ASYMPTOTICS FOR SELFDUAL VORTICES ON THE TORUS AND ON THE PLANE: A GLUING TECHNIQUE*

MARTA MACRÌ†, MARGHERITA NOLASCO‡, AND TONIA RICCIARDI†

Abstract. We consider multivortex solutions for the selfdual Abelian Higgs model, as the ratio of the vortex core size to the separation distance between vortex points (the scaling parameter) tends to zero. To this end, we use a gluing technique (a shadowing lemma) for solutions to the corresponding semilinear elliptic equation on the plane, allowing any number (finite or countable) of arbitrarily prescribed singular sources. Our approach is particularly convenient and natural for the study of the asymptotics. In particular, in the physically relevant cases where the vortex points are either finite or periodically arranged in the plane, we prove that a frequently used factorization ansatz for multivortex solutions is rigorously satisfied, up to an error which is exponentially small.

Key words. selfdual Abelian Higgs model, elliptic equation, shadowing lemma

1. Introduction. We consider the energy density for the static, two-dimensional selfdual Abelian Higgs model in the following form:

$$\mathcal{E}_\delta(A,\phi) = \delta^2|\mathrm{d}A|^2 + |D\phi|^2 + \frac{1}{4\delta^2}\left(|\phi|^2-1\right)^2,$$

where $A = A_1\mathrm{d}x_1 + A_2\mathrm{d}x_2$, $A_1(x), A_2(x) \in \mathbb{R}$ is a gauge potential (a connection over a principal $U(1)$ bundle), ϕ, $\phi(x) \in \mathbb{C}$ is a Higgs matter field (a section over an associated complex line bundle), $D = \mathrm{d} - iA$ is the covariant derivative, and $\delta > 0$ is the scaling parameter. $\mathcal{E}_\delta$ is a rescaling of $\mathcal{E}_1 = \mathcal{E}_\delta|_{\delta=1}$, which coincides with the two-dimensional Ginzburg–Landau energy density in the so-called Bogomol'nyi limit. Such a limit describes the borderline between type I and type II superconductors; see, e.g., Jaffe and Taubes [12]. By the selfdual structure, solutions to the Euler–Lagrange equations of $\mathcal{E}_\delta$ may be obtained from solutions to the first order system:

$$(D_1 \pm iD_2)\phi = 0, \tag{1.1}$$

$$F_{12} = \partial_1 A_2 - \partial_2 A_1 = \pm\frac{1}{2\delta^2}(1-|\phi|^2). \tag{1.2}$$

The vortex-type critical points for the energy associated with $\mathcal{E}_\delta$, namely, the solutions of (1.1)–(1.2), have received considerable attention in recent years, in view of both their physical and geometrical interest; see, e.g., García-Prada [8], Hong, Jost, and Struwe [10], Stuart [17], Taubes [19], Wang and Yang [20], and the references therein. In particular, Hong, Jost, and Struwe [10] consider (1.1)–(1.2) on a compact

Riemannian surface and perform a detailed analysis of the asymptotics as $\delta \to 0^+$. Indeed, the small $\delta > 0$ regime, corresponding to the limit of small vortex core size with respect to the separation distance between vortices, is an appropriate approximation for the analysis near the vortex points of solutions of (1.1)–(1.2) with $\delta = 1$. This type of asymptotics is also relevant in the context of Ginzburg–Landau vortices; see, e.g., Aftalion, Sandier, and Serfaty [2], Alama and Bronsard [3], André, Bauman, and Phillips [4], Bethuel, Brezis, and Hélein [6], Lin [13], Rubinstein and Sternberg [16], just to mention a few. It has also been widely investigated in the context of other selfdual gauge theories; see the monographs of Tarantello [18] and Yang [22].

The fundamental results concerning finite energy solutions of (1.1)–(1.2) on $\mathbb{R}^2$ were obtained by Taubes [12, 19]. In particular, Taubes showed that such solutions are completely determined by solutions to the singular elliptic problem

$$\begin{cases} -\Delta u = \delta^{-2}(1 - \mathrm{e}^u) - 4\pi \sum_{j=1}^s m_j \delta_{p_j} & \text{on } \mathbb{R}^2, \\ u(x) \to 0 & \text{as } |x| \to +\infty. \end{cases} \tag{1.3}$$

Here $s \in \mathbb{N}$, and for $j = 1, 2, \dots, s$, $p_j \in \mathbb{R}^2$ are the vortex points, $m_j \in \mathbb{N}$ is the multiplicity of p_j, and δ_{p_j} is the Dirac measure at p_j. By variational methods, Taubes proved that, for any $\delta > 0$, there exists a unique solution of (1.3) such that the configuration (A, ϕ) defined in complex notation by

$$\begin{cases} \phi(z) = \exp\{\frac{1}{2}u(z) \pm i \sum_{j=1}^s m_j \arg(z - p_j)\}, \\ A_1 \mp iA_2 = -i(\partial_1 \pm i\partial_2) \ln \phi \end{cases} \tag{1.4}$$

is a smooth, finite energy solution of (1.1)–(1.2) on $\mathbb{R}^2$, satisfying $\phi(p_j) = 0$ (with the corresponding multiplicity $m_j \in \mathbb{N}$) and $E = \int_{\mathbb{R}^2} \mathcal{E}_\delta(A, \phi) = \pm \int_{\mathbb{R}^2} F_{12} = 2\pi \sum_{j=1}^s m_j = 2\pi N$, where $F_{12} = \partial_1 A_2 - \partial_2 A_1$ is the magnetic field (the curvature of A).

In connection with Abrikosov's mixed states in superconductivity [1], it is also of physical interest to analyze (1.1)–(1.2) on the flat torus $\mathbb{T}^2 \equiv \mathbb{R}^2/(a\mathbb{Z} \times b\mathbb{Z})$, where $a, b > 0$. Such a case has been considered by Wang and Yang in [20]. It is shown in [20] that solutions of (1.1)–(1.2) with $\delta = 1$ exist for any given set of vortex points $p_j \in \mathbb{T}^2$, $j = 1, 2, \dots, s$, with multiplicity $m_j \in \mathbb{N}$, if and only if $N = \sum_{j=1}^s m_j < |\mathbb{T}^2|/(4\pi)$. In particular, on $\mathbb{T}^2$ the total number of vortices N cannot be arbitrarily large. Similarly as on $\mathbb{R}^2$, denoting $\Omega = (0, a) \times (0, b)$, solutions of (1.1)–(1.2) on $\mathbb{T}^2$ correspond to solutions for the singular elliptic problem

$$\begin{cases} -\Delta u = \delta^{-2}(1 - \mathrm{e}^u) - 4\pi \sum_{j=1}^s m_j \delta_{p_j} & \text{in } \Omega, \\ u \text{ doubly periodic} & \text{on } \partial\Omega. \end{cases} \tag{1.5}$$

The periodic boundary conditions are justified by certain more general gauge invariant conditions on the configuration (A, ϕ) introduced by 't Hooft [11]. Such conditions force the magnetic flux through a lattice cell to be a "quantized" value proportional to the number of vortices confined. Namely, the 't Hooft boundary conditions imply the topological constraint $\pm\int_\Omega F_{12} = 2\pi \sum_{j=1}^s m_j = 2\pi N$ on the solutions of (1.5), exactly as for finite energy solutions on $\mathbb{R}^2$. Integrating (1.5) on the periodic cell Ω, we obtain that a necessary condition to the solvability of (1.5) is $\delta^2 < |\Omega|/(4\pi N)$. This is obviously satisfied for any finite vortex number N provided $\delta > 0$ is sufficiently small.

Our aim in this note is to show that a "shadowing-type lemma" as introduced in the context of elliptic PDEs by Angenent [5] (see also Nolasco [15]) may be adapted to elliptic equations with singular sources in order to construct solutions for the following more general equation:

$$-\Delta u = \delta^{-2}(1 - \mathrm{e}^u) - 4\pi \sum_{j\in\mathcal{P}} m_j \delta_{p_j} \qquad \text{in } \mathbb{R}^2, \tag{1.6}$$

where the set of indices $\mathcal{P}$ may be either finite or countable, and the vortex points p_j, $j \in \mathbb{N}$, are *arbitrarily* distributed in the plane with the only constraint that

$$d := \inf_{k\neq j} |p_j - p_k| > 0 \qquad \text{and} \qquad m := \sup_{j\in\mathcal{P}} m_j < +\infty. \tag{1.7}$$

The solution we obtain for (1.6) coincides with the solution obtained by Taubes for problem (1.3) when $\mathcal{P}$ is finite and with the solution obtained by Wang and Yang for problem (1.5) when $\mathcal{P}$ is infinite and the vortex points are periodically arranged in $\mathbb{R}^2$. In fact, unlike the previous approaches, our method provides a unified analysis of (1.3) and (1.5). It should be mentioned that suitable modifications to the method described in [5] are necessary due to the singular sources appearing in (1.6). The case where $\mathcal{P}$ is countable and the vortex points are arbitrarily arranged in $\mathbb{R}^2$ does not seem to have been considered before. Of course, if $\mathcal{P}$ is countable, the energy of such a solution is infinite and only locally bounded. On the other hand, our "gluing" technique is, particularly, convenient and natural to analyze the asymptotics as $\delta \to 0^+$. In particular, as a by-product of our construction, we derive a rigorous proof of the following *approximate product formula*:

$$\phi(x) = \prod_{j\in\mathcal{P}} \Phi_{m_j}\left(\frac{x - p_j}{\delta}\right) + \eta_\delta, \tag{1.8}$$

where $\|\eta_\delta\|_{L^\infty(\mathbb{R}^2)} \le C\mathrm{e}^{-c/\delta}$ with $C, c > 0$ independent of δ. Here (A_{m_j}, Φ_{m_j}) is the unique, up to gauge transformation, single vortex (or antivortex) solution with multiplicity m_j to (1.1)–(1.2) with $\delta = 1$ on $\mathbb{R}^2$. We note that in the small $\delta > 0$ regime, a product formula of the form (1.8) is a widely used ansatz in the physics literature, in particular in the study of the dynamics of vortices in the Ginzburg–Landau model; see, e.g., E [7], Neu [14], and Weinstein and Xin [21]. However, we have found a rigorous proof of (1.8) only for the case $N = 2$ on $\mathbb{R}^2$ in Stuart [17]. The asymptotic behavior of solutions of (1.1)–(1.2) as $\delta \to 0^+$ is readily derived from formula (1.8) as well as the convergence rates. In fact, in the case of $\mathbb{T}^2$, our asymptotic description improves the previous result obtained (for general compact Riemann surfaces) by Hong, Jost, and Struwe [10] (see Corollary 2.1).

Although we have chosen to consider the Abelian Higgs model for the sake of simplicity, we will show in a forthcoming note that our method may be adapted to other selfdual gauge theories as considered, e.g., in the monographs [18, 22].

2. Main results and outline of the proof. In order to state precisely our results, we denote by U_N the unique radial solution for the problem (see [12])

$$\begin{cases} -\Delta U_N = 1 - \mathrm{e}^{U_N} - 4\pi N \delta_0 & \text{in } \mathbb{R}^2, \\ U_N(x) \to 0 & \text{as } |x| \to +\infty. \end{cases} \tag{2.1}$$

Our main result is the following theorem.

THEOREM 2.1. *Let $p_j \in \mathbb{R}^2$, $m_j \in \mathbb{N}$, $j \in \mathcal{P} \subseteq \mathbb{N}$, and assume that conditions* (1.7) *hold. Then there exists a constant $\delta_1 > 0$ (depending on* d *and* m *only) such* *that for every $\delta \in (0, \delta_1)$ there exists a solution u_δ for* (1.6)*. Furthermore, u_δ satisfies the approximate superposition rule*

$$u_\delta(x) = \sum_{j \in \mathcal{P}} U_{m_j}\left(\frac{|x - p_j|}{\delta}\right) + \omega_\delta, \tag{2.2}$$

where the error term ω_δ satisfies $\|\omega_\delta\|_\infty \le C\mathrm{e}^{-c/\delta}$ for some $C, c > 0$ independent of δ. In particular, u_δ satisfies the following properties:

(i) $0 \le \mathrm{e}^{u_\delta} < 1$, *$\mathrm{e}^{u_\delta}$ vanishes exactly at p_j, $j \in \mathcal{P}$;*

(ii) *for every compact subset K of $\mathbb{R}^2 \setminus \cup_{j\in\mathcal{P}}\{p_j\}$, there exist $C, c > 0$ such that $\sup_K(1 - \mathrm{e}^{u_\delta}) \le C\mathrm{e}^{-c/\delta}$ as $\delta \to 0^+$;*

(iii) $\pm F_{12} = \frac{1}{2\delta^2}(1 - \mathrm{e}^{u_\delta}) \to 2\pi \sum_{j\in\mathcal{P}} m_j \delta_{p_j}$ *in the sense of distributions as $\delta \to 0^+$.*

In the case that $\mathcal{P}$ is countable, we say that the vortex points p_j, $j \in \mathcal{P}$, are doubly periodically arranged in $\mathbb{R}^2$ if there exists $s \in \mathbb{N}$ such that

$$\{p_k\}_{k\in\mathcal{P}} = \{p_j + m\underline{e}_1 + n\underline{e}_2 \ : \ j = 1, \dots, s;\ m, n \in \mathbb{Z}\}, \tag{2.3}$$

where $\underline{e}_1$ and $\underline{e}_2$ are the unit vectors in $\mathbb{R}^2$ defining the periodic cell domain Ω (for simplicity, we assume $a = b = 1$). Under this condition, solving (1.6) is equivalent to solving (1.5). Namely, we deal with the physically relevant case of a finite number of vortex points $p_1, \dots, p_s \in \Omega$, with the corresponding multiplicity m_j, $j = 1, \dots, s$, such that $\sum_{j=1}^s m_j = N$, where N is the vortex number and Ω is the periodic cell domain. As a consequence of Theorem 2.1, and proving in addition that if (2.3) is satisfied, then the solution u_δ for (1.6) is in fact doubly periodic with periodic cell domain Ω, we derive the following result.

Corollary 2.1. *If the p_j's are doubly periodically arranged in $\mathbb{R}^2$, there exists a constant $\delta_1 > 0$ (depending on N only) such that for every $\delta \in (0, \delta_1)$ the solution u_δ, given in Theorem* 2.1*, is a solution for* (1.5)*. Furthermore, the corresponding vortex configurations (A_δ, ϕ_δ) satisfy the approximate factorization rule*

$$\phi_\delta(x) = \prod_{j=1}^{s} \Phi_{m_j}\left(\frac{x - p_j}{\delta}\right) + \eta_\delta, \qquad x \in \Omega,$$

where the error term η_δ satisfies $\|\eta_\delta\|_\infty \le C\mathrm{e}^{-c/\delta}$ for some $C, c > 0$ independent of δ, and (A_{m_j}, Φ_{m_j}) is the unique, up to gauge transformation, single vortex (or antivortex) solution with multiplicity m_j, to (1.1)–(1.2) *with $\delta = 1$ on $\mathbb{R}^2$. In particular, we have the following:*

(i) $0 \le |\phi_\delta|^2 < 1$, *$\phi_\delta$ vanishes exactly at p_j, $j = 1, \dots, s$;*

(ii) *for every compact subset K of $\Omega \setminus \{p_1, \dots, p_s\}$, there exist $C, c > 0$ such that $0 \le \sup_K(1 - |\phi_\delta|^2) \le C\mathrm{e}^{-c/\delta}$ as $\delta \to 0^+$;*

(iii) $\pm F_{12}(A_\delta, \phi_\delta) = \frac{1}{2\delta^2}(1 - |\phi_\delta|^2) \to 2\pi \sum_{j=1}^s m_j \delta_{p_j}$ *in the sense of distributions (on Ω) as $\delta \to 0^+$;*

(iv) $\int_\Omega \mathcal{E}_\delta(A_\delta, \phi_\delta) = \pm \int_\Omega F_{12}(A_\delta, \phi_\delta) = 2\pi N$.

An outline of the proof is as follows. Our starting point in proving Theorem 2.1 is to consider $\delta > 0$ as a scaling parameter. Setting $\hat{u}(x) = u(\delta x)$, we have that $\hat{u}$ satisfies

$$-\Delta \hat{u} = 1 - \mathrm{e}^{\hat{u}} - 4\pi \sum_{j\in\mathcal{P}} m_j \delta_{\hat{p}_j} \qquad \text{in } \mathbb{R}^2, \tag{2.4}$$

where $\hat{p}_j = p_j/\delta$. Note that the vortex points $\hat{p}_j$ "separate" as $\delta \to 0^+$. Section 3 contains some properties of the radial solutions U_N to (2.1). We rely on the results of Taubes [19] for the existence and uniqueness of U_N as well as for the exponential decay properties at infinity. We also prove a nondegeneracy property of U_N. The exponential decay of solutions justifies the following approximate superposition picture for small values of δ, i.e., for vortex points $\hat{p}_j$ which are "far apart":

$$\hat{u}(x) \approx \sum_{j\in\mathcal{P}} U_{m_j}\left(|x - \hat{p}_j|\right).$$

In fact, we take the following preliminary form of the superposition rule:

$$\hat{u} = \sum_{j\in\mathcal{P}} \hat{\varphi}_j U_{m_j}(x - \hat{p}_j) + z \tag{2.5}$$

as an *ansatz* for $\hat{u}_\delta$. Here, radial solutions centered at $\hat{p}_j$ are "glued" together by the functions $\hat{\varphi}_j$, which belong to a suitable locally finite partition of unity. Section 4 contains the definition and the main properties of the partition as well as of the appropriate functional spaces $\hat{X}_\delta, \hat{Y}_\delta$, which are also obtained by "gluing" $H^2(\mathbb{R}^2)$ and $L^2(\mathbb{R}^2)$, respectively. Hence, we are reduced to show that for small values of $\delta > 0$, there exists an exponentially small "error" z such that $\hat{u}$ defined by (2.5) is a solution of (2.4). The existence of such a $z \in \hat{X}_\delta$ is the aim of section 5 (see Proposition 5.1). To this end, we use the shadowing lemma. We characterize z by the property $F_\delta(z) = 0$, where $F_\delta : \hat{X}_\delta \to \hat{Y}_\delta$ is suitably defined. The nondegeneracy property of U_N is essential in order to prove that the operator $DF_\delta(0)$ is invertible, and that its inverse is bounded independently of $\delta > 0$ (Lemma 5.3). At this point, the Banach fixed point argument applied to $\mathbb{I} - (DF_\delta(0))^{-1} F_\delta$ yields the existence of the desired error term z. In section 6 we show that (2.5) implies (2.2) and we derive the asymptotic behavior of solutions, thus concluding the proof of Theorem 2.1. Finally, we derive Corollary 2.1 by showing that periodically arranged vortex points lead to periodic solutions.

Henceforth, unless otherwise stated, we denote by $C, c > 0$ general constants independent of $\delta > 0$ and of $j \in \mathcal{P}$.

3. Single vortex point solutions. In this section, we consider the solution U_N to the radially symmetric equation (2.1). For every $r > 0$, we denote $B_r = \{x \in \mathbb{R}^2 : |x| < r\}$. The following lemma contains some properties of U_N that will be needed in the following. The proof is a consequence of the results of Taubes [12, 19] on the existence, uniqueness, and the exponential decay of U_N together with standard elliptic theory as in, e.g., [9]. Therefore, it is omitted.

LEMMA 3.1. *The following properties hold:*

(i) $e^{U_N(x)} < 1$ *for any* $x \in \mathbb{R}^2$*;*

(ii) *for every* $r > 0$ *there exist constants* $C_N > 0$ *and* $\alpha_N > 0$*, depending on* r *and* N *only, such that*

$$|1 - e^{U_N(x)}| + |\nabla U_N(x)| + |U_N(x)| \le C_N e^{-\alpha_N |x|}$$

for all $x \in \mathbb{R}^2 \setminus B_r$.

We consider the bounded linear operator

$$L_N = -\Delta + e^{U_N} : H^2(\mathbb{R}^2) \to L^2(\mathbb{R}^2).$$

In order to apply the shadowing lemma, we also need the following nondegeneracy property of U_N.

LEMMA 3.2. *The operator L_N is invertible and for every $N > 0$ there exists $C_N > 0$ such that $\|L_N^{-1}\| \le C_N$.*

Proof. It is readily seen that L_N is injective. Indeed, suppose $L_N u = 0$ for some $u \in H^2(\mathbb{R}^2)$. Multiplying by u and integrating on $\mathbb{R}^2$, we have

$$\int |\nabla u|^2 + \int \mathrm{e}^{U_N} u^2 = 0.$$

Therefore, $u = 0$. Now, we claim that L_N is a Fredholm operator. Indeed, we write

$$L_N = (-\Delta + 1)(\mathbb{I} - T)$$

with $T = (-\Delta + 1)^{-1}(1 - \mathrm{e}^{U_N}) : H^2(\mathbb{R}^2) \to H^2(\mathbb{R}^2)$. Clearly, T is continuous. Let us check that T is compact. To this end, let $u_n \in H^2(\mathbb{R}^2)$, $\|u_n\|_{H^2} = 1$. We have to show that $T u_n$ has a convergent subsequence. Note that by the Sobolev embedding

$$\|u\|_{L^\infty(\mathbb{R}^2)} \le C_S \|u\|_{H^2(\mathbb{R}^2)}, \tag{3.1}$$

for all $u \in H^2(\mathbb{R}^2)$, we have $\|u_n\|_\infty \le C'$, for some $C' > 0$ independent of n, and there exists u_∞, $\|u_\infty\|_{H^2} \le 1$, such that $u_{n_k} \to u_\infty$ strongly in L^2_{loc} for a subsequence u_{n_k}. Now, by Lemma 3.1, for any fixed $\varepsilon > 0$, there exists $R > 0$ such that $\|1 - \mathrm{e}^{U_N}\|_{L^2(\mathbb{R}^2 \setminus B_R)} \le \varepsilon$. Consequently, $\|(1 - \mathrm{e}^{U_N})(u_{n_k} - u_\infty)\|_{L^2(\mathbb{R}^2 \setminus B_R)} \le 2C'\varepsilon$. On the other hand, $\|(1 - \mathrm{e}^{U_N})(u_{n_k} - u_\infty)\|_{L^2(B_R)} \to 0$. We conclude that $(1 - \mathrm{e}^{U_N})(u_{n_k} - u_\infty) \to 0$ in L^2. In turn, we have $T(u_{n_k} - u_\infty) = (-\Delta + 1)^{-1}(1 - \mathrm{e}^{U_N})(u_{n_k} - u_\infty) \to 0$ in H^2, which implies that T is compact. It follows that L_N is a Fredholm operator. Consequently, L_N is also surjective. At this point, the open mapping theorem concludes the proof. □

4. A partition of unity. In this section, we introduce a partition of unity and we prove some technical results which will be needed in the following. Let $p_j \in \mathbb{R}^2$ ($j \in \mathcal{P} \subseteq \mathbb{N}$) be the vortex points. By assumption (1.7), $r_0 = d/8 = \inf_{j \ne k} |p_j - p_k|/8 > 0$. We consider the set $K = (-\frac{3}{4}r_0, \frac{3}{4}r_0) \times (-\frac{3}{4}r_0, \frac{3}{4}r_0)$. Then, for any $\underline{n} \in \mathbb{Z}^2$, we introduce $K_{\underline{n}} = K + \underline{n} r_0$. The collection of sets $\{K_{\underline{n}}\}_{\underline{n} \in \mathbb{Z}^2}$ is a locally finite covering of $\mathbb{R}^2$. We consider an associated partition of unity defined as follows: let $0 \le \zeta \in C_c^\infty(K)$ be such that $\sum_{\underline{n} \in \mathbb{Z}^2} \zeta_{\underline{n}} = 1$ pointwise on $\mathbb{R}^2$, where $\zeta_{\underline{n}}(x) = \zeta(x - \underline{n} r_0)$ for all $x \in \mathbb{R}^2$. Then, for any $j \in \mathcal{P}$, we introduce the set

$$\mathcal{P}_j = \left\{ \underline{n} \in \mathbb{Z}^2 \,:\, d(p_j, K_{\underline{n}}) < \frac{r_0}{4} \right\}.$$

Note that the cardinality of $\mathcal{P}_j$ is uniformly bounded, namely, $|\mathcal{P}_j| \le 4$ for any $j \in \mathcal{P}$. We set

$$P_j = \bigcup_{\underline{n} \in \mathcal{P}_j} K_{\underline{n}}, \qquad \varphi_j = \sum_{\underline{n} \in \mathcal{P}_j} \zeta_{\underline{n}}$$

for any $j \in \mathcal{P}$. Since, by choice of r_0, $\mathbb{Z}^2 \setminus \bigcup_{j \in \mathcal{P}} \mathcal{P}_j$ is a countable set (even in the case that $\mathcal{P}$ is countable), there exists a bijection $\mathcal{I} : \mathbb{N} \to \mathbb{Z}^2 \setminus \bigcup_{j \in \mathcal{P}} \mathcal{P}_j$. For convenience of notation, we denote by $\mathcal{Q}$ the countable set of indices defined by

$$\mathcal{Q} = \mathcal{I}^{-1}\Big(\mathbb{Z}^2 \setminus \bigcup_{j \in \mathcal{P}} \mathcal{P}_j \Big).$$

We set

$$Q_k = K_{\mathcal{I}(k)}, \quad \psi_k = \zeta_{\mathcal{I}(k)} \quad \forall k \in \mathcal{Q}.$$

Then, $\{P_j, Q_k\}_{(j,k)\in\mathcal{P}\times\mathcal{Q}}$ is a locally finite open covering of $\mathbb{R}^2$ with the property that $P_j \cap P_{j'} = \emptyset$ for every $j' \neq j$. Moreover, $\{\varphi_j, \psi_k\}_{(j,k)\in\mathcal{P}\times\mathcal{Q}}$ is a partition of unity associated with $\{P_j, Q_k\}_{(j,k)\in\mathcal{P}\times\mathcal{Q}}$ such that

$$\operatorname{supp}\varphi_j \subset P_j, \qquad \operatorname{supp}\psi_k \subset Q_k$$

and such that

$$\sup_{j\in\mathcal{P}}\{\|\nabla\varphi_j\|_\infty,\ \|D^2\varphi_j\|_\infty\} < +\infty, \qquad \sup_{k\in\mathcal{Q}}\{\|\nabla\psi_k\|_\infty,\ \|D^2\psi_k\|_\infty\} < +\infty.$$

In particular,

$$0 \le \varphi_j, \psi_k \le 1 \qquad \text{and} \qquad \sum_{j\in\mathcal{P}}\varphi_j + \sum_{k\in\mathcal{Q}}\psi_k = \sum_{\underline{n}\in\mathbb{Z}^2}\zeta_{\underline{n}} = 1.$$

We define a rescaled covering

$$\hat{P}_j = P_j/\delta, \qquad \hat{Q}_k = Q_k/\delta.$$

Then, $\{\hat\varphi_j, \hat\psi_k\}_{(j,k)\in\mathcal{P}\times\mathcal{Q}}$ defined by

$$\hat\varphi_j(x) = \varphi_j(\delta x), \qquad \hat\psi_k(x) = \psi_k(\delta x)$$

is a partition of unity associated with $\{\hat{P}_j, \hat{Q}_k\}_{(j,k)\in\mathcal{P}\times\mathcal{Q}}$. It will also be convenient to define the sets

$$\hat{C}_j = \{x \in \hat{P}_j \,:\, \hat\varphi_j(x) = 1\}, \qquad j \in \mathcal{P}.$$

Note that

$$\operatorname{supp}\{\nabla\hat\varphi_j, D^2\hat\varphi_j\} \subset \hat{P}_j \setminus \hat{C}_j$$

and

$$\sup_{(j,k)\in\mathcal{P}\times\mathcal{Q}}\{\|\nabla\hat\varphi_j\|_\infty + \|\nabla\hat\psi_k\|_\infty\} \le C\delta, \qquad \sup_{(j,k)\in\mathcal{P}\times\mathcal{Q}}\{\|D^2\hat\varphi_j\|_\infty + \|D^2\hat\psi_k\|_\infty\} \le C\delta^2. \tag{4.1}$$

For every fixed $x \in \mathbb{R}^2$, we define the following subsets of indices:

$$J(x) = \{j \in \mathcal{P} \,:\, \hat\varphi_j(x) \neq 0\}, \qquad K(x) = \{k \in \mathcal{Q} \,:\, \hat\psi_k(x) \neq 0\}.$$

Note that, for every $x \in \mathbb{R}^2$,

$$|J(x)| \le 1, \qquad |K(x)| \le 4, \tag{4.2}$$

where $|J(x)|$ and $|K(x)|$ denote the cardinality of $J(x)$ and $K(x)$, respectively. We shall use the following Banach spaces:

$$\hat{X}_\delta = \left\{u \in H^2_{\mathrm{loc}}(\mathbb{R}^2) \,:\, \sup_{(j,k)\in\mathcal{P}\times\mathcal{Q}}\left\{\|\hat\varphi_j u\|_{H^2(\mathbb{R}^2)}, \|\hat\psi_k u\|_{H^2(\mathbb{R}^2)}\right\} < +\infty\right\},$$

$$\hat{Y}_\delta = \left\{f \in L^2_{\mathrm{loc}}(\mathbb{R}^2) \,:\, \sup_{(j,k)\in\mathcal{P}\times\mathcal{Q}}\left\{\|\hat\varphi_j f\|_{L^2(\mathbb{R}^2)}, \|\hat\psi_k f\|_{L^2(\mathbb{R}^2)}\right\} < +\infty\right\}.$$

We collect in the following lemma some estimates that will be used in what follows.

LEMMA 4.1. *There exists a constant $C>0$ such that for any $u\in\hat X_\delta$ and $j\in\mathcal{P}$, we have*

(i) $\|u\|_{H^2(\hat P_j)}\le C\|u\|_{\hat X_\delta}$,

(ii) $\|u\|_{L^\infty(\mathbb{R}^2)}\le C\|u\|_{\hat X_\delta}$.

Proof. (i) For every fixed $j\in\mathcal{P}$, let $\mathcal{J}(j)=\{k\in\mathcal{Q}\,:\,\operatorname{supp}\hat\varphi_j\cap\operatorname{supp}\hat\psi_k\neq\emptyset\}$. Then, $\sup_{j\in\mathcal{P}}|\mathcal{J}(j)|<+\infty$, and we estimate

$$\begin{aligned}\|u\|_{H^2(\hat P_j)}=&\Big\|\hat\varphi_j u+\sum_{k\in\mathcal{J}(j)}\hat\psi_k u\Big\|_{H^2(\hat P_j)}\le\|\hat\varphi_j u\|_{H^2(\hat P_j)}+\sum_{k\in\mathcal{J}(j)}\|\hat\psi_k u\|_{H^2(\hat P_j)}\\ &\le(1+|\mathcal{J}(j)|)\,\|u\|_{\hat X_\delta}\le C\|u\|_{\hat X_\delta}.\end{aligned}$$

(ii) For any fixed $x\in\mathbb{R}^2$, we have in view of (3.1) and (4.2)

$$\begin{aligned}|u(x)|&=\sum_{j\in\mathcal{P}}\hat\varphi_j(x)|u(x)|+\sum_{k\in\mathcal{Q}}\hat\psi_k(x)|u(x)|\\ &=\sum_{j\in J(x)}\hat\varphi_j(x)|u(x)|+\sum_{k\in K(x)}\hat\psi_k(x)|u(x)|\\ &\le\sum_{j\in J(x)}C_S\|\hat\varphi_j u\|_{H^2(\mathbb{R}^2)}+\sum_{k\in K(x)}C_S\|\hat\psi_k u\|_{H^2(\mathbb{R}^2)}\\ &\le\sup_{x\in\mathbb{R}^2}(|J(x)|+|K(x)|)C_S\|u\|_{\hat X_\delta}=C\|u\|_{\hat X_\delta}.\end{aligned}$$

Hence, (ii) is established. ∎

We shall also need the following family of functions:

$$\hat g_j(x)=\frac{\hat\varphi_j(x)}{\Big(\sum_{k\in\mathcal{P}}\hat\varphi_k^2+\sum_{k\in\mathcal{Q}}\hat\psi_k^2\Big)^{1/2}},\qquad \hat h_k(x)=\frac{\hat\psi_k(x)}{\Big(\sum_{j\in\mathcal{P}}\hat\varphi_j^2+\sum_{j\in\mathcal{Q}}\hat\psi_j^2\Big)^{1/2}}.$$

In view of (4.1), it is readily checked that the following lemma follows.

LEMMA 4.2. *The family $\{\hat g_j,\hat h_k\}_{(j,k)\in\mathcal{P}\times\mathcal{Q}}$ satisfies $\operatorname{supp}\hat g_j\subset\hat P_j$, $\operatorname{supp}\hat h_k\subset\hat Q_k$ and furthermore,*

(i) $\sum_{j\in\mathcal{P}}\hat g_j^2(x)+\sum_{k\in\mathcal{Q}}\hat h_k^2(x)=1\ \forall x\in\mathbb{R}^2$;

(ii) $C^{-1}\hat\varphi_j(x)\le\hat g_j(x)\le C\hat\varphi_j(x)$ *and* $C^{-1}\hat\psi_k(x)\le\hat h_k(x)\le C\hat\psi_k(x)\ \forall x\in\mathbb{R}^2$;

(iii) $\sup_{(j,k)\in\mathcal{P}\times\mathcal{Q}}\{\|\nabla\hat g_j\|_\infty+\|\nabla\hat h_k\|_\infty\}\le C\delta$ *and* $\sup_{(j,k)\in\mathcal{P}\times\mathcal{Q}}\{\|D^2\hat g_j\|_\infty+\|D^2\hat h_k\|_\infty\}\le C\delta^2$.

5. The shadowing lemma. Recall from the introduction that $\hat p_j=p_j/\delta$, $j\in\mathcal{P}$. For every $j\in\mathcal{P}$ we define

$$\hat U_j(x)=U_{m_j}(x-\hat p_j).$$

We make the following ansatz for solutions $\hat u$ to (2.4):

$$\hat u=\sum_{j\in\mathcal{P}}\hat\varphi_j\hat U_j+z. \tag{5.1}$$

Our aim in this section is to prove the following.

Proposition 5.1. *There exists $\delta_1>0$ such that for all $\delta\in(0,\delta_1)$ there exists $z_\delta\in\hat X_\delta$ such that $\hat u_\delta$ defined by $\hat u_\delta=\sum_{j\in\mathcal P}\hat\varphi_j\hat U_j+z_\delta$ is a solution of* (2.4). *Moreover, $\|z_\delta\|_{\hat X_\delta}\le C\mathrm{e}^{-c/\delta}$.*

We note that the functional $F_\delta:\hat X_\delta\to\hat Y_\delta$ given by

$$F_\delta(z)=-\Delta z+\sum_{j\in\mathcal P}\hat\varphi_j(1-\mathrm{e}^{\hat U_j})-(1-\mathrm{e}^{\sum_{j\in\mathcal P}\hat\varphi_j\hat U_j+z})-\sum_{j\in\mathcal P}[\hat\varphi_j,\Delta]\hat U_j$$

is well defined as well as C^1. Here $[\Delta,\hat\varphi_j]=\Delta\hat\varphi_j+2\nabla\hat\varphi_j\nabla$. Moreover, if $z\in\hat X_\delta$ satisfies $F_\delta(z)=0$, then $\hat u$ defined by (5.1) is a solution of (2.4).

Lemma 5.1. *For $\delta>0$ sufficiently small, we have*

$$\|F_\delta(0)\|_{\hat Y_\delta}\le C\mathrm{e}^{-c/\delta}\qquad \textit{as } \delta\to0^+ \tag{5.2}$$

for some constants $C,c>0$ independent of δ.

Proof. Let

$$\begin{aligned}\mathcal R&=\sum_{j\in\mathcal P}\hat\varphi_j(1-\mathrm{e}^{\hat U_j})-(1-\mathrm{e}^{\sum_{j\in\mathcal P}\hat\varphi_j\hat U_j}),\\ \mathcal C&=\sum_{j\in\mathcal P}[\hat\varphi_j,\Delta]\hat U_j.\end{aligned}$$

Note that $\{\operatorname{supp}\mathcal R,\operatorname{supp}\mathcal C\}\subset\cup_{j\in\mathcal P}\hat P_j\setminus\hat C_j$. We fix $x\in\cup_{j\in\mathcal P}\hat P_j$. We estimate

$$\begin{aligned}|\mathcal R(x)|\le&\sup_{j\in\mathcal P}\|\hat\varphi_j(1-\mathrm{e}^{\hat U_j})\|_{L^\infty(\hat P_j\setminus\hat C_j)}+\sup_{j\in\mathcal P}\|1-\mathrm{e}^{\hat\varphi_j\hat U_j}\|_{L^\infty(\hat P_j\setminus\hat C_j)}\\ \le& C\sup_{j\in\mathcal P}\|\hat U_j\|_{L^\infty(\hat P_j\setminus\hat C_j)}\le C_1\mathrm{e}^{-c_1/\delta}.\end{aligned}$$

On the other hand, in view of (4.1) and Lemma 3.1, for $x\in\cup_{j\in\mathcal P}\hat P_j$, we have

$$\begin{aligned}|\mathcal C(x)|\le&\sup_{j\in\mathcal P}\|\,[\Delta,\hat\varphi_j]\hat U_j\|_{L^\infty(\hat P_j\setminus\hat C_j)}\\ \le& C\left(\sup_{j\in\mathcal P}\|\hat U_j\,\Delta\hat\varphi_j\|_{L^\infty(\hat P_j\setminus\hat C_j)}+\sup_{j\in\mathcal P}\|\,|\nabla\hat U_j|\,|\nabla\hat\varphi_j|\,\|_{L^\infty(\hat P_j\setminus\hat C_j)}\right)\le C_2\mathrm{e}^{-c_2/\delta}.\end{aligned}$$

Here and above, $c_1,C_1,c_2,C_2>0$ are positive constants independent of $\delta>0$. Hence, we conclude that, as $\delta\to0^+$,

$$\|F_\delta(0)\|_{\hat Y_\delta}\le C\sup_{j\in\mathcal P}\left(\|\mathcal R\|_{L^2(\hat P_j)}+\|\mathcal C\|_{L^2(\hat P_j)}\right)\le C\mathrm{e}^{-c/\delta}$$

for some constants $C,c>0$ independent of $\delta>0$. ∎

Now, we consider the operator $L_\delta\equiv DF_\delta(0):\hat X_\delta\to\hat Y_\delta$ given by

$$L_\delta=-\Delta+\mathrm{e}^{\sum_{j\in\mathcal P}\hat\varphi_j\hat U_j}.$$

For every $j\in\mathcal P$, we define the operators

$$\hat L_j=-\Delta+\mathrm{e}^{\hat U_j}.$$

It will also be convenient to define

$$\hat{L}_0 = -\Delta + 1.$$

The following lemma holds.

Lemma 5.2. *There exist $C, c > 0$ such that for any $u \in \hat{X}_\delta$, we have*

$$\|(L_\delta - \hat{L}_j)\hat{\varphi}_j u\|_{L^2} \le C\mathrm{e}^{-c/\delta}\|\hat{\varphi}_j u\|_{L^2}, \qquad j \in \mathcal{P},$$
$$\|(L_\delta - \hat{L}_0)\hat{\psi}_k u\|_{L^2} \le C\mathrm{e}^{-c/\delta}\|\hat{\psi}_k u\|_{L^2}, \qquad k \in \mathcal{Q}.$$

Proof. For any $j \in \mathcal{P}$, by Lemma 3.1, we have, as $\delta \to 0^+$,

$$\begin{aligned}\|(L_\delta - \hat{L}_j)\hat{\varphi}_j u\|_{L^2} &\le \Big(\|1 - \mathrm{e}^{\hat{U}_j}\|_{L^\infty(\hat{P}_j \setminus \hat{C}_j)} + \|1 - \mathrm{e}^{\hat{\varphi}_j \hat{U}_j}\|_{L^\infty(\hat{P}_j \setminus \hat{C}_j)}\Big)\|\hat{\varphi}_j u\|_{L^2}\\ &\le C\|1 - \mathrm{e}^{\hat{U}_j}\|_{L^\infty(\hat{P}_j \setminus \hat{C}_j)}\|\hat{\varphi}_j u\|_{L^2} \le C\mathrm{e}^{-c/\delta}\|\hat{\varphi}_j u\|_{L^2}.\end{aligned}$$

Similarly, as $\delta \to 0^+$,

$$\begin{aligned}\|(L_\delta - \hat{L}_0)\hat{\psi}_k u\|_{L^2} \le& \|(1 - \mathrm{e}^{\sum_{j\in\mathcal{P}} \hat{\varphi}_j \hat{U}_j})\hat{\psi}_k u\|_{L^2}\\ &\le \sup_{j\in\mathcal{P}} \|1 - \mathrm{e}^{\hat{\varphi}_j \hat{U}_j}\|_{L^\infty(\hat{P}_j \setminus \hat{C}_j)}\|\hat{\psi}_k u\|_{L^2} \le C\mathrm{e}^{-c/\delta}\|\hat{\psi}_k u\|_{L^2}.\end{aligned}$$ ∎

Now, we prove an essential nondegeneracy property of L_δ.

Lemma 5.3. *There exists $\delta_0 > 0$ such that for any $\delta \in (0, \delta_0)$, the operator L_δ is invertible. Moreover, $L_\delta^{-1} : \hat{Y}_\delta \to \hat{X}_\delta$ is uniformly bounded with respect to $\delta \in (0, \delta_0)$.*

Proof. Following a gluing technique introduced in [5], we construct an "approximate inverse" $S_\delta : \hat{Y}_\delta \to \hat{X}_\delta$ for L_δ^{-1} as follows:

$$S_\delta = \sum_{j\in\mathcal{P}} \hat{g}_j \hat{L}_j^{-1} \hat{g}_j + \sum_{k\in\mathcal{Q}} \hat{h}_k \hat{L}_0^{-1} \hat{h}_k,$$

where $\hat{g}_j$ and $\hat{h}_k$ are the functions introduced in section 4. We claim that the operator S_δ is well defined and uniformly bounded with respect to δ. That is, we claim that

$$\|S_\delta f\|_{\hat{X}_\delta} \le C\|f\|_{\hat{Y}_\delta} \tag{5.3}$$

for some $C > 0$ independent of $f \in \hat{X}_\delta$ and of $\delta > 0$.

Indeed, for any $f \in \hat{Y}_\delta$, we have

$$\|S_\delta f\|_{\hat{X}_\delta} = \sup_{(j,k)\in\mathcal{P}\times\mathcal{Q}} \{\, \|\hat{\varphi}_j S_\delta f\|_{H^2}, \|\hat{\psi}_k S_\delta f\|_{H^2}\}$$

and

$$\|\hat{\varphi}_j S_\delta f\|_{H^2} \le \|\hat{\varphi}_j \hat{g}_j \hat{L}_j^{-1} \hat{g}_j f\|_{H^2} + \Big\|\hat{\varphi}_j \sum_{k\in\mathcal{Q}} \hat{h}_k \hat{L}_0^{-1} \hat{h}_k f\Big\|_{H^2},$$
$$\|\hat{\psi}_k S_\delta f\|_{H^2} \le \Big\|\hat{\psi}_k \sum_{j\in\mathcal{P}} \hat{g}_j \hat{L}_j^{-1} \hat{g}_j f\Big\|_{H^2} + \Big\|\hat{\psi}_k \sum_{j\in\mathcal{Q}} \hat{h}_j \hat{L}_0^{-1} \hat{h}_j f\Big\|_{H^2}.$$

We estimate, recalling the properties of $\hat{\varphi}_j$ and $\hat{g}_j$ as in Lemma 4.2, and in view of Lemma 3.2

$$\|\hat{\varphi}_j \hat{g}_j \hat{L}_j^{-1} \hat{g}_j f\|_{H^2} \le C\|\hat{L}_j^{-1} \hat{g}_j f\|_{H^2} \le C\|\hat{g}_j f\|_{L^2} \le C\|\hat{\varphi}_j f\|_{L^2} \le C\|f\|_{\hat{Y}_\delta}.$$

We have

$$\left\|\hat{\varphi}_j \sum_{k\in\mathcal{Q}} \hat{h}_k \hat{L}_0^{-1} \hat{h}_k f\right\|_{H^2} \le \left\|\hat{\varphi}_j \sum_{k\in\mathcal{J}(j)} \hat{h}_k \hat{L}_0^{-1} \hat{h}_k f\right\|_{H^2} \le \sum_{k\in\mathcal{J}(j)} \|\hat{\varphi}_j \hat{h}_k \hat{L}_0^{-1} \hat{h}_k f\|_{H^2},$$

where $\mathcal{J}(j) = \{k \in \mathcal{Q} \,:\, \operatorname{supp}\hat{\psi}_k \cap \operatorname{supp}\hat{\varphi}_j \ne \emptyset\}$ satisfies $\sup_{j\in\mathcal{P}} |\mathcal{J}(j)| < +\infty$. In view of Lemmas 4.2 and 3.2, we estimate

$$\begin{aligned}\sum_{k\in\mathcal{J}(j)} \|\hat{\varphi}_j \hat{h}_k \hat{L}_0^{-1} \hat{h}_k f\|_{H^2} &\le C \sum_{k\in\mathcal{J}(j)} \|\hat{L}_0^{-1} \hat{h}_k f\|_{H^2} \le C \sum_{k\in\mathcal{J}(j)} \|\hat{h}_k f\|_{L^2} \\ &\le C \sum_{k\in\mathcal{J}(j)} \|\hat{\psi}_k f\|_{L^2} \le C|\mathcal{J}(j)| \sup_{k\in\mathcal{Q}} \|\hat{\psi}_k f\|_{L^2} \le C\|f\|_{\hat{Y}_\delta}.\end{aligned}$$

Therefore,

$$\sup_{j\in\mathcal{P}} \left\|\hat{\varphi}_j \sum_{k\in\mathcal{Q}} \hat{h}_k \hat{L}_0^{-1} \hat{h}_k f\right\|_{H^2} \le C\|f\|_{\hat{Y}_\delta}.$$

Similarly, we obtain that

$$\sup_{k\in\mathcal{Q}} \left\|\hat{\psi}_k \sum_{j\in\mathcal{P}} \hat{g}_j \hat{L}_j^{-1} \hat{g}_j f\right\|_{H^2} \le C\|f\|_{\hat{Y}_\delta}, \qquad \sup_{k\in\mathcal{Q}} \left\|\hat{\psi}_k \sum_{j\in\mathcal{Q}} \hat{h}_j \hat{L}_0^{-1} \hat{h}_j f\right\|_{H^2} \le C\|f\|_{\hat{Y}_\delta},$$

and (5.3) follows.

Now, we claim that there exists δ_0 such that for any $\delta \in (0, \delta_0)$, the operator $S_\delta L_\delta : \hat{X}_\delta \to \hat{X}_\delta$ is invertible, and furthermore, $\|S_\delta L_\delta\| \le C$ for some $C > 0$ independent of $\delta > 0$. We note that $(L_\delta - \hat{L}_j)\hat{g}_j : \hat{X}_\delta \to \hat{Y}_\delta$ and $(L_\delta - \hat{L}_0)\hat{h}_k : \hat{X}_\delta \to \hat{Y}_\delta$ are well-defined bounded linear operators. Thus, we decompose

$$\begin{aligned} S_\delta L_\delta =& \mathbb{I}_{\hat{X}_\delta} + \sum_{j\in\mathcal{P}} \hat{g}_j \hat{L}_j^{-1}(\hat{g}_j L_\delta - \hat{L}_j \hat{g}_j) + \sum_{k\in\mathcal{Q}} \hat{h}_k \hat{L}_0^{-1}(\hat{h}_k L_\delta - \hat{L}_0 \hat{h}_k) \\ =& \mathbb{I}_{\hat{X}_\delta} + \sum_{j\in\mathcal{P}} \hat{g}_j \hat{L}_j^{-1}(L_\delta - \hat{L}_j)\hat{g}_j + \sum_{k\in\mathcal{Q}} \hat{h}_k \hat{L}_0^{-1}(L_\delta - \hat{L}_0)\hat{h}_k \\ &+ \sum_{j\in\mathcal{P}} \hat{g}_j \hat{L}_j^{-1}[\Delta, \hat{g}_j] + \sum_{k\in\mathcal{Q}} \hat{h}_k \hat{L}_0^{-1}[\Delta, \hat{h}_k]. \end{aligned} \tag{5.4}$$

Hence, it suffices to prove that the last four terms in (5.4) are sufficiently small, in the operator norm, provided $\delta > 0$ is sufficiently small. By Lemmas 5.2 and 4.2, we have, for any $u \in \hat{X}_\delta$,

$$\begin{aligned}\left\|\sum_{j\in\mathcal{P}} \hat{g}_j \hat{L}_j^{-1}(L_\delta - \hat{L}_j)\hat{g}_j u\right\|_{\hat{X}_\delta} &\le C \sup_{j\in\mathcal{P}} \|\hat{L}_j^{-1}(L_\delta - \hat{L}_j)\hat{g}_j u\|_{H^2} \\ &\le C \sup_{j\in\mathcal{P}} \|(L_\delta - \hat{L}_j)\hat{g}_j u\|_{L^2} \\ &\le C\mathrm{e}^{-c/\delta} \sup_{j\in\mathcal{P}} \|\hat{\varphi}_j u\|_{L^2} \le C\mathrm{e}^{-c/\delta}\|u\|_{\hat{X}_\delta}.\end{aligned}$$

Similarly, for $u \in \hat{X}_\delta$, we have

$$\Big\| \sum_{j\in\mathcal{P}} \hat{g}_j \hat{L}_j^{-1}[\Delta, \hat{g}_j]u \Big\|_{\hat{X}_\delta} \le C \sup_{j\in\mathcal{P}} \|\hat{L}_j^{-1}[\Delta, \hat{g}_j]u\|_{H^2} \le C \sup_{j\in\mathcal{P}} \|[\Delta, \hat{g}_j]u\|_{L^2}.$$

Recalling that $[\Delta, \hat{g}_j]u = 2\nabla u \nabla \hat{g}_j + u\Delta \hat{g}_j$, by Lemmas 4.2 and 4.1(i) we derive that

$$\|[\Delta, \hat{g}_j]u\|_{L^2} \le C\delta \|u\|_{H^1(\hat{P}_j)} \le C\delta \|u\|_{\hat{X}_\delta}.$$

The remaining terms are estimated similarly. Hence, $\|S_\delta L_\delta - \mathbb{I}_{\hat{X}_\delta}\| \to 0$ as $\delta \to 0^+$. Now, we observe that $L_\delta^{-1} = (S_\delta L_\delta)^{-1} S_\delta$. It follows that for any $f \in \hat{Y}_\delta$, we have

$$\|L_\delta^{-1} f\|_{\hat{X}_\delta} = \|(S_\delta L_\delta)^{-1} S_\delta f\|_{\hat{X}_\delta} \le C\|S_\delta f\|_{\hat{Y}_\delta} \le C\|f\|_{\hat{Y}_\delta}$$

with $C > 0$ independent of δ. Hence, L_δ is invertible and its inverse is bounded independently of δ, as asserted. □

Now we can provide the following proof.

Proof of Proposition 5.1. We use the Banach fixed point argument. For any $\delta \in (0, \delta_0)$, with $\delta_0 > 0$ given by Lemma 5.3, we introduce the nonlinear map $G_\delta \in C^1(\hat{X}_\delta, \hat{X}_\delta)$ defined by

$$G_\delta(z) = z - L_\delta^{-1} F_\delta(z).$$

Then, fixed points of G_δ correspond to solutions of the functional equation $F_\delta(z) = 0$. First, note that $DG_\delta(0) = 0$ and that

$$DF(z) = -\Delta + \mathrm{e}^{\sum_{j\in\mathcal{P}} \hat{\varphi}_j \hat{U}_j + z}.$$

By Lemma 5.3, for any $z \in \hat{X}_\delta$ and $u \in \hat{X}_\delta$, we have

$$\begin{aligned}\|DG_\delta(z)u\|_{\hat{X}_\delta} &= \|(DG_\delta(z) - DG_\delta(0))u\|_{\hat{X}_\delta} = \|L_\delta^{-1}(DF_\delta(z) - L_\delta)u\|_{\hat{X}_\delta} \\ &\le C\|(DF_\delta(z) - L_\delta)u\|_{\hat{Y}_\delta} = C\|\mathrm{e}^{\sum_{j\in\mathcal{P}} \hat{\varphi}_j \hat{U}_j}(\mathrm{e}^z - 1)u\|_{\hat{Y}_\delta} \le C\|(\mathrm{e}^z - 1)u\|_{\hat{Y}_\delta}.\end{aligned}$$

By the elementary inequality $\mathrm{e}^t - 1 \le Ct\mathrm{e}^t$, for all $t > 0$, where $C > 0$ does not depend on t, and in view of Lemma 4.1, we have

$$\|\mathrm{e}^z - 1\|_\infty \le \mathrm{e}^{\|z\|_\infty} - 1 \le C\|z\|_\infty \mathrm{e}^{\|z\|_\infty} \le C\|z\|_{\hat{X}_\delta} \mathrm{e}^{\|z\|_{\hat{X}_\delta}}.$$

Hence,

$$\|DG_\delta(z)u\|_{\hat{X}_\delta} \le C\|(\mathrm{e}^z - 1)u\|_{\hat{Y}_\delta} \le C\|z\|_{\hat{X}_\delta} \mathrm{e}^{\|z\|_{\hat{X}_\delta}} \|u\|_{\hat{Y}_\delta} \le C\|z\|_{\hat{X}_\delta} \mathrm{e}^{\|z\|_{\hat{X}_\delta}} \|u\|_{\hat{X}_\delta}.$$

Consequently, there exists $R_0 > 0$ such that for every $R \in (0, R_0)$, we have

$$\|DG_\delta(z)\| < \frac{1}{2} \qquad \forall z \in \mathcal{B}_R$$

for all $\delta > 0$, where

$$\mathcal{B}_R = \{u \in \hat{X}_\delta \,:\, \|u\|_{\hat{X}_\delta} < R\}.$$

Now, for every $R \in (0, R_0)$,

$$\begin{aligned}\|G_\delta(z)\|_{\hat{X}_\delta} &\le \|G_\delta(z) - G_\delta(0)\|_{\hat{X}_\delta} + \|G_\delta(0)\|_{\hat{X}_\delta} \\ &\le \frac{1}{2}\|z\|_{\hat{X}_\delta} + \|L_\delta^{-1}F_\delta(0)\|_{\hat{X}_\delta}.\end{aligned}$$

By Lemmas 5.3 and 5.1, there exist $C_0, c_0 > 0$ independent of $\delta > 0$ such that

$$\|L_\delta^{-1}F_\delta(0)\|_{\hat{X}_\delta} \le C\|F_\delta(0)\|_{\hat{Y}_\delta} \le C_0 \mathrm{e}^{-c_0/\delta}.$$

Choosing $R = R_\delta = 2C_0\mathrm{e}^{-c_0/\delta}$, we obtain that $G_\delta(B_{R_\delta}) \subset B_{R_\delta}$. Hence, G_δ is a strict contraction in B_{R_δ}, for any $\delta \in (0, \delta_1)$, with $\delta_1 = c_0/(\ln(2C_0/R_0))$. By the Banach fixed-point theorem, for any $\delta \in (0, \delta_1)$, there exists a unique $z_\delta \in B_{R_\delta}$ such that $F_\delta(z_\delta) = 0$. ◻

6. Proof of the main results. In this section, we finally provide the proof of Theorem 2.1 and derive Corollary 2.1. In view of Proposition 5.1, the function $\hat{u}_\delta$ defined by

$$\hat{u}_\delta = \sum_{j\in\mathcal{P}} \hat{\varphi}_j \hat{U}_j + z_\delta$$

is a solution of (2.4). Consequently, u_δ defined by

$$u_\delta(x) = \hat{u}_\delta\left(\frac{x}{\delta}\right) = \sum_{j\in\mathcal{P}} \varphi_j(x) U_{m_j}\left(\frac{x-p_j}{\delta}\right) + z_\delta\left(\frac{x}{\delta}\right) \tag{6.1}$$

is a solution of (1.6).

Lemma 6.1. *The solution u_δ defined in* (6.1) *satisfies the approximate superposition rule*

$$u_\delta(x) = \sum_{j\in\mathcal{P}} U_{m_j}\left(\frac{x-p_j}{\delta}\right) + \omega_\delta(x)$$

with $\|\omega_\delta\|_\infty \le C\mathrm{e}^{-c/\delta}$.

Proof. In view of (6.1) and of the definition of $J(x)$ in section 4, we have

$$u_\delta(x) = \sum_{j\in J(x)} U_{m_j}\left(\frac{x-p_j}{\delta}\right) + \tilde{\omega}_\delta(x),$$

where

$$\tilde{\omega}_\delta(x) = -\sum_{j\in J(x)} (1-\varphi_j(x)) U_{m_j}\left(\frac{x-p_j}{\delta}\right) + z_\delta\left(\frac{x}{\delta}\right).$$

In view of Lemma 3.1, we estimate

$$\left\| \sum_{j\in J(x)} (1-\varphi_j(x)) U_{m_j}\left(\frac{x-p_j}{\delta}\right)\right\|_\infty \le \sum_{j\in J(x)} \sup_{\mathbb{R}^2\setminus C_j} \left| U_{m_j}\left(\frac{x-p_j}{\delta}\right)\right| \le C\mathrm{e}^{-c/\delta}.$$

On the other hand, by Proposition 5.1 and Lemma 4.1(ii), we have

$$\left\| z_\delta\left(\frac{\cdot}{\delta}\right)\right\|_\infty = \|z_\delta\|_\infty \le C\mathrm{e}^{-c/\delta}.$$

Therefore, $\|\tilde\omega_\delta\|_\infty \le C\mathrm{e}^{-c/\delta}$. We have to show that

$$\left\| \sum_{j\in\mathcal{P}\setminus J(x)} U_{m_j}\left(\frac{x-p_j}{\delta}\right)\right\|_\infty \le C\mathrm{e}^{-c/\delta}.$$

To this end, we fix $x\in\mathbb{R}^2$ and for every $M\in\mathbb{N}$ we define $B_M=\{y\in\mathbb{R}^2\,:\,|y-x|<dM\}$. Then,

$$\sum_{j\in\mathcal{P}\setminus J(x)} U_{m_j}\left(\frac{x-p_j}{\delta}\right) = \sum_{M\in\mathbb{N}}\sum_{p_j\in B_{M+1}\setminus B_M} U_{m_j}\left(\frac{x-p_j}{\delta}\right).$$

Since $\inf_{j\neq k}|p_j-p_k|=d>0$, there exists $C>0$ independent of $M\in\mathbb{N}$ and of $x\in\mathbb{R}^2$ such that

$$|\{p_j\in B_{M+1}\setminus B_M\}|\le CM.$$

Hence, we estimate

$$\left| \sum_{j\in\mathcal{P}\setminus J(x)} U_{m_j}\left(\frac{x-p_j}{\delta}\right)\right| \le C\sum_{M\in\mathbb{N}} M\mathrm{e}^{-cM/\delta} \le C\mathrm{e}^{-c/\delta}.$$

This implies the statement of the lemma. □

We are left to analyze the asymptotic behavior of u_δ as $\delta\to 0^+$. Such behavior is a direct consequence of (6.1).

Lemma 6.2. *Let u_δ be given by (6.1). The following properties hold:*

(i) $\mathrm{e}^{u_\delta}<1$ *on $\mathbb{R}^2$ and vanishes exactly at p_j with multiplicity $2m_j$, $j\in\mathcal{P}$;*

(ii) *for every compact subset K of $\mathbb{R}^2\setminus\cup_{j\in\mathcal{P}}\{p_j\}$, there exist $C,c>0$ such that $1-\mathrm{e}^{u_\delta}\le C\mathrm{e}^{-c/\delta}$ as $\delta\to 0^+$;*

(iii) $\delta^{-2}(1-\mathrm{e}^{u_\delta})\to 4\pi\sum_{j\in\mathcal{P}} m_j\delta_{p_j}$ *in the sense of distributions as $\delta\to 0^+$.*

Proof. (i) Since u_δ is a solution of (1.6), $\mathrm{e}^{u_\delta}<1$ follows by the maximum principle. Moreover, since

$$U_{m_j}\left(\frac{x-p_j}{\delta}\right) = \ln|x-p_j|^{2m_j}+v_j \tag{6.2}$$

with v_j a continuous function (see [12]), we have near p_j that $\mathrm{e}^{u_\delta}=|x-p_j|^{2m_j}f_{j,\delta}(x)$ with $f_{j,\delta}(x)$ a continuous strictly positive function. Hence, (i) is established.

(ii) Let K be a compact subset of $\mathbb{R}^2\setminus\cup_{j\in\mathcal{P}}\{p_j\}$. In view of Lemma 3.1 and Proposition 5.1, we have as $\delta\to 0^+$

$$\begin{aligned}\sup_{x\in K\cap P_j} 1-\mathrm{e}^{\varphi_j(x)U_{m_j}((x-p_j)/\delta)} &\le C\mathrm{e}^{-c/\delta}\left\|z_\delta\left(\frac{\cdot}{\delta}\right)\right\|_\infty\\ &\le C\|z_\delta\|_{\hat X_\delta}\le CR_\delta\le C\mathrm{e}^{-c/\delta}.\end{aligned}$$

Therefore, we have that for any compact set $K \subset \mathbb{R}^2 \setminus \cup_{j\in\mathcal{P}}\{p_j\}$,

$$0 \le \sup_{x\in K}(1-\mathrm{e}^{u_\delta}) \le C\sup_{j\in\mathcal{P}}\sup_{x\in K\cap P_j}(1-\mathrm{e}^{u_\delta}) \le C\mathrm{e}^{-c/\delta}.$$

(iii) Let $\varphi \in C_c^\infty(\mathbb{R}^2)$. Then,

$$-\int_{\mathbb{R}^2} u_\delta\Delta\varphi = \delta^{-2}\int_{\mathbb{R}^2}(1-\mathrm{e}^u)\varphi - 4\pi\sum_{j\in\mathcal{P}} m_j\varphi(p_j).$$

We claim that

$$\int_{\mathbb{R}^2} u_\delta\Delta\varphi \to 0 \qquad \text{as } \delta\to 0. \tag{6.3}$$

Indeed, let $j_k \in \mathcal{P}$, $k=1,\dots,n$, be such that $\operatorname{supp}\varphi \subset \cup_{k=1}^n P_{j_k}\cup K$ with K a compact subset of $\mathbb{R}^2\setminus\cup_{j\in\mathcal{P}}\{p_j\}$. Since $\sup_K|u_\delta| \le C\mathrm{e}^{-c/\delta}$, we have

$$\left|\int_K u_\delta\Delta\varphi\right| \le C\|\Delta\varphi\|_\infty \mathrm{e}^{-c/\delta} \to 0.$$

On the other hand, in view of Lemma 6.1, in P_{j_k} we have $u_\delta(x) = U_{m_{j_k}}(|x-p_{j_k}|/\delta) + O(\mathrm{e}^{-c/\delta})$. Note that $U_{m_{j_k}} \in L^1(\mathbb{R}^2)$ in view of (6.2) and Lemma 3.1. Therefore,

$$\begin{aligned}\sup_{1\le k\le n}\left|\int_{P_{j_k}} u_\delta\Delta\varphi\right| &\le \sup_{1\le k\le n}\left|\int_{P_{j_k}} U_{m_{j_k}}\left(\frac{x-p_{j_k}}{\delta}\right)\Delta\varphi\right| + O(\mathrm{e}^{-c/\delta})\\ &\le \delta^2\sup_{1\le k\le n}\|\Delta\varphi\|_\infty\|U_{m_{j_k}}\|_{L^1} + O(\mathrm{e}^{-c/\delta}) \le C\delta^2 \to 0.\end{aligned}$$

Hence, (6.3) follows, and (iii) is established. ∎

Proof of Theorem 2.1. For every $\delta\in(0,\delta_1)$, where δ_1 is given in Proposition 5.1, we obtain a solution u_δ of (1.6). Furthermore, u_δ satisfies (2.2) in view of Lemma 6.1. Finally, u_δ satisfies the asymptotic behavior as in (i)–(iii) in view of Lemma 6.2. Hence, Theorem 2.1 is completely established. ∎

Proof of Corollary 2.1. To begin, we want to prove that if p_j's are doubly periodically arranged in $\mathbb{R}^2$, then u_δ is in fact a doubly periodic solution of (1.5). Recall that the p_j's are doubly periodically arranged in $\mathbb{R}^2$ if (2.3) holds. We define $\hat{\underline{e}}_k = \underline{e}_k/\delta$, $k=1,2$. Equivalently, we show $\hat{u}_\delta(x+\hat{\underline{e}}_k) = \hat{u}_\delta(x)$ for any $x\in\mathbb{R}^2$ and for $k=1,2$. Indeed, we may assume that $\hat{\varphi}_j(x+\hat{\underline{e}}_k) = \hat{\varphi}_j(x)$, $\hat{\psi}_j(x+\hat{\underline{e}}_k) = \hat{\psi}_j(x)$ for any $j\in\mathbb{N}$, $x\in\mathbb{R}^2$, $k=1,2$. Then,

$$\hat{u}_\delta(x+\hat{\underline{e}}_k) = \sum_{j\in\mathbb{N}}\hat{\varphi}_j(x)\hat{U}_j(x) + z_\delta(x+\hat{\underline{e}}_k).$$

Hence, it is sufficient to prove that $z_\delta(x+\hat{\underline{e}}_k) = z_\delta(x)$ for every $x\in\mathbb{R}^2$ and for $k=1,2$. First, we claim that $z_\delta(\,\cdot\,+\hat{\underline{e}}_k) \in \mathcal{B}_{R_\delta}$. Indeed, for every $j\in\mathbb{N}$ there exists exactly one $j'\in\mathbb{N}$ such that

$$\|\hat{\varphi}_j z_\delta(\,\cdot\,+\hat{\underline{e}}_k)\|_{H^2} = \|\hat{\varphi}_{j'}z_\delta\|_{H^2}. \tag{6.4}$$

Hence, we obtain

$$\|z_\delta(\,\cdot\,+\hat{\underline{e}}_k)\|_{\hat{X}_\delta} = \|z_\delta\|_{\hat{X}_\delta} \le R_\delta. \tag{6.5}$$

Moreover, if $F_\delta(z_\delta) = 0$ we also have $F_\delta(z_\delta(\,\cdot\, + \hat{\underline{e}}_k)) = 0$. Therefore, $z_\delta(\,\cdot\, + \hat{\underline{e}}_k)$ is a fixed point of G_δ in $\mathcal{B}_{R_\delta}$. By uniqueness, we conclude that $z_\delta(\,\cdot\, + \hat{\underline{e}}_k) = z_\delta$, $k = 1, 2$, as asserted. At this point, the remaining statements follow recalling that in the periodic cell domain Ω, (A_δ, ϕ_δ) is given, up to gauge transformations, by (1.4). □

LOCAL GEOMETRY OF DEFORMABLE TEMPLATES*

ALAIN TROUVÉ† AND LAURENT YOUNES‡

Abstract. In this paper, we discuss a geometrical model of a space of deformable images or shapes, in which infinitesimal variations are combinations of elastic deformations (warping) and of photometric variations. Geodesics in this space are related to velocity-based image warping methods, which have proved to yield efficient and robust estimations of diffeomorphisms in the case of large deformation. Here, we provide a rigorous and general construction of this infinite dimensional "shape manifold" on which we place a Riemannian metric. We then obtain the geodesic equations, for which we show the existence and uniqueness of solutions for all times. We finally use this to provide a geometrically founded linear approximation of the deformations of shapes in the neighborhood of a given template.

Key words. infinite dimensional Riemannian manifolds, deformable templates, shape representation and recognition, warping

1. Introduction.

The theoretical developments which are addressed in this paper are motivated by the theory of deformable templates, as it emerged from the work of Grenander and his collaborators in the 1980's [19, 21, 22, 20], to handle image processing problems. This theory has an abstract formulation, in which the purpose is to represent the variability within an object class by the variations in shape, or color, etc., of a single object, submitted to the action of "deformations." For instance, a model designed to describe a picture of a human face should be able to explain inter-individual variations but also variations caused by the change of expression of a given individual, and by the changing of imaging conditions, such as lighting, occultations, etc. The interesting feature in Grenander's construction is that it assigns a large part, sometimes all, of the variations to a fixed structure, describing the deformation, which is independent of the particular instance of the observed image. This structure most of the time belongs to a group, the group of deformations, which is acting on the set of objects. The specific choice of the group depends on the application and on the type of visual features which are modeled, like pixelized images [18] and discretized shapes [20, 29, 23]. In such discrete settings, the group action is used to generate variations of the constituting generators of the object (pixels for an image, segments for polygons) and therefore are modeled as finite dimensional groups, generally products of linear or affine groups. In the simple example of labeled collections of points (landmarks), the deformation may simply correspond to independent translations of each point, but when the question is raised of the similarity of two collections of landmarks, one would like to figure out the amount of deformation which is required to transform one of them into the other. When evaluating this deformation, it is clear that the lengths of the induced translations should have some impact, but that this is not the

only factor and often not even the main factor. One would also like to draw conclusions on the smoothness of the deformation, based on the fact that, in the context of large deformations of shapes, a lower similarity must be associated to a collection of translations which point to erratic directions, compared to a more homogeneous displacement. We see, in this case, that a global point of view on the displacements is needed. Spline-based landmark matching [9, 26] specifically addresses this issue by seeking the smoothest function which interpolates the considered displacements.

When dealing with image deformation, the need to pass to the continuum is even more obvious. In this case, deformations, which should provide nonambiguous point displacements, must be diffeomorphisms on the image support. This nonambiguity constraint, however, has been relaxed in most of the early attempts to deal with this issue, working preferably with linear spaces of deformations [6, 7, 8, 2, 1, 14], which can be seen as first order approximations. Dealing explicitly with true deformations, i.e., diffeomorphisms acting on the support of images, was rigorously formalized by Riemannian metric arguments on the groups of diffeomorphisms in [32] for one-dimensional problems, and in [31] in full generality (see also [30]). Stemming from the simple representation of right invariant metrics on groups of diffeomorphisms along a path in this space, i.e., time-dependent deformations, in terms of the Eulerian velocity, this last reference built diffeomorphisms as flows associated to ODEs (a construction which was already present in [3]) and transferred the modeling effort to the linear space of velocities, i.e., of vector fields defined on the image support. Under suitable Banach space structures on these linear spaces, the extension of the ODE solutions for infinite time and the existence of minimizers to general variational problems in this space can be ensured, providing rigorous sufficient conditions for the well-posedness of many practical problems in template matching. This analysis rejoined the line of work of Miller and his collaborators on the estimation of large deformation diffeomorphisms [13, 26], in which velocity-based models have been introduced, and variational properties studied in [16]. In [27], the interest in considering a lifted group action, on the cross product of the group itself and of the image space, was demonstrated in a wide variety of applications. The final metric on the image space was obtained by projecting a right-invariant Riemannian distance designed on the product space.

The approach we follow in this paper addresses the same kind of construction as in [27], which focused on the metric aspects, but from a different point of view. Our purpose is to start from the infinitesimal analysis of small deformations of images in order to model and measure image variations and define differentiable and geodesic curves in the image space. We shall accept conditions which ensure enough smoothness on the diffeomorphisms but try whenever possible to avoid placing such smoothness assumptions on the images themselves. Such a choice, which is very important given the discontinuous nature of images, is made at the cost of increasing technicalities and notation, as will be seen in section 3, in which the basic geometry of the model is presented. Here, we define the tangent space at a given square integrable image i as an equivalent class for all possible variations resulting from an infinitesimal combination of a deformation (geometry) and of the addition of a square integrable function (photometry), yielding what can be called a morphometrical variation. We then equip it with an inner product and define from it lengths and energies of curves. This metric is based on the best tradeoff between geometrical and photometrical variations. Still, in this general setting, we show the existence of minimizing geodesics (curves of minimal energy) between any two images.

The rest of the paper is devoted to the study of geodesics and their generation from initial conditions. The motivation in this study is the possibilities it offers for prototype-based image representation and the generation of image variations and deformations from initial conditions belonging to a vector space. In this context, the geodesic equations are derived under the assumption that the deformed prototype is smooth (H^1), but with no restriction on the other endpoint. This is done in section 5.2.2. The obtained evolution equations are then generalized to a form which does not require the smoothness of the initial position and that we conjecture to represent a comprehensive class of image evolutions. The equations, under this form, are studied in section 7, where we prove that they have a unique solution over arbitrary finite time intervals. Our last result shows the local nonambiguity of this representation, at least in the smooth case: from a smooth prototype, the solutions of the geodesic equations in small time cannot coincide if they have been generated from distinct smooth initial conditions. This is done in section 9. The last section, 10, presents numerical experiments, which illustrate the feasibility of retrieving a target from the initial conditions associated to the minimizing geodesic starting from the template.

2. Notation. For further reference, we present in a single definition some of the main functional spaces we use throughout the paper.

DEFINITION 1. *Let $k, p \in \mathbb{N}_*$, $l \in \mathbb{N}$, and Ω be a bounded domain of $\mathbb{R}^k$ with C^1 boundary.*

(1) *We denote $C_c^\infty(\Omega, \mathbb{R}^p)$ the space of smooth compactly supported $\mathbb{R}^p$-valued functions on Ω.*

(2) *We denote $C^l(\overline{\Omega}, \mathbb{R}^p)$ the set of the restrictions to Ω of the l times continuously differentiable $\mathbb{R}^p$-valued functions on $\mathbb{R}^k$.*
Let $f \in C^l(\overline{\Omega}, \mathbb{R}^p)$. We define the norm $|f|_{l,\infty}$ by

$$|f|_{l,\infty} \triangleq \sum_{\alpha,\ 0 \le |\alpha| \le l} \sup_{x \in \Omega} |\frac{\partial^{|\alpha|} f}{\partial x_1^{\alpha_1} \cdots \partial x_d^{\alpha_d}},$$

where for any $\alpha \triangleq (\alpha_1, \ldots, \alpha_d) \in \mathbb{N}_*^d$ we denote $|\alpha| \triangleq \sum \alpha_i$.

(3) *We denote $C_0^l(\Omega, \mathbb{R}^p)$ the completion of $C_c^\infty(\Omega, \mathbb{R}^p)$ for the norm $|\ |_{l,\infty}$.*

(4) *We denote $L^2(\Omega, \mathbb{R}^p)$ the Hilbert space of square integrable functions in $\mathbb{R}^p$ with dot product defined for $f, g \in L^2(\Omega, \mathbb{R}^p)$ by*

$$\langle f, g \rangle_2 \triangleq \int_\Omega \langle f(x), g(x) \rangle_{\mathbb{R}^p} dx.$$

(5) *We denote $H^1(\Omega, \mathbb{R}^p)$ the Hilbert space of square integrable $\mathbb{R}^p$-valued functions with square integrable first partial (generalized) derivatives. The dot product is defined for any $f, g \in H^1(\Omega, \mathbb{R}^p)$ by*

$$\langle f, g \rangle_{H^1} \triangleq \langle f, g \rangle_2 + \sum_{i=1}^k \left\langle \frac{\partial f}{\partial x_i}, \frac{\partial g}{\partial x_i} \right\rangle_2 .$$

3. Measuring distances on the image space.

3.1. Infinitesimal transformations. Let us consider a space $\mathcal{J}_W$ of functions defined on $\bar{\Omega}$, and taking values on $\mathbb{R}^d$, which will be explicitly defined later. To somewhat fix the ideas, we shall speak of elements of $\mathcal{J}_W$ as "images" and use the corresponding photometric vocabulary, although our constructions apply to generic graphs of vector-valued functions.

We want to build a distance, denoted hereafter $d_{\mathcal{J}_W}$, on $\mathcal{J}_W$ through a Riemannian analysis. Let $j \in \mathcal{J}_W$ and $h \in \mathbb{R}$, and consider a small perturbation j_h of j such that

$$j_h(x) = j(x - hv(x)) + h\sigma^2 z(x) + o(h),$$

where v is a displacement field and z is an $\mathbb{R}^d$-valued function on Ω. Here and in the following, σ^2 is a fixed positive parameter. The transformation from j to j_h is therefore divided in two complementary processes. The first, which we call the "geometric transformation," is a pure deformation of the support for which a point located at x in the first image is pushed to location $x + hv(x)$. The second process, called the "photometric transformation," is the residual, obtained by the addition of $\sigma^2 hz$. Both transformations are the main ingredients of any morphing process between two images. When j is smooth, we have

$$\frac{\partial j}{\partial h}_{|h=0} \triangleq \lim_{h\to 0} \frac{j_h - j}{h} = \sigma^2 z - dj(v). \tag{1}$$

The usual geometric interpretation is that $\gamma \triangleq \frac{\partial j}{\partial h}_{|h=0}$ is an element of the tangent space $T_j\mathcal{J}_W$, and, given our representation, it is sensible to let the length $|\gamma|_j$ depend on $w \triangleq (z, v)$ and to let w vary in some chosen vector space W. The solution cannot merely be to set $|\gamma|_j = |w|_W$, where $|\ |_W$ is a norm on W, because the representation $(z, v) \mapsto \gamma$ is not one-to-one: if $w' = (v', z')$ is such that

$$\sigma^2(z' - z) - dj(v' - v) = 0, \tag{2}$$

then the transformations along w and w' of j are infinitesimally equivalent. Hence, looking for the best tradeoff between geometric and photometric transformations, we can choose for the metric on the tangent space $T_j\mathcal{J}_W$

$$|\gamma|_j = \inf \left\{ |w|_W \mid w = (v, z),\ \gamma = \sigma^2 z - dj(v)\ \right\}. \tag{3}$$

Now, we can define formally

$$d_{\mathcal{J}_W}(j_0, j_1) \triangleq \inf \left\{ \int_0^1 \left| \frac{\partial \mathrm{j}}{\partial t} \right|_{j_t},\ \mathrm{j} \text{ path from } j_0 \text{ to } j_1 \right\}. \tag{4}$$

3.2. Differentiable structure. The previous construction is now made rigorous for $\mathcal{J}_W \triangleq L^2(\Omega, \mathbb{R}^d)$.

Remark 1. Since $L^2(\Omega, \mathbb{R}^d)$ is a Hilbert space, it has a natural structure of smooth infinite dimensional manifold. However, the differential structure we need to consider here is different from the standard L^2 structure. To see this, consider the following example: $\Omega =]0, 1[^k$, and $j_h(x) \triangleq j_0(x - hv(x))$, where

- $j_0(x) \triangleq \mathbf{1}_{x_1 \geq 1/2}$,
- $v \in C_c^\infty(\Omega, \mathbb{R}^k)$ is such that the first coordinate, v_1, of v is strictly positive at the center $c \triangleq (1/2, \ldots, 1/2)$ of Ω.

Then, $|j_h - j_0|_2/h \to +\infty$ so that j_h is not differentiable at $h = 0$ for the usual L^2 differentiable structure, whereas, by the construction above, it will be so for the differential structure on $\mathcal{J}_W$ (this is a justification for keeping the nonstandard notation $\mathcal{J}_W$ for the image space).

Our construction starts with the definition of C^1 paths on $\mathcal{J}_W$. We first need to specify the allowed geometric as well as grey-level infinitesimal transformations.

3.2.1. Infinitesimal transformation spaces.

Geometric transformation. We denote $\mathcal{B}$ the space of the displacement fields underlying the infinitesimal geometric transformation. We assume that $\mathcal{B}$ is a Hilbert space with dot product denoted by $\langle\, ,\, \rangle_{\mathcal{B}}$ and norm denoted by $|\ |_{\mathcal{B}}$. We assume throughout this paper that $\mathcal{B}$ is continuously embedded in $C_0^p(\Omega, \mathbb{R}^k)$, where $p = 1$ at least but may be larger if specified. As a reminder, we recall that $\mathcal{B}$ is continuously embedded in some Banach space $\mathcal{B}'$ (with norm $|\ |_{\mathcal{B}'}$) of functions if and only if each element v of $\mathcal{B}$ can be considered as an element of $\mathcal{B}'$ and there exists a constant C such that, for all $v \in \mathcal{B}$,

$$|v|_{\mathcal{B}'} \leq C\, |v|_{\mathcal{B}}\, .$$

Moreover, $\mathcal{B}$ is compactly embedded in $\mathcal{B}'$ if it is continuously embedded and any bounded set for the norm on $\mathcal{B}$ is relatively compact in the $\mathcal{B}'$-topology.

We shall also assume that $C_c^\infty(\Omega, \mathbb{R}^k)$ is dense in $\mathcal{B}$.

Photometric transformation. Grey-level transformations are assumed to belong to the space $L^2(\Omega, \mathbb{R}^d)$.

Finally, we denote $W \triangleq \mathcal{B} \times L^2(\Omega, \mathbb{R}^d)$ on which we place the dot product defined for $w = (v, z)$ and $w' = (v', z')$ by

$$\langle w, w' \rangle_W \triangleq \langle v, v' \rangle_{\mathcal{B}} + \sigma^2 \langle z, z' \rangle_2.$$

3.2.2. Differentiable curves and tangent space. For any smooth image j, we have, for any $u \in C_c^\infty(\Omega, \mathbb{R}^d)$ and any $w = (v, z) \in W$,

$$\langle \sigma^2 z - dj(v), u \rangle_2 = \sigma^2 \langle z, u \rangle_2 + \langle j, \operatorname{div}(u \otimes v) \rangle_2, \tag{5}$$

where $\operatorname{div}(u \otimes v) \in C_0(\Omega, \mathbb{R}^d)$ is defined by $\operatorname{div}(u \otimes v)_i = \operatorname{div}(u_i v)$. The right-hand side of the equality is well defined for arbitrary $j \in \mathcal{J}_W$, which leads us to the following definition.

Definition 2 (C^1 curves in $\mathcal{J}_W$). *Let I be an interval in $\mathbb{R}$. We say that* $\mathrm{j} : I \to \mathcal{J}_W$ *is a continuously differentiable curve if there exists* $\mathrm{w} \triangleq (\mathrm{v}, \mathrm{z}) \in C(I, W)$ *such that*

(1) $\mathrm{j} \in C(I, L^2(\Omega, \mathbb{R}^d))$ *for the usual L^2-topology,*

(2) *for any $u \in C_c^\infty(\Omega, \mathbb{R}^d)$, $t \to \langle \mathrm{j}_t, u \rangle_2$ is a continuously differentiable real-valued function and* $\frac{\partial}{\partial t} \langle \mathrm{j}_t, u \rangle_2 = \sigma^2 \langle \mathrm{z}_t, u \rangle_2 + \langle \mathrm{j}_t, \operatorname{div}(u \otimes \mathrm{v}_t) \rangle_2$.

If we define as usual tangent vectors via classes of first order equivalent curves, we can identify the tangent bundle of $\mathcal{J}_W$ from the definition of C^1 path on $\mathcal{J}_W$ as follows.

Definition 3.

(1) *For any $j \in \mathcal{J}_W$ and any $u \in C_c^\infty(\Omega, \mathbb{R}^d)$, we denote $l_{j,u}$ the continuous linear form on W (the continuity stems from the continuous embedding of $\mathcal{B}$ in $C_0^1(\Omega, \mathbb{R}^k)$) defined for any $w = (v, z) \in W$ by*

$$l_{j,u}(w) \triangleq \sigma^2 \langle z, u \rangle_2 + \langle j, \operatorname{div}(u \otimes v) \rangle_2. \tag{6}$$

(2) *We define*

$$E_j \triangleq \{\ w \in W \mid l_{j,u}(w) = 0,\ \forall u \in C_c^\infty(\Omega, \mathbb{R}^d)\ \}, \tag{7}$$

and

$$T_j \mathcal{J}_W \triangleq \{j\} \times W / E_j, \tag{8}$$

where W/E_j is the quotient space, the elements of which are denoted $\overline{w}$.

Remark 2. The use of a quotient space is a consequence of the nonuniqueness of the representation of the derivative by an element $w \in W$ as explained by (2).

We consider $T_j\mathcal{J}_W$ as a vector space where for any $\gamma = (j, \overline{w})$ and $\gamma' = (j', \overline{w}') \in T_j\mathcal{J}_W$, we have $\gamma + \lambda'\gamma' \triangleq (j, \overline{w} + \lambda\overline{w}')$. Now, if we define

$$T\mathcal{J}_W \triangleq \bigcup_{j \in \mathcal{J}_W} T_j\mathcal{J}_W,$$

$T\mathcal{J}_W$ plays the role of the tangent bundle of the manifold $\mathcal{J}_W$.

Definition 4.

(1) *We denote $\pi : T\mathcal{J}_W \to \mathcal{J}_W$ the canonical projection defined by $\pi(\gamma) = j$ for any $\gamma \triangleq (j, \overline{w}) \in T_j\mathcal{J}_W$.*

(2) *Let $\gamma \triangleq (j, \overline{w}) \in T\mathcal{J}_W$ and $w = (z, v) \in \overline{w}$. For any $u \in C_c^\infty(\Omega, \mathbb{R}^d)$, we denote*

$$\langle \gamma\, ,\, u \rangle \triangleq \sigma^2 \langle z, u \rangle_2 + \langle j, \mathrm{div}(u \otimes v) \rangle_2.$$

(Note that the right-hand side does not depend on the choice of $w \in \overline{w}$).

(3) *For any function $\gamma : I \to T\mathcal{J}_W$ where I is a real interval, we say that γ is measurable if $\pi \circ \gamma$ is measurable from I to $\mathcal{J}_W$ and for any $u \in C_c^\infty(\Omega, \mathbb{R}^d)$, $\langle \gamma_t\, ,\, u \rangle$ is measurable from I to $\mathbb{R}$.*

Returning to Definition 2, we see that C^1 curves j admit a lifting $t \mapsto \gamma_t = (\mathrm{j}_t, \overline{w}_t)$ to $T\mathcal{J}_W$ such that for all $u \in C_c^\infty(\Omega, \mathbb{R}^d)$

$$\frac{d}{dt} \langle \mathrm{j}_t\, ,\, u \rangle_2 = \langle \gamma_t\, ,\, u \rangle$$

so that it is natural to define $\frac{d\mathrm{j}_t}{dt} \triangleq \gamma_t \in T_{\mathrm{j}_t}\mathcal{J}_W$ leading to the formula

$$\frac{d}{dt} \langle \mathrm{j}_t\, ,\, u \rangle_2 = \left\langle \frac{d\mathrm{j}_t}{dt}\, ,\, u \right\rangle. \tag{9}$$

The next step, for our Riemannian construction, is to place a metric on $T_j\mathcal{J}_W$ for all $j \in \mathcal{J}_W$.

3.3. Riemannian structure.

Definition 5. *For any $j \in \mathcal{J}_W$, we define on $T_j\mathcal{J}_W$ the norm*

$$|\gamma|_j \triangleq \inf\{\ |w|_W \ |\ (j, w) \in \gamma\ \}.$$

The infimum is attained at a unique point, as stated in the following proposition.

Proposition 1. *For any $j \in \mathcal{J}_W$ and any $\gamma = (j, \overline{w}) \in T_j\mathcal{J}_W$, since $\overline{w}$ is a closed subspace of W, there exists a unique $w \in W$ denoted $\overline{p}(\gamma)$ such that*

$$\overline{p}(\gamma) \triangleq \operatorname*{Argmin}_{w \in \overline{w}} |w|_W.$$

Hence, $|\gamma|_j \triangleq |\overline{p}(\gamma)|_W$. Moreover, $\overline{p}$ is linear from $T_j\mathcal{J}_W$ to W.

Proof. Since $\overline{w}$ is a close subspace of W, it is sufficient to note that if p is the orthogonal projection from W to $E_j^\perp$, then $p(w) = 0$ for any $w \in E_j$ so that p can be factorized as a linear map $\overline{p}$ from W/E_j to $E_j^\perp$. Now, one easily checks that $\overline{p}(\gamma) \in \overline{w}$ and that $\overline{p}(\gamma)$ minimizes the norm. ∎

We can now define the geodesic distance between arbitrary points j_0, j_1 in $\mathcal{J}_W$ by

$$d_{\mathcal{J}_W}(j_0, j_1) \triangleq \inf \left\{ \int_0^1 \left| \frac{d\mathrm{j}}{dt} \right|_{\mathrm{j}_t} dt \mid \mathrm{j} \in C^1_{\mathrm{pw}}([0,1], \mathcal{J}_W),\ \mathrm{j}_0 = j_0,\ \mathrm{j}_1 = j_1 \right\}, \tag{10}$$

where $C^1_{\mathrm{pw}}([0,1], \mathcal{J}_W)$ is the set of piecewise C^1 curves in $\mathcal{J}_W$ which are straightforwardly defined from the definition of C^1 curves. This definition is the usual definition for finite dimensional Riemannian manifolds. There is, however, a measurability issue, since it is not obvious from our definition of a measurable path in $T\mathcal{J}_W$ that $t \mapsto |\gamma_t|_{\pi(\gamma_t)}$ is measurable. This issue is addressed in Proposition 2, the proof of which is provided in Appendix A.

PROPOSITION 2. *Let $\gamma : [0,1] \to T\mathcal{J}_W$ be a measurable path in $T\mathcal{J}_W$. Then, $\overline{p} \circ \gamma$ is a measurable path in W and $|\gamma|_{\pi \circ \gamma}$ is a measurable real-valued function.*

4. Groups of diffeomorphisms. Curves in W naturally generate diffeomorphisms on Ω by integration of their first component, which is a time-dependent vector field on Ω which vanishes at $\partial\Omega$. The relations between the Hilbert structure on $\mathcal{B}$ and the class of diffeomorphisms which can be generated in that way have been investigated, in particular, in [30] and [16], in which sufficient smoothness conditions on the vector field are derived to ensure existence, uniqueness, and smoothness of the flow for all time.

For $T > 0$, define the set $L^1([0,T], \mathcal{B})$ as the Banach space of measurable functions $\mathrm{v} : [0,T] \to \mathcal{B}$ such that

$$|\mathrm{v}|_{1,T} \triangleq \int_0^T |\mathrm{v}|_{\mathcal{B}}\, dt < \infty.$$

Similarly, $L^2([0,T], \mathcal{B})$ denotes the Hilbert space of square integrable functions defined on $[0,T]$ and taking values in $\mathcal{B}$, with the norm

$$|\mathrm{v}|_{2,T} \triangleq \left(\int_0^T |\mathrm{v}|^2_{\mathcal{B}}\, dt \right)^{1/2}.$$

For $\mathrm{v} \in L^1([0,T], \mathcal{B})$, consider the ODE

$$\frac{dy}{dt} = \mathrm{v}_t(y). \tag{11}$$

A global flow solution of this equation is a time-dependent family of functions $t \to \varphi_t$ such that, for all $x \in \Omega$, $\varphi_0(x) = x$ and

$$\varphi_t = \int_0^t \mathrm{v}_s \circ \varphi_s\, ds.$$

When the dependence of this flow on v must be emphasized, it is denoted by φ^{v}.

Results in [30, 16] essentially relate the existence and smoothness of such flows to embedding conditions of $\mathcal{B}$ into standard sets of continuous functions. We quote these results in the following theorem.

THEOREM 1 (Trouvé). *If $\mathcal{B}$ is continuously embedded in $C^1_0(\Omega, \mathbb{R}^k)$, then for all $T > 0$ and all $\mathrm{v} \in L^1([0,T], \mathcal{B})$, the ODE (11) can be integrated over $[0,T]$, and its associated flow φ^{v} is such that at all times $x \to \varphi^{\mathrm{v}}_t$ is a homeomorphism of Ω.*

NOTATION 1. *Assume that $\mathcal{B}$ is continuously embedded in $C_0^1(\Omega, \mathbb{R}^k)$, and introduce the map*

$$\begin{array}{rrcl} \mathbf{A}_T: & L^1([0,T],\mathcal{B}) & \to & C(\overline{\Omega},\mathbb{R}^k), \\ & \mathrm{v} & \mapsto & \varphi_T^{\mathrm{v}}. \end{array}$$

Then, the set $\mathbf{A}_1(L^1([0,1],\mathcal{B}))$ will be denoted $G_{\mathcal{B}}$.

The fact that $G_{\mathcal{B}}$ is a group is proved in [30]. Further results on these groups and on A_T can be found in Appendix C.

The relation between algebraic and metric properties of groups of diffeomorphisms and some of the fundamental equations of fluid mechanics has been the subject of several studies, starting with [5], in which the Euler equation is related to the geodesic equations of groups of diffeomorphisms with an L^2 metric on its Lie algebra (see also [3, 4, 24]). Another important equation, the Camassa–Holm equation, which describes the motion of the waves in shallow water, can be interpreted along the same lines with an H_α^1 metric on the Lie algebra [11, 17]. Here, since the energy derives from both geometric and photometric variations, the geodesic equations that we derive can be formally interpreted as conservation of momentum on a semidirect product of the group of diffeomorphisms and the space of images, as studied in [25]. However, our point of view of smooth deformations acting on nonsmooth images requires a specific approach. This is also related to developments in optimal design [28].

5. Geodesics on $\mathcal{J}$.

5.1. Minimizing geodesics. The space of C^1 curves is not well suited to deal with proofs of the existence of curves of minimal length between two images j_0 and j_1, i.e., minimizing geodesics. We introduce below the more tractable space of curves with square integrable speed.

We need first a preliminary proposition saying that square integrable paths in $T\mathcal{J}_W$ are uniquely identified by their trace on smooth space-time vector fields in $\mathbb{R}^d$. The proof of this proposition is postponed to Appendix A.

PROPOSITION 3. *Let $\gamma : [0,1] \to T\mathcal{J}_W$ be a measurable path in $T\mathcal{J}_W$. Then, if $\int_0^1 |\gamma_t|^2_{\pi(\gamma_t)} dt < +\infty$ and, for any $\mathrm{u} \in C_c^\infty(\Omega \times]0,1[, \mathbb{R}^d)$, we have $\int_0^1 \langle \gamma_t\, , \mathrm{u}_t \rangle dt = 0$, then $\gamma = 0$ a.e.*

We can now introduce the space $H^1([0,1], \mathcal{J}_W)$ of regular curves.

DEFINITION 6. *We say that a path $\mathrm{j} \in C([0,1], L^2(\Omega, \mathbb{R}^d))$ is regular if there exists a measurable path $\gamma : [0,1] \to T\mathcal{J}_W$ such that $\pi(\gamma) = \mathrm{j}$, $\int_0^1 |\gamma_t|^2 dt < \infty$, and, for any $\mathrm{u} \in C_c^\infty(]0,1[\times\Omega, \mathbb{R}^d)$, we have $-\int_0^1 \langle \mathrm{j}_t, \frac{\partial \mathrm{u}}{\partial t} \rangle_2 dt = \int_0^1 \langle \gamma_t\, , \mathrm{u}_t \rangle dt$. From Proposition 3, the path γ is uniquely defined; using the notation $\frac{\partial \mathrm{j}}{\partial t} \triangleq \gamma_t$, we get the integration by parts formula*

$$\int_0^1 \left\langle \mathrm{j}_t, \frac{\partial \mathrm{u}}{\partial t} \right\rangle_2 dt = -\int_0^1 \left\langle \frac{\partial \mathrm{j}}{\partial t}\, , \mathrm{u}_t \right\rangle dt. \tag{12}$$

We denote $H^1([0,1], \mathcal{J}_W)$ as the set of all the regular paths in $C([0,1], L^2(\Omega, \mathbb{R}^d))$.

PROPOSITION 4. *We have $C^1([0,1], \mathcal{J}_W) \subset H^1([0,1], \mathcal{J}_W)$ and both definitions of $\frac{\partial \mathrm{j}}{\partial t}$ coincide.*

Proof. Let $\mathrm{j} \in C^1([0,1], \mathcal{J}_W)$. There exists $\mathrm{w} = (\mathrm{v}, \mathrm{z}) \in C([0,1], W)$ such that for any $u \in C_c^\infty(\Omega, \mathbb{R}^d)$, $t \to \langle \mathrm{j}_t, u \rangle_2$ is C^1 and

$$\frac{\partial}{\partial t} \langle \mathrm{j}_t, \mathrm{u} \rangle_2 = \sigma^2 \langle \mathrm{z}_t, \mathrm{u} \rangle_2 + \langle \mathrm{j}_t, \mathrm{div}(\mathrm{u} \otimes \mathrm{v}_t) \rangle_2.$$

Certainly, $\mathrm{w} \in L^2([0,1], W)$. Moreover, for any $\mathrm{u} \in C_c^\infty(\Omega, \mathbb{R}^d)$ and any $f \in C_c^\infty(]0,1[, \mathbb{R})$, we have by integration by parts (we denote $f'(t) \triangleq \frac{df}{dt}$)

$$\int_0^1 \langle j_t, f'(t)\mathrm{u}\rangle_2 = \int_0^1 f'(t)\langle \mathrm{j}_t, \mathrm{u}\rangle_2 dt = -\int_0^1 f(t)\frac{d}{dt}\langle \mathrm{j}_t, \mathrm{u}\rangle_2 dt$$

so that (12) is true for $u \otimes f \in C_c^\infty(]0,1[\times\Omega, \mathbb{R}^d)$. The complete proof follows by usual density arguments. □

We carry on with an important result which characterizes regular paths in $\mathcal{J}_W$. For a path v in $L^1([0,1], \mathcal{B})$, we define for any $s, t \in [0,1]$

$$\varphi_{t,s}^{\mathrm{v}} \triangleq \varphi_s^{\mathrm{v}} \circ (\varphi_t^{\mathrm{v}})^{-1}.$$

THEOREM 2. *A path* $\mathrm{j} : [0,1] \to \mathcal{J}_W$ *is regular (resp., is in* $C^1([0,1], \mathcal{J}_W)$*) if and only if there exists* $\mathrm{w} = (\mathrm{v}, \mathrm{z}) \in L^2([0,1], W)$ *(resp.,* $\in C([0,1], W)$*) such that*

$$\mathrm{j}_t = \mathrm{j}_0 \circ \varphi_{t,0}^{\mathrm{v}} + \sigma^2 \int_0^t \mathrm{z}_s \circ \varphi_{t,s}^{\mathrm{v}} ds.$$

Proof. The proof is postponed to Appendix B. □

THEOREM 3. *Let* j_0 *and* j_1 *be in* $\mathcal{J}_W$. *Then we have*

$$d_{\mathcal{J}_W}(j_0, j_1) = \inf\left\{ \int_0^1 \left|\frac{\partial \mathrm{j}}{\partial t}\right|_{j_t} dt \mid \mathrm{j} \in H^1([0,1], \mathcal{J}_W),\ \mathrm{j}_0 = j_0,\ \mathrm{j}_1 = j_1 \right\}. \tag{13}$$

Proof. Let $\mathrm{j} \in H^1([0,1], \mathcal{J}_W)$ be a regular path from j_0 to j_1 and let $\mathrm{w} \in L^2([0,1], W)$ such that $\mathrm{w}_t = \overline{p}_{\mathrm{j}_t}(\frac{\partial \mathrm{j}}{\partial t})$ for any t. There exists a sequence $(\mathrm{w}^n = (\mathrm{v}^n, \mathrm{z}^n) \in C([0,1], W),\ n \in \mathbb{N})$ such that $\int_0^1 |\mathrm{w}_t - \mathrm{w}_t^n|_W^2 dt \to 0$. Define

$$\mathrm{j}_t^n = j_0 \circ \varphi_{t,0}^{\mathrm{v}^n} + \sigma^2 \int_0^t \mathrm{z}_s^n \circ \varphi_{t,s}^{\mathrm{v}^n} ds.$$

We get from Theorem 2 that $\mathrm{j}^n \in C^1([0,1], \mathcal{J}_W)$. Now, considering $\tilde{\mathrm{w}}^n \triangleq (\tilde{\mathrm{v}}^n, \tilde{\mathrm{z}}^n)$ with $\tilde{\mathrm{z}}_t^n \triangleq \mathrm{z}_t^n + (j_1 - \mathrm{j}_1^n) \circ \varphi_{s,1}^{\mathrm{v}^n}$ and $\tilde{\mathrm{v}}^n \triangleq \mathrm{v}^n$ we get from Theorem 9 (see Appendix C) that $\tilde{\mathrm{w}}^n \in C([0,1], W)$. Using Theorem 2, we deduce that if $\tilde{\mathrm{j}}^n$ is defined by

$$\tilde{\mathrm{j}}_t^n = j_0 \circ \varphi_{t,0}^{\mathrm{v}^n} + \sigma^2 \int_0^t \tilde{\mathrm{z}}_s^n \circ \varphi_{t,s}^{\mathrm{v}^n} ds,$$

then $\tilde{\mathrm{j}}^n \in C^1([0,1], \mathcal{J}_W)$ and $\tilde{\mathrm{j}}_1^n = j_1$. However,

$$\int_0^1 \left|\frac{\partial \tilde{\mathrm{j}}^n}{\partial t}\right|_{\tilde{\mathrm{j}}_t^n} dt \le \int_0^1 |\tilde{\mathrm{w}}_t^n|_W dt \to \int_0^1 |\mathrm{w}_t|_W dt$$

when $n \to \infty$. Therefore, we deduce that $d_{\mathcal{J}_W}(j_0, j_1) \le \int_0^1 |\frac{\partial \mathrm{j}}{\partial t}|_{\mathrm{j}_t} dt$ for any regular path from j_0 to j_1. Finally, since $C^1([0,1], \mathcal{J}_W) \subset H^1([0,1], \mathcal{J}_W)$, we get the result. □

DEFINITION 7. *Let* $j_0, j_1 \in \mathcal{J}_W$. *We say that* $\mathrm{j} \in C([0,1], L^2(\Omega, \mathbb{R}^d))$ *is a minimizing geodesic path from* j_0 *to* j_1 *if* j *is regular and*

$$\left(\int_0^1 \left|\frac{\partial \mathrm{j}}{\partial t}\right|_{\mathrm{j}_t}^2 dt\right)^{\frac{1}{2}} = d_{\mathcal{J}_W}(j_0, j_1).$$

We denote $G_{\mathcal{J}_W}(j_0, j_1)$ *as the set of the minimizing geodesic paths from* j_0 *to* j_1.

5.2. Characterization of geodesics.

5.2.1. Photometric optimality.

THEOREM 4. *Let $j_0, j_1 \in \mathcal{J}_W$ and $j \in G_{\mathcal{J}_W}(j_0, j_1)$ be a minimizing geodesic path from j_0 to j_1. Let $\mathrm{w} = (\mathrm{v}, \mathrm{z}) \in L^2([0,1], W)$ be defined by $\mathrm{w}_t \triangleq \overline{p}(\frac{\partial j}{\partial t})$ for any $t \in [0,1]$. Then $\mathrm{z} \in C([0,1], L^2(\Omega, \mathbb{R}^d))$ and for any $t \in [0,1]$ we have*

$$\mathrm{z}_t = \mathrm{z}_0 \circ \varphi^{\mathrm{v}}_{t,0} \left| d\varphi^{\mathrm{v}}_{t,0} \right|. \tag{14}$$

Proof. Let $\mathrm{j} \in H^1([0,1], \mathcal{J}_W)$ be a minimizing geodesic from j_0 to j_1, and let $\mathrm{w} = (\mathrm{v}, \mathrm{z}) \in L^2([0,1], W)$ such that for any $t \in [0,1]$, $\mathrm{w}_t = \overline{p}(\frac{d\mathrm{j}}{dt})$. For any $\mathrm{u} \in C_c^\infty(]0,1[\times \Omega, \mathbb{R}^d)$ and any $\varepsilon \in \mathbb{R}$, define

$$\tilde{\mathrm{j}}_t = j_0 \circ \varphi^{\mathrm{v}}_{t,0} + \sigma^2 \int_0^t \left(\mathrm{z}_s + \varepsilon \frac{\partial \mathrm{u}_s}{\partial s} \circ \varphi^{\mathrm{v}}_{s,1} \right) \circ \varphi_{t,s} ds.$$

Since $t \to (\mathrm{v}_t, \mathrm{z}_t + \varepsilon \frac{\partial \mathrm{u}_t}{\partial t} \circ \varphi^{\mathrm{v}}_{t,1}) \in L^2([0,1], W)$, we get from Theorem 2 that $\tilde{\mathrm{j}} \in H^1([0,1], \mathcal{J}_W)$. Moreover, $\tilde{\mathrm{j}}_0 = j_0$ and $\tilde{\mathrm{j}}_1 = j_1$ so that

$$\begin{aligned}\int_0^1 \left| \frac{d\mathrm{j}_t}{dt} \right|^2_{\mathrm{j}_t} dt = \int_0^1 \left(|\mathrm{v}_t|^2_{\mathcal{B}} + \sigma^2 |\mathrm{z}_t|_2^2 \right) dt &\leq \int_0^1 \left| \frac{d\tilde{\mathrm{j}}_t}{dt} \right|^2_{\tilde{\mathrm{j}}_t} dt \\ &\leq \int_0^1 \left(|\mathrm{v}_t|^2_{\mathcal{B}} + \sigma^2 \left| \mathrm{z}_t + \varepsilon \frac{\partial \mathrm{u}_t}{\partial t} \circ \varphi^{\mathrm{v}}_{t,1} \right|_2^2 \right) dt.\end{aligned}$$

Since ε is arbitrary, we get

$$0 = \int_0^1 \left\langle \mathrm{z}_t, \frac{\partial \mathrm{u}_t}{\partial t} \circ \varphi^{\mathrm{v}}_{t,1} \right\rangle_2 dt = \int_0^1 \left\langle \mathrm{z}_t \circ \varphi^{\mathrm{v}}_{1,t} \left| d\varphi^{\mathrm{v}}_{1,t} \right|, \frac{\partial \mathrm{u}_t}{\partial t} \right\rangle_2 dt.$$

Choosing arbitrary $\mathrm{u} \in C_c^\infty(]0,1[\times \Omega, \mathbb{R}^d)$, we get that there exists $\tilde{z}_1 \in L^2(\Omega, \mathbb{R}^d)$ such that t-a.e. we have $\mathrm{z}_t \circ \varphi^{\mathrm{v}}_{1,t} \left| d\varphi^{\mathrm{v}}_{1,t} \right| = \tilde{z}_1$. Hence, if $\tilde{\mathrm{z}}_t = \tilde{z}_1 \circ \varphi^{\mathrm{v}}_{t,1} \left| d\varphi^{\mathrm{v}}_{t,1} \right|$, we have $\tilde{\mathrm{z}} \in C([0,1), L^2([0,1], \mathbb{R}^d))$ and $\mathrm{z}_t = \tilde{\mathrm{z}}_t$ t-a.e. Note that $\tilde{\mathrm{z}}_0 \circ \varphi^{\mathrm{v}}_{1,0} \left| d\varphi^{\mathrm{v}}_{1,0} \right| = \tilde{z}_1$ so that

$$\tilde{\mathrm{z}}_t = \left(\tilde{\mathrm{z}}_0 \circ \varphi^{\mathrm{v}}_{1,0} \left| d\varphi^{\mathrm{v}}_{1,0} \right| \right) \circ \varphi^{\mathrm{v}}_{t,1} \left| d\varphi^{\mathrm{v}}_{t,1} \right| = \tilde{\mathrm{z}}_0 \circ \varphi^{\mathrm{v}}_{t,0} \left| d\varphi^{\mathrm{v}}_{t,0} \right|,$$

and the proof is ended. ∎

This leads to the following definition.

DEFINITION 8. *A regular path $\mathrm{j} \in H^1([0,1], \mathcal{J}_W)$ is called a pregeodesic path if and only if the following equations are satisfied almost everywhere in t:*

$$\begin{cases} \mathrm{j}_t = \mathrm{j}_0 \circ \varphi^{\mathrm{v}}_{t,0} + \sigma^2 \displaystyle\int_0^t \mathrm{z}_s \circ \varphi^{\mathrm{v}}_{t,s} ds, \\ \mathrm{z}_t = \mathrm{z}_0 \circ \varphi^{\mathrm{v}}_{t,0} \left| d\varphi^{\mathrm{v}}_{t,0} \right|, \\ (\mathrm{v}_t, \mathrm{z}_t) = \overline{p} \left(\dfrac{d\mathrm{j}}{dt} \right). \end{cases} \tag{15}$$

5.2.2. Study of the geodesic equation.

Directional derivatives in ^{2}. In this section, we try to clarify the last equation of system (15), at least in some situations of interest. The difficulty comes from the fact that, unless j_t is smooth enough, this equation does not, in general, specify a unique correspondence $\mathrm{z}_t \mapsto \mathrm{v}_t$.

To be more precise, let us analyze the condition that, for all t,

$$(\mathrm{v}_t, \mathrm{z}_t) = \overline{p}\left(\frac{d\mathrm{j}}{dt}\right).$$

For this purpose, we first introduce a weak version of the directional derivative $dj.v$ when $j \in \mathcal{J}_W$ and $v \in \mathcal{B}$.

Definition 9. *Let $j \in \mathcal{J}_W$.*

(1) *We define the operator $Dj : \mathcal{D}_j \to L^2(\Omega, \mathbb{R}^d)$ by*

$$\mathcal{D}_j \triangleq \{\ v \in \mathcal{B} \mid \exists C,\ s.t.\ \forall u \in C_c^\infty(\Omega, \mathbb{R}^d),\ |\langle j\,,\, \mathrm{div}(u \otimes v)\rangle_2| \le C\,|u|_2\ \},$$

and for any $v \in \mathcal{D}_j$, $Dj.v$ is the unique element in $L^2(\Omega, \mathbb{R}^d)$ such that

$$\langle Dj.v\,,\, u\rangle_2 = -\langle j\,,\, \mathrm{div}(u \otimes v)\rangle_2$$

for any $u \in C_c^\infty(\Omega, \mathbb{R}^d)$.

(2) *We define the adjoint operator $Dj^* : \mathcal{D}_j^* \to \mathcal{B}$, where*

$$\mathcal{D}_j^* \triangleq \{\ u \in L^2(\Omega, \mathbb{R}^d) \mid \exists C,\ s.t.\ \forall v \in \mathcal{D}_j\ \ |\langle Dj.v\,,\, u\rangle_2| \le C\,|v|_B\ \},$$

and, for any $u \in \mathcal{D}_j^*$, Dj^* is the unique element in $\overline{\mathcal{D}_j}$ (closure of $\mathcal{D}_j$) such that

$$\langle Dj^*.u\,,\, v\rangle_{\mathcal{B}} = \langle u\,,\, Dj.v\rangle_2 \tag{16}$$

for any $v \in \mathcal{D}_j$.

Remark 3. The existence of $Dj.v$ comes from the extension of the linear form $u \to \langle j\,,\, \mathrm{div}(u \otimes v)\rangle$ for smooth u into a continuous linear form on $L^2(\Omega, \mathbb{R}^d)$ for $v \in \mathcal{D}_j$. For the definition of the adjoint Dj^*, the adjoint is uniquely defined as an element of $\overline{\mathcal{D}_j}$ by (16) ($\mathcal{D}_j$ is not necessarily dense in $\mathcal{B}$).

Fix $j \in \mathcal{J}_W$. We may characterize elements $v \in \mathcal{D}_j$ as follows. (We denote hereafter $\varphi^v_{\cdot}$ as the flow associated with the constant speed $v_t \equiv v$ for any $t \in [0, 1]$.)

Theorem 5. *The vector field $v \in \mathcal{B}$ belongs to $\mathcal{D}_j$ if and only if there exists a square integrable function $\xi : \Omega \to \mathbb{R}^d$ such that*

$$j \circ \varphi^v_{0,t}(x) = j(x)\left|d_x\varphi^v_{0,t}\right|^{-1} + \int_0^t \xi \circ \varphi^v_{0,s}(x)\left|d_{\varphi^v_{0,s}(x)}\varphi^v_{s,t}\right|^{-1} ds. \tag{17}$$

We have in such a case $Djv = \xi - j\mathrm{div}(v)$.

Proof. We first notice that, if $v \in \mathcal{B}$,

$$-\langle j\,,\, \mathrm{div}(u \otimes v)\rangle_2 = \frac{d}{d\varepsilon}\int_\Omega \left\langle j(x)\,,\, u \circ \varphi^v_{\varepsilon,0}(x)\right\rangle \left|d_x\varphi^v_{\varepsilon,0}\right| dx = \frac{d}{d\varepsilon}\int_\Omega \left\langle j \circ \varphi^v_{0,\varepsilon}(x)\,,\, u(x)\right\rangle dx.$$

Assuming that (17) holds, the last expression yields

$$\begin{aligned}\frac{d}{d\varepsilon}\int_\Omega \langle j(x)\,,\, u(x)\rangle \left|d_x\varphi^v_{0,\varepsilon}\right|^{-1} dx + \frac{d}{d\varepsilon}\int_\Omega\int_0^\varepsilon \left\langle \xi \circ \varphi^v_{0,s}\,,\, u(x)\right\rangle \left|d_{\varphi^v_{0,s}(x)}\varphi^v_{s,\varepsilon}\right|^{-1} dx \\ = -\int_\Omega \langle j(x)\,,\, u(x)\rangle \mathrm{div}(v) dx + \int_\Omega \langle \xi(x)\,,\, u(x)\rangle dx = \langle \xi - j\mathrm{div}(v)\,,\, u\rangle_2,\end{aligned}$$

which implies that $v \in \mathcal{D}_j$ and $Djv = \xi - j\mathrm{div}(v)$.

Conversely, let $v \in \mathcal{D}_j$ and $\xi = Djv + j\mathrm{div}(v)$. Fix $u \in C^1(\Omega, \mathbb{R}^d)$. Consider the function f, defined on $[0,1]$ by $f(t) = \left\langle j \circ \varphi^v_{0,t}\, ,\, u\right\rangle_2$. Denote by $\tilde{\jmath}(t)$ the left-hand term of (17), and $g(t) = \langle \tilde{\jmath}_t\, ,\, u\rangle_2$. We have

$$\begin{aligned} g'(t) &= -\left\langle j\, ,\, u\mathrm{div}_{\varphi^v_{0,t}(x)} v \left| d_x \varphi^v_{0,t}\right|^{-1}\right\rangle_2 + \left\langle \xi \circ \varphi^v_{0,t}\, ,\, u\right\rangle_2 \\ &\qquad - \int_0^t \left\langle \xi \circ \varphi^v_{0,s} \left| d_{\varphi^v_{0,s}} \varphi^v_{s,t}\right|^{-1} ,\, u\mathrm{div}_{\varphi^v_{0,t}} v\right\rangle_2 ds \\ &= \left\langle \xi \circ \varphi^v_{0,t} - \tilde{\jmath}_t \mathrm{div}_{\varphi^v_{0,t}} v\, ,\, u\right\rangle_2. \end{aligned}$$

Since $f(t+\varepsilon) = \left\langle j \circ \varphi^v_{t,t+\varepsilon}\, ,\, u \circ \varphi^v_{t,0} \left| d\varphi^v_{t,0}\right|\right\rangle_2$, we have

$$f'(t) = \left\langle Djv\, ,\, u \circ \varphi^v_{t,0} \left| d\varphi^v_{t,0}\right|\right\rangle_2 = \left\langle (Djv) \circ \varphi^v_{0,t}\, ,\, u\right\rangle_2.$$

Therefore, computing the integral of the difference and using the definition of ξ,

$$\left\langle j \circ \varphi^v_{0,t} - \tilde{\jmath}_t\, ,\, u\right\rangle_2 = \int_0^t \left\langle j \circ \varphi^v_{0,s} - \tilde{\jmath}_s\, ,\, u\mathrm{div}_{\varphi^v_{0,t}} v\right\rangle_2 ds \le |u|_2\, |v|_{\mathcal{B}} \int_0^t \left| j \circ \varphi^v_{0,s} - \tilde{\jmath}_s\right|_2 ds.$$

Taking the supremum of the left-hand term over continuously differentiable u with L^2-norm equal to 1 yields

$$\left| j \circ \varphi^v_{0,t} - \tilde{\jmath}_t\right|_2 \le |v|_{\mathcal{B}} \int_0^t \left| j \circ \varphi^v_{0,s} - \tilde{\jmath}_s\right|_2 ds,$$

which implies $\left| j \circ \varphi^v_{0,t} - \tilde{\jmath}_t\right|_2 = 0$ for all t. ◻

An interesting consequence of this is the following lemma.

LEMMA 1. *For any $j \in L^2(\Omega, \mathbb{R}^d)$, one has $j \in D^*_j$ and, for $v \in D_j$,*

$$\langle Djv\, ,\, j\rangle_2 = -\frac{1}{2}\left\langle |j|^2\, ,\, \mathrm{div} v\right\rangle_2.$$

Proof. Indeed, let $v \in D_j$. Consider the function

$$f(t) = \int_\Omega \left| j \circ \varphi^v_{0,t}(x)\right|^2 dx.$$

Since $f(t) = \left\langle |j|^2\, ,\, |d\varphi_{t,0}|\right\rangle_2$, we have $f'(0) = -\langle |j|^2\, ,\, \mathrm{div} v\rangle_2$. Using, on the other hand, expression (17) yields $f'(0) = 2\langle Djv\, ,\, j\rangle_2$. ◻

Interpretation of the pregeodesic equations. The property that $w = (v,z) \in W$ belongs to E_j, which states that, for all $u \in C^\infty_c(\Omega, \mathbb{R}^d)$,

$$\sigma^2 \langle z, u\rangle_2 + \langle j, \mathrm{div}(u \otimes v)\rangle_2 = 0$$

is equivalent to $v \in \mathcal{D}_j$ and $\sigma^2 z - Dj.v = 0$. Consider now some tangent vector $\gamma \in T_j \mathcal{J}_W$, and study the property that, for some $w = (v,z) \in W$, one has $\overline{p}(\gamma) = w$. This implies, in particular, that, for all $(v', z') \in E_j$,

$$|v + v'|^2_{\mathcal{B}} + \sigma^2\, |z + z'|^2_2 \ge |v|^2_{\mathcal{B}} + \sigma^2\, |z|^2_2\,,$$

which is in turn equivalent to the following: for all $v' \in \mathcal{D}_j$, $\langle v\,,\,v'\rangle_{\mathcal{B}} + \langle z\,,\,Dj.v'\rangle_2 = 0$. This implies that $z \in \mathcal{D}_j^*$ and that $\langle v\,,\,v'\rangle_{\mathcal{B}} + \langle Dj^* z\,,\,v'\rangle_{\mathcal{B}} = 0$, so that $v = -Dj^* z + \gamma_\perp$, where $\gamma_\perp$ is the projection of v onto $\mathcal{D}_j^\perp$. Note that this orthogonal component does not depend on the choice of (v,z) from the equivalence class defining γ (hence the notation). We thus may conclude that $(v,z) = \overline{p}(\gamma)$ if and only if $z \in \mathcal{D}_j^*$ and

$$v = -Dj^* z + \gamma_\perp.$$

The first conclusion we may draw from this is that, whenever $\mathcal{D}_j$ is dense in $\mathcal{B}$, v_t is uniquely determined by z_t and the condition $(\mathrm{v}_t, \mathrm{z}_t) = \overline{p}(\frac{d\mathrm{j}}{dt})$. It is given by $\mathrm{v}_t = -D\mathrm{j}_t^* \mathrm{z}_t$. This is true, for example, when $\mathrm{j}_t \in H^1(\Omega, \mathbb{R}^d)$ at all times, since, in this case $\mathcal{D}_{\mathrm{j}_t} = \mathcal{B}$ (notice that, by Theorem 4, this is true along a geodesic as soon as j_0 and j_1 belong to $H^1(\Omega, \mathbb{R}^d)$).

However, this is not the general situation. As an example, consider the case when j is the indicator function of a subdomain Ω_1 of Ω with smooth boundary. If v is a vector field on Ω and u is a smooth function on Ω, we have

$$\langle j\,,\,\mathrm{div} uv\rangle = \int_{\partial\Omega_1} u\langle v\,,\,\nu_1\rangle_{\mathbb{R}^k} d\sigma_1,$$

where ν_1 is the outward normal to $\partial\Omega_1$ and σ_1 is the surface measure on $\partial\Omega_1$. This implies that djv may be identified to a singular measure supported to $\partial\Omega_1$, which does not belong to L^2 unless it vanishes. Thus, $\mathcal{D}_j$ consists exactly of vector fields on Ω which belong to $\mathcal{B}$ and have vanishing normal components on $\partial\Omega_1$. For $a \in \mathbb{R}^k$ and $x \in \mathbb{R}$, denote by $K_x a$ the element of $\mathcal{B}$ such that $\langle K_x a\,,\,u\rangle_{\mathcal{B}} = \langle u(x)\,,\,a\rangle_{\mathbb{R}^k}$. Then, $K_x \nu(x)$ belongs to $D_j^\perp$ for any $x \in \partial\Omega$, and so does any linear combination of these vector fields. We see that in this case $D_j^\perp$ is nontrivial.

This discussion implies that the pregeodesic condition for a path may be written

$$\begin{cases} \mathrm{j}_t = \mathrm{j}_0 \circ \varphi^{\mathrm{v}}_{t,0} + \sigma^2 \displaystyle\int_0^t \mathrm{z}_s \circ \varphi^{\mathrm{v}}_{t,s} ds, \\[2ex] \mathrm{z}_t = \mathrm{z}_0 \circ \varphi^{\mathrm{v}}_{t,0} \left| d\varphi^{\mathrm{v}}_{t,0} \right|, \\[2ex] \mathrm{z}_t \in D_j^*, \ \text{ and } \mathrm{v}_t - D\mathrm{j}_t^* \mathrm{z}_t \in D_{j_t}^\perp. \end{cases} \tag{18}$$

These equations are not complete yet (in the sense that they cannot be solved from the initial values (j_0, v_0, z_0)) since they provide no information on the choice of $\mathrm{v}_t - D\mathrm{j}_t^* \mathrm{z}_t$ at time t (unless of course $D_{j_t}^\perp = \{0\}$). We need to specify the mode of propagation of this singular component along a geodesic. The following computation provides a hint on possible ways to achieve this. Assume that j is pregeodesic and $(\mathrm{v}_t, \mathrm{z}_t) = \overline{p}(\frac{d\mathrm{j}}{dt})$. In such a case, we have

$$|\mathrm{z}_s|_2^2 = \int_\Omega |z_0 \circ \varphi^{\mathrm{v}}_{s,0}|^2 |d\varphi^{\mathrm{v}}_{s,0}|^2 dx = \int_\Omega |z_0|^2 |d\varphi^{\mathrm{v}}_{0,s}|^{-1} dy$$

and

$$z_0(x) = \frac{1}{\sigma^2}(j_1 \circ \varphi^{\mathrm{v}}_{0,1}(x) - j_0(x)) \int_0^1 |d\varphi^{\mathrm{v}}_{0,s}|^{-1} ds.$$

Thus

$$\int_0^1 |\mathrm{z}_s|_2^2\, ds = \frac{1}{\sigma^4} \int_\Omega \frac{\left|j_1 \circ \varphi^{\mathrm{v}}_{0,1} - j_0\right|^2}{\int_0^1 |d\varphi^{\mathrm{v}}_{0,s}|^{-1} ds}.$$

Making the change of variables $y = \varphi^{\mathrm{v}}_{0,1}(x)$ yields

$$\int_0^1 |z_s|_2^2\, ds = \frac{1}{\sigma^4} \int_\Omega \frac{\left|j_1 - j_0 \circ \varphi^{\mathrm{v}}_{1,0}\right|^2}{\int_0^1 |d_{\varphi^{\mathrm{v}}_{1,0}(x)} \varphi^{\mathrm{v}}_{0,s}|^{-1} |d\varphi^{\mathrm{v}}_{1,0}(x)|^{-1} ds},$$

i.e.,

$$\int_0^1 |\mathrm{z}_s|_2^2\, ds = \frac{1}{\sigma^4} \int_\Omega \frac{\left|j_1 - j_0 \circ \varphi^{\mathrm{v}}_{1,0}\right|^2}{\int_0^1 |d\varphi^{\mathrm{v}}_{1s}|^{-1} ds},$$

and the geodesic energy is given by

$$\int_0^1 |\mathrm{v}_s|_{\mathcal{B}}^2\, ds + \frac{1}{\sigma^2} \int_\Omega \frac{\left|j_1 - j_0 \circ \varphi^{\mathrm{v}}_{1,0}\right|^2}{\int_0^1 |d\varphi^{\mathrm{v}}_{1,s}|^{-1} ds}. \tag{19}$$

We can obtain more precise information on the geodesic by studying variations of this expression with respect to v. This will be handled below, under a smoothness assumption on j_0. Before this, we need some notation for the reproducing kernel on $\mathcal{B}$. They will be useful throughout the paper.

Kernels for the inner-product on $\mathcal{B}$.

PROPOSITION 5. *There exists a continuous operator K (resp., K_∇) on $L^1(\Omega, \mathbb{R}^k)$ (resp., $L^1(\Omega, \mathbb{R})$) with values in $\mathcal{B}$ such that, for all $u \in L^1(\Omega, \mathbb{R}^k)$ (resp., $u \in L^1(\Omega, \mathbb{R})$), for all $v \in \mathcal{B}$,*

$$\langle Ku\, ,\, v\rangle_{\mathcal{B}} = \langle u, v\rangle_2,$$

and

$$\langle K_\nabla u\, ,\, v\rangle_{\mathcal{B}} = -\langle u, \mathrm{div} v\rangle_2.$$

Proof of Proposition 5. Let $u \in L^1(\Omega, \mathbb{R}^k)$. Since we assume that $\mathcal{B}$ is continuously embedded in C_0^1, the linear form defined on $\mathcal{B}$ by $v \mapsto \langle u, v\rangle_2$ is continuous because $|\langle u, v\rangle_2| \le |u|_1\, |v|_\infty$. Therefore, there exists a unique element in $\mathcal{B}$, denoted Ku, such that, for all $v \in \mathcal{B}$, $\langle Ku\, ,\, v\rangle_{\mathcal{B}} = \langle u, v\rangle_2$ and continuity comes from the inequality $\langle Ku\, ,\, v\rangle_{\mathcal{B}} \le |u|_1\, |v|_\infty \le \mathrm{cst}\ |u|_1\, |v|_{\mathcal{B}}$.

The same proof holds for K_∇, since $|\mathrm{div} v|_\infty$ is also controlled by $|v|_{\mathcal{B}}$. ∎

It can be remarked that, for smooth u, $K_\nabla u = K(\nabla u)$.

Remark 4. When j is smooth (e.g., $j \in H^1(\Omega, \mathbb{R}^d)$), the operator Dj^* introduced in the previous paragraph is given by $Dj^* z = K(dj^*.z)$, in which dj^* is the standard matrix adjoint of dj. Indeed, we have in this case

$$\langle z\, ,\, Dj.v\rangle_2 = \langle z\, ,\, dj.v\rangle_2 = \langle dj^*.z\, ,\, v\rangle_2 = \langle K(dj^*.z)\, ,\, v\rangle_{\mathcal{B}}.$$

Characterization with a smooth endpoint. We study the effect of small variations in v on the geodesic energy (19), under the additional hypothesis that $j_0 \in H^1(\Omega, \mathbb{R}^d)$. Thus, fix $h \in L^2([0,1], \mathcal{B})$, and consider a perturbation $\mathrm{v} + \varepsilon h$ of v. We compute the corresponding variation of the geodesic energy. The variation of the first term being $2\int_0^1 \langle \mathrm{v}_t \, , \, h_t \rangle_{\mathcal{B}} dt$, we can focus on the second term, namely,

$$U^\varepsilon \triangleq \frac{1}{\sigma^2} \int_\Omega \frac{\left| j_0 \circ \varphi_{1,0}^{\mathrm{v}+\varepsilon h} - j_1 \right|^2}{\int_0^1 |d\varphi_{1s}^{\mathrm{v}+\varepsilon h}|^{-1} ds} dx.$$

The variations of U^ε are given in Lemma 2, which is proved in Appendix E.

LEMMA 2. *We have, at $\varepsilon = 0$,*

$$\frac{dU^\varepsilon}{d\varepsilon} = \sigma^2 \int_0^1 \left\langle \Big(K_\nabla (q_t^{\mathrm{v}} \left|\mathrm{z}_t\right|^2) + K(\left|\mathrm{z}_t\right|^2 \nabla q_t^{\mathrm{v}}) \Big) + 2K([d\varphi_{t,0}^{\mathrm{v}}]^* d_{\varphi_{t,0}^{\mathrm{v}}} j_0^* \mathrm{z}_t), h_t \right\rangle_{\mathcal{B}} dt, \tag{20}$$

with $q_t^{\mathrm{v}} = \int_0^t |d\varphi_{t,s}^{\mathrm{v}}|^{-1} ds$.

We can deduce from this our additional condition for a regular path to be a minimizing geodesic: for almost all $t \in [0,1]$,

$$\mathrm{v}_t + \frac{1}{2} (K D_t^{\mathrm{v}} + K_\nabla C_t^{\mathrm{v}})_{\mathcal{B}} = 0,$$

where

$$D_t^{\mathrm{v}} \triangleq \sigma^2 \left|\mathrm{z}_t\right|^2 \nabla q_t^{\mathrm{v}} + 2[d\varphi_{t,0}^{\mathrm{v}}]^* d_{\varphi_{t,0}^{\mathrm{v}}} j_0^* \mathrm{z}_t,$$

and

$$C_t^{\mathrm{v}} \triangleq \sigma^2 q_t^{\mathrm{v}} \left|\mathrm{z}_t\right|^2.$$

It may be interesting to check that this condition boils down to the one we have obtained before for smooth trajectories, namely,

$$\mathrm{v}_t + K(dj_t^* \mathrm{z}_t) = 0.$$

It suffices to notice that, for pregeodesic trajectories, $j_t = j_0 \circ \varphi_{t,0}^{\mathrm{v}} + \sigma^2 \mathrm{z}_t q_t^{\mathrm{v}}$ and that, when z_t is smooth,

$$K D_t^{\mathrm{v}} + K_\nabla C_t^{\mathrm{v}} = K(D_t^{\mathrm{v}} + \nabla C_t^{\mathrm{v}}).$$

We now define geodesic paths (not necessarily minimizing).

DEFINITION 10. *Let $j_0 \in H^1(\Omega, \mathbb{R}^d)$. A regular path $\mathrm{j} \in H^1([0,1], \mathcal{J}_W)$ starting at j_0 is called a geodesic path if and only if there exists $\mathrm{w} = (\mathrm{v}, \mathrm{z}) \in L^2([0,1], W)$ such that the following equations are satisfied almost everywhere in t:*

$$\begin{cases} \mathrm{j}_t = \mathrm{j}_0 \circ \varphi_{t,0}^{\mathrm{v}} + \sigma^2 \displaystyle\int_0^t \mathrm{z}_s \circ \varphi_{t,s}^{\mathrm{v}} ds, \\ \mathrm{z}_t = \mathrm{z}_0 \circ \varphi_{t,0}^{\mathrm{v}} \left| d\varphi_{t,0}^{\mathrm{v}} \right|, \\ \mathrm{v}_t + K([d\varphi_{t,0}^{\mathrm{v}}]^* d_{\varphi_{t,0}^{\mathrm{v}}} j_0^* \mathrm{z}_t) + \dfrac{\sigma^2}{2} \Big(K_\nabla (q_t^{\mathrm{v}} \left|\mathrm{z}_t\right|^2) + K(\left|\mathrm{z}_t\right|^2 \nabla q_t^{\mathrm{v}}) \Big) = 0, \end{cases} \tag{21}$$

with $q^{\mathrm{v}}_t = \int_0^t |d\varphi^{\mathrm{v}}_{t,s}|^{-1} ds$.

These equations are complete; it will be shown in section 7 that initial conditions (j_0, z_0) uniquely specify the solutions. It is interesting to check that geodesics as defined in (21) also are pregeodesics. For this, we first show that, for all times t, $z_t \in \mathcal{D}^*_{j_t}$. Noting that the first equation in (21) may also be written

$$\mathrm{j}_t = \mathrm{j}_0 \circ \varphi^{\mathrm{v}}_{t,0} + \sigma^2 \mathrm{z}_t q_t$$

it is clear that $\mathcal{D}_{j_t} = D_{z_t}$, and $z_t \in D^*_{z_t}$ is proved in Lemma 1. The same lemma also provides the fact that, for $w \in \mathcal{D}_{z_t}$,

$$\langle z_t\,,\, Dj_t w\rangle_2 = \langle z_t\,,\, d(\mathrm{j}_0 \circ \varphi^{\mathrm{v}}_{t,0})w\rangle_2 + \sigma^2 \Big\langle |z_t|^2 \,\nabla q_t\,,\, w\Big\rangle_2 - \frac{\sigma^2}{2}\Big\langle |z_t|^2\,,\, \mathrm{div}(q^{\mathrm{v}}_t w)\Big\rangle,$$

and this is equal to $-\langle \mathrm{v}_t\,,\, w\rangle_{\mathcal{B}}$ by definition of K and K_∇. We thus obtain the fact that $v_t + Dj_t^* z_t \in D^\perp_{j_t}$ as required.

We shall prove existence of solutions for a broader class of evolution equations, extending the range of initial values v_0. Consider the term $\mathrm{u}_t = K([d\varphi^{\mathrm{v}}_{t,0}]^* d_{\varphi^{\mathrm{v}}_{t,0}} j_0^* \mathrm{z}_0 \circ \varphi^{\mathrm{v}}_{t,0}\,|d\varphi^{\mathrm{v}}_{t,0}|)$ which appears in the third equation of (21). We have, letting $\omega_0 = -dj_0^* z_0$, and, for $w \in \mathcal{B}$,

$$\begin{aligned}\langle \mathrm{u}_t\,,\, w\rangle_{\mathcal{B}} &= \Big\langle [d\varphi^{\mathrm{v}}_{t,0}]^* d_{\varphi^{\mathrm{v}}_{t,0}} j_0 \mathrm{z}_0 \circ \varphi^{\mathrm{v}}_{t,0}\,|d\varphi^{\mathrm{v}}_{t,0}|\,,\, w\Big\rangle_{L^2}\\ &= \Big\langle d_{\varphi^{\mathrm{v}}_{t,0}} j_0 \mathrm{z}_0 \circ \varphi^{\mathrm{v}}_{t,0}\,|d\varphi^{\mathrm{v}}_{t,0}|\,,\, d\varphi^{\mathrm{v}}_{t,0} w\Big\rangle_{L^2}\\ &= \langle \omega_0\,,\, (d\varphi^{\mathrm{v}}_{0,t})^{-1} w \circ \varphi^{\mathrm{v}}_{0,t}\rangle_{L^2}.\end{aligned}$$

We know, by Appendix C, that $\varphi^{\mathrm{v}}_{0,t}$ belongs to $C^p(\overline{\Omega})$ as soon as $\mathcal{B}$ is continuously embedded in $C^p_0(\Omega, \mathbb{R}^k)$, which implies in this case (with $p \geq 1$) that

$$\big|(d\varphi^{\mathrm{v}}_{0,t})^{-1} w \circ \varphi^{\mathrm{v}}_{0,t}\big|_{p-1,\infty} \leq \mathrm{Const}\, |w|_{\mathcal{B}}\,,$$

the constant depending on $|v|_{1,\mathcal{B}}$. But this implies in turn that, if the L^2 inner product is replaced by the action of any continuous functional, ω_0, on $C^{p-1}_0(\Omega, \mathbb{R}^k)$, which will be denoted

$$\big(\omega_0, (d\varphi^{\mathrm{v}}_{0,t})^{-1} w \circ \varphi^{\mathrm{v}}_{0,t}\big),$$

there exists an element of $\mathcal{B}$ that we shall still denote u_t such that

$$\langle u_t\,,\, w\rangle_{\mathcal{B}} = \big(\omega_0, (d\varphi^{\mathrm{v}}_{0,t})^{-1} w \circ \varphi^{\mathrm{v}}_{0,t}\big).$$

With this notation, we may formulate the following definition.

DEFINITION 11. *Let* $j_0 \in L^2(\Omega, \mathbb{R}^d)$. *Let* ω_0 *be a continuous linear functional on* $C^{p-1}(\Omega, \mathbb{R}^k)$ *and* $z_0 \in L^2(\Omega, \mathbb{R}^d)$. *A regular path* $\mathrm{j} \in H^1([0,1], \mathcal{J}_W)$ *starting at* j_0 *with initial direction* (ω_0, z_0) *is called a generalized geodesic if and only if, for all* $u \in \mathcal{D}_{j_0}$, *one has*

$$(\omega_0, u) + \langle z_0\,,\, Dj_0 u\rangle = 0,$$

and there exists $\mathrm{w} = (\mathrm{v}, \mathrm{z}) \in L^2([0,1], W)$ *such that the following equations are satisfied almost everywhere in* t*:*

$$
\begin{cases}
\mathrm{j}_t = \mathrm{j}_0 \circ \varphi^{\mathrm{v}}_{t,0} + \sigma^2 \displaystyle\int_0^t \mathrm{z}_s \circ \varphi^{\mathrm{v}}_{t,s} ds, \\
\mathrm{z}_t = \mathrm{z}_0 \circ \varphi^{\mathrm{v}}_{t,0} \left| d\varphi^{\mathrm{v}}_{t,0} \right|, \\
\mathrm{v}_t - \mathrm{u}^{\mathrm{v}}_t + \dfrac{\sigma^2}{2} \Big(K_\nabla (q^{\mathrm{v}}_t \left|\mathrm{z}_t\right|^2) + K(\left|\mathrm{z}_t\right|^2 \nabla q^{\mathrm{v}}_t) \Big) = 0, \\
\forall w \in \mathcal{B} \ \langle \mathrm{u}^{\mathrm{v}}_t \,,\, w \rangle_{\mathcal{B}} = \big(\omega_0, (d\varphi^{\mathrm{v}}_{0,t})^{-1} w \circ \varphi^{\mathrm{v}}_{0,t} \big)
\end{cases}
\tag{22}
$$

with $q^{\mathrm{v}}_t = \int_0^t |d\varphi^{\mathrm{v}}_{t,s}|^{-1} ds$.

Recall that when j_0 is smooth, the only choice is $\omega_0 = dj_0^* z_0$, and if z_0 is also smooth, the system may be written under the simple form

$$
\begin{cases}
\mathrm{j}_t = \mathrm{j}_0 \circ \varphi^{\mathrm{v}}_{t,0} + \sigma^2 \displaystyle\int_0^t \mathrm{z}_s \circ \varphi^{\mathrm{v}}_{t,s} ds, \\
\mathrm{z}_t = \mathrm{z}_0 \circ \varphi^{\mathrm{v}}_{t,0} \left| d\varphi^{\mathrm{v}}_{t,0} \right|, \\
\mathrm{v}_t + \sigma^2 K(dj_t^* z_t) = 0.
\end{cases}
\tag{23}
$$

As an example of the nonsmooth applications we have in mind, assume that j_0 is a binary, plane image, which is the indicator function of the interior of a connected open subset Ω_1 of Ω with smooth boundary $\partial\Omega_1$. We have seen that any element $w \in \mathcal{D}_{j_0}$ should be tangent to $\partial\Omega_1$ and that in this case $Dj_0 w = 0$ and $\mathcal{D}^*_{j_0} = L^2(\Omega, \mathbb{R})$. We therefore may choose z_0 arbitrarily in L^2, and (ω_0, w) should vanish for $w \in \mathcal{D}_{j_0}$, which is true, for example, when ω_0 is defined by

$$
(\omega_0, w) = \int_{\partial\Omega_1} \langle w \,,\, \nu_1 \rangle d\sigma_1,
$$

where ν_1 is the outward normal to $\partial\Omega_1$ and σ_1 is the surface measure on $\partial\Omega_1$.

6. Existence of minimizing geodesics. The next theorem states that minimizing geodesics always exist between two elements of $\mathcal{J}_W$.

THEOREM 6. *Assume that* $\mathcal{B}$ *is compactly embedded in* $C^1_0(\Omega, \mathbb{R}^d)$*, and let* $j_0, j_1 \in \mathcal{J}_W$*. Then* $G_{\mathcal{J}_W}(j_0, j_1)$ *is nonempty.*

Proof. Let $(\mathrm{j}^n)_{n\in\mathbb{N}}$ be a minimizing family of paths in $H^1([0,1], \mathcal{J}_W)$ from j_0 to j_1; for any $n \in \mathbb{N}$, let $\mathrm{w}^n_t \triangleq \overline{p}(\frac{d\mathrm{j}^n}{dt})$ so that $(\mathrm{w}^n)_{n\in\mathbb{N}}$ is a bounded sequence in $L^2([0,1], W)$. Up to the extraction of a subsequence, we can assume that w^n converges weakly to a w^∞ in $L^2([0,1], W)$. By lower semicontinuity, we have

$$
\int_0^1 |\mathrm{w}^\infty_t|^2_W dt \leq d_{\mathcal{J}_W}(j_0, j_1).
$$

By a time change argument, which is classical in the proof that minimizing geodesics travel at constant speed (see [12]), we may furthermore assume that $|\mathrm{w}^n_t|_W$ is uniformly bounded by, say, $d_{\mathcal{J}_W}(j_0, j_1) + 1$. Denoting $w^n = (\mathrm{v}^n, \mathrm{z}^n)$, consider $\mathrm{j}'_t \triangleq j_0 \circ \varphi^\infty_{t,0} + \sigma^2 \int_0^t \mathrm{z}^\infty_s \circ \varphi^\infty_{t,s} ds$, where φ^∞ is the flow associated to v^∞. Since j'

is a regular path, it is sufficient to prove that $\mathrm{j}_1' = j_1$. However, if φ^n denotes the flow associated with v^n, we know, from Theorem 9, that $\varphi^n_{1,0}$ converges uniformly to $\varphi^\infty_{1,0}$ so that $j_0 \circ \varphi^n_{t,0} \to j_0 \circ \varphi^\infty_{t,0}$ in $L^2(\Omega, \mathbb{R}^d)$. Now, let $u \in C_c^\infty(\Omega, \mathbb{R}^d)$. We have $\int_0^1 \langle \mathrm{z}^n_s \circ \varphi^n_{1,s}, u\rangle_2 ds = \int_0^1 \langle \mathrm{z}^n_s, u \circ \varphi^n_{s,1} \left|d\varphi^n_{s,1}\right|\rangle_2 ds$. Since u has bounded derivatives and using Theorem 9 implies the uniform convergence of φ^n_{s1} to φ^∞_{s1} and the pointwise convergence of the derivatives (because of the uniform boundedness of $|v^n_s|_{\mathcal{B}}$), we have

$$\int_0^1 \langle \mathrm{z}^n_s, u \circ \varphi^n_{s,1} \left|d\varphi^n_{s,1}\right|\rangle_2 ds - \int_0^1 \langle \mathrm{z}^n_s, u \circ \varphi^\infty_{s,1} \left|d\varphi^\infty_{s,1}\right|\rangle_2 ds \to 0. \tag{24}$$

Moreover, from the weak convergence of z^n to z^∞, we get

$$\int_0^1 \langle \mathrm{z}^n_s, u \circ \varphi^\infty_{s,1} \left|d\varphi^\infty_{s,1}\right|\rangle_2 ds \to \int_0^1 \langle \mathrm{z}^\infty_s, u \circ \varphi^\infty_{s,1} \left|d\varphi^\infty_{s,1}\right|\rangle_2 ds, \tag{25}$$

so that finally $\langle \mathrm{j}_1 - \mathrm{j}_1', u\rangle_2 = 0$ for any $u \in C_c^\infty(\Omega, \mathbb{R}^d)$. Hence $\mathrm{j}' \in H^1([0,1], \mathcal{J}_W)$ and the result is proved. ∎

7. Initial value problem for the geodesic equation. We have the following theorem.

THEOREM 7. *Assume that $\mathcal{B}$ is continuously embedded in $C_0^p(\Omega, \mathbb{R}^p)$ for $p \geq 3$. Then, for all $T > 0$, there exists a unique solution $(\mathrm{v}, \mathrm{j}, \mathrm{z})$ of (21) over $[0,T]$, with initial values $j_0 \in H^1(\Omega, \mathbb{R}^d)$, $z_0 \in L^2(\Omega, \mathbb{R}^d)$, and $\omega_0 \in C^{p-1}([0,1], \mathbb{R}^k)'$ (where $C^{p-1}([0,1], \mathbb{R}^k)'$ denotes the topological dual of $C^{p-1}([0,1], \mathbb{R}^k)$ with the norm $|\omega| \triangleq \sup_{|v|_{p-1,\infty} \leq 1} (\omega, v)$) which continuously depends on these initial conditions.*

Continuity of the solution $(\mathrm{v}, \mathrm{j}, \mathrm{z})$ as a function of (j_0, z_0) is meant according to $H^1(\Omega, \mathbb{R}^d) \times L^2(\Omega, \mathbb{R}^d)$-norms for the initial conditions, $L^2([0,T], W)$-norm for (v, z), and $C([0,1], L^2(\Omega, \mathbb{R}^d))$-norm for j.

8. Proof of Theorem 7. To prove Theorem 7, we show the existence of solutions for short time and then extend them to all time. Fix $T > 0$. For a given $\mathrm{v} \in L^2([0,T], \mathcal{B})$, let $\Psi(\mathrm{v}) \in L^2([0,T], \mathcal{B})$ be defined by

$$\begin{cases} \Psi(\mathrm{v})_t = \mathrm{u}^v_t - \dfrac{\sigma^2}{2}\left(K_\nabla(q^{\mathrm{v}}_t \left|\mathrm{z}^{\mathrm{v}}_t\right|^2) + K(\left|\mathrm{z}^{\mathrm{v}}_t\right|^2 \nabla q^{\mathrm{v}}_t)\right), \\ \mathrm{z}^{\mathrm{v}}_t = \mathrm{z}_0 \circ \varphi^{\mathrm{v}}_{t,0} \left|d\varphi^{\mathrm{v}}_{t,0}\right|, \\ \langle \mathrm{u}^v_t\, ,\, w\rangle_{\mathcal{B}} = \left(\omega_0, (d\varphi^{\mathrm{v}}_{0,t})^{-1} w \circ \varphi^{\mathrm{v}}_{0,t}\right). \end{cases} \tag{26}$$

To estimate the Lipschitz coefficient of Ψ, we introduce $\mathrm{v}, \mathrm{v}' \in L^1([0,T], \mathcal{B})$ and compute the variation of each term in $\Psi(\mathrm{v})_t - \Psi(\mathrm{v}')_t$. Fix $w \in \mathcal{B}$ with $|w|_{\mathcal{B}} = 1$. We have

$$\begin{aligned} \langle \Psi(\mathrm{v})_t\, ,\, w\rangle_{\mathcal{B}} =& \frac{\sigma^2}{2}\left\langle \left|z^v_t\right|^2, \, q^{\mathrm{v}}_t \operatorname{div}(w)\right\rangle_2 - \frac{\sigma^2}{2}\left\langle \left|z^v_t\right|^2, \, dq^{\mathrm{v}}_t w\right\rangle_2 + \left(\omega_0, (d\varphi^{\mathrm{v}}_{0,t})^{-1} w \circ \varphi^{\mathrm{v}}_{0,t}\right) \\ =& \left(\omega_0, (d\varphi^{\mathrm{v}}_{0,t})^{-1} w \circ \varphi^{\mathrm{v}}_{0,t}\right) + \frac{\sigma^2}{2}\left\langle |z_0|^2, \, \left|d\varphi^{\mathrm{v}}_{0,t}\right|^{-1} q^{\mathrm{v}}_t \circ \varphi^{\mathrm{v}}_{0,t} \operatorname{div}(w) \circ \varphi^{\mathrm{v}}_{0,t}\right\rangle_2 \\ & - \frac{\sigma^2}{2}\left\langle |z_0|^2, \, \left|d\varphi^{\mathrm{v}}_{0,t}\right|^{-1} d_{\varphi^{\mathrm{v}}_{0,t}} q^{\mathrm{v}}_t w \circ \varphi^{\mathrm{v}}_{0,t}\right\rangle_2. \end{aligned} \tag{27}$$

We have

$$q_t^{\mathrm{v}} \circ \varphi_{0,t}^{\mathrm{v}}(x) = \int_0^t \left| d_{\varphi_{0,t}^{\mathrm{v}}(x)} \varphi_{t,s}^{\mathrm{v}} \right|^{-1} ds = \int_0^t \left| d_{\varphi_{0,s}^{\mathrm{v}}(x)} \varphi_{s,t}^{\mathrm{v}} \right| ds = \int_0^t \frac{\left| d_x \varphi_{0,t}^{\mathrm{v}} \right|}{\left| d_x \varphi_{0,s}^{\mathrm{v}} \right|} ds,$$

and letting $\xi_{s,t}^{\mathrm{v}} = \frac{\left| d_x \varphi_{0,t}^{\mathrm{v}} \right|}{\left| d_x \varphi_{0,s}^{\mathrm{v}} \right|}$ and $\lambda_t^{\mathrm{v}}(w) = (d\varphi_{0,t}^{\mathrm{v}})^{-1} w \circ \varphi_{0,t}^{\mathrm{v}}$,

(28)

$$\begin{aligned} \langle \Psi(\mathrm{v})_t \,,\, w \rangle_{\mathcal{B}} = \frac{\sigma^2}{2} \int_0^t \Big\langle |z_0|^2 \,,\, (\left| d\varphi_{0,s}^{\mathrm{v}} \right|^{-1} \operatorname{div}(w) \circ \varphi_{0,t}^{\mathrm{v}} - \left| d\varphi_{0,t}^{\mathrm{v}} \right|^{-1} \left\langle \nabla \xi_{s,t}^{\mathrm{v}} \,,\, \lambda_t^{\mathrm{v}}(w) \right\rangle) \Big\rangle ds \\ +(\omega_0, \lambda_t^{\mathrm{v}}(w)). \end{aligned}$$

This implies

$$\begin{aligned} |\Psi(\mathrm{v}')_t - \Psi(\mathrm{v})_t|_{\mathcal{B}} \le \frac{\sigma^2}{2} |z_0|_2^2 \sup \Bigg\{ \int_0^t \Bigg(& \left| d\varphi_{0,s}^{\mathrm{v}} \right|^{-1} \operatorname{div}(w) \circ \varphi_{0,t}^{\mathrm{v}} \\ & - \left| d\varphi_{0,s}^{\mathrm{v}'} \right|^{-1} \operatorname{div}(w) \circ \varphi_{0,t}^{\mathrm{v}'} \Bigg) ds : |w|_{\mathcal{B}} = 1 \Bigg\} \\ + \frac{\sigma^2}{2} |z_0|_2^2 \sup \Bigg\{ \int_0^t \Bigg(& \left| d\varphi_{0,t}^{\mathrm{v}} \right|^{-1} \left\langle \nabla \xi_{s,t}^{\mathrm{v}} \,,\, \lambda_t^{\mathrm{v}}(w) \right\rangle \\ & - \left| d\varphi_{0,t}^{\mathrm{v}'} \right|^{-1} \left\langle \nabla \xi_{s,t}^{\mathrm{v}'} \,,\, \lambda_t^{\mathrm{v}'}(w) \right\rangle \Bigg) ds : |w|_{\mathcal{B}} = 1 \Bigg\} \\ + |\omega_0| \sup \Bigg\{ & \left| \lambda_t^{\mathrm{v}}(w) - \lambda_t^{\mathrm{v}'}(w) \right|_{p-1,\infty} : |w|_{\mathcal{B}} = 1 \Bigg\}. \end{aligned}$$

The problem is thus reduced to the estimation of variations, with respect to v, of $\lambda_t^{\mathrm{v}}(w)$, $\nabla \xi_{s,t}^{\mathrm{v}}$ and of $\left| d\varphi_{0,s}^{\mathrm{v}} \right|^{-1} \operatorname{div}(w) \circ \varphi_{0,t}^{\mathrm{v}}$. They involve differentials of φ^{v}, $\varphi^{\mathrm{v}'}$, and w up to the second degree. The inclusion of $\mathcal{B}$ in $C^3([0,1], \mathbb{R}^k)$ and an application of Lemmas 7 and 11 in the appendix directly lead to the estimate

$$|\Psi(\mathrm{v})_t - \Psi(\mathrm{v}')_t|_{\mathcal{B}} \le C \left(\sigma^2 |z_0|_2^2 + |\omega_0| \right) |\mathrm{v} - \mathrm{v}'|_{1,T} \, e^{C' \max(|\mathrm{v}|_{1,T}, |\mathrm{v}'|_{1,T})}, \tag{29}$$

and finally

$$\begin{aligned} |\Psi(\mathrm{v}) - \Psi(\mathrm{v}')|_{2,T} &\le C\sqrt{T} \left(\sigma^2 |z_0|_2^2 + |\omega_0| \right) |\mathrm{v} - \mathrm{v}'|_{1,T} \, e^{C' \max(|\mathrm{v}|_{1,T}, |\mathrm{v}'|_{1,T})} \\ &\le CT \left(\sigma^2 |z_0|_2^2 + |\omega_0| \right) |\mathrm{v} - \mathrm{v}'|_{2,T} \, e^{C'\sqrt{T} \max(|\mathrm{v}|_{2,T}, |\mathrm{v}'|_{2,T})}. \end{aligned} \tag{30}$$

Therefore, Ψ is q-Lipschitz with $q < 1$ for T small enough, and its unique fixed point yields a unique solution of (21). This is stated below.

LEMMA 3. *There exists a time $T > 0$ depending only on $|z_0|_2$ and $|j_0|_{H^1}$ such that a unique solution of* (21) *exists on* $[0,T]$.

We now show that this solution can be extended to all times. For this, we prove that there exists a unique fixed point for Ψ at all times. Denote by Ψ_T this mapping when defined on $L^2([0,T], \mathcal{B})$. Clearly, if v is a fixed point of Ψ_T, its restriction to $[0,S]$ is a fixed point of Ψ_S. Thus, if T_0 is the largest T such that Ψ_S has a unique fixed point v^S in $L^2([0,S], \mathcal{B})$ for any $S < T$, then each v^T for $T < T_0$ is an extension of v^S whenever $S \le T$. We can show that $T_0 = \infty$ by showing that, if $T_0 < \infty$, then there exists $\varepsilon > 0$ (depending only on T_0 and the initial conditions) such that, for all $T < T_0$, there exists a unique extension of v^T to $[T, T+\varepsilon]$. Fix such a T; the issue of extending a fixed point of Ψ_T on $[T, T+\varepsilon]$ can be rephrased as a fixed point problem for small time with the following notation. For $\mathrm{v} \in L^2([0,T], \mathcal{B})$ and $\mathrm{v}' \in L^2([0,\varepsilon], \mathcal{B})$, define $\mathrm{v} \vee \mathrm{v}' \in L^2([0, T+\varepsilon], \mathcal{B})$, equal to v on $[0,T]$ and equal to $(t \mapsto \mathrm{v}'(t-T))$ on $[T, T+\varepsilon]$. Introduce the function $\Psi^\varepsilon : L^2([0,\varepsilon], \mathcal{B}) \to L^2([0,\varepsilon], \mathcal{B})$ defined by

$$\Psi^\varepsilon(\mathrm{v})(t) = \Psi_{T+\varepsilon}(\mathrm{v}^T \vee \mathrm{v})(t-T).$$

For $t > T$,

$$q_t^{\mathrm{v}^T \vee \mathrm{v}} = q_1^{\mathrm{v}^T} + q_{t-T}^{\mathrm{v}},$$

$\mathrm{z}_t = \mathrm{z}_T \circ \varphi_{Tt}^{\mathrm{v}} |d\varphi_{Tt}^{\mathrm{v}}|^{-1}$, and

$$\begin{aligned}
\langle \mathrm{u}_t^{\mathrm{v}}\,,\, w\rangle_{\mathcal{B}} &= \big(\omega_0, (d\varphi_{0,t}^{\mathrm{v}})^{-1} w \circ \varphi_{0,t}^{\mathrm{v}}\big) \\
&= \Big(\omega_0, (d\varphi_{0,T}^{\mathrm{v}})^{-1} (d_{\varphi_{0,T}^{\mathrm{v}}} \varphi_{Tt}^{\mathrm{v}})^{-1} w \circ \varphi_{Tt}^{\mathrm{v}} \circ \varphi_{0,T}^{\mathrm{v}}\Big) \\
&= \big(\omega_T, d\varphi_{Tt}^{\mathrm{v}})^{-1} w \circ \varphi_{Tt}^{\mathrm{v}}\big)
\end{aligned}$$

with $(\omega_T, w) = \big(\omega_0, (d\varphi_{0,T}^{\mathrm{v}})^{-1} w \circ \varphi_{0,T}^{\mathrm{v}}\big)$. It is clear that the study of Ψ^ε can follow exactly the lines of the study of Ψ_T, yielding a unique fixed point if ε is small enough, the size of admissible ε being controlled by the L^2-norms of z_T and the norm of ω_T as a linear form on $C_0^{p-1}(\Omega, \mathbb{R}^k)$. These norms can in turn be bounded by the L^2-norms of z_0 and the norm of ω_0, respectively, multiplied by a continuous function of $\max(|\varphi_{0,T}^{\mathrm{v}^T}|_{1,\infty}, |\varphi_{T,0}^{\mathrm{v}^T}|_{1,\infty})$. Proving that this is uniformly bounded for $T < T_0$ is therefore sufficient to get the contradiction we aim for, that is, that the solution can be uniquely extended beyond T_0.

So, everything relies on proving the uniform boundedness of $\varphi_{0,T}^{\mathrm{v}^T}$, $\varphi_{T,0}^{\mathrm{v}^T}$, and their derivatives over Ω. By Lemmas 7 and 9, these quantities are bounded by functions of $|\mathrm{v}^T|_{1,T}$ so that we have to prove that these can be bounded uniformly in T. However, it suffices to use the facts that v^T satisfies a geodesic equation and that geodesics travel at constant speed. More precisely, defining, for $t \le T < T_0$,

$$\psi_t = \left|\mathrm{v}_t^T\right|_{\mathcal{B}}^2 + \sigma^2 \left|\mathrm{z}_t\right|_2^2,$$

we have (recall that this does not depend on T as soon as $T \ge t$) $\psi_t \equiv \psi(0)$ so that

$$\left|\mathrm{v}^T\right|_{1,T} \le T\psi(0)$$

for all T. It is well known that *minimizing* geodesics have constant speed, but we must check that this property remains true for all the solutions of (22). This is proved in the appendix and is stated, for further reference, in the next lemma.

LEMMA 4. *If (j, v, z) is a solution of system* (22) *on $[0, T[$, then $|v_t|_{\mathcal{B}}^2 + \sigma^2 |z_t|_2^2$ is constant with respect to time.*

To prove the continuity of the solution, let (v, j, z) and (v', j', z') be two solutions of system (22) with initial conditions (ω_0, z_0) and (ω_0', z_0'), respectively. Using, in particular, the computation leading from (28) to (29), it is not to difficult to obtain the estimate

$$\begin{aligned}
|v_t - v_t'|_{\mathcal{B}} \le C &\left(|\omega_0 - \omega_0'| + \frac{\sigma^2}{2} \left||z_0|^2 - |z_0'|^2\right|\right) e^{C|\mathrm{v}|_{1,T}} \\
&+ C\left(\sigma^2 |z_0'|_2^2 + |\omega_0'|\right) |\mathrm{v} - \mathrm{v}'|_{1,T}\, e^{C|\mathrm{v}'|_{1,T}}.
\end{aligned}$$

As we just have shown, $|\mathrm{v}|_{1,T} = T\,|\mathrm{v}_0|_{\mathcal{B}}$, and this is smaller (up to a universal multiplicative constant) than $|\omega_0|$ so that

$$\begin{aligned} |v_t - v_t'|_{\mathcal{B}} \le{}& C\left(|\omega_0 - \omega_0'| + \frac{\sigma^2}{2}\left||z_0|^2 - |z_0'|^2\right|\right)e^{CT|\omega_0|} \\ &+ C\left(\sigma^2\,|z_0'|_2^2 + |\omega_0'|\right)|\mathrm{v} - \mathrm{v}'|_{1,T}\,e^{CT|\omega_0'|}. \end{aligned}$$

Gronwall's lemma now allows us to conclude that, for some constant C which may now depend on $T, |\omega_0|\,, |\omega_0'|\,, |z_0|_2$, and $|z_0'|_2$,

$$|v_t - v_t'|_{\mathcal{B}} \le C\left(|\omega_0 - \omega_0'| + \frac{\sigma^2}{2}\left||z_0|^2 - |z_0'|^2\right|\right). \tag{31}$$

9. Normal coordinates in $\ ^{1}$**.** We now consider the question, which motivated this paper, of whether the previous construction could be used as an indexing device for characterizing the deformations and variations of an object relative to a prototype.

Fix an image $j_0 \in H^1(\Omega, \mathbb{R}^d)$. The computationally simplest way to describe an image j in a neighborhood of j_0 is by the difference $j - j_0$. However, one cannot be satisfied with this representation which takes no account of the metric we have placed on $\mathcal{J}_W$. Among local charts related to the metric, normal coordinates on a Riemannian manifold are radial flattenings of this manifold onto its tangent space in the sense that radial lines in this space correspond to geodesics on the manifold. They provide a very efficient linear representation of the manifold and of its metric. Existence of such coordinates is a standard theorem in finite dimensions, and our purpose is to check how much of this result remains valid in our infinite dimensional framework.

In the previous sections, another candidate for local coordinates has emerged, which turns out to be closely related (it is in fact dual) to normal coordinates. We have proved that, for a fixed $j_0 \in H^1(\Omega, \mathbb{R}^d)$, one can associate to any $z_0 \in L^2(\Omega, \mathbb{R}^d)$ a unique solution of system (21). We introduce the function $M_{j_0} : L^2 \to L^2$, which assigns to $z_0 \in L^2$ the "image" j_1, where j_t is the solution of (21) at time t.

The following theorem shows that M_{j_0} shares some features of local coordinates on $\mathcal{J}_W$.

THEOREM 8. *Let $\mathcal{B}_{H^1}(0, \varepsilon)$ denote the open ball in $H^1(\Omega, \mathbb{R}^d)$ containing all $z_0 \in H^1(\Omega, \mathbb{R}^d)$ such that $|z_0|_{H^1} < \varepsilon$. Then, for all $j_0 \in H^1(\Omega, \mathbb{R}^d)$, there exists $\varepsilon > 0$ such that M_{j_0} restricted to $\mathcal{B}_{H^1}(0, \varepsilon)$ is continuous and one-to-one onto its image, equipped with the L^2-topology.*

Proof of Theorem 8. Continuity of $M_{j_0} : L^2(\Omega, \mathbb{R}^d) \to L^2(\Omega, \mathbb{R}^d)$ is a consequence of Theorem 7, and it trivially implies the continuity of the restriction $M_{j_0} : H^1(\Omega, \mathbb{R}^d) \to L^2(\Omega, \mathbb{R}^d)$ for the $H^1(\Omega, \mathbb{R}^d)$-topology. We show that this map is one-to-one in a neighborhood of 0. We first have the following lemma.

LEMMA 5. *Let $j_0, z_0, \tilde{z}_0 \in H^1(\Omega, \mathbb{R}^d)$, with $\max(|z_0|_{H^1}\,, |\tilde{z}_0|_{H^1}) \le 1$. Denote $\tilde{\mathrm{v}}$ the time-dependent vector field along the solution of (21) with initial condition $(j_0, \tilde{z}_0)$. Then, there exist a constant C and a function ε which depend only on j_0 such that, for $t > 0$,*

$$\begin{aligned} &\left|(M_{j_0}(t\tilde{z}_0) - M_{j_0}(tz_0)) \circ \varphi_{0,t}^{\tilde{\mathrm{v}}} - t[\sigma^2(\tilde{z}_0 - z_0) + dj_0 K(dj_0^*(\tilde{z}_0 - z_0))]\right|_2 \\ &\le Ct\,|\tilde{z}_0 - z_0|_2\,\varepsilon(t), \end{aligned}$$

and $\lim_{t\to 0}\varepsilon(t) = 0$.

The proof of Lemma 5 is given in Appendix G. To prove Theorem 8, we first remark that

$$\left|\sigma^2(\tilde z_0 - z_0) + dj_0 K(dj_0^*(\tilde z_0 - z_0))\right|_2 \geq \sigma^2 \left|\tilde z_0 - z_0\right|_2$$

so that

$$\left|(M_{j_0}(t\tilde z_0) - M_{j_0}(tz_0)) \circ \varphi^{\tilde{\mathrm{v}}}_{0,t}\right|_2 \geq t\sigma^2 \left|\tilde z_0 - z_0\right|_2 \left(1 - \frac{C}{\sigma^2}\varepsilon(j_0, t)\right),$$

and the lower bound is nonvanishing as soon as t is small enough. □

Remark that we have, for $j_1, j_2 \in H^1(\Omega, \mathbb{R}^d)$, the inequality

$$d(j_1, j_2) \leq \frac{1}{\sigma} \left|j_1 - j_2\right|_2$$

since the right-hand side is an upper bound of the length of the curve $\mathrm{j}_t = (1-t)j_1 + tj_2$ (since choosing $\mathrm{v} \equiv 0$ and $\sigma^2 \mathrm{z} \equiv j_2 - j_1$, we have $\mathrm{w}_t \triangleq (v_t, z_t) \in \frac{\partial j_t}{\partial t}$ and $\sigma^2 \int_0^1 \left|z_t\right|_2^2 = \left|j_2 - j_1\right|_2^2 / \sigma^2$). So continuity of M_{j_0} for the d-topology on its image is also true.

According to Lemma 5, normal coordinates (which are time derivatives at $t = 0$ of geodesics) are related to M by the relation (we use the standard exponential notation)

$$\exp_{j_0}(Sz_0) = M_{j_0}(z_0),$$

where S is defined by

$$Sz \triangleq \sigma^2 z + Dj_0 K(Dj_0^* z).$$

This indicates that a good approximation of the metric in terms of the z-coordinate would be

$$\left|z_1 - z_2\right|_{j_0}^2 = \langle z_1 - z_2\,,\, S(z_1 - z_2)\rangle_2,$$

which satisfies

$$\left|z_1\right|_{j_0} = d(j_0, M_{j_0}(z_1))$$

in a neighborhood of 0.

10. Experiments. In this section, we propose a preliminary set of experiments to illustrate the information contained in the z-coordinate described above. Experiments in Figures 1, 2, and 3 were conducted in two steps: given two images j_0 and j_1, we first computed the minimizing geodesic between them, yielding a trajectory $(\mathrm{j}_t, \mathrm{z}_t, \mathrm{v}_t)$ and the corresponding flow φ^{v}_t. Then, using j_0 again, and the obtained value z_0 on the minimizing geodesic, we computed the solution of (21) until time $t = 1$. The obtained values $(\mathrm{j}'_t, \mathrm{z}'_t, \mathrm{v}'_t)$ could then be compared with those which have been computed along the geodesics. In Figure 4, the initial j_0 is the same as in Figures 2 and 3, but the z_0 is the average of the two so that it does not correspond to any precomputed geodesic in the image space. The result is quite interesting, because it still possesses characteristics of a human face and can be compared to the result of a simple linear combination of the target images in Figures 2 and 3.

The numerical implementation of both operations (minimization of the geodesic energy and integration of (21)) must be done with some care in order, in particular, to avoid instabilities due to the conservation part of the energy. Details will be provided in a forthcoming paper.

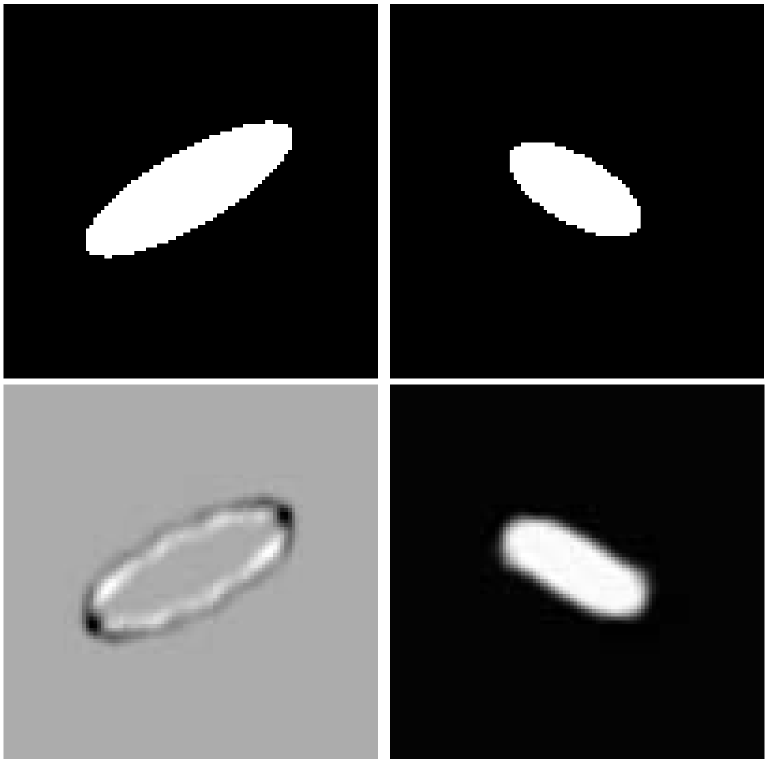

FIG. 1. *From top to bottom and from left to right: Initial image, target image, z-coordinate, reconstructed target image.*

Appendix A. Proofs of Propositions 2 and 3.

A.1. Proof of Proposition 2. The proof relies on a sequence of standard measurability arguments, of which we sketch only the main steps. First let $(w_n)_{n\in\mathbb{N}}$ be a Hilbert basis of W. Since, for any $u \in C_c^\infty(\Omega, \mathbb{R}^d)$ and $w = (v, z) \in W$, $j \to l_{j,u}(w)$ (which has been defined in (6) by $\sigma^2\langle z, u\rangle_2 + \langle j, \operatorname{div}(u \otimes v)\rangle_2$) is continuous from $L^2(\Omega, \mathbb{R}^d)$ to $\mathbb{R}$, the map

$$j \mapsto w_{j,u} \triangleq \sum_{n\geq 0} l_{j,u}(w_n) w_n$$

is measurable from $L^2(\Omega, \mathbb{R}^d)$ to W. By construction, we have, for $w \in W$,

$$\langle w\,,\, w_{ju}\rangle_W = \sum_{n\geq 0} l_{j,u}(w_n)\langle w\,,\, w_n\rangle_W = l_{j,u}(w).$$

Thus, for $\gamma \in T_j\mathcal{J}_W$, we have

$$\overline{p}(\gamma) = \operatorname{Argmin}\left\{|w|_W : \langle w\,,\, w_{j,u}\rangle = \langle \gamma\,,\, u\rangle \text{ for all } u \in C_c^\infty(\Omega, \mathbb{R}^d)\right\}.$$

Introducing a family $(u_n)_{n\in\mathbb{N}}$ in $C_c^\infty(\Omega, \mathbb{R}^d)$ which is dense in $H_0^1(\Omega, \mathbb{R}^d)$, the previous expression may be replaced by

$$\overline{p}(\gamma) = \operatorname{Argmin}\left\{|w|_W : \langle w\,,\, w_{j,u_n}\rangle = \langle \gamma\,,\, u_n\rangle \text{ for all } n \geq 0\right\}.$$

FIG. 2. *From top to bottom and from left to right: Initial image, target image, z-coordinate, reconstructed target image.*

For $N \in \mathbb{N}$ and $\lambda > 0$, we define

$$\overline{p}^{N,\lambda}(\gamma) = \text{Argmin}\left\{ |w|_W^2 + \lambda \sum_{n=0}^{N} \left(\langle w\,,\, w_{j,u_n} \rangle_W - \langle \gamma\,,\, u_n \rangle \right)^2 \right\}. \tag{32}$$

Clearly, we must have $\overline{p}^{N,\lambda}(\gamma) = \sum_{i=1}^{N} x_i w_{j,u_i}$, where

$$x = \underset{x' \in \mathbb{R}^{N+1}}{\text{Argmin}} \left\{ \left| \sum_{n=0}^{N} x'_n w_{j,u_n} \right|_W^2 + \lambda \sum_{n=0}^{N} \left(\sum_{n'=1}^{N} x'_{n'} \langle w_{j,u_{n'}}\,,\, w_{j,u_n} \rangle_W - \langle \gamma\,,\, u_i \rangle \right)^2 \right.$$
$$\left. + \ \frac{1}{\lambda} |x'|^2 \right\}.$$

For $\lambda > 0$, the optimal x is given by $x = (A + I/\lambda)^{-1} y$, where $y \in \mathbb{R}^{N+1}$ is such that $y_i = \langle \gamma\,,\, u_i \rangle$ and A is an $(N+1) \times (N+1)$ matrix with coefficients given

FIG. 3. *From top to bottom and from left to right: Initial image, target image, z-coordinate, reconstructed target image.*

by $a_{n,n'} = \left\langle w_{j,u_{n'}}\,,\, w_{j,u_n}\right\rangle_W$. This implies that, if γ_t is a measurable path, the function $t \mapsto \overline{p}^{N,\lambda}(\gamma_t)$ is measurable. The measurability of $\overline{p}(\gamma_t)$ is a consequence of the pointwise convergence of $\overline{p}^{N,N}(\gamma_t)$ to $\overline{p}(\gamma_t)$, which comes from the following argument: for all N and λ, we have $\left|\overline{p}^{N,\lambda}(\gamma)\right|_W \leq |\overline{p}(\gamma)|_W$, since the last term in (32) vanishes for $w = \overline{p}(\gamma)$. For the same reason,

$$\sum_{n=0}^{N} \left(\left\langle \overline{p}^{N,\lambda}(\gamma)\,,\, w_{j,u_n}\right\rangle - \langle \gamma\,,\, u_n\rangle\right)^2 \leq \frac{1}{\lambda}\,|\overline{p}(\gamma)|_W\,,$$

which implies that for all n, $\left\langle \overline{p}^{N,N}(\gamma)\,,\, w_{j,u_n}\right\rangle \to \langle \gamma\,,\, u_n\rangle$ when N tends to infinity. Moreover, for any weakly converging subsequence extracted from $\overline{p}^{N,N}(\gamma)$ (which forms a weakly compact set in W), we have, and denoting w^* its limit, $|w^*|_W \leq \liminf \left|\overline{p}^{N,N}(\gamma)\right|_W \leq |\overline{p}(\gamma)|_W$, and, for all n, $\langle w^*\,,\, w_{j,u_n}\rangle = \langle \gamma\,,\, u_n\rangle$ by weak convergence, which is only possible when $w^* = \overline{p}(\gamma)$.

Hence $t \mapsto \overline{p}(\gamma_t)$ is measurable if γ_t is measurable, and the proof of Proposition 2 is ended.

FIG. 4. *From top to bottom and from left to right: Initial image, target image, z-coordinate, obtained by averaging the z-coordinate in Figures* 2 *and* 3, *and obtained target image.*

A.2. Proof of Proposition 3. We deduce from Proposition 2 that it is sufficient to prove the next proposition.

PROPOSITION 6. *Let $w \in L^2([0,1], W)$ such that for any $u \in C_c^\infty(\Omega \times]0,1[, \mathbb{R}^d)$ we have*

$$\int_0^1 \left(\sigma^2 \langle z_t, u_t \rangle_2 + \langle j_t, \operatorname{div}(u_t \otimes v_t) \rangle_2\right) \, dt = 0. \tag{33}$$

Then almost everywhere in t, $w_t \in E_{j_t}$.

Proof. Let $(u_n)_{n \in \mathbb{N}}$ be a family in $C_c^\infty(\Omega, \mathbb{R}^d)$ dense in $C_c^\infty(\Omega, \mathbb{R}^d)$ for the $H^1(\Omega, \mathbb{R}^d)$-norm. If we prove that for any $n \in \mathbb{N}$, the function c_n defined by $c_n(t) \triangleq \sigma^2 \langle z_t, u_n \rangle_2 + \langle j_t, \operatorname{div}(u_n \otimes v_t) \rangle_2$ is vanishing almost everywhere, then by density, there exists a negligible set $\mathcal{N}$ such that for any $t \in [0,1] \setminus \mathcal{N}$ and any $u \in C_c^\infty(\Omega, \mathbb{R}^d)$

$$\sigma^2 \langle z_t, u \rangle_2 + \langle j_t, \operatorname{div}(u \otimes v_t) \rangle_2 = 0,$$

which implies Proposition 6. Hence, let us consider $n \in \mathbb{N}$. For any $f \in C_c^\infty([0,1],\mathbb{R})$, if $u(t,x) \triangleq f(t)u_n(x)$, we have from (33) that

$$\int_0^1 c_n(t)f(t)dt = 0$$

so that, by standard arguments, we get $c_n = 0$ almost everywhere. ☐

Appendix B. Proof of Theorem 2. We start the ($\Leftarrow$) part in the case $L^2([0,1],W)$.

LEMMA 6. *Let* $\mathrm{w} = (\mathrm{z},\mathrm{v}) \in L^2([0,1],W)$. *Let us define for any* $t \in [0,1]$

$$\mathrm{j}_t \triangleq \mathrm{j}_0 \circ \varphi_{t,0} + \sigma^2 \int_0^t \mathrm{z}_s \circ \varphi_{t,s} ds,$$

where φ_t *is the flow at time* t *associated with* v. *Then* j *is regular.*

Proof. Let us notice first that

$$\mathrm{j}_{t+h} = \mathrm{j}_t \circ \varphi_{t+h,t} + \sigma^2 \int_t^{t+h} \mathrm{z}_s \circ \varphi_{t+h,s} dt. \tag{34}$$

From equality (34), the continuity in $\mathcal{J}_W$ of j is straightforward.

It is sufficient to prove that for any $u \in C_c^\infty(\Omega\times]0,1[,\mathbb{R}^d)$, we have

$$-\int_0^1 \left\langle \mathrm{j}_t, \frac{\partial u}{\partial t} \right\rangle_2 dt = \int_0^1 \left(\sigma^2 \langle \mathrm{z}_t, u_t\rangle_2 + \langle \mathrm{j}_t, \mathrm{div}(u_t \otimes \mathrm{v}_t)\rangle_2\right) dt. \tag{35}$$

Indeed, if (35) is proved, if for any $t \in [0,1]$ we denote $\gamma_t \triangleq (\mathrm{j}_t, \overline{\mathrm{w}}_t)$, we have for any $u \in C_c^\infty(\Omega,\mathbb{R}^d)$, $t \to \langle \gamma_t\, ,\, u\rangle = \sigma^2\langle \mathrm{z}_t, u\rangle_2 + \langle \mathrm{j}_t, \mathrm{div}(u\otimes \mathrm{v}_t)\rangle_2$ measurable, and $|\gamma_t|_{\mathrm{j}_t} \le |\mathrm{w}_t|_W$ so that $\int_0^1 |\gamma_t|_t^2 dt \le \int_0^1 |\mathrm{w}_t|_W^2 dt < +\infty$, and the lemma is proved.

We have

$$-\int_0^1 \left\langle \mathrm{j}_t, \frac{\partial u}{\partial t}\right\rangle_2 dt = -\lim_{h\to 0}\int_0^1 \left\langle \mathrm{j}_t, \frac{u_t - u_{t-h}}{h}\right\rangle_2 dt = \lim_{h\to 0}\int_0^1 \left\langle \frac{\mathrm{j}_{t+h}-\mathrm{j}_t}{h}, u_t\right\rangle_2 dt$$

so that

$$-\int_0^1 \left\langle \mathrm{j}_t, \frac{\partial u}{\partial t}\right\rangle_2 = \lim_{h\to 0}\frac{1}{h}\int_0^1 \left(\langle \mathrm{j}_t\circ\varphi_{t+h,t} - \mathrm{j}_t, u_t\rangle_2 dt + \sigma^2 \int_t^{t+h} \langle \mathrm{z}_s \circ \varphi_{t+h,s}, u_t\rangle_2 ds\right) dt.$$

However, $\langle \mathrm{j}_t\circ\varphi_{t+h,t} - \mathrm{j}_t, u_t\rangle_2 = \int_t^{t+h} \langle \mathrm{j}_t \circ \varphi_{s,t}, \mathrm{div}(u_t\otimes \mathrm{v}_s)\rangle_2 ds$ so that

$$-\int_0^1 \left\langle \mathrm{j}_t, \frac{\partial u}{\partial t}\right\rangle_2 dt = \lim_{h\to 0}\int_0^1 \frac{1}{h}\left(\int_t^{t+h} \langle \mathrm{j}_t\circ\varphi_{s,t}, \mathrm{div}(u_t\otimes \mathrm{v}_s)\rangle_2 + \sigma^2\langle \mathrm{z}_s\circ\varphi_{t+h,s}, u_t\rangle_2 ds\right) dt$$

$$= \lim_{h\to 0}\int_0^1 \frac{1}{h}\left(\int_t^{t+h} \langle \mathrm{j}_t, \mathrm{div}(u_t\otimes \mathrm{v}_s)\circ\varphi_{t,s}|d\varphi_{t,s}|\rangle_2 + \sigma^2\langle \mathrm{z}_s, u_t\circ\varphi_{s,t+h}|d\varphi_{s,t+h}|\rangle_2 ds\right) dt.$$

Since j_t is uniformly bounded on L^2 and $|\varphi_{t,s} - I|_{1,\infty} = \epsilon(|t-s|)$ (since $\mathcal{B}$ is continuously embedded in $C^1(\overline{\Omega},\mathbb{R}^k)$), there exists $C > 0$ such that

$$\left|\int_0^1 \frac{1}{h}\int_t^{t+h} \langle \mathrm{j}_t, \mathrm{div}(u_t\otimes \mathrm{v}_s)\circ(\varphi_{t,s}|d\varphi_{t,s}| - I)\rangle_2 ds dt\right| \le C\epsilon(h)\int_0^1 |\mathrm{v}_t|_{1,\infty}\, dt \tag{36}$$

$$\le C'\epsilon(h)\left(\int_0^1 |\mathrm{w}_t|_W^2 dt\right)^{1/2}. \tag{37}$$

Now, using again the fact that j_t is uniformly bounded in L^2 and fact that $C([0,1],L^2(\Omega,\mathbb{R}^k))$ is dense in $L^2([0,1],L^2(\Omega,\mathbb{R}^k))$, we get

$$\left|\int_0^1 \frac{1}{h}\int_t^{t+h} \langle \mathrm{j}_t, \mathrm{div}(u_t\otimes \mathrm{v}_s) - \mathrm{div}(u_t\otimes \mathrm{v}_t)\rangle_2 ds dt\right| \tag{38}$$
$$\leq C\int_0^1 \frac{1}{h}\int_t^{t+h} |\mathrm{div}(u_t\otimes \mathrm{v}_s) - \mathrm{div}(u_t\otimes \mathrm{v}_t)|_2 ds dt$$
$$\to 0 \text{ when } h\to 0.$$

At this point we have proved that

$$\lim_{h\to 0}\frac{1}{h}\int_0^1 \langle \mathrm{j}_t\circ\varphi_{t+h,t} - \mathrm{j}_t, u_t\rangle_2 dt = \int_0^1 \langle \mathrm{j}_t, \mathrm{div}(u_t\otimes \mathrm{v}_t)\rangle_2 dt. \tag{39}$$

Still using the fact that $|\varphi_{t,s}-I|_{1,\infty} = \epsilon(|t-s|)$ and the fact that $|u_t|_{1,\infty}$ is uniformly bounded, we have

$$\sigma^2\int_0^1 \frac{1}{h}\int_t^{t+h} \langle \mathrm{z}_s, u_t\circ(\varphi_{s,t+h}|d\varphi_{s,t+h}| - I)\rangle_2 \; ds dt \leq C\sigma^2\epsilon(h)\int_0^1 |\mathrm{z}_s|_2 ds \tag{40}$$
$$\leq C\sigma\epsilon(h)\left(\int_0^1 |\mathrm{w}_t|_2^2\right)^{1/2}. \tag{41}$$

Finally, since $|u_t|_\infty$ is uniformly bounded, we get

$$\lim_{h\to 0}\left|\int_0^1 \frac{1}{h}\int_t^{t+h} \langle \mathrm{z}_s - \mathrm{z}_t, u_t\rangle_2 ds dt\right| \leq \lim_{h\to 0} C\int_0^1\int_t^{t+h} |\mathrm{z}_s-\mathrm{z}_t|_2 \; ds dt = 0.$$

Hence the proof of the lemma is ended. □

Let us consider the ($\Rightarrow$) part of Theorem 2 for $H^1([0,1],\mathcal{J}_W)$. Let $j\in H^1([0,1],\mathcal{J}_W)$ be a regular path, and let $\mathrm{w}_t = \overline{p}(\frac{\partial j}{\partial t})$ for any $t\in[0,1]$. We get from Proposition 2 that $\mathrm{w}\in L^2([0,1],W)$. Hence, let us define the new path j' by

$$\mathrm{j}'_t = \mathrm{j}_0\circ\varphi_{t,0} + \sigma^2\int_0^t \mathrm{z}_s\circ\varphi_{t,s} ds,$$

where φ is the flow associated with v. From the ($\Leftarrow$) part, we get that j' is regular and that $\frac{\partial \mathrm{j}'}{\partial t} = \frac{\partial j}{\partial t}$. Now let $u_0\in C_c^\infty(\Omega,\mathbb{R}^d)$. For any $f\in C_c^\infty(]0,1[,\mathbb{R})$ if $u(t,x) = u_0(x)f(t)$ for any $x\in\Omega$ and $t\in[0,1]$, we have from the integration by parts formula for a regular path

$$\int_0^1 r(t)f'(t)dt = 0,$$

where $r(t) = \langle \mathrm{j}_t, u\rangle_2 - \langle \mathrm{j}'_t, u\rangle_2$. Since r is continuous and $r(0)=0$, we get $r\equiv 0$. Considering arbitrary u_0, we get finally $\mathrm{j}_t = \mathrm{j}'_t$ for any $t\in[0,1]$.

Since the ($\Rightarrow$) part for $C^1([0,1],\mathcal{J}_W)$ is a straightforward consequence of the definition of C^1 curves and of the ($\Rightarrow$) part for $H^1([0,1],\mathcal{J}_W)$, we consider the ($\Leftarrow$) part for $\mathrm{w}\in C([0,1],W)$. We get from the corresponding part for $L^2([0,1],W)$ that (35) is still true. For any $f\in C_c^\infty([0,1],\mathbb{R})$ and any $u\in C_c^\infty(\Omega,\mathbb{R}^d)$ we have

$$-\int_0^t f'(t)\langle \mathrm{j}_t, u\rangle_2 dt = \int_0^1 f(t)\left(\sigma^2\langle \mathrm{z}_t, u_t\rangle_2 + \langle \mathrm{j}_t, \mathrm{div}(u\otimes \mathrm{v}_t)\rangle_2\right)dt.$$

One easily checks that $t \to \sigma^2\langle \mathrm{z}_t, u_t\rangle_2 + \langle \mathrm{j}_t, \mathrm{div}(u \otimes \mathrm{v}_t)\rangle_2$ is continuous as well as $t \to \langle \mathrm{j}_t, u\rangle_2$ so that, considering smooth approximates of step functions, we deduce that

$$\langle \mathrm{j}_s, u\rangle_2 = \langle \mathrm{j}_0, u\rangle_2 + \int_0^s \left(\sigma^2\langle \mathrm{z}_t, u_t\rangle_2 + \langle \mathrm{j}_t, \mathrm{div}(u \otimes \mathrm{v}_t)\rangle_2\right) dt,$$

and the result is proved.

Appendix C. Regularity results for A . In this section, we collect a few useful results on how the regularity of the diffeomorphism $\mathbf{A}_T(\mathrm{v}) = \varphi_T^{\mathrm{v}}$ may be related to the norm on $\mathcal{B}$, provided this norm can in turn control a sufficient number of derivatives; the first result deals with boundedness. In the following, we assume at least that $\mathcal{B}$ is continuously embedded in $C_0^1(\Omega, \mathbb{R}^k)$ so that $\mathbf{A}_T$ is well defined for all T. In this case,

$$\varphi_T^{\mathrm{v}}(x) = x + \int_0^T \mathrm{v}_s(\varphi_s^{\mathrm{v}}(x))ds.$$

If v_s had p space derivatives for all s, a formal differentiation of this equality yields

$$d^p\varphi_T^{\mathrm{v}} = d^p\mathrm{id} + \int_0^T d^p(\mathrm{v}_s \circ \varphi_s^{\mathrm{v}})ds. \tag{42}$$

This can be proved rigorously from rather standard arguments in the study of ODEs and is stated in the next lemma, for which we provide a proof for completeness, because of the small complication due to the fact that we have only an L^1 control with respect to the t variable, instead of the usual uniform one.

LEMMA 7. *If $p \geq 1$ and $\mathcal{B}$ is embedded in $C_0^p(\Omega, \mathbb{R}^k)$, then, for all $\mathrm{v} \in L^1([0,T], \Omega)$, φ^{v} is p times differentiable and, for all $q \leq p$,*

$$\frac{\partial}{\partial t} d^q\varphi_t^{\mathrm{v}} = d^q(\mathrm{v}_t \circ \varphi_t^{\mathrm{v}}).$$

Moreover, there exist constants C, C' such that, for all $\mathrm{v} \in L^1([0,T], \Omega)$,

$$\sup_{s\in[0,T]} |\varphi_s^{\mathrm{v}}|_{p,\infty} \leq Ce^{C'|\mathrm{v}|_{1,T}}. \tag{43}$$

Proof. For further reference, we first state Gronwall's lemma.

LEMMA 8 (Gronwall). *Asume that α and β are two positive, continuous functions on the interval $[0,c]$ and that*

$$w(t) \leq \alpha(t) + \int_0^t \beta(s)w(s)ds.$$

Then,

$$w(t) \leq \alpha(t) + \int_0^t \alpha(s)\beta(s)e^{\int_s^t \beta(u)du}ds.$$

The continuity of $x \mapsto \varphi^{\mathrm{v}}_{0,t}(x)$ is a direct consequence of this lemma since, for $x, y \in \Omega$,

$$\begin{aligned}|\varphi^{\mathrm{v}}_{0,t}(x) - \varphi^{\mathrm{v}}_{0,t}(y)| &= \left| x - y + \int_0^t \left(\mathrm{v}_s(\varphi^{\mathrm{v}}_{0,s}(x)) - \mathrm{v}_s(\varphi^{\mathrm{v}}_{0,s}(y))\right) ds \right| \\ &\leq |x-y| + \int_0^t \|\mathrm{v}_s\|_{1,\infty} |\varphi^{\mathrm{v}}_{0,s}(x) - \varphi^{\mathrm{v}}_{0,s}(y)| ds,\end{aligned}$$

and Gronwall's lemma implies

$$|\varphi^{\mathrm{v}}_{0,t}(x) - \varphi^{\mathrm{v}}_{0,t}(y)| \leq |x-y| \exp(C\,|\mathrm{v}|_{1,T}). \tag{44}$$

Assume $p = 1$ and pass now to the differential of $\varphi^{\mathrm{v}}_{0,t}$. Fix $x \in \Omega$ and introduce the linear differential equation, formally obtained in (42) for $p = 1$,

$$\frac{\partial W_t}{\partial t} = d_{\varphi^{\mathrm{v}}_{0,t}(x)} \mathrm{v}_t W_t \tag{45}$$

with initial condition $W(0) = \delta \in \mathbb{R}^k$. We skip the argument ensuring the existence and uniqueness of a solution of this equation on $[0, 1]$ and proceed to identifying it as $W_t = d_x \varphi^{\mathrm{v}}_{0,t} \delta$. Denote

$$a_\varepsilon(t) = \left(\varphi^{\mathrm{v}}_{0,t}(x + \varepsilon\delta) - \varphi^{\mathrm{v}}_{0,t}(x)\right)/\varepsilon - W_t.$$

For $\alpha > 0$, introduce

$$\mu_t(\alpha) = \max\left\{|d_x \mathrm{v}_t - d_y \mathrm{v}_t| : x, y \in \Omega, |x - y| \leq \alpha\right\}.$$

The function $d_x \mathrm{v}_t \in C^1_0(\Omega)$ being uniformly continuous on the compact set $\overline{\Omega}$, we have $\lim_{\alpha \to 0} \mu_t(\alpha) = 0$. We may write

$$\begin{aligned}a_\varepsilon(t) = &\frac{1}{\varepsilon} \int_0^t \left(\mathrm{v}_s(\varphi^{\mathrm{v}}_{0,s}(x + \varepsilon\delta)) - \mathrm{v}_s(\varphi^{\mathrm{v}}_{0,s}(x))\right) ds - \int_0^t d_{\varphi^{\mathrm{v}}_{0,s}(x)} \mathrm{v}_s W_s ds \\ = &\int_0^t d_{\varphi^{\mathrm{v}}_{0,s}(x)} \mathrm{v}_s a_\varepsilon(s) ds \\ &+ \frac{1}{\varepsilon} \int_0^t (\mathrm{v}_s(\varphi^{\mathrm{v}}_{0,s}(x + \varepsilon\delta)) - \mathrm{v}_s(\varphi^{\mathrm{v}}_{0,s}(x)) - \varepsilon d_{\varphi^{\mathrm{v}}_{0,s}(x)} \mathrm{v}_s(\varphi^{\mathrm{v}}_{0,s}(x + \varepsilon\delta) - \varphi^{\mathrm{v}}_{0,s}(x))) ds.\end{aligned}$$

Since for all $y, y' \in \Omega$

$$|\mathrm{v}_t(y') - \mathrm{v}_t(y) - d_y \mathrm{v}_t(y' - y)| \leq \mu_s(|y' - y|)\,|y' - y|,$$

we may write

$$|a_\varepsilon(t)| \leq \int_0^t |\mathrm{v}_s|_{1,\infty} |a_\varepsilon(s)|\, ds + C(\mathrm{v})\,|\delta| \int_0^1 \mu_s(\varepsilon C(\mathrm{v})\,|\delta|) ds$$

for some constant $C(\mathrm{v})$ which depends only on v. The fact that $a_\varepsilon(t)$ tends to 0 when $\varepsilon \to 0$ now is a direct consequence of Gronwall's lemma and of the fact that

$$\lim_{\alpha \to 0} \int_0^1 \mu_s(\alpha) ds = 0,$$

which is true by the dominated convergence theorem, since μ_s pointwise converges to 0 and $\mu_s(\alpha) \leq 2\,|\mathrm{v}|_{1,\infty}$. This proves Lemma 7 in the case $p = 1$. The rest of the proof is by induction: let $q_0 \leq p$, $q_0 > 1$, and assume that the result is proved for all $q < q_0$:

$$\frac{\partial}{\partial t} d^q \varphi_t^{\mathrm{v}} = d^q(\mathrm{v}_t \circ \varphi_t^{\mathrm{v}}).$$

This implies that for $\delta_1, \ldots, \delta_q \in \mathbb{R}^k$, we may write

$$\frac{\partial}{\partial t} d^q \varphi_t^{\mathrm{v}}(\delta_1, \ldots, \delta_q) = d_{\varphi_{0,t}^{\mathrm{v}}} \mathrm{v}_t d^q \varphi_t^{\mathrm{v}}(\delta_1, \ldots, \delta_q) + \sum_{l=2}^{q} d^l \mathrm{v}_t(\delta_1^{(l)}, \ldots, \delta_l^{(l)}),$$

each vector $\delta_k^{(l)}$ being a linear combination (with universal coefficients) of terms of the kind $d^{l'} \varphi_{0,t}^{\mathrm{v}}(\delta_{i_1}, \ldots, \delta_{i_{l'}})$ with $l' \leq q + 1 - l$ (this result on the differentials of the composition of two functions can be easily proved by induction). This is a linear equation in $d^q \varphi_t^{\mathrm{v}}(\delta_1, \ldots, \delta_q)$, which is valid for $q = q_0 - 1$, and the proof of its validity for q_0 follows exactly the same lines as for $p = 1$.

This expression also shows (using Gronwall's lemma) that $|d^q \varphi_t^{\mathrm{v}}|_\infty$ may be bounded by an expression of the kind

$$|\mathrm{v}|_{1,T}\, \tilde{C}\left(|d\varphi_t^{\mathrm{v}}|_\infty, \ldots, \left|d^{q-1}\varphi_t^{\mathrm{v}}\right|_\infty\right) \exp\left(C\,|\mathrm{v}|_{1,T}\right),$$

where $\tilde{C}$ is a polynomial, which in turn implies (43). $\square$

The same estimate is true for $(\varphi^{\mathrm{v}})^{-1}$.

Lemma 9. *If $p \geq 1$ and $\mathcal{B}$ is continuously embedded in $C_0^p(\Omega, \mathbb{R}^k)$, there exist constants C, C' such that, for all $\mathrm{v} \in L^1([0,T], \Omega)$,*

$$\sup_{s \in [0,T]} \left|(\varphi_s^{\mathrm{v}})^{-1}\right|_{p,\infty} \leq C e^{C' |\mathrm{v}|_{1,T}}.$$

Lemma 9 is a consequence of Lemma 7 and of the fact that $(\varphi_t^{\mathrm{v}})^{-1} = \varphi_t^{\mathrm{w}}$ with $\mathrm{w}_s = -\mathrm{v}_{t-s}$ on $[0,\, t]$.

We now pass to sufficient conditions for Lipschitz continuity of $\mathbf{A}_T$. For this, let $\mathrm{v}, \mathrm{v}' \in L^1([0,T], \mathcal{B})$. For $\xi \in [0,1]$, denote $\mathrm{v}^\xi = (1-\xi)\mathrm{v} + \xi \mathrm{v}'$ and $\varphi^\xi = \varphi^{\mathrm{v}^\xi}$.

Lemma 10.

$$\frac{\partial}{\partial \xi} \varphi_{s,t}^{\mathrm{v}^\xi}(x) = \int_s^t d_{\varphi_{s,u}^{\mathrm{v}^\xi}(x)} \varphi_{ut}^{\mathrm{v}^\xi}(\mathrm{v}'_u - \mathrm{v}_u) \circ \varphi_{s,u}^{\mathrm{v}^\xi}(x) du. \tag{46}$$

Proof. Let us first start with a formal differentiation of

$$\frac{\partial \varphi_{s,t}^{\mathrm{v}^\xi}}{\partial t} = v_t^\xi \circ \varphi_{s,t}^{\mathrm{v}^\xi}$$

with respect to ξ, which yields

$$\frac{\partial}{\partial t} \frac{\partial}{\partial \xi} \varphi_{s,t}^{\mathrm{v}^\xi} = (v'_t - v_t) \circ \varphi_t^{\mathrm{v}^\xi} + d_{\varphi_{s,t}^{\mathrm{v}^\xi}} v_t^\xi \frac{d}{d\xi} \varphi_{s,t}^{\mathrm{v}^\xi},$$

which naturally leads us to introduce the solution of the differential equation

$$\frac{\partial}{\partial t} W_t = (v'_t - v_t) \circ \varphi_t^{\mathrm{v}^\xi} + d_{\varphi_{s,t}^{\mathrm{v}^\xi}} v_t^\xi W_t \tag{47}$$

with initial condition $W_s = 0$. Noting that we have already encountered this equation without the constant term in (45), the solution of which is of the form $d_x\varphi^{\mathrm{v}^\xi}_{0,t}\delta$, a standard argument by variation of the constant shows that the solution of (47) is given by the right-hand term of (46). Therefore, the proof boils down to show that the interversion of derivatives underlying the formal argument above can be made rigorous.

For this, it clearly suffices to consider the problem in the vicinity of $\xi = 0$. The proof in fact follows the same lines as the proof of Lemma 7: letting W_t be the solution of (47), we let

$$a_\xi(t) = \left(\varphi^{\mathrm{v}^\xi}_{s,t}(x) - \varphi^{\mathrm{v}}_{s,t}(x)\right)/\xi - W_t$$

and express it under the form, letting $h_u = v'_u - v_u$,

$$\begin{aligned} a_\xi(t) = &\int_s^t d_{\varphi^{\mathrm{v}}_{s,u}} \mathrm{v}_u a_\xi(u) du + \int_s^t (h_u(\varphi^{\mathrm{v}^\xi}_{s,u}(x)) - h_u(\varphi^{\mathrm{v}}_{s,u}(x)))du \\ &+ \frac{1}{\xi}\int_s^t \left(\mathrm{v}_u(\varphi^{\mathrm{v}^\xi}_{s,u}(x)) - \mathrm{v}_u(\varphi^{\mathrm{v}}_{s,u}(x)) - \xi d_{\varphi^{\mathrm{v}}_{s,u}(x)}\mathrm{v}_u \left(\varphi^{\mathrm{v}^\xi}_{s,u}(x) - \varphi^{\mathrm{v}}_{s,u}(x)\right)\right) du. \end{aligned}$$

The proof can proceed exactly as that of Lemma 7, provided it has been shown that $|\varphi^{\mathrm{v}^\xi}_{s,u}(x) - \varphi^{\mathrm{v}}_{s,u}(x)|$ tends to 0 with ξ, which is again a direct consequence of Gronwall's lemma and of the inequality

$$\left|\varphi^{\mathrm{v}^\xi}_{s,t}(x) - \varphi^{\mathrm{v}}_{s,t}(x)\right| \le \int_s^t |\mathrm{v}_u|_{1,\infty} \left|\varphi^{\mathrm{v}^\xi}_{s,u}(x) - \varphi^{\mathrm{v}}_{s,u}(x)\right| du + \xi \int_s^t |h_u|_\infty du. \qquad \square$$

This lemma implies, in particular, that

$$\varphi^{\mathrm{v}'}_{s,t}(x) - \varphi^{\mathrm{v}}_{s,t}(x) = \int_0^1 \int_s^t d_{\varphi^{\mathrm{v}^\xi}_{s,u}(x)} \varphi^{\mathrm{v}^\xi}_{ut}(\mathrm{v}'_u - \mathrm{v}_u) \circ \varphi^{\mathrm{v}^\xi}_{s,u}(x) du d\xi, \tag{48}$$

which almost immediately leads to the following result (by computing differentials and applying Lemma 7).

LEMMA 11. *Assume that $\mathcal{B}$ is continuously embedded in $C^p_0(\Omega)$. If $\mathrm{v}, \mathrm{v}' \in L^1([0,T], \mathcal{B})$, we have, for $t \le T$,*

$$\left|\varphi^{\mathrm{v}}_t - \varphi^{\mathrm{v}'}_t\right|_{p-1,\infty} \le C_p \left|\mathrm{v} - \mathrm{v}'\right|_{1,t} e^{C_p(|\mathrm{v}|_{1,t} + |\mathrm{v}'|_{1,t})}$$

for some constant C_p which depends only on p.

The same results apply on $L^2([0,1], \mathcal{B})$, since $|\mathrm{v}|_{1,T} \le \sqrt{T}\,|\mathrm{v}|_{2,T}$, but, in this space, weak continuity is true under more general conditions.

THEOREM 9 (Trouvé, Dupuis, et al). *Assume that $\mathcal{B}$ is continuously embedded in $C^p_0(\Omega, \mathbb{R}^k)$. Then the map*

$$\begin{array}{rccl} \tilde{\mathbf{A}}_T : & L^2([0,T], \mathcal{B}) & \to & C^p([0,T] \times \overline{\Omega}, \mathbb{R}^k), \\ & \mathrm{v} & \mapsto & \varphi^{\mathrm{v}}_{\cdot}(.) \end{array}$$

is continuous for the weak *topology on $L^2([0,1], \mathcal{B})$ and the norm $|.|_{T,p-1,\infty}$ on $C^p([0,T] \times \overline{\Omega}, \mathbb{R}^k)$ defined by $|\varphi|_{T,p-1,\infty} = \text{ess.sup}(|\varphi_t|_{p-1,\infty}, t \in [0,T])$.*

Moreover, assume that the embedding is compact, that v^n *converges weakly to* v*, and that there exists a constant* A *such that, for all* n *and almost all* $s \in [0,1]$, $|v_s^n|_{\mathcal{B}} \leq A$*. Then, for all* $x \in \Omega$ *and* $t \in [0,T]$,

$$d_x^p \varphi_t^{\mathrm{v}^n} \to d_x^p \varphi_t^{\mathrm{v}}.$$

Recall that v_n converges to v in the weak topology on $L^2([0,1],\mathcal{B})$ if and only if, for all $\mathrm{w} \in L^2([0,1],\mathcal{B})$,

$$\lim_{n\to\infty} \int_0^1 \int_\Omega \langle \mathrm{v}_n(t)\,,\,\mathrm{w}(t)\rangle_{\mathcal{B}} dt = \int_0^1 \int_\Omega \langle \mathrm{v}(t)\,,\,\mathrm{w}(t)\rangle_{\mathcal{B}} dt.$$

Proof. The proof of this theorem, which is sketched here for completeness, relies on the remark that, since v_n weakly converges, it is bounded in $L^2([0,1],\mathcal{B})$, and Lemma 7 readily implies that (φ^{v_n}) and their space derivatives up to order $p-1$ are equicontinuous sequences in space. Equicontinuity in time comes by applying the Cauchy–Schwarz inequality to

$$d^q \varphi_t^{\mathrm{v}} - d^q \varphi_s^{\mathrm{v}} = \int_s^t d^q(\mathrm{v}_u \circ \varphi_u^{\mathrm{v}}) du.$$

Ascoli's theorem implies compactness of (φ^{v_n}) for the $|.|_{T,p-1,\infty}$-topology, and it remains to identify a limit of any converging subsequence as φ^{v}. Denoting this limit by ψ, one deduces from

$$\varphi_{0,t}^{\mathrm{v}^n}(x) = \int_0^t \mathrm{v}_s^n(\varphi_{0,s}^{\mathrm{v}^n}(x)) ds$$

and the convergence of $\varphi_{0,t}^{\mathrm{v}^n}$ to φ_t the fact that

$$\psi_t(x) = \int_0^t \mathrm{v}_s^n(\psi_s(x)) ds + o(n),$$

and the conclusion comes after the remark that $\mathrm{w} \mapsto \int_0^t \mathrm{w}_s(\psi_s(x)) ds$ is a continuous linear functional on $L^2([0,1],\mathcal{B})$ so that the weak convergence of v^n to v implies that

$$\psi_t(x) = \int_0^t \mathrm{v}_s(\psi_s(x)) ds$$

and $\psi_t = \varphi_{0,t}^{\mathrm{v}}$.

We now prove the pointwise convergence of the pth derivative. We know that

$$\frac{d}{dt} d_x^p \varphi_t^{\mathrm{v}} = d_{\varphi_t^{\mathrm{v}}} \mathrm{v} d_x^p \varphi_t^{\mathrm{v}} + Q_t^{\mathrm{v}}(x),$$

where $Q_t^{\mathrm{v}}(x)$ depends on the derivatives of v evaluated at $\varphi_t^{\mathrm{v}}(x)$ and on the $p-1$ first space derivatives of φ_t^{v}. We may therefore write

$$\begin{aligned} d_x^p \varphi_t^{\mathrm{v}} - d_x^p \varphi_t^{\mathrm{v}^n} = \int_0^t d_{\varphi_s^{\mathrm{v}^n}} \mathrm{v}(d_x^p \varphi_s^{\mathrm{v}} - d_x^p \varphi_s^{\mathrm{v}^n}) ds + \int_0^t (d_{\varphi_s^{\mathrm{v}}} \mathrm{v} - d_{\varphi_s^{\mathrm{v}^n}} \mathrm{v}^n) d_x^p \varphi_s^{\mathrm{v}} ds \\ + \int_0^t (Q_s^{\mathrm{v}}(x) - Q_s^{\mathrm{v}^n}(x)) ds. \end{aligned}$$

The first integral may be bounded by $C(|\mathrm{v}^n|_{1,T})\int_0^t \left|d_x^p\varphi_s^{\mathrm{v}} - d_x^p\varphi_s^{\mathrm{v}^n}\right| ds$, and the result will be a consequence of Gronwall's lemma, provided we show that the remaining terms tend to 0. Consider the second integral, which may be written

$$\int_0^t (d_{\varphi_s^{\mathrm{v}}}\mathrm{v} - d_{\varphi_s^{\mathrm{v}}}\mathrm{v}^n)d_x^p\varphi_s^{\mathrm{v}}ds + \int_0^t (d_{\varphi^{\mathrm{v}_s}}\mathrm{v}^n - d_{\varphi_s^{\mathrm{v}^n}}\mathrm{v}^n)d_x^p\varphi_s^{\mathrm{v}}ds.$$

The first term tends to 0 because

$$w \mapsto \int_0^t d_{\varphi_s^{\mathrm{v}}(x)}w d_x^p\varphi_s^{\mathrm{v}}ds$$

is a continuous linear functional on $L^2([0,t],\mathcal{B})$ and v^n weakly converges to v in this space. To estimate the second one, introduce, for $A, \varepsilon > 0$, the number

$$C(A,\varepsilon) = \max\left\{|d_x w - d_y w| : x, , y \in \Omega, |x-y| \le \varepsilon, |w|_{\mathcal{B}} \le A\right\}.$$

The compact embedding assumption implies that, A being fixed, $C(A,\varepsilon)$ tends to 0 when ε tends to 0. Using this notation, we have

$$\begin{aligned}\int_0^t (d_{\varphi^{\mathrm{v}_s}}\mathrm{v}^n - d_{\varphi_s^{\mathrm{v}^n}}\mathrm{v}^n)d_x^p\varphi_s^{\mathrm{v}}ds &\le \int_0^t C\left(|\mathrm{v}_s^n|_{\mathcal{B}}, |\varphi_s^{\mathrm{v}} - \varphi_s^{\mathrm{v}_n}|_\infty\right)|d_x^p\varphi_s^{\mathrm{v}}|_\infty ds \\ &\le \int_0^t C\left(A, |\varphi_s^{\mathrm{v}} - \varphi_s^{\mathrm{v}_n}|_\infty\right)|\mathrm{v}|_{\mathcal{B}}\, ds,\end{aligned}$$

where $A = \text{ess.sup}\left\{|\mathrm{v}_s^n|_{\mathcal{B}}, n \ge 0, s \in [0,1]\right\}$. The last upper bound now tends to 0, by dominated convergence.

Finally, a generic term of Q_t^{v} being

$$d^k_{\varphi_t^{\mathrm{v}}(x)}\mathrm{v}_t(d^{i_1}\varphi_t^{\mathrm{v}}, \dots, d^{i_k}\varphi_t^{\mathrm{v}}),$$

we can use the same argument to prove its pointwise convergence. ∎

Appendix D. Action of diffeomorphisms on images. The next theorem provides results concerning the regularity of the action of diffeomorphisms on $L^2(\Omega,\mathbb{R}^d)$ and $H^1(\Omega,\mathbb{R}^d)$.

THEOREM 10.

(i) *Let φ be a diffeomorphism of Ω such that φ and φ^{-1} have uniformly bounded first derivatives on Ω. Then, if $i \in L^2(\Omega,\mathbb{R}^d)$ (resp., $i \in H^1(\Omega,\mathbb{R}^d)$), also $i\circ\varphi \in L^2(\Omega,\mathbb{R}^d)$ (resp., $i\circ\varphi \in H^1(\Omega,\mathbb{R}^d)$ and $d_x(i\circ\varphi) = d_{\varphi(x)}i.d_x\varphi$).*

(ii) *Moreover, for all $M > 0$ and for all $i \in L^2(\Omega,\mathbb{R}^d)$, there exists a function $\varepsilon_M(i,\eta)$ such that, for all φ, φ' such that*

$$\max\left(|\varphi|_{1,\infty}, \left|\varphi^{-1}\right|_{1,\infty}, |\varphi'|_{1,\infty}, \left|\varphi'^{-1}\right|_{1,\infty}\right) \le M,$$

we have

$$|i\circ\varphi' - i\circ\varphi|_2 \le \varepsilon_M(i, |\varphi - \varphi'|_{1,\infty}),$$

and $\varepsilon_M(i,\eta) \to 0$ when $\eta \to 0$. The same statement is true for $i \in H^1(\Omega,\mathbb{R}^d)$, the $L^2(\Omega,\mathbb{R}^d)$-norm being replaced by the $H^1(\Omega,\mathbb{R}^d)$-norm.

Proof. We start with (i) and give the proof for $H^1(\Omega, \mathbb{R}^d)$, since it contains exactly the arguments which are valid for $L^2(\Omega, \mathbb{R}^d)$. Fix φ and let L_φ be defined by $L_\varphi(i) = i \circ \varphi$. The vector space $C_d^\infty = C^\infty(\Omega, \mathbb{R}^d)$ of restrictions to Ω of infinitely differentiable functions on $\mathbb{R}^k$ taking values in $\mathbb{R}^d$ is dense in $H^1(\Omega, \mathbb{R}^d)$ [10]. The linear map L_φ is continuous from C_d^∞ (with the topology induced by $H^1(\Omega, \mathbb{R}^d)$) to $H^1(\Omega, \mathbb{R}^d)$; indeed, for $i \in C_d^\infty$,

$$|L_\varphi(i)|_{H^1}^2 = |i \circ \varphi|_2^2 + |d_\varphi i \, d\varphi|_2^2 \leq |i|_2^2 \left| d\varphi^{-1} \right|_\infty + |di|_2^2 |d\varphi|_\infty^2 |d\varphi^{-1}|_\infty \leq C \, |i|_{H^1}^2$$

since the first derivatives of φ and φ^{-1} are bounded. Thus, L_φ restricted to C_d^∞ can be extended to a continuous function $\tilde{L}_\varphi$ on $H^1(\Omega, \mathbb{R}^d)$. If $i \in H^1(\Omega, \mathbb{R}^d)$ and i_n is a sequence of elements of C_d^∞ which converges to i when n tends to infinity (so that $i_n \circ \varphi \to \tilde{L}_\varphi(i)$ in $H^1(\Omega, \mathbb{R}^d)$), then, because convergence in $H^1(\Omega, \mathbb{R}^d)$ implies convergence in $L^2(\Omega, \mathbb{R}^d)$, a subsequence of i_n can be extracted which converges almost everywhere to i and such that $i_n \circ \varphi$ converges almost everywhere to $\tilde{L}_n(i)$. If $N \subset \Omega$ has null Lebesgue measure, then it is also the case for $\varphi^{-1}(N)$ (by boundedness of $\left| d\varphi^{-1} \right|$), so that $i_n \circ \varphi$ also converges almost everywhere to $i \circ \varphi$, yielding $\tilde{L}_\varphi = L_\varphi$. Now, since the map $i \to di$ is obviously continuous from H^1 to L^2, so is $i \to d(L_\varphi(i))$. But, since this map coincides with $i \to d_\varphi i \, d\varphi$ on C_d^∞, and this last map is also continuous on $H^1(\Omega, \mathbb{R}^d)$ (by the previous computation), we get equality over all $H^1(\Omega, \mathbb{R}^d)$, again by density of C_d^∞.

For (ii), we first consider the $L^2(\Omega, \mathbb{R}^d)$ case. Let i, φ', φ, and M be as in the theorem, and fix $s \in C^\infty(\Omega, \mathbb{R}^d)$; we have

$$|i \circ \varphi' - i \circ \varphi|_2 \leq |i \circ \varphi' - s \circ \varphi'|_2 + |s \circ \varphi - s \circ \varphi'|_2 + |i \circ \varphi - s \circ \varphi|_2 .$$

First notice that

$$|i \circ \varphi' - s \circ \varphi'|_2^2 = \int_\Omega \left| d{\varphi'}^{-1} \right| |i - s|^2 dx \leq C \left| {\varphi'}^{-1} \right|_{1,\infty} |i - s|_2^2$$

for some constant C. For the middle term, we have

$$\begin{aligned} |s \circ \varphi - s \circ \varphi'|_2 &\leq \int_0^1 \left| d_{\varphi + t(\varphi' - \varphi)} s (\varphi' - \varphi) \right|_2 dt \\ &\leq |\varphi' - \varphi|_\infty \int_0^1 \left| d_{\varphi + t(\varphi' - \varphi)} s \right|_2 dt \\ &\leq C(M) \, |ds|_2 \, |\varphi' - \varphi|_\infty . \end{aligned}$$

We thus get

$$|i \circ \varphi' - i \circ \varphi|_2 \leq C(M) \left(|i - s|_2 + |ds|_2 \, |\varphi' - \varphi|_\infty \right) .$$

Letting

$$\varepsilon_M(i, \eta) \triangleq C(M) \inf_{s \in C^\infty(\Omega)} \left(|i - s|_2 + |ds|_2 \, \eta \right)$$

yields the conclusion of the theorem in the $L^2(\Omega, \mathbb{R}^d)$ case, the $H^1(\Omega, \mathbb{R}^d)$ case being handled similarly. $\square$

Appendix E. Proof of Lemma 2. We must compute the derivative at $\varepsilon = 0$ of

$$U^\varepsilon = \frac{1}{\sigma^2}\int_\Omega \frac{\left|j_0\circ\varphi_{1,0}^{\mathrm{v}+\varepsilon h} - j_1\right|^2}{\int_0^1 |d\varphi_{1,s}^{\mathrm{v}+\varepsilon h}|^{-1}ds}dx.$$

First, we notice the equation

$$\sigma^2 z_t(x) = \frac{j_1\circ\varphi_{t,1}^{\mathrm{v}} - j_0\circ\varphi_{t,0}^{\mathrm{v}}}{\int_0^1 |d\varphi_{t,s}^{\mathrm{v}}|^{-1}ds}, \tag{49}$$

which implies that (differentiating at $\varepsilon = 0$)

$$\frac{dU^\varepsilon}{d\varepsilon} = -2\left\langle z_1\,,\, d_{\varphi_{1,0}^{\mathrm{v}}}j_0\frac{d}{d\varepsilon}\varphi_{1,0}^{\mathrm{v}+\varepsilon h}\right\rangle_2 - \sigma^2\int_0^1\left\langle |z_1|^2\,,\,\frac{d}{d\varepsilon}\left|d\varphi_{1,s}^{\mathrm{v}+\varepsilon h}\right|^{-1}\right\rangle_2 ds.$$

Starting with the first term and using Lemma 10, we have

$$\begin{aligned}\left\langle z_1\,,\, d_{\varphi_{1,0}^{\mathrm{v}}}j_0\frac{d}{d\varepsilon}\varphi_{1,0}^{\mathrm{v}+\varepsilon h}\right\rangle_2 &= -\int_0^1\left\langle d_{\varphi_{1,0}^{\mathrm{v}}}j_0^* z_1\,,\, d_{\varphi_{1t}^{\mathrm{v}}}\varphi_{t,0}^{\mathrm{v}}h_t\circ\varphi_{1t}^{\mathrm{v}}\right\rangle_2 dt\\ &= -\int_0^1\left\langle d_{\varphi_{t,0}^{\mathrm{v}}}j_0^* z_1\circ\varphi_{t1}^{\mathrm{v}}\,|d\varphi_{t1}^{\mathrm{v}}|\,,\, d\varphi_{t,0}^{\mathrm{v}}h_t\right\rangle_2 dt\\ &= -\int_0^1\left\langle (d\varphi_{t,0}^{\mathrm{v}})^* d_{\varphi_{t,0}^{\mathrm{v}}}j_0^* z_t\,,\, h_t\right\rangle_2 dt\\ &= -\int_0^1\left\langle K\left((d\varphi_{t,0}^{\mathrm{v}})^* d_{\varphi_{t,0}^{\mathrm{v}}}j_0^* z_t\right)\,,\, h_t\right\rangle_{\mathcal{B}} dt\end{aligned}$$

because of the identity $z_t = z_1\circ\varphi_{t1}^{\mathrm{v}}\,|d\varphi_{t1}^{\mathrm{v}}|$.

We now pass to the second term, for which we use the equality

$$\left|d\varphi_{t,s}^{\mathrm{v}+\varepsilon h}\right|^{-1} = \exp\left[\int_s^t \operatorname{div}(\mathrm{v}_u+\varepsilon h_u)\circ\varphi_{t,u}^{\mathrm{v}+\varepsilon h}du\right],$$

which is a consequence of Lemma 7 and standard computations on the derivative of the determinant. This implies that

$$\begin{aligned}\frac{d}{d\varepsilon}\left(\left|d\varphi_{t,s}^{\mathrm{v}+\varepsilon h}\right|^{-1}\right) &= \left|d\varphi_{t,s}^{\mathrm{v}}\right|^{-1}\int_s^t \operatorname{div}(h_u)\circ\varphi_{t,u}^{\mathrm{v}}du\\ &\quad+\left|d\varphi_{t,s}^{\mathrm{v}}\right|^{-1}\int_s^t d_{\varphi_{t,u}^{\mathrm{v}}}\operatorname{div}(\mathrm{v}_u)\int_t^u d_{\varphi_{t\tau}^{\mathrm{v}}}\varphi_{\tau u}^{\mathrm{v}}h_\tau\circ\varphi_{t\tau}^{\mathrm{v}}d\tau du\\ &= \left|d\varphi_{t,s}^{\mathrm{v}}\right|^{-1}\int_s^t \operatorname{div}(h_u)\circ\varphi_{t,u}^{\mathrm{v}}du\\ &\quad-\left|d\varphi_{t,s}^{\mathrm{v}}\right|^{-1}\int_s^t\int_s^\tau d_{\varphi_{t,u}^{\mathrm{v}}}\operatorname{div}(\mathrm{v}_u)d_{\varphi_{t\tau}^{\mathrm{v}}}\varphi_{\tau u}^{\mathrm{v}}h_\tau\circ\varphi_{t\tau}^{\mathrm{v}}du d\tau.\end{aligned}$$

We may notice that

$$\left\langle\nabla\,|d\varphi_{\tau s}^{\mathrm{v}}|^{-1}\,,\,\xi\right\rangle = |d\varphi_{\tau s}^{\mathrm{v}}|^{-1}\int_s^\tau d_{\varphi_{\tau u}^{\mathrm{v}}}(\operatorname{div}v_u)d\varphi_{\tau u}^{\mathrm{v}}(\xi)du$$

to identify the last term as

$$\left|d\varphi^{\mathrm{v}}_{t,s}\right|^{-1}\int_s^t \left|d_{\varphi^{\mathrm{v}}_{t\tau}}\varphi^{\mathrm{v}}_{\tau s}\right|\left\langle\nabla_{\varphi^{\mathrm{v}}_{t\tau}}\left|d\varphi^{\mathrm{v}}_{\tau s}\right|^{-1},\, h_\tau\circ\varphi^{\mathrm{v}}_{t\tau}\right\rangle d\tau$$

so that

$$\begin{aligned}\frac{d}{d\varepsilon}\left(\left|d\varphi^{\mathrm{v}+\varepsilon h}_{t,s}\right|^{-1}\right) &= \left|d\varphi^{\mathrm{v}}_{t,s}\right|^{-1}\int_s^t \operatorname{div}(h_u)\circ\varphi^{\mathrm{v}}_{t,u}du \\ &\quad - \int_s^t \left|d\varphi^{\mathrm{v}}_{t\tau}\right|^{-1}\left\langle\nabla_{\varphi^{\mathrm{v}}_{t\tau}}\left|d\varphi^{\mathrm{v}}_{\tau s}\right|^{-1},\, h_\tau\circ\varphi^{\mathrm{v}}_{t\tau}\right\rangle d\tau.\end{aligned}$$

Therefore,

$$\begin{aligned}\int_0^1\left\langle |z_1|^2,\, \frac{d}{d\varepsilon}\left|d\varphi^{\mathrm{v}+\varepsilon h}_{1,s}\right|^{-1}\right\rangle_2 ds &= \int_0^1\int_s^1\left\langle |z_1|^2,\, \left|d\varphi^{\mathrm{v}}_{1s}\right|^{-1}\operatorname{div}(h_u)\circ\varphi^{\mathrm{v}}_{1u}\right\rangle_2 duds \\ &\quad -\int_0^1\int_s^1\left\langle |z_1|^2,\, \left|d\varphi^{\mathrm{v}}_{1u}\right|^{-1}\left\langle\nabla_{\varphi^{\mathrm{v}}_{1u}}\left|d\varphi^{\mathrm{v}}_{us}\right|^{-1},\, h_u\circ\varphi^{\mathrm{v}}_{1u}\right\rangle\right\rangle_2 duds \\ &= \int_0^1\int_s^1\left\langle |z_u|^2,\, \left|d\varphi^{\mathrm{v}}_{u1}\right|^{-1}\left|d_{\varphi^{\mathrm{v}}_{u1}}\varphi^{\mathrm{v}}_{1s}\right|^{-1}\operatorname{div}(h_u)\right\rangle_2 duds \\ &\quad -\int_0^1\int_s^1\left\langle |z_u|^2,\, \left\langle\nabla\left|d\varphi^{\mathrm{v}}_{us}\right|^{-1},\, h_u\right\rangle\right\rangle_2 duds.\end{aligned}$$

Introducing

$$q^{\mathrm{v}}_u \triangleq \int_0^u \left|d\varphi^{\mathrm{v}}_{us}\right|^{-1}ds,$$

this may be written

$$\begin{aligned}\int_0^1\left\langle |z_1|^2,\, \frac{d}{d\varepsilon}\left|d\varphi^{\mathrm{v}+\varepsilon h}_{1,s}\right|^{-1}\right\rangle_2 ds &= \int_0^1\left\langle q^{\mathrm{v}}_u\,|z_u|^2,\, \operatorname{div}(h_u)\right\rangle_2 du \\ &\quad -\int_0^1\left\langle |z_u|^2,\, \langle\nabla q^{\mathrm{v}}_u,\, h_u\rangle\right\rangle_2 du \\ &= -\int_0^1\left\langle K_\nabla(q^{\mathrm{v}}_u\,|z_u|^2),\, h_u\right\rangle_{\mathcal{B}} du \\ &\quad -\int_0^1\left\langle K(|z_u|^2\,\nabla q^{\mathrm{v}}_u),\, h_u\right\rangle_{\mathcal{B}} du.\end{aligned}$$

Now, defining functions

$$C^{\mathrm{v}}_t \triangleq \sigma^2 q^{\mathrm{v}}_t\,|z_t|^2 \tag{50}$$

and

$$D^{\mathrm{v}}_t \triangleq \sigma^2\,|z_t|^2\,\nabla q^{\mathrm{v}}_t + 2[d\varphi^{\mathrm{v}}_{t,0}]^* d_{\varphi^{\mathrm{v}}_{t,0}} j_0^* z_t, \tag{51}$$

Proposition 5 implies

$$\frac{dU^\varepsilon}{d\varepsilon} = \int_0^1 \langle h_t\,,\, K.D^{\mathrm{v}}_t + K_\nabla C^{\mathrm{v}}_t\rangle_{\mathcal{B}} dt,$$

which is the conclusion of Lemma 2.

Appendix F. Proof of Lemma 4. We prove that solutions of system (22) travel at constant speed and therefore compute the derivative of $|v_t|^2_{\mathcal{B}} + \sigma^2 |z_t|^2_2$ for such a solution. Starting with the second term, we have $z_t = z_0 \circ \varphi^{\mathrm{v}}_{t,0} \left| d\varphi^{\mathrm{v}}_{t,0} \right|$, which implies, after a change of variables,

$$|z_t|^2_2 = \int_\Omega |z_0|^2_2 \left| d\varphi^{\mathrm{v}}_{0,t} \right|^{-1} dx.$$

Using the identity

$$\left| d\varphi^{\mathrm{v}}_{s,t} \right| = \exp\left(\int_s^t \operatorname{div}(v_u) \circ \varphi^{\mathrm{v}}_{s,u} du \right), \tag{52}$$

we obtain

$$\frac{d}{dt} |z_t|^2_2 = - \int_\Omega |z_0|^2_2 \left| d\varphi^{\mathrm{v}}_{0,t} \right|^{-1} \operatorname{div}(v_t) \circ \varphi^{\mathrm{v}}_{0,t} dx. \tag{53}$$

To study the variation of $|\mathrm{v}_t|^2_{\mathcal{B}}$, we start with the computation of the derivative of $\langle \mathrm{v}_t \,,\, w \rangle$ for a fixed $w \in \mathcal{B}$. Applying formula (28) for a solution of (22) yields

$$\begin{aligned}\langle \mathrm{v}_t \,,\, w \rangle_{\mathcal{B}} = {} & \frac{\sigma^2}{2} \int_0^1 \Big\langle |z_0|^2 \,,\, (\left| d\varphi^{\mathrm{v}}_{0,s} \right|^{-1} \operatorname{div}(w) \circ \varphi^{\mathrm{v}}_{0,t} - \left| d\varphi^{\mathrm{v}}_{0,t} \right|^{-1} \left\langle \nabla \xi^{\mathrm{v}}_{s,t} \,,\, \lambda^{\mathrm{v}}_t(w) \right\rangle) \Big\rangle ds \\ & + (\omega_0, \lambda^{\mathrm{v}}_t(w))\end{aligned}$$

with $\xi^{\mathrm{v}}_{s,t} = \left| d\varphi^{\mathrm{v}}_{0,t} \right| / \left| d\varphi^{\mathrm{v}}_{0,s} \right|$ and $\lambda^{\mathrm{v}}_t(w) = (d\varphi^{\mathrm{v}}_{0,t})^{-1} w \circ \varphi^{\mathrm{v}}_{0,t}$. From formula (52), we have

$$\xi^{\mathrm{v}}_{s,t} = \exp\left(\int_s^t (\operatorname{div} v_u) \circ \varphi^{\mathrm{v}}_{0u} du \right),$$

which implies that

$$d\xi^{\mathrm{v}}_{s,t} = \xi^{\mathrm{v}}_{s,t} \int_s^t d_{\varphi^{\mathrm{v}}_{0u}} (\operatorname{div} v_u) d\varphi^{\mathrm{v}}_{0u} du$$

so that

$$\begin{aligned}\langle \mathrm{v}_t \,,\, w \rangle_{\mathcal{B}} &= (\omega_0, \lambda^{\mathrm{v}}_t(w)) + \frac{\sigma^2}{2} \int_0^t \Big\langle |z_0|^2 \,,\, \left| d\varphi^{\mathrm{v}}_{0,s} \right|^{-1} \operatorname{div}(w) \circ \varphi^{\mathrm{v}}_{0,t} \Big\rangle ds \\ &\quad - \frac{\sigma^2}{2} \int_0^t \int_s^t \Big\langle |z_0|^2 \,,\, \left| d\varphi^{\mathrm{v}}_{0,s} \right|^{-1} d_{\varphi^{\mathrm{v}}_{0u}} (\operatorname{div} v_u) d\varphi^{\mathrm{v}}_{0u} \lambda^{\mathrm{v}}_t(w) \Big\rangle du ds \\ &= (\omega_0, \lambda^{\mathrm{v}}_t(w)) + \frac{\sigma^2}{2} \int_0^t \Big\langle |z_0|^2 \,,\, \left| d\varphi^{\mathrm{v}}_{0,s} \right|^{-1} \operatorname{div}(w) \circ \varphi^{\mathrm{v}}_{0,t} \Big\rangle ds \\ &\quad - \frac{\sigma^2}{2} \int_0^t \int_0^u \Big\langle |z_0|^2 \,,\, \left| d\varphi^{\mathrm{v}}_{0,s} \right|^{-1} d_{\varphi^{\mathrm{v}}_{0u}} (\operatorname{div} v_u) d\varphi^{\mathrm{v}}_{0u} \lambda^{\mathrm{v}}_t(w) \Big\rangle ds du.\end{aligned}$$

We now compute the time differential of each term which appears in this expression. Denote $\overline{\lambda}^{\mathrm{v}}_t(w) = \frac{d}{dt} \lambda^{\mathrm{v}}_t(w)$. We have

$$\overline{\lambda}^{\mathrm{v}}_t(w) = \frac{d}{dt} \left((d\varphi^{\mathrm{v}}_{0,t})^{-1} w \circ \varphi_{0,t} \right) = -(d\varphi^{\mathrm{v}}_{0,t})^{-1} d_{\varphi^{\mathrm{v}}_{0,t}} v_t w \circ \varphi_{0,t} + (d\varphi^{\mathrm{v}}_{0,t})^{-1} d_{\varphi^{\mathrm{v}}_{0,t}} w v_t \circ \varphi_{0,t}.$$

Next, we have

$$\frac{d}{dt}\int_0^t \left\langle |z_0|^2 \,,\, \left|d\varphi^{\mathrm{v}}_{0,s}\right|^{-1} \mathrm{div}(w)\circ\varphi^{\mathrm{v}}_{0,t}\right\rangle ds = \left\langle |z_0|^2 \,,\, \left|d\varphi^{\mathrm{v}}_{0,t}\right|^{-1} \mathrm{div}(w)\circ\varphi^{\mathrm{v}}_{0,t}\right\rangle + \int_0^t \left\langle |z_0|^2 \,,\, \left|d\varphi^{\mathrm{v}}_{0,s}\right|^{-1} \nabla_{\varphi^{\mathrm{v}}_{0,t}}(\mathrm{div}(w))v_t\circ\varphi^{\mathrm{v}}_{0,t}\right\rangle ds$$

and

$$\begin{aligned}\frac{d}{dt}\int_0^t\int_0^u &\left\langle |z_0|^2 \,,\, \left|d\varphi^{\mathrm{v}}_{0,s}\right|^{-1} d_{\varphi^{\mathrm{v}}_{0u}}(\mathrm{div}v_u)d\varphi^{\mathrm{v}}_{0u}\lambda^{\mathrm{v}}_t(w)\right\rangle dsdu\\ &= \int_0^t \left\langle |z_0|^2 \,,\, \left|d\varphi^{\mathrm{v}}_{0,s}\right|^{-1} d_{\varphi^{\mathrm{v}}_{0,t}}(\mathrm{div}v_t)d\varphi^{\mathrm{v}}_{0,t}\lambda^{\mathrm{v}}_t(w)\right\rangle dsdu\\ &+ \int_0^t\int_0^u \left\langle |z_0|^2 \,,\, \left|d\varphi^{\mathrm{v}}_{0,s}\right|^{-1} d_{\varphi^{\mathrm{v}}_{0u}}(\mathrm{div}v_u)d\varphi^{\mathrm{v}}_{0u}\overline{\lambda}^{\mathrm{v}}_t(w)\right\rangle dsdu.\end{aligned}$$

Putting everything together, we have

$$\begin{aligned}\frac{d}{dt}\langle \mathrm{v}_t \,,\, w\rangle_{\mathcal{B}} &= \left(\omega_0, \overline{\lambda}^{\mathrm{v}}_t(w)\right) + \frac{\sigma^2}{2}\left\langle |z_0|^2 \,,\, \left|d\varphi^{\mathrm{v}}_{0,t}\right|^{-1} \mathrm{div}(w)\circ\varphi^{\mathrm{v}}_{0,t}\right\rangle\\ &+ \frac{\sigma^2}{2}\int_0^t \left\langle |z_0|^2 \,,\, \left|d\varphi^{\mathrm{v}}_{0,s}\right|^{-1} d_{\varphi^{\mathrm{v}}_{0,t}}(\mathrm{div}w)v_t\circ\varphi^{\mathrm{v}}_{0,t}\right\rangle dsdu\\ &- \frac{\sigma^2}{2}\int_0^t \left\langle |z_0|^2 \,,\, \left|d\varphi^{\mathrm{v}}_{0,s}\right|^{-1} d_{\varphi^{\mathrm{v}}_{0,t}}(\mathrm{div}v_t)d\varphi^{\mathrm{v}}_{0,t}\lambda^{\mathrm{v}}_t(w)\right\rangle dsdu\\ &- \frac{\sigma^2}{2}\int_0^t\int_0^u \left\langle |z_0|^2 \,,\, \left|d\varphi^{\mathrm{v}}_{0,s}\right|^{-1} d_{\varphi^{\mathrm{v}}_{0u}}(\mathrm{div}v_u)d\varphi^{\mathrm{v}}_{0u}\overline{\lambda}^{\mathrm{v}}_t(w)\right\rangle dsdu.\end{aligned}$$

A little care must be taken in writing, as we did above, $\frac{d}{dt}(\omega_0, \lambda^{\mathrm{v}}_t(w)) = (\omega_0\overline{\lambda}^{\mathrm{v}}_t(w))$, since this requires proving that $(\lambda^{\mathrm{v}}_{t+\varepsilon}(w) - \lambda^{\mathrm{v}}_t(w))/\varepsilon$ converges to $\overline{\lambda}^{\mathrm{v}}_t(w)$ for the $(p-1,\infty)$-norm. This is indeed true in our case, because of the fact that $w\in\mathcal{B}$ allows us to control the uniform norm of its differentials up to order p, and the differentials of φ^{v}_t up to the same order are solutions of a linear differential equation which ensures their uniform continuity.

We now use the identity (which is justified below)

$$\frac{d}{dt}\left|\mathrm{v}_t\right|^2_{\mathcal{B}} = 2\lim_{\varepsilon\to 0}\langle \mathrm{v}_{t+\varepsilon} - \mathrm{v}_t \,,\, \mathrm{v}_t\rangle_{\mathcal{B}}/\varepsilon, \tag{54}$$

which implies that, to compute the time differential of $\left|\mathrm{v}_t\right|^2_{\mathcal{B}}$, it suffices to use the obtained expression for the derivative of $\langle \mathrm{v}_t \,,\, w\rangle_{\mathcal{B}}$ with $w = \mathrm{v}_t$ and multiply it by 2. Since $\overline{\lambda}^{\mathrm{v}}_t(v_t) = 0$, and because of (53), we see that all terms cancel, yielding $\frac{d}{dt}(\left|\mathrm{v}_t\right|^2_{\mathcal{B}} + \sigma^2\left|z_t\right|^2_2) = 0$.

To show (54), one writes

$$(\left|\mathrm{v}_t\right|^2_{\mathcal{B}} - \left|\mathrm{v}_t\right|^2_{\mathcal{B}} - \langle \mathrm{v}_{t+\varepsilon} - \mathrm{v}_t \,,\, \mathrm{v}_t\rangle_{\mathcal{B}})/\varepsilon = \left|\mathrm{v}_{t+\varepsilon} - \mathrm{v}_t\right|^2_{\mathcal{B}}/\varepsilon,$$

and the result is obtained by proving that, for $w\in\mathcal{B}$,

$$\left|\langle \mathrm{v}_{t+\varepsilon} - \mathrm{v}_t \,,\, w\rangle_{\mathcal{B}}\right| = O(\varepsilon)\left|w\right|_{\mathcal{B}},$$

which can be done by a direct estimation of $\frac{d}{dt}\langle \mathrm{v}_t \,,\, w\rangle_{\mathcal{B}}$.

Appendix G. Proof of Lemma 5. It suffices to prove this result for smooth $z_0, \tilde{z}_0, j_0$. It is straightforward that $M_{j_0}(tz_0) = \mathrm{j}_t$, where j is the solution of (21) with initial conditions (j_0, z_0). Let $\tilde{\mathrm{j}}_t = M_{j_0}(t\tilde{z}_0)$. Introduce also the corresponding $(\mathrm{v}_t, \mathrm{z}_t)$ and $(\tilde{\mathrm{v}}_t, \tilde{\mathrm{z}}_t)$.

Introduce the notation $\eta = \tilde{\mathrm{j}} - \mathrm{j}$, $\zeta = \tilde{\mathrm{z}} - \mathrm{z}$, and $\alpha = \tilde{\mathrm{v}} - \mathrm{v}$. Since we have assumed smooth trajectories, we may write

$$\frac{\partial \mathrm{j}_t}{\partial t} = \sigma^2 \mathrm{z}_t - d\mathrm{j}_t \mathrm{v}_t$$

and

$$\frac{\partial \mathrm{z}_t}{\partial t} = -\mathrm{div}(\mathrm{z}_t \otimes \mathrm{v}_t)$$

and similar equations for the trajectory with initial condition $(j_0, \tilde{z}_0)$. Computing the differences along both trajectories yields

$$\left\{ \begin{array}{l} \frac{\partial \eta_t}{\partial t} + d\eta_t \tilde{\mathrm{v}}_t = \sigma^2 \zeta_t - d\mathrm{j}_t \alpha_t, \\ \\ \frac{\partial \zeta_t}{\partial t} + \mathrm{div}(\zeta_t \otimes \tilde{\mathrm{v}}_t) = -\mathrm{div}(\mathrm{z}_t \otimes \alpha_t). \end{array} \right. \tag{55}$$

Since

$$\begin{aligned} \frac{\partial}{\partial t}\left[\left|d\varphi^{\tilde{\mathrm{v}}}_{0,t}\right| \zeta_t \circ \varphi^{\tilde{\mathrm{v}}}_{0,t}\right] &= \left|d\varphi^{\tilde{\mathrm{v}}}_{0,t}\right| \left(\frac{\partial \zeta_t}{\partial t} + \mathrm{div}(\zeta_t \otimes \tilde{\mathrm{v}}_t)\right) \circ \varphi^{\tilde{\mathrm{v}}}_{0,t} \\ &= -\left|d\varphi^{\tilde{\mathrm{v}}}_{0,t}\right| \mathrm{div}(\mathrm{z}_t \otimes \alpha_t) \circ \varphi^{\tilde{\mathrm{v}}}_{0,t}, \end{aligned}$$

the second term yields

$$\zeta_s \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} = \left|d\varphi^{\tilde{\mathrm{v}}}_{0,s}\right|^{-1} (\tilde{z}_0 - z_0) - \left(\int_0^s \left|d\varphi^{\tilde{\mathrm{v}}}_{s,u}\right| \mathrm{div}(\mathrm{z}_u \otimes \alpha_u) \circ \varphi^{\tilde{\mathrm{v}}}_{s,u} du\right) \circ \varphi^{\tilde{\mathrm{v}}}_{0,s},$$

and the first one implies

$$\eta_t \circ \varphi^{\tilde{\mathrm{v}}}_{0,t} = \sigma^2 \int_0^t \zeta_s \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} ds - \int_0^t [d\mathrm{j}_s \alpha_s] \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} ds.$$

Replacing ζ in the last equation gives

(56)
$$\begin{aligned} \eta_t \circ \varphi^{\tilde{\mathrm{v}}}_{0,t} &= t[\sigma^2(\tilde{z}_0(.) - z_0(.)) - dj_0(\tilde{v}_0 - v_0)] \\ &\quad - \sigma^2 \int_0^t \left(\int_0^s \left|d\varphi^{\tilde{\mathrm{v}}}_{s,u}\right| \mathrm{div}(\mathrm{z}_u \otimes \alpha_u) \circ \varphi^{\tilde{\mathrm{v}}}_{s,u} du\right) \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} ds \\ &\quad - \int_0^t \left\{[d\mathrm{j}_s \alpha_s] \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} - dj_0(\tilde{v}_0 - v_0)\right\} ds + \int_0^t \left(\left|d\varphi^{\tilde{\mathrm{v}}}_{0,s}\right|^{-1} - 1\right) (\tilde{z}_0 - z_0) ds \end{aligned}$$

so that Lemma 5 reduces to evaluating the L^2-norm of the last three integrals. We shall use the fact that, for a function $f \in L^2([0,1] \times \Omega, \mathbb{R}^d)$,

$$\left|\int_0^t f_s ds\right|_2 \leq \int_0^t |f_s|_2 \, ds.$$

For $t \in [0,1]$, we also have, from (31), with $\omega_0 = dj_0^* z_0$ and $\omega_0' = dj_0^* z_0'$ (here and in the following, we denote by const any quantity which depends only on j_0, z_0 and $\tilde{z}_0$),

$$|\alpha_t|_{\mathcal{B}} \le \text{const } |z_0 - \tilde{z}_0|_2 \,. \tag{57}$$

This implies that

$$\begin{aligned}
&\left|\int_0^t \left(\int_0^s \left|d\varphi^{\tilde{\mathrm{v}}}_{s,u}\right| \operatorname{div}(\mathrm{z}_u \otimes \alpha_u) \circ \varphi^{\tilde{\mathrm{v}}}_{s,u} du\right) \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} ds\right|_2 \\
&\quad \le \int_0^t \int_0^s \left|\left|d_{\varphi^{\tilde{\mathrm{v}}}_{0,s}} \varphi^{\tilde{\mathrm{v}}}_{s,u}\right| \operatorname{div}(\mathrm{z}_u \otimes \alpha_u) \circ \varphi^{\tilde{\mathrm{v}}}_{0,u}\right|_2 du ds \\
&\quad = \int_0^t \int_0^s \left|\left|d\varphi^{\tilde{\mathrm{v}}}_{0,s}\right|^{-1} \operatorname{div}(\mathrm{z}_u \otimes \alpha_u)\right|_2 ds \\
&\quad \le \text{const } \int_0^t \int_0^s |\operatorname{div}(\mathrm{z}_u \otimes \alpha_u)|_2 \, du ds \\
&\quad \le \text{const } \int_0^t \int_0^s |\mathrm{z}_u|_{H^1} \, |\alpha_u|_{\mathcal{B}} \, du ds.
\end{aligned}$$

The relation $\mathrm{z}_t = z_0 \circ \varphi^{\mathrm{v}}_{t,0} \left|d\varphi^{\mathrm{v}}_{t,0}\right|$ implies that $|\mathrm{z}_u|_{H^1} \le \text{const } |z_0|_{H^1}$ so that

$$\left|\int_0^t \left(\int_0^s \left|d\varphi^{\tilde{\mathrm{v}}}_{s,u}\right| \operatorname{div}(\mathrm{z}_u \otimes \alpha_u) \circ \varphi^{\tilde{\mathrm{v}}}_{s,u} du\right) \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} ds\right|_2 \le \text{const } t^2 \, |\tilde{z}_0 - z_0|_2 \,.$$

A similar estimate is valid for the last integral in (56), since $||d\varphi^{\mathrm{v}}_{0,s}|^{-1} - 1|_\infty \le \text{const } s$. We finally consider the second integral in this equation.

Since

$$\mathrm{j}_s = j_0 \circ \varphi^{\mathrm{v}}_{s,0} + \sigma^2 z_0 \circ \varphi^{\mathrm{v}}_{s,0} \int_0^s |d\varphi^{\mathrm{v}}_{u0}| \circ \varphi^{\mathrm{v}}_{s,u} du,$$

we have, letting $\gamma_s = \varphi^{\mathrm{v}}_{s,0} \circ \varphi^{\tilde{\mathrm{v}}}_{0,s}$,

$$d_{\varphi^{\tilde{\mathrm{v}}}_{0,s}} \mathrm{j}_s \, \alpha \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} = d_{\gamma_s} j_0 \, d_{\varphi^{\tilde{\mathrm{v}}}_{0,s}} \varphi^{\mathrm{v}}_{s,0} \, \alpha \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} + R_s,$$

and it is easy to check that $|R_t|_2 \le \text{const } t \, |z_0|_{H^1} \, |\tilde{z}_0 - z_0|_2$. We need to estimate

$$\begin{aligned}
&\int_0^t \left(d_{\gamma_s} j_0 \, d_{\varphi^{\tilde{\mathrm{v}}}_{0,s}} \varphi^{\mathrm{v}}_{s,0} \, \alpha_s \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} - dj_0 \alpha_0\right) ds \\
&\qquad = \int_0^t \left(d_{\gamma_s} j_0 (d_{\varphi^{\tilde{\mathrm{v}}}_{0,s}} \varphi^{\mathrm{v}}_{s,0} \, \alpha_s \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} - \alpha_0)\right) ds + \int_0^t (d_{\gamma_s} j_0 \, \alpha_0 - dj_0 \, \alpha_0) \, ds.
\end{aligned} \tag{58}$$

Start with the first term, for which we must bound, for the L^∞-norm, the difference $d_{\varphi^{\tilde{\mathrm{v}}}_{0,s}} \varphi^{\mathrm{v}}_{s,0} \, \alpha \circ \varphi^{\tilde{\mathrm{v}}}_{0,s} - \alpha_0$ or, equivalently,

$$d\varphi^{\mathrm{v}}_{s,0} \alpha_s - \alpha_0 \circ \varphi^{\tilde{\mathrm{v}}}_{s,0}.$$

It is simple to check, from (57) and estimates we have used several times on the variations of the diffeomorphisms, that $(d\varphi^{\mathrm{v}}_{s,0} - I)\alpha_s$ and $\alpha_0 \circ \varphi^{\tilde{\mathrm{v}}}_{s,0} - \alpha_0$ are bounded by const $s \, |\tilde{z}_0 - z_0|_2$. We now proceed to an upper bound for $\alpha_s - \alpha_0$, for which we need to return to the expression obtained in (28), which yields

$$\begin{aligned}
\langle \mathrm{v}_s - \mathrm{v}_0, w\rangle_{\mathcal{B}} = \frac{\sigma^2}{2} \int_0^s \Big\langle |z_0|^2 \,, (|d\varphi^{\mathrm{v}}_{0u}|^{-1} \operatorname{div}(w) \circ \varphi^{\mathrm{v}}_{0,s} \\
- \left|d\varphi^{\mathrm{v}}_{0,s}\right|^{-1} \langle \nabla \xi^{\mathrm{v}}_{us} \,, \, \lambda^{\mathrm{v}}_s(w)\rangle)\Big\rangle \, du + \langle z_0 \,, \, dj_0(\lambda^{\mathrm{v}}_s(w) - w)\rangle_2
\end{aligned}$$

so that

$$\begin{aligned}\langle \alpha_s - \alpha_0\,,\, w\rangle_{\mathcal{B}} &= \frac{\sigma^2}{2}\int_0^s \Big\langle \left|\tilde z_0\right|^2,\, (\left|d\varphi^{\tilde{\mathrm{v}}}_{0u}\right|^{-1}\operatorname{div}(w)\circ\varphi^{\tilde{\mathrm{v}}}_{0,s} - \left|d\varphi^{\tilde{\mathrm{v}}}_{0,s}\right|^{-1}\left\langle \nabla\xi^{\tilde{\mathrm{v}}}_{us}\,,\,\lambda^{\tilde{\mathrm{v}}}_s(w)\right\rangle)\Big\rangle du\\ &\quad- \frac{\sigma^2}{2}\int_0^s \Big\langle \left|z_0\right|^2,\, (\left|d\varphi^{\mathrm{v}}_{0u}\right|^{-1}\operatorname{div}(w)\circ\varphi^{\mathrm{v}}_{0,s} - \left|d\varphi^{\mathrm{v}}_{0,s}\right|^{-1}\left\langle \nabla\xi^{\mathrm{v}}_{us}\,,\,\lambda^{\mathrm{v}}_s(w)\right\rangle)\Big\rangle du\\ &\quad+ \left\langle \tilde z_0\,,\, dj_0(\lambda^{\tilde{\mathrm{v}}}_s(w)-w)\right\rangle_2 - \left\langle z_0\,,\, dj_0(\lambda^{\mathrm{v}}_s(w)-w)\right\rangle_2.\end{aligned}$$

The difference of the first two integrals takes the form

$$\frac{\sigma^2}{2}\int_0^s \left(\left\langle \tilde z_0\,,\, Q^{\tilde{\mathrm{v}}}_{us}(w)\right\rangle - \left\langle z_0\,,\, Q^{\mathrm{v}}_{us}(w)\right\rangle\right) du \tag{59}$$

with $Q^{\mathrm{v}}_{us}(w) = \left|d\varphi^{\mathrm{v}}_{0u}\right|^{-1}\operatorname{div}(w)\circ\varphi^{\mathrm{v}}_{0,s} - \left|d\varphi^{\mathrm{v}}_{0,s}\right|^{-1}\left\langle\nabla\xi^{\mathrm{v}}_{us}\,,\,\lambda^{\mathrm{v}}_s(w)\right\rangle$. From Lemmas 7 and 11, and from (57), we obtain the fact that $\left|Q^{\tilde{\mathrm{v}}}_{us}(w) - Q^{\mathrm{v}}_{us}(w)\right| \le \text{const }\left|\tilde z_0 - z_0\right|_2 \left|w\right|_{\mathcal{B}}$ so that the quantity in (59) is bounded by const $s\left|\tilde z_0 - z_0\right|_2$. Writing

$$\begin{aligned}\left\langle \tilde z_0\,,\, dj_0(\lambda^{\tilde{\mathrm{v}}}_s(w)-w)\right\rangle_2 - \left\langle z_0\,,\, dj_0(\lambda^{\mathrm{v}}_s(w)-w)\right\rangle_2 &= \left\langle \tilde z_0 - z_0\,,\, dj_0(\lambda^{\tilde{\mathrm{v}}}_s(w)-w)\right\rangle_2\\ &\quad+ \left\langle z_0\,,\, dj_0(\lambda^{\tilde{\mathrm{v}}}_s(w)-\lambda^{\mathrm{v}}_s(w))\right\rangle_2\end{aligned}$$

and using $\left|\lambda^{\tilde{\mathrm{v}}}_s(w) - w\right|_\infty \le$ const s (which is deduced from Lemma 7 and a computation of the differential of $\lambda^{\tilde{\mathrm{v}}}_s(w)$ with respect to s) and $\left|\lambda^{\tilde{\mathrm{v}}}_s(w) - \lambda^{\mathrm{v}}_s(w)\right|_\infty \le$ const $s\left|\tilde z_0 - z_0\right|_2$ (from Lemma 11 and (57)), we finally conclude that

$$\left|d_{\varphi^{\tilde{\mathrm{v}}}_{0,s}}\varphi^{\mathrm{v}}_{s,0}\,\alpha\circ\varphi^{\tilde{\mathrm{v}}}_{0,s} - \alpha_0\right|_\infty \le \text{const } s\left|\tilde z_0 - z_0\right|_2,$$

which implies that the first integral in the right-hand term of (58) is bounded by const $t^2\left|\tilde z_0 - z_0\right|_2$.

Consider now the last term of (58), namely,

$$\int_0^t (dj_0\circ\gamma_s - dj_0)\,\alpha_0 ds.$$

Since $\left|\alpha_0\right|_\infty \le C\left|\tilde z_0 - z_0\right|_2$, we must estimate $\left|d_{\gamma_s}j_0 - dj_0\right|_2$. By Theorem 10, this is a function of the kind

$$\varepsilon_M(dj_0, \left|\gamma_s - \mathrm{Id}\right|_\infty) = \varepsilon_M(dj_0, \left|\varphi^{\tilde{\mathrm{v}}}(s) - \varphi^{\mathrm{v}}(s)\right|_\infty),$$

where M depends only on $\left|j_0\right|_{H^1}, \left|z_0\right|_2, \left|\tilde z_0\right|_2$. Since $|\varphi^{\tilde{\mathrm{v}}}_{0,s} - \varphi^{\mathrm{v}}_{0,s}|_\infty = O(s)$, we get (with another function ε)

$$\int_0^t (dj_0\circ\gamma_s - dj_0)\,\alpha_0 ds \le \varepsilon(j_0,t)t\left|\tilde z_0 - z_0\right|_2.$$

We need finally to consider the last line of (56) which can be easily bounded from above by $\varepsilon(j_0,t)t\left|\tilde z_0 - z_0\right|_2$. We now can collect the estimates we have obtained to conclude the proof of Lemma 5.

MATHEMATICAL ANALYSIS OF A NONLINEAR PARABOLIC EQUATION ARISING IN THE MODELLING OF NON-NEWTONIAN FLOWS*

ERIC CANCÈS†, ISABELLE CATTO‡, AND YOUSRA GATI†

Abstract. The mathematical properties of a nonlinear parabolic equation arising in the modelling of concentrated suspension flows are investigated. The peculiarity of this equation is that it may degenerate into a hyperbolic equation (in fact, a linear advection equation). Depending on the initial data, at least two situations can be encountered: the equation may have a unique solution in a convenient class, or it may have infinitely many solutions. The present article is the theoretical side of a joint project with rheologists, aiming at better understanding the flows of complex fluids.

Key words. nonlinear parabolic equation, degenerate parabolic equation, viscosity solutions, non-Newtonian flows, complex fluids, concentrated suspensions

1. Introduction and description of the model.

Complex fluids are substances that are neither really liquid nor really solid in the classical sense. They include melt polymers, colloids, emulsions, foams, gels, liquid crystals, suspensions, and other materials that form flowable microstructures. Modelling the flow of such fluids is a very intricate problem which is far from being solved up to now. The model we are interested in is an attempt to recover the rheological behavior of the particular type of concentrated suspensions. Examples of such suspensions are numerous and can be found, e.g., in food (pastes), cosmetics (tooth paste), medicine (blood), and building industry (cement). In contrast to some complex fluids such as polymeric liquids for which elaborate rheological models, based on fine mesoscopic physical descriptions, are available, the modelling of concentrated suspensions is still in its infancy.

When simple fluids are sheared, stress and shear rate are linked by a linear relation. The linear response coefficients are well understood and their relation to the microstructure of the fluid are known [7]. On the contrary, complex systems, such as concentrated suspensions of hard or soft spheres, exhibit very nonlinear flow properties far from being understood. These nonlinear properties occur not only at high shear rates, where one expects that linear response theory does not apply, but also at very low shear rates. Let us for instance consider a concentrated suspension of particles. At low concentrations, thermally induced structural relaxations of the particles positions occur. The system behaves as a Newtonian fluid at low shear rates[1]. But, when the concentration is increased, the energetical cost of particles reorganizations

[1]At higher shear rates, due to hydrodynamics interactions, the relation between the stress and the shear rate may be sublinear, and the system is said to be shear-thinning. We neglect all hydrodynamics interactions in the following description.

is much higher than thermal energy, and structural relaxations are arrested. This implies that, once at rest, the system is not at thermal equilibrium, and exhibits general properties of glasses [1, 11, 13, 14]. This property has a striking consequence on the low shear rate flow of these systems: the stress σ tends to a finite nonzero value σ_c when shear rate goes to zero. This discontinuity of the shear stress *versus* shear rate is an experimental very common feature, but is very poorly understood. One of the most common physical explanations relies on the hypothesis that the system may locally store deformation. It relies on observations of the structures of concentrated dispersions that appear to be frozen in nonequilibrium positions: particular configurations of the dynamically arrested suspension store deformation energy. They do not correspond to configurations of minimal energy, and may thus store finite values of stress and strain. The system may thus be described as an heterogeneous field of stress and strain. Microscopic description of these fields does not exist, and, besides studies which aim at improving phenomenological models (such as the celebrated Herschel–Bulkley model [9]), a few attempts have been made to recover the rheological behavior of complex fluids from elementary physical processes. We consider here the model proposed by Hébraud and Lequeux, in which the system is divided in mesoscopic blocks whose size is large enough so that stress and strain tensors may be defined for each block, but small compared to the characteristic length scale of the stress field. A mesoscopic evolution equation of the stress of each block is then written as:

(i) At low shear, each particle keeps the same neighbors, and a block behaves as an Einstein elastic solid, in which the elasticity arises from interactions between neighboring particles.

(ii) Then, deformation induces local reorganization of the particles, at a given stress threshold σ_c. Above this threshold, the block flows as an Eyring fluid: the configuration reached by shearing the suspension relaxes with a characteristic time T_0 towards a completely relaxed state, where no stress is stored.

(iii) Lastly, coupling between the flow of neighboring blocks must be included. This is taken into account by the introduction of a diffusion term in the evolution equation, where it is assumed that the diffusion coefficient is proportional to the number of reorganizations per unit time.

In the model, each block carries a given shear stress σ (σ is a real number; it is in fact an extra-diagonal term of the stress tensor in convenient coordinates). The evolution of the blocks is described through a probability density $p(t,\sigma)$ which represents the distribution of stress in the assembly of blocks at time t. The equation for the probability density $p(t,\sigma)$ for a block to be under stress σ at time t is written as

$$\begin{cases} \partial_t p = -b(t)\partial_\sigma p + D(p(t))\partial^2_{\sigma\sigma} p - \dfrac{\mathbb{1}_{\mathbb{R}\setminus[-\sigma_c,\sigma_c]}(\sigma)}{T_0} p + \dfrac{D(p(t))}{\alpha}\delta_0(\sigma), \\ t \in (0;T), \quad \sigma \in \mathbb{R}, \\ p \geq 0, \\ p(0,\sigma) = p_0(\sigma), \end{cases} \tag{1.1}$$

where for $f \in L^1(\mathbb{R})$, we denote

$$D(f) = \frac{\alpha}{T_0}\int_{|\sigma|>\sigma_c} f(\sigma)d\sigma. \tag{1.2}$$

The equation satisfied by p in (1.1) is referred to as the SP equation in the following. In this equation, $\mathbb{1}_{\mathbb{R}\setminus[-\sigma_c,\sigma_c]}$ denotes the characteristic function of the open set $\mathbb{R}\setminus[-\sigma_c,\sigma_c]$ and δ_0 the Dirac delta function on $\mathbb{R}$. The three terms arising from the right-hand side of the HL equation model the three physical features described above. When a block is submitted to a shear rate $\dot\gamma(t)$, the stress of this block evolves with a variation rate $b(t) = G_0\dot\gamma(t)$, where G_0 is an elasticity constant. (In this study, the shear rate $\dot\gamma(t)$, and therefore the function $b(t)$, are assumed to be in $L^2_{\mathrm{loc}}(\mathbb{R}^+)$.) When the modulus of the stress overcomes the critical value σ_c, the block becomes unstable and may relax into a state with zero stress after a characteristic relaxation time T_0. This property is expressed by the last two terms in (1.1). This relaxation phenomenon induces a rearrangement of the other blocks and this is finally modelled through the diffusion term $D(p(t))\partial^2_{\sigma\sigma}p$. The diffusion coefficient $D(p(t))$ as given by (1.2) is assumed to be proportional to the density of blocks that rearrange during time T_0, by a proportional parameter α which depends on the microscopic properties of the sample and which is supposed to represent the "mechanical fragility" of the material. This nonlinear diffusion term is introduced to display the importance of collective effects in this kind of samples. For more details on the physical meaning of the model, we refer to the original article by Hébraud and Lequeux [8].

In all that follows, the parameters α, T_0 and σ_c are positive, and the initial data p_0 in (1.1) is a given probability density; that is,

$$p_0 \geq 0, \quad p_0 \in L^1(\mathbb{R}), \quad \int_{\mathbb{R}} p_0 = 1. \tag{1.3}$$

We will be looking for solutions $p = p(t,\sigma)$ in $C^0_t(L^1_\sigma \cap L^2_\sigma)$ such that σp belongs to $L^\infty_t(L^1_\sigma)$ of the nonlinear parabolic partial differential equation (1.1). The subscript σ refers to integration over $\mathbb{R}$ with respect to σ, whereas the subscript t refers to time integration on $[0,T]$ for any $T > 0$. Note that under a mean-field assumption the macroscopic stress in the material is given by

$$\tau(t) = \int_{\mathbb{R}} \sigma p(t,\sigma)d\sigma, \tag{1.4}$$

and therefore the above condition on σp ensures that the average stress is an essentially bounded function of time.

Actually in practice, the shear rate is not uniform in the flow (the shear creates elastic waves in the fluid), and in order to better describe the coupling between the macroscopic flow and the evolution of the microstructure we introduce and study in a second paper [2] a micro-macro model where the shear rate is a function of the velocity of the macroscopic flow. In this model p is also a function of the macroscopic space variables and the average stress defined by (1.4) is inserted into the macroscopic equation governing the velocity of the macroscopic flow (see also section 6 below).

In order to lighten the notation and without loss of generality we assume from now on that $\sigma_c = 1$ and $T_0 = 1$. This amounts to changing the time and stress scales.

The main difficulties one encounters in the mathematical analysis come from the nonlinearity in the diffusion term and even more from the fact that the parabolic equation may degenerate when the viscosity coefficient $D(p)$ vanishes, and this will be shown to appear only when $D(p_0) = 0$. This difficulty is illustrated on a simplified example just below and also in section 5 where we discuss the existence of stationary solutions in the case when the shear rate b is a constant.

Let us first of all look at the following simplified model which already includes the difficulties we are going to face to in the study of (1.1). We consider the equation

$$\begin{cases} \partial_t u = D(u(t))\partial^2_{\sigma\sigma} u, \\ u(0,\sigma) = \frac{1}{2}\mathbb{1}_{]-1,1[}(\sigma), \end{cases} \tag{1.5}$$

where $\mathbb{1}_{]-1,1[}$ is the characteristic function of the interval $]-1,1[$. The initial condition is purposely chosen in such a way that $D(u(t=0)) = 0$. The function $u = \frac{1}{2}\mathbb{1}_{]-1,1[}(\sigma)$ is a stationary solution to this equation and for this solution $D(u(t))$ is identically zero. But it is not the unique solution to (1.5) in $C^0_t(L^2_\sigma) \cap L^\infty_t(L^1_\sigma)$. It is indeed possible to construct a so-called *vanishing viscosity solution* for which $D(u(t)) > 0$ for all $t > 0$, and there are actually infinitely many solutions to this equation. (This statement is obtained as a corollary of Lemma 4.3 in section 4 below.)

As far as (1.1) is concerned, we show that, in the case when $D(p_0) = 0$ and $b \equiv 0$, we may have either a unique or infinitely many solutions, depending on the initial data (see Proposition 4.1 in section 4).

On the other hand, we are able to prove the following existence and uniqueness result in the nondegenerate case when $D(p_0) > 0$.

THEOREM 1.1. *Let the initial data p_0 satisfy the conditions*

$$p_0 \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R}), \quad p_0 \geq 0, \int_{\mathbb{R}} p_0 = 1, \text{ and } \int_{\mathbb{R}} |\sigma| p_0 < +\infty, \tag{1.6}$$

and assume that

$$D(p_0) > 0.$$

Then, for every $T > 0$, there exists a unique solution p to (1.1) *in $L^\infty_t(L^1_\sigma \cap L^2_\sigma) \cap L^2_t(H^1_\sigma)$. Moreover, $p \in L^\infty_{t,\sigma} \cap C^0_t(L^1_\sigma \cap L^2_\sigma)$, $\int_{\mathbb{R}} p(t,\sigma)d\sigma = 1$ for all $t > 0$, $D(p) \in C^0_t$ and for every $T > 0$ there exists a positive constant $\nu(T)$ such that*

$$\min_{0 \leq t \leq T} D(p(t)) \geq \nu(T).$$

Besides $\sigma p \in L^\infty_t(L^1_\sigma)$ so that the average stress $\tau(t)$ is well-defined by (1.4) *in L^∞_t.*

The first step towards the existence proof of solutions to (1.1) will consist of the study of so-called vanishing viscosity approximations, which are the unique solutions to the following family of equations:

$$\begin{cases} \partial_t p_\varepsilon = -b(t)\partial_\sigma p_\varepsilon + (D(p_\varepsilon(t)) + \varepsilon)\partial^2_{\sigma\sigma} p_\varepsilon - \mathbb{1}_{\mathbb{R}\setminus[-1,1]} p_\varepsilon + \dfrac{D(p_\varepsilon(t))}{\alpha}\delta_0(\sigma), \\ p_\varepsilon \geq 0, \\ p_\varepsilon(0,\cdot) = p_0. \end{cases} \tag{1.7}$$

(Recall that we have rescaled the time and stress units to get $T_0 = 1$ and $\sigma_c = 1$.) Section 2 below is devoted to the proof of the following proposition.

PROPOSITION 1.2 (existence and uniqueness of vanishing viscosity approximations). *Let $T > 0$ be given. We assume that the initial data satisfies the same conditions* (1.6) *as in the statement of the theorem. Then, for every $T > 0$ and*

$0 < \varepsilon \leq 1$, there exists a unique solution p_ε to (1.7) *in $L^\infty_t(L^1_\sigma \cap L^2_\sigma) \cap L^2_t(H^1_\sigma)$. Moreover, $p_\varepsilon \in L^\infty_{t,\sigma} \cap C^0_t(L^1_\sigma \cap L^2_\sigma)$, $D(p_\varepsilon) \in C^0_t$,*

$$\int_{\mathbb{R}} p_\varepsilon = 1, \tag{1.8}$$

$$0 \leq p_\varepsilon \leq \|p_0\|_{L^\infty_\sigma} + \sqrt{\frac{\alpha}{\pi}}\sqrt{T}, \tag{1.9}$$

and for every $T > 0$, there exist positive constants $C_1(T, p_0)$, $C_2(T, p_0)$, and $C_3(T, p_0)$ which are independent of ε such that

$$\sup_{0 \leq t \leq T} \int_{\mathbb{R}} |\sigma| p_\varepsilon \leq C_1(T, p_0), \tag{1.10}$$

$$\sup_{0 \leq t \leq T} \int_{\mathbb{R}} p_\varepsilon^2 \leq C_2(T, p_0), \tag{1.11}$$

and

$$\int_0^T \big(\varepsilon + D(p_\varepsilon)\big) \int_{\mathbb{R}} |\partial_\sigma p_\varepsilon|^2 \leq C_3(T, p_0). \tag{1.12}$$

Theorem 1.1 is then proved in section 3 while the degenerate case is investigated in section 4. Lastly, the description of stationary solutions in the constant shear rate case is carried out in section 5.

2. The vanishing viscosity approximation. This section is devoted to the proof of Proposition 1.2. We begin with the following lemma.

LEMMA 2.1 (uniqueness). *Let p_0 satisfy* (1.3). *Then for every $T > 0$ and $0 < \varepsilon$, there exists at most one solution p_ε to* (1.7) *in $L^\infty_t(L^1_\sigma \cap L^2_\sigma) \cap L^2_t(H^1_\sigma)$. Moreover, $p_\varepsilon \in C^0_t(L^2_\sigma)$ (thus, the initial condition makes sense) and*

$$\int_{\mathbb{R}} p_\varepsilon = 1, \tag{2.1}$$

for almost every t in $[0, T]$.

Proof. We begin by proving that every solution to (1.7) in $L^\infty_t(L^1_\sigma \cap L^2_\sigma) \cap L^2_t(H^1_\sigma)$ satisfies (2.1). We fix $R > 1$ and we consider a cut-off C^2 function $\phi_R = \phi_R(\sigma)$ with compact support which is equal to 1 when $0 \leq |\sigma| \leq R$ and to 0 when $|\sigma| \geq 2R$ and such that

$$|\phi_R'| \leq \frac{C}{R}, \tag{2.2}$$

where here and below C denotes a positive constant that is independent of R. Notice that ϕ' is equal to 0 on $]-\infty, -2R]$, on $[-R, R]$ and on $[2R, +\infty[$.

Now, we multiply (1.7) by ϕ_R and integrate over $[0, t] \times \mathbb{R}$ to obtain

$$\begin{aligned}
&\int_{\mathbb{R}} p_\varepsilon(t)\phi_R - \int_{\mathbb{R}} p_0\phi_R \\
&\quad = -\int_0^t b(s) \int_{\mathbb{R}} \partial_\sigma p_\varepsilon(s)\phi_R - \int_0^t (D(p_\varepsilon(s)) + \varepsilon) \int_{\mathbb{R}} \partial_\sigma p_\varepsilon(s)\phi_R' \\
&\qquad - \int_0^t \int_{|\sigma|>1} p_\varepsilon(s)\phi_R + \frac{1}{\alpha}\int_0^t D(p_\varepsilon(s))\phi_R(0).
\end{aligned}$$

We bound the terms on the right-hand side from above as follows. First, we have

$$\begin{aligned}\left|\int_0^t b(s)\int_{\mathbb{R}}\partial_\sigma p_\varepsilon(s)\phi_R\right| &\le \int_0^t |b(s)|\int_{\mathbb{R}} p_\varepsilon(s)|\phi_R'|\\ &\le \frac{C}{R}\int_0^t |b(s)|\int_{R\le|\sigma|\le 2R} p_\varepsilon(s) \le \frac{C}{R},\end{aligned}$$

thanks to (2.2) and using that $p_\varepsilon \in L_t^\infty(L_\sigma^1)$ and $b \in L_t^1$. Next,

$$\begin{aligned}\int_0^t (D(p_\varepsilon)+\varepsilon)\left|\int_{\mathbb{R}}\partial_\sigma p_\varepsilon \phi'\right| &\le (\varepsilon + \alpha\|p_\varepsilon\|_{L_t^\infty(L_\sigma^1)})\int_0^t \|\partial_\sigma p_\varepsilon\|_{L_\sigma^2}\|\phi_R'\|_{L_\sigma^2}\\ &\le \frac{C\sqrt{t}}{R^{1/2}}\|\partial_\sigma p_\varepsilon\|_{L_{t,\sigma}^2} \le \frac{C}{R^{1/2}},\end{aligned}$$

thanks again to (2.2), the Cauchy–Schwarz inequality and since $\partial_\sigma p_\varepsilon$ is in $L_{t,\sigma}^2$. Finally,

$$\begin{aligned}0 \le \frac{1}{\alpha}\int_0^t D(p_\varepsilon) - \int_0^t\int_{|\sigma|>1} p_\varepsilon\phi_R &= \int_0^t\int_{|\sigma|>1} p_\varepsilon(1-\phi_R)\\ &\le \int_0^t\int_{|\sigma|>R} p_\varepsilon,\end{aligned}$$

and the right-hand side goes to 0 as R goes to infinity since p_ε is in $L_t^\infty(L_\sigma^1)$. All this together yields

$$\int_{\mathbb{R}} p_\varepsilon(t) = \lim_{R\to+\infty}\int_{\mathbb{R}} p_\varepsilon(t)\phi_R = \lim_{R\to+\infty}\int_{\mathbb{R}} p_0\phi_R = \int_{\mathbb{R}} p_0 = 1,$$

for almost every t in $[0,T]$. In particular, this implies that $D(p_\varepsilon)\le\alpha$.

Let us now argue by contradiction by assuming that there exist two solutions p_1 and p_2 to (1.7) corresponding to the same initial data p_0. By subtracting the equations satisfied by p_1 and p_2, respectively, we obtain

$$\begin{cases}\partial_t q = -b(t)\partial_\sigma q + D(q)\partial_{\sigma\sigma}^2 p_1 + (D(p_2)+\varepsilon)\partial_{\sigma\sigma}^2 q\\ \qquad -\mathbb{1}_{\mathbb{R}\setminus[-1,1]}q + \dfrac{D(q)}{\alpha}\delta_0(\sigma),\\ q(0,\sigma)=0,\end{cases}\tag{2.3}$$

where $q = p_1 - p_2$. We multiply (2.3) by q and integrate over $\mathbb{R}$ with respect to σ to obtain, after integrations by parts,

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}} q^2 + (D(p_2)+\varepsilon)\int_{\mathbb{R}}|\partial_\sigma q|^2 + \int_{|\sigma|>1} q^2\\ &\quad = \frac{D(q)}{\alpha}q(t,0) - D(q)\int_{\mathbb{R}}\partial_\sigma p_1\partial_\sigma q.\end{aligned}\tag{2.4}$$

We first remark that since $\int_{\mathbb{R}} p_1 = \int_{\mathbb{R}} p_2 = 1$ thanks to (2.1), we get

$$|D(q)| = \alpha\left|\int_{|\sigma|<1} q\right| \le \alpha\sqrt{2}\|q\|_{L_\sigma^2},$$

with the help of the Cauchy–Schwarz inequality. Next, using the Sobolev embedding of $H^1(\mathbb{R})$ into $L^\infty(\mathbb{R})$, we bound the terms on the right-hand side from above in the following way:

$$\begin{aligned}
&\left|\frac{D(q)}{\alpha}q(t,0) - D(q)\int_{\mathbb{R}} \partial_\sigma p_1 \partial_\sigma q\right| \\
&\quad \le \sqrt{2}\|q\|_{L^2_\sigma}\|q\|_{L^\infty_\sigma} + \sqrt{2}\alpha\|q\|_{L^2_\sigma}\int_{\mathbb{R}} |\partial_\sigma p_1 \partial_\sigma q| \\
&\quad \le \sqrt{2}\|q\|_{L^2_\sigma}\left(\|q\|^2_{L^2_\sigma} + \|\partial_\sigma q\|^2_{L^2_\sigma}\right)^{\frac{1}{2}} + \sqrt{2}\alpha\|q\|_{L^2_\sigma}\|\partial_\sigma p_1\|_{L^2_\sigma}\|\partial_\sigma q\|_{L^2_\sigma} \\
&\quad \le \frac{1}{\varepsilon}\|q\|^2_{L^2_\sigma} + \frac{\alpha^2}{\varepsilon}\|q\|^2_{L^2_\sigma}\|\partial_\sigma p_1\|^2_{L^2_\sigma} + \frac{\varepsilon}{2}\|q\|^2_{L^2_\sigma} + \varepsilon\|\partial_\sigma q\|^2_{L^2_\sigma}.
\end{aligned}$$

Therefore, comparing with (2.4) we deduce that

$$\frac{1}{2}\frac{d}{dt}\|q\|^2_{L^2_\sigma} \le \left(\frac{1}{\varepsilon} + \frac{\alpha^2}{\varepsilon}\|\partial_\sigma p_1\|^2_{L^2_\sigma} + \frac{\varepsilon}{2}\right)\|q\|^2_{L^2_\sigma}.$$

Finally, by applying the Gronwall lemma, we prove that $\|q\|^2_{L^2_\sigma} \le 0$, thus $q = 0$. The uniqueness of the solution follows. ∎

Remark 2.2. The same proof shows that if there exists a solution to (1.1) in $L^\infty_t(L^1_\sigma \cap L^2_\sigma) \cap L^2_t(H^1_\sigma)$ such that $\inf_{0\le t\le T} D(p(t)) > 0$, then it is unique in this space.

We now turn to the existence part in the statement of Proposition 1.2. From now on we fix a positive constant $\varepsilon \le 1$. The proof of Proposition 1.2 will be carried out by the Schauder fixed point theorem. For given positive constants $M(\ge \varepsilon)$ and R, we introduce $\mathcal{D}_{\varepsilon,M}$ and Y_R two closed convex subsets of, respectively, L^2_t and $L^2_{t,\sigma}$ as follows:

$$\begin{aligned}
\mathcal{D}_{\varepsilon,M} &= \left\{a \in L^2_t;\ \varepsilon \le a \le M\right\} \\
Y_R &= \left\{p \in L^2_{t,\sigma};\ p \ge 0,\ \sup_{0\le t\le T}\int_{\mathbb{R}} |\sigma| p \le R\right\}.
\end{aligned}$$

To simplify notation we denote

$$\begin{cases} \varphi_\eta(x) = \dfrac{1}{\sqrt{2\pi}\eta}\exp\left(-\dfrac{x^2}{2\eta^2}\right) & \text{if } \eta > 0, \\ \varphi_0 = \delta_0. \end{cases}$$

We first prove the following proposition.

Proposition 2.3. *Let $T > 0$ and let $p_0 \in L^2(\mathbb{R})$ such that $p_0 \ge 0$. Then, for every a in $\mathcal{D}_{\varepsilon,M}$ and q in Y_R, there exists a unique solution p in $L^\infty_t(L^2_\sigma) \cap L^2_t(H^1_\sigma)$ to*

$$\begin{cases} \partial_t p(t,\sigma) = -b(t)\partial_\sigma p(t,\sigma) + a(t)\partial^2_{\sigma\sigma} p(t,\sigma) \\ \qquad\qquad - \mathbb{1}_{\mathbb{R}\setminus[-1,1]}(\sigma)p(t,\sigma) + \dfrac{D(q)}{\alpha}\delta_0(\sigma), \\ p(0,\sigma) = p_0(\sigma). \end{cases} \tag{2.5}$$

Moreover, $p \in C^0_t(L^2_\sigma)$, p is nonnegative and

$$p_- \le p \le p_+, \tag{2.6}$$

with

$$p_-(t,\sigma) = e^{-t}\int_{-\infty}^{+\infty} p_0(\sigma')\varphi_{\sqrt{2\int_0^t a}}(\sigma-\sigma'-\chi(t))d\sigma' \tag{2.7}$$

and

$$\begin{aligned} p_+(t,\sigma) = &\int_{-\infty}^{+\infty} p_0(\sigma')\varphi_{\sqrt{2\int_0^t a}}(\sigma-\sigma'-\chi(t))d\sigma' \\ &+\frac{1}{\alpha}\int_0^t D(q(s))\varphi_{\sqrt{2\int_s^t a}}(\sigma-\chi(t)+\chi(s))ds, \end{aligned} \tag{2.8}$$

where $\chi(t) = \int_0^t b(s)ds$. *In addition,*

(i) *If* $p_0 \in L^\infty(\mathbb{R})$, *then* p *is in* $L^\infty_{t,\sigma}$ *and*

$$0 \le p \le \|p_0\|_{L^\infty} + \frac{R\sqrt{T}}{\sqrt{\pi}\sqrt{\varepsilon}}. \tag{2.9}$$

(ii) *If* $\int_{\mathbb{R}} |\sigma|p_0 < +\infty$ *(thus* $p_0 \in L^1(\mathbb{R})$*), then* $|\sigma|p \in L^\infty_t(L^1_\sigma)$. *More precisely, we have*

$$\begin{aligned} \sup_{0\le t\le T}\int_{\mathbb{R}}|\sigma|p \le &\int_{\mathbb{R}}|\sigma|p_0 + \sqrt{T}\|b\|_{L^2(0,T)}\|p_0\|_{L^1} + \frac{2R}{3}T^{3/2}\|b\|_{L^2(0,T)} \\ &+\frac{2}{\sqrt{\pi}}(MT)^{1/2}\|p_0\|_{L^1} + \frac{4R\sqrt{M}}{3\sqrt{\pi}}T^{3/2}. \end{aligned} \tag{2.10}$$

Moreover, $p \in C^0_t(L^1_\sigma)$ *and* $D(p) \in C^0_t$.

Proof. Let us first observe that for every q in Y_R, $D(q) \in L^\infty_t$ since

$$0 \le D(q(t)) \le \alpha\int_{|\sigma|>1}|\sigma|q \le \alpha R, \tag{2.11}$$

for almost every t in $[0,T]$. Therefore the source term $D(q(t))\delta_0(\sigma)$ in (2.5) is in $L^\infty_t(H^{-1}_\sigma)$ and the existence and uniqueness of a solution $p \in C^0_t(L^2_\sigma)\cap L^2_t(H^1_\sigma)$ to the system (2.5) is well known (see, for example, [4]). In particular, the initial condition makes sense. Owing to the fact that the source term is nonnegative, the proof that $p \ge 0$ is also standard (see again [4]).

We now check the pointwise inequality (2.6).

This is ensured by the maximum principle with observing that p_- and p_+ given, respectively, by (2.7) and (2.8), are the unique solutions to the systems

$$\begin{cases} \partial_t p_- = -b\partial_\sigma p_- + a\partial^2_{\sigma\sigma}p_- - p_-, \\ p_-(0,\sigma) = p_0(\sigma), \end{cases}$$

and

$$\begin{cases} \partial_t p_+ = -b\partial_\sigma p_+ + a\partial^2_{\sigma\sigma}p_+ + \dfrac{D(q)}{\alpha}\delta_0(\sigma), \\ p_+(0,\sigma) = p_0(\sigma), \end{cases}$$

respectively. We now turn to the proof of statement (i), and assume that p_0 belongs to $L^\infty(\mathbb{R})$. Then, using the two facts that for every $\nu > 0$, $\int_{\mathbb{R}} \varphi_\nu = 1$ and $\varphi_\nu \leq \frac{1}{\sqrt{2\pi\nu}}$, (2.9) is easily deduced from $p \leq p_+$ with the help of (2.11) and since $a \geq \varepsilon$.

Suppose now that $\int_{\mathbb{R}} |\sigma| p_0 < +\infty$. This together with the assumption $p_0 \in L^2(\mathbb{R})$, guarantees that $p_0 \in L^1(\mathbb{R})$ (see also below). Using (2.6) again, we now have

$$
\begin{aligned}
\int_{\mathbb{R}} |\sigma| p &\leq \int_{\mathbb{R}} |\sigma| p_+ \\
&\leq \int_{\mathbb{R}} \int_{\mathbb{R}} p_0(\sigma') |\sigma| \varphi_{\sqrt{2\int_0^t a}}(\sigma - \chi(t) - \sigma') d\sigma d\sigma' \\
&\quad + \frac{1}{\alpha} \int_0^t D(q(s)) \Big(\int_{\mathbb{R}} |\sigma| \varphi_{\sqrt{2\int_s^t a}}(\sigma - \chi(t) + \chi(s)) d\sigma \Big) ds \\
&= \int_{\mathbb{R}} \int_{\mathbb{R}} p_0(\sigma') |\sigma + \sigma' + \chi(t)| \varphi_{\sqrt{2\int_0^t a}}(\sigma) d\sigma d\sigma' \\
&\quad + \frac{1}{\alpha} \int_0^t D(q(s)) \Big(\int_{\mathbb{R}} |\sigma + (\chi(t) - \chi(s))| \varphi_{\sqrt{2\int_s^t a}}(\sigma) d\sigma \Big) ds \\
&\leq \int_{\mathbb{R}} |\sigma| p_0(\sigma) d\sigma + |\chi(t)| \|p_0\|_{L^1} + \frac{1}{\alpha} \int_0^t |\chi(t) - \chi(s)| D(q(s)) ds \\
&\quad + \frac{2}{\sqrt{\pi}} \Big(\int_0^t a \Big)^{1/2} \|p_0\|_{L^1} + \frac{2}{\alpha\sqrt{\pi}} \int_0^t D(q(s)) \Big(\int_s^t a \Big)^{1/2} ds,
\end{aligned}
\tag{2.12}
$$

since $\int_{\mathbb{R}} |\sigma| \varphi_\nu(\sigma) d\sigma = (2/\pi)^{1/2} \nu$ and $\int_{\mathbb{R}} \varphi_\nu = 1$. With the help of (2.11), and observing that $|\chi(t) - \chi(s)| \leq \sqrt{t-s} \|b\|_{L^2(0,T)}$, we then deduce (2.10).

We now use this bound to check that $p \in C_t^0(L^1_\sigma)$ and $D(p) \in C_t^0$. Indeed, for any t in $[0,T]$, any $A > 1$, and any sequence t_n in $[0,T]$ which converges to t, we have

$$
\begin{aligned}
\int_{\mathbb{R}} \big| p(t_n) - p(t) \big| &= \int_{|\sigma| \leq A} \big| p(t_n) - p(t) \big| + \int_{|\sigma| \geq A} \big| p(t_n) - p(t) \big| \\
&\leq \sqrt{2A} \Big(\int_{\mathbb{R}} \big| p(t_n) - p(t) \big|^2 \Big)^{1/2} + \frac{1}{A} \int_{\mathbb{R}} |\sigma| \big(|p(t_n)| + |p(t)| \big) \\
&\leq \sqrt{2A} \Big(\int_{\mathbb{R}} \big| p(t_n) - p(t) \big|^2 \Big)^{1/2} + \frac{2}{A} \sup_{0 \leq t \leq T} \int_{\mathbb{R}} |\sigma| |p(t)|.
\end{aligned}
\tag{2.13}
$$

For any fixed A, the first term on the right-hand side goes to 0 as n goes to infinity since $p \in C_t^0(L^2_\sigma)$ and then the second term is arbitrarily small as A goes to infinity. The same argument yields the continuity of $D(p(t))$ with respect to t. ∎

The following proposition aims at checking the required assumptions to apply the Schauder fixed point theorem.

PROPOSITION 2.4. *Let $T_f > 0$ be given. We assume that*

$$p_0 \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R}), \quad p_0 \geq 0, \int_{\mathbb{R}} p_0 = 1, \text{ and } \int_{\mathbb{R}} |\sigma| p_0 < +\infty. \tag{2.14}$$

Let $0 < \varepsilon \leq 1$, $R = 1 + \int_{\mathbb{R}} |\sigma| p_0$, and $M = 1 + 2\alpha$. We define

$$T_c = \frac{9}{25} \left[\|b\|_{L^2(0,T_f)} + \frac{2\sqrt{1+2\alpha}}{\sqrt{\pi}} \right]^{-2}. \tag{2.15}$$

Then, for every $T \leq \min(\frac{1}{R}; T_c)$, the function $\mathcal{T} : (a; q) \mapsto (D(p) + \varepsilon; p)$, with p being the solution to the system (2.5), *maps $\mathcal{D}_{\varepsilon,M} \times Y_R$ into itself. Moreover, $\mathcal{T}$ is continuous and $\mathcal{T}(\mathcal{D}_{\varepsilon,M} \times Y_R)$ is relatively compact in $L^2(0,T) \times L^2_{t,\sigma}$.*

Proof. **Step 1.** *$\mathcal{T}$ is well-defined.* According to Proposition 2.3, p is in $C^0_t(L^1_\sigma)$ and $D(p) \in C^0_t$. We now prove that with our choice for M (which ensures that $\varepsilon + D(p_0) \leq 1 + \alpha \leq M$), $D(p) + \varepsilon \in \mathcal{D}_{\varepsilon,M}$. For this, we again use the inequality $p \leq p_+$, the definition (2.8) of p_+, the rough estimate $\int_{|\sigma|>1} \varphi_\nu \leq \int_{\mathbb{R}} \varphi_\nu = 1$ and (2.11) to obtain

$$\sup_{0 \leq t \leq T} D(p(t)) \leq \sup_{0 \leq t \leq T} D(p_+(t)) \leq \alpha + \alpha R T \leq 2\alpha,$$

for $T \leq \frac{1}{R}$. It only remains now to check that $\sup_{0 \leq t \leq T} \int_{\mathbb{R}} |\sigma| p \leq R$. We thus go back to (2.10) and observe that this condition holds provided

$$T \leq \max \left\{ t > 0; \|b\|_{L^2(0,T_f)} \sqrt{t} \left(1 + \frac{2R}{3} t \right) + \frac{2\sqrt{Mt}}{\sqrt{\pi}} + \frac{4R\sqrt{M} t^{3/2}}{3\sqrt{\pi}} \leq 1 \right\}.$$

Since we have already demanded that $t \leq T \leq \frac{1}{R}$, a sufficient condition is then

$$\sqrt{T} \left[\frac{5}{3} \|b\|_{L^2(0,T_f)} + \frac{10\sqrt{1+2\alpha}}{3\sqrt{\pi}} \right] \leq 1,$$

which reduces to $T \leq T_c$ with T_c given by (2.15).

Our next step will consist of establishing a priori bounds on p in $L^\infty_t(L^2_\sigma) \cap L^2_t(H^1_\sigma)$.

Step 2. *A priori bounds.* If we multiply (2.5) by p and integrate by parts over $\mathbb{R}$ with respect to σ we easily obtain

$$\frac{1}{2} \frac{d}{dt} \int_{\mathbb{R}} p^2 + a \int_{\mathbb{R}} |\partial_\sigma p|^2 \leq \frac{D(q)}{\alpha} p(t, 0).$$

Since from the Sobolev embedding of $H^1(\mathbb{R})$ into $L^\infty(\mathbb{R})$ and the bound (2.11) on $D(q)$, we get

$$\begin{aligned} \left| \frac{D(q)}{\alpha} p(t,0) \right| &\leq R \|p\|_{L^\infty_\sigma} \\ &\leq R \big(\|p\|^2_{L^2_\sigma} + \|\partial_\sigma p\|^2_{L^2_\sigma} \big)^{\frac{1}{2}} \\ &\leq \frac{R^2}{2\varepsilon} + \frac{\varepsilon}{2} \|p\|^2_{L^2_\sigma} + \frac{\varepsilon}{2} \|\partial_\sigma p\|^2_{L^2_\sigma}, \end{aligned}$$

we may write

$$\frac{1}{2} \frac{d}{dt} \|p\|^2_{L^2_\sigma} + \left(a - \frac{\varepsilon}{2} \right) \|\partial_\sigma p\|^2_{L^2_\sigma} \leq \frac{R^2}{2\varepsilon} + \frac{\varepsilon}{2} \|p\|^2_{L^2_\sigma}. \tag{2.16}$$

We recall that $a \geq \varepsilon$ and we apply the Gronwall lemma to obtain

$$\sup_{0\leq t\leq T} \|p\|^2_{L^2_\sigma} \leq e^{\varepsilon T}\left(\|p_0\|^2_{L^2_\sigma} + \frac{TR^2}{\varepsilon}\right). \tag{2.17}$$

We now return to (2.16) and integrate it over $[0;T]$ to obtain

$$\varepsilon\|\partial_\sigma p\|^2_{L^2_{t,\sigma}} \leq \|p_0\|^2_{L^2_\sigma}(1+\varepsilon T e^{\varepsilon T}) + \frac{TR^2}{\varepsilon}(1+\varepsilon T e^{\varepsilon T}). \tag{2.18}$$

Step 3. *The function $\mathcal{T}$ is continuous.* We consider a sequence $(a_n;q_n)$ in $\mathcal{D}_{\varepsilon,M}\times Y_R$ such that a_n converges to a strongly in L^2_t and q_n converges to q strongly in $L^2_{t,\sigma}$, and we denote $\mathcal{T}(a_n;q_n) = (D(p_n)+\varepsilon;p_n)$. We have to prove that p_n converges strongly to p in $L^2_{t,\sigma}$ and $D(p_n)$ converges to $D(p)$ strongly in L^2_t, with $(D(p)+\varepsilon;p) = \mathcal{T}(a;q)$.

In virtue of (2.17) and (2.18), the sequence p_n is bounded in $L^\infty_t(L^2_\sigma)\cap L^2_t(H^1_\sigma)$. Then, $\partial_\sigma p_n$ is bounded in $L^\infty_t(H^{-1}_\sigma)$ and $\partial^2_{\sigma\sigma}p_n$ is bounded in $L^2_t(H^{-1}_\sigma)$. Since $a_n\partial^2_{\sigma\sigma}p_n$ is bounded in $L^2_t(H^{-1}_\sigma)$, $b\in L^2_t$ and $D(q_n)\delta_0$ is bounded in $L^2_t(H^{-1}_\sigma)$, $\partial_t p_n$ is bounded in $L^2_t(H^{-1}_\sigma)$. This together with the fact that p_n is bounded in $L^2_t(H^1_\sigma)$ implies that, up to a subsequence, p_n converges strongly towards p in $L^2_t(L^2_{\mathrm{loc},\sigma})$ (the convergence being weak in $L^2_t(H^1_\sigma)$) thanks to a well-known compactness result [10]. In particular, p_n converges to p almost everywhere. Thus $p\geq 0$ and by Fatou's lemma, $\int_{\mathbb{R}}|\sigma|p\leq R$ almost everywhere on $[0;T]$. Hence p belongs to Y_R. We are going to show that the convergence is actually strong in $L^2_{t,\sigma}$.

In virtue of (2.9) in Proposition 2.3, we dispose of a uniform a priori bound on p_n in $L^\infty_{t,\sigma}$ (hence also on p). For the strong convergence in $L^2_{t,\sigma}$ we then argue as follows. For any fixed positive real number K, we have

$$\begin{aligned}\int_0^T\int_{\mathbb{R}}|p_n-p|^2 &\leq \int_0^T\int_{|\sigma|\leq K}|p_n-p|^2 + \int_0^T\int_{|\sigma|>K}|p_n-p|^2\\ &\leq \int_0^T\int_{|\sigma|\leq K}|p_n-p|^2 + (\|p_n\|_{L^\infty_{t,\sigma}} + \|p\|_{L^\infty_{t,\sigma}})\frac{2RT}{K},\end{aligned}$$

owing to the fact that p_n and p belong to a bounded subset of $Y_R\cap L^\infty_{t,\sigma}$. We then conclude by letting n, then K, go to infinity.

We now prove that $D(p_n)$ converges to $D(p)$ strongly in L^2_t. We shall actually prove that $D(p_n)$ converges to $D(p)$ strongly in L^1_t and then use the fact that $D(p_n)$ is bounded in L^∞_t, in virtue of (2.11) and because p_n lies in Y_R. Let us fix $K>1$. Then, we have

$$\begin{aligned}\frac{1}{\alpha}\int_0^T|D(p_n)-D(p)| &= \int_0^T\left|\int_{|\sigma|>1}(p_n-p)\right|\\ &\leq \int_0^T\int_{1<|\sigma|<K}|p_n-p| + \frac{1}{K}\int_0^T\int_{|\sigma|>K}|\sigma|(|p_n|+|p|)\\ &\leq \int_0^T\int_{1<|\sigma|<K}|p_n-p| + \frac{2RT}{K},\end{aligned} \tag{2.19}$$

because p and p_n belong to Y_R. Since p_n converges to p strongly in $L^1_t(L^1_{\mathrm{loc},\sigma})$, we conclude that $D(p_n)$ converges to $D(p)$ in L^1_t by letting n, then K, go to infinity in (2.19).

In order to pass to the limit in the equation satisfied by p_n (thereby proving that $(D(p)+\varepsilon;p) = \mathcal{T}(a;q)$), we now observe that the strong convergence of q_n to q in $L^2_{t,\sigma}$, together with the argument in (2.19) above shows that $D(q_n)$ converges to $D(q)$ strongly in L^2_t. It is then easily proved that p is a weak solution to (1.7) and since p is in $L^2_t(H^1_\sigma)$ it is the unique solution to (2.5) corresponding to a and q. In particular, the whole sequence p_n converges and not only a subsequence.

Step 4. *$\mathcal{T}(\mathcal{D}_\varepsilon \times Y_R)$ is relatively compact.* Let $(D(p_n)+\varepsilon;p_n) = \mathcal{T}(a_n;q_n)$ be a sequence in $\mathcal{T}(\mathcal{D}_{\varepsilon,M} \times Y_R)$. We have to prove that we may extract a subsequence which converges strongly in $L^2_t \times L^2_{t,\sigma}$. Exactly as for the proof of the continuity, the a priori estimates (2.17) and (2.18) ensure that the sequence p_n is bounded in $L^\infty_t(L^2_\sigma) \cap L^2_t(H^1_\sigma)$. Since $|\sigma|p_n$ is bounded $L^\infty_t(L^1_\sigma)$, we can mimic the argument in Step 3 above to deduce that up to a subsequence the sequence p_n converges to some p in Y_R strongly in $L^2_{t,\sigma}$ and that $D(p_n)$ converges to $D(p)$ strongly in L^2_t. □

We are now in position to conclude the proof of Proposition 1.2.

Let $T_f > 0$ and $0 < \varepsilon \le 1$ being given. We are going to prove the existence of a unique solution on $[0;T_f]$.

Being given an initial data p_0 which satisfies (1.6), existence of a solution p_ε is ensured from Proposition 2.4 by applying the Schauder fixed point theorem on "short" time interval $[0;T_1]$ with $T_1 = \min(\frac{1}{R_1}, T_c)$ and where $R_1 = 1 + \int_{\mathbb{R}} |\sigma| p_0$. This solution is uniquely defined in virtue of Lemma 2.1 and we know from (2.1) that $\int_{\mathbb{R}} p_\varepsilon(T_1) = 1$. Moreover, from Proposition 2.3 $p_\varepsilon(T_1) \in L^\infty_\sigma$ and by construction $\int_{\mathbb{R}} |\sigma| p_\varepsilon(T_1) \le R_1$. Therefore $p_\varepsilon(T_1)$ satisfies the same conditions (2.14) as p_0. Then, repeating the same argument we may build a solution to (1.7) with initial data $p_\varepsilon(T_1)$ on $[T_1;T_2]$ with $T_2 = \min(\frac{1}{R_2}, T_c)$, where $R_2 = R_1 + 1 = \int_{\mathbb{R}} |\sigma| p_0 + 2$. Thanks to the uniqueness result (Lemma 2.1), if we now glue this solution to p_ε at $t = T_1$ we obtain the unique solution to (1.7) on $[0;T_1+T_2]$. It is now clearly seen that for any integer $n \ge 1$ we may build a solution to (1.7) on $[0;\sum_{1\le k\le n} T_k]$ with $T_k = \min((k + \int_{\mathbb{R}} |\sigma| p_0)^{-1}; T_c)$. Since $\sum_{1\le k\le n} T_k$ obviously goes to $+\infty$ together with n, existence (and uniqueness) of the solution p_ε to (1.7) is obtained on every time interval.

For the proof of (1.9) we argue as for the proof of (2.9) in Proposition 2.3. Defining p^+_ε as in (2.8) with a replaced by $D(p_\varepsilon)+\varepsilon$ and $D(q)$ by $D(p_\varepsilon)$, we obtain

$$
\begin{aligned}
0 \le p_\varepsilon \le p^+_\varepsilon &\\
&\le \|p_0\|_{L^\infty} + \frac{1}{\alpha\sqrt{\pi}} \int_0^t \frac{D(p_\varepsilon(s))}{2\sqrt{\varepsilon + \int_s^t D(p_\varepsilon)}} ds \\
&\le \|p_0\|_{L^\infty} + \frac{1}{\alpha\sqrt{\pi}} \left[\sqrt{\varepsilon + \int_0^t D(p_\varepsilon)} - \sqrt{\varepsilon} \right] \\
&\le \|p_0\|_{L^\infty} + \frac{1}{\alpha\sqrt{\pi}} \sqrt{\int_0^t D(p_\varepsilon)} \\
&\le \|p_0\|_{L^\infty} + \frac{\sqrt{\alpha}\sqrt{T}}{\sqrt{\pi}}.
\end{aligned}
$$

Then

$$\int_{\mathbb{R}} p_\varepsilon^2 \le \|p_\varepsilon\|_{L^\infty_\sigma} \int_{\mathbb{R}} p_\varepsilon,$$

from which (1.11) follows gathering together (2.1) and (1.9) and, with the notation of the proposition,

$$C_2(T,p_0) = \|p_0\|_{L^\infty} + \frac{\sqrt{\alpha}\sqrt{T}}{\sqrt{\pi}}.$$

The proof of (1.10) follows the same lines as the proof of (2.12). Indeed, we again use the pointwise inequality $p_\varepsilon \le p_\varepsilon^+$ and replace $D(q)$ by $D(p_\varepsilon)(\le \alpha)$ and a by $D(p_\varepsilon) + \varepsilon(\le \alpha + 1)$ in (2.12) and use (2.14) to deduce

$$\sup_{0\le t\le T} \int_{\mathbb{R}} |\sigma| p_\varepsilon \le \int_{\mathbb{R}} |\sigma| p_0 + \sqrt{T}\left(\frac{2\sqrt{1+\alpha}}{\sqrt{\pi}} + \|b\|_{L^2(0,T)}\right) + \frac{2}{3}T^{3/2}\left(1 + \frac{2\sqrt{1+\alpha}}{\sqrt{\pi}}\right),$$

whence (1.10) with $C_1(T,p_0)$ being the quantity in the right-hand side of the above inequality.

In order to prove (1.12), we apply p_ε to (1.7) and we integrate by parts over $\mathbb{R}$ with respect to σ to obtain

$$\frac{1}{2}\frac{d}{dt}\int_{\mathbb{R}} p_\varepsilon^2 + (D(p_\varepsilon)+\varepsilon)\int_{\mathbb{R}} |\partial_\sigma p_\varepsilon|^2 + \int_{|\sigma|>1} p_\varepsilon^2 = \frac{D(p_\varepsilon)}{\alpha} p_\varepsilon(t,0). \tag{2.20}$$

We use the L^∞ bound (1.9) to bound the right-hand side and we integrate (2.20) with respect to t over $[0;T]$ to deduce (1.12) with

$$C_3(T,p_0) = \|p_0\|_{L^\infty}\left(\frac{1}{2} + T\right) + \frac{\sqrt{\alpha}}{\sqrt{\pi}}T^{3/2},$$

using $\|p_0\|^2_{L^2_\sigma} \le \|p_0\|_{L^\infty}\int_{\mathbb{R}} p_0$.

3. The nondegenerate case: $\mathbf{D(p_0)}$ 0. The main result of this section corresponds to the statement of Theorem 1.1 and fully describes the issue of existence and uniqueness of solutions to the HL equation (1.1) in the nondegenerate case. It is summarized in the following proposition.

PROPOSITION 3.1. *Let p_0 satisfy* (1.6). *We assume that $D(p_0) > 0$. Then, the HL equation* (1.1) *has a unique solution p in $C^0_t(L^2_\sigma) \cap L^2_t(H^1_\sigma)$ and p is the limit (in $L^2_{t,\mathrm{loc}}(L^2_\sigma) \cap C^0_{t,\mathrm{loc}}(L^2_\sigma)$) of (p_ϵ) when ϵ goes to 0 where p_ε is the vanishing viscosity solution whose existence and uniqueness is ensured by Proposition* 1.2. *Moreover, $p \in L^\infty_{t,\sigma} \cap C^0_t(L^1_\sigma)$, $\sigma p \in L^\infty_t(L^1_\sigma)$ and $\int_{\mathbb{R}} p = 1$. Furthermore, $D(p) \in C^0_t$ and for every $T > 0$ there exists a positive constant $\nu(T)$ such that*

$$\min_{0\le t\le T} D(p(t)) \ge \nu(T). \tag{3.1}$$

We begin by proving the following lemma.

LEMMA 3.2. *We assume that p_0 satisfies* (1.6). *Then, if $D(p_0) > 0$, $D(p_\varepsilon)(t) > 0$ for every $t \in [0,T]$, with p_ε being the unique solution to* (1.7) *provided by Proposition* 1.2 *and, actually, for every $T > 0$ there exists a positive constant $\nu(T)$ such that*

$$\min_{0\le t\le T} D(p_\varepsilon(t)) \ge \nu(T), \tag{3.2}$$

for every $0 < \varepsilon \le 1$.

Remark 3.3. Note that this bound from below is independent of ε, but it comes out from the proof that it depends on p_0 and on the shear b.

Proof. The proof relies on the bound from below in (2.6) that we integrate over $|\sigma| > 1$ to obtain

$$\begin{aligned} D(p_\varepsilon(t)) &\geq \alpha \int_{|\sigma|>1} p_\varepsilon^- \\ &\geq \alpha e^{-t} \int_{\mathbb{R}} p_0(\sigma') \left(\int_{|\sigma|>1} \varphi_{\sqrt{2\int_0^t (D(p_\varepsilon)+\varepsilon)}} (\sigma - \sigma' - \chi(t)) d\sigma \right) d\sigma'. \end{aligned} \tag{3.3}$$

Let us define $K_\chi = [-1 - \chi(t), 1 - \chi(t)]$. The function $\sigma \mapsto \varphi_{\sqrt{2\int_0^t (D(p_\varepsilon)+\varepsilon)}}(\sigma - \sigma' - \chi(t))$ is a Gaussian probability density with mean $\sigma' + \chi(t)$ and squared width $2\int_0^t (D(p_\varepsilon) + \varepsilon)$. Therefore, for every $\sigma' \in \mathbb{R} \setminus K_\chi$, we have

$$\int_{|\sigma|>1} \varphi_{\sqrt{2\int_0^t (D(p_\varepsilon)+\varepsilon)}} (\sigma - \sigma' - \chi(t)) d\sigma \geq \frac{1}{2},$$

which implies (3.3) is

$$\geq \frac{\alpha}{2} e^{-T} \int_{\mathbb{R}\setminus K_\chi} p_0 = \frac{\alpha}{2} e^{-T} \int_{|\sigma+\chi(t)|>1} p_0.$$

In the zero shear case ($b \equiv 0$, thus $\chi \equiv 0$) the proof is over and

$$\min_{0\leq t\leq T} D(p(t)) \geq \frac{1}{2} e^{-T} D(p_0).$$

In the general case, a strictly positive bound from below is available as long as the support of p_0 is not contained in K_χ. We thus define

$$t^* = \inf \left\{ t > 0; \int_{|\sigma+\chi(t)|>1} p_0 = 0 \right\}. \tag{3.4}$$

Then $0 < t^*$ (t^* possibly even infinite), the support of p_0 is contained in $[-1-\chi(t^*), 1-\chi(t^*)[$, and for every $T < \frac{t^*}{2}$, (3.2) holds for some positive constant $\nu_1(T)$ defined by

$$\nu_1(T) = \frac{\alpha}{2} e^{-T} \min_{0\leq t\leq T} \int_{|\sigma+\chi(t)|>1} p_0. \tag{3.5}$$

It is worth emphasizing that this quantity is independent of ε. If $t^* = +\infty$, the proof is over and $\nu(T) = \nu_1(T)$ fits. Let us now examine the case when $t^* < +\infty$ and $T \geq \frac{t^*}{2}$.

We go back to (3.3), take t in $[\frac{t^*}{2}; T]$, and denote $x = \int_0^t (D(p_\varepsilon) + \varepsilon)$ for shortness.

Then

$$\begin{aligned}
D(p_\varepsilon(t)) &\geq \alpha e^{-T} \int_{-1-\chi(t^*)}^{1-\chi(t^*)} p_0(\sigma') \left(\int_{|\sigma|>1} \varphi_{\sqrt{2x}}(\sigma - \sigma' - \chi(t)) d\sigma \right) d\sigma' \\
&= \alpha e^{-T} \int_{-1-\chi(t^*)}^{1-\chi(t^*)} p_0(\sigma') \left(\int_{|\sigma|>1} \frac{e^{-(\sigma-\sigma'-\chi(t))^2/4x}}{2\sqrt{\pi}\sqrt{x}} d\sigma \right) d\sigma' \\
&= \frac{\alpha}{\sqrt{\pi}} e^{-T} \int_{-1-\chi(t^*)}^{1-\chi(t^*)} p_0(\sigma') \Bigg(\int_{-\infty}^{-1+\sigma'+\chi(t)} \frac{e^{-\sigma^2/4x}}{2\sqrt{x}} d\sigma \\
&\qquad\qquad + \int_{1+\sigma'+\chi(t)}^{+\infty} \frac{e^{-\sigma^2/4x}}{2\sqrt{x}} d\sigma \Bigg) d\sigma' \\
&= \frac{\alpha}{\sqrt{\pi}} e^{-T} \int_{-1-\chi(t^*)}^{1-\chi(t^*)} p_0(\sigma') \left(\int_{\frac{1+\sigma'+\chi(t)}{2\sqrt{x}}}^{+\infty} e^{-t^2} dt + \int_{\frac{1-\sigma'-\chi(t)}{2\sqrt{x}}}^{+\infty} e^{-t^2} dt \right) d\sigma' \\
&\geq \frac{\alpha}{\sqrt{\pi}} e^{-T} \left(\int_{-1-\chi(t^*)}^{1-\chi(t^*)} p_0(\sigma') d\sigma' \right) \Bigg(\int_{\frac{2-\chi(t^*)+\chi(t)}{\sqrt{2t^*\nu_1(t^*/2)}}}^{+\infty} e^{-t^2} dt \\
&\qquad\qquad + \int_{\frac{2+\chi(t^*)-\chi(t)}{\sqrt{2t^*\nu_1(t^*/2)}}}^{+\infty} e^{-t^2} dt \Bigg);
\end{aligned}$$

hence

$$D(p_\varepsilon(t)) \geq \frac{\alpha}{\sqrt{\pi}} e^{-T} \min_{t^*/2 \leq t \leq T} \left(\int_{\frac{2-\chi(t^*)+\chi(t)}{\sqrt{2t^*\nu_1(t^*/2)}}}^{+\infty} e^{-t^2} dt + \int_{\frac{2+\chi(t^*)-\chi(t)}{\sqrt{2t^*\nu_1(t^*/2)}}}^{+\infty} e^{-t^2} dt \right), \tag{3.6}$$

since $\int_{-1-\chi(t^*)}^{1-\chi(t^*)} p_0 = 1$ and $x \geq \int_0^{t^*/2} D(p_\varepsilon) \geq t^*\nu_1(t^*/2)/2$ thanks to (3.5). The proof of Lemma 3.2 then follows by defining

$$\nu(T) = \min(\nu_1(T); \nu_2(T)),$$

with $\nu_1(T)$ given by (3.5) and $\nu_2(T)$ being the positive quantity on the right-hand side of (3.6), that is

$$\nu_2(T) = \frac{\alpha}{\sqrt{\pi}} e^{-T} \min_{t^*/2 \leq t \leq T} \left(\int_{\frac{2-\chi(t^*)+\chi(t)}{\sqrt{2t^*\nu_1(t^*/2)}}}^{+\infty} e^{-t^2} dt + \int_{\frac{2+\chi(t^*)-\chi(t)}{2\sqrt{2t^*\nu_1(t^*/2)}}}^{+\infty} e^{-t^2} dt \right). \qquad \square$$

Proof of Proposition 3.1. We first go back to the proof of the bound (1.12) on $\partial_\sigma p_\varepsilon$, and more precisely we look at (2.20), and observe that in virtue of (3.1)

$$\nu(T) \int_0^T \int_{\mathbb{R}} |\partial_\sigma p_\varepsilon|^2 \leq C_3(T, p_0). \tag{3.7}$$

Now let ε_n denote any sequence in $[0,1]$ which goes to 0 as n goes to infinity. To shorten the notation we denote by p_n instead of p_{ε_n} the corresponding sequence of solutions to (1.7). With the above bound (3.7) on p_n and (1.11), we know that p_n is bounded in $L^2_t(H^1_\sigma)$ independently of n. Moreover, thanks to (2.1) and (1.9), p_n is bounded in $L^\infty_t(L^1_\sigma \cap L^\infty_\sigma)$ and we also dispose of a uniform bound on $\int_{\mathbb{R}} |\sigma| p_n$ in virtue of (1.10). Therefore arguing exactly as in the proof of Proposition 2.4 (Step 4) where we have proved that the mapping $\mathcal{T}$ is relatively compact in $L^2_t \times L^2_{t,\sigma}$ we show that p_n converges to some p strongly in $L^2_{t,\sigma}$ and $D(p_n)$ converges to $D(p)$ in L^2_t. Therefore, the nonlinear term $D(p_n)\partial^2_{\sigma\sigma}p_n$ converges to $D(p)\partial^2_{\sigma\sigma}p$ strongly in $L^1_t(H^{-2}_\sigma)$ (for instance). Then p is a weak solution to the initial problem (1.1) in $L^2_t(H^1_\sigma) \cap L^\infty_t(L^1_\sigma \cap L^\infty_\sigma)$, $\int_{\mathbb{R}} p = 1$ and $\int_{\mathbb{R}} |\sigma| p < +\infty$. Moreover,

$$\inf_{0 \le t \le T} D(p(t)) \ge \nu(T).$$

This nondegeneracy condition on the viscosity coefficient ensures that there is at most one solution to (1.1) in $L^2_t(H^1_\sigma) \cap L^\infty_t(L^2_\sigma)$ (this follows by an obvious adaptation of the proof of Lemma 2.1 to this case). Therefore the limiting function p is uniquely defined and does not depend on the sequence ε_n. Moreover, the whole sequence p_n converges to this unique limit and not only a subsequence. $\square$

As a conclusion of this subsection let us make the following comment which is a by product of Proposition 3.1. If p is a solution to (1.1) in $C^0_t(L^1_\sigma \cap L^2_\sigma)$, then as soon as $D(p(t))$ is positive for some time t it remains so afterwards since the solution can be continued in a unique way starting at time t.

4. The degenerate case: $\mathbf{D(p_0) = 0}$. Throughout this section we assume that p_0 satisfies (1.3) and that $D(p_0) = 0$. Therefore the support of p_0 is included in $[-1; +1]$. Assume that we dispose of a solution to (1.1) in $C^0_t(L^1_\sigma \cap L^2_\sigma)$. We may define $t_* \in \mathbb{R}^+ \cup \{+\infty\}$ by

$$t_* = \max\left\{t > 0; \int_0^t D(p) = 0\right\}. \tag{4.1}$$

According to the comment at the end of the previous section for every $t > t_*$, $D(p(t)) > 0$ while $D(p(t)) = 0$ for all t in $[0; t_*]$. On $[0; t_*[$, the HL equation (1.1) reads

$$\begin{cases} \partial_t p = -b(t)\partial_\sigma p, \\ p \ge 0, \\ p(0, \cdot) = p_0, \\ D(p(t)) = 0. \end{cases}$$

The above system reduces to

$$\begin{cases} p(t,\sigma) = p_0(\sigma - \chi(t)), \\ D(p(t)) = 0 \quad \text{for all } t \text{ in } [0; t_*]. \end{cases} \tag{4.2}$$

The second equation in (4.2) is compatible with the first one as long as

$$\int_{|\sigma + \chi(t)| > 1} p_0 = 0 \quad \text{for all } t \text{ in } [0; t_*].$$

Therefore there exists a maximal time interval $[0; T_c]$ on which the HL equation may reduce to a mere transport equation and this is for an intrinsic time T_c (possibly infinite) defined by

$$T_c = \inf\left\{t > 0; \int_{|\sigma + \chi(t)| > 1} p_0 > 0\right\}. \tag{4.3}$$

Note that T_c is completely determined by the data p_0 and b. If $T_c = +\infty$, the steady state $p(t,\sigma) = p_0(\sigma - \chi(t))$ is a solution of the HL equation for all time. We shall now exhibit circumstances under which it is not the unique solution. For convenience, we restrict ourselves to the case when $b \equiv 0$ (we then have obviously $T_c = +\infty$).

For $p_0 \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R})$ such that $p_0 \geq 0$, let us denote by F_{p_0} the function from $\mathbb{R}^+$ to $\mathbb{R}^+$ defined by $F_{p_0}(0) = D(p_0)$ and by

$$\text{for all } x > 0, \qquad F_{p_0}(x) = \alpha \int_{|\sigma|>1} \left(\int_{\mathbb{R}} p_0(\sigma')\varphi_{\sqrt{2x}}(\sigma - \sigma')d\sigma' \right) d\sigma.$$

Proposition 4.1. *Let p_0 satisfy* (1.6) *and be such that $D(p_0) = 0$, then*

(i) *If F_{p_0} satisfies*

$$\int_0^1 \frac{dx}{F_{p_0}(x)} = +\infty, \tag{4.4}$$

then $p(t,\sigma) = p_0(\sigma)$ is the unique solution to (1.1) *in $C^0_t(L^2_\sigma)$.*

(ii) *Otherwise,* (1.1) *has an infinite number of solutions in $C^0_t(L^2_\sigma)$. The set of solutions to* (1.1) *is made of the steady state $p(t,\sigma) = p_0(\sigma)$ and of the functions $(q_{t_0})_{t_0 \geq 0}$ defined by*

$$q_{t_0}(t,\sigma) = \left| \begin{array}{ll} p_0(\sigma), & \text{if } t \leq t_0 \\ q(t - t_0, \sigma), & \text{if } t > t_0, \end{array} \right.$$

where q is the unique solution to (1.1) *in $C^0_t(L^2_\sigma)$ such that $D(q) > 0$ on $]0,+\infty[$. Besides,*

$$p_\epsilon \underset{\epsilon \to 0}{\longrightarrow} q \quad \text{strongly in } L^2_{t,\mathrm{loc}}(L^2_\sigma). \tag{4.5}$$

Lemma 4.2. *Let $p_0 \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R})$ such that*

$$p_0 \geq 0, \qquad \int_{\mathbb{R}} p_0 = 1, \qquad D(p_0) = 0.$$

The function F_{p_0} is in $C^0([0,+\infty[) \cap C^\infty(]0,+\infty[)$, and is positive on $]0,+\infty[$. In addition, $F'_{p_0} > 0$ on $]0,+\infty[$.

Proof. It is easy to check that $F_{p_0} \in C^0([0,+\infty[) \cap C^\infty(]0,+\infty[)$, and that $F_{p_0} > 0$ on $]0,+\infty[$. Since $D(p_0) = 0$, the function p_0 is supported in $[-1,1]$. Thus, for any $x > 0$,

$$\begin{aligned} F_{p_0}(x) &= \alpha \int_{|\sigma|>1} \left(\int_{\mathbb{R}} p_0(\sigma')\varphi_{\sqrt{2x}}(\sigma - \sigma')d\sigma' \right) d\sigma \\ &= \alpha \int_{-1}^1 p_0(\sigma') \left(\int_{|\sigma|>1} \frac{e^{-(\sigma-\sigma')^2/4x}}{2\sqrt{\pi}\sqrt{x}} d\sigma \right) d\sigma' \\ &= \alpha \int_{-1}^1 p_0(\sigma') \left(\int_{-\infty}^{-1+\sigma'} \frac{e^{-\sigma^2/4x}}{2\sqrt{\pi}\sqrt{x}} d\sigma + \int_{1+\sigma'}^{+\infty} \frac{e^{-\sigma^2/4x}}{2\sqrt{\pi}\sqrt{x}} d\sigma \right) d\sigma' \\ &= \alpha \frac{1}{\sqrt{\pi}} \int_{-1}^1 p_0(\sigma') \left(\int_{\frac{1+\sigma'}{2\sqrt{x}}}^{+\infty} e^{-t^2} dt + \int_{\frac{1-\sigma'}{2\sqrt{x}}}^{+\infty} e^{-t^2} dt \right) d\sigma'. \end{aligned} \tag{4.6}$$

It follows that for any $x > 0$,

$$F'_{p_0}(x) = \alpha \frac{1}{\sqrt{\pi}} \int_{-1}^{1} p_0(\sigma') \left(\frac{1+\sigma'}{4x^{3/2}} e^{-\frac{(1+\sigma')^2}{4x}} + \frac{1-\sigma'}{4x^{3/2}} e^{-\frac{(1-\sigma')^2}{4x}} \right) d\sigma' > 0. \qquad \square$$

LEMMA 4.3. *Let $\gamma \geq 0$ and $p_0 \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R})$ such that*

$$p_0 \geq 0, \qquad \int_{\mathbb{R}} p_0 = 1, \qquad \int_{\mathbb{R}} |\sigma| p_0 < +\infty, \qquad D(p_0) = 0.$$

Let us consider the problem

$$\begin{cases} \partial_t w = D(w(t)) \partial^2_{\sigma\sigma} w - \gamma w, \\ w(0,\sigma) = p_0(\sigma). \end{cases} \tag{4.7}$$

(i) *If F_{p_0} satisfies* (4.4), *then $p(t,\sigma) = p_0(\sigma)$ is the unique solution to* (4.7) *in $C^0_t(L^2_\sigma)$.*

(ii) *Otherwise,* (4.7) *has an infinite number of solutions in $C^0_t(L^2_\sigma)$. The set of solutions to* (4.7) *is made of the steady state $w(t,\sigma) = p_0(\sigma)$ and of the functions $(v_{t_0})_{t_0 \geq 0}$ defined by*

$$v_{t_0}(t,\sigma) = \left| \begin{array}{ll} p_0(\sigma), & \text{if } t \leq t_0, \\ v(t-t_0,\sigma), & \text{if } t > t_0, \end{array} \right.$$

where v is the unique solution to (4.7) *in $C^0_t(L^2_\sigma)$ such that $D(v) > 0$ on $]0,+\infty[$.*

COROLLARY 4.4. *The initial data $p_0 = \frac{1}{2} \mathbb{1}_{]-1,1[}$ fulfills the assumptions of the above lemma and $\int_0^1 \frac{dx}{F_{p_0}(x)} < +\infty$. Therefore there are infinitely many solutions to* (1.5) *in the introduction.*

Proof of Corollary 4.4. The only point to be checked is that $\int_0^1 \frac{dx}{F_{p_0}(x)} < +\infty$. With the standard notation $\operatorname{erfc}(z) \equiv \int_z^{+\infty} e^{-t^2} dt$, and by using (4.6) and symmetry considerations, simple calculations yield

$$\begin{aligned} F_{p_0}(x) &= \frac{2\alpha\sqrt{x}}{\sqrt{\pi}} \int_0^{\frac{1}{\sqrt{x}}} \operatorname{erfc}(\sigma) d\sigma \\ &= \frac{2\alpha}{\sqrt{\pi}} \left[\operatorname{erfc}\left(\frac{1}{\sqrt{x}} \right) - \frac{1}{2}\sqrt{x} e^{-\frac{1}{x}} + \frac{1}{2}\sqrt{x} \right]. \end{aligned}$$

Since $\operatorname{erfc}(z) \sim \frac{1}{2} e^{-z^2}/z$ for z going to $+\infty$, $F_{p_0}(x) \sim \frac{\alpha}{\sqrt{\pi}} \sqrt{x}$ near 0 and the integrability of $1/F_{p_0}$ on $[0;1]$ follows. $\square$

Proof of Lemma 4.3. Let us consider a nonnegative continuous function D on $\mathbb{R}^+$. The unique solution in $C^0_t(L^2_\sigma)$ to the problem

$$\begin{cases} \partial_t w_D = D(t) \partial^2_{\sigma\sigma} w_D - \gamma w_D, \\ w_D(0,\sigma) = p_0(\sigma), \end{cases} \tag{4.8}$$

is given by

$$w_D(t,\sigma) = \left| \begin{array}{ll} e^{-\gamma t} p_0(\sigma), & \text{if } t \leq t^*, \\ e^{-\gamma t} \displaystyle\int_{\mathbb{R}} p_0(\sigma') \varphi_{\sqrt{2\int_0^t D(s)ds}}(\sigma - \sigma') d\sigma', & \text{if } t > t^*, \end{array} \right. \tag{4.9}$$

where $t^* = \inf\{t > 0; \int_0^t D > 0\}$. Any solution to (4.7) thus satisfies $w = w_{D(w)}$ and therefore

$$\begin{aligned}
D(w(t)) &= D(w_{D(w)}(t)) \\
&= \alpha \int_{|\sigma|>1} w_{D(w)}(t,\sigma) d\sigma \\
&= \alpha e^{-\gamma t} \int_{|\sigma|>1} \left(\int_{\mathbb{R}} p_0(\sigma') \varphi_{\sqrt{2\int_0^t D(w(s))ds}}(\sigma - \sigma') d\sigma' \right) d\sigma \\
&= e^{-\gamma t} F_{p_0} \left(\int_0^t D(w(s)) ds \right).
\end{aligned}$$

It follows that the function $D(w)$ is the solution in $C^0([0,+\infty[)$ to the nonlinear integral equation

$$y(t) = e^{-\gamma t} F_{p_0} \left(\int_0^t y(s) ds \right). \tag{4.10}$$

On the other hand, if $D \in C^0([0,+\infty[)$ is solution to (4.10) it is easy to check that the function w_D defined by (4.9) is solution to (4.8).

If condition (4.4) is fulfilled, (4.10) has a unique solution in $C^0([0,+\infty[)$ (the constant function equal to zero) and the steady state $w(t,\cdot) = p_0$ is therefore the unique solution to (4.7) in $C_t^0(L_\sigma^2)$; otherwise, the set of solutions to (4.10) is made of the steady state $w(t,\cdot) = p_0$ and of the family $(y_{t_0})_{t_0 \geq 0}$ with

$$y_{t_0}(t) = \left| \begin{array}{ll} 0, & \text{if } t \leq t_0, \\ z(t - t_0), & \text{if } t > t_0, \end{array} \right.$$

where the function z is defined on $[0, +\infty[$ by

$$\int_0^{z(t)} \frac{dx}{F(x)} = \begin{cases} \dfrac{1 - e^{-\gamma t}}{\gamma}, & \text{if } \gamma > 0, \\ t, & \text{otherwise.} \end{cases}$$

Statement (ii) is obtained by denoting by v the solution to (4.8) associated with the function $z(t)$. ∎

Proof of Proposition 4.1. The solution p_ϵ to (1.7) satisfies the inequalities

$$p_\epsilon^-(t,\sigma) \leq p_\epsilon(t,\sigma) \leq p_\epsilon^+(t,\sigma) \quad \text{almost everywhere,}$$

where p_ϵ^- and p_ϵ^+ are defined in $C_t^0(L_\sigma^2)$ by

$$\begin{cases} \partial_t p_\epsilon^- = (D(p_\epsilon(t)) + \epsilon)\, \partial_{\sigma\sigma}^2 p_\epsilon^- - p_\epsilon^-, \\ p_\epsilon^-(0,\sigma) = p_0(\sigma), \end{cases}$$

and

$$\begin{cases} \partial_t p_\epsilon^+ = (D(p_\epsilon(t)) + \epsilon) \partial_{\sigma\sigma}^2 p_\epsilon^+ + \dfrac{D(p_\epsilon)}{\alpha} \delta_0, \\ p_\epsilon^+(0,\sigma) = p_0(\sigma). \end{cases}$$

Therefore, on the one hand,

$$D(p_\epsilon(t)) \geq D(p_\epsilon^-(t)) = e^{-t} F_{p_0}\left(\int_0^t (D(p_\epsilon)+\epsilon)\right) \tag{4.11}$$

and, on the other hand,

$$\begin{aligned} D(p_\epsilon(t)) &\leq D(p_\epsilon^+(t)) \\ &= F_{p_0}\left(\int_0^t (D(p_\epsilon)+\epsilon)\right) + \int_0^t \frac{D(p_\epsilon)(s)}{\alpha}\left(\int_{|\sigma|>1} \varphi_{\sqrt{2\int_s^t (D(p_\epsilon)+\epsilon)}}\right) ds \\ &\leq F_{p_0}\left(\int_0^t (D(p_\epsilon)+\epsilon)\right) + \frac{1}{\alpha}\int_0^t D(p_\epsilon)(s) ds. \end{aligned}$$

If (4.4) is not fulfilled, using (4.11) and the property that F_{p_0} is strictly increasing on $[0, +\infty[$, we obtain that

$$D(p_\epsilon) \geq z(t),$$

where $z(t)$ is the function defined in the proof of Lemma 4.3. As for any $0 < t_0 \leq T$ there exists $\eta > 0$ such that $z(t) \geq \eta$ on $[t_0, T]$ the same reasoning as in the nondegenerate case leads to the conclusion that (p_ϵ) converges up to an extraction to p in $\mathcal{D}'(]0, +\infty[\times\mathbb{R})$ and in $L^2([t_0, T], L^2(\mathbb{R}))$ for any $0 < t_0 < T < +\infty$, p being a solution to (1.1) in $C^0(]0, +\infty[, L^2_\sigma)$ such that $D(p) > 0$ on $]0, +\infty[$. □

5. Steady states. Throughout this section the shear rate b is assumed to be a given constant and we are looking for solutions in $L^1(\mathbb{R})$ to the following system:

$$\begin{cases} -b\partial_\sigma p + D(p)\partial^2_{\sigma\sigma} p - \mathbb{1}_{\mathbb{R}\setminus[-1,1]} p + \dfrac{D(p)}{\alpha}\delta_0(\sigma) = 0 \quad \text{on } (0;T)\times\mathbb{R}, \\ p \geq 0, \quad \displaystyle\int_{\mathbb{R}} p = 1, \\ D(p) = \alpha \displaystyle\int_{|\sigma|>1} p(\sigma) d\sigma. \end{cases} \tag{5.1}$$

Our main results are summarized in the following proposition.

PROPOSITION 5.1 (existence of steady states).

(i) *If $b \equiv 0$, any probability density which is compactly supported in $[-1; +1]$ is a solution to (5.1) which satisfies $D(p) = 0$. If $\alpha \leq \frac{1}{2}$, these are the only stationary solutions (and there are infinitely many), whereas when $\alpha > \frac{1}{2}$ there exists a unique stationary solution corresponding to a positive value of D, which is explicitly given in (5.2) and (5.4) below. This solution is even and with exponential decay at infinity.*

(ii) *If $b \not\equiv 0$, for any $\alpha > 0$, there exists a unique stationary solution to (5.1), and it corresponds to a positive value for D, which is implicitly given in (5.5) and (5.6) below. This solution has exponential decay at infinity.*

Remark 5.2. The statement in the above proposition was already pointed out by Hébraud and Lequeux [8].

Proof. **The case when $\mathbf{b \equiv 0}$.** We first observe that any nonnegative function p which is normalized in $L^1(\mathbb{R})$ and with support in $[-1; +1]$ is a solution to the system (5.1) since in that case all terms in the equation satisfied by p in (5.1) cancel. We now examine the issue of existence of solutions of (5.1) such that $D(p) > 0$. For simplicity we denote $D = D(p)$. For given constant $D > 0$, it is very easy to calculate explicitly the solutions to (5.1) on each of the three regions $\sigma < -1$, $\sigma \in [-1; +1]$ and $\sigma > 1$. Using compatibility conditions on $\mathbb{R}$ and the fact that p has to be in $L^1(\mathbb{R})$, one obtains

$$p(\sigma) = \begin{cases} \frac{\sqrt{D}}{2\alpha} e^{(1+\sigma)/\sqrt{D}}, & \text{if } \sigma \leq -1, \\ \frac{1}{2\alpha}\sigma + \frac{\sqrt{D}+1}{2\alpha}, & \text{if } -1 \leq \sigma \leq 0, \\ -\frac{1}{2\alpha}\sigma + \frac{\sqrt{D}+1}{2\alpha}, & \text{if } 0 \leq \sigma \leq 1, \\ \frac{\sqrt{D}}{2\alpha} e^{(1-\sigma)/\sqrt{D}}, & \text{if } 1 \leq \sigma. \end{cases} \tag{5.2}$$

The compatibility condition $D = D(p)$ happens to then be automatically satisfied and the normalization constraint $\int_{\mathbb{R}} p = 1$ imposes that D solves

$$D + \sqrt{D} = \alpha - \frac{1}{2}. \tag{5.3}$$

Since $D \geq 0$, we immediately reach a contradiction when $\alpha < \frac{1}{2}$, whereas when $\alpha > \frac{1}{2}$ (5.3) admits a unique positive solution; namely

$$D = -\frac{1}{2} + \frac{\sqrt{4\alpha} - 1}{2}. \tag{5.4}$$

The case when $\mathbf{b} \not\equiv \mathbf{0}$. First of all, we observe that if $D = 0$ all terms in the equation satisfied by p in (5.1) but $b\partial_\sigma p$ vanish. Thus p has to be a nonzero constant which is in contradiction with $p \in L^1(\mathbb{R})$. So necessarily $D > 0$. For given positive constant D, we then solve (5.1) as above and obtain

$$p(\sigma) = \begin{cases} a_1 e^{\beta^+ \sigma}, & \text{if } \sigma \leq -1, \\ a_2 e^{\frac{b}{D}\sigma} + a_2 - \frac{D}{b\alpha}, & \text{if } -1 \leq \sigma \leq 0, \\ \left(a_2 - \frac{D}{b\alpha}\right) e^{\frac{b}{D}\sigma} + a_2, & \text{if } 0 \leq \sigma \leq 1, \\ a_1 e^{\beta^- \sigma}, & \text{if } 1 \leq \sigma, \end{cases} \tag{5.5}$$

with

$$\beta^\pm = \frac{b}{2D} \pm \frac{1}{2}\sqrt{\frac{b^2 + 4D}{D^2}},$$

$$a_1 = \frac{e^{\frac{1}{2}\sqrt{\frac{b^2}{D^2} + \frac{4}{D}}}}{\alpha\left(\beta^+ e^{b/2D} - \beta^- e^{-b/2D}\right)},$$

and

$$a_2 = \frac{D\beta^+ e^{b/2D}}{\alpha b(\beta^+ e^{b/2D} - \beta^- e^{-b/2D})}.$$

It is tedious but easy to check that this function always fulfills the self-consistency condition $D = D(p)$ and that the normalization condition $\int_{\mathbb{R}} p = 1$ reads

$$\frac{D}{b} \frac{(1 + \beta^+) + (\beta^- - 1)e^{-b/D}}{\beta^+ - \beta^- e^{-b/D}} + D = \alpha. \tag{5.6}$$

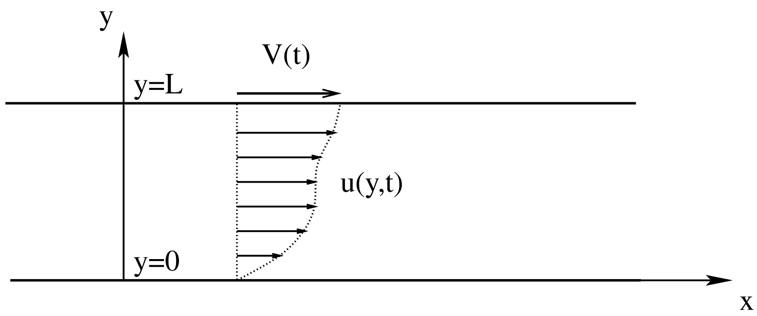

FIG. 1. *Planar Couette flow.*

For any $b > 0$ (the negative values of b are dealt with by replacing σ by $-\sigma$), the left-hand side of (5.6) is a continuous function which goes to $+\infty$ when D goes to infinity and goes to zero when D goes to 0. This already ensures the existence of at least one steady state for any $\alpha > 0$. Moreover, setting $z = b^2/D$ (for example) we may rewrite the left-hand side of (5.6) as

$$f(z) = \frac{b^2}{z} + \frac{2b^2}{z}\left[\frac{1 + \frac{1}{2b} z \coth(z/2b) + \frac{1}{2b}(z^2+4z)^{1/2}}{z + (z^2+4z)^{1/2}\coth(z/2b)}\right].$$

Next we check that the function f is monotone decreasing (thus, the left-hand side of (5.6) is increasing with respect to D), whence the uniqueness result. $\square$

6. Conclusion and future trends. Theorem 1.1 shows that the Hébraud–Lequeux model (1.1) is well-posed when the initial data p_0 is such that $D(p_0) > 0$. On the other hand, Proposition 4.1 claims that the model may have infinitely many solutions for certain p_0 such that $D(p_0) = 0$. This pathological behavior might be a flaw of the model but we think that is not the case. Indeed, our interpretation is that an initial data p_0 such that $D(p_0) = 0$ can be considered as admissible only if it is the long-time limit of a solution $p > 0$ of (1.1) with zero shear rate ($b = 0$); in view of both numerical simulations and heuristic arguments, we suspect that such a p_0 necessarily fulfills condition (4.4). We are currently studying the long-time asymptotics of the HL equation [3] and hope to be able to provide mathematical justifications of this statement in the near future.

To conclude, let us mention that the present article is the theoretical side of a joint project with rheologists aiming at better understanding the flows of complex fluids.

We are currently working on a multiscale model for planar Couette flows of concentrated suspensions (see Figure 1), in which the mesoscopic behavior of the suspension is described by the HL equation. It is indeed experimentally observed that the shear rate $b(t)$ is not homogeneous in space (in particular, the term $-b(t)\partial_\sigma p$ generates elastic waves in the fluid). In order to better describe the coupling between the macroscopic flow and the evolution of the mesostructure, we propose the following multiscale model:

$$
\begin{cases}
\rho\partial_t u(t,y) = \partial_y \tau(t,y) + \mu \partial_{yy} u(t,y), \\
\partial_t p(t,y,\sigma) = -G_0 \partial_y u(t,y) \partial_\sigma p(t,y,\sigma) + D(p(t,y)) \partial^2_{\sigma\sigma} p(t,y,\sigma) \\
\qquad\qquad -\dfrac{\mathbb{1}_{\mathbb{R}\setminus[-\sigma_c,\sigma_c]}(\sigma)}{T_0} p(t,y,\sigma) + \dfrac{1}{T_0}\left(\displaystyle\int_{|\sigma'|>\sigma_c} p(t,\sigma',y)\,d\sigma'\right)\delta_0(\sigma), \\
\tau(t,y) = \displaystyle\int_{\mathbb{R}} \sigma p(t,y,\sigma)\,d\sigma.
\end{cases}
\tag{6.1}
$$

In the above equations, $u(t,y)$ denotes the component along e_x of the velocity field (the flow being laminar and incompressible, the velocity field is of the form $\vec{u} = u(t,y)e_x$ and the pressure does not play any role), ρ is the volumic mass of the fluid and μ some nonnegative viscosity coefficient. This system is complemented by the no-slip boundary conditions

$$
\begin{cases}
u(t,0) = 0 & \text{for almost all } t, \\
u(t,L) = V(t) & \text{for almost all } t.
\end{cases}
$$

The theoretical study of this multiscale model will be the matter of another article. Numerical simulations of (6.1) have already been performed by one of us [6]. The results of these simulations will be compared in the near future with experimental data obtained with a NMR rheometer [12] (this very modern equipment allows measurements of local velocities in opaque fluids).

Acknowledgments. We would like to thank Philippe Coussot for pointing out the Hébraud–Lequeux equation to us. We also warmly thank Pascal Hébraud and Claude Le Bris for helpful discussions.

A BIRKHOFF–LEWIS-TYPE THEOREM FOR SOME HAMILTONIAN PDES*

DARIO BAMBUSI† AND MASSIMILIANO BERTI‡

Abstract. In this paper we give an extension of the Birkhoff–Lewis theorem to some semilinear PDEs. Accordingly we prove existence of infinitely many periodic orbits with large period accumulating at the origin. Such periodic orbits bifurcate from resonant finite dimensional invariant tori of the fourth order normal form of the system. Besides standard nonresonance and nondegeneracy assumptions, our main result is obtained assuming a regularizing property of the nonlinearity. We apply our main theorem to a semilinear beam equation and to a nonlinear Schrödinger equation with smoothing nonlinearity.

Key words. infinite dimensional Hamiltonian systems, periodic solutions, Birkhoff normal form, variational methods, perturbation theory

1. Introduction. In 1933, Birkhoff and Lewis [9] (see also [16], [17]) proved their celebrated theorem on existence of periodic orbits with large period close to elliptic equilibria of Hamiltonian systems.[1] Here we give a generalization of their result to some semilinear Hamiltonian PDEs.

The Birkhoff–Lewis procedure consists in putting the system in fourth order (Birkhoff) normal form, namely in the form

$$H = H_0 + G_4 + R_5, \qquad H_0 := \sum_{j=1}^{n} \omega_j \frac{p_j^2 + q_j^2}{2}, \tag{1}$$

where G_4 is a homogeneous polynomial of degree 2 in the actions $I_j := (p_j^2 + q_j^2)/2$ and R_5 is a remainder having a zero of fifth order at the origin. Then system (1) is a perturbation of the integrable system H_0+G_4. Under a nondegeneracy condition (that also plays a fundamental role in KAM theory) the action-to-frequency map of this integrable system is one-to-one, and therefore there exist infinitely many resonant tori on which the motion is periodic. The question is: Do some of these periodic orbits persist under the perturbation due to the term R_5? Birkhoff and Lewis used the implicit function theorem and a topological argument to prove that there exists a sequence of resonant tori accumulating at the origin with the property that at least two periodic orbits bifurcate from each one of them.

In order to extend this result to infinite dimensional systems describing Hamiltonian PDEs one meets two difficulties: the first is the generalization of Birkhoff normal form to PDEs and the second is the appearance of a small denominator problem.

[1]Actually [9] considers the neighborhood of an elliptic, nonconstant, periodic orbit, but the scheme is essentially the same for elliptic equilibria.

Here we work in a way which is as straightforward as possible, so, instead of considering the standard Birkhoff normal form of the system, whose extension to PDEs is not completely understood at present,[2] we consider its "seminormal form," namely the kind of normal form employed to construct lower dimensional tori. Precisely, having fixed a positive n, we split the phase variables into two groups, namely the variables with index smaller than n and the variables with index larger than n. We will denote by $\hat{z}$ the whole set of variables with index larger than n. We construct a canonical transformation putting the system in the form

$$H_0 + \overline{G} + \hat{G} + K, \tag{2}$$

where $\overline{G}$ depends only on the actions, $\hat{G}$ is at least cubic in the variables $\hat{z}$ with index larger than n, and K has a zero of sixth order at the origin. The interest of such a seminormal form is that the normalized system $H_0 + \overline{G} + \hat{G}$ has the invariant $2n$-dimensional manifold $\hat{z} = 0$ which is filled by n-dimensional invariant tori.

Under a nondegeneracy condition, the frequencies of the flow in such tori cover an open subset of $\mathbf{R}^n$. We concentrate on the resonant tori filled by periodic orbits, and we prove that at least n geometrically distinct periodic orbits of each torus survive the perturbation due to the term K. Since the orbits bifurcate from lower dimensional tori, we have to impose a further nondegeneracy condition in order to avoid resonances between the frequency of the periodic orbit and the frequencies of the transversal oscillations.

The proof is based on a variational Lyapunov–Schmidt reduction similar to that employed in [6] and inspired by [1]. It turns out that in the present case the range equation involves small denominators. To solve the corresponding problem we use an approach similar to that of [2]. In particular we impose a strong condition on the small denominators and we show that, if the vector field of the nonlinearity is smoothing, then the range equation can be solved by the contraction mapping principle. Next, the kernel equation is solved by noting that it is the Euler–Lagrange equation of the action functional restricted to the solutions of the range equation. The restricted functional turns out to be defined on $\mathbf{T}^n$, and so existence and multiplicity of solutions (critical points) follows by the classical Lusternik–Schnirelmann theory.

Finally, we apply the general theorem to the nonlinear beam equation

$$u_{tt} + u_{xxxx} + mu = f(u), \tag{3}$$

with Dirichlet boundary conditions on a segment. We consider m as a parameter varying in the segment $[0, L]$, and we show that the assumptions of the abstract theorem are fulfilled provided one excludes from the interval a finite number of values of m. As a second application we will deal with a nonlinear Schrödinger equation with a smoothing nonlinearity of the type considered in [20].

We recall that families of periodic solutions to Hamiltonian PDEs have been constructed by many authors (see, e.g., [14], [21], [19], [12], [10], [2]). The main difference is that the periodic orbits of the above quoted papers are a continuation of the linear normal modes to the nonlinear system. In particular their period is close to one of the periods of the linearized system. Moreover (except in the resonant case; see [5], [7], [8]) each periodic solution involves only one of the linear oscillators.[3]

On the contrary, the periodic orbits constructed in the present paper are the shadows of resonant tori; they are a purely nonlinear phenomenon, have long period,

[2] See, however, the recent works [3], [4].

[3] In the sense that all the other ones have a much smaller amplitude of oscillation.

and moreover each periodic motion involves n linear oscillators that oscillate with amplitudes of the same order of magnitude.

2. Main result. Consider a real Hamiltonian system with real[4] Hamiltonian function

$$H(z,\overline{z}) = \sum_{j\geq 1} \omega_j z_j \overline{z}_j + P(z,\overline{z}) \equiv H_0 + P, \tag{4}$$

where P has a zero of third order at the origin and the symplectic structure is given by $\mathrm{i}\sum_j dz_j \wedge d\bar{z}_j$. Here z and $\bar{z}$ are considered as independent variables. Often we will write only the equation for z since the equation for $\bar{z}$ is obtained by complex conjugation. The formal Hamiltonian vector field of the system is $X_H(z,\overline{z}) := (\mathrm{i}\frac{\partial H}{\partial \overline{z}_j}, -\mathrm{i}\frac{\partial H}{\partial z_j})$, and therefore the equations of motion have the form

$$\dot{z}_j = \mathrm{i}\omega_j z_j + \mathrm{i}\frac{\partial P}{\partial \overline{z}_j}\ , \quad \dot{\overline{z}}_j = -\mathrm{i}\omega_j \overline{z}_j - \mathrm{i}\frac{\partial P}{\partial z_j}. \tag{5}$$

Define the complex Hilbert space

$$\mathcal{H}^{a,s}(\mathbf{C}) := \left\{ w = (w_1, w_2, \ldots) \in \mathbf{C}^\infty \ \middle|\ ||w||^2_{a,s} := \sum_{j\geq 1} |w_j|^2 j^{2s} e^{2ja} < \infty \right\}.$$

We fix $s \geq 0$ and $a \geq 0$ and will study the system in the phase space

$$\mathcal{P}_{a,s} := \mathcal{H}^{a,s}(\mathbf{C}) \times \mathcal{H}^{a,s}(\mathbf{C}) \ni (z,\bar{z}).$$

Fix any finite integer $n \geq 2$ and denote $\omega := (\omega_1, \ldots, \omega_n)$, $\Omega := (\omega_{n+1}, \omega_{n+2}, \ldots)$. We assume that

(A) The frequencies grow at least linearly at infinity; namely there exist $a > 0$ and $d_1 \geq 1$ such that

$$\omega_j \sim a j^{d_1}.$$

(NR) For any $k \in \mathbf{Z}^n$, $l \in \mathbf{Z}^\infty$ with $|l| \leq 2$ and $0 < |k| + |l| \leq 5$, one has

$$\omega \cdot k + \Omega \cdot l \neq 0. \tag{6}$$

(S) There exist a neighborhood of the origin $\mathcal{U} \subset \mathcal{P}_{a,s}$ and $d \geq 0$ such that $X_P \in C^\omega(\mathcal{U}, \mathcal{P}_{a,s+d})$; namely it is analytic.

Remark 2.1. In applications to PDEs, property (S) is usually a consequence of the smoothness of the Nemitsky operator defined by the nonlinear part of the equation. In order to ensure (S) one has usually to restrict to the case where the functions with Fourier coefficients in $\mathcal{P}_{a,s}$ form an algebra (with the product of convolution between sequences). This imposes some limitations on the choice of the indexes a, s.

Proposition 2.1. *Assume* (A), (NR), (S). *There exists a real analytic, symplectic change of variables $\mathcal{T}$ defined in some neighborhood $\mathcal{U}' \subset \mathcal{P}_{a,s}$ of the origin, transforming the Hamiltonian H in seminormal form up to order six, namely into*

$$H \circ \mathcal{T} \equiv \mathcal{H} = H_0 + \overline{G} + \hat{G} + K \tag{7}$$

[4] i.e., if $\overline{z}$ is actually the complex conjugate to z, then the Hamiltonian H takes real values.

with

$$\overline{G} = \frac{1}{2} \sum_{\min(i,j)\le n} \overline{G}_{ij} |z_i|^2 |z_j|^2,$$

$\overline{G}_{ij} = \overline{G}_{ji}$, $\hat{G} = O(||\hat{z}||^3_{a,s})$, *where* $\hat{z} := (z_{n+1}, z_{n+2}, \dots)$ *and* $K = O(||z||^6_{a,s})$. *Moreover*

$$X_{\overline{G}}, X_{\hat{G}}, X_K \in C^\omega(\mathcal{U}', \mathcal{P}_{a,s+d}), \quad \|z - \mathcal{T}(z)\|_{a,s+d} \le C\|z\|^2_{a,s}. \tag{8}$$

We defer the proof of this proposition to the appendix where we also give a formula for $\bar{G}$ (see (69)).

The interest of such a seminormal form is that the system obtained by neglecting the reminder K has the invariant manifold $\hat{z} = 0$ on which the system is integrable.

As a variant with respect to the standard finite dimensional procedure we have left the third order term $\hat{G}$ but normalized the system up to order six (instead of five). This is needed in Lemma 3.2.

We also remark that, assuming just the nonresonance condition (NR), one can not hope (in general) to transform the Hamiltonian H into the infinite dimensional analogue of the standard Birkhoff normal form.

We rewrite the Hamiltonian $\mathcal{H}$ in the form

$$\mathcal{H} := \omega \cdot I + \Omega \cdot Z + \frac{1}{2} AI \cdot I + (BI, Z) + \hat{G} + K, \tag{9}$$

where $I := (|z_1|^2, \dots, |z_n|^2)$, $Z := (|z_{n+1}|^2, |z_{n+2}|^2, \dots)$ are the actions, A is the $n \times n$ matrix

$$A = (\overline{G}_{ij})_{1\le i,j\le n}, \tag{10}$$

and B is the $\infty \times n$ matrix

$$B = (\overline{G}_{ij})_{1\le j\le n<i}. \tag{11}$$

Remark 2.2. Due to (8), (9), one has $|(BI)_j| \le C|I|j^{-d}$ for a suitable C. Indeed, since $X_{\overline{G}}$ maps $\mathcal{P}_{a,s}$ to $\mathcal{P}_{a,s+d}$, the operator $z_j \mapsto (BI)_j z_j$ maps $\mathcal{P}_{a,s}$ to $\mathcal{P}_{a,s+d}$, and therefore its eigenvalues $(BI)_j$ must fulfill the above property.

Introduce action angle variables for the first n modes by $z_j = |z_j| e^{\mathrm{i}\phi_j} = \sqrt{I_j} e^{\mathrm{i}\phi_j}$ for $j = 1, \dots, n$.

Perform the rescaling $I_j \to \eta^2 I_j$, $\phi_j \to \phi_j$ for $j = 1, \dots, n$, $z_j \to \eta z_j$, $\overline{z}_j \to \eta \overline{z}_j$ for $j \ge n+1$ and divide the Hamiltonian by η^2. We get

$$\mathcal{H}(I, \phi, \hat{z}, \bar{\hat{z}}) = \omega \cdot I + \Omega \cdot Z + \eta \hat{G}_\eta + \eta^2 \Big(\frac{1}{2} AI \cdot I + (BI, Z) \Big) + \eta^4 K_\eta, \tag{12}$$

where $\hat{G}_\eta = O(||\hat{z}||^3_{a,s})$ and $K_\eta(z) = O(||z||^6_{a,s})$. We will still denote by $\mathcal{P}_{a,s} \equiv \mathbf{R}^n \times \mathbf{T}^n \times \mathcal{H}^{a,s} \times \mathcal{H}^{a,s}$ the phase space.

We will find periodic solutions of the Hamiltonian system (12) close to periodic solutions of the integrable Hamiltonian system

$$\dot{I} = 0, \quad \dot{\phi} = \omega + \eta^2 (AI + B^T Z), \quad \dot{z}_j = \mathrm{i}\Big(\Omega_j + \eta^2 (BI)_j\Big) z_j, \quad j \ge n+1 \tag{13}$$

in which $\hat{G}_\eta$ and K_η are neglected. The manifold $\{\hat{z}=0\}$ is invariant for the Hamiltonian system (13) and is completely filled up by the invariant tori

$$\mathcal{T}(I_0) := \{I = I_0,\ \phi \in \mathbf{T}^n,\ \hat{z}=0\}$$

on which the motion is linear with frequencies

$$\widetilde{\omega} \equiv \widetilde{\omega}(I_0) := \omega + \eta^2 A I_0 .$$

Such a torus is linearly stable, and the frequencies of small oscillation about the torus $\mathcal{T}(I_0)$ are the "shifted elliptic frequencies," namely

$$\widetilde{\Omega}_j(I_0) := (\Omega + \eta^2 B I_0)_j . \tag{14}$$

If all the $\widetilde{\omega}$'s are integer multiples of a single frequency, namely if

$$\widetilde{\omega} := \omega + \eta^2 A I_0 = \frac{1}{T} 2\pi k \in \frac{1}{T} 2\pi \mathbf{Z}^n , \tag{15}$$

then $\mathcal{T}(I_0)$ is a *completely resonant* torus, supporting the family of T-periodic motions

$$\mathcal{P} := \big\{ I(t) = I_0, \quad \phi(t) = \phi_0 + \widetilde{\omega} t, \quad \hat{z}(t) = 0 \big\}. \tag{16}$$

The whole family $\mathcal{P}$ will not persist in the dynamics of the complete Hamiltonian system (12). We will show that, under suitable assumptions, at least n geometrically distinct T-periodic solutions persist. More precisely, we will show that this happens for η small enough and for any choice of I_0 and T with

$$\|I_0\| \le C, \qquad \frac{1}{\eta^2} \le T \le \frac{2}{\eta^2}, \tag{17}$$

where C is independent of η, fulfilling the following.

(H1) Equation (15) holds.

(H2) There exist $\delta > 0$ and $\tau < d$ such that

$$|\widetilde{\Omega}_j T - 2\pi l| \ge \frac{\delta}{j^\tau} \quad \forall l \in \mathbf{Z},\ \forall j \ge n+1. \tag{18}$$

PROPOSITION 2.2. *Fix* $\tau > 1$. *Assume* (A), $\det A \neq 0$, *and*

$$\hat{\Omega}_j := \big(\Omega - B A^{-1} \omega\big)_j \neq 0 \qquad \forall j \ge n+1; \tag{19}$$

then, for any $\eta > 0$ *and almost any* T *fulfilling* (17) *there exists* I_0 *such that* (H1,H2) *hold.*

Proof. Fix η; we define $I_0 := I_0(T)$ as a function of T so that (15) is identically satisfied. Then we find T so that the nonresonance property (18) holds. Fix η and define

$$I_0 := I_0(T) := \frac{2\pi}{\eta^2 T} A^{-1} \Big(\Big[\frac{\omega T}{2\pi} \Big] - \frac{\omega T}{2\pi} \Big), \tag{20}$$

$$k := k(T) = \Big[\frac{\omega T}{2\pi} \Big], \tag{21}$$

where $[(x_1, \dots, x_n)] := ([x_1], \dots, [x_n])$ and $[x] \in \mathbf{Z}$ denotes the integer part of $x \in \mathbf{R}$. With the choice (20), (21), $\omega T + T\eta^2 A I_0 = 2\pi k$, and I_0 is of order 1 since $T\eta^2 \ge 1$.

We come to the nonresonance property (18). To study it, we remark that the function $T \to [\omega T/2\pi]$ is piecewise constant. Hence, for any $T_0 \in (\eta^{-2}, 2\eta^{-2})$ there exists an interval $\mathcal{I}_0 = (T_0 - a, T_0 + b) \subset [\eta^{-2}, 2\eta^{-2}]$ such that $[\omega T/2\pi] := k_0$ is constant for $T \in \mathcal{I}_0$. Moreover the union of such intervals covers the whole set of values in which we are interested. We will construct a subset of full measure of $\mathcal{I}_0$, in which condition (H2) is fulfilled.

So, for fixed j, l consider the set

$$B_{jl}(\tau, \delta) := \left\{ T \in \mathcal{I}_0 \ : \ |\widetilde{\Omega}_j T - 2\pi l| < \frac{\delta}{j^\tau} \right\}. \tag{22}$$

Remark that

$$\widetilde{\Omega}_j T = \hat{\Omega}_j T + \left(2\pi B A^{-1} \left[\frac{\omega T}{2\pi} \right] \right)_j ,$$

so that, in $\mathcal{I}_0$

$$\frac{d}{dT} \left(\widetilde{\Omega}_j T - 2\pi l \right) = \hat{\Omega}_j .$$

By (A) and Remark 2.2, there exists C such that

$$\left| \widetilde{\Omega}_j \right| \geq C j^{d_1} \ , \quad \left| \hat{\Omega}_j \right| \geq C j^{d_1} . \tag{23}$$

Then B_{jl} is an interval with length $|B_{jl}|$ controlled by

$$|B_{jl}| < 2 \frac{\delta}{C j^{\tau + d_1}} . \tag{24}$$

Fix j and estimate the number of l for which the set B_{jl} is (possibly) nonempty. First remark that, due to (A), one has that, as T varies in $\mathcal{I}_0$, the quantity $\widetilde{\Omega}_j T$ varies in a segment of length smaller than $C j^{d_1}$, with a suitable C. This means that there are at most $C j^{d_1}$ values of l which fall in such an interval (with redefined C). So, one has

$$\left| \bigcup_l B_{jl} \right| \leq \frac{C\delta}{j^\tau} . \tag{25}$$

Thus, provided $\tau > 1$ as we assumed, one has that

$$\left| \bigcup_{jl} B_{jl} \right| \leq C\delta . \tag{26}$$

By this estimate, the intersection over δ of such sets has zero measure, which is the thesis. ∎

THEOREM 2.3. *Consider the system* (9)*; let T and I_0 fulfill* (17) *and* (H1), (H2). *Then, provided η is small enough, there exist n geometrically distinct periodic orbits of the Hamiltonian system $\mathcal{H}$ (cf.* (9)*) with period T which are η^2 close in $\mathcal{P}_{a,s}$ to the torus $\mathcal{T}(I_0)$.*

Going back to the original system, one has the following corollary.

COROLLARY 2.4. *Consider the Hamiltonian system* (5) *and fix a positive n. Assume that* (A), (NR), (S) *hold, that* $\det A \neq 0$ *(cf.* (10)*), and that $\hat{\Omega}_j \neq 0$ for all $j \geq n+1$ (cf.* (19)*). Finally assume $d > 1$.*

Then, for any positive $\eta \ll 1$ there exist at least n distinct periodic orbits $z^{(1)}(t), \dots, z^{(n)}(t)$ with the following properties:

- $\|z^{(l)}(t)\|_{a,s} \le C\eta$ *for* $l = 1, \dots, n$ *and* $t \in \mathbf{R}$*;*
- $\|\Pi_{>n} z^{(l)}(t)\|_{a,s} \le C\eta^2$ *for* $l = 1, \dots, n$ *and* $t \in \mathbf{R}$*; here* $\Pi_{>n}$ *is the projector on the modes with index larger than* n*;*
- *the period* T *of* $z^{(l)}$ *does not depend on* l *and fulfills* $\eta^{-2} \le T \le 2\eta^{-2}$*.*

Remark 2.3. By Theorem 2.3 the results of Corollary 2.4 remain true even if the Hamiltonian system (5) does not fulfill one of the assumptions (A), (NR) but nevertheless one is able to transform it to the form (7).

Remark 2.4. If the integer numbers $(k_1, \dots, k_n) = \widetilde{\omega} T/2\pi$ are relatively prime, then T is the minimal period of the periodic solutions $z^{(l)}$. Indeed $z^{(l)}$ are T-periodic functions close to the functions defined in (16) which have minimal period T.

3. Proof of Theorem 2.3. Since the problem is Hamiltonian, any periodic solution of the system is a critical point of the action functional

$$S(I, \phi, \hat{z}, \hat{\bar{z}}) = \int_0^T \left(I \cdot \dot{\phi} + \mathrm{i} \sum_{j \ge n+1} z_j \dot{\bar{z}}_j - \mathcal{H}(I, \phi, \hat{z}, \hat{\bar{z}}) \right) dt \tag{27}$$

in the space of T-periodic, $\mathcal{P}_{a,s}$-valued functions. Here $\mathcal{H}$ is given by (12).

We look for a periodic solution $\zeta := (\phi, I, \hat{z}, \hat{\bar{z}})$ of the form

$$\phi(t) = \phi_0 + \widetilde{\omega} t + \psi(t), \quad I(t) = I_0 + J(t), \tag{28}$$

where $(\psi, J, \hat{z}, \hat{\bar{z}})$ are periodic functions of period T taking values in the covering space $\mathbf{R}^n \times \mathbf{R}^n \times \mathcal{H}^{a,s} \times \mathcal{H}^{a,s}$ of $\mathcal{P}_{a,s}$ (that for simplicity will still be denoted by $\mathcal{P}_{a,s}$). Hence $(\psi,\ J,\ \hat{z})$ must satisfy (in what follows for simplicity of notation we will only consider the equation for $\hat{z}$)

$$\nabla_\phi S(\zeta) = 0 \iff \dot{J} = R_\phi(\zeta), \tag{29}$$

$$\nabla_I S(\zeta) = 0 \iff \dot{\psi} - \eta^2 A\, J = R_I(\zeta), \tag{30}$$

$$\nabla_{\bar{z}_j} S(\zeta) = 0 \iff \dot{z}_j - \mathrm{i}\widetilde{\Omega}_j z_j = (R_{\bar{z}})_j(\zeta), \tag{31}$$

where

$$\left\{ \begin{array}{lcc} R_\phi(\zeta) & := & -\eta^4 \partial_\phi K_\eta(I_0 + J, \phi_0 + \widetilde{\omega} t + \psi, \hat{z}) - \eta \partial_\phi \hat{G}_\eta, \\ R_I(\zeta) & := & \eta^2 B^T Z + \eta^4 \partial_I K_\eta(I_0 + J, \phi_0 + \widetilde{\omega} t + \psi, \hat{z}) + \eta \partial_I \hat{G}_\eta, \\ (R_{\bar{z}})_j(\zeta) & = & \mathrm{i}\eta^2 (BJ)_j z_j + \mathrm{i}\eta \partial_{\bar{z}_j} \hat{G}_\eta + \mathrm{i}\eta^4 \partial_{\bar{z}_j} K_\eta(I_0 + J, \phi_0 + \widetilde{\omega} t + \psi, \hat{z}). \end{array} \right. \tag{32}$$

Remark that, since one expects J, ψ, and $\hat{z}$ to be small (they will turn out to be of order η^2), and by Proposition 2.1 one has $\partial_{\bar{z}} \hat{G}_\eta(\zeta) = O(\|\hat{z}\|^2_{a,s})$, $\partial_\phi \hat{G}_\eta(\zeta) = O(\|\hat{z}\|^3_{a,s})$, $\partial_I \hat{G}_\eta(\zeta) = O(\|\hat{z}\|^3_{a,s})$ the r.h.s. of (29), (30), (31) remain small even when they are multiplied by $T = O(\eta^{-2})$ (see Lemma 3.2).

Define the Hilbert space $H^1_P((0,T); \mathcal{P}_{a,s})$ of the T-periodic $\mathcal{P}_{a,s}$-valued periodic functions of class H^1. In order to simplify notations we will denote this space by $H^1_{P,s}$.

Denote for $\zeta = (\psi, J, w) \in H^1_{P,s}$,

$$|J|^2_{L^2,T} := \frac{1}{T} \int_0^T |J|^2 \ dt, \quad |\psi|^2_{L^2,T} := \frac{1}{T} \int_0^T |\psi|^2 \ dt, \tag{33}$$

$$||w||^2_{L^2,T,a,s} := \frac{1}{T} \int_0^T ||w(t)||^2_{a,s} \ dt, \tag{34}$$

$$\|\zeta\|_{L^2,T,a,s} := |J|_{L^2,T} + |\psi|_{L^2,T} + ||w||_{L^2,T,a,s}. \tag{35}$$

We will endow $H^1_P((0,T);\mathcal{P}_{a,s}) \equiv H^1_{P,s}$ with the norm

$$\|\zeta\|_{T,a,s} := \|\zeta\|_{L^2,T,a,s} + T\|\dot{\zeta}\|_{L^2,T,a,s}. \tag{36}$$

Remark 3.1. With this choice one has

$$\|\zeta(t)\|_{\mathcal{P}_{a,s}} \le C\|\zeta\|_{T,a,s} \quad \forall t \in \mathbf{R}$$

with a constant independent of T. Therefore, with this choice of the norm, the space $H^1_{P,s}$ is a "Banach algebra," and the T,a,s norm of the product of any component of a vector ζ with any component of a vector ζ' is bounded by $C\|\zeta\|_{T,a,s}\|\zeta'\|_{T,a,s}$ *with a constant* C *independent of* T.

We will consider the system (29), (30), (31) as a functional equation in $H^1_{P,s}$.

Remark 3.2. As a consequence of (8) and Remark 3.1, the map $\zeta \mapsto R(\zeta) := (R_\phi(\zeta), R_I(\zeta), R_{\overline{z}}(\zeta))$ is a C^∞ map from $H^1_{P,s}$ to $H^1_{P,s+d}$.

We are going to use the method of Lyapunov–Schmidt decomposition in order to solve (29), (30), (31). To this end remark that the kernel of the linear operator $\mathcal{L}$ at the l.h.s. of (29), (30), (31) is given by $(\phi,0,0)$ with constant $\phi \in \mathbf{T}^n$. The range of $\mathcal{L}$ is the space of the functions $\zeta = (\psi, J, \hat{z})$ with $\psi(t)$ having zero mean value. So, there is a natural decomposition of $H^1_{P,s}$ into Range+Kernel. Explicitly, we write

$$\zeta = (\phi + \psi, J, \hat{z}) = (\psi, J, \hat{z}) + (\phi, 0, 0) \equiv \zeta_R + \phi$$

with ψ having zero mean value and ϕ being constant. Then we fix ϕ, take the projection of the system (29), (30), (31) on the range, and solve it. The solution is a function $\zeta_R(\eta,\phi)$. Finally, we insert this function in the variational principle in order to find critical points of S.

3.1. The range equation. The range equation has the form

$$\begin{cases} \dot{J} & = & R_\phi(\zeta) - \langle R_\phi(\zeta)\rangle, \\ \dot{\psi} - \eta^2 A\, J & = & R_I(\zeta), \\ \dot{z}_j - \mathrm{i}\widetilde{\Omega}_j z_j & = & (R_{\overline{z}})_j(\zeta), \end{cases} \tag{37}$$

where $\langle R_\phi(\zeta)\rangle := (1/T)\int_0^T R_\phi(\zeta)dt$. We look for its solution in the range, namely in the space

$$\overline{H}^1_{P,s} \subset H^1_{P,s}$$

of the functions $\zeta_R \equiv (\psi, J, \hat{z})$ with ψ having zero average.

First of all we analyze the linear problem defined by the l.h.s. of (37). A "small denominator problem" appears since inverting this linear system the denominators $\widetilde{\Omega}_j T - 2\pi l$, $j \ge n+1$, $l \in \mathbf{Z}$ are present. So, define the linear operator

$$\mathcal{L}(\psi, J, \hat{z}) \equiv \mathcal{L}\zeta_R := (\dot{J}, \dot{\psi} - \eta^2 AJ, \dot{w}_j - \mathrm{i}\widetilde{\Omega}_j w_j)$$

and study

$$\mathcal{L}\zeta_R = (\widetilde{\psi}, \widetilde{J}, \widetilde{w}) \tag{38}$$

with $(\widetilde{\psi}, \widetilde{J}, \widetilde{w}) \in \overline{H}^1_{P,s+\tau}$ given.

LEMMA 3.1. *Assume* (H2). *If*

$$\widetilde{\zeta}_R \equiv (\widetilde{\psi}, \widetilde{J}, \widetilde{w}) \in \overline{H}^1_{P,s+\tau}, \qquad \text{i.e., in } H^1_{P,s+\tau} \text{ with } \int_0^T \widetilde{\psi}(t)\, dt = 0,$$

then (38) *has a unique solution,*

$$\zeta_R \equiv (\psi, J, w) \in \overline{H}^1_{P,s}.$$

Moreover for $T \in (\eta^{-2}, 2\eta^{-2})$ and a constant $C := C(\delta)$

$$\|\zeta_R\|_{T,a,s} \le \frac{C}{\eta^2} \|\widetilde{\zeta}_R\|_{T,a,s+\tau}.$$

Proof. Since A is symmetric and invertible it has an orthonormal basis of eigenvectors $e_1, \dots, e_n$ with eigenvalues $\lambda_1, \dots, \lambda_n$. In these coordinates $J(t) = \sum_{k=1}^n J_k(t) e_k$, $\psi(t) = \sum_{k=1}^n \psi_k(t) e_k$, and the solution ζ_R of (38) with $\psi_0 = 0$ has Fourier coefficients

$$J_{kl} = \frac{T\widetilde{\psi}_{kl}}{\mathrm{i}2\pi l} \quad \text{for} \quad l \neq 0, \qquad J_{k0} = -\frac{\widetilde{J}_{k0}}{\eta^2 \lambda_k},$$

$$\psi_{kl} = T\frac{\widetilde{J}_{kl} + \eta^2 J_{kl}\lambda_k}{\mathrm{i}2\pi l} \quad \text{for} \quad l \neq 0,$$

and, for $j \ge n+1$,

$$w_{jl} := \frac{T\widetilde{w}_{jl}}{\mathrm{i}(2\pi l - \widetilde{\Omega}_j T)}.$$

We then find

$$\begin{aligned} |J|^2_{L^2,T} = \sum_{kl} J^2_{kl} &= \sum_k \left(\frac{\widetilde{J}_{k0}}{\eta^2\lambda_k}\right)^2 + \sum_{k,l\neq 0} \left(\frac{T\widetilde{\psi}_{kl}}{\mathrm{i}2\pi l}\right)^2 \\ &\le \frac{C}{\eta^4} |\widetilde{J}|^2_{L^2,T} + CT^2 |\widetilde{\psi}|^2_{L^2,T}. \end{aligned} \tag{39}$$

A similar estimate for $|\psi|_{L^2,T}$ holds. Moreover

$$|\dot{\psi}|_{L^2,T} \le \eta^2 |J|_{L^2,T} + |\widetilde{\psi}|_{L^2,T} \le C(|\widetilde{J}|_{L^2,T} + |\widetilde{\psi}|_{L^2,T}), \tag{40}$$

using (39). Finally, the solution $w = (w_j)_{j \ge n+1}$ of (38) is

$$w_j(t) = \sum_{l\in\mathbf{Z}} \frac{T\widetilde{w}_{jl}}{\mathrm{i}(2\pi l - \widetilde{\Omega}_j T)} e^{\mathrm{i}(2\pi/T)lt},$$

where $\widetilde{w}_j(t) = \sum_{l\in\mathbf{Z}} \widetilde{w}_{jl} e^{\mathrm{i}(2\pi/T)lt}$. From (H2) we get

$$||w||_{L^2,T,a,s} \le C\frac{T}{\delta} ||\widetilde{w}||_{L^2,T,a,s+\tau}, \qquad ||\dot{w}||_{L^2,T,a,s} \le C\frac{T}{\delta} ||\dot{\widetilde{w}}||_{L^2,T,a,s+\tau}. \tag{41}$$

By (39), (40), and (41) the last estimate of the lemma follows. ∎

Thus $\mathcal{L}^{-1}$ defines a linear bounded operator $L : \overline{H}^1_{P,s+\tau} \to \overline{H}^1_{P,s}$.

In order to find a solution $\zeta_R = (\psi, J, \hat{z})$ of the range equation it is sufficient to find a fixed point of

$$\zeta_R = \Phi(\zeta_R) := L\big(N(\zeta_R; \phi)\big) \tag{42}$$

in the space $\overline{H}^1_{P,s}$, where $N := N(\zeta_R; \phi)$ denotes the r.h.s. of (37).

LEMMA 3.2. *Assume $d > \tau$. Then there exists a constant C sufficiently large such that $\forall \eta \ll 1$ the map Φ is a contraction of a ball of radius $C\eta^2$.*

Proof. Consider a $\zeta_R \in \overline{H}^1_{P,s}$ with $\|\zeta_R\|_{T,a,s} \le \rho$ with some positive (small) ρ. Since $H^1_{P,s}$ is an algebra with constants independent of T (cf. Remark 3.1), one has, by (32),

$$\|N(\zeta_R)\|_{T,a,s+d} \le C(\eta^4 + \eta\rho^2)$$

with a suitable C. Therefore, by Lemma 3.1 one has

$$\|\Phi(\zeta_R)\|_{T,a,s} \le \|\Phi(\zeta_R)\|_{T,a,s+d-\tau} \le C\left(\eta^2 + \frac{\rho^2}{\eta}\right),$$

which is smaller than ρ, provided $C(\eta^2 + \rho^2/\eta) < \rho$, which is implied, e.g., by $\rho = 2C\eta^2$ and η small enough.

Similarly one estimates the Lipschitz constant of Φ by the norm of its differential. Such a differential is bounded in a ball of radius ρ by $C(\eta^2 + \rho/\eta)$, from which the thesis follows. ∎

COROLLARY 3.3. *There exists a unique smooth function $\mathbf{T}^n \ni \phi \mapsto \zeta_R(\phi, \eta) \in \overline{H}^1_{P,s}$ solving* (37) *and fulfilling*

$$\|\zeta_R(\phi, \eta)\|_{T,a,s} \le C\eta^2.$$

3.2. The kernel equation. The geometric interpretation of the construction of the previous subsection is that we have found a submanifold $\mathcal{T}^n \equiv \{\zeta_{\phi_0} := (\phi_0 + \widetilde{\omega}t, I_0, 0) + \zeta_R(\phi_0, \eta),\ \phi_0 \in \mathbf{T}^n\} \subset H^1_{P,s}$, diffeomorphic to an n-dimensional torus, on which the partial derivatives of the action functional S with respect to the variables ζ_R vanish. We claim that at a critical point of S restricted to $\mathcal{T}^n$, all the partial derivatives of the complete functional S vanish and therefore that such a point is critical also for the nonrestricted functional.

Indeed, let $S_n : \mathbf{T}^n \to \mathbf{R}$ be the functional defined by $S_n(\phi_0) := S(\zeta_{\phi_0})\ \forall \phi_0 \in \mathbf{T}^n$.

LEMMA 3.4. *If $\phi_0 \in \mathbf{T}^n$ is a critical point of $S_n : \mathbf{T}^n \to \mathbf{R}$, then ζ_{ϕ_0} is a critical point of the nonrestricted functional S.*

Proof. Since $\zeta_R(\phi_0, \eta) = (\psi_{\phi_0}, J_{\phi_0}, \hat{z}_{\phi_0}) \in \overline{H}^1_{P,s}$ solves (37), then ζ_{ϕ_0} satisfies $\forall \phi_0 \in \mathbf{T}^n$,

$$\nabla_\phi S(\zeta_{\phi_0}) = \langle R_\phi(\zeta_{\phi_0})\rangle, \qquad \nabla_I S(\zeta_{\phi_0}) = 0, \qquad \nabla_{\overline{z}_j} S(\zeta_{\phi_0}) = 0 \tag{43}$$

(∇S denote the L^2-gradients). By (43) and since $\int_0^T \partial_{\phi_0}\psi_{\phi_0}(t)\, dt = 0\ \forall \phi_0 \in \mathbf{T}^n$,

$$\partial_{\phi_0} S_n(\phi_0) := (\nabla_\phi S(\zeta_{\phi_0}), \partial_{\phi_0}\zeta_{\phi_0})_{L^2} = T\langle R_\phi(\zeta_{\phi_0})\rangle.$$

Therefore, if $\phi_0 \in \mathbf{T}^n$ is a critical point of S_n, then $\langle R_\phi(\zeta_{\phi_0})\rangle = 0$, and at $\zeta_{\phi_0} \in \mathcal{T}^n$ all the partial derivatives of the complete functional S vanish. ∎

By standard Lusternik–Schnirelmann theory there exist at least n geometrically distinct T-periodic solutions, i.e., solutions not obtained from each other simply by time-translations. Indeed, restrict S_n to the plane $E := [\widetilde{\omega}]^{\perp}$ orthogonal to the periodic flow $\widetilde{\omega} = (1/T)2\pi k$ with $k \in \mathbf{Z}^n$. The set $\mathbf{Z}^n \cap E$ is a lattice of E, and hence S_n defines a functional $S_{n|\Gamma}$ on the quotient space $\Gamma := E/(\mathbf{Z}^n \cap E) \sim \mathbf{T}^{n-1}$.

Due to the invariance of S_n with respect to the time shift, a critical point of $S_{n|\Gamma}$ is also a critical point of $S_n : \mathbf{T}^n \to \mathbf{R}$. By the Lusternik–Schnirelmann category theory since $\mathrm{cat}\Gamma = \mathrm{cat}\mathbf{T}^{n-1} = n$, we can define the n min-max critical values $c_1 \leq c_2 \leq \cdots \leq c_n$ for $S_{n|\Gamma}$. If the critical levels c_i are all distinct, the corresponding T-periodic solutions are geometrically distinct, since their actions c_i are all different. On the other hand, if some min-max critical level c_i coincides, then, by the Lusternik–Schnirelmann theory, $S_{n|\Gamma}$ possesses infinitely many critical points. However *not* all the corresponding T-periodic solutions are necessarily geometrically distinct, since two different critical points could belong to the same orbit. Nevertheless, since a periodic solution can cross Γ at most a finite number of times, the existence of infinitely many geometrically distinct orbits follows. For further details, see [6].

This concludes the proof of Theorem 2.3.

4. Applications.

4.1. The nonlinear beam equation. Consider the beam equation

$$u_{tt} + u_{xxxx} + mu = f(u) \tag{44}$$

subject to hinged boundary conditions

$$u(0,t) = u(\pi,t) = u_{xx}(0,t) = u_{xx}(\pi,t) = 0, \tag{45}$$

where the nonlinearity $f(u)$ is a real analytic odd function of the form

$$f(u) = au^3 + \sum_{k \geq 5} f_k u^k, \qquad a \neq 0.$$

The beam equation (44) is a Hamiltonian PDE with associated Hamiltonian

$$H = \int_0^{\pi} \frac{u_t^2}{2} + \frac{u_{xx}^2}{2} + \frac{mu^2}{2} - g(u)\ dx,$$

where $g(u) := \int_0^u f(s)\ ds$ is a primitive of f.

Write the system in first order form

$$\begin{cases} \dot{u} &= \quad v, \\ \dot{v} &= -u_{xxxx} - mu + f(u). \end{cases} \tag{46}$$

The standard phase space[5] for (46) is $\mathcal{F}_s := H_C^s \times H_C^{s-2} \ni (u,v)$, where H_C^s is the space of the functions which extend to skew symmetric H^s periodic functions over $[-\pi,\pi]$. Note that $H_C^s = \{u(x) = \sum_{j\geq 1} u_j \sin(jx) \mid \sum_{j \geq 1} |u_j|^2 j^{2s} < +\infty\}$. It is then immediate to realize that, due to the regularity and skew symmetry of the vector field of the nonlinear part, f defines a smoothing operator, namely a smooth map from $\mathcal{F}_s$ to $\mathcal{F}_{s+2}$, provided $s \geq 1$.

[5] An equivalent definition makes use of the so-called compatibility conditions required for the smoothness of solutions of second order equations with Dirichlet boundary conditions; see, e.g., [11, Theorem X.8].

Here we are also interested in spaces of analytic functions, namely functions whose Fourier coefficients belong to $\mathcal{H}^{a,s}$ with some positive a. It is easy to see that the smoothing property of the nonlinearity holds also for these spaces.

Introduce coordinates $q = (q_1, q_2, \dots)$, $p = (p_1, p_2, \dots)$ through the relations

$$u(x) = \sum_{j \geq 1} \frac{q_j}{\sqrt{\omega_j}} \phi_j(x), \qquad v(x) = \sum_{j \geq 1} p_j \sqrt{\omega_j} \phi_j(x),$$

where $\phi_j(x) = \sqrt{2/\pi} \sin(jx)$ and

$$\omega_j^2 = j^4 + m. \tag{47}$$

Remark also that

$$\omega_j \sim j^2.$$

Passing to complex coordinates

$$z_j := \frac{q_j + \mathrm{i} p_j}{\sqrt{2}}, \qquad \bar{z}_j := \frac{q_j - \mathrm{i} p_j}{\sqrt{2}},$$

the Hamiltonian takes the form (4), and the nonlinearity fulfills (S) with $s \geq 1$ a suitable a, depending on the anayticity strip of f, and $d = 2$ (for more details, see [19], [13]).

In order to verify the nonresonance property we use m as a parameter belonging to the set $[0, L]$ with an arbitrary L.

LEMMA 4.1. *There exists a finite set $\Delta \subset [0, L]$ such that, if $m \in [0, L] \backslash \Delta$, then condition* (NR) *holds.*

Proof. First remark that, due to the growth property of the frequencies, there is at most a finite number of vectors $l \in \mathbf{Z}^2$ at which $\omega \cdot k + \Omega \cdot l$ is small. It follows that, having fixed an arbitrary constant C, there is at most a finite set of k's and l's over which $|\omega \cdot k + \Omega \cdot l| < C$. Denote by $\mathcal{S}$ such a set.

For $(k, l) \in \mathcal{S}$ consider

$$f_{kl}(m) = \omega(m) \cdot k + \Omega(m) \cdot l;$$

since f_{kl} is an analytic function, it has only isolated zeros. So at most finitely many of them fall in $[0, L]$. The set Δ is the union over $k, l \in \mathcal{S}$ of such points. Fix $m \in [0, L] \backslash \Delta$. $\square$

Then one can put the system in seminormal form. The explicit computation was essentially done in [15] (see also [19], [13]), obtaining that the matrices A and B are given by

$$A = \frac{6}{\pi} \begin{pmatrix} \frac{3}{\omega_1^2} & \frac{4}{\omega_1 \omega_2} & \cdots & \frac{4}{\omega_1 \omega_n} \\ \frac{4}{\omega_2 \omega_1} & \frac{3}{\omega_2^2} & \cdots & \frac{4}{\omega_2 \omega_n} \\ \cdots & \cdots & \cdots & \cdots \\ \frac{4}{\omega_1 \omega_n} & \frac{4}{\omega_n \omega_2} & \cdots & \frac{3}{\omega_n^2} \end{pmatrix}, \; B = \frac{6}{\pi} \begin{pmatrix} \frac{4}{\omega_{n+1} \omega_1} & \cdots & \frac{4}{\omega_{n+1} \omega_n} \\ \frac{4}{\omega_{n+2} \omega_1} & \cdots & \frac{4}{\omega_{n+2} \omega_n} \\ \vdots & \vdots & \vdots \end{pmatrix}. \tag{48}$$

Remark that, defining the matrices

$$S_1 := \mathrm{diag}(\omega_1, \dots, \omega_n) \qquad \text{and} \qquad S_2 := \mathrm{diag}(\omega_{n+1}, \omega_{n+2}, \dots),$$

one can write $A = \frac{6}{\pi} S_1^{-1} \widetilde{A} S_1^{-1}$, $B = \frac{6}{\pi} S_2^{-1} \widetilde{B} S_1^{-1}$ with

$$\widetilde{A} = \begin{pmatrix} 3 & 4 & \dots & 4 \\ 4 & 3 & \dots & 4 \\ \dots & \dots & \dots & \dots \\ 4 & 4 & \dots & 3 \end{pmatrix}, \quad \widetilde{B} = \begin{pmatrix} 4 & \dots & 4 \\ 4 & \dots & 4 \\ \vdots & \vdots & \vdots \end{pmatrix}. \tag{49}$$

With these expressions at hand it is immediate to verify that $\det A \neq 0$. For what pertains $\hat{\Omega}_j$ (cf. (19)) by exactly the same argument in the proof of Lemma 4.1 one has that they are different from zero except for at most finitely many values of $m \in [0, L]$.

Thus, provided m does not belong to a finite subset of $[0, L]$, Theorem 2.4 and its Corollary 2.4 apply.

4.2. A nonlinear Schrödinger equation. Consider the space H^s_C as in the previous section. Following Pöschel [20] we define a smoothing operator as follows. Fix a sequence $\{\rho_j\}_{j\geq 1}$ with the property

$$\forall j \geq 1, \qquad \rho_j \neq 0 \;\text{ and }\; |\rho_j| \leq C j^{-d/2}, \quad d > 1. \tag{50}$$

Consider the even, 2π-periodic, real function $\rho(x) := \sum_j \rho_j \cos(jx)$ and define

$$\Gamma : H^s_C \to H^{s+d/2}_C, \quad \Gamma u := \rho * u, \tag{51}$$

where the star denotes convolution (it is defined first by extending the function u to an odd 2π-periodic function).

Remark 4.1. It is easy to see that, expanding u in Fourier series

$$u(x) = \sum_{j\geq 1} z_j \sqrt{\frac{2}{\pi}} \sin(jx),$$

the jth Fourier coefficient of Γu is proportional to $\rho_j z_j$.

Consider the Hamiltonian system with Hamiltonian function

$$H(u, \overline{u}) = \int_0^\pi |u_x|^2 + F\left(|\Gamma u|^2\right)\, dx \tag{52}$$

with F an analytic function having a zero of order 2 at the origin, i.e., $F''(0) \neq 0$.

The equations of motion are

$$-\mathrm{i} u_t = u_{xx} + \Gamma\left(F'\left(|\Gamma u|^2\right)\Gamma u\right). \tag{53}$$

Inserting the Fourier expansion of u, the Hamiltonian H takes the form (4),

$$H(z, \overline{z}) = \sum_{j\geq 1} \omega_j z_j \overline{z}_j + P_4(z, \overline{z}) + \text{higher order terms of degree at least 6},$$

with $\omega_j = j^2$,

$$P_4 = a \sum_{i_1, i_2, i_3, i_4 \in \mathbf{N}} F_{i_1 i_2 i_3 i_4} z_{i_1} z_{i_2} \overline{z}_{i_3} \overline{z}_{i_4}, \qquad a \neq 0, \tag{54}$$

$$F_{i_1 i_2 i_3 i_4} = \rho_{i_1}\rho_{i_2}\rho_{i_3}\rho_{i_4} \int_0^\pi \sin(i_1 x)\, \sin(i_2 x)\, \sin(i_3 x)\, \sin(i_4 x) dx. \tag{55}$$

Then the Hamiltonian vector field fulfills (S) with d given by (50).

It results in $F_{i_1 i_2 i_3 i_4} = 0$ unless $i_1 \pm i_2 \pm i_3 \pm i_4 = 0$ for some choice of the signs. Thus only a codimension 1 set of coefficients $F_{i_1 i_2 i_3 i_4}$ is actually different from zero, and the sum in (54) extends only over $i_1 \pm i_2 \pm i_3 \pm i_4 = 0$.

The nonresonance assumption (NR) is here violated. So one could expect the seminormal form (9) of Proposition 2.1 not to hold for this system. Indeed one could only expect to transform H into a "resonant normal form." Nevertheless, it turns out that such resonant normal form *depends on the actions only*, and so the Hamiltonian H can still be written in the form (9). Actually, even a stronger result holds (as in [15]): the Hamiltonian H can be brought into the infinite dimensional analogue of the classical Birkhoff normal form. More precisely, we have the following proposition.

PROPOSITION 4.2. *There exists a real analytic, symplectic change of variables $\mathcal{T}$ defined in some neighborhood $\mathcal{U}' \subset \mathcal{P}_{a,s}$ of the origin, transforming the Hamiltonian H into*

$$H \circ \mathcal{T} \equiv \mathcal{H} = H_0 + \overline{G} + K \tag{56}$$

with

$$\overline{G} = \frac{1}{2} \sum_{i,j \geq 1} \overline{G}_{ij} |z_i|^2 |z_j|^2, \qquad \overline{G}_{ij} = \alpha \rho_i^2 \rho_j^2 (4 - \delta_{ij}), \qquad \alpha \neq 0, \tag{57}$$

and $K = O(||z||^6_{a,s})$. Moreover

$$X_{\overline{G}}, X_{\hat{G}}, X_K \in C^\omega(\mathcal{U}', \mathcal{P}_{a,s+d}), \quad \|z - \mathcal{T}(z)\|_{a,s+d} \leq C \|z\|^2_{a,s}. \tag{58}$$

The proof follows section 3 of [15] and, for the reader's convenience, we reproduce it at the end of the appendix. The key ingredient is that the relevant divisors in the normalizing transformation are uniformly bounded away from 0 since they are nonvanishing integers.

Clearly the Birkhoff normal form Hamiltonian $\mathcal{H}$ given in (56) can be written also in the seminormal form (9). By (57), also in this case the matrices A and B (cf. (10)–(11)) have the structure $A = \alpha S_1 \widetilde{A} S_1$, $B = 2\alpha S_2 \widetilde{B} S_1$ with matrices $\widetilde{A}$ and $\widetilde{B}$ still given by (49), $S_1 := \operatorname{diag}(\rho_1^2, \ldots, \rho_n^2)$ and $S_2 := \operatorname{diag}(\rho_{n+1}^2, \rho_{n+2}^2, \ldots)$. So the determinant of A is still different from zero. The frequencies $\hat{\Omega}_j$ (cf. (19)) now have the structure

$$\hat{\Omega}_j(\rho) = j^2 - \rho_j^2 a(\rho) \quad \forall j \geq n+1,$$

where a is a function of $\rho_1^2, \ldots, \rho_n^2$. So, except for exceptional choices of $\{\rho_j\}_{j \geq n+1}$, the nondegeneracy conditions are fulfilled, Theorem 2.3 applies to the Hamiltonian system generated by $\mathcal{H}$ in (56), and (see Remark 2.3) Corollary 2.4 applies to (53).

5. Appendix: Proof of the normal form propositions.

Proof of Proposition. 2.1. The idea is to proceed as in the proof of the standard Birkhoff normal form theorem, i.e., by successive elimination of the nonresonant monomials. As a variant with respect to the standard procedure one does not eliminate terms which are at least cubic in the variables $\hat{z}$. Remark that the estimates involved in the proofs are much more complicated than in the finite dimensional case.

To start with, expand P in a Taylor series up to order five: $P = P_3 + P_4 + P_5$+higher order terms. Then we begin by looking for the transformation simplifying P_3. So write

$$P_3 = P_3^1 + \hat{G}_3(z)$$

with

$$\hat{G}_3(z) = O(\|\hat{z}\|^3),$$

and P_3^1 is composed by the first three terms of the Taylor expansion of P_3 in the variables $\hat{z}$ only (so it contains only terms of degree 0, 1, and 2 in such variables). We use the Lie transform to eliminate from P_3^1 all the nonresonant terms; i.e., we make a canonical transformation which is the time 1 flow Φ^1 of an auxiliary Hamiltonian system with a Hamiltonian function χ of degree 3. By considering the Taylor expansion of Φ^1 at zero, one has

$$H \circ \Phi^1 = H_0 + P_3^1 + \{\chi, H_0\} + O(\|z\|^4) + O(\|\hat{z}\|^3). \tag{59}$$

One wants to determine χ so that

$$\overline{G}_3 := P_3^1 + \{\chi, H_0\}$$

is a function of the actions $|z_j|^2$ only. Since $\overline{G}_3$ has to be a function of the actions only and moreover it is a polynomial of degree 3, it must vanish. To this end we proceed as usual in the theory of Birkhoff normal form.

Denote by $x = (x_1, \ldots, x_n) \equiv (z_1, \ldots, z_n)$ the first n variables and take χ to be a homogeneous polynomial of degree 3. Write

$$\chi = \sum_{|j_1|+|j_2|+|j_3|+|j_4|=3} \chi_{j_1 j_2 j_3 j_4} x^{j_1} \overline{x}^{j_2} \hat{z}^{j_3} \overline{\hat{z}}^{j_4} \tag{60}$$

with multi-indexes j_1, j_2, j_3, j_4. For a multi-index $j_l \equiv (j_{l,1}, \ldots, j_{l,n})$ we used the notation $|j_l| := |j_{l,1}| + \cdots + |j_{l,n}|$ and $x^{j_l} := x_1^{j_{l,1}}, \ldots, x_n^{j_{l,n}}$, and similarly for a multi-index with infinitely many components. So, one has

$$\{\chi, H_0\} = \sum_{|j_1|+|j_2|+|j_3|+|j_4|=3} \mathrm{i}\left(\omega \cdot (j_1 - j_2) + \Omega \cdot (j_3 - j_4)\right) \chi_{j_1 j_2 j_3 j_4} x^{j_1} \overline{x}^{j_2} \hat{z}^{j_3} \overline{\hat{z}}^{j_4}.$$

Write now

$$P_3^1 = \sum_{|j_1|+|j_2|+|j_3|+|j_4|=3} P_{j_1 j_2 j_3 j_4} x^{j_1} \overline{x}^{j_2} \hat{z}^{j_3} \overline{\hat{z}}^{j_4} \tag{61}$$

and remark that the indexes are here subjected to the further limitation $|j_3|+|j_4| \leq 2$. So, in order to have $\overline{G}_3 := P_3^1 + \{\chi, H_0\} = 0$, one is led to the choice

$$\chi_{j_1 j_2 j_3 j_4} := \frac{-P_{j_1 j_2 j_3 j_4}}{\mathrm{i}\left(\omega \cdot (j_1 - j_2) + \Omega \cdot (j_3 - j_4)\right)}, \quad j_1 - j_2 + j_3 - j_4 \neq 0, \tag{62}$$

and zero otherwise.

Since $|j_1| + |j_2| + |j_3| + |j_4| = 3$, then $0 < |j_1 - j_2| + |j_3 - j_4| \leq 5$ and so, due to assumption (NR) (recall also $|j_3| + |j_4| \leq 2$), the denominators appearing in (62) are all different from zero. Moreover, due to the growth of the frequencies ω_j (assumption (A)), they are actually bounded away from zero. Then in order to conclude the proof (at least for what concerns the elimination of the third order part) one has to ensure that the function χ is well defined and that it has a smooth Hamiltonian vector field. The terms of χ of different degree in $\hat{z}$ have to be treated in a different way, so we will denote by χ_0, χ_1, χ_2 the homogeneous parts of degree 0, 1, and 2, respectively, with respect to the variables $\hat{z}$.

We need a few lemmas.

LEMMA 5.1. *Let $\mathbf{R}^n \ni x \mapsto f(x) \in \ell^2$ be a homogeneous bounded polynomial of degree r. Write*

$$f(x) = \sum_{j\in\mathbf{N}^n,|j|=r} \sum_{k\geq 1} f_{jk} x^j e_k,$$

where e_k is the standard basis of ℓ^2. Let $\{\rho_{j,k}\}_{j\in\mathbf{N}^n}^{k\geq 1}$ be a sequence with the property $|\rho_{jk}| \geq C$, and define a function g by

$$g(x) = \sum_{j\in\mathbf{N}^n,|j|=r} \sum_{k\geq 1} \frac{f_{jk}}{\rho_{jk}} x^j e_k. \tag{63}$$

Then there exists $\overline{C}$ such that $\|g(x)\| \leq \overline{C}\|x\|^r$.

Proof. Write $g(x) = \sum_j g_j x^j$ and remark that the cardinality of the set over which the sum is carried out is finite. We estimate each of the vectors g_j's. Therefore, one has

$$\|g_j\|^2 = \sum_k \left(\frac{f_{kj}}{\rho_{kj}}\right)^2 \leq \frac{1}{C^2} \sum_k f_{kj}^2 = \frac{1}{C_0^2}\|f_j\|^2.$$

Now the norms of the vectors f_j are bounded, and therefore the thesis follows. ∎

Remark 5.1. By the same proof, the same result holds if the space ℓ^2 is substituted by the spaces $\mathcal{H}^{a,s}$.

LEMMA 5.2. *Let $\mathbf{R}^n \times \ell^2 \ni (x,z) \mapsto f(x,z) \in \mathbf{R}$ be a homogeneous bounded polynomial of degree r in x, linear and bounded in z. Write*

$$f(x,z) = \sum_{\substack{k\geq 1\\ j\in\mathbf{N}^n,|j|=r}} f_{jk} x^j z_k.$$

Let$\{\rho_{j,k}\}_{j\in\mathbf{N}^n}^{k\geq 1}$ be as above, and define a function g by

$$g(x,z) = \sum_{\substack{k\geq 1\\ j\in\mathbf{N}^n,|j|=r}} \frac{f_{jk}}{\rho_{jk}} x^j z_k. \tag{64}$$

Then there exists C such that $|g(x,z)| \leq C\|x\|^r\|z\|$.

Proof. Just write $g(x,z) = \sum_j g_j(z) x^j$. Fix j and study the linear functional $g_j(z)$; one has

$$|g_j(z)| = \left|\sum_{k\geq 1} f_{jk} \frac{z_k}{\rho_{jk}}\right| \leq \|f_j\| \left\|\frac{z}{\rho}\right\|,$$

where f_j is defined in analogy to g_j, its norm is the norm as a linear functional, and z/ρ is the vector of ℓ^2 with kth component equal to z_k/ρ_{jk}. From this inequality, summing over j, the thesis follows. ∎

In order to estimate the vector field of χ_2 we will need the following lemma.

LEMMA 5.3. [Lemma A. 1 of [18]]. *If $A = (A_{kl})$ is a bounded linear operator on ℓ^2, then also $B = (B_{kl})$ with*

$$B_{kl} := \frac{|A_{kl}|}{1 + |k - l|} \tag{65}$$

is a bounded linear operator on ℓ^2.

For the proof we refer to [18].

LEMMA 5.4. *Let $\mathbf{R}^n \times \ell^2 \ni (x, z) \mapsto f(x, z) \in \ell^2$ be a homogeneous bounded polynomial of degree r in x linear and bounded in z. Write*

$$f(x, z) = \sum_{\substack{k,l \geq 1 \\ j \in \mathbf{N}^n, |j| = r}} f_{jkl} x^j z_k e_l.$$

Let $\{\rho_{j,k,l}\}_{j \in \mathbf{N}^n}^{k,l \geq 1}$ be a sequence fulfilling,

$$|\rho_{jkl}| \geq C_1 (1 + |k - l|) \tag{66}$$

and define a function g by

$$g(x, z) = \sum_{\substack{k,l \geq 1 \\ j \in \mathbf{N}^n, |j| = r}} \frac{f_{jkl}}{\rho_{jkl}} x^j z_k. \tag{67}$$

Then there exists C such that $\|g(x, z)\| \leq C \|x\|^r \|z\|$.

Proof. Write $g(x, z) = \sum_j g_j(z) x^j$. Fix j and apply Lemma 5.3 to such operators, obtaining the result. □

Remark 5.2. An identical statement holds for functions from $\mathbf{R} \times \mathcal{H}_{a,s}$ to $\mathcal{H}_{a,s+d}$. To obtain the proof just remark that the boundedness of a linear operator $B = (B_{kl})$ (g_j in the proof) as an operator from $\mathcal{H}^{a,s}$ to $\mathcal{H}^{a,s+d}$ is equivalent to the boundedness of $\widetilde{B} := (v_k B_{kl} s_l)$ as an operator from ℓ^2 to itself, where v_k, s_l are suitable weights.

With the above lemmas at hand it easy to estimate the vector field of χ. We treat explicitly only χ_1.

LEMMA 5.5. *Let χ_1 be the component linear in $\hat{z}$ and $\overline{\hat{z}}$ of the function χ defined by* (62)*. Then there exists a constant C such that its vector field is bounded by*

$$\|X_{\chi_1}(z, \overline{z})\|_{a,s+d} \leq C \|z\|_{a,s}^2.$$

Proof. Write χ_1 as follows:

$$\chi_1(x, \overline{x}, \hat{z}, \overline{\hat{z}}) = \langle \chi_{01}(x, \overline{x}); \hat{z} \rangle_{\ell^2} + \left\langle \chi_{10}(x, \overline{x}); \overline{\hat{z}} \right\rangle_{\ell^2}.$$

Consider the first term. Separating the $x, \overline{x}$, and $\overline{\hat{z}}$ components, its vector field is given by

$$\left(\mathrm{i} \left\langle \frac{\partial \chi_{01}}{\partial \overline{x}}; \hat{z} \right\rangle_{\ell^2}, -\mathrm{i} \left\langle \frac{\partial \chi_{01}}{\partial x}; \hat{z} \right\rangle_{\ell^2}, -\mathrm{i} \chi_{01}(x, \overline{x}) \right).$$

Explicitly χ_{01} is given by

$$\sum_{\substack{|j_1| + |j_2| = 2 \\ l \geq n+1}} \frac{-P_{j_1 j_2 e_l}}{\mathrm{i}(\omega \cdot (j_1 - j_2) + \Omega_l)} x^{j_1} \overline{x}^{j_2} e_l.$$

It follows that each of the x (and $\overline{x}$) components of the vector field has the structure considered in Lemma 5.2, which therefore gives the estimate of such part of the vector field. Concerning the $\overline{\hat{z}}$ component, Lemma 5.1 applies and gives the result. The remaining components can be treated exactly in the same way. ∎

The estimate of the vector fields of χ_0 and χ_2 are obtained in a similar way. In order to apply Lemma 5.4 to the estimate of the vector field of χ_2 one has just to remark that from (A) and (NR) one has the estimate

$$|\omega \cdot k + \Omega_j - \Omega_l| \geq C(1 + |j - l|).$$

Thus we have the following proposition.

PROPOSITION 5.6. *The vector field of the function* χ *defined by* (62) *fulfills the inequality*

$$\|X_\chi(z, \overline{z})\|_{a,s+d} \leq C\|z\|^2_{a,s}.$$

Then by standard existence and uniqueness theory one has that such vector fields define a unique smooth time 1 flow in a neighborhood of the origin both in $\mathcal{P}_{a,s}$ and in $\mathcal{P}_{a,s+d}$. It follows that the transformation is well defined. Transforming the vector field of H, one gets a vector field having the same smoothness properties of the original one. Moreover the transformed Hamiltonian will have the form

$$\widetilde{H} := H \circ \Phi^1 = H_0 + \hat{G}_3 + \widetilde{P}_4 + \widetilde{P}_5 + \cdots, \tag{68}$$

where $\widetilde{P}_j$ is a homogeneous polynomial of degree j. In particular it turns out that

$$\widetilde{P}_4 = P_4 + \{\chi, P_3^1\} + \frac{1}{2}\{\chi, \{\chi, H_0\}\} = P_4 + \frac{1}{2}\{\chi, P_3^1\} + \left\{\chi, \hat{G}_3\right\}$$

since $P_3 = P_3^1 + \hat{G}_3$ and, by the definition of χ, $P_3^1 + \{\chi, H_0\} = 0$.

Thus one can iterate the construction and eliminate the unwanted terms of degree 4. Define $\widetilde{P}_4^1$ (in analogy to P_3^1), setting $\widetilde{P}_4 = \widetilde{P}_4^1 + \hat{G}_4(z)$, where $\hat{G}_4(z) = O(\|\hat{z}\|^3)$ and $\widetilde{P}_4^1$ is composed of the first three terms of the Taylor expansion of $\widetilde{P}_4$ in the variables $\hat{z}$ only. Next we perform a new canonical transformation which is the time 1 flow of another auxiliary Hamiltonian $\widetilde{\chi}$ of degree 4, such that $\widetilde{P}_4^1 + \{\widetilde{\chi}, H_0\}$ is a function of the actions $|z_j|^2$ only. Remark that in this case a nonvanishing normalized part of the Hamiltonian exists (in general) since $\omega \cdot (j_1 - j_2) + \Omega \cdot (j_3 - j_4) = 0 \ \forall \ j_1 = j_2$, $j_3 = j_4$, $|j_1| + |j_2| + |j_3| + |j_4| = 4$. Since, by (NR), $\omega \cdot (j_1 - j_2) + \Omega \cdot (j_3 - j_4) \neq 0$ for all the remaining $|j_1| + |j_2| + |j_3| + |j_4| = 4$, $|j_3| + |j_4| \leq 2$, the normalized part $\overline{G}_4$ is explicitly given by

$$\overline{G}_4 := \sum_{|j_1|+|j_3|=2, |j_3|\leq 1} \widetilde{P}^1_{j_1 j_1 j_3 j_3} |x|^{2j_1} |\hat{z}|^{2j_3}, \tag{69}$$

where $\widetilde{P}^1_{j_1 j_2 j_3 j_4}$ are the coefficients of $\widetilde{P}_4^1$ and $|x|^2 := x\overline{x}$, $|\hat{z}|^2 := \hat{z}\overline{\hat{z}}$. $\overline{G}_4$ is the function $\overline{G}$ introduced in (7). The regularity and estimates for the canonical transformation generated by $\widetilde{\chi}$ are obtained as before.

Finally, using again (NR), one iterates the construction with an auxiliary Hamiltonian of degree 5, eliminating all the terms of order 5 and concluding the proof of Proposition 2.1 (getting no further contributions to the function $\overline{G}$ which is of order 4).

Remark 5.3. If the Hamiltonian contains only monomials of even degree then the terms of order 3 and 5 are not present in the Hamiltonian. Thus by just *one* symplectic change of coordinates it is possible to eliminate the nonnormalized terms of order 4, and the remaining higher order terms are yet of order 6.

Proof of Proposition 4.2. The proof follows Lemma 4 of [15] (and Proposition 2.1).

The Hamiltonian function H contains only monomials of even degree, and the 4th order term of the nonlinearity is given explicitly by (54). Therefore, let us define the auxiliary Hamiltonian χ of degree 4,

$$\chi := \sum_{i_1 \pm i_2 \pm i_3 \pm i_4 = 0, \{i_1, i_2\} \neq \{i_3, i_4\}} \frac{-aF_{i_1 i_2 i_3 i_4}}{\mathrm{i}(i_1^2 - i_2^2 + i_3^2 - i_4^2)} z_{i_1} z_{i_2} \overline{z}_{i_3} \overline{z}_{i_4}.$$

By Lemma 5 of [15], if $i_1 \pm i_2 \pm i_3 \pm i_4 = 0$ and the nonordered pair $\{i_1, i_2\} \neq \{i_3, i_4\}$, then $i_1^2 - i_2^2 + i_3^2 - i_4^2 \neq 0$, and so χ is well defined.

The fourth order term of the transformed Hamiltonian via the time 1 flow map generated by χ is given by

$$\begin{aligned} P_4 + \{\chi, H_0\} &= \sum_{i_1 \pm i_2 \pm i_3 \pm i_4 = 0} \Big(aF_{i_1 i_2 i_3 i_4} - \mathrm{i}(i_1^2 - i_2^2 + i_3^2 - i_4^2) \chi_{i_1 i_2 i_3 i_4} \Big) \\ &= \sum_{\{i_1, i_2\} = \{i_3, i_4\}} aF_{i_1 i_2 i_3 i_4} z_{i_1} z_{i_2} \overline{z}_{i_3} \overline{z}_{i_4} \\ &= \frac{\alpha}{2} \sum_{i,j \geq 1} \rho_i^2 \rho_j^2 (4 - \delta_{ij}) |z_i|^2 |z_j|^2 := \overline{G} \end{aligned}$$

recalling (55) and since $F_{ijij} = a\rho_i^2 \rho_j^2 \int_0^\pi \sin^2(ix) \sin^2(jx) dx = (8a/\pi) \rho_i^2 \rho_j^2 (2 + \delta_{ij})$.

The estimates for the vector field generated by χ and the corresponding time 1 flow map can be carried out as in Proposition 2.1.

Finally, note that the remaining terms, which constitute the higher order term K, are yet of order 6 or more (see Remark 5.3).

Acknowledgments. The authors thank L. Biasco, P. Bolle, and M. Procesi for interesting discussions.

SCALAR CONSERVATION LAWS WITH MIXED LOCAL AND NONLOCAL DIFFUSION-DISPERSION TERMS*

CHRISTIAN ROHDE†

Abstract. We consider a nonlinear scalar conservation law that is regularized by a local viscous term and a *nonlocal* dispersive term. This nonstandard regularization is motivated by phase transition problems that take into account long range interactions close to the interface.

We identify a parameter regime such that this mixed-type regularization provides a new example that is able to drive *nonclassical undercompressive shock waves* in the limit of vanishing regularization parameter. In view of the applications this shows that nonlocal regularizations can be used to model dynamical phase transition processes.

In the next step we establish the existence and uniqueness of classical solutions for the Cauchy problem in multiple space dimensions. In the main part of the paper we then deduce appropriate a priori estimates to analyze the sharp-interface limit for vanishing regularization parameter with the method of compensated compactness in one space dimension and, using measure-valued solutions, in multiple space dimensions. It is shown that the limits exist and are weak solutions of the corresponding Cauchy problem for the hyperbolic conservation law.

Key words. nonlocal free energy, diffusion-dispersion, sharp-interface limit, undercompressive shock waves

DOI. 10.1137/S0036141004443300

1. Introduction.

In this paper we are concerned with weak solutions of the Cauchy problem for the scalar conservation law

$$u_t(\mathbf{x},t) + \operatorname{div}(\mathbf{f}(u(\mathbf{x},t))) = 0 \quad ((\mathbf{x},t) \in \mathbb{R}^d \times \mathbb{R}_{>0},\ d \in \mathbb{N}). \tag{1.1}$$

The unknown function $u : \mathbb{R}^d \times \mathbb{R}_{>0} \to \mathbb{R}$ is a function of the d-dimensional space variable $\mathbf{x} = (x_1, \dots, x_d)^T$ and time $t > 0$. By $\mathbf{f} = (f_1, \dots, f_d)^T : \mathbb{R} \to \mathbb{R}^d$ we denote the vector of flux functions. It is well known that the Cauchy problem for equations of type (1.1) cannot have global smooth solutions for arbitrary initial datum. Prototype discontinuous solutions that satisfy the Cauchy problem in a weak sense are planar shock waves. Let us consider for simplicity the one-dimensional case $d = 1$ with a scalar flux function. If we choose the flux function as a convex function the only physically relevant type of shock waves are so-called Laxian (or classical) shock waves. If the flux function is not assumed to be convex also a *nonclassical type of shock wave* can arise: the undercompressive shock wave. While a Laxian shock wave on the level of (1.1) is completely compressive, i.e., the characteristics run into the discontinuity, for an undercompressive shock only one of the characteristics crosses the shock line. In recent years many important examples of problems have been identified that involve undercompressive shock waves: combustion fronts, precursors in thin film flow, kinematic waves in suspensions, and, most notably for this paper, phase transitions. In applications, the conservation law (1.1) is equipped with dissipative terms that lead to a regularization of the weak solutions of (1.1). Let us denote the

†Albert-Ludwigs-Universität Freiburg, Institut für Mathematik, Hermann-Herder Str. 10, D-79104 Freiburg, Germany (chris@mathematik.uni-freiburg.de).

regularized problem by

$$u_t^\varepsilon(\mathbf{x},t) + \operatorname{div}(\mathbf{f}(u^\varepsilon(\mathbf{x},t))) = R[\varepsilon; u^\varepsilon](\mathbf{x},t) \quad ((\mathbf{x},t) \in \mathbb{R}^d \times \mathbb{R}_{>0}), \tag{1.2}$$

where $\varepsilon > 0$ is a small regularization parameter.

It is an interesting question to identify physically relevant spatial regularization operators R such that

(i) the Cauchy problem for (1.2) has a global smooth solution u^ε in $\mathbb{R}^d \times \mathbb{R}_{>0}$,

(ii) the sequence $\{u^\varepsilon\}_{\varepsilon>0}$ converges for $\varepsilon \to 0$ almost everywhere to a limit function $u \in L^1_{loc}(\mathbb{R}^d \times \mathbb{R}_{>0})$ which is a weak solution of (1.1),

(iii) the function u contains undercompressive shock waves with reasonable physical interpretation.

For $w \in C^2(\mathbb{R}^d)$ consider the simplest possible local dissipation term

$$R[\varepsilon; w](\mathbf{x}) := \varepsilon \Delta w(\mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^d.$$

The fundamental work of Kruzkov shows that tasks (i) and (ii) hold true for this choice of R ([24]). However, the regularization does rule out undercompressive shocks in the limit $\varepsilon \to 0$ which are known to contradict the Kruzkov entropy condition. Another picture results if one takes into account local diffusion and dispersion. For $w \in C^3(\mathbb{R}^d)$ and $\gamma > 0$ let

$$R[\varepsilon; w](\mathbf{x}) := \varepsilon \Delta w(\mathbf{x}) + \gamma \varepsilon^2 \sum_{j=1}^{d} \Delta w_{x_j}(\mathbf{x}), \quad \mathbf{x} \in \mathbb{R}^d. \tag{1.3}$$

This regularization is motivated from phase transition problems like, e.g., the dynamics of liquid-vapor transitions governed by the Navier–Stokes–Korteweg equations ([5, 18, 2, 11, 17, 34, 14]). There the physical density ρ^ε takes the rôle of u^ε. While the second order term in (1.3) stands for effects of viscosity, the third order term models the effects of surface tension forces close to the phase boundary. It can be directly referred to the free energy functional

$$E^\varepsilon_{local}[\rho^\varepsilon] = \int_{\mathbb{R}^d} W(\rho^\varepsilon(\mathbf{x})) + \gamma \varepsilon^2 \frac{|\nabla \rho^\varepsilon(\mathbf{x})|^2}{2} \, d\mathbf{x}. \tag{1.4}$$

Here W is the free energy function having double well structure. Minima of E_{local} describe static equilibrium solutions.

On the level of the model problem (1.2) with R from (1.3) it has been shown that undercompressive shock waves can occur in the limit of vanishing regularization. We refer to the papers [4, 19, 28, 22, 21, 32, 20, 23] and moreover to the monograph [27]. A special feature is that the limit depends on the number γ describing the ratio between diffusion and dispersion: shock waves are regularization-sensitive. The occurrence of undercompressive shocks has also been analyzed for local nonlinear and fourth order regularizations ([7]).

If one looks to the derivation of the free energy functional E^ε_{local} one observes that it is a simplification (see even the first paper on diffuse interface theories by Van der Waals: [36]). On a more basic level one has to consider the nonlocal energy

$$E^\varepsilon_{global}[\rho^\varepsilon] = \int_{\mathbb{R}^d} W(\rho^\varepsilon(\mathbf{x})) + \frac{\gamma}{4} \int_{\mathbb{R}^d} \phi_\varepsilon(\mathbf{x}-\mathbf{y})(\rho^\varepsilon(\mathbf{x}) - \rho^\varepsilon(\mathbf{y}))^2 \, d\mathbf{y} d\mathbf{x}. \tag{1.5}$$

For background on nonlocal energies in the framework of phase transition problems, we refer to [25, 1, 15, 30, 31] and references therein. To pass to dynamical models usually the action principle is used. This approach can be performed for local and nonlocal energies. In the first case for E_{local} equation (1.2) with choice (1.3) would be the most basic model problem. In the nonlocal case it means that we have to choose for $w \in C^2(\mathbb{R}^d)$

$$R[\varepsilon; w](\mathbf{x}) := \varepsilon \Delta w(\mathbf{x}) + \gamma \sum_{j=1}^{d} \left[[\phi_\varepsilon * w_{x_j}](\mathbf{x}) - w_{x_j}(\mathbf{x}) \right], \quad \mathbf{x} \in \mathbb{R}^d. \tag{1.6}$$

Here we have used for an arbitrary function $v \in L^1_{loc}(\mathbb{R}^d, \mathbb{R})$ the convolution $\phi_\varepsilon * v$ given by

$$[\phi_\varepsilon * v](\mathbf{x}) = \int_{\mathbb{R}^d} \phi_\varepsilon(\mathbf{x} - \mathbf{y}) v(\mathbf{y})\, d\mathbf{y}.$$

The kernel function ϕ_ε is defined by

$$\phi_\varepsilon(\mathbf{x}) = \frac{1}{\varepsilon^d} \phi\left(\frac{\mathbf{x}}{\varepsilon}\right). \tag{1.7}$$

ϕ is a smooth even nonnegative function with $\operatorname{supp}(\phi) \subset [-1, 1]^d$. Moreover let $\int_{\mathbb{R}^d} \phi(\mathbf{x})\, d\mathbf{x} = 1$. The kernel function ϕ_ε models the long-range interaction.

To show that (1.3) is in fact a simplification of (1.6), assume for simplicity $d = 1$ and that w is a sufficiently smooth function. By Taylor expansion of w around $x = x_1$ we obtain

$$[\phi_\varepsilon * w](x) - w(x) = \frac{1}{\varepsilon} \int_{\mathbb{R}} \phi\left(\frac{x - y}{\varepsilon}\right) (w(y) - w(x))\, dy = \sum_{i=1}^{\infty} c_{2i} \varepsilon^{2i} w^{(2i)}(x),$$

where $c_{2i} = \int_{\mathbb{R}} y^{2i} \phi(y)\, dy/(2i)!$. Neglecting the terms with $i > 1$ we obtain the third order derivative in (1.3) with $d = 1$.

In this paper we start the analysis of the three issues (i), (ii), (iii) for the new regularization (1.6). First we focus on planar wave solutions for (1.2), (1.6) in section 2. We show in particular that as the local model (1.2), (1.3) also the nonlocal model admits traveling wave solutions which correspond to undercompressive shock waves. Nonlocal dispersion is strong enough to drive these nonclassical shocks. Physically speaking the model is able to permit phase transitions. We observe also a striking sensitive dependence on the ratio parameter γ as in the local case.

In section 3 we establish the existence and uniqueness of smooth solutions for the Cauchy problem to (1.2), (1.6) in multiple space dimensions. Essentially we state that the L^2-norm is a Lyapunov functional for the flow associated with the evolution equation (1.2). Furthermore we remark that the existence is achieved using techniques for second order parabolic problems and not (as would be necessary in the case of the local regularization (1.3)) with the much more complicated techniques for third order equations. The main result is given in Theorem 3.2.

Finally in section 4 we study the limit $\varepsilon \to 0$ for general Cauchy problems. For the spatially one-dimensional case it turns out that one can obtain a priori estimates with respect to the L^2- and L^4-norm that are uniform in the parameter ε. These two estimates have also been identified in the local case. The dissipation estimates on spatial derivatives which come along with the estimates on the solution itself are

not as strong as in the local case. However, the obtained uniform bounds are strong enough to apply the method of compensated compactness. We show in the proof of Theorem 4.5 that the limit process can be performed in a (strong) L^p-norm and the limit function is moreover a weak solution of (1.1). We conclude with a study of the limit in the multidimensional case in section 5 based on measure-valued solutions.
In all sections we compare the results and used techniques with those for the local model (1.2), (1.3).

2. Traveling-wave analysis for the scalar model problem. In this section we seek special solutions u^ε of (1.2) with regularization given by (1.6): planar waves. It suffices to consider the one-dimensional version with $f := f_1 \in C^2(\mathbb{R})$ and $x := x_1$:

$$u_t^\varepsilon + f(u^\varepsilon)_x = \alpha\varepsilon u_{xx}^\varepsilon + \big[\phi_\varepsilon * u^\varepsilon - u^\varepsilon\big]_x \quad \text{in } \mathbb{R}\times(0,\infty). \tag{2.1}$$

The kernel ϕ_ε is defined as in (1.7) with $d = 1$. Note that we have introduced the factor $\alpha \geq 0$ in (2.1) while γ from (1.6) has been set to be 1. Shifting the weight for the ratio between local diffusion and nonlocal dispersion to the diffusion term turns out to be more convenient in this section. To include the purely dispersive case we allow $\alpha = 0$.

2.1. Shock waves for the limit problem. We start the investigations with a review on different types of shock wave solutions for the limit problem which we obtain by neglecting the terms on the right-hand side of (2.1):

$$u_t + f(u)_x = 0 \quad \text{in } \mathbb{R}\times(0,\infty). \tag{2.2}$$

Let some states $u_- \in \mathbb{R}$ and $u_+ \in \mathbb{R}$ with $u_- \neq u_+$ be given and define the speed $s \in \mathbb{R}$ by the ratio

$$s = \frac{f(u_-) - f(u_+)}{u_- - u_+}. \tag{2.3}$$

Then the discontinuous function $U : \mathbb{R}\times(0,\infty) \to \mathbb{R}$ given by

$$U(x,t) := \begin{cases} u_- : x - st \leq 0 \\ u_+ : x - st > 0, \end{cases} \tag{2.4}$$

is a weak solution of (2.2). We call it a **shock wave** provided $f'(u_\pm) \neq s$. If the states u_- and u_+ satisfy the condition

$$f'(u_-) > s > f'(u_+), \tag{2.5}$$

the function U is called a **compressive (or Laxian) shock wave**. If either

$$s < f'(u_-),\ s < f'(u_+) \text{ or } s > f'(u_-),\ s > f'(u_+) \tag{2.6}$$

holds the associated shock wave U is called **undercompressive**. An entropy solution of (2.2) is a function $u \in L^\infty_{loc}(\mathbb{R}\times(0,\infty))$ such that the entropy inequality

$$\int_0^T \int_{\mathbb{R}} \eta(u(x,t))\psi_t(x,t) + q(u(x,t))\psi_x(x,t)\,dxdt \geq 0 \tag{2.7}$$

holds for all entropy pairs (η, q) and all $\psi \in C_0^\infty(\mathbb{R}\times(0,\infty))$. Here an entropy pair (η, q) consists of the entropy function $\eta \in C^2(\mathbb{R})$, supposed to satisfy $\eta'' \geq 0$, and the entropy flux $q \in C^2(\mathbb{R})$, supposed to satisfy $\eta' f' = q'$. We remark that the discontinuous solution U is an entropy solution if and only if the inequality

$$D_{(\eta,q)}(u_-, u_+) := -s(\eta(u_+) - \eta(u_-)) + q(u_+) - q(u_-) \leq 0 \tag{2.8}$$

is satisfied for all entropy pairs. It is well known that for convex fluxes a shock wave is an entropy solution of (2.2) if and only if it is compressive ([8]). However, the condition (2.7) is quite restrictive since in the systems case often only one entropy pair is available.

Let us now consider (2.2) for the nonconvex cubic flux $f(u) = u^3$ and choose—for simplicity—the state $u_- \in (0, \infty)$ as an arbitrary but fixed number. Then we get from (2.3) the equation

$$s = u_-^2 + u_- u_+ + u_+^2. \tag{2.9}$$

Conditions (2.5) and (2.7) are satisfied for $u_+ \in (-u_-/2, u_-)$. We neglect the characteristic case $u_+ = u_-/2$ which does not correspond to a shock wave in the sense of a strict inequality as required in (2.5) or (2.6). For $u_+ \in (-\infty, -u_-/2)$, we observe that only one of the characteristics runs into the propagating shock wave. The first case in (2.6) applies and the associated shock wave U is undercompressive. Straightforward calculations reveal the following statements.

(i) Let u_+ be in $(-u_-, -u_-/2)$. For the entropy pair $(\eta(u), q(u)) = (u^2/2, 3u^4/4)$ we have

$$D_{(\eta,q)}(u_-, u_+) = \frac{1}{4}(u_+ - u_-)^2(u_+^2 - u_-^2) < 0.$$

(ii) Let u_+ be in $(-u_-, -\tau u_-)$ for $\tau \in (1/2, 1)$ and let $l \in \mathbb{N} \setminus \{2\}$ be even. For the entropy pair

$$(\eta_l(u), q_l(u)) = \begin{cases} (u^l/l, 3u^{l+2}/(l+2)) : u < 0, \\ \qquad (0, 0) \qquad\qquad : u \geq 0, \end{cases}$$

we have

$$\begin{aligned} D_{(\eta_l,q_l)}(u_-, u_+) &= \eta_l(u_+)\Big(2\frac{l-1}{l+2}u_+^2 - u_- u_+ - u_-^2\Big) \\ &> 2\eta_l(u_+)u_-^2\Big(\frac{l-1}{l+2}\tau^2 + \frac{1}{2}\tau - \frac{1}{2}\Big). \end{aligned}$$

Thus for each $\tau \in (1/2, 1)$ there is an $l_0 \in \mathbb{N}$ such that for $l > l_0$ we have

$$D_{(\eta_l,q_l)}(u_-, u_+) > 0.$$

(iii) Let u_+ with $u_+ < -u_-$ be given. For the entropy pair from (i) we have

$$D_{(\eta,q)}(u_-, u_+) > 0. \tag{2.10}$$

Thus U is for $u_+ < -u_-/2$ not an entropy solution anymore, but if u_+ is not too small, i.e., not less or equal than $-u_-$, an entropy inequality holds for the entropy pair with quadratic entropy. Exactly this entropy is important for our regularized problem (cf. Theorem 3.2 and estimate (3.5) below).

These considerations can be done for any nonconvex flux function. For a more extensive study we refer to [26]. The possible occurrence of undercompressive shock waves is the reason why (1.1) can be seen as a simple model for phase transitions. Note that phase transitions in realistic models can take the form of undercompressive waves (cf. [17] for instance).

2.2. Nonlocal diffusion-dispersion profiles. Let $u_-, u_+ \in \mathbb{R}$, compute s through (2.3), and define the shock wave U by (2.4). The function $v \in C^2(\mathbb{R})$ is called a **nonlocal diffusion-dispersion profile for the shock wave** U if it solves

(2.11)
$$\begin{aligned} \alpha\dot{v}(\xi) + ([\phi * v](\xi) - v(\xi)) &= f(v(\xi)) - sv(\xi) - (f(u_-) - su_-) \quad (\xi \in \mathbb{R}), \\ v(\pm\infty) &= u_\pm. \end{aligned}$$

If there is a nonlocal diffusion-dispersion profile for some shock wave U we can define the traveling-wave function $u^\varepsilon \in C^2(\mathbb{R} \times (0,\infty))$ through

$$u^\varepsilon(x,t) = v\left(\frac{x - st}{\varepsilon}\right) \quad ((x,t) \in \mathbb{R} \times \mathbb{R}_{>0}). \tag{2.12}$$

We see that u^ε is a classical solution of (2.1). Moreover we have for $(x,t) \in \mathbb{R} \times (0,\infty)$ with $x - st \neq 0$

$$\lim_{\varepsilon \to 0} u^\varepsilon(x,t) = U(x,t) = \begin{cases} u_- : x - st < 0, \\ u_+ : x - st > 0. \end{cases} \tag{2.13}$$

It is the issue of this section to show that for our nonlocal equation there are traveling waves such that the weak solution U represents an undercompressive shock wave.

NOTE 2.1. *The problem* (2.11) *itself does not depend on ε. This is a consequence of the scaling with respect to ε between the local diffusive and nonlocal dispersive term. For other scalings, e.g. $\gamma = \gamma(\varepsilon)$, the problem* (2.11) *can depend on ε. We shall see below that the chosen scaling leads to nonlocal diffusion-dispersion profiles for shock waves that are undercompressive shock waves. We conjecture that all other scalings lead to either classical behavior excluding undercompressive waves or purely dispersive behavior without any distinguished wave structure.*

The problem (2.11) belongs to the class of ordinary but nonlocal boundary value problems. These kinds of problems have been studied by [3, 12, 9], for instance. Our analysis relies on the result by Bates et al. ([3]) which we recall now.

THEOREM 2.2. *For $r \in \mathbb{N}$ let the function $\phi \in C^r(\mathbb{R},[0,\infty)) \cap W^{r,1}(\mathbb{R})$ be even and satisfy*

$$\int_{\mathbb{R}} \phi(x)\,dx = 1, \quad \int_{\mathbb{R}} \phi(x)|x|dx < \infty. \tag{2.14}$$

Let $u_-, u_+ \in \mathbb{R}$ and $F \in C^r(\mathbb{R})$ be given. For the unknowns $v : \mathbb{R} \to \mathbb{R}$ and $\alpha \in \mathbb{R}$ consider the problem

$$\begin{aligned} \alpha\dot{v}(\xi) + ([\phi * v](\xi) - v(\xi)) &= F(v(\xi)) \quad (\xi \in \mathbb{R}), \\ v(\pm\infty) &= u_\pm. \end{aligned} \tag{2.15}$$

We suppose that the states $u_\pm \in \mathbb{R}$ and the function F satisfy

$$\begin{aligned} &\text{(i)} \quad u_- > u_+, \\ &\text{(ii)} \quad F(u_\pm) = 0,\ F'(u_\pm) > 0, \\ &\text{(iii)} \quad \exists!\ u_0 \in (u_+, u_-)\ :\ F(u_0) = 0, \\ &\text{(iv)} \quad u \in [u_+, u_-] \Rightarrow F'(u) + 1 > 0. \end{aligned} \tag{2.16}$$

Then exactly one of the following statements holds true.

(a) *There is a monotonely decreasing function* $v \in C^{r+1}(\mathbb{R})$ *and a unique* $\alpha \in \mathbb{R} \setminus \{0\}$ *such that* (2.15) *holds.*
In this case we have

$$\alpha = H(u_-, u_+) \left(\int_{-\infty}^{\infty} (\dot{v}(\xi))^2 \, d\xi \right)^{-1}, \quad H(u_-, u_+) := \int_{u_-}^{u_+} F(u) \, du. \tag{2.17}$$

(b) *There is a monotonely decreasing function* $v \in C^r(\mathbb{R})$ *such that* (2.11) *holds for* $\alpha = 0$.
In this case we have

$$H(u_-, u_+) = 0.$$

In both cases the function v *is unique up to translation.*

Proof. See Theorems 2.7, 3.1, and 4.1 in [3]. ∎

The differential equation in problem (2.15) should be seen as the nonlocal counterpart to

$$\alpha \dot{v}(\xi) + \ddot{v}(\xi) = F(v(\xi)) \quad (\xi \in \mathbb{R}). \tag{2.18}$$

Then it is clear that condition (ii) from Theorem 2.2 ensures that u_- and u_+ are hyperbolic rest points of saddle type. With (iii) we just simplify the problem to exclude having more than the (necessary) three equilibria. The local problem (2.18) is a classical bistable equation for which the existence and bifurcation of traveling waves (local diffusion-dispersion profiles) is completely understood. Condition (iv) is not a necessary condition for the existence of orbits (cf. [3, Theorem 3.1]). However, if it is violated, the relation $H(u_-, u_+)$ in case (b) is substituted by a more complicated relation. Since here we only want to show that the nonlocal regularization is strong enough to drive nonclassical undercompressive waves, we do not pursue this issue. We return to our problem (2.11) and define

$$F = F(v) := f(v) - sv - (f(u_-) - su_-) \tag{2.19}$$

for $v \in \mathbb{R}$. A necessary structural assumption on f to construct undercompressive shock waves is the *nonconvexity* of f as we have seen in section 2.1. We choose again

$$f(u) = u^3. \tag{2.20}$$

Furthermore we require that the states u_-, u_+ satisfy

$$u_- > 0 > -\frac{u_-}{2} > u_+. \tag{2.21}$$

Using (2.9) we see that $s < f'(u_-)$ and $s < f'(u_+)$ holds. Thus the function U defined by (2.4) is an undercompressive shock wave. The choice $u_+ = -u_-/2$ leads to the excluded characteristic case $f'(u_+) = s$. We now prove the existence of a nonlocal diffusion-dispersion profile for U.

PROPOSITION 2.3. *We consider the problem* (2.11) *with cubic flux* (2.20) *and choose* $u_-, u_+ \in \mathbb{R}$ *such that* (2.21) *holds. We suppose that the kernel function* ϕ *is even, in the set* $C^1(\mathbb{R}, [0, \infty)) \cap W^{1,1}(\mathbb{R})$, *and satisfies*

$$\int_{\mathbb{R}} \phi(x) \, dx = 1, \quad \int_{\mathbb{R}} \phi(x)|x| dx < \infty. \tag{2.22}$$

Moreover, if the states u_-, u_+ *fulfill*

$$(u_+ + u_-)^2 - u_- u_+ < 1, \tag{2.23}$$

we have

(i) *for* $u_+ \in (-u_-, -u_-/2)$ *that there is a function* $v \in C^2(\mathbb{R})$ *and a unique* $\alpha > 0$ *solving* (2.11),

(ii) *for* $u_+ = -u_-$ *that there is a function* $v \in C^1(\mathbb{R})$ *solving* (2.11) *with* $\alpha = 0$.

The functions v *are unique up to translation.*

Proof. With the assumptions of the proposition we can apply Theorem 2.2 with $r = 1$. We have to verify the conditions (i),…,(iv) in (2.16). Condition (i) is satisfied due to (2.21). The Rankine–Hugoniot relation (2.3) and (2.9) imply $F(u_\pm) = 0$. For the derivative $F'(v) = 3v^2 - s$ we obtain with the upper bound for u_+ in (2.21) the estimates

$$F'(u_-) = 2u_-^2 - u_- u_+ - u_+^2 > u_-^2 - u_- u_+ > 0,$$
$$F'(u_+) = 2u_+^2 - u_- u_+ - u_-^2 > \tfrac{1}{2}u_-^2 + \tfrac{1}{2}u_-^2 - u_-^2 = 0.$$

Thus condition (ii) in Theorem 2.2 holds. Since F from (2.19) is cubic the condition (iii) is a consequence of $F'(u_\pm) > 0$. The function $F'(u) + 1$ has a minimum in $u_{min} = 0 \in [u_+, u_-]$ with

$$F(u_{min}) = 1 - (u_+ + u_-)^2 + u_- u_+.$$

This is condition (iv) due to (2.23).

We can apply the theorem and compute in our case for H defined in (2.17) the value

$$\begin{aligned} H(u_-, u_+) &= \int_{u_-}^{u_+} u^3 - su - (u_-^3 - su_-)\, du \\ &= -\frac{1}{4}\big(u_+^4 - 2u_+^3 u_- + 2u_+ u_-^3 - u_-^4\big) \\ &= -\frac{1}{4}(u_+ + u_-)(u_+ - u_-)^3. \end{aligned}$$

For fixed u_- the function $H(u_-, .)$ vanishes in $u_+ = -u_-$ and is positive in $(-u_-, -u_-/2)$. This implies the two statements of the proposition since exactly one of the two cases (a), (b) in Theorem 2.2 must hold true. ∎

Some remarks are in order.

NOTE 2.4.

(i) *The condition* (2.23) *can be satisfied for sufficiently small values of* u_-. *It holds for instance in the case* $u_- = 1$. *Together with the discussion in section* 2.1 *on undercompressivity we have shown that nonlocal dispersive terms can drive nonclassical shock waves of this type. We stress that condition* (2.23) *is used to verify* (iv) *in Theorem* 2.2 *which is not a necessary assumption for the existence of solutions.*

(ii) *Using the local term* (1.3) *in* (1.2) *leads to the study of* (2.18) *for traveling waves. As long as condition* (2.23) *holds we get exactly the same result on the existence of nonlocal diffusion-dispersion profile as in the case of the local dispersion term. Moreover the coefficient* α *for given* u_- *and* u_+ *is the same in the local and nonlocal case. We refer to* [21, 19]. *In the nonlocal case the results do not rely on the form of the kernel* ϕ_ε *as long as the assumptions in* (2.14) *are satisfied. This freedom in modelling is not present for the local regularization.*

(iii) *According to Proposition* 2.3 *the case* $u_+ = -u_-$ *can be solved only with* $\alpha = 0$ *(or equivalently* $\gamma = \infty$*) . This is of no interest to us since we want to have a positive parameter in front of the diffusion term in the original regularization* (1.6)*. However, it is interesting to see that this situation is detected by the analysis. The choice* $u_+ = -u_-$ *in the definition of the shock wave* U *is the extreme nonclassical one. If one takes* u_+ *strictly less than* $-u_-$ *the entropy condition* (2.7) *does not hold for the quadratic entropy function (cf.* (2.10)*). The overall importance of this entropy becomes clear in sections* 3, 4, *and* 5*. It is a Lyapunov functional for solutions* $u^\varepsilon(.,t)$ *of the Cauchy problem to* (1.2) *with* (1.6)*.*

(iv) *Theorem* 2.2 *is applied in* [3] *to a Ginzburg–Landau-type problem. However, the meaning of the parameter* α *is completely different. While here it is the diffusion parameter it plays the rôle of the traveling-wave speed in* [3]*. In our case the wave speed parameter is given a priori by* (2.3)*.*

3. Existence of classical solutions for the scalar model problem. In this section we consider (1.2) for the regularization (1.6), that is,

$$u_t^\varepsilon + \operatorname{div}(\mathbf{f}(u^\varepsilon)) = \varepsilon\Delta u^\varepsilon + \gamma\sum_{j=1}^{d}\left[\phi_\varepsilon * u_{x_j}^\varepsilon - u_{x_j}^\varepsilon\right] \quad \text{in } \mathbb{R}^d \times (0,T), \tag{3.1}$$

with initial condition

$$u^\varepsilon(.,0) = u_0 \text{ in } \mathbb{R}^d. \tag{3.2}$$

The time $T > 0$ is an arbitrary but fixed number and we recall the definition of ϕ_ε from (1.7). Under appropriate conditions on the initial function u_0, the flux $\mathbf{f}$, and the function ϕ specified below, we prove the existence of classical solutions for the Cauchy problem (3.1), (3.2).

3.1. Some notations and assumptions. For a multi-index $\alpha = (\alpha_1, \dots, \alpha_d)^T \in \mathbb{N}_0^d$, we define the differential operator

$$D^\alpha := \frac{\partial^{\alpha_1 + \cdots \alpha_d}}{\partial_{x_1}^{\alpha_1}\cdots\partial_{x_d}^{\alpha_d}}.$$

For the partial derivative with respect to the space coordinate x_j, $j = 1, \dots, d$, we also use the symbol ∂_{x_j}. The open set Ω_R, $R \in [0,T]$ is defined by $\Omega_R = \mathbb{R}^d \times (0,R)$. The following assumption on the flux functions and the function ϕ hold throughout the following two sections on the scalar model problem if nothing else is stated explicitly.

ASSUMPTION 3.1.

(i) *There is a number* $k > d/2 + 1$ *such that* $f_1, \dots, f_d \in C^k(\mathbb{R})$*. Furthermore, for each* $r > 0$ *let* $L_{\mathbf{f}}(r) > 0$ *be a number such that*

$$\sum_{j=1}^{d}|f_j'(u)| \le L_{\mathbf{f}}(r) \qquad (|u| \le r).$$

(ii) *The function* $\phi \in C^\infty(\mathbb{R}^d)$ *is even, bounded, nonnegative, and satisfies*

$$\int_{\mathbb{R}^d}\phi(\mathbf{x})\,d\mathbf{x} = 1, \quad \operatorname{supp}(\phi) \subset [-1,1]^d.$$

We introduce the set $K_0(r)$ for $r > 0$ by

$$K_0(r) = \{w \in L^\infty(\mathbb{R}^d) \,|\, \|w\|_{L^\infty(\mathbb{R}^d)} \leq r\}.$$

For $R > 0$ we denote by $C_1^2(\Omega_R)$ the set of real-valued functions on $\bar{\Omega}_R$ such that all spatial derivatives up to order two and the first order time derivative exist and are continuous in Ω_R. A function $u^\varepsilon \in C([0,R]; L^\infty(\mathbb{R}^d) \cap L^2(\mathbb{R}^d)) \cap C_1^2(\Omega_R)$ is called a **classical solution of** (3.1)**,** (3.2) **in** Ω_R if it satisfies (3.1) in Ω_R and (3.2) almost everywhere in $\mathbb{R}^d$.

For $\varepsilon > 0$ we also introduce the operator $q^\varepsilon : L^\infty(\mathbb{R}^d) \to L^\infty(\mathbb{R}^d)$ with

$$q^\varepsilon[w] = \gamma(\phi_\varepsilon * w - w) \quad (w \in L^\infty(\mathbb{R}^d)).$$

We note that q^ε satisfies for almost all $\mathbf{x} \in \mathbb{R}^d$ the simple estimate

$$|q^\varepsilon[w](\mathbf{x})| \leq 2\gamma \|w\|_{L^\infty(\mathbb{R}^d)}. \tag{3.3}$$

3.2. The main result. The main result in this section is the following theorem.

THEOREM 3.2 (global existence). *Let $r_\infty > 0$ be given and suppose that Assumption* 3.1 *holds. Then there exists a number $r_2 = r_2(r_\infty) > 0$ such that for all*

$$u_0 \in K_0(r_\infty) \cap L^2(\mathbb{R}^d) \tag{3.4}$$

with

$$\|u_0\|_{L^2(\mathbb{R}^d)} \leq r_2$$

there is a classical solution u^ε of (3.1), (3.2) *in Ω_T that is unique in the set of classical solutions. We have for $t \in [0,T]$*

$$\frac{1}{2}\|u^\varepsilon(.,t)\|^2_{L^2(\mathbb{R}^d)} + \varepsilon \sum_{j=1}^d \|\partial_{x_j} u^\varepsilon\|^2_{L^2(\Omega_t)} = \frac{1}{2}\|u_0\|^2_{L^2(\mathbb{R}^d)}. \tag{3.5}$$

The proof of the theorem will be presented in section 3.4 below and relies on a local-in-time existence result presented in section 3.3. We add some comments. The smallness condition on the L^2-norm of u_0 is a consequence of the fact that (3.1) is not equipped with a maximum principle if $\gamma > 0$ holds. This cannot be expected in the framework of local or nonlocal dispersive regularizations.

In this section the dependence of results and estimates on ε does not play a role so that we take $\varepsilon > 0$ as arbitrary but fixed. However, we note for later use that (3.5) provides an ε-independent estimate on the $L^\infty([0,T]; L^2(\mathbb{R}^d))$-norm of u^ε and for $\sqrt{\varepsilon}\|\nabla u^\varepsilon\|_{L^2(\mathbb{R}^d \times [0,T])}$.

3.3. Local existence. At first we provide a local-in-time existence and uniqueness result for (3.1), (3.2) which we then extend to arbitrary times. For both steps we use a method which has been developed for parabolic systems that do not allow for an a priori L^∞-bound ([33, Chapter 6.2]). It is one of the advantages of regularization (1.6) in comparison to (1.3) that the more flexible second order theory can still be applied while the local counterpart requires dealing with a more complicated third order differential operator.

We make use of the scaled heat kernel

$$K_\varepsilon(\mathbf{x},t) = (4\pi\varepsilon t)^{-d/2} \exp\Big(-\frac{|\mathbf{x}|^2}{4\pi\varepsilon t}\Big) \quad ((\mathbf{x},t) \in \Omega_T).$$

For $t > 0$ we collect the following properties for K_ε:

(3.6)

$$\int_{\mathbb{R}^d} K_\varepsilon(\mathbf{x},t)\,d\mathbf{x} = 1,$$

$$\exists\, C_\varepsilon > 0: \; \sum_{j=1}^{d} \|\partial_{x_j} K_\varepsilon(.,t) * w\|_{L^p(\mathbb{R}^d)} \leq \frac{C_\varepsilon}{\sqrt{t}} \|w\|_{L^p(\mathbb{R}^d)}, \quad w \in L^p(\mathbb{R}^d),\; p = 2, \infty.$$

Now let $r_\infty \in \mathbb{R}$ and $\bar{r} \in \mathbb{R}$ be numbers such that

$$\bar{r} > r_\infty > 0. \tag{3.7}$$

Note that these numbers $\bar{r}$ and r_∞ are arbitrary but fixed throughout the section. Finally we also fix a number $\bar{t} \in (0,T)$ such that

$$r_\infty \;+ 2C_\varepsilon(L_{\mathbf{f}}(\bar{r}) + 2\gamma d)\bar{r}\sqrt{\bar{t}} < \bar{r} \tag{3.8}$$

and

$$2C_\varepsilon(L_{\mathbf{f}}(\bar{r}) + 2\gamma d)\sqrt{\bar{t}} < 1 \tag{3.9}$$

hold.

Lemma 3.3. *Suppose that Assumption* 3.1 *holds and let* $u_0 \in K_0(r_\infty) \cap L^2(\mathbb{R}^d)$. *Then there exists a unique fixed point* $u^\varepsilon \in L^\infty(\Omega_{\bar{t}}) \cap L^\infty(0,\bar{t};L^2(\mathbb{R}^d))$ *of the mapping* $L_\varepsilon : L^\infty(\Omega_{\bar{t}}) \to L^\infty(\Omega_{\bar{t}})$ *which is defined for* $v \in L^\infty(\Omega_{\bar{t}})$ *and* $\varepsilon > 0$ *by*

(3.10)

$$\begin{aligned}(L_\varepsilon v)(\mathbf{x},t) \;\;=\;\; & \big[K_\varepsilon(.,t) * u_0\big](\mathbf{x}) + \int_0^t \sum_{j=1}^{d} \big[\partial_{x_j} K_\varepsilon(.,t-s) * f_j(v(.,s))\big](\mathbf{x})\,ds \\ & - \int_0^t \sum_{j=1}^{d} \big[\partial_{x_j} K_\varepsilon(.,t-s) * q^\varepsilon[v(.,s)]\big](\mathbf{x})\,ds \quad ((\mathbf{x},t) \in \Omega_{\bar{t}}).\end{aligned}$$

For the function u^ε *there is a constant* $C_0 > 0$ *such that we have*

$$\|u^\varepsilon\|_{L^\infty(\Omega_{\bar{t}})} + \|u^\varepsilon\|_{L^\infty(0,\bar{t};L^2(\mathbb{R}^d))} \;\;\leq\;\; C_0. \tag{3.11}$$

The number C_0 *depends on* $r_\infty, \varepsilon,\, f_1,\ldots,f_d, \phi$ *and* $\|u_0\|_{L^2(\mathbb{R}^d)}$.

Proof. At first we show that under condition (3.8) for $\bar{t}$ the inclusion $L_\varepsilon(K(\bar{r})) \subset K(\bar{r})$ holds. Here we denote $K(\bar{r}) = \{v \in L^\infty(\Omega_{\bar{t}}) \,|\, \|v\|_{L^\infty(\Omega_{\bar{t}})} \leq \bar{r}\}$ and $\bar{r}$ is the number from (3.7). Using the definition of L_ε and the properties of the kernel in (3.6) we deduce for $t \in [0,\bar{t}\,]$

$$\begin{aligned}&\|(L_\varepsilon v)(.,t)\|_{L^\infty(\mathbb{R}^d)} \leq \|u_0\|_{L^\infty(\mathbb{R}^d)} \\ &\quad + (L_{\mathbf{f}}(\bar{r}) + 2\gamma d)\|v\|_{L^\infty(\Omega_{\bar{t}})} \int_0^t \int_{\mathbb{R}^d} \sum_{j=1}^{d} \big|\partial_{x_j} K_\varepsilon(\mathbf{x},t-s)\big|\,d\mathbf{x}ds.\end{aligned}$$

We have used Assumption 3.1 and the estimate (3.3) and proceed with the estimate on $\partial_{x_j} K_\varepsilon$ in (3.6) and observe for $t \in [0,\bar{t}\,]$

$$\|(L_\varepsilon v)(.,t)\|_{L^\infty(\mathbb{R}^d)} \leq r_\infty \;+ 2C_\varepsilon(L_{\mathbf{f}}(\bar{r}) + 2\gamma d)\|v\|_{L^\infty(\Omega_{\bar{t}})}\sqrt{t}. \tag{3.12}$$

From (3.8) we get $L_\varepsilon(K(\bar r)) \subset K(\bar r)$ since $\bar r > r_\infty$. With the same arguments we obtain for $v_1, v_2 \in L^\infty(\Omega_{\bar t})$ and $t \in [0,\bar t\,]$

$$\|(L_\varepsilon v_1)(.,t) - (L_\varepsilon v_2)(.,t)\|_{L^\infty(\mathbb{R}^d)} \le 2C_\varepsilon(L_{\mathbf{f}}(\bar r) + 2\gamma d)\sqrt{t}\|v_1 - v_2\|_{L^\infty(\Omega_{\bar t})}. \tag{3.13}$$

Since $\bar t$ satisfies (3.9) we see that L_ε is a contraction in $L^\infty(\Omega_{\bar t})$ and has a unique fixed point u^ε in this space. With the arguments above one obtains the similar estimates in $L^\infty(0,\bar t; L^2(\mathbb{R}^d))$:

(3.14)
$$\begin{aligned} \|(L_\varepsilon v)(.,t)\|_{L^2(\mathbb{R}^d)} &\le \|u_0\|_{L^2(\mathbb{R}^d)} + 2C_\varepsilon(L_{\mathbf{f}}(\bar r) + 2\gamma d)\sqrt{t}\|v\|_{L^\infty(0,\bar t;L^2(\mathbb{R}^d))}, \\ \|(L_\varepsilon v_1)(.,t) - (L_\varepsilon v_2)(.,t)\|_{L^2(\mathbb{R}^d)} &\le 2C_\varepsilon(L_{\mathbf{f}}(\bar r) + 2\gamma d)\sqrt{t}\|v_1 - v_2\|_{L^\infty(0,\bar t;L^2(\mathbb{R}^d))}. \end{aligned}$$

Consider now the sequence $\{u^\varepsilon_m\}_{m\in\mathbb{N}}$ defined by

$$u^\varepsilon_{m+1}(\mathbf{x},t) := (L_\varepsilon u^\varepsilon_m)(\mathbf{x},t), \quad u^\varepsilon_1(\mathbf{x},t) = u_0(\mathbf{x}) \quad ((\mathbf{x},t) \in \Omega_{\bar t}). \tag{3.15}$$

This sequence is a Cauchy sequence in the Banach space $L^\infty(0,\bar t; L^2(\mathbb{R}^d))$ by (3.14). A subsequence must converge also in $L^\infty(0,\bar t; L^\infty(\mathbb{R}^d))$ by (3.13). The limit is the unique fixed point u^ε of L_ε. The estimate (3.11) follows from (3.12) and (3.14) with $v = u^\varepsilon$ and taking into account $2C_\varepsilon(L_{\mathbf{f}}(\bar r) + 2\gamma d)\sqrt{\bar t} < 1$. □

The fixed point u^ε of L_ε is a weak solution of (3.1) that satisfies (3.2). The implicit representation formula (3.10) shows $u^\varepsilon \in C^2_1(\Omega_{\bar t})$ (with $u^\varepsilon(.,0) := u_0$, $u^\varepsilon(.,\bar t) := \lim_{s\to\bar t, s<t} u^\varepsilon(.,s)$). For $p = 2,\infty$ we observe $u^\varepsilon \in C([0,\bar t\,]; L^p(\mathbb{R}^d))$ by means of (3.10), the L^p-bound for u^ε and the continuity of convolutions with the heat kernel. Thus u^ε is a classical solution of (3.1), (3.2). We now estimate the Sobolev norms of derivatives of u^ε. Due to the regularizing behavior of the heat kernel we obtain estimates on the Sobolev norm of each order that do not depend on the regularity of the initial function.

Lemma 3.4 (estimates for derivatives). *Suppose that Assumption* 3.1 *holds and let $u_0 \in K_0(r_\infty) \cap L^2(\mathbb{R}^d)$ with r_∞ from* (3.7) *be given. Then the fixed point u^ε of L_ε satisfies $u^\varepsilon \in L^\infty(0,\bar t; W^{k,2}(\mathbb{R}^d) \cap W^{k,\infty}(\mathbb{R}^d))$ with $k \in \mathbb{N}$ given by Assumption* 3.1*. Moreover for all $t^* \in (0,\bar t\,]$ there is a continuous function $\mathcal{C}^\alpha : [0,\infty) \to [0,\infty)$ such that for all $\alpha \in \mathbb{N}^d_0$, $|\alpha| \in \{1,\dots,k\}$ and $t \in (t^*,\bar t\,]$ we have*

(3.16)
$$\|(t-t^*)^{\frac12} D^\alpha u^\varepsilon(.,t)\|_{L^p(\mathbb{R}^d)} \le \mathcal{C}^\alpha\Big(\|u_0\|_{L^\infty(\mathbb{R}^d)} + \|u_0\|_{L^2(\mathbb{R}^d)} + \frac{1}{\sqrt{t^*}}\Big) \quad (p = 2,\infty).$$

The function $\mathcal{C}$ depends in particular on k and $\bar t$ but not on u_0.

Proof. For $m \in \mathbb{N}$, we define the iterates u^ε_m as in (3.15). Let $t^* \in (0,\bar t\,]$. For a continuous function $\mathcal{C}^\alpha : [0,\infty) \to [0,\infty)$ independent of m we shall prove below the following uniform estimate:

(3.17)
$$\|(t-t^*)^{\frac12} D^\alpha u^\varepsilon_m(.,t)\|_{L^p(\mathbb{R}^d)} \le \mathcal{C}^\alpha\Big(\|u_0\|_{L^\infty(\mathbb{R}^d)} + \|u_0\|_{L^2(\mathbb{R}^d)} + \frac{1}{\sqrt{t^*}}\Big) \quad (p = 2,\infty).$$

Here $\alpha \in \mathbb{N}^d_0$ is a multi-index with $|\alpha| \le k$. From Lemma 3.3 we have $u^\varepsilon_m \to u^\varepsilon$ in $L^\infty(\Omega_{\bar t})$. By (3.17) there is then for each $\alpha \in \mathbb{N}^d_0$, $|\alpha| \le k$, a function $v^\varepsilon_\alpha \in L^\infty(\mathbb{R}^d \times (t^*,\bar t))$ such that (for a subsequence) $D^\alpha u^\varepsilon_m \overset{*}{\rightharpoonup} v^\varepsilon_\alpha$. We conclude

$u^\varepsilon \in L^\infty(t^*,\bar t;W^{k,\infty}(\mathbb{R}^d))$ and $D^\alpha u^\varepsilon = v_\alpha$. Since t^* is arbitrary we get $u^\varepsilon \in L^\infty(0,\bar t;W^{k,\infty}(\mathbb{R}^d))$. A similar argument applies to show $u^\varepsilon \in L^\infty(0,\bar t;W^{k,2}(\mathbb{R}^d))$. The estimate (3.16) follows from (3.17) by taking the limit $m\to\infty$. It remains to prove (3.17). For $v \in W^{2,k}(\mathbb{R}^d)\cap W^{\infty,k}(\mathbb{R}^d)$ and $\beta\in\mathbb{N}_0^d$, $|\beta|\in\{1,\ldots,k\}$ we deduce from $f_j\in C^k(\mathbb{R}^d)$ that there is a continuous monotone increasing function $\mathcal{A}^\beta:[0,\infty)\to[0,\infty)$ independent of v such that

(3.18)
$$\sum_{j=1}^d \|D^\beta(f_j(v)) - f_j'(v)D^\beta v\|_{L^p(\mathbb{R}^d)} \le \begin{cases} \mathcal{A}^\beta\big(\|v\|_{W^{2,|\beta|-1}(\mathbb{R}^d)} + \|v\|_{W^{\infty,|\beta|-1}(\mathbb{R}^d)}\big) : p=2, \\ \mathcal{A}^\beta\big(\|v\|_{W^{\infty,|\beta|-1}(\mathbb{R}^d)}\big) \qquad : p=\infty. \end{cases}$$

Note that $D^\beta f_j(v) - f_j'(v)D^\beta v$ contains only derivatives of v up to order $|\beta|-1$ but there are derivatives of the fluxes up to order $|\beta|$.

We return to the proof of (3.17). The case $|\alpha|=0$ has been proven in Lemma 3.3. We start with $|\alpha|=1$ and obtain from the iteration formula (3.10) with (3.6) for $i=1,\ldots,d$, $p=2,\infty$, and $t\in(0,\bar t\,]$,

$$\begin{aligned} &\|\partial_{x_i} u^\varepsilon_{m+1}(.,t)\|_{L^p(\mathbb{R}^d)} \\ &\le \|\partial_{x_i} K_\varepsilon(.,t)*u_0\|_{L^p(\mathbb{R}^d)} + \sum_{j=1}^d \int_0^t \|\partial_{x_j} K_\varepsilon(.,t-s)*\partial_{x_i}(f_j(u^\varepsilon_m(.,s)))\|_{L^p(\mathbb{R}^d)}\,ds \\ &\quad + \sum_{j=1}^d \int_0^t \|\partial_{x_j} K_\varepsilon(.,t-s)*\partial_{x_i}(q^\varepsilon[u^\varepsilon_m(.,s)])\|_{L^p(\mathbb{R}^d)}\,ds \\ &\le \frac{C_\varepsilon}{\sqrt t}\|u_0\|_{L^p(\mathbb{R}^d)} + 2C_\varepsilon(L_{\mathbf f}(\bar r)+2\gamma d)\sqrt t\|\partial_{x_i} u^\varepsilon_m\|_{L^p(0,\bar t;L^p(\mathbb{R}^d))}. \end{aligned}$$

Multiplication with $(t-t^*)^{1/2}$ implies (3.16) for $|\alpha|=1$. We proceed by induction with respect to α and choose $p=\infty$ first. For $t^*\in(0,\bar t\,]$, $l\in\{1,\ldots,k\}$, $i\in\{1,\ldots,d\}$, $\alpha = le_i$, e_i the ith unit vector and $t\in(t^*,\bar t\,]$ we can write

$$\begin{aligned} &\|D^\alpha u^\varepsilon_{m+1}(.,t)\|_{L^\infty(\mathbb{R}^d)} \\ &\le \|\partial_{x_i} K_\varepsilon(.,t-t^*)*D^{\alpha-e_i}u^\varepsilon_{m+1}(.,t^*)\|_{L^\infty(\mathbb{R}^d)} \\ &\quad + \int_{t^*}^t \sum_{j=1}^d \|\partial_{x_j} K_\varepsilon(.,t-s)*D^\alpha f_j(u^\varepsilon_m(.,s))\|_{L^\infty(\mathbb{R}^d)}\,ds \\ &\quad + \int_{t^*}^t \sum_{j=1}^d \|\partial_{x_j} K_\varepsilon(.,t-s)*D^\alpha q^\varepsilon[u^\varepsilon_m(.,s)])\|_{L^\infty(\mathbb{R}^d)}\,ds \\ &\le \frac{C_\varepsilon}{\sqrt{t-t^*}}\|D^{\alpha-e_i}u^\varepsilon_{m+1}(.,t^*)\|_{L^\infty(\mathbb{R}^d)} \\ &\quad + 2C_\varepsilon\sqrt{t-t^*}\left(\sum_{j=1}^d |f_j'(u^\varepsilon_m)| + 2\gamma d\right)\|D^\alpha u^\varepsilon_m\|_{L^\infty(\Omega_{t^*,\bar t})} \\ &\quad + 2C_\varepsilon\sqrt{t-t^*}\sum_{j=1}^d \|D^\alpha(f_j(u^\varepsilon_m)) - f_j'(u^\varepsilon_m)D^\alpha u^\varepsilon_m\|_{L^\infty(\Omega_{t^*,\bar t})}. \end{aligned}$$

Here we used $\Omega_{t^*,\bar{t}} := \mathbb{R}^d \times (t^*, \bar{t}]$. The estimate (3.18) implies

$$
\begin{aligned}
&\|D^\alpha u^\varepsilon_{m+1}(.,t)\|_{L^\infty(\mathbb{R}^d)} \\
&\leq \frac{C_\varepsilon}{\sqrt{t-t^*}} \|D^{\alpha-e_i} u^\varepsilon_{m+1}(.,t^*)\|_{L^\infty(\mathbb{R}^d)} + 2C_\varepsilon \sqrt{t-t^*}(L_{\mathbf{f}}(\bar{r}) + 2\gamma d)\|D^\alpha u^\varepsilon_m\|_{L^\infty(\Omega_{t^*,\bar{t}})} \\
&+ 2C_\varepsilon \sqrt{t-t^*} \mathcal{A}^\alpha\big(\|u^\varepsilon_m\|_{L^\infty(t^*,\bar{t};W^{\infty,|\alpha|-1}(\mathbb{R}^d))}\big).
\end{aligned} \tag{3.19}
$$

The first and third term on the right-hand side of (3.19) contain only derivatives of lower order than $|\alpha|$. Therefore we can apply the induction hypothesis (3.17). The first term is evaluated in t^* directly. The induction hypothesis holds for arbitrary $t^* \in (0, \bar{t}]$ and if we apply it for, e.g., $t^*/2$ at the position of t^* in (3.17) we see that there is a continuous function $\mathcal{B}^\alpha_1 : [0,\infty) \to [0,\infty)$ (depending on $\mathcal{C}^{\alpha-e_i}$ in (3.17)) such that

$$
\|D^{\alpha-e_i} u^\varepsilon_{m+1}(.,t^*)\|_{L^\infty(\mathbb{R}^d)} \leq \mathcal{B}^\alpha_1\Big(\|u_0\|_{L^\infty(\mathbb{R}^d)} + \|u_0\|_{L^2(\mathbb{R}^d)} + \frac{1}{\sqrt{t^*}}\Big)
$$

holds. For the third term we obtain directly from the hypothesis that there is a continuous function $\mathcal{B}^\alpha_2 : [0,\infty) \to [0,\infty)$ (depending on $\mathcal{A}^\alpha$ in (3.19) and $\mathcal{C}^{\alpha-e_i}$ in (3.17)) such that

$$
\mathcal{A}^\alpha\big(\|u^\varepsilon_m\|_{L^\infty(t^*,\bar{t};W^{\infty,|\alpha|-1}(\mathbb{R}^d))}\big) \leq \mathcal{B}^\alpha_2\Big(\|u_0\|_{L^\infty(\mathbb{R}^d)} + \|u_0\|_{L^2(\mathbb{R}^d)} + \frac{1}{\sqrt{t^*}}\Big)
$$

holds. Altogether with $2C_\varepsilon\sqrt{t-t^*}(L_{\mathbf{f}}(\bar{r}) + 2\gamma d) < 1$ we see that there is a continuous function $\mathcal{C}^\alpha : [0,\infty) \to [0,\infty)$ (depending on $\mathcal{B}^\alpha_1$, $\mathcal{B}^\alpha_2$) such that

$$
\|D^\alpha u^\varepsilon_m(.,t)\|_{L^\infty(\mathbb{R}^d)} \leq \frac{1}{\sqrt{t-t^*}} \mathcal{C}^\alpha\Big(\|u_0\|_{L^\infty(\mathbb{R}^d)} + \frac{1}{\sqrt{t^*}}\Big).
$$

Mixed derivatives are treated in the same manner. Also the case $p = 2$ can be treated analogously. ∎

3.4. Proof of Theorem 3.2. In this section we extend the local existence results from Lemmas 3.3 and 3.4 to time intervals $[0,T]$ for the arbitrary but fixed number $T > 0$. The key tool is the following a priori estimate.

LEMMA 3.5 (a priori estimate). *Let the assumptions of Theorem* 3.2 *be valid. For* $\varepsilon > 0$ *and* $T > 0$ *assume that* $u^\varepsilon \in C^2_1(\Omega_T)$ *is a classical solution of* (3.1), (3.2) *that satisfies for* $t \in (0,T]$ *the decay estimates*

$$
\lim_{|\mathbf{x}|\to\infty} |D^\alpha u^\varepsilon(\mathbf{x},t)| = 0 \quad (\alpha \in \mathbb{N}^d_0, |\alpha| \leq 1). \tag{3.20}
$$

Then u^ε *satisfies for* $t \in [0,T]$

$$
\frac{1}{2}\|u^\varepsilon(.,t)\|^2_{L^2(\mathbb{R}^d)} + \varepsilon \sum_{j=1}^d \|\partial_{x_j} u^\varepsilon\|^2_{L^2(\Omega_t)} = \frac{1}{2}\|u_0\|^2_{L^2(\mathbb{R}^d)}. \tag{3.21}
$$

Proof. Let $w \in C^1(\mathbb{R}^d)$ be a function that tends to 0 for $|\mathbf{x}| \to \infty$ and $j \in \{1, \ldots, d\}$. Since ϕ_ε is even we observe

$$\begin{aligned}\int_{\mathbb{R}^d} w(\mathbf{x})\big[[\phi_\varepsilon * w](\mathbf{x})\big]_{x_j}\,d\mathbf{x} &= -\int_{\mathbb{R}^d} w(\mathbf{y})\int_{\mathbb{R}^d}\phi_\varepsilon(\mathbf{y}-\mathbf{x})w_{x_j}(\mathbf{x})\,d\mathbf{x}d\mathbf{y}\\ &= -\int_{\mathbb{R}^d} w(\mathbf{y})[\phi_\varepsilon * w_{x_j}](\mathbf{y})\,d\mathbf{y}\\ &= -\int_{\mathbb{R}^d} w(\mathbf{y})\big[[\phi_\varepsilon * w](\mathbf{y})\big]_{y_j}\,d\mathbf{y}.\end{aligned} \tag{3.22}$$

Interchanging the rôles of $\mathbf{x}$ and $\mathbf{y}$ in the last term we obtain

$$\int_{\mathbb{R}^d} w(\mathbf{x})\big[[\phi_\varepsilon * w](\mathbf{x})\big]_{x_j}\,d\mathbf{x} = 0 \quad (j = 1, \ldots, d). \tag{3.23}$$

To prove (3.21) we multiply (3.1) by u^ε, integrate with respect to space and time, and obtain by (3.2), (3.20) the equality

$$\begin{aligned}&\frac{1}{2}\|u^\varepsilon(.,t)\|^2_{L^2(\mathbb{R}^d)} + \varepsilon\sum_{j=1}^d \|\partial_{x_j}u^\varepsilon\|^2_{L^2(\Omega_T)}\\ =\;& \frac{1}{2}\|u_0\|^2_{L^2(\mathbb{R}^d)} + \gamma\sum_{j=1}^d\int_0^t\int_{\mathbb{R}^d} u^\varepsilon(\mathbf{x},s)\Big[\big[\phi_\varepsilon * u^\varepsilon(.,s)\big](\mathbf{x}) - u^\varepsilon(\mathbf{x},s)\Big]_{x_j}\,d\mathbf{x}ds.\end{aligned}$$

Using (3.23) leads to the statement (3.21). ◻

For the proof of Theorem 3.2 we rely on the L^2-a priori estimate in Lemma 3.5 and Sobolev's inequalities.

Proof of Theorem 3.2. Let u^ε be the unique fixed point of L_ε which has been determined in Lemma 3.3. From Lemma 3.4 we have $u^\varepsilon(.,s) \in W^{k,\infty}(\mathbb{R}^d)\cap W^{k,2}(\mathbb{R}^d)$ for $s \in (0, \bar{t}\,]$. Since $k > d/2$ we deduce by Sobolev's inequality that there is a constant $C > 0$ such that

$$\begin{aligned}\|u^\varepsilon(.,s)\|_{L^\infty(\mathbb{R}^d)} &\le C\|u^\varepsilon(.,s)\|_{W^{k,2}(\mathbb{R}^d)}\\ &\le C\|u^\varepsilon(.,s)\|^{1-\theta}_{L^2(\mathbb{R}^d)}\left(\sum_{|\alpha|=k}\|D^\alpha u^\varepsilon(.,s)\|_{L^2(\mathbb{R}^d)}\right)^\theta.\end{aligned}$$

The last estimate follows from the interpolation theory for Sobolev spaces with $\theta \in (0,1)$ (cf. [6]). Moreover the regularity of u^ε implies that (3.20) holds in $(0, \bar{t}\,]$. Thus the estimate (3.21) applies and we obtain with Lemma 3.4 for $s \in (\bar{t}/4, \bar{t})$ and $t^* = \bar{t}/4$ the estimate

$$\|u^\varepsilon(.,s)\|_{L^\infty(\mathbb{R}^d)} \le C\|u_0\|^{1-\theta}_{L^2(\mathbb{R}^d)}\mathcal{C}\Big(\|u_0\|_{L^\infty(\mathbb{R}^d)} + \|u_0\|_{L^2(\mathbb{R}^d)} + \frac{2}{\sqrt{\bar{t}}}\Big)^\theta (s - \bar{t}/4)^{-\frac{\theta}{2}}.$$

The function $\mathcal{C}$ is a continuous nonnegative function depending on the functions $\mathcal{C}^\alpha$, $|\alpha| = k$, in (3.16). Now we fix s, say $s = \bar{t}/2$, and choose r_2 so small such that for all u_0 with $\|u_0\|_{L^2(\mathbb{R}^d)} \le r_2$ the right-hand side in the last inequality is bounded from above by $\|u_0\|_{L^\infty(\mathbb{R}^d)}$. For the (new) initial function $u_0 = u^\varepsilon(.,s)$ with $s = \bar{t}/2$ the assumptions of Lemma 3.3 are satisfied. We can extend our local solution to the time interval $[0, 3\bar{t}/2)$. Repeating all arguments we finally obtain a global unique solution u^ε for $t \in [0,T]$. The function u^ε satisfies $u^\varepsilon \in C_1^2(\Omega_T)$. Since we have (after extension of u_m^ε to Ω_T) $u_m^\varepsilon \in C([0,T]; L^2(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d))$ by construction and $u_m^\varepsilon \to u^\varepsilon$ in $L^\infty(0,T; L^2(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d))$ from the proof of Lemma 3.3 we have also $u^\varepsilon \in C([0,T]; L^2(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d))$. Thus u^ε provides a classical solution of (3.1), (3.2). It is unique in this class since each classical solution is a fixed point of (3.10), which is unique. □

4. Sharp-interface limits for the scalar model problem in one dimension. We let $d = 1$. For $x = x_1$ and $f(u) = f_1(u)$ (1.2) with (1.6) takes the form

$$u_t^\varepsilon + f(u^\varepsilon)_x = \varepsilon u_{xx}^\varepsilon + \gamma \big[\phi_\varepsilon * u^\varepsilon - u^\varepsilon\big]_x \tag{4.1}$$

in $\mathbb{R} \times (0,T)$, $T > 0$. As before we consider the Cauchy problem for (4.1) with initial condition

$$u^\varepsilon(x,0) = u_0(x) \quad (x \in \mathbb{R}). \tag{4.2}$$

The assumptions on u_0 will be specified below. We restrict ourselves to the choice

$$f(u) = u^3.$$

In this section we assume that a unique classical solution of the Cauchy problem for (4.1) with certain properties exists. Actually this can be proven using Theorem 3.2. For a short discussion of this issue and restrictions concerning f, we refer to Note 4.6. We study the sharp-interface limit $\varepsilon \to 0$. Section 4.1 is devoted to the derivation of certain a priori estimates. Using the compensated compactness framework in section 4.2 we treat the limit problem in one space dimension with $\gamma = \mathcal{O}(1)$.

4.1. A priori estimates. For $\varepsilon, \gamma > 0$ we introduce the mapping $E^\varepsilon : L^2(\mathbb{R}) \to L^1(\mathbb{R})$ by

$$E^\varepsilon[w](x) = \frac{\gamma}{4} \int_{\mathbb{R}} \phi_\varepsilon(x-y)\big(w(y) - w(x)\big)^2 \, dy \quad (w \in L^2(\mathbb{R}),\ x \in \mathbb{R}). \tag{4.3}$$

We assume that Assumption 3.1 for $d = 1$ is valid throughout the section. We need the following technical lemma.

LEMMA 4.1. *Let $w \in C_1^2(\mathbb{R} \times (0,T))$ such that we have for all $t \in (0,T)$*

$$w(.,t),\ w_t(.,t),\ w_x(.,t),\ w_{xx}(.,t) \in L^2(\mathbb{R}).$$

Then we have for $t \in (0,T)$

$$\frac{d}{dt} \int_{\mathbb{R}} E^\varepsilon[w(.,t)](x) \, dx = -\gamma \int_{\mathbb{R}} \Big[\big[\phi_\varepsilon * w(.,t)\big](x) - w(x,t)\Big] w_t(x,t) \, dx \tag{4.4}$$

and

$$2 \int_{\mathbb{R}} E^\varepsilon[w_x(.,t)](x) \, dx = \gamma \int_{\mathbb{R}} \Big[\big[\phi_\varepsilon * w(.,t)\big](x) - w(x,t)\Big] w_{xx}(x,t) \, dx. \tag{4.5}$$

Proof. We compute for $t \in (0,T)$

$$\begin{aligned}
&\frac{\gamma}{4}\frac{d}{dt}\int_{\mathbb{R}}\int_{\mathbb{R}}\phi_\varepsilon(x-y)(w(y,t)-w(x,t))^2\,dydx\\
&= \frac{\gamma}{2}\int_{\mathbb{R}}\int_{\mathbb{R}}\phi_\varepsilon(x-y)(w(y,t)-w(x,t))w_t(y,t)\,dydx\\
&\quad +\frac{\gamma}{2}\int_{\mathbb{R}}\int_{\mathbb{R}}\phi_\varepsilon(y-x)(w(x,t)-w(y,t))w_t(x,t)\,dydx\\
&= \gamma\int_{\mathbb{R}}\int_{\mathbb{R}}\phi_\varepsilon(x-y)(w(y,t)-w(x,t))w_t(y,t)\,dydx\\
&= -\gamma\int_{\mathbb{R}}\big([\phi_\varepsilon * w(.,t)](x)-w(x,t)\big)w_t(x,t)\,dx.
\end{aligned}$$

This is (4.4). Note that we used the symmetry of ϕ. To derive (4.5) consider for $t \in (0,T)$

$$\begin{aligned}
\int_{\mathbb{R}}\int_{\mathbb{R}} E^\varepsilon[w_x(.,t)](x)\,dx &= -\frac{\gamma}{2}\int_{\mathbb{R}}\int_{\mathbb{R}}\phi_\varepsilon(x-y)(w_x(x,t)w_x(y,t)-w_x^2(x,t))\,dydx\\
&= -\frac{\gamma}{2}\int_{\mathbb{R}} w_x(x,t)\big([\phi_\varepsilon * w_x(.,t)](x)-w_x(x,t)\big)\,dx\\
&= \frac{\gamma}{2}\int_{\mathbb{R}} w_{xx}(x,t)\big([\phi_\varepsilon * w(.,t)]-w(x,t)\big)\,dx. \qquad \square
\end{aligned}$$

With this lemma we now prove the crucial a priori estimates on u^ε.

LEMMA 4.2. *Assume that we have $u_0 \in L^2(\mathbb{R})\cap L^\infty(\mathbb{R})$. Let $u^\varepsilon \in C([0,T];L^2(\mathbb{R})\cap L^\infty(\mathbb{R}))\cap C_1^2(\mathbb{R}\times(0,T))$ be a classical solution of (4.1), (4.2) that satisfies for $t \in (0,T]$ the relations*

$$u_t^\varepsilon(.,t),\ u_x^\varepsilon(.,t),\ u_{xx}^\varepsilon(.,t) \in L^2(\mathbb{R}). \tag{4.6}$$

Then we have for all $t \in [0,T]$

$$\frac{1}{2}\|u^\varepsilon(.,t)\|^2_{L^2(\mathbb{R})} + \varepsilon\|u_x^\varepsilon\|^2_{L^2(\mathbb{R}\times(0,t))} = \frac{1}{2}\|u_0\|^2_{L^2(\mathbb{R})} \tag{4.7}$$

and

$$\begin{aligned}
&\frac{1}{4}\|u^\varepsilon(.,t)\|^4_{L^4(\mathbb{R})}\\
&\quad+\int_{\mathbb{R}} E^\varepsilon[u^\varepsilon(.,t)](x)\,dx + 3\varepsilon\|u^\varepsilon u_x^\varepsilon\|^2_{L^2(\mathbb{R}\times(0,t))}\\
&\quad+2\varepsilon\gamma\|E^\varepsilon[u_x^\varepsilon]\|_{L^1(\mathbb{R}\times(0,t))} = \frac{1}{4}\|u_0\|^4_{L^4(\mathbb{R})} + \int_{\mathbb{R}} E^\varepsilon[u_0](x)\,dx.
\end{aligned} \tag{4.8}$$

Proof. The proof of (4.7) has already been given in Lemma 3.5. We turn to prove the second estimate (4.8). By (4.6) and Sobolev embedding we get for $t \in (0,T]$ the limit

$$\lim_{|x|\to\infty}\big(|u^\varepsilon(x,t)| + |u_x^\varepsilon(x,t)|\big) = 0. \tag{4.9}$$

Using (4.9) we obtain by multiplication of (4.1) with $f(u) = u^3$

$$\begin{aligned}
&\frac{1}{4}\|u^\varepsilon(.,t)\|^4_{L^4(\mathbb{R})} + 3\varepsilon\|u^\varepsilon u^\varepsilon_x\|^2_{L^2(\mathbb{R}\times(0,t))} \\
&\quad = \frac{1}{4}\|u_0\|^4_{L^4(\mathbb{R})} - \gamma\int_0^t\int_{\mathbb{R}} [(u^\varepsilon(x,s))^3]_x\big[[\phi_\varepsilon * u^\varepsilon(.,s)](x) - u^\varepsilon(x,s)\big]\,dxds.
\end{aligned} \tag{4.10}$$

Moreover, multiplication of (4.1) with the term $-\gamma[\phi_\varepsilon * u^\varepsilon(.,t) - u^\varepsilon]$ leads to

$$\begin{aligned}
&-\gamma\int_0^t\int_{\mathbb{R}} u^\varepsilon_t(x,s)\big[[\phi_\varepsilon * u^\varepsilon(.,s)](x) - u^\varepsilon(x,s)\big]\,dxds \\
&-\gamma\int_0^t\int_{\mathbb{R}} [(u^\varepsilon(x,s))^3]_x\big[[\phi_\varepsilon * u^\varepsilon(.,s)](x) - u^\varepsilon(x,s)\big]\,dxds \\
&\quad = -\varepsilon\gamma\int_0^t\int_{\mathbb{R}} u^\varepsilon_{xx}(.,s)\big[[\phi_\varepsilon * u^\varepsilon(.,s)](x) - u^\varepsilon(x,s)\big]\,dxds.
\end{aligned}$$

We now apply both identities from Lemma 4.1 with $w = u^\varepsilon$. Then the last equation simplifies to

$$\begin{aligned}
&\int_0^t \frac{d}{ds}\left(\int_{\mathbb{R}} E^\varepsilon[u^\varepsilon(.,s)](x)dx\right)ds - \gamma\int_0^t\int_{\mathbb{R}} (u^\varepsilon(x,s))^3_x[[\phi_\varepsilon * u^\varepsilon(.,s)](x) - u^\varepsilon(x,s)]dxds \\
&\quad = -2\varepsilon\gamma\int_0^t\int_{\mathbb{R}} E^\varepsilon[u^\varepsilon_x(.,s)](x)dxds.
\end{aligned} \tag{4.11}$$

Adding (4.10) and (4.11) implies the estimate (4.8). ∎

It is interesting to compare estimate (4.8) with analogous estimates that can be obtained for the local counterpart of (4.1) where the convolution-type term $[\phi_\varepsilon * u^\varepsilon(.,s)](x) - u^\varepsilon(x,s)$ is substituted by the dispersive term $\varepsilon^2 u^\varepsilon_{xxx}$ (cf. (1.3)). In the latter case one gets ([19])

$$\begin{aligned}
&\frac{1}{4}\|u^\varepsilon(.,t)\|^4_{L^4(\mathbb{R})} + \frac{\gamma\varepsilon^2}{2}\int_{\mathbb{R}}(u^\varepsilon_x(x,t))^2\,dx + 3\varepsilon\|u^\varepsilon u^\varepsilon_x\|^2_{L^2(\mathbb{R}\times(0,t))} + \varepsilon^3\gamma\|(u^\varepsilon_{xx})^2\|_{L^1(\mathbb{R}\times(0,t))} \\
&\quad = \frac{1}{4}\|u_0\|^4_{L^4(\mathbb{R})} + \frac{\gamma\varepsilon^2}{2}\int_{\mathbb{R}}(u_{0,x}(x))^2\,dx.
\end{aligned}$$

The term $\frac{\gamma\varepsilon^2}{2}(u^\varepsilon_x)^2$ takes the rôle of E^ε. In the realistic models for phase transitions like, e.g., the Navier–Stokes–Korteweg system these two expressions are exactly the additional terms in the free energy functional that model the contributions of surface tension ([31]).

Note moreover that the energy estimate for the nonlocal dispersion does not involve the spatial derivative $u_{0,x}$. It is a major advantage of nonlocal regularizations that they come along with less restrictive assumptions on the regularity of the problem.

In the limit process one main difficulty is to deal with mixed terms which include local and nonlocal terms. To cope with this problem we shall use the following lemma.

Lemma 4.3. *Let the assumptions of Lemma* 4.2 *be valid. Then there exists a constant $C > 0$ such that*

$$\|\phi_\varepsilon * u^\varepsilon - u^\varepsilon\|_{L^2(\mathbb{R}\times(0,T))} \le C\sqrt{\varepsilon}.$$

The constant C depends on T, u_0 and ϕ but not on ε.

Proof. Let $(x,t) \in \mathbb{R} \times (0,T)$ be arbitrary but fixed. Denote $B_\varepsilon(x) = \{y \in \mathbb{R} \,|\, |x-y| \leq \varepsilon\}$. We consider $I : \mathbb{R} \times (0,T) \to \mathbb{R}$ with

$$I(x,t) = [\phi_\varepsilon * u^\varepsilon(.,t)](x) - u^\varepsilon(x,t) = \int_{\mathbb{R}} \phi_\varepsilon(x-y)(u^\varepsilon(x,t) - u^\varepsilon(y,t))\, dy.$$

Assumption 3.1(ii) and the Morrey-type inequality (see [13, section 5.6.2])

$$|w(x) - w(y)| \leq C_1 \sqrt{\varepsilon} \Big(\int_{x-2\varepsilon}^{x+2\varepsilon} |w_x(z)|^2 \, dz \Big)^{1/2} \quad (x \in \mathbb{R},\, y \in B_\varepsilon(x),\, w \in C^1(\mathbb{R}))$$

show that the following estimate holds:

$$\begin{aligned}
|I(x,t)| &\leq \int_{B_\varepsilon(x)} \phi_\varepsilon(x-y) |(u^\varepsilon(x,t) - u^\varepsilon(y,t))| \, dy \\
&\leq C_1 \sqrt{\varepsilon} \int_{B_\varepsilon(x)} \phi_\varepsilon(x-y) \left(\int_{x-2\varepsilon}^{x+2\varepsilon} |u_x^\varepsilon(z,t)|^2 \, dz \right)^{1/2} dy \\
&= C_1 \sqrt{\varepsilon} \left(\int_{x-2\varepsilon}^{x+2\varepsilon} |u_x^\varepsilon(z,t)|^2 \, dz \right)^{1/2}.
\end{aligned}$$

Now we integrate $|I(x,t)|^2$ with respect to space and obtain with the substitution $z = x + \frac{4\varepsilon}{\pi} \arctan(\tilde{z})$,

$$\begin{aligned}
\int_{\mathbb{R}} |I(x,t)|^2 \, dx &= C_1 \varepsilon \int_{\mathbb{R}} \left(\int_{x-2\varepsilon}^{x+2\varepsilon} |u_x^\varepsilon(z,t)|^2 \, dz \right) dx, \\
&= C_1 \varepsilon \int_{\mathbb{R}} \left(\int_{\mathbb{R}} \Big| u_x^\varepsilon \Big(x + \frac{4\varepsilon}{\pi} \arctan(\tilde{z}), t \Big) \Big|^2 \, dx \right) \frac{4\varepsilon}{\pi} \frac{1}{1+\tilde{z}^2} \, d\tilde{z}, \\
&= C_1 \frac{4\varepsilon^2}{\pi} \int_{\mathbb{R}} \left(\int_{\mathbb{R}} |u_x^\varepsilon(x,t)|^2 \, dx \right) \frac{1}{1+\tilde{z}^2} \, d\tilde{z}, \\
&\leq C_2 \varepsilon^2 \|u_x^\varepsilon(.,t)\|^2_{L^2(\mathbb{R})}.
\end{aligned}$$

Integration with respect to time and estimate (4.7) of Lemma 4.2 yield

$$\|I\|_{L^2(\mathbb{R} \times (0,T))} \leq C_3 \varepsilon \|u_x^\varepsilon\|_{L^2(\mathbb{R} \times (0,T))} \leq C\sqrt{\varepsilon}.$$

This is the statement of the lemma. ∎

4.2. The limit process of vanishing diffusion and dispersion. We now prove that the classical solutions of the regularized problem (4.1), (4.2) converge in a strong norm for vanishing ε to a limit function u which is a weak solution of

$$u_t(x,t) + f(u(x,t))_x = 0, \quad f(u) = u^3. \tag{4.12}$$

We need a more general notation of an entropy pair as in section 2. The pair $(\eta, q) \in C^2(\mathbb{R})$ is called an entropy pair for (4.12) if and only if $\eta \in C^2(\mathbb{R})$ and the consistency relation $\eta'(w) f'(w) = q'(w)$ holds for all $w \in \mathbb{R}$. Convexity of η is not claimed in this section. To perform the limit $\varepsilon \to 0$ for the problem (4.1), (4.2) we make use of the following theorem which is an adaption of the original work of Schonbek and Murat [29, 32].

Theorem 4.4 (Schonbek/Murat). *We suppose that the family* $\{u^\varepsilon\}_{\varepsilon>0}$ *of classical solutions of* (4.1), (4.2) *is uniformly bounded in* $L^p(\mathbb{R}\times(0,T))$ *for some* $p>1$ *and satisfies*

$$\frac{\partial}{\partial t}\eta(u^\varepsilon)+\frac{\partial}{\partial x}q(u^\varepsilon)\subset \text{ compact set in } W^{-1,2}(Q) + \text{ bounded set in } \mathcal{M}(Q) \tag{4.13}$$

for all entropy pairs (η,q) *for* (4.12) *such that there is a constant* $C>0$ *with*

$$|\eta'(w)|+|\eta''(w)|\le C \quad (w\in\mathbb{R}) \tag{4.14}$$

and all open bounded sets $Q\subset\mathbb{R}\times(0,T)$.
Then the following statements are valid.

(i) *There is a subsequence* $\{u^{\varepsilon_k}\}_{k\in\mathbb{N}}$ *of* $\{u^\varepsilon\}_{\varepsilon>0}$ *and a function* $u\in L^p(\mathbb{R}\times(0,T))$ *such that* $\varepsilon_k\to 0$ *for* $k\to\infty$ *and the subsequence converges for* $k\to\infty$ *to* u *in* $L^r_{loc}(\mathbb{R}\times(0,T))$, $r\in[1,p)$.

(ii) *If moreover* $p>3$ *and Assumption* 3.1(ii) *with* $d=1$ *holds, we have that* u *is a weak solution of* (4.12), *i.e.,*

$$\int_0^T\int_{\mathbb{R}} u(x,t)\psi_t(x,t)+f(u(x,t))\psi_x(x,t)\,dxdt=0 \tag{4.15}$$

for all $\psi\in C_0^\infty(\mathbb{R}\times(0,T))$.

Proof. The first statement (i) is the content of Theorem 3.2 and Corollary 3.2 in [32]. We note that the origin of the sequence $\{u^\varepsilon\}_{\varepsilon>0}$ as a solution of an initial-value problem with nonlocal regularization is not important in order to apply these results but only the compactness property (4.13) related to the flux f via the entropy pairs. In this form the compactness property has been introduced in [29]. To prove (ii) we state that the converging subsequence $\{u^{\varepsilon_k}\}_{k\in\mathbb{N}}$ is a family of classical solutions of (4.1), (4.2) and satisfies in particular for all $\psi\in C_0^\infty(\mathbb{R}\times(0,T))$,

$$\begin{aligned}
&\int_0^T\int_{\mathbb{R}} u^{\varepsilon_k}(x,t)\psi_t(x,t)+f(u^{\varepsilon_k}(x,t))\psi_x(x,t)\,dxdt\\
&\quad= -\int_0^T\int_{\mathbb{R}}\varepsilon_k u^{\varepsilon_k}(x,t)\psi_{xx}(x,t)\,dxdt\\
&\qquad +\gamma\int_0^T\int_{\mathbb{R}}\big([\phi_{\varepsilon_k}*u^{\varepsilon_k}(.,t)](x)-u^{\varepsilon_k}(x,t)\big)\psi_x(x,t)\,dxdt.
\end{aligned} \tag{4.16}$$

From (i), $p>3$, and f being the cubic function, we deduce that the left-hand side in (4.16) converges to the expression on the left-hand side in (4.15) if k tends to ∞. It remains to be seen whether the terms on the right-hand side in (4.16) converge to 0. This is clear for the viscosity term. For the capillarity term we have

$$\begin{aligned}
&\left|\gamma\int_0^T\int_{\mathbb{R}}\big([\phi_{\varepsilon_k}*u^{\varepsilon_k}(.,t)](x)-u^{\varepsilon_k}(x,t)\big)\psi_x(x,t)\,dxdt\right|\\
&\quad= \left|\gamma\int_0^T\int_{\mathbb{R}}u^{\varepsilon_k}(x,t)\big([\phi_{\varepsilon_k}*\psi_x(.,t)](x)-\psi_x(x,t)\big)\,dxdt\right|\\
&\quad\le \gamma C\|u^{\varepsilon_k}\|_{L^p(\Omega_T)}\|\phi_{\varepsilon_k}*\psi_x-\psi_x\|_{L^2(\Omega_T)}\\
&\quad\to 0 \quad (k\to\infty).
\end{aligned}$$

The last line follows from the pointwise convergence of the convolution of a smooth function towards the function if the convolution parameter vanishes. Note moreover that the L^p-norm of $\{u^{\varepsilon_k}\}_{k\in\mathbb{N}}$ is uniformly bounded and that $p > 2$ holds; C is an interpolation constant that depends on the support of ψ_x and its convolution. Statement (ii) is now proven. $\square$

We now have all the tools to prove the main theorem of this section.

THEOREM 4.5. *Suppose that we have $u_0 \in L^2(\mathbb{R}) \cap L^\infty(\mathbb{R})$ and that the function $\phi \in C^\infty(\mathbb{R}^d)$ is even, bounded, nonnegative, and satisfies*

$$\int_{\mathbb{R}} \phi(x)\,dx = 1, \quad \operatorname{supp}(\phi) \subset [-1,1].$$

Let $u^\varepsilon \in C([0,T]; L^\infty(\mathbb{R})\cap L^2(\mathbb{R})) \cap C_1^2(\mathbb{R}\times(0,T))$ be a classical solution of (4.1), (4.2) *that satisfies the decay estimate* (4.6) *for $t \in (0,T]$. Then there exists a subsequence $\{u^{\varepsilon_k}\}_{k\in\mathbb{N}}$ of $\{u^\varepsilon\}_{\varepsilon>0}$ and a function $u \in L^p(\mathbb{R}\times(0,T))$, $p \in [2,4]$, such that*

(i) *the subsequence converges to u in $L^r_{loc}(\mathbb{R}\times(0,T))$, $r \in [1,4)$,*

(ii) *u is a weak solution of* (4.12).

Proof. From Lemma 4.2 we know that $\{u^\varepsilon\}_{\varepsilon>0}$ is bounded uniformly in $L^p(\mathbb{R}\times(0,T))$ for each $p \in [2,4]$. Let (η,q) be an arbitrary but fixed entropy pair with the property (4.14). We obtain

$$\begin{aligned} \eta(u^\varepsilon)_t + q(u^\varepsilon)_x &= \varepsilon\eta(u^\varepsilon)_{xx} - \varepsilon\eta''(u^\varepsilon)(u^\varepsilon_x)^2 \\ &\quad + \gamma[\eta'(u^\varepsilon)(\phi_\varepsilon * u^\varepsilon - u^\varepsilon)]_x - \gamma\eta''(u^\varepsilon)u^\varepsilon_x(\phi_\varepsilon * u^\varepsilon - u^\varepsilon) \\ &=: I_1^\varepsilon + I_2^\varepsilon + I_3^\varepsilon + I_4^\varepsilon. \end{aligned}$$

We will now prove that we have for each bounded open subset Q of $\mathbb{R}\times(0,T)$ the relations

$$|\langle I_1^\varepsilon,\theta\rangle| \overset{\varepsilon\to 0}{\longrightarrow} 0 \quad \forall\,\theta \in W_0^{1,2}(Q), \tag{4.17}$$

$$|\langle I_2^\varepsilon,\psi\rangle| \;\le\; C_2\|\psi\|_{L^\infty(Q)} \quad \forall\,\psi \in C_0^\infty(Q), \tag{4.18}$$

$$|\langle I_3^\varepsilon,\theta\rangle| \overset{\varepsilon\to 0}{\longrightarrow} 0 \quad \forall\,\theta \in W_0^{1,2}(Q), \tag{4.19}$$

$$|\langle I_4^\varepsilon,\psi\rangle| \;\le\; C_4\|\psi\|_{L^\infty(Q)} \quad \forall\,\psi \in C_0^\infty(Q). \tag{4.20}$$

The lemma of Murat ([29]) implies then that assumption (4.13) of Theorem 4.4 can be satisfied for $p \in (1,4]$. Thus the statement of Theorem 4.5 is proven. We start with I_1^ε and observe with (4.14), Hölder's inequality, and Lemma 4.2 that

$$\begin{aligned} |\langle I_1^\varepsilon,\theta\rangle| &= \left|\int_Q \varepsilon\eta(u^\varepsilon(x,t))_{xx}\theta(x,t)\,dxdt\right| \\ &\le \varepsilon\|\eta'(u^\varepsilon)u^\varepsilon_x\|_{L^2(Q)}\|\theta_x\|_{L^2(Q)} \\ &\le \varepsilon C_1\|u^\varepsilon_x\|_{L^2(Q)}\|\theta\|_{W^{1,2}(Q)} \\ &\le \sqrt{\varepsilon}C_1\|\theta\|_{W^{1,2}(Q)} \overset{\varepsilon\to 0}{\longrightarrow} 0. \end{aligned}$$

This is (4.17). To check (4.18) we use again Lemma 4.2 and consider the estimate

$$
\begin{aligned}
|\langle I_2^\varepsilon,\psi\rangle| &= \left|\int_Q \varepsilon\eta''(u^\varepsilon(x,t))(u_x^\varepsilon(x,t))^2\psi(x,t)\,dxdt\right| \\
&\le \varepsilon C_2\|u_x^\varepsilon\|^2_{L^2(Q)}\|\psi\|_{L^\infty(Q)} \\
&\le C_2\|\psi\|_{L^\infty(Q)}.
\end{aligned}
$$

Statement (4.19) is a consequence of

$$
\begin{aligned}
|\langle I_3^\varepsilon,\theta\rangle| &= \left|\gamma\int_Q \Big[\eta'(u^\varepsilon(x,t))[\phi_\varepsilon * u^\varepsilon(.,t)](x) - u^\varepsilon(x,t)\Big]_x\theta(x,t)\,dxdt\right| \\
&\le C_3\gamma\|\phi_\varepsilon * u^\varepsilon - u^\varepsilon\|_{L^2(Q)}\|\theta_x\|_{L^2(Q)} \\
&\le C_3\gamma\sqrt{\varepsilon}\|\theta\|_{W^{1,2}(Q)} \overset{\varepsilon\to 0}{\longrightarrow} 0.
\end{aligned}
$$

For the last inequality we used Lemma 4.3. Finally we have for I_ε^4

$$
\begin{aligned}
|\langle I_4^\varepsilon,\psi\rangle| &= \left|\gamma\int_Q \eta''(u^\varepsilon(x,t))u_x^\varepsilon(x,t)([\phi_\varepsilon * u^\varepsilon(.,t)](x) - u^\varepsilon(x,t))\psi(x,t)\,dxdt\right| \\
&\le C_4\gamma\|u_x^\varepsilon\|_{L^2(Q)}\|\phi_\varepsilon * u^\varepsilon - u^\varepsilon\|_{L^2(Q)}\|\psi\|_{L^\infty(Q)} \\
&\le C_4\gamma\|\psi\|_{L^\infty(Q)}.
\end{aligned}
$$

For the last inequality we used Lemmas 4.2 and 4.3. □

NOTE 4.6.

(i) *In Theorem* 4.5 *we supposed that a classical solution* $u^\varepsilon \in C([0,T];L^\infty(\mathbb{R})\cap L^2(\mathbb{R}))\cap C_1^2(\mathbb{R}\times(0,T))$ *of* (4.1), (4.2) *exists and satisfies the decay estimate* (4.6) *for* $t\in(0,T]$. *In view of Lemma* 3.4, *in particular the estimate* (3.16), *we can guarantee all these properties if Theorem* 3.2 *applies, i.e., if* $\|u_0\|_{L^2(\mathbb{R})}$ *is small enough.*

(ii) *Theorem* 4.5 *is tailored to the choice* $f(u) = u^3$. *To apply the* L^p*-theory of Schonbek a growth condition on the flux* f *is necessary. However, the restriction to cubic functions can be avoided. One can apply similar techniques as in* [23] *to treat the case of arbitrary fluxes which are only assumed to have a globally bounded derivative.*

5. Sharp-interface limit in the case of multiple space dimensions. In this section we return to multiple space dimensions and consider the Cauchy problem for (3.1), (3.2). We do not consider a special choice for the flux functions $f_1,\dots,f_d$ as in section 4.2 but we require them to satisfy Assumption 3.1 and for some $p>1$ to be specified below the following growth condition:

(5.1) $\quad \exists\, C>0: \quad |f_j(u)| \le C(1+u^r)$ for all $u\in\mathbb{R}$, $r\in[0,p)$, and $j=1,\dots,d$.

Throughout the section we assume that (3.1), (3.2) has a unique classical solution u^ε in $\Omega_T := \mathbb{R}^d\times(0,T)$, $T>0$. This is true, e.g., under the conditions of Theorem 3.2. We study the sharp-interface limit $\varepsilon\to 0$. A similar study for the Cauchy problem with the local diffusion and dispersion term has been performed in [23].

5.1. Review of the theory of -measure-valued solutions. In the limit $\varepsilon \to 0$ we will deal with Kruzkov solutions for the first order conservation law

$$u_t + \operatorname{div}(\mathbf{f}(u)) = 0 \quad \text{in } \Omega_T. \tag{5.2}$$

A **Kruzkov solution of** (5.2)

$$u(.,0) = u_0 \text{ in } \mathbb{R}^d.$$

Equation [24] is a function $u \in L^p_{loc}(\Omega_T)$ such that for all $k \in \mathbb{R}$ and all $\psi \in C_0^\infty(\Omega_T)$, $\psi \geq 0$,

$$\int_{\Omega_T} |u(\mathbf{x},t) - k|\psi_t(\mathbf{x},t) + \operatorname{sgn}(u(\mathbf{x},t) - k)\sum_{j=1}^{d}(f_j(u(\mathbf{x},t)) - f_j(k))\psi_{x_j}(\mathbf{x},t)\, d\mathbf{x}dt \geq 0$$

holds and moreover the initial condition is satisfied in the sense that for all compact subsets K of $\mathbb{R}^d$,

$$\lim_{T\to 0^+} \frac{1}{T}\int_0^T \int_K |u(\mathbf{x},t) - u_0(\mathbf{x})|\, d\mathbf{x}dt = 0 \tag{5.3}$$

holds.

By an **entropy solution of** (5.2)

$$u(.,0) = u_0 \text{ in } \mathbb{R}^d,$$

we mean in this section function $u \in L^p_{loc}(\Omega_T)$ such that for all smooth functions $\eta, q_1, \dots, q_d : \mathbb{R} \to \mathbb{R}$ with η' bounded and $\eta' f_j' = q_j'$, $j = 1, \dots, d$ and all test functions $\psi \in C_0^\infty(\Omega_T)$, $\psi \geq 0$, we have

$$\int_{\Omega_T} \eta(\mathbf{x},t)\psi_t(\mathbf{x},t) + \sum_{j=1}^{d} q_j(u(\mathbf{x},t)\psi_{x_j}(\mathbf{x},t)\, d\mathbf{x}dt \geq 0$$

and also (5.3). Let us mention that Kruzkov solutions are entropy solutions and vice versa [16] but we need both notions in what follows. Our analysis relies on results by Schonbek and Szepessy [32, 35] which are extensions of the concept of measure-valued solutions initiated by DiPerna [10] for L^∞-functions to the case of L^p-functions.

We need some preparatory notations. Let $p \in (1,\infty)$ be arbitrary but fixed. Denote by Prob($\mathbb{R}$) the set of probability measures on $\mathbb{R}$. A mapping $\nu = \nu_{(\mathbf{x},t)}$ from Ω_T to Prob($\mathbb{R}$) is called a **p-Young measure** if the function

$$(\mathbf{x},t) \mapsto \langle \nu_{(\mathbf{x},t)}, g(\lambda)\rangle := \int_{\mathbb{R}} g(\lambda)\, d\nu_{(\mathbf{x},t)}(\lambda)$$

is in $L^p(\Omega_T)$ for all $g \in C^0(\mathbb{R})$ with

$$g(\lambda) = \mathcal{O}(1 + |\lambda|^r) \quad (r \in [0,p)). \tag{5.4}$$

A p-Young measure is called a **measure-valued Kruzkov solution of** (5.2)

$$u(.,0) = u_0 \text{ in } \mathbb{R}^d,$$

if it satisfies for all $k \in \mathbb{R}$ and $\psi \in C_0^\infty(\Omega_T)$, $\psi \geq 0$, the inequality

(5.5)
$$\int_{\Omega_T} \langle \nu_{(\mathbf{x},t)}, |\lambda - k| \rangle \psi_t(\mathbf{x},t) + \sum_{j=1}^{d} \langle \nu_{(\mathbf{x},t)}, \operatorname{sgn}(\lambda - k)(f_j(\lambda) - f_j(k)) \rangle \psi_{x_j}(\mathbf{x},t)\, d\mathbf{x}dt \geq 0$$

and moreover

$$\lim_{T \to 0^+} \frac{1}{T} \int_0^T \int_K \langle \nu_{(\mathbf{x},t)}, |\lambda - u_0(\mathbf{x})| \rangle \, d\mathbf{x}dt = 0 \tag{5.6}$$

for all compact subsets K of $\mathbb{R}^d$. We recover the definition of the Kruzkov solution if we set $\nu_{(\mathbf{x},t)} = \delta_{u(\mathbf{x},t)}$, where $\delta_{u(\mathbf{x},t)}$ is the Dirac-measure concentrated in $u(\mathbf{x},t)$ for almost all $(\mathbf{x},t) \in \Omega_T$.

Now we collect in a theorem results that have been proven in [32, 35].

THEOREM 5.1 (Schonbek, Szepessy). *For $p > 1$ let $\{u^\varepsilon\}_{\varepsilon > 0} \subset L^p(\Omega_T)$ be a sequence of functions that is uniformly bounded in $L^p(\Omega_T)$. Then there exists a p-Young measure $\nu = \nu_{(\mathbf{x},t)}$ such that*

$$g(u^\varepsilon) \rightharpoonup \langle \nu_{(\mathbf{x},t)}, g(\lambda) \rangle \ \textit{in}\ L^p(\Omega) \tag{5.7}$$

holds for all continuous functions g satisfying (5.4)*.*

Let $u_0 \in L^p(\mathbb{R}^d)$. If $\{u^\varepsilon\}_{\varepsilon>0}$ is uniformly bounded in $L^\infty(0,T;L^p(\mathbb{R}^d))$ and ν provides a measure-valued Kruzkov solution of (1.1) *the following statements are valid:*

(i) *There is a function $u \in L^p(\Omega_T)$ such that $\lim_{\varepsilon\to 0} \|u - u^\varepsilon\|_{L^p_{loc}(\Omega_T)} = 0$.*

(ii) *The function u is a Kruzkov solution of* (5.2)*,* (5.3)*.*

5.2. The main result. We conclude with the main result of the section: the convergence of the sequence $\{u^\varepsilon\}_{\varepsilon>0}$ of classical solutions of (3.1), (3.2) to a Kruzkov solution of the corresponding first order problem (5.2), (5.3). We relax the scaling of the nonlocal term with respect to ε and suppose that the parameter $\gamma > 0$ satisfies

$$\gamma = \gamma(\varepsilon) = o(\sqrt{\varepsilon}). \tag{5.8}$$

THEOREM 5.2. *Let Assumption* 3.1 *and condition* (5.1) *with $p = 2$ for $f_1, \ldots, f_d$ be satisfied. For $u_0 \in L^2(\Omega_T)$ assume that $\{u^\varepsilon\}_{\varepsilon>0}$ is a sequence of classical solutions for* (3.1)*,* (3.2)*. If we choose γ according to* (5.8) *then there is a Kruzkov solution u of the Cauchy problem* (5.2)*,* (3.2) *such that*

$$\lim_{\varepsilon \to 0} \|u - u^\varepsilon\|_{L^2_{loc}(\Omega_T)} = 0.$$

Since u in Theorem 5.2 is a Kruzkov solution it is not only an entropy solution in the sense of this section but also in the sense of the definition in section 2 for $d = 1$. Then we conjecture that the existence of undercompressive waves in the limit is excluded.

However, the result of Theorem 5.2 shows that the new nonlocal regularization leads also in multiple space dimensions to a well-defined limit behavior at least in the regime governed by (5.8).

Proof of Theorem 5.2. From Lemma 3.5 we know that the sequence $\{u^\varepsilon\}_{\varepsilon>0}$ is in particular uniformly bounded in $L^\infty(0,T;L^2(\mathbb{R}^d)) \subset L^2(\Omega_T)$. Thus choose $p = 2$

to apply Theorem 5.1. The first part of that theorem defines the 2-Young measure $\nu = \nu_{(\mathbf{x},t)}$ associated with $\{u^\varepsilon\}_{\varepsilon>0}$. We show first that ν satisfies (5.5). It suffices to show that

$$\int_{\Omega_T} \langle \nu_{(\mathbf{x},t)}\eta(\lambda)\rangle \psi_t(\mathbf{x},t) + \sum_{j=1}^{d} \langle \nu_{(\mathbf{x},t)}, q_j(\lambda)\rangle \psi_{x_j}(\mathbf{x},t)\, d\mathbf{x}dt \geq 0 \tag{5.9}$$

holds for all nonnegative test functions $\psi \in C_0^\infty(\Omega_T)$ and all smooth functions $\eta, q_1, \ldots, q_d$ such that η' is a bounded function and $\eta' f_j' = q_j'$, $j = 1, \ldots, d$ is satisfied. An approximation argument for the less regular Kruzkov entropies $|\cdot - k|$ yields that ν satisfies (5.9). We obtain for arbitrary nonnegative test function $\psi \in C_0^\infty(\Omega_T)$ after multiplication of (3.1) with $\eta'(u^\varepsilon)$ and integration with respect to $(\mathbf{x}, t) \in \Omega_T$,

(5.10)

$$\begin{aligned}
&\int_{\Omega_T} \eta(u^\varepsilon(\mathbf{x},t))\psi_t(\mathbf{x},t) + \sum_{j=1}^{d} q_j(u^\varepsilon(\mathbf{x},t))\psi_{x_j}(\mathbf{x},t)\, d\mathbf{x}dt \\
&= \quad -\varepsilon \int_{\Omega_T} \eta(u^\varepsilon(\mathbf{x},t))\Delta\psi(\mathbf{x},t)\, dxdt + \varepsilon \int_{\Omega_T} \eta''(u^\varepsilon(\mathbf{x},t))|\nabla u^\varepsilon(\mathbf{x},t)|^2 \psi(\mathbf{x},t)\, d\mathbf{x}dt \\
&\quad\quad + \gamma(\varepsilon) \int_{\Omega_T} \eta'(u^\varepsilon(\mathbf{x},t))([\phi_\varepsilon * u^\varepsilon(.,t)](\mathbf{x}) - u^\varepsilon(\mathbf{x},t)) \sum_{j=1}^{d} \psi_{x_j}(\mathbf{x},t)\, d\mathbf{x}dt \\
&\quad\quad + \gamma(\varepsilon) \int_{\Omega_T} \eta''(u^\varepsilon(\mathbf{x},t)) \left(\sum_{j=1}^{d} u^\varepsilon_{x_j}(\mathbf{x},t) \right) ([\phi_\varepsilon * u^\varepsilon(.,t)](\mathbf{x}) - u^\varepsilon(\mathbf{x},t))\psi(\mathbf{x},t)\, d\mathbf{x}dt \\
&= \quad I_1^\varepsilon + I_2^\varepsilon + I_3^\varepsilon + I_4^\varepsilon.
\end{aligned}$$

With Lemma 3.5 and $\|\phi_\varepsilon * u^\varepsilon\|_{L^2(\Omega_T)} \leq \|u^\varepsilon\|_{L^2(\Omega_T)}$ we can estimate for appropriate ε-independent constants $C_1, C_3, C_4 > 0$

$$|I_1^\varepsilon| \leq C_1 \varepsilon \|\eta'(u^\varepsilon)\|_{L^\infty(\Omega_T)} \|\nabla u^\varepsilon\|_{L^2(\Omega_T)} \|\nabla\psi\|_{L^2(\Omega_T)} \leq C_1\sqrt{\varepsilon} \tag{5.11}$$

and

$$|I_3^\varepsilon| \leq C_3\gamma(\varepsilon) \|\eta'(u^\varepsilon)\|_{L^\infty(\Omega_T)} \|[\phi_\varepsilon * u^\varepsilon] - u^\varepsilon\|_{L^2(\Omega_T)} \|\nabla\psi\|_{L^2(\Omega_T)} \leq C_3\gamma(\varepsilon) \tag{5.12}$$

and

(5.13)

$$|I_4^\varepsilon| \leq \gamma(\varepsilon) \|\eta''(u^\varepsilon)\|_{L^\infty(\Omega_T)} \|\nabla u^\varepsilon\|_{L^2(\Omega_T)} \|[\phi_\varepsilon * u^\varepsilon] - u^\varepsilon\|_{L^2(\Omega_T)} \|\psi\|_{L^\infty(\Omega_T)} \leq C_4 o(\varepsilon).$$

If we use (5.11), (5.12), (5.13), and $I_2^\varepsilon \geq 0$ for the limit $\varepsilon \to 0$ in (5.10), the weak convergence statement (5.7) in Theorem 5.1 shows that the Young measure $\nu_{(\mathbf{x},t)}$ satisfies (5.9). Note that $\eta, q_1, \ldots, q_d$ satisfies (5.4) by construction.

It remains to be seen whether the initial condition (5.6) is valid. We follow the argumentation in [35, Theorem 3.2] where it turns out that it is sufficient to prove that there is a constant $C_5 > 0$ such that

$$J = -\frac{1}{T} \int_0^T \int_{\mathbb{R}^d} \int_0^t u_t^\varepsilon(\mathbf{x},s)\rho(\mathbf{x})\, dsd\mathbf{x}dt \leq C_5 T \tag{5.14}$$

holds for all $\rho \in C_0^\infty(\mathbb{R}^d)$. The constant $C_5 > 0$ might depend on ρ but not on ε. Since u^ε is a classical solution of (3.1) we can use the differential equation and estimate

$$\begin{aligned} J &\leq -\frac{1}{T}\int_0^T \int_0^t \int_{\mathbb{R}^d} \sum_{j=1}^d f_j(u^\varepsilon(\mathbf{x},s))\rho_{x_j}(\mathbf{x}) + \varepsilon u^\varepsilon(\mathbf{x},s)\Delta\rho(\mathbf{x})\, d\mathbf{x}dsdt \\ &\quad + \frac{1}{T}\int_0^T \int_0^t \int_{\mathbb{R}^d} \sum_{j=1}^d \gamma(\varepsilon)\big([\phi_\varepsilon * u^\varepsilon(.,s)](\mathbf{x}) - u^\varepsilon(\mathbf{x},s)\big)\rho_{x_j}(\mathbf{x})\, d\mathbf{x}dsdt \\ &\leq C(\mathrm{supp}(\rho),\mathbf{f})\Big((1 + \|u^\varepsilon\|_{L^\infty(0,T;L^2(\mathbb{R}^d))})\|\nabla\rho\|_{L^\infty(\mathbb{R}^d)} \\ &\quad + \varepsilon\|u^\varepsilon\|_{L^\infty(0,T;L^2(\mathbb{R}^d))}\|\Delta\rho\|_{L^\infty(\mathbb{R}^d)} + \gamma(\varepsilon)\|u^\varepsilon\|_{L^\infty(0,T;L^2(\mathbb{R}^d))}\|\nabla\rho\|_{L^\infty(\mathbb{R}^d)}\Big)T. \end{aligned}$$

Note that we used (5.4) to estimate the fluxes in terms of the L^2-norm of $u^\varepsilon(.,t)$ for $t \in [0,T]$ and (3.3). Since $\|u^\varepsilon\|_{L^\infty(0,T;L^2(\mathbb{R}^d))}$ is bounded uniformly with respect to ε due to Lemma 3.5 we have proven (5.14). The second part of Theorem 5.1 concludes the proof. $\square$

ANALYSIS OF A THERMOMECHANICAL MODEL FOR SHAPE MEMORY ALLOYS*

ULISSE STEFANELLI†

Abstract. This note addresses the mathematical study of a nonlinear model arising in the description of the macroscopic thermomechanical behavior of shape memory materials and previously introduced in [R. Peyroux, A. Chrysochoos, Ch. Licht, and M. Löbel, *J. Phys. C4 Suppl.,* 6 (1996), pp. 347–356]. In particular, we discuss the model derivation and investigate a system of PDEs coupled with a vectorial variational inequality. We develop the analysis in both the dissipative and the nondissipative cases, providing indeed a quantitative asymptotic connection between the two regimes. Moreover, we prove the global in time well-posedness for suitable initial and boundary value problems. As a by-product of the well-posedness analysis, we address a variable time-step discretization procedure, proving indeed its convergence and providing some a priori error bounds. Finally, we deal with the asymptotic behavior of the system for large times and establish the convergence of the trajectories to the solution of a suitable stationary problem.

Key words. shape memory alloys, well-posedness, discretization, long-time behavior

1. Introduction.

The present analysis is concerned with the evolution of four unknown fields θ, χ_1, χ_2, and u governed by the following system of equations and inclusion:

$$\partial_t(c_s\theta - \ell\chi_1) - k\Delta\theta = r, \tag{1.1}$$

$$\operatorname{div}\sigma + b = 0, \tag{1.2}$$

$$\mathbb{A}(\varepsilon(u) + \beta\chi_2) = \sigma, \tag{1.3}$$

$$\mu\partial_t\begin{pmatrix}\chi_1\\ \chi_2\end{pmatrix} + \gamma\begin{pmatrix}\chi_1\\ \chi_2\end{pmatrix} + \begin{pmatrix}\frac{\ell}{\theta_*}(\theta-\theta_*)\\ \sigma:\beta\end{pmatrix} + \partial I_K\begin{pmatrix}\chi_1\\ \chi_2\end{pmatrix} \ni \begin{pmatrix}0\\ 0\end{pmatrix}. \tag{1.4}$$

These relations are asked to be fulfilled in the space-time domain $Q := \Omega\times(0,T)$ for some open and bounded subset $\Omega\subset\mathbb{R}^3$ with smooth boundary Γ and some reference time $T>0$. In addition c_s, ℓ, k, γ, and θ_* are positive parameters, $\mathbb{A}$ and β are, respectively, a 4-tensor and a 2-tensor, and μ is a nonnegative constant (see below). Here, $u=(u_1,u_2,u_3)\in\mathbb{R}^3$ and $\varepsilon(u)$ denotes the 2-tensor

$$\varepsilon_{ij}(u) = \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right) \quad \text{for } i,j = 1,2,3,$$

while ∂I_K stands for the subdifferential of the indicator function of the nonempty, bounded, convex, and closed subset K of $\mathbb{R}^2$, i.e., $I_K(x) = 0$ if $x\in K$ and

$I_K(x) = +\infty$ elsewhere. Namely, $\partial I_K : \mathbb{R}^2 \to 2^{\mathbb{R}^2}$ is defined by

$$y \in \partial I_K(x) \ \text{ iff } \ x \in K \ \text{ and } \ y \cdot (w - x) \leq 0 \quad \forall w \in K.$$

Moreover, $\sigma : \beta := \sigma_{ij}\beta_{ij}$ (summation convention) denotes the standard contraction product of 2-tensors, $(\operatorname{div} \sigma)_i := \partial(\sigma_{ij})/\partial x_j$ for $i = 1, 2, 3$, and $r : Q \to \mathbb{R}$ and $b : Q \to \mathbb{R}^3$ are given functions.

The nonlinear system (1.1)–(1.4) arises in connection with the study of the thermomechanical behavior of shape memory materials. These are metallic alloys with an intrinsic ability of undergoing a thermoelastic solid-solid transformation between crystallographic configurations with different physical and mechanical properties: *austenite*, which is stable at higher temperatures, and variants of *martensite*, stable at lower temperatures [2, 21]. At the macroscopic level such a reversible phase transformation results in the so-called *shape memory effect*. Namely, shape memory alloys can be permanently deformed (up to 8% under traction) and then be forced to recover their original shape just by thermal means. This unusual macroscopic mechanical effect is nowadays exploited in several innovative devices. Indeed shape memory materials are actually used in order to realize a variety of actuators (also of microscopic size) and structures. The field of application of shape memory technologies ranges from bioengineering to structures-engineering and aerospace sciences [13, 16, 30]. Here we are concerned with a macroscopic modelization previously introduced in [31] and able to describe the shape memory effect in a small deformation realm. We refer the reader to section 2 for a derivation of the model as well as for some discussion of its thermodynamical consistency. As for the justification of this modeling perspective as well as some experimental validation one should refer to the original paper [31] as well as to [14, 20, 32]. For the purposes of this introductory discussion, let us remark that the scalar field θ in (1.1)–(1.4) represents the absolute temperature of the medium while the vector field u is its displacement. Hence, the 2-tensors σ and $\varepsilon(u)$ stand for the tension and the linearized strain, respectively. Finally, K is the admissible convex and closed range for the internal variables $[\chi_1, \chi_2]$ (see below).

The current literature on the mathematical modeling of shape memory alloys is quite rich, and it is not our purpose to provide here an exhaustive review. Indeed, let us just mention that the problem of describing the thermomechanical behavior of shape memory alloys has been tackled both from the microscopic [2, 4, 5] and the macroscopic viewpoint [1, 3, 6, 18, 19, 33]. Among the latter, we shall particularly mention the so-called Frémond model for shape memory alloys. This model was originally presented in [19] and analyzed in [9]. Indeed both the present model and Frémond's model [19] are formulated in the framework of generalized standard materials by means of analogous free-energy and dissipation considerations. In particular, the phase relation of Frémond's model corresponds, in the present setting, to the choices $\mu > 0$ and $\gamma = 0$. On the contrary, the modeling considerations and the experimental evidence of [31] suggests considering the degenerate case $\mu = 0$ (taking indeed $\gamma > 0$). We will refer to the situation $\mu > 0$ as the *dissipative case* and $\mu = 0$ as the *nondissipative* one.

From the mathematical point of view, the present situation appears to be more delicate with respect to that of [9] because of the time-degeneracy of the phase relation (1.4). Moreover, let us stress that the momentum balance equation of [9] includes of a fourth order regularizing term that is actually not present in our situation.

The system (1.1)–(1.4) has to be supplied with suitable initial and boundary conditions. To this aim we ask for

$$\theta(\cdot,0) = \theta^0 \quad \text{on} \quad \Omega, \tag{1.5}$$

$$\mu\big[\chi_1(\cdot,0),\chi_2(\cdot,0)\big] = \mu\big[\chi_1^0,\chi_2^0\big] \quad \text{on} \quad \Omega, \tag{1.6}$$

$$k\partial_\nu\theta + h(\theta-\theta_e) = f \quad \text{on} \quad \Gamma, \tag{1.7}$$

$$\sigma\nu = g \quad \text{on} \quad \Gamma_t, \tag{1.8}$$

$$u = 0 \quad \text{on} \quad \Gamma_0, \tag{1.9}$$

where θ^0, χ_1^0, χ_2^0 are initial values, $h, \theta_e > 0$, $f : \Gamma \to \mathbb{R}$, and $g : \Gamma_t \to \mathbb{R}^3$ are prescribed. Moreover, ν is the unit outward normal vector to the boundary, and $\{\Gamma_0, \Gamma_t\}$ is a partition of Γ into two disjoint subsets of positive surface measure.

This paper addresses the mathematical study of the system (1.1)–(1.9) in both the dissipative ($\mu > 0$) and nondissipative ($\mu = 0$) regimes. First of all, we shall comment on the model derivation and its thermodynamical consistency. Then, we investigate the dissipative situation and provide a well-posedness result for a global variational solution (Theorem 4.1). As a by-product of this analysis we provide a variable time-step discretization scheme which turns out to be stable and convergent. Moreover, we are in the position of providing an a priori bound of optimal order on the discretization error. Then, we prove an asymptotic result that connects the dissipative and the nondissipative regimes. In particular, we prove that, as μ goes to zero, the solution of the dissipative model converges to the solution of the nondissipative one (Theorem 4.2). Indeed, we also achieve some estimate in terms of μ on the distance between the latter two solutions. As a corollary of this asymptotic result, one obtains the global variational well-posedness for the nondissipative case as well (Theorem 4.1). Then, we focus on the long-time behavior of solutions for the nondissipative model. In particular, we prove that the model actually converges to a unique equilibrium which is characterized as the solution of a suitable elliptic problem (Theorem 4.3). Finally, we turn to the proof of a suitable maximum principle which entails an essential lower bound for the temperature in terms of data (Theorem 4.4). The latter in particular ensures that, starting from a positive datum, the temperature θ remains positive for all times.

The paper is outlined as follows. We shall discuss the derivation of the model in section 2. Then, we introduce the variational formulation of the problem in section 3. Our main results are stated in section 4, while section 5 is devoted to the study of the dissipative case. In particular, it contains the details of the discretization method. The nondissipative model is investigated in section 6, and section 7 focuses on the long-time behavior of solutions. The crucial proof of the positivity of the temperature is then given in section 8.

2. Model. We devote this section to a derivation of the thermomechanical model in study [31]. Our aim is to possibly clarify the meaning of relations (1.1)–(1.4) and check for the thermodynamical consistency of the model. In particular, it is beyond our purposes to provide the reader with a full justification of this modeling perspective. Indeed, for a comprehensive discussion on the model as well as some experimental validation, the reader should refer to [31], where the model was introduced.

We will describe the thermomechanical evolution of a shape memory material with respect to its smooth reference configuration $\Omega \subset \mathbb{R}^3$ by means of the absolute temperature θ, the (small) deformation $\varepsilon(u)$ (u is the displacement), and a pair of internal variables $[\chi_1, \chi_2]$ introduced below. In particular, for the purposes of this section, θ is *assumed* to be strictly positive (this will turn out to be Theorem 4.4 later on). Let us suppose from the very beginning that only two martensitic variants are present besides one austenite and indicate the respective local proportions as η_1, η_2, and η_A, respectively. This assumption is of course extremely reductive since, in some particular alloy, up to 24 martensitic variants have been detected. Nevertheless our somewhat crude simplification is still suitable for describing the basic features of the physical phenomenon [9, 31]. We, moreover, assume that the phases possibly coexist at each point of the body, that no overlapping between different phases can occur, and that no void appears in the mixture. Hence, the phase proportions η_1, η_2, and η_A are constrained to fulfill the obvious relations

$$0 \leq \eta_1, \eta_2, \eta_A \leq 1, \quad \eta_1 + \eta_2 + \eta_A = 1.$$

We exploit these relations in order to eliminate η_A by introducing the internal variables

$$\chi_1 := \eta_1 + \eta_2, \quad \chi_2 := \eta_1 - \eta_2.$$

Of course the set $\{\chi_1 = 1\}$ corresponds to the situation where no austenite is present, the set $\{\chi_1 = \chi_2\}$ corresponds to the set where just the first variant of martensite is present, etc. Owing to the above discussion it is clear that $[\chi_1, \chi_2]$ are constrained in the triangle

$$K := \{[x_1, x_2] \in \mathbb{R}^2 : 0 \leq |x_2| \leq x_1 \leq 1\}. \tag{2.1}$$

In order to deduce the differential relations governing the evolutions of the state quantities above we will follow the approach via *microscopic motions* originally proposed by Frémond. The basic novelty of this theory is to take into account the thermomechanical effect of the microscopic rearrangements of the phases at the macroscales. In particular, one admits that the microscopic movements of the substance might give rise to some thermal macroscopic effect which influences the overall energy balance of the body. We will not review here the full theory of thermomechanics of continua with microscopic motions and just refer the reader to the recent monograph [20] for both a comprehensive discussion and a specific application to the description of shape memory materials.

To the aim of dealing with microscopic motions, let us postulate from the very beginning that the proper quantities describing such micromovements are $[\dot\chi_1, \dot\chi_2]$, where of course the dot denotes time differentiation (as it is customary, at this stage we assume that all the quantities occurring in the analysis are as smooth as needed in order to go through the differentiations).

Hence, it seems convenient to regard the vector $(u, [\dot\chi, \dot\chi_2])$ as an *actual rigid velocity vector*. Moreover, let us assume that there exists a suitable linear space of virtual rigid body velocities R (see [20] for a full discussion). Finally, we suppose that, for all times $t \in [0, T]$, the virtual power of the internal forces of the body with respect to the generic smooth subdomain $D \subset \Omega$ and virtual rigid body velocities $(v, c) \in R$ is

$$P_{int}(D, v, c) := -\int_D \sigma : \varepsilon(v) - \int_D B \cdot c.$$

The first term above is classical while the second one describes the power of microscopic internal forces. In the latter the quantity $B(\cdot) \in \mathbb{R}^2$ comes into play and an obvious dimensional argument entails that it shall be regarded as an *energy density*.

In particular, B represents and vector energy density per units of $[\dot\chi_1, \dot\chi_2]$ (see [20, sect. 13.3, p. 360]). We now introduce the virtual power of the external and acceleration forces as

$$P_{ext}(D, v, c) := \int_D b \cdot v + \int_{\partial D} g \cdot v \, d\mathcal{H}^{n-1}, \quad P_{acc}(D, v, c) := \int_D \rho \, \zeta \cdot v.$$

Here b represents an action density at distance (body force) while g is an action density at contact (traction) and we use a standard notation for the Hausdorff measure. Moreover, $\zeta = \ddot u$ is the macroscopic acceleration and ρ is the material density (no microscopic accelerations are considered). By recalling the *virtual power principle* [23], choosing arbitrarily the regular and connected domain D and the virtual rigid body velocities $(v, c) \in R$ we deduce from the relation

$$P_{acc}(D, v, c) = P_{int}(D, v, c) + P_{ext}(D, v, c)$$

two systems of momentum balance equations, namely, [20, sect. 2.4, p. 5]

$$\rho \ddot u = \operatorname{div} \sigma + b \quad \text{in } \Omega \times (0, T), \tag{2.2}$$

$$\sigma \nu = g \quad \text{on } \Gamma \times (0, T), \tag{2.3}$$

which stands for the *macroscopic momentum balance*, and

$$B = 0 \quad \text{in } \Omega \times (0, T), \tag{2.4}$$

which corresponds to the *microscopic momentum balance*. Of course, ν stands for the unit normal vector field pointing outward Γ.

Now letting e denote the internal energy density of the system and Q the entropy flux, we can follow [20, sect. 13.4, p. 361] and deduce that, in our situation, the energy balance is expressed by

$$\dot e + \operatorname{div}(\theta Q) - r = \sigma : \varepsilon(\dot u) + B \cdot [\dot\chi_1, \dot\chi_2] \quad \text{in } \Omega \times (0, T), \tag{2.5}$$

$$-\theta Q \cdot \nu = \pi \quad \text{on } \Gamma \times (0, T), \tag{2.6}$$

where r and π denote some volume and surface heat source densities, respectively. In particular, we note that the right-hand side of (2.5) takes into account the contribution to the energy balance provided by both macroscopic and microscopic movements.

The next step is to define the quantities e, Q, σ, and B in terms of the state variables in such a way that the second principle of thermodynamics, in the form of the Clausius–Duhem inequality, is fulfilled. In particular, the latter in our case reduces to

$$\dot s + \operatorname{div} Q - \frac{r}{\theta} \geq 0 \quad \text{in } \Omega \times (0, T), \tag{2.7}$$

where s is the entropy of the system and r/θ represents an external entropy source density. In order to accomplish the above requirement we will exploit the Ginzburg–Landau theory by introducing the *free energy density* $\psi = \psi(\theta, [\chi_1, \chi_2], \varepsilon(u))$ and the *pseudopotential of dissipation* $\phi = \phi(\nabla\theta, [\dot\chi_1, \dot\chi_2])$ and defining

$$s := -\frac{\partial \psi}{\partial \theta}, \quad e := \psi + \theta s, \quad Q := -\frac{\partial \phi}{\partial(\nabla\theta)}, \tag{2.8}$$

$$\sigma := \frac{\partial \psi}{\partial(\varepsilon(u))}, \tag{2.9}$$

$$B := [B_1, B_2], \quad B_j := \frac{\partial \psi}{\partial \chi_j} + \frac{\partial \phi}{\partial (\dot{\chi}_j)}, \quad j = 1, 2. \tag{2.10}$$

The above choice splits B into a *nondissipative* and a *dissipative* part, respectively, and is inspired by thermodynamic considerations (see below and [20]). Moreover, the latter notions of derivative are intended to be properly generalized in case ψ, ϕ are nonsmooth functions. At the present stage, our only requirement on the potentials ψ and ϕ is that [20, 27] ϕ is convex, nonnegative, and vanishes at 0.

We shall now check for the thermodynamic consistency of this class of models by recalling (2.5) and the above definitions in order to compute that

$$\begin{aligned} \dot{s} + \operatorname{div} Q - \frac{r}{\theta} &= \frac{1}{\theta}\left(\theta \dot{s} + \operatorname{div}(\theta Q) - r\right) - \frac{1}{\theta} Q \cdot \nabla \theta \\ &= \frac{1}{\theta}\left(\left[\frac{\partial \phi}{\partial \dot{\chi}_1}, \frac{\partial \phi}{\partial \dot{\chi}_2} \right] \cdot [\dot{\chi}_1, \dot{\chi}_2] - Q \cdot \nabla \theta \right) \geq 0, \end{aligned}$$

where we used the properties of the pseudopotential ϕ. Hence, the Clausius–Duhem inequality (2.7) easily follows from the positivity of θ. As a consequence, the general positivity proof implied by Theorem 4.4 entails the thermodynamic consistency of the whole class of models.

We now come to our actual choice of ψ [31]. In particular, we let

$$\begin{aligned} \psi(\theta, [\chi_1, \chi_2], \varepsilon(u)) &= -c_s \theta \ln \theta + \frac{1}{2}(\varepsilon(u) + \beta \chi_2) : \mathbb{A}(\varepsilon(u) + \beta \chi_2) \\ &\quad + \ell \frac{\theta_* - \theta_{**}}{2\theta_*}(\chi_1^2 + \chi_2^2) + \frac{\ell}{\theta_*}(\theta - \theta_*)\chi_1 + I_K(\chi_1, \chi_2). \end{aligned} \tag{2.11}$$

In the latter expression, the first term is purely caloric and c_s represents a specific heat density. The second term corresponds to the mechanical energy. In particular $\mathbb{A}$ is the elasticity tensor and the extra term $\beta \chi_2$ represents the mechanical effect of the presence of the two different martensitic variants. Indeed, one assumes that the mechanical potential of the material is

$$\frac{1}{2}(\varepsilon(u) + \beta_1 \eta_1 + \beta_2 \eta_2) : \mathbb{A}(\varepsilon(u) + \beta_1 \eta_1 + \beta_2 \eta_2),$$

where β_j are *transformation strain tensors* encoding the mechanical effect of the martensite-austenite phase change and are assumed to verify $\beta_1 = -\beta_2 =: \beta$ in order to take into account the so-called *self-accommodating* properties of the two martensitic variants [20, 31]. Note that the thermal expansion of the system is neglected.

The indicator function I_K forces $[\chi_1, \chi_2]$ to take solely admissible values in K and the term $\frac{\ell}{\theta_*}(\theta - \theta_*)\chi_1$ classically represents the phase–temperature interaction. In particular, ℓ is a latent heat density related to the martensite-austenite transformation and $\theta_* > 0$ is the critical martensite-to-austenite transition temperature.

The modeling novelty of this framework with respect to the original Frémond model for shape memory alloys [9, 19] consists in including into ψ the term

$$\ell \frac{\theta_* - \theta_{**}}{2\theta_*}(\chi_1^2 + \chi_2^2), \tag{2.12}$$

where a second critical transition temperature $0 < \theta_{**} < \theta_*$ is introduced for the austenite-to-martensite transformation. By referring to the zero-stress situation, one observes that in Frémond's model [9] no austenite is present for temperatures θ

below θ_* nor martensites for $\theta > \theta_*$. This simplification is, however, fairly crude and experiments suggest that one should consider a suitable temperature range where the three phases may coexist in the zero-stress situation [14, 32]. The present model [31] extends Frémond's approach in the direction of including some description of this effect. In particular, looking back to (2.4) in the zero-stress equilibrium ($[\dot\chi_1, \dot\chi_2] = 0$, $\sigma = 0$) the internal variables are asked to fulfill

$$\ell \frac{\theta_* - \theta_{**}}{\theta_*} \begin{pmatrix} \chi_1 \\ \chi_2 \end{pmatrix} + \begin{pmatrix} \frac{\ell}{\theta_*}(\theta - \theta_*) \\ 0 \end{pmatrix} + \partial I_K \begin{pmatrix} \chi_1 \\ \chi_2 \end{pmatrix} \ni \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$

which entails that

$$\chi_1 = \min \left\{ \max \left\{ \frac{\theta_* - \theta}{\theta_* - \theta_{**}}, 0 \right\}, 1 \right\}, \quad \chi_2 = 0.$$

Hence, no martensites are present for $\theta > \theta_*$, no austenite is allowed for $\theta < \theta_{**}$, and possibly all the phases are admissible for intermediate temperatures [31] (see also [20, Rem. 13.4, p. 364]).

As for the pseudopotential of dissipation we will ask for

$$\phi(\nabla\theta, [\dot\chi_1, \dot\chi_2]) := \frac{k}{2\theta} |\nabla\theta|^2 + \frac{\mu}{2} \dot\chi_1^2 + \frac{\mu}{2} \dot\chi_2^2.$$

Here $k > 0$ stands for a constant thermal conductivity coefficient and $\mu \geq 0$ measures some dissipation effect on the phase variables. In particular, the heat flux $q := \theta Q = -k\nabla\theta$ is of Fourier type.

Finally, the balance relations (2.5), (2.2), and (2.4) read as follows:

$$c_s \dot\theta - \ell \dot\chi_1 - k\Delta\theta - r = -\frac{\ell}{\theta_*}(\theta - \theta_*)\dot\chi_1 + \mu \dot\chi_1^2 + \mu \dot\chi_2^2, \tag{2.13}$$

$$\rho \ddot u = \operatorname{div} \sigma + b, \tag{2.14}$$

$$\mu \begin{pmatrix} \dot\chi_1 \\ \dot\chi_2 \end{pmatrix} + \ell \frac{\theta_* - \theta_{**}}{\theta_*} \begin{pmatrix} \chi_1 \\ \chi_2 \end{pmatrix} + \begin{pmatrix} \frac{\ell}{\theta_*}(\theta - \theta_*) \\ \sigma : \beta \end{pmatrix} + \partial I_K \begin{pmatrix} \chi_1 \\ \chi_2 \end{pmatrix} \ni \begin{pmatrix} 0 \\ 0 \end{pmatrix}. \tag{2.15}$$

We shall focus our attention from the very beginning on the *quasi-static* situation where the inertial term $\rho \ddot u$ is negligible in (2.14). Indeed, let us stress that the latter approximation of the momentum balance equation is rather standard in connection with the Frémond model [9, 10, 12, 24] and translates into the belief that the mechanical evolution takes place on some faster time scale when compared with the thermal evolution. On the other hand, the reader is referred to [8], where the full momentum problem is considered for Frémond's model (see also [15, 22, 25] and the recent monograph [26] for the analysis of mechanical evolution under different nonconvex settings).

In order to deduce the system (1.1)–(1.4) from (2.9) and (2.13)–(2.15) we now apply some further modification to the balance relations by means of suitable small perturbation assumptions. At first, one supposes to be interested in a temperature range close to the critical temperature θ_* and neglects the first term in the right-hand side of (2.13). By setting, for the sake of notational simplicity, $\gamma := \ell(\theta_* - \theta_{**})/\theta_*$, we readily check that the system (1.1)–(1.4) in the nondissipative regime $\mu = 0$ follows directly from (2.9) and (2.13), (2.15), and (2.14) in its quasi-static form.

As for the nondissipative regime $\mu > 0$ we shall additionally assume to be interested in a situation where the phase evolution is suitably slow, i.e., $\mu \dot\chi_j^2 = 0$ in the energy balance equation (2.13). On the other hand we retain the dissipation term $\mu[\dot{\chi}_1, \dot{\chi}_2]$ in (2.15). This is of course again an assumption of small perturbation type.

Finally, as for boundary conditions (1.7)–(1.9), one assumes to know g in (2.3) just on Γ_t and imposes the body to be clamped on Γ_0. Moreover, we choose $\pi := f + h(\theta_e - \theta)$, where f is a prescribed surface heat source density, $h > 0$ is a thermal exchange coefficient, and $\theta_e > 0$ is a given external temperature.

3. Variational formulation. We start by fixing some notation. Let

$$H := L^2(\Omega), \quad \mathcal{H} := H \times H \times H, \quad V := H^1(\Omega),$$
$$\mathbb{H} := \{\sigma : \Omega \to \mathbb{R}^{3\times 3}_{symm} \text{ measurable such that } \sigma : \sigma \in L^1(\Omega)\},$$

where $\mathbb{R}^{3\times 3}_{symm}$ denotes of course the space of 3×3 symmetric tensors. All the above spaces are endowed with their respective natural scalar products. In particular, we will use the symbols $(\cdot, \cdot)$ and $\|\cdot\|$ for all products and norms in the above L^2-type spaces. Moreover, the notation $(\cdot, \cdot)_\Gamma$ will stand for the scalar product in both $L^2(\Gamma)$ and $(L^2(\Gamma))^3$, $|\cdot|$ denotes any Euclidean norm, $\|\cdot\|_E$ will stand for the norm in the generic normed space E, and $[\cdot, \cdot]$ denotes the generic pair. We introduce the Hilbert space

$$\mathcal{V} := \{v \in V^3 \text{ such that } v = 0 \text{ on } \Gamma_0\},$$

endowed with the standard norm, and set, for any $u, v \in \mathcal{V}$,

$$a(u, v) := (\mathbb{A}\varepsilon(u), \varepsilon(v)),$$

where $\varepsilon : \mathcal{V} \to \mathbb{H}$ stands for the linearized strain tensor. Following the classic linear elasticity theory, we ask $\mathbb{A} = (a_{ijkh})$ to be symmetric and positive definite on $\mathbb{R}^{3\times 3}_{symm}$, namely,

$$a_{ijkh} = a_{ijhk} = a_{khij} \quad \forall i, j, h, k = 1, 2, 3 \quad \text{and} \quad \mathbb{A}\sigma : \sigma > 0 \quad \forall \sigma \in \mathbb{R}^{3\times 3}_{symm}/\{0\}.$$

Namely, for all $\sigma, \tau \in \mathbb{R}^{3\times 3}_{symm}$ one has that $\mathbb{A}\sigma : \tau = \sigma : \mathbb{A}\tau = \mathbb{A}^{\frac{1}{2}}\sigma : \mathbb{A}^{\frac{1}{2}}\tau$, where $\mathbb{A}^{\frac{1}{2}}$ stands for the well-defined square root of $\mathbb{A}$. In particular, since $\beta \neq 0$, we readily compute that $\mathbb{A}^{\frac{1}{2}}\beta \neq 0$ as well. Moreover, recalling the Γ_0 has a positive surface measure, and thanks to Korn's inequality (see, e.g., [17, Thm. 3.3, p. 115]), there exists a positive constant $c_\mathcal{V}$ depending on $\mathbb{A}$ such that

$$a(v, v) \ = \ \|\mathbb{A}^{\frac{1}{2}}\varepsilon(v)\|^2 \ \geq \ c_\mathcal{V}\|v\|^2_\mathcal{V} \quad \forall v \in \mathcal{V}.$$

Finally, let the notation $\langle \cdot, \cdot \rangle$ stand for the duality pairing between V' and V or $\mathcal{V}'$ and $\mathcal{V}$, where the prime denotes the topological duals. Since the special triangular form of K specified above is not needed for our analysis, let K be an arbitrary nonempty, bounded, convex, and closed subset of $\mathbb{R}^2$, and define the (convex and closed) set $\mathcal{K} := \big\{[x_1, x_2] \in (L^2(\Omega))^2 \text{ such that } [x_1, x_2] \in K \text{ a.e. in } \Omega\big\}$. For almost every $t \in (0, T)$ let us define the functionals $F(t) : V \to V'$ and $G(t) : \mathcal{V} \to \mathcal{V}'$ as

$$\langle F(t), \varphi \rangle := (r(t), \varphi) + (f(t), \varphi)_\Gamma \quad \forall \varphi \in V,$$
$$\langle G(t), v \rangle := (b(t), v) + (g(t), v)_\Gamma \quad \forall v \in \mathcal{V}.$$

We shall make precise our variational formulation of (1.1)–(1.9) by posing the following problem.

Problem P_μ. Find $\theta \in H^1(0,T;H) \cap L^\infty(0,T;V)$, $[\chi_1, \chi_2] \in (H^1(0,T;H) \cap L^\infty(Q))^2$, and $u \in H^1(0,T;\mathcal{V})$ such that $\mu(\chi_1,\chi_2) \in (W^{1,\infty}(0,T;H))^2$ and

$$\big((c_s\theta - \ell\chi_1)_t, \varphi\big) + k(\nabla\theta, \nabla\varphi) + h(\theta - \theta_e, \varphi)_\Gamma = \langle F, \varphi\rangle \quad \forall \varphi \in V \quad \text{a.e. in } (0,T), \tag{3.1}$$

$$a(u,v) + (\mathbb{A}\beta\chi_2, \varepsilon(v)) = \langle G, v\rangle \quad \forall v \in \mathcal{V} \text{ a.e. in } (0,T), \tag{3.2}$$

$$\mathbb{A}(\varepsilon(u) + \beta\chi_2) = \sigma \quad \text{a.e. in } Q, \tag{3.3}$$

$$\mu\partial_t\begin{pmatrix}\chi_1\\ \chi_2\end{pmatrix} + \gamma\begin{pmatrix}\chi_1\\ \chi_2\end{pmatrix} + \partial I_K\begin{pmatrix}\chi_1\\ \chi_2\end{pmatrix} \ni \begin{pmatrix}\frac{\ell}{\theta_*}(\theta_* - \theta)\\ -\sigma : \beta\end{pmatrix} \quad \text{a.e. in } Q, \tag{3.4}$$

$$c_s\theta(\cdot,0) - \ell\chi_1(\cdot,0) = c_s\theta^0 - \ell\chi_1^0 \quad \text{a.e. in } \Omega, \tag{3.5}$$

$$\mu\big[\chi_1(\cdot,0), \chi_2(\cdot,0)\big] = \mu\big[\chi_1^0, \chi_2^0\big] \quad \text{a.e. in } \Omega. \tag{3.6}$$

Remark 3.1. Let us stress that the above regularity requirements and (3.3) entail, in particular, that $\sigma \in H^1(0,T;\mathbb{H})$. Namely, relation (3.4) makes sense.

4. Main results. We shall assume the following:

(A1) $F \in L^2(0,T;H) + W^{1,1}(0,T;V')$, $G \in H^1(0,T;\mathcal{V}')$,
(A2) $\theta^0 \in V$,
(A3) $[\chi_1^0, \chi_2^0] \in \mathcal{K}$.

In particular, the first formula in (A1) entails that there exist $F_1 \in L^2(0,T;H)$ and $F_2 \in W^{1,1}(0,T;V')$ such that $F = F_1 + F_2$. We observe that whenever $r \in L^2(0,T;H)$, $f \in W^{1,1}(0,T;L^2(\Gamma))$, $b \in H^1(0,T;\mathcal{H})$, and $g \in H^1(0,T;(L^2(\Gamma))^3)$ the regularities in (A1) follow. As a consequence of (A1)–(A3), we introduce $u^0 \in \mathcal{V}$ as the unique solution to (3.2) at time $t=0$, $\sigma^0 \in \mathbb{H}$ via u^0 and (3.3), and finally

$$\mu[\chi_{1,\mu,t}(0), \chi_{2,\mu,t}(0)] := \left[\frac{\ell}{\theta_*}(\theta_* - \theta^0) - \gamma\chi_1^0, -\sigma^0 : \beta - \gamma\chi_2^0\right].$$

In particular, we observe that the left-hand side above is bounded in $H \times H$, uniformly with respect to μ, and that relation (3.4) is fulfilled also for $t=0$.

We are now in a position to state our results.

THEOREM 4.1 (well-posedness). *Let $\mu \geq 0$. Under the assumptions* (A1)–(A3), *there exists a unique solution to Problem P_μ. Moreover, given two sets of data $(F_i, G_i, \theta_i^0, \chi_{1,i}^0, \chi_{2,i}^0)$ fulfilling* (A1)–(A3) *and two external temperatures $\theta_{e,i}$, for $i=1,2$, the respective solutions $(\theta_i, \chi_{1,i}, \chi_{2,i}, u_i)$ to the corresponding problems P_μ fulfill*

$$\begin{aligned}
&\|\theta_1 - \theta_2\|^2_{L^2(0,T;H)} + \sup_{t\in[0,T]}\left\|\int_0^t \nabla(\theta_1 - \theta_2)\right\|^2 + \sup_{t\in[0,T]}\left\|\int_0^t (\theta_1 - \theta_2)\right\|^2_{L^2(\Gamma)} \\
&\quad + \sum_{j=1}^2 \big(\mu\|\chi_{j,1} - \chi_{j,2}\|^2_{C([0,T];H)} + \|\chi_{j,1} - \chi_{j,2}\|^2_{L^2(0,T;H)}\big) + \|u_1 - u_2\|^2_{L^2(0,T;\mathcal{V})} \\
&\leq c_0\left(\int_0^T \left\|\int_0^t (F_{1,1} - F_{1,2})\right\|^2 dt + \|F_{2,1} - F_{2,2}\|^2_{L^1(0,T;V')} + \|G_1 - G_2\|^2_{L^2(0,T;\mathcal{V}')}\right. \\
&\qquad \left. + \|c_s(\theta_1^0 - \theta_2^0) - \ell(\chi_{1,1}^0 - \chi_{1,2}^0)\|^2 + \mu\|\chi_{2,1}^0 - \chi_{2,2}^0\|^2 + |\theta_{e,1} - \theta_{e,2}|^2\right),
\end{aligned} \tag{4.1}$$

where c_0 depends on c_s, k, h, ℓ, γ, Γ, $\mathbb{A}^{\frac12}\beta$, θ_*, and $c_{\mathcal{V}}$ but is independent of μ.

THEOREM 4.2 (dissipation asymptotics). *Under the assumptions* (A1)–(A3), *the solution* $(\theta_\mu, \chi_{1,\mu}, \chi_{2,\mu}, u_\mu)$ *to Problem* P_μ *converges as* $\mu \to 0$ *to the solution* $(\theta, \chi_1, \chi_2, u)$ *of Problem* P_0 *at least weakly in the respective natural spaces.*

Moreover, we will address the study of the long-time behavior of the solution to Problem P_0. Indeed, the reader should notice that the above-stated well-posedness result is actually independent of the choice of the reference time T. Hence, in particular, the solution $(\theta, \chi_1, \chi_2, u)$ to Problem P_0 may be uniquely extended for all times. Now let the ω-limit set be defined as

$$\begin{aligned}\omega\big(\theta, \chi_1, \chi_2, u\big) := \{\big(\theta_\infty, \chi_{1,\infty}, \chi_{2,\infty}, u_\infty\big) \in H \times H \times H \times \mathcal{V} \quad &\text{such that there exists}\\ \text{a sequence of positive real numbers} \quad \{t_n\} \quad \text{with} \quad t_n \longrightarrow +\infty \quad &\text{and}\\ \big(\theta(t_n), \chi_1(t_n), \chi_2(t_n), u(t_n)\big) \longrightarrow \big(\theta_\infty, \chi_{1,\infty}, \chi_{2,\infty}, u_\infty\big) \quad \text{in} \quad &H \times H \times H \times \mathcal{V}\}.\end{aligned}$$

To establish a long-time behavior result, we need some further assumptions on the data. In particular, we ask for

(A4) $F \in L^2(0, +\infty; H)$, $G \in H^1(0, +\infty, \mathcal{V}')$.

Hence, the following holds true.

THEOREM 4.3 (long-time behavior). *Under assumptions* (A2)–(A4)*, the* ω*-limit set* $\omega\big(\theta, \chi_1, \chi_2, u\big)$ *reduces to the unique solution to the problem*

$$\theta_\infty = \theta_e \quad a.e. \ in \ \ \Omega, \tag{4.2}$$

$$a(u_\infty, v) + (\mathbb{A}\beta\chi_{2,\infty}, \varepsilon(v)) = 0 \quad \forall v \in \mathcal{V}, \tag{4.3}$$

$$\mathbb{A}(\varepsilon(u_\infty) + \beta\chi_{2,\infty}) = \sigma_\infty \quad a.e. \ in \ \ \Omega, \tag{4.4}$$

$$\gamma\begin{pmatrix}\chi_{1,\infty}\\ \chi_{2,\infty}\end{pmatrix} + \partial I_K\begin{pmatrix}\chi_{1,\infty}\\ \chi_{2,\infty}\end{pmatrix} \ni \begin{pmatrix}\frac{\ell}{\theta_*}(\theta_* - \theta_e)\\ -\sigma_\infty : \beta\end{pmatrix} \quad a.e. \ in \ \ \Omega. \tag{4.5}$$

Namely, the whole trajectory converges to $(\theta_\infty, \chi_{1,\infty}, \chi_{2,\infty}, u_\infty)$ *as* $t \to +\infty$*.*

We close this section by stating precisely a maximum principle for the temperature θ which entails its positivity in the frame of our concrete modeling situation. To this aim, of course some sign assumption on the external heat sources is needed and we will ask for

(A5) $\langle F(t), v\rangle \geq 0$ for a.e. $t \in (0, T)$ and all $v \in V$ with $v \geq 0$ a.e. in Ω.

The latter follows for instance when f, $r \geq 0$ almost everywhere in their respective domains and could clearly be weakened. One has the following.

THEOREM 4.4 (lower bound). *Let* $\mu \geq 0$*. Under assumptions* (2.1), (A1)–(A3), *and* (A5)*, let* $\theta_d \in \mathbb{R}$ *be such that*

$$\gamma + \frac{\ell}{\theta_*}(\theta_d - \theta_*) \leq 0. \tag{4.6}$$

Then, the unique solution $(\theta, [\chi_1, \chi_2], u)$ *to Problem* P_μ *fulfills*

$$\inf\{\inf \theta_0, \, \theta_e, \, \theta_*, \theta_d\} \leq \theta(x, t) \quad for\ a.e. \ \ (x, t) \in Q, \tag{4.7}$$

where $\inf \theta_0$ *stands for the essential infimum of* θ_0 *on* Ω*.*

Clearly, in order to deduce from the above-stated lower bound (4.7) a positivity result for θ (and consequently a proof of the thermodynamical consistency of the model; see section 2) one has to start from a positive initial datum θ_0 and ask for the existence of a positive constant θ_d fulfilling (4.6). Let us stress that this second requirement is compatible with our modeling situation since, owing to the discussion of section 2,

$$\gamma+\frac{\ell}{\theta_*}(\theta_d-\theta_*)=\frac{\ell}{\theta_*}(\theta_*-\theta_{**})+\frac{\ell}{\theta_*}(\theta_d-\theta_*)=\frac{\ell}{\theta_*}(\theta_d-\theta_{**}),$$

and it suffices to choose $0<\theta_d\leq\theta_{**}$ in order to achieve (4.6).

5. Dissipative problem. Throughout this section, the dissipation parameter μ is fixed and strictly positive.

5.1. Continuous dependence. Let us denote by $(\theta_i,\chi_{1,i},\chi_{2,i},u_i)$ for $i=1,2$ two solutions to Problem P_μ associated to the given two sets of data $(F_i,G_i,\theta_i^0,\chi_{1,i}^0,$ $\chi_{2,i}^0)$, and $\theta_{e,i}$ for $i=1,2$. We set $\overline{\theta}:=\theta_1-\theta_2$, $\overline{u}:=u_1-u_2$, and so on. Let us take the integral on $(0,t)$, for $t\in(0,T]$, of relation (3.1) written for $(\theta_1,\chi_{1,1},\chi_{2,1},u_1)$ and subtract the same relation for $(\theta_2,\chi_{1,2},\chi_{2,2},u_2)$, choose $\varphi:=\overline{\theta}$, and integrate on $(0,t)$ for $t\in(0,T]$. We readily obtain that

$$\begin{aligned}(5.1)\qquad & c_s\int_0^t\|\overline{\theta}\|^2+\frac{k}{2}\left\|\int_0^t\nabla\overline{\theta}\right\|^2+\frac{h}{2}\left\|\int_0^t\overline{\theta}\right\|^2_{L^2(\Gamma)}\\ &\leq\int_0^t\left(\|c_s\overline{\theta}^0-\ell\overline{\chi}_1^0\|+\left\|\int_0^s\overline{F}_1\right\|\right)\|\overline{\theta}\|\,ds\\ &+\int_0^t\left\langle\int_0^s\overline{F}_2,\overline{\theta}\right\rangle ds+h\int_0^t(s\overline{\theta}_e,\overline{\theta})_\Gamma ds+\ell\int_0^t(\overline{\theta},\overline{\chi}_1).\end{aligned}$$

Let us now take the difference between relation (3.4) written for $(\theta_1,\chi_{1,1},\chi_{2,1},u_1)$ and the same relation for $(\theta_2,\chi_{1,2},\chi_{2,2},u_2)$, multiply the corresponding relation by $[\overline{\chi}_1,\overline{\chi}_2]$, exploit the monotonicity of the subdifferential, and integrate on $\Omega\times(0,t)$ for $t\in(0,T]$. We get

$$(5.2)\quad \sum_{j=1}^2\left(\frac{\mu}{2}\|\overline{\chi}_j(t)\|^2+\gamma\int_0^t\|\overline{\chi}_j\|^2\right)\leq\sum_{j=1}^2\frac{\mu}{2}\|\overline{\chi}_j^0\|^2-\frac{\ell}{\theta_*}\int_0^t(\overline{\theta},\overline{\chi}_1)-\int_0^t(\overline{\sigma}:\beta,\overline{\chi}_2).$$

As for the last term in the right-hand side of (5.2) we take advantage of (3.2)–(3.3) and readily compute that

$$(5.3)\qquad -\overline{\sigma}:\beta=-\mathbb{A}^{\frac12}\varepsilon(\overline{u}):\mathbb{A}^{\frac12}\beta-|\mathbb{A}^{\frac12}\beta|^2\overline{\chi}_2,$$

$$(5.4)\qquad \int_0^t\|\mathbb{A}^{\frac12}\varepsilon(\overline{u})\|^2=-\int_0^t(\mathbb{A}^{\frac12}\varepsilon(\overline{u}):\mathbb{A}^{\frac12}\beta,\overline{\chi}_2)+\int_0^t\langle\overline{G},\overline{u}\rangle.$$

Hence, by choosing $1<\rho<(\gamma+|\mathbb{A}^{\frac12}\beta|^2)/|\mathbb{A}^{\frac12}\beta|^2$, we take the sum between (5.2) and (5.4) in order to obtain

$$\begin{aligned}&\sum_{j=1}^2\left(\frac{\mu}{2}\left(\|\overline{\chi}_j(t)\|^2-\|\overline{\chi}_j^0\|^2\right)+\gamma\int_0^t\|\overline{\chi}_j\|^2\right)+\int_0^t\|\mathbb{A}^{\frac12}\varepsilon(\overline{u})\|^2\\ &\quad\leq-\frac{\ell}{\theta_*}\int_0^t(\overline{\theta},\overline{\chi}_1)-2\int_0^t(\mathbb{A}^{\frac12}\varepsilon(\overline{u}):\mathbb{A}^{\frac12}\beta,\overline{\chi}_2)-|\mathbb{A}^{\frac12}\beta|^2\int_0^t\|\overline{\chi}_2\|^2+\int_0^t\langle\overline{G},\overline{u}\rangle\\ &\quad\leq-\frac{\ell}{\theta_*}\int_0^t(\overline{\theta},\overline{\chi}_1)+(\rho-1)|\mathbb{A}^{\frac12}\beta|^2\int_0^t\|\overline{\chi}_2\|^2+\frac{1}{\rho}\int_0^t\|\mathbb{A}^{\frac12}\varepsilon(\overline{u})\|^2+\int_0^t\langle\overline{G},\overline{u}\rangle.\end{aligned}$$

Then, multiplying (5.2) by $1/\theta_*$ and taking the sum with the above relation, one has

$$
\begin{aligned}
(5.5)\quad & \frac{c_s}{\theta_*}\int_0^t \|\overline{\theta}\|^2 + \frac{k}{2\theta_*}\left\|\int_0^t \nabla\overline{\theta}\right\|^2 + \frac{h}{2\theta_*}\left\|\int_0^t \overline{\theta}\right\|^2_{L^2(\Gamma)} + \frac{\mu}{2}\sum_{j=1}^{2}\|\overline{\chi}_j(t)\|^2 \\
&+\gamma\int_0^t \|\overline{\chi}_1\|^2 + \big(\gamma+(1-\rho)|\mathbb{A}^{\frac12}\beta|^2\big)\int_0^t \|\overline{\chi}_2\|^2 + \frac{\rho-1}{\rho}\int_0^t \|\mathbb{A}^{\frac12}\varepsilon(\overline{u})\|^2 \\
&\le \frac{1}{\theta_*}\int_0^t \left(\|c_s\overline{\theta}^0 - \ell\overline{\chi}_1^0\| + \left\|\int_0^s \overline{F}_1\,ds\right\|\right)\|\overline{\theta}\| + \frac{1}{\theta_*}\int_0^t \left\langle \int_0^s \overline{F}_2\,ds, \overline{\theta}\right\rangle \\
&+\frac{h}{\theta_*}\int_0^t (s\overline{\theta}_e,\overline{\theta})_\Gamma ds + \sum_{j=1}^{2}\frac{\mu}{2}\|\overline{\chi}_j^0\|^2 + \int_0^t \langle \overline{G},\overline{u}\rangle.
\end{aligned}
$$

Finally, the assertion follows from an integration by parts.

5.2. Discretization. Let us introduce our variable time-step discretization of P_μ. To this aim we define the partition $\mathcal{P} := \big\{0 = t_0 < t_1 < \cdots < t_{N-1} < t_N = T\big\}$ with variable time-step $\tau_i := t_i - t_{i-1}$ and let $\tau := \max_{1\le i\le N}\tau_i$ denote the diameter of the partition $\mathcal{P}$. In the forthcoming analysis the following notation will be extensively used: $\{w_i\}_{i=0}^N$ being a vector, we denote by $w_{\mathcal{P}}$ and $\overline{w}_{\mathcal{P}}$ two functions of the time interval $[0,T]$ which interpolate the values of the vector $\{w_i\}$ piecewise linearly and backward constantly on the partition $\mathcal{P}$, respectively. Namely,

$$
\begin{aligned}
w_{\mathcal{P}}(0) &:= w_0, \quad w_{\mathcal{P}}(t) := g_i(t)w_i + \big(1-g_i(t)\big)w_{i-1}, \\
\overline{w}_{\mathcal{P}}(0) &:= w_0, \quad \overline{w}_{\mathcal{P}}(t) := w_i \quad \text{for } t\in(t_{i-1},t_i], \quad i=1,\dots,N,
\end{aligned}
$$

where $g_i(t) := (t-t_{i-1})/\tau_i$ for $t\in(t_{i-1},t_i]$, $i=1,\dots,N$. Moreover, given a vector $\{w_i\}_{i=0}^N$, we define another vector $\{\delta w_i\}_{i=1}^N$ as $\delta w_i := (w_i - w_{i-1})/\tau_i$.

Finally, we introduce some approximation of the data. Hence, let $F = F_1 + F_2$, where $F_1 \in L^2(0,T;H)$ and $F_2 \in W^{1,1}(0,T;V')$, and set

$$(5.6)\qquad F_{1,i} := \frac{1}{\tau_i}\int_{t_{i-1}}^{t_i} F_1(s)\,ds \ \in H \quad \text{for } i=1,\dots,N,$$

$$(5.7)\qquad F_{2,1} := F_2(t_i) \ \in V' \quad \text{for } i=0,1,\dots,N,$$

$$(5.8)\qquad G_i := G(t_i) \ \in \mathcal{V}' \quad \text{for } i=0,1,\dots,N.$$

Of course, owing to (A1), the latter positions are justified. In particular, let us remark that one has

$$(5.9)\qquad \overline{F}_{1,\mathcal{P}} \to F_1 \ \text{ strongly in } L^2(0,T;H),$$

$$(5.10)\qquad F_{2,\mathcal{P}} \to F_2 \ \text{ strongly in } W^{1,1}(0,T;V'),$$

$$(5.11)\qquad G_{\mathcal{P}} \to G \ \text{ strongly in } H^1(0,T;\mathcal{V}')$$

whenever the diameter τ of partition $\mathcal{P}$ goes to 0.

Hence, we are interested in the following discrete problem.

Problem D_μ. Find $\{\theta_i\}_{i=0}^N \in V^{N+1}$, $\{[\chi_{1,i},\chi_{2,i}]\}_{i=0}^N \in \mathcal{K}^{N+1}$, and $\{u_i\}_{i=1}^N \in \mathcal{V}^N$ such that, for all $i=1,\dots,N$,

$$\big((c_s\delta\theta_i - \ell\delta\chi_{1,i}),\varphi\big) + k(\nabla\theta_i,\nabla\varphi) + h(\theta_i-\theta_e,\varphi)_\Gamma = \langle F_i,\varphi\rangle \quad \forall\varphi\in V, \tag{5.12}$$

$$a(u_i,v) + (\mathbb{A}\beta\chi_{2,i},\varepsilon(v)) = \langle G_i,v\rangle \quad \forall v\in\mathcal{V}, \tag{5.13}$$

$$\mathbb{A}(\varepsilon(u_i)+\beta\chi_{2,i}) = \sigma_i \quad \text{a.e. in } \Omega, \tag{5.14}$$

$$\mu\begin{pmatrix}\delta\chi_{1,i}\\ \delta\chi_{2,i}\end{pmatrix} + \gamma\begin{pmatrix}\chi_{1,i}\\ \chi_{2,i}\end{pmatrix} + \begin{pmatrix}\frac{\ell}{\theta_*}(\theta_i-\theta_*)\\ \sigma_i:\beta\end{pmatrix} + \partial I_K\begin{pmatrix}\chi_{1,i}\\ \chi_{2,i}\end{pmatrix} \ni \begin{pmatrix}0\\0\end{pmatrix} \quad \text{a.e. in } \Omega, \tag{5.15}$$

$$\theta_0 = \theta^0 \quad \text{a.e. in } \Omega, \tag{5.16}$$

$$\mu[\chi_{1,0},\chi_{2,0}] = \mu[\chi_1^0,\chi_2^0] \quad \text{a.e. in } \Omega. \tag{5.17}$$

5.3. Discrete well-posedness. We prove the following lemma.

LEMMA 5.1. *Under the assumptions* (A1)–(A3), (5.6)–(5.8)*, and for all* τ *sufficiently small, problem* D_μ *has a unique solution.*

Proof. We proceed by induction. Namely, we assume to know the solution of the problem up to level $i-1$ and solve for level i. In particular, we are concerned with the problem of finding $\theta_i\in V$, $[\chi_{1,i},\chi_{2,i}]\in\mathcal{K}$, and $u_i\in\mathcal{V}$ such that

$$\big((c_s\theta_i - \ell\chi_{1,i}),\varphi\big) + \tau_i k(\nabla\theta_i,\nabla\varphi) + \tau_i h(\theta_i-\theta_e,\varphi)_\Gamma = \langle F_i^*,\varphi\rangle \quad \forall\varphi\in V, \tag{5.18}$$

$$a(u_i,v) + (\mathbb{A}\beta\chi_{2,i},\varepsilon(v)) = \langle G_i,v\rangle \quad \forall v\in\mathcal{V}, \tag{5.19}$$

$$\mathbb{A}(\varepsilon(u_i)+\beta\chi_{2,i}) = \sigma_i \quad \text{a.e. in } \Omega, \tag{5.20}$$

$$\mu\begin{pmatrix}\chi_{1,i}\\ \chi_{2,i}\end{pmatrix} + \tau_i\begin{pmatrix}\gamma\chi_{1,i}+\frac{\ell}{\theta_*}(\theta_i-\theta_*)\\ \gamma\chi_{2,i}+\sigma_i:\beta\end{pmatrix} + \partial I_K\begin{pmatrix}\chi_{1,i}\\ \chi_{2,i}\end{pmatrix} \ni \mu\begin{pmatrix}\chi_{1,i-1}\\ \chi_{2,i-1}\end{pmatrix} \quad \text{a.e. in } \Omega, \tag{5.21}$$

where we collected in the right-hand sides of (5.18)–(5.19) and (5.21) the quantities known at level i and let $F_i^* := \tau_i F_i + c_s\theta_{i-1} - \ell\chi_{1,i-1}$. We shall stress that the latter scheme is of course fully implicit.

Let us now fix $[\tilde\chi_1,\tilde\chi_2]\in\mathcal{K}$. It is then straightforward to find the unique solutions $\theta\in V$ and $u\in\mathcal{V}$ to (5.18) with $\tilde\chi_1$ instead of $\chi_{1,i}$ and (5.19) with $\tilde\chi_2$ instead of $\chi_{2,i}$, respectively. Hence, we have implicitly defined a mapping $T_1:\mathcal{K}\to V\times\mathcal{V}$ as $T_1[\tilde\chi_1,\tilde\chi_2] := [\theta,u]$. On the other hand, for all $(\tilde\theta,\tilde u,\tilde\chi_2)\in V\times\mathcal{V}\times H$ there exists a unique pair $[\chi_1,\chi_2]\in\mathcal{K}$ solving relation (5.21) with $(\tilde\theta,\tilde u)$ instead of (θ_i,u_i) and σ_i is defined by (5.20) with $\tilde\chi_2$ instead of $\chi_{2,i}$. Thus, one may define a mapping $T_2: V\times\mathcal{V}\times H\to\mathcal{K}$ as $T_2(\tilde\theta,\tilde u,\tilde\chi_2) = [\chi_1,\chi_2]$.

Our next aim is to prove that, for sufficiently small τ, the mapping $T_3:\mathcal{K}\to\mathcal{K}$ defined as $T_3[\tilde\chi_1,\tilde\chi_2] := T_2(T_1[\tilde\chi_1,\tilde\chi_2],\tilde\chi_2)$ is a contraction in $H\times H$. To this end let $[\tilde\chi_{1,j},\tilde\chi_{2,j}]\in\mathcal{K}$, $[\theta_j,u_j] = T_1[\tilde\chi_{1,j},\tilde\chi_{2,j}]$, $[\chi_{1,j},\chi_{2,j}] := T_3[\tilde\chi_{1,j},\tilde\chi_{2,j}]$ for $j=1,2$, and define $\overline\theta := \theta_1-\theta_2$, $\overline u := u_1-u_2$, etc. Hence, we readily check that

$$(c_s\overline\theta,\varphi) + \tau_i(\nabla\overline\theta,\nabla\varphi) + \tau_i h(\overline\theta,\varphi)_\Gamma = (\ell\overline{\tilde\chi}_1,\varphi) \quad \forall\varphi\in V,$$
$$a(\overline u,v) + (\mathbb{A}\beta\overline{\tilde\chi}_2,\varepsilon(v)) = 0 \quad \forall v\in\mathcal{V},$$
$$\sigma:\beta = \mathbb{A}\varepsilon(\overline u):\beta + \mathbb{A}\beta\overline{\tilde\chi}_2:\beta.$$

Namely, by choosing $[\varphi,v] = [\overline\theta,\overline u]$ above one gets that

$$\|\overline\theta\| \le \frac{\ell}{c_s}\|\overline{\tilde\chi}_1\|, \quad \|\mathbb{A}^{\frac12}\varepsilon(\overline u)\| \le c_1\|\overline{\tilde\chi}_2\|, \quad \|\overline\sigma:\beta\| \le c_1\|\overline{\tilde\chi}_2\|, \tag{5.22}$$

where c_1 depends only on $\mathbb{A}^{\frac{1}{2}}\beta$. On the other hand, we exploit (5.21) and get that

$$\begin{pmatrix}\chi_{1,j}\\ \chi_{2,j}\end{pmatrix} = (1+\partial I_K)^{-1}\left(\frac{\tau_i}{\mu+\tau_i\gamma}\right)\begin{pmatrix}\frac{\ell}{\theta_*}(\theta_*-\theta_j)+\mu\chi_{1,i-1}/\tau_i\\ -\sigma_j:\beta+\mu\chi_{2,i-1}/\tau_i\end{pmatrix} \quad \text{for} \quad j=1,2.$$

In particular, also using (5.22), one computes that

$$\begin{aligned}\|\overline{\chi}_1\|^2+\|\overline{\chi}_2\|^2 &\le \left(\frac{\tau_i}{\mu+\tau_i\gamma}\right)^2\left(\left\|\frac{\ell}{\theta_*}\overline{\theta}\right\|^2+\|\overline{\sigma}:\beta\|^2\right)\\ &\le \left(\frac{\tau_i}{\mu+\tau_i\gamma}\right)^2\left(\frac{\ell^4}{c_s^2\theta_*^2}\|\overline{\widetilde{\chi}}_1\|^2+c_1^2\|\overline{\widetilde{\chi}}_2\|^2\right).\end{aligned}$$

Finally it suffices to fix $\tau\le\mu/\max\{\ell^2/(c_s\theta_*),c_1\}$ in order to get that T_3 is actually a contraction in $H\times H$. The assertion follows from the fact that $T_3(H)\subset\mathcal{K}$ which is closed in $H\times H$. □

For the sake of later convenience, we rewrite the scheme (5.12)–(5.15) in more compact form as

$$\begin{aligned}&(5.23)\quad \big(\partial_t(c_s\theta_{\mathcal{P}}-\ell\chi_{1,\mathcal{P}}),\varphi\big)+k(\nabla\overline{\theta}_{\mathcal{P}},\nabla\varphi)+h(\overline{\theta}_{\mathcal{P}}-\theta_e,\varphi)_\Gamma\\ &\qquad\qquad =\langle\overline{F}_{\mathcal{P}},\varphi\rangle\quad\forall\varphi\in V,\ \text{ a.e. in } (0,T),\\ &(5.24)\quad a(\overline{u}_{\mathcal{P}},v)+(\mathbb{A}\beta\overline{\chi}_{2,\mathcal{P}},\varepsilon(v))=\langle\overline{G}_{\mathcal{P}},v\rangle\quad\forall v\in\mathcal{V},\ \text{ a.e. in } (0,T),\\ &(5.25)\quad \mathbb{A}(\varepsilon(\overline{u}_{\mathcal{P}})+\beta\overline{\chi}_{2,\mathcal{P}})=\overline{\sigma}_{\mathcal{P}}\quad\text{a.e. in } Q,\\ &(5.26)\quad \mu\partial_t\begin{pmatrix}\chi_{1,\mathcal{P}}\\ \chi_{2,\mathcal{P}}\end{pmatrix}+\gamma\begin{pmatrix}\overline{\chi}_{1,\mathcal{P}}\\ \overline{\chi}_{2,\mathcal{P}}\end{pmatrix}+\partial I_K\begin{pmatrix}\overline{\chi}_{1,\mathcal{P}}\\ \overline{\chi}_{2,\mathcal{P}}\end{pmatrix}\ni\begin{pmatrix}\frac{\ell}{\theta_*}(\theta_*-\overline{\theta}_{\mathcal{P}})\\ -\overline{\sigma}_{\mathcal{P}}:\beta\end{pmatrix}\quad\text{a.e. in } Q.\end{aligned}$$

Remark 5.2. In order to completely justify the above notation one could consider, for instance, $u_0:=u^0$ and $\sigma_0:=\sigma^0$, where u^0 and σ^0 are defined above.

5.4. Stability. Our approximation scheme fulfills some suitable *conditional stability* property. In particular, this subsection brings us to the proof of the following lemma.

LEMMA 5.3. *Under the assumptions* (A1)–(A3), (5.6)–(5.8), *and for all τ sufficiently small, let $\{\theta_i\}_{i=0}^N\in V^{N+1}$, $\{[\chi_{1,i},\chi_{2,i}]\}_{i=0}^N\in\mathcal{K}^{N+1}$, and $\{u_i\}_{i=1}^N\in\mathcal{V}^N$ be the unique solution to Problem D_μ. Then there exists a positive constant c_2 depending only on c_s, k, h, θ_e, Γ, θ_*, γ, $\mathbb{A}^{\frac{1}{2}}\beta$, $c_{\mathcal{V}}$, θ^0, $[\chi_1^0,\chi_2^0]$, $\|F_1\|_{L^2(0,T;H)}$, $\|F_2\|_{W^{1,1}(0,T;V')}$, and $\|G\|_{H^1(0,T;\mathcal{V}')}$ such that*

$$\begin{aligned}(5.27)\qquad &\|\theta_{\mathcal{P}}\|_{H^1(0,T;H)\cap C^0([0,T];V)}+\|[\chi_{1,\mathcal{P}},\chi_{2,\mathcal{P}}]\|_{(H^1(0,T;H))^2}\\ &+\sqrt{\mu}\|[\chi_{1,\mathcal{P}},\chi_{2,\mathcal{P}}]\|_{(W^{1,\infty}(0,T;H))^2}+\|u\|_{H^1(0,T;\mathcal{V})}\le c_2.\end{aligned}$$

In particular, c_2 is independent of μ and τ.

Proof. Henceforth we will denote by c any positive constant, possibly depending on data but on neither μ nor $\mathcal{P}$. In particular, c may vary from line to line.

Let us take the difference between relation (5.15) written at level i and the same relation at level $i-1$. By defining $[\delta\chi_{1,0},\delta\chi_{2,0}]:=[\chi_{1,\mu,t}(0),\chi_{2,\mu,t}(0)]$ we are entitled to do so for $i=1,\dots,N$. Next, we multiply the resulting relation by $[\delta\chi_{1,i},\delta\chi_{2,i}]$, integrate in space, and sum for $i=1,\dots,m$ for some $m=1,\dots,N$. By exploiting the monotonicity of the subdifferential, we obtain that

$$\sum_{j=1}^{2}\left(\frac{\mu}{2}\|\delta\chi_{j,m}\|^2-\frac{\mu}{2}\|\delta\chi_j(0)\|^2+\gamma\sum_{i=1}^{m}\tau_i\|\delta\chi_{j,i}\|^2\right)$$
$$\leq -\frac{\ell}{\theta_*}\sum_{i=1}^{m}\tau_i(\delta\theta_i,\delta\chi_{1,i})-\sum_{i=1}^{m}\tau_i(\delta\sigma_i:\beta,\delta\chi_{2,i}). \tag{5.28}$$

We now take the difference between relation (5.13) written at level i and the same relation at level $i-1$, choose $v:=\delta u_i$, and sum for $i=1,\dots,m$. One readily gets that

$$\sum_{i=1}^{m}\tau_i\|\mathbb{A}^{\frac12}\varepsilon(\delta u_i)\|^2=\sum_{i=1}^{m}\tau_i\langle\delta G_i,\delta u_i\rangle-\sum_{i=1}^{m}\tau_i(\mathbb{A}^{\frac12}\varepsilon(\delta u_i):\mathbb{A}^{\frac12}\beta,\delta\chi_{2,i}). \tag{5.29}$$

On the other hand, owing to (5.14), it may be easily computed that

$$\delta\sigma_i:\beta=\mathbb{A}^{\frac12}\varepsilon(\delta u_i):\mathbb{A}^{\frac12}\beta+|\mathbb{A}^{\frac12}\beta|^2\delta\chi_{2,i}\quad\forall i=1,\dots,N. \tag{5.30}$$

Hence, taking into account (5.30) and adding (5.28) to (5.29), we may again choose a suitable ρ such that $1<\rho<(\gamma+|\mathbb{A}^{\frac12}\beta|^2)/|\mathbb{A}^{\frac12}\beta|^2$ and deduce that

$$\sum_{j=1}^{2}\left(\frac{\mu}{2}\|\delta\chi_{j,m}\|^2-\frac{\mu}{2}\|\delta\chi_j(0)\|^2\right)$$
$$+\sum_{i=1}^{m}\tau_i\Big(\gamma\|\delta\chi_{1,i}\|^2+(\gamma+|\mathbb{A}^{\frac12}\beta|^2-\rho|\mathbb{A}^{\frac12}\beta|^2)\|\delta\chi_{2,i}\|^2\Big)$$
$$+\frac{\rho-1}{\rho}\sum_{i=1}^{m}\tau_i\|\mathbb{A}^{\frac12}\varepsilon(\delta u_i)\|^2$$
$$\leq -\frac{\ell}{\theta_*}\sum_{i=1}^{m}\tau_i(\delta\theta_i,\delta\chi_{1,i})+\sum_{i=1}^{m}\tau_i\langle\delta G_i,\delta u_i\rangle. \tag{5.31}$$

Next, we test relation (5.12) by $\varphi=\tau_i\delta\theta_i$ and take the sum for $i=1,\dots,m$. Because of (A2) we obtain that

$$c_s\sum_{i=1}^{m}\tau_i\|\delta\theta_i\|^2+\frac{k}{2}\|\nabla\theta_m\|^2+\frac{h}{2}\|\theta_m\|^2_{L^2(\Gamma)}$$
$$\leq c+h(\theta_e,\theta_m)_\Gamma+\ell\sum_{i=1}^{m}\tau_i(\delta\theta_i,\delta\chi_{1,i})$$
$$+\sum_{i=1}^{m}\tau_i(F_{1,i},\delta\theta_i)+\langle F_{2,m},\theta_m\rangle-\langle F_{2,1},\theta^0\rangle-\sum_{i=2}^{m}\langle F_{2,i}-F_{2,i-1},\theta_{i-1}\rangle. \tag{5.32}$$

Finally, it suffices to take the sum between (5.31) and (5.32) multiplied by $1/\theta_*$, consider (A3), and perform some standard computations in order to obtain that

$$\begin{aligned}(5.33)\qquad & \mu\sum_{j=1}^{2}\|\delta\chi_{j,m}\|^2+\|\theta_m\|_V^2+\sum_{i=1}^{m}\tau_i\left(\sum_{j=1}^{2}\|\delta\chi_{j,i}\|^2+\|\delta\theta_i\|^2+\|\delta u_i\|_{\mathcal{V}}^2\right)\\ & \le c\sum_{i=2}^{m-1}\tau_i\langle\delta F_{2,i},\theta_{i-1}\rangle\\ & +c\left(1+\|F_{2,m}\|_{V'}^2+\|F_{2,1}\|_{V'}^2+\sum_{i=1}^{m}\tau_i\left(\|\delta_i G\|_{\mathcal{V}'}^2+\|F_{1,i}\|^2\right)\right).\end{aligned}$$

Finally, from (5.6) and (5.8) and an application of the discrete Gronwall lemma we readily obtain the bounds of (5.28). □

5.5. Convergence. Let us now consider the limit as the diameter τ of partition $\mathcal{P}$ goes to zero. We are actually in a position to prove the following.

LEMMA 5.4. *Under the assumptions* (A1)–(A3), (5.6)–(5.8)*, and for all τ sufficiently small, let $\{\theta_i\}_{i=0}^N\in V^{N+1}$, $\{[\chi_{1,i},\chi_{2,i}]\}_{i=0}^N\in\mathcal{K}^{N+1}$, and $\{u_i\}_{i=1}^N\in\mathcal{V}^N$ be the unique solution to problem D_μ. Then the following convergences hold:*

$$\begin{aligned}(5.34)\qquad & \theta_{\mathcal{P}}\longrightarrow\theta_\mu \quad \textit{weakly star in}\ \ H^1(0,T;H)\cap L^\infty(0,T;V)\\ & \qquad\qquad \textit{and strongly in}\ \ C([0,T];H),\\ (5.35)\qquad & \overline{\theta}_{\mathcal{P}}\longrightarrow\theta_\mu \quad \textit{weakly star in}\ \ L^\infty(0,T;V)\\ & \qquad\qquad \textit{and strongly in}\ \ L^\infty(0,T;H),\\ (5.36)\qquad & \chi_{j,\mathcal{P}}\longrightarrow\chi_{j,\mu} \quad \textit{weakly star in}\ \ W^{1,\infty}(0,T;H)\\ & \qquad\qquad \textit{and strongly in}\ \ C([0,T];H),\quad j=1,2,\\ (5.37)\qquad & \overline{\chi}_{j,\mathcal{P}}\longrightarrow\chi_{j,\mu} \quad \textit{strongly in}\ \ L^\infty(0,T;H),\quad j=1,2,\\ (5.38)\qquad & u_{\mathcal{P}}\longrightarrow u_\mu \quad \textit{weakly in}\ \ H^1(0,T;\mathcal{V})\\ & \qquad\qquad \textit{and strongly in}\ \ C([0,T];\mathcal{V}),\\ (5.39)\qquad & \overline{u}_{\mathcal{P}}\longrightarrow u_\mu \quad \textit{strongly in}\ \ L^\infty(0,T;\mathcal{V}),\end{aligned}$$

where $(\theta_\mu,\chi_{1,\mu},\chi_{2,\mu},u_\mu)$ is the unique solution to Problem P_μ.

In particular, let us stress that the latter lemma entails the proof of the existence statement of Theorem 4.1.

Proof. Taking into account the estimate (5.28) and well-known compactness results, we readily find a quadruple $(\theta_\mu,\chi_{1,\mu},\chi_{2,\mu},u_\mu)$ such that, possibly taking nonrelabeled subsequences, the weak and weak-star convergences of Lemma 5.4 hold true together with the following:

$$\begin{aligned}(5.40)\qquad & \theta_{\mathcal{P}}\longrightarrow\theta_\mu \quad \text{strongly in}\ \ C([0,T];H),\\ (5.41)\qquad & \overline{\theta}_{\mathcal{P}}\longrightarrow\theta_\mu \quad \text{strongly in}\ \ L^\infty(0,T;H).\end{aligned}$$

We now turn to the proof of some strong convergence for $\chi_{1,\mathcal{P}},\chi_{2,\mathcal{P}}$, and $u_{\mathcal{P}}$ by a direct Cauchy argument. To this aim, let $\mathcal{P}_m$ denote the extracted sequence of partitions. We denote $\theta_m:=\theta_{\mathcal{P}_m}$, $u_m:=u_{\mathcal{P}_m}$, etc. By taking the difference between (5.26) written for $\mathcal{P}_n$ and the same relation for $\mathcal{P}_m$, multiplying it by $[\overline{\chi}_{1,n}-\overline{\chi}_{1,m},\overline{\chi}_{2,n}-\overline{\chi}_{2,m}]$, integrating on Ω, and exploiting the monotonicity of the subdifferential we readily obtain that

$$
\begin{aligned}
(5.42)\quad & \frac{\mu}{2}\frac{d}{dt}\sum_{j=1}^{2}\|(\chi_{j,n}-\chi_{j,m})(t)\|^2+\gamma\sum_{j=1}^{2}\|(\overline{\chi}_{j,n}-\overline{\chi}_{j,m})(t)\|^2\\
&\leq \frac{\ell}{\theta_*}\|(\overline{\theta}_n-\overline{\theta}_m)(t)\|\,\|(\overline{\chi}_{1,n}-\overline{\chi}_{1,m})(t)\|-\big((\overline{\sigma}_n-\overline{\sigma}_m)(t):\beta,(\overline{\chi}_{2,n}-\overline{\chi}_{2,m})(t)\big)
\end{aligned}
$$

for almost every $t\in(0,T)$. In particular, we made a crucial use of the fact that, given any vector $\{w_i\}_{i=0}^N\in H^{N+1}$, one has that $(w'_{\mathcal{P}},\overline{w}_{\mathcal{P}})\geq(w'_{\mathcal{P}},w_{\mathcal{P}})$ since of course the residual term $(w'_{\mathcal{P}},\overline{w}_{\mathcal{P}}-w_{\mathcal{P}})$ is nonnegative. On the other hand, by taking the difference of the corresponding relations (5.24) with $v=\overline{u}_n-\overline{u}_m$ and of (5.25) we readily check that

$$
\begin{aligned}
(5.43)\qquad \|\mathbb{A}^{\frac12}\varepsilon(\overline{u}_n-\overline{u}_m)\|^2 &= -\big(\mathbb{A}^{\frac12}\varepsilon(\overline{u}_n-\overline{u}_m):\mathbb{A}^{\frac12}\beta,(\overline{\chi}_{2,n}-\overline{\chi}_{2,m})\big)\\
&\quad+\langle\overline{G}_n-\overline{G}_m,\overline{u}_n-\overline{u}_m\rangle,
\end{aligned}
$$

$$
\begin{aligned}
(5.44)\qquad & -\big((\overline{\sigma}_n-\overline{\sigma}_m):\beta,\overline{\chi}_{2,n}-\overline{\chi}_{2,m}\big)\\
&= -\,(\mathbb{A}^{\frac12}\varepsilon(\overline{u}_n-\overline{u}_m):\mathbb{A}^{\frac12}\beta,\overline{\chi}_{2,n}-\overline{\chi}_{2,m})-|\mathbb{A}^{\frac12}\beta|^2\|\overline{\chi}_{2,n}-\overline{\chi}_{2,m}\|^2.
\end{aligned}
$$

Hence, owing to the latter relation, taking the sum of (5.42) and (5.43) and integrating on $(0,t)$ for some $t\in(0,T]$ we easily infer that

$$
\begin{aligned}
&\sum_{j=1}^{2}\left(\frac{\mu}{2}\|(\chi_{j,n}-\chi_{j,m})(t)\|^2+\gamma\int_0^t\|\overline{\chi}_{j,n}-\overline{\chi}_{j\,m}\|^2\right)+\int_0^t\|\mathbb{A}^{\frac12}\varepsilon(\overline{u}_n-\overline{u}_m)\|^2\\
&\leq\frac{\ell}{\theta_*}\int_0^t\|\overline{\theta}_n-\overline{\theta}_m\|\,\|\overline{\chi}_{1,n}-\overline{\chi}_{1,m}\|-2\int_0^t(\mathbb{A}^{\frac12}\varepsilon(\overline{u}_n-\overline{u}_m):\mathbb{A}^{\frac12}\beta,\overline{\chi}_{2,n}-\overline{\chi}_{2,m})\\
&-|\mathbb{A}^{\frac12}\beta|^2\int_0^t\|\overline{\chi}_{2,n}-\overline{\chi}_{2,m}\|^2+\int_0^t\langle\overline{G}_n-\overline{G}_m,\overline{u}_n-\overline{u}_m\rangle\\
&\leq\frac{\gamma}{2}\int_0^t\|\overline{\chi}_{1,n}-\overline{\chi}_{1,m}\|^2+(\rho-1)|\mathbb{A}^{\frac12}\beta|^2\int_0^t\|\overline{\chi}_{2,n}-\overline{\chi}_{2,m}\|^2\\
&+\frac{1}{\rho}\int_0^t\|\mathbb{A}^{\frac12}\varepsilon(\overline{u}_n-\overline{u}_m)\|^2+\frac{\ell^2}{2\theta_*^2\gamma}\int_0^t\|\overline{\theta}_n-\overline{\theta}_m\|^2+\int_0^t\langle\overline{G}_n-\overline{G}_m,\overline{u}_n-\overline{u}_m\rangle
\end{aligned}
$$

for some $1<\rho<(\gamma+|\mathbb{A}^{\frac12}\beta|^2)/|\mathbb{A}^{\frac12}\beta|^2$. Hence, in particular,

$$
\begin{aligned}
(5.45)\quad & \sum_{j=1}^{2}\left(\mu\|\chi_{j,n}-\chi_{j,m}\|^2_{C([0,t];H)}+\int_0^t\|\overline{\chi}_{j,n}-\overline{\chi}_{j\,m}\|^2\right)+\int_0^t\|\overline{u}_n-\overline{u}_m\|^2_{\mathcal{V}}\\
&\leq c\left(\int_0^t\|\overline{\theta}_n-\overline{\theta}_m\|^2+\int_0^t\|\overline{G}_n-\overline{G}_m\|^2_{\mathcal{V}'}\right),
\end{aligned}
$$

where c depends on ℓ, θ_*, γ, and $c_{\mathcal{V}}$. Finally it suffices to exploit (5.11) and (5.41) in order to obtain that $[\chi_{1,\mathcal{P}},\chi_{2,\mathcal{P}}]$ is a Cauchy sequence in $(C([0,T];H))^2$. Namely, we checked the strong convergences in (5.36)–(5.37). The strong convergences of (5.38)–(5.39) are now an easy consequence of (5.11), (5.36)–(5.37), and (5.43).

We prove that indeed the quadruple $(\theta_\mu, \chi_{1,\mu}, \chi_{2,\mu}, u_\mu)$ solves Problem P_μ. Let us introduce the new auxiliary variables $[\overline{\xi}_{1,\mathcal{P}}, \overline{\xi}_{2,\mathcal{P}}] \in \partial I_K(\overline{\chi}_{1,\mathcal{P}}, \overline{\chi}_{2,\mathcal{P}})$ almost everywhere in Q such that (5.26) reduces to the following equality:

$$\mu\partial_t\begin{pmatrix}\chi_{1,\mathcal{P}}\\ \chi_{2,\mathcal{P}}\end{pmatrix} + \gamma\begin{pmatrix}\overline{\chi}_{1,\mathcal{P}}\\ \overline{\chi}_{2,\mathcal{P}}\end{pmatrix} + \begin{pmatrix}\frac{\ell}{\theta_*}(\overline{\theta}_{\mathcal{P}} - \theta_*)\\ \overline{\sigma}_{\mathcal{P}} : \beta\end{pmatrix} + \begin{pmatrix}\overline{\xi}_{1,\mathcal{P}}\\ \overline{\xi}_{2,\mathcal{P}}\end{pmatrix} = \begin{pmatrix}0\\ 0\end{pmatrix} \quad \text{a.e. in } Q.$$

Hence, moving from (5.28), it is straightforward to possibly extract a further subsequence such that the convergences of Lemma 5.4 hold and there exists $[\xi_{1,\mu}, \xi_{2,\mu}]$ such that

$$\xi_{j,\mathcal{P}} \to \xi_{j,\mu} \quad \text{weakly in } L^2(0,T;H) \quad \text{for } j = 1,2.$$

Owing to the convergences proved above and to (5.9)–(5.11) it is now possible to pass to the limit as the diameter τ of partition $\mathcal{P}$ goes to zero and check that $(\theta_\mu, \chi_{1,\mu}, \chi_{2,\mu}, u_\mu, \xi_{1,\mu}, \xi_{2,\mu})$ fulfills relations (3.1)–(3.3), (3.5)–(3.6), and

$$\mu\partial_t\begin{pmatrix}\chi_{1,\mu}\\ \chi_{2,\mu}\end{pmatrix} + \gamma\begin{pmatrix}\chi_{1,\mu}\\ \chi_{2,\mu}\end{pmatrix} + \begin{pmatrix}\xi_{1,\mu}\\ \xi_{2,\mu}\end{pmatrix} \ni \begin{pmatrix}\frac{\ell}{\theta_*}(\theta_* - \theta_\mu)\\ -\sigma_\mu : \beta\end{pmatrix} \quad \text{a.e. in } Q. \tag{5.46}$$

Moreover, it is straightforward to check that

$$\int_0^T (\overline{\xi}_{j,\mathcal{P}}, \overline{\chi}_{j,\mathcal{P}}) \to \int_0^T (\xi_{j,\mu}, \chi_{j,\mu}) \qquad \text{for } j = 1,2.$$

In particular, classical results on maximal monotone operators [7, Prop. 2.5, p. 27] entail that $[\xi_{1,\mu}, \xi_{2,\mu}] \in \partial I_K(\chi_{1,\mu}, \chi_{2,\mu})$ almost everywhere in Q and the assertion of the lemma follows. Before closing this proof, we observe that the convergences stated in the lemma hold for all the sequence of partitions and not just for a subsequence since the solution to Problem P_μ is unique. □

5.6. Error estimates. For the sake of completeness, we state here a priori bound on the discretization error. To this aim, recalling from (A1) that $F := F_1 + F_2$, we sharpen our regularity requirements by asking for

$$F_1 \in BV([0,T];H), \tag{5.47}$$

where the above notation refers to the space of real functions valued in H with bounded variation. We have the following estimate.

LEMMA 5.5. *Under the assumptions* (A1)–(A3), (5.6)–(5.8), *and* (5.47), *let* $(\theta, [\chi_1, \chi_2], u)$ *and* $\{\theta_i\}_{i=0}^N \in V^{N+1}$, $\{[\chi_{1,i}, \chi_{2,i}]\}_{i=0}^N \in \mathcal{K}^{N+1}$, *and* $\{u_i\}_{i=1}^N \in \mathcal{V}^N$ *be the unique solutions to Problems* P_μ *and* D_μ, *respectively. Hence, there exists a positive constant* c_3 *depending on* c_2 *such that, possibly taking* τ *small enough, one has that*

$$\begin{aligned} &\|\theta - \theta_{\mathcal{P}}\|_{L^2(0,t;H)} + \sup_{s\in[0,t]}\left\|\int_0^s \nabla(\theta - \overline{\theta}_{\mathcal{P}})\right\| + \sup_{s\in[0,t]}\left\|\int_0^s (\theta - \overline{\theta}_{\mathcal{P}})\right\|_{L^2(\Gamma)} \\ &\quad + \mu\sum_{j=1}^2 \|\chi_j - \chi_{j,\mathcal{P}}\|_{C([0,t];H)} + \sum_{j=1}^2 \|\chi_j - \chi_{j,\mathcal{P}}\|_{L^2(0,t,H)} \\ &\quad + \|u - u_{\mathcal{P}}\|_{C([0,t];\mathcal{V})} \le c_3\tau \quad \forall t \in [0,T]. \end{aligned} \tag{5.48}$$

We will not give here the detailed proof of the latter result. Indeed, the argument follows closely the lines of the proof of the continuous dependence estimate (4.1). The additional intricacy related to the fact that the continuous and the discrete solutions do not solve the same equations may be overcome by the same techniques of the two papers [34, 35], where indeed the abstract analysis of [28, 29] is applied in a similar context. On the other hand, some comment is in order. We point out that the latter estimate is *optimal* with respect to the order of convergence, since the backward Euler scheme is used in order to approximate time derivatives in Problem P_μ. Moreover, no a priori constraints between consecutive time-steps are imposed. Hence (5.48) ensures the possibility of implementing an adaptive procedure as in [29]. Finally, let us remark that c_3 depends exponentially on T since the Gronwall lemma is used in the proof of (5.48).

6. Nondissipative problem. We now proceed to the proof of Theorem 4.1 for $\mu = 0$ and Theorem 4.2. To this aim $(\theta_\mu, \chi_{1,\mu}, \chi_{2,\mu}, u_\mu)$ will denote a sequence of solutions to Problem P_μ as μ converges toward 0.

6.1. Continuous dependence. First of all, we address the continuous dependence claim in the nondissipative situation. To this end, it suffices to follow exactly the lines of the corresponding proof of subsection 5.1 with the choice of the parameter $\mu = 0$.

6.2. A priori estimates. We shall prove the following.

LEMMA 6.1. *Under the assumptions* (A1)–(A3)*, let* $(\theta_\mu, \chi_{1,\mu}, \chi_{2,\mu}, u_\mu)$ *be solutions to Problem* P_μ*. Then, there exists a positive constant* c_4 *depending only on* c_s, k, h, θ_e, Γ, γ, $\mathbb{A}^{\frac{1}{2}}\beta$, $c_{\mathcal{V}}$, θ_*, θ^0, $[\chi_1^0, \chi_2^0]$, $\|F_1\|_{L^2(0,T;H)}$, $\|F_2\|_{W^{1,1}(0,T;V')}$*, and* $\|G\|_{H^1(0,T;\mathcal{V}')}$ *such that*

$$\|\theta_\mu\|_{H^1(0,T;H)\cap L^\infty(0,T;V)} + \|[\chi_{1,\mu}, \chi_{2,\mu}]\|_{(H^1(0,T;H))^2} + \|u_\mu\|_{H^1(0,T;\mathcal{V})} \le c_4. \tag{6.1}$$

In particular, c_4 *is independent of* μ.

Proof. This argument is just sketched here since it is very close to that of Lemma 5.3. Indeed, the above-stated result represents the continuous version of the stability estimates for the discrete scheme. Namely, the key a priori estimate consists in taking the sum between (3.1) with $\varphi := \theta_t/\theta_*$, the time derivative of (3.4) multiplied by $[\chi_{1,\mu,t}, \chi_{2,\mu,t}]$, and the time derivative of (3.2) with $v = u_{\mu,t}$. We shall remark that the latter choices of test functions are not admissible at the present stage. However, the above calculation is to be intended at an appropriate approximation level (for instance, that of the discrete scheme). We prefer to skip the details of this discussion for the sake of clarity. Next, taking the integral on $(0,t)$ for some $t \in (0,T]$ of the upcoming relation, the assertion of Lemma 6.1 follows along the same lines as the proof of Lemma 5.3. ◻

6.3. Passage to the limit. Let us now finally turn to the proof of Theorem 4.2. Precisely, we prove the following.

LEMMA 6.2. *Under the assumptions* (A1)–(A3)*, let* $(\theta_\mu, \chi_{1,\mu}, \chi_{2,\mu}, u_\mu)$ *be the solution to Problem* P_μ*. Then the following convergences hold:*

$$\theta_\mu \longrightarrow \theta \quad \textit{weakly star in } H^1(0,T;H) \cap L^\infty(0,T;V) \text{ and strongly in } C([0,T];H), \tag{6.2}$$

$$\chi_{j,\mu} \longrightarrow \chi_j \quad \textit{weakly in } H^1(0,T;H) \text{ and strongly in } C([0,T];H), \quad j = 1,2, \tag{6.3}$$

$$u_\mu \longrightarrow u \quad \textit{weakly in} \ \ H^1(0,T;\mathcal{V}) \ \textit{and strongly in} \ \ C([0,T];\mathcal{V}), \tag{6.4}$$

where (θ,χ_1,χ_2,u) *is the unique solution to* P_0.

Proof. This argument is very close to that of Lemma 5.4. Thanks to Lemma 6.1 we are in the position of finding a quadruple (θ,χ_1,χ_2,u) such that, possibly taking non-relabeled subsequences and owing to well-known compactness results, the following convergences hold:

$$\theta_\mu \longrightarrow \theta \quad \text{weakly star in} \ \ H^1(0,T;H)\cap L^\infty(0,T;V) \ \text{and strongly in} \ \ C([0,T];H), \tag{6.5}$$

$$\chi_{j,\mu} \longrightarrow \chi_j \quad \text{weakly in} \ \ H^1(0,T;H), \quad j=1,2, \tag{6.6}$$

$$u_\mu \longrightarrow u \quad \text{weakly in} \ \ H^1(0,T;\mathcal{V}). \tag{6.7}$$

We now turn to the proof of a direct Cauchy argument. To this aim, we fix two parameters μ_n,μ_m of the extracted subsequence and denote by $(\theta_r,\chi_{1,r},\chi_{2,r},u_r)$ the solution to Problem P_{μ_r} for $r=n,m$ (σ_n, σ_m are defined accordingly). Next, we take the difference between (3.4) written for μ_1 and the same relation for μ_2, multiply it by $(\chi_{1,n}-\chi_{1,m},\chi_{2,n}-\chi_{2,m})$, and integrate in space. We readily obtain that, for almost all $t\in(0,T)$,

$$\begin{aligned}\gamma\sum_{j=1}^{2}\|(\chi_{j,n}-\chi_{j,m})(t)\|^2 &\le \frac{\ell}{\theta_*}\|(\theta_n-\theta_m)(t)\|\,\|(\chi_{1,n}-\chi_{1,m})(t)\|\\ &- \big(\beta:(\sigma_n-\sigma_m)(t),(\chi_{2,n}-\chi_{2,m})(t)\big)\\ &+\sum_{j=1}^{2}\|(\mu_n\chi_{j,n,t}-\mu_m\chi_{j,m,t})(t)\|\,\|(\chi_{j,n}-\chi_{j,m})(t)\|.\end{aligned} \tag{6.8}$$

Once again we readily compute that

$$\|\mathbb{A}^{\frac12}\varepsilon(u_n-u_m)\|^2 = -(\mathbb{A}^{\frac12}\varepsilon(u_n-u_m):\mathbb{A}^{\frac12}\beta,\chi_{2,n}-\chi_{2,m}) \quad \text{a.e. in} \ \ (0,T), \tag{6.9}$$

$$\begin{aligned}&-(\sigma_n-\sigma_m):\beta(\chi_{2,n}-\chi_{2,m})\\ &\quad= -\mathbb{A}^{\frac12}\varepsilon(u_n-u_m):\mathbb{A}^{\frac12}\beta(\chi_{2,n}-\chi_{2,m}) - |\mathbb{A}^{\frac12}\beta|^2(\chi_{2,n}-\chi_{2,m})^2 \quad \text{a.e. in} \ \ Q.\end{aligned} \tag{6.10}$$

Finally, taking the sum between (6.8) and (6.9) and using (6.11), we readily obtain that

$$\begin{aligned}&\gamma\|(\chi_{1,n}-\chi_{1,m})(t)\|^2 + \big(\gamma+|\mathbb{A}^{\frac12}\beta|^2-\rho|\mathbb{A}^{\frac12}\beta|^2\big)\|(\chi_{2,n}-\chi_{2,m})(t)\|^2\\ &\quad+\frac{\rho-1}{\rho}\|\mathbb{A}^{\frac12}\varepsilon(u_n-u_m)(t)\|^2 \le \frac{\ell}{\theta_*}\|(\theta_n-\theta_m)(t)\|\,\|(\chi_{1,n}-\chi_{1,m})(t)\|\\ &\quad+\sum_{j=1}^{2}\|(\mu_n\chi_{j,n,t}-\mu_m\chi_{j,m,t})(t)\|\,\|(\chi_{j,n}-\chi_{j,m})(t)\|,\end{aligned}$$

where once again ρ is such that $1<\rho<(\gamma+|\mathbb{A}^{\frac12}\beta|^2)/|\mathbb{A}^{\frac12}\beta|^2$. Now, it suffices to recall (5.28) and (6.5) in order to infer the strong convergences

$$\begin{aligned}\chi_{j,\mu} &\longrightarrow \chi_j \quad \text{strongly in} \ \ C([0,T];H) \ \ \text{for} \ \ j=1,2,\\ u_\mu &\longrightarrow u \quad \text{strongly in} \ \ C([0,T];\mathcal{V}).\end{aligned}$$

Moving from the above positions, the proof of this lemma may be concluded exactly as that of Lemma 5.4. ∎

6.4. Error control. The Cauchy argument devised in the latter subsection may be used in order to achieve some quantitative control on the distance between the dissipative and the nondissipative regimes. In particular, we have the following.

LEMMA 6.3. *Under the assumptions* (A1)–(A3)*, let* $(\theta_\mu, \chi_{1,\mu}, \chi_{2,\mu}, u_\mu)$ *and* $(\theta, \chi_1, \chi_2, u)$ *denote the unique solutions to Problems* P_μ *and* P_0*, respectively. Then, there exists a constant* c_5 *with the same dependences of* c_2 *(in particular independent of* μ*) such that*

$$\|\theta - \theta_\mu\|_{L^2(0,T;H)} + \sup_{t\in[0,T]} \left\| \int_0^t \nabla(\theta - \theta_\mu) \right\| + \sup_{t\in[0,T]} \left\| \int_0^t (\theta - \theta_\mu) \right\|_{L^2(\Gamma)}$$
$$+ \sum_{j=1}^2 \|\chi_j - \chi_{j,\mu}\|_{L^2(0,T;H)} + \|u - u_\mu\|_{L^2(0,T;\mathcal{V})} \le c_5\sqrt{\mu}.$$

The proof of Lemma 6.3 follows along the same lines as subsections 5.1 and 6.3 and is therefore omitted.

6.5. Discretization. Let us comment here the possible discretization of Problem P_0. First of all we observe that the limit procedure of section 5 is completely independent of μ. On the other hand, the positivity of μ is exploited in order to implement the contraction argument. Namely, one could choose $\mu = \mu(\tau) > 0$ such that $\lim_{\tau\to 0^+} \mu(\tau) = 0$ and prove that the resulting discrete solution exists and converges indeed to a solution to Problem P_0.

It is, however, remarkable that we would also be in the position of providing a variable time-step discretization scheme for Problem P_0 as well. Namely, we could directly work at the nondissipative level $\mu = 0$ and prove Lemmas 5.1, 5.3, and 5.4 (and hence Theorem 4.1) directly for Problem D_0. On the other hand, we prefer to analyze here the discretization of the dissipative problem because the well-posedness proof for Problem D_0 relies on some nonconstructive technique (Schauder fixed point) and hence shows a merely theoretical interest (while the scheme for problem D_μ is effectively computable). Finally, we are interested in establishing the asymptotic connection within the dissipative and the nondissipative models at all levels, namely, the continuous and the discrete ones.

As for the discretization error estimate (5.48) one could actually prove that an analogous bound holds true in the case $\mu = 0$. In particular, in the latter nondissipative case we will be forced to replace τ with $\sqrt{\tau}$, i.e., we reduce ourselves to a suboptimal convergence rate.

7. Long-time behavior. Let us now turn to the proof of Theorem 4.3. In particular, let us recall that the dissipation parameter μ is set to be zero throughout this section. Namely, we will carry out the long-time behavior analysis in the nondissipative regime. Owing to Theorem 4.1 it is a standard matter to check for the existence and uniqueness of a quadruple $(\theta, \chi_1, \chi_2, u)$ such that, for each $T \in (0, +\infty)$, one has that $\theta \in H^1(0,T;H) \cap L^\infty(0,T;V)$, $[\chi_1, \chi_2] \in (H^1(0,T;H))^2$, $u \in H^1(0,T;\mathcal{V})$, fulfilling conditions (3.1)–(3.5) with $\mu = 0$. We proceed by establishing some lemmas.

LEMMA 7.1. *Under the assumptions* (A2)–(A4)*, there exists a positive constant* c_6 *depending on* c_s, k, h, θ_e, Γ, γ, $\mathbb{A}^{\frac{1}{2}}\beta$, $c_{\mathcal{V}}$, θ_*, θ^0, $[\chi_1^0, \chi_2^0]$, $\|F\|_{L^2(0,+\infty;H)}$, *and* $\|G\|_{H^1(0,+\infty;\mathcal{V}')}$ *such that*

$$\int_0^t \left(\|\theta_t\|^2 + \sum_{j=1}^2 \|\chi_{j,t}\|^2 + \|u_t\|_{\mathcal{V}}^2 \right) + \|\theta(t) - \theta_e\|_V^2 \le c_6 \qquad \forall t > 0. \tag{7.1}$$

We do not provide here a detailed proof of the latter estimate. Indeed, the argument of Lemma 6.1 (together with the long-time assumption (A4)) may be easily adapted to ensure the validity of (7.1).

A first consequence of Lemma 7.1 is that the set

$$\big\{(\theta(t),\chi_1(t),\chi_2(t),u(t)),\ t>0\big\}\ \text{ is bounded in }\ V\times H\times H\times\mathcal{V}.$$

Therefore, there exists a sequence $t_n\to+\infty$ and a quadruple $(\theta_\infty,\chi_{1,\infty},\chi_{2,\infty},u_\infty)$ such that

$$\begin{aligned}\theta(t_n)&\longrightarrow\theta_\infty &&\text{strongly in }\ H,\\ \chi_j(t_n)&\longrightarrow\chi_{j,\infty} &&\text{weakly in }\ H,\ j=1,2,\\ u(t_n)&\longrightarrow u_\infty &&\text{weakly in }\ \mathcal{V}.\end{aligned}$$

Indeed, by observing that relations (3.2)–(3.4) are actually fulfilled everywhere in time and almost everywhere in Ω and arguing as in the proof of Lemma 6.2, we easily check that the direct Cauchy argument devised above entails that the latter convergences are strong. In particular, the set $\omega(\theta,\chi_1,\chi_2,u)$ is nonempty.

Consider now any $(\theta_\infty,\chi_{1,\infty},\chi_{2,\infty},u_\infty)\in\omega(\theta,\chi_1,\chi_2,u)$. Hence, there is a sequence $\{t_n\}$ of positive real numbers such that $t_n\to+\infty$ and

$$(\theta(t_n),\chi_1(t_n),\chi_2(t_n),u(t_n))\longrightarrow(\theta_\infty,\chi_{1,\infty},\chi_{2,\infty},u_\infty)\quad\text{in }\ H\times H\times H\times\mathcal{V}. \tag{7.2}$$

For n and $t\ge 0$, we define

$$\theta_n(t):=\theta(t_n+t),\quad \chi_{j,n}(t):=\chi_j(t_n+t),\quad j=1,2,\quad u_n(t):=u(t_n+t).$$

We can introduce a pair of auxiliary functions $[\xi_{1,n},\xi_{2,n}]$ such that the functions $\theta_n,\chi_{1,n},\ \chi_{2,n},u_n,\sigma_n,\xi_{1,n},\xi_{2,n}$ solve relations

$$\gamma\begin{pmatrix}\chi_{1,n}\\ \chi_{2,n}\end{pmatrix}+\begin{pmatrix}\frac{\ell}{\theta_*}(\theta_n-\theta_*)\\ \sigma_n:\beta\end{pmatrix}+\begin{pmatrix}\xi_{1,n}\\ \xi_{2,n}\end{pmatrix}=\begin{pmatrix}0\\0\end{pmatrix}\qquad\text{a.e. in }\ \Omega\times(0,T), \tag{7.3}$$

$$\begin{pmatrix}\xi_{1,n}\\ \xi_{2,n}\end{pmatrix}\in\partial I_{\mathcal{K}}(\chi_1,\chi_2)\qquad\text{a.e. in }\ \Omega\times(0,T), \tag{7.4}$$

as well as the relations (3.1)–(3.3), for all $T\in(0,+\infty)$. However, note that in (3.1)–(3.2) F and G have to be replaced by $F_n:=F(\cdot+t_n)$ and $G_n:=G(\cdot+t_n)$, respectively. We also point out the initial condition $\theta_n(\cdot,0)=\theta(\cdot,t_n)$ almost everywhere in Ω.

Owing to Lemma 7.1 it is not difficult to prove some estimates for the functions $\theta_n,\chi_{1,n},\ \chi_{2,n},\ u_n,\xi_{1,n}$, and $\xi_{2,n}$ which are uniform with respect to n. The proof of the next result is omitted since it is analogous to the proof of Lemma 5.3.

LEMMA 7.2. *Let $T>0$. Under the above assumptions, letting $\xi_{1,n}$ and $\xi_{2,n}$ be as in* (7.3)–(7.4)*, there exists a positive constant c_7 with the same dependencies of c_6 such that*

$$\begin{aligned}&\|\theta_n\|_{H^1(0,T;H)\cap L^\infty(0,T;V)}+\|u_n\|_{H^1(0,T;\mathcal{V})}\\ &\quad+\sum_{j=1}^{2}\|\chi_{j,n}\|_{H^1(0,T;H)}+\sum_{j=1}^{2}\|\xi_{j,n}\|_{H^1(0,T;H)}\le c_7.\end{aligned} \tag{7.5}$$

Another consequence of Lemma 7.1 is to allow the identification of the limit of $\theta_n, \chi_{1,n}, \chi_{2,n}$, and u_n as $n \to +\infty$. More precisely, we have the following.

LEMMA 7.3. *Under the above assumptions, for every $T > 0$ there holds*

$$\theta_n \longrightarrow \theta_\infty \quad \text{strongly in } H^1(0,T;H), \tag{7.6}$$

$$\chi_{j,n} \longrightarrow \chi_{j,\infty} \quad \text{strongly in } H^1(0,T;H), \quad j=1,2, \tag{7.7}$$

$$u_n \longrightarrow u_\infty \quad \text{strongly in } H^1(0,T;\mathcal{V}). \tag{7.8}$$

Proof. Taking into account (7.1) it is straightforward to check that

$$\int_0^T \|\theta_{n,t}\|^2 = \int_{t_n}^{t_n+T} \|\theta_t\|^2 \longrightarrow 0 \quad \text{as } n \longrightarrow +\infty. \tag{7.9}$$

An analogous computation applies to $\chi_{1,n,t}, \chi_{2,n,t}$, and $u_{n,t}$, as well. Hence, we easily deduce that

$$\begin{aligned}\|\theta_n(t) - \theta_\infty\| &\le \|\theta_n(t) - \theta_n(0)\| + \|\theta(t_n) - \theta_\infty\| \\ &\le T^{1/2}\|\theta_{n,t}\|_{L^2(0,T;H)} + \|\theta(t_n) - \theta_\infty\|.\end{aligned}$$

Owing to (7.2) and (7.9), the right-hand side of the latter inequality goes to zero as $n \to +\infty$. Hence, (7.6) is proved. A similar argument ensures that (7.7)–(7.8) hold true. $\square$

After these preliminaries, we may prove Theorem 4.3 by passing to the limit as $n \to +\infty$ in (3.1)–(3.3) for the quadruple $(\theta_n, u_n, \chi_{1,n}, \chi_{2,n})$ and data $[F_n, G_n]$ and in relations (7.3)–(7.4). Thanks to the above lemmas and well-known compactness results we find a subsequence (not relabeled) of $\theta_n, \chi_{1,n}, \chi_{2,n}$, and u_n and a pair $(\xi_{1,\infty}, \xi_{2,\infty})$ such that, in addition to (7.6)–(7.8), the following convergences hold:

$$\theta_n \longrightarrow \theta_\infty \quad \text{weakly star in } L^\infty(0,T;V), \tag{7.10}$$

$$\xi_{j,n} \longrightarrow \xi_{j,\infty} \quad \text{weakly in } H^1(0,T;H), \quad j=1,2. \tag{7.11}$$

The convergences proved above and (A4) are sufficient in order to pass to the limit in (3.1)–(3.3). In particular, it turns out that $\theta_\infty = \theta_e$ almost everywhere in Ω. As far as relations (7.3)–(7.4) are concerned, we observe that we also have

$$\begin{pmatrix} \frac{\ell}{\theta_*}(\theta_n - \theta_*) \\ \sigma_n : \beta \end{pmatrix} \longrightarrow \begin{pmatrix} \frac{\ell}{\theta_*}(\theta_\infty - \theta_*) \\ \sigma_\infty : \beta \end{pmatrix} \quad \text{strongly in } (C([0,T];H))^2.$$

Hence, we just need to identify the limit of $[\xi_{1,n}, \xi_{2,n}]$. Indeed, from (7.7) and (7.11), one easily infers that

$$(\xi_{i,n}, \chi_{i,n}) \longrightarrow (\xi_{i,\infty}, \chi_{i,\infty}) \quad \text{a.e. in } (0,T) \text{ for } i=1,2.$$

The classical theory of maximal monotone operators (see, e.g., [7, Prop. 2.5, p. 27]) then entails that $[\xi_{1,\infty}, \xi_{2,\infty}] \in \partial I_K(\chi_{1,\infty}, \chi_{2,\infty})$ almost everywhere in Ω, and we have finally proved (4.2)–(4.5). In order to conclude the proof of Theorem 4.3 we provide the following stronger result.

LEMMA 7.4. *Let the external temperatures $\theta_{e,1}, \theta_{e,2}$ be given and let $(\chi_{1,i}, \chi_{2,i}, u_i) \in H \times H \times \mathcal{V}$ fulfill*

$$\begin{aligned} a(u_i, v) + \big(\mathbb{A}\beta\chi_{2,i}, \varepsilon(v)\big) = 0 \quad \forall v \in \mathcal{V}, \\ \mathbb{A}\big(\varepsilon(u_i) + \beta\chi_{2,i}\big) = \sigma_i \quad \textit{a.e. in } \Omega, \\ \gamma\begin{pmatrix}\chi_{1,i} \\ \chi_{2,i}\end{pmatrix} + \partial I_K \begin{pmatrix}\chi_{1,i} \\ \chi_{2,i}\end{pmatrix} \ni \begin{pmatrix} \frac{\ell}{\theta_*}(\theta_* - \theta_{e,i}) \\ -\sigma_i : \beta \end{pmatrix} \quad \textit{a.e. in } \Omega \end{aligned}$$

for $i=1,2$. *Then, there exists a positive constant* c_8 *depending just on* ℓ, θ_*, γ, $\mathbb{A}^{\frac{1}{2}}\beta$, *and* $c_{\mathcal{V}}$ *such that*

$$\sum_{j=1}^{2}\|\chi_{j,1}-\chi_{j,2}\|+\|u_1-u_2\|_{\mathcal{V}}\le c_8\,|\theta_{e,1}-\theta_{e,2}|. \tag{7.12}$$

Once again the proof of Lemma 7.4 may be easily obtained by adapting the argument of subsection 5.1. A consequence of the above continuous dependence result is that, since $(\theta_\infty,\chi_{1,\infty},\chi_{2,\infty},u_\infty)$ are uniquely determined, we readily check that the ω-limit set reduces to a point and the whole trajectory $(\theta(t),\chi_1(t),\chi_2(t),u(t))$ converges to $(\theta_\infty,\chi_{1,\infty},\chi_{2,\infty},u_\infty)$ as $t\to+\infty$. In particular, this concludes the proof of Theorem 4.3.

8. Lower bound for the temperature. Let us now turn to the proof of Theorem 4.4. This argument is very close to that of [11] and will be just sketched, referring to the latter paper for details. We will start by checking (4.7) in the dissipative case $\mu>0$. In this situation we claim that

$$\left(\gamma\chi_1+\frac{\ell}{\theta_*}(\theta-\theta_*)\right)^+\ge-\mu\chi_{1,t}\quad\text{a.e. in }\ Q, \tag{8.1}$$

where we used the standard notation for the positive part. Indeed, $\chi_{1,t}=0$ almost everywhere on the measurable set $\{\chi_1=1\}$. On the other hand, for almost every $(x,t)\in\{\chi_1<1\}$, one readily checks from (3.4) that (see [11])

$$\left(\mu\chi_{1,t}+\gamma\chi_1+\frac{\ell}{\theta_*}(\theta-\theta_*)\right)(x,t)\ge 0.$$

Let us now consider

$$\underline{\theta}:=\inf\{\inf\theta_0,\,\theta_e,\,\theta_*,\,\theta_d\}\in\mathbb{R}$$

(the case $\underline{\theta}=-\infty$ being obvious), choose $\varphi=-(\theta-\underline{\theta})^-\in V$ in (3.1), and take the integral on $(0,t)$ for $t\in(0,T]$, obtaining

$$\begin{aligned}\frac{c_s}{2}\|(\theta-\underline{\theta})^-(t)\|^2+k\int_0^t\|\nabla((\theta-\underline{\theta})^-)\|^2-h\int_0^t(\theta-\theta_e,(\theta-\underline{\theta})^-)_\Gamma\\ =-\int_0^t\langle F,(\theta-\underline{\theta})^-\rangle-\ell\int_0^t(\chi_{1,t},(\theta-\underline{\theta})^-).\end{aligned}\tag{8.2}$$

Owing to (A5) and (8.1) one gets that the above right-hand side may be controlled as follows:

$$\begin{aligned}&-\int_0^t\langle F,(\theta-\underline{\theta})^-\rangle-\ell\int_0^t(\chi_{1,t},(\theta-\underline{\theta})^-)\\ &\le\frac{\ell}{\mu}\int_0^t\left(\left(\gamma\chi_1+\frac{\ell}{\theta_*}(\theta-\theta_*)\right)^+,(\theta-\underline{\theta})^-\right)\\ &\le\frac{\ell}{\mu}\int_0^t\left(\left(\gamma+\frac{\ell}{\theta_*}(\underline{\theta}-\theta_*)\right)^+,(\theta-\underline{\theta})^-\right)=0,\end{aligned}$$

since $\underline{\theta}\le\theta_d$ and (4.6) holds . Hence, looking back to (8.2) and considering that $\underline{\theta}\le\theta_e$ as well, we readily check that $\theta\ge\underline{\theta}$ almost everywhere in Q. The proof of the lower bound for the temperature in the nondissipative case $\mu=0$ simply follows by approximation owing to (6.5).

Acknowledgments. The kind hospitality of Laboratoire de Mécanique et Génie Civil de Montpellier is acknowledged. Moreover, the author is gratefully indebted to the referee for some interesting remarks on the model.

EXISTENCE AND UNIQUENESS OF THE MILD SOLUTION FOR THE 1D VLASOV–POISSON INITIAL-BOUNDARY VALUE PROBLEM*

M. BOSTAN†

Abstract. We prove the existence and uniqueness of the mild solution for the 1D Vlasov–Poisson system with initial-boundary conditions by using iterated approximations. The same arguments yield existence and uniqueness for the free space or space periodic system. The major difficulty is the treatment of the boundary conditions. The main idea consists of splitting the velocities range by introducing critical velocities corresponding to each boundary. One of the crucial points is to estimate the critical velocity change in term of relative field. A result concerning the continuity of the mild solution upon the initial-boundary conditions is presented as well.

Key words. Vlasov–Poisson equations, Vlasov–Maxwell equations, weak/mild formulation

1. Introduction.

Many studies in the physics of charged particles are modeled by kinetic equations (Vlasov, Boltzmann, etc.) coupled with electromagnetic equations (Poisson, Maxwell). A few application domains are semiconductors, particle accelerators, electron guns, etc.

Various results have been obtained for the free space systems. Weak solutions for the Vlasov–Poisson system were constructed by Arseneev [1] and Horst and Hunze [16]. The existence of classical solutions has been studied in two and three dimensions by Ukai and Okabe [21], Horst [15], Batt [2], and Pfaffelmoser [18]. Classical solutions for the Vlasov–Poisson equations with small initial data have been constructed by Bardos and Degond [3]. The propagation of the velocity moments for the Vlasov–Poisson system in three dimensions has been studied by Lions and Perthame in [17]. They prove also a uniqueness result under a Lipschitz continuity assumption on the initial data. Another uniqueness result has been obtained by Robert for bounded, compactly supported initial data, [20]. A uniqueness result for solutions with bounded variation was obtained by Guo, Shu, and Zhou [14].

The existence of weak solutions for the Vlasov–Maxwell system in three dimensions was shown by DiPerna and Lions [9]. The relativistic Vlasov–Maxwell system was studied by Glassey and Schaeffer [10]. In one dimension, the existence and uniqueness have been obtained by Cooper and Klimas [7].

The boundary value problem has been studied as well. The existence of weak solutions for the Vlasov–Poisson initial-boundary value problem in three dimensions is a result of Abdallah [4]. The existence of weak solutions for the three-dimensional Vlasov–Maxwell initial-boundary value problem has been analyzed by Guo [12]. The stationary one-dimensional Vlasov–Poisson system has been studied by Greengard and Raviart [11]. An asymptotic analysis of the Vlasov–Poisson system has been performed by Degond and Raviart [8] in the case of the plane diode. The stationary Vlasov–Maxwell system in three dimensions was analyzed by Poupaud [19]. The

†Université de Franche-Comté, 16 route de Gray F-25030 Besançon Cedex, France (mbostan@math.univ-fcomte.fr).

regularity of the solutions for the Vlasov–Maxwell system in a half line has been studied by Guo [13]. Results for the time periodic case can be found in [6] for the Vlasov–Poisson system and in [5] for the Vlasov–Maxwell system.

In this paper we study the existence and uniqueness of the mild solution for the Vlasov–Poisson initial-boundary value problem in one dimension:

$$\begin{aligned}
\partial_t f + v\cdot\partial_x f + E(t,x)\cdot\partial_v f = 0,\ (t,x,v) \in]0,T[\times]0,1[\times\mathbb{R}_v,\\
f(t=0,x,v) = f_0(x,v),\ (x,v)\in]0,1[\times\mathbb{R}_v,\\
f(t,x,v) = g(t,x,v),\ (t,x,v)\in]0,T[\times\Sigma^-,\\
E(t,x) = -\partial_x U,\ \partial_x E = -\partial_x^2 U = \rho(t,x) := \int_{\mathbb{R}_v} f(t,x,v)dv,\ (t,x)\in]0,T[\times]0,1[,\\
U(t,x=0) = U_0(t),\ U(t,x=1) = U_1(t),\ t\in]0,T[.
\end{aligned}$$

The function $f(t,x,v)$ represents the particles distribution depending on the time t, the position x, and the velocity v. The electric field $E(t,x)$ derives from an electrostatic potential U verifying the Poisson equation with the charge density $\rho(t,x) := \int_{\mathbb{R}_v} f(t,x,v)dv$. Here Σ^- is the subset of $\Sigma = \{0,1\}\times\mathbb{R}_v$ corresponding to the incoming velocities:

$$\Sigma^- = \{(0,v)\mid v>0\}\cup\{(1,v)\mid v<0\} = \Sigma_0^-\cup\Sigma_1^-.$$

Similarly, we define also $\Sigma^+ = \{(0,v)\mid v<0\}\cup\{(1,v)\mid v>0\} = \Sigma_0^+\cup\Sigma_1^+$, which corresponds to the outgoing velocities and $\Sigma^0 = \{(0,0),(1,0)\}$. With the notation $g|_{]0,T[\times\Sigma_0^-} = g_0, g|_{]0,T[\times\Sigma_1^-} = g_1$, the boundary condition is written

$$f(t,x=0,v>0) = g_0(t,v>0),\quad f(t,x=1,v<0) = g_1(t,v<0),\quad t\in]0,T[.$$

The existence of a weak solution for the Vlasov–Poisson initial-boundary value problem has been obtained in previous works; in [4] weak solutions of finite total (kinetic and electric) energy are constructed in dimension d, $d\le 3$, by assuming initial-boundary conditions of finite kinetic, respectively flux of kinetic, energy:

$$\int_0^1\int_{\mathbb{R}_v} f_0(x,v)|v|^2dxdv + \sup_{0\le t\le T}\left\{\int_{v>0} v|v|^2 g_0(t,v)dv - \int_{v<0} v|v|^2 g_1(t,v)dv\right\} < +\infty,$$

and $|v|^\lambda f_0 \in L^\infty(]0,1[\times\mathbb{R}_v), |v|^\lambda g_0 \in L^\infty(]0,T[\times\mathbb{R}_v^+), |v|^\lambda g_1 \in L^\infty(]0,T[\times\mathbb{R}_v^-)$ for some $\lambda > d+1$. The main goal of this paper is to establish the existence and uniqueness of the mild solution (or solution by characteristics) in one dimension under a less restrictive hypothesis, say, for initial-boundary conditions of finite charge. As is usual when studying coupled equations, we search the solutions as fixed points for some nonlinear application. For the 1D Vlasov–Poisson system this application is written, for example, as $\mathcal{F}: B_R(X_T)\to B_R(X_T)$, where

$$\mathcal{F}E(t,x) = \int_0^x \rho_E(t,y)dy - \int_0^1 (1-y)\rho_E(t,y)dy - U_1(t) + U_0(t),$$
$$(t,x)\in]0,T[\times]0,1[,$$

where $\rho_E(t,x) = \int_{\mathbb{R}_v} f_E(t,x,v)dv$ and f_E solves the linear Vlasov problem associated with the field E and $B_R(X_T)$ is the ball of radius R of some space X_T. Naturally, in order to construct solutions by characteristics, which are written as

$$\frac{d}{ds}X(s;t,x,v) = V(s;t,x,v), \quad \frac{d}{ds}V(s;t,x,v) = E(s, X(s;t,x,v)),$$
$$s_{in}(t,x,v) \le s \le s_{out}(t,x,v),$$

the space X_T to be considered is $L^\infty(]0,T[;W^{1,\infty}(]0,1[))$. Here s_{in}/s_{out} represent the entry/exit time of the characteristics in the domain $]0,1[$ (see the next section for exact definitions). Since by construction $\partial_x \mathcal{F}E = \rho_E$ (conforming to the Poisson equation), it is clear that $B_R(X_T)$ is preserved by $\mathcal{F}$, provided that the charge density remains uniformly bounded in $L^\infty(]0,T[\times]0,1[)$. Therefore the natural hypotheses are

$$\int_{\mathbb{R}_v} \sup_{0<x<1} f_0(x,v)dv + \int_{v>0} \sup_{0<t<T} g_0(t,v)dv + \int_{v<0} \sup_{0<t<T} g_1(t,v)dv < +\infty$$

and

$$\max\{\|f_0\|_{L^\infty(]0,1[\times\mathbb{R}_v)}, \|g_0\|_{L^\infty(]0,T[\times\mathbb{R}_v^+)}, \|g_1\|_{L^\infty(]0,T[\times\mathbb{R}_v^-)}\} < +\infty.$$

We intend to show the existence of a unique fixed point for $\mathcal{F}$ by using the iterated approximations method, which requires us to estimate $\mathcal{F}A - \mathcal{F}B$ in terms of $A - B$ for A, B different fields of X_T. This can be done by using the mild formulation of the Vlasov problem. Indeed, by using the continuity equation $\partial_t \rho_E + \partial_x j_E = 0$, $\mathcal{F}E$ can be represented also in term of the current density. Or estimate $\int_0^t j_A(s,x)ds - \int_0^t j_B(s,x)ds$ in $L^\infty(]0,1[)$ reduces to a duality calculation by taking the product by L^1 functions φ:

$$\begin{aligned}\left\langle \int_0^t (j_A(s,\cdot) - j_B(s,\cdot))ds, \varphi(\cdot) \right\rangle &= \int_0^t \int_0^1 \int_{\mathbb{R}_v} (f_A(s,x,v) - f_B(s,x,v)) v\varphi(x) ds dx dv \\ &= \int_0^t \int_{v>0} v g_0(\tau, v) \int_{X_B(s_{out}^0)}^{X_A(s_{out}^0)} \varphi(u) du d\tau dv \\ &\quad - \int_0^t \int_{v<0} v g_1(\tau, v) \int_{X_B(s_{out}^1)}^{X_A(s_{out}^1)} \varphi(u) du d\tau dv \\ &\quad + \int_0^1 \int_{\mathbb{R}_v} f_0(x,v) \int_{X_B(s_{out}^i)}^{X_A(s_{out}^i)} \varphi(u) du dx dv,\end{aligned}$$

where $s_{out}^0 = s_{out}(\tau,0,v), s_{out}^i = s_{out}(0,x,v), s_{out}^1 = s_{out}(\tau,1,v)$ represent the exit times of the characteristics (see the next sections for the exact definitions). Note that for large velocities the integrand of the left boundary term vanishes since

$$X_A(s_{out}(\tau,0,v)) = X_B(s_{out}(\tau,0,v)) = 1.$$

This suggests the definition of some critical velocities $v^0(t;\tau,0), v^1(t;\tau,0)$ such that

$$s_{out}(\tau,0,v) < t, \ X(s_{out}(\tau,0,v);\tau,0,v) = 0, \ 0 < v < v^0(t;\tau,0),$$
$$s_{out}(\tau,0,v) = t, \ 0 < X(s_{out}(\tau,0,v);\tau,0,v) < 1, \ v^0(t;\tau,0) < v < v^1(t;\tau,0),$$
$$s_{out}(\tau,0,v) < t, \ X(s_{out}(\tau,0,v);\tau,0,v) = 1, \ v > v^1(t;\tau,0).$$

Similar definitions hold for the right boundary term. One of the key points of our analysis consists of estimating the relative critical velocity. For nondecreasing fields with respect to x, we have

$$|v_A^k(t;\tau,k) - v_B^k(t;\tau,k)| \leq \int_\tau^t \|A(s) - B(s)\|_{L^\infty(]0,1[)} ds,\ k = 0, 1,$$

and finally one gets

$$\|\mathcal{F}A(t) - \mathcal{F}B(t)\|_{L^\infty(]0,1[)} \leq C \int_0^t \|A(\tau) - B(\tau)\|_{L^\infty(]0,1[)} d\tau,$$

where C depends only on the $L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ norms of A, B and the initial-boundary conditions. We prove the following existence and uniqueness result.

THEOREM. *Assume that there are $n_0, h_0, h_1 : [0,+\infty[\to [0,+\infty[$ bounded nonincreasing functions such that $f_0(x,v) \leq n_0(|v|)$ $\forall (x,v) \in]0,1[\times \mathbb{R}_v$, $g_0(t,v) \leq h_0(v)$ $\forall (t,v) \in]0,T[\times \mathbb{R}_v^+$, $g_1(t,v) \leq h_1(-v)$ $\forall (t,v) \in]0,T[\times \mathbb{R}_v^-$, and*

$$\int_{\mathbb{R}_v} n_0(|v|)dv + \int_{v>0} h_0(v)dv + \int_{v<0} h_1(-v)dv < +\infty,$$

$$\max\{\|n_0\|_{L^\infty(\mathbb{R}_v^+)}, \|h_0\|_{L^\infty(\mathbb{R}_v^+)}, \|h_1\|_{L^\infty(\mathbb{R}_v^+)}, \|U_1 - U_0\|_{L^\infty(]0,T[)}\} < +\infty.$$

Then there is a unique mild solution for the 1D *Vlasov–Poisson initial-boundary value problem.*

The estimate of the relative critical velocity, which is used for the treatment of the boundary terms, relies on some comparison results for characteristics associated with nondecreasing fields, presented in section 4. This is why, when studying the Vlasov–Poisson initial-boundary value problem, we consider only one species of charged particles. All the definitions concerning the weak/mild formulations for the Vlasov or Vlasov–Poisson problem are recalled in sections 2 and 3. The main result on the existence and uniqueness of the mild solution, as well as a continuity result upon the initial-boundary conditions, is developed in section 5. The same method applies when studying the free or periodic space problem. Moreover, in this cases there are no boundary terms and thus the analysis on critical velocities not need to be used. This time the existence and uniqueness result can be obtained for general electric fields (not necessarily nondecreasing in space) which allows us to treat systems with two species of charged particles (globally neutral plasma). Statements and sketches of proofs can be found in sections 6 and 7.

2. The Vlasov equation. The equation that models the transport of charged particles is called the Vlasov equation. In one dimension, if the particles move only under the action of an electric field this equation is written

$$\partial_t f + v \cdot \partial_x f + E(t,x) \cdot \partial_v f = 0,\ (t,x,v) \in]0,T[\times]0,1[\times \mathbb{R}_v. \tag{2.1}$$

Here $E(t,x)$ is a given electric field which derives from a potential $U(t,x)$:

$$E(t,x) = -\partial_x U,\ (t,x) \in]0,T[\times]0,1[.$$

The initial-boundary conditions for the particle distribution are given by

$$f(t=0,x,v) = f_0(x,v),\ (x,v) \in]0,1[\times \mathbb{R}_v, \tag{2.2}$$

(2.3) $\quad f(t,x=0,v>0)=g_0(t,v>0),\quad f(t,x=1,v<0)=g_1(t,v<0),\quad t\in\,]0,T[.$

Now let us briefly recall the definitions of weak and mild solutions for the Vlasov problem formed by (2.1), (2.2), and (2.3).

2.1. Weak solutions for the Vlasov–Poisson problem.

DEFINITION 2.1. *Assume that* $E\in L^\infty(]0,T[\times]0,1[)$, $f_0\in L^1_{loc}(]0,1[\times\mathbb{R}_v)$, $vg_0\in L^1_{loc}(]0,T[\times\mathbb{R}_v^+)$, $vg_1\in L^1_{loc}(]0,T[\times\mathbb{R}_v^-)$. *We say that* $f\in L^1_{loc}\,(]0,T[\times]0,1[\times\mathbb{R}_v)$ *is a weak solution for the Vlasov problem* (2.1), (2.2), (2.3) *iff*

$$
\begin{aligned}
&-\int_0^T\!\!\int_0^1\!\!\int_{\mathbb{R}_v} f(t,x,v)\cdot(\partial_t\varphi+v\cdot\partial_x\varphi+E(t,x)\cdot\partial_v\varphi)dtdxdv\\
&\quad=\int_0^1\!\!\int_{\mathbb{R}_v} f_0(x,v)\varphi(0,x,v)dxdv+\int_0^T\!\!\int_{v>0} vg_0(t,v)\varphi(t,0,v)dtdv\\
&\qquad-\int_0^T\!\!\int_{v<0} vg_1(t,v)\varphi(t,1,v)dtdv
\end{aligned}
$$

for all test function $\varphi\in\mathcal{T}_w$, *where*

$$
\begin{aligned}
\mathcal{T}_w=\{&\varphi\in W^{1,\infty}(]0,T[\times]0,1[\times\mathbb{R}_v)\mid \varphi|_{]0,T[\times\Sigma^+}=\varphi(T,\cdot,\cdot)=0,\\
&\exists R:\mathrm{supp}(\varphi)\subset[0,T]\times[0,1]\times B_R\}.
\end{aligned}
$$

2.2. Mild solutions for the Vlasov problem. We need to consider also some special solutions of (2.1), (2.2), (2.3), which are called mild solutions or solutions by characteristics. These solutions require more regularity on the electric field and they are particular cases of weak solutions. Assume that $E\in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$, and for $(t,x,v)\in\{[0,T[\times]0,1[\times\mathbb{R}_v\}\cup\{]0,T[\times\Sigma^-\}$ let us denote by $(X(s;t,x,v),V(s;t,x,v))$ the unique solution of the ordinary differential system of equations

(2.4)

$$
\begin{aligned}
&\frac{d}{ds}X(s;t,x,v)=V(s;t,x,v),\\
&\frac{d}{ds}V(s;t,x,v)=E(s,X(s;t,x,v)),\qquad s_{in}\le s\le s_{out},
\end{aligned}
$$

which verify the conditions

$$X(s=t;t,x,v)=x,\quad V(s=t;t,x,v)=v.$$

Here $s_{in}=s_{in}(t,x,v)$ (resp., $s_{out}=s_{out}(t,x,v)$) represents the incoming (resp., outgoing) time of the characteristics in the domain $]0,1[$ defined by

(2.5) $$s_{in}(t,x,v)=\max\{0,\sup\{0\le s\le t\ :\ X(s;t,x,v)\in\{0,1\}\}\},$$

and

(2.6) $$s_{out}(t,x,v)=\min\{T,\inf\{T\ge s\ge t\ :\ X(s;t,x,v)\in\{0,1\}\}\}.$$

The total travel time through the domain (lifetime) is written $\tau(t,x,v)=s_{out}(t,x,v)-s_{in}(t,x,v)\le T$. Now we replace in Definition 2.1 the function $\partial_t\varphi+v\cdot\partial_x\varphi+E(t,x)\cdot\partial_v\varphi$ with ψ, which gives, after integration,

$$\varphi(t,x,v)=-\int_t^{s_{out}(t,x,v)}\psi(s,X(s;t,x,v),V(s;t,x,v))ds,$$

and we define the mild solution as follows.

DEFINITION 2.2. *Assume that* $E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$, $f_0 \in L^1_{loc}(]0,1[\times\mathbb{R}_v)$, $vg_0 \in L^1_{loc}(]0,T[\times\mathbb{R}_v^+)$, $vg_1 \in L^1_{loc}(]0,T[\times\mathbb{R}_v^-)$. *We say that* $f \in L^1_{loc}(]0,T[\times]0,1[\times\mathbb{R}_v)$ *is a mild solution for the Vlasov problem* (2.1), (2.2), (2.3) *iff*

$$\begin{aligned}
&\int_0^T\!\!\int_0^1\!\!\int_{\mathbb{R}_v} f(t,x,v)\psi(t,x,v)dtdxdv\\
&\quad= \int_0^1\!\!\int_{\mathbb{R}_v} f_0(x,v)\int_0^{s_{out}(0,x,v)} \psi(s,X(s;0,x,v),V(s;0,x,v))dsdxdv\\
&\qquad+\int_0^T\!\!\int_{v>0} vg_0(t,v)\int_t^{s_{out}(t,0,v)}\psi(s,X(s;t,0,v),V(s;t,0,v))dsdtdv\\
&\qquad-\int_0^T\!\!\int_{v<0} vg_1(t,v)\int_t^{s_{out}(t,1,v)}\psi(s,X(s;t,1,v),V(s;t,1,v))dsdtdv,
\end{aligned}$$

for all test functions $\psi \in \mathcal{T}_m$, *where*

$$\mathcal{T}_m = \{\psi \in L^\infty(]0,T[\times]0,1[\times\mathbb{R}_v) \mid \exists R>0 : \mathrm{supp}(\psi) \subset [0,T]\times[0,1]\times B_R\}.$$

In order to simplify the formulas we shall use the following notation:

$$\begin{aligned}
(X(s),V(s)) &= (X(s;t,x,v),V(s;t,x,v)), (X^0(s),V^0(s))\\
&= (X(s;t,0,v),V(s;t,0,v)),\\
(X^1(s),V^1(s)) &= (X(s;t,1,v),V(s;t,1,v)), (X^i(s),V^i(s))\\
&= (X(s;0,x,v),V(s;0,x,v))
\end{aligned}$$

and

$$\begin{aligned}
s_{in} = s_{in}(t,x,v),\quad s_{out} = s_{out}(t,x,v),\quad s^0_{out} = s_{out}(t,0,v),\\
s^1_{out} = s_{out}(t,1,v),\quad s^i_{out} = s_{out}(0,x,v).
\end{aligned}$$

Remark 2.3. It is well known that the mild solution is unique and is given by $f(t,x,v) = g_k(s_{in},V(s_{in}))$ if $s_{in}(t,x,v) > 0$, $X(s_{in}(t,x,v);t,x,v) = k, k = 0,1$, $f(t,x,v) = f_0(X(s_{in}),V(s_{in}))$ if $s_{in}(t,x,v) = 0$.

Note that every mild solution is also a weak solution. Moreover, the existence of a weak solution for the Vlasov problem with bounded initial-boundary conditions f_0, g_0, $g_1 \in L^\infty$ follows by regularization of the electric field with respect to x by convolution with $\zeta_\varepsilon(\cdot) = \frac{1}{\varepsilon}\zeta\left(\frac{\cdot}{\varepsilon}\right)$, $\zeta \in C_0^\infty$, $\mathrm{supp}(\zeta) = [-1,1], \zeta \geq 0$, $\int_{\mathbb{R}}\zeta(u)du = 1$, and by passing to the limit for $\varepsilon \searrow 0$ in the weak formulation of f^ε, the mild solution associated with $E^\varepsilon = E \star \zeta_\varepsilon$.

3. The Vlasov–Poisson system. The self-consistent electric field solves the Poisson equation

$$\partial_x E = -\partial_x^2 U = \rho(t,x) := \int_{\mathbb{R}_v} f(t,x,v)dv,\ (t,x) \in]0,T[\times]0,1[\tag{3.1}$$

with the boundary conditions

$$U(t,x=0) = U_0(t),\ \ U(t,x=1) = U_1(t),\ \ t \in]0,T[. \tag{3.2}$$

The system formed by (2.1), (2.2), (2.3), (3.1), (3.2) is called the Vlasov–Poisson initial-boundary value problem in one dimension. Obviously, the electric field is written

$$E(t,x) = \int_0^x \rho(t,y)dy - \int_0^1 (1-y)\rho(t,y)dy - U_1(t) \\ + U_0(t),\ (t,x) \in]0,T[\times]0,1[, \tag{3.3}$$

and therefore we can give the following definitions.

DEFINITION 3.1. *Assume that* $f_0 \in L^1_{loc}(]0,1[\times\mathbb{R}_v)$, $vg_0 \in L^1_{loc}(]0,T[\times\mathbb{R}_v^+)$, $vg_1 \in L^1_{loc}(]0,T[\times\mathbb{R}_v^-)$, $U_1 - U_0 \in L^\infty(]0,T[)$. *We say that* $(f,E) \in L^1(]0,T[\times]0,1[\times\mathbb{R}_v)\times L^\infty(]0,T[\times]0,1[)$ (*resp.*, $(f,E) \in L^1(]0,T[\times]0,1[\times\mathbb{R}_v)\times L^\infty(]0,T[;W^{1,\infty}(]0,1[))$) *is a weak* (*resp., mild*) *solution for the Vlasov–Poisson problem iff f is a weak* (*resp., mild*) *solution for the Vlasov problem* (2.1), (2.2), (2.3) *corresponding to the electric field* (3.3) *given by the Poisson problem.*

4. Characteristics. The main tool of our analysis is the mild formulation of the Vlasov problem. In order to estimate the charge and current densities, we need more informations about the characteristics. We present here some properties of the characteristics associated with regular, nondecreasing with respect to x, fields.

PROPOSITION 4.1. *Assume that* $E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ *is nondecreasing with respect to x and that* $(X_1(s),V_1(s))$, $(X_2(s),V_2(s))$ *are two characteristics such that there is* $s_1 < s_2$ *verifying* $X_1(s_i) = X_2(s_i)$, $i = 1,2$. *Then the characteristics coincide:* $(X_1(s),V_1(s)) = (X_2(s),V_2(s))\ \forall s$.

Proof. The conclusion follows easily after multiplication of the equation $\frac{d^2}{ds^2}(X_1(s) - X_2(s)) = E(s,X_1(s)) - E(s,X_2(s))$ by $X_1(s) - X_2(s)$ and integration by parts on $[s_1,s_2]$. ☐

PROPOSITION 4.2. *Assume that* $E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ *is nondecreasing with respect to x. If* $v_1 < v_2$, *then we have*

$$X(s;t,x,v_1) < X(s;t,x,v_2),\ V(s;t,x,v_1) < V(s;t,x,v_2) \\ \forall s \in]t, s_{out}(t,x,v_1)] \cap]t, s_{out}(t,x,v_2)]$$

and

$$X(s;t,x,v_1) > X(s;t,x,v_2),\ V(s;t,x,v_1) < V(s;t,x,v_2) \\ \forall s \in [s_{in}(t,x,v_1), t[\cap [s_{in}(t,x,v_2)[.$$

Proof. Suppose that there is $s \in [s_{in}(t,x,v_1), s_{out}(t,x,v_1)] \cap [s_{in}(t,x,v_2), s_{out}(t,x,v_2)]$, $s \neq t$, such that $X(s;t,x,v_1) = X(s;t,x,v_2)$. Since $X(t;t,x,v_1) = X(t;t,x,v_2) = x$, by Proposition 4.1 it follows that the characteristics coincide, and thus $v_1 = v_2$, which is in contradiction with the hypothesis. Therefore $X(s;t,x,v_1) - X(s;t,x,v_2)$ has constant sign on the intervals $[s_{in}(t,x,v_1), t[\cap [s_{in}(t,x,v_2), t[$ and $]t, s_{out}(t,x,v_1)] \cap]t, s_{out}(t,x,v_2)]$. On the other hand, we have

$$\frac{d}{ds}(X(s;t,x,v_1) - X(s;t,x,v_2))|_{s=t} = v_1 - v_2 < 0,$$

and therefore $X(s;t,x,v_1) - X(s;t,x,v_2)$ is decreasing locally in $s = t$. We deduce that

$$X(s;t,x,v_1) > X(s;t,x,v_2),\ s \in [s_{in}(t,x,v_1), t[\cap [s_{in}(t,x,v_2), t[,$$

and

$$X(s;t,x,v_1) < X(s;t,x,v_2),\ s \in]t, s_{out}(t,x,v_1)] \cap]t, s_{out}(t,x,v_2)].$$

By using the characteristics equations, one gets

$$\frac{d}{ds}(V(s;t,x,v_1) - V(s;t,x,v_2)) = E(s, X(s;t,x,v_1)) - E(s, X(s;t,x,v_2)),$$

and thus $V(s;t,x,v_1) - V(s;t,x,v_2)$ is nondecreasing on $[s_{in}(t,x,v_1), t[\cap [s_{in}(t,x,v_2), t[$ and nonincreasing on $]t, s_{out}(t,x,v_1)] \cap]t, s_{out}(t,x,v_2)]$. We deduce that

$$V(s;t,x,v_1) - V(s;t,x,v_2) \le v_1 - v_2 < 0,$$
$$s \in [s_{in}(t,x,v_1), s_{out}(t,x,v_1)] \cap [s_{in}(t,x,v_2), s_{out}(t,x,v_2)]. \qquad \square$$

When using the mild formulation of the Vlasov problem it is important to distinguish the characteristics with respect to the exit point. This justifies the following definitions: for $(t,x) \in \{[0,T[\times]0,1[\} \cup \{]0,T[\times\{0,1\}\}$ we denote by $\mathcal{V}^0, \mathcal{V}^1, \mathcal{V}^T$ the subsets of $\mathbb{R}_v$ given by

$$\mathcal{V}^0(T;t,x) := \{v \in \mathbb{R}_v : s_{out}(t,x,v) < T,\ X(s_{out}(t,x,v);t,x,v) = 0\}, \tag{4.1}$$

$$\mathcal{V}^1(T;t,x) := \{v \in \mathbb{R}_v : s_{out}(t,x,v) < T,\ X(s_{out}(t,x,v);t,x,v) = 1\}, \tag{4.2}$$

$$\mathcal{V}^T(T;t,x) := \{v \in \mathbb{R}_v : s_{out}(t,x,v) = T,\ 0 < X(T;t,x,v) < 1\}. \tag{4.3}$$

Note that when E is bounded there is R large enough such that $]-\infty, -R[\subset \mathcal{V}^0(T;t,x)$ and $]R, +\infty[\subset \mathcal{V}^1(T;t,x)$, and thus $\mathcal{V}^0(T;t,x) \neq \emptyset, \mathcal{V}^1(T;t,x) \neq \emptyset$. By the definition $\mathcal{V}^0(T;t,x) \cap \mathcal{V}^1(T;t,x) = \emptyset$ and $\mathcal{V}^T(T;t,x) \cap \{\mathcal{V}^0(T;t,x) \cup \mathcal{V}^1(T;t,x)\} = \emptyset$.

PROPOSITION 4.3. *Assume that $E \in L^\infty(]0,T[; W^{1,\infty}(]0,1[))$ is nondecreasing with respect to x. Then we have that*

(1) *if $v_2 \in \mathcal{V}^0(T;t,x)$, then $v_1 \in \mathcal{V}^0(T;t,x)$ $\forall v_1 < v_2$;*
(2) *if $v_1 \in \mathcal{V}^1(T;t,x)$, then $v_2 \in \mathcal{V}^1(T;t,x)$ $\forall v_2 > v_1$;*
(3) *if $v_1 \in \mathcal{V}^0(T;t,x)$, $v_2 \in \mathcal{V}^1(T;t,x)$, then $v_1 < v_2$.*

Proof. (1) Suppose that $s_{out}(t,x,v_1) \ge s_{out}(t,x,v_2)$. By Proposition 4.2 we deduce that

$$X(s;t,x,v_1) < X(s;t,x,v_2)\ \forall s \in]t, s_{out}(t,x,v_1)] \cap]t, s_{out}(t,x,v_2)] =]t, s_{out}(t,x,v_2)].$$

In particular, for $s = s_{out}(t,x,v_2)$ we find that

$$0 \le X(s_{out}(t,x,v_2);t,x,v_1) < X(s_{out}(t,x,v_2);t,x,v_2) = 0,$$

which is not possible. Finally, we have $s_{out}(t,x,v_1) < s_{out}(t,x,v_2) < T$ and

$$X(s_{out}(t,x,v_1);t,x,v_1) < X(s_{out}(t,x,v_1);t,x,v_2) < 1.$$

We deduce that $X(s_{out}(t,x,v_1);t,x,v_1) = 0$ or $v_1 \in \mathcal{V}^0(T;t,x)$.

(2) Similarly, if $v_1 \in \mathcal{V}^1(T;t,x)$ and $v_1 < v_2$ we have $s_{out}(t,x,v_2) < s_{out}(t,x,v_1) < T$ (otherwise $1 = X(s_{out}(t,x,v_1);t,x,v_1) < X(s_{out}(t,x,v_1);t,x,v_2)$) and $0 < X(s_{out}(t,x,v_2);t,x,v_1) < X(s_{out}(t,x,v_2);t,x,v_2)$. We deduce that $X(s_{out}(t,x,v_2);t,x,v_2) = 1$ and $v_2 \in \mathcal{V}^1(T;t,x)$.

(3) Suppose that $v_1 \ge v_2$. Since $v_1 \in \mathcal{V}^0(T;t,x)$, by (1) it follows that $v_2 \in \mathcal{V}^0(T;t,x) \cap \mathcal{V}^1(T;t,x) = \emptyset$. Therefore we have $v_1 < v_2$. $\square$

We introduce the critical velocities $v^0(T;t,x), v^1(T;t,x)$ given by

$$v^0(T;t,x) := \sup \mathcal{V}^0(T;t,x),\quad v^1(T;t,x) := \inf \mathcal{V}^1(T;t,x). \tag{4.4}$$

Obviously, we have $-\infty < v^0(T;t,x) \le v^1(T;t,x) < +\infty$.

PROPOSITION 4.4. *Assume that* $E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ *is nondecreasing with respect to* x. *We have*

(1) $]-\infty, v^0(T;t,x)[\subset \mathcal{V}^0(T;t,x) \subset]-\infty, v^0(T;t,x)]$;

(2) $]v^1(T;t,x), +\infty[\subset \mathcal{V}^1(T;t,x) \subset [v^1(T;t,x), +\infty[$;

(3) $]v^0(T;t,x), v^1(T;t,x)[\subset \mathcal{V}^T(T;t,x) \subset [v^0(T;t,x), v^1(T;t,x)]$.

Proof. From Proposition 4.3 and the definitions of v^0, v^1 we deduce (1) and (2). On the other hand, $\mathcal{V}^T(T;t,x) \subset \mathbb{R}_v - \{\mathcal{V}^0(T;t,x) \cup \mathcal{V}^1(T;t,x)\} \subset \mathbb{R}_v - \{]-\infty, v^0(T;t;x)[\cup]v^1(T;t,x), +\infty[\} = [v^0(T;t,x), v^1(T;t,x)]$. Let us prove that $]v^0, v^1[\subset \mathcal{V}^T$. Consider $v^0 < v < v^1$ if $v^0 < v^1$. Suppose that $s_{out}(t,x,v) < T$ with $X(s_{out}(t,x,v);t,x,v) = 0$ or $v \in \mathcal{V}^0(T;t,x)$. By Proposition 4.3 we deduce that $\tilde{v} \in \mathcal{V}^0(T;t,x)\ \forall v^0 < \tilde{v} < v$, which is in contradiction with $\tilde{v} > v^0 = \sup \mathcal{V}^0(T;t,x)$. The same arguments apply for $s_{out}(t,x,v) < T, X(s_{out}(t,x,v);t,x,v) = 1$ by taking $v < \tilde{v} < v^1$. We have that $s_{out}(t,x,v) = T\ \forall v^0 < v < v^1$. Suppose now that $X(T;t,x,v) = 0$. If we take $v^0 < \tilde{v} < v$, we deduce that $s_{out}(t,x,\tilde{v}) = T$ and by Proposition 4.2 we find that $0 \le X(T;t,x,\tilde{v}) < X(T;t,x,v) = 0$. Similarly, we can show that $X(T;t,x,v) = 1$ is not possible. Finally, we deduce that $X(T;t,x,v) \in]0,1[\forall v^0 < v < v^1$, and thus $]v^0, v^1[\subset \mathcal{V}^T$. $\square$

Let us consider two fields A, B. In order to prove the uniqueness of the mild solution for the Vlasov–Poisson problem, it will be useful to estimate the change of critical velocity $|v_A^k - v_B^k|, k = 0, 1$, with respect to the relative field $A - B$. For this we need to introduce the notion of sub-/supercharacteristics as follows.

DEFINITION 4.5. *Assume that* $E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ *is nondecreasing with respect to* x. *We say that* $(X(s), V(s))$ *is a subcharacteristic* (*resp., supercharacteristic*) *iff* X *is twice differentiable with respect to* s *and*

$$\frac{dX}{ds} = V(s), \quad \frac{dV}{ds} \le E(s, X(s)), \quad s_{in} \le s \le s_{out}$$

$$\left(resp., \frac{dX}{ds} = V(s), \quad \frac{dV}{ds} \ge E(s, X(s)), \quad s_{in} \le s \le s_{out} \right)$$

with the same definitions for s_{in}, s_{out} *as before.*

We have the following comparison result.

PROPOSITION 4.6 (forward comparison). *Assume that* $E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ *is nondecreasing with respect to* x. *Consider* $(\underline{X}(s), \underline{V}(s)), (\overline{X}(s), \overline{V}(s))$ *to be a subcharacteristic, resp., a supercharacteristic, such that* $\underline{X}(t) \le \overline{X}(t),\ \underline{V}(t) \le \overline{V}(t)$. *Then we have*

$$\underline{X}(s) \le \overline{X}(s) \ \ \underline{V}(s) \le \overline{V}(s) \ \ \forall s \in [t, \underline{s}_{out}] \cap [t, \overline{s}_{out}].$$

Proof. We can extend the field E to $]0,T[\times\mathbb{R}_x$ by $\tilde{E}(t,x) = E(t,0), x < 0$, and $\tilde{E}(t,x) = E(t,1), x > 1$. We have $\|\tilde{E}\|_{L^\infty(]0,T[;W^{1,\infty}(]0,1[))} \le \|E\|_{L^\infty(]0,T[;W^{1,\infty}(]0,1[))}$ and $\tilde{E}$ is nondecreasing with respect to x. Consider $(x,v) \in \mathbb{R}_x \times \mathbb{R}_v$ such that $\underline{X}(t) \le x \le \overline{X}(t),\ \underline{V}(t) \le v \le \overline{V}(t)$. Denote by $(X(s;t,x,v), V(s;t,x,v))$ the characteristic associated with the field $\tilde{E}$,

$$\frac{dX}{ds} = V(s), \quad \frac{dV}{ds} = \tilde{E}(s, X(s)),$$

with the conditions $X(s=t;t,x,v)=x, \quad V(s=t;t,x,v)=v$. We show that $\underline{X}(s) \le X(s) \le \overline{X}(s),\ \underline{V}(s) \le V(s) \le \overline{V}(s)\ \forall s \in [t, \underline{s}_{out}] \cap [t, \overline{s}_{out}]$. For this we can use the iterated approximations method. For example, in order to prove that $\underline{X} \le X, \underline{V} \le V$ we consider as first approximation $X^0 = \underline{X}, V^0 = \underline{V}$ and we define $X^{n+1}(s) = x + \int_t^s V^n(\tau)d\tau,\ V^{n+1}(s) = v + \int_t^s \tilde{E}(\tau, X^n(\tau))d\tau\ \forall s \in [t, \underline{s}_{out}]\ \forall n \ge 0$. We check easily that $X^n(s) \ge \underline{X}(s), V^n(s) \ge \underline{V}(s)\ \forall s \in [t, \underline{s}_{out}]$ and by passing to the limit for $n \to +\infty$ we find that $X(s) \ge \underline{X}(s),\ V(s) \ge \underline{V}(s)\ \forall s \in [t, \underline{s}_{out}]$. In the same way, by taking as initial approximation $(X^0, V^0) = (\overline{X}, \overline{V})$ we prove that $X(s) \le \overline{X}(s), V(s) \le \overline{V}(s) \forall s \in [t, \overline{s}_{out}]$. Finally, we have

$$\underline{X}(s) \le X(s) \le \overline{X}(s), \quad \underline{V}(s) \le V(s) \le \overline{V}(s) \quad \forall s \in [t, \underline{s}_{out}] \cap [t, \overline{s}_{out}]. \qquad \square$$

Remark 4.7. In fact, since $0 \le \underline{X}(s), \overline{X}(s) \le 1\ \forall\ t \le s \le \min\{\underline{s}_{out}, \overline{s}_{out}\}$ it follows that $0 \le X(s) \le 1\ \forall\ t \le s \le \min\{\underline{s}_{out}, \overline{s}_{out}\}$, and therefore (X, V) coincide with the characteristic associated with the field E. Moreover, $s_{out}(t, x, v) \ge \min\{\underline{s}_{out}, \overline{s}_{out}\}$.

Now we are ready to prove a result of continuous dependence of the critical velocities with respect to the electric field. We have the following lemma.

LEMMA 4.8 (critical velocity change). *Assume that $A, B \in L^\infty(]0, T[; W^{1,\infty}(]0, 1[))$ are nondecreasing with respect to x. Then $\forall (t, x) \in [0, T[\times [0, 1]$ we have the following inequality:*

$$|v_A^k(T; t, x) - v_B^k(T; t, x)| \le \int_t^T \|A(s) - B(s)\|_{L^\infty(]0,1[)} ds, \ \ k = 0, 1. \tag{4.5}$$

Proof. Denote $m = \|A - B\|_{L^1(]t,T[; L^\infty(]0,1[))}$. Let us prove, for example, that $|v_A^0 - v_B^0| \le m$. Suppose that $v_A^0 - v_B^0 > m$. Therefore there is $v > v_B^0$ such that $\tilde{v} = v + m < v_A^0$, and thus we deduce from Proposition 4.4 that $X_B(s_{out}^B(t, x, v); t, x, v) > 0$, $X_A(s_{out}^A(t, x, \tilde{v}); t, x, \tilde{v}) = 0,\ s_{out}^A(t, x, \tilde{v}) < T$. Consider the solution (X_C, V_C) of the following system of ordinary differential equations:

$$\frac{dX_C}{ds} = V_C(s), \quad \frac{dV_C}{ds} = B(s, X_A(s)), \ \ t \le s \le s_{out}^C(t, x, v),$$

with the conditions $X_C(t) = x, V_C(t) = v$. With the notation

$$(X_A(s), V_A(s)) = (X_A(s; t, x, \tilde{v}), V_A(s; t, x, \tilde{v})),\ t \le s \le s_{out}^A(t, x, \tilde{v}),$$

and

$$(X_B(s), V_B(s)) = (X_B(s; t, x, v), V_B(s; t, x, v)),\ t \le s \le s_{out}^B(t, x, v),$$

we have also

$$\frac{dX_A}{ds} = V_A(s), \quad \frac{dV_A}{ds} = A(s, X_A(s)), \ \ t \le s \le s_{out}^A(t, x, \tilde{v}),$$

with $X_A(t) = x, V_A(t) = \tilde{v}$, and

$$\frac{dX_B}{ds} = V_B(s), \quad \frac{dV_B}{ds} = B(s, X_B(s)), \ \ t \le s \le s_{out}^B(t, x, v),$$

with $X_B(t) = x, V_B(t) = v$. We deduce that

$$\begin{aligned}\frac{d}{ds}(X_A - X_C) = V_A(s) - V_C(s), \frac{d}{ds}&(V_A - V_C) \\ &= (A - B)(s, X_A(s)), t \le s \le \min\{s_{out}^A, s_{out}^C\},\end{aligned}$$

and $X_A(t) - X_C(t) = 0,\ V_A(t) - V_C(t) = \tilde{v} - v = m$. We have

$$|V_A(s) - V_C(s) - V_A(t) + V_C(t)| \leq \int_t^s \|A(\tau) - B(\tau)\|_{L^\infty(]0,1[)} d\tau$$
$$\leq m, t \leq s \leq \min\{s_{out}^A, s_{out}^C\},$$

and thus $V_A(s) - V_C(s) \geq V_A(t) - V_C(t) - m = 0,\ \ t \leq s \leq \min\{s_{out}^A, s_{out}^C\}$. Moreover, since $X_A(t) = X_C(t) = x$, it follows that $X_A(s) \geq X_C(s),\ t \leq s \leq \min\{s_{out}^A, s_{out}^C\}$. If we suppose that $s_{out}^A < s_{out}^C$, we deduce that $X_C(s_{out}^A; t, x, v) \leq X_A(s_{out}^A; t, x, \tilde{v}) = 0$, and thus we have $s_{out}^C \leq s_{out}^A$, which is in contradiction with the previous supposition. Therefore we have $s_{out}^C \leq s_{out}^A < T$. In particular, $X_C(s_{out}^C; t, x, v) \in \{0, 1\}$ and $X_C(s_{out}^C; t, x, v) \leq X_A(s_{out}^C; t, x, \tilde{v})$. Note also that $X_A(s_{out}^C; t, x, \tilde{v}) = 1$ implies that $s_{out}^A \leq s_{out}^C$, and thus it follows that $s_{out}^A = s_{out}^C < T$, which is not possible because $X_A(s_{out}^A; t, x, \tilde{v}) = 0$ and $X_A(s_{out}^C; t, x, \tilde{v}) = 1$. We obtain that $X_C(s_{out}^C; t, x, v) \leq X_A(s_{out}^C; t, x, \tilde{v}) < 1$ and we deduce that $X_C(s_{out}^C; t, x, v) = 0$. On the other hand,

$$\frac{d^2}{ds^2} X_C = B(s, X_A(s)) \geq B(s, X_C(s)),\ t \leq s \leq s_{out}^C,$$

and

$$\frac{d^2}{ds^2} X_B = B(s, X_B(s)),\ t \leq s \leq s_{out}^B.$$

Note that $X_C(t) = X_B(t) = x$ and $V_C(t) = V_B(t) = v$. Thus by applying the forward comparison (see Proposition 4.6) we deduce that $X_C(s) \geq X_B(s), V_C(s) \geq V_B(s),\ t \leq s \leq \min\{s_{out}^B, s_{out}^C\}$. If we suppose that $s_{out}^C < s_{out}^B$, we deduce that

$$0 = X_C(s_{out}^C; t, x, v) \geq X_B(s_{out}^C; t, x, v),$$

and thus we have $s_{out}^B \leq s_{out}^C$, which is in contradiction with the previous supposition. Therefore we have $s_{out}^B \leq s_{out}^C \leq s_{out}^A < T$ and

$$X_B(s) \leq X_C(s) \leq X_A(s),\ V_B(s) \leq V_C(s) \leq V_A(s),\ \ t \leq s \leq s_{out}^B.$$

Since $v > v_B^0$ and $s_{out}^B < T$ we have $X_B(s_{out}^B; t, x, v) = 1$. Now, by taking $s = s_{out}^B$ in the previous inequality we obtain

$$1 = X_B(s_{out}^B; t, x, v) \leq X_A(s_{out}^B; t, x, \tilde{v}),$$

which implies that $X_A(s_{out}^B; t, x, \tilde{v}) = 1$ and $s_{out}^A \leq s_{out}^B$ or $s_{out}^A = s_{out}^B$. As before we obtain a contradiction because $X_A(s_{out}^A; t, x, \tilde{v}) = 0$ and $X_A(s_{out}^B; t, x, \tilde{v}) = 1$. Finally, we have proved that the supposition $v_A^0 - v_B^0 > m$ is false and thus $v_A^0 - v_B^0 \leq m$. By changing A to B we obtain also that $v_B^0 - v_A^0 \leq m$ or $|v_A^0 - v_B^0| \leq m$. The same arguments apply for the critical velocities v_A^1, v_B^1. ∎

We end this section with some usual calculations concerning the continuity of the characteristics with respect to the field.

PROPOSITION 4.9. *Assume that* $A, B \in L^\infty(]0, T[; W^{1,\infty}(]0,1[))$ *and consider* $(t, x, v) \in \{[0, T[\times]0, 1[\times\mathbb{R}_v\} \cup \{]0, T[\times\Sigma^-\}$. *Then for* $s \in [s_{in}^A(t, x, v), s_{out}^A(t, x, v)] \cap [s_{in}^B(t, x, v), s_{out}^B(t, x, v)]$ *we have*

$$|X_A(s; t, x, v) - X_B(s; t, x, v)| + |V_A(s; t, x, v) - V_B(s; t, x, v)|$$
$$\leq \left| \int_t^s \|A(\tau) - B(\tau)\|_{L^\infty(]0,1[)} d\tau \right| \cdot \exp\left(\left| \int_t^s (1 + \|\partial_x B(\tau)\|_{L^\infty(]0,1[)}) d\tau \right| \right).$$

5. Existence and uniqueness of the mild solution. In this section we intend to prove the existence and the uniqueness of the mild solution for the Vlasov–Poisson initial-boundary value problem in one dimension by using the iterated approximations method. We consider the application $\mathcal{F}$ defined for a regular electric field $E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ as follows:

$$E \to f_E \to \rho_E = \int_{\mathbb{R}_v} f_E(t,x,v)dv \to E_1 = \mathcal{F}(E), \tag{5.1}$$

where f_E is the mild solution of the Vlasov problem associated with the field E and E_1 is the Poisson electric field corresponding to the charge density ρ_E . Before analyzing the application $\mathcal{F}$ let us introduce some notation. If $u : [0,+\infty[\to [0,+\infty[$ is a bounded nonincreasing real function and $R > 0$, we denote by $u^R : [-R,+\infty[\to [0,+\infty[$ the function given by $u^R(t) = u(0)$ if $-R \le t \le R$ and $u^R(t) = u(t-R)$ if $t > R$. If we assume that u belongs to $L^1(\mathbb{R}^+)$, and therefore,

$$\|u^R\|_{L^1(-R,+\infty)} = 2R\|u\|_{L^\infty(\mathbb{R}^+)} + \|u\|_{L^1(\mathbb{R}^+)}.$$

5.1. Estimate of $\mathcal{F}$. We assume that the initial-boundary conditions verify the following hypothesis denoted by (H): there are $n_0, h_0, h_1 : [0,+\infty[\to [0,+\infty[$ bounded, nonincreasing functions such that

$$(H)\quad \begin{aligned} &f_0(x,v) \le n_0(|v|), \quad (x,v) \in]0,1[\times \mathbb{R}_v,\\ &g_0(t,v) \le h_0(v), \quad (t,v) \in]0,T[\times \mathbb{R}_v^+,\\ &g_1(t,v) \le h_1(-v), \quad (t,v) \in]0,T[\times \mathbb{R}_v^-, \end{aligned}$$

and

$$(H_0)\quad M_0 := \int_{\mathbb{R}_v} n_0(|v|)dv + \int_{v>0} h_0(v)dv + \int_{v<0} h_1(-v)dv < +\infty,$$

$$(H_\infty)\quad M_\infty := \max\{\|n_0\|_{L^\infty(\mathbb{R}_v^+)}, \|h_0\|_{L^\infty(\mathbb{R}_v^+)}, \|h_1\|_{L^\infty(\mathbb{R}_v^+)}\} < +\infty.$$

Under the previous hypothesis we can prove the following proposition.

Proposition 5.1. *Assume that f_0, g_0, g_1 satisfy the hypotheses (H), (H_0), (H_∞) and $U_0 - U_1 \in L^\infty(]0,T[)$. Then for every $E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ we have $f_E \in L^\infty(]0,T[;L^1(]0,1[\times\mathbb{R}_v))$, $\rho_E \in L^\infty(]0,T[;L^1(]0,1[)) \cap L^\infty(]0,T[\times]0,1[)$, $\mathcal{F}E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$. Moreover, the following estimates hold:*

$$\begin{aligned} \|f_E\|_{L^\infty(]0,t[;L^1(]0,1[\times\mathbb{R}_v))} &= \|\rho_E\|_{L^\infty(]0,t[;L^1(]0,1[))}\\ &\le 6\cdot M_\infty \int_0^t \|E(\tau)\|_{L^\infty(]0,1[)}d\tau + M_0,\\ \|\rho_E\|_{L^\infty(]0,t[\times]0,1[)} &= \|\partial_x \mathcal{F}E\|_{L^\infty(]0,t[\times]0,1[)}\\ &\le 6\cdot M_\infty \int_0^t \|E(\tau)\|_{L^\infty(]0,1[)}d\tau + M_0,\\ \|\mathcal{F}E\|_{L^\infty(]0,t[;W^{1,\infty}(]0,1[))} &\le 12\cdot M_\infty \int_0^t \|E(s)\|_{L^\infty(]0,1[)}ds\\ &\quad + 2M_0 + \|U_0 - U_1\|_{L^\infty(]0,t[)}, \end{aligned}$$

$$\lim_{R_1\to+\infty} \int_{|v|>R_1} f_E(t,x,v)dv = 0 \text{ uniformly with respect to } (t,x) \in]0,T[\times]0,1[,$$

and the mild formulation of the Vlasov problem holds for test functions $\psi \in L^\infty(]0,T[\times]0,1[\times\mathbb{R}_v)$.

Proof. By Remark 2.3 we have

$$\begin{aligned}\rho_E(t,x) &= \int_{\mathbb{R}_v} f_E(t,x,v)dv = \int_{\mathbb{R}_v} f_0(X(0;t,x,v),V(0;t,x,v))\mathbf{1}_{\{s_{in}(t,x,v)=0\}}dv \\ &\quad + \sum_{k=0}^{1}\int_{\mathbb{R}_v} g_k(s_{in}(t,x,v),V(s_{in}(t,x,v);t,x,v))\mathbf{1}_{\{s_{in}(t,x,v)>0\}} \\ &\quad \times \mathbf{1}_{\{X(s_{in}(t,x,v);t,x,v)=k\}}dv \\ &= \mathcal{I}^i + \mathcal{I}^0 + \mathcal{I}^1.\end{aligned}$$

Let us estimate the first integral $\mathcal{I}^i$. For this, we consider $R = \int_0^t \|E(\tau)\|_{L^\infty(]0,1[)}d\tau$ and remark that $|V(0;t,x,v)| \geq |v| - R$, which implies that $n_0(|V(0;t,x,v)|) \leq n_0^R(|v|)$. By using the hypothesis (H), we find

$$\begin{aligned}\mathcal{I}^i &\leq \int_{\mathbb{R}_v} n_0(|V(0;t,x,v)|)\mathbf{1}_{\{s_{in}(t,x,v)=0\}}dv \\ &\leq \int_{\mathbb{R}_v} n_0^R(|v|)dv = 2R\|n_0\|_{L^\infty(\mathbb{R}_v^+)} + 2\cdot\|n_0\|_{L^1(\mathbb{R}_v^+)}.\end{aligned}$$

In the same way, by writing $v \geq V(s_{in}(t,x,v);t,x,v) - R \geq -R$ when $X(s_{in}(t,x,v);t,x,v) = 0$ and $v \leq V(s_{in}(t,x,v);t,x,v) + R \leq R$ when $X(s_{in}(t,x,v);t,x,v) = 1$, one gets

$$\begin{aligned}\mathcal{I}^0 + \mathcal{I}^1 &\leq \int_{v>-R} h_0^R(v)dv + \int_{v<R} h_1^R(-v)dv \\ &\leq 2\cdot R\cdot(\|h_0\|_{L^\infty(\mathbb{R}_v^+)} + \|h_1\|_{L^\infty(\mathbb{R}_v^+)}) + \|h_0\|_{L^1(\mathbb{R}_v^+)} + \|h_1\|_{L^1(\mathbb{R}_v^+)}.\end{aligned}$$

Finally, we deduce that

$$\rho_E(t,x) \leq 6\cdot M_\infty \int_0^t \|E(\tau)\|_{L^\infty(]0,1[)}d\tau + M_0, (t,x) \in]0,T[\times]0,1[,$$

and therefore

$$\begin{aligned}|\mathcal{F}E(t,x)| &= \left|\int_0^x \rho_E(t,y)dy - \int_0^1 (1-y)\rho_E(t,y)dy - U_1(t) + U_0(t)\right| \\ &\leq \|\rho_E\|_{L^\infty(]0,t[;L^1(]0,1[))} + \|U_0 - U_1\|_{L^\infty]0,t[}.\end{aligned}$$

We remark that in order to estimate the charge outside a ball of radius R_1, we can write, for example,

$$\begin{aligned}\mathcal{I}^i_{R_1} &= \int_{|v|>R_1} f_0(X(0;t,x,v),V(0;t,x,v))\mathbf{1}_{\{s_{in}(t,x,v)=0\}}dv \\ &\leq \int_{|v|>R_1} n_0^R(|v|)dv = \int_{|v|>R_1-R} n_0(|v|)dv\end{aligned}$$

for $R_1 > R$. Finally, one gets that

$$\int_{|v|>R_1} f_E(t,x,v)dv \leq \int_{|v|>R_1-R} n_0(|v|)dv + \int_{v>R_1-R} h_0(v)dv + \int_{v<-R_1+R} h_1(-v)dv \to 0$$

as $R_1 \to +\infty$ uniformly with respect to $(t,x) \in]0,T[\times]0,1[$. Consider now $\psi \in L^\infty(]0,T[\times]0,1[\times\mathbb{R}_v)$ and $\psi_{R_1} = \chi_{R_1}(v)\psi(t,x,v)$, where $\chi_{R_1}(\cdot) = \chi(\cdot/R_1)$ and $\chi \in C_c^1(\mathbb{R}), \chi(u) = 1, |u| \le 1, \chi(u) = 0, |u| \ge 2, 0 \le \chi(u) \le 1, 1 \le |u| \le 2$. Obviously, $\psi_{R_1} \in \mathcal{T}_m$, and thus

$$\begin{aligned}
&\int_0^T\int_0^1\int_{\mathbb{R}_v} f_E(t,x,v)\psi_{R_1}(t,x,v)dtdxdv \\
&\quad= \int_0^1\int_{\mathbb{R}_v} f_0(x,v)\int_0^{s_{out}(0,x,v)} \psi_{R_1}(s, X(s;0,x,v), V(s;0,x,v))dsdxdv \\
&\quad+ \int_0^T\int_{v>0} vg_0(t,v)\int_t^{s_{out}(t,0,v)} \psi_{R_1}(s, X(s;t,0,v), V(s;t,0,v))dsdtdv \\
&\quad- \int_0^T\int_{v<0} vg_1(t,v)\int_t^{s_{out}(t,1,v)} \psi_{R_1}(s, X(s;t,1,v), V(s;t,1,v))dsdtdv.
\end{aligned}$$

We have

$$\begin{aligned}
\left|\int_0^T\int_0^1\int_{\mathbb{R}_v} f_E\psi_{R_1}dtdxdv - \int_0^T\int_0^1\int_{\mathbb{R}_v} f_E\psi dtdxdv\right| &\le \int_0^T\int_0^1\int_{\mathbb{R}_v} f_E(1-\chi_{R_1}(v))|\psi|dtdxdv \\
&\le \|\psi\|_{L^\infty}\int_0^T\int_0^1\int_{|v|>R_1} f_E dtdxdv \to 0 \\
&\quad \text{as } R_1 \to +\infty.
\end{aligned}$$

In order to apply the dominated convergence theorem of Lebesgue, observe that

$$|f_0(x,v)\int_0^{s_{out}^i} \psi_{R_1}(s, X^i(s), V^i(s))ds| \le f_0(x,v)\|\psi\|_{L^\infty}T \in L^1(]0,1[\times\mathbb{R}_v).$$

Note also that for $R = \|E\|_{L^1(]0,T[;L^\infty(]0,1[))}$ we have

$$\begin{aligned}
|vg_0(t,v)\int_t^{s_{out}^0}\psi_{R_1}(s, X^0(s), V^0(s))ds| &\le 2Rg_0(t,v)T\|\psi\|_{L^\infty}\mathbf{1}_{\{0<v\le 2R\}} \\
&\quad + vg_0(t,v)\|\psi\|_{L^\infty}\frac{1}{v-R}\mathbf{1}_{\{v>2R\}} \\
&\le 2RT\|\psi\|_{L^\infty}g_0(t,v)\mathbf{1}_{\{0<v\le 2R\}} \\
&\quad + 2\|\psi\|_{L^\infty}g_0(t,v)\mathbf{1}_{\{v>2R\}} \in L^1(]0,T[\times\mathbb{R}_v^+)
\end{aligned}$$

since $V^0(s) \ge v - R$ and $s_{out}^0 - t \le \frac{1}{v-R}$ for $v > R$. The same arguments apply for the right boundary term. Finally, by passing $R_1 \to +\infty$ we deduce that the mild formulation holds for every $\psi \in L^\infty(]0,T[\times]0,1[\times\mathbb{R}_v)$. ∎

Remark 5.2. Consider $x(t) = (M_0 + \|U_0 - U_1\|_{L^\infty(]0,T[)})\exp(6\cdot M_\infty t)$ and

$$X_T = \{E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[)) \mid \|E\|_{L^\infty(]0,t[\times]0,1[)} \le x(t)\forall\, 0 \le t \le T\}.$$

Then $\mathcal{F}X_T \subset X_T$ and

$$\|\mathcal{F}E\|_{L^\infty(]0,T[;W^{1,\infty}(]0,1[))} \le 2\cdot x(T) - \|U_0 - U_1\|_{L^\infty(]0,T[)}.$$

5.2. Estimate of $\mathcal{F}\quad - \mathcal{F}\quad$. The aim of this section is to estimate the L^∞ norm of $\mathcal{F}A - \mathcal{F}B$ with respect to the L^∞ norm of $A - B$. First, we perform our computations by introducing the current density $j_E(t,x) := \int_{\mathbb{R}_v} v f_E(t,x,v)dv$. This requires an additional hypothesis on the initial-boundary conditions. For the moment we assume also that

$$(H_1)\ \ M_1 := \int_{\mathbb{R}_v} n_0(|v|)|v|dv + \int_{v>0} h_0(v)vdv - \int_{v<0} h_1(-v)vdv < +\infty.$$

Later on we shall see that this hypothesis can be removed.

PROPOSITION 5.3. *Assume that f_0, g_0, g_1 satisfy $(H), (H_1), (H_\infty)$ and $U_0 - U_1 \in L^\infty(]0,T[)$. Then for every $E \in L^\infty(]0,T[; W^{1,\infty}(]0,1[)) f_E|v| \in L^\infty(]0,T[; L^1(]0,1[\times\mathbb{R}_v))$, $|j_E|(t,x) := \int_{\mathbb{R}_v} f_E(t,x,v)|v|dv \in L^\infty(]0,T[; L^1(]0,1[)) \cap L^\infty(]0,T[\times]0,1[)$, $\mathcal{F}E + U_1 - U_0 \in W^{1,\infty}(]0,T[\times]0,1[)$. Moreover, the following estimates hold:*

$$\max\{\|\,|j_E|\,\|_{L^\infty(]0,T[;L^1(]0,1[))}, \||j_E|\,\|_{L^\infty(]0,T[\times]0,1[)}\} \le 3\cdot M_\infty \left(\int_0^t \|E(s)\|_{L^\infty(]0,1[)}ds\right)^2 + M_0\int_0^t \|E(s)\|_{L^\infty(]0,1[)}ds + M_1,$$

$$\partial_t\{\mathcal{F}E + U_1 - U_0\} = -j_E(t,x) + \int_0^1 j_E(t,y)dy,\ (t,x) \in]0,T[\times]0,1[,$$

$$\lim_{R_1\to+\infty} \int_{|v|>R_1} |v| f_E(t,x,v)dv = 0 \ \ \textit{uniformly with respect to } (t,x) \in]0,T[\times]0,1[,$$

and the mild formulation of the Vlasov problem holds for every function ψ such that $|\psi(t,x,v)| \le C(1+|v|)$.

Proof. Exactly as before, we have

$$\begin{aligned}|j_E|(t,x) &= \int_{\mathbb{R}_v} |v| f_E(t,x,v)dv = \int_{\mathbb{R}_v} |v| f_0(X(0;t,x,v), V(0;t,x,v))\mathbf{1}_{\{s_{in}(t,x,v)=0\}} \\ &\quad + \sum_{k=0}^1 \int_{\mathbb{R}_v} |v| g_k(s_{in}(t,x,v), V(s_{in}(t,x,v);t,x,v))\mathbf{1}_{\{s_{in}(t,x,v)>0\}} \\ &\quad \times \mathbf{1}_{\{X(s_{in}(t,x,v);t,x,v)=k\}}dv \\ &= \mathcal{J}^i + \mathcal{J}^0 + \mathcal{J}^1.\end{aligned}$$

Consider $R = \int_0^t \|E(s)\|_{L^\infty(]0,1[)}ds$ and thus $|V(0;t,x,v)| \ge |v| - R$, which implies that

$$\mathcal{J}^i \le \int_{\mathbb{R}_v} |v| n_0^R(|v|)dv = R^2 n_0(0) + \int_{\mathbb{R}_v} |v| n_0(|v|)dv + R\int_{\mathbb{R}_v} n_0(|v|)dv.$$

The terms $\mathcal{J}^k, k \in \{0,1\}$ can be estimated in the same manner and, finally, one gets

$$|j_E|(t,x) \le 3\cdot R^2 M_\infty + RM_0 + M_1, \qquad (t,x) \in]0,T[\times]0,1[.$$

By performing the same computations on $\mathbb{R}_v - B_{R_1}$, we get that $\lim_{R_1\to+\infty} \int_{|v|>R_1} |v| f_E\, dv = 0$ uniformly with respect to $(t,x) \in]0,T[\times]0,1[$. In order to check that the mild formulation holds $\forall\psi$ such that $|\psi(t,x,v)| \le C(1+|v|)$, consider $\psi_{R_1} = \chi_{R_1}(v)\psi \in \mathcal{T}_m$. This time we have

$$\begin{aligned}\left|\int_0^T\int_0^1\int_{\mathbb{R}_v} f_E\psi_{R_1}dtdxdv - \int_0^T\int_0^1\int_{\mathbb{R}_v} f_E\psi dtdxdv\right| &\le \int_0^T\int_0^1\int_{\mathbb{R}_v} f_E(1-\chi_{R_1}(v))|\psi(t,x,v)|dtdxdv\\ &\le \int_0^T\int_0^1\int_{|v|>R_1} f_E\cdot C(1+|v|)dtdxdv \to 0,\\ &\quad \text{as } R_1\to+\infty.\end{aligned}$$

In order to pass to the limit in the other terms of the mild formulation for the test function ψ_{R_1}, take $R = \|E\|_{L^1(]0,T[;L^\infty(]0,1[))}$ and note that

$$\left|f_0(x,v)\int_0^{s^i_{out}}\psi_{R_1}(s,X^i(s),V^i(s))ds\right| \le f_0(x,v)\cdot T\cdot C(1+|v|+R) \in L^1(]0,1[\times\mathbb{R}_v),$$

$$\begin{aligned}\left|vg_k(t,v)\int_t^{s^k_{out}}\psi_{R_1}(s,X^k(s),V^k(s))ds\right| &\le 2Rg_k(t,v)\cdot T\cdot C(1+|v|+R)\mathbf{1}_{\{|v|\le 2R\}}\\ &\quad + |v|g_k(t,v)\frac{C(1+|v|+R)}{|v|-R}\mathbf{1}_{\{|v|>2R\}}\\ &\le 2R\cdot T\cdot C\cdot g_k(t,v)(1+|v|+R)\mathbf{1}_{\{|v|\le 2R\}}\\ &\quad + C\left(3+\frac{1}{R}\right)|v|g_k(t,v)\mathbf{1}_{\{|v|>2R\}}\\ &\qquad\qquad \in L^1(]0,T[\times\mathbb{R}_v^{\pm}).\end{aligned}$$

By passing to the limit in the mild formulation for $R_1 \to +\infty$ and using the dominated convergence theorem, our conclusion follows. Let us compute now the time derivative of $\mathcal{F}E + U_1 - U_0$. First of all, by using the mild formulation with the test function $\psi(t,x,v) = \partial_t\varphi + v\partial_x\varphi$, $\varphi \in C^1_c(]0,T[\times]0,1[)$ (note that $|\psi(t,x,v)| \le C(1+|v|)$) we deduce the continuity equation $\partial_t\rho_E + \partial_x j_E = 0$ in $\mathcal{D}'(]0,T[\times]0,1[)$. By direct computation, the continuity equation implies that

$$\partial_t\{\mathcal{F}E + U_1 - U_0\} = -j_E(t,x) + \int_0^1 j_E(t,y)dy \in L^\infty(]0,T[\times]0,1[).$$

Obviously $\partial_x\{\mathcal{F}E + U_1 - U_0\} = \rho_E \in L^\infty(]0,T[\times]0,1[)$ and thus we obtain that $\mathcal{F}E + U_1 - U_0 \in W^{1,\infty}(]0,T[\times]0,1[)$. □

Remark 5.4. We have

$$\begin{aligned}\mathcal{F}E(t,x) + U_1(t) - U_0(t) &= -\int_0^t j_E(s,x)ds + \int_0^t\int_0^1 j_E(s,y)dsdy + \mathcal{F}E(0,x)\\ &\quad + U_1(0) - U_0(0)\\ &= -\int_0^t j_E(s,x)ds + \int_0^t\int_0^1 j_E(s,y)dsdy\\ &\quad + \int_0^x\int_{\mathbb{R}_v} f_0(y,v)dydv - \int_0^1\int_{\mathbb{R}_v}(1-y)f_0(y,v)dydv.\end{aligned}$$

By using the formula given above we can estimate $\mathcal{F}A - \mathcal{F}B$. This will be done in the following two propositions. One of the key points is the critical velocity change result (see Lemma 4.8).

PROPOSITION 5.5. *Assume that $A, B \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ are nondecreasing with respect to x and the hypotheses $(H),(H_1),(H_\infty)$ hold. Then for $0 \le t \le T$ we have*

$$\left\| \int_0^t j_A(s,\cdot)ds - \int_0^t j_B(s,\cdot)ds \right\|_{L^\infty(]0,1[)} \le C \cdot \int_0^t \|A(s) - B(s)\|_{L^\infty(]0,1[)} ds,$$

where C is a constant depending only on $\|A\|_{L^1(]0,T[;W^{1,\infty}(]0,1[))}, \|B\|_{L^1(]0,T[;W^{1,\infty}(]0,1[))}$, T and the initial-boundary conditions.

Proof. Consider $\varphi \in L^1(]0,1[)$ bounded and let us estimate $\int_0^1\int_0^t (j_A(s,x) - j_B(s,x))\varphi(x)dxds$. By applying the mild formulation with $\psi(t,x,v) = \varphi(x)v$ (which is possible since $|\psi(t,x,v)| \le \|\varphi\|_{L^\infty}|v|$) we have

$$\begin{aligned}
&\int_0^1\int_0^t (j_A(s,x) - j_B(s,x))\varphi(x)dxds \\
&= \int_0^t\int_0^1\int_{\mathbb{R}_v} (f_A(s,x,v) - f_B(s,x,v))v\varphi(x)dsdxdv \\
&= \int_0^1\int_{\mathbb{R}_v} f_0(x,v)\left[\int_0^{s_A^i} V_A^i(\tau)\varphi(X_A^i(\tau))d\tau - \int_0^{s_B^i} V_B^i(\tau)\varphi(X_B^i(\tau))d\tau\right]dxdv \\
&\quad + \int_0^t\int_{v>0} vg_0(s,v)\left[\int_s^{s_A^0} V_A^0(\tau)\varphi(X_A^0(\tau))d\tau - \int_s^{s_B^0} V_B^0(\tau)\varphi(X_B^0(\tau))d\tau\right]dsdv \\
&\quad - \int_0^t\int_{v<0} vg_1(s,v)\left[\int_s^{s_A^1} V_A^1(\tau)\varphi(X_A^1(\tau))d\tau - \int_s^{s_B^1} V_B^1(\tau)\varphi(X_B^1(\tau))d\tau\right]dsdv \\
&= \int_0^1\int_{\mathbb{R}_v} f_0(x,v)\left[\int_x^{X_A^i(s_A^i)} \varphi(u)du - \int_x^{X_B^i(s_B^i)} \varphi(u)du\right]dxdv \\
&\quad + \int_0^t\int_{v>0} vg_0(s,v)\left[\int_0^{X_A^0(s_A^0)} \varphi(u)du - \int_0^{X_B^0(s_B^0)} \varphi(u)du\right]dsdv \\
&\quad - \int_0^t\int_{v<0} vg_1(s,v)\left[\int_1^{X_A^1(s_A^1)} \varphi(u)du - \int_1^{X_B^1(s_B^1)} \varphi(u)du\right]dsdv \\
&= \mathcal{I}_{AB}^i + \mathcal{I}_{AB}^0 + \mathcal{I}_{AB}^1.
\end{aligned}$$

We introduce the notation $\Phi_C^i = \int_x^{X_C^i(s_C^i)}\varphi(u)du$, $\Phi_C^k = \int_k^{X_C^k(s_C^k)}\varphi(u)du$, $k \in \{0,1\}$, $C \in \{A,B\}$. Here s_C^i, s_C^k represent the exit times associated with the domain $]0,t[\times]0,1[\times\mathbb{R}_v$, with $k \in \{0,1\}, C \in \{A,B\}$. The term $\mathcal{I}_{AB}^i$ is written

$$\begin{aligned}
\mathcal{I}_{AB}^i &= \int_0^1\int_{\mathbb{R}_v} f_0(x,v)[\Phi_A^i\mathbf{1}_{\{v<v_A^0\}} - \Phi_B^i\mathbf{1}_{\{v<v_B^0\}}]dxdv \\
&\quad + \int_0^1\int_{\mathbb{R}_v} f_0(x,v)[\Phi_A^i\mathbf{1}_{\{v_A^0<v<v_A^1\}} - \Phi_B^i\mathbf{1}_{\{v_B^0<v<v_B^1\}}]dxdv \\
&\quad + \int_0^1\int_{\mathbb{R}_v} f_0(x,v)[\Phi_A^i\mathbf{1}_{\{v>v_A^1\}} - \Phi_B^i\mathbf{1}_{\{v>v_B^1\}}]dxdv \\
&= \mathcal{I}_0^i + \mathcal{I}_t^i + \mathcal{I}_1^i,
\end{aligned}$$

where $v_C^k = v_C^k(t;0,x)$ are the critical velocities corresponding to the domain $]0,t[\times]0,1[$, the point $(0,x)$, and the field C, with $k = 0,1,\ C = A,B$. The first and third integrals are easy to estimate since for $v < v_A^0$ we have $X_A^i(s_A^i) = 0$ and thus $\Phi_A^i = \int_x^0 \varphi(u)du$; for $v > v_A^1$ we have $X_A^i(s_A^i) = 1$ and $\Phi_A^i = \int_x^1 \varphi(u)du$. By using the critical velocity change, we obtain

$$\begin{aligned}|\mathcal{I}_0^i| &\leq \|\varphi\|_{L^1(]0,1[)}\|f_0\|_{L^\infty(]0,T[\times]0,1[\times\mathbb{R}_v)}\int_0^1 |v_A^0(t;0,x) - v_B^0(t;0,x)|dx\\ &\leq \|\varphi\|_{L^1(]0,1[)}\|f_0\|_{L^\infty(]0,T[\times]0,1[\times\mathbb{R}_v)}\int_0^t \|A(s) - B(s)\|_{L^\infty(]0,1[)}ds\end{aligned}$$

and also

$$|\mathcal{I}_1^i| \leq \|\varphi\|_{L^1(]0,1[)}\|f_0\|_{L^\infty(]0,T[\times]0,1[\times\mathbb{R}_v)}\int_0^t \|A(s) - B(s)\|_{L^\infty(]0,1[)}ds.$$

Let us estimate now the second integral $\mathcal{I}_t^i$. We remark that when $v_A^0 < v < v_A^1$ we have $s_{out}^A(0,x,v) = t$ and thus $\Phi_A^i = \int_x^{X_A(t)}\varphi(u)du$. Similarly, $\Phi_B^i = \int_x^{X_B(t)}\varphi(u)du$ when $v_B^0 < v < v_B^1$. We can write

$$\begin{aligned}|\mathcal{I}_t^i| \leq &\left|\int_0^1\int_{\mathbb{R}_v} f_0(x,v)\Phi_A^i \mathbf{1}_{\{v_A^0 < v < \max\{v_A^0,v_B^0\}\}}dxdv\right|\\ &+\left|\int_0^1\int_{\mathbb{R}_v} f_0(x,v)\Phi_A^i \mathbf{1}_{\{\min\{v_A^1,v_B^1\} < v < v_A^1\}}dxdv\right|\\ &+\left|\int_0^1\int_{\mathbb{R}_v} f_0(x,v)\Phi_B^i \mathbf{1}_{\{v_B^0 < v < \max\{v_A^0,v_B^0\}\}}dxdv\right|\\ &+\left|\int_0^1\int_{\mathbb{R}_v} f_0(x,v)\Phi_B^i \mathbf{1}_{\{\min\{v_A^1,v_B^1\} < v < v_B^1\}}dxdv\right|\\ &+\left|\int_0^1\int_{\mathbb{R}_v} f_0(x,v)(\Phi_A^i - \Phi_B^i) \mathbf{1}_{\{\max\{v_A^0,v_B^0\} < v < \min\{v_A^1,v_B^1\}\}}dxdv\right|.\end{aligned}$$

By using Lemma 4.8 we deduce

$$\max\{|v_A^0 - \max\{v_A^0,v_B^0\}|, |v_B^0 - \max\{v_A^0,v_B^0\}|\} \leq \int_0^t \|A(s) - B(s)\|_{L^\infty(]0,1[)}ds$$

and

$$\max\{|v_A^1 - \min\{v_A^1,v_B^1\}|, |v_B^1 - \min\{v_A^1,v_B^1\}|\} \leq \int_0^t \|A(s) - B(s)\|_{L^\infty(]0,1[)}ds.$$

The first four terms can be estimated by $4\cdot\|\varphi\|_{L^1}\|f_0\|_{L^\infty}\int_0^t \|A(s) - B(s)\|_{L^\infty}ds$. When $\max\{v_A^0,v_B^0\} < v < \min\{v_A^1,v_B^1\}$ we have

$$\begin{aligned}|\Phi_A^i - \Phi_B^i| &= \left|\int_{X_B(t)}^{X_A(t)}\varphi(u)du\right|\\ &\leq \int_0^1 |\varphi(u)|\mathbf{1}_{\{|u - X_A(t)| \leq |X_A(t) - X_B(t)|\}}du.\end{aligned}$$

Therefore, by using Proposition 4.9, we write the last term of $\mathcal{I}_t^i$ as

$$|\mathcal{I}_5| = \left| \int_0^1 \int_{\mathbb{R}_v} f_0(x,v)(\Phi_A^i - \Phi_B^i) \mathbf{1}_{\{\max\{v_A^0, v_B^0\} < v < \min\{v_A^1, v_B^1\}\}} dxdv \right|$$

$$\leq \int_0^1 |\varphi(u)| \int_0^1 \int_{\mathbb{R}_v} f_0(x,v) \mathbf{1}_{\{v_A^0 < v < v_A^1\}} \mathbf{1}_{\{|u - X_A(t)| \leq C \int_0^t \|A(s) - B(s)\|_{L^\infty} ds\}} dxdvdu, \tag{5.2}$$

where $C = \exp(\int_0^t (1 + \|\partial_x B(s)\|_{L^\infty(]0,1[)}) ds)$. By the change of variables $y = X_A(t;0,x,v)$, $w = V_A(t;0,x,v)$ on $\{(x,v) \in]0,1[\times \mathbb{R}_v \ : \ v_A^0(t;0,x) < v < v_A^1(t;0,x)\}$, one gets

$$\begin{aligned}
|\mathcal{I}_5| &\leq \int_0^1 |\varphi(u)| \int_0^1 \int_{\mathbb{R}_w} f_0(X_A(0;t,y,w), V_A(0;t,y,w)) \mathbf{1}_{\{|u-y| \leq C \int_0^t \|A(s)-B(s)\|_{L^\infty} ds\}} dydwdu \\
&\leq \int_0^1 |\varphi(u)| \int_0^1 \int_{\mathbb{R}_w} n_0^R(|w|) \mathbf{1}_{\{|u-y| \leq C \int_0^t \|A(s)-B(s)\|_{L^\infty} ds\}} dydwdu \\
&\leq 2 \cdot C \cdot \int_0^t \|A(s) - B(s)\|_{L^\infty} ds (2 \cdot R \cdot \|n_0\|_{L^\infty(\mathbb{R}_v^+)} + 2 \cdot \|n_0\|_{L^1(\mathbb{R}_v^+)}) \|\varphi\|_{L^1(]0,1[)},
\end{aligned}$$

where as usual $R = \int_0^t \|A(s)\|_{L^\infty(]0,1[)} ds$. Finally, we proved that

$$\begin{aligned}
|\mathcal{I}_{AB}^i| &\leq \left\{ 6\|f_0\|_{L^\infty} + 4C \left(\int_0^t \|A(s)\|_{L^\infty} ds \|n_0\|_{L^\infty(\mathbb{R}_v^+)} + \|n_0\|_{L^1(\mathbb{R}_v^+)} \right) \right\} \\
&\quad \times \int_0^t \|A(s) - B(s)\|_{L^\infty} ds \cdot \|\varphi\|_{L^1} \\
&\leq C^i \cdot \int_0^t \|A(s) - B(s)\|_{L^\infty} ds \cdot \|\varphi\|_{L^1(]0,1[)}.
\end{aligned}$$

Let us analyze the term $\mathcal{I}_{AB}^0$. As before, we have

$$\begin{aligned}
\mathcal{I}_{AB}^0 &= \int_0^t \int_{\mathbb{R}_v} v g_0(s,v) [\Phi_A^0 \mathbf{1}_{\{0 < v < v_A^0\}} - \Phi_B^0 \mathbf{1}_{\{0 < v < v_B^0\}}] dsdv \\
&\quad + \int_0^t \int_{\mathbb{R}_v} v g_0(s,v) [\Phi_A^0 \mathbf{1}_{\{v_A^0 < v < v_A^1\}} - \Phi_B^0 \mathbf{1}_{\{v_B^0 < v < v_B^1\}}] dsdv \\
&\quad + \int_0^t \int_{\mathbb{R}_v} v g_0(s,v) [\Phi_A^0 \mathbf{1}_{\{v > v_A^1\}} - \Phi_B^0 \mathbf{1}_{\{v > v_B^1\}}] dsdv \\
&= \mathcal{I}_0^0 + \mathcal{I}_t^0 + \mathcal{I}_1^0.
\end{aligned}$$

Taking into account that for $0 < v < v_C^0(t;s,0)$ we have $X_C^0(s_{out,C}^0) = 0$, we deduce that $\Phi_C^0 = 0$ for $C = A, B$ and thus $\mathcal{I}_0^0 = 0$. By the other hand, for $v > v_C^1$ we have $X_C^0(s_{out,C}^0) = 1$ and thus $\Phi_C^0 = \int_0^1 \varphi(u) du$ for $C = A, B$. One gets

$$|\mathcal{I}_1^0| \leq \left| \int_0^t \int_{v_A^1}^{v_B^1} v g_0(s,v) \int_0^1 \varphi(u) dsdvdu \right| \leq t \cdot \|v g_0\|_{L^\infty(]0,T[\times \mathbb{R}_v^+)} |v_A^1 - v_B^1| \cdot \|\varphi\|_{L^1(]0,1[)}.$$

By applying Lemma 4.8 we have

$$|v_A^1(t;s,0) - v_B^1(t;s,0)| \leq \int_s^t \|A(\tau) - B(\tau)\|_{L^\infty(]0,1[)} d\tau,$$

and therefore

$$|\mathcal{I}_1^0| \leq t \cdot \|vg_0\|_{L^\infty(]0,T[\times\mathbb{R}_v^+)} \cdot \|\varphi\|_{L^1(]0,1[)} \cdot \int_0^t \|A(s)-B(s)\|_{L^\infty(]0,1[)}ds.$$

The term $\mathcal{I}_t^0$ is written

$$\begin{aligned}|\mathcal{I}_t^0| \leq & \left|\int_0^t\int_{\mathbb{R}_v} vg_0(s,v)\Phi_A^0\mathbf{1}_{\{v_A^0<v<\max\{v_A^0,v_B^0\}\}}dsdv\right| \\ &+\left|\int_0^t\int_{\mathbb{R}_v} vg_0(s,v)\Phi_A^0\mathbf{1}_{\{\min\{v_A^1,v_B^1\}<v<v_A^1\}}dsdv\right| \\ &+\left|\int_0^t\int_{\mathbb{R}_v} vg_0(s,v)\Phi_B^0\mathbf{1}_{\{v_B^0<v<\max\{v_A^0,v_B^0\}\}}dsdv\right| \\ &+\left|\int_0^t\int_{\mathbb{R}_v} vg_0(s,v)\Phi_B^0\mathbf{1}_{\{\min\{v_A^1,v_B^1\}<v<v_B^1\}}dsdv\right| \\ &+\left|\int_0^t\int_{\mathbb{R}_v} vg_0(s,v)(\Phi_A^0-\Phi_B^0)\mathbf{1}_{\{\max\{v_A^0,v_B^0\}<v<\min\{v_A^1,v_B^1\}\}}dsdv\right|.\end{aligned}$$

The first four terms can be estimated as before by

$$t \cdot \|vg_0\|_{L^\infty(]0,T[\times\mathbb{R}_v^+)} \cdot \|\varphi\|_{L^1(]0,1[)} \cdot \int_0^t \|A(s)-B(s)\|_{L^\infty(]0,1[)}ds.$$

Since for $\max\{v_A^0,v_B^0\} < v < \min\{v_A^1,v_B^1\}$ we have $\Phi_A^0 - \Phi_B^0 = \int_{X_B(t)}^{X_A(t)} \varphi(u)du$, the last term is written

$$\begin{aligned}|\mathcal{I}_5| \leq & \left|\int_0^t\int_{v>0} vg_0(s,v)\int_{X_B(t)}^{X_A(t)}\varphi(u)\mathbf{1}_{\{\max\{v_A^0,v_B^0\}<v<\min\{v_A^1,v_B^1\}\}}dsdvdu\right| \\ \leq & \int_0^1|\varphi(u)|\int_0^t\int_{v>0} vg_0(s,v)\mathbf{1}_{\{|u-X_A(t;s,0,v)|<|X_A(t;s,0,v)-X_B(t;s,0,v)|\}} \\ & \times\mathbf{1}_{\{\max\{v_A^0,v_B^0\}<v<\min\{v_A^1,v_B^1\}\}} \\ \leq & \int_0^1|\varphi(u)|\int_0^t\int_{v>0} vg_0(s,v)\mathbf{1}_{\{|u-X_A(t;s,0,v)|<C\cdot\int_0^t\|A(\tau)-B(\tau)\|_{L^\infty}d\tau\}}\mathbf{1}_{\{v_A^0<v<v_A^1\}}dudsdv.\end{aligned}$$

This time we perform the change of variables $(y,w) = S(s,v)$, with $y = X_A(t;s,0,v)$, $w = V_A(t;s,0,v)$ on the set $D = \{(s,v) \in]0,t[\times\mathbb{R}_v : v_A^0(t;s,0) < v < v_A^1(t;s,0)\}$. By standard computations one gets that

$$\left|\frac{\partial(y,w)}{\partial(s,v)}\right| = |v|,$$

and thus

$$\begin{aligned}|\mathcal{I}_5| \leq & \int_0^1|\varphi(u)|\int_0^1\int_{w>-R}\mathbf{1}_{\{(y,w)\in S(D)\}}g_0(s_{in}(t,y,w), \\ & \qquad \cdot V(s_{in}(t,y,w);t,y,w))\mathbf{1}_{\{|u-y|<C\cdot\int_0^t\|A(\tau)-B(\tau)\|_{L^\infty}d\tau\}} \\ \leq & \int_0^1|\varphi(u)|\int_0^1\int_{w>-R}h_0^R(w)\mathbf{1}_{\{|u-y|<C\cdot\int_0^t\|A(\tau)-B(\tau)\|_{L^\infty}d\tau\}}dydwdu \\ \leq & \, 2C\int_0^t\|A(\tau)-B(\tau)\|_{L^\infty}d\tau\cdot(2R\|h_0\|_{L^\infty(\mathbb{R}_v^+)}+\|h_0\|_{L^1(\mathbb{R}_v^+)})\cdot\|\varphi\|_{L^1(]0,1[)},\end{aligned}$$

where $R = \int_0^t \|A(\tau)\|_{L^\infty} d\tau$. Finally, one gets

$$\begin{aligned}|\mathcal{I}^0_{AB}| \le &\left\{5 \cdot t \cdot \|vh_0\|_{L^\infty(\mathbb{R}^+_v)} + 2\exp\left(\int_0^t (1 + \|\partial_x B(s)\|_{L^\infty(]0,1[)})ds\right)\right.\\ &\left.\cdot\left(2 \cdot \|h_0\|_{L^\infty(\mathbb{R}^+_v)} \cdot \int_0^t \|A(s)\|_{L^\infty(]0,1[)}ds + \|h_0\|_{L^1(\mathbb{R}^+_v)}\right)\right\}\\ &\cdot \int_0^t \|A(s) - B(s)\|_{L^\infty} ds \cdot \|\varphi\|_{L^1(]0,1[)}\\ \le\ & C^0 \cdot \int_0^t \|A(s) - B(s)\|_{L^\infty(]0,1[)} ds \cdot \|\varphi\|_{L^1(]0,1[)}.\end{aligned}$$

The same arguments apply for $\mathcal{I}^1_{AB}$, and we deduce that

$$\begin{aligned}\left|\int_0^1\left(\int_0^t j_A(s,x)ds - \int_0^t j_B(s,x)ds\right)\varphi(x)dx\right| &\le |\mathcal{I}^i_{AB}| + |\mathcal{I}^0_{AB}| + |\mathcal{I}^1_{AB}|\\ &\le (C^i + C^0 + C^1)\int_0^t \|A(s)\\ &\quad - B(s)\|_{L^\infty(]0,1[)} ds \cdot \|\varphi\|_{L^1}\end{aligned}$$

$\forall\, \varphi \in L^1(]0,1[)$ bounded, in particular $\forall\, \varphi \in C_0(]0,1[)$. Since $\int_0^t j_A(s,\cdot)ds - \int_0^t j_B(s,\cdot)ds$ belongs to $L^\infty(]0,1[)$ we deduce by density that the previous inequality holds $\forall\, \varphi \in L^1(]0,1[)$, and we have the estimate

$$\left\|\int_0^t j_A(s,\cdot)ds - \int_0^t j_B(s,\cdot)ds\right\|_{L^\infty(]0,1[)} \le C \cdot \int_0^t \|A(s) - B(s)\|_{L^\infty(]0,1[)} ds, \quad 0 \le t \le T,$$

with $C = C^i + C^0 + C^1$ a constant which depends on $\|A\|_{L^1(]0,T[;W^{1,\infty}(]0,1[))}$, $\|B\|_{L^1(]0,T[;W^{1,\infty}(]0,1[))}$, $\|n_0\|_{L^\infty}$, $\|h_0\|_{L^\infty}$, $\|h_1\|_{L^\infty}$, $\|n_0\|_{L^1}$, $\|h_0\|_{L^1}$, $\|h_1\|_{L^1}$ but not on $\|vn_0\|_{L^1}$, $\|vh_0\|_{L^1}$, $\|vh_1\|_{L^1}$ (note also that since h_k are nonincreasing we have $\|vh_k\|_{L^\infty(\mathbb{R}^+_v)} \le \|h_k\|_{L^1(\mathbb{R}^+_v)}$, $k = 0, 1$). $\square$

PROPOSITION 5.6. *Assume that* $A, B \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ *are nondecreasing with respect to* x *and that the hypotheses* (H), (H_1), (H_∞) *hold. Then* $\forall\, 0 \le t \le T$ *we have*

$$\|\mathcal{F}A(t) - \mathcal{F}B(t)\|_{L^\infty(]0,1[)} \le 2 \cdot C \cdot \int_0^t \|A(s) - B(s)\|_{L^\infty(]0,1[)} ds$$

with $C = C^i + C^0 + C^1$ *as before.*

Proof. By Remark 5.4 we have

$$\begin{aligned}|\mathcal{F}A(t,x) - \mathcal{F}B(t,x)| &\le \left|\int_0^t j_A(s,x)ds - \int_0^t j_B(s,x)ds\right| + \int_0^1\left|\int_0^t j_A(s,y)ds\right.\\ &\qquad\left. - \int_0^t j_B(s,y)ds\right| dy\\ &\le 2 \cdot \left\|\int_0^t j_A(s,\cdot)ds - \int_0^t j_B(s,\cdot)ds\right\|_{L^\infty(]0,1[)}\\ &\le 2 \cdot C \cdot \int_0^t \|A(s) - B(s)\|_{L^\infty(]0,1[)} ds, \quad 0 \le t \le T. \qquad \square\end{aligned}$$

5.3. Existence and uniqueness of the mild solution.

THEOREM 5.7. *Assume that the hypotheses* (H), (H_1), (H_∞) *hold and* $U_1 - U_0 \in L^\infty(]0,T[)$. *Then there is a unique mild solution* (f,E) *for the* 1D *Vlasov–Poisson initial-boundary value problem. Moreover, we have the estimates*

$$\|\rho_E\|_{L^\infty(]0,T[\,\times\,]0,1[)} \le B(\exp(TA)-1)+C,$$

$$\||j_E|\|_{L^\infty(]0,T[\,\times\,]0,1[)} \le \frac{B^2}{2A}(\exp(TA)-1)^2 + \frac{BC}{A}(\exp(TA)-1)+M_1,$$

$$\|E\|_{L^\infty(]0,T[;W^{1,\infty}(]0,1[))} \le 2B\exp(TA)+C-B,$$

where $A = 6\cdot M_\infty$, $B = M_0 + \|U_1-U_0\|_{L^\infty(]0,T[)}$, $C = M_0$.

Proof. Consider $X_T = \{E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[)) \,|\, \|\partial_x E(t)\|_{L^\infty(]0,1[)} \le B\exp(tA)+C-B,\ \|E(t)\|_{L^\infty(]0,1[)} \le B\exp(tA),\ 0\le t\le T\}$. By Proposition 5.1 and Remark 5.2 we know that $\mathcal{F}: X_T \to X_T$ is well defined, and by Proposition 5.6 there is a constant $C_1 = C_1(M_0, M_\infty, \|U_0-U_1\|_{L^\infty(]0,T[)}, T)$ such that

$$\|\mathcal{F}A(t)-\mathcal{F}B(t)\|_{L^\infty(]0,1[)} \le C_1\cdot\int_0^t \|A(s)-B(s)\|_{L^\infty(]0,1[)}ds,\ \ A,B\in X_T.$$

We deduce that $\mathcal{F}$ has a unique fixed point $E\in X_T$, and therefore (f_E,E) is the unique mild solution of the 1D Vlasov–Poisson initial-boundary value problem. The estimation $|j_E|$ follows by Proposition 5.3. ∎

5.4. Existence and uniqueness of the mild solution in the general case. In this section we study the existence and uniqueness of the mild solution when assuming only the hypotheses (H), (H_0), (H_∞). In order to do this we need only prove that Proposition 5.6 still holds under the above hypotheses. For $\alpha>0$ let us consider the initial-boundary conditions given by

$$\begin{aligned} f_0^\alpha(x,v) &= \frac{f_0(x,v)}{1+\alpha|v|},\ \ (x,v)\in\,]0,1[\,\times\mathbb{R}_v,\\ g_0^\alpha(t,v) &= \frac{g_0(t,v)}{1+\alpha v},\ \ (t,v)\in\,]0,T[\,\times\mathbb{R}_v^+,\\ g_1^\alpha(x,v) &= \frac{g_1(t,v)}{1-\alpha v},\ \ (t,v)\in\,]0,T[\,\times\mathbb{R}_v^-. \end{aligned}$$

It is easy to check that if (H), (H_0), (H_∞) hold, then the same hypotheses (H^α), (H_0^α), (H_∞^α), corresponding to the initial-boundary conditions $f_0^\alpha, g_0^\alpha, g_1^\alpha$, hold with the functions $n_0^\alpha(v) := \frac{n_0(v)}{1+\alpha v}$, $h_k^\alpha(v) := \frac{h_k(v)}{1+\alpha v}$, $v\in\mathbb{R}_v^+$, $k=0,1$, and we have $M_0^\alpha \le M_0 < +\infty$, $M_\infty^\alpha \le M_\infty < +\infty$. Moreover, note also that (H_1^α) is satisfied with $M_1^\alpha \le \frac{M_0}{\alpha} < +\infty$. Since $n_0, h_0, h_1 \in L^1(\mathbb{R}_v^+)$ are nonincreasing we check easily that $n_0^\alpha, h_0^\alpha, h_1^\alpha$ are nonincreasing and

$$\|vh_k^\alpha\|_{L^\infty(\mathbb{R}_v^+)} \le \|vh_k\|_{L^\infty(\mathbb{R}_v^+)} \le \|h_k\|_{L^1(\mathbb{R}_v^+)},\ k=0,1,\alpha>0.$$

PROPOSITION 5.8. *Assume that* $A,B\in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ *are nondecreasing with respect to* x *and that* $(H),(H_0),(H_\infty)$ *hold. Then* $\forall\, 0\le t\le T$ *we have*

$$\|\mathcal{F}A(t)-\mathcal{F}B(t)\|_{L^\infty(]0,1[)} \le C\cdot\int_0^t \|A(s)-B(s)\|_{L^\infty(]0,1[)}ds,$$

where C *depends only on* $\|A\|_{L^1(]0,T[;W^{1,\infty}(]0,1[))}, \|B\|_{L^1(]0,T[;W^{1,\infty}(]0,1[))}, M_0, M_\infty, T$.

Proof. By Proposition 5.6 we have

$$\|\mathcal{F}^\alpha A(t) - \mathcal{F}^\alpha B(t)\|_{L^\infty(]0,1[)} \le C^\alpha \cdot \int_0^t \|A(s) - B(s)\|_{L^\infty(]0,1[)} ds, \tag{5.3}$$

where $\mathcal{F}^\alpha$ corresponds to the initial-boundary conditions $f_0^\alpha, g_0^\alpha, g_1^\alpha$. $(C^\alpha)_{\alpha>0}$ is bounded since we have

$$\begin{aligned} C^\alpha &= C(\|A\|_{L^1(]0,T[;W^{1,\infty}(]0,1[))}, \|B\|_{L^1(]0,T[;W^{1,\infty}(]0,1[))}, M_0^\alpha, M_\infty^\alpha, T) \\ &\le C(\|A\|_{L^1(]0,T[;W^{1,\infty}(]0,1[))}, \|B\|_{L^1(]0,T[;W^{1,\infty}(]0,1[))}, M_0, M_\infty, T). \end{aligned}$$

The conclusion follows by passing to the limit in inequality (5.3) for $\alpha \to 0$ and by using the monotone convergence theorem. □

Now we can state the existence and uniqueness result in the general case.

THEOREM 5.9. *Assume that the hypotheses* $(H), (H_0), (H_\infty)$ *hold and* $U_1 - U_0 \in L^\infty(]0,T[)$. *Then there is a unique mild solution of the* 1D *Vlasov–Poisson initial-boundary value problem* (f_E, E), *which verifies the estimates*

$$\begin{aligned} \|\partial_x E\|_{L^\infty} = \|\rho_E\|_{L^\infty} &\le (M_0 + \|U_1 - U_0\|_{L^\infty}) \exp(6 \cdot T M_\infty) - \|U_1 - U_0\|_{L^\infty}, \\ \|E\|_{L^\infty} &\le (M_0 + \|U_1 - U_0\|_{L^\infty}) \exp(6 \cdot T M_\infty). \end{aligned}$$

5.5. Continuity upon the initial-boundary conditions. The goal of this section is to estimate the difference between two mild solutions $(f^k, E^k), k = 1,2$, with respect to the initial-boundary conditions. Consider two sets of initial-boundary conditions $f_0^k, g_0^k, g_1^k, U_0^k - U_1^k \in L^\infty$ verifying the hypotheses $(H^k), (H_0^k), (H_\infty^k)$, $k = 1,2$. We define the applications $\mathcal{F}^k$ as before. We have for $t \in [0,T]$

$$\|\partial_x \mathcal{F}^k E(t)\|_{L^\infty} = \|\rho_E^k\|_{L^\infty} \le 6 \cdot M_\infty^k \int_0^t \|E(s)\|_{L^\infty} ds + M_0^k$$

and

$$\|\mathcal{F}^k E(t)\|_{L^\infty} \le 6 \cdot M_\infty^k \int_0^t \|E(s)\|_{L^\infty} ds + M_0^k + |U_0^k(t) - U_1^k(t)|.$$

First of all let us assume the hypotheses (H), (H_1), and (H_∞). We have the following proposition.

PROPOSITION 5.10. *Assume that* $E \in L^\infty(]0,T[;W^{1,\infty}(]0,1[))$ *is nondecreasing with respect to* x *and that the hypotheses* $(H^k), (H_1^k), (H_\infty^k)$ *hold. We suppose also that the functions*

$$(H_{\mathrm{i}}) \;\; l_k(v) = \sup_{0\le t\le T} |g_k^1(t, (-1)^k v) - g_k^2(t, (-1)^k v)|, \; k = 0,1,$$

are nonincreasing with respect to $v \in \mathbb{R}_v^+$, *or*

$$(H_{\mathrm{ii}}) \;\; \int_0^T \int_{v>0} v|g_0^1(t,v) - g_0^2(t,v)| dt dv - \int_0^T \int_{v<0} v|g_1^1(t,v) - g_1^2(t,v)| dt dv < +\infty.$$

Then $\forall\, 0 \le t \le T$ *we have*

$$\begin{aligned} &\|\mathcal{F}^1 E(t) - \mathcal{F}^2 E(t)\|_{L^\infty} \le C(\|E\|_{L^1(]0,t[;L^\infty(]0,1[))}) \\ &\cdot \left(\|f_0^1 - f_0^2\|_{L^1(]0,1[\times\mathbb{R}_v)} + \sum_{k=0}^1 (\|l_k\|_{L^1} + \|l_k\|_{L^\infty}) \right) + |U_1^1(t) - U_0^1(t) - U_1^2(t) + U_0^2(t)| \end{aligned}$$

in case (i) *or*

$$\|\mathcal{F}^1E(t)-\mathcal{F}^2E(t)\|_{L^\infty}\le 2\bigg(\|f_0^1-f_0^2\|_{L^1(]0,1[\times\mathbb{R}_v)}+\sum_{k=0}^{1}\|v(g_k^1-g_k^2)\|_{L^1(]0,t[\times\mathbb{R}_v^+)}\bigg)$$
$$+|U_1^1(t)-U_0^1(t)-U_1^2(t)+U_0^2(t)|$$

in case (ii).

Proof. Consider $\varphi\in L^1(]0,1[)$ and calculate

$$\begin{aligned}
&\int_0^1\!\!\int_0^t(j_E^1(s,x)-j_E^2(s,x))\varphi(x)dxds\\
&\quad=\int_0^t\!\!\int_0^1\!\!\int_{\mathbb{R}_v}(f_E^1-f_E^2)v\varphi(x)dsdxdv\\
&\quad=\int_0^1\!\!\int_{\mathbb{R}_v}(f_0^1(x,v)-f_0^2(x,v))\int_0^{s^i_{out}}V^i(s)\varphi(X^i(s))dxdvds\\
&\qquad+\sum_{k=0}^{1}(-1)^k\int_0^t\!\!\int_{(-1)^kv>0}v(g_k^1-g_k^2)\int_s^{s^k_{out}}V^k(\tau)\varphi(X^k(\tau))dsdvd\tau\\
&\quad=\int_0^1\!\!\int_{\mathbb{R}_v}(f_0^1(x,v)-f_0^2(x,v))\int_x^{X^i(s^i_{out})}\varphi(u)dxdvdu\\
&\qquad+\sum_{k=0}^{1}(-1)^k\int_0^t\!\!\int_{(-1)^kv>0}v(g_k^1(s,v)-g_k^2(s,v))\int_k^{X^k(s^k_{out})}\varphi(u)dsdvdu\\
&\quad=\mathcal{I}^i+\Sigma_{k=0}^1\mathcal{I}^k.
\end{aligned}$$

Obviously we have

$$|\mathcal{I}^i|\le\|f_0^1-f_0^2\|_{L^1(]0,1[\times\mathbb{R}_v)}\cdot\|\varphi\|_{L^1(]0,1[)}.$$

On the other hand, with the notation $\Phi^k=\int_k^{X^k(s^k_{out})}\varphi(u)du$, we have

$$\begin{aligned}
\mathcal{I}^0&=\int_0^t\!\!\int_{\mathbb{R}_v}v(g_0^1(s,v)-g_0^2(s,v))dsdv\Phi^0\mathbf{1}_{\{0<v<v_E^0\}}\\
&\quad+\int_0^t\!\!\int_{\mathbb{R}_v}v(g_0^1(s,v)-g_0^2(s,v))dsdv\Phi^0\mathbf{1}_{\{v_E^0<v<v_E^1\}}\\
&\quad+\int_0^t\!\!\int_{\mathbb{R}_v}v(g_0^1(s,v)-g_0^2(s,v))dsdv\Phi^0\mathbf{1}_{\{v>v_E^1\}}\\
&=\mathcal{I}_0^0+\mathcal{I}_t^0+\mathcal{I}_1^0,
\end{aligned}$$

where $v_E^k = v_E^k(t;s,k)$ are the critical velocities corresponding to the domain $]0,t[\times]0,1[$, the point (s,k), and the field E. Calculate now

$$
\begin{aligned}
&\int_0^1 \left(\int_0^1 \int_0^t (j_E^1(s,y) - j_E^2(s,y)) ds dy \right) \varphi(x) dx \\
&= \int_0^t \int_0^1 \int_{\mathbb{R}_v} v(f_E^1(s,y,v) - f_E^2(s,y,v)) ds dy dv \cdot \int_0^1 \varphi(u) du \\
&= \int_0^1 \varphi(u) du \cdot \Big\{ \int_0^1 \int_{\mathbb{R}_v} (f_0^1 - f_0^2) \int_0^{s^i_{out}} V^i(s) dx dv ds \\
&\qquad + \sum_{k=0}^1 (-1)^k \int_0^t \int_{(-1)^k v > 0} v(g_k^1 - g_k^2) \int_s^{s^k_{out}} V^k(\tau) ds dv d\tau \Big\} \\
&= \int_0^1 \varphi(u) du \cdot \Big\{ \int_0^1 \int_{\mathbb{R}_v} (f_0^1 - f_0^2)(X^i(s^i_{out}) - x) dx dv \\
&\qquad + \sum_{k=0}^1 (-1)^k \int_0^t \int_{(-1)^k v > 0} v(g_k^1 - g_k^2)(X^k(s^k_{out}) - k) ds dv \Big\} \\
&= \mathcal{J}^i + \sum_{k=0}^1 \mathcal{J}^k.
\end{aligned}
$$

Obviously we have $|\mathcal{J}^i| \le \|f_0^1 - f_0^2\|_{L^1(]0,1[\times\mathbb{R}_v)} \cdot \|\varphi\|_{L^1(]0,1[)}$. On the other hand, we have

$$
\begin{aligned}
\mathcal{J}^0 &= \int_0^t \int_{\mathbb{R}_v} v(g_0^1 - g_0^2)(X^0(s^0_{out}) - 0) \mathbf{1}_{\{0<v<v_E^0\}} ds dv \int_0^1 \varphi(u) du \\
&\quad + \int_0^t \int_{\mathbb{R}_v} v(g_0^1 - g_0^2)(X^0(s^0_{out}) - 0) \mathbf{1}_{\{v_E^0<v<v_E^1\}} ds dv \int_0^1 \varphi(u) du \\
&\quad + \int_0^t \int_{\mathbb{R}_v} v(g_0^1 - g_0^2)(X^0(s^0_{out}) - 0) \mathbf{1}_{\{v>v_E^1\}} ds dv \int_0^1 \varphi(u) du \\
&= \mathcal{J}_0^0 + \mathcal{J}_t^0 + \mathcal{J}_1^0.
\end{aligned}
$$

For $0 < v < v_E^0$ we have $X^0(s^0_{out}) = 0$ and thus $\mathcal{I}_0^0 = \mathcal{J}_0^0$. For $v > v_E^1$ we have $X^0(s^0_{out}) = 1$ and thus $\mathcal{I}_1^0 = \mathcal{J}_1^0$. In order to evaluate $\mathcal{I}_t^0$ and $\mathcal{J}_t^0$ we can perform the change of variables $(y,w) = S(s,v)$,

$$
y = X^0(t;s,0,v), \quad w = V^0(t;s,0,v), \quad \left| \frac{\partial(y,w)}{\partial(s,v)} \right| = |v|,
$$

on $D = \{(s,v) \in]0,t[\times\mathbb{R}_v^+ \mid v_E^0(t;s,0) < v < v_E^1(t;s,0)\}$. In case (i) one gets

$$
\begin{aligned}
|\mathcal{I}_t^0| &\le \int_0^1 |\varphi(u)| du \cdot \int_0^t \int_{\mathbb{R}_v} v |g_0^1(s,v) - g_0^2(s,v)| \mathbf{1}_{\{v_E^0<v<v_E^1\}} ds dv \\
&= \int_0^1 |\varphi(u)| du \cdot \int_0^1 \int_{w>-R} |g_0^1 - g_0^2|(s^0_{in}(t,y,w), V^0(s^0_{in}(t,y,w);t,y,w)) \mathbf{1}_{S(D)} dy dw \\
&\le \int_{w>-R} l_0^R(w) dw \cdot \|\varphi\|_{L^1(]0,1[)} = (2R\|l_0\|_{L^\infty(\mathbb{R}_v^+)} + \|l_0\|_{L^1(\mathbb{R}_v^+)}) \cdot \|\varphi\|_{L^1(]0,1[)},
\end{aligned}
$$

where $R = \int_0^t \|E(s)\|_{L^\infty(]0,1[)} ds$. In a similar manner we find that

$$\begin{aligned}|\mathcal{J}_t^0| &\leq \int_0^t \int_{\mathbb{R}_v} v|g_0^1 - g_0^2| \mathbf{1}_{\{v_E^0 < v < v_E^1\}} ds dv \cdot \|\varphi\|_{L^1(]0,1[)} \\ &\leq \int_{w > -R} h_0^R(w) dw \cdot \|\varphi\|_{L^1(]0,1[)}.\end{aligned}$$

Finally, one gets that

$$\begin{aligned}|\mathcal{I} - \mathcal{J}| &= \left| \int_0^1 \left(\int_0^t (j_E^1(s,x) - j_E^2(s,x)) ds - \int_0^1 \int_0^t (j_E^1(s,y) - j_E^2(s,y)) dy ds \right) \varphi(x) dx \right| \\ &= |\mathcal{I}^i + \mathcal{I}^0 + \mathcal{I}^1 - \mathcal{J}^i - \mathcal{J}^0 - \mathcal{J}^1| \\ &\leq |\mathcal{I}^i| + |\mathcal{J}^i| + |\mathcal{I}_t^0| + |\mathcal{J}_t^0| + |\mathcal{I}_t^1| + |\mathcal{J}_t^1| \\ &\leq C(R) \left(\|f_0^1 - f_0^2\|_{L^1} + \sum_{k=0}^1 (\|l_k\|_{L^\infty} + \|l_k\|_{L^1}) \right) \cdot \|\varphi\|_{L^1(]0,1[)},\end{aligned}$$

and the conclusion follows in case (i) by using Remark 5.4. For case (ii) it is sufficient to remark that

$$\max\{|\mathcal{I}_t^k|, |\mathcal{J}_t^k|\} \leq \int_0^t \int_{(-1)^k v > 0} (-1)^k v |g_k^1(s,v) - g_k^2(s,v)| ds dv \cdot \|\varphi\|_{L^1(]0,1[)}, \ k = 0, 1. \quad \square$$

Remark 5.11. The conclusion of Proposition 5.10 still holds if we replace hypothesis (H_1^k) with (H_0^k), $k = 0, 1$ (proceed as in the proof of Proposition 5.8).

PROPOSITION 5.12. *Assume that $E^1, E^2 \in L^\infty(]0,T[; W^{1,\infty}(]0,1[))$ are nondecreasing with respect to x and that $(H^k), (H_0^k), (H_\infty^k)$ hold. We suppose also that (H_{i}) or (H_{ii}) is verified. Then $\forall\ 0 \leq t \leq T$ we have*

$$\|\mathcal{F}^1 E^1(t) - \mathcal{F}^2 E^2(t)\|_{L^\infty(]0,1[)} \leq C_1 + C_2 \int_0^t \|E^1(s) - E^2(s)\|_{L^\infty(]0,1[)} ds,$$

where $C_2 = C_2(\|E^k\|_{L^1(]0,T[; W^{1,\infty}(]0,1[))}, M_0^k, M_\infty^k, T)$ and

$$\begin{aligned}C_1 &= C_1(\|E^k\|_{L^1(]0,T[; L^\infty(]0,1[))}) \left(\|f_0^1 - f_0^2\|_{L^1} + \Sigma_{k=0}^1 (\|l_k\|_{L^1} + \|l_k\|_{L^\infty}) \right) \\ &\quad + |U_1^1 - U_0^1 - U_1^2 + U_0^2|(t)\end{aligned}$$

in case (i) *or*

$$\begin{aligned}C_1 = 2 &\left(\|f_0^1 - f_0^2\|_{L^1} + \|v(g_0^1 - g_0^2)\|_{L^1} + \|v(g_1^1 - g_1^2)\|_{L^1} \right) \\ &+ |U_1^1 - U_0^1 - U_1^2 + U_0^2|(t)\end{aligned}$$

in case (ii).

Proof. We can write

$$\|\mathcal{F}^1 E^1(t) - \mathcal{F}^2 E^2(t)\|_{L^\infty} \leq \|\mathcal{F}^1 E^1(t) - \mathcal{F}^1 E^2(t)\|_{L^\infty} + \|\mathcal{F}^1 E^2(t) - \mathcal{F}^2 E^2(t)\|_{L^\infty}.$$

By using Proposition 5.5 we find

$$\|\mathcal{F}^1 E^1(t) - \mathcal{F}^1 E^2(t)\|_{L^\infty(]0,1[)} \leq C_2 \int_0^t \|E^1(s) - E^2(s)\|_{L^\infty(]0,1[)} ds,$$

where C_2 depends on $\|E^k\|_{L^1(]0,T[;W^{1,\infty}(]0,1[))}, M_0^1, M_\infty^1, T$. The conclusion follows by Proposition 5.10 and Remark 5.11. ☐

THEOREM 5.13. *Assume that* $f_0^k, g_0^k, g_1^k, U_1^k - U_0^k \in L^\infty(]0,T[)$, $k = 1, 2$, *are two sets of initial-boundary conditions verifying the hypotheses* $(H^k), (H_0^k), (H_\infty^k)$, *and* $(H_{\rm i})$ *or* $(H_{\rm ii})$. *Denote by* (f^k, E^k), $k = 1, 2$, *the corresponding unique mild solutions. Then we have* $\forall\, 0 \le t \le T$

$$\|E^1(t) - E^2(t)\|_{L^\infty(]0,1[)} \le C\left\{ \|f_0^1 - f_0^2\|_{L^1} + \sum_{k=0}^{1}(\|l_k\|_{L^1} + \|l_k\|_{L^\infty}) \right. \\ \left. + |U_1^1 - U_0^1 - U_1^2 + U_0^2|(t) \right\}$$

in case (i) *or*

$$\|E^1(t) - E^2(t)\|_{L^\infty(]0,1[)} \le C\left\{ \|f_0^1 - f_0^2\|_{L^1(]0,1[\times\mathbb{R}_v)} + \sum_{k=0}^{1} \|v(g_k^1 - g_k^2)\|_{L^1(]0,T[\times\mathbb{R}_v^\pm)} \right. \\ \left. + |U_1^1 - U_0^1 - U_1^2 + U_0^2|(t) \right\}$$

in case (ii), *where* C *is a constant depending on* $M_0^k, M_\infty^k, \|U_0^k - U_1^k\|_{L^\infty}, T$.

Proof. Since (f^k, E^k) are mild solutions, we have $\mathcal{F}^k E^k = E^k$, E^k are nondecreasing with respect to x, and we know that

$$\|E^k\|_{L^\infty(]0,T[;W^{1,\infty}(]0,1[))} \le C(M_0^k, M_\infty^k, \|U_1^k - U_0^k\|_{L^\infty(]0,T[)}, T).$$

By Proposition 5.12 we have $\forall\, 0 \le t \le T$

$$\begin{aligned}\|E^1(t) - E^2(t)\|_{L^\infty(]0,1[)} &= \|\mathcal{F}^1 E^1(t) - \mathcal{F}^2 E^2(t)\|_{L^\infty(]0,1[)} \\ &\le C_1 + C_2 \int_0^t \|E^1(s) - E^2(s)\|_{L^\infty(]0,1[)} ds,\end{aligned}$$

with C_1, C_2 as before. The conclusion of the theorem follows by using the Gronwall lemma. ☐

6. The 1D Vlasov–Maxwell system. In this section we study the 1D Vlasov–Maxwell system with initial conditions by adapting the method used previously. Since the proofs are quite similar we only sketch them. Moreover, as explained in the introduction, in this case we can consider different species of particles. Recall that results on the existence and uniqueness have already been obtained by Cooper and Klimas [7]. Let us introduce the equations

$$\partial_t f^\pm + v \cdot \partial_x f^\pm \pm E \cdot \partial_v f^\pm = 0, \quad (t, x, v) \in]0, T[\times \mathbb{R}_x \times \mathbb{R}_v, \tag{6.1}$$

$$\begin{aligned}\partial_t E &= -j(t, x) := -j^+ + j^- \\ &= -\int_{\mathbb{R}_v} v(f^+(t, x, v) - f^-(t, x, v)) dv, \quad (t, x) \in]0, T[\times \mathbb{R}_x,\end{aligned} \tag{6.2}$$

with the initial conditions

$$f^\pm(t = 0, x, v) = f_0^\pm(x, v), \quad (x, v) \in \mathbb{R}_x \times \mathbb{R}_v, \tag{6.3}$$

$$E(t = 0, x) = E_0(x) = \int \rho_0(y) dy, \quad x \in \mathbb{R}_x, \tag{6.4}$$

where $\rho_0 = \rho_0^+ - \rho_0^- = \int_{\mathbb{R}_v}(f_0^+ - f_0^-)dv$ and $\int \rho_0(y)dy$ denotes an arbitrary primitive of ρ_0. Assume that $E \in L^\infty(]0,T[;W^{1,\infty}(\mathbb{R}_x)), f_0^\pm \in L^1_{loc}(\mathbb{R}_x \times \mathbb{R}_v)$. We denote by $(X^\pm(s), V^\pm(s))$ the characteristics associated with $\pm E$. As usual we say that $f^\pm \in L^1_{loc}(]0,T[\times \mathbb{R}_x \times \mathbb{R}_v)$ is a mild solution for the Vlasov problem (6.1), (6.3) iff

$$\int_0^T\int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f^\pm(t,x,v)\psi(t,x,v)dtdxdv = \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^\pm \int_0^T \psi(s, X^\pm(s;0,x,v), \\ \times V^\pm(s;0,x,v))dxdvds$$

for all test functions $\psi \in L^\infty(]0,T[\times \mathbb{R}_x \times \mathbb{R}_v)$ compactly supported in $[0,T]\times\mathbb{R}_x\times\mathbb{R}_v$. Assume now that $f_0^\pm \in L^1(\mathbb{R}_x \times \mathbb{R}_v)$. We say that $(f^\pm, E) \in L^1(]0,T[\times\mathbb{R}_x\times\mathbb{R}_v) \times L^\infty(]0,T[;W^{1,\infty}(\mathbb{R}_x))$ is a mild solution of the 1D Vlasov–Maxwell problem iff $f^\pm$ is a mild solution for the Vlasov problem (6.1), (6.3) corresponding to the electric field $\pm E$ such that

$$\begin{aligned}\int_{\mathbb{R}_x} E(t,x)\varphi(x)dx = &- \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^+(x,v)\int_x^{X^+(t;0,x,v)} \varphi(u)dudxdv \\ &+ \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^-(x,v)\int_x^{X^-(t;0,x,v)} \varphi(u)dudxdv \\ &+ \int_{\mathbb{R}_x} E_0(x)\varphi(x)dx \ \ \forall \varphi \in L^1(\mathbb{R}_x).\end{aligned}$$

Remark 6.1. Note that the previous formula defines a unique function $E \in L^\infty(]0,T[\times\mathbb{R}_x)$. This definition can be derived formally from (6.2) by using the mild formulation

$$\begin{aligned}\int_{\mathbb{R}_x} E(t,x)\varphi(x) &= -\int_0^t\int_{\mathbb{R}_x}\int_{\mathbb{R}_v} v(f^+(s,x,v) - f^-(s,x,v))\varphi(x)dsdxdv + \int_{\mathbb{R}_x} E_0(x)\varphi(x)dx \\ &= -\int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^+(x,v)\int_0^t V^+(s)\varphi(X^+(s))dsdxdv + \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^-(x,v) \\ &\quad \times \int_0^t V^-(s)\varphi(X^-(s))dsdxdv + \int_{\mathbb{R}_x} E_0(x)\varphi(x)dx \\ &= -\int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^+(x,v)\int_x^{X^+(t;0,x,v)} \varphi(u)dudxdv \\ &\quad + \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^-(x,v)\int_x^{X^-(t;0,x,v)} \varphi(u)dudxdv + \int_{\mathbb{R}_x} E_0(x)\varphi(x)dx.\end{aligned}$$

As before we define the application $\mathcal{F}$ for $E \in L^\infty(]0,T[;W^{1,\infty}(\mathbb{R}_x))$ by

$$E \to f_E^\pm \to E_1(t) = \mathcal{F}E(t) = E_0 - \int_0^t\int_{\mathbb{R}_v} v(f_E^+ - f_E^-)dsdv,$$

where $f_E^\pm$ are the mild solutions of the Vlasov problem (6.1), (6.3) associated with the field $\pm E$, E_0 is given by (6.4), and $-\int_0^t\int_{\mathbb{R}_v} v(f_E^+ - f_E^-)dsdv$ is defined as in Remark 6.1.

6.1. Estimate of $\mathcal{F}$. We assume that there is $n_0^\pm : [0,+\infty[\to [0,+\infty[$ nonincreasing, such that

$$(H^\pm)\ f_0^\pm(x,v) \le n_0^\pm(|v|),\ \ (x,v)\in\mathbb{R}_x\times\mathbb{R}_v,$$
$$(H_0^\pm)\ M_0^\pm := \int_{\mathbb{R}_v} n_0^\pm(|v|)dv < +\infty,$$
$$(H_\infty^\pm)\ M_\infty^\pm := \|n_0^\pm\|_{L^\infty(\mathbb{R}_v^+)} < +\infty,$$
$$(H_{\rho_0})\ M_{\rho_0} := \sup_{x\in\mathbb{R}_x}\left|\int_0^x(\rho_0^+(y)-\rho_0^-(y))dy\right| < +\infty.$$

Proposition 6.2. *Assume that $f_0^\pm\in L^1(\mathbb{R}_x\times\mathbb{R}_v)$ satisfy $(H^\pm),(H_0^\pm),(H_\infty^\pm)$. Then for every $E\in L^\infty(]0,T[;W^{1,\infty}(\mathbb{R}_x))$ we have $f_E^\pm\in L^\infty(]0,T[;L^1(\mathbb{R}_x\times\mathbb{R}_v))$, $\rho_E^\pm\in L^\infty(]0,T[\times\mathbb{R}_x)$, $\mathcal{F}E\in L^\infty(]0,T[;W^{1,\infty}(\mathbb{R}_x))$. Moreover, the following estimates hold:*

$$\|f_E^\pm\|_{L^\infty(]0,T[;L^1(\mathbb{R}_x\times\mathbb{R}_v))} = \|\rho_E^\pm\|_{L^\infty(]0,T[;L^1(\mathbb{R}_x))} = \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^\pm(x,v)dxdv,$$
$$\|\rho_E^\pm\|_{L^\infty(]0,T[\times\mathbb{R}_x)} \le 2M_\infty^\pm\int_0^t\|E(s)\|_{L^\infty(\mathbb{R}_x)}ds + M_0^\pm,$$
$$\|\mathcal{F}E\|_{L^\infty(]0,T[\times\mathbb{R}_x)} \le C + M_{\rho_0} + \|f_0^+\|_{L^1(\mathbb{R}_x\times\mathbb{R}_v)} + \|f_0^-\|_{L^1(\mathbb{R}_x\times\mathbb{R}_v)},$$
$$\|\partial_x\mathcal{F}E\|_{L^\infty(]0,T[\times\mathbb{R}_x)} \le 2(M_\infty^+ + M_\infty^-)\int_0^t\|E(s)\|_{L^\infty(\mathbb{R}_x)}ds + M_0^+ + M_0^-,$$
$$\lim_{R_1\to+\infty}\int_{|v|>R_1} f_E^\pm(t,x,v)dv = 0 \text{ uniformly with respect to } (t,x)\in]0,T[\times\mathbb{R}_x,$$

and the mild formulation of the Vlasov problem holds $\forall\,\psi\in L^\infty(]0,T[\times\mathbb{R}_x\times\mathbb{R}_v)$.

Proof. We have

$$\begin{aligned}\rho_E^\pm(t,x) &= \int_{\mathbb{R}_v} f_E^\pm dv = \int_{\mathbb{R}_v} f_0^\pm(X^\pm(0;t,x,v),V^\pm(0;t,x,v))dv\\ &\le \int_{\mathbb{R}_v} n_0^\pm(|V^\pm(0;t,x,v)|)dv \le \int_{\mathbb{R}_v} n_0^{\pm,R}(|v|)dv\\ &= 2RM_\infty^\pm + M_0^\pm,\end{aligned}$$

where $R=\int_0^t\|E(s)\|_{L^\infty(\mathbb{R}_x)}ds$. By the definition of $\mathcal{F}E$, taking into account that $E_0(x)=C+\int_0^x\rho_0(y)dy$, we deduce that

$$\|\mathcal{F}E(t)\|_{L^\infty(\mathbb{R}_x)} \le C + M_{\rho_0} + \|f_0^+\|_{ofL^1(\mathbb{R}_x\times\mathbb{R}_v)} + \|f_0^-\|_{L^1(\mathbb{R}_x\times\mathbb{R}_v)},\ \ 0\le t\le T.$$

By using the definition of $\mathcal{F}E(t)$ and the mild formulation we check that $\partial_x\mathcal{F}E(t)=\rho(t)$ in $\mathcal{D}'(\mathbb{R}_x)$, $0\le t\le T$, and we deduce that $\|\partial_x\mathcal{F}E\|_{L^\infty}\le\|\rho_E^+\|_{L^\infty}+\|\rho_E^-\|_{L^\infty}\le 2R(M_\infty^+ + M_\infty^-)+M_0^+ + M_0^-$. The last two assertions follow by standard calculations as was done for the Vlasov–Poisson problem. ∎

Remark 6.3. If we note $X_T=\{E\in L^\infty(]0,T[;W^{1,\infty}(\mathbb{R}_x))\mid \|E\|_{L^\infty(]0,T[\times\mathbb{R}_x)}\le \|E_0\|_{L^\infty(\mathbb{R}_x)}+\|f_0^+\|_{L^1}+\|f_0^-\|_{L^1}\}$, then $\mathcal{F}(X_T)\subset X_T$ and

$$\|\partial_x\mathcal{F}E\|_{L^\infty(]0,T[\times\mathbb{R}_x)} \le 2(M_\infty^+ + M_\infty^-)\cdot T\cdot(\|E_0\|_{L^\infty(\mathbb{R}_x)}+\|f_0^+\|_{L^1}+\|f_0^-\|_{L^1})+M_0^+ + M_0^-.$$

6.2. Estimate of $\mathcal{F} \quad - \mathcal{F} \quad$.

PROPOSITION 6.4. *Assume that* $A, B \in L^\infty(]0,T[; W^{1,\infty}(\mathbb{R}_x))$ *and* $f_0^\pm \in L^1(\mathbb{R}_x \times \mathbb{R}_v)$ *verify the hypotheses* $(H^\pm), (H_0^\pm), (H_\infty^\pm)$. *Then* $\forall\, 0 \le t \le T$ *we have*

$$\|\mathcal{F}A(t) - \mathcal{F}B(t)\|_{L^\infty(\mathbb{R}_x)} \le C \int_0^t \|A(s) - B(s)\|_{L^\infty(\mathbb{R}_x)} ds,$$

with C *a constant depending on* $\|A\|_{L^1(]0,T[;W^{1,\infty}(\mathbb{R}_x))}, \|B\|_{L^1(]0,T[;W^{1,\infty}(\mathbb{R}_x))}, M_0^\pm$, $M_\infty^\pm, T$.

Proof. Take $\varphi \in L^1(\mathbb{R}_x)$ and calculate

$$\begin{aligned}
&\left| \int_{\mathbb{R}_x} (\mathcal{F}A(t,x) - \mathcal{F}B(t,x))\varphi(x)dx \right| \\
&\quad = \left| - \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^+ \int_{X_B^+(t)}^{X_A^+(t)} \varphi(u)dudxdv + \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^- \int_{X_B^-(t)}^{X_A^-(t)} \varphi(u)dudxdv \right| \\
&\quad \le \sum_{k=\pm} \int_{\mathbb{R}_u} |\varphi(u)| \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^k(x,v) \mathbf{1}_{\{|u - X_A^k(t)| < |X_B^k(t) - X_A^k(t)|\}} dudxdv \\
&\quad \le \sum_{k=\pm} \int |\varphi(u)| \int\int f_0^k(X_A^k(0;t,y,w), V_A^k(0;t,y,w)) \mathbf{1}_{\{|u-y| \le C \cdot R\}} \\
&\quad \le \|\varphi\|_{L^1(\mathbb{R}_x)} 2CR \left(M_0^+ + M_0^- + 2\int_0^t \|A(s)\|_{L^\infty} ds (M_\infty^+ + M_\infty^-) \right),
\end{aligned}$$

where $C = \exp(\int_0^t (1 + \|\partial_x B(s)\|_{L^\infty(\mathbb{R}_x)})ds)$ and $R = \int_0^t \|A(s) - B(s)\|_{L^\infty(\mathbb{R}_x)}$ ds. $\square$

We can prove the following theorem by using the iterated approximations method.

THEOREM 6.5. *Assume that* $f_0^\pm \in L^1(\mathbb{R}_x \times \mathbb{R}_v)$ *verify the hypotheses* $(H^\pm), (H_0^\pm)$, $(H_\infty^\pm)$. *Then, for a fixed choice of primitive in* (6.4)*, there is a unique mild solution for the* 1D *Vlasov–Maxwell initial value problem.*

Remark 6.6. If in addition we assume that $|v|^p f_0^\pm \in L^1(\mathbb{R}_x \times \mathbb{R}_v)$ and

$$(H_p^\pm) \;\; M_p^\pm := \int_{\mathbb{R}_v} |v|^p n_0^\pm(|v|)dv < +\infty,$$

for some integer $p \ge 1$ we can prove that

$$|v|^p f^\pm \in L^\infty(]0,T[; L^1(\mathbb{R}_x \times \mathbb{R}_v)), \;\; \int_{\mathbb{R}_v} |v|^p f^\pm(t,x,v)dv \in L^\infty(]0,T[\times \mathbb{R}_x).$$

In particular $j^\pm = \int_{\mathbb{R}_v} v f^\pm dv \in L^\infty(]0,T[\times\mathbb{R}_x)$ and $\partial_t E = -j$, $\lim_{R_1 \to +\infty} \int_{|v|>R_1} |v|^p f^\pm dv = 0$ uniformly with respect to $(t,x) \in]0,T[\times \mathbb{R}_x$ and the mild formulation of the Vlasov problem holds for all functions $|\psi(t,x,v)| \le C(1 + |v|^p)$.

Proof. Multiplying the Vlasov equation by $|v|^p$, we get

$$\frac{d}{dt} \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f^\pm(t,x,v)|v|^p dxdv = \pm \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} E f^\pm p|v|^{p-2} v dxdv.$$

Therefore we deduce that

$$\begin{aligned}
\int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f^\pm(t,x,v)|v|^p dxdv \le \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f_0^\pm(x,v)|v|^p dxdv + p\|E\|_{L^\infty(]0,T[\times\mathbb{R}_x)} \\
\cdot \int_0^t \int_{\mathbb{R}_x}\int_{\mathbb{R}_v} f^\pm |v|^{p-1} dxdvds,
\end{aligned}$$

and the conclusion follows by induction on p. On the other hand,

$$\begin{aligned}\int_{\mathbb{R}_v} |v|^p f^{\pm}(t,x,v)dv &= \int_{\mathbb{R}_v} |v|^p f_0^{\pm}(X^{\pm}(0;t,x,v),V^{\pm}(0;t,x,v))dv \\ &\le \int_{\mathbb{R}_v} |v|^p n_0^{\pm,R}(|v|)dv \\ &\le C(R)(\|n_0^{\pm}\|_{L^\infty(\mathbb{R}_v^+)} + \||v|^p n_0^{\pm}(|v|)\|_{L^1(\mathbb{R}_v)}),\end{aligned}$$

with $R = \int_0^t \|E(s)\|_{L^\infty(\mathbb{R}_x)}ds$. In order to verify that $\partial_t E = -j$ in $\mathcal{D}'(]0,T[\times\mathbb{R}_x)$, take $\varphi \in C_0^1(]0,T[\times\mathbb{R}_x)$ and use the mild formulation with the test function $\psi(t,x,v) = v\varphi(t,x)$. $\square$

7. The periodic 1D Vlasov–Poisson problem. In this section we analyze the space periodic 1D Vlasov–Poisson problem:

$$\partial_t f^{\pm} + v\cdot\partial_x f^{\pm} \pm E\cdot\partial_v f^{\pm} = 0,\ \ (t,x,v)\in]0,T[\times]0,1[\times\mathbb{R}_v, \tag{7.1}$$

(7.2)

$$\partial_x E = \rho(t,x) := \rho^+ - \rho^- = \int_{\mathbb{R}_v} (f^+(t,x,v) - f^-(t,x,v))dv,\ \ (t,x)\in]0,T[\times]0,1[,$$

with the space periodic initial conditions

$$f^{\pm}(t=0,x,v) = f_0^{\pm}(x,v),\ (x,v)\in]0,1[\times\mathbb{R}_v. \tag{7.3}$$

The electric field derives from a space periodic potential and thus $\int_0^1 E(t,x)dx = 0$. In this case the Poisson field can be written as

$$E(t,x) = \int_0^x \rho(t,y)dy - \int_0^1 (1-y)\rho(t,y)dy,\ x\in[0,1],\ t\in[0,T]. \tag{7.4}$$

We introduce the mild formulation as before by taking space periodic test functions. This time it is convenient to define the application $\mathcal{F}$ for 1-periodic with respect to x fields $E \in L^\infty(]0,T[\times\mathbb{R}_x)$ by

$$E \to f_E^{\pm} \to \rho_E^{\pm} \to \int_0^x \rho_E(t,y)dy - \int_0^1 (1-y)\rho_E(t,y)dy = \mathcal{F}E.$$

Remark 7.1. $\mathcal{F}E$ is 1-periodic in x iff $\int_0^1 \rho_E(t,y)dy = 0,\ 0\le t\le T$ and therefore, by the conservation of the total charge, iff $\int_0^1\int_{\mathbb{R}_v} f_0^+(x,v)dxdv = \int_0^1\int_{\mathbb{R}_v} f_0^-(x,v)dxdv$.

7.1. Estimate of $\mathcal{F}$. We assume that $f_0^{\pm}$ verify the hypotheses $(H^{\pm})$, $(H_0^{\pm})$, $(H_\infty^{\pm})$. We suppose also that the neutrality condition holds:

$$(N)\ \ \int_0^1\int_{\mathbb{R}_v} f_0^+(x,v)dxdv = \int_0^1\int_{\mathbb{R}_v} f_0^-(x,v)dxdv.$$

Proposition 7.2. *Assume that $f_0^\pm$ are 1-periodic in x and satisfy $(H^\pm), (H_0^\pm)$, $(H_\infty^\pm)$, and (N). Then for every $E \in L^\infty(]0,T[; W^{1,\infty}(\mathbb{R}_x))$ 1-periodic in x we have*

$$\|\rho_E^\pm\|_{L^\infty(]0,T[\,\times\mathbb{R}_x)} \le 2M_\infty^\pm \int_0^t \|E(s)\|_{L^\infty(\mathbb{R}_x)} ds + M_0^\pm,$$

$$\|\mathcal{F}E\|_{L^\infty(]0,T[\,\times\mathbb{R}_x)} \le \int_0^1\!\!\int_{\mathbb{R}_v} f_0^+(x,v)dxdv + \int_0^1\!\!\int_{\mathbb{R}_v} f_0^-(x,v)dxdv \le M_0^+ + M_0^-,$$

$$\|\partial_x\mathcal{F}E\|_{L^\infty(]0,T[\,\times\mathbb{R}_x)} \le 2(M_\infty^+ + M_\infty^-)\int_0^t \|E(s)\|_{L^\infty(\mathbb{R}_x)} ds + M_0^+ + M_0^-.$$

Moreover, $\lim_{R_1\to+\infty}\int_{|v|>R_1} f_E^\pm(t,x,v)dv = 0$ uniformly with respect to $(t,x) \in\,]0,T[\,\times\mathbb{R}_x$ and the mild formulation of the Vlasov problem holds for all functions $\psi \in L^\infty(]0,T[\,\times\mathbb{R}_x\times\mathbb{R}_v)$ 1-periodic in x.

7.2. Estimate of $\mathcal{F}$ $-\,\mathcal{F}$.

Proposition 7.3. *Assume that $A, B \in L^\infty(]0,T[; W^{1,\infty}(\mathbb{R}_x))$ are 1-periodic in x and the hypotheses $(H^\pm), (H_0^\pm), (H_\infty^\pm), (N)$ hold. Then $\forall\, 0 \le t \le T$ we have*

$$\|\mathcal{F}A(t) - \mathcal{F}B(t)\|_{L^\infty(\mathbb{R}_x)} \le C\int_0^t \|A(s)-B(s)\|_{L^\infty(\mathbb{R}_x)} ds,$$

where the constant C depends on $\|A\|_{L^1(]0,T[;W^{1,\infty}(\mathbb{R}_x))}, \|B\|_{L^1(]0,T[;W^{1,\infty}(\mathbb{R}_x))}, M_0^\pm$, $M_\infty^\pm, T$.

Proof. Take $\varphi \in L^1_{loc}(\mathbb{R}_x)$ and calculate

$$\begin{aligned}
\mathcal{I}_1^\pm &= \left|\int_0^1 \varphi(x)\int_0^x (\rho_A^\pm(t,y) - \rho_B^\pm(t,y))dydx\right| \\
&= \Bigg|\iint (f_0^\pm(X_A^\pm(0;t,y,v), V_A^\pm(0;t,y,v)) - f_0^\pm(X_B^\pm(0;t,y,v), V_B^\pm(0;t,y,v))) \\
&\qquad \cdot \int_y^1 \varphi(x)dxdydv\Bigg| \\
&= \left|\iint f_0^\pm(\xi,\eta)\int_{X_A^\pm(t;0,\xi,\eta)}^{X_B^\pm(t;0,\xi,\eta)} \varphi(x)dxd\xi d\eta\right| \\
&\le \int_0^1 |\varphi(u)| \iint f_0^\pm(\xi,\eta)\mathbf{1}_{\{|u-X_A^\pm(t)|<|X_A^\pm(t)-X_B^\pm(t)|\}} d\xi d\eta du \\
&\le \int_0^1 |\varphi(u)| \iint f_0^\pm(X_A^\pm(0;t,y,w), V_A^\pm(0;t,y,w))\mathbf{1}_{\{|u-y|<CR\}} dydw \\
&\le 2CR\left(2\int_0^t \|A(s)\|_{L^\infty} ds \cdot M_\infty^\pm + M_0^\pm\right)\cdot\|\varphi\|_{L^1(]0,1[)},
\end{aligned}$$

where $C = \exp(\int_0^t (1 + \|\partial_x B(s)\|_{L^\infty})ds)$ and $R = \int_0^t \|A(s) - B(s)\|_{L^\infty} ds$. In order to estimate $\mathcal{I}_2^\pm = |\int_0^1 (1-y)(\rho_A^\pm(t,y) - \rho_B^\pm(t,y))dy|$ take $\varphi \equiv 1$ in the previous computation. ∎

Finally we obtain the existence and uniqueness of the space periodic mild solution.

Theorem 7.4. *Assume that $f_0^\pm$ are 1-periodic in x and satisfy the hypotheses $(H^\pm), (H_0^\pm)$, $(H_\infty^\pm)$, (N). Then there is a unique mild solution for the space periodic*

1D *Vlasov–Poisson problem. Moreover, we have the estimates*

$$\|\rho^{\pm}\|_{L^\infty(]0,T[\,\times\mathbb{R}_x)} \le 2M_\infty^{\pm}\cdot T\cdot(M_0^+ + M_0^-) + M_0^{\pm},$$
$$\|E\|_{L^\infty(]0,T[\,\times\mathbb{R}_x)} \le M_0^+ + M_0^-.$$

THE NONLINEAR SCHRÖDINGER EQUATION WITH A STRONGLY ANISOTROPIC HARMONIC POTENTIAL*

NAOUFEL BEN ABDALLAH†, FLORIAN MÉHATS†, CHRISTIAN SCHMEISER‡, AND RADA M. WEISHÄUPL§

Abstract. The nonlinear Schrödinger equation with general nonlinearity of polynomial growth and harmonic confining potential is considered. More precisely, the confining potential is strongly anisotropic; i.e., the trap frequencies in different directions are of different orders of magnitude. The limit as the ratio of trap frequencies tends to zero is carried out. A concentration of mass on the ground state of the dominating harmonic oscillator is shown to be propagated, and the lower-dimensional modulation wave function again satisfies a nonlinear Schrödinger equation. The main tools of the analysis are energy and Strichartz estimates, as well as two anisotropic Sobolev inequalities. As an application, the dimension reduction of the three-dimensional Gross–Pitaevskii equation is discussed, which models the dynamics of Bose–Einstein condensates.

Key words. energy estimates, Strichartz estimates, anisotropic Sobolev embedding, Gross–Pitaevskii equation, Bose–Einstein condensate

1. Introduction and main result. The main goal of the present work is the analysis of the space dimension reduction of the $(n+d)$-dimensional nonlinear Schrödinger equation with external confining potential. We are interested in the case where the external potential is anisotropic and strongly confining in d directions. This work follows the approach used in [3] for analyzing a dimension reduction (from dimension 3 to dimension 2) for the Schrödinger–Poisson system and where asymptotics for strong partial confinement was introduced. In other words, we deal with the asymptotic behavior of solutions of the $(n+d)$-dimensional Schrödinger equation

$$i\psi_t = -\frac{1}{2}\Delta\psi + V^\varepsilon(x,z)\psi + f(\delta|\psi|)\psi\,, \tag{1}$$

$$\psi_I(x,z) = \psi(0,x,z)\,, \tag{2}$$

$$V^\varepsilon(x,z) = \frac{|x|^2}{2} + \frac{|z|^2}{2\varepsilon^4}\,, \qquad x\in R^n\,, \quad z\in R^d\,,$$

as $\varepsilon \to 0$. Here V^ε is the trapping harmonic potential and $\Delta = \Delta_x + \Delta_z$ is the Laplacian in R^{n+d} and ψ satisfies the normalization condition

$$\int_{R^{n+d}} |\psi|^2 dx dz = 1\,, \tag{3}$$

which is preserved by (1). Since the sign of the function f is not specified, we are dealing with both focusing and defocusing nonlinearities. Performing the limit $\varepsilon \to 0$ in this system will enable us to write a reduced model involving a nonlinear Schrödinger equation in dimension n. In section 4, an application to the dynamics of Bose–Einstein condensates is presented; we justify mathematically the effective models which can be found in the physics literature [13]. In this context, as was remarked in [1], the use of such approximate models significantly reduces the complexity of numerical simulations.

In order to balance the kinetic and potential energy terms in the z-direction, we introduce the rescaling $z \to \varepsilon z$. In order to keep the wavefunction normalized we have to rescale by $\psi \to \varepsilon^{-d/2}\psi^\varepsilon(t,x,z)$. As we want to balance the nonlinearity with the terms of order 1, we choose $\delta = \varepsilon^{d/2}$; thus we consider weak nonlinearities. The rescaled problem reads

$$\begin{aligned} &i\psi_t^\varepsilon = H^\perp \psi^\varepsilon + \frac{1}{\varepsilon^2} H\psi^\varepsilon + f(|\psi^\varepsilon|)\psi^\varepsilon\,, \\ &\psi^\varepsilon(t=0,x,z) = \psi_I(x,z)\,, \end{aligned} \tag{4}$$

with $H^\perp = -\frac{1}{2}\Delta_x + \frac{|x|^2}{2}$ and $H = -\frac{1}{2}\Delta_z + \frac{|z|^2}{2}$, harmonic oscillators in the x- and z-directions, respectively.

We introduce a new time scale $\tau = t/\varepsilon^2$, so that we have the fast oscillations in z corresponding to the fast time scale τ. If we let $\varepsilon \to 0$, we formally obtain the equation

$$i\Psi_\tau = H\Psi\,,$$

which we can solve explicitly in terms of the spectral decomposition of H:

$$\Psi = \sum_{k\geq 0} \phi_k e^{-i\mu_k \tau} \omega_k(z)\,.$$

Here $(\mu_k, \omega_k(z))_{k\geq 0}$ are the eigenvalues and normalized (with respect to $L^2(R^d)$) eigenfunctions of H, and $(\phi_k)_{(k\geq 0)}$ are coefficients independent of τ and z. The eigenvalue problem can be solved explicitly with the eigenvalues $\mu_k = k + \frac{d}{2}$ (see [18, Theorem 8.4]). The eigenfunctions are products of a Gaussian with Hermite polynomials, and, in particular, the ground state eigenfunction is given by

$$\omega_0(z) = \left(\frac{1}{\pi}\right)^{d/4} e^{-\frac{|z|^2}{2}}\,.$$

By modulation, thus introducing the slow variables x and t, we would have ϕ_k depending on (t,x). This motivates us to expand ψ^ε with respect to the eigenstates of H:

$$\psi^\varepsilon(t,x,z) = \sum_{k\geq 0} e^{-i\mu_k t/\varepsilon^2} \phi_k^\varepsilon(t,x)\omega_k(z)\,. \tag{5}$$

Actually, our aim is to determine and justify approximations of the form

$$\psi^\varepsilon(t,x,z) \approx \varphi(t,x)e^{-i\mu_0 t/\varepsilon^2}\omega_0(z)\,, \tag{6}$$

i.e., modulations of the ground state, under an assumption of well-prepared initial data (see (11) below). A formal analysis indicates that the general case, where the transport occurs on several modes, is more complicated and might involve coupling terms between the limiting n-dimensional Schrödinger equations (this is not the case for the Schrödinger–Poisson system [3], where the nonlinearity is weaker).

The projection Π onto the eigenspace generated by the groundstate $\omega_0(z)$ is given by

$$\Pi\psi^\varepsilon(t,x,z) = e^{-i\mu_0 t/\varepsilon^2}\phi^\varepsilon(t,x)\omega_0(z)$$

with

$$\phi^\varepsilon(x,t) := e^{i\mu_0 t/\varepsilon^2}\int_{R^d}\psi^\varepsilon(t,x,z)\omega_0(z)dz\,. \tag{7}$$

It is obvious that the projection has the following properties:

$$\partial_t\Pi = \Pi\partial_t\,, \qquad \Pi H^\perp = H^\perp\Pi\,, \qquad \Pi H = \mu_0\Pi\,.$$

By projecting (4) we obtain

$$i\phi^\varepsilon_t = H^\perp\phi^\varepsilon + e^{i\mu_0 t/\varepsilon^2}\int_{R^d} f(|\psi^\varepsilon|)\psi^\varepsilon\omega_0 dz\,. \tag{8}$$

The nonlinearity can be written as

$$\begin{aligned} & e^{i\mu_0 t/\varepsilon^2}\int_{R^d} f(|\psi^\varepsilon|)\psi^\varepsilon\omega_0 dz = \overline{f}(|\phi^\varepsilon|)\phi^\varepsilon + h^\varepsilon \\ & \text{with} \quad \overline{f}(|\phi|) = \int_{R^d} f(|\phi|\omega_0)\omega_0^2 dz \\ & \text{and} \quad h^\varepsilon = e^{i\mu_0 t/\varepsilon^2}\int_{R^d}[f(|\psi^\varepsilon|)\psi^\varepsilon\omega_0 - f(|\phi^\varepsilon|\omega_0)e^{-i\mu_0 t/\varepsilon^2}\phi^\varepsilon\omega_0^2]dz\,. \end{aligned} \tag{9}$$

Then the formal limit of (8) as $\varepsilon \to 0$ is the n-dimensional Schrödinger equation

$$i\varphi_t = H^\perp\varphi + \overline{f}(|\varphi|)\varphi\,. \tag{10}$$

When the initial data for the full problem (4) are chosen compatible with the ansatz (6), i.e.,

$$\psi_I(x,z) = \varphi_I(x)\omega_0(z)\,, \tag{11}$$

then appropriate initial conditions for the solution of (10) are

$$\varphi(0,x) = \varphi_I(x)\,. \tag{12}$$

The main result of this work is a justification of the limit problem (10), (12) under the following assumptions on the initial data and on the nonlinearity.

Assumption 1. The function φ_I satisfies

$$\int_{R^n} \left(|\nabla_x \varphi_I(x)|^2 + |x\varphi_I(x)|^2\right) dx < \infty, \quad \int_{R^n} |\varphi_I(x)|^2 dx = 1\,.$$

Assumption 2. The nonlinearity f satisfies

$$|f(|u|)u - f(|v|)v)| \le C(|u|^\alpha + |v|^\alpha)|u-v|\,,$$

where either $f \ge 0$ (defocusing case) and $0 \le \alpha < \frac{4}{n+d-2}$, or $0 \le \alpha < \min\{\frac{4}{n+d-2}, \frac{4}{n}\}$. Additionally, $\alpha \le \frac{2}{n-2}$ if $n > 2$.

Remark. The assumptions are sufficient for proving existence and uniqueness of local solutions of both the full problem (4), (11) and the limit problem (10), (12) (see [6, 15, 5]). Note that the property of f required in Assumption 2 carries over to $\overline{f}$. In the repulsive case, global existence is a straightforward consequence of energy conservation (see section 2). Without sign assumptions on the nonlinearity, the additional requirement $\alpha < 4/n$ leads to global solvability of the limit problem [15]. Here, however, it is used for proving ε-independent estimates for the full problem on finite time intervals.

THEOREM 1. *Let Assumptions* 1 *and* 2 *be satisfied and let* ψ^ε *and* φ *be the unique solutions of* (4), (11) *and* (10), (12), *respectively. Then for every* $T < \infty$ *there exists a constant* c_T *such that*

$$\sup_{t\in(0,T)} \|\psi^\varepsilon(t,\cdot,\cdot)) - e^{-i\mu_0 t/\varepsilon^2}\varphi(t,\cdot)\omega_0\|_{L^2(R^{n+d})} \le c_T\,\varepsilon\,.$$

The rest of the paper is organized as follows. In the following section, conservation of energy is used to derive uniform estimates of H^1-norms of the solution of the $(n+d)$-dimensional problem and its ground state contribution. Whereas for repulsive nonlinearities these results follow directly from the energy conservation, in the general case the nonlinearity needs to be controlled by an anisotropic generalization of the Gagliardo–Nirenberg inequality. Also the difference between the full solution and its projection to the ground state is shown to be small. In section 3, the difference between the ground state contribution and its formal limit is estimated. The main tools are Strichartz estimates [6, 10, 17] and an anisotropic Sobolev inequality.

Section 4 deals with an application, the Gross–Pitaevskii equation, which has a cubic nonlinearity and models the dynamics of Bose–Einstein condensates. In this case, dimension reduction means obtaining disk-shaped or cigar-shaped condensates. Finally, in the appendix the anisotropic Sobolev embedding and the anisotropic Gagliardo–Nirenberg inequality are proved.

2. Uniform estimates. In this section we derive some ε-independent estimates from energy conservation. The energy is defined by

$$E^\varepsilon[\psi^\varepsilon(t)] := \left\langle H^\perp\psi^\varepsilon(t), \psi^\varepsilon(t)\right\rangle + \frac{1}{\varepsilon^2}\left\langle H\psi^\varepsilon(t), \psi^\varepsilon(t)\right\rangle + 2\mathcal{F}[\psi^\varepsilon(t)]\,,$$

where $\langle\cdot,\cdot\rangle$ denotes the scalar product in $L^2(R^{n+d})$ and

$$\mathcal{F}[\psi] = \int_{R^{n+d}} F(|\psi|)dx\,dz\,, \quad \text{with } F(s) = \int_0^s f(\sigma)\sigma d\sigma\,.$$

Note that the first two terms in the energy are nonnegative quadratic forms controlling the H^1-norms in the x- and z-directions, respectively.

With Assumption 1, the initial data (11) satisfy $E^\varepsilon[\psi_I] < \infty$ for fixed ε. From [6] (Theorem 9.2.5 and Remark 9.2.7) and Assumption 2 we obtain local-in-time existence for the $(n+d)$-dimensional problem (4) as well as energy and mass conservation:

$$E^\varepsilon[\psi^\varepsilon(t)] = E^\varepsilon[\psi_I]\,, \qquad \|\psi^\varepsilon(t)\|_{2,2} = \|\psi_I\|_{2,2} = \|\varphi_I\|_2\,. \tag{13}$$

Considering the limit of $\varepsilon^2 E^\varepsilon$ when $\varepsilon \to 0$, we immediately obtain uniform bounds for the dominant term. The main difficulty consists in finding uniform bounds on $\left\langle H^\perp \psi^\varepsilon(t), \psi^\varepsilon(t)\right\rangle$. Once we have this, we can derive uniform bounds on the H^1-norm of $\psi^\varepsilon(t)$.

For the notation of norms we use the following conventions.

Definition 2. *Let $0 < T \le \infty$, $1 \le p, q, r \le \infty$, and $u(t,x)$, $v(t,x,z)$ functions of $t \in (0,T)$, $x \in R^n$, and $z \in R^d$. Then we define the norms*

$$\begin{aligned} \|u(t)\|_p &:= \|u(t,\cdot)\|_{L^p(R^n)}\,, \\ \|u\|_{r(p)} &:= \Big\| \|u(\cdot)\|_p \Big\|_{L^r((0,T))}\,, \\ \|v(t)\|_{q,p} &:= \Big\| \|v(t,\cdot)\|_p \Big\|_{L^q(R^d)}\,, \\ \|v\|_{r(q,p)} &:= \Big\| \|v(\cdot)\|_{q,p} \Big\|_{L^r((0,T))}\,, \end{aligned}$$

and the corresponding Banach spaces are denoted by L^p_x, $L^r_t L^p_x$, $L^q_z L^p_x$, and $L^r_t L^q_z L^p_x$.

Taking into account the expansion (5) of the $(n+d)$-dimensional wavefunction ψ^ε with respect to the orthonormal basis $(\omega_k)_{k\ge 0}$ of eigenfunctions gives

$$\|\psi^\varepsilon(t)\|_{2,2}^2 = \sum_{k=0}^{\infty} \|\phi_k^\varepsilon(t)\|_2^2, \tag{14}$$

$$\|\nabla_x \psi^\varepsilon(t)\|_{2,2}^2 = \sum_{k=0}^{\infty} \|\nabla_x \phi_k^\varepsilon(t)\|_2^2. \tag{15}$$

At first sight, the energy equation seems to be of limited use, since it is dominated by the contributions in the z-direction. However, with the mass conservation this part can be written as

$$\begin{aligned} \langle H\psi^\varepsilon(t), \psi^\varepsilon(t)\rangle &= \sum_{k=0}^{\infty} \mu_k \|\phi_k^\varepsilon(t)\|_2^2 \\ &= \sum_{k=1}^{\infty} (\mu_k - \mu_0)\|\phi_k^\varepsilon(t)\|_2^2 + \mu_0 \|\varphi_I\|_2^2\,, \end{aligned} \tag{16}$$

and, on the other hand,

$$\langle H\psi_I, \psi_I\rangle = \mu_0 \|\varphi_I\|_2^2\,. \tag{17}$$

By using (16) and (17) we can rewrite the energy conservation as

$$\begin{aligned} &\left\langle H^\perp \psi^\varepsilon(t), \psi^\varepsilon(t)\right\rangle + \frac{1}{\varepsilon^2}\sum_{k=1}^{\infty}(\mu_k - \mu_0)\|\phi_k^\varepsilon(t)\|_2^2 + 2\mathcal{F}[\psi^\varepsilon(t)] \\ &= \left\langle H^\perp \psi_I, \psi_I\right\rangle + 2\mathcal{F}[\psi_I]\,. \end{aligned} \tag{18}$$

In the case of defocusing nonlinearities all terms in this equation are nonnegative, and we immediately obtain uniform boundedness of $\psi^\varepsilon(t)$ in $H^1(R^{n+d})$, as well as the statement that the mass remains concentrated to the ground state as $\varepsilon \to 0$. The rest of this section is devoted to proving the same results (Lemmas 3 and 4) without sign assumption on the nonlinearity.

By applying Lemma 5 from the appendix with $r = \alpha + 2$, we can control the term coming from the nonlinearity:

$$|\mathcal{F}[\psi^\varepsilon(t)]| \le \|\psi^\varepsilon(t)\|_{2+\alpha,2+\alpha}^{2+\alpha} \le c\|\nabla_x \psi^\varepsilon(t)\|_{2,2}^{n\alpha/2} \|\nabla_z \psi^\varepsilon(t)\|_{2,2}^{d\alpha/2}\,, \tag{19}$$

where here and in the following c denotes possibly different ε-independent, positive constants. Consequently, the energy conservation multiplied by ε^2 yields

$$\varepsilon^2 \|\nabla_x \psi^\varepsilon(t)\|_{2,2}^2 + \|\nabla_z \psi^\varepsilon(t)\|_{2,2}^2 \le c + c\varepsilon^2 \|\nabla_x \psi^\varepsilon(t)\|_{2,2}^{n\alpha/2} \|\nabla_z \psi^\varepsilon(t)\|_{2,2}^{d\alpha/2}\,,$$

and, from the Young inequality,

$$\varepsilon^2 \|\nabla_x \psi^\varepsilon(t)\|_{2,2}^2 + \|\nabla_z \psi^\varepsilon(t)\|_{2,2}^2 \le c + \varepsilon^2 \eta \|\nabla_x \psi^\varepsilon(t)\|_{2,2}^2 + \varepsilon^2 C(\eta) \|\nabla_z \psi^\varepsilon(t)\|_{2,2}^{\frac{2d\alpha}{4-n\alpha}}\,.$$

Remark. The constraint $\alpha < \frac{4}{n}$ in Assumption 2 guarantees that the exponent remains positive.

With the choice $\eta = \frac{1}{2}$ we deduce

$$\|\nabla_z \psi^\varepsilon(t)\|_{2,2}^2 \le c + \varepsilon^2 c \|\nabla_z \psi^\varepsilon(t)\|_{2,2}^{\frac{2d\alpha}{4-n\alpha}}\,.$$

In the case $\theta = \frac{2d\alpha}{4-n\alpha} < 2$ we conclude that

$$\|\nabla_z \psi^\varepsilon\|_{\infty(2,2)} \le c. \tag{20}$$

For $\theta > 2$ we obtain the result by the standard bootstrap argument, since $\|\nabla_z \psi_I\|_{2,2}$ is independent of ε (see [4, Lemma 2.9]). Using (19) with (20) in (18), we get

$$\|\nabla_x \psi^\varepsilon(t)\|_{2,2}^2 + \|x\psi^\varepsilon(t)\|_{2,2}^2 + \frac{1}{\varepsilon^2}\sum_{k=1}^{\infty} (\mu_k - \mu_0)\|\phi_k^\varepsilon(t)\|_2^2 \le c + c\|\nabla_x \psi^\varepsilon(t)\|_{2,2}^{n\alpha/2}\,. \tag{21}$$

Since, by $\alpha < 4/n$, the exponent in the last term is smaller than 2, uniform boundedness of $\|\nabla_x \psi^\varepsilon(t)\|_{2,2}$ follows.

It is now easy to prove the following two results on uniform boundedness and on the uniform smallness of the contributions from excited states.

LEMMA 3. *Let the assumptions of Theorem 1 be satisfied, let ψ^ε be the solution of* (4), (11), *let ϕ^ε be defined by* (7), *and let φ be the solution of* (10), (12). *Then*

$$\psi^\varepsilon \in L^\infty((0,\infty);\, H^1(R^{n+d}))\,, \qquad \phi^\varepsilon, \varphi \in L^\infty((0,\infty);\, H^1(R^n))\,,$$

uniformly in ε.

Proof. From (16) and (21) it is immediately clear that $\langle H^\perp \psi^\varepsilon(t), \psi^\varepsilon(t)\rangle + \langle H\psi^\varepsilon(t), \psi^\varepsilon(t)\rangle$ is uniformly bounded with respect to ε and t. The observation that this term dominates the $H^1(R^{n+d})$-norm completes the proof of the first statement of the lemma.

The representation of ψ^ε in terms of the eigenstates shows

$$\langle H^\perp \psi^\varepsilon(t), \psi^\varepsilon(t)\rangle \ge \frac{1}{2}(\|\nabla_x \phi^\varepsilon\|_2^2 + \|x\phi^\varepsilon\|_2^2)\,,$$

which proves the statement for ϕ^ε. Finally, the statement for the ε-independent φ is a consequence of the existence theory. ∎

LEMMA 4. *With the assumptions of the previous lemma,*

$$\|(I-\Pi)\psi^\varepsilon\|_{\infty(p,2)} \le c\,\varepsilon$$

holds with an ε-independent constant c and with $p \in [2, \frac{2d}{d-2}]$ if $d \ge 3$, $p \in [2,\infty)$ if $d = 2$, and $p \in [2,\infty]$ if $d = 1$.

Proof. Using (21) we obtain

$$\begin{aligned}\|(I-\Pi)\psi^\varepsilon(t)\|_{2,2}^2 &= \sum_{k=1}^\infty \|\phi_k^\varepsilon(t)\|_2^2 \\ &\le \frac{1}{\mu_1-\mu_0}\sum_{k=1}^\infty (\mu_k-\mu_0)\|\phi_k^\varepsilon(t)\|_2^2 \le c\varepsilon^2\,,\end{aligned}$$

i.e., the statement of the lemma with $p = 2$. On the other hand we estimate

$$\begin{aligned}\|\nabla_z(I-\Pi)\psi^\varepsilon(t)\|_{2,2}^2 &\le \langle H(I-\Pi)\psi^\varepsilon(t), (I-\Pi)\psi^\varepsilon(t)\rangle = \sum_{k=1}^\infty \mu_k\|\phi_k^\varepsilon(t)\|_2^2 \\ &= \sum_{k=1}^\infty (\mu_k-\mu_0)\|\phi_k^\varepsilon(t)\|_2^2 + \mu_0\|(I-\Pi)\psi^\varepsilon(t)\|_{2,2}^2 \le c\varepsilon^2\,.\end{aligned}$$

The result is now a consequence of the Sobolev embedding $H^1(R^d) \hookrightarrow L^p(R^d)$ in z-space. ∎

3. Proof of the main result. The approximation error in Theorem 1 can be split into two parts:

$$\begin{aligned}\|\psi^\varepsilon - \varphi\omega_0 e^{-i\mu_0 t/\varepsilon^2}\|_{\infty(2,2)} &\le \|(I-\Pi)\psi^\varepsilon\|_{\infty(2,2)} + \|\omega_0 e^{-i\mu_0 t/\varepsilon^2}(\phi^\varepsilon-\varphi)\|_{\infty(2,2)} \\ &= \|(I-\Pi)\psi^\varepsilon\|_{\infty(2,2)} + \|\phi^\varepsilon-\varphi\|_{\infty(2)}\,.\end{aligned}$$

The first term is taken care of by Lemma 4. The difference $\chi^\varepsilon := \phi^\varepsilon - \varphi$ solves the problem

$$\begin{aligned}&i\chi_t^\varepsilon = H^\perp\chi^\varepsilon + g^\varepsilon + h^\varepsilon, \\ &\chi^\varepsilon(t=0) = 0\,,\end{aligned} \tag{22}$$

where

$$g^\varepsilon = \overline{f}(|\phi^\varepsilon|)\phi^\varepsilon - \overline{f}(|\varphi|)\varphi$$

and h^ε given by (9).

For the nonlinear Schrödinger equation (22) with harmonic potential, a local dispersion result can be established (see [8, 9], [6, Lemma 9.2.4]). This property allows us to use Strichartz estimates (see [6, Theorem 3.4.1], [5, 12]), and we obtain the following for any admissible pair (q^*, q) and a *bounded* time interval $T < \infty$:

$$\|\chi^\varepsilon\|_{\infty(2)} \le c_T(\|g^\varepsilon\|_{q^*(q)} + \|h^\varepsilon\|_{q^*(q)})\,. \tag{23}$$

A pair (q, q^*) is admissible iff

$$\frac{2n}{n+2} \le q \le 2 \text{ for } n \ge 3\,, \quad 1 < q \le 2 \text{ for } n = 2\,, \quad 1 \le q \le 2 \text{ for } n = 1\,, \tag{24}$$

$$q^* = \frac{4}{4 - n(2/q - 1)}\,. \tag{25}$$

Note that the definition of admissible pair is not the usual one.

Remark. We need a bounded time interval because the constant depends on the length of the time interval. For more details, see [6].

Assumption 2 implies the pointwise estimate

$$|g^\varepsilon| \le c(|\phi^\varepsilon|^\alpha + |\varphi|^\alpha)|\chi^\varepsilon|\,.$$

Applying the Hölder inequality, we obtain

$$\|g^\varepsilon(t)\|_q \le c(\|\phi^\varepsilon\|^\alpha_{2\alpha q/(2-q)} + \|\varphi\|^\alpha_{2\alpha q/(2-q)})\|\chi^\varepsilon\|_2\,.$$

The assumption $\alpha \le 2/(n-2)$ for $n \ge 3$ allows us to choose q such that both (24) is satisfied and $H^1(R^n) \hookrightarrow L_x^{2\alpha q/(2-q)}$. Therefore we can use Lemma 3 to obtain

$$\|g^\varepsilon(t)\|_{q^*(q)} \le c\|\chi^\varepsilon\|_{q^*(2)}\,. \tag{26}$$

For h^ε we also employ Assumption 2 to obtain a pointwise estimate:

$$|h^\varepsilon| \le c\int_{R^d} (|\psi^\varepsilon|^\alpha + |\Pi\psi^\varepsilon|^\alpha)|(I-\Pi)\psi^\varepsilon|\omega_0\,dz\,.$$

Computing the $L^q(R^n)$-norm and applying the Hölder inequality twice (to the x- and z-integrals, respectively) lead to

$$\|h^\varepsilon\|_q \le c(\|\psi^\varepsilon\|^\alpha_{\alpha p', 2\alpha q/(2-q)} + \|\phi^\varepsilon\|^\alpha_{2\alpha q/(2-q)})\|(I-\Pi)\psi^\varepsilon\|_{p,2}\,,$$

whereby $p' = \frac{p}{p-1}$.

Let us recall all the conditions on p and q:

(i) the assumptions of Lemma 4 for p and condition (24) for q are satisfied;

(ii) the embeddings $H^1(R^n) \hookrightarrow L_x^{2\alpha q/(2-q)}$ and $H^1(R^{n+d}) \hookrightarrow L_z^{\alpha p'} L_x^{2\alpha q/(2-q)}$ (see Lemma 5 in the appendix) hold.

All this is possible since $\alpha \le 4/(n+d-2)$ and $\alpha \le 2/(n-2)$ for $n \ge 3$. As a consequence of Lemmas 3 and 4 we obtain

$$\|h^\varepsilon\|_{\infty(q)} \le c\varepsilon\,. \tag{27}$$

With (26) and (27), the Strichartz estimate (23) becomes

$$\|\chi^\varepsilon\|_{\infty(2)} \le c_T(\|\chi^\varepsilon\|_{q^*(2)} + \varepsilon)\,.$$

Using this estimate on the time interval $(0, t)$ with $t \le T$ gives

$$\|\chi^\varepsilon(t)\|_2^{q^*} \le \tilde{c}_T \left(\int_0^t \|\chi^\varepsilon(s)\|_2^{q^*} ds + \varepsilon^{q^*} \right)\,.$$

Now, an application of the Gronwall lemma concludes the proof of Theorem 1.

4. Application: The Gross–Pitaevskii equation. The three-dimensional nonlinear Schrödinger equation with cubic nonlinearity and an external potential is called the Gross–Pitaevskii equation. It models the temporal evolution of Bose–Einstein condensates at temperatures much smaller than the critical condensation temperature [7, 14, 16]. In dimensional form, the Gross–Pitaevskii equation reads

$$i\hbar\psi_t = -\frac{\hbar^2}{2m}\Delta\psi + \frac{m}{2}\left(\omega_x^2|x|^2 + \omega_z^2|z|^2\right)\psi + Ng|\psi|^2\psi\,, \tag{28}$$

where m is the atomic mass, $\hbar$ is the Planck constant, N is the number of atoms in the condensate, and ω_x, ω_z are the trap frequencies in x- and z-directions, respectively. The parameter g describes the interaction between the atoms in the condensate and has the form $g = \hbar^2 a/m$, where a is the scattering length, positive for repulsive interactions and negative for attractive interactions. We consider the cases $n = 1$ and $n = 2$ with $d = 3 - n$. Characteristic lengths of the condensate in the x- and z-directions are $a_x = \sqrt{\hbar/(m\omega_x)}$ and $a_z = \sqrt{\hbar/(m\omega_z)}$, respectively.

Let us write (28) in dimensionless form. With the scaling

$$x = a_x\tilde{x}\,, \quad z = a_z\tilde{z}\,, \quad \psi = \frac{\tilde{\psi}}{\sqrt{a_x^n a_z^{3-n}}}\,, \quad t = \frac{\tilde{t}}{\omega_x}\,,$$

and skipping the tildes, we obtain

$$i\psi_t = -\frac{1}{2}\Delta_x\psi + \frac{|x|^2}{2}\psi + \frac{\omega_z}{\omega_x}\left(-\frac{1}{2}\Delta_z\psi + \frac{|z|^2}{2}\psi\right) + N\frac{a}{a_z^{3-n}a_x^{n-2}}|\psi|^2\psi\,.$$

In experiments it is observed that in a strongly anisotropic confinement the motion of particles is quenched in one or two directions. This means that by changing the shape of the confining potential, lower-dimensional Bose–Einstein condensates are obtained. They are called disk-shaped or cigar-shaped condensates, respectively. This is the motivation to consider the Gross–Pitaevskii equation with strongly anisotropic confining harmonic potential; thus

$$\varepsilon^2 := \frac{\omega_x}{\omega_z} \ll 1\,.$$

Furthermore we assume the case of weak coupling, namely,

$$\gamma := \frac{Na}{a_z^{3-n}a_x^{n-2}} = \mathcal{O}(1)\,.$$

We then have the equation

$$i\psi_t = -\frac{1}{2}\Delta_x\psi + \frac{|x|^2}{2}\psi + \frac{1}{\varepsilon^2}\left(-\frac{1}{2}\Delta_z\psi + \frac{|z|^2}{2}\psi\right) + \gamma|\psi|^2\psi\,,$$

where $\gamma|\psi|^2 = f(|\psi|)$ with γ positive, if we consider repulsive interactions, e.g., for ^{23}Na and ^{87}Rb, or negative for attractive interactions, e.g., for ^{7}Li. Obviously, Assumption 2 on f holds with $\alpha = 2$.

For *repulsive interactions* ($\gamma > 0$) we have global existence of the solution of the $(n+d)$-dimensional Schrödinger equation if $\alpha < 4/(n+d-2)$. Since $\alpha = 2$ we obtain the condition $n+d<4$, which includes the physically interesting case $n+d=3$. The limiting lower-dimensional Gross–Pitaevskii equation is

$$i\varphi_t = H^{\perp}\varphi + \gamma_0|\varphi|^2\varphi \quad \text{with } \gamma_0 = \gamma\int_{R^d}\omega_0^4(z)dz\,.$$

On the one hand, if we consider the strong confinement in one direction ($d=1$), we obtain a two-dimensional approximate equation ($n=2$). In this case we speak about a *disk-shaped condensate*. On the other hand, we consider a strong confinement in 2 dimensions ($d=2$). Accordingly, the approximate equation is one-dimensional ($n=1$) and we call the condensate a *cigar-shaped condensate*. Theorem 1 can be applied in both cases.

In the case of *attractive interactions*, thus for $\gamma<0$, we get stronger constraints on the dimensions, namely, $n=1$ and $d<3$. Thus, Theorem 1 can only be applied for the reduction from three dimensions to one (cigar-shaped condensate).

Appendix. Anisotropic Sobolev inequalities. In this section, we state anisotropic Sobolev embeddings and a generalized Gagliardo–Nirenberg inequality. The proof of this lemma, rather straightforward, is skipped. It uses standard Sobolev embeddings and Gagliardo–Nirenberg inequalities, combined with interpolation estimates. We generalize here a result of [2] (see also [11], where a similar Sobolev embedding is obtained). Recall that in this paper the whole dimension is $n+d$ and the space variable is written (x,z), where $x\in R^n$ and $z\in R^d$.

LEMMA 5. *Let $2\le p,q\le\infty$ be such that*

$$\frac{n}{p(n+d)}+\frac{d}{q(n+d)}\ge\frac{1}{2}-\frac{1}{n+d}$$

(with $q<\infty$ if $d=2$; $p<\infty$ if $n=2$; and strict inequality if $n=d=1$). Then

$$H^1(R^{n+d})\hookrightarrow L^q_z(R^d;L^p_x(R^n)).$$

Furthermore, for any $r\in[2,\frac{2(n+d)}{n+d-2}]$ we have

$$\|u\|_{L^r_{x,z}}\le C\|u\|_{L^2_{x,z}}^{1-(n+d)(\frac{1}{2}-\frac{1}{r})}\|\nabla_x u\|_{L^2_{x,z}}^{n(\frac{1}{2}-\frac{1}{r})}\|\nabla_z u\|_{L^2_{x,z}}^{d(\frac{1}{2}-\frac{1}{r})}\,.$$

STABLE DETERMINATION OF AN INCLUSION BY BOUNDARY MEASUREMENTS*

G. ALESSANDRINI† AND M. DI CRISTO‡

Abstract. We deal with the problem of determining an inclusion within an electrical conductor from electrical boundary measurements. Under mild a priori assumptions we establish an optimal stability estimate.

Key words. Dirichlet-to-Neumann map, discontinuous conductivity, optimal stability

AMS subject classifications. 35R30, 35A08

DOI. 10.1137/S003614100444191X

1. Introduction.

In this paper we deal with an inverse boundary value problem which is a special instance of the well-known Calderón's inverse conductivity problem [C]. Given a bounded domain Ω in $\mathbb{R}^n$, $n \geq 2$, with reasonably smooth boundary, an open set D, compactly contained in Ω, and a constant $k > 0$, $k \neq 1$, consider, for any $f \in H^{1/2}(\partial\Omega)$, the weak solution $u \in H^1(\Omega)$ to the Dirichlet problem

$$\operatorname{div}((1 + (k-1)\chi_D)\nabla u) = 0 \qquad \text{in } \Omega, \tag{1.1}$$

$$u = f \qquad \text{on } \partial\Omega, \tag{1.2}$$

where χ_D denotes the characteristic function of the set D. We will denote by $\Lambda_D : H^{1/2}(\partial\Omega) \to H^{-1/2}(\partial\Omega)$ the so-called Dirichlet-to-Neumann map, that is the operator which maps the Dirichlet data onto the corresponding Neumann data $\frac{\partial u}{\partial \nu}_{|\partial\Omega}$. The inverse problem that we examine here is to determine D when Λ_D is given.

In 1988 Isakov [I1] proved the uniqueness. The purpose of the present paper is to prove a result of stability. In fact we prove that, under mild a priori assumptions on the regularity and topology of D, there is a continuous dependence of D (in the Hausdorff metric) from Λ_D with a modulus of continuity of logarithmic type; see Theorem 2.4. Let us stress that, indeed, this rate of continuity is the optimal one, as it was shown by examples in the recent paper [DC-R] by the second author and Luca Rondi.

We wish to mention here a closely related, but different, problem which attracted a lot of attention starting with the papers of Friedman [F] and Friedman and Gustafsson [F-G]. That is the one of determining D when, instead of full knowledge of the Dirichlet-to-Neumann map, only one, or few, pairs of Dirichlet and Neumann data are available; see [A-I], [I2] for extended bibliographical accounts. Unfortunately, for such a problem, the uniqueness question, not to mention stability, remains a largely open issue.

Let us illustrate briefly the main steps of our arguments. We must recall that Isakov's approach to uniqueness is essentially based on two arguments,

(a) the Runge approximation theorem,

(b) the use of solutions with Green's function type singularities.

Also, here we shall use singular solutions, and indeed we shall need an accurate study of their asymptotic behavior when the singularity gets close to the set of discontinuity ∂D of the conductivity coefficient $1+(k-1)\chi_D$ in (1.1); see Proposition 3.4. On the other hand, it seems that Runge's theorem, in its whole generality, is typically based on nonconstructive arguments (Lax [L], Kohn and Vogelius [K-V]) and thus, is not suited for stability estimates. We wish to mention here that a constructive version of a Runge type theorem, for special geometrical configurations and for Helmholtz equation, has indeed been used by Potthast [P1, P2] for the purpose of stability estimates in the different, but related, inverse problem of obstacle scattering. Unfortunately, by this approach, very restrictive geometrical assumptions on the unknown obstacle are required. In this paper we introduce a different approach based on quantitative estimates of unique continuation (see Proposition 3.5) which avoids the use of Runge type arguments and allows one to treat a wide generality of inclusions.

In section 2 we formulate our main hypotheses and state the stability result, Theorem 2.4. In section 3 we prove Theorem 2.4 on the basis of some auxiliary propositions, whose proofs are deferred to in section 4.

2. The main result. Let us introduce our regularity and topological assumptions on the conductor Ω and on the unknown inclusion D. To this purpose we shall need the following definitions. In places, we shall denote a point $x\in\mathbb{R}^n$ by $x=(x',x_n)$, where $x'\in\mathbb{R}^{n-1}$, $x_n\in\mathbb{R}$.

Definition 2.1. *Let Ω be a bounded domain in $\mathbb{R}^n$. Given α, $0<\alpha\le 1$, we shall say that a portion S of $\partial\Omega$ is of class $C^{1,\alpha}$ with constants $\overline{r}$, $L>0$ if, for any $P\in S$, there exists a rigid transformation of coordinates under which we have $P=0$ and*

$$\Omega\cap B_{\overline{r}}(0)=\{x\in B_{\overline{r}}\,:\,x_n>\varphi(x')\},$$

where φ is a $C^{1,\alpha}$ function on $B_{\overline{r}}(0)\subset\mathbb{R}^{n-1}$ satisfying $\varphi(0)=|\nabla\varphi(0)|=0$ and $\|\varphi\|_{C^{1,\alpha}(B_{\overline{r}}(0))}\le L\overline{r}$.

Definition 2.2. *We shall say that a portion S of $\partial\Omega$ is of Lipschitz class with constants $\overline{r}$, $L>0$ if for any $P\in S$, there exists a rigid transformation of coordinates under which we have $P=0$ and*

$$\Omega\cap B_{\overline{r}}(0)=\{x\in B_{\overline{r}}\,:\,x_n>\varphi(x')\},$$

where φ is a Lipschitz continuous function on $B_{\overline{r}}(0)\subset\mathbb{R}^{n-1}$ satisfying $\varphi(0)=0$ and $\|\varphi\|_{C^{0,1}(B_{\overline{r}}(0))}\le L\overline{r}$.

Remark 2.3. We have chosen to scale all norms in a such a way that they are dimensionally equivalent to their argument. For instance, for any $\varphi\in C^{1,\alpha}(B_{\overline{r}}(0))$ we set

$$\|\varphi\|_{C^{1,\alpha}(B_{\overline{r}}(0))}=\|\varphi\|_{L^\infty(B_{\overline{r}}(0))}+\overline{r}\|\nabla\varphi\|_{L^\infty(B_{\overline{r}}(0))}+\overline{r}^{1+\alpha}|\nabla\varphi|_{\alpha,B_{\overline{r}}(0)}.$$

For given numbers $\overline{r}$, M, $\widetilde{\delta}$, $L>0$, $0<\alpha<1$, we shall assume

(H1) the domain Ω satisfies the following conditions:

$$|\Omega|\le M\overline{r}^n, \tag{2.1}$$

where $|\cdot|$ denotes the Lebesgue measure of Ω,

$$\partial\Omega \text{ is of class } C^{1,\alpha} \text{ with constants } \overline{r},\ L, \tag{2.2}$$

(H2) the inclusion D satisfies the following conditions:

$$\Omega \setminus \overline{D} \quad \text{is connected,} \tag{2.3}$$

$$\text{dist}(D, \partial\Omega) \geq \widetilde{\delta}, \tag{2.4}$$

$$\partial D \text{ is of class } C^{1,\alpha} \text{ with constants } \overline{r},\ L. \tag{2.5}$$

In what follows, we shall refer to numbers k, n, $\overline{r}$, M, $\widetilde{\delta}$, L, α as to the a priori data. We shall denote by D_1 and D_2 two possible inclusions in Ω, both satisfying the properties mentioned. We shall denote by Λ_{D_i}, $i = 1, 2$, the Dirichlet-to-Neumann map Λ_D when $D = D_i$. We can now state the main theorem.

Theorem 2.4. *Let $\Omega \subset \mathbb{R}^n$, $n \geq 2$, satisfy* (H1). *Let $k > 0$, $k \neq 1$ be given. Let D_1 and D_2 be two inclusions in Ω satisfying* (H2). *If, given $\varepsilon > 0$, we have*

$$\|\Lambda_{D_1} - \Lambda_{D_2}\|_{\mathcal{L}(H^{1/2}, H^{-1/2})} \leq \varepsilon, \tag{2.6}$$

then

$$d_{\mathcal{H}}(\partial D_1, \partial D_2) \leq \omega(\varepsilon),$$

where ω is an increasing function on $[0, +\infty)$, which satisfies

$$\omega(t) \leq C|\log t|^{-\eta}, \qquad \text{for every} \quad 0 < t < 1$$

and C, η, $C > 0$, $0 < \eta \leq 1$, are constants only depending on the a priori data.

Here $d_{\mathcal{H}}$ denotes the Hausdorff distance between bounded closed sets of $\mathbb{R}^n$ and $\|\cdot\|_{\mathcal{L}(H^{1/2}H^{-1/2})}$ denotes the operator norm on the space of bounded linear operators between $H^{1/2}(\partial\Omega)$ and $H^{-1/2}(\partial\Omega)$.

Remark 2.5. It should be emphasized that in this statement the unknown inclusion may be disconnected.

Remark 2.6. Several variations of the above results could be devised with minor adaptations on the arguments. Just to mention one, an analogous result would be obtained if the Neumann-to-Dirichlet maps N_{D_i} are available instead of the Dirichlet-to-Neumann maps Λ_{D_i}.

3. Proof of Theorem 2.4. Before proving Theorem 2.4, we shall state some auxiliary propositions, whose proofs are collected in section 4. Here and in what follows, we shall deal with various sets associated to Ω, D_1, and D_2. We shall use the following notation.

Definition 3.1. *We denote by $\mathcal{G}$ the connected component of $\Omega \setminus (D_1 \cup D_2)$, whose boundary contains $\partial\Omega$, $\Omega_D = \Omega \setminus \overline{\mathcal{G}}$, $\Omega_{\overline{r}} = \{x \in \mathcal{C}\Omega : dist(x, \Omega) \leq \overline{r}\}$ and $\mathcal{S}_{2\overline{r}} = \{x \in \mathbb{R}^n : \overline{r} \leq dist(x, \Omega) \leq 2\overline{r}\}$.*

We introduce a variation of the Hausdorff distance which we call *modified distance*.

Definition 3.2. *We shall call the modified distance between D_1 and D_2 the number*

$$d_\mu(D_1, D_2) = \max\left\{ \sup_{x \in \partial D_1 \cap \partial\Omega_D} \text{dist}(x, D_2), \sup_{x \in \partial D_2 \cap \partial\Omega_D} \text{dist}(x, D_1) \right\}. \tag{3.1}$$

This notion is an adaptation of the one introduced in [A-B-R-V], which was also called *modified distance*. In order to distinguish such notions, we call d_μ the present one, whereas the one in [A-B-R-V] was denoted by d_m. On the other hand, we need to stress the common peculiarities: such modified distances do not satisfy the axioms of a metric and in general do not dominate the Hausdorff distance (see section 3 in [A-B-R-V] for related arguments). The following proposition provides sufficient conditions under which d_μ dominates $d_{\mathcal{H}}$; see [A-B-R-V, Proposition 3.6] for a related statement.

PROPOSITION 3.3. *Let Ω be an open set in $\mathbb{R}^n$ satisfying* (H1). *Let D_1, D_2 be two bounded open inclusions of Ω satisfying* (H2). *Then*

$$d_{\mathcal{H}}(\partial D_1, \partial D_2) \le c d_\mu(D_1, D_2), \tag{3.2}$$

where c depends only on the a priori assumptions.

With no loss of generality, we can assume that there exists a point O of $\partial D_1 \cap \partial\Omega_D$, where the maximum in Definition 3.1 is attained, that is

$$d_\mu = d_\mu(D_1, D_2) = \operatorname{dist}(O, D_2). \tag{3.3}$$

As is well known, the Dirichlet-to-Neumann map Λ_D associated to problem (1.1), (1.2) is defined by

$$< \Lambda_D u, v >= \int_\Omega (1 + (k-1)\chi_D)\nabla u \cdot \nabla v, \tag{3.4}$$

for every $u \in H^1(\Omega)$ solution to (1.1) and for every $v \in H^1(\Omega)$. Here $< \cdot, \cdot >$ denotes the dual pairing between $H^{-1/2}(\partial\Omega)$ and $H^{1/2}(\partial\Omega)$. With a slight abuse of notation we shall write

$$< g, f >= \int_{\partial\Omega} g f \, d\sigma,$$

for any $f \in H^{1/2}(\partial\Omega)$ and $g \in H^{-1/2}(\partial\Omega)$. Let $\Gamma_D(x, y)$ be the fundamental solution for the operator $\operatorname{div}((1 + (k-1)\chi_D)\nabla \cdot)$, thus

$$\operatorname{div}((1 + (k-1)\chi_D)\nabla\Gamma_D(\cdot, y)) = -\delta(\cdot - y), \tag{3.5}$$

where $y, w \in \mathbb{R}^n$, δ denotes the Dirac distribution. We shall denote by Γ_{D_1}, Γ_{D_2} such fundamental solutions when $D = D_1$, D_2, respectively. Recalling the well-known identity

$$\int_\Omega (1 + (k-1)\chi_{D_1})\nabla u_1 \cdot \nabla u_2 - \int_\Omega (1 + (k-1)\chi_{D_2})\nabla u_1 \cdot \nabla u_2 = \int_{\partial\Omega} u_1 [\Lambda_{D_1} - \Lambda_{D_2}] u_2,$$

which holds for every $u_i \in H^1(\Omega)$, $i = 1, 2$, solutions to (1.1) when $D = D_i$, respectively (see [I2] formula (5.0.4), section 5.0), we have

$$\begin{aligned} &\textstyle\int_\Omega (1 + (k-1)\chi_{D_1})\nabla\Gamma_{D_1}(\cdot, y) \cdot \nabla\Gamma_{D_2}(\cdot, w) \\ &\textstyle- \int_\Omega (1 + (k-1)\chi_{D_2})\nabla\Gamma_{D_1}(\cdot, y) \cdot \nabla\Gamma_{D_2}(\cdot, w) \\ = &\textstyle\int_{\partial\Omega} \Gamma_{D_1}(\cdot, y)[\Lambda_{D_1} - \Lambda_{D_2}](\Gamma_{D_2}(\cdot, w)) d\sigma \qquad \forall\, y, w \in \mathcal{C}\overline{\Omega}. \end{aligned} \tag{3.6}$$

Let us define, for $y, w \in \mathcal{G} \cup \mathcal{C}\Omega$

$$S_{D_1}(y, w) = (k-1) \int_{D_1} \nabla\Gamma_{D_1}(\cdot, y) \cdot \nabla\Gamma_{D_2}(\cdot, w), \tag{3.7}$$

$$S_{D_2}(y, w) = (k-1) \int_{D_2} \nabla\Gamma_{D_1}(\cdot, y) \cdot \nabla\Gamma_{D_2}(\cdot, w), \tag{3.8}$$

$$f(y, w) = S_{D_1}(y, w) - S_{D_2}(y, w). \tag{3.9}$$

Thus (3.6) can be rewritten as

$$f(y,w) = \int_{\partial\Omega} \Gamma_{D_1}(\cdot, y)[\Lambda_{D_1} - \Lambda_{D_2}](\Gamma_{D_2}(\cdot, w))d\sigma \qquad \forall\, y, w \in \mathcal{C}\overline{\Omega}. \tag{3.10}$$

From now on we shall consider the dimension $n \geq 3$, since the case $n = 2$ can be treated similarly through minor adaptations regarding the fundamental solutions. Up to a transformation of coordinates, we can assume that O, defined in (3.3), is the origin of the coordinate system. Let $\nu(O)$ be the outer unit normal vector to $\partial\Omega_D$ in the origin O. Such a normal is indeed well defined since we are assuming that O realizes the modified distance between D_1 and D_2; therefore, in a small neighborhood of O, $\partial\Omega_D$ is made of a part of ∂D_1, which is known to be $C^{1,\alpha}$. We will rotate the coordinate system in such a way that $\nu(O) = (0, \dots, 0, -1)$. Taking $y = w = h\nu(O)$, with $h > 0$, we want to evaluate $f(y,y)$ and $S_{D_1}(y,y)$ in term of h, for h small. Then, evaluating S_{D_2} in term of d_μ, we will get the stability estimate for the modified distance and thus, using Proposition 3.3, for the Hausdorff distance. An important ingredient for evaluating f and S_{D_1} is the behavior of the fundamental solution. We state now a proposition that collects all the results on Γ_{D_i}, $i = 1, 2$, that we will need throughout the paper. For $x = (x', x_n)$, where $x' \in \mathbb{R}^{n-1}$ and $x_n \in \mathbb{R}$, we set $x^\star = (x', -x_n)$. We shall denote with χ^+ the characteristic function of the half-space $\{x_n > 0\}$ and with Γ_+ the fundamental solution of the operator $\mathrm{div}((1+(k-1)\chi^+)\nabla\cdot)$. If Γ is the standard fundamental solution of the Laplace operator, we have that (see, for instance, [A-I-P], Theorem 4)

$$\Gamma_+(x,y) = \begin{cases} \frac{1}{k}\Gamma(x,y) + \frac{k-1}{k(k+1)}\Gamma(x,y^\star) & \text{for } x_n > 0, y_n > 0, \\ \frac{2}{k+1}\Gamma(x,y) & \text{for } x_n y_n < 0, \\ \Gamma(x,y) - \frac{k-1}{k+1}\Gamma(x,y^\star) & \text{for } x_n < 0, y_n < 0. \end{cases} \tag{3.11}$$

The following proposition holds.

Proposition 3.4. *Let $D \subset \mathbb{R}^n$ be an open set whose boundary is of class $C^{1,\alpha}$, with constants $\overline{r}$, L.*

(i) *There exists a constant $c_1 > 0$ depending on k, n, α and L only, such that*

$$|\nabla_x \Gamma_D(x,y)| \leq c_1 |x-y|^{1-n}, \tag{3.12}$$

for every $x, y \in \mathbb{R}^n$,

(ii) *There exist constants c_2, $c_3 > 0$ depending on k, n, α and L only, such that*

$$\left|\Gamma_D(x,y) - \Gamma_+(x,y)\right| \leq \frac{c_2}{\overline{r}^\alpha}|x-y|^{2-n+\alpha}, \tag{3.13}$$

$$\left|\nabla_x\Gamma_D(x,y) - \nabla_x\Gamma_+(x,y)\right| \leq \frac{c_3}{\overline{r}^{\alpha^2}}|x-y|^{1-n+\alpha^2}, \tag{3.14}$$

for every $x \in D \cap B_r(O)$, and for every $y = h\nu(O)$, with $0 < r < \overline{r}_0$, $0 < h < \overline{r}_0$, where $\overline{r}_0 = \left(\min\left\{\frac{1}{2}(8L)^{-1/\alpha}, \frac{1}{2}\right\}\right)\frac{\overline{r}}{2}$.

The next two propositions give us quantitative estimates on f and S_{D_1} when we move y towards O, along $\nu(O)$. Proposition 3.5 makes use of quantitative estimates of unique continuation, whereas Proposition 3.6 is mainly based on the asymptotic estimates of fundamental solutions obtained in Proposition 3.4.

Proposition 3.5. *Let Ω be an open set in $\mathbb{R}^n$ satisfying* (H1)*. Let D_1, D_2 be two inclusions in Ω verifying* (H2) *and let $y = h\nu(O)$, with O defined in* (3.3)*. If,* *given $\varepsilon > 0$, we have*

$$\|\Lambda_{D_1} - \Lambda_{D_2}\|_{\mathcal{L}(H^{1/2},H^{-1/2})} \leq \varepsilon,$$

then for every h, $0 < h < \overline{c}\,\overline{r}$, where $0 < \overline{c} < 1$, depends on L,

$$|f(y,y)| \leq C\frac{\varepsilon^{Bh^F}}{h^A}, \tag{3.15}$$

where $0 < A < 1$ and $C, B, F > 0$ are constants that depend only on the a priori data.

Proposition 3.6. *Let Ω be an open set in $\mathbb{R}^n$ satisfying* (H1). *Let D_1, D_2 be two inclusions in Ω verifying* (H2) *and $y = h\nu(O)$. Then for every h, $0 < h < \overline{r}_0/2$,*

$$|S_{D_1}(y,y)| \geq c_1 h^{2-n} - c_2 d_\mu^{2-2n} + c_3, \tag{3.16}$$

where c_1, c_2, and c_3 are positive constants depending only on the a priori data. Here $\overline{r}_0$ is the number introduced in Proposition 3.4.

Now we have all the tools that we need to prove Theorem 2.4.

Proof of Theorem 2.4. Let $O \in \partial D_1$ satisfying (3.3), that is

$$d_\mu(D_1, D_2) = \operatorname{dist}(O, D_2) = d_\mu.$$

Then, for $y = h\nu(O)$, with $0 < h < h_1$, where $h_1 = \min\{d_\mu, \overline{c}\,\overline{r}, \overline{r}_0/2\}$, using (3.12), we have

$$|S_{D_2}(y,y)| \leq c\int_{D_2} \frac{1}{(d_\mu - h)^{n-1}}\frac{1}{(d_\mu - h)^{n-1}}dx = c\frac{1}{(d_\mu - h)^{2n-2}}|D_2|. \tag{3.17}$$

Using Proposition 3.5, we have

$$\begin{aligned}|S_{D_1}(y,y)| - |S_{D_2}(y,y)| &\leq |S_{D_1}(y,y) - S_{D_2}(y,y)| \\ = |f(y,y)| \leq c\frac{\varepsilon^{Bh^F}}{h^A}&.\end{aligned}$$

On the other hand, by Proposition 3.6 and (3.17)

$$|S_{D_1}(y,y)| - |S_{D_2}(y,y)| \geq c_1 h^{2-n} - c_2(d_\mu - h)^{2-2n}.$$

Thus we have

$$c_3 h^{2-n} - c_4(d_\mu - h)^{2-2n} \leq \frac{\varepsilon^{Bh^F}}{h^A}.$$

That is

$$\begin{aligned}c_4(d_\mu - h)^{2-2n} &\geq c_3 h^{2-n} - \frac{\varepsilon^{Bh^F}}{h^A} = h^{2-n}\big(c_3 - \varepsilon^{Bh^F}h^{\widetilde{A}}\big) \\ &\geq c_5 h^{2-n}\big(1 - \varepsilon^{Bh^F}h^{\widetilde{A}}\big),\end{aligned} \tag{3.18}$$

where $\widetilde{A} = n - 2 - A$, $\widetilde{A} > 0$. Let $h = h(\varepsilon)$ where $h(\varepsilon) = \min\{|\ln\varepsilon|^{-\frac{1}{2F}}, d_\mu\}$, for $0 < \varepsilon \leq \varepsilon_1$, with $\varepsilon_1 \in (0,1)$ such that $\exp(-B|\ln\varepsilon_1|^{1/2}) = 1/2$. If $d_\mu \leq |\ln\varepsilon|^{-\frac{1}{2F}}$ the theorem follows using Proposition 3.3. In the other case we have

$$\varepsilon^{Bh(\varepsilon)^F}h(\varepsilon)^{\widetilde{A}} \leq \varepsilon^{B|\ln\varepsilon|^{-1/2}} \leq \exp\big(-B|\ln\varepsilon|^{1/2}\big).$$

Then, for any ε, $0 < \varepsilon < \varepsilon_1$,

$$(d_\mu - h(\varepsilon))^{2-2n} \geq c_6 h(\varepsilon)^{2-n},$$

that is, solving for d_μ, and recalling that, in this case, $h(\varepsilon) = |\ln \varepsilon|^{-\frac{1}{2F}}$,

$$d_\mu \leq c_7 |\ln \varepsilon|^{-\delta \frac{n-2}{2n-2}}, \tag{3.19}$$

where $\delta = 1/(2F)$. When $\varepsilon \geq \varepsilon_1$, then

$$d_\mu \leq \operatorname{diam} \Omega$$

and, in particular, when $\varepsilon_1 \leq \varepsilon < 1$

$$d_\mu \leq \operatorname{diam} \Omega \frac{|\ln \varepsilon|^{-\frac{1}{2F}}}{|\ln \varepsilon_1|^{-\frac{1}{2F}}}.$$

Finally, using Proposition 3.3, the theorem follows. ∎

4. Proofs of the auxiliary propositions. We premise the proof of Proposition 3.3 with one lemma.

LEMMA 4.1. *Let Ω be an open set in $\mathbb{R}^n$ satisfying* (H1). *Let D be a bounded open inclusion of Ω satisfying* (H2). *Then for every $P \in \partial D$, there exists a continuous path γ in $\Omega \setminus \overline{D}$ with one endpoint in P and the other on $\partial\Omega$, such that for every $z \in \gamma$*

$$|z - P| \leq c \operatorname{dist}(z, D), \tag{4.1}$$

where c is a positive constant depending on the a priori data only.

Proof. Using Lemma 5.2 of [A-B-R-V], (which adapted arguments due to Lieberman [Li]), we approximate $\operatorname{dist}(\cdot, \partial D)$ with a regularized distance $\tilde{d}$ such that $\tilde{d} \in C^2(\Omega \setminus D) \cup C^{1,\alpha}(\overline{\Omega \setminus D})$ and the following facts hold:

$$\gamma_0 \leq \frac{\operatorname{dist}(x, \partial D)}{\tilde{d}(x)} \leq \gamma_1,$$
$$|\nabla \tilde{d}(y)| \geq c_1 \quad \text{for every } y \in \Omega \text{ s.t. } \operatorname{dist}(y, \partial D) < b\overline{r},$$
$$\|\tilde{d}\|_{1,\alpha} \leq c_2 \overline{r},$$

where γ_0, γ_1, b, c_1 and c_2 are positive constants only depending on L and α. We define for $0 < h < a\overline{r}$, with a depending on L and α only,

$$E_h = \{x \in \Omega \setminus \overline{D} \, : \, \tilde{d}(x) > h\}.$$

Arguing as in Lemma 5.3 of [A-B-R-V], E_h is connected with boundary of class C^1 and

$$\widetilde{c}_1 h \leq \operatorname{dist}(x, \partial D) \leq \widetilde{c}_2 h \qquad \forall\, x \in \partial E_h \cap \Omega, \tag{4.2}$$

where $\widetilde{c}_1$, $\widetilde{c}_2$ are positive constants depending on L and α only. Let us fix $P \in \partial D$. Let $\nu(P)$ be the outer unit normal to ∂D in P (we recall that ∂D is $C^{1,\alpha}$). Since (4.2), there exists a point $P' \in E_h$ such that $P' = \tilde{h}\nu(P)$, where $\tilde{h}$ is a positive constant $\widetilde{c}_1 h < \tilde{h} < \widetilde{c}_2 h$. We denote by $\overline{PP'}$ the segment whose endpoints are P and P'. Since E_h is connected, there exists a continuous path $\gamma' \subset E_h$ with one endpoint P' and the other on $\partial\Omega$. Since $\gamma' \subset E_h$ we have that for every $x \in \gamma'$, $\operatorname{dist}(x, \partial D) \geq ch$, where c is a positive constant. We then define $\gamma = \gamma' \cup \overline{PP'}$ and the lemma follows. ∎

Proof of Proposition 3.3. Let us fix $P \in \partial D_1$. We distinguish the following two cases:

(i) $P \in \partial D_1 \cap \partial \mathcal{G}$,
(ii) $P \in \partial D_1 \setminus \partial \mathcal{G}$.
If case (i) occurs then,

$$\mathrm{dist}(P, \partial D_2) = \mathrm{dist}(P, \overline{D}_2) \leq d_\mu.$$

Let us consider case (ii). Let γ be the continuous path constructed in Lemma 4.1 from P to $\partial\Omega$. Since $P \notin \partial\mathcal{G}$, there exists $z \in \gamma \cap \partial D_2 \cap \partial\Omega_D$.

$$\mathrm{dist}(z, D_1) \leq \sup_{x \in \partial D_2 \cap \partial \Omega_D} \big\{ \mathrm{dist}(x, D_1) \big\} \leq d_\mu(D_1, D_2).$$

Thus

$$|z - P| \leq c d_\mu(D_1, D_2),$$

where $c > 0$ is the constant appearing in (4.1). On the other hand,

$$\mathrm{dist}(P, \partial D_2) \leq |z - P|.$$

So we obtain that for every $P \in \partial D_1$,

$$\mathrm{dist}(P, \partial D_2) \leq c d_\mu(D_1, D_2).$$

Similarly, one can show that for every $Q \in \partial D_2$

$$\mathrm{dist}(Q, \partial D_1) \leq c d_\mu(D_1, D_2).$$

Then we conclude that

$$d_{\mathcal{H}}(\partial D_1, \partial D_2) \leq c d_\mu(D_1, D_2). \qquad \square$$

Proof of Proposition 3.4. Let us prove (i).
Let us consider the case $x \in D$ and $y \in \partial D$. The cases in which $x, y \in D$ or $x, y \in \mathcal{C}D$ are trivial. Let $h = |x - y|$. Let c be a positive number less than $\frac{1}{1+2\sqrt{n}}$. We distinguish the following two cases:
(a) $\mathrm{dist}(x, \partial D) < ch$,
(b) $\mathrm{dist}(x, \partial D) \geq ch$.
Let us consider the case (a). Let $P \in \partial D$ be such that $|P - x| = \mathrm{dist}(x, \partial D)$. For every $r > 0$, let $Q_r(P)$ be the cube centered at P, with sides of length $2r$ and parallel to the coordinates axes. We have that the ball $B_r(P)$ is inscribed into $Q_r(P)$; in particular, $x \in Q_{ch}(P)$. On the other hand,

$$|P - y| \geq |y - x| - |P - x| \geq h(1 - c).$$

Then, due to our choice of c, $|P - y| > (2ch)\sqrt{n}$, that is $y \notin Q_{2ch}(P)$. Thus

$$\mathrm{div}_z\big((1 + (k-1)\chi_D)\nabla_z \Gamma_D(z, y)\big) = 0 \qquad \text{in } Q_{\frac{3}{2}ch}(P)$$

and for the piecewise $C^{1,\alpha}$ regularity of Γ_D, proved in [DB-E-F], see also [L-V], we have

$$\|\nabla \Gamma_D(\cdot, y)\|_{L^\infty(Q_{ch}(P))} \leq \frac{\overline{c}_1}{h} \|\Gamma_D(\cdot, y)\|_{L^\infty(Q_{\frac{3}{2}ch}(P))}, \tag{4.3}$$

where $\overline{c}_1$ depends on L, k, n, and α only. Using the pointwise bound of Γ_D with Γ (see [L-S-W]), we have

$$\|\Gamma_D(\cdot,y)\|_{L^\infty\left(Q_{\frac{3}{2}ch}(P)\right)} \leq \overline{c}_2\left(\frac{ch}{2}\right)^{2-n}, \tag{4.4}$$

where $\overline{c}_2$ depends on n and k only. Hence, by (4.3) and (4.4) we get

$$|\nabla_x\Gamma_D(x,y)| \leq \|\nabla\Gamma_D(\cdot,y)\|_{L^\infty(Q_{ch}(P))} \leq \overline{c}_3 h^{1-n} = \overline{c}_3|x-y|^{1-n}, \tag{4.5}$$

where $\overline{c}_3$ depends on L, k, n, and α only.

If case (b) occurs, then $Q_{\frac{ch}{\sqrt{n}}}(x) \subset D$. Hence

$$\begin{aligned}
|\nabla_x\Gamma_D(x,y)| &\leq \|\nabla\Gamma_D(\cdot,y)\|_{L^\infty\left(Q_{\frac{ch}{2\sqrt{n}}}(x)\right)} \leq \frac{\overline{c}_4}{h}\|\Gamma_D(\cdot,y)\|_{L^\infty\left(Q_{\frac{c}{\sqrt{n}}}(P)\right)} \\
&\leq \frac{\overline{c}_4}{h}(h(1-c))^{2-n} = \overline{c}_4' h^{1-n} = \overline{c}_4'|x-y|^{1-n},
\end{aligned}$$

where $\overline{c}_4$, $\overline{c}_4'$ depend on L, k, n, and α only.

Let us prove (ii).

Let us fix $r_1 = \min\left\{\frac{1}{2}(8L)^{-1/\alpha}\overline{r}, \frac{\overline{r}}{2}\right\}$. Recalling Definition 2.1, we have that

$$\partial D \cap B_{\overline{r}}(0) = \{x \in B_{\overline{r}}(0) \,:\, x_n = \varphi(x')\},$$

where $\varphi \in C^{1,\alpha}(\mathbb{R}^{n-1})$ satisfying $\varphi(0) = |\nabla\varphi(0)| = 0$. Let $\theta \in C^\infty(\mathbb{R})$ be such that $0 \leq \theta \leq 1$, $\theta(t) = 1$, for $|t| < 1$, $\theta(t) = 0$, for $|t| > 2$ and $|\frac{d\theta}{dt}| \leq 2$. We consider the following change of variables $\xi = \Phi(x)$ defined by

$$\begin{cases} \xi' = x' \\ \xi_n = x_n - \varphi(x')\theta\left(\frac{|x'|}{r_1}\right)\theta\left(\frac{x_n}{r_1}\right). \end{cases}$$

It can be verified that, with the given choice of r_1, the following properties of Φ hold:

$$\Phi(Q_{2r_1}(0)) = Q_{2r_1}(0), \tag{4.6}$$

$$\Phi(Q_{r_1}(0) \cap D) = Q^+_{r_1}(0), \tag{4.7}$$

$$c^{-1}|x_1 - x_2| \leq |\Phi(x_1) - \Phi(x_2)| \leq c|x_1 - x_2| \qquad \forall\, x_1, x_2 \in \mathbb{R}^n, \tag{4.8}$$

$$|\Phi(x) - x| \leq \frac{c}{\overline{r}^\alpha}|x|^{1+\alpha} \qquad \forall\, x \in \mathbb{R}^n, \tag{4.9}$$

$$|D\Phi(x) - I| \leq \frac{c}{\overline{r}^\alpha}|x|^\alpha \qquad \forall\, x \in \mathbb{R}^n, \tag{4.10}$$

where $Q^+_{r_1}(0) = \{x \in Q_{r_1}(0) \,:\, x_n > 0\}$ and $c \geq 1$ depends on L and α only. Φ is a $C^{1,\alpha}$ diffeomorphism from $\mathbb{R}^n$ into itself. Let us define the cylinder C_{r_1} as

$$C_{r_1} = \{x \in \mathbb{R}^n \,:\, |x'| < r_1, |x_n| < r_1\}.$$

For $x, y \in C_{r_1}$, we have that $\widetilde{\Gamma}_D(\xi,\eta) = \Gamma_D(x,y)$, where $\xi = \Phi(x)$, $\eta = \Phi(y)$, is solution of

$$\mathrm{div}_\xi((1 + (k-1)\chi^+)B(\xi)\nabla_\xi\widetilde{\Gamma}_D(\xi,\eta)) = -\delta(\xi - \eta), \tag{4.11}$$

where $B = \frac{JJ^T}{\det J}$, with $J = \frac{\partial\xi}{\partial x}(\Phi^{-1}(\xi))$. We observe that B is of class C^α and $B(0) = I$. Let us consider

$$\widetilde{R}(x,y) = \widetilde{\Gamma}_D(x,y) - \Gamma_+(x,y),$$

where we keep the notation x, y to indicate ξ, η. By the properties of Γ_+ and by (4.11), $\widetilde{R}$ satisfies

$$\operatorname{div}_x((1+(k-1)\chi^+)\nabla_x\widetilde{R}(x,y)) = \operatorname{div}_x((1+(k-1)\chi^+)(I-B)\nabla_x\widetilde{\Gamma}_D(x,y)).$$

Let $\widetilde{L} > 0$, depending on the a priori data only, be such that $\overline{\Omega} \subset B_{\widetilde{L}}(0)$. Thus, using the fundamental solution Γ_+ we obtain

$$\begin{aligned}
-\widetilde{R}(x,y) &= \int_{B_{\widetilde{L}}(0)} (1+(k-1)\chi^+)(B-I)\nabla_z\Gamma_+(z,y)\cdot\nabla_z\widetilde{\Gamma}_D(z,x)dz \\
&+ \int_{\partial B_{\widetilde{L}}(0)} (1+(k-1)\chi^+)\left[\widetilde{R}(x,z)\frac{\partial\Gamma_+}{\partial\nu}(z,y) - \Gamma_+(z,y)\frac{\partial\widetilde{R}}{\partial\nu}(x,z)\right]d\sigma(z) \\
&= \int_{B_{\widetilde{L}}(0)\cap C_{r_1}} (1+(k-1)\chi^+)(B-I)\nabla_z\Gamma_+(z,y)\cdot\nabla_z\widetilde{\Gamma}_D(z,x)dz \\
&+ \int_{B_{\widetilde{L}}(0)\setminus C_{r_1}} (1+(k-1)\chi^+)(B-I)\nabla_z\Gamma_+(z,y)\cdot\nabla_z\widetilde{\Gamma}_D(z,x)dz \\
&+ \int_{\partial B_{\widetilde{L}}(0)} \left[\widetilde{R}(x,z)\frac{\partial\Gamma_+}{\partial\nu}(z,y) - \Gamma_+(z,y)\frac{\partial\widetilde{R}}{\partial\nu}(x,z)\right]d\sigma(z).
\end{aligned}$$

For $|x|, |y| < r_1/2$, the last two integrals are bounded. Using (3.12) we obtain

$$\begin{aligned}
|\widetilde{R}(x,y)| &\le c\left(1 + \int_{C_{r_1}} |z|^\alpha |x-z|^{1-n}|y-z|^{1-n}dz\right) \\
&= c\left(1 + I_1 + I_2\right),
\end{aligned}$$

where c depends on L, α, k, and n and

$$\begin{aligned}
I_1 &= \int_{\{|z|<4h\}\cap C_{r_1}} |z|^\alpha|x-z|^{1-n}|y-z|^{1-n}dz, \\
I_2 &= \int_{\{|z|>4h\}\cap C_{r_1}} |z|^\alpha|x-z|^{1-n}|y-z|^{1-n}dz.
\end{aligned}$$

Now

$$\begin{aligned}
I_1 &\le \int_{|w|<4} h^\alpha|w|^\alpha h^{1-n}\Big|\frac{x}{h}-w\Big|^{1-n} h^{1-n}\Big|\frac{y}{h}-w\Big|^{1-n}h^n dw \\
&= h^{\alpha+2-n}\int_{|w|<4}|w|^\alpha\Big|\frac{x}{h}-w\Big|^{1-n}\Big|\frac{y}{h}-w\Big|^{1-n}dw \\
&\le h^{\alpha+2-n}F(\xi,\eta),
\end{aligned}$$

where $h = |x-y|$ and

$$F(\xi,\eta) = 4^{\alpha}\int_{|w|<4} |\xi - w|^{1-n}|\eta - w|^{1-n}dw$$

and $\xi = x/h$ and $\eta = y/h$. From standard bounds (see, for instance, [M, Chapter 2, section 11]) it is not difficult to see that

$$F(\xi,\eta) \leq \text{const.} < \infty,$$

for all $\xi,\eta \in \mathbb{R}^n$, $|\xi-\eta| = 1$. Thus

$$I_1 \leq c|x-y|^{\alpha+2-n}.$$

Let us now consider I_2. Since $|y| = -y_n \leq |x-y| = h$, we can deduce and $|z| \leq \frac{4}{3}|y-z|$ and $|z| \leq 2|x-z|$ and thus obtain that

$$I_2 \leq c\int_{|z|>4h} |z|^{\alpha+1-n+1-n}dz \leq ch^{\alpha+2-n}.$$

Then we conclude that

$$|\widetilde{R}(x,y)| \leq c|x-y|^{\alpha+2-n}, \tag{4.12}$$

for every $|x|, |y| < r_1/2$, where c depends on L, α, k, and n only. Let us go back to the original coordinates system. We observe that if $x \in \Phi^{-1}(B^+_{r_1/2}(0))$ and $y = e_n y_n$, with $y_n \in (-r_1/2, 0)$, then $|\Phi(x) - x|$ is bounded by $c|x-y|^{1+\alpha}$. Namely, since $\Phi(x)\cdot y \leq 0$ and $\Phi(y) = y$, by (4.8) we have

$$c^{-1}|x| \leq |\Phi(x)| \leq |\Phi(x) - y| \leq c|x-y|. \tag{4.13}$$

On the other hand, by (4.9) and (4.13)

$$|\Phi(x) - x| \leq \frac{c}{\overline{r}^{\alpha}}|x|^{1+\alpha} \leq \frac{c'}{\overline{r}^{\alpha}}|x-y|^{1+\alpha}. \tag{4.14}$$

We have

$$\begin{aligned}
R(x,y) &= \Gamma_D(x,y) - \Gamma_+(x,y)\\
&= \Gamma_D(x,y) - \Gamma_+(x,y) + \Gamma_+(\Phi(x),\Phi(y)) - \Gamma_+(\Phi(x),\Phi(y))\\
&= \widetilde{R}(\Phi(x),\Phi(y)) + \Gamma_+(\Phi(x),y) - \Gamma_+(x,y).
\end{aligned}$$

Using (4.8), (4.9), (4.12), and (4.14) we obtain

$$\begin{aligned}
&|\Gamma_D(x,y) - \Gamma_+(x,y)|\\
&\leq \frac{c}{\overline{r}^{\alpha}}|x-y|^{\alpha+2-n} + \frac{c}{\overline{r}^{\alpha}}\|\nabla\Gamma_+(\cdot,y)\|_{L^\infty(Q_{r_1})}|x-\Phi(x)|\\
&\leq \frac{c}{\overline{r}^{\alpha}}|x-y|^{\alpha+2-n} + \frac{c'}{\overline{r}^{\alpha}}|x-y|^{1+\alpha}h^{1-n}\\
&\leq \frac{c''}{\overline{r}^{\alpha}}|x-y|^{\alpha+2-n},
\end{aligned}$$

where c'' depends on k, n, α, and L only. We estimate now the first derivative of R. To estimate the first derivative of $\widetilde{R}$ let us consider a cube $Q \subset B^+_{r_1/4}(x)$ of side $cr_1/4$, with $0 < c < 1$, such that $x \in \partial Q$. The following interpolation inequality holds:

$$\|\nabla \widetilde{R}(\cdot, y)\|_{L^\infty(Q)} \leq c \|\widetilde{R}(\cdot, y)\|^{1-\delta}_{L^\infty(Q)} |\nabla \widetilde{R}(\cdot, y)|^{\delta}_{\alpha, Q},$$

where $\delta = \frac{1}{1+\alpha}$, c depends on L only, and

$$|\nabla \widetilde{R}|_{\alpha, Q} = \sup_{x, x' \in Q, x \neq x'} \frac{|\nabla \widetilde{R}(x, y) - \nabla \widetilde{R}(x', y)|}{|x - x'|^\alpha}.$$

Since, from the piecewise Hölder continuity of $\nabla \Gamma_D$ (see (4.3)), and also of $\nabla \Gamma_+$, (see (3.11)), we have that

$$|\nabla \widetilde{R}(\cdot, y)|_{\alpha, Q} \leq |\nabla \widetilde{\Gamma}_D(\cdot, y)|_{\alpha, Q} + |\nabla \Gamma_+(\cdot, y)|_{\alpha, Q} \leq c h^{-\alpha + 1 - n},$$

where c depends on L only, thus we conclude that

$$|\nabla_x \widetilde{R}(x, y)| \leq \frac{c}{\overline{r}^\eta} h^{(\alpha + 2 - n)(1 - \delta)} h^{(-\alpha + 1 - n)\delta} = \frac{c}{\overline{r}^\eta} h^{1 - n + \eta},$$

where $\eta = \frac{\alpha^2}{1+\alpha}$. Thus

$$|\nabla_x \widetilde{R}(x, y)| \leq \frac{c}{\overline{r}^\eta} |x - y|^{\eta + 1 - n}, \tag{4.15}$$

where $\eta = \frac{\alpha^2}{1+\alpha}$ and c depends on L only. Concerning Γ_+ we have

$$\begin{aligned}
&|\nabla_x \Gamma_+(\Phi(x), y) - \nabla_x \Gamma_+(x, y)| \\
&= |D\Phi(x)^T \nabla \Gamma_+(\cdot, y)_{|\Phi(x)} - \nabla_x \Gamma_+(x, y)| \\
&\leq |(D\Phi(x)^T - I) \nabla \Gamma_+(\cdot, y)_{|\Phi(x)}| \\
&\quad + |\nabla \Gamma_+(\cdot, y)_{|\Phi(x)} - \nabla_x \Gamma_+(x, y)| \\
&\leq \frac{c}{\overline{r}^\alpha} \|\nabla \Gamma_+(\cdot, y)\|_{L^\infty(Q_{r_1})} |x - \Phi(x)| + |\nabla \Gamma_+(\cdot, y)|_{\alpha, Q} |\Phi(x) - x|^\alpha \\
&\leq \frac{c'}{\overline{r}^\alpha} h^{1+\alpha} h^{1-n} + \frac{c}{\overline{r}^{\alpha^2}} h^{-\alpha + 1 - n} h^{(1+\alpha)\alpha} \\
&\leq \frac{c}{\overline{r}^{\alpha^2}} h^{1 - n + \alpha^2},
\end{aligned}$$

where c depends on k, n, α, and L only. $\square$

Proof of Proposition 3.5. Let us fix $\overline{y} \in \mathcal{S}_{2\overline{r}}$, where $\mathcal{S}_{2\overline{r}}$ is the set introduced in Definition 3.1, and let us consider $f(\overline{y}, \cdot)$. We have that

$$\Delta_w f(\overline{y}, w) = 0 \qquad \text{in } \mathcal{C}\overline{\Omega}_D. \tag{4.16}$$

For $w \in \mathcal{S}_{2\overline{r}}$, by (2.6), (3.10), and (3.12) we have

$$|f(\overline{y}, w)| \leq C(\overline{r}, L, M) \|\Lambda_{D_1} - \Lambda_{D_2}\| = \widetilde{\varepsilon}. \tag{4.17}$$

Let us now estimate $f(\overline{y}, w)$ when $w \in \mathcal{G}$. Again recalling Definition 3.1, we define $\mathcal{G}^h = \{x \in \mathcal{G} : \mathrm{dist}(x, \Omega_D) \geq h\}$. For every $w \in \mathcal{G}^h$, we have that

$$|S_{D_1}(\overline{y}, w)| \leq |k-1| \int_{D_1} |\nabla_x \Gamma_{D_1}(x, \overline{y})|\, |\nabla_x \Gamma_{D_2}(x, w)| dx$$

$$\leq c \int_{D_1} |x - w|^{1-n} dx \leq c h^{1-n}. \tag{4.18}$$

Similarly, $|S_{D_2}(\overline{y}, w)| \leq c h^{1-n}$. Then we conclude that

$$|f(\overline{y}, w)| \leq c h^{1-n} \qquad \text{in } \mathcal{G}^h.$$

At this stage we shall make use of the three spheres inequality for supremum norms of harmonic functions v; see, for instance, [K-M], [K]. For every l_1, l_2, $1 < l_1 < l_2$ and for every $x \in \mathcal{G} \cup \mathcal{S}_{2\overline{r}} \cup \Omega_{\overline{r}}$ there exists $\tau \in (0, 1]$, depending only on l_1, l_2 and n such that

$$\|v\|_{L^\infty(B_{l_1 r}(x))} \leq \|v\|^{\tau}_{L^\infty(B_r(x))} \|v\|^{1-\tau}_{L^\infty(B_{l_2 r}(x))}.$$

We apply it for $v(\cdot) = f(\overline{y}, \cdot)$ in the ball $B_{\overline{r}}(\overline{x})$, where $\overline{x} \in \mathcal{S}_{2\overline{r}}$ be such that $\mathrm{dist}(\overline{x}, \Gamma) = \overline{r}/2$, where $\Gamma = \{x \in \mathbb{R}^n : \mathrm{dist}(x, \Omega) = \overline{r}\} \subset \partial \mathcal{S}_{2\overline{r}}$, $l_1 = 3r = 3\overline{r}/2$, and $l_2 = 4r = 2\overline{r}$, then we obtain

$$\|f(\overline{y}, \cdot)\|_{L^\infty(B_{3\overline{r}/2}(\overline{x}))} \leq \|f(\overline{y}, \cdot)\|^{\tau}_{L^\infty(B_{\overline{r}/2}(\overline{x}))} \|f(\overline{y}, \cdot)\|^{1-\tau}_{L^\infty(B_{2\overline{r}}(\overline{x}))}. \tag{4.19}$$

For every $\overline{w} \in \mathcal{G}^h$, we denote with γ a simple arc in $\overline{\mathcal{G}} \cup \overline{\Omega}_{\overline{r}} \cup \overline{\mathcal{S}}_{2\overline{r}}$ joining $\overline{x}$ to $\overline{w}$. Let us define $\{x_i\}$, $i = 1, \ldots, s$ as follows $x_1 = \overline{x}$, $x_{i+1} = \gamma(t_i)$, where $t_i = \max\{t : |\gamma(t) - x_i| = \overline{r}\}$ if $|x_i - \overline{w}| > \overline{r}$, otherwise let $i = s$ and stop the process. By construction, the balls $B_{\overline{r}/2}(x_i)$ are pairwise disjoint, $|x_{i+1} - x_i| = \overline{r}$ for $i = 1, \ldots, s-1$, $|x_s - \overline{w}| \leq \overline{r}$. For (2.1), there exists β such that $s \leq \beta$. An iterated application of the three spheres inequality (4.19) for $f(\overline{y}, \cdot)$ (see, for instance, [A-B-R-V, pg. 780], [A-DB, Appendix E]) gives that for any r, $0 < r < \overline{r}$,

$$\|f(\overline{y}, \cdot)\|_{L^\infty(B_{r/2}(\overline{w}))} \leq \|f(\overline{y}, \cdot)\|^{\tau^s}_{L^\infty(B_{r/2}(\overline{x}))} \|f(\overline{y}, \cdot)\|^{1-\tau^s}_{L^\infty(\mathcal{G})}. \tag{4.20}$$

We can now estimate the right-hand side of (4.20) by (4.17) and (4.18) and obtain, for any r, $0 < r < \overline{r}$

$$\|f(\overline{y}, \cdot)\|_{L^\infty(B_{r/2}(\overline{w}))} \leq c (h^{1-n})^{1-\tau^s} \varepsilon^{\tau^s} \leq c (h^{1-n})^{A} \varepsilon^{\widetilde{\beta}}, \tag{4.21}$$

where $\widetilde{\beta} = \tau^\beta$ and $A = 1 - \widetilde{\beta}$. Let $O \in \partial D_1$, as defined in (3.3), that is

$$d(O, D_2) = d_\mu(D_1, D_2).$$

There exists a $C^{1,\alpha}$ neighborhood U of O in $\partial \Omega_D$ with constants $\overline{r}$ and L. Thus there exists a nontangential vector field $\widetilde{\nu}$, defined on U such that the truncated cone

$$C(O, \widetilde{\nu}(O), \theta, \overline{r}) = \left\{ x \in \mathbb{R}^n : \frac{(x - O) \cdot \widetilde{\nu}(O)}{|x - O|} > \cos\theta,\ |x - O| < \overline{r} \right\} \tag{4.22}$$

satisfies

$$C(O, \widetilde{\nu}(O), \theta, \overline{r}) \subset \mathcal{G},$$

where $\theta = \arctan(1/\overline{L})$. Let us define

$$\lambda_1 = \min\left\{\frac{\overline{r}}{1+\sin\theta}, \frac{\overline{r}}{3\sin\theta}\right\},$$

$$\theta_1 = \arcsin\left(\frac{\sin\theta}{4}\right),$$

$$w_1 = O + \lambda_1\nu,$$

$$\rho_1 = \lambda_1 \sin\theta_1.$$

We have that $B_{\rho_1}(w_1) \subset C(O, \widetilde{\nu}(O), \theta_1, \overline{r})$, $B_{4\rho_1}(w_1) \subset C(O, \widetilde{\nu}(O), \theta, \overline{r})$. Let $\overline{w} = w_1$, since $\rho_1 \leq \overline{r}/2$, we can use (4.21) in the ball $B_{\rho_1}(\overline{w})$ and we can approach $O \in \partial D_1$ by constructing a sequence of balls contained in the cone $C(O, \widetilde{\nu}(O), \theta_1, \overline{r})$. We define, for $k \geq 2$

$$w_k = O + \lambda_k\nu, \qquad \lambda_k = \chi\lambda_{k-1}, \qquad \rho_k = \chi\rho_{k-1}, \qquad \text{with } \chi = \frac{1-\sin\theta_1}{1+\sin\theta_1}.$$

Hence $\rho_k = \chi^{k-1}\rho_1$, $\lambda_k = \chi^{k-1}\lambda_1$, and

$$B_{\rho_{k+1}}(w_{k+1}) \subset B_{\rho_{3k}}(w_k) \subset B_{\rho_{4k}}(w_k) \subset C(O, \nu, \theta, \overline{r}).$$

Denoting $d(k) = |w_k - O| - \rho_k = \lambda_k - \rho_k$, we have $d(k) = \chi^{k-1}d(1)$, with $d(1) = \lambda_1(1 - \sin\theta)$. For any r, $0 < r \leq d(1)$, let $k(r)$ be the smallest integer such that $d(k) \leq r$, that is

$$\frac{\left|\log\frac{r}{d(1)}\right|}{\left|\log\chi\right|} \leq k(r) - 1 \leq \frac{\left|\log\frac{r}{d(1)}\right|}{\left|\log\chi\right|} + 1.$$

By an iterated application of the three spheres inequality over the chain of balls $B_{\rho_1}(w_1), \dots, B_{\rho_{k(r)}}(w_{k(r)})$, we have

$$\begin{aligned} \|f(\overline{y}, \cdot)\|_{L^\infty(B_{\rho_{k(r)}}(w_{k(r)}))} &\leq c(h^{1-n})^{A(1-\tau^{k(r)-1})}\varepsilon^{\beta\tau^{k(r)-1}} \\ &\leq c(h^{1-n})^{A}\varepsilon^{\beta\tau^{k(r)-1}}, \end{aligned} \tag{4.23}$$

for $0 < r < c\overline{r}$, where $0 < c < 1$ depends on L only.

Let us now consider $f(y, w)$ as a function of y. First observe that

$$\Delta_y f(y, w) = 0 \qquad \text{in } \mathcal{C}\Omega_D, \qquad \forall\, w \in \mathcal{C}\Omega_D.$$

For $y, w \in \mathcal{G}^h$, $y \neq w$, using (3.12), we have

$$|S_{D_1}(y, w)| \leq c\int_{D_1} |x - y|^{1-n}|x - w|^{1-n}dx \leq ch^{2-n};$$

similarly, for S_{D_2}. Therefore

$$|f(y, w)| \leq ch^{2-2n} \qquad \text{with } y, w \in \mathcal{G}^h.$$

Finally, for $y \in \mathcal{S}_{2\overline{r}}$ and $w \in \mathcal{G}^h$, using (4.23), we have

$$|f(y, w)| \leq c(h^{1-n})^A\varepsilon^{\beta\tau^{k(h)-1}}.$$

Proceeding as before, let us fix $w \in \mathcal{G}$ such that $\mathrm{dist}(w, \partial\Omega_D) = h$ and $\widetilde{y} \in \mathcal{S}_{2\overline{r}}$ such that $\mathrm{dist}(\widetilde{y}, \Gamma) = \overline{r}/2$. Taking $r = \overline{r}/2$, $l_1 = 3r$, $l_2 = 4r$, $y_1 = O + \lambda_1 \nu$, and using iteratively the three spheres inequality, we have

$$\|f(y,w)\|_{L^\infty(B_{\overline{r}/2}(y_1))} \leq \|f(y,w)\|^{\tau^s}_{L^\infty(B_{\overline{r}/2}(\widetilde{y}))} \|f(y,w)\|^{1-\tau^s}_{L^\infty(\mathcal{G})},$$

where τ and s are the same number established previously. Therefore

$$\begin{aligned}
\|f(y,w)\|^{\tau^s}_{L^\infty(B_{\overline{r}/2}(y_1))} &\leq c(h^{2-2n})^{1-\tau^s}(h^{1-n})^{A\tau^s}(\varepsilon^{\beta\tau^{k(h)-1}})^{\tau^s} \\
&\leq c(h^{2-2n})^{1-\gamma}(h^{1-n})^{A\tau^s}(\varepsilon^{\beta\tau^{k(h)-1}})^{\gamma} \\
&\leq c(h^{2-2n})^{A'}(\varepsilon^{\beta\tau^{k(h)-1}})^{\gamma},
\end{aligned}$$

where $\gamma = \tau^\beta$, with β as before, so $0 < \gamma < 1$, and $A' = A\tau^s + 1 - \gamma$. Once more, let us apply iteratively the three spheres inequality over a chain of balls contained in a cone with vertex in O and we obtain

$$\|f(y,w)\|_{L^\infty(B_{\rho_k}(y_{k(h)}))} \leq c(h^{2-2n})^{A'(1-\tau^{k(h)-1})}(\varepsilon^{\beta\tau^{k(h)-1}})^{\gamma\tau^{k(h)-1}}. \tag{4.24}$$

Now, from (4.24), choosing $y = w = h\nu(O)$, where $\nu(O)$ is the exterior unit normal to $\partial\Omega_D$ in O, we obtain

$$|f(y,y)| \leq ch^{A''}(\varepsilon^{\beta\tau^{k(h)-1}})^{\gamma\tau^{k(h)-1}}, \tag{4.25}$$

where $A'' = -(2-2n)\beta A' > 0$. We observe that, for $0 < h < c\overline{r}$, where $0 < c < 1$ depends on L, $k(h) \leq c|\log h| = -c\log h$, so we can write

$$\tau^{k(h)} = \mathrm{e}^{-c\log h \log(\tau)} = h^{-c\log\tau} = h^{c|\log\tau|} = h^F,$$

with $F = c|\log\tau|$. Therefore

$$\begin{aligned}
|f(y,y)| &\leq h^{-A''}\varepsilon^{B\tau^{k(h)}} \\
&= \mathrm{e}^{-A''\log h}\mathrm{e}^{B\tau^{k(h)}\log\varepsilon} \\
&= \mathrm{e}^{-A''\log h + B'h^F\log\varepsilon}.
\end{aligned}$$

Then in (4.25) we obtain that

$$|f(y,y)| \leq \mathrm{e}^{-A'\log h + B'h^F\log\varepsilon} = \frac{\varepsilon^{B'h^F}}{h^{A'}}. \qquad \square$$

Proof of Proposition 3.6. Let us consider $y = h\nu(O)$, where $\nu(O)$ is the exterior outer normal to $\partial\Omega_D$ in O with O defined as in (3.3), $0 < h < \overline{r}_0$, where $\overline{r}_0$ is the number introduced in Proposition 3.4 and $x \in D_1$ such that $|x-y| < r$, with $0 < r < \overline{r}_0$. Let us first observe that since $O \in \partial D_1$ and $x \in D_1$, for Γ_{D_1} we have the asymptotic formula (3.14), which says that

$$\left|\nabla_x\Gamma_{D_1}(x,y) - \nabla_x\Gamma_+(x,y)\right| \leq c_1|x-y|^{1-n+\delta}.$$

Furthermore, since we are in the situation in which $x \in D_1$ and $y \notin D_1$, for (3.11), $\Gamma_+(x,y) = 2/(k+1)\Gamma(x,y)$, where $\Gamma(x,y)$ denotes the standard fundamental solution of the Laplace operator. Let us now consider $\Gamma_{D_2}(x,y)$. With our choice of O, x and y, we know that $y \notin D_2$ but we do not have any information on x; that is, we do not know in which side of the interface ∂D_2 it is. Thus we have to distinguish different situations.

If $x \in B_r(O) \cap D_1 \cap D_2$, then we have the asymptotic formula (3.11) for Γ_{D_2} and from Lemma 3.1 of [A] the following formula holds:

$$\nabla_x \Gamma_{D_1}(x,y) \cdot \nabla_x \Gamma_{D_2}(x,y) \geq c|x-y|^{2-2n}. \tag{4.26}$$

Now consider the case $x \in (D_1 \setminus D_2) \cap B_r(O)$. In this region let us consider a smaller ball $B_\rho(O)$ centered in O with radius ρ where $0 < \rho < d_\mu$. Since the definition of d_μ, we have $B_\rho \cap D_2 = \emptyset$. If x and y are in $B_\rho(O)$, we have

$$\begin{cases} \Delta_x\big(\Gamma_{D_2}(x,y) - \Gamma(x,y)\big) = 0 & \text{in } B_\rho(O), \\ \big[\Gamma_{D_2}(x,y) - \Gamma(x,y)\big]_{|\partial B_\rho(O)} \leq c\rho^{2-n}. \end{cases} \tag{4.27}$$

Thus by the maximum principle

$$\big|\Gamma_{D_2}(x,y) - \Gamma(x,y)\big| \leq c_1\rho^{2-n} \qquad \forall\, x, y \in B_\rho(O), \tag{4.28}$$

and by interior gradient bound

$$\big|\nabla_x \Gamma_{D_2}(x,y) - \nabla_x \Gamma(x,y)\big| \leq c_2\rho^{1-n} \qquad \forall\, x \in B_{\rho/2}(O), \forall\, y \in B_\rho(O). \tag{4.29}$$

Thus, using Lemma 3.1 of [A], in $B_{\rho/2}(O)$ we obtain the formula

$$\nabla_x \Gamma_{D_1}(x,y) \cdot \nabla_x \Gamma_{D_2}(x,y) \geq c_3|x-y|^{2-2n} - c_4\rho^{2-2n}. \tag{4.30}$$

Let us consider $h \leq \overline{r}_0/2$ and $B_r(O) = \{x \in \mathbb{R}^n : |x - O| < r\}$, with $0 < r < \overline{r}_0$. Then we have

$$\begin{aligned} &|S_{D_1}(y,y)| \\ &= |k-1| \left| \int\limits_{D_1 \cap B_r(O)} \nabla\Gamma_{D_1} \cdot \nabla\Gamma_{D_2} dx + \int\limits_{D_1 \setminus B_r(O)} \nabla\Gamma_{D_1} \cdot \nabla\Gamma_{D_2} dx \right| \\ &\geq |k-1| \left| \int\limits_{D_1 \cap B_r(O)} \nabla\Gamma_{D_1} \cdot \nabla\Gamma_{D_2} dx \right| - |k-1| \left| \int\limits_{D_1 \setminus B_r(O)} \nabla\Gamma_{D_1} \cdot \nabla\Gamma_{D_2} dx \right| \end{aligned}$$

The first term can be estimated as follows:

$$\begin{aligned} &\left| \int_{D_1 \cap B_r(O)} \nabla\Gamma_{D_1} \cdot \nabla\Gamma_{D_2} dx \right| \\ &= \left| \int_{(D_1 \cap D_2) \cap B_r(O)} \nabla\Gamma_{D_1} \cdot \nabla\Gamma_{D_2} dx + \int_{(D_1 \setminus D_2) \cap B_r(O)} \nabla\Gamma_{D_1} \cdot \nabla\Gamma_{D_2} dx \right| \\ &\geq \left| \int_{(D_1 \cap D_2) \cap B_r(O)} \nabla\Gamma_{D_1} \cdot \nabla\Gamma_{D_2} dx + \int_{(D_1 \setminus D_2) \cap B_\rho(O)} \nabla\Gamma_{D_1} \cdot \nabla\Gamma_{D_2} dx \right| \\ &\quad - \left| \int_{[(D_1 \setminus D_2) \cap B_r(O)] \setminus B_\rho(O)} \nabla\Gamma_{D_1} \cdot \nabla\Gamma_{D_2} dx \right|. \end{aligned}$$

In conclusion, choosing $\rho = d_\mu/2$ and using (4.26) and (3.12) we obtain

$$
\begin{aligned}
|S_D(y,y)| \geq c_1 & \int\limits_{[(D_1\cap D_2)\cap B_r(O)]\cup[(D_1\setminus D_2)\cap B_{d_\mu/2}(O)]} |x-y|^{2-2n}dx \\
& - c_2 \int\limits_{[(D_1\setminus D_2)\cap B_r(O)]\setminus B_{d_\mu/2}(O)} |x-y|^{1-n}|x-y|^{1-n}dx \\
& - c_3 \int\limits_{D_1\setminus B_r(O)} |x-y|^{1-n}|x-y|^{1-n}dx \\
& \geq c_4 h^{2-n} - c_5 d_\mu^{2-2n} - c_7. \qquad \square
\end{aligned}
$$

AXISYMMETRIC TE-MODES IN A SELF-FOCUSING DIELECTRIC*

CHARLES A. STUART† AND HUAN-SONG ZHOU‡

Abstract. We extend and improve earlier work on the existence of positive solutions $u \in H_0^1(0,\infty)$ of the nonlinear eigenvalue problem

$$u''(r) - \frac{3}{4r^2}u(r) + g\left(r, \frac{u(r)}{\sqrt{r}}\right)u(r) - k^2u(r) = 0 \quad \text{for } r > 0,$$

where $g \in C([0,\infty)^2)$ is such that

(i) $0 < A \leq g(r,s) \leq B < \infty$ for all $r, s \geq 0$, and

(ii) $g(r,s)$ is a nondecreasing function of s for each $r \geq 0$.

This problem is central to the study of guided TE-modes propagating in an axisymmetric, self-focusing dielectric such as an optical fiber. The function g is a nonlinear refractive index and we are now able to dispense with unnecessary restrictions about its behavior.

Key words. Nonlinear dielectric, guided waves, mountain pass theorem

DOI. 10.1137/S0036141004441751

1. Introduction.

This paper is concerned with the existence of positive solutions $u \in H_0^1(0,\infty)$ of the nonlinear eigenvalue problem

$$u''(r) - \frac{3}{4r^2}u(r) + g\left(r, \frac{u(r)}{\sqrt{r}}\right)u(r) - k^2u(r) = 0 \quad \text{for } r > 0, \tag{1.1}$$

where $g \in C([0,\infty)^2)$ is such that

(i) $0 < A \leq g(r,s) \leq B < \infty$ for all $r, s \geq 0$, and

(ii) $g(r,s)$ is a nondecreasing function of s for each $r \geq 0$.

As was shown in [9], this problem is central to the study of guided transverse electric field modes (TE-modes) propagating in an axisymmetric, self-focusing dielectric such as an optical fiber. These modes are typical examples of what are more generally known as spatial solitons [8]. The derivation of (1.1) from Maxwell's equation as a model for guided waves in a self-focusing dielectric medium is reviewed in section 2.

The present contribution extends and improves our earlier work [12] on (1.1), which dealt only with the case of a homogeneous medium, $g(r,s) = g(s)$. In this situation, our main result, Theorem 5.2 in section 5, shows that (1.1) has a solution, provided that $g(0) < k^2 < \lim_{s\to\infty} g(s)$. In [12], we obtained the same conclusion, but the function g was required to satisfy several additional technical conditions, namely, (H1)–(H3) in Theorem 2.1 of [12], which we are now able to avoid. This improvement has been made possible by recent progress on several related problems [1, 4, 5, 13, 15], which will be discussed presently.

‡Wuhan Institute of Physics and Mathematics, Chinese Academy of Sciences, P.O. Box 71010, Wuhan 430071, People's Republic of China (hszhou@wipm.ac.cn).

Our approach to (1.1) is based on the characterization of solutions of (1.1) as critical points of an energy functional $\Phi_k : H_0^1(0,\infty) \to \mathbb{R}$. For the values of k for which there are positive solutions, this functional is indefinite in the sense that $\inf \Phi_k = -\infty$ and $\sup \Phi_k = \infty$, and the critical points which we discuss, are saddle points of mountain pass type. Furthermore, by (i), all the terms in $\Phi_k(u)$ have quadratic growth as $u \to \infty$ in $H_0^1(0,\infty)$. As we pointed out in [12], this means that the main difficulty, which has to be overcome in using a mountain pass method, is to establish the boundedness in $H_0^1(0,\infty)$ of the Palais–Smale sequences, which are found due to the mountain pass geometry of Φ_k. It was for this step in [12] that we required the undesirable additional hypotheses about g mentioned above. Later, using an argument from [4], we were able to establish the boundedness of Palais–Smale sequences for a similar energy functional in [13] without such assumptions about g. We now return to the physical problem (1.1) and, by following the same approach, we are able to avoid the unnecessary restrictions on g and also to extend the discussion to inhomogeneous media. Compared to our work in [13], there is a further improvement here in that we are now able to avoid any assumptions about the behavior of $g(r,s)$ as $r \to \infty$. In [13] we assumed that $g(r,0)$ is independent of r and that $\lim_{r\to\infty} g_\infty(r)$ exists, where $g_\infty(r) = \lim_{s\to\infty} g(r,s)$. Again, this kind of situation has been treated recently in a similar type of problem [5].

In (1.1) the lack of compactness in the embeddings of $H_0^1(0,\infty)$ into spaces such as $L^p(0,\infty)$ is compensated for by the radial symmetry of the underlying problem, which means that g depends on $r^{-1/2}u(r)$ rather than simply on $u(r)$. The related work in [1, 4, 5] deals with elliptic equations without such radial symmetry and the lack of compactness is handled by arguments of the concentration-compactness type.

Finally, let us mention that (1.1) was first treated by a constrained variational principle in which k^2 occurs as a Lagrange multiplier [9]. In that method the constraint is the power of the guided mode and so it has the advantage of establishing the existence of such modes with prescribed power. On the other hand, it does not yield the existence of guided modes for all wave numbers in the admissible range. We have restricted our attention to positive solutions of (1.1) since they lead to the fundamental TE-mode but, as Ruppen has shown [7], an infinity of higher modes exist under suitable assumptions about g. Guided TE-modes can also propagate in a defocusing axisymmetric medium under appropriate conditions [6].

The rest of this paper is organized as follows. In the next section we show how (1.1) is related to TE-modes as special solutions of Maxwell's equations in a nonlinear dielectric. The variational formulation on which our work is based is set out in section 3 and the mountain pass structure of the associated energy functional is established in section 4. The main result is Theorem 5.2, which asserts the existence of solutions of (1.1) provided that $-\Lambda_0 < k^2 < -\Lambda_\infty$, where Λ_0 and Λ_∞ are numbers determined by the functions $g_0(r) = g(r,0)$ and $g_\infty(r) = \lim_{s\to\infty} g(r,s)$, respectively, in (4.2), (4.3). This result is established by showing that any Palais–Smale sequence (4.4), which arises from the mountain pass geometry of Φ_k, has a strongly convergent subsequence. Finally, we show that, if $k^2 \notin [-\Lambda_0, -\Lambda_\infty]$, then (1.1) has no positive solutions in $H_0^1(0,\infty)$.

2. Guided TE-modes. In a medium without free charges, Maxwell's equations can be written as

$$
\begin{array}{llll}
(1) & \partial_t B = -c\nabla \wedge E, & (2) & \partial_t D = c\nabla \wedge H, \\
(3) & \nabla \cdot B = 0, & (4) & \nabla \cdot D = 0,
\end{array} \tag{2.1}
$$

where $c > 0$ is the speed of light in a vacuum.

A field $F : \mathbb{R}^4 \to \mathbb{R}^3$ is monochromatic if it has the form

$$F(x,t) = F_1(x)\cos\omega t + F_2(x)\sin\omega t \quad \text{for } x \in \mathbb{R}^3 \text{ and } t \in \mathbb{R} \tag{2.2}$$

for some frequency $\omega > 0$ and functions $F_1, F_2 : \mathbb{R}^3 \to \mathbb{R}^3$. We are concerned with solutions of (2.1) in which all the fields are monochromatic.

In this case, the constitutive assumptions used in the study of wave propagation in optical fibers can be expressed in the form

$$H = B \text{ and } D(x,t) = \epsilon\left(\omega, x, \frac{1}{2}\left[|E_1(x)|^2 + |E_2(x)|^2\right]\right) E(x,t) \tag{2.3}$$

when $E(x,t) = E_1(x)\cos\omega t + E_2(x)\sin\omega t$, where the function $\epsilon : J \times \mathbb{R}^3 \times [0,\infty) \to (0,\infty)$ is the dielectric response for an isotropic dielectric medium without absorption for frequencies ω in the interval J.

When the medium is axisymmetric (as in an optical fiber), it is convenient to use cylindrical polar coordinates (r, θ, z), where the z-axis is chosen to be the axis of symmetry of the medium and we use the standard notation

$$i_r = (\cos\theta, \sin\theta, 0), \quad i_\theta = (-\sin\theta, \cos\theta, 0), \quad i_z = (0,0,1).$$

Then the response has the following properties:

$$\text{(A)} \begin{cases} \text{For } \omega \in J, \text{ there is a function } \varepsilon(\omega,\cdot,\cdot) : [0,\infty) \times [0,\infty) \to (0,\infty) \\ \text{such that } \epsilon(\omega, x, s) = \varepsilon(\omega, r, s), \text{ where } \varepsilon(\omega,\cdot) \in C([0,\infty)^2) \text{ and} \\ \text{there are constants } a(\omega) \text{ and } b(\omega) \text{ such that} \\ \qquad 0 < a(\omega) \le \varepsilon(\omega, r, s) \le b(\omega) < \infty \text{ for all } r, s \ge 0. \\ \text{Furthermore, } \varepsilon(\omega, r, s) \to \varepsilon(\omega, r, 0) \text{ as } s \to 0, \text{ uniformly for } r \ge 0. \end{cases}$$

A self-focusing medium is characterized by the following further property of the dielectric response:

(AS) For $\omega \in J$ and $r \ge 0$ fixed, $\varepsilon(\omega, r, s)$ is a nondecreasing function of s.

A field $F : \mathbb{R}^4 \to \mathbb{R}^3$ is a traveling wave if it has the form

$$F(x,t) = w(x - t\xi) \text{ for } x \in \mathbb{R}^3 \text{ and } t \in \mathbb{R} \tag{2.4}$$

for some nonzero vector $\xi \in \mathbb{R}^3$ and function $w : \mathbb{R}^3 \to \mathbb{R}^3$. Here $|\xi|$ is the wave speed and $\xi/|\xi|$ is the direction of propagation. For waves propagating in the direction of the axis of symmetry, we can suppose that $\xi = (0,0,s)$ for some wave speed $s > 0$.

A field $F : \mathbb{R}^4 \to \mathbb{R}^3$ is axisymmetric (with respect to the x_3-axis) if

$$F(\Gamma_\theta x, t) = \Gamma_\theta F(x,t) \text{ for } x \in \mathbb{R}^3 \text{ and } t \in \mathbb{R}$$

for all rotations Γ_θ around the x_3-axis.

A TE-mode is a solution of Maxwell's equations in which the electric field is an axisymmetric, monochromatic traveling wave which is everywhere transverse to the direction of propagation. In such modes, the electric field can be expressed as

$$E(x,t) = v(r) i_\theta \cos(kz - \omega t), \tag{2.5}$$

where $v : [0,\infty) \to \mathbb{R}$ is the amplitude and $k > 0$ is the wave number, related to the wave speed by $s = \omega/k$. To ensure that (2.5) defines a field which is continuously differentiable on $\mathbb{R}^4$, we must suppose that v has the properties

$$v \in C^1([0,\infty)) \quad \text{and} \quad v(0) = 0. \tag{2.6}$$

To establish the existence of TE-modes, one must show that there exist functions $v \not\equiv 0$ satisfying (2.6) and constants $k > 0$ and $\omega \in J$ such that (2.1), (2.3) are satisfied by electromagnetic fields, where E has the form (2.5). As is shown in [9], this reduces to satisfying the second order differential equation

$$\begin{gathered} v''(r) + \frac{1}{r}v'(r) - \frac{1}{r^2}v(r) + \left(\frac{\omega}{c}\right)^2 \varepsilon\left(\omega, r, \frac{1}{2}v(r)^2\right) v(r) - k^2 v(r) = 0 \quad \text{for } r > 0, \\ \text{where} \quad v \in C^2((0,\infty)) \text{ and } v(0) = 0. \end{gathered} \tag{2.7}$$

In fact, if v satisfies (2.7) and E is defined by (2.5), a complete solution of (2.1) and (2.3) is obtained by setting

$$\begin{aligned} D(x,t) &= \varepsilon\left(\omega, r, \frac{1}{2}v(r)^2\right) v(r) i_\theta \cos(kz - \omega t) \text{ and} \\ B(x,t) &= H(x,t) \\ &= \frac{c}{\omega}\left\{\frac{1}{r}[rv(r)]' i_z \sin(kz - \omega t) - kv(r) i_r \cos(kz - \omega t)\right\}. \end{aligned} \tag{2.8}$$

A guided TE-mode must also satisfy the following guidance conditions, which ensure that the electromagnetic energy is finite and that all the fields decay to zero as the distance from the axis of symmetry becomes infinite. As is shown in [9], these physical boundary conditions reduce to

$$\int_0^\infty \{v(r)^2 + v'(r)^2\}\, r dr < \infty, \tag{2.9}$$

$$v(r) \to 0 \text{ and } v'(r) \to 0 \text{ as } r \to \infty \tag{2.10}$$

for TE-modes in the form (2.5).

From now on we fix a value of ω in J and try to find pairs (k, v) such that (2.7)–(2.10) are satisfied. To simplify the notation we set

$$g(r,s) = \left(\frac{\omega}{c}\right)^2 \varepsilon\left(\omega, r, \frac{1}{2}s^2\right) \text{ for } r \geq 0 \text{ and } s \in \mathbb{R} \tag{2.11}$$

and

$$u(r) = r^{1/2} v(r). \tag{2.12}$$

Equation (2.7) becomes

$$u''(r) - \frac{3}{4r^2}u(r) + g\left(r, \frac{u(r)}{\sqrt{r}}\right) u(r) - k^2 u(r) = 0 \quad \text{for } r > 0 \tag{2.13}$$

and, as we verify in Theorem 5.2, the other conditions in (2.7)–(2.10) are all satisfied provided that u belongs to the Sobolev space

$$H = H_0^1(0,\infty) = \{u \in H^1(0,\infty) : u(0) = 0\}. \tag{2.14}$$

More precisely, if $(k,u)\in(0,\infty)\times H$ and (2.13) is satisfied in the weak sense, namely,

(2.15)
$$\int_0^\infty u'(r)\varphi'(r)dr=\int_0^\infty\left\{g\left(r,\frac{u(r)}{\sqrt{r}}\right)-k^2-\frac{3}{4r^2}\right\}u(r)\varphi(r)dr \text{ for all } \varphi\in C_0^\infty((0,\infty)),$$

then the function v defined by (2.12) satisfies (2.7)–(2.10) and, consequently, it generates a guided TE-mode through the formulae (2.5) and (2.8).

The remainder of the paper deals with problem (2.13) so, for future reference, we recall some basic properties of elements of H.

We reserve $\langle\cdot,\cdot\rangle$ and $|\cdot|_2$ as notation for the usual scalar product and norm on $L^2(0,\infty)$ and, more generally, $|\cdot|_p$ denotes the usual norm on $L^p(0,\infty)$ for $1\le p\le\infty$. Then H is a Hilbert space with scalar product

$$\langle u,v\rangle_1=\langle u',v'\rangle+\langle u,v\rangle=\int_0^\infty[u'v'+uv]dr \tag{2.16}$$

and norm

$$\|u\|_1=\{|u'|_2^2+|u|_2^2\}^{1/2}. \tag{2.17}$$

An element $z\in H$ is, after modification on a set of measure zero, continuous on $[0,\infty)$ and satisfies the inequalities

$$|z|_\infty^2\le|z|_2|z'|_2, \tag{2.18}$$

$$r^{-1/2}|z(r)|\le|z'|_2 \text{ for all } r>0, \tag{2.19}$$

$$\lim_{r\to0}r^{-1/2}z(r)=0, \tag{2.20}$$

$$|z/r|_2\le2|z'|_2 \quad \text{(Hardy's inequality)}, \tag{2.21}$$

and

$$\int_0^\infty\left[z'+\frac{z}{2r}\right]^2dr=\int_0^\infty\left\{(z')^2+\frac{3z^2}{4r^2}\right\}dr\le4|z'|_2^2. \tag{2.22}$$

3. Variational formulation. Positive solutions of (2.15) are the critical points of a functional $\Phi_k:H\to\mathbb{R}$, which we now introduce. With g defined by (2.11) for a response satisfying conditions (A) and (AS), we set

$$g_0(r)=g(r,0) \text{ and } g_\infty(r)=\lim_{s\to\infty}g(r,s), \tag{3.1}$$

$$\widetilde{g}(r,s)=g(r,s)-g_0(r), \tag{3.2}$$

and then

$$\overline{G}(r,s)=\int_0^s g(r,\tau^+)\tau d\tau=\frac{1}{2}g_0(r)s^2+\widetilde{G}(r,s) \text{ with } \widetilde{G}(r,s)=\int_0^s\widetilde{g}(r,\tau^+)\tau d\tau$$

$$\text{and}\quad G(r,s)=\int_0^s g(r,r^{-1/2}\tau^+)\tau d\tau=r\overline{G}(r,r^{-1/2}s) \tag{3.3}$$

$$=\frac{1}{2}g_0(r)s^2+r\widetilde{G}(r,r^{-1/2}s). \tag{3.4}$$

Note that, for all $r > 0$, $G(r, \cdot) \in C^1(\mathbb{R})$ with

$$\partial_s G(r,s) = g(r, r^{-1/2}s^+)s$$

and

$$\frac{1}{2}A(\omega)s^2 \leq \frac{1}{2}g_0(r)s^2 \leq G(r,s) \leq \frac{1}{2}g_\infty(r)s^2 \leq \frac{1}{2}B(\omega)s^2 \tag{3.5}$$

for all $r > 0$ and $s \in \mathbb{R}$, where $A(\omega) = \left(\frac{\omega}{c}\right)^2 a(\omega)$ and $B(\omega) = \left(\frac{\omega}{c}\right)^2 b(\omega)$.

Recalling (2.21), we can now define a functional Φ_k on H by setting

$$\Phi_k(u) = \frac{1}{2}\int_0^\infty \left\{ |u'(r)|^2 + \frac{3}{4r^2}u(r)^2 + k^2 u(r)^2 \right\} dr - \int_0^\infty G(r, u(r))dr$$

for $u \in H$.

Lemma 3.1. *Under assumptions* (A) *and* (AS), *we have the following:*

(a) $\Phi_k \in C^1(H, \mathbb{R})$ *and*

$$\Phi_k'(u)v = \int_0^\infty u'(r)v'(r)dr - \int_0^\infty \left\{ g\left(r, \frac{u(r)^+}{\sqrt{r}}\right) - k^2 - \frac{3}{4r^2} \right\} u(r)v(r)dr \tag{3.6}$$

for all $u, v \in H$.

(b) *Furthermore, for* $t > 0$ *and* $u \in H$,

$$\Phi_k(tu) \leq \frac{1}{2}(t^2 - 1)\Phi_k'(u)u + \Phi_k(u).$$

Remark 3.1. It follows from (3.6) that if $\Phi_k'(u) = 0$ and $u \geq 0$, then (k, u) satisfies (2.15).

Proof. (a) First, we note that $G : (0, \infty) \times \mathbb{R} \to \mathbb{R}$ is a function of Carathéodory type having the following properties:

(i) $G(r, \cdot) \in C^1(\mathbb{R})$ for all $r > 0$.

(ii) $0 \leq G(r,s) \leq \frac{1}{2}B(\omega)s^2$ for all $s \in \mathbb{R}$.

(iii) $|\partial_s G(r,s)| \leq B(\omega)|s|$ for all $s \in \mathbb{R}$.

Using standard results about Nemytskii operators [14], it follows easily that

$$u \longmapsto \int_0^\infty G(r, u(r))dr$$

is a continuously Fréchet differentiable mapping of $L^2(0, \infty)$ into $\mathbb{R}$. (See Theorem 2.8 of [2], for example.) Since H is continuously embedded in $L^2(0, \infty)$, the same is true when it is considered as mapping from H into $\mathbb{R}$.

Using (2.21), it follows immediately that

$$\int_0^\infty \left\{ u'v' + \frac{3}{4r^2}uv + k^2 uv \right\} dr$$

is a bounded, symmetric bilinear form on H. Thus

$$u \longmapsto \int_0^\infty \left\{ u'(r)^2 + \frac{3}{4r^2}u(r)^2 + k^2 u(r)^2 \right\} dr$$

is a continuously Fréchet differentiable mapping of H into $\mathbb{R}$.

Combining these observations we see that $\Phi_k \in C^1(H, \mathbb{R})$.

(b) For $t > 0$ and $u \in H$,

$$\begin{aligned}
\Phi_k(tu) &= \frac{t^2}{2} \int_0^\infty \left\{ u'(r)^2 + \frac{3}{4r^2} u(r)^2 + k^2 u(r)^2 \right\} dr - \int_0^\infty G(r, tu(r)) dr \\
&= \frac{t^2}{2} \left[\Phi_k'(u)u + \int_0^\infty g\left(r, \frac{u(r)^+}{\sqrt{r}}\right) u(r)^2 dr \right] - \int_0^\infty G(r, tu(r)) dr \\
&= \frac{t^2}{2} \Phi_k'(u)u + \int_0^\infty \left\{ \frac{1}{2} g\left(r, \frac{u(r)^+}{\sqrt{r}}\right) t^2 u(r)^2 - G(r, tu(r)) \right\} dr.
\end{aligned}$$

For $r > 0$ fixed, set

$$h(t) = \frac{1}{2} g\left(r, \frac{u(r)^+}{\sqrt{r}}\right) t^2 u(r)^2 - G(r, tu(r)).$$

Then

$$\begin{aligned}
h'(t) &= g\left(r, \frac{u(r)^+}{\sqrt{r}}\right) tu(r)^2 - [\partial_s G(r, tu(r))] u(r) \\
&= g\left(r, \frac{u(r)^+}{\sqrt{r}}\right) tu(r)^2 - g(r, r^{-1/2} tu(r)^+) tu(r)^2 \\
&= tu(r)^2 \left\{ g\left(r, \frac{u(r)^+}{\sqrt{r}}\right) - g\left(r, \frac{tu(r)^+}{\sqrt{r}}\right) \right\}.
\end{aligned}$$

The monotonicity of $g(r, \cdot)$ shows that $h'(t) \geq 0$ for $0 < t \leq 1$ and $h'(t) \leq 0$ for $t > 1$. Consequently, $h(t) \leq h(1)$ for all $t > 0$ and so

$$\frac{1}{2} g\left(r, \frac{u(r)^+}{\sqrt{r}}\right) t^2 u(r)^2 - G(r, tu(r)) \leq \frac{1}{2} g\left(r, \frac{u(r)^+}{\sqrt{r}}\right) u(r)^2 - G(r, u(r)).$$

Thus

$$\begin{aligned}
\Phi_k(tu) &\leq \frac{t^2}{2} \Phi_k'(u)u + \int_0^\infty \left\{ \frac{1}{2} g\left(r, \frac{u(r)^+}{\sqrt{r}}\right) u(r)^2 - G(r, u(r)) \right\} dr \\
&= \frac{t^2}{2} \Phi_k'(u)u + \Phi_k(u) - \frac{1}{2} \Phi_k'(u)u. \qquad \square
\end{aligned}$$

4. Mountain pass geometry. Recalling (3.5), we set

(4.1)
$$\Lambda_0 = \inf \left\{ \int_0^\infty \left(|u'(r)|^2 + \left[\frac{3}{4r^2} - g_0(r) \right] u(r)^2 \right) dr : u \in H \text{ and } \int_0^\infty u(r)^2 dr = 1 \right\}$$

(4.2)
$$\Lambda_\infty = \inf \left\{ \int_0^\infty \left(|u'(r)|^2 + \left[\frac{3}{4r^2} - g_\infty(r) \right] u(r)^2 \right) dr : u \in H \text{ and } \int_0^\infty u(r)^2 dr = 1 \right\}$$

and observe that

$$(k^2 + \Lambda_\infty) \int_0^\infty u(r)^2 dr \leq \Phi_k(u) \leq (k^2 + \Lambda_0) \int_0^\infty u(r)^2 dr$$

for all $u \in H$. Furthermore, since

$$\inf\left\{\int_0^\infty \left(|u'(r)|^2 + \frac{3}{4r^2}u(r)^2\right) dr : u \in H \text{ and } \int_0^\infty u(r)^2 dr = 1\right\} = 0,$$

as is easily seen using (2.21), it follows from (3.5) that

$$-\frac{1}{2}B(\omega) \le \Lambda_\infty \le \Lambda_0 \le -\frac{1}{2}A(\omega) < 0. \tag{4.3}$$

LEMMA 4.1. *Consider* $k^2 > -\Lambda_0$. *Then*

(a) $\left(\int_0^\infty \left\{|u'(r)|^2 + \left[\frac{3}{4r^2} + k^2 - g_0(r)\right] u(r)^2\right\} dr\right)^{1/2}$

defines a norm, denoted by $\|u\|_0$, *which is equivalent to the usual norm* $\|u\|_1$ *on* H *defined by* (2.17).

(b) *There exist constants* $\alpha, \rho > 0$ *such that*

$$\Phi_k(u) \ge \alpha > 0 \textit{ for all } u \in S_\rho = \{u \in H : \|u\|_0 = \rho\}.$$

Remark 4.1. The norm $\|u\|_0$ is derived from a scalar product on H which we denote by $\langle\cdot,\cdot\rangle_0$.

Proof. (a) First we note that

$$\begin{aligned}\int_0^\infty &\left\{|u'(r)|^2 + \left[\frac{3}{4r^2} + k^2 - g_0(r)\right] u(r)^2\right\} dr \\ &\le \int_0^\infty \{|u'(r)|^2 + 3|u'(r)|^2 + k^2 u(r)^2\} dr \\ &\le \max\{4, k^2\} \|u\|_1^2 \text{ for all } u \in H\end{aligned}$$

by (2.21) and $g_0 \ge 0$.

On the other hand, for $t \in (0,1)$,

$$\begin{aligned}&\int_0^\infty \left\{|u'(r)|^2 + \left[\frac{3}{4r^2} + k^2 - g_0(r)\right] u(r)^2\right\} dr \\ &\quad = k^2 \int_0^\infty u(r)^2 dr + t\int_0^\infty \left\{|u'(r)|^2 + \left[\frac{3}{4r^2} - g_0(r)\right] u(r)^2\right\} dr \\ &\qquad\qquad + (1-t)\int_0^\infty \left\{|u'(r)|^2 + \left[\frac{3}{4r^2} - g_0(r)\right] u(r)^2\right\} dr \\ &\quad \ge (k^2 + t\Lambda_0)\int_0^\infty u(r)^2 dr + (1-t)\int_0^\infty \left\{|u'(r)|^2 + \left[\frac{3}{4r^2} - g_0(r)\right] u(r)^2\right\} dr \\ &\quad \ge \{k^2 + t\Lambda_0 - (1-t)|g_0|_\infty\}\int_0^\infty u(r)^2 dr + (1-t)\int_0^\infty |u'(r)|^2 dr\end{aligned}$$

for all $u \in H$. Since $k^2 + \Lambda_0 > 0$, we can choose $t_k \in (0,1)$ such that $k^2 + t_k\Lambda_0 - (1 - t_k)|g_0|_\infty > 0$, and then

$$\begin{aligned}\int_0^\infty &\left\{|u'(r)|^2 + \left[\frac{3}{4r^2} + k^2 - g_0(r)\right] u(r)^2\right\} dr \\ &\ge \min\{k^2 + t\Lambda_0 - (1-t)|g_0|_\infty, 1 - t_k\} \|u\|_1^2 \text{ for all } u \in H.\end{aligned}$$

(b) By (2.19) and part (a), there is a constant C such that

$$r^{-1/2}\left|u(r)\right| \leq \left\|u\right\|_1 \leq C\left\|u\right\|_0 \text{ for all } r>0 \text{ and } u\in H.$$

It follows from (A) that, given any $\eta>0$, there exists $\gamma>0$ such that

$$g\left(r,\frac{u(r)}{\sqrt{r}}\right) \leq g(r,0)+\eta = g_0(r)+\eta$$

for all $r>0$ and all $u\in H$ with $\left\|u\right\|_0<\gamma$. Hence

$$G(r,u(r)) = r\int_0^{u(r)/\sqrt{r}} g(r,\tau^+)\tau d\tau \leq \frac{1}{2}\{g_0(r)+\eta\}u(r)^2$$

and so, for $\left\|u\right\|_0<\gamma$,

$$\begin{aligned}
\Phi_k(u) &= \frac{1}{2}\int_0^\infty \left\{|u'(r)|^2+\left[\frac{3}{4r^2}+k^2\right]u(r)^2\right\}dr - \int_0^\infty G(r,u(r))dr \\
&\geq \frac{1}{2}\int_0^\infty \left\{|u'(r)|^2+\frac{3}{4r^2}u(r)^2+[k^2-g_0(r)-\eta]u(r)^2\right\}dr \\
&= \frac{1}{2}\left\|u\right\|_0^2-\frac{\eta}{2}\left|u\right|_2^2 \\
&\geq \frac{1}{2}\left\|u\right\|_0^2-\frac{\eta C^2}{2}\left\|u\right\|_0^2 = \frac{1}{2}(1-\eta C^2)\left\|u\right\|_0^2.
\end{aligned}$$

Choosing $\eta=1/2C^2$, it suffices to set $\rho=\gamma/2$ and $\alpha=\rho^2/4$. ∎

LEMMA 4.2. *Suppose that* $-\Lambda_0<k^2<-\Lambda_\infty$. *There exists* $e\in H$ *such that*

$$\left\|e\right\|_0>\rho \text{ and } \Phi_k(e)<0,$$

where ρ *is given by Lemma* 4.1(b).

Proof. Choose $\varepsilon>0$ such that $k^2+\Lambda_\infty+\varepsilon<0$. By the definition of Λ_∞, there exists an element $w\in H,\ w\not\equiv 0$ such that

$$\int_0^\infty \left\{|w'(r)|^2+\left[\frac{3}{4r^2}-g_\infty(r)\right]w(r)^2\right\}dr < (\Lambda_\infty+\varepsilon)\int_0^\infty w(r)^2dr$$

and, replacing w by $|w|$, we may assume that $w\geq 0$. Now, for $t>0$,

$$\frac{\Phi_k(tw)}{t^2} = \frac{1}{2}\int_0^\infty \left\{|w'(r)|^2+\left[\frac{3}{4r^2}+k^2\right]w(r)^2\right\}dr - t^{-2}\int_0^\infty G(r,tw(r))dr,$$

where

$$0\leq t^{-2}G(r,tw(r)) \leq \frac{1}{2}B(\omega)w(r)^2$$

by (3.5). The dominated convergence theorem implies that

$$\lim_{t\to\infty}\frac{\Phi_k(tw)}{t^2} = \frac{1}{2}\int_0^\infty \left\{|w'(r)|^2+\left[\frac{3}{4r^2}+k^2\right]w(r)^2\right\}dr - \int_0^\infty \lim_{t\to\infty} t^{-2}G(r,tw(r))dr.$$

For $r,s>0$,

$$s^{-2}G(r,s) = rs^{-2}\int_0^{s/\sqrt{r}} g(r,\tau)\tau d\tau = \int_0^1 g\left(r,\frac{s\sigma}{\sqrt{r}}\right)\sigma d\sigma \to g_\infty(r)\int_0^1 \sigma d\sigma = \frac{1}{2}g_\infty(r)$$

as $s \to \infty$ by dominated convergence. Hence

$$\lim_{t\to\infty} t^{-2}G(r,tw(r)) = \lim_{t\to\infty}[tw(r)]^{-2}G(r,tw(r))w(r)^2 = \frac{1}{2}g_\infty(r)w(r)^2$$

if $w(r) > 0$, whereas $\lim_{t\to\infty} t^{-2}G(r,tw(r)) = 0$ if $w(r) = 0$. Thus, since $w \geq 0$, we have that

$$\begin{aligned}\lim_{t\to\infty}\frac{\Phi_k(tw)}{t^2} &= \frac{1}{2}\int_0^\infty \left\{|w'(r)|^2 + \left[\frac{3}{4r^2}+k^2\right]w(r)^2\right\}dr - \int_0^\infty \left[\frac{1}{2}g_\infty(r)w(r)^2\right]dr \\ &= \frac{1}{2}\int_0^\infty \left\{|w'(r)|^2 + \left[\frac{3}{4r^2}-g_\infty(r)\right]w(r)^2\right\}dr + \frac{1}{2}k^2\int_0^\infty w(r)^2dr \\ &< \frac{1}{2}(\Lambda_\infty+\varepsilon+k^2)\int_0^\infty w(r)^2dr < 0\end{aligned}$$

by the choice of w and ε. It suffices to set $e = tw$ for t large enough. □

Lemmas 4.1 and 4.2 show that for $-\Lambda_0 < k^2 < -\Lambda_\infty$, the functional Φ_k has what is called the mountain pass geometry. Indeed, setting

$$\begin{aligned}c &= \inf_{\gamma\in\Gamma}\max_{t\in[0,1]}\Phi_k(\gamma(t)), \text{ where}\\ \Gamma &= \{\gamma \in C([0,1],H) : \gamma(0) = 0 \text{ and } \gamma(1) = e\},\end{aligned}$$

the mountain pass geometry described in Lemmas 4.1 and 4.2 implies that

$$\text{there exists a sequence } \{u_n\} \subset H \text{ such that} \tag{4.4}$$

$$\Phi_k(u_n) \xrightarrow{n} c > 0, \tag{4.5}$$

$$\Phi_k'(u_n)u_n \xrightarrow{n} 0, \tag{4.6}$$

$$\Phi_k'(u_n)\varphi \xrightarrow{n} 0, \text{ for all } \varphi \in H. \tag{4.7}$$

The properties (4.5) and (4.7) follow from the existence of what is often called a Palais–Smale sequence at level c, and the fact that the additional property (4.6) is also available was first shown by Cerami; see [3, Chapter IV], for example. If $\{u_n\}$ has a subsequence converging strongly u in H,

$$\Phi_k'(u_n)\varphi \xrightarrow{n} 0 \text{ for all } \varphi \in H$$

and we have a critical point of $\Phi_k$with $\Phi_k(u) = c$, so $u \not\equiv 0$. In the next section we show that $\{u_n\}$ has such a subsequence.

5. Existence of a ground state. We begin by establishing some further properties of the sequence (4.4)–(4.7). The main problems are to show that

(i) $\{u_n\}$ is bounded in H_0^1, and then

(ii) $u_n \xrightarrow{n} u$ weakly in $H \Longrightarrow u_n \xrightarrow{n} u$ strongly in H.

LEMMA 5.1. *The sequence* (4.4)–(4.7) *is bounded in H.*

Proof. If $\{u_n\}$ is not bounded in H, there is a subsequence, which we can still denote by $\{u_n\}$, such that $\|u_n\|_0 \xrightarrow{n} \infty$.

Next we set

$$w_n = 2\sqrt{c}\frac{u_n}{\|u_n\|_0} \text{ and } t_n = \frac{2\sqrt{c}}{\|u_n\|_0}. \tag{5.1}$$

By passing to a further subsequence, we can assume that $w_n \overset{n}{\rightharpoonup} w$ weakly in H. The rest of the proof is split into the following steps. First we show that $w \not\equiv 0$, and then we deduce that $w > 0$. Finally we obtain a contradiction, showing that $\{u_n\}$ must be bounded in H.

Step 1 ($w \not\equiv 0$). By Lemma 3.1(b),

$$\Phi_k(w_n) = \Phi_k(t_n u_n) \leq \frac{1}{2}(t_n^2 - 1)\Phi_k'(u_n)u_n + \Phi_k(u_n)$$

and so

$$\limsup_{n\to\infty} \Phi_k(w_n) \leq c \tag{5.2}$$

by (4.5) and (4.6) since $t_n \to 0$.

On the other hand, in the notation (3.4),

$$\begin{aligned}\Phi_k(u) &= \frac{1}{2}\int_0^\infty \left\{|u'(r)|^2 + \left[\frac{3}{4r^2} + k^2 - g_0(r)\right]u(r)^2\right\}dr - \int_0^\infty r\widetilde{G}(r, r^{-1/2}u(r))dr \\ &= \frac{1}{2}\|u\|_0^2 - \int_0^\infty r\widetilde{G}(r, r^{-1/2}u(r))dr,\end{aligned}$$

where

$$\begin{aligned}0 \leq r\widetilde{G}(r, r^{-1/2}u(r)) &= r\int_0^{u(r)/\sqrt{r}} \{g(r,\tau^+) - g_0(r)\}\tau d\tau \\ &\leq r\{g_\infty(r) - g_0(r)\}\int_0^{u(r)/\sqrt{r}} \tau d\tau \leq \frac{1}{2}B(\omega)u(r)^2.\end{aligned}$$

Hence for any $R > 0$,

$$\begin{aligned}0 &\leq \int_0^\infty r\widetilde{G}(r, r^{-1/2}u(r))dr \\ &\leq \int_0^R \frac{1}{2}B(\omega)u(r)^2 dr + \int_R^\infty r\widetilde{G}(r, r^{-1/2}u(r))dr,\end{aligned}$$

and for $r \geq R$,

$$\begin{aligned}0 \leq r\widetilde{G}(r, r^{-1/2}u(r)) &= r\int_0^{u(r)/\sqrt{r}} \widetilde{g}(r,\tau^+)\tau dt \\ &\leq r\widetilde{g}(r, r^{-1/2}u(r)^+)\int_0^{u(r)/\sqrt{r}} \tau dt \leq \frac{1}{2}\widetilde{g}(r, r^{-1/2}|u|_\infty)u(r)^2\end{aligned}$$

by the monotonicity of the function $\widetilde{g}(r,s) = g(r,s) - g_0(r)$ in s.

Hence

$$\begin{aligned}0 &\leq \int_0^\infty r\widetilde{G}(r, r^{-1/2}u(r))dr \\ &\leq \int_0^R \frac{1}{2}B(\omega)u(r)^2 dr + \int_R^\infty \frac{1}{2}\widetilde{g}(r, r^{-1/2}|u|_\infty)u(r)^2 dr \\ &\leq \frac{1}{2}B(\omega)\int_0^R u(r)^2 dr + \frac{1}{2}\sup_{r\geq R}\widetilde{g}(r, r^{-1/2}|u|_\infty)\int_R^\infty u(r)^2 dr. \qquad (5.3)\end{aligned}$$

Since $\|w_n\|_0 = 2\sqrt{c}$ for all n, there is a constant $K > 0$ such that $|w_n|_2 \leq K$ and $|w_n|_\infty \leq K$. Thus putting $u = w_n$ in (5.3),

$$\begin{aligned} 0 &\leq \int_0^\infty r\widetilde{G}(r, r^{-1/2} w_n(r))dr \\ &\leq \frac{1}{2} B(\omega) \int_0^R w_n(r)^2 dr + \frac{1}{2} \sup_{r \geq R} \widetilde{g}(r, r^{-1/2} K) K^2 \end{aligned}$$

for all n. If $w_n \overset{n}{\rightharpoonup} 0$ weakly in H, $\int_0^R w_n(r)^2 dr \xrightarrow{n} 0$ for any $R > 0$, and so

$$\limsup_{n\to\infty} \int_0^\infty r\widetilde{G}(r, r^{-1/2} w_n(r))dr \leq \frac{1}{2} \sup_{r \geq R} \widetilde{g}(r, r^{-1/2} K) K^2$$

for all $R > 0$. But it follows from (A) that

$$\lim_{R\to\infty} \sup_{r \geq R} \widetilde{g}(r, r^{-1/2} K) = 0,$$

so in fact,

$$\limsup_{n\to\infty} \int_0^\infty r\widetilde{G}(r, r^{-1/2} w_n(r))dr = 0.$$

Finally,

$$\begin{aligned} \liminf_{n\to\infty} \Phi_k(w_n) &= \liminf_{n\to\infty} \left\{ \frac{1}{2} \|w_n\|_0^2 - \int_0^\infty r\widetilde{G}(r, r^{-1/2} w_n(r))dr \right\} \\ &= 2c - \limsup_{n\to\infty} \int_0^\infty r\widetilde{G}(r, r^{-1/2} w_n(r))dr \\ &\geq 2c, \end{aligned}$$

contradicting (5.2). Hence $w \not\equiv 0$.

Step 2 ($w > 0$). For all $\varphi \in C_0^\infty((0,\infty))$,

$$\begin{aligned} \langle w_n, \varphi \rangle_0 &= \int_0^\infty \left\{ w_n' \varphi' + \left[k^2 + \frac{3}{4r^2} - g_0(r) \right] w_n \varphi \right\} dr \\ &= t_n \int_0^\infty \left\{ u_n' \varphi' + \left[k^2 + \frac{3}{4r^2} - g_0(r) \right] u_n \varphi \right\} dr \\ &= t_n \left\{ \Phi_k'(u_n)\varphi + \int_0^\infty \widetilde{g}(r, r^{-1/2} u_n(r)^+) u_n \varphi dr \right\} \\ &= t_n \Phi_k'(u_n)\varphi + \int_0^\infty \widetilde{g}(r, r^{-1/2} u_n(r)^+) w_n \varphi dr. \end{aligned}$$

By (4.7), $t_n \Phi_k'(u_n)\varphi \to 0$ since $t_n \to 0$. Furthermore,

$$\begin{aligned} \widetilde{g}(r, r^{-1/2} u_n(r)^+) w_n(r) &= \widetilde{g}\left(r, \frac{w_n(r)^+}{t_n \sqrt{r}}\right) w_n(r) \\ &\to \begin{cases} [g_\infty(r) - g_0(r)] w(r) & \text{if } w(r) > 0, \\ 0 & \text{if } w(r) \leq 0 \end{cases} \end{aligned}$$

as $n \to \infty$ and

$$\left| \widetilde{g}\left(r, \frac{w_n(r)^+}{t_n\sqrt{r}}\right) w_n(r) \right| \le B(\omega)K \text{ for all } r > 0.$$

Hence, by dominated convergence we have that

$$\int_0^\infty \widetilde{g}(r, r^{-1/2}u_n(r)^+)w_n\varphi dr \xrightarrow{n} \int_0^\infty [g_\infty(r) - g_0(r)]w(r)^+\varphi(r)dr$$

and, consequently,

$$\langle w, \varphi\rangle_0 = \int_0^\infty [g_\infty(r) - g_0(r)]w(r)^+\varphi(r)dr \tag{5.4}$$

for all $\varphi \in C_0^\infty((0,\infty))$. But $C_0^\infty((0,\infty))$ is dense in H and it follows easily that (5.4) holds for all $\varphi \in H$. Putting $\varphi = w^-$ in (5.4), we obtain

$$\left\|w^-\right\|_0 = \left\langle w, w^-\right\rangle_0 = 0,$$

showing that $w^- \equiv 0$. Hence $w \equiv w^+$ and (5.4) can be written as

$$\int_0^\infty \left\{ w'\varphi' + \left[k^2 + \frac{3}{4r^2} - g_\infty(r)\right] w\varphi \right\} dr = 0 \text{ for all } \varphi \in C_0^\infty((0,\infty)). \tag{5.5}$$

It follows that w' has a generalized derivative on $(0,\infty)$ and that

$$w''(r) = \left\{ k^2 + \frac{3}{4r^2} - g_\infty(r) \right\} w(r) \text{ on } (0,\infty). \tag{5.6}$$

Since $w \ge 0$ on $(0,\infty)$, but $w \not\equiv 0$, the maximum principle implies that $w > 0$ on $(0,\infty)$.

Step 3 ($\{u_n\}$ is bounded). We show that, for $k^2 > -\Lambda_\infty$, (5.5) cannot have a positive solution.

For $R > 0$, set

$$m(R) = \inf \left\{ \int_0^R \left(|u'(r)|^2 + \left[\frac{3}{4r^2} - g_\infty(r)\right] u(r)^2 \right) dr : \ u \in H_0^1(0,R) \text{ and } \int_0^R u(r)^2 dr = 1 \right\}.$$

Recalling that $g_\infty \in L^\infty$ and that $H_0^1(0,R)$ is compactly embedded in $L^2(0,R)$, it follows easily that there exists an element $u_R \in H_0^1(0,R)\backslash\{0\}$ such that

$$\int_0^R \left\{ |u_R'(r)|^2 + \left[\frac{3}{4r^2} - g_\infty(r)\right] u_R(r)^2 \right\} dr = m(R) \int_0^R u_R(r)^2 dr$$

and, replacing u_R by $|u_R|$, we can suppose that $u_R \ge 0$ on $[0,R]$. But there is a Lagrange multiplier λ such that

$$\int_0^R \left\{ u_R'\varphi' + \left[\frac{3}{4r^2} - g_\infty(r)\right] u_R\varphi \right\} dr = \lambda \int_0^R u_R\varphi dr \text{ for all } \varphi \in H_0^1(0,R)$$

and, putting $\varphi = u_R$, we have $\lambda = m(R)$. Thus, u_R has a generalized derivative on $(0, R)$ and

$$-u_R''(r) + \left[\frac{3}{4r^2} - g_\infty(r)\right] u_R(r) = m(R) u_R(r) \text{ on } (0, R), \tag{5.7}$$

$$u_R(0) = u_R(R) = 0. \tag{5.8}$$

It follows that $u_R \in H^2(\delta, R)$ for all $\delta \in (0, R)$. We do not claim that $u_R \in H^2(0, R)$ but we can assume that $u_R \in C^1((0, R])$. Since $k^2 < -\Lambda_\infty$, we can choose $\varepsilon > 0$ such that $k^2 + 2\varepsilon < -\Lambda_\infty$. By the definition of Λ_∞, there exists $z \in H\backslash\{0\}$ such that

$$\int_0^\infty \left\{|z'(r)|^2 + \left[\frac{3}{4r^2} - g_\infty(r)\right] z(r)^2\right\} dr \le (\Lambda_\infty + \varepsilon) \int_0^\infty z(r)^2 dr$$

and then, by (2.21) and the density of $C_0^\infty((0, \infty))$ there exists an element $v \in C_0^\infty((0, \infty))$ such that

$$\int_0^\infty \left\{|v'(r)|^2 + \left[\frac{3}{4r^2} - g_\infty(r)\right] v(r)^2\right\} dr \le (\Lambda_\infty + 2\varepsilon) \int_0^\infty v(r)^2 dr.$$

Now choose R such that $\operatorname{supp} v \subset (0, R)$. It follows that $m(R) \le \Lambda_\infty + 2\varepsilon$. From (5.7) we obtain

$$-u_R'(R)w(R) + u_R'(\delta)w(\delta) + \int_\delta^R u_R' w' + \left\{\frac{3}{4r^2} - g_\infty(r)\right\} u_R w dr = m(R) \int_\delta^R u_R w dr$$

for any $\delta \in (0, R)$. Hence

$$\lim_{\delta \to 0} u_R'(\delta)w(\delta) = u_R'(R)w(R) - \int_0^R u_R' w' + \left\{\frac{3}{4r^2} - g_\infty(r) - m(R)\right\} u_R w dr$$

since $r^{-2} u_R(r) w(r)$ is integrable on $(0, R)$ by (2.21).

By (2.21) and the density of $C_0^\infty((0, \infty))$ in H, it follows that (5.5) holds for all $\varphi \in H$. We denote by $\widetilde{u_R}$ the function obtained by extending u_R by zero for all $r \ge R$. Setting $\varphi = \widetilde{u_R}$ in (5.5), we have that

$$\int_0^R u_R' w' dr + \int_0^R \left\{\frac{3}{4r^2} - g_\infty(r)\right\} u_R w dr = -k^2 \int_0^R u_R w dr.$$

Hence,

$$\begin{aligned}
\lim_{\delta \to 0} u_R'(\delta)w(\delta) &= u_R'(R)w(R) + \{m(R) + k^2\} \int_0^R u_R w dr \\
&\le u_R'(R)w(R) + \{\Lambda_\infty + 2\varepsilon + k^2\} \int_0^R u_R w dr \\
&< u_R'(R)w(R)
\end{aligned}$$

by the positivity of w and u_R and the choice of ε and R. Since $u_R \ge 0$ on $[0, R]$ and $u_R(R) = 0$, we have $u_R'(R)w(R) \le 0$ and, consequently, there exists $\delta_0 > 0$ such that $u_R'(r)w(r) < 0$ for all $r \in (0, \delta_0)$. Recalling that $u_R \in H_0^1(0, R)$ and that $w > 0$ on $(0, R)$, this yields

$$u_R(\delta_0) = \int_0^{\delta_0} u_R'(r) dr < 0,$$

contradicting the positivity of u_R on $(0, R)$.

Thus the initial assumption that the sequence $\{u_n\}$ is unbounded implies the existence of an element w whose properties lead to a contradiction. This establishes the boundedness of $\{u_n\}$. $\square$

We are now ready to prove the main result of this paper.

THEOREM 5.2. *Let the dielectric response satisfy the assumptions* (A) *and* (AS). *Let* $\omega \in J$ *be such that* $\Lambda_\infty < \Lambda_0$. *Then for every wave number* $k > 0$ *such that* $\Lambda_\infty < -k^2 < \Lambda_0$ *there is a positive solution* $u \in H\backslash\{0\}$ *of* (2.15). *Furthermore, the function* v *defined by* (2.12) *has the following properties:*

(i) $v \in C^2([0,\infty))$ *with* $v(0) = v''(0) = 0$ *and* $v > 0$ *on* $(0, \infty)$.

(ii) v *satisfies* (2.9) *and* (2.10).

Remark 5.1. Observe that the conditions (A) and (AS) are satisfied by a linear dielectric response,

$$\varepsilon(\omega, r, s) = \varepsilon_0(\omega, r) \text{ for all } r, s \geq 0,$$

provided that $\varepsilon_0(\omega, \cdot) \in C([0,\infty))$ and $0 < a(\omega) \leq \varepsilon_0(\omega, r) \leq b(\omega) < \infty$ for all $r, s \geq 0$. In this case, $\Lambda_\infty = \Lambda_0$. Thus the requirement that $\Lambda_\infty < \Lambda_0$ in Theorem 5.2 ensures that the dielectric response is in fact nonlinear.

Remark 5.2. In a homogeneous medium, $\varepsilon(\omega, r, s) = \varepsilon(\omega, 0, s)$ for all $r, s \geq 0$, and so

$$\Lambda_0 = \left(\frac{\omega}{c}\right)^2 \varepsilon(\omega, 0, 0) \text{ and } \Lambda_\infty = \lim_{s\to\infty} \left(\frac{\omega}{c}\right)^2 \varepsilon(\omega, 0, s).$$

Thus for a homogeneous self-focusing material, $\Lambda_\infty = \Lambda_0$ if and only if the dielectric response is linear.

Proof. We fix $k > 0$ such that $\Lambda_\infty < -k^2 < \Lambda_0$ and consider the sequence (4.4)–(4.7). By Lemma 5.1 this sequence is bounded in H and so we can suppose that $u_n \xrightarrow{n} u$ weakly in H.

Putting $\varphi = u$ in (3.6) we get

$$\begin{aligned}
\Phi_k'(u_n)u &= \int_0^\infty \left\{ u_n'(r) + \left[\frac{3}{4r^2} + k^2\right] u_n(r) \right\} u(r)dr - \int_0^\infty g(r, r^{-1/2}u_n(r)^+)u_n(r)u(r)dr \\
&= \int_0^\infty \left\{ u_n'(r) + \left[\frac{3}{4r^2} + k^2 - g_0(r)\right] u_n(r) \right\} u(r)dr - \int_0^\infty \widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)u(r)dr \\
&= \langle u_n, u\rangle_0 - \int_0^\infty \widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)u(r)dr.
\end{aligned}$$

Similarly,

$$\Phi_k'(u_n)u_n = \|u_n\|_0^2 - \int_0^\infty \widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)u_n(r)dr$$

and hence,

$$\begin{aligned}
\|u_n - u\|_0^2 &= \|u_n\|_0^2 - \langle u_n, u\rangle_0 - \langle u, u_n - u\rangle_0 \\
&= \Phi_k'(u_n)u_n + \int_0^\infty \widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)u_n(r)dr \\
&\qquad - \Phi_k'(u_n)u - \int_0^\infty \widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)u(r)dr - \langle u, u_n - u\rangle_0 \\
&= \Phi_k'(u_n)u_n - \Phi_k'(u_n)u - \langle u, u_n - u\rangle_0 + \int_0^\infty \widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)[u_n(r) - u(r)]dr.
\end{aligned}$$

From the properties of (4.4)–(4.7) and the weak convergence of $\{u_n\}$, we see that $\|u_n - u\|_0 \overset{n}{\to} 0$ provided that

$$\int_0^\infty \widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)[u_n(r) - u(r)]dr \xrightarrow{n} 0.$$

For any $R > 0$,

$$\begin{aligned}
&\left|\int_0^\infty \widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)[u_n(r) - u(r)]dr\right| \\
&\leq \int_0^R \left|\widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)[u_n(r) - u(r)]\right| dr \\
&\qquad\qquad + \int_R^\infty \left|\widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)[u_n(r) - u(r)]\right| dr \\
&\leq \int_0^R B(\omega)\left|u_n(r)[u_n(r) - u(r)]\right| dr + \int_R^\infty \widetilde{g}(r, r^{-1/2}\left|u_n\right|_\infty)\left|u_n(r)[u_n(r) - u(r)]\right| dr
\end{aligned}$$

by the monotonicity of $\widetilde{g}(r, \cdot)$. The boundedness of $\{u_n\}$ in H ensures that there is a constant $K > 0$ such that $|u_n|_2 \leq K$ and $|u_n|_\infty \leq K$ for all n. Hence

$$\begin{aligned}
&\int_R^\infty \widetilde{g}(r, r^{-1/2}\left|u_n\right|_\infty)\left|u_n(r)[u_n(r) - u(r)]\right| dr \\
&\qquad \leq \sup_{r \geq R} \widetilde{g}(r, r^{-1/2}K) \int_R^\infty \left|u_n(r)[u_n(r) - u(r)]\right| dr \\
&\qquad \leq \sup_{r \geq R} \widetilde{g}(r, r^{-1/2}K) 2K^2 \text{ for all } n.
\end{aligned}$$

Since $u_n \xrightarrow{n} u$ uniformly on $[0, R]$, we have that

$$\limsup_{n\to\infty} \left|\int_0^\infty \widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)[u_n(r) - u(r)]dr\right| \leq \sup_{r \geq R} \widetilde{g}(r, r^{-1/2}K)2K^2$$

for all R. But it follows from (A) that

$$\lim_{R\to\infty} \sup_{r \geq R} \widetilde{g}(r, r^{-1/2}K) = 0,$$

and consequently,

$$\lim_{n\to\infty} \int_0^\infty \widetilde{g}(r, r^{-1/2}u_n(r)^+)u_n(r)[u_n(r) - u(r)]dr = 0.$$

Hence $\|u_n - u\|_0 \xrightarrow{n} 0$ and Lemma 3.1, together with properties (4.5) and (4.7), imply that $\Phi_k(u) = c > 0$ and $\Phi_k'(u)\varphi = 0$ for all $\varphi \in H$. Thus $u \not\equiv 0$ and, choosing $\varphi = u^-$, we have that

$$0 = \Phi_k'(u)u^- = \left\|u^-\right\|_0^2.$$

Thus $u \geq 0$, and u satisfies (2.15). This implies that u' has a generalized derivative on $(0, \infty)$ and that (2.13) is satisfied. Thus $u \in C^2((0, \infty))$. Setting

$$h(r) = \frac{3}{4r^2} + k^2 - g\left(r, \frac{u(r)}{\sqrt{r}}\right) \text{ for } r > 0,$$

we have that $h \in C((0,\infty))$ and $u''(r) = h(r)u(r)$ for all $r > 0$. Since $u \geq 0$, but $u \not\equiv 0$ on $(0,\infty)$, we must have that $u(r) > 0$ for all $r > 0$.

Setting $v(r) = r^{-1/2}u(r)$ for $r > 0$, we have that $v \in C^2((0,\infty))$ and, by (2.20), $\lim_{r\to 0} v(r) = 0$. Setting $v(0) = 0$, this means that $v \in C([0,\infty))$. Furthermore, v satisfies (2.7), which can be written as

$$\left[v' + \frac{v}{r}\right]' = \{k^2 - g(r, v(r))\}v(r), \tag{5.9}$$

showing that

$$\lim_{r\to 0}\left[v' + \frac{v}{r}\right]' = 0$$

since $A(\omega) \leq g(r,s) \leq B(\omega)$ for all $r, s \geq 0$ and $v(0) = 0$. This implies that there exists $L \in \mathbb{R}$ such that $\lim_{r\to 0}[v' + \frac{v}{r}] = L$. But $v' + \frac{v}{r} = \frac{1}{r}(rv)'$ and, using L'Hospital's rule,

$$\lim_{r\to 0}\frac{v(r)}{r} = \lim_{r\to 0}\frac{rv(r)}{r^2} = \lim_{r\to 0}\frac{(rv)'}{2r} = \frac{1}{2}\lim_{r\to 0}\left[v' + \frac{v}{r}\right] = \frac{L}{2}.$$

This proves that v is differentiable at 0 with $v'(0) = \frac{L}{2}$. Also,

$$\begin{aligned}\lim_{r\to 0} v'(r) &= \lim_{r\to 0}\left\{v'(r) + \frac{v(r)}{r} - \frac{v(r)}{r}\right\}\\ &= \lim_{r\to 0}\left\{v' + \frac{v}{r}\right\} - \lim_{r\to 0}\frac{v(r)}{r} = L - \frac{L}{2}\\ &= \frac{L}{2}\end{aligned}$$

and we have shown that $v \in C^1([0,\infty))$.

Setting $w(r) = v(r)/r$, we find that (5.9) can be written as

$$[r^3w']' = r^3h(r)w, \text{ where } h(r) = \{k^2 - g(r, v(r))\} \text{ for } r > 0, \tag{5.10}$$

and hence,

$$r^3w'(r) - s^3w'(s) = \int_s^r t^3h(t)w(t)dt \text{ for } 0 < s < r.$$

Since $r^3w'(r) = r^2v'(r) - rv(r) \to 0$ as $r \to 0$, we have that

$$w'(r) = r^{-3}\int_0^r t^3h(t)w(t)dt \text{ for } r > 0,$$

where $h(t)w(t)$ remains bounded as $t \to 0$. Thus $\lim_{r\to 0} w'(r) = 0$. But then,

$$\begin{aligned}\lim_{r\to 0} v''(r) &= \lim_{r\to 0}\left\{\left[v' + \frac{v}{r}\right]' - w'\right\}\\ &= \lim_{r\to 0}\left[v' + \frac{v}{r}\right]' - \lim_{r\to 0} w' = 0,\end{aligned}$$

from which it follows that $v \in C^2([0,\infty))$ with $v''(0) = 0$.

Since $u \in H$ and $A(\omega) \le g(r,s) \le B(\omega)$ for all $r, s \ge 0$, it follows from (2.13) that $u \in H^2(1,\infty)$. This implies that $\lim_{r\to\infty} u(r) = \lim_{r\to\infty} u'(r) = 0$, and hence that

$$\lim_{r\to\infty} v(r) = \lim_{r\to\infty} v'(r) = 0.$$

Straightforward substitution shows that

$$\int_0^\infty v(r)^2\, r dr = \int_0^\infty u(r)^2\, dr \text{ and } \int_0^\infty v'(r)^2\, r dr = \int_0^\infty \left[u' - \frac{u}{2r}\right]^2 dr$$

and it follows from (2.21) that $u' - \frac{u}{2r} \in L^2(0,\infty)$ since $u \in H$. Thus v satisfies (2.9). This completes the proof. □

Finally, we show that the restrictions imposed on k in Theorem 5.2 are quite sharp.

THEOREM 5.3. *Let the dielectric response satisfy assumptions* (A) *and* (AS). *If the wave number k is such that $-k^2 \notin [\Lambda_\infty, \Lambda_0]$, then there is no nonnegative solution u of* (2.15) *in $H\backslash\{0\}$.*

Proof. Suppose that $u \in H\backslash\{0\}$ satisfies (2.15) and that $u \ge 0$ on $(0,\infty)$. As in the proof of Theorem 5.2, it follows that $u \in C^2((0,\infty))$ and $u(r) > 0$ for all $r > 0$.

Putting $\varphi = u$ in (2.15), we find that

$$\int_0^\infty |u'|^2 + \left[\frac{3}{4r^2} + k^2\right] u^2 dr = \int_0^\infty g\left(r, \frac{u(r)}{\sqrt{r}}\right) u^2 dr \le \int_0^\infty g_\infty(r) u^2 dr$$

since $g(r,\cdot)$ is nondecreasing for all $r > 0$. Hence

$$\int_0^\infty |u'|^2 + \left[\frac{3}{4r^2} - g_\infty(r)\right] u^2 dr = -k^2 \int_0^\infty u^2 dr.$$

But the definition of Λ_∞ implies that

$$\int_0^\infty |u'|^2 + \left[\frac{3}{4r^2} - g_\infty(r)\right] u^2 dr \ge \Lambda_\infty \int_0^\infty u^2 dr$$

so we must have $-k^2 \ge \Lambda_\infty$.

Suppose now that $-k^2 > \Lambda_0$. We can choose $\varepsilon > 0$ such that $-k^2 > \Lambda_0 + 2\varepsilon$ and then, by the definition of Λ_0, there exists $v \in H\backslash\{0\}$ such that

$$\int_0^\infty |v'|^2 + \left[\frac{3}{4r^2} - g_0(r)\right] v^2 dr \le [\Lambda_0 + \varepsilon] \int_0^\infty v^2 dr.$$

Using (2.21), it follows from the density of $C_0^\infty((0,\infty))$ in H that there exists $w \in C_0^\infty((0,\infty))\backslash\{0\}$ such that

$$\int_0^\infty |w'|^2 + \left[\frac{3}{4r^2} - g_0(r)\right] w^2 dr \le [\Lambda_0 + 2\varepsilon] \int_0^\infty w^2 dr.$$

For $R > 0$, we now set

$$m(R) = \inf\left\{\int_0^R |z'|^2 + \left[\frac{3}{4r^2} - g_0(r)\right] z^2 dr : z \in H_0^1((0,R)) \text{ and } \int_0^R z^2 dr = 1\right\}$$

and observe that, for any R such that $\operatorname{supp} w \subset (0,R)$, we must have $m(R) \le \Lambda_0 + 2\varepsilon$. For any $R \in (0,\infty)$, it follows from the compactness of the embedding of $H_0^1((0,R))$

in $L^2((0,R))$ and the weak sequential lower semicontinuity of $\int_0^R |z'|^2 + \frac{3}{4r^2}z^2 dr$ on $H_0^1((0,R))$ that there exists $u_R \in H_0^1((0,R))$ such that $\int_0^R u_R^2 dr = 1$ and

$$\int_0^R |u_R'|^2 + \left[\frac{3}{4r^2} - g_0(r)\right] u_R^2 dr = m(R).$$

We may assume that $u_R \geq 0$ on $(0,R)$ and that

$$\int_0^R u_R' z' + \left[\frac{3}{4r^2} - g_0(r)\right] u_R z dr = m(R) \int_0^R u_R z dr \text{ for all } z \in H_0^1((0,R)).$$

This implies that $u_R \in H^2((\delta, R))$ for any $\delta \in (0,R)$ with

$$-u_R'' + \left[\frac{3}{4r^2} - g_0(r)\right] u_R = m(R) u_R \text{ on } (0,R),$$

so we can suppose that $u_R \in C^1((0,R])$. Multiplying by u and integrating we get

$$-u_R'(R)u(R) + u_R'(\delta)u(\delta) + \int_\delta^R u_R' u' + \left[\frac{3}{4r^2} - g_0(r)\right] u_R u dr = m(R) \int_\delta^R u_R u dr$$

for any $\delta \in (0,R)$. Hence

$$\lim_{\delta \to 0} u_R'(\delta)u(\delta) = u_R'(R)u(R) - \int_0^R u_R' u' + \left[\frac{3}{4r^2} - g_0(r) - m(R)\right] u_R u dr$$

since $r^{-2}u_R(r)u(r)$ is integrable on $(0,R)$ by (2.21). On the other hand, if $\widetilde{u_R}$ is the function obtained by extending u_R by zero for $r \geq R$, we can set $\varphi = \widetilde{u_R}$ in (2.15), and this yields

$$\int_0^R u' u_R' + \left[\frac{3}{4r^2} + k^2 - g\left(r, \frac{u(r)}{\sqrt{r}}\right)\right] u_R u dr = 0.$$

Thus we have that

$$\begin{aligned}
\lim_{\delta \to 0} u_R'(\delta)u(\delta) &= u_R'(R)u(R) - \int_0^R \left[g\left(r, \frac{u(r)}{\sqrt{r}}\right) - k^2 - g_0(r) - m(R)\right] u_R u dr \\
&\leq u_R'(R)u(R) + [k^2 + m(R)] \int_0^R u_R u dr \\
&\leq u_R'(R)u(R) + [k^2 + \Lambda_0 + 2\varepsilon] \int_0^R u_R u dr
\end{aligned}$$

for $R > 0$ such that supp $w \subset (0,R)$. But $u > 0$ and $u_R \geq 0$ on $(0,R)$ with $u_R(R) = 0$, so $u_R'(R)u(R) \leq 0$. Also $\int_0^R u_R u dr > 0$ since $u_R \not\equiv 0$ on $(0,R)$. Hence

$$\lim_{\delta \to 0} u_R'(\delta)u(\delta) \leq [k^2 + \Lambda_0 + 2\varepsilon] \int_0^R u_R u dr < 0,$$

since $k^2 + \Lambda_0 + 2\varepsilon < 0$ by the choice of ε. But this means that there exists $\delta_0 > 0$ such that $u_R'(r)u(r) < 0$ for all $r \in (0, \delta_0)$. Recalling that $u_R \in H_0^1((0,R))$, we now have that

$$u_R(\delta_0) = \int_0^{\delta_0} u_R'(r) dr < 0,$$

contradicting the fact that $u_R \geq 0$ on $(0, R)$. Hence we must have $-k^2 \leq \Lambda_0$, completing the proof. $\square$

Remark 5.3. The proceeding result concerns positive solutions, but the first part of the proof shows that, in fact, (2.15) has no solutions at all in $H\backslash\{0\}$ for $-k^2 < \Lambda_\infty$. By strengthening slightly the assumptions on the dielectric response, arguments similar to those used for planar waveguides in Theorem 3.1 of [10] show that (2.15) may have no solutions in $H\backslash\{0\}$ if $-k^2 > \Lambda_0$. See also Theorems 4.2 and 4.4 in [11] for other nonexistence results of this kind used in a related problem concerning cylindrical waveguides.

RECONSTRUCTION OF A POLYNOMIAL FROM ITS RADON PROJECTIONS*

BORISLAV BOJANOV† AND YUAN XU‡

Abstract. A polynomial of degree n in two variables is shown to be uniquely determined by its Radon projections taken over $[n/2]+1$ parallel lines in each of the $(2[(n+1)/2]+1)$ equidistant directions along the unit circle.

Key words. Radon projection, polynomials of two variables, interpolation

1. Introduction.

Let f be a function defined on the unit disk B^2 on the plane. A Radon projection of f is the integral of f over a line segment inside B^2. More precisely, for any given pair (θ, t) of a real number $t \in [-1,1]$ and any angle θ, let $I(\theta, t)$ denote the line segment inside the unit disk B^2, where the line passes through the point $(t\cos\theta, t\sin\theta)$ and is perpendicular to the vector $(\cos\theta, \sin\theta)$. Then

$$\mathcal{R}_\theta(f;t) := \int_{I(\theta,t)} f(x,y)dxdy \tag{1.1}$$

defines the Radon projection of f on the line segment $I(\theta, t)$.

The Radon transform $f \mapsto \{\mathcal{R}_\theta(f;t)\}$ associates with f a family of univariate functions of t parameterized by θ. The problem of reconstructing f from full or partial knowledge of $\{\mathcal{R}_\theta(f;t)\}$ has been studied by many authors. It plays an essential role in computer tomography. It is well known that the set of Radon projections $\{\mathcal{R}_\theta(f;t) : 0 \le t \le 1,\ 0 \le \theta \le 2\pi\}$ determines f completely. Furthermore, it is known that if f has compact support in B^2, then f is uniquely determined by any infinite set of Radon projections [16]. In practice, however, the data set is usually finite. Thus, the main problem is to obtain a good approximation to the function from a large collection of its Radon projections. See [13] for background and detailed discussions. Using a finite data set, one may determine a polynomial whose Radon projections agree with the given data. Such an approach has been considered in [10, 11, 12] in connection with computer tomography.

The present paper is concerned with the problem of whether a polynomial of degree n in two variables can be uniquely determined from a set of $(n+1)(n+2)/2$ distinct Radon projections. The solution depends on the arrangement of the lines on which the projections are taken. One early solution was given in [12], in which the Radon projections are taken over all possible line segments $[\mathbf{x}_i, \mathbf{x}_j]$ joining $\mathbf{x}_i$ and $\mathbf{x}_j$, where $\mathbf{x}_0, \mathbf{x}_1, \ldots, \mathbf{x}_{n+1}$ are $n+2$ equally spaced points on the boundary of the unit disk

B^2. In [7] (see also [4, 5]), a more general result was proved, in which $\mathbf{x}_0, \mathbf{x}_1, \ldots, \mathbf{x}_{n+1}$ are $n+2$ distinct points on the boundary of a convex set, and the result was extended in [8] to higher dimensions. Recently the problem was considered in [1], in which the lines are taken in $(n+1)$ directions, with one line in the first direction, two lines in the second direction, etc. This set has the drawback of lacking symmetry.

The main result of the present paper shows that a set of Radon projections taken over $2\lfloor n/2 \rfloor + 1$ parallel lines on each of the $2\lfloor (n+1)/2 \rfloor + 1$ equidistant directions can determine a polynomial of degree n uniquely. The set of the corresponding line segments possesses a rotation symmetry. If $n = 2m$ is a fixed positive integer, then our method requires the Radon data in $2m+1$ directions, which are taken to be in equally spaced angles along the unit circle, and in each direction we take $m+1$ parallel lines associated with $t_0, t_1, \ldots, t_m$. We prove that for almost all choices of $\{t_k\}$ a polynomial P_n of degree $n = 2m$ in two variables is uniquely determined by the set of its Radon projections over these line segments; more precisely, for any given f, P_n is uniquely determined such that

$$\mathcal{R}_{\phi_j}(P_n; t_k) = \mathcal{R}_{\phi_j}(f; t_k), \quad 0 \le j \le 2m, \quad 0 \le k \le m. \tag{1.2}$$

A similar construction works for $n = 2m-1$. Several examples of the sets of points $\{t_k\}$ that define regular interpolation are given. Furthermore, the polynomial P_n can be easily computed. Thus, the result appears to offer a simple way to recover a polynomial from its Radon data.

The number of conditions (1.2) is equal to $(n+1)(n+2)/2$, which is the dimension of the space of bivariate polynomials of total degree at most n. Hence, (1.2) can be interpreted as an interpolation problem by polynomials based on line integrals. As in the case of interpolation based on points, this bivariate problem is not always regular. The only general configurations in the literature that hold for every integer n are that of Hakopian [8], mentioned above, and the nonsymmetric configuration given recently in [1]. The result of the present paper provides another family of examples. The proof is based on an observation that recovering polynomials from their Radon projections can be reduced, using a formula in [12], to a family of univariate interpolation problems that uses certain special classes of algebraic polynomials. In the case of [1], the strategy of solving the interpolation problem resembles the approach that uses the Bezout theorem for pointwise interpolation. The approach in the present paper follows the strategy of [2], which uses equally spaced points on circles for pointwise interpolation and allows one to step beyond the limitation of the Bezout theorem.

The paper is organized as follows. In the following section we prove the existence and uniqueness of the reconstructing problem. In section 3 we show how to construct the polynomial and we give an outline of the algorithm.

2. Existence and uniqueness of the solution.

2.1. Preliminary. Let $B^2 = \{(x,y) : x^2 + y^2 \le 1\}$ denote the unit disk on the plane. Let θ be the angle in the polar coordinates

$$x = r\cos\theta, \quad y = r\sin\theta, \qquad r \ge 0, \quad 0 \le \theta \le 2\pi.$$

A line ℓ whose slope is $-\cot\theta$ is defined by the equation

$$\ell(x,y) := x\cos\theta + y\sin\theta - t = 0,$$

where t is a real number. Clearly the line ℓ passes through the point $(t\cos\theta, t\sin\theta)$ and is perpendicular to the vector $\xi = (\cos\theta, \sin\theta)$. Since, for a fixed t, the line corresponding to (θ, t) coincides with the line corresponding to $(\pi + \theta, -t)$, we could assume $\theta \in [0, \pi)$. Alternatively, we could assume that $\theta \in [0, 2\pi)$ and $t \geq 0$.

We will also use ℓ to denote the set of points on the line ℓ and introduce the notation

$$I(\theta, t) = \ell \cap B^2, \qquad 0 \leq \theta < \pi, \quad -1 \leq t \leq 1$$

to denote the line segment of ℓ inside B^2. The points on $I(\theta, t)$ can be represented as

$$x = t\cos\theta - s\sin\theta, \quad y = t\sin\theta + s\cos\theta$$

for $s \in [-\sqrt{1-t^2}, \sqrt{1-t^2}]$.

The Radon projection of a function f in the direction θ with a parameter $t \in [-1, 1]$ is denoted by $\mathcal{R}_\theta(f; t)$,

$$\begin{aligned} \mathcal{R}_\theta(f; t) &:= \int_{I(\theta,t)} f(x, y)\,dxdy \\ &= \int_{-\sqrt{1-t^2}}^{\sqrt{1-t^2}} f(t\cos\theta - s\sin\theta, t\sin\theta + s\cos\theta)\,ds. \end{aligned}$$

In the literature it is also called an X-ray. It is clear that $\mathcal{R}_\theta(f; t) = \mathcal{R}_{\pi+\theta}(f; -t)$, so we can assume, for the sake of definiteness, either $0 \leq \theta < \pi$ or $0 \leq t \leq 1$.

2.2. Polynomial bases. Let Π_n^2 denote the space of polynomials of total degree n in two variables, which has dimension $\dim \Pi_n^2 = (n+1)(n+2)/2$. If $P \in \Pi_n^2$, then

$$P(\mathbf{x}) = \sum_{k=0}^{n} \sum_{j=0}^{k} c_{k,j} x^j y^{k-j}, \qquad \mathbf{x} = (x, y).$$

Let U_k denote the Chebyshev polynomial of the second kind [15],

$$U_k(x) = \frac{\sin(k+1)\theta}{\sin\theta}, \qquad x = \cos\theta.$$

For $\xi = (\cos\theta, \sin\theta)$ and $\mathbf{x} = (x, y)$, the ridge polynomial $U_k(\theta; \cdot)$ is defined by

$$U_k(\theta; \mathbf{x}) := U_k(\langle \mathbf{x}, \xi \rangle) = U_k(x\cos\theta + y\sin\theta).$$

Clearly, U_k is an element of Π_k^2 and it is constant on every line that is perpendicular to ξ. The Radon projection of this function in any direction can be easily computed. This is a result due to Marr [12] and it plays a central role in our discussion below.

LEMMA 2.1. *For each $t \in (-1, 1)$, $0 \leq \theta, \phi \leq 2\pi$,*

$$\mathcal{R}_\phi(U_k(\theta; \cdot); t) = \frac{2}{k+1}\sqrt{1-t^2}\,U_k(t)U_k(\cos(\phi - \theta)).$$

The following useful relation follows easily from Marr's formula [11]:

$$\frac{1}{\pi}\int_{B^2} U_k(\theta; \mathbf{x})U_k(\phi; \mathbf{x})\,d\mathbf{x} = \frac{1}{k+1}U_k(\cos(\phi - \theta)). \tag{2.1}$$

Let $\mathcal{V}_n$ denote the space of orthogonal polynomials of degree n on B^2 with respect to the unit weight function; that is, $P \in \mathcal{V}_n$ if P is of degree n and

$$\int_{B^2} P(\mathbf{x})Q(\mathbf{x})\,d\mathbf{x} = 0 \qquad \text{for all } Q \in \Pi_{n-1}^2.$$

For special choices of θ and ϕ, (2.1) becomes an orthogonal relation. Indeed, for $k \in \mathbb{N}$, let

$$\xi_{j,k} = (\cos\theta_{j,k}, \sin\theta_{j,k}), \qquad \theta_{j,k} := \frac{j\pi}{k+1}, \quad 0 \le j \le k.$$

For fixed k, the points $\cos\theta_{j,k}$, $1 \le j \le k$, are zeros of U_k. The ridge polynomials $U_k(\theta; \mathbf{x})$ have the remarkable orthogonal property that $U_k(\theta; \cdot) \in \mathcal{V}_k$. Since the dimension of $\mathcal{V}_k$ is $k+1$, it follows from (2.1) that the set

$$\mathbb{P}_k := \{U_k(\theta_{j,k}; \mathbf{x}) : 0 \le j \le k\}$$

is a basis for $\mathcal{V}_k$. In particular, this shows that the set $\{\mathbb{P}_k : 0 \le k \le n\}$ is a basis for Π_n^2. Together with Lemma 2.1, this proves the following result.

Lemma 2.2. *Every polynomial $P_n \in \Pi_n^2$ can be written uniquely as*

$$P_n(\mathbf{x}) = \sum_{k=0}^{n} \sum_{j=0}^{k} c_{j,k} U_k(\theta_{j,k}; \mathbf{x}). \tag{2.2}$$

Furthermore, for each ϕ and t,

$$\mathcal{R}_\phi(P_n; t) = \sqrt{1-t^2} \sum_{k=0}^{n} \frac{2}{k+1} U_k(t) \sum_{j=0}^{k} c_{j,k} U_k(\cos(\phi - \theta_{j,k})). \tag{2.3}$$

There are several other explicit orthogonal bases for $\mathcal{V}_n$; see, for example, [6]. If $\{Q_j^k : 0 \le k \le n\}$ is an orthogonal basis of $\mathcal{V}_n$, then, as was shown in [17],

$$U_k(\theta_{j,k}; \mathbf{x}) = \frac{1}{k+1} \sum_{l=0}^{k} Q_l^k(x,y) Q_l^k(\cos\theta_{j,k}, \sin\theta_{j,k}). \tag{2.4}$$

One explicit basis of $\mathcal{V}_n$, denoted by $Q_{j,i}(\mathbf{x})$, is given in terms of polar coordinates as (cf. [6])

$$\begin{aligned} Q_{j,1}(x,y) &= h_{n-2j,1} P_j^{(0,n-2j)}(2r^2-1) r^{n-2j} \cos(n-2j)\theta, \quad 0 \le 2j \le n, \\ Q_{j,2}(x,y) &= h_{n-2j,2} P_j^{(0,n-2j)}(2r^2-1) r^{n-2j} \sin(n-2j)\theta, \quad 0 \le 2j \le n-1, \end{aligned}$$

where $P_j^{(\alpha,\beta)}$ denotes the usual Jacobi polynomial, $h_{0,1} = 1/(n+1)$, and $h_{j,1} = h_{j,2} = 1/(2n+2)$ for $1 \le 2j \le n-1$. Using this basis and restricting $\mathbf{x}$ to the boundary of B^2, (2.4) becomes

$$\begin{aligned} U_{2k}(\cos(\phi - \theta_{j,2k})) &= 1 + 2\sum_{l=1}^{k} \left(\cos 2l\theta_{j,2k} \cos 2l\phi + \sin 2l\theta_{j,2k} \sin 2l\phi\right), \\ U_{2k-1}(\cos(\phi - \theta_{j,2k-1})) &= 2\sum_{l=1}^{k} \left(\cos(2l-1)\theta_{j,2k-1} \cos(2l-1)\phi \right. \\ &\qquad\qquad \left. + \sin(2l-1)\theta_{j,2k-1} \sin(2l-1)\phi\right). \end{aligned} \tag{2.5}$$

The above equations also follow from the elementary trigonometric identities

$$1 + 2\sum_{j=1}^{k} \cos 2j\theta = \frac{\sin(2k+1)\theta}{\sin\theta} \quad \text{and} \quad 2\sum_{j=1}^{k} \cos(2j-1)\theta = \frac{\sin 2k\theta}{\sin\theta}$$

with θ replaced by $\phi - \theta_{j,2k}$ and $\phi - \theta_{j,2k-1}$, respectively. These relations allow us to rewrite (2.3) in a form that is easier to work with. In the following we use $\lfloor x \rfloor$ to denote the integer part of x.

LEMMA 2.3. *Let P_n be given as in* (2.2). *Then*

$$\frac{\mathcal{R}_\phi(P_n;t)}{\sqrt{1-t^2}} = \sum_{l=0}^{\lfloor n/2 \rfloor} U_{2l}(t)\left[a_{0,2l} + 2\sum_{j=1}^{l}(a_{j,2l}\cos 2j\phi + b_{j,2l}\sin 2j\phi)\right] + \sum_{l=1}^{\lfloor (n+1)/2 \rfloor} U_{2l-1}(t)\left[2\sum_{j=1}^{l}(a_{j,2l-1}\cos(2j-1)\phi + b_{j,2l-1}\sin(2j-1)\phi)\right], \tag{2.6}$$

in which the coefficients $c_{j,k}$ in (2.2) *and $a_{j,k}$, $b_{j,k}$ are related by*

$$c_{j,2l} = \frac{1}{2}a_{0,2l} + \sum_{k=1}^{l}(a_{k,2l}\cos 2k\theta_{j,2l} + b_{k,2l}\sin 2k\theta_{j,2l}) \tag{2.7}$$

for $0 \le j \le 2l$, $0 \le l \le \lfloor n/2 \rfloor$, and

$$c_{j,2l-1} = \sum_{k=1}^{l}(a_{k,2l-1}\cos(2k-1)\theta_{j,2l-1} + b_{k,2l-1}\sin(2k-1)\theta_{j,2l-1}) \tag{2.8}$$

for $0 \le j \le 2l-1$, $1 \le l \le \lfloor (n+1)/2 \rfloor$.

Proof. We prove only the case of $n = 2m$. Comparing (2.3) and (2.6) shows that

$$\frac{1}{2l+1}\sum_{j=0}^{2l} c_{j,2l}U_{2l}(\cos(\phi - \theta_{j,2l})) = \frac{1}{2}a_{0,2l} + \sum_{j=1}^{l}(a_{j,2l}\cos 2j\phi + b_{j,2l}\sin 2j\phi),$$

$$\frac{1}{2l}\sum_{j=0}^{2l-1} c_{j,2l-1}U_{2l-1}(\cos(\phi - \theta_{j,2l-1})) = \sum_{j=1}^{l}(a_{j,2l-1}\cos(2j-1)\phi + b_{j,2l-1}\sin(2j-1)\phi).$$

Using (2.5) we can rewrite the left-hand side in the form of the right-hand side, which leads to

$$a_{j,2l} = \frac{2}{2l+1}\sum_{k=0}^{2l} c_{k,2l}\cos 2j\theta_{k,2l}, \qquad b_{j,2l} = \frac{2}{2l+1}\sum_{k=0}^{2l} c_{k,2l}\sin 2j\theta_{k,2l}$$

for $1 \le j \le l$, and $2a_{0,2l}$ satisfies the above formula with $j = 0$, and

$$a_{j,2l-1} = \frac{1}{l}\sum_{k=0}^{2l-1} c_{k,2l-1}\cos(2j-1)\theta_{k,2l-1},$$
$$b_{j,2l-1} = \frac{1}{l}\sum_{k=0}^{2l-1} c_{k,2l-1}\sin(2j-1)\theta_{k,2l-1}$$

for $1 \le j \le l$. For fixed l, the above linear relations can be written in the matrix form. After a proper normalization, the coefficient matrix turns out to be an orthogonal matrix. For example, for the even indices, we have

$$\frac{1}{\sqrt{2l+1}}\begin{bmatrix} 1 & 1 & \cdots & 1 \\ \sqrt{2} & \sqrt{2}\cos\frac{2\pi}{2l+1} & \cdots & \sqrt{2}\cos\frac{2l\pi}{2l+1} \\ 0 & \sqrt{2}\sin\frac{2\pi}{2l+1} & \cdots & \sqrt{2}\sin\frac{2l\pi}{2l+1} \\ \vdots & \vdots & \cdots & \vdots \\ \sqrt{2} & \sqrt{2}\cos 2l\frac{2\pi}{2l+1} & \cdots & \sqrt{2}\cos 2l\frac{2l\pi}{2l+1} \\ 0 & \sqrt{2}\sin 2l\frac{2\pi}{2l+1} & \cdots & \sqrt{2}\sin 2l\frac{2l\pi}{2l+1} \end{bmatrix} \cdot \begin{bmatrix} c_{0,2l} \\ c_{1,2l} \\ \vdots \\ c_{2l,2l} \end{bmatrix} = \frac{1}{\sqrt{2l+1}}\begin{bmatrix} a_{0,2l} \\ \frac{a_{1,2l}}{\sqrt{2}} \\ \frac{b_{1,2l}}{\sqrt{2}} \\ \vdots \\ \frac{a_{l,2l}}{\sqrt{2}} \\ \frac{b_{l,2l}}{\sqrt{2}} \end{bmatrix}.$$

The $(l+1)\times(l+1)$ matrix in the left-hand side, including the factor $1/\sqrt{2l+1}$, is orthogonal. Hence, the linear system of equations can be easily reversed, which leads to the stated relations, (2.7) and (2.8). The formulas can also be verified directly by inserting (2.7) and (2.8) into the equations of $a_{j,k}$ and $b_{j,k}$ and using the well-known trigonometric identities

$$\frac{1}{m+1}\sum_{k=0}^{m}\cos 2j\theta_{k,m} + i\frac{1}{m+1}\sum_{k=0}^{m}\sin 2j\theta_{k,m} = \frac{1}{m+1}\sum_{k=0}^{m} e^{2ij\theta_{k,m}} = \delta_{0,j}$$

for $0 \le j \le m$, where $\delta_{0,j} = 1$ if $j \ne 0$ and $\delta_{0,j} = 0$ otherwise, and using the elementary trigonometric identities $2\cos\theta\cos\phi = \cos(\theta+\phi)+\cos(\theta-\phi)$. ∎

To reconstruct the polynomial, we will determine the coefficients $a_{j,k}$ and $b_{j,k}$ and use them in (2.7) and (2.8) to determine $c_{j,k}$ in (2.2). The following representation is useful.

LEMMA 2.4. *Let $n = 2m$ or $n = 2m-1$. Let P_n be given as in* (2.2). *Then*

$$\frac{\mathcal{R}_\phi(P_n;t)}{\sqrt{1-t^2}} = A_0(t) + \sum_{j=1}^{n}\left[A_j(t)\cos j\phi + B_j(t)\sin j\phi\right], \tag{2.9}$$

where

$$A_0(t) = \sum_{l=0}^{\lfloor n/2\rfloor} a_{0,2l}U_{2l}(t),$$

and for $1 \le j \le m$,

$$A_{2j}(t) = 2\sum_{l=j}^{\lfloor n/2\rfloor} a_{j,2l}U_{2l}(t), \qquad B_{2j}(t) = 2\sum_{l=j}^{\lfloor n/2\rfloor} b_{j,2l}U_{2l}(t), \tag{2.10}$$

$$A_{2j-1}(t) = 2\sum_{l=j}^{\lfloor n/2\rfloor} a_{j,2l-1}U_{2l-1}(t), \qquad B_{2j-1}(t) = 2\sum_{l=j}^{\lfloor n/2\rfloor} b_{j,2l-1}U_{2l-1}(t). \tag{2.11}$$

Proof. The proof is obtained from changing the order of summations in (2.6). ∎

2.3. Existence and uniqueness of the solution. We now state the Radon projections from which the polynomial P_n can be uniquely recovered. These are given by

$$\mathcal{R}_{\phi_{j,m}}(P_n;t_k), \qquad 0 \le k \le \lfloor n/2\rfloor, \quad 0 \le j \le 2m, \quad m = \lfloor (n+1)/2\rfloor, \tag{2.12}$$

which has a total of $(\lfloor n/2 \rfloor + 1)(2\lfloor (n+1)/2 \rfloor + 1) = (n+1)(n+2)/2$ projections, which is the same as the dimension of Π_n^2. The angles are chosen to be equidistant,

$$\Theta_m := \left\{ \phi_{j,m} = \frac{2j\pi}{2m+1} : \quad 0 \le j \le 2m \right\}. \tag{2.13}$$

The reason that we choose the equidistant angles lies in the lemma below, which plays a key role in our study. Such a lemma appeared first in [2] and has been used in [3] and [18].

LEMMA 2.5. *For $\phi \in \Theta_m$ and $P_n \in \Pi_n^2$ with $n = 2m$ or $n = 2m-1$,*

$$\frac{\mathcal{R}_\phi(P_n;t)}{\sqrt{1-t^2}} = A_0(t)$$
$$+ \sum_{j=1}^{m} \left[\big(A_j(t) + A_{2m-j+1}(t)\big) \cos j\phi + \big(B_j(t) - B_{2m-j+1}(t)\big) \sin j\phi \right],$$

where we assume that $A_{2m} = B_{2m} = 0$ if $n = 2m-1$.

Proof. Using the expression in the previous lemma, the proof follows from the fact that

$$\cos(2m-j+1)\phi = \cos j\phi \quad \text{and} \quad \sin(2m-j+1)\phi = -\sin j\phi$$

for $\phi \in \Theta_m$. $\square$

For the expression in this lemma, the variable t is in $(-1,1)$. We can also state the result for $\phi \in \widetilde{\Theta}_m = \{(2j+1)\pi/(2m+1) : 0 \le j \le 2m\}$, for which the sign before A_{2m-j+1} and B_{2m-j+1} will be reversed. It is easy to see that $\widetilde{\Theta}_m = \Theta_m + \pi$ modulus 2π. The two expressions are consistent with the fact that $\mathcal{R}_\theta(f;t) = \mathcal{R}_{\pi+\theta}(f;-t)$.

We are now ready to prove our main result, which shows that the polynomial P_n can be uniquely determined by the data (2.12). We need the following function classes: For $n = 2m$ define

$$X_j(t) = \{U_{2m}(t), U_{2m-2}(t), \ldots, U_{2j}(t), U_{2m-1}(t), U_{2m-3}(t), \ldots, U_{2m-2j+1}(t)\}$$

for $1 \le j \le m-1$. We also consider X_j as a column vector in $\mathbb{R}^{m+1}$ and regard

$$\Xi_j(\mathbf{t}) = [X_j(t_0), X_j(t_1), \ldots, X_j(t_m)]$$

as an $(m+1) \times (m+1)$ matrix.

A set of points $\mathbf{t} = \{t_0, t_1, \ldots, t_m\}$ in $(-1,1)$ is said to be asymmetric if t and $-t$ do not both belong to $\mathbf{t}$.

THEOREM 2.1. *Let $\mathbf{t} := \{t_0, t_1, \ldots, t_m\}$ be a set of asymmetric distinct points in $(-1,1)$ such that the matrices $\Xi_1(\mathbf{t}), \Xi_2(\mathbf{t}), \ldots, \Xi_{m-1}(\mathbf{t})$ are all nonsingular; then the polynomial $P \in \Pi_{2m}^2$ is uniquely determined by the set (2.12) of its Radon projections.*

Proof. In order to prove that there is a unique solution, it is sufficient to show that if $\mathcal{R}_{\phi_{j,m}}(P;t_k) = 0$ for $0 \le j \le 2m$ and $0 \le k \le m$, then $P(\mathbf{x}) \equiv 0$.

Setting its left-hand side to zero, the expression in Lemma 2.5 shows that

$$A_0(t_k) + \sum_{j=1}^{m} \left[\big(A_j(t_k) + A_{2m-j+1}(t_k)\big) \cos j\phi + \big(B_j(t_k) - B_{2m-j+1}(t_k)\big) \sin j\phi \right] = 0$$

for $0 \le k \le m$ and $\phi \in \Theta_m$. The left-hand side is a trigonometric polynomial of degree m and it vanishes on $2m+1$ points. Hence, it follows from the uniqueness of the trigonometric interpolation that the coefficients have to be zero, that is,

$$
\begin{aligned}
(2.14)\qquad A_0(t_k) = 0, \qquad & A_j(t_k) + A_{2m-j+1}(t_k) = 0, \\
& B_j(t_k) - B_{2m-j+1}(t_k) = 0, \qquad 1 \le j \le m
\end{aligned}
$$

for $0 \le k \le m$. Since A_j and A_{2m-j+1} have different parities, the coefficients in $A_j(t) + A_{2m-j+1}(t)$ will not combine, and there are exactly $m+1$ terms in this polynomial, which are written as a linear combination of the Chebyshev polynomials $\{U_k\}$. Let $Y_0(t) = \{U_{2m}(t), U_{2m-2}(t), \dots, U_2(t), U_0(t)\}$ and let

$$
\begin{aligned}
Y_{2j}(t) &= \{U_{2m}(t), U_{2m-2}(t), \dots, U_{2j}(t), U_{2m-1}(t), U_{2m-3}(t), \dots, U_{2m-2j+1}(t)\}, \\
Y_{2j-1}(t) &= \{U_{2m-1}(t), U_{2m-3}(t), \dots, U_{2j+1}(t), U_{2m}(t), U_{2m-2}(t), \dots, U_{2m-2j}(t)\}.
\end{aligned}
$$

Furthermore, let Ξ_{Y_j} denote the matrix $\Xi_{Y_j} = [Y_j(t_0), Y_j(t_1), \dots, Y_j(t_m)]$. The coefficients of the linear systems of equations in (2.14) are Ξ_{Y_0}, $\Xi_{Y_{2j}}$ for $1 \le j \le m/2$, and $\Xi_{Y_{2j-1}}$ for $1 \le j \le (m+1)/2$. Hence, in order to prove that (2.14) implies $A_0(t) \equiv 0$, $A_j(t) = B_j(t) \equiv 0$ for $1 \le j \le m$, we need to show that these matrices are all invertible. However, it is easy to see that we have the relation $\Xi_{Y_{2(m-j)-1}} = \Xi_{Y_{2j}}$, which shows, in particular, that $\Xi_{Y_m} = \Xi_{Y_{m-1}}$. Thus, we can deal with $\Xi_{Y_{2j}}$ for $0 \le j \le m-1$. Furthermore, Y_0 contains only even polynomials U_{2l}, $0 \le l \le m$. Using the notation $s = t^2$, it follows that $U_{2l}(\sqrt{s})$ is a polynomial of degree l so that the matrix Ξ_{Y_0} is always invertible as $\mathbf{t}$ is a set of asymmetric distinct points. Thus, since $\Xi_{Y_{2j}} = \Xi_j(\mathbf{t})$, our assumption on $\mathbf{t}$ implies that all matrices are invertible. $\square$

A similar theorem holds in the case of $n = 2m-1$. First, we need to define for $n = 2m-1$,

$$
X_j(t) = \{U_{2m-2}(t), U_{2m-4}(t), \dots, U_{2j}(t), U_{2m-1}(t), U_{2m-3}(t), \dots, U_{2m-2j+1}(t)\}
$$

for $1 \le j \le m-1$ and

$$
X_m(t) = \{U_{2m-1}(t), U_{2m-3}(t), \dots, U_3(t), U_1(t)\}.
$$

We will keep the notion $\Xi_j(\mathbf{t})$ for the matrix built upon from the columns of X_j, which is an $m \times m$ matrix.

THEOREM 2.6. *Let $\mathbf{t} = \{t_0, t_1, \dots, t_{m-1}\}$ be a set of asymmetric distinct points in $(-1,0) \cup (0,1)$ such that the matrices $\Xi_1(\mathbf{t}), \Xi_2(\mathbf{t}), \dots, \Xi_m(\mathbf{t})$ are all nonsingular. Then the polynomial $P \in \Pi^2_{2m-1}$ is uniquely determined by the set* (2.12) *of its Radon projections.*

That the points $t_0, t_1, \dots, t_m$ are all in $(-1,0) \cup (0,1)$ means that none of the points can be zero. In fact, since U_{2k-1} is an odd polynomial, $\Xi_m(\mathbf{t})$ contains only odd polynomials, which vanish at the origin. Otherwise, the proof of this theorem is similar to that of the previous theorem. In the case of $n = 2m$, the set $X_0 = \{U_{2m}, U_{2m-2}, \dots, U_0\}$ does not appear in the conditions of the theorem since the interpolation at distinct points in $[0,1)$ by X_0 is always regular. Such a reduction of conditions does not appears to happen for $n = 2m-1$.

For each fixed j, the determinant of $\Xi_j(\mathbf{t})$ can be considered as a polynomial function in $\mathbf{t} = (t_0, t_1, \dots, t_m)$ so that $\det \Xi_j(\mathbf{t}) = 0$ defines a hypersurface of dimension m. Hence, the determinant is not zero for almost all choices of $\mathbf{t} \in \mathbb{R}^{m+1}$. Evidently, the same holds true for $m+1$ matrices. Hence, we have the following corollary.

COROLLARY 2.7. *For $n = 2m$ or $2m-1$, and for almost all choices of distinct points $t_0, t_1, \dots, t_m$ in $(-1,1)$ for $n = 2m$ or in $(-1,0) \cup (0,1)$ for $n = 2m-1$, the polynomial $P_n \in \Pi^2_n$ is uniquely determined by the set* (2.12) *of its Radon projections.*

2.4. Choices of . We have shown that almost all choices of $\mathbf{t} = \{t_0, t_1, \ldots, t_m\}$ will lead to the unique solution of recovering the polynomial. One may ask if *any* choice of $\mathbf{t} \subset (-1,1)^{m+1}$ will work. The answer, however, is negative, as the following example shows.

Example: $m = 2$. By Theorem 2.1 we have only to choose t_0, t_1, t_2 in $(0,1)$ such that the set $X_2 = \{U_2, U_3, U_4\}$ has nonsingular determinant $\Xi_2(\mathbf{t})$. Recall that

$$U_2(t) = 4t^2 - 1, \quad U_3(t) = 8t^3 - 4t, \quad U_4(t) = 16t^4 - 12t^2 + 1.$$

We can compute the determinant $\Xi_2(\mathbf{t})$ explicitly, and the result is

$$\det \Xi_2(\mathbf{t}) = 32 \prod_{1 \le i < j \le 3} (t_i - t_j)$$
$$\times \left[8t_1^2t_2^2t_3^2 + 4t_1t_2t_3(t_1+t_2+t_3) + (2t_1^2-1)(2t_2^2-1)(2t_3^2-1)\right].$$

Since $t_i \in (0,1)$, the first two terms in the square brackets are positive, while the third term could be negative. This shows, in particular, that $\det \Xi_2(\mathbf{t}) \ne 0$ if one of the t_i's is $\sqrt{2}/2$, or if two of t_1, t_2, t_3 are less than $\sqrt{2}/2$ and one is greater than $\sqrt{2}/2$. However, $\det \Xi_2(\mathbf{t})$ can be zero for some choices of t_0, t_1, t_2.

On the positive side, we give two results that provide sets of points that will ensure the uniqueness of the reconstruction. The first result uses the following theorem due to Obrechkoff [14].

Lemma 2.8. *Let $d\mu$ be a nonnegative weight function on an interval and let $P_0, P_1, P_2, \ldots$ be the orthogonal polynomials with respect to $d\mu$. Denote by α_n the largest zero of P_n. Then the number of zeros of the polynomial $a_0P_0 + a_1P_2 + \cdots + a_nP_n$, where $a_0, a_1, \ldots, a_n$ are real numbers, in the interval $(\alpha_n, +\infty)$ is at most the number of sign changes in the sequence of the coefficients $a_0, a_1, \ldots, a_n$.*

The Chebyshev polynomials $U_0, U_1, U_2, \ldots$ are orthogonal with respect to the weight function $\sqrt{1-x^2}$ on $[-1,1]$ so that the above lemma implies the following.

Proposition 2.9. *Let $\mathbf{t} = \{t_0, t_1, \ldots, t_m\}$ be a set of numbers that satisfies*

$$\cos\frac{\pi}{2m+1} < t_0 < t_1 < \cdots < t_m < 1. \tag{2.15}$$

Then the matrices $\Xi_1(\mathbf{t}), \ldots, \Xi_{m-1}(\mathbf{t})$ are all nonsingular.

Proof. If one of the matrices, say $\Xi_j(\mathbf{t})$, were singular, there would be a nonzero polynomial $P \in \operatorname{span} X_j$ that vanishes on $\mathbf{t}$. This means that the number of zeros of P in (α_n, ∞) would be $m+1$. However, each set Ξ_j has cardinality $m+1$ so that the number of sign changes in the sequence of the coefficients of P is at most m. This is a contradiction to the conclusion of the lemma. ∎

The set of points given in this proposition ensures the uniqueness of determining a polynomial by the set of its Radon projections. Condition (2.15) implies that all points are clustered toward one end of the interval $[-1,1]$. This appears to be neither a practical nor a good choice for computation. In fact, the numerical test indicates that some of the matrices Ξ_j tend to have very large condition numbers.

Our second positive result is more interesting. Here the points $\{t_k\}$ are based on the zeros of the Chebyshev polynomials U_{2m}. It is well known that these zeros are given by

$$\eta_{j,2m} := \cos\frac{j\pi}{2m+1}, \qquad j = 1, 2, \ldots, 2m.$$

We state the result for $n = 2m$ first.

THEOREM 2.10. *Let t_0 be any point in $(-1, 1)$ such that $U_{2m}(t_0) \neq 0$. Let $t_j = \eta_{2j,2m}$ for $j = 1, 2, \ldots, m$. Then the matrices $\Xi_1(\mathbf{t}), \Xi_2(\mathbf{t}), \ldots, \Xi_{m-1}(\mathbf{t})$ in Theorem 2.1 are all nonsingular. Consequently, the polynomial $P \in \Pi^2_{2m}$ is uniquely determined by the set (2.12) of its Radon projection.*

Proof. It is easy to see that the set $\mathbf{t}$ is asymmetric. Hence, according to Theorem 2.1, we need only show that $\Xi_j(\mathbf{t})$ is invertible for each $j = 1, 2, \ldots, m-1$. Using the explicit expression of $U_{2m}(t)$, it is easy to see that

$$U_{2m-2j}(t_k) = U_{2m-2j}(\eta_{2k,2m}) = -U_{2j-1}(\eta_{2k,2m}) = -U_{2j-1}(t_k). \tag{2.16}$$

Indeed, since $\sin(2m+1)\eta_{2k,2m} = 0$ and $\cos(2m+1)\eta_{2k,2m} = 1$, it follows from the addition formula that $\sin(2m-2j+1)\eta_{2k,2m} = -\sin 2j\eta_{2k,2m}$, from which the equation follows.

Since $U_{2m}(t_1) = \cdots = U_{2m}(t_m) = 0$, we evidently have

$$\det \Xi_j(\mathbf{t}) = U_{2m}(t_0) \det \widetilde{\Xi}_j(\mathbf{t}),$$

where $\widetilde{\Xi}_j(\mathbf{t})$ is a submatrix of $\Xi_j(\mathbf{t})$ with the column $X_j(t_0)$ and the row containing $U_{2m}(t_j)$ of $\Xi_j(\mathbf{t})$ removed. Using (2.16), we can replace all rows of $\widetilde{\Xi}_j(\mathbf{t})$ that contain even Chebyshev polynomials with rows that contain odd Chebyshev polynomials. More precisely, we replace the rows $(U_{2i}(t_1), \ldots, U_{2i}(t_m))$ for $i = j, j+1, \ldots, m-1$ with rows $(U_{2m-2i-1}(t_1), \ldots, U_{2m-2i-1}(t_m))$, respectively. The new matrix has all elements given in terms of the Chebyshev polynomials of the odd degree; hence,

$$\det \widehat{\Xi}_j(\mathbf{t}) = \varepsilon \det(U_{2i-1}(t_k))_{i=1,k=1}^{m,\ m},$$

where $\varepsilon = \pm 1$. Assume now that this determinant is zero. Then there exists a nonzero polynomial Q of the form

$$Q(x) = \sum_{i=1}^{m} b_i U_{2i-1}(x),$$

which vanishes at $t_1, \ldots, t_m$. Since Q is odd, it vanishes also at $-t_1, \ldots, -t_m$. Observe that the sets $(-t_1, \ldots, -t_m)$ and $(t_1, \ldots, t_m)$ do not overlap. We conclude that the polynomial Q of degree $2m-1$ vanishes at $2m$ distinct points and, consequently, it vanishes identically, which is a contradiction. □

A similar theorem holds for $n = 2m-1$, which we state below.

THEOREM 2.11. *Let $t_j = \eta_{2j,2m}$ for $j = 1, 2, \ldots, m$. Then the matrices $\Xi_1(\mathbf{t})$, $\Xi_2(\mathbf{t}), \ldots, \Xi_m(\mathbf{t})$ in Theorem 2.6 are all nonsingular. Consequently, the polynomial $P \in \Pi^2_{2m-1}$ is uniquely determined by the set (2.12) of its Radon projection.*

The proof is similar to that of Theorem 2.10 and uses

$$U_{2m-2j}(\eta_{2k-1,2m}) = U_{2j-1}(\eta_{2k-1,2m}),$$

which can be verified using elementary trigonometric identities.

We have conducted some numerical tests for identifying other sets of t_k, for which the matrices $\Xi_1(\mathbf{t}), \ldots, \Xi_{m-1}(\mathbf{t})$ are nonsingular, so that the reconstruction of a polynomial from the set (2.12) of its Radon projections is unique. For $n \leq 20$, it turns out that both the equidistant points in $(0, 1)$ and the Chebyshev points in $(0, 1)$ work out. See, however, the discussion at the end of the next section.

3. Reconstruction of polynomials. In this section we set up the algorithm that can be used to compute P_n from the Radon projections. We consider only the case $n = 2m$. Let $\gamma_{j,k}$ be the data

$$\gamma_{j,k} = \mathcal{R}_{\phi_j}(f; t_k) \Big/ \sqrt{1 - t_k^2}, \qquad 0 \le j \le 2m, \quad 0 \le k \le m, \tag{3.1}$$

where $\phi_{j,m}$ are given as in (2.13) and t_k are distinct numbers in $[0, 1)$, chosen in advance, such that the linear systems of equations (3.2) and (3.3) below have unique solutions for all j.

Recall that the Lagrange interpolation by trigonometric polynomials is used in the proof of Theorem 2.1. The Lagrange interpolation based on the points in (2.13) is given explicitly by (see, for example, [19])

$$L_n f(\phi) = \sum_{j=0}^{2m} f(\phi_{j,m}) \ell_j(\phi), \qquad \ell_j(\phi) = \frac{\sin(m + \frac{1}{2})(\phi - \phi_{j,m})}{(2m + 1) \sin \frac{1}{2}(\phi - \phi_{j,m})},$$

where we assume that f is the function being interpolated; that is, $L_n f(\phi_{j,m}) = f(\phi_{j,m})$ for $0 \le j \le 2m$. Using the well-known formula

$$1 + 2\cos\phi + \cdots + 2\cos m\phi = \frac{\sin(m + \frac{1}{2})\phi}{\sin \frac{\phi}{2}},$$

we can write $L_n f$ in the standard form of a trigonometric polynomial,

$$L_n f(\phi) = m_0(f) + 2 \sum_{j=1} \left(m_j^C(f) \cos j\phi + m_j^S(f) \sin j\phi \right),$$

where

$$m_j^C(f) = \frac{1}{2m + 1} \sum_{l=0}^{2m} f(\phi_{l,m}) \cos j\phi_{l,m},$$
$$m_j^S(f) = \frac{1}{2m + 1} \sum_{l=0}^{2m} f(\phi_{l,m}) \sin j\phi_{l,m}.$$

For each k, $0 \le k \le m$, we will use the above formulas with $f(\phi_{j,m}) = \gamma_{j,k}$ and write $m_{j,k}^C = m_j^C(f)$ and $m_{j,k}^S = m_j^S(f)$ for this particular f. This will allow us to determine the values $A_0(t_k)$, $A_j(t_k) + A_{2m-j+1}(t_k)$, and $B_j(t_k) - B_{2m-j+1}(t_k)$ for $1 \le j \le m$.

The next step is to fix j and use the values of $A_0(t_k)$, or $A_j(t_k) + A_{2m-j+1}(t_k)$, or $B_j(t_k) - B_{2m-j+1}(t_k)$ for $k = 0, 1, \ldots, m$ to determine the coefficients of A_j and B_j. For this purpose we consider the following linear systems of equations: For $1 \le j \le m/2$,

$$\sum_{l=j}^{m} d_{j,2l} U_{2l}(t_k) + \sum_{l=m-j+1}^{m} d_{m-j+1,2l} U_{2l-1}(t_k) = m_{2j,k}, \quad 0 \le k \le m, \tag{3.2}$$

and for $1 \le j \le (m + 1)/2$,

$$\sum_{l=j}^{m} d_{j,2l-1} U_{2l-1}(t_k) + \sum_{l=m-j+1}^{m} d_{m-j+1,2l} U_{2l}(t_k) = m_{2j-1,k}, \quad 0 \le k \le m. \tag{3.3}$$

The quantities $m_{j,k}$ will be specified later. It is easy to see that the coefficient matrix of these systems of equations is Ξ_j as in Theorem 2.1. There are a total of m systems of linear equations, each of size $(m+1)\times(m+1)$. Solving these equations with proper $m_{j,k}$ will determine the coefficients of A_j and B_j.

The last step is to use (2.7) and (2.8) to get $c_{j,k}$, which are the coefficients of P_n in (2.2).

ALGORITHM.

Step 1. For $1 \le l \le m$ and $0 \le k \le m$, compute

$$m^C_{l,k} = \frac{1}{2m+1}\sum_{j=0}^{2m}\gamma_{j,k}\cos l\theta_j \qquad \text{and} \qquad m^S_{l,k} = \frac{1}{2m+1}\sum_{j=0}^{2m}\gamma_{j,k}\sin l\theta_j. \tag{3.4}$$

Step 2. Solve the systems of equations (3.2) and (3.3) to get the coefficients $a_{j,k}$ and $b_{k,j}$ in (2.6):

Case 1. Solve the m systems of (3.2) and (3.3) for $m_{j,k} = m^C_{j,k}$ to get

$$a_{j,k} := d_{j,k}, \qquad 1 \le j \le m, \quad 0 \le k \le 2m.$$

Case 2. Solve the m systems of (3.2) and (3.3) for $m_{j,k} = m^S_{j,k}$ to get

$$b_{j,2l} := d_{j,2l}, \quad 1 \le j \le m/2 \quad \text{and} \quad b_{j,2l} := -d_{j,2l}, \quad \frac{m+2}{2} \le j \le m,$$
$$b_{j,2l-1} := d_{j,2l-1}, \quad 1 \le j \le \frac{m+1}{2} \quad \text{and} \quad b_{j,2l-1} := -d_{j,2l-1}, \quad \frac{m+1}{2} \le j \le m,$$

where $1 \le l \le m$.

Step 3. Substitute the outputs $a_{j,k}$ and $b_{j,k}$ from Step 2 into (2.7) and (2.8) to get $c_{j,k}$. Then the polynomial P is given by (2.2).

The output of this algorithm is the polynomial P that satisfies (1.2). The main computation appears to be Step 2. Initial numerical experiments indicate that the linear systems of equations (3.2) and (3.3) are ill-conditioned. However, among the set of points that we tested, the largest condition number of the matrices corresponding to the equidistant points $t_k = (k+1)/(m+2)$, $0 \le k \le m$ of $(0,1)$ is smaller than that corresponding to the Chebyshev points $t_k = \cos(k+1)\pi/(2m+4)$, $0 \le k \le m$, or the points in Theorem 2.10.

As pointed out by a referee, it is perhaps not surprising that the matrices of the linear systems (3.2) and (3.3) are ill-conditioned. Solving these linear systems means inverting the Radon transform while it is known that the Radon reconstruction problem is ill posed. Thus, for m large, the algorithm may not be useful for practical computation. On the other hand, our result shows that it is possible to determine a polynomial of degree n uniquely from a set of $(n+1)(n+2)/2$ Radon data that concurs with the parallel geometry. This appears to be of independent interest.

GLOBAL ATTRACTORS AND STEADY STATES FOR UNIFORMLY PERSISTENT DYNAMICAL SYSTEMS*

PIERRE MAGAL† AND XIAO-QIANG ZHAO‡

Abstract. By appealing to the theory of global attractors on complete metric spaces, we obtain weaker sufficient conditions for the existence of interior global attractors for uniformly persistent dynamical systems, and hence generalize the earlier results on coexistence steady states. We also provide examples to show applicability of our interior fixed point theorem in the case of convex κ-contracting maps, and to prove the existence of discrete- and continuous-time dynamical systems that admit global attractors, but no strong global attractors, which gives an affirmative answer to an open question presented by Sell and You [*Dynamics of Evolutionary Equations*, Springer-Verlag, New York, 2002] in the case of continuous-time semiflows.

Key words. uniform persistence, global attractors, steady states

1. Introduction.

Uniform persistence is an important concept in population dynamics since it characterizes the long-term survival of some or all interacting species in an ecosystem. There have been extensive investigations on uniform persistence for discrete- and continuous-time dynamical systems. We refer to [13, 27, 30] for surveys and reviews. Looked at abstractly, uniform persistence is the notion that a closed subset of the state space (e.g., the set of extinction for one or more populations) is repelling for the dynamics on the complementary set. A natural question concerns the existence of "interior" global attractors and "coexistence" steady states for uniformly persistent dynamical systems. The existence of interior global attractors was addressed by Hale and Waltman [10], and the existence of coexistence steady states under a general setting was investigated by Zhao [29]. In [10, 29] the traditional concept of global attractors was employed: a global attractor is a compact, invariant set which attracts every bounded set in the phase space (see, e.g., Hale [7], Temam [24], and Raugel [20]).

Recently, the following weaker concept of global attractors was introduced by Hirsch, Smith, and Zhao [11] and Sell and You [22]: a global attractor is a compact, invariant set which attracts some neighborhood of itself and every point in the phase space. For convenience, we refer to a traditional global attractor as a strong global attractor. With the concept of strong global attractor, Zhao [29, Theorem 2.3] assumed more conditions than necessary for the existence of a coexistence fixed point. However, the proof of [29, Theorem 2.3] needs only the property that the interior attractor attracts every compact set, and hence actually implies a general fixed point theorem that, if a continuous and κ-condensing map T has an interior global attractor, then it has a coexistence fixed point (see Theorem 4.1). So an important problem is to obtain sufficient conditions for the existence of interior global attractors for uniformly

persistent dynamical systems. This is a nontrivial problem since the phase space M_0 is an open subset of a complete metric space (M, d).

The main purpose of this paper is to establish the existence of the interior global attractor (i.e., the global attractor for $T : (M_0, d) \to (M_0, d)$) and a fixed point in M_0.

There is the following open question on the weaker concept of global attractor (see pages 55 and 56 of [22]): Does there exist an example of a κ-contracting semiflow that is point dissipative on a complete metric space W in which the global attractor does not attract every bounded set in W? In other words, we expect to find a dynamical system which has a global attractor, but no strong global attractor. In the case of discrete-time semiflows (i.e., maps), such a question has already been answered positively by Cholewa and Hale [4] (see also Raugel [20]) who developed an original result of Cooperman [5] and introduced an appropriate κ-contraction map on the Hilbert space of square summable series. As a byproduct of our investigations on interior global attractors, we will provide examples of both discrete- and continuous-time semiflows to give an affirmative answer to Sell and You's question (see sections 5.2 and 5.3). It is worth pointing out that our continuous-time dynamical systems are solution semiflows associated with a class of evolutionary equations with age structure.

It is obvious that we should start with the development of the theory of strong global attractors into that of global attractors on complete metric spaces. Note that the metric space (M_0, d) is not complete since M_0 is an open subset of the complete metric space (M, d). In order to apply the theory of global attractors to $T : (M_0, d) \to (M_0, d)$, we introduce a new metric $d_0(x, y)$ on M_0 (see equation (2) for its definition) so that (M_0, d_0) is a complete metric space. It turns out that the strongly bounded sets introduced in [10] correspond to the bounded sets in (M_0, d_0). This metric function $d_0(x, y)$ is the key tool for both the existence of a global attractor for $T : (M_0, d) \to (M_0, d)$ and four counterexamples of dynamical systems on the complete metric space (M_0, d_0). The theory of global attractors was already developed for continuous-time semiflows in the book [22], where the concept of κ-contracting maps was introduced (i.e., for each bounded set $B \subset M$, $\kappa(T^n(B)) \to 0$ as $n \to +\infty$). It seems that this strong notion may not be applied to $T : (M_0, d_0) \to (M_0, d_0)$. In fact, if $T : (M_0, d_0) \to (M_0, d_0)$ is κ-contracting, then $T^n(B)$ is strongly bounded for all sufficiently large integers n whenever B is a strongly bounded subset of M_0. But this property may not be satisfied in general in the applications (see the first example in section 5.1). So we will use the concept of asymptotically smooth maps introduced in [7] to establish the existence of global attractors.

Using our established theory of global attractor in M_0, we further investigate the existence of a fixed point of T in M_0. We also generalize the aforementioned coexistence fixed point theorem for κ-condensing maps to convex κ-contracting maps (see Definition 4.3), a new concept motivated by the fixed point theorem of Hale and Lopes [9] and the Poincaré maps associated with periodic age-structured population models. In terms of uniform persistence, our fixed point theorem (see Theorem 4.5) and its corollary (see Corollary 4.6) generalize earlier results due to Browder [2], Nussbaum [18, 19], Zhao [29], and Magal and Arino [15]. Clearly, there are analogues of interior global attractors and fixed point results for continuous-time semiflows (see Remark 3.10 and Theorem 4.7).

This paper is organized as follows. In section 2, we recall some basic concepts and results for dissipative dynamical systems based on the book of Hale [7] and establish sufficient conditions for the existence of global attractors and strong global attractors. In section 3, we prove the existence of a global attractor for $T : (M_0, d) \to (M_0, d)$. In section 4, we present the fixed point theorems and their corollaries. In section 5, we provide four examples to show the existence of discrete- and continuous-time dynamical systems that admit global attractors, but no strong global attractors. A simple periodic age-structured model is also studied in this section to illustrate applicability of Theorem 4.5 in the case of convex κ-contracting maps.

2. Preliminaries. Let (M, d) be a complete metric space. Recall that a set U in M is said to be a neighborhood of another set V provided V is in the interior $\mathrm{int}(U)$ of U. For any subsets A, $B \subset M$ and any $\epsilon > 0$, we define

$$d(x, A) := \inf_{y \in A} d(x, y), \quad \delta(B, A) := \sup_{x \in B} d(x, A),$$

$$N(A, \epsilon) := \{x \in M : d(x, A) < \epsilon\} \text{ and } \overline{N}(A, \epsilon) := \{x \in M : d(x, A) \leq \epsilon\}.$$

The *Kuratowski measure of noncompactness*, κ, is defined by

$$\kappa(B) = \inf\{r : B \text{ has a finite open cover of diameter } \leq r\}$$

for any bounded set B of M. We set $\kappa(B) = +\infty$ whenever B is unbounded.

For various properties of Kuratowski's measure of noncompactness, we refer to [17, 6] and [22, Lemma 22.2]. The proof of the following lemma is straightforward.

LEMMA 2.1. *The following statements are valid:*

(a) *Let $I \subset [0, +\infty)$ be unbounded, and let $\{A_t\}_{t \in I}$ be a nonincreasing family of nonempty closed subsets (i.e., $t \leq s$ implies $A_s \subset A_t$). Assume that $\kappa(A_t) \to 0$, as $t \to +\infty$. Then $A_\infty = \cap_{t \geq 0} A_t$ is nonempty and compact, and $\delta(A_t, A_\infty) \to 0$, as $t \to +\infty$.*

(b) *For each $A \subset M$ and $B \subset M$, we have $\kappa(B) \leq \kappa(A) + \delta(B, A)$.*

Let $T : M \to M$ be a continuous map. We consider the discrete-time dynamical system $T^n : M \to M$ $\forall n \geq 0$, where $T^0 = Id$ and $T^n = T \circ T^{n-1}$ $\forall n \geq 1$. We denote for each subset $B \subset M$, $\gamma^+(B) = \cup_{m \geq 0} T^m(B)$ the *positive orbit of B for T*, and denote

$$\omega(B) = \bigcap_{n \geq 0} \overline{\bigcup_{m \geq n} T^m(B)}$$

the *omega-limit set of B*. A subset $A \subset M$ is *positively invariant* for T if $T(A) \subset A$. A is *invariant* for T if $T(A) = A$. We say that a subset $A \subset M$ *attracts* a subset $B \subset M$ for T if $\lim_{n \to \infty} \delta(T^n(B), A) = 0$.

It is easy to see that B is precompact (i.e., $\overline{B}$ is compact) if and only if $\kappa(B) = 0$. A continuous mapping $T : X \to X$ is said to be *compact* (*completely continuous*) if T maps any bounded set to a precompact set in M.

The theory of attractors is based on the following fundamental result, which is related to [7, Lemmas 2.1.1 and 2.1.2].

LEMMA 2.2. *Let B be a subset of M, and assume that there exists a compact subset $C \subset M$, which attracts B for T. Then $\omega(B)$ is nonempty, compact, invariant for T, and attracts B.*

Proof. Let $I = N$, the set of all nonnegative integers, and

$$A_n = \overline{\bigcup_{m \geq n} T^m(B)} \ \forall n \geq 0.$$

Since C attracts B, from Lemma 2.1(b) we deduce that

$$\kappa(A_n) \leq \kappa(C) + \delta(A_n, C) = \delta(A_n, C) \to 0 \text{ as } n \to +\infty.$$

So the family $\{A_n\}_{n\geq 0}$ satisfies the conditions of assertion (a) in Lemma 2.1, and we deduce that $\omega(B)$ is nonempty, compact, and $\delta(A_n, \omega(B)) \to 0$, as $n \to +\infty$. So $\omega(B)$ attracts B for T. Moreover, we have

$$T\left(\bigcup_{m\geq n} T^m(B)\right) = \bigcup_{m\geq n+1} T^m(B) \; \forall n \geq 0,$$

and since T is continuous, we obtain

$$T(A_n) \subset A_{n+1}, \text{ and } A_{n+1} \subset \overline{T(A_n)} \; \forall n \geq 0.$$

Finally, since $\delta(A_n, \omega(B)) \to 0$, as $n \to +\infty$, we have $T(\omega(B)) = \omega(B)$. □

Definition 2.3. *A continuous mapping* $T : M \to M$ *is said to be* point (compact, bounded) dissipative *if there is a bounded set* B_0 *in* M *such that* B_0 *attracts each point (compact set, bounded set) in* M*;* T *is* κ-condensing (κ-contraction *of order* k, $0 \leq k < 1$) *if* T *takes bounded sets to bounded sets and* $\kappa(T(B)) < \kappa(B)(\kappa(T(B)) \leq k\kappa(B))$ *for any nonempty closed bounded set* $B \subset M$ *with* $0 < \kappa(B) < +\infty$*;* T *is* asymptotically smooth *if, for any nonempty closed bounded set* $B \subset M$ *for which* $T(B) \subset B$*, there is a compact set* $J \subset B$ *such that* J *attracts* B*.*

Clearly, a compact map is a κ-contraction of order 0, and a κ-contraction of order k is κ-condensing. It is well known that κ-condensing maps are asymptotically smooth (see, e.g., [7, Lemma 2.3.5]). By Lemma 2.1, it follows that $T : M \to M$ is asymptotically smooth if and only if $\lim_{n\to\infty} \kappa(T^n(B)) = 0$ for any nonempty closed bounded subset $B \subset M$ for which $T(B) \subset B$.

A positively invariant subset $B \subset M$ for T is said to be *stable* if for any neighborhood V of B there exists a neighborhood $U \subset V$ of B such that $T^n(U) \subset V \; \forall n \geq 0$. We say that A is *globally asymptotically stable* for T if, in addition, A attracts points of M for T.

By the proof that (i) implies (ii) in [7, Theorem 2.2.5], we have the following result.

Lemma 2.4. *Let* $B \subset M$ *be compact and positively invariant for* T*. If* B *attracts compact subsets of one of its neighborhoods, then* B *is stable.*

Definition 2.5. *A nonempty, compact, and invariant set* $A \subset M$ *is said to be an* attractor for T *if* A *attracts one of its neighborhoods; a* global attractor for T *if* A *is an attractor that attracts every point in* M*; and a* strong global attractor for T *if* A *attracts every bounded subset of* M*.*

We remark that the notions of attractor and global attractor were used in [11, 22, 30]. The strong global attractor was defined as a global attractor in [7, 24, 20]. The following result is essentially the same as [8, Theorem 3.2]. Note that the proof of this result was not provided in [8]. For completeness, we state it in terms of global attractors and give an elementary proof below.

Theorem 2.6. *Let* T *be a continuous map on a complete metric space* (M, d)*. Assume that*

(a) T *is point dissipative and asymptotically smooth;*

(b) *positive orbits of compact subsets of* M *for* T *are bounded.*

Then T *has a global attractor* $A \subset M$*. Moreover, for each subset* B *of* M*, if there exists* $k \geq 0$ *such that* $\gamma^+(T^k(B))$ *is bounded, then* A *attracts* B *for* T*.*

Proof. Assume that (a) is satisfied. Since T is point dissipative, we can find a closed and bounded subset B_0 in (M,d) such that, for each $x \in M$, there exists $k = k(x) \geq 0$, $T^n(x) \in B_0 \ \forall n \geq k$. Define

$$J(B_0) := \{y \in B_0 : T^n(y) \in B_0 \ \forall n \geq 0\}.$$

Thus, $T(J(B_0)) \subset J(B_0)$, and for every $x \in M$, there exists $k = k(x) \geq 0$ such that $T^k(x) \in J(B_0)$. Since $J(B_0)$ is closed and bounded, and T is asymptotically smooth, Lemma 2.2 implies that $\omega(J(B_0))$ is compact invariant and attracts points of M.

Assume, in addition, that (b) is satisfied. We claim that there exists an $\varepsilon > 0$ such that $\gamma^+(N(\omega(J(B_0)),\varepsilon))$ is bounded. Assume, by contradiction, that $\gamma^+(N(\omega(J(B_0)), \frac{1}{n+1}))$ is unbounded for each $n > 0$. Let $z \in M$ be fixed. Then we can find a sequence $x_n \in N(\omega(J(B_0)), \frac{1}{n+1})$, and a sequence of integers $m_n \geq 0$ such that $d(z, T^{m_n}(x_n)) \geq n$. Since $\omega(J(B_0))$ is compact, we can always assume that $x_n \to x \in \omega(J(B))$ as $n \to +\infty$. Since $H := \{x_n : n \geq 0\} \cup \{x\}$ is compact, assumption (b) implies that $\gamma^+(H)$ is bounded, which is a contradiction. Let $D = \overline{\gamma^+(N(\omega(J(B_0)),\varepsilon))}$. Then D is closed, bounded, and positively invariant for T. Since $\omega(J(B_0))$ attracts points of M for T, and $\omega(J(B_0)) \subset N(\omega(J(B_0)),\varepsilon) \subset \operatorname{int}(D)$, we deduce that, for each $x \in M$, there exists $k = k(x) \geq 0$ such that $T^k(x) \in \operatorname{int}(D)$. It then follows that, for each compact subset C of M, there exists an integer $k \geq 0$ such that $T^k(C) \subset D$. Thus, the set $A := \omega(D)$ attracts every compact subset of M. Fix a bounded neighborhood V of A. By Lemma 2.4, it follows that A is stable, and hence, there is a neighborhood W of A such that $T^n(W) \subset V \ \forall n \geq 0$. Clearly, the set $U := \cup_{n\geq 0} T^n(W)$ is a bounded neighborhood of A, and $T(\overline{U}) \subset \overline{U}$. Since T is asymptotically smooth, there is a compact set $J \subset \overline{U}$ such that J attracts $\overline{U}$. By Lemma 2.2, $\omega(\overline{U})$ is nonempty, compact, invariant for T, and attracts $\overline{U}$. Since A attracts $\omega(\overline{U})$, then $\omega(\overline{U}) \subset A$. Thus, A is a global attractor for T.

To prove the last part of the theorem, without loss of generality we assume that B is a bounded subset of M and $\gamma^+(B)$ is bounded. We set $K = \overline{\gamma^+(B)}$. Then $T(K) \subset K$. Since K is bounded and T is asymptotically smooth, there exists a compact C which attracts K for T. Note that $T^k(B) \subset T^k(\gamma^+(B)) \subset T^k(K) \ \forall k \geq 0$. Thus, C attracts B for T. By Lemma 2.2, we deduce that $\omega(B)$ is nonempty, compact, invariant for T, and attracts B. Since A is a global attractor for T, it follows that A attracts compact subsets of M. By the invariance of $\omega(B)$ for T, we deduce that $\omega(B) \subset A$, and hence, A attracts B for T. ☐

Remark 2.7. From the first part of the proof of Theorem 2.6, it is easy to see that if T is point dissipative and asymptotically smooth, then there exists a nonempty, compact, and invariant subset C of M for T such that C attracts every point in M for T.

The following lemma provides sufficient conditions for the positive orbit of a compact set to be bounded.

LEMMA 2.8. *Assume that T is point dissipative. If C is a compact subset of M with the property that, for every bounded sequence $\{x_n\}_{n\geq 0}$ in $\gamma^+(C)$, $\{x_n\}_{n\geq 0}$ or $\{T(x_n)\}_{n\geq 0}$ has a convergent subsequence, then $\gamma^+(C)$ is bounded in M.*

Proof. Since T is point dissipative, we can choose a bounded and open subset V of M such that for each $x \in M$ there exists $n_0 = n_0(x) \geq 0$ such that $T^n(x) \in V \ \forall n \geq n_0$. By the continuity of T and the compactness of C, it follows that there exists a positive integer $r = r(C)$ such that for any $x \in C$ there exists an integer $k = k(x) \leq r$ such that $T^k(x) \in V$. Let $z \in M$ be fixed. Assume, by contradiction, that $\gamma^+(C)$ is unbounded. Then there exists a sequence $\{x_p\}$ in $\gamma^+(C)$ such that

$$x_p = T^{m_p}(z_p),\ z_p \in C,\ \text{and}\ \lim_{p\to\infty} d(z, x_p) = \infty.$$

Since T is continuous and C is compact, without loss of generality we can assume that

$$\lim_{p\to\infty} m_p = \infty,\ \text{ and }\ m_p > r,\ x_p \notin V\ \forall p \geq 1.$$

For each $z_p \in C$, there exists an integer $k_p \leq r$ such that $T^{k_p}(z_p) \in V$. Since $x_p = T^{m_p}(z_p) \notin V$, there exists an integer $n_p \in [k_p, m_p)$ such that

$$y_p = T^{n_p}(z_p) \in V,\ \text{ and }\ T^l(y_p) \notin V\ \forall 1 \leq l \leq l_p = m_p - n_p.$$

Clearly, $x_p = T^{l_p}(y_p)\ \forall p \geq 1$, and $\{y_p\}$ is a bounded sequence in $\gamma^+(C)$.

We consider only the case where $\{y_p\}$ has a convergent subsequence, since the proof for the case where $\{T(y_p)\}$ has a convergent subsequence is similar. Thus, without loss of generality we can assume that $\lim_{p\to\infty} y_p = y \in \overline{V}$. In the case where the sequence $\{l_p\}$ is bounded, there exist an integer $\hat{l}$ and sequence $p_k \to \infty$ such that $l_{p_k} = \hat{l}\ \forall k \geq 1$, and hence,

$$d(z, T^{\hat{l}}(y)) = \lim_{k\to\infty} d(z, T^{\hat{l}}(y_{p_k})) = \lim_{k\to\infty} d(z, x_{p_k}) = \infty,$$

which is impossible. In the case where the sequence $\{l_p\}$ is unbounded, there exists a subsequence $l_{p_k} \to \infty$ as $k \to \infty$. Then for each fixed $m \geq 1$ there exists an integer k_m such that $m \leq l_{p_k}\ \forall k \geq k_m$, and hence,

$$T^m(y_{p_k}) \in M \setminus V\ \forall k \geq k_m.$$

Letting $k \to \infty$, we obtain

$$T^m(y) \in M \setminus V\ \forall m \geq 1,$$

which contradicts the definition of V. ∎

The following result on the existence of strong global attractors is implied by [8, Theorems 3.1 and 3.4]. Since the proof of this result was not provided in [8], we include a simple proof of it.

THEOREM 2.9. *Let T be a continuous map on a complete metric space (M, d). Assume that T is point dissipative on M, and one of the following conditions holds:*

(a) *T^{n_0} is compact for some integer $n_0 \geq 1$, or*

(b) *T is asymptotically smooth and, for each bounded set $B \subset M$, there exists $k = k(B) \geq 0$ such that $\gamma^+(T^k(B))$ is bounded.*

Then there is a strong global attractor A for T.

Proof. The conclusion in case (b) is an immediate consequence of Theorem 2.6. In the case of (a), since T^{n_0} is compact for some integer $n_0 \geq 1$, it suffices to show that for each compact subset $C \subset M$, $\cup_{n\geq 0} T^n(C)$ is bounded. By applying Lemma 2.8 to $\widetilde{T} = T^{n_0}$, we deduce that for each compact subset $C \subset M$, $\cup_{n\geq 0}\widetilde{T}^n(C)$ is bounded. So Theorem 2.6 implies that $\widetilde{T}$ has a global attractor $\widetilde{A} \subset M$. We set $\widetilde{B} = \cup_{0\leq k\leq n_0-1} T^k(\widetilde{A})$. By the continuity of T, it then follows that $\widetilde{B}$ is compact and attracts every compact subset of M for T, and hence, the result follows from Theorem 2.6. ∎

Remark 2.10. It is easy to see that a metric space (M, d) is complete if and only if for any subset B of M, $\kappa(B) = 0$ implies that $\overline{B}$ is compact. However, we can prove that Lemmas 2.2 and 2.4 also hold for noncomplete metric spaces by employing the equivalence between the compactness and the sequential compactness for metric spaces. It then follows that Theorems 2.6 and 2.9 are still valid for any metric space. We refer to [3, 20] for the existence of strong global attractors of continuous-time semiflows on a metric space.

3. Persistence and attractors. Let (M, d) be a complete metric space, and let $\rho : M \to [0, +\infty)$ be a continuous function. We define

$$M_0 := \{x \in M : \rho(x) > 0\} \text{ and } \partial M_0 := \{x \in M : \rho(x) = 0\}.$$

A subset $B \subset M_0$ is said to be *ρ-strongly bounded* if B is bounded in (M, d) and $\inf_{x \in B} \rho(x) > 0$. Throughout this section, we always assume that $T : M \to M$ is a continuous map with $T(M_0) \subset M_0$.

DEFINITION 3.1. *T is said to be* ρ-uniformly persistent *if there exists $\varepsilon > 0$ such that* $\liminf_{n\to+\infty} \rho(T^n(x)) \geq \varepsilon$, $\forall x \in M_0$*;* weakly ρ-uniformly persistent *if there exists $\varepsilon > 0$ such that* $\lim_{n\to+\infty} \sup \rho(T^n(x)) \geq \varepsilon\ \forall x \in M_0$. *The set ∂M_0 is said to be* ρ-ejective *for T if there exists $\varepsilon > 0$ such that for every $x \in M$ with $0 < \rho(x) < \varepsilon$ there is $n_0 = n_0(x) \geq 0$ such that $\rho(T^{n_0}(x)) \geq \varepsilon$.*

For a given open subset $M_0 \subset M$, let $\partial M_0 := M \setminus M_0$. Then we can use the continuous function $\rho : M \to [0, \infty)$, defined by $\rho(x) = d(x, \partial M_0)\ \forall x \in M$, to obtain the traditional definition of persistence.

PROPOSITION 3.2. *Assume that there is a compact subset C of M that attracts every point in M for T. Then the following statements are equivalent:*

(1) *T is weakly ρ-uniformly persistent.*

(2) *T is ρ-uniformly persistent.*

(3) *∂M_0 is ρ-ejective for T.*

Proof. The observations (1)⇔(3) and (2)⇒(1) are obvious. Let us prove that (1)⇒(2). Let $\varepsilon > 0$ be fixed such that

$$\lim_{n\to+\infty} \sup \rho(T^n(x)) \geq \varepsilon\ \forall x \in M_0. \tag{1}$$

Then for each $x \in M_0$, and each $n \geq 0$, there exists $p \geq 0$ such that $\rho(T^{n+p}(x)) \geq \varepsilon/2$. Assume that T is not ρ-uniformly persistent. Then we can find a sequence $\{x_m\}_{m\geq 0} \subset M_0$ such that

$$\lim_{n\to+\infty} \inf \rho(T^n(x_m)) \leq \frac{1}{m+1}\ \forall m \geq 0.$$

So there exist $l_m \geq 1$ and $n_m \geq 0$ such that

$$\begin{aligned} &d(T^{n_m}(x_m), C) \leq \frac{1}{m+1},\ \rho(T^{n_m}(x_m)) \geq \varepsilon/2, \\ &\rho\left(T^{n_m+k}(x_m)\right) \leq \varepsilon/2\,\forall\ k = 1, \ldots, l_m, \text{ and} \\ &\rho\left(T^{n_m+l_m}(x_m)\right) \leq \frac{1}{m+1}. \end{aligned}$$

Since C is compact, by taking a subsequence that we denote with the same index, we can always assume that $y_m = T^{n_m}(x_m) \to y \in C$. Since ρ and T are continuous, we deduce that

$$\rho(y) \geq \varepsilon/2, \text{ and } \rho\left(T^k(y)\right) \leq \varepsilon/2\ \ \forall k = 1, \ldots, l,$$

where $l = \lim_{m\to+\infty} \inf l_m$. If $l < +\infty$, we have $\rho\left(T^l(y)\right) = 0$, which is impossible because $T(M_0) \subset M_0$. If $l = +\infty$, we have

$$\lim_{n\to+\infty} \sup \rho\left(T^n(y)\right) \le \varepsilon/2 < \varepsilon,$$

which contradicts (1). ◻

We note that the concept of general ρ-persistence was used in [27, 23, 30]. It was also shown in [27] that the ρ-uniform persistence implies the weak ρ-uniform persistence for nonautonomous semiflows under appropriate conditions. The following result shows that the notion of ρ-uniform persistence is independent of the choice of continuous function ρ.

PROPOSITION 3.3. *Let $\xi : M \to [0,+\infty)$ be a continuous function such that $\partial M_0 = \{x \in M : \xi(x) = 0\}$. Assume that there is a compact subset of M that attracts every point in M. Then T is ρ-uniformly persistent if and only if T is ξ-uniformly persistent.*

Proof. It suffices to prove that ρ-uniform persistence implies ξ-uniform persistence since the problem is symmetric. Let us first remark that T is ρ-uniformly persistent if and only if there exists $\varepsilon > 0$ such that

$$\inf_{x\in M_0} \inf_{y\in\omega(x)} \rho(y) \ge \varepsilon,$$

where $\omega(x)$ is the omega-limit set of the positive orbit of x. Define

$$A_\omega = \cup_{x\in M_0}\omega(x) \text{ and } V = \{y \in M : \rho(y) \ge \varepsilon\}.$$

Then

$$\inf_{x\in M_0} \inf_{y\in\omega(x)} \rho(y) = \inf_{x\in A_\omega} \rho(x) \ge \varepsilon.$$

Clearly, $A_\omega \subset C$, so $\overline{A}_\omega$ is compact. Since A_ω is included in $V \subset M_0$, which is closed, we deduce that $\overline{A}_\omega \subset V \cap C \subset M_0$. So $\overline{A}_\omega \subset M_0$ is compact, and hence, there exists $\eta > 0$ such that $\inf_{x\in\overline{A_\omega}} \xi(x) \ge \eta$, which implies that T is ξ-uniformly persistent. ◻

Let A be a nonempty subset of M. A is said to be *ejective for T* if there exists a neighborhood V of A such that for every $x \in (M \setminus A) \cap V$ there is $n_0 = n_0(x) \ge 0$ such that $T^{n_0}(x) \in M \setminus V$.

PROPOSITION 3.4. *Assume that $\partial M_0 \ne \emptyset$ and that there is a compact subset C of M which attracts every point in M for T. Then the following statements are equivalent:*

(1) *T is ρ-uniformly persistent.*

(2) *∂M_0 is ejective for T.*

Proof. Assume first that (1) is true. Let $\varepsilon > 0$ be fixed such that

$$\lim_{n\to+\infty} \sup \rho\left(T^n(x)\right) \ge \varepsilon \ \forall x \in M_0.$$

Then it is clear that ∂M_0 is ejective for T, with $V = \{x \in M : \rho(x) \le \varepsilon/2\}$.

Conversely, assume that ∂M_0 is ejective for T. Let V be a neighborhood of ∂M_0 such that for every $x \in M_0 \cap V$ there is $n_0 = n_0(x) \ge 0$ such that $T^{n_0}(x) \in M \setminus V$. By Proposition 3.3, it is sufficient to prove that T is ρ-uniformly persistent when

$\rho(x) = d(x, \partial M_0)$. Assume, by contradiction, that T is not ρ-uniformly persistent. Then for each $n \geq 1$ there exists $x_n \in M_0$, such that

$$\lim_{m\to+\infty} \sup \rho\left(T^m(x_n)\right) \leq \frac{1}{n}.$$

By the attractivity of C, it follows that for each $n \geq 1$ there exists $l_n \geq 0$ such that each $y_n := T^{l_n}(x_n) \in M_0$ satisfies

$$d\left(T^k\left(y_n\right), C\right) \leq \frac{2}{n} \text{ and } d\left(T^k\left(y_n\right), \partial M_0\right) \leq \frac{2}{n} \ \forall k \geq 0.$$

Since C is compact and V is a neighborhood of ∂M_0, there exists $\delta > 0$ such that

$$\{x \in M : d(x, C) \leq \delta \text{ and } d(x, \partial M_0) \leq \delta\} \subset V.$$

Let $n_0 \geq 2/\delta$ be fixed. Then we have $y_{n_0} \in M_0$, and

$$d\left(T^k\left(y_{n_0}\right), C\right) \leq \delta \text{ and } d\left(T^k\left(y_n\right), \partial M_0\right) \leq \delta \ \forall k \geq 0.$$

Thus, we obtain

$$y_{n_0} \in M_0 \cap V \text{ and } T^k\left(y_{n_0}\right) \in V \ \forall k \geq 0,$$

which is a contradiction. □

Observe that M_0 is an open subset in (M, d). In order to make M_0 become a complete metric space, we define a new metric function d_0 on M_0 by

$$d_0(x, y) = \left|\frac{1}{\rho(x)} - \frac{1}{\rho(y)}\right| + d(x, y) \ \forall x, y \in M_0. \tag{2}$$

LEMMA 3.5. *(M_0, d_0) is a complete metric space.*

Proof. It is easy to see that d_0 is a metric function. Let $\{x_n\}_{n\geq 0}$ be a Cauchy sequence in (M_0, d_0). Since $d(x, y) \leq d_0(x, y) \ \forall x, y \in M_0$, we deduce that $\{x_n\}_{n\geq 0}$ is a Cauchy sequence in (M, d), and there exists $x \in M$, such that $d(x_n, x) \to 0$ as $n \to +\infty$. To prove that $d_0(x_n, x) \to 0$ as $n \to +\infty$, it is sufficient to show that $x \in M_0$. Given $\varepsilon > 0$, since $\{x_n\}_{n\geq 0}$ is a Cauchy sequence in (M_0, d_0), there exists $n_0 \geq 0$ such that $d_0(x_n, x_p) \leq \varepsilon \ \forall n, p \geq n_0$. In particular, we have $d_0(x_n, x_{n_0}) \leq \varepsilon \ \forall n \geq n_0$. Then

$$\left|\frac{1}{\rho(x_n)} - \frac{1}{\rho(x_{n_0})}\right| \leq \varepsilon \ \forall n \geq n_0.$$

So there exists $r > 0$ such that $\inf_{n\geq 0} \rho(x_n) \geq r$. Since ρ is continuous and $d(x_n, x) \to 0$ as $n \to +\infty$, we deduce that $\rho(x) \geq r$, and hence $x \in M_0$. Thus, (M_0, d_0) is complete. □

For any two subsets $A, B \subset M$, we denote

$$\delta(B, A) = \sup_{x\in B} \inf_{y\in A} d(x, y),$$

and if $A, B \subset M_0$, we denote

$$\delta_0(B, A) = \sup_{x\in B} \inf_{y\in A} d_0(x, y).$$

LEMMA 3.6. *The following two statements are valid:*

(1) *Let* $\{B_t\}_{t\in I}$ *be a family of subsets of* M_0, *where* I *is a unbounded subset of* $[0,+\infty)$. *If* $A \subset M_0$ *is compact in* (M,d) *and* $\lim_{t\to\infty} \delta(B_t, A) = 0$, *then* $\lim_{t\to\infty} \delta_0(B_t, A) = 0$.

(2) *If* T *is asymptotically smooth, then* T *is asymptotically smooth in* (M_0, d_0).

Proof. (1) We denote $k := \frac{1}{2}\inf_{x\in A}\rho(x) > 0$. Assume, by contradiction, that $\lim_{t\to+\infty}\sup \delta_0(B_t, A) > \varepsilon > 0$. Then we can find a sequence $\{t_p\}_{p\geq 0} \subset I$ such that $t_p \to +\infty$, $p \to +\infty$, and a sequence $\left\{x_{t_p}\right\}_{p\geq 0} \subset M_0$ such that $x_{t_p} \in B_{t_p}$, $d_0\left(x_{t_p}, A\right) \geq \varepsilon\ \forall p \geq 0$. Since $d\left(x_{t_p}, A\right) \to 0$, as $p \to +\infty$, without loss of generality we can assume that there exists $x \in A$ such that $d(x_{t_p}, x) \to 0$, as $p \to +\infty$. Since ρ is continuous and $\rho(x) > k$, there exists $p_0 \geq 0$ such that $\rho(x_{t_p}) \geq k\ \forall p \geq p_0$. Thus, we have

$$0 < \varepsilon \leq d_0\left(x_{t_p}, x\right) \leq k^{-2}\left|\rho(x_{t_p}) - \rho(x)\right| + d(x_{t_p}, x) \to 0 \text{ as } p \to +\infty,$$

which is a contradiction.

(2) It is easy to see that $T : (M_0, d_0) \to (M_0, d_0)$ is continuous. Let B be a bounded subset in (M_0, d_0) such that $T(B) \subset B$. Since T is asymptotically smooth, there exists a compact subset $C \subset M$ that attracts B for T. So $C_0 = C \cap \overline{B} \subset M_0$ is compact and attracts B for T. It easily follows that C_0 is also compact in (M_0, d_0). Since C_0 attracts B for T, statement (1) implies that C_0 attracts B for $T : (M_0, d_0) \to (M_0, d_0)$. ∎

The main result of this section is the following theorem.

THEOREM 3.7. *Assume that* T *is asymptotically smooth and* ρ*-uniformly persistent, and that* T *has a global attractor* A. *Then* $T : (M_0, d) \to (M_0, d)$ *has a global attractor* A_0. *Moreover, for each subset* B *of* M_0, *if there exists* $k \geq 0$ *such that* $\gamma^+\left(T^k(B)\right)$ *is* ρ*-strongly bounded, then* A_0 *attracts* B *for* T.

Proof. We consider the continuous map $T : (M_0, d_0) \to (M_0, d_0)$. Since T is point dissipative and ρ-uniformly persistent, T is point dissipative in (M_0, d_0). Moreover, Lemma 3.6 implies that T is asymptotically smooth in (M_0, d_0). Let C be a compact subset in (M_0, d_0), and $\{x_p\}$ a bounded sequence in $\gamma^+(C)$ in (M_0, d_0). Then $x_p = T^{m_p}(z_p)$, $z_p \in C\ \forall p \geq 1$, and the sequence $\{x_p\}$ is ρ-strongly bounded in (M, d). Since C is also compact in (M, d), we have $\lim_{m\to\infty}\delta(T^m(C), A) = 0$. Thus, $\{x_p\}$ has a convergent subsequence $x_{p_k} \to x$ in (M, d) as $k \to \infty$. By the continuity of ρ and the ρ-strong boundedness of $\{x_p\}$, it follows that $\rho(x) > 0$, i.e., $x \in M_0$, and hence, $x_{p_k} \to x$ in (M_0, d_0) as $k \to \infty$. Thus, Lemma 2.8 implies that positive orbits of compact sets are bounded for $T : (M_0, d_0) \to (M_0, d_0)$. Then the conclusion for $T : (M_0, d) \to (M_0, d)$ follows from Theorem 2.6, as applied to $T : (M_0, d_0) \to (M_0, d_0)$. ∎

THEOREM 3.8. *Assume that* T *is point dissipative on* M *and* ρ*-uniformly persistent, and that one of the following conditions holds:*

(a) *There exists some integer* $n_0 \geq 1$ *such that* T^{n_0} *is compact on* M, *and* T^{n_0} *maps* ρ*-strongly bounded subsets of* M_0 *onto* ρ*-strongly bounded sets in* M_0, *or*

(b) T *is asymptotically smooth on* M, *and for every* ρ*-strongly bounded subset* $B \subset M_0$, *there exists* $k = k(B) \geq 0$ *such that* $\gamma^+\left(T^k(B)\right)$ *is* ρ*-strongly bounded in* M_0.

Then $T : (M_0, d) \to (M_0, d)$ *has a global attractor* A_0, *and* A_0 *attracts every* ρ*-strongly bounded subset in* M_0 *for* T.

Proof. Clearly, $T : (M_0, d_0) \to (M_0, d_0)$ is point dissipative. It is easy to see that condition (a) implies that $T^{n_0} : (M_0, d_0) \to (M_0, d_0)$ is compact, and that condition (b) implies that condition (b) of Theorem 2.9 holds for $T : (M_0, d_0) \to (M_0, d_0)$.

By Theorem 2.9, there is a strong global attractor A_0 for $T : (M_0, d_0) \to (M_0, d_0)$. Consequently, A_0 is a global attractor for $T : (M_0, d) \to (M_0, d)$, and A_0 attracts every ρ-strongly bounded subset in M_0 for T. ∎

Remark 3.9. A result similar to Theorem 3.8 was already presented for discrete- and continuous-time dynamical systems in [29] and [10], respectively. The only difference, compared with the earlier results, is that we add a ρ-boundedness assumption for case (a). In fact, this assumption is necessary for the existence of a strong global attractor in M_0 for T (see two examples in section 5.1).

Remark 3.10. A family of mappings $\Phi(t) : M \to M$, $t \geq 0$, is called a continuous-time semiflow if $(x, t) \to \Phi(t)x$ is continuous, $\Phi(0) = Id$, and $\Phi(t) \circ \Phi(s) = \Phi(t + s)$ for $t, s \geq 0$. By similar arguments we can prove the analogues of Theorems 3.7 and 3.8 for a continuous-time semiflow $\Phi(t)$ on M with $\Phi(t)(M_0) \subset M_0$ $\forall t \geq 0$.

4. Coexistence steady states. In this section, we establish the existence of a coexistence steady state (i.e., the fixed point in M_0) for uniformly persistent dynamical systems.

Throughout this section we always assume that M is a closed and convex subset of a Banach space $(X, \|\cdot\|)$, that $\rho : M \to [0, +\infty)$ is a continuous function such that $M_0 = \{x \in M : \rho(x) > 0\}$ is nonempty and convex, and that $T : M \to M$ is a continuous map with $T(M_0) \subset M_0$. For convenience, we set $\partial M_0 := M \setminus M_0$.

Assume that $T : M_0 \to M_0$ has a global attractor A_0. By Definition 2.5, it easily follows that for every compact set $K \subset M_0$ there exists an open neighborhood of K which is attracted by A_0. This property of A_0 is enough to support the arguments in the proof of [29, Theorem 2.3] (see also [30, Theorem 1.3.6]) instead of the property that A_0 attracts ρ-strongly bounded sets in M_0. Thus, the proof of [29, Theorem 2.3] actually implies the following fixed point theorem.

THEOREM 4.1. *Assume that T is κ-condensing. If $T : M_0 \to M_0$ has a global attractor A_0, then T has a fixed point $x_0 \in A_0$.*

Note that a fixed point theorem for κ-condensing maps in [9] was used in the proof of [29, Theorem 2.3]. To generalize Theorem 4.1 to another class of maps, we need the following fixed point theorem, which is a combination of Theorems 3 and 5 in [9] (see also [7, Lemma 2.6.5]).

LEMMA 4.2 (Hale–Lopes fixed point theorem). *Assume that $K \subset B \subset S$ are convex subsets of a Banach space X, with K compact, S closed and bounded, and B open in S. If $T : S \to X$ is continuous, $T^n B \subset S$ $\forall n \geq 0$, and K attracts compact subsets of B, then there exists a closed bounded and convex subset $C \subset S$ such that $C = \overline{co}\left(\cup_{j \geq 1} T^j (B \cap C)\right)$. Moreover, if C is compact, then T has a fixed point in B.*

We should point out that in the above fixed point theorem the claim that T has a fixed point in B follows from the proof of [7, Lemma 2.6.5], where Horn's fixed point theorem [12] was used.

Motivated by Lemma 4.2 and the Poincaré maps associated with age-structured population models, we give the following definition.

DEFINITION 4.3. *Let M be a closed and convex subset of a Banach space X, and let $T : M \to M$ be a continuous map. Define $\widehat{T}(B) = \overline{co}\,(T(B))$ for each $B \subset M$. T is said to be convex κ-contracting if $\lim_{n\to\infty} \kappa(\widehat{T}^n(B)) = 0$ for each bounded subset $B \subset M$.*

Now we are ready to generalize Theorem 4.1 to convex κ-contracting maps.

THEOREM 4.4. *Assume that T is convex κ-contracting. If $T : M_0 \to M_0$ has a global attractor A_0, then T has a fixed point $x_0 \in A_0$.*

Proof. Since A_0 is a global attractor for $T : M_0 \to M_0$, the proof of [29, Theorem

2.3] (see also [30, Theorem 1.3.6]) implies that there are three convex subsets, $K \subset B \subset S \subset M$, such that $K \subset M_0$, $B \subset M_0$, and the assumptions of Lemma 4.2 hold for T. Let C be defined in Lemma 4.2. Define $\widehat{C} := \cup_{j\geq 1} T^j (B \cap C)$. Then we have

$$\widehat{C} = T(B \cap C) \cup T\left(\widehat{C}\right) \text{ and } C = \overline{co}\left(\widehat{C}\right),$$

and hence, $\widehat{C} \subset T(C)$. Thus, we further obtain

$$C \subset \widehat{T}(C) \subset \widehat{T}^2(C) \subset \cdots \subset \widehat{T}^n(C) \; \forall n \geq 0.$$

Since T is convex κ-contracting, it follows that $\kappa(C) \leq \kappa(\widehat{T}^n(C)) \to 0$ as $n \to \infty$. Then $\kappa(C) = 0$, and hence, C is compact. Now Lemma 4.2 implies the existence of a fixed point of T in A_0. ∎

Combining Theorems 2.6, 2.9, 3.7, 4.1, and 4.4 we have the following result on the existence of coexistence steady states for uniformly persistent systems, which is a generalization of [29, Theorem 2.3].

THEOREM 4.5. *Assume that*

(1) *T is point dissipative and ρ-uniformly persistent.*

(2) *One of the following two conditions holds:*

  (2a) *T^{n_0} is compact for some integer $n_0 \geq 1$, or*

  (2b) *for each compact subset $C \subset M$, $\gamma^+(C)$ is bounded.*

(3) *Either T is κ-condensing or T is convex κ-contracting.*

Then $T : M_0 \to M_0$ admits a global attractor A_0, and T has a fixed point in A_0.

Let $A \subset M$ and $B \subset M \setminus A$. A is said to be *ejective for T in B* if there exists a neighborhood V of A such that for each $x \in V \cap B$ there exists $n = n(x) \geq 0$ such that $T^n(x) \in M \setminus V$. A is said to be *ejective for T* if A is ejective for T in $M \setminus A$.

The following corollary is a generalization of [15, Theorem 4.1] on semi-ejective fixed points.

COROLLARY 4.6. *Assume that $T(\partial M_0) \subset \partial M_0$ and that there exists $\overline{x}_\partial \in \partial M_0$, a fixed point of T, which is globally asymptotically stable for $T : \partial M_0 \to \partial M_0$. Assume, in addition, that*

(1) *T is point dissipative and $\overline{x}_\partial$ is ejective for T in M_0.*

(2) *One of the following two conditions holds:*

  (2a) *T^{n_0} is compact for some integer $n_0 \geq 1$, or*

  (2b) *positive orbits of compact subsets of M are bounded.*

(3) *Either T is κ-condensing or convex κ-contracting.*

Then $T : M_0 \to M_0$ admits a global attractor A_0, and T has a fixed point in A_0.

Proof. By [29, Theorem 2.2] (see also [30, Theorem 1.3.1]), we deduce that T is ρ-uniformly persistent with $\rho(x) = d(x, \partial M_0)$. Now Theorem 4.5 completes the proof. ∎

We remark that when $\partial M_0 = \{\overline{x}_\partial\}$ in Corollary 4.6, we obtain a generalization of the classical Browder [2] ejective fixed point theorem.

A point $e \in M$ is said to be an equilibrium of a continuous-time semiflow $\Phi(t)$ on M if $\Phi(t)e = e \; \forall \, t \geq 0$. As a consequence of Theorems 4.1 and 4.4 and the proof of [29, Theorem 2.4] (see also [30, Theorem 1.3.7]), we have the following result on the existence of equilibrium in M_0 for $\Phi(t)$.

THEOREM 4.7. *Let $\Phi(t)$ be a continuous-time semiflow on M with $\Phi(t)(M_0) \subset M_0 \; \forall \, t \geq 0$. Assume that either $\Phi(t)$ is κ-condensing for each $t > 0$, or $\Phi(t)$ is convex κ-contracting for each $t > 0$, and that $\Phi(t) : M_0 \to M_0$ has a global attractor A_0. Then $\Phi(t)$ has an equilibrium $x_0 \in A_0$.*

In the rest of this section, we establish sufficient conditions for T to be convex κ-contracting.

LEMMA 4.8. *Let M be a closed and convex subset of a Banach space X, and let $T : M \to M$ be a continuous map which takes bounded sets to bounded sets. Assume that there exists a sequence of bounded linear operators $\{P_k\}_{k\geq 1} \in \mathcal{L}(X, X)$ such that*

(1) *for each bounded subset $B \subset M$, $(Id - P_1)T(B)$ is relatively compact;*
(2) *one of the following conditions holds:*
  (2a) *There exists $n_0 \geq 0$ such that P_{n_0} is compact, and if $k \in \{1, \ldots, n_0 - 1\}$, $C \subset M$, and $(Id - P_k)C$ is compact, then $(Id - P_{k+1})\,T(C)$ is compact.*
  (2b) *There exists $c \in (0, 1)$ such that $\|P_{k+1}T(x)\| \leq c\,\|P_k x\|$ $\forall\, x \in M$, $\forall\, k \geq 1$, and if $k \geq 1$, $C \subset M$, and $(Id - P_k)C$ is compact, then $(Id - P_{k+1})\,T(C)$ is compact.*

Then T is convex κ-contracting.

Proof. Let $B \subset M$ be a bounded subset of M. Since $(Id - P_1)T(B)$ is relatively compact and P_1 is linear, it follows that

$$(I - P_1)\overline{co}(T(B)) = \overline{co}((I - P_1)T(B)) \text{ is compact,}$$

$$\text{and } (Id - P_1)\overline{co}(T(B)) \text{ is compact.}$$

Thus, $(Id - P_2)\overline{co}(T(\overline{co}(T(B))))$ is compact, and, by induction, $(Id - P_{k+1})\widehat{T}^k(B)$ is compact $\forall k \in \{1, \ldots, n_0 - 1\}$ if (2a) holds, and $\forall\, k \geq 1$ if (2b) holds. If (2a) holds, since P_{n_0} is compact, we deduce that $\widehat{T}^{n_0}(B)$ is compact, and hence, $\kappa(\widehat{T}^n(B)) = 0$ $\forall n \geq n_0$. If (2b) holds, then the boundedness of linear operator P_1 implies that

$$\sup_{y\in\overline{co}(T(B))} \|P_1 y\| = \sup_{x\in T(B)} \|P_1 x\| \leq c \sup_{x\in B} \|x\|\,.$$

Similarly, we have

$$\begin{aligned}\sup_{y\in\overline{co}(T(\widehat{T}(B)))} \|P_2 y\| = \sup_{x\in T(\widehat{T}(B))} \|P_2 x\| &\leq c \sup_{x\in\widehat{T}(B)} \|P_1 x\| \\ &\leq c^2 \sup_{x\in B} \|x\|\,.\end{aligned}$$

By induction, it follows that

$$\sup_{y\in\widehat{T}^k(B)} \|P_k y\| \leq c^k \sup_{x\in B} \|x\| \;\; \forall k \geq 1.$$

Let $\delta_k := c^k \sup_{x\in B} \|x\|$. Since $(Id - P_k)\widehat{T}^k(B)$ is compact, there exists $x_1, \ldots, x_{m(k)} \in (Id - P_k)\widehat{T}^k(B)$ such that

$$(Id - P_k)\widehat{T}^k(B) \subset \cup_{j=1,\ldots,m(k)} B_M\left(x_j, \delta_k\right),$$

where $B_M\left(x_j, \delta_k\right) = \{x \in M : \|x - x_j\| < \delta_k\}$. Thus, we have

$$(Id - P_k)\widehat{T}^k(B) + P_k\widehat{T}^k(B) \subset \cup_{j=1,\ldots,m(k)} B_M\left(x_j, 2\delta_k\right).$$

Since $\widehat{T}^k(B) \subset (Id - P_k)\widehat{T}^k(B) + P_k\widehat{T}^k(B)$, it follows that

$$\kappa(\widehat{T}^k(B)) \leq \kappa\left((Id - P_k)\widehat{T}^k(B) + P_k\widehat{T}^k(B)\right) \leq 2\delta_k \to 0 \text{ as } k \to +\infty.$$

Thus, T is convex κ-contracting. $\square$

We complete this section with an example of convex κ-contracting maps.

Example 4.9. Consider $T : L^1_+(0,c) \to L^1_+(0,c)$, with $c \in (1,+\infty]$, defined by

$$T(\varphi)(a) = \begin{cases} \chi(\varphi)\varphi(a-1) \text{ if } 1 \leq a < c, \\ \lambda \text{ if } a \in (0,1), \end{cases}$$

where $\lambda > 0$, and $\chi : L^1_+(0,c) \to [0,\alpha]$ (with $0 < \alpha$) is a continuous map. We choose for each integer $k \geq 1$, $P_k : L^1(0,c) \to L^1(0,c)$ the operator defined by

$$P_k(\varphi)(a) = \begin{cases} \varphi(a) \text{ if } a \in (0,c) \cap (k,+\infty), \\ 0 \text{ otherwise.} \end{cases}$$

If $c < +\infty$, then (2a) holds. If $c = +\infty$ and $\alpha < 1$, then (2b) holds. Thus, Lemma 4.8 implies that T is convex κ-contracting. Note that in this example we need to impose some additional conditions on χ to show that T is κ-condensing.

5. Five examples. In this section, we first provide four examples of discrete- and continuous-time semiflows which admit global attractors, but no strong global attractors, in the complete metric spaces (M_0, d_0) introduced in section 3. Then we give an example showing applicability of Theorem 4.5 in the case of a convex κ-contracting map. Our examples are highly motivated by age-structured population models. We refer to Webb [28], Iannelli [14], and Anita [1] for the classical approach and to Thieme [25] and Magal and Thieme [16] (and references therein) for the integrated semigroup approach to this class of evolutionary equations.

5.1. Asymptotically smooth semiflows on (0 0). Let $C([0,1],\mathbb{R})$ be endowed with the usual norm $\|\varphi\|_\infty = \sup_{a\in[0,1]} |\varphi(a)|$. Let $M := C_+([0,1],\mathbb{R})$ be endowed with the metric $d(x,y) = \|x-y\|$, and $T : M \to M$ be defined by

$$T(\varphi) = \delta \frac{\mathcal{F}_\beta(\varphi)}{1+\mathcal{F}_\beta(\varphi)} 1_{[0,1]},$$

where $1_{[0,1]}(a) = 1\ \forall a \in [0,1]$, and $\mathcal{F}_\beta(\varphi) = \int_0^1 \beta(a)\varphi(a)da\ \forall \varphi \in X$. We assume that

(A1) $\delta > 1, \beta \in C([0,1],\mathbb{R}),\ \int_0^1 \beta(a)da = 1,\ \beta(a) > 0\ \forall a \in [0,1)$, and $\beta(1) = 0$.

Consider the following discrete-time system on M:

$$u_{n+1} = T(u_n)\ \ \forall n \geq 0, \text{ and } u_0 \in M.$$

It is easy to see that the map T is continuous and maps bounded sets into compact sets of M. Note that $T(M) \subset [0,\delta]\, 1_{[0,1]} = \left\{\alpha 1_{[0,1]} : \alpha \in [0,\delta]\right\}$ is bounded. So T is compact and point dissipative and has a strong global attractor in M. Set

$$\partial M_0 = \{0\}, \quad M_0 = M \setminus \{0\}, \quad \rho(x) = \|x\|_\infty.$$

Clearly, $T(M_0) \subset M_0$, $T(\partial M_0) \subset \partial M_0$, and the fixed points of T are 0 and $\overline{u} = (\delta-1)1_{[0,1]}$. Then it is easy to see that for each $\varphi \in M_0$, $T^m(\varphi) \to \overline{u}$, as $m \to +\infty$. So T is ρ-uniformly persistent. Let $\overline{\alpha} = (\delta - 1)$ and $B := \{x \in M : \|x\|_\infty = \overline{\alpha}\}$. Since $\beta(1) = 0$, we have $\mathcal{F}_\beta(B) = (0,\overline{\alpha}]$. Moreover, $T(B) = \{\alpha 1_{[0,1]} : \alpha \in (0,\overline{\alpha}]\}$, and $T^n(B) = T(B)\ \forall n \geq 1$. Thus, there exists no compact subset in M_0 that attracts B for T. In particular, there is no strong global attractor for $T : (M_0,d_0) \to (M_0,d_0)$, where d_0 is defined as in (2).

Next we consider the continuous-time semiflow $\{U(t)\}_{t\geq 0}$ on $M := L^1_+(0,1)$, which is generated by the following age-structured model:

$$(3)\qquad \begin{cases} \frac{\partial u(t)}{\partial t} + \frac{\partial u(t)}{\partial a} = -\mu(a)u(t)(a) - \mathcal{F}_\Gamma(u(t))\,u(t)(a), \quad a \in (0,1), \\ u(t,0) = \mathcal{F}_\beta(u(t)), \\ u(0) = \varphi \in L^1_+(0,1), \end{cases}$$

where for each $\chi \in L^\infty(0,1)$, and each $\varphi \in L^1(0,1)$, $\mathcal{F}_\chi(\varphi) = \int_0^1 \chi(a)\varphi(a)da$. We assume that

(A2) $\beta \in (0,+\infty)$, $\mu \in L^1_{loc}[0,1)$, $\mu \geq 0$, $\lim_{a\to 1^-}\int_0^a \mu(r)dr = +\infty$, $\int_0^1 \beta\exp(-\int_0^a \mu(s)ds)da > 1$, and

$$\Gamma(a) = \frac{1}{\int_0^1 \exp(-\int_0^s \mu(r) + \lambda_0 dr)ds}\int_a^1 \exp\left(-\int_a^s \mu(r) + \lambda_0 dr\right)ds \;\forall a \in [0,1],$$

where $\lambda_0 > 0$ is the unique solution of $\int_0^1 \beta\exp\left(-\int_0^a \mu(s) + \lambda_0 ds\right)da = 1$.

Let $\{T(t)\}_{t\geq 0}$ be the C_0-semigroup of bounded linear operators generated by $A : D(A) \subset L^1(0,1) \to L^1(0,1)$ with

$$A\varphi = -\frac{d\varphi}{da} - \mu\varphi \;\forall\; \varphi \in D(A),$$
$$D(A) = \left\{\varphi \in W^{1,1}(0,1) : \mu\varphi \in L^1(0,1) \text{ and } \varphi(0) = \int_0^1 \beta\varphi(a)da\right\}.$$

Let $P : L^1(0,1) \to L^1(0,1)$ be the bounded linear operator of projection defined by

$$P(\varphi)(a) = \int_0^1 \Gamma(s)\varphi(s)ds\chi(a) \;\forall\varphi \in L^1(0,1),$$

where $\chi(a) = \alpha\exp\left(-\int_0^a \mu(s) + \lambda_0 ds\right)$, and

$$\alpha = \left(\int_0^1 \Gamma(s)\exp\left(-\int_0^a \mu(s) + \lambda_0 ds\right)ds\right)^{-1}.$$

Then $PT(t) = T(t)P = e^{\lambda_0 t}P \;\forall t \geq 0$, and there exist $\delta > 0$ and $M \geq 1$ such that

$$\|(Id - P)T(t)\| \leq Me^{(\lambda_0-\delta)t} \;\forall t \geq 0.$$

Moreover, we have

$$U(t)x = \frac{T(t)x}{1 + \int_0^t \mathcal{F}_\Gamma(T(s)x)\,ds} \;\forall t \geq 0, \forall x \in M.$$

It is easy to see that for each $\varphi \in M_0$, $U(t)\varphi \to \lambda_0\chi$, as $t \to +\infty$. Since $T(t)$ is compact for $t \geq 2$, $U(t)$ is compact for $t \geq 2$. So $\{U(t)\}_{t\geq 0}$ has a strong global attractor. Set

$$\partial M_0 = \{0\}, \quad M_0 = M \setminus \{0\}, \quad \rho(\varphi) = \|\varphi\|_{L^1(0,1)} \;\forall\varphi \in M.$$

Since $T(t)$ is irreducible, we have $U(t)(\partial M_0) \subset \partial M_0$, and $U(t)M_0 \subset M_0 \;\forall t \geq 0$. Since $U(t)\varphi \to \lambda_0\chi$, as $t \to +\infty$, we deduce that $U(t)$ is ρ-uniformly persistent. So $U(t) : (M_0, d) \to (M_0, d)$ has a global attractor. Let

$$B := \left\{\varphi \in L^1_+(0,1) : \|\varphi\|_{L^1(0,1)} = 1\right\}.$$

Then B is ρ-strongly bounded. Since $\Gamma(1) = 0$, we deduce that there exists $c > 0$ such that $(0, c] \subset \mathcal{F}_\Gamma(B)$. We further claim that for each $\varepsilon > 0$ and $t_0 > 0$, there exist $t_1 > t_0$ and $\varphi \in B$ such that $\|U(t_1)\varphi\|_{L^1(0,1)} < \varepsilon$. Indeed, given $\varepsilon > 0$ and $t_0 > 0$, we can choose $t_1 > t_0$ such that $Me^{-\delta t_1} \leq \varepsilon/2$. Then for every $\varphi \in B$, we have

$$\|U(t_1)\varphi\| \leq \frac{\mathcal{F}_\Gamma(\varphi)\|\chi\|}{\left[1 - \frac{\mathcal{F}_\Gamma(\varphi)}{\lambda_0}\right] e^{-\lambda_0 t_1} + \frac{\mathcal{F}_\Gamma(\varphi)}{\lambda_0}} + \frac{\varepsilon}{2},$$

and hence, by choosing $\varphi \in B$ with $\mathcal{F}_\Gamma(\varphi)$ small enough, we obtain $\|U(t_1)\varphi\| \leq \varepsilon$. This claim shows that for each $t_0 > 0$, $\cup_{t \geq t_0} U(t)B$ is not ρ-strongly bounded. So there exists no compact set in M_0 that attracts B for $U(t)$. In particular, there exists no strong global attractor for the semiflow $U(t) : (M_0, d_0) \to (M_0, d_0)$, where d_0 is defined as in (2).

5.2. -contracting maps on (0 0). In this subsection, we construct κ-contracting maps on (M_0, d_0) such that they admit a global attractor, but no strong global attractor.

We set

$$X = L^1((0, +\infty), \mathbb{R}) \times \mathbb{R}, \; X_+ = L^1_+((0, +\infty), \mathbb{R}) \times \mathbb{R}_+$$

and endow X with the product norm $\|(\varphi, y)\| = \|\varphi\|_{L^1} + |y|$. Define $1_{[0,1]} \in X$ by $1_{[0,1]}(l) = 1 \; \forall l \in (0, 1)$, and $1_{[0,1]}(l) = 0 \; \forall l \in [1, \infty)$. Let a, b, and c be three real numbers. Define $T : X_+ \to X_+$ by $T(\varphi, y) = (T_1(\varphi, y), T_2(\varphi, y))$ with

$$T_1(\varphi, y) = a\varphi(\cdot + 1) + \left[a \int_0^1 \varphi(l)dl + c \frac{\int_0^1 \varphi(l)dl}{1 + \|(\varphi, y)\|}\right] 1_{[0,1]},$$
$$T_2(\varphi, y) = ay + b \frac{\|(\varphi, y)\|}{1 + \|(\varphi, y)\|}.$$

We assume that

(A3) $a \in (0, 1)$, $b > 0$, $c > 0$, $\sqrt{a} < a + b < 1$, and $a + c > 1$.

Consider the discrete-time system

$$x_{n+1} = T(x_n) \; \forall n \geq 0, \text{ and } x_0 \in X_+.$$

It is easy to see that $T^n(0, y) \to 0$, as $n \to +\infty$. Clearly, T is not uniformly persistent for $X_+ \setminus \{0\}$. We will find a closed subset M of X_+, such that it contains 0 and is positively invariant for T, and show that T is uniformly persistent for $M \setminus \{0\}$.

LEMMA 5.1. *There exists a nondecreasing and right-continuous function $f : \mathbb{R}_+ \to \mathbb{R}_+$ such that $f(0) = 0, f(x) > 0 \; \forall x > 0$, $\lim_{x \to 0} f(x) = 0$, and the set $M := \{(\varphi, y) \in X_+ : y \leq f(\|\varphi\|)\}$ is positively invariant for T.*

Proof. We define $F : \mathbb{R}^2_+ \to \mathbb{R}^2_+$ by

$$F(x_1, x_2) = \left(ax_1, ax_2 + b \frac{x_1 + x_2}{1 + x_1 + x_2}\right) \; \forall x = (x_1, x_2) \in \mathbb{R}^2_+.$$

Then F is nondecreasing on $\mathbb{R}^2_+$. Set

$$\chi(t) = (ta + (1 - t), 1) \; \forall t \in [0, 1].$$

By induction, we define $\chi : \mathbb{R}_+ \to \mathbb{R}_+^2$ by

$$\chi(t) = F(\chi(t-1)) \ \forall t \in (n, n+1], \ \ \forall n \geq 1.$$

Note that $\chi(1)_1 = F\left(\chi(0)\right)_1$ and $a < 1$. Then the function $t \to \chi(t)_1$ is strictly decreasing and continuous. Since $F\left(1,1\right) \leq \left(a,1\right)$, the function $t \to \chi(t)_2$ is nonincreasing and left-continuous. Moreover, since $a+b<1$, we have $\lim_{t\to+\infty} \chi(t) = 0$. We further set

$$\chi(t) = (1-t, 1) \ \ \forall t \in (-\infty, 0]\,.$$

Since $\chi(t)_1$ is strictly decreasing in $t \in \mathbb{R}$, we can define

$$f(x) = \begin{cases} \chi(\chi(x)_1^{-1})_2 \text{ if } x > 0, \\ 0 \text{ if } x = 0. \end{cases}$$

It is easy to see that f has the desired properties.

Let $D := \left\{(x_1, x_2) \in \mathbb{R}_+^2 : x_2 \leq f(x_1)\right\}$. Since f is nondecreasing and right-continuous, it easily follows that D is closed. Now we show that $F(D) \subset D$. Let $x = (x_1, x_2) \in D$; then $x_2 \leq f\left(x_1\right)$. If $x_1 = 0$, there is nothing to prove because $F(0) = 0$. Assume that $x_1 > 0$; then there exists $t \in \mathbb{R}$ such that $\chi(t)_1 = x_1$, and hence, $x_2 \leq f(x_1) = \chi(t)_2$. Clearly, $x = (x_1, x_2) \leq \chi(t)$, and $F(x) \leq F(\chi(t))$. In the case where $t \geq 0$, we have

$$\chi(t+1)_1 = F\left(\chi(t)\right)_1 = F\left(x\right)_1,$$

and hence,

$$f(F(x)_1) = \chi(t+1)_2 = F\left(\chi(t)\right)_2 \geq F\left(x\right)_2,$$

which implies that $F(x) \in D$. In the case where $t \leq 0$, we have

$$x_1 \geq F\left(x\right)_1 = F\left(\chi(t)\right)_1 = a\chi(t)_1 = a\left(1-t\right) \geq a = \chi(1)_1,$$

and hence, there exists $s \in [t, 1]$ such that $\chi(s)_1 = F\left(x\right)_1$. It then follows that

$$f(F(x)_1) = \chi(s)_2 = 1 \geq F(\chi(t))_2 \geq F(x)_2,$$

which implies that $F(x) \in D$. This proves that $F(D) \subset D$.

Finally, we prove that $T(M) \subset M$. For any $(\varphi, y) \in M$, we have $(\|\varphi\|, y) \in D$, and hence, the positive invariance of D for F implies that $F(\|\varphi\|, y)_2 \leq f(F(\|\varphi\|, y)_1)$. Note that $\|T_1(\varphi, y)\| \geq a\|\varphi\| = F(\|\varphi\|, y)_1$ and $T_2(\varphi, y) = F(\|\varphi\|, y)_2$. By the monotonicity of f, it then follows that

$$T_2(\varphi, y) = F(\|\varphi\|, y)_2 \leq f(F(\|\varphi\|, y)_1) \leq f(\|T_1(\varphi, y)\|),$$

which implies that $T(\varphi, y) \in M$. Thus, M is positively invariant for T. ◻

Now we consider $T : M \to M$, where M is endowed with the usual distance $d(x, \widehat{x}) = \|x - \widehat{x}\|$. We set

$$\partial M_0 = \{0\}\,, \ M_0 = M \setminus \{0\}\,, \text{ and } \rho(x) = \|x\|\,.$$

Since T is the sum of a compact operator and a linear operator with norm being a, we have $\kappa\left(T(B)\right) \leq a\kappa\left(B\right)$ for any bounded set $B \subset M$. Thus, T is a κ-contraction. Moreover, for each $x \in M$, we have $\|T(x)\| \leq a\|x\| + b + c$, and hence

$$\|T^n(x)\| \leq a^n\|x\| + \left(\sum_{i=0}^{n-1} a^i\right)(b+c)\ \forall n \geq 1.$$

It then follows that $B = \{x \in M : \|x\| \leq \frac{b+c}{1-a}\}$ is positively invariant for T, and attracts every bounded subset of M for T. So $T : (M, d) \to (M, d)$ has a strong global attractor.

Let $\varepsilon > 0$ be fixed such that $a + \frac{c}{1+\varepsilon} > 1$. We claim that

$$\limsup_{n\to\infty} \|T^n x\| \geq \varepsilon\ \forall x = (\varphi, y) \in M_0.$$

Assume, by contradiction, that $\limsup_{n\to\infty} \|T^n x\| < \varepsilon$ for some $x = (\varphi, y) \in M_0$. We set $(\varphi_n, y_n) = T^n x\ \forall n \geq 0$. By the definition of M, we have $\varphi \in L^1_+\left((0, +\infty), \mathbb{R}\right) \backslash \{0\}$. It then follows that there exists $n_0 \geq 0$ such that $\int_0^1 \varphi_{n_0}(l)dl > 0$ and

$$\int_0^1 \varphi_{n+1}(l)dl \geq \left(a + \frac{c}{1+\varepsilon}\right)\int_0^1 \varphi_n(l)dl\ \forall n \geq n_0.$$

Thus, we obtain

$$\int_0^1 \varphi_n(l)dl \to +\infty \text{ as } n \to +\infty,$$

which is a contradiction. By Proposition 3.2, we conclude that T is ρ-uniformly persistent. Since $T : (M, d) \to (M, d)$ has a global attractor, it follows from Theorem 3.7 that $T : (M_0, d_0) \to (M_0, d_0)$ has a global attractor.

To avoid possible confusion, we denote by κ_0 the Kuratowski measure of non-compactness on the complete metric (M_0, d_0). We now consider $T : (M_0, d_0) \to (M_0, d_0)$. Let $\varepsilon > 0$ be fixed such that

$$\sqrt{a} < d := a + \frac{b}{1+\varepsilon} < 1.$$

Then for each $x \in M$, we have

$$\|T(x)\| \geq a\|x\| + b\frac{\|x\|}{1+\|x\|} \geq d\min(\varepsilon, \|x\|).$$

Let $B \subset M_0$ be a ρ-bounded set. We set $\rho_0 = \inf_{x\in B}\rho(x)$. Then for each $x \in B$, we obtain

$$\|T(x)\| \geq a\|x\| + b\frac{\|x\|}{1+\|x\|} \geq d\min(\varepsilon, \|x\|).$$

By induction, it follows that

$$\rho\left(T^n\left(x\right)\right) \geq d^n \min\left(\varepsilon, \rho_0\right)\ \forall n \geq 1, \forall x \in B.$$

Thus, for each $x, y \in B$, we have

$$\begin{aligned} d_0\left(T^n(x), T^n(y)\right) &= \left|\frac{1}{\rho\left(T^n\left(x\right)\right)} - \frac{1}{\rho\left(T^n\left(y\right)\right)}\right| + \left\|T^n\left(x\right) - T^n\left(y\right)\right\| \\ &\leq \left[\frac{1}{\rho\left(T^n\left(x\right)\right)\rho\left(T^n\left(y\right)\right)} + 1\right]\left\|T^n\left(x\right) - T^n\left(y\right)\right\| \\ &\leq \left[\frac{1}{d^{2n}\min\left(\varepsilon, \rho_0\right)^2} + 1\right] d(T^n\left(x\right), T^n\left(y\right)), \end{aligned}$$

and hence,

$$\begin{aligned} \kappa_0\left(T^n(B)\right) &\leq \left[\frac{1}{d^{2n}\min\left(\varepsilon, \rho_0\right)^2} + 1\right]\kappa\left(T^n(B)\right) \\ &\leq a^n\left[\frac{1}{d^{2n}\min\left(\varepsilon, \rho_0\right)^2} + 1\right]\kappa\left(B\right). \end{aligned}$$

Since $d > \sqrt{a}$, we obtain $\kappa_0\left(T^n(B)\right) \to 0$ as $n \to +\infty$. So $T : (M_0, d_0) \to (M_0, d_0)$ is κ_0-contracting.

It remains to show that $T : (M_0, d_0) \to (M_0, d_0)$ has no strong global attractor. Let $\delta > 0$ be fixed, and consider the ρ-strongly bounded set

$$B_\delta = \left\{x \in M : \rho\left(x\right) = \delta\right\}.$$

For each $m \geq 0$, we set $x^m := (\varphi^m, 0)$ with $\varphi^m = \delta 1_{[m,m+1]}$, and

$$x_n^m := (\varphi_n^m, y_n^m) = T^n\left(x^m\right) \quad \forall n \geq 0.$$

Then for each $m \geq 1$ and each $n \in \{0, \ldots, m-1\}$, we have $\int_0^1 \varphi_n^m(l)dl = 0$, and hence,

$$\begin{cases} \varphi_{n+1}^m(\cdot) = a\varphi_n^m(\cdot + 1) + a\int_0^1 \varphi_n^m(l)dl 1_{[0,1]}(\cdot), \\ y_{n+1}^m = ay_n^m + b\frac{\|x_n^m\|}{1+\|x_n^m\|}. \end{cases}$$

Thus, for each $m \geq 1$ and each $n \in \{0, \ldots, m-1\}$, we obtain

$$\left\|x_{n+1}^m\right\| \leq (a+b)\left\|x_n^m\right\| \leq (a+b)^n\,\delta.$$

It follows that $\inf_{x \in B_\delta} \rho\left(T^n\left(x\right)\right) \to 0$ as $n \to +\infty$. So the κ_0-contracting map $T : (M_0, d_0) \to (M_0, d_0)$ has a global attractor, but no strong global attractor.

5.3. -contracting semiflows on ($_0$ $_0$). In this subsection, we construct continuous-time κ-contracting semiflows on (M_0, d_0) such that they admit a global attractor, but no strong global attractor.

Let X and X_+ be defined as in the previous subsection. Consider the following age-structured model:

$$\begin{cases} \frac{\partial u}{\partial t} + \frac{\partial u}{\partial a} = -\mu u(t,a), \ t \geq 0, a \in (0, \infty), \\ u(t,0) = \frac{\int_0^{+\infty}\beta(a)u(t,a)da}{1+\|(u(t),y(t))\|}, \\ \frac{dy(t)}{dt} = -\mu y(t) + \gamma\frac{\|(u(t),y(t))\|}{1+\|(u(t),y(t))\|}, \\ u(0,.) = u_0 \in L_+^1\left((0,+\infty), \mathbb{R}\right), \ y(0) = y_0 \in \mathbb{R}_+. \end{cases} \tag{4}$$

We assume that

(A4) $\mu > 0$, $\gamma \in (\frac{\mu}{2}, \mu)$, $\beta : \mathbb{R}_+ \to \mathbb{R}_+$ is uniformly continuous, bounded, $\int_0^\infty \beta(a)e^{-\mu a}da > 1$, and there exists a sequence of real numbers $\{a_n\}_{n\geq 0} \subset [0, +\infty)$ such that $a_n < a_{n+1}$ $\forall n \geq 0$, $\lim_{n\to+\infty}(a_{2n+2} - a_{2n+1}) = +\infty$, and

$$\beta(a) > 0 \Leftrightarrow a \in \bigcup_{n\geq 0} (a_{2n}, a_{2n+1}).$$

For each $\chi \in L^\infty((0,+\infty), \mathbb{R})$ and each $\varphi \in L^1((0,+\infty), \mathbb{R})$, we define

$$\mathcal{F}_\chi(\varphi) = \int_0^{+\infty} \chi(s)\varphi(s)ds.$$

Let $\{U(t)\}_{t\geq 0}$ be the solution semiflow on X_+ generated by system (4), and let $(u(t), y(t)) = U(t)(u_0, y_0)$. Then we have the following Volterra formulation of system (4):

$$u(t,a) = \begin{cases} e^{-\mu t}u_0(a-t) \text{ if } a > t, \\ e^{-\mu a}B(t-a) \text{ if } a \leq t, \end{cases}$$

with $B(t) = \frac{\mathcal{F}_\beta(u(t))}{1+\mathcal{F}_1(u(t))+y(t)}$, and for each $t \geq 0$,

$$\begin{cases} \frac{d\mathcal{F}_1(u(t))}{dt} = -\mu\mathcal{F}_1(u(t)) + \frac{\mathcal{F}_\beta(u(t))}{1+\mathcal{F}_1(u(t))+y(t)}, \\ \frac{dy(t)}{dt} = -\mu y(t) + \gamma\frac{\mathcal{F}_1(u(t))+y(t)}{1+\mathcal{F}_1(u(t))+y(t)}, \end{cases} \tag{5}$$

and

$$\mathcal{F}_\beta(u(t)) = e^{-\mu t}\int_t^{+\infty} \beta(s)u_0(s-t)ds + \int_0^t \beta(s)e^{-\mu a}\frac{\mathcal{F}_\beta(u(t-a))}{1+\mathcal{F}_1(u(t-a))+y(t-a)}da.$$

LEMMA 5.2. *There exists a continuous and nondecreasing function $f : \mathbb{R}_+ \to \mathbb{R}_+$ such that $f(0) = 0$, $f(x) > 0$ $\forall x > 0$, and the set*

$$M := \{(\varphi, y) \in X_+ : y \leq f(\|\varphi\|)\}$$

is positively invariant for $\{U(t)\}_{t\geq 0}$.

Proof. Let $(\widehat{x}(t), \widehat{y}(t))$ be the unique solution on $[0,\infty)$ of the following cooperative system:

$$\begin{cases} \frac{dx(t)}{dt} = -\mu x(t), \\ \frac{dy(t)}{dt} = -\mu y(t) + \gamma\frac{x(t)+y(t)}{1+x(t)+y(t)} \end{cases} \tag{6}$$

with

$$(\widehat{x}(0), \widehat{y}(0)) = \left(\frac{\gamma}{\mu} + 1, \frac{\gamma}{\mu} + 1\right).$$

Since $\widehat{x}'(0) < 0$ and $\widehat{y}'(0) < 0$, $(\widehat{x}(t), \widehat{y}(t))$ is nonincreasing on some small interval $[0, \epsilon]$. By the monotonicity of the solution semiflow of system (6) on $\mathbb{R}^2_+$, it follows that $(\widehat{x}(t), \widehat{y}(t))$ is nonincreasing on $[0,\infty)$, and $(\widehat{x}(t), \widehat{y}(t)) \to (0,0)$ as $t \to +\infty$. Set

$$\widehat{x}(t) = \frac{\gamma}{\mu} + 1 - t, \text{ and } \widehat{y}(t) = \frac{\gamma}{\mu} + 1 \quad \forall t \in (-\infty, 0].$$

Clearly, $\widehat{x}(t)$ is strictly decreasing in $t \in \mathbb{R}$. Define $f : \mathbb{R}_+ \to \mathbb{R}_+$ by

$$f(\alpha) = \begin{cases} \widehat{y}(\widehat{x}^{-1}(\alpha)) \text{ if } \alpha > 0, \\ 0 \text{ if } \alpha = 0. \end{cases}$$

Then f satisfies the desired properties. Note that the set $D := \{(x, y) \in \mathbb{R}_+^2 : y \leq f(x)\}$ is positively invariant for the solution semiflow of (6). By using the monotonicity of f and the planar vector field associated with (5), one can easily prove that $U(t)M \subset M$ $\forall t \geq 0$. $\square$

Now we consider $U(t) : (M, d) \to (M, d)$, where $d(x, \widehat{x}) = \|x - \widehat{x}\|$. Set

$$\partial M_0 = \{0\}, \ M_0 = M \setminus \{0\}, \text{ and } \rho(x) = \|x\|.$$

Since $\beta : \mathbb{R}_+ \to \mathbb{R}_+$ is uniformly continuous, it follows from [28] that for any bounded set $B \subset M$, we have

$$\kappa(U(t)B) \leq e^{-\mu t} \kappa(B) \ \ \forall t \geq 0.$$

Let $z(t) := \mathcal{F}_1(u(t)) + y(t)$. Then we obtain

$$\frac{dz(t)}{dt} \leq -\mu z(t) + (\|\beta\|_\infty + \gamma) \ \ \forall t \geq 0.$$

Consequently, $U(t) : (M, d) \to (M, d)$ has a strong global attractor.

Let $\varepsilon > 0$ be such that

$$\frac{\int_0^{+\infty} \beta(a) e^{-\mu a} da}{1 + \varepsilon} > 1.$$

We claim that $\limsup_{t\to\infty} \|U(t)x\| \geq \varepsilon$ $\forall x \in M_0$. Assume, by contradiction, that $\limsup_{t\to\infty} \|U(t)x\| < \varepsilon$ for some $x = (u_0, y_0) \in M_0$. Then there exists $t_0 \geq 0$ such that $\|U(t + t_0)x\| < \varepsilon$ $\forall t \geq 0$. By the definition of M, we have $u_0 \neq 0$, and hence, $u(t) \neq 0$ $\forall t \geq 0$. It follows that $u(t + t_0) \geq \widehat{T}(t) u(t_0)$ $\forall t \geq 0$, where $\{\widehat{T}(t)\}_{t\geq 0}$ is the strongly continuous semigroup of bounded linear operators on $L^1((0, +\infty), \mathbb{R})$, which is generated by $\widehat{A}\varphi = -\varphi' - \mu\varphi$ with

$$D(\widehat{A}) = \left\{ \varphi \in W^{1,1}((0, +\infty), \mathbb{R}) : \varphi(0) = \frac{\int_0^{+\infty} \beta(a)\varphi(a) da}{1 + \varepsilon} \right\}.$$

Since $u(t_0) \neq 0$, it follows from [28] that

$$\|u(t + t_0)\|_{L^1} \geq \left\| \widehat{T}(t) u(t_0) \right\|_{L^1} \to +\infty \text{ as } t \to +\infty,$$

which is a contradiction. By the continuous-time version of Proposition 3.2, we deduce that $U(t) : (M, d) \to (M, d)$ is ρ-uniformly persistent, and hence, $U(t) : (M_0, d_0) \to (M_0, d_0)$ has a global attractor (see Theorem 3.7 and Remark 3.10).

We now prove that $U(t) : (M_0, d_0) \to (M_0, d_0)$ is κ_0-contracting. Let $\varepsilon > 0$ be such that $\mu - \frac{2\gamma}{1+\varepsilon} < 0$. Let B be a ρ-strongly bounded set of M_0. We set $\rho_0 = \inf_{x\in B} \rho(x)$. For each $x \in B$, if we set $z(t) = \rho(U(t)x)$ $\forall t \geq 0$, we then have

$$\frac{dz(t)}{dt} \geq -\mu z(t) + \gamma \frac{z(t)}{1 + z(t)} \ \ \forall t \geq 0,$$

and hence,

$$\rho\left(U(t)x\right) \geq e^{\left(-\mu+\frac{\gamma}{1+\varepsilon}\right)t} \min\left(\varepsilon, \rho_0\right) \ \forall t \geq 0.$$

It then follows that for each $x, y \in B$, we have

$$d_0\left(U(t)x, U(t)y\right) \leq \left[\frac{1}{e^{2\left(-\mu+\frac{\gamma}{1+\varepsilon}\right)t} \min\left(\varepsilon, \rho_0\right)^2} + 1\right] d\left(U(t)x, U(t)y\right),$$

and hence,

$$\begin{aligned}\kappa_0\left(U(t)B\right) &\leq \left[\frac{1}{e^{2\left(-\mu+\frac{\gamma}{1+\varepsilon}\right)t} \min\left(\varepsilon, \rho_0\right)^2} + 1\right] \kappa\left(U(t)B\right) \\ &\leq e^{-\mu t}\left[\frac{1}{e^{2\left(-\mu+\frac{\gamma}{1+\varepsilon}\right)t} \min\left(\varepsilon, \rho_0\right)^2} + 1\right] \kappa\left(B\right).\end{aligned}$$

Since $\mu - \frac{2\gamma}{1+\varepsilon} < 0$, we deduce that $\kappa_0\left(U(t)B\right) \to 0$ as $t \to +\infty$. So $U(t) : (M_0, d_0) \to (M_0, d_0)$ is κ_0-contracting.

It remains to show that $U(t) : (M_0, d_0) \to (M_0, d_0)$ has no strong global attractor. We fix a real number $\delta > 0$ and set

$$B := \left\{x \in M : \rho\left(x\right) = \delta\right\}.$$

Let $x^n = \left(u_0^n, 0\right)$, with $u_0^n = \delta 1_{[a_{2n+1}, a_{2n+1}+1]}(\cdot)$, and $(u^n(t), y^n(t)) = U(t)x^n \ \forall t \geq 0$. Then for each $t \geq 0$, we have

$$\begin{aligned}\mathcal{F}_\beta\left(u^n(t)\right) &= e^{-\mu t}\int_t^{+\infty} \beta(s) u_0^n(s-t) ds \\ &+ \int_0^t \beta(s) e^{-\mu a} \frac{\mathcal{F}_\beta\left(u^n(t-a)\right)}{1+\mathcal{F}_1\left(u^n(t-a)\right) + y^n(t-a)} da\end{aligned} \tag{7}$$

and

$$\begin{aligned}\int_t^{+\infty} \beta(s) u_0^n(s-t) ds &= \int_0^{+\infty} \beta(s+t) u_0^n(s) ds \\ &= \delta \int_{a_{2n+1}}^{a_{2n+1}+1} \beta(s+t) ds = \delta \int_{t+a_{2n+1}}^{t+a_{2n+1}+1} \beta(s) ds.\end{aligned}$$

Since $a_{2n+2} - a_{2n+1} \to +\infty$ as $n \to +\infty$, there exists $n_0 \geq 0$ such that $a_{2n+2} - a_{2n+1} > 1 \ \forall n \geq n_0$. Then we have

$$\int_t^{+\infty} \beta(s) u_0^n(s-t) ds = 0 \ \forall t \in [0, a_{2n+2} - (a_{2n+1}+1)], \ \forall n \geq n_0.$$

Since $\mathcal{F}_\beta\left(u^n(t)\right)$ is a solution of (7), we deduce that for each $n \geq n_0$, and $t \in [0, a_{2n+2} - (a_{2n+1}+1)]$, $\mathcal{F}_\beta\left(u^n(t)\right) = 0$. It then follows that $z_n(t) := \|U(t)x^n\|$ satisfies $z_n(0) = \delta$ and

$$\frac{dz_n(t)}{dt} = -\mu z_n(t) + \gamma \frac{z_n(t)}{1+z_n(t)} \ \forall t \in [0, a_{2n+2} - (a_{2n+1}+1)], \ \forall n \geq n_0.$$

Thus, we have

$$z_n(t) \leq e^{(-\mu+\gamma)t}\delta \ \forall t \in [0, a_{2n+2} - (a_{2n+1}+1)],$$

which implies that $\inf_{x\in B} \rho\left(U(t)x\right) \to 0$, as $t \to +\infty$. So $U(t) : (M_0, d_0) \to (M_0, d_0)$ has no strong global attractor.

5.4. A periodic age-structured model. In this subsection, we illustrate applicability of Theorem 4.5 in the case of convex κ-contracting maps.

Consider the 1-periodic nonautonomous age-structured model

$$(8)\quad \begin{cases} \frac{\partial u}{\partial t} + \frac{\partial u}{\partial a} = -\left(\mu + m(t, \int_0^{+\infty} u(t,l)dl)(a)\right) u(t,a),\ t \geq 0,\ a \in (0,+\infty), \\ u(t,0) = \frac{\int_0^{+\infty} \beta(t,a)u(t,a)da}{1+\int_0^{+\infty} u(t,a)da}, \\ u(0,.) = u_0 \in L^1_+ ((0,+\infty), \mathbb{R}). \end{cases}$$

We assume that

(A5) $\mu > 0$ and the following conditions are satisfied:

(a) $\beta : \mathbb{R}^2_+ \to \mathbb{R}_+$ is uniformly continuous, positive, bounded, and $t \to \beta(t,a)$ is 1-periodic.

(b) $m \in C\left(\mathbb{R}^2_+, L^\infty_+ ((0,+\infty), \mathbb{R})\right)$ and the map $t \to m(t,\cdot)$ is 1-periodic.

(c) There exist a bounded and uniformly continuous map $\widehat{\beta} : \mathbb{R}_+ \to \mathbb{R}_+$ and a continuous and bounded map $\widehat{m} : \mathbb{R}_+ \to \mathbb{R}_+$ such that

$$\beta(t,\cdot) \geq \widehat{\beta}(\cdot) \text{ and } m(t,\cdot) \leq \widehat{m}(\cdot)\ \forall t \in [0,1],$$

and for any $a \geq 0$, there exists $r \geq a$ such that $\widehat{\beta}(r) > 0$ and

$$\int_0^{+\infty} \widehat{\beta}(a) e^{-\int_0^a \mu + \widehat{m}(r)dr} da > 1.$$

Let $Y = L^1_+ ((0,+\infty), \mathbb{R})$ and $Y_+ = L^1_+ ((0,+\infty), \mathbb{R})$, and let $\{U(t,s)\}_{0 \leq s \leq t}$ be the nonautonomous semiflow generated by system (8). Set

$$M = Y_+,\ \partial M_0 = \{0\} \text{ and } M_0 = Y_+ \setminus \{0\}.$$

Then $U(t,s)0 = 0$, and $U(t,s)M_0 \subset M_0\ \forall t \geq s \geq 0$. For a 1-periodic solution of system (8) in $Y_+ \setminus \{0\}$, it suffices to find a fixed point of $T = U(1,0)$. By setting $x(t) := \mathcal{F}_1 (U(t,s)x)$, we have

$$\frac{dx(t)}{dt} \leq -\mu x(t) + \|\beta\|_\infty \frac{x(t)}{1+x(t)},$$

which implies that T is bounded dissipative on M. Moreover, by using the results in [28] and assumptions (A5)(a),(b), we obtain

$$U(t,s) = C(t,s) + N(t,s),$$

where $C(t,s)$ is a compact operator, and

$$\|N(t,s)x\| \leq e^{-\mu(t-s)} \|x\|\ \forall t \geq s \geq 0, \forall x \in M.$$

Thus, T is κ-contracting in the sense that $\kappa(T^n(B)) \to 0$ as $n \to +\infty$ for any bounded set $B \subset M$. It follows from Theorem 2.9 that T has a strong global attractor in M. Using assumption (A5)(c) and comparison arguments, we can further prove that the fixed point 0 of T is ejective. In order to apply Theorem 4.5, we need to verify that T is convex κ-contracting.

Let $V(t,s) = (V_1(t,s), V_2(t,s))$ be the nonautonomous semiflow on $Y_+ \times Y_+$, which is generated by the following system:

$$\begin{cases} \frac{\partial u_1}{\partial t} + \frac{\partial u_1}{\partial a} = -\left(\mu + m(t, \int_0^{+\infty} (u_1 + u_2)(t,l)dl)(a)\right) u_1(t,a), \ a \in (0,+\infty), \\ u_1(t,0) = 0, \\ \frac{\partial u_2}{\partial t} + \frac{\partial u_2}{\partial a} = -\left(\mu + m(t, \int_0^{+\infty} (u_1 + u_2)(t,l)dl)(a)\right) u_2(t,a), \ a \in (0,+\infty), \\ u_2(t,0) = \frac{\int_0^{+\infty} \beta(t,a)(u_1+u_2)(t,a)da}{1+\alpha \int_0^{+\infty} (u_1+u_2)(t,a)da}, \\ (u_1(0,.), u_2(0,.)) = \left(u_0^1, u_0^2\right) \in L_+^1\left((0,+\infty), \mathbb{R}^2\right). \end{cases}$$

We define $P_n : Y \to Y$ by

$$P_n(\varphi) = \varphi 1_{[n,+\infty)} \ \forall n \geq 0.$$

Then for each $n \geq 0$, we have

$$P_{n+1}T(x) = V_1(1,0)(P_n x, (I - P_n)x)$$

and

$$(I - P_{n+1})T(x) = V_2(1,0)(P_n x, (I - P_n)x).$$

Moreover, if B is bounded and $(I - P_n)(B)$ is relatively compact, then

$$\{(I - P_{n+1})T(x) : x \in B\} = \{V_2(1,0)(P_n x, (I - P_n)x) : x \in B\}$$

is relatively compact. Note that for each $x \in M$, we have

$$\|P_{n+1}T(x)\| = \|V_1(1,0)(P_n x, (I - P_n)x)\| \leq e^{-\mu} \|P_n x\|.$$

By Lemma 4.8, it follows that T is convex κ -contracting. Thus, Theorem 4.5 implies that T has a fixed point in M_0, and hence, system (8) admits a nontrivial 1-periodic solution.

Finally, we remark that the similar approach can be applied to more general age-structured models.

Acknowledgments. We would like to express our gratitude to three anonymous referees for their helpful comments and suggestions which led to an important improvement of our original manuscript.

ASYMPTOTIC BEHAVIOR OF THE ELECTROMAGNETIC FIELD FOR A MICROMAGNETISM EQUATION WITHOUT EXCHANGE ENERGY*

FRANK JOCHMANN†

Abstract. This paper deals with the transient Landau–Lifschitz equations describing ferromagnetic media without exchange interaction coupled with Maxwell's equations. The asymptotic behavior of the solutions to this system is investigated.

Key words. asymptotic behavior of solutions, ferromagnetism, Maxwell's equations, existence of solutions

AMS subject classifications. 35Q60, 35L25, 78A40

DOI. 10.1137/S0036141004443324

1. Introduction. This paper is concerned with a mathematical model for micromagnetism consisting of Maxwell's equations

$$\varepsilon\partial_t\mathbf{E} = \text{curl } \mathbf{H} - \sigma\mathbf{E} - \mathbf{j}, \quad \mu\partial_t\mathbf{H} = -\text{ curl } \mathbf{E} - \mu\partial_t\tilde{\mathbf{M}}, \tag{1.1}$$

coupled with the equation

$$\partial_t\mathbf{M} = F(x, \mathbf{M}) \cdot [\mathbf{H} - A(x)\mathbf{M}] \tag{1.2}$$

for the unknown electromagnetic field quantities $\mathbf{E}, \mathbf{H}$ depending on the time $t \geq 0$ and the space variable $x \in \mathbb{R}^3$. The magnetization $\mathbf{M}$ defined on $\mathbb{R}^+ \times G$ is also an unknown function which solves the ordinary differential equation (1.2); see [1], [6], [5], [8]. Here the set $G \subset \mathbb{R}^3$ represents the ferromagnetic medium. In (1.1) the function $\tilde{\mathbf{M}}$ is the extension of $\mathbf{M}$ on $\mathbb{R}^+ \times \mathbb{R}^3$ defined by zero on the set $\mathbb{R}^+ \times (\mathbb{R}^3 \setminus G)$. This system is supplemented by the initial conditions

$$\mathbf{E}(0, x) = \mathbf{E}_0(x), \quad \mathbf{H}(0, x) = \mathbf{H}_0(x) \tag{1.3}$$

and

$$\mathbf{M}(0, x) = \mathbf{M}_0(x) \text{ on } G. \tag{1.4}$$

From the physical point of view it is reasonable to assume that the initial state for the magnetic induction $\mathbf{B}_0 \stackrel{\text{def}}{=} \mu(\mathbf{H}_0 + \tilde{\mathbf{M}}_0)$ is divergence free.

In (1.2) the term $A(x)\mathbf{M}$ describes a possible anisotropy of the medium, where $A(x)$ is a symmetric positive semidefinite matrix. The precise assumptions on the nonlinear function $F : G \times \mathbb{R}^3 \to \mathbb{R}^{3\times 3}$ will be given in the next section. A physically relevant example for F is

$$F(x, \mathbf{m})\mathbf{h} = -\gamma\mathbf{m} \wedge \mathbf{h} - \alpha|\mathbf{m}|^{-1}\mathbf{m} \wedge (\mathbf{m} \wedge \mathbf{h}), \tag{1.5}$$

including a damping term $\alpha\mathbf{m} \wedge (\mathbf{m} \wedge \mathbf{h})$ with $\alpha \geq 0$.

The main topic of this paper is the investigation of the large time asymptotic behavior of the solutions. If F is given by (1.5), one obtains the energy dissipation law

$$\frac{1}{2}\frac{d}{dt}\left(\int_{\mathbb{R}^3}(\varepsilon|\mathbf{E}|^2+\mu|\mathbf{H}|^2)dx+\int_G \mu\mathbf{M}\cdot A\mathbf{M}dx\right) \tag{1.6}$$

$$= -\int_{\mathbb{R}^3}\mathbf{E}\mathbf{j}dx-\int_{\mathbb{R}^3}\sigma|\mathbf{E}|^2dx-\int_G \mu\alpha|\mathbf{M}|^{-1}|\mathbf{M}\wedge[\mathbf{H}-A\mathbf{M}]|^2dx$$

for the system (1.1)–(1.4) including dissipative terms arising from the electrical conductivity σ and the damping for $\partial_t\mathbf{M}$ on the set where $\alpha > 0$. In the autonomous case where $\mathbf{j} = 0$, the energy occurring in (1.6) is a nonincreasing function of the time t. However, no information about the asymptotic behavior of $\mathbf{M}$ and the magnetic field $\mathbf{H}$ (even on sets of nonvanishing electrical conductivity) can be obtained directly from this dissipation law, since there is no direct damping for any component of $\mathbf{H}$. In this paper the damping coefficient α may vanish on some part of the set G, which means that on this subset there is even no damping for $\partial_t\mathbf{M}$.

The main goal of section 3 is to show that the solenoidal part of the magnetic field decays in the weak topology and that the electric field converges for $t \to \infty$ weakly to some asymptotic state which is determined by the prescribed initial data $\mathbf{E}_0, \mathbf{H}_0, \mathbf{M}_0$ and the external current $\mathbf{j}$ (Theorem 2.2).

In section 4 it is shown that this convergence of the electromagnetic field is strong with respect to the energy norm for $t \to \infty$ on bounded sets of nonvanishing electrical conductivity (Theorem 2.4). Here, the main idea is to prove local energy estimates using a vector potential which provides additional dissipative terms for the magnetic field. Since the system (1.1)–(1.4) does not admit strong solutions with bounded derivatives for $t \to \infty$ in general, this strong convergence cannot be obtained from standard embedding results.

The existence of solutions to (1.1)–(1.4) has been proved in [6] for constant coefficients ε, μ and in [5] for nonsmooth coefficients ε, μ. In the spatially one-dimensional case the local decay of the transverse components is shown in [7]. Uniqueness of solutions to (1.1)–(1.4) is still an open question, at least for nonsmooth coefficients as considered here. The quasi-stationary limit for this system is studied in [5], in which the size of the ferromagnetic medium is very small in comparison to the electromagnetic wave length. It is shown in [5] that in this case the magnetic field is governed by the equations of the magnetostatic approximation.

Existence and quasi-stationary limit for the Landau–Lifschitz equation for the magnetic moment with exchange interaction coupled with Maxwell's equations are studied in [2] and [3]; see also [11]. Furthermore it is shown in [2] and [3] that all points of the weak ω-limit set are solutions of the corresponding stationary equations by using the $H^1(G)$ estimate coming from the second order exchange-energy term which does not occur in the system (1.1)–(1.4).

2. Definitions, assumptions, and statement of main results. All assumptions stated in this section shall be fulfilled throughout this paper. Let $G \subset \mathbb{R}^3$ be an open subset of finite measure. The dielectric and magnetic susceptibilities $\varepsilon, \mu \in L^\infty(\mathbb{R}^3)$ are assumed to have a positive lower bound, which means that

$$\varepsilon(x), \mu(x) \geq a_0 \text{ on } \mathbb{R}^3 \text{ with some } a_0 > 0. \tag{2.1}$$

The assumptions on the initial data $(\mathbf{E}_0, \mathbf{H}_0) \in X$ and $\mathbf{j}$ are

$$\mathbf{j} \in L^1((0,\infty), L^2(\mathbb{R}^3)) \cap L^\infty((0,\infty), L^2(\mathbb{R}^3)), \quad \mathbf{E}_0 \in L^2(\mathbb{R}^3), \quad \mathbf{H}_0 \in L^2(\mathbb{R}^3), \tag{2.2}$$

and

$$\mathbf{M}_0 \in L^\infty(G) \text{ with div } [\mu(\mathbf{H}_0 + \tilde{\mathbf{M}}_0)] = 0 \text{ on } \mathbb{R}^3. \tag{2.3}$$

Next, $A \in L^\infty(G, \mathbb{R}^{3\times 3})$ is assumed to be a positive semidefinite matrix-valued function, which means that $A(x) \in \mathbb{R}^{3\times 3}$ is symmetric and

$$y \cdot A(x)y \geq 0 \text{ for all } x \in G,\, y \in \mathbb{R}^3. \tag{2.4}$$

It is assumed that the nonlinear function $F : G \times \mathbb{R}^3 \to \mathbb{R}^{3\times 3}$ satisfies

$$\mathbf{m} \cdot F(x, \mathbf{m})\mathbf{h} = 0 \text{ for all } x \in G,\, \mathbf{h} \in \mathbb{R}^3, \text{ and } \mathbf{m} \in \mathbb{R}^3, \tag{2.5}$$

and that there is some nonnegative function $\beta \in L^\infty(G)$ such that

$$\mathbf{h} \cdot F(x, \mathbf{m})\mathbf{h} \geq \beta(x)|F(x, \mathbf{m})\mathbf{h}|^2 \tag{2.6}$$

for all $x \in G$, $\mathbf{h} \in \mathbb{R}^3$, and $\mathbf{m} \in \mathbb{R}^3$ with $|\mathbf{m}| \leq \|\mathbf{M}_0\|_{L^\infty(G)}$, where $\mathbf{M}_0$ is as in (2.2). Furthermore, F is assumed to be locally Lipschitz-continuous with respect to $\mathbf{M}$; i.e., for $k \in (0,\infty)$ there exists $L_k \in (0,\infty)$ such that

$$|F(x, y) - F(x, \tilde{y})| \leq L_k|y - \tilde{y}| \tag{2.7}$$

for all $x \in G$, $y \in \mathbb{R}^3$, and $\tilde{y} \in \mathbb{R}^3$ with $|y| + |\tilde{y}| \leq k$. Finally,

$$F(\cdot, 0) \in L^\infty(G). \tag{2.8}$$

The conductivity satisfies

$$\sigma \in L^\infty(\mathbb{R}^3) \quad \text{and} \quad \sigma \geq 0. \tag{2.9}$$

Let

$$G_0 \stackrel{\text{def}}{=} \{x \in G : \beta(x) = 0\} \tag{2.10}$$

with the nonnegative function $\beta \in L^\infty(G)$ occurring in assumption (2.6), and let

$$S_\sigma \stackrel{\text{def}}{=} \{x \in \mathbb{R}^3 : \sigma(x) > 0\} \tag{2.11}$$

be the conducting region.

It is assumed that there is a nonempty open set $\mathcal{U} \subset S_\sigma$ such that

$$\overline{G_0} \subset \mathcal{U} \subset S_\sigma. \tag{2.12}$$

Roughly speaking this condition requires that the medium is conducting on a neighborhood of the region of undamped magnetization contained in G_0. Furthermore,

$$\varepsilon(x) = \mu(x) = 1 \text{ on } \mathbb{R}^3 \setminus \mathcal{U}. \tag{2.13}$$

The physical meaning of this condition is that the set $\mathbb{R}^3 \setminus S_\sigma \subset \mathbb{R}^3 \setminus \mathcal{U}$ represents the vacuum region.

Remark 1. If F is given by (1.5) with some nonnegative function $\alpha \in L^\infty(G)$, one obtains

$$\mathbf{h} \cdot F(x, \mathbf{m})\mathbf{h} = -\alpha(x)|\mathbf{m}|^{-1}\mathbf{h} \cdot \mathbf{m} \wedge (\mathbf{m} \wedge \mathbf{h}) = \alpha(x)|\mathbf{m}|^{-1}|\mathbf{m} \wedge \mathbf{h}|^2$$

$$\geq \alpha(x)\|\mathbf{M}_0\|^{-1}_{L^\infty(G)}|\mathbf{m} \wedge \mathbf{h}|^2$$

and

$$|F(x, \mathbf{m})\mathbf{h}|^2 \leq 2\|\gamma\|^2_{L^\infty(G)}|\mathbf{m} \wedge \mathbf{h}|^2 + 2\|\alpha\|^2_{L^\infty(G)}|\mathbf{m} \wedge \mathbf{h}|^2$$

for all $x \in G$, $\mathbf{h} \in \mathbb{R}^3$, and $\mathbf{m} \in \mathbb{R}^3$ with $|\mathbf{m}| \leq \|\mathbf{M}_0\|_{L^\infty(G)}$, whence assumption (2.6). Furthermore, the set G_0 occurring in (2.10) can be chosen as $G_0 = \{x \in G : \alpha(x) = 0\}$ in this case.

Next, let H_{curl} be the space of all $\mathbf{e} \in L^2(\mathbb{R}^3, \mathbb{R}^3)$ with $\operatorname{curl} \mathbf{e} \in L^2(\mathbb{R}^3)$. As in [5] let $1 - P_E$ and $1 - P_H$ be the orthogonal projectors on $H_{curl,0} \stackrel{\text{def}}{=} \{\mathbf{f} \in H_{curl} : \operatorname{curl} \mathbf{f} = 0\}$ with respect to the weighted scalar products

$$\langle \mathbf{e}, \mathbf{f} \rangle_\varepsilon \stackrel{\text{def}}{=} \int_{\mathbb{R}^3} \varepsilon \mathbf{e} \cdot \mathbf{f} dx \quad \text{and} \quad \langle \mathbf{g}, \mathbf{h} \rangle_\mu \stackrel{\text{def}}{=} \int_{\mathbb{R}^3} \mu \mathbf{g} \cdot \mathbf{h} dx,$$

respectively. Furthermore, let P_0 be the orthogonal projector on $H_{div,0} \stackrel{\text{def}}{=} \{\mathbf{f} \in H_{curl} : \operatorname{div} \mathbf{f} = 0\}$ with respect to the standard scalar product. It can be regarded as a pseudodifferential operator of order zero and can be expressed by using a Fourier transform:

$$(1 - P_0)\mathbf{u} = \mathcal{F}^{-1}\left(|k|^{-2} k \cdot \widehat{\mathbf{u}}(k) k\right). \tag{2.14}$$

One of the main results in [5] is the existence of solutions.

Proposition 2.1. *Assume* (2.1)–(2.9). *Then problem* (1.1)–(1.4) *admits a weak solution* $(\mathbf{E}, \mathbf{H}, \mathbf{M})$ *with the properties*

$$(\mathbf{E}, \mathbf{H}) \in C([0, \infty), X) \quad \textit{and} \quad \mathbf{M} \in W^{1,\infty}_{loc}([0, \infty), L^2(G)) \cap L^\infty_{loc}([0, \infty), L^\infty(G)).$$

Here and in what follows, the space variable $x \in \mathbb{R}^3$ is often omitted in the notation for the sake of brevity. The Maxwell system (1.1) is fulfilled in the sense that

$$(\mathbf{E}(t), \mathbf{H}(t)) = \exp(tB)(\mathbf{E}_0, \mathbf{H}_0) \tag{2.15}$$

$$- \int_0^t \exp((t - s)B)\left[\mathcal{R}\partial_t \mathbf{M}(s) + (\varepsilon^{-1}\mathbf{j}(s), 0) + F_\sigma(\mathbf{E}(s), \mathbf{H}(s))\right] ds,$$

where $(\exp(tB))_{t \in \mathbb{R}}$ is the unitary group generated by the skew adjoint operator B in the Hilbert space $X \stackrel{\text{def}}{=} L^2(\mathbb{R}^3, \mathbb{C}^6)$ introduced in [5, sect. 2]; see [9]. The definitions of $F_\sigma : X \to X$ and $\mathcal{R} : L^2(G) \to X$ can also be found in [5, sect. 2].

In what follows let $\mathcal{Z}$ be the set of all $\mathbf{f} \in H_{curl,0}$ with $\mathbf{f}(x) = 0$ for all $x \in S_\sigma$, where S_σ is given in (2.11).

Let P_1 be the orthogonal projector on $\mathcal{Z}$ in $L^2(\mathbb{R}^3)$ with respect to the weighted scalar product $\langle \cdot, \cdot \rangle_\varepsilon$. Now the main result of this paper concerning weak convergence for $t \to \infty$ can be stated.

THEOREM 2.2. *Assume* (2.1)–(2.13). *Then every solution* $(\mathbf{E}, \mathbf{H}, \mathbf{M})$ *(with the previously mentioned properties) to problem* (1.1)–(1.4) *satisfies*

$$\mathbf{E}(t) \stackrel{t\to\infty}{\longrightarrow} P_1 \left(\mathbf{E}_0 - \int_0^\infty \varepsilon^{-1} \mathbf{j}(s) ds \right) \text{ in } L^2(\mathbb{R}^3) \text{ weakly,}$$

$$P_H \mathbf{H}(t) \stackrel{t\to\infty}{\longrightarrow} 0 \text{ and } P_0 \mathbf{H}(t) \stackrel{t\to\infty}{\longrightarrow} 0 \text{ in } L^2(\mathbb{R}^3) \text{ weakly.} \tag{2.16}$$

COROLLARY 2.3. *Suppose that, in addition to the assumptions of Theorem* 2.2*,*

$$\int_{\mathbb{R}^3} \mathbf{D}_0 \mathbf{f} dx = 0 \text{ for all } \mathbf{f} \in \mathcal{Z}, \tag{2.17}$$

where $\mathbf{D}_0 \stackrel{\text{def}}{=} \varepsilon \mathbf{E}_0 - \int_0^\infty \mathbf{j}(s) ds$. *Then every solution* $(\mathbf{E}, \mathbf{H}, \mathbf{M})$ *to problem* (1.1)–(1.4) *satisfies*

$$\mathbf{E}(t) \stackrel{t\to\infty}{\longrightarrow} 0 \text{ in } L^2(\mathbb{R}^3) \text{ weakly.}$$

Since $\nabla\varphi \in \mathcal{Z}$ for all $\varphi \in C_0^\infty(\mathbb{R}^3 \setminus \overline{S_\sigma})$, condition (2.17) includes

$$\text{div } \mathbf{D}_0 = 0 \text{ on } \mathbb{R}^3 \setminus \overline{S_\sigma}.$$

By (1.1) one has

$$\text{div } [\varepsilon \mathbf{E}(t)] = \text{div } \left[\varepsilon \mathbf{E}_0 - \int_0^t \mathbf{j}(s) ds \right] \stackrel{t\to\infty}{\longrightarrow} \text{div } \mathbf{D}_0 = 0 \text{ in } \mathcal{D}'(\mathbb{R}^3 \setminus \overline{S_\sigma})$$

if condition (2.17) is fulfilled. The physical meaning of this is that the space charge $\rho \stackrel{\text{def}}{=} \text{div } [\varepsilon \mathbf{E}(t)]$ determined by the initial state $(\mathbf{E}_0, \mathbf{H}_0)$ and the prescribed current $\mathbf{j}$ decays on the nonconducting region $\mathbb{R}^3 \setminus S_\sigma$ as $t \to \infty$.

The next theorem concerns the local energy decay of $\mathbf{E}$ and $Q_H \mathbf{H}$ on the conducting part of the medium.

THEOREM 2.4. *Suppose that the assumptions of Theorem* 2.2 *are satisfied and that, in addition to assumption* (2.3)*, there exists some* $\mathbf{A}_0 \in H_{curl}$ *with*

$$\text{curl } \mathbf{A}_0 = \mu[\mathbf{H}_0 + \tilde{\mathbf{M}}_0]. \tag{2.18}$$

Let $K \subset \mathbb{R}^3$ *be a compact set such that* σ *has a positive lower bound on some open neighborhood* U *of* K*; i.e., let* $U \subset \mathbb{R}^3$ *be open and* $K \subset U$ *be compact with*

$$\sigma(x) \geq c_0 \text{ for all } x \in U \tag{2.19}$$

with some $c_0 > 0$. *Then every solution* $(\mathbf{E}, \mathbf{H}, \mathbf{M})$ *to problem* (1.1)–(1.4) *satisfies*

$$\|\mathbf{E}(t)\|_{L^2(K)} + \|Q_H \mathbf{H}(t)\|_{L^2(K)} + \|Q_0 \mathbf{H}(t)\|_{L^2(K)} \stackrel{t\to\infty}{\longrightarrow} 0.$$

3. Weak convergence for $\to \infty$, proof of Theorem 2.2. This section is concerned with the proof of Theorem 2.2 concerning the weak convergence of the field quantities for $t \to \infty$. For this purpose the basic energy dissipation law is proved first.

LEMMA 3.1. *Assume* (2.1)–(2.13). *Then every solution* $(\mathbf{E}, \mathbf{H}, \mathbf{M})$ *to problem* (1.1)–(1.4) *satisfies*

$$(\mathbf{E}, \mathbf{H}) \in L^\infty((0,\infty), X), \quad \partial_t \mathbf{M} \in L^\infty((0,\infty), L^2(G)), \tag{3.1}$$

$$\beta^{1/2} \partial_t \mathbf{M} \in L^2((0,\infty), L^2(G)) \tag{3.2}$$

with the nonnegative function $\beta \in L^\infty(G)$ *occurring in assumption* (2.6). *Furthermore,*

$$|\mathbf{M}(t,x)| = |\mathbf{M}_0(x)| \le C_0 \tag{3.3}$$

and

$$\int_0^\infty \int_{\mathbb{R}^3} \sigma |\mathbf{E}(t)|^2 dx dt < \infty, \tag{3.4}$$

in particular

$$F_\sigma(\mathbf{E}(\cdot), \mathbf{H}(\cdot)) \in L^2((0,\infty), X). \tag{3.5}$$

Proof. By assumption (2.5) multiplication of both sides of (1.2) with $\mathbf{M}$ gives $\mathbf{M}\partial_t \mathbf{M} = 0$, whence (3.3). By the standard energy estimate for (2.15) one has

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}&\|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2 \\ &= -\langle (\mathbf{E}(t),\mathbf{H}(t)), F_\sigma(\mathbf{E}(t),\mathbf{H}(t)) + (\varepsilon^{-1}\mathbf{j}(t),0) + \mathcal{R}\partial_t \mathbf{M}(t)\rangle_X \\ &= -\int_{\mathbb{R}^3} \mathbf{E}(t)\left[\sigma \mathbf{E}(t) + \mathbf{j}(t)\right] dx - \int_G \mu \mathbf{H}(t) \cdot \partial_t \mathbf{M}(t) dx.\end{aligned} \tag{3.6}$$

Hence the energy functional

$$\mathcal{E}(t) \stackrel{\text{def}}{=} \frac{1}{2}\left(\|(\mathbf{E}(t),\mathbf{H}(t))\|_X^2 + \int_G \mu \mathbf{M}(t)\cdot A\mathbf{M}(t) dx \right) \tag{3.7}$$

satisfies

$$\begin{aligned}\mathcal{E}'(t) \le \|&\varepsilon^{-1/2}\mathbf{j}(t)\|_{L^2(\mathbb{R}^3}\mathcal{E}(t)^{1/2} \\ &- \int_{\mathbb{R}^3} \sigma |\mathbf{E}(t)|^2 - \int_G \mu [\mathbf{H}(t) - A\mathbf{M}(t)]\cdot \partial_t \mathbf{M}(t) dx.\end{aligned} \tag{3.8}$$

With

$$\begin{aligned}[\mathbf{H} - A\mathbf{M}]\cdot \partial_t \mathbf{M} &= [\mathbf{H} - A\mathbf{M}]\cdot F(x,\mathbf{M})[\mathbf{H} - A\mathbf{M}] \\ &\ge \beta |F(x,\mathbf{M})[\mathbf{H} - A\mathbf{M}]|^2 = \beta |\partial_t \mathbf{M}|^2\end{aligned}$$

by (3.3) and assumption (2.6), it follows from (3.8) that

$$\mathcal{E}'(t) \le -\int_{\mathbb{R}^3} \sigma |\mathbf{E}(t)|^2 dx + \|\varepsilon^{-1/2}\mathbf{j}(t)\|_{L^2}\mathcal{E}(t)^{1/2} - \int_G \mu\beta |\partial_t \mathbf{M}|^2 dx. \tag{3.9}$$

Since $\mathbf{j} \in L^1((0,\infty), L^2(\mathbb{R}^3))$, this completes the proof. ∎

Next the weak ω-limit set of $(\mathbf{E},\mathbf{H})$ will be characterized by means of the following proposition.

PROPOSITION 3.2. *Assume* (2.13) *and let* $\mathbf{g} \in X$ *with*

$$\underline{(\exp(tB)\mathbf{g})}_1 = 0 \text{ on } \mathcal{U} \text{ for all } t \in \mathbb{R}. \tag{3.10}$$

Then $\mathbf{g} \in H_{curl,0} \times H_{curl,0} = \ker B$.

Here and in what follows, $\underline{\mathbf{u}}_1 \in \mathbb{C}^3$ denotes the first three and $\underline{\mathbf{u}}_2 \in \mathbb{C}^3$ denotes the last three components of a vector $\mathbf{u} \in \mathbb{C}^6$.

Proof. In Lemma 2 of [10] this assertion is proved for the scalar wave equation with smooth coefficients and Maxwell's equations with constant coefficients on arbitrary spatial domains. In [4] this has been generalized to discontinuous coefficients ε and μ satisfying (2.13). However, in the whole space case a shorter proof is possible. For this purpose let

$$\mathcal{A}(f)\mathbf{u} \overset{\text{def}}{=} \int_{\mathbb{R}} \hat{f}(t) \exp(-tB)\mathbf{u}dt \tag{3.11}$$

for $f \in C_0^\infty(\mathbb{R})$ and $\mathbf{u} \in X$, where $\hat{f}$ denotes the Fourier transform of f. Then $\mathcal{A}(f)\mathbf{u} \in D(B^k)$, and with $f_k(\lambda) = (-i\lambda)^k f(\lambda)$ one has

$$B^k \mathcal{A}(f)\mathbf{u} = \int_{\mathbb{R}} \hat{f}^{(k)}(t) \exp(-tB)\mathbf{g}dt = \mathcal{A}(f_k)\mathbf{u}. \tag{3.12}$$

Suppose that $\mathbf{g} \in X$ satisfies (3.10). Let $f \in C_0^\infty(\mathbb{R})$, $\mathbf{G} \overset{\text{def}}{=} \mathcal{A}(f)\mathbf{g} \in D(B)$. Then (3.10), (3.11), and (3.12) yield $\underline{(B^k\mathbf{G})}_1 = 0$ on $\mathcal{U}$. Since

$$B^{k+1}\mathbf{G} = \Big(\varepsilon^{-1} \text{ curl } \underline{(B^k\mathbf{G})}_2, -\mu^{-1} \text{ curl } \underline{(B^k\mathbf{G})}_1\Big),$$

this also gives $\underline{(B^k\mathbf{G})}_2 = 0$ on the open set $\mathcal{U}$ and, thus,

$$B^k\mathbf{G} = 0 \text{ on } \mathcal{U} \text{ for all } k \geq 1. \tag{3.13}$$

By assumption (2.13) it follows from (3.13) that

$$B^{k+1}\mathbf{G} = \Big(\varepsilon\underline{(B^{k+1}\mathbf{G})}_1, \mu\underline{(B^{k+1}\mathbf{G})}_2\Big) = \Big(\text{curl } \underline{(B^k\mathbf{G})}_2, -\text{ curl } \underline{(B^k\mathbf{G})}_1\Big) \tag{3.14}$$

for all $k \geq 0$ on $\mathbb{R}^3$ in the sense of distributions. By induction (3.14) yields

$$(1-\Delta)^k B\mathbf{G} = \mathcal{A}(h_k)\mathbf{g} \in L^2(\mathbb{R}^3) \tag{3.15}$$

in the sense of distributions with $h_k(\lambda) \overset{\text{def}}{=} -i\lambda(1+\lambda^2)^k f(\lambda)$. By (3.11) and (3.15) one obtains

$$\begin{aligned} \|(1-\Delta)^k B\mathbf{G}\|_{L^2(\mathbb{R}^3)} &\leq \|\widehat{h_k}\|_{L^1(\mathbb{R})}\|\mathbf{g}\|_X \leq C_1\|(1+\xi^2)\widehat{h_k}(\xi)\|_{L^\infty(\mathbb{R})} \\ &\leq C_2\|h_k - h_k''\|_{L^1(\mathbb{R})} \leq C_3^k \text{ for all } k \in \mathbb{N}. \end{aligned} \tag{3.16}$$

By Sobolev's embedding theorem one obtains from (3.16) $B\mathbf{G} \in C^\infty(\mathbb{R}^3)$ and

$$\|\partial^\alpha B\mathbf{G}\|_{L^\infty} \leq C_4\|\partial^\alpha B\mathbf{G}\|_{H^2(\mathbb{R}^3)} \leq C_5\|(1-\Delta)^{n+1}B\mathbf{G}\|_{L^2(\mathbb{R}^3)} \leq C_6^{n+1} \tag{3.17}$$

for all $n \in \mathbb{N}$ and $|\alpha| \leq 2n$ with $C_1 - C_6 \in (0,\infty)$ independent of n. This yields the real analyticity of $B\mathbf{G}$. By (3.13) this analyticity implies $B\mathbf{G} = 0$ on all of $\mathbb{R}^3$, i.e.,

$$\mathcal{A}(f)\mathbf{g} \in \ker B \text{ for all } f \in C_0^\infty(\mathbb{R}). \tag{3.18}$$

Since $\ker B$ is a closed subspace of $X = L^2(\mathbb{R}^3)$ and there is a sequence $f_n \in C_0^\infty(\mathbb{R})$ with $\mathcal{A}(f_n)\mathbf{g} \overset{n\to\infty}{\longrightarrow} \mathbf{g}$, (3.18) completes the proof. $\square$

In what follows let ω_0 denote the ω-limit set of $(\mathbf{E},\mathbf{H})$ with respect to the weak topology of X, i.e., the set of all $\mathbf{g}\in X$ such that there exists a sequence $t_n \overset{n\to\infty}{\longrightarrow} \infty$ with $(\mathbf{E}(t_n),\mathbf{H}(t_n)) \overset{n\to\infty}{\longrightarrow} \mathbf{g}$ in X weakly. Since $(\mathbf{E},\mathbf{H})\in L^\infty((0,\infty),X)$ by Lemma 3.1 this set is nonempty.

LEMMA 3.3. *Under the assumptions of Theorem* 2.2 *it follows that* $\omega_0 \subset \mathcal{Z}\times H_{curl,0} \subset \ker B$.

Proof. Suppose $\mathbf{g}\in X$ and $t_n \overset{n\to\infty}{\longrightarrow} \infty$ with

$$(\mathbf{E}(t_n),\mathbf{H}(t_n)) \overset{n\to\infty}{\longrightarrow} \mathbf{g} \text{ in } X \text{ weakly.} \tag{3.19}$$

Let $\mathbf{u}^{(n)}(t) \overset{\text{def}}{=} (\mathbf{E}(t_n+t),\mathbf{H}(t_n+t))$ for $t\in(-t_n,\infty)$ and $\mathbf{u}^{(n)}(t)\overset{\text{def}}{=} 0$ for $t\le -t_n$. Next, let $\mathbf{m}^{(n)}(t)\overset{\text{def}}{=}\mathbf{M}(t_n+t)$ for $t\in(-t_n,\infty)$ and $\mathbf{m}^{(n)}(t)\overset{\text{def}}{=}0$ for $t\le -t_n$. After passing to a further subsequence, one has by (3.1)

$$\partial_t \mathbf{m}^{(n)} \overset{n\to\infty}{\longrightarrow} \mathbf{r}^{(\infty)} \text{ in } L^\infty(\mathbb{R},L^2(G)) \text{ weak-}*. \tag{3.20}$$

Let $t\in\mathbb{R}$. By (2.15) one has

$$\begin{aligned}
\mathbf{u}^{(n)}(t) &= \exp(tB)(\mathbf{E}(t_n),\mathbf{H}(t_n)) \\
&\quad - \int_{t_n}^{t_n+t} \exp((t_n+t-\tau)B)\left[F_\sigma(\mathbf{E}(\tau),\mathbf{H}(\tau)) + \mathcal{R}\partial_t\mathbf{M}(\tau) + (\varepsilon^{-1}\mathbf{j}(\tau),0)\right] d\tau \\
&= \exp(tB)(\mathbf{E}(t_n),\mathbf{H}(t_n)) \\
&\quad - \int_0^t \exp((t-s)B)\left[F_\sigma(\mathbf{E}(s+t_n),\mathbf{H}(s+t_n)) + \mathcal{R}\partial_t\mathbf{m}^{(n)}(s) + (\varepsilon^{-1}\mathbf{j}(s+t_n),0)\right] ds
\end{aligned}$$

for all $n\in\mathbb{N}$ with $t_n+t\ge 0$. (In order to apply Proposition 3.2 it is necessary also to consider $t\le 0$.) With $\mathbf{j}\in L^1((0,\infty),L^2(\mathbb{R}^3))$, it follows from (3.5) and (3.19) that

$$\begin{aligned}
\mathbf{u}^{(n)}(t) &\overset{n\to\infty}{\longrightarrow} \mathbf{u}^{(\infty)}(t) \\
&\overset{\text{def}}{=} \exp(tB)\mathbf{g} - \int_0^t \exp((t-s)B)\mathcal{R}\mathbf{r}^{(\infty)}(s)ds \text{ in } X \text{ weakly for all } t\in\mathbb{R}.
\end{aligned} \tag{3.21}$$

In particular, $\mathbf{u}_\infty\in C(\mathbb{R},X)$ is a generalized solution of

$$\partial_t \mathbf{u}^{(\infty)} = B\mathbf{u}^{(\infty)} - \mathcal{R}\mathbf{r}^{(\infty)} \tag{3.22}$$

in the sense of (2.15). For all $a,b\in\mathbb{R}$ with $a<b$ it follows from (3.21) that

$$\int_a^b \sigma\underline{\mathbf{u}^{(n)}}_1(t)dt \overset{n\to\infty}{\longrightarrow} \int_a^b \sigma\underline{\mathbf{u}^{(\infty)}(t)}_1 dt \text{ in } L^2(S_\sigma). \tag{3.23}$$

On the other hand, it follows from (3.5) that

$$\left\|\int_a^b \sigma\underline{\mathbf{u}^{(n)}}_1(t)dt\right\|_{L^2(S_\sigma)} \le (b-a)^{1/2}\left(\int_{a+t_n}^{b+t_n} \|\sigma\mathbf{E}(t)\|^2_{L^2(S_\sigma)}dt\right)^{1/2} \overset{n\to\infty}{\longrightarrow} 0. \tag{3.24}$$

Now (3.23) and (3.24) yield $\int_a^b \sigma \underline{\mathbf{u}^{(\infty)}}_1(t)dt = 0$ on S_σ for all $a, b \in \mathbb{R}$, $a < b$, which implies that

$$\underline{\mathbf{u}^{(\infty)}}_1(t) = 0 \text{ on } S_\sigma \text{ for all } t \in \mathbb{R}. \tag{3.25}$$

Let $\widetilde{\mathbf{r}}^{(\infty)}(t)$ denote the extension of $\mathbf{r}^{(\infty)}(t)$ by zero outside G. Then (3.22) and (3.25) yield, by assumption (2.12),

$$\operatorname{curl} \underline{\mathbf{u}^{(\infty)}}_2 = \partial_t(\varepsilon \underline{\mathbf{u}^{(\infty)}}_1) = 0 \tag{3.26}$$

and

$$\partial_t(\mu \underline{\mathbf{u}^{(\infty)}}_2) + \mu \widetilde{\mathbf{r}}^{(\infty)} = -\operatorname{curl} \underline{\mathbf{u}^{(\infty)}}_1 = 0 \tag{3.27}$$

on $\mathbb{R} \times \mathcal{U}$ in the sense of distributions. Since $\mu^{-1} \in L^\infty(\mathbb{R}^3, \mathbb{R}^{3\times 3})$ is independent of t, it follows easily from (3.27) that

$$\partial_t \underline{\mathbf{u}^{(\infty)}}_2 + \widetilde{\mathbf{r}}^{(\infty)} = 0 \text{ on } \mathbb{R} \times \mathcal{U}.$$

Invoking (3.26) yields

$$\operatorname{curl} \widetilde{\mathbf{r}}^{(\infty)} = -\partial_t \operatorname{curl} \underline{\mathbf{u}^{(\infty)}}_2 = 0 \tag{3.28}$$

on $\mathbb{R} \times \mathcal{U}$ in the sense of distributions.

Next, it follows from (3.2) that for all $a < b$,

$$\left\| \beta^{1/2} \int_a^b \partial_t \mathbf{m}^{(n)}(t)dt \right\|_{L^2(G)} \leq (b-a)^{1/2} \left(\int_{a+t_n}^{b+t_n} \|\beta^{1/2} \partial_t \mathbf{M}(t)\|^2_{L^2(G)} dt \right)^{1/2} \stackrel{n\to\infty}{\longrightarrow} 0,$$

which implies that

$$\int_a^b \mathbf{r}^{(\infty)}(t, x)dt = 0 \text{ for all } x \in G \text{ with } \beta(x) > 0.$$

Hence, one obtains by (2.10)

$$\mathbf{r}^{(\infty)}(t) = 0 \text{ a.e. on } G \setminus G_0$$

and, thus,

$$\widetilde{\mathbf{r}}^{(\infty)}(t) = 0 \text{ a.e. on } \mathbb{R}^3 \setminus \overline{G_0}, \tag{3.29}$$

since $\widetilde{\mathbf{r}}^{(\infty)}(t)$ is the extension of $\mathbf{r}^{(\infty)}(t)$ by zero outside G. Recall that $\overline{G_0} \subset \mathcal{U}$ by assumption (2.12). Hence, (3.28) and (3.29) imply

$$\widetilde{\mathbf{r}^{(\infty)}(t)} \in H_{curl,0} \text{ for all } t \in \mathbb{R}.$$

In particular,

$$\mathcal{R}\mathbf{r}^{(\infty)}(t) \in \ker B \text{ for all } t \in \mathbb{R}. \tag{3.30}$$

Going back to (3.21), one obtains from (3.30)

$$\mathbf{u}^{(\infty)}(t) = \exp(tB)\mathbf{g} - \int_0^t \mathcal{R}\mathbf{r}^{(\infty)}(s)ds \text{ for all } t \in \mathbb{R}.$$

Since $\underline{(\mathcal{R}\mathbf{r}^{(\infty)}(s))}_1 = 0$, one has

$$\underline{\mathbf{u}^{(\infty)}(t)}_1 = \underline{(\exp{(tB)}\mathbf{g})}_1 \text{ for all } t \in \mathbb{R},$$

in particular

$$\underline{(\exp{(tB)}\mathbf{g})}_1 = 0 \text{ on } S_\sigma \text{ for all } t \in \mathbb{R}, \tag{3.31}$$

by (3.25). Now it follows from assumption (2.12), (3.31), and Proposition 3.2 that $\mathbf{g} \in H_{curl,0} \times H_{curl,0}$. Furthermore, $\underline{\mathbf{g}}_1 = 0$ on S_σ by (3.31), whence $\underline{\mathbf{g}}_1 \in \mathcal{Z}$. ◻

Remark 2. The open neighborhood U of G_0 with positive conductivity in assumption (2.12) is necessary to show that $\widetilde{\mathbf{r}}^{(\infty)}(t)$, the extension of $\mathbf{r}^{(\infty)}(t)$ by zero outside G, is curl free on all of $\mathbb{R}^3$. (In particular, the fact that $\mathbf{r}^{(\infty)}(t)$ is supported in G_0 is used here.) If only $G_0 \subset S_\sigma$ instead of (2.12) is assumed, one can only conclude that curl $\mathbf{r}^{(\infty)} = 0$ on $\mathbb{R} \times G_0$, but in general not curl $\widetilde{\mathbf{r}}^{(\infty)} = 0$ on $\mathbb{R} \times \mathbb{R}^3$, which is required for (3.30).

LEMMA 3.4. *Under the assumptions of Theorem* 2.2 *it follows that*

$$\left\| P_1\mathbf{E}(t) - P_1\left[\mathbf{E}_0 - \int_0^\infty \varepsilon^{-1}\mathbf{j}(s)ds\right]\right\|_{L^2(\mathbb{R}^3)} \stackrel{t\to\infty}{\longrightarrow} 0 \tag{3.32}$$

and

$$(1-P_H)\mathbf{H}(t) = -(1-P_H)\tilde{\mathbf{M}}(t) \tag{3.33}$$

for every solution $(\mathbf{E}, \mathbf{H}, \mathbf{M})$ *to problem* (1.1)–(1.4).

Proof. Since

$$\text{ran } P_H = \{\mathbf{h} \in L^2(\mathbb{R}^3) : \text{div } (\mu\mathbf{h}) = 0\},$$

it follows from (2.3) that

$$(1-P_H)(\mathbf{H}_0 + \tilde{\mathbf{M}}_0) = 0. \tag{3.34}$$

Let $\mathbf{a} \in \mathcal{Z} \times H_{curl,0} \subset \ker B$, which means $\mathbf{a} \in \ker B$ and $\underline{\mathbf{a}}_1 = 0$ on S_σ. Then (2.15) and (3.34) yield

$$\begin{aligned} \langle (P_1\mathbf{E}(t), (1-P_H)\mathbf{H}(t)), \mathbf{a}\rangle_X &= \langle (\mathbf{E}(t), \mathbf{H}(t)), \mathbf{a}\rangle_X \\ = \left\langle (\mathbf{E}_0, \mathbf{H}_0) - \int_0^t \left[\mathcal{R}\partial_t\mathbf{M}(s) + F_\sigma(\mathbf{E}(s), \mathbf{H}(s)) + (\varepsilon^{-1}\mathbf{j}(s), 0)\right] ds, \mathbf{a}\right\rangle_X \\ &= \left\langle \left(\mathbf{E}_0 - \int_0^t \varepsilon^{-1}\mathbf{j}(s)ds, \mathbf{H}_0 + \tilde{\mathbf{M}}_0 - \tilde{\mathbf{M}}(t)\right), \mathbf{a}\right\rangle_X \\ &= \left\langle \left(P_1\left[\mathbf{E}_0 - \int_0^t \varepsilon^{-1}\mathbf{j}(s)ds\right], -(1-P_H)\tilde{\mathbf{M}}(t)\right), \mathbf{a}\right\rangle_X, \end{aligned}$$

whence (3.33) and

$$P_1\mathbf{E}(t) = P_1\left[\mathbf{E}_0 - \int_0^t \varepsilon^{-1}\mathbf{j}(s)ds\right], \tag{3.35}$$

from which the assertion follows, since $\mathbf{j} \in L^1(0, \infty, L^2(\mathbb{R}^3))$. ◻

Completion of the proof of Theorem 2.2. Since $1 - P_1$ and P_H are the orthogonal projectors on $\mathcal{Z}^\perp$ and $H^\perp_{curl,0}$, respectively, it follows from Lemma 3.3 that zero is the only possible accumulation point of $((1-P_1)\mathbf{E}(t), P_H\mathbf{H}(t))$ and $((1-P_1)\mathbf{E}(t), P_0\mathbf{H}(t))$ for $t \to \infty$ with respect to the weak topology of X. Hence, by Lemma 3.1,

$$P_0\mathbf{H}(t) \overset{t\to\infty}{\longrightarrow} 0 \text{ in } L^2(\mathbb{R}^3) \text{ weakly}$$

and

$$((1-P_1)\mathbf{E}(t), P_H\mathbf{H}(t)) \overset{t\to\infty}{\longrightarrow} 0 \text{ in } X \text{ weakly.} \tag{3.36}$$

Finally, the assertion follows from Lemma 3.4 and (3.36). ∎

4. Local strong decay, proof of Theorem 2.4. In what follows let $(\mathbf{E}, \mathbf{H}, \mathbf{M})$ be a solution to problem (1.1)–(1.4). The following lemma is based on a result in [5].

LEMMA 4.1. *Let $T > 0$ and $\mathbf{g} \in W^{1,\infty}((0,\infty), L^2(\mathbb{R}^3))$. Then*

$$\int_0^T \chi(s) \int_{\mathbb{R}^3} \psi\mathbf{g}(t+s) \cdot P_H\mathbf{H}(t+s)dxds \overset{t\to\infty}{\longrightarrow} 0 \tag{4.1}$$

for all $\chi \in C_0^\infty(0,T)$ and $\psi \in C_0^\infty(\mathbb{R}^3)$.

Proof. Let $\{t_n\}_{n\in\mathbb{N}}$ with $t_n \overset{n\to\infty}{\longrightarrow} \infty$, $\mathbf{h}_n(t) \overset{\text{def}}{=} P_H\mathbf{H}(t_n + t)$, and $\mathbf{G}_n(t) \overset{\text{def}}{=} \chi(t)\psi\mathbf{g}(t_n + t)$. Then it follows from (2.16) that

$$\mathbf{h}_n \overset{n\to\infty}{\longrightarrow} 0 \text{ in } L^\infty((0,T), L^2(\mathbb{R}^3)) \text{ weak-}*. \tag{4.2}$$

Since ran $(1 - P_H) \subset H_{curl,0}$, one has by (1.1)

$$\int_{\mathbb{R}^3} \mathbf{h}_n(t) \text{ curl } \varphi dx = \int_{\mathbb{R}^3} \mathbf{H}(t_n+t) \text{ curl } \varphi dx = \frac{d}{dt}\int_{\mathbb{R}^3} \mathbf{D}_n(t)\cdot\varphi dx \tag{4.3}$$

for all $\varphi \in C_0^\infty(\mathbb{R}^3)$ with

$$\mathbf{D}_n(t) \overset{\text{def}}{=} \varepsilon\mathbf{E}(t_n+t) + \int_{t_n}^{t_n+t} (\sigma\mathbf{E}(s) + \mathbf{j}(s))ds.$$

By Lemma 3.1 the sequences $\{\mathbf{D}_n\}_{n\in\mathbb{N}}$, $\{\mathbf{G}_n\}_{n\in\mathbb{N}}$, and $\{\mathbf{h}_n\}_{n\in\mathbb{N}}$ are bounded sequences in $L^\infty((0,T), L^2(\mathbb{R}^3))$. Furthermore, $\{\mathbf{G}_n\}_{n\in\mathbb{N}}$ is equicontinuous in the sense that for all $\theta > 0$ there exists some $\delta > 0$ such that

$$\|\mathbf{G}_n(t) - \mathbf{G}_n(s)\|_{L^2(\mathbb{R}^3)} \le \theta \text{ for all } n \in \mathbb{N} \text{ and } s,t \in (0,T) \text{ with } |s-t| \le \delta.$$

Hence, $\{\mathbf{D}_n\}_{n\in\mathbb{N}}$, $\{\mathbf{G}_n\}_{n\in\mathbb{N}}$, and $\{\mathbf{h}_n\}_{n\in\mathbb{N}}$ satisfy all assumptions required for Lemma 3.4 in [5]. Since ψ has compact support, Lemma 3.4 in [5] yields

$$\int_0^T \chi(s) \int_{\mathbb{R}^3} \psi\mathbf{g}(t_n+s)\cdot P_H\mathbf{H}(t_n+s)dxds = \int_0^T\int_{\text{supp }\psi} \psi\mathbf{G}_n(s)\cdot P_H\mathbf{h}_n(s)dxds \overset{n\to\infty}{\longrightarrow} 0,$$

which completes the proof. ∎

Proof of Theorem 2.4. The decay of $P_H\mathbf{H}$ does not follow directly from (3.9), since $\mathbf{H}$ does not occur in the right-hand side of (3.9). In order to obtain a dissipative term also for the magnetic field, a vector potential $\mathbf{A}$ is introduced.

Let $\mathbf{A}_1 \stackrel{\text{def}}{=} P_0\mathbf{A}_0 \in H_{curl} \cap \operatorname{ran} P_0 = H_{curl} \cap H_{div,0}$ with $\mathbf{A}_0 \in H_{curl}$ as in (2.18). Then

$$\text{curl } \mathbf{A}_1 = \text{curl } \mathbf{A}_0 = \mu[\mathbf{H}_0 + \tilde{\mathbf{M}}_0] \tag{4.4}$$

by (2.18). Let

$$\mathbf{A}(t) \stackrel{\text{def}}{=} \mathbf{A}_1 - \int_0^t P_0\mathbf{E}(s)ds \in H_{curl} \cap H_{div,0}. \tag{4.5}$$

Then it follows from (1.1), (4.4), and (4.5) that for all $\mathbf{g} \in H_{curl}$, one has

$$\begin{aligned}\int_{\mathbb{R}^3} \mathbf{A}(t) \text{ curl } \mathbf{g}dx &= \int_{\mathbb{R}^3} \mathbf{A}_1 \text{ curl } \mathbf{g}dx - \int_0^t\int_{\mathbb{R}^3} P_0\mathbf{E}(s)\cdot \text{curl } \mathbf{g}dxds \\ &= \int_{\mathbb{R}^3} \mu[\mathbf{H}_0 + \tilde{\mathbf{M}}_0]\cdot \mathbf{g}dx - \int_0^t\int_{\mathbb{R}^3} \mathbf{E}(s) \text{ curl } \mathbf{g}dxds \\ &= \int_{\mathbb{R}^3} \mu(\mathbf{H}(t) + \tilde{\mathbf{M}}(t))\cdot \mathbf{g}dx.\end{aligned}$$

Hence, $\mathbf{A}(t) \in H_{curl} \cap H_{div,0}$ and, by (3.33),

$$\text{curl } \mathbf{A}(t) = \mu(\mathbf{H}(t) + \tilde{\mathbf{M}}(t)) = \mu P_H(\mathbf{H}(t) + \tilde{\mathbf{M}}(t)). \tag{4.6}$$

By a classical estimate one has

$$\|\mathbf{a}\|_{L^6(\mathbb{R}^3)} \le C_2 \|\text{curl } \mathbf{a}\|_{L^2(\mathbb{R}^3)} \text{ for all } \mathbf{a} \in H_{curl} \cap H_{div,0}. \tag{4.7}$$

Thus, (4.6) yields

$$\|\mathbf{A}(t)\|_{L^6(\mathbb{R}^3)} \le C_2\|P_H(\mathbf{H}(t) + \tilde{\mathbf{M}}(t))\|_{L^2(\mathbb{R}^3)} \le C_3, \tag{4.8}$$

where C_1–C_3 are independent of t. By (4.6) and the estimates (3.1) and (4.8), one has $\mathbf{A} \in L^\infty((0,\infty), L^6(\mathbb{R}^3))$ and curl $\mathbf{A} \in L^\infty((0,\infty), L^2(\mathbb{R}^3))$. Therefore, it follows that

$$\{\mathbf{A}(t) : t \in (0,\infty)\} \text{ is precompact in } L^2(K) \tag{4.9}$$

for all compact subsets $K \subset \mathbb{R}^3$. Now let $U \subset \mathbb{R}^3$ and $K \subset U$ be as in (2.19) and choose $\psi \in C_0^\infty(U)$ with $\psi = 1$ on K. First, it follows from Lemma 3.1 and (2.19) that

$$\int_0^T \|\psi^{1/2}\mathbf{E}(t+s)\|_{L^2(\mathbb{R}^3)}ds \stackrel{t\to\infty}{\longrightarrow} 0 \text{ for all } T > 0. \tag{4.10}$$

Let

$$g(t) \stackrel{\text{def}}{=} \int_{\mathbb{R}^3} \psi\varepsilon\mathbf{E}(t)\mathbf{A}(t)dx. \tag{4.11}$$

By (4.8), Hölder's inequality, and (4.10) one has, for all $T > 0$,

$$\int_0^T |g(t+s)|ds \le C_1 \int_0^T \|\psi\mathbf{E}(t+s)\|_{L^2(\mathbb{R}^3)}ds \stackrel{t\to\infty}{\longrightarrow} 0. \tag{4.12}$$

From (1.1), (3.1) again, (4.6), (4.5), and (4.11) it follows that

$$
\begin{aligned}
(4.13)\qquad g'(t) &= \int_{\mathbb{R}^3} \mathbf{H}(t) \text{ curl } (\psi \mathbf{A}(t)) dx - \int_{\mathbb{R}^3} \psi[\sigma \mathbf{E}(t) + \mathbf{j}(t)]\mathbf{A}(t) dx \\
&\quad - \int_{\mathbb{R}^3} \psi \varepsilon \mathbf{E}(t) \cdot P_0 \mathbf{E}(t) dx \\
&\geq \int_{\mathbb{R}^3} \mathbf{H}(t) \text{ curl } (\psi \mathbf{A}(t)) dx - C_1 \|\psi \mathbf{E}(t)\|_{L^2(\mathbb{R}^3)} - C_1 \|\psi \mathbf{j}(t)\|_{L^2(\mathbb{R}^3)}.
\end{aligned}
$$

With (4.6) one obtains

$$
\begin{aligned}
\int_{\mathbb{R}^3} \mathbf{H}(t) \text{ curl } (\psi \mathbf{A}(t)) dx &= \int_{\mathbb{R}^3} (P_H \mathbf{H}(t)) \text{ curl } (\psi \mathbf{A}(t)) dx \\
&= \int_{\mathbb{R}^3} \psi |\mu^{1/2} P_H \mathbf{H}(t)|^2 dx + \int_{\mathbb{R}^3} \psi \mu \cdot (P_H \mathbf{H}(t)) \cdot P_H \tilde{\mathbf{M}}(t) dx \\
&\quad + \int_{\mathbb{R}^3} (\nabla \psi) \wedge \mathbf{A}(t) \cdot P_H \mathbf{H}(t) dx
\end{aligned}
$$

and hence, by (4.13),

$$
\begin{aligned}
(4.14)\qquad \int_{\mathbb{R}^3} \psi |\mu^{1/2} P_H \mathbf{H}(t)|^2 dx &\leq g'(t) + C_1 \|\psi \mathbf{E}(t)\|_{L^2(\mathbb{R}^3)} + C_1 \|\psi \mathbf{j}(t)\|_{L^2(\mathbb{R}^3)} \\
&\quad - \int_{\mathbb{R}^3} \psi \mu \cdot (P_H \mathbf{H}(t)) \cdot P_H \tilde{\mathbf{M}}(t) dx - \int_{\mathbb{R}^3} (\nabla \psi) \wedge \mathbf{A}(t) \cdot P_H \mathbf{H}(t) dx.
\end{aligned}
$$

It follows from (2.16) and (4.9) that

$$
(4.15)\qquad \int_{\mathbb{R}^3} (\nabla \psi) \wedge \mathbf{A}(t) \cdot P_H \mathbf{H}(t) dx \overset{t \to \infty}{\longrightarrow} 0.
$$

Now a time average is estimated in (4.14). For this purpose let $\chi \in C_0^\infty((0,1),[0,\infty))$. Then Lemma 4.1 yields

$$
(4.16)\qquad \int_0^1 \chi(s) \int_{\mathbb{R}^3} \psi \mu \cdot (P_H \mathbf{H}(t+s)) \cdot P_H \tilde{\mathbf{M}}(t+s) dx ds \overset{t \to \infty}{\longrightarrow} 0,
$$

since $\mathbf{G} \overset{\text{def}}{=} P_H(\tilde{\mathbf{M}}(\cdot)) \in W^{1,\infty}((0,\infty), L^2(\mathbb{R}^3))$ by (3.1). It follows from (4.10), (4.12), and (4.14)–(4.16) that

$$
\begin{aligned}
(4.17)\qquad \limsup_{t \to \infty} \int_0^1 \chi(s) \int_{\mathbb{R}^3} \psi |\mu^{1/2} P_H \mathbf{H}(t+s)|^2 dx ds \\
\leq \limsup_{t \to \infty} \int_0^1 \chi'(t+s) g(t+s) ds = 0.
\end{aligned}
$$

Note that (4.10) and (4.17) do not immediately yield the assertion of Theorem 2.4. The aim of the following considerations is to show that the localized energy $E : [0,\infty) \to \mathbb{R}$ defined by

$$
(4.18)\qquad E(t) \overset{\text{def}}{=} \int_{\mathbb{R}^3} \psi [|\varepsilon^{1/2} \mathbf{E}(t)|^2 + |\mu^{1/2} P_H \mathbf{H}(t)|^2] dx
$$

is uniformly continuous on $[0, \infty)$. With curl $(1 - P_H)\mathbf{g} = 0$ for all $\mathbf{g} \in L^2(\mathbb{R}^3)$, it follows from (1.1) that

$$\partial_t \mathbf{E} = \varepsilon^{-1} \text{ curl } (P_H \mathbf{H}(\cdot)) + \mathbf{f}_1, \quad \partial_t (P_H \mathbf{H}(\cdot)) = -\mu^{-1} \text{ curl } \mathbf{E} + \mathbf{f}_2$$

on $\mathbb{R}^+ \times \mathbb{R}^3$ weakly in the sense of (2.15) with

$$\mathbf{f}_1(t) \stackrel{\text{def}}{=} -\varepsilon^{-1}\sigma \mathbf{E}(t) - \varepsilon^{-1}\mathbf{j}(t), \quad \mathbf{f}_2(t) \stackrel{\text{def}}{=} -P_H \partial_t \tilde{\mathbf{M}}(t).$$

Since $\mathbf{f} \stackrel{\text{def}}{=} (\mathbf{f}_1, \mathbf{f}_2) \in L^\infty((0,\infty), X)$ by Lemma 3.1, the standard energy estimate and (3.1) again yield

$$\begin{aligned} |E'(t)| &= \left| 2 \int_{\mathbb{R}^3} \psi \cdot [\varepsilon \mathbf{E}(t) \mathbf{f}_1(t) + \mu (P_H \mathbf{H}(t)) \mathbf{f}_2(t)] \, dx + 2 \int_{\mathbb{R}^3} (\nabla \psi) \wedge \mathbf{E}(t) \cdot P_H \mathbf{H}(t) dx \right| \\ &\leq C_6 \end{aligned}$$

with some $C_1 \in (0, \infty)$ independent of t. Hence, E satisfies

$$\sup_{s \in (0,a)} |E(t) - E(t+s)| \leq C_3 a \text{ for all } a > 0. \tag{4.19}$$

Now, choose $\chi \in C_0^\infty(0,1)$ with

$$\int_{\mathbb{R}} \chi dt = 1 \tag{4.20}$$

and let $\chi_m(t) \stackrel{\text{def}}{=} m\chi(mt)$ for $m \in \mathbb{N}$. Since $\int_0^1 \chi_m(t) dt = 1$ by (4.20) and supp $\chi_m \subset (0, 1/m)$, it follows that

$$\left| E(t) - \int_0^1 \chi_m(s) E(t+s) ds \right| \leq \sup_{s \in (0,1/m)} |E(t) - E(t+s)| \stackrel{m \to \infty}{\longrightarrow} 0 \tag{4.21}$$

uniformly with respect to t. On the other hand (4.10) and (4.17) yield

$$\int_0^1 \chi_m(s) E(t+s) ds \stackrel{t \to \infty}{\longrightarrow} 0 \text{ for all } m \in \mathbb{N}. \tag{4.22}$$

From (4.21) and (4.22) one obtains $E(t) \stackrel{t \to \infty}{\longrightarrow} 0$, which yields by (4.18)

$$\|\mathbf{E}(t)\|_{L^2(K)} + \|Q_H \mathbf{H}(t)\|_{L^2(K)} \stackrel{t \to \infty}{\longrightarrow} 0. \tag{4.23}$$

It remains to show

$$\|Q_0 \mathbf{H}(t)\|_{L^2(K)} \stackrel{t \to \infty}{\longrightarrow} 0.$$

Since $(1 - Q_H)\mathbf{H}(t) \in H_{curl,0}$, one has

$$\begin{aligned} \|\psi Q_0 \mathbf{H}(t)\|_{L^2(\mathbb{R}^3)} &= \|\psi Q_0 Q_H \mathbf{H}(t)\|_{L^2(\mathbb{R}^3)} = \|\psi Q_0 Q_H \mathbf{H}(t)\|_{L^2(B_R(0))} \\ &\leq \|\psi Q_H \mathbf{H}(t)\|_{L^2(B_R(0))} + \|[\psi, Q_0] Q_H \mathbf{H}(t)\|_{L^2(B_R(0))}, \end{aligned} \tag{4.24}$$

where $R > 0$ with supp $\psi \subset B_R(0)$. By (2.19) assertion (4.23) holds for all compact subsets of U, in particular for supp (ψ). Hence

$$\|\psi Q_H \mathbf{H}(t)\|_{L^2(\mathbb{R}^3)} \stackrel{t \to \infty}{\longrightarrow} 0. \tag{4.25}$$

Since the commutator $[\psi, Q_0]$ is a compact operator from $L^2(\mathbb{R}^3)$ to $L^2(B_R(0))$, it follows from (2.16) that

$$\|[\psi, Q_0]Q_H \mathbf{H}(t)\|_{L^2(B_R(0))} \stackrel{t\to\infty}{\longrightarrow} 0. \tag{4.26}$$

Finally, the assertion follows from (4.24)–(4.26). $\square$

Remark 3. For all compact sets $K \subset \mathbb{R}^3$ satisfying assumption (2.19), one has by Theorem 2.4

$$\|\mathbf{H}(t) - \mathbf{H}^{(q)}(t)\|_{L^2(K)} = \|P_H \mathbf{H}(t)\|_{L^2(K)} \stackrel{t\to\infty}{\longrightarrow} 0, \tag{4.27}$$

where $\mathbf{H}^{(q)}(t) \in L^2(\mathbb{R}^3)$ is given by $\mathbf{H}^{(q)}(t) = (1 - P_H)\mathbf{H}(t) = -(1 - P_H)\tilde{\mathbf{M}}(t)$; i.e.,

$$\operatorname{curl} \mathbf{H}^{(q)}(t) = 0 \text{ and } \operatorname{div} (\mu[\mathbf{H}^{(q)}(t) + \tilde{\mathbf{M}}(t)]) = 0 \text{ on } \mathbb{R}^3.$$

This means that $\mathbf{H}^{(q)}$ is determined by the quasi-stationary approximation obtained in [5]. Therefore, (4.27) provides a further justification of the magnetostatic approximation in which $\mathbf{H}$ is replaced by $\mathbf{H}^{(q)}$.

EXISTENCE OF WEAK SOLUTIONS FOR THE MULLINS–SEKERKA FLOW*

MATTHIAS RÖGER†

Abstract. The long-time existence of solutions for the Mullins–Sekerka problem in a new weak formulation is proved. Using a variational approach introduced by Luckhaus and Sturzenhecker [*Calc. Var. Partial Differential Equations*, 3 (1995), pp. 253–271], time-discrete solutions are constructed, satisfying approximate Gibbs–Thomson laws in a BV-formulation. But since the passage to a limit allows a loss of surface area for the phase interfaces, convergence in this setting is in general not true. We consider the surface measure of the phase interfaces and use the theory of varifolds to obtain a rigorous passage to a limit in a suitable weak formulation of the Gibbs–Thomson law.

Key words. free boundaries, Mullins–Sekerka flow, varifolds

1. Introduction.

The Mullins–Sekerka flow is a variant of the classical Stefan problem and describes phase transitions, such as melting or solidification processes, where a negligible specific heat of the material under consideration can be assumed. In this situation the energy balance is expressed by a quasi-stationary parabolic equation. A geometric condition on the phase interface, known as Gibbs–Thomson law, accounts for surface tension effects. In contrast to the classical Stefan problem, the Mullins–Sekerka flow allows for superheating and undercooling, i.e., temperatures above the melting point in the solid phase or temperatures below the melting point in the liquid phase.

To state the problem we consider a given time interval $(0, T)$ and an open bounded region $\Omega \subset \mathbb{R}^3$ representing the body of the material. Denote $\Omega_T := (0, T) \times \Omega$. The state variables are the relative temperature

$$u : \Omega_T \to \mathbb{R}$$

($u = 0$ denoting the melting point) and a phase function

$$\mathcal{X} : \Omega_T \to \{0, 1\},$$

which partitions Ω at a time $t \in (0, T)$ into a *liquid phase* $\{\mathcal{X}(t, .) = 1\}$ and a *solid phase* $\{\mathcal{X}(t, .) = 0\}$ separated by the *phase interface*, that is, their common boundary in Ω. The energy balance for the classical Stefan problem reads

$$\partial_t(cu + L\mathcal{X}) - k\Delta u = f \tag{1.1}$$

in the sense of distributions, with a given heat source $f : \Omega \to \mathbb{R}$ and phase independent constants c, L, and k describing the specific heat, latent heat, and heat capacity,

respectively. Assuming that c is negligibly small and setting for simplicity $L = k = 1$, we get the *quasi-stationary energy balance*

$$\partial_t \mathcal{X} - \Delta u = f. \tag{1.2}$$

In the classical Stefan problem the temperature at the phase interface equals the melting temperature, that is,

$$u(t,.) = 0 \quad \text{on the phase interface.} \tag{1.3}$$

Surface tension effects are taken into consideration by the *Gibbs–Thomson law*

$$H(t,.) = u(t,.) \quad \text{on the phase interface,} \tag{1.4}$$

where $H(t,.)$ denotes the scalar mean curvature of the phase interface, which we take as positive for convex liquid phases.

The Mullins–Sekerka problem is given by (1.2) and (1.4). An initial condition for $\mathcal{X}$ and a boundary condition for u on $\partial\Omega$ are prescribed. This model can be seen as a quasi-stationary variant of the *Stefan problem with Gibbs–Thomson law* given by (1.1) and (1.4). Existence of classical solutions for the Mullins–Sekerka problem locally in time was proved by Chen, Hong, and Li [CHY96] and by Escher and Simonett [ES97]. In general, classical solutions can develop singularities. To derive long-time existence results one has to turn to weak formulations. Chen [Che96] obtains solutions globally in time studying the limit of a certain Cahn–Hilliard model. Here the Gibbs–Thomson law is satisfied in a rather weak and complex formulation. In particular, the measures giving the energy density are not necessarily rectifiable.

Luckhaus and Sturzenhecker give in [LS95] another weak formulation of the Mullins–Sekerka problem. Phase and temperature function

$$\mathcal{X} \in \mathrm{L}^\infty(0,T;\mathrm{BV}(\Omega;\{0,1\})), \quad u \in \mathrm{L}^2(0,T;\mathrm{H}^{1,2}(\Omega))$$

satisfy (1.2) in the sense of distributions and (1.4) in the *BV-formulation of the Gibbs–Thomson law*, that is,

$$\int_0^T \int_\Omega \left(\nabla \cdot \xi - \frac{\nabla \mathcal{X}}{|\nabla \mathcal{X}|} \cdot D\xi \frac{\nabla \mathcal{X}}{|\nabla \mathcal{X}|} \right)(t,.)|\nabla \mathcal{X}|(t,.)\,dt = \int_{\Omega_T} \nabla \cdot (u\xi)\mathcal{X}$$

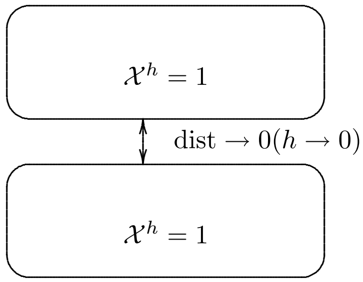
for all $\xi \in C_c^\infty(\Omega_T;\mathbb{R}^3)$.

Whereas this weak formulation is comparatively simple, the convergence of time-discrete approximations $\mathcal{X}^h$ and u^h to correct weak solutions of (1.2) and (1.4) is only shown under an additional condition on the approximations, which reads

$$\lim_{h\to 0} \int_{\Omega_T} |\nabla \mathcal{X}^h| \to \int_{\Omega_T} |\nabla \mathcal{X}|. \tag{1.5}$$

This excludes a loss of surface area for the phase interfaces and allows one to prove the convergence of approximate Gibbs–Thomson laws within the BV-formulation.

In the present paper we use the time-discrete approximation scheme of [LS95] but drop condition (1.5). Difficulties which arise are captured in the following time-independent example. Assume two solid parts of approximations $\mathcal{X}^h$ which merge to one when letting $h \to 0$.



A part of the boundary, indicated by the dashed line, has ceased to separate two different phases. We call this part the *hidden boundary*, whereas the *phase interface* represents the physically relevant part of the boundary. Cusp singularities occur due to the cancellation of phase interfaces. As shown in [Sch97], the BV-formulation of the Gibbs–Thomson law breaks down.

These difficulties are tackled in [Rög03] and [Rög04], where the Stefan problem with Gibbs–Thomson law is treated. Following an idea of Schätzle [Sch01] we consider the surface measure of the phase interfaces to master possible cancellations. In the above example the surface measures $|\nabla \mathcal{X}^h|$ converge with $h \to 0$ to a Radon measure that has double multiplicity on the hidden boundary. This suggests the use of the concept of integral varifolds introduced by Almgren [Alm65]. Geometric measure theory provides a notion of mean curvature for integral varifolds; Schätzle [Sch01] investigates the convergence of approximate Gibbs–Thomson equations in this context. However, the control about the hidden boundaries is quite weak and we have to focus on the physically relevant part of the boundary. For this purpose the following Proposition, which we have proved in an earlier work, will be crucial (for the notations, consult section 2).

Proposition 1.1 (see [Rög04, Proposition 3.1]). *Let $\Omega \subset \mathbb{R}^n$ be open, $E \subset \Omega$, and $\mathcal{X}_E \in \mathrm{BV}(\Omega)$. Assume that there are two integral $(n-1)$-varifolds μ_1, μ_2 on Ω such that for $i = 1, 2$ the following hold:*

$$\partial^* E \subset \operatorname{spt}(\mu_i), \tag{1.6}$$

$$\mu_i \text{ has locally bounded first variation with mean curvature vector } \vec{H}_{\mu_i}, \tag{1.7}$$

$$\vec{H}_{\mu_i} \in \mathrm{L}^s_{\mathrm{loc}}(\mu_i),\ s > n-1,\ s \geq 2. \tag{1.8}$$

Then

$$\vec{H}_{\mu_1}|_{\partial^* E} = \vec{H}_{\mu_2}|_{\partial^* E}$$

is satisfied $\mathcal{H}^{n-1}$-almost everywhere on $\partial^* E$.

This proposition justifies the following definition.

Definition 1.2. *Let $E \subset \Omega$ and $\mathcal{X}_E \in \mathrm{BV}(\Omega)$, and assume that there exists an integral $(n-1)$-varifold μ on Ω satisfying* (1.6)–(1.8). *Then we call*

$$\vec{H} := \vec{H}_\mu|_{\partial^* E}$$

the generalized mean curvature vector of $\partial^* E$ and define a scalar mean curvature by

$$H := \vec{H} \cdot \frac{\nabla \mathcal{X}}{|\nabla \mathcal{X}|} \text{ on } \partial^* E.$$

The essential boundary $\partial^* E$ represents the phase interface, whereas $\mathrm{spt}(\mu) \setminus \partial^* E$ can be seen as a hidden boundary. Proposition 1.1 shows that the varifold's mean curvature restricted to the phase interface is a property of the phase interface itself and independent of the location of hidden boundaries.

Our solutions of the Mullins–Sekerka problem satisfy the Gibbs–Thomson in the sense that for almost all times a generalized mean curvature for the phase interface exists and is given pointwise almost everywhere by (1.4).

THEOREM 1.3. *Let $\Omega \subset \mathbb{R}^3$ be an open bounded set with Lipschitz boundary, Γ_D a $\mathcal{H}^2$-measurable subset of $\partial\Omega$ with $\mathcal{H}^2(\Gamma_D) > 0$, and define $M_0 := \{v \in \mathrm{H}^{1,2}(\Omega) : v = 0$ on $\Gamma_D\}$. For given data*

$$\begin{aligned} \mathcal{X}_0 &\in \mathrm{BV}(\Omega; \{0,1\}), \\ u_D &\in \mathrm{H}^{1,2}(\Omega), \\ f &\in \mathrm{L}^2(\Omega), \end{aligned}$$

there exists functions

$$\begin{aligned} \mathcal{X} &\in \mathrm{L}^\infty(0,T; \mathrm{BV}(\Omega; \{0,1\})), \\ u &\in \mathrm{L}^2(0,T; u_D + M_0), \end{aligned}$$

such that

$$\int_{\Omega_T} \mathcal{X} \partial_t \varphi + \int_\Omega \mathcal{X}_0 \varphi(0,.) - \int_{\Omega_T} \nabla u \cdot \nabla \varphi = - \int_{\Omega_T} f \varphi \tag{1.9}$$

for all $\varphi \in C_c^\infty([0,T) \times \bar{\Omega})$, $\varphi = 0$ on Γ_D. For almost all $t \in (0,T)$ a generalized mean curvature $H(t)$ of $\partial^*\{\mathcal{X}(t,.) = 1\}$ exists and satisfies $\mathcal{H}^2$-almost everywhere on $\partial^*\{\mathcal{X}(t,.) = 1\}$:

$$H(t,.) = u(t,.). \tag{1.10}$$

As shown in [Rög04], (1.10) is well defined since for $u \in \mathrm{L}^2(0,T; \mathrm{H}^{1,2}(\Omega))$ trace values of $u(t,.)$ exist $\mathcal{H}^2$-almost everywhere for almost all $t \in (0,T)$. Furthermore, our formulation of the Gibbs–Thomson law generalizes the BV-formulation. Nevertheless we remark that this solution concept does not include a weak formulation of a boundary condition on the angle between the phase interface and the fixed boundary $\partial\Omega$ (see also the comments in [Rög03]). Moreover, since our focus is on the validation of the Gibbs–Thomson law, we have restricted our investigation to the case of a nonvanishing Dirichlet boundary. In the case of a pure Neumann boundary condition one has to take care of Lagrange multipliers occurring in the approximate Gibbs–Thomson laws. For a discussion of this topic we refer to [BGS98], where a multiphase Mullins–Sekerka system under a pure Neumann boundary condition is investigated.

The proof of Theorem 1.3 is given in sections 3 and 4. Compared to the Stefan problem with Gibbs–Thomson law, the technical difficulty is due to the degeneracy of the energy balance equation and the lack of $\mathrm{L}^1(\Omega_T)$-compactness for the approximate temperature functions.

2. General definitions and notations. We fix some notations and basic definitions. As a general reference for geometric measure theory, see the book by Simon [Sim83].

For functions depending on time and space variables we denote "∇" as the spatial gradient and "$\nabla\cdot$" as the spatial divergence. For a differentiable function $f : \mathbb{R}^n \to \mathbb{R}^n$ and a k-dimensional subspace T of $\mathbb{R}^n$ we define the *divergence restricted to* T as

$$\operatorname{div}_T f(x) := \sum_{i=1}^{k} t_i \cdot Df(x)t_i,$$

where $\{t_i\}_{i=1,\dots,k}$ is any orthonormal basis of T.

For $\Omega \subset \mathbb{R}^n$ open, μ a Radon measure on Ω, $x \in \Omega$, and $\varrho > 0$, define the *scaled measures*

$$\mu_{x,\varrho}(A) := \varrho^{-n+1}\mu(x + \varrho A). \tag{2.1}$$

A k-dimensional subspace $P \subset \mathbb{R}^n$ is called the *k-dimensional tangential plane* of μ in x, denoted by $T_x\mu$, if there is $\theta > 0$ such that

$$\mu_{x,\varrho} \to \theta\mathcal{H}^k\lfloor P \text{ as Radon measures}$$

as ϱ tends to zero. In this case θ is the *multiplicity* of μ in x.

We call μ a *rectifiable* $(n-1)$*-varifold* if for μ-almost all $x \in \Omega$ the $(n-1)$-dimensional tangential plane $T_x\mu$ exists, and an *integral* $(n-1)$*-varifold* if in addition the multiplicity of μ is μ-almost everywhere integer-valued. A *general* $(n-1)$*-varifold* is a Radon measure on the Grassmannian $G^{n-1}\Omega$, which denotes the product of Ω and the space of $(n-1)$-dimensional subspaces of $\mathbb{R}^n$. In the present paper we identify a rectifiable $(n-1)$-varifold μ and the related Radon measure V_μ on $G^{n-1}\Omega$, defined by

$$V_\mu(\zeta) := \int_\Omega \zeta(x, T_x\mu)\, d\mu(x) \quad \text{for } \zeta \in C^0_c(G^{n-1}\Omega).$$

The *first variation* of a rectifiable $(n-1)$-varifold μ is given by

$$\delta\mu(\xi) := \int_\Omega \operatorname{div}_{T_x\mu} \xi(x)\, d\mu(x) \quad \text{for } \xi \in C^1_c(\Omega; \mathbb{R}^n).$$

We say that μ is of *locally bounded first variation* with *mean curvature vector* $\vec{H}_\mu$ if $\vec{H}_\mu \in \mathrm{L}^1_{loc}(\mu)$ and

$$\delta\mu(\xi) = \int_\Omega -\vec{H}_\mu \cdot \xi\, d\mu \quad \text{for all } \xi \in C^1_c(\Omega; \mathbb{R}^n).$$

For a $\mathcal{L}^n$-measurable set $E \subset \Omega$ of finite perimeter let $\partial^* E$ denote the reduced boundary of E in Ω, that is, the subset of $\partial E \cap \Omega$ where a generalized inner normal exists as Radon–Nikodým derivative $\nabla\mathcal{X}_E/|\nabla\mathcal{X}_E|$ with length one. Then $|\nabla\mathcal{X}_E| = \mathcal{H}^{n-1}\lfloor\partial^* E$ is an integral (with density 1) $(n-1)$-varifold on Ω (see [AFP00, paragraph 3.5]).

3. Time discretization. We use the scheme introduced by Luckhaus and Sturzenhecker [LS95] to construct time-discrete approximations. Given a time step $h > 0$, determine iteratively step functions in time

$$u^h : (0,T) \to (u_{\mathrm{D}} + M_0), \quad \mathcal{X}^h : (0,T) \to \mathrm{BV}(\Omega; \{0,1\})$$

by the following procedure. We use the abbreviations $\mathcal{X}_t^h = \mathcal{X}^h(t,.)$, $u_t^h = u^h(t,.)$ and set

$$\mathcal{X}_t^h := \mathcal{X}_0 \quad \text{for } 0 \le t < h.$$

For known $u_{t-h}^h, \mathcal{X}_{t-h}^h$ we define functionals $F_t^h : \mathrm{BV}(\Omega;\{0,1\}) \to \mathbb{R}$,

$$F_t^h(\mathcal{X}) := \int_\Omega |\nabla \mathcal{X}| + \frac{1}{2}\int_\Omega B^h(\mathcal{X} - \mathcal{X}_{t-h}^h - hf)(\mathcal{X} - \mathcal{X}_{t-h}^h - hf), \tag{3.1}$$

where for $v \in \mathrm{L}^2(\Omega)$ the function $B^h(v)$ denotes the solution of

$$-h\Delta B^h(v) = v, \qquad B^h(v)|_{\Gamma_D} = u_{\mathrm{D}}, \quad \nabla B^h(v)\cdot \nu_\Omega|_{\partial\Omega\setminus\Gamma_D} = 0. \tag{3.2}$$

Let $\mathcal{X}_t^h$ be a global minimizer of F_t^h and define

$$u_t^h := -B^h(\mathcal{X}_t^h - \mathcal{X}_{t-h}^h - hf). \tag{3.3}$$

(3.3) yields the approximate energy-balance

$$\partial_t^{-h}\mathcal{X}^h = \Delta u^h + f. \tag{3.4}$$

Since the first variation of F_t^h vanishes in $\mathcal{X}_t^h$, we get for all $\xi \in C_c^1(\Omega,\mathbb{R}^3)$

$$\int_\Omega \left(\nabla\cdot\xi - \frac{\nabla\mathcal{X}_t^h}{|\nabla\mathcal{X}_t^h|}\cdot D\xi\frac{\nabla\mathcal{X}_t^h}{|\nabla\mathcal{X}_t^h|}\right)|\nabla\mathcal{X}_t^h| = \int_\Omega \mathcal{X}_t^h\,\nabla\cdot(u_t^h\xi), \tag{3.5}$$

which is the BV-formulation of the approximate Gibbs–Thomson law

$$H_t^h = u_t^h,$$

where H_t^h denotes the mean curvature of $\partial^*\{\mathcal{X}_t^h = 1\}$.

To derive compactness properties for the approximate solutions we first observe $B^h(hv) = B^1(v)$ and

$$\begin{aligned}\int_\Omega B^h(v)v &= h\int_\Omega |\nabla B^h(v)|^2 - h\int_\Omega \nabla B^h(v)\cdot\nabla u_{\mathrm{D}} + \int_\Omega vu_{\mathrm{D}}\\ &\ge \frac{h}{2}\int_\Omega|\nabla B^h(v)|^2 - \frac{h}{2}\int_\Omega|\nabla u_{\mathrm{D}}|^2 + \int_\Omega vu_{\mathrm{D}}.\end{aligned}$$

With $F_\tau^h(\mathcal{X}_\tau^h) \le F_\tau^h(\mathcal{X}_{\tau-h}^h)$, we calculate for all $0<\tau<T$

$$\begin{aligned}&\int_\Omega|\nabla\mathcal{X}_\tau^h| + \frac{h}{4}\int_\Omega|\nabla u_\tau^h|^2 - \frac{h}{4}\int_\Omega|\nabla u_{\mathrm{D}}|^2 + \frac{1}{2}\int_\Omega(\mathcal{X}_\tau^h - \mathcal{X}_{\tau-h}^h - hf)u_{\mathrm{D}}\\ &\le \int_\Omega|\nabla\mathcal{X}_{\tau-h}^h| + \frac{h}{2}\int_\Omega B^1(f)f.\end{aligned} \tag{3.6}$$

Now, for any $t\in(0,T)$, $t\in[Mh,(M+1)h)$ with $M\in\mathbb{N}_0$, we take inequality (3.6) for $\tau_i = ih$ and sum over $i = 1,\dots,M$, which yields

$$\begin{aligned}&\int_\Omega|\nabla\mathcal{X}_t^h| + \frac{1}{4}\int_0^t\int_\Omega|\nabla u^h|^2\\ &\le \int_\Omega|\nabla\mathcal{X}_0| + \frac{T}{4}\int_\Omega|\nabla u_{\mathrm{D}}|^2 + \frac{1}{2}\int_\Omega|u_{\mathrm{D}}|(1+T|f|) + \frac{T}{2}\int_\Omega B^1(f)f.\end{aligned} \tag{3.7}$$

In particular we get

$$\sup_{h>0} \|\mathcal{X}^h\|_{\mathrm{L}^\infty(0,T;\mathrm{BV}(\Omega))} < \infty, \quad \sup_{h>0} \|u^h\|_{\mathrm{L}^2(0,T;\mathrm{H}^{1,2}(\Omega))} < \infty \tag{3.8}$$

and Fatou's lemma ensures

$$\liminf_{h\to 0} \Big(t \mapsto \|u^h(t,.)\|_{\mathrm{H}^{1,2}(\Omega)} \Big) \in \mathrm{L}^2(0,T). \tag{3.9}$$

In [LS95] an estimate for time differences of $\mathcal{X}^h$ is derived from (3.8); that is,

$$\int_\tau^T \int_\Omega |\mathcal{X}^h_t - \mathcal{X}^h_{t-\tau}| \, d\mathcal{L}^3 \, dt \le C\tau^{\frac{1}{4}} \tag{3.10}$$

holds for all $0 < \tau < T$. The Fréchet–Kolmogorov–Riesz theorem (see, for example, [DS88, IV.8, Theorem 21]), the weak*-compactness of $\mathrm{L}^2(0,T;\mathrm{H}^{1,2}(\Omega))$, and (3.8), (3.9), and (3.10) yield the following proposition.

PROPOSITION 3.1. *There exists a subsequence $h \to 0$ and functions $\mathcal{X} \in \mathrm{L}^\infty(0,T;\mathrm{BV}(\Omega))$, $u \in \mathrm{L}^2(0,T;u_D + M_0)$, such that*

$$u^h \rightharpoonup u \quad \textit{weakly in } \mathrm{L}^2(0,T;\mathrm{H}^{1,2}(\Omega)), \tag{3.11}$$

$$\mathcal{X}^h \to \mathcal{X} \quad \textit{in } \mathrm{L}^1(\Omega_T), \tag{3.12}$$

and for almost all $t \in (0,T)$ we have

$$\mathcal{X}^h(t) \to \mathcal{X}(t) \quad \textit{in } \mathrm{L}^1(\Omega), \tag{3.13}$$

$$\sup_{h>0} \|\mathcal{X}^h(t,.)\|_{\mathrm{BV}(\Omega)} < \infty, \tag{3.14}$$

$$\liminf_{h\to 0} \|u^h(t,.)\|_{\mathrm{H}^{1,2}(\Omega)} < \infty. \tag{3.15}$$

4. Convergence to solutions. Let $u, \mathcal{X}$ and a subsequence $h \to 0$ be given as in Proposition 3.1. To prove Theorem 1.3 we pass (3.4) and (3.5) to a limit and show $u, \mathcal{X}$ to be a correct weak solution of the Mullins–Sekerka problem. The energy balance is derived in a standard way. Use any $\varphi \in C_c^\infty([0,T) \times \bar{\Omega})$ with $\varphi|_{\Gamma_D} = 0$ as a test function in (3.4), perform a discrete partial integration, and use (3.11) and (3.12) to obtain (1.9).

The main effort is the passage to a limit in the approximate Gibbs–Thomson law (3.5). To use a convergence result of Schätzle [Sch01] we argue pointwise in time. Due to the lack of strong $\mathrm{L}^1(\Omega_T)$-compactness of the approximate temperatures, we have to consider any limit point of $(u^h(t,.))_{h>0}$ in the weak-$\mathrm{H}^{1,2}(\Omega)$ topology and identify their traces on $\partial^*\{\mathcal{X}(t,.) = 1\}$ with the trace of the weak limit u in (3.11).

Let us denote by μ^h_t the integral 2-varifolds with density one associated to the surface measure of the phase interfaces

$$\mu^h_t(\eta) := \int_\Omega \eta \, |\nabla \mathcal{X}^h_t| \qquad \text{for } \eta \in C^0_c(\Omega).$$

For the first variation of μ^h_t we obtain, recalling (3.5),

$$\delta\mu^h_t(\xi) = \int_\Omega \left(\nabla\cdot\xi - \frac{\nabla\mathcal{X}^h_t}{|\nabla\mathcal{X}^h_t|} \cdot D\xi \frac{\nabla\mathcal{X}^h_t}{|\nabla\mathcal{X}^h_t|} \right) |\nabla\mathcal{X}^h_t| = \int_\Omega \mathcal{X}^h_t \, \nabla\cdot(u^h_t \xi)$$

for all $\xi \in C^1_c(\Omega,\mathbb{R}^3)$. Finally, we define $T^h : \mathrm{L}^2(0,T;C^1_c(\Omega,\mathbb{R}^3))^* \to \mathbb{R}$ by

$$T^h(\xi) = \int_0^T \delta\mu^h_t(\xi(t,.))\,dt \tag{4.1}$$

and observe from (3.5) and (3.8) that

$$\|\delta\mu^h_t\|_{C^1_c(\Omega,\mathbb{R}^3)^*} \le C(\Omega)\|u^h_t\|_{H^{1,2}(\Omega)}, \tag{4.2}$$

$$\|T^h\|_{\mathrm{L}^2(0,T;C^1_c(\Omega,\mathbb{R}^3))^*} \le C'(\Omega), \tag{4.3}$$

where $C(\Omega), C'(\Omega)$ are independent of $h > 0$.

In a first step we will prove that the phase interfaces $\partial^*\{\mathcal{X}(t,.) = 1\}$ have a generalized mean curvature. Due to Proposition 1.1 this mean curvature is determined by the phase interface itself and thus given by the strong convergence in (3.12) and (3.13). Even more, any limit of the first variations $(\delta\mu^h_t)_{h>0}$ is determined by (3.12).

LEMMA 4.1. *For almost all $t \in (0,T)$ the phase interface $\partial^*\{\mathcal{X}(t,.) = 1\}$ has a generalized mean curvature $\vec{H}(t)$ in the sense of Definition* 1.2 *with*

$$\vec{H}(t) \in \mathrm{L}^4_{\mathrm{loc}}(|\nabla\mathcal{X}(t,.)|). \tag{4.4}$$

For any subsequence $(h_i)_{i\in\mathbb{N}}$, $h_i \to 0 (i \to \infty)$, with $\sup_{i\in\mathbb{N}} \|u^{h_i}(t,.)\|_{\mathrm{H}^{1,2}(\Omega)} < \infty$ *and for all $\xi \in C^1_c(\Omega,\mathbb{R}^3)$ we obtain*

$$\delta\mu^{h_i}_t(\xi) \;\to\; \int_\Omega -\vec{H}(t)\cdot\xi\,|\nabla\mathcal{X}(t,.)|. \tag{4.5}$$

Defining the functionals $T(t) \in C^1_c(\Omega,\mathbb{R}^3)^*$ by

$$\langle \xi, T(t)\rangle \;:=\; \int_\Omega -\vec{H}(t)\cdot\xi\,|\nabla\mathcal{X}(t,.)|, \tag{4.6}$$

we finally observe that

$$T \in \mathrm{L}^2(0,T;C^1_c(\Omega,\mathbb{R}^3))^* \tag{4.7}$$

holds.

Proof. Fix any $t \in (0,T)$ such that (3.13)–(3.15) hold and let $(h_i)_{i\in\mathbb{N}}$ be an arbitrary subsequence with

$$\sup_{i\in\mathbb{N}} \|u^{h_i}(t,.)\|_{\mathrm{H}^{1,2}(\Omega)} \;<\; \infty. \tag{4.8}$$

Define $V^h \in C^0_c(G^2\Omega)^*$ as the general varifold associated to the density-one integer varifold $|\nabla\mathcal{X}^h(t,.)|$. Recalling (3.14) and (4.8), there is a subsequence $(\tilde{h}_i)_{i\in\mathbb{N}}$, a function $v \in \mathrm{H}^{1,2}(\Omega)$, and a Radon measure $V \in C^0_c(G^2\Omega)^*$ such that

$$u^{\tilde{h}_i}(t,.) \rightharpoonup v \qquad \text{weakly in } \mathrm{H}^{1,2}(\Omega), \tag{4.9}$$

$$V^{\tilde{h}_i} \overset{*}{\rightharpoonup} V \qquad \text{weakly* in } C^0_c(G^2\Omega)^*. \tag{4.10}$$

With (3.5), (3.12), and (4.9), (4.10) all assumptions of Theorem 1.1 in [Sch01] are fulfilled and we obtain that

$$V \;=\; V_\mu \quad \text{for an integral} \quad 2\text{-varifold } \mu, \tag{4.11}$$

$$\mu \text{ has locally bounded first variation with mean curvature vector } \vec{H}_\mu, \tag{4.12}$$

$$\vec{H}_\mu \;\in\; \mathrm{L}^4_{\mathrm{loc}}(\mu), \tag{4.13}$$

and that

$$\vec{H}_\mu = v\nu(t,.) \tag{4.14}$$

holds μ-almost everywhere, with

$$\nu(t,.) = \begin{cases} \frac{\nabla\mathcal{X}(t,.)}{|\nabla\mathcal{X}(t,.)|} & \text{on } \partial^*\{\mathcal{X}(t,.)=1\}, \\ 0 & \text{elsewhere.} \end{cases}$$

According to Definition 1.2 the phase interface $\partial^*\{\mathcal{X}(t,.)=1\}$ has the generalized mean curvature vector $\vec{H}(t,.) = \vec{H}_\mu|_{\partial^*\{\mathcal{X}(t,.)=1\}}$ and (4.13) yields (4.4). Moreover, due to [Sch01, Theorem 1.2], we have

$$\vec{H}(t,.) = 0 \quad \mu\text{-almost everywhere in } \{\theta^2(\mu,.) \neq 1\}. \tag{4.15}$$

From (4.10) and (4.11) we obtain the convergence of $\mu_t^{\tilde{h}_i}$ to μ and therefore also the convergence of their first variations. Using (4.12), (4.14), and (4.15) we calculate

$$\begin{aligned} \lim_{i\to\infty} \delta\mu_t^{\tilde{h}_i}(\xi) &= \delta\mu(\xi) \\ &= \int_\Omega -\vec{H}_\mu \cdot \xi \, d\mu = \int_\Omega -\vec{H}(t,.) \cdot \xi \, |\nabla\mathcal{X}(t,.)| = \langle \xi, T(t,.)\rangle. \end{aligned}$$

Since $\vec{H}(t)$ is determined by $\mathcal{X} \in \mathrm{BV}(\Omega;\{0;1\})$ the functional $T(t)$ does not depend on the choices of v, V, and $(\tilde{h}_i)$. Thus we deduce

$$\delta\mu_t^{h_i} \overset{*}{\rightharpoonup} T(t)$$

for the whole sequence $(h_i)_{i\in\mathbb{N}}$ and for all subsequences of $h \to 0$ for which (4.8) holds. We choose $h_i \to 0$ such that

$$\lim_{i\to\infty} \|u^{h_i}(t,.)\|_{\mathrm{H}^{1,2}(\Omega)} = \liminf_{h\to 0} \|u^h(t,.)\|_{\mathrm{H}^{1,2}(\Omega)} < \infty$$

and the lower semicontinuity of the norm with respect to weak*-convergence, and thus (4.2) yields

$$\begin{aligned} \|T(t,.)\|_{C_c^1(\Omega;\mathbb{R}^3)^*} &\le \liminf_{i\to\infty} \|\delta\mu_t^{h_i}\|_{C_c^1(\Omega;\mathbb{R}^3)^*} \\ &\le \liminf_{i\to\infty} C(\Omega)\|u^{h_i}(t,.)\|_{\mathrm{H}^{1,2}(\Omega)} \\ &= C(\Omega) \liminf_{h\to 0} \|u^h(t,.)\|_{\mathrm{H}^{1,2}(\Omega)}. \end{aligned}$$

Recalling (3.9) we get $T \in \mathrm{L}^2(0,T;C_c^1(\Omega;\mathbb{R}^3))^*$. ∎

To prove that the mean curvature of the phase interface is given as trace of the weak limit u in (3.11), the weak*-convergence of T^h in $L^2(0,T;C_c^1(\Omega))^*$ will be crucial. The difficulty is that the pointwise convergence (4.5) holds only for time-dependent subsequences. We use an argument similar to a refined dominated convergence theorem in [PS93].

Lemma 4.2. *There is a subsequence $h \to 0$ such that*

$$T^h \overset{*}{\rightharpoonup} T \quad \text{in } \mathrm{L}^2(0,T;C_c^1(\Omega;\mathbb{R}^3))^*. \tag{4.16}$$

Proof. Fix an arbitrary $\xi \in \mathrm{L}^2(0,T;C^1_c(\Omega;\mathbb{R}^3))$. For $\alpha > 0$ we define functions $T^h_\alpha : (0,T) \to C^1_c(\Omega;\mathbb{R}^3)^*$:

$$T^h_\alpha(t) := \begin{cases} \delta\mu^h_t & \text{if} \quad \|u^h(t,.)\|_{\mathrm{H}^{1,2}(\Omega)} \le \alpha, \\ T(t) & \text{if} \quad \|u^h(t,.)\|_{\mathrm{H}^{1,2}(\Omega)} > \alpha. \end{cases} \tag{4.17}$$

For all $t \in (0,T)$, for which the assertions of Lemma 4.1 hold, the definition of T^h_α and (4.5) yield

$$\langle \xi(t,.), T^h_\alpha(t)\rangle \to \langle \xi(t,.), T(t)\rangle \quad (h \to 0).$$

The estimate

$$|\langle \xi(t,.), T^h_\alpha(t)\rangle| \le \|\xi(t,.)\|_{C^1_c(\Omega;\mathbb{R}^3)} \Big(C\alpha + \|T(t)\|_{C^1_c(\Omega;\mathbb{R}^3)^*}\Big)$$

and (4.7) give a $\mathrm{L}^1(0,T)$-dominator. Thus the Lebesgue theorem ensures

$$\int_0^T \langle \xi(t,.), T^h_\alpha(t)\rangle \, dt \to \int_0^T \langle \xi(t,.), T(t)\rangle \, dt \quad (h \to 0). \tag{4.18}$$

Next, consider the sets $A^h := \{t \in (0,T) \,:\, \|u^h(t,.)\|_{\mathrm{H}^{1,2}(\Omega)} > \alpha\}$ and observe

$$\begin{aligned} &\Big| \int_0^T \big\langle \xi(t,.), \delta\mu^h_t - T^h_\alpha(t)\big\rangle \, dt \Big| \\ \le &\int_{A^h} \Big| \big\langle \xi(t,.), \delta\mu^h_t - T(t)\big\rangle \Big| \, dt \\ \le &\Big(\int_{A^h} \|\xi(t,.)\|^2_{C^1_c(\Omega;\mathbb{R}^3)} dt\Big)^{\frac{1}{2}} \Big(\|T^h\|_{\mathrm{L}^2(0,T;C^1_c(\Omega;\mathbb{R}^3)^*)} + \|T\|_{\mathrm{L}^2(0,T;C^1_c(\Omega;\mathbb{R}^3)^*)}\Big). \end{aligned}$$

By (4.3) and (4.7) the norms $\|T^h\|_{\mathrm{L}^2(0,T;C^1_c(\Omega;\mathbb{R}^3)^*)}$ and $\|T\|_{\mathrm{L}^2(0,T;C^1_c(\Omega;\mathbb{R}^3)^*)}$ are bounded uniformly in $h > 0$. Estimating

$$|A^h| \le \frac{1}{\alpha^2} \|u^h\|^2_{\mathrm{L}^2(0,T;\mathrm{H}^{1,2}(\Omega))} \le \frac{1}{\alpha^2} C$$

by (3.8), we end up with

$$\int_0^T \langle \xi(t,.), T^h - T^h_\alpha(t)\rangle \, dt \to 0 \quad (\alpha \to \infty) \tag{4.19}$$

uniformly in $h > 0$. Putting this together with (4.18) proves the lemma. ∎

By establishing the Gibbs–Thomson law we finish the proof of Theorem 1.3.

LEMMA 4.3. *For all* $\xi \in \mathrm{L}^2(0,T;C^1_c(\Omega;\mathbb{R}^3))$ *we obtain*

$$\int_0^T \langle \xi(t,.), T(t)\rangle \, dt = \int_{\Omega_T} \mathcal{X} \, \nabla \cdot (u\xi).$$

In particular, for almost all $t \in (0,T)$,

$$H(t,.) = u(t,.)$$

holds $\mathcal{H}^2$*-almost everywhere on* $\partial^*\{\mathcal{X}(t,.) = 1\}$.

Proof. We get from (3.5), (3.11), (4.1) and Lemma 4.2

$$\begin{aligned}\int_{\Omega_T} \mathcal{X}\nabla\cdot(u\xi) &= \lim_{h\to 0}\int_{\Omega_T}\mathcal{X}^h\nabla\cdot(u^h\xi)\\ &= \lim_{h\to 0}\int_0^T \langle \xi(t,.),\delta\mu_t^h\rangle\,dt\\ &= \int_0^T \langle \xi(t,.),T(t)\rangle\,dt.\end{aligned}$$

Since no time derivative is involved we deduce that for almost all $t\in(0,T)$ and all $\xi\in C_c^1(\Omega;\mathbb{R}^3)$,

$$\int_\Omega \mathcal{X}(t,.)\nabla\cdot(u(t,.)\xi) = \langle \xi, T(t)\rangle$$

holds. The Gauss–Green theorem [EG92, Theorem 5.8.1] and (4.6) yield

$$\int_\Omega -u(t,.)\nu(t,.)\cdot\xi\,|\nabla\mathcal{X}(t,.)| = \int_\Omega -\vec{H}(t,.)\cdot\xi\,|\nabla\mathcal{X}(t,.)|,$$

with $\nu(t,.)=\nabla\mathcal{X}(t,.)/|\nabla\mathcal{X}(t,.)|$ on $\partial^*\{\mathcal{X}(t,.)=1\}$. This proves the Gibbs–Thomson law. ∎

Acknowledgment. I thank R. Schätzle for many fruitful discussions and for referring me to geometric measure theory.

ANALYTICITY OF DIRICHLET–NEUMANN OPERATORS ON HÖLDER AND LIPSCHITZ DOMAINS*

BEI HU† AND DAVID P. NICHOLLS†

Abstract. In this paper we take up the question of analyticity properties of Dirichlet–Neumann operators with respect to boundary deformations. In two separate results, we show that if the deformation is sufficiently small and lies either in the class of $C^{1+\alpha}$ (any $\alpha > 0$) or Lipschitz functions, then the Dirichlet–Neumann operator is analytic with respect to this deformation. The proofs of both results utilize the "domain flattening" change of variables recently advocated by Nicholls and Reitich for the stable, high-order numerical simulation of Dirichlet–Neumann operators. We extend their analyticity results through the use of more specialized function spaces, and our new theorems are *optimal* in terms of boundary regularity. In the case of $C^{1+\alpha}$ boundary perturbations the underlying field also lies in the Hölder class $C^{1+\alpha}$ and the theorem follows by appealing to familiar Schauder theory arguments. In contrast, for Lipschitz deformations the field must lie in an L^p-based Sobolev space ($W^{1,p}$), so the relevant elliptic estimates come from Sobolev theory. Additionally, in the case of Lipschitz domains, the Dirichlet–Neumann operator must be reformulated weakly in order to accommodate the lack of regularity at the boundary which these Sobolev-class fields possess.

Key words. Dirichlet–Neumann operators, geometric perturbations, free-boundary problems, boundary value problems, Hölder regularity, Sobolev regularity

1. Introduction. Many problems of fundamental importance in engineering and the sciences are posed in terms of partial differential equations formulated on irregular and/or moving boundaries. In many instances the differential equations are quite simple (linear and constant coefficient); however, the nonlinearity of the boundary conditions and/or the geometrical difficulties of the domain usually prevent analytic solution of these problems. Classical examples of such problems are the free-surface evolution of an ideal fluid [15], scattering of electromagnetic radiation from an irregular grating [2], and precipitate growth [13]. For these problems a simplification and reduction in dimension can be achieved by considering surface quantities and, if applicable, the shape of the boundary as fundamental variables. Then, if desired, bulk quantities can be recovered from these boundary measurements via appropriate integral formulas. In general this procedure is complicated by the necessity of normal derivatives of field quantities at the boundary. Therefore, Dirichlet–Neumann operators (DNOs), which deliver normal derivatives ("Neumann data") given boundary measurements ("Dirichlet data"), play a crucial role.

Among the many ways in which the DNO can be simulated numerically (e.g., boundary integrals/elements, finite differences, finite elements, etc.), methods based upon boundary perturbations are particularly appealing. These approaches view the shape of the domain as a (small) deformation of a separable geometry (e.g., disk, torus, infinite strip) and seek solutions as a Taylor series expanded in powers of this small parameter. Aside from being highly accurate within their domain of applicability,

a particularly appealing property of these methods is that, in contrast with most alternative approaches, the spatial dimension of the problem does not affect their implementation or performance. See [18, 19, 20] for a complete discussion of these issues and presentation of numerical results.

Since perturbation algorithms play such a crucial role in the study of DNOs we take up the mathematical question of their analyticity with respect to boundary perturbations, i.e., with respect to ε, which measures the *size* of the perturbation. The first results along these lines can be derived from the work of Calderón [4] and of Coifman and Meyer [6], who showed that if the upper boundary of a two-dimensional domain is a (one-dimensional) Lipschitz curve, then the DNO maps H^1 to L^2 and is analytic in ε (sufficiently small). Next, Craig, Schanz, and Sulem [10] showed that the DNO maps $W^{k+1,p}$ to $W^{k,p}$ for $k \geq 0$ and is analytic in ε (sufficiently small) for three-dimensional domains provided that the two-dimensional upper boundary is C^1; Craig and Nicholls [8] extended this result to general d dimensions ($(d-1)$–dimensional upper boundary) by the same techniques but, due to the application at hand, also required the boundary deformation to be in the class $W^{k+1,p}$ for $k \geq 0$.

These results are the most general to date but rely heavily on an implicit boundary integral formulation for the DNO which, from a numerical standpoint, undermines the computational advantages of boundary perturbation approaches. With this consideration in mind, Nicholls and Reitich studied analyticity through the transformed field expansion (TFE) approach [18, 19, 20]. While this method did not deliver the sharpest results from a theoretical standpoint (the boundary deformation was required to be in the class $C^{3/2+\delta}$ for any $\delta > 0$), it did produce a new, *stabilized*, high-order numerical procedure for the approximation of DNOs with all the advantages of boundary perturbation methods (e.g., ease of implementation, dimension independent performance) without the shortcomings of classical implementations (e.g., cancellations and high-order instability); please see [18, 19, 20] for a complete discussion and [21, 22] for recent advancements in the setting of acoustic and electromagnetic scattering applications. Finally, we mention the recent work of Buffoni [3] who, in the setting of an existence theory for two-dimensional traveling capillary-gravity waves, utilized the DNO in Zakharov's formulation [23] of surface water wave evolution. However, since other techniques prevailed, the analyticity of the DNO with respect to boundary perturbations was not used.

The goal of this paper is to show that the TFE approach can, in addition to providing a stabilized numerical approach, be used to realize the most general analyticity results possible (in terms of boundary regularity) in *arbitrary* dimension. Concerning smoothness of the boundary, this matches the theorems of Calderón [4] and Coifman and Meyer [6] in two dimensions. However, the underlying function spaces are quite different being based upon L^p-Sobolev spaces rather than L^2-Sobolev spaces. Our results extend those of Craig, Schanz, and Sulem [10] and Craig and Nicholls [8] in higher dimensions. Of course, our method can be extended to spaces with higher regularity if greater smoothness is assumed on the boundary deformation and Dirichlet data. We begin by showing that the TFE method analyzed with Schauder theory in Hölder spaces gives a simple and elegant analyticity theorem for surface deformations in the class $C^{1+\alpha}$ for any $\alpha > 0$. We then follow this analysis with a more involved calculation in $W^{k,p}$ spaces using Sobolev theory and demonstrate that, in fact, the regularity of the surface shape can be reduced to Lipschitz.

The paper is organized as follows: In section 2 we introduce the TFE change of variables and state our main results. In section 3.1 we work in the classical Hölder spaces via Schauder theory and conclude analyticity for boundary deformations of class $C^{1+\alpha}$ for any $\alpha > 0$, and we show that the DNO will map $C^{1+\alpha}$ Dirichlet data to C^{α} Neumann data and is uniformly analytic in ε. In section 3.2 we utilize the Sobolev theory of $W^{k,p}$ spaces and show that, in fact, the regularity of the boundary deformation can be reduced to Lipschitz in *any* spatial dimension; in this case, the DNO is analytic in ε and maps $W^{1-1/p,p}$ Dirichlet data to $W^{-1/p,p}$ Neumann data (see section 2 for the precise definition of $W^{-1/p,p}$). In Appendix A, we review the key elliptic estimates which enable our analysis of the DNO.

2. Problem statement and change of variables. To focus upon a particular problem we consider the classical free-boundary problem of the evolution of a d-dimensional ideal fluid under the effects of gravity. The fluid sits above the bottom of a flat ocean bed at mean depth h and is bounded above by the free surface $\eta(x,t)$, giving the domain

$$S_{h,\eta} = \{(x,y) \in \mathbf{R}^{d-1} \times \mathbf{R} \mid -h < y < \eta\}.$$

The fundamental variables for this problem are the shape of the free surface, η, and the velocity potential $\varphi(x,y,t)$ which gives the velocity of the fluid from $\vec{v} = \nabla\varphi$. The equations of motion are [15]

$$\Delta\varphi = 0 \qquad \text{in } S_{h,\eta}, \tag{2.1a}$$

$$\partial_y \varphi(x,-h) = 0, \tag{2.1b}$$

$$\partial_t \eta + \nabla_x \varphi \cdot \nabla_x \eta - \partial_y \varphi = 0 \qquad \text{at } y = \eta, \tag{2.1c}$$

$$\partial_t \varphi + \frac{1}{2}|\nabla\varphi|^2 + g\eta = 0 \qquad \text{at } y = \eta. \tag{2.1d}$$

These equations must be supplemented with initial conditions and lateral boundary conditions, which we discuss later.

In a fundamental paper on stability of free-surface ocean waves, Zakharov [23] noted that the Euler equations, (2.1), could be stated as a Hamiltonian system in terms of the canonical variables $(\eta(x,t), \xi(x,t) \equiv \varphi(x,\eta(x,t),t))$. This observation, coupled with the solvability of Laplace's equation on the domain $S_{h,\eta}$ given ξ, leads to the realization that (2.1) can be equivalently stated *at the surface* of the domain $S_{h,\eta}$. The restatement was first made by Craig and Sulem [11] as

$$\partial_t \eta = G(\eta)\,\xi, \tag{2.2a}$$

$$\partial_t \xi = -g\eta - \frac{1}{2(1+|\nabla_x\eta|^2)}\Big[|\nabla_x\xi|^2 - (G(\eta)\,\xi)^2$$

$$-2(G(\eta)\,\xi)\nabla_x\xi\cdot\nabla_x\eta + |\nabla_x\xi|^2|\nabla_x\eta|^2 - (\nabla_x\xi\cdot\nabla_x\eta)^2\Big], \tag{2.2b}$$

where $G(\eta)\,\xi$ is the DNO. This set of equations, (2.2), has been useful in a variety of analytical [8, 7] and numerical [16, 17, 9, 14] treatments of the Euler equations, and clearly a detailed understanding of the DNO is at the heart of these analyses.

Inspired by the geometry of the Euler equations (2.1) and the reduction of Craig and Sulem, we study the DNO, $G(\eta)$, and its associated boundary value problem:

$$\Delta v(x,y) = 0 \qquad \text{in } S_{h,\eta}, \tag{2.3a}$$

$$\partial_y v(x,-h) = 0, \tag{2.3b}$$

$$v(x,\eta(x)) = \xi(x). \tag{2.3c}$$

Upon the solution of (2.3) the DNO is defined as

$$G(\eta)\,\xi = \nabla v|_{y=\eta} \cdot N_\eta = [-\nabla_x \eta \cdot \nabla_x v + \partial_y v]_{y=\eta}\,, \tag{2.4}$$

where the normal $N = (-\nabla_x \eta, 1)^T$ (not of unit length) is chosen to simplify the restatement of the kinematic condition (2.1c) as (2.2a). Regarding lateral boundary conditions, it is well known that bounded solutions to (2.3) are unique. Thus, $v(x, y)$ is periodic in x if $\eta(x)$ and $\xi(x)$ are periodic in x; similarly, the behavior of $v(x)$ as $x \to \pm\infty$ will be uniquely determined by the behavior of $\xi(x)$ near infinity. In this way we incorporate quite general boundary conditions into the definition of the DNO.

In order to work with more general Lipschitz boundaries, we now derive a weak formulation of the DNO: Take any test function $\psi \in T^1_R(\overline{S_{h,\eta}})$, where

$$T^1_R(\overline{S_{h,\eta}}) = \left\{ f \in C^1(\overline{S_{h,\eta}}) \mid f = 0 \text{ on } \{|x| > R\} \text{ for some large } R \right\}.$$

Then

$$\begin{aligned}
0 &= \int_{S_{h,\eta}} (\Delta v)\psi \, \mathrm{d}V \\
&= \int_{y=\eta(x)} (\partial_\nu v)\psi \, \mathrm{d}S - \int_{S_{h,\eta}} (\nabla_x v \cdot \nabla_x \psi + \partial_y v \ \partial_y \psi) \, \mathrm{d}V \\
&= \int_{\mathbf{R}^{d-1}} \frac{G(\eta)\ \xi}{\sqrt{1 + |\nabla_x \eta|^2}} \ \psi(x, \eta(x)) \ \sqrt{1 + |\nabla_x \eta|^2} \, \mathrm{d}x - \int_{S_{h,\eta}} (\nabla_x v \cdot \nabla_x \psi + \partial_y v \ \partial_y \psi) \, \mathrm{d}V.
\end{aligned}$$

Thus

$$\int_{\mathbf{R}^{d-1}} (G(\eta)\ \xi)\psi(x, \eta(x)) \, \mathrm{d}x = \int_{S_{h,\eta}} \nabla_x v \cdot \nabla_x \psi + \partial_y v \ \partial_y \psi \, \mathrm{d}V. \tag{2.5}$$

For any $\psi \in T^1_R(\overline{S_{h,\eta}})$ we can always approximate ψ with $\psi_j \in C^1(\overline{S_{h,\eta}})$ such that

$$\begin{aligned}
\psi_j &\to \psi && \text{strongly in } C(\overline{S_{h,\eta}}), \\
\nabla \psi_j &\to \nabla \psi && \text{weak* in } L^\infty(S_{h,\eta})^d.
\end{aligned}$$

Using this approximation, we find that (2.5) also extends to functions $\psi \in T^{0,1}_R(\overline{S_{h,\eta}})$, where

$$T^{0,1}_R(\overline{S_{h,\eta}}) = \left\{ f \in C^{0,1}(\overline{S_{h,\eta}}) \mid f = 0 \text{ on } \{|x| > R\} \text{ for some large } R \right\}.$$

Using the notation

$$\langle a, b \rangle = \int_{\mathbf{R}^{d-1}} a(x)\ b(x) \, \mathrm{d}x,$$

we restate (2.5) as follows: For any $\psi \in T^{0,1}_R(\overline{S_{h,\eta}})$,

$$\langle G(\eta)\ \xi, \psi(x, \eta(x)) \rangle = \int_{S_{h,\eta}} (\nabla_x v \cdot \nabla_x \psi + \partial_y v \ \partial_y \psi) \, \mathrm{d}V. \tag{2.6}$$

It is clear that the right-hand side of this equality requires v only to be $W^{1,1}_{loc}(\overline{S_{h,\eta}})$.

It has been discovered [18, 19, 20] that an effective technique for establishing the analyticity of DNOs is to make a "domain flattening" change of variables

$$x' = x, \qquad y' = h\frac{y-\eta}{h+\eta}, \tag{2.7}$$

which maps $S_{h,\eta}$ to $S_{h,0}$. Considering the transformed field

$$u(x', y') = v(x', (h+\eta)y'/h+\eta), \tag{2.8}$$

the change of variables induces the formulas

$$(h+\eta)\nabla_x = (h+\eta)\nabla_{x'} - (h+y')(\nabla_{x'}\eta)\partial_{y'}, \tag{2.9a}$$
$$(h+\eta)\ \mathrm{div}_x = (h+\eta)\ \mathrm{div}_{x'} - (h+y')(\nabla_{x'}\eta)\cdot\partial_{y'}, \tag{2.9b}$$
$$(h+\eta)\partial_y = h\partial_{y'}, \tag{2.9c}$$

which include a prefactor of $(h+\eta)$ in order to realize transformed equations with *no quotients involving* η. Upon making this transformation, (2.3) becomes

$$\Delta u(x', y') = F(x', y') \qquad \text{in } S_{h,0}, \tag{2.10a}$$
$$\partial_y u(x', -h) = 0, \tag{2.10b}$$
$$u(x', 0) = \xi(x'), \tag{2.10c}$$

where

$$F(x', y') = \mathrm{div}_{x'}\left[F^{(1)}(x', y')\right] + \partial_{y'}F^{(2)}(x', y') + F^{(3)}(x', y'). \tag{2.11}$$

The form for F can be found most easily from the following calculation:

$$\begin{aligned}
0 &= (h+\eta)^2\{\Delta_x v + \partial_y^2 v\} \\
&= (h+\eta)^2\Delta_x v + (h+\eta)^2\partial_y^2 v \\
&= (h+\eta)\mathrm{div}_x\left[(h+\eta)\nabla_x v\right] - \nabla_x\eta\cdot(h+\eta)\nabla_x v + (h+\eta)\partial_y\left[(h+\eta)\partial_y v\right].
\end{aligned}$$

Using (2.9) it is straightforward to show that

$$\begin{aligned}
0 = {} & h^2\Delta'_x u + h^2\partial_{y'}^2 u \\
& +\eta\ \mathrm{div}_{x'}\left[h\nabla_{x'}u\right] + h\ \mathrm{div}_{x'}\left[\eta\nabla_{x'}u\right] + \eta\ \mathrm{div}_{x'}\left[\eta\nabla_{x'}u\right] - h\ \mathrm{div}_{x'}\left[(h+y)\nabla_{x'}\eta\partial_{y'}u\right] \\
& -\eta\ \mathrm{div}_{x'}\left[(h+y)\nabla_{x'}\eta\partial_{y'}u\right] - (h+y)\nabla_{x'}\eta\cdot\partial_{y'}\left[h\nabla_{x'}u\right] \\
& -(h+y)\nabla_{x'}\eta\cdot\partial_{y'}\left[\eta\nabla_{x'}u\right] + (h+y)\nabla_{x'}\eta\cdot\partial_{y'}\left[(h+y')\nabla_{x'}\eta\partial_{y'}u\right] \\
& -h\nabla_{x'}\eta\cdot\nabla_{x'}u - \eta\nabla_{x'}\eta\cdot\nabla_{x'}u + (h+y')\left|\nabla_{x'}\eta\right|^2\partial_{y'}u.
\end{aligned}$$

From this point, several manipulations can be effected to realize the divergence structure of F. Upon dropping primes, this results in

$$F^{(1)} = -\frac{2}{h}\eta\nabla_x u - \frac{1}{h^2}\eta^2\nabla_x u + \frac{h+y}{h}\nabla_x\eta\partial_y u + \frac{(h+y)}{h^2}\eta\nabla_x\eta\partial_y u, \tag{2.12a}$$
$$F^{(2)} = \frac{h+y}{h}\nabla_x\eta\cdot\nabla_x u + \frac{(h+y)}{h^2}\eta\nabla_x\eta\cdot\nabla_x u - \frac{(h+y)^2}{h^2}\left|\nabla_x\eta\right|^2\partial_y u, \tag{2.12b}$$
$$F^{(3)} = \frac{1}{h}\nabla_x\eta\cdot\nabla_x u + \frac{1}{h^2}\eta\nabla_x\eta\cdot\nabla_x u - \frac{(h+y)}{h^2}\left|\nabla_x\eta\right|^2\partial_y u, \tag{2.12c}$$

where $F^{(1)}$, $F^{(2)}$, and $F^{(3)}$ are all $\mathcal{O}(\eta)$. At this point we note that, as claimed above, the right-hand side of (2.10a) contains no quotients involving η.

Of course, we are primarily concerned with the DNO; formula (2.4) transforms as

$$\begin{aligned}(h+\eta)G(\eta)\ \xi \\ &= \{-\nabla_x\eta\cdot(h+\eta)\nabla_x v+(h+\eta)\partial_y v\}\Big|_{y'=0} \\ &= \{h\partial_{y'}u-h\nabla_{x'}\eta\cdot\nabla_{x'}u-\eta\nabla_{x'}\eta\cdot\nabla_{x'}u+(h+y')\left|\nabla_{x'}\eta\right|^2\partial_{y'}u\}\Big|_{y'=0}.\end{aligned}\tag{2.13}$$

Therefore, again dropping primes,

$$G(\eta)\ \xi(x)=\partial_y u(x,0)+J(x),\tag{2.14}$$

where

$$\begin{aligned}J=&-\frac{\eta}{h}G(\eta)\ \xi-\nabla_x\eta\cdot\nabla_x u(x,0)\\ &-\frac{1}{h}\eta\nabla_x\eta\cdot\nabla_x u(x,0)+\left|\nabla_x\eta\right|^2\partial_y u(x,0),\end{aligned}$$

and clearly $J=\mathcal{O}(\eta)$. The weak statement of the DNO, (2.6), transforms as

$$\begin{aligned}&\langle G(\eta)\ \xi,\psi(x,0)\rangle\\ &=\int_{S_{h,0}}\left\{\left(\nabla_x u-\frac{h+y}{h+\eta}(\nabla_x\eta)\partial_y u\right)\cdot\left(\nabla_x\psi-\frac{h+y}{h+\eta}(\nabla_x\eta)\partial_y\psi\right)\right.\\ &\qquad\left.+\frac{h^2}{(h+\eta)^2}(\partial_y u)\partial_y\psi\right\}\frac{h+\eta}{h}\,\mathrm{d}V\end{aligned}\tag{2.15}$$

for any $\psi\in T_R^{0,1}(\overline{S_{h,0}})$. Finally, we point out that sometimes it is more convenient to write the DNO in the following form:

$$G(\eta)\ \xi(x)=\ -\nabla_x\eta\cdot\nabla_x\xi+\left.\frac{h(1+\left|\nabla_x\eta\right|^2)}{h+\eta}\partial_y u\right|_{y=0},\tag{2.16}$$

where we have used the fact that $u(x,0)=\xi(x)$.

In the spirit of the boundary perturbation methods we alluded to in the Introduction, we now suppose that we are considering η to be a *small* perturbation of a flat geometry, i.e., $\eta(x)=\varepsilon f(x)$. In this case, for future reference, (2.16) becomes

$$G(\eta)\ \xi(x)=\ -\varepsilon\nabla_x f\cdot\nabla_x\xi+\left.\frac{h(1+\left|\varepsilon\nabla_x f\right|^2)}{h+\varepsilon f}\partial_y u\right|_{y=0}.\tag{2.17}$$

We show the following theorem in section 3.1.

THEOREM 2.1. *Let $f,\xi\in C^{1+\alpha}(\mathbf{R}^{d-1})$, $0<\alpha<1$. Let $v(x,y)$ be the solution of* (2.3) *in the region $S_{h,\eta}$ with $\eta=\varepsilon f$ and define*

$$u(x,y,\varepsilon)=v\left(x,\frac{(h+\varepsilon f)y}{h}+\varepsilon f\right),\quad -\infty<x<\infty,-h<y<0$$

(cf. (2.8)*). Define the DNO $G(\varepsilon f)$ by* (2.14) *with $\eta=\varepsilon f$. Then both the solution $u(x,y,\varepsilon)$ and the DNO $G(\varepsilon f)$ are analytic as functions of ε; i.e., they can be expressed*

as the convergent series

$$u(x,y,\varepsilon)=\sum_{n=0}^{\infty}u_n(x,y)\ \varepsilon^n,\quad G(\varepsilon f)=\sum_{n=0}^{\infty}G_n(f)\ \varepsilon^n, \tag{2.18}$$

for small ε, where u_n and $G_n(f)$ satisfy, for some constants B and C independent of ε,

$$|u_n|_{C^{1+\alpha}(S_{h,0})}\le CB^n\,|\xi|_{C^{1+\alpha}(\mathbf{R}^{d-1})}\,,\quad |G_n(f)|_{\mathcal{L}(C^{1+\alpha}(\mathbf{R}^{d-1}),C^{\alpha}(\mathbf{R}^{d-1}))}\le CB^n.$$

This theorem implies that the DNO maps $C^{1+\alpha}$ Dirichlet data to C^α Neumann data.

By working in L^p-based Sobolev spaces, $W^{k,p}$ $(p>d)$, we can refine this result by requiring the boundary to be only Lipschitz continuous. In dealing with these Sobolev spaces, we must appeal to the trace operator and its mapping properties (see [1, Chapter 7 (e.g., Theorem 7.53)] for trace theorems); in particular, if $\partial\Omega\in C^k$, then the trace operator $W^{k,p}(\Omega)\to W^{k-1/p,p}(\partial\Omega)$ is continuous and surjective.

To state the next result with complete accuracy we first define a pair of function spaces. We denote by $B_r(x^*)$ the ball of radius r centered at x^*, and for $p>1$ define

$$X^p=\{\xi\mid \xi\in W^{1-1/p,p}(B_1(x^*))\text{ for any }x^*\in\mathbf{R}^{d-1}\}.$$

For $\xi\in X^p$ we define

$$\|\xi\|_{X^p}=\sup_{x^*\in\mathbf{R}^{d-1}}\|\xi\|_{W^{1-1/p,p}(B_1(x^*))}.$$

Recall that [1, Chapter 7]

$$\|\xi\|_{W^{1-1/p,p}(B_1(x^*))}=\inf\|\zeta\|_{W^{1,p}(B_1(x^*)\times[-h,0])}\,,$$

where the infimum is taken over all functions $\zeta\in W^{1,p}(B_1(x^*)\times[-h,0])$ such that $\zeta(x,0)=\xi(x)$ in the trace sense; i.e., for any C^∞ function $\gamma(x,y)$ such that $\gamma=0$ on

$$\{\partial B_1(x^*)\times[-h,0]\}\cup\{B_1(x^*)\times\{y=-h\}\}\,,$$

$\gamma(\zeta-\xi)\in W_0^{1,p}((B_1(x^*)\times(-h,0)))$. It is clear that with this definition

$$\|\xi\|_{X^p}\le\sup_{x^*\in\mathbf{R}^{d-1}}\|\xi\|_{W^{1-1/p,p}(B_2(x^*))}\le 2^{(d-1)/p}\,\|\xi\|_{X^p}\,.$$

We also define

$$Y^{k,p}=\{u\mid u\in W^{k,p}(B_1(x^*)\times[-h,0])\text{ for any }x^*\in\mathbf{R}^{d-1}\}$$

and

$$\|u\|_{Y^{k,p}}=\sup_{x^*\in\mathbf{R}^{d-1}}\|u\|_{W^{k,p}(B_1(x^*)\times[-h,0])}\,.$$

In the case of boundary data in X^p, the solution $u(x,y,\varepsilon)$ will only be in the space $W^{1,p}$ in the domain. Therefore, the first order derivative ∇u will only be an L^p function in the domain and the trace operator in (2.14) is not well defined. Thus we shall use the weak formulation (2.15). Since the DNO is local in nature, we shall discuss the DNO only in a neighborhood of an arbitrarily fixed point $\hat{x} \in \mathbf{R}^{d-1}$. We will establish the following in section 3.2.

THEOREM 2.2. *If $f \in C^{0,1}(\mathbf{R}^{d-1})$, $\xi \in X^p$, $p > d$. Let $v(x,y)$ be the solution of* (2.3) *in the region $S_{h,\eta}$ with $\eta = \varepsilon f$ and define*

$$u(x,y,\varepsilon) = v\left(x, \frac{(h+\varepsilon f)y}{h} + \varepsilon f\right), \quad -\infty < x < \infty, -h < y < 0$$

(cf. (2.8)*). Define the DNO $G(\varepsilon f)$ by* (2.15) *with $\eta = \varepsilon f$. Then both the solution $u(x,y,\varepsilon)$ and the DNO $G(\varepsilon f)$ are analytic as functions of ε; i.e., they can be expressed as the convergent series*

$$u(x,y,\varepsilon) = \sum_{n=0}^{\infty} u_n(x,y)\ \varepsilon^n, \quad G(\varepsilon f) = \sum_{n=0}^{\infty} G_n(f)\ \varepsilon^n,$$

for small ε, where u_n and $G_n(f)$ satisfy, for some constants B and C independent of ε,

$$\|u_n\|_{Y^{1,p}} \le CB^n \|\xi\|_{X^p}, \quad \|G_n(f)\|_{\mathcal{L}(X^p,(X_c^q(\hat{x}))^*)} \le CB^n \tag{2.19}$$

for any fixed $\hat{x} \in \mathbf{R}^{d-1}$. In these formulas, q is the conjugate of p, i.e., $q = p/(p-1)$, and $(X_c^q(\hat{x}))^*$ is the dual space of $X_c^q(\hat{x})$:

$$\begin{aligned} X_c^q(\hat{x}) &= \{\varphi \in X^q \mid \varphi = 0 \text{ for } |x - \hat{x}| > 1\} \\ &\cong W_0^{1-1/q,q}(B_1(\hat{x})). \end{aligned}$$

Remark. Roughly speaking, X^p behaves like $W^{1-1/p,p}$ and X^q behaves like $W^{1-1/q,q}$. Thus, the dual space of $W^{1-1/q,q}$ behaves locally like $W^{-(1-1/q),p} = W^{-1/p,p}$. Therefore, the above theorem states that the DNO "loses one spatial derivative" and is analytic in ε. This is the *optimal* regularity that one can expect for the DNO.

Remark. Theorem 2.2 concerns a field, v, in $W^{1,p}$ with boundary trace, ξ, in $W^{1-1/p,p}$. Such assumptions were made to enable a proof which demands the *weakest* possible regularity on the boundary perturbation. Of course, if the boundary deformation and Dirichlet data are more regular, then the field and DNO will be smoother as well. Results mentioned in the Introduction (e.g., Calderón [4], Coifman and Meyer [6], Craig, Schanz, and Sulem [10], Craig and Nicholls [8], and Nicholls and Reitich [18, 20]) provide such results in a wide array of function spaces.

Remark. We introduced the spaces X^p and $Y^{k,p}$ in order to include quite general behavior at infinity. For instance, we can accommodate periodicity or convergence (at infinity) to a constant. If we specialize to periodic boundary conditions, say on the period cell $Q \subset \mathbf{R}^{d-1}$, we can simplify the statements of the theorem by replacing X^p with $W^{1-1/p,p}(Q)$, $Y^{1,p}$ with $W^{1,p}(Q \times [-h,0])$, and $B_1(\hat{x})$ with Q in Theorem 2.2.

Remark. Finally, a direct, "method of majorants" approach could be pursued to derive these results; cf. [18, 19, 20]. This would involve (for Theorem 2.1) inserting the expansions (2.18) into (2.10) and (2.14), finding equations satisfied by the u_n and G_n, and then estimating them directly in an appropriate function space. Since our purpose is to simply establish analyticity in ε (rather than *joint* analyticity in x, y, and ε; cf. [20]), we have found that a *complexification* approach greatly simplifies the argument while delivering the most general result possible.

3. Analyticity. In this section we establish analyticity of $u(x, y, \varepsilon)$ in ε via a complexification argument. Of course, in the original system (2.3) we cannot allow ε to be complex-valued as ε measures the magnitude of the (real) deformation of the domain. On the other hand, in the transformed system (2.10) ε has no such interpretation and we are free to allow $\varepsilon = \varepsilon_1 + \mathrm{i}\varepsilon_2 \in \mathbf{C}$ and to look for *complex* solutions, u. The advantage of this approach is the availability of the formulas of complex analysis which readily deliver analyticity provided that straightforward estimates are established. Once this is accomplished we may set $\varepsilon_2 = 0$ and obtain the series expansion for u which must be real-valued.

The complexification approach requires us to simply show that $u(x, y, \varepsilon)$ is differentiable in $\varepsilon = \varepsilon_1 + \mathrm{i}\varepsilon_2$ for $|\varepsilon|$ sufficiently small. To this end we define the finite difference operator as follows:

$$T_\delta[u](x, y, \varepsilon) = \frac{1}{\delta}[u(x, y, \varepsilon + \delta) - u(x, y, \varepsilon)], \quad \delta = \delta_1 + \mathrm{i}\delta_2.$$

A simple computation shows that

$$T_\delta[u \cdot w](x, y, \varepsilon) = T_\delta[u](x, y, \varepsilon) \cdot w(x, y, \varepsilon) + u(x, y, \varepsilon + \delta) \cdot T_\delta[w](x, y, \varepsilon). \tag{3.1}$$

In the next two subsections we show that $T_\delta[u](x, y, \varepsilon)$ converges as $\delta \to 0$, for ε in a small disk. This is done in Hölder spaces in section 3.1 and in $W^{k,p}$ spaces in section 3.2.

3.1. Hölder estimates. To begin this section we recall the following well-known algebra property of the space C^α.

LEMMA 3.1. *Let $0 \le \alpha \le 1$. For $f \in C^\alpha(\mathbf{R}^{d-1})$, $u \in C^\alpha(S_{h,0})$, the product $fu \in C^\alpha(S_{h,0})$, and*

$$|fu|_{C^\alpha} \le |f|_{C^\alpha} |u|_{C^\alpha}.$$

For convenience, we often use $C^{k+\alpha}$ to denote either $C^{k+\alpha}(\mathbf{R}^{d-1})$ or $C^{k+\alpha}(S_{h,0})$; the meaning should be clear from the context. Now, recalling that since $\varepsilon \in \mathbf{C}$, solutions u of (2.10) will generally be complex-valued (with the real and imaginary parts individually satisfying (2.10)), we establish the following lemma regarding existence and uniqueness of solutions.

LEMMA 3.2. *Given $f, \xi \in C^{1+\alpha}$ for any $\alpha \in (0, 1)$, there exists $c_0 > 0$ such that* (2.10) *(with the right-hand side of* (2.10) *given by* (2.12)*) has a unique solution $u \in C^{1+\alpha}$ for all ε in the disk $|\varepsilon| \le c_0$. Furthermore,*

$$|u|_{C^{1+\alpha}} \le C|\xi|_{C^{1+\alpha}}, \tag{3.2}$$

where the constant C is independent of ε.

Proof. The contraction mapping principle will be utilized. Consider the space

$$X = \{u \in C^{1+\alpha} \mid u(x, 0) = \xi, \partial_y u(x, -h) = 0\}$$

and the map Φ, defined by the following steps: For $u \in X$, compute $R(x, y) = F(x, y, u(x, y))$ from (2.11) and (2.12), and find the solution of

$$\begin{aligned} &\Delta w(x, y) = R(x, y) && \text{in } S_{h,0}, \\ &w(x, 0) = \xi(x), \\ &\partial_y w(x, -h) = 0, \end{aligned}$$

guaranteed by Theorem A.2. Setting $\eta = \varepsilon f$, we note that if $u \in C^{1+\alpha}$, then

$$
\begin{aligned}
\left|F^{(1)}\right|_{C^\alpha} &\le \frac{2}{h}\left|\varepsilon f \nabla_x u\right|_{C^\alpha} + \frac{1}{h^2}\left|\varepsilon^2 f^2 \nabla_x u\right|_{C^\alpha} + \left|\frac{h+y}{h}\varepsilon(\nabla_x f)\partial_y u\right|_{C^\alpha} \\
&\quad + \left|\frac{(h+y)}{h^2}\varepsilon^2 f(\nabla_x f)\partial_y u\right|_{C^\alpha} \\
&\le \frac{2|\varepsilon|}{h}\left|f\right|_{C^\alpha}\left|u\right|_{C^{1+\alpha}} + \frac{|\varepsilon|^2}{h^2}\left|f\right|_{C^\alpha}^2\left|u\right|_{C^{1+\alpha}} + \frac{Y|\varepsilon|}{h}\left|f\right|_{C^{1+\alpha}}\left|u\right|_{C^{1+\alpha}} \\
&\quad + \frac{Y|\varepsilon|^2}{h^2}\left|f\right|_{C^\alpha}\left|f\right|_{C^{1+\alpha}}\left|u\right|_{C^{1+\alpha}} \\
&\le |\varepsilon| K_{1,1}\left|f\right|_{C^{1+\alpha}}\left|u\right|_{C^{1+\alpha}} + |\varepsilon|^2 K_{1,2}\left|f\right|_{C^{1+\alpha}}^2\left|u\right|_{C^{1+\alpha}},
\end{aligned}
$$

where we have used Lemma 3.1, and Y is defined by

$$
\left|(h+y)u\right|_{C^\alpha} \le Y\left|u\right|_{C^\alpha}.
$$

Similarly, it can be shown that

$$
\begin{aligned}
\left|F^{(2)}\right|_{C^\alpha} &\le |\varepsilon| K_{2,1}\left|f\right|_{C^{1+\alpha}}\left|u\right|_{C^{1+\alpha}} + |\varepsilon|^2 K_{2,2}\left|f\right|_{C^{1+\alpha}}^2\left|u\right|_{C^{1+\alpha}}, \\
\left|F^{(3)}\right|_{L^\infty} &\le |\varepsilon| K_{3,1}\left|f\right|_{C^1}\left|u\right|_{C^1} + |\varepsilon|^2 K_{3,2}\left|f\right|_{C^1}^2\left|u\right|_{C^1},
\end{aligned}
$$

so that from (A.1) of Theorem A.2, $w \in C^{1+\alpha}$. Thus, $\Phi : X \to X$ defined by $w = \Phi u$ is well-defined.

Now, if we choose $u, \tilde{u} \in X$, this will generate $w, \tilde{w} \in X$, respectively. Furthermore,

$$
\begin{aligned}
\left|w - \tilde{w}\right|_{C^{1+\alpha}} &\le C_e\left[\left|R^{(1)} - \tilde{R}^{(1)}\right|_{C^\alpha} + \left|R^{(2)} - \tilde{R}^{(2)}\right|_{C^\alpha} + \left|R^{(3)} - \tilde{R}^{(3)}\right|_{L^\infty}\right] \\
&\le |\varepsilon| K_{4,1}\left|f\right|_{C^{1+\alpha}}\left|u - \widetilde{u}\right|_{C^{1+\alpha}} + |\varepsilon|^2 K_{4,2}\left|f\right|_{C^{1+\alpha}}^2\left|u - \widetilde{u}\right|_{C^{1+\alpha}} \\
&\le \gamma\left|u - \widetilde{u}\right|_{C^{1+\alpha}}
\end{aligned}
$$

for $\gamma < 1$ if

$$
|\varepsilon| \le c_0 \equiv \max\left\{\frac{\gamma}{2K_{4,1}\left|f\right|_{C^{1+\alpha}}}, \frac{\sqrt{\gamma}}{\sqrt{2K_{4,2}}\left|f\right|_{C^{1+\alpha}}}\right\}.
$$

Clearly the estimate is uniformly valid for all ε in the disk $|\varepsilon| \le c_0$, and thus the contraction mapping principle gives existence and uniqueness of solutions. Repeating the above estimation procedure we find that (3.2) is valid. ∎

We next establish differentiability of u in ε.

LEMMA 3.3. *By shrinking the constant c_0 in Lemma 3.2 if necessary, we have*

$$
\left|T_\delta[u]\right|_{C^{1+\alpha}} \le C \quad \textit{for } |\varepsilon| \le c_0, |\delta| \le c_0, \tag{3.3}
$$

where the constant C is independent of ε and δ.

Proof. We begin by applying the difference operator T_δ to (2.10) as follows:

$$
\Delta T_\delta[u] = \operatorname{div}_x\left[T_\delta[F^{(1)}]\right] + \partial_y T_\delta[F^{(2)}] + T_\delta[F^{(3)}]. \tag{3.4}
$$

The product rule (3.1) can be used to derive

$$
\begin{aligned}
&T_\delta[F^{(1)}] \\
&= -\frac{2}{h}\varepsilon f \nabla_x T_\delta[u](\varepsilon) - \frac{2}{h} f \nabla_x u(\varepsilon+\delta) - \frac{\varepsilon^2}{h^2} f^2 \nabla_x T_\delta[u](\varepsilon) - \frac{2\varepsilon}{h^2} f^2 \nabla_x u(\varepsilon+\delta) \\
&\quad -\frac{\delta}{h^2} f^2 \nabla_x u(\varepsilon+\delta) + \frac{\varepsilon(h+y)}{h} \nabla_x f \partial_y T_\delta[u](\varepsilon) + \frac{(h+y)}{h} \nabla_x f \partial_y u(\varepsilon+\delta) \\
&\quad +\frac{\varepsilon^2(h+y)}{h^2} f \nabla_x f \partial_y T_\delta[u](\varepsilon) + \frac{2\varepsilon(h+y)}{h^2} f \nabla_x f \partial_y u(\varepsilon+\delta) \\
&\quad +\frac{\delta(h+y)}{h^2} f \nabla_x f \partial_y u(\varepsilon+\delta).
\end{aligned} \tag{3.5}
$$

Estimating this in C^α we find

$$
\begin{aligned}
\left|T_\delta[F^{(1)}]\right|_{C^\alpha} \leq& \left\{K_{5,1}|\varepsilon|\,|f|_{C^{1+\alpha}} + K_{5,2}|\varepsilon|^2\,|f|^2_{C^{1+\alpha}}\right\} |T_\delta[u](\varepsilon)|_{C^{1+\alpha}} \\
&+K_6\left\{|f|_{C^{1+\alpha}} + |\varepsilon|\,|f|_{C^{1+\alpha}} + |\delta|\,|f|_{C^{1+\alpha}}\right\} |u(\cdot,\cdot,\varepsilon+\delta)|_{C^{1+\alpha}}\,;
\end{aligned}
$$

similar expressions for $\left|T_\delta[F^{(2)}]\right|_{C^\alpha}$ and $\left|T_\delta[F^{(3)}]\right|_{L^\infty}$ can be found. These results coupled with Theorem A.2 imply that

$$
\begin{aligned}
|T_\delta[u]|_{C^{1+\alpha}} &\leq C_e\left[\left|T_\delta[F^{(1)}]\right|_{C^\alpha} + \left|T_\delta[F^{(2)}]\right|_{C^\alpha} + \left|T_\delta[F^{(3)}]\right|_{L^\infty}\right] \\
&\leq C_e\left[\left\{K_{7,1}\,|\varepsilon|\,|f|_{C^{1+\alpha}} + K_{7,2}\,|\varepsilon|^2\,|f|^2_{C^{1+\alpha}}\right\}|T_\delta[u]|_{C^{1+\alpha}}\right. \\
&\qquad \left. +K_8\left\{|f|_{C^{1+\alpha}} + |\varepsilon|\,|f|^2_{C^{1+\alpha}} + |\delta|\,|f|^2_{C^{1+\alpha}}\right\}|u|_{C^{1+\alpha}}\right].
\end{aligned}
$$

Clearly, if ε and δ are chosen sufficiently small, then $|T_\delta[u]|_{C^{1+\alpha}}$ is bounded independently of ε and δ. □

In the next step we show that this difference quotient converges to the derivative of u with respect to ε.

LEMMA 3.4. *There exists a small positive constant c_0 such that, in the disk $\{|\varepsilon| \leq c_0\}$, the complexified solution u of* (2.10) *is differentiable in the complex variable ε in the space $C^{1+\beta}$, for any $\beta \in (0,\alpha)$, i.e.,*

$$T_\delta[u] \to \partial_\varepsilon u \quad \textit{as } |\delta| \to 0.$$

Proof. For any $\beta \in (0,\alpha)$, we can use the compactness of $C^{1+\alpha}$ to conclude that there exists a subsequence $\delta_n \to 0$ such that

$$T_{\delta_n}[u] \to w \quad \text{in } C^{1+\beta}(\overline{S_{0,h}} \cap \{|x| \leq K\})$$

for any $K > 1$. By passing δ_n to 0 in the equation, we find that w satisfies

$$\Delta w = \operatorname{div}_x\left[H^{(1)}\right] + \partial_y H^{(2)} + H^{(3)},$$

where

$$
\begin{aligned}
H^{(1)} = &-\frac{2}{h}\varepsilon f \nabla_x w - \frac{2}{h} f \nabla_x u - \frac{\varepsilon^2}{h^2} f^2 \nabla_x w - \frac{2\varepsilon}{h^2} f^2 \nabla_x u \\
&+\frac{\varepsilon(h+y)}{h} \nabla_x f \partial_y w + \frac{(h+y)}{h} \nabla_x f \partial_y u \\
&+\frac{\varepsilon^2(h+y)}{h^2} f \nabla_x f \partial_y w + \frac{2\varepsilon(h+y)}{h^2} f \nabla_x f \partial_y u,
\end{aligned}
$$

and similar expressions hold for $H^{(2)}$ and $H^{(3)}$. Similar to the proof of Lemma 3.2, the $C^{1+\beta}$ solution w to such a system is unique. This uniqueness implies that the convergence is independent of the subsequence of δ_n. $\square$

At this point we can prove Theorem 2.1.

Proof of Theorem 2.1. By Cauchy's formula, for $|\varepsilon| < c_0$,

$$u(x,y,\varepsilon) = \frac{1}{2\pi \mathrm{i}} \int_{|\zeta|=c_0} \frac{u(x,y,\zeta)}{\zeta - \varepsilon} \, \mathrm{d}\zeta = \sum_{n=0}^{\infty} u_n(x,y) \, \varepsilon^n,$$

where

$$u_n(x,y) = \frac{1}{2\pi i} \int_{|\zeta|=c_0} \frac{u(x,y,\zeta)}{\zeta^{n+1}} \, \mathrm{d}\zeta.$$

From this formula, we obtain the estimates on u_n from the estimates for u as follows:

$$|u_n|_{C^{1+\alpha}} \le \frac{1}{c_0^{n+1}} \max_{|\zeta|=c_0} |u(\cdot,\cdot,\zeta)|_{C^{1+\alpha}} \le CB^n \, |\xi|_{C^{1+\alpha}} \,,$$

where $B = 1/c_0$. Since $G(\varepsilon f) \; \xi(x)$ is expressed in terms of u and its first order derivatives (see (2.17)), we can extend $G(\varepsilon f) \; \xi(x)$ to complex ε. Using the (complex) analyticity of u in ε, we immediately have the differentiability of $G(\varepsilon f) \; \xi$ with respect to ε and

$$|G(\varepsilon f) \; \xi|_{C^\alpha} \le C \, |u|_{C^{1+\alpha}} \le C \, |\xi|_{C^{1+\alpha}} \,.$$

Thus, for $|\varepsilon| < c_0$,

$$G(\varepsilon f) \; \xi = \frac{1}{2\pi \mathrm{i}} \int_{|\zeta|=c_0} \frac{G(\zeta f) \; \xi}{\zeta - \varepsilon} \, \mathrm{d}\zeta = \sum_{n=0}^{\infty} (G_n(f) \; \xi) \; \varepsilon^n,$$

where

$$G_n(f) \; \xi = \frac{1}{2\pi \mathrm{i}} \int_{|\zeta|=c_0} \frac{G(\zeta f) \; \xi}{\zeta^{n+1}} \, \mathrm{d}\zeta.$$

From this, we obtain

$$|G_n(f) \; \xi|_{C^\alpha} \le \frac{1}{c_0^{n+1}} \max_{|\zeta|=c_0} |G(\zeta f) \; \xi|_{C^\alpha} \le \frac{C}{c_0^{n+1}} \max_{|\zeta|=c_0} |u(\cdot,\cdot,\zeta)|_{C^{1+\alpha}} \le CB^n \, |\xi|_{C^{1+\alpha}} \,.$$

This implies

$$|G_n(f)|_{\mathcal{L}(C^{1+\alpha}(\mathbf{R}^{d-1}), C^\alpha(\mathbf{R}^{d-1}))} \le CB^n.$$

The theorem is proved. $\square$

3.2. ^{1,} **estimates.** Using $W^{1,p}(S_{h,\eta})$ ($W^{1-1/p,p}$ on the boundary) estimates, we will extend the result of the previous section to Lipschitz boundaries; i.e., we will assume

$$f \in C^{0,1}, \quad \xi \in X^p \quad (p > d),$$

and approximate f and ξ by smooth functions where necessary. The key result which allows the estimation of Lipschitz boundaries is the following.

LEMMA 3.5. *For $f \in C^{0,1}$, $u \in Y^{0,p}$, the product $(\nabla_x f)u \in Y^{0,p}$, and*

$$\|(\nabla_x f)u\|_{Y^{0,p}} \leq |f|_{C^{0,1}} \|u\|_{Y^{0,p}} .$$

Given this result we can prove the following lemma.

LEMMA 3.6. *Given $f \in C^{0,1}$, $\xi \in X^p$ $(p > d)$, there exists $c_0 > 0$ such that* (2.10) *has a unique solution $u \in Y^{1,p}$ for all ε in the disk $|\varepsilon| \leq c_0$. Furthermore,*

$$\|u\|_{Y^{1,p}} \leq C \|\xi\|_{X^p} , \tag{3.6}$$

where the constant C is independent of ε.

Proof. The proof is the same as in Lemma 3.2, with the $C^{1+\alpha}$ Hölder estimate (Theorem A.2) replaced by the $W^{1,p}$ estimate (Theorem A.3) given in Appendix A. For instance, the key estimate which guaranteed the contraction property in Lemma 3.2 now reads

$$\begin{aligned}
\left\|F^{(1)}\right\|_{Y^{0,p}} &\leq \frac{2}{h} \|\varepsilon f \nabla_x u\|_{Y^{0,p}} + \frac{1}{h^2} \left\|\varepsilon^2 f^2 \nabla_x u\right\|_{Y^{0,p}} + \left\|\frac{h+y}{h} \varepsilon (\nabla_x f) \partial_y u\right\|_{Y^{0,p}} \\
&\quad + \left\|\frac{(h+y)}{h^2} \varepsilon^2 f (\nabla_x f) \partial_y u\right\|_{Y^{0,p}} \\
&\leq \frac{2|\varepsilon|}{h} |f|_{C^{0,1}} \|u\|_{Y^{1,p}} + \frac{|\varepsilon|^2}{h^2} |f|^2_{C^{0,1}} \|u\|_{Y^{1,p}} \\
&\quad + \frac{\tilde{Y}|\varepsilon|}{h} |f|_{C^{0,1}} \|u\|_{Y^{1,p}} + \frac{\tilde{Y}|\varepsilon|^2}{h^2} |f|^2_{C^{0,1}} \|u\|_{Y^{1,p}} \\
&\leq |\varepsilon| \tilde{K}_{1,1} |f|_{C^{0,1}} \|u\|_{Y^{1,p}} + |\varepsilon|^2 \tilde{K}_{1,2} |f|^2_{C^{0,1}} \|u\|_{Y^{1,p}} ,
\end{aligned}$$

where $\tilde{Y}$ is defined by

$$\|(h+y)u\|_{Y^{0,p}} \leq \tilde{Y} \|u\|_{Y^{0,p}} .$$

From this calculation, using Lemma 3.5, we see the *explicit* appearance of the Lipschitz norm on the boundary deformation $f(x)$. ☐

To establish the differentiability in complex ε, we apply the finite difference operator, $T_\delta[\cdot]$.

LEMMA 3.7. *By shrinking the positive constant c_0 in Lemma* 3.6 *if necessary, we have*

$$\|T_\delta[u]\|_{Y^{1,p}} \leq C \quad \textit{for } |\varepsilon| \leq c_0, |\delta| \leq c_0, \tag{3.7}$$

where the constant C is independent of ε.

Proof. Again, the proof is essentially the same as for Lemma 3.3 with the $C^{1+\alpha}$ Hölder estimate (Theorem A.2) replaced by the $W^{1,p}$ estimate (Theorem A.3) given in Appendix A. ☐

Now we are ready to establish the differentiability in complex ε.

LEMMA 3.8. *If $|\varepsilon| \leq c_0$ and u is the solution of* (2.10)*, then u is differentiable in ε as a complex function almost everywhere; i.e.,*

$$T_\delta[u] \to \partial_\varepsilon u \quad \textit{as } |\delta| \to 0.$$

Proof. The proof is similar to that of Lemma 3.4. However, since we no longer have compactness for the first order derivatives, the subsequential convergence as

$\delta_n \to 0$ must be replaced by the following:

$$T_{\delta_n}[u] \to w \quad \text{strongly in } C^0(\{|x|<K\}\times[-h,0]) \text{ for any } K>1,$$
$$(\nabla_x,\partial_y)T_{\delta_n}[u] \to (\nabla_x,\partial_y)w \quad \text{weakly in } [L^p(\{|x|<K\}\times[-h,0])]^d \text{ for any } K>1.$$

We note that $T_{\delta_n}[u]$ satisfies equation (3.4) from Lemma 3.3. The terms in (3.5) are all *linear* in $T_{\delta_n}[u]$ and its first order of derivatives; furthermore, all the coefficients are in L^∞ since we assume that f is Lipschitz continuous. These key facts allow us to use weak convergence to take the limit $\delta_n \to 0$. Thus we obtain the equation for w. The rest of the proof remains the same as that of Lemma 3.4. □

Proof of Theorem 2.2. The analyticity of $u(x,y,\varepsilon)$ in ε, and the corresponding estimate for u_n in $Y^{1,p}$, can be obtained in the same manner as in the proof of Theorem 2.1. However, the estimates on $G(\varepsilon f)$ must be modified since we are only permitted the weak formulation of the DNO in this case. It is clear that this weak formulation, (2.15), allows the complexification in ε. To use this definition, however, we have to show that (2.15) defines a DNO in the appropriate space also for complex ε. Namely, we have to show that the value on the right-hand side of (2.15) is *independent* of the way the function $\psi(x,0)$ is extended to $\mathbf{R}^{d-1}\times[-h,0]$.

Since

$$T_R^\infty(\overline{S_{h,0}}) = \big\{ f\in C^\infty(\overline{S_{h,0}}) \mid f=0 \text{ on } \{|x|>R\} \text{ for some large } R \big\}$$

is dense in $T_R^{0,1}(\overline{S_{h,0}})$, we only need to show that the right-hand side of (2.15) is independent of the extension for such ψ; namely, we need to show

$$\begin{aligned}\int_{S_{h,0}} \bigg\{ \Big(\nabla_x u - \frac{h+y}{h+\eta}(\nabla_x\eta)\partial_y u\Big)\cdot\Big(\nabla_x\psi - \frac{h+y}{h+\eta}(\nabla_x\eta)\partial_y\psi\Big) \\ + \frac{h^2}{(h+\eta)^2}(\partial_y u)\partial_y\psi\bigg\}\frac{h+\eta}{h}\,\mathrm{d}V = 0,\end{aligned} \tag{3.8}$$

for any $\psi\in C^\infty(\overline{S_{h,0}})$ such that $\psi(x,0)\equiv 0$ for all $x\in\mathbf{R}^{d-1}$ and $\psi(x,y)\equiv 0$ for $|x|>R$ for some $R>1$. Under our assumptions, all boundary terms vanish upon utilization of integration by parts in (3.8), so we can establish (3.8) by using the weak formulation of the complexified equation for u.

We next proceed to establish the estimates for $G(\varepsilon f)$. As in the proof of Theorem 2.1,

$$\langle G(\varepsilon f)\ \xi,\psi(x,0)\rangle = \frac{1}{2\pi\mathrm{i}}\int_{|\zeta|=c_0}\frac{\langle G(\zeta f)\ \xi,\psi(x,0)\rangle}{\zeta-\varepsilon}\,\mathrm{d}\zeta = \sum_{n=0}^\infty \langle G_n(f)\ \xi,\psi(x,0)\rangle\ \varepsilon^n,$$

where $\psi(x,0)\in C_c^{0,1}(\mathbf{R}^{d-1})$, and

$$\langle G_n(f)\ \xi,\varphi(x,0)\rangle = \frac{1}{2\pi\mathrm{i}}\int_{|\zeta|=c_0}\frac{\langle G(\zeta f)\ \xi,\varphi(x,0)\rangle}{\zeta^{n+1}}\,\mathrm{d}\zeta.$$

Thus the conclusion of our theorem will follow if we can establish the estimate

$$\|G(\varepsilon f)\|_{\mathcal{L}(X^p,(X_c^q(\hat{x}))^*)} \le C \tag{3.9}$$

for some C, independent of ε, and for all $|\varepsilon|\le c_0$.

For any $\Psi \in X_c^q(\hat{x})$, we use the definition of $X_c^q(\hat{x})$ to extend Ψ to a function $\psi \in W_{loc}^{1,q}(\mathbf{R}^{d-1} \times [-h, 0])$ such that

$$\psi(x,0) = \Psi(x) \quad \text{in the trace sense,} \tag{3.10a}$$

$$\psi(x,y) = 0 \quad \text{for } |x-\hat{x}| > 1, \quad -h < y < 0, \tag{3.10b}$$

$$\|\psi\|_{W^{1,q}(B_1(\hat{x})\times(-h,0))} \le C \|\Psi\|_{X^q}. \tag{3.10c}$$

Since we have already established a $W^{1,p}(B_1(\hat{x}) \times (-h,0))$ estimate for u, we can approximate ψ with $C^{0,1}$ functions so that its first order derivatives converge weakly in $L^q(B_1(\hat{x}) \times (-h,0))$. Thus the test function defined in (3.10) can be used in (2.15). Using (2.15) we find that, for all $\Psi \in X_c^q(\hat{x})$,

$$\begin{aligned} |\langle G(\varepsilon f)\ \xi, \Psi\rangle| &\le C \|u\|_{W^{1,p}(B_1(\hat{x})\times(-h,0))} \|\nabla\psi\|_{L^q(B_1(\hat{x})\times(-h,0))} \\ &\le C \|\xi\|_{X^q} \|\Psi\|_{X^q}. \end{aligned}$$

This implies that

$$\|G(\varepsilon f)\ \xi\|_{(X_c^q(\hat{x}))^*} \le C \|\xi\|_{X^p};$$

i.e., the estimate (3.9) is valid. □

Appendix A. Elliptic estimates. In this appendix we present the statements (together with brief proofs) of the elliptic estimates which are at the heart of the analyticity results, Theorems 2.1 and 2.2. Of course, the great simplification of our approach was the use of the "domain flattening" change of variables, (2.7), which maps the domain $S_{h,\eta}$ to the strip $S_{h,0}$. Consequently, it is sufficient to analyze (inhomogeneous) elliptic equations on a much simpler geometry. This, in turn, allows the simple establishment of the following results which, we point out, are true on much more general domains (e.g., see [5]).

We begin with the "comparison principle" on a domain, which implies the uniqueness of bounded solutions.

THEOREM A.1. *If w is bounded and satisfies (in the weak sense)*

$$\begin{aligned} &-\Delta w(x,y) \ge 0 && \textit{in } S_{h,0}, \\ &-\partial_y w(x,-h) \ge 0, \\ &w(x,0) \ge 0, \end{aligned}$$

then

$$w(x,y) \ge 0 \qquad \textit{in } S_{h,0}.$$

Proof. Since we can only use weak comparison in the bounded domain, we choose $M = |w|_{L^\infty}$ and let

$$\Phi = \frac{2(d-1)}{R} M \Big[\frac{x_1^2 + \cdots + x_{d-1}^2}{2(d-1)} - \frac{(y+h)^2}{2} + \frac{h^2}{2} \Big] + w.$$

It is clear that

$$\begin{aligned} &-\Delta\Phi \ge 0 && \text{in } S_{h,0}, \\ &-\partial_y \Phi(x,-h) \ge 0, \\ &\Phi \ge 0 && \text{on } \{y=0\} \cup \{x_1^2 + \cdots + x_{d-1}^2 = R^2\}. \end{aligned}$$

We can now apply the comparison principle on the bounded domain $\{x \mid x_1^2 + \cdots + x_{d-1}^2 < R^2\} \times (-h, 0)$ to conclude that $\Phi \geq 0$ there. If we fix (x, y) and let $M \to \infty$, we obtain $w > 0$ on $S_{h,0}$. ◻

We next state the Hölder estimate used in section 3.1.

THEOREM A.2. *For any $\alpha \in (0,1)$ there exists a constant C_e such that for any $R^{(1)}, R^{(2)} \in C^\alpha$, $R^{(3)} \in L^\infty$, and $\xi \in C^{1+\alpha}$ there exists a unique solution $w(x,y)$ of*

$$\begin{aligned} &\Delta w = div_x \left[R^{(1)}\right] + \partial_y R^{(2)} + R^{(3)} && \text{in } S_{h,0},\\ &\partial_y w(x,-h) = 0, &&\\ &w(x,0) = \xi(x), && \end{aligned}$$

which satisfies

$$|w|_{C^{1+\alpha}} \leq C_e \left\{ \left|R^{(1)}\right|_{C^\alpha} + \left|R^{(2)}\right|_{C^\alpha} + \left|R^{(3)}\right|_{L^\infty} + |\xi|_{C^{1+\alpha}} \right\}. \tag{A.1}$$

Proof. The uniqueness is a corollary of the comparison principle. The existence can be proved using a continuation argument once we obtain the estimate, (A.1), in this theorem. This estimate is a special case of the general $C^{1+\alpha}$ theory for elliptic systems in divergence form which is established using Campanato spaces $\mathcal{L}^{p,\mu}$ (see [5, Theorems 2.6 and 2.7, pp. 152–154]).

Since our system is of constant coefficients and in a special domain, we provide a short proof here. We write

$$w = \sum_{j=1}^{d-1} \partial_{x_j} w_j^{(1)} + \partial_y w^{(2)} + w^{(3)} + w^{(4)} + w^{(5)},$$

where

$$\Delta w_j^{(1)} = R_j^{(1)} \quad \text{in } S_{h,0}, \tag{A.2a}$$

$$\partial_y w_j^{(1)}(x,-h) = 0, \tag{A.2b}$$

$$w_j^{(1)}(x,0) = 0; \tag{A.2c}$$

$$\Delta w^{(2)} = R^{(2)} \quad \text{in } S_{h,0}, \tag{A.3a}$$

$$\partial_y w^{(2)}(x,-h) = 0, \tag{A.3b}$$

$$w^{(2)}(x,0) = 0; \tag{A.3c}$$

$$\Delta w^{(3)} = R_j^{(3)} \quad \text{in } S_{h,0}, \tag{A.4a}$$

$$\partial_y w^{(3)}(x,-h) = 0, \tag{A.4b}$$

$$w^{(3)}(x,0) = 0; \tag{A.4c}$$

$$\Delta w^{(4)} = 0 \quad \text{in } S_{h,0}, \tag{A.5a}$$

$$\partial_y w^{(4)}(x,-h) = 0, \tag{A.5b}$$

$$w^{(4)}(x,0) = \xi(x); \tag{A.5c}$$

and, finally,

$$\Delta w^{(5)} = 0 \qquad \text{in } S_{h,0}, \tag{A.6a}$$

$$\partial_y w^{(5)}(x,-h) = -\partial_{yy} w^{(2)}(x,-h) = -R^{(2)}(x,-h), \tag{A.6b}$$

$$w^{(5)}(x,0) = 0. \tag{A.6c}$$

We can apply standard Schauder theory [12] to $w^{(1)}$ and $w^{(2)}$ to obtain $C^{2+\alpha}$ estimates for $w^{(1)}$ and $w^{(2)}$. We can apply $W^{2,p}$ estimates to $w^{(3)}$ for $p > d/(1-\alpha)$ and then use an embedding theorem to obtain the $C^{1+\alpha}$ estimate for $w^{(3)}$. Since the Dirichlet boundary data for $w^{(4)}$ is $C^{1+\alpha}$, we obtain $C^{1+\alpha}$ estimates for $w^{(4)}$. Finally, if we let

$$z(x,y) = \int_{-h}^{y} w^{(5)}(x,s)\, \mathrm{d}s,$$

then

$$\begin{aligned} &\Delta z = w_y^{(5)}(x,-h) = -R^{(2)}(x,-h) \qquad \text{in } S_{h,0},\\ &\partial_y z(x,-h) = 0,\\ &z(x,0) = 0. \end{aligned}$$

Since $R^{(2)}$ is in C^α, we can apply the Schauder $C^{2+\alpha}$ estimate for z and obtain an $C^{1+\alpha}$ estimate for $w^{(5)} = \partial_y z$. ◻

Finally, we state the $W^{k,p}$ estimate used in section 3.2.

THEOREM A.3. *For any $p > d$ there exists a constant $\tilde{C}_e$ such that for any $R^{(1)}, R^{(2)}, R^{(3)} \in Y^{0,p}$, and $\xi \in X^p$ there exists a unique solution $w(x,y)$ of*

$$\Delta w = \mathrm{div}_x R^{(1)} + \partial_y\{(h+y)R^{(2)}\} + R^{(3)} \qquad \text{in } S_{h,0}, \tag{A.7a}$$

$$\partial_y w(x,-h) = 0, \tag{A.7b}$$

$$w(x,0) = \xi(x), \tag{A.7c}$$

which satisfies

$$\|w\|_{Y^{1,p}} \le \tilde{C}_e \left\{ \left\|R^{(1)}\right\|_{Y^{0,p}} + \left\|R^{(2)}\right\|_{Y^{0,p}} + \left\|R^{(3)}\right\|_{Y^{0,p}} + \|\xi\|_{X^p} \right\}.$$

Proof. This estimate is a special case of the general L^p theory for elliptic systems in divergence form which is established in [5] (see page 157, Theorem 2.2 for interior estimates; the boundary estimates can be done in a similar way). In this short proof for our special system, we will assume that the involved functions are smooth since we can always approximate them with smooth functions. The estimate is valid as long as the constants involved are independent of the smoothness. We use the ideas of the earlier proof (Theorem A.2) and divide the proof into two cases.

Case 1: $\xi(x) \equiv 0$. The proof is similar to the proof of Theorem A.2. For any $x^* \in \mathbf{R}^{d-1}$, it suffices to establish estimates on $B_1(x^*) \times (-h,0)$ in terms of norms of $R^{(1)}$, $R^{(2)}$, and $R^{(3)}$ on $B_2(x^*) \times (-h,0)$. We decompose w into $w^{(j)}$ $(j = 1,2,3,4,5)$ as before, and we can then apply the standard $W^{2,p}$ interior-boundary estimates to $w^{(1)}$, $w^{(2)}$, and $w^{(3)}$. Since we have a factor $(h+y)$ on the right-hand side of (A.7) in the $R^{(2)}$ term, $w^{(5)}$ vanishes. Since we have assumed, in this case, that $\xi \equiv 0$, $w^{(4)}$ also vanishes and the estimate is established.

Case 2: General case. We need only estimate $w^{(4)}$; by the maximum principle,

$$\left|w^{(4)}\right|_{L^\infty} \le |\xi|_{L^\infty}.$$

Since $p > d$, we have, by embedding, $|\xi|_{L^\infty} \le C \|\xi\|_{X^p}$. Thus we can use the standard elliptic regularity estimates to derive

$$\left\| w^{(4)} \right\|_{C^2(B_2(x^*)\times[-h,-h/2])} \le C \|\xi\|_{X^p}.$$

For any $x^* \in \mathbf{R}^{d-1}$, we use the definition of X^p to extend the function ξ to a function $\Phi(x,y) \in W^{1,p}_{loc}(B_2(x^*) \times [-h,0]) \cap C^2(\overline{B}_2(x^*) \times [-h,-h/2])$ so that

$$\|\Phi\|_{W^{1,p}(B_2(x^*)\times(-h,0))} \le C \|\xi\|_{X^p}, \tag{A.8}$$

where we understand that $\Phi(\cdot,0) = \xi(\cdot)$ in the trace sense. By using a cut-off function if necessary, we may assume, without loss of generality, that

$$\Phi(x,y) \equiv w^{(4)}(x,y) \quad \text{ for } x \in B_2(x^*), -h \le y \le \frac{-h}{2}.$$

It is clear that $w^{(4)}$ satisfies

$$\begin{aligned}
&\Delta(w^{(4)} - \Phi) = -\mathrm{div}_x \left[\mu_1(y)\nabla_x \Phi\right] - \partial_y\Big((y+h)\frac{\mu_1(y)}{y+h}\partial_y\Phi\Big) \quad \text{ in } S_{h,0},\\
&\partial_y(w^{(4)} - \Phi)(x,-h) = 0,\\
&w^{(4)}(x,0) - \Phi(x,0) = 0,
\end{aligned}$$

where

$$\mu_1(y) = 1 \quad \text{ for } \frac{-h}{2} \le y < 0, \qquad \mu_1(y) = 0 \quad \text{ for } -h \le y < \frac{-h}{2};$$

we point out that, in fact, $w^{(4)} - \Phi \equiv 0$ for $-h \le y \le -h/2$. Using (A.8), we have

$$\left\| \frac{\mu_1(y)}{(h+y)}\partial_y\Phi \right\|_{L^p(B_2(x^*)\times(-h,0))} \le \frac{2}{h} \|\partial_y \Phi\|_{L^p(B_2(x^*)\times(-h,0))} \le C \|\xi\|_{X^p}$$

and

$$\|\mu_1(y)\nabla_x\Phi\|_{L^p(B_2(x^*)\times(-h,0))} \le C \|\xi\|_{X^p}.$$

We can now apply Case 1 to obtain

$$\left\| w^{(4)} \right\|_{W^{1,p}(B_1(x^*)\times(-h,0))} \le C \|\xi\|_{X^p}.$$

Combining all the estimates for $w^{(j)}$ $(j = 1,2,3,4,5)$ and taking the supremum over all $x^* \in \mathbf{R}^{d-1}$, we conclude the theorem. □

ON BOUND STATES CONCENTRATING ON SPHERES FOR THE MAXWELL–SCHRÖDINGER EQUATION*

TERESA D'APRILE† AND JUNCHENG WEI‡

Abstract. We study the semiclassical limit for the following system of Maxwell–Schrödinger equations:

$$-\frac{\hbar^2}{2m}\Delta v + v + \omega\phi v - \gamma v^p = 0, \quad -\Delta\phi = 4\pi\omega v^2,$$

where $\hbar$, m, ω, $\gamma > 0$, v, $\phi : \mathbb{R}^3 \to \mathbb{R}$, $1 < p < \frac{11}{7}$. This system describes standing waves for the nonlinear Schrödinger equation interacting with the electrostatic field: the unknowns v and ϕ represent the *wave function* associated to the particle and the electric potential, respectively. By using localized energy method, we construct a family of positive radially symmetric bound states $(v_\hbar, \phi_\hbar)$ such that $v_\hbar$ concentrates around a sphere $\{|x| = s_0\}$ when $\hbar \to 0$.

Key words. bound states, Maxwell–Schrödinger equation, finite dimensional reduction

1. Introduction.

In this paper we consider the following system of Maxwell–Schrödinger equations in the following electrostatic case:

$$\begin{cases} -\hbar^2\Delta v + v + \omega\phi v - \gamma v^p = 0 \text{ in } \mathbb{R}^3, \\ -\Delta\phi = 4\pi\omega v^2 \text{ in } \mathbb{R}^3, \\ v,\ \phi > 0, \quad v,\ \phi \to 0 \text{ as } |x| \to +\infty, \end{cases} \tag{1.1}$$

where $\hbar$, ω, $\gamma > 0$ and $p > 1$. This system was first introduced in [6]; it provides a physical model which describes the interaction of a charged particle with the electrostatic field. In (1.1) we have assumed, for the sake of simplicity, $2m = 1$, where m is the mass of the particle. ω denotes the electric charge of the particle, while $\hbar$ is a constant which is known under the name of *Planck's constant*. The unknowns of the system are the wave function v associated to the particle and the electric potential ϕ. The presence of the nonlinear term in (1.1) simulates the interaction effect among many particles.

The eigenvalue problem for the system (1.1) with $\gamma = 0$ has been studied in [6] (in the case in which the charged particle lies in a bounded space region Ω) and in [8] (under the action of an external nonzero potential). Existence results for (1.1) have been established in [11].

In all the above-mentioned results the size of $\hbar$ is not relevant, hence one may assume, without loss of generality, $\hbar = 1$. This paper deals with the *semiclassical limit* of the system (1.1); i.e., it is concerned with the problem of finding nontrivial solutions and studying their asymptotic behavior when $\hbar \to 0^+$. Hence such solutions

are usually referred to as *semiclassical* ones. Letting $\hbar$ go to zero has great physical interest since it formally describes the transition from quantum mechanics to classical mechanics; as one expects, the solutions exhibit some kind of notable behavior in the semiclassical limit, a concentration behavior: their form consists of very sharp peaks which become highly concentrated when $\hbar$ is small.

The study of semiclassical phenomena for nonlinear Schrödinger equations has attracted considerable attention in recent years; in particular, a large number of papers have been devoted to studying single and multiple spike solutions for the following stationary Schrödinger equation in the presence of an external potential V:

$$-\hbar^2\Delta v + V(x)v - \gamma|v|^{p-1}v = 0, \quad x \in \Omega, \quad V : \Omega \to \mathbb{R}, \tag{1.2}$$

where Ω is an open subset of $\mathbb{R}^N$ $(N \geq 1)$. In the case $p \in (1, \frac{N+2}{N-2})$ for $N \geq 3$ and $p > 1$ for $N = 1, 2$, (1.2) admits solutions, called *spike layers*, concentrating at one or multiple points of $\overline{\Omega}$, in the sense that their shape consists of sharp peaks near those points while it vanishes everywhere else as $\hbar \to 0^+$.

Concerning (1.2) in bounded domains Ω with $V \equiv 1$ and Neumann boundary conditions, in [16], [20], [22], [23], [26], [32], [31], [41] the authors look for solutions exhibiting a concentration at one or more points of the boundary which are proved to be critical for the mean curvature of $\partial\Omega$. As regards interior spike solutions, the distance function from the boundary $\partial\Omega$ plays a role similar to that of the mean curvature: in [19], [21], [33], [35], [42] single or multiple spikes are constructed for the Neumann or the Dirichlet problem associated to (1.2) with Ω bounded and $V \equiv 1$, and concentration occurs, roughly speaking, at critical points of the distance function d from the boundary $\partial\Omega$.

When $\Omega \equiv \mathbb{R}^N$ and $V \not\equiv$ const, spike layer solutions are constructed around the critical points of the potential V. The first result in this line seems due to Floer and Weinstein [17]. These authors considered the one-dimensional case and constructed for small $\hbar > 0$ such a concentrating family via a Lyapunov–Schmidt reduction around any nondegenerate critical point of the potential V, under the condition that V is bounded and $p = 3$. This line of research has been extensively pursued in a set of recent papers (we recall, among many others, [1], [12], [14], [13], [15], [18], [24], [25], [36], [37], [38], [40]) and semiclassical states are produced using minimax methods or, under suitable nondegeneracy conditions, by finite dimensional reductions.

In contrast to pointwise concentration, only very recently has concentration at higher dimensional sets been proved. The first progress was the recent paper [29], in which, assuming $V \equiv$ const, the authors prove the existence of positive solutions for (1.2) in a smooth bounded subset $\Omega \subset \mathbb{R}^2$ with the Neumann boundary conditions; such solutions concentrate at the whole boundary $\partial\Omega$ or at some of its components. This result has been extended to higher dimensions in [28]. Under symmetry assumptions, higher dimensional spike layers are proved to exist. In [2] and [4], assuming that V is radial, the existence of radially symmetric solutions for (1.2) in $\mathbb{R}^N$ concentrating on a sphere centered in zero is established, and it is shown that the location of the concentration arises as a balance between the effect of the potential energy due to V and the volume energy of the solutions. In [5] and [9] concentration on circles in $\mathbb{R}^2$ and $\mathbb{R}^3$, respectively, is produced for a special class of solutions of (1.2). Concerning (1.2) in a ball with Dirichlet or Neumann boundary conditions and V radial, in [3] the effect of the boundary of the domain is analyzed; more precisely, it is proved that there exists a family of radial solutions concentrating on the boundary. Finally, we recall the recent papers [27] and [30], in which other phenomena of concentration on manifolds are studied.

Motivated by this rich literature, in this paper we want to study which kind of phenomena occur for the system of Maxwell–Schrödinger equations (1.1) in the semiclassical limit.

More precisely, for small values of the parameter $\hbar$, we prove the existence of a positive radially symmetric wave $v_\hbar$ and a potential $\phi_\hbar$ satisfying (1.1). Furthermore, in the limit when $\hbar \to 0^+$, $v_\hbar$ exhibits a concentration behavior around a sphere $\{|x| = s_0\}$: the analysis reveals that most of the support of $v_\hbar$ is concentrated in a neighborhood of such a sphere whose size depends on $\hbar$ and shrinks to zero as $\hbar \to 0^+$. The radius s_0 is determined by the exponent p and the charge ω. In order to state the exact result, denote by $w(y)$ the unique solution for the following ODE:

$$\begin{cases} w'' - w + w^p = 0 \text{ in } \mathbb{R}, \\ w > 0, \quad w(0) = \max_{y\in\mathbb{R}} w(y), \\ w(y) \to 0 \text{ as } |y| \to +\infty. \end{cases}$$

It is well known that $w(y)$ can be written explicitly as

$$w(y) = \left(\frac{p+1}{2}\right)^{\frac{1}{p-1}} \left(\cosh\left(\frac{p-1}{2}y\right)\right)^{-\frac{2}{p-1}}. \tag{1.3}$$

Then, roughly speaking, the limit profile of our solutions $v_\hbar$ resembles, after a suitable rescaling in the coordinates, the function w.

More precisely, the main result of this paper is the following.

THEOREM 1.1. *Assume that $1 < p < \frac{11}{7}$. Then there exists $\hbar_0 > 0$ such that for every $\hbar \in (0, \hbar_0)$ the system* (1.1) *has a solution $(v_\hbar, \phi_\hbar)$ with $\gamma = \gamma_\hbar = \hbar^{(p-1)/2}$ and*

(1) *$v_\hbar$, $\phi_\hbar$ are radially symmetric, $v_\hbar$, $|\nabla v_\hbar|$, $|\nabla \phi_\hbar| \in L^2(\mathbb{R}^3)$,*

(2) *$v_\hbar(r) = \hbar^{-(1/2)}\alpha_\hbar^{1/(p-1)} w\big(\sqrt{\alpha_\hbar}\frac{r-s_\hbar}{\hbar}\big) + o(1)\exp\big(-\mu\frac{|r-s_\hbar|}{\hbar}\big)$ uniformly in $\mathbb{R}^3$ for a suitable $\mu \in (0,1)$,*

(3) *$\phi_\hbar(r) = 4\pi\omega(1+o(1))\alpha_\hbar^{(5-p)/2(p-1)}(\int_{\mathbb{R}} w^2 dy)G(r; s_\hbar)$, where $G(r;\rho)$ is defined as follows:*

$$G(r;\rho) = \frac{\rho}{r}\min(r,\rho). \tag{1.4}$$

Furthermore, as $\hbar \to 0^+$,

$$\alpha_\hbar \to \alpha_0 := \frac{p+3}{11-7p} \tag{1.5}$$

and

$$s_\hbar \to s_0 := (\alpha_0 - 1)\alpha_0^{\frac{p-5}{2(p-1)}} \left(4\pi\omega^2 \int_{\mathbb{R}} w^2 dy\right)^{-1}. \tag{1.6}$$

REMARK 1.2. *The case $1 < p < \frac{3}{2}$ has been proved in* [10] *by variational method. Here we use localized energy method to cover the whole range for $p \in (1, \frac{11}{7})$. Notice that for $p \geq \frac{11}{7}$ it results in $\alpha_0 - 1 \leq 0$, hence formula* (1.6) *does not make sense; this suggests that the range $(1, \frac{11}{7})$ is also necessary to get concentration around a sphere. Furthermore, unlike* [10]*, the different method used in this paper allows us to provide the more precise description of the profile of the solutions $(v_\hbar, \phi_\hbar)$ given by* (2)–(3) *of Theorem* 1.1.

Remark 1.3. *Notice that by* (2) *of Theorem* 1.1 *it immediately follows that*

$$\int_{\mathbb{R}^3} |v_\hbar|^2 dx = 4\pi\alpha_\hbar^{\frac{5-p}{2(p-1)}} \int_{-\sqrt{\alpha_\hbar}\frac{s_\hbar}{\hbar}}^{+\infty} \left(\frac{\hbar y}{\sqrt{\alpha_\hbar}} + s_\hbar\right)^2 |w|^2 dy + o(1)$$
$$= 4\pi\alpha_0^{\frac{5-p}{2(p-1)}} s_0^2 \int_{\mathbb{R}} |w|^2 dy + o(1);$$

i.e., the L^2-norm of the waves $v_\hbar$ becomes bounded from below and from above. Furthermore, for every $\delta > 0$ and for small $\hbar$,

$$v_\hbar(r) \le C \exp\left(-\mu\frac{|r - s_\hbar|}{\hbar}\right) \ \text{for}\ |r - s_\hbar| \ge \delta,$$

where C is independent on $\hbar$ and δ. Hence the solutions $v_\hbar$ can be viewed as small perturbations of the function w rescaled in such a way to be very concentrated *near a suitable neighborhood of s_0; then their profile has the form of a solitary elevation which becomes a very sharp peak when $\hbar$ is small.*

The proof of Theorem 1.1 relies on a local approach and is related to the arguments employed in [34], in which a phenomenon of concentration around a sphere has been obtained for the stationary Gierer–Meinhardt system in $\mathbb{R}^N$. This approach is based on a finite dimensional reduction by using the classical Lyapunov–Schmidt reduction method. We first construct some approximate solution (obtained as a small perturbation of rescalation of w) and we solve (1.1) in its normal direction, and then we study the remaining finite dimensional equation. After this reduction process, by using the implicit function theorem we solve (1.1) in a suitable neighborhood of the approximate solution.

The paper consists of four more sections. In section 2 we introduce some notations and prove some preliminary estimates that play a key role in the rest of the arguments. In sections 3 and 4 we construct the approximate solutions and we carry out the Lyapunov–Schmidt procedure that allows us to reduce the problem to the study of a finite dimensional functional. Finally, the proof of Theorem 1.1 is given in section 5.

Notations.

- If $u : \mathbb{R}^N \to \mathbb{R}$ is a radially symmetric function, we will continue to denote by u the real function $r > 0 \mapsto u(r)$ with $|x| = r$.
- If u is a real valued function, then u_+ is its positive part and u_- its negative part.
- We will often use the symbol C for denoting a positive constant independent on ε. The value of C is allowed to vary from line to line (and also in the same formula).
- Given $A_\varepsilon \subset \mathbb{R}^N$, $f_\varepsilon, g_\varepsilon : A_\varepsilon \to \mathbb{R}$ two families of functions on A_ε and $k \in \mathbb{R}$, we write $f_\varepsilon = o(\varepsilon^k)g_\varepsilon$ *on* A_ε (resp. $f_\varepsilon = O(\epsilon^k)g_\varepsilon$ *on* A_ε) to mean that $\frac{f_\varepsilon}{g_\varepsilon} \to 0$ (resp. $|f_\varepsilon| \le C\varepsilon^k|g|$) uniformly on A_ε as $\varepsilon \to 0$.

2. Preliminaries. In order to obtain solutions of (1.1) we choose a suitable functional setting. Let $H_r^1(\mathbb{R}^3)$ and $L_r^2(\mathbb{R}^3)$ denote the subspace of the Sobolev space $H^1(\mathbb{R}^3)$ and $L^2(\mathbb{R}^3)$, respectively, formed by the radially symmetric functions endowed with the norms

$$\|u\|_{H^1(\mathbb{R}^3)}^2 = \int_{\mathbb{R}^3} \left(|\nabla u|^2 + |u|^2\right) dx, \quad \|u\|_{L^2(\mathbb{R}^3)}^2 = \int_{\mathbb{R}^3} |u|^2\, dx.$$

It is well known that $H_r^1(\mathbb{R}^3)$ is compactly imbedded in $L^p(\mathbb{R}^3)$ for $2 < p < 6$ (see [7, Theorem A.I', p. 341] or [39]). Furthermore, if $u \in H_r^1(\mathbb{R}^3)$, then

$$|u(x)| \leq (4\pi)^{-\frac{1}{2}} |x|^{-1} \|u\|_{H^1} \text{ a.e. in } \mathbb{R}^3$$

(see [39]). Define $D^1(\mathbb{R}^3)$ as the completion of $C_0^\infty(\mathbb{R}^3)$ with respect to the norm

$$\|u\|^2_{D^1(\mathbb{R}^3)} \equiv \int_{\mathbb{R}^3} |\nabla u|^2 \, dx,$$

and let $D_r^1(\mathbb{R}^3)$ denote the closed subspace consisting of the radially symmetric functions.

The following proposition holds (see [10] for the proof).

PROPOSITION 2.1. *For every $u \in H_r^1(\mathbb{R}^3)$ denote by $(-\Delta)^{-1}[u^2]$ the unique solution in $D_r^1(\mathbb{R}^3)$ of*

$$-\Delta v = u^2.$$

Then the following representation formula holds:

$$(-\Delta)^{-1}[u^2](x) = \frac{1}{4\pi} \int_{\mathbb{R}^3} \frac{1}{|x-y|} u^2(y) dy = \int_0^{+\infty} G(|x|, \rho) u^2(\rho) d\rho,$$

where $G(s, \rho)$ has been defined in (1.4). *Furthermore, the functional $F : u \in H_r^1(\mathbb{R}^3) \mapsto \int_{\mathbb{R}^3} u^2 (-\Delta)^{-1}[u^2] dx$ is compact and C^1, and*

$$F'(u)[w] = 4 \int_{\mathbb{R}^3} uw(-\Delta)^{-1}[u^2] dx \quad \forall u, w \in H_r^1(\mathbb{R}^3).$$

By suitably scaling, (1.1) can be reduced to the following system of equations:

$$\begin{cases} -\Delta u + u + \Gamma u\psi - u^p = 0 \text{ in } \mathbb{R}^3, \\ -\Delta \psi = \varepsilon u^2 \text{ in } \mathbb{R}^3, \\ u, \, \psi > 0, \quad u, \, \psi \to 0 \text{ as } |x| \to +\infty, \end{cases} \tag{2.1}$$

where

$$\varepsilon = \hbar = \gamma^{\frac{2}{p-1}}, \quad \Gamma = 4\pi\omega^2, \quad u(x) = \sqrt{\varepsilon} v(\varepsilon x), \quad \psi(x) = \frac{1}{4\pi\omega} \phi(\varepsilon x). \tag{2.2}$$

Associated with (2.1) is the following energy functional $E_\varepsilon \in C^1(H_r^1(\mathbb{R}^3), \mathbb{R})$:

$$E_\varepsilon[u] := \frac{1}{2} \int_{\mathbb{R}^3} \left(|\nabla u|^2 + u^2 \right) dx - \frac{1}{p+1} \int_{\mathbb{R}^3} u_+^{p+1} dx + \frac{\Gamma}{4} \varepsilon \int_{\mathbb{R}^3} u^2 (-\Delta)^{-1}[u^2] dx.$$

By using Proposition 2.1 the energy functional can be rewritten as

$$\begin{aligned} E_\varepsilon[u] = 2\pi \int_0^{+\infty} r^2 \left(|u'|^2 + |u|^2 \right) dr - \frac{4\pi}{p+1} \int_0^{+\infty} r^2 |u_+|^{p+1} dr \\ + \Gamma \pi \varepsilon \int_0^{+\infty} \int_0^{+\infty} r^2 G(r, \rho) u^2(r) u^2(\rho) dr d\rho. \end{aligned}$$

Before going on we define in the following lemma two suitable functions which will be useful in order to locate the asymptotic peak of the solutions.

Lemma 2.2. *Assume $p, N \in \mathbb{R}$ such that $N \geq 3$ and $1 < p < \frac{7N-10}{3N-2}$, and consider the two functions*

$$\rho(t) = (1+t)^{\frac{p-5}{2(p-1)}} t^2[(3p-7)t + 4(p-1)], \quad t > \hat{t} := \frac{2(p-1)}{7-3p},$$

and $t = t(s)$ the inverse function of

$$s(t) = \left(\Gamma \int_{\mathbb{R}} w^2 dy\right)^{-1} (1+t)^{\frac{p-5}{2(p-1)}} t, \quad t > \hat{t}.$$

Then the function $s^{N-3}\rho(t(s))$ has a unique (and nondegenerate) minimum point s_0 for $s \in (0, s(\hat{t}))$. In particular, if $N = 3$, then s_0 is given by (1.6).

Proof. Since $\frac{7N-10}{3N-2} < \frac{7}{3}$, it is easy to see that s is a strictly decreasing function for $t > \hat{t}$. Thus the inverse function $t = t(s)$ exists for $s \in (0, s(\hat{t}))$. Now compute

$$\begin{aligned}\left(s^{N-3}\rho\right)'(t) = &\left(\Gamma \int_{\mathbb{R}} w^2 dy\right)^{3-N} t^{N-2}(1+t)^{\frac{(p-5)N+4(3-p)}{2(p-1)}} \\ &\times\left(\frac{(7-3p)N + 2(p-5)}{2(p-1)} t - 2(N-1)\right)\big((7-3p)t - 2(p-1)\big).\end{aligned}$$

For $t > \hat{t}$, $\rho(t)$ has the following unique critical point:

$$t_0 = \frac{4(N-1)(p-1)}{(7-3p)N + 2(p-5)}. \tag{2.3}$$

Moreover, $\rho''(t_0) > 0$, which means that t_0 is also nondegenerate. Set $s_0 = s(t_0)$. Then the function $\rho(t(s))$ has a unique (and nondegenerate) minimum point s_0 for $s \in (0, s(\hat{t}))$. $\square$

Now we are in position to introduce our approximate solutions. As we have already stated in the introduction, we construct the approximations by suitably rescaling the function w and then using suitable truncations. Fix $s_1, s_2 \in (0, s(\hat{t}))$ such that $s_1 < s_2$ and, according to Lemma 2.2,

$$s_0 \in (s_1, s_2), \quad \frac{2t(s)}{1+t(s)} \neq \frac{4(p-1)}{5-p} \quad \forall s \in [s_1, s_2]. \tag{2.4}$$

Let $\eta(r)$ be a cut-off function satisfying

$$\eta(r) = 1 \text{ for } r \in (-\delta, \delta), \quad \eta(r) = 0 \text{ for } r \notin (-2\delta, +2\delta), \tag{2.5}$$

where $\delta > 0$ is a fixed number such that $s_1 - 2\delta > 0$. For every $s \in [s_1, s_2]$ define

$$w_s(y) := (1+t(s))^{\frac{1}{p-1}} w(\sqrt{1+t(s)}y)$$

and

$$U_{\varepsilon,s}(y) := w_s(y)\eta(\varepsilon y). \tag{2.6}$$

We immediately see that w_s satisfies

$$w_s'' - (1+t(s))w_s + w_s^p = 0, \quad w_s > 0, \quad w_s(y) = w_s(-y). \tag{2.7}$$

The definitions of $U_{\varepsilon,s}$ in (2.6) and w in (1.3) imply that for every $i \in \mathbb{N}$, denoting by $U^i_{\varepsilon,s}$ and $w^i_{\varepsilon,s}$ the derivatives of order i of the functions $U_{\varepsilon,s}$ and w_s, respectively, we have

$$U^i_{\varepsilon,s}(y) = O(1)e^{-|y|}, \quad U^i_{\varepsilon,s}(y) = w^i_s(y) + o(\varepsilon)e^{-|y|} \tag{2.8}$$

uniformly for $s \in [s_1, s_2]$. We need to recall the following well-known facts on the functions w and w_s which will be frequently used later on.

LEMMA 2.3. (1) *For every $s \in [s_1, s_2]$ the following identities hold:*

$$\int_{\mathbb{R}} (w_s')^2 dy = \frac{p-1}{2(p+1)} \int_{\mathbb{R}} w_s^{p+1} dy, \quad \int_{\mathbb{R}} w_s^2 dy = \frac{p+3}{2(1+t(s))(p+1)} \int_{\mathbb{R}} w_s^{p+1} dy. \tag{2.9}$$

(2) *Let $L_0 : H^2(\mathbb{R}) \to L^2(\mathbb{R})$ be the linear operator defined by*

$$L_0[\phi] = \phi'' - \phi + pw^{p-1}\phi.$$

Then

$$L_0\left[\frac{1}{p-1}w + \frac{1}{2}yw'\right] = w \tag{2.10}$$

and $\phi \in H^2(\mathbb{R})$ satisfies

$$L_0[\phi] = 0$$

if and only if $\phi = cw'$ for some constant c. As a consequence, if we consider the kernel $\mathcal{K}_0$ and the cokernel $\mathcal{C}_0$ of the operator L_0,

$$\mathcal{K}_0 = \{cw' \mid c \in \mathbb{R}\} \subset H^2(\mathbb{R}), \ \ \mathcal{C}_0 = \{cw' \mid c \in \mathbb{R}\} \subset L^2(\mathbb{R}),$$

then L_0 is an invertible operator from $\mathcal{K}_0^\perp$ to $\mathcal{C}_0^\perp$.

Proof. Since each w_s satisfies (2.7), we have $\left((w_s')^2\right)' = (1+t(s))(w_s^2)' - \frac{2}{p+1}(w_s^{p+1})'$, by which $(w_s')^2 = (1+t(s))w_s^2 - \frac{2}{p+1}w_s^{p+1}$. Combining this with the identity

$$\int_{\mathbb{R}} (w_s')^2 dy + (1+t(s)) \int_{\mathbb{R}} w_s^2 dy = \int_{\mathbb{R}} w_s^{p+1} dy$$

we deduce (2.9). To prove (2.10), it is sufficient to observe that $L_0[w] = (p-1)w^p$, $L_0[yw'] = 2(w - w^p)$.

The last part of the lemma follows from the uniqueness of w. ∎

Fix $\lambda > 0$. We conclude this section by analyzing the following nonlocal operator:

$$L : H^2(\mathbb{R}) \to L^2(\mathbb{R}), \ \ L[\phi] := L_0[\phi] - \lambda(p-1)\frac{\int_{\mathbb{R}} w\phi dy}{\int_{\mathbb{R}} w^2 dy} w.$$

The following lemma characterizes the kernel of L.

LEMMA 2.4. *If $\lambda \neq \frac{4}{5-p}$, then $\phi \in H^2(\mathbb{R})$ satisfies*

$$L[\phi] = 0$$

if and only if $\phi = cw'$ for some constant c.

Proof. Assume $L[\phi]=0$. From (2.10) we deduce that

$$L_0\left[\phi-\lambda\frac{\int_{\mathbb{R}} w\phi dy}{\int_{\mathbb{R}} w^2 dy}\left(w+\frac{p-1}{2}yw^{'}\right)\right]=L[\phi]=0.$$

By (2) of Lemma 2.3, we have

$$\phi-\lambda\frac{\int_{\mathbb{R}} w\phi dy}{\int_{\mathbb{R}} w^2 dy}\left(w+\frac{p-1}{2}yw^{'}\right)=cw^{'} \tag{2.11}$$

for some c. Multiplying (2.11) by w and integrating over $\mathbb{R}$, we obtain

$$(1-\lambda)\int_{\mathbb{R}} w\phi dy-\lambda\frac{p-1}{2}\frac{\int_{\mathbb{R}} w\phi dy}{\int_{\mathbb{R}} w^2 dy}\int_{\mathbb{R}} yww' dy=0.$$

After an integration by parts we deduce $\int_{\mathbb{R}} yww'dy=-\frac{1}{2}\int_{\mathbb{R}} w^2dy$, by which

$$\left(1-\lambda\left(1-\frac{p-1}{4}\right)\right)\int_{\mathbb{R}} w\phi dy=0,$$

and hence $\int_{\mathbb{R}} w\phi dy=0$, which implies $L_0[\phi]=L[\phi]=0$; then Lemma 2.3 leads to $\phi=cw^{'}$. □

3. The linearized problem. For every $s\in[s_1,s_2]$, where s_1, s_2 have be chosen in (2.4), we set

$$I_{\varepsilon,s}:=\left(-\frac{s}{\varepsilon},+\infty\right).$$

Denote by $L^p_\varepsilon(I_{\varepsilon,s})$ the space of the functions $\phi: I_{\varepsilon,s}\to\mathbb{R}$ such that, setting $u_\phi(x)=\phi\big(|x|-\frac{s}{\varepsilon}\big)$, it results in $u_\phi\in L^p(\mathbb{R}^3)$. $L^2_\varepsilon(I_{\varepsilon,s})$ can be equipped with the following scalar product:

$$\langle\phi,\psi\rangle_\varepsilon=\int_{I_{\varepsilon,s}}\phi\psi(s+\varepsilon y)^2dy\quad\forall\phi,\psi\in L^2_\varepsilon(I_{\varepsilon,s})$$

(which is equivalent to the norm $\|u_\phi\|_{L^2(\mathbb{R}^3)}$).

We define the following operator:

$$T_{\varepsilon,s}[\phi](y)=\int_{I_{\varepsilon,s}}G(s+\varepsilon y,s+\varepsilon z)\phi(z)dz,\ \ y\in I_{\varepsilon,s},\ \ \phi\in L^1_\varepsilon(I_{\varepsilon,s}).$$

Notice that

$$s-\varepsilon(2|z|+|y|)\le G(s+\varepsilon y,s+\varepsilon z)\le s+\varepsilon z\quad\forall y,z\in I_{\varepsilon,s}; \tag{3.1}$$

hence, by using (2.8) and Lemma 2.2, we get

$$\begin{aligned}T_{\varepsilon,s}[U^2_{\varepsilon,s}](y)&=s\int_{\mathbb{R}}U^2_{\varepsilon,s}dz+O(\varepsilon)(|y|+1)=s\int_{\mathbb{R}}w_s^2dz+O(\varepsilon)(|y|+1)\\&=s(1+t(s))^{\frac{5-p}{2(p-1)}}\int_{\mathbb{R}}w^2dz+O(\varepsilon)(|y|+1)=\frac{1}{\Gamma}t(s)+O(\varepsilon)(|y|+1)\end{aligned} \tag{3.2}$$

uniformly for $s \in [s_1, s_2]$. In the same way, we define $H^1_\varepsilon(I_{\varepsilon,s})$, the space of the functions $\phi : I_{\varepsilon,s} \to \mathbb{R}$, such that $u_\phi \in H^1_r(\mathbb{R}^3)$. We can equip $H^1_\varepsilon(I_{\varepsilon,s})$ with the following scalar product:

$$(\phi,\psi)_\varepsilon = \int_{I_{\varepsilon,s}} [\phi'\psi' + (1+\Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])\phi\psi](s+\varepsilon y)^2 dy \quad \forall \phi,\psi \in H^1_\varepsilon(I_{\varepsilon,s})$$

(which is equivalent to the norm $\|u_\phi\|_{H^1(\mathbb{R}^3)}$ since $0 \le T_{\varepsilon,s}[U^2_{\varepsilon,s}](y) \le \int_{I_{\varepsilon,s}}(s+\varepsilon z)U^2_{\varepsilon,s}dz$).

We introduce the following functions:

$$Z_{\varepsilon,s}(y) = U'''_{\varepsilon,s}(y) + \frac{2\varepsilon}{s+\varepsilon y}U''_{\varepsilon,s}(y) - (1+\Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])U'_{\varepsilon,s}(y), \quad y \in I_{\varepsilon,s}. \tag{3.3}$$

By integration by parts we immediately prove that

$$(\phi, U'_{\varepsilon,s})_\varepsilon = -\langle \phi, Z_{\varepsilon,s}\rangle_\varepsilon \quad \forall \phi \in H^1_\varepsilon(I_{\varepsilon,s}); \tag{3.4}$$

then orthogonality of the functions $U'_{\varepsilon,s}$ in $H^1_\varepsilon(I_{\varepsilon,s})$ is equivalent to orthogonality of $Z_{\varepsilon,s}$ in $L^2_\varepsilon(I_{\varepsilon,s})$.

First we study a linear problem: given $h \in C(\bar I_{\varepsilon,s}) \cap L^2_\varepsilon(I_{\varepsilon,s})$, find a function $\phi \in H^1_\varepsilon(I_{\varepsilon,s})$ and $c \in \mathbb{R}$ satisfying

$$\begin{cases} L_{\varepsilon,s}[\phi] = h + cZ_{\varepsilon,s}, \\ \phi'\left(-\frac{s}{\varepsilon}\right) = 0, \quad \langle \phi, Z_{\varepsilon,s}\rangle_\varepsilon = 0, \end{cases} \tag{3.5}$$

where

$$L_{\varepsilon,s}[\phi] := \phi'' + \frac{2\varepsilon}{s+\varepsilon y}\phi' - (1+\Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])\phi + pU^{p-1}_{\varepsilon,s}\phi - 2\Gamma T_{\varepsilon,s}[U_{\varepsilon,s}\phi]U_{\varepsilon,s}.$$

In order to solve the system (3.5) we need the following result based on ODE estimates.

Lemma 3.1. *Let $\phi \in C^2(\bar I_{\varepsilon,s})$ satisfy*

$$\left|\phi''(y) + \frac{2\varepsilon}{s+\varepsilon y}\phi'(y) - (1+\Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])\phi(y)\right| \le c_0 e^{-\mu|y|}, \quad \phi'\left(-\frac{s}{\varepsilon}\right) = 0,$$

for some $c_0 > 0$, and

$$\phi(y) \to 0 \quad \text{as } y \to +\infty.$$

Then, provided that $\mu > 0$ is sufficiently small,

$$|\phi(y)| \le 2e^2(|\phi(0)| + c_0)e^{-\mu|y|} \quad \forall y \in I_{\varepsilon,s}.$$

Proof. We use a comparison principle. Take $\chi(t)$, a smooth cut-off function such that

$$\chi(t) = 1 \text{ for } |t| \le 1, \quad \chi(t) = 0 \text{ for } |t| \ge 2, \quad 0 \le \chi \le 1.$$

Now consider the following auxiliary function:

$$\Phi(y) = A\Big[e^{\mu y} + (e^{\mu y_0} - e^{\mu y})\chi\Big(\mu\Big(y + \frac{s}{\varepsilon}\Big)\Big)\Big],$$

where

$$y_0 = -\frac{s}{\varepsilon} + \frac{1}{\mu}, \quad A = 2e(|\phi(0)| + c_0).$$

If $y \in (-\frac{s}{\varepsilon}, y_0)$, $\Phi(y) = Ae^{\mu y_0} \le Ae^{\mu y+1}$ and hence

$$\Phi'' + \frac{2\varepsilon}{s+\varepsilon y}\Phi' - (1 + \Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])\Phi = -A(1 + T_{\varepsilon,s}[U^2_{\varepsilon,s}])e^{\mu y_0} \le -c_0 e^{\mu y}.$$

If $y \in (-\frac{s}{\varepsilon} + \frac{2}{\mu}, 0)$, $\Phi(y) = Ae^{\mu y}$, and $\frac{\varepsilon}{s+\varepsilon y} \le \frac{\mu}{2}$, then

$$\Phi'' + \frac{2\varepsilon}{s+\varepsilon y}\Phi' - (1 + \Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])\Phi = A[2\mu^2 - (1 + T_{\varepsilon,s}[U^2_{\varepsilon,s}])]e^{\mu y} \le -c_0 e^{\mu y}$$

provided that μ is sufficiently small. Finally, it is easy to see that for $y \in (y_0, y_0 + \frac{1}{\mu})$,

$$e^{\mu y_0} \le e^{\mu y} \le e e^{\mu y_0}, \quad \Phi(y) \ge Ae^{\mu y - 1}, \quad \frac{\mu}{2} \le \frac{\varepsilon}{s+\varepsilon y} \le \mu;$$

hence

$$\Phi'' + \frac{2\varepsilon}{s+\varepsilon y}\Phi' - (1 + \Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])\Phi \le AO(\mu^2)e^{\mu y} - A(1 + \Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])e^{\mu y-1} \le -c_0 e^{\mu y}$$

provided that μ is sufficiently small.

In any case, we have that for $y \in (-\frac{s}{\varepsilon}, 0)$, $\Phi(y)$ satisfies

$$\begin{gathered} \Phi'' + \frac{2\varepsilon}{s+\varepsilon y}\Phi' - (1 + \Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])\Phi \le -c_0 e^{\mu y}, \\ \Phi'\left(-\frac{s}{\varepsilon}\right) = 0, \quad \Phi(0) \ge |\phi(0)|. \end{gathered} \tag{3.6}$$

Combining (3.6) with the hypothesis we obtain

$$(\Phi - \phi)''(y) + \frac{2\varepsilon}{s+\varepsilon y}(\Phi - \phi)'(y) - (1 + \Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])(\Phi - \phi)(y) \le 0 \tag{3.7}$$

for every $y \in \left[-\frac{s}{\varepsilon}, 0\right]$ and

$$(\Phi - \phi)(0) > 0, \quad (\Phi - \phi)'\left(-\frac{s}{\varepsilon}\right) = 0;$$

we claim that $(\Phi - \phi)(y) \ge 0$ for $y \in [-\frac{s}{\varepsilon}, 0)$. Otherwise, if we call $\bar{y}$ the minimum point of $\Phi - \phi$ in $[-\frac{s}{\varepsilon}, 0)$, then it would be $(\Phi - \phi)(\bar{y}) < 0$ and $(\Phi - \phi)'(\bar{y}) = 0$, $(\Phi - \phi)''(\bar{y}) > 0$, in contradiction to (3.7). Hence we have proved that $\phi \le \Phi$ in $[-\frac{s}{\varepsilon}, 0]$. On the other hand, by (3.6) and the hypothesis we also get

$$(\Phi + \phi)''(y) + \frac{2\varepsilon}{s+\varepsilon y}(\Phi + \phi)'(y) - (1 + \Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])(\Phi + \phi)(y) \le 0 \ \ \forall y \in \left[-\frac{s}{\varepsilon}, 0\right]$$

and $(\Phi + \phi)(0) > 0$, $(\Phi + \phi)'(-\frac{s}{\varepsilon}) = 0$. Proceeding as before we conclude $\phi \ge -\Phi$ in $[-\frac{s}{\varepsilon}, 0]$.

For $y \in [0, +\infty)$, we use $\hat{\Phi}(y) = Ae^{-\mu y}$ and hence

$$\hat{\Phi}'' + \frac{2\varepsilon}{s+\varepsilon y}\hat{\Phi}' - (1 + \Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])\hat{\Phi} \le A(\mu^2 - (1 + \Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}]))e^{-\mu y} \le -c_0 e^{-\mu y}$$

provided that μ is sufficiently small. By repeating the previous argument we obtain $|\phi| \leq \hat{\Phi}$ in $[0, +\infty)$ and the conclusion follows. $\square$

Let $\mu \in (0,1)$ be a number sufficiently small such that Lemma 3.1 holds and for every function $\phi : I_{\varepsilon,s} \to \mathbb{R}$ define

$$\|\phi\|_* = \|e^{\mu\langle y\rangle}\phi(y)\|_{L^\infty(I_{\varepsilon,s})},$$

where $\langle y\rangle = (1+y^2)^{1/2}$. Since $\frac{2\varepsilon}{s+\varepsilon y}U''_{\varepsilon,s} = O(\varepsilon)e^{-|y|}$, by using (2.7), (2.8), and (3.2) we obtain

$$\begin{aligned} Z_{\varepsilon,s}(y) &= w_s'''(y) - (1+t(s))w_s'(y) + O(\varepsilon)e^{-\mu\langle y\rangle} \\ &= -pw_s^{p-1}(y)w_s'(y) + O(\varepsilon)e^{-\mu\langle y\rangle} \end{aligned} \tag{3.8}$$

uniformly for $s \in [s_1, s_2]$.

Next we prove the following a priori estimate for (3.5).

LEMMA 3.2. *There exists a constant $C > 0$ such that, provided that ε is sufficiently small, if $s \in [s_1, s_2]$ and (ϕ, c, h) satisfy* (3.5)*, the following holds:*

$$\|\phi\|_* \leq C\|h\|_*.$$

Proof. We argue by contradiction. Assume the existence of a sequence $\varepsilon_k \to 0$, $(s_k) \subset [s_1, s_2]$ and $(\tilde{\phi}_k, \tilde{c}_k) \in H^1_\varepsilon(I_{\varepsilon_k,s_k}) \times \mathbb{R}$, $h_k \in L^2_\varepsilon(I_{\varepsilon_k,s_k}) \cap C(\bar{I}_{\varepsilon_k,s_k})$ satisfying (3.5) such that

$$\|\tilde{\phi}_k\|_* > k\|\tilde{h}_k\|_*.$$

In particular, $\|\tilde{h}_k\|_* < +\infty$ for every k. For the sake of simplicity, in the remaining part of the proof we replace the subscript (ε_k, s_k) with k. By standard regularity results $\tilde{\phi}_k \in C^2(\bar{I}_k)$; furthermore, for every k $\|T_k(U_k\tilde{\phi}_k)\|_\infty \leq \int_{I_k}(s_k+\varepsilon_k z)U_k\tilde{\phi}_k dz < +\infty$ and, consequently, $\| -pU_k^{p-1}\tilde{\phi}_k + 2\Gamma T_k[U_k\tilde{\phi}_k]U_k + \tilde{h}_k + \tilde{c}_k Z_k\|_* < +\infty$. Then Lemma 3.1 implies $\|\tilde{\phi}_k\|_* < +\infty$ for every k. Hence it makes sense to set $\phi_k = \frac{\tilde{\phi}_k}{\|\tilde{\phi}_k\|_*}$, $c_k = \frac{\tilde{c}_k}{\|\tilde{\phi}_k\|_*}$, $h_k = \frac{\tilde{h}_k}{\|\tilde{\phi}_k\|_*}$. We obtain that (ϕ_k, c_k, h_k) satisfies (3.5) and

$$\|\phi_k\|_* = 1, \quad \|h_k\|_* = o(1).$$

Assume without loss of generality that $s_k \to s$ as $k \to +\infty$. By multiplying the equation $L_k[\phi_k] = h_k + c_k Z_k$ by U_k' and integrating over I_k, we get

$$c_k \int_{I_k} Z_k U_k' dy = -\int_{I_k} h_k U_k' dy + \int_{I_k} L_k[\phi_k]U_k' dy. \tag{3.9}$$

First examine the left-hand side of (3.9): by using (2.8) and (3.8) we deduce

$$\int_{I_k} Z_k U_k' dy = -p\int_{\mathbb{R}} w_{s_k}^{p-1}(w_{s_k}')^2 dy + o(1) = -p\int_{\mathbb{R}} w_s^{p-1}(w_s')^2 dy + o(1). \tag{3.10}$$

The first term on the right-hand side of (3.9) can be estimated as

$$\int_{I_k} |h_k U_k'| dy \leq \|h_k\|_* \int_{\mathbb{R}} |U_k'| e^{\mu\langle y\rangle} dy = O(1)\|h_k\|_* = o(1). \tag{3.11}$$

The last term in (3.9) equals

$$
\begin{aligned}
&\int_{I_{\varepsilon_k}} (L_k[\phi_k])U_k' dy \\
&= \int_{I_k} \phi_k \left[U_k''' + \frac{2\varepsilon_k^2}{(s_k+\varepsilon_k y)^2} U_k' - \frac{2\varepsilon_k}{s_k+\varepsilon_k y} U_k'' - (1+\Gamma T_k[U_k^2])U_k' + pU_k^{p-1}U_k' \right] dy \\
&\quad -2\Gamma \int_{I_k} T_k[U_k\phi_k]U_k U_k' dy \\
&= \int_{I_k} \phi_k \Big[U_k'''(y) - (1+\Gamma T_k[U_k^2])U_k'(y) + pU_k^{p-1}U_k' \Big] dy + O(\varepsilon_k)\|\phi_k\|_* \\
&\quad -2\Gamma \int_{I_k} T_k[U_k\phi_k]U_k U_k' dy
\end{aligned}
$$

since, according to the definition of U_k in (2.6) and to (2.8), $\frac{2\varepsilon_k^2}{(s_k+\varepsilon_k y)^2}U_k' = O(\varepsilon_k)e^{-|y|}$ and $\frac{2\varepsilon_k}{s_k+\varepsilon_k y}U_k' = O(\varepsilon_k)e^{-|y|}$. By (2.7), (2.8), and (3.2) we obtain

$$
\int_{I_k} \phi_k \big[U_k'''(y) - (1+\Gamma T_k[U_k^2])U_k' + pU_k^{p-1}U_k' \big] dy = O(\varepsilon_k)\|\phi_k\|_*. \tag{3.12}
$$

On the other hand, by (2.8) and (3.1) we deduce

$$
T_k[U_k\phi_k](y) = s\int_{I_k} U_k\phi_k dy + O(\varepsilon_k)(|y|+1)\|\phi_k\|_*, \tag{3.13}
$$

by which

$$
\int_{I_k} T_k[U_k\phi_k]U_k U_k' dy = O(\varepsilon_k)\|\phi_k\|_* \int_{I_k} (|y|+1)|U_k U_k'| dy = O(\varepsilon_k)\|\phi_k\|_*.
$$

Hence we have proved that

$$
\int_{I_k} L_k[\phi_k]U_k' dz = O(\varepsilon_k)\|\phi_k\|_* = O(\varepsilon_k). \tag{3.14}
$$

Combining (3.9), (3.10), (3.11), and (3.14) we achieve $|c_k| = o(1)$, by which $\|h_k + c_k Z_k\|_* = o(1)$.

Next we claim that $\phi_k \to 0$ uniformly in any compact interval of $\mathbb{R}$.

By multiplying (3.5) by $(s_k+\varepsilon_k y)^2\phi_k$ and integrating by parts we immediately get that the sequence $(\phi_k,\phi_k)_\varepsilon = \int_{I_k}(s_k+\varepsilon_k y)^2(|\phi_k'|^2+|\phi_k|^2)dy$ is bounded. Now we consider $\bar\phi_k(y) = \phi_k(y)\eta(\varepsilon_k y) \in H^1(\mathbb{R})$, where η has been defined in (2.5). Then it is easy to see that $\bar\phi_k$ is bounded in $H^1(\mathbb{R})$, and hence $\bar\phi_k \to \bar\phi_0$ weakly in $H^1(\mathbb{R})$. Taking into account of (3.2) and (3.13), $\bar\phi_0$ satisfies

$$
\Delta\bar\phi_0 - (1+t(s))\bar\phi_0 + pw_s^{p-1}\bar\phi_0 - 2s\Gamma\left(\int_{\mathbb{R}} w_s\bar\phi_0 dy\right) w_s = 0 \text{ in } \mathbb{R}, \ \ |\bar\phi_0| \le e^{-\mu\langle y\rangle}.
$$

By rescaling, setting $\phi_0(y) = \bar\phi_0(\frac{y}{\sqrt{1+t(s)}})$, and recalling the definition of w_s in (2.6), we obtain

$$
\phi_0'' - \phi_0 + pw^{p-1}\phi_0 - 2\frac{t(s)}{1+t(s)}\frac{\int_{\mathbb{R}} w\phi_0 dy}{\int_{\mathbb{R}} w^2 dy} w = 0.
$$

By (2.4), because of the choice of s,

$$2\frac{t(s)}{1+t(s)} \neq \frac{4(p-1)}{5-p};$$

Lemma 2.4 implies $\phi_0 = cw'$. On the other hand, $\int_{I_k} \phi_k Z_k(s_k+\varepsilon_k y)^2 dy = 0$ and hence, since by (3.8) $Z_k(s_k+\varepsilon_k y)^2 \to -s^2 p w_s^{p-1} w_s'$ for every $y \in \mathbb{R}$, by Lebesgue's dominated convergence theorem $\int_{\mathbb{R}} \bar{\phi}_0 w_s^{p-1} w_s' = 0$, that is, $\int_{\mathbb{R}} \phi_0 w^{p-1} w' = 0$, by which $c = 0$; we have proved that $\phi_k \to 0$ in any compact interval of $\mathbb{R}$. Taking into account (2.8), this shows that

$$\|U_k^{p-1}\phi_k\|_* \leq \sup_{y\in I_k} |e^{\mu\langle y\rangle} w_{s_k}^{p-1}(y)\phi_k(y)| = o(1).$$

By using again Lebesgue's dominated convergence theorem, we have that

$$\int_{I_k} U_k \phi_k dy \to 0,$$

which implies, using (3.13),

$$\big\|T_k[U_k\phi_k]U_k\big\|_* = o(1).$$

Thus we have arrived at the following situation: ϕ_k satisfies

$$\phi_k^{''} + \frac{2\varepsilon_k}{s_k+\varepsilon_k y}\phi_k^{'} - (1+\Gamma T_k[U_k^2])\phi_k = o(1)e^{-\mu\langle y\rangle},$$

$$\phi_k^{'}\Big(-\frac{s_k}{\varepsilon_k}\Big) = 0, \quad \phi_k \to 0 \text{ as } y \to \infty.$$

Furthermore, $\phi_k(0) = o(1)$. Hence we can apply Lemma 3.1 and obtain that $\phi_k(y) = o(1)e^{-\mu\langle y\rangle}$, which is a contradiction since $\|\phi_k\|_* = 1$. This proves the lemma. ∎

Now we are in position to provide the existence of a solution for the system (3.5).

LEMMA 3.3. *For $\varepsilon > 0$ sufficiently small, for every $s \in [s_1, s_2]$ and $h \in L_\varepsilon^2(I_{\varepsilon,s}) \cap C(\bar{I}_{\varepsilon,s})$, there exists a unique pair (ϕ, c) solving* (3.5). *Moreover, by Lemma* 3.2,

$$\|\phi\|_* \leq C\|h\|_*. \tag{3.15}$$

Proof. The existence follows from Fredholm alternative. To this aim, let us consider $\mathcal{H}_\varepsilon$ the closed subset of $H_\varepsilon^1(I_{\varepsilon,s})$ defined by

$$\mathcal{H}_\varepsilon = \{u \in H_\varepsilon^1(I_{\varepsilon,s}) \,|\, (u, U_{\varepsilon,s}^{'})_\varepsilon = 0\}.$$

Notice that, by (3.4), ϕ solves the system (3.5) if and only if $\phi \in \mathcal{H}_\varepsilon$ and

$$(\phi,\psi)_\varepsilon - p\langle U_{\varepsilon,s}^{p-1}\phi,\psi\rangle_\varepsilon + 2\Gamma\langle T_{\varepsilon,s}[U_{\varepsilon,s}\phi]U_{\varepsilon,s},\psi\rangle_\varepsilon = -\langle h,\psi\rangle_\varepsilon \ \ \forall\psi \in \mathcal{H}_\varepsilon. \tag{3.16}$$

Once we know ϕ we can determine a unique c from the equation

$$-p\langle U_{\varepsilon,s}^{p-1}\phi, U_{\varepsilon,s}'\rangle_\varepsilon + 2\Gamma\langle T_{\varepsilon,s}[U_{\varepsilon,s}\phi]U_{\varepsilon,s}, U_{\varepsilon,s}'\rangle_\varepsilon = -\langle h, U_{\varepsilon,s}'\rangle_\varepsilon + c(U_{\varepsilon,s}', U_{\varepsilon,s}')_\varepsilon.$$

Thus it remains to solve (3.16). According to Riesz's representation theorem, take $\mathcal{K}_\varepsilon(\phi)$, $\bar{h} \in \mathcal{H}_\varepsilon$ such that

$$(\mathcal{K}_\varepsilon(\phi),\psi)_\varepsilon = -p\langle U_{\varepsilon,s}^{p-1}\phi,\psi\rangle_\varepsilon + 2\Gamma\langle T_{\varepsilon,s}[U_{\varepsilon,s}\phi]U_{\varepsilon,s},\psi\rangle_\varepsilon \ \ \forall\psi \in \mathcal{H}_\varepsilon,$$

$$(\bar{h}, \psi)_\varepsilon = -\langle h, \psi \rangle_\varepsilon \ \ \forall \psi \in \mathcal{H}_\varepsilon.$$

Then problem (3.16) consists in finding $\phi \in \mathcal{H}_\varepsilon$ such that

$$\phi + \mathcal{K}_\varepsilon(\phi) = \bar{h}. \tag{3.17}$$

It is easy to prove that $\mathcal{K}_\varepsilon$ is a linear compact operator from $\mathcal{H}_\varepsilon$ to $\mathcal{H}_\varepsilon$.

Using Fredholm's alternatives, (3.17) has a unique solution for each $\bar{h}$ if and only if (3.17) has a unique solution for $\bar{h} = 0$. Let $\phi \in \mathcal{H}_\varepsilon$ be a solution of $\phi + \mathcal{K}_\varepsilon(\phi) = 0$; then ϕ solves the system (3.5) with $h = 0$ for some $c \in \mathbb{R}$. Lemma 3.2 implies $\phi \equiv 0$. ◻

4. Finite dimensional reduction. This section is devoted to solving the following nonlinear system with the unknowns $(\phi, \beta) \in H^1_\varepsilon(I_{\varepsilon,s}) \times \mathbb{R}$:

$$\begin{cases} S_{\varepsilon,s}[U_{\varepsilon,s} + \phi] = \beta Z_{\varepsilon,s}, & y \in I_{\varepsilon,s}, \\ \phi'\left(-\frac{s}{\varepsilon}\right) = 0, & \langle \phi, Z_{\varepsilon,s} \rangle_\varepsilon = 0, \end{cases} \tag{4.1}$$

where

$$S_{\varepsilon,s}[\psi] = \psi'' + \frac{2\varepsilon}{s + \varepsilon y}\psi' - \psi + \psi_+^p - \Gamma \psi T_{\varepsilon,s}[\psi^2].$$

LEMMA 4.1. *Fix $\sigma \in (\frac{1}{2}, 1)$. Provided that $\varepsilon > 0$ is sufficiently small, for every $s \in [s_1, s_2]$ there is a unique pair $(\phi_{\varepsilon,s}, \beta_{\varepsilon,s}) \in H^1_\varepsilon(I_{\varepsilon,s}) \times \mathbb{R}$ satisfying* (4.1) *and*

$$\|\phi_{\varepsilon,s}\|_* \le \varepsilon^\sigma, \ \ (\phi_{\varepsilon,s}, \phi_{\varepsilon,s})_\varepsilon \le \varepsilon^\sigma. \tag{4.2}$$

Furthermore, setting $\Phi_{\varepsilon,s}(x) = \phi_{\varepsilon,s}\big(|x| - \frac{s}{\varepsilon}\big)$, the maps $\Phi_\varepsilon : s \in [s_1, s_2] \mapsto \Phi_{\varepsilon,s} \in H^1_r(\mathbb{R}^3)$ and $\beta_\varepsilon : s \in [s_1, s_2] \mapsto \beta_{\varepsilon,s} \in \mathbb{R}$ are continuous.

Proof. We write the equation in (4.1) in the form

$$L_{\varepsilon,s}[\phi] = E_{\varepsilon,s} + M_{\varepsilon,s}[\phi] + \beta Z_{\varepsilon,s} \tag{4.3}$$

and use contraction mapping theorem. Here

$$-E_{\varepsilon,s} = U''_{\varepsilon,s} + \frac{2\varepsilon}{s + \varepsilon y} U'_{\varepsilon,s} - (1 + \Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])U_{\varepsilon,s} + U^p_{\varepsilon,s} \tag{4.4}$$

and

$$M_{\varepsilon,s}[\phi] = -(U_{\varepsilon,s} + \phi)^p_+ + U^p_{\varepsilon,s} + pU^{p-1}_{\varepsilon,s}\phi + \Gamma\big[(U_{\varepsilon,s} + \phi)T_{\varepsilon,s}[\phi^2] + 2\phi T_{\varepsilon,s}[U_{\varepsilon,s}\phi]\big].$$

By (2.7), (2.8), and (3.2) we immediately obtain

$$\|E_{\varepsilon,s}\|_* = \|U''_{\varepsilon,s} - (1 + t(s))U_{\varepsilon,s} + U^p_{\varepsilon,s}\|_* + C\varepsilon \le C\varepsilon \ \ \forall s \in [s_1, s_2], \tag{4.5}$$

where we have also used the estimate $\frac{2\varepsilon}{s+\varepsilon y}U'_{\varepsilon,s} = O(\varepsilon)e^{-|y|}$ uniformly for $s \in [s_1, s_2]$. Now we have to estimate the term $M_{\varepsilon,s}[\phi]$. Set $\mathcal{B}_{\varepsilon,s} = \{\phi \in C(\bar{I}_{\varepsilon,s}) \,|\, \|\phi\|_* \le \varepsilon^\sigma\}$. Given ϕ_1, $\phi_2 \in \mathcal{B}_{\varepsilon,s}$, we compute

$$\begin{aligned} &\|-(U_{\varepsilon,s} + \phi_1)^p_+ + pU^{p-1}_{\varepsilon,s}\phi_1 + (U_{\varepsilon,s} + \phi_2)^p_+ - pU^{p-1}_{\varepsilon,s}\phi_2\|_* \\ &\qquad \le \|\phi_1 - \phi_2\|_* \sup_{\xi \in \mathcal{B}_{\varepsilon,s}} \|p(U_{\varepsilon,s} + \xi)^{p-1}_+ - pU^{p-1}_{\varepsilon,s}\|_\infty \\ &\qquad \le C\varepsilon^{\sigma(p-1)}\|\phi_1 - \phi_2\|_* \ \ \forall s \in [s_1, s_2]. \end{aligned}$$

For every $\phi \in C(\bar{I}_{\varepsilon,s})$: $|T_{\varepsilon,s}[\phi](y)| \le \|\phi\|_* \int_{I_{\varepsilon,s}} (s+\varepsilon z)e^{-\mu\langle z\rangle} dz \le C\|\phi\|_*$,

$$\begin{aligned}\|(U_{\varepsilon,s}+\phi_1)T_{\varepsilon,s}[\phi_1^2] - (U_{\varepsilon,s}+\phi_2)T_{\varepsilon,s}[\phi_2^2]\|_* \\ \le \|(U_{\varepsilon,s}+\phi_1)(T_{\varepsilon,s}[\phi_1^2-\phi_2^2])\|_* + \|(\phi_1-\phi_2)T_{\varepsilon,s}[\phi_2^2]\|_* \\ \le C\|\phi_1^2-\phi_2^2\|_* + C\|\phi_1-\phi_2\|_*\varepsilon^\sigma \le C\|\phi_1-\phi_2\|_*\varepsilon^\sigma \quad \forall s \in [s_1,s_2].\end{aligned}$$

In a similar way

$$\|\phi_1 T_{\varepsilon,s}[U_{\varepsilon,s}\phi_1] - \phi_2 T_{\varepsilon,s}[U_{\varepsilon,s}\phi_2]\|_* \le C\|\phi_1-\phi_2\|_*\varepsilon^\sigma \quad \forall s \in [s_1,s_2],$$

by which

$$\|M_{\varepsilon,s}(\phi_1) - M_{\varepsilon,s}(\phi_2)\|_* \le C(\varepsilon^\sigma + \varepsilon^{\sigma(p-1)})\|\phi_1-\phi_2\|_* \quad \forall \phi_1,\phi_2 \in \mathcal{B}_{\varepsilon,s}, \ \forall s \in [s_1,s_2]. \tag{4.6}$$

According to Lemma 3.3, for every $\phi \in \mathcal{B}_{\varepsilon,s}$ we define $\mathcal{A}_{\varepsilon,s}[\phi] \in H^1_\varepsilon(I_{\varepsilon,s})$ to be the unique solution to the system (3.5) with $h = E_{\varepsilon,s} + M_{\varepsilon,s}[\phi]$. Then by Lemma 3.3 we have

$$\|\mathcal{A}_{\varepsilon,s}[\phi]\|_* \le C\|E_{\varepsilon,s} + M_{\varepsilon,s}[\phi]\|_* \le C(\varepsilon + \varepsilon^{2\sigma} + \varepsilon^{\sigma p}) \le \varepsilon^\sigma \quad \forall s \in [s_1,s_2]$$

and hence $\mathcal{A}_{\varepsilon,s}[\phi] \in \mathcal{B}_{\varepsilon,s}$. Moreover, since $\mathcal{A}_{\varepsilon,s}[\phi_1] - \mathcal{A}_{\varepsilon,s}[\phi_2]$ solves the system (3.5) with $h = M_{\varepsilon,s}[\phi_1] - M_{\varepsilon,s}[\phi_2]$, by (4.6) we also have that

$$\|\mathcal{A}_\varepsilon[\phi_1] - \mathcal{A}_\varepsilon[\phi_2]\|_* \le C\|M_{\varepsilon,s}[\phi_1] - M_{\varepsilon,s}[\phi_2]\|_* < \|\phi_1-\phi_2\|_* \quad \forall s \in [s_1,s_2]; \tag{4.7}$$

i.e., the map $\mathcal{A}_{\varepsilon,s}$ is a contraction map from $\mathcal{B}_{\varepsilon,s}$ to $\mathcal{B}_{\varepsilon,s}$. By the contraction mapping theorem, (4.1) has a unique solution $(\phi_{\varepsilon,s}, \beta_{\varepsilon,s}) \in \mathcal{B}_{\varepsilon,s} \times \mathbb{R}$. By multiplying both members of (4.3) by $(s+\varepsilon z)^2\phi_{\varepsilon,s}$ and integrating by parts we obtain

$$(\phi_{\varepsilon,s}, \phi_{\varepsilon,s})_\varepsilon = \langle pU_{\varepsilon,s}^{p-1}\phi_{\varepsilon,s} - 2\Gamma T_{\varepsilon,s}[U_{\varepsilon,s}\phi_{\varepsilon,s}]U_{\varepsilon,s} - E_{\varepsilon,s} - M_{\varepsilon,s}[\phi_{\varepsilon,s}], \phi_{\varepsilon,s}\rangle_\varepsilon \le \varepsilon^\sigma, \tag{4.8}$$

where we have used (4.5) and (4.6); in particular, since $\|\Phi_{\varepsilon,s}\|^2_{H^1(\mathbb{R}^3)} \le \varepsilon^{-2}4\pi(\phi_{\varepsilon,s}, \phi_{\varepsilon,s})_\varepsilon$, fixed $\varepsilon > 0$, the family $\Phi_{\varepsilon,s}$ is bounded in $H^1_r(\mathbb{R}^3)$. On the other hand, by using (3.4) we have

$$\begin{aligned}(\phi_{\varepsilon,s}, U'_{\varepsilon,s})_\varepsilon = &\langle pU_{\varepsilon,s}^{p-1}\phi_{\varepsilon,s} - 2\Gamma T_{\varepsilon,s}[U_{\varepsilon,s}\phi_{\varepsilon,s}]U_{\varepsilon,s} - E_{\varepsilon,s} - M_{\varepsilon,s}[\phi_{\varepsilon,s}], U'_{\varepsilon,s}\rangle_\varepsilon \\ &+\beta_{\varepsilon,s}(U'_{\varepsilon,s}, U'_{\varepsilon,s})_\varepsilon,\end{aligned}$$

by which we deduce that the family $\beta_{\varepsilon,s}$ is also bounded for fixed $\varepsilon > 0$.

Now consider $\{s_n\} \subset [s_1,s_2]$ such that $s_n \to \bar{s}$. Up to a subsequence, $\Phi_{\varepsilon,s_n} \rightharpoonup \bar{\Phi}$ weakly in $H^1_r(\mathbb{R}^3)$ and $\beta_{\varepsilon,s_n} \to \bar{\beta}$. Then, setting $\bar{\phi}(y) = \bar{\Phi}(y + \frac{\bar{s}}{\varepsilon})$ for $y \in I_{\varepsilon,\bar{s}}$, $(\bar{\phi}, \bar{\beta})$ solves the equation

$$L_{\varepsilon,\bar{s}}(\bar{\phi}) = E_{\varepsilon,\bar{s}} + M_{\varepsilon,\bar{s}}[\bar{\phi}] + \bar{\beta}Z_{\varepsilon,\bar{s}}, \quad \bar{\phi}'\left(\frac{\bar{s}}{\varepsilon}\right) = 0, \quad \langle\bar{\phi}, Z_{\varepsilon,\bar{s}}\rangle = 0, \quad \|\bar{\phi}\|_* \le \varepsilon^\sigma.$$

From uniqueness it follows that $\bar{\phi} = \phi_{\varepsilon,\bar{s}}$ and $\bar{\beta} = \beta_{\varepsilon,\bar{s}}$. By (4.8) we get

$$(\phi_{\varepsilon,s_n}, \phi_{\varepsilon,s_n})_\varepsilon \to \langle pU_{\varepsilon,\bar{s}}^{p-1}\bar{\phi} - 2\Gamma T_{\varepsilon,\bar{s}}[U_{\varepsilon,\bar{s}}\bar{\phi}]U_{\varepsilon,\bar{s}} - E_{\varepsilon,\bar{s}} - M_{\varepsilon,\bar{s}}[\bar{\phi}], \bar{\phi}\rangle_\varepsilon = (\bar{\phi}, \bar{\phi})_\varepsilon,$$

hence (since the norm $(\phi,\phi)_\varepsilon$ is equivalent to $\|\Phi\|_{H^1(\mathbb{R}^3)}$), we deduce $\Phi_{\varepsilon,s_n}\to\Phi_{\varepsilon,\bar s}$ in $H^1(\mathbb{R}^3)$. ∎

LEMMA 4.2. *For $\varepsilon>0$ sufficiently small, the map $\Phi_\varepsilon : s\in[s_1,s_2]\mapsto\Phi_{\varepsilon,s}\in H^1_r(\mathbb{R}^3)$ constructed in Lemma 4.1 is C^1.*

Proof. Consider the following map $H_\varepsilon:[s_1,s_2]\times H^1_r(\mathbb{R}^3)\times\mathbb{R}\to H^1_r(\mathbb{R}^3)\times\mathbb{R}$ of class C^1:

$$H_\varepsilon(s,\Phi,\beta)=\begin{pmatrix}\Big(\Delta-(1+\Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])\Big)^{-1}\Big(S_{\varepsilon,s}[U_{\varepsilon,s}+\phi]-\beta Z_{\varepsilon,s}\Big)(|x|-\frac{s}{\varepsilon})\\ (\phi,U'_{\varepsilon,s})_\varepsilon\end{pmatrix},$$

where $\Phi(x)=\phi(|x|-\frac{s}{\varepsilon})$ and $v=\big(\Delta-(1+\Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])\big)^{-1}(h)$ is defined as the unique solution in $H^1_\varepsilon(I_{\varepsilon,s})$ of

$$v''+\frac{2\varepsilon}{s+\varepsilon y}v'-\big(1+\Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}]\big)v=h,\ \ v'\Big(-\frac{s}{\varepsilon}\Big)=0,\ \ y\in I_{\varepsilon,s}. \tag{4.9}$$

It is immediate that (ϕ,β) solves the system (4.1) if and only if $H_\varepsilon(s,\Phi,\beta)=0$. We are going to prove that, provided that ε is sufficiently small, for every $s\in[s_1,s_2]$ the linear operator

$$\frac{\partial H_\varepsilon(s,\Phi,\beta)}{\partial(\Phi,\beta)}|_{(s,\Phi_{\varepsilon,s},\beta_{\varepsilon,s})}:H^1_r(\mathbb{R}^3)\times\mathbb{R}\to H^1_r(\mathbb{R}^3)\times\mathbb{R}$$

is invertible. But first notice how, assuming this, the thesis easily follows; indeed, the continuity of the map Φ_ε proved in Lemma 4.1 implies that Φ_ε actually coincides with the implicit function associated to H_ε, hence the C^1-regularity of Φ_ε will follow from the implicit function theorem.

Now we compute

$$\frac{\partial H_\varepsilon(s,\Phi,\beta)}{\partial(\Phi,\beta)}|_{(s,\Phi_{\varepsilon,s},\beta_{\varepsilon,s})}[\Phi,c]$$
$$=\begin{pmatrix}\Big(\Delta-(1+\Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}])\Big)^{-1}\Big(S'_{\varepsilon,s}[U_{\varepsilon,s}+\phi_{\varepsilon,s}](\phi)-cZ_{\varepsilon,s}\Big)(|x|-\frac{s}{\varepsilon})\\ (\phi,U'_{\varepsilon,s})_\varepsilon\end{pmatrix}.$$

Proceeding as in the proof of Lemma 3.3, (Φ,c) solves the system

$$\frac{\partial H_\varepsilon(s,\Phi,\beta)}{\partial(\Phi,\beta)}|_{(s,\Phi_{\varepsilon,s},\beta_{\varepsilon,s})}[\Phi,c]=(\Theta,d)$$

if and only if $\phi=\bar\phi+\frac{d}{(U'_{\varepsilon,s},U'_{\varepsilon,s})_\varepsilon}U'_{\varepsilon,s}$, where $\bar\phi\in\mathcal{H}_\varepsilon$ ($\mathcal{H}_\varepsilon$ is the closed subset of $H^1_\varepsilon(I_{\varepsilon,s})$ defined in Lemma 3.3) and

$$\Big(\big(\Delta-\big(1+\Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}]\big)\big)^{-1}\big(S'_{\varepsilon,s}[U_{\varepsilon,s}+\phi_{\varepsilon,s}](\phi)-cZ_{\varepsilon,s}\big),\psi\Big)_\varepsilon=(\theta,\psi)_\varepsilon\ \ \forall\psi\in\mathcal{H}_\varepsilon, \tag{4.10}$$

where $\Theta(x)=\theta(|x|-\frac{s}{\varepsilon})$. By (4.9) we have $((\Delta-(1+\Gamma T_{\varepsilon,s}[U^2_{\varepsilon,s}]))^{-1}(h),\psi)_\varepsilon=-\langle h,\psi\rangle_\varepsilon$; hence (4.10) may be rewritten as

$$\begin{aligned}(\bar\phi,\psi)_\varepsilon-&p\langle(U_{\varepsilon,s}+\phi_{\varepsilon,s})^{p-1}_+\phi,\psi\rangle_\varepsilon+\Gamma\langle T_{\varepsilon,s}[\phi^2_{\varepsilon,s}+2U_{\varepsilon,s}\phi_{\varepsilon,s}]\phi,\psi\rangle_\varepsilon\\ &+2\Gamma\langle(U_{\varepsilon,s}+\phi_{\varepsilon,s})T_{\varepsilon,s}[(U_{\varepsilon,s}+\phi_{\varepsilon,s})\phi],\psi\rangle_\varepsilon=(\theta,\psi)_\varepsilon\ \ \forall\psi\in\mathcal{H}_\varepsilon.\end{aligned}$$

Once we know $\bar\phi$, the related c is given by the identity

$$\begin{aligned} d-&p\langle (U_{\varepsilon,s}+\phi_{\varepsilon,s})_+^{p-1}\phi, U'_{\varepsilon,s}\rangle_\varepsilon + \Gamma d'\langle T_{\varepsilon,s}[\phi_{\varepsilon,s}^2+2U_{\varepsilon,s}\phi_{\varepsilon,s}]\phi, U'_{\varepsilon,s}\rangle_\varepsilon \\ &+2\Gamma d'\langle (U_{\varepsilon,s}+\phi_{\varepsilon,s})T_{\varepsilon,s}[(U_{\varepsilon,s}+\phi_{\varepsilon,s})\phi], U'_{\varepsilon,s}\rangle_\varepsilon = c(U'_{\varepsilon,s},U'_{\varepsilon,s})_\varepsilon + (\theta, U'_{\varepsilon,s})_\varepsilon, \end{aligned}$$

where we have set $d' = \frac{d}{(U'_{\varepsilon,s},U'_{\varepsilon,s})_\varepsilon}$. According to Riesz's representation theorem, take $\mathcal{W}_{\varepsilon,t}(\bar\phi)$, $\bar\theta \in \mathcal{H}_\varepsilon$ such that

$$\begin{aligned} (\mathcal{W}_{\varepsilon,t}(\bar\phi),\psi)_\varepsilon =& -p\langle (U_{\varepsilon,t}+\phi_{\varepsilon,t})_+^{p-1}\bar\phi,\psi\rangle_\varepsilon + \Gamma\langle T_\varepsilon[\phi_{\varepsilon,t}^2+2U_{\varepsilon,t}\phi_{\varepsilon,t}]\bar\phi,\psi\rangle_\varepsilon \\ &+2\Gamma\langle (U_{\varepsilon,t}+\phi_{\varepsilon,t})T_\varepsilon[(U_{\varepsilon,t}+\phi_{\varepsilon,t})\bar\phi],\psi\rangle_\varepsilon \quad \forall\psi\in\mathcal{H}_\varepsilon, \end{aligned}$$

$$\begin{aligned} (\bar\theta,\psi)_\varepsilon =& -pd'\langle (U_{\varepsilon,t}+\phi_{\varepsilon,t})_+^{p-1}U'_{\varepsilon,t},\psi\rangle + \Gamma d'\langle T_\varepsilon[\phi_{\varepsilon,t}^2+2U_{\varepsilon,t}\phi_{\varepsilon,t}]U'_{\varepsilon,t},\psi\rangle_\varepsilon \\ &+2\Gamma d'\langle (U_{\varepsilon,t}+\phi_{\varepsilon,t})T_\varepsilon[(U_{\varepsilon,t}+\phi_{\varepsilon,t})U'_{\varepsilon,t}],\psi\rangle_\varepsilon \quad \forall\psi\in\mathcal{H}_\varepsilon. \end{aligned}$$

Then problem (4.10) consists in finding $\bar\phi \in \mathcal{H}_\varepsilon$ such that

$$\bar\phi + \mathcal{W}_\varepsilon(\bar\phi) = \theta - \bar\theta. \tag{4.11}$$

Since $\|\phi_{\varepsilon,s}\|_* \le \varepsilon^\sigma$, combining the definition of $\mathcal{W}_\varepsilon$ with that of $\mathcal{K}_\varepsilon$ (see Lemma 3.3), when $\varepsilon \to 0$ we have

$$\mathcal{W}_\varepsilon - \mathcal{K}_\varepsilon \to 0.$$

Since we have proved that $I+\mathcal{K}_\varepsilon$ is invertible, then the theory of the linear operator assures the invertibility of $I+\mathcal{W}_\varepsilon$ for small ε. This concludes the proof of the lemma. □

5. The reduced energy functional: Proof of Theorem 1.1. For every $s \in [s_1,s_2]$ set

$$v_{\varepsilon,s}(x) = U_{\varepsilon,s}\Big(|x|-\frac{s}{\varepsilon}\Big) + \phi_{\varepsilon,s}\Big(|x|-\frac{s}{\varepsilon}\Big),$$

where $\phi_{\varepsilon,s}$ has been constructed in Lemma 4.1, and consider the function

$$K_\varepsilon : [s_1,s_2] \to \mathbb{R}, \quad K_\varepsilon(s) := \frac{\varepsilon^2}{4\pi}E_\varepsilon[v_{\varepsilon,s}].$$

First we provide the following estimate.

Lemma 5.1. *For $s \in [s_1,s_2]$, we have*

$$K_\varepsilon(s) = \frac{1}{8(p+1)}\frac{\int_{\mathbb{R}} w^{p+1}dy}{(\int_{\mathbb{R}} w^2dy)^2}\rho(t(s)) + o(1), \tag{5.1}$$

where $\rho(t)$ and $t(s)$ have been defined in Lemma 2.2.

Proof. We compute

$$\begin{aligned} &K_\varepsilon(s) \\ &= \int_{-\frac{s}{\varepsilon}}^{+\infty}\left[\frac12|(U_{\varepsilon,s}+\phi_{\varepsilon,s})'|^2 + \frac12|U_{\varepsilon,s}+\phi_{\varepsilon,s}|^2 - \frac{1}{p+1}(U_{\varepsilon,s}+\phi_{\varepsilon,s})_+^{p+1}\right](s+\varepsilon y)^2dy \\ &\quad + \frac{\Gamma}{4}\int_{-\frac{s}{\varepsilon}}^{\infty}(U_{\varepsilon,s}+\phi_{\varepsilon,s})^2T_{\varepsilon,s}[(U_{\varepsilon,s}+\phi_{\varepsilon,s})^2](s+\varepsilon y)^2dy \\ &= \frac{s^2}{2}\int_{\mathbb{R}}|w_s'|^2dy + \frac{s^2}{2}\int_{\mathbb{R}}w_s^2dy - \frac{s^2}{p+1}\int_{\mathbb{R}}w_s^{p+1}dy + \frac{s^2}{4}t(s)\int_{\mathbb{R}}w_s^2dy + o(1), \end{aligned}$$

where we have used (2.8), (3.2), and the estimates $\|\phi_{\varepsilon,s}\|_*$, $(\phi_{\varepsilon,s},\phi_{\varepsilon,s})_\varepsilon \le \varepsilon^\sigma$ given by Lemma 4.1. Now we use (2.9) to obtain

$$\begin{aligned}
K_\varepsilon(s) &= s^2\frac{(3p-7)t(s)+4(p-1)}{8(p+1)(1+t(s))}\int_{\mathbb{R}} w_s^{p+1}dy + o(1)\\
&= s^2\frac{(3p-7)t(s)+4(p-1)}{8(p+1)}(1+t(s))^{\frac{5-p}{2(p-1)}}\int_{\mathbb{R}} w^{p+1}dy + o(1)\\
&= s^2\frac{\rho(t(s))}{8t(s)^2(p+1)}(1+t(s))^{\frac{5-p}{p-1}}\int_{\mathbb{R}} w^{p+1}dy + o(1)\\
&= \frac{\rho(t(s))}{8(p+1)}\frac{\int_{\mathbb{R}} w^{p+1}dy}{\left(\Gamma\int_{\mathbb{R}} w^2dy\right)^2} + o(1). \qquad \square
\end{aligned}$$

COROLLARY 5.2. *For ε sufficiently small, the function $s\in[s_1,s_2]\mapsto K_\varepsilon(s)$ has a minimum $s_\varepsilon = s_0 + o(1)$.*

Proof. This follows immediately from the previous lemma. By Lemma 2.2 the function $\rho(t(s))$ has a unique local minimum point $s_0\in[s_1,s_2]$ and, moreover, s_0 is nondegenerate; thus, by (5.1) and by the continuity of $K_\varepsilon(s)$, for ε small enough the minimum point of K_ε is attained at some s_ε which tends to s_0 as $\varepsilon\to 0$. $\square$

Proof of Theorem 1.1. Fix $\varepsilon>0$ sufficiently small such that Lemma 4.1 and Lemma 4.2 hold for $\varepsilon\in(0,\varepsilon_0)$. According to Lemma 4.1, for every $\varepsilon\in(0,\varepsilon_0)$ and $s\in[s_1,s_2]$ the function $v_{\varepsilon,s}$ solves the equation in $\mathbb{R}^3$ as follows:

$$\Delta v_{\varepsilon,s}(x) - v_{\varepsilon,s}(x) + (v_{\varepsilon,s})_+^p(x) - \varepsilon\Gamma(-\Delta)^{-1}[v_{\varepsilon,s}^2](x) = \beta_{\varepsilon,s}Z_{\varepsilon,s}\Big(|x|-\frac{s}{\varepsilon}\Big). \tag{5.2}$$

Set $u_\varepsilon = v_{\varepsilon,s_\varepsilon}$, where $s_\varepsilon\in(s_1,s_2)$ is the minimum point of K_ε, according to Corollary 5.2. Then we have

$$\frac{d}{ds}E_\varepsilon(v_{\varepsilon,s})_{|_{s=s^\varepsilon}} = 0; \tag{5.3}$$

by using the C^1 regularity of the map $s\in[s_1,s_2]\mapsto\Phi_{\varepsilon,s}\in H_r^1(\mathbb{R}^3)$, (5.3) can be rewritten as

$$\int_{\mathbb{R}^3}\left[\nabla u_\varepsilon\nabla\frac{d}{ds}v_{\varepsilon,s} + u_\varepsilon\frac{d}{ds}v_{\varepsilon,s} - (u_\varepsilon)_+^p\frac{d}{ds}v_{\varepsilon,s} + \varepsilon\Gamma u_\varepsilon(-\Delta)^{-1}[u_\varepsilon^2]\frac{d}{ds}v_{\varepsilon,s}\right]dx\bigg|_{s=s^\varepsilon} = 0,$$

which is equivalent, by (5.2), to

$$\beta_{\varepsilon,s_\varepsilon}\int_{\mathbb{R}^3} Z_{\varepsilon,s_\varepsilon}\Big(|x|-\frac{s_\varepsilon}{\varepsilon}\Big)\frac{d}{ds}v_{\varepsilon,s}dx\bigg|_{s=s_\varepsilon} = 0,$$

that is,

$$\beta_{\varepsilon,s_\varepsilon}\int_{I_{\varepsilon,s}} Z_{\varepsilon,s_\varepsilon}(y)\frac{d}{ds}(v_{\varepsilon,s})\bigg|_{s=s_\varepsilon}\Big(y+\frac{s_\varepsilon}{\varepsilon}\Big)(s_\varepsilon+\varepsilon y)^2dy = 0. \tag{5.4}$$

Notice that, by (2.8), we easily compute

$$\begin{aligned}
&\frac{d}{ds}\Big[U_{\varepsilon,s}\Big(\cdot-\frac{s}{\varepsilon}\Big)\Big]\Big(y+\frac{s}{\varepsilon}\Big)\\
&\quad= \frac{t'(s)}{(p-1)(1+t(s))}w_s(y) + w_s'(y)\left(\frac{t'(s)y}{2\sqrt{1+t(s)}} - \frac{\sqrt{1+t(s)}}{\varepsilon}\right) + o(\varepsilon)e^{-\mu\langle y\rangle}\\
&\quad= -\frac{\sqrt{1+t(s)}}{\varepsilon}w_s'(y) + O(1)e^{-\mu\langle y\rangle}.
\end{aligned} \tag{5.5}$$

Differentiating the equation $\int_{\mathbb{R}^3} \Phi_{\varepsilon,s} Z_{\varepsilon,s}(|x|-\frac{s}{\varepsilon})dx = \varepsilon^{-2}\langle \phi_{\varepsilon,s}, Z_{\varepsilon,s}\rangle_\varepsilon = 0$ with respect to s, we get

$$\int_{I_{\varepsilon,s}} Z_{\varepsilon,s}\frac{d}{ds}(\Phi_{\varepsilon,s})\Big(y+\frac{s}{\varepsilon}\Big)(s+\varepsilon y)^2 dy = -\int_{I_{\varepsilon,s}} \phi_{\varepsilon,s}\frac{d}{ds}\Big[Z_{\varepsilon,s}\Big(\cdot-\frac{s}{\varepsilon}\Big)\Big]\Big(y+\frac{s}{\varepsilon}\Big)(s+\varepsilon y)^2 dy.$$

By computing similarly as in (5.5) we get

$$\frac{d}{ds}\Big[Z_{\varepsilon,s}\Big(\cdot-\frac{s}{\varepsilon}\Big)\Big]\Big(y+\frac{s}{\varepsilon}\Big) = O(\varepsilon^{-1})e^{-\mu\langle y\rangle},$$

by which

$$\int_{I_{\varepsilon,s}} Z_{\varepsilon,s}\frac{d}{ds}(\Phi_{\varepsilon,s})\Big(y+\frac{s}{\varepsilon}\Big)(s+\varepsilon y)^2 dy = O(\varepsilon^{\sigma-1}). \tag{5.6}$$

Combining (3.8), (5.5), and (5.6) we obtain

$$\int_{I_{\varepsilon,s}} Z_{\varepsilon,s}\frac{d}{ds}(v_{\varepsilon,s})\Big(y+\frac{s}{\varepsilon}\Big)(s+\varepsilon y)^2 dy = -\frac{s^2 p\sqrt{1+t(s)}}{\varepsilon}\int_{\mathbb{R}} w_s^{p-1}(w_s')^2 dy + O(\varepsilon^{\sigma-1}).$$

In particular, $\int_{I_{\varepsilon,s_\varepsilon}} Z_{\varepsilon,s_\varepsilon}\frac{d}{ds}(v_{\varepsilon,s})\big|_{s=s_\varepsilon}\big(y+\frac{s_\varepsilon}{\varepsilon}\big)(s_\varepsilon+\varepsilon y)^2 dy \neq 0$ for ε sufficiently small, then (5.4) implies $\beta_{\varepsilon,s_\varepsilon}=0$. Hence u_ε solves the equation

$$\Delta u_\varepsilon - u_\varepsilon + (u_\varepsilon)_+^p - \varepsilon\Gamma u_\varepsilon(-\Delta)^{-1}[u_\varepsilon^2] = 0 \text{ in } \mathbb{R}^3. \tag{5.7}$$

By multiplying both members of (5.7) by $(u_\varepsilon)_-$ and integrating by parts we get

$$\int_{\mathbb{R}^3}|\nabla(u_\varepsilon)_-|^2 dx + \int_{\mathbb{R}^3}|(u_\varepsilon)_-|^2 + \varepsilon\Gamma\int_{\mathbb{R}^3}(u_\varepsilon)_-^2(-\Delta)^{-1}[u_\varepsilon^2]dx = 0,$$

by which $(u_\varepsilon)_-=0$. From the strong maximum principle it follows that $u_\varepsilon>0$. Hence u_ε and $\psi_\varepsilon=\varepsilon(-\Delta)^{-1}[u_\varepsilon^2]$ actually solve the system (2.1). In order to obtain (2) of Theorem 1.1, using (2.8) and the estimate $\|\phi_{\varepsilon,s}\|_*\leq\varepsilon^\sigma$ we obtain

$$\begin{aligned}\frac{1}{\sqrt{\varepsilon}}u_\varepsilon\Big(\frac{r}{\varepsilon}\Big) &= \frac{1}{\sqrt{\varepsilon}}U_{\varepsilon,s_\varepsilon}\Big(\frac{r-s_\varepsilon}{\varepsilon}\Big)+\frac{1}{\sqrt{\varepsilon}}\phi_{\varepsilon,s_\varepsilon}\Big(\frac{r-s_\varepsilon}{\varepsilon}\Big)\\ &= \frac{1}{\sqrt{\varepsilon}}(1+t(s_\varepsilon))^{\frac{1}{p-1}}w\Big(\sqrt{1+t(s_\varepsilon)}\frac{r-s_\varepsilon}{\varepsilon}\Big)+o(1)\exp\Big(-\mu\frac{|r-s_\varepsilon|}{\varepsilon}\Big).\end{aligned}$$

Finally, notice that for every $r,\rho\in(0,+\infty)$ it results in $|G\big(r,\rho\big)-G(r,s_\varepsilon)|\leq|\rho-s_\varepsilon|\frac{1}{s_\varepsilon}\Big(2+\frac{\rho}{s_\varepsilon}\Big)G(r,s_\varepsilon)$, by which

$$\begin{aligned}\psi_\varepsilon\Big(\frac{r}{\varepsilon}\Big) &= \frac{1}{\varepsilon}\int_0^{+\infty}G\big(r,\rho\big)u_\varepsilon^2\Big(\frac{\rho}{\varepsilon}\Big)d\rho\\ &= \frac{1}{\varepsilon}G(r,s_\varepsilon)\int_0^{+\infty}u_\varepsilon^2\Big(\frac{\rho}{\varepsilon}\Big)d\rho+O(1)G(r,s_\varepsilon)\frac{1}{\varepsilon s_\varepsilon}\int_0^{+\infty}|\rho-s_\varepsilon|\Big(2+\frac{\rho}{s_\varepsilon}\Big)u_\varepsilon^2\Big(\frac{\rho}{\varepsilon}\Big)d\rho\\ &= G(r,s_\varepsilon)\left((1+t(s_\varepsilon))^{\frac{5-p}{2(p-1)}}\int_{\mathbb{R}}w^2 d\rho+o(1)\right).\end{aligned}$$

Taking into account (2.2), Theorem 1.1 is proved. ∎

REMARK 5.3. *In order to better understand the presence of the critical power* $\frac{11}{7}$*, it could be useful to look at the system* (1.1) *in higher dimension* $N \geq 3$*, apart from the physical model under consideration. Proceeding similarly as in the case* $N = 3$*, we can construct the family of functions* $v^N_{\varepsilon,s}$ *lying in the normal direction of the approximated solution surface, and we can prove that the following asymptotic expansion of the energy holds:*

$$\frac{\varepsilon^2}{\omega_N} E_\varepsilon[v^N_{\varepsilon,s}] = \frac{1}{8(p+1)} \frac{\int_{\mathbb{R}} w^{p+1} dy}{(\int_{\mathbb{R}} w^2 dy)^2} s^{N-3} \rho(t(s)) + o(1),$$

where ω_N *denotes the surface measure of the unit sphere of* $\mathbb{R}^N$*. Then, by using Lemma* 2.2*, we deduce that the dimension-dependent critical number appearing in higher dimension is given by* $\frac{7N-10}{3N-2}$ *and, repeating the same computations as in* $N = 3$*, for every* $1 < p < \frac{7N-10}{3N-2}$ *we can prove the existence of a family of solutions concentrating on the sphere whose radius is given by the unique minimum point* s_0 *of the function* $s^{N-3}\rho(t(s))$ *in* $(0, s(\hat{t}))$*.*

REMARK 5.4. *It is possible to prove the existence of radial solutions to the system* (1.1) *for every* $1 < p < 5$ *by a simple rescaling argument; indeed, it is sufficient to minimize the functional*

$$T(u) = \frac{1}{2} \int_{\mathbb{R}^3} \left(|\nabla u|^2 + u^2\right) dx + \frac{\omega}{4} \int_{\mathbb{R}^3} u^2 (-\Delta)^{-1} [4\pi\omega u^2]\, dx$$

over the manifold

$$\mathcal{M} := \left\{ u \in H^1_r \;\Big|\; \int_{\mathbb{R}^3} |u|^{p+1} dx = 1 \right\}.$$

According to the compact injection $H^1_r \hookrightarrow L^p$ *for* $1 < p < 5$*,* $\mathcal{M}$ *is a compact manifold, while* T *is weakly lower semicontinuous on* H^1_r*. Hence we easily get the existence of a minimizing function* u*. The constraint causes a Lagrange multiplier to appear, and one obtains that* u *solves* $-\Delta u + u + \omega u(-\Delta)^{-1}[4\pi\omega u^2] = \gamma |u|^{p-1} u$*. We notice that since* $T(u) = T(|u|)$*, we may assume that* $u \geq 0$*; then, from the strong maximum principle,* $u > 0$*. Setting* $v_\hbar(x) = \hbar^{-1} u(\frac{x}{\hbar})$ *and* $\phi_\hbar(x) = (-\Delta)^{-1}[4\pi\omega v_\hbar^2](x) = (-\Delta)^{-1}[4\pi\omega u^2](\frac{x}{\hbar})$*, we obtain that* $(v_\hbar, \phi_\hbar)$ *solves* (1.1) *with* $\gamma_\hbar = \gamma \hbar^{p-1}$*.*

LACK OF COMPACTNESS IN TWO-SCALE CONVERGENCE*

MARC BRIANE† AND JUAN CASADO-DÍAZ‡

Abstract. This article deals with the links between compensated compactness and two-scale convergence. More precisely, we ask the following question: Is the div-curl compactness assumption sufficient to pass to the limit in a product of two sequences which two-scale converge with respect to the pair of variables $(x, x/\varepsilon)$? We reply in the negative. Indeed, the div-curl assumption allows us to control oscillations which are faster than $1/\varepsilon$ but not the slower ones.

Key words. two-scale convergence, compensated compactness, counterexample

1. Introduction. In order to study the asymptotic behavior of periodic problems arising in homogenization theory, Nguetseng introduced in [7] (see also Allaire [1]) the notion of two-scale convergence:

Let Ω be a bounded open subset of $\mathbb{R}^d$, $Y := (-\frac{1}{2}, \frac{1}{2})^d$, and let M be a positive integer. A bounded sequence u_ε in $L^1_{\text{loc}}(\Omega)^M$ two-scale converges to a function $\hat{u}$ in $L^1_{\text{loc}}(\Omega \times \mathbb{R}^d)^M$ and Y-periodic with respect to the last variable if, for any $\psi \in C_c^\infty(\Omega, C_\#^\infty(Y))^M$, we have

$$\lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(x)\, \psi\left(x, \frac{x}{\varepsilon}\right) dx = \int_\Omega \int_Y \hat{u}(x,y)\, \psi(x,y)\, dx\, dy. \tag{1.1}$$

A compactness theorem due to Nguetseng [7] establishes that if u_ε is bounded in $L^p(\Omega)^M$, then there exists a subsequence of u_ε which two-scale converges to $\hat{u} \in L^p(\Omega; L^p_\#(Y))^M$.

Taking in (1.1) $\psi(x,y)$ independent of y, we deduce that if u_ε two-scale converges to $\hat{u}$, then it converges weakly in $L^p(\Omega)^M$ to $u := \int_Y \hat{u}(x,y)\, dy$. On the other hand, if u_ε strongly converges to u in $L^1(\Omega)^M$, then it also two-scale converges to u. Therefore two-scale convergence is stronger than weak convergence and weaker than the strong one. Moreover, it provides an expression of the limit of the product $u_\varepsilon\, \psi(x, \frac{x}{\varepsilon})$ of (1.1) in which each term only weakly converges.

In the periodic homogenization we usually deal with a sequence u_ε which is not only bounded in $L^p(\Omega)^M$ but whose some combinations of its derivatives are also bounded. In this context, let us recall that if u_ε converges weakly in $W^{1,p}(\Omega)^M$, for $1 \le p < +\infty$, to a function u, then it converges strongly in $L^p_{\text{loc}}(\Omega)^M$ ($L^p(\Omega)^M$ if Ω smooth) and so u_ε two-scale converges to u. Then we can conjecture that the classical results of the compensated compactness theory due to Murat and Tartar (see, e.g., [6] and [8]), and in particular the div-curl theorem, still hold true when we replace the weak convergence in $L^p(\Omega)^M$ with two-scale convergence. In fact we have the following result:

PROPOSITION 1.1. *Let $(Y, Y_1, \dots, Y_n)$ be $(n+1)$ parallelotops of $\mathbb{R}^d$ of Lebesgue measure equal to 1, and let U, V be two vector-valued functions in $L^2(\Omega; C_\#(Y \times Y_1 \times \cdots \times Y_n))^d$, where $C_\#(Y \times Y_1 \times \cdots \times Y_n)$ denotes the set of the continuous functions on $(\mathbb{R}^d)^{n+1}$ which are Y-periodic with respect to the variable y and Y_k-periodic with respect to the variable y_k for any $k = 1, \dots, n$. Let $\varepsilon_k = \varepsilon_k(\varepsilon)$ for $k = 1, \dots, n$ be n well-ordered scales such that*

$$\lim_{\varepsilon \to 0} \frac{\varepsilon_1}{\varepsilon} = \lim_{\varepsilon \to 0} \frac{\varepsilon_{k+1}}{\varepsilon_k} = 0 \quad \textit{for any } k = 1, \dots, n-1. \tag{1.2}$$

Consider the vector-valued sequences u_ε and v_ε defined by

$$u_\varepsilon(x) := U\left(x, \frac{x}{\varepsilon}, \frac{x}{\varepsilon_1}, \dots, \frac{x}{\varepsilon_n}\right) \quad \textit{and} \quad v_\varepsilon(x) := V\left(x, \frac{x}{\varepsilon}, \frac{x}{\varepsilon_1}, \dots, \frac{x}{\varepsilon_n}\right), \tag{1.3}$$

and assume that

$$\operatorname{div} u_\varepsilon \textit{ is compact in } H^{-1}(\Omega) \quad \textit{and} \quad \operatorname{curl} v_\varepsilon \textit{ is compact in } H^{-1}(\Omega)^{d\times d}. \tag{1.4}$$

Then the two-scale limits $\hat{u}$ of u_ε, $\hat{v}$ of v_ε, and $\hat{w}$ of $u_\varepsilon \cdot ? v_\varepsilon$ exist and satisfy

$$\hat{w} = \hat{u} \cdot \hat{v}. \tag{1.5}$$

Proposition 1.1 shows that the div-curl condition (1.4) implies some compactness in the two-scale convergence process (as in the classical case) when the oscillations of the sequences are faster than $\frac{1}{\varepsilon}$. Unfortunately, this is not the case for general sequences, particularly when the oscillations are slower than $\frac{1}{\varepsilon}$. This assertion follows from the following theorem, which is the main result of the present paper:

THEOREM 1.2. *Assume that $d \geq 2$. Then there exist two functions $U, V \in C^\infty_\#(2Y)^d$ such that the sequence $u_\varepsilon(x) := U(\frac{x}{\varepsilon})$ is divergence-free, the sequence $v_\varepsilon(x) := V(\frac{x}{\varepsilon})$ is curl-free, but the two-scale limits of u_ε, v_ε, and $u_\varepsilon \cdot v_\varepsilon$ do not satisfy* (1.5).

The key ingredient of this counterexample is that 2-periodic functions are considered although the test functions are 1-periodic.

In order to understand the lack of compactness in two-scale convergence, let us recall the equivalence between the two-scale convergence theory and the method introduced by Arbogast, Douglas, and Hornung [3] to study the oscillations of a sequence u_ε in $L^1_{\text{loc}}(\mathbb{R}^d)^M$. Their method consists in introducing the function $\hat{u}_\varepsilon : \mathbb{R}^d \times Y \to \mathbb{R}^M$ defined by

$$\hat{u}_\varepsilon(x, y) = \sum_{k \in \mathbb{Z}^d} 1_{\varepsilon k + \varepsilon Y}(x)\, u_\varepsilon(\varepsilon k + \varepsilon y). \tag{1.6}$$

The equivalence between the two approaches is then given by the following result (see, e.g., [5] and [4]):

THEOREM 1.3. *Assume that u_ε is bounded in $L^p(\Omega)^M$, with $1 < p < +\infty$. Then $\hat{u}_\varepsilon$ converges weakly to $\hat{u}$ in $L^p(\Omega; L^p(Y))^M$ if and only if u_ε two-scale converges to $\hat{u}$.*

The functions $\hat{u}_\varepsilon(x, y)$ are not continuous with respect to the variable x. If a combination of derivatives of u_ε is bounded, we also get a bound for the same combination of derivatives with respect to the variable y of $\hat{u}_\varepsilon$ but not with respect to the variable x. This explains the lack of compactness in two-scale convergence.

2. Proof of the results. In this section we prove Proposition 1.1 and Theorem 1.2.

Proof of Proposition 1.1. We follow the multiscale procedure of [2]. Thanks to the separation of scales (1.2) the sequences u_ε, v_ε, and $u_\varepsilon \cdot v_\varepsilon$, respectively, two-scale converge to $\hat{u} := \int_{Y_1} \cdots \int_{Y_n} U$, $\hat{v} := \int_{Y_1} \cdots \int_{Y_n} V$, and $\hat{w} := \int_{Y_1} \cdots \int_{Y_n} U \cdot V$. Putting test functions of type $\varepsilon_k\, \Phi(x, \frac{x}{\varepsilon}, \frac{x}{\varepsilon_1}, \dots, \frac{x}{\varepsilon_k})$ from $k = n$ to 1 in the div-curl assumption (1.4) implies that

$$\operatorname{div}_{y_k} \left(\int_{Y_{k+1}} \cdots \int_{Y_n} U \right) = 0 \text{ and } \operatorname{curl}_{y_k} \left(\int_{Y_{k+1}} \cdots \int_{Y_n} V \right) = 0 \quad \text{for } k = 1, \dots, n,$$

whence, integrating by parts the product of $\int_{Y_{k+1}} \cdots \int_{Y_n} U$ and $\int_{Y_{k+1}} \cdots \int_{Y_n} V$ (which is equal to the gradient in y_k of a periodic function plus a function depending only on the other variables $y_1, \dots, y_{k-1}$) successively from $k = n$ to 1, yields

$$\hat{w} = \int_{Y_1} \cdots \int_{Y_n} U \cdot V = \left(\int_{Y_1} \cdots \int_{Y_n} U \right) \cdot \left(\int_{Y_1} \cdots \int_{Y_n} V \right) = \hat{u} \cdot \hat{v},$$

which implies the desired equality (1.5).

Proof of Theorem 1.2. Let us consider two vector-valued functions $\Phi, \Psi \in C_c^\infty(Y)^d$ such that $\operatorname{div} \Phi = 0$, $\operatorname{curl} \Psi = 0$, and $\Phi \cdot \Psi \neq 0$ (this is possible since $d > 1$), which we extend to $\mathbb{R}^d$ by Y-periodicity. Let $\eta : \mathbb{R} \to \mathbb{R}$ be the 1-periodic function $\eta := \sum_{i \in \mathbb{Z}} 1_{(i - \frac{1}{4}, i + \frac{1}{4})}$ and let us define the following sequences

$$u_\varepsilon(x) := \eta \left(\frac{x_1}{2\,\varepsilon} \right) \Phi \left(\frac{x}{\varepsilon} \right) \quad \text{and} \quad v_\varepsilon(x) := \eta \left(\frac{x_1}{2\,\varepsilon} \right) \Psi \left(\frac{x}{\varepsilon} \right).$$

Since in each cube $\varepsilon k + \varepsilon Y$, for $k \in \mathbb{Z}^d$, $\eta(\frac{x_1}{2\,\varepsilon})$ is constant, and $\Phi(\frac{x}{\varepsilon})$, $\Psi(\frac{x}{\varepsilon})$ vanish on the boundary of $\varepsilon k + \varepsilon Y$, we have $u_\varepsilon, v_\varepsilon \in C^\infty(\mathbb{R}^N)$, $\operatorname{div} u_\varepsilon = 0$, and $\operatorname{curl} v_\varepsilon = 0$ in $\mathbb{R}^d$. Moreover, since $\eta(\frac{x_1}{2\,\varepsilon})$ is constant in $\varepsilon k + \varepsilon Y$ for any $k \in \mathbb{Z}^d$, it is invariant by the transformation (1.6). So we get

$$\hat{u}_\varepsilon(x, y) = \eta \left(\frac{x_1}{2\,\varepsilon} \right) \Phi(y), \quad \hat{v}_\varepsilon(x, y) = \eta \left(\frac{x_1}{2\,\varepsilon} \right) \Psi(y), \quad \widehat{u_\varepsilon \cdot v_\varepsilon}(x, y) = \eta^2 \left(\frac{x_1}{2\,\varepsilon} \right) \Phi(y) \cdot \Psi(y).$$

By Theorem 1.3 the two-scale limits $\hat{u}$ of u_ε, $\hat{v}$ of v_ε, and $\hat{w}$ of $u_\varepsilon \cdot v_\varepsilon$ are thus given by

$$\hat{u}(x, y) = \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} \eta(s)\, ds \right) \Phi(y) = \frac{1}{2}\, \Phi(y), \quad \hat{v}(x, y) = \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} \eta(s)\, ds \right) \Psi(y) = \frac{1}{2}\, \Psi(y),$$
$$\text{and} \quad \hat{w}(x, y) = \left(\int_{-\frac{1}{2}}^{\frac{1}{2}} \eta^2(s)\, ds \right) \Phi(y) \cdot \Psi(y) = \frac{1}{2}\, \Phi(y) \cdot \Psi(y),$$

whence $\hat{w} \neq \hat{u} \cdot \hat{v}$.

UNIVERSAL BOUNDS ON COARSENING RATES FOR MEAN-FIELD MODELS OF PHASE TRANSITIONS*

SHIBIN DAI† AND ROBERT L. PEGO‡

Abstract. We prove one-sided universal bounds on coarsening rates for two kinds of mean-field models of phase transitions, one with a coarsening rate $l \sim t^{1/3}$ and the other with $l \sim t^{1/2}$. Here l is a characteristic length scale. These bounds are both proved by following a strategy developed by Kohn and Otto [*Comm. Math. Phys.*, 229 (2002), pp. 375–395]. The $l \sim t^{1/2}$ rate is proved using a new dissipation relation which extends the Kohn–Otto method. In both cases, the dissipation relations are subtle and their proofs are based on a residual lemma (Lagrange identity) for the Cauchy–Schwarz inequality.

1. Introduction.

In the late stages of heterogeneously nucleated phase transitions, a two-phase mixture is created, composed of particles of one phase dispersed in a matrix of the other. Initially the particles are small and their total surface area is large. According to thermodynamics, the system evolves in order to decrease the total surface area and conserve the total mass or volume of the particles. Smaller particles shrink and disappear and larger ones grow. As a result, the typical length scale that characterizes the particle size increases. It is widely observed that the length scale behaves as a temporal power law.

In this paper, we will try to give this power-law behavior a rigorous mathematical explanation in the context of mean-field models. In mean-field models, particles exchange mass by some interaction through a mean field $\theta(t)$ which is determined as a function of time t by the conservation of mass. There are many mechanisms that can dominate the mass transfer process [15]. We will consider two of them in this paper that correspond to two kinds of mean-field models with different power-law behaviors.

In the first model, particle growth is controlled by bulk or volume diffusion, with or without kinetic drag at the interface. Each particle radius R obeys the growth law

$$\dot{R} = \frac{1}{R+\beta}\left(\theta(t) - \frac{1}{R}\right), \tag{1.1}$$

where $\beta \geq 0$ is a constant. The particle size distribution $f(t, R)$ satisfies the transport equation

$$\partial_t f + \partial_R \left(\frac{1}{R+\beta}\left(\theta - \frac{1}{R}\right) f\right) = 0. \tag{1.2}$$

To conserve the total mass, the mean field θ satisfies

$$\theta(t) = \frac{\int_0^\infty (R+\beta)^{-1} R^{n-2} f(t,R)\, dR}{\int_0^\infty (R+\beta)^{-1} R^{n-1} f(t,R)\, dR}, \tag{1.3}$$

where n is the dimension of space. When $\beta = 0$, (1.1)–(1.3) is the classical model by Lifshitz and Slyozov [9] and Wagner [16]. Equation (1.1) is an approximation to the Mullins–Sekerka sharp-interface model with a modified Gibbs–Thomson law in the situation in which the particles are sparsely located in a domain Ω:

$$-\Delta u = 0 \quad \text{outside the particles,} \tag{1.4}$$

$$n \cdot \nabla u = V \quad \text{on } \Gamma, \tag{1.5}$$

$$u = \kappa + \beta V \quad \text{on } \Gamma. \tag{1.6}$$

Here Γ is the boundary of the particles, u is a chemical potential, n is the outer normal to Γ, κ is the mean curvature, and V is the normal velocity of Γ. Note that (1.6) is the Gibbs–Thomson law modified by a kinetic drag term βV. In [10, 11], Niethammer rigorously derived the model (1.1)–(1.3) in ^{3} for $\beta = 0$ and $\beta > 0$, respectively, from a model similar to (1.4)–(1.6) under the condition that the total capacity of the particles was small.

The second model arises formally by taking $\beta \to \infty$ after rescaling time by β. In this model, particle growth is controlled by the attachment reaction at the interface [1]. Now each particle radius R obeys the law

$$\dot{R} = \theta(t) - \frac{1}{R}. \tag{1.7}$$

The corresponding transport equation of the particle size distribution becomes

$$\partial_t f + \partial_R\left(\left(\theta - \frac{1}{R}\right) f\right) = 0. \tag{1.8}$$

In this case, the mean field θ satisfies

$$\theta(t) = \frac{\int_0^\infty R^{n-2} f(t,R)\, dR}{\int_0^\infty R^{n-1} f(t,R)\, dR}. \tag{1.9}$$

Equation (1.7) is the normalized mean curvature flow for a collection of spheres; i.e., it is a special case of the following sharp-interface model:

$$V = -\kappa + \frac{1}{|\Gamma|} \int_\Gamma \kappa\, dS, \tag{1.10}$$

where $|\Gamma|$ is the total area of the particle surface, κ is the mean curvature of the particle surface, and V is the normal velocity of the particle surface.

As in many systems, the coarsening rates for these mean-field models can be predicted by heuristic reasoning based on scaling invariance. The models we are considering are invariant under the scalings

$$R = \eta \hat{R}, \quad t = \eta^3 \hat{t}, \quad \theta = \eta^{-1} \hat{\theta} \quad \text{for (1.1) if } \beta = 0; \tag{1.11}$$

$$R = \eta \hat{R}, \quad t = \eta^2 \hat{t}, \quad \theta = \eta^{-1} \hat{\theta} \quad \text{for (1.7).} \tag{1.12}$$

If one expects that over long times the behavior of the coarsening system will appear scale invariant in some rough or statistical sense, then this kind of scaling invariance suggests that a characteristic length scale $l(t)$ ought to satisfy $l(t) = \eta l(t/\eta^p)$ with $p = 3$ or 2, respectively, so that $l(t)$ will be given by a temporal power law

$$l(t) \sim t^{1/3} \quad \text{for (1.1)}, \tag{1.13}$$

$$l(t) \sim t^{1/2} \quad \text{for (1.7)}. \tag{1.14}$$

When $\beta \neq 0$, under the scaling (1.11) equation (1.1) keeps its form if β is replaced by $\widehat{\beta} = \beta/\eta$. Then (1.1) is not invariant since we assume β to be a constant. However, this suggests that as the length scale becomes large, the influence of kinetic drag can be neglected and should not influence the ultimate coarsening rate for the volume-diffusion–controlled growth model.

In three dimensions ($n = 3$), the classical Lifshitz–Slyozov–Wagner (LSW) theory suggests that the size distribution function approaches a universal self-similar solution where the critical radius $R_c = \theta^{-1}$ follows the temporal power law $R_c \sim t^{1/3}$. Such a power law is observed in experiments. However, Niethammer and Pego [12] proved that, mathematically, for solutions of (1.2) the size distribution function does not necessarily converge to the predicted universal similarity solution, and the long-time behavior need not be self-similar.

Thus, the question is whether anything can be said universally about the coarsening rate of solutions in classical LSW theory. We cannot expect all solutions to coarsen at the same rate. For example, if initially all the particles are of the same size, then the system does not coarsen at all. One would like to be able to show that the expected power-law behavior is typical in some sense. What is "typical" is not clear, but a related question is whether it is possible that some solutions coarsen faster than expected. We know of no heuristic reason that would prevent such behavior.

Recently, Kohn and Otto [6] introduced a powerful method to answer this question. They obtain rigorous, universally valid time-averaged upper bounds on coarsening rates, in the setting of Cahn–Hilliard equations, which are diffuse-interface models for phase transitions (see also [3, 7, 8] for subsequently related results). Kohn and Otto consider the standard Cahn–Hilliard equation, whose sharp-interface limit is the Mullins–Sekerka model (1.4)–(1.6) with $\beta = 0$, and the Cahn–Hilliard equation with degenerate mobility, whose sharp interface limit is the surface diffusion model. Scaling invariance suggests that these two models have coarsening rates $l \sim t^{1/3}$ and $l \sim t^{1/4}$, respectively. Define $⨍_0^T := \frac{1}{T}\int_0^T$ to indicate the time-averaged integral. The results of Kohn and Otto, in their simplest form, are estimates of the following forms:

(i) $⨍_0^T E^2(t)\, dt \geq C_2 ⨍_0^T (t^{-1/3})^2\, dt$ for $T \geq C_3 L(0)^3$ (standard Cahn–Hilliard);

(ii) $⨍_0^T E^3(t)\, dt \geq C_2 ⨍_0^T (t^{-1/4})^3\, dt$ for $T \geq C_3 L(0)^4$ (Cahn–Hilliard with degenerate mobility).

Here E is the volume-averaged free energy, which is a decreasing function of time and scales as inverse to length, L is a "length scale" that is dual to E, and C_2 and C_3 are positive constants that depend only on the dimension of space n. Thus, these estimates are time-averaged versions of $E \geq C_2 t^{-1/3}$ and $E \geq C_2 t^{-1/4}$, respectively, which correspond to upper bounds on the length scale E^{-1}. These results show that, in a time-averaged sense, it is impossible for solutions to coarsen at a rate faster than the expected power law.

Our goal in this paper is to prove universal time-averaged upper bounds on corresponding coarsening rates for the mean-field models—see (2.4) and (2.5) below.

Again, we find that no solution can coarsen at a rate faster than that expected from scaling. The mean-field models that we study have three aspects that distinguish them from those models considered in [3, 6, 7, 8]:

(i) Mean-field models concern the evolution of dilute systems; i.e., the second phase consists of only a small fraction of the whole mixture. Kohn and Otto's analysis for the Cahn–Hilliard equations breaks down in this extreme case.

(ii) There is no spatial information and hence no pattern scale in mean-field models. This requires a different definition and interpretation of the dual length scale L.

(iii) For the normalized mean curvature flow (1.10), there is no result available for the corresponding diffuse-interface model—the conserved Allen–Cahn equation (see [14] for an asymptotic analysis of this correspondence).

To handle these differences, we will need to define all relevant quantities in terms of the distribution of particle radii. For the interface-reaction–controlled model, we will establish a new dissipation relation that extends the Kohn–Otto method and enables us to prove bounds that correspond to a coarsening rate of the form $l \sim t^{1/2}$. The proof of the dissipation relations in both mean-field models requires a different technique from previous works. A key ingredient in our proofs is the use of residual lemma (Lagrange identity) for the Cauchy–Schwarz inequality to compare the dissipation rates of E and L.

2. Strategy and main results. Let us describe our strategy for obtaining bounds on coarsening rates for the mean-field models (1.2) and (1.8) and state our main results. We work at first with a collection of finitely many particles undergoing coarsening with growth laws (1.1) and (1.7), respectively, for each particle. Such a system of particles has a discrete size distribution. We will apply a strategy similar to that of Kohn and Otto [6] to get time-averaged bounds for such discrete systems, and then pass to limits in section 5 to establish the bounds for arbitrary size distributions that have finite $(n+1)$st moment.

Kohn and Otto's strategy involves two quantities that measure length scales and three key steps. The first quantity is a volume-averaged free energy or negative entropy that decreases with time and scales as inverse to length. The second quantity scales like length, but its physical interpretation is not as clear. What is important is that, in a sense to be made precise, the second quantity is dual to the first one while at the same time being controlled by it.

In our situation, thermodynamics suggests that a natural quantity that is decreasing is the surface energy, which is proportional to the total surface area S of all the particles. Analogous to the cases considered in [3, 6, 7, 8], we will consider a kind of volume average of the surface area, which gives a quantity scaling as inverse to length. Because the total volume V of the particles is conserved, it is reasonable to consider the ratio S/V. For a finite particle system, we therefore define

$$E := \frac{\sum R_i^{n-1}}{\sum R_i^n}, \tag{2.1}$$

where n is the dimension of space and the sum goes over all surviving particles. E can also be considered as the volume-weighted average of curvatures $\{1/R_i\}$. In sections 3 and 4, we will prove that E is indeed decreasing in both models considered.

We need a length scale L that is dual to E. Since radius is dual to curvature, we define L to be the volume-weighted average of the radii $\{R_i\}$, i.e.,

$$L := \frac{\sum R_i^{n+1}}{\sum R_i^n}. \tag{2.2}$$

The first step of the Kohn–Otto method is to establish an *interpolation inequality* that expresses the duality of E and L. With the definitions (2.1) and (2.2) this is easy. By the Cauchy–Schwarz inequality,

$$\sum R_i^n = \sum R_i^{(n-1)/2} R_i^{(n+1)/2} \leq \left(\sum R_i^{n-1} \sum R_i^{n+1}\right)^{1/2},$$

and this immediately yields the required interpolation inequality,

$$EL \geq 1. \tag{2.3}$$

The second step is to obtain a *dissipation inequality* that controls $\dot{L}$ in terms of $\dot{E}$. In sections 3 and 4 below, we will prove that

$$\begin{aligned} |\dot{L}|^2 &\leq C_1\,(-\dot{E}) \quad \text{for volume-diffusion–controlled growth (1.1)},\\ |\dot{L}|^2 &\leq D_1\,(-\dot{E})\,L \quad \text{for interface-reaction–controlled growth (1.7)}, \end{aligned}$$

where C_1 and D_1 are positive constants depending only on the dimension of space n. We remark that in the cases considered in [3, 6, 7, 8], the difficult part is proving the interpolation inequalities; the dissipation relations are rather easy to prove. By contrast, in the situation of the mean-field models considered here, under definitions (2.1) and (2.2) the interpolation inequality is a simple consequence of the Cauchy–Schwarz inequality and it is the dissipation relations that need careful treatment.

The third step is an ODE argument. For the case of volume-diffusion–controlled growth, Lemma 3 in [6] and the two inequalities $EL \geq 1$ and $|\dot{L}|^2 \leq C_1(-\dot{E})$ directly give us appropriate time-averaged bounds on coarsening rates. Those that involve only E, the volume-averaged surface area, take a simple form, saying that for any $1 < p < 3$ there exist positive constants C_2 and C_3, depending only on n, p, and nothing else, such that

$$\fint_0^T E(t)^p\,dt \geq C_2 \fint_0^T \left(t^{-1/3}\right)^p\,dt \quad \text{for} \quad T \geq C_3 L(0)^3. \tag{2.4}$$

This is exactly a time-averaged version of $E \geq t^{-1/3}$, which corresponds to an upper bound on the "length scale" E^{-1}.

For the case of interface-reaction–controlled growth, we will establish an ODE lemma in section 4 to show that the inequalities $EL \geq 1$ and $|\dot{L}|^2 \leq D_1 L(-\dot{E})$ give us appropriate time-averaged estimates. In particular, for any $1 < p < 2$ there exist positive constants D_2 and D_3, depending only on n, p, and nothing else, such that

$$\fint_0^T E(t)^p\,dt \geq D_2 \fint_0^T \left(t^{-1/2}\right)^p\,dt \quad \text{for} \quad T \geq D_3 L(0)^2. \tag{2.5}$$

This is a time-averaged version of $E \geq t^{-1/2}$.

Once these results for discrete systems are established, we will pass to the case of general size distributions in section 5 by applying the well-posedness and compactness results for a family of mean-field models established by Niethammer and Pego in [13].

All of our models under consideration are included in that work except for the two-dimensional (2D) volume-diffusion–controlled growth model with $\beta = 0$. Thus this case is not included in our main theorems on coarsening rates for general size distributions.

The results in [13] enable us to approximate a general distribution by a sequence of discrete ones. These results, together with an extended moment compactness result proved here in an appendix, enable us to take limits in the estimates for the discrete sequence. This leads to our main results on coarsening rates for general size distributions.

We consider such size distributions to belong to $\mathcal{P}_n$, the set of Borel probability measures on $[0,\infty)$ with finite nth moment. Topologically we regard $\mathcal{P}_n$ as a subset of the Banach space of finite Radon measures on $[0,\infty)$, which is dual to $C_0([0,\infty))$, the space of continuous functions on $[0,\infty)$ that vanish at infinity. A *measure-valued solution* of the transport equation (1.2) or (1.8) is a weak-star continuous map $t \mapsto \nu_t$ taking $[0,\infty) \to \mathcal{P}_n$ that is a solution in the sense of distributions on $(0,\infty)\times(0,\infty)$. Based on the results in [13], we will see that for each initial size distribution $\mu \in \mathcal{P}_n$, there is a unique measure-valued solution with initial value $\nu_0 = \mu$ that preserves the nth moment (total volume). The corresponding mean field is given for a.e. $t > 0$ by

$$\theta(t) = \int_0^\infty \frac{R^{n-2}}{R+\beta} d\nu_t(R) \Big/ \int_0^\infty \frac{R^{n-1}}{R+\beta} d\nu_t(R) \tag{2.6}$$

in the case of volume-diffusion–controlled growth and

$$\theta(t) = \int_0^\infty R^{n-2} d\nu_t(R) \Big/ \int_0^\infty R^{n-1} d\nu_t(R) \tag{2.7}$$

in the case of interface-reaction–controlled growth. The quantities corresponding to (2.1) and (2.2) are defined by

$$E(t) := \int_0^\infty R^{n-1}\, d\nu_t(R) \Big/ \int_0^\infty R^n\, d\nu_t(R), \tag{2.8}$$

$$L(t) := \int_0^\infty R^{n+1}\, d\nu_t(R) \Big/ \int_0^\infty R^n\, d\nu_t(R). \tag{2.9}$$

Our main results take the following form.

THEOREM 2.1 (volume-diffusion–controlled growth). *Let $n \geq 2$ be an integer and $\beta \geq 0$, with $\beta > 0$ if $n = 2$, and let p be real with $1 < p < 3$. Then there exist positive constants C_2 and C_3, depending on p, n, and nothing else, such that whenever ν is a measure-valued solution of the transport equation* (1.2) *and ν_0 has finite nth and $(n+1)$st moments, we have*

$$⨍_0^T E(t)^p\, dt \geq C_2 ⨍_0^T \left(t^{-1/3}\right)^p dt \quad \textit{for } T \geq C_3\, L(0)^3. \tag{2.10}$$

THEOREM 2.2 (interface-reaction–controlled growth). *Let $n \geq 2$ be an integer and let p be real with $1 < p < 2$. Then there exist positive constants D_2 and D_3, depending on p, n, and nothing else, such that whenever ν is a measure-valued solution of the transport equation* (1.8) *and ν_0 has finite nth and $(n+1)$st moments, we have*

$$⨍_0^T E(t)^p\, dt \geq D_2 ⨍_0^T \left(t^{-1/2}\right)^p dt \quad \textit{for } T \geq D_3\, L(0)^2. \tag{2.11}$$

3. Discrete systems I: Volume-diffusion–controlled growth. In this section, our aim is to prove the coarsening estimate (2.4) for any collection of finitely many spherical particles in ^{n} that undergoes coarsening controlled by volume diffusion with or without kinetic drag. The following growth law holds for each particle:

$$\dot{R}_i = \frac{1}{R_i + \beta}\left(\theta - \frac{1}{R_i}\right), \quad (1 \le i \le N(t)), \tag{3.1}$$

where R_i is the radius of the ith particle, $N(t)$ is the number of surviving particles at time t, θ is the mean field, and the dot denotes the time derivative.

By the conservation of total mass,

$$0 = \frac{d}{dt}\sum R_i^n = n\sum R_i^{n-1}\dot{R}_i = n\sum \frac{R_i^{n-1}}{R_i + \beta}\left(\theta - \frac{1}{R_i}\right). \tag{3.2}$$

Here the sum goes over all surviving particles. Thus

$$\theta = \frac{\sum (R_i + \beta)^{-1} R_i^{n-2}}{\sum (R_i + \beta)^{-1} R_i^{n-1}}. \tag{3.3}$$

The right-hand side of (3.1) is smooth as long as there is no particle disappearing. The conservation of total mass guarantees that the solution for (3.1) and (3.3) cannot blow up in finite time. So the solution is smooth and unique from time $t_0 = 0$ up to t_1 when some particles disappear. Restarting from t_1 with the remaining particles, we again get a smooth solution until a next time t_2 when some other particles disappear. In this way, we can find finitely many times $\{t_i\}$ such that the solution for (3.1) and (3.3) globally exists, is unique, and is smooth in each time interval $(t_i, t_{i+1}), i = 0, 1, \dots$.

By definition (2.1),

$$E = \frac{\sum R_i^{n-1}}{\sum R_i^n}. \tag{3.4}$$

Notice that E is nonincreasing in time—we have

$$\begin{aligned} \dot{E} &= \frac{n-1}{\sum R_i^n}\sum R_i^{n-2}\dot{R}_i = \frac{n-1}{\sum R_i^n}\sum \frac{R_i^{n-2}}{R_i + \beta}\left(\theta - \frac{1}{R_i}\right) \\ &= \frac{n-1}{\sum R_i^n}\left[\frac{\left(\sum (R_i + \beta)^{-1} R_i^{n-2}\right)^2}{\sum (R_i + \beta)^{-1} R_i^{n-1}} - \sum \frac{R_i^{n-3}}{R_i + \beta}\right] \le 0 \end{aligned} \tag{3.5}$$

since, by the Cauchy–Schwarz inequality,

$$\sum \frac{R_i^{n-2}}{R_i + \beta} = \sum \left[\frac{R_i^{(n-1)/2}}{(R_i + \beta)^{1/2}} \frac{R_i^{(n-3)/2}}{(R_i + \beta)^{1/2}}\right] \le \left(\sum \frac{R_i^{n-1}}{R_i + \beta}\sum \frac{R_i^{n-3}}{R_i + \beta}\right)^{1/2}.$$

By definition (2.2),

$$L = \frac{\sum R_i^{n+1}}{\sum R_i^n}. \tag{3.6}$$

Inequality (2.3) gives us the required interpolation inequality $EL \ge 1$. Next we establish a dissipation relation that controls $\dot{L}$ in terms of $\dot{E}$. Taking the time derivative of L, we get

$$\dot{L} = \frac{n+1}{\sum R_i^n} \sum R_i^n \dot{R}_i \;=\; \frac{n+1}{\sum R_i^n} \sum \frac{R_i^n}{R_i+\beta}\left(\theta - \frac{1}{R_i}\right) \tag{3.7}$$
$$= \frac{n+1}{\sum R_i^n}\left[\frac{\sum (R_i+\beta)^{-1}R_i^n \cdot \sum (R_i+\beta)^{-1}R_i^{n-2}}{\sum (R_i+\beta)^{-1}R_i^{n-1}} - \sum \frac{R_i^{n-1}}{R_i+\beta}\right].$$

We can infer $\dot{L} \ge 0$ using again the Cauchy–Schwarz inequality, but we will not need this fact. We want to prove a dissipation inequality

$$|\dot{L}|^2 \le C_1(-\dot{E}) \tag{3.8}$$

for some constant C_1 depending only on n. Choosing $C_1(n) = (n+1)^2/(n-1)$, and plugging in the expressions (3.5) and (3.7), (3.8) becomes

$$\left[\sum \frac{R_i^n}{R_i+\beta} \sum \frac{R_i^{n-2}}{R_i+\beta} - \left(\sum \frac{R_i^{n-1}}{R_i+\beta}\right)^2\right]^2 \tag{3.9}$$
$$\le \sum R_i^n \sum \frac{R_i^{n-1}}{R_i+\beta} \cdot \left[\sum \frac{R_i^{n-1}}{R_i+\beta} \sum \frac{R_i^{n-3}}{R_i+\beta} - \left(\sum \frac{R_i^{n-2}}{R_i+\beta}\right)^2\right].$$

LEMMA 3.1. *Inequality* (3.9) *holds for any sequence of positive numbers* $\{R_i\}_{i=1}^N$.

To prove Lemma 3.1, we need the following lemma from [2].

LEMMA 3.2 (Lagrange identity).

$$\left(\sum_{i=1}^N x_i^2\right)\left(\sum_{i=1}^N y_i^2\right) - \left(\sum_{i=1}^N x_i y_i\right)^2 = \sum_{\substack{i,j=1\\ i<j}}^N (x_i y_j - x_j y_i)^2 \tag{3.10}$$

for any sequences of real numbers $\{x_i\}_{i=1}^N$ *and* $\{y_i\}_{i=1}^N$.

Proof of Lemma 3.1. The proof consists of several careful applications of the Lagrange identity and the Cauchy–Schwarz inequality. Taking $x_i = (R_i^n/(R_i+\beta))^{1/2}$ and $y_i = (R_i^{n-2}/(R_i+\beta))^{1/2}$ in (3.10), we get

$$I := \sum \frac{R_i^n}{R_i+\beta} \; \sum \frac{R_i^{n-2}}{R_i+\beta} - \left(\sum \frac{R_i^{n-1}}{R_i+\beta}\right)^2 \tag{3.11}$$
$$= \sum_{\substack{i,j=1\\ i<j}}^N \left[\left(\frac{R_i^n}{R_i+\beta}\right)^{1/2}\left(\frac{R_j^{n-2}}{R_j+\beta}\right)^{1/2} - \left(\frac{R_j^n}{R_j+\beta}\right)^{1/2}\left(\frac{R_i^{n-2}}{R_i+\beta}\right)^{1/2}\right]^2$$
$$= \sum_{\substack{i,j=1\\ i<j}}^N \frac{R_i^{n-2}R_j^{n-2}}{(R_i+\beta)(R_j+\beta)}(R_i-R_j)^2$$
$$\le \left\{\sum_{\substack{i,j=1\\ i<j}}^N \frac{R_i^{n-1}R_j^{n-1}(R_i-R_j)^2}{(R_i+\beta)(R_j+\beta)}\right\}^{1/2} \cdot \left\{\sum_{\substack{i,j=1\\ i<j}}^N \frac{R_i^{n-3}R_j^{n-3}(R_i-R_j)^2}{(R_i+\beta)(R_j+\beta)}\right\}^{1/2}.$$

Taking $x_i = R_i^{n/2}$ and $y_i = (R_i^{n-1}/(R_i+\beta))^{1/2}$ in (3.10), we get

$$\sum R_i^n \sum \frac{R_i^{n-1}}{R_i+\beta} \tag{3.12}$$

$$= \left[\sum\left(\frac{R_i^{2n-1}}{R_i+\beta}\right)^{1/2}\right]^2 + \sum_{\substack{i,j=1\\ i<j}}^N \left[R_i^{n/2}\left(\frac{R_j^{n-1}}{R_j+\beta}\right)^{1/2} - R_j^{n/2}\left(\frac{R_i^{n-1}}{R_i+\beta}\right)^{1/2}\right]^2$$
$$\geq \sum_{\substack{i,j=1\\ i<j}}^N \frac{R_i^{n-1}R_j^{n-1}}{(R_i+\beta)(R_j+\beta)}\left[R_i^{1/2}(R_i+\beta)^{1/2} - R_j^{1/2}(R_j+\beta)^{1/2}\right]^2.$$

Taking $x_i = (R_i^{n-1}/(R_i+\beta))^{1/2}$ and $y_i = (R_i^{n-3}/(R_i+\beta))^{1/2}$ in (3.10), we get

$$\sum \frac{R_i^{n-1}}{R_i+\beta}\sum\frac{R_i^{n-3}}{R_i+\beta} - \left(\sum\frac{R_i^{n-2}}{R_i+\beta}\right)^2 \tag{3.13}$$
$$= \sum_{\substack{i,j=1\\ i<j}}^N \left[\left(\frac{R_i^{n-1}}{R_i+\beta}\right)^{1/2}\left(\frac{R_j^{n-3}}{R_j+\beta}\right)^{1/2} - \left(\frac{R_j^{n-1}}{R_j+\beta}\right)^{1/2}\left(\frac{R_i^{n-3}}{R_i+\beta}\right)^{1/2}\right]^2$$
$$= \sum_{\substack{i,j=1\\ i<j}}^N \frac{R_i^{n-3}R_j^{n-3}}{(R_i+\beta)(R_j+\beta)}(R_i-R_j)^2.$$

Thus

$$II := \sum R_i^n \sum\frac{R_i^{n-1}}{R_i+\beta}\left[\sum\frac{R_i^{n-1}}{R_i+\beta}\sum\frac{R_i^{n-3}}{R_i+\beta} - \left(\sum\frac{R_i^{n-2}}{R_i+\beta}\right)^2\right] \tag{3.14}$$
$$\geq \sum_{\substack{i,j=1\\ i<j}}^N \frac{R_i^{n-1}R_j^{n-1}}{(R_i+\beta)(R_j+\beta)}\left[R_i^{1/2}(R_i+\beta)^{1/2} - R_j^{1/2}(R_j+\beta)^{1/2}\right]^2$$
$$\cdot \sum_{\substack{i,j=1\\ i<j}}^N \frac{R_i^{n-3}R_j^{n-3}}{(R_i+\beta)(R_j+\beta)}(R_i-R_j)^2.$$

Comparing (3.11) and (3.14), $I^2 \leq II$ is an immediate consequence of the inequality

$$(R_i-R_j)^2 \leq \left[R_i^{1/2}(R_i+\beta)^{1/2} - R_j^{1/2}(R_j+\beta)^{1/2}\right]^2 \quad \text{for all } i,j. \tag{3.15}$$

Inequality (3.15) holds since

$$\left[R_i^{1/2}(R_i+\beta)^{1/2} - R_j^{1/2}(R_j+\beta)^{1/2}\right]^2 - (R_i-R_j)^2$$
$$= \beta(R_i+R_j) + 2R_iR_j - 2R_i^{1/2}R_j^{1/2}(R_i+\beta)^{1/2}(R_j+\beta)^{1/2},$$

and

$$\left[\beta(R_i+R_j)+2R_iR_j\right]^2 - \left[2R_i^{1/2}R_j^{1/2}(R_i+\beta)^{1/2}(R_j+\beta)^{1/2}\right]^2$$
$$= \beta^2(R_i-R_j)^2 \geq 0. \qquad \square$$

The dissipation inequality (3.8) follows from Lemma 3.1. Applying Lemma 3 in [6], we directly get the following estimates.

THEOREM 3.3. *For any $0 \leq \lambda \leq 1$ and $0 < r < 3$ satisfying $\lambda r > 1$ and $(1-\lambda)r < 2$, there exist positive constants C_2 and C_3, depending only on λ, r, and the dimension of space n, such that for any solution $\{R_i\}$ of equations* (3.1) *and* (3.3), *we have*

$$⨍_0^T E^{\lambda r}L^{-(1-\lambda)r}\,dt \geq C_2 ⨍_0^T \left(t^{-1/3}\right)^r dt \quad for \quad T \geq C_3\, L(0)^3, \tag{3.16}$$

where E and L are defined in terms of (2.1) *and* (2.2), *respectively.*

Proof. Lemma 3.1 guarantees that the dissipation relation (3.8) holds. Together with the interpolation inequality (2.3), we have

$$EL \geq 1 \quad \text{and} \quad |\dot{L}|^2 \leq C_1(-\dot{E}).$$

Lemma 3 in [6] leads directly to (3.3). ∎

Taking $\lambda = 1$ and $r = p$ for $1 < p < 3$ in Theorem 3.3 yields (2.4).

4. Discrete systems II: Interface-reaction–controlled growth. Our aim in this section is to prove the coarsening estimate (2.5) for any collection of finitely many spherical particles in $\mathbb{R}^n$ that undergoes coarsening controlled by interface reactions. Each particle obeys the growth law

$$\dot{R}_i = \theta - \frac{1}{R_i}, \quad (1 \leq i \leq N(t)), \tag{4.1}$$

where R_i is the radius of the ith particle and θ is the mean field.

By the conservation of total mass,

$$0 = \frac{d}{dt}\sum R_i^n = n\sum R_i^{n-1}\dot{R}_i = n\sum R_i^{n-1}\left(\theta - \frac{1}{R_i}\right), \tag{4.2}$$

and thus

$$\theta = \frac{\sum R_i^{n-2}}{\sum R_i^{n-1}}. \tag{4.3}$$

Solutions of the system (4.1) and (4.3) have the same global existence and piecewise smooth properties as that of (3.1) and (3.3). Taking the time derivative of $E = \sum R_i^{n-1}/\sum R_i^n$, we have

$$\begin{aligned} \dot{E} &= \frac{n-1}{\sum R_i^n}\sum R_i^{n-2}\dot{R}_i = \frac{n-1}{\sum R_i^n}\sum R_i^{n-2}\left(\theta - \frac{1}{R_i}\right) \\ &= \frac{n-1}{\sum R_i^n}\left[\frac{\left(\sum R_i^{n-2}\right)^2}{\sum R_i^{n-1}} - \sum R_i^{n-3}\right] \leq 0, \end{aligned} \tag{4.4}$$

since

$$\sum R_i^{n-2} = \sum\left[R_i^{(n-1)/2}R_i^{(n-3)/2}\right] \leq \left(\sum R_i^{n-1}\right)^{1/2}\left(\sum R_i^{n-3}\right)^{1/2}. \tag{4.5}$$

Taking the time derivative of $L = \sum R_i^{n+1}/\sum R_i^n$, we have

$$\dot{L} = \frac{n+1}{\sum R_i^n}\sum R_i^n\dot{R}_i = \frac{n+1}{\sum R_i^n}\left[\frac{\sum R_i^n\sum R_i^{n-2}}{\sum R_i^{n-1}} - \sum R_i^{n-1}\right]. \tag{4.6}$$

Again, by the Cauchy–Schwarz inequality, we can infer $\dot{L} \geq 0$.

As described in section 2, we will need a dissipation inequality that relates $\dot{L}$ and $\dot{E}$. We claim that

$$|\dot{L}|^2 \leq D_1 L(-\dot{E}) \tag{4.7}$$

for some positive constant D_1 depending only on n. Choosing $D_1(n) = (n+1)^2/(n-1)$, and plugging in the expressions (4.4) and (4.6), inequality (4.7) becomes

$$\left[\sum R_i^n \sum R_i^{n-2} - \left(\sum R_i^{n-1}\right)^2\right]^2 \\ \leq \sum R_i^{n-1} \sum R_i^{n+1} \cdot \left[\sum R_i^{n-1} \sum R_i^{n-3} - \left(\sum R_i^{n-2}\right)^2\right]. \tag{4.8}$$

LEMMA 4.1. *Inequality* (4.8) *holds for any sequence of positive numbers* $\{R_i\}_{i=1}^N$.

Proof. Similar to the proof of Lemma 3.1, we will apply the Lagrange identity (3.10) and the Cauchy–Schwarz inequality. Taking $x_i = R_i^{n/2}$ and $y_i = R_i^{(n-2)/2}$ in (3.10), we have

$$\begin{aligned} I &:= \sum R_i^n \sum R_i^{n-2} - \left(\sum R_i^{n-1}\right)^2 \\ &= \sum_{\substack{i,j=1 \\ i<j}}^N \left[R_i^{n/2} R_j^{(n-2)/2} - R_j^{n/2} R_i^{(n-2)/2}\right]^2 \\ &= \sum_{\substack{i,j=1 \\ i<j}}^N R_i^{n-2} R_j^{n-2} (R_i - R_j)^2 \\ &\leq \left[\sum_{\substack{i,j=1 \\ i<j}}^N R_i^{n-1} R_j^{n-1} (R_i - R_j)^2\right]^{1/2} \left[\sum_{\substack{i,j=1 \\ i<j}}^N R_i^{n-3} R_j^{n-3} (R_i - R_j)^2\right]^{1/2}. \end{aligned} \tag{4.9}$$

Taking $x_i = R_i^{(n-1)/2}$ and $y_i = R_i^{(n+1)/2}$ in (3.10), we have

$$\begin{aligned} \sum R_i^{n-1} \sum R_i^{n+1} &= \left(\sum R_i^n\right)^2 + \sum_{\substack{i,j=1 \\ i<j}}^N \left(R_i^{(n-1)/2} R_j^{(n+1)/2} - R_j^{(n-1)/2} R_i^{(n+1)/2}\right)^2 \\ &= \left(\sum R_i^n\right)^2 + \sum_{\substack{i,j=1 \\ i<j}}^N R_i^{n-1} R_j^{n-1} (R_j - R_i)^2. \end{aligned} \tag{4.10}$$

Taking $x_i = R_i^{(n-1)/2}$ and $y_i = R_i^{(n-3)/2}$ in (3.10), we have

$$\begin{aligned} \sum R_i^{n-1} \sum R_i^{n-3} - \left(\sum R_i^{n-2}\right)^2 &= \sum_{\substack{i,j=1 \\ i<j}}^N \left[R_i^{(n-1)/2} R_j^{(n-3)/2} - R_j^{(n-1)/2} R_i^{(n-3)/2}\right]^2 \\ &= \sum_{\substack{i,j=1 \\ i<j}}^N R_i^{n-3} R_j^{n-3} (R_i - R_j)^2. \end{aligned} \tag{4.11}$$

Thus

$$\begin{aligned} II &:= \sum R_i^{n-1} \sum R_i^{n+1} \left[\sum R_i^{n-1} \sum R_i^{n-3} - \left(\sum R_i^{n-2}\right)^2\right] \\ &\geq \sum_{\substack{i,j=1 \\ i<j}}^N R_i^{n-1} R_j^{n-1} (R_j - R_i)^2 \sum_{\substack{i,j=1 \\ i<j}}^N R_i^{n-3} R_j^{n-3} (R_j - R_i)^2 \\ &\geq I^2. \qquad \square \end{aligned} \tag{4.12}$$

At this point we have established the desired interpolation and dissipation inequalities. The third step toward our coarsening estimates is an ODE lemma.

LEMMA 4.2 (ODE lemma). *Let $E(t)$ and $L(t)$ be two continuous and piecewise smooth positive functions. Assume that for some T_1, $0 \le T_1 \le \infty$, $E(t)$ satisfies*

$$\dot{E} < 0 \text{ a.e. on } (0, T_1), \quad \dot{E} = 0 \text{ on } (T_1, \infty). \tag{4.13}$$

If $E(t)$ and $L(t)$ satisfy

$$EL \ge 1 \quad \text{and} \quad |\dot{L}|^2 \le D_1 L(-\dot{E}), \tag{4.14}$$

then for any $0 \le \lambda \le 1$ and $r > 0$ satisfying

$$r < 3, \quad \lambda r > 1 \quad \text{and} \quad (1-\lambda) r < 2, \tag{4.15}$$

we have

$$\fint_0^T E(t)^{\lambda r} L(t)^{1-(1-\lambda)r}\, dt \ge D_2 \fint_0^T (t^{-1/2})^{r-1}\, dt \ \text{ for } T \ge D_3 L(0)^2, \tag{4.16}$$

where D_2 and D_3 are positive constants depending only on λ, r, and D_1.

We remark that this lemma is key for obtaining bounds on coarsening rates for the $t^{1/2}$ growth law. We will extend the ideas in the proof of Lemma 3 in [6] to establish this result. A special case of Lemma 4.2 is to take $r = p + 1$ and $\lambda = p/(p + 1)$ for $1 < p < 2$. In this case, we obtain (2.5)

$$\fint_0^T E(t)^p\, dt \ge D_2 \fint_0^T (t^{-1/2})^p\, dt \ \text{ for } T \ge D_3 L(0)^2, \tag{4.17}$$

where D_2 and D_3 are positive constants depending only on p and D_1.

Proof of Lemma 4.2. (1) If $T_1 = 0$, then $\dot{E} = 0$ on $(0, \infty)$. By assumption (4.14), we get $\dot{L} = 0$ on $(0, \infty)$. Hence $E(t) = E(0)$ and $L(t) = L(0)$ for all $t \in (0, \infty)$. By (4.15), $\lambda r > 1$ and $0 \le \lambda \le 1$ imply that $r > 1/\lambda \ge 1$. Hence we have $1 < r < 3$. Then

$$\begin{aligned}\fint_0^T E(t)^{\lambda r} L(t)^{1-(1-\lambda)r}\, dt &= E(0)^{\lambda r} L(0)^{1-(1-\lambda)r} \\ &\ge L(0)^{1-r} \\ &\ge \frac{2}{3-r} T^{(1-r)/2} \quad \text{ if } T \ge \left(\frac{2}{3-r}\right)^{2/(r-1)} L(0)^2 \\ &= D_2' \fint_0^T (t^{-1/2})^{r-1}\, dt \quad \text{ if } T \ge D_3' L(0)^2,\end{aligned} \tag{4.18}$$

where

$$D_2' = 1 \quad \text{and} \quad D_3' = \left(\frac{2}{3-r}\right)^{2/(r-1)}.$$

(2) Now we consider the case when $T_1 > 0$. $\dot{E}(t) < 0$ on $(0, T_1)$ implies that E is a strictly decreasing function of t on $(0, T_1)$. Hence $E(t)$ is invertible on $(0, T_1)$ and we regard $t \in (0, T_1)$ as a function of ε, with ε denoting the independent variable to distinguish it from $E = E(t)$ and avoid confusion. Note that ε ranges from $E(0)$ to

$E(\infty) := \lim_{t\to\infty} E(t)$, since $\dot{E}(t) = 0$ for $t \in (T_1, \infty)$ implies that $E(t) = E(T_1)$ for any $t > T_1$. Consequently, for $t \in (0, T_1)$, $L(t)$ can be viewed as a function of ε. Thus

$$\frac{dL}{dt} = \frac{dL}{d\varepsilon}\frac{dE}{dt} \quad \text{for } t \in (0, T_1) \tag{4.19}$$

and $|\dot{L}|^2 \le D_1 L(-\dot{E})$ implies that

$$\left|\frac{dL}{d\varepsilon}\right|^2 (-\dot{E}) \le D_1 L(\varepsilon). \tag{4.20}$$

Multiplying both sides by a positive function $f(\varepsilon)$ and integrating from 0 to T, we have

$$\int_0^T f(E(t))L(t)\,dt \ge \frac{1}{D_1}\int_{E_T}^{E_0} f(\varepsilon)\left(\frac{dL}{d\varepsilon}\right)^2 d\varepsilon \tag{4.21}$$

if $T < T_1$, and

$$\int_0^T f(E(t))L(t)\,dt \ge \int_0^{T_1} f(E(t))L(t)\,dt \ge \frac{1}{D_1}\int_{E_T}^{E_0} f(\varepsilon)\left(\frac{dL}{d\varepsilon}\right)^2 d\varepsilon \tag{4.22}$$

if $T \ge T_1$, where $E_0 = E(0)$ and $E_T = E(T)$. Taking $f(\varepsilon) = \varepsilon^{\lambda r} L(\varepsilon)^{-(1-\lambda)r}$, we get

$$\int_0^T E(t)^{\lambda r} L(t)^{1-(1-\lambda)r}\,dt \ge \frac{1}{D_1}\int_{E_T}^{E_0} \varepsilon^{\lambda r} L(\varepsilon)^{-(1-\lambda)r}\left(\frac{dL}{d\varepsilon}\right)^2 d\varepsilon. \tag{4.23}$$

We will change variables so that the right-hand side becomes an integral of a square of some gradient. Consider

$$\hat{\varepsilon} = \frac{1}{\lambda r - 1}\varepsilon^{-(\lambda r - 1)}, \quad \hat{L} = \frac{1}{1 - r(1-\lambda)/2} L^{1-r(1-\lambda)/2}. \tag{4.24}$$

Our requirements $\lambda r > 1$ and $(1-\lambda)r < 2$ guarantee that $\hat{\varepsilon} > 0, \hat{L} > 0$ and $\hat{\varepsilon} \to \infty, \hat{L} \to \infty$ as $\varepsilon \to 0$ and $L \to \infty$, respectively. Also, we have

$$\frac{d\hat{\varepsilon}}{d\varepsilon} = -\varepsilon^{-\lambda r} \tag{4.25}$$

and

$$\left(\frac{d\hat{L}}{d\hat{\varepsilon}}\right)^2 d\hat{\varepsilon} = \left(\frac{d\hat{L}}{dL}\right)^2 \left(\frac{dL}{d\varepsilon}\right)^2 \left(\frac{d\varepsilon}{d\hat{\varepsilon}}\right)^2 \left(\frac{d\hat{\varepsilon}}{d\varepsilon}\right) d\varepsilon = -\varepsilon^{\lambda r} L^{-(1-\lambda)r}\left(\frac{dL}{d\varepsilon}\right)^2 d\varepsilon. \tag{4.26}$$

Hence

$$\int_{E_T}^{E_0} \varepsilon^{\lambda r} L^{-(1-\lambda)r}\left(\frac{dL}{d\varepsilon}\right)^2 d\varepsilon = \int_{\hat{E}_0}^{\hat{E}_T} \left(\frac{d\hat{L}}{d\hat{\varepsilon}}\right)^2 d\hat{\varepsilon}. \tag{4.27}$$

The right-hand side is bounded below by its minimum over all functions $\hat{L}(\hat{\varepsilon})$ with the same endpoint values

$$\hat{L}_0 := \hat{L}(\hat{E}_0) = \frac{1}{1 - r(1-\lambda)/2} L(0)^{1-r(1-\lambda)/2}$$

and

$$\hat{L}_T := \hat{L}(\hat{E}_T) = \frac{1}{1-r(1-\lambda)/2} L(t)^{1-r(1-\lambda)/2},$$

and the minimum is achieved when $\hat{L}$ is a linear function of $\hat{\varepsilon}$. Thus

$$\int_0^T E^{\lambda r}(t) L^{1-(1-\lambda)r}(t)\, dt \geq \frac{1}{D_1} \frac{(\hat{L}_T - \hat{L}_0)^2}{\hat{E}_T - \hat{E}_0}. \tag{4.28}$$

(2a) If $L(T) \geq 2L(0)$, then

$$\hat{L}_0 \leq 2^{r(1-\lambda)/2-1} \hat{L}_T < \hat{L}_T.$$

Hence

$$\hat{L}_T - \hat{L}_0 \geq \left(1 - 2^{r(1-\lambda)/2-1}\right) \hat{L}_T$$

and, consequently,

$$\begin{aligned} \int_0^T E^{\lambda r}(t) L^{1-(1-\lambda)r}(t)\, dt &\geq \frac{1}{D_1} \frac{(\hat{L}_T - \hat{L}_0)^2}{\hat{E}_T - \hat{E}_0} \geq \frac{\left(1 - 2^{r(1-\lambda)/2-1}\right)^2}{D_1} \frac{\hat{L}_T^2}{\hat{E}_T} \\ &\geq \frac{\left(1 - 2^{r(1-\lambda)/2-1}\right)^2}{D_1} \frac{(\lambda r - 1)}{(1-r(1-\lambda)/2)^2}\, E^{\lambda r - 1} L^{2-(1-\lambda)r} \\ &= \hat{D}_2\, (EL)^{((2\lambda-1)r+1)/(r-1)} \cdot \left(E^{\lambda r} L^{1-(1-\lambda)r}\right)^{-(r-3)/(1-r)}, \end{aligned} \tag{4.29}$$

where

$$\hat{D}_2 := \frac{(\lambda r - 1)}{D_1} \left(\frac{1 - 2^{r(1-\lambda)/2-1}}{1 - r(1-\lambda)/2} \right)^2.$$

Since $1 < r < 3$ and $\lambda r > 1$,

$$(2\lambda - 1)r + 1 = 2\lambda r + 1 - r > 3 - r > 0.$$

Thus

$$\frac{(2\lambda-1)r+1}{r-1} > 0 \quad \text{and} \quad \frac{r-3}{1-r} > 0.$$

So $EL \geq 1$ implies $(EL)^{((2\lambda-1)r+1)/(r-1)} \geq 1$ and hence

$$\int_0^T E^{\lambda r}(t) L^{1-(1-\lambda)r}(t)\, dt \geq \hat{D}_2 \left(E^{\lambda r} L^{1-(1-\lambda)r}\right)^{-(r-3)/(1-r)} \quad \text{if } L_T \geq 2L_0. \tag{4.30}$$

Define

$$h(T) := \int_0^T E^{\lambda r}(t) L^{1-(1-\lambda)r}(t)\, dt. \tag{4.31}$$

Then $h'(T) = E^{\lambda r}(T) L^{1-(1-\lambda)r}(T)$ and (4.30) can be rewritten as

$$h(T) \geq \hat{D}_2 (h'(T))^{-(r-3)/(1-r)} \quad \text{if } L_T \geq 2L_0 \tag{4.32}$$

or, equivalently,

$$h'(T)\big(h(T)\big)^{(r-1)/(3-r)} \geq \hat{D}_2^{(r-1)/(3-r)} \quad \text{if } L_T \geq 2L_0. \tag{4.33}$$

(2b) If $L(T) < 2L(0)$, then by $EL \geq 1$,

$$E_T \geq L_T^{-1} \geq \frac{1}{2}L_0^{-1},$$

$$E_T^{\lambda r} L_T^{1-(1-\lambda)r} = \Big(E_T L_T\Big)^{\lambda r} L_T^{1-r} \geq L_T^{1-r} \geq L_0^{1-r}\, 2^{1-r}.$$

Thus

$$h'(T) \geq L_0^{1-r}\, 2^{1-r} \quad \text{if } \ L(T) \leq 2L(0). \tag{4.34}$$

Combining (4.33) and (4.34), we have

$$h'(T)\Big[h(T) + L_0^{3-r}\Big]^{(r-1)/(3-r)} \geq \min\{2^{1-r}, \hat{D}_2^{(r-1)/(3-r)}\} =: m \quad \text{for all } T.$$

Thus

$$\frac{d}{dt}\Big[h(t) + L_0^{3-r}\Big]^{2/(3-r)} = \frac{2}{3-r} h'(t)\Big[h(t) + L_0^{3-r}\Big]^{(r-1)/(3-r)} \geq \frac{2m}{3-r}. \tag{4.35}$$

By integration over time from 0 to T, we get

$$\begin{aligned} h(T) &\geq \left[\frac{2m}{3-r}T + L_0^2\right]^{(3-r)/2} - L_0^{3-r} \\ &\geq \left(\frac{2m}{3-r}\right)^{(3-r)/2} T^{(3-r)/2} - L_0^{3-r} \\ &\geq \frac{1}{2}\left(\frac{2m}{3-r}\right)^{(3-r)/2} T^{(3-r)/2} \quad \text{if } \ T > 2^{2/(3-r)}\frac{(3-r)}{2m}L_0^2. \end{aligned} \tag{4.36}$$

Equivalently,

$$⨍_0^T E(t)^{\lambda r} L(t)^{1-(1-\lambda)r}\, dt \geq D_2''⨍_0^T (t^{-1/2})^{r-1}\, dt \quad \text{for } T > D_3'' L_0^2, \tag{4.37}$$

where

$$D_2'' = \frac{3-r}{4}\left(\frac{2m}{3-r}\right)^{(3-r)/2} \quad \text{and} \quad D_3'' = 2^{2/(3-r)}\frac{(3-r)}{2m}.$$

(3) Combining (1) and (2), we conclude that

$$⨍_0^T E(t)^{\lambda r} L(t)^{1-(1-\lambda)r}\, dt \geq D_2⨍_0^T (t^{-1/2})^{r-1}\, dt \quad \text{for } T > D_3 L_0^2, \tag{4.38}$$

where

$$D_2 = \min\{D_2', D_2''\} \quad \text{and} \quad D_3 = \max\{D_3', D_3''\}. \qquad \square$$

We claim the following estimate for the collection of particles that undergoes coarsening determined by (4.1).

THEOREM 4.3. *For any* $0 \le \lambda \le 1$ *and* $0 < r < 3$ *satisfying* $\lambda r > 1$ *and* $(1-\lambda)r < 2$, *there exist positive constants* D_2 *and* D_3, *depending only on* λ, r, *and the dimension of space* n, *such that for any solution* $\{R_i\}$ *of equations* (4.1) *and* (4.3), *we have*

$$(4.39) \qquad \fint_0^T E(t)^{\lambda r} L(t)^{1-(1-\lambda)r}\, dt \ge D_2 \fint_0^T (t^{-1/2})^{r-1}\, dt \quad \text{for } T \ge D_3 L(0)^2,$$

where E *and* L *are defined in terms of* (2.1) *and* (2.2), *respectively.*

Proof. As we discussed at the beginning of this section, solutions $\{R_i\}$ of equations (4.1) and (4.3) are continuous and piecewise smooth. Hence E and L defined by (2.1) and (2.2) are continuous and piecewise smooth. Furthermore, by (4.4), $\dot{E} \le 0$ and $\dot{E} = 0$ if and only if all R_i are equal. Notice that if all R_i are equal, then the system (4.1) and (4.3) reaches an equilibrium point and the solution stops coarsening. Consequently, if $\dot{E} = 0$ at some time t_1, then $\dot{E}(t) = 0$ for all $t \ge t_1$. Hence, $\dot{E}$ satisfies the condition (4.13) of Lemma 4.2.

On the other hand, the interpolation inequality (2.3) and the dissipation relation (4.7) say

$$EL \ge 1 \quad \text{and} \quad |\dot{L}|^2 \le D_1 L(-\dot{E}).$$

The theorem is then an immediate consequence of Lemma 4.2. $\square$

5. Coarsening rates for particle systems with general size distributions. Now it is time to consider our mean-field models with more general size distributions. Definitions (2.1) and (2.2) imply that, in the more general case, E and L should be defined in terms of the $(n-1)$st, nth, and $(n+1)$st moments of the size distributions. Thus it is necessary to require the initial size distributions to be in $\mathcal{P}_{n+1}$, the set of Borel probability measures on $[0, \infty)$ with finite $(n+1)$st moments. By Hölder's inequality, it is immediate to see that $\mathcal{P}_{n+1}$ is a subset of $\mathcal{P}_n$.

In [13], Niethammer and Pego proved well-posedness and compactness results for a family of mean-field models. All of our models under consideration are included in that work except for the 2D volume-diffusion–controlled growth model with $\beta = 0$. Their results guarantee the existence and uniqueness of measure-valued solutions of equation (1.2) or (1.8). A measure-valued solution is a weak-star continuous map $t \mapsto \nu_t$ taking $[0, \infty) \to \mathcal{P}_n$ that is a solution in the sense of distributions on $(0, \infty) \times (0, \infty)$; i.e., for all $\phi \in C_c^\infty([0, \infty) \times (0, \infty))$ (smooth functions with compact support),

$$(5.1) \qquad \int_0^\infty \int_0^\infty \left(\partial_t \phi + \frac{1}{R+\beta}\left(\theta(t) - \frac{1}{R}\right) \partial_R \phi \right) d\nu_t\, dt + \int_0^\infty \phi(0, \cdot)\, d\nu_0 = 0$$

in the case of volume-diffusion–controlled growth (1.2), or

$$(5.2) \qquad \int_0^\infty \int_0^\infty \left(\partial_t \phi + \left(\theta(t) - \frac{1}{R}\right) \partial_R \phi \right) d\nu_t\, dt + \int_0^\infty \phi(0, \cdot)\, d\nu_0 = 0$$

in the case of interface-reaction–controlled growth (1.8).

Our main results are estimates in terms of these measure-valued solutions.

THEOREM 5.1 (volume-diffusion–controlled growth). *Let* $n \ge 2$ *be an integer and* $\beta \ge 0$, *with* $\beta > 0$ *if* $n = 2$. *For any* $0 \le \lambda \le 1$ *and* $0 < r < 3$ *satisfying* $\lambda r > 1$ *and* $(1-\lambda)r < 2$, *there exist positive constants* C_2 *and* C_3, *depending only on* λ, r, *and the* *dimension of space n, such that whenever ν is a measure-valued solution of the transport equation* (1.2) *and the initial value ν_0 has finite nth and $(n+1)$st moments, we have*

$$\fint_0^T E(t)^{\lambda r} L(t)^{-(1-\lambda)r}\, dt \geq C_2 \fint_0^T (t^{-1/3})^r\, dt \quad \text{for } T \geq C_3 L(0)^3, \tag{5.3}$$

where $E(t)$ and $L(t)$ are defined by (2.8) *and* (2.9)*, respectively, and the mean field $\theta(t)$ is defined by* (2.6)*.*

Taking $r = p$ and $\lambda = 1$ for $1 < p < 3$ in Theorem 5.1 gives Theorem 2.1.

THEOREM 5.2 (interface-reaction–controlled growth). *Let $n \geq 2$ be an integer. For any $0 \leq \lambda \leq 1$ and $0 < r < 3$ satisfying $\lambda r > 1$ and $(1-\lambda)r < 2$, there exist positive constants D_2 and D_3, depending only on λ, r, and the dimension of space n, such that whenever ν is a measure-valued solution of the transport equation* (1.8) *and the initial value ν_0 has finite nth and $(n+1)$st moments, we have*

$$\fint_0^T E(t)^{\lambda r} L(t)^{1-(1-\lambda)r}\, dt \geq D_2 \fint_0^T (t^{-1/2})^{r-1}\, dt \quad \text{for } T \geq D_3 L(0)^2, \tag{5.4}$$

where $E(t)$ and $L(t)$ are defined by (2.8) *and* (2.9)*, respectively, and the mean field $\theta(t)$ is defined by* (2.7)*.*

Taking $r = p+1$ and $\lambda = p/(p+1)$ for $1 < p < 2$ in Theorem 5.2 gives Theorem 2.2.

The remaining part of this section is devoted to proving the theorems above. To do this, we will need a change of variables as is done in [13]. In that paper, rather than directly working on distributions of particle radii R, Niethammer and Pego change the problems into equivalent ones expressed in terms of rescaled particle volumes $x(:= R^n)$ and work with a size-ranking function for particle volumes.

According to (1.1) and (1.7), the particle volume x satisfies the following growth law:

$$\dot{x} = a(x)\theta - b(x), \tag{5.5}$$

where

$$a(x) = \frac{n x^{1-1/n}}{x^{1/n} + \beta}, \quad b(x) = \frac{n x^{1-2/n}}{x^{1/n} + \beta} \quad \text{for volume-diffusion–controlled case,} \tag{5.6}$$

$$a(x) = n x^{1-1/n}, \quad b(x) = n x^{1-2/n} \quad \text{for interface-reaction–controlled case,} \tag{5.7}$$

and $\theta(t) = \int b(x)\, d\nu_t(x) / \int a(x)\, d\nu_t(x)$. Here ν is the measure-valued solution in the sense of distributions for the transport equation

$$\partial_t u + \partial_x\big((a(x)\theta - b(x))u\big) = 0. \tag{5.8}$$

The results of Niethammer and Pego are established by a further change of variables ([13]; see also [12]). For any size distribution of particles which is a probability measure μ on $[0, \infty)$, they define a *size-ranking function* $x = \hat{x}(\mu) : (0, 1] \to [0, \infty)$ by

$$x(\varphi) = \begin{cases} \sup\{y \mid \mu([y, \infty)) > \varphi\} & \text{for} \quad 0 < \varphi < 1, \\ 0 & \text{for} \quad \varphi = 1. \end{cases} \tag{5.9}$$

This is the right-continuous inverse of the tail distribution function $\varphi(x) = \mu([x, \infty))$. The map $\hat{x}$ gives a 1–1 correspondence between the set of Borel probability measures on $[0, \infty)$ and the set of right-continuous decreasing functions x on $(0, 1]$ with $x(1) = 0$.

The following space for size ranking is introduced in [13]:

$$L^1_d = \{x : (0,1] \to \quad | \; x \in L^1((0,1)),\ x(1) = 0,\ \text{and } x \text{ is decreasing} \\ \text{and right continuous on } (0,1]\}.$$

It is a closed subspace of $L^1((0,1))$. We will also perform our estimates in this space.

By statement 2.5.18(3) in [5], for any continuous function $f : (0, \infty) \to \mathbf{R}$ with compact support,

$$\int_0^1 f(x(\varphi))\, d\varphi = \int_0^\infty f(y)\, d\mu(y). \tag{5.10}$$

For any positive number $\alpha > 0$, $y \mapsto y^\alpha$ can be approximated by a monotonically increasing sequence of such functions, and thus by the monotone convergence theorem

$$\int_0^1 x(\varphi)^\alpha\, d\varphi = \int_0^\infty y^\alpha\, d\mu(y), \tag{5.11}$$

where both sides may be infinite. Hence $\mu \in \mathcal{P}_\alpha$ (Borel probability measures with finite αth moment) if and only if x is right-continuous decreasing on $(0, 1]$ with $x(1) = 0$ and $\int_0^1 x(\varphi)^\alpha\, d\varphi < \infty$.

The growth law (5.5) can be rewritten as an integral equation,

$$x(t,\varphi) = x(0,\varphi) + \int_0^t (a(x(s,\varphi))\theta(s) - b(x(s,\varphi)))\, ds \tag{5.12}$$

with

$$\theta(t) = \int_0^{\bar{\varphi}(t)} b(x(t,\varphi))\, d\varphi \Big/ \int_0^1 a(x(t,\varphi))\, d\varphi \quad \text{for a.e. } t > 0, \tag{5.13}$$

where $\bar{\varphi}(t) := \sup\{\varphi | x(t,\varphi) > 0\}$.

Theorem 2.3 of [13] established the existence and uniqueness of the initial value problem for (5.12) and (5.13) under some assumptions ((H1)–(H5) in [13]) which our problems satisfy except for the 2D volume-diffusion–controlled growth model with $\beta = 0$. This theorem claims that for any $x_0 \in L^1_d$, there exists a unique function $x \in C([0, \infty), L^1_d)$ such that (5.12) and (5.13) hold with $x(0, \varphi) = x_0(\varphi)$. This is equivalent to the existence and uniqueness (Theorem 2.1 of [13]) of a weak-star continuous solution $\nu : [0, \infty) \to \mathcal{P}_1$ for the transport equation (5.8) in the sense of distributions on $(0, \infty) \times (0, \infty)$ with initial value $\nu_0 = \hat{x}^{-1}(x_0)$.

Proposition 6.1 of [13] established an L^1 compactness result for (5.12) and (5.13); namely, given $T \in (0, \infty)$, for a compact sequence of initial values $\{x_{0k}\} \subset L^1_d$, the corresponding sequence of solutions x_k is compact in $C([0, T], L^1_d)$ and any limit x is again a solution of (5.12) and (5.13).

Based on this result, in the appendix we prove an L^p compactness result for (5.12) and (5.13) for any $1 < p < \infty$; namely, given $T \in (0, \infty)$, for a sequence of initial values $\{x_{0k}\} \subset L^1_d \cap L^p((0, 1))$ which is compact in $L^p((0, 1))$, the corresponding sequence of solutions x_k is compact in $C([0, T], L^p((0, 1)))$ and any limit x is again a solution of (5.12) and (5.13).

Given $x_0 \in L^1_d \cap L^{(n+1)/n}((0,1))$, for any positive integer N, we divide the interval $(0,1)$ uniformly into N subintervals and define a function $x_{0N}(\varphi)$ by

$$x_{0N}(\varphi) = N \int_{(i-1)/N}^{i/N} x_0(\psi)\, d\psi \ (=: x_{0N}^i), \qquad \frac{i-1}{N} \le \varphi < \frac{i}{N},\ (i = 1, \ldots, N). \tag{5.14}$$

Then $x_{0N} \in L^1_d \cap L^{(n+1)/n}((0,1))$ is piecewise constant, and $x_{0N} \to x_0$ in $L^{(n+1)/n}((0,1))$ as $N \to \infty$.

By the above compactness and uniqueness results, the solutions $\{x_N\}$ for (5.12) and (5.13) with initial values $\{x_{0N}\}$ converge in the space $C([0,T], L^{(n+1)/n}((0,1)))$ to the solution x for (5.12) and (5.13) with initial value x_0.

For any N, $\{x_{0N}^i\}_{i=1}^N$ gives a discrete collection of particles and the corresponding collection of radii $\{R_i := (x_{0N}^i)^{1/n}\}$ undergoes coarsening determined by (1.1) or (1.7). Hence the estimates (3.16) and (4.39) claimed in Theorems 3.3 and 4.3 hold for

$$E_N(t) = \frac{\sum R_i(t)^{n-1}}{\sum R_i(t)^n} = \int_0^1 x_N(t,\varphi)^{(n-1)/n}\, d\varphi \Big/ \int_0^1 x_N(t,\varphi)\, d\varphi$$

and

$$L_N(t) = \frac{\sum R_i(t)^{n+1}}{\sum R_i(t)^n} = \int_0^1 x_N(t,\varphi)^{(n+1)/n}\, d\varphi \Big/ \int_0^1 x_N(t,\varphi)\, d\varphi.$$

We will establish the convergence results for $E_N(t)$ and $L_N(t)$ in Lemma 5.4. To do this, let us first prove a general convergence result for L^p functions.

LEMMA 5.3. *For nonnegative functions $f_k, f \in L^p(\Omega)$ $(k = 1, 2, \ldots)$ with $1 < p < \infty$ and Ω a bounded open subset of* ^{n}, *if*

$$\int_\Omega |f_k(y)^p - f(y)^p|\, dy \to 0 \qquad \text{as } k \to \infty, \tag{5.15}$$

then

$$\int_\Omega |f_k(y) - f(y)|^p\, dy \to 0 \qquad \text{as } k \to \infty. \tag{5.16}$$

Proof. The convergence (5.15) implies that $\{f_k\}$ is bounded in $L^p(\Omega)$. Notice that $L^p(\Omega)$ is a reflexive Banach space since $1 < p < \infty$. Thus there exist a subsequence $\{f_{k_j}\}$ and $w \in L^p(\Omega)$ such that f_{k_j} converges weakly to w: $f_{k_j} \rightharpoonup w$ as $j \to \infty$. Hence

$$||w||_{L^p(\Omega)} \le \liminf_{j\to\infty} ||f_{k_j}||_{L^p(\Omega)} = ||f||_{L^p(\Omega)}. \tag{5.17}$$

By $f_{k_j}^p \to f^p$ in $L^1(\Omega)$, there exists a further subsequence, denoted the same, such that $f_{k_j}(y) \to f(y)$ for a.e. $y \in \Omega$. Hence, by Fatou's lemma and Hölder's inequality,

$$\int_\Omega f^p = \int_\Omega \liminf_{j\to\infty} f^{p-1} f_{k_j} \le \liminf_{j\to\infty} \int_\Omega f^{p-1} f_{k_j} = \int_\Omega f^{p-1} w \le \left(\int_\Omega f^p\right)^{1-\frac{1}{p}} \left(\int_\Omega w^p\right)^{1/p}.$$

Thus

$$||f||_{L^p(\Omega)} \le ||w||_{L^p(\Omega)}. \tag{5.18}$$

Comparing inequalities (5.17) and (5.18), we get $||f||_{L^p(\Omega)} = ||w||_{L^p(\Omega)}$. Thus

$$f_{k_j} \rightharpoonup w \quad \text{in} \quad L^p(\Omega), \tag{5.19}$$

$$||f_{k_j}||_{L^p(\Omega)} \to ||w||_{L^p(\Omega)}. \tag{5.20}$$

Thus (see, e.g., [4])

$$f_{k_j} \to w \quad \text{in} \quad L^p(\Omega), \tag{5.21}$$

and there exists a further subsequence of f_{k_j} that converges a.e. to w. Since $f_{k_j} \to f$ a.e. in Ω, we have $w = f$ and hence

$$f_{k_j} \to f \quad \text{in} \quad L^p(\Omega). \tag{5.22}$$

The above argument works for every weakly convergent subsequence and hence the whole sequence f_k converges strongly to f in $L^p(\Omega)$. ∎

LEMMA 5.4. *For any $t > 0$, we have*

$$E_N(t) \to E(t) := \int_0^1 x(t,\varphi)^{(n-1)/n}\, d\varphi \Big/ \int_0^1 x(t,\varphi)\, d\varphi \quad \textit{as} \;\; N \to \infty, \tag{5.23}$$

$$L_N(t) \to L(t) := \int_0^1 x(t,\varphi)^{(n+1)/n}\, d\varphi \Big/ \int_0^1 x(t,\varphi)\, d\varphi \quad \textit{as} \;\; N \to \infty. \tag{5.24}$$

Proof. Fix $t > 0$. By the conservation of total mass and the convergence of initial value $x_{0N} \to x_0$ in $L^1((0,1))$,

$$\int_0^1 x_N(t,\varphi)\, d\varphi = \int_0^1 x_{0N}(\varphi)\, d\varphi \to \int_0^1 x_0(\varphi)\, d\varphi = \int_0^1 x(t,\varphi)\, d\varphi \tag{5.25}$$

as $N \to \infty$. By the compactness of $\{x_N\}$ in $C\big([0,T], L^p((0,1))\big)$ for all $T > 0$ and all $p > 1$,

$$\int_0^1 x_N(t,\varphi)^{(n+1)/n}\, d\varphi \to \int_0^1 x(t,\varphi)^{(n+1)/n}\, d\varphi \quad \text{as} \;\; N \to \infty. \tag{5.26}$$

The convergence of $L_N(t)$ to $L(t)$ is an immediate consequence of (5.25) and (5.26).

Define $f_N = x_N(t,\varphi)^{(n-1)/n}, f = x(t,\varphi)^{(n-1)/n}$, and $p = n/(n-1)$. Equation (5.25) implies that $f_N^p \to f^p$ as $N \to \infty$. Thus Lemma 5.3 implies $f_N \to f$ in $L^p((0,1))$ and consequently $f_N \to f$ in $L^1((0,1))$. Hence

$$\int_0^1 x_N(t,\varphi)^{(n-1)/n}\, d\varphi \to \int_0^1 x(t,\varphi)^{(n-1)/n}\, d\varphi. \tag{5.27}$$

The convergence of $E_N(t)$ to $E(t)$ is an immediate consequence of (5.25) and (5.27). ∎

To enable us to take limit in the estimates (3.16) and (4.39) claimed in Theorems 3.3 and 4.3, we will prove the following boundedness lemma for $E_N(t)$ and $L_N(t)$ and then apply Lebesgue's dominated convergence theorem.

LEMMA 5.5. *Given $T > 0$, there exist positive constants M_1, m_2, and M_2, depending only on n and T, such that*

$$0 < E_N(t) \le M_1, \quad m_2 < L_N(t) < M_2$$

uniformly in N and $0 \le t \le T$, with M_1, m_2, and M_2 positive constants depending only on n and T.

Proof. By (5.25), there exist positive constants $\hat{m}_1$ and $\hat{M}_1$ such that for all N and all $t \ge 0$,

$$\hat{m}_1 \le \int_0^1 x_N(t,\varphi)\,d\varphi \le \hat{M}_1, \quad \hat{m}_1 \le \int_0^1 x(t,\varphi)\,d\varphi \le \hat{M}_1. \tag{5.28}$$

Then by Hölder's inequality,

$$\int_0^1 x_N(t,\varphi)^{(n-1)/n}\,d\varphi \le \left(\int_0^1 x_N(t,\varphi)\,d\varphi\right)^{(n-1)/n} \le \hat{M}_1^{(n-1)/n}. \tag{5.29}$$

Hence

$$E_N(t) = \int_0^1 x_N(t,\varphi)^{(n-1)/n}\,d\varphi \Big/ \int_0^1 x_N(t,\varphi)\,d\varphi \le \hat{M}_1^{(n-1)/n}/\hat{m}_1 =: M_1. \tag{5.30}$$

By Hölder's inequality,

$$\hat{m}_1 \le \int_0^1 x_N(t,\varphi)\,d\varphi \le \left\{\int_0^1 x_N(t,\varphi)^{(n+1)/n}\,d\varphi\right\}^{n/(n+1)}. \tag{5.31}$$

Thus

$$L_N(t) = \int_0^1 x_N(t,\varphi)^{(n+1)/n}\,d\varphi \Big/ \int_0^1 x_N(t,\varphi)\,d\varphi \ge \hat{m}_1^{(n+1)/n}/\hat{M}_1 =: m_2. \tag{5.32}$$

In the appendix, we will prove that there exists a positive increasing function $G(t)$ such that $\int_0^1 x_N(t,\varphi)^{(n+1)/n}\,d\varphi \le G(t) \le G(T)$. Thus, for all $0 \le t \le T$,

$$L_N(t) = \int_0^1 x_N(t,\varphi)^{(n+1)/n}\,d\varphi \Big/ \int_0^1 x_N(t,\varphi)\,d\varphi \le G(T)/\hat{m}_1 =: M_2. \tag{5.33}$$ ∎

The above boundedness results and Lebesgue's dominated convergence theorem guarantee that we can take limit as $N \to \infty$ in the estimates for coarsening rates for discrete systems (Theorems 3.3 and 4.3). This procedure gives us the estimates in Theorems 5.1 and 5.2, with E and L defined as in Lemma 5.4, for the coarsening rates for solutions of (5.12)+(5.13) with initial value $x_0 \in L_d^1 \cap L^{(n+1)/n}((0,1))$.

Our ultimate goal is to get estimates for coarsening rates for measure-valued solutions of the transport equations (1.2) and (1.8), respectively. To do this, we will establish the 1–1 correspondence between these measure-valued solutions, which are distributions of particle radii, and volume size-ranking solutions for (5.12)+(5.13). The estimates for coarsening rates for these measure-valued solutions are immediate consequences of this 1–1 correspondence and the estimates for these size-ranking solutions.

For any initial particle radius distribution $\mu(R) \in \mathcal{P}_{n+1}$, we define a particle volume distribution $\hat{\mu}(x) = (T\mu)(x)$ by requiring

$$\int_0^\infty f(x)\,d\hat{\mu}(x) = \int_0^\infty f(R^n)\,d\mu(R) \tag{5.34}$$

for all continuous functions f with compact support. Then $\hat{\mu} \in \mathcal{P}_{(n+1)/n}$.

The size-ranking function $x_0(\varphi) = \hat{x}(\hat{\mu})$ defined as in (5.9) belongs to $L^1_d \cap L^{(n+1)/n}((0,1))$. Hence the solution $x(t,\varphi)$ of problem (5.12)+(5.13) with $x(0,\cdot) = x_0(\cdot)$ belongs to L^1_d and we can get the estimates as in Theorems 5.1 and 5.2 by the procedure described above.

It is proved in [13] that the mapping (5.9) is invertible and that under the assumptions (H1)–(H5), the weak-star continuous mapping $\hat{\nu} : [0,\infty) \to \mathcal{P}_1$ related with $x(t,\varphi)$ through (5.9) is the unique measure-valued solution of the transport equation (5.8) in the sense of distributions with initial value $\hat{\mu}$. For any $t \in [0,\infty)$, we define a Borel measure ν_t by requiring

$$\int_0^\infty f(R)\, d\nu_t(R) = \int_0^\infty f(x^{1/n})\, d\hat{\nu}_t(x) \tag{5.35}$$

for all continuous functions f with compact support. Then $\nu : [0,\infty) \to \mathcal{P}_n$ is weak-star continuous and is a measure-valued solution of the transport equation (1.2) or (1.8), with initial value $\nu_0 = \mu$. Again, since we can approximate a power function $y \mapsto y^\alpha (\alpha > 0)$ by a monotonically increasing sequence of continuous functions with compact support, we get the following moment equivalence identity for ν and $\hat{\nu}$:

$$\int_0^\infty R^\alpha\, d\nu_t(R) = \int_0^\infty x^{\alpha/n}\, d\hat{\nu}_t(x) \quad \text{for any } \alpha > 0. \tag{5.36}$$

On the other hand, if we have a measure-valued solution $\nu : [0,\infty) \to \mathcal{P}_n$ for (1.2) or (1.8) with a given initial value μ, we can define $\hat{\nu} : [0,\infty) \to \mathcal{P}_1$ by (5.35) and $\hat{\nu}$ will be a measure-valued solution for (5.8) with initial value $\hat{\mu}$ defined by (5.34). The uniqueness of $\hat{\nu}$ then implies the uniqueness of ν.

The above analysis, together with the moment equivalence statements (5.11) and (5.36), gives us Theorems 5.1 and 5.2 on coarsening rates for mean-field models with general initial distributions of particle radii.

Appendix. In this appendix, we will establish a compactness result for solutions $x(t,\varphi)$ of problem (5.12)+(5.13) with $x(0,\cdot) = x_0(\cdot)$ for any $x_0 \in L^1_d \cap L^p((0,1))$ with $1 < p < \infty$ under the same assumptions (H1)–(H4) as in [13]. Note that the two models we considered fall into this category except for the case $n = 2, \beta = 0$ of the volume-diffusion–controlled growth model (and this is the reason why we do not include this case in our estimates for coarsening rates with general size distribution).

Proposition A.1. *Fix $T \in (0,\infty)$ and consider a sequence $\{x_k\}_{k=1}^\infty$ of solutions to* (5.12)+(5.13) *for $0 \le t \le T$ with initial values $x_k(0,\varphi) = x_{0k}(\varphi)$ $(\varphi \in (0,1))$. Assume that the sequence of initial data $\{x_{0k}\} \subset L^1_d \cap L^p((0,1))$ is compact in $L^p((0,1))$ for some $1 < p < \infty$ with $c_1 := \inf_k \int_0^1 x_{0k} > 0$. Then $\{x_k\}$ is compact in $C([0,T], L^p((0,1)))$ and any limit x is again a solution of* (5.12)+(5.13).

Proof. By Hölder's inequality, the assumption that $\{x_{0k}\} \subset L^1_d \cap L^p((0,1))$ is compact in $L^p((0,1))$ implies that $\{x_{0k}\}$ is compact in $L^1((0,1))$. Hence, by Proposition 6.1 in [13], $\{x_k\}$ is compact in $C([0,T], L^1_d)$ and any limit x is again a solution of (5.12)+(5.13). We will follow the strategy of the proof of Lemma 6.2 in [13] to prove that x_k is compact in $L^p((0,1))$.

It has been shown in [13] that $\theta(t)$ is uniformly bounded on [0,T]. The assumptions $(H1)$–$(H4)$ together with the boundedness of θ imply that there exists a positive constant C, depending only on T, such that

$$|a(x)\theta(t) - b(x)| \le C(1+x)$$

for all $x \geq 0$. By the generalized Arzelà–Ascoli theorem, to show that $\{x_k\}$ is compact in $C([0,T], L^p((0,1)))$, we need to prove the following three steps:

(1) uniform boundedness of $\{\int_0^1 x_k^p(t,\varphi)\, d\varphi\}$ for all $t \in [0,T]$ and all k,

(2) for fixed $t \in (0,T)$, $\{x_k(t,\cdot)\}$ is compact in $L^p((0,1))$,

(3) $\sup_k ||x_k(t_1,\cdot) - x_k(t_2,\cdot)||_{L^p((0,1))} \to 0$ as $|t_1 - t_2| \to 0$.

To show (1), define $F_\delta(t) = \int_\delta^1 x_k^p(t,\varphi)\, d\varphi$ for $\delta > 0$. Then $F_\delta < \infty$ since $x_k(t,\cdot)$ is decreasing and

$$\begin{aligned} F_\delta(t) &= \int_\delta^1 x_{0k}^p(\varphi)\, d\varphi + \int_\delta^1 \int_0^t p x_k^{p-1} \partial_s x_k(s,\varphi)\, ds\, d\varphi \\ &= \int_\delta^1 x_{0k}^p(\varphi)\, d\varphi + \int_\delta^1 \int_0^t p x_k^{p-1} (a(x_k)\theta - b(x_k))\, ds\, d\varphi \\ &\leq \int_\delta^1 x_{0k}^p(\varphi)\, d\varphi + Cp \int_\delta^1 \int_0^t x_k^{p-1}(1 + x_k)\, dt\, d\varphi. \end{aligned}$$

By Young's inequality,

$$x_k^{p-1} \leq \frac{p-1}{p} x_k^p + \frac{1}{p}. \tag{A.1}$$

Thus

$$\begin{aligned} F_\delta(t) &\leq \int_\delta^1 x_{0k}^p(\varphi)\, d\varphi + C \int_\delta^1 \int_0^t ((2p-1)x_k^p + 1)\, dt\, d\varphi \\ &\leq \int_\delta^1 x_{0k}^p(\varphi)\, d\varphi + CT + C(2p-1) \int_0^t \int_\delta^1 x_k^p\, d\varphi\, dt. \end{aligned}$$

By Gronwall's inequality,

$$F_\delta(t) \leq \int_\delta^1 x_{0k}^p(\varphi)\, d\varphi + CT + C(2p-1)e^{C(2p-1)t} \left(\int_\delta^1 x_{0k}^p(\varphi)\, d\varphi + CT \right). \tag{A.2}$$

The compactness of x_{0k} in $L^p((0,1))$ implies that there exists positive constant C_1 such that $\int_0^1 x_{0k}^p(\varphi)\, d\varphi \leq C_1$ for all k. Thus, by taking $\delta \to 0$ in (A.2) we get

$$\int_0^1 x_k^p(t,\varphi)\, d\varphi \leq C_1 + CT + C(2p-1)e^{C(2p-1)t}(C_1 + CT) =: G(t) \leq G(T). \tag{A.3}$$

Here G is an increasing function of t and does not depend on k. Hence (1) is proved.

It is shown in the proof of Lemma 6.2 in [13] that, for fixed t, there exists a pointwise convergent subsequence, still denoted as $\{x_k\}$ for simplicity. Therefore, to prove (2) we need only show that $\{x_k\}$ is equi-integrable. Since $x_k(t,\cdot)$ are decreasing, it is enough to show

$$\sup_k \int_0^\varepsilon x_k(t,\varphi)\, d\varphi \to 0 \quad \text{as } \varepsilon \to 0. \tag{A.4}$$

$$\begin{aligned} \int_0^\varepsilon x_k^p(t,\varphi)\, d\varphi &= \int_0^\varepsilon x_{0k}^p(\varphi)\, d\varphi + \int_0^\varepsilon \int_0^t p x_k^{p-1}(s,\varphi) \partial_s x_k(s,\varphi)\, ds\, d\varphi \\ &= \int_0^\varepsilon x_{0k}^p(\varphi)\, d\varphi + \int_0^\varepsilon \int_0^t p x_k^{p-1}(s,\varphi)(a(x_k)\theta - b(x_k))\, ds\, d\varphi \end{aligned} \tag{A.5}$$

$$\begin{aligned}
&\le \int_0^\varepsilon x_{0k}^p(\varphi)\,d\varphi + Cp\int_0^\varepsilon\int_0^t x_k^{p-1}(1+x_k)\,ds\,d\varphi \\
&\le \int_0^\varepsilon x_{0k}^p(\varphi)\,d\varphi + C\int_0^\varepsilon\int_0^t ((2p-1)x_k^p+1)\,ds\,d\varphi \quad \text{by (A.1)} \\
&\le \int_0^\varepsilon x_{0k}^p(\varphi)\,d\varphi + CT\varepsilon + C(2p-1)\int_0^t\int_0^\varepsilon x_k^p\,d\varphi\,ds.
\end{aligned}$$

By Gronwall's inequality,

$$\begin{aligned}
\text{(A.6)}\qquad \int_0^\varepsilon x_k^p(t,\varphi)\,d\varphi \le{}& \int_0^\varepsilon x_{0k}^p(\varphi)\,d\varphi + CT\varepsilon \\
&+(2p-1)Ce^{(2p-1)Ct}\left(\int_0^\varepsilon x_{0k}^p(\varphi)\,d\varphi + CT\varepsilon\right).
\end{aligned}$$

We can assume without loss of generality that $x_{0k}\to x_0$ in $L^p((0,1))$. Hence $\sup_k \int_0^\varepsilon x_{0k}^p(\varphi)\,d\varphi \to 0$ as $\varepsilon\to 0$. By (A.6), $\sup_k\int_0^\varepsilon x_k^p(t,\varphi)\,d\varphi\to 0$ as $\varepsilon\to 0$ and (2) is proved.

Now let us prove (3). Assume $t_1<t_2$.

$$\begin{aligned}
\text{(A.7)}\quad \int_0^1 |x_k^p(t_1,\varphi)-x_k^p(t_2,\varphi)|\,d\varphi &= p\int_0^1\left|\int_{t_1}^{t_2} x_k^{p-1}\partial_t x_k(t,\varphi)\,dt\right| d\varphi \\
&= p\int_0^1\left|\int_{t_1}^{t_2} x_k^{p-1}(a(x_k)\theta(t)-b(x_k))\,dt\right| d\varphi \\
&\le Cp\int_0^1\int_{t_1}^{t_2} x_k^{p-1}(1+x_k)\,dt\,d\varphi \\
&\le C\int_0^1\int_{t_1}^{t_2}((2p-1)x_k^p+1)\,dt\,d\varphi \quad \text{by (A.1)} \\
&\le C(2p-1)(G(T)+1)|t_2-t_1| \quad \text{by (A.3)}.
\end{aligned}$$

Thus (3) is true and the proposition is proved. ∎

ON A HELE–SHAW-TYPE DOMAIN EVOLUTION WITH CONVECTED SURFACE ENERGY DENSITY*

MATTHIAS GÜNTHER† AND GEORG PROKERT‡

Abstract. Interest is directed to a moving boundary problem with a gradient flow structure which generalizes surface tension–driven Hele–Shaw flow to the case of nonconstant surface tension coefficient taken along with the liquid particles at the boundary. In the case with kinetic undercooling regularization, well-posedness of the resulting evolution problem in Sobolev scales is proved, including cases in which the surface tension coefficient degenerates. The problem is reformulated as a vector-valued, degenerate parabolic Cauchy problem. To solve this, we prove and apply an abstract result on Galerkin approximations with variable bilinear forms.

Key words. free boundary motion, degenerate nonlocal parabolic evolution

1. Introduction. Various experimental studies investigate the influence of spatial variations of the surface energy density (corresponding to the surface tension coefficient γ) on surface tension–driven Hele–Shaw flows (cf., e.g., [15]). However, a mathematical model for such flows seems to be lacking. In this paper, a first step is attempted to close this gap. We derive and investigate a moving boundary problem which arises, at least from a mathematical point of view, as a natural generalization from the case where γ is a positive constant to the case of variable, nonnegative γ. Let us give an informal description of this generalization here; for details we refer to section 2.

The Hele–Shaw moving boundary problem with constant γ is well investigated. In particular, our starting point is the following observation [1, 8]: On the Fréchet manifold M of the surfaces Γ that bound a domain of fixed given volume, an evolution $t \mapsto \Gamma_t$ satisfying the moving boundary problem can be interpreted as a gradient flow with respect to (w.r.t.) the energy functional

$$\mathcal{E} = \mathcal{E}(\Gamma) := \gamma \operatorname{meas}(\Gamma) \tag{1.1}$$

and the Riemannian metric g given by (2.4).

In our generalization to nonconstant γ we use the energy functional

$$\mathcal{E} = \mathcal{E}(\Gamma, \gamma) := \int_\Gamma \gamma \, d\Gamma \tag{1.2}$$

and keep the demand that the evolution be given by a gradient flow w.r.t. the same Riemannian metric. (A parallel procedure applied to viscous free boundary flows leads to the usual description of the Marangoni effect.) This leads to two related difficulties: First, the functional $\mathcal{E}$ no longer depends on Γ only. This is resolved in

the following way: Instead of the manifold M we consider the vector bundle F over M, having as fiber space at Γ the (smooth) functions on Γ. On this bundle, $\mathcal{E}$ is well defined. Second, one also has to prescribe an evolution law for γ as a function on the moving surface $t \mapsto \Gamma_t$. Again, we make a simple choice: We assume γ to be transported along with the velocity field at the boundary, and we allow the tangential transport to be diminished by a "slip factor" $\delta \in [0, 1]$. The case $\delta = 1$ describes a fixed coupling of the values of γ to the moving liquid particles. Physically, this would occur, e.g., if γ is temperature-dependent and heat conduction is negligible. On the other hand, the case $\delta = 0$ corresponds to transport in the normal direction only. In differential geometric terms, this transport law is realized by introducing a suitable connection D on F and demanding parallel transport of γ; see (2.7)–(2.10).

Let us note here that we do not claim that these assumptions are necessarily in accordance with the physics of an actual Hele–Shaw flow with nonuniform surface energy density, e.g., induced by the presence of a surfactant. It is well conceivable that the interface dynamics in such a situation might be dominated by more complex phenomena like the occurrence of boundary layers, thin surfactant films, or other effects. For instance, if a surfactant is present, one has to solve a transport equation for the surfactant concentration and determine γ from this. (See [17] for the case of Stokes flow; such a modification of our problem would not present new principal difficulties.)

To test our assumptions in a concrete situation, numerical work as well as comparison with experiments would be necessary. However, even our simple model is of mathematical interest in its own right and as a typical example for nonlocal, degenerate parabolic evolutions.

In section 2 of this paper we derive the moving boundary problem (2.12), (2.13) from the gradient flow formulation. In what follows, we prove our main result, namely, a local existence and uniqueness result for this problem in scales of Sobolev spaces. For the precise formulation and further results concerning continuous dependence on the initial data, see Theorems 3.1 and 3.2. If the surface Γ_t and the coefficient γ_t are known at some time t, then the velocity potential ϕ_t is completely determined by (2.12). If one parametrizes Γ_t over a fixed reference surface S, the moving boundary problem can be interpreted as an evolution equation with nonlinear, nonlocal pseudodifferential operators. The parametrization can be constructed in at least two different ways: On one hand, it is possible to parametrize the surfaces using one scalar function, e.g., the normal distance to the reference surface. Then γ_t has to satisfy a transport equation whose coefficients depend on the parametrization and on the velocity potential. On the other hand, the moving boundary can also be represented by mappings $u(\cdot, t) : S \to \mathbb{R}^m$ whose time derivatives are given by the velocity vector, i.e.,

$$\partial_t u = \mathcal{F}(u) := \big((\nabla_N + \delta\nabla_T)\phi_t\big) \circ u,$$

where ∇_N and ∇_T denote the normal and tangential component of the gradient, respectively.

This formulation, which we will use in what follows, is $\mathbb{R}^m$-valued. Therefore, the corresponding Cauchy problem will be necessarily degenerate, even if γ is strictly positive (or even constant). However, this is no crucial disadvantage, as our problem couples a transport equation with a parabolic evolution and we allow γ to degenerate as well. Our approach has two favorable properties: γ now appears only as a known, time-independent function on the reference domain, and the additional freedom in the choice of the diffeomorphisms can be used to derive generalized chain rules for our nonlocal operators which reduce the technical effort in the proofs of the necessary estimates.

As long as γ is nonnegative, the normal component of the linearization $\mathcal{F}'(u)v$ behaves as a degenerate elliptic second order operator on the normal component of v, so that we have, e.g., w.r.t. the L^2-inner product

$$\left\langle n\cdot v, n\cdot\mathcal{F}'(u)v\right\rangle_{L^2} \le C\|v\|_{L^2}^2.$$

An estimate like this does not hold for the complete linearization, including the tangential components. Due to the special structure of $\mathcal{F}$, however, it is possible to define inner products $\langle\ ,\ \rangle_u$ which define equivalent norms on L^2 and satisfy

$$\left\langle v, \mathcal{F}'(u)v\right\rangle_u \le C\|v\|_{L^2}^2.$$

Defining higher order inner products $\langle\ ,\ \rangle_{u,s}$ on the basis of $\langle\cdot,\cdot\rangle_u$, one finally can show an H^s-energy estimate

$$\left\langle \mathcal{F}(u), u\right\rangle_{u,s} \le C\|u\|_s^2 \tag{1.3}$$

for s sufficiently large, and, on the other hand, the dependence of these inner products on u can be controlled by a weaker Sobolev norm. In a suitable abstract functional analytic framework, these estimates can be used to obtain proofs for our main results. Moreover, these results imply the existence of a unique solution $w := (\mathrm{Id}-\lambda\mathcal{F})^{-1}$ of the equation $w-\lambda\mathcal{F}(w)=v$ provided $\lambda\ge 0$ sufficiently small. The solution of the Cauchy problem for the evolution equation is given by the exponential formula

$$u(t) = \lim_{n\to\infty}\Big(\mathrm{Id}-\frac{t}{n}\mathcal{F}\Big)^{-n}u(0)$$

with convergence in H^s provided $u(0)\in H^s$, s sufficiently large.

The structure of the paper after section 2 is as follows: In section 3, we introduce the necessary notation and announce our main results together with the abstract existence theorems which are used. Section 4 is devoted to the behavior of our (nonlocal) operators in scales of Sobolev spaces, and in section 5 the u-dependent inner products are introduced and the necessary estimates are shown. Finally, the main results (Theorems 3.1 and 3.2) are proved in section 6. The proof of a general abstract existence result (Theorem 3.4), which may be of independent interest, is given in the appendix.

2. The equations of motion. Here we characterize the moving boundary problem as abstract gradient flow on the manifold of the natural configuration space. We start by recalling the following general properties of incompressible, source-free Hele–Shaw flows. One looks for a family of domains $\Omega(t)\subset\mathbb{R}^m$ parametrized by time $t\ge 0$ and corresponding velocity fields $\mathbf{v}(\cdot,t)$ such that (according to Darcy's law)

$$\mathbf{v}(\cdot,t) = \nabla\varphi(\cdot,t)\ \text{ in }\ \Omega(t) \tag{2.1}$$

with a potential field $\varphi(\cdot,t)$ proportional to negative pressure. As we also demand that the boundary $\Gamma(t)$ of $\Omega(t)$ moves along with the velocity field, we find the kinematic boundary condition

$$V_n(t) = \partial_n\varphi(\cdot,t)\ \text{ on }\ \Gamma(t), \tag{2.2}$$

where $V_n(t)$ is the normal velocity of the moving boundary $\Gamma(t)$ and $\partial_n=\partial/\partial n$ is the derivative in direction of the unit outward normal $n(t)$ of $\Gamma(t)$. As $\mathbf{v}$ is divergence-free,

$$\Delta\varphi(\cdot,t) = 0\ \text{ in }\ \Omega(t). \tag{2.3}$$

Thus, in any Hele–Shaw flow, the complete velocity field is determined by the normal velocity at the boundary.

If the surface tension coefficient is a positive constant, the corresponding surface energy is proportional to the surface area and the Hele–Shaw flow driven by surface tension can be interpreted as abstract gradient flow of this functional w.r.t. an appropriately chosen inner product; cf. [1, 8]. As this formulation is a main ingredient in our derivation of the moving boundary problem below, we define this inner product more precisely. Consider for the time being a fixed smooth domain Ω with boundary Γ and define

$$V_\Gamma := \left\{ v \in C^\infty(\Gamma) \;\middle|\; \int_\Gamma v \, d\Gamma = 0 \right\}.$$

The space V_Γ can be interpreted as the space of all possible normal boundary velocities; the restriction expresses conservation of volume. We fix $\beta \geq 0$ and introduce on V_Γ the bilinear form g_Γ given by

$$g_\Gamma(v_1, v_2) := \int_\Omega \nabla\varphi_1 \nabla\varphi_2 \, dx + \beta \int_\Gamma v_1 v_2 \, d\Gamma, \tag{2.4}$$

where the φ_i, $i = 1, 2$, are (weak) solutions of the Neumann problems

$$\Delta\varphi_i = 0 \;\text{ in }\; \Omega, \quad \partial_n \varphi_i = v_i \;\text{ on }\; \Gamma.$$

To give a physical interpretation of the quadratic functional $v \mapsto g_\Gamma(v, v)$ we remark that the first term represents energy dissipation by the corresponding Hele–Shaw flow (cf. [8]), while for $\beta > 0$ the second term is a penalty for large normal boundary velocities. Note that, by Green's formula,

$$g_\Gamma(v_1, v_2) = \int_\Gamma \big(\varphi_1 + \beta \partial_n \varphi_1\big) v_2 \, d\Gamma. \tag{2.5}$$

In differential geometric terms, this inner product defines a Riemannian metric on the Fréchet manifold M of boundaries $\Gamma = \partial\Omega$ to smooth compact domains $\Omega \subset \mathbb{R}^m$ with given fixed volume. By interpreting a tangent vector at $\Gamma \in M$ as the normal velocity field of the boundary, there is a natural way of thinking of vector fields X on M as sections in the Fréchet vector bundle $E = \cup_{\Gamma \in M} V_\Gamma$ with base M and fiber V_Γ; i.e., there is a natural isomorphism $T_\Gamma M \simeq V_\Gamma$ and we have for any real functional $J \in C^\infty(M)$

$$(XJ)(\Gamma) = \partial_\varepsilon J(\Gamma_\varepsilon)|_{\varepsilon=0},$$

where $\varepsilon \mapsto \Gamma_\varepsilon \in M$ is a path of admissibles shapes with normal velocity v for $\varepsilon = 0$,

$$\Gamma_\varepsilon := \big\{ x_\varepsilon \;\big|\; x \in \Gamma \big\}, \qquad x_\varepsilon := x + \varepsilon\big(v(x) + O(\varepsilon)\big) n(x). \tag{2.6}$$

Thus, identifying a vector $X_\Gamma \in T_\Gamma M$ in this sense with its image $v \in V_\Gamma$ and considering smooth domain dependence of the solution to a Neumann problem, $\Gamma \mapsto g_\Gamma$ defines a Riemannian metric g on the manifold M. It is remarkable that in the case $\beta = 0$ a geodetic line w.r.t. this metric g represents the motion of an incompressible irrotational perfect fluid with a free boundary; for the corresponding Levi-Civita derivative, Riemannian curvature, and an analysis of the Jacobi equation from a differential geometric point of view, we refer to [3].

Now, considering first the surface energy (1.1) with constant γ, the normal velocity $V_n \in V_\Gamma$ of a surface tension–driven Hele–Shaw flow is determined by

$$g_\Gamma\big(V_n, v\big) = -\mathcal{E}'(\Gamma)\{v\} \;\text{ for all }\; v \in V_\Gamma,$$

where $\mathcal{E}'(\Gamma)\{v\} := (X\mathcal{E})(\Gamma)$ denotes the derivative of the energy in the direction of $X_\Gamma \simeq v$. As a consequence, at each instant of time t the flow reduces the surface energy as rapidly as possible among all normal velocities with prescribed norm corresponding to the inner product (2.4); in particular, the flow is volume preserving and surface area decreasing. By a well-known formula for the first variation of surface area, we find

$$\mathcal{E}'(\Gamma)\{v\} = -\int_\Gamma \kappa v \, d\Gamma,$$

where κ is the mean curvature of Γ with sign determined by the above variation formula (negative sign if Ω is convex); for notational convenience, throughout the paper the usual normalization of κ has been changed by a cofactor $m-1$. To model the influence of a variable surface tension coefficient which is coupled on a transport mechanism, it is now quite natural to consider a surface energy functional of the form (1.2) where $\gamma \geq 0$ denotes a surface energy density function along Γ, not necessarily constant. It should be noted that we don't assume a priori a one-to-one correspondence between the surface Γ and density γ, as is the case in simpler situations, e.g., where a known global function generates the density via restriction or where an anisotropic surface energy density is considered, i.e.,

$$\gamma = f|_\Gamma \quad \text{or} \quad \gamma = f \circ n \;\text{ on }\; \Gamma,$$

given $f \in C^\infty(\mathbb{R}^m)$ or $f \in C^\infty(\mathbb{S}^{m-1})$, respectively; the latter energy density is commonly used to model crystal growth problems. In fact, in our setting the functional $\mathcal{E}$ is uniquely defined on the vector bundle $F := \cup_{\Gamma \in M} C^\infty(\Gamma)$ with base M only. In such a case, computation of the derivative of the surface energy in the direction of a given vector field requires a law for the change of γ on the moving surface. Using differential geometric terms we make the following assumption: along a path c in M the energy density is transported by parallel displacement w.r.t. a given connection D_X which acts on sections γ in F, i.e.,

$$D_{\dot{c}}\gamma = 0 \;\text{ along }\; c. \tag{2.7}$$

In further considerations we restrict our attention to the connection D_X, defined as follows: Let X be any vector field, let $\Gamma \in M$, and let $v \in V_\Gamma$ with $X_\Gamma \simeq v$; then we set for any section γ in F

$$D_X\gamma|_\Gamma := \partial_\varepsilon \bar{\gamma}_\varepsilon\,|_{\varepsilon=0} + \delta \nabla_\Gamma \psi \nabla_\Gamma \gamma, \quad \delta \in [0,1], \tag{2.8}$$

where in terms of the notation (2.6)

$$\bar{\gamma}_\varepsilon(x) := \bar{\gamma}_{\Gamma_\varepsilon}(x_\varepsilon), \quad (\varepsilon, x) \in (-\varepsilon_0, \varepsilon_0) \times \Gamma, \tag{2.9}$$

and ψ is a solution of the Neumann problem

$$\Delta\psi = 0 \;\text{ in }\; \Omega, \quad \partial_n \psi = v \;\text{ on }\; \Gamma. \tag{2.10}$$

Interpretation of D_X and parallel transport w.r.t. D_X is quite obvious in terms of the underlying Hele–Shaw flow. In contrast to the case of constant γ, we also have to consider the influence of the tangential motion at the boundary which results from a normal variation of the boundary. As pointed out before, in a Hele–Shaw flow the velocity field corresponding to a normal boundary velocity $v \in V_\Gamma$ is $\nabla\psi$, where ψ solves (2.10). Hence, in the case $\delta = 1$, (2.7), (2.8) express that the surface energy density is transported along with the liquid particles, i.e., with the velocity field $\nabla\psi$ at the boundary. On the other hand, in the case of $\delta = 0$, transport in the normal direction without any tangential movement is expressed. The other cases are intermediate. On V_Γ we define the linear operator A_{ND} (Neumann-to-Dirichlet operator) by

$$A_{ND}v := \psi|_\Gamma,$$

where ψ satisfies (2.10) and $\int_\Gamma \psi \, d\Gamma = 0$. Hence, again in terms of the notation (2.6), the assumption $D_v\gamma|_\Gamma = 0$ implies

$$\partial_\varepsilon \bar{\gamma}_\varepsilon \,|_{\varepsilon=0} = -\delta \nabla_\Gamma \gamma \nabla_\Gamma A_{ND} v$$

and we obtain for

$$\mathcal{E}'(\gamma,\Gamma)\{v\} := \frac{d}{d\varepsilon}\mathcal{E}(\gamma_\varepsilon,\Gamma_\varepsilon)\Big|_{\varepsilon=0}$$

using again the formula for the first variation of area

$$\mathcal{E}'(\gamma,\Gamma)\{v\} = \int_\Gamma \big(\partial_\varepsilon \bar{\gamma}_\varepsilon \,|_{\varepsilon=0} - \kappa\gamma v\big)\, d\Gamma = -\int_\Gamma \big(\kappa\gamma v + \delta\nabla_\Gamma\gamma\nabla_\Gamma\psi\big)\, d\Gamma.$$

It easily follows from Green's formula that A_{ND} is symmetric w.r.t. the usual L^2-inner product on Γ, and thus

$$\mathcal{E}'(\gamma,\Gamma)\{v\} = -\int_\Gamma (\gamma\kappa v - \delta\Delta_\Gamma\gamma\, A_{ND}v)\, d\Gamma = -\int_\Gamma (\gamma\kappa - \delta A_{ND}\Delta_\Gamma\gamma) v \, d\Gamma. \tag{2.11}$$

We have to consider (2.7), (2.11) as a differential rule for the change of surface energy dependent upon surface and energy density. They allow the computation of the energy along any path in M starting from a known initial shape $\Gamma(0)$ with known energy density γ_0. But of course, in general, this computation is path-dependent; i.e., the resulting energy in the endpoint of the path will depend on the history along the whole path.

Now, as in the case of constant γ, we define the normal velocity $V_n \in V_\Gamma$ as a solution of the variational problem

$$g_\Gamma(V_n, v) = -\mathcal{E}'(\gamma,\Gamma)\{v\} \text{ for all } v \in V_\Gamma.$$

Together with (2.2), (2.5), and (2.11), this yields the dynamic boundary condition

$$\varphi + \beta\partial_n\varphi = \gamma\kappa - \delta A_{ND}\Delta_\Gamma\gamma.$$

Summarizing and using an auxiliary function ψ instead of the nonlocal operator A_{ND}, we have obtained the following moving boundary problem: For a given bounded domain $\Omega(0) \subset \mathbb{R}^m$ and a given nonnegative function γ_0 defined on $\partial\Omega(0)$ one looks for a family of C^2-domains $\Omega(t) \subseteq \mathbb{R}^m$, $t > 0$, and functions $\varphi(\cdot,t), \psi(\cdot,t) \in C^2\big(\overline{\Omega(t)}\big)$, $\gamma_t \in C^2\big(\Gamma(t)\big)$ such that

$$
\left\{
\begin{aligned}
\Delta\varphi(\cdot,t) &= 0 && \text{in } \Omega(t),\\
\Delta\psi(\cdot,t) &= 0 && \text{in } \Omega(t),\\
\partial_n\psi(\cdot,t) &= \Delta_{\Gamma(t)}\gamma_t && \text{on } \Gamma(t),\\
\varphi(\cdot,t) + \beta\partial_n\varphi(\cdot,t) &= \gamma_t\kappa(t) - \delta\psi(\cdot,t) && \text{on } \Gamma(t),\\
V_n(t) &= \partial_n\varphi(\cdot,t) && \text{on } \Gamma(t),
\end{aligned}
\right.
\tag{2.12}
$$

where $\kappa(t)$ is the curvature of $\Gamma(t)$. In the main part of this paper, we restrict our attention to the case $\delta = 1$. The generalization to $\delta \in [0,1)$ is sketched at the end of section 5. Additionally, we describe the transport of γ by (2.7), (2.8) with $\delta = 1$. Introducing Lagrangian coordinates $x = x(\xi,t)$, $\xi \in \Gamma(0)$ corresponding to the velocity field via

$$
\partial_t x(\xi,t) = \nabla\varphi\big(x(\xi,t),t\big) \quad \text{for} \quad t \geq 0, \qquad x(\xi,0) = \xi,
\tag{2.13}
$$

we obtain from (2.2) that $x = x(\cdot,t)$ is a diffeomorphism from $\Gamma(0)$ onto $\Gamma(t)$, and the transport law for γ_t takes the form

$$
\gamma_t\big(x(\xi,t)\big) = \gamma_0(\xi), \qquad \xi \in \Gamma(0),\ t \geq 0.
\tag{2.14}
$$

In (2.12), $\varphi(\cdot,t)$ and $\psi(\cdot,t)$ are determined up to a constant only, but this is without significance for the evolution of both $\Omega(t)$ and γ_t. Note that in the case $\beta = 0$, by setting $\Phi = \varphi + \psi$, (2.12) simplifies to

$$
\left\{
\begin{aligned}
\Delta\Phi(\cdot,t) &= 0 && \text{in } \Omega(t),\\
\Phi(\cdot,t) &= \gamma_t\kappa(t) && \text{on } \Gamma(t),\\
V_n &= \partial_n\Phi(\cdot,t) - \Delta_{\Gamma(t)}\gamma_t && \text{on } \Gamma(t).
\end{aligned}
\right.
\tag{2.15}
$$

In what follows, however, we will restrict our attention to the case $\beta > 0$. Without loss of generality, we can assume $\beta = 1$. In the case $\beta > 0$, $\delta = 1$, we can show well-posedness of our moving boundary problem even if γ is zero on parts of the boundary, provided its square root is smooth. This seems to be particular to this situation. We intend to discuss the case $\beta = 0$, which leads to a third order problem, in a forthcoming paper.

For $\gamma_t = \gamma = \text{const}$ and $\gamma > 0$, ψ is constant, and (2.12) is known as the so-called Hele–Shaw flow problem with kinetic undercooling and surface tension regularization. From a modeling point of view, this problem can be seen as the quasi-stationary version of the well-known Stefan problem. In this context, the boundary condition incorporates both the Gibbs–Thomson surface energy and a nonequilibrium effect of temperature decrease at the advancing phase boundary. A short-time existence proof for this problem and a proof that its solution is the limit for the solutions of the corresponding Stefan problems can be found in [20]. For existence results concerning a corresponding two-phase problem we refer to [5, 21]. Both effects are known to regularize the motion of the interface, and this is also true for Hele–Shaw flow problems [13, 18, 19]. In the case $\gamma \equiv 0$, with internal sources or sinks as driving forces, existence results are given in [11] for the two-dimensional case and analytic data and in [16] for arbitrary dimensions in the framework of Sobolev spaces.

If γ is a positive constant, the moving boundary has stable, attractive equilibria which are given by the spheres (see, e.g., [4, 6, 7] for the case $\beta = 0$). In general, however, after prescribing a nonconstant function γ on the reference domain and an initial diffeomorphism u, it is not a priori clear (even with γ near a constant and the moving domain near a ball) what the long-time evolution and the corresponding equilibrium will be. Instead, determining the equilibria belonging to a γ prescribed on the reference domain leads to a stationary free boundary problem in ψ whose solvability and stability (for Γ near a sphere and γ near a constant) we intend to discuss elsewhere.

3. Notation and main results. We list some notation. $C, C_1, \dots$, etc., denote generic constants; their dependences on other quantities is indicated only if not obvious from the context. Let $E \subseteq \mathbb{R}^m$, $m \geq 2$, be a bounded domain with smooth boundary $S := \partial E$ and ν the outer unit normal on S. For $M = S$ or $M = E$, we make constant use of the usual L^2-based Sobolev spaces $H^s(S)$, $H^s(S, \mathbb{R}^m)$ of order s with values in $\mathbb{R}$ and $\mathbb{R}^m$, respectively. If no confusion is likely, we just write H^s. The norms of these spaces will be denoted by $\|\cdot\|_s^M$; for $M = S$ the upper index M is dropped in most cases. When Fréchet derivatives of operator-valued mappings are considered, the additional arguments describing the variations are written in braces ($\{\,\}$).

3.1. Well-posedness for the moving boundary problem. Now, as already mentioned in the introduction, we reformulate the moving boundary problem (2.12)–(2.14) by describing $\Gamma(t)$ as an embedding $u(\cdot, t) : S \to \mathbb{R}^m$ such that the curves $t \mapsto u(y, t)$ for fixed $y \in S$ are trajectories belonging to the velocity field and γ_t is constant along these curves. This approach enables us to consider γ_t as a known function during the evolution at the cost of describing the moving boundary by m functions. To do so, let

$$U := \bigl\{u : S \to \mathbb{R}^m \bigm| u = w|_S \text{ with } w \in \mathrm{Diff}(\bar{E}, \Omega_u \cup \Gamma_u)\bigr\}, \tag{3.1}$$

where

$$\Omega_u := w(E) \quad \text{and} \quad \Gamma_u := \partial\Omega_u = u(S).$$

Throughout this paper, we use the abbreviation

$$U_s := U \cap H^s(S, \mathbb{R}^m).$$

Now, (2.12)–(2.14) is reduced to the following Cauchy problem, which will be investigated in what follows: Given $u_0 \in U_s$, s sufficiently large, we look for $T > 0$ and a mapping $[0, T] \ni t \mapsto u(t) \in U_s$, such that

$$u'(t) = \mathcal{F}\bigl(u(t)\bigr), \quad t \in [0, T], \tag{3.2}$$

$$u(0) = u_0. \tag{3.3}$$

Thereby, for $u \in U$, we have set

$$\mathcal{F}(u) := F(u)\bigl(\mathcal{G}(u)\bigr) \quad \text{with} \quad \mathcal{G}(u) := H(u) + G(u), \tag{3.4}$$

where, for any given function f on S,

$$F(u)f := \nabla\varphi(u, f) \circ u, \tag{3.5}$$

and $\varphi = \varphi(u, f)$ denotes the solution of the Robin boundary value problem

$$\Delta\varphi = 0 \text{ in } \Omega_u, \quad \partial_n\varphi + \varphi = f \circ u^{-1} \text{ on } \Gamma_u. \tag{3.6}$$

Further, $H(u)$, $G(u)$ are given by

$$H(u) := \gamma(\kappa_{\Gamma_u} \circ u), \quad G(u) := -A(u)\big(\Delta(u)\gamma\big). \tag{3.7}$$

Here $\gamma \in C^\infty(S)$ is a fixed and given nonnegative function, κ_{Γ_u} denotes the mean curvature of Γ_u with sign and scaling conventions as above,

$$\Delta(u)w := \Delta_{\Gamma_u}(w \circ u^{-1}) \circ u \tag{3.8}$$

is the pullback to S of the Laplace–Beltrami operator Δ_{Γ_u} on Γ_u, and

$$A(u)f := \varphi_N\big(u, f\big) \circ u \tag{3.9}$$

is the Neumann–Dirichlet operator, i.e., $\varphi_N = \varphi_N(u, f)$ solves the Neumann problem

$$\Delta\varphi_N = 0 \text{ in } \Omega_u, \quad \partial_n \varphi_N = c + f \circ u^{-1} \text{ on } \Gamma_u, \quad \textstyle\int_{\Gamma_u} \varphi_N \, dx = 0. \tag{3.10}$$

The constant $c = c(u, f) \in \mathbb{R}$ in (3.10) is determined by the solvability condition

$$\int_{\Gamma_u} (f \circ u + c)\, d\Gamma_u = 0; \tag{3.11}$$

clearly $c(u, f) = 0$ for $f = \Delta(u)\gamma$. For fixed smooth γ on S, the mappings $u \mapsto H(u)$ and $u \mapsto \Delta(u)\gamma$ constitute quasi-linear second order differential operators on S. Moreover, the solutions of the boundary value problems (3.6), (3.10) depend smoothly on the domain Ω_u, i.e., on $u \in H^s$, $s > (m+1)/2$, and $f \mapsto F(u)f$, $f \mapsto A(u)f$ represent pseudodifferential operators of order zero and minus one, respectively. In particular, G is a pseudodifferential operator of lower order than H and may be considered as a correction term to ensure the gradient flow structure of the evolution problem. For precise formulations of the mapping properties of F and A and detailed proofs, see section 4. As a consequence, this leads to

$$[u \mapsto \mathcal{F}(u)] \in C^\infty\big(U_s, H^{s-2}(S, \mathbb{R}^m)\big) \tag{3.12}$$

for $s > (m+3)/2$. Now we are in position to formulate our main results.

THEOREM 3.1 (short-time existence and uniqueness). *Fix an integer $s_0 > (m+5)/2$ and assume $\gamma = \rho^2$ with $\rho \in C^\infty(S)$. Let $s \geq s_0$ be an integer and let $u_0 \in U_s$. Then there exists $T > 0$ and a unique solution*

$$u \in C\big([0, T], U_s\big) \cap C^1\big([0, T], H^{s-2}(S, \mathbb{R}^m)\big) \tag{3.13}$$

of the initial value problem (3.2), (3.3). *Additionally, any given $\bar{u}_0 \in U_{s_0}$ has a suitable H^{s_0}-neighborhood K, such that for initial values u_0 varying in $K \cap H^s$, there are $T > 0$ and C independent of u_0 such that*

$$\|u(t)\|_s \leq C(1 + \|u(0)\|_s) \text{ for all } t \in [0, T]. \tag{3.14}$$

THEOREM 3.2 (regularity and continuous dependence on initial values). *Under the assumptions of Theorem* 3.1 *let u be any solution to* (3.2) *in the class* (3.13) *with some $T > 0$. Then the following holds:*

(i) $u(0) \in H^{s+1}(S, \mathbb{R}^m)$ *implies*

$$u \in C\big([0, T], U_{s+1}\big) \cap C^1\big([0, T], H^{s-1}(S, \mathbb{R}^m)\big).$$

(ii) *Assume $u_0^n \to u_0$ in $H^s(S, \mathbb{R}^m)$ for $n \to \infty$. Then, for n sufficiently large, there exist solutions u_n of* (3.2) *in the class* (3.13) *with initial values $u_n(0) = u_0^n$, and there holds $u_n \to u$ in $C\big([0, T], H^s(S, \mathbb{R}^m)\big)$.*

The proofs of both theorems are given in section 6.

3.2. An existence result for abstract evolution equations. Here we consider (3.2), (3.3) as an abstract nonlinear Cauchy problem for an unknown function $u = u(t)$ with values in a Banach space and prove existence of a solution if the nonlinearity $\mathcal{F}$ satisfies a certain condition of semiboundedness w.r.t. a family of bilinear forms. As a general framework we adopt the following assumptions:

$$\text{(H)}\quad \begin{cases} \text{Let } X \subseteq Y \subseteq Z \text{ be real, separable Banach spaces with dense and} \\ \text{continuous embeddings and } \mathcal{U} \subseteq Y \text{ open. For every } u \in \mathcal{U} \text{ let } \langle \cdot,\cdot \rangle_u : \\ X \times Z \to \mathbb{R} \text{ be a continuous and nondegenerate bilinear form, such} \\ \text{that with fixed constants } C \geq 1,\ M \geq 0, \\ \text{(H1)} \quad \langle v, w\rangle_u = \langle w, v\rangle_u \text{ for all } v, w \in X; \\ \text{(H2)} \quad C^{-1}\|v\|_Y^2 \leq \langle v,v\rangle_u \leq C\|v\|_Y^2 \text{ for all } v \in X,\ u \in \mathcal{U}; \\ \text{(H3)} \quad \langle v,v\rangle_u \leq \langle v,v\rangle_w \big(1 + M\|u-w\|_Z\big) \text{ for all } v \in X,\ u,w \in \mathcal{U}; \\ \text{(H4)} \quad \text{weak convergences } u_n \rightharpoonup u \text{ in } Y,\ u_n, u \in \mathcal{U}, \text{ and } w_n \rightharpoonup w \text{ in} \\ \qquad\quad Z \text{ imply } \langle v, w_n\rangle_{u_n} \to \langle v, w\rangle_u \text{ for all } v \in X. \end{cases}$$

Assuming (H) holds, by the dense embedding $X \subseteq Y$ and

$$\big|\langle v, w\rangle_u\big|^2 \leq \langle v,v\rangle_u \langle w,w\rangle_u \leq C^2\|v\|_Y^2\|w\|_Y^2 \ \text{ for } \ v, w \in X$$

there exists for each $u \in \mathcal{U}$ an inner product $(\cdot,\cdot)_u$ on Y, which is compatible with $\langle\cdot,\cdot\rangle_u$; i.e., we have

$$(v,w)_u = \langle v,w\rangle_u \ \text{ for } \ v \in X, w \in Y.$$

Moreover, for $u_n, u \in \mathcal{U}$, $u_n \rightharpoonup u$, $w_n \rightharpoonup w$ in Y implies

$$(v, w_n)_{u_n} \to (v,w)_u \ \text{ for all } \ v \in X.$$

In further considerations, for the sake of brevity we put

$$\|v\|_u = (v,v)_u^{1/2}, \quad |||u||| = (u,u)_u^{1/2}\ .$$

Assumption (H2) implies that $\|\cdot\|_Y$ and $\|\cdot\|_u$ are equivalent, and hence Y has all topological properties of a Hilbert space—in particular, Y is reflexive. From $u_n, u \in \mathcal{U}$, $u_n \rightharpoonup u$ in Y it follows that

$$|||u||| \leq \underline{\lim}_{\,n\to\infty} |||u_n|||\ ;$$

if $|||u||| = \lim_{n\to\infty} |||u_n|||$, one concludes hereby that $u_n \to u$ in Y.

THEOREM 3.3. *Let* (H) *be valid and let* $\mathcal{F} : \mathcal{U} \to Z$ *be a weakly sequentially continuous mapping such that for every* $u_0 \in \mathcal{U}$ *there exists a neighborhood* $B(u_0) \subset \mathcal{U}$ *of* u_0 *in* Y *with*

$$\sup\big\{\langle u, \mathcal{F}(u)\rangle_u \ \big|\ u \in B(u_0) \cap X\big\} < +\infty. \tag{3.15}$$

Then for any $u_0 \in \mathcal{U}$, *there exist* $T > 0$ *and a solution* u *of* (3.2), (3.3) *in the class*

$$C_w\big([0,T],\mathcal{U}\big) \cap C_w^1\big([0,T], Z\big). \tag{3.16}$$

Additionally, this solution satisfies $u(t) \to u_0$ *in* Y *for* $t \to +0$. *Moreover,* $T > 0$ *can be chosen uniformly for initial values taken from a suitable neighborhood of* u_0 *in* Y.

In (3.16), we denote by $C_w\big([0,T],\mathcal{U}\big)$ the space of functions from $[0,T]$ to $\mathcal{U}$ which are continuous w.r.t. weak convergence in Y. Similarly, $C_w^1\big([0,T],Z\big)$ denotes the set of weakly differentiable functions from $[0,T]$ to Z with the derivative in $C_w\big([0,T],Z\big)$. It should be noted that in general there is no uniqueness and no continuous dependence on initial data in any sense in Theorem 3.3. This theorem can be easily derived from a more elaborate, quantitative formulation given in the next theorem. Note that, for the limit case $R=+\infty$ and bilinear forms independent of u, this theorem coincides with Theorem A in [14], but, as already mentioned in the introduction, our application requires only the generalization to such variable bilinear forms.

Theorem 3.4. *Assume* (H) *is satisfied with some ball*

$$\mathcal{U}=B:=\big\{u\in Y\;\big|\;\|u\|_Y<R\big\},\quad R>0,$$

and $\mathcal{G}:B\to Z$ is a weakly sequentially continuous mapping such that

$$2\langle u,\mathcal{G}(u)\rangle_u+M\,\|\mathcal{G}(u)\,\|_Z|||u|||\le\beta\big(|||u|||^2\big)\ \text{ for all }\ u\in X\cap B \tag{3.17}$$

with a C^1-function $\beta:\mathbb{R}_+\to\mathbb{R}_+=[0,\infty)$. Let $u_0\in B$,

$$|||u_0|||<r:=R/(2C^3)^{1/2},$$

and $T>0$ such that the solution ρ of the scalar Cauchy problem

$$d\rho/dt=\beta\big(\rho(t)\big),\quad \rho(0)=|||u_0|||^2 \tag{3.18}$$

exists on $[0,T]$ and satisfies $\rho(t)<r^2$ there. Then the Cauchy problem

$$u'(t)=\mathcal{G}(u(t)),\qquad u(0)=u_0 \tag{3.19}$$

possesses a solution u in the class (3.16) *for which additionally*

$$\begin{gathered}|||u(t)|||^2\le\rho(t)\ \text{ for all }\ t\in[0,T],\\ u(t)\to u_0\ \text{ in }\ Y\ \text{ for }\ t\to+0.\end{gathered}$$

The proof of this theorem will be given in the appendix.

Proof of Theorem 3.3. Let $u_0\in\mathcal{U}$ and $B(u_0)$ as in Theorem 3.3 be given. We set

$$\begin{gathered}\mathcal{G}(v)=\mathcal{F}(v+w_0)\ \text{ for }\ v\in B:=\big\{v\in Y\;\big|\;\|v\|_Y<R\big\},\\ \langle\cdot,\cdot\rangle_{v,1}:=\langle\cdot,\cdot\rangle_{v+w_0},\quad |||v|||_1:=(v,v)_{v+w_0}^{1/2},\end{gathered}$$

whereby the density of X in Y enables us to choose $w_0\in X$ and $R>0$ such that

$$\|w_0-u_0\|_Y<R/(32C^5)^{1/2},\quad \big\{w_0+v\;\big|\;v\in B\big\}\subseteq B(u_0).$$

Clearly, the bilinear form $\langle\cdot,\cdot\rangle_{v,1}$, $v\in B$, satisfies the assumptions (H) again (with the same constants as $\langle\cdot,\cdot\rangle_u$, $u\in\mathcal{U}$). Further, by (3.15), there exists $L>0$ such that

$$\langle v+w_0,\mathcal{G}(v)\rangle_{v,1}\le L\ \text{ for all }\ v\in B\cap X$$

and, by the weak sequential continuity of $\mathcal{F}$, the reflexivity of Y and (H4),

$$\big|\langle w_0,\mathcal{G}(v)\rangle_{v,1}\big|,\|\mathcal{G}(v)\|_Z\le L\ \text{ for all }\ v\in B.$$

Thus

$$2\langle v, \mathcal{G}(v)\rangle_{v,1} + M\|\mathcal{G}(v)\|_Z |||v|||_1 \le K \text{ for all } v \in B \cap X$$

with $K := L(4 + MCR)$. Now, for any given $w \in Y$ with

$$\|w - u_0\|_Y \le R/(32C^5)^{1/2},$$

we apply Theorem 3.4 to solve the initial value problem

$$dv/dt = \mathcal{G}(v), \quad v(0) = w - w_0,$$

which corresponds to (3.2) with initial value $u(0) = w$. As

$$|||w - w_0|||_1 \le C\big(\|w - u_0\|_Y + \|u_0 - w_0\|_Y\big) < r/2, \quad r := R/(2C^3)^{1/2},$$

Theorem 3.4 ensures the existence of a solution in the class (3.16) with $T = 3r^2/(4K)$ and $v(t) \to w - w_0$ in Y for $t \to +0$. ∎

4. Smooth domain dependence of the nonlocal operators. In this section we study the domain dependence, i.e., dependence on $u \in U_s$, of the Robin problem (3.6) by transforming it into a boundary value problem on the fixed reference domain E. In particular, we derive multilinear estimates for the Fréchet derivatives w.r.t. u. The crucial tools here will be estimates for (multiple) pointwise products in our scale of Sobolev spaces and a differentiation rule based on invariance properties of the nonlocal operators.

To begin with, we recall some well-known basic properties and estimates concerning Sobolev spaces. For $s > d/2$, where M is E or S and $d = \dim M/2$, the spaces $H^s(M)$ turn into Banach algebras and the pointwise product of functions $w_1, \dots, w_n \in H^s(M)$ allows the estimate

$$\|w_1 w_2 \cdots w_n\|_s^M \le C \sum_{i=1}^{n} \Big(\|w_i\|_s^M \prod_{j\ne i} \|w_j\|_{s_0}^M\Big) \tag{4.1}$$

if $s \ge s_0 > d/2$. Moreover, for such values of s the composition of C^∞-functions with H^s-functions leads to H^s-functions again: e.g., $\Psi \in C^\infty(\bar{M} \times \mathbb{R})$ and $w \in H^s(M)$ imply $\Psi(\cdot, w(\cdot)) \in H^s(M)$ (note the continuity of w by Sobolev's embedding),

$$\big[w \mapsto \Psi(\cdot, w(\cdot))\big] \in C^\infty\big(H^s(M), H^s(M)\big), \tag{4.2}$$

and it holds that

$$\|\Psi(\cdot, w(\cdot))\|_s^M \le C\big(1 + \|w\|_s^M\big) \tag{4.3}$$

for all w from bounded subsets of $H^{s_0}(M)$, where the constant depends, in addition to s_0, s, and M, on Ψ and on upper bounds of $\|w\|_{s_0}$. In particular,

$$\|1/w\|_s^M \le C\big(\alpha, \|w\|_{s_0}^M\big)\|w\|_s^M \tag{4.4}$$

for all $w \in H^s(M)$ with $w \ge \alpha > 0$ on M. On the other hand, we have the following counterpart of (4.1) for the product of functions $w_1 \in H^{s_1}(M), \dots, w_n \in H^{s_n}(M)$:

$$\|w_1 w_2 \cdots w_n\|_s^M \le c\, \|w_1\|_{s_1}^M \|w_2\|_{s_2}^M \cdots \|w_n\|_{s_n}^M \tag{4.5}$$

if $0 \le s \le s_1, \dots, s_n \le s_0$ with $s_1 + \dots + s_n \ge s + (n-1)s_0$ and $s_0 > d/2$.

In the following, for functions w defined on S let $\mathcal{E}w$ be an extension into $\bar{E}$, i.e., $\mathcal{E}w|_S = w$, whereby the trace mapping theorem permits us to choose

$$\mathcal{E} \in \mathcal{L}\big(H^s(S), H^{s+1/2}(E)\big) \text{ for all } s > 0. \tag{4.6}$$

For $\mathbb{R}^m$-valued functions we apply $\mathcal{E}$ componentwise.

Our first technical concern is the extension of the mapping $u \in U_s$ to a suitable diffeomorphism $\widetilde{u}$ from $\bar{E}$ to $\Omega_u \cup \Gamma_u$. For fixed, smooth $u_0 \in \operatorname{Diff}(\bar{E}, \Omega_u \cup \Gamma_u)$, (4.7) clearly defines a possible extension for all u in U_s such that $\|u_0|_S - u\|_s < \varepsilon$ for sufficiently small $\varepsilon > 0$. However, ε depends on u_0 in an uncontrolled way. Eventually, this would restrict our existence results to evolutions in an open and dense subset of U_s containing $U_s \cap C^\infty(S, \mathbb{R}^m)$ but being uncharacterized otherwise. The following lemma provides a way to avoid this unnecessary restriction.

Lemma 4.1. *Let $v \in U_s$, $s > (m+1)/2$. Then there exist an H^s-neighborhood $V_s \subseteq U_s$ of v and a map $u_0 \in C^\infty(\bar{E}, \mathbb{R}^m)$ such that for every $u \in V_s$ the mapping*

$$\widetilde{u} := u_0 + \mathcal{E}(u - u_0) \tag{4.7}$$

defines a diffeomorphism of $\bar{E}$ onto $\bar{\Omega}_u$.

Proof. By the definition (3.1) of U, every $v \in U$ has an extension $v_1 \in \operatorname{Diff}(\bar{E}, \bar{\Omega}_v)$ and there exists an $\varepsilon > 0$ such that $w \in \operatorname{Diff}(\bar{E}, \bar{\Omega}_{w|_S})$ for all $w \in C^1(\bar{E}, \mathbb{R}^n)$ with $\|w - v_1\|_{C^1}^{\bar{E}} \le \varepsilon$. Thus it suffices to find u_0 and V_s with

$$\|\widetilde{u} - v_1\|_{C^1}^{\bar{E}} \le \varepsilon \text{ for all } u \in V_s, \tag{4.8}$$

where $\widetilde{u}$ is given by (4.7). Let

$$\mathcal{E}_1 \in \mathcal{L}\big(C^1(S, \mathbb{R}^m), C^1(\bar{E}, \mathbb{R}^m)\big) \tag{4.9}$$

be an extension operator which maps $C^\infty(S, \mathbb{R}^m)$ into $C^\infty(\bar{E}, \mathbb{R}^m)$. Setting

$$u_0 = w_1 + \mathcal{E}_1 w_2 \quad \text{with} \quad w_1 \in C^\infty(\bar{E}, \mathbb{R}^m),\ w_2 \in C^\infty(S, \mathbb{R}^m)$$

to be chosen later, we get by Sobolev embedding $H^{s+1/2}(E) \hookrightarrow C^1(\bar{E})$ and (4.6), (4.9)

$$\begin{aligned}
\|\widetilde{u} - v_1\|_{C^1}^{\bar{E}} &\le C\|u - u_0\|_{H^s}^S + \|u_0 - v_1\|_{C^1}^{\bar{E}} \\
&\le C\left(\|w_2\|_{C^1}^S + \|u - u_0\|_{H^s}^S\right) + \|w_1 - v_1\|_{C^1}^{\bar{E}} \\
&\le C\left(\|w_1 - v_1\|_{C^1}^{\bar{E}} + \|w_2 + w_1 - v\|_{H^s}^S + \|v - u_0\|_{H^s}^S + \|u - v\|_{H^s}^S\right).
\end{aligned}$$

Hence, letting $\delta = \varepsilon/(4C)$ and choosing first w_1 with $\|w_1 - v_1\|_{C^1}^{\bar{E}} \le \delta$ and, afterwards, w_2 with $\|w_2 + w_1 - v\|_{H^s}^S \le \delta$, then (4.8) is valid with $V_s = \big\{u \mid \|u - v\|_{H^s}^S < \delta\big\}$. □

Fix $s > (m+1)/2$, $v \in U_s$, and V_s according to Lemma 4.1. Maintaining notation and construction of this lemma, let

$$\bar{E} \ni x \to y = \widetilde{u}(x) = \big(\widetilde{u}_1(x), \dots, \widetilde{u}_m(x)\big) \in \bar{\Omega}_u, \quad u \in V_s, \tag{4.10}$$

be the corresponding diffeomorphism (4.7), $J = (\partial_i \widetilde{u}_j)$ its Jacobian, and $(g_{ij}) = J^\top J$ the Euclidean metric tensor relative to the above coordinates. Furthermore let (g^{ij}) be the inverse of (g_{ij}) and $g = \det(g_{ij})$. Then we have $(g^{ij}) = g^{-1}(\operatorname{Cof} J)^\top(\operatorname{Cof} J)$, where

$\operatorname{Cof} J = (a_{ij})$ and a_{ij} is the algebraic complement of $\partial_i \widetilde{u}_j$ in J. Note that, uniformly in $u \in V_s$, the function g is strictly positive in E. Moreover, for the transformation $\omega = d\Gamma_u/dS$ of surface area elements via (4.10) and the outer normals n of Ω_u and ν of S, the following holds:

$$\omega = |(\operatorname{Cof} J)\nu|, \quad n \circ \widetilde{u} = (\operatorname{Cof} J)\nu / |(\operatorname{Cof} J)\nu|.$$

By definition, all of the quantities g, g_{ij}, a_{ij}, and g^{ij} are polynomials in the first derivatives of $\widetilde{u}$ and, in the case of g^{ij}, additionally in $1/g$. Consequently, remembering (4.1)–(4.5) and the construction (4.7) of $\widetilde{u}$, we obtain smooth dependence of these quantities on u. More precisely, we have

$$[u \mapsto q] \in C^\infty\big(V_s, H^{s-1/2}(E)\big), \quad q = g, g_{ij}, a_{ij}, \text{ or } g^{ij}, \tag{4.11}$$

and (4.5) implies an estimate of the kth Fréchet derivative:

$$\|q^{(k)}(u)\{u_1, \dots, u_k\}\|^E_{t-1/2} \le C\|u_1\|_{s_1} \cdots \|u_k\|_{s_k} \tag{4.12}$$

if $1/2 \le t \le s_1, \dots, s_k \le s$ and $s_1 + \cdots + s_k \ge t + (k-1)s$. The constant is independent of $u \in V_s$ and of $u_1 \in H^{s_1}(S), \dots, u_k \in H^{s_k}(S)$. Similar arguments lead to

$$[u \mapsto p] \in C^\infty\big(V_s, H^{s-1}(S)\big), \quad p = \omega \text{ or } n \circ \widetilde{u}, \tag{4.13}$$

with an estimate of the derivatives corresponding to (4.12).

Now, introducing the transformed velocity potential $\psi = \psi(u)f = \varphi(u, f) \circ \widetilde{u}$ and the transformed Laplace and boundary operator according to

$$L(u)\psi = \partial_i\big(\sqrt{g} g^{ij} \partial_j \psi\big), \quad B(u)\psi = \omega\psi + \nu_i \sqrt{g} g^{ij} \partial_j \psi,$$

the Robin problem (3.6) may be written as

$$L(u)\psi = 0 \ \text{ in } \ E, \quad B(u)\psi = \omega f \ \text{ on } \ S. \tag{4.14}$$

Note that the values of $\psi(u)f$ in E depend not only on u and f, but also on the diffeomorphism $\tilde{u}$, i.e., on the chosen V_s. On the other hand, $\psi(u)f|_S$ is completely determined by u and f. The symmetry of the operator $h \mapsto \varphi(u)h$ w.r.t. the L^2-inner product on Γ_u implies

$$\int_S w\, \psi(u)f\, dS = \int_S \omega f\, \psi(u)(w\omega^{-1})\, dS \tag{4.15}$$

(recall that $\omega = d\Gamma_u/dS$) and the operator F from (3.5) gets the form

$$F(u)f = (F_1(u)f, \dots, F_m(u)f), \quad F_i(u)f = a_{ij}\partial_j \psi(u)f/\sqrt{g}. \tag{4.16}$$

We start the investigation of F by discussing a generalized version of (4.14). Note that we have to deal with two technical difficulties here concerning nonsmooth coefficients and uniformity of the estimates for “large” subsets of U_s. Therefore, we need the following preparation.

Lemma 4.2. *Let $\Omega \subset \mathbb{R}^m$ be a bounded smooth domain, let $x_0 \in \Omega$, $\chi \in C_0^\infty(\mathbb{R}^m)$, and let*

$$\chi_\varepsilon(x) := \chi((x - x_0)/\varepsilon), \qquad x \in \mathbb{R}^m.$$

Moreover, let $\mu \in H^s(\Omega)$ with $s > m/2$ and $\mu(x_0) = 0$. Then there is an $s_1 \in (m/2, s)$ such that

$$\lim_{\varepsilon\downarrow 0} \|\chi_\varepsilon \mu\|^\Omega_{s_1} = 0.$$

Proof. Note at first that

$$\|\chi_\varepsilon\|^{\mathbb{R}^m}_s \le C\varepsilon^{m/2-s}.$$

This is immediately clear for integer s; the general case follows by interpolation. By Sobolev's embedding, we have $\mu \in C^\alpha(\overline{\Omega})$ for some $\alpha > 0$, and consequently, due to $\mu(x_0) = 0$,

$$|\mu(x)| \le C\varepsilon^\alpha, \qquad x \in \mathrm{supp}\chi_\varepsilon \cap \Omega.$$

Thus,

$$\|\chi_\varepsilon\mu\|^\Omega_0 \le C\varepsilon^\alpha \|\chi_\varepsilon\|^\Omega_0 \le C\varepsilon^{\alpha+m/2}$$

and

$$\|\chi_\varepsilon\mu\|^\Omega_s \le C\|\chi_\varepsilon\|^\Omega_s \|\mu\|^\Omega_s \le C\varepsilon^{m/2-s}.$$

The assertion follows now from interpolation. ◻

LEMMA 4.3. *Let $s > (m+1)/2$, $s_0 \in ((m+1)/2, s)$ be given.*

For any $v \in U_s$ there is an H^{s_0}-neighborhood V_{s_0} such that the boundary value problem

$$L(u)w = \partial_i h_i \text{ in } E, \quad B(u)w = \omega e + \nu_i h_i \text{ on } S$$

is uniquely solvable for $u \in V_{s_0} \cap H^s(S, \mathbb{R}^m)$, $e \in H^{s-1}(S)$, $h \in H^{s-1/2}(E, \mathbb{R}^m)$. Moreover, we have

$$\|w\|^E_t \le C\big(\|h\|^E_{t-1} + \|e\|^S_{t-3/2}\big) \tag{4.17}$$

for $t \in [1, s+1/2]$ with C independent of h, e, and u varying in H^s-bounded subsets of $V_{s_0} \cap H^s(S, \mathbb{R}^m)$.

Proof. 1. Fix $v \in U_s$ and choose V_{s_0} according to Lemma 4.1. Fix $u \in V_{s_0} \cap H^s(S, \mathbb{R}^m)$. For $t = 1$, the assertions are easily seen from the variational formulation. For $t = s + 1/2$, the assertions follow from the H^s-regularity theory of elliptic boundary value problems (with operators in divergence form). Our coefficients $\sqrt{g}g^{ij}$, however, are only in $H^{s-1/2}(E)$, which is slightly nonstandard. To prove the necessary regularity result in this case, we can proceed as in the proof of Theorem A.14 in [12], replacing the Hölder norms there by Sobolev norms. To control the error terms occurring from the freezing of coefficients, we use the estimate

$$\|\mu_{ij}\partial_j w\|^E_{s-1/2} \le C\big(\|\mu_{ij}\|^E_{s_1}\|w\|^E_{s+1/2} + \|\mu_{ij}\|^E_{s-1/2}\|w\|^E_{s_1+1/2}\big)$$

(and a corresponding one for the boundary term) with s_1 from Lemma 4.2. Recalling that μ_{ij} has a form to which that lemma applies, (4.17) can be established for $t = s + 1/2$ by a usual perturbation argument, with a constant $C = C(u)$. The general case follows by interpolation.

2. To show uniformity w.r.t. $u \in V_{s_0} \cap H^s(S, \mathbb{R}^m)$, we proceed in a similar way: For $t = s + 1/2$, pick $u_1, u_2 \in V_{s_0} \cap H^s(S, \mathbb{R}^m)$, denote the corresponding coefficients by $\sqrt{g_k} g_k^{ij}$, $k = 1, 2$, and estimate

$$\begin{aligned} &\big\|\big(\sqrt{g_1} g_1^{ij} - \sqrt{g_2} g_2^{ij}\big)\partial_j w\big\|_{s-1/2}^E \\ &\qquad \le C\big(\|\widetilde{u}_1 - \widetilde{u}_2\|_{s_0+1/2}^E \|w\|_{s+1/2}^E + \|\widetilde{u}_1 - \widetilde{u}_2\|_{s+1/2}^E \|w\|_{s_0+1/2}^E\big) \\ &\qquad \le C\big(\|u_1 - u_2\|_{s_0}^S \|w\|_s^E + \|w\|_1^E\big), \end{aligned}$$

where an interpolation inequality has been used. A similar estimate can be given for the boundary term. After shrinking V_{s_0} if necessary, one can show the uniformity by another perturbation argument. ∎

Under the assumptions of Lemma 4.3, as a first trivial consequence we obtain the estimate

$$\|\psi(u) f\|_t^E, \|\psi(u) f\|_{t-1/2}^S \le C\|f\|_{t-3/2} \tag{4.18}$$

for $t \in [1, s + 1/2]$. Note for later reference that these estimates continue to hold for $t \in [0, s + 1/2]$, provided $s > \max\{m + 1, 5\}/2$. To see this, it is sufficient to show (4.18) for $t = 0$; the general case follows by interpolation again. Fix u, pick $\phi \in L^2(S)$ arbitrary and define $w \in H^{3/2}(E)$ by

$$L(u)w = 0 \text{ in } E, \quad B(u)w = \phi \text{ on } S.$$

Then, by Green's formula rewritten in the form

$$\int_E \big(\phi_1 L(u)\phi_2 \, dx - \phi_2 L(u)\phi_1\big)\, dx = \int_S \big(\phi_1 B(u)\phi_2 - \phi_2 B(u)\phi_1\big)\, dS$$

and (4.17) with $t = 2$,

$$\begin{aligned} \int_S \phi\psi(u) f \, dS = \int_S B(u) w \psi(u) f \, dS &= \int_S w\omega f \, dS \\ &\le C\|w\|_{3/2}\|f\|_{-3/2} \le C\|\phi\|_{1/2}\|f\|_{-3/2}. \end{aligned}$$

This proves the second estimate in (4.18). Analogously, picking $\zeta \in L^2(E)$ and defining $v \in H^2(E)$ by

$$L(u)v = \zeta \text{ in } E, \quad B(u)w = 0 \text{ on } S,$$

we get

$$\int_e \zeta\psi(u) f \, dx = \int_E L(u) w \psi(u) f \, dx = -\int_S v\omega_f \, dS \le C\|\zeta\|_0 \|f\|_{-3/2}.$$

This proves the first estimate in (4.18).

Furthermore, concerning the smooth dependence of $\psi(u)f$ on u, Lemma 4.3 together with (4.11), (4.13) implies via a perturbation argument

$$[u \mapsto \psi(u)] \in C^\infty\big(V_s, \mathcal{L}\big(H^{t-3/2}(S), H^t(E)\big)\big). \tag{4.19}$$

Replacing t by $t - 3/2$ and considering (4.16), leads to the following corollary.

Corollary 4.4. *Let $s > (m+1)/2$ and $-1/2 \le t \le s-1$. Then*

$$[u \mapsto F(u)] \in C^\infty\big(U_s, \mathcal{L}\big(H^t(S), H^t(S,\mathbb{R}^m)\big)\big).$$

Recall that our ultimate goal is to prove the energy estimate (1.3). Since we will translate spatial derivatives into Fréchet derivatives later, higher order Fréchet derivatives will have to be estimated. The operator $(u,f) \mapsto F(u)f$ is of order one w.r.t. u and of order zero w.r.t. f; note that the estimates (4.20) are standard for *local* operators of this type, e.g.,

$$(u,f) \mapsto [x \mapsto \Psi(\nabla u(x))f(x)].$$

The nonstandard aspect here is that F involves the solution of an elliptic boundary value problem, and therefore the same is true for its Fréchet derivatives.

Lemma 4.5. *Let $s > (m+1)/2$, $u \in U_s$, and $t \in [1,s]$ be given. Then for any choice of $s_1, \dots s_{k+1} \in [t,s]$ with $s_1 + \dots + s_{k+1} \ge t + ks$ there exists a constant $C > 0$ such that for all $f \in H^{s-1}(S)$ and all $u_1, \dots, u_k \in H^s(S,\mathbb{R}^m)$ the following holds:*

$$\big\|F^{(k)}(u)\{u_1,\dots,u_k\}f\big\|_{t-1} \le C\|u_1\|_{s_1}\cdots\|u_k\|_{s_k}\|f\|_{s_{k+1}-1}. \tag{4.20}$$

The constant may be chosen independently of u as long as u varies in H^s-bounded subsets of U_s which are H^{s_0}-closed for some $s_0 \in ((m+1)/2, s)$.

Proof. 1. Fix $v \in U_s$ and a neighborhood V_{s_0} according to Lemma 4.3. We show (4.20) with C independent of $u \in V_{s_0} \cap H^s(S,\mathbb{R}^m)$. To begin with, recall the estimate (4.18) in the form

$$\|\nabla\psi(u)f\|^S_{t-1},\ \|\psi(u)f\|^E_{t+1/2} \le C\|f\|_{t-1} \tag{4.21}$$

for $t \in [1,s]$; concerning the estimate of $\nabla\psi$ along S in the limit case $t=1$, note that the boundary condition allows a representation of $\nabla\psi$ as a suitable linear combination of ψ, f, and tangential derivatives of ψ. In view of (4.16) this implies the asserted estimate (4.20) for the simplest case $k=0$. To obtain similar estimates for the Fréchet derivatives $\psi^{(k)} = \psi^{(k)}(u)\{u_1,\dots,u_k\}f$, $k = 1,2,\dots$, we have to examine the corresponding derivatives of the coefficients in the transformed Laplacian and the boundary terms. For $\psi^{(k)}$ we get

$$\begin{aligned} L(u)\psi^{(k)} &= -\sum L^{(l)}(u)\{u_{i_1},\dots,u_{i_j}\}\psi^{(k-l)}(u)\{u_{i_{j+1}},\dots,u_{i_k}\}f \ \text{ in } E,\\ B(u)\psi^{(k)} &= -\sum B^{(l)}(u)\{u_{i_1},\dots,u_{i_j}\}\psi^{(k-l)}(u)\{u_{i_{j+1}},\dots,u_{i_k}\}f\\ &\qquad + \omega^{(k)}\{u_1,\dots,u_k\}f \ \text{ on } S, \end{aligned} \tag{4.22}$$

where

$$\begin{aligned} L^{(l)}(u)\{u_{i_1},\dots,u_{i_j}\}\varphi &= \partial_i\big((\sqrt{g}g^{ij})^{(k)}\{u_{i_1},\dots,u_{i_j}\}\partial_j\varphi\big),\\ B^{(l)}(u)\{u_{i_1},\dots,u_{i_j}\}\varphi &= \nu_i(\sqrt{g}g^{ij})^{(k)}\{u_{i_1},\dots,u_{i_j}\}\partial_j\varphi + \omega^{(l)}\{u_{i_1},\dots,u_{i_j}\}\varphi, \end{aligned}$$

and the sums are extended over $1 \le l \le k$ and all decompositions $i_1 < \dots < i_l$ and $i_{j+1} < \dots < i_k$ of the indices $1,2,\dots,n$. In particular, if $k=1$, we obtain for $\psi' = \psi'(u)\{u_1\}f$ the boundary value problem

$$\begin{aligned} L(u)\psi' &= -\partial_i\big((\sqrt{g}g^{ij})'\{u_1\}\partial_j\psi\big) \ \text{ in } E,\\ B(u)\psi' &= -\nu_i\big(\sqrt{g}g^{ij}\big)'\{u_1\}\partial_j\psi + \omega'\{u_1\}(f-\psi) \ \text{ on } S. \end{aligned} \tag{4.23}$$

Thus, for any $t \in [1, s]$, Lemma 4.3 implies

$$\|\psi'(u)\{u_1\}f\|^E_{t+1/2} \le C\big(\|(\sqrt{g}g^{ij})'\{u_1\}\partial_j\psi\|^E_{t-1/2} + \|\omega'\{u_1\}(f-\psi)\|^S_{t-1}\big).$$

To estimate the terms on the right-hand side, by (4.5) we obtain

$$\|(\sqrt{g}g^{ij})'\{u_1\}\partial_j\psi\|^E_{t-1/2} \le C\|(\sqrt{g}g^{ij})'\{u_1\}\|^E_{s_1-1/2}\|\partial_j\psi\|^E_{s_2-1/2},$$

and accordingly

$$\|\omega'\{u_1\}(f-\psi)\|^S_{t-1} \le C\|\omega'\{u_1\}\|^S_{s_1-1}\big(\|f\|_{s_2-1} + \|\psi\|^S_{s_2-1}\big)$$

for any choice of $s_1, s_2 \in [t, s]$ with $s_1 + s_2 \ge t + s$. As

$$\|\psi\|^S_{s_2-1}, \|\partial_j\psi\|^E_{s_2-1/2} \le C\|\psi\|^E_{s_2+1/2} \le C'\|f\|_{s_2-1},$$

by (4.21), using (4.12), (4.13), we find

$$\big\|(\sqrt{g}g^{ij})'\{u_1\}\partial_j\psi\big\|^E_{t-1/2}, \big\|\omega'\{u_1\}(f-\psi)\big\|^S_{t-1} \le C'\|u_1\|_{s_1}\|f\|_{s_2-1},$$

and hence

$$\|\nabla\psi'(u)\{u_1\}f\|^S_{t-1},\ \|\psi'(u)\{u_1\}f\|^E_{t+1/2} \le C\|u_1\|_{s_1}\|f\|_{s_2-1},$$

where the same remark applies to the estimate of $\nabla\psi'$ along S as to (4.21). Using (4.22), these estimates are extended inductively to $\psi^{(k)}$:

$$\|\nabla\psi^{(k)}\|^S_{t-1},\ \|\psi^{(k)}\|^E_{t+1/2} \le C\|u_1\|_{s_1}\cdots\|u_k\|_{s_k}\|f\|_{s_{k+1}-1}, \tag{4.24}$$

provided $t \in [1, s]$, $s_1, \dots, s_{k+1} \in [t, s]$ with $s_1 + \cdots + s_{k+1} \ge t + ks$. In view of (4.16), these estimates together with (4.11) and (4.5) imply the asserted estimate (4.20).

2. Let $K \subset U_s$ be H^{s_0}-closed and bounded in $H^s(S, \mathbb{R}^m)$. As shown in part 1 of this proof, K can be covered by H^{s_0}-open sets $V_{s_0,v}$, $v \in K$, such that (4.20) holds uniformly for $u \in V_{s_0,v} \cap K$. Now the assertion follows from the compactness of K in $H^{s_0}(S, \mathbb{R}^m)$. □

Now we use invariance properties w.r.t. diffeomorphisms (cf., e.g., [10]). Let $\tau \in \mathrm{Diff}(S)$. Then by definition

$$\varphi(u, f) = \varphi(u \circ \tau, f \circ \tau) \text{ in } \Omega_u. \tag{4.25}$$

Recalling the definition of F, we have

$$\begin{aligned}(F(u)f) \circ \tau &= \big(\nabla\varphi(u, f)\big) \circ (u \circ \tau),\\ F(u \circ \tau)(f \circ \tau) &= \big(\nabla\varphi(u \circ \tau, f \circ \tau)\big) \circ (u \circ \tau)p;\end{aligned}$$

consequently (4.25) implies

$$(F(u)f) \circ \tau = F(u \circ \tau)(f \circ \tau) \text{ on } S. \tag{4.26}$$

Any smooth vector field D on S, identified with a first order differential operator, generates a one-parameter group of smooth diffeomorphisms $t \mapsto \tau_t$ with $\tau_t = id$ for $t = 0$. Setting $\tau = \tau_t$ in (4.26) and differentiating w.r.t. t at $t = 0$ gives

$$DF(u)f = F'(u)\{Du\}f + F(u)Df \tag{4.27}$$

for $u \in U_s$ and $f \in H^{s-1}(S)$, $s > (m+1)/2$. Furthermore, by differentiation w.r.t. u,

$$\begin{aligned} DF^{(k)}(u)\{\dots\}f &= F^{(k+1)}(u)\{Du,\dots\}f + F^{(k)}(u)\{\dots\}Df \\ &\quad + \sum_{j=1}^{k} F^{(k)}(u)\{u_1,\dots,u_{j-1},Du_j,u_{j+1},\dots,u_k\}f, \end{aligned} \tag{4.28}$$

where the dots indicate the arguments $u_1,\dots,u_k \in H^s(S,\mathbb{R}^m)$. We choose m smooth vector fields $D_1,\dots,D_m$ on S such that

$$\operatorname{span}\{D_1,\dots,D_m\} = T_x \text{ for all } x \in S$$

and use the multi-index notation $D^\alpha = D_1^{\alpha_1}\dots D_m^{\alpha_m}$, $\alpha = (\alpha_1,\dots,\alpha_m)$, for higher order derivatives. Note that, for $s \ge 0$ integer, we can use

$$(u,v)_s = \sum_{|\alpha|\le s} (D^\alpha u, D^\alpha v)_{L^2(S)}$$

as the inner product generating the norm in $H^s(S)$. As a consequence of (4.27), (4.28), by induction we obtain a differentiation rule which resembles Leibniz's rule at an abstract level: For any multi-index α and $u \in U_s$, $f \in H^{s-1}(S)$, $s > |\alpha|+(m+1)/2$, it holds that

$$D^\alpha F(u)f = \sum c_{\beta_1,\dots,\beta_{k+1}} F^{(k)}(u)\{D^{\beta_1}u,\dots,D^{\beta_k}u\}D^{\beta_{k+1}}f, \tag{4.29}$$

where the sum has to be extended over all integers k and systems of nonnegative multi-indices $\beta_1,\dots,\beta_{k+1}$ with

$$0 \le k \le |\alpha|, \quad 1 \le |\beta_1|,\dots,|\beta_k|, \quad \beta_1+\dots+\beta_{k+1} = \alpha. \tag{4.30}$$

The coefficients are nonnegative integers, in particular, $c_\alpha = c_{\alpha,0} = 1$.

The differentiation rule (4.29) and Lemma 4.5 enable us to prove estimates involving spatial derivatives of F. Concerning the second part of the following proposition, note that (4.31) provides a splitting of $D^\alpha F(u)f$ according to (4.29), with $R_\alpha(u)f$ containing the lower order terms, i.e., the terms involving spatial derivatives up to order $|\alpha|-1$ only. Again, the results (as well as the techniques used in the proof) are standard for local operators of corresponding types.

PROPOSITION 4.6.

(i) *Let $s \ge s_0 > (m+1)/2$ integer, $u \in U_{s+1}$. Then*

$$\|F(u)f\|_s \le C\big(\|u\|_{s+1}\|f\|_{s_0} + \|f\|_s\big).$$

(ii) *Assume additionally $s \ge s_0+1$ and let α be any multi-index with $|\alpha| = s$. Then we have*

$$D^\alpha F(u)f = F(u)D^\alpha f + F'(u)\{D^\alpha u\}f + R_\alpha(u)f, \tag{4.31}$$

where the remainder term allows the estimate

$$\|R_\alpha(u)f\|_0 \le C\big(\|u\|_s\|f\|_{s_0} + \|f\|_{s-1}\big).$$

The constants in both estimates can be chosen uniformly as u varies in H^{s_0}-closed, H^{s_0+1}-bounded subsets of U_{s+1}.

Proof. We consider the more complicated situation (ii) only. According to (4.29), the remainder term has a representation as a sum of terms

$$I_\beta = F^{(k)}(u)\{D^{\beta_1}u, \dots, D^{\beta_k}u\}D^{\beta_{k+1}}f,$$

where the multi-indices satisfy (4.30) and additionally $|\beta_i| < s = |\alpha|$. Thus $k \geq 1$ and $|\beta_i| \geq 1$ for at least two indices, say $i = i_1, i_2$. We estimate I_β using (4.20) with $s_i = 1 + (1-\theta_i)(s_0-1)$ and

$$\theta_i = (|\beta_i| - 1)/(s-2), \quad i = i_1, i_2, \qquad \theta_i = |\beta_i|/(s-2), \quad i \notin \{i_1, i_2\}.$$

Then $s_i \in [1, s_0]$ and $s_1 + \cdots + s_{k+1} = 1 + ks_0$; hence applying (4.20) (with $t = 1$, $s = s_0$) yields

$$\|I_\beta\|_0 \leq C\|u\|_{|\beta_1|+s_1} \dots \|u\|_{|\beta_1|+s_k}\|f\|_{|\beta_{k+1}|+s_{k+1}-1}.$$

Note that $\theta_1 + \cdots + \theta_{k+1} = 1$ and set $\lambda := \theta_1 + \cdots + \theta_k$. From

$$|\beta_i| + s_i \leq (1-\theta_i)(s_0+1) + \theta_i s$$

we get by norm convexity and Young's inequality

$$\begin{aligned}\|I_\beta\|_0 &\leq C\|u\|_{s_0+1}^{k-1}\big(\|u\|_{s_0+1}\|f\|_{s-1}\big)^{1-\lambda}\big(\|u\|_s\|f\|_{s_0}\big)^{\lambda} \\ &\leq C\|u\|_{s_0+1}^{k-1}\big(\|u\|_{s_0+1}\|f\|_{s-1} + \|u\|_s\|f\|_{s_0}\big).\end{aligned}$$

This proves the assertion. ∎

We conclude this section with remarks concerning the Neumann–Dirichlet operator A defined by (3.9), (3.10). It is obvious that the regularity properties of $u \mapsto A(u)$ are the same as for $u \mapsto \psi(u)|_S$; hence (4.19) reappears as

$$[u \mapsto A(u)] \in C^\infty\big(U_s, \mathcal{L}\big(H^t(S), H^{t+1}(S)\big)\big) \tag{4.32}$$

for $s > (m+1)/2$ and $-1/2 \leq t \leq s-1$. Moreover, the differentiation rule (4.28) also holds for A, and $\psi_N(u)f := \varphi_N(u)f \circ \tilde{u}$ satisfies estimates parallel to (4.24). Hence we get

$$\|A^{(k)}(u)\{u_1, \dots, u_k\}f\|_t \leq C\|u_1\|_{s_1} \cdots \|u_k\|_{s_k}\|f\|_{s_{k+1}-1}, \tag{4.33}$$

provided $s_1, \dots, s_{k+1} \in [t, s]$ with $s_1 + \cdots + s_{k+1} \geq t + ks$. Thus we have the following analogue to Proposition 4.6.

Proposition 4.7.

(i) *Let $s \geq s_0 > (m+1)/2$ integer, $u \in U_s$, and $f \in H^{s-1}(S)$. Then*

$$\|A(u)f\|_s \leq C\big(\|u\|_s\|f\|_{s_0-1} + \|f\|_{s-1}\big)$$

with a uniform constant as long as u varies in H^{s_0}-closed, H^{s_0}-bounded subsets of U_s.

(ii) *Assume additionally $s \geq s_0+1$, and let α be any multi-index with $|\alpha| = s-1$. Then we have*

$$\|D^\alpha A(u)f - A(u)D^\alpha f\|_1 \leq C\big(\|u\|_s\|f\|_{s_0-1} + \|f\|_{s-2}\big),$$

where now the constant can be chosen uniformly as u varies in H^{s_0}-closed, H^{s_0+1}-bounded subsets of U_{s+1}.

Finally, for later reference we point out the simple commutator estimate

$$\|A(u)(hf) - hA(u)f\|_1 \leq C\|h\|_s\|f\|_{-1} \tag{4.34}$$

for $u \in U_s,\ f, h \in H^s(S),\ s > (m+1)/2$. Fixing any neighborhood V_s according to Lemma 4.1, fixing $u \in V_s$ with corresponding diffeomorphism (4.10), and considering

$$A(u)f = \psi(u)\big(f - \omega A(u)f\big)|_S$$

reduces (4.34) to

$$\|h\psi(u)f - \psi(u)(hf)\|_1^S \leq C\|h\|_s\|f\|_{-1}. \tag{4.35}$$

Let $\tilde h$ be the extension of h into E determined by solving the Dirichlet problem

$$L(u)\tilde h = 0 \ \text{ in } \ E, \quad \tilde h = h \ \text{ on } \ S.$$

Clearly $\|\tilde h\|_{s+1/2}^E \leq C\|h\|_s$ and $\tilde\psi := h\psi(u)f - \psi(u)(hf)$ solves the boundary value problem

$$\begin{aligned} L(u)\tilde\psi &= 2\partial_i\big(\sqrt{g}g^{ij}\partial_i\tilde h\,\psi(u)f\big) \ \text{ in } \ E,\\ B(u)\tilde\psi &= -\omega\nu_i g^{ij}\partial_i\tilde h\,\psi(u)f \ \text{ on } \ S. \end{aligned}$$

Hence by Lemma 4.3

$$\|\tilde\psi\|_{3/2}^E \leq C\|\sqrt{g}g^{ij}\partial_i\tilde h\|_{s-1/2}\|\psi(u)f\|_{1/2}^E \leq C\|h\|_s\|\psi(u)f\|_{1/2}^E.$$

Together with (4.18) this implies (4.35).

5. The main estimate. In this section we prove H^s a priori estimates for the nonlinear operator $\mathcal{F}$ w.r.t. variable bilinear forms, which we define in what follows. As already mentioned in the introduction, these estimates are the main ingredient in the existence proof.

To begin with, for $u \in U_s,\ s > (m+1)/2$, we define

$$P(u)v := v \cdot \big(n(u) \circ u\big), \quad N(u)w := w\,\big(n(u) \circ u\big), \tag{5.1}$$

$$\Lambda(u)w := \nabla_{\Gamma_u}(w \circ u^{-1}) \circ u \tag{5.2}$$

as the Euclidean inner product and multiplication with outer normal $n(u)$ of Γ_u and pullback of tangential gradient ∇_{Γ_u} along Γ_u, respectively. If $P(u)$, $N(u)$, and $\Lambda(u)$ are considered as operators in v and w, their coefficients are smooth functions of u and its first derivatives. Thus, using (4.1)–(4.5),

$$P(u) \in \mathcal{L}\big(H^t(S,\mathbb{R}^m), H^t(S)\big), \quad N(u) \in \mathcal{L}\big(H^t(S), H^t(S,\mathbb{R}^m)\big), \tag{5.3}$$

$$\Lambda(u) \in \mathcal{L}\big(H^t(S), H^{t-1}(S,\mathbb{R}^m)\big) \tag{5.4}$$

depend smoothly on $u \in U_s$ for $0 \leq t \leq s-1$ and $1 \leq t \leq s$, respectively. Clearly, the operators P, N, Λ satisfy invariance properties as stated for F in (4.26). As a consequence, the differentiation rule (4.27) and its corollary (4.28) are also true for P, N, Λ; we make use of that without explicit mention. Further, recall that the pullback $\Delta(u)w$ of the Laplace–Beltrami operator Δ_{Γ_u} on Γ_u according to (3.8) and the operator $H(u)$ according to (3.7) may be expressed as

$$\Delta(u)w = \Lambda_i(u)\big(\Lambda_i(u)w\big), \quad H(u) = -\gamma\Lambda_i(u)\big(n_i(u) \circ u\big),$$

respectively (see, e.g., [9, sect. 15.1]). Thus, recalling (4.32), the operator $\mathcal{G}$ defined by (3.4), (3.7) satisfies

$$[u \mapsto \mathcal{G}(u)] \in C^\infty\big(U_s, H^{s-2}(S)\big),$$

provided $s > (m+3)/2$. Together with Corollary 4.4 this implies the smoothness of $\mathcal{F}$ as stated in (3.12).

In further considerations of this section we fix the integer $s_0 := [(m+5)/2] + 1$ and set

$$\widetilde{U}_s := U_s \cap K \ \text{ for all } \ s \geq s_0$$

with an H^{s_0}-bounded and L^2-closed subset $K \subseteq U_{s_0}$. Note that

$$1 \leq C\|u\|_{s_0} \leq C'\|u\|_s, \quad \|u\|_{C^3(S)} \leq C$$

for all $u \in \widetilde{U}_s$, $s \geq s_0$. By transforming the well-known integration by parts formula for the differential operator ∇_{Γ_u} onto S, we get the form

$$\int_S \omega \Lambda_i(u) f \, dS = -\int_S \omega (\kappa_{\Gamma_u} \circ u)(n_i(u) \circ u) f \, dS.$$

Consequently, for $u \in \widetilde{U}_s$, $s \geq s_0$, and any $f \in C^1(S)$, we have

$$\left| \int_S \Lambda_i(u) f \, dS \right| \leq C \int_S |f| \, dS. \tag{5.5}$$

Furthermore, note the estimates

$$\|\mathcal{G}(u)\|_{s-2}, \|\mathcal{F}(u)\|_{s-2} \leq C\|u\|_s \ \text{ for all } \ u \in \widetilde{U}_s, s \geq s_0.$$

The following lemma is crucial, as it identifies the leading (first) order term in the linearization of $u \mapsto F(u)$ in an explicit way.

Lemma 5.1. *Let $s \geq s_0$. Then for $u \in U_s$, $v \in H^s(S, \mathbb{R}^m)$, and $f \in H^{s-1}(S)$ it holds that*

$$F'(u)\{v\}f = F(u)\big(\Lambda(u)\big(P(u)v\big) \cdot F(u)f\big) + R(u)\{v\}f,$$

where R allows the estimate

$$\|R(u)\{v\}f\|_0 \leq C\|f\|_{s-1}\|v\|_0.$$

The constant is independent of u as long as u varies in $\widetilde{U}_s$.

Proof. As in the proof of Lemma 4.5 we can assume $u \in V_s$. We have

$$F_i'(u)\{v\}f = \partial_i \varphi' \circ u + v_j \partial_i \partial_j \varphi \circ u,$$

where $\varphi' = \varphi'(u,f)\{v\}$ denotes the derivative w.r.t. u of the velocity potential $\varphi = \varphi(u,f)$ in Ω_u. As

$$\|\varphi(u,f)\|_{C^2(\bar{\Omega}_u)} \leq C_1\|\psi(u)f\|_{C^2(\bar{E})} \leq C_2\|\psi(u)f\|_{H^{s+1/2}(E)} \leq C_3\|f\|_{s-1}$$

by Sobolev's embedding and (4.21), we obtain

$$\|v_j \partial_i \partial_j \varphi \circ u\|_0^S \leq C\|f\|_{s-1}\|v\|_0.$$

Furthermore, φ' satisfies $\Delta\varphi' = 0$ in Ω_u and the boundary condition

$$\varphi' + n \cdot \nabla\varphi' + n' \cdot \nabla\varphi + (\partial_i\varphi + n_j\partial_i\partial_j\varphi)v_i \circ u^{-1} = 0 \text{ on } \Gamma_u,$$

where we have used the abbreviation

$$n' = \partial_\varepsilon\big(n(u+\varepsilon v) \circ (id + \varepsilon v \circ u^{-1})\big)|_{\varepsilon=0}$$

for the variation of the outer normal on Γ_u. A simple calculation (cf. Lemma 1.1 in [3]) shows

$$n' = -\nabla_{\Gamma_u}\big(n \cdot v \circ u^{-1}\big) + v_i \circ u^{-1}\nabla_{\Gamma_u} n_i. \tag{5.6}$$

By retransformation onto the reference domain E, for $\tilde{\psi}' = \varphi' \circ u$ to satisfy the boundary value problem, this implies

$$L(u)\tilde{\psi}' = 0 \text{ in } E, \quad B(u)\tilde{\psi}' = \Lambda(u)\big(P(u)v\big) \cdot F(u)f + R_1(u)\{v\}f \text{ on } S.$$

The operator R_1 acts by pointwise multiplications w.r.t. the components of v, and hence by the same reasoning as above we get the estimate

$$\|R_1(u)\{v\}f\|_0^S \le C\|f\|_{s-1}\|v\|_0.$$

Thus the result follows. $\square$

For $u \in U_s$ let $M(u) \in \mathcal{L}\big(L^2(S,\mathbb{R}^m)\big)$ be the operator defined by

$$M(u)v := v - \Lambda(u)\big(\psi(u)P(u)v\big). \tag{5.7}$$

By (4.19) and (5.4),

$$M(u) \in \mathcal{L}\big(H^t(S,\mathbb{R}^m), H^t(S,\mathbb{R}^m)\big), \quad 0 \le t \le s-1,$$

depends smoothly on $u \in U_s$, $s > (m+1)/2$; for later reference we state explicitly

$$\|M^{(k)}(u)\{u_1,\dots,u_k\}v\|_t \le C\|u_1\|_s \cdots \|u_k\|_s\|v\|_t. \tag{5.8}$$

Because of $P(u)\Lambda(u) = 0$ the operator $M(u)$ constitutes an isomorphism in $L^2(S,\mathbb{R}^m)$ with inverse

$$M(u)^{-1}v = v + \Lambda(u)\big(\psi(u)P(u)v\big), \tag{5.9}$$

and we have

$$C^{-1}\|v\|_0 \le \|M(u)v\|_0 \le C\|v\|_0 \tag{5.10}$$

for all $v \in L^2(S,\mathbb{R}^m)$ with a positive constant C independent of $u \in \widetilde{U}_s$.

The operator M will be used for the definition of our variable inner products; see (5.12) below. The technique used here is comparable to the symmetrization of hyperbolic systems. The following lemma exhibits the crucial property on which the choice of M is based. Note that it relates, up to lower order terms, an inner product for vector-valued functions to an inner product for scalar-valued ones.

Lemma 5.2. *Let $s > (m+3)/2$. There exists a positive constant C such that for all $u \in \widetilde{U}_s$ and $f \in L^2(S)$, $w \in L^2(S,\mathbb{R}^m)$*

$$\big|\big(M(u)F(u)f, M(u)w\big)_0 - \big(f, P(u)w\big)_0\big| \le C\|f\|_{-1}\|w\|_0. \tag{5.11}$$

Proof. Reformulating the boundary condition satisfied by $\psi(u)f$, we have

$$P(u)\big(F(u)f\big) = f - \psi(u)f, \quad F(u)f - \Lambda(u)\big(\psi(u)f\big) = N(u)\big(f - \psi(u)f\big),$$

and consequently

$$\begin{aligned} M(u)F(u)f &= F(u)f - \Lambda(u)\psi(u)\big(f - \psi(u)f\big) \\ &= N(u)\big(f - \psi(u)f\big) + \Lambda(u)\psi(u)^2 f. \end{aligned}$$

Further, recalling $P(u)\Lambda(u) = 0$,

$$\big(N(u)f, M(u)w\big)_0 = \big(f, P(u)M(u)w\big)_0 = \big(f, P(u)w\big)_0,$$

and we obtain

$$\big(M(u)F(u)f, M(u)w\big)_0 = \big(f - \psi(u)f, P(u)w\big)_0 + \big(\Lambda(u)\psi(u)^2 f, M(u)w\big)_0.$$

Together with

$$\|\Lambda(u)\psi(u)^2 f\|_0^S, \|\psi(u)f\|_0^S \le C\|f\|_{-1}$$

from (4.18), this immediately implies (5.11). ∎

In view of (5.10), for every fixed $u \in U_s$, $s \ge s_0$,

$$(v, w)_{s,u} := \big(M(u)v, M(v)w\big)_0 + \sum_{|\alpha|=s} \big(M(u)D^\alpha v, M(u)D^\alpha w\big)_0 \tag{5.12}$$

defines a inner product on $H^s(S, \mathbb{R}^m)$, which is equivalent to the usual one. This inner product (and corresponding bilinear forms) will be used when we apply the abstract existence theorem, Theorem 3.4, to our evolution problem. The next two lemmas provide the properties necessary for this.

LEMMA 5.3. *Let $s \ge s_0$ and $u \in \widetilde{U}_s$.*

(i) *There exists a $C > 0$ independent of u such that for all $v \in H^{s+2}(S, \mathbb{R}^m)$ and $w \in H^s(S, \mathbb{R}^m)$*

$$(v, w)_{s,u} \le C\|v\|_{s+2}\|w\|_{s-2}. \tag{5.13}$$

(ii) *There exist $\lambda_0, c_0 > 0$ independent of u such that for all $v \in H^{s+4}(S, \mathbb{R}^m)$ and $\lambda \ge \lambda_0$*

$$\big(v, (\Delta_0^2 + \lambda)v\big)_{s,u} \ge c_0\|v\|_{s+2}^2 \tag{5.14}$$

with the elliptic operator $\Delta_0 := D_i D_i$ on S.

Proof. (i) We consider a typical term of (5.12) and show

$$I_\alpha(v, w) := \big(M(u)D^\alpha v, M(u)D^\alpha w\big)_0 \le C\|v\|_{s+2}\|w\|_{s-2} \tag{5.15}$$

for smooth v, w and multi-indices α with $|\alpha| = s$. Recalling (5.8), we have

$$\|M^{(k)}(u)\{D^{\alpha_1}u, \dots, D^{\alpha_k}u\}w\|_0 \le C\|w\|_0$$

if $|\alpha_1|, \dots, |\alpha_k| \le 2$. Thus, writing $D^\alpha w = D^\beta D^\delta w$ with $|\beta| = 2$ and $|\delta| = s - 2$, multiple application of the differentiation rule gives a representation

$$M(u)D^\alpha w = \sum (-1)^{|\alpha_0|} D^{\alpha_0} M^{(k)}(u)\{D^{\alpha_1}u, \dots, D^{\alpha_k}u\} D^\delta w, \tag{5.16}$$

where $|\alpha_i| \le 2$ (in fact $\alpha_0 + \cdots + \alpha_k = \beta$); hence

$$\|M^{(k)}(u)\{D^{\alpha_1}u, \dots, D^{\alpha_k}u\}D^\delta w\|_0 \le C\|w\|_{s-2}.$$

Furthermore, using the differentiation rule again, we have

$$\|M(u)D^\alpha v\|_2 \le C\|v\|_{s+2},$$

and consequently

$$\big(M(u)D^\alpha w, D^{\alpha_0}M^{(k)}(u)\{D^{\alpha_1}u, \dots, D^{\alpha_k}u\}D^\delta v\big)_0 \le C\|v\|_{s+2}\|w\|_{s-2}.$$

This implies (5.15).

(ii) Using the same type of argument as in the proof of part (i), we obtain

$$\big(v, \Delta_0^2 v\big)_{s,u} \ge \big(D_iD_jv, D_iD_jv\big)_{s,u} - C\|v\|_{s+1}\|v\|_{s+2},$$

and consequently

$$\big(v, (\Delta_0^2 + \lambda)v\big)_{s,u} \ge c_0\big(\|v\|_{s+2}^2 + \lambda\|v\|_s^2\big) - C\|v\|_{s+1}^2$$

with a positive constant c_0. Hence applying

$$\|v\|_{s+1}^2 \le \sigma\|v\|_{s+2}^2 + C(\sigma)\|v\|_s^2$$

with $\sigma = c_0/2$ and choosing λ sufficiently large, we get the claim. ∎

An immediate consequence of Lemma 5.3(i) is the existence of a continuous bilinear form $\langle\cdot,\cdot\rangle_{s,u}$ on $H^{s+2}(S,\mathbb{R}^m) \times H^{s-2}(S,\mathbb{R}^m)$ compatible with $(\cdot,\cdot)_{s,u}$; i.e., it holds that $\langle v,w\rangle_{s,u} = (v,w)_{s,u}$ for all $v, w \in H^{s+2}(S,\mathbb{R}^m)$. Further, we put for $\varepsilon \in (0,1]$

$$\langle v,w\rangle_{s,u}^\varepsilon := \langle v,w\rangle_{s_0,u} + \varepsilon^2\langle v,w\rangle_{s,u}. \tag{5.17}$$

LEMMA 5.4. *We assume as above that $s \ge s_0$, $\varepsilon \in (0,1]$.*

(i) *For fixed $u \in U_s$, the mapping $\langle\cdot,\cdot\rangle_{s,u}^\varepsilon : H^{s+2}(S,\mathbb{R}^m) \times H^{s-2}(S,\mathbb{R}^m) \to \mathbb{R}$ constitutes a continuous, nondegenerate bilinear form, symmetric on $H^{s+2}(S,\mathbb{R}^m) \times H^{s+2}(S,\mathbb{R}^m)$.*

(ii) *With constants $C > 0$ independent of ε, u, v, w, one has for $u, w \in \tilde{U}_s$ and $v \in H^{s+2}(S,\mathbb{R}^m)$*

$$C\big(\|v\|_{s_0}^2 + \varepsilon^2\|v\|_s^2\big) \le \langle v,v\rangle_{s,u}^\varepsilon \le C^{-1}\big(\|v\|_{s_0}^2 + \varepsilon^2\|v\|_s^2\big), \tag{5.18}$$

$$\langle v,v\rangle_{s,u}^\varepsilon \le \langle v,v\rangle_{s,w}^\varepsilon\big(1 + C\|u-w\|_{s_0-2}\big). \tag{5.19}$$

(iii) *The weak convergences $u_n \rightharpoonup u \in H^s$, $w_n \rightharpoonup w \in H^{s-2}$ imply for each $v \in H^{s+2}$*

$$\langle v,w_n\rangle_{s,u_n}^\varepsilon \to \langle v,w\rangle_{s,u}^\varepsilon.$$

Proof. (i) It remains only to show nondegeneracy. First note that Lemma 5.3(ii) implies for every $v \in H^{s+2}$ and $\lambda \ge \lambda_0$

$$\big\langle v, \Delta_0^2 v + \lambda v\big\rangle_{s,u}^\varepsilon \ge c_0\|v\|_0^2.$$

Let ε, u, w be fixed such that $\langle v,w\rangle_{s,u}^\varepsilon = 0$ for every $v \in H^{s+2}$. Let λ be sufficiently large and let $v \in H^{s+2}$ be the unique solution of the fourth order elliptic equation

$$\Delta_0^2 v + \lambda v = w \ \text{ on } \ S.$$

Thus we have

$$0 = \big\langle v, w\big\rangle_{s,u}^{\varepsilon} = \big\langle v, \Delta_0^2 v + \lambda v\big\rangle_{s,u}^{\varepsilon} \geq c_0 \|v\|_0^2$$

for our special v; consequently it follows that $v = 0$ and then $w = 0$.

(ii) The estimates (5.18) are immediate consequences of (5.10). Concerning (5.19) we note only that by (5.8)

$$\|M(u)f - M(w)f\|_0 \leq C\|u - w\|_{s_0-2}\|f\|_0,$$

from which the assertion can easily be derived.

(iii) Fix $v \in H^{s+2}$, $u \in U_s$, and, for the time being, $w \in H^s$. Using the representation (5.14), we get for $|\alpha| = s$

$$\begin{aligned}&\big(M(u)D^\alpha v, M(u)D^\alpha w\big)_0 \\ &\qquad = \sum (-1)^{|\alpha_0|}\big(M(u)D^\alpha v, D^{\alpha_0}M^{(k)}(u)\{D^{\alpha_1}u, \dots, D^{\alpha_k}u\}D^\delta w\big)_0\end{aligned}$$

with $|\alpha_i| \leq 2$, $|\delta| = s - 2$. Now assume $u_n \rightharpoonup u$ in U_s; thus $u_n \to u$ in $H^{s'}$ with $s \in [0, s)$, and $w_n \rightharpoonup w$ in H^{s-2}. According to the above remark, $\big\langle v, w_n\big\rangle_{s,u_n}$ can essentially be represented as a sum of terms

$$\sum (-1)^{|\alpha_0|}\big\langle M(u_n)D^\alpha v, D^{\alpha_0}M^{(k)}(u_n)\{D^{\alpha_1}u_n, \dots, D^{\alpha_k}u_n\}D^\delta w_n\big\rangle_{H^2\times H^{-2}}$$

with α, α_i, and δ as above, where $\langle\cdot,\cdot\rangle_{H^2\times H^{-2}}$ denotes the L^2-duality map on $H^2(S, \mathbb{R}^m) \times H^{-2}(S, \mathbb{R}^m)$. From the smoothness properties of M we conclude that

$$M(u_n)D^\alpha v \to M(u)D^\alpha v \ \text{ in } \ H^2(S, \mathbb{R}^m). \tag{5.20}$$

Similarly, uniform boundedness of $\|w_n\|_{s-2}$ and convergence $u_n \to u$ in H^{s_0-2} imply via (5.8)

$$M^{(k)}(u_n)\{D^{\alpha_1}u_n, \dots, D^{\alpha_k}u_n\}D^\delta w_n - M^{(k)}(u)\{D^{\alpha_1}u, \dots, D^{\alpha_k}u\}D^\delta w_n \to 0$$

in L^2. Since strong continuity of linear operators implies weak continuity, we have

$$M^{(k)}(u)\{D^{\alpha_1}u, \dots, D^{\alpha_k}u\}D^\delta w_n \rightharpoonup M^{(k)}(u)\{D^{\alpha_1}u, \dots, D^{\alpha_k}u\}D^\delta w$$

weakly in L^2, and consequently

$$D^{\alpha_0}M^{(k)}(u_n)\{D^{\alpha_1}u_n, \dots, D^{\alpha_k}u_n\}D^\delta w_n \rightharpoonup D^{\alpha_0}M^{(k)}(u)\{D^{\alpha_1}u, \dots, D^{\alpha_k}u\}D^\delta w$$

weakly in H^{-2}. Together with (5.20), this completes the proof. ∎

The following estimates, given in Lemma 5.5 and Proposition 5.6, form the core of the existence proof. The techniques are quite standard (cf. (4.1), (4.5)), but it is crucial to use the structure of $\mathcal{G}$ given by (5.25), which provides "coercivity w.r.t. the normal component"; cf. (5.24). Finally, in the proof of Proposition 5.6 we will couple the results concerning the operators F and $\mathcal{G}$ and use an integration by parts to deal with the possible degeneration of γ.

Lemma 5.5. *Let $s \geq s_0$ be an integer, let $u \in \widetilde{U}_s$, and assume $\gamma = \rho^2$ with $\rho \in C^\infty(S)$.*

(i) *There exist positive constants* c, C*, independent of* u*, such that*

$$\|\mathcal{G}'(u)v\|_0 \le C\big(\|\rho P(u)v\|_2 + \|v\|_1\big), \tag{5.21}$$

$$\big(DP(u)v, D\mathcal{G}'(u)v\big)_0 \le -c\|\rho P(u)Dv\|_1^2 + C\|v\|_1^2 \tag{5.22}$$

for all $v \in H^2(S, \mathbb{R}^m)$ *and any derivative* $D = D^\alpha$, $|\alpha| \le 1$.

(ii) *Moreover, for* $|\alpha| = s$ *we have*

$$\|D^\alpha \mathcal{G}(u)\|_{-1} \le C\big(\|\rho P(u) D^\alpha u\|_1 + \|u\|_s\big), \tag{5.23}$$

$$\big(P(u)D^\alpha u, D^\alpha \mathcal{G}(u)\big)_0 \le -c\|\rho P(u)D^\alpha u\|_1^2 + C\|u\|_s^2. \tag{5.24}$$

Proof. (i) To show (5.21), (5.22) it suffices to construct a representation of the form

$$\mathcal{G}'(u)v = \gamma\Delta(u)(P(u)v) + \rho R_1(u)v + R_2(u)v \tag{5.25}$$

with operators $R_1(u)$, $R_2(u)$ such that

$$\|R_1(u)v\|_0, \|R_2(u)v\|_1 \le C\|v\|_1. \tag{5.26}$$

For the part $H'(u)v$ of $\mathcal{G}'(u)v$, which is a second order differential operator in v, this is quite clear using the well-known fact that the linearization of the mean curvature has $\Delta(u)(P(u)v)$ as its main part. Concerning $G'(u)v$ we note

$$\begin{aligned} -G'(u)v &= A(u)\Delta'(u)\{v\}\gamma + A'(u)\{v\}\Delta(u)\gamma, \\ \Delta'(u)\{v\}\gamma &= 2\rho\Delta'(u)\{v\}\rho + 4\Lambda_i'(u)\{v\}\rho\Lambda_i(u)\rho; \end{aligned}$$

hence we have the representation $-G'(u)v = \rho R_1(u) + R_2(u)$ with

$$\begin{aligned} R_1(u) &:= 2A(u)\Delta'(u)\{v\}\rho, \\ R_2(u) &:= 2\big(A(u)(\rho\Delta'(u)\{v\}\rho) - \rho A(u)\Delta'(u)\{v\}\rho\big) \\ &\quad + 4A(u)\Lambda_i'(u)\{v\}\rho\Lambda_i(u)\rho + A'(u)\{v\}\Delta(u)\gamma. \end{aligned}$$

Due to

$$\|\Delta(u)\rho\|_{s_0-2} \le C, \quad \|\Delta'(u)\{v\}\rho\|_{-1}, \|\Lambda_i'(u)\{v\}\rho\|_0 \le C\|v\|_1,$$

the estimate (5.26) for R_1 is now a consequence of

$$\|A(u)f\|_0 \le C\|f\|_{-1}, \quad \|\Delta'(u)\{v\}\rho\|_{-1} \le C\|v\|_1,$$

whereas the estimate for R_2 follows from the commutator estimate (4.34) together with

$$\|A(u)f\|_1 \le C\|f\|_0, \quad \|A'(u)\{v\}f\|_1 \le C\|v\|_1\|f\|_{s_0-2}.$$

(ii) Similar to part (i), it suffices to show the existence of a decomposition

$$D^\alpha\mathcal{G}(u) = \gamma\Delta(u)(P(u)D^\alpha u) + \rho R_1(u) + R_2(u),$$

with operators R_1, R_2 allowing the estimates

$$\|R_1(u)\|_{-1}, \|R_2(u)\|_0 \le C\|u\|_s.$$

Again, for the part $D^\alpha H$ of $D^\alpha \mathcal{G}$ this is quite clear, where R_1, R_2 are now local differential operators w.r.t. u of order $s+1$ and s, respectively. Concerning $D^\alpha G(u)$ we write $\alpha = \beta + \delta$ with $|\beta| = 1$, $|\delta| = s-1$ and calculate

$$-D^\alpha G(u) = 2\rho D^\beta A(u)\Delta'(u)\{D^\delta u\}\rho + Q_1 + \cdots + Q_5$$

with

$$\begin{aligned}
Q_1 &:= D^\beta\big(D^\delta A(u)\Delta(u)\gamma - A(u)D^\delta\Delta(u)\gamma\big),\\
Q_2 &:= D^\beta A(u)\big(D^\delta\Delta(u)\gamma - \Delta'(u)\{D^\delta u\}\gamma\big),\\
Q_3 &:= 4D^\beta A(u)\Lambda_i'(u)\{D^\delta u\}\rho\Lambda_i(u)\rho,\\
Q_4 &:= 2D^\beta\big(A(u)(\rho\Delta'(u)\{D^\delta u\}\rho) - \rho A(u)\Delta'(u)\{D^\delta u\}\rho\big),\\
Q_5 &:= 2(D^\beta\rho)A(u)\Delta'(u)\{D^\delta u\}\rho.
\end{aligned}$$

Now we set $R_1 := 2D^\beta A(u)\Delta'(u)\{D^\delta u\}\rho$ and $R_2 := Q_1 + \cdots + Q_5$. The necessary estimates follow from the properties of A—in particular, Proposition 4.7 (ii) and (4.34)—and from the additional commutator estimate

$$\|D^\delta\Delta(u)\gamma - \Delta'(u)\{D^\delta u\}\gamma\|_0 \le C\|u\|_s. \qquad \square$$

Now we are prepared to formulate and prove the following a priori estimates for $\mathcal{F}$ w.r.t. the bilinear forms $\langle\cdot,\cdot\rangle_{s,u}$.

PROPOSITION 5.6. *Let $s \ge s_0$ be an integer. Then*

$$\big\langle v, \mathcal{F}'(u)v\big\rangle_{1,u} \le C\|v\|_1^2, \tag{5.27}$$

$$\big\langle u, \mathcal{F}(u)\big\rangle_{s,u} \le C\|u\|_s^2 \tag{5.28}$$

for all $u \in \widetilde{U}_s$ and $v \in H^2(S,\mathbb{R}^m)$ with constants independent of u and v.

Proof. We start with the proof of (5.27). Due to (5.21), for any derivative D

$$\big\|D\mathcal{F}'(u)v - F'(u)\{Dv\}\mathcal{G}(u) - F(u)\big(D\mathcal{G}'(u)v\big)\big\|_0 \le C\big(\|v\|_1 + \|\rho P(u)v\|_2\big),$$

and consequently by Lemma 5.1

$$D\mathcal{F}'(u)v = F(u)\big(\mathcal{F}(u)\cdot\Lambda(u)(P(u)Dv) + D\mathcal{G}'(u)v\big) + R(u)v,$$

where the remainder term satisfies

$$\|R(u)v\|_0 \le C\big(\|v\|_1 + \|\rho P(u)v\|_2\big).$$

Further, by (5.21) we have

$$\|D\mathcal{G}'(u)v\|_{-1} \le C\big(\|v\|_1 + \|\rho P(u)v\|_2\big),$$

and moreover

$$\|\mathcal{F}(u)\cdot\Lambda(u)(P(u)Dv)\|_{-1} \le C\|v\|_1.$$

Hence by Lemma 5.2 it follows that

$$\big\langle Dv, D\mathcal{F}'(u)v\big\rangle_{0,u} \le \big(P(u)Dv, \mathcal{F}(u)\cdot\Lambda(u)(P(u)Dv) + D\mathcal{G}'(u)v\big)_0 + I(u)v^2,$$

where now

$$I(u)v^2 \le C\big(\|v\|_1 + \|\rho P(u)v\|_2\big)\|v\|_1.$$

Writing

$$\begin{aligned}\big(P(u)Dv, \mathcal{F}(u)\cdot\Lambda(u)(P(u)Dv)\big)_0 \\ = \frac{1}{2}\int_S \Big(\Lambda_i(u)\big(\mathcal{F}_i(u)(P(u)Dv)^2\big) - (P(u)Dv)^2\Lambda_i(u)\mathcal{F}_i(u)\Big)\, dS,\end{aligned}$$

an integration by parts on S using (5.5) yields

$$\big|\big(P(u)Dv, \mathcal{F}(u)\cdot\Lambda(u)(P(u)Dv)\big)_0\big| \le C\|v\|_1^2;$$

hence together with Lemma 5.5 and (5.22) we obtain the estimate (5.27).

Further, to prove (5.28) we use the abbreviation

$$\|u\|'_{s+1} := \left(\|u\|_s + \sum_{|\alpha|=s}\|\rho P(u)D^\alpha u\|_1\right).$$

Using Proposition 4.6(ii) we write

$$D^\alpha\mathcal{F}(u) = F(u)D^\alpha\mathcal{G}(u) + F'(u)\{D^\alpha u\}\mathcal{G}(u) + R_1(u),$$

where R_1 allows the estimate

$$\|R_1(u)\|_0 \le C\big(\|u\|_s\|\mathcal{G}(u)\|_{s_0-2} + \|\mathcal{G}(u)\|_{s-1}\big) \le C\|u\|'_{s+1}$$

because of

$$\|\mathcal{G}(u)\|_{s-1} \le C\left(\sum_{|\alpha|=s}\|D^\alpha\mathcal{G}(u)\|_{-1} + \|\mathcal{G}(u)\|_0\right)$$

and (5.23). Further, using Lemma 5.1 we have

$$D^\alpha\mathcal{F}(u) = F(u)\big(D^\alpha\mathcal{G}(u) + \mathcal{F}(u)\cdot\Lambda(u)(P(u)D^\alpha u)\big) + R_1(u) + R_2(u),$$

where again

$$\|R_2(u)\|_0 \le C\|D^\alpha u\|_0 \le C\|u\|_s,$$

and consequently

$$\big\langle R_1(u) + R_2(u), D^\alpha u\big\rangle_{0,u} \le C\|u\|'_{s+1}\|u\|_s.$$

By (5.11) we obtain

$$\big\langle D^\alpha u, D^\alpha\mathcal{F}(u)\big\rangle_{0,u} = \big(P(u)D^\alpha u, \mathcal{F}(u)\cdot\Lambda(u)(P(u)D^\alpha u) + D^\alpha\mathcal{G}(u)\big)_0 + I(u),$$

where $I(u)$ allows the estimate

$$\begin{aligned}I(u) &\le C\|D^\alpha u\|_0\big(\|D^\alpha\mathcal{G}(u)\|_{-1} + \|\mathcal{F}(u)\cdot\Lambda(u)(P(u)D^\alpha u)\|_{-1}\big) \\ &\le C\big(1 + \|u\|'_{s+1}\big)\|u\|_s.\end{aligned}$$

Finally, by an integration by parts as above we get

$$\big(D^\alpha u, \mathcal{F}(u)\cdot\Lambda(u)(P(u)D^\alpha u\big)_0 \le C\|u\|_s^2.$$

Together with (5.24), this completes the proof. ∎

The structure of $F'(u)$ as stated in Lemma 5.1 and the integration by parts argument used in the above proof are necessary to cover the case of a γ which can degenerate. If γ is strictly positive, the argumentation can be simplified by using Lemma 5.1 to obtain the estimate

$$\|F'(u)\{v\}f\|_0 \le C\big(\|P(u)v\|_1 + \|v\|_0\big)\|f\|_{s_0-1}. \tag{5.29}$$

To conclude this section we add some remarks about the case of a slip factor δ (introduced in (2.8)) different from one. The nonlinear operator of the evolution equation is now

$$\mathcal{F}_1(u) := F_1(u)\big(\mathcal{G}_1(u)\big)$$

with

$$F_1(u)f := \big(\delta\, id + (1-\delta)N(u)P(u)\big)F(u)f, \quad \mathcal{G}_1(u) = H(u) + \delta G(u).$$

Clearly, Lemma 4.5 and Proposition 4.6 continue to hold also for F_1. To see that $F_1'(u)$ satisfies an estimate parallel to (5.29) as well, note that due to (5.6) we have

$$\|P'(u)\{v\}w\|_0 \le C\big(\|P(u)v\|_1 + \|v\|_0\big)\|w\|_{s_0-2},$$
$$\|N'(u)\{v\}z\|_0 \le C\big(\|P(u)v\|_1 + \|v\|_0\big)\|z\|_{s_0-2}.$$

This implies such an estimate for F_1. Hence, by changing the definition (5.7) of M into

$$M(u)v := v - \delta\Lambda(u)\big(\psi(u)P(u)v\big)$$

and $\langle\cdot,\cdot\rangle_{s,u}$ accordingly, we obtain the crucial estimates (5.27), (5.28) of Proposition 5.6 also for $\mathcal{F}_1$, at least in the case of strictly positive γ. Note that for $\delta = 0$ the bilinear forms $\langle\cdot,\cdot\rangle_{s,u}$ are in fact independent of u.

6. Proofs of Theorems 3.1 and 3.2. As pointed out earlier, the abstract existence results, Theorems 3.3 and 3.4, provide neither uniqueness of the solution nor strong continuity. The corresponding statements of Theorem 3.1 have to be proved separately. We start with a result on (Lipschitz) continuous dependence on the initial data in a weak norm which immediately implies uniqueness but will also be used in the proof of strong continuity. The techniques (Gronwall's lemma and Taylor expansion, together with the use of estimates obtained earlier) are quite standard.

LEMMA 6.1. *Fix $\widetilde{U}_{s_0} \subset U_{s_0}$. Let $u, v \in C_w\big([0,T], H^{s_0}\big) \cap C_w^1\big([0,T], H^{s_0-2}\big)$ be two solutions of* (3.2) *with*

$$u(t), v(t) \in \widetilde{U}_{s_0} \ \text{ for } \ t \in [0,T].$$

There exists a real number C depending only on T and $\widetilde{U}_{s_0}$ such that

$$\|u(t) - v(t)\|_1 \le C\|u(0) - v(0)\|_1 \ \text{ for all } \ t \in [0,T]. \tag{6.1}$$

Proof. We put $w(t) := v(t) - u(t)$ and remark

$$u, v \in C\big([0,T], H^s\big) \cap C^1\big([0,T], H^{s-2}\big) \ \text{ for } \ 2 \le s < s_0;$$

in particular, the mapping $[0,T] \ni t \mapsto \big\langle w(t), w(t)\big\rangle_{0,u(t)}$ is differentiable and we will show

$$\frac{d}{dt}\big\langle w(t), w(t)\big\rangle_{1,u(t)} \le C\big\langle w(t), w(t)\big\rangle_{1,u(t)}, \tag{6.2}$$

which implies (6.1) via Gronwall's lemma. Recalling that H is a quasi-linear second order differential operator, we have

$$\|H'(z)w\|_1 \le C\|w\|_3, \quad \|H''(z)\{w,w\}\|_1 \le C\|w\|_3\|w\|_{s_0-2}$$

and, accordingly by (4.33),

$$\|G'(z)w\|_1 \le C\|v\|_3, \quad \|G''(z)\{w,w\}\|_1 \le C\|w\|_3\|w\|_{s_0-2}.$$

Consequently, together with Lemma 4.5 and (4.20), we obtain

$$\|\mathcal{F}''(z)\{w,w\}\|_1 \le C\|w\|_3\|w\|_{s_0-2}. \tag{6.3}$$

Using Taylor's theorem we have

$$w'(t) := \frac{d}{dt}w(t) = \mathcal{F}\big(v(t)\big) - \mathcal{F}\big(u(t)\big) = \mathcal{F}'\big(u(t)\big)w(t) + R\big(u(t), v(t)\big);$$

the remainder term therein can be estimated by (6.3) and norm convexity

$$\big\|R\big(u(t), v(t)\big)\big\|_1 \le C_1\|w(t)\|_{s_0-2}\|w(t)\|_3 \le C_2\|w(t)\|_{s_0}\|w(t)\|_1 \le C_3\|w(t)\|_1.$$

From this and (5.27), we obtain

$$\big\langle w(t), w'(t)\big\rangle_{1,u(t)} = \big\langle w(t), \mathcal{F}'\big(u(t)\big)w(t) + R\big(u(t), v(t)\big)\big\rangle_{1,u(t)} \le C\|w(t)\|_1^2. \tag{6.4}$$

Furthermore, recalling (5.8), we have

$$\big\|M'\big(u(t)\big)\{u'(t)\}w(t)\big\|_1 \le C_2\|u'(t)\|_{s_0-2}\|w(t)\|_1.$$

Hence

$$\|u'(t)\|_{s_0-2} = \|\mathcal{F}(u(t))\|_{s_0-2} \le C$$

gives

$$\big\|M'\big(u(t)\big)\{u'(t)\}w(t)\big\|_1 \le C\|w(t)\|_1. \tag{6.5}$$

Consequently, considering

$$\begin{aligned}\frac{1}{2}\tfrac{d}{dt}\big\langle w(t), w(t)\big\rangle_{1,u(t)} \\ &= \big\langle w(t), w'(t)\big\rangle_{1,u(t)} + \Big(M\big(u(t)\big)w(t), M'\big(u(t)\big)\{u'(t)\}w(t)\Big)_1,\end{aligned}$$

we obtain the desired estimate (6.1) from (6.4), (6.5). $\square$

We note a result on nonlinear interpolation, whose proof can be found in [2, Prop. A.1 and Rem. A.2]. It will be crucial in the proof of strong continuity of the solution in time.

LEMMA 6.2. *Let $\mathcal{U} \subseteq H^s(S,\mathbb{R}^m)$, $s \geq 1$, be an open set. Let $T_\alpha : \mathcal{U} \to H^1(S,\mathbb{R}^m)$ be mappings with $T_\alpha(\mathcal{U}\cap H^{s+1}) \subseteq H^{s+1}$; α runs through a certain index set I. Further, assume Lipschitz continuity of T_α in H^1 and boundedness of T_α in H^{s+1}:*

$$\|T_\alpha(u) - T_\alpha(v)\|_1 \leq C\|u - v\|_1 \ \textit{ for all } \ u, v \in \mathcal{U},$$
$$\|T_\alpha(u)\|_{s+1} \leq C\big(1 + \|u\|_{s+1}\big) \ \textit{ for all } \ u \in \mathcal{U} \cap H^{s+1}$$

with a constant C independent of u, v and $\alpha \in I$. Then $T_\alpha(\mathcal{U} \cap H^s) \subseteq H^s$ and the mappings $T_\alpha : \mathcal{U} \subseteq H^s \to H^s$ are continuous, uniformly w.r.t. $\alpha \in I$.

Now we are prepared for the proof of our theorems. In many respects, it is parallel to the proof of the main results in [10].

Proof of Theorem 3.1.

Step 1. We show that for any given $\bar{u}_0 \in U_{s_0}$ and any integer $s \geq s_0$ there exist $T = T(\bar{u}_0, s) > 0$ and $\delta = \delta(\bar{u}_0, s) > 0$ such that the Cauchy problem (3.2) has a unique solution in the class

$$u \in C_w\big([0,T], U_s\big) \cap C_w^1\big([0,T], H^{s-2}\big)$$

for all initial values $u_0 \in H^s$ with $\|u_0 - \bar{u}_0\|_{s_0} \leq \delta$. The uniqueness of the solution follows immediately from Lemma 6.1. In order to prove the existence we use Theorem 3.4. With a fixed $s \geq s_0$ and an $\varepsilon \in (0,1]$ which will be fixed below, we put

$$X = H^{s+2}(S,\mathbb{R}^m), \quad \|\cdot\|_X = \|\cdot\|_{s_0+2} + \varepsilon\|\cdot\|_{s+2};$$
$$Y = H^{s}(S,\mathbb{R}^m), \quad \|\cdot\|_Y = \|\cdot\|_{s_0} + \varepsilon\|\cdot\|_{s};$$
$$Z = H^{s-2}(S,\mathbb{R}^m), \quad \|\cdot\|_Z = \|\cdot\|_{s_0-2} + \varepsilon\|\cdot\|_{s-2}.$$

Further, let $\widetilde{U}_s$ be as in section 5 and assume that the given $\bar{u}_0$ is an interior point. Then, according to the results of section 5, for $u \in \widetilde{U}_s$ the bilinear forms $\langle v, w\rangle_{s,u}^\varepsilon$: $X \times Z \to \mathbb{R}$ satisfy the requirements (H) of section 3; note that the constants C, M in (H) can be chosen independently of ε. As in the proof of Theorem 3.3 we choose $w_0 \in C^\infty(S,\mathbb{R}^m)$ and $R > 0$ (both independent of ε) such that

$$\|w_0 - u_0\|_{s_0} \leq R/(32C^5)^{1/2}, \quad \{w_0 + v \mid v \in B\} \subseteq \widetilde{U}_{s_0}$$

with the ball $B := \big\{v \in Y \mid \|v\|_Y < R\big\}$. We set

$$\langle v, w\rangle_u := \langle v, w\rangle_{s,w_0+u}^\varepsilon, \quad |||v||| = \langle v, v\rangle_{w_0+v}$$

and define a map $\mathcal{H} : B \subseteq Y \to Z$ by

$$\mathcal{H}(v) := \mathcal{F}(v + w_0), \quad u \in B.$$

Further, the mapping $\mathcal{H} : B \subseteq Y \to Z$ is weakly sequentially continuous and

$$\langle w_0 + v, \mathcal{H}(v)\rangle \leq C_1\|w_0 + v\|_Y^2 \leq C_2$$

by Proposition 5.6. Moreover we have

$$\|\mathcal{H}(v)\|_Z \leq C_3\|v + w_0\|_Y \leq C_4$$

and

$$|\langle w_0, \mathcal{H}(v)\rangle_v| \le C_5 \|w_0\|_X \|\mathcal{H}(v)\|_Z \le C_6.$$

These estimates hold for all $v \in B$ with constants $C_1, \ldots,$ which may depend on C, M, R, s and $\bar{u}_0, w_0$, but not on v. Gathering them, we obtain the inequality

$$2\langle v, \mathcal{H}(v)\rangle_v + M\|\mathcal{H}(v)\|_Z |\!|\!| v |\!|\!| \le C_7 \ \text{ for all } \ v \in B \cap X.$$

Now, let $u_0 \in H^s(S, \mathbb{R}^m)$ be given such that

$$\|u_0 - \bar{u}_0\|_{s_0} \le R/(32C^5)^{1/2}. \tag{6.6}$$

Hence, with $r := R/(2C^3)^{1/2}$ we find

$$|\!|\!| u_0 - w_0 |\!|\!| \le C\big(\|u_0 - \bar{u}_0\|_{s_0} + \|\bar{u}_0 - w_0\|_{s_0} + \varepsilon(\|u_0\|_s + \|w_0\|_s)\big) \le r$$

if ε is chosen according to

$$\varepsilon := \min\big\{1, r/4C(\|u_0\|_s + \|w_0\|_s)\big\}. \tag{6.7}$$

By Theorem 3.4, applied to $\mathcal{H}$, there exist $T > 0$, independent of u_0 with (6.6), and a solution

$$v \in C_w\big([0,T], B \cap H^s\big) \cap C^1_w\big([0,T], H^{s-2}\big)$$

of

$$dv(t)/dt = \mathcal{G}(v(t)) \ \text{ for } \ t \in [0,T], \quad v(0) = u_0 - w_0.$$

Then $u := v + w_0$ is a solution of (3.2) with initial value $u(0) = u_0$, and we have

$$\|u(t)\|_s \le \|w_0\|_s + \|v(t)\|_s \le \|w_0\|_s + \varepsilon^{-1}\|v(t)\|_Y,$$

which in view of (6.7) implies

$$\|u(t)\|_s \le C(1 + \|u(0)\|_s). \tag{6.8}$$

Step 2. Let $u, \tilde{u}$ be two solutions of (3.2) in $[0,T]$ according to Step 1 with initial values

$$u(0), \tilde{u}(0) \in \mathcal{U}, \quad \mathcal{U} := \big\{v \in H^s \mid \|v - \bar{u}_0\|_{s_0} \le \delta\big\},$$

$\delta > 0$ sufficiently small. Lemma 6.1 gives

$$\|u(t) - \tilde{u}(t)\|_1 \le C\|u(0) - \tilde{u}(0)\|_1. \tag{6.9}$$

For fixed $t \in [0,T]$ we consider the evolution operator

$$\mathcal{U} \ni u_0 \mapsto T_t(u_0) := u(t) \in H^s,$$

assigning to any initial value u_0 the value of the corresponding solution of (3.2) at time t. By Step 1 with s replaced by $s+1$ we obtain $T_t(\mathcal{U} \cap H^{s+1}) \subseteq H^{s+1}$ and the estimate

$$\|T_t(u_0)\|_{s+1} \le C\big(1 + \|u_0\|_{s+1}\big). \tag{6.10}$$

Equations (6.9) and (6.10) together with the interpolation result from Lemma 6.2 show the continuity of the mapping

$$\mathcal{U} \cap H^s \ni u_0 \mapsto u(t) \in H^s \ \text{ for } \ s \geq s_0,$$

uniformly w.r.t. $t \in [0, T]$.

Step 3. To complete the proof of Theorem 3.1 it remains to show that the solutions according to Step 1 actually belong to

$$u \in C\big([0,T], H^s\big) \cap C^1\big([0,T], H^{s-2}\big). \tag{6.11}$$

To do this, we approximate the initial value $u_0 = u(0)$ by a sequence $u_0^n \in H^{s+1}$ such that $u_0^n \to u_0$ in H^s. Then by Step 1, for n sufficiently large, there exist solutions u_n of (3.2) with $u_n(0) = u_0^n$ in the class

$$u_n \in C_w\big([0,T], H^{s+1}\big) \cap C_w^1\big([0,T], H^{s-1}\big),$$

which in particular implies

$$u_n \in C\big([0,T], H^s\big) \cap C^1\big([0,T], H^{s-2}\big).$$

On the other hand, by Step 2, we have $u_n(t) \to u(t)$ in H^s uniformly w.r.t. $t \in [0,T]$. Since the uniform limit of continuous functions is continuous again, this implies (6.11). ∎

Proof of Theorem 3.2. Let a solution $u \in C([0,T], U_s) \cap C^1([0,T], H^{s-2})$ be given. The set $\{u(t) \,|\, t \in [0,T]\}$ is compact in H^s and can be covered by the open sets $\{v \in H^s \,|\, \|v - u(t)\|_s < \delta(u(t), s+1)\}$, $t \in [0,T]$, where $\delta(u(t), s+1)$ are the same as in the proof of Theorem 3.1. Choosing a finite subcover, we find from this theorem and the autonomous character of (3.2) that there is a $T_0 > 0$ such that for any $t \in [0,T]$ with $u(t) \in H^{s+1}$, we have

$$u|_{[t,T_1]} \in C([t,T_1], U_{s+1}) \cap C^1([t,T_1], H^{s-1}), \quad T_1 := \min\{t + T_0, T\}.$$

Proceeding stepwise, we obtain (i).

A similar compactness argument together with Theorem 3.1 and its proof ensures the existence of $T_2 > 0$ such that the following is true for all $t \in [0,T]$: Problem (3.2) is solvable on the time interval $[0, T_2]$ (in the class (3.13)) for all initial values z sufficiently near $u(t)$, and the mapping which assigns to z its corresponding solution $V(\cdot, z)$ is continuous with values in $C([0,T_2], H^s)$. We choose $t_i \in [0,T]$ such that $0 = t_0 < \cdots < t_n = T$, $t_i - t_{i-1} < T_2$, and open H^s-neighborhoods K_i of $u(t_i)$ small enough to ensure that V is defined on K_i and $V(t_i - t_{i-1}, K_{i-1}) \subset K_i$, $i = n-1, \dots, 1$. Now (ii) follows from the continuity of the composition of continuous maps. ∎

Appendix. Proof of Theorem 3.4. We will construct a solution of (3.19) by implicit time discretization, solving the nonlinear problems in each timestep by Galerkin approximations. For this purpose, we need the following lemma.

LEMMA A.1. *For any $K \in (0, r^2)$ there is an $\varepsilon_0 > 0$ such that for any $\varepsilon \in (0, \varepsilon_0]$ and any $v \in Y$ satisfying $|||v|||^2 \leq K$ there is a $u^* \in B$ satisfying*

$$u^* = v + \varepsilon \mathcal{G}(u^*) \tag{A.1}$$

and the estimate

$$|||u^*|||^2 \leq |||v|||^2 + \varepsilon \beta\big(|||u^*|||^2\big) \leq 2K. \tag{A.2}$$

Proof. For arbitrary $v \in Y$, $u \in X \cap B$ we have

$$\begin{aligned}\langle u, u - \varepsilon\mathcal{G}(u) - v\rangle_u &= |||u|||^2 - \varepsilon\langle u, \mathcal{G}(u)\rangle_u - (u,v)_u \\ &\geq |||u|||^2 - \frac{\varepsilon}{2}\beta\big(|||u|||^2\big) + \frac{\varepsilon M}{2}\|\mathcal{G}(u)\|_Z|||u|||^2 - |||u|||\|v\|_u \\ &\geq \frac{1}{2}\Big(|||u|||^2 - \varepsilon\beta\big(|||u|||^2\big) - \|v\|_u^2 + \varepsilon M\|\mathcal{G}(u)\|_Z|||u|||^2\Big). \end{aligned} \tag{A.3}$$

Choose $\varepsilon_0 > 0$ such that for all $\varepsilon \in (0, \varepsilon_0]$ and for all $s \in [0, 2C^4K]$

$$K - \varepsilon\beta(s) \geq 0, \tag{A.4}$$

$$1 - \varepsilon\beta'(s) \geq 0. \tag{A.5}$$

Assume now that $v \in B$, $|||v|||^2 \leq K$. Let

$$\mathcal{B} := \{u \in Y \mid \|u\|_Y^2 \leq 2KC^3\}$$

and note that $\mathcal{B}$ is a closed convex subset of B. Assume $\|u\|_Y^2 = 2KC^3$. Then

$$\begin{gathered} 2C^2K = C^{-1}\|u\|_Y^2 \leq |||u|||^2 \leq C\|u\|_Y^2 = 2C^4K, \\ \|v\|_u^2 \leq C\|v\|_Y^2 \leq C^2|||v|||^2 \leq C^2K. \end{gathered}$$

Therefore, for $\varepsilon \in (0, \varepsilon_0]$,

$$\langle u, u - \varepsilon\mathcal{G}(u) - v\rangle_u \geq \frac{1}{2}(C^2K - \varepsilon\beta(|||u|||^2)) \geq 0. \tag{A.6}$$

Let $\{M_n\}$ be an increasing sequence of finite-dimensional subspaces of X whose union is dense in X. We fix n, choose a basis $\{e_1, \ldots, e_n\}$ of M_n, and show that the variational equality

$$\langle w, u_n - \varepsilon\mathcal{G}(u_n) - v\rangle_u = 0 \;\text{ for all }\; w \in M_n \tag{A.7}$$

has a solution $u_n \in M_n \cap \mathcal{B}$. Note that (A.7) is equivalent to $g(u_n) = 0$, where $g : M_n \cap \mathcal{B} \to M_n$ is defined by

$$g(u) := P_u(u - \varepsilon\mathcal{G}(u) - v) \quad \text{with} \quad P_u(z) := \sum_{i=1}^{n}\langle e_i, z\rangle_u e_i.$$

Due to (H4), g is continuous. Assume now that $g(u) \neq 0$ for all $u \in M_n \cap \mathcal{B}$. Then we define the continuous operator $f : M_n \cap \mathcal{B} \to M_n$ by

$$f(u) := -\sqrt{2KC^3}g(u)/\|g(u)\|_Y.$$

As $\|f(u)\|_Y^2 = 2KC^3$, f maps the closed convex set $M_n \cap \mathcal{B}$ into itself. Therefore, by Brouwer's fixed point theorem, there is a $\overline{u} \in M_n \cap \mathcal{B}$ such that $\overline{u} = f(\overline{u})$. Consequently, $\|\overline{u}\|_Y^2 = 2KC^3$, and from (A.6) we obtain the contradictory inequality

$$\begin{aligned} 0 < |||\overline{u}|||^2 = \big\langle \overline{u}, f(\overline{u})\big\rangle_{\overline{u}} &= -\frac{\sqrt{2KC^3}}{\|g(u)\|_Y}\big\langle \overline{u}, g(\overline{u})\big\rangle_{\overline{u}} \\ = -\frac{\sqrt{2KC^3}}{\|g(u)\|_Y}\big\langle \overline{u}, \overline{u} - \varepsilon\mathcal{G}(\overline{u}) - v\big\rangle_{\overline{u}} &\leq 0. \end{aligned}$$

Therefore, (A.7) is solvable for every n, and as $\{u_n\}$ is bounded in Y, we can assume without loss of generality that $u_n \rightharpoonup u^*$ in Y for some $u^* \in \mathcal{B}$. Passage to the limit in (A.7) yields by (H4)

$$\langle w, u^* - \varepsilon\mathcal{G}(u^*) - v\rangle_{u^*} = 0 \text{ for all } w \in M_n, n = 1, 2, \dots,$$

and consequently by the density assumption

$$\langle w, u^* - \varepsilon\mathcal{G}(u^*) - v\rangle_{u^*} = 0 \text{ for all } w \in X.$$

The nondegeneracy of $\langle\cdot,\cdot\rangle_{u^*}$ yields (A.1). To show the estimate (A.2), note first that

$$|||u^*|||^2 \le \underline{\lim}_{\,n\to\infty} |||u_n|||^2 \le 2C^4K.$$

Thus, the second inequality in (A.2) follows from (A.4). To show the first inequality we assume without loss of generality that $|||v||| \le |||u^*|||$ and use (A.5), (A.3), and (H4) to obtain

$$\begin{aligned}
|||u^*|||^2 - \varepsilon\beta(|||u^*|||^2) &\le \underline{\lim}_{\,n\to\infty}\big(|||u_n|||^2 - \varepsilon\beta\big(|||u_n|||^2\big)\big)\\
&\le \underline{\lim}_{\,n\to\infty}\big(\|v\|_{u_n}^2 - M\varepsilon\|\mathcal{G}(u_n)\|_Z|||u_n|||^2\big) \le \|v\|_{u^*}^2 - M\varepsilon\|\mathcal{G}(u^*)\|_Z|||u^*|||^2\\
&\le |||v|||^2 + M\|u^* - v\|_Z|||v|||^2 - M\varepsilon\|\mathcal{G}(u^*)\|_Z|||u^*|||^2\\
&= |||v|||^2 + M\varepsilon\|\mathcal{G}(u^*)\|_Z|||v|||^2 - M\varepsilon\|\mathcal{G}(u^*)\|_Z|||u^*|||^2 \le |||v|||^2. \qquad \square
\end{aligned}$$

As further preparation for the proof of Theorem 3.4 we need the following simple result on approximate solutions of the ordinary differential equation (3.18).

LEMMA A.2. *Assume $u_0 \in B$ and let $\rho \in C^1[0,T]$ be the solution of (3.18). There is an $n_0 \in \mathbb{N}$ such that for $n \ge n_0$ and $k = 1, \dots, n$ there are $\rho_n^k, r_n \in \mathbb{R}$ such that*

$$\rho_n^0 = |||u_0|||^2, \quad \rho_n^k + \delta_n\beta(\rho_n^{k+1}) \le \rho_n^{k+1} \le \rho\big((k+1)\delta_n\big) + r_n, \quad r_n \to 0,$$

where $\delta_n := T/n$.

Proof. If n_0 is sufficiently large, $n \ge n_0$, there exist solutions $\rho_n \in C^1[0,T]$ to the initial value problems

$$\rho_n'(t) = \beta\big(\rho_n(t)\big) + 1/\sqrt{n}, \quad \rho_n(0) = |||u_0|||^2.$$

We set

$$\rho_n^k := \rho_n(k\delta_n), \qquad k = 0, \dots, n.$$

Then

$$\rho_n^{k+1} - \rho_n^k = \delta_n\rho_n'(\xi) = \delta_n\beta(\rho_n(\xi)) + \delta_n n^{-1/2}$$

for some $\xi \in \big(k\delta_n, (k+1)\delta_n\big)$. Moreover,

$$\big|\beta\big(\rho_n(\xi)\big) - \beta\big(\rho_n^{k+1}\big)\big| \le S\big|\rho_n(\xi) - \rho_n^{k+1}\big| \le S'n^{-1}$$

with constants S, S' independent of n. Thus

$$\rho_n^{k+1} - \rho_n^k \ge \delta_n\beta(\rho_n^{k+1}) + \delta_n n^{-1/2} - S'\delta_n n^{-1} \ge \delta_n\beta(\rho_n^{k+1})$$

for $n \geq n_0$, n_0 sufficiently large. Moreover, well-known results on the dependence of the solution of ordinary differential equation's on their right-hand sides ensure

$$r_n := \max_{t\in[0,T]} |\rho_n(t) - \rho(t)| \to 0, \qquad n \to \infty,$$

and hence

$$\rho_n(t) \leq \rho(t) + r_n, \qquad t \in [0,T].$$

This proves the lemma. □

Proof of Theorem 3.4. In a first step, we construct approximations u_n^k for the solution at time kT/n. Choose $K \in \big(\max_{t\in[0,T]} \rho(t), r^2\big)$ and choose $\varepsilon_0 > 0$ such that the assertions of Lemma A.1 and (A.5) hold. Let $n_0 \in \mathbb{N}$ be at least as large as in Lemma A.2 and assume additionally that $n_0 \geq T/\varepsilon_0$ and

$$\rho(t) + r_n \leq K \quad \text{for } n \geq n_0 \text{ and } t \in [0,T].$$

Now we fix $n \geq n_0$ and show the existence of $u_n^k \in B$, $k = 0, \dots, n$, such that

$$\begin{aligned} u_n^{k+1} &= u_n^k + \delta_n \mathcal{G}(u_n^{k+1}), \quad k = 0, \dots, n-1, \\ u_n^0 &= u_0, \\ |||u_n^k|||^2 &\leq \rho_n^k, \end{aligned}$$

where the ρ_n^k are given by Lemma A.2. For $k = 0$, existence and the estimate are clear. Assume now that $u_n^0, \dots, u_n^k$ are constructed according to these conditions for $0 \leq k \leq n-1$. Our assumptions imply $\delta_n \leq \varepsilon_0$ and $|||u_n^k|||^2 \leq K$; hence the existence of u_n^{k+1} follows from Lemma A.1. Moreover, by (A.2), $|||u_n^{k+1}|||^2 \leq 2K$ and

$$|||u_n^{k+1}|||^2 \leq |||u_n^k|||^2 + \delta_n \beta\big(|||u_n^{k+1}|||^2\big) \leq \rho_n^k + \delta_n \beta\big(|||u_n^{k+1}|||^2\big);$$

hence

$$|||u_n^{k+1}|||^2 - \delta_n \beta\big(|||u_n^{k+1}|||^2\big) \leq \rho_n^{k+1} - \delta_n \beta\big(\rho_n^{k+1}\big).$$

Note that (A.5) implies that the mapping $s \mapsto s - \delta_n \beta(s)$ is monotone increasing on $[0, 2K]$, and hence $|||u_n^{k+1}|||^2 \leq \rho_n^{k+1}$.

In a second step, we approximate u on $[0,T]$ by piecewise linear functions u_n and piecewise constant functions $\overline{u}_n$, $n \geq n_0$, given by

$$\begin{aligned} u_n(t) &:= u_n^k + \delta_n^{-1}(t - k\delta_n)(u_n^{k+1} - u_n^k) \ \text{ for } \ k\delta_n \leq t \leq (k+1)\delta_n, \\ &\qquad k = 0, \dots, n-1, \\ \overline{u}_n(t) &:= u_n^{k+1} \text{ for } k\delta_n < t \leq (k+1)\delta_n, \ k = 0, \dots, n-1, \ \overline{u}_n(0) = u_n^0. \end{aligned}$$

Then

$$u_n(t) = u_0 + \int_0^t \mathcal{G}\big(\overline{u}_n(\tau)\big)\, d\tau, \quad t \in [0,T],$$

and with a suitable constant S independent of $t \in [0,T]$ and $n \geq n_0$,

$$\|u_n(t)\|_Y, \|\overline{u}_n(t)\|_Y \leq S.$$

Consequently, $\|\mathcal{G}\big(\overline{u}_n(t)\big)\|_Z$ is bounded independently of n and thus

$$\|u_n(t) - u_n(t')\|_Z \le L|t - t'|$$

with L independent of n. Hence, the sequence $\{u_n\}$ is bounded and equicontinuous with values in Z, and hence by Ascoli's theorem, we can assume without loss of generality that

$$u_n \to u \ \text{ in } \ C\big([0,T], Z\big).$$

Moreover,

$$u_n(t) \rightharpoonup u(t) \ \text{ in } \ Y, \quad t \in [0,T]. \tag{A.8}$$

To show this, fix $t \in [0,T]$ and choose an arbitrary subsequence $\{u_{n'}(t)\}$. As it is bounded in Y, it has a weakly convergent subsequence $\{u_{n''}(t)\}$ for which $u_{n''}(t) \rightharpoonup u^\star$ in Y, and hence also in Z, and thus $u^\star = u(t)$. Now (A.8) follows from a standard argument. An analogous argument shows

$$u \in C_w\big([0,T], Y\big).$$

Furthermore, for $t \in \big(k\delta_n, (k+1)\delta_n\big]$ we have

$$\|\overline{u}_n(t) - u_n(t)\|_Z = \|u_n\left((k+1)\delta_n\right) - u_n(t)\|_Z \le L\delta_n,$$

hence also

$$\overline{u}_n \to u \ \text{ in } \ C\big([0,T], Z\big),$$

and, by the same arguments as for u_n above,

$$\overline{u}_n(t) \rightharpoonup u(t) \ \text{ in } \ Y, \quad t \in [0,T].$$

As $\mathcal{G}$ is weakly sequentially continuous,

$$\mathcal{G}\big(\overline{u}_n(t)\big) \rightharpoonup \mathcal{G}\big(u(t)\big) \ \text{ in } \ Z, \quad t \in [0,T],$$

and $\mathcal{G} \circ u \in C_w\big([0,T], Z\big)$. If f is any bounded linear functional on Z, it follows that

$$f\left(\int_0^t \mathcal{G}(\overline{u}_n(\tau))\, d\tau\right) = \int_0^t f\big(\mathcal{G}(\overline{u}_n(\tau))\big)\, d\tau \to \int_0^t f\big(\mathcal{G}(u(\tau))\big)\, d\tau, \qquad n \to \infty,$$

and hence

$$f\big(u(t)\big) = f(u_0) + \int_0^t f\big(\mathcal{G}(u(\tau))\big)\, d\tau, \quad t \in [0,T].$$

Consequently,

$$f\left(\frac{u(t+h) - u(t)}{h}\right) \to f\big(\mathcal{G}(u(t))\big), \quad h \to 0,$$

i.e.,

$$\frac{u(t+h) - u(t)}{h} \rightharpoonup \mathcal{G}\big(u(t)\big) \ \text{ in } \ Z, \quad h \to 0.$$

Therefore $u \in C^1_w([0,T],Z)$ and u satisfies (3.19). Finally, for $t \in (k\delta_n,(k+1)\delta_n]$ we get

$$|||\overline{u}_n(t)|||^2 = |||u_n^{k+1}|||^2 \le \rho\big((k+1)\delta_n\big) + r_n,$$

and hence

$$|||\overline{u}_n(t)|||^2 \le \rho(t+\delta_n) + r_n \quad \text{for } \; 0 \le t \le T-\delta_n.$$

Thus

$$|||u(t)|||^2 \le \underline{\lim}_{\,n\to\infty} |||\overline{u}_n(t)|||^2 \le \rho(t), \quad t \in [0,T].$$

For $t \to 0$ this implies, in particular,

$$\overline{\lim}_{\,t\to 0} |||u(t)|||^2 \le \lim_{t\to 0} \rho(t) = |||u(0)|||^2 \le \underline{\lim}_{\,t\to 0} |||u(t)|||^2;$$

hence $|||u(t)||| \to |||u(0)|||$ and consequently $u(t) \to u(0)$ in Y as $t \to 0$. $\square$

LIMITS OF SOLUTIONS OF -LAPLACE EQUATIONS AS GOES TO INFINITY AND RELATED VARIATIONAL PROBLEMS*

HITOSHI ISHII† AND PAOLA LORETI‡

Abstract. We show that the convergence, as $p \to \infty$, of the solution u_p of the Dirichlet problem for $-\Delta_p u(x) = f(x)$ in a bounded domain $\Omega \subset \mathbf{R}^n$ with zero-Dirichlet boundary condition and with continuous f in the following cases: (i) one-dimensional case, radial cases; (ii) the case of no balanced family; and (iii) two cases with vanishing integral. We also give some properties of the maximizers for the functional $\int_\Omega f(x)v(x)\,\mathrm{d}x$ in the space of functions $v \in C(\overline{\Omega}) \cap W^{1,\infty}(\Omega)$ satisfying $v|_{\partial\Omega} = 0$ and $\|Dv\|_{L^\infty(\Omega)} \le 1$.

DOI. 10.1137/S0036141004432827

1. Introduction. We study the asymptotic behavior, as $p \to \infty$, of the solution u_p of the Dirichlet problem

$$\begin{cases} -\Delta_p u(x) = f(x) & \text{in } \Omega, \\ u(x) = 0 & \text{for } x \in \partial\Omega. \end{cases} \tag{1.1}$$

Here and henceforth Δ_p denotes the p-Laplacian, i.e.,

$$\Delta_p u(x) := \sum_{i=1}^{n} \frac{\partial}{\partial x_i}\left(|Du|^{p-2}\frac{\partial u}{\partial x_i}\right),$$

$\Omega \subset \mathbf{R}^n$ is a bounded open set, the exponent p satisfies $p > 1$, and $f \in C(\overline{\Omega})$.

The PDE in (1.1) is the Euler–Lagrange equation of the maximization problem for the functional

$$I_p(u) := \int_\Omega \left(f(x)u(x) - \frac{1}{p}|Du(x)|^p\right)\mathrm{d}x \quad \text{over } W_0^{1,p}(\Omega). \tag{1.2}$$

As is well known, the two problems (1.1) and (1.2) are equivalent. The problem (1.1) has a unique solution $u \in W_0^{1,p}(\Omega)$, and so does (1.2). For the existence and uniqueness of a solution of (1.1), we refer to [L]. According to the regularity results for (1.1), the solution u_p has Hölder continuous derivatives in Ω. That is, $u_p \in C^{1,\gamma}(\Omega)$ for some constant $\gamma \in (0,1)$ which depends on p. Moreover, if the boundary $\partial\Omega$ is smooth, then $u_p \in C^{1,\gamma}(\overline{\Omega})$. See [U, D, Lb, T] for these regularity properties.

The asymptotic problem for (1.1) as $p \to \infty$ appears in modeling of a torsional creep phenomenon for a prismatic elastoplastic rod. This corresponds to the case

where $n = 2$ and f is a positive constant (see, for instance, [BDM, K, PP]). In fact, if $f > 0$, then the limit of u_p in $C(\overline{\Omega})$ exists and is the distance function from the boundary $\partial\Omega$, i.e., the function $d(x) := \operatorname{dist}(x, \partial\Omega)$. See [IK, IL1, IL2, FIN, BK, JLM] for some related topics.

This convergence result is then generalized to the case of general nonnegative functions f by using the ∞-Laplace equation in the region ω where f vanishes, i.e, solving the problem

$$\begin{cases} -\Delta_\infty w(x) = 0 & \text{in } \omega, \\ \qquad w(x) = d(x) & \text{on } \partial\omega, \end{cases} \tag{1.3}$$

where

$$\Delta_\infty w(x) := \sum_{i,j=1}^{n} \frac{\partial w(x)}{\partial x_i} \frac{\partial w(x)}{\partial x_j} \frac{\partial^2 w(x)}{\partial x_i \partial x_j} \quad \text{and} \quad \omega := \operatorname{int}\{x \in \Omega \mid f(x) = 0\}.$$

Due to [J] (see also [BB]), the problem (1.3) has a unique viscosity solution $w \in C(\overline{\omega})$ which is Lipschitz continuous in ω and satisfies $\|Dw\|_{L^\infty(\omega)} \leq 1$. If we assume that $f \geq 0$ in Ω and define $U \in C(\overline{\Omega})$ by

$$U(x) = \begin{cases} d(x) & \text{for } x \in \overline{\Omega} \setminus \omega, \\ w(x) & \text{for } x \in \omega, \end{cases}$$

where w is the unique viscosity solution of (1.3), then U gives the limit of u_p in $C(\overline{\Omega})$ as $p \to \infty$. See Remark 5.2 in [BDM], where the above idea of finding the limit function appears. See also [CIL] for an introduction to viscosity solutions.

In 1967 G. Aronsson initiated the study of the ∞-Laplace equation in his study of absolutely minimal Lipschitz extensions (AMLE), also called canonical Lipschitz extensions, to a domain ω of a function given on $\partial\omega$. The AMLE and ∞-Laplace equation are subjects which have seen intensive research activities recently. For these developments, we refer to [A1, A2, CEG, ACJ].

As we will see in section 5, the family $\{u_p\}_{p>q}$, with $q > n$, is precompact in $C(\overline{\Omega})$. Therefore, $\{u_p\}_{p>1}$ has a sequence $\{u_{p_j}\}_{j\in\mathbf{N}}$ convergent in $C(\overline{\Omega})$, where $p_j \to \infty$ as $j \to \infty$. However, it is not clear whether the whole family $\{u_p\}_{p>1}$ is convergent in $C(\overline{\Omega})$ or not, except in the case where $f \geq 0$.

In this paper we address ourselves to the question of whether the whole family $\{u_p\}_{p>1}$ is convergent in $C(\overline{\Omega})$ as $p \to \infty$. We present only partial positive answers to this question in this paper.

In the cases where $n = 1$ or when Ω is an open ball and f is a radial function, we show the convergence of u_p in $C(\overline{\Omega})$ and identify the limit function. In these cases, our proof relies heavily on an explicit formula for u_p.

In the general situation we do not know any convenient formula for u_p and in our approach we make a careful study (especially the structure of its maximizers) of the variational problem for the functional

$$I_\infty(u) := \int_\Omega f(x)u(x)\mathrm{d}x \tag{1.4}$$

over the set $X := \{v \in C(\overline{\Omega}) \cap W^{1,\infty}(\Omega) \mid v|_{\partial\Omega} = 0,\ \|Dv\|_{L^\infty(\Omega)} \leq 1\}$. This variational problem appears as the limit problem of (1.2). (See Proposition 5.3 below.) This problem may be conceived of an L^∞ variational problem because of the L^∞ bound on the gradient Du and because it appears as the limit problem for the variational problem (1.2) as $p \to \infty$.

As a generalization of the case where $f \geq 0$, we show the convergence of u_p in $C(\overline{\Omega})$ under the condition of *no balanced family*, i.e., under the assumption that for any nonempty family $\mathcal{C}$ of Lipschitz-connected components of $\{x \in \Omega \mid f(x) \neq 0\}$ that stay away from $\partial\Omega$ and $\omega := \bigcup\{U \in \mathcal{C}\}$ (the union of the sets U, where U ranges over all $U \in \mathcal{C}$),

$$\int_\omega f(x)\,\mathrm{d}x \neq 0.$$

Here the standard definition of connected components is not appropriate and we have used the notion of Lipschitz-connected (L-connected, for short) components. See section 2 for the precise assumption, (2.4), and for the definition of L-connected components.

We also consider the case when

$$\int_\Omega f(x)\,\mathrm{d}x = 0 \quad \text{and} \quad f \neq 0. \tag{1.5}$$

This is the case when the above assumption (the assumption of no balanced family) is not satisfied. Also, this is the case related to the Monge–Kantorovich mass transfer problem. The Monge–Kantorovich mass transfer problem has received much attention in the last decade. We refer to [EG, BBD, ACBBV] for the recent developments of the Monge–Kantorovich mass transfer problem and the role of the asymptotic problem for (1.1) as $p \to \infty$ in the mass transfer problem.

In the Monge–Kantorovich case, i.e., the case where (1.5) holds, we have only two special results besides those in the cases when $n = 1$ or when Ω is an open ball and f is radial. One of them says that if Ω is symmetric with respect to the origin and f is an odd function, u_p converges in $C(\overline{\Omega})$, and the other roughly says that if the diameter of Ω is relatively small compared with support of f, $\operatorname{spt} f$, then the convergence of u_p in $C(\overline{\Omega})$ is valid.

The main results of this paper, concerned with convergence of u_p, are precisely stated in section 2. The proof of convergence in the one-dimensional case and the radial case are presented in sections 3 and 4, respectively. Section 5 is devoted to general properties of $\{u_p\}$, the set $\mathcal{M}$ of maximizers of the variational problem (1.4), the set $\mathcal{A}$ of the limits of u_p, i.e.,

$$\mathcal{A} = \{U \in C(\overline{\Omega}) \mid \text{there is a sequence } p_j \to \infty \text{ such that } u_{p_j} \to U \text{ in } C(\overline{\Omega})\}. \tag{1.6}$$

Section 6 is devoted to further properties of the set $\mathcal{M}$ which are useful in our study of convergence of u_p. These observations on $\mathcal{M}$ comprise the main results of this paper together with our results on the convergence of u_p.

We prove our convergence results in the case of no balanced family and in the vanishing integral case (the case of (1.5)), respectively, in sections 7 and 8.

We explain the notation in this paper. For $a, b \in \mathbf{R}$ we write $a \vee b = \max\{a,\, b\}$, $a \wedge b = \min\{a,\, b\}$, $a^+ = a \vee 0$, and $a^- = a \wedge 0$. We use the same notation for functions. We denote by $\mu(A)$ the Lebesgue measure of the measurable set $A \subset \mathbf{R}^n$. If needed, we denote by $\mu_n(A)$ in order to specify the dimension of the space where A lives. We denote by $B(x, a)$ the closed ball of radius a with x as its center.

Finally, we remark that most of the results in this paper have already been announced in [IL4].

2. Main results on the convergence. In this section we state our results concerning the limit, as $p \to \infty$, of the solution u_p of the Dirichlet problem

$$\begin{cases} -\Delta_p u(x) = f(x) & \text{in } \Omega, \\ u(x) = 0 & \text{for } x \in \partial\Omega. \end{cases} \tag{2.1}$$

Here, as before, $\Omega \subset \mathbf{R}^n$ is a bounded, open subset of $\mathbf{R}^n$ and $f \in C(\overline{\Omega})$.

To begin with, let us recall that the problem (2.1) has a unique solution $u_p \in W_0^{1,p}(\Omega)$ for any $p \in (1, \infty)$. See, e.g., [L].

Let $X = \{v \in C(\overline{\Omega}) \cap W^{1,\infty}(\Omega) \mid v|_{\partial\Omega} = 0,\ \|Dv\|_{L^\infty(\Omega)} \le 1\}$. We will recall that the family $\{u_p\}_{p>r}$ is bounded in $W^{1,q}(\Omega)$ for any $q > 1$ and $r > 1$, which guarantees that for any sequence $p_j \to \infty$, there is a subsequence $\{p_{j_k}\}_{k\in\mathbf{N}}$ such that $u_{p_{j_k}}$ converges to a function $U \in X$ uniformly in $\overline{\Omega}$ as $k \to \infty$.

We are interested in whether the following claim (C) is true or not:

(C) *The solution u_p converges uniformly to a function $U \in X$ as $p \to \infty$.*

We are not yet able to determine if the claim (C) is always true or not, and in what follows we present a couple of sufficient conditions for (C) to hold as our main results in this paper.

First we treat the case when $n = 1$. In this case we can not only show that (C) holds but also identify the limit, as the next theorem states.

Let $n = 1$ and $\Omega = (0, a)$, where $a > 0$ is a constant. We define the function $F \in C^1([0,\ a])$ by

$$F(x) = \int_0^x f(t)\, \mathrm{d}t.$$

We define

$$h(r) = \mu(\{x \in \Omega \mid F(x) < r\}), \quad \beta^* = \sup\left\{r \in \mathbf{R} \mid h(r) \le \frac{a}{2}\right\},$$
$$O_- = \{x \in \Omega \mid F(x) < \beta^*\},\ O_+ = \{x \in \Omega \mid F(x) > \beta^*\},\ O_0 = \{x \in \Omega \mid F(x) = \beta^*\},$$
$$k = \begin{cases} 0 & \text{if } \mu(O_0) = 0, \\ \frac{\mu(O_+) - \mu(O_-)}{\mu(O_0)} & \text{if } \mu(O_0) > 0. \end{cases}$$

Then we introduce the function $U \in C([0,\ a])$ by

$$U(x) = \int_0^x (\mathbf{1}_{O_-}(t) - \mathbf{1}_{O_+}(t) + k\mathbf{1}_{O_0}(t))\, \mathrm{d}t. \tag{2.2}$$

Here and henceforth $\mathbf{1}_A$ denotes the characteristic function of the set A. We will see in the next section (Lemma 3.5) that $|k| \le 1$, which assures that $U \in X$.

THEOREM 2.1. *If $n = 1$ and $\Omega = (0,\ a)$, then* (C) *holds and, moreover, the limit function U is given by* (2.2).

As above in the radial case we can show that (C) is valid and give an explicit formula for the limit function.

Let $a > 0$ be a constant and assume that $\Omega = \operatorname{int} B(0, a)$ and $f(x) = g(|x|)$ for some $g \in C([0, a])$.

We define $O_\pm \subset \mathbf{R}^n$ by

$$O_+ = \left\{t \in (0, a) \middle| \int_{B(0,t)} f(x)\, \mathrm{d}x > 0\right\}, \quad O_- = \left\{t \in (0, a) \middle| \int_{B(0,t)} f(x)\, \mathrm{d}x < 0\right\}$$

and $U \in X$ by

$$U(x) = \int_{|x|}^{a} (\mathbf{1}_{O_+}(t) - \mathbf{1}_{O_-}(t))\,\mathrm{d}t. \tag{2.3}$$

THEOREM 2.2. *If $\Omega = \operatorname{int} B(0,a)$ and $f(x) = g(|x|)$ is a radial function, then* (C) *holds and the limit function U is given by* (2.3).

The next condition under which (C) holds is a generalization of the well-known observation due to [BDM] and [J] (see Remark 5.2 of [BDM] and the uniqueness result of [J]) that if $f \geq 0$ in Ω, then (C) holds.

In order to make a precise statement, we need to introduce some notation.

We write

$$\Omega_+ = \{x \in \Omega \mid f(x) > 0\}, \quad \Omega_- = \{x \in \Omega \mid f(x) < 0\}, \quad \text{and} \quad \Omega_* = \Omega_+ \cup \Omega_-.$$

Note that $\operatorname{spt} f = \overline{\Omega}_*$. Let $\mathcal{O}_*$ denote the sets of all connected components of Ω_*.

We modify the notion of "connectedness" for a better formulation, as follows. Let $A, B \subset \mathbf{R}^n$. Define $\rho(A,B) \in [0,\infty]$ by setting

$$\rho(A,B) = \inf\{d(A,U_1) + d(U_1,U_2) + \cdots + d(U_m,B) \mid U_1,\ldots,U_m \in \mathcal{O}_*\},$$

where $d(U,V) = \inf\{|x-y| \mid x \in U, y \in V\}$. Notice that $\rho(A,B) = \infty$ if and only if either $A = \emptyset$ or $B = \emptyset$. Since, as is easily checked,

$$\rho(A,B) = \rho(B,A) \geq 0, \qquad \rho(A,B) \leq \rho(A,C) + \rho(C,B)$$

for any $A, B, C \subset \mathbf{R}^n$, if we write $A \sim B$ for $A, B \subset \mathbf{R}^N$ when $\rho(A,B) = 0$, then this relation $\sim$ defines an equivalence relation in $\mathcal{O}_*$.

Using the above equivalence relation, we classify $\mathcal{O}_*$ as

$$\mathcal{O}_* = \bigcup \{\mathcal{O}_\lambda \mid \lambda \in \Lambda\},$$

where

(i) for each $\lambda \in \Lambda$, $\mathcal{O}_\lambda \neq \emptyset$;
(ii) for each $\lambda \in \Lambda$, if $U \in \mathcal{O}_\lambda$, then $\mathcal{O}_\lambda = \{V \in \mathcal{O}_* \mid V \sim U\}$;
(iii) if $\lambda_1, \lambda_2 \in \Lambda$ and $\lambda_1 \neq \lambda_2$, then $\mathcal{O}_{\lambda_1} \cap \mathcal{O}_{\lambda_2} = \emptyset$.

We set

$$G_\lambda = \bigcup \{U \mid U \in \mathcal{O}_\lambda\} \quad \text{for } \lambda \in \Lambda$$

and define

$$\Lambda_0 = \{\lambda \in \Lambda \mid \rho(G_\lambda, \partial\Omega) = 0\}.$$

We note that $\{G_\lambda \mid \lambda \in \Lambda\}$ classifies the set Ω_*. Each G_λ, with $\lambda \in \Lambda$, is called an L-connected component of Ω_*.

As the proof of Lemma 7.1 below shows, if w is a Lipschitz continuous function on Ω and $Dw(x) = 0$ for almost every (a.e.) $x \in \Omega_*$, then w is constant on each G_λ, with $\lambda \in \Lambda$. Conversely, one can show the following: Let U, V be connected components of Ω_* having the property that if w is Lipschitz continuous on Ω and $Dw(x) = 0$ for a.e. $x \in \Omega_*$, then w is constant on $U \cup V$. Then $U \sim V$, i.e., U, V are subsets of an L-connected component G_λ. In light of these observations, we have chosen the term "Lipschitz-connected" (L-connected).

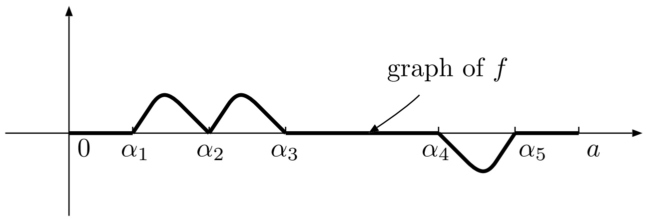

FIG. 1.

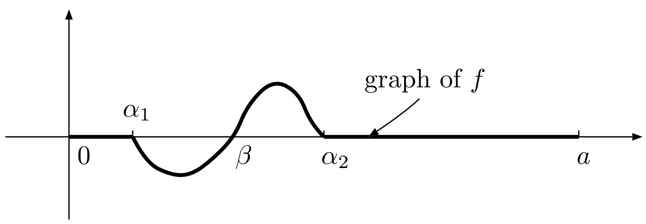

FIG. 2.

Our assumption on (f,Ω) is as follows:

$$\text{For any nonempty } \Gamma \subset \Lambda \setminus \Lambda_0 \text{ and } \omega := \bigcup\{G_\lambda \mid \lambda \in \Gamma\}, \tag{2.4}$$

$$\int_\omega f(x)\,\mathrm{d}x \neq 0.$$

We call this condition that of *no balanced family* (of L-connected components).

Figure 1 gives pictorially an example of a function f which satisfies condition (2.4). Here $\int_{\alpha_1}^{\alpha_2} f(x)\,\mathrm{d}x = \int_{\alpha_2}^{\alpha_3} f(x)\,\mathrm{d}x = -\int_{\alpha_4}^{\alpha_5} f(x)\,\mathrm{d}x$ is assumed. In this example, $\Omega_+ = (\alpha_1,\alpha_2)\cup(\alpha_2,\alpha_3)$, $\Omega_- = (\alpha_4,\alpha_5)$, and the L-connected components are Ω_+ and Ω_-. The integral of f over $\omega = \Omega_+$, Ω_-, or $\Omega_+ \cup \Omega_-$ does not vanish. On the other hand, the connected components of Ω_* are (α_1,α_2), (α_2,α_3), and (α_4,α_5), and the integral of f over $\omega = (\alpha_1,\alpha_2)\cup(\alpha_4,\alpha_5)$ vanishes. For this f, the condition similar to (2.4) but with the usual notion of connectedness in place of that of L-connectedness does not hold.

Next, we examine the function f given pictorially by Figure 2, where $\int_{\alpha_1}^{\alpha_2} f(x)\,\mathrm{d}x = 0$ is assumed. For this function f, $\Omega_* = (\alpha_1,\alpha_2)$ is the only L-connected component of Ω_*, and condition (2.4) does not hold. This function f will appear in Example 3.2 in section 3.

THEOREM 2.3. *Under the assumption* (2.4)*,* (C) *holds.*

Regarding the cases when (2.4) is violated, we restrict ourselves to the case where

$$\int_\Omega f(x)\,\mathrm{d}x = 0 \quad \text{and} \quad f \neq 0, \tag{2.5}$$

and

$$\Omega_+ \text{ and } \Omega_- \text{ are connected.} \tag{2.6}$$

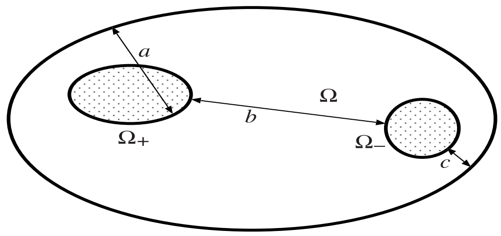

FIG. 3. *A case where* $b \geq a + c$.

We give two sufficient conditions for (C) to hold. One is a symmetry requirement on (f, Ω). That is, we assume that

$$\Omega \text{ is symmetric with respect to the origin, i.e., } -\Omega = \Omega, \tag{2.7}$$

and

$$f \text{ is an odd function, i.e., } f(-x) = -f(x) \quad \text{for all } x \in \Omega. \tag{2.8}$$

The asymptotic problem, as $p \to \infty$, for (1.1) has applications to the Monge–Kantorovich mass transfer problem. In the mass transfer problem, the condition of vanishing integral, (2.5), is a natural compatibility condition, which means conservation of the total mass in the process of mass transfer.

The second one is the condition that

$$\min\left\{ \inf_{x \in \Omega_+} \sup_{y \in \Omega_-} [d(x) + d(y) - |x - y|],\ \inf_{y \in \Omega_-} \sup_{x \in \Omega_+} [d(x) + d(y) - |x - y|] \right\} \leq 0 \tag{2.9}$$

holds. Here and henceforth $d(x)$ denotes the distance between x and $\partial\Omega$, i.e., $d(x) = \operatorname{dist}(x, \partial\Omega)$. See Figure 3.

THEOREM 2.4. *Under the assumptions* (2.5) *and* (2.6), *if either* (2.7) *and* (2.8) *or* (2.9) *are satisfied, then* (C) *holds.*

3. One-dimensional case. In this section we prove Theorem 2.1.

Let $\Omega = (0, a)$, where $a > 0$ is a constant, and $f \in C([0, a])$. Fix $p > 1$ and consider the $(p+1)$-Laplace equation with the inhomogeneous term f,

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(|u'(x)|^{p-1}u'(x)\right) = -f(x) \quad \text{in } \Omega, \tag{3.1}$$

together with the Dirichlet condition

$$u(0) = u(a) = 0. \tag{3.2}$$

Here u' denotes the derivative of u. The unique solution in $W_0^{1,p+1}(\Omega)$ of (3.1) (i.e., the solution of (3.1)–(3.2)) is denoted by u_{p+1} as in the previous sections.

We seek an explicit formula for u_{p+1}. For this, noting that $u := u_{p+1} \in C^1([0, a])$ and integrating both sides of (3.1), we get

$$|u'(x)|^{p-1}u'(x) = |u'(0)|^{p-1}u'(0) - F(x) \quad \text{for } x \in \Omega,$$

where $F(x) := \int_0^x f(t)\,\mathrm{d}t$.

Let ψ_p be the inverse function of $r \mapsto |r|^{p-1}r$. That is, $\psi_p(s) = |s|^{\frac{1}{p}-1}s$ for $s \in \mathbf{R}$. Note that as $p \to \infty$,

$$\psi_p(r) \to \begin{cases} 1 & \text{for } r > 0, \\ -1 & \text{for } r < 0. \end{cases}$$

Observe, moreover, that for any $\varepsilon \in (0,1)$, the above convergence is uniform for $|r| \in [\varepsilon, \varepsilon^{-1}]$.

Writing $\beta = |u'(0)|^{p-1}u'(0)$ and integrating the equality $u'(x) = \psi_p(\beta - F(x))$, we get

$$u(x) = \int_0^x \psi_p(\beta - F(t))\,\mathrm{d}t \quad \text{for } x \in \overline{\Omega}. \tag{3.3}$$

Conversely, if we can choose $\beta \in \mathbf{R}$ so that

$$\int_0^a \psi_p(\beta - F(t))\,\mathrm{d}t = 0,$$

then the function u defined by (3.3) is in $C^1([0,\,a])$ and the unique solution of (3.1)–(3.2).

We show directly that there is a unique constant $\beta_p \in \mathbf{R}$ such that

$$\int_0^a \psi_p(\beta_p - F(t))\,\mathrm{d}t = 0, \tag{3.4}$$

although this can be deduced from the general existence and uniqueness result for solutions of (1.1).

Set

$$G_p(r) = \int_0^a \psi_p(r - F(t))\,\mathrm{d}t$$

for $r \in \mathbf{R}$. Since the function $\psi_p(r)$ is strictly increasing, the function G_p is strictly increasing on $\mathbf{R}$. In view of the monotone convergence theorem, we see that the function G_p is continuous on $\mathbf{R}$. If $f = 0$, then it is clear that $\beta_p = 0$ gives the unique solution of (3.4).

We may thus assume in what follows that $f \neq 0$. We set

$$F_- = \min_{[0,a]} F, \quad F_+ = \max_{[0,a]} F, \quad \delta(F) = F_+ - F_-. \tag{3.5}$$

Note that $F_- \le 0 \le F_+$ and $\delta(F) > 0$. Since $F_- - F(x) \le 0$ for all $x \in \Omega$ and $\delta(F) > 0$, we have $G_p(F_-) < 0$. Similarly, we have $G_p(F_+) > 0$. Thus we see that there is a unique constant $\beta_p \in (F_-, F_+)$ such that $G_p(\beta_p) = 0$, and we find an explicit formula

$$u_{p+1}(x) = \int_0^x \psi_p(\beta_p - F(t))\,\mathrm{d}t \quad \text{for } x \in \overline{\Omega}. \tag{3.6}$$

Next, we study the asymptotic behavior of the function u_{p+1} given by (3.6) as $p \to \infty$. Recall that

$$h(r) = \mu(\{x \in \Omega \mid F(x) < r\}), \qquad \beta^* = \sup\left\{r \in \mathbf{R} \mid h(r) \le \frac{a}{2}\right\},$$
$$O_- = \{x \in \Omega \mid F(x) < \beta^*\},\ \ O_+ = \{x \in \Omega \mid F(x) > \beta^*\},\ \ O_0 = \{x \in \Omega \mid F(x) = \beta^*\}.$$

We define open sets $O(r) \subset \mathbf{R}$ for $r \in \mathbf{R}$ by

$$O(r) = \{x \in \Omega \mid F(x) < r\}.$$

We have (i) for $r \le s$, $O(r) \subset O(s)$; (ii) $O(F_-) = \emptyset$; (iii) $O(r) = (0, a)$ for all $r > F_+$; and (iv)

$$\bigcup_{t<r} O(t) = O(r), \qquad \bigcap_{t>r} O(t) = \{x \in \Omega \mid F(x) \le r\}.$$

Consequently, we have (i) h is nondecreasing in $\mathbf{R}$; (ii) $h(r)=\mu(\emptyset)=0$ for $r\in(-\infty, F_-]$; (iii) $h(r) = \mu(\Omega) = a$ for $r \in (F_+, \infty)$; and (iv)

$$\lim_{t \nearrow r} h(t) = h(r) \le \mu(\{x \in \Omega \mid F(x) \le r\}) = \lim_{t \searrow r} h(t).$$

Now, property (iv) for h and the definition of β^* implies that

$$h(\beta^*) \le \frac{a}{2} \le h(\beta^* + 0) := \lim_{t \searrow \beta^*} h(t).$$

A key step in the proof of Theorem 2.1 is the following lemma.

LEMMA 3.1. *We have*

$$\lim_{p \to \infty} \beta_p = \beta^*.$$

We use three lemmas to prepare for the proof of Lemma 3.1.

LEMMA 3.2. *Let $r \in (F_-, F_+)$. Then, if $s > r$ (resp., $s < r$), then $h(s) > h(r)$ (resp., $h(s) < h(r)$).*

Proof. We consider the case when $s > r$. We may assume that $s \in (F_-, F_+)$. By the intermediate value theorem, we have

$$F(y) = \frac{s + r}{2}$$

for some $y \in \overline{\Omega}$. By the continuity of F, we can choose $\delta > 0$ so that

$$F(x) \in (r, s) \quad \text{ for all } x \in \omega := (y - \delta, y + \delta) \cap \Omega.$$

It is clear that $\omega \subset O(s)$, $\mu(\omega) > 0$, and $\omega \cap O(r) = \emptyset$. Hence we have

$$h(s) = \mu(O(s)) = \mu(O(r)) + \mu(O(s) \setminus O(r)) \ge \mu(O(r)) + \mu(\omega) > \mu(O(r)) = h(r).$$

The proof for the case when $s < r$ is similar and will be omitted. □

LEMMA 3.3. *Let $\beta \in [F_-, F_+]$. We have*

$$|\psi_p(\beta - F(x))| \le \psi_p(\max\{\delta(F), 1\}) \le \psi_1(\max\{\delta(F), 1\}) \quad \textit{for } x \in \Omega.$$

Proof. For $x \in \Omega$ we have

$$-\delta(F) = F_- - F_+ \le \beta - F(x) \le F_+ - F_- = \delta(F),$$

and hence $|\psi_p(\beta - F(x))| \le \psi_p(\max\{\delta(F), 1\}) \le \psi_1(\max\{\delta(F), 1\})$. □

Lemma 3.4. *Let $\{\alpha_j\} \subset [F_-, F_+]$ be a sequence converging to some $r \in \mathbf{R}$, let $\{p_j\} \subset (1,\infty)$ be a sequence such that $p_j \to \infty$ as $j \to \infty$, and let $\phi \in L^1(\Omega)$. Set*

$$O_-(r) = \{x \in \Omega \mid F(x) < r\} \quad \text{and} \quad O_+(r) = \{x \in \Omega \mid F(x) > r\}.$$

Then

$$\int_{O_-(r)} \psi_{p_j}(\alpha_j - F(x))\phi(x)\,\mathrm{d}x \to \int_{O_-(r)} \phi(x)\,\mathrm{d}x,$$
$$\int_{O_+(r)} \psi_{p_j}(\alpha_j - F(x))\phi(x)\,\mathrm{d}x \to -\int_{O_+(r)} \phi(x)\,\mathrm{d}x.$$

Proof. Fix $x \in O_-(r)$. Since $r - F(x) > \delta$ for some constant $\delta > 0$, there is a $J \in \mathbf{N}$ such that for all $j \geq J$,

$$\delta < \alpha_j - F(x) \leq \delta(F),$$

which implies that

$$\lim_{j\to\infty} \psi_{p_j}(\alpha_j - F(x)) = 1.$$

Now, in view of Lemma 3.3 and the Lebesgue convergence theorem, we conclude that

$$\lim_{j\to\infty} \int_{O_-(r)} \psi_{p_j}(\alpha_j - F(x))\phi(x)\,\mathrm{d}x = \int_{O_-(r)} \phi(x)\,\mathrm{d}x.$$

In the same way we see that

$$\lim_{j\to\infty} \int_{O_+(r)} \psi_{p_j}(\alpha_j - F(x))\phi(x)\,\mathrm{d}x = -\int_{O_+(r)} \phi(x)\,\mathrm{d}x. \qquad \square$$

Proof of Lemma 3.1. First of all we show that $\liminf_{p\to\infty} \beta_p \geq \beta^*$. For this, we argue by contradiction and thus suppose that $r := \liminf_{p\to\infty} \beta_p < \beta^*$. There is a sequence $\{p_j\} \subset (1,\infty)$ such that $\lim_{j\to\infty} p_j = \infty$ and $\lim_{j\to\infty} \beta_{p_j} = r$. By Lemma 3.2, we see that $h(r+0) < h(\beta^*) \leq a/2$. Therefore, setting $A = \{x \in \Omega \mid F(x) \leq r\}$ and $B = \{x \in \Omega \mid F(x) > r\}$, we have

$$h(r+0) = \mu(A) < \frac{a}{2}, \qquad \mu(B) = a - \mu(A) > \frac{a}{2}.$$

Since $|\psi_p(\beta_p - F(x))| \leq \psi_p(\max\{\delta(F), 1\})$ for $x \in \Omega$ by Lemma 3.3, we have

$$\begin{aligned}&\limsup_{j\to\infty} \left| \int_A \psi_{p_j}(\beta_{p_j} - F(x))\,\mathrm{d}x \right| \\ &\quad\leq \limsup_{j\to\infty} \int_A \psi_{p_j}(\max\{\delta(F), 1\})\,\mathrm{d}x = \int_A \mathrm{d}x = \mu(A) < \frac{a}{2}.\end{aligned}$$

Observe next by Lemma 3.4 that

$$\lim_{j\to\infty} \int_B \psi_{p_j}(\beta_{p_j} - F(x))\,\mathrm{d}x = -\mu(B) < -\frac{a}{2}.$$

Since

$$0 = \int_A \psi_{p_j}(\beta_{p_j} - F(x))\,\mathrm{d}x + \int_B \psi_{p_j}(\beta_{p_j} - F(x))\,\mathrm{d}x,$$

we find that $0 < \frac{a}{2} - \frac{a}{2} = 0$, which is a contradiction. This shows that $\liminf_{p\to\infty} \beta_p \geq \beta^*$.

An argument similar to the above shows that $\limsup_{p\to\infty} \beta_p \leq \beta^*$, and we conclude that $\lim_{p\to\infty} \beta_p = \beta^*$. ∎

Recall that $k = 0$ if $\mu(O_0) = 0$, and otherwise

$$k = \frac{\mu(O_+) - \mu(O_-)}{\mu(O_0)}.$$

LEMMA 3.5. *We have* $|k| \leq 1$.

Proof. Since

$$\mu(O_-) = h(\beta^*) \leq \frac{a}{2} \leq h(\beta^* + 0) = \mu(O_-) + \mu(O_0),$$

we have

$$\begin{aligned} &0 \geq 2\mu(O_-) - a = \mu(O_-) - \mu(O_+) - \mu(O_0), \\ &0 \leq 2\mu(O_-) + 2\mu(O_0) - a = \mu(O_-) + \mu(O_0) - \mu(O_+). \end{aligned}$$

Hence, if $k \neq 0$, then

$$-1 \leq k = \frac{\mu(O_+) - \mu(O_-)}{\mu(O_0)} \leq 1. \qquad ∎$$

Proof of Theorem 2.1. We show first that the family $\{u_p\}_{p>2}$ is uniformly bounded and equicontinuous on $\overline{\Omega}$.

To see this, fix $x \in \Omega$ and $p > 1$. By Lemma 3.3, we have

$$|u_{p+1}(x)| \leq \int_0^x \psi_1(\max\{\delta(F), 1\})\,\mathrm{d}x \leq a\psi_1(\max\{\delta(F), 1\})$$

and $|u'_{p+1}(x)| \leq \psi_1(\max\{\delta(F), 1\})$. These show that the family $\{u_p\}_{p>2}$ is uniformly bounded and equicontinuous on $\overline{\Omega}$.

Next we show that

$$\lim_{p\to\infty} \psi_p(\beta_p - \beta^*) = k \quad \text{ if } \mu(O_0) > 0. \tag{3.7}$$

In fact, we have

$$\begin{aligned} 0 = \int_0^a \psi_p(\beta_p - F(x))\mathrm{d}x &= \int_{O_-} \psi_p(\beta_p - F(x))\mathrm{d}x \\ &\quad + \psi_p(\beta_p - \beta^*)\mu(O_0) + \int_{O_+} \psi_p(\beta_p - F(x))\mathrm{d}x, \end{aligned}$$

and then Lemma 3.4 yields

$$0 = \mu(O_-) - \mu(O_+) + \lim_{p\to\infty} \psi_p(\beta_p - \beta^*)\mu(O_0),$$

which shows (3.7).

Since $\{u_p\}_{p>2}$ is precompact in $C([0, a])$, we need to show only that for each fixed $x \in \Omega$,

$$u_{p+1}(x) \to U(x) := \int_0^x (\mathbf{1}_{O_-}(t) - \mathbf{1}_{O_+}(t) + k\mathbf{1}_{O_0}(t))\,\mathrm{d}t \quad \text{ as } p \to \infty.$$

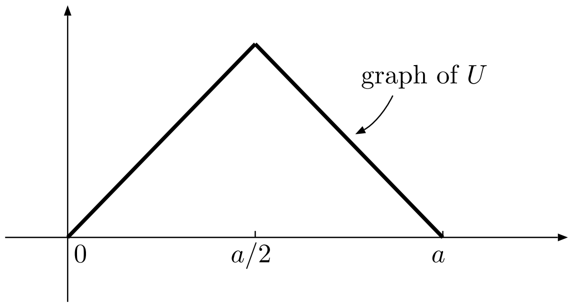

FIG. 4. *A case where* $f > 0$.

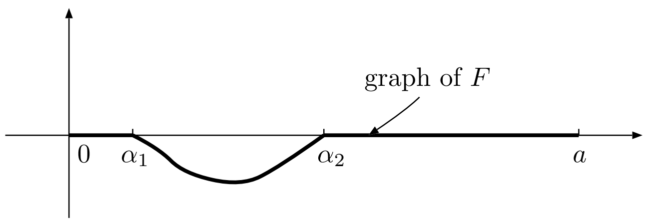

FIG. 5.

Fix $x \in \Omega$ and note that

$$u_{p+1}(x) = \int_{(0,x)\cap O_-} \psi_p(\beta_p - F(t))\,\mathrm{d}t + \int_{(0,x)\cap O_+} \psi_p(\beta_p - F(t))\,\mathrm{d}t + \psi_p(\beta_p - \beta^*) \int_{(0,x)\cap O_0} \mathrm{d}t.$$

Sending $p \to \infty$ and using Lemma 3.4, we get

$$\lim_{p\to\infty} u_p(x) = \int_{(0,x)\cap\Omega_-} \mathrm{d}t - \int_{(0,x)\cap\Omega_+} \mathrm{d}t + k \int_{(0,x)\cap\Omega_0} \mathrm{d}t = U(x). \qquad \square$$

Next we examine the limit function U in a few cases.

Example 3.1. We consider the case when $f(x) > 0$ for all $x \in \Omega$. Then the function F is strictly increasing in $\overline{\Omega}$. Therefore we have $O_- = (0, a/2)$ and $O_+ = (a/2, a)$, and hence

$$U(x) = \int_0^x \left(\mathbf{1}_{O_-}(t) - \mathbf{1}_{O_+}(t)\right) dt = \begin{cases} x & \text{for } 0 \le x \le a/2, \\ a - x & \text{for } a/2 \le x \le a. \end{cases}$$

This is the distance function from $\partial\Omega = \{0, a\}$ and, as is well known, it is the unique viscosity solution of $|U'(x)| = 1$ in Ω and $U(0) = U(a) = 0$. See Figure 4.

Example 3.2. Let $0 < \alpha_1 < \alpha_2 < a$ satisfy $\alpha_2 - \alpha_1 < \frac{a}{2}$. Let F satisfy $F(x) = 0$ for $x \in [0, \alpha_1] \cup [\alpha_2, a]$ and $F(x) < 0$ for $x \in (\alpha_1, \alpha_2)$. (See Figure 5.) Then we have $\beta^* = 0$, $O_- = (\alpha_1, \alpha_2)$, $O_+ = \emptyset$, and $O_0 = (0, \alpha_1) \cup (\alpha_2, a)$. Furthermore, we have $k = -(\alpha_2 - \alpha_1)/(a - (\alpha_2 - \alpha_1))$, and

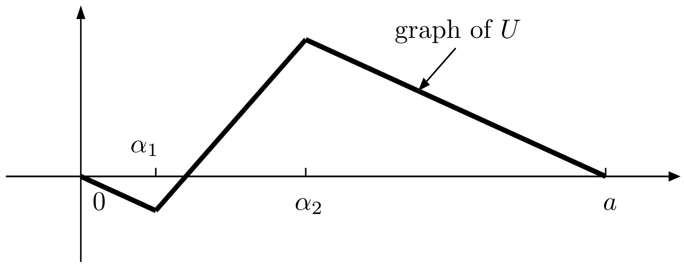

FIG. 6. *A case where* $|k| < 1$.

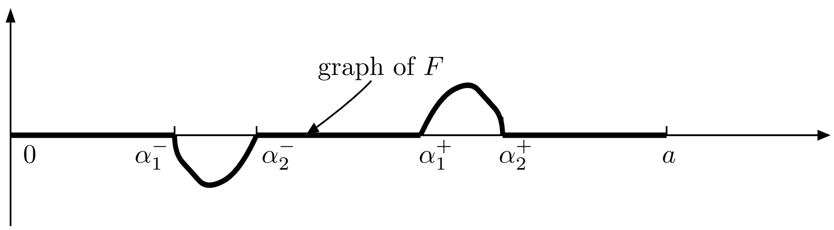

FIG. 7.

$$U(x) = \int_0^x \big(\mathbf{1}_{O_-}(t) + k\mathbf{1}_{O_0}(t)\big)\,dt = \begin{cases} kx & \text{for } 0 \le x \le \alpha_1, \\ k\alpha_1 + x - \alpha_1 & \text{for } \alpha_1 \le x \le \alpha_2, \\ k(x-a) & \text{for } \alpha_2 \le x \le a. \end{cases}$$

See Figure 6.

Example 3.3. Let $0 < \alpha_1^- < \alpha_2^- < \alpha_1^+ < \alpha_2^+ < a$ satisfy $\alpha_2^- - \alpha_1^- = \alpha_2^+ - \alpha_1^+ < \frac{a}{2}$. Let F satisfy the following: $F(x) = 0$ for $x \in [0, \alpha_1^-] \cup [\alpha_2^-, \alpha_1^+] \cup [\alpha_2^+, a]$, $F(x) < 0$ for $x \in (\alpha_1^-, \alpha_2^-)$, and $F(x) > 0$ for $x \in (\alpha_1^+, \alpha_2^+)$. (See Figure 7.) Then we have $\beta^* = 0$ and $k = (\alpha_2^+ - \alpha_1^+ - (\alpha_2^- - \alpha_1^-))/(a - (\alpha_2^+ - \alpha_1^+) - (\alpha_2^- - \alpha_1^-)) = 0$, and the limit function U is given by

$$U(x) = \begin{cases} 0 & \text{for } x \in [0, \alpha_1^-] \cup [\alpha_2^+, a], \\ x - \alpha_1^+ & \text{for } x \in (\alpha_1^-, \alpha_2^-), \\ \alpha_2^- - \alpha_1^- & \text{for } x \in [\alpha_2^-, \alpha_1^+], \\ -x + \alpha_2^+ & \text{for } x \in (\alpha_1^+, \alpha_2^+). \end{cases}$$

See Figure 8.

4. Radial case. In this section we give a proof of Theorem 2.2, which is rather close to that of Theorem 2.1 presented in the previous section.

Let $a > 0$ and $g \in C([0, a])$, and define $f \in C(B(0, a))$ by $f(x) = g(|x|)$. Set $\Omega = \operatorname{int} B(0, a)$.

We consider the Dirichlet problem for u_{p+1} as in the previous section:

$$\begin{cases} -\Delta_{p+1} u(x) = f(x) & \text{in } \Omega, \\ u(x) = 0 & \text{on } \partial\Omega. \end{cases} \tag{4.1}$$

By the uniqueness of the solution of (4.1), we see that the function u_{p+1} is a radial function, i.e., $u_{p+1}(x) = v_p(|x|)$ for some $v_p \in C([0, a])$. By the regularity results for

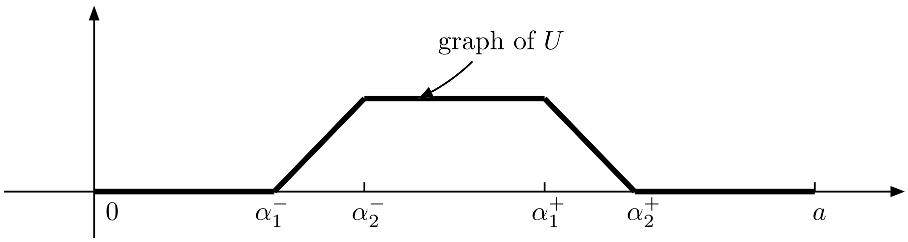

FIG. 8. *A case where* $k = 0$.

(4.1), we know that $u_{p+1} \in C^{1,\gamma}(\overline{\Omega})$ for some $\gamma \in (0, 1)$. In particular, we have

$$v_p \in C^1([0, a]), \quad v_p'(0) = 0.$$

The PDE (4.1) is now reduced to the following ODE for v_p:

$$\big(r^{n-1}|v'(r)|^{p-1}v'(r)\big)' = -r^{n-1}g(r) \quad \text{in } (0, a); \tag{4.2}$$

and the boundary condition for v_p is $v'(0) = v(a) = 0$. Integrating twice yields

$$v(r) = \alpha - \int_0^r \psi_p\Big(t^{1-n}\int_0^t s^{n-1}g(s)\,\mathrm{d}s\Big)\,\mathrm{d}t \quad \text{for all } r \in [0,\, a]$$

and for some $\alpha \in \mathbf{R}$, where $\psi_p \in C(\mathbf{R})$ is the function given by $\psi_p(s) = |s|^{\frac{1}{p}-1}s$ as in the previous section. Here the constant α for $v = v_p$ should be determined by

$$\alpha = \int_0^a \psi_p\Big(t^{1-n}\int_0^t s^{n-1}g(s)\,\mathrm{d}s\Big)\,\mathrm{d}t.$$

Setting

$$\alpha_p = \int_0^a \psi_p\Big(t^{1-n}\int_0^t s^{n-1}g(s)\,\mathrm{d}s\Big)\,\mathrm{d}t,$$

we have

$$v_p(r) = \alpha_p - \int_0^r \psi_p\Big(t^{1-n}\int_0^t s^{n-1}g(s)\,\mathrm{d}s\Big)\,\mathrm{d}t \quad \text{for } r \in [0, r].$$

At this point one can check directly and easily that $v_p \in C^1([0, a])$, and it satisfies (4.2) and the boundary condition $v_p'(0) = v_p(a) = 0$.

Completion of the proof of Theorem 2.2. It is easy to see that as $p \to \infty$,

$$\alpha_p \to \alpha^* := \int_0^a \big(\mathbf{1}_{O_+}(r) - \mathbf{1}_{O_-}(r)\big)\mathrm{d}r,$$

and

$$v_p(r) \to V(r) := \alpha^* + \int_0^r \big(\mathbf{1}_{O_-}(t) - \mathbf{1}_{O_+}(t)\big)\,\mathrm{d}t \quad \text{for each } r \in [0, a],$$

where

$$O_+ = \left\{ t \in (0,a) \,\middle|\, \int_0^t s^{n-1} g(s)\,\mathrm{d}s > 0 \right\} = \left\{ t \in (0,a) \,\middle|\, \int_{B(0,t)} f(x)\,\mathrm{d}x > 0 \right\},$$
$$O_- = \left\{ t \in (0,a) \,\middle|\, \int_0^t s^{n-1} g(s)\,\mathrm{d}s < 0 \right\} = \left\{ t \in (0,a) \,\middle|\, \int_{B(0,t)} f(x)\,\mathrm{d}x < 0 \right\}.$$

As in the previous section, it is easy to show that the collection of functions $v_p(|x|)$, with $p > 1$, is precompact in $C(\overline{\Omega})$. Thus the above pointwise convergence is enough for us to conclude that $u_p(x)$ converges to $U(x) := V(|x|)$ uniformly for $x \in \overline{\Omega}$ as $p \to \infty$. □

Remark. Contrary to the general one-dimensional case, the limit function V has the property that $V'(r) \in \{-1, 0, 1\}$ for all $r \in [0, a]$.

Remark. We also have a convergence result in the case when Ω is an annulus and f is radial. Indeed, let $0 < r_1 < r_2$, $\Omega = \{x \in \mathbf{R}^n \mid r_1 < |x| < r_2\}$, and $f(x) = g(|x|)$ for some $g \in C([r_1, r_2])$. Let u_p be the solution of (1.1). We define, for $r \in \mathbf{R}$,

$$G(r) = \int_{r_1}^{r} t^{n-1} g(t)\,\mathrm{d}t \quad \text{for } r \in [r_1, r_2], \quad h(r) = \mu_1(\{t \in (r_1,\, r_2) \mid G(t) < r\})$$

$$\beta^* = \sup\left\{ t \in (r_1,\, r_2) \middle| h(r) \le \frac{r_2 - r_1}{2} \right\},\ \ O_+ = \{r \in (r_1,\, r_2) \mid G(r) > \beta^*\},$$

$$O_- = \{r \in (r_1,\, r_2) \mid G(r) < \beta^*\},\ \ O_0 = \{r \in (r_1,\, r_2) \mid G(r) = \beta^*\},$$

$$k = \begin{cases} 0 & \text{for } \mu_1(O_0) = 0, \\ \frac{\mu_1(O_+) - \mu_1(O_-)}{\mu_1(O_0)} & \text{otherwise,} \end{cases}$$

$$U(x) = \int_{r_1}^{|x|} \big(\mathbf{1}_{O_-}(t) - \mathbf{1}_{O_+}(t) + k\mathbf{1}_{O_0}(t)\big)\,\mathrm{d}t \quad \text{for } x \in \overline{\Omega}.$$

Then we have

$$u_p \to U \quad \text{in } C(\overline{\Omega}) \quad \text{as } p \to \infty.$$

We do not give the proof of this result here since it is a simple combination of the proofs of Theorems 2.1 and 2.2.

5. General observations. Here we study a few general properties of the solution u_p of (1.1), the set $\mathcal{A}$ of the limits of u_p defined by (1.6), and the set $\mathcal{M}$ of the maximizers of the variational problem (1.4), i.e.,

$$\mathcal{M} = \Big\{ v \in X \mid I_\infty(v) = \sup_{u \in X} I_\infty(u) \Big\}.$$

We start by observing that the estimate

$$\|Du_p\|_{L^p(\Omega)} \le C \tag{5.1}$$

holds, where the constant C can be chosen independently of p for $p > 2$. Indeed, using the test function $u = u_p$ in the weak formulation of (1.1), we get

$$\int_\Omega |Du|^p \,\mathrm{d}x = \int_\Omega f u \,\mathrm{d}x,$$

and hence by the Poincaré inequality for functions in $W_0^{1,1}(\Omega)$,

$$\begin{aligned}\int_\Omega |Du|^p \,\mathrm{d}x &\le \|f\|_{L^\infty(\Omega)} \|u\|_{L^1(\Omega)} \le C_1 \|f\|_{L^\infty(\Omega)} \|Du\|_{L^1(\Omega)} \\ &\le C_1 \|f\|_{L^\infty(\Omega)} \mu(\Omega) \int_\Omega |Du| \frac{\mathrm{d}x}{\mu(\Omega)} \le C_1 \|f\|_{L^\infty(\Omega)} \mu(\Omega) \left(\int_\Omega |Du|^p \frac{\mathrm{d}x}{\mu(\Omega)} \right)^{\frac{1}{p}} \\ &\le C_1 \|f\|_{L^\infty(\Omega)} \mu(\Omega)^{1-\frac{1}{p}} \|Du\|_{L^p(\Omega)},\end{aligned}$$

where C_1 is a positive constant independent of p. Hence, we obtain

$$\|Du\|_{L^p(\Omega)} \le \left(C_1 \|f\|_{L^\infty(\Omega)} \right)^{\frac{1}{p-1}} \mu(\Omega)^{\frac{1}{p}},$$

which shows (5.1).

From the above estimate (5.1), we have the following well-known observations (see [BDM], for instance).

PROPOSITION 5.1. (i) *For any $q > n$, the collection $\{u_p\}_{p \ge q}$ is precompact in $C(\overline{\Omega})$. In particular, for any sequence $1 < p_k \to \infty$ there is a subsequence p_{k_j} such that $u_{p_{k_j}}(x) \to U(x)$ uniformly on $\overline{\Omega}$ for some $U \in C(\overline{\Omega})$.*

(ii) *Let $U \in C(\overline{\Omega})$ be as above. Then $U \in W^{1,\infty}(\Omega)$ and $|DU(x)| \le 1$ for a.e. $x \in \Omega$.*

Proof. We first show (i). For $p \ge q$, we have

$$\|Du_p\|_{L^q(\Omega)} \le \mu(\Omega)^{\frac{1}{q} - \frac{1}{p}} \|Du_p\|_{L^p(\Omega)}. \tag{5.2}$$

For $q > n$, by the Sobolev embedding theorem (see, e.g., [GT]), we have

$$\|u_p\|_{C^{0,\gamma}(\overline{\Omega})} \le C_q \|Du\|_{L^q(\Omega)}$$

for some constants $\gamma \in (0, 1)$ and $C_q > 0$. These together with (5.1) imply that for any $q > n$, the collection $\{u_p\}_{p \ge q}$ is precompact.

Next, we prove (ii). The estimates (5.1) and (5.2) and the weak compactness of the balls in $W_0^{1,q}(\Omega)$, with $1 < q < \infty$, guarantee that $U \in W_0^{1,q}(\Omega)$ for any $q \in (1, \infty)$. This weak compactness, (5.1), and (5.2) yield

$$\|DU\|_{L^q(\Omega)} \le \mu(\Omega)^{\frac{1}{q}} \quad \text{for any } q > 1,$$

which implies that $|DU(x)| \le 1$ almost everywhere in Ω. ∎

Recalling the definition (1.6) of the set $\mathcal{A}$, from Proposition 5.1 we immediately have the following proposition.

PROPOSITION 5.2. (i) *$\mathcal{A} \ne \emptyset$ and $\mathcal{A} \subset X$.* (ii) *$u_p \to U$ in $C(\overline{\Omega})$ as $p \to \infty$ if and only if $\mathcal{A} = \{U\}$.*

Next, we consider the functional $I_\infty(u)$ for $u \in X$ defined by (1.4) and study the set $\mathcal{M}$ of maximizers of this functional.

The following proposition states a basic relation between $\mathcal{A}$ and $\mathcal{M}$.

PROPOSITION 5.3. (i) $\mathcal{A} \subset \mathcal{M}$. (ii) *As* $p \to \infty$, $I_p(u_p) \to \sup_{u\in X} I_\infty(u)$.

Proof. Let $U \in \mathcal{A}$ and $p_j \to \infty$ be such that $u_{p_j} \to U$ in $C(\overline{\Omega})$ as $j \to \infty$. As $p = p_j \to \infty$, we have

$$I_p(u_p) = I_\infty(u_p) - \frac{1}{p}\int_\Omega |Du_p|^p \, dx \le I_\infty(u_p) \to I_\infty(U).$$

Fix any $V \in X$ and observe that as $p \to \infty$,

$$I_p(u_p) \ge I_p(V) = I_\infty(V) - \frac{1}{p}\int_\Omega |DV(x)|^p \, dx \to I_\infty(V).$$

Hence we get

$$I_\infty(U) \ge \limsup_{j\to\infty} I_{p_j}(u_{p_j}) \ge \liminf_{p\to\infty} I_p(u_p) \ge I_\infty(V).$$

Since $U \in X$ by Proposition 5.2, we thus conclude that

$$I_\infty(U) = \sup_{u\in X} I_\infty(u), \qquad \lim_{j\to\infty} I_{p_j}(u_{p_j}) = \sup_{u\in X} I_\infty(u),$$

and $\mathcal{A} \subset \mathcal{M}$. Using (i) of Proposition 5.1, we deduce that

$$I_p(u_p) \to \sup_{u\in X} I_\infty(u) \quad \text{ as } p \to \infty. \qquad \square$$

PROPOSITION 5.4. *If* $u \in \mathcal{A}$, *then* u *satisfies*

$$-\Delta_\infty u(x) \le 0 \quad \text{ in } \Omega \setminus \overline{\Omega}_+ \quad \text{ and } \quad -\Delta_\infty u(x) \ge 0 \quad \text{ in } \Omega \setminus \overline{\Omega}_-$$

in the viscosity sense.

Proof. We prove only the first inequality, as the proof of the other inequality is similar. We set $W = \Omega \setminus \overline{\Omega}_+$. Let $\varphi \in C^2(W)$ and $\hat{x} \in W$. We assume that $u - \varphi$ attains a strict maximum at $\hat{x}$ and will show that $-\Delta_\infty\varphi(\hat{x}) \le 0$. For this, we argue by contradiction, and hence we assume that $-\Delta_\infty\varphi(\hat{x}) > 0$. Here we may assume that $u(\hat{x}) = \varphi(\hat{x})$.

Since $u \in \mathcal{A}$, there is a sequence $1 < p_j \to \infty$ such that $u_{p_j} \to u$ in $C(\overline{\Omega})$ as $j \to \infty$. Fix an $r > 0$ so that $B(\hat{x}, r) \subset W$ and $\Delta_\infty\varphi(x) < 0$ for all $x \in B(\hat{x}, r)$. Since

$$\Delta_p\varphi(x) = |D\varphi(x)|^{p-4}(|D\varphi(x)|^2\Delta\varphi(x) + (p-2)\Delta_\infty\varphi(x)) \quad \text{ for } x \in B(\hat{x}, r),$$

and

$$\min_{B(\hat{x},\,r)} |D\varphi| > 0 \quad \text{ and } \quad \max_{B(\hat{x},\,r)} \Delta_\infty\varphi < 0,$$

we see that if p is large enough, then $\Delta_p\varphi(x) < 0$ for all $x \in B(\hat{x}, r)$.

Set $\omega = \operatorname{int} B(\hat{x}, r)$. Choose an $\varepsilon > 0$ so that $(u - \varphi)|_{\partial\omega} < -3\varepsilon$. If we choose $j \in \mathbf{N}$ large enough, then we have $(u_{p_j} - \varphi)|_{\partial\omega} < -2\varepsilon$ and $(u_{p_j} - \varphi)(\hat{x}) > -\varepsilon$. Fix such a j and set $v = u_{p_j} + \varepsilon$ and $q = p_j$ for notational simplicity. We may assume as well that $\Delta_q\varphi(x) < 0$ for all $x \in \omega$.

Since $f \le 0$ in ω and $(v-\varphi)^+ \in W_0^{1,q}(\omega)$, we have

$$\int_\omega |Dv|^{q-2}Dv \cdot D(v-\varphi)^+ \,\mathrm{d}x = \int_\omega f(v-\varphi)^+ \,\mathrm{d}x \le 0,$$
$$\int_\omega |D\varphi|^{q-2}D\varphi \cdot D(v-\varphi)^+ \,\mathrm{d}x = -\int_\omega \Delta_q\varphi(v-\varphi)^+ \,\mathrm{d}x > 0,$$

and hence

$$\int_{\omega_+} (|Dv|^{q-2}Dv - |D\varphi|^{q-2}D\varphi) \cdot D(v-\varphi) \,\mathrm{d}x < 0,$$

where $\omega_+ = \{x \in \omega \mid v(x) > \varphi(x)\}$. On the other hand, because of the convexity of the function, $\xi \mapsto |\xi|^q$, we know that

$$\int_{\omega_+} (|Dv|^{q-2}Dv - |D\varphi|^{q-2}D\varphi) \cdot D(v-\varphi) \,\mathrm{d}x \ge 0,$$

which contradicts the above inequality. ◻

Remark. Let $u \in \mathcal{A}$. By an argument similar to the above proof, we can prove that $\min\{|Du(x)| - 1, -\Delta_\infty u(x)\} \le 0$ in Ω in the viscosity sense. However, we have a stronger conclusion that

$$|Du(x)| \le 1 \quad \text{in } \Omega \text{ in the viscosity sense.} \tag{5.3}$$

Indeed, if $u \in \mathcal{A}$, then $u \in X$, which implies that u satisfies (5.3) (see, for instance, Proposition 3.4 in [Ln]).

DEFINITION. *Let $Y \subset X$. We call Y essentially single if for any u, $v \in Y$, $u = v$ on* spt f.

PROPOSITION 5.5. *Let $Y \subset X$ be such that $\mathcal{A} \subset Y$. If Y is essentially single, then $\mathcal{A}$ is a singleton. In particular, the whole family $\{u_p\}_{p>1}$ converges in $C(\overline{\Omega})$.*

The following proof has already been explained in the introduction.

Proof. Let u, $v \in \mathcal{A}$. By assumption, we have $u = v$ on spt f. By Proposition 5.4, we see that u and v are both viscosity solutions of

$$-\Delta_\infty w(x) = 0 \quad \text{in } \Omega \setminus \operatorname{spt} f.$$

By the uniqueness result for this PDE due to [J], we conclude that $u = v$ in $\Omega \setminus \operatorname{spt} f$, which guarantees that $u = v$ in $\overline{\Omega}$. ◻

6. Properties of the set $\mathcal{M}$. In this section we collect some properties of the set $\mathcal{M}$ of the maximizers of the functional I_∞.

PROPOSITION 6.1. *Let $u \in \mathcal{M}$. Then*

$$u(x) = \inf\{u(y) + |x-y| \mid y \in \Omega_- \cup \partial\Omega\} \quad \text{for all } x \in \Omega_+ \tag{6.1}$$

and

$$u(x) = \sup\{u(y) - |x-y| \mid y \in \Omega_+ \cup \partial\Omega\} \quad \text{for all } x \in \Omega_-. \tag{6.2}$$

A proposition similar to this can be found in [EG] (Lemma 3.1 of [EG]), the proof of which can be easily adapted to our case, but we give a proof here for completeness.

Proof. We prove only (6.1), since the proof of (6.2) is similar. Let $u \in X$. Then

$$|u(x) - u(y)| \leq |x - y| \quad \text{for all } x, y \in \overline{\Omega},$$

from which we have

$$u(x) \leq \inf\{u(y) + |x - y| \mid y \in A\}$$

for all $x \in \overline{\Omega}$ and any $A \subset \overline{\Omega}$. In particular, we have

$$u(x) \leq \inf\{u(y) + |x - y| \mid y \in \Omega_- \cup \partial\Omega\} \quad \text{for all } x \in \overline{\Omega}. \tag{6.3}$$

Now, let $u \in \mathcal{M}$. Since $\mathcal{M} \subset X$, inequality (6.3) holds with this u. Setting

$$v(x) = \inf\{u(y) + |x - y| \mid y \in \Omega_- \cup \partial\Omega\} \quad \text{for } x \in \overline{\Omega},$$

we see immediately from the definition of v that

$$v(x) - v(y) \leq |x - y| \quad \text{for all } x, y \in \overline{\Omega},$$

which implies that $|Dv(x)| \leq 1$ almost everywhere in Ω. Also, we have

$$u(x) \leq v(x) \quad \text{for all } x \in \overline{\Omega}, \text{ by (6.3)},$$

and

$$v(x) \leq u(x) \quad \text{for all } x \in \Omega_- \cup \partial\Omega, \quad \text{by the definition of } v.$$

Combining these we find that $u(x) = v(x)$ for all $x \in \Omega_- \cup \partial\Omega$. In particular, $v(x) = 0$ for all $x \in \partial\Omega$. Thus we see that $v \in X$.

Next note that $I_\infty(u) = \max_{w \in X} I_\infty(w) \geq I_\infty(v)$. On the other hand, since $u = v$ on Ω_- and $v \geq u$ on Ω_+, we get $I_\infty(u) \leq I_\infty(v)$. Hence, we see that $I_\infty(v) = I_\infty(u)$. Now, since

$$\int_{\Omega_+} f(x)u(x)\,\mathrm{d}x = \int_{\Omega_+} f(x)v(x)\,\mathrm{d}x$$

and $v \geq u$ on Ω_+, we conclude that $u = v$ on Ω_+, which completes the proof. ∎

Remark. As one can see from the above proof, the set $\Omega_- \cup \partial\Omega$ in (6.1) can be replaced by any set $A \subset \overline{\Omega}$ satisfying $\Omega_- \cup \partial\Omega \subset A$. Similarly, the set $\Omega_+ \cup \partial\Omega$ in (6.2) can be replaced by any set $A \subset \overline{\Omega}$ satisfying $\Omega_+ \cup \partial\Omega \subset A$.

PROPOSITION 6.2. *Let $u, v \in \mathcal{M}$ and $k \geq 0$. Then $u \wedge (v + k)$, $(u - k) \vee v \in \mathcal{M}$.*

Proof. It is easy to see that $u \wedge (v + k)$, $(u - k) \vee v \in X$. In particular, we have

$$\max\{I_\infty(u \wedge (v + k)),\ I_\infty((u - k) \vee v)\} \leq I_\infty(u) = I_\infty(v).$$

Noting that $u \wedge (v + k) = u - (u - v - k)^+$ and $(u - k) \vee v = v + (u - v - k)^+$, we see that

$$I_\infty(u \wedge (v+k)) = I_\infty(u) - I_\infty((u-v-k)^+), \quad I_\infty((u-k) \vee v) = I_\infty(v) + I_\infty((u-v-k)^+),$$

and hence

$$\begin{aligned} 0 &\leq I_\infty(u) - I_\infty(u \wedge (v + k)) \\ &= I_\infty((u - v - k)^+) = I_\infty((u - k) \vee v) - I_\infty(v) \leq 0. \end{aligned}$$

Consequently, we have

$$I_\infty(u \wedge (v+k)) = I_\infty((u-k) \vee v) = I_\infty(u),$$

Thus we conclude that $u \wedge (v+k),\ (u-k) \vee v \in \mathcal{M}$. $\square$

The following proposition establishes the existence of the maximal and minimal elements of $\mathcal{M}$.

PROPOSITION 6.3. *Define* $V, W : \overline{\Omega} \to \mathbf{R}$ *by*

$$V(x) = \sup\{v(x) \mid v \in \mathcal{M}\} \quad \textit{and} \quad W(x) = \inf\{v(x) \mid v \in \mathcal{M}\}.$$

Then $V, W \in \mathcal{M}$.

Proof. We prove only the identity for V, since the proof of the other is similar.

First of all, note that $V \in X$. Choose a dense subset $\{y_k\}_{k\in\mathbf{N}}$ of Ω. For each $k \in \mathbf{N}$ we choose a sequence $\{v_{kj}\}_{j\in\mathbf{N}} \subset \mathcal{M}$ such that $\lim_{j\to\infty} v_{kj}(y_k) = V(y_k)$. By the definition of V, we have $v(x) \le V(x)$ for all $x \in \Omega$ and $v \in \mathcal{M}$. Therefore, we find that

$$V(y_l) = \sup\{v_{kj}(y_l) \mid k, j \in \mathbf{N}\} \quad \text{for } l \in \mathbf{N}.$$

Define $w \in X$ by setting

$$w(x) = \sup\{v_{kj}(x) \mid k, j \in \mathbf{N}\} \quad \text{for } x \in \overline{\Omega}.$$

It is immediate to see that $V = w$ on $\overline{\Omega}$.

We intend to show that $V \in \mathcal{M}$. Relabeling the countable set $\{v_{kj}\}_{k,j\in\mathbf{N}}$, we find a sequence $\{v_m\}_{m\in\mathbf{N}} \subset \mathcal{M}$ such that

$$V(x) = \sup\{v_m(x) \mid m \in \mathbf{N}\} \quad \text{for all } x \in \overline{\Omega}.$$

We define the nondecreasing sequence $\{w_j\}_{j\in\mathbf{N}}$ by induction as follows:

$$w_1 = v_1, \quad w_{j+1} = w_j \vee v_{j+1} \ \text{ for } j \in \mathbf{N}.$$

By Proposition 6.2, we see that $w_j \in \mathcal{M}$ for all $j \in \mathbf{N}$. It is clear that

$$\lim_{j\to\infty} w_j(x) = V(x) \quad \text{for all } x \in \overline{\Omega}.$$

Therefore we see by the monotone convergence theorem that

$$I_\infty(V) = \lim_{j\to\infty} I_\infty(w_j) = \max_{v\in X} I_\infty(v)$$

and conclude that $V \in \mathcal{M}$. $\square$

PROPOSITION 6.4. *For any* $u, v \in \mathcal{M}$*, we have*

$$\sup_{\Omega_+}(u-v)^+ = \sup_{\Omega_-}(u-v)^+.$$

Proof. Set $k = \sup_{\Omega_-}(u-v)^+$ and observe that $u(y) \le v(y) + k$ for $y \in \Omega_- \cup \partial\Omega$. Using Proposition 6.1, we see that for $x \in \Omega_+$,

$$u(x) = \inf\{u(y) + |x-y| \mid y \in \Omega_- \cup \partial\Omega\} \le \inf\{v(y) + |x-y| \mid y \in \Omega_- \cup \partial\Omega\} + k.$$

Hence, we have $u(x) \le v(x) + k$ for all $x \in \Omega_+$, and therefore

$$\sup_{\Omega_+}(u-v)^+ \le \sup_{\Omega_-}(u-v)^+.$$

Exchanging the role of Ω_+ and Ω_- in the above argument, we get

$$\sup_{\Omega_-}(u-v)^+ \le \sup_{\Omega_+}(u-v)^+$$

and finish the proof. ∎

PROPOSITION 6.5. *If $u \in \mathcal{M}$, then in the viscosity sense u satisfies*

$$|Du(x)| = 1 \quad \text{in } \Omega_+ \quad \text{and} \quad -|Du(x)| = -1 \quad \text{in } \Omega_-. \tag{6.4}$$

This proposition is an easy consequence of Proposition 6.1. For completeness we give a proof here.

Proof. Fix $u \in \mathcal{M}$. Let $\varphi \in C^1(\Omega)$ and $\hat{x} \in \Omega_+$. Assume that $u - \varphi$ attains a maximum at $\hat{x}$. Then, since $|u(x) - u(\hat{x})| \le |x - \hat{x}|$ for all $x \in \Omega$, we have as $x \to \hat{x}$

$$-|x-\hat{x}| \le u(x) - u(\hat{x}) \le \varphi(x) - \varphi(\hat{x}) = D\varphi(\hat{x}) \cdot (x - \hat{x}) + o(|x-\hat{x}|).$$

Substituting $\hat{x} - tD\varphi(\hat{x})$ for x and sending $t \searrow 0$, we see that $|D\varphi(\hat{x})| \le 1$.

Now, we assume that $u - \varphi$ attains a minimum at $\hat{x}$. In view of Proposition 6.1, we choose a point $y \in \overline{\Omega}_- \cup \partial\Omega$ so that $u(\hat{x}) = u(y) + |\hat{x} - y|$ holds. As before, we have as $x \to \hat{x}$

$$|x-y| - |\hat{x}-y| \ge u(x) - u(\hat{x}) \ge \varphi(x) - \varphi(\hat{x}) \ge -|D\varphi(\hat{x})||x-\hat{x}| + o(|x-\hat{x}|).$$

Substituting $\hat{x} + t(y - \hat{x})$ for x and sending $t \searrow 0$, we see that $|D\varphi(\hat{x})| \ge 1$.

Thus we see that u is a viscosity solution of $|Du(x)| = 1$ in Ω_+. A parallel argument shows that u is a viscosity solution of $-|Du(x)| = -1$ in Ω_-. ∎

PROPOSITION 6.6. *$\mathcal{M}$ is a convex set as a subset of $C(\overline{\Omega})$.*

Proof. Note that $X \subset C(\overline{\Omega})$ is a convex set. Since I_∞ is a linear functional on $C(\overline{\Omega})$, we conclude that $\mathcal{M}$ is convex. ∎

PROPOSITION 6.7. *Let $u, v \in \mathcal{M}$. Then*

$$Du(x) = Dv(x) \quad \textit{for a.e. } x \in \Omega_*.$$

Proof. Let u and $v \in \mathcal{M}$. Define $w \in C(\overline{\Omega})$ by

$$w = \frac{1}{2}(u + v).$$

According to Proposition 6.6, we have $w \in \mathcal{M}$. By Rademacher's theorem, we see that functions u, v, w are almost everywhere differentiable in Ω. Now, Proposition 6.5 yields

$$|Du(x)| = |Dv(x)| = |Dw(x)| = 1 \quad \text{for a.e. } x \in \Omega_*,$$

and therefore the strict convexity of the Euclidean norm in $\mathbf{R}^n$ implies that

$$Du(x) = Dv(x) = Dw(x) \quad \text{for a.e. } x \in \Omega_*. \qquad ∎$$

7. Case of no balanced family. In this section we first prove Theorem 2.3 and then examine a case where the hypothesis (2.4) is satisfied.

We begin with a lemma. Let $\{\mathcal{O}_\lambda\}_{\lambda\in\Lambda}$ be the classification of $\mathcal{O}_*$,

$$G_\lambda := \bigcup\{U \mid U \in \mathcal{O}_\lambda\} \quad \text{for } \lambda \in \Lambda,$$

as in section 2. Also, let $\Lambda_0 \subset \Lambda$ be as in section 2.

LEMMA 7.1. *If u,$v \in \mathcal{M}$, then $u - v$ is constant on any G_λ, with $\lambda \in \Lambda$.*

Proof. Let u, $v \in \mathcal{M}$. First of all, we observe that for any A, $B \subset \Omega$,

$$\begin{aligned}\inf_{(x,y)\in A\times B} |(u-v)(x)-(u-v)(y)| &\le \inf_{(x,y)\in A\times B}(|u(x)-u(y)|+|v(x)-v(y)|) \\ &\le 2d(A,B).\end{aligned} \tag{7.1}$$

Fix $\lambda \in \Lambda$ and $U, V \in \mathcal{O}_\lambda$. By Proposition 6.7, we have

$$(u-v)(x) = \begin{cases} k_U & \text{for } x \in U, \\ k_V & \text{for } x \in V \end{cases}$$

for some constants k_U, k_V. Fix any $\varepsilon > 0$. Since $\rho(U, V) = 0$, there is a finite family $W_1, \dots, W_m \in \mathcal{O}_*$ such that $d(U, W_1) + d(W_1, W_2) + \cdots + d(W_m, V) < \varepsilon$. By Proposition 6.7, for each $i \in \{1, \dots, m\}$ there is a constant k_i such that $(u-v)(x) = k_i$ for all $x \in U_i$.

Now, using (7.1), we get

$$\begin{aligned}|k_U - k_V| &\le |k_U - k_1| + |k_1 - k_2| + \cdots + |k_m - k_V| \\ &\le 2(d(U, W_1) + d(W_1, W_2) + \cdots + d(W_m, V)) < 2\varepsilon.\end{aligned}$$

Since $\varepsilon > 0$ is arbitrary, we conclude that $k_U = k_V$. This shows that $u - v$ is constant on G_λ. □

LEMMA 7.2. *Let u, $v \in \mathcal{M}$ and $\lambda \in \Lambda_0$. Then $u = v$ on G_λ.*

Proof. In view of Lemma 7.1, let $k \in \mathbf{R}$ be a constant such that $u = v + k$ on G_λ. Fix any $U \in \mathcal{O}_\lambda$ and $\varepsilon > 0$. There is a finite sequence $U_1, \dots, U_m \in \Omega$ such that $d(U, U_1) + d(U_1, U_2) + \cdots + d(U_m, \partial\Omega) < \varepsilon$. As in the proof of Lemma 7.1, since $u = v = 0$ on $\partial\Omega$, we find that $|k| \le 2(d(U, U_1) + d(U_1, U_2) + \cdots + d(U_m, \partial\Omega)) < 2\varepsilon$. This is enough for us to conclude that $u = v$ on G_λ. □

Proof of Theorem 2.3. In view of Proposition 5.5, it is enough to show that $\mathcal{M}$ is essentially single.

For this we argue by contradiction. Thus we let $u, v \in \mathcal{M}$ and assume that $u \ne v$ on $\operatorname{spt} f$. We may assume that u and v are, respectively, the maximal and minimal elements of $\mathcal{M}$, i.e.,

$$u(x) \ge w(x) \ge v(x) \quad \text{ for all } x \in \Omega \text{ and } w \in \mathcal{M}.$$

Fix any $k > 0$ so that $k < \sup_{\Omega_*}(u - v)$. For $t \in (0, k]$ we set $w_t = u \wedge (v + t)$. Note that for $x \in \Omega$ and $0 \le t < s \le k$,

$$v(x) \le w_t(x) \le w_s(x) \le w_k(x).$$

Also, since $0 < k < \sup_{\Omega_*}(u - v)$, we see that $w_k - v$ attains the maximum value k at some point of Ω_*.

By Proposition 6.2, we have $w_t \in \mathcal{M}$ for all $t \in (0,\, k]$. Hence we have $I_\infty(w_k) = I_\infty(w_t)$ for all $t \in (0, k)$, which reads

$$0 = \int_\Omega \frac{(w_k - w_t)(x)}{k - t} f(x)\,\mathrm{d}x \quad \text{ for all } t \in (0, k).$$

For $0 \le t < k$, we set

$$A_t = \{x \in \Omega_* \mid w_t(x) < w_k(x)\} \quad \text{ and } \quad B = \bigcap_{0<t<k} A_t.$$

Note that $A_t \supset A_s$ for $0 < t < s < k$.

We claim here that

$$B = \{x \in \Omega_* \mid (w_k - v)(x) = k\}.$$

To see this, we write C for the right-hand side of the above identity. Let $x \in B$. By definition, we have $w_t(x) < w_k(x)$ for all $t \in (0, k)$. This implies that $w_t(x) = v(x) + t$ for all $t \in (0, k)$, and hence that $v(x) + t < u(x)$ for all $t \in (0, k)$. Therefore, we have $v(x) + k \le u(x)$ and, moreover, $w_k(x) = v(x) + k$. Thus, we see that $B \subset C$.

Next, let $x \in C$. We then have $w_k(x) = v(x) + k$, which yields that $u(x) \ge v(x) + k > v(x) + t$ for all $t \in [0, k)$. Hence we have $w_t(x) < w_k(x)$ for all $t \in (0, k)$. That is, we have $x \in B$, which concludes that $C \subset B$ and, moreover, $B = C$.

Since $w_k - v$ takes the value k at some point of Ω_*, we have $B \neq \emptyset$.

Now we go back to the equality

$$0 = \int_\Omega \frac{(w_k - w_t)(x)}{k - t} f(x)\, \mathrm{d}x = \int_{A_t} \frac{(w_k - w_t)(x)}{k - t} f(x)\, \mathrm{d}x \quad \text{for } t \in (0, k).$$

We are going to apply the Lebesgue convergence theorem. Since $A_t \supset A_s$ for $0 < t < s < k$ and $\bigcap_{0<t<k} A_t = B$, we see that as $t \nearrow k$,

$$\mathbf{1}_{A_t}(x) \to \mathbf{1}_B(x) \quad \text{for all } x \in \Omega.$$

Note that $|(w_k - w_t)(x)| \le |k - t|$ for all $t \in (0, k)$ and $x \in A_t$, and hence

$$\mathbf{1}_{A_t}(x) \left| \frac{(w_k - w_t)(x)}{k - t} f(x) \right| \le |f(x)| \quad \text{for all } t \in (0, k) \text{ and } x \in \Omega.$$

For $x \in B$, we have $w_k(x) = v(x) + k$ and $w_t(x) = v(x) + t$, and therefore

$$\frac{(w_k - w_t)(x)}{k - t} = 1.$$

Therefore, as $t \nearrow k$,

$$\mathbf{1}_{A_t}(x) \frac{(w_k - w_t)(x)}{k - t} f(x) \to \mathbf{1}_B(x) f(x).$$

We apply the Lebesgue convergence theorem along any sequence $t_k \nearrow k$, to conclude that $\int_B f(x)\, \mathrm{d}x = 0$.

Finally, noting by Lemma 7.1 that the function $w_k - v$ is constant on any G_λ, with $\lambda \in \Lambda$, and setting

$$\Gamma = \{\lambda \in \Lambda \mid (w_k - v)(x) = k \ \text{ on } G_\lambda\},$$

we have

$$B = \bigcup \{G_\lambda \mid \lambda \in \Gamma\}.$$

We see from Lemma 7.2 that $\Gamma \subset \Lambda \setminus \Lambda_0$. Recalling that $B \neq \emptyset$, by the assumption (2.4) we have $\int_B f(x)\, \mathrm{d}x \neq 0$. This is a contradiction. □

Let us examine the case where

$$\mu(\{x \in \Omega \mid f(x) = 0\}) = 0. \tag{7.2}$$

We have the following theorem as a corollary of Proposition 6.7.

THEOREM 7.3. *Under the assumption* (7.2), $\mathcal{M}$ *is a singleton. As a consequence, the whole family* $\{u_p\}_{p>1}$ *converges in* $C(\overline{\Omega})$.

Proof. Let $u, v \in \mathcal{M}$. By Proposition 6.7, we have $Du(x) = Dv(x)$ almost everywhere in Ω_*. By (7.2), we have $Du(x) = Dv(x)$ almost everywhere in Ω. Hence, $u = v$ in Ω. □

We wish to explain here that the convergence result in Theorem 7.3 can be shown as a consequence of Theorem 2.3.

PROPOSITION 7.4. *If* (7.2) *holds, then* $\Lambda = \Lambda_0$ *and hence* (2.4) *is satisfied.*

Proof. We need to show only that $\rho(U, \partial\Omega) = 0$ for all $U \in \mathcal{O}_*$.

To do this, we fix $U \in \mathcal{O}_*$ and $x \in U$. Choose a closest point y in $\partial\Omega$ to the point x. Set $R = |y - x|$. Choose a constant $r \in (0, R)$ so that $B(x, r) \subset U$. Let H be the hyperplane normal to the vector $y - x$ and passing through the point x, i.e., $H = \{\xi \in \mathbf{R}^n \mid (\xi - x) \cdot (y - x) = 0\}$. Let C be the truncated open cone generated by the point y and the $(n-1)$-dimensional sphere $H \cap B(x, r)$. That is, we write

$$C = \{ty + (1-t)\xi \mid (t, \xi) \in (0, 1) \times (H \cap B(x, r))\}.$$

Note that $C \subset \operatorname{int} B(x, R) \subset \Omega$.

By the assumption (7.2), we have

$$\mu(C) = \mu(C \cap \Omega_*).$$

Using the Fubini theorem, from this we deduce that for μ_{n-1}-almost all $\xi \in H \cap B(x, r)$, we have $\mu_1(\{t \in (0, 1) \mid ty + (1-t)\xi \in \Omega_*\}) = 1$.

Fix a point $\xi \in H \cap B(x, r)$ so that $\mu_1(\{t \in (0, 1) \mid ty + (1-t)\xi \in \Omega_*\}) = 1$. Define $I \subset (0, 1)$ by setting $I = \{t \in (0, 1) \mid ty + (1-t)\xi \in \Omega_*\}$. Since I is an open subset of $(0, 1)$, there is a sequence $\{I_j\}_{j \in J}$, with $J \subset \mathbf{N}$, of nonempty open intervals $I_j \subset (0, 1)$ such that $I = \bigcup\{I_j \mid j \in J\}$. We may assume as well that if $i, j \in J$ and $i \neq j$, then $I_i \cap I_j = \emptyset$. Since $\mu_1(I) = 1$, we have $\sum_{j \in J} \mu_1(I_j) = 1$.

Fix any $\varepsilon > 0$. There is a finite subset $J_\varepsilon \subset J$ such that $\sum_{j \in J_\varepsilon} \mu_1(I_j) > 1 - \varepsilon$. We may assume that $J_\varepsilon = \{1, \dots, m\}$, where m is a positive integer which depends on ε. For each $j \in J_\varepsilon$, we choose $a_j, b_j \in [0, 1]$ so that $I_j = (a_j, b_j)$. We may further assume that $a_1 < b_1 \leq a_2 < b_2 \leq \cdots \leq a_m < b_m$. Then we have $\sum_{j \in J_\varepsilon} \mu_1(I_j) = \sum_{j \in J_\varepsilon}(b_j - a_j) > 1 - \varepsilon$.

For each $j \in J_\varepsilon$, since $ty + (1-t)\xi \in \Omega_*$ for $t \in I_j$, and the set $\{ty + (1-t)\xi \mid t \in I_j\}$ is connected, we see that there is a $U_j \in \mathcal{O}_*$ such that

$$ty + (1-t)\xi \in U_j \text{ for } t \in I_j.$$

Observe that

$$\begin{aligned}
d(U, U_1) &\leq |\xi - (a_1 y + (1 - a_1)\xi)| \leq a_1 |y - \xi|, \\
d(U_{j-1}, U_j) &\leq |(b_{j-1} y + (1 - b_{j-1})\xi) - (a_j y + (1 - a_j)\xi)| \\
&\leq (a_j - b_{j-1})|y - \xi| \quad \text{ for all } j \in \{2, \dots, m\}, \\
d(U_m, \partial\Omega) &\leq |y - (b_m y + (1 - b_m)\xi)| \leq (1 - b_m)|y - \xi|.
\end{aligned}$$

Adding all of these, we get

$$\begin{aligned}
d(U, U_1) + d(U_1, U_2) + \cdots + d(U_m, \partial\Omega) &\leq (a_1 + (a_2 - b_1) + \cdots + (1 - b_m))|y - \xi| \\
&= \left(1 - \sum_{j \in J_\varepsilon} (b_j - a_j)\right) |y - \xi| < \varepsilon |y - \xi|.
\end{aligned}$$

Thus we see that $\rho(U, \partial\Omega) = 0$ and finish the proof. $\square$

8. Cases with vanishing integral. In this section we prove Theorem 2.4.

Proof of Theorem 2.4. Assume that (2.5) and (2.6) are satisfied.

First, we assume that (2.7) and (2.8) are satisfied and show in view of Proposition 5.5 that $\mathcal{A}$ is essentially single.

We observe that every $u \in \mathcal{A}$ is an odd function. This follows from the uniqueness of solutions of the Dirichlet problem

$$\begin{cases} -\Delta_p u(x) = f(x) & \text{in } \Omega, \\ \quad u(x) = 0 & \text{on } \partial\Omega. \end{cases} \tag{8.1}$$

Indeed, if u is a solution of (8.1), then the function $-u(-x)$ is a solution of (8.1) as well and, by the uniqueness, $u(x) = -u(-x)$ for all $x \in \overline{\Omega}$. This shows that every function $u \in \mathcal{A}$ is an odd function.

Now, let $u, v \in \mathcal{A}$. Since Ω_+ and Ω_- are connected and $Du(x) = Dv(x)$ for a.e. $x \in \Omega_*$, there is a constant $k \in \mathbf{R}$ such that $u(x) = v(x) + k$ for all $x \in \Omega_+$. By symmetry in u and v, we may assume that $k \geq 0$.

Since u and v are odd functions, we have

$$-u(-x) = -v(-x) + k \quad \text{ for all } x \in \Omega_+.$$

That is, $u(x) = v(x) - k$ for all $x \in \Omega_-$. Using Proposition 6.4, we thus get

$$k = \max_{\Omega_+}(u - v)^+ = \max_{\Omega_-}(u - v)^+ = 0,$$

which shows that $u(x) = v(x)$ for all $x \in \Omega_*$ and hence $\mathcal{A}$ is essentially single.

Next we turn to the case where (2.9) is satisfied. It is enough to show that $\mathcal{M}$ is essentially single. Let $u, v \in \mathcal{M}$; we will show that $u = v$ on Ω_*.

By Proposition 6.4, we have

$$\sup_{\Omega_+}(u - v)^+ = \sup_{\Omega_-}(u - v)^+. \tag{8.2}$$

We argue by contradiction, and hence suppose that $u(z) \neq v(z)$ for some $z \in \Omega_*$. We may assume that $u(z) > v(z)$. In view of (8.2), there is a constant $k > 0$ such that $u(x) - v(x) = k$ for all $x \in \Omega_*$.

From (2.9) we have either

$$\inf_{x\in\Omega_+} \sup_{y\in\Omega_-} [d(x) + d(y) - |x - y|] \leq 0 \tag{8.3}$$

or

$$\inf_{y\in\Omega_-} \sup_{x\in\Omega_+} [d(x) + d(y) - |x - y|] \leq 0. \tag{8.4}$$

We consider only the case where (8.3) holds, since the other case can be treated similarly.

For each $\varepsilon > 0$ there exists a point $x_\varepsilon \in \Omega_+$ such that $d(x_\varepsilon) + d(y) - |x_\varepsilon - y| \leq \varepsilon$ for all $y \in \Omega_-$. Since $u, v \in X$, we have $|u(x)| \vee |v(x)| \leq d(x)$ for all $x \in \Omega$. From these we get

$$d(x_\varepsilon) \leq \inf\{v(y) + |x_\varepsilon - y| \mid y \in \Omega_-\} + \varepsilon.$$

Since $v = 0$ on $\partial\Omega$, we have

$$d(x_\varepsilon) = \inf\{v(y) + |x_\varepsilon - y| \mid y \in \partial\Omega\}.$$

Therefore, using Proposition 6.1, we have

$$d(x_\varepsilon) \le \inf\{v(y) + |x_\varepsilon - y| \mid y \in \Omega_- \cup \partial\Omega\} + \varepsilon = v(x_\varepsilon) + \varepsilon.$$

Thus we obtain $u(x_\varepsilon) \le d(x_\varepsilon) \le v(x_\varepsilon) + \varepsilon$, which yields a contradiction by choosing $\varepsilon \in (0, k)$. This completes the proof. $\square$

A GENERALIZED ENERGY FUNCTIONAL FOR PLANE COUETTE FLOW*

R. KAISER†, A. TILGNER‡, AND W. VON WAHL†

Abstract. We present a generalized energy functional $\mathcal{E}$ for plane Couette flow providing conditional nonlinear stability for Reynolds numbers Re below $\mathrm{Re}_{\mathcal{E}} := 177.2$, which is larger than the ordinary energy stability limit. The method allows the explicit calculation of so-called stability balls in the $\mathcal{E}^{1/2}$-norm; i.e., the system is stable with respect to any perturbation with $\mathcal{E}^{1/2}$-norm in this ball.

Key words. hydrodynamical stability, plane Couette flow

1. Introduction. Plane Couette flow is a paradigm with a long history of scientific investigation for a whole class of hydrodynamic stability problems, viz. plane parallel shear flows (cf. [DR, SH]). For these flows there is no obvious physical mechanism which triggers instability as, e.g., in circular Couette flow or in convection problems. Instead, viscous stresses seem to play the dominant role at the onset of instability. So, despite the striking simplicity of the set-up of these systems the onset of instability is up to the present insufficiently understood and its nature is the subject of ongoing research [TTRD, Gr].

The classical methods which yield rigorous stability results are the method of linearized stability and the energy method. The former method provides the critical value Re_c of the Reynolds number Re, below which the system is conditionally stable and above which it is unstable. In the case of Couette flow[1] it turns out that $\mathrm{Re}_c = \infty$, i.e., the system is linearly completely stable [Ro]. The second method provides global asymptotic stability below some value Re_E. For Couette flow $\mathrm{Re}_E = 82.6$ if Re is defined with the separation of the walls and their velocity difference [Jo]. This has to be compared with the experimentally observed onset of instability, which occurs at $\mathrm{Re} \approx 1300$ [Gr, DD]. Thus, none of the classical methods describes the instability behavior of Couette flow satisfactorily.

A more recent method which has successfully been applied to a couple of hydrodynamic stability problems uses generalized energy functionals which are better adjusted to the specific problems under consideration [J1, J2, GP, St]. A generalized energy functional $\mathcal{E}$ is a bilinear form of the dynamic variables of the problem. In comparison with the ordinary energy these variables are, however, differently weighted by additional coupling parameters and appear possibly in the form of higher derivatives. A first part $\mathcal{E}_1$ of the functional determines (analogously to the energy method) via a variational problem the stability boundary $\mathrm{Re}_{\mathcal{E}}$. The coupling parameters are chosen such that $\mathrm{Re}_{\mathcal{E}}$ becomes as large as possible—in particular, larger than Re_E.

[1]Henceforth Couette flow always means *plane* Couette flow.

Contrary to the energy balance the nonlinear terms in general do not drop from the generalized energy balance. Therefore, a second part $\mathcal{E}_2$ involving higher derivatives of the dynamic variables is needed in $\mathcal{E}$ in order to dominate these terms. If the method works one obtains conditional stability for all Reynolds numbers below $\mathrm{Re}_{\mathcal{E}}$ together with explicit stability balls in the $\mathcal{E}^{1/2}$-norm. This is different from the method of linearized stability which gives no estimates for stability balls.

Generalized energy functionals have already been applied to plane parallel shear flows, however, under the assumption of stress-free boundary conditions for the perturbations [RM]. This assumption clearly overestimates the stability of these flows since wall induced stresses are neglected. In fact, the authors find conditional stability for all Reynolds numbers not only for Couette flow but also for Poiseuille flow, a system with finite critical Reynolds number if rigid boundary conditions are used.

If rigid boundary conditions are used no generalized energy functionals have been found so far, neither in plane parallel shear flows nor in any other hydrodynamical system with nontrivial basic flow and unrestricted (three-dimensional) perturbations. Moreover, in the case of Couette flow it has been argued that the generalized energy method as applied to systems with stress-free boundary conditions is incompatible with rigid boundary conditions [KT].

We present in this paper a generalized energy functional $\mathcal{E}$ for Couette flow (with correct rigid boundary conditions), which provides conditional stability for all Reynolds numbers below $\mathrm{Re}_{\mathcal{E}} = 177.2$. This number is still far below what is desired. However, there is now hope that still more appropriate functionals can be found which cover a larger stability region. The crucial point which allows the treatment of rigid boundary conditions is a more refined calculus inequality that takes advantage of the special geometry of the system.

The following point is of some historical interest: For Couette flow $\mathrm{Re}_{\mathcal{E}} = 177.2$ is just the two-dimensional energy stability limit, where perturbations are not allowed to vary in the spanwise direction. Following Orr [Or], early researchers in the field took this number for the correct energy stability limit. It came as a surprise when Joseph [Jo] showed that the complementary two-dimensional problem provided a considerably lower limit. Busse proved subsequently that the latter limit is in fact the correct energy stability limit [Bu]. Thus, our result may be viewed as a late justification of (a weakened version of) Orr's original claim.

The paper is organized as follows: Section 2 sets the mathematical framework for the subsequent analysis. In particular, we introduce the so-called poloidal-toroidal decomposition of divergence-free vector fields. This decomposition eliminates the divergence constraint and provides appropriate building blocks for generalized energy functionals. In section 3 a linear auxiliary problem is solved, viz. the variational problem associated with $\mathcal{E}_1$ which determines the stability limit $\mathrm{Re}_{\mathcal{E}}$. Section 4 provides estimates of the remaining terms in the energy balance of $\mathcal{E}_1 + \mathcal{E}_2$, the nonlinear terms in particular, and it formulates the basic stability result. Some well-known inequalities as well as the refined calculus inequality are collected in Appendix A, and the results of a numerical computation related to the variational problem are contained in Appendix B.

2. Mathematical setting. The Couette system is appropriately modeled by an infinite layer $\mathbb{R} \times (-\frac{1}{2}, \frac{1}{2})$ of thickness 1 with horizontal coordinates x, y and vertical coordinate z. The basic flow in this system takes the dimensionless form

$$\mathbf{U}_0 = \mathbf{U}_0(z) = \mathrm{Re} \begin{pmatrix} -z \\ 0 \\ 0 \end{pmatrix} \tag{2.1}$$

with Re being the Reynolds number based on the distance between bottom and top boundaries of the layer and their velocity difference. In order to investigate the stability of $\mathbf{U}_0$ we impose perturbations $\mathbf{u} = (u_x, u_y, u_z)$. These are governed by the system

$$\begin{aligned} \partial_t \mathbf{u} - \Delta \mathbf{u} - \mathrm{Re}(z\,\partial_x \mathbf{u} + u_z \mathbf{e}_x) + \mathbf{u} \cdot \nabla \mathbf{u} + \nabla p &= 0, \\ \nabla \cdot \mathbf{u} &= 0 \end{aligned} \tag{2.2}$$

in $\mathbb{R}^2 \times (-\frac{1}{2}, \frac{1}{2}) \times (0, T)$, $T > 0$, and satisfy the boundary conditions

$$\mathbf{u}(x, y, z, t) = 0 \qquad \text{for} \quad (x, y, z) \in \mathbb{R}^2 \times \left\{-\frac{1}{2}, \frac{1}{2}\right\},\ t > 0. \tag{2.3}$$

Here $\mathbf{e}_x = (1, 0, 0)^{\mathrm{T}}$. The initial value $\mathbf{u}(\cdot, \cdot, \cdot, 0) = \mathbf{u}_0$ is assumed to be given (and of course solenoidal). $\mathbf{u}$ corresponds to the velocity field of the perturbation and p denotes the pressure perturbation. Both $\mathbf{u}$ and ∇p are assumed to be x, y-periodic with respect to a rectangle $\mathcal{P} = (-\frac{\pi}{\alpha}, \frac{\pi}{\alpha}) \times (-\frac{\pi}{\beta}, \frac{\pi}{\beta})$ with wave numbers $(\alpha, \beta) \in \mathbb{R}^2_+$. In the following it suffices, therefore, to consider functions over the box

$$\Omega = \mathcal{P} \times \left(-\frac{1}{2}, \frac{1}{2}\right) = \left(-\frac{\pi}{\alpha}, \frac{\pi}{\alpha}\right) \times \left(-\frac{\pi}{\beta}, \frac{\pi}{\beta}\right) \times \left(-\frac{1}{2}, \frac{1}{2}\right).$$

As basic function space we take $L^2(\Omega)$. In what follows, $\|\cdot\|$ is always the norm in $L^2(\Omega)$ except in the case when applied to a function defined on $(-\frac{1}{2}, \frac{1}{2})$. Then, $\|\cdot\|$ means the norm in $L^2(-\frac{1}{2}, \frac{1}{2})$; the correct notion should be clear from the context. $(\cdot, \cdot)$ always denotes the scalar product associated with $\|\cdot\|$.

In order to cope with the divergence constraint $(2.2)_2$ we make use of the poloidal-toroidal decomposition [SW]:

$$\begin{aligned} \mathbf{u} &= \nabla \times (\nabla \times (\varphi\, \mathbf{e}_z)) + \nabla \times (\psi\, \mathbf{e}_z) + \mathbf{F} \\ &=: \ \ \varphi + \ \ \psi + \mathbf{F}. \end{aligned} \tag{2.4}$$

Here $\mathbf{e}_z = (0, 0, 1)^{\mathrm{T}}$. The functions φ and ψ are determined uniquely if one requires them to be periodic with respect to $\mathcal{P}$ and to fulfill $\int_{\mathcal{P}} \varphi(x, y, z)\, dx\, dy = \int_{\mathcal{P}} \psi(x, y, z)\, dx\, dy = 0$ for every $z \in (-\frac{1}{2}, \frac{1}{2})$. The first part in (2.4) is called the poloidal part of $\mathbf{u}$ and the second part the toroidal one. The third part, the mean flow, depends only on z and has a constant third component. These three parts are mutually orthogonal in $L^2(\Omega)^3$. The vector operators and have the form

$$\varphi = \begin{pmatrix} \partial_x \partial_z \varphi \\ \partial_y \partial_z \varphi \\ (-\Delta_2)\varphi \end{pmatrix}, \qquad \psi = \begin{pmatrix} \partial_y \psi \\ -\partial_x \psi \\ 0 \end{pmatrix},$$

where $\Delta_2 = \partial_x^2 + \partial_y^2$ is the horizontal Laplacian. The boundary conditions (2.3) for $\mathbf{u}$ transform into

$$\varphi = \partial_z \varphi = 0, \quad \psi = 0, \quad F_x = F_y = 0 \qquad \text{for} \quad z = \pm\frac{1}{2}, \tag{2.5}$$

and $F_z(z) \equiv 0$. Applying the operators and to $(2.2)_1$ as well as taking the mean with respect to $\mathcal{P}$, the system (2.2) can equivalently be formulated in terms of the new variables $(\varphi, \psi, F_x, F_y)$:

(2.6)
$$
\begin{aligned}
(-\Delta)(-\Delta_2)\partial_t\varphi + \Delta^2(-\Delta_2)\varphi - \operatorname{Re} z\,(-\Delta)(-\Delta_2)\partial_x\varphi + \quad \cdot (\mathbf{u} \cdot \nabla\mathbf{u}) &= 0,\\
(-\Delta_2)\partial_t\psi + (-\Delta)(-\Delta_2)\psi - \operatorname{Re} z\,(-\Delta_2)\partial_x\psi + \operatorname{Re}(-\Delta_2)\partial_y\varphi - \quad \cdot (\mathbf{u} \cdot \nabla\mathbf{u}) &= 0,\\
\partial_t F_x + (-\partial_z^2)F_x + \tfrac{1}{|\mathcal{P}|}\textstyle\int_{\mathcal{P}} \tilde{\mathbf{u}} \cdot \nabla\tilde{u}_x \, dxdy &= 0,\\
\partial_t F_y + (-\partial_z^2)F_y + \tfrac{1}{|\mathcal{P}|}\textstyle\int_{\mathcal{P}} \tilde{\mathbf{u}} \cdot \nabla\tilde{u}_y \, dxdy &= 0.
\end{aligned}
$$

$\tilde{\mathbf{u}} := \quad \varphi + \quad \psi$ is that part of $\mathbf{u}$ which has vanishing mean value over $\mathcal{P}$, and $|\mathcal{P}| := \frac{4\pi^2}{\alpha\beta}$ denotes the volume of $\mathcal{P}$.

With $\Phi := (\varphi, \psi, F_x, F_y)^{\mathrm{T}}$ a neat matrix notation can be used for system (2.6):

$$
\mathcal{B}\,\partial_t\Phi + \mathcal{A}\Phi - \operatorname{Re}\mathcal{C}\Phi + \mathcal{M}(\Phi, \Phi) = 0. \tag{2.7}
$$

Here, $\mathcal{B}$ and $\mathcal{A}$ are diagonal matrix operators, $\mathcal{C}$ is a nonnormal interaction matrix, and $\mathcal{M}$ is a bilinear form. The operator $\mathcal{A}$, for example, has the form

$$
\mathcal{A} = \operatorname{diag}\big(\Delta^2(-\Delta_2), (-\Delta)(-\Delta_2), (-\partial_z^2), (-\partial_z^2)\big)
$$

acting in the Hilbert space

$$
\mathcal{H} := L^2_M(\Omega) \times L^2_M(\Omega) \times L^2\left(\left(-\frac{1}{2}, \frac{1}{2}\right)\right) \times L^2\left(\left(-\frac{1}{2}, \frac{1}{2}\right)\right),
$$

where $L^2_M(\Omega)$ denotes the space $\{f \in L^2(\Omega) \mid \int_{\mathcal{P}} f(x,y,z)\,dxdy = 0$ for a.e. $z \in (-\frac{1}{2}, \frac{1}{2})\}$. The domain $D(\mathcal{A})$ is most easily described in terms of a Fourier mode expansion for φ and ψ with respect to the horizontal variables x and y:

$$
\varphi(x,y,z) = \frac{1}{\sqrt{|\mathcal{P}|}} \sum_{\in\mathbb{Z}^2\setminus\{0\}} a \;\; (z) e^{i(\alpha\kappa_1 x + \beta\kappa_2 y)}, \tag{2.8}
$$

$$
\psi(x,y,z) = \frac{1}{\sqrt{|\mathcal{P}|}} \sum_{\in\mathbb{Z}^2\setminus\{0\}} b \;\; (z) e^{i(\alpha\kappa_1 x + \beta\kappa_2 y)}. \tag{2.9}
$$

We then define (cf. [KS, Wa])

$$
D(\mathcal{A}) = D(\Delta^2(-\Delta_2)) \times D((-\Delta)(-\Delta_2)) \times D(-\partial_z^2) \times D(-\partial_z^2),
$$

where

$$
\begin{aligned}
D(\Delta^2(-\Delta_2)) = \Bigg\{\varphi \;\Bigg|\; &\varphi \text{ expanded as in (2.8)},\\
&a \;\; \in H^4\left(\left(-\frac{1}{2}, \frac{1}{2}\right)\right), \quad a \;\; = \partial_z a \;\; = 0 \quad \text{at} \quad z = \pm\frac{1}{2},\\
&\sum_{\in\mathbb{Z}^2\setminus\{0\}} (\alpha^2\kappa_1^2 + \beta^2\kappa_2^2)^2 \int_{-1/2}^{1/2} |(-\partial_z^2 + \alpha^2\kappa_1^2 + \beta^2\kappa_2^2)^2 a \;\; (z)|^2 \, dz < \infty \Bigg\},
\end{aligned}
$$

$$D((-\Delta)(-\Delta_2)) = \Bigg\{ \psi \;\Bigg|\; \psi \text{ expanded as in (2.9)},$$

$$b \;\in H^2\left(\left(-\frac{1}{2}, \frac{1}{2}\right)\right), \quad b \;= 0 \quad \text{at} \quad z = \pm\frac{1}{2},$$

$$\sum_{\in \mathbb{Z}^2\setminus\{0\}} (\alpha^2\kappa_1^2 + \beta^2\kappa_2^2)^2 \int_{-1/2}^{1/2} |(-\partial_z^2 + \alpha^2\kappa_1^2 + \beta^2\kappa_2^2) b \;(z)|^2\, dz < \infty \Bigg\},$$

and

$$D(-\partial_z^2) = H^2\left(\left(-\frac{1}{2}, \frac{1}{2}\right)\right) \cap \mathring{H}^1\left(\left(-\frac{1}{2}, \frac{1}{2}\right)\right).$$

With these definitions $\mathcal{A}$ is a self-adjoint and strictly positive operator. Thus, fractional powers of $\mathcal{A}$ make sense and can analogously be explained in terms of the expansions (2.8) and (2.9). Similar definitions apply to the operators $\mathcal{B}$ and $\mathcal{C}$.

A natural class of vector fields within which (2.7) can locally be uniquely solved is given by (cf. [Wa])

$$\Phi \in L^2((0,T), \mathcal{D}(\mathcal{A})), \qquad \partial_t \Phi \in L^2((0,T), \mathcal{D}(\mathcal{B})), \tag{2.10}$$

and, as a consequence,

$$\Phi \in C^0([0,T], I)$$

with I being an appropriate interpolation space between $D(\mathcal{A})$ and $D(\mathcal{B})$. Going back to (2.2) we obtain from (2.10) at least a solution $(\mathbf{u}, p)$ with

(2.11)

$$\mathbf{u} \in L^2((0,T), D(-\Delta)) \cap C^0([0,T], D((-\Delta)^{1/2})), \qquad \partial_t \mathbf{u} \in L^2((0,T), L^2(\Omega)),$$

$$\nabla p \in L^2((0,T), L^2(\Omega)),$$

where $D(-\Delta) = \{\mathbf{u} \in (H^2(\Omega))^3 \mid \mathbf{u} \text{ periodic in } x \text{ and } y,\ \mathbf{u} = 0 \text{ at } z = \pm\frac{1}{2}\}$. This is the usual notion of a strong solution. On the other hand, strong solutions have further regularity properties. In particular, decomposing $\mathbf{u}$ from the class (2.11) in its poloidal and toroidal part and the mean flow, Φ can be shown to lie in the class (2.10). In the following we work with solutions within this class. All manipulations with $\mathbf{u}$ (or Φ) and its horizontal derivatives $\partial_x \mathbf{u}, \partial_y \mathbf{u}$ in the subsequent sections are then justified.

The energy of the system (in the volume Ω) becomes in the new variables[2]

$$E = \frac{1}{2}\,\|\mathbf{u}\|^2 = \frac{1}{2}\Big\{\| \;\varphi\|^2 + \| \;\psi\|^2 + |\mathcal{P}|\|\mathbf{F}\|^2\Big\}, \tag{2.12}$$

and the variational expression determining Re_E takes the form (cf. [KS])

$$\frac{|\Re(u_x, u_z)|}{\|\nabla \mathbf{u}\|^2} = \frac{|\Re((-\Delta_2)\varphi, \partial_x\partial_z\varphi + \partial_y\psi + F_x)|}{\|(-\Delta) \;\varphi\|^2 + \| \;\psi\|^2 + |\mathcal{P}|\|\partial_z \mathbf{F}\|^2}. \tag{2.13}$$

[2] We use the usual notation for L^2-scalar products of vector- or tensor-type quantities. Thus, there is, e.g., $\|\mathbf{u}\|^2 = (\mathbf{u}, \mathbf{u}) = \sum_{i=1}^3 (u_i, u_i)$ or $\|\nabla \mathbf{u}\|^2 = (\nabla \mathbf{u}, \nabla \mathbf{u}) = \sum_{i,j=1}^3 (\partial_i u_j, \partial_i u_j)$. Note that $\nabla \mathbf{u}$ is understood in the sense of a tensor product, whereas $\mathbf{u} \cdot \nabla = \sum_{i=1}^3 u_i \partial_i$ means the scalar product in $\mathbb{R}^3$.

For later convenience we admit here complex valued velocity fields. Thus, the real part (denoted by $\Re$) of the interaction term appears in the numerator of (2.13). Re_E is then given by

$$\mathrm{Re}_E^{-1} = \sup_{(\alpha,\beta)\in\mathbb{R}_+^2} \sup_{(\varphi,\psi)\in\mathcal{V}_{\alpha\beta}} \frac{|\Re((-\Delta_2)\varphi,(\partial_x\partial_z\varphi+\partial_y\psi))|}{\|(-\Delta)\ \ \varphi\|^2+\|\ \ \psi\|^2}. \tag{2.14}$$

Note that $\mathbf{F}$ does not depend on x or y and, therefore, drops from the numerator of (2.13). Thus, $\mathbf{F}$ does not contribute to the supremum of (2.13) and can be omitted altogether.

The variational class $\mathcal{V}_{\alpha\beta}$ should reflect the mean value condition, the boundary conditions, and the periodicity of the functions φ and ψ. Moreover, it should ensure that the supremum is in fact attained. A suitable choice is $\mathcal{V}_{\alpha\beta} = D(\tilde{\mathcal{A}}^{1/2}) \setminus \{(0,0)\}$, where $\tilde{\mathcal{A}}$ is that part of $\mathcal{A}$ that is operating on (φ,ψ) in the Hilbert space $\tilde{\mathcal{H}} := L_M^2(\Omega)\times L_M^2(\Omega)$.

If the class $\mathcal{V}_{\alpha\beta}$ of admissible functions is restricted to the class $\mathcal{V}_\alpha$ of functions depending only on x and z, or to the class $\mathcal{V}_\beta$ of functions depending only on y and z, the corresponding two-dimensional limits Re_E^x and Re_E^y are determined by the following simplified variational expressions:

$$\frac{1}{\mathrm{Re}_E^y} = \sup_{\beta\in\mathbb{R}_+} \sup_{(\varphi,\psi)\in\mathcal{V}_\beta} \frac{|\Re((-\Delta_2)\varphi,\partial_y\psi)|}{\|(-\Delta)\partial_y\varphi\|^2+\|\ \ \psi\|^2}, \tag{2.15}$$

$$\frac{1}{\mathrm{Re}_E^x} = \sup_{\alpha\in\mathbb{R}_+} \sup_{(\varphi,0)\in\mathcal{V}_\alpha} \frac{|\Re((-\Delta_2)\varphi,\partial_x\partial_z\varphi)|}{\|(-\Delta)\partial_x\varphi\|^2}. \tag{2.16}$$

It is well known that $\mathrm{Re}_E = \mathrm{Re}_E^y = 82.6\ldots$ and $\mathrm{Re}_E^x = 177.2\ldots$ (cf. [Or, Jo, Bu]).

Applying the matrix notation the variational expression (2.13) takes the form

$$\frac{|(\Phi,\hat{\mathcal{C}}\Phi)|}{\|\mathcal{A}^{1/2}\Phi\|^2}$$

with the symmetric lower order operator

$$\hat{\mathcal{C}} = \frac{1}{2}\begin{pmatrix} 2(-\Delta_2)\partial_x\partial_z & (-\Delta_2)\partial_y & (-\Delta_2) & 0 \\ -(-\Delta_2)\partial_y & 0 & 0 & 0 \\ (-\Delta_2) & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

Thus, $\mathcal{A}^{-1/2}\hat{\mathcal{C}}\mathcal{A}^{-1/2}$ is a self-adjoint and compact operator in $\mathcal{H}$ and the supremum (with respect to $(\varphi,\psi)\in D(\tilde{\mathcal{A}}^{1/2})$) in (2.14) is actually a maximum. This argument applies, of course, also to the suprema in (2.15) and (2.16).

3. Generalized functional and variational problem. The usual method to proceed from the energy functional to a generalized one is to introduce additional coupling parameters and possibly additional derivatives in order to weigh the dynamic variables in an optimal way. For this purpose the generalized energy balance is considered and (analogously to the energy method) the ratio of the interaction term over the dissipative term is maximized with respect to the admissible functions. This maximum still depends on the coupling parameters and possibly discrete parameters counting the additional derivatives. Minimizing with respect to these parameters furnishes optimal (generalized) energy limits. Therefore, the first problem is to find functionals which furnish larger stability limits than those provided by the energy functional. Considering the functional (2.12) with $\mathbf{F} \equiv 0$ (as already noted, the mean flow does not contribute to the maximum in the variational problem) there is, however, not much freedom to introduce additional parameters. An obvious choice is the functional

$$\mathcal{E}_1[\varphi, \psi] := \frac{1}{2}\Big\{\| \ \ \varphi\|^2 + \lambda \, \| \ \ \psi\|^2\Big\} \tag{3.1}$$

with $0 < \lambda < \infty$. Taking the scalar product of $(2.6)_{1,2}$ with (φ, ψ) in $\tilde{\mathcal{H}}$ and using the boundary conditions (2.5) one obtains the generalized energy balance

$$\partial_t \mathcal{E}_1 = -\mathcal{D}_1 + \mathrm{Re}\, \mathcal{I}_1 + \mathcal{N}_1 \tag{3.2}$$

with

$$\begin{aligned} \mathcal{D}_1[\varphi, \psi] &:= \|(-\Delta) \ \ \varphi\|^2 + \lambda \| \ \ \psi\|^2, \\ \mathcal{I}_1[\varphi, \psi] &:= \Re\big((-\Delta_2)\varphi, \partial_x \partial_z \varphi\big) + \lambda \, \Re\big((-\Delta_2)\varphi, \partial_y \psi\big), \\ \mathcal{N}_1[\varphi, \psi, \mathbf{F}] &:= -\Re\big((\mathbf{u} \cdot \nabla \mathbf{u}), \ \ \varphi + \lambda \ \ \psi\big). \end{aligned} \tag{3.3}$$

The generalized energy limit $\mathrm{Re}_{\mathcal{E}}$ is then determined by

$$\begin{aligned} {\mathrm{Re}_{\mathcal{E}}}^{-1} &= \sup_{(\alpha,\beta) \in \mathbb{R}^2_+} \ \sup_{(\varphi,\psi) \in \mathcal{V}_{\alpha\beta}} \frac{\mathcal{I}_1}{\mathcal{D}_1}[\varphi, \psi] \\ &= \sup_{(\alpha,\beta) \in \mathbb{R}^2_+} \ \sup_{(\varphi,\psi) \in \mathcal{V}_{\alpha\beta}} \frac{|\Re((-\Delta_2)\varphi, \partial_x \partial_z \varphi) + \lambda \, \Re((-\Delta_2)\varphi, \partial_y \psi)|}{\|(-\Delta) \ \ \varphi\|^2 + \lambda \, \| \ \ \psi\|^2}. \end{aligned} \tag{3.4}$$

Note that in (3.4) $\mathcal{I}_1$ can always be replaced by $|\mathcal{I}_1|$; as with $(\varphi(x, y, z), \psi(x, y, z)) \in \mathcal{V}_{\alpha\beta}$, $(\varphi(-x, -y, z), \psi(-x, -y, z))$ is also admissible. Thus, $\mathcal{I}_1$ can always be chosen positive without affecting $\mathcal{D}_1$.

A comparison of (3.4) with the two-dimensional variational expressions (2.15) and (2.16) already furnishes some bounds on $\mathrm{Re}_{\mathcal{E}}$: Setting $\varphi = \varphi(x, z)$, $\psi = 0$ in (3.4) reduces the variational expression to that in (2.16), which implies the bound $\mathrm{Re}_{\mathcal{E}} \le \mathrm{Re}_E^x = 177.2\ldots$ for all $0 < \lambda < \infty$. For $\lambda \ge 1$ the substitution $\tilde{\psi} := \lambda \psi$ allows the estimate

$$\begin{aligned} &\frac{|\Re((-\Delta_2)\varphi, \partial_x \partial_z \varphi) + \lambda \, \Re((-\Delta_2)\varphi, \partial_y \psi)|}{\|(-\Delta) \ \ \varphi\|^2 + \lambda \, \| \ \ \psi\|^2} = \frac{|\Re((-\Delta_2)\varphi, \partial_x \partial_z \varphi) + \Re((-\Delta_2)\varphi, \partial_y \tilde{\psi})|}{\|(-\Delta) \ \ \varphi\|^2 + \frac{1}{\lambda} \| \ \ \tilde{\psi}\|^2} \\ &\ge \frac{|\Re((-\Delta_2)\varphi, \partial_x \partial_z \varphi) + \Re((-\Delta_2)\varphi, \partial_y \tilde{\psi})|}{\|(-\Delta) \ \ \varphi\|^2 + \| \ \ \tilde{\psi}\|^2}, \end{aligned}$$

and restricting φ and $\tilde{\psi}$ to functions independent of x furnishes the bound $\mathrm{Re}_{\mathcal{E}} \le \mathrm{Re}_E^y = \mathrm{Re}_E = 82.6\ldots$ for $\lambda \ge 1$. Thus the question remains whether $\mathrm{Re}_{\mathcal{E}}$ does exceed Re_E for some $0 < \lambda < 1$.

A numerical computation indicates that $\mathrm{Re}_{\mathcal{E}}$ attains its upper bound Re_E^x for sufficiently small values of λ (cf. Appendix B). In order to prove this, consider the variational expression

$$\frac{\mathcal{I}_1}{\mathcal{D}_1}[\varphi, \hat{\psi}] = \frac{|\Re((-\Delta_2)\varphi, \partial_x \partial_z \varphi) + \sqrt{\lambda}\, \Re((-\Delta_2)\varphi, \partial_y \hat{\psi})|}{\|(-\Delta) \ \ \varphi\|^2 + \| \ \ \hat{\psi}\|^2}, \tag{3.5}$$

where $\hat{\psi} := \sqrt{\lambda}\,\psi$. Now, inserting the mode expansions (2.8) and (2.9) for φ and $\hat{\psi}$ in (3.5) observe that the maximum for a fixed periodicity cell $\mathcal{P}$ is attained by a single mode. This can be seen as follows: Assume the maximum is attained by a (possibly infinite) linear combination of modes. By inserting this combination into the variational expression (3.5), the numerator as well as the denominator decomposes into a sum of bilinear terms each containing a single mode. Without restriction the modes can be chosen such that the expansion of the numerator contains only nonnegative terms. Applying Lemma 1 (cf. Appendix A) we can select a single mode with maximal ratio, which at most increases the value of the variational expression. Let $\ \in \mathbb{Z}^2 \setminus \{0\}$ be this maximal mode. With the abbreviation $\tilde{\alpha} := \kappa_1\alpha$, $\tilde{\beta} := \kappa_2\beta$, $\tilde{a}(z) := a\ \ (z)$, $\tilde{b}(z) := b\ \ (z)$ we obtain

$$\frac{\mathcal{I}_1}{\mathcal{D}_1}[\tilde{a},\tilde{b},\tilde{\alpha},\tilde{\beta}] = \frac{\tilde{\alpha}\,|\Im(\tilde{a},\tilde{a}')| + \sqrt{\lambda}\,\tilde{\beta}\,|\Im(\tilde{a},\tilde{b})|}{\|(\tilde{\alpha}^2+\tilde{\beta}^2)\tilde{a}-\tilde{a}''\|^2 + (\tilde{\alpha}^2+\tilde{\beta}^2)\|\tilde{b}\|^2 + \|\tilde{b}'\|^2}$$

(3.6)

$$\leq \max\left\{ \frac{\tilde{\alpha}\,|\Im(\tilde{a},\tilde{\alpha}')|}{\tilde{\alpha}^4\|\tilde{a}\|^2 + 2\tilde{\alpha}^2\|\tilde{a}'\|^2 + \|\tilde{a}''\|^2},\ \sqrt{\lambda}\,\frac{\tilde{\beta}\,|\Im(\tilde{a},\tilde{b})|}{\tilde{\beta}^4\|\tilde{a}\|^2 + 2\tilde{\beta}^2\|\tilde{a}'\|^2 + \tilde{\beta}^2\|\tilde{b}\|^2 + \|\tilde{b}'\|^2} \right\},$$

where we used partial integration and Lemma 1 in the last line. Abbreviating the first term in (3.6) with $\mathcal{F}_1[\tilde{a},\tilde{\alpha}]$ and the second with $\mathcal{F}_2[\tilde{a},\tilde{b},\tilde{\alpha}]$, it follows from (3.4)–(3.6) that

$$\text{(3.7)}\qquad {\mathrm{Re}_{\mathcal{E}}}^{-1} = \max\left\{ \sup_{\tilde{\alpha}\in\mathbb{R}_+}\ \sup_{(\tilde{a},0)\in\mathcal{W}} \mathcal{F}_1[\tilde{a},\tilde{\alpha}],\ \sqrt{\lambda}\sup_{\tilde{\beta}\in\mathbb{R}_+}\ \sup_{(\tilde{a},\tilde{b})\in\mathcal{W}} \mathcal{F}_2[\tilde{a},\tilde{b},\tilde{\beta}] \right\},$$

with

$$\mathcal{W} = \left\{ (a,b) \in H^4\left(\left(-\frac{1}{2},\frac{1}{2}\right)\right) \times H^2\left(\left(-\frac{1}{2},\frac{1}{2}\right)\right) \,\middle|\, a = \partial_z a = b = 0 \text{ at } z = \pm\frac{1}{2} \right\} \setminus \{0\}.$$

Inserting the mode expansion (2.8) into (2.16), the first term in (3.7) turns out to be $\frac{1}{\mathrm{Re}_E^x}$, whereas $\mathcal{F}_2[\tilde{a},\tilde{b},\tilde{\beta}]$ is estimated with the help of inequality (A.2) as follows:

$$\begin{aligned}\mathcal{F}_2[\tilde{a},\tilde{b},\tilde{\beta}] &\leq \frac{\tilde{\beta}\,\|\tilde{a}\|\|\tilde{b}\|}{(\tilde{\beta}^4+2\tilde{\beta}^2\pi^2)\|\tilde{a}\|^2 + (\tilde{\beta}^2+\pi^2)\|\tilde{b}\|^2} \leq \frac{\tilde{\beta}}{2[(\tilde{\beta}^4+2\tilde{\beta}^2\pi^2)(\tilde{\beta}^2+\pi^2)]^{1/2}} \\ &\leq \frac{1}{2\sqrt{2}\,\pi^2}.\end{aligned}$$

Therefore, by choosing $\sqrt{\lambda} \leq \frac{2\sqrt{2}\,\pi^2}{\mathrm{Re}_E^x}$, (3.7) yields $\mathrm{Re}_{\mathcal{E}} \geq \mathrm{Re}_E^x$, hence

$$\mathrm{Re}_{\mathcal{E}} = \mathrm{Re}_E^x.$$

We formulate this result in the following proposition.

Proposition 1. *For* $0 < \lambda < \frac{8\pi^4}{\mathrm{Re}_E^x} \approx 0.025$, $0 < \mathrm{Re} < \mathrm{Re}_{\mathcal{E}}$ *with* $\mathrm{Re}_{\mathcal{E}} = \mathrm{Re}_E^x = 177.2\ldots$, $(\alpha,\beta) \in \mathbb{R}_+^2$, *and* $(\varphi,\psi) \in \mathcal{V}_{\alpha,\beta} = D(\tilde{\mathcal{A}}^{1/2}) \setminus \{(0,0)\}$ *with* $D(\tilde{\mathcal{A}}^{1/2})$, *as explained in section* 2, *we have the bound*

$$\text{(3.8)}\qquad \mathrm{Re}\,\frac{\mathcal{I}_1}{\mathcal{D}_1} \leq \frac{\mathrm{Re}}{\mathrm{Re}_{\mathcal{E}}} < 1,$$

where

$$\frac{\mathcal{I}_1}{\mathcal{D}_1} = \frac{|\Re((-\Delta_2)\varphi, \partial_x\partial_z\varphi) + \lambda\,\Re((-\Delta_2)\varphi, \partial_y\psi)|}{\|(-\Delta)\ \ \varphi\|^2 + \lambda\,\|\ \ \psi\|^2}.$$

Remarks. 1. The numerical computation in Appendix B indicates coincidence of $\mathrm{Re}_{\mathcal{E}}$ with Re_E^x for values of λ up to $\lambda \approx 0.042$.

2. Whether other functionals provide even larger stability limits is an open problem. Another candidate which failed to provide a larger stability limit has been discussed in [KT].

4. Nonlinear stability. For $\lambda \neq 1$ the nonlinear term $\mathcal{N}_1$ in (3.2) does not vanish. In order to dominate this term we introduce a second part $\mathcal{E}_2$ of the generalized energy functional $\mathcal{E}$,

$$\mathcal{E}_2[\mathbf{u}, \mathbf{F}] := \frac{1}{2}\{\sigma\|\ \ \mathbf{u}\|^2 + \rho\,|\mathcal{P}|\|\mathbf{F}\|^2\}, \tag{4.1}$$

with yet undetermined nonnegative coupling parameters σ and ρ.

By scalar multiplication of (2.2) with $\sigma\Delta_2\mathbf{u}$ and of $(2.6)_{3,4}$ with ρF_x, ρF_y and using (2.3) and (2.5), we arrive at

$$\partial_t\mathcal{E}_2 = -\mathcal{D}_2 + \mathrm{Re}\,\mathcal{I}_2 + \mathcal{N}_2, \tag{4.2}$$

where[3]

$$\begin{aligned} &\mathcal{D}_2[\mathbf{u}, \mathbf{F}] = \sigma\|\ \ \mathbf{u}\|^2 + \rho\,|\mathcal{P}|\|\mathbf{F}'\|^2, \\ &\mathcal{I}_2[\mathbf{u}, \mathbf{F}] = \sigma\,\Re(\ \ u_z,\ \ u_x), \\ &\mathcal{N}_2[\mathbf{u}, \mathbf{F}] = -\sigma\,\Re(\ \ \mathbf{u}\cdot\nabla\mathbf{u},\ \ \mathbf{u}) - \rho\,\Re(\tilde{\mathbf{u}}\cdot\nabla\tilde{\mathbf{u}}, \mathbf{F}). \end{aligned} \tag{4.3}$$

By defining

$$\Delta\mathrm{Re} := 1 - \frac{\mathrm{Re}}{\mathrm{Re}_{\mathcal{E}}} \tag{4.4}$$

and

$$\mathcal{D} := \Delta\mathrm{Re}\,\mathcal{D}_1 + \mathcal{D}_2, \tag{4.5}$$

the interaction term $\mathrm{Re}\,\mathcal{I}_2$ can be estimated in terms of $\mathcal{D}$:

$$\mathcal{I}_2 \leq \sigma|(\ \ u_z,\ \ u_x)| \leq \sigma^{1/2}\|\ \ (-\Delta_2)\varphi\|\,\sigma^{1/2}\|\ \ \mathbf{u}\| \leq \sigma^{1/2}\mathcal{D}_1^{1/2}(2\mathcal{E}_2)^{1/2}.$$

Using $2\mathcal{E}_2 \leq \frac{\mathcal{D}_2}{\pi^2}$, which follows with (A.2), and setting

$$\sigma := \frac{\pi^2\,\Delta\mathrm{Re}}{\mathrm{Re}^2}, \tag{4.6}$$

we obtain

$$\mathrm{Re}\,\mathcal{I}_2 \leq (\Delta\mathrm{Re})^{1/2}\mathcal{D}_1^{1/2}\mathcal{D}_2^{1/2} \leq \frac{1}{2}\,(\Delta\mathrm{Re}\,\mathcal{D}_1 + \mathcal{D}_2) = \frac{1}{2}\,\mathcal{D}. \tag{4.7}$$

[3]Note that no boundary terms arise in (4.2) since the terms in $\mathcal{E}_2$ differ from those in the ordinary energy at most by *horizontal* derivatives.

We estimate next the nonlinear parts in terms of $\mathcal{D}\mathcal{E}^{1/2}$, $\mathcal{E} := \mathcal{E}_1 + \mathcal{E}_2$, and begin with $\mathcal{N}_1$:

$$\mathcal{N}_1 \le |(\mathbf{u}\cdot\nabla\mathbf{u},\ \ \varphi + \lambda\ \ \psi)| \le \operatorname{ess\,sup}_\Omega |\mathbf{u}|\,\|\nabla\mathbf{u}\|(\|\ \ \varphi\| + \lambda\,\|\ \ \psi\|).$$

The three factors are estimated separately. With (A.8) we obtain for the first factor

$$\|\mathbf{u}\|_\infty \le \frac{C}{\sqrt{2}}\,\|\ \ \tilde{\mathbf{u}}\| + \sqrt{\frac{2}{\pi}}\|\mathbf{F}'\|,$$

where $C = 8(\frac{\sqrt{2}}{m})^{3/2}$, and under the condition

$$\rho \ge \frac{4\,\sigma}{\pi\, C^2|\mathcal{P}|} \tag{4.8}$$

we get further

$$\|\mathbf{u}\|_\infty \le \frac{C}{\sqrt{2\sigma}}\Big\{\sqrt{\sigma}\,\|\ \ \tilde{\mathbf{u}}\| + (\rho\,|\mathcal{P}|)^{1/2}\|\mathbf{F}'\|\Big\} \le \frac{C}{\sqrt{\sigma}}\mathcal{D}_2^{1/2} \le \frac{C}{\sqrt{\sigma}}\mathcal{D}^{1/2}. \tag{4.9}$$

With the conditions

$$\rho \ge \lambda\,\Delta\mathrm{Re}, \qquad 0 < \lambda < 1 \tag{4.10}$$

we obtain for the second factor

$$\|\nabla\mathbf{u}\|^2 = \|\nabla\tilde{\mathbf{u}}\|^2 + |\mathcal{P}|\|\mathbf{F}'\|^2 \le \frac{\mathcal{D}_1}{\lambda} + \frac{\mathcal{D}_2}{\rho} \le \frac{1}{\lambda\,\Delta\mathrm{Re}}\,\mathcal{D};$$

thus

$$\|\nabla\mathbf{u}\| \le \frac{1}{\sqrt{\lambda\,\Delta\mathrm{Re}}}\,\mathcal{D}^{1/2}. \tag{4.11}$$

Finally, we have

$$\|\ \ \varphi\| + \lambda\,\|\ \ \psi\| \le \sqrt{1+\lambda}\,(2\mathcal{E}_1)^{1/2} \le \sqrt{2}\,\sqrt{1+\lambda}\,\mathcal{E}^{1/2}. \tag{4.12}$$

The conditions (4.8) and (4.10) are satisfied for the choice

$$\rho := \Delta\mathrm{Re}\max\Big\{\lambda, \frac{\alpha\,\beta\,m^3}{\sqrt{2}\,2^7\pi\,\mathrm{Re}^2}\Big\}, \tag{4.13}$$

and by collecting the estimates (4.9), (4.11), and (4.12) we have

$$\mathcal{N}_1 \le \frac{\sqrt{2}\,C}{\sqrt{\sigma\,\Delta\mathrm{Re}}}\,\sqrt{1+1/\lambda}\,\mathcal{D}\,\mathcal{E}^{1/2}. \tag{4.14}$$

As to $\mathcal{N}_2$, we obtain by partial integration

$$\begin{aligned}\mathcal{N}_2 &= -\sigma\,\Re\sum_{i,j=1}^{3}\sum_{n=1}^{2}\int_\Omega \partial_n u_i \partial_i u_j \partial_n \overline{u}_j\,d\tau - \rho\,\Re\sum_{i,j=1}^{3}\int_\Omega \tilde{u}_i\partial_i\tilde{u}_j\overline{F}_j\,d\tau\\ &= \sigma\,\Re\sum_{i,j=1}^{3}\sum_{n=1}^{2}\int_\Omega \partial_n u_i \partial_n\partial_i\overline{u}_j u_j\,d\tau + \rho\,\Re\sum_{n=1}^{2}\int_\Omega \tilde{u}_z\tilde{u}_n\overline{F}'_n\,d\tau.\end{aligned}$$

Estimates analogous to those for $\mathcal{N}_1$, in particular (4.9), then yield

$$
\begin{aligned}
\mathcal{N}_2 &\leq \sigma \|\mathbf{u}\|_\infty \| \;\; \mathbf{u}\| \| \;\; \mathbf{u}\| + \rho\, \|\tilde{\mathbf{u}}\|_\infty\, |\mathcal{P}|^{1/2} \|\mathbf{F}'\|\, \|\tilde{u}_z\| \\
&\leq \frac{C}{\sqrt{\sigma}}\, \mathcal{D}^{1/2} \sqrt{\sigma}\, \| \;\; \mathbf{u}\|\, (2\mathcal{E}_2)^{1/2} + \frac{C}{\sqrt{\sigma}}\, \mathcal{D}^{1/2}\, \rho\, |\mathcal{P}|^{1/2} \|\mathbf{F}'\|\, (2\mathcal{E}_1)^{1/2} \\
&\leq \frac{C}{\sqrt{\sigma}}\, \mathcal{D}^{1/2} \sqrt{1+\rho}\, \mathcal{D}_2^{1/2} (2\mathcal{E})^{1/2} \leq \frac{\sqrt{2}\, C}{\sqrt{\sigma}}\, \sqrt{1+\rho}\, \mathcal{D}\, \mathcal{E}^{1/2}.
\end{aligned} \tag{4.15}
$$

Summarizing (4.14) and (4.15) we have

$$
\mathcal{N}_1 + \mathcal{N}_2 \leq \frac{1}{2}\, \mathcal{D} \left(\frac{\mathcal{E}}{\delta} \right)^{1/2} \tag{4.16}
$$

with

$$
\delta := \frac{\sigma}{8\, C^2} \left(\sqrt{1 + 1/\lambda}\, \frac{1}{\sqrt{\Delta \mathrm{Re}}} + \sqrt{1+\rho} \right)^{-2}.
$$

Observe that the estimate (4.15) is based on the estimate (4.9), which increases the number of z-derivatives by only one. Previously used estimates (cf. [GP] or [St]) increase this number by two and do not work in our situation. On the other hand, functionals involving more z-derivatives do not work either, since there is not enough information about boundary values which would allow the necessary partial integrations [KT].

Finally, we add up equations (3.2) and (4.2), apply Proposition 1, and use the estimates (4.7) and (4.16). This yields the following for $\mathcal{E} = \mathcal{E}_1 + \mathcal{E}_2$:

$$
\begin{aligned}
\partial_t \mathcal{E} &= -\left[\mathcal{D}_1 \left(1 - \frac{\mathrm{Re}\, \mathcal{I}_1}{\mathcal{D}_1} \right) + \mathcal{D}_2 \right] + \mathrm{Re}\, \mathcal{I}_2 + \mathcal{N}_1 + \mathcal{N}_2 \\
&\leq -\mathcal{D} + \frac{1}{2}\, \mathcal{D} + \frac{1}{2}\, \mathcal{D} \left(\frac{\mathcal{E}}{\delta} \right)^{1/2} \\
&\leq -\frac{1}{2}\, \mathcal{D} \left[1 - \left(\frac{\mathcal{E}}{\delta} \right)^{1/2} \right].
\end{aligned} \tag{4.17}
$$

Inequality (4.17) implies that $\mathcal{E}(t)$ is monotonically nonincreasing if $\mathcal{E}(0) < \delta$. With

$$
\frac{1}{2}\, \mathcal{D} = \frac{1}{2}\, (\Delta \mathrm{Re}\, \mathcal{D}_1 + \mathcal{D}_2) \geq \pi^2 (\Delta \mathrm{Re}\, \mathcal{E}_1 + \mathcal{E}_2) \geq \pi^2\, \Delta \mathrm{Re}\, \mathcal{E},
$$

which follows from (A.2), (A.3), and $0 < \Delta \mathrm{Re} < 1$, we therefore have

$$
\partial_t \mathcal{E} \leq -\frac{1}{2}\, \mathcal{D} \left[1 - \left(\frac{\mathcal{E}(0)}{\delta} \right)^{1/2} \right] \leq -\pi^2\, \Delta \mathrm{Re}\, \mathcal{E} \left[1 - \left(\frac{\mathcal{E}(0)}{\delta} \right)^{1/2} \right],
$$

and integration yields

$$
\mathcal{E}(t) \leq \mathcal{E}(0) \exp \left\{ -\pi^2\, \Delta \mathrm{Re} \left[1 - \left(\frac{\mathcal{E}(0)}{\delta} \right)^{1/2} \right] t \right\}. \tag{4.18}
$$

We formulate our stability result in the following theorem.

THEOREM 2. *Let us consider perturbations* $\Phi = (\varphi, \psi, \mathbf{F})^{\mathrm{T}}$ *of the basic flow* $\mathbf{U}_0 = \mathrm{Re}(-z, 0, 0)^{\mathrm{T}}$ *in the plane Couette system satisfying globally (in time) the system* (2.6) *as a strong solution (i.e., in the sense of* (2.10)*) under rigid boundary conditions* (2.5) *and being periodic in the horizontal variables* x, y *with wave numbers* $(\alpha, \beta) \in \mathbb{R}^2_+$. *Let* $0 < \mathrm{Re} < \mathrm{Re}_{\mathcal{E}} = 177.2\ldots$, $\Delta\mathrm{Re} = 1 - \frac{\mathrm{Re}}{\mathrm{Re}_{\mathcal{E}}}$, $C = 8(\frac{\sqrt{2}}{m})^{3/2}$, *and* $m = \min(\alpha, \beta)$. *Consider, furthermore, the generalized energy functional*

$$\mathcal{E}[\varphi, \psi, \mathbf{F}] = \frac{1}{2}\left\{\| \ \varphi\|^2 + \lambda \, \| \ \psi\|^2 + \sigma \, \| \ \mathbf{u}\|^2 + \rho \, \frac{4\pi^2}{\alpha\beta} \, \|\mathbf{F}\|^2\right\}$$

with coupling parameters $0 < \lambda < \frac{8\pi^4}{\mathrm{Re}_{\mathcal{E}}}$ *and*

$$\sigma = \frac{\pi^2 \, \Delta\mathrm{Re}}{\mathrm{Re}^2}, \qquad \rho = \Delta\mathrm{Re} \max\left\{\lambda, \frac{\alpha \, \beta \, m^3}{\sqrt{2} \, 2^7 \pi \, \mathrm{Re}^2}\right\}.$$

Then, the solution $(\varphi, \psi, \mathbf{F})$ *of* (2.5) *and* (2.6) *decays in the norm* $\mathcal{E}^{1/2}$ *exponentially to zero provided the initial value satisfies*

$$\mathcal{E}(0) < \delta = \frac{\sigma}{8\,C^2}\left(\sqrt{1 + 1/\lambda}\,\frac{1}{\sqrt{\Delta\mathrm{Re}}} + \sqrt{1+\rho}\right)^{-2}. \tag{4.19}$$

Remarks. 1. The functional $\mathcal{E}$ dominates the classical energy $E = \frac{1}{2}\,\|\mathbf{u}\|^2$. Therefore, $E(t)$ also decays to zero for $\mathrm{Re} < \mathrm{Re}_{\mathcal{E}}$. However, for $\mathrm{Re} > \mathrm{Re}_E$, $E(t)$ does not necessarily decay monotonically.

2. We did not try to obtain optimal (i.e., as large as possible) stability balls δ. Considering the restricted Reynolds number range the stability balls have not yet any importance for experiments. The emphasis of the present paper is on demonstrating that the method of generalized energy functionals also works for rigid boundary conditions.

3. The stability balls δ vanish in the limit $\Delta\mathrm{Re} \to 0$ or $m \to 0$. Asymptotically we have

$$\delta^{1/2} \sim \begin{cases} \Delta\mathrm{Re} & \text{in the limit} \quad \Delta\mathrm{Re} \to 0, \\ m^{3/2} & \text{in the limit} \quad m \to 0. \end{cases}$$

This behavior seems to be intrinsic to the functional method and it is independent of the choice of boundary conditions (cf. [RM]). The decay constant (in time) in (4.18) for a fixed value $\frac{\mathcal{E}(0)}{\delta} = const < 1$ decreases likewise with $\Delta\mathrm{Re}$ to zero, but it is independent of m. This is different from the case of free boundary conditions,[4] where arbitrarily slowly decaying modes always exist; e.g.,

$$\mathbf{u} = e^{-\alpha^2 t} \sin \alpha y \, \mathbf{e}_x, \qquad p \equiv 0$$

for any $\alpha = m > 0$.

4. There is another interesting approach, which is at least in parts rigorous and which aims at providing stability balls of power law type in the Reynolds number; they have the form $c\,\mathrm{Re}^{-\gamma}$, where c depends on the geometry but is independent of Re. The starting point of the method is a power law bound on the resolvent of the linearized

[4]Note that the Poincaré-type inequalities in [RM] have to be corrected; cf. [KX].

operator, which has been obtained so far only by numerical methods. In a second step the exponent γ can then rigorously be derived whereas c remains unknown. Such bounds, valid for all Reynolds numbers, have been obtained for Couette flow [KLH] and have recently been improved [LK].

5. More generally, Theorem 2 applies to (not necessarily global) strong solutions on their maximal intervals of existence. In particular, it provides an a priori bound on the horizontal derivatives of $\mathbf{u}$ in the $L^2(\Omega)$-norm under an explicit condition on its initial values. An interesting (but so far open) question is whether this condition, viz. (4.19), guarantees already global existence of the solution in time. The following is known in this respect [KW]: A strong solution which is conditionally stable in the energy norm on the maximal interval of existence exists globally in time (in the class (2.10)) provided its initial value is small in the norm of the interpolation space $\mathcal{I}$. This norm is, however, stronger than $\mathcal{E}^{1/2}$; in particular, it involves nontangential derivatives of $\mathbf{u}$, which are not controlled by $\mathcal{E}^{1/2}$. The required smallness depends on the steady flow to be perturbed and the stability behavior of the kinetic energy of the perturbation.

Appendix A. We collect in this appendix some more-or-less standard inequalities we made use of in the main text. Only Lemma 3, which presents a refined calculus inequality, is proved.

LEMMA 1. *Let $n \in \mathbb{N}$ and $a_\nu \geq 0$, $b_\nu > 0$ for $1 \leq \nu \leq n$. Then*

$$\frac{\sum_{\nu=1}^{n} a_\nu}{\sum_{\nu=1}^{n} b_\nu} \leq \max\left\{ \frac{a_\nu}{b_\nu} \,\middle|\, 1 \leq \nu \leq n \right\} =: M \tag{A.1}$$

and equality holds if and only if $a_\nu = M\, b_\nu$ for every ν.

Note that inequality (A.1) remains valid for $n \to \infty$.

Frequent use is made of the Poincaré-type inequalities

$$\|f\| \leq \frac{1}{\pi}\|\nabla f\|, \tag{A.2}$$

$$\|\nabla f\| \leq \frac{1}{\pi}\|\nabla\nabla f\| = \frac{1}{\pi}\|\Delta f\|, \tag{A.3}$$

which are valid for $\mathcal{P}$-periodic functions f decomposed according to

$$f(x,y,z) = \frac{1}{\sqrt{\mathcal{P}}} \sum_{\ \in \mathbb{Z}^2} f_{\ }(z) e^{i(\alpha\kappa_1 x + \beta\kappa_2 y)} \tag{A.4}$$

with (at least) $f_{\ } \in H^1((-\frac{1}{2},\frac{1}{2}))$ and (weakly) satisfying the boundary conditions $f_{\ }(\pm\frac{1}{2}) = 0$, $\ \in \mathbb{Z}^2$ (cf. Appendix A in [KX]). The inequalities (A.2) and (A.3) hold likewise for vector valued functions if each component satisfies such a decomposition.

The next two lemmata provide bounds on the sup-norm $\|\cdot\|_\infty = \operatorname{ess\,sup}|\cdot|$ in terms of the L_2-norm $\|\cdot\|_2 = \|\cdot\|$ in one and three dimensions.

LEMMA 2. *Let $f \in H^1((-\frac{1}{2},\frac{1}{2}))$ with (weakly) $f(-\frac{1}{2}) = 0$. Then*

$$\|f\|_\infty^2 \leq 2\,\|f\|\,\|f'\|. \tag{A.5}$$

LEMMA 3. *Let $f : \mathbb{R}^2 \times [-\frac{1}{2},\frac{1}{2}] \to \mathbb{R}$ be $\mathcal{P}$-periodic and decomposed according to* (A.4) *with $f_{\ } \in H^1((-\frac{1}{2},\frac{1}{2}))$ and weakly satisfying the boundary conditions $f_{\ }(\pm\frac{1}{2}) = 0$ for $\ \in \mathbb{Z}^2 \setminus \{0\}$, $f_0 = \frac{1}{\sqrt{|\mathcal{P}|}} \int_{\mathcal{P}} f(x,y,z)\, dxdy = 0$. Then*

$$\|f\|_\infty \leq C\,\|(-\Delta_2)^{1/2}\partial_z f\|^{1/2}\|(-\Delta_2) f\|^{1/2} \tag{A.6}$$

with $C := 8(\frac{\sqrt{2}}{m})^{3/2}$, $m := \min\{\alpha,\beta\}$.

Proof. With (A.4) and Lemma 2 one obtains

$$\begin{aligned}\operatorname{ess\,sup}_{\Omega}|f(x,y,z)| &\leq \operatorname{ess\,sup}_{[-1/2,1/2]} \sum_{\in\mathbb{Z}^2\setminus\{0\}} |f\ \ (z)| \\ &\leq \sqrt{2} \sum_{\in\mathbb{Z}^2\setminus\{0\}} \|f'\ \|^{1/2}\|f\ \ \|^{1/2}.\end{aligned}$$

Therefore, with Hölder's inequality

$$\begin{aligned}\|f\|_\infty &\leq \sqrt{2} \sum_{\in\mathbb{Z}^2\setminus\{0\}} \|f'\ \|^{1/2}(\alpha^2\kappa_1^2+\beta^2\kappa_2^2)^{1/4}\,\|f\ \ \|^{1/2}(\alpha^2\kappa_1^2+\beta^2\kappa_2^2)^{1/2} \\ &\qquad\qquad \times(\alpha^2\kappa_1^2+\beta^2\kappa_2^2)^{-3/4} \\ &\leq \sqrt{2}\left(\sum_{\in\mathbb{Z}^2\setminus\{0\}} \|f'\ \|^2(\alpha^2\kappa_1^2+\beta^2\kappa_2^2)\right)^{1/4}\left(\sum_{\in\mathbb{Z}^2\setminus\{0\}} \|f\ \ \|^2(\alpha^2\kappa_1^2+\beta^2\kappa_2^2)^2\right)^{1/4} \\ &\qquad \times\left(\sum_{\in\mathbb{Z}^2\setminus\{0\}}(\alpha^2\kappa_1^2+\beta^2\kappa_2^2)^{-3/2}\right)^{1/2} \\ &\leq C\,\|(-\Delta_2)^{1/2}\partial_z f\|^{1/2}\|(-\Delta_2)f\|^{1/2}.\end{aligned}$$

In the last line we used the estimate

$$\left(\sum_{\in\mathbb{Z}^2\setminus\{0\}}(\alpha^2\kappa_1^2+\beta^2\kappa_2^2)^{-3/2}\right)^{1/2} \leq 2^{5/2}\left(\frac{\sqrt{2}}{m}\right)^{3/2}$$

(cf. Lemma 4.1 in [BK]). ◻

A more convenient form of (A.6) is

$$\|f\|_\infty \leq \frac{C}{\sqrt{2}}\|\ \ f\|, \tag{A.7}$$

which follows from (A.6) by

$$\begin{aligned}\|f\|_\infty^2 &\leq \frac{C^2}{2}\left[\|(-\Delta_2)^{1/2}\partial_z f\|^2+\|(-\Delta_2)f\|^2\right] \\ &= \frac{C^2}{2}\left[(\Delta_2 f,\partial_z^2 f)+(\Delta_2 f,\Delta_2 f)\right] \\ &= \frac{C^2}{2}(\Delta_2 f,\Delta f) = \frac{C^2}{2}\|\ \ f\|^2.\end{aligned}$$

If f has a nonzero mean value f_0 the inequalities (A.2), (A.5), and (A.7) furnish

$$\|f\|_\infty \leq \|\tilde{f}\|_\infty + \|f_0\|_\infty \leq \frac{C}{\sqrt{2}}\|\ \ \tilde{f}\| + \sqrt{\frac{2}{\pi}}\,\|f_0'\|, \tag{A.8}$$

where $\tilde{f} = f - f_0$.

The inequalities (A.5)–(A.8) hold likewise for vector valued functions if each component satisfies the appropriate conditions.

Appendix B. In this appendix the variational problem (3.4) with $0 \le \lambda \le 1$ is treated on a numerical basis. We first solve the eigenvalue problem associated with the variational problem with fixed periodicity cell $\mathcal{P}$ and subsequently perform the variation with respect to $\mathcal{P}$.

The Euler–Lagrange equations with Lagrange parameter μ read

$$\begin{aligned} \Delta^2(-\Delta_2)\varphi - \frac{\mu}{2}\Big(2\,(-\Delta_2)\partial_x\partial_z\varphi + \lambda\,(-\Delta_2)\partial_y\psi\Big) &= 0, \\ \lambda\,(-\Delta)(-\Delta_2)\psi + \frac{\mu}{2}\,\lambda\,(-\Delta_2)\partial_y\varphi &= 0. \end{aligned} \tag{B.1}$$

By inserting the mode expansions (2.8) and (2.9) the system (B.1) becomes equivalent to

$$\left.\begin{aligned} D^2_{\kappa_1\alpha,\kappa_2\beta}\, a\ \ (z) - i\frac{\mu}{2}\Big(2\alpha\kappa_1\partial_z a\ \ (z) + \lambda\,\beta\kappa_2 b\ \ (z)\Big) &= 0, \\ D_{\kappa_1\alpha,\kappa_2\beta}\, b\ \ (z) + i\frac{\mu}{2}\beta\kappa_2 a\ \ (z) &= 0, \end{aligned}\right. \qquad \in \mathbb{Z}^2 \setminus \{0\} \tag{B.2}$$

with $D_{\tilde\alpha,\tilde\beta} := \tilde\alpha^2 + \tilde\beta^2 - \partial_z^2$. The system (B.2) has to be complemented with the boundary conditions

$$a\ \ = \partial_z a\ \ = b\ \ = 0 \quad \text{at} \quad z = \pm\frac{1}{2}, \qquad \in \mathbb{Z}^2 \setminus \{0\},$$

in order to have a well-posed eigenvalue problem. As explained in section 3, the maximum is attained by a single mode. Since we are ultimately interested in the maximum with respect to all periodicity cells, it is sufficient to consider the finite dimensional system

$$\begin{aligned} D^2_{\tilde\alpha,\tilde\beta}\,\tilde a(z) - i\frac{\mu}{2}\Big(2\tilde\alpha\partial_z\tilde a(z) + \lambda\,\tilde\beta\tilde b(z)\Big) &= 0, \\ D_{\tilde\alpha,\tilde\beta}\,\tilde b(z) + i\frac{\mu}{2}\tilde\beta\tilde a(z) &= 0 \end{aligned} \tag{B.3}$$

together with

$$\tilde a = \partial_z\tilde a = \tilde b = 0 \quad \text{at} \quad z = \pm\frac{1}{2}. \tag{B.4}$$

$\mathrm{Re}_{\mathcal{E}}$ is then given by

$$\mathrm{Re}_{\mathcal{E}} = \min_{(\tilde\alpha,\tilde\beta)\in\mathbb{R}^2} \mu_0(\tilde\alpha,\tilde\beta,\lambda),$$

with μ_0 being the smallest positive eigenvalue in (B.3) and (B.4). Applying a standard shooting method based on a fourth order Runge–Kutta integration, μ_0 is determined as a function of $\tilde\alpha$, $\tilde\beta$, and λ. Subsequent minimization with respect to $\tilde\alpha$ and $\tilde\beta$ furnishes $\mathrm{Re}_{\mathcal{E}}$ as a function of λ. The result is displayed in Figure 1: With decreasing λ the stability limit $\mathrm{Re}_{\mathcal{E}}$ increases from the ordinary energy limit $\mathrm{Re}_E = 82.6\ldots$ ($\lambda = 1$) up to the value $\mathrm{Re}_E^x = 177.2\ldots$ (Figure 1, left), and this value is, in fact, attained for finite λ ($\lambda \approx 0.042$; see Figure 1, right).

Acknowledgment. The authors would like to thank an anonymous referee whose comments led to an improvement of the manuscript.

WRIGGLED LAMELLAR SOLUTIONS AND THEIR STABILITY IN THE DIBLOCK COPOLYMER PROBLEM*

XIAOFENG REN† AND JUNCHENG WEI‡

Abstract. In a diblock copolymer system the free energy field depends nonlocally on the monomer density field. In addition there are two positive parameters in the constitutive relation. One of them is small, with respect to which we do singular perturbation analysis. The second one is of order 1, with respect to which we do bifurcation analysis. Combining the two techniques we find wriggled lamellar solutions of the Euler–Lagrange equation of the total free energy under a hypothesis regarding the simplicity of the principal eigenvalue, which is generically satisfied. The wriggled lamellar solutions bifurcate from the perfect lamellar solutions. The stability of the wriggled lamellar solutions is reduced to a relatively simple finite dimensional problem, which may be solved accurately by a numerical method. Our tests show that most of them are stable. The existence of such stable wriggled lamellar solutions explains why in reality the lamellar phase is fragile and often exists in distorted forms.

Key words. distortion, bifurcation, singular perturbation, stability, wriggled lamellar solution, perfect lamellar solution, diblock copolymer

1. Introduction.

Symmetry breaking distortions often appear for intrinsic reasons in systems of condensed matters that exhibit self-organization and pattern formation. We study this phenomenon in diblock copolymers. A diblock copolymer is a soft material, characterized by fluidlike disorder on the molecular scale and a high degree of order at longer length scales. A molecule in a diblock copolymer melt is a linear subchain of A monomers grafted covalently to another subchain of B monomers. Because of the repulsion between the unlike monomers, the different type subchains tend to segregate below some critical temperature, but as they are chemically bonded in chain molecules, even a complete segregation of subchains cannot lead to a macroscopic phase separation. Only a local microphase separation occurs: microdomains rich in A and B are formed. These microdomains form morphology patterns/phases in a larger scale. The most commonly observed undistorted phases are the spherical, cylindrical, and lamellar, depicted in Figure 1. Here we seek distorted, defective lamellar patterns, where the interfaces separating the microdomains, unlike the ones in Figure 1(c), are wriggled (Figure 2(b)).

We consider a scenario that a diblock copolymer melt is placed in a domain D and maintained at fixed temperature. D is scaled to have unit volume in space. Let $a \in (0,1)$ be the relative number of the A monomers in a chain molecule, and $b = 1-a$ be the relative number of the B monomers in a chain. The relative A monomer density field u is an order parameter. $u \approx 1$ stands for high concentration of A monomers.

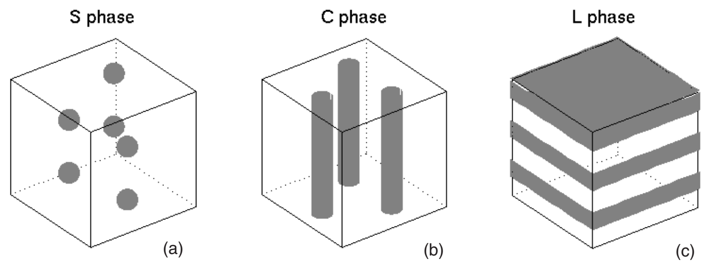

FIG. 1. *The* (a) *spherical,* (b) *cylindrical, and* (c) *lamellar morphology phases commonly observed in diblock copolymer melts. The dark color indicates the concentration of type A monomer, and the white color indicates the concentration of type B monomer.*

The melt is incompressible, and thus the relative B monomer density is $1-u$ and $u \approx 0$ stands for high concentration of B monomers.

Ohta and Kawasaki [11] introduced an equilibrium theory in which the free energy of the system is a functional of the relative A monomer density,

$$I(u) = \int_D \left\{ \frac{\epsilon^2}{2}|\nabla u|^2 + \frac{\epsilon\gamma}{2}|(-\Delta)^{-1/2}(u-a)|^2 + W(u) \right\}, \tag{1.1}$$

defined in $X_a = \{u \in W^{1,2}(D) : \overline{u} = a\}$, where $\overline{u} := \int_D u$ is the average of u on D. The original formula in [11] is given on the entire $\mathbf{R}^3$. The expression here on a bounded domain D first appeared in Nishiura and Ohnishi [9]. A mathematically more rigorous derivation is in Choksi and Ren [3]. The local function W is smooth and has the shape of a double well. It has the global minimum value 0 at two numbers: 0 and 1. To avoid unnecessary technical difficulties we assume that $W(p) = W(1-p)$. The two global minimum points are nondegenerate: $W''(0) = W''(1) \neq 0$.

The most unusual feature in (1.1) is the nonlocal expression $(-\Delta)^{-1/2}(u-a)$. It reflects the connectivity of polymer chains. $(-\Delta)^{-1/2}$ is the square root of the positive operator $(-\Delta)^{-1}$ from $\{w \in L^2(D) : \overline{w} = 0\}$ to itself. The integral of the nonlocal part in (1.1) may be rewritten as

$$\int_D |(-\Delta)^{-1/2}(u-a)|^2 = \int_D \int_D G_D(x,y)(u(x)-a)(u(y)-a)\,dxdy.$$

G_D is the Green function of $-\Delta$ with the Neumann boundary condition. It splits to a fundamental solution part and a regular part. The fundamental solution in $\mathbf{R}^3$ is

$$\frac{1}{4\pi|x-y|},$$

a long range Coulomb-type interaction, which is common in many important physical systems (see Muratov [7]).

The dimensionless parameters ϵ and γ are positive and depend on various physical quantities [3]. In the strong segregation region where morphology patterns form, ϵ is very small. The second parameter γ is of order 1 when we choose the size of the sample to be comparable to the size of the microdomains [3]. We develop a particular two-parameter perturbation method. We do singular perturbation analysis

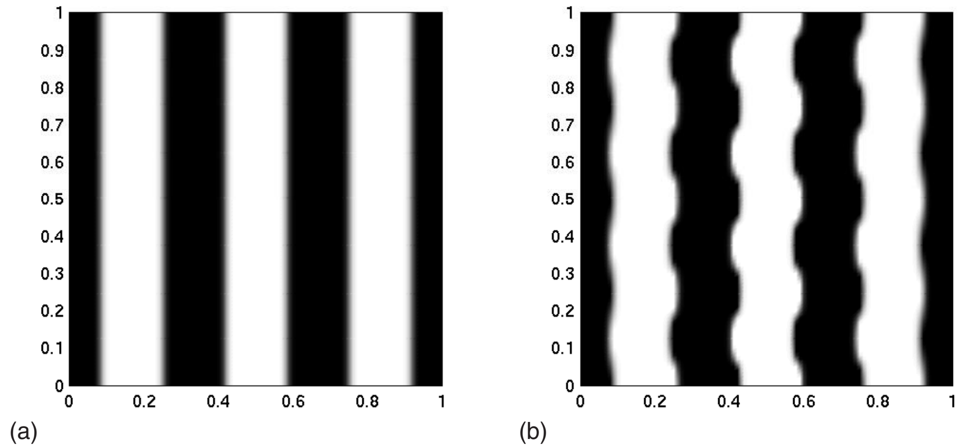

FIG. 2. *A perfect lamellar solution* (a) *and a wriggled lamellar solution* (b)*. In the dark regions the solutions are close to* 1 *and in the light regions the solutions are close to* 0*.*

with respect to ϵ and bifurcation analysis with respect to γ. The challenge is to combine these two techniques to derive fine analytical results. Even though this mathematical method is tailored for the diblock copolymer problem, we believe that it may be applied to other ones with multiple parameters. Examples include the Seul–Andelman membrane problem [25, 19], charged Langmuir monolayers [1, 16], and smectic films [24].

The Euler–Lagrange equation of I is

$$-\epsilon^2\Delta u + f(u) - \overline{f(u)} + \epsilon\gamma(-\Delta)^{-1}(u-a) = 0, \quad \partial_\nu u = 0 \text{ on } \partial D. \tag{1.2}$$

The function f is the derivative of W. The term $\overline{f(u)}$ is equal to the Lagrange multiplier corresponding to the constraint $\overline{u} = a$. Equation (1.2) may also be written as an elliptic system:

$$\begin{cases} -\epsilon^2\Delta u + f(u) + \epsilon\gamma v = \text{const}, \\ -\Delta v = u - a, \\ \partial_\nu u = \partial_\nu v = 0 \text{ on } \partial D, \\ \overline{u} - a = \overline{v} = 0. \end{cases} \tag{1.3}$$

Here const is the Lagrange multiplier.

In Ren and Wei [12] a family of lamellar solutions is found. When $D = (0,1)$, for each positive integer K there exists a 1-dimensional (1-D) local minimizer of I having K sharp interfaces if ϵ is sufficiently small (see Theorem 2.1). This 1-D local minimizer may be extended trivially to a three-dimensional (3-D) solution of (1.2) on a box. Such a solution, illustrated in Figure 2(a), models the lamellar phase, Figure 1(c), only if it is stable in the sense that it is a local minimizer of I in three dimensions. A local minimizer in three dimensions is called a *metastable* state of the physical system. It survives mild thermal fluctuation.

However, in Ren and Wei [15] it is shown that such 1-D local minimizers are not necessarily 3-D local minimizers after trivial extension. Detailed spectral information at each 1-D solution is found (see Theorem 3.1; a similar analysis for the FitzHugh–Nagumo system was carried out by Nishiura [8]). In summary, these 1-D local minimizers are not 3-D local minimizers unless K is sufficiently large or γ is sufficiently small. Moreover, the 1-D global minimizer, which is one of the 1-D local minimizers with the optimal number of interfaces

$$K_{opt} \approx \left(\frac{a^2 b^2 \gamma}{3\tau}\right)^{1/3},$$

where τ is defined in (2.2), has a delicate stability property. It actually lies near the *borderline* that separates the stable 1-D solutions from the unstable 1-D solutions.

All this suggests that the lamellar phase is only a metastable, transient state of the material. Thermal fluctuation will eventually destroy this phase. In reality one often observes the lamellar phase in distorted forms. We predict based on the model (1.1) that a defective, wriggled lamellar pattern (Figure 2(b)) exists in diblock copolymers. We point out that the wriggled lamellar pattern is typically observed in systems with competing interactions [25].

To simplify the presentation of our results, we consider wriggled lamellar solutions in two dimensions. We take $D = (0,1) \times (0,1)$ to be a 2-D square instead of a 3-D box. The 1-D local minimizers are trivially extended to D. Generalization of our results to 3-D is straightforward.

The existence of wriggled lamellar solutions is shown by a bifurcation analysis. Each perfect lamellar solution u_γ with K interfaces is stable when γ is sufficiently small. The spectrum of the second variation of I at u_γ, which consists of real eigenvalues only, lies to the right of 0. If we increase γ, the spectrum moves to the left. When γ reaches a critical value γ_{B}, the principal (smallest) eigenvalue in the spectrum becomes 0. Under Hypothesis 4.1, which is generically satisfied, the principal eigenvalue is simple. Then a new solution branch bifurcates out of $u_{\gamma_{\mathrm{B}}}$. This is a wriggled lamellar solution (Figure 2(b)). If we further increase γ, then another eigenvalue of u_γ, which is not the principal eigenvalue, may become 0, and another new solution also of a wriggled lamellar pattern bifurcates from u_γ. However, wriggled lamellar solutions that bifurcate from larger eigenvalues are unstable and physically less interesting.

Whether the wriggled lamellar solution associated with the principal eigenvalue of $u_{\gamma_{\mathrm{B}}}$ is stable is a subtle question. It is relatively easy to see that the bifurcation diagram has the shape of a pitchfork (Figure 3). The stability of the wriggled solution depends on the direction of the fork. Here we face a formidable problem. The direction is determined by the sign of a number which turns out to be terribly small (of order ϵ^5; see Lemma 5.2). To find this number we have to expand the "trivial solution" $u_{\gamma_{\mathrm{B}}}$, its principal eigenfunction corresponding to the 0 eigenvalue, and the third function $g'(0)$ defined in (5.4), with respect to ϵ. As we prove Lemma 5.2, these expansions have to be carefully managed. All the lower order terms up to ϵ^4 vanish. In the end we arrive at a quantity $S(a,K)$ that depends on a and K only. The bifurcating solution is stable if $S(a,K) > 0$ and unstable if $S(a,k) < 0$. The quantity $S(a,K)$ may be accurately calculated by a simple numerical method. Our tests, reported in section 5, show that for most values of a and K the wriggled lamellar solution bifurcating out of the principal eigenvalue is stable.

Our study of defects in diblock copolymers is partially motivated by the work of Tsori, Andelman, and Schick [27]. They considered two tilt lamellar patterns: chevron morphology and omega morphology. They used a model different from (1.1), which agrees well with experiments in the so-called weak segregation regime. In this regime interfaces separating microdomains are not sharp compared to the size of the microdomains. In our work we deal with the strong segregation regime using (1.1). Here microdomains are separated by sharp interfaces. The calculations in [27] are restricted to an ansatz without solving the Euler–Lagrange equation of their free energy functional. The wriggled lamellar patterns we find are solutions of the Euler–Lagrange equation (1.2). Many of them are proved to be stable. They are therefore genuine metastable states of the system.

Moreover, we are able to answer the question whether a 1-D global minimizer, mentioned earlier, is stable in 2-D. We will find cases where the 1-D global minimizer is stable and also cases where the 1-D global minimizer is unstable.

The paper is organized as follows. In section 2 we recall some properties of the perfect lamellar solutions u_γ. Section 3 contains some spectral information of the second variation of I at u_γ. Hypothesis 4.1, which guarantees the simplicity of the principal eigenvalue, is given in section 4. Under this condition the existence of the wriggled lamellar solutions is given in Theorem 4.2. The reduction of their stability to the positivity of $S(a,K)$ culminates in Theorem 5.4. The stability of the 1-D global minimizer is discussed after Theorem 5.4. The lengthy calculations that prove Lemma 5.2 are in Appendices B and C.

To avoid clumsy notations a quantity's dependence on ϵ is usually suppressed. For example, we write u, the lamellar solution, instead of u_ϵ. On the other hand we often emphasize a quantity's independence of ϵ with a superscript 0. For example, the limit of a lamellar solution u as $\epsilon \to 0$ is denoted by u^0. The parameter γ may vary in a compact interval of positive numbers. It is understood in this paper that all estimates are uniform in such γ. In estimates C is always a positive constant independent of ϵ and γ. Its value may vary from line to line. The L^2 inner product is denoted by $\langle \cdot, \cdot \rangle$ and the L^p norm by $\| \cdot \|_p$.

References on the mathematical aspects of the block copolymer theory include, in addition to the ones cited already, Ohnishi et al. [10], Choksi [2], Fife and Hilhorst [5], Henry [6], and Ren and Wei [14, 13, 20, 21, 22] on diblock copolymers, and Ren and Wei [17, 18] on triblock copolymers.

2. The perfect lamellar solution. The perfect lamellar solutions that serve as "trivial solutions" in the bifurcation theory are constructed in [12] by the Γ-limit theory. The findings there are summarized in the following theorem.

THEOREM 2.1 (see Ren and Wei [12]). *In 1-D for each positive integer K the functional*

$$I_1(u) = \int_0^1 \left\{ \frac{\epsilon^2}{2} \left(\frac{du}{dx} \right)^2 + \frac{\epsilon\gamma}{2} \left| \left(-\frac{d^2}{dx^2} \right)^{-1/2} (u-a) \right|^2 + W(u) \right\} dx,$$

in $\{u \in W^{1,2}(0,1) : \overline{u} = a\}$, has a local minimizer u near u^0, under the L^2 norm, when ϵ is sufficiently small. It satisfies the Euler–Lagrange equation

$$-\epsilon^2 u'' + f(u) - \overline{f(u)} + \epsilon\gamma G_0[u-a] = 0, \ u'(0) = u'(1) = 0$$

and has the properties

$$\lim_{\epsilon\to 0} \|u - u^0\|_2 = 0 \text{ and } \lim_{\epsilon \to 0} \epsilon^{-1} I_1(u) = \tau K + \frac{\gamma}{2} \int_0^1 \left| \left(-\frac{d^2}{dx^2} \right)^{-1/2} (u^0 - a) \right|^2 dx.$$

Let H be the solution of

$$-H'' + f(H) = 0 \text{ in } \mathbf{R}, \ H(-\infty) = 0, \ H(\infty) = 1, \ H(0) = \frac{1}{2}. \tag{2.1}$$

The constant τ in the theorem is defined by

$$\tau := \int_{\mathbf{R}} (H'(t))^2\, dt. \tag{2.2}$$

τ is often called the surface tension in the literature. u^0 is a step function with K jump discontinuity points, defined to be

$$u^0(x) = 1 \text{ on } (0, x_1^0),\ 0 \text{ on } (x_1^0, x_2^0),\ 1 \text{ on } (x_2^0, x_3^0),\ 0 \text{ on } (x_3^0, x_4^0),\ 1 \text{ on } (x_4^0, x_5^0), \dots$$

with (recall $b = 1 - a$)

$$x_1^0 = \frac{a}{K},\ x_2^0 = \frac{1+b}{K},\ x_3^0 = \frac{2+a}{K},\ x_4^0 = \frac{3+b}{K},\ x_5^0 = \frac{4+a}{K}, \dots. \tag{2.3}$$

G_0 is the solution operator of $-v'' = g$, $v'(0) = v'(1) = \overline{v} = 0$; i.e., $v = G_0[g] = (-\frac{d^2}{dx^2})^{-1} g$.

There is another K-interface 1-D local minimizer whose limiting value as $\epsilon \to 0$ is 0 instead of 1 on the first interval $(0, b/K)$. It is just $1 - \tilde{u}$, where $\tilde{u}$ is a solution constructed in Theorem 2.1, but with $\overline{\tilde{u}} = b$ instead. $1 - \tilde{u}$ has the same properties as u does, so we focus on u. u is periodic in the following sense.

Theorem 2.2 (see Ren and Wei [15]). *Let u be a 1-D local minimizer constructed in Theorem 2.1. When ϵ is small, for every $x \in (0, 1/K)$,*

$$\begin{aligned} u(x) &= u\left(\frac{2}{K} - x\right) = u\left(x + \frac{2}{K}\right) = u\left(\frac{4}{K} - x\right) \\ &= u\left(x + \frac{4}{K}\right) = \cdots = \begin{cases} u(1-x) & \text{if } K \text{ is even,} \\ u(x + \frac{K-1}{K}) & \text{if } K \text{ is odd.} \end{cases} \end{aligned}$$

Moreover, when ϵ is small, u is the unique local minimizer of I_1 in an L^2 neighborhood of u^0. If u on $((j-1)/K, j/K)$ for some $j = 1, 2, \dots, K$ is scaled to a function on $(0,1)$, then it is exactly a one-layer local minimizer of I_1 with ϵ and γ replaced by $\tilde{\epsilon} = \epsilon K$ and $\tilde{\gamma} = \gamma/K^3$.

Let us denote this u of K interfaces by u_γ, to emphasize its dependence on γ. We need asymptotic expansions of u_γ in terms of ϵ. According to [15, Lemma A.1] there exist exactly K points x_j, $j = 1, 2, \dots, K$ in $(0,1)$ so that $u(x_j) = 1/2$. These K points identify the interfaces of u. Theorem 2.2 implies that $x_2 = \frac{2}{K} - x_1$, $x_3 = \frac{4}{K} - x_2$, $x_4 = \frac{6}{K} - x_3$, etc. The zeroth order approximation of u_γ is

$$\begin{aligned} s(x) &= H\left(-\frac{x - x_1}{\epsilon}\right) + H\left(\frac{x - x_2}{\epsilon}\right) \\ &\quad + H\left(-\frac{x - x_3}{\epsilon}\right) - 1 + \cdots + \begin{cases} H(\frac{x - x_K}{\epsilon}) & \text{if } K \text{ is even,} \\ H(-\frac{x - x_K}{\epsilon}) - 1 & \text{if } K \text{ is odd.} \end{cases} \end{aligned} \tag{2.4}$$

The ϵ order outer expansion term is z^0, defined to be

$$z^0(x) = -\frac{\gamma(v^0(x) - v^0(x_j^0))}{f'(0)},\quad v^0 = \left(-\frac{d^2}{dx^2}\right)^{-1} (u^0 - a), \tag{2.5}$$

and the ϵ order inner expansion term is 0. Because of the periodicity, $v^0(x_j^0)$ is independent of j and z^0 is well defined. The ϵ^2 order inner expansion term is P, where P is the solution of

$$-P'' + f'(H)P = -\gamma(v^0)'(x_j^0)t,\ P \perp H'. \tag{2.6}$$

There are two different P's depending on whether j is odd or even. But they just differ by a sign, and it is always easy to tell from the context which one is referred to.

LEMMA 2.3 (see Ren and Wei [15]). *Let z be defined by $u_\gamma = s + \epsilon z$.*

1. $\|z - z^0\|_\infty = O(\epsilon)$.
2. *There exists a constant $C > 0$ independent of ϵ so that $|\epsilon^{-1} z(x_j + \epsilon t)| \le C(1 + |t|)$ for all $t \in (-\frac{x_j}{\epsilon}, \frac{1-x_j}{\epsilon})$. $\epsilon^{-1} z(x_j + \epsilon\cdot)$ converges to P in $C^2_{loc}(\mathbf{R})$.*

Proof. See [15, Lemmas 2.4 and 2.5]. ∎

It is proved in [15] that u_γ is a nondegenerate 1-D local minimizer in the sense that the 1-D spectrum at u_γ lies to the right of the origin (see part 2 of Theorem 3.1). This allows us to apply the implicit function theorem to conclude that u_γ depends on γ smoothly.

Next we estimate $du_\gamma/d\gamma$. The inner approximation is

$$q_j(x) = cH'\left(\frac{x - x_j}{\epsilon}\right) + \epsilon^2 R\left(\frac{x - x_j}{\epsilon}\right) \tag{2.7}$$

near each x_j. The constant c is chosen so that

$$\frac{du_\gamma}{d\gamma}(x_j) = cH'(0). \tag{2.8}$$

We will show in Appendix A that

$$\lim_{\epsilon\to 0} c = c_0 := -\frac{v^0(x^0_j)}{Kf'(0)}. \tag{2.9}$$

The function R is the solution of

$$-R'' + f'(H)R + c_0 f''(H)H'P + tv'(x_j) = \zeta,\ R(0) = 0. \tag{2.10}$$

The constant ζ is chosen so that

$$\int_{\mathbf{R}} (c_0 f''(H)H'P + v(x_j) - \zeta)H'\,dt = 0 \tag{2.11}$$

for solvability. Because of the periodicity of u_γ in Theorem 2.2, neither c nor R depends on j. However, they do depend on ϵ. Our argument here is a bit different from the formal matched asymptotics method. If we compare (2.10) to (2.6) we find that

$$\lim_{\epsilon\to 0} R = \frac{1}{\gamma}P + \tilde{R}, \tag{2.12}$$

where $\tilde{R}$ is the solution of

$$-\tilde{R}'' + f'(H)\tilde{R} + c_0 f''(H)H'P = \zeta_0,\ \tilde{R}(0) = 0, \tag{2.13}$$

where ζ_0 satisfies

$$\int_{\mathbf{R}} (c_0 f''(H)H'P + v^0(x^0_j) - \zeta)H'\,dt = 0. \tag{2.14}$$

The inner approximation (2.7) is used in the interval $(x_j - \epsilon^\alpha, x_j + \epsilon^\alpha)$, where α satisfies

$$\alpha \in \left(\frac{1}{2}, 1\right). \tag{2.15}$$

The outer approximation is denoted by q_o:

$$q_o = \frac{\eta - \epsilon\gamma r - \epsilon v}{f'(u_\gamma)}, \tag{2.16}$$

where

$$r = G_0\left[\frac{du_\gamma}{d\gamma}\right], \; v = G_0[u_\gamma - a]. \tag{2.17}$$

The outer approximation is used in

$$[0,1]\backslash(\cup_{j=1}^K (x_j - 2\epsilon^\alpha, x_j + 2\epsilon^\alpha)). \tag{2.18}$$

The inner approximation is matched to the outer approximation in the matching intervals $(x_j - 2\epsilon^\alpha, x_j - \epsilon^\alpha)$ and $(x_j + \epsilon^\alpha, x_j + 2\epsilon^\alpha)$, $j = 1, 2, \ldots, K$. Let χ_j be smooth cut-off functions so that

$$\chi_j(x) = \begin{cases} 0 & \text{if } x \notin (x_j - 2\epsilon^\alpha, x_j + 2\epsilon^\alpha), \\ 1 & \text{if } x \in (x_j - \epsilon^\alpha, x_j + \epsilon^\alpha); \end{cases}$$

moreover, $\chi_j' = O(\epsilon^{-\alpha})$ and $\chi_j'' = O(\epsilon^{-2\alpha})$ in $(x_j - 2\epsilon^\alpha, x_j - \epsilon^\alpha)$ and $(x_j + \epsilon^\alpha, x_j + 2\epsilon^\alpha)$. We glue the two approximations to form a uniform approximation

$$q = \sum_{j=1}^K \chi_j q_j + \left(1 - \sum_{j=1}^K \chi_j\right) q_o. \tag{2.19}$$

Lemma 2.4. $q - u = o(\epsilon^2)$.

The proof of this lemma is technical. We include it in Appendix A.

3. The 2-D spectrum at . The 1-D local minimizer u_γ of I_1 is now viewed as a function on D, through extension to the second dimension trivially, so $u_\gamma(x, y) = u_\gamma(x)$. It is a solution of (1.2) and $I_1(u_\gamma) = I(u_\gamma)$. In two dimensions it has straight interfaces. We call it a perfect lamellar solution of (1.2).

The linearized operator of (1.2) at u_γ is

$$L_\gamma\varphi := -\epsilon^2\Delta\varphi + f'(u_\gamma)\varphi - \overline{f'(u_\gamma)\varphi} + \epsilon\gamma(-\Delta)^{-1}\varphi, \;\; \varphi \in W^{2,2}(D), \;\; \partial_\nu\varphi = 0 \text{ on } \partial D, \; \overline{\varphi} = 0. \tag{3.1}$$

This is an unbounded self-adjoint operator defined densely on $\{\phi \in L^2(D) : \overline{\phi} = 0\}$ whose spectrum consists of real eigenvalues only.

For an eigenpair (λ, φ) of L_γ, separation of variables shows that $\varphi(x, y) = \phi_m(x)\cos(m\pi y)$, where m, a nonnegative integer, is called the mode of φ. We denote a λ that is associated with m by λ_m. We have the following reduced eigenvalue problems for (λ_m, ϕ_m).

1. When $m = 0$,

$$-\epsilon^2\phi_0'' + f'(u_\gamma)\phi_0 - \overline{f'(u_\gamma)\phi_0} + \epsilon\gamma G_0[\phi_0] = \lambda_0\phi_0, \;\; \phi_0'(0) = \phi_0'(1) = \overline{\phi_0} = 0. \tag{3.2}$$

2. When $m \neq 0$,

$$-\epsilon^2(\phi_m'' - m^2\pi^2\phi_m) + f'(u_\gamma)\phi_m + \epsilon\gamma G_m[\phi_m] = \lambda_m\phi_m, \;\; \phi_m'(0) = \phi_m'(1) = 0. \tag{3.3}$$

Here G_m are the solution operators of the differential equations

$$-X'' = \phi_0, \;\; X'(0) = X'(1) = 0, \; \overline{X} = 0 \text{ if } m = 0, \tag{3.4}$$

$$-X'' + m^2\pi^2 X = \phi_m, \quad X'(0) = X'(1) = 0 \text{ if } m \neq 0; \tag{3.5}$$

i.e., $G_m[\phi_m] = X$. We often identify the operators G_m with the Green functions of (3.4) and (3.5).

THEOREM 3.1 (see Ren and Wei [15]). *The following three statements hold when ϵ is sufficiently small.*

1. *There exists $M(K)$ depending on K but not ϵ so that when $m \geq M(K)$, $\lambda_m \geq C\epsilon^2$ for some $C > 0$ independent of ϵ.*
2. *When $m = 0$, there are K small positive λ_0's. One of them is of order ϵ. The other $K-1$ λ_0's are of order ϵ^2. The remaining λ_0's are positive and bounded below by a positive constant independent of ϵ.*
3. *When $1 \leq m < M(K)$, there are K λ_m's of order ϵ^2, which are not necessarily positive. The remaining λ_m's are positive and bounded below by a positive constant independent of ϵ. For every $\gamma > 0$ there exist $K_0 > 0$ and $\epsilon_0 > 0$ such that for $\epsilon < \epsilon_0$ and $K > K_0$ all the eigenvalues of L are positive and the solution u, of K interfaces, is stable. For every positive integer K there exist $\gamma_0 > 0$ and $\epsilon_0 > 0$ so that for $\epsilon < \epsilon_0$ and $\gamma < \gamma_0$ all the eigenvalues of L are positive and u is stable.*

Actually, [15, Theorem 1.1] is formulated for a 3-D box. Here we have stated the simpler 2-D version.

The eigenvalues λ_0 in part 2 of Theorem 3.1 are just the 1-D eigenvalues of u_γ. The asymptotic expansions of the λ_0's are given in [15, sections 4 and 5]. One of the small λ_0's satisfies

$$\lim_{\epsilon \to 0} \epsilon^{-1}\lambda_0 > 0.$$

The other $K-1$ small λ_0's satisfy

$$\lim_{\epsilon \to 0} \epsilon^{-2}\lambda_0 > 0.$$

That these eigenvalues are positive is consistent with the fact that u_γ is a local minimizer of I_1.

Bifurcation occurs at a zero eigenvalue, and thus we focus on the λ_m's of part 3, the proof of which is in [15, sections 6 and 7]. There we obtained asymptotic expansions of the K eigenpairs (λ_m, ϕ_m) of (3.3) satisfying $\lambda_m \to 0$ as $\epsilon \to 0$. Define

$$h_j(x) = H'\left(\frac{x - x_j}{\epsilon}\right)\chi\left(\frac{x - x_j}{\sqrt{\epsilon}}\right) = H'\left(\frac{x - x_j}{\epsilon}\right) + e.s., \tag{3.6}$$

where χ is a smooth, even cut-off function

$$\chi(s) = \begin{cases} 1 & \text{if } |s| \leq 1, \\ 0 & \text{if } |s| \geq 2. \end{cases}$$

Here $e.s.$ is an exponentially small quantity with respect to ϵ because of the exponentially fast decay rate of H': $H'(t) \leq C_1 e^{-C_2|t|}$. Therefore $h_j(0) = h_j(1) = h_j'(0) = h_j'(1) = 0$, $\|h_j' - \epsilon^{-1}H''(\frac{\cdot - x_j}{\epsilon})\|_\infty = O(\epsilon^{-C/\epsilon})$, and $\|h_j'' - \epsilon^{-2}H'''(\frac{\cdot - x_j}{\epsilon})\|_\infty = O(\epsilon^{-C/\epsilon})$. When $m \geq 1$,

$$\lambda_m = \epsilon^2\left(\frac{\gamma}{\tau}\left(\Lambda - \frac{ab}{K}\right) + m^2\pi^2\right) + o(\epsilon^2), \ \ \phi_m = \sum_j c_j h_j + \epsilon^2 \phi_m^\perp. \tag{3.7}$$

As mentioned in the introduction, the estimate of λ_m in (3.7) is uniform in γ when γ varies in a compact interval of positive numbers. Here the Λ's are the K eigenvalues of the K by K matrix $[G_m(x_j^0, x_k^0)]$. $[G_m(x_j^0, x_k^0)]$ is diagonalized in [15, section 7]. When $K = 1$, it has, for each $m \geq 1$, one eigenpair (Λ, c^0):

$$\Lambda = \frac{1}{m\pi(\tanh(m\pi a) + \tanh(m\pi b))}, \ c^0 \propto 1. \tag{3.8}$$

When $K = 2$, there are two eigenpairs (Λ, c^0):

$$\Lambda = \frac{1}{m\pi(\coth(m\pi a) + \cot(m\pi b) - \operatorname{csch}(m\pi a) + \operatorname{csch}(m\pi b))}, \ \ c^0 \propto (-1, 1),$$

$$\Lambda = \frac{1}{m\pi(\coth(m\pi a) + \cot(m\pi b) - \operatorname{csch}(m\pi a) - \operatorname{csch}(m\pi b))}, \ \ c^0 \propto (1, 1). \tag{3.9}$$

When $K \geq 3$, there are K eigenpairs

$$\Lambda = \frac{1}{d - q}, \ c^0. \tag{3.10}$$

Here q is one of the K eigenvalues of the trigonal matrix

$$Q = \begin{bmatrix} \alpha & \beta & & & \\ \beta & 0 & \alpha & & \\ & \alpha & 0 & \beta & \\ & & \beta & 0 & \alpha \\ & & & \cdots & \end{bmatrix}, \tag{3.11}$$

where

$$\alpha = m\pi \operatorname{csch} \frac{2m\pi a}{K}, \ \beta = m\pi \operatorname{csch} \frac{2m\pi b}{K}, \ d = m\pi \left(\coth \frac{2m\pi a}{K} + \coth \frac{2m\pi b}{K} \right),$$

and c^0 is a corresponding eigenvector of Q.

In (3.7) ϕ_m is decomposed to $\sum_j c_j h_j$ in the subspace spanned by h_j, $j = 1, 2, \ldots, K$, and $\epsilon^2 \phi_m^\perp$ in the orthogonal complement of the subspace. Moreover, $\|\phi_m^\perp\|_2 = O(|c|)$ (see [15, Formula (6.4)]). As $\epsilon \to 0$, $c_j \to c_j^0$.

Within each mode m the K eigenvalues λ_m described in (3.7) are all different when ϵ is sufficiently small because the K eigenvalues Λ of $[G_m(x_j^0, x_k^0)]$ are all different [15, sections 5 and 7]. However, this does not imply that each λ_m is a simple eigenvalue. It is possible that there exists a different mode m' such that a $\lambda_{m'}$ happens to equal λ_m. This problem will appear when we consider the simplicity of the principal eigenvalue in the next section.

In this section we improve the estimate $\|\phi_m^\perp\|_2 = O(|c|)$ to $\|\phi_m^\perp\|_\infty = O(|c|)$ and find the limiting behavior of $\phi_m^\perp$ near each x_j. Define Π to be the solution of

$$-\Pi'' + f'(H)\Pi = \frac{\gamma}{\tau} \left(\Lambda - \frac{ab}{K} \right) H' + \text{const}, \quad \Pi \perp H' \tag{3.12}$$

in $\mathbf{R}$. Recall P from (2.6).

LEMMA 3.2.

1. $\|\phi_m^\perp\|_\infty = O(|c|)$.
2. *At each* x_j, $\phi_m^\perp(x_j+\epsilon\cdot)$ *converges in* $C^2_{loc}(\mathbf{R})$ *to* $c_j^0(P'+\Pi)$.

Proof. We define an operator L_m so that the left side of (3.3) is $L_m\phi_m$. Note that this L_m differs from the one in [15] slightly. The function $\phi_m^\perp$ satisfies the equation

$$L_m\phi_m^\perp - \lambda_m\phi_m^\perp = \sum_j c_j\left\{-m^2\pi^2 h_j - \frac{1}{\epsilon^2}(f'(u_\gamma)-f'(H))h_j - \gamma G_m\left[\frac{h_j}{\epsilon}\right] + \frac{\lambda_m}{\epsilon^2}h_j\right\}. \tag{3.13}$$

We claim that the right side of (3.13) is $O(|c|)$. The first term inside {} on the right side is obviously $O(1)$. The last term is $O(1)$ by (3.7). The third term is $O(1)$ because $G_m[\frac{h_j}{\epsilon}] \to G_m(x,x_j^0)$ as $\epsilon\to 0$. The least obvious is the second term. It is $O(1)$ by Lemma 2.3.

Suppose that part 1 of Lemma 3.2 is false. Let

$$\psi = \frac{\phi_m^\perp}{\|\phi_m^\perp\|_\infty}.$$

Then ψ satisfies

$$L_m\psi = o(1). \tag{3.14}$$

There exists $x_*\in[0,1]$ so that $|\psi(x_*)| = \max|\psi| = 1$. Without the loss of generality we assume $\psi(x_*)=1$. Otherwise just change ψ to $-\psi$. Then $x_*-x_j = O(\epsilon)$ for some x_j. If this is not the case, (3.14) cannot be satisfied at x_* since, by a maximum principle argument,

$$L_m\psi(x_*) = -\epsilon^2(\psi''(x_*)-m^2\pi^2\psi(x_*))+f'(u_\gamma(x_*))\psi(x_*)+\epsilon\gamma G_m[\psi](x_*) \ge f'(0)+o(1).$$

Here $\psi''(x_*)\le 0$ because x_* is a maximum, and because the Neumann boundary condition in case x_* is on the boundary. Define $\Psi(t) = \psi(x_j+\epsilon t)$. On the rescaled interval $(x_j/\epsilon,(1-x_j)/\epsilon)$ Ψ satisfies

$$-\Psi_{tt}+\epsilon^2m^2\pi^2\Psi+f'(u_\gamma)\Psi+\epsilon\gamma G_m[\psi](x_j+\epsilon t) = o(1),\quad \Psi'\left(-\frac{x_j}{\epsilon}\right) = \Psi'\left(\frac{1-x_j}{\epsilon}\right) = 0.$$

On every bounded subinterval of $\mathbf{R}$, because Ψ is bounded and the terms $\epsilon^2m^2\pi^2\Psi$, $f'(u_\gamma)\Psi$, and $\epsilon\gamma G_m[\psi](x_j+\epsilon t)$ are bounded, by the elliptic regularity theory Ψ is bounded in $W^{2,p}$ for any $p>1$. A bootstrapping argument shows that Ψ is bounded in $C^{2,\alpha}$ on the subinterval.

As $\epsilon\to 0$, Ψ converges in $C^2_{loc}(\mathbf{R})$, along a subsequence of ϵ, to a bounded nonzero solution Ψ_∞ of

$$-\Psi_\infty'' + f'(H)\Psi_\infty = 0.$$

There are infinitely many solutions to the last equation. However, only H' and its scalar multiples are bounded on $\mathbf{R}$. Therefore $\Psi_\infty \propto H'$. But $\psi\perp h_j$ implies that $\Psi_\infty \perp H'$. Hence $\Psi_\infty = 0$, a contradiction.

To prove part 2 we let $\Phi^\perp(t) = \phi_m^\perp(x_j+\epsilon t)$. By part 1 we can pass the limit in (3.13) to find that $\Phi^\perp\to\Phi_\infty^\perp$ in $C^2_{loc}(\mathbf{R})$, which is a solution of

$$-(\Phi_\infty^\perp)'' + f'(H)\Phi_\infty^\perp = c_j^0\left(-f''(H)H'P + \frac{\gamma}{\tau}\left(\Lambda - \frac{ab}{K}\right)H' + \text{const}\right). \tag{3.15}$$

By differentiating the equation for P we find

$$-(P')'' + f'(H)P' = -f''(H)H'P - \frac{\gamma ab}{K}.$$

Thus $\Phi_\infty^\perp$ and $c_j^0(P'+\Pi)$ satisfy the same equation (3.15). Moreover, $\phi_m^\perp \perp h_j$ implies $\Phi_\infty^\perp \perp H'$. Hence $\Phi_\infty^\perp = c_j^0(P'+\Pi)$. □

4. Bifurcation at (B B). We use γ as a bifurcation parameter. Since we are mainly interested in stable wriggled solutions, we study bifurcation from the principal eigenvalue, i.e., the smallest eigenvalue, which we denote by $\lambda(\gamma)$. We must find $\gamma_{\rm B}$ so that $\lambda(\gamma_{\rm B}) = 0$ and make sure that $\lambda(\gamma_{\rm B})$ is a simple eigenvalue. The following procedure easily finds the critical $\gamma_{\rm B}$.

1. According to [15, section 7], for each m the eigenvalues Λ of the matrix $[G_m(x_j^0, x_k^0)]$ are all different and the smallest one is

$$\Lambda_m = \frac{1}{m\pi(\tanh(m\pi a) + \tanh(m\pi b))} \quad \text{if } K = 1,$$

$$\Lambda_m = \frac{1}{m\pi(\coth(m\pi a) + \cot(m\pi b) - \operatorname{csch}(m\pi a) + \operatorname{csch}(m\pi b))} \quad \text{if } K = 2, \tag{4.1}$$

$$\Lambda_m = \frac{1}{d + \sqrt{\alpha^2 + \beta^2 + 2\alpha\beta\cos\theta}}, \quad \theta = \frac{2\pi}{K} \quad \text{if } K \geq 3.$$

   Recall that α, β, and d are defined after (3.11).

2. For each $m \geq 1$ we define γ_m^0 to be the solution of

$$\frac{\gamma_m^0}{\tau}\left(\Lambda_m - \frac{ab}{K}\right) + m^2\pi^2 = 0. \tag{4.2}$$

   According to (3.7) at $\gamma = \gamma_m^0$, $\lambda_m = o(\epsilon^2)$ where

$$\lambda_m = \epsilon^2\left(\frac{\gamma_m^0}{\tau}\left(\Lambda_m - \frac{ab}{K}\right) + m^2\pi^2\right) + o(\epsilon^2)$$

   is the smallest eigenvalue of the mode m. The solution γ_m^0 may or may not be positive. If $\gamma_m^0 \leq 0$, this means that the mode m does not yield a zero eigenvalue for any $\gamma > 0$. We discard nonpositive γ_m^0.

3. We minimize the positive γ_m^0's with respect to m. Because $\lim_{m\to\infty} \gamma_m^0 = \infty$, the minimum is achieved and is denoted by ${\gamma_{\rm B}}^0$. If m is the mode where $\gamma_m^0 = {\gamma_{\rm B}}^0$ and m' is another mode such that $\gamma_{m'}^0 > {\gamma_{\rm B}}^0$, then, since for m'

$$\Lambda_{m'} - \frac{ab}{K} < 0,$$

   a consequence of $\gamma_{m'}^0$ being positive, we find that

$$\frac{{\gamma_{\rm B}}^0}{\tau}\left(\Lambda_{m'} - \frac{ab}{K}\right) + (m')^2\pi^2 > \frac{\gamma_{m'}^0}{\tau}\left(\Lambda_{m'} - \frac{ab}{K}\right) + (m')^2\pi^2 = 0.$$

   Hence at $\gamma = {\gamma_{\rm B}}^0$ the smallest eigenvalue associated with a mode m of ${\gamma_{\rm B}}^0$ vanishes up to order ϵ^2 while the greater eigenvalues associated with the mode m and the eigenvalues associated with the modes m' satisfying $\gamma_{m'}^0 > {\gamma_{\rm B}}^0$ are positive and of order ϵ^2. Then there exists $\gamma_{\rm B}$ such that $\lim_{\epsilon\to 0}\gamma_{\rm B} = {\gamma_{\rm B}}^0$ and at $\gamma = \gamma_{\rm B}$ the principal eigenvalue $\lambda(\gamma_{\rm B})$ is zero.

The simplicity of $\lambda(\gamma_{\rm B})$ is more complex. For most a and τ, the minimum ${\gamma_{\rm B}}^0$ of γ_m^0 is achieved at one m. Then, for sufficiently small ϵ, the mode of $\lambda(\gamma_{\rm B})$ is the unique m and $\lambda(\gamma_{\rm B})$ is a simple eigenvalue.

However, it is possible, for some particular a and τ, that two modes, m and $m+1$, both minimize γ_m^0, and thus ${\gamma_{\rm B}}^0$ is achieved by two modes. This does not necessarily mean that the principal eigenvalue $\lambda(\gamma_{\rm B})$ has multiplicity two because there is the effect of the $o(\epsilon^2)$ order term in (3.7). Nevertheless we cannot exclude the possibility. Throughout the rest of the paper we impose the following condition which can be easily tested numerically for given a and τ.

HYPOTHESIS 4.1. *The positive γ_m^0's defined in* (4.2) *are minimized at a unique m.*

Being a simple eigenvalue now, $\lambda(\gamma_{\rm B})$ is continued smoothly to a curve of simple eigenvalues $\lambda(\gamma)$ of L_γ as γ varies. $\lambda(\gamma)$, which is estimated in (3.7), is valid uniformly in γ when γ varies in a neighborhood (such as $[\gamma_{\rm B}/2, 2\gamma_{\rm B}]$) of $\gamma_{\rm B}$. Denote the eigenfunction associated with $\lambda(\gamma_{\rm B})$ by $\varphi_{\rm B}(x,y) = \phi_{\rm B}(x)\cos(m\pi y)$, where m from now on is the unique mode in Hypothesis 4.1. We write $u_{\rm B} := u_{\gamma_{\rm B}}$ and $L_{\rm B} := L_{\gamma_{\rm B}}$ for simplicity. Let

$$(4.3)\quad X := \{w \in W^{2,2}(D) :\ \partial_\nu w = 0 \text{ on } \partial D,\ \overline{w} = 0\},\quad Y := \{z \in L^2(D) :\ \overline{z} = 0\}.$$

Here X is a dense subspace of Y equipped with the $W^{2,2}$ norm; Y is a Hilbert space with the usual inner product $\langle \cdot, \cdot \rangle$ inherited from $L^2(D)$.

A nonlinear map $F : (0,\infty) \times X \to Y$ is defined by

$$(4.4)\ F(\gamma, w) := -\epsilon^2\Delta(u_\gamma + w) + f(u_\gamma + w) - \overline{f(u_\gamma + w)} + \epsilon\gamma(-\Delta)^{-1}(u_\gamma + w - a).$$

Obviously the trivial branch $(\gamma, 0)$ is a solution branch of $F(\gamma, w) = 0$. It corresponds to the K-interface, perfect lamellar solution u_γ of (1.2), parameterized by γ. We look for another solution branch, a bifurcating branch, $(\gamma(s), w(s))$ of F. It gives another solution $u_{\gamma(s)} + w(s)$ of (1.2).

THEOREM 4.2. *Under Hypothesis* 4.1*, when ϵ is sufficiently small, at $\gamma = \gamma_{\rm B}$ another solution branch $(\gamma(s), w(s))$ bifurcates from the trivial branch $(\gamma, 0)$. Here $w(s) = s\varphi_{\rm B} + sg(s)$, where the parameter s is in a neighborhood of* 0 *with $\gamma(0) = \gamma_{\rm B}$ and $w(0) = 0$. Moreover, $\gamma : s \to \gamma(s) \in \mathbf{R}$ and $g : s \to g(s) \in X$ are both continuously differentiable, g satisfies $g(s) \perp \varphi_{\rm B}$, and $g(0) = 0$.*

Note that $u_{\gamma(s)} + w(s)$ is approximately $u_{\gamma(s)}(x) + s\phi_{\rm B}(x)\cos(m\pi y)$ since $g(s)$ is a smaller term compared to $\varphi_{\rm B}(x,y) = \phi_{\rm B}(x)\cos(m\pi y)$. Figure 2(b) is made based on this observation.

Proof. We appeal to the standard bifurcation from the simple eigenvalue theorem (see [26, Theorem 13.5, page 173]). Denote the Fréchet derivatives of F with respect to γ by D_1 and with respect to w by D_2. We need to verify the following three properties.

1. $D_2F(\gamma_{\rm B}, 0)$, which is just $L_{\rm B} : X \to Y$, has a 1-D kernel spanned by $\varphi_{\rm B}$.
2. $\mathcal{R}(D_2F(\gamma_{\rm B}, 0))$, the range of $D_2F(\gamma_{\rm B}, 0)$, has codimension 1.
3. $D_1D_2F(\gamma_{\rm B}, 0)\varphi_{\rm B}$ is not in $\mathcal{R}(D_2F(\gamma_{\rm B}, 0))$.

Property 1 follows from the simplicity of $\lambda(\gamma)$. To prove 2 we claim that there exists a positive constant $c(\epsilon, \gamma_{\rm B})$ depending on ϵ and $\gamma_{\rm B}$ so that

$$(4.5)\qquad \|\psi\|_2 \le c(\epsilon, \gamma_{\rm B})\|L_{\rm B}\psi\|_2 \text{ for all } \psi \perp \varphi_{\rm B},\ \psi \in X.$$

Suppose (4.5) is false. There would exist a sequence $\psi_n \in X$, $\psi_n \perp \varphi_{\mathrm{B}}$, $\|\psi_n\|_2 = 1$ so that $\|L_{\mathrm{B}}\psi_n\|_2 \to 0$. Let $\psi_n \to \psi_*$ weakly in $L^2(D)$. Then $\psi_* \perp \varphi_{\mathrm{B}}$. For every $\omega \in X$,

$$\langle \psi_*, L_{\mathrm{B}}\omega\rangle = \lim_{n\to\infty} \langle \psi_n, L_{\mathrm{B}}\omega\rangle = \lim_{n\to\infty}\langle L_{\mathrm{B}}\psi_n, \omega\rangle = 0.$$

By the self-adjointness of L_{B}, $\psi_* \in X$ and $L_{\mathrm{B}}\psi_* = 0$. Hence $\psi_* = 0$ from property 1. Rewrite $L_{\mathrm{B}}\psi_n$ as

$$-\epsilon^2\Delta\psi_n = -f'(u_{\mathrm{B}})\psi_n + \overline{f'(u_{\mathrm{B}})\psi_n} - \epsilon\gamma_{\mathrm{B}}(-\Delta)^{-1}\psi_n + L_{\mathrm{B}}\psi_n.$$

Since $\|\psi_n\|_2 = 1$ and $\|L_{\mathrm{B}}\psi_n\|_2 \to 0$, the right side is bounded in $L^2(D)$. The elliptic regularity theory asserts that ψ_n is precompact in $L^2(D)$. Hence $\psi_n \to 0$ in $L^2(D)$. This is inconsistent with the fact $\|\psi_n\|_2 = 1$. Hence (4.5) holds.

We now prove 2. by showing $\mathcal{R}(L_{\mathrm{B}}) = \{\varphi_{\mathrm{B}}\}^\perp$. The self-adjointness of L_{B} and 1. imply that every $\psi \in \mathcal{R}(L_{\mathrm{B}})^\perp$ is φ_{B} multiplied by a constant. It suffices to show that $\mathcal{R}(L_{\mathrm{B}})$ is closed. Take $\omega_n \in \mathcal{R}(L_{\mathrm{B}})$ so that $\omega_n \to \omega_*$ in $L^2(D)$. Let $\psi_n \in X$, $\psi_n \perp \varphi_{\mathrm{B}}$ such that $L_{\mathrm{B}}\psi_n = \omega_n$. Since ω_n is a Cauchy sequence, by (4.5) ψ_n is also a Cauchy sequence. Let $\psi_n \to \psi_*$ in $L^2(D)$. Note that L_{B} is a closed operator since it is self-adjoint. Hence $\psi_* \in X$ and $L_{\mathrm{B}}\psi_* = \omega_*$. This proves property 2.

To prove 3, note that the linear map $D_1D_2F(\gamma_{\mathrm{B}}, 0) : X \to Y$ is

$$\psi \to f''(u_{\mathrm{B}})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\mathrm{B}}}\psi - \overline{f''(u_{\mathrm{B}})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\mathrm{B}}}\psi} + \epsilon(-\Delta)^{-1}\psi. \tag{4.6}$$

Since $\mathcal{R}(L_{\mathrm{B}}) = \{\varphi_{\mathrm{B}}\}^\perp$, it suffices to show

$$\langle D_1D_2F(\gamma_{\mathrm{B}},0)\varphi_{\mathrm{B}}, \varphi_{\mathrm{B}}\rangle \neq 0, \text{ i.e., } \int_D \left\{ f''(u_{\mathrm{B}})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\mathrm{B}}}\varphi_{\mathrm{B}}^2 + \epsilon\varphi_{\mathrm{B}}(-\Delta)^{-1}\varphi_{\mathrm{B}}\right\} \neq 0. \tag{4.7}$$

This fact is established in the next lemma. ∎

Lemma 4.3. *When ϵ is sufficiently small,*

$$\int_D \left\{ f''(u_{\mathrm{B}})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\mathrm{B}}}\varphi_{\mathrm{B}}^2 + \epsilon\varphi_{\mathrm{B}}(-\Delta)^{-1}\varphi_{\mathrm{B}}\right\} = -\frac{\epsilon^3|c^0|^2\tau m^2\pi^2}{2\gamma_{\mathrm{B}}} + o(\epsilon^3|c^0|^2) < 0.$$

Here τ is given in (2.2), *and c^0 is in* (3.8)–(3.10), *a nonzero vector.*

Proof. Note that $\varphi_{\mathrm{B}}(x,y) = \phi_{\mathrm{B}}(x)\cos(m\pi y)$ and $(-\Delta)^{-1}\varphi_{\mathrm{B}}(x,y) = G_m[\phi_{\mathrm{B}}](x)\cos(m\pi y)$. Hence after integrating out the y variable we deduce

$$\begin{aligned}&\int_D \left\{ f''(u_{\mathrm{B}})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\mathrm{B}}}\varphi_{\mathrm{B}}^2 + \epsilon\varphi_{\mathrm{B}}(-\Delta)^{-1}\varphi_{\mathrm{B}}\right\}\\ &= \int_0^1 \left\{ \frac{1}{2}f''(u_{\mathrm{B}})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\mathrm{B}}}\phi_{\mathrm{B}}^2 + \frac{\epsilon}{2}G_m[\phi_{\mathrm{B}}]\phi_{\mathrm{B}}\right\} dx.\end{aligned} \tag{4.8}$$

By Lemmas 2.4 and 3.2, we find

$$\begin{aligned}\int_0^1 f''(u_{\mathrm{B}})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\mathrm{B}}}\phi_{\mathrm{B}}^2 &= \int_0^1 f''(u_{\mathrm{B}})\left(\sum_j (ch_j + \epsilon^2 R)\right)\phi_{\mathrm{B}}^2 + o(\epsilon^3)\\ &= \int_0^1 f''(u_{\mathrm{B}})\left(\sum_j (ch_j + \epsilon^2(\gamma^{-1}P + \tilde{R})\right)\phi_{\mathrm{B}}^2 + o(\epsilon^3|c|^2)\\ &= \epsilon^2\int_0^1 f''(u_{\mathrm{B}})(\gamma^{-1}P)\phi_{\mathrm{B}}^2 + o(\epsilon^3|c|^2).\end{aligned}$$

We have used the fact that P is odd, and $\tilde{R}$ and H_t are even. Hence we arrive at

$$\int_0^1 f''(u_{\mathrm{B}})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\mathrm{B}}}\phi_{\mathrm{B}}^2 = \epsilon^3\int_{\mathbf{R}} f''(H)\gamma^{-1}P\left(\sum_j c_j^2\right)(H')^2\,dt + o(\epsilon^3|c|^2)$$
$$= -\frac{\epsilon^3|c^0|^2ab}{K} + o(\epsilon^3|c^0|^2),$$

where the last equation follows after we differentiate the equation for $\gamma^{-1}P$,

$$-(\gamma^{-1}P)''' + f'(H)(\gamma^{-1}P)' + f''(H)H'(\gamma^{-1}P) = -\frac{ab}{K},$$

multiply by H', and integrate: $\int_{\mathbf{R}} f''(H)\gamma^{-1}P(H')^2\,dt = -ab/K$. By Lemma 3.2 we obtain

$$\int_0^1 \epsilon G_m[\phi_{\mathrm{B}}]\phi_{\mathrm{B}} = \epsilon^3\int_0^1\left(\sum_j c_j G_m\left[\frac{h_j}{\epsilon}\right]\right)\left(\sum_k c_k\frac{h_k}{\epsilon}\right) + o(\epsilon^3|c|^2)$$
$$= \epsilon^3\sum_{j,k} c_j c_k G_m(x_k, x_j) + o(\epsilon^3|c|^2) \;=\; \epsilon^3\Lambda|c^0|^2 + o(\epsilon^3|c^0|^2).$$

Here Λ is an eigenvalue of the K by K matrix $G_m(x_k^0, x_j^0)$ and c^0 is a corresponding eigenvector, satisfying $\lim_{\epsilon\to 0} c_j = c_j^0$.

Hence the right side of (4.8) becomes

$$\frac{\epsilon^3|c^0|^2}{2}\left(\Lambda - \frac{ab}{K}\right) + o(\epsilon^3|c^0|^2).$$

To determine the sign of this quantity we recall (3.7):

$$\lambda(\gamma_{\mathrm{B}}) = \epsilon^2\left[\frac{\gamma_{\mathrm{B}}}{\tau}\left(\Lambda - \frac{ab}{K}\right) + m^2\pi^2\right] + o(\epsilon^2).$$

But here $\lambda(\gamma_{\mathrm{B}}) = 0$. Hence

$$\Lambda - \frac{ab}{K} = -\frac{\tau m^2\pi^2}{\gamma_{\mathrm{B}}} + o(1).$$

This proves the lemma. ∎

Remark 4.4. The proof of Theorem 4.2 does not use the fact that $\lambda(\gamma_{\mathrm{B}})$ is a principal eigenvalue. The theorem continues to hold if $\lambda(\gamma_{\mathrm{B}})$ is just a zero, simple eigenvalue, not necessarily principal. However, the bifurcating solution from a non-principal eigenvalue is unstable, and hence less interesting to us.

5. Stability of the bifurcating solutions. The eigenvalue $\lambda(\gamma)$ of the trivial branch u_γ corresponds to an eigenvalue $\lambda_*(s)$ of the bifurcating solution $u_{\gamma(s)} + w(s)$. The sign of $\lambda_*(s)$ may be determined from the shape of $\gamma(s)$. Thus we proceed to compute $\gamma'(0)$ and $\gamma''(0)$.

Place $w(s) = s\varphi_{\mathrm{B}} + sg(s)$ into $F(\gamma, w) = 0$ and divide by s:

$$-\epsilon^2\Delta\left(\frac{u_{\gamma(s)}}{s} + \varphi_{\mathrm{B}} + g(s)\right) + \frac{f(u_{\gamma(s)} + w(s))}{s}$$
$$+\,\epsilon\gamma(s)(-\Delta)^{-1}\left(\frac{u_{\gamma(s)} - a}{s} + \varphi_{\mathrm{B}} + g(s)\right) = \text{const}, \tag{5.1}$$

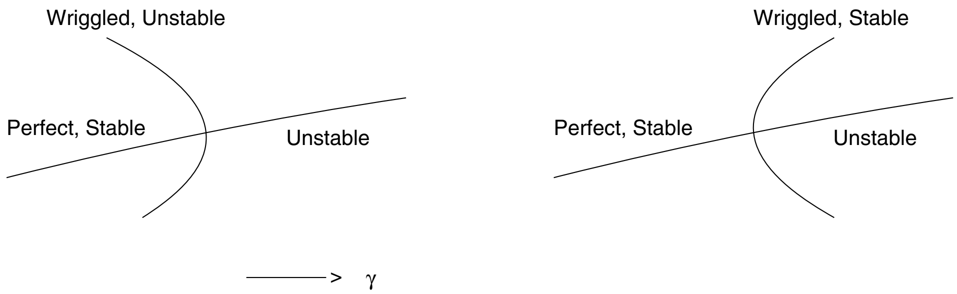

FIG. 3. *The two possible diagrams of wriggled lamellar solutions bifurcating out of perfect lamellar solutions. The bifurcating solutions are unstable in the first case (left) where $\gamma''(0) < 0$, and stable in the second case (right) where $\gamma''(0) > 0$.*

where const refers to the term coming from the average of f, which is independent of (x, y). Here we do not need its exact value. On the other hand, divide (1.2) of $u_{\gamma(s)}$ by s and subtract the result from (5.1):

(5.2)
$$-\epsilon^2\Delta(\varphi_{\rm B} + g(s)) + \frac{f(u_{\gamma(s)} + w(s)) - f(u_{\gamma(s)})}{s} + \epsilon\gamma(s)(-\Delta)^{-1}(\varphi_{\rm B} + g(s)) = \text{const.}$$

Differentiate (5.2) with respect to s and set $s = 0$ afterwards:

$$L_{\rm B}g'(0) + \gamma'(0)\left\{f''(u_{\rm B})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\rm B}}\varphi_{\rm B} + \epsilon(-\Delta)^{-1}\varphi_{\rm B}\right\} + \frac{1}{2}f''(u_{\rm B})\varphi_{\rm B}^2 = \text{const.} \tag{5.3}$$

Then we multiply (5.3) by $\varphi_{\rm B}$ and integrate over D:

$$\gamma'(0)\int_D \left\{f''(u_{\rm B})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\rm B}}\varphi_{\rm B}^2 + \epsilon\varphi_{\rm B}(-\Delta)^{-1}\varphi_{\rm B}\right\} = -\int_D \frac{1}{2}f''(u_{\rm B})\varphi_{\rm B}^3. \tag{5.4}$$

Clearly the right side of (5.4) is 0 since $\varphi_{\rm B}(x, y) = \phi_{\rm B}(x)\cos(m\pi y)$ and integration with respect to y yields 0. Lemma 4.3 then implies the following.

COROLLARY 5.1. $\gamma'(0) = 0$.

Consequently, (5.3) is simplified to

$$L_{\rm B}g'(0) = -\frac{1}{2}f''(u_{\rm B})\varphi_{\rm B}^2 + \text{const}, \quad g'(0) \perp \varphi_{\rm B}. \tag{5.5}$$

The right side of (5.5) is perpendicular to $\varphi_{\rm B}$ since the integration of the right side multiplied by $u_{\rm B}$ with respect to y yields 0, so there is a solution of $g'(0)$. $g'(0) \perp \varphi_{\rm B}$ follows from $g(s) \perp \varphi_{\rm B}$ in Theorem 4.2, so $g'(0)$ is uniquely determined.

Corollary 5.1 implies that the bifurcation diagram has the shape of a pitchfork. There are two possibilities illustrated in Figure 3. To determine which of the two cases occurs, we need to find $\gamma''(0)$. Differentiate (5.2) with respect to s twice and set $s = 0$ afterwards:

$$\begin{aligned} &L_{\rm B}g''(0) + \gamma''(0)\left\{f''(u_{\rm B})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\rm B}}\varphi_{\rm B}^2 + \epsilon(-\Delta)^{-1}\varphi_{\rm B}\right\} \\ &+2f''(u_{\rm B})\varphi_{\rm B}g'(0) + \frac{1}{3}f'''(u_{\rm B})\varphi_{\rm B}^3 = \text{const.} \end{aligned} \tag{5.6}$$

We have used Corollary 5.1 in deriving (5.6). Again we multiply (5.6) by φ_{B} and integrate:

$$\begin{aligned}&\gamma''(0)\int_D\left\{f''(u_{\mathrm{B}})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\mathrm{B}}}\varphi_{\mathrm{B}}^2+\epsilon\varphi_{\mathrm{B}}(-\Delta)^{-1}\varphi_{\mathrm{B}}\right\}\\ &\quad=-\int_D\left\{2f''(u_{\mathrm{B}})\varphi_{\mathrm{B}}^2g'(0)+\frac{1}{3}f'''(u_{\mathrm{B}})\varphi_{\mathrm{B}}^4\right\}.\end{aligned}\tag{5.7}$$

The integral on the left side of (5.7) has been calculated in Lemma 4.3. We now need to know the right side.

Lemma 5.2.

$$\begin{aligned}&-\int_D\left\{2f''(u_{\mathrm{B}})\varphi_{\mathrm{B}}^2g'(0)+\frac{1}{3}f'''(u_{\mathrm{B}})\varphi_{\mathrm{B}}^4\right\}\\ &=-\epsilon^5 m\pi\gamma_{\mathrm{B}}\sum_{j=1}^K c_j^4\left[\frac{2+\cosh(2m\pi)}{8\sinh(2m\pi)}+\frac{\cosh(2m\pi(1-2x_j^0))}{8\sinh(2m\pi)}\right.\\ &\qquad\left.+\frac{\cosh(m\pi(1-2x_j^0))}{4\sinh(m\pi)}-\frac{3(m\pi)^3\tau}{8\gamma_{\mathrm{B}}}\right]+o(\epsilon^5|c|^4).\end{aligned}$$

The proof of Lemma 5.2 is formidable. We have to expand the quantity to the ϵ^5 order term, because all the lower order terms up to ϵ^4 vanish. Our main idea is to expand $u_{\mathrm{B}}, \phi_{\mathrm{B}}, 2g'(0)$ as $(\cdots)+\epsilon^2(\cdots)$ near each interface x_j and then show that the quantity in Lemma 5.2 depends "locally" on these expansions near x_j. This is a very long computation; we do not know if there is a simpler proof. We include the computation in Appendices B and C. The reader may skip it in a first reading. Combining Lemmas 4.3 and 5.2 we obtain the following.

Corollary 5.3. *As* $\epsilon\to 0$, $\epsilon^{-2}\gamma''(0)\to$

$$\begin{aligned}&\frac{2({\gamma_{\mathrm{B}}}^0)^2}{|c^0|^2 m\pi\tau}\sum_{j=1}^K(c_j^0)^4\left[\frac{2+\cosh(2m\pi)}{8\sinh(2m\pi)}+\frac{\cosh(2m\pi(1-2x_j^0))}{8\sinh(2m\pi)}\right.\\ &\qquad\left.+\frac{\cosh(m\pi(1-2x_j^0))}{4\sinh(m\pi)}-\frac{3(m\pi)^3\tau}{8{\gamma_{\mathrm{B}}}^0}\right],\end{aligned}$$

where ${\gamma_{\mathrm{B}}}^0=\lim_{\epsilon\to0}\gamma_{\mathrm{B}}$ *is given in section* 4.

Define

$$\begin{aligned}S(a,K):=&\sum_{j=1}^K\left(\frac{c_j^0}{|c^0|}\right)^4\left[\frac{2+\cosh(2m\pi)}{8\sinh(2m\pi)}+\frac{\cosh(2m\pi(1-2x_j^0))}{8\sinh(2m\pi)}\right.\\ &\qquad\left.+\frac{\cosh(m\pi(1-2x_j^0))}{4\sinh(m\pi)}-\frac{3(m\pi)^3\tau}{8{\gamma_{\mathrm{B}}}^0}\right].\end{aligned}\tag{5.8}$$

Note that $S(a,K)$ depends on a and K only. It does not depend on τ. Since τ depends on the shape of W, $S(a,K)$ is independent of the exact shape of W. Then Corollary 5.3 implies

$$\lim_{\epsilon\to0}\epsilon^{-2}\gamma''(0)=\frac{2({\gamma_{\mathrm{B}}}^0)^2|c^0|^2}{m\pi\tau}S(a,K).\tag{5.9}$$

THEOREM 5.4. *Under Hypothesis* 4.1 *when* ϵ *is sufficiently small, the bifurcating solution* $u_{\gamma(s)} + w(s)$ *of* K *wriggled interfaces is stable if* $S(a, K) > 0$ *and unstable if* $S(a, K) < 0$.

Proof. We first find $\lambda'(\gamma_{\mathrm{B}})$. Differentiate the equation $L_\gamma \varphi = \lambda\varphi$ with respect to γ:

$$-\epsilon^2\Delta\varphi_\gamma + f'(u_\gamma)\varphi_\gamma + \epsilon\gamma(-\Delta)^{-1}\varphi_\gamma + f''(u_\gamma)\frac{du_\gamma}{d\gamma}\varphi_\gamma + \epsilon(-\Delta)^{-1}\varphi = \lambda\varphi_\gamma + \lambda'(\gamma)\varphi + \text{const.}$$

Set $\gamma = \gamma_{\mathrm{B}}$ in the equation, multiply the equation by φ_{B}, and integrate over D.

$$\int_D \left\{ f''(u_{\mathrm{B}})\frac{du_\gamma}{d\gamma}|_{\gamma=\gamma_{\mathrm{B}}}\varphi_{\mathrm{B}}^2 + \epsilon\varphi_{\mathrm{B}}(-\Delta)^{-1}\varphi_{\mathrm{B}} \right\} = \lambda'(\gamma_{\mathrm{B}}) \int_D \varphi_{\mathrm{B}}^2.$$

The left side is calculated in Lemma 4.3. The integral on the right side is

$$\int_D \varphi_{\mathrm{B}}^2 = \int_D \left(\sum_j c_j h_j \right)^2 \cos^2(m\pi y)\, dxdy + o(\epsilon|c|^2) = \frac{\epsilon\tau}{2}\sum_j c_j^2 + o(\epsilon|c|^2).$$

Therefore

$$\lambda'(\gamma_{\mathrm{B}}) = -\frac{\epsilon^2 m^2\pi^2}{\gamma_{\mathrm{B}}} + o(\epsilon^2) < 0. \tag{5.10}$$

According to Crandall and Rabinowitz [4, Theorem 1.16], who generalize an earlier result of Sattinger [23], near $s = 0$, $\lambda_*(s)$ and $-s\gamma'(s)\lambda'(\gamma_{\mathrm{B}})$ have the same zeros, and

$$\lim_{s\to 0,\ \lambda_*(s)\neq 0} \frac{-s\gamma'(s)\lambda'(\gamma_{\mathrm{B}})}{\lambda_*(s)} = 1. \tag{5.11}$$

Here $\lambda_*(s)$ is the principal eigenvalue of the bifurcating solution $u_{\gamma(s)}+w(s)$. Whether the bifurcating solution is stable depends on whether $\lambda_*(s)$ is positive. The theorem follows from (5.9), (5.10), and (5.11). □

Let us use Theorem 5.4 to work out some examples. The quantity $S(a, K)$ may be accurately calculated following these numerical steps.

1. Follow the procedure in section 4 to find ${\gamma_{\mathrm{B}}}^0/\tau$ and m.
2. Make certain that Hypothesis 4.1 is satisfied.
3. Find c^0 from Q corresponding to Λ of (4.1).
4. Find $S(a, K)$ from (5.8).

Tables 1, 2, and 3 report our numerical calculations based on this method for the cases $a = 1/2$, $1/8$, and $7/8$. In each table the first column is the number of the interfaces in the perfect lamellar solution u_{B}. The second column gives the value of m associated with the principal eigenvalue 0 of u_{B}. Note that m does not increase as fast as K does. The third column has the value of ${\gamma_{\mathrm{B}}}^0/\tau$. We will explain the fourth in a moment. The fifth column has the value of $S(a, K)$. The last column indicates the stability of the bifurcating solution with K wriggled interfaces.

We have deliberately chosen $a = 1/8$ and $a = 7/8$ because they are somehow "symmetric." With the exception of $K = 2$, the ${\gamma_{\mathrm{B}}}^0/\tau$'s are identical in Tables 2 and 3 for the same value of K. Moreover, the $S(a, K)$ values are the same in the two tables when K is odd. All these symmetries and asymmetries can be explained

from (4.1) for Λ and the matrix (3.11) of Q. In summary, our problem is invariant under the reflection $u(x) \to u(1-x)$ with respect to $x = 1/2$, and the exchange $u(x) \to 1 - u(x)$ of A and B monomers. When K is odd the perfect lamellar solution u_γ studied in Table 2 becomes u_γ in Table 3, and vice versa, after we perform the last two transformations. However, this is not true when K is even.

There is an interesting relationship between the perfect lamellar solution $u_{\rm B}$ whose principal eigenvalue is 0 and the 1-D global minimizer. In [15, section 8] it is shown that the 1-D global minimizer (the global minimizer of I_1 in Theorem 2.1, also a perfect lamellar solution on D after trivial extension), which is one of the 1-D local minimizers, has the number of interfaces K_{opt} which minimizes (among positive integers N) $\tau N + \gamma a^2 b^2/(6N^2)$. If we take $\gamma = \gamma_{\rm B}$ so that the K-interface, perfect lamellar solution $u_{\rm B}$ has 0 principal eigenvalue, we find the 1-D global minimizer corresponding to $\gamma_{\rm B}$. The number of interfaces K_{opt} of this 1-D global minimizer is reported in the fourth columns in Tables 1, 2, and 3.

It is known [15] that for any γ the 1-D global minimizer sits near the 2-D stability borderline. But it has not been determined whether the 1-D global minimizer is stable in 2-D. Now we show that the 1-D global minimizer is stable in two dimensions for some γ and unstable for other γ.

First consider $\gamma = \gamma_{\rm B}$. Then $u_{\rm B}$ is the borderline of 2-D stability. By examining the formulae (3.7) and (4.1) we find that for each γ the principal eigenvalue increases as K increases. If $\gamma = \gamma_{\rm B}$ and K is the number of the interfaces of $u_{\rm B}$ whose principal eigenvalue is zero, then Tables 1–3 show that in most cases $K_{opt} = K + 1$, and hence the 1-D global minimizer is stable.

However, in some cases, such as the third row of Table 2, $K = K_{opt}$. Then $u_{\rm B}$ is the 1-D global minimizer. Since the principal eigenvalue of $u_{\rm B}$ is zero, the linear stability of $u_{\rm B}$ is undetermined. However, if we consider γ in a small neighborhood of $\gamma_{\rm B}$, then u_γ continues to be the 1-D global minimizer. But Figure 3 shows that when γ is slightly greater than $\gamma_{\rm B}$ the 1-D global minimizer is unstable in two dimensions.

Appendix A. Proof of Lemma 2.4.

We differentiate the 1-D Euler–Lagrange equation in Theorem 2.1 with respect to γ to deduce

$$-\epsilon^2 \Delta \left(\frac{du_\gamma}{d\gamma} \right) + f'(u_\gamma) \frac{du_\gamma}{d\gamma} - \eta + \epsilon \gamma G_0 \left[\frac{du_\gamma}{d\gamma} \right] + \epsilon v = 0, \tag{A.1}$$

where

$$\eta = \overline{f'(u_\gamma) \frac{du_\gamma}{d\gamma}}. \tag{A.2}$$

We first show that $du_\gamma/d\gamma = O(1)$ so that c defined in (2.8) is of order $O(1)$. By the periodicity of u_γ and $du_\gamma/d\gamma$ we consider (A.1) in one half period $(0, l)$ where $l = 1/K$. Decompose

$$\frac{du_\gamma}{d\gamma} = \beta \phi_0 + \phi_0^\perp,\ \phi_0 \perp \phi_0^\perp, \tag{A.3}$$

where ϕ_0 is the eigenfunction associated with the ϵ order eigenvalue λ_0 described in part 2 of Theorem 3.1. Note that λ_0 is the only small eigenvalue of mode zero now. In [15, section 4] it was shown that

$$\phi_0 = h_1 - \overline{h_1} + O(\epsilon). \tag{A.4}$$

Denote the operator on the left side of (A.1) by L_0. Then

$$L_0 \phi_0^\perp = -\beta L_0 \phi_0 - \epsilon v = -\beta \lambda_0 - \epsilon v = O(\epsilon |\beta|) + O(\epsilon).$$

This equation and the fact that $\phi_0 \perp \phi_0^\perp$ imply, as in the proof of Lemma 3.2, that

$$\phi_0^\perp = O(\epsilon |\beta|) + O(\epsilon). \tag{A.5}$$

We rewrite (A.1) as $\beta L_0\phi_0 + L_0\phi_0^\perp = -\epsilon v$, multiply by ϕ_0, and integrate to deduce

$$\beta\lambda_0\|\phi_0\|_2^2 = -\epsilon\int_0^l v\phi_0\,dx.$$

It follows from (A.4) that

$$\beta = O(1), \tag{A.6}$$

and (A.5) in turn becomes

$$\phi_0^\perp = O(\epsilon). \tag{A.7}$$

Therefore $du_\gamma/d\gamma = O(1)$. We can assume that along a subsequence of ϵ, $c \to c_0$. After we prove Lemma 2.4 we will find the value of c_0. Then $c \to c_0$ along all $\epsilon \to 0$.

We now return to the whole interval $(0,1)$ as we prove Lemma 2.4. We first construct a preliminary approximation $p = c\sum_j h_j$. The difference

$$\frac{du_\gamma}{d\gamma} - p$$

satisfies

$$-\epsilon^2\Delta\left(\frac{du_\gamma}{d\gamma} - p\right) + f'(u_\gamma)\left(\frac{du_\gamma}{d\gamma} - p\right) = \eta + O(\epsilon). \tag{A.8}$$

Together with the fact that

$$\frac{du_\gamma}{d\gamma}(x_j) = p(x_j),$$

we deduce that

$$\frac{du_\gamma}{d\gamma} - p = O(\epsilon) + O(|\eta|). \tag{A.9}$$

If we multiply (A.8) by a h_i and integrate, then

$$\eta = O\left(\epsilon^2\|\frac{du_\gamma}{d\gamma} - p\|_\infty\right) + O(\epsilon). \tag{A.10}$$

We conclude from (A.9) and (A.10) that

$$\frac{du_\gamma}{d\gamma} - p = O(\epsilon),\ \eta = O(\epsilon), \tag{A.11}$$

and consequently (recall $r = G_0[du_\gamma/d\gamma]$)

$$r = O(\epsilon). \tag{A.12}$$

We are now ready to consider the approximation q of $du_\gamma/d\gamma$. In the inner and matching regions,

$$\begin{aligned}
&-\epsilon^2\Delta q_j + f'(u_\gamma)q_j\\
&= -\epsilon^2\Delta(cH_j' + \epsilon^2R_j) + f'(u_\gamma)(cH_j' + \epsilon^2R_j)\\
&= c(f'(u_\gamma) - f'(H))H_j' - \epsilon^2(c_0PH_j'f''(H) + tv'(x_j) - \zeta) + \epsilon^2(f'(u_\gamma) - f'(H))R_j\\
&= \epsilon^2(c - c_0)f''(H)PH_j' - \epsilon^2(tv'(x_j) - \zeta) + \epsilon^2(f'(u_\gamma) - f'(H))R_j\\
&= -\epsilon^2(tv'(x_j) - \zeta) + o(\epsilon^2) + \epsilon^2O(\epsilon|t|)\\
&= \epsilon^2(\zeta - tv'(x_j)) + o(\epsilon^2).
\end{aligned}$$

Therefore, with the help of $\alpha \in (1/2, 1)$,

$$-\epsilon^2 \Delta q_j + f'(u_\gamma) q_j - \eta + \epsilon\gamma r + \epsilon v = -\eta + \epsilon\gamma r + \epsilon v(x_j) + \epsilon^2 \zeta + o(\epsilon^2). \tag{A.13}$$

In the outer region, the definition of q_0 in (2.16) implies that

$$-\epsilon^2 \Delta q_o + f'(u_\gamma) q_o - \eta + \epsilon\gamma r + \epsilon v = O(\epsilon^3), \tag{A.14}$$

because $\Delta q_o = O(\epsilon)$ on the outer region.

We now estimate the difference of q_j and q_o on a matching region. First, from (2.10) we find

$$\epsilon^2 \Delta q_j = O(\epsilon^3).$$

Then (A.13) implies that

$$f'(u_\gamma) q_j - \eta + \epsilon\gamma r + \epsilon\gamma v = \sigma + o(\epsilon^2),$$

where

$$\sigma = -\eta + \epsilon\gamma r(x_j) + \epsilon v(x_j) + \epsilon^2 \zeta. \tag{A.15}$$

Comparing this to (2.16) we deduce that

$$q_j - q_0 = O(|\sigma|) + o(\epsilon^2) \tag{A.16}$$

on the matching regions $(x_j - 2\epsilon^\alpha, x_j - \epsilon^\alpha)$ and $(x_j + \epsilon^\alpha, x_j + 2\epsilon^\alpha)$. Then we consider q in the matching region. Here by (A.16)

$$\begin{aligned}
&-\epsilon^2 \Delta q + f'(u_\gamma) q - \eta + \epsilon\gamma r + \epsilon v \\
&= -\epsilon^2 \Delta q_o + f'(u_\gamma) q_o - \eta + \epsilon\gamma r + \epsilon v + O(\|q_j - q_o\|_\infty) \\
&= -\epsilon^2 \Delta q + O(|\sigma|) + o(\epsilon^2) \\
&= -\epsilon^2 \Delta q - \epsilon^2 \Delta(\chi_j (q_j - q_o)) + O(|\sigma|) + o(\epsilon^2) \\
&= -\epsilon^2 (\chi_j''(q_j - q_o) + 2\chi_j'(q_j - q_o)' + \chi_j (q_j - q_o)'') + O(|\sigma|) + o(\epsilon^2) \\
&= O(|\sigma|) + o(\epsilon^2).
\end{aligned} \tag{A.17}$$

If we let $g = u - q$, then (A.13), (A.14), and (A.17) imply that

$$-\epsilon^2 \Delta g + f'(u_\gamma) g = \begin{cases} \sigma + o(\epsilon^2) & \text{in an inner region,} \\ O(|\sigma|) + o(\epsilon^2) & \text{in a matching region,} \\ O(\epsilon^3) & \text{in the outer region.} \end{cases} \tag{A.18}$$

We deduce from (A.18) and $g(x_j) = 0$ that

$$g = O(|\sigma|) + o(\epsilon^2). \tag{A.19}$$

On the other hand, if we multiply (A.18) by H_j' and integrate, then

$$\int_0^1 [(f'(u_\gamma) - f'(H)) g H_j'] \, dx = \epsilon \sigma_j + O(\epsilon^2 |\sigma|) + o(\epsilon^3).$$

But the integral on the left side is $O(\epsilon^2 \|g\|_\infty)$, from which we conclude that

$$\sigma = O(\epsilon \|g\|_\infty) + o(\epsilon^2). \tag{A.20}$$

Inserting (A.20) into (A.19) we find that

$$g = o(\epsilon^2), \tag{A.21}$$

proving Lemma 2.4; and substituting (A.21) into (A.20) we deduce that

$$\sigma = o(\epsilon^2). \tag{A.22}$$

Then we deduce

$$\eta = \epsilon v(x_j) + o(\epsilon). \tag{A.23}$$

Because $\overline{du_\gamma/d\gamma} = 0$,

$$0 = \overline{q} + o(\epsilon^2) = \epsilon \int_0^1 \frac{v^0(x_j^0) - v^0(x)}{f'(0)}\,dx + c\int_0^1 \sum_j h_j + o(\epsilon) = \epsilon\left(\frac{v^0(x_j^0)}{f'(0)} + c_0 K\right) + o(\epsilon).$$

Thus we obtain the value for c_0 in (2.8). ∎

Appendix B. Expansion of 2 ′(0).

In Appendices B and C we use the following simplified notations:

$$u := u_{\mathrm{B}},\ v := G_0[u_{\mathrm{B}} - a],\ \gamma := \gamma_{\mathrm{B}},\ \phi := \phi_{\mathrm{B}},\ \omega := \phi_{\mathrm{B}}^{\perp},\ f' := f'(H),\ f'' := f''(H), \text{ etc.} \tag{B.1}$$

The vector c_j in the expansion of ϕ satisfies $|c| = 1$.

Define a linear operator $\mathcal{L}$ by

$$\mathcal{L}U := U'' - f'U, \tag{B.2}$$

where U is defined on $\mathbf{R}$. Then

$$\mathcal{L}H_t = 0, \tag{B.3}$$

$$\mathcal{L}H_{tt} = f''H_t^2, \tag{B.4}$$

$$\mathcal{L}H_{ttt} = 3f''H_tH_{tt} + f'''H_t^3. \tag{B.5}$$

Let $u = s + \epsilon^2 p$, where s is given in (2.4). Then p satisfies

$$\epsilon^2 p'' - f'p = \frac{1}{\epsilon^2}[\gamma\epsilon G_0[u-a] - \text{const}] + \epsilon^2 f''\frac{p^2}{2} + O(\epsilon^4). \tag{B.6}$$

By Lemma 2.3, as $\epsilon \to 0$, $p(x_j + \epsilon\cdot) \to P$ in $C^2_{loc}(\mathbf{R})$, where P satisfies

$$\mathcal{L}P = \gamma(v^0)'(x_j^0)t. \tag{B.7}$$

Note that $P(t)$ is an odd function (and hence $P \perp H_t$). It is easy to compute that

$$\mathcal{L}P_t = f''H_tP + \gamma(v^0)'(x_j^0), \tag{B.8}$$

$$\mathcal{L}P_{tt} = (f''H_t)_tP + 2f''H_tP_t, \tag{B.9}$$

$$\mathcal{L}P_{ttt} = (f''H_t)_{tt}P + 3(f''H_t)_tP + 3f''H_tP_{tt}. \tag{B.10}$$

Recall Lemma 3.2. Set the decomposition

$$\phi(x) = \sum_{j=1}^{K} c_jh_j + \epsilon^2\omega,\ h_j \perp \omega, \tag{B.11}$$

for the zero principal eigenfunction ϕ. ω satisfies

$$\begin{aligned}&\epsilon^2\omega'' - \epsilon^2(m\pi)^2\omega - f'(u)\omega - \epsilon\gamma G_m[\omega]\\ &= -\frac{1}{\epsilon^2}\sum_{j=1}^{K} c_j[(f' - f'(u))h_j - \epsilon^2(m\pi)^2 h_j] + \frac{\gamma}{\epsilon}\sum_{k=1}^{K} c_k G_m[h_k].\end{aligned} \tag{B.12}$$

We further expand (B.12):

$$\begin{aligned}\epsilon^2\omega'' - f'\omega = &\sum_{j=1}^{K} c_j[f''H_t p - m^2\pi^2 H_t] \ + \frac{\gamma}{\epsilon}\sum_j c_j G_m[h_j]\\ &+\gamma\epsilon G_m[\omega] + \epsilon^2\left[f''p\omega + m^2\pi^2\omega + f'''\left(\sum_j c_j h_j\right)\frac{p^2}{2}\right] + O(\epsilon^3).\end{aligned} \tag{B.13}$$

As $\epsilon \to 0$, we have $\omega(x_j + \epsilon\cdot) \to c_j^0\Omega$ in $C^2_{loc}(\mathbf{R})$ just as in the proof of Lemma 3.2, where Ω satisfies

$$\mathcal{L}\Omega = f''H_t P - (m\pi)^2 H_t + \text{const},\ \Omega \text{ is even, and } \Omega \perp H_t. \tag{B.14}$$

Hence

$$\mathcal{L}\Omega_t = f''H_t\Omega + (f''H_t)_t P + f''H_t P_t - (m\pi)^2 H_{tt}. \tag{B.15}$$

Finally, we calculate $2g'(0)$. Since $\varphi_{\mathrm{B}}^2 = \phi^2(x)\cos^2(m\pi y)$, we decompose the solution of (5.5) into

$$2g'(0)(x,y) = \frac{g_1(x)}{2} + \frac{g_2(x)\cos(2m\pi y)}{2}, \tag{B.16}$$

where g_1 and g_2 are solutions of the following two equations:

$$\epsilon^2 g_1'' - f'(u)g_1 + \overline{f'(u)g_1} - \epsilon\gamma G_0[g_1] = f''(u)\phi^2 - \overline{f''(u)\phi^2},\ \ g_1'(0) = g_1'(1) = \overline{g_1} = 0; \tag{B.17}$$

$$\epsilon^2(g_2'' - 4m^2\pi^2 g_2) - f'(u)g_2 - \epsilon\gamma G_{2m}[g_2] = f''(u)\phi^2,\ g_2'(0) = g_2'(1) = 0. \tag{B.18}$$

Both equations are uniquely solvable, since the eigenvalues of the two operators in (B.17) and (B.18) are nonzero (the zero eigenvalue is associated with m); i.e., both operators are invertible.

We write

$$2g'(0) = \psi_1 + \epsilon^2\psi_2, \tag{B.19}$$

where

$$\psi_1(x,y) = \sum_j c_j^2 H_{tt}\left(\frac{x - x_j}{\epsilon}\right)\cos^2(m\pi y),\ \psi_2 = \frac{g_{11}}{2} + \frac{g_{21}}{2}\cos(2m\pi y). \tag{B.20}$$

Here

$$g_1 = \sum_j c_j^2 H_{tt}\left(\frac{x - x_j}{\epsilon}\right) + \epsilon^2 g_{11},\ g_2 = \sum_j c_j^2 H_{tt}\left(\frac{x - x_j}{\epsilon}\right) + g_{21}. \tag{B.21}$$

The equation for g_{11} is

$$
\begin{aligned}
&\epsilon^2 g_{11}'' - f'(u)g_{11} - \epsilon\gamma G_0[g_{11}] \\
&= \frac{\gamma c_j^2}{\epsilon} G_0[H_{tt}] + \frac{1}{\epsilon^2}[f''(u)\phi_m^2 - c_j^2 f'' H_t^2 - \overline{f''(u)\phi_m^2}] \\
&= \frac{\gamma c_j^2}{\epsilon} G_0[H_{tt}] + c_j^2 f''' H_t^2 p + 2f'' H_t c_j \omega + c_j^2 f'' H_{tt} p \\
&+\epsilon^2 \left[c_j^2 f^{(4)} H_t^2 \frac{p^2}{2} + c_j^2 f''' H_{tt} \frac{p^2}{2} + 2c_j f''' H_t p\omega + f''\omega^2 \right] + O(\epsilon^4) + C_1,
\end{aligned} \tag{B.22}
$$

where $C_1 = \epsilon^{-2}\overline{f''(u)\phi_m^2}$. By (B.15), it is easy to see that

$$
C_1 = \frac{1}{\epsilon^2}\int_0^1 f''(u)\phi_m^2 = \frac{1}{\epsilon^2}\sum_{j=1}^K f''(H+\epsilon^2 p)c_j^2 H_t^2 + o(1) = o(1). \tag{B.23}
$$

Similarly, the equation for g_{21} is

$$
\begin{aligned}
&\epsilon^2 g_{21}'' - 4m^2\pi^2 g_{21} - f'(u)g_{21} - \epsilon\gamma G_{2m}[g_{21}] \\
&= 4m^2\pi^2 c_j^2 H_{tt} + \frac{\gamma c_j^2}{\epsilon} G_{2m}[H_{tt}] + c_j^2 f''' H_t^2 p + 2f'' H_t c_j \omega + c_j^2 f'' H_{tt} p \\
&+\epsilon^2 \left[c_j^2 f^{(4)} H_t^2 \frac{p^2}{2} + c_j^2 f''' H_{tt} \frac{p^2}{2} + 2c_j f''' H_t p\omega + f''\omega^2 \right] + O(\epsilon^4).
\end{aligned} \tag{B.24}
$$

We state the following lemma.

LEMMA B.1. *As $\epsilon \to 0$, near x_j we have $g_{11}(x_j+\epsilon\cdot) \to (c_j^0)^2 G_{11}, g_{21}(x_j+\epsilon\cdot) \to (c_j^0)^2 G_{21}$, where G_{11} satisfies*

$$
\mathcal{L}G_{11} = f''' H_t^2 P + 2f'' H_t \Omega + f'' H_{tt} P,\ G_{11} \text{ is odd}
$$

and G_{21} satisfies

$$
\mathcal{L}G_{21} = f''' H_t^2 P + 2f'' H_t \Omega + f'' H_{tt} P + (2m\pi)^2 H_{tt},\ G_{21} \text{ is odd.}
$$

Proof. We only prove the convergence of g_{11}. The convergence of g_{21} is similar. To this end, let us decompose

$$
g_{11} = \sum_{j=1}^K \alpha_j (h_j - \overline{h_j}) + G_{11} + \hat{g}_{11},
$$

where $\hat{g}_{11} \perp h_j, j = 1, \ldots, K$, and $\int_0^1 \hat{g}_{11} = 0$. The key is to show that $\alpha_j = o(1)$.

Simple calculations show that $\hat{g}_{11}$ satisfies

$$
\epsilon^2 \hat{g}_{11}'' - f'(u)\hat{g}_{11} - \epsilon\gamma G_0[\hat{g}_{11}] = O\left(\epsilon^2 \sum_{j=1}^K |\alpha_j|\right) + o(1).
$$

Since $\hat{g}_{11} \perp h_j, j = 1, \ldots, K$, and $\int \hat{g}_{11} = 0$, standard arguments show that

$$
\hat{g}_{11} = O\left(\sum_{j=1}^K |\alpha_j|\epsilon^2\right) + o(1). \tag{B.25}
$$

We multiply (B.22) by h_j and integrate over $(0,1)$ to find

$$\begin{aligned}\epsilon C_1+\alpha_j\int_0^1(f'-f'(u))H_t^2 &= \int_0^1[c_j^2f'''H_t^2p+2c_jf''H_t\omega+c_j^2f''H_{tt}p]H_t+o(\epsilon^3)\\ &= \int_0^1[c_j^2f'''H_t^2p+c_j^2f''H_{tt}p]H_t+2c_j\int_0^1\mathcal{L}H_{tt}\omega+o(\epsilon^3)\\ &= \int_0^1[c_j^2f'''H_t^2p+3c_j^2f''H_{tt}p]H_t+o(\epsilon^3)\\ &= c_j^2\int_0^1(\mathcal{L}H_{ttt})p+o(\epsilon^3) \;=\; o(\epsilon^3).\end{aligned}$$

Thus we obtain the first identity

$$C_1+\epsilon^2\alpha_j\int_{\mathbf{R}}f''PH_t^2=o(\epsilon^2). \tag{B.26}$$

Next, we integrate (B.22) over $(0,1)$ and make use of (B.25) to deduce that

$$0=\int_0^1 f'(u)g_{11}=\int_0^1 f'(u)\left(\sum_j\alpha_j(h_j-\overline{h_j})+\hat{g}_{11}\right).$$

Thus we obtain the second identity

$$\sum_j\alpha_jf'(0)=o(1). \tag{B.27}$$

Substituting (B.27) into (B.26), we have that

$$C_1=o(\epsilon^2),\ \alpha_j=o(1), \tag{B.28}$$

and hence $\hat{g}_{11}=o(1)$. ∎

Appendix C. Proof of Lemma 5.2.

In this appendix we omit $\sum_j$ most of the time. When c_j appears in a quantity, $\sum_j$ is usually implied. We use the notation $A\approx B$ for $A-B=o(\epsilon^5)$.

Define a linear operator S by

$$S\psi:=\epsilon^2\Delta\psi-f'(u)\psi+\epsilon\gamma\Delta^{-1}\psi, \tag{C.1}$$

where ψ is a function on D. Recall ψ_1 and ψ_2 defined in (B.20). Note

$$\begin{aligned}S\psi_1 &= c_j^2\{(f'-f'(u))H_{tt}\cos^2(m\pi y)+f''H_t^2\cos^2(m\pi y)\\ &\quad -2\epsilon^2(m\pi)^2H_{tt}\cos(2m\pi y)+\epsilon\gamma\Delta^{-1}(H_{tt}\cos^2(m\pi y))\},\end{aligned} \tag{C.2}$$

$$\begin{aligned}S\psi_2 &= 2(m\pi)^2c_j^2H_{tt}\cos(2m\pi y)-\frac{\gamma c_j^2}{\epsilon}\Delta^{-1}(H_{tt}\cos^2(m\pi y))\\ &\quad +\frac{1}{\epsilon^2}(f''(u)\phi^2-c_j^2f''H_t^2)\cos^2(m\pi y)+\frac{c_j^2}{\epsilon^2}(f'(u)-f')H_{tt}\cos^2(m\pi y).\end{aligned} \tag{C.3}$$

Then

$$\begin{aligned}\int_D f''(u)\varphi^2(2g'(0)) \;&=\; \int_D(S(2g'(0)))(2g'(0))\\ &= \int_D(S\psi_1)\psi_1+2\epsilon^2\int_D(S\psi_2)\psi_1+\epsilon^4\int_D(S\psi_2)\psi_2 \;:=\; I_1+I_2+I_3,\end{aligned} \tag{C.4}$$

where the last equation defines I_1, I_2, and I_3. To prove Lemma 5.2 we compute

$$\int_D f''(u)\phi^2(2g'(0)) + \frac{1}{3}\int_D f'''(u)\phi^4 = I_1 + I_2 + I_3 + \frac{1}{3}\int_D f'''(u)\phi^4. \tag{C.5}$$

We start with I_2. From (C.3) we obtain

$$\begin{aligned}
I_2 &\approx 4\epsilon^3(m\pi)^2 c_j^4 \int_{\mathbf{R}} H_{tt}^2 \int_0^1 \cos^2(m\pi y)\cos(2m\pi y) \\
&\quad -2\epsilon\gamma c_j^4 \int_D (\Delta^{-1}(H_{tt}\cos^2(m\pi y)))H_{tt}\cos^2(m\pi y) \\
&\quad +2\epsilon c_j^2 \int_{\mathbf{R}} (f''(u)\phi^2 - c_j^2 f'' H_t^2)H_{tt} \int_0^1 \cos^4(m\pi y) \\
&\quad +2\epsilon c_j^4 \int_{\mathbf{R}} (f'(u) - f')H_{tt}^2 \int_0^1 \cos^4(m\pi y) \\
&\approx \epsilon^3(m\pi)^2 c_j^4 \int_{\mathbf{R}} H_{tt}^2 + \epsilon\gamma c_j^4 \int_0^1 (2G_0 + G_{2m})[H_{tt}]\frac{H_{tt}}{4} \\
&\quad +\frac{3\epsilon c_j^2}{4}\int_{\mathbf{R}} (f''(u)\phi^2 - c_j^2 f'' H_t^2)H_{tt} + \frac{3\epsilon c_j^4}{4}\int_{\mathbf{R}} (f'(u) - f')H_{tt}^2.
\end{aligned} \tag{C.6}$$

The last two terms in (C.6) are estimated as follows:

$$\begin{aligned}
&\frac{3\epsilon}{4}\int_{\mathbf{R}} (f''(u)\phi^2 - c_j^2 f'' H_t^2)H_{tt} \\
&\approx \frac{3\epsilon^3}{4}\int_{\mathbf{R}} \left(c_j^2 f''' p H_t^2 + 2c_j f'' H_t\omega + \epsilon^2 f''\omega^2 + 2\epsilon^2 c_j f''' p\omega + \epsilon^2 c_j^2 f^{(4)}\frac{p^2}{2}H_t^2\right)H_{tt}, \\
&\frac{3\epsilon}{4}\int_{\mathbf{R}} (f'(u) - f')H_{tt}^2 \\
&\approx \frac{3\epsilon^3}{4}\int_{\mathbf{R}} \left(f'' H_{tt}^2 p + \epsilon^2 f''' H_{tt}^2 \frac{p^2}{2}\right).
\end{aligned} \tag{C.7}$$

We substitute (C.7) into (C.6) to obtain

$$\begin{aligned}
I_2 &\approx \epsilon^3(m\pi)^2 c_j^4 \int_{\mathbf{R}} H_{tt}^2 + \epsilon\gamma c_j^4 \int_0^1 (2G_0 + G_{2m})[H_{tt}]\frac{H_{tt}}{4} \\
&\quad +\frac{3\epsilon^3 c_j^3}{4}\int_{\mathbf{R}} (c_j f''' H_t^2 H_{tt} p + c_j f'' H_{tt}^2 p + 2f'' H_t H_{tt}\omega) \\
&\quad +\frac{3\epsilon^5 c_j^2}{4}\int_{\mathbf{R}} \left(f'' H_{tt}\omega^2 + 2c_j f''' H_t H_{tt} p\omega + c_j^2 (f^{(4)} H_t^2 H_{tt} + f''' H_{tt}^2)\frac{p^2}{2}\right).
\end{aligned} \tag{C.8}$$

On the other hand,

$$\begin{aligned}
\frac{1}{3}\int_D f'''(u)\varphi^4 &= \frac{1}{8}\int_0^1 f'''(H + \epsilon^2 p)(c_j H_t + \epsilon^2\omega)^4 \\
&\approx \frac{\epsilon c_j^4}{8}\int_{\mathbf{R}} f''' H_t^4 + \frac{\epsilon^3 c_j^3}{8}\int_{\mathbf{R}} (c_j f^{(4)} H_t^4 p + 4f''' H_t^3\omega) \\
&\quad +\frac{\epsilon^5 c_j^2}{8}\int_{\mathbf{R}} \left(c_j^2 f^{(5)} H_t^4 \frac{p^2}{2} + 4c_j f^{(4)} H_t^3 p\omega + 6f''' H_t^2\omega^2\right).
\end{aligned}$$

We combine the last with (C.8) to deduce

$$
\begin{aligned}
& I_2 + \frac{1}{3}\int_D f'''(u)\varphi^4 \\
& \approx \frac{\epsilon c_j^4}{8}\int_{\mathbf{R}} f''' H_t^4 + \epsilon^3 (m\pi)^2 c_j^4 \int_{\mathbf{R}} H_{tt}^2 + \epsilon\gamma c_j^4 \int_0^1 (2G_0 + G_{2m})[H_{tt}]\frac{H_{tt}}{4} \\
& \quad + \frac{\epsilon^3 c_j^3}{8}\int_{\mathbf{R}} \{c_j (f^{(4)} H_t^4 + 6 f''' H_t^2 H_{tt} + 6 f'' H_{tt}^2) p + 4 (f''' H_t^3 + 3 f'' H_t H_{tt})\omega\} \\
& \quad + \frac{\epsilon^5 c_j^2}{8}\int_{\mathbf{R}} \Big\{ (6 f''' H_t^2 + 6 f'' H_{tt})\omega^2 + c_j (4 f^{(4)} H_t^3 + 12 f''' H_t H_{tt}) p\omega \\
& \quad + c_j^2 (f^{(5)} H_t^4 + 6 f^{(4)} H_t^2 H_{tt} + 6 f''' H_{tt}^2)\frac{p^2}{2}\Big\}.
\end{aligned} \tag{C.9}
$$

One term in the integral after $\epsilon^3 c_j^3/8$ is simplified using (B.5) and (B.13):

$$
\begin{aligned}
& \int_{\mathbf{R}} (f''' H_t^3 + 3 f'' H_t H_{tt})\omega \\
& = \int_{\mathbf{R}} (\mathcal{L} H_{ttt})\omega \;=\; \int_{\mathbf{R}} (\mathcal{L}\omega) H_{ttt} \;=\; \int_{\mathbf{R}} \{(f'(u) - f')H_{ttt}\omega + (\omega'' - f'(u)\omega) H_{ttt}\} \\
& = \epsilon^2 \int_{\mathbf{R}} f'' H_{ttt} p\omega + \epsilon^2 (m\pi)^2 \int_{\mathbf{R}} H_{ttt}\omega + \epsilon\gamma \int_0^1 G_m[\omega] H_{ttt} - (m\pi)^2 c_j \int_{\mathbf{R}} H_{tt}^2 \\
& + \frac{\gamma c_j}{\epsilon}\int_0^1 G_m[H_t] H_{ttt} + c_j \int_{\mathbf{R}} \left(f'' H_t H_{ttt} p + \epsilon^2 f''' H_t H_{ttt} \frac{p^2}{2}\right) + o(\epsilon^2).
\end{aligned} \tag{C.10}
$$

Here we have dropped $\int_0^1 G_m[\omega] H_{ttt} = \int_0^1 G_m[H_{ttt}]\omega = o(\epsilon)$. Substituting (C.10) into (C.9) we deduce

$$
\begin{aligned}
& I_2 + \frac{1}{3}\int_D f'''(u)\varphi^4 \\
& \approx \frac{\epsilon c_j^4}{8}\int_{\mathbf{R}} f''' H_t^4 + \frac{\epsilon^3 (m\pi)^2 c_j^4}{2}\int_{\mathbf{R}} H_{tt}^2 + \frac{\epsilon^5 (m\pi)^2 c_j^4}{2}\int_{\mathbf{R}} H_{ttt}\omega \\
& \quad + \epsilon\gamma c_j^4 \int_0^1 \left\{ (2G_0 + G_{2m})[H_{tt}]\frac{H_{tt}}{4} + G_m[H_t]\frac{H_{ttt}}{2}\right\} \\
& \quad + \frac{\epsilon^3 c_j^4}{8}\int_{\mathbf{R}} (f^{(4)} H_t^4 + 6 f''' H_t^2 H_{tt} + 6 f'' H_{tt}^2 + 4 f'' H_t H_{ttt}) p \\
& \quad + \frac{\epsilon^5 c_j^2}{8}\int_{\mathbf{R}} \Big\{ (6 f''' H_t^2 + 6 f'' H_{tt})\omega^2 + c_j (4 f^{(4)} H_t^3 + 12 f''' H_t H_{tt} + 4 f'' H_{ttt}) p\omega \\
& \quad + c_j^2 (f^{(5)} H_t^4 + 6 f^{(4)} H_t^2 H_{tt} + 4 f''' H_t H_{ttt} + 6 f''' H_{tt}^2)\frac{p^2}{2}\Big\}.
\end{aligned} \tag{C.11}
$$

Next we compute I_1. From (C.2) we deduce

$$
\begin{aligned}
I_1 \approx & \frac{3\epsilon c_j^4}{8}\int_{\mathbf{R}} f'' H_t^2 H_{tt} + \frac{3\epsilon c_j^4}{8}\int_{\mathbf{R}} (f' - f'(u)) H_{tt}^2 - \frac{\epsilon^3 (m\pi)^2 c_j^4}{2}\int_{\mathbf{R}} H_{tt}^2 \\
& + \epsilon\gamma c_j^4 \int_D (\Delta^{-1}(H_{tt}\cos^2(m\pi y)))(H_{tt}\cos^2(m\pi y))
\end{aligned}
$$

$$\approx \frac{3\epsilon c_j^4}{8}\int_{\mathbf{R}} f'' H_t^2 H_{tt} - \frac{3\epsilon^3 c_j^4}{8}\int_{\mathbf{R}} f'' H_{tt}^2 p - \frac{3\epsilon^5 c_j^4}{8}\int_{\mathbf{R}} f''' H_{tt}^2 \frac{p^2}{2} - \frac{\epsilon^3 (m\pi)^2 c_j^4}{2}\int_{\mathbf{R}} H_{tt}^2$$

$$-\epsilon\gamma c_j^4 \int_0^1 (2G_0 + G_{2m})[H_{tt}]\frac{H_{tt}}{8}. \tag{C.12}$$

(C.12) is added to (C.11). The ϵ order terms and the $\epsilon^3(m\pi)^2$ terms cancel out:

$$\begin{aligned}
&I_1 + I_2 + \frac{1}{3}\int_D f'''(u)\varphi^4 \\
&\approx \frac{\epsilon^5 (m\pi)^2 c_j^3}{2}\int_{\mathbf{R}} H_{ttt}\omega + \epsilon\gamma c_j^4 \int_0^1 \left\{(2G_0 + G_{2m})[H_{tt}]\frac{H_{tt}}{8} + G_m[H_t]\frac{H_{ttt}}{2}\right\} \\
&\quad + \frac{\epsilon^3 c_j^4}{8}\int_{\mathbf{R}} (f^{(4)} H_t^4 + 6f''' H_t^2 H_{tt} + 3f'' H_{tt}^2 + 4f'' H_t H_{ttt})p \\
&\quad + \frac{\epsilon^5 c_j^2}{8}\int_{\mathbf{R}} \Big\{(6f''' H_t^2 + 6f'' H_{tt})\omega^2 + c_j(4f^{(4)} H_t^3 + 12 f''' H_t H_{tt} + 4f'' H_{ttt})p\omega \\
&\quad + c_j^2 (f^{(5)} H_t^4 + 6f^{(4)} H_t^2 H_{tt} + 4f''' H_t H_{ttt} + 3f''' H_{tt}^2)\frac{p^2}{2}\Big\}.
\end{aligned} \tag{C.13}$$

The integral after $\epsilon^3 c_j^4/8$ is, by (B.6),

$$\begin{aligned}
&\int_{\mathbf{R}} (f^{(4)} H_t^4 + 6f''' H_t^2 H_{tt} + 3f'' H_{tt}^2 + 4f'' H_t H_{ttt})p \\
&= \int_{\mathbf{R}} (\mathcal{L} H_{tttt})p \;=\; \int_{\mathbf{R}} (\mathcal{L} p) H_{tttt} \\
&= \frac{\gamma}{\epsilon}\int_{\mathbf{R}} v H_{tttt} + \epsilon^2 \int_{\mathbf{R}} f'' H_{tttt}\frac{p^2}{2} + o(\epsilon^2) \;=\; \epsilon\gamma\int_{\mathbf{R}} v_{xx} H_{tt} + \epsilon^2\int_{\mathbf{R}} f'' H_{tttt}\frac{p^2}{2} + o(\epsilon^2) \\
&= -\epsilon\gamma \int_{\mathbf{R}} (H + \epsilon^2 p - a) H_{tt} + \epsilon^2 \int_{\mathbf{R}} f'' H_{tttt}\frac{p^2}{2} \;=\; \epsilon\gamma\int_{\mathbf{R}} H_t^2 + \epsilon^2 \int_{\mathbf{R}} f'' H_{tttt}\frac{p^2}{2} + o(\epsilon^2).
\end{aligned}$$

Hence (C.13) becomes

$$\begin{aligned}
&I_1 + I_2 + \frac{1}{3}\int_D f'''(u)\varphi^4 \\
&\approx \epsilon\gamma c_j^4 \int_0^1 \left\{(2G_0 + G_{2m})[H_{tt}]\frac{H_{tt}}{8} + G_m[H_t]\frac{H_{ttt}}{2}\right\} \\
&\quad + \frac{\epsilon^4 \gamma c_j^4}{8}\int_{\mathbf{R}} H_t^2 + \frac{\epsilon^5 (m\pi)^2 c_j^3}{2}\int_{\mathbf{R}} H_{ttt}\omega \\
&\quad + \frac{\epsilon^5 c_j^2}{8}\int_{\mathbf{R}} \Big\{(6f''' H_t^2 + 6f'' H_{tt})\omega^2 + c_j(4f^{(4)} H_t^3 + 12f''' H_t H_{tt} + 4f'' H_{ttt})p\omega \\
&\quad + c_j^2 (f^{(5)} H_t^4 + 6f^{(4)} H_t^2 H_{tt} + 4f''' H_t H_{ttt} + 3f''' H_{tt}^2 + f'' H_{tttt})\frac{p^2}{2}\Big\} \\
&= \epsilon\gamma c_j^4 \int_0^1 \left\{(2G_0 + G_{2m})[H_{tt}]\frac{H_{tt}}{8} + G_m[H_t]\frac{H_{ttt}}{2}\right\} \\
&\quad + \frac{\epsilon^4\gamma c_j^4}{8}\int_{\mathbf{R}} H_t^2 + \frac{\epsilon^5 (m\pi)^2 c_j^3}{2}\int_{\mathbf{R}} H_{ttt}\omega \\
&\quad + \frac{\epsilon^5 c_j^2}{8}\int_{\mathbf{R}} \left\{6(f'' H_t)_t \omega^2 + 4c_j (f'' Ht)_{tt} p\omega + c_j^2 (f'' H_t)_{ttt}\frac{p^2}{2}\right\}.
\end{aligned} \tag{C.14}$$

Finally, we compute I_3. By (C.3) we find

$$\begin{aligned}
I_3 &= \epsilon^4 \int_D (S\psi_2)\psi_2 \\
&\approx \epsilon^4 \Bigg\{ c_j^3 \int_D (c_j(f''H_t)_t p + 2f''H_t\omega)\cos^2(m\pi y)\left(\frac{g_{11}}{2} + \frac{g_{21}}{2}\cos(2m\pi y)\right) \\
&\quad +2(m\pi)^2 c_j^4 \int_D H_{tt}\cos(2m\pi)\left(\frac{g_{11}}{2} + \frac{g_{21}}{2}\cos(2m\pi y)\right) \\
&\quad -\frac{\gamma c_j^4}{\epsilon}\int_D (\Delta^{-1}(H_{tt}\cos^2(m\pi y)))\left(\frac{g_{11}}{2} + \frac{g_{21}}{2}\cos(2m\pi y)\right)\Bigg\} \\
&\approx \frac{\epsilon^5 (c_j^0)^4}{8}\int_{\mathbf{R}} ((f''(H_t)_t P + 2f''H_t\Omega)(2G_{11} + G_{21})) + \frac{\epsilon^5 (m\pi)^2 (c_j^0)^4}{2}\int_{\mathbf{R}} H_{tt}G_{21},
\end{aligned} \tag{C.15}$$

where we have used Lemma B.1. We have dropped the last integral of the second-last line because it is of order $o(\epsilon^2)$. Combining (C.14) and (C.15) we arrive at

$$\begin{aligned}
&I_1 + I_2 + I_3 + \frac{1}{3}\int_D f'''(u)\varphi^4 \\
&\approx \epsilon\gamma c_j^4 \int_0^1 \left\{(2G_0 + G_{2m})[H_{tt}]\frac{H_{tt}}{8} + G_m[H_t]\frac{H_{ttt}}{2}\right\} \\
&\quad + \frac{\epsilon^4\gamma c_j^4}{8}\int_{\mathbf{R}} H_t^2 + \frac{\epsilon^5 (m\pi)^2 (c_j^0)^4}{2}\int_{\mathbf{R}} H_{tt}(G_{21} - \Omega_t) \\
&\quad + \frac{\epsilon^5 (c_j^0)^4}{8}\int_{\mathbf{R}} \Bigg\{ 6(f''H_t)_t\Omega^2 + 4(f''Ht)_{tt}P\Omega + (f''H_t)_{ttt}\frac{P^2}{2} \\
&\quad +3((f''H_t)_t P + 2f''H_t\Omega)\Gamma \Bigg\}.
\end{aligned} \tag{C.16}$$

Here we have introduced

$$\Gamma := \frac{2G_{11} + G_{21}}{3}. \tag{C.17}$$

We simplify the last integral in (C.16). Let

$$\Omega = P_t + \Pi,\ \Gamma = P_{tt} + \Psi. \tag{C.18}$$

Note that by (3.12) and $\lambda(\gamma_{\mathrm{B}}) = 0$,

$$\mathcal{L}\Pi = (m\pi)^2 H_t + \text{const}, \quad \mathcal{L}\Psi = 2f''H_t\Pi + \frac{4(m\pi)^2}{3}H_{tt}. \tag{C.19}$$

The integral after $\epsilon^5 (c_j^0)^4/8$ in (C.16) is

$$\begin{aligned}
&\int_{\mathbf{R}} \left\{ (f''H_t)_{ttt}\frac{P^2}{2} + 6(f''H_t)_t P_t^2 + 4(f''H_t)_{tt}PP_t + 3((f''H_t)_t P + 2f''H_t P_t)P_{tt} \right\} \\
&+ \int_{\mathbf{R}} \{ 4(f''H_t)_{tt}P\Pi + 12(f''H_t)_t P_t\Pi + 6(f''H_t)_t\Pi^2 \\
&\quad +3((f''H)_t P + 2f''H_t P_t)\Psi + 6f''H_t\Pi\Psi + 6f''H_t\Pi P_{tt} \Bigg\}.
\end{aligned} \tag{C.20}$$

The first integral in (C.20) is 0 after integration by parts. To calculate the second integral note, by (B.9),

(C.21)

$$\int_{\mathbf{R}} 3((f''H_t)_t P + 2f''H_t P_t)\Psi$$
$$= 3\int_{\mathbf{R}} (\mathcal{L}P_{tt})\Psi = 3\int_{\mathbf{R}} (\mathcal{L}\Psi)P_{tt} = 6\int_{\mathbf{R}} f''H_t\Pi P_{tt} + 4(m\pi)^2\int_{\mathbf{R}} H_{tt}P_{tt},$$

(C.22)

$$\int_{\mathbf{R}} 6f''H_t\Pi\Psi$$
$$= 6\int_{\mathbf{R}} (\mathcal{L}\Pi_t - (m\pi)^2 H_{tt})\Psi \;=\; 6\int_{\mathbf{R}} \left(2f''H_t\Pi + \frac{4(m\pi)^2}{3}H_{tt}\right)\Pi_t - 6(m\pi)^2\int_{\mathbf{R}} H_{tt}\Psi$$
$$= -6\int_{\mathbf{R}} (f''H_t)_t\Pi^2 + 8(m\pi)^2\int_{\mathbf{R}} H_{tt}\Pi_t - 6(m\pi)^2\int_{\mathbf{R}} H_{tt}\Psi.$$

Substituting (C.21) and (C.22) into the second integral in (C.20) we find, with the help of (B.10) and (C.19),

(C.23)

$$\begin{aligned}
(\text{C.20}) = & \int_{\mathbf{R}} (4(f'H_t)_{tt}P + 12(f''H_t)_t P_t + 12f''H_t P_{tt})\Pi \\
& +4(m\pi)^2\int_{\mathbf{R}} H_{tt}P_{tt} + 8(m\pi)^2\int_{\mathbf{R}} H_{tt}\Pi_t - 6(m\pi)^2\int_{\mathbf{R}} H_{tt}\Psi \\
= & \, 4\int_{\mathbf{R}} (\mathcal{L}P_{ttt})\Pi + 4(m\pi)^2\int_{\mathbf{R}} H_{tt}P_{tt} + 8(m\pi)^2\int_{\mathbf{R}} H_{tt}\Pi_t - 6(m\pi)^2\int_{\mathbf{R}} H_{tt}\Psi \\
= & \, 4(m\pi)^2\int_{\mathbf{R}} H_t P_{ttt} + 4(m\pi)^2\int_{\mathbf{R}} H_{tt}P_{tt} + 8(m\pi)^2\int_{\mathbf{R}} H_{tt}\Pi_t - 6(m\pi)^2\int_{\mathbf{R}} H_{tt}\Psi \\
= & \, 8(m\pi)^2\int_{\mathbf{R}} H_{tt}\Pi_t - 6(m\pi)^2\int_{\mathbf{R}} H_{tt}\Psi.
\end{aligned}$$

(C.24)

Substituting (C.24) back into (C.16) we find

$$\begin{aligned}
& I_1 + I_2 + I_3 + \frac{1}{3}\int_D f'''(u)\varphi^4 \\
& \approx \epsilon\gamma c_j^4 \int_0^1 \left\{(2G_0 + G_{2m})[H_{tt}]\frac{H_{tt}}{8} + G_m[H_t]\frac{H_{ttt}}{2}\right\} + \frac{\epsilon^4\gamma c_j^4}{8}\int_{\mathbf{R}} H_t^2 \\
& + \frac{\epsilon^5(m\pi)^2(c_j^0)^4}{2}\int_{\mathbf{R}} H_{tt}\left(G_{21} - \Omega_t + 2\Pi_t - \frac{3}{2}\Psi\right).
\end{aligned} \tag{C.25}$$

Note that

$$\begin{aligned}
& \mathcal{L}\left(G_{21} - \Omega_t + 2\Pi_t - \frac{3}{2}\Psi\right) \\
& = 4(m\pi)^2 H_{tt} + f'''H_t^2 P + 2f''H_t\Omega + f''H_{tt}P \\
& \quad -2f''H_t\Omega - (f''H_t)_t P + f''H_t\Pi - (m\pi)^2 H_{tt}
\end{aligned} \tag{C.26}$$

$$+2f''H_t\Pi + 2(m\pi)^2 H_{tt} - \left(\frac{3}{2}\right) 2f''H_t\Pi - \left(\frac{3}{2}\right) \frac{4(m\pi)^2 H_{tt}}{3}$$
$$= 3(m\pi)^2 H_{tt}.$$

On the other hand, we may solve the last equation to find

$$G_{21} - \Omega_t + 2\Pi_t - \frac{3}{2}\Psi = \frac{3(m\pi)^2}{2} tH_t$$

since $\mathcal{L}(\frac{t}{2}H_t) = H_{tt}$. Hence the last integral in (C.25) is

$$\int_{\mathbf{R}} H_{tt}\left(G_{21} - \Omega_t + 2\Pi_t - \frac{3}{2}\Psi\right) = \frac{3(m\pi)^2}{2}\int_{\mathbf{R}} tH_tH_{tt} = -\frac{3(m\pi)^2\tau}{4}.$$

Putting this back into (C.25) we deduce

$$I_1 + I_2 + I_3 + \frac{1}{3}\int_D f'''(u)\varphi^4$$
$$\approx \epsilon\gamma c_j^4 \int_0^1 \left\{(2G_0 + G_{2m})[H_{tt}]\frac{H_{tt}}{8} + G_m[H_t]\frac{H_{ttt}}{2}\right\} + \frac{\epsilon^4\gamma c_j^4}{8}\int_{\mathbf{R}} H_t^2 - \frac{3\epsilon^5(m\pi)^2\tau(c_j^0)^4}{8}. \tag{C.27}$$

We now compute the first term in (C.27). Note that

$$\int_0^1 G_0[H_{tt}]H_{tt} = \epsilon^3\int_{\mathbf{R}} H_t^2 + o(\epsilon^4), \tag{C.28}$$

since $G_0[H_{tt}] = \epsilon^2(\overline{H(\frac{\cdot - x_j}{\epsilon})} - H(\frac{\cdot - x_j}{\epsilon}))$.

Recall that G_{2m} is identified with the Green function of

$$-G_{2m}'' + (2m\pi)^2 G_{2m} = \delta(\cdot - y), \quad G_{2m}'(0,y) = G_{2m}'(1,y) = 0.$$

G_{2m} splits to the fundamental solution part and the regular part:

$$G_{2m}(x,y) = \frac{1}{4m\pi}e^{-2m\pi|x-y|} - R_{2m}(x,y).$$

Note that R_{2m} is smooth in both variables x and y. We write down $G_{2m}(x,y)$ explicitly:

$$G_{2m}(x,y) = \frac{\cosh(2m\pi(1-|x-y|)) + \cosh(2m\pi(1-x-y))}{4m\pi\sinh(2m\pi)}.$$

Thus

$$R_{2m}(x,y) = \frac{1}{4m\pi}e^{-2m\pi|x-y|} - \frac{\cosh(2m\pi(1-|x-y|)) + \cosh(2m\pi(1-x-y))}{4m\pi\sinh(2m\pi)}.$$

We need to compute

$$R_{2m,xy}(y,y) := \left.\frac{\partial^2 R_{2m}}{\partial x\partial y}\right|_{x=y} = -m\pi + \frac{m\pi\cosh(2m\pi) - 2m\pi\cosh(2m\pi(1-2y))}{\sinh(2m\pi)}. \tag{C.29}$$

Then we have

$$G_{2m}[H_{tt}](x) = \int_0^1 G_{2m}(x,y) H_{tt}\left(\frac{y-x_j}{\epsilon}\right) dy.$$

By simple computations, we have that

$$\begin{aligned} G_{2m}[H_{tt}](x_j+\epsilon t) &= \epsilon \int_{-x_j/\epsilon}^{(1-x_j)/e} G_{2m}(x_j+\epsilon t, x_j+\epsilon z) H_{tt}(z)\, dz \\ &= \epsilon \int_{\mathbf{R}} \left[\frac{1}{4m\pi} e^{-2m\pi\epsilon|t-z|} - R_{2m}(x_j+\epsilon t, x_j+\epsilon z)\right] H_{zz} dz + o(\epsilon^4). \end{aligned} \tag{C.30}$$

We expand $e^{-2m\pi\epsilon|t-z|}$ to deduce

$$\begin{aligned} \int_{\mathbf{R}} e^{-2m\pi\epsilon|t-z|} H_{zz}\, dz &= \int_{\mathbf{R}} (1 - 2m\pi\epsilon|t-z| + 2(m\pi\epsilon)^2|t-z|^3 + O(\epsilon^3|t-z|^3)) H_{zz}\, dz \\ &= -4m\pi\epsilon H(t) + 4(m\pi\epsilon)^2 t + O(\epsilon^3). \end{aligned}$$

Hence (C.30) becomes

$$G_{2m}[H_{tt}](x_j+\epsilon t) = -\epsilon^2 H(t) + m\pi\epsilon^3 t - \epsilon \int_{\mathbf{R}} R_{2m}(x_j+\epsilon t, x_j+\epsilon z) H_{zz}\, dz. \tag{C.31}$$

Next we expand $R_{2m}(x_j+\epsilon t, x_j+\epsilon z)$ so that

$$\int_0^1 G_{2m}[H_{tt}]H_{tt} = \epsilon^3 \int_{\mathbf{R}} H_t^2 - m\pi\epsilon^4 - \epsilon^4 R_{2m,xy}(x_j^0, x_j^0) + o(\epsilon^4). \tag{C.32}$$

For the term involving G_m, by integrating by parts we obtain

$$\int_0^1 G_m[H_t]H_{ttt} = -\int_0^1 G_m^D[H_{tt}]H_{tt},$$

where $G_m^D[H_{tt}]$ is the Green function of

$$-(G_m^D)'' + (m\pi)^2 G_m^D = \delta(\cdot - y), \quad G_m^D(0,y)(0) = G_m^D(1,y) = 0. \tag{C.33}$$

The superscript D emphasizes the Dirichlet boundary condition. Similar to the Neumann boundary case we find

$$\begin{aligned} G_m^D(x,y) &= \frac{\cosh(m\pi(1-|x-y|)) - \cosh(m\pi(1-x-y))}{2m\pi\sinh(m\pi)}, \\ R_m^D(x,y) &:= \frac{1}{2m\pi} e^{-m\pi|x-y|} - \frac{\cosh(m\pi(1-|x-y|)) - \cosh(m\pi(1-x-y))}{2m\pi\sinh(m\pi)}, \\ R_{m,xy}^D(y,y) &:= \left.\frac{\partial^2 R_m^D}{\partial x \partial y}\right|_{x=y} = -\frac{m\pi}{2} + \frac{m\pi\cosh(m\pi) + m\pi\cosh(m\pi(1-2y))}{2\sinh(m\pi)}. \end{aligned} \tag{C.34}$$

By the same argument leading to (C.32), we arrive at

$$\int_0^1 G_m[H_t]H_{ttt} = -\epsilon^3 \int_{\mathbf{R}} H_t^2 + \frac{\epsilon^4 m\pi}{2} + \epsilon^4 R_{m,xy}^D(x_j^0, x_j^0) + o(\epsilon^4). \tag{C.35}$$

Substituting (C.28), (C.32), and (C.35) into (C.27), we obtain

$$\begin{aligned}
&I_1 + I_2 + I_3 + \frac{1}{3}\int_D f'''(u)\varphi^4 \\
&\approx \sum_{j=1}^K c_j^4 \left[\frac{\epsilon^5 \gamma m\pi}{8} - \frac{\epsilon^5\gamma}{8} R_{2m,xy}(x_j^0, x_j^0) + \frac{\epsilon^5\gamma}{2} R^D_{m,xy}(x_j^0, x_j^0) - \frac{3\epsilon^5 (m\pi)^4 \tau}{8} \right] \\
&\approx \epsilon^5 m\pi\gamma \sum_{j=1}^K (c_j^0)^4 \left[\frac{2+\cosh(2m\pi)}{8\sinh(2m\pi)} + \frac{\cosh(2m\pi(1-2x_j^0))}{8\sinh(2m\pi)} \right. \\
&\qquad\qquad \left. + \frac{\cosh(m\pi(1-2x_j^0))}{4\sinh(m\pi)} - \frac{3(m\pi)^3\tau}{8\gamma} \right]
\end{aligned}$$

using (C.29) and (C.34) (restoring the $\sum_j$ sign). This completes the proof. $\square$

Acknowledgments. We thank Professors R. Kohn and C. Muratov for conversations on the subject of block copolymers during the 50th annual SIAM conference in Philadelphia. Thanks also go to Professor D. Sattinger for discussion on the bifurcation theory. The support from The Institute of Mathematical Sciences at The Chinese University of Hong Kong is much appreciated.

LARGE SOLUTIONS FOR A SYSTEM OF ELLIPTIC EQUATIONS ARISING FROM FLUID DYNAMICS*

J. I. DÍAZ†, M. LAZZO‡, AND P. G. SCHMIDT§

Abstract. This paper is concerned with the elliptic system

$$\Delta v = \phi, \qquad \Delta \phi = |\nabla v|^2 \tag{0.1}$$

posed in a bounded domain $\Omega \subset \mathbb{R}^N$, $N \in \mathbb{N}$. Specifically, we are interested in the existence and uniqueness or multiplicity of "large solutions," that is, classical solutions of (0.1) that approach infinity at the boundary of Ω. Assuming that Ω is a ball, we prove that the system (0.1) has a unique radially symmetric and nonnegative large solution with $v(0) = 0$ (obviously, v is determined only up to an additive constant). Moreover, if the space dimension N is sufficiently small, there exists exactly one additional radially symmetric large solution with $v(0) = 0$ (which, of course, fails to be nonnegative). We also study the asymptotic behavior of these solutions near the boundary of Ω and determine the exact blow-up rates; those are the same for all radial large solutions and independent of the space dimension. Our investigation is motivated by a problem in fluid dynamics. Under certain assumptions, the unidirectional flow of a viscous, heat-conducting fluid is governed by a pair of parabolic equations of the form

$$v_t - \Delta v = \theta, \qquad \theta_t - \Delta \theta = |\nabla v|^2, \tag{0.2}$$

where v and θ represent the fluid velocity and temperature, respectively. The system (0.1), with $\phi = -\theta$, is the stationary version of (0.2).

Key words. elliptic system, boundary blow-up, large solutions, radial solutions, existence and multiplicity, asymptotic behavior

1. Introduction and main results. This paper is a contribution to the study of "explosive behavior" in certain systems of elliptic and parabolic PDEs. Our investigation is motivated by a question regarding the dynamics of a viscous, heat-conducting fluid.

In general, the flow of such a fluid is governed by a system of balance equations for momentum, mass, and energy. Under the assumptions of the so-called Boussinesq approximation, this system reduces to the Navier–Stokes equations for an incompressible fluid, along with a heat equation; the equations are nonlinearly coupled through the buoyancy force and viscous heating. If viscous heating (that is, the production of heat due to internal friction) is neglected, the resulting boundary and initial-boundary value problems are well posed in the same sense as for the classical Navier–Stokes equations without thermal coupling; but if viscous heating is taken into account, well-posedness is an open question. In fact, we conjecture that the solutions,

§Department of Mathematics and Statistics, Parker Hall, Auburn University, AL 36849–5310 (pgs@cam.auburn.edu).

in this case, may exhibit "explosive behavior." Such behavior would have implications for the viability of the Boussinesq approximation in situations where viscous heating cannot be neglected.

To address this issue, we are studying a simple prototype problem, which can be physically justified by considering a unidirectional flow, independent of distance in the flow direction:

$$v_t - \Delta v = \theta, \qquad \theta_t - \Delta\theta = |\nabla v|^2. \tag{1.1}$$

Here, v (the velocity) and θ (the temperature) are scalar functions of time t and position x; the spatial variable x varies over a bounded domain $\Omega \subset \mathbb{R}^N$ with $N \in \mathbb{N}$ ($N = 2$ in the physically relevant case, where Ω is the cross-section of the flow channel). The source terms θ and $|\nabla v|^2$ represent the buoyancy force and viscous heating, respectively. The system (1.1) must be supplemented by suitable initial conditions at time $t = 0$ and boundary conditions on the boundary $\partial\Omega$ of the domain Ω (for example, a homogeneous Dirichlet condition for v and a homogeneous Neumann condition for θ if the walls of the flow channel are impermeable and thermally insulated).

Note that we cannot hope to find weak solutions of the resulting initial-boundary value problem in the usual Hilbert-space setting: if v takes values in $H^1(\Omega)$, then the right-hand side of the second equation in (1.1) maps, a priori, only into $L^1(\Omega)$. However, local-in-time existence and uniqueness of a strong solution can be established by means of semigroup theory in a suitable L^p-space setting. We conjecture that this solution may blow up in finite time, in the sense that a suitable norm of (v, θ) approaches infinity as $t \to T^-$, for some $T > 0$. Preliminary analytical and numerical results for the parabolic problem will appear in a forthcoming publication.

In the present paper, we consider the stationary version of (1.1), that is, the elliptic system

$$-\Delta v = \theta, \qquad -\Delta\theta = |\nabla v|^2 \tag{1.2}$$

posed in a domain $\Omega \subset \mathbb{R}^N$ with $N \in \mathbb{N}$. Specifically, we are interested in the possibility of "boundary blow-up," that is, the existence of classical solutions (v, θ) of (1.2) with $|(v(x), \theta(x))| \to \infty$ as $\operatorname{dist}(x, \partial\Omega) \to 0$ (so-called large solutions). Note that the θ-component of any solution of (1.2) is superharmonic in Ω and thus cannot approach ∞ at the boundary (maximum principle); for a similar reason, v and θ cannot simultaneously approach $-\infty$ at the boundary. We therefore expect any large solution (v, θ) of (1.2) to satisfy $v(x) \to \infty$ and $\theta(x) \to -\infty$ as $\operatorname{dist}(x, \partial\Omega) \to 0$.

The preceding observation implies that large solutions of (1.2) cannot be expected to describe the asymptotics of explosive solutions of the parabolic system (1.1). Assuming, for example, that the temperature θ in (1.1) satisfies a homogeneous Neumann boundary condition on $\partial\Omega$, the temperature minimum is a nondecreasing function of time (parabolic maximum principle); thus, θ cannot approach $-\infty$ at the boundary. Nevertheless, boundary blow-up in the elliptic system (1.2) would have implications for the dynamics of the parabolic system (1.1) and its controllability. For example, large solutions of (1.2) may be used to construct "universal distributed bounds" (that is, interior bounds independent of the boundary data) for solutions of associated initial-boundary value problems and their steady states. We refer the reader to [3, 6, 7, 14, 23] and the references therein for similar arguments and applications in the context of other semilinear or quasilinear parabolic problems with superlinear nonlinearities.

Henceforth, we assume that Ω is a ball in $\mathbb{R}^N$, centered at the origin; that is, $\Omega = B_R^N(0)$ for some $R > 0$. For convenience, we introduce the function $\phi = -\theta$ and seek radially symmetric large solutions of the problem

$$\Delta v = \phi, \qquad \Delta\phi = |\nabla v|^2 \qquad \text{in } B_R^N(0), \tag{1.3}$$

that is, radial solutions (v, ϕ) with $|(v(x), \phi(x))| \to \infty$ as $|x| \to R^-$.

Remark 1.1. The problem (1.3) has a scaling property that we will exploit repeatedly. Suppose (v_1, ϕ_1) is a (large) solution of (1.3) with $R = R_1$. For $\lambda \in (0, \infty)$, let $R_\lambda := \lambda^{-1} R_1$. For $x \in B_{R_\lambda}^N(0)$, define

$$v_\lambda(x) := \lambda^2 v_1(\lambda x)\,, \quad \phi_\lambda(x) := \lambda^4 \phi_1(\lambda x)\,.$$

Then $(v_\lambda, \phi_\lambda)$ is a (large) solution of (1.3) with $R = R_\lambda$.

Remark 1.2. If (v, ϕ) is a (large) solution of (1.3), then so is $(v + c, \phi)$, for any constant $c \in \mathbb{R}$. Thus, we may restrict attention to solutions with $v(0) = 0$.

We will now state our main results, the first of which guarantees the existence of a unique (up to a shift in v) radially symmetric and nonnegative large solution for any space dimension.

Theorem 1.3. *For every $N \in \mathbb{N}$ and $R > 0$, the problem* (1.3) *has a unique radially symmetric large solution (v, ϕ) with $v(0) = 0$ and $\phi(0) > 0$. Both components of this solution are increasing functions of the radial variable r.*

If the space dimension is sufficiently small, there exists exactly one additional radially symmetric large solution with $v(0) = 0$, which, of course, fails to be nonnegative.

Theorem 1.4. *For every $N \in \mathbb{N}$ with $N \leq 10$ and every $R > 0$, the problem* (1.3) *has a unique radially symmetric large solution (v, ϕ) with $v(0) = 0$ and $\phi(0) < 0$. The ϕ-component of this solution is an increasing function of the radial variable r, while the v-component is decreasing to a negative minimum and increasing thereafter.*

Let us note that the bound on N in the above result is not sharp. In fact, based on numerical evidence (see Remarks 3.5 and 4.4), we conjecture that the solution of Theorem 1.4 exists if and only if $N \leq 14$.

With regard to asymptotic behavior, we find that, as expected, both components of a large solution approach infinity at the boundary, and we determine the exact blow-up rates; those are the same for all radially symmetric large solutions and independent of the space dimension. Here and in what follows, we write $f(x) \sim g(x)$ if the mappings $f, g : B_R^N(0) \to \mathbb{R}$ satisfy $f(x)/g(x) \to 1$ as $|x| \to R^-$.

Theorem 1.5. *Let (v, ϕ) be any radially symmetric large solution of* (1.3)*, for a given $N \in \mathbb{N}$ and $R > 0$. Then, as $|x| \to R^-$,*

$$v(x) \sim \frac{30}{(R - |x|)^2} \quad \textit{and} \quad \phi(x) \sim \frac{180}{(R - |x|)^4}\,.$$

The study of "explosive behavior," be it finite-time blow-up in evolutionary problems or boundary blow-up in stationary problems, has a long history going back to seminal work by Keller [15] and Osserman [20] in the 1950s; we refer the reader to the papers [2, 4, 8, 24] and the references therein. However, virtually all of the existing literature is concerned with scalar equations. Coupled systems of equations have been attacked only recently; see, for example, [5, 9, 10, 11, 16]. Due to the lack of variational structure and comparison principles, methods that have proven successful for scalar equations will, in general, fail to be useful for systems, even if the expected results are analogous. For example, our existence and multiplicity result for the problem (1.3) (existence of one large nonnegative solution for any space dimension, existence of a second large solution for sufficiently small space dimension) is analogous to a result by McKenna, Reichel, and Walter [17] for a class of scalar equations with variational structure. However, our method of proof is entirely different, and our result appears to be the first of its kind for an elliptic system. We expect that our work, while currently focussed on a very specific problem, will lead to general insights and new methods with potential applications to a much wider class of elliptic and parabolic systems.

The rest of the paper is organized as follows. In section 2 we reduce our problem to the study of a system of first-order ODEs, establish some basic properties of its solutions, and prove the existence and uniqueness of a nonnegative large radial solution for the problem (1.3); Theorem 1.3 is an immediate consequence of Proposition 2.5. Section 3 is devoted to the proof of Theorem 1.4 (existence of a second large radial solution for sufficiently small space dimension), which follows from Proposition 3.1. This section also includes a discussion of numerical experiments, suggesting a sharper version of Theorem 1.4, and observations about a related parameter-dependent fixed-point equation, leading to a Liouville-type theorem for the Dirichlet problem associated with the elliptic system (1.2). In section 4 we analyze the asymptotic behavior of large radial solutions of (1.3); Theorem 1.5 follows from Proposition 4.1, whose proof relies on dynamical-systems theory applied to an asymptotically autonomous and cooperative ODE system in $\mathbb{R}^3$. In an appendix at the end of the paper, we describe a Maple algorithm for the computer-aided construction of a priori bounds needed in the proof of Proposition 3.1.

2. Preliminaries and nonnegative large solutions. Given $N \in \mathbb{N}$ and $R > 0$, radially symmetric solutions of the problem (1.3) correspond to solutions of the ODE system

$$\begin{cases} v'' + \dfrac{N-1}{r}\, v' = \phi, \\ \phi'' + \dfrac{N-1}{r}\, \phi' = |v'|^2 \end{cases} \qquad \text{in } (0,R)$$

with $v'(0) = \phi'(0) = 0$; large solutions are those with $|(v(r),\phi(r))| \to \infty$ as $r \to R^-$. In view of Remark 1.2, we may impose the initial condition $v(0) = 0$. Finding radially symmetric large solutions of the problem (1.3) is therefore equivalent to finding initial conditions $\phi(0) = p$ such that the solution of the Cauchy problem

$$\begin{cases} v'' + \dfrac{N-1}{r}\, v' = \phi, & v(0) = 0,\ v'(0) = 0, \\ \phi'' + \dfrac{N-1}{r}\, \phi' = |v'|^2, & \phi(0) = p,\ \phi'(0) = 0 \end{cases} \tag{2.1}$$

exists on the interval $[0, R)$ and "blows up" at R.

Despite the singularity at $r = 0$ for $N > 1$, the Cauchy problem (2.1) is well posed. Indeed, for every $p \in \mathbb{R}$, there exists a unique maximal solution, which depends continuously on p (in the usual sense); see Lemma 2.3 for details.

Remark 2.1. The scaling property of the elliptic problem (1.3), as described in Remark 1.1, and the well-posedness of (2.1) imply that all solutions of the Cauchy problem with $p > 0$ ($p < 0$) are "rescalings" of the solution with $p = 1$ ($p = -1$). Indeed, if (v_1, ϕ_1) is the maximal solution with initial value $p = 1$ ($p = -1$), then the maximal solution with initial value $p > 0$ ($p < 0$) is given by $(v_\lambda, \phi_\lambda)$, as defined in Remark 1.1, with $\lambda = |p|^{1/4}$. Consequently, if the maximal solution with initial value $p = 1$ ($p = -1$) blows up at R_1, then the maximal solution with initial value $p > 0$ ($p < 0$) blows up at $R_p = |p|^{-1/4} R_1$.

REMARK 2.2. In light of the preceding remark, it is clear that the elliptic problem (1.3) has large radial solutions, for any given $R > 0$, if and only if the solutions of the Cauchy problem (2.1) with $p = \pm 1$ exhibit finite-time blow-up. More precisely, (1.3) has exactly one large radial solution with $v(0) = 0$ and $\phi(0) > 0$ if and only if the solution of (2.1) with $p = 1$ blows up in finite time; (1.3) has exactly one large radial solution with $v(0) = 0$ and $\phi(0) < 0$ if and only if the solution of (2.1) with $p = -1$ blows up in finite time. In particular, (1.3) cannot have more than two large radial solutions.

The Cauchy problem (2.1) is equivalent to the first-order system

$$\begin{cases} v' = w, & v(0) = 0, \\ w' + \dfrac{N-1}{r}\, w = \phi, & w(0) = 0, \\ \phi' = \psi, & \phi(0) = p, \\ \psi' + \dfrac{N-1}{r}\, \psi = w^2, & \psi(0) = 0. \end{cases}$$

Obviously, we can eliminate v and drop the first equation and initial condition; v is recovered from w via antidifferentiation. Furthermore, we may replace the nonnegative integer $N - 1$ with a continuous parameter $\mu \in \mathbb{R}_+$. Thus, we are led to the Cauchy problem

$$\begin{cases} w' + \dfrac{\mu}{r}\, w = \phi, & w(0) = 0, \\ \phi' = \psi, & \phi(0) = p, \\ \psi' + \dfrac{\mu}{r}\, \psi = w^2, & \psi(0) = 0. \end{cases} \tag{2.2}$$

LEMMA 2.3. *For every $\mu \in \mathbb{R}_+$ and $p \in \mathbb{R}$, the Cauchy problem* (2.2) *has a unique maximal, that is, noncontinuable, solution $(w, \phi, \psi) \in C^1([0, R), \mathbb{R}^3)$, for some $R \in (0, \infty]$. If $R < \infty$, then $|(w(r), \phi(r), \psi(r))| \to \infty$ as $r \to R^-$. Moreover, (w, ϕ, ψ) depends continuously on μ and p.*

Proof. What we claim is that, despite the singularity at $r = 0$ in the case $\mu > 0$, the Cauchy problem (2.2) has the usual, well-known properties of a regular initial-value problem in $\mathbb{R}^3$. Since we could not find a general result in the literature that would cover our problem, we provide a few remarks on the proof.

Note that the first equation in (2.2) can be written as $(r^\mu w)' = r^\mu \phi$. Together with the initial condition $w(0) = 0$, this is equivalent to the integral equation

$$w(r) = \int_0^r \left(\frac{s}{r}\right)^\mu \phi(s)\, ds. \tag{2.3}$$

Similarly, the remaining differential equations and initial conditions in (2.2) are equivalent to the integral equations

$$\phi(r) = p + \int_0^r \psi(s)\, ds \tag{2.4}$$

and

$$\psi(r) = \int_0^r \left(\frac{s}{r}\right)^\mu w^2(s)\, ds. \tag{2.5}$$

Since we have $0 < s/r < 1$ for $0 < s < r$, the "singular term" $(s/r)^\mu$ does not cause any difficulties in proving the existence and uniqueness of a solution (w, ϕ, ψ) in $C([0, \varepsilon], \mathbb{R}^3)$ of (2.3)–(2.5), for some $\varepsilon > 0$, by means of the contraction mapping principle. Clearly, w, ϕ, and ψ are continuously differentiable on $(0, \varepsilon]$ and satisfy the differential equations and initial conditions in (2.2). In fact, all three components are continuously differentiable on the *closed* interval $[0, \varepsilon]$. This is obvious for ϕ, but less so for w and ψ. Note, however, that

$$\begin{aligned}
\lim_{r\to 0^+} w'(r) &= \lim_{r\to 0^+} \Big(\phi(r) - \frac{\mu}{r}\, w(r)\Big) = p - \mu \lim_{r\to 0^+} \frac{1}{r}\int_0^r \Big(\frac{s}{r}\Big)^\mu \phi(s)\, ds \\
&= p - \mu \lim_{r\to 0^+} \frac{1}{r^{\mu+1}} \int_0^r s^\mu \phi(s)\, ds = p - \mu \lim_{r\to 0^+} \frac{r^\mu \phi(r)}{(\mu+1)\, r^\mu} \\
&= p - \mu \lim_{r\to 0^+} \frac{\phi(r)}{\mu+1} = p - \mu \frac{p}{\mu+1} = \frac{p}{\mu+1}\,,
\end{aligned}$$

where we used l'Hôspital's rule to get the fourth equality. Thus, $w \in C^1([0, \varepsilon], \mathbb{R})$ and $w'(0) = p/(\mu+1)$. Similarly, one shows that $\psi \in C^1([0, \varepsilon], \mathbb{R})$ with $\psi'(0) = 0$.

Once existence and uniqueness of a local C^1-solution are established, the remaining claims about maximal continuation and continuous dependence on parameters and initial data can be proved in the same way as for regular initial-value problems. □

LEMMA 2.4. *Let $(w, \phi, \psi) \in C^1([0, R), \mathbb{R}^3)$ be the maximal solution of the Cauchy problem* (2.2), *for some $\mu \in \mathbb{R}_+$ and $p \in \mathbb{R}$ with $p \neq 0$. Then the function ϕ is strictly increasing on $[0, R)$, and $L := \lim_{r\to R^-} \phi(r)$ is either zero or infinity. In fact,*

(a) *if $L < \infty$, then $R = \infty$ and $L = 0$;*

(b) *if $L = \infty$, then $R < \infty$ and $w(R^-) = \phi(R^-) = \psi(R^-) = \infty$.*

Proof. Taking into account the equations and initial conditions in (2.2), it is easy to see that the function $\Psi(r) := r^\mu \psi(r)$ is strictly increasing on $[0, R)$. As a consequence, Ψ (and thus ψ) is positive on $(0, R)$, and this implies that ϕ is strictly increasing on $[0, R)$, with $L := \lim_{r\to R^-} \phi(r) \in (p, \infty]$.

(a) Assume $L < \infty$, that is, ϕ is bounded. By (2.3), $w(r)$ grows at most linearly with r, and, by (2.5), $\psi(r)$ grows no faster than r^3. In particular, $|(w(r), \phi(r), \psi(r))|$ cannot go to infinity in finite time. Thus, $R = \infty$.

Now suppose that $L \neq 0$. If $L > 0$, choose a number $r_0 > 0$ such that $\phi(r) \geq L/2$ for every $r \geq r_0$. It follows that

$$w(r) \geq \int_0^{r_0} \Big(\frac{s}{r}\Big)^\mu \phi(s)\, ds + \frac{L}{2}\int_{r_0}^r \Big(\frac{s}{r}\Big)^\mu ds$$

for every $r \geq r_0$, and we conclude that $\lim_{r\to\infty} w(r) = \infty$ (note that the last integral is of order r). If $L < 0$, we infer in a similar way that $\lim_{r\to\infty} w(r) = -\infty$. In any case, we can choose a number $r_1 > 0$ such that $w^2(r) \geq 1$ for every $r \geq r_1$. As a consequence,

$$\psi(r) \geq \int_0^{r_1} \Big(\frac{s}{r}\Big)^\mu w^2(s)\, ds + \int_{r_1}^r \Big(\frac{s}{r}\Big)^\mu ds$$

for every $r \geq r_1$, and thus $\lim_{r\to\infty} \psi(r) = \infty$. But this implies

$$L = \lim_{r\to\infty} \phi(r) = p + \lim_{r\to\infty} \int_0^r \psi(s)\, ds = \infty\,,$$

a contradiction. It follows that $L = 0$.

(b) Assume $L = \infty$ and, by way of contradiction, suppose that $R = \infty$. Then there exist c_0, $r_0 > 0$ such that $\phi(r) \geq c_0$ for every $r \geq r_0$, and as in the proof of part (a) it follows that $w(r) \to \infty$ and $\psi(r) \to \infty$ as $r \to \infty$. In particular, we can choose $r_* > 0$ such that $w(r)$, $\phi(r)$, $\psi(r) > 0$ for every $r \geq r_*$. Define $\eta := w\,\phi\,\psi$. Then we have

$$\begin{aligned}\eta' &= \phi^2\psi + w\psi^2 + w^3\phi - \frac{2\mu}{r}\,w\,\phi\,\psi \\ &= Q\big(w,\phi,\psi\big)\,\eta^{13/12} - \frac{2\mu}{r}\,\eta \qquad \text{in } [r_*,\infty),\end{aligned} \tag{2.6}$$

where Q is defined by

$$Q(x,y,z) := \frac{y^2z + xz^2 + x^3y}{(xyz)^{13/12}}\,,$$

for x, y, $z > 0$. Note that $Q = Q_1 + Q_2 + Q_3$, with

$$Q_1 := \frac{y^2z}{(xyz)^{13/12}}\,, \quad Q_2 := \frac{xz^2}{(xyz)^{13/12}}\,, \quad Q_3 := \frac{x^3y}{(xyz)^{13/12}}\,.$$

It is easy to see that $Q_1^5\,Q_2^4\,Q_3^3 \equiv 1$, which implies that $\max(Q_1, Q_2, Q_3) \geq 1$. Hence, we have $Q(x,y,z) \geq 1$ for all x, y, $z > 0$, and (2.6) yields

$$\eta' \geq \eta\left(\eta^{1/12} - \frac{2\mu}{r_*}\right) \qquad \text{in } [r_*,\infty). \tag{2.7}$$

Recall that $w(r)$, $\phi(r)$, $\psi(r) \to \infty$ as $r \to \infty$ and choose $r^* \geq r_*$ such that $\eta(r^*) > (2\mu/r_*)^{12}$. Then the maximal solution ζ of the initial-value problem

$$\zeta' = \zeta\Big(\zeta^{1/12} - \frac{2\mu}{r_*}\Big)\,, \qquad \zeta(r^*) = \eta(r^*)$$

approaches infinity in finite time. But due to (2.7), ζ is bounded from above by η on $[r^*,\infty)$. This is a contradiction, and it follows that R is finite.

In order to prove our last claim, we first note that both w and ψ have (proper or improper) limits as $r \to R^-$. Indeed, since ϕ is eventually positive, the function $W(r) := r^\mu w(r)$ is eventually increasing, and thus has a limit as $r \to R^-$. As we observed earlier, the same holds for the function $\Psi(r) := r^\mu\psi(r)$. Since R is finite, it follows that $w(r)$ and $\psi(r)$, too, have limits as $r \to R^-$. Moreover, since R is finite, all three of the functions w, $\phi\,,\psi$ would be bounded if one of them were. But ϕ is unbounded (by assumption) and thus w and ψ are unbounded as well. Clearly, this implies that $w(R^-) = \phi(R^-) = \psi(R^-) = \infty$. ∎

PROPOSITION 2.5. *For every $\mu \in \mathbb{R}_+$, the maximal solution of the Cauchy problem* (2.2) *with $p = 1$ blows up in finite time.*

Proof. Fix $\mu \in \mathbb{R}_+$ and let $(w,\phi,\psi) \in C^1([0,R),\mathbb{R}^3)$ be the maximal solution of (2.2) with $p = 1$. According to Lemma 2.4, ϕ is increasing and $L := \lim_{r\to R^-}\phi(r)$ is either zero or infinity. Since $\phi(0) > 0$, we have $L = \infty$, and then part (b) of the same lemma implies that R is finite. ∎

Proof of Theorem 1.3. Thanks to Remark 2.2, the preceding proposition guarantees that the problem (1.3), for arbitrary $N \in \mathbb{N}$ and $R > 0$, has exactly one large radial solution (v, ϕ) with $v(0) = 0$ and $\phi(0) > 0$. By Lemma 2.4, ϕ is a strictly increasing function of the radial variable r, and the same then holds for v. (Note that, by Lemma 2.4, $\phi(r)$ approaches infinity as $r \to R^-$, and so do $v'(r)$ and $\phi'(r)$. That the same holds for $v(r)$ is not obvious at this point, but will follow from the blow-up estimates in section 4.) ∎

Figure 1 shows computed profiles of the nonnegative large radial solutions (v, ϕ) of the problem (1.3), with $R = 1$, for two values of the space dimension N (see Remark 4.4 for comments regarding the numerical method).

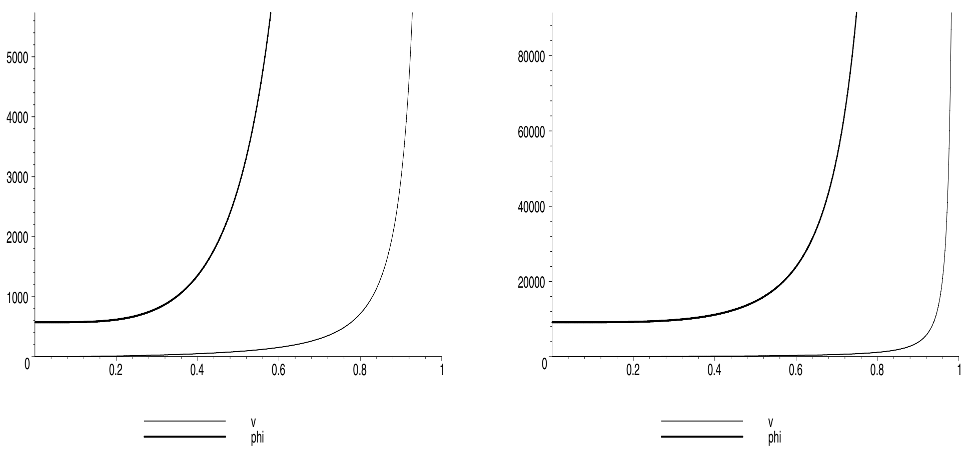

FIG. 1. *Large radial solutions* (v, ϕ) *with* $v(0) = 0$ *and* $\phi(0) > 0$ *of problem* (1.3) *with* $R = 1$ *for* $N = 1$ (*left*) *and* $N = 6$ (*right*).

3. Existence of a second large solution. To prove Theorem 1.4, we need to investigate for which values of $\mu \in \mathbb{R}_+$ (if any) the maximal solution of the Cauchy problem (2.2) with $p = -1$ blows up in finite time.

It is easy to see that blow-up occurs at least if $\mu \in [0, 1]$. Indeed, suppose that $\mu \in \mathbb{R}_+$ and that the corresponding maximal solution (w, ϕ, ψ) of (2.2) with $p = -1$ exists globally. Lemma 2.4 then implies that $\phi(r) \to 0$ as $r \to \infty$; thus, $\int_0^\infty \psi(s)\,ds = 1$, due to (2.4). On the other hand, since $\Psi(r) := r^\mu \psi(r)$ is strictly increasing for $r \geq 0$, we have $c := \Psi(1) > 0$ and $\psi(r) = \Psi(r)\,r^{-\mu} \geq c\,r^{-\mu}$ for all $r \geq 1$, which implies $\int_0^\infty \psi(s)\,ds \geq c \int_1^\infty s^{-\mu}\,ds$. Unless μ is greater than 1, this shows that $\int_0^\infty \psi(s)\,ds = \infty$, and we arrive at a contradiction.

Recalling Remark 2.2, we conclude that the elliptic problem (1.3) has a second large radial solution at least if the space dimension N is 1 or 2. The following proposition allows us to draw the same conclusion for any space dimension up to and including 10.

PROPOSITION 3.1. *For every* $\mu \in [0, 9]$, *the maximal solution of the Cauchy problem* (2.2) *with* $p = -1$ *blows up in finite time.*

Proof. Fix $\mu \in \mathbb{R}_+$ and let $(w, \phi, \psi) \in C^1([0, R), \mathbb{R}^3)$ be the corresponding maximal solution of (2.2) with $p = -1$. By Lemma 2.4, R is finite if and only if ϕ is eventually positive. We will prove the proposition by constructing explicit lower bounds for ϕ that are eventually positive if μ is small enough.

Clearly, since ϕ is an increasing function, we have

$$\phi(r) \geq \phi(0) = -1 =: \underline{\phi}_0(r)$$

for all $r \in [0, R)$. From this, we derive a lower bound for w; indeed,

$$w(r) = \int_0^r \left(\frac{s}{r}\right)^\mu \phi(s)\, ds \geq \int_0^r \left(\frac{s}{r}\right)^\mu \underline{\phi}_0(s)\, ds = -\frac{r}{\mu+1} =: \underline{w}_1(r)$$

for all $r \in [0, R)$. As long as $w \leq 0$, a lower bound for w yields an upper bound for ψ; in particular,

$$\psi(r) = \int_0^r \left(\frac{s}{r}\right)^\mu w^2(s)\, ds \leq \int_0^r \left(\frac{s}{r}\right)^\mu \underline{w}_1^2(s)\, ds = \frac{r^3}{(\mu+1)^2(\mu+3)} =: \overline{\psi}_1(r)$$

for all $r \in [0, R)$ with $w(r) \leq 0$ (note that $w(r) \leq 0$ implies $\underline{w}_1 \leq w \leq 0$ on $[0, r]$). Next, we find an upper bound for ϕ, namely,

$$\phi(r) = -1 + \int_0^r \psi(s)\, ds \leq -1 + \int_0^r \overline{\psi}_1(s)\, ds = -1 + \frac{r^4}{4(\mu+1)^2(\mu+3)} =: \overline{\phi}_1(r),$$

still valid for all $r \in [0, R)$ with $w(r) \leq 0$. Continuation of this process yields an upper bound for w,

$$w(r) \leq \int_0^r \left(\frac{s}{r}\right)^\mu \overline{\phi}_1(s)\, ds = -\frac{r}{\mu+1} + \frac{r^5}{4(\mu+1)^2(\mu+3)(\mu+5)} =: \overline{w}_1(r),$$

valid for all $r \in [0, R)$ with $w(r) \leq 0$, and then a lower bound for ψ,

$$\psi(r) \geq \int_0^r \left(\frac{s}{r}\right)^\mu \overline{w}_1^2(s)\, ds =: \underline{\psi}_1(r),$$

valid for all $r \in [0, r_0]$, where $r_0 := (4(\mu+1)(\mu+3)(\mu+5))^{1/4}$ is the unique positive root of $\overline{w}_1$ (note that $r_0 < R$ and $w \leq \overline{w}_1 \leq 0$ on $[0, r_0]$). Finally, we obtain an improved lower bound for ϕ,

$$\phi(r) \geq -1 + \int_0^r \underline{\psi}_1(s)\, ds =: \underline{\phi}_1(r),$$

valid for all $r \in [0, r_0]$.

If $\underline{\phi}_1(r_0)$ were nonnegative, the same would hold for $\phi(r_0)$, and this would imply blow-up. Now, $\underline{\phi}_1(r_0)$ is easily seen to be a rational function of μ, with a unique positive root μ_1, near 3.512, and positive on the interval $[0, \mu_1)$. Hence, blow-up does occur if $\mu \leq \mu_1$.

To improve this result, we iterate the preceding estimates and construct the improved bounds $\underline{w}_2$, $\overline{\psi}_2$, $\overline{\phi}_2$, $\overline{w}_2$, $\underline{\psi}_2$, and $\underline{\phi}_2$; since $w \leq \overline{w}_2 \leq \overline{w}_1 \leq 0$ on $[0, r_0]$, these are still valid on the entire interval $[0, r_0]$. The actual construction is best done with the aid of a computer-algebra system. All the bounds being polynomials, the computations amount to symbolic operations on the coefficients and can be implemented very efficiently. (A more naïve approach, using symbolic antidifferentiation, is likely to fail.) In an appendix at the end of the paper, we describe a Maple implementation of the algorithm.

Once the improved lower bound $\underline{\phi}_2$ for ϕ is constructed, we may determine the sign of $\underline{\phi}_2(r_0)$; this is once again a rational function of μ, with a unique positive root μ_2, near 4.307, and positive on the interval $[0,\mu_2)$. We conclude that blow-up does occur if $\mu \le \mu_2$.

Any attempt to push this method further by performing another round of estimates turns out to be futile—the computational cost is prohibitive, the gain marginal (the positive root of $\underline{\phi}_3(r_0)$ is located near 4.311). Instead, we will extend the lower bound $\underline{\phi}_2$ of ϕ beyond the interval $[0,r_0]$. To this end, let $r_1 \in (r_0,R)$ be such that $\phi(r_1) \le 0$. Then we have $\phi \le \overline{\phi}_2$ on $[0,r_0]$ and $\phi \le 0$ on $[r_0,r_1]$. It follows that for all $r \in [r_0,r_1]$,

$$w(r) \le \int_0^{r_0} \left(\frac{s}{r}\right)^{\mu} \overline{\phi}_2(s)\,ds = \left(\frac{r_0}{r}\right)^{\mu} \int_0^{r_0} \left(\frac{s}{r_0}\right)^{\mu} \overline{\phi}_2(s)\,ds = \alpha \left(\frac{r_0}{r}\right)^{\mu},$$

where $\alpha := \overline{w}_2(r_0) \le 0$, and then

$$\psi(r) \ge \int_0^{r_0} \left(\frac{s}{r}\right)^{\mu} \overline{w}_2^2(s)\,ds + \int_{r_0}^{r} \left(\frac{s}{r}\right)^{\mu} \alpha^2 \left(\frac{r_0}{s}\right)^{2\mu} ds = \beta \left(\frac{r_0}{r}\right)^{\mu} - \gamma \left(\frac{r_0}{r}\right)^{2\mu-1},$$

where $\beta := \gamma + \underline{\psi}_2(r_0)$, $\gamma := r_0\alpha^2/(\mu-1)$, and we have implicitly assumed that $\mu \ne 1$ (the case $\mu = 1$ will not be needed). Finally, we see that for all $r \in [r_0,r_1]$,

$$\begin{aligned}\phi(r) &\ge -1 + \int_0^{r_0} \underline{\psi}_2(s)\,ds + \int_{r_0}^{r} \left(\beta \left(\frac{r_0}{s}\right)^{\mu} - \gamma \left(\frac{r_0}{s}\right)^{2\mu-1}\right) ds \\ &= \widetilde{\alpha} \left(\frac{r_0}{r}\right)^{2(\mu-1)} - \widetilde{\beta} \left(\frac{r_0}{r}\right)^{\mu-1} + \widetilde{\gamma}\,,\end{aligned}$$

with $\widetilde{\alpha} := (1/2)r_0\gamma/(\mu-1)$, $\widetilde{\beta} := r_0\beta/(\mu-1)$, $\widetilde{\gamma} := (1/2)r_0(2\beta-\gamma)/(\mu-1) + \underline{\phi}_2(r_0)$, and hence,

$$0 \ge (\mu-1)^2\phi(r) \ge a \left(\frac{r_0}{r}\right)^{2(\mu-1)} - b \left(\frac{r_0}{r}\right)^{\mu-1} + c\,, \tag{3.1}$$

where

$$a := (\mu-1)^2\widetilde{\alpha} = \frac{1}{2} r_0^2\, \overline{w}_2^2(r_0)\,,$$

$$b := (\mu-1)^2\widetilde{\beta} = r_0^2\, \overline{w}_2^2(r_0) + (\mu-1)r_0\underline{\psi}_2(r_0)\,,$$

$$c := (\mu-1)^2\widetilde{\gamma} = \frac{1}{2} r_0^2\, \overline{w}_2^2(r_0) + (\mu-1)r_0\underline{\psi}_2(r_0) + (\mu-1)^2\underline{\phi}_2(r_0)\,.$$

The estimate (3.1) holds for every $r \in [r_0,R)$, provided that $\phi(r) \le 0$, and for any value of μ (trivially if $\mu = 1$). The coefficients a, b, and c are rational functions of μ (note that r_0^4 is a polynomial in μ, while $r^2\overline{w}_2^2(r)$, $r\underline{\psi}_2(r)$, and $\underline{\phi}_2(r)$ are polynomials in r^4, whose coefficients are rational functions of μ); this facilitates their symbolic computation and analysis. In particular, it is easily verified (see the appendix) that c has a unique root, $\bar{\mu} \approx 9.073$, in the interval $(1,\infty)$ and is positive on $(1,\bar{\mu})$. It follows that if $\mu \in (1,\bar{\mu})$, the right-hand side of the inequality (3.1) becomes positive as $r \to \infty$. But then, the inequality cannot hold for all $r \ge r_0$, which implies that R is finite. Since this is already known to be true if $\mu \in [0,1]$, the proposition is proved. $\square$

Remark 3.2. We emphasize that the proof of Proposition 3.1, while relying heavily on the use of a computer-algebra system, does not involve any numerical techniques or floating-point arithmetic. In fact, all the computations amount to symbolic algebra on the coefficients of certain polynomials. The crucial fact that the coefficient c in the estimate (3.1), a rational function of μ, has a unique root, $\bar{\mu} \approx 9.073$, in the interval $(1, \infty)$ can be verified by applying Descartes's rule of signs (and the intermediate-value theorem) to the numerator polynomial (the roots of the denominator polynomial are negative integers). We refer the reader to the appendix for implementation details.

Remark 3.3. The estimates in the proof of Proposition 3.1 involve some deliberate choices, but are in some sense optimal. Of course, it is computationally much less expensive to use the bounds $\overline{w}_1$, $\underline{\psi}_1$, and $\underline{\phi}_1$ (instead of $\overline{w}_2$, $\underline{\psi}_2$, and $\underline{\phi}_2$) for the "tail estimate" (3.1); also, the estimate itself is simpler in this case, since the coefficient a vanishes. Again, the coefficient c has a unique root in the interval $(1, \infty)$, but it is located near 5.606, leading to a much weaker result. A slight improvement is achieved by using the polynomial bounds $\overline{w}_1$, $\underline{\psi}_1$, and $\underline{\phi}_1$ only on the smaller interval $[0, \tilde{r}_0]$ (instead of $[0, r_0]$), where $\tilde{r}_0 := (4(\mu+1)^2(\mu+3))^{1/4}$ is the unique positive root of $\overline{\phi}_1$. The coefficient c in (3.1) then has a unique positive root near 5.955. Using the improved bounds $\overline{w}_2$, $\underline{\psi}_2$, and $\underline{\phi}_2$ (as in the proof of Proposition 3.1), but on the smaller interval $[0, \tilde{r}_0]$ (instead of $[0, r_0]$), yields a coefficient c with a unique positive root near 7.709. It is natural to ask whether it would make sense to construct the bounds $\overline{w}_3$, $\underline{\psi}_3$, and $\underline{\phi}_3$ before proceeding with the "tail estimate." The answer is negative; in fact, the symbolic computations would require an enormous amount of virtual memory, without leading to a tangibly improved result (the relevant root of the coefficient c in (3.1) is located near 9.170).

Remark 3.4. The estimates in the proof of Proposition 3.1 yield explicit a priori bounds for the zero z_0 of ϕ (the ϕ-component of the maximal solution of the Cauchy problem (2.2) with $\mu \in \mathbb{R}_+$ and $p = -1$), assuming that it exists. Clearly, a lower bound is given by $\tilde{r}_0 := (4(\mu+1)^2(\mu+3))^{1/4}$, the unique positive root of $\overline{\phi}_1$. To establish an upper bound, note that either $z_0 \le r_0$, where $r_0 := (4(\mu+1)(\mu+3)(\mu+5))^{1/4}$ is the unique positive root of $\overline{w}_1$, or $z_0 > r_0$. In the latter case, which can arise only if $\mu > \mu_2 \approx 4.307$, (3.1) implies that

$$a \left(\frac{r_0}{z_0}\right)^{2(\mu-1)} - b \left(\frac{r_0}{z_0}\right)^{\mu-1} + c \;\le\; 0$$

and thus

$$s_1 \;\le\; \left(\frac{r_0}{z_0}\right)^{\mu-1} \;\le\; s_2\,,$$

where $s_{1,2} := (b \pm \sqrt{d})/(2a)$ with $d := b^2 - 4ac$ (the discriminant d is positive for $\mu \ne 1$, zero for $\mu = 1$). As long as $\mu > 1$ and s_1 is positive (which is the case for $1 < \mu < \bar{\mu} \approx 9.073$), it follows that $z_0 \le r_0 s_1^{1/(1-\mu)}$. Hence, an upper bound for z_0 is given by r_0 if $0 \le \mu \le \mu_2$ and by $r_0 s_1^{1/(1-\mu)}$ if $\mu_2 < \mu < \bar{\mu}$. A little computation shows that this upper bound may be written, more concisely yet equivalently, as $r_0 \max(1, s_0^{1/(1-\mu)})$, where $s_0 := (b - \operatorname{sign}(\mu-1)\sqrt{d})/(2a)$. Summarizing, we have

$$\tilde{r}_0 \le z_0 \le r_0 \max(1, s_0^{1/(1-\mu)})$$

for every $\mu \in [0, \bar{\mu})$; the upper bound is a continuous function of μ, positive on $[0, \bar{\mu})$, with a vertical asymptote at $\bar{\mu}$.

Proof of Theorem 1.4. Due to Remark 2.2, Proposition 3.1 implies that the elliptic problem (1.3), for arbitrary $R > 0$, has exactly one large radial solution (v, ϕ) with $v(0) = 0$ and $\phi(0) < 0$ if $\mu = N - 1 \leq 9$, that is, if $N \leq 10$. Lemma 2.4 shows that ϕ is a strictly increasing function of the radial variable r and crosses zero at a point $z_0 \in (0, R)$. Hence, the function $W(r) := r^\mu w(r)$, with $w = v'$, is strictly decreasing for $r < z_0$ and strictly increasing for $r > z_0$; it crosses zero at a point $z_1 \in (z_0, R)$. Thus, v' is negative on $(0, z_1)$, positive on (z_1, R), and consequently, v is strictly decreasing to a negative minimum at z_1, strictly increasing thereafter. ∎

Remark 3.5. Numerical evidence suggests that Proposition 3.1 (and with it, Theorem 1.4) may be significantly improved. In fact, there appears to be a number $\tilde{\mu}$, approximately equal to 13.755, such that the maximal solution of the Cauchy problem (2.2) with $p = -1$ blows up in finite time if and only if $\mu < \tilde{\mu}$. Consequently, we conjecture that the large solution of Theorem 1.4 exists if and only if $N \leq 14$.

Figure 2 depicts computed profiles of the large radial solutions (v, ϕ) with $v(0) = 0$ and $\phi(0) < 0$ of the problem (1.3), with $R = 1$, for several values of the space dimension N (see Remark 4.4 for comments on the numerical method). In particular, the solution is shown for $N = 10$, the largest space dimension for which we proved its existence, and for $N = 14$, the largest space dimension for which we found it numerically. Of course, we can compute the large solution (v, ϕ) with $v(0) = 0$ and $\phi(0) < 0$ of the radial version of (1.3) for every value of $\mu = N - 1$, not necessarily integer, up to $\tilde{\mu} \approx 13.755$. As $\mu \to \tilde{\mu}$, the ϕ-component of the solution appears to approach $c_R\delta_R - c_0\delta_0$, for some positive constants c_0 and c_R, where δ_0 and δ_R denote the Dirac distributions centered at 0 and R, respectively.

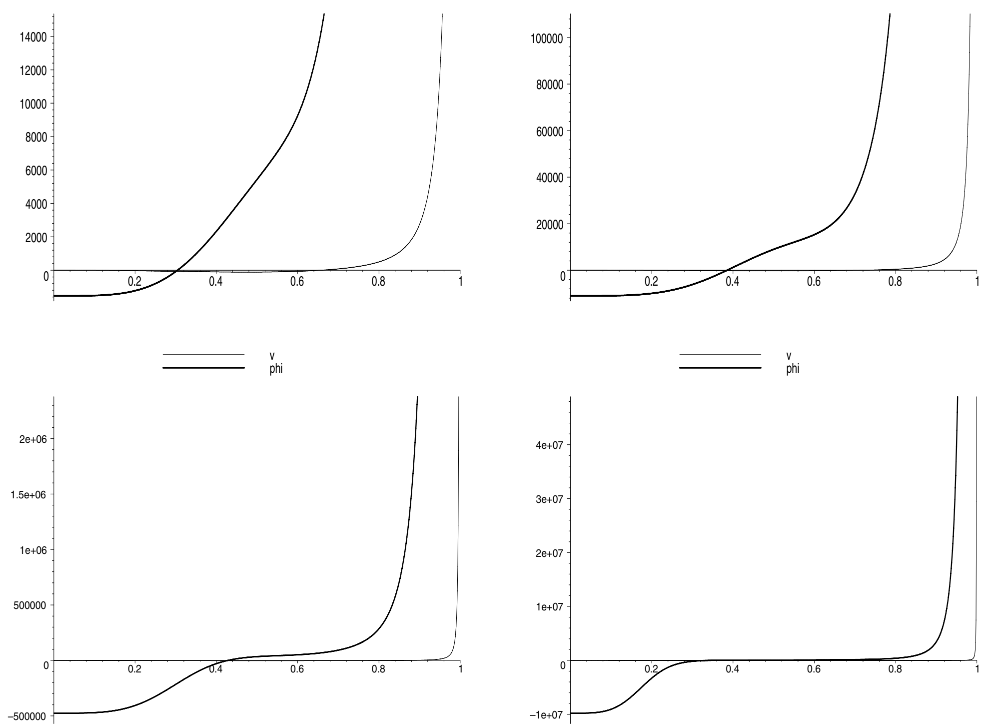

Fig. 2. *Large radial solutions (v, ϕ) with $v(0) = 0$ and $\phi(0) < 0$ of problem (1.3) with $R = 1$ for $N = 1$ (top left), $N = 3$ (top right), $N = 10$ (bottom left), and $N = 14$ (bottom right).*

We will now describe how the question of finite-time blow-up in the Cauchy problem (2.2) can be recast as a question regarding the existence of nontrivial solutions of a related boundary-value problem or, equivalently, a parameter-dependent fixed-point equation. This approach will allow us to exploit standard tools of nonlinear analysis (such as the degree of mapping and bifurcation theory) and to gain some additional information not otherwise available. As a corollary, we will obtain a Liouville-type result (existence of a positive solution) for the Dirichlet problem associated with the elliptic system (1.2), which is of independent interest.

Given $\mu \in \mathbb{R}_+$, the maximal solution (w, ϕ, ψ) of the Cauchy problem (2.2) with $p = -1$ blows up in finite time if and only if ϕ crosses zero at some point $r > 0$. Due to the scaling property of the system (see Remark 2.1), this happens if and only if there exists a (necessarily negative and unique) initial value p such that the ϕ-component of the corresponding maximal solution of (2.2) crosses zero at $r = 1$. In other words, the maximal solution of (2.2) with $p = -1$ blows up in finite time if and only if the boundary-value problem

$$\begin{cases} w' + \dfrac{\mu}{r}\, w = \phi, & w(0) = 0, \\ \phi' = \psi, & \phi(1) = 0, \\ \psi' + \dfrac{\mu}{r}\, \psi = w^2, & \psi(0) = 0 \end{cases} \tag{3.2}$$

has a (necessarily unique) nontrivial solution.

The problem (3.2) can be written as a parameter-dependent fixed-point equation of the form

$$u = T(\mu, u) \tag{3.3}$$

in $X := C([0,1], \mathbb{R}^3)$, where $T : \mathbb{R}_+ \times X \to X$ is a completely continuous operator, defined by

$$T(\mu, u)(r) := \left(\int_0^r \left(\frac{s}{r}\right)^{\mu} \phi(s)\, ds\, ,\ -\int_r^1 \psi(s)\, ds\, ,\ \int_0^r \left(\frac{s}{r}\right)^{\mu} w^2(s)\, ds \right),$$

for $\mu \in \mathbb{R}_+$, $u = (w, \phi, \psi) \in X$, and $r \in [0, 1]$. We are interested in the structure of the solution set

$$\Sigma := \{(\mu, u) \in \mathbb{R}_+ \times X : u = T(\mu, u)\}.$$

Clearly, Σ contains the branch of trivial solutions of (3.3), $\mathbb{R}_+ \times \{0\}$. Also, as mentioned above, (3.3) cannot have more than one nontrivial solution for any $\mu \in \mathbb{R}_+$; hence, the set $\Sigma \setminus (\mathbb{R}_+ \times \{0\})$ is the graph of a function $\mu \mapsto u_\mu$. Let M denote the domain of this function, that is,

$$M := \{\mu \in \mathbb{R}_+ : u = T(\mu, u) \text{ for some } u \in X \setminus \{0\}\}, \tag{3.4}$$

and define

$$\mu^* := \sup(\{\mu \in \mathbb{R}_+ \,:\, [0, \mu] \subset M\}), \tag{3.5}$$

with the understanding that $\sup(\emptyset) = 0$ and $\sup(A) = \infty$ if $A \subset \mathbb{R}_+$ is unbounded.

Remark 3.6. From the discussion leading to (3.3), it is evident that M, as defined in (3.4), coincides with the set of all $\mu \in \mathbb{R}_+$ for which the maximal solution of the Cauchy problem (2.2) with $p = -1$ blows up in finite time. Thus, M contains the interval $[0, 9]$, by Proposition 3.1. The subsequent arguments will prove this once again (we will only need the a priori estimates from Remark 3.4).

Remark 3.7. We can characterize M as the set of all $\mu \in \mathbb{R}_+$ for which the ϕ-component of the maximal solution of (2.2) with $p = -1$ is eventually positive. Since the solution depends continuously on μ, this property is stable under small perturbations of μ. It follows that the set M is open in $\mathbb{R}_+$ and, hence, μ^* is not an element of M. On the other hand, it is clear from the definition of μ^* that M contains the interval $[0, \mu^*)$.

Remark 3.8. Suppose that $\mu \in M$, $u_\mu = (w_\mu, \phi_\mu, \psi_\mu)$ is the corresponding nontrivial solution of (3.3), and $u = (w, \phi, \psi)$ is the corresponding maximal solution of the Cauchy problem (2.2) with $p = -1$. Then, due to the scaling property of the problem, u_μ is a "rescaling" of u. In fact, denoting the unique zero of ϕ by z_μ, we have $w_\mu(r) = z_\mu^3\, w(z_\mu r)$, $\phi_\mu(r) = z_\mu^4\, \phi(z_\mu r)$, and $\psi_\mu(r) = z_\mu^5\, \psi(z_\mu r)$, for all $r \in [0, 1]$. Since $u = (w, \phi, \psi)$ depends continuously on μ, so does z_μ. It follows that the function $\mu \mapsto u_\mu$ is continuous as a mapping from $M \subset \mathbb{R}_+$ into X.

Lemma 3.9. *Given $\mu \in M$, let u_μ denote the unique nontrivial solution of* (3.3). *Then $\|u_\mu\|_\infty \geq 4(\mu + 1)^2(\mu + 3) \geq 12$. Moreover, there exists a continuous function $\bar{f} : [0, \bar{\mu}) \to \mathbb{R}_+$, with $\bar{\mu} \approx 9.073$, such that $\|u_\mu\|_\infty \leq \bar{f}(\mu)$, provided that $\mu \in [0, \bar{\mu})$.*

Proof. Fix a number $\mu \in M$, let $u_\mu = (w_\mu, \phi_\mu, \psi_\mu)$ denote the corresponding nontrivial solution of (3.3), and let $u = (w, \phi, \psi)$ denote the corresponding maximal solution of the Cauchy problem (2.2) with $p = -1$. According to Remark 3.8, we have $\phi_\mu(r) = z_\mu^4\, \phi(z_\mu r)$ for all $r \in [0, 1]$, where z_μ is the zero of ϕ; in particular, $|\phi_\mu(0)| = z_\mu^4$. Recalling the a priori bounds in Remark 3.4, we obtain the estimate

$$|\phi_\mu(0)| \geq 4(\mu + 1)^2(\mu + 3) \geq 12 \tag{3.6}$$

and, furthermore, the existence of a continuous function $f : [0, \bar{\mu}) \to [1, \infty)$, with $\bar{\mu} \approx 9.073$, such that

$$|\phi_\mu(0)| \leq 4(\mu + 1)(\mu + 3)(\mu + 5) f(\mu)\,, \tag{3.7}$$

provided that $\mu \in [0, \bar{\mu})$. Next, observe that

$$\|\phi_\mu\|_\infty = |\phi_\mu(0)|\,, \qquad \|w_\mu\|_\infty \leq \frac{|\phi_\mu(0)|}{\mu + 1} \leq |\phi_\mu(0)|\,,$$

and

$$\|\psi_\mu\|_\infty \leq \frac{|\phi_\mu(0)|^2}{(\mu + 1)^2(\mu + 3)} \leq \frac{1}{3}\, |\phi_\mu(0)|^2\,;$$

since $|\phi_\mu(0)| \geq 12$ by (3.6), this implies that $\|(w_\mu, \phi_\mu, \psi_\mu)\|_\infty \leq |\phi_\mu(0)|^2$. Consequently, we have

$$|\phi_\mu(0)| \leq \|u_\mu\|_\infty \leq |\phi_\mu(0)|^2,$$

and now the assertions of the lemma follow from (3.6) and (3.7). ∎

PROPOSITION 3.10. *For every $\mu \in [0,\mu^*)$, with μ^* defined by (3.5), the unique nontrivial solution u_μ of (3.3) has a fixed-point index of -1. The graph $\mathcal{C} := \{(\mu,u_\mu) : \mu \in [0,\mu^*)\}$ is an unbounded, continuous curve in $\mathbb{R}_+ \times X$, and μ^* is greater than 9.*

Proof. We begin by computing the (Leray–Schauder) fixed-point index of the map $T(0,\cdot)$ in u_0, the nontrivial solution of (3.3) for $\mu = 0$. (While the existence of u_0 was established previously, the following argument will prove it once again.) Inspired by similar reasoning in [1], we define a completely continuous operator $S : \mathbb{R}_+ \times X \to X$, with $X := C([0,1],\mathbb{R}^3)$, by

$$S(\lambda,u)(r) := \Big(\int_0^r \phi(s)\,ds\,,\ -\int_r^1 \psi(s)\,ds\,,\ \int_0^r \big(w^2(s)+\lambda\big)\,ds\Big),$$

for $\lambda \in \mathbb{R}_+$, $u = (w,\phi,\psi) \in X$, and $r \in [0,1]$, and consider the parameter-dependent fixed-point problem in X,

$$u = S(\lambda,u). \tag{3.8}$$

Note that $S(0,\cdot) = T(0,\cdot)$; that is, if $\lambda = 0$, then (3.8) coincides with (3.3) with $\mu = 0$.

Now let $\lambda \in \mathbb{R}_+$ and suppose that $u_{0\lambda} = (w_{0\lambda},\phi_{0\lambda},\psi_{0\lambda})$ is a solution of (3.8). Since $\phi_{0\lambda}'' = w_{0\lambda}^2 + \lambda \geq 0$, the function $\phi_{0\lambda}$ is convex; thus, $\phi_{0\lambda}(r) \leq \phi_{0\lambda}(0)(1-r)$ for all $r \in [0,1]$. Arguing as in the proof of Proposition 3.1, we derive an upper bound for $w_{0\lambda}$, then a lower bound for $\psi_{0\lambda}$. Since $|\phi_{0\lambda}(0)| = \int_0^1 \psi_{0\lambda}(s)\,ds$, the lower bound for $\psi_{0\lambda}$ yields a quadratic inequality for $|\phi_{0\lambda}(0)|$, namely, $|\phi_{0\lambda}(0)|^2 - 24\,|\phi_{0\lambda}(0)| + 12\lambda \leq 0$. It follows that $\lambda \leq 12$ and $|\phi_{0\lambda}(0)| \leq 24$. This shows that (3.8) does not have any solutions if $\lambda > 12$; moreover, the uniform bound on $|\phi_{0\lambda}(0)|$ implies a uniform bound on $\|u_{0\lambda}\|_\infty$.

Choosing a sufficiently large $\rho > 0$, we infer that $\deg\big(Id_X - S(\lambda,\cdot), B_\rho^X(0), 0\big)$ is well defined for $\lambda \in \mathbb{R}_+$, independent of λ (due to homotopy invariance), and in fact equal to zero (since (3.8) has no solutions for $\lambda > 12$). It follows that

$$\deg\big(Id_X - T(0,\cdot), B_\rho^X(0), 0\big) = \deg\big(Id_X - S(0,\cdot), B_\rho^X(0), 0\big) = 0\,.$$

However, a routine homotopy argument shows that the index of $T(0,\cdot)$ in the trivial fixed point 0 equals 1. This proves, once again, the existence of the nontrivial fixed point u_0 (and thereby the fact that $\mu^* > 0$) and shows, more importantly, that the index of $T(0,\cdot)$ in u_0 is -1. But then, by homotopy along the continuous curve $\mathcal{C} := \{(\mu,u_\mu) : \mu \in [0,\mu^*)\}$, the fixed-point index of $T(\mu,\cdot)$ in u_μ is -1 for every $\mu \in [0,\mu^*)$.

We are now in a position to complete the proof of the proposition by applying a Rabinowitz-type argument (see [21]). Suppose that the curve $\mathcal{C}$ is bounded. Then $\mu^* < \infty$ and there exists a constant $\rho > 0$ such that $\|u_\mu\|_\infty < \rho$ for all $\mu \in [0,\mu^*)$. Also, due to Lemma 3.9, $\|u_\mu\|_\infty \geq 12$ for all $\mu \in [0,\mu^*)$ and, according to Remark 3.7, the equation (3.3) has no nontrivial solution for $\mu = \mu^*$. It follows that $\deg\big(Id_X - T(\mu,\cdot), B_\rho^X(0) \setminus \overline{B}_1^X(0), 0\big)$ is well defined for $\mu \in [0,\mu^*]$, independent of μ, and in fact equal to zero. Clearly, this contradicts the fact that $T(0,\cdot)$ has index -1 in u_0. It follows that $\mathcal{C}$ is unbounded in $\mathbb{R}_+ \times X$. In conjunction with Lemma 3.9, according to which $\mathcal{C} \cap ([0,\hat\mu] \times X)$ is bounded for every $\hat\mu \in \mathbb{R}_+$ with $\hat\mu < \bar\mu \approx 9.073$, this proves, once again, that $\mu^* \geq \bar\mu$ and thus $\mu^* > 9$. ∎

REMARK 3.11. In light of the numerical evidence described in Remark 3.5, we conjecture that $\mu^* \approx 13.755$, that the set M coincides with the interval $[0, \mu^*)$, and that the solution branch $\mathcal{C}$ bifurcates from infinity at μ^*.

We conclude this section with a comment on the Dirichlet problem for the elliptic system (1.2) on a ball in $\mathbb{R}^N$,

$$\begin{cases} -\Delta v = \theta & \text{in } B_R^N(0), \\ -\Delta\theta = |\nabla v|^2 & \text{in } B_R^N(0), \\ v = \theta = 0 & \text{on } \partial B_R^N(0). \end{cases} \tag{3.9}$$

Assuming that $R = 1$ (due to the scaling property, this entails no loss of generality), there is a one-to-one correspondence between the radial solutions of (3.9) and the solutions of the boundary-value problem (3.2) or the equivalent fixed-point equation (3.3), with $\mu = N - 1$, $\theta = -\phi$, and $v(r) = -\int_r^1 w(s)\,ds$ for $r \in [0, 1]$. Hence, Proposition 3.10 implies that (3.9) has a unique nontrivial radial solution (v, θ) as long as the space dimension N does not exceed 10; it is easily checked that both components of this solution are positive and strictly decreasing functions of the radial variable r.

COROLLARY 3.12. *For every $N \in \mathbb{N}$ with $N \leq 10$ and every $R > 0$, the Dirichlet problem* (3.9) *has a unique nontrivial radially symmetric solution (v, θ). Both components of this solution are positive and decreasing functions of the radial variable r.*

Our numerical evidence (see Remark 3.5) suggests that the solution of Corollary 3.12 exists, in fact, if and only if $N \leq 14$. Figure 3 shows computed profiles of this solution for $R = 1$ and the two extreme values of the space dimension, $N = 1$ and $N = 14$. Of course, we can compute the nontrivial solution (v, θ) of the radial version of (3.9) for any $\mu \in [0, \tilde{\mu})$, with $\tilde{\mu} \approx 13.755$, in place of the integer $N - 1$. As $\mu \to \tilde{\mu}$, the θ-component of the solution appears to approach a multiple of δ_0 (the Dirac distribution centered at 0).

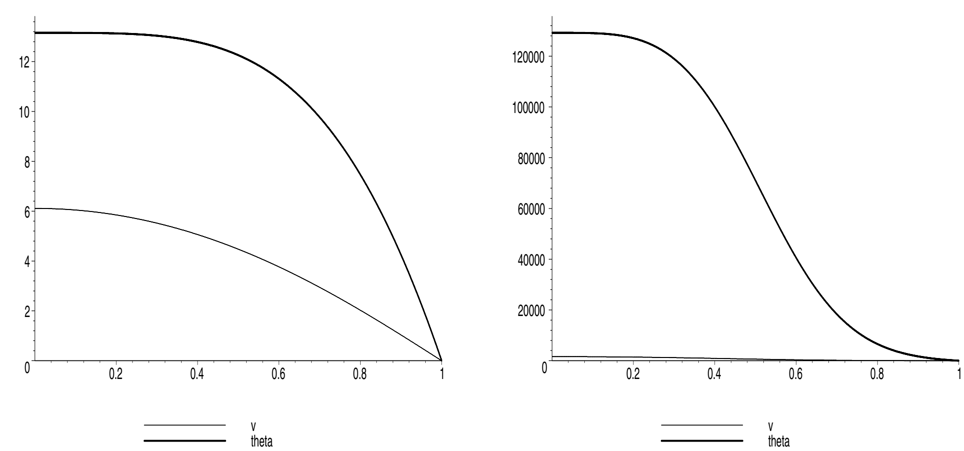

FIG. 3. *Positive radial solutions (v, θ) of the Dirichlet problem* (3.9) *with $R = 1$ for $N = 1$* (*left*) *and $N = 14$* (*right*).

4. Asymptotic behavior. Let $(w, \phi, \psi) \in C^1([0,R), \mathbb{R}^3)$ be the maximal solution of the Cauchy problem (2.2) for a given $\mu \in \mathbb{R}_+$ and $p \in \mathbb{R}$. By Lemma 2.4, we know that R is finite if and only if $\phi(r)$ is eventually positive and that in this case $w(r)$, $\phi(r)$, $\psi(r) \to \infty$ as $r \to R^-$. In view of the existing literature on boundary blow-up in elliptic equations (see, for example, [4, 24]), it is natural to expect asymptotic behavior of the form $Q/(R-r)^q$, with positive constants Q and q. In fact, we will prove the following result.

PROPOSITION 4.1. *Let $(w, \phi, \psi) \in C^1([0,R), \mathbb{R}^3)$ be the maximal solution of the Cauchy problem* (2.2)*, for a given $\mu \in \mathbb{R}_+$ and $p \in \mathbb{R}$, and suppose that R is finite. Then, as $r \to R^-$,*

$$w(r) \sim \frac{60}{(R-r)^3}\,, \quad \phi(r) \sim \frac{180}{(R-r)^4}\,, \quad \psi(r) \sim \frac{720}{(R-r)^5}\,.$$

Let us note that if all three of the functions w, ϕ, ψ exhibit asymptotic behavior of the form $Q/(R-r)^q$, it is easy to see that the constants Q and q are necessarily as above.

We will prove Proposition 4.1 under the assumption that $R = 1$; thanks to the scaling property, this entails no loss of generality. The proof will be achieved by analyzing a system of equations derived from (2.2) by a suitable change of variables.

Given any solution (w, ϕ, ψ) of (2.2), define functions α, β, γ by

$$\alpha(r) := \frac{(1-r)^3}{60}\, w(r)\,, \quad \beta(r) := \frac{(1-r)^4}{180}\, \phi(r)\,, \quad \gamma(r) := \frac{(1-r)^5}{720}\, \psi(r)\,;$$

then (α, β, γ) is a solution of

$$\begin{cases} (1-r)\left(\alpha' + \dfrac{\mu}{r}\,\alpha\right) = 3(\beta - \alpha)\,, & \alpha(0) = 0\,, \\ (1-r)\,\beta' = 4(\gamma - \beta)\,, & \beta(0) = \dfrac{p}{180}\,, \\ (1-r)\left(\gamma' + \dfrac{\mu}{r}\,\gamma\right) = 5(\alpha^2 - \gamma)\,, & \gamma(0) = 0\,. \end{cases} \tag{4.1}$$

Just like (2.2), the system (4.1) is singular at $r = 0$, but this does not affect the well-posedness of the initial value problem; in addition, (4.1) is singular at $r = 1$.

REMARK 4.2. Suppose that (w, ϕ, ψ) is the maximal solution of (2.2), for a given $\mu \in \mathbb{R}_+$ and $p \in \mathbb{R}$, with interval of existence $[0, R_p)$; let (α, β, γ) be the corresponding solution of (4.1), as defined above. Clearly, if $R_p < 1$, then (α, β, γ) ceases to exist before reaching the singularity at $r = 1$; in fact, $\alpha(r)$, $\beta(r)$, $\gamma(r) \to \infty$ as $r \to R_p^-$. Also, if $R_p > 1$, then (α, β, γ) can be continued beyond the singularity at $r = 1$, and $\alpha(r)$, $\beta(r)$, $\gamma(r) \to 0$ as $r \to 1^-$. Finally, if $R_p = 1$, then (α, β, γ) exists up to the singularity at $r = 1$, but the behavior near the singularity is not obvious. The assertion of Proposition 4.1 (with $R = 1$) is that, in this case, $\alpha(r)$, $\beta(r)$, $\gamma(r) \to 1$ as $r \to 1^-$.

REMARK 4.3. Recall that for every $\mu \in \mathbb{R}_+$, there is exactly one initial value $p_\mu^+ > 0$ and at most one initial value $p_\mu^- < 0$ such that the maximal solution of (2.2) with $p = p_\mu^\pm$ blows up at $r = 1$. Let p_μ^* denote one such value. Due to the scaling property of the problem, all solutions with $\operatorname{sign}(p) = \operatorname{sign}(p_\mu^*)$ blow up in finite time. Moreover, there is a one-to-one correspondence between the initial value p and the exit time R_p of the solution; in fact, $R_p^4 = p_\mu^*/p$ (see Remark 2.1). It follows that if $p > p_\mu^* > 0$ or $p < p_\mu^* < 0$, then $R_p < 1$, and consequently $\alpha(r)$, $\beta(r)$, $\gamma(r) \to \infty$ as $r \to R_p^-$. Also, if $0 < p < p_\mu^*$ or $p_\mu^* < p < 0$, then $R_p > 1$, and consequently $\alpha(r)$, $\beta(r)$, $\gamma(r) \to 0$ as $r \to 1^-$.

REMARK 4.4. The observations in the preceding remark allow us to use a shooting method to numerically approximate p_μ^+ and, if it exists, p_μ^-, that is, the critical initial values p for which the maximal solution of (2.2), for a given $\mu \in \mathbb{R}_+$, blows up at $r = 1$. Solving the Cauchy problem (4.1) with $p = p_\mu^\pm$, we can then construct the solutions of (2.2) that blow up at $r = 1$, and thereby the large radial solutions of the problem (1.3) with $R = 1$. All the graphs in the preceding sections were generated in this way (with a suitable rescaling in the case of Figure 3).

Our experiments suggest that p_μ^- exists if and only if $\mu < \tilde{\mu}$, for some number $\tilde{\mu} \approx 13.755$, which, due to the scaling property, must coincide with the number μ^* defined in (3.5). In fact, we find that p_μ^- is a strictly decreasing function of μ that approaches $-\infty$ as $\mu \to \tilde{\mu}$.

To prove Proposition 4.1 for $R = 1$, we must show that all three components of the maximal solution (α, β, γ) of the Cauchy problem (4.1) with $\mu \in \mathbb{R}_+$ and $p = p_\mu^\pm$ converge to 1 as $r \to 1^-$ (recall Remarks 4.2 and 4.3). While our numerical experiments leave no doubt about this (see Figure 4 for examples of computed solutions), the proof requires a small detour in dynamical systems; we refer the reader to [22] for terminology and basic properties.

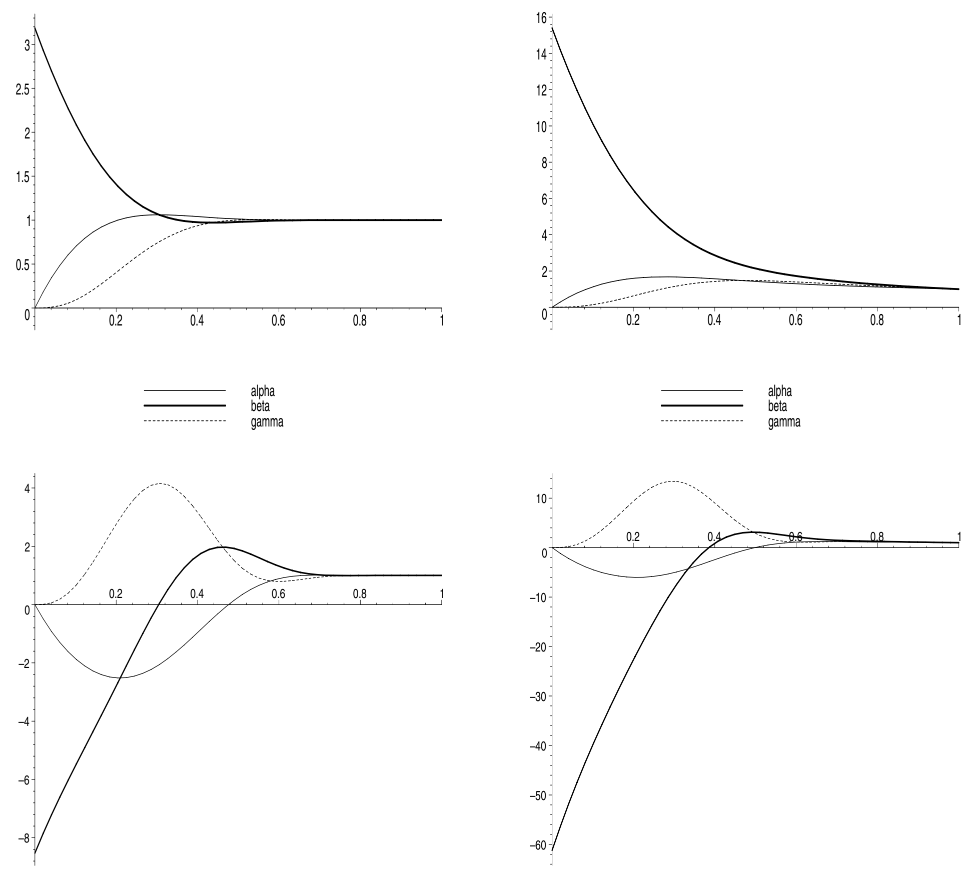

FIG. 4. *Critical solutions* (α, β, γ) *of problem* (4.1) *for* $\mu = 0$, $p = p_0^+ \approx 180 \times 3.185739467$ (*top left*), $\mu = 2$, $p = p_2^+ \approx 180 \times 15.39874038$ (*top right*), $\mu = 0$, $p = p_0^- \approx -180 \times 8.525812707$ (*bottom left*), *and* $\mu = 2$, $p = p_2^- \approx -180 \times 61.20559852$ (*bottom right*).

It is convenient to perform another change of variables in the system (4.1), letting $r = 1 - e^{-t}$ and $a(t) = \alpha(r)$, $b(t) = \beta(r)$, $c(t) = \gamma(r)$. With this rescaling of the independent variable, (4.1) is equivalent to

$$\text{(4.2)} \qquad \begin{cases} a' + \dfrac{\mu}{e^t - 1}\, a = 3(b - a), & a(0) = 0, \\ b' = 4(c - b), & b(0) = \dfrac{p}{180}, \\ c' + \dfrac{\mu}{e^t - 1}\, c = 5(a^2 - c), & c(0) = 0. \end{cases}$$

Note that the singularity of (4.1) at $r = 1$ has been moved to $t = \infty$; moreover, the system (4.2) is *autonomous* for $\mu = 0$ and *asymptotically autonomous* for $\mu > 0$. For notational convenience, we write the system of differential equations in (4.2) as

$$\text{(4.3)} \qquad x' + \frac{\mu}{e^t - 1}\, E(x) = F(x),$$

where $x = (a, b, c)$ takes values in $\mathbb{R}^3$, $E : \mathbb{R}^3 \to \mathbb{R}^3$ is the linear mapping defined by $E(a, b, c) := (a, 0, c)$, and $F : \mathbb{R}^3 \to \mathbb{R}^3$ is the vector field defined by

$$F(a, b, c) := \big(3(b - a), 4(c - b), 5(a^2 - c)\big).$$

Remark 4.5. For $t > 0$ and $a \geq 0$, the system (4.3), with arbitrary $\mu \in \mathbb{R}_+$, satisfies the well-known Kamke condition and, thus, a comparison principle (see, for example, [25]). To be precise, let t_0, $t_1 \in [0, \infty]$ with $t_0 < t_1$ and suppose that x_1, $x_2 \in C([t_0, t_1), \mathbb{R}^3) \cap C^1((t_0, t_1), \mathbb{R}^3)$. If x_1 is a subsolution of (4.3) with $a_1 \geq 0$, if x_2 is a supersolution of (4.3), and if $x_1(t_0) \leq x_2(t_0)$ $(x_1(t_0) < x_2(t_0))$, then we have $x_1(t) \leq x_2(t)$ $(x_1(t) < x_2(t))$ for all $t \in [t_0, t_1)$.

By a subsolution (supersolution) of (4.3) we mean a function $x = (a, b, c)$ satisfying the differential inequality obtained from (4.3) by replacing "=" with "$\leq$" ("$\geq$"). Also, given vectors x_1, $x_2 \in \mathbb{R}^3$, we write $x_1 \leq x_2$ or $x_2 \geq x_1$ ($x_1 < x_2$ or $x_2 > x_1$) if the respective inequality holds componentwise, and we call a vector $x \in \mathbb{R}^3$ nonnegative (positive) if $x \geq \bar{0}$ ($x > \bar{0}$), where $\bar{0} := (0, 0, 0)$.

Remark 4.6. For every $\lambda \in [0, \infty]$, let $\bar{\lambda}$ denote the vector $(\lambda, \lambda, \lambda)$. For arbitrary $\mu \in \mathbb{R}_+$, $\bar{0}$ is a solution of (4.3), and $\bar{1}$ is a supersolution (a solution if $\mu = 0$). More generally, for every $\lambda \in [0, 1]$, $\bar{\lambda}$ is a supersolution. Furthermore, for every $\lambda \in (1, \infty)$, there exists a number $\tau \in [0, \infty)$, depending only on λ and μ, such that $((\lambda + 1)/2, \lambda, \lambda)$ is a subsolution on the interval (τ, ∞) (where $\tau = 0$ if $\mu = 0$).

Proposition 4.7. *For a given $\mu \in \mathbb{R}_+$, let x be a nonnegative maximal forward solution of* (4.3)*.*

(a) *If x is unbounded, then x blows up in finite time and approaches $\overline{\infty}$.*

(b) *If x is bounded, then x converges to either $\bar{0}$ or $\bar{1}$.*

Proof. Fix $\mu \in \mathbb{R}_+$ and let $x = (a, b, c)$ be a nonnegative maximal forward solution of the system (4.3).

(a) Suppose that $x = (a, b, c)$ is unbounded. First we will show that b is unbounded. By way of contradiction, suppose that $b \leq b_0$ for some positive constant b_0. Then we have

$$a' \leq a' + \frac{\mu}{e^t - 1}\, a = 3(b - a) \leq 3(b_0 - a)\,,$$

which implies that a is bounded. A similar argument then shows that c is bounded as well, and this contradicts the unboundedness of $x = (a, b, c)$. Thus, b is unbounded.

Now fix a number $p_0 > 0$ such that the solution (w_0, ϕ_0, ψ_0) of the initial-value problem (2.2) with $p = p_0$ blows up at a point $R_0 < 1$. The corresponding solution $x_0 = (a_0, b_0, c_0)$ of the initial-value problem (4.2) then blows up at $-\log(1 - R_0)$. Recall that the b-component of the trajectory $x = (a, b, c)$ is unbounded and choose a point τ in the interval of existence of x such that $b(\tau) \geq p_0/180$; define $\tilde{x} := x(\tau + \cdot\,)$. Then we have

$$\tilde{x}' + \frac{\mu}{e^t - 1}\, E(\tilde{x}) \;\geq\; \tilde{x}' + \frac{\mu}{e^{\tau+t} - 1}\, E(\tilde{x}) \;=\; F(\tilde{x})$$

and

$$\tilde{x}(0) = x(\tau) = \big(a(\tau), b(\tau), c(\tau)\big) \geq \Big(0, \frac{p_0}{180}, 0\Big) = x_0(0)\,.$$

Thanks to the comparison principle in Remark 4.5, it follows that $\tilde{x} \geq x_0$. In particular, $\tilde{x}$ blows up in finite time, and then so does x. By reasoning as in the proof of Lemma 2.4(b), it is now easy to verify that all three components of x approach infinity.

(b) Suppose that x is bounded. First, consider the autonomous case, $\mu = 0$. The vector field F is cooperative in the half-space $a \geq 0$ and, in particular, in the nonnegative cone $\mathbb{R}^3_+$; moreover, $\operatorname{div}(F) \equiv -12$ and F has exactly two zeros, at $\bar{0}$ and $\bar{1}$. Thus, F generates a monotone, volume-contracting semiflow Φ in $\mathbb{R}^3_+$, with exactly two equilibria, at $\bar{0}$ and $\bar{1}$. The equilibrium at $\bar{0}$ is a stable node; the equilibrium at $\bar{1}$ is a saddle point with a two-dimensional stable manifold (the eigenvalues are 1 and $-13/2 \pm i\sqrt{71}/2$).

Moreover, the system can be embedded into a cooperative system in all of $\mathbb{R}^3$ by replacing the nonlinear term a^2 in the third component of the vector field F with $a|a|$; the extended system still has negative divergence, and it has equilibria at $\bar{0}$ and $\pm\bar{1}$. Morris Hirsch proved (see [13, Theorem 1]) that every compact limit set of a cooperative or competitive system in $\mathbb{R}^3$ is either a cycle or contains an equilibrium. Another result of Hirsch's (see [12, Theorem 7]) guarantees that a cooperative system in $\mathbb{R}^3$ with negative divergence cannot have any cycles. Moreover, for our particular system, it is easy to see that any compact limit set containing one of the equilibria is in fact a singleton. Combining these results we infer that every bounded (forward or backward) trajectory of the system converges. In particular, the trajectory x converges to either $\bar{0}$ or $\bar{1}$.

Now consider the nonautonomous case, $\mu > 0$. As we observed before, the system (4.3) is asymptotically autonomous. An old result of Markus [18] implies that the ω-limit set K of the trajectory x is a nonempty compact and connected subset of $\mathbb{R}^3_+$; moreover, $\operatorname{dist}(x(t), K) \to 0$ as $t \to \infty$, and K is invariant under the semiflow Φ of the autonomous limit system, that is, (4.3) with $\mu = 0$. A more recent result by Mischaikow, Smith, and Thieme (see [19, Theorem 1.8]) implies that K is also *chain-recurrent* under Φ.

We claim that $K \subset \{\bar{0}, \bar{1}\}$. By way of contradiction, suppose there is a point $z \in K \setminus \{\bar{0}, \bar{1}\}$. In light of what we proved for the autonomous case, since K is compact and Φ-invariant, the Φ-trajectory through z must converge, both forward and backward in time. Backward in time, it can only converge to $\bar{1}$ (since $\bar{0}$ is stable). Thus, z belongs to the unstable manifold of $\bar{1}$, and it follows that, forward in time, the Φ-trajectory through z can only converge to $\bar{0}$. Hence, K consists of the two equilibria, $\bar{0}$ and $\bar{1}$, and a heteroclinic orbit connecting the two; such a set is obviously not chain-recurrent. The contradiction proves that $K \subset \{\bar{0}, \bar{1}\}$. In fact, since K is nonempty and connected, we have either $K = \{\bar{0}\}$ or $K = \{\bar{1}\}$; that is, x converges to either $\bar{0}$ or $\bar{1}$. $\square$

COROLLARY 4.8. *Let $\mu \in \mathbb{R}_+$ and $p \in \mathbb{R}$ be such that the maximal solution (w, ϕ, ψ) of the Cauchy problem* (2.2) *blows up at $r = 1$. Then the maximal solution (a, b, c) of* (4.2) *converges to $\bar{1}$.*

Proof. Under the assumptions of the corollary, (w, ϕ, ψ) approaches $\overline{\infty}$ at $r = 1$; thus, the corresponding solution (α, β, γ) of (4.1) is eventually positive and exists on $[0, 1)$ (see Remark 4.2). This means that $x = (a, b, c)$ is eventually positive and exists on $[0, \infty)$. By part (a) of Proposition 4.7, it follows that x is bounded, and then part (b) of the same proposition implies that x converges to either $\bar{0}$ or $\bar{1}$. Now suppose that $x(t) \to \bar{0}$ as $t \to \infty$ and choose $t_0 \in (0, \infty)$ such that $\bar{0} < x(t_0) < \bar{1}$. Since the solution of (4.2) depends continuously on p, we can find a value $\tilde{p}$ close to p, with $|\tilde{p}| > |p|$ such that the corresponding maximal solution $\tilde{x}$ of (4.2) exists at $t = t_0$ and satisfies $\bar{0} < \tilde{x}(t_0) < \bar{1}$. Since $\bar{0}$ is a solution and $\bar{1}$ is a supersolution of (4.3), the comparison principle in Remark 4.5 implies that $\bar{0} < \tilde{x}(t) < \bar{1}$ for all $t \geq t_0$, as long as $\tilde{x}$ exists. From Remark 4.3, however, we know that $\tilde{x}$ goes to $\overline{\infty}$ (in finite time). This contradiction proves that x does not converge to $\bar{0}$, and therefore it must converge to $\bar{1}$. ∎

Proof of Proposition 4.1. Due to the scaling property of the system (2.2) (see Remark 2.1), it suffices to prove the assertion of the proposition for $R = 1$; in this case, it is an immediate consequence of Corollary 4.8 (see Remark 4.2). ∎

Proof of Theorem 1.5. Since every large radial solution (v, ϕ) of the problem (1.3), for a given $R > 0$, corresponds to a solution (w, ϕ, ψ) of (2.2) that blows up at R, the asymptotic behavior of ϕ is clear from Proposition 4.1. Moreover, the asymptotic behavior of v, given by $v(r) = \int_0^r w(s)\, ds$ for $0 \leq r < R$, follows readily from that of w. ∎

In closing, we note that Hirsch's results on cooperative systems in $\mathbb{R}^3$ (see [12, 13]) allow us to completely describe the dynamics of the monotone, volume-contracting semiflow Φ in $\mathbb{R}^3_+$, induced by the vector field F. First, it is easily verified that Φ is, in fact, *strongly* monotone (even though F is irreducible only for $a > 0$). As shown in the first part of the proof of Proposition 4.7(b), Hirsch's results imply that every forward trajectory of Φ either converges to $\bar{0}$ (a stable node) or to $\bar{1}$ (a saddle point), or it approaches $\overline{\infty}$, necessarily in finite time. Clearly, both $\bar{0}$ and $\overline{\infty}$ are stable attractors. In fact, using the sub- and super-solutions constructed in Remark 4.6, we see that the open order intervals $(\bar{0}, \bar{1})$ and $(\bar{1}, \overline{\infty})$ are positively invariant and contained in the basins of attraction of $\bar{0}$ and $\overline{\infty}$, respectively. The two basins of attraction are separated by the (two-dimensional) stable manifold $W_s(\bar{1})$ of the saddle point. The (one-dimensional) unstable manifold $W_u(\bar{1})$ has a positive tangent vector at $\bar{1}$, which implies that $W_u(\bar{1}) \setminus \{\bar{1}\}$ is contained in the union of the order intervals $(\bar{0}, \bar{1})$ and $(\bar{1}, \overline{\infty})$. Thus, every forward trajectory on $W_u(\bar{1}) \setminus \{\bar{1}\}$ either converges to $\bar{0}$ or approaches $\overline{\infty}$. It follows that $W_u(\bar{1}) \setminus \{\bar{1}\}$ consists of two heteroclinic orbits connecting $\bar{1}$ to $\bar{0}$ and $\overline{\infty}$, respectively.

Appendix. The following algorithm allows the construction of increasing sequences of polynomial lower bounds and decreasing sequences of polynomial upper bounds for the maximal solution (w, ϕ, ψ) of the Cauchy problem (2.2) with $p = -1$ and arbitrary $\mu \in \mathbb{R}_+$. The bounds being polynomials, the computations amount to symbolic algebra on the coefficients. We used Maple (Version 9.5) to perform these computations; the relevant commands are provided below.

Given a polynomial P in r (whose coefficients are rational functions of another variable), the command

```
L:=normal(CoefficientList(P,r)):
```

generates the list of coefficients of P (in increasing order, starting with the zero-order term) and writes each coefficient in "normal form" (that is, as a quotient of polynomials). The command

```
n:=nops(L):
```

gives the number of entries in the list L; that is, $n-1$ is the degree of P.

Algorithm: Construction of Polynomial Bounds.

0. Specify a lower (or an upper) bound ϕ_0 for ϕ (ϕ_0 a suitable polynomial in r).

```
with(PolynomialTools):
phi0:=-1;  # Other choices are possible.
```

1. Compute a lower (upper) bound w_0 for w: $w_0 := \int_0^r (s/r)^\mu \phi_0(s)\,ds$.

```
L:=normal(CoefficientList(phi0,r)):  n:=nops(L):
      w0:=sum(L[i]*r^i/(mu+i),i=1..n);
```

2. Compute an upper (lower) bound ψ_0 for ψ, valid as long as $\max(w, w_0) \le 0$: $\psi_0 := \int_0^r (s/r)^\mu w_0^2(s)\,ds$.

```
L:=normal(CoefficientList(w0^2,r)):  n:=nops(L):
      psi0:=sum(L[i]*r^i/(mu+i),i=1..n);
```

3. Compute an upper (lower) bound ϕ_0 for ϕ: $\phi_0 := -1 + \int_0^r \psi_0(s)\,ds$.

```
L:=normal(CoefficientList(psi0,r)):  n:=nops(L):
      phi0:=-1+sum(L[i]*r^i/i,i=1..n);
```

4. Return to Step 1 (or proceed to "Computation of coefficient c" below).

Starting with the trivial lower bound $\underline{\phi}_0 := -1$ for ϕ, the algorithm produces the bounds $\underline{w}_1$, $\overline{\psi}_1$, $\overline{\phi}_1$, $\overline{w}_1$, $\underline{\psi}_1$, $\underline{\phi}_1$, ..., referred to in the proof of Proposition 3.1; these bounds are valid on the interval $[0, r_0]$, where $r_0 := (4(\mu+1)(\mu+3)(\mu+5))^{1/4}$ is the unique positive root of $\overline{w}_1$ (note that for all $k \in \mathbb{N}$, $\underline{w}_1 \le \underline{w}_k \le w \le \overline{w}_k \le \overline{w}_1 \le 0$ on $[0, r_0]$).

Now suppose that w_0, ψ_0, and ϕ_0 have been constructed according to Steps 1–3 of the algorithm, starting with an initially negative upper bound for ϕ. Then we have $w \le w_0 \le 0$, $\psi \ge \psi_0 \ge 0$, and $\phi \ge \phi_0$ on some interval $[0, r_0]$ with $r_0 > 0$. The arguments in the proof of Proposition 3.1 show that the following "tail estimate" holds for every $r > r_0$, provided that $\phi(r) \le 0$:

$$0 \ge (\mu-1)^2\phi(r) \ge a\left(\frac{r_0}{r}\right)^{2(\mu-1)} - b\left(\frac{r_0}{r}\right)^{\mu-1} + c\,,$$

where

$$a := \frac{1}{2}r_0^2\, w_0^2(r_0)\,, \qquad b := r_0^2\, w_0^2(r_0) + (\mu-1)r_0\psi_0(r_0)\,,$$

$$c := \frac{1}{2}r_0^2\, w_0^2(r_0) + (\mu-1)r_0\psi_0(r_0) + (\mu-1)^2\phi_0(r_0)\,.$$

If we use the bounds $w_0 = \overline{w}_k$, $\psi_0 = \underline{\psi}_k$, and $\phi_0 = \underline{\phi}_k$, for some $k \in \mathbb{N}$, and choose r_0 to be the positive root of $\overline{w}_1$ (or the positive root of $\overline{\phi}_1$), the coefficients a, b, c, and various other relevant quantities, such as $\phi_0(r_0)$, are rational functions of μ; in fact, r_0^4 is a polynomial in μ, while $r^2 w_0^2(r)$, $r\psi_0(r)$, and $\phi_0(r)$ are polynomials in r^4, whose coefficients are rational functions of μ. This facilitates the symbolic computation of these quantities and allows us to locate their positive roots by inspecting the coefficients of the respective numerator polynomials (the roots of the denominator polynomials are negative integers). Recall that finding the positive roots of c, in particular, is a crucial step in the proof of Proposition 3.1.

Algorithm: Computation of Coefficient c.

0. Specify $\rho := r_0^4$ (ρ a suitable polynomial in μ).

```
rho:=4*(mu+1)*(mu+3)*(mu+5):
# Alternatively:  rho:=4*(mu+1)^2*(mu+3):
```

1. Compute coefficients of $(1/2)r^2 w_0^2(r) + (\mu-1)r\psi_0(r) + (\mu-1)^2\phi_0(r)$.

```
P:=r^2*w0^2/2+(mu-1)*r*psi0+(mu-1)^2*phi0:
L:=normal(CoefficientList(P,r)):  n:=(nops(L)-1)/4+1:
```

2. Compute coefficient $c = c_1/c_2$, with numerator polynomial c_1 and denominator polynomial c_2.

```
c:=normal(sum(L[4*i-3]*rho^(i-1),i=1..n)):
c1:=sort(numer(c));  c2:=denom(c);
```

If we choose $w_0 = \overline{w}_2$, $\psi_0 = \underline{\psi}_2$, $\phi_0 = \underline{\phi}_2$, and $\rho = 4(\mu+1)(\mu+3)(\mu+5)$, as in the proof of Proposition 3.1, then the numerator polynomial c_1 of c has exactly two positive roots (by Descartes's rule of signs and the intermediate-value theorem), one near 0.747 and the other near 9.073.

Acknowledgments. This project was started while M. Lazzo and P. G. Schmidt were visiting the Universidad Politécnica de Madrid and the Universidad Complutense de Madrid; both wish to express their gratitude to J. F. Padial and J. I. Díaz for their generous support. Most of the work was done while M. Lazzo was visiting Auburn University; she would like to thank the faculty and staff of the Department of Mathematics and Statistics for their kind hospitality. Both M. Lazzo and P. G. Schmidt are grateful for stimulating discussions with W. Shen and G. Hetzer at Auburn. Finally, the authors wish to thank the anonymous referees for their constructive criticism and valuable suggestions.

A MODEL FOR THE OPTIMAL PLANNING OF AN URBAN AREA*

GIUSEPPE BUTTAZZO† AND FILIPPO SANTAMBROGIO‡

Abstract. We propose a model to describe the optimal distributions of residents and services in a prescribed urban area. The cost functional takes into account the transportation costs (according to a Monge–Kantorovich-type criterion) and two additional terms which penalize concentration of residents and dispersion of services. The tools we use are the Monge–Kantorovich mass transportation theory and the theory of nonconvex functionals defined on measures.

Key words. urban planning, mass transportation, nonconvex functionals over measures

1. Introduction.

The efficient planning of a city is a tremendously complicated problem, both for the high number of parameters which are involved as well as for the several relations which intervene among them (price of the land, kind of industries working in the area, quality of the life, prices of transportations, geographical obstacles, etc.). Perhaps a careful description of the real situations could be only obtained through evolution models which take into account the dynamical behavior of the different parameters involved.

An interesting mathematical model for the description of the equilibrium structure of a city is presented by Carlier and Ekeland in [3], where Monge–Kantorovich optimal transport theory plays an important role.

In the present paper we consider a geographical area as given, and we represent it through a subset Ω of $\mathbb{R}^n$ ($n = 2$ in the applications to concrete urban planning problems). We want to study the optimal location in Ω of a mass of inhabitants, which we denote by μ, as well as of a mass of services (working places, stores, offices, etc.), which we denote by ν. We assume that μ and ν are probability measures on Ω. This means that the total amounts of population and production are fixed as problem data, and this is a difference from the model in [3]. The measures μ and ν represent the unknowns of our problem that have to be found in such a way that a suitable total cost functional $\mathfrak{F}(\mu, \nu)$ is minimized. The definition of this total cost functional takes into account some criteria we want the two densities μ and ν to satisfy:

(i) there is a transportation cost for moving from the residential areas to the services areas;
(ii) people do not want to live in areas where the density of population is too high;
(iii) services need to be concentrated as much as possible in order to increase efficiency and decrease management costs.

Fact (i) will be described through a Monge–Kantorovich mass transportation model; the transportation cost will indeed be given by using a p-Wasserstein distance ($p \geq 1$). We set

$$T_p(\mu,\nu) = W_p^p(\mu,\nu) = \inf_\gamma \left(\int_{\Omega\times\Omega} |x-y|^p \gamma(dx,dy) \right), \tag{1.1}$$

where the infimum is taken over all possible transport plans γ between μ and ν (i.e., probabilities on the product space having μ, ν as marginal measures). We refer to [7] for the whole theory on mass transportation. When $p = 1$ we are in the classical Monge case, and for this particular case we refer to [1] and [5].

Fact (ii) will be described by a penalization functional, a kind of total unhappiness of citizens due to high density of population, obtained by integrating with respect to the citizens' density their personal unhappiness.

Fact (iii) is modeled by a third term representing costs for managing services once they are located according to the distribution ν, taking into account that efficiency depends strongly on how much ν is concentrated.

The cost functional we will consider is then

$$\mathfrak{F}^p(\mu,\nu) = T_p(\mu,\nu) + F(\mu) + G(\nu), \tag{1.2}$$

and thus the optimal location of μ and ν will be determined by the minimization problem

$$\min \left\{ \mathfrak{F}^p(\mu,\nu) \ : \ \mu,\nu \text{ probabilities on } \Omega \right\}. \tag{1.3}$$

In this way, our model takes into consideration only the optimization of a total welfare parameter of the city, disregarding the effects on each single citizen. In particular, no equilibrium condition is considered. This may appear as a fault in the model, since the personal welfare of the citizens (depending on the population density of their zone and on the cost of moving from home to services) could be nonconstant. As a consequence, nonstable optimal solutions may occur, where some citizens would prefer to move elsewhere in the city in order to get better conditions. However, this is not the case, since our model also disregards prices of land and houses in the city, since they do not affect the total wealth of the area. It turns out that by a proper, market-determined choice of prices, welfare differences could be compensated and equilibrium recovered. This fact turns out to be a major difference between our model and the model in [3], both for the importance given in [3] to the variable represented by the price of land and for the fact that Carlier and Ekeland specifically look for an equilibrium solution instead of an optimal one.

The present paper, after this introduction, contains three sections. Section 2 is devoted to presenting precise choices for the functionals F and G and justifying them as reasonable choices. In the same section we also give a simple existence result for an optimal solution (μ,ν) as a starting point for the rest of the paper. In section 3 we consider the functional on μ obtained by keeping the measure ν as fixed: in this case the functional G does not play any role, and we obtain a convex minimization problem, which is interesting in itself. We also obtain some necessary optimality conditions in the very general case where no assumption is taken on the fixed measure ν. In section 4 we apply these results to the case where G is of the particular form presented in section 2, which forces ν to be atomic (i.e., services are concentrated in countably many points of the city area Ω). In the case where Ω is bounded, we give a quite precise description of the solution (μ, ν), and then we give an existence result also for the case $\Omega = \mathbb{R}^n$.

Both in the case $\Omega = \mathbb{R}^n$ and Ω bounded, optimal choices for μ and ν are given by the formation of a certain number of subcities, which are circular areas with a pole of services in the center (an atom for the measure ν) around which the population is distributed with a decreasing radial density.

Since we have considered only a very simplified model, our goal is neither to suggest a realistic way to design the ideal city nor to describe in a variational way the formation of existing cities. Nevertheless, from the analysis of our optimality results (and in particular from the subcities phenomena we referred to), we can infer some conclusions.

- Our model is not a proper choice to describe the shape of a single existing city, since the delocalization of services we find in an optimal solution does not reflect what reality suggests (in fact, we find finitely many disjoint, independent subcities with services only in the center).
- Our model is likely to be more realistic on a larger scale, when Ω represents a large urban area composed of several cities: in this case every atom of the optimal ν stands for the center of one of them and includes a complex system of services, located downtown, whose complexity cannot be seen in this scale.
- In our model the concentrated measure ν gives a good representation of the areas where services are offered to citizens and not of areas where commodities are produced (factories), due to the assumption that no land is actually occupied by the service poles (since ν is atomic).
- We do not believe that our model may actually be used to plan a future city or to improve the efficiency of an existing one, as a consequence of its oversimplified nature. However, we do not exclude the possibility of using it in the planning of less complex agglomerations, such as tourist villages, university campuses, etc.
- We conclude by stressing that the same model may be applied as a first simplified approach to other kinds of problems, where we have to choose in some efficient way the distributions of two different parameters, the first spread and the second concentrated, keeping them as close as possible to each other in some mass transportation sense.

2. The model. We now define the three terms appearing in our functional $\mathfrak{F}^p$. We must go through the definition of F and G, since the first term will be a Monge–Kantorovich transport cost, as explained in the previous section. For the functional F we take

$$F(\mu) = \begin{cases} \int_\Omega f(u(x))\,dx & \text{if } \mu = u \cdot \mathcal{L}^n,\ u \in L^1(\Omega), \\ +\infty & \text{otherwise,} \end{cases} \tag{2.1}$$

where the integrand $f : [0, +\infty] \to [0, +\infty]$ is assumed to be lower semicontinuous and convex, with $f(0) = 0$ and superlinear at infinity, that is,

$$\lim_{t \to +\infty} \frac{f(t)}{t} = +\infty. \tag{2.2}$$

In this form we have a local semicontinuous functional on measures. Without loss of generality, by subtracting constants to the functional F, we can suppose $f'(0) = 0$. Due to the assumption $f(0) = 0$, the ratio $f(t)/t$ is an incremental ratio of the convex function f and thus it is increasing in t. Then, if we write the functional F as

$$\int_\Omega \frac{f(u(x))}{u(x)} u(x)\, dx,$$

we can see the quantity $f(u)/u$, which is increasing in u, as the unhappiness of a single citizen when he lives in a place where the population density is u. Integrating it with respect to $\mu = u \cdot \mathcal{L}^n$ gives a quantity to be seen as the total unhappiness of the population.

As far as the concentration term $G(\nu)$ is concerned, we set

$$G(\nu) = \begin{cases} \sum_{i=0}^{\infty} g(a_i) & \text{if } \nu = \sum_{i=0}^{\infty} a_i \delta_{x_i}, \\ +\infty & \text{if } \nu \text{ is not atomic.} \end{cases} \tag{2.3}$$

We require the function g to be subadditive, lower semicontinuous, and such that $g(0) = 0$ and

$$\lim_{t \to 0} \frac{g(t)}{t} = +\infty. \tag{2.4}$$

Every single term $g(a_i)$ in the sum in (2.3) represents the cost of building and managing a service pole of size a_i, located at the point $x_i \in \Omega$.

In our model, as already pointed out, we fix as a datum the total production of services; moreover, in each service pole the production is required as a quantity proportionally depending on its size (or on the number of inhabitants making use of such a pole). We may define the productivity P of a pole of mass (size) a as the ratio between the production and the cost to get such a production. Then we have $P(a) = a/g(a)$ and

$$\sum_{i=0}^{\infty} g(a_i) = \sum_{i=0}^{\infty} \frac{a_i}{P(a_i)}.$$

As a consequence of assumption (2.4) we have that the productivity in very small service poles is near 0.

Notice that in the functional G we do not take into account distances between service poles. It would be interesting to consider nonlocal functionals involving such distances, taking into account possible cooperation and the consequent gain in efficiency. Those functionals could be matters of investigation in a subsequent paper, in which the results shown in the next section (since they do not depend on the choice of G) could be useful as well as in the present setting.

For the problem introduced in (1.3), existence results are straightforward, especially when we use as an environment a compact set Ω. In fact, functionals of the form of both F and G have been studied in a general setting by Bouchitté and Buttazzo in [2], and lower semicontinuity results were proven.

THEOREM 2.1. *Suppose Ω is compact, $p \geq 1$, and f and g satisfy the conditions listed above. Then the minimization problem* (1.3) *has at least one solution.*

Proof. By the direct method of calculus of variations, this result is an easy consequence of the weak-* compactness of the space $\mathcal{P}(\Omega)$, the space of probability measures on Ω when Ω itself is compact, and of the weak-* semicontinuity of the functional $\mathfrak{F}^p$. The second and third terms in (1.2) are, in fact, local semicontinuous functionals (due to results in [2]), while the first term is nothing but a Wasserstein distance raised to a certain power. Since it is known that in compact spaces this distance metrizes the weak-* topology, T_p is actually continuous. ◻

In [6], where we first presented the model, other existence results were shown. For instance, the case of a noncompact bounded convex set $\Omega \subset \mathbb{R}^n$ was considered. We will not go through this proof here and will discuss just one existence result in a noncompact setting, obtained as a consequence of a proper use of the optimality conditions presented in the next section.

3. A necessary condition of optimality. In this section we find optimality conditions for probability measures on Ω minimizing the functional

$$\mathfrak{F}^p_\nu(\mu) = T_p(\mu,\nu) + F(\mu).$$

It is clear that if (μ,ν) is an optimal pair for the whole functional $\mathfrak{F}^p$, μ is a minimizer for $\mathfrak{F}^p_\nu$. The goal of this section is to derive optimality conditions for $\mathfrak{F}^p_\nu$, for any ν, without any link to the minimization of $\mathfrak{F}^p$. The main part of the section will be devoted to presenting an approach obtained by starting with the easier case $p > 1$ and ν "regular" in some sense and then recovering the general case by an approximation argument. The reason for doing so relies on some conditions ensuring uniqueness properties of the Kantorovich potential. Similar approximation arguments were also used in [6]: purely atomic probability measures (i.e., finite sums of Dirac masses) were considered first, and then, by approximation, the result was extended to any measure ν. At the end of the section we also provide a sketch of a different proof, suggested to us by an anonymous referee, which is based on some convex analysis tools and strongly uses the convex structure of the problem.

For simplicity, let us call domains those sets which are the closure of a nonempty connected open subset of $\mathbb{R}^n$ with negligible boundary. From now on Ω will be a bounded domain and its diameter will be denoted by D. The function f in (2.1) will be assumed to be strictly convex and C^1, and we will denote by k the continuous, strictly increasing function $(f')^{-1}$. Strict convexity of f will ensure uniqueness for the minimizer of $\mathfrak{F}^p_\nu$.

LEMMA 3.1. *If μ is optimal for $\mathfrak{F}^p_\nu$, then for any other probability measure μ_1 with density u_1 such that $\mathfrak{F}^p_\nu(\mu_1) < +\infty$, the following inequality holds:*

$$T_p(\mu_1,\nu) - T_p(\mu,\nu) + \int_\Omega f'(u(x))[u_1(x) - u(x)]dx \geq 0.$$

Proof. For any $\varepsilon > 0$, due to the convexity of the transport term, it holds that

$$\begin{aligned} T_p(\mu,\nu) + F(\mu) &\leq T_p(\mu + \varepsilon(\mu_1 - \mu)) + F(\mu + \varepsilon(\mu_1 - \mu),\nu) \\ &\leq T_p(\mu,\nu) + \varepsilon(T_p(\mu_1,\nu) - T_p(\mu,\nu)) + F(\mu + \varepsilon(\mu_1 - \mu)). \end{aligned}$$

Therefore the quantity $T_p(\mu_1,\nu) - T_p(\mu,\nu) + \varepsilon^{-1}\left[F(\mu + \varepsilon(\mu_1 - \mu)) - F(\mu)\right]$ is nonnegative. If we let $\varepsilon \to 0$, we obtain the thesis if we prove

$$\lim_{\varepsilon\to 0} \int \frac{f(u + \varepsilon(u_1 - u)) - f(u)}{\varepsilon}\, d\mathcal{L}^n = \int f'(u)(u_1 - u)\, d\mathcal{L}^n.$$

By using the monotonicity of the incremental ratios of convex functions we can see that, for $\varepsilon < 1$,

$$\frac{|f(u + \varepsilon(u_1 - u)) - f(u)|}{\varepsilon} \leq |f(u) - f(u_1)|.$$

This is sufficient in order to apply Lebesgue dominated convergence theorem, since $F(\mu)$ and $F(\mu_1)$ are finite. ∎

LEMMA 3.2. *Let us suppose $\nu = \nu^s + v \cdot \mathcal{L}^n$, with $v \in L^\infty(\Omega)$, $\nu^s \perp \mathcal{L}^n$, $v > 0$ a.e. in Ω. If μ is optimal for $\mathfrak{F}^p_\nu$, then $u > 0$ a.e. in Ω.*

Proof. The lemma will be proven by contradiction. We will find, if the set $A = \{u = 0\}$ is not negligible, a measure μ_1 for which Lemma 3.1 is not verified. Let N be a Lebesgue-negligible set where ν^s is concentrated and t is an optimal transport map between μ and ν. Such an optimal transport exists, since $\mu \ll \mathcal{L}^n$. A proof of this fact can be found in [7] as long as we deal with the case $p > 1$, while for $p = 1$ we refer to [1].

Let $B = t^{-1}(A)$. Up to modifying t on the μ-negligible set A, we may suppose $B \cap A = \emptyset$. Set $\mu_1 = 1_{B^c} \cdot \mu + 1_{A\setminus N} \cdot \nu$; it is a probability measure with density u_1 given by $1_{B^c}u + 1_A v = 1_{B^c\setminus A}u + 1_A v$ (this equality comes from $u = 0$ on A). We have

$$F(\mu_1) = \int_{B^c\setminus A} f(u)\, d\mathcal{L}^n + \int_A f(v)\, d\mathcal{L}^n \le F(\mu) + ||f(v)||_\infty |\Omega| < +\infty.$$

Setting

$$t^*(x) = \begin{cases} t(x) & \text{if } x \in (A \cup B)^c, \\ x & \text{if } x \in (A \cup B), \end{cases}$$

we can see that t^* is a transport map between μ_1 and ν. In fact, for any Borel set $E \subset \Omega$, we may express $(t^*)^{-1}(E)$ as the disjoint union of $E \cap A$, $E \cap B$, and $t^{-1}(E) \cap B^c \cap A^c$. Thus,

$$\begin{aligned} \mu_1((t^*)^{-1}(E)) &= \nu(E \cap A) + \nu(E \cap B \cap A) + \mu(t^{-1}(E) \cap B^c \cap A^c) \\ &= \nu(E \cap A) + \mu(t^{-1}(E \cap A^c)) = \nu(E), \end{aligned}$$

where we used the fact that $A \cap B = \emptyset$ and that A^c is a set of full measure for μ. Consequently,

$$T_p(\mu_1, \nu) \le \int_{(A\cup B)^c} |x - t(x)|^p u(x) dx < \int_\Omega |x - t(x)|^p u(x) dx = T_p(\mu, \nu). \tag{3.1}$$

From this it follows that for μ_1 Lemma 3.1 is not satisfied, since the integral term $\int_\Omega f'(u)(u_1 - u) d\mathcal{L}^n$ is nonpositive, because $u_1 > u$ only on A, where $f'(u)$ vanishes. The strict inequality in (3.1) follows from the fact that if $\int_{A\cup B} |x - t(x)|^p u(x) dx = 0$, then for a.e. $x \in B$ it holds $u(x) = 0$ or $x = t(x)$, which, by definition of B, implies $x \in A$; in both cases we are led to $u(x) = 0$. This would give $\nu(A) = \mu(B) = 0$, contradicting the assumptions $|A| > 0$ and $v > 0$ a.e. in Ω. ∎

We need some results from duality theory in mass transportation that can be found in [7]. In particular, we point out the notation of c-transform (a kind of generalization of the well-known Legendre transform): given a function χ on Ω we define its c-transform (or c-conjugate function) by

$$\chi^c(y) = \inf_{x\in\Omega} c(x, y) - \chi(x).$$

We will generally use $c(x, y) = |x - y|^p$.

THEOREM 3.3. *Under the same hypotheses of Lemma 3.2, assuming also that $p > 1$, if μ is optimal for $\mathfrak{F}^p_\nu$ and we denote by ψ the unique, up to additive constants,* *Kantorovich potential for the transport between μ and ν, there exists a constant l such that the following relation holds:*

$$u = k(l - \psi) \text{ a.e. in } \Omega. \tag{3.2}$$

Proof. Let us choose an arbitrary measure μ_1 with bounded density u_1 (so that $F(\mu_1) < +\infty$) and define $\mu_\varepsilon = \mu + \varepsilon(\mu_1 - \mu)$. Let us denote by ψ_ε a Kantorovich potential between μ_ε and ν, chosen so that all the functions ψ_ε vanish at a same point. We can use the optimality of μ to write

$$T_p(\mu_\varepsilon, \nu) + F(\mu_\varepsilon) - T_p(\mu, \nu) - F(\mu) \geq 0.$$

By means of the duality formula, as $T_p(\mu_\varepsilon, \nu) = \int \psi_\varepsilon d\mu_\varepsilon + \int \psi_\varepsilon^c d\nu$ and $T_p(\mu, \nu) \geq \int \psi_\varepsilon d\mu + \int \psi_\varepsilon^c d\nu$, we can write

$$\int \psi_\varepsilon d(\mu_\varepsilon - \mu) + F(\mu_\varepsilon) - F(\mu) \geq 0.$$

Recalling that $\mu_\varepsilon - \mu = \varepsilon(\mu_1 - \mu)$ and that

$$F(\mu_\varepsilon) - F(\mu) = \int \left(f(u + \varepsilon(u_1 - u)) - f(u)\right) d\mathcal{L}^n,$$

we can divide by ε and pass to the limit. We know from Lemma 3.4 that ψ_ε converge towards the unique Kantorovich potential ψ for the transport between μ and ν. For the limit of the F part we use Lebesgue dominated convergence, as in Lemma 3.1. We then obtain at the limit

$$\int_\Omega (\psi(x) + f'(u(x)))(u_1(x) - u(x))dx \geq 0.$$

This means that for every probability μ_1 with bounded density u_1 we have

$$\int (\psi(x) + f'(u(x)))u_1(x)\, dx \geq \int (\psi(x) + f'(u(x)))u(x)\, dx.$$

Define first $l = \operatorname{ess\,inf}_{x \in \Omega} \psi(x) + f'(u(x))$. The left-hand side, by properly choosing u_1, can be made as close to l as we want. Then we get that the function $\psi + f'(u)$, which is $\mathcal{L}^n$-a.e., and so also μ-a.e., greater than l, integrated with respect to the probability μ gives a result less than or equal to l. It follows that

$$\psi(x) + f'(u(x)) = l, \quad \mu\text{-a.e. } x \in \Omega.$$

Together with the fact that, by Lemma 3.2, $u > 0$ a.e., we get an equality valid $\mathcal{L}^n$-a.e., and so it holds that

$$f'(u) = l - \psi.$$

We can then compose with k and get the thesis. $\square$

To establish Lemma 3.4, which we used in the proof of Theorem 3.3, we have first to point out the following fact. In the transport between two probabilities, if we look at the cost $c(x, y) = |x - y|^p$ with $p > 1$, there exists just one Kantorovich potential, up to additive constants, provided the absolutely continuous part of one of the measures has strictly positive density a.e. in the domain Ω.

LEMMA 3.4. *Let ψ_ε be Kantorovich potentials for the transport between $\mu_\varepsilon = \mu + \varepsilon(\mu_1 - \mu)$ and ν, all vanishing at a same point $x_0 \in \Omega$. Suppose that $\mu = u \cdot \mathcal{L}^n$ and $u > 0$ a.e. in Ω, and let ψ be the unique Kantorovich potential between μ and ν vanishing at the same point; then ψ_ε converge uniformly to ψ.*

Proof. First, notice that the family $(\psi_\varepsilon)_\varepsilon$ is equicontinuous since any c-concave function with respect to the cost $c(x,y) = |x-y|^p$ is pD^{p-1}-Lipschitz continuous (and Kantorovich potentials are optimal c-concave functions in the duality formula). Moreover, thanks to $\psi_\varepsilon(x_0) = 0$, we also get equiboundedness and thus, by the Ascoli–Arzelà theorem, the existence of uniform limits up to subsequences. Let $\overline{\psi}$ be one of these limits, arising from a certain subsequence. From the optimality of ψ_ε in the duality formula for μ_ε and ν we have, for any c-concave function φ,

$$\int \psi_\varepsilon \, d\mu_\varepsilon + \int \psi_\varepsilon^c \, d\nu \geq \int \varphi \, d\mu_\varepsilon + \int \varphi^c \, d\nu.$$

We want to pass to the limit as $\varepsilon \to 0$: we have uniform convergence of ψ_ε but we need uniform convergence of ψ_ε^c as well. To get it, note that

$$\psi_\varepsilon^c(x) = \inf_y |x-y|^p - \psi_\varepsilon(y), \quad \overline{\psi}^c(x) = \inf_y |x-y|^p - \overline{\psi}(y),$$
$$|\psi_\varepsilon^c(x) - \overline{\psi}^c(x)| \leq ||\psi_\varepsilon - \overline{\psi}||_\infty.$$

Passing to the limit as $\varepsilon \to 0$ along the considered subsequence we get, for any φ,

$$\int \overline{\psi} \, d\mu + \int \overline{\psi}^c \, d\nu \geq \int \varphi \, d\mu + \int \varphi^c \, d\nu.$$

This means that $\overline{\psi}$ is a Kantorovich potential for the transport between μ and ν. Then, taking into account that $\overline{\psi}(x_0) = 0$, we get the equality $\overline{\psi} = \psi$. Then we derive that the whole sequence converges to ψ. ◻

We now highlight that the relation we have proved in Theorem 3.3 enables us to choose a density u which is continuous. Moreover, it is also continuous in a quantified way, since it coincides with k composed with a Lipschitz function with a fixed Lipschitz constant. As a next step we will try to extend such results to the case of general ν and then to the case $p = 1$. The uniform continuity property we proved will be essential for an approximation process.

In order to go through our approximation approach, we need the following lemma, requiring the well-known theory of Γ-convergence. For all details about this theory, we refer to [4].

LEMMA 3.5. *Given a sequence $(\nu_h)_h$ of probability measures on Ω, supposing $\nu_h \rightharpoonup \nu$ and $p > 1$, it follows that the sequence of functionals $(\mathfrak{F}^p_{\nu_h})_h$ Γ-converges to the functional $\mathfrak{F}^p_\nu$ with respect to weak-$*$ topology on $\mathcal{P}(\Omega)$. Moreover, if ν is fixed and we let p vary, we have Γ-convergence, according to the same topology, of the functionals $\mathfrak{F}^p_\nu$ to the functional $(\mathfrak{F}^1_\nu)$ as $p \to 1$.*

Proof. For the first part of the statement, just notice that the Wasserstein distance is a metrization of weak-$*$ topology: consequently, since $T_p(\mu,\nu) = W_p^p(\mu,\nu)$, as $\nu_h \rightharpoonup \nu$ we have uniform convergence of the continuous functionals $T_p(\cdot, \nu_h)$. This implies Γ-convergence and pointwise convergence. In view of Proposition 6.25 in [4], concerning Γ-convergence of sums, we achieve the proof. The second assertion follows the same scheme once we notice that, for each $p > 1$ and every pair (μ,ν) of probability measures, it holds that

$$W_1(\mu,\nu) \leq W_p(\mu,\nu) \leq D^{1-\frac{1}{p}} W_1^{\frac{1}{p}}(\mu,\nu).$$

This gives uniform convergence of the transport term, as

$$\begin{aligned} T_p(\mu,\nu) - T_1(\mu,\nu) &\le (D^{p-1}-1)T_1(\mu,\nu) \\ &\le D(D^{p-1}-1) \to 0. \\ T_p(\mu,\nu) - T_1(\mu,\nu) &\ge T_1^p(\mu,\nu) - T_1(\mu,\nu) \\ &\ge (p-1)c(T_1(\mu,\nu)) \ge \bar{c}\,(p-1) \to 0, \end{aligned}$$

where $c(t) = t\log t$, $\bar{c} = \inf c$, and we used the fact $T_1(\mu,\nu) \le D$. ◻

We now state in the form of lemmas two extensions of Theorem 3.3

LEMMA 3.6. *Suppose $p > 1$ and fix an arbitrary $\nu \in \mathcal{P}(\Omega)$. If μ is optimal for $\mathfrak{F}^p_\nu$, then there exists a Kantorovich potential ψ for the transport between μ and ν such that* (3.2) *holds.*

Proof. We choose a sequence $(\nu_h)_h$ approximating ν in such a way that each ν_h satisfies the assumptions of Theorem 3.3. By Lemma 3.5 and the properties of Γ-convergence, the space $\mathcal{P}(\Omega)$ being compact and the functional $\mathfrak{F}^p_\nu$ having an unique minimizer (see, for instance, Chapter 7 in [4]), we get that $\mu_h \rightharpoonup \mu$, where each μ_h is the unique minimizer of $\mathfrak{F}^p_{\nu_h}$. Each measure μ_h is absolutely continuous with density u_h. We use (3.2) to express u_h in terms of Kantorovich potentials ψ_h and get uniform continuity estimates on u_h. We would like to extract converging subsequences by the Ascoli–Arzelà theorem, but we also need equiboundedness. We may obtain this by using together the integral bound $\int u_h d\mathcal{L}^n = \int k(-\psi_h) d\mathcal{L}^n = 1$ and the equicontinuity. So, up to subsequences, we have the following situation:

$$\begin{gathered} \mu_h = u_h \cdot \mathcal{L}^n, \qquad u_h = k(-\psi_h), \\ u_h \to u, \qquad \psi_h \to \psi \text{ uniformly}, \\ \mu_h \rightharpoonup \mu, \quad \mu = u \cdot \mathcal{L}^n, \qquad \nu_h \rightharpoonup \nu, \end{gathered}$$

where we have absorbed the constants l into the Kantorovich potentials. Clearly it is sufficient to prove that ψ is a Kantorovich potential between μ and ν to reach our goal.

To see this, we consider that for any c-concave function φ, it holds that

$$\int \psi_h \, d\mu_h + \int \psi_h^c \, d\nu_h \ge \int \varphi \, d\mu_h + \int \varphi^c \, d\nu_h.$$

The thesis follows passing to the limit with respect to h, as in Lemma 3.4. ◻

The next step is proving the same relation when ν is generic and $p = 1$. We are in the same situation as before, and we simply need approximation results on Kantorovich potentials in the more difficult situation when the cost functions $c_p(x,y) = |x-y|^p$ vary with p.

LEMMA 3.7. *Suppose $p = 1$ and fix an arbitrary $\nu \in \mathcal{P}(\Omega)$. If μ is optimal for $\mathfrak{F}^1_\nu$, then there exists a Kantorovich potential ψ for the transport between μ and ν with cost $c(x,y) = |x-y|$ such that* (3.2) *holds.*

Proof. For any $p > 1$ we consider the functional $\mathfrak{F}^p_\nu$ and its unique minimizer μ_p. Thanks to Lemma 3.6 we get the existence of densities u_p and Kantorovich potential ψ_p between μ_p and ν with respect to the cost c_p, such that

$$\mu_p = u_p \cdot \mathcal{L}^n, \quad u_p = k(-\psi_p).$$

By the Ascoli–Arzelà compactness result, as usual, we may suppose, up to subsequences,

$$u_p \to u, \quad \psi_p \to \psi \text{ uniformly},$$

and due to the Γ-convergence result in Lemma 3.5, since $\mathfrak{F}^1_\nu$ has an unique minimizer denoted by μ we also get

$$\mu_p \rightharpoonup \mu, \qquad \mu = u \cdot \mathcal{L}^n.$$

As in Lemma 3.6, we simply need to prove that ψ is a Kantorovich potential between μ and ν for the cost c_1. The limit function ψ is Lipschitz continuous with Lipschitz constant less than or equal to $\liminf_{p\to 1} pD^{p-1} = 1$, since it is approximated by ψ_p. Consequently ψ is c-concave for $c = c_1$. We need to show that it is optimal in the duality formula.

Let us recall that, for any real function φ and any cost function c, it holds that $\varphi^{cc} \geq \varphi$ and φ^{cc} is a c-concave function whose c-transform is $\varphi^{ccc} = \varphi^c$. Consequently, by the optimality of ψ_p, we get

$$\int \psi_p d\mu_p + \int \psi_p^{c_p} d\nu \geq \int \varphi^{c_p c_p} d\mu_p + \int \varphi^{c_p} d\nu \geq \int \varphi d\mu_p + \int \varphi^{c_p} d\nu. \tag{3.3}$$

We want to pass to the limit in the inequality between the first and the last term. We start by proving that, for an arbitrary sequence $(\varphi_p)_p$, if $\varphi_p \to \varphi_1$, we have the uniform convergence $\varphi_p^{c_p} \to \varphi_1^{c_1}$. Let us take into account that we have uniform convergence on bounded sets of $c_p(x,y) = |x-y|^p$ to $c_1(x,y) = |x-y|$. Then we have

$$\varphi_p^{c_p}(x) = \inf_y |x-y|^p - \varphi_p(y), \quad \varphi_1^{c_1}(x) = \inf_y |x-y| - \varphi_1(y),$$
$$|\varphi_p^{c,p}(x) - \varphi_1^{c,1}(x)| \leq ||c_p - c_1||_\infty + ||\varphi_p - \varphi_1||_\infty,$$

which gives us the convergence we needed. We then obtain, passing to the limit as $p \to 1$ in (3.3),

$$\int \psi \, d\mu + \int \psi^{c_1} \, d\nu \geq \int \varphi \, d\mu + \int \varphi^{c_1} \, d\nu.$$

By restricting this inequality to all φ which are c_1-concave, we get that ψ is a Kantorovich potential for the transport between μ and ν and the cost c_1. □

We can now state the main theorem of this section, whose proof consists only of putting together all the results we have obtained above.

THEOREM 3.8. *Let Ω be a bounded domain in $\mathbb{R}^n$, f be a C^1 strictly convex function, $p \geq 1$, and ν be a probability measure on Ω. Then there exists a unique measure $\mu \in \mathcal{P}(\Omega)$ minimizing $\mathfrak{F}^p_\nu$ and it is absolutely continuous with density u. Moreover, there exists a Kantorovich potential ψ for the transport between μ and ν and the cost $c(x,y) = |x-y|^p$ such that $u = k(-\psi)$ holds, where $k = (f')^{-1}$.*

Consequences on the regularity of u come from this expression, which gives Lipschitz-type continuity, and from the relationship between Kantorovich potentials and optimal transport, which can be expressed through some PDEs. It is not difficult, for instance, in the case $p = 2$, to obtain a Monge–Ampère equation for the density u.

As we have already mentioned, we provide a sketch of an alternative proof to Theorem 3.8. The idea of such a proof consists of looking at the subdifferential of the functional $\mathfrak{F}^p_\nu$ in order to get optimality conditions on the unique minimizer measure μ and its density u (here we will identify any absolutely continuous probability measure with its density).

Sketch of Proof. Step 1. Consider the minimizing probability μ with density $u \in L^1(\Omega)$ and define the vector space $X = span\,(L^\infty(\Omega), \{u\})$, with dual

$$X' = \left\{ \xi \in L^1(\Omega) : \int_\Omega |\xi| u \, d\mathcal{L}^n < +\infty \right\}.$$

Then we consider the minimization problem for the functional H defined on X by

$$H(v) = \begin{cases} \mathfrak{F}^p_\nu(v) & \text{if } v \in \mathcal{P}(\Omega), \\ +\infty & \text{otherwise.} \end{cases}$$

It is clear that u minimizes H. We will prove

$$\partial H(u) = \left\{ f'(u) + \psi : \psi \text{ maximizes } \int_\Omega \phi d\mu + \int_\Omega \phi^c d\nu \text{ for } \phi \in X' \right\} \tag{3.4}$$

and then consider as an optimality condition $0 \in \partial H(u)$. The subdifferential ∂H of the convex functional H is to be considered in the sense of the duality between X and X'. Notice that, in this setting, the c-transform ϕ^c of a function $\phi \in X'$ has to be defined replacing the inf with an ess inf. Finally, in order to achieve the proof, it is sufficient to recognize that for a function ψ attaining the maximum in the duality formula, it necessarily holds that $\psi = \psi^{cc}$ a.e. on $\{u > 0\}$ and that this, together with $0 = f'(u) + \psi$, implies $\psi = \psi^{cc} \wedge 0$. This means that ψ is an optimal c-concave function (since it is expressed as an infimum of two c-concave functions) in the duality formula between μ and ν, and so it is a Kantorovich potential. In this way the thesis of Theorem 3.8 is achieved, provided (3.4) is proved.

Step 2. By using the same computations as in Lemma 3.1, for any $u_1 \in X \cap \mathcal{P}(\Omega)$, if we set $u_\varepsilon = u + \varepsilon(u_1 - u)$, we may prove that

$$\lim_{\varepsilon \to 0} \frac{F(\mu_\varepsilon) - F(\mu)}{\varepsilon} = \int_\Omega f'(u)(u_1 - u) \, d\mathcal{L}^n.$$

Notice that, since $\int_\Omega f'(u)|u_1 - u| \, d\mathcal{L}^n < +\infty$, by choosing $u_1 = 1/|\Omega|$ it follows that $f'(u)$ and $f'(u)u$ are L^1 functions; i.e., $f'(u) \in X'$. Then it is possible to prove that this implies $\partial H(u) = f'(u) + \partial T(u)$, where T is the convex functional $T_p(\cdot, \nu)$.

Step 3. It remains to prove that

$$\partial T(u) = \left\{ \psi : \psi \text{ maximizes } \int_\Omega \phi d\mu + \int_\Omega \phi^c d\nu \text{ for } \phi \in X' \right\}. \tag{3.5}$$

In fact, if we define $K(\phi) = \int_\Omega \phi^c d\nu$, the key point is to prove that K is concave and upper semicontinuous in ϕ. Then, by standard convex analysis tools, (3.5) is a consequence of the equality $T(v) = \sup_\phi v \cdot \phi + K(\phi)$, where $v \cdot \phi$ stands for the duality product between X and X' and equals $\int_\Omega v\phi \, d\mathcal{L}^n$.

4. Applications to urban planning problems (with atomic services). In this section we go through the consequences that Theorem 3.8 has in the problem of minimizing $\mathfrak{F}^p$, when this functional is built by using a term G as in (2.3), which forces the measure ν, representing services, to be purely atomic. We have two goals: trying to have an explicit expression for u in the case of a bounded domain Ω and proving an existence result in the case $\Omega = \mathbb{R}^n$.

THEOREM 4.1. *Suppose* (μ,ν) *is optimal for problem* (1.3)*. Suppose also that the function* g *is locally Lipschitz in* $]0,1]$*: then* ν *has finitely many atoms and is of the form* $\nu=\sum_{i=1}^m a_i\delta_{x_i}$*.*

Proof. It is clear that ν is purely atomic, i.e., a countable sum of Dirac masses. We want to show their finiteness. Consider $a=\max a_i$ (such a maximum exists since $\lim_i a_i=0$ and $a_i>0$) and let L be the Lipschitz constant of g on $[a,1]$. Now consider an atom with mass a_i and modify ν by moving its mass onto the atom x_j whose mass a_j equals a, obtaining a new measure ν'. The G-part of the functional decreases, while it may happen that the transport part increases. Since we do not change μ, the F-part remains the same. By optimality of ν we get $T_p(\mu,\nu)+G(\nu)\le T_p(\mu,\nu')+G(\nu')$ and thus

$$g(a_i)-La_i\le g(a_i)+g(a)-g(a+a_i)\le T_p(\mu,\nu')-T_p(\mu,\nu)\le a_iD.$$

This implies

$$\frac{g(a_i)}{a_i}\le D+L,$$

and by the assumption on the behavior of g at 0, this gives a lower bound δ on a_i. Since we have proved that every atom of ν has a mass greater than δ, we may conclude that ν has finitely many atoms. ∎

Now we can use the results from last section.

THEOREM 4.2. *For any* $\nu\in\mathcal{P}(\Omega)$ *such that* ν *is purely atomic and composed by finitely many atoms at the points* $x_1,\dots,x_m$*, if* μ *minimizes* $\mathfrak{F}^p_\nu$*, there exist constants* c_i *such that*

$$u(x)=k\left((c_1-|x-x_1|^p)\vee\cdots\vee(c_m-|x-x_m|^p)\vee 0\right). \tag{4.1}$$

In particular the support of u *is the intersection with* Ω *of a finite union of balls centered around the atoms of* ν*.*

Proof. On the Kantorovich potential ψ appearing in Theorem 3.8, we know that

$$\begin{aligned}\psi(x)+\psi^c(y)&=|x-y|^p\quad\forall(x,y)\in spt(\gamma),\\ \psi(x)+\psi^c(y)&\le|x-y|^p\quad\forall(x,y)\in\Omega\times\Omega,\end{aligned}$$

where γ is an optimal transport plan between μ and ν. Taking into account that ν is purely atomic we obtain, defining $c_i=\psi^c(x_i)$,

$$\begin{aligned}-\psi(x)&=c_i-|x-x_i|^p\quad\mu\text{-a.e. }x\in\Omega_i,\\ -\psi(x)&\ge c_i-|x-x_i|^p\quad\forall x\in\Omega,\,\forall i,\end{aligned}$$

where $\Omega_i=t^{-1}(x_i)$, where t is an optimal transport map between μ and ν. Since $\mu-$a.e. point in Ω is transported to a point x_i, we know that $u=0$ a.e. in the complement of $\bigcup_i\Omega_i$. Since, by $f'(u)=-\psi$, it holds that $-\psi(x)\ge 0$, one gets that everywhere in Ω the function $-\psi$ is greater than each of the terms $c_i-|x-x_i|^p$ and 0, while a.e. it holds equality with at least one of them. By changing u on a negligible set, one obtains (4.1). The support of μ, consequently, turns out to be composed of the union of the intersection with Ω of the balls $B_i=B(x_i,c_i^{1/p})$. ∎

Theorem 4.2 allows us to have an almost explicit formula for the density of μ. Formula (4.1) becomes more explicit when the balls B_i are disjoint. We now give a sufficient condition on ν under which this fact occurs.

LEMMA 4.3. *There exists a positive number $\overline{R}$, depending on the function k, such that any of the balls B_i has a radius not exceeding $\overline{R}$. In particular, for any atomic probability ν such that the distance between any two of its atoms is larger than $2\overline{R}$, the balls B_i are disjoint.*

Proof. Set $R_i = c_i^{1/p}$ and notice that

$$1 = \int_\Omega u \geq \int_{B_i} k(c_i - |x - x_i|^p)\, dx = \int_0^{R_i} k(R_i^p - r^p) n\omega_n r^{n-1}\, dr,$$

where the number ω_n stands for the volume of the unit ball in $\mathbb{R}^n$. This inequality gives the required upper bound on R_i, since

$$\int_0^{R_i} k(R_i^p - r^p) n\omega_n r^{n-1}\, dr \geq C \int_0^{R_i - 1} n r^{n-1}\, dr = C(R_i - 1)^n. \qquad \square$$

When the balls B_i are disjoint, we have $B_i = \Omega_i$ for every i and we get a simple relation between radii and masses corresponding to each atom. The constants c_i can then be found by using $R_i = c_i^{1/p}$. In fact, by imposing the equality of the mass of μ in the ball and of ν in the atom, the radius $R(m)$ corresponding to a mass m satisfies

$$m = \int_0^{R(m)} k(R(m)^p - r^p) n\omega_n r^{n-1} dr. \tag{4.2}$$

For instance, if $f(s) = s^2/2$, we have

$$R(m) = \left(\frac{m(n+p)}{\omega_n p} \right)^{\frac{1}{n+p}}.$$

The second aim of this section is to obtain an existence result for the problem (1.3) when $\Omega = \mathbb{R}^n$. A difference from the bounded case is the fact that we must look for minimization among all pairs of measures in $\mathcal{W}_p(\mathbb{R}^n)$, the p-th Wasserstein metric space (i.e., the space of measures $\lambda \in \mathcal{P}(\mathbb{R}^n)$ such that $\int |x|^p \lambda(dx) < +\infty$, endowed with the distance W_p), rather than in $\mathcal{P}(\mathbb{R}^n)$.

We start with some simple results about the minimization problem for $\mathfrak{F}_\nu^p$.

LEMMA 4.4. *For every fixed $\nu \in \mathcal{P}(\mathbb{R}^n)$ there exists a (unique if f is strictly convex) minimizer μ for $\mathfrak{F}_\nu^p$: it belongs to $\mathcal{W}_p(\mathbb{R}^n)$ if and only if $\nu \in \mathcal{W}_p(\mathbb{R}^n)$, and if ν does not belong to this space, the functional $\mathfrak{F}_\nu^p$ is infinite on the whole $\mathcal{W}_p(\mathbb{R}^n)$. Moreover, if ν is compactly supported, the same happens for μ.*

Proof. The existence of μ comes from the direct method of the calculus of variations and the fact that if $(T_p(\mu_h, \nu))_h$ is bounded, then $(\mu_h)_h$ is tight. The behavior of the functional with respect to the space $\mathcal{W}_p(\mathbb{R}^n)$ is trivial. Finally, the last assertion can be proved by contradiction, supposing $\mu(B(0,R)^c) > 0$ for every $R < +\infty$ and replacing μ with

$$\mu_R = 1_{B_R} \cdot \mu + \frac{\mu(B_R^c)}{|B_r|} 1_{B_r} \cdot \mathcal{L}^n,$$

where $B(0,r)$ is a ball containing the support of ν. By optimality, we should have

$$T_p(\mu_R, \nu) + F(\mu_R) \geq T_p(\mu, \nu) + F(\mu), \tag{4.3}$$

but we have

$$T_p(\mu_R,\nu) - T_p(\mu,\nu) \le -((R-r)^p - (2r)^p)\mu(B_R^c), \tag{4.4}$$

$$F(\mu_R) - F(\mu) \le \int_{B_r} \left[f\left(u + \frac{\mu(B_R^c)}{|B_r|} \right) - f(u) \right] d\mathcal{L}^n. \tag{4.5}$$

By summing up (4.4) and (4.5), dividing by $\mu(B_R^c)$, and taking into account (4.3), we get

$$-((R-r)^p - (2r)^p) + \frac{1}{\mu(B_R^c)} \int_{B_r} \left[f\left(u + \frac{\mu(B_R^c)}{|B_r|} \right) - f(u) \right] d\mathcal{L}^n \ge 0. \tag{4.6}$$

Yet, by passing to the limit as $R \to +\infty$ and $\mu(B_R^c) \to 0$, the first term in (4.6) tends to $-\infty$, while the second is decreasing as $R \to +\infty$. This last one tends to $\int_{B_r} f'(u) d\mathcal{L}^n$, provided it is finite for at least a value of R (which ensures the finiteness of the limit as well). To conclude, it is sufficient to prove that

$$\int_{B_r} \left[f\left(u + \frac{\mu(B_R^c)}{|B_r|} \right) - f(u) \right] d\mathcal{L}^n < +\infty.$$

This is quite easy in the case $f(z) = Az^q$ with $q > 1$, while for general f the assertion comes from the fact that u is continuous on $\overline{B_r}$ and hence bounded. If $u = 0$ a.e. in B_r, this is trivial; otherwise take the probability measures $\mu' = 1_{B_r}/\mu(B_r)\cdot\mu$ and $\nu' = t_\sharp \mu'$ for an optimal transport map t between μ and ν. It is clear that μ' minimizes $\mathfrak{F}^p_{\nu'}$ in the new domain $\Omega' = \overline{B_r}$. Then we may apply Theorem 3.8 and get the continuity of its density, which ensures the continuity of u on $\overline{B_r}$. ∎

To go through our proof we need to manage minimizing sequences, in the sense of the following lemma.

LEMMA 4.5. *It is possible to choose a minimizing sequence $((\mu_h,\nu_h))_h$ in $\mathcal{W}_p(\mathbb{R}^n)\times \mathcal{W}_p(\mathbb{R}^n)$ such that for every h the measure ν_h is finitely supported, and the density of μ_h is given by* (4.1)*, with disjoint balls centered at the atoms of ν_h.*

Proof. First we start from an arbitrary minimizing sequence $((\mu'_h,\nu'_h))_h$. Then we approximate each ν'_h in $\mathcal{W}_p$ by a finite support measure ν''_h. To do this we truncate the sequence of its atoms and move the mass in excess to the origin. In this way, we have $G(\nu''_h) \le G(\nu'_h)$, by the subadditivity of g, while the value of the transport term increases by an arbitrary small quantity. Consequently, $((\mu'_h,\nu''_h))_h$ is still a minimizing sequence. Then we replace μ'_h by μ''_h, chosen in such a way that it minimizes $\mathfrak{F}^p_{\nu''_h}$. By Lemma 4.4, each μ''_h has a compact support. Then we translate every atom of each ν''_h, together with its own set Ω_i, to some disjoint sets Ω_i^*. In this way we get new measures μ'''_h and ν'''_h. The value of the functional in this step has not changed. We may choose to place the atoms of each ν'''_h so far from each other that each distance between atoms is at least $2\overline{R}$. Then we minimize again in μ, getting a new sequence of pairs $((\mu''''_h,\nu'''_h))_h$, and we set $\nu_h = \nu'''_h$ and $\mu_h = \mu''''_h$. Thanks to Theorem 4.2 and Lemma 4.3 the requirements of the thesis are fulfilled. ∎

It is clear now that if one can obtain a uniform estimate on the number of atoms of the measures ν_h, the existence problem is easily solved. In fact we already know that each ball belonging to the support of μ_h is centered at an atom of ν_h and has a radius not larger than $\overline{R}$. Provided we are able to prove an estimate like $\sharp\,\{\text{atoms of } \nu_h\} \le N$, it would be sufficient to act by translation on the atoms and their corresponding balls, obtaining a new minimizing sequence (the value of $\mathfrak{F}^p$ does not change) with supports all contained in a same bounded set (for instance, the ball $B_{N\overline{R}}$).

We now try to give sufficient conditions in order to find minimizing sequences where the number of atoms stays bounded. Notice that on sequences of the form given by Lemma 4.5, the functional $\mathfrak{F}^p$ has the expression

$$\mathfrak{F}^p(\mu_h,\nu_h)=\sum_{i=1}^{k(h)} E(m_{i,h}),\quad \text{if } \nu_h=\sum_{i=1}^{k(h)} m_{i,h}\delta_{x_{i,h}}, \tag{4.7}$$

where the quantity $E(m)$ is the total contribute given by an atom with mass m to the functional. We may compute

$$E(m) \;=\; g(m)+\int_0^{R(m)}\left[f(k(R(m)^p-r^p))+k(R(m)^p-r^p)r^p\right]n\omega_n r^{n-1}dr, \tag{4.8}$$

taking into account the particular form of the density in the ball.

THEOREM 4.6. *Let us suppose $f\in C^2((0,+\infty))$, and $g\in C^2((0,1])\cap C^0([0,1])$, in addition to all previous assumptions. Then the minimization problem for $\mathfrak{F}^p$ in $\mathcal{W}_p(\mathbb{R}^n)\times\mathcal{W}_p(\mathbb{R}^n)$ has a solution, provided*

$$\limsup_{R\to 0^+} g''\left(\int_0^R k(R^p-r^p)n\omega_n r^{n-1}dr\right)\int_0^R k'(R^p-r^p)n\omega_n r^{n-1}dr<-1.$$

Proof. According to what has been previously proven, it is sufficient to produce a minimizing sequence of the form of Lemma 4.5 with a bounded number of atoms. We claim that it is enough to prove that the function E is subadditive on an interval $[0,m_0]$. In fact, having proven it, we start from a sequence $((\mu_h,\nu_h))_h$ built as in Lemma 4.5 and use the characterization of $\mathfrak{F}^p$ given in (4.7). Then we modify our sequence by replacing in each ν_h any pair of atoms of mass less than $m_0/2$ with a single atom with the sum of the masses. We keep atoms far away from each other in order to use (4.7). We may perform such a replacement as far as we find more than one atom whose mass is less than or equal to $m_0/2$. At the end we get a new pair $((\mu'_h,\nu'_h))_h$, where the number of atoms of ν'_h is less than $N=1+\lfloor 2/m_0\rfloor$. The value of the functional $\mathfrak{F}^p$ has not increased, thanks to the subadditivity of E on $[0,m_0]$.

Taking into account that $E(0)=0$ and that concave functions vanishing at 0 are subadditive, we look at concavity properties of the function E in an interval $[0,m_0]$. It is sufficient to compute the second derivative of E and find it negative in a neighborhood of the origin.

By means of the explicit formula (4.8) and also taking into account (4.2), setting $E(m)=g(m)+K(R(m))$, we start by computing dK/dr. Using the facts that $f'\circ k=id$ and that $k(0)=0$, we can obtain the formula

$$\frac{dK(R(m))}{dm}(m)=R(m)^p.$$

From another derivation and some standard computation we finally obtain

$$E''(m)=g''(m)+\frac{1}{\int_0^{R(m)}k'(R(m)^p-r^p)n\omega_n r^{n-1}dr}.$$

The assumption of this theorem ensures that such a quantity is negative for small m, and so the proof is achieved. $\square$

Remark 4.7. Notice that when the functions f and g are of the form $f(t) = at^q$, $q > 1$, $g(t) = bt^r$, $r < 1$, with a and b positive constants, it holds that

$$g''\left(\int_0^R k(R^p - r^p) n\omega_n r^{n-1} dr\right) \le -CR^{(n+\frac{p}{q-1})(r-2)},$$

$$\int_0^R k'(R^p - r^p) n\omega_n r^{n-1} dr \le CR^{n+p\frac{2-q}{q-1}},$$

and so the lim sup in Theorem 4.6 may be estimated from above by

$$\lim_{R\to 0^+} -CR^{\frac{p}{q-1}(r-q)+n(r-1)} = -\infty.$$

Consequently the assumption in Theorem 4.6 is always verified when f and g are power functions.

Remark 4.8. From the proof of the existence theorem it is clear that there exists a minimizing pair $(\mu, \nu) \in \mathcal{W}_p(\mathbb{R}^n) \times \mathcal{W}_p(\mathbb{R}^n)$ where ν has finitely many atoms and μ is supported in a finite, disjoint union of balls centered at the atoms of ν and contained in a bounded domain Ω_0, with a density given by Theorem 4.2. The same happens if we look for the minimizers in a bounded domain Ω, provided Ω is large enough to contain Ω_0, and hence a solution to the problem in $\mathbb{R}^n$. For example, all the open sets containing N balls of radius $\overline{R}$ admit a minimizing solution supported in disjoint balls.

We conclude by stressing the fact that in order to solve the problem in $\mathbb{R}^n$, we have only to look at the function E and find out the number of atoms and their respective masses $(m_i)_{i=1\dots k}$. The problem to solve is then

$$\min\left\{\sum_{i=1}^k E(m_i) \,:\, k \in \mathbb{N}, \sum_{i=1}^k m_i = 1\right\}. \tag{4.9}$$

Typically, for instance when f and g are power functions, the function E involved in (4.9) is a concave-convex function, as sketched in Figure 1. Due to such a concave-convex behavior, in general it is not clear whether the values of the numbers m_i solving (4.9) and representing subcities' sizes are all equal or may be different.

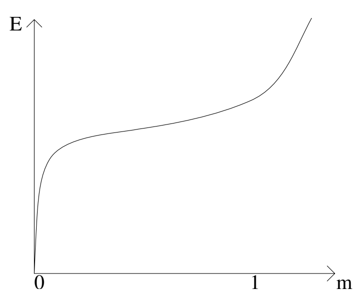

FIG. 1. *Typical behavior of E.*

Acknowledgments. The authors wish to thank an anonymous referee for pointing out the alternative proof sketched in section 3.

STEADY STATES FOR A COAGULATION-FRAGMENTATION EQUATION WITH VOLUME SCATTERING*

PHILIPPE LAURENÇOT† AND CHRISTOPH WALKER‡

Abstract. A coagulation-fragmentation equation including volume scattering and collisional breakage is considered. We prove that the equation admits steady states of arbitrary mass provided that the kernels satisfy some suitable growth conditions. On the other hand, we also show that zero is the only steady state in particular cases.

Key words. coagulation-fragmentation equation, volume scattering, stationary solution

1. Introduction. The aim of this paper is to investigate the existence of steady states for a coagulation-fragmentation equation including a volume scattering effect. Recall that coagulation-fragmentation models describe the time evolution of a system consisting of a very large number of particles, which can either coalesce to form larger particles or split into smaller ones. Usually, these particles are supposed to be identified only by their size (mass, volume), which in the conventional continuous models might be any positive real number. In the model considered in the present paper, a critical particle size $y_0 \in (0,\infty)$ is introduced beyond which no particle can survive. This feature requires an additional mechanism, called *scattering* in what follows, preventing the occurrence of particles of size larger than the maximal size y_0 [6]. In addition to this scattering phenomenon, the subsequent model also includes the possibility of collisional breakage.

Denoting by $f(t,y) \geq 0$ the density of particles of size $y \in Y := (0,y_0)$ at time $t \geq 0$ (per unit volume), the evolution of the system of particles simultaneously undergoing coagulation and fragmentation can be described by the equation

$$\begin{aligned} \partial_t f &= L(f), \quad (t,y) \in (0,\infty)\times Y, \\ f(0,y) &= f_0(y), \quad y \in Y, \end{aligned} \tag{1.1}$$

where f_0 is a given initial distribution. The reaction terms $L(f) := L_{\mathsf{b}}(f) + L_{\mathsf{c}}(f) + L_{\mathsf{s}}(f)$ are defined by

$$\begin{aligned} L_{\mathsf{b}}(f)(y) &:= \int_y^{y_0} \gamma(y',y)\ f(y')\ \mathrm{d}y' - f(y)\ \int_0^y \frac{y'}{y}\ \gamma(y,y')\ \mathrm{d}y', \\ L_{\mathsf{c}}(f)(y) &:= \frac{1}{2}\ \int_0^y K(y',y-y')\ P(y',y-y')\ f(y-y')\ f(y')\ \mathrm{d}y' \\ &\quad + \frac{1}{2}\int_y^{y_0}\int_0^{y'} K(y'',y'-y'')\ Q(y'',y'-y'')\ \beta_{\mathsf{c}}(y',y)\ f(y'')\ f(y'-y'')\ \mathrm{d}y''\mathrm{d}y' \end{aligned}$$

$$
\begin{aligned}
&\quad - f(y) \int_0^{y_0-y} K(y,y')\ \left\{P(y,y')+Q(y,y')\right\}\ f(y')\ \mathrm{d}y', \\
L_{\mathsf{s}}(f)(y) &:= \frac{1}{2} \int_{y_0}^{2y_0} \int_{y'-y_0}^{y_0} K(y'',y'-y'')\ \beta_{\mathsf{s}}(y',y)\ f(y'')\ f(y'-y'')\ \mathrm{d}y''\mathrm{d}y' \\
&\quad - f(y) \int_{y_0-y}^{y_0} K(y,y')\ f(y')\ \mathrm{d}y'
\end{aligned}
$$

for $y \in Y$ and describe the following reactions:

- The linear operator $L_{\mathsf{b}}(f)$ accounts for the gain and loss of particles of size y due to multiple spontaneous breakage, where $\gamma(y,y') \geq 0$ denotes the rate at which a particle of size $y \in Y$ decays into a particle of size $y' \in (0,y)$.
- Furthermore, two particles y and y' with cumulative size $y+y' < y_0$ can collide at a rate $K(y,y') \geq 0$ and either nothing happens—meaning that the involved particles remain unchanged, for instance in the case of grazing particles—or they merge with probability $P(y,y')$ or, in the case of high-energy collisions, shatter with probability $Q(y,y')$ into several particles according to the shattering distribution $\beta_{\mathsf{c}}(y+y',y'')$ (the latter process is also referred to as collisional breakage). Consistency of the model then demands

$$0 \leq P(y,y')+Q(y,y') \leq 1, \quad y+y' < y_0. \tag{1.2}$$

  These processes are reflected by the operator $L_{\mathsf{c}}(f)$.
- Finally, the scattering operator $L_{\mathsf{s}}(f)$ represents the interaction of two particles y and y' with cumulative size beyond the maximal size y_0. They can coalesce but the resulting particle instantaneously splits into particles all with size within the admissible range Y. The daughter particles are then distributed according to $\beta_{\mathsf{s}}(y+y',y'') \geq 0$. We refer to [6], where the volume scattering mechanism was introduced (see also [5] for a more detailed discussion on the modelling issue).

Since there is no particle inlet or outlet, one intuitively expects the total mass to be preserved during time, i.e.,

$$\int_0^{y_0} y\ f(t,y)\ \mathrm{d}y = \int_0^{y_0} y\ f_0(y)\ \mathrm{d}y, \quad t \geq 0. \tag{1.3}$$

Provided that the shattering and the scattering processes are mass preserving (see assumptions (1.10) and (1.12)), this is indeed the case.

From a mathematical viewpoint, some properties of the coagulation-fragmentation equation with volume scattering (1.1) have been investigated recently; in particular, results concerning the well-posedness of (1.1) are to be found in [3, 6, 14, 15], while results on the large time behavior of the solutions in some cases have been obtained in [16]. As for numerical simulations, we refer to [12]. We also mention at this point that, formally, the classical coagulation-fragmentation model usually contemplated in the literature can be derived from (1.1) by putting $y_0 := \infty$ and $P \equiv 1$ (implying $Q \equiv 0$ according to (1.2)). In particular, the shattering and scattering terms vanish in this case. A survey of the present state of knowledge on the classical coagulation-fragmentation equations and references to further literature for this case can be found in [2, 11].

In the present paper, we will focus on existence of nontrivial steady states to (1.1), that is, on nonzero solutions to the equation

$$L(f) = 0 \quad \text{in } Y. \tag{1.4}$$

Addressing this issue is mainly motivated by the study of the asymptotic behavior of solutions to (1.1). Note that the equality (1.3) entails a natural side condition, namely, to solve (1.4) subject to

$$\varrho = \int_0^{y_0} y\ f(y)\ \mathrm{d}y, \tag{1.5}$$

where $\varrho > 0$ is a given positive real number. Let us point out right now that (1.4), (1.5) do not always possess solutions for $\varrho > 0$. In particular, if $\gamma \equiv 0$ and merely binary shattering and binary scattering are taken into account, zero is the only steady state (see section 4). So far, existence of solutions to (1.4) apart from zero is known only if the kernels satisfy an extended version of the so-called detailed balance condition [15, 16], namely that there exists $H \in L^1(Y)$ such that

$$\gamma(y+y',y)\ H(y+y')\ =\ P(y,y')\ K(y,y')\ H(y)\ H(y')$$

for $0 < y+y' < y_0$, that

$$\begin{aligned}&\beta_{\mathsf{c}}(y,y')\ Q(y'',y-y'')\ K(y'',y-y'')\ H(y'')\ H(y-y'')\\ &\quad =\ \beta_{\mathsf{c}}(y,y'')\ Q(y',y-y')\ K(y',y-y')\ H(y')\ H(y-y')\end{aligned}$$

for $0 < y+y'\ ,\ y+y'' < y_0$, and that

$$\beta_{\mathsf{s}}(y,y')\ K(y'',y-y'')\ H(y'')\ H(y-y'')\ =\ \beta_{\mathsf{s}}(y,y'')\ K(y',y-y')\ H(y')\ H(y-y')$$

for $0 < y-y_0 < y',y'' < y_0$. In this case, each function $f_\alpha(y) := H(y)\,\alpha^y$, $y \in Y$, with $\alpha \geq 0$ satisfies (1.4). For the classical coagulation-fragmentation equation, that is, (1.1) with $y_0 = \infty$ and $P \equiv 1$, this condition has previously been used in various papers (for instance, see [1, 7, 9, 10]) and the long-time behavior of solutions has been investigated. That the latter equation admits nontrivial and smooth steady state solutions of arbitrary mass without assuming the detailed balance condition has been proven in [8] for constant fragmentation kernels γ and coagulation kernels

$$K(y,y') = a + b(y+y'),\quad y,y' > 0,$$

with $a, b \geq 0$. More recently, existence of nontrivial stationary solutions (in a weak sense) is shown for kernels of the form

$$\gamma(y,y') = y^\sigma B(y'/y),\quad K(y,y') = y^\alpha (y')^\nu + y^\nu (y')^\alpha$$

with $-1 \leq \alpha \leq 0 \leq \nu \leq 1$, $\alpha+\nu \in [0,1)$, $\sigma \geq -1$, and some suitable function B [4]. To the best of our knowledge, these are the only available results on existence of steady states for the classical coagulation-fragmentation equation ($y_0 = \infty$, $P \equiv 1$) in the absence of the detailed balance condition.

As for (1.4), (1.5), no result seems to be known but the existence of steady states is strongly supported by the numerical simulations in [12]. In this paper, we identify a class of data $(\gamma, K, \beta_{\mathsf{c}}, \beta_{\mathsf{s}})$ for which (1.4), (1.5) has at least one solution for every $\varrho > 0$. Before stating precisely our assumptions, let us first outline the approach we employ to solve (1.4), (1.5): in such a situation, a natural tool is the Schauder fixed point theorem, but its application requires some strong compactness which is not likely to be available here. Indeed, the operator L is an integral operator and does not seem to be compact. To overcome this difficulty, we consider the regularised problem $-\varepsilon\, f'' = L(f)$ in Y with suitable boundary conditions, where f'' denotes the second derivative of f and $\varepsilon \in (0,1)$. It is then possible to use the Schauder fixed point theorem to establish the existence of a solution f_ε to this problem which satisfies (1.5). The next step is to show that (f_ε) is relatively weakly sequentially compact in $L^1(Y)$ and that its cluster points for this topology solve (1.4), (1.5). Let us further mention that another way to remedy to the lack of strong compactness properties of L has been developed in [4] and relies on the Tikhonov fixed point theorem which only demands weak compactness.

The assumptions made throughout this paper are as follows. We suppose that the coagulation kernel K belongs to $L^\infty(Y\times Y)$ and satisfies

$$K_\star (yy')^\sigma \le K(y,y') = K(y',y) \le K^\star (yy')^\sigma, \quad (y,y') \in Y\times Y, \tag{1.6}$$

for some $K_\star, K^\star > 0$, $\sigma \in [0,1]$, and the monotonicity condition

$$K(y-y',y') \le K(y,y') \quad \text{for } \ 0<y'<y<y_0. \tag{1.7}$$

The probabilities P and Q are nonnegative symmetric functions defined on

$$\Xi := \{(y,y') \in Y\times Y;\, y+y' < y_0\}$$

obeying (1.2), and there is $P_\star \in (0,1)$ such that

$$P(y,y') + 2\, Q(y,y') \ge P_\star > 0 \quad \text{for a.a. } \ (y,y') \in \Xi. \tag{1.8}$$

In addition, P satisfies the monotonicity condition

$$P(y-y',y') \le P(y,y') \quad \text{for a.a. } \ (y,y') \in \Xi \quad \text{with } \ 0<y'<y<y_0. \tag{1.9}$$

The fragmentation kernel γ and the shattering distribution β_{c} are nonnegative measurable functions defined on

$$\Delta := \{(y,y') \in Y\times Y;\, 0<y'<y<y_0\},$$

and shattering is supposed to be a mass preserving process, that is,

$$Q(y,y') \left(\int_0^{y+y'} y''\ \beta_{\mathsf{c}}(y+y',y'')\,\mathrm{d}y'' - y - y' \right) = 0 \tag{1.10}$$

for a.a. $(y,y') \in \Xi$. We also assume that shattering is suitably dominated by coagulation, i.e., we assume that there exist $z_0 \in Y$ and $\kappa_0 > 0$ with

$$Q(y,y') \int_0^{y+y'} \beta_{\mathsf{c}}(y+y',y'')\,\mathrm{d}y'' \ \le\ P(y,y') + 2\, Q(y,y') - \kappa_0 \tag{1.11}$$

for a.a. $y+y' < z_0$. The scattering kernel β_{s} is a nonnegative measurable function defined on $(y_0,2y_0)\times(0,y_0)$ and satisfies

$$\int_0^{y_0} y'\ \beta_{\mathsf{s}}(y,y')\,\mathrm{d}y' = y \quad \text{for a.a. } \ y \in (y_0,2y_0). \tag{1.12}$$

Finally, we suppose that there are $p>1$ and μ_γ, μ_{c}, $\mu_{\mathsf{s}} > 0$ such that

$$\int_0^y (y')^{\sigma(1-2p)}\ \gamma(y,y')^p\ \mathrm{d}y' \le \mu_\gamma \quad \text{for a.a. } \ y \in Y, \tag{1.13}$$

$$Q(y,y')\int_0^{y+y'} (y'')^{\sigma(1-p)}\ \beta_{\mathsf{c}}(y+y',y'')^p\ \mathrm{d}y'' \le \mu_{\mathsf{c}} \quad \text{for a.a.} \quad (y,y')\in\Xi, \tag{1.14}$$

$$\int_0^{y_0} (y')^{\sigma(1-p)}\ \beta_{\mathsf{s}}(y,y')^p\ \mathrm{d}y' \le \mu_{\mathsf{s}} \quad \text{for a.a.} \quad y\in(y_0,2y_0). \tag{1.15}$$

Note that (1.13)–(1.15) and Hölder's inequality imply

$$\int_0^{y} \gamma(y,y')\ \mathrm{d}y' \le\ m_\gamma\ y^\sigma \quad \text{for a.a.} \quad y\in Y, \tag{1.16}$$

$$Q(y,y')\int_0^{y+y'} \beta_{\mathsf{c}}(y+y',y'')\ \mathrm{d}y'' \le\ m_{\mathsf{c}} \quad \text{for a.a.} \quad (y,y')\in\Xi, \tag{1.17}$$

$$\int_0^{y_0} \beta_{\mathsf{s}}(y,y')\ \mathrm{d}y' \le\ m_{\mathsf{s}} \quad \text{for a.a.} \quad y\in(y_0,2y_0) \tag{1.18}$$

for some constants $m_\gamma, m_{\mathsf{c}}, m_{\mathsf{s}} > 0$.

Possible (and reasonable) choices of kernels obeying all of the assumptions above are as follows: suppose that K is of the form

$$K(y,y') := A + B(yy')^\theta + C(y+y')^\mu$$

with $A>0$ and $B,C,\theta,\mu\ge 0$. In particular, the positivity of A and $y_0\in(0,\infty)$ warrant that (1.6) holds true with $\sigma := 0$. Let P and Q be nonnegative functions such that, for some $\tau, q>0$,

$$Q(y,y') := q(y+y)^\tau, \quad y+y'<y_0,$$

and such that (1.2), (1.8), and (1.9) hold. For $\bar\gamma,\alpha>0$ and $0\ge\zeta,\xi,\nu>-1$ define

$$\begin{aligned}\gamma(y,y') &:= \bar\gamma\ y^{\alpha-\zeta-1}\ (y')^\zeta,\\ \beta_{\mathsf{c}}(y,y') &:= (\xi+2)\ y^{-1-\xi}\ (y')^\xi,\\ \beta_{\mathsf{s}}(y,y') &:= (\nu+2)\ y_0^{-2-\nu}\ y\ (y')^\nu.\end{aligned}$$

We may then choose $p\in(1,1+\tau)$ with $-1/p<\min\{\nu,\xi,\zeta,\alpha-1\}$ so that all assumptions are satisfied with $\sigma=0$.

On the other hand, if $K(y,y') := \tilde K(yy')^\sigma$, $\sigma\in(0,1]$, $\tilde K>0$, and if $P,Q,\gamma,\beta_{\mathsf{c}},\beta_{\mathsf{s}}$ are as above with additionally $\alpha>\sigma$ and $1+\zeta>\sigma$, we again find $p>1$ which is sufficiently close to 1 and such that (1.13)–(1.15) hold.

Our main result is the following theorem.

THEOREM 1.1. *Let* (1.6)–(1.15) *hold. Then, given any* $\varrho>0$, *there exists a nonnegative function* $f\in L^1_+(Y,y^\sigma\mathrm{d}y)$ *satisfying* $L(f)=0$ *a.e. in* Y *and*

$$\int_0^{y_0} y\ f(y)\ \mathrm{d}y = \varrho,$$

where $L^1_+(Y,y^\sigma\mathrm{d}y)$ *denotes the positive cone of* $L^1(Y,y^\sigma\mathrm{d}y)$.

Recall that the positive cone $L^1_+(Y,y^\sigma\mathrm{d}y)$ of $L^1(Y,y^\sigma\mathrm{d}y)$ is the set of functions of $L^1(Y,y^\sigma\mathrm{d}y)$ which are nonnegative almost everywhere in Y.

The solution f to (1.4), (1.5) we construct in Theorem 1.1 actually belongs to $L^p(Y,y^\sigma\mathrm{d}y)$, but it is yet unclear whether f enjoys additional regularity properties. Also, uniqueness of a solution to (1.4), (1.5) does not seem to be obvious.

As already mentioned, the main idea in order to prove this theorem is to consider first a parameter-dependent regularized problem, which can be solved by a Schauder fixed point argument, and to show afterwards that the family of solutions is weakly compact in $L^p(Y, y^\sigma \mathrm{d}y)$. This then guarantees the existence of nontrivial steady states. In the next section we state and solve the regularized problem. Subsequently, we derive in section 3 some uniform estimates leading to the desired weak compactness. In the concluding section, we show that problem (1.4), (1.5) does not necessarily have a solution.

2. A regularized problem: Existence. Note that (1.6), (1.16), (1.17), and (1.18) imply, for $f \in L^1(Y, y^\sigma \,\mathrm{d}y)$, that the reaction terms $L_{\mathsf{b}}(f)$, $L_{\mathsf{c}}(f)$, and $L_{\mathsf{s}}(f)$ belong to $L^1(Y)$. In addition, given $\psi \in L^\infty(Y)$, we have the identities (see [14, Lemma 2.6] or [15, Lemma 2.7])

$$\int_0^{y_0} \psi(y)\ L_{\mathsf{b}}(f)(y)\ \mathrm{d}y = \int_0^{y_0} \int_0^{y} \left[\psi(y') - \frac{y'}{y}\ \psi(y)\right]\ \gamma(y,y')\ \mathrm{d}y'\ f(y)\ \mathrm{d}y, \tag{2.1}$$

$$\int_0^{y_0} \psi(y)\ L_{\mathsf{c}}(f)(y)\ \mathrm{d}y = \frac{1}{2}\ \int_0^{y_0} \int_0^{y_0-y} \psi_{\mathsf{c}}(y,y')\ K(y,y')\ f(y)\ f(y')\ \mathrm{d}y'\mathrm{d}y, \tag{2.2}$$

$$\int_0^{y_0} \psi(y)\ L_{\mathsf{s}}(f)(y)\ \mathrm{d}y = \frac{1}{2}\ \int_0^{y_0} \int_{y_0-y}^{y_0} \psi_{\mathsf{s}}(y,y')\ K(y,y')\ f(y)\ f(y')\ \mathrm{d}y'\mathrm{d}y, \tag{2.3}$$

where

$$\begin{aligned}\psi_{\mathsf{c}}(y,y') &:= P(y,y')\ \psi(y+y') - [P(y,y')+Q(y,y')]\ [\psi(y)+\psi(y')]\\ &\qquad +\ Q(y,y')\ \int_0^{y+y'} \psi(y'')\ \beta_{\mathsf{c}}(y+y',y'')\ \mathrm{d}y'',\\ \psi_{\mathsf{s}}(y,y') &:= \int_0^{y_0} \psi(y'')\ \beta_{\mathsf{s}}(y+y',y'')\ \mathrm{d}y'' - \psi(y) - \psi(y').\end{aligned}$$

If $f \in L^q(Y; y^k \mathrm{d}y)$ for some $q \in [1,\infty)$ and $k \in \mathbb{R}$, we define

$$M_{k,q}(f) := \int_0^{y_0} y^k\ |f|^q(y)\ \mathrm{d}y \quad \text{and} \quad M_k(f) := M_{k,1}(f).$$

Given $\delta \in (0,1)$, we set

$$K_\delta(y,y') := K(y,y') + \delta$$

and notice that

$$\|K_\delta\|_\infty \le \|K\|_\infty + 1.$$

Hereafter, we denote by $L_\delta(f)$ the reaction terms $L(f)$ but with K_δ instead of K. For $\varepsilon \in (0,\delta)$ and $\varrho \in (0,\infty)$ we define

$$\begin{aligned}&\omega^2 := \frac{\|K_\delta\|_\infty}{\varepsilon} + m_\gamma\ y_0^\sigma\\ &\text{and}\\ &R := \frac{1}{4\,\varepsilon\,y_0}\left(6\ \varepsilon\ \varrho + 5\ \omega^2\ y_0^2\ \varrho + 3\ \|K_\delta\|_\infty\ y_0\ \varrho^2\right).\end{aligned} \tag{2.4}$$

We next introduce

$$F(f) := \varphi_\varepsilon(f)\ L_\delta(f) + \omega^2 f$$

for $f \in L^1_+(Y)$, where

$$\varphi_\varepsilon(f) := \frac{1}{1+\varepsilon\, M_0(f)},$$

and observe that $F(f)$ belongs to $L^1(Y)$. We then denote by u_f the unique solution in $W^{2,1}(Y)$ to the boundary-value problem

$$-\varepsilon\ u_f'' + \omega^2\ u_f = F(f) \quad \text{in} \quad Y, \tag{2.5}$$

$$u_f(0) = y_0\ u_f'(y_0) - u_f(y_0) = 0. \tag{2.6}$$

Finally, let $\mathcal{C}$ be the subset of $L^1(Y)$ defined by

$$\mathcal{C} := \left\{ f \in L^1_+(Y);\ M_1(f) = \varrho,\ M_0(f) \le R \right\}. \tag{2.7}$$

Clearly, $\mathcal{C}$ is a nonempty, bounded, and closed convex subset of $L^1(Y)$. In addition, we have the following property.

LEMMA 2.1. *If $f \in \mathcal{C}$, then $u_f \in \mathcal{C}$.*

Proof. Since $f \ge 0$, it follows from (1.2), (1.6), and (1.16) that

$$\begin{aligned} F(f)(y) &\ge \omega^2\ f(y) - \varphi_\varepsilon(f)\ f(y)\ \left(\int_0^y \frac{y'}{y}\ \gamma(y,y')\ \mathrm{d}y' + \int_0^{y_0} K_\delta(y,y')\ f(y')\ \mathrm{d}y' \right) \\ &\ge \omega^2\ f(y) - \varphi_\varepsilon(f)\ f(y)\ \left(m_\gamma\ y_0^\sigma + \|K_\delta\|_\infty\ M_0(f)\right) \\ &\ge 0. \end{aligned}$$

The comparison principle then entails that $u_f \ge 0$. We next readily infer from (1.10), (1.12), and (2.1)–(2.3) that

$$\int_0^{y_0} y\ F(f)(y)\ \mathrm{d}y = \omega^2\ M_1(f),$$

while (2.6) yields that

$$-\varepsilon \int_0^{y_0} y\ u_f''(y)\ \mathrm{d}y = 0.$$

Consequently, we deduce from (2.5) after multiplication by y and integration over Y the equality $M_1(u_f) = M_1(f)$.

We now multiply (2.5) by y^3 and integrate over Y. Observe first that

$$-\int_0^{y_0} y^3\ u_f''(y)\ \mathrm{d}y = 2\ y_0^2\ u_f(y_0) - 6\ M_1(u_f)$$

by (2.6), while (1.2) and (1.10) entail that, for $(y,y') \in \Xi$, the function $\left(y^3\right)_{\mathsf{c}}$ (defined in (2.2) with $\psi(y) = y^3$) satisfies

$$\begin{aligned} \left(y^3\right)_{\mathsf{c}}(y,y') &= P(y,y')\ \left[y^3 + (y')^3 + 3\ y^2\ y' + 3\ y\ (y')^2 - y^3 - (y')^3\right] \\ &\quad +\ Q(y,y')\ \left[\int_0^{y+y'} (y'')^3\ \beta_{\mathsf{c}}(y+y',y'')\ \mathrm{d}y'' - y^3 - (y')^3\right] \\ &\le 3\ P(y,y')\ y\ y'\ (y+y') + Q(y+y')\ \left[(y+y')^2\ (y+y') - y^3 - (y')^3\right] \\ &\le 3\ (P+Q)(y,y')\ y\ y'\ (y+y') \\ &\le 3\ y\ y'\ (y+y'). \end{aligned}$$

We also infer from (1.12) that, for $(y,y') \in Y \times Y \setminus \Xi$, the function $\left(y^3\right)_{\mathsf{s}}$ (defined in (2.3) with $\psi(y) = y^3$) satisfies

$$\begin{aligned}\left(y^3\right)_{\mathsf{s}}(y,y') &\le y_0^2 \int_0^{y+y'} y''\ \beta_{\mathsf{s}}(y+y',y'')\ \mathrm{d}y'' - y^3 - (y')^3 \\ &\le y_0^2\ (y+y')\ - y^3 - (y')^3 \\ &\le (y+y')^3 - y^3 - (y')^3 \\ &\le 3\ y\ y'\ (y+y').\end{aligned}$$

At last, we notice that, for $(y,y') \in \Delta$,

$$(y')^3 - \frac{y'}{y}\ y^3 = y'\ \left((y')^2 - y^2\right) \le 0.$$

Now, since $f \in \mathcal{C}$, it follows from (2.1) to (2.3) and the previous upper bounds that

$$\begin{aligned}&\int_0^{y_0} y^3\ F(f)(y)\ \mathrm{d}y \\ &\le \omega^2\ M_3(f) + \frac{3}{2}\ \varphi_\varepsilon(f)\ \int_0^{y_0} \int_0^{y_0-y} \left(y^2\ y' + y\ (y')^2\right)\ K_\delta(y,y')\ f(y)\ f(y')\ \mathrm{d}y'\mathrm{d}y \\ &+\ \frac{3}{2}\ \varphi_\varepsilon(f)\ \int_0^{y_0} \int_{y_0-y}^{y_0} \left(y^2\ y' + y\ (y')^2\right)\ K_\delta(y,y')\ f(y)\ f(y')\ \mathrm{d}y'\mathrm{d}y \\ &\le \omega^2\ y_0^2\ M_1(f) + \frac{3\ \|K_\delta\|_\infty}{2}\ \varphi_\varepsilon(f)\ \int_0^{y_0} \int_0^{y_0} \left(y^2\ y' + y\ (y')^2\right)\ f(y)\ f(y')\ \mathrm{d}y'\mathrm{d}y \\ &\le \omega^2\ y_0^2\ \varrho + 3\ \|K_\delta\|_\infty\ \varphi_\varepsilon(f)\ \int_0^{y_0} \int_0^{y_0} y^2\ y'\ f(y)\ f(y')\ \mathrm{d}y'\mathrm{d}y \\ &\le \omega^2\ y_0^2\ \varrho + 3\ \|K_\delta\|_\infty\ y_0\ \varrho^2.\end{aligned}$$

Therefore, we obtain

$$2\ \varepsilon\ y_0^2\ u_f(y_0) \le 6\ \varepsilon\ \varrho + \omega^2\ y_0^2\ \varrho + 3\ \|K_\delta\|_\infty\ y_0\ \varrho^2. \tag{2.8}$$

On the other hand, due to

$$\begin{aligned}&\int_0^{y_0} y^2\ F(f)(y)\ \mathrm{d}y \\ &\ge\ -\varphi_\varepsilon(f)\ \int_0^{y_0} \int_0^{y} y\ y'\ \gamma(y,y')\ \mathrm{d}y'\ f(y)\ \mathrm{d}y \\ &-\frac{\varphi_\varepsilon(f)}{2}\ \int_0^{y_0} \int_0^{y_0-y} (y^2 + y'^2)\ K_\delta(y,y')\ \left\{P(y,y') + Q(y,y')\right\}\ f(y')\ f(y)\ \mathrm{d}y'\mathrm{d}y \\ &-\frac{\varphi_\varepsilon(f)}{2}\ \int_0^{y_0} \int_{y_0-y}^{y_0} (y^2 + y'^2)\ K_\delta(y,y')\ f(y')\ f(y)\ \mathrm{d}y'\mathrm{d}y \\ &\ge\ -m_\gamma\ y_0^{1+\sigma}\ M_1(f) - \varrho\ y_0\ \|K_\delta\|_\infty\ \frac{M_0(f)}{1+\varepsilon\, M_0(f)}\end{aligned}$$

and

$$-\int_0^{y_0} y^2\ u_f''(y)\ \mathrm{d}y\ =\ y_0\ u_f(y_0) - 2\ M_0(u_f),$$

we deduce from (2.5) that

$$\varepsilon\ y_0\ u_f(y_0) - 2\ \varepsilon\ M_0(u_f) + \omega^2\ M_2(u_f) \geq -m_\gamma\ y_0^{1+\sigma}\ \varrho - \varrho\ y_0\ \frac{\|K_\delta\|_\infty}{\varepsilon}.$$

Consequently, taking into account (2.8) and the definition of ω, we end up with

$$2\ \varepsilon\ M_0(u_f) \leq \varepsilon\ y_0\ u_f(y_0) + \omega^2\ y_0\ M_1(u_f) + m_\gamma\ y_0^{1+\sigma}\ \varrho + \varrho\ y_0\ \frac{\|K_\delta\|_\infty}{\varepsilon} \leq 2\ \varepsilon\ R,$$

and the proof is complete. ∎

PROPOSITION 2.2. *There is a function $f \in \mathcal{C} \cap W^{2,1}(Y)$ such that*

$$-\varepsilon\ f'' = \varphi_\varepsilon(f)\ L_\delta(f) \quad \text{in} \quad Y, \tag{2.9}$$

$$f(0) = y_0\ f'(y_0) - f(y_0) = 0. \tag{2.10}$$

Proof. By Lemma 2.1, the mapping $f \longmapsto u_f$ maps $\mathcal{C}$ into itself. In addition, it is clearly a continuous and compact mapping from $\mathcal{C}$ into itself for the norm-topology of $L^1(Y)$. Indeed, we recall that, for $f \in L^1(Y)$, u_f is given by

$$u_f(y) = \left(\lambda - \int_0^y e^{-\bar\omega y'}\ F(f)(y')\ \mathrm{d}y'\right)\ \frac{e^{\bar\omega y}}{2\,\varepsilon\,\bar\omega}\ -\ \left(\lambda - \int_0^y e^{\bar\omega y'}\ F(f)(y')\ \mathrm{d}y'\right)\ \frac{e^{-\bar\omega y}}{2\,\varepsilon\,\bar\omega}$$

for $y \in [0, y_0]$, where $\bar\omega := \omega\ \varepsilon^{-1/2}$ and

$$\lambda := \vartheta\ \int_0^{y_0} e^{-\bar\omega y'}\ F(f)(y')\ \mathrm{d}y'\ +\ (1-\vartheta)\ \int_0^{y_0} e^{\bar\omega y'}\ F(f)(y')\ \mathrm{d}y'$$

with

$$\vartheta := \frac{y_0\ \bar\omega - 1}{y_0\ \bar\omega - 1 + (y_0\ \bar\omega + 1)\ e^{-2\bar\omega y_0}}.$$

In particular, there is a constant Γ depending on y_0 and ε such that

$$\|u_f\|_{W^{1,\infty}(Y)} \leq \Gamma\ \|F(f)\|_{L^1(Y)}.$$

Since F is a locally Lipschitz continuous map from $L^1(Y)$ into $L^1(Y)$ (see [14, Lemma 2.1]), the claimed continuity and compactness of $f \longmapsto u_f$ follow.

Now, since $\mathcal{C}$ is a nonempty, closed, and convex subset of $L^1(Y)$, we are in a position to apply the Schauder fixed point theorem and conclude that there is $f \in \mathcal{C}$ such that $u_f = f$. Proposition 2.2 readily follows. ∎

3. A regularized problem: Uniform estimates. For $\delta \in (0,1)$, $\varepsilon \in (0,\delta)$, and $\varrho > 0$, we denote by $f_{\varepsilon,\delta}$ the solution to (2.9), (2.10) given by Proposition 2.2. In particular, we have

$$\int_0^{y_0} y\ f_{\varepsilon,\delta}(y)\ \mathrm{d}y = \varrho. \tag{3.1}$$

The aim of this section is to prove that $(f_{\varepsilon,\delta})$ is weakly sequentially compact first with respect to ε and subsequently with respect to δ. In the following, we denote by C various positive constants which do neither depend on ε nor on δ. Dependence on δ, for instance, will be indicated explicitly by writing $C(\delta)$.

We first proceed as in Lemma 2.1 to bound $f_{\varepsilon,\delta}(y_0)$.

LEMMA 3.1. *For $\delta \in (0,1)$ and $\varepsilon \in (0,\delta)$, we have*

$$f'_{\varepsilon,\delta}(0) \geq 0 \quad \text{and} \quad \varepsilon\, f_{\varepsilon,\delta}(y_0) \leq C.$$

Proof. Clearly, $f'_{\varepsilon,\delta}(0) \geq 0$ since $f_{\varepsilon,\delta}(0) = 0$ and $f_{\varepsilon,\delta}(y) \geq 0$ for $y \in Y$. We next multiply (2.9) by y^3 and integrate over Y. As in the proof of Lemma 2.1, we use (2.10) and (3.1) to obtain

$$\varepsilon \left(2\ y_0^2\ f_{\varepsilon,\delta}(y_0) - 6\ \varrho\right) \leq 3\ \|K_\delta\|_\infty\ y_0\ \varrho^2 \leq 3\ (\|K\|_\infty + 1)\ y_0\ \varrho^2. \qquad \square$$

We next estimate the L^1-norm of $f_{\varepsilon,\delta}$ using a different argument than in the previous section.

LEMMA 3.2. *For $\delta \in (0,1)$ and $\varepsilon \in (0,\delta)$, we have*

$$\delta^{1/2}\ M_0(f_{\varepsilon,\delta}) + M_\sigma(f_{\varepsilon,\delta}) \leq C. \tag{3.2}$$

Proof. We integrate (2.9) over Y. We first notice that

$$-\varepsilon \int_0^{y_0} f''_{\varepsilon,\delta}(y)\ \mathrm{d}y \ = \ -\varepsilon\ \left(f'_{\varepsilon,\delta}(y_0) - f'_{\varepsilon,\delta}(0)\right) \geq -\varepsilon\ \frac{f_{\varepsilon,\delta}(y_0)}{y_0} \geq -C$$

by (2.10) and Lemma 3.1, while the function $(1)_{\mathsf{c}}$ (defined in (2.2) with $\psi(y) = 1$) satisfies

$$\begin{aligned}
(1)_{\mathsf{c}}(y,y') &= P(y,y') - 2\ (P+Q)(y,y') + Q(y,y') \int_0^{y+y'} \beta_{\mathsf{c}}(y+y',y'')\ \mathrm{d}y'' \\
&\leq -\kappa_0\ \mathbf{1}_{[0,z_0]}(y+y') + Q(y,y') \int_0^{y+y'} \beta_{\mathsf{c}}(y+y',y'')\ \mathrm{d}y''\ \mathbf{1}_{[z_0,y_0]}(y+y') \\
&\leq -\kappa_0\ \mathbf{1}_{[0,z_0]}(y+y') + m_{\mathsf{c}}\ \mathbf{1}_{[z_0,y_0]}(y+y')
\end{aligned}$$

for $(y,y') \in \Xi$ by (1.11) and (1.17), since P and Q are nonnegative. Moreover, the function $(1)_{\mathsf{s}}$ (defined in (2.3) with $\psi(y) = 1$) satisfies

$$(1)_{\mathsf{s}}(y,y') = \int_0^{y_0} \beta_{\mathsf{s}}(y+y',y'')\ \mathrm{d}y'' - 2 \leq m_{\mathsf{s}} - 2$$

for $(y,y') \in Y \times Y \setminus \Xi$ by (1.18). Because of the above inequalities, we deduce from (1.16), (2.1)–(2.3), and (2.9) that

$$\begin{aligned}
-\frac{C}{\varphi_\varepsilon(f_{\varepsilon,\delta})} &\leq -\frac{\varepsilon}{\varphi_\varepsilon(f_{\varepsilon,\delta})} \int_0^{y_0} f''_{\varepsilon,\delta}(y)\ \mathrm{d}y \\
&\leq \int_0^{y_0} \int_0^y \left(1 - \frac{y'}{y}\right)\ \gamma(y,y')\ \mathrm{d}y'\ f_{\varepsilon,\delta}(y')\ \mathrm{d}y \\
&\quad - \frac{\kappa_0}{2} \int_0^{y_0} \int_0^{y_0-y} \mathbf{1}_{[0,z_0]}(y+y')\ K_\delta(y,y')\ f_{\varepsilon,\delta}(y')\ f_{\varepsilon,\delta}(y)\ \mathrm{d}y'\mathrm{d}y \\
&\quad + \frac{1}{2}\ m_{\mathsf{c}} \int_0^{y_0} \int_0^{y_0-y} \mathbf{1}_{[z_0,y_0]}(y+y')\ K_\delta(y,y')\ f_{\varepsilon,\delta}(y')\ f_{\varepsilon,\delta}(y)\ \mathrm{d}y'\mathrm{d}y \\
&\quad + \frac{1}{2}\ (m_{\mathsf{s}} - 2) \int_0^{y_0} \int_{y_0-y}^{y_0} K_\delta(y,y')\ f_{\varepsilon,\delta}(y')\ f_{\varepsilon,\delta}(y)\ \mathrm{d}y'\mathrm{d}y \\
&\leq m_\gamma\ M_\sigma(f_{\varepsilon,\delta}) - \frac{\kappa_0}{2} \int_0^{y_0} \int_0^{y_0} K_\delta(y,y')\ f_{\varepsilon,\delta}(y')\ f_{\varepsilon,\delta}(y)\ \mathrm{d}y'\mathrm{d}y \\
&\quad + C \int_0^{y_0} \int_0^{y_0} \mathbf{1}_{[z_0,y_0]}(y+y')\ K_\delta(y,y')\ f_{\varepsilon,\delta}(y')\ f_{\varepsilon,\delta}(y)\ \mathrm{d}y'\mathrm{d}y.
\end{aligned}$$

Owing to (1.6) and the definition of K_δ, we have

$$\mathbf{1}_{[z_0,y_0]}(y+y')\ K_\delta(y,y') \le \frac{y+y'}{z_0}\ \big(K^\star(yy')^\sigma+\delta\big), \quad (y,y')\in Y\times Y,$$

and thus, thanks to (3.1),

$$\begin{aligned}
-\frac{C}{\varphi_\varepsilon(f_{\varepsilon,\delta})} &\le m_\gamma\ M_\sigma(f_{\varepsilon,\delta}) - \frac{\kappa_0}{2}\ \big(K_\star\ M_\sigma(f_{\varepsilon,\delta})^2 + \delta\ M_0(f_{\varepsilon,\delta})^2\big) \\
&\quad + C\int_0^{y_0}\int_0^{y_0} y\ \left(K^\star\ (y\ y')^\sigma+\delta\right)\ f_{\varepsilon,\delta}(y')\ f_{\varepsilon,\delta}(y)\ \mathrm{d}y'\mathrm{d}y \\
&\le m_\gamma\ M_\sigma(f_{\varepsilon,\delta}) - \frac{\kappa_0}{2}\ \big(K_\star\ M_\sigma(f_{\varepsilon,\delta})^2 + \delta\ M_0(f_{\varepsilon,\delta})^2\big) \\
&\quad + C\ \left(K^\star\ \varrho\ y_0^\sigma\ M_\sigma(f_{\varepsilon,\delta}) + \varrho\ \delta\ M_0(f_{\varepsilon,\delta})\right) \\
&\le C - \frac{\kappa_0}{4}\ \big(K_\star\ M_\sigma(f_{\varepsilon,\delta})^2 + \delta\ M_0(f_{\varepsilon,\delta})^2\big)
\end{aligned}$$

by the Young inequality. Since $\varepsilon\le\delta$, a further application of the Young inequality entails that

$$K_\star\ M_\sigma(f_{\varepsilon,\delta})^2 + \delta\ M_0(f_{\varepsilon,\delta})^2 \le C\ \left(1+\delta\ M_0(f_{\varepsilon,\delta})\right) \le C + \frac{\delta}{2}\ M_0(f_{\varepsilon,\delta})^2,$$

whence (3.2). □

We next turn to the cornerstone of the proof, that is, the weak compactness of $(f_{\varepsilon,\delta})$ with respect to ε. More precisely, the following result is true.

Lemma 3.3. *For $\delta\in(0,1)$ and $\varepsilon\in(0,\delta)$, we have*

$$\int_0^{y_0} \big(f_{\varepsilon,\delta}(y)\big)^p\ \mathrm{d}y\ \le\ C(\delta). \tag{3.3}$$

Proof. Owing to (2.10) and the Hölder inequality, we first notice that

$$\begin{aligned}
\big(f_{\varepsilon,\delta}(y_0)\big)^{(1+p)/2} &= \int_0^{y_0} \frac{\mathrm{d}}{\mathrm{d}y}\,[f_{\varepsilon,\delta}(y)]^{(1+p)/2}\ \mathrm{d}y \\
&= \frac{1+p}{2}\ \int_0^{y_0} \big(f_{\varepsilon,\delta}(y)\big)^{1/2}\ \big(f_{\varepsilon,\delta}(y)\big)^{(p-2)/2}\ f'_{\varepsilon,\delta}(y)\ \mathrm{d}y \\
&\le \frac{1+p}{2}\ M_0(f_{\varepsilon,\delta})^{1/2}\ \left(\int_0^{y_0} \big(f_{\varepsilon,\delta}(y)\big)^{p-2}\ |f'_{\varepsilon,\delta}(y)|^2\ \mathrm{d}y\right)^{1/2}
\end{aligned}$$

and therefore

$$C(\delta)\ \big(f_{\varepsilon,\delta}(y_0)\big)^{1+p} \le \int_0^{y_0} \big(f_{\varepsilon,\delta}(y)\big)^{p-2}\ |f'_{\varepsilon,\delta}(y)|^2\ \mathrm{d}y \tag{3.4}$$

by Lemma 3.2. We now multiply (2.9) by $p\,(f_{\varepsilon,\delta}(y))^{p-1}$ and integrate over Y. From (2.10) and (3.4), we infer that

$$\begin{aligned}
-\varepsilon\ p\ \int_0^{y_0} \big(f_{\varepsilon,\delta}(y)\big)^{p-1}\ f''_{\varepsilon,\delta}(y)\ \mathrm{d}y &= -\ \varepsilon\ p\ \big(f_{\varepsilon,\delta}(y_0)\big)^{p-1}\ f'_{\varepsilon,\delta}(y_0) \\
&\quad + \varepsilon\ p\ (p-1)\ \int_0^{y_0} \big(f_{\varepsilon,\delta}(y)\big)^{p-2}\ |f'_{\varepsilon,\delta}(y)|^2\ \mathrm{d}y \\
&\ge -\ \frac{\varepsilon\,p}{y_0}\ \big(f_{\varepsilon,\delta}(y_0)\big)^p + \varepsilon\ p\ (p-1)C(\delta)\big(f_{\varepsilon,\delta}(y_0)\big)^{p+1}.
\end{aligned} \tag{3.5}$$

Since

$$r^p \le \frac{p}{p+1}\ \xi\ r^{p+1} + \frac{1}{p+1}\ \xi^{-p}$$

for $r \ge 0$ and $\xi \in (0,\infty)$ by the Young inequality, we use this inequality with $r = f_{\varepsilon,\delta}(y_0)$ and $\xi = (p^2-1)\ y_0\ C(\delta)/p$ to bound from below the right-hand side of (3.5) and obtain that

$$-\varepsilon\ p \int_0^{y_0} \big(f_{\varepsilon,\delta}(y)\big)^{p-1}\ f''_{\varepsilon,\delta}(y)\ \mathrm{d}y \ge -\frac{\varepsilon\ p\ \xi^{-p}}{(p+1)\ y_0} \ge -\varepsilon\ C(\delta).$$

Consequently,

$$\begin{aligned} -\ C(\delta)\ &\le\ -\ \varepsilon\ C(\delta)\ \le\ -\ \varepsilon\ p \int_0^{y_0} \big(f_{\varepsilon,\delta}(y)\big)^{p-1}\ f''_{\varepsilon,\delta}(y)\ \mathrm{d}y \\ -\ C(\delta)\ &\le\ \varphi_\varepsilon(f_{\varepsilon,\delta})\ \left(I_1+I_2+I_3+I_4-I_5-I_6\right), \end{aligned} \tag{3.6}$$

where we put

$$\begin{aligned} I_1 &:= \frac{p}{2} \int_0^{y_0}\int_{y_0}^{2y_0}\int_{y'-y_0}^{y_0} K_\delta(y'',y'-y'')\ \beta_{\mathsf{s}}(y',y) \\ &\qquad\qquad \times\ f_{\varepsilon,\delta}(y'-y'')\ f_{\varepsilon,\delta}(y'')\ \big(f_{\varepsilon,\delta}(y)\big)^{p-1}\ \mathrm{d}y''\mathrm{d}y'\mathrm{d}y, \\ I_2 &:= \frac{p}{2} \int_0^{y_0}\int_{y}^{y_0}\int_0^{y'} \beta_{\mathsf{c}}(y',y)\ K_\delta(y'',y'-y'')\ Q(y'',y'-y'') \\ &\qquad\qquad \times\ f_{\varepsilon,\delta}(y'-y'')\ f_{\varepsilon,\delta}(y'')\ \big(f_{\varepsilon,\delta}(y)\big)^{p-1}\ \mathrm{d}y''\mathrm{d}y'\mathrm{d}y, \\ I_3 &:= p \int_0^{y_0}\int_y^{y_0} \gamma(y',y)\ f_{\varepsilon,\delta}(y')\ \big(f_{\varepsilon,\delta}(y)\big)^{p-1}\ \mathrm{d}y'\mathrm{d}y, \\ I_4 &:= \frac{p}{2} \int_0^{y_0}\int_0^{y} K_\delta(y',y-y')\ P(y',y-y')\ f_{\varepsilon,\delta}(y-y')\ f_{\varepsilon,\delta}(y')\ (f_{\varepsilon,\delta}(y))^{p-1}\ \mathrm{d}y'\mathrm{d}y, \\ I_5 &:= p \int_0^{y_0}\int_0^{y_0-y} K_\delta(y,y')\ \big\{P(y,y')+Q(y,y')\big\}\ f_{\varepsilon,\delta}(y')\ (f_{\varepsilon,\delta}(y))^p\ \mathrm{d}y'\mathrm{d}y, \\ I_6 &:= p \int_0^{y_0}\int_{y_0-y}^{y_0} K_\delta(y,y')\ f_{\varepsilon,\delta}(y')\ (f_{\varepsilon,\delta}(y))^p\ \mathrm{d}y'\mathrm{d}y. \end{aligned}$$

Observe then that (1.15) and the Young inequality imply that, for $\xi \in (0,1)$, there is a constant $C_\xi > 0$ such that

$$\int_0^{y_0} \beta_{\mathsf{s}}(y',y)\ p\ f_{\varepsilon,\delta}(y)^{p-1}\ \mathrm{d}y\ \le\ C_\xi\ \mu_{\mathsf{s}} + \xi \int_0^{y_0} y^\sigma \big(f_{\varepsilon,\delta}(y)\big)^p\ \mathrm{d}y\ =\ C_\xi\ \mu_{\mathsf{s}} + \xi\ M_{\sigma,p}\big(f_{\varepsilon,\delta}\big).$$

Therefore, (1.6) and Lemma 3.2 entail that

$$\begin{aligned} I_1 &= \frac{1}{2}\int_{y_0}^{2y_0}\int_{y'-y_0}^{y_0}\int_0^{y_0} \beta_{\mathsf{s}}(y',y)\ p\ \big(f_{\varepsilon,\delta}(y)\big)^{p-1}\ \mathrm{d}y \\ &\qquad\qquad \times\ K_\delta(y'',y'-y'')\ f_{\varepsilon,\delta}(y'-y'')\ f_{\varepsilon,\delta}(y'')\ \mathrm{d}y''\mathrm{d}y' \\ &\le \big(C_\xi\ \mu_{\mathsf{s}} + \xi\ M_{\sigma,p}\big(f_{\varepsilon,\delta}\big)\big) \int_0^{y_0}\int_{y_0-y'}^{y_0} K_\delta(y'',y')\ f_{\varepsilon,\delta}(y')\ f_{\varepsilon,\delta}(y'')\ \mathrm{d}y''\mathrm{d}y' \\ &\le \big(C_\xi\ \mu_{\mathsf{s}} + \xi\ M_{\sigma,p}\big(f_{\varepsilon,\delta}\big)\big) \left(K^\star\ M_\sigma(f_{\varepsilon,\delta})^2 + \frac{2}{y_0}\ \varrho\ \delta\ M_0(f_{\varepsilon,\delta})\right), \end{aligned}$$

$$I_1 \;\le\; C\;\left(C_\xi + \xi\; M_{\sigma,p}\big(f_{\varepsilon,\delta}\big)\right). \tag{3.7}$$

We estimate I_2 analogously and thus obtain from (1.2), (1.6), (1.14), and Lemma 3.2 that, for $\xi \in (0,1)$,

$$\begin{aligned} I_2 &= \frac{1}{2}\;\int_0^{y_0}\int_0^{y'}\int_0^{y'} \beta_{\mathsf{c}}(y',y)\; p\;\left(f_{\varepsilon,\delta}(y)\right)^{p-1}\;\mathrm{d}y\; Q(y'',y'-y'') \\ &\qquad\qquad\qquad\qquad \times\; K_\delta(y'',y'-y'')\; f_{\varepsilon,\delta}(y'-y'')\; f_{\varepsilon,\delta}(y'')\;\mathrm{d}y''\mathrm{d}y' \\ &\le \left(C_\xi\;\mu_{\mathsf{c}} + \xi\; M_{\sigma,p}\big(f_{\varepsilon,\delta}\big)\right)\;\int_0^{y_0}\int_0^{y_0-y} K_\delta(y,y')\; f_{\varepsilon,\delta}(y)\; f_{\varepsilon,\delta}(y')\;\mathrm{d}y'\mathrm{d}y \\ &\le \left(C_\xi\;\mu_{\mathsf{c}} + \xi\; M_{\sigma,p}\big(f_{\varepsilon,\delta}\big)\right)\;\left(K^\star\; M_\sigma(f_{\varepsilon,\delta})^2 + \delta\; M_0(f_{\varepsilon,\delta})^2\right) \end{aligned}$$

$$I_2 \;\le\; C\;\left(C_\xi\; + \xi\; M_{\sigma,p}\big(f_{\varepsilon,\delta}\big)\right). \tag{3.8}$$

In a similar way, the Young inequality and (1.13) yield

$$\begin{aligned} I_3 &= \int_0^{y_0} f_{\varepsilon,\delta}(y')\;\int_0^{y'} \gamma(y',y)\; p\;\left(f_{\varepsilon,\delta}(y)\right)^{p-1}\;\mathrm{d}y\,\mathrm{d}y' \\ &\le \int_0^{y_0} y'^{\sigma}\; f_{\varepsilon,\delta}(y')\;\int_0^{y'} p\; y^{-\sigma}\;\gamma(y',y)\;\left(f_{\varepsilon,\delta}(y)\right)^{p-1}\;\mathrm{d}y\,\mathrm{d}y' \\ &\le \int_0^{y_0} y'^{\sigma}\; f_{\varepsilon,\delta}(y')\;\int_0^{y'} p\; y^{\sigma(1-2p)/p}\;\gamma(y',y)\;\left(y^{\sigma/p} f_{\varepsilon,\delta}(y)\right)^{p-1}\;\mathrm{d}y\,\mathrm{d}y' \\ &\le \int_0^{y_0} y'^{\sigma}\; f_{\varepsilon,\delta}(y')\;\left(C_\xi\;\mu_\gamma + \xi\; M_{\sigma,p}\big(f_{\varepsilon,\delta}\big)\right)\;\mathrm{d}y', \end{aligned}$$

whence, by Lemma 3.2,

$$I_3 \;\le\; C\;\left(C_\xi + \xi\; M_{\sigma,p}\big(f_{\varepsilon,\delta}\big)\right)\; M_\sigma(f_{\varepsilon,\delta}) \;\le\; C\;\left(C_\xi + \xi\; M_{\sigma,p}\big(f_{\varepsilon,\delta}\big)\right). \tag{3.9}$$

We now estimate $I_4 - I_5 - I_6$. For that purpose, observe first that, by the Young inequality,

$$\begin{aligned} I_4 &= \frac{1}{2}\;\int_0^{y_0}\int_0^{y} K_\delta(y',y-y')\; P(y',y-y')\; f_{\varepsilon,\delta}(y-y')\; f_{\varepsilon,\delta}(y')\; p\;\left(f_{\varepsilon,\delta}(y)\right)^{p-1}\mathrm{d}y'\mathrm{d}y \\ &\le \frac{1}{2}\;\int_0^{y_0}\int_0^{y_0-y'} K_\delta(y',y)\; P(y',y)\; f_{\varepsilon,\delta}(y)\;\left(f_{\varepsilon,\delta}(y')\right)^{p}\;\mathrm{d}y\;\mathrm{d}y' \\ &\quad + \frac{1}{2}\;(p-1)\;\int_0^{y_0}\int_0^{y} K_\delta(y-y',y')\; P(y-y',y')\; f_{\varepsilon,\delta}(y')\;\left(f_{\varepsilon,\delta}(y)\right)^{p}\;\mathrm{d}y'\,\mathrm{d}y. \end{aligned}$$

Therefore, we derive that

$$\begin{aligned} I_4 - I_5 - I_6 \le{}& \frac{1}{2}\;\int_0^{y_0}\int_0^{y_0-y} K_\delta(y,y')\; P(y,y')\; f_{\varepsilon,\delta}(y')\;\left(f_{\varepsilon,\delta}(y)\right)^{p}\;\mathrm{d}y'\mathrm{d}y \\ &+ \frac{1}{2}\;(p{-}1)\int_0^{y_0}\int_0^{y} K_\delta(y-y',y')\; P(y-y',y')\; f_{\varepsilon,\delta}(y')\big(f_{\varepsilon,\delta}(y)\big)^{p}\mathrm{d}y'\mathrm{d}y \\ &- p\;\int_0^{y_0}\int_0^{y_0-y} K_\delta(y,y')\;(P+Q)(y,y')\; f_{\varepsilon,\delta}(y')\;\left(f_{\varepsilon,\delta}(y)\right)^{p}\;\mathrm{d}y'\mathrm{d}y \end{aligned}$$

$$\begin{aligned}
& - p \int_0^{y_0} \int_{y_0-y}^{y_0} K_\delta(y,y')\ f_{\varepsilon,\delta}(y')\ \big(f_{\varepsilon,\delta}(y)\big)^p\ \mathrm{d}y'\mathrm{d}y \\
\le & -\frac{1}{2}\ p \int_0^{y_0} \int_0^{y_0-y} K_\delta(y,y')\ (P+2\ Q)(y,y')\ f_{\varepsilon,\delta}(y')\ \big(f_{\varepsilon,\delta}(y)\big)^p\ \mathrm{d}y'\mathrm{d}y \\
& -\frac{1}{2}\ (p+1) \int_0^{y_0} \int_{y_0-y}^{y_0} K_\delta(y,y')\ f_{\varepsilon,\delta}(y')\ \big(f_{\varepsilon,\delta}(y)\big)^p\ \mathrm{d}y'\mathrm{d}y \\
\le & -\frac{1}{2}\ p\ P_\star \int_0^{y_0} \int_0^{y_0} K_\delta(y,y')\ f_{\varepsilon,\delta}(y')\ \big(f_{\varepsilon,\delta}(y)\big)^p\ \mathrm{d}y'\mathrm{d}y,
\end{aligned}$$

where we have used the monotonicity conditions (1.7) and (1.9) to obtain the second inequality and (1.8) for the last inequality (recall that $P_\star \le 1$). Since $\varrho = M_1(f_{\varepsilon,\delta}) \le y_0\, M_0(f_{\varepsilon,\delta})$ and $\varrho = M_1(f_{\varepsilon,\delta}) \le y_0^{1-\sigma}\ M_\sigma(f_{\varepsilon,\delta})$, we deduce from (1.6) that

$$I_4 - I_5 - I_6 \le -\ \frac{1}{2}\ p\ P_\star\ \left(K_\star\ M_\sigma\big(f_{\varepsilon,\delta}\big)\ M_{\sigma,p}\big(f_{\varepsilon,\delta}\big) + \delta\ M_0\big(f_{\varepsilon,\delta}\big)\ M_{0,p}\big(f_{\varepsilon,\delta}\big)\right),$$

$$I_4 - I_5 - I_6 \le -\ \frac{1}{2}\ p\ \varrho\ P_\star\ \left(K_\star\ y_0^{\sigma-1}\ M_{\sigma,p}\big(f_{\varepsilon,\delta}\big) + \delta\ y_0^{-1}\ M_{0,p}\big(f_{\varepsilon,\delta}\big)\right). \tag{3.10}$$

Gathering (3.6)–(3.10) we end up with

$$-\frac{C(\delta)}{\varphi_\varepsilon(f_{\varepsilon,\delta})}\ \le\ C\ \left(C_\xi + \xi\ M_{\sigma,p}\big(f_{\varepsilon,\delta}\big)\right)\ -\ \frac{1}{2\,y_0}\ p\ P_\star\ \varrho\ \delta\ M_{0,p}\big(f_{\varepsilon,\delta}\big).$$

Then choosing $\xi \in (0,1)$ sufficiently small and noticing that $(\varphi_\varepsilon(f_{\varepsilon,\delta}))^{-1} \le (1 + \delta\, M_0(f_{\varepsilon,\delta})) \le C$ due to $\varepsilon \in (0,\delta)$ and Lemma 3.2, the assertion follows since $M_{\sigma,p}(f_{\varepsilon,\delta}) \le y_0^\sigma\ M_{0,p}(f_{\varepsilon,\delta})$. ∎

The fact that the monotonicity condition (1.7) on the coagulation kernel K yields L^p-estimates has already been used in [9] for the classical coagulation equation (see also [11] and the references therein). In addition, the weak compactness in $L^1(Y)$ of the trajectories of (1.1) established in [15] relies on a similar observation. We adapt here this strategy to estimate $I_4 - I_5 - I_6$ under more general assumptions than the one used in [15].

Now the proof of Theorem 1.1 is a consequence of the previous considerations.

Proof of Theorem 1.1. Keeping $\delta \in (0,1)$ fixed, the set $\{f_{\varepsilon,\delta};\, \varepsilon \in (0,\delta)\}$ is bounded in $L^p(Y)$ according to Lemma 3.3. Therefore, there are a sequence $(f_{\varepsilon_n,\delta})$ and $f_\delta \in L^p(Y)$ such that

$$f_{\varepsilon_n,\delta} \rightharpoonup f_\delta \quad \text{in} \quad L^p(Y) \quad \text{as} \quad \varepsilon_n \to 0. \tag{3.11}$$

Since $f_{\varepsilon_n,\delta}$ is nonnegative and satisfies $M_1(f_{\varepsilon_n,\delta}) = \varrho$ by (3.1) for each $n \ge 1$, it readily follows from (3.11) that

$$f_\delta \ge 0 \quad \text{a.e. in} \quad Y \quad \text{and} \quad M_1(f_\delta) = \varrho. \tag{3.12}$$

We then claim that $L_\delta(f_\delta) = 0$. Indeed, on the one hand, it is well known that L_δ is weakly continuous in $L^1(Y)$ (see either the pioneering work [13] or [15, Appendix A] for a complete proof), and the convergence (3.11) ensures that $L_\delta(f_{\varepsilon_n,\delta}) \rightharpoonup L_\delta(f_\delta)$ in $L^1(Y)$. On the other hand, by (3.2), $(-\varepsilon_n\, f''_{\varepsilon_n,\delta})$ converges to zero in $\mathcal{D}'(Y)$. Consequently,

$$\int_0^{y_0} L_\delta(f_\delta)(y)\ \psi(y)\ \mathrm{d}y = 0 \qquad \text{for each} \quad \psi \in C_0^\infty(Y), \tag{3.13}$$

whence,

$$L_\delta(f_\delta) = 0 \quad \text{a.e. in } Y. \tag{3.14}$$

We may now test (3.14) with $p\,\left(f_\delta\right)^{p-1}$ and obtain

$$0 \;=\; p \int_0^{y_0} \left(f_\delta(y)\right)^{p-1}\, L_\delta(f_\delta)(y)\, \mathrm{d}y \;\le\; I_1 + I_2 + I_3 + I_4 - I_5 - I_6, \tag{3.15}$$

where the I_k's are defined as in the proof of Lemma 3.3 but with $f_{\varepsilon,\delta}$ replaced by f_δ. Since (3.2) and (3.11) imply that

$$\delta^{1/2}\, M_0(f_\delta) \le C \quad \text{and} \quad M_\sigma(f_\delta) \le C, \tag{3.16}$$

we can proceed as in the proof of (3.7), (3.8), (3.9), and (3.10) in Lemma 3.3 to deduce that, for $\xi \in (0,1)$,

$$I_1 + I_2 + I_3 \;\le\; C\; \left(C_\xi + \xi\; M_{\sigma,p}(f_\delta)\right) \tag{3.17}$$

and

$$I_4 - I_5 - I_6 \;\le\; -\,\frac{1}{2}\; p\; \varrho\; P_\star\; K_\star\; y_0^{\sigma-1}\; M_{\sigma,p}\big(f_\delta\big). \tag{3.18}$$

Combining (3.15), (3.17), and (3.18) and choosing $\xi \in (0,1)$ sufficiently small, we finally obtain that

$$\int_0^{y_0} y^\sigma \left(f_\delta(y)\right)^p\, \mathrm{d}y \;\le C.$$

Therefore, we may extract a subsequence (f_{δ_n}) and find $f \in L^p(Y, y^\sigma\,\mathrm{d}y)$ such that

$$f_{\delta_n} \rightharpoonup f \quad \text{in} \quad L^p(Y, y^\sigma\,\mathrm{d}y) \quad \text{as} \quad \delta_n \to 0. \tag{3.19}$$

Clearly,

$$f \ge 0 \qquad \text{and} \qquad M_1(f) = \varrho \tag{3.20}$$

owing to (3.12) and $\sigma \le 1$. In particular, $f \not\equiv 0$ since $\varrho > 0$.

It therefore remains to prove that $L(f) = 0$ a.e. in Y. For that purpose, we observe that (3.14) also reads as

$$L(f_\delta) = L(f_\delta) - L_\delta(f_\delta) \quad \text{a.e. in} \quad Y. \tag{3.21}$$

On the one hand, we have $L(f_\delta) = \tilde{L}(g_\delta)$, where $g_\delta(y) := y^\sigma\; f_\delta(y)$, $y \in Y$, and $\tilde{L}$ is defined as L with $\tilde{\gamma}(y,y') := y^{-\sigma}\; \gamma(y,y')$ and $\tilde{K}(y,y') := (y\,y')^{-\sigma}\; K(y,y')$ instead of γ and K. Owing to (1.6) and (1.16), $\tilde{L}$ is weakly continuous in $L^1(Y)$ (see, e.g., [13, 15]). We then deduce from this property and the convergence (3.19) that

$$L(f_{\delta_n}) = \tilde{L}(g_{\delta_n}) \rightharpoonup \tilde{L}(g) = L(f) \quad \text{in} \quad L^1(Y) \tag{3.22}$$

with $g(y) := y^\sigma\; f(y)$, $y \in Y$.

On the other hand, let ψ be an arbitrary function in $C_0^\infty(Y)$ and choose $a > 0$ such that the support of ψ is contained in $[a, y_0 - a]$. Then, $\psi(y) \le (\|\psi\|_\infty\; y)/a$. This fact, together with (1.2), (1.10), and (1.12) allow us to deduce that the functions ψ_{c} and ψ_{s} defined in (2.2) and (2.3), respectively, satisfy

$$\begin{aligned}
|\psi_{\mathsf{c}}(y,y')| &\le |\psi(y+y')| + |\psi(y)| + |\psi(y')| \\
&\qquad + \frac{\|\psi\|_\infty\ Q(y,y')}{a}\ \int_0^{y+y'} y''\ \beta_{\mathsf{c}}(y+y',y'')\ \mathrm{d}y'' \\
&\le \frac{3\ \|\psi\|_\infty}{a}\ (y+y'), \\
|\psi_{\mathsf{s}}(y,y')| &\le \frac{\|\psi\|_\infty}{a}\ \int_0^{y_0} y''\ \beta_{\mathsf{s}}(y+y',y'')\ \mathrm{d}y'' + |\psi(y)| + |\psi(y')| \le \frac{2\ \|\psi\|_\infty}{a}\ (y+y').
\end{aligned}$$

We then infer from (2.2), (2.3), (3.12), and (3.16) that

$$\begin{aligned}
\left|\int_0^{y_0} \psi(y)\ (L(f_\delta) - L_\delta(f_\delta))(y)\ \mathrm{d}y\right| &\le \frac{\delta}{2}\ \int_0^{y_0}\int_0^{y_0-y} |\psi_{\mathsf{c}}(y,y')|\ f_\delta(y)\ f_\delta(y')\ \mathrm{d}y'\mathrm{d}y \\
&\quad + \frac{\delta}{2}\ \int_0^{y_0}\int_{y_0-y}^{y_0} |\psi_{\mathsf{s}}(y,y')|\ f_\delta(y)\ f_\delta(y')\ \mathrm{d}y'\mathrm{d}y \\
&\le \frac{5\ \|\psi\|_\infty\ \delta}{a}\ \int_0^{y_0}\int_0^{y_0} y\ f_\delta(y)\ f_\delta(y')\ \mathrm{d}y'\mathrm{d}y \\
&\le \frac{5\ \varrho\ \|\psi\|_\infty\ \delta^{1/2}}{a}\ \left(\delta^{1/2}\ M_0(f_\delta)\right) \\
&\le \frac{C\ \|\psi\|_\infty}{a}\ \delta^{1/2}.
\end{aligned}$$

Letting $\delta \to 0$ then implies that

$$L(f_\delta) - L_\delta(f_\delta) \to 0 \quad \text{in} \quad \mathcal{D}'(Y) \tag{3.23}$$

as $\delta \to 0$. As a consequence of (3.22) and (3.23), we may pass to the limit as $\delta_n \to 0$ in (3.21) and conclude that $L(f) = 0$ in $\mathcal{D}'(Y)$. Since $L(f)$ actually belongs to $L^1(Y)$, we conclude that $L(f) = 0$ a.e. in Y, which completes the proof of Theorem 1.1. ∎

4. Nonexistence of nonzero solutions. In this concluding section we show that the problem (1.4), (1.5) is not always well-posed if either (1.13)–(1.15) or (1.11) is violated. To this end, we first assume that there is no spontaneous breakage, i.e., $\gamma \equiv 0$, and that K and P are strictly positive a.e. on their domains. Furthermore, we suppose that shattering and scattering are mass preserving and binary processes, that is, that (1.10) and (1.12) are satisfied and additionally that

$$\beta_{\mathsf{c}}(y,y') = \beta_{\mathsf{c}}(y,y-y'), \qquad 0 < y' < y < y_0, \tag{4.1}$$

$$\beta_{\mathsf{s}}(y,y') = \beta_{\mathsf{s}}(y,y-y') > 0, \quad 0 < y - y_0 < y' < y_0 \tag{4.2}$$

and

$$\beta_{\mathsf{s}}(y,y') = 0, \quad 0 < y' < y - y_0 < y_0. \tag{4.3}$$

The latter assumption is due to consistency of the model since each of the daughter particles y' and $y - y'$ in (4.2) has to belong to Y. Note that (1.10), (1.12), and (4.1)–(4.3) imply

$$Q(y,y')\int_0^{y+y'} \beta_{\mathsf{c}}(y+y',y'')\ \mathrm{d}y'' = 2\ Q(y,y') \quad \text{for a.a. } (y,y') \in \Xi,$$

and

$$\int_{y-y_0}^{y_0} \beta_{\mathsf{s}}(y,y')\ \mathrm{d}y' = 2 \quad \text{for a.a. } y \in (y_0, 2y_0);$$

in particular, (1.15) is violated due to the Hölder inequality.

PROPOSITION 4.1. *If $\gamma \equiv 0$, K and P are strictly positive a.e. on their domains and if β_{c} and β_{s} satisfy* (4.1)–(4.3), *the only solution $f \in L^1_+(Y)$ to* (1.4) *is $f \equiv 0$.*

Proof. Let $u \in L^1_+(Y)$ be a solution to (1.4). Then we deduce from (2.1)–(2.3) with $\psi \equiv 1$ that

$$\begin{aligned} 0 = &-\int_0^{y_0} L(u)(y)\ \mathrm{d}y \ = \ \frac{1}{2}\int_0^{y_0}\int_0^{y_0-y} K(y,y')\ P(y,y')\ u(y)\ u(y')\ \mathrm{d}y'\mathrm{d}y \\ \geq &\ \frac{1}{2}\int_0^{y_0/2}\int_0^{y_0/2} K(y,y')\ P(y,y')\ u(y)\ u(y')\ \mathrm{d}y'\mathrm{d}y \ \geq \ 0, \end{aligned}$$

whence $u \equiv 0$ on $(0, y_0/2)$ and $L_{\mathsf{c}}(u)(y) = 0$ for a.e. $y \in Y$. Therefore,

$$\begin{aligned} 0 = L(u)(y) = &\ \frac{1}{2}\int_{y_0}^{y_0+y}\int_{y'-y_0}^{y_0} K(y'', y'-y'')\ \beta_{\mathsf{s}}(y',y)\ u(y'')\ u(y'-y'')\ \mathrm{d}y''\mathrm{d}y' \\ &- u(y)\int_{y_0-y}^{y_0} K(y,y')\ u(y')\ \mathrm{d}y' \end{aligned} \tag{4.4}$$

for a.e. $y \in Y$. We claim that this implies that $u \equiv 0$ on $(\xi \vee (y_0-\xi), (y_0+\xi)/2)$ for a.e. $\xi \in (y_0/3, y_0)$ such that $u(\xi) = 0$ (recall that $\xi \vee (y_0-\xi) := \max\{\xi, y_0-\xi\}$). Indeed, consider $\xi \in \big(y_0/3, y_0\big)$ such that $u(\xi) = 0$. Since

$$\big(\xi \vee (y_0-\xi), (y_0+\xi)/2\big)^2 \subset \big\{(y'', y')\ ;\ \xi < y'' < y_0,\ y_0 < y'+y'' < y_0+\xi\big\},$$

we infer from (4.4) that

$$\begin{aligned} 0 = &\int_{y_0}^{y_0+\xi}\int_{y'-y_0}^{y_0} K(y'', y'-y'')\ \beta_{\mathsf{s}}(y',\xi)\ u(y'')\ u(y'-y'')\ \mathrm{d}y''\mathrm{d}y' \\ = &\int_0^{y_0}\int_{y_0}^{y_0+(y''\wedge\xi)} K(y'', y'-y'')\ \beta_{\mathsf{s}}(y',\xi)\ u(y'')\ u(y'-y'')\ \mathrm{d}y'\mathrm{d}y'' \\ = &\int_\xi^{y_0}\int_{y_0-y''}^{y_0+\xi-y''} K(y'', y')\ \beta_{\mathsf{s}}(y'+y'',\xi)\ u(y'')\ u(y')\ \mathrm{d}y'\mathrm{d}y'' \\ \geq &\int_{\xi\vee(y_0-\xi)}^{(y_0+\xi)/2}\int_{\xi\vee(y_0-\xi)}^{(y_0+\xi)/2} K(y'', y')\ \beta_{\mathsf{s}}(y'+y'',\xi)\ u(y'')\ u(y')\ \mathrm{d}y'\mathrm{d}y'' \\ \geq &\ 0, \end{aligned}$$

whence $u \equiv 0$ on $\big((\xi \vee y_0-\xi), (y_0+\xi)/2\big)$. Defining $\xi_k := (1-2^{-k-1})y_0$, we inductively infer that $u \equiv 0$ on $(0, \xi_k)$ for $k \in \mathbb{N}$ by a density argument, whence $u \equiv 0$ on Y. ☐

On the other hand, integrating (1.4) over Y and recalling that scattering produces at least two daughter particles, i.e.,

$$\int_0^{y_0} \beta_{\mathsf{s}}(y,y')\ \mathrm{d}y' \ \geq\ 2, \quad y \in (y_0, 2y_0),$$

we easily see that zero is the only steady state provided that, in addition,

$$Q(y,y') \int_0^{y+y'} \beta_{\mathsf{c}}(y+y',y'')\ \mathrm{d}y'' \ \geq\ 2\ Q(y,y') + P(y,y'), \quad y+y' \in Y,$$

and

$$\int_0^y \left(1-\frac{y'}{y}\right)\ \gamma(y,y')\ \mathrm{d}y' > 0\ , \quad y \in Y.$$

Obviously, the former assumption contradicts (1.11).

Acknowledgments. We thank Prof. Herbert Amann for stimulating discussions. This work was initiated during a visit of the first author to the Institute of Mathematics of the University of Zürich. He gratefully thanks this institution for hospitality and support. We also thank the referees for useful comments.

MICROLOCAL DISPERSIVE SMOOTHING FOR THE NONLINEAR SCHRÖDINGER EQUATION*

JÉRÉMIE SZEFTEL†

Abstract. We prove a dispersive smoothing result for the nonlinear Schrödinger equation. We deal with the linear term by using the method of Craig, Kappeler, and Strauss. We rewrite the nonlinear term as the sum of a paradifferential operator and a remainder using Bony's theorem. We prove an interpolation result between weighted L^2 spaces and Sobolev spaces which enables us to deal with the remainder. Finally, we deal with the paradifferential operator using the symbolic calculus.

Key words. nonlinear Schrödinger equation, smoothing effect, interpolation, weighted L^2 space, paradifferential calculus

1. Introduction.

Lascar [12] obtained the first propagation results for the linear Schrödinger equation (see also Boutet de Monvel [3]). He introduced a parabolic wave front set and proved its propagation along the flow of the Laplacian at any fixed time $t \neq 0$. However, we cannot use this result to link the initial data to the singularities of the solution at a positive time. The following example illustrates the link between u_0 and $u(t,.)$:

$$\begin{cases} i\dfrac{\partial u}{\partial t} + \Delta u = 0, \quad t > 0, \quad x \in \mathbb{R}^d, \\ u|_{t=0} = u_0. \end{cases} \tag{1.1}$$

If we take $u_0 = \delta$, then the solution $u(t,.)$ is in $C^\infty(\mathbb{R}^d)$ for all positive times. Conversely, if we take the smooth data $u_0 = e^{-i|x|^2}$, then the solution $u(t,.)$ is singular at $t = 1$. We notice that the smoothness of $u(t,.)$ for $t > 0$ depends on the behavior of u_0 at infinity. This idea has been extended (microlocalization, Laplacians which are flat perturbation at infinity of the constant coefficient case) in many recent works. See Craig, Kappeler, and Strauss [6]; Wunsch [17]; Robbiano and Zuily [14], [15]; and Doi [7]; we refer the reader to [6] for a more complete bibliography.

In the case of the nonlinear Schrödinger equation, there are several works proving the existence of a smoothing effect (see, for instance, Hayashi, Nakamitsu, Tsutsumi [8], Kenig, Ponce, Vega [11], and Chihara [5]).

To our knowledge, there is no result on the microlocal smoothing effect for the nonlinear Schrödinger equation, and this is the aim of this study. The present work consists of four parts.

- We first state our result of microlocal smoothing effect for the equation

$$\begin{cases} i\dfrac{\partial u}{\partial t} + \dfrac{1}{2}\displaystyle\sum_{j,l=1}^{d} \partial_{x_j} a^{jl}(x)\partial_{x_l} u = f(u,\bar{u}), \quad 0 < t < T, \quad x \in \mathbb{R}^d, \\ u|_{t=0} = u_0, \end{cases} \tag{1.2}$$

  where $\sum_{j,l=1}^{d} \partial_{x_j} a^{jl}(x)\partial_{x_l}$ is an asymptotically constant elliptic self-adjoint operator and f is C^∞ and vanishes at 0. We also give an outline of the proof.
- We recall technical tools obtained by Craig, Kappeler, and Strauss [6]. We will use these tools to adapt the proof of [6] to our nonlinear equation.
- Then we prove technical lemmas which will be useful in what follows. Among others, we establish interpolation results between Sobolev spaces and weighted L^2 spaces and we construct a paradifferential algebra well-suited to our problem.
- Finally, we prove the microlocal smoothing effect for (1.2) stated in the first part. We paralinearize $f(u,\bar{u})$ using Bony's theorem [2]. We get a paradifferential operator evaluated at u, a paradifferential operator evaluated at $\bar{u}$, and a regular remainder. We treat the remainder like a right-hand side using the result of the second part. As we do not know how to deal with the paradifferential operator evaluated at $\bar{u}$, we introduce $v = u - Q\bar{u}$, where Q is chosen such that v satisfies the same kind of equation as u without term evaluated at $\bar{v}$. Then, we adapt the strategy of [6] to the operator evaluated at v which is the sum of $i\partial_t + 1/2\sum_{j,l=1}^{d} \partial_{x_j} a^{jl}(x)\partial_{x_l}$ and a paradifferential operator. Finally, the smoothing effect for v implies a smoothing effect for u.

2. Statements of the main results and outline of the proof.

2.1. Statements of the main results. We first recall some usual definitions and properties of microlocal analysis. A subset V of $T^*(\mathbb{R}^d)\setminus\{0\}$ is conic if $(x,\xi) \in V$ implies $(x,\lambda\xi) \in V$ for all $\lambda > 0$. To a symbol $a(x,\xi)$, we associate the operator $a(x,D)$ acting on functions u defined on $\mathbb{R}^d$ by

$$a(x,D)u(x) = \int_{\mathbb{R}^d}\int_{\mathbb{R}^d} e^{i(x-y)\xi} a(x,\xi)u(y)dy\, d\xi.$$

The usual pseudodifferential algebra S^m consists of the symbols $a(x,\xi)$ such that

$$\left|\partial_x^\alpha \partial_\xi^\beta a(x,\xi)\right| \le C_{\alpha\beta}\langle\xi\rangle^{m-|\beta|}$$

for all multi-indices α,β in $\mathbb{N}^d$, where $\langle\xi\rangle = (1+|\xi|^2)^{1/2}$. For $a(x,\xi)$ in S^m, $a(x,D)$ is bounded from H^s to H^{s-m} for all real numbers s. Finally, let u be in $\mathcal{S}'(\mathbb{R}^d)$. u is microlocally H^s at (x_0,ξ_0) if there is $a(x,\xi)$ in S^0 such that $\liminf_{\lambda\to+\infty} |a(x_0,\lambda\xi_0)| \ne 0$ and $a(x,D)u \in H^s$.

Let τ be an increasing function from $\mathbb{N}$ to $\mathbb{R}$ such that

$$\tau(m) > m+1 \text{ for } m \ge 0 \tag{2.1}$$

and let the C^∞ coefficients $a^{jl}(x)$ satisfy

$$\left|\partial_x^\alpha\left(a^{jl}(x) - a_0^{jl}\right)\right| \le \frac{C_\alpha}{\langle x\rangle^{\tau(|\alpha|)}} \quad \forall\alpha \in \mathbb{N}^d, \tag{2.2}$$

where a_0^{jl} are constants and where $\langle x\rangle = (1+|x|^2)^{1/2}$. The Schrödinger equation studied in [6] is

$$\begin{cases} i\dfrac{\partial u}{\partial t} + \dfrac{1}{2}\displaystyle\sum_{j,l=1}^{d} \partial_{x_j} a^{jl}(x)\partial_{x_l} u = 0, \quad 0<t<T, \quad x\in\mathbb{R}^d, \\ u|_{t=0} = u_0. \end{cases} \tag{2.3}$$

The principal symbol $a_2(x,\xi) = 1/2\sum_{j,l=1}^{d} a^{jl}(x)\xi_j\xi_l$ is elliptic:

$$a_2(x,\xi) \geq C|\xi|^2, \quad C>0. \tag{2.4}$$

The bicharacteristics are orbits of the flow $\varphi(s,x,\xi) = (X(s,x,\xi),\Xi(s,x,\xi)) : T^*(\mathbb{R}^d) \to T^*(\mathbb{R}^d)$ of the Hamiltonian system with Hamiltonian $a_2(x,\xi)$:

$$\frac{dX}{ds} = \partial_\Xi a_2(X,\Xi), \quad \frac{d\Xi}{ds} = -\partial_X a_2(X,\Xi). \tag{2.5}$$

We will say that a point $(x_0,\xi_0)\in T^*(\mathbb{R}^d)$, $\xi_0\neq 0$, is not trapped by the backward flow if

$$|X(s,x_0,\xi_0)| \to +\infty \quad \text{when} \quad s\to-\infty. \tag{2.6}$$

For such (x_0,ξ_0), we consider conic neighborhoods $\mathcal{E}$ of $\{\varphi(s,x_0,\xi_0), s\leq 0\}$ such that there is a $\Xi_1\in\mathbb{R}^d$ and the asymptotic behavior of the neighborhood $\mathcal{E}$ as $|x|\to+\infty$ is given by

$$\mathcal{E} \simeq \left\{(x,\xi)\Big/ \left|\frac{\xi.\Xi_1}{|\xi||\Xi_1|}-1\right|<\epsilon, \quad \left|\frac{x.\xi}{|x||\xi|}+1\right|<\epsilon\right\} \tag{2.7}$$

for some $\epsilon>0$.

Definition 2.1. *The C^∞ function $a(x,\xi)$ is a symbol of class $S(m,k)$ if*

$$\left|\partial_x^\alpha\partial_\xi^\beta a(x,\xi)\right| \leq C_{\alpha\beta}\langle\xi\rangle^{m-|\beta|}\langle x\rangle^{k-|\alpha|} \tag{2.8}$$

for all multi-indices α,β in $\mathbb{N}^d$.

We will adapt the results of [6] to the following equation:

$$\begin{cases} i\dfrac{\partial u}{\partial t} + \dfrac{1}{2}\displaystyle\sum_{j,l=1}^{d} \partial_{x_j} a^{jl}(x)\partial_{x_l} u = f(u,\bar u), \quad 0<t<T, \quad x\in\mathbb{R}^d, \\ u|_{t=0} = u_0, \end{cases} \tag{2.9}$$

where the coefficients satisfy (2.1), (2.2), and (2.4) and where f is in $C^\infty(\mathbb{C}^2)$ and vanishes at $(0,0)$. In that follows, we consider functions u belonging to spaces of the type $L^\infty(0,T,H^s)$. We choose $s>d/2$ such that $s-d/2$ is not an integer to be in the frame of Bony's paradifferential calculus. Moreover, to construct a function $v=u-Q\bar u$ satisfying an equation of type (2.9) without term evaluated at $\bar v$, we ask that for any integer k such that $2k<s-d/2+2$, $s-2k\geq 0$.

Lemma 2.2. *The set of real numbers s such that $s>d/2$, $s-d/2$ is not an integer, and $s-2k\geq 0$ for all integer k satisfying $2k<s-d/2+2$ is the subset I_d of $\mathbb{R}$ given by*

$$
\begin{aligned}
&\textit{if } d=1, \quad I_d=\bigcup_{k\geq 1}[2k,2k+1/2[,\\
&\textit{if } d=2, \quad I_d=\bigcup_{k\geq 1}]2k,2k+1[,\\
&\textit{if } d=3, \quad I_d=\bigcup_{k\geq 1}[2k,2k+1/2[\cup]2k+1/2,2k+3/2[,\\
&\textit{if } d\geq 4, \quad I_d=\bigcup_{k\geq 0}]k+d/2,k+1+d/2[.
\end{aligned}
\tag{2.10}
$$

Proof. If $2k < s-d/2+2$, $s-2k > d/2-2$, so $s-2k>0$ for $d\geq 4$. Therefore, when $d\geq 4$, I_d is the set of $s>d/2$ such that $s-d/2$ is not an integer, which is given by

$$I_d=\bigcup_{k\geq 0}]k+d/2,k+1+d/2[.$$

We suppose now that $1\leq d\leq 3$. It suffices to consider the biggest integer k such that $2k<s-d/2+2$. As $s-d/2$ is not an integer, k satisfies

$$2k<s-d/2+2<2(k+1),$$

which together with $s\geq 2k$ yields

$$2k\leq s<2k+d/2.$$

Thus, for $1\leq d\leq 3$, we have

$$I_d=\{s>d/2\,/\,s-d/2\notin\mathbb{N}\}\cap\bigcup_{k\geq 1}[2k,2k+d/2[,$$

which yields (2.10) for $1\leq d\leq 3$. ∎

The following theorems describe the microlocal smoothing effect for the nonlinear Schrödinger equation. We will prove them in section 5.

THEOREM 2.3. *Let (x_0,ξ_0) not be trapped backwards. Let there exist a conic neighborhood $\mathcal{E}$ of $\{\varphi(s,x_0,\xi_0), s\leq 0\}$ satisfying* (2.7). *Let $T>0$, s in I_d, and u in $C(0,T,L^2(\mathbb{R}^d))$ be a solution of* (2.9). *Assume that there exists $\theta(x)$ in $S(0,0)$ equal to 1 on $\mathcal{E}$ such that θu is in $L^\infty(0,T,H^s)$ and $\langle x\rangle^s\theta u$ is in $L^\infty(0,T,L^2)$. Moreover, assume that there exists $s(x,\xi)$ in $S(0,2s-d/2)$ such that $\langle x\rangle^{2(2s-d/2)}\leq s^2(x,\xi)$ on the set $\mathcal{E}$. Assume that u_0 satisfies*

$$\langle s(x,D)u_0, s(x,D)u_0\rangle<+\infty, \tag{2.11}$$

$$\langle s(x,D)\overline{u_0}, s(x,D)\overline{u_0}\rangle<+\infty. \tag{2.12}$$

If $u(t,.)$ is microlocally H^σ at $(x_0,-\xi_0)$ for a time t, $0<t\leq T$, then $u(t,.)$ is microlocally $H^{\min(\sigma+2,2s-d/2)}$ at (x_0,ξ_0).

If there exists a pseudodifferential operator with a symbol $c(x,\xi)$ in S^0 elliptic at $(x_0,-\xi_0)$ such that

$$\int_0^T t^{2(2s-d/2)+\delta}\|c(x,D)u(t,.)\|^2_{H^\sigma}dt<+\infty \tag{2.13}$$

for a $\delta > 0$, then there exists a pseudodifferential operator with a symbol $c_1(x,\xi)$ in S^0 elliptic at (x_0,ξ_0) such that

$$\int_0^T t^{2(2s-d/2)+\delta}\|c_1(x,D)u(t,.)\|^2_{H^{\min(\sigma+2,2s-d/2+1/2)}}dt < +\infty. \tag{2.14}$$

Finally, assume that $\partial_{\bar{u}}f(0,0) = 0$. Then, we do not need assumption (2.12)*.*

Remark. The assumptions (2.11) and (2.12) mean that u_0 and $\overline{u_0}$ are decreasing like $\langle x\rangle^{-(2s-d/2)}$ along $\{\varphi(s,x_0,\xi_0), s \le 0\}$ when $|x|$ converges towards infinity.

THEOREM 2.4. *Let (x_0,ξ_0) be such that (x_0,ξ_0) and $(x_0,-\xi_0)$ are not trapped backwards. Let a conic neighborhood $\mathcal{E}_1$ of $\{\varphi(s,x_0,\xi_0), s \le 0\}$ and a conic neighborhood $\mathcal{E}_2$ of $\{\varphi(s,x_0,-\xi_0), s \le 0\}$ be such that $\mathcal{E}_1$ and $\mathcal{E}_2$ satisfy* (2.7)*. Let $T > 0$, s in I_d, and u in $C(0,T,L^2(\mathbb{R}^d))$ be a solution of* (2.9)*. Assume there exists $\theta(x)$ in $S(0,0)$ equal to 1 on $\mathcal{E}_1 \cup \mathcal{E}_2$ such that θu is in $L^\infty(0,T,H^s)$ and $\langle x\rangle^s\theta u$ is in $L^\infty(0,T,L^2)$. Moreover, assume that for $j = 1,2$, there exists $s_j(x,\xi)$ in $S(0,2s-d/2)$ such that $\langle x\rangle^{2(2s-d/2)} \le s_j^2(x,\xi)$ on the set $\mathcal{E}_j$. Assume that u_0 satisfies*

$$\langle s_j(x,D)u_0, s_j(x,D)u_0\rangle < +\infty, \quad j = 1,2, \tag{2.15}$$

$$\langle s_j(x,D)\overline{u_0}, s_j(x,D)\overline{u_0}\rangle < +\infty, \quad j = 1,2. \tag{2.16}$$

Then, $u(t,.)$ is microlocally $H^{2s-d/2}$ at (x_0,ξ_0) for all $0 < t \le T$. Moreover, there exists a pseudodifferential operator with symbol $c(x,\xi)$ in S^0 elliptic at (x_0,ξ_0) such that

$$\int_0^T t^{2(2s-d/2)+\delta}\|c(x,D)u(t,.)\|^2_{H^{2s-d/2+1/2}}dt < +\infty \tag{2.17}$$

for all $\delta > 0$. Finally, suppose that $\partial_{\bar{u}}f(0,0) = 0$. Then, we do not need assumption (2.16)*.*

Theorem 2.4 implies, in particular, the following corollary.

COROLLARY 2.5. *Assume that no point of $T^*(\mathbb{R}^d)\setminus\{0\}$ is trapped backwards. Let $T > 0$, s in I_d, and u in $C(0,T,L^2(\mathbb{R}^d))$ be a solution of* (2.9)*. Assume that u is in $L^\infty(0,T,H^s)$ and $\langle x\rangle^s u$ is in $L^\infty(0,T,L^2)$. Moreover, assume that $\langle x\rangle^{2s-d/2}u_0$ is in L^2. Then, $u(t,.)$ is in $H^{2s-d/2}_{loc}$ for all $0 < t \le T$. Moreover, for any ϕ in $C_0^\infty(\mathbb{R}^d)$,*

$$\int_0^T t^{2(2s-d/2)+\delta}\|\phi u(t,.)\|^2_{H^{2s-d/2+1/2}}dt < +\infty \tag{2.18}$$

for all $\delta > 0$.

The reader interested in other applications of Theorem 2.4 is referred to [16], where we combine it with a reflection of singularities result to compute the Dirichlet-to-Neumann map of the nonlinear Schrödinger equation with the flat Laplacian outside a convex obstacle.

2.2. Outline of the proof. For the sake of simplicity, we assume here that u is in $L^\infty(0,T,H^s)$ and $\langle x\rangle^s u$ is in $L^\infty(0,T,L^2)$. The proof contains three steps.

- *First step.* We define

$$\lambda_1 = \partial_u f(0,0), \quad \lambda_2 = \partial_{\bar{u}}f(0,0), \quad g(u,\bar{u}) = f(u,\bar{u}) - \lambda_1 u - \lambda_2\bar{u}, \tag{2.19}$$

g vanishes to the second order at 0, and u is a solution of

(2.20)
$$i\frac{\partial u}{\partial t}+\frac{1}{2}\sum_{j,l=1}^{d}\partial_{x_j}a^{jl}(x)\partial_{x_l}u=\lambda_1 u+\lambda_2\bar{u}+g(u,\bar{u}),\quad 0<t<T,\quad x\in\mathbb{R}^d.$$

We paralinearize $g(u,\bar{u})$ using Bony's theorem [2]:

$$g(u,\bar{u})=T_{\frac{\partial g}{\partial u}(u,\bar{u})}u+T_{\frac{\partial g}{\partial \bar{u}}(u,\bar{u})}\bar{u}+r(u,\bar{u}).$$

$T_{\frac{\partial g}{\partial u}(u,\bar{u})}$ and $T_{\frac{\partial g}{\partial \bar{u}}(u,\bar{u})}$ are linear operators and $r(u,\bar{u})$ is a smooth remainder in the sense that it belongs to $L^\infty(0,T,H^{2s-d/2})$. Moreover, as $\langle x\rangle^s u$ is in $L^\infty(0,T,L^2)$ and as g vanishes to the second order at 0, we prove that $\langle x\rangle^{2s-d/2}r(u,\bar{u})$ is in $L^\infty(0,T,L^2)$. Finally, u is a solution of

(2.21)
$$i\frac{\partial u}{\partial t}+\frac{1}{2}\sum_{j,l=1}^{d}\partial_{x_j}a^{jl}(x)\partial_{x_l}u=\lambda_1 u+\lambda_2\bar{u}+T_{\frac{\partial g}{\partial u}(u,\bar{u})}u+T_{\frac{\partial g}{\partial \bar{u}}(u,\bar{u})}\bar{u}+r(u,\bar{u}).$$

- *Second step.* We want to adapt the strategy of [6] to (2.21). However, we do not know how to deal with the terms $\lambda_2\bar{u}$ and $T_{\frac{\partial g}{\partial \bar{u}}(u,\bar{u})}\bar{u}$. In fact a microlocal information on u at (x_0,ξ_0) implies for $\bar{u}$ a microlocal information at $(x_0,-\xi_0)$, but not at (x_0,ξ_0). Therefore, we introduce $v=u-Q\bar{u}$ and we choose the operator Q such that v satisfies the same kind of equation as u without term evaluated at $\bar{v}$:

$$i\frac{\partial v}{\partial t}+\frac{1}{2}\sum_{j,l=1}^{d}\partial_{x_j}a^{jl}(x)\partial_{x_l}v=Lv+r(u,\bar{u}), \tag{2.22}$$

  where L is a paradifferential operator.
- *Third step.* We adapt the strategy of [6], which relies on energy estimates, to (2.22). We have to check that the terms Lv and $r(u,\bar{u})$ coming from the nonlinearity do not perturb the energy estimates of [6] to obtain a smoothing effect for v. Finally, using the smoothing effect for v, the fact that $u=v+Q\bar{u}$ and the fact that Q is bounded from H^σ to $H^{\sigma+2}$ for any σ implies a smoothing effect for u.

Remark. Kenig, Ponce, and Vega [11] and Chihara [5] prove a smoothing effect for the nonlinear Schrödinger equation. Unlike Theorems 2.3 and 2.4, these results are not microlocal, but we would like to compare them with Corollary 2.5. In [11], the authors consider the second order operator $\sum_{j\le k}\partial_{x_j}^2-\sum_{j>k}\partial_{x_j}^2, 1\le k\le d$ (i.e., a constant coefficient not necessarily elliptic operator), and the nonlinearity contains also gradient terms, but they prove a gain of $1/2$ derivative, whereas we prove a gain of $s-d/2$ derivatives. The results in [5] give a gain of m derivatives for any integer m and the nonlinearity contains also gradient terms, but the results apply to the flat Laplacian with a nonlinearity vanishing at least at order 3 at 0, which in addition satisfies a gauge invariance. We rely on Bony's theorem, whereas these works rely on sharp estimates for linear nonhomogeneous Schrödinger equations. However, there are some similarities in these methods. For instance, Chihara [5] uses an argument similar to the second step of our proof to get rid of the term in $\bar{u}$, and Kenig, Ponce, and Vega [11] use a construction of symbols which has a link with that of Craig, Kappeler, and Strauss [6], reviewed in the following section, to obtain their sharp estimates.

3. Review of the results of Craig, Kappeler, and Strauss. The results in [6] rely on the construction of symbol pairs $(b(x,\xi), c(x,\xi))$ satisfying

$$\{a_2, b\} = \sum_{j=1}^{d} \partial_{\xi_j} a_2 \partial_{x_j} b - \partial_{x_j} a_2 \partial_{\xi_j} b = -c \tag{3.1}$$

($\{\,,\}$ is the Poisson bracket) and

$$b(x,\xi) \geq 0, \quad c(x,\xi) \geq 0. \tag{3.2}$$

The following proposition is proved in [6] and gives the existence of pairs of symbols $(b(x,\xi), c(x,\xi))$ satisfying (3.1) and (3.2).

PROPOSITION 3.1. *Let m and k be real and positive and let (x_0, ξ_0) not be trapped backwards. Let there be a conic neighborhood $\mathcal{E}$ of $\{\varphi(s, x_0, \xi_0), s \leq 0\}$ satisfying* (2.7). *There is a conic neighborhood $\mathcal{E}^0 \subset \mathcal{E}$ of $\{\varphi(s, x_0, \xi_0), s \leq 0\}$ satisfying* (2.7) *with a smaller $\epsilon_0 < \epsilon$ and a pair of symbols $b(x,\xi) \in S(m,k)$ and $c(x,\xi) \in S(m+1, k-1)$ with support in $\mathcal{E}$ such that* (3.1) *and* (3.2) *hold and $b(x_0,\xi_0) = c(x_0,\xi_0) = 1$. We can choose b and c such that $\sqrt{b} \in S(m/2, k/2)$ and $\sqrt{c} \in S((m+1)/2, (k-1)/2)$. Moreover, there is a constant C such that on the set $\mathcal{E}^0 \cap \{|\xi| \geq 1\}$ they satisfy*

$$\langle \xi \rangle^m \langle x \rangle^k \leq b(x,\xi), \quad \frac{1}{C} \langle \xi \rangle^{m+1} \langle x \rangle^{k-1} \leq c(x,\xi). \tag{3.3}$$

If $k = 0$, then there is the exception that for any $\nu < -1$ we may choose $c(x,\xi)$ in $S(m+1,-1)$ such that $1/C\langle \xi \rangle^{m+1} \langle x \rangle^{\nu} \leq c(x,\xi)$.

We recall some properties of the algebra $S(m,k)$ that we use in what follows (see [6] or [9] for a more general treatment). As $S(m,0) \subset S^m$, where S^m is the usual pseudodifferential algebra, $a(x,D)$ is bounded from H^t to H^{t-m} and from C^t to C^{t-m} for all $a(x,\xi)$ in $S(m,0)$ and for all t (when t is an integer, C^t is the Zygmund class C^t_* [10]). The following proposition is on the composition of operators.

PROPOSITION 3.2. *Let a in $S(m,k)$ and b in $S(m_1,k_1)$ be two symbols. Let N be an integer. Then*

$$a(x,D)b(x,D) = \sum_{|\alpha|<N} \frac{1}{i^{|\alpha|}\alpha!} \big(\partial_\xi^\alpha a \partial_x^\alpha b\big)(x,D) + r_N(x,D), \tag{3.4}$$

where r_N is in $S(m_1+m_2-N, k_1+k_2-N)$. Moreover, the seminorms of r_N can be estimated by a sum of products of seminorms of $\partial_\xi^\alpha a$ in $S(m_1-N,k_1)$ and of $\partial_x^\alpha b$ in $S(m_2, k_2-N)$, where $|\alpha| = N$.

We prove this proposition as it is more precise than the result established in [6].

Proof. From the usual procedures in the pseudodifferential calculus, we have

$$\begin{aligned} a(x,D)b(x,D)u &= \int\!\!\int e^{i\eta(x-z)} \int\!\!\int e^{i\xi(z-y)} a(x,\eta) b(z,\xi) u(y)dy\, d\xi\, dz\, d\eta \\ &= \sum_{|\alpha|<N} \frac{1}{i^{|\alpha|}\alpha!} \int\!\!\int e^{i(x-y)\xi} \partial_\xi^\alpha a(x,\xi) \partial_x^\alpha b(x,\xi) u(y) dy\, d\xi \\ &\quad + r_N(x,D)u, \end{aligned} \tag{3.5}$$

where

$$r_N[a,b](x,\xi) = r_N(x,\xi) = \sum_{|\alpha|=N} \frac{N}{i^{|\alpha|}\alpha!}\int_0^1\int\int e^{i(\xi-\eta)(z-x)}t^{N-1}\partial_\xi^\alpha a(x,\xi+t(\eta-\xi))\partial_x^\alpha b(z,\xi)dz\,d\eta\,dt. \tag{3.6}$$

As $\partial_x r_N[a,b] = r_N[\partial_x a,b] + r_N[a,\partial_x b]$ and $\partial_\xi r_N[a,b] = r_N[\partial_\xi a,b] + r_N[a,\partial_\xi b]$, it suffices to prove that

$$|r_N[a,b](x,\xi)| \le C\langle\xi\rangle^{m_1+m_2-N}\langle x\rangle^{k_1+k_2-N}, \tag{3.7}$$

where C is estimated by sums of products of seminorms of $\partial_\xi^\alpha a$ in $S(m_1-N,k_1)$ and of $\partial_x^\alpha b$ in $S(m_2,k_2-N)$ with $|\alpha|=N$. Then let χ be in $C_0^\infty(\mathbb{R}^d)$ such that $\chi(s)=1$ if $|s|\le 1/9$ and $\chi(s)=0$ if $|s|\ge 1/4$. Using

$$\begin{aligned}1 = {}&\chi(|\xi-\eta|^2/\langle\xi\rangle^2)\chi(|x-z|^2/\langle x\rangle^2)\\ &+\chi(|\xi-\eta|^2/\langle\xi\rangle^2)(1-\chi(|x-z|^2/\langle x\rangle^2))\\ &+(1-\chi(|\xi-\eta|^2/\langle\xi\rangle^2))\chi(|x-z|^2/\langle x\rangle^2)\\ &+(1-\chi(|\xi-\eta|^2/\langle\xi\rangle^2))(1-\chi(|x-z|^2/\langle x\rangle^2)),\end{aligned}$$

it suffices to prove (3.7) for each of the following cases:

$$|\xi-\eta|\le 1/2\langle\xi\rangle \quad\text{and}\quad |x-z|\le 1/2\langle x\rangle, \tag{3.8}$$

$$|\xi-\eta|\le 1/2\langle\xi\rangle \quad\text{and}\quad |x-z|\ge 1/3\langle x\rangle, \tag{3.9}$$

$$|\xi-\eta|\ge 1/3\langle\xi\rangle \quad\text{and}\quad |x-z|\le 1/2\langle x\rangle, \tag{3.10}$$

$$|\xi-\eta|\ge 1/3\langle\xi\rangle \quad\text{and}\quad |x-z|\ge 1/3\langle x\rangle. \tag{3.11}$$

When $|x-z|\le 1/2\langle x\rangle$, we have $\langle z\rangle\simeq\langle x\rangle$. Let P be an integer, $P>d/2$. We use $(1+|x-z|^{2P})^{-1}(1+(-\Delta_\eta)^P)e^{i(\xi-\eta)(z-x)} = e^{i(\xi-\eta)(z-x)}$, integrations by parts, and the fact that $\int(1+|x-z|^{2P})^{-1}dz<+\infty$.

When $|x-z|\ge 1/3\langle x\rangle$, we have $\langle z\rangle\le\langle x\rangle+\langle z-x\rangle$. Let $P>d/2$. We use $|x-z|^{-2P}(-\Delta_\eta)^P e^{i(\xi-\eta)(z-x)} = e^{i(\xi-\eta)(z-x)}$, integrations by parts, and the fact that

$$\int_{|x-z|\ge 1/3\langle x\rangle}|x-z|^{-2P}dz\le C\langle x\rangle^{d-2P}.$$

We deal with the integrations in η in the same way, replacing x by ξ and z by η. Moreover, for $0\le t\le 1$, $\langle\xi+t(\eta-\xi)\rangle\le\langle\xi\rangle+\langle\eta-\xi\rangle$ and $\langle\xi+t(\eta-\xi)\rangle\simeq\langle\xi\rangle$ when $|\xi-\eta|\le 1/2\langle\xi\rangle$. Finally, for an integer $P>d/2+\max(|k_2-N|,|m_1-N|)/2$,

$$\begin{aligned}&|r_N[a,b](x,\xi)|\le C\langle\xi\rangle^{m_1+m_2-N}\langle x\rangle^{k_1+k_2-N} && \text{in (3.8)},\\ &|r_N[a,b](x,\xi)|\le C\langle\xi\rangle^{m_1+m_2-N}\langle x\rangle^{k_1+2|k_2-N|+d-2P} && \text{in (3.9)},\\ &|r_N[a,b](x,\xi)|\le C\langle\xi\rangle^{2|m_1-N|+d-2P+m_2}\langle x\rangle^{k_1+k_2-N} && \text{in (3.10)},\\ &|r_N[a,b](x,\xi)|\le C\langle\xi\rangle^{2|m_1-N|+d-2P+m_2}\langle x\rangle^{k_1+2|k_2-N|+d-2P} && \text{in (3.11)},\end{aligned}$$

which yields (3.7) by taking $P\ge d/2+3/2\max(|k_2-N|,|m_1-N|)$. ∎

PROPOSITION 3.3. *Let a be in $S(m,k)$. The adjoint operator satisfies*

$$a(x,D)^* = \sum_{|\alpha|<N} \frac{1}{i^{|\alpha|}\alpha!}\big(\partial_\xi^\alpha \partial_x^\alpha \bar{a}\big)(x,D) + R_N, \tag{3.12}$$

where N is an integer such that $N \geq \max(k,m)$ and R_N is a bounded operator on L^2.

The following lemmas are proved in [6].

LEMMA 3.4. *Let $b(x,\xi)$ be in $S(m,k)$ such that $b(x,\xi) = s^2(x,\xi)$ with $s(x,\xi)$ in $S(m/2,k/2)$. Then there exists $e(x,\xi)$ in $S(m-1,k-1)$ with $\operatorname{supp}(e) \subset \operatorname{supp}(b)$ such that*

$$\operatorname{Re}\langle u, b(x,D)u\rangle \geq \|s(x,D)u\|_{L^2}^2 + \operatorname{Re}\langle u, e(x,D)u\rangle - C\|u\|_{L^2}^2,$$

where $\langle , \rangle$ is the scalar product in $L^2(\mathbb{R}^d)$.

LEMMA 3.5. *Let $b_0(x,\xi)$ be in $S(m,k)$ such that $0 \leq b_0(x,\xi) = s_0^2(x,\xi)$ with s_0 in $S(m/2,k/2)$. Define the set*

$$\mathcal{E}^0 = \{(x,\xi)/\langle x\rangle^{-k}\langle \xi\rangle^{-m} b_0(x,\xi) \geq 1\}.$$

Suppose that b in $S(m,k)$ has support in $\mathcal{E}^0$. Then there exists $c(x,\xi)$ in $S(0,0)$ and R bounded on L^2 such that

$$b(x,D) = s_0^*(x,D)c(x,D)s_0(x,D) + R.$$

4. Technical lemmas. In this section, we prove, among other things, Lemma 4.7 and Proposition 4.12, which are useful for bounding the terms coming from the nonlinearity in the energy estimates of the third step of the proof. Moreover, in order to construct the operator Q in the second step of the proof, we define a paradifferential algebra and study its properties in Proposition 4.11. In what follows, the various spaces are all defined on $\mathbb{R}^d$.

The following proposition will be used when proving Proposition 4.3, Lemma 4.7, and Proposition 4.8.

PROPOSITION 4.1. *Let k and l be two real numbers with $l \geq 0$ and let p be an integer. Let $\theta \in C_0^\infty(\mathbb{R}^d)$, let $a(x)$ be in $S(0,k)$ and let j be an integer such that $j \geq l$. Then*

$$\theta(2^{-p}D)a(x) = \sum_{0\leq|\alpha|<j} \frac{2^{-p|\alpha|}}{i^{|\alpha|}\alpha!}\partial_x^\alpha a(x)\big(\partial_\xi^\alpha\theta\big)(2^{-p}D) + \frac{\langle x\rangle^{k-j}}{2^{p(j-l)}}R_1 \tag{4.1}$$

and

$$a(x)\theta(2^{-p}D) = \sum_{0\leq|\alpha|<j} \frac{2^{-p|\alpha|}i^{|\alpha|}}{\alpha!}\big(\partial_\xi^\alpha\theta\big)(2^{-p}D)\partial_x^\alpha a(x) + \frac{\langle x\rangle^{k-j}}{2^{p(j-l)}}R_2, \tag{4.2}$$

where R_1 and R_2 are continuous from H^t to H^{t+l} and from C^t to C^{t+l} for all t with norms independent of p.

Proof. $2^{p(j-l)}\langle x\rangle^{j-k}\theta(2^{-p}\xi)$ is in $S(j-l,j-k)$ and $a(x)$ is in $S(0,k)$. Therefore, Proposition 3.2 implies

$$\begin{aligned} &2^{p(j-l)}\langle x\rangle^{j-k}\theta(2^{-p}D)a(x) \\ &\quad= \sum_{0\leq|\alpha|<j} \frac{2^{-p|\alpha|}}{i^{|\alpha|}\alpha!}2^{p(j-l)}\langle x\rangle^{j-k}\partial_x^\alpha a(x)\big(\partial_\xi^\alpha\theta\big)(2^{-p}D) + r(x,D), \end{aligned} \tag{4.3}$$

where r is in $S(-l,0)$ with its seminorms bounded by sums of products of seminorms of $\partial_\xi^\alpha(2^{p(j-l)}\langle x\rangle^{j-k}\theta(2^{-p}\xi))$ in $S(-l,j-k)$ and of $\partial_x^\alpha a(x)$ in $S(0,k-j)$ with $|\alpha|=j$. For $|\alpha|=j$, $\partial_\xi^\alpha(2^{p(j-l)}\langle x\rangle^{j-k}\theta(2^{-p}\xi)) = 2^{-pl}\langle x\rangle^{j-k}(\partial_\xi^\alpha\theta)(2^{-p}\xi)$ has its seminorms in $S(-l,j-k)$ bounded independently of p. Therefore, $r(x,\xi)$ has its seminorms in $S(-l,0)$ (and hence in S^{-l}) bounded independently of p. Multiplying (4.3) by $2^{p(l-j)}\langle x\rangle^{k-j}$,

$$\theta(2^{-p}D)a(x) = \sum_{0\le|\alpha|<j}\frac{2^{-p|\alpha|}}{i^{|\alpha|}\alpha!}\partial_x^\alpha a(x)\big(\partial_\xi^\alpha\theta\big)(2^{-p}D) + \frac{\langle x\rangle^{k-j}}{2^{p(j-l)}}r(x,D). \tag{4.4}$$

Thus, (4.1) is satisfied with $R_1 = r(x,D)$. Moreover, R_1 is continuous from H^t to H^{t+l} and from C^t to C^{t+l} for all t with norms independent of p since the seminorms of $r(x,\xi)$ in S^{-l} are bounded independently of p.

Equation (4.4) with $\bar a$ and $\overline\theta$ gives

$$\overline\theta(2^{-p}D)\bar a(x) = \sum_{0\le|\alpha|<j}\frac{2^{-p|\alpha|}}{i^{|\alpha|}\alpha!}\partial_x^\alpha \bar a(x)\big(\partial_\xi^\alpha\overline\theta\big)(2^{-p}D) + \frac{\langle x\rangle^{k-j}}{2^{p(j-l)}}r_1(x,D), \tag{4.5}$$

where $r_1(x,\xi)$ has seminorms in $S(-l,0)$ bounded independently of p. Using Proposition 3.2, $\langle x\rangle^{k-j}r_1(x,D)\langle x\rangle^{j-k} = r_2(x,D)$ and $r_2(x,\xi)$ has seminorms in $S(-l,0)$ bounded independently of p. Equation (4.5) becomes

$$\overline\theta(2^{-p}D)\bar a(x) = \sum_{0\le|\alpha|<j}\frac{2^{-p|\alpha|}}{i^{|\alpha|}\alpha!}\partial_x^\alpha \bar a(x)\big(\partial_\xi^\alpha\overline\theta\big)(2^{-p}D) + 2^{-p(j-l)}r_2(x,D)\langle x\rangle^{k-j} \tag{4.6}$$

and, taking the adjoint,

$$a(x)\theta(2^{-p}D) = \sum_{0\le|\alpha|<j}\frac{2^{-p|\alpha|}i^{|\alpha|}}{\alpha!}\big(\partial_\xi^\alpha\theta\big)(2^{-p}D)\partial_x^\alpha a(x) + \frac{\langle x\rangle^{k-j}}{2^{p(j-l)}}r_2(x,D)^*. \tag{4.7}$$

Thus, (4.2) is satisfied with $R_2 = r_2(x,D)^*$. The properties of S^{-l} imply $r_2(x,D)^* = r_3(x,D)$ with r_3 in S^{-l}. R_2 is continuous from H^t to H^{t+l} and from C^t to C^{t+l} for all t with norms independent of p since $r_3(x,\xi)$ has seminorms in S^{-l} bounded independently of p. $\square$

Following Meyer [13], we introduce a positive function φ in $C_0^\infty(\mathbb{R}^d)$ equal to 1 for $|\xi|\le 1/2$ and to 0 for $|\xi|\ge 1$. For all integers p we define S_p by $\widehat{S_pu}(\xi)=\varphi(2^{-p}\xi)\hat u(\xi)$. We also define Δ_p by $\Delta_p = S_{p+1}-S_p$, i.e., by $\widehat{\Delta_pu}(\xi)=\psi(2^{-p}\xi)\hat u(\xi)$, where $\psi(\xi)=\varphi(\xi/2)-\varphi(\xi)$. Littlewood–Paley decomposition of $u\in\mathcal{S}'(\mathbb{R}^d)$ is

$$u=\sum_{p\ge -1}\Delta_p(u),$$

where the sum converges for the topology of $\mathcal{S}'(\mathbb{R}^d)$ and $\Delta_{-1}=S_0$. We have a simple characterization of the spaces H^s and C^s (see, for example, [4]),

$$H^s = \left\{u\in\mathcal{S}'(\mathbb{R}^d)\Big/\sum_{p\ge-1}4^{ps}\|\Delta_pu\|_{L^2}^2<+\infty\right\} \tag{4.8}$$

and $(\sum_{p\geq -1} 4^{ps}\|\Delta_p u\|_{L^2}^2)^{1/2}$ is equivalent to the usual norm on H^s.

$$C^s = \left\{ u \in \mathcal{S}'(\mathbb{R}^d) / \sup_{p\geq -1} 2^{ps}\|\Delta_p u\|_{L^\infty} < +\infty \right\}, \tag{4.9}$$

and $\sup_{p\geq -1} 2^{ps}\|\Delta_p u\|_{L^\infty}$ is equivalent to the usual norm on C^s. Moreover, let $0 < r_1 < r_2$ and suppose $(u_q)_{q\in\mathbb{N}}$ is a sequence in $\mathcal{S}'(\mathbb{R}^d)$. Then

$$\text{supp } \hat{u}_q \subset \{r_1 2^q \leq |\xi| \leq r_2 2^q\} \text{ and } \sum_{q\geq 0} 4^{qs}\|u_q\|_{L^2}^2 < +\infty \Rightarrow u = \sum_{q\geq 0} u_q \in H^s, \tag{4.10}$$

and if $s > 0$,

$$\text{supp } \hat{u}_q \subset \{|\xi| \leq r_2 2^q\} \text{ and } \sum_{q\geq 0} 4^{qs}\|u_q\|_{L^2}^2 < +\infty \Rightarrow u = \sum_{q\geq 0} u_q \in H^s. \tag{4.11}$$

The following definition will be useful in defining a paradifferential algebra well-suited to our problem.

Definition 4.2. *Let s and s' be two real numbers such that $s > 0$. The space $H^s_{s'}$ is defined by*

$$H^s_{s'} = \{u \in H^{s+s'} / \langle x\rangle^s u \in H^{s'}\}.$$

The following proposition, among others, will be used in the third step of the proof to bound the remainder term in the energy estimates.

Proposition 4.3. *Let s and s' be two real numbers such that $s > 0$. Let u in $H^s_{s'}$. Then for all $0 \leq \theta \leq 1$, $\langle x\rangle^{\theta s} u$ is in $H^{(1-\theta)s+s'}$.*

Proof. Using (4.1) with $k = \theta s$, $l = (s+s')_-$, where $(s+s')_- = \max(-(s+s'), 0)$, $j = [\max(s, |s+s'|)] + 1$, $a(x) = \langle x\rangle^{\theta s}$, and $\chi = \psi$ yields

$$\Delta_p \langle x\rangle^{\theta s} = \sum_{0\leq|\alpha|<j} \frac{2^{-p|\alpha|}}{i^{|\alpha|}\alpha!} \partial_x^\alpha \langle x\rangle^{\theta s} \big(\partial_\xi^\alpha \psi\big)(2^{-p}D) + \frac{\langle x\rangle^{\theta s - j}}{2^{p(j-l)}} R, \tag{4.12}$$

where R is bounded from $H^{s+s'}$ to L^2 with a norm independent of p. Thus

$$\begin{aligned} &2^{p(1-\theta)s+ps'}\|\Delta_p \langle x\rangle^{\theta s} u\|_{L^2} \\ &\leq \sum_{0\leq|\alpha|<j} \frac{2^{p((1-\theta)s+s'-|\alpha|)}}{\alpha!} \|\partial_x^\alpha \langle x\rangle^{\theta s} \big(\partial_\xi^\alpha \psi\big)(2^{-p}D) u\|_{L^2} \\ &\quad + 2^{-p(j-l-(1-\theta)s-s')}\|\langle x\rangle^{\theta s - j} R u\|_{L^2}. \end{aligned} \tag{4.13}$$

As $\theta s - [s] - 1 \leq 0$,

$$2^{-p(j-l-(1-\theta)s-s')}\|\langle x\rangle^{\theta s-j} R u\|_{L^2} \leq 2^{p(s+s'-[|s+s'|]-1)} C\|Ru\|_{L^2} \leq C\varepsilon_p \|u\|_{H^{s+s'}}, \tag{4.14}$$

where $(\epsilon_p)_{p\geq -1}$ is in $l^2(\mathbb{N})$ because $s + s' - [|s+s'|] - 1 < 0$. Moreover, by Hölder and Young inequalities

$$\begin{aligned} &2^{p((1-\theta)s+s')}\|\partial_x^\alpha \langle x\rangle^{\theta s} \big(\partial_\xi^\alpha \psi\big)(2^{-p}D) u\|_{L^2} \\ &\leq 2^{p((1-\theta)s+s')}\|\big(\partial_x^\alpha \langle x\rangle^{\theta s}\big)^{1/\theta} \big(\partial_\xi^\alpha \psi\big)(2^{-p}D) u\|_{L^2}^\theta \|\big(\partial_\xi^\alpha \psi\big)(2^{-p}D) u\|_{L^2}^{1-\theta} \\ &\leq C 2^{ps'}\|\langle x\rangle^{s-|\alpha|/\theta} \big(\partial_\xi^\alpha \psi\big)(2^{-p}D) u\|_{L^2} + C 2^{ps+ps'}\|\big(\partial_\xi^\alpha \psi\big)(2^{-p}D) u\|_{L^2}. \end{aligned} \tag{4.15}$$

Looking at the support of $\partial_\xi^\alpha\psi$ we have

$$\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)=\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)(\Delta_{p-1}+\Delta_p+\Delta_{p+1}).$$

Thus, as u is in $H^{s+s'}$,

$$\begin{aligned}(4.16)\qquad 2^{p(s+s')}\big\|\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)u\big\|_{L^2}\le C2^{p(s+s')}(&\|\Delta_{p-1}u\|_{L^2}\\ &+\|\Delta_p u\|_{L^2}+\|\Delta_{p+1}u\|_{L^2})\le\varepsilon_p,\end{aligned}$$

where $(\epsilon_p)_{p\ge-1}$ is in $l^2(\mathbb{N})$ by (4.8).

$$\big\|\langle x\rangle^{s-|\alpha|/\theta}\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)u\big\|_{L^2}\le C\big\|\langle x\rangle^{s}\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)u\big\|_{L^2}.$$

Using (4.8), (4.13), (4.14), (4.15), and (4.16), it suffices to prove

$$(4.17)\qquad 2^{ps'}\big\|\langle x\rangle^{s}\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)u\big\|_{L^2}\le\epsilon_p,$$

where $(\epsilon_p)_{p\ge-1}$ is in $l^2(\mathbb{N})$. Using (4.2) with $k=s$, $l=s'_-$, $j=[\max(s,|s'|)]+1$, $a(x)=\langle x\rangle^s$, and $\chi=\partial_\xi^\alpha\psi$,

$$\begin{aligned}(4.18)\qquad \langle x\rangle^{s}\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)=\sum_{0\le|\beta|<j}&\frac{2^{-p|\beta|}i^{|\beta|}}{\beta!}\big(\partial_\xi^{\alpha+\beta}\psi\big)(2^{-p}D)\partial_x^\beta\langle x\rangle^s\\ &+2^{-p(j-l)}\langle x\rangle^{s-j}R,\end{aligned}$$

where R is bounded from $H^{s'}$ to L^2 with a norm independent of p. Thus

$$\begin{aligned}(4.19)\qquad &2^{ps'}\big\|\langle x\rangle^{s}\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)u\big\|_{L^2}\\ &\le\sum_{0\le|\beta|<j}\frac{2^{-p|\beta|+ps'}}{\beta!}\big\|\big(\partial_\xi^{\alpha+\beta}\psi\big)(2^{-p}D)\partial_x^\beta(\langle x\rangle^s)u\big\|_{L^2}\\ &\quad+2^{-p(j-l-s')}\|\langle x\rangle^{s-j}Ru\|_{L^2}.\end{aligned}$$

As $s-j\le0$,

$$\begin{aligned}(4.20)\qquad 2^{-p(j-l-s')}\|\langle x\rangle^{s-j}Ru\|_{L^2}&\le C2^{-p([|s'|]+1-|s'|)}\|Ru\|_{L^2}\\ &\le C2^{-p([|s'|]+1-|s'|)}\|u\|_{H^{s'}}\le\varepsilon_p,\end{aligned}$$

where $(\epsilon_p)_{p\ge-1}$ is in $l^2(\mathbb{N})$. Looking at the support of $\partial_\xi^{\alpha+\beta}\psi$ we have

$$\begin{aligned}(4.21)\qquad 2^{ps'}\big\|\big(\partial_\xi^{\alpha+\beta}\psi\big)(2^{-p}D)\partial_x^\beta(\langle x\rangle^s)u\big\|_{L^2}&\le C2^{ps'}\big(\big\|\Delta_{p-1}\partial_x^\beta(\langle x\rangle^s)u\big\|_{L^2}\\ &+\big\|\Delta_{p}\partial_x^\beta(\langle x\rangle^s)u\big\|_{L^2}+\big\|\Delta_{p+1}\partial_x^\beta(\langle x\rangle^s)u\big\|_{L^2}\big).\end{aligned}$$

Since $\langle x\rangle^s u$ is in $H^{s'}$ and the multiplication by $(\partial_x^\beta\langle x\rangle^s)\langle x\rangle^{-s}$ is bounded on L^2, we have from (4.8) and (4.21) that

$$(4.22)\qquad 2^{ps'}\big\|\big(\partial_\xi^{\alpha+\beta}\psi\big)(2^{-p}D)\partial_x^\beta(\langle x\rangle^s)u\big\|_{L^2}\le\epsilon_p,$$

where $(\epsilon_p)_{p\ge-1}$ is in $l^2(\mathbb{N})$. Finally, (4.19), (4.20), and (4.22) imply (4.17). ∎

We study the action of operators with symbol in $S(m,k)$ on the spaces $H^s_{s'}$.

LEMMA 4.4. *Let m and k with $k \le 0$ be two real numbers, and let $b(x,\xi)$ be in $S(m,k)$. Then $b(x,D)$ is bounded from $H^s_{s'}$ to $H^{s-k}_{s'-m+k}$.*

Proof. As $k \le 0$, $S(m,k)$ is included in S^m. So $b(x,D)$ is bounded from $H^{s+s'}$ to $H^{s+s'-m}$. As $H^{s+s'-m}$ is included in $H^{s+s'-m+k}$, $b(x,D)$ is bounded from $H^{s+s'}$ to $H^{s+s'-m+k}$. Moreover, $\langle x\rangle^{s-k} b(x,D)\langle x\rangle^{-s} = b_1(x,D)$ with $b_1(x,\xi)$ in $S(m,0)$ by using Proposition 3.2. Thus, $\langle x\rangle^{s-k} b(x,D)\langle x\rangle^{-s}$ is bounded from $H^{s'}$ to $H^{s'-m}$. As $H^{s'-m}$ is included in $H^{s'-m+k}$, $\langle x\rangle^{s-k} b(x,D)\langle x\rangle^{-s}$ is bounded from $H^{s'}$ to $H^{s'-m+k}$. $\square$

The following corollary gives an example of a solution u of the nonlinear Schrödinger equation (4.23) such that u is in $L^\infty(0,T,H^s)$ and $\langle x\rangle^s u$ is in $L^\infty(0,T,L^2)$, therefore satisfying the assumptions of Corollary 2.5.

COROLLARY 4.5. *Let $s > d/2$ and let u_0 be in $H^s(\mathbb{R}^d)$. Then, for $T > 0$ sufficiently small, there exists a unique solution u in $C(0,T,H^s)$ of*

$$\begin{cases} i\dfrac{\partial u}{\partial t} + \dfrac{1}{2}\displaystyle\sum_{j,l=1}^{d} \partial_{x_j} a^{jl}(x)\partial_{x_l} u = f(u,\bar u), \quad 0 < t < T, \quad x \in \mathbb{R}^d, \\ u|_{t=0} = u_0, \end{cases} \tag{4.23}$$

where $A = -1/2\sum_{j,l=1}^{d} \partial_{x_j} a^{jl}(x)\partial_{x_l}$ is an elliptic self-adjoint operator and f is C^∞ and vanishes at 0. Moreover, assume the symbol of A is in $S(2,0)$ and $\langle x\rangle^s u_0$ is in L^2. $\langle x\rangle^s u$ is then in $L^\infty(0,T,L^2)$.

Proof. The local existence and uniqueness in $C(0,T,H^s)$ of the u solution of (4.23) is well known. We recall the proof. Since A is an unbounded self-adjoint operator, $-iA$ is the generator of a semigroup of isometry on L^2. Let L be the operator on $C(0,T,H^s)$ defined by

$$Lu(t) = e^{-itA}u_0 - i\int_0^t e^{-i(t-\tau)A} f(u(\tau),\bar u(\tau))d\tau$$

for $0 \le t \le T$. As e^{-iAt} commutes with $(I+A)^{s/2}$ on H^s and as

$$C_1\|u\|_{H^s} \le \left\|(I+A)^{\frac{s}{2}}u\right\|_{L^2} \le C_2\|u\|_{H^s}$$

for u in H^s,

$$\begin{aligned} &\|Lu\|_{C(0,T,H^s)} \le C\big(\|u_0\|_{H^s} + T\|f(u,\bar u)\|_{C(0,T,H^s)}\big), \\ &\|Lu - Lv\|_{C(0,T,H^s)} \le CT\|f(u,\bar u) - f(v,\bar v)\|_{C(0,T,H^s)}. \end{aligned} \tag{4.24}$$

Moreover, f is C^∞ and vanishes at 0 and H^s is embedded in L^∞. Thus (see, for example, [1])

$$\|f(u,\bar u)\|_{H^s} \le \theta(\|u\|_{H^s}), \tag{4.25}$$

where θ is an increasing function. We define the C^∞ function g by

$$g(u,\bar u) = f(u,\bar u) - \partial_u f(0,0)u - \partial_{\bar u} f(0,0)\bar u.$$

H^s is an algebra and $\partial_u g$ and $\partial_{\bar u} g$ vanish at 0. Thus, by (4.25),

$$\begin{aligned} \|g(u,\bar u) - g(v,\bar v)\|_{H^s} &\le C\int_0^1 (\|\partial_u g(ru+(1-r)v, r\bar u + (1-r)\bar v)\|_{H^s} \\ &\quad + \|\partial_{\bar u} g(ru+(1-r)v, r\bar u+(1-r)\bar v)\|_{H^s})dr\|u-v\|_{H^s} \\ &\le \theta(\|u\|_{H^s} + \|v\|_{H^s})\|u-v\|_{H^s}, \end{aligned} \tag{4.26}$$

where θ is an increasing function. We have

$$\|\partial_u f(0,0)u + \partial_{\bar u} f(0,0)\bar u - \partial_u f(0,0)v - \partial_{\bar u} f(0,0)\bar v\|_{H^s} \le C\|u-v\|_{H^s},$$

which together with (4.26) yields

$$\|f(u,\bar u) - f(v,\bar v)\|_{H^s} \le \theta(\|u\|_{H^s} + \|v\|_{H^s})\|u-v\|_{H^s}, \tag{4.27}$$

where θ is an increasing function. Inequalities (4.24), (4.25), and (4.27) imply

$$\begin{aligned}&\|Lu\|_{C(0,T,H^s)} \le C\big(\|u_0\|_{H^s} + T\theta(\|u\|_{C(0,T,H^s)})\big),\\ &\|Lu - Lv\|_{C(0,T,H^s)} \le CT\theta\big(\|u\|_{C(0,T,H^s)} + \|v\|_{C(0,T,H^s)}\big)\|u-v\|_{C(0,T,H^s)}.\end{aligned} \tag{4.28}$$

We choose

$$0 < T \le \min(\|u_0\|_{H^s}(1+\theta(2C\|u_0\|_{H^s}))^{-1}, (1+C\theta(4C\|u_0\|_{H^s}))^{-1}),$$

and we use the contraction mapping principle with the operator L and the function space

$$\big\{v \in C(0,T,H^s)\,/\,\|v\|_{C(0,T,H^s)} \le 2C\|u_0\|_{H^s}\big\}.$$

So, we have the existence and uniqueness in $C(0,T,H^s)$ of the solution u of (4.23).

Moreover, suppose that the symbol of A is in $S(2,0)$ and $\langle x\rangle^s u_0$ is in L^2. For any operator B,

$$\begin{aligned}\partial_t\langle Bu,u\rangle &= \langle B\partial_t u,u\rangle + \langle Bu,\partial_t u\rangle + \left\langle \frac{\partial B}{\partial t}u,u\right\rangle\\ &= \langle B(-iAu - if(u,\bar u)),u\rangle + \langle Bu,-iAu-if(u,\bar u)\rangle + \left\langle \frac{\partial B}{\partial t}u,u\right\rangle\\ &= -i\langle [B,A]u,u\rangle - i\langle Bf(u,\bar u),u\rangle + i\langle Bu,f(u,\bar u)\rangle + \left\langle \frac{\partial B}{\partial t}u,u\right\rangle.\end{aligned} \tag{4.29}$$

Choosing $Bu = \langle x\rangle^{2s}u$ and integrating (4.29) between 0 and t, we obtain

$$\begin{aligned}\|\langle x\rangle^s u(t)\|_{L^2}^2 \le \|\langle x\rangle^s u_0\|_{L^2}^2 &+ \int_0^t |\langle [B,A]u(\tau),u(\tau)\rangle| d\tau\\ +2\int_0^t \|\langle x\rangle^s f(u(\tau),\bar u(\tau))\|_{L^2}&\|\langle x\rangle^s u(\tau)\|_{L^2} d\tau.\end{aligned} \tag{4.30}$$

The mean value theorem and the fact that f vanishes at 0 imply

$$|f(u(t,x),\bar u(t,x))| \le \theta\big(\|u\|_{L^\infty(0,T,L^\infty(\mathbb{R}^d))}\big)|u(t,x)|.$$

Thus

$$\begin{aligned}&\int_0^t \|\langle x\rangle^s f(u(\tau),\bar u(\tau))\|_{L^2}\|\langle x\rangle^s u(\tau)\|_{L^2} d\tau\\ &\qquad\le \theta(\|u\|_{L^\infty})\int_0^t \|\langle x\rangle^s u(\tau)\|_{L^2}^2 d\tau.\end{aligned} \tag{4.31}$$

As A is in $Op(S(2,0))$ and B is in $Op(S(0,2s))$, $[A,B]$ is in $Op(S(1,2s-1))$ by Proposition 3.2. Therefore, by Proposition 3.2, $\langle x\rangle^{-s+1/2}[A,B]\langle x\rangle^{-s+1/2}=R$, where R is in $Op(S(1,0))$. Thus,

$$\begin{aligned} |\langle [B,A]u(\tau),u(\tau)\rangle| &= |\langle R\langle x\rangle^{s-1/2}u(\tau),\langle x\rangle^{s-1/2}u(\tau)\rangle| \\ &\le \|R\langle x\rangle^{s-1/2}u(\tau)\|_{H^{-1/2}}\|\langle x\rangle^{s-1/2}u(\tau)\|_{H^{1/2}} \\ &\le C\|\langle x\rangle^{s-1/2}u(\tau)\|^2_{H^{1/2}}. \end{aligned} \tag{4.32}$$

Moreover, as $s>d/2\ge 1/2$, Proposition 4.3 implies

$$\big\|\langle x\rangle^{s-1/2}u(\tau)\big\|^2_{H^{1/2}} \le C\big(\|\langle x\rangle^{s}u(\tau)\|^2_{L^2}+\|u(\tau)\|^2_{H^s}\big). \tag{4.33}$$

$\langle x\rangle^s u_0$ is in L^2 and u is in $C(0,T,H^s)$ and in $C(0,T,L^\infty)$ as $s>d/2$. Thus, (4.30), (4.31), (4.32), and (4.33) imply

$$\|\langle x\rangle^s u(t)\|^2_{L^2}\le C+C\int_0^t \|\langle x\rangle^s u(\tau)\|^2_{L^2}d\tau. \tag{4.34}$$

Therefore, $\langle x\rangle^s u$ is in $L^\infty(0,T,L^2)$ by Gronwall's lemma. $\square$

The following corollary will be useful to construct the operator Q in the second step of the proof.

COROLLARY 4.6. *Let $s>d/2$ and $T>0$ be two real numbers, and let there be a solution u of* (4.23). *We assume that the symbol of A is in $S(2,0)$ and that there exists two real functions $\theta_1(x)$ and $\theta_2(x)$ in $S(0,0)$ such that $\theta_2\equiv 1$ in a neighborhood of the support of θ_1, and that $\theta_2 u$ is in $L^\infty(0,T,H^s_0)$. Then, $\theta_1\partial_t^k u$ is in $L^\infty(0,T,H^s_{-2k})$ for all integers k such that $2k<s-d/2+2$. Moreover, assume g is in $C^\infty(\mathbb{C}^2)$ and vanishes at 0 and s in I_d defined by* (2.10). *Then $\partial_t^k g(\theta_1 u,\overline{\theta_1 u})$ is in $L^\infty(0,T,H^s_{-2k})$ for all integers k such that $2k<s-d/2+2$.*

Proof. As u is a solution of (4.23), $\partial_t^k u$ satisfies for $k\ge 1$ at least formally

$$\begin{aligned} \partial_t^k u &= i^k A^k u \\ &\quad + \sum_{|\alpha_1|+\cdots+|\alpha_p|+|\beta_1|+\cdots+|\beta_q|\le 2(k-1)} g_{\alpha_1,\dots,\beta_q}(x)\partial_x^{\alpha_1}u\cdots\partial_x^{\alpha_p}u\partial_x^{\beta_1}\bar u\cdots \\ &\quad \times\partial_x^{\beta_q}\bar u f_{\alpha_1,\dots,\beta_q}(u,\bar u), \end{aligned} \tag{4.35}$$

where the $g_{\alpha_1,\dots,\beta_q}(x)$ are in $S(0,0)$ and where $f_{\alpha_1,\dots,\beta_q}$ are C^∞ functions. As $\theta_2\equiv 1$ in a neighborhood of the support of θ_1, (4.35) implies

$$\begin{aligned} \theta_1\partial_t^k u &= i^k\theta_1 A^k\theta_2 u \\ &\quad + \sum_{|\alpha_1|+\cdots+|\alpha_p|+|\beta_1|+\cdots+|\beta_q|\le 2(k-1)} g_{\alpha_1,\dots,\beta_q}(x)\partial_x^{\alpha_1}\theta_2 u\cdots \\ &\quad \times\partial_x^{\beta_q}\overline{\theta_2 u} f_{\alpha_1,\dots,\beta_q}\big(\theta_2 u,\overline{\theta_2 u}\big). \end{aligned} \tag{4.36}$$

For all $|\alpha|\le 2(k-1)$, $\partial_x^\alpha\theta_2 u$ is in $L^\infty(0,T,H^{s-2(k-1)})$. As $s-2(k-1)>d/2$, we get

(4.37)

$$\sum_{|\alpha_1|+\cdots+|\alpha_p|+|\beta_1|+\cdots+|\beta_q|\le 2(k-1)} g_{\alpha_1,\dots,\beta_q}(x)\partial_x^{\alpha_1}\theta_2 u\cdots\partial_x^{\beta_q}\overline{\theta_2 u} f_{\alpha_1,\dots,\beta_q}\big(\theta_2 u,\overline{\theta_2 u}\big)$$

is in $L^\infty(0,T,H^{s-2(k-1)})$

(see, for example, [13]). A^k has its symbol in $S(2k,0)$ by Proposition 3.2. This implies that $A^k\theta_2 u$ is in $L^\infty(0,T,H^s_{-2k})$ by Lemma 4.4. Thus, $A^k\theta_2 u$ is in $L^\infty(0,T,H^{s-2k})$, and (4.36) and (4.37) imply that $\theta_1\partial_t^k u$ is in $L^\infty(0,T,H^{s-2k})$.

We prove now that $\langle x\rangle^s\theta_1\partial_t^k u$ is in $L^\infty(0,T,H^{-2k})$.

$$g_{\alpha_1,\dots,\beta_q}(x)\partial_x^{\alpha_2}\theta_2 u\cdots\partial_x^{\beta_q}\overline{\theta_2 u}f_{\alpha_1,\dots,\beta_q}(\theta_2 u,\overline{\theta_2 u}) \text{ is in } L^\infty\big(0,T,H^{s-2(k-1)+|\alpha_1|}\big), \tag{4.38}$$

since $|\alpha_2|+\cdots+|\beta_q|\le 2(k-1)-|\alpha_1|$. Moreover, Bony's decomposition in the paraproduct and remainder of uv yields

$$\|uv\|_{H^{r_1}}\le C\|u\|_{H^{r_1}}\|v\|_{H^{r_2}}\quad \forall r_2>d/2 \text{ and } -r_2\le r_1\le r_2 \tag{4.39}$$

(see, for example, [4] for the properties of the paraproduct and of the remainder). As $\langle x\rangle^s\partial^{\alpha_1}\theta_2 u$ is in $L^\infty(0,T,H^{-|\alpha_1|})$ by Lemma 4.4, (4.38) and (4.39) with $r_1=-|\alpha_1|$ and $r_2=s-2(k-1)+|\alpha_1|$ imply that

$$\langle x\rangle^s g_{\alpha_1,\dots,\beta_q}(x)\partial_x^{\alpha_1}\theta_2 u\cdots\partial_x^{\beta_q}\overline{\theta_2 u}f_{\alpha_1,\dots,\beta_q}\big(\theta_2 u,\overline{\theta_2 u}\big)\quad \text{is in } L^\infty(0,T,H^{-|\alpha_1|}). \tag{4.40}$$

As $\langle x\rangle^s A^k\theta_2 u$ is in $L^\infty(0,T,H^{-2k})$, (4.36) and (4.40) imply that $\langle x\rangle^s\theta_1\partial_t^k u$ is in $L^\infty(0,T,H^{-2k})$.

We assume in addition that g is in $C^\infty(\mathbb{C}^2)$ and vanishes at 0, that s is in I_d, and that k is an integer satisfying $2k<s-d/2+2$. Lemma 2.2 shows that $s-2k\ge 0$. Moreover, we have

$$\begin{aligned}\partial_t^k g(\theta_1 u,\overline{\theta_1 u})\\ =\sum_{j_1+\cdots+j_p+l_1+\cdots+l_q=k}\partial_t^{j_1}\theta_1 u\cdots\partial_t^{j_p}\theta_1 u\partial_t^{l_1}\overline{\theta_1 u}\cdots\partial_t^{l_q}\overline{\theta_1 u}\frac{\partial^{p+q}g}{\partial u^p\partial\bar u^q}(\theta_1 u,\overline{\theta_1 u}).\end{aligned} \tag{4.41}$$

As $\theta_1 u$ is in $L^\infty(0,T,H^s)$, and as $s>d/2$,

$$\frac{\partial^{p+q}g}{\partial u^p\partial\bar u^q}(\theta_1 u,\overline{\theta_1 u})-\frac{\partial^{p+q}g}{\partial u^p\partial\bar u^q}(0,0) \text{ is in } L^\infty(0,T,H^s).$$

As $\partial_t^{j_2}\theta_1 u,\dots,\partial_t^{l_q}\overline{\theta_1 u}$ are in $L^\infty(0,T,H^{s-2(k-j_1)})$, and as $s-2(k-j_1)>d/2$, the product

$$\partial_t^{j_2}\theta_1 u\cdots\partial_t^{j_p}\theta_1 u\partial_t^{l_1}\overline{\theta_1 u}\cdots\partial_t^{l_q}\overline{\theta_1 u}\frac{\partial^{p+q}g}{\partial u^p\partial\bar u^q}\big(\theta_1 u,\overline{\theta_1 u}\big) \text{ is in } L^\infty\big(0,T,H^{s-2(k-j_1)}\big). \tag{4.42}$$

Moreover, $\partial_t^{j_1}\theta_1 u$ is in $L^\infty(0,T,H^{s-2j_1})$. Therefore, $\partial_t^k g(\theta_1 u,\overline{\theta_1 u})$ is in $L^\infty(0,T,H^{s-2k})$ by using (4.39) with $r_2=s-2(k-j_1)$ and $r_1=s-2j_1$ and by using (4.41). In the same way, (4.42) and the fact that $\langle x\rangle^s\partial_t^{j_1}\theta_1 u$ belongs to $L^\infty(0,T,H^{-2j_1})$ imply that $\langle x\rangle^s\partial_t^k g(\theta_1 u,\overline{\theta_1 u})$ is in $L^\infty(0,T,H^{-2k})$ by using (4.39) with $r_2=s-2(k-j_1)$ and $r_1=-2j_1$. So, $\partial_t^k g(\theta_1 u,\overline{\theta_1 u})$ is in $L^\infty(0,T,H^s_{-2k})$ for all integers k such that $2k<s-d/2+2$. ◻

Bony [2] defines the paraproduct of v by u as the following bilinear operator:

$$T_u v=\sum_{q\ge 2}S_{q-2}(u)\Delta_q(v). \tag{4.43}$$

Let $R(u,v)$ be the following bilinear operator:

$$R(u,v)=\sum_{|p-q|\leq 2}\Delta_p(u)\Delta_q(v). \tag{4.44}$$

We have $uv = T_u v + T_v u + R(u,v)$. Let $s > d/2$. Then for all u in H^s and all functions f in $C^\infty(\mathbb{R})$ such that $f(0)=0$, Bony's paralinearization theorem with the improvement of Meyer [13] is

$$f(u)=T_{f'(u)}u+r(u), \tag{4.45}$$

where $r(u)\in H^{2s-d/2}$. The generalization to several variables of (4.45) implies, for $f\in C^\infty(\mathbb{C}^2)$ such that $f(0,0)=0$,

$$f(u,\bar u)=T_{\frac{\partial f}{\partial u}(u,\bar u)}u+T_{\frac{\partial f}{\partial \bar u}(u,\bar u)}\bar u+r(u,\bar u), \tag{4.46}$$

where $r(u,\bar u)\in H^{2s-d/2}$.

The following lemma will be used in the first step of the proof to show moreover that the remainder satisfies that $\langle x\rangle^{2s-d/2}r(u,\bar u)$ is in L^2.

LEMMA 4.7. *Let $s > d/2$ and let u be in H_0^s. Let $f\in C^\infty(\mathbb{C}^2)$ such that f vanishes to the second order at* 0 *and let $r(u,\bar u)$ be defined by* (4.46). *$\langle x\rangle^{2s-d/2}f(u,\bar u)$ and $\langle x\rangle^{2s-d/2}r(u,\bar u)$ are in L^2.*

Proof. Since f vanishes to the second order at 0 and u is in L^∞, we have

$$|f(u(x),\bar u(x))|\leq C|u(x)|^2,$$

which, using the Sobolev embedding of $H^{d/4}$ in L^4, yields

$$\|\langle x\rangle^{2s-d/2}f(u,\bar u)\|_{L^2}\leq C\big\|\langle x\rangle^{s-d/4}u\big\|_{L^4}^2\leq C\big\|\langle x\rangle^{s-d/4}u\big\|_{H^{d/4}}^2. \tag{4.47}$$

Since u is in H_0^s, $\langle x\rangle^{s-d/4}u$ is in $H^{d/4}$ by Proposition 4.3. This implies that $\langle x\rangle^{2s-d/2}f(u,\bar u)$ is in L^2 using (4.47).

By (4.46), $r(u,\bar u)$ is equal to

$$f(u,\bar u)-T_{\frac{\partial f}{\partial u}(u,\bar u)}u-T_{\frac{\partial f}{\partial \bar u}(u,\bar u)}\bar u. \tag{4.48}$$

In order to prove that $\langle x\rangle^{2s-d/2}r(u,\bar u)$ is in L^2, it remains to establish

$$\langle x\rangle^{2s-d/2}\Big(T_{\frac{\partial f}{\partial u}(u,\bar u)}u+T_{\frac{\partial f}{\partial \bar u}(u,\bar u)}\bar u\Big)\in L^2. \tag{4.49}$$

It suffices to prove

$$\langle x\rangle^{2s-d/2}T_{\frac{\partial f}{\partial u}(u,\bar u)}u\in L^2, \tag{4.50}$$

since we can use the same argument for $T_{\partial_{\bar u}f(u,\bar u)}\bar u$. As $\partial_u f$ vanishes at 0 and u is in L^∞,

$$\left|\frac{\partial f}{\partial u}(u(x),\bar u(x))\right|\leq C|u(x)|.$$

This implies that $\langle x\rangle^s\partial_u f(u,\bar u)$ is in L^2. Moreover, as u is in H^s and $\partial_u f$ is C^∞ and vanishes at 0, $\partial_u f(u,\bar u)$ is in H^s. Therefore, $\langle x\rangle^{s-d/4}\partial_u f(u,\bar u)$ is in $H^{d/4}$ by

Proposition 4.3. Let $b = \partial_u f(u,\bar{u})$. Thus, $\langle x\rangle^{s-d/4} b$ is in $C^{-d/4}$ using the Sobolev embedding from $H^{d/4}$ to $C^{-d/4}$. To prove (4.50), it suffices to establish that

$$\langle x\rangle^{2s-d/2} T_b u \in L^2 \quad \text{if } \langle x\rangle^{s-d/4} b \in C^{-d/4}. \tag{4.51}$$

Using (4.2) with $k = s - d/4$, $l = 0$, $j = [s - d/4] + 2$, $a(x) = \langle x\rangle^{s-d/4}$, and $\chi = \psi$,

$$\langle x\rangle^{s-d/4}\Delta_p = \sum_{0\le|\alpha|<j} \frac{2^{-p|\alpha|} i^{|\alpha|}}{\alpha!}\big(\partial_\xi^\alpha \psi\big)(2^{-p}D)\partial_x^\alpha \langle x\rangle^{s-d/4} + \frac{\langle x\rangle^{s-d/4-j}}{2^{pj}} R, \tag{4.52}$$

where R is bounded on L^2 with a norm independent of p. Using (4.2) with $k = s - d/4$, $l_1 = d/4 + 1$, $j_1 = [s - d/4] + 3$, $a(x) = \langle x\rangle^{s-d/4}$, and $\chi = \varphi$,

$$\langle x\rangle^{s-d/4} S_p = \sum_{0\le|\beta|<j_1} \frac{2^{-p|\beta|} i^{|\beta|}}{\beta!}\big(\partial_\xi^\beta \varphi\big)(2^{-p}D)\partial_x^\beta \langle x\rangle^{s-d/4} + \frac{\langle x\rangle^{s-d/4-j_1}}{2^{p(j_1-l_1)}} R_1, \tag{4.53}$$

where R_1 is bounded from $C^{-d/4}$ to L^∞ with a norm independent of p since $C^1 \subset L^\infty$ and R_1 is bounded from $C^{-d/4}$ to C^1. Then, we get

$$\begin{aligned}
\langle x\rangle^{2s-d/2} T_b u(x) &= \sum_{p\ge2} \langle x\rangle^{s-d/4} S_{p-2} b(x) \langle x\rangle^{s-d/4}\Delta_p u(x)\\
&= \sum_{0\le|\alpha|<j}\ \sum_{0\le|\beta|<j_1} \frac{i^{|\alpha|+|\beta|}}{\alpha!\beta!} 4^{|\beta|} \sum_{p\ge2} a^p_{\alpha,\beta}(x)\\
&\quad + \sum_{0\le|\alpha|<j} \frac{i^{|\alpha|}}{\alpha!} 4^{j_1-l_1} \langle x\rangle^{s-d/4-j_1} \sum_{p\ge2} a^p_\alpha(x)\\
&\quad + \sum_{0\le|\beta|<j_1} \frac{i^{|\beta|}}{\beta!} 4^{|\beta|} \langle x\rangle^{s-d/4-j} \sum_{p\ge2} a^p_\beta(x)\\
&\quad + \sum_{p\ge2} 4^{j_1-l_1} \langle x\rangle^{2s-d/2-j-j_1} a^p(x),
\end{aligned} \tag{4.54}$$

where

$$\begin{aligned}
a^p_{\alpha,\beta} &= 2^{-p|\beta|}\big(\partial_\xi^\beta\varphi\big)\big(2^{-(p-2)}D\big)\partial_x^\beta(\langle x\rangle^{s-d/4}) b 2^{-p|\alpha|}\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)\partial_x^\alpha(\langle x\rangle^{s-d/4})u,\\
a^p_\alpha &= 2^{-p(j_1-l_1+|\alpha|)} R_1 b\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)\partial_x^\alpha(\langle x\rangle^{s-d/4})u,\\
a^p_\beta &= 2^{-p(|\beta|+j)}\big(\partial_\xi^\beta\varphi\big)\big(2^{-(p-2)}D\big)\partial_x^\beta(\langle x\rangle^{s-d/4}) bRu,\\
a^p &= 2^{-p(j_1-l_1+j)} R_1 bRu.
\end{aligned}$$

We have

$$\begin{aligned}
\sum_{p\ge2}\|a^p\|_{L^2} &\le \sum_{p\ge2} 2^{-p(j_1-l_1+j)}\|R_1 b\|_{L^\infty}\|Ru\|_{L^2}\\
&\le C\sum_{p\ge2} 2^{-2p}\|b\|_{C^{-d/4}}\|u\|_{L^2} < +\infty,
\end{aligned} \tag{4.55}$$

$$\begin{aligned}
\sum_{p\ge2}\|a^p_\alpha\|_{L^2} &\le \sum_{p\ge2} 2^{-p(j_1-l_1+|\alpha|)}\|R_1 b\|_{L^\infty}\|\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)\partial_x^\alpha(\langle x\rangle^{s-d/4})u\|_{L^2}\\
&\le C\sum_{p\ge2} 2^{-p}\|b\|_{C^{-d/4}}\|\partial_x^\alpha(\langle x\rangle^{s-d/4})u\|_{L^2} \le C\|\langle x\rangle^{s-d/4}u\|_{L^2} < +\infty,
\end{aligned} \tag{4.56}$$

and

$$
\begin{aligned}
(4.57)\qquad \sum_{p\geq 2}\|a^p_\beta\|_{L^2} &\leq \sum_{p\geq 2} 2^{-p(|\beta|+j)}\|\big(\partial^\beta_\xi\varphi\big)(2^{-(p-2)}D)\partial^\beta_x(\langle x\rangle^{s-d/4})b\|_{L^\infty}\|Ru\|_{L^2}\\
&\leq C\sum_{p\geq 2} 2^{-p(|\beta|+j-d/4)}\|\partial^\beta_x(\langle x\rangle^{s-d/4})b\|_{C^{-d/4}}\|u\|_{L^2}\\
&\leq C\sum_{p\geq 2} 2^{-p}\|\langle x\rangle^{s-d/4}b\|_{C^{-d/4}} < +\infty.
\end{aligned}
$$

Moreover,

$$
\begin{aligned}
(4.58)\qquad \|a^p_{\alpha,\beta}\|_{L^2} &\leq 2^{-p(|\beta|+|\alpha|)}\|\big(\partial^\beta_\xi\varphi\big)(2^{-(p-2)}D)\partial^\beta_x(\langle x\rangle^{s-d/4})b\|_{L^\infty}\\
&\quad\ \|(\partial^\alpha_\xi\psi)(2^{-p}D)\partial^\alpha_x(\langle x\rangle^{s-d/4})u\|_{L^2}\\
&\leq C2^{pd/4}\|\partial^\beta_x(\langle x\rangle^{s-d/4})b\|_{C^{-d/4}}(\|\Delta_{p-1}\partial^\alpha_x(\langle x\rangle^{s-d/4})u\|_{L^2}\\
&\quad +\|\Delta_p\partial^\alpha_x(\langle x\rangle^{s-d/4})u\|_{L^2}+\|\Delta_{p+1}\partial^\alpha_x(\langle x\rangle^{s-d/4})u\|_{L^2})\\
&\leq C\|\langle x\rangle^{s-d/4}b\|_{C^{-d/4}}\|\partial^\alpha_x(\langle x\rangle^{s-d/4})u\|_{H^{d/4}}\varepsilon_p \leq C\varepsilon_p,
\end{aligned}
$$

where (ε_p) is in $l^2(\mathbb{N})$. Let $\mathcal{F}$ be the Fourier transform on $\mathbb{R}^d$. As $\mathcal{F}a^p_{\alpha,\beta}$ has support in $\{2^{p-2}\leq|\xi|\leq 9.2^{p-2}\}$, (4.10) and (4.58) imply that $\sum_{p\geq 2}a^p_{\alpha,\beta}$ is in L^2, which together with (4.54), (4.55), (4.56), and (4.57) yield (4.51). ∎

When $l(x,\xi)$ is homogeneous of degree m in ξ, C^∞ in ξ for $\xi\neq 0$, and C^ρ in x (i.e., all the derivatives $\partial^\alpha_\xi l(x,\xi)$ are C^ρ in x), Bony [2] defines the operator T_l by

$$T_l(x,D)u=\sum_{p\geq 2}S_{p-2}(\phi l)(x,D)\Delta_p u,$$

where ϕ is a C^∞ function of ξ vanishing in a neighborhood of 0 and equal to 1 outside a compact and where the Fourier multiplier S_p acting on ϕl with respect to x gives $S_p(\phi l)(x,\xi)$.

The following proposition will be used when proving Propositions 4.11 and 4.12.

PROPOSITION 4.8. *Let m, k, l, and ρ be real numbers such that $l\geq 0$ and $\rho\neq 0$. Let $b(x,\xi)$ be such that $\langle x\rangle^l b$ is homogeneous of degree m in ξ, C^∞ in ξ for $\xi\neq 0$, and C^ρ in x.*

When $\rho<0$, $\langle x\rangle^k T_b\langle x\rangle^{l-k}$ is bounded from H^t to $H^{t+\rho-m}$ for all t.

When $\rho>0$, $\langle x\rangle^k T_b\langle x\rangle^{l-k}$ is bounded from H^t to H^{t-m} for all t. Moreover, we have

$$\langle x\rangle^k T_b\langle x\rangle^{l-k}=\sum_{|\alpha|\leq\rho}\frac{1}{i^{|\alpha|}\alpha!}T_{\partial^\alpha_x(\langle x\rangle^{l-k})\langle x\rangle^k\partial^\alpha_\xi b}+R, \tag{4.59}$$

where R is bounded from H^t to $H^{t+\rho-m}$ for $t>-\rho+m$.

Proof. We start with the case $m=0$ and $b(x,\xi)=b(x)$, b in C^ρ. Using (4.2) with $k=k-l$, $l=(t+\rho)_+-t$, where $(t+\rho)_+=\max(t+\rho,0)$, $j=[\max(k-l,|\rho+t|)]+2$, $a(x)=\langle x\rangle^{k-l}$, and $\chi=\psi$,

$$\langle x\rangle^{k-l}\Delta_p=\sum_{0\leq|\alpha|<j}\frac{2^{-p|\alpha|}i^{|\alpha|}}{\alpha!}\big(\partial^\alpha_\xi\psi\big)(2^{-p}D)\partial^\alpha_x\langle x\rangle^{k-l}+\frac{\langle x\rangle^{k-l-j}}{2^{p(j-(t+\rho)_++t)}}R_1, \tag{4.60}$$

where R_1 is bounded from H^t to $H^{(t+\rho)_+}$ with a norm independent of p. Using (4.2) with $k=l$, $l=(t+\rho)_++1-\rho$, $j_1=[\max(l,|\rho+t|)]+2$, $a(x)=\langle x\rangle^l$, and $\chi=\varphi$,

$$\langle x\rangle^l S_p=\sum_{0\le|\beta|<j_1}\frac{2^{-p|\beta|}i^{|\beta|}}{\beta!}\big(\partial_\xi^\beta\varphi\big)(2^{-p}D)\partial_x^\beta\langle x\rangle^l+\frac{\langle x\rangle^{l-j_1}}{2^{p(j_1-(t+\rho)_+-1+\rho)}}R_2, \tag{4.61}$$

where R_2 is bounded from C^ρ to $C^{(t+\rho)_++1}$ with a norm independent of p. We have

$$\begin{aligned}\langle x\rangle^k T_b\langle x\rangle^{l-k}u(x)&=\sum_{p\ge2}\langle x\rangle^l S_{p-2}b(x)\langle x\rangle^{k-l}\Delta_p\langle x\rangle^{l-k}u(x)\\&=\sum_{0\le|\alpha|<j}\sum_{0\le|\beta|<j_1}\frac{i^{|\alpha|+|\beta|}}{\alpha!\beta!}4^{|\beta|}\sum_{p\ge2}a^p_{\alpha,\beta}(x)\\&\quad+\sum_{0\le|\alpha|<j}\frac{i^{|\alpha|}}{\alpha!}4^{j_1-(t+\rho)_+-1+\rho}\langle x\rangle^{l-j_1}\sum_{p\ge2}a^p_\alpha(x)\\&\quad+\sum_{0\le|\beta|<j_1}\frac{i^{|\beta|}}{\beta!}4^{|\beta|}\langle x\rangle^{k-l-j}\sum_{p\ge2}a^p_\beta(x)\\&\quad+\sum_{p\ge2}4^{j_1-(t+\rho)_+-1+\rho}\langle x\rangle^{k-j-j_1}a^p(x),\end{aligned}\tag{4.62}$$

where

$$\begin{aligned}a^p_{\alpha,\beta}&=2^{-p|\beta|}\big(\partial_\xi^\beta\varphi\big)(2^{-(p-2)}D)\partial_x^\beta(\langle x\rangle^l)b2^{-p|\alpha|}(\partial_\xi^\alpha\psi)(2^{-p}D)\partial_x^\alpha(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u,\\a^p_\alpha&=2^{-p(j_1-(t+\rho)_+-1+\rho+|\alpha|)}R_2b\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)\partial_x^\alpha(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u,\\a^p_\beta&=2^{-p(|\beta|+j-(t+\rho)_++t)}\big(\partial_\xi^\beta\varphi\big)(2^{-(p-2)}D)\partial_x^\beta(\langle x\rangle^l)bR_1u,\\a^p&=2^{-p(j_1-(t+\rho)_+-1+\rho+j-(t+\rho)_++t)}R_2bR_1u.\end{aligned}$$

The operator T defined by (4.43) is bounded from $L^\infty\times H^{t+\rho}$ to $H^{t+\rho}$ and the operator R defined by (4.44) is bounded from $C^1\times H^{(t+\rho)_+}$ to $H^{(t+\rho)_+}$ since we have $1+(t+\rho)_+>0$ (see, for example, [4]). Moreover, (4.9) implies

$$\begin{aligned}\|T_uv\|_{H^{t+\rho}}&\le\sum_{p\ge2}\|S_{p-2}u\Delta_pv\|_{H^{t+\rho}}\le C\sum_{p\ge2}2^{p(t+\rho)}\|S_{p-2}u\|_{L^2}\|\Delta_pv\|_{L^\infty}\\&\le C\sum_{p\ge2}2^{-p}\|u\|_{L^2}\|v\|_{C^{t+\rho+1}}\le C\|u\|_{L^2}\|v\|_{C^{t+\rho+1}}.\end{aligned}$$

Thus, T is bounded from $C^{t+\rho+1}\times L^2$ to $H^{t+\rho}$. As $uv=T_uv+T_vu+R(u,v)$, we get

$$\|uv\|_{H^{t+\rho}}\le C\|u\|_{H^{(t+\rho)_+}}\|v\|_{C^{(t+\rho)_++1}},$$

which implies

$$\begin{aligned}\sum_{p\ge2}\|a_p\|_{H^{t+\rho}}&\le\sum_{p\ge2}2^{-p(j_1+j-1-|t+\rho|)}\|R_2b\|_{C^{(t+\rho)_++1}}\|R_1u\|_{H^{(t+\rho)_+}}\\&\le C\sum_{p\ge2}2^{-p(1+[|t+\rho|]-|t+\rho|)}\|b\|_{C^\rho}\|u\|_{H^t}<+\infty,\end{aligned}\tag{4.63}$$

$$
\begin{aligned}
\sum_{p\geq 2}\|a^p_\alpha\|_{H^{t+\rho}} &\leq \sum_{p\geq 2} 2^{-p(j_1-(t+\rho)_+-1+\rho+|\alpha|)}\|R_2 b\|_{C^{(t+\rho)_++1}}\\
&\quad\times 2^{p((t+\rho)_+-t)}\|\big(\partial^\alpha_\xi\psi\big)(2^{-p}D)\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{H^t}\\
&\leq C\sum_{p\geq 2}2^{-p([|\rho+t|]+1-|\rho+t|)}\|b\|_{C^\rho}\|\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{H^t}\\
&\leq C\|u\|_{H^t}<+\infty,
\end{aligned}
\tag{4.64}
$$

and

$$
\begin{aligned}
\sum_{p\geq 2}\|a^p_\beta\|_{H^{t+\rho}} &\leq \sum_{p\geq 2}2^{-p(|\beta|+j-(t+\rho)_++t)}\|\big(\partial^\beta_\xi\varphi\big)(2^{-(p-2)}D)\\
&\quad\times\partial^\beta_x(\langle x\rangle^l)b\|_{C^{(t+\rho)_++1}}\|R_1u\|_{H^{(t+\rho)_+}}\\
&\leq C\sum_{p\geq 2}2^{-p(|\beta|+j-(t+\rho)_++t)}2^{p((t+\rho)_++1-\rho)}\|\partial^\beta_x(\langle x\rangle^l)b\|_{C^\rho}\|u\|_{H^t}\\
&\leq C\sum_{p\geq 2}2^{-p([|t+\rho|]+1-|t+\rho|)}\|\langle x\rangle^l b\|_{C^\rho}<+\infty.
\end{aligned}
\tag{4.65}
$$

If $\rho<0$,

$$
\begin{aligned}
2^{p(t+\rho)}\|a^p_{\alpha,\beta}\|_{L^2} &\leq 2^{p(t+\rho)}2^{-p(|\beta|+|\alpha|)}\|\big(\partial^\beta_\xi\varphi\big)(2^{-(p-2)}D)\partial^\beta_x(\langle x\rangle^l)b\|_{L^\infty}\\
&\quad\|\big(\partial^\alpha_\xi\psi\big)(2^{-p}D)\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{L^2}\\
&\leq C2^{p(t+\rho)}2^{-p\rho}\|\partial^\beta_x(\langle x\rangle^l)b\|_{C^\rho}2^{-pt}\|\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{H^t}\varepsilon_p\\
&\leq C\|\langle x\rangle^l b\|_{C^\rho}\|u\|_{H^t}\varepsilon_p\leq C\varepsilon_p,
\end{aligned}
\tag{4.66}
$$

where (ε_p) is in $l^2(\mathbb{N})$. As $\mathcal{F}a^p_{\alpha,\beta}$ has its support in $\{2^{p-2}\leq|\xi|\leq 9.2^{p-2}\}$, (4.10) and (4.66) imply that

$$
\sum_{p\geq 2}a^p_{\alpha,\beta}\quad\text{is in } H^{t+\rho}\quad\forall t\text{ and }\forall(\alpha,\beta).
\tag{4.67}
$$

Then (4.62), (4.63), (4.64), (4.65), and (4.67) show that $\langle x\rangle^kT_b\langle x\rangle^{l-k}$ is bounded from H^t to $H^{t+\rho}$ for all t if $\rho<0$.

If $\rho>0$,

$$
\begin{aligned}
2^{pt}\|a^p_{\alpha,\beta}\|_{L^2} &\leq 2^{pt}2^{-p(|\beta|+|\alpha|)}\|\big(\partial^\beta_\xi\varphi\big)(2^{-(p-2)}D)\partial^\beta_x(\langle x\rangle^l)b\|_{L^\infty}\\
&\quad\|\big(\partial^\alpha_\xi\psi\big)(2^{-p}D)\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{L^2}\\
&\leq C2^{pt}\|\partial^\beta_x(\langle x\rangle^l)b\|_{C^\rho}2^{-pt}\|\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{H^t}\varepsilon_p\\
&\leq C\|\langle x\rangle^l b\|_{C^\rho}\|u\|_{H^t}\varepsilon_p\leq C\varepsilon_p,
\end{aligned}
\tag{4.68}
$$

where (ε_p) is in $l^2(\mathbb{N})$. As $\mathcal{F}a^p_{\alpha,\beta}$ has its support in $\{2^{p-2}\leq|\xi|\leq 9.2^{p-2}\}$, (4.10) and (4.68) imply

$$
\sum_{p\geq 2}a^p_{\alpha,\beta}\quad\text{is in } H^{t}\quad\forall t\text{ and }\forall(\alpha,\beta).
\tag{4.69}
$$

Then (4.62), (4.63), (4.64), (4.65), and (4.69) show that $\langle x\rangle^kT_b\langle x\rangle^{l-k}$ is bounded from H^t to H^t for all t if $\rho>0$.

Assume now that $\rho > 0$ and $t + \rho > 0$. From

$$\sum_{p\geq 2} a^p_{0,0} = \sum_{p\geq 2} \varphi(2^{-(p-2)}D)(\langle x\rangle^l b)\psi(2^{-p}D)u = T_{\langle x\rangle^l b}u,$$

(4.62), (4.63), (4.64), and (4.65), we get (4.59) if we can prove

$$\sum_{p\geq 2} a^p_{\alpha,\beta} \in H^{t+\rho}, \quad 0 \leq |\alpha| \leq j,\ 0 \leq |\beta| \leq j_1, \text{ and } (\alpha,\beta) \neq 0. \tag{4.70}$$

When $|\beta| \geq 1$, $\partial^\beta_\xi \varphi$ has its support in $\{1/2 \leq |\xi| \leq 1\}$. Thus, for $|\beta| \geq 1$,

$$\begin{aligned}
2^{p(t+\rho)}\|a^p_{\alpha,\beta}\|_{L^2} &\leq 2^{p(t+\rho)}2^{-p(|\beta|+|\alpha|)}\|\big(\partial^\beta_\xi\varphi\big)(2^{-(p-2)}D)\partial^\beta_x(\langle x\rangle^l)b\|_{L^\infty} \\
&\quad \|\big(\partial^\alpha_\xi\psi\big)(2^{-p}D)\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{L^2} \\
&\leq C2^{p(t+\rho)}2^{-p\rho}\|\partial^\beta_x(\langle x\rangle^l)b\|_{C^\rho}2^{-pt}\|\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{H^t}\varepsilon_p \\
&\leq C\|\langle x\rangle^l b\|_{C^\rho}\|u\|_{H^t}\varepsilon_p \leq C\varepsilon_p,
\end{aligned} \tag{4.71}$$

where (ε_p) is in $l^2(\mathbb{N})$. As $\mathcal{F}a^p_{\alpha,\beta}$ has its support in $\{2^{p-2} \leq |\xi| \leq 9.2^{p-2}\}$, (4.10) and (4.71) imply that $\sum_{p\geq 2} a^p_{\alpha,\beta}$ is in $H^{t+\rho}$ for $|\beta| \geq 1$. In order to prove (4.70), it remains to show the case $\beta = 0$ and $|\alpha| \geq 1$. For $|\alpha| \geq 1$,

$$(\partial^\alpha_\xi\varphi)(\xi) + \sum_{p\geq 0} 2^{-p|\alpha|}\big(\partial^\alpha_\xi\psi\big)(2^{-p}\xi) = \partial^\alpha_\xi\left(\varphi(\xi) + \sum_{p\geq 0}\psi(2^{-p}\xi)\right) = \partial^\alpha_\xi 1 = 0.$$

Thus,

$$\big(\partial^\alpha_\xi\varphi\big)(D) + \sum_{p\geq 0} 2^{-p|\alpha|}\big(\partial^\alpha_\xi\psi\big)(2^{-p}D) = 0,$$

which yields

$$\begin{aligned}
0 &= \sum_{q\geq -1}\Delta_q(\langle x\rangle^l b)\Big(\big(\partial^\alpha_\xi\varphi\big)(D)(\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u) \\
&\quad + \sum_{p\geq 0} 2^{-p|\alpha|}\big(\partial^\alpha_\xi\psi\big)(2^{-p}D)(\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u)\Big) \\
&= \sum_{p\geq 2} S_{p-2}(\langle x\rangle^l b)2^{-p|\alpha|}\big(\partial^\alpha_\xi\psi\big)(2^{-p}D)\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u \\
&\quad + \sum_{q\geq 2}\Delta_q(\langle x\rangle^l b)2^{-(q-2)|\alpha|}\big(\partial^\alpha_\xi\varphi\big)(2^{-(q-2)}D)\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u \\
&\quad + \sum_{|p-q|\leq 2}\Delta_q(\langle x\rangle^l b)2^{-p|\alpha|}\big(\partial^\alpha_\xi\psi\big)(2^{-p}D)\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u.
\end{aligned}$$

Finally, for $|\alpha| \geq 1$,

$$\begin{aligned}
\sum_{p\geq 2} a^p_{\alpha,0} &= \sum_{p\geq 2} S_{p-2}(\langle x\rangle^l b)2^{-p|\alpha|}\big(\partial^\alpha_\xi\psi\big)(2^{-p}D)\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u \\
&= -\sum_{q\geq 2}\Delta_q(\langle x\rangle^l b)2^{-(q-2)|\alpha|} \\
&\quad \times\big(\partial^\alpha_\xi\varphi\big)(2^{-(q-2)}D)\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u \\
&\quad - \sum_{|p-q|\leq 2}\Delta_q(\langle x\rangle^l b)2^{-p|\alpha|}\big(\partial^\alpha_\xi\psi\big)(2^{-p}D)\partial^\alpha_x(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u.
\end{aligned} \tag{4.72}$$

As $\partial_\xi^\alpha \varphi$ has its support in $\{1/2 \leq |\xi| \leq 1\}$,

$$\begin{aligned}
\tag{4.73} &\|\Delta_q(\langle x\rangle^l b)2^{-(q-2)|\alpha|}\big(\partial_\xi^\alpha\varphi\big)(2^{-(q-2)}D)\partial_x^\alpha(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{L^2}\\
&\leq C2^{-q|\alpha|}\|\Delta_q(\langle x\rangle^l b)\|_{L^\infty}\\
&\|\big(\partial_\xi^\alpha\varphi\big)(2^{-(q-2)}D)\partial_x^\alpha(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{L^2}\\
&\leq C2^{-q\rho}\|\langle x\rangle^l b\|_{C^\rho}2^{-qt}\|u\|_{H^t}\varepsilon_q \leq C2^{-q(t+\rho)}\varepsilon_q,
\end{aligned}$$

where (ε_q) is in $l^2(\mathbb{N})$. Moreover, for $|q-p| \leq 2$,

$$\begin{aligned}
\tag{4.74} &\|\Delta_q(\langle x\rangle^l b)2^{-p|\alpha|}\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)\partial_x^\alpha(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{L^2}\\
&\leq C2^{-p|\alpha|}\|\Delta_q(\langle x\rangle^l b)\|_{L^\infty}\\
&\|\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)\partial_x^\alpha(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u\|_{L^2}\\
&\leq C2^{-q\rho}\|\langle x\rangle^l b\|_{C^\rho}2^{-pt}\|u\|_{H^t}\varepsilon_p \leq C2^{-p(t+\rho)}\varepsilon_p,
\end{aligned}$$

where (ε_q) is in $l^2(\mathbb{N})$.

The Fourier transform of the term from which we take the L^2 norm in (4.73) (resp., in (4.74)) has support in $\{|\xi| \leq 9.2^{q-2}\}$ (resp., in $\{|\xi| \leq 10.2^p\}$). Therefore, (4.11) yields

$$\begin{aligned}
&\sum_{q\geq 2}\Delta_q(\langle x\rangle^l b)2^{-(q-2)|\alpha|}\big(\partial_\xi^\alpha\varphi\big)(2^{-(q-2)}D)\partial_x^\alpha(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u \in H^{t+\rho},\\
&\sum_{|p-q|\leq 2}\Delta_q(\langle x\rangle^l b)2^{-p|\alpha|}\big(\partial_\xi^\alpha\psi\big)(2^{-p}D)\partial_x^\alpha(\langle x\rangle^{k-l})\langle x\rangle^{l-k}u \in H^{t+\rho}
\end{aligned}$$

as $t+\rho > 0$. This implies that $\sum_{p\geq 2} a^p_{\alpha,0}$ is in $H^{t+\rho}$ by (4.72). Finally, we have (4.70), which ends the proof of (4.59) when $m=0$ and $b(x,\xi)=b(x)$ with b in C^ρ.

We prove now the general case. Let $b(x,\xi)$ be such that $\langle x\rangle^l b$ is homogeneous of degree m in ξ, C^∞ in ξ for $\xi \neq 0$, and C^ρ in x. We decompose $b(x,\xi)$ in spherical harmonics

$$b(x,\xi) = \sum_\nu b_\nu(x)h_\nu(\xi),$$

where $\langle x\rangle^l b_\nu(x)$ belong to C^ρ with $\|\langle .\rangle^l b_\nu\|_{C^\rho} \leq 1$ and where h_ν are homogeneous of degree m, C^∞ for $\xi \neq 0$, and the sequence $\|h_\nu\|_{C^M(\mathcal{S}^{d-1})}$ is rapidly decreasing for any M. Then,

$$\begin{aligned}
\tag{4.75} \langle x\rangle^k T_b\langle x\rangle^{l-k} &= \sum_\nu \langle x\rangle^k T_{b_\nu}(\phi h_\nu)(D)\langle x\rangle^{l-k}\\
&= \sum_\nu \langle x\rangle^k T_{b_\nu}\langle x\rangle^{l-k}\langle x\rangle^{k-l}(\phi h_\nu)(D)\langle x\rangle^{l-k}.
\end{aligned}$$

If $\rho < 0$, the first part of the proof yields

$$\tag{4.76} \|\langle x\rangle^k T_{b_\nu}\langle x\rangle^{l-k}\|_{\mathcal{L}(H^t,H^{t+\rho})} \leq C \quad \forall t \quad \forall \nu$$

since $\|\langle x\rangle^l b_\nu\|_{C^\rho} \leq 1$. Moreover, Proposition 3.2 yields $\langle x\rangle^{k-l}(\phi h_\nu)(D)\langle x\rangle^{l-k} = h^1_\nu(x,D)$ with $h^1_\nu(x,D)$ in $S(m,0)$. As $\|h_\nu\|_{C^M(\mathcal{S}^{d-1})}$ is rapidly decreasing for any

M, the seminorms of $h^1_\nu(x,\xi)$ in $S(m,0)$ are rapidly decreasing. Therefore, the sequence

$$\|\langle x\rangle^{k-l}(\phi h_\nu)(D)\langle x\rangle^{l-k}\|_{\mathcal{L}(H^t,H^{t-m})} \text{ is rapidly decreasing.} \tag{4.77}$$

Formulas (4.75), (4.76), and (4.77) show that $\langle x\rangle^k T_b\langle x\rangle^{l-k}$ is bounded from H^t to $H^{t+\rho-m}$ for all t.

Assume now $\rho>0$. The first part of the proof yields

$$\|\langle x\rangle^k T_{b_\nu}\langle x\rangle^{l-k}\|_{\mathcal{L}(H^t)} \leq C \quad \forall t \quad \forall \nu. \tag{4.78}$$

So, (4.75), (4.78), and (4.77) imply that $\langle x\rangle^k T_b\langle x\rangle^{l-k}$ is bounded from H^t to H^{t-m} for all t. From (4.59) we get

$$\langle x\rangle^k T_{b_\nu}\langle x\rangle^{l-k} = T_{\langle x\rangle^l b_\nu} + R^1_\nu, \tag{4.79}$$

where R^1_ν is continuous from H^t to $H^{t+\rho}$ for all $t>-\rho$ with a norm bounded by a constant independent of ν since $\|\langle x\rangle^l b_\nu\|_{C^\rho}\leq 1$. Moreover, Proposition 3.2 and the fact that ϕ is equal to 1 outside a compact imply that

$$\begin{aligned}&\langle x\rangle^{k-l}(\phi h_\nu)(D)\langle x\rangle^{l-k}\\ &\quad=\sum_{|\alpha|\leq\rho}\frac{1}{i^{|\alpha|}\alpha!}\partial^\alpha_x(\langle x\rangle^{l-k})\langle x\rangle^{k-l}((\partial^\alpha_\xi h_\nu)\phi)(D)+R^2_\nu,\end{aligned} \tag{4.80}$$

where $R^2_\nu = r^2_\nu(x,D)$ with $r^2_\nu(x,\xi)$ in $S(m-[\rho]-1,-[\rho]-1)$. The seminorms of $r^2_\nu(x,\xi)$ in $S(m-[\rho],-[\rho])$ are rapidly decreasing. Therefore, $\|R^2_\nu\|_{\mathcal{L}(H^t,H^{t-m+[\rho]+1})}$ is rapidly decreasing.

$\langle x\rangle^l b_\nu(x)$ belongs to C^ρ, which implies that $T_{b_\nu}(\phi h_\nu)(D)$ is bounded from H^t to H^t (see [2]). As $\|\langle .\rangle^l b_\nu\|_{C^\rho}\leq 1$, the norms of $T_{b_\nu}(\phi h_\nu)(D)$ are bounded by a constant independent of ν. Moreover, the sequence of operators

$$\sum_{|\alpha|\leq\rho}\frac{1}{i^{|\alpha|}\alpha!}\partial^\alpha_x(\langle x\rangle^{l-k})\langle x\rangle^{k-l}((\partial^\alpha_\xi h_\nu)\phi)(D)$$

is bounded from H^t to H^{t-m} with rapidly decreasing norms. Together with the properties of R^1_ν and R^2_ν, this implies that

$$\begin{aligned}&\sum_\nu T_{\langle x\rangle^l b_\nu}R^2_\nu + R^1_\nu\left(\sum_{|\alpha|\leq\rho}\frac{1}{i^{|\alpha|}\alpha!}\partial^\alpha_x(\langle x\rangle^{l-k})\langle x\rangle^{k-l}((\partial^\alpha_\xi h_\nu)\phi)(D)+R^2_\nu\right)\\ &\text{is bounded from } H^t \text{ to } H^{t-m+\rho} \text{ for } t>-\rho+m.\end{aligned} \tag{4.81}$$

Therefore, (4.75), (4.79), (4.80), and (4.81) yield

$$\begin{aligned}&\langle x\rangle^k T_b\langle x\rangle^{l-k}\\ &\quad=\sum_\nu T_{\langle x\rangle^l b_\nu}\sum_{|\alpha|\leq\rho}\frac{1}{i^{|\alpha|}\alpha!}\partial^\alpha_x(\langle x\rangle^{l-k})\langle x\rangle^{k-l}((\partial^\alpha_\xi h_\nu)\phi)(D)+R_3\\ &\quad=T_{\langle x\rangle^l b}+\sum_\nu T_{\langle x\rangle^l b_\nu}\sum_{0<|\alpha|\leq\rho}\frac{1}{i^{|\alpha|}\alpha!}\partial^\alpha_x(\langle x\rangle^{l-k})\langle x\rangle^{k-l}((\partial^\alpha_\xi h_\nu)\phi)(D)+R_3,\end{aligned} \tag{4.82}$$

where R_3 is bounded from H^t to $H^{t-m+\rho}$ for $t > -\rho + m$. As $\partial_x^\alpha(\langle x\rangle^{l-k})\langle x\rangle^{k-l}$ is in S^0, $\partial_x^\alpha(\langle x\rangle^{l-k})\langle x\rangle^{k-l} - T_{\partial_x^\alpha(\langle x\rangle^{l-k})\langle x\rangle^{k-l}}$ is bounded from H^t to $H^{+\infty}$ for all t in $\mathbb{R}$ (see, for example, [10]). Together with (4.82), this yields

$$\begin{aligned}
&\sum_\nu T_{\langle x\rangle^l b_\nu} \sum_{0<|\alpha|\le\rho} \frac{1}{i^{|\alpha|}\alpha!}\partial_x^\alpha(\langle x\rangle^{l-k})\langle x\rangle^{k-l}((\partial_\xi^\alpha h_\nu)\phi)(D)\\
&= \sum_\nu \sum_{0<|\alpha|\le\rho} \frac{1}{i^{|\alpha|}\alpha!} T_{\langle x\rangle^l b_\nu} T_{\partial_x^\alpha(\langle x\rangle^{l-k})\langle x\rangle^{k-l}}((\partial_\xi^\alpha h_\nu)\phi)(D) + R_4,
\end{aligned} \tag{4.83}$$

where R_4 is continuous from H^t to $H^{+\infty}$. As $\langle x\rangle^l b$ is in C^ρ and the symbol ∂_x^α $(\langle x\rangle^{l-k})\langle x\rangle^{k-l}$ is in C^ρ, the symbolic calculus for the paradifferential operators (see, for example, [2]) implies

$$T_{\langle x\rangle^l b_\nu} T_{\partial_x^\alpha(\langle x\rangle^{l-k})\langle x\rangle^{k-l}} = T_{\partial_x^\alpha(\langle x\rangle^{l-k})\langle x\rangle^k b_\nu} + R_5, \tag{4.84}$$

where R_5 is bounded from H^t to $H^{t+\rho}$ for all t with a norm bounded by a constant independent of ν since $\|\langle.\rangle^l b_\nu\|_{C^\rho} \le 1$. Equations (4.82), (4.83), and (4.84) yield (4.59). ∎

When $\rho > 0$ is not an integer, Bony [2] defines the class Σ_ρ^m of symbols $l(x,\xi) = \sum_{j<\rho} l_{m-j}(x,\xi)$, where $l_{m-j}(x,\xi)$ is homogeneous of degree $m-j$ in ξ, C^∞ in ξ for $\xi \ne 0$, and $C^{\rho-j}$ in x. We define two other classes of symbols allowing us to construct the operator Q in the second step of the proof.

Definition 4.9. *Let there exist two real numbers m and s. We call $\Sigma_{s,s'}^m$ the class symbols $l(x,\xi)$, where $l(x,\xi)$ is homogeneous of degree m in ξ, C^∞ in ξ for $\xi \ne 0$, and $H_{s'}^s$ in x.*

Let there exist two real numbers m and $s > d/2$ such that $s-d/2$ is not an integer. We call $\widetilde{\Sigma}_s^m$ the class of symbols $l(x,\xi) = \sum_{j<s-d/2} l_{m-j}(x,\xi)$, where $l_{m-j}(x,\xi)$ is in $\Sigma_{s,-j}^{m-j}$.

Lemma 4.10.

(a) *Let m and s be two real numbers. Assume $l(x,\xi)$ is in $\Sigma_{s,s'}^m$. Then, $\partial_x^\alpha l(x,\xi)$ is in $\Sigma_{s,s'-|\alpha|}^m$ for all $|\alpha|$.*

(b) *Let m, m', s, s', and s'' be real numbers such that $s' \le 0$, $s'' \le 0$, $s + \max(s', s'') > d/2$, and $s + s' + s'' \ge 0$. Let p be in $\Sigma_{s,s'}^m$ and q in $\Sigma_{s,s''}^{m'}$. Then, pq is in $\Sigma_{s,s'+s''}^{m+m'}$.*

(c) *Let m, m', s, and s' be two real numbers. Let p be in $\Sigma_{s,s'}^m$ and q in $S(m',0)$. Then, pq is in $\Sigma_{s,s'}^{m+m'}$.*

Proof. (a) ∂_x^α has its symbol in $S(|\alpha|,0)$ and $l(x,\xi)$ is $H_{s'}^s$ in x. So, $\partial_x^\alpha l(x,\xi)$ is $H_{s'-|\alpha|}^s$ in x by Lemma 4.4. Thus, $\partial_x^\alpha l(x,\xi)$ is in $\Sigma_{s,s'-|\alpha|}^m$.

(b) We may assume that $s'' \ge s'$, which yields $s + s'' > d/2$. So, as p is $H^{s+s'}$ in x and q is $H^{s+s''}$ in x, pq is $H^{s+s'}$ in x using (4.39) with $r_1 = s + s'$ and $r_2 = s + s''$. Moreover, as $\langle x\rangle^s p$ is $H^{s'}$ in x and q is $H^{s+s''}$ in x, $\langle x\rangle^s pq$ is $H^{s'}$ in x using (4.39) with $r_1 = s'$ and $r_2 = s + s''$. So, pq is $H_{s'+s''}^s$ in x, which yields that pq is in $\Sigma_{s,s'+s''}^{m+m'}$.

(c) q is C^∞ in x with bounded derivatives. So, pq is in $H^{s+s'}$ and $\langle x\rangle^s pq$ is in $H^{s'}$. Therefore, pq is in $\Sigma_{s,s'}^{m+m'}$. ∎

The following proposition states the symbolic calculus properties needed to construct the operator Q in the second step of the proof.

Proposition 4.11. *Let m, m', and s be real numbers such that $s > d/2$ and $s - d/2$ is not an integer.*

(i) *Let p be in $\widetilde{\Sigma}^m_s$. Then, T_p is bounded from $H^t_{t'}$ to $H^t_{t'-m}$ for all t and t'. Moreover, $\langle x\rangle^{s-d/4+k}T_p\langle x\rangle^{-k}$ is bounded from H^t to $H^{t-d/4-m}$ for all t.*

(ii) *Let p be in $\widetilde{\Sigma}^m_s$ and q in $\widetilde{\Sigma}^{m'}_s$. Then*

$$T_p\circ T_q=\sum_{j+k+|\alpha|<s-d/2}\frac{1}{i^\alpha\alpha!}T_{\partial^\alpha_\xi p_{m-j}\partial^\alpha_x q_{m'-k}}+R,$$

where R is bounded from $H^t_{t'}$ to $H^{t+s-d/2}_{t'-m-m'}$ for all t and t'.

(iii) *Let p be in $\widetilde{\Sigma}^m_s$ and let $q(x,\xi)=\sum_{j<s-d/2}q_{m'-j}(x,\xi)$ with $q_{m'-j}(x,\xi)$ in $S(m'-j,0)$ homogeneous of degree $m'-j$ in ξ. Then*

$$T_p\circ q(x,D)=\sum_{j+k+|\alpha|<s-d/2}\frac{1}{i^\alpha\alpha!}T_{\partial^\alpha_\xi p_{m-j}\partial^\alpha_x q_{m'-k}}+R,$$

where R is bounded from $H^t_{t'}$ to $H^{t+s-d/2}_{t'-m-m'}$ for all t and t'.

(iv) *Let $p=\sum_{j<s-d/2}p_{m-j}(x,\xi)$ with $p_{m-j}(x,\xi)$ in $S(m-j,0)$ homogeneous of degree $m-j$ in ξ, and q is in $\widetilde{\Sigma}^{m'}_s$. Then*

$$p(x,D)\circ T_q=\sum_{j+k+|\alpha|<s-d/2}\frac{1}{i^\alpha\alpha!}T_{\partial^\alpha_\xi p_{m-j}\partial^\alpha_x q_{m'-k}}+R,$$

where R is bounded from $H^t_{t'}$ to $H^{t+s-d/2}_{t'-m-m'}$ for all t and t'.

Proof. (i) As $\widetilde{\Sigma}^m_s\subset\Sigma^m_{s-d/2}$, T_p is bounded from H^t to H^{t-m} using the symbolic calculus of paradifferential operators (see [2]). Moreover, $\langle x\rangle^kT_p\langle x\rangle^{-k}$ is bounded from H^t to H^{t-m} for all t and k by using Proposition 4.8 for each p_{m-j}. Thus, T_p is bounded from $H^t_{t'}$ to $H^t_{t'-m}$ for all t and t'. Finally, as $\langle x\rangle^{s-d/4}p_{m-j}$ is in $C^{-d/4-j}$, $\langle x\rangle^{s-d/4+k}T_p\langle x\rangle^{-k}$ is bounded from H^t to $H^{t-d/4-m}$ for all t, using Proposition 4.8 for each p_{m-j}.

(ii) As $\widetilde{\Sigma}^m_s\subset\Sigma^m_{s-d/2}$ and $\widetilde{\Sigma}^{m'}_s\subset\Sigma^{m'}_{s-d/2}$, R is $s-d/2-m-m'$-regularizing by using the symbolic calculus of paradifferential operators (see [2]).

It remains to prove that $\langle x\rangle^{t+s-d/2}Ru$ is in $H^{t'-m-m'}$ for u in $H^t_{t'}$. By Proposition 4.3, it suffices to prove that $\langle x\rangle^{t+s-d/2}R\langle x\rangle^{-t+d/4}$ is bounded from $H^{t'+d/4}$ to $H^{t'-m-m'}$. As $\sum_{j+k+|\alpha|<s-d/2}\frac{1}{i^\alpha\alpha!}\partial^\alpha_\xi p_{m-j}\partial^\alpha_x q_{m'-k}$ is in $\widetilde{\Sigma}^{m+m'}_s$ by (b) of Lemma 4.10, $\langle x\rangle^{t+s-d/2}\sum_{j+k+|\alpha|<s-d/2}\frac{1}{i^\alpha\alpha!}T_{\partial^\alpha_\xi p_{m-j}\partial^\alpha_x q_{m'-k}}\langle x\rangle^{-t+d/4}$ is bounded from $H^{t'+d/4}$ to $H^{t'-m-m'}$ by (i). It remains to show that the operator $\langle x\rangle^{t+s-d/2}T_pT_q\langle x\rangle^{-t+d/4}$ is bounded from $H^{t'+d/4}$ to $H^{t'-m-m'}$.

As

$$\langle x\rangle^{t+s-d/2}T_pT_q\langle x\rangle^{-t+d/4}=\langle x\rangle^{t+s-d/2}T_p\langle x\rangle^{-t+d/4}\langle x\rangle^{t-d/4}T_q\langle x\rangle^{-t+d/4},$$

$\langle x\rangle^{t+s-d/2}T_pT_q\langle x\rangle^{-t+d/4}$ is bounded from $H^{t'+d/4}$ to $H^{t'-m-m'}$ by using (i) with $\langle x\rangle^{t+s-d/2}T_p\langle x\rangle^{-t+d/4}$ and with $\langle x\rangle^{t-d/4}T_q\langle x\rangle^{-t+d/4}$.

(iii) As $q(x,\xi)$ is in $S^{m'}$, $q(x,D)-T_q$ is bounded from H^t to $H^{+\infty}$ (see, for example, [10]). As $\widetilde{\Sigma}^m_s\subset\Sigma^m_{s-d/2}$ and $S^{m'}\subset\Sigma^{m'}_{s-d/2}$, the symbolic calculus for the paradifferential operators (see [2]) implies that

$$T_p\circ T_q-\sum_{j+k+|\alpha|<s-d/2}\frac{1}{i^\alpha\alpha!}T_{\partial^\alpha_\xi p_{m-j}\partial^\alpha_x q_{m'-k}}$$

is $s-d/2-m-m'$-regularizing. Thus, Ru is in $H^{t+s-d/2-m-m'}$.

It remains to prove that $\langle x\rangle^{t+s-d/2}Ru$ is in $H^{t'-m-m'}$ for u in $H^t_{t'}$. By Proposition 4.3, it suffices to show that $\langle x\rangle^{t+s-d/2}R\langle x\rangle^{-t+d/4}$ is bounded from $H^{t'+d/4}$ to $H^{t'-m-m'}$. As $\sum_{j+k+|\alpha|<s-d/2}\frac{1}{i^\alpha\alpha!}\partial_\xi^\alpha p_{m-j}\partial_x^\alpha q_{m'-k}$ is in $\widetilde{\Sigma}_s^{m+m'}$ by (c) of Lemma 4.10, $\langle x\rangle^{t+s-d/2}\sum_{j+k+|\alpha|<s-d/2}\frac{1}{i^\alpha\alpha!}T_{\partial_\xi^\alpha p_{m-j}\partial_x^\alpha q_{m'-k}}\langle x\rangle^{-t+d/4}$ is bounded from $H^{t'+d/4}$ to $H^{t'-m-m'}$ by (i). It remains to show that the operator $\langle x\rangle^{t+s-d/2}T_pq(x,D)\langle x\rangle^{-t+d/4}$ is bounded from $H^{t'+d/4}$ to $H^{t'-m-m'}$.

We have

$$\langle x\rangle^{t+s-d/2}T_pq(x,D)\langle x\rangle^{-t+d/4}=\langle x\rangle^{t+s-d/2}T_p\langle x\rangle^{-t+d/4}\langle x\rangle^{t-d/4}q(x,D)\langle x\rangle^{-t+d/4},$$

$\langle x\rangle^{t-d/4}q(x,D)\langle x\rangle^{-t+d/4} = q_1(x,D)$ with $q_1(x,\xi)$ in $S(0,m')$ by Proposition 3.2. $\langle x\rangle^{t-d/4}q(x,D)\langle x\rangle^{-t+d/4}$ is bounded from $H^{t'+d/4}$ to $H^{t'+d/4-m'}$ since $q_1(x,\xi)$ is in $S(0,m')$, and $\langle x\rangle^{t+s-d/2}T_p\langle x\rangle^{-t+d/4}$ is bounded from $H^{t'+d/4-m'}$ to $H^{t'-m-m'}$ by (i). Thus, $\langle x\rangle^{t+s-d/2}T_pq(x,D)\langle x\rangle^{-t+d/4}$ is bounded from $H^{t'+d/4}$ to $H^{t'-m-m'}$.

The proof of (iv) is similar to the proof of (iii). ◻

The following proposition will be used to bound the terms coming from the nonlinearity in the energy estimates of the third step of the proof.

PROPOSITION 4.12. *Let $s>d/2$ such that $s-d/2$ is not an integer. Let $m\geq 0$ and $k\geq 0$ such that $k+m=2s-d/2$. Let $p(x,\xi)$ be in $S(m,k)$ and q in $\widetilde{\Sigma}_s^0$. Let u be in H_0^s. Then, there exist N symbols p_j, $1\leq j\leq N$, in $S(m,k)$ with support included in the support of $p(x,\xi)$ such that*

$$\|p(x,D)T_qu\|_{L^2}\leq C\left(\sum_{1\leq j\leq N}\|p_j(x,D)u\|_{L^2}+1\right). \tag{4.85}$$

Moreover, when $m=0$ or when $q\equiv 0$ in a neighborhood of the support of p, we can take $p_j(x,\xi)=0$ for all $1\leq j\leq N$.

Proof. By Proposition 3.2, $p(x,D)=p_1(x,D)\langle x\rangle^k$, where $p_1(x,\xi)$ is in $S(m,0)$. If $m=0$, $p_1(x,D)$ is bounded on L^2. It remains to show that $\langle x\rangle^{2s-d/2}T_qu$ belongs to L^2. As u is in H_0^s, $\langle x\rangle^{s-d/4}u$ is in $H^{d/4}$ by Proposition 4.3. Moreover, $\langle x\rangle^{2s-d/2}T_q\langle x\rangle^{d/4-s}$ is bounded from $H^{d/4}$ to L^2 by (i) of Proposition 4.11. This concludes the case $m=0$.

If $0<m\leq 2s-d/2$, we choose a real number ζ such that $\max(0,k-s)\leq\zeta\leq k$ and $s-\zeta-d/2$ is not an integer. Then

$$p(x,D)T_qu=p_1(x,D)\langle x\rangle^kT_q\langle x\rangle^{-k+\zeta}\langle x\rangle^{k-\zeta}u. \tag{4.86}$$

As $0\leq k-\zeta\leq s$ and u is in H_0^s, $\langle x\rangle^{k-\zeta}u$ is in $H^{s-k+\zeta}$ by Proposition 4.3. Let $0\leq j<s-d/2$. As $s-\zeta-d/2$ is not an integer, we consider the cases $s-\zeta-d/2-j<0$ and $s-\zeta-d/2-j>0$. If $s-\zeta-d/2-j<0$, $\langle x\rangle^kT_{q_{-j}}\langle x\rangle^{-k+\zeta}$ is bounded from H^t to $H^{t+s-\zeta-d/2}$ for all t by Proposition 4.8. Thus, $\langle x\rangle^kT_{q_{-j}}\langle x\rangle^{-k+\zeta}$ is bounded from $H^{s-k+\zeta}$ to H^m. As $\langle x\rangle^{k-\zeta}u$ is in $H^{s-k+\zeta}$, and $p_1(x,D)$ is bounded from H^m to L^2, we get

$$\|p(x,D)T_{q_{-j}}u\|_{L^2}\leq C,\quad s-\zeta-d/2<j. \tag{4.87}$$

If $s-\zeta-d/2-j>0$, then Proposition 4.8 implies

$$\langle x\rangle^kT_{q_j}\langle x\rangle^{-k+\zeta}=\sum_{|\alpha|\leq s-\zeta-d/2-j}\frac{1}{i^\alpha\alpha!}T_{\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j}}+R_1^j, \tag{4.88}$$

where R_1^j is bounded from $H^{s-k+\zeta}$ to H^m. As $\langle x\rangle^{k-\zeta}u$ is in $H^{s-k+\zeta}$, and $p_1(x,D)$ is bounded from H^m to L^2, we get

$$\|p_1(x,D)\langle x\rangle^{k-\zeta}R_1^j u\|_{L^2} \leq C.$$

Moreover, as p_1 is in S^m,

$$\forall t \text{ in } \mathbb{R},\ p_1(x,D) - T_{p_1} \text{ is bounded from } H^t \text{ to } H^{+\infty} \tag{4.89}$$

(see, for example, [10]). So, it suffices to look at

$$T_{p_1}T_{\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j}}.$$

As p_1 is $C^{s-\zeta-d/2-j}$ in x and $\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j}$ is $C^{s-\zeta-d/2-j}$ in x, the symbolic calculus for the paradifferential operators (see, for example, [10]) yields

$$T_{p_1}T_{\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j}} = \sum_{|\beta|<s-\zeta-d/2-j}\frac{1}{i^\beta\beta!}T_{\partial_\xi^\beta p_1\partial_x^\beta\left(\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j}\right)} + R_2^j, \tag{4.90}$$

where R_2^j is $s-\zeta-d/2-m$-regularizing. When $q\equiv 0$ in a neighborhood of the support of p, (4.86), (4.87), (4.88), and (4.90) imply (4.85) with $p_j(x,\xi)=0$ for all $1\leq j\leq N$.

It remains to prove the general case. Let c_γ, $\gamma\in\mathbb{R}^d$, be defined by

$$c_0 = 1,\quad c_\gamma = -\sum_{0<\omega\leq\gamma}\frac{1}{i^{|\omega|}\omega!}c_{\gamma-\omega}.$$

The equalities

$$\sum_{0\leq\omega\leq\gamma}\frac{1}{i^{|\omega|}\omega!}c_{\gamma-\omega} = \delta_{\gamma 0}$$

and the symbolic calculus for the paradifferential operators imply that

$$\begin{aligned}&\sum_{|\gamma|<s-\zeta-d/2-j-|\beta|} c_\gamma T_{\partial_\xi^\gamma\partial_x^\beta\left(\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j}\right)}T_{\partial_x^\gamma\partial_\xi^\beta p_1}\\ &\quad = T_{\partial_\xi^\beta p_1\partial_x^\beta\left(\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j}\right)} + R_3^j,\end{aligned} \tag{4.91}$$

where R_3^j is $s-\zeta-d/2-m$-regularizing. By using the analogue of (4.89) for $\partial_x^\gamma\partial_\xi^\beta p_1$, (4.91) becomes

$$\begin{aligned}&\sum_{|\gamma|<s-\zeta-d/2-j-|\beta|} c_\gamma T_{\partial_\xi^\gamma\partial_x^\beta\left(\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j}\right)}\partial_x^\gamma\partial_\xi^\beta p_1(x,D)\\ &\quad = T_{\partial_\xi^\beta p_1\partial_x^\beta\left(\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j}\right)} + R_4^j,\end{aligned} \tag{4.92}$$

where R_4^j is $s-\zeta-d/2-m$-regularizing. As R_2^j and R_4^j are $s-\zeta-d/2-m$-regularizing, we have

$$\|R_2^j\langle x\rangle^{k-\zeta}u\|_{L^2} + \|R_4^j\langle x\rangle^{k-\zeta}u\|_{L^2} \leq C, \tag{4.93}$$

since $\langle x\rangle^{k-\zeta}u$ is in $H^{s-k+\zeta}$. Finally, (4.86), (4.87), (4.88), (4.90), (4.92), and (4.93) imply

$$\begin{aligned}\|p(x,D)T_q u\|_{L^2} \le C\Bigg(&\sum_{\max(j+|\alpha|,j+|\beta|+|\gamma|)<s-\zeta-d/2}\\ &\times \left\|T_{\partial_\xi^\gamma\partial_x^\beta(\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j})}\partial_x^\gamma\partial_\xi^\beta p_1(x,D)\langle x\rangle^{k-\zeta}u\right\|_{L^2}+1\Bigg).\end{aligned} \tag{4.94}$$

As $j+|\beta|+ < s-\zeta-d/2$, $\partial_\xi^\gamma\partial_x^\beta(\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j})$ is in $\Sigma^{-j-|\gamma|}_{s-\zeta-d/2-j-|\beta|}$ and the paradifferential operator $T_{\partial_\xi^\gamma\partial_x^\beta(\partial_x^\alpha(\langle x\rangle^{-k+\zeta})\langle x\rangle^k\partial_\xi^\alpha q_{-j})}$ is bounded on L^2. Inequality (4.94) becomes

$$\begin{aligned}&\|p(x,D)T_q u\|_{L^2}\\ &\le C\left(\sum_{\max(j+|\alpha|,j+|\beta|+|\gamma|)<s-\zeta-d/2}\|\partial_x^\gamma\partial_\xi^\beta p_1(x,D)\langle x\rangle^{k-\zeta}u\|_{L^2}+1\right).\end{aligned} \tag{4.95}$$

Proposition 3.2 implies that $\partial_x^\gamma\partial_\xi^\beta p_1(x,D)\langle x\rangle^{k-\zeta} = p_{j,\alpha,\beta,\gamma}(x,D)$ with $p_{j,\alpha,\beta,\gamma}(x,\xi)$ in $S(m-|\beta|,k-|\gamma|-\zeta)$. As $\zeta\ge 0$, $p_{j,\alpha,\beta,\gamma}(x,\xi)$ is in $S(m,k)$, which together with (4.95) implies (4.85). ∎

5. Proof of the main theorems. We extend the results of [6] to the following equation:

$$\begin{cases} i\dfrac{\partial u}{\partial t}+\dfrac{1}{2}\displaystyle\sum_{j,l=1}^d \partial_{x_j}a^{jl}(x)\partial_{x_l}u = f(u,\bar u), \quad 0<t<T, \quad x\in\mathbb{R}^d,\\ u|_{t=0}=u_0,\end{cases} \tag{5.1}$$

where the coefficients satisfy (2.1), (2.2), and (2.4) and where f is in $C^\infty(\mathbb{C}^2)$ and vanishes at $(0,0)$. Then

$$-\frac{1}{2}\sum_{j,l=1}^d \partial_{x_j}a^{jl}(x)\partial_{x_l}u = Au = a_2(x,D)u + a_1(x,D)u, \tag{5.2}$$

where

$$a_2(x,\xi) = 1/2\sum_{j,l=1}^d a^{jl}(x)\xi_j\xi_l \in S(2,0) \tag{5.3}$$

and

$$a_1(x,\xi) = -i\sum_{j,l=1}^d \partial_{x_j}a^{jl}(x)\xi_l \in S(1,-1). \tag{5.4}$$

By eventually shrinking $\mathcal{E}$ and the size of the support of θ, we may assume in the following the existence of a real function $\theta_1(x)$ in $S(0,0)$ such that θ_1 is equal to 1 on the support of θ and $\theta_1 u$ is in $L^\infty(0,T,H_0^s)$.

We now start with the first step of the proof. We define

$$\lambda_1 = \partial_u f(0,0), \quad \lambda_2 = \partial_{\bar u}f(0,0), \quad g(u,\bar u) = f(u,\bar u)-\lambda_1 u-\lambda_2\bar u, \tag{5.5}$$

g vanishes to the second order at 0, and θu is a solution of

$$i\frac{\partial \theta u}{\partial t} - A\theta u = \lambda_1\theta u + \lambda_2\overline{\theta u} + \theta g\big(\theta_1 u, \overline{\theta_1 u}\big) + [\theta, A]u, \quad 0 < t < T, \quad x \in \mathbb{R}^d. \tag{5.6}$$

As $\theta_1 u$ is in $L^\infty(0,T,H^s_0)$, and as g vanishes to the second order at 0, (4.46) and Lemma 4.7 imply that θu is a solution of

$$\begin{aligned} i\frac{\partial \theta u}{\partial t} - A\theta u = {}& \lambda_1\theta u + \lambda_2\overline{\theta u} + \theta T_{\frac{\partial g}{\partial u}\left(\theta_1 u, \overline{\theta_1 u}\right)}\theta_1 u + \theta T_{\frac{\partial g}{\partial \bar{u}}\left(\theta_1 u, \overline{\theta_1 u}\right)}\overline{\theta_1 u} \\ & + \theta r\big(\theta_1 u, \overline{\theta_1 u}\big) + [\theta, A]u, \quad 0 < t < T, \quad x \in \mathbb{R}^d, \end{aligned} \tag{5.7}$$

where $r(\theta_1 u, \overline{\theta_1 u})$ is in $L^\infty(0,T,H^{2s-d/2}_0)$. As $\theta_1 u$ is in $L^\infty(0,T,H^s_0)$ and as g vanishes to the second order at 0, we have seen when proving Lemma 4.7 that $\partial_u g(\theta_1 u, \overline{\theta_1 u})$ and $\partial_{\bar{u}} g(\theta_1 u, \overline{\theta_1 u})$ are in $L^\infty(0,T,H^s_0)$. Therefore, $\partial_u g(\theta_1 u, \overline{\theta_1 u})$ and $\partial_{\bar{u}} g(\theta_1 u, \overline{\theta_1 u})$ are in $L^\infty(0,T,\widetilde{\Sigma}^0_s)$. Items (iii) and (iv) of Proposition 4.11 yield

$$\begin{aligned} &[\theta, T_{\frac{\partial g}{\partial u}(\theta_1 u, \overline{\theta_1 u})}] = T_{l_\theta} + R, \\ &[\theta, T_{\frac{\partial g}{\partial \bar{u}}(\theta_1 u, \overline{\theta_1 u})}] = T_{\widetilde{l_\theta}} + \widetilde{R}, \end{aligned} \tag{5.8}$$

where l_θ and $\widetilde{l_\theta}$ are in $L^\infty(0,T,\widetilde{\Sigma}^0_s)$ with support included in the support of $\nabla\theta$, and where R and $\widetilde{R}$ are bounded from $L^\infty(0,T,H^t_{t'})$ to $L^\infty(0,T,H^{t+s-d/2}_{t'})$. We define $r_1(u,\bar{u}) = R\theta_1 u + \widetilde{R}\overline{\theta_1 u} + \theta r(\theta_1 u, \overline{\theta_1 u})$. Then, (5.7) becomes

$$\begin{aligned} i\frac{\partial \theta u}{\partial t} - A\theta u = {}& \lambda_1\theta u + \lambda_2\overline{\theta u} + T_{\frac{\partial g}{\partial u}(\theta_1 u, \overline{\theta_1 u})}\theta u + T_{\frac{\partial g}{\partial \bar{u}}(\theta_1 u, \overline{\theta_1 u})}\overline{\theta u} \\ & + r_1(u,\bar{u}) + T_{l_\theta}\theta_1 u + T_{\widetilde{l_\theta}}\overline{\theta_1 u} + [\theta, A]u, \quad 0 < t < T, \quad x \in \mathbb{R}^d, \end{aligned} \tag{5.9}$$

where $r_1(u,\bar{u})$ is in $L^\infty(0,T,H^{2s-d/2}_0)$.

We want to adapt the strategy of [6] to (5.9). However, we do not know how to deal with the terms evaluated at $\overline{\theta u}$. In fact, if $Jz = \bar{z}$ for any complex number z and if $b(x,\xi)$ is a symbol, we have

$$Jb(x,D) = b^J(x,D)J, \text{ where } b^J(x,\xi) = \bar{b}(x,-\xi). \tag{5.10}$$

So, microlocal information on θu at (x_0,ξ_0) implies for $\overline{\theta u}$ microlocal information at $(x_0,-\xi_0)$, but not at (x_0,ξ_0). Therefore, we now proceed with the second step of the proof. We look for an operator Q such that $v = \theta u - Q\overline{\theta u}$ satisfies an equation of type (5.9) without term evaluated at $\bar{v}$. This is the aim of the following proposition.

Proposition 5.1. *Let u be the solution of* (5.1) *and let s be in I_d defined by* (2.10). *Assume there exist real functions $\theta(x)$ and $\theta_1(x)$ in $S(0,0)$ such that θ_1 is equal to 1 on the support of θ and $\theta_1 u$ is in $L^\infty(0,T,H^s_0)$. Then, there exists an operator Q with $Q = q_1(x,D) + T_{q_2}$ such that $q_1(x,\xi)$ is in $S(-2,0)$ and $q_2(t,x,\xi)$ is in $L^\infty(0,T,\widetilde{\Sigma}^{-2}_s)$. Moreover, $v = \theta u - Q\overline{\theta u}$ is in $L^\infty(0,T,H^s_0)$ and satisfies*

$$\begin{cases} i\dfrac{\partial v}{\partial t} - Av = (l_1(x,D) + T_{l_2})v + r_2(u,\bar{u}) \\ \quad +(l^1_\theta(x,D) + T_{l^2_\theta})\theta_1 u + (\widetilde{l^1_\theta}(x,D) + T_{\widetilde{l^2_\theta}})\overline{\theta_1 u}, \quad 0 < t < T, \quad x \in \mathbb{R}^d, \\ v|_{t=0} = \theta u_0 - (q_1(x,D) + T_{q_2(0,.)})\overline{\theta u_0} = v_0, \end{cases} \tag{5.11}$$

where $r_2(u,\bar{u})$ is in $L^\infty(0,T,H_0^{2s-d/2})$, $l_1(x,\xi)$ is in $S(0,0)$, $l^1_\theta(x,\xi)$ and $\widetilde{l^1_\theta}(x,\xi)$ are in $S(1,-1)$, $l_2(t,x,\xi)$, $l^2_\theta(t,x,\xi)$, and $\widetilde{l^2_\theta}(t,x,\xi)$ are in $L^\infty(0,T,\widetilde{\Sigma}^0_s)$, and where the support of l^1_θ, $\widetilde{l^1_\theta}$, l^2_θ and of $\widetilde{l^2_\theta}$ are included in the support of $\nabla\theta$. Finally, when $\lambda_2=\partial_{\bar{u}}f(0,0)=0$, we may take $q_1(x,\xi)\equiv 0$.

The proof of Proposition 5.1 is a consequence of the following lemmas.

LEMMA 5.2. *Let u be the solution of (5.1) and let $s>d/2$ such that $s-d/2$ is not an integer. Assume there exist real functions $\theta(x)$ and $\theta_1(x)$ in $S(0,0)$ such that θ_1 is equal to 1 on the support of θ and $\theta_1 u$ is in $L^\infty(0,T,H_0^s)$. Let an operator Q with $Q=q_1(x,D)+T_{q_2}$ be such that $q_1(x,\xi)$ is in $S(-2,0)$, $q_2(t,x,\xi)$ is in $L^\infty(0,T,\widetilde{\Sigma}^{-2}_s)$, and $\partial_t q_2(t,x,\xi)$ is in $L^\infty(0,T,\widetilde{\Sigma}^0_s)$. Then, $v=\theta u-Q\overline{\theta u}$ is in $L^\infty(0,T,H_0^s)$ and satisfies*

$$(5.12)\qquad \begin{cases} i\dfrac{\partial v}{\partial t}-Av=(l_1(x,D)+T_{l_2})v+(\widetilde{l_1}(x,D)+T_{\widetilde{l_2}})\bar{v}+r_2(u,\bar{u})\\ \quad +(l^1_\theta(x,D)+T_{l^2_\theta})\theta_1 u+(\widetilde{l^1_\theta}(x,D)+T_{\widetilde{l^2_\theta}})\overline{\theta_1 u},\quad 0<t<T,\quad x\in\mathbb{R}^d,\\ v|_{t=0}=\theta u_0-(q_1(x,D)+T_{q_2(0,.)})\overline{\theta u_0}=v_0, \end{cases}$$

where $r_2(u,\bar{u})$ is in $L^\infty(0,T,H_0^{2s-d/2})$, $l_1(x,\xi)$ and $\widetilde{l_1}(x,\xi)$ are in $S(0,0)$, $l^1_\theta(x,\xi)$ and $\widetilde{l^1_\theta}(x,\xi)$ are in $S(1,-1)$, $l_2(t,x,\xi)$, $\widetilde{l^2}(t,x,\xi)$, $l^2_\theta(t,x,\xi)$, and $\widetilde{l^2_\theta}(t,x,\xi)$ are in $L^\infty(0,T,\widetilde{\Sigma}^0_s)$, and where the support of l^1_θ, $\widetilde{l^1_\theta}$, l^2_θ and of $\widetilde{l^2_\theta}$ are included in the support of $\nabla\theta$.

LEMMA 5.3. *There exists $q_1(x,\xi)$ in $S(-2,0)$ such that v satisfies (5.12) with $\widetilde{l_1}(x,\xi)=0$. Moreover, when $\lambda_2=\partial_{\bar{u}}f(0,0)=0$, we may take $q_1(x,\xi)\equiv 0$.*

LEMMA 5.4. *We make the assumptions of Lemma 5.2 and we assume furthermore that s is in I_d defined by (2.10). With the choice of $q_1(x,\xi)$ made in Lemma 5.3, there exists $q_2(t,x,\xi)$ in $L^\infty(0,T,\widetilde{\Sigma}^{-2}_s)$ with $\partial_t q_2(t,x,\xi)$ in $L^\infty(0,T,\widetilde{\Sigma}^0_s)$ such that v satisfies (5.11).*

Proof of Lemma 5.2. φ and ψ are real functions and may be chosen even in ξ. So, J commutes with S_p and Δ_p. Therefore, (5.10) yields $JT_p=T_{p^J}J$.

As θu is in $L^\infty(0,T,H_0^s)$ and as $v=\theta u-Q\overline{\theta u}$, v is in $L^\infty(0,T,H_0^s)$ by Lemma 4.4 and (i) of Proposition 4.11. As θu satisfies (5.9), v is a solution of

$$(5.13)\qquad \begin{aligned} i\frac{\partial v}{\partial t}-Av&=\lambda_1\theta u+\lambda_2\overline{\theta u}+T_{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})}\theta u+T_{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})}\overline{\theta u}\\ &\quad +r_1(u,\bar{u})+T_{l_\theta}\theta_1 u+T_{\widetilde{l_\theta}}\overline{\theta_1 u}+[\theta,A]\theta_1 u\\ &\quad -iT_{\partial_t q_2}\overline{\theta u}-Qi\partial_t\overline{\theta u}-AQ\overline{\theta u},\quad 0<t<T,\quad x\in\mathbb{R}^d. \end{aligned}$$

Taking the conjugate of (5.9), we have

$$(5.14)\qquad \begin{aligned} i\frac{\partial\overline{\theta u}}{\partial t}-A\overline{\theta u}&=\overline{\lambda_1\theta u}+\overline{\lambda_2}\theta u+T_{\overline{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})}}\overline{\theta u}+T_{\overline{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})}}\theta u\\ &\quad +\overline{r_1(u,\bar{u})}+T_{l^J_\theta}\overline{\theta_1 u}\\ &\quad +T_{\widetilde{l_\theta}^J}\theta_1 u+[\theta,A]\overline{\theta_1 u},\quad 0<t<T,\quad x\in\mathbb{R}^d, \end{aligned}$$

which together with (5.13) yields

$$
\begin{aligned}
i\frac{\partial v}{\partial t} - Av = {} & (\lambda_1 + T_{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})} + Q(\overline{\lambda_2} + T_{\overline{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})}}))\theta u \\
& + \Big(\lambda_2 + T_{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})} - iT_{\partial_t q_2} - QA + Q\big(\overline{\lambda_1} + T_{\overline{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})}}\big) \\
& \quad - AQ\Big)\overline{\theta u} + r_1(u,\bar{u}) + Q\overline{r_1(\theta_1 u,\overline{\theta_1 u})} + \big(T_{l_\theta} + QT_{\widetilde{l_\theta}^J}\big)\theta_1 u \\
& + (T_{\widetilde{l_\theta}} + QT_{l_\theta^J})\overline{\theta_1 u} + [\theta, A]\theta_1 u \\
& + Q[\theta, A]\overline{\theta_1 u}, \quad 0 < t < T, \quad x \in \mathbb{R}^d.
\end{aligned} \tag{5.15}
$$

Proposition 3.2 implies that

$$[\theta, A] = l_\theta^1(x, D) \quad \text{and} \quad q_1(x, D)[\theta, A] = \widetilde{l_\theta^1}(x, D),$$

where $l_\theta^1(x,\xi)$ is in $S(1,-1)$ and $\widetilde{l_\theta^1}(x,\xi)$ is in $S(-1,-1)$, and where $l_\theta^1(x,\xi)$ and $\widetilde{l_\theta^1}(x,\xi)$ have their support included in the support of $\nabla\theta$. Items (iii) and (iv) of Proposition 4.11 imply that

$$
\begin{aligned}
& T_{l_\theta} + QT_{\widetilde{l_\theta}^J} = T_{l_\theta^2} + R, \\
& T_{\widetilde{l_\theta}} + QT_{l_\theta^J} + T_{q_2}[\theta, A] = T_{\widetilde{l_\theta^2}} + \widetilde{R},
\end{aligned} \tag{5.16}
$$

where l_θ^2 and $\widetilde{l_\theta^2}$ are in $L^\infty(0, T, \widetilde{\Sigma}_s^0)$ with support included in the support of $\nabla\theta$ and where R and $\widetilde{R}$ are bounded from $L^\infty(0, T, H_{t'}^t)$ to $L^\infty(0, T, H_{t'}^{t+s-d/2})$. We define

$$r_2(u,\bar{u}) = R\theta_1 u + \widetilde{R}\overline{\theta_1 u} + r_1\big(\theta_1 u, \overline{\theta_1 u}\big) + Q\overline{r_1\big(\theta_1 u, \overline{\theta_1 u}\big)}.$$

Equation (5.15) becomes

$$
\begin{aligned}
i\frac{\partial v}{\partial t} - Av = {} & \Big(\lambda_1 + T_{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})} + Q(\overline{\lambda_2} + T_{\overline{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})}})\Big)\theta u \\
& + \Big(\lambda_2 + T_{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})} - iT_{\partial_t q_2} - QA + Q\big(\overline{\lambda_1} + T_{\overline{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})}}\big) \\
& \quad - AQ\Big)\overline{\theta u} + r_2(u,\bar{u}) + \big(l_\theta^1(x, D) + T_{l_\theta^2}\big)\theta_1 u \\
& + \Big(\widetilde{l_\theta^1}(x, D) + T_{\widetilde{l_\theta^2}}\Big)\overline{\theta_1 u}, \quad 0 < t < T, \quad x \in \mathbb{R}^d,
\end{aligned} \tag{5.17}
$$

where $r_2(u,\bar{u})$ is in $L^\infty(0, T, H_0^{2s-d/2})$.

Taking the conjugate of $v = \theta u - Q\overline{\theta u}$, we get $\bar{v} = \overline{\theta u} - Q^J\theta u$. So

$$
\begin{aligned}
& (1 - QQ^J)\theta u = v + Q\bar{v}, \\
& (1 - Q^J Q)\overline{\theta u} = \bar{v} + Q^J v.
\end{aligned} \tag{5.18}
$$

By Propositions 3.2 and 4.11, there exist two operators P and $\widetilde{P}$, with $P = p_1(x, D) + T_{p_2}$ and $\widetilde{P} = \widetilde{p_1}(x, D) + T_{\widetilde{p_2}}$, such that $p_1(x,\xi)$ is in $S(0,0)$, $p_2(t,x,\xi)$ is in $L^\infty(0, T, \widetilde{\Sigma}_s^0)$, $\widetilde{p_1}(x,\xi)$ is in $S(0,0)$, and $\widetilde{p_2}(t,x,\xi)$ is in $L^\infty(0, T, \widetilde{\Sigma}_s^0)$ with

$$
\begin{aligned}
& P(1 - QQ^J) = 1 + R_1, \\
& \widetilde{P}(1 - Q^J Q) = 1 + R_2,
\end{aligned} \tag{5.19}
$$

where R_1 and R_2 are bounded from $L^\infty(0,T,H^t_{t'})$ to $L^\infty(0,T,H^{t+s-d/2}_{t'})$. Then, (5.17) becomes

$$i\frac{\partial v}{\partial t} - Av = L_3 v + \widetilde{L_3}\bar{v} + r_3(u,\bar{u}) + \big(l^1_\theta(x,D) + T_{l^2_\theta}\big)\theta_1 u + \big(\widetilde{l^1_\theta}(x,D) + T_{\widetilde{l^2_\theta}}\big)\overline{\theta_1 u}, \quad 0 < t < T, \quad x \in \mathbb{R}^d, \tag{5.20}$$

where

(5.21)

$$\begin{aligned} L_3 &= \Big(\lambda_1 + T_{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})} + Q(\overline{\lambda_2} + T_{\overline{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})}})\Big)P \\ &\quad + \Big(\lambda_2 + T_{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})} - iT_{\partial_t q_2} + QA + Q\Big(\overline{\lambda_1} + T_{\overline{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})}}\Big) + AQ\Big)\widetilde{P}Q^J, \\ \widetilde{L_3} &= \Big(\lambda_2 + T_{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})} - iT_{\partial_t q_2} + QA + Q(\overline{\lambda_1} + T_{\overline{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})}}) + AQ\Big)\widetilde{P} \\ &\quad + \Big(\lambda_1 + T_{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})} + Q(\overline{\lambda_2} + T_{\overline{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})}})\Big)PQ, \\ r_3(u,\bar{u}) &= r_2(u,\bar{u}) - \Big(\lambda_1 + T_{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})} + Q(\overline{\lambda_2} + T_{\overline{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})}})\Big)R_1\theta u \\ &\quad - \Big(\lambda_2 + T_{\frac{\partial g}{\partial \bar{u}}(\theta_1 u,\overline{\theta_1 u})} - iT_{\partial_t q_2} + QA + Q(\overline{\lambda_1} + T_{\overline{\frac{\partial g}{\partial u}(\theta_1 u,\overline{\theta_1 u})}}) + AQ\Big)R_2\overline{\theta u}. \end{aligned}$$

By assumption, $\partial_t q_2(t,x,\xi)$ is in $L^\infty(0,T,\widetilde{\Sigma}^0_s)$. $r_3(u,\bar{u})$ is then in $L^\infty(0,T,H^{2s-d/2}_0)$ by Lemma 4.4 and by (i) of Proposition 4.11. Moreover, by (ii), (iii), and (iv) of Proposition 4.11, we have

$$\begin{aligned} L_3 &= l_1(x,D) + T_{l_2} + R_3, \\ \widetilde{L_3} &= \widetilde{l_1}(x,D) + T_{\widetilde{l_2}} + R_4, \end{aligned} \tag{5.22}$$

where $l_1(x,\xi)$ and $\widetilde{l_1}(x,\xi)$ are in $S(0,0)$, $l_2(t,x,\xi)$ and $\widetilde{l_2}(t,x,\xi)$ are in $L^\infty(0,T,\widetilde{\Sigma}^0_s)$, and R_3 and R_4 are bounded from $L^\infty(0,T,H^t_{t'})$ to $L^\infty(0,T,H^{t+s-d/2}_{t'})$. Then, (5.20) becomes

(5.23)

$$\begin{aligned} i\frac{\partial v}{\partial t} - Av &= l_1(x,D)v + T_{l_2}v + \widetilde{l_1}(x,D)\bar{v} + T_{\widetilde{l_2}}\bar{v} + r_4(u,\bar{u}) \\ &\quad + \big(l^1_\theta(x,D) + T_{l^2_\theta}\big)\theta_1 u + \big(\widetilde{l^1_\theta}(x,D) + T_{\widetilde{l^2_\theta}}\big)\overline{\theta_1 u}, \quad 0 < t < T, \quad x \in \mathbb{R}^d, \end{aligned}$$

where $r_4(u,\bar{u}) = r_3(u,\bar{u}) + R_3\theta u + R_4\overline{\theta u}$ is in $L^\infty(0,T,H^{2s-d/2}_0)$. This ends the proof of (5.12). ∎

Proof of Lemma 5.3. To obtain $\widetilde{l_1}(x,\xi) = 0$, it suffices by (5.19), (5.21), and (5.22) to find $p_1(x,\xi)$ and $\widetilde{p^1}(x,\xi)$ in $S(0,0)$ and $q_1(x,\xi)$ in $S(-2,0)$ satisfying

$$\begin{aligned} &p_1(x,D)\big(1 - q_1(x,D)q_1^J(x,D)\big) = 1 + r_1(x,D), \\ &\widetilde{p_1}(x,D)\big(1 - q_1^J(x,D)q_1(x,D)\big) = 1 + r_2(x,D), \\ &\big(\lambda_2 + q_1(x,D)A + \overline{\lambda_1}q_1(x,D) + Aq_1(x,D)\big)\widetilde{p_1}(x,D) \\ &\quad + \big(\lambda_1 + \overline{\lambda_2}q_1(x,D)\big)p_1(x,D)q_1(x,D) = r_3(x,D), \end{aligned} \tag{5.24}$$

where $r_1(x,\xi)$, $r_2(x,\xi)$, and $r_3(x,\xi)$ belong to $S(-(s-d/2),-(s-d/2))$. We look for $p_1(x,\xi)$, $\widetilde{p^1}(x,\xi)$, and $q_1(x,\xi)$ with $p_1(x,\xi)=\sum_{j<s-d/2}p^1_{-j}(x,\xi)$, $\widetilde{p_1}(x,\xi)=\sum_{j<s-d/2}\widetilde{p^1_{-j}}(x,\xi)$, and $q_1(x,\xi)=\sum_{j<s-d/2}q^1_{-j}(x,\xi)$, where $p^1_j(x,\xi)$ and $\widetilde{p^1_j}(x,\xi)$ are in $S(-j,-j)$ and $q^1_{-j}(x,\xi)$ is in $S(-2-j,-j)$. By Proposition 3.2, it suffices to look for $p^1_j(x,\xi)$, $\widetilde{p^1_j}(x,\xi)$, and $q^1_{-j}(x,\xi)$, $0\le j<s-d/2$, satisfying

$$p^1_{-j}-\sum_{|\alpha|+|\beta|+k+l+m=j}\frac{1}{i^{|\alpha|+|\beta|}\alpha!\beta!}\partial^\alpha_\xi p^1_{-k}\partial^\alpha_x\left(\partial^\beta_\xi q^1_{-l}\partial^\beta_x q^{1J}_{-m}\right)=\delta_{j0}, \tag{5.25}$$

$$\widetilde{p^1_{-j}}-\sum_{|\alpha|+|\beta|+k+l+m=j}\frac{1}{i^{|\alpha|+|\beta|}\alpha!\beta!}\partial^\alpha_\xi \widetilde{p^1_{-k}}\partial^\alpha_x\left(\partial^\beta_\xi q^{1J}_{-l}\partial^\beta_x q^{1}_{-m}\right)=\delta_{j0}, \tag{5.26}$$

and

$$\begin{aligned}
&\lambda_2\widetilde{p^1_{-j}}-\sum_{|\alpha|+|\beta|+k+l+m=j}\frac{1}{i^{|\alpha|+|\beta|}\alpha!\beta!}\Big(\partial^\alpha_\xi q^1_{-k}\partial^\alpha_x\left(\partial^\beta_\xi a_{2-l}\partial^\beta_x\widetilde{p^1_{-m}}\right)\\
&\qquad+\partial^\alpha_\xi a_{2-k}\partial^\alpha_x\left(\partial^\beta_\xi q^1_{-l}\partial^\beta_x\widetilde{p^1_{-m}}\right)\Big)\\
&\qquad+\sum_{|\alpha|+k+l=j}\frac{1}{i^{|\alpha|}\alpha!}\left(\overline{\lambda_1}\partial^\alpha_\xi q^1_{-k}\partial^\alpha_x\widetilde{p^1_{-l}}+\lambda_1\partial^\alpha_\xi p^1_{-k}\partial^\alpha_x q^1_{-l}\right)\\
&\qquad+\sum_{|\alpha|+|\beta|+k+l+m=j}\frac{1}{i^{|\alpha|+|\beta|}\alpha!\beta!}\overline{\lambda_2}\partial^\alpha_\xi q^1_{-k}\partial^\alpha_x\left(\partial^\beta_\xi p^1_{-l}\partial^\beta_x q^1_{-m}\right)=0.
\end{aligned}\tag{5.27}$$

For $j=0$, (5.25), (5.26), and (5.27) imply

$$\begin{array}{ll}
\text{(i)} & p^1_0\left(1-q^1_0q^{1J}_0\right)=1,\\
\text{(ii)} & \widetilde{p^1_0}\left(1-q^{1J}_0q^1_0\right)=1,\\
\text{(iii)} & \left(\lambda_2+q^1_0a_2+\overline{\lambda_1}q^1_0+a_2q^1_0\right)\widetilde{p^1_0}+\left(\lambda_1+\overline{\lambda_2}q^1_0\right)p^1_0q^1_0=0.
\end{array}\tag{5.28}$$

(i) and (ii) imply $p^1_0=\widetilde{p^1_0}\neq 0$. Thus, (iii) yields

$$\overline{\lambda_2}\left(q^1_0\right)^2+2(a_2+\mathrm{Re}(\lambda_1))q^1_0+\lambda_2=0. \tag{5.29}$$

We set

$$q^1_0(x,\xi)=\frac{-\mathrm{Re}(\lambda_1)-a_2(x,\xi)+\left((\mathrm{Re}(\lambda_1)+a_2(x,\xi))^2-|\lambda_2|^2\right)^{1/2}}{\overline{\lambda_2}}. \tag{5.30}$$

Thus, $q^1_0(x,\xi)$ is in $S(-2,0)$ and satisfies (5.29). Then, $p^1_0(x,\xi)$ is in $S(0,0)$ by (i) and $\widetilde{p^1_0(x,\xi)}$ is in $S(0,0)$ by (ii).

Let $1\le j<s-d/2$. Assume we have found q^1_{-l}, p^1_{-l}, and $\widetilde{p^1_{-l}}$, $0\le l\le j-1$, satisfying (5.25), (5.26), and (5.27) for $0\le l\le j-1$ and such that q^1_{-l} belongs to $S(-2-l,-l)$, and p^1_{-l} and $\widetilde{p^1_{-l}}$ are in $S(-l,-l)$. Equations (5.25), (5.26), and (5.27)

for j yield

$$
\begin{aligned}
&\text{(i)}_{\mathrm{j}} \quad \big(1 - q_0^1 q_0^{1J}\big) p_{-j}^1 - p_0^1 q_0^1 q_{-j}^{1J} - p_0^1 q_{-j}^1 q_0^{1J} = \alpha_j^1,\\
&\text{(ii)}_{\mathrm{j}} \quad \big(1 - q_0^1 q_0^{1J}\big) \widetilde{p_{-j}^1} - \widetilde{p_0^1} q_0^1 q_{-j}^{1J} - \widetilde{p_0^1} q_{-j}^1 q_0^{1J} = \alpha_j^2,\\
&\text{(iii)}_{\mathrm{j}} \quad \big(\lambda_2 + 2q_0^1 a_2 + \overline{\lambda_1} q_0^1\big)\widetilde{p_{-j}^1} + \big(\lambda_1 + \overline{\lambda_2} q_0^1\big) q_0^1 p_{-j}^1\\
&\qquad\qquad + s\big(2a_2 + 2\mathrm{Re}(\lambda_1) + 2\overline{\lambda_2} q_0^1\big) p_0^1 q_{-j}^1 = \alpha_j^3,
\end{aligned}
\tag{5.31}
$$

where α_j^1, α_j^2, and α_j^3 are polynomials of the derivatives of q_{-l}^1, p_{-l}^1, and $\widetilde{p_{-l}^1}$, $0 \le l \le j-1$, and are in $S(-j,-j)$ since q_{-l}^1 is in $S(-2-l,-l)$, and p_{-l}^1 and $\widetilde{p_{-l}^1}$ are in $S(-l,-l)$. Since $p_0^1 = \widetilde{p_0^1}$, (i)$_{\mathrm{j}}$ and (ii)$_{\mathrm{j}}$ yield

$$\big(1 - q_0^1 q_0^{1J}\big)\big(p_{-j}^1 - \widetilde{p_{-j}^1}\big) = \alpha_j^1 - \alpha_j^2.$$

So, $p_{-j}^1 - \widetilde{p_{-j}^1} = \alpha_j^4$, where α_j^4 is a polynomial of the derivatives of q_{-l}^1, p_{-l}^1, and $\widetilde{p_{-l}^1}$, $0 \le l \le j-1$, and is in $S(-j,-j)$. Using (5.29), we get

$$
\begin{aligned}
&\big(\lambda_2 + 2q_0^1 a_2 + \overline{\lambda_1} q_0^1\big)\widetilde{p_{-j}^1} + \big(\lambda_1 + \overline{\lambda_2} q_0^1\big) q_0^1 p_{-j}^1 = \big(\lambda_2 + 2q_0^1 a_2 + \overline{\lambda_1} q_0^1\big)\big(\widetilde{p_{-j}^1} - p_{-j}^1\big)\\
&\quad = -\big(\lambda_2 + 2q_0^1 a_2 + \overline{\lambda_1} q_0^1\big)\alpha_j^4 = \alpha_j^5,
\end{aligned}
\tag{5.32}
$$

where α_j^5 is a polynomial in the derivatives of q_{-l}^1, p_{-l}^1, and $\widetilde{p_{-l}^1}$, $0 \le l \le j-1$, and is in $S(-j,-j)$. (iii)$_{\mathrm{j}}$ and (5.32) imply that

$$\big(2a_2 + 2\mathrm{Re}(\lambda_1) + 2\overline{\lambda_2} q_0^1\big) p_0^1 q_{-j}^1 = \alpha_j^3 - \alpha_j^5. \tag{5.33}$$

Equation (5.33) gives q_{-j}^1 in $S(-2-j,-j)$ as a function of the derivatives of q_{-l}^1, p_{-l}^1, and $\widetilde{p_{-l}^1}$, $0 \le l \le j-1$. Then, (i)$_{\mathrm{j}}$ gives p_{-j}^1 in $S(-j,-j)$ as a function of q_{-j}^1 and the derivatives of q_{-l}^1, p_{-l}^1, and $\widetilde{p_{-l}^1}$, $0 \le l \le j-1$, and (ii)$_{\mathrm{j}}$ gives $\widetilde{p_{-j}^1}$ in $S(-j,-j)$ as a function of q_{-j}^1 and the derivatives of q_{-l}^1, p_{-l}^1, and $\widetilde{p_{-l}^1}$, $0 \le l \le j-1$. So, we obtain $p_1(x,\xi)$ and $\widetilde{p^1}(x,\xi)$ in $S(0,0)$ and $q_1(x,\xi)$ in $S(-2,0)$ satisfying (5.24) by iteration.

Finally, when $\lambda_2 = \partial_{\bar u} f(0,0) = 0$, $q_1(x,\xi) = 0$ and $p_1(x,\xi) = \widetilde{p_1}(x,\xi) = 1$ is a solution of (5.24). So, we may take $q_1(x,\xi) \equiv 0$. ∎

Proof of Lemma 5.4. Assume that $p_1(x,\xi)$, $\widetilde{p^1}(x,\xi)$, and $q_1(x,\xi)$ are given as above. In particular, $p_1(x,\xi)$, $\widetilde{p^1}(x,\xi)$, and $q_1(x,\xi)$ satisfy (5.24). Moreover, we see from (5.30) that $q_0^1(x,\xi)$ has an asymptotic expansion of the form

$$q_0^1(x,\xi) = \sum_{l<s-d/2} q_{0,-2-l}^{1h}(x,\xi) + r(x,\xi), \quad r(x,\xi) \in S(-(s-d/2)-2, 0),$$

where $q_{0,-2-l}^{1h}(x,\xi)$ is in $S(-2-l,0)$ and is homogeneous of degree $-2-l$ in ξ outside a neighborhood of $\xi = 0$. Then, (i) and (ii) of (5.28) imply that

$$
\begin{aligned}
p_0^1(x,\xi) &= \sum_{l<s-d/2} p_{0,-l}^{1h}(x,\xi) + r(x,\xi), \quad r(x,\xi) \in S(-(s-d/2),0),\\
\widetilde{p_0^1}(x,\xi) &= \sum_{l<s-d/2} \widetilde{p_{0,-l}^{1h}}(x,\xi) + r(x,\xi), \quad r(x,\xi) \in S(-(s-d/2),0),
\end{aligned}
$$

where $p^{1h}_{0,-l}(x,\xi)$ and $\widetilde{p^{1h}_{0,-l}}(x,\xi)$ are in $S(-l,0)$ and are homogeneous of degree $-l$ in ξ outside a neighborhood of $\xi=0$.

Similarly, we show by iteration on $0\le j<s-d/2$ that

$$\begin{aligned}
p^1_{-j}(x,\xi) &= \sum_{l<s-d/2} p^{1h}_{j,-l}(x,\xi)+r(x,\xi), \quad r(x,\xi)\in S(-(s-d/2),0),\\
\widetilde{p^1_{-j}}(x,\xi) &= \sum_{l<s-d/2} \widetilde{p^{1h}_{j,-l}}(x,\xi)+r(x,\xi), \quad r(x,\xi)\in S(-(s-d/2),0),\\
q^1_{-j}(x,\xi) &= \sum_{l<s-d/2} q^{1h}_{j,-2-l}(x,\xi)+r(x,\xi), \quad r(x,\xi)\in S(-(s-d/2)-2,0),
\end{aligned}$$

where $p^{1h}_{j,-l}(x,\xi)$ and $\widetilde{p^{1h}_{j,-l}}(x,\xi)$ are in $S(-l,0)$ and are homogeneous of degree $-l$ in ξ outside a neighborhood of $\xi=0$, and $q^{1h}_{j,-2-l}(x,\xi)$ is in $S(-2-l,0)$ and is homogeneous of degree $-2-l$ in ξ outside a neighborhood of $\xi=0$. Grouping the various expansions, we obtain that $p_1(x,\xi)$, $\widetilde{p_1}(x,\xi)$, and $q_1(x,\xi)$ have asymptotic expansions of the form

$$\begin{aligned}
p_1(x,\xi) &= \sum_{j<s-d/2} p^{1h}_{-j}(x,\xi)+r_1(x,\xi), \quad r_1(x,\xi)\in S(-(s-d/2),0),\\
\widetilde{p_1}(x,\xi) &= \sum_{j<s-d/2} \widetilde{p^{1h}_{-j}}(x,\xi)+r_2(x,\xi), \quad r_2(x,\xi)\in S(-(s-d/2),0),\\
q_1(x,\xi) &= \sum_{j<s-d/2} q^{1h}_{-2-j}(x,\xi)+r_3(x,\xi), \quad r_3(x,\xi)\in S(-(s-d/2)-2,0),
\end{aligned} \tag{5.34}$$

where $p^{1h}_{-j}(x,\xi)$ and $\widetilde{p^{1h}_{-j}}(x,\xi)$ are in $S(-j,0)$ and are homogeneous of degree $-j$ in ξ outside a neighborhood of $\xi=0$ and $q^{1h}_{-2-j}(x,\xi)$ is in $S(-2-j,0)$ and is homogeneous of degree $-2-j$ in ξ outside a neighborhood of $\xi=0$. In particular, we have

$$p^{1h}_0(x,\xi)=1, \quad \widetilde{p^{1h}_0}(x,\xi)=1, \quad q^{1h}_{-2}(x,\xi)=-\frac{\lambda_2}{2a_2}. \tag{5.35}$$

We look for $p_2(t,x,\xi)$ and $\widetilde{p_2}(t,x,\xi)$ in $L^\infty(0,T,\widetilde{\Sigma}^0_s)$ and $q_2(t,x,\xi)$ in $L^\infty(0,T,\widetilde{\Sigma}^{-2}_s)$ such that Q, P, and $\widetilde{P}$ satisfy (5.19) and $\widetilde{l_2}(t,x,\xi)=0$, and such that $\partial_t q_2(t,x,\xi)$ is in $L^\infty(0,T,\widetilde{\Sigma}^0_s)$. It suffices to find q^2_{-2-j}, p^2_{-j}, and $\widetilde{p^2_{-j}}$, $0\le j<s-d/2$, such that $\partial^k_t q^2_{-2-j}(t,x,\xi)$ is in $L^\infty(0,T,\Sigma^{-2-j}_{s,-j-2k})$, and $\partial^k_t p^2_{-j}(t,x,\xi)$ and $\partial^k_t\widetilde{p^2_{-j}}(t,x,\xi)$ are in $L^\infty(0,T,\Sigma^{-j}_{s,-j-2k+4})$ for $2k<s+2-d/2-j$. Moreover, by (ii), (iii), and (iv) of Proposition 4.11, q^2_{-2-j}, p^2_{-j}, and $\widetilde{p^2_{-j}}$ must satisfy for $0\le j<s-d/2$ the following equalities:

$$p^2_{-j}=\alpha^1_j\big(\partial^\alpha_x\partial^\beta_\xi p^{1h}_{-l},\partial^\alpha_x\partial^\beta_\xi p^2_{-l},\partial^\alpha_x\partial^\beta_\xi q^{1h}_{-2-l},\partial^\alpha_x\partial^\beta_\xi q^2_{-2-l}, \quad 0\le l\le j-4\big), \tag{5.36}$$

$$\widetilde{p^2_{-j}}=\alpha^2_j\big(\partial^\alpha_x\partial^\beta_\xi \widetilde{p^{1h}_{-l}},\partial^\alpha_x\partial^\beta_\xi \widetilde{p^2_{-l}},\partial^\alpha_x\partial^\beta_\xi q^{1h}_{-2-l},\partial^\alpha_x\partial^\beta_\xi q^2_{-2-l}, \quad 0\le l\le j-4\big), \tag{5.37}$$

and

(5.38)

$$\begin{aligned}
2a_2\big(1+\widetilde{p_0^2}\big)q^2_{-2-j} &= \alpha^3_j\left(\partial^\alpha_x\partial^\beta_\xi a_{2-l}, \partial^\alpha_x\partial^\beta_\xi \widetilde{p^{1h}_{-l}}, \partial^\alpha_x\partial^\beta_\xi \widetilde{p^2_{-l}}, \partial^\alpha_x\partial^\beta_\xi q^{1h}_{-2-l}, \quad 0\le l\le j\right)\\
&\quad+\alpha^4_j\left(\partial^\alpha_x\partial^\beta_\xi a_{2-l}, \partial^\alpha_x\partial^\beta_\xi \widetilde{p^{1h}_{-l}}, \partial^\alpha_x\partial^\beta_\xi \widetilde{p^2_{-l}}, \partial^\alpha_x\partial^\beta_\xi q^{1h}_{-2-l}, \partial^\alpha_x\partial^\beta_\xi q^2_{-2-l}, \quad 0\le l\le j-1\right)\\
&\quad+\alpha^5_j\left(\partial^\alpha_x\partial^\beta_\xi \widetilde{p^{1h}_{-l}}, \partial^\alpha_x\partial^\beta_\xi \widetilde{p^2_{-l}}, \partial^\alpha_x\partial^\beta_\xi \partial_t q^2_{-2-l}, \quad 0\le l\le j-2\right)\\
&\quad+\alpha^6_j\left(\partial^\alpha_x\partial^\beta_\xi p^{1h}_{-l}, \partial^\alpha_x\partial^\beta_\xi p^2_{-l}, \partial^\alpha_x\partial^\beta_\xi \widetilde{p^{1h}_{-l}}, \partial^\alpha_x\partial^\beta_\xi \widetilde{p^2_{-l}}, \partial^\alpha_x\partial^\beta_\xi q^{1h}_{-2-l}, \partial^\alpha_x\partial^\beta_\xi q^2_{-2-l}, \ 0\le l\le j-2\right)\\
&\quad+\alpha^7_j\left(\partial^\alpha_x\partial^\beta_\xi \widetilde{p^{1h}_{-l}}, \partial^\alpha_x\partial^\beta_\xi \widetilde{p^2_{-l}}, \partial^\alpha_x\partial^\beta_\xi q^{1h}_{-2-l}, \partial^\alpha_x\partial^\beta_\xi q^2_{-2-l}, \quad 0\le l\le j-4, \quad \partial^\alpha_x\frac{\partial g}{\partial u}, \partial^\alpha_x\frac{\partial g}{\partial \bar u}\right),
\end{aligned}$$

where the α^l_j, $1\le l\le 7$, are given polynomials with complex coefficients.

Remark. In (5.36), (5.37), and (5.38), we do not write the terms containing $r_1(x,\xi)$, $r_2(x,\xi)$, and $r_3(x,\xi)$ defined in (5.34). In fact, when $r(x,\xi)$ is in $S(-(s-d/2),0)$ and $q(x,\xi)$ is in $\widetilde{\Sigma}^0_s$, $q(x,D)r(x,D)$ and $r(x,D)q(x,D)$ are continuous from $H^t_{t'}$ to $H^{t+s-d/2}_{t'}$ by Lemma 4.4 and (i) of Proposition 4.11. So, the terms containing $r_1(x,\xi)$, $r_2(x,\xi)$, and $r_3(x,\xi)$ can be incorporated in the remainder $r_2(u,\bar u)$ of (5.12).

For $j=0$, (5.36), (5.37), and (5.38) imply

$$p^2_0=0,\quad \widetilde{p^2_0}=0\quad\text{ and }\quad 2a_2q^2_{-2}=\frac{\partial g}{\partial\bar u}(\theta_1u,\overline{\theta_1u}). \tag{5.39}$$

$\partial^k_t p^2_0(t,x,\xi)$ and $\partial^k_t\widetilde{p^2_0}(t,x,\xi)$ are in $L^\infty(0,T,\Sigma^0_{s,-2k+4})$ for $2k<s+2-d/2$. By restricting the support of θ_1, we may assume there exists $\theta_2(x)$ in $S(0,0)$ equal to 1 on the support of θ_1 such that θ_2u is in $L^\infty(0,T,H^s_0)$. Therefore, as s is in I_d and $\partial_{\bar u}g(0,0)=0$, Corollary 4.6 implies that $\partial^k_t\partial_{\bar u}g(\theta_1u,\overline{\theta_1u})$ is in $L^\infty(0,T,H^s_{-2k})$ for $2k<s-d/2+2$. As $a_2(x,\xi)$ is in $S(2,0)$, homogeneous of degree 2 in ξ, and elliptic, $\partial^k_t q^2_{-2}(t,x,\xi)$ is in $L^\infty(0,T,\Sigma^{-2}_{s,-2k})$ for $2k<s-d/2+2$ by (5.39), which ends the construction of $p^2_0(t,x,\xi)$, $\widetilde{p^2_0}(t,x,\xi)$, and q^2_{-2}.

Let $1\le j<s-d/2$. Assume q^2_{-2-l}, p^2_{-l}, and $\widetilde{p^2_{-l}}$ are given for $0\le l\le j-1$ such that they satisfy (5.36), (5.37), and (5.38) for $0\le l\le j-1$, and such that $\partial^k_t q^2_{-2-l}(t,x,\xi)$ is in $L^\infty(0,T,\Sigma^{-2-l}_{s,-l-2k})$, and $\partial^k_t p^2_{-l}(t,x,\xi)$ and $\partial^k_t p^2_{-l}(t,x,\xi)$ are in $L^\infty(0,T,\Sigma^{-l}_{s,-l-2k+4})$ for $2k<s+2-d/2-l$. Equations (5.36) and (5.37) for j give p^2_{-j} and p^2_{-j} and (5.38) gives q^2_{-2-j}. It remains to show that $\partial^k_t q^2_{-2-j}(t,x,\xi)$ is in $L^\infty(0,T,\Sigma^{-2-j}_{s,-j-2k})$, and that $\partial^k_t p^2_{-j}(t,x,\xi)$ and $\partial^k_t p^2_{-j}(t,x,\xi)$ are in $L^\infty(0,T,\Sigma^{-j}_{s,-j-2k+4})$ for $2k<s+2-d/2-j$. By (5.36), (5.37), and (5.38), it suffices to show that $\partial^k_t\alpha^1_j(t,x,\xi)$ and $\partial^k_t\alpha^2_j(t,x,\xi)$ are in $L^\infty(0,T,\Sigma^{-j}_{s,-j-2k+4})$ and that $\partial^k_t\alpha^l_j(t,x,\xi)$, $3\le l\le 7$, is in $L^\infty(0,T,\Sigma^{-j}_{s,-j-2k})$ for $2k<s+2-d/2-j$. Furthermore, $\alpha^l_j(t,x,\xi)$, $1\le l\le 7$, is the sum of the following terms:

1. $\partial^\alpha_\xi p_{-k}\partial^\alpha_x(\partial^\beta_\xi q_{-2-l}\partial^\beta_x(q_{-2-m}))$ and $\partial^\alpha_\xi q_{-2-k}\partial^\alpha_x(\overline{\frac{\partial g}{\partial\bar u}}(\theta_1u,\overline{\theta_1u})\partial^\beta_\xi(p_{-l})\partial^\beta_x q_{-2-m})$, where $|\alpha|+|\beta|+k+l+m=j-4$,
2. $\partial^\alpha_\xi\partial_t q^2_{-2-k}\partial^\alpha_x\widetilde{p_{-l}}$, $\partial^\alpha_\xi q_{-2-k}\partial^\alpha_x p_{-l}$, and $\partial^\alpha_\xi q_{-2-k}\partial^\alpha_x(\overline{\frac{\partial g}{\partial u}}(\theta_1u,\overline{\theta_1u})p_{-m})$, where $|\alpha|+k+l=j-2$,
3. $\partial^\alpha_\xi q_{-2-k}\partial^\alpha_x(\partial^\beta_\xi a_{2-l}\partial^\beta_x p_{-m})$, where $|\alpha|+|\beta|+k+l+m=j$,
4. p^2_{-j} and $\frac{\partial g}{\partial\bar u}\widetilde{p_{-j}}$,

where p_{-l} is either p^{1h}_{-l}, p^2_{-l}, $\widetilde{p^{1h}_{-l}}$, or $\widetilde{p^2_{-l}}$, and q_{-2-l} is either q^{1h}_{-2-l} or q^2_{-2-l}. It suffices to consider the products of two terms, and using Leibniz rule we have to prove that

$$\begin{aligned}&S(m',0)\Sigma^{m''}_{s,-l''-2k''} \subset \Sigma^{-j}_{s,-l''-2k''},\\ &\qquad \text{where } m'+m''=-j,\ k''\leq k,\ l''\leq j,\\ &\text{and } \Sigma^{m'}_{s,-l'-2k'}\Sigma^{m''}_{s,-l''-2k''} \subset \Sigma^{-j}_{s,-l'-l''-2k},\\ &\qquad \text{where } m'+m''=-j,\ k'+k''=k,\ l'+l''=j-2,\ \text{ or } j-4.\end{aligned} \tag{5.40}$$

By (c) of Lemma 4.10,

$$S(m',0)\Sigma^{m''}_{s,-l''-2k''} \subset \Sigma^{m'+m''}_{s,-l''-2k''} = \Sigma^{-j}_{s,-l''-2k''}. \tag{5.41}$$

We set $s'=-l'-2k'$ and $s''=-l''-2k''$. Then, since $l'+l''\leq j-2$ we have

$$s+s'+s''=s-l'-l''-2k\geq s-j-2k+2>0$$

and

$$s+\max(s',s'')=s+\max(-l'-2k',-l''-2k'')\geq s-l'-l''-2k\geq s-j-2k+2>d/2.$$

Item (b) of Lemma 4.10 implies that

$$\Sigma^{m'}_{s,-l'-2k'}\Sigma^{m''}_{s,-l''-2k''} \subset \Sigma^{m'+m''}_{s,-l'-l''-2k'-2k''} = \Sigma^{-j}_{s,-l'-l''-2k}. \tag{5.42}$$

Equations (5.41) and (5.42) yield (5.40). So, $\partial_t^k q^2_{-2-j}(t,x,\xi)$ is in $L^\infty(0,T,\Sigma^{-2-j}_{s,-j-2k})$, and $\partial_t^k p^2_{-j}(t,x,\xi)$ and $\partial_t^k p^2_{-j}(t,x,\xi)$ are in $L^\infty(0,T,\Sigma^{-j}_{s,-j-2k+4})$ for $2k<s+2-d/2-j$.

Finally, we obtain $q_2(t,x,\xi)$ in $L^\infty(0,T,\widetilde{\Sigma}^{-2}_s)$ such that $\partial_t q_2(t,x,\xi)$ is in $L^\infty(0,T,\widetilde{\Sigma}^0_s)$ and $\widetilde{l_2}(t,x,\xi)=0$ by iteration. Moreover, $\widetilde{l_1}(x,\xi)=0$ by Lemma 5.3. Since v satisfies (5.12) with $\widetilde{l_1}(x,\xi)=\widetilde{l_2}(t,x,\xi)=0$, v satisfies (5.11). □

We finally proceed with the third and last step of the proof. Adapting the strategy of [6] to (5.11), we prove a microlocal smoothing effect result for v which in turn yields a result of microlocal smoothing effect for u.

Let $b(x,\xi)$ be in $S(m,k)$. Proposition 3.2 yields

$$\begin{aligned} i[A,b(x,D)] &= i[a(x,D),b(x,D)]+i[a_1(x,D),b(x,D)]\\ &= \{a,b\}(x,D)+e(x,D)+R_L,\end{aligned} \tag{5.43}$$

where $L=[\max(m+2,k)]+1$. R_L is a bounded operator on L^2 and $e(x,\xi)$ in $S(m,k-2)$ is defined by

$$\begin{aligned} e(x,\xi) &= \sum_{2\leq|\alpha|<L}\frac{1}{i^{|\alpha|-1}\alpha!}\big(\partial_\xi^\alpha a\partial_x^\alpha b-\partial_x^\alpha a\partial_\xi^\alpha b\big)\\ &\quad+\sum_{1\leq|\alpha|<L}\frac{1}{i^{|\alpha|-1}\alpha!}\big(\partial_\xi^\alpha a_1\partial_x^\alpha b-\partial_x^\alpha a_1\partial_\xi^\alpha b\big).\end{aligned} \tag{5.44}$$

Let v a solution of (5.11) and B an operator. Then,

(5.45)

$$\begin{aligned}
&\partial_t\langle Bv,v\rangle = \langle B\partial_t v,v\rangle + \langle Bv,\partial_t v\rangle + \left\langle \frac{\partial B}{\partial t}v,v\right\rangle \\
&= \langle -iB\big(Av + l_1(x,D)v + T_{l_2}v + r_2(u,\bar u) + \big(l^1_\theta(x,D) + T_{l^2_\theta}\big)\theta_1 u \\
&\quad + \big(\widetilde{l^1_\theta}(x,D) + T_{\widetilde{l^2_\theta}}\big)\overline{\theta_1 u}\big),v\rangle + \langle Bv, -i\big(Av + l_1(x,D)v + T_{l_2}v \\
&\quad + r_2(u,\bar u) + \big(l^1_\theta(x,D) + T_{l^2_\theta}\big)\theta_1 u + \big(\widetilde{l^1_\theta}(x,D) + T_{\widetilde{l^2_\theta}}\big)\overline{\theta_1 u}\big)\rangle + \left\langle \frac{\partial B}{\partial t}v,v\right\rangle \\
&= -i\langle [B,A]v,v\rangle - i\langle B\big(l_1(x,D)v + T_{l_2}v + r_2(u,\bar u) \\
&\quad + \big(l^1_\theta(x,D) + T_{l^2_\theta}\big)\theta_1 u + \big(\widetilde{l^1_\theta}(x,D) + T_{\widetilde{l^2_\theta}}\big)\overline{\theta_1 u}\big),v\rangle + i\langle Bv, l_1(x,D)v + T_{l_2}v \\
&\quad + r_2(u,\bar u) + \big(l^1_\theta(x,D) + T_{l^2_\theta}\big)\theta_1 u + \big(\widetilde{l^1_\theta}(x,D) + T_{\widetilde{l^2_\theta}}\big)\overline{\theta_1 u}\rangle + \left\langle \frac{\partial B}{\partial t}v,v\right\rangle.
\end{aligned}$$

Integrating (5.45) for $B = b(x,D)$ between 0 and t and taking the real part,

$$\begin{aligned}
(5.46)\quad &\mathrm{Re}\langle b(x,D)v(t),v(t)\rangle + \int_0^t \mathrm{Re}\langle c(x,D)v(\tau),v(\tau)\rangle d\tau \\
&\le \mathrm{Re}\langle b(x,D)v_0,v_0\rangle + \int_0^t \mathrm{Re}\langle e(x,D)v(\tau),v(\tau)\rangle d\tau \\
&\quad + \int_0^t (|\langle b(x,D)(l_1(x,D)v + T_{l_2}v + r_2(u,\bar u) + \big(l^1_\theta(x,D) + T_{l^2_\theta}\big)\theta_1 u \\
&\quad + \big(\widetilde{l^1_\theta}(x,D) + T_{\widetilde{l^2_\theta}}\big)\overline{\theta_1 u}),v\rangle| + |\langle b(x,D)v, l_1(x,D)v + T_{l_2}v + r_2(u,\bar u) \\
&\quad + (l^1_\theta(x,D) + T_{l^2_\theta})\theta_1 u + (\widetilde{l^1_\theta}(x,D) + T_{\widetilde{l^2_\theta}})\overline{\theta_1 u}\rangle|)d\tau + C\int_0^t \|v\|^2_{L^2}d\tau,
\end{aligned}$$

where $c = -\{a_2,b\}$. Let $\mu > 0$. Integrating (4.29) for $B = t^\mu b(x,D)$ between 0 and t and taking the real part,

(5.47)

$$\begin{aligned}
&t^\mu \mathrm{Re}\langle b(x,D)v(t),v(t)\rangle + \int_0^t \tau^\mu \mathrm{Re}\langle c(x,D)v(\tau),v(\tau)\rangle d\tau \\
&\le \int_0^t \tau^\mu \mathrm{Re}\langle e(x,D)v(\tau),v(\tau)\rangle d\tau + \int_0^t \mu\tau^{\mu-1}\langle b(x,D)v(\tau),v(\tau)\rangle d\tau \\
&\quad + \int_0^t \tau^\mu(|\langle b(x,D)\big(l_1(x,D)v + T_{l_2}v + r_2(u,\bar u) + \big(l^1_\theta(x,D) + T_{l^2_\theta}\big)\theta_1 u \\
&\quad + \big(\widetilde{l^1_\theta}(x,D) + T_{\widetilde{l^2_\theta}}\big)\overline{\theta_1 u}\big),v\rangle| + |\langle b(x,D)v, l_1(x,D)v + T_{l_2}v + r_2(u,\bar u) \\
&\quad + \big(l^1_\theta(x,D) + T_{l^2_\theta}\big)\theta_1 u + \big(\widetilde{l^1_\theta}(x,D) + T_{\widetilde{l^2_\theta}}\big)\overline{\theta_1 u}\rangle|)d\tau + C\int_0^t \|v\|^2_{L^2}d\tau.
\end{aligned}$$

Theorem 5.5 shows that if v_0 decreases along the backward bicharacteristic through (x_0,ξ_0), then $v(t,.)$ decreases at the same speed for all $t > 0$ along this curve. Theorem 5.6 uses the decrease established in Theorem 5.5 to prove a result of regularity for v at (x_0,ξ_0) by iteration.

Theorem 5.5. *Let (x_0,ξ_0) not be trapped backwards. Let there exist two conic neighborhoods $\mathcal{E}^0 \subset \mathcal{E}$ of $\{\varphi(s,x_0,\xi_0), s \le 0\}$. Let $T > 0$, s in I_d, and u in $C(0,T,L^2(\mathbb{R}^d))$ be a solution of* (5.1). *Suppose there is $\theta(x)$ in $S(0,0)$ equal to 1 on $\mathcal{E}$ such that θu is in $L^\infty(0,T,H_0^s)$. Let v in $L^\infty(0,T,H_0^s)$ be a solution of* (5.11). *Moreover, suppose there exists $s_0(x,\xi)$ in $S(0,2s-d/2)$ with support in $\mathcal{E}$ such that $(s_0^2,-\{a_2,s_0^2\})$ satisfies* (3.1) *and* (3.2) *and $\langle x\rangle^{2(2s-d/2)} \le s_0^2(x,\xi)$ on the set $\mathcal{E}^0 \cap \{|\xi| \ge 1\}$. Suppose v_0 satisfies*

$$\langle s_0(x,D)v_0, s_0(x,D)v_0\rangle < +\infty. \tag{5.48}$$

Then, there exists a neighborhood $\mathcal{D}^0 \subset \mathcal{E}^0$ containing the backward bicharacteristic $\{\varphi(s,x_0,\xi_0), s \le 0\}$ and a pair of symbols (b^0,c^0),

$$\begin{aligned} &0 \le b^0(x,\xi) \in S(0,2(2s-d/2)),\\ &0 \le c^0(x,\xi) = -\{a_2,b^0\}(x,\xi) \in S(1,2(2s-d/2)-1), \end{aligned} \tag{5.49}$$

such that

$$\begin{aligned} &\big\{(x,\xi)\,/\,c^0(x,\xi) \ge \langle x\rangle^{2(2s-d/2)-1}\langle\xi\rangle\big\}\\ &\qquad\qquad \cap \big\{(x,\xi)\,/\,b^0(x,\xi) \ge \langle x\rangle^{2(2s-d/2)}\big\} = \mathcal{D}^0, \end{aligned} \tag{5.50}$$

and for all $T > 0$,

$$\sup_{0\le t\le T} \|\sqrt{b^0}(x,D)v(t)\|_{L^2}^2 + \int_0^T \|\sqrt{c^0}(x,D)v(t)\|_{L^2}^2 dt < +\infty. \tag{5.51}$$

Theorem 5.6. *Let (x_0,ξ_0) not be trapped backwards. Let there exist two conic neighborhoods $\mathcal{E}^0 \subset \mathcal{E}$ of $\{\varphi(s,x_0,\xi_0), s \le 0\}$. Let $T > 0$, s in I_d, and u in $C(0,T,L^2(\mathbb{R}^d))$ be a solution of* (5.1). *Suppose there is $\theta(x)$ in $S(0,0)$ equal to 1 on $\mathcal{E}$ such that θu is in $L^\infty(0,T,H_0^s)$. Let v in $L^\infty(0,T,H_0^s)$ be a solution of* (5.11). *Moreover, suppose there exists $s_0(x,\xi)$ in $S(0,2s-d/2)$ with support in $\mathcal{E}$ such that $(s_0^2,-\{a_2,s_0^2\})$ satisfies* (3.1) *and* (3.2) *and $\langle x\rangle^{2(2s-d/2)} \le s_0^2(x,\xi)$ on the set $\mathcal{E}^0 \cap \{|\xi| \ge 1\}$. Suppose v_0 satisfies* (5.48). *We define $\kappa = 2(2s-d/2) - [2(2s-d/2)]$ and there are nested neighborhoods $\mathcal{D}^l \subset \mathcal{D}^{l-1} \subset \cdots \subset \mathcal{D}^0 \subset \mathcal{E}^0$ containing the backward bicharacteristic $\{\varphi(s,x_0,\xi_0), s \le 0\}$ and symbol pairs (b_l,c_l),*

$$\begin{aligned} &0 \le b_l(x,\xi) \in S(l+\kappa, 2(2s-d/2)-l-\kappa),\\ &0 \le c_l(x,\xi) = -\{a_2,b_l\}(x,\xi) \in S(l+\kappa+1, 2(2s-d/2)-l-\kappa-1), \end{aligned} \tag{5.52}$$

with $0 \le l \le [2(2s-d/2)]$ such that for $l > 0$,

$$\begin{aligned} \operatorname{supp}(b_l(x,\xi)) \subset &\big\{(x,\xi)/c_{l-1}(x,\xi) \ge \langle x\rangle^{2(2s-d/2)-l-\kappa}\langle\xi\rangle^{l+\kappa}\big\}\\ &\cap \big\{(x,\xi)/b_{l-1}(x,\xi) \ge \langle x\rangle^{2(2s-d/2)-l-\kappa+1}\langle\xi\rangle^{l+\kappa-1}\big\} = \mathcal{D}^{l-1}, \end{aligned} \tag{5.53}$$

and for all $T > 0$,

$$\sup_{0\le t\le T} t^{\mu_l}\|\sqrt{b_l}(x,D)v(t)\|_{L^2}^2 + \int_0^T t^{\mu_l}\|\sqrt{c_l}(x,D)v(t)\|_{L^2}^2 dt < +\infty. \tag{5.54}$$

The exponents can be chosen $\mu_l = l + \kappa(1+\delta)$ for any $\delta > 0$. When $l = [2(2s-d/2)]$ there is an exception to (5.53) *that for any choice of $\nu < -1$, we may take $c_{[2(2s-d/2)]}(x,\xi)$ such that*

$$\mathcal{D}^{[2(2s-d/2)]} = \big\{(x,\xi)/c_{[2(2s-d/2)]}(x,\xi) \ge \langle x\rangle^{\nu}\langle\xi\rangle^{2(2s-d/2)}\big\} \ne \emptyset. \tag{5.55}$$

Remarks.

1. Suppose u_0 is in $H_0^s(\mathbb{R}^d)$. Then, the solution u of (5.1) is in $L^\infty(0,T,H_0^s)$ by Corollary 4.5. In this case, we can choose $\theta(x)=1$ in Theorem 5.6.
2. Let $b(x,\xi)$ be one of the symbols in the statement of Theorem 5.5 or 5.6. We will construct those symbols using Proposition 3.1. Therefore, we can choose b and c such that $\sqrt{b}$ is in $S(m/2,k/2)$ and $\sqrt{c}$ is in $S((m+1)/2,(k-1)/2)$ for $b\in S(m,k)$ and $c\in S(m+1,k-1)$.

Proof of Theorem 5.5. Let L be an integer defined by $L=[2s-d/2]+1$ and $0<\eta<1/2$ defined by $\eta=(2s-d/2)/(2L)$. Starting with $(s_0^2,-\{a_2,s_0^2\})$ and $\mathcal{E}^0$ and using Proposition 3.1, we construct a sequence of conic neighborhoods $\mathcal{E}^l\subset\mathcal{E}^{l-1}\subset\cdots\subset\mathcal{E}^0$ containing the backward bicharacteristic $\{\varphi(s,x_0,\xi_0), s\leq 0\}$ for $1\leq l\leq 2L$ and pairs of symbols (b_l^0,c_l^0) satisfying (3.1) and (3.2) with $b_l^0(x,\xi)$ in $S(0,2l\eta)$, $c_l^0(x,\xi)$ in $S(1,2l\eta-1)$, and

$$\operatorname{supp}(b_l^0(x,\xi))\subset\{(x,\xi)\,/\,b_{l-1}^0(x,\xi)\geq\langle x\rangle^{2(l-1)\eta}\}=\mathcal{E}^{l-1}. \tag{5.56}$$

Equation (5.46) implies

$$\begin{aligned}\operatorname{Re}\,\langle\ & b_l^0(x,D)v(t),v(t)\rangle+\int_0^t\operatorname{Re}\langle c_l^0(x,D)v(\tau),v(\tau)\rangle d\tau\\ &\leq\operatorname{Re}\langle b_l^0(x,D)v_0,v_0\rangle+\int_0^t\operatorname{Re}\langle e(x,D)v(\tau),v(\tau)\rangle d\tau\\ &\quad+\int_0^t(|\langle b_l^0(x,D)(l_1(x,D)v+T_{l_2}v+r_2(u,\bar u)+(l_\theta^1(x,D)+T_{l_\theta^2})\theta_1u\\ &\quad+(\widetilde{l_\theta^1}(x,D)+T_{\widetilde{l_\theta^2}})\overline{\theta_1u}),v\rangle|+|\langle b_l^0(x,D)v,l_1(x,D)v+T_{l_2}v+r_2(u,\bar u)\\ &\quad+(l_\theta^1(x,D)+T_{l_\theta^2})\theta_1u+(\widetilde{l_\theta^1}(x,D)+T_{\widetilde{l_\theta^2}})\overline{\theta_1u}\rangle|)d\tau+C,\end{aligned} \tag{5.57}$$

where $e(x,\xi)$ is in $S(0,2l\eta-2)$ and hence in $S(0,2(l-1)\eta)$. As $\operatorname{supp}b_l^0(x,\xi)\subset\{s_0(x,\xi)\geq\langle x\rangle^{2s-d/2}\}$, Lemma 3.5 and (5.48) yield

$$|\langle b_l^0(x,D)v_0,v_0\rangle|\leq C(\|s_0(x,D)v_0\|_{L^2}^2+\|v_0\|_{L^2}^2)<+\infty. \tag{5.58}$$

As $\theta=1$ on the support of $b_l^0(x,\xi)$, and as the support of $l_\theta^1(x,\xi)$ and of $\widetilde{l_\theta^1}(x,\xi)$ are included in the support of $\nabla\theta$, Proposition 3.2 implies

$$\begin{aligned}&\int_0^t(|\langle b_l^0(x,D)(l_\theta^1(x,D)\theta_1u(\tau)+\widetilde{l_\theta^1}(x,D)\overline{\theta_1u}(\tau)),v(\tau)\rangle|\\ &\quad+|\langle b_l^0(x,D)v(\tau),l_\theta^1(x,D)\theta_1u(\tau)+\widetilde{l_\theta^1}(x,D)\overline{\theta_1u}(\tau)\rangle|)d\tau\\ &\leq C\int_0^T\|u(\tau)\|_{L^2}^2<+\infty.\end{aligned} \tag{5.59}$$

Using Proposition 3.2, we have

$$\begin{aligned}b_l^0(x,D)&=\sqrt{b_l^0}(x,D)^*\sqrt{b_l^0}(x,D)+e_1(x,D),\\ b_l^0(x,D)l_1(x,D)&=\sqrt{b_l^0}(x,D)^*l_1(x,D)\sqrt{b_l^0}(x,D)+e_2(x,D),\end{aligned} \tag{5.60}$$

where $e_1(x,\xi)$ and $e_2(x,\xi)$ are in $S(-1,2l\eta-1)$ and, hence, in $S(0,2(l-1)\eta)$. So

$$
\begin{aligned}
(5.61)\quad & |\langle b_l^0(x,D)((l_1(x,D)+T_{l_2})v+r_2(u,\bar{u})+T_{l_\theta^2}\theta_1 u+T_{\widetilde{l_\theta^2}}\overline{\theta_1 u}),v(\tau)\rangle| \\
& \leq C(\|\sqrt{b_l^0}(x,D)v(\tau)\|_{L^2}^2+\|\sqrt{b_l^0}(x,D)(T_{l_2}v+r_2(u,\bar{u})+T_{l_\theta^2}\theta_1 u+T_{\widetilde{l_\theta^2}}\overline{\theta_1 u})\|_{L^2}^2) \\
& \quad +|\langle e_1(x,D)(T_{l_2}v+r_2(u,\bar{u})+T_{l_\theta^2}\theta_1 u+T_{\widetilde{l_\theta^2}}\overline{\theta_1 u}),v(\tau)\rangle| \\
& \quad +|\langle e_2(x,D)v(\tau),v(\tau)\rangle|.
\end{aligned}
$$

Moreover, as $\sqrt{b_l^0}(x,D)\langle x\rangle^{-(2s-d/2)}$ is bounded on L^2 and $\langle x\rangle^{2s-d/2}r_2(u,\bar{u})$ is in $L^\infty(0,T,L^2)$, we get

$$
\big\|\sqrt{b_l^0}(x,D)r_2(u,\bar{u})\big\|_{L^2}^2\leq C. \tag{5.62}
$$

As l_2, l_θ^2, and $\widetilde{l_\theta^2}$ are in $L^\infty(0,T,\widetilde{\Sigma}_s^0)$, as $\sqrt{b_l^0}(x,\xi)$ is in $S(0,2s-d/2)$ for all l, and as v and $\theta_1 u$ are in $L^\infty(0,T,H_0^s)$, Proposition 4.12 implies

$$
\big\|\sqrt{b_l^0}(x,D)(T_{l_2}v+T_{l_\theta^2}\theta_1 u+T_{\widetilde{l_\theta^2}}\overline{\theta_1 u})\big\|_{L^2}^2\leq C. \tag{5.63}
$$

Finally, Lemma 3.4 with b_l^0 and c_l^0 yields

$$
\begin{aligned}
& \|\sqrt{b_l^0}(x,D)v(t)\|_{L^2}^2+\int_0^t\|\sqrt{c_l^0}(x,D)v(\tau)\|_{L^2}^2d\tau \\
(5.64)\quad & \leq \mathrm{Re}\langle b_l^0(x,D)v(t),v(t)\rangle+\int_0^t\mathrm{Re}\langle c_l^0(x,D)v(\tau),v(\tau)\rangle d\tau \\
& \quad +\mathrm{Re}\langle e_3(x,D)v(t),v(t)\rangle+\int_0^t\mathrm{Re}\langle e_4(x,D)v(\tau),v(\tau)\rangle d\tau+C,
\end{aligned}
$$

where $e_3(x,\xi)$ and $e_4(x,\xi)$ are in $S(0,2(l-1)\eta)$.

When $l=1$, $e(x,D)$, $e_1(x,D)$, $e_2(x,D)$, $e_3(x,D)$, and $e_4(x,\xi)$ are bounded on L^2. Thus, (5.57), (5.58), (5.59), (5.61), (5.62), (5.63), and (5.64) imply

$$
\begin{aligned}
(5.65)\quad & \|\sqrt{b_1^0}(x,D)v(t)\|_{L^2}^2+\int_0^t\|\sqrt{c_1^0}(x,D)v(\tau)\|_{L^2}^2d\tau \\
& \leq C\int_0^t\|\sqrt{b_1^0}(x,D)v(\tau)\|_{L^2}^2d\tau+C.
\end{aligned}
$$

Gronwall's lemma yields

$$
\sup_{0\leq t\leq T}\|\sqrt{b_1^0}(x,D)v(t)\|_{L^2}^2+\int_0^T\|\sqrt{c_1^0}(x,D)v(t)\|_{L^2}^2dt<+\infty. \tag{5.66}
$$

Assume

$$
\sup_{0\leq t\leq T}\|\sqrt{b_{l-1}^0}(x,D)v(t)\|_{L^2}^2+\int_0^T\|\sqrt{c_{l-1}^0}(x,D)v(t)\|_{L^2}^2dt<+\infty \tag{5.67}
$$

for $2 \le l \le L$. As $e_1(x,\xi)$ and $e_2(x,\xi)$ are in $S(0, 2(l-1)\eta)$ with support in $\{b^0_{l-1}(x,\xi) \ge \langle x\rangle^{2(l-1)\eta}\}$ by (5.56), Lemma 3.5 implies

$$\begin{aligned} &|\langle e_1(x,D)(T_{l_2}v + r_2(u,\bar u) + T_{l^2_\theta}\theta_1 u + T_{\widetilde{l^2_\theta}}\overline{\theta_1 u}), v(\tau)\rangle| \\ &\quad + |\langle e_2(x,D)v(\tau), v(\tau)\rangle| \\ &\le C(\|\sqrt{b^0_{l-1}}(x,D)v\|^2_{L^2} + \|\sqrt{b^0_{l-1}}(x,D)r_2(u,\bar u)\|^2_{L^2} \\ &\quad + \|\sqrt{b^0_{l-1}}(x,D)(T_{l_2}v + T_{l^2_\theta}\theta_1 u + T_{\widetilde{l^2_\theta}}\overline{\theta_1 u})\|^2_{L^2}) + C. \end{aligned} \tag{5.68}$$

As for (5.62) and (5.63), we have

$$\begin{aligned} &\big\|\sqrt{b^0_{l-1}}(x,D)r_2(u,\bar u)\big\|^2_{L^2} \le C, \\ &\big\|\sqrt{b^0_{l-1}}(x,D)(T_{l_2}v + T_{l^2_\theta}\theta_1 u + T_{\widetilde{l^2_\theta}}\overline{\theta_1 u})\big\|^2_{L^2} \le C. \end{aligned} \tag{5.69}$$

Inequality (5.67) implies

$$\big\|\sqrt{b^0_{l-1}}(x,D)v(\tau)\big\|^2_{L^2} \le C. \tag{5.70}$$

Then (5.57), (5.58), (5.59), (5.61), (5.62), (5.63), (5.64), (5.68), (5.69), and (5.70) yield

$$\begin{aligned} &\|\sqrt{b^0_l}(x,D)v(t)\|^2_{L^2} + \int_0^t \|\sqrt{c^0_l}(x,D)v(\tau)\|^2_{L^2}d\tau \\ &\qquad \le C\int_0^t \|\sqrt{b^0_l}(x,D)v(\tau)\|^2_{L^2}dt + C + \mathrm{Re}\langle e_3(x,D)v(t), v(t)\rangle \\ &\qquad + \int_0^t \mathrm{Re}\langle e_5(x,D)v(\tau), v(\tau)\rangle dt, \end{aligned} \tag{5.71}$$

where $e_5(x,\xi) = e(x,\xi) + e_4(x,\xi)$ is in $S(0, 2(l-1)\eta)$ with support included in $\{b^0_{l-1}(x,\xi) \ge \langle x\rangle^{2(l-1)\eta}\}$. Lemma 3.5 and (5.67) imply

$$\begin{aligned} &|\langle e_3(x,D)v(t), v(t)\rangle| + \int_0^t |\langle e_5(x,D)v(\tau), v(\tau)\rangle| d\tau \\ &\le C\left(\|\sqrt{b^0_{l-1}}(x,D)v(t)\|^2_{L^2} + \int_0^t \|\sqrt{b^0_{l-1}}(x,D)v(\tau)\|^2_{L^2}d\tau\right) + C < +\infty, \end{aligned} \tag{5.72}$$

which together with (5.71) yields

$$\sup_{0\le t\le T}\|\sqrt{b^0_l}(x,D)v(t)\|^2_{L^2} + \int_0^T \|\sqrt{c^0_l}(x,D)v(t)\|^2_{L^2}dt < +\infty, \tag{5.73}$$

using Gronwall's lemma. Hence, (5.73) is true for $1 \le l \le 2L$ by induction. It suffices to define $(b^0, c^0) = (b^0_l, c^0_l)$ with $l = 2L$. ◻

Proof of Theorem 5.6. Starting with (b^0, c^0) given by Theorem 5.5 and

$$\mathcal{D}_0 = \{(x,\xi)/b^0(x,\xi) \ge \langle x\rangle^{2(2s-d/2)}\} \cap \{(x,\xi)/c^0(x,\xi) \ge \langle x\rangle^{2(2s-d/2)-1}\langle\xi\rangle\}, \tag{5.74}$$

and using Proposition 3.1, we construct a sequence of conic neighborhoods $\mathcal{D}^l \subset \mathcal{D}^{l-1} \subset \cdots \subset \mathcal{D}^0 \subset \mathcal{D}_0 \subset \mathcal{E}^0$ containing $\{\varphi(s, x_0, \xi_0), s \le 0\}$ for $0 \le l \le [2(2s - d/2)]$

and pairs of symbols (b_l, c_l) satisfying (3.1), (3.2), (5.52), and (5.53). For $\mu_l > 0$, (5.47) implies

(5.75)
$$\begin{aligned}
&t^{\mu}\mathrm{Re}\langle b_l(x,D)v(t),v(t)\rangle+\int_0^t\tau^{\mu}\mathrm{Re}\langle c_l(x,D)v(\tau),v(\tau)\rangle d\tau\\
&\leq\int_0^t\tau^{\mu}\mathrm{Re}\langle e(x,D)v(\tau),v(\tau)\rangle d\tau+\int_0^t\mu\tau^{\mu-1}\langle b_l(x,D)v(\tau),v(\tau)\rangle d\tau\\
&+\int_0^t\tau^{\mu}(|\langle b_l(x,D)(l_1(x,D)v+T_{l_2}v+r_2(u,\bar{u})+(l^1_\theta(x,D)+T_{l^2_\theta})\theta_1u+(\widetilde{l^1_\theta}(x,D)\\
&+T_{\widetilde{l^2_\theta}})\overline{\theta_1 u}),v\rangle|+|\langle b_l(x,D)v,l_1(x,D)v+T_{l_2}v+r_2(u,\bar{u})+(l^1_\theta(x,D)+T_{l^2_\theta})\theta_1u\\
&+(\widetilde{l^1_\theta}(x,D)+T_{\widetilde{l^2_\theta}})\overline{\theta_1 u}\rangle|)d\tau+C,
\end{aligned}$$

where $e(x,\xi)$ is in $S(\kappa+l,2(2s-d/2)-l-\kappa-2)$ and hence in $S(\kappa+l,2(2s-d/2)-l-\kappa)$. As $\theta=1$ on the support of $b_l(x,\xi)$, and as the support of $l^1_\theta(x,\xi)$ and of $\widetilde{l^1_\theta}(x,\xi)$ are included in the support of $\nabla\theta$, Proposition 3.2 yields

$$\begin{aligned}
&\int_0^t(|\langle\tau^{\mu_l}b_l(x,D)(l^1_\theta(x,D)\theta_1u(\tau)+\widetilde{l^1_\theta}(x,D)\overline{\theta_1u}(\tau)),v(\tau)\rangle|\\
&\qquad+|\langle\tau^{\mu_l}b_l(x,D)v(\tau),l^1_\theta(x,D)\theta_1u(\tau)\\
&\qquad+\widetilde{l^1_\theta}(x,D)\overline{\theta_1u}(\tau)\rangle|)d\tau\leq C\int_0^T\|u(\tau)\|^2_{L^2}<+\infty.
\end{aligned}\tag{5.76}$$

Moreover, Lemma 3.4 with b_l and c_l implies

$$\begin{aligned}
&t^{\mu_l}\|\sqrt{b_l}(x,D)v(t)\|^2_{L^2}+\int_0^t\tau^{\mu_l}\|\sqrt{c_l}(x,D)v(\tau)\|^2_{L^2}d\tau\\
&\leq\mathrm{Re}\langle t^{\mu_l}b_l(x,D)v(t),v(t)\rangle+\int_0^t\mathrm{Re}\langle\tau^{\mu_l}c_l(x,D)v(\tau),v(\tau)\rangle d\tau\\
&\quad+\mathrm{Re}\langle t^{\mu_l}e_2(x,D)v(t),v(t)\rangle+\int_0^t\mathrm{Re}\langle\tau^{\mu_l}e_3(x,D)v(\tau),v(\tau)\rangle d\tau+C,
\end{aligned}\tag{5.77}$$

where $e_2(x,\xi)$ belongs to $S(l+\kappa-1,2(2s-d/2)-l-\kappa-1)$ and $e_3(x,\xi)$ belongs to $S(l+\kappa,2(2s-d/2)-l-\kappa-2)$.

We define a symbol $d_l(x,\xi)$. If $l=0$, as $b_0(x,\xi)$ is in $S(\kappa,2(2s-d/2)-\kappa)$ and its support is in $\mathcal{D}_0$ defined by (5.74), there exists $d_0(x,\xi)$ in $S(\kappa,2(2s-d/2)-\kappa)$ with $\sqrt{d_0}(x,\xi)\in S(\kappa/2,(2s-d/2)-\kappa/2)$ such that $d_0(x,\xi)$ has its support in $\mathcal{D}_0$ and

$$\mathrm{supp}(b_0(x,\xi))\subset\{(x,\xi)/d_0(x,\xi)\geq\langle x\rangle^{2(2s-d/2)-\kappa}\langle\xi\rangle^{\kappa}\}.\tag{5.78}$$

If $l\geq 1$, as $b_l(x,\xi)$ is in $S(l+\kappa,2(2s-d/2)-l-\kappa)$ and has its support in $\{c_{l-1}(x,\xi)\geq\langle x\rangle^{2(2s-d/2)-l-\kappa}\langle\xi\rangle^{l+\kappa}\}$, there exists $d_l(x,\xi)$ in $S(l+\kappa,2(2s-d/2)-l-\kappa)$ with $\sqrt{d_l}(x,\xi)\in S((l+\kappa)/2,(2s-d/2)-(l+\kappa)/2)$ such that

$$\mathrm{supp}(b_l(x,\xi))\subset\{(x,\xi)\,/\,d_l(x,\xi)\geq\langle x\rangle^{2(2s-d/2)-l-\kappa}\langle\xi\rangle^{l+\kappa}\}\tag{5.79}$$

and

$$\mathrm{supp}(d_l(x,\xi))\subset\{(x,\xi)\,/\,c_{l-1}(x,\xi)\geq\langle x\rangle^{2(2s-d/2)-l-\kappa}\langle\xi\rangle^{l+\kappa}\}.\tag{5.80}$$

By (5.78) and (5.79), Lemma 3.5 implies

(5.81)
$$|\langle b_l(x,D)(l_1(x,D)v + T_{l_2}v + r_2(u,\bar u) + T_{l^2_\theta})\theta_1 u + T_{\widetilde{l^2_\theta}})\overline{\theta_1 u}), v(\tau)\rangle| \\ \leq C(\|\sqrt{d_l}(x,D)v(\tau)\|^2_{L^2} + \|\sqrt{d_l}(x,D)r_2(u,\bar u)\|^2_{L^2} \\ + \|\sqrt{d_l}(x,D)T_{l_2}v\|^2_{L^2} + \|\sqrt{d_l}(x,D)(T_{l^2_\theta}\theta_1 u + T_{\widetilde{l^2_\theta}}\overline{\theta_1 u})\|^2_{L^2}).$$

Moreover, $\sqrt{d_l}(x,D)\langle x\rangle^{(\kappa+l)/2-(2s-d/2)}(1+|D|^2)^{-(\kappa+l)/4}$ is bounded on L^2, and $(1+|D|^2)^{(\kappa+l)/4}\langle x\rangle^{2s-d/2-(\kappa+l)/2}r_2(u,\bar u)$ is in L^2 using Proposition 4.3 and the fact that $r_2(u,\bar u)$ is in $L^\infty(0,T,H_0^{2s-d/2})$. So

$$\|\sqrt{d_l}(x,D)r_2(u,\bar u)\|^2_{L^2} \leq C. \tag{5.82}$$

l^2_θ and $\widetilde{l^2_\theta}$ are in $L^\infty(0,T,\widetilde\Sigma^0_s)$ and they vanish in a neighborhood of the support of $\sqrt{d_l}(x,\xi)$, $\sqrt{d_l}(x,\xi)$ is in $S((l+\kappa)/2,(2s-d/2)-(l+\kappa)/2)$, and v and $\theta_1 u$ are in $L^\infty(0,T,H^s_0)$. Therefore, Proposition 4.12 implies that

$$\|\sqrt{d_l}(x,D)(T_{l^2_\theta}\theta_1 u + T_{\widetilde{l^2_\theta}}\overline{\theta_1 u})\|^2_{L^2} \leq C. \tag{5.83}$$

Finally, Proposition 4.12 implies that

$$\|\sqrt{d_l}(x,D)T_{l_2}v\|^2_{L^2} \leq C\left(\sum_{1\leq j\leq N}\|\sqrt{d^j_l}(x,D)v\|^2_{L^2}+1\right), \tag{5.84}$$

where $d^j_l(x,\xi)$ is in $S((l+\kappa)/2,(2s-d/2)-(l+\kappa)/2)$ and its support is included in the support of $\sqrt{d_l}(x,\xi)$. Inequalities (5.81), (5.82), (5.83), and (5.84) yield

(5.85)
$$|\langle b_l(x,D)(l_1(x,D)v + T_{l_2}v + r_2(u,\bar u) + T_{l^2_\theta}\theta_1 u + T_{\widetilde{l^2_\theta}}\overline{\theta_1 u}), v(\tau)\rangle| \\ \leq C\left(\|\sqrt{d_l}(x,D)v(\tau)\|^2_{L^2} + \sum_{1\leq j\leq N}\|d^j_l(x,D)v(\tau)\|^2_{L^2}\right) + C.$$

First we prove (5.54) when $l=0$. Propositions 3.2 and 3.3 imply the existence of $e_4(x,\xi)$ in $S(\kappa, 2(2s-d/2)-\kappa)$ with support in $\mathcal{D}_0$ such that

$$\sqrt{d_0}(x,D)^*\sqrt{d_0}(x,D) + \sum_{1\leq j\leq N} d^j_0(x,D)^* d^j_0(x,D) = e_4(x,D), \tag{5.86}$$

which together with (5.75), (5.76), (5.77), and (5.85) yields

(5.87)
$$t^{\mu_0}\|\sqrt{b_0}(x,D)v(t)\|^2_{L^2} + \int_0^t \tau^{\mu_0}\|\sqrt{c_0}(x,D)v(\tau)\|^2_{L^2}d\tau \\ \leq \mathrm{Re}\langle t^{\mu_0}e_2(x,D)v(t),v(t)\rangle + \int_0^t \mathrm{Re}\langle \tau^{\mu_0}e_5(x,D)v(\tau),v(\tau)\rangle d\tau \\ + \int_0^t \mu_0\mathrm{Re}\langle\tau^{\mu_0-1}b_0(x,D)v(\tau),v(\tau)\rangle d\tau + C,$$

where $e_5(x,\xi) = e(x,\xi) + e_3(x,\xi) + e_4(x,\xi)$. As $e_2(x,\xi)$ is in $S(\kappa - 1, 2s - d/2 - \kappa - 1)$ and has its support in $\mathcal{D}_0$, Lemma 3.5 and Theorem 5.5 yield

$$\mathrm{Re}\langle e_2(x,D)v(t), v(t)\rangle \le C\|\sqrt{b^0}(x,D)v(t)\|_{L^2}^2 + C < +\infty. \tag{5.88}$$

We choose μ_0 such that $\kappa < \mu_0 < 1$, which implies that $t^{-(1-\mu_0)/(1-\kappa)}$ is locally integrable in t. As $e_5(x,\xi)$ and $b_0(x,\xi)$ have their support in $\mathcal{D}_0$ defined by (5.74), we have

$$\begin{aligned} |t^{\mu_0} e_5(x,\xi)| &\le C(b^0(x,\xi))^{1-\kappa}(t^{\mu_0/\kappa}c^0(x,\xi))^{\kappa} \le C(b^0(x,\xi) + t^{\mu_0/\kappa}c^0(x,\xi)),\\ |t^{\mu_0-1}b_0(x,\xi)| &\le C(t^{-(1-\mu_0)/(1-\kappa)}b^0(x,\xi))^{1-\kappa}(c^0(x,\xi))^{\kappa}\\ &\le C(t^{-(1-\mu_0)/(1-\kappa)}b^0(x,\xi) + c^0(x,\xi)), \end{aligned}$$

and Lemma 3.4 with $C(b^0(x,\xi) + t^{\mu_0/\kappa}c^0(x,\xi)) - t^{\mu_0}e_5(x,\xi)$ and $C(b^0(x,\xi) + t^{(1-\mu_0)/(1-\kappa)}c^0(x,\xi)) - t^{\kappa/(1-\kappa)(1-\mu_0)}b_0(x,\xi)$ implies

$$\begin{aligned} &\int_0^t \mathrm{Re}\langle \tau^{\mu_0} e_5(x,D)v(\tau), v(\tau)\rangle d\tau + \int_0^t \mu_0 \mathrm{Re}\langle \tau^{\mu_0-1} b_0(x,D)v(\tau), v(\tau)\rangle d\tau\\ &\quad \le C \sup_{0\le t\le T} \mathrm{Re}\langle b^0(x,D)v(t), v(t)\rangle + C\int_0^t \mathrm{Re}\langle c^0(x,D)v(\tau), v(\tau)\rangle d\tau\\ &\qquad + C\sup_{0\le t\le T} \mathrm{Re}\langle e_6(t,x,D)v(t), v(t)\rangle + C, \end{aligned} \tag{5.89}$$

where $e_6(t,x,\xi)$ is in $S(0, 2(2s - d/2))$ with seminorms bounded independently of t for $0 \le t \le T$ and with support in $\mathcal{D}_0$. Lemma 3.5 and Theorem 5.5 yield

$$\begin{aligned} \sup_{0\le t\le T} \mathrm{Re}\langle b^0(x,D)v(t), v(t)\rangle &+ \int_0^T \mathrm{Re}\langle c^0(x,D)v(\tau), v(\tau)\rangle d\tau\\ &+ \sup_{0\le t\le T} \mathrm{Re}\langle e_6(t,x,D)v(t), v(t)\rangle < +\infty, \end{aligned} \tag{5.90}$$

which together with (5.87), (5.88), and (5.89) implies

$$\sup_{0\le t\le T} t^{\mu_0}\|\sqrt{b_0}(x,D)v(t)\|_{L^2}^2 + \int_0^T t^{\mu_0}\|\sqrt{c_0}(x,D)v(t)\|_{L^2}^2 dt < +\infty. \tag{5.91}$$

We define $\mu_l = \mu_0 + l$. Assume

$$\sup_{0\le t\le T} t^{\mu_{l-1}}\|\sqrt{b_{l-1}}(x,D)v(t)\|_{L^2}^2 + \int_0^T t^{\mu_{l-1}}\|\sqrt{c_{l-1}}(x,D)v(t)\|_{L^2}^2 dt < +\infty \tag{5.92}$$

for $1 \le l \le [2(2s - d/2)]$. As $\sqrt{d_l}(x,D)^*\sqrt{d_l}(x,D) + \sum_{1\le j\le N} d_l^j(x,D)^* d_l^j(x,D)$ is in $Op(S(l+\kappa, 2(2s-d/2) - l - \kappa))$ and as its symbol is supported in $\{c_{l-1}(x,\xi) \ge \langle x\rangle^{2(2s-d/2)-l-\kappa}\langle\xi\rangle^{l+\kappa}\}$, Lemma 3.5 and (5.92) imply

$$\begin{aligned} &\int_0^t \tau^{\mu_l}\left(\|\sqrt{d_l}(x,D)v(\tau)\|_{L^2}^2 + \sum_{1\le j\le N}\|d_l^j(x,D)v(\tau)\|_{L^2}^2\right)d\tau\\ &\quad \le C\int_0^t \tau^{\mu_{l-1}}\|\sqrt{c_{l-1}}(x,D)v(\tau)\|_{L^2}^2 d\tau + C < +\infty. \end{aligned} \tag{5.93}$$

Then (5.75), (5.76), (5.77), (5.85), and (5.93) yield

$$
\begin{aligned}
(5.94)\qquad & t^{\mu_l}\|\sqrt{b_l}(x,D)v(t)\|_{L^2}^2+\int_0^t \tau^{\mu_l}\|\sqrt{c_l}(x,D)v(\tau)\|_{L^2}^2 d\tau \\
&\le \mathrm{Re}\langle t^{\mu_l}e_2(x,D)v(t),v(t)\rangle+\int_0^t \mathrm{Re}\langle \tau^{\mu_l}e_5(x,D)v(\tau),v(\tau)\rangle d\tau \\
&\quad +\int_0^t \mu_l \mathrm{Re}\langle \tau^{\mu_l-1}b_l(x,D)v(\tau),v(\tau)\rangle d\tau + C.
\end{aligned}
$$

$b_l(x,\xi)$ and $e_5(x,\xi)$ are in $S(l+\kappa,2(2s-d/2)-l-\kappa)$ and have their support in $\{c_{l-1}(x,\xi)\ge \langle x\rangle^{2(2s-d/2)-l-\kappa}\langle\xi\rangle^{l+\kappa}\}$. $e_2(x,\xi)$ is in $S(l+\kappa-1,2(2s-d/2)-l-\kappa-1)$ and has its support in $\{b_{l-1}(x,\xi)\ge\langle x\rangle^{2(2s-d/2)-l-\kappa+1}\langle\xi\rangle^{l+\kappa-1}\}$. Thus, Lemma 3.5 implies

$$
\begin{aligned}
(5.95)\qquad & \mathrm{Re}\langle t^{\mu_l}e_2(x,D)v(t),v(t)\rangle+\int_0^t \mathrm{Re}\langle \tau^{\mu_l}e_5(x,D)v(\tau),v(\tau)\rangle d\tau \\
&+\int_0^t \mu_l\mathrm{Re}\langle \tau^{\mu_l-1}b_l(x,D)v(\tau),v(\tau)\rangle d\tau \le C\sup_{0\le t\le T} t^{\mu_{l-1}}\|\sqrt{b_{l-1}}(x,D)v\|_{L^2}^2 \\
&+C\int_0^t \tau^{\mu_{l-1}}\|\sqrt{c_{l-1}}(x,D)v(\tau)\|_{L^2}^2 d\tau + C,
\end{aligned}
$$

which together with (5.94) and (5.92) implies

$$
(5.96)\qquad t^{\mu_l}\|\sqrt{b_l}(x,D)v(t)\|_{L^2}^2+\int_0^t \tau^{\mu_l}\|\sqrt{c_l}(x,D)v(\tau)\|_{L^2}^2 d\tau \le C.
$$

Thus, (5.54) is true for all $0\le l\le[2(2s-d/2)]$ by induction. □

We can now prove Theorems 2.3 and 2.4.

Proof of Theorem 2.3. We first check that v_0 satisfies (5.48). As $\mathcal{E}$ satisfies (2.7), Proposition 3.1 implies the existence of a conic neighborhood $\mathcal{E}^0\subset\mathcal{E}$ of $\{\varphi(s,x_0,\xi_0), s\le 0\}$ and of $s_0(x,\xi)$ in $S(0,2s-d/2)$ with support in $\mathcal{E}$ such that $(s_0^2,-\{a_2,s_0^2\})$ satisfies (3.1) and (3.2) and $\langle x\rangle^{2(2s-d/2)}\le s_0^2(x,\xi)$ on the set $\mathcal{E}^0\cap\{|\xi|\ge 1\}$. As θu_0 is in H_0^s, as $q_2(0,x,\xi)$ is in $\widetilde{\Sigma}_s^0$ and as $s_0(x,\xi)$ is in $S(0,2s-d/2)$, we have

$$
(5.97)\qquad \|s_0(x,D)T_{q_2(0,.)}\overline{\theta u_0}\|_{L^2}\le C
$$

by Proposition 4.12. Moreover, by the assumptions of Theorem 2.3, $s(x,\xi)$ is in $S(0,2s-d/2)$ and $\langle x\rangle^{2(2s-d/2)}\le s^2(x,\xi)$ on the set $\mathcal{E}$. As θ is in $S(0,0)$, Lemma 3.5 and (2.11) yield

$$
(5.98)\qquad \|s_0(x,D)\theta u_0\|_{L^2}\le C\|s(x,D)u_0\|_{L^2}\le C,
$$

and as $q_1(x,\xi)$ and θ are in $S(0,0)$, Lemma 3.5 and (2.12) yield

$$
(5.99)\qquad \|s_0(x,D)q_1(x,D)\overline{\theta u_0}\|_{L^2}\le C\|s(x,D)\overline{u_0}\|_{L^2}\le C.
$$

Finally, as $v_0=\theta u_0-(q_1(x,D)+T_{q_2(0,.)})\overline{\theta u_0}$, (5.98), (5.97), and (5.99) imply that v_0 satisfies (5.48). So, the assumptions of Theorem 5.6 are satisfied.

For $l=[2(2s-d/2)]$, the symbol $b_l(x,\xi)$ of Theorem 5.6 is in $S(2(2s-d/2),0)$. Therefore, $\sqrt{b_l}(x,\xi)$ is in $S(2s-d/2,0)$ and hence in $S^{2s-d/2}$. Inequality (5.54) yields for all $0<t\le T$,

$$
(5.100)\qquad \|\sqrt{b_l}(x,D)v(t)\|_{L^2}<+\infty,
$$

which implies that $v(t,.)$ is microlocally $H^{2s-d/2}$ in (x_0,ξ_0) for all $0<t\le T$ since $\sqrt{b_l}(x,\xi)$ is elliptic at (x_0,ξ_0).

Moreover, for $l=[2(2s-d/2)]$, the symbol $c_l(x,\xi)$ of Theorem 5.6 is in $S(2(2s-d/2)+1,-1)$. Therefore, $\sqrt{c_l}(x,\xi)$ is in $S(2s-d/2+1/2,-1/2)$ and hence in $S^{2s-d/2+1/2}$. Inequality (5.54) yields for all $0<t\le T$ and for all $\delta>0$

$$\int_0^T t^{2(2s-d/2)+\delta}\|\sqrt{c_l}(x,D)v(t,.)\|_{L^2}^2 dt<+\infty. \tag{5.101}$$

Assume that $u(t,.)$ is microlocally H^σ at $(x_0,-\xi_0)$ for a time t, $0<t\le T$. So, $\overline{\theta u}(t,.)$ is microlocally H^σ at (x_0,ξ_0). As $q_1(x,\xi)$ is in S^{-2} and $q_2(t,x,\xi)$ is in Bony's class $\Sigma^{-2}_{s-d/2}$, $(q_1(x,D)+T_{q_2(t,.)})\overline{\theta u}$ is microlocally $H^{\sigma+2}$ at (x_0,ξ_0). Therefore, $u(t,.)$ is microlocally $H^{\min(\sigma+2,2s-d/2)}$ at (x_0,ξ_0) since $v(t,.)$ is microlocally $H^{2s-d/2}$ at (x_0,ξ_0) and $\theta u=v+(q_1(x,D)+T_{q_2})\overline{\theta u}$.

Assume there exists a pseudodifferential operator whose symbol $c(x,\xi)$ is in S^0 and is elliptic at $(x_0,-\xi_0)$ such that

$$\int_0^T t^{2(2s-d/2)+\delta}\|c(x,D)u(t,.)\|_{H^\sigma}^2 dt<+\infty \tag{5.102}$$

for a $\delta>0$. We may assume that $c(x,\xi)$ is equal to 1 in a conic neighborhood of $(x_0,-\xi_0)$ and that θ is equal to 1 in a neighborhood of the support of $c^J(x,\xi)$. We choose $c_1(x,\xi)$ in $S(0,0)$ with compact support in x, such that $\sqrt{c_l}(x,\xi)$ is elliptic and $c^J(x,\xi)\equiv 1$ in a neighborhood of the support of $c_1(x,\xi)$. Lemma 3.5 and (5.101) yield

$$\begin{aligned}\int_0^T & t^{2(2s-d/2)+\delta}\|c_1(x,D)v(t,.)\|_{H^{2s-d/2+1/2}}^2 dt\\ &\le \int_0^T t^{2(2s-d/2)+\delta}\|\sqrt{c_l}(x,D)v(t,.)\|_{L^2}^2 dt<+\infty.\end{aligned} \tag{5.103}$$

Moreover,

$$\begin{aligned}c_1(x,D)Q\overline{\theta u}&=c_1(x,D)Qc^J(x,D)\overline{\theta u}+c_1(x,D)Q(1-c^J(x,D))\overline{\theta u}\\ &=c_1(x,D)Q\theta\overline{c(x,D)u}+c_1(x,D)Q[c^J(x,D),\theta]\bar u\\ &\quad+c_1(x,D)Q(1-c^J(x,D))\overline{\theta u}.\end{aligned} \tag{5.104}$$

θ is equal to 1 in a neighborhood of the support of $c^J(x,\xi)$ and $c^J(x,\xi)\equiv 1$ in a neighborhood of the support of $c_1(x,\xi)$. Thus, $[c^J(x,D),\theta]$ and $c_1(x,D)q_1(x,D)(1-c^J(x,D))$ are bounded from L^2 to $H^{2s-d/2+1/2}$. Moreover, the symbolic calculus of Bony implies that $c_1(x,D)T_{q_2}(1-c^J(x,D))$ is bounded from L^2 to $H^{2s-d/2+2}$. So, (5.104) yields

$$\begin{aligned}\int_0^T & t^{2(2s-d/2)+\delta}\|c_1(x,D)Q\overline{\theta u}\|_{H^{\min(\sigma+2,2s-d/2+1/2)}}^2 dt\\ &\le \int_0^T t^{2(2s-d/2)+\delta}\|c_1(x,D)Q\theta\overline{c(x,D)u}\|_{H^{\sigma+2}}^2 dt+C\\ &\le C\left(\int_0^T t^{2(2s-d/2)+\delta}\|c(x,D)u\|_{H^\sigma}^2 dt+1\right)<+\infty.\end{aligned} \tag{5.105}$$

As $\theta u = v + (q_1(x,D) + T_{q_2})\overline{\theta u}$, (5.103) and (5.105) imply that

$$\int_0^T t^{2(2s-d/2)+\delta} \|c_1(x,D)u(t,.)\|^2_{H^{\min(\sigma+2,2s-d/2+1/2)}} dt < +\infty, \tag{5.106}$$

since θ is equal to 1 in a neighborhood of the support of $c_1(x,\xi)$.

Finally, assume that $\partial_{\bar{u}} f(0,0) = 0$. Then, we may choose $q_1(x,\xi) \equiv 0$ by Proposition 5.1. Therefore, inequality (5.99) is always satisfied. So, we do not need assumption (2.12). □

Proof of Theorem 2.4. As θu is in $L^\infty(0,T,H^s)$, $u(t,.)$ is microlocally H^s in (x_0,ξ_0) and in $(x_0,-\xi_0)$ for all $0 < t \leq T$. Moreover, there exists $c_1(x,\xi)$ and $c_2(x,\xi)$ in S^0, with $c_1(x,\xi)$ elliptic in (x_0,ξ_0) and $c_2(x,\xi)$ elliptic in $(x_0,-\xi_0)$, such that

$$\int_0^T t^{2(2s-d/2)+\delta} \|c_j(x,D)u(t,.)\|^2_{H^s} dt < +\infty, \quad j = 1,2. \tag{5.107}$$

Starting from $\sigma = s$, it suffices to use Theorem 2.3 with (x_0,ξ_0) and with $(x_0,-\xi_0)$ as many times as needed. □

EXISTENCE, UNIQUENESS, AND VARIATIONAL METHODS FOR SCATTERING BY UNBOUNDED ROUGH SURFACES*

SIMON N. CHANDLER-WILDE† AND PETER MONK‡

Abstract. In this paper we study, via variational methods, the problem of scattering of time harmonic acoustic waves by an unbounded sound soft surface. The boundary ∂D is assumed to lie within a finite distance of a flat plane and the incident wave is that arising from an inhomogeneous term in the Helmholtz equation whose support lies within some finite distance of the boundary ∂D. Via analysis of an equivalent variational formulation, we provide the first proof of existence of a unique solution to a three-dimensional rough surface scattering problem for an arbitrary wave number. Our method of analysis does not require any smoothness of the boundary which can, for example, be the graph of an arbitrary bounded continuous function. An attractive feature is that all constants in a priori bounds, for example the inf-sup constant of the sesquilinear form, are bounded by explicit functions of the wave number and the maximum surface elevation.

Key words. nonsmooth boundary, radiation condition, a priori estimate, inf-sup constant, Helmholtz equation

DOI. 10.1137/040615523

1. Introduction. This paper is concerned with the development and analysis of a variational formulation for scattering by unbounded surfaces, in particular, with the study of what are termed *rough surface scattering problems* in the engineering literature. We shall use the phrase *rough surface* to denote surfaces which are a (usually nonlocal) perturbation of an infinite plane surface such that the whole surface lies within a finite distance of the original plane. Such problems arise frequently in applications, for example in modeling acoustic and electromagnetic wave propagation over outdoor ground and sea surfaces, and are the subject of intensive studies in the engineering literature, with a view to developing both rigorous methods of computation and approximate, asymptotic, or statistical methods (see, e.g., the reviews and monographs by Ogilvy [23], Voronovich [26], Saillard and Sentenac [24], Warnick and Chew [27], and de Santo [13]).

In this paper we will focus on a particular, typical problem of the class, which models time harmonic acoustic scattering by a sound soft rough surface. In particular, we seek to solve the Helmholtz equation with wave number $k>0$, $\Delta u + k^2 u = g$, in the perturbed half-plane or half-space $D \subset \mathbb{R}^n$, $n = 2, 3$. We suppose that the homogeneous Dirichlet boundary condition $u = 0$ holds on ∂D, and a suitable radiation condition is imposed to select a unique solution to this problem. We shall give in the next section complete details about our assumptions on D and on the radiation condition, but we now note that the inhomogeneous term g might be in $L^2(D)$ with bounded support, or be a more general distribution. In addition the boundary ∂D may or may not be the graph of a function.

The main results of the paper are the following. In the next section we formulate the boundary value problem precisely, in the case when $g \in L^2(D)$ with support lying within a finite distance of ∂D. We also establish the equivalent variational formulation that we use and study in this paper. As part of the boundary value problem formulation we require the radiation condition often used in a formal manner in the rough surface scattering literature (e.g., [13]) that, above the rough surface and the support of g, the solution can be represented in integral form as a superposition of upward traveling and evanescent plane waves. This radiation condition is equivalent to the upward propagating radiation condition proposed for two-dimensional (2D) rough surface scattering problems in [11], and has recently been analyzed carefully in the 2D case by Arens and Hohage [5]. Arens and Hohage also propose a further equivalent radiation condition (a "pole condition").

In section 3 we analyze the variational formulation in the long wavelength case, showing that the sesquilinear form is then elliptic, so that unique existence of solution and explicit bounds on the solution in terms of the data g follow from the Lax–Milgram lemma.

In section 4 we show that, for an arbitrary wave number k, the variational problem and the equivalent boundary value problem remain well-posed in the case when the rough surface has the property that if x lies in D, then every point above x lies in D. Our methods of argument, which depend on an a priori estimate established via a Rellich-type identity, application of the generalized Lax–Milgram theory of Babuška, and results on approximation of nonsmooth by smooth domains, lead to simple, explicit lower bounds on the inf-sup constant of the sesquilinear form and corresponding explicit bounds on the solution in terms of the data g. We note that, in contrast to earlier uniqueness and existence results for rough surface scattering problems, no additional regularity conditions on the boundary are required; our theorem applies, for example, whenever the boundary ∂D is the graph of a bounded continuous function.

The results and methods of our paper are closest to those of Kirsch [20] and Elschner [16]. These authors study the same problem tackled in this paper, but consider the 2D diffraction grating case when $\partial D = \{(x_1, f(x_1)) : x_1 \in \mathbb{R}\}$ with f periodic and g quasi-periodic (i.e., $g(x)e^{i\alpha x_1}$ is periodic with the same period as f for some $\alpha \in \mathbb{R}$). The variational formulation we propose for the rough surface scattering problem is analogous to that considered for the periodic case in [20, 16]. We note, however, that the periodicity simplifies the mathematical arguments considerably compared to the case we study; the variational formulation is over a bounded region, part of a single period of the domain, so that compact embedding arguments can be applied and the sesquilinear form which arises satisfies a Gårding inequality for all wave numbers. We note, moreover, that the methods of [20, 16] require f to be at least Lipschitz continuous, and do not lead to explicit bounds on stability constants.

The methods of argument used to prove uniqueness in [20, 16] derive, in part, from Alber [2] and Cadilhac [7]. In fact the argument outlined in [7] for the 2D diffraction grating problem could be adapted to prove uniqueness of solution for our boundary value problem in the case when ∂D is the graph of a sufficiently smooth function. However, we will prefer to establish uniqueness via an a priori bound which also leads to an existence result.

In the general 2D case when f is not periodic, existence of a unique solution to the boundary value problem we study has been established via integral equation methods in the case that $f \in C^2(\mathbb{R})$ (∂D is C^2), and well-posedness of the integral equation formulation has been established in a variety of function spaces [11, 10, 9, 3, 4]. The extension to the case when ∂D is Lipschitz is outlined in Zhang [28]. To date, however, the only existence result [8] for the three-dimensional rough surface problem, derived via integral equation methods, applies only to the Dirichlet boundary value problem for the Helmholtz equation when the rough surface is the graph of a sufficiently smooth function with sufficiently small surface slope, and deals only with the case when the wave number is sufficiently small.

In another, somewhat related body of work existence of solution to the Dirichlet problem for the Helmholtz equation, with ∂D unbounded, is established by the limiting absorption method, via a priori estimates in weighted Sobolev spaces (see Eidus and Vinnik [14], Vogelsang [25], Minskii [22], and references therein). The results obtained apply to the problem considered in this paper, but only if we assume that the rough surface approaches a flat boundary sufficiently rapidly at infinity and/or that the sign of $x \cdot \nu(x)$ is constant on ∂D outside a large sphere, where $\nu(x)$ denotes the unit normal at $x \in \partial D$. Moreover, this body of work requires that g decrease sufficiently rapidly at infinity so that a Rellich–Sommerfeld radiation condition is satisfied.

An attractive feature of our results is the explicit bounds we obtain on the solution in terms of the data g, which exhibit explicitly dependence of constants on the wave number and on the geometry of the domain. In part our methods of argument to obtain our bounds are inspired by the work of Melenk [21] and by the closely related work of Cummings and Feng [12]. In these publications bounds, exhibiting explicit dependence on the wave number, are developed for the impedance boundary value problem for the Helmholtz equation in a bounded domain which is either convex or smooth and star-like.

In this paper we propose a variational formulation and exploit it as a theoretical tool to study the well-posedness of the boundary value problem. We anticipate that the variational formulation will also be very suitable for numerical solution via finite element discretization, as are similar formulations for the 2D diffraction grating case [6, 15, 16]. Moreover, the explicit bounds we obtain should be helpful in establishing the dependence, on the wave number and the domain, of the constants in a priori error estimates for finite element schemes. These numerical analysis aspects will be considered in a future paper.

2. The boundary value problem and variational formulation. In this section we shall define some notation related to the rough surface scattering problem and write down the boundary value problem and equivalent variational formulation that will be analyzed in later sections. For $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$ $(n = 2, 3)$ let $\tilde{x} = (x_1, \ldots, x_{n-1})$ so that $x = (\tilde{x}, x_n)$. For $H \in \mathbb{R}$ let $U_H := \{x : x_n > H\}$ and $\Gamma_H := \{x : x_n = H\}$. Let $D \subset \mathbb{R}^n$ be a connected open set such that for some constants $f_- < f_+$ it holds that

$$U_{f_+} \subset D \subset U_{f_-}. \tag{2.1}$$

This definition of D (the domain of the acoustic field) allows the rough surface $\Gamma = \partial D$ to be more general than the graph of a function. The variational problem will be posed on the open set $S_H := D \setminus \overline{U}_H$, for some $H \geq f_+$, and we denote the unit outward normal to S_H by ν.

Given a source $g \in L^2(D)$ of compact support, the problem we wish to analyze is to find an acoustic field u such that

$$\Delta u + k^2 u = g \quad \text{in } D, \tag{2.2}$$

$$u = 0 \quad \text{on } \Gamma, \tag{2.3}$$

and such that u satisfies an appropriate radiation condition.

This problem has been studied in a rigorous manner by integral equation methods [10, 9, 30, 3, 4, 28, 8] in the case when Γ is the graph of a sufficiently smooth-bounded function f so that

$$\Gamma = \left\{(\tilde{x}, x_n) \ : \ x_n = f(\tilde{x}), \quad \tilde{x} \in \mathbb{R}^{n-1}\right\} \tag{2.4}$$

with f at least bounded and continuous. The most general results are restricted to the 2D case [10, 9, 30, 3, 4, 28]. In the case $n = 2$ with (2.2) understood in a distributional sense, a solution $u \in C^1(D) \cap C(\overline{D})$ is sought such that u is bounded in every strip S_H, $H > f_+$, and such that u satisfies the upward propagating radiation condition (UPRC) proposed in [10], which states that

$$u(x) = 2\int_{\Gamma_H} \frac{\partial\Phi(x,y)}{\partial y_n} u(y)\, ds(y), \quad x \in U_H, \tag{2.5}$$

for all H such that the support of g is contained in S_H. Here the fundamental solution of the Helmholtz equation Φ is given by

$$\Phi(x,y) = \begin{cases} \dfrac{\mathrm{i}}{4} H_0^{(1)}(k|x-y|), & n = 2, \\ \dfrac{\exp(\mathrm{i}k|x-y|)}{4\pi|x-y|}, & n = 3, \end{cases}$$

for $x, y \in \mathbb{R}^n$, $x \neq y$, where $H_0^{(1)}$ is the Hankel function of the first kind of order zero. Under the assumption that Γ is Lipschitz (i.e., that $f \in C^{0,1}(\mathbb{R}^{n-1})$), and that Γ is piecewise Lyapunov, uniqueness of solution is shown in the 2D case in [11].

To show existence of solution to (2.2)–(2.5) one approach is to first convert the boundary value problem to an equivalent Dirichlet boundary value problem. To do this we need to split u into an incident and scattered field. Introducing the Dirichlet Green's function for the half-space U_a, defined by

$$\mathcal{G}_a(x,y) = \Phi(x,y) - \Phi(x, y_a'),$$

where y_a' is the reflection of y in Γ_a, we define the incident field u_a^i, for $a < f_-$, by

$$u_a^i(x) = -\int_D \mathcal{G}_a(x,y) g(y)\, dy.$$

Then $u_a^i \in H^2_{\mathrm{loc}}(U_a)$ and satisfies (2.2) in a distributional sense in U_a. Choosing $a < f_-$, we write u as

$$u = u_a^i + u^s, \tag{2.6}$$

and seek the scattered field $u^s \in C^2(D) \cap C(\overline{D})$ that satisfies

$$\begin{aligned} \Delta u^s + k^2 u^s &= 0 \quad \text{in } D, \\ u^s &= G \quad \text{on } \Gamma, \end{aligned}$$

where $G := -u_a^i|_\Gamma$. Then u, given by (2.6), satisfies (2.2)–(2.5) provided u^s satisfies (2.5).

In the case $n = 2$ and $f \in C^{1,1}(\mathbb{R})$ it has been shown, for arbitrary bounded and continuous data G, that this Dirichlet problem for u^s has exactly one solution that satisfies the radiation condition (2.5) [10]. Moreover, in the case that $G = -u^i_a|_\Gamma$ it holds that $G(x) = O(|x|^{-3/2})$ as $|x| \to \infty$, and it is shown in [9, 3, 4] that u^s and u inherit this property; precisely that $u(x) = O(|x|^{-3/2})$ as $|x_1| \to \infty$ with $x_2 = O(1)$. Thus $G \in L^2(\Gamma)$ and $u \in L^2(S_H)$ for each $H > f_-$. It follows from local regularity estimates up to the boundary that $u \in C^1(\overline{D})$. Further, by an application of Green's theorem, the Helmholtz equation, and the a priori estimates up to the boundary of [11, Theorem 3.1], it follows also that $u \in H^1(S_H)$ for every $H > f_+$. This in turn implies that $u|_{\Gamma_H} \in H^{1/2}(\Gamma_H) \subset L^2(\Gamma_H)$ for every $H \geq f_+$.

In the case that $u|_{\Gamma_H} \in L^2(\Gamma_H)$ we can rewrite (2.5) in terms of the Fourier transform of $u|_{\Gamma_H}$. For $\phi \in L^2(\Gamma_H)$, which we identify with $L^2(\mathbb{R}^{n-1})$, we denote by $\hat{\phi} = \mathcal{F}\phi$ the Fourier transform of ϕ which we define by

$$\mathcal{F}\phi(\xi) = (2\pi)^{-(n-1)/2} \int_{\mathbb{R}^{n-1}} \exp(-\mathrm{i}\tilde{x}\cdot\xi)\phi(\tilde{x})\, d\tilde{x}, \quad \xi \in \mathbb{R}^{n-1}. \tag{2.7}$$

Our choice of normalization of the Fourier transform ensures that $\mathcal{F}$ is a unitary operator on $L^2(\mathbb{R}^{n-1})$ so that, for $\phi, \psi \in L^2(\mathbb{R}^{n-1})$,

$$\int_{\mathbb{R}^{n-1}} \phi\bar{\psi} d\tilde{x} = \int_{\mathbb{R}^{n-1}} \hat{\phi}\bar{\hat{\psi}} d\xi. \tag{2.8}$$

If $F_H := u|_{\Gamma_H} \in L^2(\Gamma_H)$, then (see [11, 5] in the case $n = 2$) (2.5) can be rewritten as

$$u(x) = \frac{1}{(2\pi)^{(n-1)/2}} \int_{\mathbb{R}^{n-1}} \exp(\mathrm{i}[(x_n - H)\sqrt{k^2 - \xi^2} + \tilde{x}\cdot\xi])\hat{F}_H(\xi)\, d\xi, \quad x \in U_H. \tag{2.9}$$

In this equation $\sqrt{k^2 - \xi^2} = \mathrm{i}\sqrt{\xi^2 - k^2}$, when $|\xi| > k$.

Equation (2.9) is a representation for u, in the upper half-plane U_H, as a superposition of upward propagating homogeneous and inhomogeneous plane waves. A requirement that (2.9) holds is commonly used (e.g., [13]) as a formal radiation condition in the physics and engineering literature on rough surface scattering. The meaning of (2.9) is clear when $F_H \in L^2(\mathbb{R}^{n-1})$ so that $\hat{F}_H \in L^2(\mathbb{R}^{n-1})$; indeed the integral (2.9) exists in the Lebesgue sense for all $x \in U_H$. Recently Arens and Hohage [5] have explained, in the case $n = 2$, in what precise sense (2.9) can be understood when $F_H \in BC(\Gamma_H)$, the space of bounded continuous functions on Γ_H, so that $\hat{F}_H$ must be interpreted as a tempered distribution.

The above discussion motivates the following precise formulation of problem (2.2)–(2.3). Let $H^1_0(D)$ denote the standard Sobolev space, the completion of $C^\infty_0(D)$ in the norm $\|\cdot\|_{H^1(D)}$ defined by $\|u\|_{H^1(D)} = \{\int_D(|\nabla u|^2 + |u|^2)dx\}^{1/2}$. The main function space in which we set our problem will be the Hilbert space V_H, defined, for $H \geq f_+$, by

$$V_H := \left\{\phi|_{S_H} \ : \ \phi \in H^1_0(D)\right\},$$

on which we impose the wave number dependent scalar product $(u, v)_{V_H} := \int_{S_H}(\nabla u \cdot \overline{\nabla v} + k^2 u\bar{v})\, dx$ and norm $\|u\|_{V_H} = \{\int_{S_H}(|\nabla u|^2 + k^2|u|^2)dx\}^{1/2}$.

The boundary value problem. Given $g \in L^2(D)$, whose support lies in $\overline{S_H}$, for some $H \geq f_+$, find $u : D \to \mathbb{C}$ such that $u|_{S_a} \in V_a$ for every $a > f_+$,

$$\Delta u + k^2 u = g \quad \text{in } D \tag{2.10}$$

in a distributional sense, and the radiation condition (2.9) holds with $F_H = u|_{\Gamma_H}$.

REMARK 2.1. *We note that, as one would hope, the solutions of the above problem do not depend on the choice of H. Precisely, if u is a solution to the above problem for one value of $H \geq f_+$ for which* $\operatorname{supp} g \subset \overline{S_H}$, *then u is a solution for all $H \geq f_+$ with this property. To see that this is true is a matter of showing that if* (2.9) *holds for one H with* $\operatorname{supp} g \subset \overline{S_H}$, *then* (2.9) *holds for all H with this property. It is shown in Lemma* 2.2 *that if* (2.9) *holds, with $F_H = u|_{\Gamma_H}$, for some $H \geq f_+$, then it holds for all larger values of H. One way to show that* (2.9) *holds also for every smaller value of H, $\tilde{H}$ say, for which $\tilde{H} \geq f_+$ and* $\operatorname{supp} g \subset \overline{S_{\tilde{H}}}$, *is to consider the function*

$$v(x) := u(x) - \frac{1}{(2\pi)^{(n-1)/2}} \int_{\mathbb{R}^{n-1}} \exp(\mathrm{i}[(x_n - \tilde{H})\sqrt{k^2 - \xi^2} + \tilde{x} \cdot \xi]) \hat{F}_{\tilde{H}}(\xi)\, d\xi, \quad x \in U_{\tilde{H}},$$

with $F_{\tilde{H}} := u|_{\Gamma_{\tilde{H}}}$, and show that v is identically zero. To see this we note that, by Lemma 2.2, *v satisfies the above boundary value problem with $D = U_{\tilde{H}}$ and $g = 0$. That $v \equiv 0$, then follows from Theorem* 4.1.

As indicated in the above discussion, it is known that the above boundary value problem has a solution in the case $n = 2$ when Γ is the graph of a sufficiently smooth function. A main result of this paper is to prove that the boundary value problem is uniquely solvable, both in two and three dimensions, under much more general conditions on the boundary Γ. Moreover, we provide explicit estimates of the norm of the solution in the strip S_H as a function of the dimensionless wave number

$$\kappa = k(H - f_-). \tag{2.11}$$

We now derive a variational formulation of the boundary value problem above. To derive this alternative formulation we require a preliminary lemma. In this lemma and subsequently we use standard fractional Sobolev space notation, except that we adopt a wave number dependent norm, equivalent to the usual norm, and reducing to the usual norm if the unit of length measurement is chosen so that $k = 1$. Thus, identifying Γ_H with $\mathbb{R}^{n-1}$, $H^s(\Gamma_H)$, for $s \in \mathbb{R}$, denotes the completion of $C_0^\infty(\Gamma_H)$ in the norm $\|\cdot\|_{H^s(\Gamma_H)}$ defined by

$$\|\phi\|_{H^s(\Gamma_H)} = \left(\int_{\mathbb{R}^{n-1}} (k^2 + \xi^2)^s |\mathcal{F}\phi(\xi)|^2 \, d\xi \right)^{1/2}.$$

We recall [1] that, for all $a > H \geq f_+$, there exist continuous embeddings $\gamma_+ : H^1(U_H \setminus U_a) \to H^{1/2}(\Gamma_H)$ and $\gamma_- : V_H \to H^{1/2}(\Gamma_H)$ (the trace operators) such that $\gamma_\pm \phi$ coincides with the restriction of ϕ to Γ_H when ϕ is C^∞. In the case when $H = f_+$, when Γ_H may not be a subset of the boundary of S_H (if part of ∂D coincides with Γ_H) we understand this trace by first extending $\phi \in V_H$ by zero to $U_{f_-} \setminus \bar{U}_{f_+}$. We recall also that if $u_+ \in H^1(U_H \setminus U_a)$, $u_- \in V_H$, and $\gamma_+ u_+ = \gamma_- u_-$, then $v \in V_a$, where $v(x) := u_+(x)$, $x \in U_H \setminus U_a$, $:= u_-(x)$, $x \in S_H$. Conversely, if $v \in V_a$ and $u_+ := v|_{U_H \setminus U_a}$, $u_- := v|_{S_H}$, then $\gamma_+ v_+ = \gamma_- v_-$. We introduce the operator T, which will prove to be a Dirichlet to Neumann map on Γ_H (see (2.20)) defined by

$$T := \mathcal{F}^{-1} M_z \mathcal{F}, \tag{2.12}$$

where M_z is the operation of multiplying by

$$z(\xi) := \begin{cases} -\mathrm{i}\sqrt{k^2 - \xi^2} & \text{if } |\xi| \leq k, \\ \sqrt{\xi^2 - k^2} & \text{for } |\xi| > k. \end{cases}$$

We shall prove shortly in Lemma 2.4 that $T : H^{1/2}(\Gamma_H) \to H^{-1/2}(\Gamma_H)$ and is bounded.

LEMMA 2.2. *If* (2.9) *holds, with* $F_H \in H^{1/2}(\Gamma_H)$, *then* $u \in H^1(U_H\backslash U_a)\cap C^2(U_H)$, *for every* $a > H$,

$$\Delta u + k^2 u = 0 \quad \text{in } U_H,$$

$\gamma_+ u = F_H$, *and*

$$\int_{\Gamma_H} \bar{v} T\gamma_+ u \, ds + k^2 \int_{U_H} u\bar{v}\, dx - \int_{U_H} \nabla u \cdot \nabla \bar{v}\, dx = 0, \quad v \in C_0^\infty(D). \tag{2.13}$$

Further, the restrictions of u *and* ∇u *to* Γ_a *are in* $L^2(\Gamma_a)$ *for all* $a > H$, *and*

$$\int_{\Gamma_a} \left[\left| \frac{\partial u}{\partial x_n} \right|^2 - |\nabla_{\tilde{x}} u|^2 + k^2 |u|^2 \right] ds \le 2k\Im \int_{\Gamma_a} \bar{u} \frac{\partial u}{\partial x_n}\, ds. \tag{2.14}$$

Moreover, for all $a > H$, *where* $F_a \in H^{1/2}(\Gamma_a)$ *denotes the restriction of* u *to* Γ_a, (2.9) *holds with* H *replaced by* a.

Proof. If $F_H \in L^2(\Gamma_H)$, then, as a function of ξ, $\exp(i[(x_n - H)\sqrt{k^2 - \xi^2} + \tilde{x}\cdot \xi])\hat{F}_H(\xi)(1 + \xi^2)^s \in L^1(\mathbb{R}^{n-1})$ for every $x \in U_H$ and $s \ge 0$. It follows that (2.9) is well-defined for every $x \in U_H$, and that $u \in C^2(U_H)$, with all partial derivatives computed by differentiating under the integral sign, so that $\Delta u + k^2 u = 0$ in U_H. Thus, for $a > H$ and almost all $\xi \in \mathbb{R}^{n-1}$,

$$\mathcal{F}(u|_{\Gamma_a})(\xi) = \exp\left(\mathrm{i}(a - H)\sqrt{k^2 - \xi^2}\,\right)\hat{F}_H(\xi), \tag{2.15}$$

$$\mathcal{F}\left(\left.\frac{\partial u}{\partial x_n}\right|_{\Gamma_a} \right)(\xi) = \mathrm{i}\sqrt{k^2 - \xi^2}\exp\left(\mathrm{i}(a - H)\sqrt{k^2 - \xi^2}\,\right)\hat{F}_H(\xi), \tag{2.16}$$

$$\mathcal{F}(\nabla_{\tilde{x}} u|_{\Gamma_a})(\xi) = \mathrm{i}\xi \exp\left(\mathrm{i}(a - H)\sqrt{k^2 - \xi^2}\,\right)\hat{F}_H(\xi).$$

Therefore, by the Plancherel identity (2.8), $u|_{\Gamma_a}$, $\nabla u|_{\Gamma_a} \in L^2(\Gamma_a)$ with

$$\int_{\Gamma_a} |u|^2 ds = \int_{\mathbb{R}^{n-1}} \left|\exp\left(2\mathrm{i}(a - H)\sqrt{k^2 - \xi^2}\,\right)\right| |\hat{F}_H(\xi)|^2\, d\xi \le \int_{\Gamma_H} |F_H|^2\, ds$$

and

$$\int_{\Gamma_a} |\nabla u|^2 ds \le \int_{\mathbb{R}^{n-1}} [|k^2 - \xi^2| + \xi^2] \left|\exp\left(2\mathrm{i}(a - H)\sqrt{k^2 - \xi^2}\,\right)\right| |\hat{F}_H(\xi)|^2\, d\xi, \tag{2.17}$$

while

$$\int_{\Gamma_a} \left[\left| \frac{\partial u}{\partial x_n} \right|^2 - |\nabla_{\tilde{x}} u|^2 + k^2|u|^2 \right] ds = 2\int_{|\xi|<k} (k^2 - \xi^2)|\hat{F}_H(\xi)|^2\, d\xi$$

and

$$\Im \int_{\Gamma_a} \bar{u} \frac{\partial u}{\partial x_n}\, ds = \int_{|\xi|<k} \sqrt{k^2 - \xi^2}\, |\hat{F}_H(\xi)|^2\, d\xi.$$

Thus (2.14) holds and

$$\int_{U_H\backslash U_a} |u|^2\, dx \le (a - H) \int_{\Gamma_H} |F_H|^2\, ds. \tag{2.18}$$

Further, from (2.17) it follows that

$$\int_{U_H\setminus U_a} |\nabla u|^2\,dx \le (a-H)k^2 \int_{|\xi|<k} |\hat{F}_H(\xi)|^2\,d\xi + \int_{|\xi|>k} \xi^2 \frac{1-\exp(-2[a-H]\sqrt{\xi^2-k^2}\,)}{\sqrt{\xi^2-k^2}} |\hat{F}_H(\xi)|^2\,d\xi \le \int_{\mathbb{R}^{n-1}} (4(a-H)k^2+\sqrt{2}|\xi|)|\hat{F}_H(\xi)|^2\,d\xi, \tag{2.19}$$

since $1-\mathrm{e}^{-z} \le z$ for $z \ge 0$ and $\sqrt{\xi^2-k^2} \ge |\xi|/\sqrt{2}$ for $\xi^2 \ge 2k^2$. Thus $u \in H^1(U_H\setminus U_a)$ if $F_H \in H^{1/2}(\Gamma_H)$. That $u|_{\Gamma_H} = F_H$ is clear when $F_H \in C_0^\infty(\Gamma_H)$, and $\gamma_+ u = F_H$ for all $F_H \in H^{1/2}(\Gamma_H)$ follows from the continuity of γ_+, (2.18) and (2.19), and the density of $C_0^\infty(\Gamma_H)$ in $H^{1/2}(\Gamma_H)$. Similarly, in the case that $F_H \in C_0^\infty(\Gamma_H)$ so that $u \in C^\infty(\overline{U_H})$, it is easily seen that

$$T\gamma_+ u = -\partial u/\partial x_n|_{\Gamma_H}, \tag{2.20}$$

and (2.13) follows by Green's theorem. The same equation for the general case follows from the density of $C_0^\infty(\Gamma_H)$ in $H^{1/2}(\Gamma_H)$, (2.18) and (2.19), and the continuity of the operator T.

That (2.9) holds with H replaced by a, for all $a > H$, is clear from (2.15). □

Now suppose that u satisfies the boundary value problem. Then $u|_{S_a} \in V_a$ for every $a > f_+$ and, by definition, since $\Delta u + k^2 u = g$ in a distributional sense,

$$\int_D [g\bar{v} + \nabla u\cdot\nabla\bar{v} - k^2 u\bar{v}]dx = 0, \quad v \in C_0^\infty(D). \tag{2.21}$$

Applying Lemma 2.2, and defining $w := u|_{S_H}$, it follows that

$$\int_{S_H} [g\bar{v} + \nabla w\cdot\nabla\bar{v} - k^2 w\bar{v}]\,dx + \int_{\Gamma_H} \bar{v}T\gamma_- w\,ds = 0, \quad v \in C_0^\infty(D).$$

From the denseness of $\{\phi|_{S_H} : \phi \in C_0^\infty(D)\}$ in V_H and the continuity of γ_- and T, it follows that this equation holds for all $v \in V_H$.

Let $\|\cdot\|_2$ and $(\cdot,\cdot)$ denote the norm and scalar product on $L^2(S_H)$ so that $\|v\|_2 = \sqrt{\int_{S_H} |v|^2\,dx}$ and

$$(u,v) = \int_{S_H} u\bar{v}\,dx,$$

and define the sesquilinear form $b : V_H \times V_H \to \mathbb{C}$ by

$$b(u,v) = (\nabla u, \nabla v) - k^2(u,v) + \int_{\Gamma_H} \gamma_-\bar{v}T\gamma_- u\,ds. \tag{2.22}$$

Then we have shown that if u satisfies the boundary value problem, then $w := u|_{S_H}$ is a solution of the following variational problem: find $u \in V_H$ such that

$$b(u,v) = -(g,v), \quad v \in V_H. \tag{2.23}$$

Conversely, suppose that w is a solution to the variational problem and define $u(x)$ to be $w(x)$ in S_H and to be the right-hand side of (2.9), with $F_H := \gamma_- w$, in

U_H. Then, by Lemma 2.2, $u \in H^1(U_H \setminus U_a)$ for every $a > H$ with $\gamma_+ u = F_H = \gamma_- w$. Thus $u|_{S_a} \in V_a$, $a \geq f_+$. Further, from (2.13) and (2.23) it follows that (2.21) holds so that $\Delta u + k^2 u = g$ in D in a distributional sense. Thus u satisfies the boundary value problem.

We have thus proved the following theorem.

THEOREM 2.3. *If u is a solution of the boundary value problem, then $u|_{S_H}$ satisfies the variational problem, Conversely, if u satisfies the variational problem, $F_H := \gamma_- u$, and the definition of u is extended to D by setting $u(x)$ equal to the right-hand side of* (2.9), *for $x \in U_H$, then the extended function satisfies the boundary value problem, with g extended by zero from S_H to D.*

It remains to prove the mapping properties of T.

LEMMA 2.4. *The Dirichlet-to-Neumann map T defined by* (2.12) *is a bounded linear map from $H^{1/2}(\Gamma_H)$ to $H^{-1/2}(\Gamma_H)$ with $\|T\| = 1$.*

Proof. From the definitions of T and the Sobolev norms we see that, as a map from $H^{1/2}(\Gamma_H)$ to $H^{-1/2}(\Gamma_H)$,

$$\|T\| = \max_{\xi \in \mathbb{R}^{n-1}} \frac{|\sqrt{k^2 - \xi^2}|}{|\sqrt{k^2 + \xi^2}|} = 1. \qquad \square$$

While the variational formulation (2.23) does not appear to have been studied previously, the analogous weak formulation for the 2D diffraction grating case has recently been studied in [16], as mentioned in the introduction. The diffraction grating case, with f periodic and g quasi-periodic with the same period, is significantly simpler because the variational problem can be formulated on a bounded domain (one period of the strip S_H) and the corresponding sesquilinear form on this bounded domain satisfies a Gårding inequality. Standard methods of analysis thus apply, in particular, existence follows from uniqueness via the Fredholm alternative. But we note that, even in the diffraction grating case, establishing uniqueness for arbitrary Lipschitz domains D (f Lipschitz) requires careful and ingenious arguments [16] which are not required for scattering by bounded domains. Indeed, uniqueness does not hold in all cases in which ∂D is not the graph of a function, as is shown by the example in Gotlib [18].

3. Analysis of the variational problem for low frequency. In this section we shall derive preliminary results and bounds used throughout, and will analyze (2.23) when k is sufficiently small that b is V_H-elliptic (we shall give an explicit bound for k to guarantee this). An attraction of our results for low wave number, in contrast to our results in section 4 for larger wave number, is that we require no additional assumption on the domain, except that κ, given by (2.11), be sufficiently small. We note also that the bounds we establish for κ small in Theorem 3.1 are somewhat sharper than those which can be established as valid for general κ by the techniques of the next section. From the point of view of numerical solution by, e.g., finite element methods, the ellipticity we establish for small k is of course highly desirable, guaranteeing, by Céa's lemma, unique existence and stability of the numerical solution method.

Let V_H^* denote the dual space of V_H, i.e., the space of continuous antilinear functionals on V_H. Then our analysis will also apply to the following slightly more general problem: given $\mathcal{G} \in V_H^*$ find $u \in V_H$ such that

$$b(u, v) = \mathcal{G}(v), \quad v \in V_H. \tag{3.1}$$

We shall prove the following theorem.

THEOREM 3.1. *Suppose the wave number k satisfies $k < \sqrt{2}/(H - f_-)$ (equivalently $\kappa < \sqrt{2}$). Then the sesquilinear form b is V_H-elliptic so that the variational problem* (3.1) *is uniquely solvable, and the solution satisfies the estimate*

$$\|u\|_{V_H} \leq C\|\mathcal{G}\|_{V_H^*}, \tag{3.2}$$

where the constant C satisfies

$$C \leq \frac{1 + \kappa^2/2}{1 - \kappa^2/2}.$$

In particular, the scattering problem (2.23) *is uniquely solvable and the solution satisfies the bound*

$$k\|u\|_{V_H} \leq \frac{\kappa}{\sqrt{2}} \frac{1 + \kappa^2/2}{1 - \kappa^2/2} \|g\|_2. \tag{3.3}$$

In order to prove Theorem 3.1 we establish a sequence of lemmas which are of some independent interest and are used extensively in the rest of the paper. The first two concern the Dirichlet to Neumann map T and the trace operator γ_- and will be proved using the Fourier transform (2.7).

LEMMA 3.2. *For all $\phi, \psi \in H^{1/2}(\Gamma_H)$,*

$$\int_{\Gamma_H} \phi T\psi \, ds = \int_{\Gamma_H} \psi T\phi \;\, ds.$$

For all $\phi \in H^{1/2}(\Gamma_H)$,

$$\Re \int_{\Gamma_H} \bar{\phi}\, T\phi \, ds \geq 0, \quad \Im \int_{\Gamma_H} \bar{\phi}\, T\phi \, ds \leq 0.$$

Proof. Let $\hat{\phi} = \mathcal{F}\phi$, $\hat{\psi} = \mathcal{F}\psi$. Then $\mathcal{F}(T\phi) = z\hat{\phi}$. Thus, using the Plancherel identity (2.8) and since $\hat{\bar{\psi}}(\xi) = \overline{\hat{\psi}(-\xi)}$ and z is even,

$$\int_{\Gamma_H} \psi\, T\phi \, ds = \int_{\mathbb{R}^{n-1}} \hat{\psi}(-\xi) z(\xi) \hat{\phi}(\xi) \, d\xi = \int_{\mathbb{R}^{n-1}} \hat{\psi}(\xi) z(\xi) \hat{\phi}(-\xi) \, d\xi = \int_{\Gamma_H} \phi\, T\psi \, ds.$$

In particular, putting $\psi = \bar{\phi}$,

$$\begin{aligned}\int_{\Gamma_H} \bar{\phi}\, T\phi \, ds &= \int_{\mathbb{R}^{n-1}} z(\xi) |\hat{\phi}(\xi)|^2 \, d\xi \\ &= \int_{|\xi|>k} \sqrt{\xi^2 - k^2} |\hat{\phi}(\xi)|^2 \, d\xi - \mathrm{i} \int_{|\xi|<k} \sqrt{k^2 - \xi^2} |\hat{\phi}(\xi)|^2 \, d\xi,\end{aligned}$$

from which the second result follows. $\square$

The above lemma implies that $b(\cdot,\cdot)$ has the following important symmetry property.

COROLLARY 3.3. *For all $u, v \in V_H$,*

$$b(v, u) = b(\bar{u}, \bar{v}).$$

LEMMA 3.4. *For all* $u \in V_H$,

$$\|\gamma_- u\|_{H^{1/2}(\Gamma_H)} \le \|u\|_{V_H}$$

and

$$\|u\|_2 \le \frac{H - f_-}{\sqrt{2}} \left\| \frac{\partial u}{\partial x_n} \right\|_2 .$$

Proof. For $u \in C_0^\infty(D) \subset C_0^\infty(U_{f_-})$ and defining $\hat{u}(\xi, x_n) = (\mathcal{F}u(\cdot, x_n))(\xi)$, we have

$$|\hat{u}(\xi, H)|^2 = \int_{f_-}^{H} \frac{\partial}{\partial x_n} |\hat{u}(\xi, x_n)|^2 \, dx_n = 2\Re \int_{f_-}^{H} \overline{\hat{u}(\xi, x_n)} \frac{\partial}{\partial x_n} \hat{u}(\xi, x_n) \, dx_n.$$

Thus, if $S = \mathbb{R}^{n-1} \times (f_-, H)$,

$$\begin{aligned}
\|u\|^2_{H^{1/2}(\Gamma_H)} &= \int_{\mathbb{R}^{n-1}} |\sqrt{\xi^2 + k^2}| \, |\hat{u}(\xi, H)|^2 \, d\xi \\
&\le 2 \int_S |\sqrt{\xi^2 + k^2}| \, |\hat{u}(\xi, x_n)| \left| \frac{\partial}{\partial x_n} \hat{u}(\xi, x_n) \right| d\xi \, dx_n \\
&\le 2 \left\{ \int_S |\xi^2 + k^2| \, |\hat{u}(\xi, x_n)|^2 \, d\xi \, dx_n \right\}^{1/2} \left\{ \int_S \left| \frac{\partial}{\partial x_n} \hat{u}(\xi, x_n) \right|^2 d\xi \, dx_n \right\}^{1/2} .
\end{aligned}$$

Now, by Parseval's theorem,

$$\begin{aligned}
\int_S \xi^2 \, |\hat{u}(\xi, x_n)|^2 \, d\xi \, dx_n &= \int_S |\mathcal{F}(\nabla_{\tilde{x}} u(\cdot, x_n))(\xi)|^2 \, d\xi \, dx_n \\
&= \int_S |\nabla_{\tilde{x}} u(x)|^2 \, dx.
\end{aligned}$$

Applying Parseval's theorem again, and since $2\sqrt{ab} \le a + b$ for $a, b \ge 0$,

$$\|u\|^2_{H^{1/2}(\Gamma_H)} \le 2 \left\{ \int_S \left\{ k^2 |u(x)|^2 + |\nabla_{\tilde{x}} u(x)|^2 \right\} dx \int_S \left| \frac{\partial}{\partial x_n} u(x) \right|^2 dx \right\}^{1/2} \le \|u\|^2_{V_H}.$$

Further, using the fact that $u \in C_0^\infty(U_{f_-})$, for $x \in S$,

$$|u(x)|^2 = \left| \int_{f_-}^{x_n} \frac{\partial}{\partial x_n} u(x) \, dx_n \right|^2 \le (x_n - f_-) \int_{f_-}^{H} \left| \frac{\partial}{\partial x_n} u(x) \right|^2 dx_n$$

so that, since $\int_{f_-}^{H} (x_n - f_-) \, dx_n = (H - f_-)^2/2$,

$$\int_S |u(x)|^2 \, dx \le \frac{(H - f_-)^2}{2} \int_S \left| \frac{\partial}{\partial x_n} u(x) \right|^2 dx. \tag{3.4}$$

Since the set $\{v|_{S_H} : v \in C_0^\infty(D)\}$ is dense in V_H these bounds hold for all $u \in V_H$. $\square$

We are now in a position to prove that the sesquilinear form $b(.,.)$ is bounded, establishing an explicit value for the bound.

LEMMA 3.5. *For all $u, v \in V_H$,*

$$|b(u,v)| \le 2\|u\|_{V_H}\|v\|_{V_H}$$

so that the sesquilinear form $b(.,.)$ is bounded.

Proof. From the definition of the sesquilinear form $b(.,.)$ and the Cauchy–Schwarz inequality, we have

$$|b(u,v)| \le \|\nabla u\|_2\|\nabla v\|_2 + k^2\|u\|_2\|v\|_2 + \|\gamma_- u\|_{H^{1/2}(\Gamma_H)}\|T\|\,\|\gamma_- v\|_{H^{1/2}(\Gamma_H)}.$$

Applying the Cauchy–Schwarz inequality and Lemmas 2.4 and 3.4 we obtain the desired estimate. □

Our last lemma of this section shows that the sesquilinear form $b(.,.)$ is V_H-elliptic provided the wave number k is not too large.

LEMMA 3.6. *For all $u \in V_H$,*

$$\Re\, b(u,u) \ge \frac{1-\kappa^2/2}{1+\kappa^2/2}\,\|u\|^2_{V_H}.$$

Proof. By Lemma 3.2,

$$\Re\, b(u,u) \ge \|u\|^2_{V_H} - 2k^2\|u\|^2_2.$$

The result follows from Lemma 3.4, implying that $\|u\|^2_{V_H} \ge k^2(2/\kappa^2+1)\|u\|^2_2$. □

Using Lemmas 3.5 and 3.6 we can now prove Theorem 3.1.

Proof. By Lemma 3.6 and under the assumption of the theorem that $k < \sqrt{2}/(H-f_-)$ we see that $b(.,.)$ is V_H-elliptic. Lemma 3.5 shows that $b(.,.)$ is bounded and hence by the Lax–Milgram lemma the existence of a unique solution u to (3.1) is assured. The estimate (3.2) also follows from the Lax–Milgram lemma. In the particular case that $\mathcal{G}(v) := -(g,v)$, for some $g \in L^2(S_H)$, we have further, by the Cauchy–Schwarz inequality and Lemma 3.4, that

$$\|\mathcal{G}\|_{V_H^*} = \sup_{v\in V_H}\frac{|(v,g)|}{\|v\|_{V_H}} \le \sup_{v\in V_H}\frac{\|v\|_2\|g\|_2}{\|v\|_{V_H}} \le \frac{H-f_-}{\sqrt{2}}\|g\|_2,$$

and (3.3) follows. □

4. Analysis of the variational problem at arbitrary frequency. The sesquilinear form $b(.,.)$ is not V_H-elliptic if the wave number k is large. In this section we shall establish, with no restriction on the wave number but some additional constraint on the domain, that the boundary value problem and the equivalent variational problem are uniquely solvable by using the generalized Lax–Milgram theory of Babuška. The domains D for which we will establish this result are those which, in addition to our assumption throughout that $U_{f_+} \subset D \subset U_{f_-}$, satisfy the condition that

$$x \in D \Rightarrow x + se_n \in D \quad \text{for all } s > 0, \tag{4.1}$$

where e_n denotes the unit vector in the direction x_n. Condition (4.1) is satisfied if Γ is the graph of a continuous function, but certainly does not require that this be the case. Nor does (4.1) impose any regularity on ∂D. Our main result in this section is the following.

THEOREM 4.1. *If* (4.1) *holds, then the variational problem* (3.1) *has a unique solution* $u \in V_H$ *for every* $\mathcal{G} \in V_H^*$ *and*

$$\|u\|_{V_H} \leq C\|\mathcal{G}\|_{V_H^*}, \tag{4.2}$$

where

$$C = 1 + \sqrt{2}\,\kappa\,(\kappa+1)^2.$$

In particular, the boundary value problem and the equivalent variational problem (2.23) *have exactly one solution, and the solution satisfies the bound*

$$k\|u\|_{V_H} \leq \frac{\kappa}{\sqrt{2}}\,(\kappa+1)^2\,\|g\|_2.$$

To apply the generalized Lax–Milgram theorem (e.g., [19, Theorem 2.15]) we need to show that b is bounded, which we have done in Lemma 3.5; to establish the inf-sup condition that

$$\beta := \inf_{0\neq u\in V_H}\sup_{0\neq v\in V_H}\frac{|b(u,v)|}{\|u\|_{V_H}\|v\|_{V_H}} > 0; \tag{4.3}$$

and to establish a "transposed" inf-sup condition. It follows easily from Corollary 3.3 that this transposed inf-sup condition follows automatically if (4.3) holds.

LEMMA 4.2. *If* (4.3) *holds, then for all nonzero* $v \in V_H$,

$$\sup_{0\neq u\in V_H}\frac{|b(u,v)|}{\|u\|_{V_H}} > 0.$$

Proof. If (4.3) holds and $v \in V_H$ is nonzero, then

$$\sup_{0\neq u\in V_H}\frac{|b(u,v)|}{\|u\|_{V_H}} = \sup_{0\neq u\in V_H}\frac{|b(\bar{v},u)|}{\|u\|_{V_H}} \geq \beta\|v\|_{V_H} > 0.$$

This proves the lemma. ∎

The following result follows from [19, Theorem 2.15] and Lemmas 3.5 and 4.2.

COROLLARY 4.3. *If* (4.3) *holds, then the variational problem* (3.1) *has exactly one solution* $u \in V_H$ *for all* $\mathcal{G} \in V_H^*$. *Moreover,*

$$\|u\|_{V_H} \leq \beta^{-1}\|\mathcal{G}\|_{V_H^*}.$$

To show (4.3) we will establish an a priori bound for solutions of (3.1), from which the inf-sup condition will follow by the following easily established lemma (see [19, Remark 2.20]).

LEMMA 4.4. *Suppose that there exists* $C > 0$ *such that for all* $u \in V_H$ *and* $\mathcal{G} \in V_H^*$ *satisfying* (3.1) *it holds that*

$$\|u\|_{V_H} \leq C\|\mathcal{G}\|_{V_H^*}. \tag{4.4}$$

Then the inf-sup condition (4.3) *holds with* $\beta \geq C^{-1}$.

The following lemma reduces the problem of establishing (4.4) to that of establishing an a priori bound for solutions of the special case (2.23).

LEMMA 4.5. *Suppose there exists $\tilde{C} > 0$ such that for all $u \in V_H$ and $g \in L^2(S_H)$ satisfying* (2.23) *it holds that*

$$\|u\|_{V_H} \leq k^{-1}\tilde{C}\,\|g\|_2. \tag{4.5}$$

Then, for all $u \in V_H$ and $\mathcal{G} \in V_H^*$ satisfying (3.1)*, the bound* (4.4) *holds with*

$$C \leq 1 + 2\,\tilde{C}.$$

Proof. Suppose $u \in V_H$ is a solution of

$$b(u,v) = \mathcal{G}(v), \quad v \in V_H, \tag{4.6}$$

where $\mathcal{G} \in V_H^*$. Let $b_0 : V_H \times V_H \to \mathbb{C}$ be defined by

$$b_0(u,v) = (\nabla u, \nabla v) + k^2(u,v) + \int_{\Gamma_H} \gamma_- \overline{v}\, T\gamma_- u\, ds, \quad u, v \in V_H.$$

It follows from Lemma 3.2 that b_0 is V_H-elliptic, in fact that

$$\Re\, b_0(v,v) \geq \|v\|^2_{V_H}, \quad v \in V_H.$$

Thus the problem of finding $u_0 \in V_H$ such that

$$b_0(u_0,v) = \mathcal{G}(v), \quad v \in V_H, \tag{4.7}$$

has a unique solution which satisfies

$$\|u_0\|_{V_H} \leq \|\mathcal{G}\|_{V_H^*}. \tag{4.8}$$

Furthermore, defining $w = u - u_0$ and using (4.6) and (4.7), we see that

$$b(w,v) = b(u,v) - b(u_0,v) = \mathcal{G}(v) - (\mathcal{G}(v) - 2k^2(u_0,v)) = 2k^2(u_0,v)$$

for all $v \in V_H$. Thus w satisfies (2.23) with $g = -2k^2 u_0$. It follows, using (4.8), (4.5), and Lemma 3.4, that

$$\|w\|_{V_H} \leq 2k\tilde{C}\|u_0\|_2 \leq 2\tilde{C}\|\mathcal{G}\|_{V_H^*}. \tag{4.9}$$

The bound (4.4), with $C \leq 1 + 2\,\tilde{C}$, follows from (4.8) and (4.9). ∎

Following these preliminary lemmas we turn now to establishing the a priori bound (4.5), at first just for the case when Γ is the graph of a smooth function. We recall that ν is the outward unit normal to S_H and $\nu_n = \nu \cdot e_n$ is the nth (vertical) component of ν.

LEMMA 4.6. *Suppose Γ is given by* (2.4) *with $f \in C^\infty(\mathbb{R}^{n-1})$. Let $H \geq f_+$, $g \in L^2(S_H)$ and suppose $w \in V_H$ satisfies*

$$b(w,\phi) = -(g,\phi) \quad \textit{for all } \phi \in V_H. \tag{4.10}$$

Then

$$\|w\|_{V_H} \leq k^{-1}\tilde{C}\|g\|_2,$$

where $\tilde{C} = \frac{\kappa}{\sqrt{2}}(\kappa+1)^2$.

Proof. The proof of this lemma is motivated by [21, 12], where a Rellich identity is used to prove estimates for solutions of the Helmholtz equation posed on bounded domains, by the proofs of the basic inequalities for rough surface scattering problems in [11, 29], and by the estimates derived for the diffraction grating problem in [16].

Let $r = |\tilde{x}|$. For $A \geq 1$ let $\phi_A \in C_0^\infty(\mathbb{R})$ be such that $0 \leq \phi_A \leq 1$, $\phi_A(r) = 1$ if $r \leq A$ and $\phi_A(r) = 0$ if $r \geq A+1$ and finally such that $\|\phi_A'\|_\infty \leq M$ for some fixed M independent of A.

Extending the definition of w to D by defining w in U_H by (2.9) with $F_H := \gamma_- w$, it follows from Theorem 2.3 that w satisfies the boundary value problem with g extended by zero from S_H to D. By standard local regularity results [17] it holds, since $g \in L^2(D)$, $w = 0$ on Γ, and the boundary is smooth, that $w \in H^2_{\mathrm{loc}}(D)$. Further, $w \in H^2(U_b \setminus U_c)$ for $c > b > f_+$ (though $w \in H^2(S_c)$ is not clear without some further constraint on the behavior of Γ at infinity). Moreover, by Lemma 2.2, w is given by the right-hand side of (2.9) in U_b for all $b > H$ if H is replaced in (2.9) by b and F_b denotes the restriction of w to Γ_b. Thus w satisfies the boundary value problem with H replaced by b for all $b > H$, and so, by Theorem 2.3,

$$\int_{S_b} (\nabla w \cdot \nabla \bar{v} - k^2 w \bar{v})\, dx = -\int_{\Gamma_b} \gamma_- \bar{v}\, T \gamma_- w\, ds - \int_{S_b} \bar{v} g\, dx \tag{4.11}$$

for all $b \geq H$.

In view of this regularity and since w satisfies the boundary value problem, we have, for all $a > H$,

$$\begin{aligned}
&2\Re \int_{S_a} \phi_A(r)(x_n - f_-) g \frac{\partial \overline{w}}{\partial x_n}\, dx \\
&= 2\Re \int_{S_a} \phi_A(r)(x_n - f_-)(\Delta w + k^2 w) \frac{\partial \overline{w}}{\partial x_n}\, dx \\
&= \int_{S_a} \Bigg\{ 2\Re \left\{ \nabla \cdot \left(\phi_A(r)(x_n - f_-) \frac{\partial \overline{w}}{\partial x_n} \nabla w \right) \right\} - 2\phi_A(r) \left| \frac{\partial w}{\partial x_n} \right|^2 \\
&\quad -(x_n - f_-)\phi_A(r) \frac{\partial |\nabla w|^2}{\partial x_n} \\
&\quad -2\phi_A'(r)(x_n - f_-) \frac{\tilde{x}}{|\tilde{x}|} \cdot \Re \left(\nabla_{\tilde{x}} w \frac{\partial \overline{w}}{\partial x_n} \right) + k^2 (x_n - f_-)\phi_A(r) \frac{\partial |w|^2}{\partial x_n} \Bigg\}\, dx.
\end{aligned}$$

Using the divergence theorem and integration by parts,

$$\begin{aligned}
&2\Re \int_{S_a} \phi_A(r)(x_n - f_-) g \frac{\partial \overline{w}}{\partial x_n}\, dx \\
&= (a - f_-) \int_{\Gamma_a} \phi_A(r) \left\{ \left| \frac{\partial w}{\partial x_n} \right|^2 - |\nabla_{\tilde{x}} w|^2 + k^2 |w|^2 \right\} ds \\
&\quad - \int_\Gamma (x_n - f_-)\phi_A(r) \left\{ \nu_n |\nabla w|^2 - 2\Re \left(\frac{\partial \overline{w}}{\partial x_n} \frac{\partial w}{\partial \nu} \right) \right\} ds \\
&\quad + \int_{S_a} \left\{ \phi_A(r) \left(|\nabla w|^2 - k^2 |w|^2 - 2 \left| \frac{\partial w}{\partial x_n} \right|^2 \right) - 2\phi_A'(r)(x_n - f_-) \Re \left(\frac{\partial \overline{w}}{\partial x_n} \frac{\partial w}{\partial r} \right) \right\} dx.
\end{aligned}$$

Using the fact that $w = 0$ on Γ so that $\nabla w = (\partial w/\partial\nu)\nu$ and

$$\frac{\partial w}{\partial x_n} = e_n \cdot \nabla w = e_n \cdot \nu \frac{\partial w}{\partial \nu} = \nu_n \frac{\partial w}{\partial \nu},$$

and rearranging terms we find that

$$\begin{aligned}
&-\int_\Gamma \phi_A(r)(x_n - f_-)\nu_n \left|\frac{\partial w}{\partial \nu}\right|^2 ds + 2\int_{S_a} \phi_A(r)\left|\frac{\partial w}{\partial x_n}\right|^2 dx \\
&= (a - f_-)\int_{\Gamma_a} \phi_A(r)\left\{\left|\frac{\partial w}{\partial x_n}\right|^2 - |\nabla_{\tilde{x}} w|^2 + k^2|w|^2\right\} ds \\
&\quad + \int_{S_a}\left\{\phi_A(r)\left(|\nabla w|^2 - k^2|w|^2\right) - 2\phi_A'(r)(x_n - f_-)\Re\left(\frac{\partial \overline{w}}{\partial x_n}\frac{\partial w}{\partial r}\right)\right\} dx \\
&\quad -2\Re\int_{S_a} \phi_A(r)(x_n - f_-) g \frac{\partial \overline{w}}{\partial x_n}\, dx.
\end{aligned} \tag{4.12}$$

We now wish to let $A \to \infty$. The only problem is the term involving ϕ_A' which we estimate as follows. Let $S_a^b = \{x \in S_a \ : \ |\tilde{x}| < b\}$ for $b \geq 1$. Then

$$\left|\int_{S_a}\left\{2\phi_A'(r)(x_n - f_-)\Re\left(\frac{\partial \overline{w}}{\partial x_n}\frac{\partial w}{\partial r}\right)\right\} dx\right| \leq 2M(a - f_-)\int_{S_a^{A+1}\setminus \overline{S}_a^A} |\nabla w|^2\, dx \to 0$$

as $A \to \infty$, where the convergence follows from the fact that $w \in H^1(S_H)$. In addition since $w \in H^2(U_b \setminus U_c)$, for $c > a > b > f_+$, $\nabla w|_{\Gamma_H} \in (H^{1/2}(\Gamma_H))^n$. Thus, taking the limit as $A \to \infty$ in (4.12), and applying the Lebesgue dominated convergence and monotone convergence theorems, we see that

$$\begin{aligned}
&-\int_\Gamma (x_n - f_-)\nu_n \left|\frac{\partial w}{\partial \nu}\right|^2 ds + 2\int_{S_a}\left|\frac{\partial w}{\partial x_n}\right|^2 dx \\
&= (a - f_-)\int_{\Gamma_a}\left\{\left|\frac{\partial w}{\partial x_n}\right|^2 - |\nabla_{\tilde{x}} w|^2 + k^2|w|^2\right\} ds \\
&\quad + \int_{S_a}\left(|\nabla w|^2 - k^2|w|^2 - 2\Re\left((x_n - f_-) g \frac{\partial \overline{w}}{\partial x_n}\right)\right) dx.
\end{aligned} \tag{4.13}$$

Now, since w satisfies the boundary value problem, including the radiation condition (2.9), applying Lemma 2.2 it follows that

$$\begin{aligned}
\int_{\Gamma_a}\left\{\left|\frac{\partial w}{\partial x_n}\right|^2 - |\nabla_{\tilde{x}} w|^2 + k^2|w|^2\right\} ds &\leq 2k\Im\int_{\Gamma_a} \overline{w}\frac{\partial w}{\partial x_n}\, ds \\
&= -2k\Im\int_{\Gamma_a} \gamma_-\overline{w} T\gamma_- w\, ds
\end{aligned} \tag{4.14}$$

on applying the Plancherel identity (2.8), noting (2.15) and (2.16). Further, setting $v = w$ in (4.11), we get

$$\int_{S_b}\left(|\nabla w|^2 - k^2|w|^2\right) dx = -\int_{\Gamma_b} \gamma_-\overline{w} T\gamma_- w\, ds - \int_{S_b} g\overline{w}\, dx \tag{4.15}$$

for $b \geq H$, so that, by Lemma 3.2,

$$\int_{S_b} [|\nabla w|^2 - k^2|w|^2]\, dx \leq -\Re \int_{S_b} g\overline{w}\, dx \tag{4.16}$$

and

$$-2k\Im \int_{\Gamma_b} \gamma_- \overline{w} T \gamma_- w\, ds = 2k\Im \int_{S_b} g\overline{w}\, dx. \tag{4.17}$$

Using (4.17) in (4.14) and then using the resulting equation and (4.16) in (4.13) and noting that $\operatorname{supp} g \subset \overline{S_H}$, we get that

$$\begin{aligned} -\int_\Gamma (x_n - f_-)\nu_n \left|\frac{\partial w}{\partial \nu}\right|^2 ds + 2\int_{S_H} \left|\frac{\partial w}{\partial x_n}\right|^2 dx \leq 2(a - f_-)k\Im \int_{S_H} g\bar{w}\, dx \\ -\Re \int_{S_H} \left[g\bar{w} + 2(x_n - f_-)g\frac{\partial \bar{w}}{\partial x_n}\right] dx. \end{aligned}$$

Since this equation holds for all $a > H$ and $\nu_n < 0$ on Γ, it follows by the Cauchy–Schwarz inequality that

$$2\left\|\frac{\partial w}{\partial x_n}\right\|_2^2 \leq \left(2\kappa\|w\|_2 + \|w\|_2 + 2(H - f_-)\left\|\frac{\partial w}{\partial x_n}\right\|_2\right)\|g\|_2.$$

Now using Lemma 3.4 to estimate $\|w\|_2$ we obtain

$$\left\|\frac{\partial w}{\partial x_n}\right\|_2 \leq (H - f_-)\left(\frac{1}{\sqrt{2}}\kappa + \frac{1}{2\sqrt{2}} + 1\right)\|g\|_2 \tag{4.18}$$

and use of Lemma 3.4 again shows that

$$\|w\|_2 \leq (H - f_-)^2\left(\frac{1}{2}\kappa + \frac{1}{4} + \frac{1}{\sqrt{2}}\right)\|g\|_2.$$

Using the above inequality in (4.16) shows that

$$\begin{aligned} \|w\|_{V_H}^2 &\leq 2k^2\|w\|_2^2 + \|g\|_2\|w\|_2 \\ &\leq \frac{(H - f_-)^2}{4}\left(\frac{\kappa^2}{2}(2\kappa + 1 + 2\sqrt{2})^2 + 2\kappa + 1 + 2\sqrt{2}\right)\|g\|_2^2. \end{aligned}$$

Thus, for $\kappa \geq 1$,

$$\|w\|_{V_H}^2 \leq \frac{(H - f_-)^2}{2}(\kappa + 1)^4\|g\|_2^2.$$

The same bound holds for $\kappa < 1$ by Theorem 3.1. ∎

REMARK 4.7. *The above argument works under milder assumptions on the boundary* Γ, *in particular that* Γ *is the graph of a function* $f \in C^2(\mathbb{R}^{n-1})$, *so that* Γ *is of class* C^2. *This assumption is enough* [17] *to deduce the necessary local regularity result that* $w \in H^2_{\mathrm{loc}}(D)$.

Combining Lemmas 4.6, 4.5, and 4.4 with Corollary 4.3, we have the following result.

LEMMA 4.8. *If Γ satisfies the conditions of Lemma* 4.6*, then the variational problem* (3.1) *has a unique solution $u \in V_H$ for every $\mathcal{G} \in V_H^*$ and the solution satisfies the estimate* (4.2).

REMARK 4.9. *The above result, combined with Lemma* 4.4*, implies that β, the* inf-sup *constant for $b(\cdot,\cdot)$, satisfies $\beta^{-1} \leq C = O(k^3)$ as $k \to \infty$. This high power of the wave number is, we suspect, not optimal. For an interior problem in a smooth starlike and bounded domain in $\mathbb{R}^2$ or $\mathbb{R}^3$ with impedance boundary data it is known that the constant in the corresponding bound satisfies the estimate $C = O(k)$ (for example, this can be proved by combining estimate* (2) *of Theorem* 1 *of* [12] *with the argument of Lemma* 4.5*, involving a function corresponding to u_0). For a somewhat analogous one-dimensional problem the* inf-sup *constant is also $O(k)$ as $k \to \infty$ (Theorem* 4.2 *of* [19]).

We proceed now to establish that Lemmas 4.6 and 4.8 hold for much more general boundaries, namely those satisfying (4.1). To establish this we first prove the following technical lemma.

LEMMA 4.10. *If* (4.1) *holds, then, for every $\phi \in C_0^\infty(D)$, there exists $f \in C^\infty(\mathbb{R}^{n-1})$ such that*

$$\operatorname{supp}\phi \subset D' := \{x \in \mathbb{R}^n : x_n > f(\tilde{x}),\, \tilde{x} \in \mathbb{R}^{n-1}\}$$

and $U_{f_+} \subset D' \subset D$.

Proof. Let $S := \operatorname{supp}\phi \setminus U_{f_+}$. Then either $S = \emptyset$, in which case $f(\tilde{x}) \equiv f_+$ has the properties claimed, or $S \neq \emptyset$.

Thus, suppose $S \neq \emptyset$ and let $\delta := \operatorname{dist}(S, \partial D)/2$. Then $\delta > 0$ and, defining $G := \{x + se_n : x \in S, s \geq 0\}$, $\operatorname{dist}(G, \partial D) = \operatorname{dist}(S, \partial D) = 2\delta$. Let $G_\delta := \{x \in \mathbb{R}^n : \operatorname{dist}(x, G) < \delta\}$ and let A and A_δ denote the projections of G and G_δ, respectively, onto the $Ox_1 \cdots x_{n-1}$ plane.

Let $N \in \mathbb{N}$ and $S_j \subset \mathbb{R}^{n-1}$, $j = 1, \ldots, N$, be such that each S_j is measurable and nonempty, $S_j \cap S_m = \emptyset$ for $j \neq m$,

$$A_\delta \subset \bigcup_{j=1}^{N} S_j,$$

and $\operatorname{diam}(S_j) \leq \delta/2$, $j = 1, \ldots, N$. For $j = 1, \ldots, N$ choose $\tilde{x}_j \in S_j$ and let

$$f_j := \inf\{x_n \in \mathbb{R} : x = (\tilde{x}_j, x_n) \in G_\delta \cup \Gamma_{f_+}\}.$$

Then $f_- \leq f_j \leq f_+$, $j = 1, \ldots, N$. Define $\tilde{f} : \mathbb{R}^{n-1} \to \mathbb{R}$ by

$$\tilde{f}(\tilde{x}) := \begin{cases} f_j & \text{if } \tilde{x} \in S_j,\ j = 1, \ldots, N, \\ f_+ & \text{otherwise.} \end{cases}$$

Then $\tilde{f} \in L^\infty(\mathbb{R}^{n-1})$; in fact $\tilde{f}$ is a simple function and $f_- \leq \tilde{f}(\tilde{x}) \leq f_+$, $\tilde{x} \in \mathbb{R}^{n-1}$. Choose ϵ with $0 < \epsilon < \delta/2$ and let $J \in C_0^\infty(\mathbb{R}^{n-1})$ be such that $J \geq 0$, $J(\tilde{x}) = 0$ if $|\tilde{x}| \geq \epsilon$, and $\int_{\mathbb{R}^{n-1}} J(\tilde{x})\, d\tilde{x} = 1$. Define $f \in C^\infty(\mathbb{R}^{n-1})$ by

$$f(\tilde{x}) := \int_{\mathbb{R}^{n-1}} J(\tilde{x} - \tilde{y}) \tilde{f}(\tilde{y})\, d\tilde{y}, \quad \tilde{x} \in \mathbb{R}^{n-1},$$

and let D' be defined as in the statement of the lemma. Then f and D' have the properties claimed.

To see that this is true note first that

$$\min_{|\tilde{y}-\tilde{x}|<\epsilon} |\tilde{f}(\tilde{y})| \le f(\tilde{x}) \le \max_{|\tilde{y}-\tilde{x}|<\epsilon} |\tilde{f}(\tilde{y})|, \quad \tilde{x} \in \mathbb{R}^{n-1}, \tag{4.19}$$

so that $U_{f_+} \subset D'$. If $\tilde{x} \in A$, then $|\tilde{y}-\tilde{x}| < \epsilon$ implies that $\tilde{y} \in A_\delta$ and so (4.19) implies that

$$f(\tilde{x}) \le \max_{j=1,\dots,N,\ |\tilde{x}_j-\tilde{x}|<\epsilon+\delta/2} f_j$$

so that $f(\tilde{x}) \le f_m$ for some m for which $|\tilde{x}_m - \tilde{x}| < \epsilon + \delta/2$. Now let $x = (\tilde{x}, f_m)$, $y = (\tilde{x}_m, f_m)$. Then $|x-y| = |\tilde{x} - \tilde{x}_m| < \epsilon + \delta/2$ and $\mathrm{dist}(y, G) = \delta$ so that

$$\mathrm{dist}(x, G) \ge \mathrm{dist}(y, G) - |x-y| \ge \delta - (\epsilon + \delta/2) > 0.$$

Thus $x \notin G$ and so $(\tilde{x}, f(\tilde{x})) \notin G$. Thus $S \subset G \subset D'$ and so $\mathrm{supp}\,\phi \subset U_{f_+} \cup S \subset D'$.

Arguing similarly, for all $\tilde{x} \in \mathbb{R}^{n-1}$, either $f(\tilde{x}) = f_+$, in which case $(\tilde{x}, x_n) \in D$ for $x_n > f(\tilde{x})$, or $f(\tilde{x}) \ge f_m$ for some m for which $|\tilde{x}_m - \tilde{x}| < \epsilon + \delta/2$. In this latter case, defining $x = (\tilde{x}, f_m)$ and $y = (\tilde{x}_m, f_m)$, it holds that

$$\mathrm{dist}(x, G) \le \mathrm{dist}(y, G) + |x-y| \le \delta + \epsilon + \delta/2 < 2\delta$$

so that $x \in D$ and hence $(\tilde{x}, f(\tilde{x})) \in D$. Thus, for all $\tilde{x} \in \mathbb{R}^{n-1}$, $(\tilde{x}, x_n) \in D$ for $x_n > f(\tilde{x})$, i.e., $D' \subset D$. ∎

With this preliminary lemma we can proceed to show that Lemma 4.6 holds whenever (4.1) holds.

LEMMA 4.11. *Suppose* (4.1) *holds,* $H \ge f_+$, $g \in L^2(S_H)$, *and* $w \in V_H$ *satisfies*

$$b(w, \phi) = -(g, \phi) \quad \textit{for all } \phi \in V_H. \tag{4.20}$$

Then

$$\|w\|_{V_H} \le k^{-1}\tilde{C}\|g\|_2,$$

where $\tilde{C} = \frac{\kappa}{\sqrt{2}}(\kappa+1)^2$.

Proof. Let $\tilde{V} := \{\phi|_{S_H} : \phi \in C_0^\infty(D)\}$. Then $\tilde{V}$ is dense in V_H. Suppose w satisfies (4.20) and choose a sequence $(w_m) \subset \tilde{V}$ such that $\|w_m - w\|_{V_H} \to 0$ as $m \to \infty$. Then $w_m = \phi_m|_{S_H}$, with $\phi_m \in C_0^\infty(D)$, and, by Lemma 4.10, there exists $f_m \in C^\infty(\mathbb{R}^{n-1})$ such that $\mathrm{supp}\,\phi_m \subset D_m$ and $U_{f_+} \subset D_m \subset D$, where $D_m := \{x \in \mathbb{R}^n : x_n > f_m(\tilde{x}),\ \tilde{x} \in \mathbb{R}^{n-1}\}$. Let $V_H^{(m)}$ and b_m denote the space and sesquilinear form corresponding to the domain D_m. That is, where $S_H^{(m)} := D_m \setminus \overline{U_H}$, $V_H^{(m)}$ is defined by $V_H^{(m)} := \{\phi|_{S_H^{(m)}} : \phi \in H_0^1(D_m)\}$ and b_m is given by (2.22) with S_H and V_H replaced by $S_H^{(m)}$ and $V_H^{(m)}$, respectively. Then $S_H^{(m)} \subset S_H$ and, if $v_m \in V_H^{(m)}$ and v denotes v_m extended by zero from $S_H^{(m)}$ to S_H, it holds that $v \in V_H$. Via this extension by zero, we can regard $V_H^{(m)}$ as a subspace of V_H and regard w_m as an element of $V_H^{(m)}$.

For all $v \in V_H^{(m)} \subset V_H$, we have

$$b_m(w_m, v) = b(w_m, v) = -(g, v) - b(w - w_m, v).$$

By Lemma 4.8, there exist unique w_m', $w_m'' \in V_H^{(m)}$ such that

$$b_m(w_m', v) = -(g, v), \quad v \in V_H^{(m)},$$

and

$$b_m(w_m'', v) = -b(w - w_m, v), \quad v \in V_H^{(m)}.$$

Clearly $w_m = w_m' + w_m''$ and, by Lemma 4.6,

$$\|w_m'\|_{V_H^{(m)}} \le k^{-1}\tilde{C}\|g\|_2$$

while, by Lemmas 4.8 and 3.4,

$$\|w_m''\|_{V_H^{(m)}} \le 2C\|w - w_m\|_{V_H}.$$

Thus

$$\|w\|_{V_H} = \lim_{m\to\infty} \|w_m\|_{V_H^{(m)}} \le k^{-1}\tilde{C}\|g\|_2. \qquad \square$$

Theorem 4.1 now follows by combining Lemmas 4.11, 4.5, and 4.4 with Corollary 4.3.

WEAK SEQUENTIAL STABILITY OF THE SET OF ADMISSIBLE VARIATIONAL SOLUTIONS TO THE NAVIER–STOKES–FOURIER SYSTEM*

EDUARD FEIREISL† AND ANTONÍN NOVOTNÝ‡

Abstract. We define and investigate variational (weak) solutions of the initial-boundary-value problem for the Navier–Stokes–Fourier system with the general pressure law. We prove that the set of these solutions is weakly sequentially stable.

Key words. Navier–Stokes–Fourier system, variational weak solutions, weak compactness

AMS subject classifications. 35Q30, 76N10

DOI. 10.1137/04061458X

1. Introduction. The state of a fluid in classical continuum mechanics is characterized through the value of three *macroscopic* quantities: the *density* $\varrho = \varrho(t,x)$, the *velocity* field $\mathbf{u} = \mathbf{u}(t,x)$, and the absolute *temperature* $\vartheta = \vartheta(t,x)$, where $t \in (0,T) \subset R$ is the time, and $x \in \Omega \subset R^3$ denotes the coordinate in the ambient Euclidean space. The basic axioms of physics, written in the spatial (Eulerian) reference system, assert the following:

(i) conservation of mass

$$\partial_t \varrho + \mathrm{div}_x(\varrho \mathbf{u}) = 0; \tag{1.1}$$

(ii) balance of (linear) momentum

$$\partial_t(\varrho \mathbf{u}) + \mathrm{div}_x(\varrho \mathbf{u} \otimes \mathbf{u}) + \nabla_x p = \mathrm{div}_x\, \mathbb{S} + \varrho \mathbf{f}; \tag{1.2}$$

(iii) balance of entropy

$$\partial_t(\varrho s) + \mathrm{div}_x(\varrho s \mathbf{u}) + \mathrm{div}_x\left(\frac{\mathbf{q}}{\vartheta}\right) = \sigma. \tag{1.3}$$

In accordance with the commonly accepted mathematical definition of a fluid, the total stress is expressed by Stokes' law $\mathbb{S} - p\mathbb{I}$, where $\mathbb{S}$ denotes the *viscous stress* tensor, and p is the *pressure*. The symbol s stands for the specific *entropy*, $\mathbf{q}$ is the *heat flux*, and σ denotes the *entropy production* rate (see, for example, Chapter 1 in [21]). The quantity $\mathbf{f}$ represents the external *body force* density—a given function of the time t and the position x.

One of the fundamental assumptions of the present theory is the requirement that the system is both thermally and mechanically *isolated*. One of the possible ways to meet this stipulation is to postulate

(iv) no-flux boundary conditions

$$\mathbf{q} \cdot \mathbf{n}|_{\partial\Omega} = 0, \ \text{ where } \mathbf{n} \text{ denotes the outer normal vector,} \tag{1.4}$$

together with

(v) no-slip boundary conditions

$$\mathbf{u}|_{\partial\Omega} = 0. \tag{1.5}$$

Consequently, the *total energy*

$$E \equiv \frac{1}{2}\varrho|\mathbf{u}|^2 + \varrho e, \text{ with } e \text{ being the specific internal energy,}$$

has to be a conserved quantity; more precisely, we have

(vi) total energy balance

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega E\,\mathrm{d}x = \int_\Omega \varrho\mathbf{f}\cdot\mathbf{u}\,\mathrm{d}x. \tag{1.6}$$

The *field equations* (1.1)–(1.3), together with the boundary conditions (1.4) and (1.5), supplemented with the total energy balance (1.6), form a suitable platform for the mathematical theory based on the concept of variational (weak) solutions. This concept will be developed in section 2. Note that we have deliberately opted for the "entropy form" (1.3) of the energy equation. Moreover, the total energy balance (1.6), which follows from (1.1) to (1.5) provided s and σ are related to the state variables through the basic thermodynamic equations and all fields are *smooth*, has been appended to the system (cf. section 2.1). Note that for weak solutions this equality may provide new information. The reason for this particular choice of the governing equations will become clear in section 2.

Of course, the general physical laws introduced above do not suffice to determine the motion of a specific fluid subject to the given loading. Before a concrete mathematical problem can be formulated, it is necessary to specify the *constitutive equations* relating the pressure p, the viscous stress $\mathbb{S}$, the heat flux $\mathbf{q}$, the entropy density s, the entropy production rate σ, and the internal energy density e to the state variables ϱ, $\mathbf{u}$, and ϑ. Here again, the reader will have noticed, there is freedom of choice of the basic state variables, yielding a variety of "equivalent" formulations provided the motion is smooth.

The constitutive equations, reflecting the *microscopic* structure of a given fluid, may be regarded as averages or expected values of molecular actions and as such they can be evaluated by the methods of statistical mechanics. When doing so, one often tacitly assumes the changes on the microscopic level to be so fast that the system at any "macroscopic" time t can be considered as being in thermodynamic equilibrium. In particular, the constitutive equations coincide with those obtained by the methods of thermostatics (cf. [20]).

The most important constitutive relation in fluid dynamics—the *state equation*—relates the pressure p to the values of the density ϱ and the absolute temperature ϑ. The best-known example is provided by Boyle's law for the perfect gas:

$$p = R\varrho\vartheta \text{ with a material constant } R > 0. \tag{1.7}$$

In light of arguments of modern statistical mechanics, however, relation (1.7) cannot be accepted without criticism even in the case of a "real perfect" gas, which means a large ensemble of identical particles with no interactive forces. Indeed there is a threshold temperature $\Theta_c = \Theta_c(\varrho)$ below which the gas exhibits *degeneration phenomena* due to quantum effects (see section 2.2 and Chapter 3 in [20]). Accordingly, for gases in low-temperature (or high-density) regimes, the dominant component of the macroscopic pressure results from the phenomenon of *pressure ionization*, with

$$p = a\varrho^{\frac{5}{3}} \text{ for } \vartheta < \Theta_c(\varrho) \tag{1.8}$$

the pressure of a completely degenerate electron gas (see, for instance, Chapter 15 in [14]).

These observations can be graphically visualized in Figure 1.1.

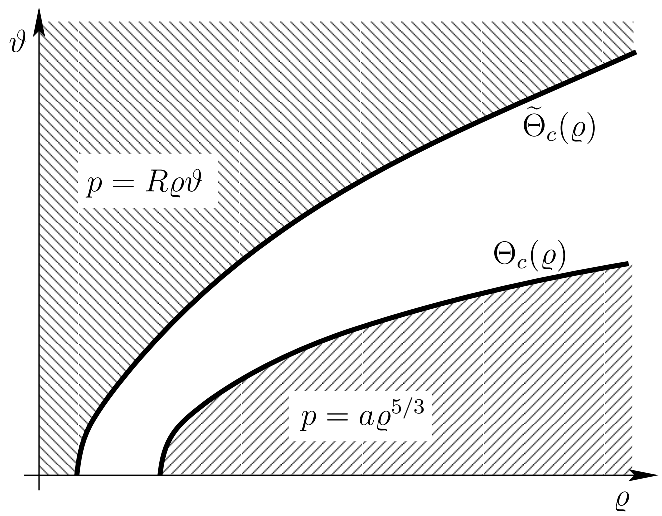

FIG. 1.1. $p = p(\varrho, \vartheta)$.

Motivated by the previous example, the main objective of this paper is to identify the class of physically relevant constitutive equations for which the set of all suitable variational solutions of problem (1.1)–(1.6) enjoys the property of *weak sequential stability.* That is to say that any sequence of (physically) admissible solutions bounded by the available a priori estimates possesses an accummulation point—another admissible solution of problem (1.1)–(1.6). Such a property was established in [16] under the main hypothesis that the pressure $p = p(\varrho, \vartheta)$ is an *affine* function of the temperature, which means

$$p(\varrho, \vartheta) = p_e(\varrho) + \vartheta p_\vartheta(\varrho)$$

for suitable functions p_e, p_ϑ. In particular, the internal energy density e can be written in the form

$$e(\varrho, \vartheta) = P_e(\varrho) + Q(\vartheta), \text{ where } P_e(\varrho) \equiv \int_1^\varrho \frac{p_e(z)}{z^2}\,\mathrm{d}z, \text{ and } Q \text{ is a given function.}$$

The possibility of separating the "elastic" part P_e from the thermal component Q gives rise to a family of rescaled (renormalized) energy equations yielding (i) suitable a priori estimates on the temperature ϑ and (ii) compatibility of the corresponding Navier–Stokes–Fourier system with the so-called biting limit procedure applied to the thermal energy equation (see Chapter 6 in [16]). Such an approach is of no use in the case of the more realistic and physically relevant pressure–density–temperature state equations considered in this paper.

Leaving aside the vast amount of literature devoted to problems in the one-dimensional space geometry (see, for instance, the monograph by Antontsev, Kazhikhov, and Monakhov [1]) as well as the "small data" problems and the problems of existence of "local in time smooth solutions" (cf. the papers by Hoff [23], Matsumura and Nishida [26], [25], among others), the most relevant references to be quoted here are represented by the monograph by Lions [24] together with the results of Vaigant and Kazhikhov [38]. In both cases, the "large data" problems are addressed concerning the so-called barotropic flows for which p can be taken as a function of ϱ only. In particular, the fundamental property of "weak continuity" of the *effective viscous flux* established in [24] (cf. also [22], [33]) will play a significant role in the analysis of the present problem (see section 5).

After an introductory section 2 defining the class of admissible variational solutions to problem (1.1)–(1.6), the paper is divided into three major parts as follows.

- Section 3 presents a general class of constitutive equations, based upon physical principles, for which the main result—the *weak sequential stability* of the solution set of problem (1.1)–(1.6)—is established (see Theorem 3.1).
- Section 4 concerns the available estimates on the state variables ϱ, $\mathbf{u}$, and ϑ resulting from boundedness of the total energy and entropy. The role of these bounds is to prevent possible *concentration phenomena* that may develop in a sequence of admissible solutions. As a by-product, we deduce the weak sequential stability of the convective terms $\varrho\mathbf{u}$, $\varrho\mathbf{u} \otimes \mathbf{u}$, and $\varrho s\mathbf{u}$.
- The central issue of compatibility of the (nonlinear) constitutive equations with weak convergence is treated in section 5. In particular, we establish a weak "continuity" property of the effective viscous flux for a general linearly viscous fluid with temperature-dependent shear and bulk viscosity coefficients. Moreover, a new class of *renormalized* solutions to the continuity equation is introduced in order to show strong L^1-compactness of the temperature field. Finally, the technique of [16] based on the concept of "oscillations defect measure" is adopted in order to show strong L^1-compactness of the density.

2. Admissible variational solutions. The purpose of this section is to introduce a suitable concept of admissible solutions to problem (1.1)–(1.6) to be dealt with in what follows. Unfortunately, the most natural choice of *smooth solutions* lies out of reach of the presently available mathematical tools. More specifically, the set of smooth solutions is not (known to be) closed with respect to a priori bounds resulting mostly from the rather poor energy or entropy estimates.

Instead our analysis is based on the concept of variational (weak) solutions, where the original system of partial differential equations is replaced by a family of *integral identities* to be satisfied when the equations are "tested" (multiplied) on a suitable smooth function. Although such an approach seems to be much closer to the underlying physical principles, the fundamental question whether or not it yields a definite theory in the sense of existence, uniqueness, and stability of solutions of meaningful initial-value problems is far from being settled.

Nonetheless, our aim is to develop a mathematical theory of (1.1)–(1.6) which conforms with the following stipulations, the rigorous verification of which is the objective of this paper and/or of future research.

- *Compatibility.* Any smooth solution of problem (1.1)–(1.6) supplemented with a suitable set of constitutive equations is an admissible solution in the sense specified later in this section. Conversely, any admissible solution which is smooth represents a classical solution of the problem.

- *Physical admissibility.* The class of admissible solutions meets all restrictions imposed by the underlying physical principles, in particular, the second law of thermodynamics.
- *Existence.* The results obtained in this paper combined with the approximation scheme developed in Chapter 7 in [16] should yield rigorous existence results (in the class of weak solutions) for the corresponding initial-boundary-value problem without any essential restriction on the size of initial data.
- *Equilibrium states (Prigogine's principle).* Minimization of the entropy production rate σ over the set of all admissible states of the system yields an equilibrium solution (cf. [30]).
- *Large time relaxation.* Any admissible solution resulting from the action of a *conservative* body force $\mathbf{f} = \nabla_x F$ tends to an equilibrium for large values of time.

2.1. General thermodynamics relations. In accordance with the common strategy delineated in section 1, the thermodynamic functions p, e, and s will be expressed in terms of the instantaneous values of the scalar state variables ϱ and ϑ. Consequently, by virtue of the basic principles of thermodynamics, the entropy density s is determined, up to an additive constant, through

$$\frac{\partial s}{\partial \varrho} = \frac{1}{\vartheta}\Big(\frac{\partial e}{\partial \varrho} - \frac{p}{\varrho^2}\Big), \quad \frac{\partial s}{\partial \vartheta} = \frac{1}{\vartheta}\frac{\partial e}{\partial \vartheta} \tag{2.1}$$

imposing Maxwell's relation (a compatibility condition) on e and p in the form

$$\frac{\partial e}{\partial \varrho} = \frac{1}{\varrho^2}\Big(p - \vartheta\frac{\partial p}{\partial \vartheta}\Big). \tag{2.2}$$

By the same token, the entropy production rate σ is a nonnegative quantity given by

$$\sigma = \mathbb{S} : \left(\frac{\nabla_x \mathbf{u}}{\vartheta}\right) - \mathbf{q} \cdot \left(\frac{\nabla_x \vartheta}{\vartheta^2}\right) \geq 0 \tag{2.3}$$

provided the flow is *smooth* (see, for instance, Chapter 1 in [21]).

Here, the assumption of smoothness is crucial since it is well known that discontinuous solutions (shock waves) of the inviscid system do increase entropy even if $\mathbb{S} = \mathbf{q} = 0$ (see, for example, the classical text by Smoller [34]). As a matter of fact, a kind of "mechanical energy defect" cannot be legitimately excluded even in the case of a viscous incompressible flow described by the classical Navier–Stokes system in three space dimensions (see Duchon and Robert [11], Eyink [15], Nagasawa [28], Caffarelli, Kohn, and Nirenberg [6], among others). If such a scenario really occurs, and if we want, at the same time, to keep the total energy balance (1.6) in force, it is necessary to replace the equality in (2.3) by a more general stipulation:

$$\sigma \geq \mathbb{S} : \left(\frac{\nabla_x \mathbf{u}}{\vartheta}\right) - \mathbf{q} \cdot \left(\frac{\nabla_x \vartheta}{\vartheta^2}\right). \tag{2.4}$$

On the other hand, it is a routine matter to check that (2.4) *together with* (1.1)–(1.6) implies, in fact, (2.3), provided s, e satisfy (2.1) and (2.2) and all quantities in question are smooth (see also section 2.3).

As the field equations are supposed to describe a system far from equilibrium, a more natural way would be to *postulate* the existence of the entropy s as a function of ϱ and e and to *define* the absolute temperature $\vartheta^{-1} \equiv \partial_e s > 0$ (see, for example, [21]). However, we have chosen the more "classical" family of the state variables as the constitutive equations we discuss below seem much more transparent in this setting.

2.2. Admissible solutions. Motivated by the previous discussion we are now ready to introduce the class of admissible solutions of problem (1.1)–(1.6).

DEFINITION 2.1. *Let $\Omega \subset R^3$ be a domain. We shall say that a quantity $\{\varrho, \mathbf{u}, \vartheta\}$ represents an admissible solution of problem* (1.1)–(1.6) *on a time interval* $(0, T)$ *provided the following conditions are fulfilled.*

- *The density ϱ and the velocity $\mathbf{u}$,*

$$\varrho \geq 0, \ \ \varrho \in L^\infty(0, T; L^\gamma(\Omega)), \ \ \mathbf{u} \in L^2(0, T; W_0^{1,2}(\Omega; R^3)), \ \ \gamma > \frac{3}{2},$$

solve a renormalized continuity equation in $\mathcal{D}'((0, T) \times R^3)$ provided they were extended to be zero outside Ω. Specifically, the integral identity

$$\int_0^T \int_\Omega (\varrho H(\varrho) \partial_t \varphi + \varrho H(\varrho) \mathbf{u} \cdot \nabla_x \varphi) \, \mathrm{d}x \, \mathrm{d}t = \int_0^T \int_\Omega h(\varrho) \mathrm{div}_x \mathbf{u} \ \varphi \, \mathrm{d}x \, \mathrm{d}t \tag{2.5}$$

holds for any test function $\varphi \in \mathcal{D}((0, T) \times R^3)$ and any

$$h \in BC[0, \infty), \ \ H(\varrho) \equiv H(1) + \int_1^\varrho \frac{h(z)}{z^2} \, \mathrm{d}z. \tag{2.6}$$

- *The momentum equation* (1.2) *is satisfied in $\mathcal{D}'((0, T) \times \Omega)$.*
- *The absolute temperature ϑ,*

$$\vartheta, \ \log(\vartheta) \in L^2(0, T; W^{1,2}(\Omega)),$$

is positive a.a. on $(0, T) \times \Omega$. The specific entropy $s = s(\varrho, \vartheta)$, related to p and e through (2.1) *and* (2.2)*, satisfies* (1.3) *in $\mathcal{D}'((0, T) \times \Omega)$ with the entropy production rate σ—a positive measure on $[0, T] \times \overline{\Omega}$ such that inequality* (2.4) *holds. More specifically, the integral identity*

$$\int_0^T \int_\Omega \left(\varrho s \ \partial_t \varphi + \varrho s \mathbf{u} \cdot \nabla_x \varphi + \frac{\mathbf{q}}{\vartheta} \cdot \nabla_x \varphi \right) \mathrm{d}x \, \mathrm{d}t + \int_0^T \int_\Omega \left[\mathbb{S} : \left(\frac{\nabla_x \mathbf{u}}{\vartheta} \right) - \mathbf{q} \cdot \left(\frac{\nabla_x \vartheta}{\vartheta^2} \right) \right] \varphi \, \mathrm{d}x \, \mathrm{d}t \leq 0 \tag{2.7}$$

is valid for any test function

$$\varphi \in \mathcal{D}((0, T) \times R^3), \quad \varphi \geq 0.$$

- *The total energy balance* (1.6) *is satisfied in $\mathcal{D}'(0, T)$.*

- *The "thermal" energy inequality*

$$\frac{\mathrm{d}}{\mathrm{dt}}\int_\Omega \varrho(e-e_c)\mathrm{d}x \geq \int_\Omega (\mathbb{S}:\nabla_x\mathbf{u} - (p-p_c)\ \mathrm{div}_x\mathbf{u})\,\mathrm{d}x \tag{2.8}$$

holds in $\mathcal{D}'(0,T)$ *with*

$$p_c(\varrho)\equiv p(\varrho,0),\ \ e_c(\varrho)\equiv \int_0^\varrho \frac{p_c(z)}{z^2}\ \mathrm{d}z.$$

2.3. Remarks. A few comments are in order.

(i) To begin with, the reader will have noticed that all quantities appearing in the integral identities introduced in Definition 2.1, and this is to be viewed as an inseparable part of the definition, are tacitly assumed to be at least locally integrable on $(0,T)\times\Omega$.

(ii) The renormalized solutions in the spirit of (2.5) were introduced by DiPerna and Lions in [10]. Here, it is easy to check that the choice $h\equiv 0$ yields the validity of (1.1) in $\mathcal{D}'((0,T)\times\Omega)$ together with *the total mass conservation law*

$$\int_\Omega \varrho(t)\,\mathrm{d}x = M \text{ for any } t\in[0,T]. \tag{2.9}$$

As a matter of fact, we shall make use of a slightly stronger formulation of (2.5), namely,

$$\begin{aligned}\partial_t(\varrho H(\varrho,\Theta)) + \mathrm{div}_x(\varrho H(\varrho,\Theta)\mathbf{u}) + h(\varrho,\Theta)\,\mathrm{div}_x\mathbf{u}\\ = \varrho\frac{\partial H(\varrho,\Theta)}{\partial\Theta}(\partial_t\Theta + \nabla_x\Theta\cdot\mathbf{u})\end{aligned} \tag{2.10}$$

in $\mathcal{D}'((0,T)\times\Omega)$ for any $\Theta\in C^1([0,T]\times\overline{\Omega})$, where

$$\begin{aligned}&\frac{\partial H}{\partial\Theta},\ h\in BC([0,\infty)\times\Theta([0,T]\times\overline{\Omega})),\\ &H(\varrho,\Theta) = H(1,\Theta)+\int_1^\varrho \frac{h(z,\Theta)}{z^2}\,\mathrm{d}z.\end{aligned} \tag{2.11}$$

However, as we show in section 5, (2.5) and (2.10) are *equivalent* in the class of admissible solutions.

(iii) Seemingly, the "correct" statement of (2.8) should read as

$$\frac{\mathrm{d}}{\mathrm{dt}}\int_\Omega \varrho e\,\mathrm{d}x \geq \int_\Omega(\mathbb{S}:\mathbb{D}_x\mathbf{u} - p\ \mathrm{div}_x\mathbf{u})\,\mathrm{d}x. \tag{2.12}$$

Unfortunately, the available a priori estimates are not strong enough to render the "cold" pressure term p_c square integrable—in other words, to legalize the product $p_c\mathrm{div}_x\mathbf{u}$. Note, however, that for smooth solutions, both (2.8) and (2.12) (with equality sign) are equivalent to (1.3).

(iv) In order to conclude, we shall show that any smooth admissible solution solves problem (1.1)–(1.6) in the classical sense. Obviously, the only nonstandard part is to show that (1.3) holds with σ given by (2.3) and that $\mathbf{q}$ satisfies the boundary condition (1.4).

If ϑ is smooth, one can take the product $\varphi\vartheta$ as a test function in (2.7) to deduce

$$\int_0^T \int_\Omega \vartheta(\partial_t(\varrho s) + \mathrm{div}_x(\varrho s \mathbf{u}))\varphi \,\mathrm{d}x\,\mathrm{d}t - \int_0^T \int_\Omega \mathbf{q}\cdot\nabla_x\varphi\,\mathrm{d}x\,\mathrm{d}t$$
$$\geq \int_0^T \int_\Omega \mathbb{S} : \nabla_x \mathbf{u}\ \varphi\,\mathrm{d}x\,\mathrm{d}t \text{ for any } \varphi \in \mathcal{D}((0,T)\times R^3),\ \varphi \geq 0,$$

where, thanks to (1.1) and (2.1),

$$\vartheta\ \partial_t(\varrho s) + \vartheta \mathrm{div}_x(\varrho s\mathbf{u}) = \vartheta\ \varrho\partial_t s + \vartheta\varrho\mathbf{u}\cdot\nabla_x s = \partial_t(\varrho e) + \mathrm{div}_x(\varrho e\mathbf{u}) + p\ \mathrm{div}_x\mathbf{u}.$$

Thus, we have obtained the *internal energy balance*

$$\int_0^T \int_\Omega \varrho e\ \partial_t\varphi + \varrho e\mathbf{u}\cdot\nabla_x\varphi + \mathbf{q}\cdot\nabla_x\varphi\,\mathrm{d}x\,\mathrm{d}t$$
$$\leq \int_0^T \int_\Omega (p\ \mathrm{div}_x\mathbf{u} - \mathbb{S}:\nabla_x\mathbf{u})\varphi\mathrm{d}x\,\mathrm{d}t \text{ for any } \varphi \in \mathcal{D}((0,T)\times R^3),\ \varphi\geq 0. \tag{2.13}$$

On the other hand, we have the *kinetic energy equation*

$$\partial_t\left(\frac{1}{2}\varrho|\mathbf{u}|^2\right) + \mathrm{div}_x\left(\frac{1}{2}\varrho|\mathbf{u}|^2\mathbf{u}\right) + \mathrm{div}_x(p\mathbf{u})$$
$$= \mathrm{div}_x(\mathbb{S}\mathbf{u}) + p\ \mathrm{div}_x\mathbf{u} - \mathbb{S}:\nabla_x\mathbf{u} + \varrho\mathbf{f}\cdot\mathbf{u}, \tag{2.14}$$

which can be deduced from (1.1) and (1.2).

Now it is easy to observe that (2.13) and (2.14) are compatible with the total energy balance (1.6) if and only if (2.13) holds as *equality* for any choice of φ. Consequently, it is a routine matter to deduce the internal energy equation

$$\partial_t(\varrho e) + \mathrm{div}_x(\varrho e\mathbf{u}) + \mathrm{div}_x\ \mathbf{q} = \mathbb{S}:\nabla_x\mathbf{u} - p\ \mathrm{div}_x\mathbf{u} \text{ in } (0,T)\times\Omega \tag{2.15}$$

together with the boundary condition (1.4) to be satisfied by the heat flux $\mathbf{q}$. Of course, (2.15) is equivalent to (1.3) provided all the relevant quantities are smooth.

3. Hypotheses and main results. The *field equations* (1.1)–(1.3), being *linear* with respect to partial derivatives, can be viewed as a family of constraints in the Fourier variable $\mathbf{x}\to\xi$ to be satisfied by any physically admissible flow while the *constitutive equations* represent, in general, *nonlinear* functional relations associated with the material properties of a given fluid. The fundamental idea advocated in the celebrated work of Tartar [35] and DiPerna [8] and [9], to name only a few, asserts that compatibility or rather incompatibility of these stipulations may result in substantial restrictions imposed on the whole set of possible solutions. One can say, very roughly indeed, that the problem will enjoy the property of *weak sequential stability*, which means that any sequence of admissible solutions in the sense of Definition 2.1 possesses an accumulation point, with respect to the topologies induced by the available a priori estimates, that represents another solution of the same problem (see Theorem 3.1). Given the rather poor estimates currently available, this is a nontrivial and usually decisive piece of information that can be directly used to build up a rigorous existence theory.

3.1. The pressure–density–temperature state equation. The constitutive equation relating the pressure p to the state variables ϱ and ϑ will play a central role in our analysis. In accordance with general principles of statistical mechanics, the pressure should obey the following hypotheses.

- In the regime of moderate densities and high temperatures, the perfect gas law (1.7) is always applicable.
- The pressure $p = p(\varrho, \vartheta)$ is a monotone nondecreasing function of ϱ for any fixed ϑ (see Chapter 5 in [20]).
- There is a critical temperature $\Theta_c(\varrho)$ below which the fluid exhibits *degeneration phenomena*. Equivalently, one can say that for any ϑ there is a critical density $\varrho_c(\vartheta)$ so that the "remaining" part $\varrho - \varrho_c$ corresponds to fluid particles with no contribution to the pressure nor to the specific heat at constant volume (see section 2.2 and Chapter 3 in [20]). On the other hand, one can assume the pressure in the "supercritical region" to be that of a degenerate (cold) electron gas given by (1.8) (see Chapter 15 in [14]).
- The pressure is augmented by an intensive *radiation* component p_R when the temperature is extremely high and the density is low (see, for instance, Chapter 15 in [14], [5], and [27]).

Accordingly, the principal mathematical hypotheses imposed on the total pressure p can be formulated as follows.

The total pressure p can be decomposed as

$$p(\varrho, \vartheta) \equiv p_G(\varrho, \vartheta) + p_R(\vartheta), \tag{3.1}$$

where p_R is the pressure due to radiation,

$$p_R(\vartheta) = \frac{d}{3}\vartheta^4, \quad d > 0. \tag{3.2}$$

The *extensive* component $p_G \in C^2((0,\infty) \times (0,\infty))$ satisfies

$$\frac{\partial p_G(\varrho, \vartheta)}{\partial \varrho} \geq 0, \quad \left| \frac{\partial p_G(\varrho, \vartheta)}{\partial \vartheta} \right| \leq c(M) \text{ for all } 0 < \varrho, \vartheta < M, \tag{3.3}$$

where $c(M)$ is bounded for bounded M.

Moreover,

$$\lim_{\varrho \to 0+} p_G(\varrho, \vartheta) = 0 \text{ for any } \vartheta > 0, \quad \lim_{\vartheta \to 0+} p_G(\varrho, \vartheta) = p_c(\varrho) \text{ for any } \varrho > 0. \tag{3.4}$$

The "cold" pressure p_c dominates its thermal complement in the neighborhood of the ϱ-axis bounded above by a graph of a continuous function $\Theta_c = \Theta_c(\varrho) : [0,\infty) \to [0,\infty)$; more specifically,

$$\left| \frac{\partial p_G(\varrho, \vartheta)}{\partial \vartheta} \right| \leq c\big(1 + p_c^{\frac{1}{3}}(\varrho) + \vartheta^3\big) \text{ for all } 0 < \vartheta < \Theta_c(\varrho). \tag{3.5}$$

Finally, we impose a rather technical but, as we have seen above, physically relevant growth condition:

$$a\varrho^\gamma - k \leq p_c(\varrho) \leq a\varrho^\gamma + k \text{ for any } \varrho \geq 0 \quad \text{with } a > 0,\ k > 0,\ \gamma > \frac{3}{2}. \tag{3.6}$$

An overall picture of hypotheses imposed on the state equation can be seen in Figure 3.1.

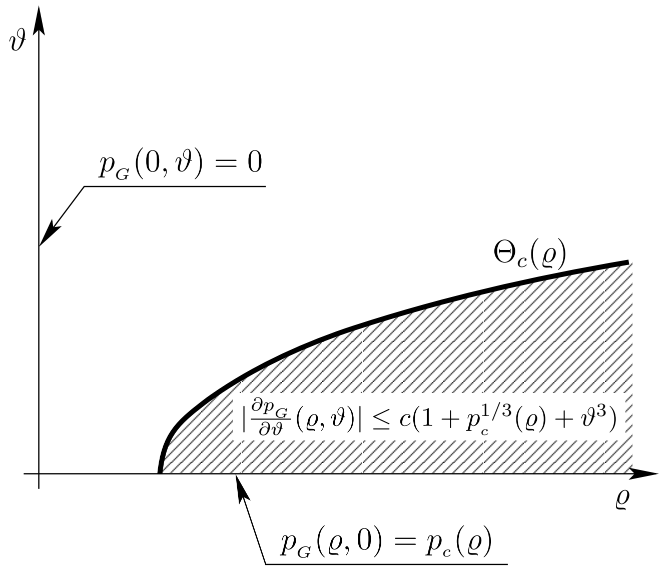

FIG. 3.1. $p_G = p_G(\varrho, \vartheta)$.

3.2. The internal energy and entropy. The specific internal energy e is uniquely determined, modulo a function depending solely on ϑ, by the pressure p through Maxwell's equation (2.2). In addition, writing

$$e(\varrho,\vartheta) = e_G(\varrho,\vartheta) + e_R(\varrho,\vartheta), \text{ with the radiation component } e_R = \frac{d\vartheta^4}{\varrho}, \tag{3.7}$$

we require e_G to satisfy

$$e_G(\varrho,\vartheta) \geq 0, \qquad \lim_{[\varrho,\vartheta]\to[0,0]} e_G(\varrho,\vartheta) = 0, \tag{3.8}$$

$$c_v \equiv \frac{\partial e_G(\varrho,\vartheta)}{\partial \vartheta} \geq 0, \quad c_v \in C([0,\infty) \times [0,\infty)), \tag{3.9}$$

$$c_1(1 + \vartheta^\omega) \leq c_v(\varrho,\vartheta) \leq c_2(1 + \vartheta^\omega), \quad \text{with } c_1 > 0, \ \omega \geq 0, \tag{3.10}$$

for all $\varrho > 0$, $\vartheta > 0$.

The growth condition (3.10) is in agreement with physical experiments predicting $\omega \in [0, 1/2]$ (cf. [40]). The quantities e_G, p_G being interrelated through (2.2) and hypotheses (3.8)–(3.10) implicitly impose certain restrictions on p_G as well.

Now it is easily seen, with p and e given, that the specific entropy s is determined, up to an additive constant, by the thermodynamic equations (2.1).

3.3. Viscosity and thermal conductivity. The fluids considered in this paper are *Newtonian*, which means that the viscous stress tensor $\mathbb{S}$ is a linear function of the velocity gradient $\nabla_x \mathbf{u}$. As a consequence of the principle of *material frame-indifference*, the only physically admissible form of $\mathbb{S}$ must read

$$\mathbb{S} \equiv 2\mu\left(\mathbb{D}_x\mathbf{u} - \frac{1}{N}\,\mathrm{div}_x\mathbf{u}\,\mathbb{I}\right) + \zeta\,\mathrm{div}_x\mathbf{u}\,\mathbb{I} \tag{3.11}$$

with

$$\mathbb{D}_x \mathbf{u} = \frac{1}{2}(\nabla_x \mathbf{u} +^t \nabla_x \mathbf{u}) \text{ being the symmetric part of the velocity gradient,}$$

where μ and ζ are the *shear* and *bulk viscosity coefficients* (see section C.1 in [37]).

In general, the quantities μ and ζ are functions of both ϱ and ϑ. Here, mainly because of technical difficulties, we restrict ourselves to the (physically relevant—see, for instance, [2]) case when μ and ζ depend only on the absolute temperature ϑ. More specifically, we suppose $\mu = \mu(\vartheta)$, $\zeta = \zeta(\vartheta) \in C^1[0,\infty)$ such that

$$m_1(1+\vartheta^\beta) \leq \mu(\vartheta), \quad |\mu'(\vartheta)| \leq m_2(\vartheta^{\beta-1}+1), \quad m_1 > 0,\ \beta \geq 0, \tag{3.12}$$

$$\zeta \geq 0, \quad m_1\vartheta^\beta - 1 \leq \zeta(\vartheta), \quad |\zeta'(\vartheta)| \leq m_2(\vartheta^{\beta-1}+1). \tag{3.13}$$

The requirement that the bulk viscosity coefficient ζ must be positive at least for large values of ϑ may be viewed as slightly restrictive from the physical viewpoint. As a matter of fact, this hypothesis could be dropped at the expense of more severe restrictions imposed on the pressure p. Note, however, that Stokes' relation $\zeta \equiv 0$ inferred from questionable hypotheses is considered unsustainable in light of current theory (cf. section E.1 in [37]).

By virtue of the second law of thermodynamics, expressed through (2.3), the scalar product $\mathbf{q} \cdot \nabla_x \vartheta$ must be nonpositive. For simplicity, we shall assume the heat flux vector $\mathbf{q}$ to be given by Fourier's law

$$\mathbf{q} = -\kappa \nabla_x \vartheta \tag{3.14}$$

with the *heat conductivity coefficient* $\kappa > 0$. To be more precise, the quantity κ itself is allowed to be a continuous function of ϱ and ϑ satisfying the growth condition

$$k_1(1+\vartheta^\alpha) \leq \kappa(\varrho,\vartheta) \leq k_2(1+\vartheta^\alpha), \text{ with } k_1 > 0, \text{ for a certain } \alpha \geq 3. \tag{3.15}$$

The lower bound on the exponent α is motivated by the presence of "radiative" heat conductivity κ_R proportional to ϑ^3 (cf. [5] or [31], [32]). On the other hand, even larger values of $\alpha \approx 4.5$–5.5 can be considered as physically relevant (see [40]).

In agreement with the previous discussion, we shall suppose that the coefficients α and β satisfy

$$0 \leq \beta \leq \frac{4}{3}, \quad \alpha \geq \frac{16}{3} - \beta.$$

These (technical) assumptions make it possible to derive the bounds for dissipation from the thermal energy balance. So far, it is an open question whether they can be relaxed.

3.4. The main result. Having introduced all the necessary hypotheses we are now in a position to state our main result.

THEOREM 3.1. *Let $\Omega \subset R^3$ be a bounded domain with a Lipschitz boundary. Assume that the quantities p, e, s are the given functions of ϱ, ϑ satisfying hypotheses* (3.1)–(3.10)*. Furthermore, let $\mathbb{S}$ and $\mathbf{q}$ be determined through* (3.11) *and* (3.14)*, respectively, where μ, ζ satisfy* (3.12)*,* (3.13) *and κ obeys* (3.15)*. Finally, let*

$$\gamma > \frac{3}{2}, \quad 0 \leq \omega \leq \frac{1}{2}, \quad 0 \leq \beta \leq \frac{4}{3}, \quad \alpha \geq \frac{16}{3} - \beta, \tag{3.16}$$

and

$$\Theta_c(\varrho) \geq c\varrho^{\frac{\gamma}{4}} - 1 \quad \textit{for a certain } c > 0, \tag{3.17}$$

where Θ_c is the critical temperature appearing in (3.5).

Suppose that

$$\left\{ \begin{array}{c} \{\varrho_n\}_{n=1}^{\infty} \subset L^{\infty}(0,T;L^{\gamma}(\Omega)) \cap C([0,T];L^1(\Omega)), \\ \\ \{\mathbf{u}_n\}_{n=1}^{\infty} \subset L^2(0,T;W_0^{1,2}(\Omega;R^3)), \\ \\ \{\vartheta_n\}_{n=1}^{\infty} \subset L^2(0,T;W^{1,2}(\Omega)) \end{array} \right\}$$

is a sequence of admissible solutions of problem (1.1)–(1.6) *on the time interval* $(0,T)$ *in the sense of Definition* 2.1 *such that*

$$\varrho_n(0,\cdot) \to \varrho_0 \ \textit{in } L^1(\Omega), \tag{3.18}$$

$$\operatorname{ess}\limsup_{t\to 0+} \int_{\Omega} \varrho_n(|\mathbf{u}_n|^2 + e(\varrho_n,\vartheta_n))(t)\,\mathrm{d}x \leq E_0, \tag{3.19}$$

$$\operatorname{ess}\liminf_{t\to 0+} \int_{\Omega} \varrho_n s_n(t)\mathrm{d}x \geq S_0,$$

and with

$$\mathbf{f}_n \to \mathbf{f} \ \textit{weakly (*) in } L^{\infty}((0,T)\times\Omega), \tag{3.20}$$

where E_0 and S_0 are constants independent of n.

Then, passing to a subsequence as the case may be, we have

$$\left\{ \begin{array}{c} \varrho_n \to \varrho \ \textit{in } C([0,T];L^1(\Omega)), \\ \\ \mathbf{u}_n \to \mathbf{u} \ \textit{weakly in } L^2(0,T;W_0^{1,2}(\Omega;R^3)), \\ \\ \vartheta_n \to \vartheta \ \textit{weakly in } L^2(0,T;W^{1,2}(\Omega)) \textit{ and strongly in } L^2((0,T)\times\Omega), \end{array} \right\}$$

where the limit quantity $\{\varrho,\mathbf{u},\vartheta\}$ represents another admissible solution of problem (1.1)–(1.6) *on the time interval* $(0,T)$.

One of the first weak stability results for the reduced *barotropic model*, where $p = p(\varrho)$ and the temperature is completely eliminated from the system, was obtained by Lions [24]. Some of the ingredients of his approach can be traced back to the work of Hoff [22] and Serre [33]. Another interesting result in this direction is due to Vaigant and Kazhikhov [38].

The same question as well as the closely related problem of global existence for the full Navier–Stokes–Fourier system with constant viscosity coefficients is studied in [16]; the case of temperature sensitive viscosity is dealt with in [17]; and, finally, these results are extended in [13] in order to include the radiation phenomena.

As already pointed out in section 1, the common feature of the above-mentioned results is that the fluid pressure p_G is always taken to be an affine function of the absolute temperature, whence the internal energy density e admits a decomposition into purely "elastic" and "thermal" components yielding a family of "renormalized" energy equations (see section 4.3.3 in Chapter 4 in [16]). Since these rescaled equations provide additional a priori estimates on the temperature, the technique based on Chacon's biting limit can be used in order to compensate for the lack of integrability of the heat flux $\mathbf{q}$ (see section 6.8.1 in Chapter 6 in [16]). Apparently, such an approach is no longer applicable in the present setting, where the pressure is a general function of ϱ and ϑ, which means that the elastic and thermal contributions to e act simultaneously.

In this work, we introduce a method which makes it possible to treat this general situation. It ranges from nontrivial modifications of approaches introduced in [12], [13], [16], [17], [18] (cf. section 4) to delicate new issues including the temperature-dependent renormalized continuity equation (treated in section 5), which is needed to pass to the limit in the general pressure term.

Regardless of the rather technical hypotheses (3.16) and (3.17), the applicability of the present approach leans essentially on the following characteristic features of the problem.

- The total pressure p is *coercive* at both extremes of the "phase space," which means that on both axes $\{\varrho = 0\}$, $\{\vartheta = 0\}$. From the physical viewpoint, this amounts to taking both radiation and the ionization pressure components into account.
- The viscosity coefficients *depend effectively* on the temperature; in particular,

$$\mu(\vartheta) \to \infty \text{ for } \vartheta \to \infty.$$

  This is a very natural hypothesis, especially for gases.
- The heat conductivity coefficient κ is a superquadratic ("supercubic," as a matter of fact) function of ϑ under large temperature regimes. Such a stipulation seems to be in good agreement with experimental results.

As already pointed out, satisfaction of these conditions does not seem to be at odds with the constitutive laws obtained by the methods of statistical mechanics or empirically, in particular, for real gases. We refer the interested reader to the monographs [2], [20], [27], [39], [40], among others, for the physical background of the present theory.

4. Estimates. The bounds imposed on the family of admissible solutions by hypotheses (3.18)–(3.20) are, very often but rather incorrectly, referred to as a priori estimates. Let us stress, to begin with, that all estimates discussed in this section are "real" estimates to be satisfied by any admissible solution of problem (1.1)–(1.6) in the sense of Definition 2.1 while the term a priori estimates is usually related to *smooth* solutions of a given problem.

4.1. Total mass conservation. As already observed in (2.9), the total mass M of the fluid is a constant of motion thanks to the conservative boundary conditions (1.5). Seeing that ϱ is always nonnegative we infer, in particular, that

$$\{\varrho_n\}_{n=1}^{\infty} \text{ is bounded in } L^\infty(0,T;L^1(\Omega)). \tag{4.1}$$

4.2. Energy estimates. Since the internal energy density e obeys Maxwell's equation (2.2), one can write

$$e_G(\varrho,\vartheta) = P_c(\varrho) + Q(\vartheta) + \int_1^{\varrho} \left(p_G(z,\vartheta) - p_G(z,0) - \vartheta \frac{\partial p_G(z,\vartheta)}{\partial \vartheta} \right) \frac{1}{z^2}\,\mathrm{d}z \tag{4.2}$$

with

$$P_c(\varrho) \equiv \int_0^{\varrho} \frac{p_c(z)}{z^2}\,\mathrm{d}z, \quad Q(\vartheta) \equiv \int_0^{\vartheta} c_v(1,s)\,\mathrm{d}s. \tag{4.3}$$

Note that $e_G(\rho,0) = P_c(\rho)$, and therefore the integral $\int_0^1 p_c(z)/z^2\,\mathrm{d}z$ is convergent in order to comply with hypotheses (3.8) and (3.9).

The total energy balance (1.6) integrated with respect to time yields

$$\int_\Omega E_n(\tau)\mathrm{d}x \le E_0 + \int_0^\tau \int_\Omega \varrho_n \mathbf{f}_n \cdot \mathbf{u}_n \,\mathrm{d}x \text{ for a.a. } \tau \in (0,T)$$

with

$$E_n \equiv \varrho_n \Big(\frac{1}{2}|\mathbf{u}_n|^2 + e(\varrho_n,\vartheta_n)\Big) \text{ and } E_0 \text{ independent of } n.$$

Thus, a straightforward application of Gronwall's lemma gives rise to

$$\{\sqrt{\varrho_n}\mathbf{u}_n\}_{n=1}^\infty \text{ bounded in } L^\infty(0,T;L^2(\Omega;R^3)) \tag{4.4}$$

together with the estimate

$$\sup_{n=1,2,\dots} \Big(\operatorname{ess}\sup_{t\in(0,T)} \int_\Omega \varrho_n e(\varrho_n,\vartheta_n)\mathrm{d}x\Big) < \infty. \tag{4.5}$$

Now, in accordance with hypotheses (3.7) and (3.8), we get

$$\{\vartheta_n\}_{n=1}^\infty \text{ bounded in } L^\infty(0,T;L^4(\Omega)). \tag{4.6}$$

Moreover, writing $e_G(\rho,\vartheta) = e_G(\rho,0) + \int_0^\vartheta \frac{\partial e_G(\rho,s)}{\partial\vartheta}\,\mathrm{d}s$, by virtue of (3.9) and (3.10), we obtain

$$\{\varrho_n\vartheta_n^{1+\omega}\}_{n=1}^\infty \text{ bounded in } L^\infty(0,T;L^1(\Omega)). \tag{4.7}$$

On the other hand, hypotheses (3.8) and (3.9) and formula (4.2) imply

$$Q(\vartheta) + \int_1^\varrho \Big(p_G(z,\vartheta) - p_G(z,0) - \vartheta\frac{\partial p_G(z,\vartheta)}{\partial\vartheta}\Big)\frac{1}{z^2}\,\mathrm{d}z \ge 0,$$

whence (4.5) together with (4.2) and hypothesis (3.6) yields

$$\{\varrho_n\}_{n=1}^\infty \text{ bounded in } L^\infty(0,T;L^\gamma(\Omega)). \tag{4.8}$$

Finally, as the pressure p_G is a nondecreasing function of the density, we obtain

$$0 \le p_G(\varrho,\vartheta) \le p_G(\varrho_c(\vartheta),\vartheta) \ \text{ for any } 0 \le \varrho \le \varrho_c(\vartheta) \le c(1+\vartheta^{\frac{4}{\gamma}}), \tag{4.9}$$

where ϱ_c is the critical density evaluated on the basis of Θ_c (cf. hypothesis (3.17)).

On the other hand, making use of hypotheses (3.5) and (3.17), we deduce

$$\begin{aligned} p_G(\varrho,\vartheta) &= p_c(\varrho) + \int_0^\vartheta \frac{\partial p_G(\varrho,s)}{\partial\vartheta}\,\mathrm{d}s \\ &\le c_1(\varrho^\gamma + \vartheta^4 + \vartheta\varrho^{\frac{\gamma}{3}}) \le c_2(1+\vartheta^4+\varrho^\gamma) \end{aligned} \tag{4.10}$$

whenever

$$0 < \vartheta < \Theta_c(\varrho) \text{ or, equivalently, } \varrho > \varrho_c(\vartheta). \tag{4.11}$$

Relation (4.10) together with (4.9) implies

$$0 \le p_G(\varrho,\vartheta) \le c(1+\varrho^\gamma+\vartheta^4) \ \text{ for all } \ \varrho \ge 0,\ \vartheta \ge 0; \tag{4.12}$$

therefore, estimates (4.6) and (4.8) can be used in combination with (4.12) in order to conclude that

$$\{p(\varrho_n,\vartheta_n)\}_{n=1}^\infty \text{ is bounded in } L^\infty(0,T;L^1(\Omega)). \tag{4.13}$$

4.3. Dissipation estimates I. The active dissipative mechanism manifested through viscosity and thermal conductivity of the fluid under consideration represents an important source of additional estimates involving the spatial derivatives of the velocity field $\mathbf{u}$ and the temperature ϑ.

The entropy production inequality (2.7), integrated with respect to time, yields

$$\int_\Omega \varrho_n s_n(\tau)\mathrm{d}x \geq S_0 + \int_0^\tau \int_\Omega \left(\frac{\mathbb{S}_n : \nabla_x \mathbf{u}_n}{\vartheta_n} + \frac{\kappa(\varrho_n, \vartheta_n)}{\vartheta_n^2} |\nabla_x \vartheta_n|^2 \right) \mathrm{d}x\, \mathrm{d}t$$

for a.a. $\tau \in (0, T)$, where Fourier's law (3.14) and hypothesis (3.19) have been taken into account.

On the other hand, in accordance with the thermodynamic equations (2.1), the specific entropy s may be written in the form

$$s(\varrho, \vartheta) = s_R(\varrho, \vartheta) + s_G(\varrho, \vartheta), \quad s_G(\varrho, \vartheta) \equiv s_G(\varrho, 1) + \int_1^\vartheta \frac{c_v(\varrho, s)}{s} \,\mathrm{d}s, \tag{4.14}$$

where

$$s_R(\varrho, \vartheta) \equiv \frac{4}{3} d \frac{\vartheta^3}{\varrho}, \quad s_G(\varrho, 1) = -\int_1^\varrho \frac{\partial p_G(z, 1)}{\partial \vartheta} \frac{1}{z^2} \,\mathrm{d}z. \tag{4.15}$$

Parallel to (4.10), hypotheses (3.3) and (3.5) can be used in order to deduce

$$|s_G(\varrho, 1)| \leq c\big(1 + \varrho^{-1} + \varrho^{\frac{\gamma}{3} - 1}\big), \tag{4.16}$$

while (3.9) and (3.10) yield

$$\left[\int_1^\vartheta \frac{c_v(\varrho, s)}{s} \,\mathrm{d}s \right]^+ \leq \left\{ \begin{matrix} c(1 + \vartheta^\omega), \ (\omega > 0) \\ c(1 + [\ln \vartheta]^+), \ (\omega = 0) \end{matrix} \right\} \text{ for all } \vartheta > 0.$$

Consequently, having already proved (4.6)–(4.8) we are allowed to conclude that

$$\operatorname*{ess\,sup}_{t \in (0,T)} \int_\Omega \varrho_n s_n(t) \mathrm{d}x \leq c(T), \tag{4.17}$$

whence

$$\left\{ \frac{\mathbb{S}_n : \nabla_x \mathbf{u}_n}{\vartheta_n} \right\}_{n=1}^\infty, \qquad \left\{ \frac{\kappa(\varrho_n, \vartheta_n)}{\vartheta_n^2} |\nabla_x \vartheta_n|^2 \right\}_{n=1}^\infty \text{ are bounded in } L^1((0,T) \times \Omega) \tag{4.18}$$

and

$$\left\{ \varrho_n \left[\int_1^{\vartheta_n} \frac{c_v(\varrho_n, s)}{s} \,\mathrm{d}s \right]^- \right\}_{n=1}^\infty \text{ is bounded in } L^\infty(0, T; L^1(\Omega)). \tag{4.19}$$

In particular, by virtue of hypothesis (3.15), estimate (4.18) yields

$$\{\nabla_x \log(\vartheta_n)\}_{n=1}^\infty, \ \big\{\nabla_x \vartheta_n^{\frac{\alpha}{2}}\big\}_{n=1}^\infty \text{ bounded in } L^2(0, T; L^2(\Omega, R^3)), \tag{4.20}$$

while by virtue of hypothesis (3.10), (4.19) implies

$$\{\varrho_n \log(\vartheta_n)\}_{n=1}^\infty \text{ bounded in } L^\infty(0, T; L^1(\Omega)). \tag{4.21}$$

At this stage, we pause to report an auxiliary result which may be viewed as a straightforward modification of the Poincaré inequality (see, for instance, Lemma 4.1 in [12]).

LEMMA 4.1. *Let $\Omega \subset R^N$, $N \geq 2$, be a bounded Lipschitz domain, and $\Gamma \geq 1$ be a constant. Let $\varrho \geq 0$ be a given function such that*

$$0 < M \leq \int_\Omega \varrho \, \mathrm{d}x, \quad \int_\Omega \varrho^\gamma \mathrm{d}x \leq K,$$

where

$$\gamma > \frac{2N}{N+2}.$$

Then there exists a constant $c = c(M, K, \gamma, \Gamma)$ such that the inequality

$$\|v\|_{L^2(\Omega)} \leq c(M,K)\left(\|\nabla_x v\|_{L^2(\Omega)} + \left[\int_\Omega \varrho |v|^{\frac{1}{\Gamma}} \mathrm{d}x \right]^\Gamma \right)$$

holds for any $v \in W^{1,2}(\Omega)$.

The total mass being conserved, more specifically,

$$M_n \equiv \int_\Omega \varrho_n(t) \mathrm{d}x = \int_\Omega \varrho_n(0) \mathrm{d}x \quad \to \quad \int_\Omega \varrho_0 \mathrm{d}x \equiv M > 0,$$

Lemma 4.1 applies, together with estimates (4.7), (4.20), and (4.21), in order to conclude

$$\{\log(\vartheta_n)\}_{n=1}^\infty, \ \{\vartheta_n^{\frac{\alpha}{2}}\}_{n=1}^\infty \text{ bounded in } L^2(0,T;W^{1,2}(\Omega)). \tag{4.22}$$

4.4. Dissipation estimates II. A short examination of the "thermal" energy inequality (2.8) yields

$$\begin{aligned} \int_0^\tau \int_\Omega \mathbb{S}_n : \nabla_x \mathbf{u}_n \, \mathrm{d}x \, \mathrm{d}t \\ \leq 2E_0 + \int_\Omega \varrho_n (e_n - e_c(\varrho_n))(\tau) \, \mathrm{d}x + \int_0^\tau \int_\Omega (p_n - p_c(\varrho_n)) \, \mathrm{div}_x \mathbf{u}_n \, \mathrm{d}x \, \mathrm{d}t \end{aligned} \tag{4.23}$$

for a.a. $\tau \in (0,T)$.

We claim, keeping in mind hypotheses (3.4) and (3.5), that there is a positive constant c such that

$$|p(\varrho,\vartheta) - p_c(\varrho)| \leq c(1 + \vartheta^4 + \vartheta \varrho^{\frac{\gamma}{3}}) \text{ for all } \varrho > 0, \ \vartheta > 0. \tag{4.24}$$

Indeed, similar to (4.10), we have

$$|p_G(\varrho,\vartheta) - p_c(\varrho)| = \left| \int_0^\vartheta \frac{\partial p_G(\varrho, s)}{\partial \vartheta} \, \mathrm{d}s \right| \leq c(1 + \vartheta^4 + \vartheta \varrho^{\frac{\gamma}{3}})$$

provided $\varrho \geq \varrho_c(\vartheta)$. Moreover, as p_G is a nondecreasing function of ϱ,

$$|p_G(\varrho,\vartheta) - p_c(\varrho)| \leq p_G(\varrho_c(\vartheta),\vartheta) - p_c(\varrho_c(\vartheta)) + 2p_c(\varrho_c(\vartheta)) \leq c(1 + \vartheta^4)$$

for all $0 \leq \varrho \leq \varrho_c(\vartheta)$; cf. estimate (4.9).

Now, by virtue of Hölder's inequality and the imbedding theorem $W^{1,2}(\Omega) \subset L^6(\Omega)$, the integral in the extreme right of (4.23) can be estimated as

$$\left| \int_0^\tau \int_\Omega (p_n - p_c(\varrho_n)) \mathrm{div}_x \mathbf{u}_n \, \mathrm{d}x \, \mathrm{d}t \right| \leq c\big(\|(1+\vartheta_n^4)\mathrm{div}_x \mathbf{u}_n\|_{L^1((0,T)\times\Omega)} + \|\vartheta_n \varrho_n^{\frac{\gamma}{3}} \mathrm{div}_x \mathbf{u}_n\|_{L^1((0,T)\times\Omega)}\big), \tag{4.25}$$

where

$$\|\vartheta_n \varrho_n^{\frac{\gamma}{3}} \mathrm{div}_x \mathbf{u}_n\|_{L^1(\Omega)} \leq \|\vartheta_n\|_{W^{1,2}(\Omega)} \|\varrho_n^\gamma\|_{L^1(\Omega)}^{\frac{1}{3}} \|\nabla_x \mathbf{u}_n\|_{L^2(\Omega;R^N)}.$$

Furthermore, writing

$$\vartheta^4 \mathrm{div}_x \mathbf{u} = \vartheta^{4-\frac{\beta}{2}} \vartheta^{\frac{\beta}{2}} \mathrm{div}_x \mathbf{u},$$

we get, by interpolation,

$$\|\vartheta^{4-\frac{\beta}{2}}\|_{L^2(\Omega)}^2 \leq \|\vartheta\|_{L^{3\alpha}(\Omega)}^{\frac{3\alpha(\beta-4)}{4-3\alpha}} \|\vartheta\|_{L^4(\Omega)}^{8-\beta-\frac{3\alpha(\beta-4)}{4-3\alpha}}, \tag{4.26}$$

where, in accordance with hypothesis (3.16), $3\alpha(\beta-4)/(4-3\alpha) \leq \alpha$. Consequently, by virtue of estimates (4.6) and (4.22),

$$\{\vartheta_n^{4-\frac{\beta}{2}}\}_{n=1}^\infty \text{ is bounded in } L^2((0,T)\times\Omega). \tag{4.27}$$

Due to (3.11), $\mathbb{S} : \nabla_x \mathbf{u} = 2\mu \langle \mathbb{D}_x \mathbf{u} \rangle : \langle \mathbb{D}_x \mathbf{u} \rangle + \zeta |\mathrm{div}_x \mathbf{u}|^2$, where $\langle \mathbb{D}_x \mathbf{u} \rangle_{i,j} = \frac{1}{2}(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}) - \frac{1}{3} \mathrm{div}_x \mathbf{u} \delta_{i,j}$. Moreover, the Korn-type inequality

$$\|\nabla_x \mathbf{u}\|_{L^p(\Omega;R^{3\times3})} \leq c(p) \|\langle \mathbb{D}_x(\mathbf{u}) \rangle\|_{L^p(\Omega;R^{3\times3}_{sym})} \tag{4.28}$$

holds true for any $1 < p < \infty$ and for any $\mathbf{u} \in W_0^{1,p}(\Omega, R^N)$ (cf. Proposition 2.4 in [36] or section 5.1 in [18]). Finally, by virtue of (4.25)–(4.27), (4.8), and (4.22),

$$\left| \int_0^T \int_\Omega (p_n - p_c(\rho_n)) \mathrm{div}_x \mathbf{u}_n \, \mathrm{d}x \, \mathrm{d}t \right| \leq c(\|\vartheta_n^{\frac{\beta}{2}} \mathrm{div}_x \mathbf{u}_n\|_{L^2((0,T)\times\Omega)} + \|\nabla \mathbf{u}_n\|_{L^2((0,T)\times\Omega)}). \tag{4.29}$$

Moreover, by virtue of (4.5) and (4.8), integral $\int_\Omega \varrho_n(e_n - e_c(\varrho_n)) \, \mathrm{d}x$ is bounded in $L^\infty(0,T)$.

Thus, combining estimate (4.23) with inequalities (4.28) and (4.29) and with hypotheses (3.12), (3.13), and (3.16), we obtain, in particular,

$$\{\mathbf{u}_n\}_{n=1}^\infty \text{ bounded in } L^2(0,T;W_0^{1,2}(\Omega;R^3)). \tag{4.30}$$

Then, of course,

$$\{\mathbb{S}_n : \nabla_x \mathbf{u}_n\}_{n=1}^\infty \text{ is bounded in } L^1((0,T)\times\Omega). \tag{4.31}$$

Finally, from (3.11), taking into account bounds (4.27) and (4.30) and hypotheses (3.12), (3.13), and (3.16), we can easily verify that

$$\{\mathbb{S}_n\}_{n=1}^\infty \text{ is bounded in } L^{\frac{5}{3}}(0,T;L^{\frac{5}{3}}(\Omega;R^{3\times3}_{sym})). \tag{4.32}$$

4.5. Refined pressure and density estimates. Refined density estimates up to the boundary can be obtained by using the quantities

$$\varphi_j = \psi\left[\mathcal{B}\left(b(\varrho) * \phi_\epsilon - \frac{1}{|\Omega|}\int_\Omega b(\varrho) * \phi_\epsilon \, \mathrm{d}x\right)\right]_j$$

as test functions in the variational formulation of the momentum equation (1.2). Here ψ is a convenient function in $C_0^\infty(I)$, $b \in C([0,\infty)$ is a function with convenient growth at infinity (see later), the symbol $*$ denotes convolution, $\phi_\epsilon \to \delta(0)$ is a regularizing sequence in the variable t, and $\mathcal{B}$ is the Bogovskii operator satisfying

$$\begin{aligned}&\mathrm{div}\mathcal{B}(v) = v, \quad \|\mathcal{B}(v)\|_{L^q(\Omega)} \le c(q)\|\mathbf{g}\|_{L^q(\Omega)}, \quad \|\nabla\mathcal{B}(v)\|_{L^p(\Omega)} \le c(p)\|v\|_{L^p(\Omega)},\\ &\text{with any } 1 < q, p < \infty,\ \mathbf{g} \in L^q(\Omega; R^N),\ v = \mathrm{div}\mathbf{g} \in L^p(\Omega), \text{ and } \mathbf{g}\cdot\mathbf{n}|_{\partial\Omega} = 0\end{aligned}$$

(cf., for instance, [3], [4], [19], or Lemma 3.17 in [29]).

With estimates (4.4), (4.8), (4.13), (4.30), and (4.32) at hand, such a procedure yields, after a tedious but straightforward computation, a bound

$$\sup_{n=1,2,\dots} \int_0^T \int_\Omega p(\varrho_n, \vartheta_n) b(\varrho_n) \, \mathrm{d}x \, dt < \infty, \tag{4.33}$$

provided $b(\varrho) \approx \varrho^\nu$, with $\nu = \nu(\gamma) > 0$ sufficiently small. Local (interior) pressure estimate of type (4.33) was first established for the barotropic flow in [24], where the optimal (largest) value of $\nu = (2/N)\gamma - 1$ was obtained. For more details concerning the techniques of the calculus leading to (4.33) see, for instance, section 7.9.5 in [29].

Now, writing

$$p(\varrho_n, \vartheta_n) = p_R(\vartheta_n) + \big(p_G(\varrho_n, \vartheta_n) - p_c(\varrho_n)\big) + p_c(\varrho_n),$$

we infer, with the help of (4.24), that the sequence

$$\int_0^T \int_\Omega \varrho_n^{\gamma+\nu} \, \mathrm{d}x \, dt \text{ is bounded.} \tag{4.34}$$

Indeed, by virtue of (4.6), (4.22) and a simple interpolation argument,

$$\{\vartheta_n\}_{n=1}^\infty \text{ is bounded in } L^p((0,T)\times\Omega) \text{ for a certain } p > 4, \tag{4.35}$$

whence (4.34) follows easily from (4.24) and (4.33). Now, by using (3.1), (3.2), and (4.12) it is easy to conclude that[1]

$$p(\rho_n, \vartheta_n) \text{ is bounded in } L^p((0,T)\times\Omega) \text{ for some } p > 1. \tag{4.36}$$

[1] Note that, in contrast with (4.13), estimates (4.34) and (4.35) render the total pressure $\{p(\varrho_n, \vartheta_n)\}_{n=1}^\infty$ *equi-integrable* and thus precompact in the weak topology of the Lebesgue space $L^1((0,T)\times\Omega)$. This is the least information which can replace (4.36) in our proof. In the light of the technical difficulties connected with the construction of $\mathcal{B}$, it seems worth noting that a weaker, but for our purposes still sufficient, result can be obtained via multipliers

$$w_j,\ j = 1, \dots, N, \quad \mathrm{div}_x[\mathbf{w}] = h, \qquad \lim_{\mathrm{dist}(x,\partial\Omega)\to 0} h(x) = \infty,$$

where $h \in L^p(\Omega)$ with $p = p(\gamma) >> 1$ large enough. Indeed in such a way we can show that

$$\{\varrho_n^\gamma\}_{n=1}^\infty \text{ is equi-integrable in } L^1((0,T)\times\Omega),$$

which means

$$\lim_{k\to\infty} \int_{\{\varrho_n \ge k\}} \varrho_n^\gamma \, \mathrm{d}x \, \mathrm{d}t \to 0 \text{ uniformly for } n = 1, 2, \dots.$$

5. Weak sequential compactness. As ϱ_n satisfies (1.1) in the sense of distributions, and since (4.4) and (4.8) hold, we may assume

$$\varrho_n \to \varrho \text{ in } C([0,T]; L^{\gamma}_{weak}(\Omega)) \tag{5.1}$$

passing to a subsequence as the case may be. (Here and in what follows, $L^p_{weak}(\Omega)$ means $L^p(\Omega)$ endowed with the weak topology.)

Similarly, by virtue of (4.30),

$$\mathbf{u}_n \to \mathbf{u} \text{ weakly in } L^2(0,T; W^{1,2}_0(\Omega; R^3)), \tag{5.2}$$

and, in accordance with (4.6) and (4.22),

$$\vartheta_n \to \vartheta \text{ weakly in } L^2(0,T; W^{1,2}(\Omega)) \text{ and weakly-(*) in } L^{\infty}(0,T; L^4(\Omega)) \tag{5.3}$$

at least for a suitable subsequence.

The main goal of this section is to show, in accordance with the conclusion of Theorem 3.1, that ϱ, $\mathbf{u}$, and ϑ represent another admissible solutions of problem (1.1)–(1.6) on the time interval $(0,T)$.

5.1. Convergence of the convective terms. The space $L^{\gamma}(\Omega)$ is compactly imbedded into the dual space $W^{-1,2}(\Omega)$ as soon as $\gamma > 6/5$. Consequently, by virtue of (5.1) and (5.2) and hypothesis (3.16),

$$\varrho_n \mathbf{u}_n \to \varrho \mathbf{u} \text{ weakly-(*) in } L^{\infty}(0,T; L^{\frac{2\gamma}{\gamma+1}}(\Omega; R^3)). \tag{5.4}$$

Moreover, since $(\rho_n, \mathbf{u}_n, \vartheta_n)$ satisfies (1.2) in the sense of distributions, keeping in mind bounds (4.8), (4.30), (4.32), and (4.36), one can sharpen (5.4) to

$$\varrho_n \mathbf{u}_n \to \varrho \mathbf{u} \text{ in } C([0,T]; L^{\frac{2\gamma}{\gamma+1}}_{weak}(\Omega; R^3)). \tag{5.5}$$

Now, since $\gamma > 3/2$, we get, similar to the above, $L^{\frac{2\gamma}{\gamma+1}}(\Omega; R^3)$ compactly imbedded into the dual space $W^{-1,2}(\Omega; R^N)$, whence we are allowed to repeat the same arguments as in (5.4) in order to deduce

$$\varrho_n \mathbf{u}_n \otimes \mathbf{u}_n \to \varrho \mathbf{u} \otimes \mathbf{u} \text{ weakly in } L^2(0,T; L^{\frac{6\gamma}{4\gamma+3}}(\Omega; R^{3\times 3}_{sym})). \tag{5.6}$$

In particular, it is possible to pass to the limit for $n \to \infty$ in (1.1) and (1.2) to obtain

$$\partial_t \varrho + \operatorname{div}_x(\varrho \mathbf{u}) = 0 \text{ in } \mathcal{D}'((0,T) \times R^3), \tag{5.7}$$

provided ϱ, $\mathbf{u}$ were extended to be zero outside Ω, and

$$\partial_t(\varrho \mathbf{u}) + \operatorname{div}_x(\varrho \mathbf{u} \otimes \mathbf{u}) + \nabla_x \overline{p} = \operatorname{div}_x \overline{\mathbb{S}} + \overline{\varrho \mathbf{f}} \text{ in } \mathcal{D}'((0,T) \times R^3)^3, \tag{5.8}$$

where

$$p(\varrho_n, \vartheta_n) \to \overline{p(\varrho, \vartheta)} \text{ weakly in } L^1((0,T) \times \Omega),$$

$$\mathbb{S}_n = \mathbb{S}\,(\mathbb{D}_x \mathbf{u}_n, \vartheta_n) \to \overline{\mathbb{S}(\mathbb{D}_x \mathbf{u}, \vartheta)} \text{ weakly in } L^{\frac{5}{3}}(0,T; L^{\frac{5}{3}}(\Omega; R^3)),$$

$$\varrho_n \mathbf{f}_n \to \overline{\varrho \mathbf{f}} \text{ weakly in } L^1(0,T; L^1(\Omega; R^3))$$

conformably to (4.32) and (4.36).

5.2. Strong convergence of the temperature. Our aim is to show that the sequence $\{\vartheta_n\}_{n=1}^\infty$ converges strongly in the Lebesgue space $L^1((0,T)\times\Omega)$, in particular, almost anywhere on $(0,T)\times\Omega$ for a suitable subsequence. This step represents one of the most delicate issues to be discussed in this paper.

To begin with, let us record the following version of the celebrated Aubin–Lions lemma (see Lemma 6.3 in Chapter 6 in [16]).

LEMMA 5.1. *Let $\Omega \subset R^N$, $N \geq 2$, be a bounded Lipschitz domain. Let $\{v_n\}_{n=1}^\infty$ be a sequence of functions bounded in*

$$L^2(0,T;L^q(\Omega)) \cap L^\infty(0,T;L^1(\Omega)) \text{ with } q > \frac{2N}{N+2}.$$

Furthermore, assume that

$$\partial_t v_n \geq g_n \text{ in } \mathcal{D}'((0,T)\times\Omega),$$

where the distributions g_n are bounded in the space $L^1(0,T;W^{-m,p}(\Omega))$ for certain $m \geq 1$, $p > 1$.

Then we have

$$v_n \to v \text{ in } L^2(0,T;W^{-1,2}(\Omega))$$

passing to a subsequence as the case may be.

Since $\{\vartheta_n\}_{n=1}^\infty$ admits the bound established in (4.6), we have

$$\{\varrho_n s_R(\varrho_n,\vartheta_n)\}_{n=1}^\infty \text{ bounded in } L^\infty(0,T;L^{\frac{4}{3}}(\Omega)). \tag{5.9}$$

Moreover, relation (4.16) yields

$$|\varrho s_G(\varrho,1)| \leq c(1+\varrho+\varrho^{\frac{\gamma}{3}}),$$

so we obtain, by virtue of (4.8), that

$$\{\varrho_n s_G(\varrho_n,1)\}_{n=1}^\infty \text{ is bounded in } L^\infty(0,T;L^p(\Omega)) \text{ with } p=\min(3,\gamma) \tag{5.10}$$

(cf. (4.14) and (4.15)).

Finally, hypotheses (3.9) and (3.10) together with estimates (4.6), (4.21), and (4.22) can be used in order to conclude that

$$\{\varrho_n \Phi(\varrho_n,\vartheta_n)\}_{n=1}^\infty \text{ is bounded in } L^\infty(0,T;L^1(\Omega)) \cap L^2(0,T;L^q(\Omega)) \tag{5.11}$$

with at least any q such that $\frac{q}{\gamma}+\frac{q}{6} \leq 1$, where we have denoted

$$\Phi(\varrho,\vartheta) \equiv \int_1^\vartheta \frac{c_v(\varrho,s)}{s}\,\mathrm{d}s. \tag{5.12}$$

Then, of course,

$$\{\varrho_n s_n \mathbf{u}_n\}_{n=1}^\infty \text{ is bounded in } L^1(0,T;L^p(\Omega,R^3)) \text{ with some } p>1. \tag{5.13}$$

Consequently, the bounds obtained in (5.9)–(5.13) together with (4.18) and (4.22) imply that the sequence $v_n = \varrho_n s_n$, satisfying the entropy production inequality (2.7), complies with the hypotheses of Lemma 5.1, where we have taken $g_n = -\mathrm{div}_x(\rho_n s_n \mathbf{u}_n) - \mathrm{div}_x(\kappa(\varrho_n,\vartheta_n)\frac{\nabla\vartheta_n}{\vartheta_n}) + \mathbb{S}_n : \frac{\nabla\mathbf{u}_n}{\vartheta_n} + \kappa(\varrho_n,\vartheta_n)\frac{|\nabla\vartheta_n|^2}{\vartheta_n^2}$.

Thus, we may assume

$$\varrho_n s_n \to \frac{4}{3} d\overline{\vartheta^3} + \overline{\varrho s_G(\varrho, 1)} + \overline{\varrho \Phi(\varrho, \vartheta)} \text{ in } L^2(0, T; W^{-1,2}(\Omega)), \tag{5.14}$$

where, as always, we have used the bar to denote the weak limits of composed functions.

The functions ϱ_n, $\mathbf{u}_n$ solve the renormalized equation (2.5). Therefore, in particular, (5.10) implies

$$\varrho_n s_G(\varrho_n, 1) \to \overline{\varrho s_G(\varrho, 1)} \text{ in } C([0, T]; L^q_{weak}(\Omega)),\ q = \min(3, \gamma).$$

Consequently, since ϑ_n are bounded by (4.22), we get

$$\varrho_n s_G(\varrho_n, 1)\vartheta_n \to \overline{\varrho s_G(\varrho, 1)}\vartheta \text{ weakly in } L^1((0, T) \times \Omega). \tag{5.15}$$

Furthermore, the function Φ is nondecreasing with respect to ϑ; in particular,

$$\int_0^T \int_\Omega \varrho_n (\Phi(\varrho_n, \vartheta_n) - \Phi(\varrho_n, \vartheta))(\vartheta_n - \vartheta)\varphi \, \mathrm{d}x \, \mathrm{d}t \geq 0 \tag{5.16}$$

for any nonnegative test function $\varphi \in \mathcal{D}((0, T) \times \Omega)$.

As we will show below,

$$\int_0^T \int_\Omega \varrho_n \Phi(\varrho_n, \vartheta)(\vartheta_n - \vartheta)\varphi \, \mathrm{d}x \, \mathrm{d}t \to 0 \text{ as } n \to \infty; \tag{5.17}$$

therefore, (5.16) reduces to

$$\liminf_{n\to\infty} \int_0^T \int_\Omega \varrho_n \Phi(\varrho_n, \vartheta_n)\vartheta_n \ \varphi \, \mathrm{d}x \, \mathrm{d}t \geq \int_0^T \int_\Omega \overline{\varrho \Phi(\varrho, \vartheta)}\vartheta \ \varphi \mathrm{d}x \, \mathrm{d}t \tag{5.18}$$

for any nonnegative $\varphi \in \mathcal{D}((0, T) \times \Omega)$.

Taking, for a moment, relation (5.17) for granted, one can deduce easily from (5.3), (5.14), (5.15), and (5.18) that

$$\begin{aligned} &\int_0^T \int_\Omega \left(\frac{4}{3} d\overline{\vartheta^3} + \overline{\varrho s_G(\varrho, 1)} + \overline{\varrho \Phi(\varrho, \vartheta)} \right) \vartheta\varphi \mathrm{d}x \, \mathrm{d}t \\ &= \lim_{n\to\infty} \int_0^T \int_\Omega \varrho_n s_n \vartheta_n \varphi \, \mathrm{d}x \, \mathrm{d}t \\ &= \lim_{n\to\infty} \int_0^T \int_\Omega \left(\frac{4}{3} d\vartheta_n^3 + \varrho_n s_G(\varrho_n, 1) + \varrho_n \Phi(\varrho_n, \vartheta_n) \right) \vartheta_n \varphi \, \mathrm{d}x \, \mathrm{d}t \\ &\geq \limsup_{n\to\infty} \int_0^T \int_\Omega \frac{4}{3} d\vartheta_n^4 \varphi \mathrm{d}x \, \mathrm{d}t \\ &+ \int_0^T \int_\Omega (\overline{\varrho s_G(\varrho, 1)} + \overline{\varrho \Phi(\varrho, \vartheta)})\vartheta\varphi \, \mathrm{d}x \, \mathrm{d}t. \end{aligned} \tag{5.19}$$

In other words

$$\limsup_{n\to\infty} \int_0^T \int_\Omega \vartheta_n^4 \varphi \, \mathrm{d}x \, \mathrm{d}t \leq \int_0^T \int_\Omega \overline{\vartheta^3}\vartheta\varphi \mathrm{d}x \, \mathrm{d}t, \quad \varphi \in \mathcal{D}((0, T) \times \Omega), \quad \varphi \geq 0.$$

On the other hand, passing to the limit $n \to \infty$ in the evident inequality $\int_0^T \int_\Omega (\vartheta_n^3 - \vartheta^3)(\vartheta_n - \vartheta)\varphi \, \mathrm{d}x \, \mathrm{d}t \geq 0$, by using (5.3) one obtains

$$\liminf_{n\to\infty} \int_0^T \int_\Omega \vartheta_n^4 \varphi \mathrm{d}x \, \mathrm{d}t \leq \int_0^T \int_\Omega \overline{\vartheta^3}\vartheta\varphi \mathrm{d}x \, \mathrm{d}t, \ \varphi \in \mathcal{D}((0,T)\times\Omega), \ \varphi \geq 0.$$

From the last two inequalities we deduce

$$\overline{\vartheta^4} = \overline{\vartheta^3}\vartheta,$$

and we conclude, making use of the standard argument of Minty (see, e.g., Lemmas 3.35 and 3.39 in [29]), that

$$\vartheta_n \to \vartheta \text{ in } L^4((0,T)\times\Omega). \tag{5.20}$$

Consequently, by virtue of (5.2) and (5.20), one can write in (5.8)

$$\overline{\mathbb{S}} = \mathbb{S}, \tag{5.21}$$

where $\mathbb{S}$ is given by (3.11) with $\mu = \mu(\vartheta)$, $\zeta = \zeta(\vartheta)$.

It remains to show (5.17). To this end, we need the generalized form (2.10) of the renormalized continuity equation (2.5). The following auxiliary result may be of independent interest.

LEMMA 5.2. *Let*

$$\varrho \geq 0, \ \varrho \in L^\infty(0,T;L^\gamma(\Omega)), \ \mathbf{u} \in L^2(0,T;W_0^{1,2}(\Omega;R^N)), \ \gamma > \frac{2N}{N+2},$$

be a renormalized solution of (1.1) *in the sense specified in Definition* 2.1.

Then ϱ, $\mathbf{u}$ *satisfy* (2.10) *in* $\mathcal{D}'((0,T)\times\Omega)$ *for any* h, H *as in* (2.11), *and* $\Theta \in C^1((0,T)\times\Omega)$.

Proof. We shall use the truncation technique introduced in [16] along with the regularizing procedure due to DiPerna and Lions [10]. To this end, consider the cutoff functions $T_k \in C^\infty(R)$,

$$T_k(\varrho) = k\mathcal{T}\Big(\frac{\varrho}{k}\Big), \quad k \geq 1, \tag{5.22}$$

where $\mathcal{T} \in C^\infty(R)$,

$$\left\{\begin{array}{c} \mathcal{T}(-z) = -\mathcal{T}(z) \text{ for all } z \in R, \\ \\ \mathcal{T}(z) = z \text{ for } 0 \leq z \leq 1, \ \mathcal{T}''(z) \leq 0 \text{ if } 1 \leq z \leq 3, \ \mathcal{T}(z) = 2 \text{ for all } z \geq 3. \end{array}\right\}$$

As ϱ, $\mathbf{u}$ satisfy (2.5), we get

$$\partial_t T_k(\varrho) + \mathrm{div}_x(T_k(\varrho)\mathbf{u}) + \big(T_k'(\varrho)\varrho - T_k(\varrho)\big)\mathrm{div}_x\mathbf{u} = 0 \tag{5.23}$$

in $\mathcal{D}'((0,T)\times\Omega)$.

Similar to [10], consider a family of Friedrichs' mollifiers $\eta^\varepsilon = \eta^\varepsilon(x) \in \mathcal{D}(R^N)$, $\varepsilon > 0$,

$$\left\{\begin{array}{c} \eta^\varepsilon \geq 0, \ \eta^\varepsilon \text{ radially symmetric and radially decreasing,} \\ \displaystyle\int_{R^N} \eta^\varepsilon \, \mathrm{d}x = 1, \ \mathrm{supp}[\eta^\varepsilon] \subset \{|x| < \varepsilon\}. \end{array}\right\}$$

Using η^ε as a test function in the variational formulation of (5.23), we obtain

$$\partial_t [T_k(\varrho)]^\varepsilon + \mathrm{div}_x([T_k(\varrho)]^\varepsilon \mathbf{u}) + [(T_k'(\varrho)\varrho - T_k(\varrho))\mathrm{div}_x \mathbf{u}]^\varepsilon = r_\varepsilon \tag{5.24}$$

with

$$[h]^\varepsilon \equiv \eta^\varepsilon * h \text{ and } r_\varepsilon \equiv \mathrm{div}_x([T_k(\varrho)]^\varepsilon \mathbf{u}) - [\mathrm{div}_x(T_k(\varrho)\mathbf{u})]^\varepsilon,$$

where the symbol $*$ denotes the convolution with respect to x. Note that (5.24) holds, in the sense of strong derivatives, for a.a. $(t,x) \in (0,T) \times \Omega$ such that $\mathrm{dist}[x, \partial\Omega] > \varepsilon$.

Now we are allowed to multiply (5.24) on

$$H([T_k(\varrho)]^\varepsilon, \Theta) + [T_k(\varrho)]^\varepsilon \frac{\partial H([T_k(\varrho)]^\varepsilon, \Theta)}{\partial \varrho},$$

with $\Theta \in C^1((0,T) \times \Omega)$, H as in (2.11), in order to obtain

$$\begin{aligned}
&\partial_t([T_k(\varrho)]^\varepsilon H([T_k(\varrho)]^\varepsilon, \Theta)) + \mathrm{div}_x([T_k(\varrho)]^\varepsilon H([T_k(\varrho)]^\varepsilon, \Theta)\mathbf{u}) + h([T_k(\varrho)]^\varepsilon, \Theta)\ \mathrm{div}_x \mathbf{u} \\
&\quad = [T_k(\varrho)]^\varepsilon \frac{\partial H([T_k(\varrho)]^\varepsilon, \Theta)}{\partial \Theta} \big(\partial_t \Theta + \nabla_x \Theta \cdot \mathbf{u}\big) \\
&\qquad + \{r_\varepsilon - [(T_k'(\varrho)\varrho - T_k(\varrho))\mathrm{div}_x \mathbf{u}]^\varepsilon\} \left\{ H([T_k(\varrho)]^\varepsilon, \Theta) + [T_k(\varrho)]^\varepsilon \frac{\partial H([T_k(\varrho)]^\varepsilon, \Theta)}{\partial \varrho} \right\}.
\end{aligned}$$

Seeing that, for k fixed,

$$r_\varepsilon \to 0 \text{ in } L^p((0,T) \times K) \text{ for any compact } K \subset \Omega \text{ as } \varepsilon \to 0,\ p \in [1,2)$$

(see, for instance, [10]), we deduce

$$\begin{aligned}
&\partial_t(T_k(\varrho) H(T_k(\varrho), \Theta)) + \mathrm{div}_x(T_k(\varrho) H(T_k(\varrho), \Theta)\mathbf{u}) \\
&\quad + h(T_k(\varrho), \Theta)\ \mathrm{div}_x \mathbf{u} = T_k(\varrho) \frac{\partial H(T_k(\varrho), \Theta)}{\partial \Theta} (\partial_t \Theta + \nabla_x \Theta \cdot \mathbf{u}) \\
&\quad + (T_k(\varrho) - T_k'(\varrho)\varrho) \left\{ H(T_k(\varrho), \Theta) + T_k(\varrho) \frac{\partial H(T_k(\varrho), \Theta)}{\partial \varrho} \right\} \mathrm{div}_x \mathbf{u}
\end{aligned} \tag{5.25}$$

in $\mathcal{D}'((0,T) \times \Omega)$. Assume, in addition to (2.11), that

$$H(\varrho, \Theta) = 0 \text{ for all } \varrho \geq M,\ \Theta \in R,\ \text{and a certain } M > 0. \tag{5.26}$$

Now it is easy to let $k \to \infty$ in (5.25) to conclude, with the help of the Lebesgue theorem, that

$$\begin{aligned}
&\partial_t\big(\varrho H(\varrho, \Theta)\big) + \mathrm{div}_x\big(\varrho H(\varrho, \Theta)\mathbf{u}\big) + h(\varrho, \Theta)\mathrm{div}_x \mathbf{u} \\
&\quad = \varrho \frac{\partial H(\varrho, \Theta)}{\partial \Theta} \big(\partial_t \Theta + \nabla_x \Theta \cdot \mathbf{u}\big) \text{ in } \mathcal{D}'((0,T) \times \Omega).
\end{aligned} \tag{5.27}$$

Finally, approximating

$$H(\varrho, \Theta) \approx H_m(\varrho, \Theta) = \chi\left(\frac{\varrho}{m}\right) H(\varrho, \Theta),\ \text{with } \chi \in \mathcal{D}(R),\ \chi(z) = 1 \text{ for } |z| \leq 1,$$

and letting $m \to \infty$ in (5.27), we obtain (2.10) for any choice of h, H, and Θ compatible with (2.11). $\square$

Now we come back to (5.17). We can easily verify that the function $H(\rho,\tilde{\vartheta}) = \Phi(T_k(\rho),\tilde{\vartheta})$, where

$$\tilde{\vartheta} \in C^1([0,T]\times\overline{\Omega}), \qquad \inf_{t\in(0,T),x\in\Omega} \tilde{\vartheta}(t,x) > 0, \tag{5.28}$$

satisfies assumptions (2.11). Consequently, it verifies renormalized continuity equation (5.27) with $\tilde{\vartheta}$ in place of Θ. From this fact, by using (5.12), (3.9), (3.10), (5.22), and (4.8) we conclude that

$$\begin{gathered}\rho_n \Phi(T_k(\varrho_n),\tilde{\vartheta}) \to \overline{\rho\Phi(T_k(\varrho),\tilde{\vartheta})} \\ \text{in } C([0,T]; L^\gamma_{weak}(\Omega)) \text{ as well as in } L^2(0,T;W^{-1,2}(\Omega)).\end{gathered} \tag{5.29}$$

Now we can write

$$\begin{aligned}\int_0^T\int_\Omega \varrho_n\Phi(\varrho_n,\vartheta)(\vartheta_n-\vartheta)\varphi\,\mathrm{d}x\,\mathrm{d}t &= \int_0^T\int_\Omega [\varrho_n\Phi(\varrho_n,\vartheta)-\varrho_n\Phi(T_k(\varrho_n),\tilde{\vartheta})](\vartheta_n-\vartheta)\varphi\,\mathrm{d}x\,\mathrm{d}t \\ &+ \int_0^T\int_\Omega [\varrho_n\Phi(T_k(\varrho_n),\tilde{\vartheta}) - \overline{\varrho\Phi(T_k(\varrho),\tilde{\vartheta})}(\vartheta_n-\vartheta)\varphi\,\mathrm{d}x\,\mathrm{d}t \\ &+ \int_0^T\int_\Omega \overline{\varrho\Phi(T_k(\varrho),\tilde{\vartheta})}(\vartheta_n-\vartheta)\varphi\,\mathrm{d}x\,\mathrm{d}t.\end{aligned}$$

Consequently, in view of (5.3), (5.20), and (5.29), in order to show (5.17), it is enough to find, for arbitrary $\varepsilon>0$, a function $\tilde{\vartheta}$ satisfying (5.28) and k large enough so that

$$\sup_{n=1,2,\dots} \big\|\varrho_n\big(\Phi(\varrho_n,\vartheta)-\Phi(T_k(\varrho_n),\tilde{\vartheta})\big)\big\|_{L^2(0,T;W^{-1,2}(\Omega))} < \varepsilon. \tag{5.30}$$

To this end, we compute

$$\Phi(T_k(\varrho_n),\vartheta)-\Phi(T_k(\varrho_n),\tilde{\vartheta}) = \int_{\tilde{\vartheta}}^{\vartheta} \frac{c_v(T_k(\varrho_n),s)}{s}\,\mathrm{d}s,$$

whence, in accordance with hypothesis (3.10),

$$|\Phi(T_k(\varrho_n),\vartheta)-\Phi(T_k(\varrho_n),\tilde{\vartheta})| \le c\big(|\vartheta-\tilde{\vartheta}| + |\log(\vartheta)-\log(\tilde{\vartheta})|\big)$$

with the constant c independent of n, k. From the last estimate, we infer

$$\begin{aligned}&\|\varrho_n(\Phi(T_k(\varrho_n),\vartheta)-\Phi(T_k(\varrho_n),\tilde{\vartheta}))\|_{L^q(\Omega)} \le c\|\rho_n\|_{L^\gamma(\Omega)}(\|\vartheta-\tilde{\vartheta}\|_{L^6(\Omega)} \\ &\quad + \|\log(\vartheta)-\log(\tilde{\vartheta})\|_{L^6(\Omega)}), \qquad \frac{q}{\gamma}+\frac{q}{6}\le 1.\end{aligned}$$

Consequently, as ϑ, $\log(\vartheta)$ belong to the space $L^2(0,T;W^{1,2}(\Omega))$ induced by estimates (4.22), and ϱ_n satisfy (4.8) with $\gamma>3/2$, it is a routine matter to find $\tilde{\vartheta}$ such that, for a given $\varepsilon>0$,

$$\sup_{n=1,2,\dots} \big\|\varrho_n\big(\Phi(T_k(\varrho_n),\vartheta)-\Phi(T_k(\varrho_n),\tilde{\vartheta})\big)\big\|_{L^2(0,T;W^{-1,2}(\Omega))} < \frac{\varepsilon}{2}. \tag{5.31}$$

On the other hand, by virtue of Hölder's inequality,

$$\begin{aligned}&\big\|\varrho_n\big(\Phi(\varrho_n,\vartheta)-\Phi(T_k(\varrho_n),\vartheta)\big)\big\|_{L^q(\Omega)} \\ &\quad \le c\|\varrho_n\|_{L^p(\{\varrho_n>k\})}\|(1+\vartheta+|\log(\vartheta)|)\|_{L^r(\Omega)}, \qquad \frac{1}{q}=\frac{1}{p}+\frac{1}{r},\end{aligned} \tag{5.32}$$

where we can choose

$$q > \frac{6}{5},\ p < \gamma,\ r < 6 \text{ provided } \gamma > \frac{3}{2}.$$

Since

$$\|\varrho_n\|_{L^p(\{\varrho_n > k\})} \le k^{\frac{p-\gamma}{p}} \|\varrho_n\|^{\frac{\gamma}{p}}_{L^\gamma(\Omega)}, \quad W^{1,2}(\Omega) \hookrightarrow L^r(\Omega), \quad \text{and} \quad L^q(\Omega) \hookrightarrow W^{-1,2}(\Omega),$$

relations (5.31) and (5.32) yield (5.30) under the condition that $k = k(\varepsilon)$ is large enough.

Thus, we have shown (5.17) and, consequently, the proof of (5.20) is now complete.

5.3. The effective viscous flux. In order to show pointwise convergence of the sequence of densities $\{\varrho_n\}_{n=1}^\infty$, we evoke the celebrated "weak continuity" property of the so-called *effective viscous flux*,

$$p - (\lambda + 2\mu)\mathrm{div}_x \mathbf{u}, \text{ with the standard notation } \lambda \equiv \zeta - \frac{2}{3}\mu,$$

established for the barotropic fluids with constants μ and λ in [24] and extended to the general case $\mu = \mu(\vartheta)$, $\lambda = \lambda(\vartheta)$ in [17].

We start with an integral identity

$$\int_0^T \int_\Omega \psi\big(\eta\ p(\varrho_n, \vartheta_n) - \mathcal{R}_{i,j}[\eta\ S_n^{i,j}]\big)\xi T_k(\varrho_n)\mathrm{d}x\,\mathrm{d}t = \sum_{j=1}^7 I_j \tag{5.33}$$

$$+ \int_0^T \int_\Omega \psi u_n^j\big(\xi T_k(\varrho_n)\mathcal{R}_{i,j}[\eta\varrho_n u_n^i] - \eta\varrho_n u_n^i \mathcal{R}_{i,j}[\xi T_k(\varrho_n)]\big)\mathrm{d}x\,\mathrm{d}t,$$

where

$$I_1 = \int_0^T \int_\Omega \psi\ \partial_{x_j}\eta\ S_n^{i,j}(\partial_{x_i}\Delta^{-1})[\xi T_k(\varrho_n)]\mathrm{d}x\,\mathrm{d}t,$$

$$I_2 = -\int_0^T \int_\Omega \psi\eta\ \varrho_n f_n^i(\partial_{x_i}\Delta^{-1})[\xi T_k(\varrho_n)]\mathrm{d}x\,\mathrm{d}t,$$

$$I_3 = -\int_0^T \int_\Omega \psi\ \partial_{x_j}\eta\ \varrho_n u_n^i u_n^j(\partial_{x_i}\Delta^{-1})[\xi T_k(\varrho_n)]\mathrm{d}x\,\mathrm{d}t,$$

$$I_4 = -\int_0^T \int_\Omega \partial_t\psi\eta\ \varrho_n u_n^i(\partial_{x_i}\Delta^{-1})[\xi T_k(\varrho_n)]\mathrm{d}x\,\mathrm{d}t,$$

$$I_5 = -\int_0^T \int_\Omega \psi\eta\varrho_n u_n^i(\partial_{x_i}\Delta^{-1})[T_k(\varrho_n)\mathbf{u}_n \cdot \nabla_x\xi]\mathrm{d}x\,\mathrm{d}t,$$

$$I_6 = \int_0^T \int_\Omega \psi\eta\ \varrho_n u_n^i(\partial_{x_i}\Delta^{-1})\big[\xi\big(T_k'(\varrho_n)\varrho_n - T_k(\varrho_n)\big)\mathrm{div}_x\mathbf{u}_n\big]\mathrm{d}x\,\mathrm{d}t,$$

$$I_7 = -\int_0^T \int_\Omega \psi\ p_n\partial_{x_i}\eta(\partial_{x_i}\Delta^{-1})[\xi T_k(\varrho_n)]\mathrm{d}x\,\mathrm{d}t,$$

$$S_n^{i,j} \equiv \mu(\vartheta_n)\big(\partial_{x_i}u_n^j + \partial_{x_j}u_n^i\big) + \lambda(\vartheta_n)\,\mathrm{div}_x\mathbf{u}_n\ \delta_{i,j},$$

and $\mathcal{R}_{i,j} = \partial_{x_i}\Delta^{-1}\partial_{x_j}$ is a pseudodifferential operator corresponding to the Fourier symbol $\xi_i\xi_j/|\xi|^2$. Formula (5.33) can be obtained through the choice of test functions

$$\varphi_i(t,x) = \psi(t)\eta(x)\partial_{x_i}\Delta^{-1}[\xi T_k(\varrho_n)],\ \psi \in \mathcal{D}(0,T),\ \eta,\ \xi \in \mathcal{D}(\Omega)$$

in the variational formulation of (1.2) (see Lemma 5.3 in Chapter 5 in [16]).

On the other hand, one can take

$$\varphi(t,x) = \psi\eta(\partial_{x_i}\Delta^{-1})[\overline{T_k(\varrho)}], \quad i = 1,2,3,$$

as test functions for (5.8), where

$$\overline{T_k(\rho)} \text{ is a limit of } T_k(\rho_n) \text{ in } C([0,T]; L^p_{weak}(\Omega)), \quad 1 < p < \infty \tag{5.34}$$

(cf. (5.22), (5.23)), to deduce

$$\begin{aligned} &\int_0^T \int_\Omega \psi\big(\eta\ \overline{p(\varrho,\vartheta)} - \mathcal{R}_{i,j}[\eta\ S^{i,j}]\big)\xi\overline{T_k(\varrho)}\,\mathrm{d}x\,\mathrm{d}t \\ &\quad = \sum_{j=1}^7 I_j \int_0^T \int_\Omega \psi u^j \big(\xi\overline{T_k(\varrho)}\mathcal{R}_{i,j}[\eta\varrho u^i] - \eta\varrho u^i \mathcal{R}_{i,j}[\xi\overline{T_k(\varrho)}]\big)\,\mathrm{d}x\,\mathrm{d}t, \end{aligned} \tag{5.35}$$

where

$$\begin{aligned} I_1 &= \int_0^T \int_\Omega \psi\ \partial_{x_j}\eta\ S^{i,j}(\partial_{x_i}\Delta^{-1})[\xi\overline{T_k(\varrho)}]\mathrm{d}x\ \mathrm{d}t, \\ I_2 &= -\int_0^T \int_\Omega \psi\eta\ \overline{\varrho f^i}(\partial_{x_i}\Delta^{-1})[\xi\overline{T_k(\varrho)}]\mathrm{d}x\,\mathrm{d}t, \\ I_3 &= -\int_0^T \int_\Omega \psi\ \partial_{x_j}\eta\ \varrho u^i u^j(\partial_{x_i}\Delta^{-1})[\xi\overline{T_k(\varrho)}]\mathrm{d}x\,\mathrm{d}t, \\ I_4 &= -\int_0^T \int_\Omega \partial_t\psi\eta\ \varrho u^i(\partial_{x_i}\Delta^{-1})[\xi\overline{T_k(\varrho)}]\mathrm{d}x\,\mathrm{d}t, \\ I_5 &= -\int_0^T \int_\Omega \psi\eta\varrho u^i(\partial_{x_i}\Delta^{-1})[\overline{T_k(\varrho)}\mathbf{u}\cdot\nabla_x\xi]\mathrm{d}x\,\mathrm{d}t, \\ I_6 &= \int_0^T \int_\Omega \psi\eta\ \varrho u^i(\partial_{x_i}\Delta^{-1})\big[\xi\overline{\big(T_k'(\varrho)\varrho - T_k(\varrho)\big)\mathrm{div}_x\mathbf{u}}\big]\mathrm{d}x\,\mathrm{d}t, \\ I_7 &= -\int_0^T \int_\Omega \psi\ \overline{p(\varrho,\vartheta)}\partial_{x_i}\eta(\partial_{x_i}\Delta^{-1})[\xi\overline{T_k(\varrho)}]\mathrm{d}x\,\mathrm{d}t. \end{aligned}$$

Note that

$$\partial_t\overline{T_k(\varrho)} + \mathrm{div}_x(\overline{T_k(\varrho)}\mathbf{u}) + \overline{\big(T_k'(\varrho)\varrho - T_k(\varrho)\big)\mathrm{div}_x\mathbf{u}} = 0 \text{ in } \mathcal{D}'((0,T)\times\Omega),$$

and, in accordance with (5.21),

$$S^{i,j} = \mu(\vartheta)\big(\partial_{x_i}u^j + \partial_{x_j}u^i\big) + \lambda(\vartheta)\mathrm{div}_x\mathbf{u}\ \delta_{i,j}.$$

It can be checked, in view of the results established in sections 5.2 and 5.3, that all the integrals $I_1,\dots,I_7$ on the right-hand side of (5.33) converge for $n\to\infty$ to their counterparts in (5.35) (see, for example, section 6.3 in Chapter 6 in [16]).

Moreover, by virtue of Corollary 6.1 in [16], the bilinear form

$$\left\{ \begin{array}{c} [\mathbf{v},\mathbf{w}] \mapsto v^i\mathcal{R}_{i,j}[w^j] - w^i\mathcal{R}_{i,j}[v^j] \text{ is weakly} \\ \text{sequentially continuous with values in } [L^s(R^N)]^N_{weak} \text{ on the} \\ \text{product } [L^p(R^N)]^N \times [L^q(R^N)]^N\ ,\ \frac{1}{p}+\frac{1}{q}=\frac{1}{s}<1,\ s \text{ finite.} \end{array} \right\} \tag{5.36}$$

Thus one can use (5.5), (5.34), and (5.36) in order to obtain

$$\begin{aligned}&\big(\xi T_k(\varrho_n)\mathcal{R}_{i,j}[\eta\varrho_n u_n^i] - \eta\varrho_n u_n^i\mathcal{R}_{i,j}[\xi T_k(\varrho_n)]\big)\\ &\quad\to \big(\xi\overline{T_k(\varrho)}\mathcal{R}_{i,j}[\eta\varrho u^i] - \eta\varrho u^i\mathcal{R}_{i,j}[\xi\overline{T_k(\varrho)}]\big)(t)\\ &\quad\text{weakly in } L^s(\Omega), \quad 1 < s < \frac{2\gamma}{\gamma+1}, \quad t \in [0,T].\end{aligned}$$

As the imbedding $L^s(\Omega) \hookrightarrow W^{-1,2}(\Omega)$ is compact, we infer

$$\begin{aligned}&\big(\xi T_k(\varrho_n)\mathcal{R}_{i,j}[\eta\varrho_n u_n^i] - \eta\varrho_n u_n^i\mathcal{R}_{i,j}[\xi T_k(\varrho_n)]\big)\\ &\quad\to \big(\xi\overline{T_k(\varrho)}\mathcal{R}_{i,j}[\eta\varrho u^i] - \eta\varrho u^i\mathcal{R}_{i,j}[\xi\overline{T_k(\varrho)}]\big) \text{ in } L^2(0,T;W^{-1,2}(\Omega)).\end{aligned}$$

Subtracting the limit as $n \to \infty$ of (5.33) and (5.35), we finally get

$$\begin{aligned}\lim_{n\to\infty}&\int_0^T\int_\Omega \psi\big(\eta\, p(\varrho_n,\vartheta_n) - \mathcal{R}_{i,j}[\eta\, S_n^{i,j}]\big)\xi T_k(\varrho_n)\mathrm{d}x\,\mathrm{d}t\\ &= \int_0^T\int_\Omega \psi\big(\eta\,\overline{p(\varrho,\vartheta)} - \mathcal{R}_{i,j}[\eta\, S^{i,j}]\big)\xi\overline{T_k(\varrho)}\mathrm{d}x\,\mathrm{d}t.\end{aligned} \tag{5.37}$$

In order to conclude, let us recall the following result that may be viewed as a variant of the abstract theory developed by Coifman et al. [7] (see Lemma 4.2 in [17]).

LEMMA 5.3. *Let*

$$\mathbf{V} \in L^2(R^N;R^N), \quad w \in W^{1,r}(R^N), \quad r > \frac{2N}{N+2}.$$

Then there exist constants $c = c(r) > 0$, $\omega = \omega(r) \in (0,1)$, $p = p(r) > 1$ such that

$$\|\mathcal{R}_{i,j}[wV_j] - w\mathcal{R}_{i,j}[V_j]\|_{W^{\omega,p}(R^N;R^N)} \le c(r)\|w\|_{W^{1,r}(R^N)}\|\mathbf{V}\|_{L^2(R^N;R^N)}, \; i = 1,\dots,N.$$

Due to (3.12), (3.13), (3.16), and (4.22) and (5.3) and (5.20), we have at least for a chosen subsequence

$$a(\vartheta_n) \to a(\vartheta) \text{ weakly in } L^2(0,T;W^{1,2}(\Omega)), \tag{5.38}$$

$$a(\vartheta_n) \to a(\vartheta) \text{ in } L^q((0,T)\times\Omega), \quad 1 \le q < 3, \tag{5.39}$$

where a stands for μ and λ. Recalling that $\mathcal{R}_{i,j}$ is a continuous linear operator from $L^q(R^N)$ to $L^q(R^N)$, $1 < q < \infty$, and taking into account (4.6) and (4.30), we verify that

$$\mathcal{R}_{i,j}[a(\vartheta_n)\partial_j\mathbf{u}_n] - a(\vartheta_n)\mathcal{R}_{i,j}[\partial_j\mathbf{u}_n] \text{ is bounded in } L^2(0,T;L^{\frac{6}{5}}(\Omega,R^3)). \tag{5.40}$$

On the other hand, using Lemma 5.3 with $w = a(\vartheta)$, $\mathbf{V} = \nabla u_k$, $k = 1,2,3$, we get that

$$\mathcal{R}_{i,j}[a(\vartheta_n)\partial_j\mathbf{u}_n] - a(\vartheta_n)\mathcal{R}_{i,j}[\partial_j\mathbf{u}_n] \text{ is bounded in } L^1(0,T;W^{\omega',s}(\Omega,R^3)) \tag{5.41}$$

with suitable numbers $\omega' \in (0,1)$ and $s > 1$. Now we interpolate (5.40) and (5.41) to get the boundedness of the sequence

$$\mathcal{R}_{i,j}[a(\vartheta_n)\partial_j\mathbf{u}_n] - a(\vartheta_n)\mathcal{R}_{i,j}[\partial_j\mathbf{u}_n]_; \text{ in } L^p(0,T;W^{\omega,p}(\Omega,R^3))$$

with suitable exponents $p > 1$ and $\omega \in (0,1)$. Finally, since according to (5.2), (5.38), and (5.40)

$$\mathcal{R}_{i,j}[a(\vartheta_n)\partial_j \mathbf{u}_n] - a(\vartheta_n)[\mathcal{R}_{i,j}\partial_j \mathbf{u}_n]$$
$$\to \mathcal{R}_{i,j}[a(\vartheta)\partial_j \mathbf{u}] - a(\vartheta)\mathcal{R}_{i,j}[\partial_j \mathbf{u})] \text{ weakly in } L^2(0,T;L^{\frac{6}{5}}(\Omega,R^3)),$$

from the last bound we deduce

$$\mathcal{R}_{i,j}[a(\vartheta_n)\partial_j \mathbf{u}_n] - a(\vartheta_n)\mathcal{R}_{i,j}[\partial_j \mathbf{u}_n]$$
$$\to \mathcal{R}_{i,j}[a(\vartheta)\partial_j \mathbf{u}] - a(\vartheta)\mathcal{R}_{i,j}[\partial_j \mathbf{u}] \text{ weakly in } L^p(0,T;W^{\omega,p}(\Omega;R^3)) \tag{5.42}$$

at least for a suitably chosen subsequence. On the other hand, as for a suitable $q \in (1,\infty)$ the imbedding $L^q(\Omega) \hookrightarrow W^{-\omega,p'}(\Omega)$ is compact, formula (5.34) implies

$$T_k(\rho_n) \to \overline{T_k(\rho)} \text{ in } L^{p'}(0,T;W^{-\omega,p'}(\Omega)). \tag{5.43}$$

Employing the obvious properties of the Riesz operator, namely, $\mathcal{R}_{i,j} = \mathcal{R}_{j,i}$ and $\mathcal{R}_{i,j}(\frac{\partial u_j}{\partial x_i}) = \operatorname{div}_x \mathbf{u}$, and using (5.42) and (5.43) in (5.37), we arrive at

$$\lim_{n\to\infty} \int_0^T \int_\Omega \varphi\big(p(\varrho_n,\vartheta_n) - (\lambda(\vartheta_n) + 2\mu(\vartheta_n)) \operatorname{div}_x \mathbf{u}_n\big) T_k(\varrho_n) \mathrm{d}x\, \mathrm{d}t \tag{5.44}$$
$$= \int_0^T \int_\Omega \varphi\big(\overline{p(\varrho,\vartheta)} - (\lambda(\vartheta) + 2\mu(\vartheta))\operatorname{div}_x \mathbf{u}\big)\overline{T_k(\varrho)} \mathrm{d}x\, \mathrm{d}t \times \Omega)$$

for any $\varphi \in \mathcal{D}(0,T)$. For more details see section 4 in [17].

5.4. Strong convergence of the density. To begin with, we show that the limit functions ϱ, $\mathbf{u}$ solve the renormalized continuity equation (2.5). Note that such a result cannot be obtained via the regularization procedure developed in [10] as the density is not (known to be) square integrable. Instead, following Chapter 6 in [16], we introduce the *oscillation defect measure*

$$\mathbf{osc}_p[\varrho_n \to \varrho](Q) \equiv \sup_{k\geq 1} \Big\{ \limsup_{n\to\infty} \int_Q |T_k(\varrho_n) - T_k(\varrho)|^p \,\mathrm{d}x \ \mathrm{d}t \Big\}.$$

We report the following assertion (see Proposition 6.3 in Chapter 6 in [16]).

LEMMA 5.4. *Let $\Omega \subset R^N$, $N = 2,3$, be a domain. Assume that $\{\varrho_n\}_{n=1}^\infty$ is a sequence of nonnegative functions such that*

$$\varrho_n \to \varrho \textit{ weakly (*) in } L^\infty(0,T;L^\gamma(\Omega)),\ \gamma > \frac{2N}{N+2}.$$

Furthermore, let ϱ_n satisfy the renormalized equation (2.5) *with* $\mathbf{u}_n$,

$$\mathbf{u}_n \to \mathbf{u} \textit{ weakly in } L^2(0,T;W_0^{1,2}(\Omega;R^N)).$$

Finally, suppose

$$\mathbf{osc}_p[\varrho_n \to \varrho](Q) < c(Q) < \infty \textit{ for some } p > 2,$$

for any bounded $Q \subset (0,T) \times \Omega$.

Then ϱ, $\mathbf{u}$ solve the renormalized equation (2.5) *for any h, H satisfying* (2.6).

In the following lemma we show that the assumptions of Lemma 5.4 are satisfied.

LEMMA 5.5. *Under the hypotheses of Theorem* 3.1*, we have*

$$\mathbf{osc}_{\gamma+1}[\varrho_n \to \varrho]((0,T)\times\Omega) < \infty.$$

Proof. As already observed in (4.24), one can write

$$p(\varrho_n,\vartheta_n) = a\varrho_n^\gamma + p_b(\varrho_n,\vartheta_n), \text{ where } |p_b(\varrho,\vartheta)| \le c(1+\vartheta^4+\vartheta\varrho^{\frac{\gamma}{3}}). \tag{5.45}$$

Now relation (5.44) may be rephrased as

$$\begin{aligned} a\lim_{n\to\infty}\int_0^T\int_\Omega &\varrho_n^\gamma T_k(\varrho_n) - \overline{\varrho^\gamma}\;\overline{T_k(\varrho)}\mathrm{d}x\,\mathrm{d}t \\ \le \lim_{n\to\infty}\int_0^T\int_\Omega &p_b(\varrho_n,\vartheta_n)(\overline{T_k(\varrho)} - T_k(\varrho_n))\mathrm{d}x\,\mathrm{d}t \\ + \lim_{n\to\infty}\int_0^T\int_\Omega &(\lambda(\vartheta_n)+2\mu(\vartheta_n))\mathrm{div}_x\mathbf{u}_n(T_k(\varrho_n)-\overline{T_k(\varrho)})\mathrm{d}x\,\mathrm{d}t. \end{aligned} \tag{5.46}$$

Exactly as in the proof of Proposition 6.2 in [16], via arguments based on the convexity of $\varrho\mapsto\varrho^\gamma$, the left-hand side of (5.46) is bounded from below as follows:

$$\begin{aligned} \limsup_{n\to\infty}\int_0^T\int_\Omega &|T_k(\varrho_n)-T_k(\varrho)|^{\gamma+1}\,\mathrm{d}x\,\mathrm{d}t \\ \le \lim_{n\to\infty}\int_0^T\int_\Omega &\varrho_n^\gamma T_k(\varrho_n) - \overline{\varrho^\gamma}\;\overline{T_k(\varrho)}\,\mathrm{d}x\,\mathrm{d}t. \end{aligned} \tag{5.47}$$

On the other hand, by virtue of hypothesis (3.16), estimates (4.8), (4.22), (4.32), and relation (4.26),

$$\sup_{n=1,2,\dots}\|p_b(\varrho_n,\vartheta_n)\|_{L^{\frac{5}{3}}((0,T)\times\Omega)} < \infty$$

and

$$\sup_{n=1,2,\dots}\|(\lambda(\vartheta_n)+2\mu(\vartheta_n))\mathrm{div}_x\mathbf{u}_n\|_{L^{\frac{5}{3}}((0,T)\times\Omega)} < \infty.$$

Thus,

$$\begin{aligned} \lim_{n\to\infty}\int_0^T\int_\Omega &p_b(\varrho_n,\vartheta_n)(\overline{T_k(\varrho)}-T_k(\varrho_n))\,\mathrm{d}x\,\mathrm{d}t \\ + \lim_{n\to\infty}\int_0^T\int_\Omega &(\lambda(\vartheta_n)+2\mu(\vartheta_n))\mathrm{div}_x\mathbf{u}_n(T_k(\varrho_n)-\overline{T_k(\varrho)})\,\mathrm{d}x\,\mathrm{d}t \\ \le c\limsup_{n\to\infty}&\|T_k(\varrho_n)-T_k(\varrho)\|_{L^{\frac{5}{2}}((0,T)\times\Omega)}, \end{aligned}$$

and, consequently, relations (5.46) and (5.47) yield the desired conclusion since $\gamma+1>5/2$. ∎

Combining Lemmas 5.4 and 5.5 we infer that ϱ, $\mathbf{u}$ solve (2.5); in particular,

$$\partial_t L_k(\varrho) + \mathrm{div}_x(L_k(\varrho)\mathbf{u}) + T_k(\varrho)\mathrm{div}_x\mathbf{u} = 0 \text{ in } \mathcal{D}'((0,T)\times R^3) \tag{5.48}$$

provided ϱ, $\mathbf{u}$ were extended to be zero outside Ω with

$$L_k(\varrho) \equiv \varrho \int_1^{\varrho} \frac{T_k(z)}{z^2}\,\mathrm{d}z.$$

Moreover, as ϱ_n, $\mathbf{u}_n$ solve (2.5) as well, it is easy to deduce

$$\partial_t \overline{L_k(\varrho)} + \mathrm{div}_x(\overline{L_k(\varrho)}\mathbf{u}) + \overline{T_k(\varrho)\,\mathrm{div}_x\mathbf{u}} = 0 \text{ in } \mathcal{D}'((0,T)\times R^3). \tag{5.49}$$

Equations (5.48) and (5.49) together with hypothesis (3.18) give rise to

$$\begin{aligned}
&\int_\Omega \big(\overline{L_k(\varrho)} - L_k(\varrho)\big)(\tau)\mathrm{d}x \\
&\quad + \int_0^\tau \int_\Omega \big(\overline{T_k(\varrho)\,\mathrm{div}_x\mathbf{u}} - \overline{T_k(\varrho)}\,\mathrm{div}_x\mathbf{u}\big)\,\mathrm{d}x\,\mathrm{d}t \\
&\quad = \int_0^\tau \int_\Omega \big(T_k(\varrho) - \overline{T_k(\varrho)}\big)\mathrm{div}_x\mathbf{u}\,\mathrm{d}x\,\mathrm{d}t \quad \text{for all } \tau \in [0,T].
\end{aligned} \tag{5.50}$$

Now it can be shown, with the help of Lemma 5.5, that

$$\int_0^T \int_\Omega \big(T_k(\varrho) - \overline{T_k(\varrho)}\big)\mathrm{div}_x\mathbf{u}\,\mathrm{d}x\,\mathrm{d}t \to 0 \text{ for } k \to \infty$$

(see section 6.6 in [16]).

Moreover, in accordance with (5.44),

$$\big(\overline{T_k(\varrho)\,\mathrm{div}_x\mathbf{u}} - \overline{T_k(\varrho)}\mathrm{div}_x\mathbf{u}\big) = (\lambda(\vartheta) + 2\mu(\vartheta))^{-1}\big(\overline{p(\varrho,\vartheta)T_k(\varrho)} - \overline{p(\varrho,\vartheta)}\;\overline{T_k(\varrho)}\big),$$

where, by virtue of (3.1) and (5.20),

$$\big(\overline{p(\varrho,\vartheta)T_k(\varrho)} - \overline{p(\varrho,\vartheta)}\;\overline{T_k(\varrho)}\big) = \big(\overline{p_G(\varrho,\vartheta)T_k(\varrho)} - \overline{p_G(\varrho,\vartheta)}\;\overline{T_k(\varrho)}\big). \tag{5.51}$$

Since p_G is a nondecreasing function of ϱ and $\{\vartheta_n\}_{n=1}^\infty$ converges almost everywhere on $(0,T)\times\Omega$, the most right expression in (5.51) is nonnegative. Thus, we conclude, using (5.50), that

$$\overline{\varrho\log(\varrho)} = \varrho\log(\varrho) \text{ on } (0,T)\times\Omega,$$

which means

$$\varrho_n \to \varrho \;\text{ in } L^1((0,T)\times\Omega). \tag{5.52}$$

5.5. Convergence. Having established the pointwise convergence of the sequences $\{\varrho_n\}_{n=1}^\infty$, $\{\vartheta_n\}_{n=1}^\infty$, and with the estimates obtained in section 4, it is a routine matter to complete the proof of Theorem 3.1, that is, to pass to the limit for $n\to\infty$ in all the integral identities appearing in the variational formulation of problem (1.1)–(1.6) introduced in Definition 2.1.

Let us only remark that we can write

$$\frac{\mathbf{q}}{\vartheta} = -\kappa(\varrho,\vartheta)\nabla_x\log(\vartheta) \quad \text{and} \quad \frac{\mathbf{q}\cdot\nabla_x\vartheta}{\vartheta^2} = -\kappa(\varrho,\vartheta)|\nabla_x\log(\vartheta)|^2.$$

In particular, by virtue of hypothesis (3.15), and estimates (4.6) and (4.22), the quantities

$$\left|\frac{\mathbf{q}_n}{\vartheta_n}\right| = \sqrt{\kappa(\varrho_n,\vartheta_n)}\sqrt{\kappa(\varrho_n,\vartheta_n)}|\nabla_x\log(\vartheta_n)| \text{ are bounded in } L^p((0,T)\times\Omega)$$

for a certain $p > 1$ and independently of $n = 1, 2, \ldots$.

In order to carry out the limit passage in the entropy production inequality (2.7), we report the following observation (see Lemmas 5.3 and 5.4 in [13]).

LEMMA 5.6.

(i) *Let $\Omega \subset R^N$ be a bounded Lipschitz domain. Suppose that ϱ is a given non-negative function satisfying*

$$0 < M \le \int_\Omega \varrho \,\mathrm{d}x, \quad \int_\Omega \varrho^\gamma \,\mathrm{d}x < K, \quad \gamma > \frac{2N}{N+2}.$$

Furthermore, let $\vartheta \in W^{1,2}(\Omega)$.

Then the following two statements are equivalent.

- *The function ϑ is strictly positive a.a. on Ω,*

$$\varrho|\log(\vartheta)| \in L^1(\Omega) \text{ and } \frac{\nabla_x \vartheta}{\vartheta} \in L^2(\Omega).$$

- *The function $\log(\vartheta)$ belongs to the Sobolev space $W^{1,2}(\Omega)$.*

Moreover, if it is the case, then

$$\nabla_x \log(\vartheta) = \frac{\nabla_x \vartheta}{\vartheta} \text{ a.a. on } \Omega.$$

(ii) *Let*

$$\vartheta_n \to \vartheta \text{ in } L^2((0,T)\times\Omega), \text{ and } \log(\vartheta_n) \to \overline{\log(\vartheta)} \text{ weakly in } L^2((0,T)\times\Omega).$$

Then ϑ is strictly positive a.a. on $(0,T)\times\Omega$, and $\log(\vartheta) = \overline{\log(\vartheta)}$.

Acknowledgment. The authors thank T. Bodnár for his help with the typesetting of figures.

EXISTENCE, UNIQUENESS, AND REGULARITY RESULTS FOR PIEZOELECTRIC SYSTEMS*

D. MERCIER† AND S. NICAISE†

Abstract. We investigate the time-harmonic piezoelectric system (a system coupling the elasticity system with the full Maxwell's equations) in polyhedral domains of the space. Existence and uniqueness results of weak solutions are proved in different cases. We describe the corner and edge singularities of that system and deduce some regularity results.

Key words. elasticity system, Maxwell's system, singularities

AMS subject classifications. 35J25, 35Q60

DOI. 10.1137/040617728

1. Introduction. Smart structures made of piezoelectric and/or piezomagnetic materials are gaining attention in applications since they are able to transform the energy from one type to another (magnetic, electric, and mechanical), allowing them to be used as sensors and/or actuators. Commonly used piezoelectric materials are ceramics and quartz. The mathematical model of this system starts to be well established [2, 8, 14, 24, 26] and corresponds to a coupling between the elasticity system and Maxwell's equations (see below). A full mathematical analysis is not yet done, except in some particular cases [13, 19]. Namely, in these two works the electric field E is assumed to be curl free, i.e., $E = \nabla\varphi$, where φ is an electric potential and a two-dimensional reduction is made. In [13], existence and uniqueness results in smooth domains are obtained using integral equations, while in [19] a variational formulation in polygonal domains is given and two-dimensional singularities are briefly described.

On the other hand, there exists an extensive list of papers from mechanics literature describing singularities of some particular piezoelectric materials with a plane crack [25, 27, 30] or along wedges [29]. But to our knowledge, an exact description of corner/edge singularities of the general piezoelectric system in three-dimensional polyhedral domains is not yet obtained. Such a description is very important since piezoelectric ceramics are very brittle, and therefore their fracture behavior must be understood. The knowledge of such singularities also has numerical implications, such as convergence speed.

This paper has, therefore, the following goals: We present a general piezoelectric system, which includes standard models of ceramics like the PZT or the $BaTiO_3$. We further develop some variational formulations which are the natural ones because they lead to solutions in the energy spaces (here called weak solutions). We prove existence and uniqueness results of weak solutions of the time-harmonic system in two different cases: the case when the magnetic permeability matrix is positive definite ($BaTiO_3$) and the case when the magnetic permeability matrix is zero (PZT). In that second case, we even give two different formulations and show that generically they give rise to the same solutions. Moreover, we describe the corner and edge singularities of our

†Université de Valenciennes et du Hainaut Cambrésis, MACS, Institut des Sciences et Techniques de Valenciennes, F-59313 Valenciennes Cedex 9, France (Denis.Mercier@univ-valenciennes.fr, Serge.Nicaise@univ-valenciennes.fr).

general system and deduce some regularity results. Some edge singular exponents are briefly described; more examples will be given in a forthcoming paper [20], where a two-dimensional model and fracture criteria will be considered.

The analysis of more sophisticated models, like coupling between piezoelectric and magnetostrictive materials [26] or piezoelectric and purely elastic materials [29, 9], will be investigated in the future.

The paper is organized as follows. Section 2 introduces the nonstationary model problem and its time-harmonic version. Existence and uniqueness results are given in section 3 when the magnetic permeability matrix is positive definite. Section 4 is devoted to existence and uniqueness results in the case of a zero magnetic permeability matrix. There we consider two different formulations: for the first one (called the E-formulation) the magnetic field H is eliminated, while for the second one (the H-formulation) the electric field E is eliminated. For the latter formulation, like for the eddy current problem, Gauge conditions are necessary. We further show their generic equivalence. After a short description of corner and edge singularities of some useful elliptic systems in section 5, we obtain the corner and edge singularities of our system in section 6. Regularity results are deduced in section 7. Some edge singular exponents are finally presented in section 8.

2. Setting of the problem. Let Ω be a bounded domain of $\mathbb{R}^3$ with a Lipschitz boundary Γ. For the sake of simplicity, we suppose that Γ is piecewise plane and connected and that Ω is simply connected. In this domain, we consider the following nonstationary piezoelectric system of constitutive equations [2, 8, 14, 24]:

$$\sigma_{ij} = a_{ijkl}\gamma_{kl}(u) - e_{kij}E_k \ \forall i, j = 1, 2, 3, \tag{2.1}$$

$$D_i = \epsilon_{ij}E_j + e_{ikl}\gamma_{kl}(u) \ \forall i = 1, 2, 3, \tag{2.2}$$

$$B_i = \mu_{ij}H_j \ \forall i = 1, 2, 3. \tag{2.3}$$

The equations of equilibrium are

$$\partial_t^2 u_i = \partial_j \sigma_{ji} + f_i \ \forall i = 1, 2, 3 \tag{2.4}$$

for the elastic displacement and

$$\partial_t D + J = \mathbf{curl}\, H, \partial_t B = -\,\mathbf{curl}\, E$$

for the electric/magnetic fields (Maxwell's equations), where f is the body force density and J is the vector current density function. As usual $\mathbf{curl}\, H = (\partial_2 H_3 - \partial_3 H_2, \partial_3 H_1 - \partial_1 H_3, \partial_1 H_2 - \partial_2 H_1)^\top$, when $H = (H_1, H_2, H_3)^\top$.

This system models the coupling between Maxwell's system and the elastic one [2, 8, 14, 24], in which $E(x,t)$, $H(x,t)$ are the electric and magnetic fields at the point $x \in \Omega$ at time t, $u(x,t)$ is the displacement field at the point $x \in \Omega$ at time t, and $(\gamma_{ij}(u))_{i,j=1}^3$ is the strain tensor given by

$$\gamma_{ij}(u) = \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right).$$

Here $(\sigma_{ij})_{i,j=1}^3$, $D = (D_1, D_2, D_3)^\top$, and $B = (B_1, B_2, B_3)^\top$ are the stress tensor, electric displacement, and magnetic induction, respectively. ϵ, μ are the electric permittivity and magnetic permeability, respectively, and are supposed to be real, symmetric 3×3 matrices. In what follows the matrix ϵ is supposed to be positive definite, while μ is only supposed to be nonnegative. The elasticity tensor $(a_{ijkl})_{i,j,k,l=1,2,3}$ is made of constant entries such that

$$a_{ijkl} = a_{jikl} = a_{klij},$$

and satisfies the ellipticity condition

$$a_{ijkl}\gamma_{ij}\gamma_{kl} \geq \alpha\gamma_{ij}\gamma_{ij}, \tag{2.5}$$

for every symmetric tensor (γ_{ij}) and some $\alpha > 0$. The piezoelectric tensor e_{kij} is also made of constant entries such that

$$e_{kij} = e_{kji}.$$

The system is completed with the Dirichlet boundary conditions for the displacement field,

$$u = 0 \text{ on } \Gamma, \tag{2.6}$$

and those of a perfect conductor,

$$E \times n = 0 \text{ on } \Gamma. \tag{2.7}$$

As usual n is the exterior unit normal vector along Γ.

In order to write the above problem in a more compact form, the strain and stress tensors are expressed as 6×1 vectors, namely

$$\begin{aligned} \gamma(u) &= (\gamma_{11}(u), \gamma_{22}(u), \gamma_{33}(u), 2\gamma_{23}(u), 2\gamma_{31}(u), 2\gamma_{12}(u))^\top, \\ \sigma &= (\sigma_{11}, \sigma_{22}, \sigma_{33}, \sigma_{23}, \sigma_{31}, \sigma_{12})^\top. \end{aligned}$$

With this notation, the constitutive equations (2.1)–(2.3) may be equivalently written as

$$\begin{pmatrix} \sigma \\ D \\ B \end{pmatrix} = M \begin{pmatrix} \gamma(u) \\ E \\ H \end{pmatrix}, \tag{2.8}$$

where M is a 12×12 matrix given by

$$M = \begin{pmatrix} C & -e^\top & 0 \\ e & \epsilon & 0 \\ 0 & 0 & \mu \end{pmatrix},$$

where C is a 6×6 symmetric matrix depending on the elasticity tensor, e is a 3×6 matrix depending on the piezoelectric tensor, and ϵ, μ are as described above. Note that the ellipticity assumption (2.5) is equivalent to the fact that C is a positive definite matrix.

For a monoclinic material with poling direction in the x_3-axis, the material constant matrices are expressed by (see, for instance, [26])

$$C = \begin{pmatrix} c_{11} & c_{12} & c_{13} & 0 & 0 & c_{16} \\ c_{12} & c_{22} & c_{23} & 0 & 0 & c_{26} \\ c_{13} & c_{23} & c_{33} & 0 & 0 & c_{36} \\ 0 & 0 & 0 & c_{44} & c_{45} & 0 \\ 0 & 0 & 0 & c_{45} & c_{55} & 0 \\ c_{16} & c_{26} & c_{36} & 0 & 0 & c_{66} \end{pmatrix}, \quad e = \begin{pmatrix} 0 & 0 & 0 & e_{14} & e_{15} & 0 \\ 0 & 0 & 0 & e_{24} & e_{25} & 0 \\ e_{31} & e_{32} & e_{33} & 0 & 0 & e_{36} \end{pmatrix},$$

$$\epsilon = \begin{pmatrix} \epsilon_{11} & \epsilon_{12} & 0 \\ \epsilon_{12} & \epsilon_{22} & 0 \\ 0 & 0 & \epsilon_{33} \end{pmatrix}, \quad \mu = \begin{pmatrix} \mu_{11} & \mu_{12} & 0 \\ \mu_{12} & \mu_{22} & 0 \\ 0 & 0 & \mu_{33} \end{pmatrix}.$$

For the orthotropic piezoelectric PZT-4, the material coefficients are given by (c_{ij} in $10^9 N/m^2$, e_{ij} in C/m^2, ϵ_{ij} in $10^{-9}C^2/Nm^2$):

$$\begin{array}{ccccc} c_{11}=c_{22}=23.8 & c_{33}=10.6 & c_{44}=2.15 & c_{55}=4.4 & c_{66}=\frac{c_{11}-c_{12}}{2}=6.43 \\ c_{12}=3.98 & c_{13}=2.19 & c_{23}=1.92 & \epsilon_{11}=\epsilon_{22}=0.110625 & \epsilon_{33}=0.106023 \\ e_{31}=-0.13 & e_{32}=-0.14 & e_{33}=-0.28 & e_{24}=e_{15}=-0.01. & \end{array}$$

Here and below, nongiven coefficients are equal to zero.

For the piezoelectric $BaTiO_3$, the material coefficients are given by (c_{ij} in $10^9 N/m^2$, e_{ij} in C/m^2, ϵ_{ij} in $10^{-9}C^2/Nm^2$, μ_{ij} in $10^{-6}Ns^2/C^2$):

$$\begin{array}{ccccc} c_{11}=c_{22}=166 & c_{33}=162 & c_{44}=c_{55}=43 & c_{66}=\frac{c_{11}-c_{12}}{2}=44.5 & \\ c_{12}=77 & c_{13}=c_{23}=78 & \epsilon_{11}=\epsilon_{22}=11.2 & \epsilon_{33}=12.6 & \\ e_{31}=e_{32}=-4.4 & e_{33}=-18.6 & e_{24}=e_{15}=11.6 & \mu_{11}=\mu_{22}=5 & \mu_{33}=10 \end{array}$$

With the above notation, the equation of equilibrium (2.4) is also equivalent to

$$\partial_t^2 u = \mathrm{Div}\sigma + f,$$

where Div is the operator-valued matrix defined by

$$\mathrm{Div} = \begin{pmatrix} \partial_1 & 0 & 0 & 0 & \partial_3 & \partial_2 \\ 0 & \partial_2 & 0 & \partial_3 & 0 & \partial_1 \\ 0 & 0 & \partial_3 & \partial_2 & \partial_1 & 0 \end{pmatrix}.$$

Assuming that u, E, H are of the form

$$u(x,t) = e^{-i\omega t}u(x), E(x,t) = e^{-i\omega t}E(x), H(x,t) = e^{-i\omega t}H(x),$$

for some real constant ω (the data being of the same form), the above system is reduced to the time-harmonic piezoelectric system in Ω consisting of the constitutive equation (2.8), the time-harmonic equilibrium equation

$$\mathrm{Div}\sigma + \omega^2 u = -f \text{ in } \Omega, \tag{2.9}$$

and the time-harmonic Maxwell's equations

$$\mathbf{curl}\, H + i\omega D = J \text{ in } \Omega, \tag{2.10}$$

$$\mathbf{curl}\, E - i\omega\mu H = 0 \text{ in } \Omega. \tag{2.11}$$

In the whole paper we consider the nonstationary case; namely, we assume that $\omega > 0$. In other words we assume that the variation in time of u, E, and H is periodic in time with a frequency equal to $2\pi/\omega$. The stationary case $\omega = 0$ requires the use of Gauss' law

$$\mathrm{div} D = \rho,$$

where ρ is the charge density function. This case is treated as in section 4.1 below and is then left to the reader.

3. Existence and uniqueness results when is positive definite. Replacing D by its expression (2.2) in the first Maxwell equation (2.10), we get

$$\mathbf{curl}\, H + i\omega(\epsilon E + e\gamma(u)) = J \text{ in } \Omega.$$

This identity is clearly equivalent to

$$i\omega\epsilon E = J - \mathbf{curl}\, H - i\omega e\gamma(u) \text{ in } \Omega. \tag{3.1}$$

With this identity, the second Maxwell equation (2.11) is then equivalent to

$$\mathbf{curl}(\epsilon^{-1}(\mathbf{curl}\, H + i\omega e\gamma(u))) - \omega^2\mu H = \mathbf{curl}(\epsilon^{-1}J) \text{ in } \Omega. \tag{3.2}$$

In the same way using the constitutive equation (2.8) in the equation of motion (2.9), we obtain

$$\operatorname{Div}\left(C\gamma(u) - e^\top E\right) + \omega^2 u = -f \text{ in } \Omega. \tag{3.3}$$

Using the identity (3.1), we arrive at

$$\begin{aligned}&\operatorname{Div}\left(C\gamma(u) + e^\top\epsilon^{-1}e\gamma(u) + \frac{1}{i\omega}e^\top\epsilon^{-1}(\mathbf{curl}\, H)\right)\\ &+\omega^2 u = -f + \frac{1}{i\omega}\operatorname{Div}\left(e^T\epsilon^{-1}J\right) \text{ in } \Omega.\end{aligned} \tag{3.4}$$

The two equations (3.2) and (3.4) constitute the system of partial differential equations that we will study and whose unknowns are u and H. Due to the boundary conditions (2.6) and (2.7), this system is completed with (2.6) and

$$\epsilon^{-1}(\mathbf{curl}\, H + i\omega e\gamma(u)) \times n = J \times n, (\mu H)\cdot n = 0 \text{ on } \Gamma. \tag{3.5}$$

The weak formulation of the above problem is obtained in the following way: We introduce the space (see [4, 5])

$$X_T(\Omega,\mu) = \{v \in L^2(\Omega)^3 : \operatorname{div}(\mu v) \in L^2(\Omega), \mathbf{curl}\, v \in L^2(\Omega)^3 \text{ and } (\mu v)\cdot n = 0 \text{ on } \Gamma\}$$

equipped with its natural norm. Then we multiply the system (3.2) by a test function $\bar{H}' \in X_T(\Omega,\mu)$, integrate the result in Ω, and integrate by parts to get (assuming that u and H are regular enough)

$$\begin{aligned}&\int_\Omega \left\{\epsilon^{-1}(\mathbf{curl}\, H + i\omega e\gamma(u))\cdot \mathbf{curl}\, \bar{H}' - \omega^2\mu H\cdot \bar{H}'\right\}\, dx\\ &= \int_\Omega \epsilon^{-1}J\cdot \mathbf{curl}\, \bar{H}'\, dx + \int_\Gamma (J\times n)\cdot \bar{H}'\, ds\ \forall H' \in X_T(\Omega,\mu).\end{aligned}$$

Since from the second Maxwell equation (2.11) $\operatorname{div}(\mu H) = 0$ in Ω, the above identity is equivalent to

$$\begin{aligned}&\int_\Omega \left\{\epsilon^{-1}(\mathbf{curl}\, H + i\omega e\cdot\gamma(u))\cdot \mathbf{curl}\, \bar{H}' + \operatorname{div}(\mu H)\operatorname{div}(\mu\bar{H}') - \omega^2\mu H\cdot \bar{H}'\right\}\, dx\\ &= \int_\Omega \epsilon^{-1}J\cdot \mathbf{curl}\, \bar{H}'\, dx + \int_\Gamma (J\times n)\cdot \bar{H}'\, ds\ \forall H' \in X_T(\Omega,\mu).\end{aligned} \tag{3.6}$$

This last equation may be called the regularized formulation of the system (3.2).

Similarly multiplying (3.4) by $\bar{v} \in H_0^1(\Omega)^3$, integrating the result in Ω, and using Green's formula

$$\int_\Omega (\mathrm{Div}\gamma) \cdot \bar{v}\, dx = -\int_\Omega \gamma \cdot \gamma(\bar{v})\, dx,$$

obtained by componentwise integration by parts in Ω, we arrive at

$$\begin{aligned}(3.7)\qquad &\int_\Omega \left\{ \left(C\gamma(u) + e^\top \epsilon^{-1} e\gamma(u) + \frac{1}{i\omega} e^\top \epsilon^{-1}\, \mathbf{curl}\, H \right) \cdot \gamma(\bar{v}) - \omega^2 u \cdot \bar{v} \right\} dx \\ &= \int_\Omega \left(f \cdot \bar{v} - \frac{1}{i\omega} e^T \epsilon^{-1} J \cdot \gamma(\bar{v}) \right) dx \ \forall v \in H_0^1(\Omega)^3.\end{aligned}$$

As these two identities are coupled, multiplying the second one by $i\omega$ and summing the result we arrive at the following problem:

$$\begin{aligned}&\int_\Omega \Big\{ \epsilon^{-1}(\mathbf{curl}\, H + i\omega e\gamma(u)) \cdot \mathbf{curl}\, \bar{H}' + \mathrm{div}(\mu H)\mathrm{div}(\mu \bar{H}') - \omega^2 \mu H \cdot \bar{H}' \\ &+ i\omega \left(C\gamma(u) + e^\top \epsilon^{-1} e\gamma(u) + \frac{1}{i\omega} e^\top \epsilon^{-1}\, \mathbf{curl}\, H \right) \cdot \gamma(\bar{v}) - i\omega^3 u \cdot \bar{v} \Big\} dx = F(v, H'),\end{aligned}$$

where we have set

$$(3.8)\quad F(v, H') = \int_\Omega \left(\epsilon^{-1} J \cdot \mathbf{curl}\, \bar{H}' - e^T \epsilon^{-1} J \cdot \gamma(\bar{v}) + i\omega f \cdot \bar{v} \right) dx + \int_\Gamma (J \times n) \cdot \bar{H}'\, ds.$$

In order to get a well-posed problem we set $u_\omega = i\omega u$. Then we see that the above problem is equivalent to finding a solution $(u_\omega, H) \in V$ of

$$(3.9)\qquad a((u_\omega, H), (v, H')) = F(v, H')\ \forall (v, H') \in V,$$

where we set

$$\begin{aligned} V &= H_0^1(\Omega)^3 \times X_T(\Omega, \mu), \\ a((u, H), (v, H')) &= \int_\Omega \big\{ \epsilon^{-1}(\mathbf{curl}\, H + e\gamma(u)) \cdot \mathbf{curl}\, \bar{H}' + \mathrm{div}(\mu H)\mathrm{div}(\mu \bar{H}') - \omega^2 \mu H \cdot \bar{H}' \\ &\quad + \left(C\gamma(u) + e^\top \epsilon^{-1} e\gamma(u) + e^\top \epsilon^{-1}\, \mathbf{curl}\, H \right) \cdot \gamma(\bar{v}) - \omega^2 u \cdot \bar{v} \big\}\, dx.\end{aligned}$$

In summary we have shown the following lemma.

LEMMA 3.1. *If u, E, H are solutions of* (2.8), (2.9), (2.10), *and* (2.11) *with the boundary conditions* (2.6) *and* (2.7), *then $(i\omega u, H)$ is a solution of* (3.9).

We now remark that the bilinear form a may be equivalently written

$$\begin{aligned}& a\ ((u, H), (v, H')) \\ &= \int_\Omega \left\{ \mathcal{A} \begin{pmatrix} \mathbf{curl}\, H \\ \gamma(u) \end{pmatrix} \cdot \begin{pmatrix} \mathbf{curl}\, \bar{H}' \\ \gamma(\bar{v}) \end{pmatrix} + \mathrm{div}(\mu H)\mathrm{div}(\mu \bar{H}') - \omega^2 \mu H \cdot \bar{H}' - \omega^2 u \cdot \bar{v} \right\} dx,\end{aligned}$$

where $\mathcal{A}$ is the 9×9 symmetric matrix defined by

$$\mathcal{A} = \begin{pmatrix} \epsilon^{-1} & \epsilon^{-1} e \\ e^\top \epsilon^{-1} & C + e^\top \epsilon^{-1} e \end{pmatrix}.$$

One easily checks that this matrix is positive definite for the material coefficients of the PZT-4 and $BaTiO_3$, for instance. In fact this is always true if ϵ and C are positive definite (always true in our setting), independently of the piezoelectric coefficients.

LEMMA 3.2. *If ϵ and C are positive definite matrices, then the matrix $\mathcal{A}$ defined above is also positive definite.*

Proof. We only need to show that

$$\mathcal{A}\begin{pmatrix} X \\ \gamma \end{pmatrix} \cdot \begin{pmatrix} X \\ \gamma \end{pmatrix} \geq 0, \forall \begin{pmatrix} X \\ \gamma \end{pmatrix} \in \mathbb{R}^9,$$
$$\mathcal{A}\begin{pmatrix} X \\ \gamma \end{pmatrix} \cdot \begin{pmatrix} X \\ \gamma \end{pmatrix} = 0 \Rightarrow \begin{pmatrix} X \\ \gamma \end{pmatrix} = 0.$$

By the definition of $\mathcal{A}$ we see that

$$\mathcal{A}\begin{pmatrix} X \\ \gamma \end{pmatrix} \cdot \begin{pmatrix} X \\ \gamma \end{pmatrix} = X^\top \epsilon^{-1} X + 2X^\top \epsilon^{-1} e\gamma + \gamma^\top C\gamma + \gamma^\top e^\top \epsilon^{-1} e\gamma.$$

Setting $\tilde{X} = \epsilon^{-1/2}X$ and $\tilde{Y} = \epsilon^{-1/2}e\gamma$ (note that both vectors are in $\mathbb{R}^3$), we see that

$$\begin{aligned}\mathcal{A}\begin{pmatrix} X \\ \gamma \end{pmatrix} \cdot \begin{pmatrix} X \\ \gamma \end{pmatrix} &= \tilde{X}^\top \tilde{X} + 2\tilde{X}^\top \tilde{Y} + \gamma^\top C\gamma + \tilde{Y}^\top \tilde{Y} \\ &= \|\tilde{X} + \tilde{Y}\|_2^2 + \gamma^\top C\gamma,\end{aligned}$$

where $\|\cdot\|_2$ clearly means the Euclidean norm of $\mathbb{R}^3$. This identity directly implies the first assertion by the positive definitiveness of C.

For the second assertion, if

$$\mathcal{A}\begin{pmatrix} X \\ \gamma \end{pmatrix} \cdot \begin{pmatrix} X \\ \gamma \end{pmatrix} = 0,$$

then the above identity and again the positive definitiveness of C imply that

$$\|\tilde{X} + \tilde{Y}\|_2^2 = \gamma^\top C\gamma = 0.$$

Therefore $\gamma = 0$ and, consequently, $\tilde{Y} = 0$ in view of its definition (independently of e). We then obtain that $\tilde{X} = 0$ and, by the positive definitiveness of ϵ, we conclude that $X = 0$. $\square$

This lemma allows us to show that problem (3.9) enters within the framework of the Fredholm alternative. Indeed, we shall prove the following lemma.

LEMMA 3.3. *There exists a discrete set S such that for $1 + \omega^2 \notin S$, the problem* (3.9) *has a unique solution for any $F \in V'$.*

Proof. Introduce the sesquilinear form

$$b((u,H),(v,H')) := a((u,H),(v,H')) + (1+\omega^2)\left(\int_\Omega \mu H \cdot \bar{H}'\,dx + \int_\Omega u \cdot \bar{v}\,dx\right).$$

Then the above considerations yield

$$\begin{aligned}&b\ ((u,H),(v,H')) \\ &= \int_\Omega \left\{\mathcal{A}\begin{pmatrix} \mathbf{curl}\,H \\ \gamma(u) \end{pmatrix} \cdot \begin{pmatrix} \mathbf{curl}\,\bar{H}' \\ \gamma(\bar{v}) \end{pmatrix} + \operatorname{div}(\mu H)\operatorname{div}(\mu\bar{H}') + \mu H \cdot \bar{H}' + u \cdot \bar{v}\right\} dx.\end{aligned}$$

It is coercive on V, since by Lemma 3.2 we have

$$b((u,H),(u,H)) \gtrsim \int_\Omega \left\{|\,\mathbf{curl}\, H|^2 + |\gamma(u)|^2 + |\mathrm{div}(\mu H)|^2 + |H|^2 + |u|^2\right\} dx.$$

Therefore by Korn's inequality we get

$$b((u,H),(u,H)) \gtrsim \|u\|^2_{1,\Omega} + \|H\|^2_{X_T(\Omega,\mu)}.$$

Since the space $X_T(\Omega,\mu)$ is compactly embedded into $L^2(\Omega)^3$ [28], and since by the Rellich–Kondrasov theorem $H^1_0(\Omega)$ is compactly embedded into $L^2(\Omega)$, we deduce that V is compactly embedded into $\mathcal{H} := L^2(\Omega)^3 \times L^2(\Omega)^3$. These facts imply that the Friedrichs extension B from $\mathcal{H}$ into $\mathcal{H}$ induced by the triple $(V,\mathcal{H},b)$ is invertible with a compact inverse. Now denote by A the Friedrichs extension of the triple $(V,\mathcal{H},a)$. The relation between a and b implies that $A = B - (1+\omega^2)I_\mu$, where the operator I_μ is defined by

$$I_\mu(u,H)^\top = (u,\mu H)^\top$$

and is clearly continuous from $\mathcal{H}$ into $\mathcal{H}$. Using this operator we may write

$$(1+\omega^2)^{-1}B^{-1}A = (1+\omega^2)^{-1}I - B^{-1}I_\mu,$$

where I is the identity operator from $\mathcal{H}$ into $\mathcal{H}$. Since $B^{-1}I_\mu$ is a compact operator, it has a discrete spectrum with positive eigenvalues. If we denote by S the set of the inverses of these eigenvalues, then for $(1+\omega^2) \notin S$, the operator $(1+\omega^2)^{-1}I - B^{-1}I_\mu$ is invertible and consequently A is as well. $\square$

Remark 3.4. Note that in the case $\mu = 0$, problem (3.9) does not enter in the Fredholm framework since $X_T(\Omega,0)$ is reduced to $H(\mathbf{curl},\Omega)$ and is no more compactly embedded into $L^2(\Omega)^3$. This drawback will be avoided by introducing Gauge conditions; see section 4.2.

Let us now show that the converse of Lemma 3.1 holds under some conditions on ω (compare with Theorem 0.1 of [4]).

THEOREM 3.5. *Assume that ω^2 is not an eigenvalue of $-\Delta^{Neu}_\mu := -\mathrm{div}(\mu\nabla\cdot)$, the (nonnegative) Laplace operator with Neumann boundary conditions in Ω. If $(u_\omega,H) \in V$ is a solution of* (3.9) *with F defined by* (3.8)*, then* $\mathrm{div}(\mu H) = 0$ *and u,E,H are solutions of* (2.9), (2.10)*, and* (2.11) *with the boundary conditions* (2.6) *and* (2.7) *when $u = \frac{u_\omega}{i\omega}$, E is given by* (3.1)*, and σ, D, B are defined by* (2.8)*.*

Proof. In (3.9) we take $v = 0$ and $H' = \nabla\bar{\Phi}$, with $\Phi \in D(\Delta^{Neu}_\mu)$. This yields

$$\int_\Omega \left\{\mathrm{div}(\mu H)\mathrm{div}(\mu\nabla\Phi) - \omega^2\mu H\cdot\nabla\Phi\right\} dx = 0.$$

By Green's formula we obtain

$$\int_\Omega \mathrm{div}(\mu H)(\Delta^{Dir}_\mu\Phi + \omega^2\Phi)\, dx = 0 \;\forall\Phi \in D(\Delta^{Neu}_\mu).$$

Since $D(\Delta^{Neu}_\mu)$ is dense in $L^2(\Omega)$, we conclude that $\mathrm{div}(\mu H) = 0$ in Ω.

The equations (2.9), (2.10), and (2.11) are obtained using Green's formula with test functions $H' \in \mathcal{D}(\Omega)^3$ or $v \in \mathcal{D}(\Omega)^3$. It then remains to show the boundary condition

$$\epsilon^{-1}(\mathbf{curl}\, H + i\omega e\gamma(u)) \times n = J \times n \text{ on } \Gamma,$$

which then implies (2.7), by the definition of E.

We first remark that the above arguments show that

$$w = \epsilon^{-1}(\mathbf{curl}\, H + i\omega e\gamma(u)) - J$$

belongs to $H(\mathbf{curl}, \Omega)$.

We now state the next Green's formula, which is a variant of the "standard" one (see Theorem I.2.11 of [10] or the identity (2.5) from [1]). A face F of Ω being fixed we denote by

$$V_F = \{\varphi \in H^1(\Omega) : \varphi = 0 \text{ on } \Gamma \setminus F\}.$$

We recall that for $\varphi \in V_F$, Theorem 2.2 of [21] implies that the trace of φ on F belongs to $H^{1/2}_{00}(F)$. By standard Green's formula

$$\int_\Omega (w \cdot \mathbf{curl}\, \varphi - \varphi \cdot \mathbf{curl}\, w)\, dx = \int_\Gamma (w \times n) \cdot \varphi,$$

valid for any $w, \varphi \in H^1(\Omega)^3$; from the fact that the above left-hand side is continuous on $H(\mathbf{curl}, \Omega) \times (V_F)^3$, we deduce that if $w \in H(\mathbf{curl}, \Omega)$, then $w \times n$ belongs to $(H^{1/2}_{00}(F)')^3$, and that Green's identity

$$\int_\Omega (w \cdot \mathbf{curl}\, \varphi - \varphi \cdot \mathbf{curl}\, w)\, dx = \langle w \times n, \varphi\rangle_F \;\; \forall \varphi \in (V_F)^3 \tag{3.10}$$

holds (where $\langle ., .\rangle_F$ means the duality pairing between $(H^{1/2}_{00}(F)')^3$ and $H^{1/2}_{00}(F)^3$).

Now for a fixed face F, we temporarily assume that the z-axis is perpendicular to F and that F is included in the plane $z = 0$. For $\varphi_1, \varphi_2 \in \mathcal{D}(F)$, we take

$$H'(x, y, z) = \eta(z)\mu^{-1} \cdot \begin{pmatrix} \varphi_1 \\ \varphi_2 \\ 0 \end{pmatrix}$$

with a cut-off function $\eta \in \mathcal{D}(\mathbb{R})$ such that $\eta(0) = 1$ and a sufficiently small support so that H' is zero on $\Gamma \setminus F$. By construction the function H' belongs to $X_T(\Omega, \mu) \cap (V_F)^3$. Therefore in (3.9), taking as a test function $v = 0$ and this function H', by Green's formula (3.10) we get

$$\langle w \times n, H'\rangle_F = 0.$$

As the third component of $w \times n$ is zero and the two first components of

$$\mu^{-1} \cdot \begin{pmatrix} \varphi_1 \\ \varphi_2 \\ 0 \end{pmatrix}$$

are arbitrary in $H^{1/2}_{00}(F)$, we deduce that

$$w \times n = 0 \text{ in } (H^{1/2}_{00}(F)')^3.$$

By the definition of w, the requested boundary condition is proved. $\square$

4. Existence and uniqueness results when = 0.

4.1. The -formulation. In the case $\mu = 0$, the second Maxwell equation (2.11) and the boundary condition (2.7) imply that

$$i\omega E = \nabla\varphi, \tag{4.1}$$

for some $\varphi \in H_0^1(\Omega)$. Therefore, in order to eliminate the vector field H, we take the divergence of the first Maxwell equation (2.10) to get

$$\operatorname{div}(i\omega D) = \operatorname{div} J,$$

and by the constitutive equation (2.8) we obtain

$$\operatorname{div}(i\omega e\gamma(u) + \epsilon i\omega E) = \operatorname{div} J.$$

As before setting $u_\omega = i\omega u$, the above identity is equivalent to

$$\operatorname{div}(e\gamma(u_\omega) + \epsilon\nabla\varphi) = \operatorname{div} J. \tag{4.2}$$

This equation is now coupled with (3.3) or, equivalently, with

$$\operatorname{Div}\left(C\gamma(u_\omega) - e^\top\nabla\varphi\right) + \omega^2 u_\omega = -i\omega f \text{ in } \Omega \tag{4.3}$$

to form our system of partial differential equations. Clearly, its weak formulation is in finding a solution $(u_\omega, \varphi) \in H_0^1(\Omega)^4$ of

$$a((u_\omega,\varphi),(v,\psi)) = F(v,\psi), \forall (v,\psi) \in H_0^1(\Omega)^4, \tag{4.4}$$

where the bilinear form a is defined by

$$a((u,\varphi),(v,\psi)) = \int_\Omega \left\{(e\gamma(u) + \epsilon\nabla\varphi)\cdot\nabla\psi + (C\gamma(u) - e^\top\nabla\varphi)\cdot\gamma(v) - \omega^2 u\cdot v\right\}\, dx,$$

and the linear form F is given by

$$F(v,\psi) = \int_\Omega (i\omega f\cdot v - J\cdot\nabla\psi)\, dx. \tag{4.5}$$

The above considerations show the following lemma.

LEMMA 4.1. *If u, E, H are solutions of* (2.8), (2.9), (2.10), *and* (2.11) *with the boundary conditions* (2.6) *and* (2.7), *then* $(i\omega u, \varphi)$, *with* φ *given by* (4.1), *is a solution of* (4.4).

As in the previous section, problem (4.4) satisfies the Fredholm alternative; namely, we shall prove the following lemma.

LEMMA 4.2. *There exists a discrete set S_0 such that for $\omega^2 \notin S_0$, the problem* (4.4) *has a unique solution for any $F \in H^{-1}(\Omega)^4$.*

Proof. Introduce the bilinear form

$$b((u,\varphi),(v,\psi)) = \int_\Omega \left\{(e\gamma(u) + \epsilon\nabla\varphi)\cdot\nabla\psi + (C\gamma(u) - e^\top\nabla\varphi)\cdot\gamma(v)\right\}\, dx.$$

This form is coercive on $H_0^1(\Omega)^4$ since

$$b((u,\varphi),(u,\varphi)) = \int_\Omega \{\epsilon\nabla\varphi\cdot\nabla\varphi + C\gamma(u)\cdot\gamma(u)\}\, dx \gtrsim \|\varphi\|_{1,\Omega}^2 + \|u\|_{1,\Omega}^2,$$

thanks to the positive definiteness of ϵ and C and Korn's inequality.

We conclude as in Lemma 3.3. $\square$

We end this subsection by the converse result of Lemma 4.1.

THEOREM 4.3. *If* $(u_\omega, \varphi) \in H_0^1(\Omega)^4$ *is the solution of* (4.4) *with* F *defined by* (4.5)*, then* u, E *are solutions of* (2.9) *and* (2.11) *with the boundary conditions* (2.6) *and* (2.7) *when* $u = \frac{u_\omega}{i\omega}$*,* E *is given by* (4.1)*, and* σ, D, B *are defined by* (2.8) *(implying* $B = 0$ *since* $\mu = 0$*). Moreover, there exists* $H \in H^1(\Omega)^3$ *such that* (2.10) *holds.*

Proof. The first part of the lemma follows from Green's formula. For the second part we simply remark that D defined by (2.8) satisfies

$$\operatorname{div}(i\omega D) = \operatorname{div} J \text{ in } \Omega,$$

or, equivalently, $J - i\omega D$ is divergence free. Therefore the existence of H such that $\mathbf{curl}\, H = J - i\omega D$ follows from Theorem I.3.4 of [10]. □

In the above lemma, we may notice that the magnetic field H is not unique, but this is not important since, in the case $\mu = 0$, only u and E are of practical interest.

4.2. The -formulation. Following the arguments of section 3, we may eliminate the electric field E and keep as unknowns u and H. Unfortunately H is no more uniquely determined, since the condition $\operatorname{div}(\mu H) = 0$ and the boundary condition $\mu H \cdot n = 0$ on Γ are trivially satisfied. Therefore as for eddy current problems [3] we impose the following Gauge conditions:

$$\operatorname{div} H = 0 \text{ in } \Omega, \tag{4.6}$$

$$H \cdot n = 0 \text{ on } \Gamma. \tag{4.7}$$

These conditions may be justified by an asymptotic argument, namely by taking $\mu = \eta I$, with $\eta > 0$ and letting η tends to 0 (cf. [6]).

These arguments imply the following lemma.

LEMMA 4.4. *If* u, E, H *are solutions of* (2.8), (2.9), (2.10), *and* (2.11) *with the boundary conditions* (2.6) *and* (2.7)*, assume that* H *satisfies the Gauge conditions* (4.6)–(4.7)*. Then* $(i\omega u, H)$ *belongs to* $V = H_0^1(\Omega)^3 \times X_T(\Omega, I)$ *and is solution of* (3.9)*, with the sesquilinear form here defined by*

$$\begin{aligned} a((u,H),(v,H')) = \int_\Omega \big\{ &\epsilon^{-1}(\mathbf{curl}\, H + e\gamma(u)) \cdot \mathbf{curl}\, \bar{H}' + \operatorname{div}(H)\operatorname{div}(\bar{H}') \\ &+ \big(C\gamma(u) + e^\top \epsilon^{-1} e\gamma(u) + e^\top \epsilon^{-1}\, \mathbf{curl}\, H\big) \cdot \gamma(\bar{v}) - \omega^2 u \cdot \bar{v} \big\}\, dx. \end{aligned}$$

Again, the above problem enters in the Fredholm alternative.

LEMMA 4.5. *There exists a discrete set* S_1 *such that for* $1 + \omega^2 \notin S_1$*, the problem* (3.9)*, with* a *and* V *defined in Lemma 4.4, has a unique solution for any* $F \in V'$*.*

Proof. Introduce the sesquilinear form

$$b((u,H),(v,H')) := a((u,H),(v,H')) + (1+\omega^2)\int_\Omega u \cdot \bar{v}\, dx.$$
