliptic, in a manner described in our previous work, [1, 2, 7]. In particular, we expect that the solution will have an algebraic singularity along this boundary segment.

Now, it is easy to see that the trivial solution $\rho(\xi, \eta) \equiv \rho_0$ solves this problem, with Σ simply the straight-line extension of the incoming shock S_a^-, except at the point where the shock meets the symmetry boundary. Thus, we must in addition impose a one-point condition at this a priori unknown point, which we label Ξ_s. We impose the condition that the curved shock is smooth for the full domain problem, and hence that $\eta'(0) = 0$. As shown in section 2.2, this is equivalent to (2.25). We may alternatively express this as a one-point Dirichlet condition at the corner Ξ_s by solving $\eta_s = s(\rho(0, \eta_s), \rho_1)$, for $\rho(\Xi_s)$, or, using the notation of equation (2.21),

$$\rho(\Xi_s) = s_{\rho_1}^{-1}(\eta_s). \tag{2.40}$$

We establish the following existence theorem.

THEOREM 2.3. *There is a value κ_* such that for any Riemann data* (2.7) *with $\kappa_a > \kappa_*$, the free boundary problem consisting of* (2.36)*,* (2.37)*,* (2.38)*,* (2.39)*, and* (2.40) *has a classical solution $\rho \in C^{2+\alpha}(\Omega) \cap C(\overline{\Omega})$ which is twice continuously differentiable up to Σ and Σ_0 except at Ξ_s and Ξ_0. The free boundary is of Hölder class $H_{2+\alpha}$ for some α which is determined by the Riemann data of the problem.*

We prove this theorem using the fixed point argument we developed in our earlier papers and in work with Lieberman [3, 4, 6] for the slightly simpler small disturbance equations. The main technical difficulty which is new in this case is that the boundary condition on the free boundary is no longer uniformly oblique. To be precise, obliqueness fails at the point Ξ_s. On the other hand, because it is the nature of the Mach stem to strengthen as it approaches the wall, we find that we can control the quantity under the square root sign in (2.38). Thus our result is not restricted to being local, as in [3] and [4], or perturbative, as in [6].

We formulate the fixed point argument in terms of the position of the free boundary. We work with a regularized, uniformly elliptic, operator $Q^\varepsilon = Q + \varepsilon\Delta$ and then, as in [4], send the regularizing parameter, ε, to zero. The mapping on the free boundary is obtained by solving a fixed boundary problem using the oblique derivative condition on the shock boundary and then integrating the shock evolution equation to update the position of the shock. However, unlike our problem in [4], obliqueness fails at the corner Ξ_s representing the foot of the Mach stem. Following ideas outlined by Lieberman [20, 21], we establish local Schauder estimates at Ξ_s which are independent of the obliqueness ratio (Theorem 3.5). In section 3.2 we apply these results to the nonlinear regularized fixed boundary problem. The regularized free boundary problem is solved in section 3.3, and results for the limit $\varepsilon \to 0$ are obtained in section 4.

Before beginning the analysis, we establish that the equations above are well-defined for the approximations we use. The following monotonicity result is used throughout.

PROPOSITION 2.4. *For a given monotonic function $\eta(\xi)$ forming the boundary Σ, suppose that $\rho \in C^1(\Omega \cup \Sigma \cup \Sigma_0) \cap C(\overline{\Omega})$ is a solution of the boundary value problem* (2.36)*,* (2.37)*,* (2.39)*, and* (2.40) *with $\rho \geq \rho_0$. Then $\rho(0, \eta_s) = \rho_{\max}$ is the maximum value of ρ in $\overline{\Omega}$ and ρ is monotonic on Σ.*

Proof. Since the operator Q in (2.36) has no undifferentiated terms, the classical and Hopf maximum principles apply. That is, the local and absolute extrema of ρ occur on the boundary $\partial\Omega$ (classical); and at any point on $\partial\Omega$ where ρ has a local extremum, the normal derivative is nonzero (Hopf [15, p. 34]). On the Neumann and oblique derivative boundaries, Σ_0 and Σ, if ρ has an extremum along the boundary then two linearly independent directional derivatives of ρ are zero, and so $\nabla\rho$ is zero there, which is impossible, by the Hopf maximum principle. Thus there are no local extrema in the interior of Σ_0 or of Σ. There cannot be absolute extrema, either, and hence $\rho_{\max} = \rho(0, \eta_s)$ is the absolute maximum of ρ in Ω, and we obtain the bounds $\rho_0 < \rho < \rho_{\max}$ in Ω from the classical maximum principle. And since in Ω we have $\xi^2 + \eta^2 < c^2(\rho_0) < c^2(\rho)$, it follows that the solution is strictly subsonic in Ω.

To prove monotonicity, we argue by contradiction. Let us first examine the C^1 function ρ restricted to Σ. This is now a function of a single variable, say, the first component of a point $\Xi = (\xi, \eta)$ on Σ. Without confusion, we can label this component by the name of the point, we can order the points along Σ by this component, and we can refer to intervals along Σ by the labels. Then lack of monotonicity means there exist points Z_1 and Z_2 on Σ with $\Xi_s < Z_1 < Z_2 < \Xi_0$ at which $\rho(Z_1) < \rho(Z_2)$. We immediately deduce that

1.
2.
$$\text{in} \quad (\Xi_s, Z_2) \quad \exists \quad \widetilde{C} \quad \text{with} \quad \rho(\widetilde{C}) = \min_{[\Xi_s, Z_2]} \rho;$$
$$\text{in} \quad (\widetilde{C}, \Xi_0) \quad \exists \quad D \quad \text{with} \quad \rho(D) = \max_{[\widetilde{C}, \Xi_0]} \rho.$$

We want to identify points C and D, $C < D$, on Σ such that the following three properties hold:

(i) $\rho(\Xi_s) \geq \rho \geq \rho(C)$ on $[\Xi_s, C]$;
(ii) $\rho(C) \leq \rho \leq \rho(D)$ on $[C, D]$;
(iii) $\rho(D) \geq \rho \geq \rho(\Xi_0)$ on $[D, \Xi_0]$.

Now, property (ii) may not hold with $C = \widetilde{C}$ because $\rho(\widetilde{C})$ is the minimum value of ρ only on the interval $[\Xi_s, Z_2]$, and we may have $D > Z_2$. So, if there is a point in (Z_2, D) at which $\rho < \rho(\widetilde{C})$, then we let C be a point at which ρ has its minimum value in this interval; if there is no such point, then let $C = \widetilde{C}$. Then all three properties hold.

Now we look at the function ρ in the domain Ω. The idea is to partition Ω into subdomains by two curves Γ_C and Γ_D from C and D, respectively, to points A and B, respectively, on Σ_0, in such a way that $\rho(A) < \rho(B)$ and so that we can deduce that there is a point m on Σ_0 at which ρ reaches a minimum on either the domain Ω_A or the domain Ω_B, thus violating the Hopf maximum principle, as stated in the first paragraph of this proof. See Figure 2.3. It is of course sufficient to show that $\rho(m)$ is the minimum value of ρ on the boundary of Ω_A or Ω_B.

It would be simplest to find curves on which ρ is monotonic, but it is not clear that such curves exist, or what properties they would have. Instead, we construct Lipschitz curves on which ρ is monotonic on average. To be precise, we construct curves on which, for a certain number μ,

$$\rho(A) \leq \rho \leq \rho(C) + \mu \quad \text{on } \Gamma_C \quad \text{and } \rho(A) < \rho(C); \tag{2.41}$$
$$\rho(B) \geq \rho \geq \rho(D) - \mu \quad \text{on } \Gamma_D \quad \text{and } \rho(B) > \rho(D). \tag{2.42}$$

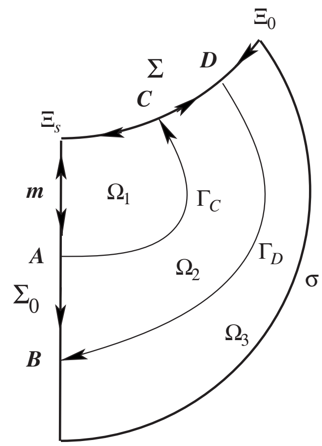

FIG. 2.3. *Illustration of the proof of Proposition* 2.4.

We begin by identifying some useful constants. Let

$$\mu = \frac{1}{4}\min\{\rho(D) - \rho(C), \rho(\Xi_s) - \rho(D), \rho(C) - \rho(\Xi_0)\}.$$

Since $\rho \in C(\overline{\Omega})$, then ρ is uniformly continuous, and there is an $\epsilon > 0$ such that $\rho(\Xi) \leq \rho_0 + \mu$ if $\operatorname{dist}(\Xi, \sigma) < \epsilon$. Let $\Omega_\epsilon = \{\Xi \in \Omega \mid \operatorname{dist}(\Xi, \sigma) > \epsilon\}$, and let $\sigma_\epsilon = \{\Xi \in \Omega \mid \operatorname{dist}(\Xi, \sigma) = \epsilon\}$. As we shall see, we can restrict our attention to $\overline{\Omega_\epsilon}$. The purpose of constructing this domain is to be able to bound $|\nabla\rho|$. Since $\rho \in C^1(\overline{\Omega_\epsilon})$, we have $|\nabla\rho| \leq M$ there, say. (We could estimate M from Schauder theory, but this is not important here.)

Now, on any ball of radius r, the oscillation of ρ is bounded by $2Mr$, and we now choose a radius, $R = \mu/(2M)$, so that

$$\operatorname*{osc}_{B_R \cap \Omega_\epsilon} \rho \leq \mu.$$

Now we construct Γ_D as follows. Consider a ball $B_R(D)$ centered at D. In $B_R(D) \cap \Omega_\epsilon$, $\rho(D)$ cannot be the maximum value of ρ (because D is not a point of local maximum in Ω); hence there are points of $\partial B_R(D) \cap \Omega_\epsilon$ where $\rho > \rho(D)$. Let X_1 be a point at which ρ attains its maximum value in $\overline{B_R(D)}$. The first segment of Γ_D is a straight line from D to X_1. We have $\rho(X_1) > \rho(D)$, and on the segment, $\rho(X) \geq \rho(D) - \mu$ and $\rho(X) < \rho(X_1)$.

Now we continue inductively, forming a sequence of line segments with corners at $\{X_i\}$ (take $D = X_0$), along which $\rho \geq \rho(D) - \mu$ and such that $\rho(X_1) < \rho(X_2) < \cdots$. To show that we can do this, let

$$\Omega_j = \Omega_\epsilon \backslash \overline{\{\cup_0^{j-1} B_R(X_i)\}};$$

we have $X_j \in \partial\Omega_j$, and we consider $B_R(X_j)$. We note that $\rho(X_j)$ is the largest value of ρ on the part of $B_R(X_j)$ inside the complement of Ω_j. However, $\rho(X_j)$ is less than the maximum value of ρ on $B_R(X_j)$, by the mean value property. Hence there is a point $X_{j+1} \in \partial B_R(X_j) \cap \Omega_j$ at which ρ attains its maximum value in $\overline{B_R(X_j)}$. Again, along the straight line from X_j to X_{j+1} we have $\rho \geq \rho(X_j) - \mu > \rho(D) - \mu$.

Now,

$$\operatorname{dist}(X_{i-1}, \Omega_i) = R$$

and

$$\Omega_j \subset \Omega_{j-1} \subset \cdots \subset \Omega_1,$$

so

$$\operatorname{dist}(X_i, \Omega_k) \geq R$$

for $k \geq i + 1$; and since $X_k \in \partial\Omega_k$, the estimate

$$\operatorname{dist}(X_{j+1}, X_i) \geq R \quad \forall \quad i \leq j$$

follows.

Hence $\operatorname{dist}(X_i, X_j) \geq R$ for $i \neq j$ for all points in the sequence. But only a finite number of balls with radius R and separated centers will fit in Ω_ϵ, so this process must terminate after a finite number of steps when we reach a point $X_L = B \in \partial\Omega_\epsilon$. By construction, Γ_D has the properties indicated in (2.42).

Similarly, we construct Γ_C, with termination point $A \in \partial\Omega_\epsilon$.

Next we show that the points A and B lie on Σ_0. First, the curves cannot cross each other, because at every point on Γ_D, $\rho \geq \rho(D) - \mu > \rho(C) + \mu$, while at every point on Γ_C we have $\rho < \rho(C) + \mu$. Also, Γ_D cannot terminate at σ_ϵ where $\rho \leq \rho_0 + \mu < \rho(D)$. For the same reason, B cannot lie on Σ in the segments $[D, \Xi_0]$ or $[C, D]$ where $\rho \leq \rho(D)$. Finally, B cannot lie in the segment $[\Xi_s, C]$ of Σ because this would trap Γ_C in a region where $\rho \geq \rho(C)$ (or, more simply, this would contradict the fact that C is not a local minimum in Ω). Hence $B \in \Sigma_0$.

Similarly, A cannot lie on Σ, where $\rho \geq \rho(C)$ in the interval $[\Xi_s, D]$, and must lie on Σ_0, between B and Ξ_s.

Now we find our final contradiction. Since there is a point, A, in the interval $[\Xi_s, B]$ of Σ_0 where ρ is smaller than its value at either endpoint, then there must be a point m where ρ, restricted to the interval $[\Xi_s, B]$ of Σ_0 attains its minimum. We recall that m cannot be a local minimum in Ω, and so it cannot be a minimum in Ω_1 or in Ω_2. The relevant domain is Ω_1 if $m \in [\Xi_s, A]$; otherwise it is Ω_2. In particular, there would have to be points on the boundary of the relevant domain at which $\rho < \rho(m)$. But the construction we have performed prevents this. To verify this, suppose first that $m \in [\Xi_s, A]$. Then $\rho \geq \rho(m)$ on $[\Xi_s, A]$. In particular, $\rho(m) \leq \rho(A) \leq \rho(X)$ for $X \in \Gamma_C$, and $\rho(m) \leq \rho(A) < \rho(C)$, by (2.41). In addition, $\rho \geq \rho(C)$ on the top boundary, $[\Xi_s, C]$ in Σ, of Ω_1. Thus, we have a contradiction to the maximum principle if $m \in [\Xi_s, A]$.

But if $m \in [A, B]$, then again there are no points on the interval $[A, B]$ of Σ_0 at which $\rho < \rho(m)$, and again $\rho \geq \rho(A) \geq \rho(m)$ along Γ_C. As before, $\rho(C) > \rho(A) \geq \rho(m)$. Now, $\rho \geq \rho(C)$ on the interval $[C, D]$ of the top boundary, Σ, of Ω_2, and by (2.42) we have $\rho \geq \rho(D) - \mu > \rho(C)$ along Γ_D. Thus in this case also, $\rho(m)$ is the smallest value of ρ along the entire boundary of Ω_2. This again contradicts the maximum principle, as stated in the first paragraph of the proof.

We conclude that C and D do not exist, and hence that Z_1 and Z_2 do not exist, and ρ is monotonic on Σ. $\square$

As a second basic result, we prove that the shock evolution equation can always be integrated, defining the mapping whose fixed point is the free boundary. Beginning with a given curve $\eta(\xi)$, assume we have solved the fixed boundary value problem (2.36), (2.37), (2.39), and (2.40). We then produce a new approximate shock position $\tilde{\eta}(\xi)$ by integrating (2.38):

$$\tilde{\eta}(\xi) = \eta_0 + \int_{\xi_0}^{\xi} f(x, \eta(x), \rho(x, \eta(x)))\, dx, \tag{2.43}$$

where f is defined in (2.38). Note that on the right side of (2.43) we evaluate all quantities along the old shock position, $\eta(\xi)$. We have the following proposition.

PROPOSITION 2.5. *Suppose that η is a monotone function and that ρ satisfies the boundary value problem* (2.36), (2.37), (2.39), *and* (2.40). *Then $\eta^2 > s^2$ and $\eta^2 + \xi^2 > s^2$ for all $\xi \in (0, \xi_0)$ so the new curve $\tilde{\eta}$ is defined for all $\xi \in [0, \xi_0]$ and is monotonic. Furthermore, $\tilde{\eta}'(0) = 0$.*

Proof. Because ρ satisfies (2.40), we see that at $\xi = 0$ the quantity under the square root sign in (2.38) is zero. Since η is monotonic, the quantity $\eta^2(\xi)$ is an increasing function of ξ. We use Proposition 2.4 to conclude that s^2 along Σ is a decreasing function of ξ (since ρ decreases and s is a monotonic function of ρ). Hence $\eta^2 - s^2$ is strictly positive when $\xi > 0$. In addition, this implies that $\xi^2 + \eta^2 - s^2$ is positive, and so the right-hand side of (2.43) is well defined (see the equivalent form in (2.23)). In addition, (2.23) also shows that $d\tilde{\eta}/d\xi$ is positive as long as $\eta^2 - s^2 > 0$. Finally, this derivative is zero at $\xi = 0$, where the right side of (2.38) vanishes. ∎

We now define $\mathcal{K} = \mathcal{K}^{\varepsilon}$, a closed, convex subset of a Hölder space $H_{1+\alpha_1}([0, \xi_0])$; the value of $\alpha_1 \in (0, 1)$ depends on the regularizing parameter ε and will be specified later. The functions in $\mathcal{K}$ satisfy

(K1) $\eta(\xi_0) = \eta_0$, and $\eta'(\xi_0) = 1/\kappa_a$, where ξ_0 and η_0 are defined in (2.26);
(K2) $\eta'(0) = 0$;
(K3) $\eta_c \le \eta(\xi) \le \eta_0$; recall that $\eta_c = \sqrt{1 + \kappa_a^2}\, s_0/\kappa_a < \eta_0 < c_0$ if $\kappa_a > \kappa_A$;
(K4) $0 \le \eta' \le \sqrt{c_0^2/s_0^2 - 1}$.

Then (2.43) defines a mapping on $\mathcal{K}$:

$$J : \eta \mapsto \tilde{\eta}. \tag{2.44}$$

The upper bound in **(K4)** is justified by the following proposition.

PROPOSITION 2.6. *If $\eta(\xi)$ is a monotonic function with $\eta(\xi_0) = \eta_0$ and ρ a solution to* (2.36), (2.37), (2.39), *and* (2.40), *then the function f given by* (2.38) *is bounded above by $\sqrt{c_0^2 - s_0^2}/s_0 \equiv 1/\kappa_A$.*

Proof. By Proposition 2.4, $s(\xi, \eta)$ is a decreasing function on $\eta(\xi)$ with $s^2(0, \eta(0)) = \eta^2(0)$, and by Proposition 2.5, $\eta \ge s$ on $\eta(\xi)$. For the function f defined by (2.38), a calculation shows

$$\frac{\partial f}{\partial \xi} = -\frac{(\eta^2 - s^2)\big(s\xi + \eta\sqrt{\xi^2 + \eta^2 - s^2}\big)}{\sqrt{\xi^2 + \eta^2 - s^2}\big(\xi\eta + \sqrt{s^2(\xi^2 + \eta^2 - s^2)}\big)^2} < 0,$$

$$\frac{\partial f}{\partial \eta} = \frac{\xi^2 + \eta^2}{\sqrt{\xi^2 + \eta^2 - s^2}\big(s\eta + \xi\sqrt{\xi^2 + \eta^2 - s^2}\big)} > 0,$$

$$\frac{\partial f}{\partial s^2} = -\frac{\frac{1}{2}\eta^2(\xi^2 + \eta^2 - s^2) + \frac{1}{2}s^2\xi^2 + \xi\eta s\sqrt{\xi^2 + \eta^2 - s^2}}{\big(\xi\eta + \sqrt{s^2(\xi^2 + \eta^2 - s^2)}\big)^2} < 0,$$

Hence, f is largest when η has its maximum value η_0, and ξ and s their minimum values, 0 and s_0, respectively. This gives the stated upper bound, which is the reciprocal of the limiting value κ_A, as calculated in [17]. ∎

We also note the upper bound for the solution ρ of (2.36), (2.37), (2.39), and (2.40) when $\eta \in \mathcal{K}$. Since $\eta_s \leq \eta_0$ and s^2 is monotonic, for given Riemann data $(\rho_0, \rho_1, \kappa_a)$, the value of $\rho_{\max}$ in Proposition 2.4 is bounded above by ρ_M, where, from (2.40),

$$\rho_M = s_{\rho_1}^{-1}(\eta_0). \tag{2.45}$$

We will use this upper bound in the proofs.

We prove Theorem 2.3 in two stages. First, in section 3 we solve the regularized free boundary value problem for $Q^\varepsilon = Q + \varepsilon\Delta$. In section 4, we consider the limit $\varepsilon \to 0$ and show that this limit yields a solution of (2.36)–(2.40).

3. The regularized problem. For a fixed $\varepsilon \in (0,1)$ we solve the free boundary problem defined at the beginning of section 2.4, but with Q replaced by the regularized operator Q^ε. The equation for ρ in the subsonic region is now

$$Q^\varepsilon \rho = Q\rho + \varepsilon\Delta\rho = 0; \tag{3.1}$$

the shock evolution equation remains the same,

$$\eta' = f(\xi, \eta, \rho), \quad \eta(\xi_0) = \eta_0; \tag{3.2}$$

and the boundary conditions are, as before,

$$M\rho = \beta \cdot \nabla\rho = 0 \quad \text{on} \quad \Sigma \equiv \{(\xi, \eta(\xi)); 0 < \xi < \xi_0\}, \tag{3.3}$$

$$\rho = \rho_0 \quad \text{on} \quad \sigma; \quad \rho_\xi = 0 \quad \text{on} \quad \Sigma_0, \tag{3.4}$$

and

$$\rho(\Xi_s) = \rho_s \equiv s_{\rho_1}^{-1}(\eta_s). \tag{3.5}$$

The theorem we prove in this section is as follows. (See (3.7) for the spaces.)

THEOREM 3.1. *For each $\varepsilon \in (0,1)$, there exists a solution $(\rho^\varepsilon, \eta^\varepsilon) \in H_{1+\alpha}^{(-\gamma)}(\Omega^\varepsilon) \times H_{1+\alpha}([0, \xi_0])$ to the regularized free boundary problem* (3.1), (3.2), (3.3), (3.4), *and* (3.5) *such that*

$$\rho_0 < \rho^\varepsilon \leq \rho_s \leq \rho_M \quad \textit{and} \quad c^2(\rho^\varepsilon) > \xi^2 + \eta^2 \quad \textit{in} \quad \overline{\Omega^\varepsilon} \setminus \sigma. \tag{3.6}$$

Here, $\alpha, \gamma \in (0,1)$ both depend on ε and on the Riemann data κ_a, ρ_0, and ρ_1. The curve $\eta^\varepsilon(\xi)$, defining the position of the free boundary Σ^ε, is in $\mathcal{K}^\varepsilon$; Ω^ε is bounded by σ, Σ_0, and Σ^ε.

We prove Theorem 3.1 in the following steps (which take up the three subsections of this section).

Step 1. First we show the existence of a solution to a linear problem with fixed boundary Σ defined by $\eta(\xi) \in \mathcal{K}$ and establish Hölder and Schauder estimates at Σ. For this, it is convenient to define a weighted Hölder space; see [15] for the general definition of weighted Hölder spaces. Let $V = \{\Xi_0\}$ denote the corner point at which Σ meets the degenerate boundary σ. Set $\Omega' = \Omega \cup \sigma \cup \Sigma_0 \setminus V$. We anticipate loss of regularity at V, because of the mixed boundary condition and the degeneracy of the operator Q at σ. At Ξ_s, we also find loss of regularity because of loss of obliqueness of the operator M. The third corner, between Σ_0 and σ, is an artifact of our decision to work in a half-domain. Since it does not contribute to any loss of regularity, we ignore it in the discussion. We define the corner region near Ξ_0:

$$\Omega_V(\delta) = \{x \in \Omega : \mathrm{dist}(V, x) \leq \delta\}.$$

In [3, 4, 6], in which the derivative condition was uniformly oblique, the only loss of regularity came from the corners. In the present problem, we overcome the loss of obliqueness at a single point on Σ, but at a cost: the Schauder estimates are no longer independent of the gradients of the coefficients, and hence we do not get a compact mapping in the same spaces. In this paper, we therefore modify the weighted Hölder spaces, as follows. We define a region which is close to Σ but does not contain the corner Ξ_0 by taking a covering of Σ with balls of radius δ centered at points on Σ which are bounded away from Ξ_0. Define $\Sigma''(\delta) = \{\Xi \in \Sigma \mid \mathrm{dist}(\Xi, \Xi_0) > \delta\}$ and

$$\Sigma(\delta) = \left\{ x \in \Omega \cap \bigcup_{\Xi \in \Sigma''(\delta)} B_\delta(\Xi) \right\},$$

where $B_\delta(\Xi)$ is a ball of radius δ centered at Ξ. We then define

$$H_a^{(b)} \equiv \left\{ \|u\|_a^{(b)} \equiv \sup_{\delta > 0} \delta^{a+b} |u|_{a, \overline{\Omega} \setminus \{\Sigma(\delta) \cup \Omega_V(\delta)\}} < \infty \right\}. \tag{3.7}$$

For the linear problem, we establish a priori Schauder and Hölder bounds at Σ, in particular near the point where the data lose obliqueness; we use Hölder estimates near V, and $C_{2+\alpha}$ estimates locally in the rest of the domain. We prove existence of a solution by regularizing the oblique boundary condition to be uniformly oblique, then passing to the limit using the a priori bounds.

Step 2. Using the Hölder gradient bounds to the linear problem, we establish existence results for the nonlinear fixed boundary problem, via the Schauder fixed point theorem.

Step 3. We apply the Schauder fixed point theorem again to prove existence of a solution to the nonlinear free boundary problem.

3.1. The regularized linear fixed boundary problem. Replace ρ in the coefficients a_{ij} of (2.36) and β_i of (2.33), (2.34) by a function w in a set $\mathcal{W}$ defined with respect to a given boundary component Σ, and depending on given values Ξ_s and ρ_s (see (3.5)), as follows.

DEFINITION 3.2. *The elements of* $\mathcal{W} \subset H_2^{(-\gamma_1)}$ *satisfy*

(W1) $\rho_0 \le w \le \rho_M$, $w = \rho_0$ *on* σ, $w(\Xi_s) = \rho_s$, $w_\xi = 0$ *on* Σ_0;

(W2) $\|w\|_2^{(-\gamma_1)} \le K$;

(W3) $|w|_{\alpha_0, \Omega'_{loc}} \le K_0$.

The weighted Sobolev space is defined by (3.7); the values of $\gamma_1, \alpha_0 \in (0,1)$ will be specified following (3.29), as will the values of K and K_0. The set $\mathcal{W}$ is clearly closed, bounded, and convex.

The quasilinear equations (3.1) and (3.3) are now replaced by linear partial differential and boundary equations (repeated indices are summed)

$$\begin{aligned} L^\varepsilon u &= D_i(a_{ij}(\Xi, w) D_j u) + \varepsilon \Delta u + b_i(\Xi) D_i u = 0 \quad \text{in} \quad \Omega, \\ N u &= \beta_i D_i u = \beta_i(\Xi, w) D_i u = 0 \quad \text{on} \quad \Sigma = \{\eta = \eta(\xi)\}, \end{aligned} \tag{3.8}$$

with a given $\eta \in \mathcal{K} \subset H_{1+\alpha_1}$ and $w \in \mathcal{W}$. Because of the bound (W1), L^ε is uniformly elliptic in Ω with ellipticity ratio depending on the Riemann data and on ε. In this section, we demonstrate the key point that for a given function $w \in \mathcal{W}$, the solution u to the linear equations (3.8) with the remaining boundary conditions

$$u = \rho_0 \text{ on } \sigma, \; u_\xi = 0 \text{ on } \Sigma_0 \text{ and } u(\Xi_s) = \rho_s, \tag{3.9}$$

satisfies Hölder and Schauder estimates in Ω' and a uniform $H_{1+p,\Sigma(d_0)}$ bound near Σ for any $p < \min\{\gamma_1, \alpha_1\}$. This bound gives rise to enough compactness to establish the existence of a solution to the quasilinear problem by applying the Schauder fixed point theorem.

We first note L^∞ a priori bounds for the solution u to the linear problem.

PROPOSITION 3.3. *The solution u to the linear problem* (3.8), (3.9) *satisfies*

$$\rho_0 < u \le \rho_s \le \rho_M \quad in \quad \Omega \cup \Sigma \cup \Sigma_0, \tag{3.10}$$

where $\rho_s = \rho(0, \eta_s)$ is defined in (3.5) *and ρ_M, defined in* (2.45), *is independent of ε. Moreover,*

$$c^2(u) > c^2(\rho_0) > \xi^2 + \eta^2 \quad in \quad \Omega \cup \Sigma \cup \Sigma_0. \tag{3.11}$$

Proof. The linear problem is uniformly elliptic for $\varepsilon > 0$ and $w \in \mathcal{W}$, so the classical maximum principle applies, as well as the boundary considerations used in the proof of Proposition 2.4. ▯

Next, we state the Schauder estimates including the Dirichlet and fixed Neumann boundaries, σ and Σ_0, and the Hölder estimates at the corner, Ξ_0.

THEOREM 3.4. *Assume that Σ is given by $\{(\xi, \eta(\xi))\}$ with $\eta \in \mathcal{K}$ for some $\alpha_1 \in (0,1)$ and that w is in $\mathcal{W}$ for given K, K_0, α_0, and γ_1. Then there exist $\gamma_V, \alpha_\Omega \in (0,1)$ such that any solution $u \in H_{2+\alpha_\Omega,\Omega'} \cap H_{\gamma_V,\Omega_V(d_0)}$ to the linear problem* (3.8), (3.9) *satisfies*

$$|u|_{\gamma,\Omega_V(d_0)} \le C_1 |u|_0 \tag{3.12}$$

for any $\gamma \le \gamma_V$ and

$$|u|_{2+\alpha,\Omega'_{loc}} \le C_2 |u|_0 \tag{3.13}$$

for any $\alpha \le \alpha_\Omega$. The exponent γ_V depends on the Riemann data, and both α_Ω and γ_V depend on ε but are independent of α_1 and γ_1. The constant C_1 is independent of the bounds K and K_0. The constant C_2 is independent of K but depends on K_0.

Proof. The proof is immediate. We refer to Theorem 1 of Lieberman [22] for the corner estimate. Here γ_V depends on the angle between Σ and σ at V, a fixed value that depends only on the Riemann data, and on the obliqueness ratio at V, which is also fixed, as well as on the ellipticity ratio ε, but not on γ_1, α_1, K, or K_0.

Standard interior and boundary Schauder estimates, for example, [15, p. 98], give the local estimate (3.13). The constant C_2 depends on ε, on the H_α norm of the coefficients a_{ij}, and on the domain. ▯

Because interior Schauder estimates can be applied once more, a solution in $H_{2+\alpha,\Omega'}$ is actually in $C^3(\Omega)$.

Finally, we establish Hölder gradient estimates at Σ. It is at this point that we need to derive basic estimates at the point Ξ_s where the boundary operator N is not oblique. To avoid discussing the Neumann boundary separately at each step of this proof, we reflect Ω across the ξ axis, without further comment; Ω includes Σ_0 and we let Σ stand for the full $H_{1+\alpha_1}$ boundary in Theorem 3.5. The remaining assumptions are the same as in Theorem 3.4.

THEOREM 3.5. *Assume that Σ is given by $\{(\xi, \eta(\xi))\}$ with $\eta \in \mathcal{K}$ for some $\alpha_1 \in (0,1)$ and that w is in $\mathcal{W}$ for given K, K_0, α_0, and γ_1. Then, there exists a* *positive constant d_0 such that for every $d \leq d_0$, any solution $u \in C^1(\Omega \cup \Sigma) \cup C^3(\Omega)$ to the linear problem* (3.8), (3.9) *satisfies*

$$|u|_{1+p,\Sigma(d)} \leq C(\varepsilon, \alpha_1, \gamma_1, K, d_0)|u|_0 \tag{3.14}$$

for any $p < \min\{\gamma_1, \alpha_1\}$.

Proof. Away from a neighborhood $B_{d_0}(\Xi_s)$ of Ξ_s the boundary operator N in (3.8) is oblique and thus we can apply known regularity theory, for example, [15, Theorem 6.30], to get (3.14) in $\Sigma(d_0) \setminus B_{d_0}(\Xi_s)$, with a constant C which depends on ε, α_1, Ω, d_0, and K_0. Hence we consider only estimates near Ξ_s in the remainder of the proof.

For a given solution u to (3.8) and (3.9) we define

$$v = \frac{u}{1 + |Du|_0} \quad \text{and} \quad z = Nv = \beta_i(\Xi)D_i v. \tag{3.15}$$

We construct a barrier function f for z on $B \equiv B_{d_0}(\Xi_s) \cap \overline{\Omega}$ to get a Hölder estimate for the gradient of the solution of (3.8), (3.9). Let $\psi = z + f(\zeta)$, where ζ is the regularized distance function (from the boundary component Σ); see [18]. A smooth approximation to $d(\Xi) = \operatorname{dist}(\Sigma, \Xi)$ is necessary since Σ has minimal regularity. The regularized distance function has the properties $1 \leq \zeta/d \leq 2$, $0 < \zeta_0 \leq |D\zeta| \leq \zeta_D$ and $|D^2\zeta| \leq \zeta_D d^{\alpha_1 - 1}$. We let $f(0) = 0$ and we first construct the lower barrier, $-f$, by finding a suitable positive, increasing function f such that $\psi > 0$. Note that, with f positive, we get $\psi \geq z$ on ∂B. Where no confusion is likely, we let subscripts denote partial derivatives and calculate

$$D_i\psi = \beta_j D_{ij} v + D_i\beta_j D_j v + f'\zeta_i, \tag{3.16}$$

whence

$$\beta_j D_{ij} v = D_i\psi - (D_i\beta_j D_j v + f'\zeta_i). \tag{3.17}$$

We also have

$$D_{ij}\psi = \beta_k D_{ijk} v + D_j\beta_k D_{ik} v + D_i\beta_k D_{jk} v + D_{ij}\beta_k D_k v + f'\zeta_{ij} + f''\zeta_i\zeta_j. \tag{3.18}$$

In addition, since w satisfies (W2) with a given constant K, we get estimates on the derivatives of a_{ij}. Using the definition of the weighted norms, we have (noting $|Dw| \leq |w|_1$ and so on)

$$\begin{aligned} |D(a_{ij})| &\leq |a_{ij,x}| + |a_{ij,u}||Dw| \leq |a_{ij,x}| + |a_{ij,u}|\|w\|_1^{(-\gamma_1)} d^{\gamma_1 - 1} \leq m d^{\gamma_1 - 1}, \\ |D^2(a_{ij})| &\leq |a_{ij,x,x}| + 2|a_{ij,x,u}||Dw| + |a_{ij,u,u}||Dw|^2 + |a_{ij,u}||D^2 w| \\ &\leq |a_{ij,x,x}| + 2|a_{ij,x,u}|\|w\|_1^{(-\gamma_1)} d^{\gamma_1 - 1} + |a_{ij,u,u}|(\|w\|_1^{(-\gamma_1)} d^{\gamma_1 - 1})^2 \\ &\quad + |a_{ij,u}|\|w\|_2^{(-\gamma_1)} d^{\gamma_1 - 2} \\ &\leq m(d^{\gamma_1 - 2} + d^{2\gamma_1 - 2}). \end{aligned} \tag{3.19}$$

Here subscripts denote derivatives of a_{ij} with respect to the variables in Ξ $(, x)$ and with respect to w $(, u)$. The symbol $m = m(K)$ denotes a quantity which depends on the structure of the derivatives of a_{ij} and the bound K on w. We absorb terms which are less singular as $d \to 0$. We also get estimates on the derivatives of β_i. Let $\gamma_2 = \min\{\gamma_1, \alpha_1\}$. Then

$$|D\beta_i| \le md^{\gamma_2 - 1}, \qquad |D^2\beta_i| \le m(d^{\gamma_2-2} + d^{2\gamma_2-2}), \tag{3.20}$$

where $m = m(K) > 0$ depends on the structure of the derivatives of β. In deriving this estimate, we use the fact that η', η'', and η''' are bounded by d^{α_1}, d^{α_1-1}, and d^{α_1-2}, respectively, as we can apply Lemma 2.8 of [14] to $\eta(\xi) - \eta$.

Since $\beta_2(\Xi_s, w) = 0$ and $\beta_1(\Xi_s, w) \neq 0$, we can take $0 < d_1 \le 1$ small enough so that for all $0 < d_0 \le d_1$ and all $w \in \mathcal{W}$ we have $\beta_1(\Xi, w) \neq 0$ in B_{d_0}. Now we solve the two equations in (3.17) along with $Lv = 0$, that is,

$$a_{ij}D_{ij}v = -(D_j a_{ij} D_i v + b_i D_i v), \tag{3.21}$$

as a linear system for the three derivatives $D_{ij}v$. The assumption that β_1 is bounded away from zero, coupled with the ellipticity of L, gives a uniform bound $c_1(\Lambda, \lambda, |\beta|_0)$ on the inverse of the coefficient matrix of the linear system. Here we may let Λ and λ be the eigenvalues of (a_{ij}) restricted to B. These are order one constants which depend only on the Riemann data. Furthermore, we can estimate the right-hand sides of (3.17) and (3.21) using (3.19) and (3.20). We get

$$|D^2 v| \le c_1(\Lambda, \lambda, |\beta|_0)\big(|D\psi| + (md^{\gamma_2-1} + |b|_0)|Dv| + f'\zeta_D\big). \tag{3.22}$$

This bounds the second derivatives of v in terms of $|D\psi|$. Now we proceed to obtain bounds for ψ. The idea is to find an elliptic operator for which ψ is a subsolution in B and simultaneously to force $\psi > 0$ on ∂B, by choice of the function f. A second-order operator for ψ involves third derivatives of v, so we estimate these. By using $Lv = 0$, (3.22), (3.19), and (3.20) (recall that $|Dv| \le 1$), we get

$$\begin{aligned}
a_{ij}D_{ijk}v &= -\big(D_k a_{ij} D_{ij}v + D_j a_{ij} D_{ik}v + b_i D_{ik}v + D_{jk}a_{ij}D_i v + D_k b_i D_i v\big)\\
&\le (md^{\gamma_2-1} + |b|_0)|D^2 v| + (md^{\gamma_2-2} + md^{2\gamma_2-2} + |b|_1)|Dv|\\
&\le c_1(md^{\gamma_2-1} + |b|_0)|D\psi| + c_1(md^{\gamma_2-1} + |b|_0)^2\\
&\quad + c_1(md^{\gamma_2-1} + |b|_0)f'\zeta_D + md^{\gamma_2-2} + md^{2\gamma_2-2} + |b|_1\\
&\le c_2\big\{(md^{\gamma_2-1} + 1)|D\psi| + (md^{\gamma_2-1} + 1)^2\\
&\quad + (md^{\gamma_2-1} + 1)f' + md^{\gamma_2-2} + md^{2\gamma_2-2} + 1\big\},
\end{aligned}$$

where $c_2 = c_2(\Lambda, \lambda, \rho_M, |\beta|_0, |b|_0, |b|_1, \zeta_D)$. Thus, using (3.18) and making the estimates indicated, we have

$$\begin{aligned}
a_{ij}D_{ij}\psi &\le c_2|\beta|_0\big\{(md^{\gamma_2-1} + 1)|D\psi| + (md^{\gamma_2-1} + 1)^2 + (md^{\gamma_2-1} + 1)f'\\
&\qquad + md^{\gamma_2-2} + md^{2\gamma_2-2} + 1\big\}\\
&\qquad + 2\Lambda md^{\gamma_2-1}c_1\big\{|D\psi| + md^{\gamma_2-1} + |b|_0 + f'\zeta_D\big\}\\
&\qquad + \Lambda m(d^{\gamma_2-2} + d^{2\gamma_2-2}) + \Lambda f'|\zeta_{ij}| + f'' a_{ij}\zeta_i\zeta_j\\
&\le c_3\big\{(md^{\gamma_2-1} + 1)|D\psi| + md^{\gamma_2-2} + (m^2 + m)d^{2\gamma_2-2}\\
&\qquad + md^{\gamma_2-1}(1 + f')\big\} + \Lambda f'|\zeta_{ij}| + f'' a_{ij}\zeta_i\zeta_j.
\end{aligned}$$

Here c_3 is a constant depending on the same parameters as c_1 and c_2, and terms which are bounded as $d \to 0$ have again been omitted. Now we define

$$L_1\psi \equiv a_{ij}D_{ij}\psi - c_3(md^{\gamma_2-1} + 1)|D\psi|$$

and we calculate

(3.23)
$$L_1\psi \le c_3\big\{md^{\gamma_2-2} + (m^2+m)d^{2\gamma_2-2} + md^{\gamma_2-1}(1+f')\big\} + \Lambda\zeta_D f' d^{\alpha_1-1} + \lambda f''\zeta_0^2.$$

To obtain this estimate, we have assumed $f'' < 0$ and estimated

$$f'' a_{ij}\zeta_i\zeta_j \le f'' \min a_{ij}\zeta_i\zeta_j = f''\lambda|D\zeta|^2 \le f''\lambda\zeta_0^2.$$

We have also used the property of regularized distance: $|\zeta_{ij}| \le \zeta_D d^{\alpha_1-1}$. We now specify $f(\zeta) = f_0\zeta^p$ for any $p < \gamma_2$, so that

$$f'' = f_0 p(p-1)\zeta^{p-2} \le f_0 p(p-1)d^{p-2} < 0,$$

and $f' d^{\alpha_1-1} \le 2^{p-1} f_0 p d^{p+\alpha_1-2}$. Finally, we choose f_0 big enough and $d_2 \in (0,1)$ small enough to get $L_1\psi < 0$ in B_{d_0} for every $d_0 \le d_2$. We now define $d_0 \equiv \min\{d_1, d_2\}$.

Additionally, since (3.14) holds near Σ, away from Ξ_s, and hence is valid on ∂B, we can choose f_0 larger if necessary so that $\psi > 0$ on ∂B. Therefore, by the maximum principle, $\psi > 0$ in B. Thus, $z > -f$ in B.

Similarly, f is an upper barrier for z. We now have an estimate for z. In addition we have, since $\psi = z + f$,

$$|\psi| \le c_4(m^2+1)d^p \quad \text{for} \quad d \le d_0.$$

Since $\psi = 0$ on Σ, we can use Schauder estimates, applying [15, Lemma 6.20] or [14, Lemma 7.1, Theorem 7.2], using the fact that ψ and $-\psi$ are upper and lower solutions of an operator L_1 with a Dirichlet boundary condition and estimating the right side of (3.23), to obtain

$$\|\psi\|^{(-p)}_{2+\gamma_2} \le C_1\big(\sup d^{-p}|\psi| + |\psi|_0 + |\psi|_{p,\partial B}\big) \le c_4(m^2+1) + c(m) = C(m).$$

The constant C_1 depends only on λ and Λ (the ellipticity constants in B) and on γ_2. To obtain the second inequality in this expression, we have used the fact that $|\psi|_{p,\partial B}$ is bounded, with a bound which depends only on $|\psi|_0$ and on Λ/λ. This follows from $\psi = 0$ on Σ and from interior Schauder estimates for v, a solution to a linear problem, on $\partial B \cap \Omega$. Finally, this leads to

$$|D\psi| \le \|D\psi\|^{(1-p)}_{\gamma_2+1} d^{p-1} \le C(m)d^{p-1} \quad \text{for} \quad d < d_0. \tag{3.24}$$

We now use (3.24) in (3.22) and drop lower-order terms to get

$$|D^2 v| \le c_1(|D\psi| + md^{\gamma_2-1} + f') \le c_1(C(m)d^{p-1} + md^{\gamma_2-1} + f_0 p d^{p-1}) \le Cd^{p-1}.$$

Now Hölder estimates on Dv follow by integrating the last inequality. More precisely, $|D^2 v| \le Cd^{p-1}$ implies that $\|Dv\|^{(-p)}_1 \le C$, and by [14, Lemma 2.1] we have

$$|Dv|_p = \|Dv\|^{(-p)}_p \le C(p)\|Dv\|^{(-p)}_1,$$

and therefore we get

$$|v|_{1+p} \le C. \tag{3.25}$$

Finally, using the definition of v in (3.15), we apply the interpolation inequality, [15, Lemma 6.32], with a small $\delta > 0$ to get

$$|u|_{1+p} \leq C(1 + |Du|_0) \leq C(1 + \delta|u|_{1+p} + C_\delta|u|_0) \tag{3.26}$$

and thus (3.14) holds. Therefore we get Hölder gradient estimates at Σ for the solution u of (3.8). ∎

Now we can establish existence of a solution to (3.8) and (3.9).

THEOREM 3.6. *Assume that* Σ *is given by* $\{(\xi, \eta(\xi))\}$ *with* $\eta \in \mathcal{K}$ *for some* $\alpha_1 \in (0,1)$ *and that* w *is in* $\mathcal{W}$ *for given* K, K_0, α_0, *and* γ_1. *Then there exist* $\gamma_V, \alpha_\Omega \in (0,1)$, *and* $d_0 > 0$, *where* γ_V, α_Ω, *and* d_0 *are independent of* γ_1 *and* α_1, *such that a solution* $u \in H_{1+p,\Sigma(d)} \cap H_{2+\alpha,\Omega'} \cap H_{\gamma,\Omega_V(d_0)}$ *for the linear problem* (3.8) *and* (3.9) *exists for any* $\alpha \leq \alpha_\Omega$, $p < \min\{\gamma_1, \alpha_1\}$, $\gamma \leq \gamma_V$, *and* $d \leq d_0$ *and satisfies* (3.12), (3.13), *and* (3.14).

Proof. To show the existence of a solution u to (3.8) and (3.9), we approximate the oblique derivative boundary condition on Σ. To be precise, noting that the unit inward normal to Σ at Ξ_s is $(0,-1)$, for $0 < \delta < 1$ we let $\beta_\delta = \beta + (0, -\delta)$ so that $\beta_\delta \cdot \nu = \beta \cdot \nu + \delta \geq \delta > 0$ at Ξ_s. Then, for sufficiently small δ, β_δ is uniformly oblique. The boundary condition is now discontinuous at the corner Ξ_s, where Σ and Σ_0 meet. Results from [21] and [19] imply that there exists a solution u^δ to $Lu^\delta = 0$ in Ω, $\beta_\delta \cdot \nabla u^\delta = 0$ on Σ, and (3.9). Now we apply Theorems 3.4 and 3.5, which are independent of δ, to see that the sequence u^δ is uniformly bounded in $H_{1+p,\Sigma(d_0)} \cap H_{2+\alpha_\Omega,\Omega'} \cap H_{\gamma_V,\Omega_V(d_0)}$ for any $p < \min\{\gamma_1, \alpha_1\}$. Thus by the Arzela–Ascoli theorem, there exists a subsequence converging uniformly to a function u. Using the uniform bounds (3.12), (3.13), and (3.14), we conclude that the limiting function solves the problem (3.8), (3.9). ∎

3.2. The regularized nonlinear fixed boundary problem. This subsection is devoted to proving the existence of solutions to the nonlinear problem (3.1) with a fixed boundary. We again assume that an approximate shock boundary Σ is given by a function $\eta = \eta(\xi) \in \mathcal{K}$. We also are given the value $\rho_s = s_{\rho_1}^{-1}(\eta(0))$. We prove the following theorem.

THEOREM 3.7. *For each* $\varepsilon \in (0,1)$, *and for given* $\eta \in \mathcal{K} \subset H_{1+\alpha_1}$, *there exists a solution* $\rho^\varepsilon \in H_{2+\alpha}^{(-\gamma)}(\Omega^\varepsilon)$ *to* (3.1), (3.3), (3.4), *and* (3.5) *such that*

$$\rho_0 < \rho^\varepsilon \leq \rho_s \leq \rho_M, \quad \textit{and} \quad c^2(\rho^\varepsilon) > \xi^2 + \eta^2 \quad \textit{in} \quad \overline{\Omega}^\varepsilon \setminus \sigma \tag{3.27}$$

for some $\alpha(\varepsilon), \gamma(\varepsilon) \in (0,1)$. *Moreover, for some* $d_0 > 0$ *the solution* ρ^ε *satisfies*

$$|\rho^\varepsilon|_{\gamma,\Sigma(d_0)\cup\Omega_V(d_0)} \leq K_1, \tag{3.28}$$

where γ *and* K_1 *depend on* ε, γ_V *and* K *but both are independent of* α_1.

Proof. We suppress the dependence on ε to simplify the notation.

Recall that $\mathcal{K} \subset H_{1+\alpha_1}([0,\xi_0])$ is a closed convex set of functions satisfying the additional conditions (K1) to (K4) given in section 2.4. For any function w in $\mathcal{W}$ we define a mapping $T : \mathcal{W} \subset H_2^{(-\gamma_1)} \to H_2^{(-\gamma_1)}$ by letting $\rho = Tw$ be the solution to the linear regularized fixed boundary problem, (3.8), (3.9) solved in Theorem 3.6. Because w satisfies (W1), L^ε is strictly elliptic, with ellipticity ratio depending on ε. By Theorem 3.6, T maps $\mathcal{W} \subset H_2^{(-\gamma_1)}$ to a bounded set in $H_{2+\alpha}^{(-\gamma_V)}$, where γ_V is the value given by Theorem 3.6. Since γ_V is independent of γ_1, we may take $\gamma_1 = \gamma_V/2$ and then $T(\mathcal{W})$ is precompact in $H_2^{(-\gamma_1)}$.

To show T maps $\mathcal{W}$ into itself, we need to show that Tw satisfies (W1), (W2), and (W3). Now, (W1) is immediate by Proposition 3.3 and the boundary conditions.

By applying interior and boundary Hölder estimates (see [15, Theorems 8.22 and 8.27]), we get the local estimate

$$|\rho|_{\alpha*,\Omega_1'} \leq C_0, \tag{3.29}$$

where $0 < \alpha* < 1$ and C_0 depend only on ε (the ellipticity ratio), the Riemann data, and on $d' = \operatorname{dist}(\Omega_1', \partial\Omega')$ with $\Omega_1' \subset \Omega'$. Notice that, as in the remark following Theorem 8.24 in [15, p. 202], the constant C_0 is nondecreasing and the constant $\alpha*$ nonincreasing with respect to d'. Since $\Omega' \subset \Omega$ is bounded, we can find an upper bound for C_0 and a lower bound for $\alpha*$ depending only on the size of Ω and the ellipticity ratio. Thus, if we define $\mathcal{W}$ with $K_0 = C_0$ and $\alpha_0 = \alpha*$, with C_0 the upper bound and $\alpha*$ the lower bound, then $\rho = Tw$ satisfies (W3). Note that K_0 and $\alpha*$ are independent of α_1 and γ_V.

To verify (W2), we need to find a value K such that

$$\sup_{\delta>0} \delta^{2-\gamma_1} |\rho|_{2,\overline{\Omega}\setminus\{\Sigma(\delta)\cup\Omega_V(\delta)\}} < K, \tag{3.30}$$

assuming $\|w\|_2^{-\gamma_1} \leq K$. We start by noting that Theorem 3.5 implies the existence of a positive constant $d_0 > 0$ such that for every $d \leq d_0$, any solution $u \in C^1(\Omega\cup\Sigma)\cup C^3(\Omega)$ to the linear problem (3.8), (3.9) satisfies the Hölder gradient estimate (3.14), where the constant C depends on K but is uniform in $d \leq d_0$. Based on this estimate, we get a local bound for the weighted norm of ρ on $\Sigma(d_0)$ of the form

$$d^{2-\gamma_1}|\rho|_2 \leq d^{1-\gamma_1+p} C \tag{3.31}$$

which holds for all $d < d_0$. Here C depends on K, α_1, and γ_1. To show (3.30) we estimate the supremum by considering separately domains $\overline{\Omega} \setminus \{\Sigma(\delta) \cup \Omega_V(\delta)\}$ for which $\delta > \tilde{d}$, where $\tilde{d} \leq d_0$ will be specified later, and domains for which $\delta \leq \tilde{d}$.

In domains of the first kind, $\overline{\Omega}\setminus\{\Sigma(\delta)\cup\Omega_V(\delta)\}$ with $\delta > \tilde{d}$, the solution is smooth and its C^2-norm bound is independent of K. More precisely, we can use the uniform Hölder estimate (3.29) and bootstrap iteratively (see [15, Theorem 6.6]) to get the local Schauder estimate

$$|\rho|_{2+\alpha_\Omega,\Omega'} \leq C(K_0). \tag{3.32}$$

Notice that since the Hölder estimate (3.29) is independent of the distance between Ω_1' and the boundary Σ, so is the Schauder estimate (3.32). The interpolation inequality [15, Lemma 6.32] gives

$$|\rho|_{2,\Omega'} \leq c|\rho|_0 + \mu|\rho|_{2+\alpha,\Omega'} \leq c\rho_M + \mu C(K_0) \tag{3.33}$$

for any $\mu > 0$ and $c = c(\mu)$. We fix $\mu = 1$ and get

$$\sup_{\delta>\tilde{d}} \delta^{2-\gamma_1} |\rho|_{2,\overline{\Omega}\setminus\{\Sigma(\delta)\cup\Omega_V(\delta)\}} \leq K', \tag{3.34}$$

where K' depends on the size of the domain Ω, on $C(K_0)$, and on ρ_M but is independent of the distance to Σ.

Next we study $\delta^{2-\gamma_1}|\rho|_{2,\overline{\Omega}\setminus\{\Sigma(\delta)\cup\Omega_V(\delta)\}}$ when $\delta \leq \tilde{d}$. We divide the subdomain $\overline{\Omega} \setminus \{\Sigma(\delta) \cup \Omega_V(\delta)\}$ into two: the part for which $\delta > \tilde{d}$ and the complement. Then the upper bound over the subdomain $\overline{\Omega} \setminus \{\Sigma(\delta) \cup \Omega_V(\delta)\}$ is equal to the larger of the suprema over the two subdomains. The supremum over the subdomain for which $\delta > \tilde{d}$ has been calculated above. The supremum over the complement is calculated using the estimates for the behavior of the solution near Σ, namely, estimate (3.31) and the corner estimate (3.12). In (3.12), the constants C_1 and γ_V are independent of K, K_0, and α_1, while $|\rho|_0$ is bounded by ρ_M from Proposition 3.10. By the interpolation inequality [14, Lemma 2.1], since $\gamma_1 = \gamma_V/2$ we have

$$|\rho|_{\gamma_1,\Omega_V(d_V)} \le C_V|\rho|_{\gamma_V,\Omega_V(d_V)} \le C_V C_1 \rho_M, \tag{3.35}$$

where $C_V = C_V(\gamma_1, \gamma_V, \Omega_V(d_V))$, for some $d_V > 0$. From here we get that

$$d^{2-\gamma_1}|\rho|_2 \le K_V \quad \forall d < d_V,$$

where K_V is independent of K. Hence we can take $K \equiv \max\{K_V, K'\}$, using the bound (3.34), and now K is independent of α_1 and of $\tilde{d}$. Since K_V and K' are independent of $\tilde{d}$ we can change $\tilde{d}$ without affecting K. Therefore, we can choose $\tilde{d} \le \min\{d_0, d_V\}/2$ in (3.31) small enough that $\tilde{d}^{1-\gamma_1+p}C < K$. Therefore, (3.30) is satisfied and we have chosen parameters K, K_0, and α_0 defining $\mathcal{W}$ so that T maps $\mathcal{W}$ into itself.

Now, by the Schauder fixed point theorem, there exists a fixed point ρ such that $T\rho = \rho \in H_2^{(-\gamma_1)}$. Thus, ρ solves (3.1), (3.3), (3.4), and (3.5). By a bootstrap argument we get $\rho \in H_{2+\alpha}^{(-\gamma_1)}$ for any $\alpha \le \alpha_\Omega$, the value given in Theorem 3.6. For reference, we note that we have chosen $\gamma_1 = \gamma_V/2$; the exponent $\gamma_V \in (0,1)$ depends on the corner angle at Ξ_0 and α_Ω and γ_V depend on ε. The bounds on ρ in Proposition 3.3 give the first estimate in (3.27), and the second follows.

Finally, since $T(\mathcal{W}) \subset \mathcal{W}$ is a bounded set in $H_2^{(-\gamma_1)}$, then by (W2) and by the interpolation inequality [14, Lemma 2.1], any fixed point ρ satisfies (3.28) for any $\gamma \le \gamma_1 = \gamma_V/2$. Note that K_1 and γ_1 are independent of α_1. ◻

3.3. The regularized nonlinear free boundary problem. We now prove existence of a solution to the regularized free boundary problem.

Proof of Theorem 3.1. Again, we suppress the ε dependence.

For each $\eta \in \mathcal{K} \subset H_{1+\alpha_1}$, using the solution ρ of the nonlinear fixed boundary problem (3.1), (3.3), (3.4), and (3.5) given by Theorem 3.7, we define the map J on $\mathcal{K}$, $\tilde{\eta} = J\eta$ as in (2.44), by integrating (2.43):

$$\tilde{\eta}(\xi) = \eta_0 + \int_{\xi_0}^{\xi} f(x, \eta(x), \rho(x, \eta(x)))\, dx. \tag{3.36}$$

First, we check that J maps $\mathcal{K}$ into itself. Property (K1) follows from (3.36). By Proposition 2.5, property (K2) holds, while the upper and lower bounds in (K4) hold by Proposition 2.6 and in turn imply (K3).

The Hölder class of ρ at Σ is given by the estimate (3.28), along with a bound on the Hölder γ-norm, and from estimate (3.28) in the proof of Theorem 3.7 we saw that we could choose $\gamma = \gamma_V/2$. Evaluating $f(\Xi, \rho(\Xi))$, we get a bound $|f|_{\gamma_V/2} \le C(K_1)$, and thus $|\tilde{\eta}|_{1+\gamma_V/2} \le C(K_1)$. The constants here are simple functions of the Riemann data and the structure of the pressure function. The important feature of the mapping is that γ_V is independent of α_1, the Hölder exponent of the space $\mathcal{K}$. Thus, we have $J(\mathcal{K}) \subset H_{1+\gamma_V/2}$; since properties (K1)–(K4) hold, we then have $J(\mathcal{K}) \subset \mathcal{K}$ if

$\alpha_1 \le \gamma_V/2$. Furthermore, J is compact if $\alpha_1 < \gamma_V/2$. We now take $\alpha_1 = \gamma_V/3$. By standard arguments, the map J is continuous.

Therefore, J has a fixed point $\eta^\varepsilon \in H_{1+\gamma_V/3}([0,\xi_0])$ by the Schauder fixed point theorem. This gives a curve Σ^ε on which (3.2) holds. Together with the corresponding solution ρ^ε from Theorem 3.7, this establishes the existence of a solution $(\rho^\varepsilon, \eta^\varepsilon) \in H_{2+\alpha}^{(-\gamma)} \times H_{1+\alpha}$ of the regularized free boundary problem (3.1), (3.2), (3.3), (3.4), and (3.5) for sufficiently small $\gamma(\varepsilon)$ and $\alpha(\varepsilon)$.

This completes the proof of Theorem 3.1. ∎

4. The limiting solution. In this section we study the limiting solution, as the elliptic regularization parameter ε tends to zero. We start with the regularized solutions of (3.1), (3.2), (3.3), (3.4), and (3.5), whose existence is guaranteed by Theorem 3.1. Denote by ρ^ε a sequence of regularized solutions of the partial differential equation.

PROPOSITION 4.1. *For each ε the constant function ρ_0 is a lower barrier for ρ^ε and $c^2(\rho_0) > \xi^2 + \eta^2$ in $\overline{\Omega^\varepsilon} \setminus \sigma$.*

Proof. For each ε we have $\rho^\varepsilon > \rho_0$, and by the monotonicity of c^2 we get $c^2(\rho^\varepsilon) > c^2(\rho_0) > \xi^2 + \eta^2$ in $\Omega^\varepsilon \cup \Sigma_0$. The same inequality holds on Σ^ε since $(\xi, \eta^\varepsilon(\xi))$ lies inside C_0. Thus $c^2(\rho_0) > \xi^2 + \eta(\xi)^2$ for $\xi \in [0, \xi_0)$ and ρ_0 is a uniform lower barrier. ∎

The existence of a uniform lower bound ρ_0 in ε allows us to apply standard local compactness arguments (see, for example, [3, Lemma 4.2]) to get a limit ρ, locally, in the interior of the domain. Here, the issue is ensuring ellipticity uniformly in ε in compact subsets of Ω. We first show that the sequence of domains Ω^ε converges to a domain Ω, as $\varepsilon \to 0$.

LEMMA 4.2. *The sequence η^ε has a convergent subsequence, whose limit η belongs to $C^\gamma([0,\xi_0])$ for all $\gamma \in (0,1)$. The limiting curve η is convex.*

Proof. Theorem 3.1 gives the existence of a sequence $(\rho^\varepsilon, \eta^\varepsilon)$ of solutions of the regularized free boundary problems for which η^ε belongs to the set $\mathcal{K}^\varepsilon$ for each ε. Now, $\rho_0 < \rho^\varepsilon \le \rho_s^\varepsilon \le \rho_M$, where ρ_M is independent of ε, and the property (K4) of $\mathcal{K}^\varepsilon$, specified in section 2.4, immediately gives a C^1 bound on η^ε, uniformly in ε. Thus by the Arzela–Ascoli theorem, η^ε has a convergent subsequence, and the limit $\eta \in C^\gamma([0,\xi_0])$ for all $\gamma \in (0,1)$.

To see that η is convex we first show that η^ε is convex for each $\varepsilon > 0$. Recall that $\eta' = f(\xi, \eta(\xi), \rho(\xi, \eta(\xi)))$ and calculate $\eta'' = f_\xi + f_\eta \eta' + f_\rho \rho'$. By observing that if ρ were constant the shock would be a straight line, we get $f_\xi + f_\eta \eta' = 0$. Therefore, the sign of η'' is determined entirely by the sign of f_ρ and ρ'. Since ρ is decreasing by Proposition 2.4, this implies $\rho' \le 0$. Furthermore, by Lemma 2.1 we have $d(s^2)/d\rho \ge 0$ and by the proof of Proposition 2.6 we have $f_{s^2} < 0$, so $f_\rho = f_{s^2}(s^2)' \le 0$. This shows that η^ε is convex for each $\varepsilon > 0$, and so the limiting function is convex. ∎

The limit value $\eta(0) = \lim \eta^\varepsilon(0)$ is also established, and the corresponding subsequence of domains Ω^ε also has a limit, Ω.

In the remaining lemmas, without further comment, we carry out the limiting argument using the convergent subsequence of η^ε, which we again call η^ε.

LEMMA 4.3. *The sequence ρ^ε has a limit $\rho \in C^{2+\alpha'}(\Omega)$ for some $\alpha' > 0$. The limit ρ satisfies the quasi-linear degenerate elliptic equation* (2.36). *In addition, $\rho_0 < \rho < \rho_M$ in Ω.*

Proof. The proof is based on local compactness arguments and on uniform L^∞ bounds for ρ^ε: $\rho_0 < \rho^\varepsilon < \rho_s^\varepsilon \le \rho_M$, where ρ_M is independent of ε. The main ideas follow those used in [13, Theorem 1] and the proof is almost identical to the proof of [4, Lemma 4.2]. We omit the details. ∎

In the next lemma, we show that the limiting functions ρ and η satisfy both the shock evolution equation (2.38) and the oblique derivative boundary condition (2.37), $M\rho = 0$, on Σ.

LEMMA 4.4. *The limits η and ρ satisfy*

$$\eta' = f(\xi, \eta, \rho) \quad \textit{and} \quad M\rho = \beta(\eta(\xi), \rho) \cdot \nabla\rho = 0 \quad \textit{on} \quad \Sigma. \tag{4.1}$$

Furthermore, $\eta \in C^{2+\alpha'}(0, \xi_0) \cap C^1([0, \xi_0))$ and $\rho \in C^{2+\alpha'}(\Omega \cup \Sigma \cup \Sigma_0 \setminus \Xi_s) \cap C(\Omega \cup \Sigma \cup \Sigma_0)$ for some $\alpha' > 0$. In addition, ρ satisfies $\rho = \rho_s$ at $\Xi_s = (0, \eta(0))$, where $\rho_s = s_{\rho_1}^{-1}(\eta(0))$.

Proof. The proof is similar to that of [4, Lemma 4.3] except for the loss of uniform obliqueness at Ξ_s. We omit the local arguments away from Ξ_s and concentrate on dealing with the behavior of the solution near Ξ_s.

The arguments presented in the proof of [4, Lemma 4.3] imply $\eta^\varepsilon(\xi) \to \eta(\xi)$ in $C_{loc}^{2+\alpha'}$ for $\xi \neq 0$, and since the subsequence ρ^ε converges to ρ in $C_{loc}^{1+\alpha'}$, we get

$$(\eta^\varepsilon)' = f(\xi, \eta^\varepsilon, \rho^\varepsilon) \to f(\xi, \eta, \rho) \quad \forall \xi \neq 0,$$

thus $\eta' = f(\xi, \eta, \rho)$ for $\xi \neq 0$. Furthermore, by continuity of β and ρ we have

$$0 = \beta(\eta^\varepsilon, \rho^\varepsilon) \cdot \nabla\rho^\varepsilon(\xi, \eta^\varepsilon(\xi)) \to \beta(\eta, \rho) \cdot \nabla\rho(\xi, \eta(\xi)) \quad \forall \xi \neq 0,$$

and thus $\beta(\eta, \rho) \cdot \nabla\rho = 0$ on $\Sigma \setminus \{(0, \eta(0))\}$.

We now focus on the behavior of the solution at Ξ_s. By Lemma 4.2 we have $\eta^\varepsilon \to \eta$ in $C^\gamma([0, \xi_0])$ for any $0 < \gamma < 1$. Furthermore, by construction, for each $\varepsilon > 0$,

$$s^2(\rho_s^\varepsilon, \rho_1) = (\eta^\varepsilon(0))^2.$$

Therefore, as $\varepsilon \to 0$, the right-hand side converges to $\eta^2(0)$; hence $s^2(\rho_s^\varepsilon, \rho_1) \to \eta^2(0)$. By continuity and monotonicity of s^2 this implies that the sequence of numbers ρ_s^ε also has a limit, R. Moreover, $s^2(R, \rho_1) = \eta^2(0)$. But, this equation defines ρ_s; therefore $R = \rho_s$ and we have shown that the sequence of traces of the functions ρ^ε evaluated at $(0, \eta^\varepsilon(0))$ converges to ρ_s. We still have to show that ρ is continuous at Ξ_s, that is, that $\lim_{\xi\to 0} \rho(\xi, \eta(\xi)) = \rho_s$.

Since η_ε' has a limit $\eta' = f(\xi, \eta(\xi), \rho(\xi, \eta(\xi)))$ in $C^{1+\alpha}$ for $\xi \neq 0$, and since for each $\varepsilon > 0$ we have $\eta_\varepsilon'(0) = 0$, then for any $\delta > 0$ there exists an $h_0 \neq 0$ such that

$$|\eta'(h)| \leq |\eta'(h) - \eta_\varepsilon'(h)| + |\eta_\varepsilon'(h)| \leq \delta$$

for $0 < h < h_0$, which implies continuity of η' at $\xi = 0$ and $\eta'(0) = 0$. Thus

$$f(h, \eta(h), \rho(h, \eta(h))) = \eta'(h) \to \eta'(0) = 0 = f(0, \eta(0), \rho_s) \text{ as } h \to 0.$$

This implies, among other things, that $\rho(h, \eta(h)) \to \rho_s$ and so ρ is continuous at Ξ_s, $\rho(\Xi_s) = \rho_s$ and the boundary condition (2.40) is satisfied. ∎

The final task is to prove continuity of ρ up to the degenerate boundary σ. It is here that we need an additional condition on the Riemann data.

LEMMA 4.5. *For Riemann data satisfying a bound $\kappa_a > \kappa_*(\rho_1, \rho_0)$, the limit ρ satisfies $\rho = \rho_0$ on σ and $\rho \in C(\overline{\Omega})$.*

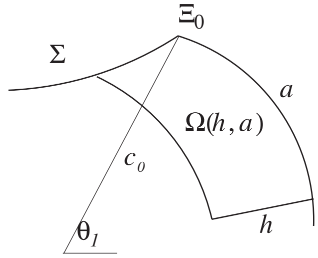

FIG. 4.1. *A sketch of the corner barrier domain.*

Proof. Continuity of solutions of $Q\rho = 0$ up to a degenerate boundary was proved as Corollary 3.3 in [7], at points where the degenerate boundary σ is convex, when the problem satisfies a Dirichlet condition on the entire boundary, and the entire boundary is degenerate. In [7], a pointwise upper barrier function ψ was constructed, uniformly in ε, with $\psi > \rho^\varepsilon$ in Ω and $\psi = \rho^\varepsilon$ at $\Xi \in \sigma$. This proof can easily be adapted to give a local barrier at every interior point of σ in our problem. Thus, to show continuity everywhere on σ we need only to show continuity at Ξ_0. We construct an upper barrier ψ with $\psi(\Xi_0) = \rho_0$ so that $\psi \geq \rho^\varepsilon$ in a fixed set $\Omega(h, a)$ (see Figure 4.1) for all $\varepsilon > 0$. Since ρ_0 is a lower barrier, we then have continuity at Ξ_0.

It is convenient to work in polar coordinates $(\xi, \eta) = (r\cos\theta, r\sin\theta)$. In this coordinate system, the operator Q^ε becomes

$$Q^\varepsilon\rho = \left(c^2(\rho) - r^2 + \varepsilon\right)\rho_{rr} + \frac{c^2}{r^2}\rho_{\theta\theta} + p''(\rho)\left(\rho_r^2 + \frac{1}{r^2}\rho_\theta^2\right) + \left(\frac{c^2}{r} - 2r\right)\rho_r.$$

To compare ψ and ρ^ε we introduce an operator $Q_1^\varepsilon(\rho^\varepsilon)$ which is partially linearized:

$$Q_1^\varepsilon(\rho^\varepsilon)u = \left(c^2(u) - r^2 + \varepsilon\right)u_{rr} + \frac{c^2(\rho^\varepsilon)}{r^2}u_{\theta\theta} + p''(\rho^\varepsilon)\left(u_r^2 + \frac{1}{r^2}u_\theta^2\right) + \left(\frac{c^2(\rho^\varepsilon)}{r} - 2r\right)u_r.$$

The barrier function has the form

$$\psi(r,\theta) = \rho_0 + A(c_0 - r)^b + B(\theta_1 - \theta)^2. \tag{4.2}$$

Here θ_1 is the angle subtended by Ξ_0; A and B are constants to be determined and the exponent b is a value, also to be determined, in $(0, 1)$. The barrier is constructed on a curvilinear quadrilateral, $c_0 \geq r \geq c_0 - h$, $\theta_1 - a \leq \theta \leq \theta^\varepsilon(r)$, where $\theta^\varepsilon(r)$ is the boundary Σ^ε in polar coordinates and h and a are small numbers to be determined. The use of a barrier function with a singular derivative is motivated by [7], following [13]. In fact, we conjecture that the solution to the equation, in this case, does have a square root singularity at C_0 and that our value of b, which can be refined a posteriori to be any number less than $1/2$, is optimal.

Before evaluating $Q_1^\varepsilon\psi$, we write $c^2 = p'$ and expand $c^2 - r^2$ as $c^2(\psi) - r^2 = c^2(\psi) - c_0^2 + c_0^2 - r^2 = (\psi - \rho_0)p''(\overline{\rho}) + c_0^2 - r^2$, where $\overline{\rho}$ is a value in the range of ρ^ε. By assumption, p'' is bounded above and below by positive numbers for $\rho \in [\rho_0, \rho_M]$.

We have

$$
\begin{aligned}
&Q_1^\varepsilon(\rho^\varepsilon)\psi \\
&= \left(p''(\overline{\rho})\left\{A(c_0-r)^b + B(\theta_1-\theta)^2\right\} + (c_0+r)(c_0-r)+\varepsilon\right) b(b-1)A(c_0-r)^{b-2} \\
&\qquad + \frac{c^2(\rho^\varepsilon)}{r^2}(2B) + p''(\rho^\varepsilon)\left\{\left(Ab(c_0-r)^{b-1}\right)^2 + \frac{1}{r^2}\left(2B(\theta_1-\theta)\right)^2\right\} \\
&\qquad + \left(\frac{c^2(\rho^\varepsilon)}{r} - 2r\right) Ab(c_0-r)^{b-1}.
\end{aligned}
$$

The coefficient of $(c_0-r)^{b-2}$, the most singular term as $r \to c_0$, is

$$p''(\overline{\rho})(B(\theta_1-\theta)^2+\varepsilon)b(b-1)A < 0.$$

The next most singular power is $(c_0-r)^{2b-2}$, and its coefficient is

$$A^2 b\left(p''(\overline{\rho})(b-1) + p''(\rho)b\right) \le A^2 k_0 < 0 \qquad \text{if} \qquad b < \frac{\min p''}{2\max p''}, \tag{4.3}$$

which we now assume. The next power is $(c_0-r)^{b-1}$, whose coefficient is a bounded multiple of A; the remaining terms are bounded and involve only powers of B. Once we have fixed the lower limit, c_0-h, for r, and have chosen B, we can then choose A, which appears quadratically in (4.3) with a negative coefficient, large enough to make the entire expression negative. This is sufficient to guarantee that $\psi-\rho^\varepsilon$ does not have a negative minimum in the interior of $\Omega(h,a)$ provided that $\psi-\rho^\varepsilon$ is nonnegative on the boundary of $\Omega(h,a)$. For at a negative interior minimum, $\nabla\psi = \nabla\rho^\varepsilon$, and

$$
\begin{aligned}
0 &\ge Q_1^\varepsilon(\rho^\varepsilon)\psi - Q^\varepsilon(\rho^\varepsilon) \\
&> \left(c^2(\psi)-c^2(\rho^\varepsilon)\right)\psi_{rr} + \left(c^2(\rho^\varepsilon)-r^2+\varepsilon\right)(\psi-\rho)_{rr} + \frac{c^2(\rho^\varepsilon)}{r^2}(\psi-\rho)_{\theta\theta}.
\end{aligned} \tag{4.4}
$$

However, $\psi < \rho^\varepsilon$ implies $c^2(\psi)-c^2(\rho) < 0$, while $\psi_{rr} < 0$ by the concavity of ψ in r; in addition $(\psi-\rho)_{rr}$ and $(\psi-\rho)_{\theta\theta}$ are nonnegative at the minimum, so the sum of the three terms is positive. This contradiction establishes the conclusion that if $\psi \ge \rho^\varepsilon$ on the boundary of $\Omega(h,a)$, then ψ is an upper barrier for each ρ^ε.

We now turn to establishing bounds for ψ on the sides of the quadrilateral. First, on σ: $\rho^\varepsilon = \rho_0 < \psi$. We fix an angular interval by choosing some $a > 0$; then we can choose B large enough that $Ba^2 > \rho_M$. This gives $\psi > \rho^\varepsilon$ on the boundary $\theta = \theta_1 - a$ of $\Omega(h,a)$.

The appropriate condition on the oblique derivative boundary is more delicate. We linearize the boundary condition, obtain an estimate of the form $N_1(\rho^\varepsilon)\psi \le 0$, and use the Hopf maximum principle to show that $\psi-\rho^\varepsilon$ is positive on Σ^ε. Getting the estimate $N_1(\rho^\varepsilon)\psi \le 0$ is rendered difficult by the fact that the part of $\nabla\psi$ which becomes singular near Ξ_0 is not the normal derivative (over which we have some control because the problem is oblique near Ξ_0) but the derivative in the direction r.

We can obtain the bound we need, at least as long as κ_a is large enough. To see this, we compute the derivative of ψ along Σ^ε, using the linearized operator $N_1(\rho^\varepsilon) = \beta(\rho^\varepsilon)\cdot\nabla$. To focus on the singular part, we write $\beta(\rho^\varepsilon)\cdot\nabla$ in terms of its radial and angular components,

$$N_1\psi = \beta^r\psi_r + \beta^\theta\psi_\theta,$$

where

$$\beta^r = \beta \cdot (\cos\theta, \sin\theta) = \frac{1}{r}(\beta_1\xi + \beta_2\eta),$$

and we have an analogous expression for β^θ. Now a calculation gives

$$\beta_1\xi + \beta_2\eta = (\eta - \eta'\xi)(\xi + \eta'\eta)\big(r^2(c^2 + 3s^2) - 4c^2s^2\big). \tag{4.5}$$

The first two factors are uniformly positive near Ξ_0, and if ρ_M is sufficiently close to ρ_0, then we claim there exists an interval $[c_0 - h, c_0]$ in which $\beta_1\xi + \beta_2\eta$ has a positive lower bound, for there will be a value $h > 0$ such that the expression in (4.5) is positive for $r > c_0 - h$ as long as $4c^2s^2/(c^2 + 3s^2) < c_0^2$ for all values in the range of ρ. Since the left side of this expression is monotone increasing in ρ, it is sufficient to impose the restriction on $c^2(\rho_M)$ and $s^2(\rho_M)$. The condition obviously holds for $\rho = \rho_0$, and so it certainly holds for ρ_M sufficiently close to ρ_0. Furthermore, for large κ_a, $\rho_M = \rho_0 + \mathcal{O}(1/\kappa_a)$, by a calculation given in [17]. That is, for κ_a large enough we have $\beta_1\xi + \beta_2\eta \geq C > 0$ in (4.5). Estimates on κ_* are given in [17].

We now complete the calculation of

$$N_1(\rho^\varepsilon)\psi = -\beta^r A(c_0 - r)^{b-1} - 2\beta^\theta B(\theta_1 - \theta)$$

by choosing A large enough that $N_1\psi \leq 0$ on Σ^ε. We also ensure $\psi - \rho^\varepsilon > 0$ at $r = c_0 - h$, by increasing A again if necessary, so that $Ah^b > \rho_M$.

Finally, we confirm that the inequality $N_1(\rho^\varepsilon)\psi < 0$ precludes negative values of $\psi - \rho^\varepsilon$ on Σ^ε. If there are negative values, then there is a negative minimum, at which the tangential derivative of $\psi - \rho^\varepsilon$ vanishes, so we have

$$0 \geq N_1(\psi - \rho^\varepsilon) = \beta^t(\psi - \rho^\varepsilon)_t + \beta^n(\psi - \rho^\varepsilon)_n = \beta^n(\psi - \rho^\varepsilon)_n,$$

where the superscripts mark the tangential and (inward) normal components of β, and the subscripts the derivatives of $\psi - \rho^\varepsilon$. Since $\beta^n > 0$, this implies that $(\psi - \rho^\varepsilon)_n \leq 0$. However, we can write $\overline{L}(\psi - \rho^\varepsilon) \leq 0$ at such a point for a suitable linear operator $\overline{L}$, and thus the Hopf maximum principle requires that $(\psi - \rho^\varepsilon)_n > 0$, a contradiction. Thus we conclude that $\psi - \rho^\varepsilon \geq 0$ on the entire boundary of $\Omega(h, a)$. By the argument following the inequality (4.4), this establishes ψ as an upper barrier. We note that this construction depends on ε only through the location of the curve $\Sigma = \Sigma^\varepsilon$ and that A, B, b, h, and a are independent of ε. Thus, since the domains Ω^ε converge, it follows that ψ is a barrier for all ρ^ε for sufficiently small ε.

Thus the solution ρ is continuous up to the degenerate boundary. ∎

Continuity of ρ at Ξ_0 allows a strengthening of Lemma 4.4, as follows.

COROLLARY 4.6. *The free boundary η is smooth up to the degenerate boundary, namely, $\eta \in C^1[0, \xi_0]$.*

Proof of Theorem 2.3. Lemmas 4.2, 4.3, 4.4, and 4.5 show that there exists a solution pair $(\rho, \eta) \in C^{2+\alpha'}(\overline{\Omega} \setminus \{\sigma \cup \Xi_s\}) \cap C(\overline{\Omega}) \times C^{2+\alpha'}(0, \xi_0)$ satisfying (2.36), (2.37), (2.38), (2.39), and (2.40). This completes the proof of Theorem 2.3. ∎

5. Conclusions. Theorem 2.3 has constructed a solution ρ of the differential equation (2.36) in Ω; combining this function with the piecewise constant solution far from the origin, we obtain a function which is piecewise constant in the supersonic region, continuous across the degenerate boundary σ, and consistent with the derived form of the Rankine–Hugoniot conditions across the Mach stem. To recover the momentum components, m and n, we could in principle integrate equations (2.4) and (2.5), which can be written as transport equations in the radial variable r,

$$\frac{\partial m}{\partial r} = \frac{1}{r} c^2(\rho)\rho_\xi, \qquad \frac{\partial n}{\partial r} = \frac{1}{r} c^2(\rho)\rho_\eta, \tag{5.1}$$

and integrated from the boundary of the subsonic region toward the origin. We note that the sonic boundary can be written $r = r_0(\theta)$ and the boundary conditions for m and n are of the form $m(r_0(\theta), \theta) = m_0(\theta)$, where m_0 is piecewise continuous on σ and is determined from the Rankine–Hugoniot relation (2.15) on Σ; the component n is treated exactly the same way.

At σ and at Ξ_s, where we have proved only that ρ is continuous, equations (5.1), may not be meaningful. Elsewhere, m and n have the same regularity as ρ, except that discontinuities in m and n on the line $\xi = \kappa_a \eta$ may persist all the way in to the origin. In addition, the behavior of $c^2\rho_\eta/r$ in (5.1) at the origin causes a logarithmic singularity in n (but not in m: $c^2\rho_\xi/r$ remains bounded since $\rho_\xi(0, 0) = 0$).

Remark. There is some evidence of the unbounded behavior near the origin in the numerical simulations in [17]. This may presage difficulties in extending these results to the gas dynamics equations.

We argue heuristically that there is a difficulty at σ. Because of the construction, (ρ, m, n) is a weak solution of the system (1.1), or equivalently of the self-similar form (2.3)–(2.5), except possibly at the sonic boundary. It can be checked that the system (1.1) and the second-order equation (2.6), $Q(\rho) = 0$, are equivalent for weak solutions (that is, they conserve the same quantities). We can write (2.6) in the form $\mathrm{div}A = S$, with

$$A = (p_\xi - \xi^2\rho_\xi - \xi\eta\rho_\eta + \xi\rho, p_\eta - \eta^2\rho_\eta - \xi\eta\rho_\xi + \eta\rho),$$

and $S = -2\rho$. The usual multiplication by a smooth test function ϕ supported on a compact set D containing a segment of the degenerate boundary σ, followed by integration by parts, gives the weak form of the equation which must be satisfied for any weak solution in which $\nabla\rho$ is integrable (as is the case for our constructed function). Integrating by parts in the opposite sense on each side of $\Gamma \equiv \sigma \cap D$ yields the condition

$$\int_\Gamma \phi[A \cdot \nu]\, ds = 0,$$

where $[\ \ ]$ denotes the jump in the quantity and ν is the normal to σ. Since this must hold for all choices of D and ϕ, it holds pointwise. Furthermore, since the normal direction is the radial direction at σ, this means we need the function ρ inside Ω to satisfy

$$\lim_{r \to r_0} r\big(c^2(\rho) - r_0^2\big)\rho_r = 0. \tag{5.2}$$

We observe that for a linear wave equation, c^2 is constant and $r_0 = c$, and so this equation holds. However, for the function we constructed in Theorem 2.3 we have only the estimate $\rho - \rho_0 < A(r_0 - r)^\beta$ with $\beta < 1/2$ (see Lemma 4.5 and [7]) and this is not strong enough to give the limit (5.2). In fact, we have calculated, in [2] and [5], that the the behavior of solutions near a degenerate boundary like σ is exactly a square root singularity ($\beta = 1/2$), and so the function we have constructed fails to give a weak solution in the neighborhood of σ.

Acknowledgment. We would like to recognize the careful reading of an earlier version of the paper by the referees, whose efforts have improved the results.

CONVERGENCE OF AN ALGORITHM FOR THE ANISOTROPIC AND CRYSTALLINE MEAN CURVATURE FLOW*

ANTONIN CHAMBOLLE† AND MATTEO NOVAGA‡

Abstract. We give a simple proof of convergence of the anisotropic variant of a well-known algorithm for mean curvature motion, introduced in 1992 by Merriman, Bence, and Osher. The algorithm consists in alternating the resolution of the (anisotropic) heat equation, with initial datum the characteristic function of the evolving set, and a thresholding at level 1/2.

Key words. anisotropic mean curvature flow, heat equation, signed distance function

DOI. 10.1137/050629641

1. Introduction: The algorithm.

More than ten years ago, Merriman, Bence, and Osher [26] proposed the following algorithm for the computation of the motion by mean curvature of a surface. Given a closed set $E \subset \mathbb{R}^N$, they let $T_h E = \{u(\cdot, h) \geq 1/2\}$, where u solves the following heat equation:

$$\left\{ \begin{array}{rcll} \dfrac{\partial u}{\partial t}(x,t) & = & \Delta u(x,t)\,, & t > 0,\ x \in \mathbb{R}^N\,, \\ u(\cdot, 0) & = & \chi_E & (t = 0)\,. \end{array} \right. \tag{1}$$

Then, they let $E_h(t) = T_h^{[t/h]} E$ (with $[t/h]$ the integer part of t/h), and conjectured that $\partial E_h(t)$ converges to $\partial E(t)$, as $h \to 0$, where $\partial E(t)$ is the (generalized) evolution by mean curvature starting from ∂E.

The proof of convergence of this scheme was established by Evans [17] and Barles and Georgelin [2]. Other proofs were given by Ishii [22] and Cao [12], where the evolution in (1) was replaced by the convolution of χ_E with a more general symmetric kernel. This was generalized by Ishii, Pires, and Souganidis [23] to the case of the convolution with an arbitrary kernel (with some growth assumptions). This approach was also studied by Ruuth and Merriman [29] (see also [28]). Vivier [34] and Leoni [25] have considered other generalizations with (1) replaced with a time and space dependent anisotropic heat equation with a lower order term. The space dependence is an additional difficulty and it is not clear how what we will present could be adapted to such situations; on the other hand, in the two latter papers, "only" the case of Riemannian anisotropies is considered, in contrast to what we will study here.

We propose here to study the generalization of this algorithm to the so-called *anisotropic* and *crystalline curvature motion*, as defined in [21, 33, 32, 31]. We follow the definition in [10]: we consider (ϕ, ϕ°) a pair of mutually polar convex 1-homogeneous functions in $\mathbb{R}^N$ (i.e., $\phi^\circ(\xi) = \sup_{\phi(\eta)\leq 1} \xi \cdot \eta$, $\phi(\eta) = \sup_{\phi^\circ(\xi)\leq 1} \xi \cdot \eta$; see [27]). These are assumed to be locally finite, and, to simplify, even. The pair

(ϕ,ϕ°) will be referred as *the anisotropy.* The local finiteness implies that there is a constant $c>1$ such that

$$c^{-1}|\eta| \le \phi(\eta) \le c|\eta| \quad\text{and}\quad c^{-1}|\xi| \le \phi^\circ(\xi) \le c|\xi|$$

for any η and ξ in $\mathbb{R}^N$. We refer to [9, 10] for the main properties of ϕ and ϕ°.

Being convex and 1-homogeneous, ϕ° (and ϕ) is also subadditive, so that the function $(x,y)\mapsto\phi(x-y)$ defines a distance—the "ϕ-distance." For $E\subset\mathbb{R}^N$ and $x\in\mathbb{R}^N$, we denote by $\mathrm{dist}^\phi(x,E) := \inf_{y\in E}\phi(x-y)$ the ϕ-distance of x to the set E, and by

$$d_E^\phi(x) \;:=\; \mathrm{dist}^\phi(x,E) \,-\, \mathrm{dist}^\phi(x,\mathbb{R}^N\setminus E)$$

the signed ϕ-distance to ∂E, negative in the interior of E and positive outside its closure. One easily checks that

$$|d_E^\phi(x)-d_E^\phi(y)| \;\le\; \phi(x-y) \;\le\; c|x-y|$$

for any $x,y\in\mathbb{R}^N$, so that d_E^ϕ is differentiable a.e. in $\mathbb{R}^N$. The former inequality shows moreover that $\nabla d_E^\phi(x)\cdot h \le \phi(h)$ for any $h\in\mathbb{R}^N$ if x is a point of differentiability; hence $\phi^\circ(\nabla d_E^\phi(x))\le 1$. If ϕ and ϕ° are smooth, one shows quite easily that d_E^ϕ is differentiable at each point x which has a unique ϕ-projection $y\in\partial E$ (solving $\min_{y\in\partial E}\phi(x-y)$). In this case, $\nabla d_E^\phi(x)$ is given by $\nabla\phi((x-y)/d_E^\phi(x))$, so that $\phi^\circ(\nabla d_E^\phi(x))=1$. If ϕ, ϕ° are just Lipschitz-continuous, one still shows that $\phi^\circ(\nabla d_E^\phi(x))=1$ a.e. in $\mathbb{R}^N$; see [9, 10] for details.

A *Cahn–Hoffman* vector field n_ϕ is a vector field on ∂E such that $n_\phi(x)\in\partial\phi^\circ(\nu_E(x))=\partial\phi^\circ(\nabla d_E^\phi(x))$ a.e. on ∂E, where $\partial\phi^\circ$ is the (0-homogeneous) subgradient of ϕ° (see [27, 16]) and ν_E is the (Euclidean) exterior normal to ∂E. If such a field is given in a neighborhood of ∂E, then it is characterized by

$$\phi^\circ(n_\phi(x)) \;=\; 1 \quad\text{and}\quad n_\phi(x)\cdot\nabla d_E^\phi(x)=1 \quad\text{a.e.}$$

This follows from Euler's identity, since ϕ° is 1-homogeneous. In this case, $\kappa_\phi=\operatorname{div} n_\phi$ is a *ϕ-curvature* of ∂E. The ϕ-curvature flow is then an evolution $E(t)$ such that at each time, the velocity of $\partial E(t)$ is given by

$$V \;=\; -\kappa_\phi\, n_\phi\,, \tag{2}$$

where n_ϕ is a Cahn–Hoffman vector field and κ_ϕ is the associated curvature. If ϕ,ϕ° are smooth (e.g., in $C^2(\Omega\setminus\{0\})$), then n_ϕ,κ_ϕ are uniquely defined, whereas if ϕ, ϕ° are merely Lipschitz (when, for instance, the *Wulff shape* $\{\phi\le 1\}$ is a convex polytope), then n_ϕ can be nonunique and the anisotropy is called *crystalline* [33, 9].

As easily shown by formal asymptotic expansion, the natural anisotropic generalization of the Merriman–Bence–Osher algorithm is as follows. Given E a closed set with compact boundary in $\mathbb{R}^N$, we let $T_h(E)=\{x : u(x,h)\ge 1/2\}$, where $u(x,t)$ is the solution of

$$\begin{cases} \dfrac{\partial u}{\partial t}(x,t) \;\in\; \operatorname{div}\Big(\phi^\circ(\nabla u)\partial\phi^\circ(\nabla u)\Big)(x,t)\,, & t>0,\ x\in\mathbb{R}^N\,,\\ u(\cdot,0) \;=\; \chi_E & (t=0)\,. \end{cases} \tag{3}$$

The function $u(x,t)$ is well defined and unique by classical results on contraction semigroups [11]: if E is compact, it corresponds to the flow in $L^2(\mathbb{R}^N)$ of the subdifferential of the functional $u \mapsto \int_{\mathbb{R}^N} \phi^\circ(\nabla u)^2/2\,dx$ if $u \in H^1(\mathbb{R}^N)$, and $+\infty$ otherwise. On the other hand, if $\mathbb{R}^N \setminus E$ is compact, one defines u by simply letting $u = 1 + v$, where v solves the same equation with initial data $\chi_E - 1$.

We are interested in the limit of the discrete evolutions $t \mapsto E_h(t) = T_h^{[t/h]}E$, as $h \to 0$. Our main result is a result of consistency with suitable "regular" evolutions: it states that if there exists a regular evolution starting from E in the sense of our Definition 2.1 (which is a variant of a definition first introduced in [9] and includes smooth evolutions when the anisotropy is smooth), then $E_h(t)$ converges to this evolution. This consistency result, together with the monotonicity of the scheme ($E \subseteq F \Rightarrow T_hE \subseteq T_hF$, as follows from the comparison principle for (3)), yields convergence also to all generalized solutions defined (in the smooth case) using barriers [7, 8] or, equivalently, viscosity solutions [14, 15, 4, 5, 3], as long as these are unique. Also, it yields the convergence of the scheme to crystalline evolutions, when the initial set is convex. Existence and uniqueness of such (regular and generalized) evolutions are established, in the convex case, in [6].

Another important consequence of our consistency result is a comparision principle for the regular evolutions of Definition 2.1, which follows from the monotonicity of the scheme. It gives an alternative proof of uniqueness for the convex crystalline evolutions studied in [6] (the original proof is based on [9]).

We observe that evolutions similar to (2) might also be obtained by convolution with appropriate kernels as studied by Ishii, Pires, and Souganidis [23]. However, a complete characterization of these motions in dimension higher than 2 is still not known (see [29, 30] in two dimensions).

Our evolution is also different from the evolutions considered by Leoni [25] (or Vivier [34]); in her paper, the heat equation (1) is replaced with an equation of the form $u_t = A(x,t) : D^2u + H(x,t,Du)$. The resulting surface motion is a variant of the mean curvature motion, with an (x,t) dependent velocity which is a function of a Riemannian curvature (depending on A) plus a lower order forcing term.

It would be interesting to prove a similar consistency result for the variational variant of (3), which is somehow simpler to solve numerically (in the truly nonlinear anisotropic cases): for $E \subset \mathbb{R}^N$ bounded, one would define $T_hE = \{u_h \geq 1/2\}$, where u_h is the solution of (with $\Omega \Supset E$ bounded or $\Omega = \mathbb{R}^N$)

$$\min_{u \in H^1(\Omega)} \int_\Omega \phi^\circ(\nabla u(x))^2 \,+\, \frac{1}{h}(u(x) - \chi_E(x))^2\,dx\,. \tag{4}$$

Although it is likely that this variant produces the same evolution as the original scheme (it is true in the isotropic case, since u_h is given by the convolution of χ_E with a radially symmetric kernel), we could not extend our proof in all cases to this new scheme.

Our proof follows the same idea as our recent proof of consistency [13] for (a generalization of) the variational algorithm of Almgren, Taylor, and Wang [1]. However, we have just learned that Goto, Ishii, and Ogawa [20, 24] have recently given a new proof of the convergence of the Merriman–Bence–Osher algorithm, in the isotropic case, which is very similar to the proof we give here.

2. The consistency result and some consequences. If $E \subset \mathbb{R}^N$ we say that E satisfies the interior rW_ϕ-condition if and only if for any $x \in \partial E$ there exist $y \in E$

with $\phi(x-y) = r$ and $\phi(x'-y) \geq r$ for any $x' \in \mathbb{R}^N \setminus E$. We say that E satisfies the exterior rW_ϕ-condition if $\mathbb{R}^N \setminus E$ satisfies the interior rW_ϕ-condition.

We will show a consistency result with regular evolutions of (2), in the sense of the following definition.

DEFINITION 2.1. *We say that $t \mapsto E(t)$ is an rW_ϕ-regular ϕ-curvature flow on $[t_0, t_1]$, $t_0 < t_1$, if and only if*

(i) *for any $t \in [t_0, t_1]$, $E(t)$ satisfies the interior and exterior rW_ϕ-conditions;*

(ii) *there exists a bounded and relatively open neighborhood A of $\bigcup_{t_0 \leq t \leq t_1} \partial E(t) \times \{t\}$ in $\mathbb{R}^N \times [t_0, t_1]$ such that $d(x,t) := d^\phi_{E(t)}(x)$ is Lipschitz in A;*

(iii) *there exists a vector field $n : A \to \mathbb{R}^N$ with $n \in \partial\phi^\circ(\nabla d)$ a.e. in A, and $\operatorname{div} n \in L^\infty(A)$; and*

(iv) *there exists $\overline{c} > 0$ such that $|\partial d/\partial t - \operatorname{div} n| \leq \overline{c}|d|$ a.e. in A.*

This definition, up to the additional requirement that $E(t)$ satisfies an interior and exterior rW_ϕ-condition, is due to Bellettini and Novaga [9, Def. 2.2].

Such evolutions are known to exist if ϕ, ϕ°, and ∂E are smooth enough (for instance, in $C^{3,\alpha}(\mathbb{R}^N \setminus \{0\})$ [1]), or for any ϕ, ϕ°, when the initial set E is convex and satisfies an interior rW_ϕ-condition (exterior is always true in the case of convex sets) [6]. They also exist in the purely crystalline case, i.e., when both ϕ and ϕ° are piecewise linear in dimension $N = 2$ [18, 19, 31] (see section 4 for an example).

Our main theorem states that the anisotropic Merriman–Bence–Osher scheme is consistent with such evolutions.

THEOREM 2.2. *Let E be a regular flow in the sense of Definition* 2.1*, on a time interval* $[t_0, t_1]$*. Then, for any t and τ with $t_0 \leq t < t + \tau \leq t_1$, $\partial T_h^{[\tau/h]} E(t)$ converges to $\partial E(t+\tau)$ in the Hausdorff sense, as $h \to 0$.*

The following corollary, also shown in [9], is obvious.

COROLLARY 2.3. *Let E, F be two flows in the sense of Definition* 2.1*, on* $[t_0, t_1]$*, and assume $E(t_0) \subseteq F(t_0)$. Then $E(t) \subseteq F(t)$ for all $t \in [t_0, t_1]$. In particular, if $E(t_0) = F(t_0)$, then $E(t) = F(t)$ for all $t \in [t_0, t_1]$.*

The next corollary follows, with a standard proof (see [4, 5]), from the monotonicity and consistency of the scheme.

COROLLARY 2.4. *Assume $E \subset \mathbb{R}^N$ is a closed set with compact boundary such that the generalized ϕ-curvature flow $E(t)$, starting from E, is uniquely defined on a time interval $[0, T)$ (e.g., ϕ, $\phi^\circ \in C^2(\mathbb{R}^N \setminus \{0\})$, and no fattening occurs* [14]*). Then $\partial T_h^{[t/h]} E(t) \to \partial E(t)$ in the Hausdorff sense for any $t < T$, as $h \to 0$. The same conclusion holds for any ϕ, ϕ° if E is convex, by the uniqueness result in* [6].

Let us observe that this result follows easily from Theorem 2.2 when evolutions according to Definition 2.1 are known to exist. If not (e.g., if ϕ, ϕ° are merely C^2), this is still true; however, the proof relies on a comparison with appropriate strict super- and subsolutions, defined according to obvious modifications of Definition 2.1 (as in [13]).

Remark 1. In case ϕ, ϕ° are not even, Theorem 2.2 still holds, but (i) the signed distance to the interface $d^\phi_{E(t)}(x)$ must be defined, in Definition 2.1, in a nonsymmetric way, and (ii) the term $\partial\phi^\circ(\nabla u)$ in (3) must be replaced with $-\partial\phi^\circ(-\nabla u)$ (since ∇u has a reverse orientation with respect to the outer normal to the set E).

3. Proof of Theorem 2.2. The proof of Theorem 2.2 is divided into several steps. The idea is to build appropriate sub- and supersolutions to (3), by means of the function $d(x,t)$, and to compare $T_h E(t)$ with $E(t+h)$.

These barriers will be built by means of the function $\gamma : \mathbb{R} \times [0,+\infty) \to [0,1]$, which solves the heat equation

$$\begin{cases} \dfrac{\partial\gamma}{\partial\tau}(\xi,\tau) \;=\; \dfrac{\partial^2\gamma}{\partial\xi^2}(\xi,\tau)\,, & \xi\in\mathbb{R}\,,\ \tau>0\,,\\ \gamma(\xi,0)=Y(\xi)\,, & \xi\in\mathbb{R}\ \ (\tau=0)\,, \end{cases} \tag{5}$$

where $Y = \chi_{[0,+\infty)}$ is the Heaviside function. It is well known that γ is given by

$$\gamma(\xi,\tau) \;=\; \frac{1}{2\sqrt{\pi\tau}}\int_{-\infty}^{\xi} e^{-\frac{s^2}{4\tau}}\,ds\,.$$

In particular, one readily sees that it is self-similar: indeed, the change of variables $s' = s/\sqrt{\tau}$ yields

$$\gamma(\xi,\tau) \;=\; \frac{1}{2\sqrt{\pi}}\int_{-\infty}^{\frac{\xi}{\sqrt{\tau}}} e^{-\frac{s'^2}{4}}\,ds' \;=\; \gamma\left(\frac{\xi}{\sqrt{\tau}},1\right) \;=:\; \gamma_1\left(\frac{\xi}{\sqrt{\tau}}\right)\,.$$

We first show the following (obvious) result.

LEMMA 3.1. *For any $\varepsilon>0$, there exists $\tau_0>0$ such that if $0\le\tau\le\tau_0$, then $\gamma(\varepsilon,\tau)\ge 1-\tau$.*

Proof. We just need to observe that $\tau\mapsto\gamma(\varepsilon,\tau)$ is C^1 with derivative 0 at 0. This derivative is indeed given by $(-\varepsilon/\tau^{3/2})\gamma_1'(\varepsilon/\sqrt{\tau}) = (-\varepsilon/\tau^{3/2})\exp(-\varepsilon^2/(4\tau))$. There exists τ_0 such that it is in $[-1,0]$ for $\tau\le\tau_0$; hence $\gamma(\varepsilon,\tau)\ge\gamma(\varepsilon,0)-\tau$ if $\tau\in[0,\tau_0]$, which shows the lemma. $\square$

Let us now consider E, $r>0$, $t_0\le t_1$, A, and the functions $d(x,t)$, $n(x,t)$, as in Definition 2.1. Possibly reducing r, we can assume that $\{|d|\le r\}\subset A$. Let us fix $t\in[t_0,t_1)$, $\delta\in[0,r/2]$ and let $F=\{d(\cdot,t)\le\delta\}$. Let u be the solution of

$$\begin{cases} \dfrac{\partial u}{\partial\tau}(x,\tau) \;\in\; \operatorname{div}\Big(\phi^\circ(\nabla u)\partial\phi^\circ(\nabla u)\Big)(x,\tau)\,, & \tau>0,\ x\in\mathbb{R}^N\,,\\ u(\cdot,0) \;=\; \chi_F \;=\; Y(-d(\cdot,t)+\delta) & (\tau=0)\,. \end{cases} \tag{6}$$

We first show the following result.

LEMMA 3.2. *For any $\varepsilon\in(0,r/2)$, there exists $\tau_0>0$ (independent of δ) such that $\tau\le\tau_0$ yields $u(x,\tau)\le\tau$ for any x such that $d(x,t)-\delta=\varepsilon$.*

Proof. Let us fix $x_0\in\mathbb{R}^N\setminus F$ with $d(x_0,t)-\delta=\varepsilon$. Since $E(t)$ satisfies the exterior rW_ϕ-condition, the function $(d(\cdot,t)-\delta)$ is, outside F, equal to $\operatorname{dist}^\phi(\cdot,F)$. Hence, letting $W=\{x : \phi(x-x_0)<\varepsilon\}$, one sees that $W\cap F=\emptyset$. We deduce that $\chi_F\le 1-\chi_W$ in $\mathbb{R}^N$, so that $u(\cdot,\tau)\le 1-w(\cdot,\tau)$, where w is the solution of

$$\begin{cases} \dfrac{\partial w}{\partial\tau}(x,\tau) \;\in\; \operatorname{div}\Big(\phi^\circ(\nabla w)\partial\phi^\circ(\nabla w)\Big)(x,\tau)\,, & \tau>0,\ x\in\mathbb{R}^N\,,\\ w(\cdot,0) \;=\; \chi_W & (\tau=0)\,. \end{cases}$$

This solution is explicitly given by $w(x,\tau)=U(\phi(x-x_0)/\varepsilon,\tau/\varepsilon^2)$, where $U(|x|,\tau)=\tilde U(x,\tau)$ and $\tilde U$ is the (radial) solution of the heat equation $\partial\tilde U/\partial t=\Delta\tilde U$ with initial datum χ_{B_1}, the characteristic function of the unit ball in $\mathbb{R}^N$. It is well known that

$$\tilde U(x,\tau)=\frac{1}{\sqrt{4\pi\tau}^N}\int_{\{|y|\le 1\}}\exp\left(-\frac{|x-y|^2}{4\tau}\right)dy$$

so that

$$U(|x|,\tau) \;=\; \frac{1}{\sqrt{4\pi\tau}^N}\int_{\{|y|\le 1\}} \exp\left(-\frac{(|x|-y_1)^2+\sum_{i=2}^N y_i^2}{4\tau}\right)\,dy\,.$$

Using arguments similar to the proof of the previous lemma (based on the fact that U is smooth near $(\xi,\tau)=0,0$ and $\partial U/\partial t(0,0)=0$), one sees that there exists $\tau_0>0$ such that if $\tau\le\tau_0$, $U(0,\tau)\ge 1-\varepsilon^2\tau$; hence $w(0,\tau)\ge 1-\tau$ if $\tau\le\tau_0'=\varepsilon^2\tau_0$. We deduce that $u(x_0,\tau)\le\tau$ if $\tau\le\tau_0'$, depending only on ε. This shows the lemma. ◻

Let us fix $\varepsilon<r/4$ and let us look for a supersolution of (6) on a time interval $[0,h]$, h small, of the form

$$v(x,\tau) \;=\; \gamma\big(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau\big)+h\,,$$

in $B=\bigcup_{0\le\tau\le h}\{x\,:\,d(x,t)-\delta\le\varepsilon\,,d(x,t+\tau)-\delta\ge-\varepsilon\}\times\{\tau\}$, where the constant $\overline{\varepsilon}$ will be made precise later on. We observe that since the speed of the motion is bounded at any time for τ small enough, if h is small enough (depending only on r,ε), B remains inside $\{(x,\tau)\in\mathbb{R}^N\times[0,h]\,:\,\delta-\varepsilon\le d(x,t+\tau)\le\delta+2\varepsilon\}$, and $(0,t)+B\subset A$.

At $\tau=0$, $v(x,0)=Y(-d(x,t)+\delta)+h$ is strictly larger than $\chi_F(x)=u(x,0)$. If $0\le\tau\le h$ and $d(x,t)-\delta=\varepsilon$, by Lemma 3.2 we have $u(x,\tau)\le\tau\le h\le v(x,\tau)$, provided h is small enough. If, on the other hand, $d(x,t+\tau)-\delta=-\varepsilon$, then by Lemma 3.1, still for h small enough, $v(x,\tau)=\gamma(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau)+h\ge\gamma(\varepsilon,\tau)+h\ge 1-\tau+h$; hence $v(x,\tau)\ge 1\ge u(x,\tau)$. We find that $v\ge u$ on $\{(x,\tau)\in\partial B\,:\,\tau<h\}$, which is the parabolic boundary of B (and, in fact, our proof even shows that $v\ge u$ in a neighborhood of this boundary).

Hence, to get that v is a supersolution of (6) in B, one has to show that $\partial v/\partial\tau\ge\operatorname{div}Z$ for some field $Z\in\phi^\circ(\nabla v)\partial\phi^\circ(\nabla v)$ inside B.

One has, a.e. in B,

$$\text{(7)}\quad \frac{\partial v}{\partial\tau}(x,\tau) \;=\; \left(-\frac{\partial d}{\partial t}(x,t+\tau)+\overline{c}\,\overline{\varepsilon}\right)\frac{\partial\gamma}{\partial\xi}(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau) + \frac{\partial\gamma}{\partial\tau}(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau)\,,$$

whereas

$$\nabla v(x,\tau) \;=\; -\frac{\partial\gamma}{\partial\xi}(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau)\nabla d(x,t+\tau)\,.$$

Using the assumption that ϕ° is even, we see that $\phi^\circ(\nabla v)=\partial\gamma/\partial\xi$ (since $\phi^\circ(\nabla d)=1$ a.e. in $\mathbb{R}^N$) and that $\partial\phi^\circ(\nabla v)=-\partial\phi^\circ(\nabla d)$ (since $\partial\gamma/\partial\xi>0$ and $\partial\phi^\circ$ is 0-homogeneous and odd). Let now

$$Z(x,\tau) \;=\; -\frac{\partial\gamma}{\partial\xi}(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau)\,n(x,t+\tau) \;=\; \phi^\circ(\nabla v(x,\tau))(-n(x,t+\tau)).$$

Since (by assumption) $n(x,t+\tau)\in\partial\phi^\circ(\nabla d(x,t+\tau))=-\partial\phi^\circ(\nabla v(x,\tau))$ for a.e. x in $\mathbb{R}^N$ and any $\tau\in(0,h)$, one has $Z(x,\tau)\in\phi^\circ(\nabla v)\partial\phi^\circ(\nabla v)(x,\tau)$. Since ϕ° is 1-homogeneous, Euler's identity yields $\nabla d\cdot n=\phi^\circ(\nabla d)=1$ as soon as $n\in\partial\phi^\circ(\nabla d)$. We deduce

$$\begin{aligned}(8)\quad \operatorname{div} Z(x,\tau) \;&=\; -\operatorname{div}\left[\frac{\partial\gamma}{\partial\xi}(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau)n(x,t+\tau)\right]\\ &=\; \frac{\partial^2\gamma}{\partial\xi^2}(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau)\\ &\qquad -\;\frac{\partial\gamma}{\partial\xi}(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau)(\operatorname{div} n(x,t+\tau))\,.\end{aligned}$$

Since we have $\partial d/\partial t \le \operatorname{div} n + \overline{c}|d|$ in B, we deduce using (7) and (8) that

$$\begin{aligned}\frac{\partial v}{\partial\tau}(x,\tau) \;&\ge\; \operatorname{div} Z(x,\tau) \;-\; \frac{\partial^2\gamma}{\partial\xi^2}(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau)\\ &+\overline{c}(\overline{\varepsilon}-|d(x,t+\tau)|)\frac{\partial\gamma}{\partial\xi}(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau) \;+\; \frac{\partial\gamma}{\partial\tau}(-d(x,t+\tau)+\delta+\overline{c}\,\overline{\varepsilon}\tau,\tau)\,.\end{aligned}$$

Now, γ satisfies the heat equation, so that if $|d(x,t+\tau)| \le \overline{\varepsilon}$ a.e. in B, we get

$$(9)\qquad \frac{\partial v}{\partial\tau}(x,\tau) \;\ge\; \operatorname{div} Z(x,\tau)\,.$$

We choose $\overline{\varepsilon} = \delta + 2\varepsilon$ so that $|d(x,t+\tau)| \le \overline{\varepsilon}$ a.e. in B and (9) holds. By standard comparison results on parabolic equations (see [11]), we deduce that $v(x,h) \ge u(x,h)$. In particular, we have shown that there exists $h_0 > 0$ (depending only on r,ε) such that if $h < h_0$,

$$\begin{aligned}T_hF \;&=\; \left\{u(\cdot,h) \ge \frac{1}{2}\right\} \;\subset\; \left\{v(\cdot,h) \ge \frac{1}{2}\right\}\\ &=\; \left\{x\in\mathbb{R}^N \,:\, d(x,t+h) \le \delta + \overline{c}\,\overline{\varepsilon}h - [\gamma(\cdot,h)]^{-1}\left(\frac{1}{2}-h\right)\right\}.\end{aligned}$$

Since $\gamma_1(0) = 1/2$, $\gamma_1'(0) = 1/(2\sqrt{\pi})$, we have $\gamma_1^{-1}(1/2-h) = -2\sqrt{\pi}h + o(h)$. Now, $\gamma(\xi,h) = \gamma_1(\xi/\sqrt{h})$, so that $[\gamma(\cdot,h)]^{-1} = \sqrt{h}\gamma_1^{-1}$. We find that $[\gamma(\cdot,h)]^{-1}(1/2-h) = (-2\sqrt{\pi}h + o(h))\sqrt{h}$. Hence, possibly reducing h_0, one gets that if $h < h_0$, then $[\gamma(\cdot,h)]^{-1}(1/2-h) \ge -4h^{3/2}$. Recalling that $\overline{\varepsilon} = \delta+2\varepsilon$, we find that if $h<h_0$,

$$T_hF \;\subset\; \left\{x\in\mathbb{R}^N \,:\, d(x,t+h) \le [\delta + (\overline{c}(\delta+2\varepsilon)+4\sqrt{h})h]\right\}.$$

Now, we deduce that ($\varepsilon \in (0,r/4)$ being fixed) if $t \in [t_0,t_1)$, $h \le h_0$, and $k \ge 1$ with $t+kh \le t_1$, one has

$$T_h^k(E(t)) \;\subset\; \left\{x\in\mathbb{R}^N \,:\, d(x,t+kh) \le \delta_k\right\}$$

with $\delta_0 = 0$ and $\delta_k = \delta_{k-1} + (\overline{c}(\delta_{k-1}+2\varepsilon)+4\sqrt{h})h$, as long as $\delta_{k-1} \le r/2$. By induction, we find

$$\delta_k \;=\; \left((1+\overline{c}h)^k - 1\right)\left(2\varepsilon + \frac{4\sqrt{h}}{\overline{c}}\right).$$

In particular, if $\tau > 0$ is fixed, with $t+\tau \le t_1$, and $k = [\tau/h]$, we see that $\lim_{h\to 0}\delta_k = 2\varepsilon(e^{\overline{c}\tau}-1)$. If $\varepsilon < r/4$ is chosen small enough (less than $(r/4)/(e^{\overline{c}\tau}-1)$), we see that for $h>0$ small enough, $\delta_{[\tau/h]} \le r/2$.

We now recall that any sequence of sets in $\mathbb{R}^N$ with equibounded boundaries has a subsequence that converges in the Hausdorff sense to a closed set. If E' is the Hausdorff limit of a converging subsequence of $T_h^{[\tau/h]}E(t)$, as $h\to 0$, we deduce that $E' \subseteq \{d(\cdot,t+\tau) \le 2\varepsilon(e^{\overline{c}\tau}-1)\}$. Since this must be true for all $\varepsilon > 0$ small enough, one sees that $E' \subseteq E(t+\tau)$. On the other hand, a symmetric argument (based on subsolutions of the equation) will yield that if $\mathbb{R}^N \setminus E''$ is the Hausdorff limit of a converging subsequence of $(\mathbb{R}^N \setminus T_h^{[\tau/h]}E(t))_{h>0}$, then $\mathbb{R}^N \setminus E'' \subseteq \overline{\mathbb{R}^N \setminus E(t+\tau)}$; that is, $\mathrm{int}(E(t+\tau)) \subseteq E''$. Without loss of generality, one can choose the same subsequence in both limits above: in this case, one can show that $E'' \subset E'$, and $E' \setminus E''$ is the Hausdorff limit of $\partial T_h^{[\tau/h]}E(t)$ (which might differ from $\partial E'$ or $\partial E''$). Since $\mathrm{int}(E(t+\tau)) \subseteq E'' \subset E' \subseteq E(t+\tau)$, we see that $E'' = \mathrm{int}(E(t+\tau))$, $E' = E(t+\tau)$, $E' \setminus E'' = \partial E(t+\tau)$, and by uniqueness of this Hausdorff limit we deduce Theorem 2.2. $\square$

4. A numerical example. The algorithm is quite easy to implement numerically. Of course, there is some difficulty in computing precisely the solution of (3) in strongly anisotropic or crystalline cases, especially when the subgradient $\partial\phi^\circ$ is multivalued. We experimented with an implicit method, based on iterative resolutions of the variational problem (4). More precisely, we approximate $u(\cdot,h)$ with $w_n(x)$, where $h = nh'$, n is a fixed (small) integer, $w_0 = \chi_E$, and for $i = 0,\dots,n-1$, w_{i+1} solves (in a domain Ω "large" with respect to E)

$$\min_{w\in H^1(\Omega)} \int_\Omega \phi^\circ(\nabla w(x))^2 + \frac{1}{h'}(w(x)-w_i(x))^2\,dx\,.$$

To solve this minimization problem in the crystalline case, we discretize (here, on a bidimensional finite differences grid) and solve the dual problem (see, for instance, [16])

$$\min_{\xi\in L^2(\Omega;\mathbb{R}^N)} \int_\Omega \phi(\xi(x))^2 + h'((w_i(x)/h') - \mathrm{div}\,\xi(x))^2\,dx\,,$$

using a conjugate-gradient method. Then, $w_{i+1} = w_i - h'\mathrm{div}\,\xi$. The thresholding at level $1/2$ is replaced by a "soft thresholding" $w_n(x) \mapsto \min\{1, \max\{1/2 + \sigma(w_n(x) - 1/2), 0\}\}$, where σ is adapted to the spatial discretization step, in order to keep a precision slightly higher than the grid's. In the example shown in Figure 1, the Wulff shape $\{\phi \le 1\}$ is a hexagon.

DISSIPATIVE SYMMETRIZERS OF HYPERBOLIC PROBLEMS AND THEIR APPLICATIONS TO SHOCK WAVES AND CHARACTERISTIC DISCONTINUITIES*

YURI TRAKHININ†

Abstract. By introducing the notations of dissipative and strictly dissipative p-symmetrizers of initial-boundary-value problems for linear hyperbolic systems we formalize the dissipative integrals technique [A. Blokhin, Yu. Trakhinin, in *Handbook of Mathematical Fluid Dynamics*, Vol. 1, North-Holland, Amsterdam, 2002, pp. 545–652] applied earlier to shock waves and characteristic discontinuities for various concrete systems of conservation laws. This enables us to prove the local in time existence of shock-front solutions of an abstract symmetric system of hyperbolic conservation laws, provided that the corresponding constant coefficients linearized problem has a strictly dissipative p-symmetrizer. Our result does not, in particular, require the fulfillment of Majda's block structure condition. A p-symmetrizer is, in some sense, a "secondary" Friedrichs symmetrizer for the symmetric system for the vector of p-derivatives of unknown functions, and the structure of p-symmetrizer takes into account (if applicable) the set of divergent constraints for the original system. After applying a p-symmetrizer, which is in general a set of matrices and vectors, the boundary conditions for a resulting symmetric system are dissipative (or strictly dissipative). We give concrete examples of p-symmetrizers. Our main examples are strictly dissipative 2-symmetrizers for shock waves in gas dynamics and magnetohydrodynamics. A general procedure for constructing a p-symmetrizer does not however exist. But, if it was somehow constructed, then we do not need to test the Lopatinski condition that is often connected with insuperable technical difficulties. As an illustration, we refer to the author's recent result [Yu. Trakhinin, *Arch. Ration. Mech. Anal.*, 177 (2005), pp. 331–366] for compressible current-vortex sheets for which the construction of a dissipative 0-symmetrizer has first enabled the finding of sufficient conditions for their weak linearized stability.

Key words. symmetric hyperbolic systems, dissipative boundary conditions, multidimensional conservation laws, shock waves

1. Introduction: Initial-boundary-value problems for quasi-linear hyperbolic systems.

Consider a system of N *conservation laws*

$$\partial_t \boldsymbol{\mathcal{P}}^0(\mathbf{U}) + \sum_{j=1}^{n} \partial_j \boldsymbol{\mathcal{P}}^j(\mathbf{U}) = 0, \tag{1.1}$$

where $\boldsymbol{\mathcal{P}}^\alpha = \boldsymbol{\mathcal{P}}^\alpha(\mathbf{U}) = (\mathcal{P}_1^\alpha, \dots, \mathcal{P}_N^\alpha)$, $\mathbf{U} = \mathbf{U}(t, \mathbf{x}) = (u_1, \dots, u_N)$, $\mathbf{x} = (x_1, \dots, x_n) \in \mathbb{R}^n$, $\partial_t := \partial/\partial t$, $\partial_j := \partial/\partial x_j$. With the notation

$$\operatorname{div} \mathbf{a} := \sum_{j=1}^{n} \partial_j a^j \qquad (\mathbf{a} = \mathbf{a}(t, \mathbf{x}) = (a^1, \dots, a^n) \quad \text{is a vector})$$

system (1.1) in componentwise form reads

$$\partial_t \mathcal{P}_i^0(\mathbf{U}) + \operatorname{div} \boldsymbol{\mathcal{P}}_i(\mathbf{U}) = 0, \quad i = \overline{1, N},$$

where $\boldsymbol{\mathcal{P}}_i = \boldsymbol{\mathcal{P}}_i(\mathbf{U}) = (\mathcal{P}_i^1, \dots, \mathcal{P}_i^n)$. Assuming that the flux functions $\mathcal{P}_i^\alpha$ are smooth enough (in practice, they are usually C^∞), one can rewrite (1.1) as the quasi-linear system

$$B_0(\mathbf{U})\mathbf{U}_t + \sum_{j=1}^{n} B_j(\mathbf{U})\mathbf{U}_{x_j} = 0, \tag{1.2}$$

with $B_\alpha = (\partial \boldsymbol{\mathcal{P}}^\alpha / \partial \mathbf{U})$.

We will assume that system (1.1) may be supplemented (but not necessarily) by a set of K *divergent constraints*

$$\operatorname{div} \boldsymbol{\Psi}_j(\mathbf{U}) = 0, \quad j = \overline{1, K}, \tag{1.3}$$

where $\boldsymbol{\Psi}_j = \boldsymbol{\Psi}_j(\mathbf{U}) = (\Psi_j^1, \dots, \Psi_j^n)$. For example, for the system of gas dynamics one has no divergent constraints at all, whereas the system of magnetohydrodynamics (MHD) is supplemented by the sole ($K = 1$) divergent constraint $\operatorname{div} \mathbf{H} = 0$ (see, e.g., [28]). We also refer, for instance, to Landau's equations of superfluid [29] (see also [11]) which are supplemented by the tree divergent constrains $\nabla \times \mathbf{v}_{\mathrm{s}} = 0$ ($\mathbf{v}_{\mathrm{s}}$ is the superfluid velocity [29, 11]).

ASSUMPTION 1.1. *The divergent constraints* (1.3) *are the restrictions on the initial data for system* (1.1)*. That is, if* (1.3) *are satisfied initially, they hold for all* $t > 0$.

Remark 1.1. Assumption 1.1 is quite natural because it holds for all the physically relevant models: MHD, Landau's equations of superfluid, etc. (see, e.g., [11] for further examples). In practice, $(1.3)|_{t>0}$ is proved by applying the operator div to appropriate subsystems of (1.1) and taking into account $(1.3)|_{t=0}$. Of course, applying div requires $n \leq N$. The last assumption will be also made for other reasons (see section 3).

Sometimes, by an appropriate choice of the vector of unknowns $\mathbf{U}$ a concrete system of conservation laws can be written in the nonconservative form (1.2) with symmetric matrices B_α. For example, the systems of gas dynamics and MHD are written as symmetric systems for the vectors of unknowns $\mathbf{U} = (p, \mathbf{v}, S)$ and $\mathbf{U} = (p, \mathbf{v}, \mathbf{H}, S)$, respectively. At the same time, it is not always possible to guess an appropriate vector $\mathbf{U}$ for which a system of conservation laws, (1.1), can be rewritten as a symmetric quasi-linear system. But, as was first shown by Godunov [23, 24], system (1.1) can be always symmetrized if we know, a priori, an *additional* conservation law ("entropy" conservation)

$$\partial_t \Phi^0(\mathbf{U}) + \operatorname{div} \boldsymbol{\Phi}(\mathbf{U}) = 0,$$

with $\boldsymbol{\Phi} = \boldsymbol{\Phi}(\mathbf{U}) = (\Phi^1, \dots, \Phi^n)$, which holds on smooth solutions of (1.1). That is, one can find an invertible change of unknowns $\mathbf{U} \to \mathbf{Q}$ such that the system

$$A^0(\mathbf{Q})\mathbf{Q}_t + \sum_{j=1}^{n} A^j(\mathbf{Q})\mathbf{Q}_{x_j} = 0 \tag{1.4}$$

is symmetric: $A^\alpha = (A^\alpha)^*$, where

$$A^\alpha = \left(\frac{\partial \boldsymbol{\mathcal{P}}^\alpha}{\partial \mathbf{Q}} \right) = B_\alpha(\mathbf{U}(\mathbf{Q})) \left(\frac{\partial \mathbf{U}}{\partial \mathbf{Q}} \right),$$

i.e., $A^\alpha = B_\alpha J^{-1}$, with $J = J(\mathbf{Q}) = (\partial\mathbf{Q}/\partial\mathbf{U})$. It should be noted that if system (1.1) is accompanied by a set of divergent constraints (1.3), then these constrains should be generically taken into account under *Godunov's symmetrization*. For the process of symmetrization itself we refer to [13] and references therein (note that, in particular, $\mathbf{Q} = (\partial\Phi^0/\partial\boldsymbol{\mathcal{P}}^0)$).

It is worth noting that the symmetric system (1.4) can be rewritten as a quasi-linear system for the original vector of unknowns $\mathbf{U}$ that is again symmetric. Indeed, (1.4) clearly implies the system

$$A_0(\mathbf{U})\mathbf{U}_t + \sum_{j=1}^{n} A_j(\mathbf{U})\mathbf{U}_{x_j} = 0, \tag{1.5}$$

where the matrices $A_\alpha = A_\alpha(\mathbf{U}) := J^*A^\alpha J = J^*B_\alpha$ are symmetric. Thus, the matrix

$$S = S(\mathbf{U}) = J^* = \left(\frac{\partial\mathbf{Q}}{\partial\mathbf{U}}\right)^*$$

is the one (called *Friedrichs symmetrizer*) that symmetrizes system (1.2):

$$A_\alpha = SB_\alpha = A_\alpha^*.$$

Recall that the quasi-linear symmetric system (1.5) is *symmetric hyperbolic* in the sense of Friedrichs [22] if $A_0(\mathbf{U}) > 0$ (or $A_0(\mathbf{U}) < 0$ if we multiply (1.5) by -1).

The main requirement for the local in time well-posedness of the Cauchy problem for a quasi-linear system of conservation laws is the hyperbolicity condition that is easily verified for symmetric systems. The local existence theorem for the Cauchy problem for symmetric hyperbolic systems was independently proved by Vol'pert and Khudyaev [47], Lax [30], and Kato [26] (see also [34]). In contrast with the Cauchy problem, the conditions for well-posedness of initial-boundary-value problems for hyperbolic systems, in the generic case, cannot be easily found even for linearized problems with constant coefficients.

1.1. Standard boundary conditions. Let us first consider quasi-linear initial-boundary-value problems with standard boundary conditions [40]:

$$L(\mathbf{U})\mathbf{U} = 0 \quad \text{in } [0,T]\times\mathbb{R}^n_+, \tag{1.6a}$$

$$M(t,\mathbf{x}',\mathbf{U})\mathbf{U} = 0 \quad \text{on } [0,T]\times\{x_1 = 0\}\times\mathbb{R}^{n-1}, \tag{1.6b}$$

$$\mathbf{U}|_{t=0} = \mathbf{U}_0 \quad \text{in } \mathbb{R}^n_+, \tag{1.6c}$$

where $L = L(\mathbf{U}) = A_0(\mathbf{U})\partial_t + \sum_{j=1}^n A_j(\mathbf{U})\partial_j$, and system (1.6a) is supposed to be symmetric hyperbolic, and the matrix M is a $d\times N$ matrix. Here and below $\mathbb{R}^n_\pm = \{x_1 \gtrless 0,\ \mathbf{x}' \in \mathbb{R}^{n-1}\}$, $\mathbf{x}' = (x_2,\dots,x_n)$. Without loss of generality we consider the problem in a half-space because the case of a smooth bounded domain Ω is reduced, in some sense, to problem (1.6) by a finite partition of unity subordinated to an open covering of $\overline{\Omega}$.

To prove a local (in time) existence theorem for problem (1.6) we should consider the following linear problem associated to (1.6):

$$L(\widehat{\mathbf{U}})\mathbf{U} = \mathbf{f} \quad \text{in } [0,T]\times\mathbb{R}^n_+, \tag{1.7a}$$

$$M(t,\mathbf{x}',\widehat{\mathbf{U}})\mathbf{U} = \mathbf{g} \quad \text{on } [0,T]\times\{x_1 = 0\}\times\mathbb{R}^{n-1}, \tag{1.7b}$$

$$\mathbf{U}|_{t=0} = \mathbf{U}_0 \quad \text{in } \mathbb{R}^n_+, \tag{1.7c}$$

where $\widehat{\mathbf{U}}$ is a given vector-function. Here we introduce the source terms $\mathbf{f}(t,\mathbf{x})$ and

$\mathbf{g}(t,\mathbf{x}')$ to make the interior equations and the boundary conditions inhomogeneous (this is needed to attack the nonlinear problem).

Recall that the boundary conditions (1.7b) are called *dissipative* if

$$-(A_1\mathbf{U},\mathbf{U})|_{x_1=0} \geq 0 \qquad \forall\ \mathbf{U} \in \ker M, \tag{1.8}$$

where $-A_1 = -A_1(\widehat{\mathbf{U}})$ is the boundary matrix, $M = M(t,\mathbf{x}',\widehat{\mathbf{U}})$. They are *strictly dissipative* if there exist a fixed constant $\gamma > 0$ such that

$$-(A_1\mathbf{U},\mathbf{U})|_{x_1=0} \geq \gamma|\mathbf{V}|^2 \qquad \forall\ \mathbf{U} \in \ker M, \tag{1.9}$$

where $\mathbf{V}$ is the "noncharacteristic part" of the trace $\mathbf{U}|_{x_1=0}$, i.e., the projection of $\mathbf{U}|_{x_1=0}$ orthogonal to $\ker A_1|_{x_1=0}$ ($\mathbf{V} = \mathbf{U}$ for the case of noncharacteristic boundary, i.e., when $\det A_1|_{x_1=0} \neq 0$). Recall also that the boundary conditions (1.7b) are called *maximally dissipative* if they are dissipative and

$$\dim\ker M = \#\ \text{nonpositive eigenvalues of } A_1|_{x_1=0} \text{ counting multiplicity} \tag{1.10}$$

(we use the definition from [39]). Property (1.10) means that the hyperbolic system (1.7a) has the correct number of boundary conditions in (1.7b), i.e.,

$$d = \#\ \text{positive eigenvalues of } A_1|_{x_1=0} \text{ counting multiplicity.}$$

In the following we always assume that the number of boundary conditions is correct and we therefore drop the word "maximally" when speaking about dissipative or strictly dissipative boundary conditions.

For the inhomogenous boundary conditions (1.7b) inequality (1.9) implies that there exists a fixed constant $\delta > 0$ such that

$$-(A_1\mathbf{U},\mathbf{U})|_{x_1=0} \geq \delta|\mathbf{V}|^2 - \delta^{-1}|\mathbf{g}|^2 \tag{1.11}$$

for all $\mathbf{U}$ satisfying (1.7b). To deduce inequality (1.11) from (1.9) it needs to reduce system (1.7a) to the form [35], $\mathcal{A}_0\mathbf{W}_t + \sum_{j=1}^{n}\mathcal{A}_j\mathbf{W}_{x_j} = \dots$, where $\mathbf{U} = \mathcal{T}\mathbf{W}$, $\mathcal{A}_\alpha = \mathcal{T}^*A_\alpha\mathcal{T}$, $\mathcal{A}_1 = \operatorname{diag}(D_1, -D_2, 0)$, $D_i > 0$, $(\mathcal{A}_1\mathbf{W},\mathbf{W}) = (D_1\mathbf{W}_1,\mathbf{W}_1) - (D_2\mathbf{W}_2,\mathbf{W}_2)$, and the boundary conditions (1.7b) are supposed to be rewritten in the form $\mathbf{W}_1 = S\mathbf{W}_2 + \tilde{\mathbf{g}}$. Analogous simple arguments show that the dissipativity hypothesis (1.8) implies that there is a matrix $B = B(t,\mathbf{x}')$ such that

$$-(A_1\mathbf{U},\mathbf{U})|_{x_1=0} \geq (B\mathbf{g},\mathbf{V}) - \gamma|\mathbf{g}|^2 \tag{1.12}$$

for all $\mathbf{U}$ satisfying (1.7b), where γ is a constant, the matrix B can be, in principle, explicitly written out (it depends on $\mathcal{T}$, etc.).

If the boundary conditions (1.6b) are *linear*, i.e., $M = M(t,\mathbf{x}')$, then the boundary conditions for the associated linear problem (1.7) can be considered to be homogenous ($\mathbf{g}$=0) and the dissipativity hypothesis (1.8) is quite enough to prove a local existence theorem for problem (1.6) by standard fixed-point argument. In this case, for the linear problem (1.7) the basic estimate following from assumption (1.8) reads [40]

$$\|\mathbf{U}(t)\|_{L_2(\mathbb{R}^n_+)} \leq C\left\{\|\mathbf{U}_0\|_{L_2(\mathbb{R}^n_+)} + \|\mathbf{f}\|_{L_2([0,T]\times\mathbb{R}^n_+)}\right\},$$

where $C = C(T)$ is a positive constant independent of the initial data and the source terms. For linear boundary conditions on a noncharacteristic boundary the local W_2^s-existence theorem for problem (1.6) was proved by Schochet [41] (see Appendix A of [41]), where $s \geq [n/2]+2$ as for the Cauchy problem [47, 30, 26]. The case of characteristic boundary was considered by Secchi [42] (he has proved a local existence theorem in anisotropic weighted Sobolev spaces [42]).

However, if the boundary conditions in (1.6b) are *nonlinear*, i.e., M depends on $\mathbf{U}$, then one has to consider inhomogenous boundary conditions in the linear problem (1.7) (even if the original conditions (1.6b) were homogenous). The usual way (see, e.g., [40]) to deal with inhomogenous boundary conditions suggests to subtract from the solution a more regular function satisfying the boundary conditions, and reduce problem (1.7) to one with homogenous boundary conditions. But, such a way leads to the loss of "1/2 derivative" from $\mathbf{g}$ (see [40]). That is, the dissipativity hypothesis is already not enough to achieve a nonlinear local existence result by standard iterations.

At the same time, when the boundary conditions in (1.6b) are nonlinear, but conditions (1.7b) are strictly dissipative, using inequality (1.11), we can easily deduce the basic a priori estimate (with no loss of derivatives)

$$\|\mathbf{U}(t)\|_{L_2(\mathbb{R}^n_+)} \leq C\Big\{\|\mathbf{U}_0\|_{L_2(\mathbb{R}^n_+)} + \|\mathbf{f}\|_{L_2([0,T]\times\mathbb{R}^n_+)} + \|\mathbf{g}\|_{L_2([0,T]\times\mathbb{R}^{n-1})}\Big\} \tag{1.13}$$

and its higher order counterparts (see Appendix A in [43]). This enables one to prove a local existence theorem for problem (1.6) by standard fixed-point argument. The proof for the general problem (1.6) has not been written out somewhere, but we can refer to [43] for a concrete example of problem (1.6). Note that the well-posedness of the linear problem (1.7) with $\mathbf{g} \neq 0$ was proved in Appendix A of [43].

That is, when conditions (1.7b) are inhomogenous but strictly dissipative, an unpleasant loss of derivatives is avoided by a direct approach to the original problem (1.7) with inhomogenous boundary conditions (for problem (1.7) this was done in Appendix A of [43]; see also section 4 for shock waves). If, however, conditions (1.7b) are just dissipative (but not strictly dissipative), such a direct approach to the linear problem (1.7) only enables us to obtain the a priori estimate with the loss of one derivative from $\mathbf{g}$:

$$\|\mathbf{U}(t)\|_{W_2^1(\mathbb{R}^n_+)} \leq C\Big\{\|\mathbf{U}_0\|_{W_2^1(\mathbb{R}^n_+)} + \|\mathbf{f}\|_{W_2^1([0,T]\times\mathbb{R}^n_+)} + \|\mathbf{g}\|_{W_2^2([0,T]\times\mathbb{R}^{n-1})}\Big\}. \tag{1.14}$$

Here we suppose that the boundary is noncharacteristic. For the case of characteristic boundary the counterpart of (1.14) indicates a loss of control on derivatives in the normal direction [39, 42, 16]. To deduce estimate (1.14) we should differentiate problem (1.7) with respect to t and $\mathbf{x}'$. Then, we take into account inequality (1.12) and integrate by parts the boundary integral (see section 3 for the case of Rankine–Hugoniot boundary conditions).

Remark 1.2. For the case of linearized Rankine–Hugoniot boundary conditions a priori estimates with loss of derivatives were proved for shock waves and characteristic discontinuities by Coulombel [17], Coulombel and Secchi [19], and the author [45] (in [45] the a priori estimates are formally with no loss of derivatives because the boundary conditions were supposed to be homogenous). For the case of standard boundary conditions, cf. (1.7b), the a priori estimate (1.14) is a basic estimate, and it is not difficult to obtain an estimate for higher order derivatives. But, of course, it will be also with the loss of one derivative from $\mathbf{g}$. This precludes one from using fixed-point argument to prove a local existence theorem. It seems that the only way to overcome the difficulty connected with the loss of derivatives phenomenon is the employment of the Nash–Moser technique (for hyperbolic problems see [2, 31, 21]). Recently, the Nash–Moser method was successfully used by Coulombel and Secchi

[20] for two-dimensional (2D) compressible vortex sheets as well as for weakly stable shock waves (see also preparatory results in this direction in [17, 18, 19]). There is also a great hope to achieve a nonlinear local existence result for current-vortex sheets [45] by using Nash–Moser iterations.

If the boundary conditions (1.7b) are not dissipative, this does not, of course, mean that problem (1.7) is ill-posed. An alternative to the energy method was first suggested by Kreiss [27] for the strictly hyperbolic case. Kreiss has proved that problem (1.7) with constant ("frozen") coefficients obeys an a priori $L_{2,\eta}$-estimate with no loss of derivatives if and only if the boundary conditions satisfy the *uniform Lopatinski condition* [27] ($\|\cdot\|_{L_{2,\eta}} = \|e^{-\eta t}(\cdot)\|_{L_2}$, and $\eta > 0$ is sufficiently large). This estimate follows from a symmetrizer construction (*Kreiss symmetrizer*) and is carried over variable coefficients by using pseudodifferential calculus. That is, the uniform Lopatinski condition is the sharp algebraic criterion of *strong* well-posedness (well-posedness "with no loss of derivatives").

Later Kreiss' symmetrizer analysis was extended by Agranovich [1], Majda and Osher [35], and Majda [32] to hyperbolic systems satisfying a so-called block structure condition, which holds in particular for hyperbolic symmetrizable systems with constant multiplicities [1, 36]. In [32] Majda extends the Kreiss theory to the case of Rankine–Hugoniot boundary conditions. Majda's approach has been then improved by Métivier [37] by using paradifferential calculus of Bony (see also discussion in section 4). And recently Métivier and Zumbrun [38] have extended the Kreiss–Majda theory to a class of hyperbolic symmetrizable systems with characteristics of variable multiplicities. These systems at points of variable multiplicity should satisfy some conditions [38] which hold in particular for the MHD system. Thus, if the symmetric hyperbolic system (1.6a) meets either the Agronovich–Majda–Osher block structure condition [1, 35] or the conditions of Métivier and Zumbrun [38], then the linear problem (1.7) is strongly well-posed, provided that the boundary conditions (1.7b) satisfy the uniform Lopatinski condition. In this case a local existence theorem for the nonlinear problem (1.6) can be proved by analogy with the proofs in [33, 37].

At the same time, it should be noted that in practice the algebraic criterion given by the Lopatinski condition often cannot be tested analytically. Sometimes one succeeds to check it numerically (see [44]), but, frequently, numerical calculations can give only a very rough description of the condition for weak/strong well-posedness because either the domain of parameters for the constant coefficients linearized problem is unbounded or the number of these parameters is too big. Usually this happens for the case of Rankine–Hugoniot boundary conditions (see below), i.e., for shock waves or characteristic discontinuities. For example, such a situation takes place for compressible current-vortex sheets [45]. In this connection, there is no sense to reject at once the energy method as soon as the boundary conditions are not dissipative. The main purpose of the present paper is to formalize the so-called *dissipative integrals technique* (see [13]), which is a kind of "higher order" extension of the usual energy method. Especially, this technique turned out to be effective for shock waves in various hyperbolic models: gas dynamics, Landau's equations of superfluid, MHD, radiation hydrodynamics, etc. (see [13] and references therein). Let us now go on to the case of Rankine–Hugoniot boundary conditions.

1.2. Rankine–Hugoniot boundary conditions. Consider system (1.1) in the whole space $\mathbb{R}^n$. Let

$$\Gamma(t) = \{x_1 - f(t, \mathbf{x}') = 0\}$$

be a smooth hypersurface in $[0,T]\times\mathbb{R}^n$. We assume that $\Gamma(t)$ is a surface of strong discontinuity for solutions of (1.1). Let $\mathbf{U}(t,\mathbf{x})$ be a classical solution of (1.1) on either side of Γ. As is known, $\mathbf{U}$ is a weak solution of (1.1) if and only if the Rankine–Hugoniot jump conditions hold at each point of Γ:

$$f_t[\boldsymbol{\mathcal{P}}^0(\mathbf{U})]+\sum_{k=2}^{n} f_{x_k}[\boldsymbol{\mathcal{P}}^k(\mathbf{U})]-[\boldsymbol{\mathcal{P}}^1(\mathbf{U})]=0, \tag{1.15}$$

where $[a]=a^+-a^-=a|_{x_1-f(t,\mathbf{x}')=+0}-a|_{x_1-f(t,\mathbf{x}')=-0}$.

It should be noted that the initial-boundary-value problem for system (1.5) in the domains $\Omega^\pm(t):=\{x_1\gtrless f(t,\mathbf{x}')\}$ with the boundary conditions (1.15) on the hypersurface $\Gamma(t)$ is a free-boundary-value problem. Indeed, the function $f(t,\mathbf{x}')$ defining Γ is one of the unknowns of problem (1.5), (1.15) with the corresponding initial data

$$f|_{t=0}=f_0 \quad \text{in } \mathbb{R}^{n-1}, \qquad \mathbf{U}|_{t=0}=\mathbf{U}_0 \quad \text{in } \Omega^+(0)\cup\Omega^-(0). \tag{1.16}$$

To work in fixed domains instead of the domains $\Omega^\pm(t)$ we make the following change of variables:

$$\widetilde{t}=t,\quad \widetilde{x}_1=x_1-f(t,\mathbf{x}'),\quad \widetilde{\mathbf{x}}'=\mathbf{x}'.$$

Then, $\widetilde{\mathbf{U}}(\widetilde{t},\widetilde{\mathbf{x}}):=\mathbf{U}(t,\mathbf{x})$ is a smooth vector-function for $\widetilde{\mathbf{x}}\in\mathbb{R}^n_\pm$, and the initial-boundary-value problem (1.5), (1.15), (1.16) is reduced to the following problem (we omit tildes to simplify the notation):

$$L(\mathbf{U},\mathbf{F})\mathbf{U}=0 \quad \text{in } [0,T]\times(\mathbb{R}^n_+\cup\mathbb{R}^n_-), \tag{1.17a}$$

$$B(\mathbf{U}^+,\mathbf{U}^-)\mathbf{F}-[\boldsymbol{\mathcal{P}}^1(\mathbf{U})]=0 \quad \text{on } [0,T]\times\{x_1=0\}\times\mathbb{R}^{n-1}, \tag{1.17b}$$

$$\mathbf{U}|_{t=0}=\mathbf{U}_0 \quad \text{in } \mathbb{R}^n_+\cup\mathbb{R}^n_-, \qquad f|_{t=0}=f_0 \quad \text{in } \mathbb{R}^{n-1}. \tag{1.17c}$$

Here

$$L=L(\mathbf{U},\mathbf{F})=A_0(\mathbf{U})\partial_t+A_\nu(\mathbf{U},\mathbf{F})\partial_1+\sum_{k=2}^{n}A_k(\mathbf{U})\partial_k,$$
$$\mathbf{F}=\mathbf{F}(t,\mathbf{x}')=(f_t,\mathbf{F}'),\quad \mathbf{F}'=\mathbf{F}'(t,\mathbf{x}')=\nabla_{\mathbf{x}'}f,\quad \nabla_{\mathbf{x}'}=(\partial_2,\dots,\partial_n),$$
$$A_\nu=A_\nu(\mathbf{U},\mathbf{F})=\sum_{\alpha=0}^{n}\nu_\alpha A_\alpha=A_1(\mathbf{U})-f_tA_0(\mathbf{U})-\sum_{k=2}^{n}f_{x_k}A_k(\mathbf{U}),$$

$\boldsymbol{\nu}=(\nu_0,\dots,\nu_n)=(-f_t,\mathbf{N})$ and $\mathbf{N}=(1,-\mathbf{F}')$ are, respectively, the space-time and space normal vectors to $\Gamma(t)$. The matrix $B=B(\mathbf{U}^+,\mathbf{U}^-)$ is of order $N\times n$ and determined from the relation

$$B(\mathbf{U}^+,\mathbf{U}^-)\mathbf{F}=f_t[\boldsymbol{\mathcal{P}}^0(\mathbf{U})]+\sum_{k=2}^{n}f_{x_k}[\boldsymbol{\mathcal{P}}^k(\mathbf{U})],\quad \mathbf{U}^\pm:=\mathbf{U}|_{x_1=\pm0}.$$

After straightening of variables above the divergent constraints (1.3) take the form

$$\operatorname{div}\boldsymbol{\psi}_j(\mathbf{U},\mathbf{F}')=0 \quad \text{in } [0,T]\times(\mathbb{R}^n_+\cup\mathbb{R}^n_-), \qquad j=\overline{1,K}, \tag{1.18}$$

where $\boldsymbol{\psi}_j = \boldsymbol{\psi}_j(\mathbf{U},\mathbf{F}') = ((\boldsymbol{\Psi}_j,\mathbf{N}),\Psi_j^2,\ldots,\Psi_j^n)$. Moreover, solutions of problem (1.17) should satisfy the jump conditions

$$(1.19)\qquad [(\boldsymbol{\Psi}_j(\mathbf{U}),\mathbf{N})] = 0 \quad \text{on } [0,T]\times\{x_1=0\}\times\mathbb{R}^{n-1}, \quad j=\overline{1,K},$$

coming from (1.3). At the same time, taking into account Assumption 1.1 and Remark 1.1, it is natural to make the following assumption that should be true for all the physically relevant models.

Assumption 1.2. *The divergent constraints* (1.18) *are the restrictions on the initial data* (1.17c)*, i.e., if* (1.18) *are satisfied initially, they hold for all* $t>0$*. Equations* (1.17b) *and* (1.19) *form a system of* N *independent boundary conditions.*

To clarify Assumption 1.2 we can refer, for example, to MHD. Namely, in MHD the jump condition $f_t[(\mathbf{H},\mathbf{N})]=0$ contained in the corresponding main system, (1.17b), is implied by the equation $[(\mathbf{H},\mathbf{N})]=0$ coming from the divergent constraint $\operatorname{div}\mathbf{H}=0$. That is, in MHD the number of independent Rankine–Hugoniot boundary conditions is equal to the number of conservation laws.

To prove the existence of solutions with a surface of strong discontinuity $\Gamma(t)$ for the system of hyperbolic conservation laws (1.1) one needs to reply to the following question: does there exist a solution $(\mathbf{U},f)$ to problem (1.17) at least locally in time? The necessary (but not sufficient) condition for this is that the hyperbolic problem (1.17) has the correct number of boundary conditions in (1.17b). In this connection, it should be noted that, in contrast with the standard boundary conditions (1.6b), one of the conditions in (1.17b) is needed for determining the function $f(t,\mathbf{x}')$. For noncharacteristic discontinuities, i.e., *shock waves,* the plane $x_1=0$ is not a characteristic boundary for system (1.17). That is, the boundary matrix A_ν is nonsingular at $x_1=0$: $\det A_\nu^\pm \neq 0$, where $A_\nu^\pm = A_\nu|_{x_1=\pm 0}$. As is known, for shock waves the correct number of Rankine–Hugoniot boundary conditions is guaranteed by the *Lax shock conditions.* They can be conveniently written in terms of the eigenvalues of the boundary matrix A_ν:

$$(1.20)\qquad \lambda_k(A_\nu^+) < 0 < \lambda_k(A_\nu^-), \quad \lambda_{k-1}(A_\nu^-) < 0 < \lambda_{k+1}(A_\nu^+),$$

where $\lambda_i(A_\nu^\pm)$ ($i=\overline{1,N}$, $\lambda_1\le\ldots\le\lambda_N$) are the eigenvalues of the matrices $A_\nu^\pm$ and k is a fixed integer number, $1\le k\le N$ (an associated shock wave is called k-shock), $\lambda_0 := -\infty$, $\lambda_{N+1} := +\infty$.

Let $(\widehat{\mathbf{U}}(t,\mathbf{x}),\hat{f}(t,\mathbf{x}'))$ be a given vector-function, where $\widehat{\mathbf{U}}$ is supposed to be smooth for $\mathbf{x}\in\mathbb{R}^n_\pm$. Then the linearization of (1.17) results in the following variable coefficients problem for determining small perturbations $(\delta\mathbf{U},\delta f)$ (below we drop δ):

$$(1.21\text{a})\qquad L(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\mathbf{U} + \widehat{C}\mathbf{U} = \big\{L(\widehat{\mathbf{U}},\widehat{\mathbf{F}})f\big\}\widehat{\mathbf{U}}_{x_1} \quad \text{in } [0,T]\times(\mathbb{R}^n_+\cup\mathbb{R}^n_-),$$

$$(1.21\text{b})\qquad B(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-)\mathbf{F} - \big[S^{-1}(\widehat{\mathbf{U}})A_\nu(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\mathbf{U}\big] = 0 \quad \text{on } [0,T]\times\{x_1=0\}\times\mathbb{R}^{n-1},$$

and the initial data for the perturbation $(\mathbf{U},f)$ coincide with (1.17c). Here, $\widehat{\mathbf{F}} = (\hat{f}_t,\widehat{\mathbf{F}}')$, $\widehat{\mathbf{F}}' = \nabla_{\mathbf{x}'}\hat{f}$, the matrix $\widehat{C} = \widehat{C}(\widehat{\mathbf{U}},\widehat{\mathbf{U}}_t,\nabla\widehat{\mathbf{U}},\widehat{\mathbf{F}})$ is determined as follows:

$$\widehat{C}\mathbf{U} = (\mathbf{U},\nabla_u A_0(\widehat{\mathbf{U}}))\widehat{\mathbf{U}}_t + (\mathbf{U},\nabla_u A_\nu(\widehat{\mathbf{U}},\widehat{\mathbf{F}}))\widehat{\mathbf{U}}_{x_1} + \sum_{k=2}^n (\mathbf{U},\nabla_u A_k(\widehat{\mathbf{U}}))\widehat{\mathbf{U}}_{x_k},$$

$(\mathbf{U},\nabla_u) := \sum_{i=1}^N u_i\partial/\partial u_i$. Recall that $S(\mathbf{U})$ is the Friedrichs symmetrizer mentioned above, i.e., $S^{-1}A_\nu = B_\nu$, where $B_\nu = \sum_{\alpha=0}^n \nu_\alpha B_\alpha$. Problem (1.21a), (1.17c) is the *genuine linearization* of (1.17) in the sense that we keep all the lower order terms in (1.21a).

It should be noted that the differential operator in system (1.21a) is a first order operator in f. This fact can give some trouble in the application of the energy method to (1.21a). To avoid this difficulty we make the change of unknowns (see [2])

$$\bar{\mathbf{U}} = \mathbf{U} - f\widehat{\mathbf{U}}_{x_1}. \tag{1.22}$$

In terms of the "good unknown" (1.22) problem (1.21a) takes the form

$$L(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\bar{\mathbf{U}} + \widehat{C}\bar{\mathbf{U}} + f\partial_1\{L(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\widehat{\mathbf{U}}\} = 0 \quad \text{in } [0,T]\times(\mathbb{R}^n_+\cup\mathbb{R}^n_-), \tag{1.23a}$$

$$\begin{aligned} B(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-)\mathbf{F} &- \left[S^{-1}(\widehat{\mathbf{U}})A_\nu(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\bar{\mathbf{U}}\right] \\ &= -f\left[S^{-1}(\widehat{\mathbf{U}})A_\nu(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\widehat{\mathbf{U}}_{x_1}\right] \quad \text{on } [0,T]\times\{x_1=0\}\times\mathbb{R}^{n-1}. \end{aligned} \tag{1.23b}$$

Actually, to prove a local existence theorem for the nonlinear problem (1.17) with strictly dissipative boundary conditions or having a strictly dissipative p-symmetrizer (see section 2), it is not necessary to consider the genuine linearization (1.21a). It is enough to keep only the principal part of the linearized equations, i.e., one can drop the lower order terms in (1.23). At the same time, for the case when the loss of derivatives takes place it needs to perform genuine linearization ("to find a differential") for the purpose of a possible use of the Nash–Moser method (see discussion in Remark 1.2). The linearized equations associated to (1.17a), (1.17b) and obtained by dropping the lower order terms in (1.23) read:

$$L(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\mathbf{U} = \mathbf{f} \quad \text{in } [0,T]\times(\mathbb{R}^n_+\cup\mathbb{R}^n_-), \tag{1.24a}$$

$$B(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-)\mathbf{F} - \left[S^{-1}(\widehat{\mathbf{U}})A_\nu(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\mathbf{U}\right] = \mathbf{g} \quad \text{on } [0,T]\times\{x_1=0\}\times\mathbb{R}^{n-1}. \tag{1.24b}$$

Here we introduce the source terms $\mathbf{f}(t,\mathbf{x})$ and $\mathbf{g}(t,\mathbf{x}')$, where $\mathbf{f}(t,\mathbf{x}) = \mathbf{f}^\pm(t,\mathbf{x})$ for $\mathbf{x}\in\mathbb{R}^n_\pm$.

For problem (1.24) the definitions of dissipative and strictly dissipative boundary conditions are analogous to those in (1.12) and (1.11). In particular, the homogenous boundary conditions (1.24b) ($\mathbf{g}=0$) are dissipative if $-[(A_\nu\mathbf{U},\mathbf{U})]|_{x_1=0}\geq 0$ for all $\mathbf{U}$ satisfying (1.24b). Assuming that the front can be eliminated, i.e., the vector-function $\mathbf{F}$ can be expressed through $\mathbf{U}^+$, $\mathbf{U}^-$, and $\mathbf{g}$ (see section 3 for more details), for shock waves the counterparts of estimates (1.14) and (1.13) are the following:

$$\begin{aligned} \|f\|_{W_2^1([0,T]\times\mathbb{R}^{n-1})} + \sum_\pm \|\mathbf{U}(t)\|_{W_2^1(\mathbb{R}^n_\pm)} \leq C\Bigg\{ &\|f_0\|_{W_2^1(\mathbb{R}^{n-1})} \\ + \sum_\pm \Big\{\|\mathbf{U}_0\|_{W_2^1(\mathbb{R}^n_\pm)} + \|\mathbf{f}^\pm\|_{W_2^1([0,T]\times\mathbb{R}^n_\pm)}\Big\} &+ \|\mathbf{g}\|_{W_2^2([0,T]\times\mathbb{R}^{n-1})}\Bigg\} \end{aligned} \tag{1.25}$$

(for dissipative boundary conditions),

$$\begin{aligned} \|f\|_{W_2^1([0,T]\times\mathbb{R}^{n-1})} + \sum_\pm \|\mathbf{U}(t)\|_{L_2(\mathbb{R}^n_\pm)} \leq C\Bigg\{ &\|f_0\|_{W_2^1(\mathbb{R}^{n-1})} \\ + \sum_\pm \Big\{\|\mathbf{U}_0\|_{L_2(\mathbb{R}^n_\pm)} + \|\mathbf{f}^\pm\|_{L_2([0,T]\times\mathbb{R}^n_\pm)}\Big\} &+ \|\mathbf{g}\|_{L_2([0,T]\times\mathbb{R}^{n-1})}\Bigg\} \end{aligned} \tag{1.26}$$

(for strictly dissipative boundary conditions).

Since the original nonlinear problem (1.17) is a reduced free-boundary-value problem, we should gain the "additional derivative" for the front perturbation f (cf. (1.26)) to use then fixed-point argument. In this sense the a priori estimate (1.25) indicates the loss of one derivative not only from the source term $\mathbf{g}$ but also from the front f. At the same time, Rankine–Hugoniot boundary conditions are usually not dissipative (not to mention strict dissipativity). Nevertheless, the energy method can be still applied to problem (1.17) under certain circumstances. The main idea is to obtain from the linearized problem a problem for higher order derivatives of $\mathbf{U}$ so that this problem has dissipative (or strictly dissipative) boundary conditions. Such an idea was first realized by Blokhin [7, 9] for shock waves in gas dynamics. In the next section we formalize this idea by introducing the notations of dissipative and strictly dissipative p-symmetrizers and give concrete examples of p-symmetrizers. In section 3 we consider the case of constant coefficients and deduce a priori estimates for Lax shock waves whose linearized problems have a p-symmetrizer. In section 4 we carry these estimates over variable coefficients and outline the proof of the local existence theorem for the original nonlinear problem (1.17), provided that the corresponding constant coefficients linearized problem has a strictly dissipative p-symmetrizer. For all the linear results obtained earlier by the dissipative integrals technique for shock waves in various concrete models (see [13] and references therein) this enables one to conclude the local existence of shock-front solutions of the corresponding nonlinear systems. Eventually, in section 5 we make concluding remarks and discuss open problems.

2. Dissipative *p*-symmetrizers: Definition and examples. We introduce the notations of dissipative and strictly dissipative p-symmetrizers for linear hyperbolic initial-boundary-value problems with constant coefficients. We give the definition of these notations for the case of Rankine–Hugoniot boundary conditions. The corresponding definition for the earthier case of standard boundary conditions (cf. (1.6b)) is given analogously and does not need a separate treatment.

The constant coefficients linearized problem for planar discontinuities is of decisive importance for the subsequent variable coefficients and nonlinear analysis. For planar discontinuities $\hat{f}(t,\mathbf{x}')$ is a linear function:

$$\hat{f}(t,\mathbf{x}') = \sigma t + (\boldsymbol{\sigma}',\mathbf{x}'), \quad \boldsymbol{\sigma} = (\sigma,\boldsymbol{\sigma}') \in \mathbb{R}^n. \tag{2.1}$$

For the case of a piecewise constant solution,

$$\widehat{\mathbf{U}} = \begin{cases} \widehat{\mathbf{U}}^+, & x_1 > \sigma t + (\boldsymbol{\sigma}',\mathbf{x}'), \\ \widehat{\mathbf{U}}^-, & x_1 < \sigma t + (\boldsymbol{\sigma}',\mathbf{x}'), \end{cases}$$

equations (1.24) have constant ("frozen") coefficients:

$$L(\widehat{\mathbf{U}}^{\pm},\boldsymbol{\sigma})\mathbf{U} = \mathbf{f}^{\pm} \quad \text{for } \mathbf{x} \in \mathbb{R}^n_{\pm}, \tag{2.2a}$$

$$\widehat{B}\mathbf{F} - \big[\widehat{S}^{-1}\widehat{A}_\nu\mathbf{U}\big] = \mathbf{g} \quad \text{for } x_1 = 0, \tag{2.2b}$$

where $\widehat{B} = B(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-)$, $\widehat{S}^{\pm} = S(\widehat{\mathbf{U}}^{\pm})$, $\widehat{A}^{\pm}_\nu = A_\nu(\widehat{\mathbf{U}}^{\pm},\boldsymbol{\sigma})$, $\widehat{A}^{\pm}_\alpha = A_\alpha(\widehat{\mathbf{U}}^{\pm})$ are constant coefficients matrices, and $\big[\widehat{S}^{-1}\widehat{A}_\nu\mathbf{U}\big] = (\widehat{S}^+)^{-1}\widehat{A}^+_\nu\mathbf{U}^+ - (\widehat{S}^-)^{-1}\widehat{A}^-_\nu\mathbf{U}^-$, etc.

ASSUMPTION 2.1. *The functions* $\Psi^i_j(\mathbf{U})$ *in* (1.3) *are linear.*

Assumption 2.1 is satisfied for most examples of constrained hyperbolic systems we know. At the same time, this assumption is made only for simplicity of arguments below and can be easily removed. Assuming the linearity of $\Psi^i_j(\mathbf{U})$, the linearized constraints (1.18) after the change of unknowns (1.22) (below we drop the bars) read:

$$\operatorname{div}\boldsymbol{\psi}_j = 0, \quad \mathbf{x} \in \mathbb{R}^n_\pm, \quad j = \overline{1, K}, \tag{2.3}$$

where $\boldsymbol{\psi}_j = \boldsymbol{\psi}_j(\mathbf{U}, \widehat{\mathbf{F}}') = ((\boldsymbol{\Psi}_j, \widehat{\mathbf{N}}), \Psi^2_j, \dots, \Psi^n_j)$, $\widehat{\mathbf{N}} = (1, -\widehat{\mathbf{F}}')$. For the case of constant coefficients (2.2), $\widehat{\mathbf{N}} = (1, -\boldsymbol{\sigma}')$.

2.1. The main definition. Given a nonnegative integer number p, we introduce the notation

$$\mathbf{W}_p := (\partial^{\alpha^1}\mathbf{U}, \dots, \partial^{\alpha^d}\mathbf{U}),$$

with

$$d = C^p_{n+p}, \quad |\alpha^i| = p, \quad i = \overline{1, d}, \quad \alpha^i \neq \alpha^j \quad \text{for } i \neq j,$$

where $\partial^\alpha := \partial_t^{\alpha_0}\partial_1^{\alpha_1}\cdots\partial_n^{\alpha_n}$, $\alpha = (\alpha_0, \dots, \alpha_n)$. In particular, $\mathbf{W}_0 = \mathbf{U}$, $\mathbf{W}_1 = (\mathbf{U}_t, \mathbf{U}_{x_1}, \dots, \mathbf{U}_{x_n})$, $\mathbf{W}_2 = (\mathbf{U}_{tt}, \mathbf{U}_{tx_1}, \dots, \mathbf{U}_{x_{n-1}x_n}, \mathbf{U}_{x_nx_n})$. Below we will usually omit the index p, i.e., $\mathbf{W} := \mathbf{W}_p$.

Differentiating systems (2.2a) (if $p \neq 0$) and taking into account relations (2.3), one gets

$$P^\pm \widetilde{L}(\widehat{\mathbf{U}}^\pm, \boldsymbol{\sigma})\mathbf{W} + \sum_{j=1}^{K}\sum_{|\alpha|=p} \mathbf{R}^\pm_{j,\alpha} \operatorname{div}\left(\boldsymbol{\psi}_j(\partial^\alpha\mathbf{U}, \boldsymbol{\sigma}')\right) = P^\pm \widetilde{\mathbf{f}}^\pm, \quad \mathbf{x} \in \mathbb{R}^n_\pm, \tag{2.4}$$

where

$$\widetilde{L}(\widehat{\mathbf{U}}^\pm, \boldsymbol{\sigma}) = I_d \otimes L(\widehat{\mathbf{U}}^\pm, \boldsymbol{\sigma}), \quad \widetilde{\mathbf{f}}^\pm = (\partial^{\alpha^1}\mathbf{f}^\pm, \dots, \partial^{\alpha^d}\mathbf{f}^\pm),$$

$\mathbf{R}^\pm_{j,\alpha} = \mathbf{R}_{j,\alpha}(\widehat{\mathbf{U}}^\pm, \boldsymbol{\sigma})$ and $P^\pm = P(\widehat{\mathbf{U}}^\pm, \boldsymbol{\sigma})$ are, respectively, vectors and nonsingular matrices of order Nd. Here and below the subscript in I_j indicates the order of the unit matrix $I_j = I$ (sometimes we omit it). Systems (2.4) can be rewritten as follows:

$$\mathcal{L}(\widehat{\mathbf{U}}^\pm, \boldsymbol{\sigma})\mathbf{W} = \boldsymbol{\mathcal{F}}^\pm, \quad \mathbf{x} \in \mathbb{R}^n_\pm, \tag{2.5}$$

where

$$\mathcal{L} = \mathcal{L}(\widehat{\mathbf{U}}^\pm, \boldsymbol{\sigma}) = \widehat{\mathcal{A}}^\pm_0\partial_t + \sum_{j=1}^{n}\widehat{\mathcal{A}}^\pm_j\partial_j, \quad \boldsymbol{\mathcal{F}}^\pm = \boldsymbol{\mathcal{F}}^\pm(\widehat{\mathbf{U}}^\pm, \boldsymbol{\sigma}) = P^\pm\widetilde{\mathbf{f}}^\pm,$$

and $\widehat{\mathcal{A}}^\pm_i = \mathcal{A}_i(\widehat{\mathbf{U}}^\pm, \boldsymbol{\sigma})$, $i = \overline{0, n}$, are matrices of order Nd (their explicit form is determined from (2.4)).

Systems (2.5) are a kind of "secondary higher order" symmetrization of the symmetric systems (2.2a) if the matrices $\widehat{\mathcal{A}}^\pm_i$ are again symmetric. Moreover, to make these matrices symmetric when writing out (2.5) one can take into account the trivial relations like

$$\partial_i\partial_j\mathbf{U} = \partial_j\partial_i\mathbf{U}, \quad \partial_i\partial_j\partial_k\mathbf{U} = \partial_j\partial_i\partial_k\mathbf{U} = \ldots = \partial_k\partial_j\partial_i\mathbf{U}, \quad \text{etc.},$$

which follow from the smoothness hypothesis (in $\mathbb{R}^n_\pm$). Clearly, systems (2.5) are not uniquely written out. It follows that a corresponding p-symmetrizer (see the definition below) is not uniquely determined and, in principle, the problem can have different p-symmetrizers. It is however quite natural and does not, of course, imply the nonuniqueness of solutions to the problem.

The boundary conditions for systems (2.5) are obtained by the tangential differentiation (with respect to t and $\mathbf{x}'$) of conditions (2.2b), and, furthermore, systems (2.4) themselves differentiated $p-1$ times and considered at $x_1 = 0$ can be used as boundary conditions. Unfortunately, the boundary conditions are difficult to present in a concrete form, but it is clear that the right-hand parts in them depend on $\partial^{\alpha}_{t,\mathrm{x}'}\mathbf{g}$, with $|\alpha| = p$, and $\partial^{\beta}\mathbf{f}^{\pm}|_{x_1=\pm 0}$, with $|\beta| = p-1$, where $\partial^{\alpha}_{t,\mathrm{x}'} := \partial_t^{\alpha_0}\partial_2^{\alpha_2}\cdots\partial_n^{\alpha_n}$, $\alpha = (\alpha_0, \alpha_2, \dots, \alpha_n)$. The corresponding vector of right-hand parts formed by $\partial^{\alpha}_{t,\mathrm{x}'}\mathbf{g}$ and $\partial^{\beta}\mathbf{f}^{\pm}|_{x_1=\pm 0}$ is below denoted by $\boldsymbol{\mathcal{G}}$.

We are now in a position to give the definition of the (strictly) dissipative p-symmetrizer.

Definition 2.1. *The set of matrices and vectors*

$$\mathbb{S} = \mathbb{S}(\widehat{\mathbf{U}}^+, \widehat{\mathbf{U}}^-, \boldsymbol{\sigma}) := \left\{P^+, P^-, \{\mathbf{R}^+_{j,\alpha}\}_{j=\overline{1,K},|\alpha|=p}, \{\mathbf{R}^-_{j,\alpha}\}_{j=\overline{1,K},|\alpha|=p}\right\}$$

($\mathbb{S} := \{P^+, P^-\}$ if system (1.1) *has no divergent constraints) is called the dissipative p-symmetrizer of problem* (2.2) *if the matrices $\widehat{\mathcal{A}}_i^{\pm}$ in* (2.5) *are symmetric and there is an open subset D of the state space $G \subset \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}^n$, a constant matrix B, and a constant γ such that*

$$\widehat{\mathcal{A}}_0^+ > 0, \quad \widehat{\mathcal{A}}_0^- > 0, \tag{2.6}$$

and (cf. (1.12)*)*

$$-\left[(\widehat{\mathcal{A}}_1\mathbf{W}, \mathbf{W})\right]\big|_{x_1=0} \geq (B\boldsymbol{\mathcal{G}}, \widetilde{\mathbf{W}}) - \gamma|\boldsymbol{\mathcal{G}}|^2 \tag{2.7}$$

for all $(\widehat{\mathbf{U}}^+, \widehat{\mathbf{U}}^-, \boldsymbol{\sigma}) \in D$ and all $\mathbf{W}$ satisfying the boundary conditions for systems (2.5)*, where $\widetilde{\mathbf{W}} = (\widetilde{\mathbf{W}}^+, \widetilde{\mathbf{W}}^-)$ and $\widetilde{\mathbf{W}}^{\pm}$ is the projection of $\mathbf{W}^{\pm}$ orthogonal to* $\ker\widehat{\mathcal{A}}_1^{\pm}$ *(for shock waves $\widetilde{\mathbf{W}}^{\pm} = \mathbf{W}^{\pm} = \mathbf{W}|_{x_1=\pm 0}$).*

The set $\mathbb{S}$ is called the strictly dissipative p-symmetrizer of problem (2.2) *if it is a dissipative p-symmetrizer of this problem and there is a fixed constant $\delta > 0$ such that*

$$-\left[(\widehat{\mathcal{A}}_1\mathbf{W}, \mathbf{W})\right]\big|_{x_1=0} \geq \delta|\widetilde{\mathbf{W}}|^2 - \delta^{-1}|\boldsymbol{\mathcal{G}}|^2. \tag{2.8}$$

Remark 2.1. For 1-shocks $\widehat{A}_{\nu}^- > 0$ (cf. (1.20)) and, therefore, the strictly dissipative p-symmetrizer can be taken in the form

$$\mathbb{S} = \left\{P^+, \gamma I, \{\mathbf{R}^+_{j,\alpha}\}_{j=\overline{1,K},|\alpha|=p}, 0, \dots, 0\right\},$$

where the constant $\gamma > 0$ is large enough, P^+, $\mathbf{R}^+_{j,\alpha}$ are such that the matrices $\widehat{\mathcal{A}}_{\alpha}^+$ are symmetric, $\widehat{\mathcal{A}}_0^+ > 0$, and the relaxed condition (2.8),

$$-(\widehat{\mathcal{A}}_1^+\mathbf{W}, \mathbf{W})|_{x_1=+0} \geq \delta|\mathbf{W}^+|^2 - \delta^{-1}\left\{|\boldsymbol{\mathcal{G}}|^2 + |\mathbf{W}^-|^2\right\},$$

is fulfilled. Thanks to the choice of γ and the condition $\widehat{\mathcal{A}}_1^- = \gamma(I_d \otimes \widehat{A}_{\nu}^-) > 0$, the last inequality implies (2.8) with an appropriate (and different) δ. That is, systems (2.5) are symmetric hyperbolic and the boundary conditions for them are strictly dissipative (cf. (1.11)).

Remark 2.2. The definition of the p-symmetrizer for the case of standard boundary conditions is analogous to Definition 2.1. Note only that for problem (1.7) (with "frozen" coefficients) the p-symmetrizer has the form $\mathbb{S} = \left\{P, \{\mathbf{R}_{j,\alpha}\}_{j=\overline{1,K},|\alpha|=p}\right\}$, where P is a nonsingular matrix of order NC^p_{n+p}, etc.

We now give some concrete examples of dissipative and strictly dissipative p-symmetrizers. Without loss of generality we will consider homogenous interior equations and homogenous boundary conditions.

2.2. Example 1: The wave equation. Consider the initial-boundary-value problem in the half-plane $\mathbb{R}^2_+$ for the 2D wave equation:

$$u_{tt} = u_{x_1x_1} + u_{x_2x_2} \quad \text{for } x_1 > 0, \tag{2.9a}$$

$$u_t + au_{x_1} + bu_{x_2} = 0 \quad \text{for } x_1 = 0, \tag{2.9b}$$

where a and b are real constants. As is known, the boundary conditions (2.9b) satisfy the uniform Lopatinski condition in the half-strip

$$|b| < 1, \quad a < 0. \tag{2.10}$$

Problem (2.9) is easily reduced in the following problem for a symmetric hyperbolic system for the vector $\mathbf{U} = (u_1, u_2, u_3) = (u_t, u_{x_1}, u_{x_2})$:

$$\mathbf{U}_t + A_1\mathbf{U}_{x_1} + A_2\mathbf{U}_{x_2} = 0 \quad \text{for } x_1 > 0, \tag{2.11a}$$

$$M\mathbf{U} = 0 \quad \text{for } x_1 = 0, \tag{2.11b}$$

with

$$A_1 = \begin{pmatrix} 0 & -1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad A_2 = \begin{pmatrix} 0 & 0 & -1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, \quad M = \begin{pmatrix} 1 & a & b \end{pmatrix}.$$

In terms of the components of the vector $\mathbf{U}$ the trivial relation $u_{x_1x_2} = u_{x_2x_1}$ satisfied by classical solutions of (2.9) reads:

$$\operatorname{div} \mathbf{\Psi}(\mathbf{U}) = 0, \quad \mathbf{\Psi} = (u_3, -u_2). \tag{2.12}$$

Let us now forget about the connection between problems (2.9) and (2.11) (it is only important that for (2.11) the uniform Lopatinski condition is also given by (2.10)). Then (2.12) should be considered as a divergent constraint for the initial data for (2.11). Indeed, one can easily show that if (2.12) is satisfied initially, it holds for solutions of (2.11a) for all $t > 0$.

We now prove that (2.11) has a strictly dissipative 0-symmetrizer which can be taken in the form $\mathbb{S} = \{P, \mathbf{R}\}$, with

$$P = \begin{pmatrix} p_1 & p_2 & p_3 \\ p_2 & p_1 & 0 \\ p_3 & 0 & p_1 \end{pmatrix}, \quad R = \begin{pmatrix} 0 \\ -p_3 \\ p_2 \end{pmatrix}, \quad p_i \in \mathbb{R},$$

and the parameter domain D (see Definition 2.1 and Remark 2.2) coincides with the the domain of fulfillment of the uniform Lopatinski condition, (2.10). Indeed, applying $\mathbb{S}$ to (2.11), (2.12) leads to the system

$$P\mathbf{U}_t + PA_1\mathbf{U}_{x_1} + PA_2\mathbf{U}_{x_2} + \mathbf{R}\operatorname{div} \mathbf{\Psi} = \mathcal{A}_0\mathbf{U}_t + \mathcal{A}_1\mathbf{U}_{x_1} + \mathcal{A}_2\mathbf{U}_{x_2} = 0, \tag{2.13}$$

where $\mathcal{A}_0 = P > 0$ if $p_1 > 0$ and $p_1^2 - p_2^2 - p_3^2 > 0$. Also,

$$\mathcal{A}_1 = \begin{pmatrix} -p_2 & -p_1 & 0 \\ -p_1 & -p_2 & -p_3 \\ 0 & -p_3 & p_2 \end{pmatrix}, \quad \mathcal{A}_2 = \begin{pmatrix} -p_3 & 0 & -p_1 \\ 0 & p_3 & -p_2 \\ -p_1 & -p_2 & -p_3 \end{pmatrix}.$$

Note that $\mathcal{A}_0 = \mathcal{T}^*\{I_2 \otimes \mathcal{H}\}\mathcal{T}$ ($\mathcal{A}_0 > 0$ if $\mathcal{H} > 0$),

$$\mathcal{A}_1 = \mathcal{T}^*\left\{\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \otimes \mathcal{H}\right\}\mathcal{T}, \quad \mathcal{A}_2 = \mathcal{T}^*\left\{\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \otimes \mathcal{H}\right\}\mathcal{T},$$

$$\mathcal{T} = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 0 & -1 \\ 0 & -1 & 0 \\ 0 & -1 & 0 \\ 1 & 0 & 1 \end{pmatrix}, \quad \mathcal{H} = \begin{pmatrix} p_1 - p_3 & -p_2 \\ -p_2 & p_1 + p_3 \end{pmatrix}.$$

Omitting calculations, one has

$$-(\mathcal{A}_1\mathbf{U}, \mathbf{U})|_{x_1=0} = -\left(\{\mathcal{S}^*\mathcal{H} + \mathcal{H}\mathcal{S}\}\mathbf{V}_2, \mathbf{V}_2\right)|_{x_1=0}, \tag{2.14}$$

where

$$\mathbf{V} = \mathcal{T}\mathbf{U} = \begin{pmatrix} \mathbf{V}_1 \\ \mathbf{V}_2 \end{pmatrix}, \quad \mathbf{V}_1|_{x_1=0} = \mathcal{S}\mathbf{V}_2|_{x_1=0}, \quad \mathcal{S} = \begin{pmatrix} \dfrac{2a}{1-b} & \dfrac{b+1}{b-1} \\ 1 & 0 \end{pmatrix}.$$

All the eigenvalues of the matrix $\mathcal{S}$ lie in the left half-plane ($\Re\lambda_i(\mathcal{S}) < 0$), provided that the uniform Lopatinski condition (2.10) holds. In this case the Lyapunov matrix equation [5]

$$\mathcal{S}^*\mathcal{H} + \mathcal{H}\mathcal{S} = -G \tag{2.15}$$

has a unique solution $\mathcal{H}$ for any symmetric matrix G, and if $G > 0$, then $\mathcal{H} = \mathcal{H}^* > 0$. Assuming that $G = G^* > 0$ and taking into account the relation $\mathbf{V} = \mathcal{T}\mathbf{U}$ and the boundary conditions $\mathbf{V}_1|_{x_1=0} = \mathcal{S}\mathbf{V}_2|_{x_1=0}$, we have

$$-(\mathcal{A}_1\mathbf{U}, \mathbf{U})|_{x_1=0} = (G\mathbf{V}_2, \mathbf{V}_2)|_{x_1=0} \geq \delta|\mathbf{U}|_{x_1=0}|^2,$$

where $\delta > 0$ is a constant depending on the norms of the matrices G, $\mathcal{S}$, and $\mathcal{T}$. Thus, $\mathbb{S}$ is the strictly dissipative 0-symmetrizer.

Remark 2.3. The constants p_1, p_2, and p_3 are found explicitly from (2.15) through the elements of the matrix $G = \{g_{ij}\}_{i,j=1,2}$. In particular,

$$p_2 = -g_{22}\frac{1-b}{2(1+b)} < 0$$

($g_{22} > 0$ since $G > 0$). The condition $p_2 \neq 0$ and the inequality $p_1^2 - p_2^2 - p_3^2 > 0$ imply that $\det \mathcal{A}_1 \neq 0$, i.e., the boundary $x_1 = 0$ is noncharacteristic for system (2.13). This could seem strange because for system (2.11a) the boundary is characteristic, but systems (2.11a) and (2.13) are equivalent (since $\det P \neq 0$). This is, however, quite natural because we should take into account the divergent constraint (2.12). Indeed, with condition (2.12) problem (2.11) has not a so-called loss of control on derivatives in the normal direction. Namely, the x_1-derivative of the "characteristic part" u_3 of $\mathbf{U}$ is estimated from (2.12). That is, problem (2.11) being formally a hyperbolic problem with characteristic boundary has the features of noncharacteristic problems.

Remark 2.4. The symmetrization of the multidimensional wave equation [8, 10] ($n \geq 3$) with strictly dissipative boundary conditions can be formalized in terms of the construction of a strictly dissipative 0-symmetrizer as well. In particular, for the case $n = 3$ the matrix P has the form

$$P = \begin{pmatrix} p_1 & p_2 & p_3 & p_4 \\ p_2 & p_1 & 0 & 0 \\ p_3 & 0 & p_1 & 0 \\ p_4 & 0 & 0 & p_1 \end{pmatrix}, \quad p_i \in \mathbb{R}, \quad p_1^2 - p_2^2 - p_3^2 - p_4^2 > 0.$$

We refer also to [13] where such a 0-symmetrizer for the 3D wave equation is used for constructing a strictly dissipative 2-symmetrizer for relativistic gas dynamical shock waves. For simplicity, in Examples 3 and 4 below we consider the 2D case for shock waves in gas dynamics and MHD, and the structure of 2-symmetrizers for them is based on a symmetrization of the 2D wave equation which is different from (2.13). For the 3D case for gas dynamical and MHD shock waves we refer to [8, 10, 14] (see also further discussion in the end of section 2).

2.3. Example 2: Compressible current-vortex sheets. For tangential discontinuities (current-vortex sheets) in MHD of ideal compressible fluid, the constant coefficients linearized problem has the form of problem (2.2) (see [45]) with

$$\widehat{A}_0^{\pm} = \operatorname{diag}\left(\frac{1}{\hat{\rho}^{\pm}(\hat{c}^{\pm})^2}, \hat{\rho}^{\pm}, \hat{\rho}^{\pm}, \hat{\rho}^{\pm}, 1, 1, 1, 1\right),$$

$$\widehat{A}_1^{\pm} = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & \widehat{H}_2^{\pm} & \widehat{H}_3^{\pm} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \widehat{H}_2^{\pm} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \widehat{H}_3^{\pm} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\widehat{A}_2^{\pm} = \begin{pmatrix} \dfrac{\hat{v}_2^{\pm}}{\hat{\rho}^{\pm}(\hat{c}^{\pm})^2} & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & \hat{\rho}^{\pm}\hat{v}_2^{\pm} & 0 & 0 & -\widehat{H}_2^{\pm} & 0 & 0 & 0 \\ 1 & 0 & \hat{\rho}^{\pm}\hat{v}_2^{\pm} & 0 & 0 & 0 & \widehat{H}_3^{\pm} & 0 \\ 0 & 0 & 0 & \hat{\rho}^{\pm}\hat{v}_2^{\pm} & 0 & 0 & -\widehat{H}_2^{\pm} & 0 \\ 0 & -\widehat{H}_2^{\pm} & 0 & 0 & \hat{v}_2^{\pm} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \hat{v}_2^{\pm} & 0 & 0 \\ 0 & 0 & \widehat{H}_3 & -\widehat{H}_2^{\pm} & 0 & 0 & \hat{v}_2^{\pm} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix},$$

$$\widehat{A}_3^{\pm} = \begin{pmatrix} \dfrac{\hat{v}_3^{\pm}}{\hat{\rho}^{\pm}(\hat{c}^{\pm})^2} & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & \hat{\rho}^{\pm}\hat{v}_3^{\pm} & 0 & 0 & -\widehat{H}_3^{\pm} & 0 & 0 & 0 \\ 0 & 0 & \hat{\rho}^{\pm}\hat{v}_3^{\pm} & 0 & 0 & -\widehat{H}_3^{\pm} & 0 & 0 \\ 1 & 0 & 0 & \hat{\rho}^{\pm}\hat{v}_3^{\pm} & 0 & \widehat{H}_2^{\pm} & 0 & 0 \\ 0 & -\widehat{H}_3^{\pm} & 0 & 0 & \hat{v}_3^{\pm} & 0 & 0 & 0 \\ 0 & 0 & -\widehat{H}_3^{\pm} & \widehat{H}_2^{\pm} & 0 & \hat{v}_3^{\pm} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \hat{v}_3^{\pm} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix},$$

$\mathbf{U} = (p, \mathbf{v}, \mathbf{H}, S)$, $\widehat{\mathbf{U}}^{\pm} = (\hat{p}^{\pm}, 0, \hat{v}_2^{\pm}, \hat{v}_3^{\pm}, 0, \widehat{H}_2^{\pm}, \widehat{H}_3^{\pm}, \widehat{S}^{\pm})$, and the boundary conditions

$$f_t = v_1^{\pm} - \hat{v}_2^{\pm} f_{x_2} - \hat{v}_3^{\pm} f_{x_3}, \quad [q] = 0, \tag{2.16a}$$

$$H_1^{\pm} = \widehat{H}_2^{\pm} f_{x_2} + \widehat{H}_3^{\pm} f_{x_3} \tag{2.16b}$$

at $x_1 = 0$. Here $q = p + (\widehat{\mathbf{H}}^{\pm}, \mathbf{H})$ for $\mathbf{x} \in \mathbb{R}^3_{\pm}$, $\widehat{\mathbf{H}}^{\pm} = (0, \widehat{H}_2^{\pm}, \widehat{H}_3^{\pm})$, $\hat{p}^{\pm} = p(\hat{\rho}^{\pm}, \widehat{S}^{\pm})$, $(\hat{c}^{\pm})^2 = p_{\rho}(\hat{\rho}^{\pm}, \widehat{S}^{\pm}) > 0$, and $p = p(\rho, S)$ is the state equation of gas, $\hat{\rho}^{\pm} > 0$ is the unperturbed density for $x_1 \gtrless 0$, etc. (see [45]). As in [45], without loss of generality we suppose that $\boldsymbol{\sigma} = 0$ (see (2.1)), i.e., $\widehat{A}_{\nu}^{\pm} = \widehat{A}_1^{\pm}$ and consider the homogenous problem ($\mathbf{f}^{\pm} = 0$ and $\mathbf{g} = 0$).

Remark 2.5. Since $\det \widehat{A}_1^{\pm} = 0$, the boundary $x_1 = 0$ is characteristic, i.e., current-vortex sheet is a characteristic discontinuity. For shock waves the correct number of boundary conditions is guaranteed by the Lax conditions (1.20). For the general case, the number of boundary conditions should be equal to

$$1 + \sum_{\pm} \# \text{ positive eigenvalues of } \pm A_{\nu}^{\pm} \text{ counting multiplicity.}$$

That is, for current-vortex sheets the correct number of boundary conditions is three. At first sight, problem (2.2a), (2.16) is overdetermined. On the other hand, one can show that for the original nonlinear problem the boundary conditions $(\mathbf{H}^{\pm}, \mathbf{N}) = 0$ (see [45]) can be regarded as the restrictions only on the initial data. This was shown in [46] for the case of incompressible MHD, but this proposition can be easily proved for compressible current-vortex sheets as well. Of course, this fact can be analogously (and easier) proved for the linear problem. That is, for problem (2.2a), (2.16) the boundary conditions (2.16b) are just the restrictions on the initial data.

Unlike, for example, MHD shock waves or Alfvén discontinuities [13, 44], for current-vortex sheets the Lopatinski determinant can be explicitly written out. At the same time, it is reduced to an algebraic equation of the tenth degree depending on seven dimensionless parameters and one more inner parameter determining the wave vector (see [45]). Moreover, the squaring was applied under the reduction of the Lopatinski determinant to this algebraic equation and, therefore, it can introduce spurious roots. For all these reasons both the analytical analysis and the *full* numerical study of the Lopatinski determinant are unacceptable for finding the Lopatinski condition. Although, one can analytically show that the uniform Lopatinski condition is never satisfied for problem (2.2a), (2.16), i.e., planar current-vortex sheets can be either violently unstable or weakly (neutrally) stable (see [45]). The alternative energy method suggested in [45] has first enabled one to find sufficient conditions for their weak stability.

The method in [45] can be now described in terms of the notation of dissipative symmetrizer. In fact, in [45] the dissipative 0-symmetrizer $\mathbb{S} = \{P^+, P^-, \mathbf{R}^+, \mathbf{R}^-\}$ was suggested for problem (2.2a), (2.16), where $P^{\pm} = P(\widehat{\mathbf{U}}^{\pm})$, $\mathbf{R}^{\pm} = \lambda(\widehat{\mathbf{U}}^{\pm})\mathbf{R}(\widehat{\mathbf{U}}^{\pm})$,

$$P = \begin{pmatrix} 1 & \dfrac{\lambda H_1}{\rho c^2} & \dfrac{\lambda H_2}{\rho c^2} & \dfrac{\lambda H_3}{\rho c^2} & 0 & 0 & 0 & 0 \\ \lambda H_1 \rho & 1 & 0 & 0 & -\rho\lambda & 0 & 0 & 0 \\ \lambda H_2 \rho & 0 & 1 & 0 & 0 & -\rho\lambda & 0 & 0 \\ \lambda H_3 \rho & 0 & 0 & 1 & 0 & 0 & -\rho\lambda & 0 \\ 0 & -\lambda & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & -\lambda & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & -\lambda & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}, \quad \mathbf{R} = -\begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \\ H_1 \\ H_2 \\ H_3 \\ 0 \end{pmatrix},$$

$\lambda = \lambda(\mathbf{U})$ is a function, and the constants $\lambda^{\pm} = \lambda(\widehat{\mathbf{U}}^{\pm})$ are chosen below. Actually, the application of $\{P, \mathbf{R}\}$ to the original nonlinear MHD system gives a new symmetric form [45] of the MHD equations with the hyperbolicity condition, $\mathcal{A}_0(\mathbf{U}) = PA_0 > 0$,

$$\rho\lambda^2 < \frac{1}{1 + c_{\mathrm{A}}^2/c^2}, \tag{2.17}$$

where $c_{\mathrm{A}} = |\mathbf{H}|/\sqrt{\rho}$ (see [45]).

Note that for current sheets, i.e., for the case when $[\hat{\mathbf{v}}] = 0$ ($\hat{\mathbf{v}}^{\pm} = (0, \hat{v}_2^{\pm}, \hat{v}_3^{\pm})$) the boundary conditions (2.16) are dissipative:

$$\big[(\widehat{A}_1\mathbf{U}, \mathbf{U})\big]\big|_{x_1=0} = 2q^+[v_1] = 2q^+\big([\hat{\mathbf{v}}'], \nabla_{\mathrm{x}'} f\big) = 0,$$

where $\hat{\mathbf{v}}'^{\pm} = (\hat{v}_2^{\pm}, \hat{v}_3^{\pm})$. That is, for current sheets one has the identical 0-symmetrizer $\mathbb{S} = \{I, 0, I, 0\}$ ($\lambda^{\pm} = 0$). Suppose now that $[\hat{\mathbf{v}}] \neq 0$ and $\widehat{\mathbf{H}}^+ \times \widehat{\mathbf{H}}^- \neq 0$ (for the particular case $\widehat{\mathbf{H}}^+ \times \widehat{\mathbf{H}}^- = 0$ we refer to [45]). The matrices $\widehat{\mathcal{A}}_1^{\pm}$ (cf. (2.5)) have the form

$$\widehat{\mathcal{A}}_1^{\pm} = \begin{pmatrix} 0 & 1 & 0 & 0 & -\lambda^{\pm} & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & \widehat{H}_2^{\pm} & \widehat{H}_3^{\pm} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -\lambda^{\pm} & 0 & 0 & 0 & 0 & -\lambda^{\pm}\widehat{H}_2^{\pm} & -\lambda^{\pm}\widehat{H}_3^{\pm} & 0 \\ 0 & \widehat{H}_2^{\pm} & 0 & 0 & -\lambda^{\pm}\widehat{H}_2^{\pm} & 0 & 0 & 0 \\ 0 & \widehat{H}_3^{\pm} & 0 & 0 & -\lambda^{\pm}\widehat{H}_3^{\pm} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

Then, by virtue of (2.16),

$$\big[(\widehat{\mathcal{A}}_1\mathbf{U}, \mathbf{U})\big]\big|_{x_1=0} = 2q^+[v_1 - \lambda H_1] = 2q^+\big([\hat{\mathbf{v}}' - \lambda\widehat{\mathbf{H}}'], \nabla_{\mathrm{x}'} f\big),$$

where $\widehat{\mathbf{H}}'^{\pm} = (\widehat{H}_2^{\pm}, \widehat{H}_3^{\pm})$.

The constants $\lambda^{\pm}$ are chosen so that $[\hat{\mathbf{v}}' - \lambda\widehat{\mathbf{H}}'] = 0$:

$$\lambda^{\pm} = -\frac{|[\hat{\mathbf{v}}]|\,\sin\varphi^{\mp}}{|\widehat{\mathbf{H}}^{\pm}|\,\sin(\varphi^+ - \varphi^-)}, \quad \cos\varphi^{\pm} = \frac{([\hat{\mathbf{v}}], \widehat{\mathbf{H}}^{\pm})}{|[\hat{\mathbf{v}}]|\,|\widehat{\mathbf{H}}^{\pm}|}.$$

For such $\lambda^{\pm}$ the boundary conditions for system (2.5) are dissipative and, therefore, $\mathbb{S}$ is the dissipative (but *not* strictly dissipative) 0-symmetrizer, provided that $\widehat{\mathcal{A}}_0^{\pm} = \mathcal{A}_0(\widehat{\mathbf{U}}^{\pm}) > 0$. In view of (2.17), the last conditions for the chosen $\lambda^{\pm}$ read:

$$|[\hat{\mathbf{v}}]| < |\sin(\varphi^+ - \varphi^-)| \min\left\{\frac{\gamma^+}{|\sin\varphi^-|}, \frac{\gamma^-}{|\sin\varphi^+|}\right\}, \tag{2.18}$$

where $\gamma^{\pm} = \hat{c}^{\pm}\hat{c}_{\mathrm{A}}^{\pm}/\big((\hat{c}^{\pm})^2 + (\hat{c}_{\mathrm{A}}^{\pm})^2\big)^{1/2}$. Inequality (2.18) represents the sufficient condition for the neutral stability of compressible current-vortex sheets. This condition is of importance for various astrophysical applications such as, for example, the heliopause model [4]. As was shown in [45, 46], in the incompressibility limit inequality (2.18) describes exactly half of the parameter domain of neutral stability.

2.4. Example 3: Gas dynamical shock waves. The system of gas dynamics is an unconstrained hyperbolic system, and gas dynamical shock waves are known to be 1-shocks. Therefore, while constructing a strictly dissipative symmetrizer one can suppose that $P^- = \gamma I$ (see Remark 2.1) and, clearly, $\mathbf{R}^{\pm}_{j,\alpha} = 0$. Keeping in mind the observation about P^-, without loss of generality the perturbation ahead the planar 1-shock can be assumed to be equal to zero: $\mathbf{U} = 0$ for $x_1 < 0$. That is, for gas dynamical shocks the constant coefficients linearized problem (see (2.2)) is formulated in the half-space $\mathbb{R}^n_+$ and the strictly dissipative p-symmetrizer for it is just a matrix: $\mathbb{S} = P^+$.

For the 2D case ($n = 2$) and in dimensionless values the constant coefficients linearized problem for gas dynamical shock waves has the form of (2.2) with $\mathbf{U}|_{x_1<0} = 0$ and $\widehat{A}_0^+ = \mathrm{diag}(1, M^2, M^2, 1)$,

$$\widehat{A}_\nu^+ = \widehat{A}_1^+ = \begin{pmatrix} 1 & 1 & 0 & 0 \\ 1 & M^2 & 0 & 0 \\ 0 & 0 & M^2 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad \widehat{A}_2^+ = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

(without loss of generality $\boldsymbol{\sigma} = 0$, $\mathbf{f}^{\pm} = 0$, and $\mathbf{g} = 0$). Here $M = \hat{v}_1^+/\hat{c}^+$ is the Mach number behind the shock (in view of the Lax shock conditions, $M < 1$), $\widehat{\mathbf{U}}^{\pm} = (\hat{p}^{\pm}, \hat{v}_1^{\pm}, 0, \widehat{S}^{\pm})$, $(\hat{c}^{\pm})^2 = (\rho^2 E_\rho)_\rho(\hat{\rho}^{\pm}, \widehat{S}^{\pm}) > 0$, and $E = E(\rho, S)$ is the state equation of gas, etc. (see, e.g., [13]). The vector $\mathbf{U} = (p, v_1, v_2, S)$ is the vector of perturbations in dimensionless values [13] and $\widehat{A}_\alpha^+ = D(\widehat{\mathbf{U}}^+)^* A_\alpha(\widehat{\mathbf{U}}^+) D(\widehat{\mathbf{U}}^+)$, where $D(\widehat{\mathbf{U}}^+)$ is a diagonal matrix reducing system $(2.2\mathrm{a})|_{x_1>0}$ to a dimensionless form.

The boundary conditions in a dimensionless form and after eliminating the function $f(t, x_2)$ read [13]:

$$v_1 + b_1 p = 0, \quad (v_2)_t = b_2 p_{x_2}, \quad S = b_3 p, \tag{2.19}$$

where

$$b_1 = \frac{a+1}{2M^2}, \quad b_2 = \frac{(a-1)R}{2M^2}, \quad b_3 = 1 - \frac{a}{M^2}, \quad a = \frac{h - R + 1}{h/M^2 - R + 1},$$

$R = \hat{\rho}^+/\hat{\rho}^-$, $h = (2E_S/(\rho E_{\rho S}))(\hat{\rho}^+, \widehat{S}^+)$. As is known (see [13, 34] and references therein), the boundary conditions (2.19) satisfy the uniform Lopatinski condition, i.e., planar gas dynamical shock waves are *uniformly stable* if and only if

$$\frac{M^2(R+1) - 1}{M^2(R-1) + 1} < a < 1. \tag{2.20}$$

The energy method enabling one to deduce an a priori estimate with no loss of derivatives for (2.2a), (2.19), provided that the uniform Lopatinski condition (2.20) holds, was suggested by Blokhin [6]. We now formalize this method by writing out a strictly dissipative 2-symmetrizer for this problem (for the 3D case we refer to [13] and references therein). The construction of this symmetrizer is based on a certain symmetrization of the wave equation for the pressure perturbation p implied by the acoustics system:

$$\tilde{\partial}_t^2 p - \tilde{\partial}_1^2 p - \tilde{\partial}_2^2 p = 0, \tag{2.21}$$

where

$$\tilde{\partial}_t = \frac{M}{b^2}\,\partial_t, \quad \tilde{\partial}_1 = \partial_1 - \frac{M^2}{b^2}\,\partial_t, \quad \tilde{\partial}_2 = \frac{1}{b}\,\partial_2, \quad b = \sqrt{1-M^2} \in \mathbb{R}_+.$$

Using the boundary conditions (2.19) and the acoustics system itself, one can obtain the following boundary condition for (2.21):

$$M^2(1+b_1)p_{tt} - b^2 p_{tx_1} + M^2 b_2 p_{x_2x_2} = 0, \quad x_1 = 0. \tag{2.22}$$

Problem (2.21), (2.22) is "symmetrized" as follows (see [13] for details):

$$B_0\mathbf{Y}_t + B_1\mathbf{Y}_{x_1} + B_2\mathbf{Y}_{x_2} = 0 \quad \text{for } x_1 > 0, \tag{2.23}$$

$$\mathcal{M}\mathbf{Y} = 0 \quad \text{for } x_1 = 0, \tag{2.24}$$

where

$$\mathbf{Y} = \begin{pmatrix} \mathbf{Y}_1 \\ \mathbf{Y}_2 \\ \mathbf{Y}_3 \end{pmatrix}, \quad \mathbf{Y}_1 = \tilde{\partial}_t \begin{pmatrix} \tilde{\partial}_t p \\ \tilde{\partial}_1 p \\ \tilde{\partial}_2 p \end{pmatrix}, \quad \mathbf{Y}_i = \tilde{\partial}_{i-1} \begin{pmatrix} \tilde{\partial}_t p \\ \tilde{\partial}_1 p \\ \tilde{\partial}_2 p \end{pmatrix}, \quad i = 2, 3,$$

$$B_0 = \frac{M}{b^2}\mathcal{T}^*\left\{\begin{pmatrix} 1 & -M \\ -M & 1 \end{pmatrix} \otimes \mathcal{H}\right\}\mathcal{T}, \quad B_1 = \mathcal{T}^*\left\{\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \otimes \mathcal{H}\right\}\mathcal{T},$$

$$B_2 = \frac{1}{b}\mathcal{T}^*\left\{\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \otimes \mathcal{H}\right\}\mathcal{T}, \quad \mathcal{T} = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 0 & -1 \\ 0 & -1 & 0 \\ 0 & -1 & 0 \\ 1 & 0 & 1 \end{pmatrix} \otimes I_3,$$

$$\mathcal{H} = \begin{pmatrix} P_1 - P_3 & -P_2 - P_4 \\ -P_2 + P_4 & P_1 + P_3 \end{pmatrix}, \quad \mathcal{M} = \begin{pmatrix} \mathcal{M}_1 & \mathcal{M}_2 & \mathcal{M}_3 \end{pmatrix},$$

$$\mathcal{M}_1 = \begin{pmatrix} 1 & 2 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad \mathcal{M}_2 = \begin{pmatrix} -2 & -1 & 0 \\ 0 & 0 & -1 \\ 0 & -Mb_1 & 0 \end{pmatrix}, \quad \mathcal{M}_3 = \begin{pmatrix} 0 & 0 & -1 \\ 0 & 1 & 0 \\ 0 & 0 & -b_0 \end{pmatrix},$$

P_k ($k = \overline{1,3}$) are arbitrary symmetric matrices of order 3, P_4 is an arbitrary antisymmetric matrix of order 3, and $b_0 = Mb_1 + (M^3b_2/b^2)$.

Referring for detailed arguments to [13], one gets (cf. (2.14))

$$-(B_1\mathbf{Y}, \mathbf{Y})|_{x_1=0} = -\left(\{\mathcal{S}^*\mathcal{H} + \mathcal{H}\mathcal{S}\}\mathbf{V}_2, \mathbf{V}_2\right)|_{x_1=0},$$

where

$$\mathbf{V} = \mathcal{T}\mathbf{Y} = \begin{pmatrix} \mathbf{V}_1 \\ \mathbf{V}_2 \end{pmatrix}, \quad \mathbf{V}_1|_{x_1=0} = \mathcal{S}\mathbf{V}_2|_{x_1=0}, \quad \mathcal{S} = \begin{pmatrix} \mathcal{S}_1 & -\mathcal{S}_2 \\ I_3 & 0 \end{pmatrix},$$

$$\mathcal{S}_1 = 2(\mathcal{M}_1 - \mathcal{M}_3)^{-1}\mathcal{M}_2, \quad \mathcal{S}_2 = (\mathcal{M}_1 - \mathcal{M}_3)^{-1}(\mathcal{M}_1 + \mathcal{M}_3).$$

One can show that all the eigenvalues of the matrix $\mathcal{S}$ lie strictly in the left half-plane ($\Re\lambda_i(\mathcal{S}) < 0$, $i = \overline{1,6}$) if and only if the uniform Lopatinski condition (2.20) holds. In this case the Lyapunov matrix equation in the form of (2.15) has the unique solution

$\mathcal{H} = \mathcal{H}^* > 0$ for any symmetric and positive definite matrix G. Moreover, since $\mathcal{H} > 0$, the matrix $B_0 > 0$. The assumption $G > 0$ yields

$$-(B_1\mathbf{Y}, \mathbf{Y})|_{x_1=0} = (G\mathbf{V}_2, \mathbf{V}_2)\,|_{x_1=0} \geq C_1|\mathbf{X}^+|^2,$$

where

$$\mathbf{X} = (p_{tt}, p_{tx_1}, p_{tx_2}, p_{x_1x_1}, p_{x_1x_2}, p_{x_2x_2}), \quad \mathbf{X}^+ = \mathbf{X}|_{x_1=0}, \quad \mathbf{Y} = \mathcal{K}\mathbf{X},$$

$\mathcal{K}$ is a 9×6 matrix which can be explicitly written out, and $C_1 = C_1(G) > 0$ is a constant depending on the norm of the matrix G (as well as on the norms of the matrices $\mathcal{S}$, $\mathcal{T}$, and $\mathcal{K}$).

In fact, we have constructed the strictly dissipative 1-symmetrizer for the subproblem, (2.21), (2.22), for the vector (p_t, p_{x_1}, p_{x_2}). We are now ready to describe the strictly dissipative 2-symmetrizer for the whole problem, (2.2a), (2.19). It has the form

$$\mathbb{S} = P^+ = I_{24} + \mathcal{N}^*\mathcal{K}^*B_0\mathcal{K}\mathcal{N}\big(I_6 \otimes (\widehat{A}_0^+)^{-1}\big),$$

where $\mathcal{N}$ is the projector of $\mathbf{W} = \mathbf{W}_2 = (\mathbf{U}_{tt}, \mathbf{U}_{tx_1}, \ldots, \mathbf{U}_{x_2x_2})$ on $\mathbf{X}$, i.e., $\mathbf{X} = \mathcal{N}\mathbf{W}$.

It is clear that $\widehat{\mathcal{A}}_0^+ = P^+(I_6 \otimes \widehat{A}_0^+) > 0$. Indeed, $(\widehat{\mathcal{A}}_0^+\mathbf{W}, \mathbf{W}) = ((I_6 \otimes \widehat{A}_0^+)\mathbf{W}, \mathbf{W}) + (B_0\mathbf{Y}, \mathbf{Y}) > 0$ for all $\mathbf{W} \neq 0$. Concerning condition (2.8), one has

$$-(\widehat{\mathcal{A}}_1^+\mathbf{W}, \mathbf{W})|_{x_1=0} = -((I_6 \otimes \widehat{A}_1^+)\mathbf{W}, \mathbf{W})|_{x_1=0} - (B_1\mathbf{Y}, \mathbf{Y})|_{x_1=0}.$$

Using the boundary conditions (2.19) and the acoustics system it is not difficult to show that $\mathbf{W}|_{x_1=0} = B\mathbf{X}|_{x_1=0}$, where B is a 24×6 matrix with elements depending on the coefficients of (2.19) and the matrices $\widehat{A}_\alpha^+$. Therefore, there exists a positive constant C_2 such that

$$-((I_6 \otimes \widehat{A}_1^+)\mathbf{W}, \mathbf{W})|_{x_1=0} \geq -C_2|\mathbf{X}^+|^2.$$

Analogous arguments show that $|\mathbf{X}^+|^2 \geq C_3|\mathbf{W}^+|^2$ with a constant $C_3 > 0$. On the other hand, by an appropriate choice of the matrix G (i.e., the choice of matrices P_i) one can achieve that $C_1 - C_2 > 0$. Hence,

$$-(\widehat{\mathcal{A}}_1^+\mathbf{W}, \mathbf{W})|_{x_1=0} \geq (C_1 - C_2)|\mathbf{X}^+|^2 \geq \delta|\mathbf{W}^+|^2,$$

where $\delta = (C_1 - C_2)C_3 > 0$. Thus, $\mathbb{S}$ is indeed the strictly dissipative 2-symmetrizer.

2.5. Example 4: Fast MHD shock waves. As gas dynamical shock waves, fast MHD shock waves are also 1-shocks (see, e.g., [13]). That is, the constant coefficient linearized problem for fast MHD shocks in 2D (for 3D see [14]) and in dimensionless values has the form of the problem for gas dynamical shock waves formulated above, with $\widehat{A}_0^+ = \mathrm{diag}(1, M^2, M^2, 1, 1, 1)$,

$$\widehat{A}_1^+ = \begin{pmatrix} 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & M^2 & 0 & 0 & h_2 & 0 \\ 0 & 0 & M^2 & 0 & -h_1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & h_2 & -h_1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}, \quad \widehat{A}_2^+ = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -h_2 & 0 & 0 \\ 1 & 0 & 0 & h_1 & 0 & 0 \\ 0 & -h_2 & h_1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$\widehat{\mathbf{U}}^{\pm} = (\hat{p}^{\pm}, \hat{v}_1^{\pm}, \hat{v}_2^{\pm}, \widehat{H}_1^{\pm}, \widehat{H}_2^{\pm}, \widehat{S}^{\pm})$, $\hat{v}_2^{+} = 0$, $h_i = \widehat{H}_i^{+}/(\hat{c}\sqrt{\hat{\rho}})$, $\mathbf{U} = (p, v_1, v_2, H_1, H_2, S)$, etc. (see [12, 13]). The boundary conditions read

$$\begin{gathered} v_1 + b_1 p = q_1 f_{x_2}, \quad f_t = b_2 p + q_2 f_{x_2}, \quad v_2 = b_3 f_{x_2} + q_3 p, \\ H_2 = h_2 b_0 f_t - h_2 v_1 + h_1 v_2, \quad H_1 = h_2 b_0 f_{x_2}, \quad S = b_4 p + q_4 f_{x_2}, \end{gathered} \tag{2.25}$$

where the coefficients b_i are explicitly written out in [12, 13] for the case of a polytropic gas and a weak magnetic field, $q = \sqrt{h_1^2 + h_2^2} \ll 1$ (for the general case, $q \in (0, +\infty)$, see [44]), the coefficients $q_i = O(q^2)$ for $q \ll 1$, and $b_0 = 1 - (\widehat{H}_2^{-}/\widehat{H}_2^{+}) \in (0,1)$ (for parallel shocks, $\widehat{H}_2^{\pm} = 0$, $b_0 := 0$).

The energy method suggested in [12] is based on the fact that the magnetoacoustics system implies the wave equation with an additional "magnetic" term:

$$\tilde{\partial}_t^2 p - \tilde{\partial}_1^2 p - \tilde{\partial}_2^2 p + \frac{q}{b^2} \triangle Q = 0 \tag{2.26}$$

(notations are the same as in (2.21)), where $Q = (\mathbf{b}, \mathbf{H})$, $\mathbf{H} = (H_1, H_2)$, and $\mathbf{b} = (-h_1/q, h_2/q)$ ($|\mathbf{b}| = 1$). Then, the counterpart of system (2.23) reads

$$B_0 \mathbf{Y}_t + B_1 \mathbf{Y}_{x_1} + B_2 \mathbf{Y}_{x_2} + \frac{q}{b^2} \begin{pmatrix} P_1 \\ P_2 \\ P_3 \end{pmatrix} \triangle \mathbf{Q} = 0 \quad \text{for } x_1 > 0, \tag{2.27}$$

where $\mathbf{Q} = (\tilde{\partial}_t Q, \tilde{\partial}_1 Q, \tilde{\partial}_2 Q)$. Moreover, for the function p we can obtain a counterpart of the boundary condition (2.22) (see [12, 14]) which implies (2.24) with the matrices $\mathcal{M}_i$ being slightly different from the corresponding matrices in gas dynamics for the case $q \ll 1$ (the norms of the differences are of order $O(q^2)$).

The crucial role in deducing the a priori estimate [12] for (2.2a), (2.25) is played by the important fact that the term

$$\left(\mathbf{Y}, \begin{pmatrix} P_1 \\ P_2 \\ P_3 \end{pmatrix} \triangle \mathbf{Q} \right) = \sum_{i=1}^{3} (\mathbf{Y}_i, P_i \triangle \mathbf{Q})$$

can be represented in a divergent form,

$$\sum_{i=1}^{3} (\mathbf{Y}_i, P_i \triangle \mathbf{Q}) = (R_0 \mathbf{W}, \mathbf{W})_t + (R_1 \mathbf{W}, \mathbf{W})_{x_1} + (R_2 \mathbf{W}, \mathbf{W})_{x_2}, \tag{2.28}$$

where $\mathbf{W} = \mathbf{W}_2$, and the quadratic forms $(R_\alpha \mathbf{W}, \mathbf{W})$ are explicitly written out in [12, 13] (if necessary, the symmetric matrices R_α of order 36 can be written out as well). While obtaining representation (2.28) the divergent constraint $\operatorname{div} \mathbf{H} = 0$ and the magnetoacoustics system itself were essentially used.

The strictly dissipative 2-symmetrizer for fast MHD shock waves has the form

$$\mathbb{S} = \left\{ P^{+}, \{\mathbf{R}_{1,\alpha}^{+}\}_{|\alpha|=2} \right\},$$

with

$$P^{+} = I_{36} + \mathcal{N}^* \mathcal{K}^* B_0 \mathcal{K} \mathcal{N} \big(I_6 \otimes (\widehat{A}_0^{+})^{-1} \big) + P_0^{+}, \quad \{\mathbf{R}_{1,\alpha}^{+}\}_{|\alpha|=2} = \{\mathbf{R}_1, \ldots, \mathbf{R}_6\}.$$

Here $\mathcal{N}$ is the projector of $\mathbf{W}$ on $\mathbf{X}$, the matrices $\mathcal{K}$ and B_0 and the vector $\mathbf{X}$ are the same as for gas dynamical shocks, the matrix P_0^{+} and the vectors $\mathbf{R}_i$, which are of order $O(q)$ for $q \ll 1$, can be explicitly written out by analyzing representation (2.28). Moreover,

$$(\widehat{\mathcal{A}}_0^+\mathbf{W},\mathbf{W}) = ((I_6 \otimes \widehat{A}_0^+)\mathbf{W},\mathbf{W}) + (B_0\mathbf{Y},\mathbf{Y}) + \frac{2q}{b^2}(R_0\mathbf{W},\mathbf{W}),$$

$$-(\widehat{\mathcal{A}}_1^+\mathbf{W},\mathbf{W})|_{x_1=0} = -\left(\left(I_6 \otimes \widehat{A}_1^+ + \frac{2q}{b^2}R_0\right)\mathbf{W},\mathbf{W}\right)\Bigg|_{x_1=0} -(B_1\mathbf{Y},\mathbf{Y})|_{x_1=0}.$$

It is clear that for $\mathcal{H} > 0$ and $q \ll 1$ the matrix $\widehat{\mathcal{A}}_0^+ > 0$. For the case of a weak magnetic field ($q \ll 1$) and a polytropic gas, one can show that all the eigenvalues of the matrix $\mathcal{S}$ lie strictly in the left half-plane. That is, $-(\widehat{\mathcal{A}}_1^+\mathbf{W},\mathbf{W})|_{x_1=0} \geq \delta|\mathbf{W}^+|^2$, where the constant $\delta > 0$ for $q \ll 1$ (see [12, 13] for more details). Thus, $\mathbb{S}$ is indeed the strictly dissipative 2-symmetrizer of (2.2a), (2.25) for the case of a weak magnetic field and a polytropic gas. Concerning the case of a general equation of state, the same is true if we require the fulfillment of (2.20) that is in fact the uniform Lopatinski condition for fast MHD shocks for $q \ll 1$.

Remark 2.6. In principle, for the general case, $q \in (0, +\infty)$, we can try to find the conditions for $\widehat{\mathbf{U}}^\pm$ guaranteeing the fulfillment of the requirements $\widehat{\mathcal{A}}_0^+ > 0$ and $-B^*\widehat{\mathcal{A}}_1^+B > 0$, where $\mathbf{W}^+ = B\mathbf{X}^+$. Then, $\mathbb{S}$ is the strictly dissipative 2-symmetrizer, provided that these conditions hold. However, rather cumbersome calculations should be unfortunately performed to find the mentioned conditions. At the same time, if they are possible to be found at least numerically, for fixed parameters $\widehat{\mathbf{U}}^\pm$, then it is interesting to compare them with the uniform stability domain for fast MHD shock waves. This domain was found in [44] by numerical testing of the uniform Lopatinski condition with the help of an algorithm suggested for 1-shocks.

2.6. Further examples. For gas dynamical shock waves we have presented a strictly dissipative 2-symmetrizer for the 2D case. For the 3D case the structure of the 2-symmetrizer is different, but the process of construction of this symmetrizer is also based on using a symmetrization of the wave equation. The same structure has the strictly dissipative 2-symmetrizer for shock waves in relativistic gas dynamics (see [13]) and in nonrelativistic radiation hydrodynamics [3]. For shock waves in relativistic radiation hydrodynamics [15] the structure of the strictly dissipative 2-symmetrizer is a little bit more complicated; however, it refers to a symmetrization of the wave equation as well.

It is interesting to note that, for instance, the system of Landau's equations of superfluid [29] is a constrained hyperbolic system, but the relations $\nabla \times \mathbf{v}_\mathrm{s} = 0$ are not used under the construction of the strictly dissipative 2-symmetrizer for shock waves in this model (see [11] and references therein), i.e., $\mathbf{R}_{j,\alpha}^\pm = 0$. Unfortunately, there is not a general method to construct a (strictly) dissipative p-symmetrizer. For most concrete examples $p = 2$ and they are based on using different symmetrizations of the wave equation. So, Definition 2.1 was given for $p \geq 0$, but we will privately suppose that $p = 0$ or $p = 1$ or $p = 2$ (actually, we do not know examples with $p \geq 3$). Moreover, for the physical cases $n = 2$ and $n = 3$ (2D and 3D) the existence of a strictly dissipative p-symmetrizer with $p \geq 3$ implies a weaker local existence theorem for the nonlinear problem (in the generic case, for a symmetrizer with $p \geq [n/2] + 2$ one obtains a weaker nonlinear result, see section 4).

Observe that in [10] also a strictly dissipative 1-symmetrizer was in fact constructed for gas dynamical shock waves. But in this case the domain D (see Definition

2.1) is only a subdomain of the whole domain of the uniform Lopatinski condition. Although, it should be noted that for nonlinear analysis (see section 4) a 1-symmetrizer has no advantages in comparison with a 2-symmetrizer.

3. The constant coefficients linear analysis. In the rest of the paper we consider *shock waves* and only make certain remarks concerning the case of characteristic discontinuities.

ASSUMPTION 3.1. *For the boundary conditions* (2.2b), rank $\widehat{B} = n$, *i.e., the vectors* $[\boldsymbol{\mathcal{P}}^0(\widehat{\mathbf{U}})]$, $[\boldsymbol{\mathcal{P}}^k(\widehat{\mathbf{U}})]$, $k=\overline{2,n}$, *are linearly independent.*

It follows from Assumption 3.1 that $n \le N$ and there is a nonsingular matrix $\mathcal{M} = \mathcal{M}(\widehat{\mathbf{U}}^+, \widehat{\mathbf{U}}^-)$ of order N such that

$$\mathcal{M}\widehat{B} = \begin{pmatrix} I_n \\ 0 \end{pmatrix}.$$

Let

$$\mathcal{M} = \begin{pmatrix} \mathcal{M}^{\mathrm{I}} \\ \mathcal{M}^{\mathrm{II}} \end{pmatrix},$$

where $\mathcal{M}^{\mathrm{I}}$ and $\mathcal{M}^{\mathrm{II}}$ are matrices of order $n \times N$ and $(N-n)\times N$, respectively. Then the boundary conditions (2.2b) can be divided into the two groups

$$\mathbf{F} = \mathcal{M}^{\mathrm{I}}\big[\widehat{S}^{-1}\widehat{A}_\nu \mathbf{U}\big] + \mathcal{M}^{\mathrm{I}}\mathbf{g}, \quad x_1 = 0, \tag{3.1}$$

$$-\mathcal{M}^{\mathrm{II}}\big[\widehat{S}^{-1}\widehat{A}_\nu \mathbf{U}\big] = \mathcal{M}^{\mathrm{II}}\mathbf{g}, \quad x_1 = 0. \tag{3.2}$$

Note that by cross differentiation one can, in principle, eliminate the front f from relations (3.1). Such a procedure results in first order boundary conditions (see, e.g., (2.19)).

Assumption 3.1 is quite natural because, as was proved in [37], it is fulfilled for uniformly stable shock waves, i.e., when (2.2) satisfies the uniform Lopatinski condition. Moreover, as was shown in [17], Assumption 3.1 is also fulfilled for weakly stable shocks under some additional supposition. At the same time, for example, for gas dynamical and MHD shock waves Assumption 3.1 is always satisfied if only $R = \hat{\rho}^+/\hat{\rho}^- \neq 1$.

THEOREM 3.1. *Suppose the Lax shock conditions* (1.20) *and all the assumptions above are fulfilled. Suppose also that* (2.2) *has a strictly dissipative p-symmetrizer. Then, the a priori estimate*

$$\begin{aligned}
&\sum_{\pm}\Big\{|||\mathbf{U}(t)|||_{W_2^p(\mathbb{R}^n_\pm)} + \|\mathbf{U}^\pm\|_{W_2^p([0,T]\times\mathbb{R}^{n-1})}\Big\} + \|f\|_{W_2^{p+1}([0,T]\times\mathbb{R}^{n-1})}\\
&\qquad \le C\Bigg\{\sum_{\pm}\Big\{\|\mathbf{f}^\pm\|_{W_2^p([0,T]\times\mathbb{R}^n_\pm)} + |||\mathbf{U}_0|||_{W_2^p(\mathbb{R}^n_\pm)}\Big\}\\
&\qquad\qquad + \|\mathbf{g}\|_{W_2^p([0,T]\times\mathbb{R}^{n-1})} + \|f_0\|_{W_2^{p+1}(\mathbb{R}^{n-1})}\Bigg\}
\end{aligned} \tag{3.3}$$

holds for any $t \in (0,T)$. *Here* T *is a positive constant,* $C = C(T)$ *is a positive constant independent of the initial data and the source terms,*

$$|||(\cdot)(t)|||^2_{W_2^k} := \sum_{j=0}^{k} \|\partial_t^j(\cdot)(t)\|^2_{W_2^{k-j}}.$$

If (2.2) *has a dissipative (but not strictly dissipative) p-symmetrizer, the following weaker a priori estimate holds*

$$\begin{aligned}\sum_{\pm}\Big\{|||\mathbf{U}(t)|||_{W_2^r(\mathbb{R}^n_\pm)}+\|\mathbf{U}^\pm\|_{W_2^{r-1}([0,T]\times\mathbb{R}^{n-1})}\Big\}+\|f\|_{W_2^r([0,T]\times\mathbb{R}^{n-1})}\\ \leq C\Bigg\{\sum_{\pm}\Big\{\|\mathbf{f}^\pm\|_{W_2^r([0,T]\times\mathbb{R}^n_\pm)}+|||\mathbf{U}_0|||_{W_2^r(\mathbb{R}^n_\pm)}\Big\}\\ +\|\mathbf{g}\|_{W_2^{r+1}([0,T]\times\mathbb{R}^{n-1})}+\|f_0\|_{W_2^r(\mathbb{R}^{n-1})}\Bigg\},\end{aligned}\tag{3.4}$$

where $r=1$ *for* $p=0$ *and* $r=p$ *for* $p\geq 1$.

Proof. We will not prove estimate (3.3) in detail since arguments to do this are quite standard. By virtue of (2.6), (2.8), it follows from (2.5) that

$$\begin{aligned}I_1(t)+\int_0^t\int_{\mathbb{R}^{n-1}}\left(|\mathbf{W}^+|^2+|\mathbf{W}^-|^2\right)d\mathbf{x}'dt\\ \leq C_1\left\{I_1(0)+J(T)+\int_0^t I_1(s)ds\right\},\end{aligned}\tag{3.5}$$

where

$$I_1(t)=\sum_{\pm}\|\mathbf{W}(t)\|^2_{L_2(\mathbb{R}^n_\pm)},\quad J(T)=\|\mathbf{g}\|^2_{W_2^p([0,T]\times\mathbb{R}^{n-1})}+\sum_{\pm}\|\mathbf{f}^\pm\|^2_{W_2^p([0,T]\times\mathbb{R}^n_\pm)}.$$

Here and below $C_i=C_i(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-,\boldsymbol{\sigma})$, $i=1,2,3,\dots$, appearing under the analysis of (2.2) are positive constants.

If $p\neq 0$, we use the elementary inequality

$$I_0(t)\leq I_0(0)+\int_0^t I(s)ds\tag{3.6}$$

coming from the trivial identity

$$\frac{d}{dt}I_0(t)=2\sum_{\pm}\int_{\mathbb{R}^n_\pm}(\mathbf{Y},\mathbf{Y}_t)\,dt,$$

where $I(t)=I_0(t)+I_1(t)$, $\mathbf{Y}=(\mathbf{W}_0,\dots,\mathbf{W}_{p-1})$, $p\geq 1$,

$$I_0(t)=\sum_{\pm}|||\mathbf{U}(t)|||^2_{W_2^{p-1}(\mathbb{R}^n_\pm)}.$$

Inequalities (3.5) and (3.6) yield

$$I(t)\leq C_1\left\{I(0)+J(T)+\int_0^t I(s)ds\right\}.$$

Applying Gronwall's lemma, one gets

$$I(t)\leq C_2(I(0)+J(T)),\quad 0\leq t\leq T.\tag{3.7}$$

From trace's property one has

$$\int_0^t\int_{\mathbb{R}^{n-1}}\left(|\mathbf{Y}^+|^2+|\mathbf{Y}^-|^2\right)d\mathbf{x}'dt\leq\int_0^t I(s)ds.\tag{3.8}$$

Adding up (3.5) and (3.8) and taking into account estimate (3.7), we obtain

$$\sum_{\pm} \|\mathbf{U}^{\pm}\|^2_{W_2^p([0,T]\times\mathbb{R}^{n-1})} \leq C_3(I(0)+J(T)). \tag{3.9}$$

Using (3.9), the boundary conditions (3.1), and an elementary inequality for f like that in (3.6) for $\mathbf{U}$, we estimate the front perturbation f:

$$\|f\|^2_{W_2^{p+1}([0,T]\times\mathbb{R}^{n-1})} \leq C_4\left\{I(0)+J(T)+\|f_0\|^2_{W_2^{p+1}(\mathbb{R}^{n-1})}\right\}. \tag{3.10}$$

Estimates (3.7), (3.9), and (3.10) imply the desired a priori estimate (3.3).

Let us now assume (2.2) has a dissipative (but not strictly dissipative) p-symmetrizer. If $p=0$ we differentiate system (2.5) with respect to t and $\mathbf{x}'$ and obtain a symmetric hyperbolic system for the vector $(\mathbf{U}_t, \mathbf{U}_{x_2}, \dots, \mathbf{U}_{x_n})$. Using this system for the case $p=0$ or system (2.5) for $p\geq 1$ and taking into account (2.6) and (2.7), we obtain the inequality

$$I_1(t) + \int_0^t \int_{\mathbb{R}^{n-1}} (\widehat{B}\boldsymbol{\mathcal{G}}, \widetilde{\mathbf{Z}})d\mathbf{x}'dt \leq C_4\left\{I_1(0)+J(T)+\int_0^t I_1(s)ds\right\}, \tag{3.11}$$

where $\widehat{B}$ is a constant matrix, $\widetilde{\mathbf{Z}} = (\mathbf{Z}^+, \mathbf{Z}^-)$, $\mathbf{Z} = (\partial_t \mathbf{W}_{r-1}, \partial_2\mathbf{W}_{r-1}, \dots, \partial_n \mathbf{W}_{r-1})$ ($r=1$ for $p=0$ and $r=p$ for $p\geq 1$). Other notations are the same as in (3.5), but for the case of 0-symmetrizer $W := W_1$, $p=1$ in J, and the vector $\boldsymbol{\mathcal{G}}$ is formed by $\partial^{\alpha}_{t,\mathrm{x}'}\mathbf{g}$ ($|\alpha|=1$) and $\mathbf{f}^{\pm}|_{x_1=\pm 0}$. While obtaining (3.11) we used the relations

$$\mathbf{U}_{x_1} = -(\widehat{A}^{\pm}_{\nu})^{-1}\widehat{A}^{\pm}_0\mathbf{U}_t - \sum_{k=2}^n (\widehat{A}^{\pm}_{\nu})^{-1}\widehat{A}^{\pm}_k \mathbf{U}_{x_k} + (\widehat{A}^{\pm}_{\nu})^{-1}\mathbf{f}^{\pm}, \quad \mathbf{x}\in\mathbb{R}^n_{\pm}$$

(recall that we consider shock waves and, therefore, $\det \widehat{A}^{\pm}_{\nu} \neq 0$).

To estimate the boundary integral in the left-hand side of inequality (3.11) we carry out standard manipulations with derivatives. For example, with the terms like $u^+_{x_2}g$ and $u^+_{x_2}h^+$ appearing in this integral we proceed as follows:

$$\int_{\mathbb{R}^{n-1}} u^+_{x_2} g\, d\mathbf{x}' = -\int_{\mathbb{R}^{n-1}} u^+ g_{x_2}\, d\mathbf{x}',$$
$$\int_{\mathbb{R}^{n-1}} u^+_{x_2} h^+\, d\mathbf{x}' = -\int_{\mathbb{R}^n_+} (u_{x_2}h)_{x_1}\, d\mathbf{x} = \int_{\mathbb{R}^n_+} (u_{x_1}h_{x_2} - u_{x_2}h_{x_1})\, d\mathbf{x},$$

where $u=\partial^{\alpha}u_j$, $h=\partial^{\beta}f_k$, $g=\partial^{\gamma}_{t,\mathrm{x}'}g_k$, $|\alpha|=|\beta|=r-1$, $|\gamma|=r$, and g_k and f_k are, respectively, components of the vectors $\mathbf{g}$ and $\mathbf{f}^+$. Analogous standard arguments were also applied in [45] to treat lower order terms in the boundary integral for the variable coefficients linearized problem for current-vortex sheets. Observe that while estimating integrals like $\int_0^t\int_{\mathbb{R}^{n-1}} u^+_t h^+\, d\mathbf{x}'dt$ we should be more careful because terms in the form $\partial_t\{\cdots\}$ do not disappear under the integration over the domain $[0,t]\times(\mathbb{R}^n_+ \cup \mathbb{R}^n_-)$ (for corresponding simple arguments see [45]). As a result, omitting details, from (3.11) we deduce estimate (3.4). □

Remark 3.1. Using

$$\mathbf{U}_t = -(\widehat{A}^{\pm}_0)^{-1}\widehat{A}^{\pm}_{\nu}\mathbf{U}_{x_1} - \sum_{k=2}^n (\widehat{A}^{\pm}_0)^{-1}\widehat{A}^{\pm}_k \mathbf{U}_{x_k} + (\widehat{A}^{\pm}_0)^{-1}\mathbf{f}^{\pm}, \quad \mathbf{x}\in\mathbb{R}^n_{\pm},$$

one can reduce estimates (3.3) and (3.4) to those with the norms $\|(\cdot)(t)\|$ instead of the norms $|||(\cdot)(t)|||$.

COROLLARY 3.2. *If the symmetric hyperbolic system* (1.5) *meets either the block structure condition* [1, 35] *or the conditions of Métivier and Zumbrun* [38] *and problem* (2.2) *for the case of Lax shocks has a strictly dissipative p-symmetrizer, then in the parameter domain D the boundary conditions* (2.2b) *satisfy the uniform Lopatinski condition.*

Proof. First of all, following arguments like those used in [34] for strictly dissipative boundary value problems, one can easily obtain an analogue of estimate (3.3) when the exponentially weighted $W^s_{2,\eta}$-norms (with $s = p$ and $s = p + 1$) are used instead of the usual Sobolev norms, where

$$\|\cdot\|_{W^s_{2,\eta}} := \sum_{|\alpha|\leq s} \eta^{s-|\alpha|}\|e^{-\eta t}\partial^\alpha(\cdot)\|_{L_2}.$$

For the case when system (1.5) satisfies the block structure condition [1, 35, 32], it was proved in [32] (see also [37]) that such an estimate (with $s = 0$ and $s = 1$) holds for problem (2.2) *if and only if* this problem meets the uniform Lopatinski condition. This result was recently extended by Métivier and Zumbrun to the case of variable multiplicities provided that some additional conditions [38] hold. It is clear that the $L_{2,\eta}$-estimate (with the $W^1_{2,\eta}$-norm for f) implies $W^s_{2,\eta}$-estimates (see [37]). Hence, the boundary conditions (2.2b) satisfy the uniform Lopatinski condition. ∎

Remark 3.2. If the linear problem (2.2) meets the uniform Lopatinski condition and the symmetric hyperbolic system (1.5) satisfies either the block structure condition [1, 35] or the conditions of Métivier and Zumbrun [38], then the solution to (2.2) obeys an a priori L_2-estimate [32, 37]. That is, if $p > 0$, the result of Theorem 3.1 obtained for the linearized problem by the energy method is weaker than that in [32, 37] obtained by Kreiss' symmetrizer analysis in the sense that in estimate (3.3) we require more regularity for $\mathbf{U}$. However, if $p < [n/2] + 2$, for the original nonlinear problem the energy method gives the same result (see Theorem 4.1) as the technique used in [32, 37]. Since $p < [n/2] + 2$ for all the known concrete examples of p-symmetrizers, we will suppose that this condition is satisfied.

Remark 3.3. In [45] the a priori estimates for the linearized problem for current-vortex sheets were written out for the case of the homogenous problem ($\mathbf{f}^{\pm} = 0$ and $\mathbf{g} = 0$). For the case of the nonhomogenous problem (2.2a), (2.16) (with the source term $\mathbf{g}$ in (2.16)), the a priori estimate

$$\begin{aligned}\sum_{\pm}\Big\{|||\mathbf{U}(t)|||_{\widetilde{W}^1_2(\mathbb{R}^3_{\pm})} + \|\mathbf{V}^{\pm}\|_{L_2([0,T]\times\mathbb{R}^2)}\Big\} + \|f\|_{W^1_2([0,T]\times\mathbb{R}^2)} \\ \leq C\Bigg\{\sum_{\pm}\Big\{\|\mathbf{f}^{\pm}\|_{W^1_2([0,T]\times\mathbb{R}^3_{\pm})} + |||\mathbf{U}_0|||_{\widetilde{W}^1_2(\mathbb{R}^3_{\pm})}\Big\} \\ +\|\mathbf{g}\|_{W^2_2([0,T]\times\mathbb{R}^2)} + \|f_0\|_{W^1_2(\mathbb{R}^{n-1})}\Bigg\}\end{aligned}$$

can be deduced, provided that the sufficient neutral stability condition (2.18) holds. Here $\mathbf{V}$ ($= (q, v_1, H_1)$, see [45]) is the "noncharacteristic part" of $\mathbf{U}$,

$$|||\mathbf{U}(t)|||^2_{\widetilde{W}^s_2(\mathbb{R}^n_{\pm})} = |||\mathbf{V}(t)|||^2_{W^s_2(\mathbb{R}^n_{\pm})} + \sum_{|\alpha|\leq s}\|(\partial^\alpha_{t,\mathrm{x}'}\mathbf{U})(t)\|^2_{L_2(\mathbb{R}^n_{\pm})}.$$

For the general case of characteristic discontinuities, if we require that in (3.1)

$$\mathcal{M}^{\mathrm{I}}\big[\widehat{S}^{-1}\widehat{A}_\nu \mathbf{U}\big] = \mathcal{M}_1\mathbf{V}^+ + \mathcal{M}_2\mathbf{V}^- \tag{3.12}$$

with corresponding matrices $\mathcal{M}_i$, i.e., the vector-function $\mathbf{F}$ can be expressed by the "noncharacteristic parts" $\mathbf{V}^\pm$ of the traces $\mathbf{U}^\pm$, then in the counterparts of estimates (3.3) and (3.4) the $\widetilde{W}_2^s(\mathbb{R}^n_\pm)$-norms are used instead of the $W_2^s(\mathbb{R}^n_\pm)$-norms, and we can control only the "noncharacteristic" traces $\mathbf{V}^\pm$. If assumption (3.12) does not hold, we have weaker a priori estimates. For example, this is so for current-vortex sheets if $\widehat{\mathbf{H}}^+ \times \widehat{\mathbf{H}}^- = 0$. For this case, the a priori estimate indicates already the loss of two derivatives from the front f (see [45]).

4. Local existence of shock-front solutions. The local existence theorem for the nonlinear problem (1.17) has been first proved by Blokhin [7, 9] for uniformly stable gas dynamical shock waves by the direct energy method. Recall that the linearized constant coefficients problem for them has a strictly dissipative 2-symmetrizer (see section 2). The functional setting in the theorem from [7, 9] (see also [13]) is provided by the usual Sobolev spaces W_2^s, where $s \geq 3$. The analogous theorem, but in the exponentially weighted Sobolev spaces $W^s_{2,\eta}$, where s is large enough, was proved by Majda [33] for Lax shocks by Kreiss' symmetrizer technique [27] and using pseudo-differential calculus, provided that the symmetric hyperbolic system satisfies the block structure condition [1, 35, 32].

Recently, the theorem from [33] (see also [34]) was considerably improved by Métivier in [37], where the nonlinear local existence theorem was formulated in the form of Blokhin's theorem from [7, 9, 13] (see below). Actually, the theorem proved in [37] is valid for shock waves for which the linearized problem admits constructing Kreiss' symmetrizer. That is, the class of hyperbolic symmetrizable systems covered by this theorem is wider than that of systems satisfying the block structure condition. Moreover, taking into account the recent result in [38] mentioned above, the local existence theorem from [37] (see also [7, 9, 13]) takes place for the hyperbolic symmetrizable systems satisfying either the block structure condition or Métivier and Zumbrun's conditions [38]. That is, for Lax shock waves for which the assumption of Corollary 3.2 is fulfilled we have the following theorem (cf. [7, 9, 13, 37]).

THEOREM 4.1. *Let that the linearized constant coefficients problem* (2.2) *has a strictly dissipative p-symmetrizer. Suppose the initial data* (1.17c) *satisfy the hyperbolicity condition* $A_0 > 0$ *(for* $\mathbf{x} \in \mathbb{R}^n_\pm$*), the Lax shock conditions* (1.20)*, and the compatibility conditions (see* [37]*). Suppose also that* $(\mathbf{U}_0|_{x_1>0}, \mathbf{U}_0|_{x_1<0}, f_0) \in D$ *for all* $\mathbf{x} \in \mathbb{R}^n_\pm$ *(see Definition* 2.1*). Then, for all*

$$(\mathbf{U}_0, f_0) \in \big\{W_2^s(\mathbb{R}^n_+) \cap W_2^s(\mathbb{R}^n_-)\big\} \times W_2^{s+1}(\mathbb{R}^{n-1}),$$

where $s \geq [n/2] + 2$*, there is a sufficiently short time* $T > 0$ *such that* (1.17) *has a unique solution*

$$(\mathbf{U}, f) \in Z_T^s = \big\{X_s([0,T], \mathbb{R}^n_+) \cap X_s([0,T], \mathbb{R}^n_-)\big\} \times W_2^{s+1}([0,T] \times \mathbb{R}^{n-1}),$$

where

$$X_k([0,T], \mathbb{R}^n_\pm) := \bigcap_{j=0}^{k} C^j([0,T], W_2^{k-j}(\mathbb{R}^n_\pm))$$

with the norm $\|\cdot\|_{X_k} = \max\limits_{t\in[0,T]} |||(\cdot)(t)|||_{W_2^k}$.

It seems that for most physical examples of hyperbolic symmetrizable systems either the block structure condition or the "nonglancing" condition of Métivier and Zumbrun [38] is satisfied. Moreover, we still do not know any concrete example of a strictly dissipative p-symmetrizer for a hyperbolic system for which both of these conditions are violated. Therefore, in view of Corollary 3.2, construction of a strictly dissipative p-symmetrizer can be considered as an indirect test of the uniform Lopatinski condition. That is, as soon as such a symmetrizer is found, we have Theorem 4.1. In the light of this, there is now no practical sense for proving Theorem 4.1 directly by the energy method (as was earlier done in [7, 9, 10] for gas dynamical shocks), i.e., without referring to [37, 38] and Corollary 3.2.

We connect further perspectives of the method of p-symmetrizers with "nonstandard" problems, in particular, for characteristic discontinuities for which the structure of the Lopatinski determinant cannot be analyzed for technical reasons (see discussion in section 5). At the same time, to demonstrate how the energy method works for Lax shock waves for the case of variable coefficients and for the original nonlinear problem, we now outline the proof of Theorem 4.1. The main attention will be given to the deduction of an a priori estimate for the variable coefficients linearized problem (1.24), (1.17c). After that, to show the existence of solutions to (1.24), (1.17c) we comment how to go back from the system for p-derivatives with strictly dissipative boundary conditions to the original problem (1.24), (1.17c). At last, the proof of the existence of solutions to the nonlinear problem (1.17) follows from a fixed-point argument and we sketch it in the end of this section.

In the following we suppose that $p < [n/2]+2$ (see Remark 3.2). We just observe that if we prove Theorem 4.1 by the energy method, then for the case $p \geq [n/2]+2$ we have to assume that $s \geq \max\{[n/2]+2, p+1\}$. We underline once more that we do not know concrete examples of p-symmetrizers with $p \geq [n/2]+2$.

We first analyze the variable coefficients linear problem (1.24). We introduce the norm of $(\mathbf{u}(t,\mathbf{x}), \varphi(t,\mathbf{x}')) \in \mathbb{R}^N \times \mathbb{R}$:

$$\mathcal{N}_T^k(\mathbf{u},\varphi) := \sum_{\pm} \left\{ \|\mathbf{u}\|_{X_k([0,T],\mathbb{R}^n_\pm)} + \|\mathbf{u}^\pm\|_{W_2^k([0,T]\times\mathbb{R}^{n-1})} \right\} + \|\varphi\|_{W_2^{k+1}([0,T]\times\mathbb{R}^{n-1})},$$

where k is a nonnegative integer number. Fix an integer $s \geq [n/2]+2$ and consider $(\widehat{\mathbf{U}}, \hat{f}) \in Z_T^s$ with a time $T > 0$. Assume that there is a constant $M > 0$ such that

$$\mathcal{N}_T^s(\widehat{\mathbf{U}}, \hat{f}) \leq M. \tag{4.1}$$

THEOREM 4.2. *Given an integer $m \geq p$, suppose that problem* (1.24) *with "frozen" coefficients*

$$(\widehat{\mathbf{U}}|_{x_1>0}, \widehat{\mathbf{U}}|_{x_1<0}, \widehat{\mathbf{F}}) = (\widehat{\mathbf{U}}^+, \widehat{\mathbf{U}}^-, \boldsymbol{\sigma})$$

has a strictly dissipative p-symmetrizer ($p < [n/2]+2$) and $(\widehat{\mathbf{U}}, \hat{f}) \in Z_T^s$, with $s = \max\{m, [n/2]+2\}$. Suppose also that the Lax shock conditions (1.20) *and inequality* (4.1) *are fulfilled. Then, the following a priori estimate holds for the initial-boundary-value problem* (1.24), (1.17c)*:*

$$\begin{aligned} \mathcal{N}_T^m(\mathbf{U}, f) \leq C(T,M) \Bigg\{ & \sum_{\pm} \left\{ \|\mathbf{f}^\pm\|_{W_2^m([0,T]\times\mathbb{R}^n_\pm)} + |||\mathbf{U}_0|||_{W_2^m(\mathbb{R}^n_\pm)} \right\} \\ & + \|\mathbf{g}\|_{W_2^m([0,T]\times\mathbb{R}^{n-1})} + \|f_0\|_{W_2^{m+1}(\mathbb{R}^{n-1})} \Bigg\}. \end{aligned} \tag{4.2}$$

Here and below $C = C(T, M)$, $C_i = C_i(T, M)$, $i = 1, 2, 3, \dots$, are positive constants independent of the data and depending on T and M.

Proof. The methods for deducing the a priori estimate (4.2) are standard and based on the application of the Gagliardo–Nirenberg inequalities (see, e.g., [34])

$$\|\partial^\alpha u\|_{L_{2p}(\Omega)} \le c_k \|u\|^{1-1/p}_{L_\infty(\Omega)} \|u\|^{1/p}_{W_2^k(\Omega)}, \quad \frac{1}{p} = \frac{|\alpha|}{k}, \tag{4.3}$$

$$\|\partial^\alpha u\|_{L_p(\Omega)} \le c_k \|u\|^{1-r}_{L_2(\Omega)} \|u\|^r_{W_2^k(\Omega)}, \quad \frac{|\alpha|}{k} < r < 1, \quad \frac{1}{p} = \frac{1}{2} + \frac{|\alpha| - rk}{\dim\Omega}, \tag{4.4}$$

where $c_k > 0$ is a constant, $2 < p < \infty$. The domain Ω can be, for example, $\mathbb{R}^n$, $\mathbb{R}^n_\pm$, $[0, T] \times \mathbb{R}^n_\pm$, or $[0, T] \times \mathbb{R}^{n-1}$ (in general, Ω is a Lipschitz domain).

Inequalities (4.3) and (4.4) imply a number of calculus inequalities (see, e.g., [47, 34]). In particular, using (4.3) and (4.4), one can obtain the inequality

$$\|uv\|_{W_2^k(\Omega)} \le c_k \|u\|_{W_2^q(\Omega)} \|v\|_{W_2^k(\Omega)}, \quad q = \max\left\{\left[\frac{n}{2}\right] + 1, k\right\} \tag{4.5}$$

(here $\dim\Omega = n$). In Appendix B of [41] the following generalization of the last inequality was proved:

$$|||(uv)(t)|||_{W_2^k(\Omega)} \le c_k |||u(t)|||_{W_2^q(\Omega)} |||v(t)|||_{W_2^k(\Omega)}, \tag{4.6}$$

where Ω is a space domain (e.g., $\Omega = \mathbb{R}^n_\pm$). It is clear that the analogous inequality holds when x_1 is fixed instead of t:

$$\langle\!\langle\!\langle uv(x_1) \rangle\!\rangle\!\rangle_k \le c_k \langle\!\langle\!\langle u(x_1) \rangle\!\rangle\!\rangle_q \, \langle\!\langle\!\langle v(x_1) \rangle\!\rangle\!\rangle_k, \tag{4.7}$$

where

$$\langle\!\langle\!\langle (\cdot)(x_1) \rangle\!\rangle\!\rangle_k := \sum_{j=0}^{k} \|\partial_1^j (\cdot)(x_1)\|^2_{W_2^{k-j}([0,T]\times\mathbb{R}^{n-1})}.$$

One can also get the more special inequality

$$\begin{aligned} &\|(\partial^{\alpha_1} u_1 \cdots \partial^{\alpha_l} u_l)(\partial^\beta_{t,\mathrm{x}'} v)(x_1)\|_{L_2([0,T]\times\mathbb{R}^{n-1})} \\ &\qquad \le c_k \|v(x_1)\|_{W_2^k([0,T]\times\mathbb{R}^{n-1})} \prod_{i=1}^{l} \langle\!\langle\!\langle u_i(x_1) \rangle\!\rangle\!\rangle_q, \end{aligned} \tag{4.8}$$

where $|\alpha_1| + \dots + |\alpha_l| + |\beta| = k$. To prove (4.8) we should follow arguments analogous to those from Appendix B of [41], and the proof is based mainly on the application of (4.4).

Let us obtain the system satisfied by the vector $\mathbf{W}_\beta = \partial^\beta_{t,\mathrm{x}'} \mathbf{W}$, with $|\beta| \le m - p$. It follows from (1.24a) that

$$L(\widehat{\mathbf{U}}, \widehat{\mathbf{F}})(\partial^{\alpha^i} \partial^\beta_{t,\mathrm{x}'} \mathbf{U}) = \mathbf{f}^\pm_{i\beta} \quad \text{if} \quad \mathbf{x} \in \mathbb{R}^n_\pm, \tag{4.9}$$

where

$$\mathbf{f}^\pm_{i\beta} = \partial^{\alpha^i} \partial^\beta_{t,\mathrm{x}'} \mathbf{f}^\pm - [\partial^{\alpha^i} \partial^\beta_{t,\mathrm{x}'}, L(\widehat{\mathbf{U}}, \widehat{\mathbf{F}})]\mathbf{U}.$$

Here and below we use the notation of commutator: $[a,b]c := a(bc) - b(ac)$. From systems (4.9) with $i = \overline{1,d}$ we construct the system for $\mathbf{W}_\beta$ (cf. (2.4), (2.5)):

$$\mathcal{L}(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\mathbf{W}_\beta = \boldsymbol{\mathcal{F}}_\beta^{\pm}\,, \quad \mathbf{x}\in\mathbb{R}^n_{\pm}\,, \tag{4.10}$$

where

$$\mathcal{L} = \mathcal{L}(\widehat{\mathbf{U}},\widehat{\mathbf{F}}) = \mathcal{A}_0(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\partial_t + \sum_{j=1}^{n}\mathcal{A}_j(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\partial_j\,, \quad \widetilde{\mathbf{f}}_\beta^{\pm} = (\mathbf{f}_{1\beta}^{\pm},\dots,\mathbf{f}_{d\beta}^{\pm}),$$

$$\boldsymbol{\mathcal{F}}_\beta^{\pm} = P(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\widetilde{\mathbf{f}}_\beta^{\pm} - \sum_{j=1}^{K}\sum_{|\alpha|=p}\mathbf{R}_{j,\alpha}(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\big[\partial^\alpha\partial^\beta_{t,\mathrm{x}'},\widehat{\mathbf{N}}\big]\partial_1\boldsymbol{\Psi}_j(\mathbf{U}),$$

the matrices $P(\widehat{\mathbf{U}},\widehat{\mathbf{F}})$ and the vectors $\mathbf{R}_{j,\alpha}(\widehat{\mathbf{U}},\widehat{\mathbf{F}})$ form the strictly dissipative p-symmetrizer $\mathbb{S}$ if we "freeze" their coefficients, and the matrices $\mathcal{A}_i$ $(i=\overline{0,n})$ with "frozen" coefficients are the same as in (2.5).

For system (4.10) with variable coefficients, the counterpart of condition (2.8) is

$$-\big[(\mathcal{A}_1(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\mathbf{W}_\beta,\mathbf{W}_\beta)\big]\big|_{x_1=0} \ge \delta\big(|\mathbf{W}_\beta^+|^2 + |\mathbf{W}_\beta^-|^2\big) - \delta^{-1}g^2, \tag{4.11}$$

where g^2 is a sum of terms in the form

$$|G_k(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-,\widehat{\mathbf{F}})\partial^\alpha_{t,\mathrm{x}'}\mathbf{g}|^2, \qquad |G_l(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-,\widehat{\mathbf{F}})\partial^\gamma\mathbf{f}^{\pm}|_{x_1=\pm0}|^2,$$

$$|G_{l_0}(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-,\widehat{\mathbf{F}})\partial^\gamma\mathbf{U}^{\pm}|^2, \qquad \text{and} \quad |G_{l_0}(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-,\widehat{\mathbf{F}})\partial^\gamma_{t,\mathrm{x}'}\mathbf{F}|^2,$$

with

$$G_i(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-,\widehat{\mathbf{F}}) = \partial^{\alpha_1}\hat{u}^+_{i_1}\cdots\partial^{\alpha_j}\hat{u}^+_{i_j}\partial^{\alpha_{j+1}}\hat{u}^-_{i_{j+1}}\cdots\partial^{\alpha_r}\hat{u}^-_{i_r}$$
$$\times\partial^{\alpha_{r+1}}_{t,\mathrm{x}'}\widehat{F}_{i_{r+1}}\cdots\partial^{\alpha_q}_{t,\mathrm{x}'}\widehat{F}_{i_q}H(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-,\widehat{\mathbf{F}}),$$

$$|\alpha_1| + \ldots + |\alpha_q| = i\,, \quad 0\le q\le 2N+n,$$

$$k+|\alpha|\le m, \quad l+|\gamma|\le m-1, \quad l_0+|\gamma|\le m, \quad |\gamma|\le m-1$$

(for constant coefficients, cf. (2.8), $k=l=0$ and there are no lower order terms, i.e., $G_{l_0}\equiv 0$). Here $\widehat{F}_{i_j}$ is a component of the vector $\widehat{\mathbf{F}}$ ($\widehat{F}_{i_j} = \hat{f}_t$ or $\widehat{F}_{i_j} = \hat{f}_{x_k}$), $H(\widehat{\mathbf{U}}^+,\widehat{\mathbf{U}}^-,\widehat{\mathbf{F}})$ is a matrix which elements are determined by the elements of the matrices A_0, A_ν, and A_k $(k=\overline{2,n})$ and their derivatives up to order m with respect to $\mathbf{U}$ and $\mathbf{F}$.

Since arguments below are standard we are quite brief in the rest of the proof. In view of (4.11), using arguments as in (3.6), (3.8) and applying energy methods to (4.10), we deduce the inequality

$$I_{\tan}(t) + \int_0^t I^{\mathrm{tr}}_{\tan}(s)ds \le C_1(T,M)\left\{I(0) + J(t) + \int_0^t I(s)ds\right\}, \tag{4.12}$$

where

$$I_{\tan}(t)=\sum_{\pm}\left\{|||\mathbf{U}(t)|||^2_{W_2^p(\mathbb{R}^n_\pm)}+\sum_{|\beta|\le m-p}\|\mathbf{W}_\beta\|^2_{L_2(\mathbb{R}^n_\pm)}\right\},$$

$$I^{\rm tr}_{\tan}(t)=\sum_{\pm}\left\{\sum_{j=0}^{p}|||\partial_1^j\mathbf{U}^\pm(t)|||^2_{W_2^{p-j}(\mathbb{R}^{n-1})}+\sum_{|\beta|\le m-p}\|\mathbf{W}^\pm_\beta\|^2_{L_2(\mathbb{R}^{n-1})}\right\},$$

$$\partial_1^j\mathbf{U}^\pm:=\partial_1^j\mathbf{U}|_{x_1=\pm0},\quad I(t)=\sum_{\pm}|||\mathbf{U}(t)|||^2_{W_2^m(\mathbb{R}^n_\pm)},$$

$$J(t)=\|g\|^2_{L_2([0,t]\times\mathbb{R}^{n-1})}+\sum_{\pm}\sum_{|\beta|\le m-p}\|\boldsymbol{\mathcal{F}}^\pm_\beta\|^2_{L_2([0,t]\times\mathbb{R}^n)}.$$

The commutator $[\partial^{\alpha^i}\partial^\beta_{t,\mathrm{x}'},L(\widehat{\mathbf{U}},\widehat{\mathbf{F}})]\mathbf{U}$ is a sum of terms $G_k(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\partial^\alpha\mathbf{U}$, where G_k are determined as G_i above (but not on the boundary), $k+|\alpha|\le m+1$, $k\ge1$, and $|\alpha|\ge1$. Since $k\ge1$ and $|\alpha|\ge1$, applying (4.6) with $k=m-1$ and using elementary inequalities like

$$\sum_{|\alpha_1|+\ldots+|\alpha_l|\le k}\|\partial^{\alpha_1}v_1\cdots\partial^{\alpha_l}v_l\|_{L_2}\le\mathrm{const}\|v_1\cdots v_l\|_{W_2^k},$$

one estimates the commutator

$$\sum_{\pm}\left\|\,[\partial^{\alpha^i}\partial^\beta_{t,\mathrm{x}'},L(\widehat{\mathbf{U}},\widehat{\mathbf{F}})]\mathbf{U}\,\right\|^2_{L_2([0,t]\times\mathbb{R}^{n-1})}\le C_2(T,M)\int_0^t I(s)ds.$$

Then, estimating analogously other terms in $\boldsymbol{\mathcal{F}}^\pm_\beta$, one gets

$$\sum_{\pm}\sum_{|\beta|\le m-p}\|\boldsymbol{\mathcal{F}}^\pm_\beta\|^2_{L_2([0,t]\times\mathbb{R}^{n-1})}\le C_3(T,M)\left\{\sum_{\pm}\|\mathbf{f}^\pm\|^2_{W_2^m([0,T]\times\mathbb{R}^n_\pm)}+\int_0^t I(s)ds\right\}.$$

To estimate the L_2-norm of g we use inequality (4.7) at $x_1=\pm0$ and trace's property. As a result, one has

$$\|g\|^2_{L_2([0,t]\times\mathbb{R}^{n-1})}\le C_4(T,M)\Big\{\|\mathbf{g}\|^2_{W_2^m([0,T]\times\mathbb{R}^{n-1})}$$
$$+\sum_{\pm}\|\mathbf{f}^\pm\|^2_{W_2^m([0,T]\times\mathbb{R}^n_\pm)}+\int_0^t\Big(I(s)+\|\mathbf{F}(s)\|^2_{W_2^{m-1}(\mathbb{R}^{n-1})}\Big)ds\Big\}.$$

Expressing $\mathbf{F}$ by $\mathbf{U}^\pm$ and $\mathbf{g}$ ((3.1) for variable coefficients is applied) and using trace's property, from (4.12) one obtains

$$I_{\tan}(t)+\int_0^t I^{\rm tr}_{\tan}(s)ds\le C_5(T,M)\left\{I(0)+J_1(T)+\int_0^t I(s)ds\right\},\tag{4.13}$$

where

$$J_1(T)=\|\mathbf{g}\|^2_{W_2^m([0,T]\times\mathbb{R}^{n-1})}+\sum_{\pm}\|\mathbf{f}^\pm\|^2_{W_2^m([0,T]\times\mathbb{R}^n_\pm)}.$$

Applying energy methods to systems for the vectors $\partial^\alpha \mathbf{U}$ with $|\alpha| \le m$ and reasoning as above one can easily obtain the inequality

$$I(t) - \int_0^t I^{\mathrm{tr}}(s)ds \le C_6(T,M)\left\{I(0) + J_1(T) + \int_0^t I(s)ds\right\}, \tag{4.14}$$

where

$$I^{\mathrm{tr}}(t) = \sum_{\pm}\sum_{j=0}^{m} |||\partial_1^j \mathbf{U}^{\pm}(t)|||^2_{W_2^{m-j}(\mathbb{R}^{n-1})}.$$

To get an inequality for $I(t)$ when "+" stands in (4.14) instead of "−", we use the great advantage that the boundary conditions are strictly dissipative and, therefore, one has the positive integral in the left-hand side of inequality (4.13). We should now estimate the "full trace" $\int_0^t I^{\mathrm{tr}}(s)ds$ by $\int_0^t I^{\mathrm{tr}}_{\tan}(s)ds$.

Using the equations

$$\mathbf{U}_{x_1}|_{x_1=\pm 0} = A_\nu^{-1}(\widehat{\mathbf{U}}, \widehat{\mathbf{F}})\left\{\mathbf{f}^{\pm} - A_0(\widehat{\mathbf{U}})\mathbf{U}_t - \sum_{k=2}^{n} A_k(\widehat{\mathbf{U}})\mathbf{U}_{x_k}\right\}\Bigg|_{x_1=\pm 0},$$

one has that $\partial^\alpha \mathbf{U}^{\pm}$ with $|\alpha| = m$ is a sum of terms $G_k(\widehat{\mathbf{U}}^{\pm}, \widehat{\mathbf{F}})\partial^\beta_{t,\mathbf{x}'}\mathbf{U}^{\pm}$ and $G_l(\widehat{\mathbf{U}}^{\pm}, \widehat{\mathbf{F}})$ $\times \partial^\gamma \mathbf{f}^{\pm}|_{x_1=\pm 0}$, where $k + |\beta| \le m$ and $l + |\gamma| \le m-1$. Applying to these terms inequalities (4.8) and (4.7) (at $x_1 = \pm 0$), respectively, one gets the desired estimate

$$\int_0^t I^{\mathrm{tr}}(s)ds \le C_7(T,M)\int_0^t I^{\mathrm{tr}}_{\tan}(s)ds. \tag{4.15}$$

Summing up (4.13) multiplied by $2C_7$ with (4.14) and using (4.15), we obtain

$$I(t) + \int_0^t I^{\mathrm{tr}}(s)ds \le C_8(T,M)\left\{I(0) + J_1(T) + \int_0^t I(s)ds\right\}, \tag{4.16}$$

where $C_8 = C_6 + 2C_5C_7$.

Throwing away the positive integral in the left-hand side of (4.16) and applying Gronwall's lemma yield

$$I(t) \le C_9(T,M)\big(I(0) + J_1(T)\big), \quad 0 \le t \le T. \tag{4.17}$$

It follows from (4.16) and (4.17) that

$$\sum_{\pm} \|\mathbf{U}^{\pm}\|^2_{W_2^m([0,T]\times\mathbb{R}^{n-1})} \le C_{10}(T,M)\big(I(0) + J_1(T)\big). \tag{4.18}$$

At last, using the boundary conditions (3.1) (for variable coefficients) and applying (4.5) with $\Omega = [0,T]\times\mathbb{R}^{n-1}$ and $k = m$, we get from (4.18) that

$$\|f\|^2_{W_2^{m+1}([0,T]\times\mathbb{R}^{n-1})} \le C_{11}(T,M)\left\{I(0) + J_1(T) + \|f_0\|^2_{W_2^{m+1}(\mathbb{R}^{n-1})}\right\}. \tag{4.19}$$

Estimates (4.17)–(4.19) imply (4.2). □

Remark 4.1. In [7, 9, 10], the estimate in the form of (4.2) was obtained for gas dynamical shock waves by an accurate use of various Sobolev's imbedding theorems.

Unlike [7, 9, 10], the proof of Theorem 4.2 above relies on the Gagliardo–Nirenberg inequalities and is, therefore, closer to arguments of Metivier [37]. But, if $\Omega = [0,T]\times\mathbb{R}^n_\pm$ or $\Omega = [0,T]\times\mathbb{R}^{n-1}$ the constants in (4.3), (4.4) blow up as $T\to 0$. This unpleasant fact can prevent the proof of existence for the nonlinear problem. To overcome this difficulty it was suggested in [37] to use some substitutes of the Gagliardo–Nirenberg inequalities for which the constants are uniform with respect to T as $T\to 0$ (we do not want to go into details and just refer to [37]). Using such substitutes allows one to prove some modifications of inequalities (4.5)–(4.8) which now include norms of $u(0)$ and $v(0)$ (see [37]). Further arguments in the proof of Theorem 4.2 remain valid (with little modification), and the constant $C(T,M)$ in (4.2) is uniform with respect to T as $T\to 0$.

Consider the system

$$\widetilde{L}(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\mathbf{Y} + C(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\mathbf{Y} = \widetilde{\mathbf{f}}^{\pm}_{p-1}, \tag{4.20a}$$

$$\mathcal{L}(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\mathbf{W} = \boldsymbol{\mathcal{F}}^{\pm}, \quad \mathbf{x}\in\mathbb{R}^n_\pm, \tag{4.20b}$$

where $\mathbf{Y} = (\mathbf{U},\mathbf{W}_1,\dots,\mathbf{W}_{p-1})$, system (4.20a) is formed by (1.24a) and systems obtained by the differentiation of (1.24a) with respect to t and $\mathbf{x}$; the matrix C can be explicitly written out, $\widetilde{\mathbf{f}}^{\pm}_{p-1} = (\partial^{\alpha^1}\mathbf{f}^{\pm},\dots,\partial^{\alpha^{d_0}}\mathbf{f}^{\pm})$, $d_0 = C^{p-1}_{n+p-1}$, etc. (see section 2); system (4.20b) coincides with (4.10) for $|\beta| = 0$. We supplement system (4.20) with the boundary conditions (1.24b). All other boundary conditions follow from (1.24b) and system (4.20) itself at $x_1 = 0$.

System (4.20a) is equivalently rewritten as

$$A_0(\widehat{\mathbf{U}})\mathbf{Y}_t \mp \mathbf{Y}_{x_1} + \sum_{k=2}^{n} A_k(\widehat{\mathbf{U}})\mathbf{Y}_{x_k} + C^{\pm}(\widehat{\mathbf{U}},\widehat{\mathbf{F}})\mathbf{W} = \widetilde{\mathbf{f}}^{\pm}_{p-1}, \quad \mathbf{x}\in\mathbb{R}^n_\pm, \tag{4.21}$$

where $C^{\pm}\mathbf{W} = C\mathbf{Y} + (A_\nu \pm I)\mathbf{Y}_{x_1}$. The boundary matrix for system (4.21), (4.20b) is $\mathrm{diag}(-I, A_\nu)$ for $x_1 > 0$ and $\mathrm{diag}(I, A_\nu)$ for $x_1 < 0$. Clearly, the boundary conditions for system (4.21), (4.20b) are strictly dissipative (see (4.11) for $|\beta| = 0$).

Thus, system (4.21), (4.20b), that is equivalent to (4.20), has strictly dissipative boundary conditions. The initial-boundary-value problem for system (4.21), (4.20b) differs from one studied in Appendix A of [43] only by the presence of the unknown function f in the boundary conditions. The compatibility conditions for (1.24) can be written by analogy with those for standard boundary conditions in [40, 43]. The existence of a smooth solution $(\mathbf{U},\mathbf{W}_1,\dots,\mathbf{W}_{p-1},\mathbf{W})\in W_2^{m-p}$ to the problem for system (4.21), (4.20b) is proved exactly in the same manner as in Appendix A of [43] for linear hyperbolic problems with strictly dissipative boundary conditions. Moreover, the component $\mathbf{U}$ of this solution satisfies the original problem (1.24). Note also that in [10] the existence of smooth solutions to the linearized problem for gas dynamical shock waves was proved by approximation by grid functions. Such an approach suggested by Godunov [25] for linear hyperbolic problems with strictly dissipative boundary conditions and applied by Blokhin [10] to gas dynamical shock waves can also be used for general Lax shocks under consideration. So, we have the following existence theorem.

THEOREM 4.3. *Let that all the assumptions of Theorem* 4.2 *are satisfied. Then, for all the data*

$$\mathbf{U}_0 \in W_2^m(\mathbb{R}^n_+) \cap W_2^m(\mathbb{R}^n_-), \quad f_0 \in W_2^{m+1}(\mathbb{R}^{n-1}),$$

$$\mathbf{f}^{\pm} \in W_2^m([0,T] \times \mathbb{R}^n_{\pm}), \quad \mathbf{g} \in W_2^m([0,T] \times \mathbb{R}^{n-1})$$

satisfying the compatibility conditions up to order $m-1$, *the initial-boundary-value problem* (1.24), (1.17c) *has a unique solution* $(\mathbf{U}, f) \in Z_T^m$ *that obeys the a priori estimate* (4.2).

Sketch of the proof of Theorem 4.1. The proof follows from a fixed-point argument and we are quite brief here. For a time $T > 0$, a constant $M > 0$, and an integer $s \geq [n/2] + 2$, we define

$$\mathcal{K} = \Big\{ (\widehat{\mathbf{U}}, \hat{f}) \in Z_T^s \;\big|\; \mathcal{N}_T^s(\widehat{\mathbf{U}}, \hat{f}) \leq M,\ \widehat{\mathbf{U}}(0,\mathbf{x}) = \mathbf{U}_0(\mathbf{x}),\ \hat{f}(0,\mathbf{x}') = f_0(\mathbf{x}')\,,$$
$$(\mathbf{U}_0, f_0) \in \big\{\textstyle\bigcap_{\pm} W_2^s(\mathbb{R}^n_{\pm})\big\} \times W_2^{s+1}(\mathbb{R}^{n-1}) \text{ is compatible to order } s-1 \Big\}.$$

We do not specify here the compatibility conditions and just refer to [37].

Consider now the mapping $\Lambda : (\widehat{\mathbf{U}}, \hat{f}) \to (\mathbf{U}, f)$, where $(\mathbf{U}, f)$ satisfies the initial-boundary-value problem (1.24), (1.17c) with $\mathbf{f}^{\pm} \equiv 0$ and

$$\mathbf{g} = \big[\boldsymbol{\mathcal{P}}^1(\widehat{\mathbf{U}})\big] - \big[S^{-1}(\widehat{\mathbf{U}})A_\nu(\widehat{\mathbf{U}}, \widehat{\mathbf{F}})\widehat{\mathbf{U}}\big].$$

Actually, with such a choice of $\mathbf{g}$ the linear conditions in (1.24b) are Newton's approximation of the nonlinear boundary conditions (1.17b) (see discussion in [34]). Theorem 4.3 guarantees the existence of $(\mathbf{U}, f) \in Z_T^s$. Moreover, it follows from estimate (4.2) that $\Lambda(\mathcal{K}) \subset \mathcal{K}$ for appropriate choices of T and M (see Remark 4.1).

Consider $(\widehat{\mathbf{U}}^i, \hat{f}^i) \in \mathcal{K}$ and let $(\mathbf{U}, f) = \Lambda(\widehat{\mathbf{U}}^i, \hat{f}^i)$, $i = 1, 2$. For the differences $\mathbf{U}^1 - \mathbf{U}^2$ and $f^1 - f^2$ we obtain problem (1.24) with the trivial initial data, the coefficients $(\widehat{\mathbf{U}}, \hat{f}) = (\widehat{\mathbf{U}}^1, \hat{f}^1)$,

$$\mathbf{f}^{\pm} = \big(L(\widehat{\mathbf{U}}^2, \widehat{\mathbf{F}}^2) - L(\widehat{\mathbf{U}}^1, \widehat{\mathbf{F}}^1)\big)\mathbf{U}^2, \quad \mathbf{x} \in \mathbb{R}^n_{\pm},$$

and a corresponding $\mathbf{g}$ (it can be easily written down as well). Applying estimate (4.2) with $m = s-1$ to this problem and using the mean-value theorem for $\mathbf{f}^{\pm}$ and $\mathbf{g}$, one gets

$$\mathcal{N}_T^{s-1}(\mathbf{U}^1 - \mathbf{U}^2, f^1 - f^2) \leq \delta\, \mathcal{N}_T^{s-1}(\widehat{\mathbf{U}}^1 - \widehat{\mathbf{U}}^2, \hat{f}^1 - \hat{f}^2),$$

where the positive constant $\delta = \delta(T, M) < 1$ for T sufficiently small (we do not describe in detail the choice of T and M and just refer to standard arguments, for example, in [34] for the Cauchy problem or in [41, 42] for initial-boundary-value problems).

That is, the mapping Λ is a contraction in the low norm $\mathcal{N}_T^{s-1}$. Hence, there exists a unique fixed point $(\mathbf{U}, f) = (\widehat{\mathbf{U}}, \hat{f}) \in \mathcal{K}$ which solves (1.17). ∎

5. Concluding remarks. By introducing the notations of dissipative and strictly dissipative p-symmetrizers we have formalized the energy method applied earlier to strong discontinuities for concrete hyperbolic systems of conservation laws. We have proved that if the constant coefficients linearized problem for Lax shocks has a strictly dissipative p-symmetrizer, then under natural assumptions this implies the local in time existence of shock-front solutions of the original nonlinear system. This result recovers Blokhin's local existence theorem for gas dynamical shock waves [7, 9] and enables one to conclude the local existence of shock-front solutions for various concrete models (MHD [12], radiation hydrodynamics [3, 15], Landau's equations of superfluid [11], etc.) for which a priori estimates with no loss of derivatives for constant coefficients linearized problems were earlier deduced by the energy method.

It seems that the result of Theorem 4.1 could be extended, under appropriate assumptions, to the case of characteristic discontinuities. Note, however, that we do not know any concrete example of a characteristic discontinuity for which one can construct a strictly dissipative p-symmetrizer. Evidently, this is because all the known characteristic discontinuities (vortex sheets, current-vortex sheets, Alfvén discontinuities, etc.) can be only neutrally stable, i.e., the uniform Lopatinski condition is never satisfied for them.

With regard to the case where the loss of derivatives phenomenon takes place, i.e., when we are able to construct only a dissipative (but not strictly dissipative) p-symmetrizer, a theorem for the variable coefficients linearized problem like Theorem 4.3 could be proved both for Lax shocks and characteristic discontinuities. In the generic case, for characteristic discontinuities the functional setting is provided by the anisotropic weighted Sobolev spaces H^s_* (see [42] and references therein). Concerning the proof of a local existence theorem, it seems that the only way to overcome difficulties connected with the loss of derivatives phenomenon is the use of the Nash–Moser method (see discussion in Remark 1.2). Note that the existence of a dissipative (but not strictly dissipative) p-symmetrizer implies the fulfillment of the (weak) Lopatinski condition, i.e., the weak stability of a corresponding strong discontinuity. In particular, the existence of a dissipative p-symmetrizer for a planar Lax shock implies the weak stability of this shock wave and, in view of the recent result of Coulombel and Secchi [20] (see Remark 1.2), the nonlinear existence of nonplanar shock waves that are close to the planar shock under consideration.

Unfortunately, there is not a general procedure to construct a p-symmetrizer. At the same time, if it was somehow constructed, we do not need to examine the Lopatinski condition, which is often untestable analytically (numerical testing is usually not so simple either). The requirements for a set $\mathbb{S}$ to be a (strictly) dissipative p-symmetrizer suggest sufficient or, sometimes, necessary and sufficient conditions for the fulfillment of the (uniform) Lopatinski condition. In this connection, the best example for illustration is the construction of the dissipative 0-symmetrizer for current-vortex sheets [45] that first enabled the finding of wide sufficient conditions for their neutral stability (i.e., sufficient conditions of the macroscopic stability of the heliopause [4]).

For Lax shock waves, the construction of a strictly dissipative p-symmetrizer can be interpreted as an indirect test of the uniform Lopatinski condition and, referring then to [37, 38], we have at once the local existence theorem for the nonlinear problem. However, to construct Kreiss' symmetrizer for the case of characteristic discontinuities it is necessary to know not only that the Lopatinski condition is satisfied but also *how* it is satisfied, i.e., to know a detailed structure of the Lopatinski determinant (see [19]). For example, for current-vortex sheets [45] we know sufficient conditions for the fulfillment of the Lopatinski condition, but the structure of the Lopatinski determinant cannot be analyzed because of insuperable technical difficulties. That is, the only way to achieve a nonlinear result is to follow the energy method in the variable coefficients and nonlinear analysis as well. In the light of this, we think that future perspectives of the method of p-symmetrizers are connected with “nonstandard” problems for which either Kreiss' symmetrizer technique does not work for technical reasons or the general theory is still not developed (as, for example, for nonhyperbolic problems appearing for incompressible fluids; see [46]).

Acknowledgments. The author gratefully thanks Alexander Blokhin for many helpful discussions. The author is indebted to Paolo Secchi for providing him with the reference to [43]. Also, the author thanks Konstantin Ilin and Vladimir Vladimirov for their kind hospitality during his stay at the Hull Institute of Mathematical Sciences and Applications of the University of Hull.

SURFACTANT SPREADING ON THIN VISCOUS FILMS: NONNEGATIVE SOLUTIONS OF A COUPLED DEGENERATE SYSTEM*

HARALD GARCKE† AND SANDRA WIELAND‡

Abstract. We consider the Navier–Stokes system for an incompressible fluid coupled with a convection-diffusion equation for surfactant molecules on the free surface. The lubrication approximation leads to a coupled system of parabolic equations, consisting of a degenerate fourth-order equation for the film height and a second-order equation for the surfactant concentration. A proof based on energy estimates shows the existence of global weak solutions which in addition fulfill an integral inequality (entropy condition) which ensures positivity properties for the solution.

Key words. partial differential equations, degenerate parabolic equation, thin liquid film, surfactant spreading, free surface, fluid interface.

1. Introduction.

The aim of this paper is to prove the existence of nonnegative, weak solutions of the following system of coupled nonlinear, degenerate parabolic partial differential equations

$$h_t + \left(\frac{1}{3}\, h^3\, h_{xxx} + \frac{1}{2}\, h^2\, \sigma(\Gamma)_x\right)_x = 0, \tag{1.1}$$

$$\Gamma_t + \left(\frac{1}{2}\, h^2\, \Gamma\, h_{xxx} + h\, \Gamma\, \sigma(\Gamma)_x\right)_x = D\, \Gamma_{xx} \tag{1.2}$$

with suitable initial and boundary conditions. The above system appears in the lubrication theory for thin films on which surfactant molecules diffuse (see [BG88], [DeG94], [GG90], [JG92], [MT99], [WJ01]). In (1.1)–(1.2) the function h describes the height of the film and Γ is the concentration of the surfactants. The monotone decreasing function σ models that the surfactant molecules lower the surface tension. The first equation follows from mass conservation for the fluid and the term in brackets is the total horizontal velocity. The second equation is a convection-diffusion equation describing mass balance for the surfactants. The term in brackets in (1.2) is the horizontal velocity on top of the film times Γ and hence this term accounts for transport of Γ induced by the velocity field. We will discuss these issues in more detail in section 2.

The analysis for (1.1)–(1.2) is difficult due to the fact that the system degenerates

as h tends to zero. Equation (1.1) with $\sigma =$ constant is the thin film equation

$$h_t + \left(\frac{1}{3}h^3\, h_{xxx}\right)_x = 0 \tag{1.3}$$

which has been studied by many authors (see [BF90], [B96], [BBD95], [BMS99], [BP96], [DG01], [DGG98], [EG96], [G03], [O98] and the references therein). Due to the fact that the equation is of fourth order and since no maximum principle is valid, it is difficult to analyze the thin film equation. For example, it is not clear how to show nonnegativity of solutions. For the thin film equation (1.3) a priori estimates follow from the identity

$$\frac{d}{dt}\int_\Omega \frac{1}{2}h_x^2 + \int_\Omega \frac{1}{3}h^3\, h_{xxx}^2 = 0 \tag{1.4}$$

which holds under appropriate boundary conditions. But also further integral estimates, of which

$$\frac{d}{dt}\int_\Omega G(h) + \frac{1}{3}\int_\Omega h\, h_{xx}^2 = 0 \tag{1.5}$$

with $G''(h) = h^{-2}$ is the easiest example, hold and give further a priori estimates (see [BF90], [BBD95], [BP96], [DGG98] for details). By now many deep results such as nonnegativity of solutions, finite speed of propagation, results on the long time behavior of solutions, waiting time behavior and regularity results have been shown by using global and local versions of the above-mentioned a priori estimates (see [BF90], [BBD95], [B96], [DGG98]). The mathematical analysis of the system (1.1)–(1.2) is even more involved. Renardy ([R1-96], [R2-96], [R97]) studied this system and variants of it. He showed local existence results and studied shock profiles in certain singular perturbed variants of (1.1)–(1.2). Barrett, Garcke and Nürnberg [BGN03] studied and analyzed a finite element method for (1.1)–(1.2) and they present several numerical simulations showing an extreme thinning of the film due to convection resulting from surface tension gradients. We also refer to Grün, Lenz and Rumpf [GLR02] for numerical simulations based on a finite volume method.

In this paper we will show global existence of weak solutions to (1.1)–(1.2). Fundamental for our approach is a proper generalization of the energy identity (1.4) to the case of surfactants. This is not straightforward and, therefore, we will reconsider the derivation for (1.1)–(1.2) from the full free boundary problem for the Navier–Stokes equations. In particular we will derive an energy inequality for the full problem and taking the scaling of the lubrication approximation into account we can derive an energy estimate for (1.1)–(1.2). This part of the paper is formal and will be presented in section 2. The formally derived energy estimates will then be used in sections 3 and 4 to derive rigorous a priori estimates which are basic ingredients of the existence theory for (1.1)–(1.2). Generalization of the integral identities ("entropy" identities) for the thin film equation in general do not seem to hold for (1.1)–(1.2). But in section 4 we will show that at least one of the "entropy" estimates still can be generalized to (1.1)–(1.2) and this will allow us to show that solutions to positive initial data can only become zero on a set of measure zero. This shows that the influence of surfactants does not lead to dead cores, i.e., sets with positive measure on which h becomes zero.

2. The models. The motion of an incompressible viscous fluid on a bounded solid substrate is governed by the Navier–Stokes equations

$$\rho_0\{\mathbf{u}_t + (\mathbf{u}\cdot\nabla)\mathbf{u}\} = \mu\,\Delta\mathbf{u} - \nabla p, \tag{2.1}$$

$$\operatorname{div}\,\mathbf{u} = 0, \tag{2.2}$$

where $\mathbf{u} = (u_1, u_2, u_3)$ is the velocity field, p the pressure and ρ_0 the constant density. We assume that the fluid does not penetrate the substrate given by $\{(x, y, z) \in \mathbb{R}^3 | z = 0\}$ and that there is no flux across the lateral boundary. We also impose no-slip boundary conditions for the velocity, i.e.,

$$\mathbf{u}_{,z=0} = 0. \tag{2.3}$$

We assume that the evolving free surface (i.e., the fluid/air interface) C_t is given as the graph of a smooth time-dependent height function $h = h(t, x, y)$ on a spatial domain $\Omega \subset \mathbb{R}^2$, i.e.,

$$C_t = \{(x, y, z) \big| \,(x, y) \in \Omega,\ z = h(t, x, y)\}. \tag{2.4}$$

At the interface (briefly abbreviated as $\{z = h\}$) a kinematic boundary condition dictates that the normal component of the liquid velocity balances the speed of the interface (the convective time-derivative $\frac{dh}{dt}$ of h), i.e.,

$$u_{3,z=h} = \frac{dh}{dt} = h_t + u_1\,h_x + u_2\,h_y. \tag{2.5}$$

In order to balance the shear stress tensor

$$T(\mathbf{u}, p) := -p\,\mathrm{Id} + \mu\left(\nabla\mathbf{u} + \nabla\mathbf{u}^T\right)$$

of the fluid we look at its normal and tangential component separately. The normal stress exhibits a jump equal to the surface tension times the curvature (later referred to as normal stress condition):

$$\boldsymbol{\nu}\cdot T\boldsymbol{\nu} = \sigma\kappa, \tag{2.6}$$

where $\boldsymbol{\nu}$ is the outer unit normal and κ is the sum of the principal curvatures of the interface at a given point on C_t.

For the description of the tangential shear stress on the interface it becomes important to clarify the role of the surface tension dependence on the surfactant concentration Γ more explicitly. A result of the surface agency of the surfactant monolayer is that the surface concentration gradient of surfactant molecules opposes the surface tension gradient. To restore the disturbed equilibrium at the surface (caused by inhomogeneously distributed surfactants), the tangential part of the surface tension gradient balances the tangential component of the shear stress $T\boldsymbol{\nu}$, i.e.,

$$\boldsymbol{\tau}\cdot T\boldsymbol{\nu} = \partial_{\boldsymbol{\tau}}\,\sigma(\Gamma) \tag{2.7}$$

for all tangents $\boldsymbol{\tau}$, where $\partial_{\boldsymbol{\tau}}$ denotes the gradient in direction of the tangent vector $\boldsymbol{\tau}$. This effect is known as the (solutal) Marangoni effect.

2.1. Mass balance for the surfactant concentration. We now derive the evolution equation for the surfactant concentration by looking at the mass balance for the surfactant on subsets $C'_t \subset C_t$. Let

$$C' = \bigcup_{t\in[t_1,t_2]} \{t\} \times C'_t \quad \text{and} \quad C = \bigcup_{t\in[t_1,t_2]} \{t\} \times C_t$$

be a smooth three-dimensional surface with boundary $\partial C'$, such that $C'_t \subset \mathbb{R}^2$ are smooth two-dimensional surfaces with boundary $\partial C'_t$. Let Γ be the concentration of the surfactant which is a function on C. Then the mass balance on C' reads as follows:

$$\frac{d}{dt}\left(\int_{C'_t} \Gamma \, dS^2\right) = -\int_{\partial C'_t} \Big(\Gamma \mathbf{u}_{tan} - D\nabla_s \Gamma\Big) \cdot \mathbf{n}_{\partial C'_t} \, dS^1 + \int_{\partial C'_t} \Gamma \, v_{\partial C'_t} \, dS^1. \tag{2.8}$$

Here $\mathbf{u}_{tan}$ is the tangential component of the velocity, i.e.,

$$\mathbf{u}_{tan} := \mathbf{u} - (\mathbf{u}\cdot\boldsymbol{\nu})\boldsymbol{\nu},$$

where $\boldsymbol{\nu} \in \mathbb{R}^3$ is the normal to the interface C'_t. Furthermore, $\nabla_s \Gamma$ denotes the surface gradient of Γ on C_t. The vector $\mathbf{n}_{\partial C'_t}$ is the outer unit normal to $\partial C'_t$, i.e., $\mathbf{n}_{\partial C'_t}$ lies in the tangent space to C'_t and is perpendicular to $\partial C'_t$. The quantity $v_{\partial C'_t}$ is the normal boundary velocity of $\partial C'_t$ as a subcurve of C'_t, i.e., $v_{\partial C'_t}$ describes the local decrease or increase of the surface area of C'_t due to the tangential velocity of the boundary $\partial C'_t$. To compute $v_{\partial C'_t}$ at a point $x \in \partial C'_t$ let $y(s) \in \partial C'_t$ be such that $y(t) = x$. Then $y'(t)$ denotes the velocity of the curve y. Any motion tangential to $\partial C'_t$ does not lead to an increase of area, i.e., only the component

$$v_{\partial C'_t} := y'(t) \cdot \mathbf{n}_{\partial C'_t}$$

changes the surface area of C'_t.

Let us briefly discuss what the two terms on the right-hand side of (2.8) describe. The first integral describes changes of mass due to convective transport by the velocity $\mathbf{u}$ and diffusional transport where $D > 0$ is the diffusion coefficient. The second integral takes into account the change of surfactant on C'_t due to the fact that the surface C'_t increases or decreases. Our goal is now to derive a pointwise identity for the surfactant concentration from the balance law (2.8). To reformulate (2.8) we need the transport theorem (for a proof see the appendix)

$$\frac{d}{dt}\left(\int_{C'_t} \Gamma \, dS^2\right) = \int_{C'_t} \Big[\partial_{(1,\mathbf{v}_{\boldsymbol{\nu}})}\Gamma - \Gamma(\mathbf{v}_{\boldsymbol{\nu}} \cdot \boldsymbol{\kappa}_{\boldsymbol{\nu}})\Big] dS^2 + \int_{\partial C'_t} \Gamma \, v_{\partial C'_t} \, dS^1. \tag{2.9}$$

In the above $\partial_{(1,\mathbf{v}_{\boldsymbol{\nu}})}\Gamma$ denotes the partial derivative of Γ in the direction $(1, \mathbf{v}_{\boldsymbol{\nu}})$. Here $\mathbf{v}_{\boldsymbol{\nu}}$ is the uniquely determined vector lying in the tangent space to C'_t such that $(1, \mathbf{v}_{\boldsymbol{\nu}})$ is tangent to C'. The quantity $\mathbf{v}_{\boldsymbol{\nu}}$ is the normal velocity vector and $\partial_{(1,\mathbf{v}_{\boldsymbol{\nu}})}\Gamma$ is the normal time-derivative in the notation of Gurtin [Gur93]. Furthermore $\boldsymbol{\kappa}_{\boldsymbol{\nu}}$ is the mean curvature vector, i.e., $\boldsymbol{\kappa}_{\boldsymbol{\nu}}$ has the direction of the normal $\boldsymbol{\nu}$ and its length is equal to the sum of the principal curvatures. Combining (2.8) and (2.9) and using the Gauss theorem for the first integral on the right-hand side of (2.8) we obtain

$$0 = \int_{C'_t} \Big[\partial_{(1,\mathbf{v}_{\boldsymbol{\nu}})}\Gamma - \Gamma(\mathbf{v}_{\boldsymbol{\nu}} \cdot \boldsymbol{\kappa}_{\boldsymbol{\nu}}) + \nabla_s \cdot (\Gamma \, \mathbf{u}_{tan} - D\nabla_s \Gamma)\Big] dS^2. \tag{2.10}$$

Since C'_t is arbitrary we obtain

$$\partial_{(1,\mathbf{v}_{\boldsymbol{\nu}})}\Gamma - \Gamma(\mathbf{v}_{\boldsymbol{\nu}} \cdot \boldsymbol{\kappa}_{\boldsymbol{\nu}}) + \nabla_s \cdot (\Gamma \mathbf{u}_{tan} - D\nabla_s \Gamma) = 0 \tag{2.11}$$

pointwise on C'. A simple computation shows

$$\mathbf{v}_{\boldsymbol{\nu}} = \frac{h_t}{1+|\nabla h|^2}(-\nabla h, 1) = \frac{h_t}{\sqrt{1+|\nabla h|^2}}\boldsymbol{\nu},$$

where the normal $\boldsymbol{\nu}$ is given by

$$\boldsymbol{\nu} = \frac{1}{\sqrt{1+|\nabla h|^2}}(-\nabla h, 1).$$

Hence we obtain from (2.5) that $\mathbf{u} \cdot \boldsymbol{\nu} = \mathbf{v}_{\boldsymbol{\nu}} \cdot \boldsymbol{\nu}$ and therefore

$$\mathbf{v}_{\boldsymbol{\nu}} \cdot \boldsymbol{\kappa}_{\boldsymbol{\nu}} = \mathbf{u} \cdot \boldsymbol{\kappa}_{\boldsymbol{\nu}} = (\mathbf{u} \cdot \boldsymbol{\nu})\kappa.$$

As a result (2.11) can be rewritten as

$$\partial_{(1,\mathbf{v}_{\boldsymbol{\nu}})}\Gamma - \Gamma(\mathbf{u} \cdot \boldsymbol{\nu})\kappa + \nabla_s \cdot (\Gamma \mathbf{u}_{tan} - D\,\nabla_s \Gamma) = 0. \tag{2.12}$$

Using $\mathbf{u} = \mathbf{u}_{tan} + (\mathbf{u} \cdot \boldsymbol{\nu})\boldsymbol{\nu}$ and the fact that $\nabla_s(\Gamma\mathbf{u} \cdot \boldsymbol{\nu}) \cdot \boldsymbol{\nu} = 0$ we obtain using the following sign convention for the curvature $\kappa = -\nabla_s \cdot \boldsymbol{\nu}$ the identity

$$\nabla_s \cdot (\Gamma \mathbf{u}) = \nabla_s \cdot (\Gamma \mathbf{u}_{tan}) - \Gamma(\mathbf{u} \cdot \boldsymbol{\nu})\kappa$$

and finally (2.12) takes the form

$$\partial_{(1,\mathbf{v}_{\boldsymbol{\nu}})}\Gamma + \nabla_s \cdot (\Gamma \mathbf{u}) = D\,\Delta_s \Gamma. \tag{2.13}$$

2.2. Energy for the free surface problem. Assuming constant temperature, a fundamental equation of chemical thermodynamics relates the concentration-dependent surface tension σ to the free energy $g(\Gamma)$ and the chemical potential $g'(\Gamma)$ (see [V00]), where both functions depend on the surfactant concentration Γ:

$$\sigma(\Gamma) = g(\Gamma) - \Gamma\, g'(\Gamma). \tag{2.14}$$

Convexity of the free energy implies a monotone decrease of surface tension for non-negative concentration, which is consistent with the surface agency of the surfactant molecules we described before.

The total energy decomposes into the kinetic energy of the flow and the free energy of the surface:

$$E(t) = \int_{\Omega_t} \frac{\rho_0}{2}\mathbf{u}^2(t,\cdot)\, dV^3 + \int_{C_t} g(\Gamma(t,\cdot))\, dS^2, \tag{2.15}$$

where $\Omega_t := \left\{(x,y,z) \in \mathbb{R}^3 \middle| \; (x,y) \in \Omega,\; 0 < z < h(t,x,y) \right\}$ is the domain occupied by the liquid. A careful computation (see appendix 5.2) reveals the dissipation of the total energy:

$$\frac{d}{dt}E(t) = -\int_{\Omega_t} \nabla \mathbf{u} : T\, dV^3 - D \int_{C_t} g''(\Gamma)\, |\nabla_s \Gamma|^2 dS^2. \tag{2.16}$$

Here the imposed boundary conditions (2.3), (2.5), (2.6) and (2.7), a no-slip boundary condition at the lateral boundary and a 90° angle condition at points where the free surface intersects the lateral boundary have been used. To avoid additional boundary contributions we choose a 90° angle condition. In a more general situation the free energy has to be supplemented by terms representing the surface energy of the boundary. The importance of (2.16) for the analysis lies in the fact that with integration over a bounded time interval $[0, T]$ a priori estimates for $\mathbf{u}, \Gamma$ and their spatial gradients result.

2.3. Lubrication approximation. As our subsequent analysis will be restricted to two spatial dimensions (x, z) we state the following derivation in the two-dimensional setting and introduce the variable $\mathbf{u} = (u, w)$ where u represents the horizontal velocity in the direction of x and w the vertical velocity in the direction of z.

Scalings appropriate for a lubrication approximation of surfactant driven thin films (see [GG90]) are

$$\hat{x} = \frac{1}{L}\, x, \quad \hat{z} = \frac{1}{H}\, z, \quad \hat{t} = \frac{\epsilon U}{H}\, t,$$

$$\hat{u} = \frac{1}{U}\, u, \quad \hat{w} = \frac{1}{\epsilon U}\, w, \quad \hat{h} = \frac{1}{H}\, h, \quad \hat{\Gamma} = \frac{1}{\Gamma_m}\, \Gamma,$$

where L represents the typical horizontal length scale, H the typical film height, U the typical horizontal velocity and Γ_m the critical surfactant concentration. Considering thin films we assume that the parameter

$$\epsilon = \frac{H}{L}$$

is small. We also need to scale the pressure and the surface energy density and in this context the scaling

$$\hat{p} = \frac{H}{S}\, p \quad \text{and} \quad \hat{\sigma} = \frac{1}{S}\big(\sigma - \sigma_m\big) \tag{2.17}$$

has been chosen (see [GG90], [JG92]). Here S is the spreading coefficient, i.e., the surface tension difference at the surfactant monolayer edge and σ_m the surface tension of the saturated surface. Defining the typical horizontal velocity as

$$U = \frac{\epsilon S}{\mu},$$

with μ being the dynamic viscosity of the fluid, ensures that the Marangoni force at the free surface remains as a dominant force in the tangential stress boundary condition.

Lubrication theory now gives

$$p(t,x,z) = -\mathcal{S}\, h_{xx}(t,x), \tag{2.18}$$

$$u(t,x,z) = z\, u_z(t,x,h(t,x)) + p_x(t,x,z)\left(\frac{1}{2}z^2 - h(t,x)\, z\right), \tag{2.19}$$

where

$$u_z(t,x,h(t,x)) = \sigma(\Gamma(t,x))_x$$

and $\mathcal{S}$ denotes the rescaled capillary constant. The incompressibility of the flow and the evolution equation for Γ imply to leading order

$$h_t = -\partial_x \left(\int_0^{h(t,x)} u(t,x,z)\, dz \right), \tag{2.20}$$

$$\Gamma_t = -\partial_x \Big(\Gamma(t,x)\, u(t,x,h(t,x)) \Big) + D\Gamma_{xx} \tag{2.21}$$

(see [GG90] for details). Using the representation of u in (2.19) we get the system (1.1)–(1.2) which we are going to analyze in what follows. Furthermore we take the scaling of the lubrication approximation to approximate the energy inequality (2.16) which gives

$$\frac{d}{dt} \int_\Omega \left(\frac{\mathcal{S}}{2} h_x^2 + g(\Gamma) \right) + \int_\Omega \int_0^{h(t,x)} u_z^2 + \mathcal{D} \int_\Omega g''(\Gamma)\, \Gamma_x^2 = 0, \tag{2.22}$$

where $\mathcal{D}$ denotes the rescaled diffusion constant. Making use of the representation (2.19) we obtain

$$\begin{aligned} \frac{d}{dt} \int_\Omega \left(\frac{\mathcal{S}}{2} h_x^2 + g(\Gamma) \right) + \int_\Omega h \left\{ (\sigma(\Gamma)_x)^2 + \mathcal{S}\, h\, h_{xxx}\, \sigma(\Gamma)_x + \frac{1}{3} h^2 \left| \mathcal{S} h_{xxx} \right|^2 \right\} \\ + \mathcal{D} \int_\Omega g''(\Gamma)\, \Gamma_x^2 = 0. \end{aligned} \tag{2.23}$$

We remark that the second term in brackets is positive since the middle term can be absorbed by the first and the third term using Young's inequality. As a result the above identity gives a priori estimates for h and Γ. These estimates will be crucial for the analysis presented in the following sections.

We observe that through lubrication approximation the complexity of the free boundary problem is reduced—compensated by higher-order spatial derivatives for h.

3. Existence of weak solutions. We are interested in solutions of the system of nonlinear partial differential equations we derived in section 2.3, namely,

$$h_t + \partial_x \Big(a_2(h)\, \sigma(\Gamma)_x + a_3(h)\, h_{xxx} \Big) = 0 \qquad \text{in } \Omega_T, \tag{3.1}$$

$$\Gamma_t + \partial_x \Big(\Gamma\, a_1(h)\, \sigma(\Gamma)_x + \Gamma\, a_2(h)\, h_{xxx} \Big) = \mathcal{D}\, \Gamma_{xx} \quad \text{in } \Omega_T, \tag{3.2}$$

where we impose the no-flux and initial boundary conditions

$$h_x = h_{xxx} = \Gamma_x = 0 \quad \text{on } (0,T) \times \partial\Omega\,, \tag{3.3}$$

$$h(0,\cdot) = h_0 \quad \text{in } \Omega\,, \tag{3.4}$$

$$\Gamma(0,\cdot) = \Gamma_0 \quad \text{in } \Omega. \tag{3.5}$$

In sections 3 and 4 the set Ω will always be assumed to be a bounded interval. For later use we introduce the coefficient functions a_i for $i = 1, 2, 3$, which will be such that the special case $a_i(s) = \frac{1}{i} s^i$ for $s \geq 0$ leads to (1.1)–(1.2). It turns out that solutions of appropriate regularity exist in a weak sense. This result is formulated in the following theorem. Before we state the result we need to formulate certain assumptions on the coefficients. In detail we assume:

(A1) The functions $a_i : \mathbb{R} \to \mathbb{R}_0^+$ are continuous for $i = 1, 2, 3$ and $a_i(s) = 0$ if $s \le 0$.

(A2) For $A : \mathbb{R} \to Mat_{2,2}(\mathbb{R}_0^+)$ there exist $d_1, d_3 \in C(\mathbb{R}, \mathbb{R}_0^+)$ with $d_i(s) = 0 <=> s \le 0$ such that

$$A : s \mapsto \begin{pmatrix} a_3(s) & a_2(s) \\ a_2(s) & a_1(s) \end{pmatrix}$$

has the property

$$\xi^T A(s)\, \xi \ge d_3(s)\, \xi_1^2 + d_1(s)\, \xi_2^2$$

for all $\xi = (\xi_1, \xi_2)^T \in \mathbb{R}^2$.

(A3) There exist $k, l > 0$ such that for all $s \in \mathbb{R}$

$$a_2(s) \le C\, s^k \sqrt{d_1(s)} \text{ and } a_3(s) \le C\, s^k \sqrt{d_3(s)},$$
$$a_2(s) \le C\, s^l \sqrt{d_3(s)} \text{ and } a_1(s) \le C\, s^l \sqrt{d_1(s)}.$$

(A4) The function g lies in $C^{2,1}_{loc}(\mathbb{R})$ where $C^{2,1}_{loc}(\mathbb{R})$ is the space of functions with locally Lipschitz continuous second derivatives.

(A5) There exists a $c_g > 0$ such that $g''(s) \ge c_g$ for all $s \in \mathbb{R}$.

(A6) There exists a $C_g > 0$ such that $g''(s) \le C_g(|s|^r + 1)$ for all $s \in \mathbb{R}$ and with $r \in (0, 2)$.

(A7) The functions σ and g are related by $\sigma(s) = g(s) - sg'(s)$.

(A8) The diffusion coefficient $\mathcal{D}$ is positive.

The above assumptions do not allow for an affine linear relation between σ and Γ which is often assumed in applications. In the following $\langle \cdot, \cdot \rangle$ denotes the dual product between a linear functional and a point in the corresponding normed space.

THEOREM 3.1. *Let the initial data fulfill $h_0 \ge 0$, $h_0 \in H^{1,2}(\Omega)$, $\Gamma_0 \in L^2(\Omega)$ and $g'(\Gamma_0) \in L^2(\Omega)$. Assume also that* (A1)–(A8) *hold. Then there exists a weak solution (h, Γ) of problem* (3.1)–(3.5) *such that*

$$\int_0^T \langle h_t, \zeta \rangle - \int_{\Omega_T} a_2(h)\, \sigma(\Gamma)_x\, \zeta_x - \int_{\Omega_T \setminus \Omega_T^0} \mathcal{S} a_3(h)\, h_{xxx}\, \zeta_x = 0, \tag{3.6}$$

$$\int_0^T \langle \Gamma_t, \zeta \rangle - \int_{\Omega_T} \Gamma\, a_1(h)\, \sigma(\Gamma)_x\, \zeta_x - \int_{\Omega_T \setminus \Omega_T^0} \mathcal{S}\Gamma\, a_2(h)\, h_{xxx}\, \zeta_x + \mathcal{D} \int_{\Omega_T} \Gamma_x\, \zeta_x = 0 \tag{3.7}$$

for all $\zeta \in L^3\big(0, T; H^{2,2}(\Omega)\big)$ with $\zeta_x = 0$ on $(0, T) \times \partial\Omega$ and

$$\Omega_T^0 := \{(t, x) \in \Omega_T;\ h(t, x) = 0\}.$$

The solutions h and Γ have the following regularity properties

$$h \in L^2\big(0, T; H^{1,2}(\Omega)\big) \cap H^{1,2}\big(0, T; (H^{1,2}(\Omega))^*\big) \cap C^{\frac{1}{8}, \frac{1}{2}}(\overline{\Omega_T}),$$

$$\Gamma \in L^\infty\big(0, T; L^2(\Omega)\big) \cap L^2\big(0, T; H^{1,2}(\Omega)\big) \cap H^{1, \frac{3}{2}}\big(0, T; (H^{1,3}(\Omega))^*\big) \cap L^6(\Omega_T),$$

and the initial conditions for h and Γ are attained in the sense of traces in the spaces $H^{1,2}(0, T; (H^{1,2}(\Omega))^*)$ and $H^{1,\frac{3}{2}}(0, T; (H^{1,3}(\Omega))^*)$, respectively. Furthermore

$h \in L^2\big(0,T;H^{3,2}(\Omega\backslash\{h<\delta\})\big)$ *for all* $\delta>0$, $h^3 h_{xxx} \in L^2(\Omega\setminus\Omega_T^0)$ *and in addition it holds* $h \geq 0$ *almost everywhere.*

To prove the above theorem we are following a two-step approach: First we *regularize the degeneracy* which is apparent for $h=0$. For this purpose we approximate the equation for h by a family of nondegenerate equations

$$h_t^\delta + \partial_x\left(a_2(h^\delta)\,\sigma(\Gamma^\delta)_x + [a_3(h^\delta)+\delta]\,\mathcal{S}h^\delta_{xxx}\right) = 0,$$

where $\delta>0$. The surfactant concentration Γ^δ is still subject to the nondegenerate equation

$$\Gamma_t^\delta + \partial_x\left(\Gamma^\delta\, a_1(h^\delta)\,\sigma(\Gamma^\delta)_x + \Gamma^\delta\, a_2(h^\delta)\,\mathcal{S}h^\delta_{xxx}\right) = \mathcal{D}\,\Gamma^\delta_{xx}$$

as we assume $\mathcal{D}>0$. On the boundary $(0,T)\times\partial\Omega$ we impose again no-flux conditions that are

$$h_x^\delta = h_{xxx}^\delta = \Gamma_x^\delta = 0 \tag{3.8}$$

and for $t=0$ we require the same initial data as for the degenerate problem

$$\begin{aligned} h^\delta(0,\cdot) &= h_0 \quad \text{in } \Omega,\\ \Gamma^\delta(0,\cdot) &= \Gamma_0 \quad \text{in } \Omega. \end{aligned}$$

In a second step we use a *Galerkin approximation* which transforms the system of partial differential equations into a system of ordinary differential equations. As basis functions for the finite dimensional space E_k we select an L^2-orthonormal basis of eigenfunctions $\phi_0 = \text{const}$, ϕ_1, $\phi_2,\dots$ of $-\partial_{xx}$ with zero Neumann boundary conditions belonging to eigenvalues $0=\lambda_0<\lambda_1\leq\lambda_2\leq\cdots$. The usual approach would be to make an ansatz for h and Γ in $E_n=\text{span}(\phi_0,\dots,\phi_n)$, but in this case it turned out that it is necessary to reformulate the equation for Γ in terms of the chemical potential $g'(\Gamma)$ and to set up a Galerkin ansatz for $g'(\Gamma)$ instead or Γ. With the help of this transformation we are able to establish the necessary a priori estimates to prove global existence of Galerkin solutions.

Since $g'\in C^1(\mathbb{R})$ and $g''>0$ there exists $W:=(g')^{-1}$ with

$$(W'\circ g')(s) = \frac{1}{g''(s)},$$

so that we can easily transform (3.2) into an equation for $v := g'(\Gamma)$ using that $\sigma(\Gamma)_x = -W(v)\,v_x$:

$$\partial_t\, W(v) - \partial_x\left(W^2(v)\,a_1(h)\,v_x\right) + \partial_x\left(W(v)\,a_2(h)\,\mathcal{S}h_{xxx}\right) = \mathcal{D}\,W(v)_{xx}. \tag{3.9}$$

Due to the approximating properties of the eigenfunctions ϕ_k there exist sequences $(\beta_{kn})_{n\in\mathbb{N}}$ and $(\gamma_{kn})_{n\in\mathbb{N}}$ for $h_0\in H^{1,2}(\Omega)$ and $g'(\Gamma_0)\in L^2(\Omega)$ such that

$$\begin{aligned} h_{0n} &= \sum_{k=0}^{n}\beta_{kn}\phi_k \quad \text{with} \quad h_{0n}\to h_0 \quad \text{in} \quad H^{1,2}(\Omega),\\ v_{0n} &= \sum_{k=0}^{n}\gamma_{kn}\phi_k \quad \text{with} \quad v_{0n}\to v_0 := g'(\Gamma_0) \quad \text{in} \quad L^2(\Omega). \end{aligned}$$

Furthermore we make a Galerkin ansatz for $h^\delta(t)$ and $v^\delta(t) = g'(\Gamma^\delta(t))$ of the form

$$h_n^\delta(t) = \sum_{k=0}^{n} b_{kn}^\delta(t)\phi_k \quad \text{for all } t \in]0,T[\quad \text{with } h_n^\delta(0) = h_{0n},$$
$$v_n^\delta(t) = \sum_{k=0}^{n} c_{kn}^\delta(t)\phi_k \quad \text{for all } t \in]0,T[\quad \text{with } v_n^\delta(0) = v_{0n},$$

where according to (3.1) and (3.9) the functions $b_{kn}^\delta(t)$ and $c_{kn}^\delta(t)$ are subject to the following *Galerkin* equations which have to hold for $j = 0, \dots, n$:

(3.10)
$$\frac{d}{dt}\Big(h_n^\delta(t), \phi_j\Big) + \Big(a_2(h_n^\delta(t))\, W(v_n^\delta(t)) v_{n,x}^\delta(t), \phi_j'\Big) - \Big(a_3(h_n^\delta(t))\, \mathcal{S} h_{n,xxx}^\delta(t) + \delta \mathcal{S} h_{n,xxx}^\delta(t), \phi_j'\Big) = 0,$$

(3.11)
$$\frac{d}{dt}\Big(W(v_n^\delta(t)), \phi_j\Big) + \Big(W^2(v_n^\delta(t))\, a_1(h_n^\delta(t))\, v_{n,x}^\delta(t), \phi_j'\Big) - \Big(W(v_n^\delta(t))\, a_2(h_n^\delta(t)) \mathcal{S} h_{n,xxx}^\delta(t) - \mathcal{D}\, W'(v_n^\delta(t)) v_{n,x}^\delta(t), \phi_j'\Big) = 0,$$

where $(\cdot,\cdot)$ denotes the L^2-scalar product.

Proof. The first step to take is to prove the existence of local solutions of the Galerkin equations (3.10)–(3.11).

In the second step we derive a priori estimates which allow us to extend the local solutions established in the first step towards global solutions of the Galerkin equations.

As the Galerkin equations are an approximation to the nondegenerate system of partial differential equations we establish in the third step the convergence of the Galerkin method.

Generalizing ideas of Bernis and Friedman [BF90] we can show in the final fourth step that solutions of the nondegenerate system converge to solutions of the degenerate system. ∎

3.1. Local existence of solutions to the Galerkin system. To make use of standard theory for systems of ordinary equations we have to work out the structure of (3.10)–(3.11). Since we can write

$$\frac{d}{dt}\big(W(v_n^\delta(t)), \phi_j\big) = \Big[B(c_n^\delta(t))\, \frac{d}{dt} c_n^\delta(t)\Big]_j,$$

where $B(c_n^\delta(t)) = \big[B_{jk}(c_n^\delta(t))\big]_{j,k}$ is the matrix

$$B_{jk}(c_n^\delta(t)) := \int_\Omega W'(v_n^\delta(t,x))\phi_k(x)\phi_j(x)\, dx$$

and $c_n^\delta(t)$ is the vector $(c_{nk}^\delta(t))_{0\le k\le n}$, we simply have to make sure that $B(c_n^\delta(t))$ is symmetric and positive definite and therefore invertible. For $\xi = (\xi_0, \dots, \xi_n) \in \mathbb{R}^{n+1}$ we obtain

$$\sum_{j,k} \xi_j B_{jk}(c_n^\delta(t))\xi_k = \int_\Omega W'(v_n^\delta(t,x)) \left(\sum_j \xi_j \phi_j(x)\right)^2 dx.$$

Since $W' > 0$ and the eigenfunctions ϕ_j are linear independent we obtain that $B(c_n^\delta(t))$ is positive definite and we can multiply (3.11) with $B^{-1}(c_n^\delta(t))$. As a result we have to solve a system of first-order ordinary differential equations of the following type: for given initial data β_n, $\gamma_n \in \mathbb{R}^{n+1}$ and for any value of $\delta > 0$ we look for functions b_n^δ, $c_n^\delta : [0,T] \to \mathbb{R}^{n+1}$ which satisfy the equations

$$\frac{d}{dt}\left(b_n^\delta, c_n^\delta\right)(t) = F\bigl(t, (b_n^\delta(t), c_n^\delta(t))\bigr)^T, \tag{3.12}$$

$$\bigl(b_n^\delta, c_n^\delta\bigr)(0) = \bigl(\beta_n, \gamma_n\bigr), \tag{3.13}$$

where

$$F : [0,T] \times \mathbb{R}^{2(n+1)} \to \mathbb{R}^{2(n+1)},$$
$$(t, y_1, y_2) \mapsto \begin{bmatrix} (f_1(y_1,y_2), \Phi') \\ \bigl(f_2(y_1,y_2), B^{-1}(c_n^\delta(t))\,\Phi'\bigr) \end{bmatrix}$$

with $\Phi = (\phi_0, \dots, \phi_n)$, and

$$\begin{aligned} f_2(y_1,y_2) &:= -W^2(y_2\cdot\Phi)\,a_1(y_1\cdot\Phi)\,y_2\cdot\Phi' + \mathcal{S}W(y_2\cdot\Phi)\,a_2(y_1\cdot\Phi)\,y_1\cdot\Phi''' \\ &\quad - \mathcal{D}\,W'(y_2\cdot\Phi)\,y_2\cdot\Phi', \\ f_1(y_1,y_2) &:= -a_2\bigl(y_1\cdot\Phi\bigr)\,W(y_2\cdot\Phi)\,y_2\cdot\Phi' + \mathcal{S}\,a_3\bigl(y_1\cdot\Phi\bigr)\,y_1\cdot\Phi''' + \delta\mathcal{S}\,y_1\cdot\Phi'''. \end{aligned}$$

By assumptions (A1)–(A3) the right-hand side F satisfies a local Lipschitz condition with respect to $\boldsymbol{y}$. Therefore by the Picard–Lindelöf theorem a unique local solution of the initial value problem (3.12),(3.13) exists.

3.2. Global existence of solutions for the Galerkin system. In this section we will use a priori estimates in order to extend the local solution to a global solution. Since ϕ_k'' is a multiple of ϕ_k we can plug in $p_n^\delta(t) = -\mathcal{S}h_{n,xx}^\delta(t)$ as a test function in (3.10) and $v_n^\delta(t)$ as test function in (3.11) and get:

$$\begin{aligned} &\mathcal{S}\Bigl(\frac{d}{dt}h_{n,x}^\delta(t), h_{n,x}^\delta(t)\Bigr) - \Bigl(a_2(h_n^\delta(t))\,W(v_n^\delta(t))v_{n,x}^\delta(t), \mathcal{S}h_{n,xxx}^\delta(t)\Bigr) \\ &\qquad + \Bigl(a_3(h_n^\delta(t))\,\mathcal{S}h_{n,xxx}^\delta(t) + \delta\mathcal{S}h_{n,xxx}^\delta(t), \mathcal{S}h_{n,xxx}^\delta(t)\Bigr) = 0, \end{aligned} \tag{3.14}$$

$$\begin{aligned} &\Bigl(\frac{d}{dt}W(v_n^\delta(t)), v_n^\delta(t)\Bigr) + \Bigl(W^2(v_n^\delta(t))\,a_1(h_n^\delta(t))\,v_{n,x}^\delta(t), v_{n,x}^\delta(t)\Bigr) \\ &\qquad - \Bigl(W(v_n^\delta(t))\,a_2(h_n^\delta(t))\mathcal{S}h_{n,xxx}^\delta(t) - \mathcal{D}\,W'(v_n^\delta(t))v_{n,x}^\delta(t), v_{n,x}^\delta(t)\Bigr) = 0. \end{aligned} \tag{3.15}$$

Defining

$$\Gamma_n^\delta := (g')^{-1}(v_n^\delta)$$

we can recalculate

$$\begin{aligned} W'(v_n^\delta)\,v_{n,t}^\delta\,v_n^\delta &= \Gamma_{n,t}^\delta\,g'(\Gamma_n^\delta) = \partial_t\,g(\Gamma_n^\delta), \\ W(v_n^\delta)\,v_{n,x}^\delta &= -\sigma(\Gamma_n^\delta)_x \quad \text{and} \quad W'(v_n^\delta)\,|v_{n,x}^\delta|^2 = g''(\Gamma_n^\delta)\,|\Gamma_{n,x}^\delta|^2. \end{aligned}$$

Using these formulas we receive by adding (3.14) and (3.15):

$$\begin{aligned}
(3.16)\quad & \frac{d}{dt}\left\{\frac{\mathcal{S}}{2}\left\|h^\delta_{n,x}(t)\right\|^2_{L^2(\Omega)} + \left\|g(\Gamma^\delta_n(t))\right\|_{L^1(\Omega)}\right\} \\
& + \int_\Omega \Big\{ a_3(h^\delta_n(t))\left|\mathcal{S}h^\delta_{n,xxx}(t)\right|^2 + 2a_2(h^\delta_n(t))\,\mathcal{S}h^\delta_{n,xxx}(t)\,\sigma(\Gamma^\delta_n(t))_x \\
& + a_1(h^\delta_n(t))\left|\sigma(\Gamma^\delta_n(t))_x\right|^2 \Big\} + \delta\left\|\mathcal{S}h^\delta_{n,xxx}(t)\right\|^2_{L^2(\Omega)} + \mathcal{D}\left\|\sqrt{g''(\Gamma^\delta_n(t))}\,\Gamma^\delta_{n,x}(t)\right\|^2_{L^2(\Omega)} = 0.
\end{aligned}$$

Assumption (A2) guarantees that the integral in the second and third line of (3.16) is nonnegative, so that by integration of (3.16) over $[0,T]$ we get for any given $0 < T < \infty$:

$$\frac{\mathcal{S}}{2}\sum_{k=1}^n \left(b^\delta_{kn}(T)\right)^2\lambda_k + \int_\Omega g(W(c^\delta_n(T)\cdot\Phi)) \le C(\beta_n,\gamma_n). \tag{3.17}$$

Taking $\phi_0 = 1$ in (3.10) gives in addition that b^δ_{0n} is bounded and we can deduce that the b^δ_n are a priori bounded. The assumption (A6) implies that $g\circ W(s)\to\infty$ if $s\to\infty$ and hence we obtain that c^δ_n is bounded and therefore the solution (b^δ_n, c^δ_n) can be extended globally. As a conclusion we have shown that the Galerkin equations have global solutions

$$h^\delta_n,\ \Gamma^\delta_n \in C^1\big(0,T;C^\infty(\Omega)\big).$$

3.3. Convergence of the Galerkin method. Let $\zeta \in L^3\big(0,T;H^{2,2}(\Omega)\big)$ be arbitrarily chosen with $\zeta_x = 0$ on $(0,T)\times\partial\Omega$. Then there exist functions $\zeta_n(t,\cdot) = P_n\zeta(t,\cdot) \in \operatorname{span}\{\phi_0,\dots,\phi_n\}$ such that for $n\to\infty$: $\zeta_n(t,\cdot)\to\zeta(t,\cdot)$ in $H^{1,3}(\Omega)$ for almost all $t\in[0,T]$. Using the convergence theorem of Lebesgue we finally get

$$\zeta_n \to \zeta \ \text{ in } \ L^3\big(0,T;H^{1,3}(\Omega)\big) \ \text{ for } \ n\to\infty.$$

Plugging ζ_n into the Galerkin equations (3.10)–(3.11) we have to show that in the following weak formulation we can pass to the limit for $n\to\infty$:

$$\begin{aligned}
(3.18)\quad & \int_0^T \langle h^\delta_{n,t}(t),\zeta_n(t)\rangle - \int_{\Omega_T} a_2(h^\delta_n)\,\sigma(\Gamma^\delta_n)_x\,\zeta_{n,x} \\
& - \int_{\Omega_T} a_3(h^\delta_n)\,\mathcal{S}h^\delta_{n,xxx}\zeta_{n,x} - \delta\int_{\Omega_T}\mathcal{S}h^\delta_{n,xxx}\zeta_{n,x} = 0, \\
(3.19)\quad & \int_0^T \langle \Gamma^\delta_{n,t}(t),\zeta_n(t)\rangle - \int_{\Omega_T} \Gamma^\delta_n\,a_1(h^\delta_n)\,\sigma(\Gamma^\delta_n)_x\,\zeta_{n,x} \\
& - \int_{\Omega_T} \Gamma^\delta_n\,a_2(h^\delta_n)\,\mathcal{S}h^\delta_{n,xxx}\zeta_{n,x} + \mathcal{D}\int_{\Omega_T}\Gamma^\delta_{n,x}\zeta_{n,x} = 0.
\end{aligned}$$

To ensure convergence we have to establish appropriate convergence properties for the integrands involved. Exploiting (3.16) together with assumption (A2) and the convergence properties of the initial data (L^2-convergence of $\big(h^\delta_{n,x}(0)\big)_{n\in\mathbb{N}} \to h_{0,x}$

and L^1-convergence of $\big(g(\Gamma_n^\delta(0))\big)_{n\in\mathbb{N}} \to g(\Gamma_0))$ we can deduce the following:

$$\left(h_{n,x}^\delta\right)_{n\in\mathbb{N}} \quad \text{is uniformly bounded in } L^\infty(0,T;L^2(\Omega)), \tag{3.20}$$

$$\left(g(\Gamma_n^\delta)\right)_{n\in\mathbb{N}} \quad \text{is uniformly bounded in } L^\infty(0,T;L^1(\Omega)), \tag{3.21}$$

$$\left((g''(\Gamma_n^\delta))^{\frac{1}{2}}\,\Gamma_{n,x}^\delta\right)_{n\in\mathbb{N}} \quad \text{is uniformly bounded in } L^2(0,T;L^2(\Omega)), \tag{3.22}$$

$$\left((d_3(h_n^\delta))^{\frac{1}{2}} h_{n,xxx}^\delta\right)_{n\in\mathbb{N}} \quad \text{is uniformly bounded in } L^2(0,T;L^2(\Omega)), \tag{3.23}$$

$$\left((d_1(h_n^\delta))^{\frac{1}{2}}\,\sigma(\Gamma_n^\delta)_x\right)_{n\in\mathbb{N}} \quad \text{is uniformly bounded in } L^2(0,T;L^2(\Omega)), \tag{3.24}$$

$$\sqrt{\delta}\left(h_{n,xxx}^\delta\right)_{n\in\mathbb{N}} \quad \text{is uniformly bounded in } L^2(0,T;L^2(\Omega)). \tag{3.25}$$

Choosing $\zeta_n \equiv 1$ in (3.18) gives that $\frac{d}{dt}\int_\Omega h_n^\delta = 0$ and hence the mean value of h_n is controlled. This fact, (3.20) and the Sobolev embedding theorem lead to

$$\exists\, C>0 \quad \forall\, n\in\mathbb{N} \quad \forall\, \delta>0 \quad \operatorname*{ess\,sup}_{t\in[0,T]} \|h_n^\delta(t)\|_{L^\infty(\Omega)} \le C.$$

Using (3.21)–(3.22) together with (A4)–(A5) we are able to establish uniform bounds for Γ_n^δ with respect to n and δ as follows:

$$\begin{aligned}
&(\Gamma_n^\delta)_{n\in\mathbb{N}} \quad \text{is uniformly bounded in } L^\infty\big(0,T;L^2(\Omega)\big),\\
&(\Gamma_n^\delta)_{n\in\mathbb{N}} \quad \text{is uniformly bounded in } L^2\big(0,T;H^{1,2}(\Omega)\big).
\end{aligned}$$

Applying an embedding theorem for parabolic function spaces (see, e.g., [DiB93]) these results can be combined to:

$$(\Gamma_n^\delta)_{n\in\mathbb{N}} \quad \text{is uniformly bounded in } L^4(0,T;L^\infty(\Omega))\cap L^6(\Omega_T).$$

Finally using (3.23)–(3.24), assumption (A3) and the previous statements allow us to prove that

$$\begin{aligned}
&\mathcal{I}_n^\delta := a_2(h_n^\delta)\,\sigma(\Gamma_n^\delta)_x + a_3(h_n^\delta)\,\mathcal{S}h_{n,xxx}^\delta + \delta\mathcal{S}h_{n,xxx}^\delta \qquad \text{is bounded uniformly in } L^2(\Omega_T),\\
&\mathcal{J}_n^\delta := \Gamma_n^\delta\, a_1(h_n^\delta)\,\sigma(\Gamma_n^\delta)_x + \Gamma_n^\delta\, a_2(h_n^\delta)\,\mathcal{S}h_{n,xxx}^\delta - \mathcal{D}\,\Gamma_{n,x}^\delta \text{ is bounded uniformly in } L^{\frac{3}{2}}(\Omega_T),
\end{aligned}$$

and therefore we obtain

$$\begin{aligned}
&(h_{n,t}^\delta)_{n\in\mathbb{N}} \text{ is uniformly bounded in } L^2(0,T;(H^{1,2}(\Omega))^*),\\
&(\Gamma_{n,t}^\delta)_{n\in\mathbb{N}} \text{ is uniformly bounded in } L^{\frac{3}{2}}(0,T;(H^{1,3}(\Omega))^*).
\end{aligned}$$

To demonstrate the convergence of (3.18)–(3.19) we list the following. Since $(h_n^\delta)_{n\in\mathbb{N}}$ is uniformly bounded in $C^{\frac{1}{8},\frac{1}{2}}(\overline{\Omega_T})$ (Hölder-continuity of $h_n^\delta(t,x)$ with respect to $t\in[0,T]$ and $x\in\Omega$, see [BF90]) we conclude that a subsequence of $(h_n^\delta)_{n\in\mathbb{N}}$ converges uniformly to h^δ for $n\to\infty$. This implies together with the reflexivity of $L^2(0,T;(H^{1,2}(\Omega))^*)$ that $\partial_t h_n^\delta \overset{*}{\rightharpoonup} \partial_t\, h^\delta$ in $L^2\big(0,T;(H^{1,2}(\Omega))^*\big)$. By Poincaré's lemma we can prove that the boundedness of $(h_{n,xxx}^\delta)_{n\in\mathbb{N}}$ in $L^2(\Omega_T)$ implies for all δ the convergence $h_n^\delta \rightharpoonup h^\delta$ in $L^2(0,T;H^{3,2}(\Omega))$. We remark that we sometimes choose subsequences but keep the original index of the sequence.

The convergence results for $(\Gamma_n^\delta)_{n\in\mathbb{N}}$ are not as good as for $(h_n^\delta)_{n\in\mathbb{N}}$. Using the compactness lemma of Aubin–Lions (see [LIO69]) we get strong convergence of $\Gamma_n^\delta \to \Gamma^\delta$ in $L^2(0,T;L^q(\Omega))$ for all $q \in [1,\infty)$. Besides we have the weak convergence of $(\partial_t \Gamma_n^\delta)_{n\in\mathbb{N}}$ to $\partial_t \Gamma^\delta$ in $L^{\frac{3}{2}}(0,T;(H^{1,3}(\Omega))^*)$ and the strong convergence of $\Gamma_n^\delta \to \Gamma^\delta$ in $L^q(\Omega_T)$ for all $q \in [2,6)$ using the boundedness of $(\Gamma_n^\delta)_{n\in\mathbb{N}}$ in $L^6(\Omega_T)$ together with an interpolation estimate for L^p norms (see [E98]).

In order to get a convergence result for $g'(\Gamma_n^\delta)$ we make use of (A4) and (A6): By Lebesgue's theorem and the strong convergence of $(\Gamma_n^\delta)_{n\in\mathbb{N}}$ in $L^q(\Omega_T)$ we first conclude the convergence of $(g''(\Gamma_n^\delta))_{n\in\mathbb{N}}$ to $g''(\Gamma^\delta)$ in $L^3(\Omega_T)$. By an interpolation estimate for L^p-norms this can be extended to $g''(\Gamma_n^\delta) \to g''(\Gamma^\delta)$ in $L^q(\Omega_T)$ for all $q \in [3, \frac{6}{r})$, $r \in (0,2)$. Combining this with the weak convergence $\Gamma_{n,x}^\delta \rightharpoonup \Gamma_x^\delta$ in $L^2(\Omega_T)$ we therefore get $(g''(\Gamma_n^\delta))^{\frac{1}{2}}\Gamma_{n,x}^\delta \rightharpoonup (g''(\Gamma^\delta))^{\frac{1}{2}}\Gamma_x^\delta$ in $L^2(\Omega_T)$ for $n \to \infty$. Since $\sigma(\Gamma_n^\delta)_x$ decomposes into $\sigma(\Gamma_n^\delta)_x = -\Gamma_n^\delta (g''(\Gamma_n^\delta))^{\frac{1}{2}} \cdot (g''(\Gamma_n^\delta))^{\frac{1}{2}}\Gamma_{n,x}^\delta$ we can prove that $\sigma(\Gamma_n^\delta)_x \rightharpoonup \sigma(\Gamma^\delta)_x$ in $L^s(\Omega_T)$ for $s \in [\frac{2}{3}, \frac{6}{4+r})$.

Applying these convergence results to (3.18)–(3.19) we get that the Galerkin solutions $(h_n^\delta, \Gamma_n^\delta)$ converge for any fixed $\delta > 0$ to a weak solution $(h^\delta, \Gamma^\delta)$ of the nondegenerate problem

(3.26)
$$\int_0^T \langle h_t^\delta, \phi\rangle - \int_{\Omega_T} a_2(h^\delta)\,\sigma(\Gamma^\delta)_x \phi_x - \int_{\Omega_T} a_3(h^\delta)\,\mathcal{S}h_{xxx}^\delta \phi_x - \delta \int_{\Omega_T} \mathcal{S}h_{xxx}^\delta \phi_x = 0,$$

(3.27)
$$\int_0^T \langle \Gamma_t^\delta, \phi\rangle - \int_{\Omega_T} \Gamma^\delta a_1(h^\delta)\,\sigma(\Gamma^\delta)_x \phi_x - \mathcal{S}\int_{\Omega_T} \Gamma^\delta a_2(h^\delta)\, h_{xxx}^\delta \phi_x + \mathcal{D}\int_{\Omega_T} \Gamma_x^\delta \phi_x = 0.$$

3.4. Existence of weak solutions of the degenerate problem. When we take the limit $\delta \to 0$ we lose control over h_{xxx}^δ in $L^2(\Omega_t)$. Therefore, similar to as in [BF90], we introduce the sets $\Omega_T \backslash \Omega_T^0$ with

$$\Omega_T^0 := \{(t,x) \in \Omega_T;\, h(t,x) = 0\}$$

on which convergence of the terms involving third derivatives of h^δ holds. This is due to the fact that $h_{xxx}^\delta \rightharpoonup h_{xxx}$ in $L^2(\Omega_T \backslash \Omega_T^\eta)$ with $\Omega_T^\eta := \{(t,x) \in \Omega_T;\, |h(t,x)| \le \eta\}$ and since

$$\begin{aligned}(3.28)\qquad \int_{\Omega_T^\eta} |a_3(h^\delta)\mathcal{S}h_{xxx}^\delta \phi_x| &\le C\|h^\delta\|_{L^\infty(\Omega_T^\eta)}^k \,\|d_3(h^\delta)^{\frac{1}{2}}\mathcal{S}h_{xxx}^\delta\|_{L^2(\Omega_T)}\,\|\phi_x\|_{L^2(\Omega_T)} \\ &\le C\eta^k,\end{aligned}$$

$$\begin{aligned}(3.29)\qquad \int_{\Omega_T^\eta} |\Gamma^\delta a_2(h^\delta)\mathcal{S}h_{xxx}^\delta \phi_x| &\le C\|h^\delta\|_{L^\infty(\Omega_T^\eta)}^l \|\Gamma^\delta d_3(h^\delta)^{\frac{1}{2}}\mathcal{S}h_{xxx}^\delta\|_{L^{\frac{3}{2}}(\Omega_T)}\,\|\phi_x\|_{L^3(\Omega_T)} \\ &\le C\eta^l,\end{aligned}$$

where we made use of (A3) and the bounds (3.20)–(3.23), which are uniform with respect to δ. In particular using the bound (3.23) we obtain the integrability of $h^3 h_{xxx}\chi_{\Omega\backslash\Omega_T^0}$.

Those terms in (3.26)–(3.27) in which h_{xxx}^δ does not occur are not affected and we can pass to the limit for $\delta \to 0$ in the same way as in section 3.3. Since $\delta\|h_{xxx}^\delta\|_{L^2(\Omega_T)}^2$ is uniformly bounded (see (3.25)) we conclude furthermore

$$\delta \int_{\Omega_T} |h_{xxx}^\delta\, \phi_x| \le \delta \|h_{xxx}^\delta\|_{L^2(\Omega_T)} \cdot \|\phi_x\|_{L^2(\Omega_T)} \to 0 \quad \text{for} \quad \delta \to 0.$$

In the remaining terms involving h^δ_{xxx} we can pass to the limit as in [BF90] using the estimates (3.28) and (3.29). Taking $h_- := \min\{h, 0\}$ as a test function in (3.6) gives $h \geq 0$ almost everywhere (see [Yin92] or the discussion in [BGN03]).

Remark. In the proof of Theorem 3.1 it was not necessary to require $\Gamma_0 \geq 0$. But physically relevant initial data for the density Γ_0 are nonnegative. In this case one would expect the solutions Γ to be nonnegative as well. Unfortunately the available methods are not sufficient to show nonnegativity of Γ under the above assumptions. Testing (3.7) by $\min(\Gamma, 0)$ is not possible since the coefficients are not smooth enough. For example, the term $a_2(h)h_{xxx}\chi_{\Omega\setminus\Omega_T^0}$ is only in $L^2(\Omega_T)$ and more regularity is needed to proceed (see, e.g., Ladyzenskaya et al. [LSU68, Chapter III, section 7, assumption (7.1)]).

4. Nonnegativity. Numerical simulations (see [BGN03]) indicate that surfactants can lead to a dramatic thinning of films. In this section we will show that solutions to (1.1)–(1.2) which have positive initial data with respect to h will remain positive besides a set of zero Lebesgue measure. This shows that surfactants do not lead to a rupture of the film on large sets. For in h positive initial data we will generate strictly positive solutions of an approximation problem. In analogy to the single thin film equation we are looking for a functional $G(h)$ such that we can derive further estimates from the identity

$$\frac{d}{dt}\int_\Omega G(h) = \int_\Omega G'(h)h_t = \frac{1}{2}\int_\Omega G''(h)h_x\, h^2\sigma(\Gamma)_x + \frac{\mathcal{S}}{3}\int_\Omega G''(h)h_x\, h^3 h_{xxx}. \tag{4.1}$$

Making the ansatz $G''(h) = h^\alpha$ for any $\alpha > 0$ a formal computation leads to

$$\frac{d}{dt}\int_\Omega G(h) = \frac{1}{2}\int_\Omega h^{2+\alpha}\, h_x\, \sigma(\Gamma)_x - \frac{\mathcal{S}\,(3+\alpha)}{3}\int_\Omega h^{2+\alpha}\, h_x^2\, h_{xx} - \frac{\mathcal{S}}{3}\int_\Omega h^{3+\alpha} h_{xx}^2,$$

which suggests to take $\alpha = -2$. For this choice the first term on the right-hand side is bounded which follows from the a priori estimates we derived in section 3 and the second term vanishes due to the Neumann boundary condition for h. After integration over $[0, T]$ we therefore receive formally the entropy equation:

$$\int_\Omega G(h(T,\cdot)) + \frac{\mathcal{S}}{3}\int_{\Omega_T} h\, h_{xx}^2 = \frac{1}{2}\int_{\Omega_T} h_x\, \sigma(\Gamma)_x + \int_\Omega G(h(0,\cdot)).$$

4.1. Approximation by positive solutions. Starting with the boundary problem

$$\begin{aligned} h_t + \partial_x\Big[a_2(h)\,\sigma(\Gamma)_x + a_3(h)\,\mathcal{S}h_{xxx}\Big] &= 0 \quad \text{in } \Omega_T,\\ \Gamma_t + \partial_x\Big[\Gamma\, a_1(h)\,\sigma(\Gamma)_x + \Gamma\, a_2(h)\,\mathcal{S}h_{xxx} - \mathcal{D}\,\Gamma_x\Big] &= 0 \quad \text{in } \Omega_T,\\ h_x = h_{xxx} = \Gamma_x &= 0 \quad \text{on } (0,T)\times\partial\Omega,\\ h(0,\cdot) &= h_0 \quad \text{in } \Omega,\\ \Gamma(0,\cdot) &= \Gamma_0 \quad \text{in } \Omega, \end{aligned}$$

we will follow an idea by [BF90] and regularize the coefficient functions $a_i(s)$ and lift the initial data h_0 such that the entropy equation can be derived rigorously and the existence proof for weak solutions can be imitated. Both requirements are fulfilled by choosing the regularization

$$a_i^\epsilon(s) = \frac{s^{n+i}}{s^n + \epsilon s^3} \quad \text{for} \quad i \in \{1, 2, 3\}. \tag{4.2}$$

We see that for any fixed $\epsilon > 0$, $i \in \{1,2,3\}$ and $n > 3$:

$$\frac{a_i^\epsilon(s)}{s^{n+i-3}} = \mathcal{O}(1) \quad \text{for} \quad s \to 0 \quad \text{and} \quad \frac{s^n}{s^n + \epsilon s^3} = \mathcal{O}(1) \quad \text{for} \quad s \to \infty.$$

As a consequence the matrix $A^\epsilon(s) := \frac{s^n}{s^n+\epsilon\, s^3}\, A(s)$ of the regularized coefficients fulfills the requirements of Theorem 3.1 as long as $A(s) = \begin{pmatrix} a_3(s) & a_2(s) \\ a_2(s) & a_1(s) \end{pmatrix}$ does. Furthermore we lift the initial data for h with ϵ^θ, $0 < \theta < \frac{1}{n-3}$, so that they become strictly positive and formulate the approximation problem P^ϵ as follows:

$$h_t^\epsilon + \partial_x \left[a_2^\epsilon(h^\epsilon)\, \sigma(\Gamma^\epsilon)_x + a_3^\epsilon(h^\epsilon)\, \mathcal{S} h_{xxx}^\epsilon \right] = 0 \qquad \text{in } \Omega_T, \tag{4.3}$$

$$\Gamma_t^\epsilon + \partial_x \left[\Gamma^\epsilon\, a_1^\epsilon(h^\epsilon)\, \sigma(\Gamma^\epsilon)_x + \Gamma^\epsilon\, a_2^\epsilon(h^\epsilon)\, \mathcal{S} h_{xxx}^\epsilon \right] = \mathcal{D}\, \Gamma_{xx}^\epsilon \qquad \text{in } \Omega_T, \tag{4.4}$$

$$h_x^\epsilon = h_{xxx}^\epsilon = \Gamma_x^\epsilon = 0 \qquad \text{on } (0,T) \times \partial\Omega, \tag{4.5}$$

$$h^\epsilon(0,\cdot) = h_0^\epsilon := h_0 + \epsilon^\theta \quad \text{in } \Omega, \tag{4.6}$$

$$\Gamma^\epsilon(0,\cdot) = \Gamma_0 \qquad \text{in } \Omega. \tag{4.7}$$

For this system we can state the following theorem.

THEOREM 4.1 (existence of positive approximative solutions). *Let the assumptions of Theorem* 3.1 *hold and assume in addition that* a_1^ϵ, a_2^ϵ, a_3^ϵ *are given by* (4.2) *with* $n \geq 5$. *Then there exist for all* $\epsilon > 0$ *functions* $(h^\epsilon, \Gamma^\epsilon)$ *with* $h^\epsilon > 0$ *in* Ω_T *and*

$$h^\epsilon \in H^{1,2}\big(0,T;(H^{1,2}(\Omega))^*\big) \cap L^2\big(0,T;H^{3,2}(\Omega)\big) \cap C^{\frac{1}{8},\frac{1}{2}}(\overline{\Omega_T}),$$

$$\Gamma^\epsilon \in H^{1,\frac{3}{2}}\big(0,T;(H^{1,3}(\Omega))^*\big) \cap L^\infty\big(0,T;L^2(\Omega)\big) \cap L^2\big(0,T;H^{1,2}(\Omega)\big),$$

which attain the initial data and are such that for all $\zeta \in L^3(0,T;H^{1,3})$ *equations* (4.3)–(4.5) *are fulfilled in the following weak sense:*

$$\int_0^T \langle h_t^\epsilon(t), \zeta(t) \rangle\, dt - \int_{\Omega_T} a_2^\epsilon(h^\epsilon)\, \sigma(\Gamma^\epsilon)_x\, \zeta_x - \mathcal{S} \int_{\Omega_T} a_3^\epsilon(h^\epsilon)\, h_{xxx}^\epsilon \zeta_x = 0, \tag{4.8}$$

$$\int_0^T \langle \Gamma_t^\epsilon(t), \zeta(t) \rangle\, dt - \int_{\Omega_T} \Gamma^\epsilon a_1^\epsilon(h^\epsilon)\, \sigma(\Gamma^\epsilon)_x\, \zeta_x - \mathcal{S} \int_{\Omega_T} \Gamma^\epsilon a_2^\epsilon(h^\epsilon)\, h_{xxx}^\epsilon \zeta_x = -\mathcal{D} \int_{\Omega_T} \Gamma_x^\epsilon \zeta_x. \tag{4.9}$$

Proof. For the existence part we can imitate the proof of existence of solutions to (3.1)–(3.2). We receive functions $(h^\epsilon, \Gamma^\epsilon)$ such that for all $\zeta \in L^3(0,T;H^{1,3})$:

$$\int_0^T \langle h_t^\epsilon(t), \zeta(t) \rangle\, dt - \int_{\Omega_T} a_2^\epsilon(h^\epsilon)^*\, \sigma(\Gamma^\epsilon)_x\, \zeta_x - \int_{\Omega_T \setminus \Omega_T^{\epsilon,0}} a_3^\epsilon(h^\epsilon)^*\, \mathcal{S} h_{xxx}^\epsilon \zeta_x = 0,$$

$$\int_0^T \langle \Gamma_t^\epsilon(t), \zeta(t) \rangle\, dt - \int_{\Omega_T} \Gamma^\epsilon a_1^\epsilon(h^\epsilon)^*\, \sigma(\Gamma^\epsilon)_x\, \zeta_x - \int_{\Omega_T \setminus \Omega_T^{\epsilon,0}} \Gamma^\epsilon a_2^\epsilon(h^\epsilon)^*\, \mathcal{S} h_{xxx}^\epsilon \zeta_x = -\mathcal{D} \int_{\Omega_T} \Gamma_x^\epsilon \zeta_x$$

with $\Omega_T^{\epsilon,0} := \{(t,x) \in \Omega_T;\, h^\epsilon(t,x) = 0\}$ and $a_i^\epsilon(s)^* := a_i^\epsilon(s)\chi_{\{s>0\}}$. We already know that $h^\epsilon \geq 0$ for all $t \in [0,T]$ and almost all $x \in \Omega$. We now want to show that the set $\Omega_T^{\epsilon,0}$ is empty. Since $(h^\epsilon)_{\epsilon>0}$ is uniformly bounded in $C^0(\overline{\Omega_T})$ there exists an $A > 0$ such that $\max h^\epsilon \leq A$ for all ϵ and we define

$$g_\epsilon(s) = -\int_s^A \frac{r}{a_3^\epsilon(r)}\, dr \leq 0 \quad \text{and} \quad G_\epsilon(s) = -\int_s^A g_\epsilon(r)\, dr \geq 0. \tag{4.10}$$

Then $G'_\epsilon(s) = g_\epsilon(s)$ and

$$g'_\epsilon(s) = G''_\epsilon(s) = \frac{s}{a_3^\epsilon(s)} = \frac{s^{n+1} + \epsilon s^4}{s^{n+3}}.$$

More precisely we obtain

$$g_\epsilon(s) := -\left(\frac{1}{s} + \frac{\epsilon s^{2-n}}{n-2}\right) + c_\epsilon$$

and

$$G_\epsilon(s) := \log\frac{1}{s} + \frac{\epsilon s^{3-n}}{(n-3)(n-2)} + c_\epsilon s + d_\epsilon$$

with constants c_ϵ and d_ϵ that depend on A. We remark that c_ϵ and d_ϵ are uniformly in ϵ bounded.

Since h_0^ϵ is strictly positive and since h^ϵ is continuous we conclude that there exists a time t^* such that h^ϵ is strictly positive on $[0, t^*]$. On this time interval the system (4.8)–(4.9) is strictly parabolic. Therefore parabolic regularity implies that h is smooth on this time interval. Hence the following computations are justified. Choosing $g_\epsilon(h^\epsilon)$ as test function for (4.3) leads to

$$\int_\Omega G_\epsilon(h^\epsilon(t^*,\cdot)) - \mathcal{S}\int_{\Omega_{t^*}} h^\epsilon h_x^\epsilon h_{xxx}^\epsilon = \int_\Omega G_\epsilon(h^\epsilon(0,\cdot)) + \int_{\Omega_{t^*}} \frac{h^\epsilon\, a_2^\epsilon(h^\epsilon)}{a_3^\epsilon(h^\epsilon)} h_x^\epsilon\, \sigma(\Gamma^\epsilon)_x.$$

Using the boundary condition (4.5) the second term reduces to

$$-\int_{\Omega_{t^*}} h^\epsilon h_x^\epsilon h_{xxx}^\epsilon = \frac{1}{3}\underbrace{\int_{\Omega_{t^*}} \partial_x\,(h_x^\epsilon)^3}_{=0} + \int_{\Omega_{t^*}} h^\epsilon (h_{xx}^\epsilon)^2$$

and we get

$$\int_\Omega G_\epsilon(h^\epsilon(t^*,\cdot)) + \int_{\Omega_{t^*}} h^\epsilon (h_{xx}^\epsilon)^2 = \int_\Omega G_\epsilon(h_0^\epsilon) + \int_{\Omega_{t^*}} h_x^\epsilon\, \sigma(\Gamma^\epsilon)_x. \tag{4.11}$$

Since $h_x^\epsilon\, \sigma(\Gamma^\epsilon)_x$ is uniformly in ϵ bounded in $L^1(\Omega_T)$ we have to check the first term on the right-hand side. By definition we know that

$$\int_\Omega G_\epsilon(h_0^\epsilon) = \int_\Omega \frac{\epsilon (h_0^\epsilon)^{3-n}}{(n-3)(n-2)} + \int_\Omega G_0(h_0^\epsilon).$$

Since h_0^ϵ is bounded away from zero we conclude from the above that for all $t \in [0, t^*]$

$$\int_\Omega G_\epsilon(h^\epsilon(t,\cdot)) \le C(\epsilon). \tag{4.12}$$

Let's assume $t_* < T$ and let $t_0 \in (t_*, T]$ be the first time such that $h^\epsilon(t_0, x_0) = 0$ for $x_0 \in \Omega$. Let $(t_n)_{n\in\mathbb{N}}$ be a sequence $t_n \nearrow t_0$ for $n \to \infty$. We then conclude

$$h^\epsilon(t_n,\cdot) \to h^\epsilon(t_0,\cdot) \quad \text{uniformly in } \Omega \text{ for} \quad n \to \infty. \tag{4.13}$$

To prove that the entropy is still bounded in t_0 we apply Fatou's lemma. Since $G_\epsilon(h^\epsilon(t_n,\cdot))$ is bounded from below uniformly with respect to n we get

$$\int_\Omega \liminf_{n\to\infty} G_\epsilon(h^\epsilon(t_n,\cdot)) \le \liminf_{n\to\infty}\int_\Omega G_\epsilon(h^\epsilon(t_n,\cdot)) \le C. \tag{4.14}$$

This leads to the following contradiction: Using the Hölder-regularity of h^ϵ we conclude that for all $x\in\Omega$,

$$h^\epsilon(t_0,x) \le C|x-x_0|^{\frac{1}{2}}$$

which gives for $n>3$

$$\int_\Omega [h^\epsilon(t_0,x)]^{3-n} \ge C\int_\Omega |x-x_0|^{\frac{3-n}{2}}. \tag{4.15}$$

The right-hand side in (4.15) is unbounded since $\frac{n-3}{2}\ge 1$ for $n\ge 5$ and this contradicts the facts (4.13) and (4.14). Hence we can conclude that h^ϵ are strictly positive for all times $t\in[0,T]$. ◻

4.2. Convergence of the regularized problem. In this subsection we show that initial data with a positive height possess solutions to (1.1)–(1.2) which do not form dead cores, i.e., regimes with zero height cannot have positive measure.

THEOREM 4.2. *Let the assumptions of Theorem* 3.1 *hold with* $a_i(s)=\frac{1}{i}s^i$ *and suppose*

$$h_0\ge 0 \quad \textit{and} \quad \int_\Omega |\log h_0| < \infty. \tag{4.16}$$

Then there exists a solution of (1.1)–(1.2) *which fulfills all properties required in Theorem* 3.1 *and in addition:*

(i) $h\ge 0$ *a.e. in* Ω_T *and* $\mathcal{L}^1\big(\{x\in\Omega \,\big|\, h(t,x)=0\}\big)=0$ *for all* $t\ge 0$,

(ii) *there exists a constant* $0<C<\infty$ *such that for all* $t\in[0,T]$

$$\int_\Omega |\log h(t,\cdot)| \le C.$$

Proof. We again will make use of the energy estimates and therefore use $-\mathcal{S}\,h^\epsilon_{xx}$ as test function for (4.3) and $g'(\Gamma^\epsilon)$ as test function for (4.4). From

$$\begin{aligned}&\frac{\mathcal{S}}{2}\int_\Omega (h^\epsilon_x(T,\cdot))^2 + \int_\Omega g(\Gamma^\epsilon(T,\cdot)) + \mathcal{D}\int_{\Omega_T} g''(\Gamma^\epsilon)(\Gamma^\epsilon_x)^2\\ &+\int_{\Omega_T} d^\epsilon_3(h^\epsilon)(\mathcal{S}h^\epsilon_{xxx})^2 + \int_{\Omega_T} d^\epsilon_1(h^\epsilon)(\sigma(\Gamma^\epsilon)_x)^2 \le \frac{\mathcal{S}}{2}\int_\Omega (h^\epsilon_x(0,\cdot))^2 + \int_\Omega g(\Gamma^\epsilon(0,\cdot)),\end{aligned}$$

we then deduce in the same way as in the existence proof of weak solutions for (3.1)–(3.2) the necessary convergence results for $\epsilon\to 0$ which enable us to show that weak solutions of (4.3)–(4.7) converge to weak solutions of (3.1)–(3.5). For the evidence of this we take a closer look at one of the terms of interest:

$$\int_{\Omega_T} \Gamma^\epsilon\, a^\epsilon_2(h^\epsilon)\, h^\epsilon_{xxx}\,\zeta_x = \int_{\Omega_T} \Gamma^\epsilon\, \tilde{a}^\epsilon_2(h^\epsilon)\,(h^\epsilon)^{\frac{3}{2}} h^\epsilon_{xxx}\,\zeta_x,$$

where

$$\tilde{a}_2^\epsilon(h^\epsilon) = (h^\epsilon)^{-\frac{3}{2}} a_2^\epsilon(h^\epsilon) = \frac{(h^\epsilon)^n}{(h^\epsilon)^n + \epsilon (h^\epsilon)^3}\,(h^\epsilon)^{\frac{1}{2}} \quad \to h^{\frac{1}{2}} \quad \text{pointwise for} \quad \epsilon \to 0.$$

Since $(h^\epsilon)_{\epsilon>0}$ is uniformly bounded in $C^{\frac{1}{8},\frac{1}{2}}(\overline{\Omega_T})$, the sequence $(\tilde{a}_2^\epsilon(h^\epsilon)\zeta_x)_{\epsilon>0}$ converges strongly to $h^{\frac{1}{2}}\zeta_x$ in $L^3(\Omega_T)$ for $\epsilon \to 0$. Hence we conclude with the uniformly boundedness of $\Gamma^\epsilon\,(h^\epsilon)^{\frac{3}{2}} h^\epsilon_{xxx}$ in $L^{\frac{3}{2}}(\Omega_T)$ and the weak convergence of $(h^\epsilon_{xxx})_\epsilon$ in $L^2(\Omega_T \backslash \Omega_T^0)$ that

$$\lim_{\epsilon\to 0} \int_{\Omega_T} \Gamma^\epsilon\, a_2^\epsilon(h^\epsilon)\, h^\epsilon_{xxx}\, \zeta_x = \int_{\Omega_T\backslash\Omega_T^0} \Gamma\, a_2(h)\, h_{xxx}\, \zeta_x .$$

We now like to establish the nonnegativity result using the entropy inequality as a crucial tool. Since $h^\epsilon \to h$ uniformly and $h^\epsilon > 0$ we obtain $h \geq 0$. Now we assume that there exists a $t_0 \in (0,T)$ such that

$$\mathcal{L}^1(E_{t_0}) > 0 \quad \text{for} \quad E_{t_0} := \{x \in \Omega \big| \, h(t_0,x) = 0\}.$$

Using the uniform convergence of h^ϵ there exists a $w(\epsilon)$ with $h_\epsilon(t_0,x) < w(\epsilon)$ for all $x \in E_{t_0}$ such that for all $x \in E_{t_0}$ and arbitrary $\eta > 0$ with $w(\epsilon) < \eta$,

$$G_\epsilon(h^\epsilon(t_0,x)) \geq -\int_{w(\epsilon)}^A g_\epsilon(s)ds \geq -\int_\eta^A g_\epsilon(s)ds.$$

Since the last integral converges to $-\int_\eta^A g_0(s)$ for $\epsilon \to 0$ and since $-\int_\eta^A g_0(s) \geq c\,\log\frac{1}{\eta}$ we obtain

$$\limsup_{\epsilon\to 0} \int_\Omega G_\epsilon(h^\epsilon(t_0,x)) \geq c \log\frac{1}{\eta}\ \mathcal{L}(E_{t_0}) \to \infty \quad \text{for} \quad \eta \to 0\,.$$

We now plan to derive a contradiction by showing that the left-hand side in the above inequality is bounded. Considering (4.11) and taking into account that $h^\epsilon_x\sigma(\Gamma^\epsilon)$ is uniformly in ϵ bounded in the $L^1(\Omega_T)$ topology we only need to control $\int_\Omega G_\epsilon(h_0^\epsilon)$. To obtain this we first observe that for $n < 3$

$$\epsilon(h_0 + \epsilon^\theta)^{3-n} \leq \epsilon^{1+\theta(3-n)} \to 0 \quad \text{for} \quad \epsilon \to 0\,.$$

This holds because we defined θ such that $0 < \theta < \frac{1}{n-3}$. Then boundedness of $\int_\Omega G_\epsilon(h_0^\epsilon)$ uniformly in ϵ follows from (4.16). As a conclusion the set of points where $h = 0$ is of Lebesgue measure zero which proves the first statement (i). The second statement (ii) we conclude from the pointwise convergence

$$G_\epsilon(h^\epsilon(t,x)) \to G_0(h(t,x)) \quad \text{for} \quad \epsilon \to 0$$

in combination with (4.12) and Fatou's lemma:

$$\int_\Omega \liminf_{\epsilon\to 0} G_\epsilon(h^\epsilon(t,x)) \leq \liminf_{\epsilon\to 0} \int_\Omega G_\epsilon(h^\epsilon(t,x)) \leq C,$$

since $G_0(s) = \log\frac{1}{s}$. $\square$

5. Appendix.

5.1. Transport identity. In this appendix we prove the transport theorem (2.9). The proof is based on the following identity which is the Gauss theorem applied to the vector field $\Gamma\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}})$:

$$\int_{C'} \nabla_{C'}\cdot\left(\Gamma\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}})\right)dS^3=\int_{\partial C'}\Gamma\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}})\cdot\mathbf{n}_{\partial C'}dS^2, \tag{5.1}$$

where $\mathbf{n}_{\partial C'}$ is the outer unit normal to $\partial C'$. First we compute the divergence under the integral on the left-hand side. Taking an orthonormal basis $\{\boldsymbol{t}_1,\boldsymbol{t}_2,\boldsymbol{t}_3\}$ of the tangent space to C' the divergence of a vector field F is defined as

$$\nabla_{C'}\cdot\, F=\sum_{i=1}^{3}(\partial_{\boldsymbol{t}_i}F)\cdot\boldsymbol{t}_i.$$

Choosing $\boldsymbol{t}_1=(0,\boldsymbol{\tau}_1)$, $\boldsymbol{t}_2=(0,\boldsymbol{\tau}_2)$, $\boldsymbol{t}_3=\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}})$ with $(\boldsymbol{\tau}_1,\boldsymbol{\tau}_2)$ being an orthonormal basis of the tangent space to C'_t and $\mathbf{v}_{\boldsymbol{\nu}}$ being such that $\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\tau}_i=0$ $(i=1,2)$ we obtain

$$\begin{aligned}\nabla_{C'}\cdot\left(\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}})\right)&=\sum_{i=1}^{2}\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}\partial_{\boldsymbol{t}_i}(1,\mathbf{v}_{\boldsymbol{\nu}})\cdot\boldsymbol{t}_i\\&\quad+\left(\partial_{\boldsymbol{t}_3}\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}\right)(1+\mathbf{v}_{\boldsymbol{\nu}}^2)\\&\quad+\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}\Big(\partial_{\boldsymbol{t}_3}(1,\mathbf{v}_{\boldsymbol{\nu}})\Big)\cdot(1,\mathbf{v}_{\boldsymbol{\nu}}),\end{aligned}$$

where we used that $\boldsymbol{\tau}_1$, $\boldsymbol{\tau}_2$ and $\mathbf{v}_{\boldsymbol{\nu}}$ are orthogonal. A straightforward computation shows that the last two terms cancel and we obtain (using the fact $\mathbf{v}_{\boldsymbol{\nu}}=\alpha\boldsymbol{\nu}$ for the scalar normal velocity α) that

$$\begin{aligned}\nabla_{C'}\cdot\left(\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}^2}}}(1,\mathbf{v}_{\boldsymbol{\nu}})\right)&=\frac{\alpha}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}\sum_{i=1}^{2}(\partial_{\boldsymbol{\tau}_i}\boldsymbol{\nu})\cdot\boldsymbol{\tau}_i\\&=-\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}^2}}}\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\kappa}_{\boldsymbol{\nu}},\end{aligned}$$

where we set $\boldsymbol{\kappa}_{\boldsymbol{\nu}}=\kappa\boldsymbol{\nu}$ with $\kappa=-\sum_{i=1}^{2}(\partial_{\boldsymbol{\tau}_i}\boldsymbol{\nu})\cdot\boldsymbol{\tau}_i$. Altogether we obtain

$$\nabla_{C'}\cdot\left(\Gamma\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}})\right)=\nabla_{C'}\Gamma\cdot\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}})-\Gamma\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\kappa}_{\boldsymbol{\nu}}.$$

Computing the surface element with the help of the above basis $\{\boldsymbol{t}_1,\boldsymbol{t}_2,\boldsymbol{t}_3\}$ one obtains that for a function f on C',

$$\int_{C'}f\,dS^3=\int_{t_1}^{t_2}\int_{C'_t}f\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}\,dS^2\,dt.$$

Hence we obtain

$$\int_{C'} \nabla_{C'} \cdot \left(\Gamma \frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}}) \right) = \int_{t_1}^{t_2} \int_{C'_t} \Big(\partial_{(1,\mathbf{v}_{\boldsymbol{\nu}})}\Gamma - \Gamma\left(\mathbf{v}_{\boldsymbol{\nu}} \cdot \boldsymbol{\kappa}_{\boldsymbol{\nu}}\right)\Big) dS^2\, dt. \tag{5.2}$$

It remains to compute the right-hand side in (5.1). Using the identity

$$C' = \bigcup_{t\in[t_1,t_2]} \{t\} \times C'_t$$

we see that $\partial C'$ contains three parts: top, bottom and lateral boundary. For the top and similarly for the bottom (with a different sign) we obtain $\mathbf{n}_{\partial C'} = \frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}})$. Hence

$$\int_{\partial C' \cap C'_{t_2}} \Gamma \frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}}) \cdot \mathbf{n}_{\partial C'}\, dS^2 = \int_{C'_{t_2}} \Gamma\, dS^2 \tag{5.3}$$

and a similar formula holds for t_1 with the different sign on the right-hand side. It remains to compute the integral on the lateral surface. We need to identify $\mathbf{n}_{\partial C'}$ on the lateral boundary. $\mathbf{n}_{\partial C'}$ has to be normal to $\partial C'$ and tangential to C'. Now we choose an orthogonal system $(0,\boldsymbol{\tau}_1)$, $(0,\boldsymbol{\tau}_2)$ and $(1,\mathbf{v}_{\boldsymbol{\nu}})$ such that $\boldsymbol{\tau}_2$ is tangential to $\partial C'_t$. Hence we can choose without loss of generality

$$\boldsymbol{\tau}_1 = \mathbf{n}_{\partial C'_t}.$$

Claim. $(1,\mathbf{v}_{\boldsymbol{\nu}}) + (0, v_{\partial C'_t}\,\mathbf{n}_{\partial C'_t})$ is tangential to $\partial C'$.

Proof. Assume $(t,x) \in \partial C'$. Choose a curve $(s,y(s)) \in \partial C'$ such that $(t,y(t)) = (t,x)$. Hence $(1,y'(t))$ is tangential to $\partial C'$. Since $(1,y'(t))$ lies in the tangent space to C', we have

$$(1,y'(t)) = (1,\mathbf{v}_{\boldsymbol{\nu}}) + \alpha(0,\boldsymbol{\tau}_1) + \beta(0,\boldsymbol{\tau}_2).$$

We defined $v_{\partial C'_t} = y'(t)\cdot \mathbf{n}_{\partial C'_t}$ and hence, since $\boldsymbol{\tau}_1 \cdot \boldsymbol{\tau}_2 = 0$, we obtain $v_{\partial C'_t} = \alpha$. This implies that

$$(1,\mathbf{v}_{\boldsymbol{\nu}}) + (0, v_{\partial C'_t}\,\mathbf{n}_{\partial C'_t})$$

is tangential to $\partial C'$.

Now we need to find numbers a and b such that

$$\mathbf{n}_{\partial C'} = a(0,\boldsymbol{\tau}_1) + b(1,\mathbf{v}_{\boldsymbol{\nu}})$$

is perpendicular to $(1, \mathbf{v}_{\boldsymbol{\nu}} + v_{\partial C'_t}\,\mathbf{n}_{\partial C'_t})$ and normal. A simple computation shows

$$b = -\frac{v_{\partial C'_t}}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2 + v_{\partial C'_t}^2}\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}$$

and hence

$$\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}}) \cdot \mathbf{n}_{\partial C'} = -\frac{v_{\partial C'_t}}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2 + v_{\partial C'_t}^2}}.$$

As a result

$$\int_{\partial C'\setminus(C'_{t_2}\bigcup C'_{t_1})} \Gamma\frac{1}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2}}(1,\mathbf{v}_{\boldsymbol{\nu}})\cdot\mathbf{n}_{\partial C'}\,dS^2 = -\int_{\partial C'\setminus(C'_{t_2}\bigcup C'_{t_1})} v_{\partial C'_t}\frac{\Gamma}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2+v_{\partial C'_t}^2}}\,dS^2.$$

Using $(0,\boldsymbol{\tau}_1)$ and $\mathbf{n}_{\partial C'}$ to compute the area element we obtain

$$-\int_{\partial C'\setminus(C'_{t_2}\bigcup C'_{t_1})} v_{\partial C'_t}\frac{\Gamma}{\sqrt{1+\mathbf{v}_{\boldsymbol{\nu}}^2+v_{\partial C'_t}^2}}\,dS^2 = -\int_{t_1}^{t_2}\int_{\partial C'_t} v_{\partial C'_t}\,\Gamma dS^1\,dt. \tag{5.4}$$

Combining (5.1), (5.2), (5.3) and (5.4) gives

$$\int_{C'_{t_2}}\Gamma\,dS^2 - \int_{C'_{t_1}}\Gamma\,dS^2 = \int_{t_1}^{t_2}\int_{C'_t}\Big(\partial_{(1,\mathbf{v}_{\boldsymbol{\nu}})}\Gamma - \Gamma\,(\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\kappa}_{\boldsymbol{\nu}})\Big)dS^2\,dt + \int_{t_1}^{t_2}\int_{\partial C'_t}\Gamma\,v_{\partial C'_t}dS^1 dt.$$

Differentiating with respect to t_2 now gives (2.9). □

5.2. Energy identity. In this subsection we show the energy inequality (2.16). Using transport theorems (see, e.g., (2.9)) we obtain

$$\begin{aligned}\frac{d}{dt}E(t) &= \int_{\Omega_t}\rho_0\,\mathbf{u}\cdot\mathbf{u}_t\,dV^3 + \int_{\partial\Omega_t}\frac{\rho_0}{2}\mathbf{u}^2(\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\nu})\,dS^2\\ &\quad+\int_{C_t}\Big(\partial_{(1,\mathbf{v}_{\boldsymbol{\nu}})}\,g(\Gamma) - g(\Gamma)(\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\kappa}_{\boldsymbol{\nu}})\Big)dS^2 + \int_{\partial C_t} g(\Gamma)\,v_{\partial C'_t}dS^1.\end{aligned}$$

The 90° angle condition at the outer boundary implies that the last term vanishes. Using the equations (2.1)–(2.2) for $\mathbf{u}$ and (2.11) for Γ and noticing that $\nabla\cdot T = -\nabla p + \mu\Delta\mathbf{u}$ we obtain

$$\begin{aligned}\frac{d}{dt}E(t) &= \int_{\Omega_t}\Big(-\rho_0\,\mathbf{u}\cdot(\mathbf{u}\cdot\nabla)\mathbf{u} + (\nabla\cdot T)\cdot\mathbf{u}\Big)\,dV^3 + \int_{C_t}\frac{\rho_0}{2}\mathbf{u}^2(\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\nu})dS^2\\ &\quad+\int_{C_t} g'(\Gamma)\Big(\Gamma(\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\kappa}_{\boldsymbol{\nu}}) - \nabla_s\cdot\big(\Gamma\mathbf{u}_{tan} - D\nabla_s\Gamma\big)\Big)dS^2 - \int_{C_t} g(\Gamma)\,(\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\kappa}_{\boldsymbol{\nu}})dS^2.\end{aligned}$$

Taking into account that $\nabla\cdot\mathbf{u}=0$, $\mathbf{u}\cdot(\mathbf{u}\cdot\nabla)\mathbf{u} = \frac{1}{2}\mathbf{u}\cdot\nabla|\mathbf{u}|^2$ and $\mathbf{u} = \mathbf{u}_{tan} + (\mathbf{u}\cdot\boldsymbol{\nu})\boldsymbol{\nu}$ on C_t and using the boundary conditions (2.6) and (2.7) we obtain after integration by parts

$$
\begin{aligned}
\frac{d}{dt}E(t) = &-\int_{\Omega_t} T : \nabla \mathbf{u}\, dV^3 - \int_{C_t} \frac{\rho_0}{2}\mathbf{u}^2\,(\mathbf{v}_{\boldsymbol{\nu}} - \mathbf{u})\cdot\boldsymbol{\nu}\, dS^2 + \int_{C_t} \mathbf{u}_{tan}\cdot\nabla_s\,\sigma(\Gamma) dS^2 \\
&+ \int_{C_t} (\mathbf{u}\cdot\boldsymbol{\nu})\sigma(\Gamma)\kappa\, dS^2 \\
&+ \int_{C_t} g'(\Gamma)\Gamma(\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\kappa}_{\boldsymbol{\nu}})\, dS^2 + g''(\Gamma)\Gamma\mathbf{u}_{tan}\cdot\nabla_s\Gamma\, dS^2 - D\int_{C_t} g''(\Gamma)|\nabla_s\Gamma|^2\, dS^2 \\
&- \int_{C_t} g(\Gamma)(\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\kappa}_{\boldsymbol{\nu}})\, dS^2 \\
= &-\int_{\Omega_t} T : \nabla\mathbf{u}\, dV^3 + \int_{C_t} \mathbf{u}_{tan}\cdot\nabla_s\Gamma\big(\Gamma\, g''(\Gamma) - \sigma'(\Gamma)\big) dS^2 \\
&+ \int_{C_t} (\mathbf{u}\cdot\boldsymbol{\nu})\kappa\left(\sigma(\Gamma) + g'(\Gamma)\Gamma - g(\Gamma)\right) dS^2 - D\int_{C_t} g''(\Gamma)|\nabla_s\Gamma|^2\, dS^2 \\
= &-\int_{\Omega_t} T : \nabla\mathbf{u}\, dV^3 - D\int_{C_t} g''(\Gamma)|\nabla_s\Gamma|^2\, dS^2,
\end{aligned}
$$

where we used (2.14) and the facts $\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\nu} = \mathbf{u}\cdot\boldsymbol{\nu}$ and $\mathbf{v}_{\boldsymbol{\nu}}\cdot\boldsymbol{\kappa}_{\boldsymbol{\nu}} = \kappa\mathbf{u}\cdot\boldsymbol{\nu}$.

Acknowledgments. The authors would like to thank Willi Alt and Felix Otto for helpful discussions.
