THEOREM 4.4. *Let the assumptions of Theorem* 3.9 *hold and let ϕ be a traveling wave solution. Let $f_0(\xi, v)$ be an initial datum for* (4.1) *and let $W_0(\xi) = \frac{1}{\varepsilon}\int_{-\infty}^{\xi} (\rho_{f_0}(\eta) - \rho_\phi(\eta)) d\eta$. Let $f_0 - \phi \in H_\xi^2(L_v^2)$ (implying that f_0 satisfies the same far-field conditions as ϕ) and $W_0 \in L_\xi^2$ (implying $W_0(\infty) = \int_{-\infty}^{\infty} (\rho_{f_0}(\xi) - \rho_\phi(\xi)) d\xi = 0$). Let*

$$\|W_0\|_{L_\xi^2} + \frac{1}{\varepsilon} \|f_0 - \phi\|_{H_\xi^2(L_v^2)} \le \delta \tag{4.23}$$

for δ small enough, but independent from ε. Then (4.1) *subject to the initial condition $f(t=0) = f_0$ has a unique global solution and*

$$\lim_{t\to\infty} \int_t^\infty \|f(s,\cdot,\cdot) - \phi\|_{H_\xi^2(L_v^2)}^2\, ds = 0\,.$$

REMARK 4.5. *The shortcomings of Theorem* 4.4 *are that it gives only local stability (i.e., the perturbations have to be small enough) of small amplitude traveling waves. Also convergence as $t \to \infty$ holds only in a very weak sense. The smallness of the wave is the basic assumption of this work allowing a perturbative treatment close to macroscopic equations. The other shortcomings are already present in the underlying results for viscous shock profiles.*

Proof. The proof is based on the construction of a Lyapunov functional H, such that both H and $-dH/dt$ measure the size of the perturbation. However, it will be impossible to estimate H in terms of $-dH/dt$, which is the reason why we do not have a result on the time decay rate.

We start by defining a partial functional for each differentiation order k appearing in Lemmas 4.1 and 4.3. By adding the corresponding inequality from Lemma 4.1 and the product of εA_k with the corresponding inequality from Lemma 4.3, we produce an inequality for the time derivative of

$$\begin{aligned} H_k &= \frac{1}{2}\|\partial_\xi^k W\|_{L^2_\xi}^2 - \varepsilon^2\langle F\partial_\xi^k W, (v-s)\partial_\xi^k g\rangle_{\xi,v} + \varepsilon^3 A_k \|\partial_\xi^k g\|^2_{L^2_\xi(L^2_v)} + \varepsilon A_k \|\partial_\xi^{k+1} W\|^2_{L^2_\xi} \\ &\geq \kappa_k(\|\partial_\xi^k W\|^2_{L^2_\xi} + \varepsilon\|\partial_\xi^{k+1} W\|^2_{L^2_\xi} + \varepsilon^3\|\partial_\xi^k g\|^2_{L^2_\xi(L^2_v)})\,, \end{aligned}$$

where the last inequality holds with an ε-independent $\kappa_k > 0$ if $A_k > 0$ is chosen independently of ε (but otherwise arbitrarily). With two more positive constants γ_1 and γ_2, we define the Lyapunov functional as $H = H_0 + \gamma_1 H_1 + \gamma_2 H_2$ and observe that it can be bounded from above and below by

$$\|W\|^2_{H^2_\xi} + \varepsilon\|\partial_\xi^3 W\|^2_\xi + \varepsilon^3\|g\|^2_{H^2_\xi(L^2_v)}\,.$$

With the aid of the Lemmas 4.1, 4.2, and 4.3, it is now straightforward to obtain an inequality of the form

$$\frac{dH}{dt} \leq -C(\|\rho\|_{L^\infty_\xi})(1 - \|W\|_{L^\infty_\xi})(\|\rho\|^2_{H^2_\xi} + \varepsilon\|g\|^2_{H^2_\xi(L^2_v)})\,, \tag{4.24}$$

with an ε-independent positive $C(\|\rho\|_{L^\infty_\xi})$. Since (by one-dimensional Sobolev embedding) H controls the L^∞_ξ-norms of W and ρ, the right-hand side is negative at $t = 0$ and remains so if $H(0)$ is small enough. This in turn is guaranteed by assumption (4.23). Note that the L^2_ξ-norm of W (and, thus, H) is not controlled by the dissipation term in (4.24), which is the reason that we cannot obtain a decay rate. The proof is completed by integrating (4.24) with respect to t. ∎

RIGOROUS DERIVATION OF FÖPPL'S THEORY FOR CLAMPED ELASTIC MEMBRANES LEADS TO RELAXATION*

SERGIO CONTI†, FRANCESCO MAGGI†, AND STEFAN MÜLLER‡

Abstract. We consider the nonlinear elastic energy of a thin membrane whose boundary is kept fixed, and assume that the energy per unit volume scales as h^β, with h the film thickness and $\beta \in (0, 4)$. We derive, by means of Γ convergence, a limiting theory for the scaled displacements, which takes a form similar to the one proposed by Föppl in 1907. Our variational approach fully incorporates the possibility of buckling already observed during the derivation of the reduced two-dimensional theory. At variance with Föppl's, our limiting model is lower semicontinuous and has an energetics that vanishes on all contractions. Therefore buckling does not need to be explicitly resolved when computing with the reduced theory. If forces normal to the membrane are included, then our result predicts that the normal displacement scales as the cube root of the force. This scaling depends crucially on the clamped boundary conditions. Indeed, if the boundary is left free, then a much softer response is obtained, as was recently shown by Friesecke, James, and Müller [*Arch. Ration. Mech. Anal.*, 180 (2006), pp. 183–236].

1. Introduction.

Reduced theories for thin elastic bodies have been proposed and used since the early days of the theory of elasticity, but only in the last decade has it become possible to derive them rigorously from three-dimensional nonlinear elasticity. The convergence criterion which has been used for these problems is Γ-convergence (which is very closely related to convergence of minimizers), and the different physical regimes are reflected by different scalings of the applied forces, and hence of the elastic energy, and different topologies on the space of deformations [17, 18, 13, 12, 22, 23, 10] (we refer to [10] for a review of the recent mathematical literature and of the mechanical context).

One key property of the elasticity of thin bodies is that tangential displacements enter the strain to first order, but normal displacements only to second order (see Figure 1.1). Therefore linear theories are not usable, as they would describe all normal displacements as completely stress-free (soft). The first nonvanishing contribution of normal displacements to strain is quadratic, and correspondingly the leading energy contribution is of fourth order.

A generalization of the linear theory which incorporates the normal displacements to leading order was proposed by Föppl [9]. In a variational language, and for the special case of isotropic elastic moduli and zero Poisson's ratio, his model corresponds

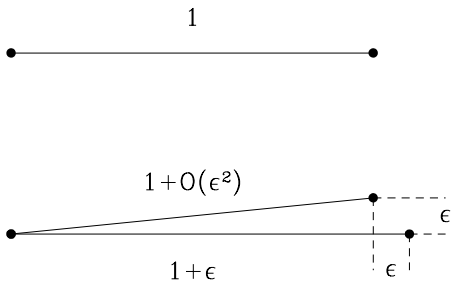

FIG. 1.1. *Consider a rod of unit length. If one endpoint is displaced tangentially by ϵ, the length also changes by ϵ. If instead the endpoint is displaced by ϵ in the normal direction, then the length changes only to order ϵ^2.*

to minimizing

$$\frac{1}{2}\int_S \left|\nabla u + \nabla u^T + \nabla v \otimes \nabla v\right|^2 + fv\, dx', \tag{1.1}$$

subject to appropriate boundary conditions. Here $S \subset \mathbb{R}^2$ represents the cross-section of the membrane, $u : S \to \mathbb{R}^2$ the tangential displacement, $v : S \to \mathbb{R}$ the normal displacement, and $f : S \to \mathbb{R}$ the applied normal force.

The functional (1.1) is not lower semicontinuous with respect to the weak $W^{1,2}(S,\mathbb{R}^2) \times W^{1,4}(S,\mathbb{R})$ topology. Physically, a sheet subject to moderate compression can relax its strain by forming fine-scale folds, which are not penalized by the functional (1.1) since it does not contain any curvature term. (We note in passing that even if bending energy is included compression is often still relaxed by fine-scale oscillations; see, e.g., [3, 7].)

It is therefore to be expected that a variational derivation will not lead to the functional (1.1), but to its relaxation. Indeed, we show here that under suitable scaling assumptions and with clamped boundary conditions three-dimensional elasticity reduces, in the sense of Γ-convergence, to a functional corresponding to the relaxation of (1.1), which, for the same special case, takes the form

$$\frac{1}{2}\int_S W_{\rm rel}\left(\nabla u + (\nabla u)^T + \nabla v \otimes \nabla v\right) dx' + fv\, dx', \tag{1.2}$$

where $W_{\rm rel}(F) = (\lambda_1^+(F))^2 + (\lambda_2^+(F))^2$, $\lambda_1(F)$ and $\lambda_2(F)$ are the eigenvalues of the symmetric matrix F, and $\lambda^+ = \max\{\lambda, 0\}$.

Our result, as will be explained in greater detail in the next section, has important consequences for the scaling behavior of the response of clamped membranes. Consider indeed application of a force $f_h(x') = h^\alpha f(x')$ normal to the membrane. If $\alpha \in (0,3)$, then our convergence result applied for $\beta = 4\alpha/3$ implies that the three-dimensional variational problems converge as $h \to 0$ to the relaxed problem $I_0(u,v) + \int_S fv dx'$, for I_0 as in (1.2). The tangential displacements scale as $h^{\beta/2} = h^{2\alpha/3}$, and the normal one as $h^{\beta/4} = h^{\alpha/3}$.

For $\alpha > 3$ one obtains a different limiting theory, which is quadratic and involves only bending energy (see, e.g., [10]). The limit functional takes the form $\int |\nabla^2 v|^2 + fv$. In this regime the out-of-plane displacement is linear in the applied force and thus scales like h^α.

Understanding the crossover from the linear to the sublinear scaling, which had also been observed experimentally, was an important motivation for the work of Föppl and von Kármán [27]. Indeed von Kármán points out that his theory interpolates between the linear (pure bending) theory and Föppl's theory [27, p. 350].[1] This crossover was analyzed quantitatively by Neubert and Sommer [20] and Way [28], finding good quantitative agreement with von Kármán's theory. Extensive experimental tests in the nonlinear regime appropriate to Föppl's theory were performed by Head and Sechler [14], finding very good agreement between Föppl's theory and the measured deflections with applied pressures varying over four orders of magnitude. While the von Kármán equations have received a lot of attention and there are several derivations available (with asymptotic expansions [5], with the implicit function theorem [19], and with Γ-convergence [10, 11]), we are not aware of any derivation of Föppl's geometrically linear membrane theory.

The scaling of the force appropriate for the present result is different than the one used in the derivation of the theory which includes bending [10]. Roughly speaking, one can say that the presence of the boundary conditions makes the membrane stiffer. In parallel, this additional stiffness of the membrane term makes the bending term irrelevant in the present scaling. The crucial difference between the present result and the hierarchy of models derived by Γ-convergence in [10] resides in the boundary conditions. In [10] natural boundary conditions are used, and as a consequence a variety of deformations $y : S \to \mathbb{R}^3$ are admissible which have zero membrane energy (isometric immersions, or developable maps). This leads to a rather soft response, dominated by the bending term. Here the boundary conditions rule out all nontrivial deformations with zero membrane energy, and as a consequence the response is much stiffer. The crucial dependence of the behavior on boundary conditions and in particular on the availability of (infinitesimally) isometric deformations was emphasized by Sanchez-Palencia [24]. In his terminology our situation corresponds to the case of ill-inhibited flexion, where the approach based on the spectral method is bound to fail. Our variational approach identifies the appropriate limiting theory, and shows that in this nonlinear regime the deformation scales as the cube root of the applied force.

Notation. The vectors e_1, e_2, and e_3 form an orthonormal basis of $\mathbb{R}^3$, and $\mathbb{R}^2$ is the space generated by e_1 and e_2. To every element $x = x_1e_1 + x_2e_2 + x_3e_3 \in \mathbb{R}^3$ we associate $x' := x_1e_1 + x_2e_2 \in \mathbb{R}^2$. Thus $x = x' + x_3e_3$.

The space of tensors generated by $\{e_i \otimes e_j\}_{i,j=1,2,3}$ is denoted by $\mathbb{R}^{3\times3}$, and $\mathbb{R}^{2\times2}$ is the subspace of $\mathbb{R}^{3\times3}$ generated by the tensors $\{e_i \otimes e_j\}_{i,j=1,2}$. To every $F = \sum_{i,j=1,2,3} F_{ij}\, e_i \otimes e_j \in \mathbb{R}^{3\times3}$ we associate $F' := \sum_{i,j=1,2} F_{ij}\, e_i \otimes e_j \in \mathbb{R}^{2\times2}$. By $\mathbb{R}^{n\times n}_{\mathrm{sym}}$ we denote the space of symmetric matrices, and by $\mathbb{R}^{n\times n}_{+}$ the subsets of positive semidefinite symmetric ones (i.e., $\{F \in \mathbb{R}^{n\times n}_{\mathrm{sym}} : F \geq 0\}$). Finally Id_n is the identity matrix in $\mathbb{R}^{n\times n}$. For scalar functions, we write for brevity $W^{1,2}_0(S) = W^{1,2}_0(S, \mathbb{R})$.

2. The relaxed Föppl functional. We consider the nonlinear elastic energy of a thin three-dimensional body $\Omega_h := S \times (-h/2, h/2)$, where $S \subset \mathbb{R}^2$ is the cross section and $h > 0$ the (small) thickness. The deformation is a map $w_h \in W^{1,2}(\Omega_h, \mathbb{R}^3)$,

[1] "In dieser Hinsicht liegt die wirkliche Platte zwischen den beiden Grenzfällen der *vollkommen steifen Platte* nach Gl. (27) und der *vollkommen biegsamen Platte*, deren Gleichungen sich aus dem System (29) mit $D = 0$ ergeben." Translation: In this regard the real plate lies in between the two limiting cases of the *completely stiff plate* according to Eq. (27) and the *completely flexible plate*, whose equations are obtained from the system (29) [i.e., the vK equations] with $D = 0$.

and its elastic energy per unit thickness is

$$E(w_h, \Omega_h) := \frac{1}{h} \int_{\Omega_h} W(\nabla w_h(x)) dx.$$

By general arguments it suffices to prove Γ-convergence without external forces [8]. The stored energy function W is assumed to satisfy the following:

(W1) $W : \mathbb{R}^{3\times 3} \to [0, \infty]$ is a Borel measurable function of class C^2 in an open neighborhood of $SO(3)$.

(W2) $W(RF) = W(F)$ for every $R \in SO(3)$ and every $F \in \mathbb{R}^{3\times 3}$; furthermore, $W(\mathrm{Id}_3) = 0$.

(W3) $W(F) \geq C \operatorname{dist}^2(F, SO(3))$ for every $F \in \mathbb{R}^{3\times 3}$.

We study the asymptotic behavior as $h \to 0$ of the minimization problems

$$\inf \left\{ \frac{E(w_h, \Omega_h)}{h^\beta} : w_h \in W^{1,2}(\Omega_h, \mathbb{R}^3),\ w_h(x) = x \text{ on } \partial S \times (-h/2, h/2) \right\}$$

in the range $\beta \in (0, 4)$, by means of Γ-convergence theory.

In order to define an appropriate convergence criterion for a sequence of deformations w_h, which are all defined on different domains, we rescale (following standard practice) to a unique domain. Precisely, for each $w_h \in W^{1,2}(\Omega_h, \mathbb{R}^3)$ we define $y_h \in W^{1,2}(\Omega_1, \mathbb{R}^3)$ by $y_h(x) = w_h(x' + hx_3 e_3)$. Then

$$E_h(w_h, \Omega_h) = \int_{\Omega_1} W(\nabla_h y_h(x)) dx,$$

where ∇_h is the operator $\nabla_h := \nabla' + (1/h)\partial_3 \otimes e_3$, i.e.,

$$\nabla_h y(x) = \partial_1 y(x) \otimes e_1 + \partial_2 y(x) \otimes e_2 + \frac{1}{h} \partial_3 y(x) \otimes e_3 \,.$$

In terms of the rescaled deformations, and including the constraint given by the boundary conditions, our problem corresponds to minimizing the functional $I_h : W^{1,2}(\Omega_1, \mathbb{R}^3) \to [0, \infty]$ given by

$$I_h(y) := \begin{cases} \displaystyle\int_{\Omega_1} W(\nabla_h y(x)) dx & \text{if } y(x) = x' + hx_3 e_3 \text{ for } x \in \partial S \times (-\tfrac{1}{2}, \tfrac{1}{2}), \\ +\infty & \text{else.} \end{cases}$$

Due to the boundary conditions and to the energy regime under consideration, the behavior of a low energy sequence y_h will be understood by considering the scaled displacements

$$u_h(x') := \frac{1}{h^{\beta/2}} \int_0^1 (y_h(x) - x)' \, dx_3, \tag{2.1}$$

$$v_h(x') := \frac{1}{h^{\beta/4}} \int_0^1 (y_h(x) - hx) \cdot e_3 \, dx_3. \tag{2.2}$$

Note that for every h we have $u_h \in W^{1,2}_0(S, \mathbb{R}^2)$ and $v_h \in W^{1,2}_0(S)$. However, for a sequence y_h such that $h^{-\beta} I_h(y_h)$ stays bounded, we shall prove that, up to extracting subsequences, (u_h, v_h) is weakly$*$ convergent only in the larger space $BD(S) \times W^{1,2}_0(S)$ (compare with part I of Theorem 2.1 below). We recall that $BD(S)$ denotes the space

of the deformations $u \in L^1(S, \mathbb{R}^2)$ such that the symmetric part of the *distributional gradient* $D'u$ is a Radon measure on S, namely

$$\operatorname{sym} D'u \in \mathcal{M}(S, \mathbb{R}^{2\times 2}_{\operatorname{sym}})$$

(the symbol $\mathcal{M}$ is used for spaces of Radon measures). The limit of the in-plane displacements u_h will take values in the smaller space

(2.3)
$$X(S) := \{u \in BD(S) : \exists M \in \mathcal{M}(\mathbb{R}^2, \mathbb{R}^{2\times 2}_+) \text{ s.t. } \operatorname{sym} D'\overline{u} + M \in L^1(\mathbb{R}^2, \mathbb{R}^{2\times 2})\},$$

where $\overline{u} := u$ in S and $\overline{u} := 0$ in $\mathbb{R}^2 \setminus S$. This corresponds to requiring that the symmetrized distributional derivative is the sum of an L^1 term and a negative definite measure, singular with respect to Lebesgue measure. This sign condition does not bring any additional regularity, as $X(S)$ still contains elements that are not in $BV(S, \mathbb{R}^2)$. The formulation of (2.3) in terms of the extension $\bar{u}$ corresponds to a sign condition on the boundary values of u (in the sense of inner traces). Precisely, functions $u \in X(S)$ obey $\operatorname{tr}(u) = \lambda \nu_S$, where $\lambda \geq 0$ and ν_S is the outer normal. The structure of $X(S)$ is discussed in more detail in the appendix.

The main result of this paper is that for all $\beta \in (0, 4)$, as $h \to 0$ the functionals $h^{-\beta} I_h$ converge (in the sense of Γ-convergence) to the limit functional $I_0 : X(S) \times W^{1,2}_0(S) \to [0, \infty]$, defined as

$$I_0(u, v) := \inf \left\{ \frac{1}{2} \int_S Q_2 \left((\operatorname{sym} D'u + M)(x') + \frac{\nabla' v(x') \otimes \nabla' v(x')}{2} \right) dx' : \right.$$
$$\left. M \in \mathcal{M}(\mathbb{R}^2, \mathbb{R}^{2\times 2}_+),\ \operatorname{sym} D'\overline{u} + M \in L^1(\mathbb{R}^2, \mathbb{R}^{2\times 2}_+) \right\}.$$

Here $Q_2 : \mathbb{R}^{2\times 2} \to [0, \infty)$ is the quadratic form

$$Q_2(A) := \min \left\{ Q_3(\operatorname{sym} A + \operatorname{sym}(a \otimes e_3)) : a \in \mathbb{R}^3 \right\},$$

and $Q_3 : \mathbb{R}^{3\times 3} \to [0, \infty)$ is the Hessian of the energy at the identity, i.e.,

$$Q_3(F) := \nabla^2 W(\mathrm{Id}_3)[F, F].$$

By (W3) the quadratic forms Q_2 and Q_3 are positive definite on symmetric matrices. If $u \in W^{1,1}(S, \mathbb{R}^2)$ and $I_0(u, v) < \infty$, as one can see, the above expression for I_0 reduces to

$$I_0(u, v) = \frac{1}{2} \int_S W_{\mathrm{F\ddot{o}}}(\nabla' u(x'), \nabla' v(x')) dx', \tag{2.4}$$

where $W_{\mathrm{F\ddot{o}}} : \mathbb{R}^{2\times 2} \times \mathbb{R}^2 \to [0, \infty)$ is defined by

$$W_{\mathrm{F\ddot{o}}}(A, b) := \min \left\{ Q_2 \left(\operatorname{sym} A + \frac{b \otimes b}{2} + M \right) : M = M^T,\ M \geq 0 \right\}.$$

We notice that $W_{\mathrm{F\ddot{o}}}$ is a convex function; see Lemma A.2 in the appendix. In the special case mentioned in the introduction, which corresponds to $Q_3(F) = |F|^2$, we get $Q_2(A) = |A|^2$, and $W_{\mathrm{F\ddot{o}}}(A, b)$ coincides, up to a normalization factor, with $W_{\mathrm{rel}}(A + b \otimes b)$ as given after (1.2).

The minimization over positive-definite matrices entering the definition of $W_{\mathrm{F\ddot{o}}}$ corresponds to the relaxation of compression by means of oscillations, and implies that $W_{\mathrm{F\ddot{o}}}$ vanishes on all contractions. This minimization was not present in the original theory by Föppl (i.e., he used $\tilde{W}_{\mathrm{F\ddot{o}}} = Q_2(\operatorname{sym} A + b \otimes b/2)$). This difference is the geometrically linear analogue of the difference between the membrane theory rigorously derived by Le Dret and Raoult [17, 18] and those that had been heuristically proposed before.

We now give a precise statement of our convergence result.

THEOREM 2.1. *Let $S \in \mathbb{R}^2$ be a bounded, strictly star-shaped, Lipschitz domain, and let W satisfy* (W1), (W2), (W3). *Then for every $\beta \in (0,4)$ the functionals $h^{-\beta} I_h$ Γ-converge (as $h \to 0$) to the relaxed Föppl functional I_0. More precisely we have the following:*

I. Compactness. For every sequence $h \to 0$ and every y_h such that

$$\limsup_{h\to 0} h^{-\beta} I_h(y_h) < \infty,$$

the sequences (u_h, v_h) defined by (2.1)–(2.2) *have a subsequence such that*

$$\begin{aligned} u_h &\rightharpoonup u \text{ weakly in } L^2(S,\mathbb{R}^2),\\ \operatorname{sym}\nabla' u_h &\overset{*}{\rightharpoonup} \operatorname{sym} D' u \text{ weakly* in } \mathcal{M}(S,\mathbb{R}^{2\times 2}),\\ v_h &\rightharpoonup v \text{ weakly in } W^{1,2}_0(S,\mathbb{R}^2) \end{aligned}$$

for some $u \in X(S)$ and $v \in W^{1,2}_0(S)$.

II. Lower bound. Under the same assumptions, and along the same subsequence,

$$\liminf_{h\to 0} \frac{I_h(y_h)}{h^\beta} \geq I_0(u,v).$$

III. Upper bound. For every pair of functions $u \in X(S)$ and $v \in W^{1,2}_0(S)$ and every sequence $h \to 0$ there exists a sequence of functions $y_h \in C^\infty(\Omega_1,\mathbb{R}^3)$ with $y_h(x) = x' + h x_3 e_3$ for $x \in \partial S \times (-1/2, 1/2)$ and such that the pair $(u_h, v_h) \in C^\infty_0(S,\mathbb{R}^2) \times C^\infty_0(S)$ defined via (2.1)–(2.2) *converges to (u,v) as above, and*

$$\lim_{h\to 0} \frac{I_h(y_h)}{h^\beta} = I_0(u,v).$$

By strictly star-shaped we mean that there is a point $x \in S$ such that for each $y \in \partial S$ the open segment (x,y) is contained in S. Parts I and II of the theorem hold for generic bounded Lipschitz domains.

We recall that such a Γ-convergence result implies convergence of minimizers, in the sense that Theorem 2.1 implies that the set of minima of I_0 coincides with the set of accumulation points of asymptotically minimizing sequences for $h^{-\beta} I_h$. Explicitly, (u,v) is a minimizer of I_0 if and only if there is a sequence y_h, converging to (u,v) as above, such that $h^{-\beta}[I_h(y_h) - \inf I_h] \to 0$.

Further, the same holds if a continuous perturbation, such as external forces, is included. In the relevant case of normal forces, this means that the sequence of functionals

$$h^{-\beta}\left[I_h(y_h) + \int_{\Omega_1} f_h(x')\,(y_h(x) - hx)\cdot e_3 dx\right]$$

Γ-converges to

$$I_0(u,v) + \int_S f(x')v(x')dx',$$

provided that $h^{3\beta/4}f_h(x')$ converges to f in $L^2(S)$.

We remark that the range of scalings covered by the present result ($\beta \in (0,4)$) is much broader than the one covered by the corresponding Γ-convergence results obtained without clamped boundary conditions. Indeed, without boundary conditions, different Γ-limits for $h^{-\beta}I_h$ have been determined for $\beta \in (0,5/3)$, $\beta = 2$, $\beta \in (2,4)$ (no result is yet known for $\beta \in [5/3,2)$). The two extreme cases $\beta = 0$ and $\beta = 4$ are special both in the presence or in the absence of clamped boundary conditions. We refer to [10] for a more complete presentation of these different regimes.

3. Proof of Theorem 2.1. We prove the three parts in sequence. We start from the argument for the compactness part, which is more specific to this situation where the energy has very little coercivity and different growth conditions in different variables. The form (1.1) shows that in this scaling regime one cannot expect to have a local coercivity. Compactness is gained by means of the boundary conditions. Indeed, the boundary values imply that ∇u_h has a zero average; hence the integral of $|\nabla v_h|^2$ is controlled by the energy. This gives control of ∇v_h in L^2, but of $\operatorname{sym}\nabla u_h$ only in L^1.

The lower bound is obtained by a standard argument exploiting the form of W close to the minimum, again with some subtleties arising from the weakness of the topologies.

Finally, in the upper bound an explicit construction is needed, which characterizes the folds which are used to reduce the energy of compressive deformations. In a first step we reduce to smooth displacements (u,v) with compact support, using the star-shapedness of S and the convexity of $W_{\mathrm{F\ddot{o}}}$. Then we provide a construction which reverses the relaxation. This is based on the explicit definition of oscillatory sequences which reduce the energy of compressive deformations. From the viewpoint of nonlinear elasticity the typical construction can be seen as a laminate between isometric deformations, whose average is, in general, a short deformation, i.e., a deformation whose gradient lies in the convex hull of the set of isometries $O(2,3)$.

Proof.

Part I: *Compactness.* We have a family of deformations y_h such that

$$y_h(x) = x' + hx_3e_3 \quad \forall x \in \partial S \times (-1/2, 1/2); \tag{3.1}$$

$$\int_{\Omega_1} W(\nabla_h y_h(x))dx \le Ch^\beta. \tag{3.2}$$

We now introduce new functions which characterize the deviation of the elastic deformation y_h from the identity $x' + hx_3e_3$. Since we are dealing with thin sheets it is natural to separate the tangential and the normal displacement. Therefore we consider $U_h \in W^{1,2}(\Omega_1, \mathbb{R}^2)$ and $V_h \in W^{1,2}(\Omega_1)$ defined by

$$y_h(x) = x' + hx_3e_3 + U_h(x) + V_h(x)e_3.$$

Equivalently,

$$U_h(x) := (y_h(x) - x)', \quad V_h(x) := (y_h(x) - hx) \cdot e_3.$$

The gradients are related by

$$\nabla_h y_h(x) = \mathrm{Id}_3 + \nabla' U_h(x) + e_3 \otimes \nabla' V_h(x) + \frac{1}{h}(\partial_3 U_h(x) + \partial_3 V_h(x) e_3) \otimes e_3.$$

The tangential nonlinear strain takes the form

$$\big[(\nabla_h y_h)^T \nabla_h y_h - \mathrm{Id}_3\big]' = 2\mathrm{sym}\,\nabla' U_h + (\nabla' U_h)^T(\nabla' U_h) + \nabla' V_h \otimes \nabla' V_h \tag{3.3}$$

(recall that F' denotes projection of F onto $\mathbb{R}^{2\times 2}$, and that $(\mathrm{Id}_3 + F)^T(\mathrm{Id}_3 + F) = \mathrm{Id}_3 + 2\mathrm{sym}\,F + F^T F$).

Integrating (3.3) over $x' \in S$ the first term cancels, since $\int_S \nabla' U(x)dx' = 0$ by (3.1). Taking the trace and integrating over $x_3 \in (-1/2, 1/2)$ leads to

$$\int_{\Omega_1} |\nabla' U_h(x)|^2 + |\nabla' V_h(x)|^2 dx = \mathrm{Tr} \int_{\Omega_1} \big[(\nabla_h y_h)^T \nabla_h y_h - \mathrm{Id}_3\big]' dx \le C h^{\beta/2}. \tag{3.4}$$

In the last step we used $|F^T F - \mathrm{Id}| \le C\mathrm{dist}(F, SO(3)) + C\mathrm{dist}^2(F, SO(3))$, (W3) and (3.2). Plugging this information back into (3.3) gives an analogous bound for $\mathrm{sym}\,\nabla' U_h$ in $L^1(\Omega_1; \mathbb{R}^{2\times 2}_{\mathrm{sym}})$. Summarizing we have

$$\int_{\Omega_1} |\mathrm{sym}\,\nabla' U_h(x)| + |\nabla' U_h(x)|^2 + |\nabla' V_h(x)|^2 dx \le C h^{\beta/2}. \tag{3.5}$$

Therefore it is natural to rescale the tangential displacement U_h by $h^{\beta/2}$, and the normal one V_h by $h^{\beta/4}$.

Taking averages over x_3, we define the rescaled displacements $u_h \in W^{1,2}_0(S, \mathbb{R}^2)$ and $v_h \in W^{1,2}_0(S)$ by

$$u_h(x') := \frac{1}{h^{\beta/2}} \int_{-1/2}^{1/2} U_h(x', x_3) dx_3, \quad v_h(x') := \frac{1}{h^{\beta/4}} \int_{-1/2}^{1/2} V_h(x', x_3) dx_3.$$

This definition is equivalent to (2.1) and (2.2) above.

By (3.5) the sequence $\nabla' v_h$ is bounded in $L^2(S, \mathbb{R}^2)$; hence there is a subsequence such that

$$v_h \rightharpoonup v \text{ weakly in } W^{1,2}_0(S). \tag{3.6}$$

By (3.5) the sequence $\mathrm{sym}\,\nabla' u_h$ is bounded in $L^1(S, \mathbb{R}^{2\times 2}_{\mathrm{sym}})$, and since $u_h \in W^{1,2}_0$ we can apply the Poincaré–Korn inequality [25] (see also [15, 16] and [26, sect. II.1]) to find

$$\|u_h\|_{L^2(S,\mathbb{R}^2)} \le C \|\mathrm{sym}\,\nabla' u_h\|_{L^1(S, \mathbb{R}^{2\times 2}_{\mathrm{sym}})} \le C.$$

In particular there is a subsequence and $u \in L^2$ such that

$$u_h \rightharpoonup u \qquad \text{weakly in } L^2(S, \mathbb{R}^2)\,. \tag{3.7}$$

Further, $\nabla' u_h$ converges to $D'u$ in the sense of distributions, and by (3.5)

$$\mathrm{sym}\,\nabla' u_h(x')dx' \overset{*}{\rightharpoonup} \mathrm{sym}\,D'u \qquad \text{weakly* in } \mathcal{M}(S, \mathbb{R}^{2\times 2}_{\mathrm{sym}})\,. \tag{3.8}$$

This is the compactness entailed in the functionals under considerations. We now use this information to obtain a lower bound that in turn will also allow us to prove that $u \in X(S)$.

Part II: *Lower bound*. The first part of the argument is along the lines of [12], and in a sense it constitutes the "generic" lower bound argument used in the regime $I_h(y_h) \to 0$, i.e., for $\nabla_h y_h$ close to $SO(3)$. In this range it is natural to "normalize" the deformation gradients $\nabla_h y_h$ in order to use the structure of W near $SO(3)$. This amounts to considering a field of rotations $R_h : \Omega_1 \to SO(3)$ such that

$$|\nabla_h y_h(x) - R_h(x)| = \operatorname{dist}(\nabla_h y_h(x), SO(3)).$$

The function R_h can be chosen to be measurable (see Lemma A.6 in the appendix), and hence in $L^\infty(\Omega_1, \mathbb{R}^{3\times 3})$. We also note (see Lemma A.1 in the appendix) that

$$R_h(x)^T \nabla_h y_h(x) \in \mathbb{R}^{3\times 3}_{\mathrm{sym}}.$$

Consider now

$$G_h := \frac{R_h^T \nabla_h y_h - \mathrm{Id}_3}{h^{\beta/2}}. \tag{3.9}$$

Since $|G_h| = \operatorname{dist}(\nabla_h y_h, SO(3))/h^{\beta/2}$, from (W3) and (3.2) we get that G_h is uniformly bounded in L^2, and taking a subsequence,

$$G_h \rightharpoonup G \quad \text{weakly in } L^2(\Omega_1, \mathbb{R}^{3\times 3}).$$

We now use Taylor's formula to obtain a lower bound in terms of the second derivatives of W at the identity. Precisely, by (W1) and (W2) there is $\rho : \mathbb{R}_+ \to \mathbb{R}$ such that $\lim_{t\to 0} \rho(t)/t^2 = 0$ and

$$\begin{aligned} W(\nabla_h y_h) &= W(\mathrm{Id}_3 + R_h^T \nabla_h y_h - \mathrm{Id}_3) \\ &\geq \frac{1}{2} Q_3(R_h^T \nabla_h y_h - \mathrm{Id}_3) - \rho\left(|R_h^T \nabla_h y_h - \mathrm{Id}_3|\right). \end{aligned}$$

It is convenient to consider separately the part of the domain where $\nabla_h y_h$ is close to a rotation, which is large, and the small exceptional set. To do this, let

$$\omega_h = \{x \in \Omega_1 : \operatorname{dist}(\nabla_h y_h(x), SO(3)) \leq h^{\beta/4}\}.$$

Let χ_h be the characteristic function of ω_h. By (W3) and (3.2) we get $|\omega_h| \to |\Omega_1|$. Restricting the integration to ω_h we get

$$\begin{aligned} \frac{I_h(y_h)}{h^\beta} \geq{}& \frac{1}{2} \int_{\Omega_1} \chi_h(x) Q_3\left(\frac{R_h(x)^T \nabla_h y_h(x) - \mathrm{Id}_3}{h^{\beta/2}}\right) dx \\ &- \frac{1}{h^\beta} \int_{\Omega_1} \chi_h(x) \rho\left(\operatorname{dist}(\nabla_h y_h(x), SO(3))\right) dx. \end{aligned} \tag{3.10}$$

The second term goes to zero as $h \to 0$, for it is equal to the integral of

$$\frac{\chi_h \ \rho\left(\operatorname{dist}(\nabla_h y_h, SO(3))\right)}{\operatorname{dist}^2(\nabla_h y_h, SO(3))} \cdot \frac{\operatorname{dist}^2(\nabla_h y_h, SO(3))}{h^\beta}.$$

By the definition of ω_h the first fraction converges uniformly to zero as $h \to 0$, at the same time the second one is uniformly bounded in L^1 by (3.2).

As $\chi_h(x) \in \{0,1\}$ we also have $\chi_h Q_3(G_h) = Q_3(\chi_h G_h)$, and since $\chi_h G_h \rightharpoonup G$ weakly in $L^2(\Omega_1, \mathbb{R}^{3\times 3})$ we easily conclude from (3.10) that

$$\liminf_{h\to 0} \frac{I_h(y_h)}{h^\beta} \geq \frac{1}{2}\int_{\Omega_1} Q_3(G(x))dx.$$

Note that G is symmetric, as was G_h.

In order to extract further information on G it is useful to express it as a limit of a sequence not involving R_h. Since $\nabla_h y_h = R_h(\mathrm{Id}_3 + h^{\beta/2}G_h)$ we get

$$(\nabla_h y_h)^T(\nabla_h y_h) = \mathrm{Id}_3 + 2h^{\beta/2}G_h + h^\beta G_h^T G_h$$

and thus

(3.11)
$$G_h - \frac{(\nabla_h y_h)^T(\nabla_h y_h) - \mathrm{Id}_3}{2h^{\beta/2}} = -\frac{h^{\beta/2}}{2}G_h^T G_h \to 0 \quad \text{strongly in } L^1(\Omega_1, \mathbb{R}^{3\times 3}).$$

In particular

$$\frac{(\nabla_h y_h)^T(\nabla_h y_h) - \mathrm{Id}_3}{2h^{\beta/2}} \rightharpoonup G \quad \text{weakly in } L^1(\Omega_1, \mathbb{R}^{3\times 3}). \tag{3.12}$$

As $G(x)$ is symmetric we have $Q_3(G(x)) \geq Q_2(G(x)')$. Furthermore, as Q_2 is convex, we can apply Jensen's inequality in the x_3 direction and find

$$\liminf_{h\to 0} \frac{I_h(y_h)}{h^\beta} \geq \frac{1}{2}\int_S Q_2(A(x'))dx',$$

where

$$A(x') = \int_{-1/2}^{1/2} G(x' + x_3 e_3)' dx_3 \quad \forall x' \in S\,.$$

It remains to relate A to u and v. To do this, we consider the integral over $x_3 \in (-1/2, 1/2)$ of the nonlinear strain,

$$A_h(x') := \int_{-1/2}^{1/2} \frac{\left[(\nabla_h y_h)^T(\nabla_h y_h) - \mathrm{Id}_3\right]'}{2h^{\beta/2}} dx_3.$$

By (3.12) we have

$$A_h \rightharpoonup A \text{ weakly in } L^1(S, \mathbb{R}^{2\times 2})\,. \tag{3.13}$$

At the same time, dividing (3.3) by $2h^{\beta/2}$ and integrating over x_3 gives

$$A_h(x') = \frac{1}{h^{\beta/2}}\int_{-1/2}^{1/2} \mathrm{sym}\,\nabla' U_h(x) + \frac{\nabla' V_h(x)\otimes\nabla' V_h(x)}{2} + \frac{\nabla' U_h(x)^T\nabla' U_h(x)}{2} dx_3.$$

The first term equals $\mathrm{sym}\,\nabla' u_h(x')$, and the other two can be bounded via Jensen's inequality, leading to

$$A_h(x') \geq \mathrm{sym}\,\nabla' u_h(x') + \frac{\nabla' v_h(x')\otimes\nabla' v_h(x')}{2} + h^{\beta/2}\nabla' u_h(x')^T\nabla' u_h(x').$$

As v_h is bounded in $W^{1,2}(S)$ we have that $\nabla v_h \otimes \nabla v_h$ converges weakly* to a measure $\mu \in \mathcal{M}(S, \mathbb{R}^{2\times 2})$, and by a standard lower semicontinuity argument $\mu \geq \nabla v \otimes \nabla v$. Using (3.8) and the fact that the third term on the right-hand side is positive semidefinite, we conclude that

$$A(x')\,dx' \geq \operatorname{sym} D'u + \frac{\nabla' v(x') \otimes \nabla' v(x')}{2}\,dx'. \tag{3.14}$$

The difference of the two sides of this inequality defines a Radon measure on S with values in $\mathbb{R}^{2\times 2}_+$ that we denote by M. In particular $\operatorname{sym} D'u + M$ is absolutely continuous with respect to the Lebesgue measure as

$$\operatorname{sym} D'u + M = \left\{ A(x') - \frac{\nabla' v(x') \otimes \nabla' v(x')}{2} \right\} dx'.$$

Finally,

$$\liminf_{h\to 0} \frac{I_h(y_h)}{h^\beta} \geq \frac{1}{2} \inf \left\{ \int_S Q_2 \left((\operatorname{sym} D'u + M)(x') + \frac{\nabla' v(x') \otimes \nabla' v(x')}{2} \right) dx' \right\},$$

where the infimum runs over all $M \in \mathcal{M}(S, \mathbb{R}^{2\times 2}_+)$ such that $\operatorname{sym} D'u + M \in L^1(S, \mathbb{R}^{2\times 2}_{\operatorname{sym}})$.

Finally, we repeat the argument for $\overline{y}_h(x) := y_h(x)$ if $x \in S \times (-h/2, h/2)$, $\overline{y}_h(x) := x' + hx_3 e_3$ if $x \in (\mathbb{R}^2 \setminus S) \times (-h/2, h/2)$. As $W(\mathrm{Id}_3) = 0$ and $Q_3(0) = Q_2(0) = 0$ the above argument can be repeated without any change, and we find that there exists a measure $M \in \mathcal{M}(\mathbb{R}^2, \mathbb{R}^{2\times 2}_+)$ such that $\operatorname{sym} D'\overline{u} + M \in L^1(\mathbb{R}^2, \mathbb{R}^{2\times 2}_{\operatorname{sym}})$. Thus $u \in X(S)$.

Part III: *Upper bound.* We are given $u \in X(S)$ and $v \in W^{1,2}_0(S)$ with $I_0(u, v) < \infty$ (otherwise there is nothing to prove), and we have to construct a recovery sequence. We shall now use the star-shapedness of S to show that it suffices to consider u and v with compact support in S; then we use convexity of $W_{\mathrm{F\ddot{o}}}$ to show that it suffices to consider smooth u and v, and finally we provide an explicit construction.

After a translation we can assume that S is star-shaped with respect to the origin. Fix $\varepsilon > 0$ and consider the functions

$$u_\varepsilon(x') = \frac{1}{1+\varepsilon}\,\bar{u}((1+\varepsilon)x')\,, \qquad v_\varepsilon(x') = \frac{1}{1+\varepsilon}\,\bar{v}((1+\varepsilon)x')\,.$$

As above, we denote by a bar extension by zero outside S, so that, e.g., $\bar{u} = u$ on S and $\bar{u} = 0$ in $\mathbb{R}^2 \setminus S$. It is clear that u_ε and v_ε are supported on $S/(1+\varepsilon) \subset\subset S$. At the same time $u_\varepsilon \in X(S)$ (as $u \in X(S)$), $v_\varepsilon \in W^{1,2}_0(S)$, and, as $\varepsilon \to 0$,

$$(u_\varepsilon, v_\varepsilon) \rightharpoonup (u, v) \qquad \text{weakly}* \text{ in } X(S) \times W^{1,2}(S),$$

(i.e., in the convergence stated in Part I). Now we remark that

$$I_0(u_\varepsilon, v_\varepsilon) \leq (1+\varepsilon)^{-2} I_0(u, v). \tag{3.15}$$

This follows from a change of variables, once one has proven that $\nabla' v_\varepsilon(x') = \nabla' v((1+\varepsilon)x')$ and that for any $M \in \mathcal{M}(\mathbb{R}^2, \mathbb{R}^{2\times 2}_+)$ such that $\operatorname{sym} D'\overline{u} + M \in L^1(\mathbb{R}^2, \mathbb{R}^{2\times 2}_+)$ we can find $M_\varepsilon \in \mathcal{M}(\mathbb{R}^2, \mathbb{R}^{2\times 2}_+)$ such that

$$\operatorname{sym} D'\overline{u_\varepsilon} + M_\varepsilon = (\operatorname{sym} D'\overline{u} + M)((1+\varepsilon)x')dx'.$$

We now show how to construct M_ε. Since

$$\operatorname{sym} D'\overline{u_\varepsilon} = \frac{1}{(1+\varepsilon)^2}\left[\frac{1}{1+\varepsilon}\mathrm{Id}_2 \# \operatorname{sym} D'\overline{u}\right]$$

(where # stands for the push-forward of measures, that is, $f\#\mu(E) := \mu(f^{-1}(E))$), it suffices to choose

$$M_\varepsilon := \frac{1}{(1+\varepsilon)^2}\left[\frac{1}{1+\varepsilon}\mathrm{Id}_2 \# M\right].$$

This concludes the proof of (3.15). From now on we assume that (u,v) is supported on $S_0 \subset\subset S$.

To show that (u,v) can be assumed to be smooth, fix $\delta < \operatorname{dist}(S_0, \partial S)$, and set

$$u_\delta(x') = \int_{S_0} \rho_\delta(x'-y')u(y')dy', \qquad v_\delta(x') = \int_{S_0} \rho_\delta(x'-y')v(y')dy',$$

where ρ_δ is a standard mollification kernel on the scale δ, i.e., $\rho_\delta(x') = \delta^{-2}\rho(x'/\delta)$ for $\rho \in C_c^\infty(B^2)$, $\int_{\mathbb{R}^2}\rho = 1$. Then automatically $(u_\delta, v_\delta) \in C_c^\infty(S,\mathbb{R}^2)\times C_c^\infty(S)$, and as $\delta \to 0$ we have $(u_\delta, v_\delta) \to (u,v)$ weakly in $X(S)\times W^{1,2}(S)$. It remains to show that $\limsup_{\delta\to 0} I_0(u_\delta, v_\delta) \le I_0(u,v)$. To see this let $M \in \mathcal{M}(\mathbb{R}^2, \mathbb{R}^{2\times 2}_+)$ be such that $f = \operatorname{sym} D'\overline{u} + M \in L^1(\mathbb{R}^2, \mathbb{R}^{2\times 2}_{\mathrm{sym}})$, and

$$I_0(u,v) \le \frac{1}{2}\int_S Q_2\left((\operatorname{sym} D'u + M)(x') + \frac{\nabla v(x')\otimes\nabla v(x')}{2}\right)dx' + \delta$$

(M and f will depend on δ). Then

$$\nabla' u_\delta(x') = \int_S \rho_\delta(x'-y')f(y')dy' - \int_S \rho_\delta(x'-y')dM(y'),$$

where the second integral takes values in the (convex) set $\mathbb{R}^{2\times 2}_+$. We now use that $W_{\mathrm{F\ddot{o}}}$ is nondecreasing in its (matrix-valued) first argument and that it is convex to obtain

$$\begin{aligned}\int_S W_{\mathrm{F\ddot{o}}}(\nabla' u_\delta, \nabla' v_\delta)dx' &\le \int_S W_{\mathrm{F\ddot{o}}}(\rho_\delta * f, \rho_\delta * \nabla' v)dx' \\ &\le \int_S W_{\mathrm{F\ddot{o}}}(f, \nabla' v)dx'.\end{aligned}$$

On the smooth functions (u_δ, v_δ) we can use (2.4), and since $W_{\mathrm{F\ddot{o}}} \le Q_2$, we get

$$I_0(u_\delta, v_\delta) \le I_0(u,v) + \delta.$$

It remains to prove the thesis for the case $u \in C_c^\infty(S,\mathbb{R}^2)$, $v \in C_c^\infty(S)$. We first show that for every $j \in \mathbb{N}$ we can find $M_j \in L^\infty(S, \mathbb{R}^{2\times 2}_+)$ and $a_j \in C_c^\infty(S,\mathbb{R}^3)$ such that

$$\frac{1}{2}\int_S Q_3\left(\operatorname{sym}\,(\nabla' u + a_j\otimes e_3) + \frac{\nabla' v\otimes\nabla' v}{2} + M_j\right)dx' \le I_0(u,v) + \frac{C}{j}, \tag{3.16}$$

with M_j taking only a finite number of values, each of them on a Lipschitz subset of S. To see this, consider a subdivision of S into small squares, say of side l_j. The

oscillation of the smooth fields ∇u and ∇v on each square is uniformly small; hence—provided l_j is small enough—on each square we can pick one value of a and one value of M so that

$$Q_3\left(\operatorname{sym}\,(\nabla' u + a_j \otimes e_3) + \frac{\nabla' v \otimes \nabla' v}{2} + M_j\right) \le W_{\mathrm{F\ddot{o}}}(\nabla' u, \nabla' v) + \frac{1}{j}\,.$$

Further, on the squares intersecting ∂S we can choose $a = 0$, since u and v have zero boundary values. This defines piecewise constant fields a_j and M_j with the required property. Smoothing a_j concludes the proof of (3.16).

Claim. Given $u \in C_0^\infty(S, \mathbb{R}^2)$, $v \in C_0^\infty(S)$, $a \in C_0^\infty(S, \mathbb{R}^3)$, and $M \in L^\infty(S, \mathbb{R}^{2\times 2}_+)$, taking finitely many values on Lipschitz subsets of S, *there exists* a sequence $y_h \in C^\infty(\Omega_1, \mathbb{R}^3)$ such that $y_h(x) = x' + hx_3 e_3$ for $x \in \partial S \times (-1/2, 1/2)$; the functions u_h and v_h defined as in (2.1) and (2.2) satisfy (3.6), (3.7), and (3.8); the scaled nonlinear strain

$$F_h := \frac{(\nabla_h y_h)^T(\nabla_h y_h) - \mathrm{Id}_3}{2h^{\beta/2}}$$

converges to

$$F_h \to \operatorname{sym}\,(\nabla' u + a \otimes e_3) + \frac{\nabla' v \otimes \nabla' v}{2} + M \quad \text{strongly in } L^2(\Omega_1, \mathbb{R}^{3\times 3}); \tag{3.17}$$

and such that there is a field of rotations $R_h \in L^\infty(\Omega_1, SO(3))$ such that

$$\|R_h^T \nabla_h y_h - \mathrm{Id}_3\|_{L^\infty(S, \mathbb{R}^{3\times 3})} \le C h^{\beta/2} \tag{3.18}$$

for some constant C which does not depend on h.

Assume for the moment that this can be done. By (W1) and (W2) we get

$$W(\nabla_h y_h) = W(R_h^T \nabla_h y_h) = \frac{1}{2} Q_3\left(R_h^T \nabla_h y_h - \mathrm{Id}_3\right) + o(|R_h^T \nabla_h y_h - \mathrm{Id}_3|^2),$$

so that by (3.18) it follows that

$$\lim_{h\to 0} \frac{1}{h^\beta} \int_{\Omega_1} W(\nabla_h y_h) dx = \lim_{h\to 0} \frac{1}{2} \int_{\Omega_1} Q_3\left(G_h\right) dx < \infty,$$

where $G_h := h^{-\beta/2}(R_h^T \nabla_h y_h - \mathrm{Id}_3)$. By (3.18) G_h is bounded in L^∞. Then $F_h - G_h = 2^{-1} h^{\beta/2} G_h^T G_h$ (compare with (3.11)) converges strongly to zero in L^∞, while by (3.17) F_h itself has a strong limit in L^2. Therefore G_h converges strongly in L^2 to the same limit as F_h, and this limit is

$$G(x) := \operatorname{sym}\,(\nabla' u(x') + a(x') \otimes e_3) + \frac{\nabla' v(x') \otimes \nabla' v(x')}{2} + M(x')\,.$$

This expression does not depend on x_3, and recalling (3.16) we get

$$\lim_{h\to 0} \frac{1}{h^\beta} \int_{\Omega_1} W(\nabla_h y_h) dx = \int_{\Omega_1} Q_3\left(G(x)\right) dx = \int_S Q_3\left(G(x')\right) dx' = I_0(u, v) + \frac{C}{j},$$

which is the thesis.

Now we prove the claim. Let us define

$$y_h(x) := x' + hx_3e_3 + h^{\beta/2}(u(x') + \xi_h(x')) + h^{\beta/4}(v(x') + \varphi_h(x'))e_3 \\ + h\,x_3\left(h^{\beta/4}b_h(x') + h^{\beta/2}s_h(x')e_3 + h^{\beta/2}a(x')\right),$$

where $b_h \in C_0^\infty(S,\mathbb{R}^2)$, $s_h \in C_0^\infty(S)$, $\xi_h \in C_0^\infty(S,\mathbb{R}^2)$, and $\varphi_h \in C_0^\infty(S)$ have to be chosen properly. The choice of these spaces ensures that the boundary condition $y_h(x) = x' + hx_3e_3$ for $x \in \partial S \times (-1/2, 1/2)$ is satisfied. Further, we shall choose all those functions to be uniformly Lipschitz (i.e., their gradients are bounded by a constant which can depend on M, u, and v, but not on h).

The linear term in x_3 cancels under integration over $x_3 \in (-1/2, 1/2)$; the sequences u_h and v_h defined via (2.1) and (2.2) satisfy

$$u_h = u + \xi_h, \quad v_h = v + \varphi_h.$$

We shall choose $\xi_h \in C_0^\infty(S,\mathbb{R}^2)$ and $\varphi_h \in C_0^\infty(S)$ in such a way that

$$\xi_h \rightharpoonup 0 \qquad \text{weakly in } W^{1,2}(S,\mathbb{R}^2), \tag{3.19}$$

$$\varphi_h \rightharpoonup 0 \qquad \text{weakly in } W^{1,4}(S), \tag{3.20}$$

$$\|(\nabla')^2\varphi_h\|_{L^\infty(S,\mathbb{R}^{2\times 2})} \le \frac{C}{\varepsilon_h} \tag{3.21}$$

for a suitable sequence $\varepsilon_h \to 0$ as $h \to 0$. Note that (3.19) and (3.20) ensure the convergence properties (3.6), (3.7), and (3.8).

Let us now note that we have

$$\nabla_h y_h = \mathrm{Id}_3 + h^{\beta/4}H_1 + h^{\beta/2}H_2 + h^{1+\beta/4}H_3 + h^{1+\beta/2}H_4, \tag{3.22}$$

where

$$H_1 := e_3 \otimes \nabla' v_h + b_h \otimes e_3,$$
$$H_2 := \nabla' u_h + a \otimes e_3 + s_h e_3 \otimes e_3,$$
$$H_3 := x_3 \nabla' b_h,$$
$$H_4 := x_3(\nabla' s_h + \nabla' a).$$

Expanding the nonlinear strain $(\nabla_h y_h)^T(\nabla_h y_h)$ via the rule $(\mathrm{Id}_3 + F)^T(\mathrm{Id}_3 + F) = \mathrm{Id}_3 + 2\mathrm{sym}\,F + F^TF$ we get

$$(\nabla_h y_h)^T(\nabla_h y_h) - \mathrm{Id}_3 = 2h^{\beta/4}\mathrm{sym}\,H_1 + h^{\beta/2}(2\mathrm{sym}\,H_2 + H_1^TH_1) + o(h^{\beta/2})J_h$$

for a suitable tensor field J_h that we shall consider again later on. In order to obtain a strain of order $h^{\beta/2}$ we need to render H_1 antisymmetric, which can be done by choosing

$$b_h := -\nabla' v_h. \tag{3.23}$$

In this way we find

$$F_h = \mathrm{sym}\,H_2 + \frac{H_1^TH_1}{2} + \frac{o(h^{\beta/2})}{2h^{\beta/2}}\,J_h \\ = \mathrm{sym}\,(\nabla' u_h + a \otimes e_3) + \left(s_h - \frac{|\nabla' v_h|^2}{2}\right)e_3 \otimes e_3 + \frac{\nabla' v_h \otimes \nabla' v_h}{2} + \frac{o(h^{\beta/2})}{2h^{\beta/2}}\,J_h.$$

Since we are looking for (3.17) we choose

$$s_h := -\frac{|\nabla' v_h|^2}{2}, \tag{3.24}$$

and then, in order to have (3.17), it remains to show that (i) ξ_h and φ_h can be chosen in such a way that (3.19), (3.20) hold and

$$\operatorname{sym}(\nabla'\xi_h + \nabla' v \otimes \nabla'\varphi_h) + \frac{\nabla'\varphi_h \otimes \nabla'\varphi_h}{2} \to M \quad \text{strongly in } L^2(S, \mathbb{R}^{2\times 2}); \tag{3.25}$$

and that (ii) the resulting tensor field J_h satisfies

$$\frac{o(h^{\beta/2})}{h^{\beta/2}} J_h \to 0 \quad \text{strongly in } L^2(S, \mathbb{R}^{2\times 2}). \tag{3.26}$$

This can be done as follows. Let us define

$$\xi_h = \psi_h - \varphi_h \nabla' v$$

for some $\psi_h \in W_0^{1,\infty}(S, \mathbb{R}^2)$ to be chosen later. Then we find

$$\begin{aligned}&\operatorname{sym}(\nabla'\xi_h + \nabla' v \otimes \nabla'\varphi_h) + \frac{\nabla'\varphi_h \otimes \nabla'\varphi_h}{2}\\ &= \operatorname{sym}\nabla'\psi_h + \frac{\nabla'\varphi_h \otimes \nabla'\varphi_h}{2} - \varphi_h(\nabla')^2 v.\end{aligned}$$

According to Lemma A.4 we can find $\psi_h \in C_0^\infty(S, \mathbb{R}^2)$ and $\varphi_h \in C_0^\infty(S)$ uniformly Lipschitz and such that (3.20) and (3.21) hold (with an ε_h that we can choose arbitrarily, provided it goes to zero), with

$$\operatorname{sym}\nabla'\psi_h + \frac{\nabla'\varphi_h \otimes \nabla'\varphi_h}{2} \to M$$

strongly in $L^2(S, \mathbb{R}^{2\times 2})$ and $\psi_h \rightharpoonup 0$ weakly in $W_0^{1,2}(S, \mathbb{R}^2)$. As a consequence the resulting sequence ξ_h will satisfy (3.19), and also (3.25) will hold true. We now prove that (3.26) is also true and (3.17) will be established. To this end let us note that, with the above choices of b_h, s_h, ξ_h and φ_h, we have that, for every h,

$$\begin{aligned}&\|H_1\|_{L^\infty(S,\mathbb{R}^{2\times 2})} + \|H_2\|_{L^\infty(S,\mathbb{R}^{2\times 2})} \le C,\\ &\|H_3\|_{L^\infty(S,\mathbb{R}^{2\times 2})} + \|H_4\|_{L^\infty(S,\mathbb{R}^{2\times 2})} \le C(1 + \|(\nabla')^2\varphi_h\|_{L^\infty(S,\mathbb{R}^{2\times 2})}).\end{aligned}$$

Then

$$\frac{o(h^{\beta/2})}{h^{\beta/2}}|J_h| \le C\left(h^{\beta/4} + h^{1-\beta/4}|(\nabla')^2\varphi_h|\right) \le C\left(h^{\beta/4} + \frac{h^{1-\beta/4}}{\varepsilon_h}\right).$$

Since we are working in the regime $0 < \beta < 4$, it suffices to choose $\varepsilon_h = h^{(1-\beta/4)/2}$.

In the end we prove (3.18). First of all let us note that for every $F \in \mathbb{R}^{3\times 3}$ we have

$$\operatorname{dist}(F, SO(3)) \le |\operatorname{sym} F - \mathrm{Id}_3| + C|F - \mathrm{Id}|^2,$$

an inequality that reflects the fact that the tangent space of $SO(3)$ at Id_3 is the space of antisymmetric matrices. Next we consider a measurable field $\mathbb{R}_h : S \to SO(3)$ such that $\operatorname{dist}(\nabla_h y_h, SO(3)) = |R_h - \nabla_h y_h|$. From (3.22) we deduce that $\|\nabla_h y_h - \mathrm{Id}_3\|_{L^\infty(S,\mathbb{R}^{3\times 3})} \le Ch^{\beta/4}$ (in particular R_h is uniquely defined) and that $\|\operatorname{sym}\nabla_h y_h - \mathrm{Id}_3\|_{L^\infty(S,\mathbb{R}^{3\times 3})} \le Ch^{\beta/2}$, as $\operatorname{sym} H_1 = 0$. Thus from the inequality we pointed out above we have $|R_h - \nabla_h y_h| \le Ch^{\beta/2}$, from which (3.18) immediately follows. ∎

4. Membranes with an applied normal force. The Γ-convergence result of Theorem 2.1 permits one to study the behavior of minimizing sequences for the physically relevant case where external forces are included without any a priori assumption on the scaling of the energy. The following discussion clarifies in particular that the scaling of the energy is dictated by the scaling of the applied forces. Precisely, we consider the extended functional

$$F_h(w_h,\Omega_h) = E(w_h,\Omega_h) - \frac{1}{h}\int_{\Omega_h} f_h(x')(w_h(x)-x)\cdot e_3\,dx\,. \tag{4.1}$$

Here and below $w_h \in \mathcal{A}_h$, where

$$\mathcal{A}_h := \left\{ w \in W^{1,2}(\Omega_h;\mathbb{R}^3) : \ \ w(x) = x \text{ on } \partial S \times \left(-\frac{h}{2},\frac{h}{2}\right)\right\}.$$

The normal force f_h is in $H^{-1}(S)$ (the dual space to $H^1_0(S) := W^{1,2}_0(S)$).

For any h and any f_h, one has $F_h(\mathrm{Id},\Omega_h) = 0$, where $\mathrm{Id}(x) = x$ is the identical map. Hence the infimum of F_h is always less than or equal to zero, and if it equals zero it is attained. Therefore we can construct sequences of almost-minimizers, i.e., sequences of deformations $w_h \in \mathcal{A}_h$ such that

$$\lim_{h\to 0} \frac{F_h(w_h,\Omega_h)}{\inf_{\mathcal{A}_h}\{F_h\}} = 1\,, \tag{4.2}$$

with the convention that $0/0 = 1$, and $t/0 = \infty$ for $t > 0$. We are interested in the behavior of such almost-minimizers of F_h for small h, assuming that the external forces f_h scale as h^α.

COROLLARY 4.1. *Let $f_h \in H^{-1}(S)$ be such that*

$$\frac{1}{h^\alpha} f_h \to f \qquad \text{in } H^{-1}(S) \tag{4.3}$$

for some $f \in H^{-1}(S)$ and some $\alpha \in (0,3)$. Let $w_h \in \mathcal{A}_h$ be a sequence of almost-minimizers of F_h, in the sense of (4.2)*. Then there exists a constant C (depending on the sequences $\{f_h\}$ and $\{w_h\}$) such that, for $\beta = 4\alpha/3$,*

$$-Ch^\beta \le \inf_{\mathcal{A}_h}\{F_h\} \le 0\,. \tag{4.4}$$

Moreover, there is a subsequence which converges to a limit $(\bar u,\bar v)$ in the sense specified in Theorem 2.1*. The limit $(\bar u,\bar v)$ minimizes the functional*

$$I_0(u,v) - \int_S f\,v\,dx', \tag{4.5}$$

and

$$\lim_{h\to 0}\frac{1}{h^\beta}\inf_{\mathcal{A}_h}\{F_h\} = \lim_{h\to 0}\frac{1}{h^\beta}F_h(w_h,\Omega_h) = I_0(\bar u,\bar v) - \int_S f\,\bar v\,dx'. \tag{4.6}$$

Finally, let $(\tilde u,\tilde v)$ be any minimizer of $I_0(u,v) - \int_S f v dx'$. Then there is a sequence $w_h \in \mathcal{A}_h$, converging in the sense specified in Theorem 2.1 *to $(\tilde u,\tilde v)$, which fulfills* (4.2) *and* (4.6)*.*

Proof. We define

$$E_h := E(w_h, \Omega_h) = \frac{1}{h}\int_{\Omega_h} W(\nabla w_h(x))dx = \int_{\Omega_1} W(\nabla_y y_h(x))dx \tag{4.7}$$

and first claim that $E_h \to 0$. Indeed, for sufficiently small h, one has $\|f_h\|_{H^{-1}} \le h^\alpha(\|f\|_{H^{-1}} + 1)$ and

$$\begin{aligned}\frac{1}{h}\int_{\Omega_h} f_h(x')(w_h(x) - x)\cdot e_3\, dx &= \int_S f_h(x')\int_{-h/2}^{h/2}(w_h(x) - x)\cdot e_3\, dx_3\, dx' \\ &\le Ch^\alpha\left(\|f\|_{H^{-1}(S)} + 1\right)\|\nabla'\bar v_h\|_{L^2(S)}\,,\end{aligned}$$

where

$$\bar v_h(x') := \int_{-h/2}^{h/2}(w_h(x) - x)\cdot e_3\, dx_3\,.$$

In turn, by assumption (W3) we have

$$|\nabla' w_h|^2 \le C\,(W(\nabla w_h) + 1)\,,$$

and therefore

$$\|\nabla'\bar v_h\|^2_{L^2(S)} \le \frac{1}{h}\|\nabla' w_h\|^2_{L^2(\Omega_h)} \le C(1 + E_h)\,.$$

We conclude that

$$F_h(w_h, \Omega_h) \ge E_h - Ch^\alpha\left(\|f\|_{H^{-1}(S)} + 1\right)(1 + E_h)^{1/2}\,.$$

By (4.2) and the fact that $\inf\{F_h\} \le F_h(\mathrm{Id}, \Omega_h) = 0$, it follows that for sufficiently small h we have

$$F_h(w_h, \Omega_h) \le 0\,. \tag{4.8}$$

Therefore $E_h \to 0$.

The proof of part I of Theorem 2.1 can now be repeated, replacing h^β by E_h in all statements, and no other change. Precisely, (4.7) replaces (3.2), in both (3.4) and (3.5) the estimate is in terms of $CE_h^{1/2}$, and the definitions of u_h and v_h are replaced by

$$\tilde u_h(x') := \frac{1}{E_h^{1/2}}\int_{-1/2}^{1/2} U_h(x', x_3)dx_3\,, \qquad \tilde v_h(x') := \frac{1}{E_h^{1/4}}\int_{-1/2}^{1/2} V_h(x', x_3)dx_3$$

(recall that $y_h(x) = w_h(x' + hx_3e_3) = x' + hx_3e_3 + U_h(x) + V_h(x)e_3$). We also obtain convergence as in (3.6), (3.7), and (3.8) for $\tilde u_h$ and $\tilde v_h$, and to some limit $\tilde u$ and $\tilde v$.

Consider now the forcing term. Arguing as above, we write

$$\frac{1}{h}\int_{\Omega_h} f_h(x')(w_h(x) - x)\cdot e_3\, dx = \int_{\Omega_1} f_h\, V_h\, dx = E_h^{1/4}\int_S f_h\, v_h\, dx'.$$

Since v_h is bounded in $W^{1,2}_0$ and $h^{-\alpha}f_h$ is bounded in the dual space H^{-1}, we obtain

$$F_h(w_h, \Omega_h) \ge E_h - CE_h^{1/4}h^\alpha\,. \tag{4.9}$$

Here and in the following C is a constant which depends on the sequences $\{f_h\}$ and $\{w_h\}$. Recalling (4.8), we see that, for sufficiently small h, $E_h \le CE_h^{1/4}h^\alpha$ and hence

$$E_h \le Ch^{4\alpha/3}. \tag{4.10}$$

In turn, this implies

$$F_h(w_h, \Omega_h) \ge -CE_h^{1/4}h^\alpha \ge -Ch^{4\alpha/3},$$

and (4.4) is proven.

By (4.10) we can apply Theorem 2.1 with $\beta = 4\alpha/3$. Let $\bar u$, $\bar v$ be the limit deformations in the sense of part I of Theorem 2.1, and fix that subsequence. Using part II of Theorem 2.1 and (4.3) we conclude that, along the same subsequence,

$$\liminf_{h\to 0} \inf_{\mathcal{A}_h} \frac{1}{h^{4\alpha/3}} F_h = \liminf_{h\to 0} \frac{1}{h^{4\alpha/3}} F_h(w_h, \Omega_h) \ge I_0(\bar u, \bar v) - \int_S f\,\bar v\,dx'. \tag{4.11}$$

At the same time, from part III of Theorem 2.1 for every $(\tilde u, \tilde v)$ there is a sequence $\tilde w_h$ converging to $(\tilde u, \tilde v)$ and such that

$$\lim_{h\to 0} \frac{1}{h^{4\alpha/3}} F_h(\tilde w_h, \Omega_h) = I_0(\tilde u, \tilde v) - \int_S f\,\tilde v\,dx'.$$

This shows in particular that

$$\liminf_{h\to 0} \inf_{\mathcal{A}_h} \frac{1}{h^{4\alpha/3}} F_h \le I_0(\tilde u, \tilde v) - \int_S f\,\tilde v\,dx';$$

hence the pair (u, v) is a minimizer of the limiting functional, and (4.11) is an equality. This concludes the proof of (4.6). Finally, taking $(\tilde u, \tilde v)$ to be any minimizer of the limiting functional we conclude the proof of the corollary. □

Appendix. We start by briefly analyzing the properties of the space $u \in X(S)$, the convex cone in $BD(S)$ that was introduced in (2.3) and that arises naturally in the determination of the domain of the Γ-limit I_0. General references for the space of functions of bounded deformation $BD(S)$ are, for example, the monograph by Temam [26] and the paper by Ambrosio, Coscia, and Dal Maso [2].

Let us recall that if $u \in BD(S)$, then

$$\operatorname{sym} D'u = f_u(x')dx' + \mu_u,$$

where $\mu_u \in \mathcal{M}(S, \mathbb{R}^{2\times 2}_{\rm sym})$ is singular with respect to the Lebesgue measure on S, and $f_u \in L^1(S, \mathbb{R}^{2\times 2})$ is the density of $\operatorname{sym} D'u$ with respect to the Lebesgue measure. Then $u \in X(S)$ if and only if $\mu_{\overline u} \le 0$, where $\overline u = u$ in S and $\overline u = 0$ in $\mathbb{R}^2 \setminus S$.

The structure of the singular part of the strain $\mu_{\overline u}$ can be further analyzed: indeed, it turns out that there is a rectifiable set J_u in S and that, once we have fixed an orientation of it in $\nu_u \in L^\infty(\mathcal{H}^1 \lfloor J_u, S^1)$, there are functions $u^+, u^- \in L^1(\mathcal{H}^1 \lfloor J_u, \mathbb{R}^2)$, and a measure $(\operatorname{sym} D'u)^c$ singular with respect to both dx' and $\mathcal{H}^1$, such that

$$\mu_{\overline u} = (\operatorname{sym} D'u)^c + \operatorname{sym}((u^+ - u^-) \otimes \nu_u) d\mathcal{H}^1 \lfloor J_u + \operatorname{sym}(-\operatorname{tr}(u) \otimes \nu_S) d\mathcal{H}^1 \lfloor \partial S,$$

where $\operatorname{tr}(u) \in L^1(\mathcal{H}^1 \lfloor \partial S, \mathbb{R}^2)$ is the trace of u on ∂S and ν_S is the outer normal to S. In particular the condition $\mu_{\overline u} \le 0$ implies the compatibility condition

$$u^+(x') - u^-(x') = -\lambda(x')\nu_u(x') \quad \text{for } \mathcal{H}^1\text{-a.e. } x' \in J_u$$

for a suitable $\lambda \in L^1(\mathcal{H}^1 \lfloor J_u, [0,\infty))$ (we recall that $\operatorname{sym} a \otimes b \leq 0$, with $b \neq 0$, if and only if $a = -\lambda b$). The sign condition on the boundary term gives analogously

$$\operatorname{tr}(u)(x') = \lambda(x')\nu_S(x') \quad \text{for } \mathcal{H}^1 \text{ a.e. } x' \in \partial S$$

for a function $\lambda \in L^1(\partial S, [0,\infty))$. The geometric meaning of the condition $(\operatorname{sym} D'u)^c \leq 0$ for the Cantor part of $\operatorname{sym} D'u$ is instead less clear as the validity of the "rank-one property" (established in the space BV by Alberti [1]) in BD is at present unknown.

One could ask if the sign condition $\mu_{\overline{u}} \leq 0$ is sufficient to gain more regularity for the distributional gradient $D'u$. It turns out that this is not the case, in the sense that there are functions in $X(S)$ that are not in $BV(S, \mathbb{R}^2)$. For example, let $S = (-1,1)^2$, and for $i > 2$ let $Q_i = (2^{-i}, 2^{-i+1})^2$. In each Q_i by [21, Theorem 1] (see also [6, Theorem 1]) there is $u_i \in C_0^\infty(Q_i, \mathbb{R}^2)$ such that

$$\int_{Q_i} |\operatorname{sym} \nabla' u_i| dx' \leq 2|Q_i|, \qquad \int_{Q_i} |\nabla' u_i| dx' \geq 2^i.$$

We set $u = u_i$ in Q_i, $u = 0$ on $S \setminus \cup Q_i$. It is clear that u is in $BD(S)$ but not in $BV(S; \mathbb{R}^2)$, and that it has zero trace on ∂S. To show that it is in X, it suffices to check that the symmetric part of the distributional gradient is absolutely continuous with respect to the Lebesgue measure. Since $u \in C^1(S \setminus \{0\}, \mathbb{R}^2)$, it suffices to check that the n-dimensional density of $\operatorname{sym} D'u$ at zero is finite. To this end let ρB^2 be the ball of radius ρ and center in the origin; then

$$|\operatorname{sym} D'u|(\rho B^2) \leq \sum_{\{i : Q_i \cap \rho B^2 \neq \emptyset\}} |\operatorname{sym} D'u|(Q_i) \leq 4|\rho B^2|\,.$$

This concludes the proof.

It is not clear if for the u constructed above we can find a $v \in W_0^{1,2}(S)$ such that $I_0(u,v) < \infty$. In other words, the question of whether the space $\{u \in X(S) : I_0(u,v) < \infty \text{ for some } v \in W_0^{1,2}(S)\}$ is contained in $BV(S, \mathbb{R}^2)$ remains open. It is, however, clear that this space is not more regular than BV. Indeed, let $f : (0,1) \to (0,1)$ be a generic monotonic BV function, and extend it to $\mathbb{R}$ by $f(t) = t$. Then set $u(x) = -(f(x_1) - x_1, 0)$, $v = 0$, $S = (-2,2)^2$. Then $I_0(u,v) < \infty$. This construction provides an example of where the jump and Cantor part of Du are nonzero.

The rest of the appendix is devoted to the statement and proof of some lemmas that were used in the proof of the upper bound. Of particular relevance in the description of the relaxation process of compressive deformations are Lemmas A.3 and A.4.

LEMMA A.1. *Let $F \in \mathbb{R}^{n\times n}$. Then there is $R \in SO(n)$ such that $\operatorname{dist}(F, SO(n)) = |R^T F - \mathrm{Id}_n|$. For all such R, the product $R^T F$ is symmetric.*

Proof. This is well known. We recall the argument for the convenience of the reader. Existence is clear. To show symmetry, observe that by replacing F by $\tilde{F} = R^T F$ one can reduce to the case $R = \mathrm{Id}_n$, i.e., it suffices to show that $\operatorname{dist}(F, SO(n)) = |F - \mathrm{Id}_n|$ implies that F is symmetric. Consider the function

$$f(Q) = |F - Q|^2 = |F|^2 - 2F : Q + |Q|^2$$

(we write $F : G = \operatorname{Tr} F^T G = \sum F_{ij} G_{ij}$). The first and last term are constant (for $Q \in SO(n)$) and can be ignored. That $Q = \mathrm{Id}$ is a local minimum among all $Q \in SO(n)$ implies that the gradient of the linear term $-2F : Q$, i.e., $-2F$, is normal

to the constraint $SO(n)$ at the identity. The tangent space to $SO(n)$ at the identity is the space of skew-symmetric matrices; hence this requirement corresponds to $-2F$ being symmetric. □

LEMMA A.2. *$W_{F\ddot{o}}$ is convex.*

Proof. Choose $\lambda \in (0,1)$, A, $A' \in \mathbb{R}^{2\times 2}_{\mathrm{sym}}$, and b, $b' \in \mathbb{R}^2$, and set

$$A_\lambda = \lambda A + (1-\lambda)A', \qquad b_\lambda = \lambda b + (1-\lambda)b'.$$

We have to show that

$$W_{\mathrm{F\ddot{o}}}(A_\lambda, b_\lambda) \le \lambda W_{\mathrm{F\ddot{o}}}(A,b) + (1-\lambda) W_{\mathrm{F\ddot{o}}}(A',b')\,.$$

The key observation is that

$$b_\lambda \otimes b_\lambda = \lambda b\otimes b + (1-\lambda) b\otimes b - \lambda(1-\lambda)(b-b')\otimes(b-b')\,.$$

Therefore for any $M_\lambda \in \mathbb{R}^{2\times 2}_+$ we have

$$\begin{aligned} W_{\mathrm{F\ddot{o}}}(A_\lambda, b_\lambda) &\le Q_2\left(\operatorname{sym} A_\lambda + \frac{1}{2} b_\lambda \otimes b_\lambda + M_\lambda\right) \\ &= Q_2\left(\lambda\left[\operatorname{sym} A + \frac{b\otimes b}{2}\right] + (1-\lambda)\left[\operatorname{sym} A' + \frac{b'\otimes b'}{2}\right] - M_b + M_\lambda\right), \end{aligned}$$

where $M_b = \lambda(1-\lambda)(b-b')\otimes(b-b') \in \mathbb{R}^{2\times 2}_+$.

Choose $M, M' \in \mathbb{R}^{2\times 2}_+$ so that

$$W_{\mathrm{F\ddot{o}}}(A,b) = Q_2\left(\operatorname{sym} A + \frac{1}{2} b\otimes b + M\right),$$

and the same condition holds for A', b', and M', and set $M_\lambda = \lambda M + (1-\lambda)M' + M_b \in \mathbb{R}^{2\times 2}_+$. Then the previous expression takes the form

$$Q_2\left(\lambda\left[\operatorname{sym} A + \frac{b\otimes b}{2} + M\right] + (1-\lambda)\left[\operatorname{sym} A' + \frac{b'\otimes b'}{2} + M'\right]\right),$$

and the convexity of Q_2 concludes the proof. □

LEMMA A.3. *For each $M \in \mathbb{R}^{2\times 2}_+$ there are $\psi_\delta \in W^{1,\infty}(\mathbb{R}^2,\mathbb{R}^2)$ and $\varphi_\delta \in W^{1,\infty}(\mathbb{R}^2)$ such that*

$$\begin{aligned} &\psi_\delta \overset{*}{\rightharpoonup} 0 \quad \textit{weakly* in } W^{1,\infty}(\mathbb{R}^2,\mathbb{R}^2), \\ &\varphi_\delta \overset{*}{\rightharpoonup} 0 \quad \textit{weakly* in } W^{1,\infty}(\mathbb{R}^2) \end{aligned}$$

as $\delta \to 0$,

$$\operatorname{sym}\nabla'\psi_\delta(x') + \frac{\nabla'\varphi_\delta(x')\otimes\nabla'\varphi_\delta(x')}{2} = M$$

for a.e. $x' \in \mathbb{R}^2$ and $\|\psi_\delta\|_{W^{1,\infty}} + \|\varphi_\delta\|_{W^{1,\infty}} \le C(|M|+1)$.

Proof. Let $\zeta(t)$ be defined as t if $0 < t < 1/2$, as $(1-t)$ if $1/2 < t < 1$ and extended periodically on the rest of $\mathbb{R}$. Let $\zeta_\delta(t) := \delta\zeta(t/\delta)$ for every $\delta > 0$ so that $\zeta_\delta \rightharpoonup^* 0$ weakly* in $W^{1,\infty}(\mathbb{R})$ as $\delta \to 0$.

We can write $M = \lambda_1 a_1 \otimes a_1 + \lambda_2 a_2 \otimes a_2$ for $a_1, a_2 \in S^1$ and $\lambda_1, \lambda_2 \geq 0$. We define

$$\psi_\delta(x') := (\sqrt{\lambda}_1 a_1 - \sqrt{\lambda}_2 a_2)\zeta_\delta((\sqrt{\lambda}_1 a_1 + \sqrt{\lambda}_2 a_2) \cdot x')$$

so that

$$\nabla' \psi_\delta(x') := \zeta'_\delta((\sqrt{\lambda}_1 a_1 + \sqrt{\lambda}_2 a_2) \cdot x')(\sqrt{\lambda}_1 a_1 - \sqrt{\lambda}_2 a_2) \otimes (\sqrt{\lambda}_1 a_1 + \sqrt{\lambda}_2 a_2).$$

In particular

$$\operatorname{sym} \nabla' \psi_\delta(x') = \begin{cases} \lambda_1 a_1 \otimes a_1 - \lambda_2 a_2 \otimes a_2 & \text{on } S^+_\delta, \\ \lambda_2 a_2 \otimes a_2 - \lambda_1 a_1 \otimes a_1 & \text{on } S^-_\delta, \end{cases}$$

where we have put $S^-_\delta = \mathbb{R}^2 \setminus S^+_\delta$ and

$$S^+_\delta := \left\{ x' \in \mathbb{R}^2 : \text{for a } k \in \mathbb{N} \text{ we have } (\sqrt{\lambda}_1 a_1 + \sqrt{\lambda}_2 a_2) \cdot x' \in \left(k\delta, k\delta + \tfrac{1}{2}\delta\right) \right\}.$$

Correspondingly we define

$$\varphi_\delta(x') := \begin{cases} \zeta_\delta(2\sqrt{\lambda}_2\, a_2 \cdot x') & \text{if } x' \in S^+_\delta, \\ \zeta_\delta(-2\sqrt{\lambda}_1\, a_1 \cdot x') & \text{if } x' \in S^-_\delta. \end{cases}$$

Note that $\varphi_\delta \in W^{1,\infty}(\mathbb{R}^2)$. Indeed if $x' \in \overline{S^+_\delta} \cap \overline{S^-_\delta}$ we have that for some $j \in \mathbb{N}$

$$j\delta = 2(\sqrt{\lambda}_1 a_1 + \sqrt{\lambda}_2 a_2) \cdot x',$$

and since ζ_δ is δ-periodic we deduce that φ_δ is continuous on the interfaces, and thus Lipschitz on $\mathbb{R}^2$. On the other hand we have that

$$\nabla' \varphi_\delta(x') = \begin{cases} 2\sqrt{\lambda}_2 \zeta'_\delta(2\sqrt{\lambda}_2\, a_2 \cdot x') a_2 & \text{if } x' \in S^+_\delta, \\ -2\sqrt{\lambda}_1 \zeta'_\delta(-2\sqrt{\lambda}_1\, a_1 \cdot x') a_1 & \text{if } x' \in S^-_\delta, \end{cases}$$

and since $\zeta'_\delta = \pm 1$ a.e. we get

$$\nabla' \varphi_\delta(x') \otimes \nabla' \varphi_\delta(x') = \begin{cases} 4\lambda_2 a_2 \otimes a_2 & \text{if } x' \in S^+_\delta, \\ 4\lambda_1 a_1 \otimes a_1 & \text{if } x' \in S^-_\delta. \end{cases}$$

The thesis follows. □

LEMMA A.4. *Let $M \in L^\infty(S, \mathbb{R}^{2\times 2}_+)$ be constant on each of finitely many Lipschitz subsets S_j covering S, and let $\varepsilon_h \to 0$, $\varepsilon_h > 0$. Then there are $\psi_h \in C^\infty_0(S, \mathbb{R}^2)$ and $\varphi_h \in C^\infty_0(S)$ such that*

$$\begin{aligned} \psi_h &\rightharpoonup 0 \quad \textit{weakly in } W^{1,2}(S, \mathbb{R}^2), \\ \varphi_h &\rightharpoonup 0 \quad \textit{weakly in } W^{1,4}(S), \\ \operatorname{sym} \nabla' \psi_h(x') + \frac{\nabla' \varphi_h(x') \otimes \nabla' \varphi_h(x')}{2} &\to M \quad \textit{strongly in } L^2(S, \mathbb{R}^{2\times 2}), \end{aligned}$$

and

$$\begin{aligned} \varepsilon_h \|(\nabla')^2 \varphi_h\|_{L^\infty(S,\mathbb{R}^{2\times 2})} &\leq 1\,, \\ \|\psi_h\|_{W^{1,\infty}(S,\mathbb{R}^2)} + \|\varphi_h\|_{W^{1,\infty}(S)} &\leq C(\|M\|_{L^\infty(S,\mathbb{R}^{2\times 2})} + 1)\,. \end{aligned}$$

Proof. We can without loss of generality assume that M is constant on the entire S (if not, we perform the construction independently on each S_j).

Let $\tilde{\psi}_\delta$, $\tilde{\varphi}_\delta$ be the functions given by Lemma A.3, let $S_\rho = \{x' \in S : \mathrm{dist}(x', \partial S) > \rho\}$, and let $\eta_\rho \in C_0^\infty(B_\rho, \mathbb{R})$ be a mollification kernel on the scale ρ, i.e., such that

$$\int_{\mathbb{R}^2} \eta_\rho(x')dx' = 1\,, \qquad \int_{\mathbb{R}^2} \rho|\nabla'\eta_\rho(x')| + \rho^2|(\nabla')^2\eta_\rho(x')|dx' \le C\,.$$

We set

$$\psi_{\delta,\rho}(x') = \int_{S_\rho} \tilde{\psi}_\delta(y')\eta_\rho(x'-y')dy'$$

and analogously $\varphi_{\delta,\rho}$. Clearly $\psi_{\delta,\rho} \in C_0^\infty(S, \mathbb{R}^2)$, $\varphi_{\delta,\rho} \in C_c^\infty(S)$, and as $\rho \to 0$

$$\psi_{\delta,\rho} \to \tilde{\psi}_\delta\,, \quad \varphi_{\delta,\rho} \to \tilde{\varphi}_\delta \qquad \text{strongly in } W^{1,2}(S,\mathbb{R}^2), \text{ resp. } W^{1,4}(S).$$

It remains to take a suitable diagonal subsequence. Indeed, for each δ we can choose $\rho(\delta)$ such that

$$\|\psi_{\delta,\rho(\delta)} - \tilde{\psi}_\delta\|_{W^{1,2}(S,\mathbb{R}^2)} + \|\varphi_{\delta,\rho(\delta)} - \tilde{\varphi}_\delta\|_{W^{1,4}(S)} \le \delta\,.$$

This ensures all desired convergence properties as $\delta \to 0$. To include the bound on the second gradient it suffices to choose $\delta(h)$ as the smallest δ for which

$$\varepsilon_h\|(\nabla')^2\varphi_{\delta,\rho(\delta)}\|_{L^\infty(S,\mathbb{R}^{2\times 2})} \le 1.$$

This is possible since $\varepsilon_h \to 0$, and for the same reason $\delta(h) \to 0$. Finally, we set $\psi_h = \psi_{\delta(h),\rho(\delta(h))}$ and define φ_h likewise. ∎

In the proof of Theorem 2.1 we have stated the existence of certain measurable functions. This can be proved by a rather standard application of the measurable selections principle, which is, however, typically disregarded in the literature. We therefore choose to provide here the simple details for the case of interest here.

The basic tool is the following slight simplification of Theorem III.6 in [4].

LEMMA A.5. *Let X be a set with a σ-algebra $\mathcal{F}$, let Y be a complete, separable metric space, and for every $x \in X$ let a nonempty subset $F(x)$ of Y be given in such a way that*

$$\{x \in X : F(x) \cap U \neq \emptyset\} \in \mathcal{F} \tag{A.1}$$

for every open set U in Y.

Then a measurable map $f : X \to Y$ can be defined in such a way that $f(x) \in F(x)$ for every $x \in X$.

For the convenience of the reader we recall the brief proof.

Proof. Let $\{y_k\}_k$ be a countable and dense subset of Y and let $f_0 : X \to Y$ be defined by

$$f_0(x) := y_{k_0(x)},$$
$$k_0(x) := \min\{k \in \mathbb{N} : F(x) \cap B(y_k, 2^0) \neq \emptyset\}.$$

Note that f_0 is measurable as it takes values in $\{y_k\}_k$ and as $(f_0)^{-1}(y_k)$ is measurable for every k, by (A.1). Assume that a measurable $f_j : X \to Y$ has been defined in

such a way that $f_j(x) = y_{k_j(x)}$, for $k_j(x)$ such that $F(x) \cap B(y_{k_j(x)}, 2^{-j}) \neq \emptyset$. Then we define $f_{j+1}(x)$ as

$$f_{j+1}(x) := y_{k_{j+1}(x)},$$
$$k_{j+1}(x) := \min\{k \in \mathbb{N} : F(x) \cap B(y_{k_j(x)}, 2^{-j}) \cap B(y_k, 2^{-j-1}) \neq \emptyset\}.$$

Once again f_{j+1} is measurable by (A.1). Furthermore we have easily that

$$\operatorname{dist}(f_j(x), F(x)) \leq 2^{-j}, \quad \operatorname{dist}(f_j(x), f_{j+1}(x)) \leq 2^{-j+1},$$

so that $\operatorname{dist}(f_j(x), f_{j+h}(x)) \to 0$ as $j \to \infty$ for every h. Since Y is complete for every $x \in X$ we find $f(x) \in F(x)$ such that $f_j(x) \to f(x)$, and in particular the map $f : X \to Y$ is measurable. This completes the proof of the lemma. □

We then state and prove some consequences of this lemma that we have used in the proof of Theorem 2.1.

LEMMA A.6. *Let $M : \Omega \to \mathbb{R}^{n\times n}$ be measurable. Then there is a measurable $R : \Omega \to SO(n)$ such that*

$$|M(x) - R(x)| = \operatorname{dist}(M(x), SO(n)) \quad \forall x \in \Omega.$$

Proof. We apply Lemma A.5 with $X = \Omega$, $\mathcal{F}$ the σ-algebra of the Lebesgue measurable sets of Ω, $Y = SO(n)$, and $F(x) = \{Q \in SO(n) : |Q - M(x)| = \operatorname{dist}(M(x), SO(n))$. Let U be an open set of $SO(3)$ and let U_k be an increasing sequence of compact sets exhausting U. Then

$$\begin{aligned}\{x \in X : F(x) \cap U \neq \emptyset\} &= \{x \in \Omega : \exists\, Q \in U,\ |Q - M(x)| = \operatorname{dist}(M(x), SO(n))\} \\ &= \bigcup_{k\in\mathbb{N}} \{x \in \Omega : \operatorname{dist}(M(x), U_k) = \operatorname{dist}(M(x), SO(n))\}\end{aligned}$$

and each set in this countable union is measurable as it is the coincidence set of two measurable functions. □

A RANGE DESCRIPTION FOR THE PLANAR CIRCULAR RADON TRANSFORM*

GAIK AMBARTSOUMIAN† AND PETER KUCHMENT†

Abstract. The transform considered in the paper integrates a function supported in the unit disk on the plane over all circles centered at the boundary of this disk. Such a circular Radon transform arises in several contemporary imaging techniques, as well as in other applications. As is common for transforms of Radon type, its range has infinite codimension in standard function spaces. Range descriptions for such transforms are known to be very important for computed tomography—for instance, when dealing with incomplete data, error correction, and other issues. A complete range description for the circular Radon transform is obtained. Range conditions include the recently found set of moment-type conditions, which happens to be incomplete, as well as other conditions that have less standard form. In order to explain the procedure better, a similar (nonstandard) treatment of the range conditions is described first for the usual Radon transform on the plane.

Key words. thermoacoustic tomography, Radon transform, range description

DOI. 10.1137/050637492

1. Introduction.

The following "circular" Radon transform, which is the main object of study in this article, arises in several applications, including the newly developing thermoacoustic tomography and its sibling, optoacoustic tomography (e.g., [5, 16, 29, 56, 67, 68, 69, 70]), as well as radar, sonar, and other applications [40, 48, 51, 52]. It has also been considered in relation to some problems of approximation theory, mathematical physics, and other areas [1, 2, 10, 13, 28, 31, 38, 39].

Let $f(x)$ be a continuous function on $\mathbb{R}^d$, $d \geq 2$.

DEFINITION 1. *The circular Radon transform of f is defined as*

$$Rf(p,\rho) = \int_{|y-p|=\rho} f(y)d\sigma(y),$$

where $d\sigma(y)$ is the surface area on the sphere $|y-p| = \rho$ centered at $p \in \mathbb{R}^d$.

In this definition we do not restrict the set of centers p or radii r. It is clear, however, that this mapping is overdetermined, since the dimension of pairs (p, r) is $d+1$, while the function f depends on d variables only. This (as well as the tomographic motivation) suggests that we restrict the set of centers to a set (hypersurface) $S \subset \mathbb{R}^d$, while not imposing any restrictions on the radii. This restricted transform is denoted by R_S:

$$R_S f(p,\rho) = Rf(p,\rho)|_{p\in S}.$$

In this paper we will be dealing with the planar case only, i.e., the dimension d will be equal to 2. Due to tomographic applications, where S is the set of locations of

transducers [29, 67, 68, 70], from now on we will be looking at the specific case when S is the unit circle $|x| = 1$ in the plane.

There are many questions one can ask concerning the circular transform R_S, e.g., concerning its injectivity, inversion formulas, stability of inversion, and range description. Experience in computerized tomography shows (e.g., [44, 46]) that all these questions are important. Although none of them has been resolved completely for R_S, significant developments have occurred recently (see, e.g., [1, 2, 5, 6, 12, 14, 16, 20, 35, 46, 47, 51, 52, 55, 59, 60, 67, 68, 69]). The goal of this article is to describe the range of R_S in the two-dimensional case, with S being the unit circle. Moreover, we will be dealing with functions supported inside the circle S only. The properties of the operator R_S (e.g., stability of the inversion, its Fourier integral operator (FIO) properties, etc.) deteriorate on functions with supports extending outside S (e.g., [2, 16, 70] and remarks in the last section of this article). However, in tomographic applications one normally deals with functions supported inside S only [29, 56, 67, 70].

As was already mentioned, the range of R_S has infinite codimension (e.g., in spaces of smooth functions, see details below) and thus infinitely many range conditions appear. It seems to be a rather standard situation for various types of Radon transforms that range conditions split into two types, one of which is usually easier to discover, while the other "half" is harder to come by. For instance, it took about a decade to find the complete range description for the so-called exponential Radon transform arising in SPECT (single photon emission computed tomography) [3, 4, 33, 34, 66]. For a more general attenuated transform arising in SPECT, it took twice as much time to move from a partial set of range conditions [44, 45] to the complete set [53]. In the circular case, a partial set of such conditions was discovered recently [56]. It happens to be incomplete, and the goal of this text is to find the complete one.

One might ask why is it important to know the range conditions. Such conditions have been used extensively in tomography (as well as in radiation therapy planning, e.g., [8, 9, 30]) for various purposes: completing incomplete data, detecting and correcting measurement errors and hardware imperfections, recovering unknown attenuation, etc. [26, 41, 42, 43, 44, 49, 50, 57, 64, 65]. Thus, as soon as a new Radon-type transform arises in an application, a quest for the range description begins.

In order to explain our approach, we start in the next section with treating a toy example of the standard Radon transform on the plane, where the range conditions are well known (e.g., [13, 17, 18, 19, 25, 44, 46]). Our approach, however, is different from the standard ones and naturally leads to the considerations of the circular transform in the rest of the paper.

2. The case of the planar Radon transform. In this section we will approach in a somewhat nonstandard way the issue of the range description for the standard Radon transform on the plane. Consider a compactly supported smooth function $f(x)$ on the plane and its Radon transform

$$(\mathcal{R}f)(\omega, s) = g(\omega, s) := \int_{x\cdot\omega=s} f(x)dl, \tag{1}$$

where $s \in \mathbb{R}$, $\omega \in S^1$ is a unit vector in $\mathbb{R}^2$, and dl is the arc length measure on the line $x \cdot \omega = s$. We want to describe the range of this transform, say on the space $C_0^\infty(\mathbb{R}^2)$. Such a description is well known (see, e.g., [13, 17, 18, 19, 25, 44, 46], or any other book or survey on Radon transforms or computed tomography).

THEOREM 2. *A function g belongs to the range of the Radon transform on C_0^∞ if and only if the following conditions are satisfied:*

1. $g \in C_0^\infty(S^1 \times \mathbb{R})$;
2. *for any $k \in \mathbb{Z}^+$ the kth moment $G_k(\omega) = \int_{-\infty}^{\infty} s^k g(\omega, s) ds$ is the restriction to the unit circle S^1 of a homogeneous polynomial of ω of degree k;*
3. $g(\omega, s) = g(-\omega, -s)$.

We would like to look at this result from a slighty different perspective, which will allow us to do a similar thing in the case of the circular Radon transform.

In order to do so, let us expand $g(\omega, s)$ into the Fourier series with respect to the polar angle ψ (i.e., $\omega = (\cos\psi, \sin\psi)$):

$$g(\omega, s) = \sum_{n=-\infty}^{\infty} g_n(s) e^{in\psi}. \tag{2}$$

We can now reformulate the last theorem in the following, somewhat unusual way.

THEOREM 3. *A function g belongs to the range of the Radon transform on C_0^∞ if and only if the following conditions are satisfied:*

1. $g \in C_0^\infty(S^1 \times \mathbb{R})$;
2. *for any n, the Mellin transform $Mg_n(\sigma) = \int_0^\infty s^{\sigma-1} g_n(s) ds$ of the nth Fourier coefficient g_n of g vanishes at any pole σ of the function $\Gamma(\frac{\sigma+1-|n|}{2})$;*
3. $g(\omega, s) = g(-\omega, -s)$.

Since the only difference in the statements of these two theorems is in conditions 2, let us check that these conditions mean the same thing in both cases. Indeed, let us expand $g(\omega, s)$ into Fourier series (2) with respect to ψ. Representing $e^{in\psi}$ as the homogeneous polynomial $(\omega_1 + i(sign\, n)\omega_2)^{|n|}$ of ω of degree $|n|$, and noticing that $\omega_1^2 + \omega_2^2 = 1$ on the unit circle, one easily concludes that condition 2 in Theorem 2 is equivalent to the following: the kth moment $\int_{\mathbb{R}} s^k g_n(s) ds$ of the nth Fourier coefficient vanishes for integers $0 \le k < |n|$ such that $k - n$ is even.

Let us now look at condition 2 in Theorem 3, still using the same Fourier expansion. Notice that when $k - |n|$ is a negative even integer, $Mg_n(\sigma)$ is one-half of the moment of order $k = \sigma - 1$ of g_n. Taking into account that $\Gamma(\frac{\sigma+1-|n|}{2}) = \Gamma(\frac{k+2-|n|}{2})$ has poles exactly when $k - |n|$ is a negative even integer, we see that conditions 2 in both theorems are in fact saying the same thing.

One can now ask the question, why should one disguise in the statement of Theorem 3 negative integers as poles of Gamma-function and usual moments as values of Mellin transforms? The answer is that in the less invariant and thus more complex situation of the circular Radon transform, one can formulate a range description in the spirit of Theorem 3, although it is unclear how to get an analogue of the version given in Theorem 2.

As a warm-up, let us derive condition 2 in Theorem 3 directly, without relying on the version given in the preceding theorem. This is in fact an easy by-product of Cormack's inversion procedure; see, e.g., [46, section II.2]. Indeed, if we write down the original function $f(x)$ in polar coordinates $r(\cos\phi, \sin\phi)$ and expand into the Fourier series with respect to the polar angle ϕ,

$$f(r(\cos\phi, \sin\phi)) = \sum_{n=-\infty}^{\infty} f_n(r) e^{in\phi}, \tag{3}$$

then the Fourier coefficients f_n and g_n of the original and of its Radon transform are

related as follows [44, formula (2.17) and further]:

$$M(rf_n(r))(s) = \frac{(Mg_n)(s)}{B_n(s)}, \tag{4}$$

where

$$B_n(s) = \text{const}\frac{\Gamma(s)2^{-s}}{\Gamma((s+1+|n|)/2)\Gamma((s+1-|n|)/2)}. \tag{5}$$

Thus, condition 2 of Theorem 3 guarantees that the function $M(rf_n(r))(s)$ does not develop singularities (which it cannot do for a C_0^∞-function f) at zeros of $B_n(s)$. It is not that hard now to prove also sufficiency in the theorem, applying Cormack's inversion procedure to g satisfying conditions 1–3. However, we are not going to do so, since in the next sections we will devote ourselves to doing a similar thing in the more complicated situation of the circular Radon transform.

3. The circular Radon transform. Formulation of the main result. Let us recall the notion of the Hankel transform (e.g., [11]). For a function $h(r)$ on $\mathbb{R}^+$, one defines its Hankel transform of an integer order n as follows:

$$(\mathcal{H}_n h)(\sigma) = \int_0^\infty J_n(\sigma r)h(r)r\,dr, \tag{6}$$

where the standard notation J_n is used for Bessel functions of the first kind.

As in the introduction, let R_S be the circular Radon transform on the plane that integrates functions compactly supported inside the unit disk D over all circles $|x-p| = \rho$ with centers p located on the unit circle $S = \{p\,|\,|p| = 1\}$. Since this transform commutes with rotations about the origin, the Fourier series expansion with respect to the polar angle partially diagonalizes the operator, and thus the nth Fourier coefficient $g_n(\rho)$ of $g = R_S f$ will depend on the nth coefficient f_n of the original f only. It was shown in [51] that the following relation between these coefficients holds:

$$g_n(\rho) = 2\pi\rho\mathcal{H}_0\{J_n\mathcal{H}_n\{f_n\}\}. \tag{7}$$

For the reader's convenience, we will provide the brief derivation from [51]. Considering a single harmonic $f = f_n(r)e^{in\phi}$ and using polar coordinates, one obtains

$$g_n(\rho) = \int_0^\infty rf_n(r)dr\int_0^{2\pi}\delta\left[(r^2+1-2r\cos\phi)^{1/2}-\rho\right]e^{-in\phi}d\phi. \tag{8}$$

Thus, the computation boils down to evaluating the integral

$$I = \int_0^{2\pi}\delta\left[(r^2+1-2r\cos\phi)^{1/2}-\rho\right]e^{-in\phi}d\phi.$$

Using the standard identity

$$\delta(\rho'-\rho) = \rho\int_0^\infty J_0(\rho' z)J_0(\rho z)z dz$$

and the identity that is easy to obtain from one of the addition formulas, e.g., from [7, formula (4.10.6)]

$$2\pi J_n(az)J_n(bz) = \int_0^{2\pi} J_0[z(a^2+b^2-2ab\cos\phi)^{1/2}]e^{-in\phi}d\phi,$$

one goes from (8) to (7).

Since Hankel transforms are involutive, it is easy to invert (7) and get Norton's inversion formulas [51]

$$f_n = \frac{1}{2\pi}\mathcal{H}_n\left\{\frac{\mathcal{H}_0\{g_n(\rho)/\rho\}}{J_n}\right\}. \tag{9}$$

Now one can clearly see analogies to the case of the Radon transform, where zeros of Bessel functions should probably introduce some range conditions. This happens to be correct and leads to the main result of this article, as follows.

THEOREM 4. *In order for the function $g(p,\rho)$ on $S^1\times\mathbb{R}$ to be representable as $R_S f$ with $f\in C_0^\infty(D)$, it is necessary and sufficient that the following conditions be satisfied:*

1. $g\in C_0^\infty(S^1\times(0,2))$.
2. *For any n, the $2k$th moment $\int_0^\infty \rho^{2k} g_n(\rho)d\rho$ of the nth Fourier coefficient of g vanishes for integers $0\le k<|n|$. (Equivalently, the $2k$th moment $\int_0^\infty \rho^{2k} g(p,\rho)d\rho$ is the restriction to the unit circle S of a (nonhomogeneous) polynomial of p of degree at most k.)*
3. *For any $n\in\mathbb{Z}$, function $\mathcal{H}_0\{g_n(\rho)/\rho\}(\sigma)=\int_0^\infty J_0(\sigma\rho)g_n(\rho)d\rho$ vanishes at any zero $\sigma\neq 0$ of Bessel function J_n. (Equivalently, the nth Fourier coefficient with respect to $p\in S^1$ of the "Bessel moment" $G_\sigma(p)=\int_0^\infty J_0(\sigma\rho)g(p,\rho)d\rho$ vanishes if $\sigma\neq 0$ is a zero of Bessel function J_n.)*

4. Proof of the main result. Let us start by proving necessity, which is rather straightforward. Indeed, the necessity of condition 1 is obvious. Let us prove the second condition. In fact, it has already been established in [56]. Let us repeat for completeness its simple proof. Let k be an integer. Consider the moment of order $2k$ of g:

$$\int_0^\infty \rho^{2k} g(p,\rho)d\rho = \int_{\mathbb{R}^2} |x-p|^{2k} f(x)dx = \int_{\mathbb{R}^2} (|x|^2 - 2x\cdot p + 1)^k f(x)dx \tag{10}$$

(we have taken into account that $|p|=1$). We see that the resulting expression is the restriction to S^1 of a (nonhomogeneous) polynomial of degree k in variable p. Expanding into Fourier series with respect to the polar angle of p, we see that the nth harmonic g_n contributes the following homogeneous polynomial of degree $|n|$ in the variable p:

$$\left(\int_0^\infty \rho^{2k} g_n(\rho)d\rho\right) e^{in\psi}.$$

Here as before $p=(\cos\psi,\sin\psi)$. Thus, for $|n|>k$, this term must vanish, which gives necessity of condition 2. We will return to a discussion of this condition below to add a new twist to it.

Necessity of condition 3 follows immediately from Norton's formula (9), which implies in particular that

$$\mathcal{H}_0\{g_n(\rho)/\rho\} = 2\pi J_n \mathcal{H}_n\{f_n\}.$$

Since both functions J_n and $\mathcal{H}_n\{f_n\}$ are entire, $\mathcal{H}_0\{g_n(\rho)/\rho\}$ vanishes whenever J_n does.

Remark 5. The reader might ask why in the third condition of the theorem we do not take into account the zero root of J_n, which in fact has order n, while nonzero

roots are all simple. The reason is that condition 2 already guarantees that $\sigma = 0$ is zero of order $2n$ of $\mathcal{H}_0\{g_n(\rho)/\rho\}$ (twice higher than that of J_n). Indeed, due to evenness of J_0, function $\mathcal{H}_0\{g_n(\rho)/\rho\}(\sigma)$ is also even. Thus, all odd order derivatives at $\sigma = 0$ vanish. The known Taylor expansion of J_0 at zero leads to the formula

$$\mathcal{H}_0\{g_n(\rho)/\rho\}(\sigma) = \sum_m \frac{(-1)^m}{(m!)^2} \left(\frac{\sigma}{2}\right)^{2m} \int_0^\infty r^{2m} g_n(r) dr.$$

We see now that the moment condition 2 guarantees that $\sigma = 0$ is zero of order $2n$ of $\mathcal{H}_0\{g_n/\rho\}(\sigma)$.

Let us move to the harder part, proving sufficiency. Assume a function g satisfies conditions of the theorem and is supported in $S \times (\epsilon, 2-\epsilon)$ for some positive ϵ. We will show that then $g = R_S f$ for some $f \in C_0^\infty(D_\epsilon)$, where D_ϵ is the disk $|x| < 1 - \epsilon$ in the plane.

Due to Norton's formulas, it is natural to expect the proof to go along the following lines: expand g into the Fourier series $g = \sum_m g_m(\rho) e^{im\psi}$ with respect to the angle variable ψ, then use (9) to construct a function f and then show that f is of an appropriate function class and that its circular Radon transform is equal to g. This is what we are going to do, with a small caveat: instead of constructing f itself, we will construct its two-dimensional Fourier transform. Besides, we will start considering the partial sums of the series $h_n = \sum_{|m| \le n} g_m(\rho) e^{im\phi}$. But first we need to get some simple estimates from below for the Bessel function of the first kind J_n.

LEMMA 6. *On the entire complex plane, except for a disk S_0 centered at the origin and a countable number of disks S_k of radii $\pi/6$ centered at points $\pi(k + \frac{2n+3}{4})$, one has*

$$|J_n(z)| \ge \frac{C e^{|\operatorname{Im} z|}}{\sqrt{|z|}}, \qquad C > 0. \tag{11}$$

Proof. Let us split the complex plane into three parts by a circle S_0 of a radius R (to be chosen later) centered at the origin and a planar strip $\{z = x + iy \,|\, |y| < a\}$, as follows: part I consists of points z satisfying $|z| \ge R$ and $|\operatorname{Im} z| \ge a$; part II consists of points such that $|z| \ge R$ and $|\operatorname{Im} z| < a$; part III is the interior of S_0, i.e., $|z| < R$. It is clearly sufficient to prove the estimate (11) in the first two parts: outside and inside the strip. Using the parity property of J_n, it suffices to consider only the right half plane $\operatorname{Re} z \ge 0$.

The Bessel function of the first kind $J_n(z)$ has the following known asymptotic representation in the sector $|\arg z| \le \pi - \delta$ (e.g., [7, formula (4.8.5)] or [36, formula (5.11.6)]):

$$\begin{aligned} J_n(z) = {} & \sqrt{\frac{2}{\pi z}} \cos\left(z - \frac{\pi n}{2} - \frac{\pi}{4}\right) (1 + O(|z|^{-2})) \\ & - \sqrt{\frac{2}{\pi z}} \sin\left(z - \frac{\pi n}{2} - \frac{\pi}{4}\right) \left(\frac{4n^2 - 1}{8z} + O(|z|^{-3})\right). \end{aligned} \tag{12}$$

Let us start estimating in the first part of the complex plane, i.e., where $|\operatorname{Im} z| > a$ and $|z| > R$ for sufficiently large a and R (and, as we have agreed, $\operatorname{Re} z \ge 0$). There, due to boundedness of $\tan z$ in this region, one concludes that $\frac{\sin z}{z} = \cos z\, (O(|z|^{-1}))$, and thus (12) implies

$$J_n(z) = \sqrt{\frac{2}{\pi z}} \cos\left(z - \frac{\pi n}{2} - \frac{\pi}{4}\right) (1 + O(|z|^{-1})),$$

which in turn for sufficiently large a, R leads to

$$|J_n(z)| \geq \frac{Ce^{|\operatorname{Im} z|}}{\sqrt{|z|}}. \tag{13}$$

In the second part of the plane (right half of the strip), due to boundedness of $\sin z$ we have

$$J_n(z) = \sqrt{\frac{2}{\pi z}} \left[\cos\left(z - \frac{\pi n}{2} - \frac{\pi}{4}\right)(1 + O(|z|^{-2})) + O(|z|^{-1})\right].$$

Consider the system of nonintersecting circles S_k with centers at $z_k = \frac{\pi}{2} + k\pi + \frac{\pi n}{2} + \frac{\pi}{4}$ and radii equal to $\frac{\pi}{6}$. Then outside these circles $|\cos(z - \frac{\pi n}{2} - \frac{\pi}{4})| \geq C$ and

$$|J_n(z)| \geq \frac{C}{\sqrt{|z|}}(1 + O(|z|^{-1})).$$

This implies that for a suitably chosen and sufficiently large R, inside of the strip and outside the circles S_k, we have

$$|J_n(z)| \geq \frac{Ce^{|\operatorname{Im} z|}}{\sqrt{|z|}} \tag{14}$$

for $|z| > R$. This proves the statement of the lemma. □

Let us now return to our task: consider the function g and the partial sums h_n of its Fourier series.

LEMMA 7.

1. *If $g(\phi, \rho) = \sum_m g_m(\rho)e^{im\psi}$ satisfies conditions of Theorem 4 and is supported in $S \times (\epsilon, 2 - \epsilon)$, then each partial sum $h_n = \sum_{|m|<n} g_m(\rho)e^{im\psi}$ does so.*
2. *For any n, h_n is representable as $R_S f_n$ for a function $f_n \in C_0^\infty(D_\epsilon)$.*

Proof. The first statement of the lemma is obvious.

Thus, it is sufficient to prove the second statement for a single term $g = g_n(\rho)e^{in\psi}$. As was just mentioned, we will reconstruct the Fourier transform F of the function f. In order to do this, we will use the standard relation between Fourier and Hankel transforms. As before, let $f(x) = f_n(r)e^{in\phi}$, where $r = |x|$ and ϕ are polar coordinates on $\mathbb{R}^2$. Then the Fourier transform $F(\xi)$ of f at points of the form $\xi = \sigma\omega$, where $\sigma \in \mathbb{C}$ and $\omega = (\cos\psi, \sin\psi) \in \mathbb{R}^2$ can be written up to a constant factor as follows:

$$F(\sigma\omega) = \mathcal{H}_n(f_n)(\sigma)e^{in\psi} \tag{15}$$

(e.g., [11, end of section 14.1]). If we knew that $g = R_S f$, then according to (7) this would mean that

$$F(\sigma\omega) = F(\sigma)e^{in\psi} = \frac{1}{2\pi}\frac{\mathcal{H}_0(g_n(\rho)/\rho)(\sigma)}{J_n(\sigma)}e^{in\psi}. \tag{16}$$

Let us now take (16) as the definition of $F(\sigma\omega)$. Due to the standard parity property of Bessel functions, such an F is a correctly defined function of $\sigma\omega$ for $\sigma \neq 0$ (i.e., $F(\sigma\omega) = F((-\sigma)(-\omega))$). We would like to show that it is the Fourier transform of a function $f \in C_0^\infty(D_\epsilon)$. Let us prove first that F belongs to the Schwartz space $\mathcal{S}(\mathbb{R}^2)$. In order to do so, we need to show its smoothness with respect to the angular variable ψ; smoothness and fast decay with all derivatives in the radial variable σ; as

well as that no singularity arises at the origin, which in principle could, due to usage of polar coordinates. Smoothness with respect to the angular variable is obvious, due to (16). Let us deal with the more complex issue of smoothness and decay with respect to σ. First of all, taking into account that $g_n(\rho)$ is supported inside $(0, 2)$, and due to the standard two-dimensional Paley–Wiener theorem, we conclude that $u(\sigma) = \mathcal{H}_0(g_n(\rho)/\rho)$ is an entire function that satisfies for any N the estimate

$$|u(\sigma)| \le C_N(1 + |\sigma|)^{-N} e^{(2-\epsilon)|\mathrm{Im}\,\sigma|}. \tag{17}$$

According to the range conditions 2 and 3 of the theorem, this function vanishes at all zeros of Bessel function $J_n(\sigma)$ at least to the order of the corresponding zero. This means that function $F(\sigma) = \frac{u(\sigma)}{2\pi J_n(\sigma)}$ is entire. Let us show that it belongs to a Paley–Wiener class.

Indeed, $\mathcal{H}(g_n(\rho)/\rho)$ is an entire function with Paley–Wiener estimate (17). Due to the estimate from below for J_n (11) given in Lemma 6, we conclude that $F(\sigma\omega)$ is an entire function of Paley–Wiener class in the radial directions, uniformly with respect to the polar angle. Namely,

$$|F(\sigma)| \le C_N(1 + |\sigma|)^{-N} e^{(1-\epsilon)|\mathrm{Im}\,\sigma|}. \tag{18}$$

Indeed, outside the family of circles S_k the estimate (11) together with (17) gives the Paley–Wiener estimate (18) we need. Inside these circles, application of the maximum principle finishes the job. Smoothness with respect to the polar angle is obvious. Thus, the only thing one needs to establish to verify that F belongs to the Schwartz class is that F is smooth at the origin. This, however, is the standard question in the Radon transform theory, the answer to which is well known (e.g., [17, pp. 108–109], [18, 19], [25, Chap. 1, proof of Theorem 2.4]). Namely, one needs to establish that for any nonnegative integer k, the kth radial (i.e., with respect to σ) derivative of $F(\sigma\omega)$ at the origin is a homogeneous polynomial of order k with respect to ω. So, let us check that this condition is satisfied in our situation. First of all, the parity of the function F is the same as that of n. Thus, we do not need to worry about the derivatives $F_\sigma^{(k)}|_{\sigma=0}$ with $k-n$ odd, since they are zero automatically. Due to the special single-harmonic form of F, we only need to check that $F_\sigma^{(k)}|_{\sigma=0} = 0$ for $k < |n|$ with $k - n$ even. This, however, as we have already discussed in Remark 5, follows from the moment conditions 2 of the theorem.

Due to the smoothness that we have just established and Paley–Wiener estimates, $F \in \mathcal{S}(\mathbb{R}^2)$. Thus, $F = \hat{f}$ for some $f \in \mathcal{S}(\mathbb{R}^2)$. It remains to show that f is supported inside the disk D_ϵ. Consider the usual Radon transform $\mathcal{R}f(s, \phi)$ of f. According to the standard Fourier-slice theorem [13, 17, 18, 19, 25, 44], the one-dimensional Fourier transform (denoted by a "hat") from the variable s to σ gives (up to a fixed constant factor) the values $\widehat{\mathcal{R}f}(\sigma, \psi) = F(\sigma\omega)$ if, as before, $\omega = (\cos\psi, \sin\psi)$. Here $\mathcal{R}$, as before, denotes the standard Radon transform in the plane. Since functions $F(\sigma\omega)$ of σ, as we have just discussed, are uniformly with respect to ω of a Paley–Wiener class, this implies that $\mathcal{R}f(s, \omega)$ has uniformly with respect to ω bounded support in $|s| < 1 - \epsilon$. Now the "hole theorem" [25, 44] (which is applicable to functions of the Schwartz class), implies that f is supported in D_ϵ.

The last step is to show that $R_S f = g = g_n(r)e^{in\phi}$. This, however, immediately follows from comparing formulas (16) and (7), which finishes the proof of the main lemma, Lemma 7. □

Let us now return to the proof of Theorem 4. We have proven so far that any partial sum h_n of the Fourier series for g belongs to the range of the operator R_S

acting on smooth functions supported inside the disk D_ϵ. The function g itself is the limit of h_n in $C_0^\infty(S\times(\epsilon,2-\epsilon))$. The only thing that remains to be proven is that the range is closed in an appropriate topology. Microlocal analysis can help with this.

Consider R_S as an operator acting from functions defined on the open unit disk D to functions defined on the open cylinder $\Omega = S\times(0,2)$. As such, it is an FIO [21, 23, 58]. If R_S^t is the dual operator, then $E = R_S^t R_S$ is an elliptic pseudodifferential operator of order -1 [21, Theorem 1], [22].[1]

LEMMA 8. *The continuous linear operator $E : H_0^2(D_\epsilon)\mapsto H_{loc}^3(D)$ has zero kernel and closed image.*

Proof. Since $E = R_S^t R_S$, the kernel of this operator coincides with the kernel of R_S acting on $H_0^2(D_\epsilon)$. Since S is closed, it is known that R_S has no compactly supported functions in its kernel [1, 2] (this also follows from analytic ellipticity of E and Theorem 8.5.6 of [27]; see also Lemma 4.4 in [2]). Thus, the statement about the kernel is proven and we only need to prove the closedness of the range.

Let P be a properly supported pseudodifferential parametrix of order 1 for E [63]. Then $PE = I + B$, where B is an infinitely smoothing operator on D. Consider the operator Π that acts as the composition of restriction to D_ϵ and then orthogonal projection onto $H_0^2(D_\epsilon)$ in $H^2(D_\epsilon)$. On $H_0^2(D_\epsilon)$ one has $\Pi PE = I + K$, where K is a compact operator on $H_0^2(D_\epsilon)$. Notice that the operator ΠP is continuous from the Fréchet space $H_{loc}^3(D)$ to $H_0^2(D_\epsilon)$. Due to the Fredholm structure of the operator $\Pi PE = I + K$ acting on $H_0^2(D_\epsilon)$, its kernel is finite-dimensional. Let $M\subset H_0^2(D_\epsilon)$ be a closed subspace of finite codimension complementary to the kernel, so $I + K$ is injective on M and has closed range. Then one can find a bounded operator A in $H_0^2(D_\epsilon)$ such that $A(I + K)$ acts as identity on M. Thus, the operator $A\Pi P$ provides a continuous left inverse to $E : M\mapsto H_{loc}^3(D)$. This shows that the range of E on M is closed in $H_{loc}^3(D)$. On the other hand, the total range of E differs only by a finite dimension from the one on M. Thus, it is also closed. ∎

We can now finish the proof of the theorem. Indeed, the last lemma shows that the function $R_S^t g$, being in the closure of the range, is in fact in the range, and thus can be represented as Ef with some $f\in H_0^2(D_\epsilon)$. In other words, $R_S^t(R_S f - g) = 0$. Since the kernel of R_S^t on compactly supported functions is orthogonal to the range of R_S, we conclude that $R_S f - g = 0$. Since $Ef = R_S^t g$ is smooth, due to ellipticity of E we conclude that f is smooth as well. This concludes the proof of the theorem. ∎

We would like to finish with some remarks.

- It should be possible to prove that the operator R_S in the situation considered in the text is semi-Fredholm between appropriate Sobolev spaces (analogously to the properties of the standard and attenuated Radon transforms; see, e.g., [24, 44]). This would eliminate the necessity of the closedness of the range discussion in the end of the proof of Theorem 4.
  Such a statement could probably be proven either by using FIO techniques, or by controlling dependence on n of the constant C and of the radius of the circle S_0 in Lemma 6. The former approach would be better, being more general.
- Proving compactness of support of function f in Lemma 7, we used the standard Radon transform and the "hole theorem." Instead, one could probably use the fact that Fourier transform of f is, by construction, a Paley–Wiener class CR-function on the three-dimensional variety of points $\sigma\omega$ in $\mathbb{C}^2$ and then use an appropriate mandatory analytic extension theorem in the spirit of [54].

[1] Bolker's injective immersion condition [21, 22], which is needed for validity of this result, is satisfied here, as shown in the proof of Lemma 4.3 in [2].

- We considered the situation most natural for tomographic imaging, when the functions to reconstruct are supported inside the aperture curve S. What happens when the supports of functions extend outside the circle S? It is known that compactly supported functions [2] (or even those belonging to L_p with sufficiently small p [1]) can still be uniquely reconstructed. Necessity of the range conditions we derived apparently still holds, and they are still sufficient for finite Fourier series. However, many things do go wrong in this case. Our proof of the closedness of the range fails (in particular, since Bolker's condition for the corresponding FIO does not hold anymore, which was also the main hurdle in proving the results of [2]). Moreover, the range will no longer be closed. Indeed, reconstruction will become unstable, since due to standard microlocal reasons [32, 35, 40, 61, 70], some parts of the wave front set of the function outside S will not be stably recoverable. This means, in particular, that nonsmooth functions can have smooth circular Radon images. This, in turn implies that the range is not closed in the spaces under consideration, and so sufficiency of the range conditions should fail. We are not sure what kind of range description, if any, could work in this situation. By the way, the nice backprojection-type inversion formulas available in odd dimensions [16] also fail for such functions.
- It would be interesting to understand range conditions in the case of a closed curve S different from a circle. Since our method uses rotational invariance, it is not directly applicable to this situation.
- Our result is stated and proven in two dimensions only. It is possible that a similar approach might work in higher dimensions. As we have been notified by D. Finch, he and Rakesh have recently obtained by different methods some range descriptions in three dimensions [15].

PERIODIC ROTATING WAVES IN AN UNDULATING ANNULUS AND THEIR HOMOGENIZATION LIMIT*

BENDONG LOU†

Abstract. We study a mean curvature flow equation in an annulus with periodically undulating boundaries and consider the homogenization limit problem as the period of the boundary undulation tends to zero. We first establish a necessary and sufficient condition for the existence of periodic rotating waves. Then we study how the average rotating speed of the periodic rotating wave depends on the geometry of the boundaries. Our results show that boundary undulation always lowers the speed of a rotating wave. We also determine the homogenization limit of the average rotating speed. Quite surprisingly, this homogenized speed depends only on the maximum opening angles of the domain boundaries.

Key words. mean curvature flow equations, periodic rotating waves, undulating annulus, homogenization limit, average rotating speed

1. Introduction.

We study a curvature-driven motion of curves in an annulus Ω_m ($m \in \mathbf{N}$), whose boundaries undulate periodically with period $\frac{2\pi}{m}$. The motion of the curves is a mean curvature flow equation,

$$V = A + \kappa, \tag{1.1}$$

where V denotes the normal velocity of plane curves, κ denotes the curvature, and $A > 0$ is a constant. Domain Ω_m is defined as follows: Let $\tilde{g}(s)$, $\tilde{h}(s)$ be 2π-periodic smooth functions satisfying

$$\begin{aligned} &\tilde{h}(0) = 0, \quad \tilde{h}(s) \geq 0, \quad \max_s \tilde{h}'(s) = \tan\alpha_1, \quad \min_s \tilde{h}'(s) = -\tan\beta_1, \\ &\tilde{g}(0) = 0, \quad \tilde{g}(s) \geq 0, \quad \max_s \tilde{g}'(s) = \tan\alpha_2, \quad \min_s \tilde{g}'(s) = -\tan\beta_2 \end{aligned}$$

for some $\alpha_i,\ \beta_i \in (0, \frac{\pi}{2})$ $(i = 1, 2)$. For $m \in \mathbf{N}$, define

$$h(s) := \frac{H}{m}\,\tilde{h}(ms), \qquad g(s) := \frac{G}{m}\,\tilde{g}(ms),$$

where $G > H > 0$ are fixed. In what follows, we use polar coordinates (r, θ) to express points in the plane. Define

$$\Omega_m := \left\{(r,\theta) \;\middle|\; H - h(\theta) < r < G + g(\theta), \quad \theta \in [0, 2\pi]\right\}.$$

Denote the outer (resp., inner) boundary of Ω_m by $\partial_2\Omega_m$ (resp., $\partial_1\Omega_m$) and call α_2 (resp., α_1) its *maximum opening angle* (see Figure 1.1).

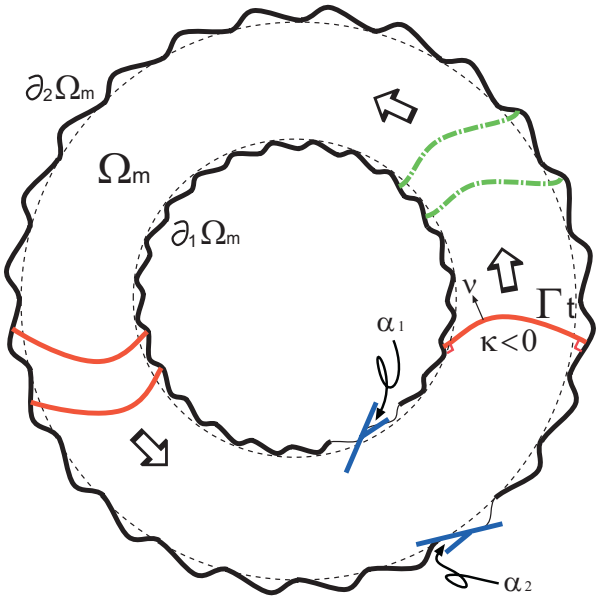

FIG. 1.1. *Undulating annulus and periodic rotating waves.*

By a solution of (1.1) we mean a time-dependent simple curve Γ_t in Ω_m which satisfies (1.1) and contacts both $\partial_1\Omega_m$ and $\partial_2\Omega_m$ perpendicularly. In this paper we are interested in those curves rotating counterclockwise along Ω_m periodically, as well as their average rotating speeds.

In the following we state the motivation and background of (i) the study of mean curvature flow equations; (ii) the study of propagation in annuli; and (iii) the study of propagation in a domain with undulating boundaries.

(i) In 1951 [3] proposed that, in the growth of crystals, the evolution of a crystal surface is governed by a curvature flow equation like (1.1). In 1956 [17] also proposed that the motion of idealized grain boundaries is governed by its curvature. Later *mean curvature flow equations* were used in the study of propagation of wave fronts in an excitable medium, in flame front propagation, in crystal growth, and in many other fields. From a mathematical point of view, it is found that sharp internal layers (or interfaces) appear in singular limit problems of reaction diffusion equations, and the motion of such layers is mean curvature flow equations. For example, a successful model used in the study of Belousov–Zhabotinsky (BZ) reactions are so-called FitzHugh–Nagumo (FHN) equations; the propagation of a pulse solution of FHN equations depends on the mean curvature of the pulse front (e.g., [11], [12], [22]), that is, the motion is a mean curvature flow equation like (1.1).

Mean curvature flow equations are also interesting in their own right from a geometrical point of view. Recently, many geometricians have studied the asymptotic behavior of mean curvature flows ([1], [2], [5], [8], [10], to name only a few). However, as far as we know, very little is known about (periodic) traveling/rotating waves of mean curvature flow equations, though periodic traveling wave solutions of reaction diffusion equations have been studied a lot (cf. [16], [23] and the references therein).

(ii) In the past twenty years many scientists have been interested in BZ reactions in annular gel (for example, [6], [18]). As we said above, one can use FHN equations

to model BZ reactions, and FHN equations can be reduced to a mean curvature flow equation. So the study of mean curvature flow equations in annuli is very helpful to the study of propagation of pulse solutions in BZ reactions in annuli. Some other motivation and studies of rotating waves in annuli can also be found in [9], [20], [22].

(iii) In some cases the domains are not necessarily equipped with flat boundaries. When we consider a propagation in a space with reticulated structure (cf. [4]), or in a media mixed with impurity which blocks the propagation, we may get a domain with undulating boundaries. Such a domain may be an undulating annulus like Ω_m provided the reticulated structure or the masses of impurity are arranged in circles. The propagation of pulses in such an annulus reduces to our problem.

In this paper, we study periodic rotating waves of mean curvature flow (1.1) in annulus Ω_m. We believe that the results in this paper can be extended to more general mean curvature flows.

To avoid sign confusion, the normal vector ν to Γ_t will always be chosen to be counterclockwise; the sign of the normal velocity V and the curvature κ will be understood in accordance with this normal direction (see details below).

We will consider the case that each curve Γ_t is expressed as a graph of a $C^{2,1}$ function $\theta = u(r,t)$ with $(r, u(r,t)) \in \Omega_m$. Let $\eta_1(t)$, $\eta_2(t)$ be the r-coordinates of the end points of Γ_t lying on $\partial_1\Omega_m$, $\partial_2\Omega_m$, respectively. In other words, $\eta_1(t) = H - h(u(\eta_1(t),t))$, $\eta_2(t) = G + g(u(\eta_2(t),t))$. Write the orthogonal coordinates as $(r\cos\theta, r\sin\theta)_\perp$ and denote the unit tangent vector of Γ_t by $\mathbf{T}$ (in the positive direction of r); then $\mathbf{T} = (\cos u - r\sin u \cdot u_r,\ \sin u + r\cos u(r,t)\cdot u_r)_\perp/\sqrt{1+r^2u_r^2}$, $\nu = (-\sin u - r\cos u\cdot u_r,\ \cos u - r\sin u(r,t)\cdot u_r)_\perp/\sqrt{1+r^2u_r^2}$ and

$$V = (-r\sin u\cdot u_t,\ r\cos u\cdot u_t)_\perp\cdot\nu = \frac{ru_t}{\sqrt{1+r^2u_r^2}}, \qquad \kappa = \frac{ru_{rr}+2u_r+r^2u_r^3}{(1+r^2u_r^2)^{3/2}}.$$

Hence (1.1) is equivalent to

$$u_t = \frac{u_{rr}}{1+r^2u_r^2} + \frac{2u_r+r^2u_r^3}{r(1+r^2u_r^2)} + A\frac{\sqrt{1+r^2u_r^2}}{r}, \qquad \eta_1(t) < r < \eta_2(t),\ t>0. \tag{1.2}$$

Denote the *clockwise* unit tangent vector of $r = H$ (resp., $r = G$, $\partial_1\Omega_m$, $\partial_2\Omega_m$) by $\mathbf{T}_1^0$ (resp., $\mathbf{T}_2^0$, $\mathbf{T}_1$, $\mathbf{T}_2$). In what follows, we say that the curve Γ_t contacts $r = H$ (resp., $r = G$, $\partial_1\Omega_m$, $\partial_2\Omega_m$) with angle γ in the sense that $\mathbf{T}\cdot\mathbf{T}_1^0 = \cos\gamma$ (resp., $\mathbf{T}\cdot\mathbf{T}_2^0 = -\cos\gamma$, $\mathbf{T}\cdot\mathbf{T}_1 = \cos\gamma$, $\mathbf{T}\cdot\mathbf{T}_2 = -\cos\gamma$). Our boundary conditions are $\mathbf{T}\cdot\mathbf{T}_i = 0$ on $\partial_i\Omega_m$ $(i=1,2)$, which are expressed as

$$u_r(\eta_1(t),t) = \frac{h'(u)}{(\eta_1(t))^2}, \qquad u_r(\eta_2(t),t) = \frac{-g'(u)}{(\eta_2(t))^2}. \tag{1.3}$$

Let $\Omega_0 = \{(r,\theta) \mid H < r < G,\ \theta\in[0,2\pi]\}$ be the trivial annulus which is *formally* a limit of Ω_m as $m\to\infty$. Problem (1.2) in Ω_0 with boundary conditions

$$u_r(H,t) = u_r(G,t) = 0 \tag{1.4}$$

is quite simple. In fact, as is shown in subsection 2.1.3, when $A > 0$, there exists a unique $\omega_0 > 0$ such that (1.2), (1.4) has a unique *rotating wave* $u(r,t) = \varphi(r) + \omega_0 t$, which has a certain nonplanar profile and rotating speed ω_0. Relevant study in trivial annulus can also be found in [9], [20].

On the other hand, in Ω_m, a rotating wave with a certain profile does not exist. In fact, as Γ_t propagates, its shape and speed fluctuate along with the undulation of the domain Ω_m. In such a situation, we adopt a generalized notion of rotating waves. A solution $U_m(r,t)$ of (1.2)–(1.3) is called a *periodic rotating wave* if it satisfies

$$U_m(r,t+T_m) = U_m(r,t) + \frac{2\pi}{m}$$

for some $T_m > 0$. Clearly, a periodic rotating wave changes its profile periodically in time (see Figure 1.1). The *average rotating speed* of a periodic rotating wave is

$$\omega_m = \frac{2\pi}{mT_m}.$$

In what follows we concentrate our attention on periodic rotating waves with average rotating speed $\omega_m = O(1)$ as $m \to \infty$.

Before stating the main results, we give some assumptions on the boundaries:

$$\alpha_1 + \beta_1 < \frac{\pi}{2}, \qquad \alpha_2 + \beta_2 < \frac{\pi}{2}, \tag{1.5}$$

$$|h'| \cdot \overline{M} < 1, \qquad |g'| \cdot \overline{M} < 1, \tag{1.6}$$

where $\overline{M} = \max\{M_1, M_2\} + 1$ with

$$M_1 := \max\left\{\frac{\tan\alpha_1}{H}, \frac{\tan\beta_1}{H}, \frac{\tan\alpha_2}{G}, \frac{\tan\beta_2}{G}\right\}, \tag{1.7}$$

and $M_2 > 0$ is such that

$$w(2 + 5H^2w^2 + H^4w^4) > A(1 + H^2w^2)^{3/2} \quad \text{for } w > M_2. \tag{1.8}$$

Roughly speaking these conditions require that the undulation of the boundaries be gradual. Assumption (1.5) excludes the possible singularity that the curve touches $\partial\Omega_m$ at some points besides the two end points. Assumption (1.6) guarantees the boundedness of $|u_r|$ on the boundaries (see Appendix A), and it also ensures that we can convert $u(r,t)$ into another unknown $v(z,t)$ defined on $z \in [0,1]$; we can then simply carry out a rigorous proof (see (A.9) in Appendix A). It should be pointed out that these conditions are not necessary ones and can be weakened in special cases.

About the existence we have the following.

THEOREM 1.1. *Assume* (1.5) *and* (1.6) *hold. Then for large* m, (1.2)–(1.3) *has a periodic rotating wave* $U_m(r,t)$ *if and only if*

$$A > \frac{2H\sin\alpha_1 + 2G\sin\alpha_2}{G^2 - H^2}. \tag{1.9}$$

Moreover, a periodic rotating wave is unique up to a time-shift when it exists.

In fact, (1.9) is a necessary and sufficient condition for the existence of rotating *lower* solutions (see subsection 2.1.3).

A more important aim in this paper is to study how the periodic rotating wave and its average speed depend on the shape of the boundaries. In chemical, physical, or biological experiments, traveling/rotating waves can be observed directly. In this sense, people concern themselves with the traveling/rotating speed rather than the

existence, though the latter is important from a mathematical point of view. Generally, traveling/rotating waves in a trivial domain with flat boundaries can be studied by converting the problem to an ODE. However, the propagation in a domain with undulating boundaries (a domain with reticulated structure) cannot be converted to an ODE. We have to deal with a PDE directly. Thus the study for the speed of traveling/rotating waves in undulating domains is important and difficult. Very little is known so far.

We estimate the average rotating speed ω_m and determine its homogenization limit as well as the homogenization limit of $U_m(r,t)$ as $m \to \infty$.

THEOREM 1.2. *Assume* (1.5), (1.6), *and* (1.9) *hold. Then for large* m,

(i) *there exists* $C = C(h', g', H, G, A) > 0$ *such that* ω_m *satisfies*

$$\omega^* - \frac{C}{m} \ < \ \omega_m \ < \ \omega^* + \frac{C}{\sqrt{m}} < \omega_0, \tag{1.10}$$

where $\omega^* = \omega^*(\alpha_1, \alpha_2, H, G, A)$ *is given by the unique solution* $(\omega^*, \varphi^*(r;\omega^*))$ *of*

$$\begin{cases} \omega = \dfrac{\varphi''}{1+r^2\varphi'^2} + \dfrac{2\varphi' + r^2\varphi'^3}{r(1+r^2\varphi'^2)} + A\dfrac{\sqrt{1+r^2\varphi'^2}}{r}, & H < r < G, \\ \varphi'(H) = \dfrac{\tan\alpha_1}{H}, \qquad \varphi'(G) = \dfrac{-\tan\alpha_2}{G}, \end{cases} \tag{1.11}$$

where ω_0 *is given by the unique rotating wave solution of* (1.2), (1.4) *in* Ω_0;

(ii) *as* $m \to \infty$, $U_m(r,t) \to \varphi^*(r;\omega^*) + \omega^* t + C$ *in* $C^{2,1}([H,G] \times [-T,T])$ *for any* $T > 0$, *where* C *is a constant independent of* T.

$\omega_m < \omega_0$ in (1.10) implies that boundary undulation always lowers the speed of the rotating wave, and $\omega^* < \omega_0$ implies that the effect of spatial inhomogeneity of Ω_m is left to the homogenization limit. Moreover, the fact that homogenized speed ω^* depends only on α_1, α_2 (besides H, G, A) is a surprising result.

In [15], we studied periodic traveling waves of (1.1) in an undulating band domain, obtaining results similar to those above. The problem in that paper is different from the present one on several points. First, since the boundaries of an annulus have period 2π anyway, Theorem 1.1 remains valid even if the smallest periods of h and g are 2π, provided the undulation of h and g is gradual. (We omit the detail in this paper.) Second, the backgrounds are different. Mean curvature flows in an *unbounded* band domain are reduced from a traveling front or a traveling pulse, but in a *bounded* annulus can be reduced only from a rotating pulse. Third, the symmetries of a band domain and an annulus are different. This can be seen from the following fact. A flat band domain is quite simple, in which we have a planar traveling wave with speed A, while a trivial annulus is not symmetric in the direction of radius, in which the rotating wave of $V = \kappa + A$ is $\varphi(r) + \omega_0 t$; its profile is not planar. Especially, in case $G - H$ is large, the graph of $\varphi(r)$ may be a spiral which turns around the origin for several rounds (cf. [9], [20], [22]). Fourth, the boundaries of the band domain in [15] are symmetric and hence the boundary conditions are symmetric. But in this paper, outer and inner boundaries of Ω_m are given by different functions h, g, and the boundary conditions (1.3) are also not symmetric.

In section 2, we prove Theorem 1.1. First, we give a *global solution* of an initial-boundary value problem for appropriate initial data. Next, we use the global solution to construct an *entire solution* by using the *renormalization method*. Then we prove the uniqueness (up to a time-shift) of the entire solution; this immediately implies the

existence and uniqueness of *periodic rotating wave*. The necessity of (1.9) is explained in section 2.5. Finally, we state without proof the stability of periodic rotating waves.

In section 3 we prove Theorem 1.2: we estimate the average rotating speed by constructing a precise upper solution. We point out that our construction for an upper solution is a peculiar method, since the upper solution is larger than the solution not only on one period and not for all time, but just in time-interval $[0,1]$. However, this is good enough to give the upper bound of the average rotating speed.

2. Existence of periodic rotating waves.

2.1. Global solutions of the initial-boundary value problem. The proof for the existence of global solutions is divided into several steps. In subsection 2.1.1 we state the comparison principle as a preliminary. In subsection 2.1.2 we construct appropriate initial data $u_0(r)$. In subsection 2.1.3 we study rotating waves in trivial annuli, and select two of them as the lower solution and the upper solution. Using them we give the estimate of $|u|$ in finite time-interval $(0,T]$. In subsection 2.1.4 we give the a priori estimates for $|u_r|$, $|u_r|_\mu$ and for $|u|_\mu$ by converting the problem of $u(r,t)$ to a problem of a new unknown $v(z,t)$ $(z \in (0,1))$. Also we show the global existence, smoothness, and $C^{2+\mu,1+\frac{\mu}{2}}$ bound of u. The proofs in subsection 2.1.4 are long and the idea is similar to that of [15]; we move the details to the appendices.

In what follows, we also write $\frac{1}{m} = \varepsilon$ for convenience.

2.1.1. Comparison principle.

DEFINITION 2.1. *Let $u_1(r,t)$, $u_2(r,t)$ $(t \ge 0)$ be two functions satisfying $(r, u_i(r,t)) \in \overline{\Omega}_m$ $(i = 1,2)$. Then u_1 is called a lower solution of* (1.2)–(1.3) *if*

$$u_{1t} \le \frac{u_{1rr}}{1 + r^2 u_{1r}^2} + \frac{2u_{1r} + r^2 u_{1r}^3}{r(1 + r^2 u_{1r}^2)} + A\frac{\sqrt{1 + r^2 u_{1r}^2}}{r} \tag{2.1}$$

for $t \ge 0$ and r with $(r, u_1(r,t)) \in \Omega_m$,

$$\begin{aligned} &u_{1r}(r,t) \ge \frac{h'(u_1)}{r^2} \qquad \text{for } t \ge 0 \quad \text{and} \quad r \text{ with } (r, u_1(r,t)) \in \partial_1\Omega_m, \\ &u_{1r}(r,t) \le \frac{-g'(u_1)}{r^2} \qquad \text{for } t \ge 0 \quad \text{and} \quad r \text{ with } (r, u_1(r,t)) \in \partial_2\Omega_m. \end{aligned} \tag{2.2}$$

u_2 is said to be an upper solution of (1.2)–(1.3) *if the opposite inequalities hold.*

LEMMA 2.2. *Assume $u_1(r,t)$ and $u_2(r,t)$ are the lower solution and the upper solution of* (1.2)–(1.3) *for $0 \le t < t_1$, respectively. If $u_1(r,0) \le u_2(r,0)$, then $u_1(r,t) \le u_2(r,t)$ for $0 \le t < t_1$ and r with $(r, u_i(r,t)) \in \overline{\Omega}_m$. If $u_1(r,0) \le u_2(r,0)$ and $u_1(r,0) \not\equiv u_2(r,0)$, then $u_1(r,t) < u_2(r,t)$ for $0 < t < t_1$ and r with $(r, u_i(r,t)) \in \overline{\Omega}_m$.*

This lemma follows from the maximum principle.

2.1.2. Appropriate initial data. Assume $\theta_1 \in (0, 2\pi\varepsilon)$ such that $h'(\theta_1) = 0$ and $h'(\theta) \le 0$ for $\theta_1 \le \theta < \theta_1 + \delta_1$ for small $\delta_1 > 0$. Since the period of the boundaries is $2\pi\varepsilon$, there exists $\theta_2 \in (-2\pi\varepsilon + \theta_1, 2\pi\varepsilon + \theta_1)$ such that $g'(\theta_2) = 0$ and $g'(\theta) \le 0$ for $\theta_2 \le \theta < \theta_2 + \delta_1$, provided $\delta_1 > 0$ is small. Denote $P_1 = (H - h(\theta_1), \theta_1)$ and $P_2 = (G + g(\theta_2), \theta_2)$. It is easy to connect P_1 and P_2 by a smooth curve Γ_0 (denote its function by $u_0(r)$) such that the parts of Γ_0 near the boundaries are straight line segments, it contacts $\partial_1\Omega_m$ (resp., $\partial_2\Omega_m$) at P_1 (resp., P_2) vertically, and

$$|u_0(r)| = O(\varepsilon), \quad |u_{0r}(r)| = O(\varepsilon), \quad |u_{0rr}(r)| = O(\varepsilon).$$

Choose $\delta_2 > 0$ small. Then function $u_0(r)+\delta_2 t$ satisfies (2.1). Moreover, for small $\sigma_1 > 0$ and $t \in [0, \sigma_1]$, this function also satisfies (2.2), which is equivalent to saying that the graph of $u_0(r) + \delta_2 t$ contacts $\partial_i \Omega_m$ with angles not less than $\frac{\pi}{2}$. Therefore, $u_0(r) + \delta_2 t$ is a lower solution of (1.2)–(1.3) on $t \in [0, \sigma_1)$.

Assume $u(r, t)$ is a solution of (1.2)–(1.3) with initial data $u_0(r)$ on time-interval $0 \le t < \sigma_2$. Denote $\sigma_3 := \min\{\sigma_1, \sigma_2\}$. Then using the comparison principle to solution $u(r, t)$ and lower solution $u_0(r) + \delta_2 t$ we have

$$u(r, t) \ge u_0(r) + \delta_2 t, \qquad 0 \le t < \sigma_3.$$

For any given $t_1, t_2 \in [0, \sigma_3)$ with $t_2 > t_1$, the above inequality implies that

$$u(r, t_2 - t_1) \ge u_0(r) + \delta_2(t_2 - t_1) > u_0(r).$$

Note that a solution starting at $u(r, t_2 - t_1)$ is nothing but $u(r, t + t_2 - t_1)$. Applying again the comparison principle again to $u(r, t + t_2 - t_1)$ and to solution $u(r, t)$ (which starts at $u_0(r)$), we have

$$u(r, t + t_2 - t_1) > u(r, t), \qquad 0 \le t < \sigma_2 - (t_2 - t_1).$$

Especially, at $t = t_1$, it is $u(r, t_2) > u(r, t_1)$. Since $t_1, t_2 \in (0, \sigma_3)$ with $t_2 > t_1$ can be chosen arbitrarily, we have

$$u_t(r, t) \ge 0, \qquad 0 \le t < \sigma_3.$$

Finally, it is easily seen that this inequality holds indeed on $[0, \sigma_2)$.

2.1.3. Rotating waves in trivial annuli. In this part we study rotating waves in trivial annuli. We shall select two such rotating waves as the lower solution and the upper solution, and then we can give an a priori estimate of $|u|$ for finite time T by using the lower and upper solutions.

Let $\widetilde{H}$ and $\widetilde{G}$ be constants satisfying $\widetilde{H} = H + O(\varepsilon), \widetilde{G} = G + O(\varepsilon)$. Let $\gamma_1, \gamma_2 \in (-\frac{\pi}{2}, \frac{\pi}{2})$ and consider the two-point boundary value problem of the ODE

$$\begin{cases} \omega = \dfrac{\varphi''}{1 + r^2\varphi'^2} + \dfrac{2\varphi' + r^2\varphi'^3}{r(1 + r^2\varphi'^2)} + A\dfrac{\sqrt{1 + r^2\varphi'^2}}{r}, & \widetilde{H} < r < \widetilde{G}, \\ \varphi'(\widetilde{H}) = \dfrac{\tan\gamma_1}{\widetilde{H}}, \quad \varphi'(\widetilde{G}) = \dfrac{-\tan\gamma_2}{\widetilde{G}}, \quad \varphi(\widetilde{H}) = 0. \end{cases} \tag{2.3}$$

If there exist ω and $\varphi(r) = \varphi(r; \omega, \widetilde{H}, \widetilde{G}, \gamma_1, \gamma_2)$ satisfying (2.3), then we call the pair $(\omega, \varphi(r))$ a solution of (2.3). This solution determines a rotating wave $\varphi(r) + \omega t$ of (1.2) in annulus $\{(r, \theta) | \widetilde{H} < r < \widetilde{G}\}$, and its graph contacts $r = \widetilde{H}$ (resp., $r = \widetilde{G}$) with angle $\frac{\pi}{2} + \gamma_1$ (resp., $\frac{\pi}{2} + \gamma_2$).

LEMMA 2.3. (i) *Assume* (1.9) *holds and* ε *is small. Let* $\gamma_i \in [0, \alpha_i + \zeta_i\varepsilon)$ $(i = 1, 2)$ *for* $\zeta_i = O(1)$. *Then* (2.3) *has a unique solution* $(\omega_l, \varphi(r; \omega_l))$, *and* $\omega_l > 0$.

(ii) *Let* $\gamma_i = -\beta_i + O(\varepsilon)$ $(i = 1, 2)$. *Then* (2.3) *has a unique solution* $(\omega_u, \varphi(r; \omega_u))$, *and* $\omega_u > 0$.

(iii) $\omega_l < \omega_u$.

Proof. Set $\psi(r) = \varphi'(r)$, and consider the following initial value problem:

$$\begin{cases} \psi' = \omega(1 + r^2\psi^2) - \dfrac{2\psi + r^2\psi^3}{r} - A\dfrac{(1 + r^2\psi^2)^{3/2}}{r}, & r \ge \widetilde{H}, \\ \psi(\widetilde{H}) = \dfrac{\tan\gamma_1}{\widetilde{H}}. \end{cases} \tag{2.4}$$

For each ω, denote the solution of (2.4) by $\psi(r;\omega)$. It is clear that $\psi(r;\omega)$ is strictly increasing in ω.

(i) First, when $\omega \geq A/\widetilde{H}$, we have $\psi(r) \geq 0$ $(r > \tilde{H})$.

Next, when $\omega = 0$, the solution of (2.4) is

$$\psi(r;0) = \frac{\frac{L}{r} - \frac{Ar}{2}}{r\sqrt{1-(\frac{L}{r} - \frac{Ar}{2})^2}} \qquad \text{for } \ r \in [\widetilde{H}, \tilde{r}),$$

where $L = \frac{A}{2}\widetilde{H}^2 + \widetilde{H}\sin\gamma_1$ and $\tilde{r} = \frac{1+\sqrt{1+2AL}}{A}$. If $\tilde{r} \leq \widetilde{G}$, then for some $\omega_1 > 0$, $\psi(r;\omega_1)$ is defined on $[\widetilde{H}, \widetilde{G}]$ and $\psi(\widetilde{G};\omega_1) < \frac{-\tan\gamma_2}{\widetilde{G}}$. If $\tilde{r} > \widetilde{G}$, then $\psi(\widetilde{G};0) < \frac{-\tan\gamma_2}{\widetilde{G}}$ if and only if the following holds:

$$A > \frac{2\widetilde{H}\sin\gamma_1 + 2\widetilde{G}\sin\gamma_2}{\widetilde{G}^2 - \widetilde{H}^2}. \tag{2.5}$$

This is true since (1.9) holds and ε is small. Then we always have $\omega_2 \geq 0$ such that $\psi(\widetilde{G};\omega_2) < \frac{-\tan\gamma_2}{\widetilde{G}}$.

Therefore, there is a unique $\omega_l > 0$ such that the solution $\psi(r;\omega_l)$ of (2.4) is defined on $[\widetilde{H}, \widetilde{G}]$ and $\psi(\widetilde{G};\omega_l) = \frac{-\tan\gamma_2}{\widetilde{G}}$, which determines a solution of (2.3): $\varphi(r) = \int_{\widetilde{H}}^{r} \psi(\zeta;\omega_l)d\zeta$.

(ii) can be proved in a way similar to (i) above, and (iii) is verified by an easy analysis of (2.4). □

Now we use this lemma to construct lower and upper solutions. We show that for appropriate choice of $\widetilde{H}$, $\widetilde{G}$, γ_1, and γ_2, the rotating wave $\varphi(r;\omega,\widetilde{H},\widetilde{G},\gamma_1,\gamma_2) + \omega t$, given by the unique solution of (2.3), is a lower/upper solution of (1.2)–(1.3).

Remark 2.1. We remark that it is complicated to state the *optimal* lower solution (cf. section 2.5). Here by *optimal* lower solution we mean a rotating wave whose graph contacts $\partial\Omega_m$ with angles not smaller than $\frac{\pi}{2}$ and, at some points, exactly $\frac{\pi}{2}$. For example, even if we choose a rotating wave whose graph contacts $\partial_1\Omega_m$ perpendicularly at point $(H - h(s_1), s_1)$ where $h'(s_1) = H\tan\alpha_1$, and contacts $\partial_2\Omega_m$ perpendicularly at point $(G + g(s_2), s_2)$ where $g'(s_2) = G\tan\alpha_2$, we are not yet clear whether the angles between the graph of the rotating wave and $\partial\Omega_m$ are larger than $\frac{\pi}{2}$ at other places, because this depends on the geometry of $\partial\Omega_m$ and the shape of the rotating wave. So for simplicity, instead of constructing the *optimal* lower solution, we construct a *good* lower solution, which is a rotating wave whose graph contacts $\partial\Omega_m$ with angles not smaller than $\frac{\pi}{2}$, and equals $\frac{\pi}{2} + O(\varepsilon)$ at some points.

In what follows, we shall use many positive constants μ, C, ζ_1, ζ_2, etc., which may be different from line to line and may depend on some of h, g, H, G, A, m and sometimes on t. When such a constant depends only on h', g', H, G, A, or even if it depends on h, g, and m but can be replaced by another constant independent of h, g, and m (as $m \to \infty$), then we will omit the dependence on h, g, h', g', H, G, A, m and just write it simply as μ or C; only when μ or C really depends on m and t do we write it out clearly, i.e., $\mu(t)$, $C(t,m)$, etc.

LEMMA 2.4. *Assume* (1.9) *holds and* ε *is small. Then* (1.2)–(1.3) *has a lower solution* $\widehat{\varphi}(r) + \widehat{\omega}t$ *and upper solution* $\widetilde{\varphi}(r) + \widetilde{\omega}t$.

Let $u(r,t)$ $(t \in [0,T))$ *be the solution of* (1.2)–(1.3) *with initial data* $u_0(r)$ *as in subsection* 2.1.2. *Then for* $t_0 \in [0,T)$ *and* $t \in [0, T - t_0)$ *we have*

$$\widehat{\omega}t - C \leq u(r, t+t_0) - u(r,t_0) \leq \widetilde{\omega}t + C \tag{2.6}$$

for some $C > 0$.

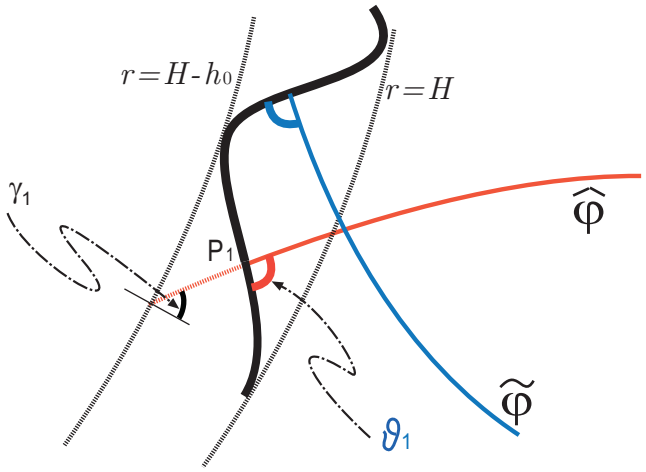

FIG. 2.1. Good *lower solution*.

Proof. Denote $h_0 = \max_s h(s)$, $g_0 = \max_s g(s)$. Consider

$$(2.7)\quad \begin{cases} \omega = \dfrac{\varphi''}{1+r^2\varphi'^2} + \dfrac{2\varphi' + r^2\varphi'^3}{r(1+r^2\varphi'^2)} + A\dfrac{\sqrt{1+r^2\varphi'^2}}{r}, \quad H-h_0 < r < G+g_0, \\ \varphi'(H-h_0) = \dfrac{\tan\gamma_1}{H-h_0}, \qquad \varphi'(G+g_0) = \dfrac{-\tan\gamma_2}{G+g_0}, \qquad \varphi(H-h_0) = 0, \end{cases}$$

with $\gamma_i = \alpha_i + \zeta_i\varepsilon$ $(i = 1, 2)$. Denote the unique solution of this problem by $(\widehat{\omega}, \widehat{\varphi}(r))$. Suppose that the graph of $\widehat{\varphi}(r)$ contacts $\partial_1\Omega_m$ (resp., $\partial_2\Omega_m$) at P_1 (resp., P_2) with angle ϑ_1 (resp., ϑ_2) (see Figure 2.1).

Then a careful analysis shows that, for large ζ_i $(i = 1, 2)$ with order $O(1)$, we have $\vartheta_i \geq \frac{\pi}{2}$ $(i = 1, 2)$, and there exist s_1 and s_2 such that

$$(2.8)\quad \vartheta_1 = \frac{\pi}{2} + O(\varepsilon) \ \text{ at } (H - h(s_1), s_1), \qquad \vartheta_2 = \frac{\pi}{2} + O(\varepsilon) \ \text{ at } (G + g(s_2), s_2).$$

Hence $\widehat{\varphi}(r) + \widehat{\omega}t$ is a *good* lower solution of (1.2)–(1.3).

In a similar way, using (ii) in Lemma 2.3 one can find a solution $(\widetilde{\omega}, \widetilde{\varphi}(r))$ of (2.3) with $\gamma_i = -\beta_i - \zeta_i\varepsilon$. It is easy to see that when $\zeta_i > 0$ is large, the graph of $\widetilde{\varphi}(r) + \widetilde{\omega}t$ contacts $\partial\Omega_\varepsilon$ with angles smaller than $\frac{\pi}{2}$, and equal to $\frac{\pi}{2} + O(\varepsilon)$ at some points. This means that $\widetilde{\varphi}(r) + \widetilde{\omega}t$ is an upper solution of (1.2)–(1.3).

Now if $u(r, t)$ is the solution of (1.2)–(1.3) on $[0, T)$, then we denote $\operatorname{osc} u(r, t) := \max_r u(r, t) - \min_r u(r, t)$ to be the oscillation of $u(r, t)$. By (i) of Lemma 2.5 below, which has nothing to do with this lemma, there exists C such that

$$\operatorname{osc} \widehat{\varphi}(r), \quad \operatorname{osc} \widetilde{\varphi}(r), \quad \operatorname{osc} u(r, t) \leq C.$$

For any $t_0 \in [0, T)$ and $t \in [0, T - t_0)$, we have

$$\widehat{\varphi}(r) + u(0, t_0) - 2C \leq u(r, t_0) \leq \widetilde{\varphi}(r) + u(0, t_0) + 2C,$$

$$\widehat{\varphi}(r) + \widehat{\omega}t + u(0, t_0) - 2C \leq u(r, t + t_0) \leq \widetilde{\varphi}(r) + \widetilde{\omega}t + u(0, t_0) + 2C.$$

Hence

$$\widehat{\omega}t - 6C \leq u(r, t + t_0) - u(r, t_0) \leq \widetilde{\omega}t + 6C. \qquad \square$$

2.1.4. A priori estimates and global existence. In this subsection, we give some a priori estimates and then prove the global existence of solutions of (1.2)–(1.3). Since the proofs are very long and are not our main purpose in this paper, we move them to the appendices.

For any $T > 0$, denote $Q_T := \{(r,t) \mid \eta_1(t) < r < \eta_2(t) \text{ and } 0 < t \le T\}$.

LEMMA 2.5. *Let $u(r,t) \in C^{2,1}(\overline{Q_T})$ be a solution of (1.2)–(1.3) with initial data $u_0(r)$. Then for $(r,t) \in \overline{Q_T}$ we have*

(i) $|u_r(r,t)| < \overline{M}$;

(ii) *there exist $\mu(T) > 0$ and $C > 0$ (independent of T) such that $|u_r|_\mu \le C$;*

(iii) *there exist $\mu(T) > 0$ and $C > 0$ (independent of T) such that $|u|_\mu \le C$.*

Based on Lemmas 2.4 and 2.5, we have the following result.

LEMMA 2.6. *Assume (1.9) holds. Then (1.2)–(1.3) with initial data u_0 has a unique, global solution $u(r,t)$ which satisfies $u_t(\cdot,t) \ge 0$.*

Moreover, for any $T > 0$, there exist positive constants $\mu(T)$, C_1, and C_2 (C_1, C_2 are independent of T) such that

$$u \in C^{2+\mu,1+\frac{\mu}{2}}(\overline{Q_T}) \qquad \text{and} \qquad \|u(r,t)\|_{C^{2+\mu,1+\frac{\mu}{2}}(\overline{Q_T})} \le C_1 T + C_2. \tag{2.9}$$

2.2. Existence of entire solutions. A solution defined on $t \in (-\infty,\infty)$ is called an *entire solution*. We use the *renormalization method* to show the existence of entire solutions.

LEMMA 2.7. *Equations (1.2)–(1.3) have an entire solution $U(r,t)$ such that $U_t(r,t) \ge 0$ and*

$$\widehat{\omega}t - \widehat{C} \le U(r,t+t_0) - U(r,t_0) \le \widetilde{\omega}t + \widetilde{C} \qquad \text{for } t_0 \in \mathbf{R} \text{ and } t \ge 0, \tag{2.10}$$

for some $\widehat{C}, \widetilde{C} > 0$.

Proof. Let u be the global solution of (1.2)–(1.3) obtained in Lemma 2.6. Take $t_n \to \infty$ in the following way:

$$\max_r u(r,t_n) = n \cdot 2\pi\varepsilon \qquad (n = n_0, n_0+1, \ldots),$$

where n_0 is a large integer. Set

$$u_n(r,t) := u(r,t+t_n) - n \cdot 2\pi\varepsilon.$$

Then u_n also satisfies (1.2)–(1.3) for $-t_n \le t < \infty$, and

$$\max_r u_n(r,0) = 0, \qquad \frac{\partial u_n}{\partial t} \ge 0 \qquad (n = n_0, n_0+1, \ldots).$$

By (2.6), there exist $\widehat{C}, \widetilde{C} > 0$ such that

$$\widehat{\omega}t - \widehat{C} \le u_n(r,t) \le \widetilde{\omega}t + \widetilde{C} \qquad \text{for} \quad -t_n \le t < \infty. \tag{2.11}$$

For any given $T > 0$, consider the problem about u_n (for large n) on $[-T,T]$. One can see that (i)–(iii) of Lemma 2.5 and (2.9) remain valid for u_n, the constant μ depends on T, and neither μ nor C depend on n. Therefore there exist $\mu = \mu(T) > 0$, $U(r,t) \in C^{2+\mu,1+\frac{\mu}{2}}(\overline{Q_T^U})$, and a sequence $n_j \to \infty$ ($j \to \infty$) such that

$$u_{n_j}(r,t) \to U(r,t) \qquad \text{in} \quad C^{2+\mu,1+\frac{\mu}{2}}(\overline{Q_T^U}),$$

where $Q_T^U := \{(r,t) \mid t \in [-T,T], r \text{ with } (r,U(r,t)) \in \Omega_m\}$.

Taking $T \to \infty$ and using Cantor's diagonal argument, one finds that there exists a sequence, still writing it as n_j ($n_j \to \infty$ as $j \to \infty$) and $U(r,t) \in C^{2,1}(\overline{Q_\infty^U})$ with $Q_\infty^U = \lim_{T\to\infty} Q_T^z$, such that for any $T > 0$, $U(r,t) \in C^{2+\mu(T),1+\frac{\mu(T)}{2}}(\overline{Q_T^U})$ for some $\mu(T) > 0$ and

$$u_{n_j}(r,t) \to U(r,t) \qquad \text{in} \quad C^{2+\mu(T),1+\frac{\mu(T)}{2}}(\overline{Q_T^U}).$$

Hence U is an entire solution of (1.2)–(1.3). It is also easy to see that U satisfies (2.10), $\max_r U(r,0) = 0$, and satisfies all the conclusions for u in Lemmas 2.5 and 2.6. □

2.3. Uniqueness of entire solution. Assume $U(r,t)$ and $W(r,t)$ are two entire solutions of (1.2)–(1.3) satisfying (2.10) and the conclusions for u in Lemmas 2.5 and 2.6. We shall prove that U is a time-shift of W. Define

$$\Lambda_{U,W}(t) := \inf\{\Lambda > 0 \mid \exists\, a \in \mathbf{R} \text{ such that } U(r,t+a) \le W(r,t) \le U(r,t+a+\Lambda)\}.$$

LEMMA 2.8. (i) *$\Lambda_{U,W}(t)$ is monotone decreasing, and there exists $M > 0$ such that $0 \le \Lambda_{U,W}(t) \le M$ for $t \in \mathbf{R}$.*

(ii) *If $\Lambda_{U,W}(t_0) = 0$ for some t_0, then there exists $a \in \mathbf{R}$ such that $U(r,t+a) \equiv W(r,t)$ for $t \ge t_0$. If $\Lambda_{U,W}(t_0) > 0$ for some t_0, then $\Lambda_{U,W}(t) > 0$ and is strictly decreasing for $t < t_0$.*

Proof. (i) For any $t \in \mathbf{R}$, by the definition of $\Lambda_{U,W}(t)$ there exist r_1 and r_2 such that

$$U(r_1, t+a) = W(r_1,t), \quad W(r_2,t) = U(r_2, t+a+\Lambda_{U,W}(t)),$$

so

$$\begin{aligned}
&\max_r U(r,t+a+\Lambda_{U,W}(t)) - \min_r U(r,t+a)\\
&\le U(r_2,t+a+\Lambda_{U,W}(t)) + \operatorname{osc} U - (U(r_1,t+a) - \operatorname{osc} U)\\
&\le W(r_2,t) - W(r_1,t) + 2\overline{M}(G-H) \le 3\overline{M}(G-H).
\end{aligned}$$

On the other hand, (2.10) implies that

$$\begin{aligned}
&\max_r U(r,t+a+\Lambda_{U,W}(t)) - \min_r U(r,t+a)\\
&\ge U(r,t+a+\Lambda_{U,W}(t)) - U(r,t+a) \ge \widehat{\omega}\cdot\Lambda_{U,W}(t) - \widehat{C}.
\end{aligned}$$

Hence

$$0 \le \Lambda_{U,W}(t) \le \frac{3\overline{M}(G-H) + \widehat{C}}{\widehat{\omega}}.$$

(ii) The first statement in (ii) is clear by the uniqueness. If $\Lambda_{U,W}(t_0) > 0$ for some t_0, then for any $t < t_0$ we have

$$U(r,t+a) \le W(r,t) \le U(r,t+a+\Lambda_{U,W}(t)) \qquad \text{for some } a = a(t).$$

By the strong comparison principle, after time $\tau = t_0 - t > 0$ we have

$$U(r,t+\tau+a(t)) < W(r,t+\tau) < U(r,t+\tau+a(t)+\Lambda_{U,W}(t)),$$

i.e.,

$$U(r,t_0+a(t)) < W(r,t_0) < U(r,t_0+a(t)+\Lambda_{U,W}(t)).$$

By the definition of $\Lambda_{U,W}(t_0)$ we have

$$U(r,t_0+a(t_0)) \le W(r,t) \le U(r,t_0+a(t_0)+\Lambda_{U,W}(t_0))$$

for some $a(t_0)$; each of the two equalities holds at some r. Since $U_t \ge 0$ we have

$$a(t) < a(t_0) \qquad \text{and} \qquad a(t)+\Lambda_{U,W}(t) > a(t_0)+\Lambda_{U,W}(t_0),$$

and so $\Lambda_{U,W}(t) > \Lambda_{U,W}(t_0)$. □

It is also easy to know the following.

LEMMA 2.9. *Let U_n and W_n be two sequences of entire solutions of* (1.2)–(1.3). *If $U_n \to U_\infty$ for $t \in \mathbf{R}$ and r with $(r, U_\infty(r,t)) \in \Omega_m$, $W_n \to W_\infty$ for all $t \in \mathbf{R}$ and r with $(r, W_\infty(r,t)) \in \Omega_m$, then $\Lambda_{U_n,W_n}(t) \to \Lambda_{U_\infty,W_\infty}(t)$ for every t.*

Our aim in this section is to prove the following.

LEMMA 2.10. *$W(r,t)$ is a time-shift of $U(r,t)$.*

Proof. We need to show only that $\Lambda_{U,W}(t) = 0$ for all $t \in \mathbf{R}$. If this is not true, then $\Lambda_{U,W}(t_0) > 0$ for some t_0.

By the monotonicity and boundedness of $\Lambda_{U,W}(t)$, we have $\lim_{t\to-\infty} \Lambda_{U,W}(t) =: \bar\Lambda$ for some $\bar\Lambda$ satisfying $0 < \Lambda_{U,W}(t_0) < \bar\Lambda \le M$.

Set $l_n = \left[\max_r U(r,-n) \cdot \frac{m}{2\pi}\right]$ and define

$$U_n(r,t) := U(r,t-n) - \frac{2\pi}{m} l_n, \qquad W_n(r,t) := W(r,t-n) - \frac{2\pi}{m} l_n.$$

Then both of U_n and W_n satisfy the inequalities for u_n in (2.11), and so a discussion similar to that in the proof of Lemma 2.7 shows that there exists a sequence $n_j \to \infty$ ($j \to \infty$) and $U_\infty, W_\infty \in C^{2,1}$, which are entire solutions of (1.2)–(1.3), such that as $j \to \infty$,

$$U_{n_j}(r,t) \to U_\infty(r,t) \qquad \text{for } t \in \mathbf{R} \quad \text{and} \quad r \text{ with } (r, U_\infty(r,t)) \in \Omega_m,$$

$$W_{n_j}(r,t) \to W_\infty(r,t) \qquad \text{for } t \in \mathbf{R} \quad \text{and} \quad r \text{ with } (r, W_\infty(r,t)) \in \Omega_m.$$

It follows from Lemma 2.9 that $\Lambda_{U_\infty,W_\infty}(t) = \lim_{j\to\infty} \Lambda_{U_{n_j},W_{n_j}}(t)$.

On the other hand, $\Lambda_{U_{n_j},W_{n_j}}(t) = \Lambda_{U,W}(t-n_j)$, so $\Lambda_{U_\infty,W_\infty}(t) = \lim_{j\to\infty} \Lambda_{U,W}(t-n_j) = \bar\Lambda$, that is, $\Lambda_{U_\infty,W_\infty}(t) \equiv \bar\Lambda$ ($t \in \mathbf{R}$). Applying (ii) of Lemma 2.8 to functions U_∞ and W_∞ we see that this is true only if $\bar\Lambda = 0$, a contradiction to $\bar\Lambda > \Lambda_{U,W}(t_0) > 0$.

Therefore, $\Lambda_{U,W}(t) = 0$ (for all $t \in \mathbf{R}$), and so there exists a_0 such that $U(r,t+a_0) \equiv W(r,t)$ for $t \in \mathbf{R}$. □

2.4. Existence and uniqueness of periodic rotating wave.

Proof for the sufficiency part of Theorem 1.1. In previous sections we obtained an entire solution $U(r,t)$ of (1.2)–(1.3). Clearly, $U(r,t)+\frac{2\pi}{m}$ is also an entire solution; Lemma 2.10 implies that $U(r,t)+\frac{2\pi}{m}$ is a time-shift of $U(r,t)$, i.e., there exists $T_m > 0$ such that

$$U(r,t) + \frac{2\pi}{m} = U(r,t+T_m) \qquad \text{for } t \in \mathbf{R} \quad \text{and} \quad r \text{ with } (r, U(r,t)) \in \Omega_m.$$

In other words, $U(r,t)$ is a periodic rotating wave.

The uniqueness follows from the uniqueness of the entire solution.

2.5. Necessity of (1.9). We show that (1.9) is a necessary condition for the existence of counterclockwise periodic rotating waves with average rotating speeds $O(1)$.

(i) Assume $A = \frac{2H\sin\alpha_1+2G\sin\alpha_2}{G^2-H^2}$.

From the proof of Lemma 2.3, one sees that when $\widetilde{H} = H, \widetilde{G} = G, \gamma_1 = \alpha_1, \gamma_2 = \alpha_2$, (2.3) has the solution $(0, \varphi(r; 0, H, G, \alpha_1, \alpha_2))$.

Extend this solution $\varphi(r)$ a little beyond $[H, G]$; suppose its graph contacts $\partial_1\Omega_m$ (resp., $\partial_2\Omega_m$) at a point $P_1' = (H - h(s_1'), s_1')$ for some s_1' (resp., $P_2' = (G + g(s_2'), s_2')$ for some s_2'). Choose $s_i \in (s_i', s_i' + 2\pi\varepsilon)$ $(i = 1, 2)$ such that $h'(s_1) = H\tan\alpha_1$, $g'(s_2) = G\tan\alpha_2$. Denote $P_1 = (H - h(s_1), s_1)$, $P_2 = (G + g(s_2), s_2)$. Then when we move the extended graph of $\varphi(r)$ such that it contacts $\partial_1\Omega_m$ at P_1, the angle ϑ_1 between the graph of $\varphi(r)$ and $\partial_1\Omega_m$ will be $\frac{\pi}{2} + O(\varepsilon)$. A similar conclusion is true at $P_2 \in \partial_2\Omega_m$.

Let us see the shape of $\partial_i\Omega_m$ near P_i $(i = 1, 2)$. First, at P_1, $h'(s_1) = \max_s h'(s) = H\tan\alpha_1$, $h''(s_1) = 0$ and $h'''(s_1) = O(\frac{1}{\varepsilon^2})$. Then for $\Delta s \in (-\varepsilon^{3/2}, \varepsilon^{3/2})$, we have

$$\begin{aligned} h'(s_1 + \Delta s) &= H\tan\alpha_1 + \frac{h'''(s_1)}{2}(\Delta s)^2 + h^{(4)}(s^*)(\Delta s)^3 \\ &= H\tan\alpha_1 + O\left(\left(\frac{\Delta s}{\varepsilon}\right)^2\right) = h'(s_1) + O(\varepsilon). \end{aligned}$$

A similar discussion is valid on $\partial_2\Omega_m$ near P_2.

Since the solution of (2.7) depends on γ_i continuously, we know that when $\gamma_i = \alpha_i - \zeta_i\varepsilon$ ($\zeta_i > 0$ are large), there is a unique $\omega^s > 0, \omega^s = O(\varepsilon)$ and $\varphi^s(r; \omega^s)$ solves (2.7). Moreover, the graph of $\varphi^s(r) + \omega^s t$ contacts $\partial_1\Omega_m$ at points $(H - h(s), s)$ for $s \in (s_1 - \varepsilon^{3/2}, s_1 + \varepsilon^{3/2})$ with angles less than $\frac{\pi}{2}$, and contacts $\partial_2\Omega_m$ at points $(G + g(s), s)$ for $s \in (s_2 - \varepsilon^{3/2}, s_2 + \varepsilon^{3/2})$ with angles less than $\frac{\pi}{2}$.

Suppose the end points of $\varphi^s(r) + \omega^s t$ reach $s_i + \varepsilon^{3/2}$ at time t_i $(i = 1, 2)$ and denote $t_3 := \min\{t_1, t_2\}$; then the discussion in the previous paragraph shows that $\varphi^s(r) + \omega^s t$ is an upper solution on $t \in [0, t_3]$. In this period the speed of $\varphi^s(r) + \omega^s t$ is $\omega^s = O(\varepsilon)$, and the θ-distance of this period is $O(\varepsilon^{3/2})$. Hence the upper solution $\varphi^s(r) + \omega^s t$ uses more time than $C\varepsilon^{1/2}$ (for some $C > 0$) to pass this period. Any rotating wave will be blocked by this kind of upper solution in each period of Ω_m such that the rotating wave passes one period in time greater than $C\varepsilon^{1/2}$. In other words, its average speed is at most $O(\varepsilon^{1/2})$. This is not the case we are interested in here.

(ii) In case $A < \frac{2H\sin\alpha_1+2G\sin\alpha_2}{G^2-H^2}$, one can even find a curve (like $\varphi^s(r)$ above) such that it rotates *clockwise temporarily* in a small period, and it blocks *counterclockwise* rotation.

Consequently, (1.9) is a necessary condition.

2.6. Stability. One has the following stability result by general theory in [19].

THEOREM 2.11. *Let $U(r, t)$ be a counterclockwise periodic rotating wave of* (1.2)–(1.3). *Then $U(r, t)$ is asymptotically stable in the C^1 sense. More precisely, any solution $u(r, t)$ of* (1.2)–(1.3) *whose initial data $u(r, 0)$ is sufficiently close to $U(r, t_0)$ for some $t_0 \in \mathbf{R}$ satisfies*

$$\lim_{t\to\infty} \|U(\cdot, t + t_1) - u(\cdot, t)\|_{C^1} = 0$$

for some $t_1 \in \mathbf{R}$, where $\|\cdot\|_{C^1}$ is understood in the following sense: $U(r, t)$ and $u(r, t)$ correspond to $V(z, t)$ $(z \in (0, 1))$ and $v(z, t)$ $(z \in (0, 1))$, respectively, by using (A.2)

in the appendices. The above limit is understood as

$$\lim_{t\to\infty} \|V(z,\, t+t_1) - v(z,\, t)\|_{C^1} = 0.$$

3. Estimate of average speed: Proof of Theorem 1.2.

3.1. Proof of (i) in Theorem 1.2. Recall that in section 2.1 we construct a *good* lower solution $\widehat{\varphi}(r) + \widehat{\omega}t$, so the average rotating speed ω_m satisfies $\omega_m \geq \widehat{\omega}$. Denote by $(\omega^*, \varphi^*(r))$ the solution of (1.11) (that is, (2.3) with $\widetilde{H} = H,\ \widetilde{G} = G,\ \gamma_1 = \alpha_1,\ \gamma_2 = \alpha_2$). Then it is easy to see by the proofs of Lemmas 2.3 and 2.4 that

$$\omega^* = \widehat{\omega} + O(\varepsilon), \quad \varphi^* = \widehat{\varphi} + C + O(\varepsilon), \quad \varphi^{*\prime} = \widehat{\varphi}\,' + O(\varepsilon). \tag{3.1}$$

Therefore $\omega_m > \omega^* - \frac{C}{m}$ for some $C > 0$.

Also from the proofs of Lemmas 2.3 and 2.4 we have $\widehat{\omega} < \omega_0$ and so $\omega^* < \omega_0$.

This proves the first and the third inequalities of (1.10).

3.1.1. Upper solution. Now we use $\widehat{\varphi}(r) + \widehat{\omega}t$ to construct an upper solution. Let $U(r,t)$ be the periodic rotating wave of (1.2)–(1.3). We note that $U(r,t)\big|_{[H,G]}$ is nothing but the solution of

$$\begin{cases} \tilde{u}_t = \dfrac{\tilde{u}_{rr}}{1+r^2\tilde{u}_r^2} + \dfrac{2\tilde{u}_r + r^2\tilde{u}_r^3}{r(1+r^2\tilde{u}_r^2)} + A\dfrac{\sqrt{1+r^2\tilde{u}_r^2}}{r}, & t>0,\ H<r<G, \\ \tilde{u}(H,t) = U(H,t),\quad \tilde{u}(G,t) = U(G,t), & t>0, \\ \tilde{u}(r,0) = U(r,0), & H<r<G. \end{cases} \tag{3.2}$$

Without loss of generality, we may assume $U(r,0) \leq \widehat{\varphi}(r)$ for $r \in [H,G]$ and $U(r_0,0) = \widehat{\varphi}(r_0)$ for some $r_0 \in [H,G]$. Recall $\varepsilon = 1/m$ and define

$$w(r,t) = E\sqrt{\varepsilon}\,\left(1 - e^{-a^2t}\,\sin(ar+b)\right) + aEF\sqrt{\varepsilon}\,t \quad \text{for } r\in[H,G],\ t\geq 0, \tag{3.3}$$

where $E = O(1)$ is determined later, $a = \frac{\pi}{G-H},\ b = \frac{-\pi H}{G-H}$, and

$$F = \max_{H-h_0\leq r\leq G+g_0} |\,F(r)\,| + 2, \tag{3.4}$$

where

$$F = \frac{2(r\widehat{\varphi}'' + 2\widehat{\varphi}' + r^2(\widehat{\varphi}')^3)r^2\widehat{\varphi}' - 2 - 2r^2(\widehat{\varphi}')^2 - 3r^2(\widehat{\varphi}')^2(1+r^2(\widehat{\varphi}')^2)}{r(1+r^2(\widehat{\varphi}')^2)^2} - \frac{Ar\widehat{\varphi}'}{\sqrt{1+r^2(\widehat{\varphi}')^2}}.$$

It is clear that

$$w - aEF\sqrt{\varepsilon}t \geq 0, \qquad w_t = w_{rr} + aEF\sqrt{\varepsilon} > 0, \qquad \min w(r,0) = 0.$$

LEMMA 3.1. *$\bar{u}(r,t) := w(r,t) + \widehat{\varphi}(r) + \widehat{\omega}t$ is an upper solution of (3.2) on $t\in[0,1]$, and hence*

$$\bar{u}(r,t) \geq U(r,t) \qquad \textit{for } r\in[H,G],\ t\in[0,1]. \tag{3.5}$$

Proof. To prove the lemma, it suffices to show that

$$\bar{u}_t \geq \frac{\bar{u}_{rr}}{1+r^2\bar{u}_r^2} + \frac{2\bar{u}_r + r^2\bar{u}_r^3}{r(1+r^2\bar{u}_r^2)} + A\frac{\sqrt{1+r^2\bar{u}_r^2}}{r} \qquad \text{for } H<r<G,\ t>0, \tag{3.6}$$

and

$$U(H,t) \le \bar{u}(H,t), \qquad t \in [0,1], \tag{3.7}$$

$$U(G,t) \le \bar{u}(G,t), \qquad t \in [0,1]. \tag{3.8}$$

We first prove (3.6). Direct calculation shows that

$$\begin{aligned} &\bar{u}_t - \frac{\bar{u}_{rr}}{1+r^2\bar{u}_r^2} - \frac{2\bar{u}_r + r^2\bar{u}_r^3}{r(1+r^2\bar{u}_r^2)} - A\frac{\sqrt{1+r^2\bar{u}_r^2}}{r} \\ &= w_t - \frac{w_{rr}}{1+r^2(w_r+\widehat{\varphi}')^2} + F_1(r)w_r + O(\varepsilon) \ge 0, \end{aligned}$$

where

$$\begin{aligned} F_1(r) = &\frac{2(r\widehat{\varphi}'' + 2\widehat{\varphi}' + r^2(\widehat{\varphi}')^3)r^2\widehat{\varphi}' - 2 - 2r^2(\widehat{\varphi}')^2 - 3r^2(\widehat{\varphi}')^2(1+r^2(\widehat{\varphi}')^2)}{r(1+r^2(\widehat{\varphi}')^2)(1+r^2(w_r+\widehat{\varphi}')^2)} \\ &- \frac{2Ar\widehat{\varphi}'}{\sqrt{1+r^2(\widehat{\varphi}')^2}+\sqrt{1+r^2(w_r+\widehat{\varphi}')^2}} = F(r) + O(\sqrt{\varepsilon}) \end{aligned}$$

satisfies

$$|F_1(r)| < F - 1 \quad \text{(note that } |w_r| \le aE\sqrt{\varepsilon}\,\text{)}.$$

Next we prove (3.7) and (3.8). Suppose that they hold on $t \in [0,\tau]$ for some $\tau < 1$; we show that they hold in fact on $t \in [0,1]$.

Construct an arc $\theta = \zeta(r)$ as follows (see Figure 3.1). Assume that $h'(s_1) = H\tan\alpha_1$. Denote $P = (H - h(s_1), s_1) \in \partial_1\Omega_m$. Choose $\zeta(r)$ to be the arc with curvature $-A$ that contacts $\partial_1\Omega_m$ perpendicularly at P. Without loss of generality, assume that $\zeta(H) = \theta_0 \in (-2\pi\varepsilon, 2\pi\varepsilon)$. Then P and (H,θ_0) are on $\zeta(r)$.

By (2.8), we know that both $\widehat{\varphi}$ and $\zeta(r)$ have almost the same slope at P:

$$\widehat{\varphi}\,'(H - h(s_1)) - \zeta'(H - h(s_1)) = O(\varepsilon).$$

Hence, there exists $M > 0$ such that

$$|\widehat{\varphi}\,'(H + l\sqrt{\varepsilon}) - \zeta'(H + l\sqrt{\varepsilon})| \le (M-1)\sqrt{\varepsilon} \qquad \text{for any } \ l \in [0,1]. \tag{3.9}$$

Choose $D(\tau) > 0$, such that $\zeta(r) + D(\tau)$ intersects $\bar{u}(r,\tau)$ at $r = H + \sqrt{\varepsilon}$, that is, $\zeta(H+\sqrt{\varepsilon}) + D(\tau) = \bar{u}(H+\sqrt{\varepsilon},\tau)$ (see Figure 3.1). Then by (3.9) we have

$$\begin{aligned} D(\tau) &= w(H+\sqrt{\varepsilon},\tau) + \widehat{\varphi}(H+\sqrt{\varepsilon}) + \widehat{\omega}\tau - \zeta(H+\sqrt{\varepsilon}) \\ &= \bar{u}(H,\tau) + w_r(H,\tau)\sqrt{\varepsilon} + \widehat{\varphi}(H+\sqrt{\varepsilon}) - \widehat{\varphi}(H) - \zeta(H+\sqrt{\varepsilon}) + o(\varepsilon) \\ &< \bar{u}(H,\tau) - aEe^{-a^2}\varepsilon + (M+2\pi)\varepsilon. \end{aligned}$$

Therefore when we choose E satisfying $aEe^{-a^2} > 8\pi + M$ we have $D(\tau) < \bar{u}(H,\tau) - 6\pi\varepsilon$.

Since $\zeta(r)$ contacts $\partial_1\Omega_m$ at P perpendicularly, there exists $\delta \in [0, 2\pi\varepsilon)$ such that the graph of $\zeta(r) + D(\tau) + \delta$ contacts $\partial_1\Omega_m$ perpendicularly and hence $\zeta(r) + D(\tau) + \delta$ is stationary. So

$$U(H+\sqrt{\varepsilon},\tau) \le \bar{u}(H+\sqrt{\varepsilon},\tau) \le \zeta(H+\sqrt{\varepsilon}) + D(\tau) + \delta$$

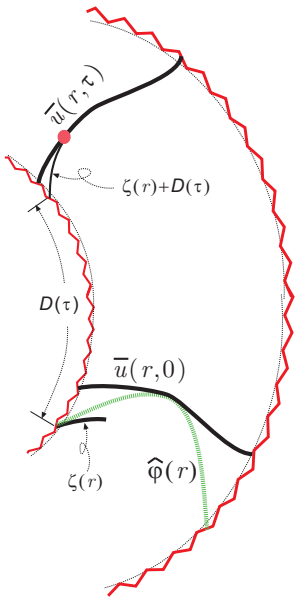

FIG. 3.1. *Upper solution.*

implies that $U(r,\tau) \le \zeta(r) + D(\tau) + \delta$ for $H < r < H + \sqrt{\varepsilon}$. Especially,

$$U(H,\tau) \le \zeta(H) + D(\tau) + \delta \le \bar{u}(H,\tau) - 2\pi\varepsilon.$$

So

$$\bar{u}(H,\tau+t) \ge \bar{u}(H,\tau) \ge U(H,\tau) + 2\pi\varepsilon \ge U(H,\tau+t) \qquad \text{for} \quad t \in [0,T_m].$$

This means that (3.7) holds on $t \in [0,\tau+T_m]$ provided $\tau < 1$. Repeating the above discussion finite times, we obtain (3.7).

Similarly, we can show (3.8) provided that E in the definition of w is chosen large enough. ∎

3.1.2. Proof of the second inequality in (1.10).

$$U(r,1) - \widehat{\varphi}(r) \le \bar{u}(r,1) - \widehat{\varphi}(r) \le (E+aEF)\sqrt{\varepsilon} + \widehat{\omega} \le \left[\frac{(E+aEF)\sqrt{\varepsilon}+\widehat{\omega}}{2\pi\varepsilon} + 1\right] \cdot 2\pi\varepsilon,$$

where $[\cdot]$ is a Gauss function. On the other hand, by the periodicity

$$U\left(r, \left[\frac{(E+aEF)\sqrt{\varepsilon}+\widehat{\omega}}{2\pi\varepsilon} + 1\right] \cdot T_m\right) \le \widehat{\varphi}(r) + \left[\frac{(E+aEF)\sqrt{\varepsilon}+\widehat{\omega}}{2\pi\varepsilon} + 1\right] \cdot 2\pi\varepsilon,$$

where " $=$ " holds at $r = r_0$. Hence time 1 is smaller than time $\left[\frac{(E+aEF)\sqrt{\varepsilon}+\widehat{\omega}}{2\pi\varepsilon}+1\right] \cdot T_m$, and so

$$\omega_m = \frac{2\pi}{mT_m} \le \widehat{\omega} + \frac{E+aEF+1}{\sqrt{m}}. \tag{3.10}$$

Therefore (3.1) implies that

$$\omega_m \le \omega^* + \frac{E+aEF+2}{\sqrt{m}}.$$

This completes the proof of (i) in Theorem 1.2.

3.2. Proof of (ii) in Theorem 1.2. In this subsection, we write the unique periodic rotating wave constructed in Lemma 2.7 by $U_m(r,t)$. Clearly, the period T_m of $U_m(r,t)$ is smaller than 1 when $m > m_0$ for some m_0.

For any given $T > 0$, by Lemma 2.7, U_m $(m = m_0, m_0+1, \ldots)$ are bounded in $C^{2+\mu,1+\frac{\mu}{2}}(\overline{Q_T^m})$, where $\mu = \mu(T)$ is independent of m and $Q_T^m := \{(r,t) | t \in [-T, T+1],\ r \text{ with } (r, U_m(r,t)) \in \Omega_m\}$. So there exists a sequence $\{m_i\}_{i=0}^{\infty}$ and $\mathcal{U}(r,t) \in C^{2,1}([H,G]\times[-T,T+1])$ such that

$$\|U_{m_i} - \mathcal{U}\|_{C^{2,1}([H,G]\times[-T,T+1])} \to 0 \qquad \text{as } \ i \to \infty.$$

Thus, for any $(r,t) \in [H,G]\times[-T,T]$, when $i \to \infty$ we have

$$\omega^* \leftarrow \omega_{m_i} = \frac{2\pi}{m_i T_{m_i}} = \frac{1}{T_{m_i}} \int_t^{T_{m_i}+t} \frac{\partial U_{m_i}(r,t)}{\partial t} dt = \frac{\partial U_{m_i}(r,s)}{\partial t} \to \mathcal{U}_t(r,t)$$

with $s \in (t, T_{m_i}+t)$. This means that $\mathcal{U}(r,t) = \mathcal{U}(r) + \omega^* t$ in $[H,G]\times[-T,T]$ for some $\mathcal{U}(r) \in C^2([H,G])$.

U_{m_i} is the solution of (1.2)–(1.3); taking limit $i \to \infty$ in these equations we have

$$\text{(3.11)} \quad \begin{cases} \omega^* = \dfrac{\mathcal{U}_{rr}}{1+r^2\mathcal{U}_r^2} + \dfrac{2\mathcal{U}_r + r^2\mathcal{U}_r^3}{r(1+r^2\mathcal{U}_r^2)} + A\dfrac{\sqrt{1+r^2\mathcal{U}_r^2}}{r}, & H \le r \le G, \\ \mathcal{U}_r(H) \in \left[\dfrac{-\tan\beta_1}{H},\ \dfrac{\tan\alpha_1}{H}\right], \qquad \mathcal{U}_r(G) \in \left[\dfrac{-\tan\alpha_2}{G},\ \dfrac{\tan\beta_2}{G}\right]. \end{cases}$$

Comparing it with (1.11) we find that when $\mathcal{U}_r(H) < \frac{\tan\alpha_1}{H}$, $\mathcal{U}_r(r) < \varphi_r^*(r;\omega^*)$ and so $\mathcal{U}_r(G) < \frac{-\tan\alpha_2}{G}$. Therefore, (3.11) has a solution if and only if

$$\mathcal{U}_r(H) = \frac{\tan\alpha_1}{H}, \quad \mathcal{U}_r(G) = \frac{-\tan\alpha_2}{G},$$

and the solution $\mathcal{U}(r)$ is nothing but $\varphi^*(r;\omega^*) + C$ for some C. Recall that we require $\max_r U_m(r,0) = 0$ in the proof of Lemma 2.7; hence $\max_r \mathcal{U}(r) = 0$, which implies that $C = -\max_r \varphi^*(r;\omega^*)$.

For any sequence $\{U_{m_j}\}$, there is a subsequence $\{U_{m_{j_k}}\}$ that converges to the same homogenized limit $\varphi^*(r;\omega^*)+\omega^* t - \max_r \varphi^*(r;\omega^*)$ in $C^{2,1}([H,G]\times[-T,T])$ as $k \to \infty$. Consequently, $U_m(r,t) \to \varphi^*(r;\omega^*) + \omega^* t - \max_r \varphi^*(r;\omega^*)$ in $C^{2,1}([H,G]\times[-T,T])$ as $m \to \infty$. This proves (ii) of Theorem 1.2.

Appendix A. Proof of Lemma 2.5.

(i) *of Lemma* 2.5. Set $w = u_r$; then for $t \in (0,T]$ and $\eta_1(t) < r < \eta_2(t)$ we have

$$\text{(A.1)} \quad \begin{cases} w_t = \dfrac{w_{rr}}{1+r^2w^2} + aw_r - \dfrac{2+5r^2w^2+r^4w^4}{r^2(1+r^2w^2)^2}w - \dfrac{A}{r^2\sqrt{1+r^2w^2}}, \\ w(\eta_1(t),t) = h'(u(\eta_1(t),t))/\eta_1^2(t), \quad w(\eta_2,t) = -g'(u(\eta_2(t),t))/\eta_2^2(t), \\ w(r,0) = u_0'(r) \qquad\qquad \text{for } \ r \ \text{ with } \ (r,u_0(r)) \in \Omega_m, \end{cases}$$

where $a = a(r,u,w)$ is a smooth function. By the boundary condition we have

$$-\frac{\tan\beta_1}{H} - \frac{C}{m} < w(\eta_1(t),t) < \frac{\tan\alpha_1}{H} + \frac{C}{m}$$

for some $C > 0$. Hence $|w(\eta_1(t), t)| \le M_1 + \frac{C}{m} < \overline{M} - \frac{1}{2}$. Similarly, $|w(\eta_2(t), t)| \le M_1 + \frac{C}{m} < \overline{M} - \frac{1}{2}$.

On the other hand, if w takes the maximum at (r_1, t) with $r_1 \in (\eta_1(t), \eta_2(t))$ and $w(r_1, t) > \overline{M} - \frac{1}{2}$, then we have

$$w_t(r_1, t) < \frac{w_{rr}(r_1, t)}{1 + r^2 w^2(r_1, t)} + a w_r(r_1, t) \le 0,$$

which implies that w will never be larger than $\overline{M} - \frac{1}{4}$. Similarly, if w takes the minimum at (r_2, t) with $r_2 \in (\eta_1(t), \eta_2(t))$ and $w(r_2, t) < -\overline{M} + \frac{1}{2}$, then, by the definition of M_2 in (1.8), we have

$$w_t(r_2, t) \ge -\frac{2 + 5r^2w^2 + r^4w^4}{r^2(1 + r^2w^2)^2} w - \frac{A}{r^2\sqrt{1 + r^2w^2}}\bigg|_{r=r_2} > 0.$$

Therefore, w will never be smaller than $-\overline{M} + \frac{1}{4}$. Thus we obtain (i) of Lemma 2.5.

We prove (ii) and (iii) of Lemma 2.5 by converting the problem of u into a problem about $v(z, t)$ $(z \in (0, 1))$.

Introduce a new variable

$$z := \frac{r - H + h(\theta)}{J(\theta)}$$

with $J(\theta) = G - H + g(\theta) + h(\theta)$. Then in the new coordinates (z, θ), domain Ω_m is expressed as a domain $\{(z, \theta) \mid z \in (0, 1), \theta \in \mathbf{R}\}$. Now, given a solution $u(r, t)$ of (1.2), we define a new unknown $v(z, t)$ by

$$v(z, t) = u(r(z, t), t), \tag{A.2}$$

where $r(z, t)$ is the inverse function of

$$z(r, t) = \frac{r - H + h(u(r, t))}{J(u(r, t))}.$$

Such an inverse function exists if

$$\frac{\partial z}{\partial r} := \frac{J(u) + [(G + g)h' + (H - h)g' - r(g' + h')]u_r}{J^2(u)} \ne 0,$$

that is,

$$J(u) + [(G + g)h' + (H - h)g' - r(g' + h')]u_r \ne 0. \tag{A.3}$$

We will see later that (A.3) always holds for any solution of (1.2)–(1.3) with appropriate initial data. From $\frac{\partial z}{\partial r} \ne 0$, we have inverse function $r(z, t)$ and

$$\frac{\partial r}{\partial z} = J(v) + (g' + h')z v_z - h' v_z \ne 0.$$

As is easily seen, we have

$$u_r = v_z \frac{\partial z}{\partial r} = \frac{v_z}{J(v)} + \frac{[(G + g)h' + (H - h)g' - r(g' + h')]u_r v_z}{J^2(v)}$$

and hence

$$u_r = \frac{J(v)v_z}{J^2(v) - [(G+g)h' + (H-h)g' - r(g'+h')]v_z} = \frac{v_z}{J(v) + I(z,v)v_z},$$

where $I(z,v) = z(g'(v) + h'(v)) - h'(v)$. Similarly,

$$u_{rr} = \frac{Jv_{zz} - 2(g'+h')v_z^2 - (z(g''+h'') - h'')v_z^3}{(J+Iv_z)^3}, \quad u_t = \frac{Jv_t}{J+Iv_z}$$

since

$$\frac{\partial z}{\partial t} = \frac{h' - z(g'+h')}{J} u_t.$$

Hence the problem about u reduces to a problem about v,

$$v_t = \frac{v_{zz}}{K} + f(z,v,v_z) \qquad \text{for } 0 < z < 1,\ t > 0, \tag{A.4}$$

with

$$f(z,v,p) = \frac{(Jz+H-h)p^3 - 2(g'+h')p^2 - [z(g''+h'') - h'']p^3}{JK} + \frac{2p(J+Ip)^2}{JK(Jz+H-h)}$$

and

$$K(z,v,p) = (J+Ip)^2 + p^2(Jz+H-h)^2.$$

Boundary conditions (1.3) reduce to

$$v_z(0,t) = \frac{Jh'}{(H-h)^2 + (h')^2}, \qquad v_z(1,t) = \frac{-Jg'}{(G+g)^2 + (g')^2}. \tag{A.5}$$

Any solution $u(r,t)$ of (1.2)–(1.3) satisfying (A.3) defines a solution $v(z,t)$ of (A.4)–(A.5) by the relation (A.2). Conversely, if $v(z,t)$ is a solution of (A.4)–(A.5), then the function $u(r,t)$ defined by

$$u(r,t) = v\left(\frac{r - H + h(u)}{J(u)}, t\right) \tag{A.6}$$

is a solution of (1.2)–(1.3). For u to be well defined by (A.6), we need to assume that

$$\frac{\partial}{\partial u}\left(u - v\left(\frac{r - H + h(u)}{J(u)}, t\right)\right) \neq 0$$

or, equivalently,

$$J(v) + [z(g'+h') - h']v_z \neq 0. \tag{A.7}$$

We will see later that any solution of (A.4)–(A.5) with appropriate initial data satisfies (A.7) everywhere.

Using initial data $u_0(r)$ constructed in subsection 2.1.2, one can define a smooth function $v_0(z)$ by (A.2). Since

$$\frac{v_{0z}(z)}{J(v_0(z)) + I(z, v_0(z))v_{0z}(z)} \equiv u_{0r}(r) = O(\varepsilon) \qquad \text{for } z \in [0,1],$$

we have $v_{0z}(z) = O(\varepsilon)$. In what follows we consider problem (A.4)–(A.5) with initial data $v_0(z)$. First, we give an a priori estimate of v_z by (i) of Lemma 2.5.

LEMMA A.1. *Let $v(z,t)$ be a solution of* (A.4)–(A.5) *with initial data v_0 on some time-interval $0 \le t < t_1$. Then*

(i) *there exists $\sigma = \sigma(v_0) > 0$ such that*

$$J(v) + I(z,v)v_z \ge \sigma \qquad \text{for } t \in [0,t_1),\ z \in [0,1];$$

(ii) *there exists $\varrho \in (0,1)$ such that*

$$|v_z(z,t)| \le \frac{G - H + \max(g(s) + h(s))}{\varrho} \cdot \overline{M} \qquad \text{for } t \in [0,t_1),\ z \in [0,1].$$

Proof. (i) Suppose that

$$J(v(z,t)) + I(z,v(z,t))v_z(z,t) \ge \sigma_1 > 0 \qquad \text{for } \ 0 \le t < \tilde{t} < t_1,\ z \in [0,1];$$

then $u(r,t)$ is well defined by (A.6) on $[0,\tilde{t})$ with

$$u_r(r,t) = \frac{v_z(z,t)}{J(v(z,t)) + I(z,v(z,t))v_z(z,t)}.$$

$u(r,t)$ is a solution of (1.2)–(1.3) and satisfies (i) of Lemma 2.5 on $t \in [0,\tilde{t})$. This means that

$$\left| \frac{v_z(z,t)}{J(v(z,t)) + I(z,v(z,t))v_z(z,t)} \right| < \overline{M} \qquad \text{for } t \in [0,\tilde{t}),\ z \in [0,1]. \tag{A.8}$$

If there exists $z_0 \in [0,1]$ such that $J(v(z_0,t)) + I(z_0,v(z_0,t))v_z(z_0,t) \to 0$ as $t \nearrow \tilde{t}$, then (A.8) indicates that $v_z(z_0,t) \to 0$ as $t \nearrow \tilde{t}$. However, this implies that

$$J(v(z_0,t)) + I(z_0,v(z_0,t))v_z(z_0,t) \to J(v(z_0,t)) \ge G - H > 0 \qquad \text{as } t \nearrow \tilde{t},$$

a contradiction. This proves (i).

(ii) From (i), we can define a function $u(r,t)$ by (A.6) on $0 \le t < t_1$, which is a solution of (1.2)–(1.3) and satisfies (i) of Lemma 2.5 on $0 \le t < t_1$.

By (1.6), there exists a $\varrho > 0$ such that $|h'|\overline{M} < 1 - 2\varrho$, $|g'|\overline{M} < 1 - 2\varrho$. Therefore, for large m, (i) of Lemma 2.5 implies that

$$\left| \frac{(G+g)h' + (H-h)g' - r(g'+h')}{G - H + g + h} \cdot u_r \right| < \left| \frac{(G-r)h'}{G-H} - \frac{(r-H)g'}{G-H} \right| \overline{M} + \varrho < 1 - \varrho. \tag{A.9}$$

Hence $|u_r| = |v_z| \cdot \left|\frac{\partial z}{\partial r}\right| > \varrho |v_z| / J(v)$ and then

$$|v_z(z,t)| < \frac{G - H + \max(g(s) + h(s))}{\varrho} \overline{M} \qquad \text{for } z \in [0,1],\ t \in [0,t_1).$$

Remark A.1. In fact, from the proof we know that the left-hand side of (A.3) is positive, that is, $\frac{\partial z}{\partial r} > 0$, so $\frac{\partial r}{\partial z} > 0$.

Next we give the Hölder estimate for v_z by a result in [13].

THEOREM A.2 (see [13, Theorem 13.16]). *Let $\Omega = \omega \times (0,T)$ for some domain $\omega \subset \mathbf{R}^n$ with $\partial\omega \in H_2$. Let $w \in C^{2,1}(\overline{\Omega})$ be a solution of*

$$\text{(A.10)}\qquad \begin{cases} w_t = \operatorname{div} A(x,t,w,Dw) + B(x,t,w,Dw) & \text{in } \ \Omega, \\ A(x,t,w,Dw)\cdot\gamma + \psi(x,t,w) = 0 & \text{on } \ \partial\omega\times(0,T), \\ w = \varphi & \text{on } \ \omega\times\{0\}, \end{cases}$$

with A a C^1 function of (x,t,w,p), ψ a C^1 function of (x,t,w), and A and B uniformly continuous with respect to (x,t,w,p), γ the inner normal to $\partial\omega$. Suppose that there are positive constants L, λ_L, Λ_L, and μ_L such that $|w|+|Dw| \le L$ and

$$\text{(A.11)}\qquad \frac{\partial A^i}{\partial p_j}\xi_i\xi_j \ge \lambda_L|\xi|^2, \qquad |A_p| \le \Lambda_L,$$

$$\text{(A.12)}\qquad |A_w| + |A_x| + |A_t| + |B| \le \mu_L, \qquad |\psi_w| + |\psi_x| + |\psi_t| + |\psi| \le \mu_L$$

for (x,t,w,p) with $|w|+|p| \le L$. Suppose also that

$$\text{(A.13)}\qquad |A(x,t,w,p) - A(x,s,w,p)| + |\psi(x,t,w) - \psi(x,s,w)| \le \mu_L|t-s|^{\frac{1}{2}}$$

for $(x,w,p) \in \partial\omega \times \mathbf{R} \times \mathbf{R}^n$ with $|w|+|p| \le L$ and all $s,t \in (0,T)$. If also $\varphi \in H_2$ and

$$A(x,t,\varphi,D\varphi)\cdot\gamma + \psi(x,t,\varphi) = 0 \quad \text{on } \ \partial\omega\times\{0\},$$

then there are positive constants $\alpha = \alpha(L,n,\lambda_L,\Lambda_L)$ and $C = C(n,\lambda_L,\Lambda_L,\mu_L,\Omega,|\varphi|_2)$ such that $|Du|_\alpha \le C$.

Define

$$A(z,v,p) = \frac{p}{K(z,v,p)} + \int_0^p \frac{pK_p(z,v,p)}{K^2(z,v,p)}dp,$$

$$\mathcal{H}(v) = \frac{J(v)h'(v)}{(H-h(v))^2 + h'(v)^2}, \quad \mathcal{G}(v) = \frac{-J(v)g'(v)}{(G+g(v))^2 + g'(v)^2}.$$

Then (A.4)–(A.5) with initial data $v_0(z)$ can be written in divergence form:

$$\text{(A.14)}\qquad \begin{cases} v_t = \dfrac{\partial}{\partial z}A(z,v,v_z) + B(z,v,v_z), & z \in (0,1), t > 0, \\ v_z(0,t) = \mathcal{H}(v(0,t)), \quad v_z(1,t) = \mathcal{G}(v(1,t)), & t > 0, \\ v(z,0) = v_0(z), & z \in (0,1), \end{cases}$$

where $\frac{\partial A}{\partial z}$ denotes the partial derivative of A on z when we regard A as a function of z and t, and a careful calculation shows that $B(z,v,p)$ is a smooth and bounded function provided v_z is bounded.

LEMMA A.3. *Let $v(z,t)$ be a solution of* (A.14) *on some time-interval $0 \le t \le T$; then there exist $\mu(T) > 0$ and $C > 0$ (independent of T) such that*

$$\text{(A.15)}\qquad |v_z|_\mu \le C \qquad \text{in } \ [0,1]\times[0,T].$$

Proof. First, (2.6) gives the a priori estimate of $u \equiv v$:

$$\widehat{\omega}t - C \le v(z,t) < \widetilde{\omega}t + C \qquad \text{for } z \in [0,1],\ t \in [0,T].$$

As T goes to $+\infty$, v also goes to $+\infty$. However, one important thing should be noticed: in our problem (A.14), v appears always in a form such as $g(v), h(v), g'(v), h'(v)$, etc. Therefore, the unboundedness of v does not cause the unboundedness of the coefficients in (A.14).

Second, the a priori estimate for v_z is given by (ii) in Lemma A.1: $|v_z(z,t)| \le C$ for $z \in [0,1]$ and $t \in [0,T]$.

A trivial and careful calculation shows that Theorem A.2 stated above is applicable to (A.14) and none of the constants λ, Λ, and μ depend on T (since the bound of z and v_z are independent of T, and v appears in the form $g(v), h(v)$, etc.). So there exist $\mu = \mu(T)$ and $C > 0$ (independent of T) such that (A.15) holds. ∎

Proof of (ii) *of Lemma* 2.5. By $u_r = \frac{v_z}{J(v)+I(z,v)v_z}$ and the a priori estimates of v, v_z, and $|v_z|_\mu$ we have $\mu(T) > 0$ and $C > 0$ (independent of T) such that $|u_r|_{\mu(T)} \le C$ for $(r,t) \in \overline{Q_T}$.

Proof of (iii) *of Lemma* 2.5. Choose a constant $\sigma > 0$ such that

$$\sigma > \max\{\max_s |\mathcal{H}'(s)|,\ \max_s |\mathcal{G}'(s)|\} + 1$$

and define $w(z,t) := v(z,t)e^{\sigma z}$. Then w is a solution of

$$\text{(A.16)} \qquad \begin{cases} w_t = \dfrac{\partial}{\partial z}\widetilde{A}(z,w,w_z) + \widetilde{B}(z,w,w_z), & z \in (0,1), t > 0, \\ w_z(0,t) = \mathcal{H}(v(0,t)) + \sigma w(0,t), & t > 0, \\ w_z(1,t) = \mathcal{G}(v(1,t))e^{\sigma} + \sigma w(1,t), & t > 0, \\ w(z,0) = v_0(z)e^{\sigma z}, & z \in (0,1), \end{cases}$$

where $\widetilde{A}$ and $\widetilde{B}$ are smooth functions like A and B. Theorem A.2 stated above can also be used for this problem and so we have $|w_z|_{\mu(T)} \le C$ for $(z,t) \in \overline{Q_T}$, where $\mu(T) > 0$ and $C > 0$ (independent of T).

Especially, at $z = 0$ we have $|w_z(0,t) - w_z(0,s)| \le C|t-s|^{\mu(T)}$. On the other hand,

$$\begin{aligned} |w_z(0,t) - w_z(0,s)| &= |\mathcal{H}(v(0,t)) - \mathcal{H}(v(0,s)) + \sigma w(0,t) - \sigma w(0,s)| \\ &= |\sigma + \mathcal{H}'(\varsigma)| \cdot |w(0,t) - w(0,s)| \ge |w(0,t) - w(0,s)|. \end{aligned}$$

Hence $|w(0,t) - w(0,s)| \le C|t-s|^{\mu(T)}$. Similarly we have $|w(1,t) - w(1,s)| \le C|t-s|^{\mu(T)}$. Finally by Theorem 1.1 of Chapter V in [14] we have $|w|_{\mu(T)} \le C$. This implies that $|v|_{\mu(T)} \le C$ for another $C > 0$. ∎

Appendix B. Proof of Lemma 2.6. It is clear that to prove Lemma 2.6 we only need to prove similar conclusions for v.

LEMMA B.1. *Assume* (1.9) *holds; then* (A.14) *has a unique, global solution* $v(z,t)$ *satisfying* $v_t(\cdot,t) \ge 0$. *Moreover, for any* $T > 0$, *let* $Q_T^z := (0,1) \times (0,T]$; *then there exist positive constants* $\mu(T)$, C_1, *and* C_2 (C_1, C_2 *are independent of* T) *such that*

(i) $v \in C^{2+\mu, 1+\frac{\mu}{2}}(\overline{Q_T^z})$;

(ii) $\|v(z,t)\|_{C^{2+\mu,1+\frac{\mu}{2}}(\overline{Q_T^z})} \le C_1 T + C_2$.

Proof. First, by Theorem 8.1 in [21] and the above a priori estimates for v, we have a unique, global solution v of (A.14). Moreover for any $T > 0$, $v \in C^\infty([0,T], H^\infty(0,1))$, where $H^\infty(0,1) := \bigcap_{k=0}^\infty H^k(0,1)$ is a Fréchet space with norms $(\|\cdot\|_k)_{k=0}^\infty$, and $H^k(0,1)$ is a Sobolev space with norm $\|\cdot\|_k$ (cf. [21]). Embedding theorem implies that we indeed obtain a global solution of (A.14): $v \in C^\infty(\overline{Q_\infty^z})$, where $Q_\infty^z = (0,1)\times(0,\infty)$. (i) is proved.

The result $u_t(\cdot,t) \geq 0$ for $t > 0$ in subsection 2.1.2 implies that $v_t(z,t) \geq 0$.

Now we use the a priori estimates in Lemma 2.5 and the interior estimate (see, for example, Theorem 5 of Chapter 3 in [7]) for problem (A.4)–(A.5) with initial data $v_0(z)$; then for any $T > 0$, there exist $\mu = \mu(T) > 0$ and $C_1 > 0$, $C_2 > 0$ (C_1, C_2 are independent of T) such that

$$\|v\|_{C^{2+\mu,1+\frac{\mu}{2}}(Q_T^z)} \leq C_1 T + C_2.$$

By the smoothness of v on $\overline{Q_T^z}$, we indeed obtain $\|v\|_{C^{2+\mu,1+\frac{\mu}{2}}(\overline{Q_T^z})} \leq C_1 T + C_2$. ∎

PACKET FLOW ON TELECOMMUNICATION NETWORKS*

CIRO D'APICE†, ROSANNA MANZO†, AND BENEDETTO PICCOLI‡

Abstract. The aim of this paper is to introduce a macroscopic fluid dynamic model dealing with the flow of information on a telecommunication network encoded in packets. Taking an intermediate time and space scale, we propose a model similar to that introduced recently for car traffic; see [G. M. Coclite, M. Garavello, and B. Piccoli, *SIAM J. Math. Anal.*, 36 (2005), pp. 1862–1886]. For dynamics at nodes we consider two "routing algorithms" and prove existence of solutions to Cauchy problems. The main difference among the two algorithms is the possibility of redirecting packets of the second algorithm, which in turn implies stability, i.e., Lipschitz continuous dependence on initial data, not granted for solutions using the first algorithm.

Key words. traffic flow on networks, conservation laws, fluid dynamic models

DOI. 10.1137/050631628

1. Introduction.

The aim of this paper is to introduce a macroscopic fluid dynamic model dealing with the flow of information on a telecommunication network encoded in packets. There are some recent works on traffic flow on road networks (see [10, 11, 14, 15, 16, 18]) that are based on macroscopic description via car densities and other conserved quantities. Our idea is to look at the network at an intermediate time scale so that packet transmission happens at a faster level but the equilibria of the whole network are reached only as asymptotic. This permits us to construct a model again relying on macroscopic description.

There exist various approaches to traffic flow on telecommunication networks, in particular for the Internet and with special focus on properties of control congestion algorithms such as TCP/IP; see, for example, [4, 17, 25]. Our idea is rather to take a large number of nodes, which use some simple routing algorithm, and via some limiting procedure obtain a partial differential equation for the packet density on the network. First we focus on a straight transmission line and justify the limiting procedure. Then we consider a network and introduce two routing algorithms for nodes with many entering and exiting lines. Let us start with the basic assumptions.

A network is formed by a finite collection of transmission lines and nodes (or routers). We assume that each node receives and sends information encoded in packets. Each packet can thus be seen as a particle on the network, but we have to take into account specific issues of telecommunications. Having in mind the Internet as our key model, we assume the following:

(1) Each packet travels on the network with a fixed speed and with assigned final destination.
(2) Nodes receive, process, and then forward packets. Packets may be lost with a probability increasing with the number of packets to be processed. Each lost packet is sent again.

*Received by the editors May 16, 2005; accepted for publication (in revised form) February 13, 2006; published electronically July 31, 2006.

We first model the behavior of a single straight transmission line on which there are some consecutive nodes. Each node sends packets to the following one a first time, then packets which are lost in this process are sent a second time, and so on. The important point is that each packet is sent until it reaches the next node; thus, looking from a macroscopic level, it is assumed that packets are conserved. This leads from the microscopic dynamics to the simple model consisting of a single conservation law:

$$\rho_t + f(\rho)_x = 0, \tag{1}$$

where ρ is the packet density, v is the velocity, and $f(\rho) = v\rho$ is the flux. Since the packet transmission velocity on the line is assumed constant, we can derive an average transmission velocity among nodes considering the amount of packets that may be lost. More precisely, assigning a loss probability as function of the density, it is possible to compute a velocity function and thus a flux function.

The conclusion is rigorously justified only for constant density, but is assumed to hold in general. This corresponds to the hypotheses that macroscopic density waves move at a velocity much smaller than the packet transmission velocity. In section 2 we derive some models and then focus the rest of the paper on a particular model that implies equivalence between the total variation of density and of flux. Even if our limiting procedure is not completely rigorous, there are other approaches, as that of [3] for supply chains, which lead to conservation laws. Moreover, since our method to solve problems at nodes is based only on flux values, every limiting procedure, which leads to a conservation law formulation, may be used to treat the problem on a network.

The aim is then to consider complex networks; thus we need to introduce a way of solving dynamics at nodes in which many lines intersect. For this, respecting rule 2, we propose two different routing algorithms:

(RA1) Packets from incoming lines are sent to outgoing ones according to their final destination (without taking into account possible high loads of outgoing lines).

(RA2) Packets are sent to outgoing lines in order to maximize the flux through the node.

The main differences of the two algorithms are the following. The first one simply sends each packet to the outgoing line which is naturally chosen according to the final destination of the packet itself. The algorithm is blind to possible overloads of some outgoing lines and, by some abuse of notation, is similar to the behavior of a "switch." The second algorithm, on the contrary, sends packets to outgoing lines taking into account the loads, and thus possibly redirecting packets. Again by some abuse of notation, this is similar to a "router" behavior.

Routing algorithm (RA1) can be described by two rules and was already used in [11] for car traffic. In particular a traffic distribution matrix A is given, which describes the percentage of packets from an incoming line that are addressed to an outgoing one. For existence of solutions to the Cauchy problem on the network, we have to restrict ourselves to the case of simple nodes with two incoming and two outgoing lines, but, differently from [11], we can obtain a precise bound on the total variation of density, thanks to the assumption on the flux function, and then derive existence of solutions to the Cauchy problem more directly by wave-front tracking. However, Lipschitz continuous dependence of solutions is not granted.

Then we analyze routing algorithm (RA2). Notice that this second algorithm

was not considered for car traffic, because redirection of cars is not expected from a modeling point of view (except special situations, as closure of a road).

In order to determine unique solutions to Riemann problems, some additional parameters are introduced, called, respectively, priority parameters and traffic distribution parameters. The former describe priorities among incoming lines, while the latter have the same meaning of the traffic distribution matrix.

The advantage of this second algorithm is that the flux variation at a node is conserved for interaction of waves from transmission lines. This permits us both to obtain estimates on the total variation of density, thus to construct solutions again by wave-front tracking, and also to obtain uniqueness and Lipschitz continuous dependence of solutions. The latter result is achieved by the method introduced in [6, 8], which considers a Riemannian-type metric on L^1. More precisely, the distance among solutions is measured by paths in L^1 which admit some generalized tangent vectors. The key point is that the norms of tangent vectors are known to decrease inside each line (i.e., for scalar conservation laws), while for interactions with nodes its evolution is determined by flux variation. As explained in section 5.2.1, other known methods to treat uniqueness for scalar conservation laws seem not to work for the network case.

The obtained results show the strong effect of the routing algorithm. More precisely, the choice of a "router"-type algorithm, i.e., (RA2), implies stability of solutions, with respect of perturbation of the data, as opposed to the instability obtained with the "switch" types.

The paper is organized as follows. Section 2 describes the dynamics of packet density on a single transmission line. Section 3 gives general definitions of a network and of the Riemann solver. Then we describe the two routing algorithms in section 4, giving explicit unique solutions to Riemann problems. Finally, section 5 provides the needed estimates for constructing solutions to Cauchy problems and for obtaining continuous dependence for the second algorithm.

2. Packet loss and velocity functions on transmission lines. We model a transmission line by a sequence of nodes N_k, representing routers, and edges which connect consecutive nodes. Thus the transmission line is represented by a real interval I union of many edges and nodes.

Each node (router) sends and receives packets. Following rule 1, we assume that packets flow at constant velocity from each node N_k to N_{k+1}. Taking a discrete time scale for the evolution, the state at time t_i is described by the packet quantities $R_k(t_i)$ on nodes N_k, and transmission happens among consecutive nodes between two discrete times. Therefore, to determine the dynamics on I we need to describe the effect of packet loss on the velocity of transmission function.

As for the Internet, we assume that each node N_k sends again packets that are lost by the following node N_{k+1}. Therefore the number of packets is conserved, i.e., at macroscopic level we expect (1) to hold. More precisely, we assume that there exists a function $p : [0, R_{max}] \to [0, 1]$ which assigns the packet loss probability as a function of the number of packets.

Let us focus now on two consecutive nodes and introduce some notation. Suppose that δ is the distance between nodes N_k and N_{k+1}. Let Δt_0 be the transmission time of packets from node N_k to node N_{k+1} if they are sent with success at the first attempt, and let Δt_{av} be the average transmission time when some packets are lost by N_{k+1}. Finally, we denote by $\bar{v} = \frac{\delta}{\Delta t_0}$ and $v = \frac{\delta}{\Delta t_{av}}$ the packet velocity in the two cases.

At the first attempt, the packets sent by node N_k reach with success node N_{k+1}

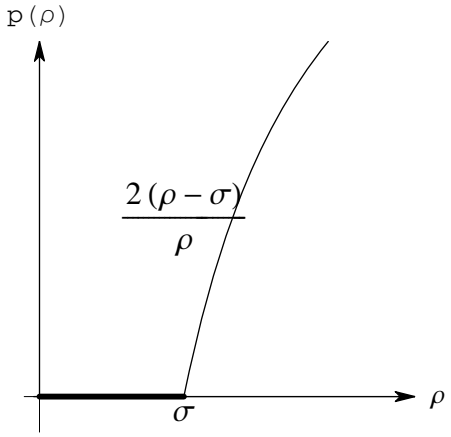

FIG. 1. *Packet loss function.*

with probability $(1-p)$ and are lost by node N_{k+1} with probability p. At the second attempt there are p of the total number of packets left to be sent again and $(1-p)p$ are sent with success while p^2 are lost. Going on at the nth attempt, $(1-p)p^{n-1}$ packets are sent successfully and p^n are lost. The average transmission time is equal to

$$\Delta t_{av} = \sum_{n=1}^{+\infty} n\Delta t_0 (1-p)p^{n-1} = \frac{\Delta t_0}{1-p}, \tag{2}$$

from which we get that the transmission velocity is given by

$$v = \frac{\delta}{\Delta t_{av}} = \frac{\delta}{\Delta t_0}(1-p) = \bar{v}(1-p). \tag{3}$$

The above reasoning works for the entire line if $R_k(t_0) = R$ for all k. In fact, one gets immediately that $R_k(t_i) = R$ for all i and k. Thus the following holds.

LEMMA 1. *Assume that $R_k(t_0) = R$ for all k. Then the average transmission time and velocity are given by* (2) *and* (3).

Clearly Lemma 1 gives an average velocity only if the density is constant. However, we assume the conclusion holds in general for the macroscopic velocity and use this together with (1). This assumption is not completely justified, but it is reasonable if the transmission velocity of packets is expected to be much bigger than the macroscopic velocity.

We may also assign the loss probability directly as a function of the packet density; then the corresponding flux is easily determined. Such loss probability should vanish for low load levels of nodes and reach the value 1 for $R = R_{max}$. We show some choice of packet loss functions and the corresponding macroscopic fluxes.

Example 2. Let us suppose that the packet loss probability is given by

$$p(\rho) = \begin{cases} 0, & 0 \le \rho \le \sigma, \\ \frac{2(\rho-\sigma)}{\rho}, & \sigma \le \rho \le \rho_{\max}, \end{cases}$$

for some $\sigma \in]0, \rho_{\max}[$; see Figure 1. Then the average transmission velocity is equal to

$$v(\rho) = \bar{v}(1-p(\rho)) = \begin{cases} \bar{v}, & 0 \le \rho \le \sigma, \\ \bar{v}\frac{(2\sigma-\rho)}{\rho}, & \sigma \le \rho \le \rho_{\max}. \end{cases}$$

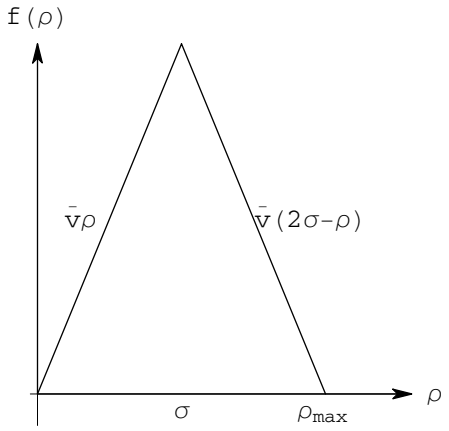

FIG. 2. *Flux function.*

Imposing that

$$v(\rho_{\max}) = \bar{v}\frac{(2\sigma - \rho_{\max})}{\rho_{\max}} = 0,$$

we get that $\sigma = \frac{\rho_{\max}}{2}$. Since $f(\rho) = v(\rho)\rho$ it follows that (see Figure 2)

$$f(\rho) = \begin{cases} \bar{v}\rho, & 0 \le \rho \le \sigma, \\ \bar{v}(2\sigma - \rho), & \sigma \le \rho \le \rho_{\max}. \end{cases}$$

The fundamental diagram (i.e., the expression of the flux as a function of the density) of Example 2 was extensively used in traffic flow literature (see [13, 20]) and is sometimes called the Daganzo–Newell flux.

Example 3. Suppose that

$$p(\rho) = \begin{cases} 0, & 0 \le \rho \le \sigma, \\ \frac{\rho - \sigma}{\sigma}, & \sigma \le \rho \le \rho_{\max}. \end{cases}$$

It follows that

$$v(\rho) = \begin{cases} \bar{v}, & 0 \le \rho \le \sigma, \\ \frac{\bar{v}(2\sigma - \rho)}{\sigma}, & \sigma \le \rho \le \rho_{\max}, \end{cases}$$

and

$$f(\rho) = \begin{cases} \bar{v}\rho, & 0 \le \rho \le \sigma, \\ \frac{\bar{v}\rho(2\sigma - \rho)}{\sigma}, & \sigma \le \rho \le \rho_{\max}. \end{cases}$$

Example 4. Suppose that

$$p(\rho) = \begin{cases} 0, & 0 \le \rho \le \sigma, \\ \frac{(\rho - \sigma)^2}{\sigma^2}, & \sigma \le \rho \le \rho_{\max}. \end{cases}$$

It follows that

$$v(\rho) = \begin{cases} \bar{v}, & 0 \le \rho \le \sigma, \\ \frac{\bar{v}\rho(2\sigma - \rho)}{\sigma^2}, & \sigma \le \rho \le \rho_{\max}, \end{cases}$$

and

$$f(\rho) = \begin{cases} \bar{v}\rho, & 0 \le \rho \le \sigma, \\ \frac{\bar{v}\rho^2(2\sigma-\rho)}{\sigma^2}, & \sigma \le \rho \le \rho_{\max}. \end{cases}$$

Remark 5. Examples 2 and 3 lead to fluxes which are not $\mathcal{C}^1$; the opposite happens for Example 4. Notice that only for Example 2 does the corresponding flux have the property that $f'(\rho\pm) \neq 0$ for every ρ. Thus the density variation along discontinuities not crossing σ is equivalent to the flux ones.

In what follows we suppose that measures on packet loss probability lead to the formulation of Example 2. This allows us to control the variation of the density function in terms of the variation of the flux function, as shown later.

We can suppose for simplicity that $\rho_{\max} = 1$, so we have the following assumptions on the flux:

(F) $f : [0,1] \to R$, $\quad f(\rho) = \begin{cases} \bar{v}\rho, & 0 \le \rho \le \sigma, \\ \bar{v}(2\sigma - \rho), & \sigma \le \rho \le 1, \end{cases}$
$f(0) = f(1) = 0$. Thus $\sigma = \frac{1}{2}$ is the unique maximum point.

3. Telecommunication networks. We consider a telecommunication network that is modeled by a finite set of intervals $I_i = [a_i, b_i] \subset \mathbb{R}$, $i = 1, \dots, N$, $a_i < b_i$, possibly with either $a_i = -\infty$ or $b_i = +\infty$, on which we consider the model of the previous section, i.e., equation (1) with assumption (F). The network evolution is described by a finite set of functions ρ_i defined on $[0, +\infty[\times I_i$.

On each transmission line I_i we want ρ_i to be a weak entropic solution of (1), that is, for every function $\varphi : [0, +\infty[\times I_i \to \mathbb{R}$ smooth, positive with compact support on $]0, +\infty[\times]a_i, b_i[$,

$$\int_0^{+\infty} \int_{a_i}^{b_i} \left(\rho_i \frac{\partial \varphi}{\partial t} + f(\rho_i) \frac{\partial \varphi}{\partial x} \right) dxdt = 0, \tag{4}$$

and for every $k \in \mathbb{R}$ and every $\tilde{\varphi} : [0, +\infty[\times I_i \to \mathbb{R}$ smooth, positive with compact support on $]0, +\infty[\times]a_i, b_i[$,

$$\int_0^{+\infty} \int_{a_i}^{b_i} \left(|\rho_i - k| \frac{\partial \tilde{\varphi}}{\partial t} + sgn(\rho_i - k)\left(f(\rho_i) - f(k)\right) \frac{\partial \tilde{\varphi}}{\partial x} \right) dxdt \ge 0. \tag{5}$$

It is well known that, for (1) on $\mathbb{R}$ and for every initial data in L^∞, there exists a unique weak entropic solution depending in a continuous way on the initial data in L^1_{loc}. Moreover, for initial data in $L^\infty \cap L^1$ we have Lipschitz continuous dependence in L^1.

We assume that the transmission lines are connected by some junctions. Each junction J is given by a finite number of incoming transmission lines and a finite number of outgoing transmission lines; thus we identify J with $((i_1, \dots, i_n), (j_1, \dots, j_m))$, where the first n-tuple indicates the set of incoming transmission lines and the second m-tuple indicates the set of outgoing transmission lines. Each transmission line can be incoming for at most one junction and outgoing for at most one junction. Hence the complete model is given by a couple $(\mathcal{I}, \mathcal{J})$, where $\mathcal{I} = \{I_i : i = 1, \dots, N\}$ is the collection of transmission lines and $\mathcal{J}$ is the collection of junctions.

Now we discuss how to define solutions at junctions. For this, fix a junction J with n incoming transmission lines, say $I_1, \dots, I_n$, and m outgoing transmission lines, say

$I_{n+1}, \dots, I_{n+m}$. A weak solution at J is a collection of functions $\rho_l : [0, +\infty[\times I_l \to \mathbb{R}$, $l = 1, \dots, n+m$, such that

$$\sum_{l=1}^{n+m} \left(\int_0^{+\infty} \int_{a_l}^{b_l} \left(\rho_l \frac{\partial \varphi_l}{\partial t} + f(\rho_l) \frac{\partial \varphi_l}{\partial x} \right) dx dt \right) = 0 \tag{6}$$

for every φ_l, $l = 1, \dots, n+m$, smooth having compact support in $]0, +\infty[\times]a_l, b_l]$ for $l = 1, \dots, n$ (incoming transmission lines) and in $]0, +\infty[\times [a_l, b_l[$ for $l = n+1, \dots, n+m$ (outgoing transmission lines), which are also smooth across the junction, i.e.,

$$\varphi_i(\cdot, b_i) = \varphi_j(\cdot, a_j), \quad \frac{\partial \varphi_i}{\partial x}(\cdot, b_i) = \frac{\partial \varphi_j}{\partial x}(\cdot, a_j), \quad i = 1, \dots, n, j = n+1, \dots, n+m.$$

Remark 6. Let $\rho = (\rho_1, \dots, \rho_{n+m})$ be a weak solution at the junction such that each $x \to \rho_i(t, x)$ has bounded variation. We can deduce that ρ satisfies the Rankine–Hugoniot condition at the junction J, namely,

$$\sum_{i=1}^{n} f(\rho_i(t, b_i-)) = \sum_{j=n+1}^{n+m} f(\rho_j(t, a_j+)) \tag{7}$$

for almost every $t > 0$.

For a scalar conservation law a Riemann problem is a Cauchy problem for an initial data of Heaviside type that is piecewise constant with only one discontinuity. One looks for centered solutions, i.e., $\rho(t, x) = \phi(\frac{x}{t})$ formed by simple waves, which are the building blocks for constructing solutions to the Cauchy problem via wave-front tracking algorithm. These solutions are formed by continuous waves called rarefactions and by traveling discontinuities called shocks. The speed of waves are related to the values of f'; see [7].

Analogously, we call the Riemann problem for a junction the Cauchy problem corresponding to an initial data which is constant on each transmission line.

DEFINITION 7. *A Riemann solver for the junction J is a map $RS : [0,1]^n \times [0,1]^m \to [0,1]^n \times [0,1]^m$ that associates to Riemann data $\rho_0 = (\rho_{1,0}, \dots, \rho_{n+m,0})$ at J a vector $\hat{\rho} = (\hat{\rho}_1, \dots, \hat{\rho}_{n+m})$ so that the solution on an incoming transmission line I_i, $i = 1, \dots, n$, is given by the wave $(\rho_{i,0}, \hat{\rho}_i)$ and on an outgoing one I_j, $j = n+1, \dots, n+m$, is given by the wave $(\hat{\rho}_j, \rho_{j,0})$. We require the following consistency condition:*

(CC) $RS(RS(\rho_0)) = RS(\rho_0)$.

Remark 8. The condition (CC) is necessary for providing a good definition of Riemann solver and thus also for uniqueness.

Assume, for example, that $RS(\rho) = \rho'$ and $RS(\rho') = \rho$ for some Riemann data $\rho \neq \rho'$. To solve the Riemann problem with datum ρ, one should use the boundary datum ρ' at the junction. In turn, when ρ' starts propagating into lines, one should go back to ρ, and so on and so forth. A solution would thus not exist.

The same kind of problem happens for uniqueness.

Once a Riemann solver is assigned we can define admissible solutions at J.

DEFINITION 9. *Assume a Riemann solver RS is assigned. Let $\rho = (\rho_1, \dots, \rho_{n+m})$ be such that $\rho_i(t, \cdot)$ is of bounded variation for every $t \geq 0$. Then ρ is an admissible weak solution of* (1) *related to RS at the junction J if and only if the following properties hold:*

(i) *ρ is a weak solution at junction J;*

(ii) *for almost every* t *setting*

$$\rho_J(t) = (\rho_1(\cdot, b_1-), \dots, \rho_n(\cdot, b_n-), \rho_{n+1}(\cdot, a_{n+1}+), \dots, \rho_{n+m}(\cdot, a_{n+m}+))$$

we have

$$RS(\rho_J(t)) = \rho_J(t).$$

For every transmission line $I_i = [a_i, b_i]$, if $a_i > -\infty$ and I_i is not the outgoing transmission line of any junction, or $b_i < +\infty$ and I_i is not the incoming transmission line of any junction, then a boundary datum $\psi_i : [0, +\infty[\to \mathbb{R}$ is given. We ask ρ_i to satisfy $\rho_i(t, a_i) = \psi_i(t)$ (or $\rho_i(t, b_i) = \psi_i(t)$) in the sense of [5]. The treatment of boundary data in the sense of [5] can be done as in [1, 2], and thus only the case without boundary data is considered. All the stated results hold also for the case with boundary data with obvious modifications.

Our aim is to solve the Cauchy problem on $[0, +\infty[$ for given initial and boundary data as in the next definition.

DEFINITION 10. *Given* $\bar\rho_i : I_i \to [0, 1]$, $i = 1, \dots, N$, *measurable functions, a collection of functions* $\rho = (\rho_1, \dots, \rho_N)$, *with* $\rho_i : [0, +\infty[\times I_i \to [0, 1]$ *continuous as functions from* $[0, +\infty[$ *into* L^1_{loc}, *is an admissible solution to the Cauchy problem on the network if* ρ_i *is a weak entropic solution to* (1) *on* I_i, $\rho_i(0, x) = \bar\rho_i(x)$ *a.e., and at each junction* ρ *is a weak solution and is an admissible weak solution in case of bounded variation.*

Remark 11. It is possible to generalize all definitions and results of upcoming sections to the case of different fluxes f_i for each line I_i. In fact, all statements are in terms of values of fluxes at junctions; thus it is sufficient that the ranges of fluxes intersect.

4. Riemann solvers at junctions. In this section we describe two different Riemann solvers at a junction that represent two different routing algorithms:

(RA1) We assume that
  - (A) the traffic from incoming transmission lines is distributed on outgoing transmission lines according to fixed coefficients;
  - (B) respecting (A), the router chooses to send packets in order to maximize fluxes (i.e., the number of packets which are processed).

(RA2) We assume that the number of packets through the junction is maximized over both incoming and outgoing lines.

Once solutions to Riemann problems are given, one can use a wave-front tracking algorithm to construct a sequence of approximate solutions. To pass to the limit one has to bound the number of waves and the BV norm of approximate solutions; see [7, 11]. In the next section we prove a BV bound on the density for the case of junctions with two incoming and two outgoing transmission lines, for both the routing algorithms.

4.1. Riemann solver for algorithm (RA1). The Riemann solver for algorithm (RA1) has already been described in [10, 11], where traffic problems for road networks have been analyzed, using different assumptions on the flux function.

Consider a junction J in which there are n transmission lines with incoming traffic and m transmission lines with outgoing traffic. To deal with (A) we fix a traffic distribution matrix $A \doteq \{\alpha_{ji}\}_{j=n+1,\dots,n+m, i=1,\dots,n} \in \mathbb{R}^{m\times n}$ such that

$$0 < \alpha_{ji} < 1, \quad \sum_{j=n+1}^{n+m} \alpha_{ji} = 1$$

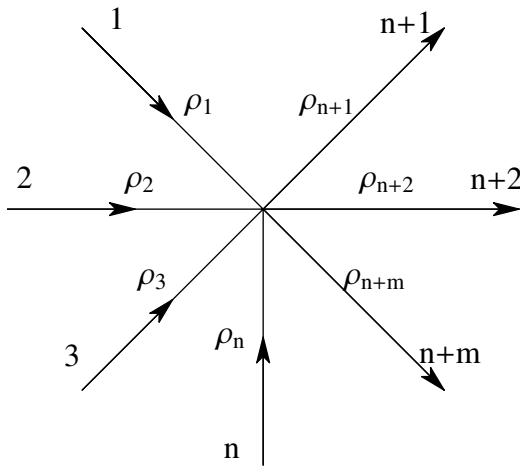

FIG. 3. *A junction.*

for each $i = 1, \dots, n$ and $j = n+1, \dots, n+m$, where α_{ji} is the percentage of packets arriving from the ith incoming transmission line that take the jth outgoing transmission line.

For simplicity we indicate by

$$(t,x) \in \mathbb{R}_+ \times I_i \to \rho_i(t,x) \in [0,1], \quad i = 1, \dots, n,$$

the densities of the packets on the transmission lines with incoming traffic and by

$$(t,x) \in \mathbb{R}_+ \times I_j \to \rho_j(t,x) \in [0,1], \quad j = n+1, \dots, n+m,$$

those on transmission lines with outgoing traffic; see Figure 3.

We need some more notation.

DEFINITION 12. *Let $\tau : [0,1] \to [0,1]$ be the map such that*

1. *$f(\tau(\rho)) = f(\rho)$ for every $\rho \in [0,1]$;*
2. *$\tau(\rho) \neq \rho$ for every $\rho \in [0,1] \backslash \{\sigma\}$.*

Clearly, τ is well defined and satisfies

$$0 \le \rho \le \sigma \Leftrightarrow \sigma \le \tau(\rho) \le 1,$$
$$\sigma \le \rho \le 1 \Leftrightarrow 0 \le \tau(\rho) \le \sigma.$$

To state the main result of this section we need some assumption on the matrix A (satisfied under generic conditions for $m = n$). Let $\{e_1, \dots, e_n\}$ be the canonical basis of $\mathbb{R}^n$ and for every subset $V \subset \mathbb{R}^n$ indicate by $V^\perp$ its orthogonal. Define for every $i = 1, \dots, n$, $H_i = \{e_i\}^\perp$, i.e., the coordinate hyperplane orthogonal to e_i, and for every $j = n+1, \dots, n+m$, let $\alpha_j = \{\alpha_{j1}, \dots, \alpha_{jn}\} \in \mathbb{R}^n$ and define $H_j = \{\alpha_j\}^\perp$. Let $\mathcal{K}$ be the set of indices $k = (k_1, \dots, k_l)$, $1 \le l \le n-1$, such that $0 \le k_1 < k_2 < \cdots < k_l \le n+m$ and for every $k \in \mathcal{K}$ set $H_k = \bigcap_{h=1}^{l} H_h$. Letting $\mathbf{1} = (1, \dots, 1) \in \mathbb{R}^n$, we assume

(C) for every $k \in \mathcal{K}$, $\mathbf{1} \notin H_k^\perp$.

THEOREM 13 (Theorem 3.1 of [11]). *Consider a junction J; assume that the flux $f : [0,1] \to \mathbb{R}$ satisfies* (F) *and the matrix A satisfies condition* (C). *For every*

$\rho_{1,0},\dots,\rho_{n+m,0} \in [0,1]$, there exists a unique admissible centered weak solution, in the sense of Definition 9; $\rho = (\rho_1,\dots,\rho_{n+m})$ of (1) at the junction J such that

$$\rho_1(0,\cdot) \equiv \rho_{1,0},\dots,\rho_{n+m}(0,\cdot) \equiv \rho_{n+m,0}.$$

Moreover, there exists a unique $(n+m)$-tuple $(\hat\rho_1,\dots,\hat\rho_{n+m}) \in [0,1]^{n+m}$ such that

$$\hat\rho_i \in \begin{cases} \{\rho_{i,0}\} \cup]\tau(\rho_{i,0}),1] & \text{if } 0 \le \rho_{i,0} \le \sigma, \\ [\sigma,1] & \text{if } \sigma \le \rho_{i,0} \le 1, \end{cases} \quad i = 1,\dots,n, \tag{8}$$

and

$$\hat\rho_j \in \begin{cases} [0,\sigma] & \text{if } 0 \le \rho_{j,0} \le \sigma, \\ \{\rho_{j,0}\} \cup [0,\tau(\rho_{j,0}))[& \text{if } \sigma \le \rho_{j,0} \le 1, \end{cases} \quad j = n+1,\dots,n+m, \tag{9}$$

and on each incoming line I_i, $i = 1,\dots,n$, the solution consists of the single wave $(\rho_{i,0},\hat\rho_i)$, while on each outgoing line I_j, $j = n+1,\dots,n+m$, the solution consists of the single wave $(\hat\rho_j,\rho_{j,0})$.

Condition (C) on A cannot hold for crossings with two incoming and one outgoing transmission lines. Following [10], it is possible to introduce a further parameter whose meaning is the following. When the number of packets is too big to let all of them go through the crossing, there is a priority rule that describes the percentage of packets, going through the crossings, that comes from the first line. Since the construction happens to be a special case of that in the next section, we omit the details and refer the reader to [10] or to the next section.

4.2. Riemann solver for algorithm (RA2). To solve Riemann problems according to (RA2) we need some additional parameters called priority and traffic distribution parameters. For simplicity of exposition, consider first a junction J in which there are two transmission lines with incoming traffic and two transmission lines with outgoing traffic. In this case we have only one priority parameter $q \in]0,1[$ and one traffic distribution parameter $\alpha \in]0,1[$. We denote by $\rho_i(t,x)$, $i = 1,2$, and $\rho_j(t,x)$, $j = 3,4$, the traffic densities, respectively, on the incoming transmission lines and on the outgoing ones and by $(\rho_{1,0},\rho_{2,0},\rho_{3,0},\rho_{4,0})$ the initial datum.

Define $\gamma_i^{\max}$ and $\gamma_j^{\max}$ as follows:

$$\gamma_i^{\max} = \begin{cases} f(\rho_{i,0}) & \text{if } \rho_{i,0} \in [0,\sigma], \\ f(\sigma) & \text{if } \rho_{i,0} \in]\sigma,1], \end{cases} \quad i = 1,2, \tag{10}$$

and

$$\gamma_j^{\max} = \begin{cases} f(\sigma) & \text{if } \rho_{j,0} \in [0,\sigma], \\ f(\rho_{j,0}) & \text{if } \rho_{j,0} \in]\sigma,1], \end{cases} \quad j = 3,4. \tag{11}$$

The quantities $\gamma_i^{\max}$ and $\gamma_j^{\max}$ represent the maximum flux that can be obtained by a single wave solution on each transmission line. In order to maximize the number of packets through the junction over incoming and outgoing lines we define

$$\Gamma = \min\{\Gamma_{in}^{\max},\Gamma_{out}^{\max}\},$$

where $\Gamma_{in}^{\max} = \gamma_1^{\max} + \gamma_2^{\max}$ and $\Gamma_{out}^{\max} = \gamma_3^{\max} + \gamma_4^{\max}$. Thus we want to have Γ as a flux through the junction.

Reasoning as in Theorem 13, one can easily see that to solve the Riemann problem, it is enough to determine the fluxes $\hat\gamma_i = f(\hat\rho_i)$, $i = 1,2$. In fact, to have simple

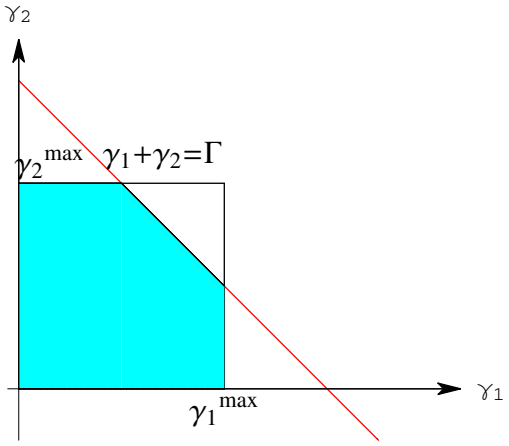

FIG. 4. *Case* $\Gamma_{in}^{\max} > \Gamma$.

waves with the appropriate velocities, i.e., negative on incoming lines and positive on outgoing ones, we get the constraints (8), (9). We have to distinguish two cases.

Case I. $\Gamma_{in}^{\max} = \Gamma$.

Case II. $\Gamma_{in}^{\max} > \Gamma$.

In the first case we set $\hat{\gamma}_i = \gamma_i^{\max}$, $i = 1, 2$.

Let us analyze the second case in which we use the priority parameter q.

Not all packets can enter the junction, so let C be the amount of packets that can go through. Then qC packets come from the first incoming line and $(1-q)C$ packets from the second. Consider the space (γ_1, γ_2) and define the following lines:

$$r_q : \gamma_2 = \frac{1-q}{q}\gamma_1,$$

$$r_\Gamma : \gamma_1 + \gamma_2 = \Gamma.$$

Define P to be the point of intersection of the lines r_q and r_Γ. Recall that the final fluxes should belong to the region (see Figure 4):

$$\Omega = \{(\gamma_1, \gamma_2) : 0 \le \gamma_i \le \gamma_i^{\max}, i = 1, 2\}.$$

We distinguish two cases.

Case (a). P belongs to Ω.

Case (b). P is outside Ω.

In the first case we set $(\hat{\gamma}_1, \hat{\gamma}_2) = P$, while in the second case we set $(\hat{\gamma}_1, \hat{\gamma}_2) = Q$, with $Q = proj_{\Omega \cap r_\Gamma}(P)$, where *proj* is the usual projection on a convex set; see Figure 5.

The reasoning can be repeated also in the case of n incoming lines. In $\mathbb{R}^n$ the line r_q is given by $r_q = tv_q$, $t \in \mathbb{R}$, with $v_q \in \Delta_{n-1}$, where

$$\Delta_{n-1} = \left\{ (\gamma_1, \ldots, \gamma_n) : \gamma_i \ge 0, i = 1, \ldots, n, \sum_{i=1}^{n} \gamma_i = 1 \right\}$$

is the $(n-1)$-dimensional simplex and

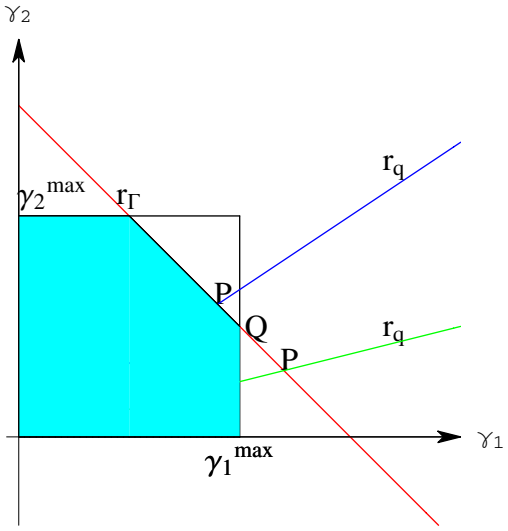

FIG. 5. *P belongs to Ω and P is outside Ω.*

$$H_\Gamma = \left\{ (\gamma_1, \dots, \gamma_n) : \sum_{i=1}^{n} \gamma_i = \Gamma \right\}$$

is a hyperplane where $\Gamma = \min\{\sum_{in} \gamma_i^{\max}, \sum_{out} \gamma_j^{\max}\}$. Since $v_q \in \Delta_{n-1}$, there exists a unique point $P = r_q \cap H_\Gamma$. If $P \in \Omega$, then we set $(\hat{\gamma}_1, \dots, \hat{\gamma}_n) = P$. If $P \notin \Omega$, then we set $(\hat{\gamma}_1, \dots, \hat{\gamma}_n) = Q = proj_{\Omega \cap H_\Gamma}(P)$, the projection over the subset $\Omega \cap H_\Gamma$. Observe that the projection is unique since $\Omega \cap H_\Gamma$ is a closed convex subset of H_Γ.

Remark 14. A possible alternative definition in the case $P \notin \Omega$ is to set $(\hat{\gamma}_1, \dots, \hat{\gamma}_n)$ as one of the vertices of $\Omega \cap H_\Gamma$.

Let us now determine $\hat{\gamma}_j$, $j = 3, 4$. As for the incoming transmission lines we have to distinguish two cases.

Case I. $\Gamma_{out}^{\max} = \Gamma$.

Case II. $\Gamma_{out}^{\max} > \Gamma$.

In the first case $\hat{\gamma}_j = \gamma_j^{\max}$, $j = 3, 4$. Let us determine $\hat{\gamma}_j$ in the second case. Recall α the traffic distribution parameter. Since not all packets can go on the outgoing transmission lines, we let C be the amount that goes through. Then αC packets go on the outgoing line I_3 and $(1-\alpha)C$ on the outgoing line I_4.

Now we can proceed exactly as in the previous case with q replaced by α. More precisely, we define r_α by the equation $\gamma_4 = \frac{1-\alpha}{\alpha}\gamma_3$, r_Γ by $\gamma_3 + \gamma_4 = \Gamma$, and P to be the point of intersection of the lines r_α and r_Γ. Setting $\Omega = \{(\gamma_3, \gamma_4) : 0 \le \gamma_j \le \gamma_j^{\max}, j = 3, 4\}$, we distinguish two cases.

Case (a). P belongs to Ω.

Case (b). P is outside Ω.

In the first case we set $(\hat{\gamma}_3, \hat{\gamma}_4) = P$, while in the second case we set $(\hat{\gamma}_3, \hat{\gamma}_4) = Q$, where $Q = proj_{\Omega \cap r_\Gamma}(P)$. Again, we can extend to the case of m outgoing lines as for the incoming lines defining the hyperplane $H_\Gamma = \{(\gamma_{n+1}, \dots, \gamma_{n+m}) : \sum_{j=n+1}^{n+m} \gamma_j = \Gamma\}$ and choosing a vector $v_\alpha \in \Delta_{m-1}$.

Remark 15. An alternative way of choosing the vector v_α is the following. We assume that a traffic distribution matrix A is assigned; then we compute $\hat{\gamma}_1, \dots, \hat{\gamma}_n$

as before and choose $v_\alpha \in \Delta_{m-1}$ by

$$v_\alpha = \Delta_{m-1} \cap \{tA(\hat\gamma_1, \dots, \hat\gamma_n) : t \in \mathbb{R}\}.$$

The solution to Riemann problems in this section is consistent, as shown by the next lemma.

LEMMA 16. (CC) *holds for the Riemann solver for* (RA2) *defined in this section.*

Proof. Let $\rho_0 = (\rho_{1,0}, \dots, \rho_{4,0})$ be the initial datum and $\hat\rho = RS(\rho_0)$. Assume, first, that $\Gamma < \Gamma_{in}^{\max}$. Define $\hat\gamma_i^{\max}$ to be the maximum flux on I_i given by a wave with left datum $\hat\rho_i$ and then set $\hat\Gamma_{in}^{\max} = \hat\gamma_1^{\max} + \hat\gamma_2^{\max}$. Then $\hat\Gamma_{in}^{\max} \geq \Gamma_{in}^{\max}$. Indeed if $\rho_{i,0} \in [0, \sigma[$, then $\hat\rho_i \in \{\rho_{i,0}\} \cup]\tau(\rho_{i,0}), \rho_{\max}]$ and $\hat\gamma_i^{\max} \geq \gamma_i^{\max} = f(\rho_{i,0})$, while if $\rho_{i,0} \in [\sigma, \rho_{\max}]$, then $\hat\rho_i \in [\sigma, \rho_{\max}]$ and so $\hat\gamma_i^{\max} = f(\sigma) = \gamma_i^{\max}$. The case $\Gamma < \Gamma_{out}^{\max}$ is treated similarly. ∎

5. Estimates on density variation. In this section we derive estimates on the total variation of the densities along a wave-front tracking approximate solution (constructed as in [11]) for both routing algorithms. This allows us to construct the solutions to the Cauchy problem in the standard way; see [7]. From now on, we assume that every junction has exactly two incoming transmission lines and two outgoing ones. This hypothesis is crucial, because the presence of more complicated junctions may provoke additional increases of the total variation of the flux and so of the density. The case where junctions have at most two incoming transmission lines and at most two outgoing ones can be treated in the same way.

From now on we fix a telecommunication network $(\mathcal{I}, \mathcal{J})$, with each node having at most two incoming and at most two outgoing lines, and a wave-front tracking approximate solution ρ, defined on the telecommunication network.

5.1. Algorithm (RA1). We first introduce the following.

DEFINITION 17. *For every transmission line I_i, $i = 1, \dots, N$, we indicate by*

$$\left(\rho_-^\beta, \rho_+^\beta\right), \quad \beta \in A = A(\rho, t, i), \quad A \text{ finite set},$$

the discontinuities on line I_i at time t, and by $x^\beta(t)$, $\lambda^\beta(t)$, $\beta \in A$, respectively, their positions and velocities at time t. We also refer to the wave β to indicate the discontinuity $(\rho_-^\beta, \rho_+^\beta)$.

We have the following.

LEMMA 18. *For some $K > 0$, we have*

$$\begin{aligned} TV(f(\rho(t,\cdot))) &\leq e^{Kt} TV(f(\rho(0+,\cdot))) \\ &\leq e^{Kt}(TV(f(\rho(0,\cdot))) + 2Nf(\sigma)) \end{aligned}$$

for each $t \geq 0$, where N is the total number of transmission lines of the network.

For the proof see Lemma 18 in [11]. To estimate the total variation of densities and to pass to the limit we need some additional notation.

DEFINITION 19. *For every line I_i, we define two curves $Y_-^{i,\rho}(t), Y_+^{i,\rho}(t)$, called the boundary of external flux (BEF), in the following way. We set the initial condition $Y_-^{i,\rho}(0) = a_i$, $Y_+^{i,\rho}(0) = b_i$ (if $a_i = -\infty$, then $Y_-^{i,\rho} \equiv -\infty$ and if $b_i = +\infty$, then $Y_+^{i,\rho} \equiv +\infty$). We let $Y_\pm^{i,\rho}(t)$ follow the generalized characteristic as defined in* [12], *letting $Y_-^{i,\rho}(t) = a_i$ (resp., $Y_+^{i,\rho}(t) = b_i$) if the generalized characteristic reaches the boundary and $f'(\rho(t, a_i)) < 0$ (resp., $f'(\rho(t, b_i)) > 0$). (In this way $Y_\pm^{i,\rho}(t)$ may coincide with a_i or b_i for some time intervals.) Let $\bar t$ be the first time such that*

$Y^{i,\rho}_-(\bar t) = Y^{i,\rho}_+(\bar t)$ *(possibly* $\bar t = +\infty$*). Then we let* $Y^{i,\rho}_\pm$ *be defined on* $[0, \bar t]$*. Finally, we define the sets*

$$D^i_1(\rho) = \left\{(t,x) : t \in [0, \bar t[: Y^{i,\rho}_-(t) < x < Y^{i,\rho}_+(t)\right\}$$

and

$$D^i_2(\rho) = [0, +\infty[\times [a_i, b_i] \setminus D^i_1(\rho).$$

Clearly $Y^{i,\rho}_\pm(t)$ bound the set on which the datum is not influenced by other transmission lines through the junctions.

DEFINITION 20. *Fix a transmission line* I_i*,* $i = 1, \dots, N$*, and a junction* J*. A wave* β *in* I_i *is said to be a big wave if*

$$sgn(\rho^\beta_- - \sigma) \cdot sgn(\rho^\beta_+ - \sigma) \le 0,$$

where $sgn(0) = 0$*. We say that an incoming transmission line* I_i *has a bad datum at* J *at time* $t > 0$ *if*

$$\rho_i(t, b_i-) \in [0, \sigma[\,,$$

while we say that an outgoing transmission line I_j *has a bad datum at* J *at time* $t > 0$ *if*

$$\rho_j(t, a_j+) \in]\sigma, 1]\,.$$

Our aim is now to bound, for each line I_i, the number of big waves inside the region $D^i_2(\rho)$, i.e., those generated by the influence of external lines.

LEMMA 21. *Let* $\bar t$ *be the time at which the two BEFs* $Y^{i,\rho}_\pm$ *interact. Assume* $\bar t < +\infty$*,* $Y^{i,\rho}_\pm(\bar t) \in]a_i, b_i[$*, and define*

$$\hat\rho_{out} = \rho\left(Y^{i,\rho}_\pm(\bar t)-\right), \quad \hat\rho_{in} = \rho\left(Y^{i,\rho}_\pm(\bar t)+\right), \quad \rho^* = \lim_{t\uparrow\bar t} \rho\left(Y^{i,\rho}_-(t)+\right) = \lim_{t\uparrow\bar t} \rho\left(Y^{i,\rho}_+(t)-\right).$$

If $\hat\rho_{in}$*, respectively,* $\hat\rho_{out}$*, is a bad datum for* I_i *as incoming line, respectively, for* I_i *as outgoing line, then there exists no value* ρ^* *of the density such that*

$$\lambda(\hat\rho_{out}, \rho^*) > \lambda(\rho^*, \hat\rho_{in}).$$

Proof. Since $\hat\rho_{out}$ and $\hat\rho_{in}$ are bad data for, respectively, an outgoing transmission line and an incoming transmission line, it follows that

$$\hat\rho_{out} \in]\sigma, 1]\,, \quad \hat\rho_{in} \in [0, \sigma[\,.$$

Observe that $\hat\rho_{out}$ and ρ^* must be connected by a single wave, and thus $\rho^* \ge \sigma$; otherwise the wave would be split in a fan of rarefaction shocks.

Similarly, ρ^* and $\hat\rho_{in}$ must be connected by a single wave, and thus $\rho^* \le \sigma$; otherwise the wave would be split in a fan of rarefaction shocks.

Finally, $\rho^* = \sigma$, but then

$$\lambda(\hat\rho_{out}, \rho^*) \le 0 \le \lambda(\rho^*, \hat\rho_{in})$$

and the conclusion holds. ∎

LEMMA 22. *For every $t \geq 0$, there are at most two big waves on*

$$\left\{x : (t,x) \in D_2^i(\rho)\right\} \subseteq [a_i, b_i]\,.$$

Proof. A big wave can originate at time t on transmission line I_i from J only if the line I_i has a bad datum at J at time t. If this happens, then, from Theorem 13, line I_i has not a bad datum at J up to the time in which a big wave is absorbed from I_i. This concludes the proof if $D_2^i(\rho)$ is formed by two connected components.

It remains to consider the time at which the two BEFs interact. By Lemma 21 we have that not both connected components can contain a big wave. Thus again there are at most two big waves. □

Up to now, we did not make use of assumption (F), which is necessary for the next lemma.

LEMMA 23. *Assume* (F)*; then for some $K > 0$, we have*

$$TV(\rho(t,\cdot)) \leq TV(\rho(0,\cdot)) + 2N\left(\frac{e^{Kt}f(\sigma)}{\bar{v}} + 1\right)$$

for each $t \geq 0$, where N is the total number of transmission lines of the network.

Proof. Let $TV(h;[a,b])$ denote the total variation of the function h over the interval $[a,b]$ and define

$$TV^j(\rho(t)) = \sum_i TV(\rho(t); D_j^i(\rho(t))), \qquad j = 1,2,$$

which are, respectively, the total variation of $\rho(t)$ due to the evolution only inside each line I_i and by interaction with junctions. Clearly,

$$TV(\rho(t)) = TV^1(\rho(t)) + TV^2(\rho(t)).$$

Since $D_1^i(\rho(t))$ is not influenced by external lines, we are in the situation of a conservation law on $\mathbb{R}$, hence

$$TV^1(\rho(t)) \leq TV(\rho(0)).$$

Let $B(t)$ denote the number of big waves generated from junctions, i.e., the number of big waves in $\bigcup_i D_2^i(\rho(t))$. Then by the chain rule for BV functions and Lemma 18,

$$TV^2(\rho(t)) \leq \frac{1}{\bar{v}} TV^2(f(\rho(t)) + B(t) \leq \frac{1}{\bar{v}} e^{Kt}(TV^2(f(\rho(0+))) + B(t). \tag{12}$$

Now that $TV^2(\rho(0)) = 0$, and thus, using again Lemmas 18 and 22, the following relation holds:

$$TV^2(\rho(t)) \leq \frac{1}{\bar{v}} e^{Kt} 2N f(\sigma) + 2N. \tag{13}$$

Finally we get

$$TV(\rho(t)) = TV^1(\rho(t)) + TV^2(\rho(t)) \leq TV(\rho(0)) + 2N\left(\frac{e^{Kt}f(\sigma)}{\bar{v}} + 1\right). \qquad \square$$

Thanks to Lemma 23 and the Lipschitz continuous dependence in L^1_{loc} of wave-front tracking approximations, we can apply the Helly theorem, as in [7], to get existence of solutions.

THEOREM 24. *Fix a telecommunication network* (I, J) *and assume* (F). *Given* $T > 0$, *for every initial data there exists an admissible solution to the Cauchy problem on the network defined on* $[0, T]$.

Let us observe that there is no Lipschitz continuous dependence by initial data with respect to the L^1 norm. In fact it is possible to choose two piecewise constant initial data, which are exactly the same except for a shift of a discontinuity, such that the L^1-distance of the two corresponding solutions increases by an arbitrary multiplicative factor (see [11]).

5.2. Algorithm (RA2). Let us now estimate the flux total variation and the density total variation for routing algorithm (RA2). We can define BEFs, bad data, and big waves as in the previous section.

Fix a junction J with two incoming transmission lines I_1 and I_2 and two outgoing ones I_3 and I_4.

Suppose that at some time $\bar{t}$ a wave interacts with the junction J and let $(\rho_1^-, \rho_2^-, \rho_3^-, \rho_4^-)$ and $(\rho_1^+, \rho_2^+, \rho_3^+, \rho_4^+)$ indicate the equilibrium configurations at the junction J before and after the interaction, respectively. Introduce the following notation:

$$\gamma_i^\pm = f(\rho_i^\pm), \quad \Gamma_{in}^\pm = \gamma_{1,\max}^\pm + \gamma_{2,\max}^\pm, \quad \Gamma_{out}^\pm = \gamma_{3,\max}^\pm + \gamma_{4,\max}^\pm,$$

$$\Gamma^\pm = \min\{\Gamma_{in}^\pm, \Gamma_{out}^\pm\},$$

where $\gamma_{i,\max}^\pm$, $i = 1, 2$, and $\gamma_{j,\max}^\pm$, $j = 3, 4$, are defined as in (10) and (11). In general $-$ and $+$ denote the values before and after the interaction, while by Δ we indicate the variation, i.e., the value after the interaction minus the value before. For example, $\Delta\Gamma = \Gamma^+ - \Gamma^-$. Let us denote by $TV(f)^\pm = TV(f(\rho(\bar{t}\pm, \cdot)))$ the flux variation of waves before and after the interaction, and by

$$TV(f)_{in}^\pm = TV(f(\rho_1(\bar{t}\pm, \cdot))) + TV(f(\rho_2(\bar{t}\pm, \cdot))),$$

$$TV(f)_{out}^\pm = TV(f(\rho_3(\bar{t}\pm, \cdot))) + TV(f(\rho_4(\bar{t}\pm, \cdot)))$$

the flux variation of waves before and after the interaction, respectively, on incoming and outgoing lines.

Let us prove some estimates which are used later to control the total variation of the density function. For simplicity, from now on we assume that

(A) the wave interacting at time $\bar{t}$ with J comes from line 1 and we let ρ_1 be the value on the left of the wave.

The case of a wave from an outgoing line can be treated similarly.

LEMMA 25. *We have*

$$sgn\,(\Delta\gamma_3) \cdot sgn\,(\Delta\gamma_4) \geq 0.$$

Proof. To prove the lemma it is enough to observe that a variation of γ_3 is due to a movement along the line r_q or along $\gamma_3 = c_1$ or $\gamma_4 = c_2$ with c_1 and c_2 constant. In each case $\Delta\gamma_3$ and $\Delta\gamma_4$ have the same sign. □

In the same way we can prove the following lemma.

LEMMA 26. *We have*

$$sgn(\gamma_1^+ - \gamma_1) \cdot sgn(\Delta\gamma_2) \geq 0,$$

where $\gamma_1 = f(\rho_1)$.

LEMMA 27. *It holds that*

$$TV(f)^+_{out} = |\Delta\Gamma|.$$

Proof. To prove the lemma it is enough to observe that

$$\Gamma^- = \gamma_3^- + \gamma_4^-, \quad \Gamma^+ = \gamma_3^+ + \gamma_4^+,$$

$$|\Delta\Gamma| = |\Gamma^+ - \Gamma^-| = |(\gamma_3^+ - \gamma_3^-) + (\gamma_4^+ - \gamma_4^-)|,$$

from which, by Lemma 25, we have

$$|\Delta\Gamma| = |\Delta\gamma_3| + |\Delta\gamma_4| = TV(f)^+_{out}. \qquad \square$$

LEMMA 28. *We have*

$$TV(f)^-_{in} = TV(f)^+_{in} + |\Delta\Gamma|. \tag{14}$$

Proof. Clearly since the wave on the first line has positive velocity, we have $0 \le \rho_1 \le \sigma$. Since $\rho_1 \le \sigma$, observe that the maximum flux for ρ_1^+, which is the solution with initial data ρ_1, is given by $\gamma_{1,\max} = f(\rho_1)$. Also

$$TV(f)^- = TV(f)^-_{in} = |\gamma_1 - \gamma_1^-|.$$

We have two possibilities.

Case 1. $\rho_1^- \le \sigma$.

Case 2. $\rho_1^- > \sigma$.

Let us first analyze Case 1. Then we further split it into two subcases.

Case 1(a). $\rho_1 < \rho_1^-$.

Case 1(b). $\rho_1 > \rho_1^-$.

If 1(a) holds true, since $\rho_1 < \rho_1^-$, we get $\gamma_{1,\max} = f(\rho_1) < f(\rho_1^-) = \gamma_{1,\max}^-$ and one of the following holds.

Case 1(a.1). $\Gamma^- = \Gamma^-_{in}$.

Case 1(a.2). $\Gamma^- = \Gamma^-_{out}$.

In Case 1(a.1) from $\gamma_{1,\max} < \gamma_{1,\max}^-$ and $\Gamma^- = \Gamma^-_{in}$, it follows that $\Gamma^+ = \Gamma^+_{in}$, from which $\gamma_2^+ = \gamma_2^-$, $\gamma_1^+ = \gamma_1$ and then $TV(f)^+_{in} = 0$.

In Case 1(a.2) we have $\gamma_{1,\max} < \gamma_{1,\max}^-$, and hence $\Gamma^-_{in} \ge \Gamma^-$ and $\gamma_{1,\max} + \gamma_{2,\max}^- < \Gamma^-_{in}$. The following distinction must be considered.

Case 1(a.2.1). $\gamma_{1,\max} + \gamma_{2,\max}^- \ge \Gamma^-$.

Case 1(a.2.2). $\gamma_{1,\max} + \gamma_{2,\max}^- < \Gamma^-$.

If Case 1(a.2.1) holds, from $\gamma_{1,\max} + \gamma_{2,\max}^- \ge \Gamma^-$, we have that $\Gamma^+ = \Gamma^-$, from which $|\Delta\Gamma| = 0$. By Lemma 26 the conclusion holds.

In the opposite Case 1(a.2.2) from $\gamma_{1,\max} + \gamma_{2,\max}^- < \Gamma^-$, one gets $\Gamma^+ = \gamma_{1,\max} + \gamma_{2,\max}^-$, from which it follows that $TV(f)^+_{in} = 0$. Then $|\Delta\Gamma| = \left|\gamma_1^- - \gamma_1\right| = TV(f)^-_{in}$. Case 1(a) is thus finished.

Let us now focus on Case 1(b). We have to distinguish two possibilities.

Case 1(b.1). $\Gamma^- = \Gamma^-_{out}$.

Case 1(b.2). $\Gamma^- = \Gamma^-_{in}$.

If Case 1(b.1) holds, from $\Gamma^- = \Gamma^-_{out}$ it follows that $\gamma_{1,\max} + \gamma_{2,\max}^- > \Gamma^-_{in}$. Then $\Gamma^+ = \Gamma^-$; hence $|\Delta\Gamma| = 0$ and by Lemma 26 the conclusion holds.

In Case 1(b.2), we have $\gamma_{1,\max} + \gamma_{2,\max}^- > \Gamma^-_{in}$ and $\Gamma^-_{out} \ge \Gamma^-_{in}$, and the following cases may happen.

Case 1(b.2.1). $\gamma_{1,\max} + \gamma^-_{2,\max} \le \Gamma^-_{out}$.

Case 1(b.2.2). $\gamma_{1,\max} + \gamma^-_{2,\max} > \Gamma^-_{out}$.

Consider Case 1(b.2.1) first. From $\gamma_{1,\max} + \gamma^-_{2,\max} \le \Gamma^-_{out}$, one has $TV(f)^+_{in} = 0$, and hence $|\Delta\Gamma| = \left|\gamma_1 - \gamma_1^-\right| = TV(f)^-_{in}$.

In Case 1(b.2.2), from $\gamma_{1,\max}+\gamma^-_{2,\max} > \Gamma^-_{out}$ we obtain $\Gamma^+ = \Gamma^+_{out}$. By Lemma 25,

$$TV(f)^+_{in} = \gamma_{1,\max} + \gamma^-_{2,\max} - \Gamma^-_{out},$$

$$TV(f)^-_{in} = \gamma_{1,\max} - \gamma^-_{1,\max},$$

and hence

$$\begin{aligned} TV(f)^-_{in} - TV(f)^+_{in} &= -\gamma^-_{1,\max} - \gamma^-_{2,\max} + \Gamma^-_{out} \\ &= \Gamma^+ - \Gamma^-_{in} = \Gamma^+ - \Gamma^- = |\Delta\Gamma|. \end{aligned}$$

Let us analyze Case (2). Since $\rho_1^- > \sigma$ it follows that $\rho_1 < \tau(\rho_1^-) < \sigma$. Observe that $\gamma_1 = f(\rho_1) < f(\rho_1^-) = \gamma_1^-$ and $\gamma^-_{1,\max} = f(\sigma)$, $\gamma_{1,\max} = f(\rho_1)$.

We have to distinguish two cases.

Case 2(a). $\Gamma^- = \Gamma^-_{in}$.

Case 2(b). $\Gamma^- = \Gamma^-_{out}$.

If Case 2(a) holds, then one gets $\gamma_{1,\max} + \gamma^-_{2,\max} < \Gamma^-$, from which it follows that $\Gamma^+ = \gamma_{1,\max} + \gamma^-_{2,\max}$. Hence $TV(f)^+_{in} = 0$ and the conclusion holds.

For the opposite Case (2b), we have $\gamma_{1,\max} + \gamma^-_{2,\max} < \Gamma^-_{in}$ and $\Gamma^-_{in} \ge \Gamma^-_{out}$. Hence the following two cases are possible.

Case 2(b.1). $\gamma_{1,\max} + \gamma^-_{2,\max} \ge \Gamma^-_{out}$.

Case 2(b.2). $\gamma_{1,\max} + \gamma^-_{2,\max} < \Gamma^-_{out}$.

In Case 2(b.1), from $\gamma_{1,\max} + \gamma^-_{2,\max} \ge \Gamma^-_{out}$, it follows that $\Gamma^+ = \Gamma^-$. The latter implies $|\Delta\Gamma| = 0$ and the conclusion follows from Lemma 26.

In Case 2(b.2) from $\gamma_{1,\max}+\gamma^-_{2,\max} < \Gamma^-_{out}$, we obtain $\Gamma^+ = \gamma_{1,\max}+\gamma^-_{2,\max}$. Thus, by Lemma 26, we get

$$TV(f)^+_{out} = \Gamma^+ - (\gamma_1 + \gamma_2^-) = (\gamma_{1,\max} + \gamma^-_{2,\max}) - (\gamma_1 + \gamma_2^-) = \gamma^-_{2,\max} - \gamma_2^-.$$

It follows that

$$\begin{aligned} |\Delta\Gamma| = \Gamma^- - \Gamma^+ &= \gamma_1^- + \gamma_2^- - (\gamma_{1,\max} + \gamma^-_{2,\max}) \\ = (\gamma_1^- - \gamma_{1,\max}) + (\gamma_2^- - \gamma^-_{2,\max}) &= TV(f)^-_{in} - TV(f)^+_{out}, \end{aligned}$$

and the conclusion holds. The proof is thus complete. ∎

From the above results, we are ready to state the following.

LEMMA 29. *The flux variation $TV(f)$ is conserved along wave-front tracking approximations.*

Notice that this result is much stronger than that obtained for routing algorithm (RA1), for which only an exponential in time bound for the flux variation is achieved.

Proof. From Lemmas 27 and 28 we get

$$TV(f)^- = TV(f)^-_{in} = TV(f)^+_{in} + |\Delta\Gamma| = TV(f)^+. \qquad ∎$$

The estimate on the number of big waves is valid also for algorithm (RA2); thus we bound the total variation of the densities as follows.

THEOREM 30. *Consider a telecommunication network* $(\mathcal{I}, \mathcal{J})$ *and assume* (F). *Let* ρ *be a wave-front tracking approximate solution. Then*

$$TV(\rho(t,\cdot)) \le TV(\rho(0,\cdot)) + 2N\left(\frac{f(\sigma)}{\bar{v}} + 1\right)$$

for each $t \ge 0$*, where* N *is the total number of transmission lines of the network. Moreover, given* $T > 0$*, there exists an admissible solution to the Cauchy problem on the network defined on* $[0,T]$ *for every initial data.*

5.2.1. Uniqueness and Lipschitz continuous dependence. The aim of this section is to prove Lipschitz continuous dependence by initial data for solutions to the Cauchy problem on the network, controlling for any two approximate solutions ρ, ρ' how their distance varies in time. We use the method introduced in [8], which is based on a Riemannian type distance on L^1. There are various alternative methods to treat uniqueness and continuous dependence for the case of scalar conservation laws on the real line, including Kruzkov entropies (cf. [7]), viscous approximations (cf. [22, 23]), and Bressan–Liu–Yang functionals (see [9]). No one of these methods seems to work for the network case. In fact, the Kruzkov method requires one to estimate integrals on a region in $\mathbb{R}^2$, which now is replaced by an integral on the topological space obtained by the product of the network and $\mathbb{R}$. On the other hand, it is not clear how to define a viscous solution on the network, in particular how to treat boundary data at nodes, and how to pass to the limit. Finally, a Bressan–Liu–Yang-type functional requires one to introduce a definition of approaching waves, but, on a general network, with complicated topology, every wave is potentially approaching each other.

The basic idea is to estimate the L^1-distance viewing L^1 as a Riemannian manifold. We consider the subspace of piecewise constant functions and "generalized tangent vectors" consisting of two components (v, ξ), where $v \in L^1$ describes the L^1 infinitesimal displacement, while $\xi \in \mathbb{R}^n$ describes the infinitesimal displacement of discontinuities. For example, take a family of piecewise constant functions $\theta \to \rho^\theta$, $\theta \in [0,1]$, each of which has the same number of jumps, say at the points $x_1^\theta < \cdots < x_N^\theta$. Assume that the following functions are well defined (Figure 6):

$$L^1 \ni v^\theta(x) \doteq \lim_{h\to 0} \frac{\rho^{\theta+h}(x) - \rho^\theta(x)}{h},$$

as well as the numbers

$$\xi_\beta^\theta \doteq \lim_{h\to 0} \frac{x_\beta^{\theta+h} - x_\beta^\theta}{h}, \qquad \beta = 1, \dots, N.$$

Then we say that γ admits tangent vectors $(v^\theta, \xi^\theta) \in T_{\rho^\theta} \doteq L^1(\mathbb{R}; \mathbb{R}^n) \times \mathbb{R}^n$. In general a path such as $\theta \to \rho^\theta$ is not differentiable with respect to the usual differential structure of L^1; in fact if $\xi_\beta^\theta \ne 0$, as $h \to 0$ the ratio $\left[\rho^{\theta+h}(x) - \rho^\theta\right]/h$ does not converge to any limit in L^1.

Moreover, we can compute the L^1-length of the path $\gamma : \theta \to \rho^\theta$ in the following way:

$$\|\gamma\|_{L^1} = \int_0^1 \left\|v^\theta\right\|_{L^1} d\theta + \sum_{\beta=1}^{N} \int_0^1 \left|\rho^\theta(x_\beta+) - \rho^\theta(x_\beta-)\right| \left|\xi_\beta^\theta\right| d\theta. \tag{15}$$

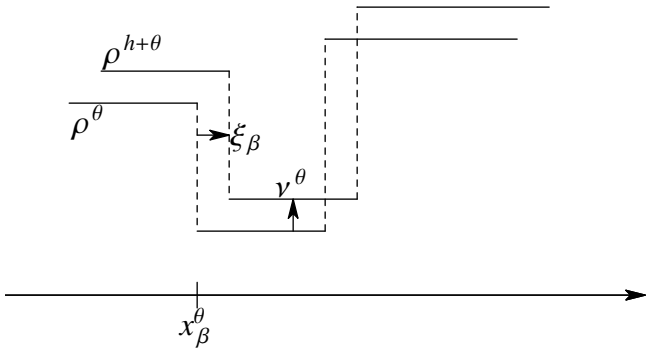

FIG. 6. *Construction of "generalized tangent vectors."*

According to (15), in order to compute the L^1-length of a path γ, we integrate the norm of its tangent vector, which is defined as follows:

$$\|(v,\xi)\| \doteq \|v\|_{L^1} + \sum_{\beta=1}^{N} |\Delta\rho_\beta|\,|\xi_\beta|\,,$$

where $\Delta\rho_\beta = \rho(x_\beta+) - \rho(x_\beta-)$ is the jump across the discontinuity x_β.

Let us introduce the following definition.

DEFINITION 31. *We say that a continuous map $\gamma : \theta \to \rho^\theta \doteq \gamma(\theta)$ from $[0,1]$ into L^1_{loc} is a regular path if the following holds. All functions ρ^θ are piecewise constant, with the same number of jumps, say at $x^\theta_1 < \cdots < x^\theta_N$, and coincide outside some fixed interval $]-M, M[$. Moreover, the function $\theta \to \rho^\theta_x$ is continuous from $[0,1]$ into L^1, and the map $\theta \to \rho^\theta$ admits a generalized tangent vector $D\gamma(\theta) = (v^\theta, \xi^\theta) \in T_{\gamma(\theta)} = L^1(\mathbb{R};\mathbb{R}^n) \times \mathbb{R}^N$, continuously depending on θ.*

Given two piecewise constant functions ρ and ρ', call $\Omega(\rho,\rho')$ the family of all regular paths $\gamma : [0,1] \to \gamma(t)$ with $\gamma(0) = \rho$, $\gamma(1) = \rho'$. The Riemannian distance between ρ and ρ' is given by

$$d(\rho,\rho') \doteq \inf\left\{\|\gamma\|_{L^1}\,, \gamma \in \Omega(\rho,\rho')\right\}.$$

To define d on all L^1, for given $\rho, \rho' \in L^1$ we set

$$d(\rho,\rho') \doteq \inf\{\|\gamma\|_{L^1} + \|\rho - \tilde\rho\|_{L^1} + \|\rho' - \tilde\rho'\|_{L^1} : \\ \tilde\rho, \tilde\rho' \text{ piecewise constant functions}, \gamma \in \Omega(\tilde\rho, \tilde\rho')\}\,.$$

It is easy to check that this distance coincides with the distance of L^1. For the systems case, one has to introduce weights; see [8].

Now we are ready to estimate the L^1-distance among solutions, studying the evolution of norms of tangent vectors along wave-front tracking approximations. Take ρ, ρ' piecewise constant functions and let $\gamma_0(\vartheta) = \rho^\vartheta$ be a regular path joining $\rho = \rho^0$ with $\rho' = \rho^1$. Define $\rho^\vartheta(t,x)$ to be a wave-front tracking approximate solution with initial data ρ^ϑ and let $\gamma_t(\vartheta) = \rho^\vartheta(t,\cdot)$.

If we can prove that, for every γ_0 (regular path) and every $t \geq 0$, γ_t is a regular path and

$$\|\gamma_t\|_{L^1} \leq \|\gamma_0\|_{L^1}\,, \tag{16}$$

then for every $t \geq 0$

$$\|\rho(t,\cdot) - \rho'(t,\cdot)\|_{L^1} \leq \inf_{\gamma_t} \|\gamma_t\|_{L^1} \leq \inf_{\gamma_0} \|\gamma_0\|_{L^1} = \|\rho(0,\cdot) - \rho'(0,\cdot)\|_{L^1}\,. \tag{17}$$

To obtain (16), hence (17), it is enough to prove that, for every tangent vector $(v,\xi)(t)$ to any regular path γ_t, one has

$$\|(v,\xi)(t)\| \leq \|(v,\xi)(0)\|\,, \tag{18}$$

i.e., the norm of a tangent vector does not increase in time. Moreover, if (17) is established, then uniqueness and Lipschitz continuous dependence of solutions to Cauchy problems is straightforwardly achieved passing to the limit on the wave-front tracking approximate solutions.

The same reasoning can be used on the network. If $\rho = (\rho_1, \ldots, \rho_N)$ is a solution on the network, then we set

$$\|\rho\|_{L^1} = \sum_i \|\rho_i\|_{L^1(I_i)}\,.$$

To estimate the distance among wave-front tracking solutions it is thus enough to prove (18). We prove the latter estimating the evolution of the tangent vector norm at each time. For this, we fix a time $\bar{t} \geq 0$ and, without loss of generality, treat the following cases:

(a) no interaction of waves takes place in any transmission line at $\bar{t}$, and no wave interacts with a junction;
(b) two waves interact at $\bar{t}$ on a transmission line, and no other interaction takes place;
(c) a wave interacts with a junction at $\bar{t}$, and no other interaction takes place.

In case (a) we can prove

$$\left[\frac{d}{dt}\,\|(v,\xi)(t)\|\right]_{t=\bar{t}} \leq 0,$$

while in cases (b) and (c), letting $(v,\xi)^{\pm}$ be the tangent vector before $(-)$ and after $(+)$ the interaction, we prove

$$\left\|(v,\xi)^+\right\| \leq \left\|(v,\xi)^-\right\|.$$

Let us first analyze case (a). Denote by x_β, σ_β, and ξ_β, respectively, the positions, sizes, and shifts of the discontinuities of the wave-front tracking approximate solution. Following [8] we get

$$\begin{aligned}
&\frac{d}{dt}\left\{\int |v(t,x)|\,dx + \sum_{\beta=1}^{N} |\xi_\beta|\,|\sigma_\beta|\right\} \\
&= -\left\{\sum_\beta \left(\lambda(\rho^-) - \dot{x}_\beta\right)\left|v^-\right| + \sum_\beta \left(\dot{x}_\beta - \lambda(\rho^+)\right)\left|v^+\right|\right\} \\
&\quad + \sum_\beta D\lambda(\rho^-,\rho^+)\cdot(v^-,v^+)\,(\operatorname{sign}\xi_\beta)\,|\sigma_\beta|\,,
\end{aligned}$$

with $\sigma_\beta = \rho^+ - \rho^-$, $\rho^\pm \doteq \rho(x_\beta \pm)$ and similarly for $v^\pm$. If the waves respect the Rankine–Hugoniot conditions, then

$$D\lambda(\rho^-, \rho^+)(v^-, v^+) = \left(\lambda(\rho^-) - \dot{x}_\beta\right) \frac{v^-}{|\sigma_\beta|} + \left(\dot{x}_\beta - \lambda(\rho^+)\right) \frac{v^+}{|\sigma_\beta|}$$

and

$$\frac{d}{dt} \left\{ \int |v(t,x)|\, dx + \sum_{\beta=1}^{N} |\xi_\beta|\, |\sigma_\beta| \right\} \leq 0. \tag{19}$$

Remark 32. To be precise, to obtain control over $TV(f)$ the wave-front tracking is slightly modified in the following way (see [11]). For every initial data ρ a sequence of piecewise constant approximations ρ_ν are constructed, converging to ρ in L^1. Then one chooses a sequence $\delta_\nu > 0$ converging to zero and construct wave-front tracking approximate solutions splitting rarefaction waves into a fan of rarefaction shocks, each of size at most δ_ν. If a rarefaction wave is originated at a junction with ρ^+ or ρ^- equal to σ, then we let $\dot{x}_\beta = 0$. However, since $\dot{x}_\beta = \frac{f(\sigma+\delta_\nu)-f(\sigma)}{\delta_\nu}$, $|\dot{x}_\beta - \bar{x}_\beta| = \delta_\nu$ we get

$$\frac{d}{dt} \left\{ \int |v(t,x)|\, dx + \sum_{\beta=1}^{N} |\xi_\beta|\, |\sigma_\beta| \right\} \leq 2\delta_\nu N,$$

where N is the number of transmission lines. In fact, by Lemma 22, there are at most two such waves on each transmission line. Hence the estimate (18) is obtained in the limit as ν tends to $+\infty$.

In case (b), we use the following lemma (see [11], for example).

LEMMA 33. *Let us consider in a transmission line two waves, with speeds λ_1 and λ_2, respectively, that interact, producing a wave with speed λ_3. If the first wave is shifted by ξ_1 and the second wave by ξ_2, then the shift of the resulting wave is given by*

$$\xi_3 = \frac{\lambda_3 - \lambda_2}{\lambda_1 - \lambda_2}\xi_1 + \frac{\lambda_1 - \lambda_3}{\lambda_1 - \lambda_2}\xi_2.$$

Moreover we have that

$$\Delta\rho_3\xi_3 = \Delta\rho_1\xi_1 + \Delta\rho_2\xi_2, \tag{20}$$

where $\Delta\rho_i$ are the signed strengths of the corresponding waves.

From (20) it follows that

$$|\Delta\rho_3\xi_3| \leq |\Delta\rho_1|\, |\xi_1| + |\Delta\rho_2|\, |\xi_2|\,,$$

from which

$$\left\|(v,\xi)^+\right\| \leq \left\|(v,\xi)^-\right\|. \tag{21}$$

For case (c) we report the lemma in [11].

LEMMA 34. *Let us consider a junction J with incoming lines I_1 and I_2 and outgoing lines I_3 and I_4. If a wave on a transmission line I_i ($i \in \{1, \dots, 4\}$) interacts*

with J and if ξ_i is the shift of the wave in I_i, then the shift ξ_j produced in a different line I_j ($j \in \{1,\dots,4\}\backslash\{i\}$) satisfies

$$\xi_j(\rho_j^+ - \rho_j^-) = \frac{\Delta\gamma_j}{\Delta\gamma_i}\xi_i(\rho_i^+ - \rho_i^-),$$

where $\Delta\gamma_l$ ($l \in \{i,j\}$) represents the variation of the flux in the line I_l and ρ_l^-, ρ_l^+ ($l \in \{i,j\}$) are the states at J in the line I_l, respectively, before and after the interaction.

Define $TV(f)^{\pm}$ to be the total variation of the flux of the solution before $(-)$ and after $(+)$ the interaction, and $TV(f)_i^{\pm}$ the same quantity on line I_i. Without loss of generality, we can assume that a wave from an incoming transmission line $\bar{\imath}$ interacts with a junction J and no other wave is present. Then $TV(f)^- = TV(f)_{\bar{\imath}}^-$ and $TV(f)^+ = \sum_j TV(f)_j^+$, where $TV(f)_j^+$ measures just the wave produced by the interaction. From Lemma 34 we have

$$|\xi_j|\,|\Delta\rho_j| = \frac{TV(f)_j^-}{TV(f)^-}\,|\xi_{\bar{\imath}}|\,|\Delta\rho_{\bar{\imath}}|\,.$$

Using Lemma 29 we conclude

$$\begin{aligned}\left\|(v,\xi)^+\right\| &= \|v\|_{L^1} + \sum_j |\xi_j|\,|\Delta\rho_j| = \|v\|_{L^1} + \sum_j \frac{TV(f)_j^-}{TV(f)_{\bar{\imath}}^-}\,|\xi_{\bar{\imath}}|\,|\Delta\rho_{\bar{\imath}}| \\ &= \|v\|_{L^1} + \frac{TV(f)^+}{TV(f)^-}\,|\xi_{\bar{\imath}}|\,|\Delta\rho_{\bar{\imath}}| = \left\|(v,\xi)^-\right\|.\end{aligned} \tag{22}$$

From (19), (21), and (22), we get the following.

THEOREM 35. *Consider a telecommunication network $(\mathcal{I},\mathcal{J})$ and assume* (F). *Then the solutions to Cauchy problems on the networks are unique and depend in a Lipschitz continuous way on initial data.*

APPROXIMATE TRAVELING WAVES IN LINEAR REACTION-HYPERBOLIC EQUATIONS*

AVNER FRIEDMAN† AND GHEORGHE CRACIUN‡

Abstract. Linear reaction-hyperbolic equations arise in the transport of neurofilaments and membrane-bound organelles in axons. The profile of the solution was shown by simulations to be approximately that of a traveling wave; this was also suggested by formal calculations [M. C. Reed, S. Venakides, and J. J. Blum, *SIAM J. Appl. Math.*, 50 (1990), pp. 167–180]. In this paper we prove such a result rigorously.

Key words. axonal transport, hyperbolic equations, asymptotic approximations, traveling waves

1. Introduction.

This paper is concerned with the mathematical analysis of reaction-hyperbolic equations which describe transport of materials along a straight ray $l_0 = \{x : 0 < x < \infty\}$. The model is motivated from biology; it describes the transport of proteins and other molecules along the axon of a neuron. The proteins are formed near the nucleus of the cell, that is, at $x = 0$, and are transported to various locations along the axon, moving towards the synaptic end. Some material is also transported back, in retrograde motion. The transported materials include, for example, vesicles, membrane-bound organelles, and neurofilaments. Motor proteins attached to a vesicle (or a neurofilament) carry this cargo as they pace along a microtubule, step by step, energized by adenosine triphosphate (ATP) molecules. While some of the motors may be moving along a microtubule, others may be "resting" on-track, or even off-track, for a while. Thus the model has to deal with several populations of vesicles, depending in what state of motion they are. Earlier models of axonal transport were developed by Reed and Blum [10, 1, 2]. Using mass reaction laws and conservation of mass, they derived a system of hyperbolic equations and studied (mostly numerically) the particle concentration profile along the axon. The numerical results show that the transport of the particle concentrations has the profile of "approximate traveling waves"; experimentally, they arise from radiolabeling proteins in the soma and then observing the progress of the wave of label as it goes down the axon. The wave goes at constant velocity, but the front spreads so it is only approximately a traveling wave. Reed, Venakides, and Blum [11] considered a mathematical problem derived from such a transport model, in the biologically relevant case when the transition between the various populations is fast relative to the transport. Recent experimental results and computational models [4, 6, 8, 12, 13] also describe the dynamics of such transport.

Consider, for example, two populations p and q, with transition rates

$$p \underset{k_2}{\overset{k_1}{\rightleftharpoons}} q,$$

where q is moving and p is resting. Then the corresponding reaction-hyperbolic system describing their transport is given by

$$\begin{aligned} \varepsilon p_t &= -k_1 p + k_2 q, \\ \varepsilon\,(q_t + v_2 q_x) &= k_1 p - k_2 q, \end{aligned} \tag{1.1}$$

where ε is a small positive constant. The general transport problem for n species may be written in the form

$$\varepsilon\,(\partial_t + v_i \partial_x)\, p_i = \sum_{j=1}^{n} k_{ij} p_j \text{ for } 0 < x < \infty,\ t > 0,\ 1 \le i \le n, \tag{1.2}$$

where $k_{ij} \ge 0$ if $i \ne j$, the velocities v_i may be positive, negative, or zero, and

$$\sum_{i=1}^{n} k_{ij} = 0 \tag{1.3}$$

by conservation of mass; thus,

$$k_{jj} = -\sum_{\substack{i=1 \\ i \ne j}}^{n} k_{ij}.$$

We need to complement (1.2) with initial conditions, and with boundary conditions at $x = 0$ for each p_i for which $v_i > 0$.

The special case

$$\begin{aligned} &v_i = 0, \quad 1 \le i \le n-1, \\ &v_n > 0, \\ &p_i(x,0) = 0, \quad 1 \le i \le n,\ 0 < x < \infty \\ &p_n(0,t) = 1, \quad t > 0, \end{aligned} \tag{1.4}$$

was studied by Reed, Venakides, and Blum [11]. They derived formulas which suggest that if we write p_n in the form

$$p_n(x,t) = Q_\varepsilon\left(\frac{x - vt}{\sqrt{\varepsilon}}, t\right), \tag{1.5}$$

then

$$Q_\varepsilon(s,t) \to Q_0(s,t) \text{ as } \varepsilon \to \infty, \tag{1.6}$$

where Q_0 is a solution of the heat equation

$$\begin{aligned} &\partial_t Q_0 - \sigma^2 \partial_s^2 Q_0 = 0, \quad -\infty < s < \infty,\ t > 0, \\ &Q_0(s,0) = 1 \text{ if } s < 0, \\ &Q_0(s,0) = 0 \text{ if } s > 0; \end{aligned} \tag{1.7}$$

the parameters $v,\ \sigma^2$ are computed from the v_j and k_{ij}. Formula (1.5), together with (1.6), (1.7), shows the approximate traveling wave profile for the transport of the concentration $p_n(x,t)$. The assertion (1.5) in [11] was only formal, but Brooks [3] developed a probabilistic model which enabled her to prove (1.5), in some sense, in the special case of (1.1).

One of the aims of the present paper is to give a rigorous proof of (1.6) for the case (1.4), or more generally for the case when all $v_j \geq 0$, and

$$p_i(x,0) = \lambda_i q_0\left(\frac{x}{\sqrt{\varepsilon}}\right),\ 1 \leq i \leq n,$$
$$p_j(0,t) = \lambda_j \text{ if } v_j > 0,$$

where either $q_0 \equiv 0$ or $q_0(s)$ has compact support and $q_0(0) = 1$; here $(\lambda_1, \ldots, \lambda_n)$ is a vector with positive components and, at the same time, a generator of the null space of the matrix (k_{ij}).

The proof, given in section 3, is by PDE methods. Since, in the case $q_0 \equiv 0$, the function Q_0 is discontinuous only at the point $(0,0)$ while Q_ε is discontinuous along the half-line $x = vt,\ t \geq 0$, we don't expect the convergence in (1.6) to be in the uniform sense, at least not near the origin $(0,0)$; we shall prove the convergence in the weak L^r-sense for any $1 < r < \infty$.

In the case of (1.1) we shall prove, in section 2, in case q_0 is not identically zero, a "strong" convergence in (1.6), namely,

$$(1.8)\quad \int_{-\frac{vT}{\sqrt{\varepsilon}}}^{\infty} \left(Q_\varepsilon(s,t) - Q_0(s,t)\right)^2 ds + \int_0^T \int_{-\frac{vT}{\sqrt{\varepsilon}}}^{\infty} \left(\partial_s Q_\varepsilon(s,t) - \partial_s Q_0(s,t)\right)^2 ds dt \leq C\sqrt{\varepsilon}.$$

This estimate also holds for the case (1.2) if $n = 2$, i.e., for $v_2 > 0$ and $v_1 \geq 0$.

In [9] Pinsky considered the system (1.2) for $-\infty < x < \infty,\ t > 0$, with initial data

$$p_i(x,0) = f\left(\frac{x}{\sqrt{\varepsilon}}\right) \text{ for all } i,\ -\infty < x < \infty,$$

and proved that

$$|Q_\varepsilon(s,t) - Q_0(s,t)| \leq C\sqrt{\varepsilon},$$

where $Q_0(s,t)$ is a solution of a heat equation as in (1.7) for $-\infty < s < \infty,\ t > 0$, with $Q_0(s,0) = f(s),\ -\infty < s < \infty$. Pinsky's dynamical system is derived from a different (stochastic) model and, in particular, he assumes that $\sum_{j=1}^n k_{ij} = 0$ instead of (1.3). His proof is based on the construction of boundary layers and estimates via the Fourier transform in x; that proof does not extend to the system (1.2), (1.4), not even in the case $n = 2$.

We conclude the introduction by pointing out several open problems:

(i) Extend the strong convergence result to $n > 2$.
(ii) Extend the results of this paper to the case of forward *and* backward velocities (i.e., anterograde and retrograde transport).
(iii) Study the case where the kinetics is nonlinear.

2. The case $n = 2$. Throughout this paper we shall use the notation

$$D = \{(x,t) : \ 0 < x < \infty, \ t > 0\}.$$

Consider the process $p \underset{k_2}{\overset{k_1}{\rightleftharpoons}} q$, where k_1, k_2 are positive constants, with dynamics

$$\varepsilon(p_t + v_1 p_x) = -k_1 p + k_2 q, \tag{2.1}$$

$$\varepsilon(q_t + v_2 q_x) = k_1 p - k_2 q \tag{2.2}$$

in D, where v_1, v_2 are given constant velocities, and ε is a small positive number. We intend to prove that, as $\varepsilon \to 0$, $q(x,t)$ will behave like $Q(\frac{x-vt}{\sqrt{\varepsilon}}, t)$, where $Q(s,t)$ is a solution of a parabolic equation. Such a result requires, of course, that the initial values for q should be of the form $q_0(\frac{x}{\sqrt{\varepsilon}})$. We also choose initial data which are in equilibrium with respect to the process $p \underset{k_2}{\overset{k_1}{\rightleftharpoons}} q$. Thus, we assume that

$$p(x,0) = \frac{k_1}{k_2} q_0\left(\frac{x}{\sqrt{\varepsilon}}\right), \ q(x,0) = q_0\left(\frac{x}{\sqrt{\varepsilon}}\right) \text{ for } 0 \le x < \infty. \tag{2.3}$$

We further assume that $v_1 \ge 0, \ v_2 > 0, v_1 \ne v_2$ and prescribe the boundary condition

$$q(0,t) = 1 \text{ for } t > 0. \tag{2.4}$$

If $v_1 = 0$, then no boundary conditions are imposed on p; however, if $v_1 > 0$, then we prescribe the boundary condition $p(0,t) = \frac{k_2}{k_1}$ for $t > 0$.

We shall require that $q_0(s)$ is in C^4 $(0 \le s < \infty)$ and that

$$\begin{aligned} &0 \le q_0(s) \le 1 \text{ if } s > 0, \ q_0(s) = 0 \text{ if } s > A_0 \text{ for some } A_0 < \infty, \\ &q_0(0) = 1, \ \partial_s^j q_0(s)|_{s=0} = 0 \text{ if } 1 \le j \le 4. \end{aligned} \tag{2.5}$$

The last two conditions ensure that the initial and boundary data fit at $(0,0)$ up to order 4. Note that (2.5) implies that $0 \le q_0(s) \le 1$.

It will be convenient to first deal with the case

$$v_1 = 0. \tag{2.6}$$

However, in order not to repeat some of the calculations, we shall perform these calculations for general v_1.

By standard ODE arguments we deduce that the solution (p,q) is continuously differentiable in $\bar{D}$, that $(\partial_x p, \partial_x q)$ satisfy the same system as (p,q), and that

$$k_1 \partial_x p(x,0) = k_2 \partial_x q(x,0) = k_2 \partial_x q_0\left(\frac{x}{\sqrt{\varepsilon}}\right), \ 0 < x < \infty;$$

furthermore, if $v_1 = 0$, then

$$\varepsilon v_2 \partial_x q(0,t) = k_1 p(0,t) - k_2 q(0,t) \to 0 \text{ if } t \to 0.$$

Since $\partial_x q(x,0) \to 0$ as $x \to 0$, the initial-boundary data are continuous at $(0,0)$. It follows, as before, that the second order derivatives of p, q are continuous in $\bar{D}$, and similarly one can prove that also the third order derivatives of p, q are continuous in $\bar{D}$.

LEMMA 2.1 (maximum principle). *The following inequalities hold:*

$$0 \le p \le \frac{k_2}{k_1},\ 0 \le q \le 1.$$

Proof. Let us first consider the system (2.1)–(2.4) in $D_L = D \cap \{x < L\}$, for $0 < L < \infty$. We modify (2.1), (2.2) by subtracting a small positive number μ from the right-hand sides, and we denote the corresponding solution by (p_μ, q_μ). We claim that

$$p_\mu < \frac{k_2}{k_1}(1+\mu),\ q_\mu < 1+\mu. \tag{2.7}$$

Indeed, if this is not true, then consider a point (x_0, t_0) with the smallest t_0 for which equality occurs in (2.7) either for p_μ or for q_μ. Suppose, for definiteness, that $q_\mu(x_0, t_0) = 1+\mu$. Because of the boundary and initial conditions, $x_0 \neq 0$ and $t_0 \neq 0$. At (x_0, t_0) we have

$$\varepsilon(\partial_t + v_2\partial_x)q_\mu = k_1 p_\mu - k_2 q_\mu - \mu \le -\mu < 0.$$

Thus, there would be an earlier time at which $q_\mu \ge 1+\mu$, which is a contradiction. Taking $\mu \to 0$ and then $L \to \infty$ we obtain the inequalities $p \le \frac{k_2}{k_1},\ q \le 1$. Similarly one can prove, by taking $\mu < 0$, that $p \ge 0,\ q \ge 0$. ∎

We now proceed to derive the asymptotic behavior for $q(x,t)$ as $\varepsilon \to 0$. We begin by deriving a second order PDE for q. From (2.1), (2.2) we obtain

$$\varepsilon(\partial_t + v_1\partial_x)(\partial_t + v_2\partial_x)q + (k_1+k_2)\partial_t q - (k_1 v_2 + k_2 v_1)\partial_x q = 0. \tag{2.8}$$

Introduce a change of variables

$$s = \frac{x - vt}{\sqrt{\varepsilon}},\ Q_\varepsilon(s,t) = q(x,t),$$

where v will be determined later on. The domain D is transformed into the domain

$$\Omega = \left\{(s,t) : -\frac{vt}{\sqrt{\varepsilon}} < s < \infty,\ t > 0\right\}.$$

Later on we shall use the notation

$$\begin{aligned}
&\Omega_T = \Omega \cap \{t < T\},\\
&\Gamma_T \equiv \Gamma_{T,\varepsilon} = \left\{(s,t) : s = -\frac{vt}{\sqrt{\varepsilon}}, 0 < t < T\right\},\ \text{where } 0 < T \le \infty,\\
&L_0 = \{(s,0) : 0 < s < \infty\},\\
&s_t \equiv s_{t,\varepsilon} = -\frac{vt}{\sqrt{\varepsilon}}.
\end{aligned}$$

Note that

$$\begin{aligned}
&\partial_t q = \partial_t Q_\varepsilon - \frac{v}{\sqrt{\varepsilon}}\partial_s Q_\varepsilon,\ \partial_x q = \frac{1}{\sqrt{\varepsilon}}\partial_s Q_\varepsilon,\ \text{and}\\
&\partial_t Q_\varepsilon = \partial_t q + v\partial_x q,\ \partial_s Q_\varepsilon = \sqrt{\varepsilon}\partial_x q.
\end{aligned} \tag{2.9}$$

It is easily seen that if we choose

$$v = \frac{k_1 v_2 + k_2 v_1}{k}, \text{ where } k = k_1 + k_2, \tag{2.10}$$

then we obtain the following equation for Q_ε:

$$\partial_t Q_\varepsilon - \sigma^2 \partial_s^2 Q_\varepsilon + \partial_{ts} K\sqrt{\varepsilon} Q_\varepsilon + \frac{\varepsilon}{k}\partial_t^2 Q_\varepsilon = 0 \text{ in } \Omega, \tag{2.11}$$

where

$$\sigma^2 = \frac{k_1 k_2}{k^3}(v_2 - v_1)^2, \; K = \frac{k_2 - k_1}{k^2}(v_2 - v_1). \tag{2.12}$$

Continuing with the assumption (2.6), we also have

$$Q_\varepsilon(s,0) = q_0(s), \; s > 0, \tag{2.13}$$

and, by (2.2), (2.3), (2.9), and (2.10),

$$\partial_t Q_\varepsilon(s,0) = -\frac{k_2(v_2 - v_1)}{k}\frac{1}{\sqrt{\varepsilon}}\partial_s q_0(s), \; s > 0. \tag{2.14}$$

Since $q(0,t) = 1$ the function $p(0,t) \equiv k_2/k_1$ is the solution of (2.1) at $x = 0$, so that also

$$\varepsilon \partial_x q(0,t) = \frac{\varepsilon}{v_2}(\partial_t q + v_2 \partial_x q) = \frac{1}{v_2}(k_1 p - k_2 q) = 0 \text{ at } (0,t).$$

Hence

$$Q_\varepsilon = 1, \partial_s Q_\varepsilon = \partial_t Q_\varepsilon = 0 \text{ on } \Gamma_T \text{ for any } T > 0. \tag{2.15}$$

If W, ϕ are bounded continuously differentiable functions in $\bar{\Omega}_T$, $T < \infty$, and $\phi(s,T) \equiv 0$, then, by integration by parts,

$$\iint_{\Omega_T} \partial_t W \cdot \phi ds dt = -\int_{\Gamma_T \cup L_0} W\phi ds - \iint_{\Omega_T} W \cdot \partial_t \phi ds dt,$$

where in the integrals along Γ_T and L_0 the variable s is increasing from left to right. Similarly, if $\phi(s,t)$ or $W(s,t)$ converges to zero as $s \to \infty$, $0 < t < T$, then

$$\iint_{\Omega_T} \partial_s W \cdot \phi ds dt = -\int_{\Gamma_T} W\phi dt - \iint_{\Omega_T} W \cdot \partial_s \phi ds dt,$$

where in the integral along Γ_T the variable t is increasing from $t = 0$ to $t = T$. With the above understanding of the integrals along Γ_T, we have

$$\int_{\Gamma_T} W\phi dt = \int_{\Gamma_T} \frac{\sqrt{\varepsilon}}{v} W\phi ds. \tag{2.16}$$

Let $\tilde{Q}_\varepsilon$ denote the unique bounded solution of the parabolic equation

$$\partial_t \tilde{Q}_\varepsilon - \sigma^2 \partial_s^2 \tilde{Q}_\varepsilon = 0 \text{ in } \Omega, \tag{2.17}$$

with the initial and boundary conditions

$$\tilde{Q}_\varepsilon(s,0) = q_0(s) \text{ on } L_0, \qquad \tilde{Q}_\varepsilon \equiv 1 \text{ on } \Gamma_\infty. \tag{2.18}$$

Recalling that $\partial^j q_0(s) = 0$ at $s = 0$ for $1 \le j \le 4$, one can easily verify that $\tilde{Q}_\varepsilon$ satisfies the consistency conditions of order 2 at $(s,t) = (0,0)$. Hence all the derivatives

$$\partial_t^k \partial_s^l \tilde{Q}_\varepsilon \quad (0 \le 2k + l \le 4) \quad \text{are continuous at } (0,0). \tag{2.19}$$

In the next two lemmas we prove that these functions are uniformly bounded in Ω, and that they converge uniformly to zero as $s \to \infty$, the uniformity being with respect to ε.

LEMMA 2.2. *The following inequalities hold:*

$$|\partial_t^k \partial_s^l \tilde{Q}_\varepsilon(s,t)| \le C \text{ in } \Omega \quad (0 \le 2k + l \le 4), \tag{2.20}$$

where C is a constant independent of ε.

Proof. Consider the function

$$U(x,t) = \tilde{Q}_\varepsilon(s,t), \text{ where } s = \frac{x - vt}{\sqrt{\varepsilon}}.$$

Since $\partial_t \tilde{Q}_\varepsilon = \partial_t U + v \partial_x U$, there holds

$$\partial_t U = \alpha \varepsilon \partial_x^2 U - \beta \partial_x U \text{ in } D, \tag{2.21}$$

where α, β are positive numbers depending only on k_i, v_i, and

$$U(x,0) = q_0\left(\frac{x}{\sqrt{\varepsilon}}\right), \quad x > 0, \tag{2.22}$$

$$U(0,t) = 1, \quad t > 0. \tag{2.23}$$

The function $V = \partial_x U$ satisfies the heat equation (2.21) and, since $\partial_t U(0,t) = 0$,

$$\partial_x V - \frac{\gamma}{\varepsilon} V = 0 \text{ at } x = 0,\ t > 0, \quad \text{where } \gamma = \frac{\beta}{\alpha}.$$

Hence V cannot take positive maximum or negative minimum at $(0,t),\ t > 0$. By the maximum principle we then deduce that

$$|\partial_x U| \le \frac{1}{\sqrt{\varepsilon}} \sup_{x>0} \left| q_0'\left(\frac{x}{\sqrt{\varepsilon}}\right)\right| \le \frac{C}{\sqrt{\varepsilon}}$$

on the set $\{(x,t) :\ x > 0,\ t > 0\}$.

We proceed to apply the above argument to the function $V_1 = \partial_t \partial_x U$, which is again a solution of the heat equation (2.21), with

$$\partial_x V_1 - \frac{\gamma}{\varepsilon} V_1 = \frac{1}{\alpha\varepsilon} \partial_t^2 U = 0 \text{ at } x = 0,\ t > 0.$$

By the maximum principle we then get

$$\begin{aligned} |\partial_x V_1|_{L^\infty(\mathbb{R}_2^+)} &\le \sup_{x>0} |V_1(x,0)| \\ &= \sup_{x>0} \left| \alpha\varepsilon \partial_x^3 q_0\left(\frac{x}{\sqrt{\varepsilon}}\right) - \beta \partial_x^2 q_0\left(\frac{x}{\sqrt{\varepsilon}}\right)\right| \\ &\le \frac{C}{\varepsilon}. \end{aligned}$$

Hence

$$\left|\partial_x(\partial_x^2 U) - \frac{\gamma}{\varepsilon}(\partial_x^2 U)\right| = \frac{|V_1|}{\alpha\varepsilon} \le \frac{C}{\varepsilon^2}.$$

Multiplying by $e^{-\gamma x/\varepsilon}$ and integrating in x over (x,∞) we get

$$|e^{-\gamma x/\varepsilon}\partial_x^2 U(x,t)| \le \frac{C}{\varepsilon}e^{-\gamma x/\varepsilon}.$$

Hence

$$|\partial_x^2 U(x,t)|_{L^\infty(\mathbb{R}_2^+)} \le \frac{C}{\varepsilon}.$$

Similarly, working with the function $V_2 = \partial_t^2 \partial_x U$, we deduce, by the maximum principle, that

$$|V_2|_{L^\infty(\mathbb{R}_2^+)} \le \frac{C}{\varepsilon^{3/2}}.$$

Hence

$$\left|\partial_x(\partial_t\partial_x^2 U) - \frac{\gamma}{\varepsilon}(\partial_t\partial_x^2 U)\right| \le \frac{C}{\varepsilon^{5/2}}.$$

As before, we deduce by integration that

$$|\partial_t\partial_x^2 U(x,t)|_{L^\infty(\mathbb{R}_2^+)} \le \frac{C}{\varepsilon^{3/2}}.$$

This implies, by (2.21), that

$$\left|\partial_x(\partial_x^3 U) - \frac{\gamma}{\varepsilon}(\partial_x^3 U)\right| \le \frac{C}{\varepsilon^{5/2}}.$$

and, by integration, as before,

$$|\partial_x^3 U(x,t)|_{L^\infty(\mathbb{R}_2^+)} \le \frac{C}{\varepsilon^{3/2}}.$$

Similarly we can estimate $\partial_x^4 U$ by working with the function $V_3 = \partial_t^3 \partial_x U$. We conclude that

$$|\partial_x^j U(x,t)|_{L^\infty(\mathbb{R}_2^+)} \le \frac{C}{\varepsilon^{j/2}} \quad \text{for } j = 0,1,2,3,4.$$

It follows that

$$|\partial_s^j \tilde{Q}_\varepsilon(s,t)| \le C \text{ in } \Omega.$$

The remaining inequalities in (2.20) follow from the differential equation (2.17). ∎

LEMMA 2.3. *For any $0 < T < \infty$, the following inequalities hold for some $\gamma > 0$:*

$$|\partial_t^k \partial_s^l \tilde{Q}_\varepsilon(s,t)| \le Ce^{-\gamma s^2} \text{ in } \Omega_T \cap \{s > 0\} \quad (0 \le 2k + l \le 4), \tag{2.24}$$

where C is a constant independent of ε.

Proof. Recall that $\tilde{Q}_\varepsilon(s,0) = 0$ if $s > A_0$, so that also $\partial_s^l \tilde{Q}_\varepsilon(s,0) = 0$ if $s > A_0$. We can then compare $\partial_s^l \tilde{Q}_\varepsilon$ with a solution of (2.17) of the form

$$\frac{C}{\sqrt{t}} e^{-\delta s^2/t} \text{ in } G \equiv \{s > A_0,\ t > 0\} \left(\text{where } \delta = \frac{1}{4\sigma^2}\right).$$

The difference

$$V = \frac{C}{\sqrt{t}} e^{-\delta s^2/t} - \partial_s^l \tilde{Q}_\varepsilon(s,t)$$

is a bounded solution of (2.17) in G, with $V(s,0) = 0$ if $s > A_0$ and $V(A_0,t) > 0$ (< 0) if C is positive and large (negative and large in absolute value). By the maximum principle for parabolic equations in an unbounded domain (see, e.g., [7, Chap. 2, Thm. 9]), we conclude that $V > 0$ $(V < 0)$ in G in the case where C was positive (negative), so that the inequality (2.24) with $k = 0$ follows. The remaining estimates follow from (2.17). □

Consider the function

$$W = Q_\varepsilon - \tilde{Q}_\varepsilon \text{ in } \Omega_T,\ 0 < T < \infty.$$

It satisfies the equation

$$\partial_t W - \sigma^2 \partial_s^2 W + K\sqrt{\varepsilon}\partial_{ts}^2 W + \frac{\varepsilon}{k}\partial_s^2 W = F_\varepsilon, \tag{2.25}$$

where

$$F_\varepsilon = -K\sqrt{\varepsilon}\partial_{ts}^2 \tilde{Q}_\varepsilon - \frac{\varepsilon}{k}\partial_t^2 \tilde{Q}_\varepsilon. \tag{2.26}$$

Clearly

$$W \equiv 0 \text{ on } L_0 \cup \Gamma_T \tag{2.27}$$

and, by (2.9), (2.15),

$$\partial_t W = -\partial_t \tilde{Q}_\varepsilon,\ \partial_s W = -\partial_s \tilde{Q}_\varepsilon = -\frac{\sqrt{\varepsilon}}{v}\partial_t \tilde{Q}_\varepsilon \text{ on } \Gamma_T. \tag{2.28}$$

Also, by (2.14),

$$\partial_t Q_\varepsilon = \partial_t q + v\partial_x q = \frac{v - v_2}{\sqrt{\varepsilon}} q_0'(s) \text{ on } L_0,$$

so that

$$\partial_t W = -\frac{k_2(v_2 - v_1)}{k\sqrt{\varepsilon}} q_0'(s) \text{ on } L_0. \tag{2.29}$$

From Lemmas 2.2 and 2.3 we deduce that

$$\iint_{\Omega_T} F_\varepsilon^2 \le \iint_{\Omega_T \cap \{s<0\}} C_0\varepsilon + \iint_{\Omega_T \cap \{s>0\}} C_0\varepsilon e^{-2\gamma s^2} \le C\sqrt{\varepsilon},$$

where C_0, C are constants (independent of ε). Hence, for any function $Z \in L^2(\Omega_T)$ and any small $\eta > 0$,

$$\left|\iint_{\Omega_T} F_\varepsilon Z\right| \le \eta \iint_{\Omega_T} Z^2 + C\sqrt{\varepsilon}, \tag{2.30}$$

where C is a constant which depends on η and T.

LEMMA 2.4. *For any $0 < T < \infty$, there exists a constant $C = C(T)$ such that*

$$\iint_{\Omega_T} W_t^2 ds dt + \sup_{0\le t\le T} \int_{s_t}^{\infty} W_s^2(s,t) ds \le C, \tag{2.31}$$

$$\iint_{\Omega_T} (W^2 + W_s^2) ds dt \le C\sqrt{\varepsilon}. \tag{2.32}$$

Proof. If we multiply (2.25) by W_t and integrate over Ω_T, we get

$$\iint_{\Omega_T} W_t^2 - \sigma^2 \iint_{\Omega_T} W_t W_{ss} + K\sqrt{\varepsilon} \iint_{\Omega_T} W_t W_{ts} + \frac{\varepsilon}{k} \iint_{\Omega_T} W_t W_{tt} = -\iint_{\Omega_T} W_t F_\varepsilon. \tag{2.33}$$

We proceed to evaluate terms on the left-hand side of (2.33). By integration by parts we obtain

$$\begin{aligned} -\iint_{\Omega_T} W_t W_{ss} &= -\iint_{\Omega_T} [\partial_s(W_t W_s) - W_{ts} W_s] \\ &= \int_{\Gamma_T} W_t W_s dt + \frac{1}{2}\int_{s_T}^{\infty} W_s^2(s,T) ds - \frac{1}{2}\int_{L_0\cup\Gamma_T} W_s^2 ds, \end{aligned}$$

and, by (2.28),

$$\int_{\Gamma_T} W_t W_s dt = \frac{\sqrt{\varepsilon}}{v} \int_{\Gamma_T} \tilde{Q}_{\varepsilon,t}^2 dt$$

and

$$\int_{L_0\cup\Gamma_T} W_s^2 ds = \int_{\Gamma_T} W_s^2 ds = \int_{\Gamma_T} \tilde{Q}_{\varepsilon,s}^2 ds = \frac{\sqrt{\varepsilon}}{v} \int_{\Gamma_T} \tilde{Q}_{\varepsilon,t}^2 dt,$$

where in the last equation we used also (2.16). Hence,

$$-\sigma^2 \iint_{\Omega_T} W_t W_{ss} = \frac{1}{2}\sigma^2 \int_{s_T}^{\infty} W_s^2(s,T) ds - \frac{1}{2}\sigma^2 \frac{\sqrt{\varepsilon}}{v} \int_{\Gamma_T} \tilde{Q}_{\varepsilon,t}^2 dt. \tag{2.34}$$

Next,

$$\begin{aligned} K\sqrt{\varepsilon} \iint_{\Omega_T} W_t W_{ts} &= \frac{1}{2} K\sqrt{\varepsilon} \iint_{\Omega_T} \partial_s(W_t^2) \\ &= -\frac{1}{2} K\sqrt{\varepsilon} \int_{\Gamma_T} W_t^2 dt = -\frac{1}{2} K\sqrt{\varepsilon} \int_{\Gamma_T} \tilde{Q}_{\varepsilon,t}^2 dt. \end{aligned} \tag{2.35}$$

Consider finally

$$\varepsilon \iint_{\Omega_T} W_t W_{tt} = \frac{\varepsilon}{2} \int_{s_T}^{\infty} W_t^2(s,T) ds - \frac{\varepsilon}{2} \int_{L_0\cup\Gamma_T} W_t^2 ds.$$

Since

$$-\frac{\varepsilon}{2} \int_{\Gamma_T} W_t^2 ds = -\frac{\varepsilon}{2} \int_{\Gamma_T} \tilde{Q}_{\varepsilon,t}^2 ds = -\frac{\sqrt{\varepsilon}}{2v} \int_{\Gamma_T} \tilde{Q}_{\varepsilon,t}^2 dt,$$

and

$$-\frac{\varepsilon}{2}\int_{L_0} W_t^2 ds = \mathcal{O}(1)$$

by (2.29) and the fact that (by (2.17), (2.18)) $\tilde{Q}_{\varepsilon,t} = 0$ on $L_0 \cap \{s > A_0\}$, we obtain

$$\varepsilon \iint_{\Omega_T} W_t W_{tt} = \frac{\varepsilon}{2}\int_{s_T}^{\infty} W_t^2(s,T)ds - \frac{\sqrt{\varepsilon}}{2v}\int_{\Gamma_T} \tilde{Q}_{\varepsilon,t}^2 dt + \mathcal{O}(1). \tag{2.36}$$

Substituting (2.34)–(2.36) into (2.33) and using also (2.30) with $Z = W_t$, $\eta = \frac{1}{2}$, and the inequality $|\tilde{Q}_{\varepsilon,t}| < C$ on Γ_T, we obtain

$$\iint_{\Omega_T} W_t^2 + \frac{1}{2}\sigma^2\int_{s_T}^{\infty} W_s^2(s,T)ds + \frac{\varepsilon}{k}\int_{s_T}^{\infty} W_t^2(s,T)ds \le C\sqrt{\varepsilon}\int_{\Gamma_T} dt + \mathcal{O}(1).$$

This implies $\iint_{\Omega_T} W_t^2 < C_1(T)$, and $\int_{s_t}^{\infty} W_s^2(s,t)ds < C_2(t)$ for $t \in [0,T]$ and some continuous function C_2, and (2.31) follows, with $C(T) = C_1(T) + \sup_{0\le t\le T} C_2(t)$.

To prove (2.32) we multiply (2.25) by W and integrate over Ω_T. By integration by parts we obtain

$$\begin{aligned}\frac{1}{2}\int_{s_T}^{\infty} W^2(s,T)ds + \sigma^2\iint_{\Omega_T} W_s^2 - K\sqrt{\varepsilon}\iint_{\Omega_T} W_s W_t \\ + \frac{\varepsilon}{k}\int_{s_T}^{\infty}(WW_t)(s,T)ds - \frac{\varepsilon}{k}\iint_{\Omega_T} W_t^2 = \iint_{\Omega_T} WF_\varepsilon.\end{aligned} \tag{2.37}$$

By Lemma 2.3 and (2.31),

$$\left|K\sqrt{\varepsilon}\iint_{\Omega_T} W_s W_t\right| \le \frac{1}{2}\sigma^2\iint_{\Omega_T} W_s^2 + \frac{K^2\varepsilon}{2\sigma^2}\iint_{\Omega_T} W_t^2 \le \frac{1}{2}\sigma^2\iint_{\Omega_T} W_s^2 + C\varepsilon.$$

Also, by (2.30),

$$\left|\iint_{\Omega_T} WF_\varepsilon\right| \le \eta\iint_{\Omega_T} W^2 + C\sqrt{\varepsilon}, \quad C = C(\eta).$$

Hence

$$\begin{aligned}\frac{1}{2}\int_{s_T}^{\infty} W^2(s,T)ds + \frac{1}{2}\sigma^2\iint_{\Omega_T} W_s^2 + \frac{\varepsilon}{2k}\int_{s_T}^{\infty}(W^2)_t(s,T)ds \\ \le \eta\iint_{\Omega_T} W^2 + C\sqrt{\varepsilon}.\end{aligned} \tag{2.38}$$

Integrating both sides with respect to T, $0 < T < T_0$, and choosing $\eta = \frac{1}{4T_0}$, we obtain

$$\iint_{\Omega_{T_0}} W^2 + \int_0^{T_0}\left(\iint_{\Omega_T} W_s^2\right)dT + \varepsilon\int_{s_{T_0}}^{\infty} W^2(s,T_0)ds \le C\sqrt{\varepsilon}, \tag{2.39}$$

where C depends on T_0. Finally, if we use the inequality

$$\int_0^{T_0}\left(\int_0^T f(t)dt\right)dT = \int_0^{T_0}(T_0 - t)f(t)dt \ge \delta_0\int_0^{T_0-\delta_0} f(t)dt$$

with $f(t) = \int_{s_t}^{\infty} W_s^2(s,t)ds$ in (2.39), we obtain the estimate (2.32). ∎

We extend the function $\tilde{Q}_\varepsilon(s,t)$ by 1 into the domain $\{s < -vt/\sqrt{\varepsilon},\ t > 0\}$, and wish to estimate $\tilde{Q}_\varepsilon - Q_0$, where Q_0 is the bounded solution of

$$\partial_t Q_0 - \sigma^2 \partial_s^2 Q_0 = 0 \text{ in } \mathbb{R}^2_+, \tag{2.40}$$

$$Q_0(s,0) = q_0(s) \text{ if } s > 0, \quad Q_0(s,0) = 1 \text{ if } s < 0. \tag{2.41}$$

LEMMA 2.5. *The following inequality holds:*

$$\int_{-\infty}^{\infty} (\tilde{Q}_\varepsilon - Q_0)^2(s,T)ds + \int_0^T \int_{-\infty}^{\infty} (\partial_s \tilde{Q}_\varepsilon - \partial_s Q_0)^2 ds dt \le C\sqrt{\varepsilon}, \tag{2.42}$$

where $0<T<\infty$ and C is a constant independent of T and ε.

Proof. We first estimate $\tilde{Q}_\varepsilon - Q_0$ on Γ_T. For this purpose we represent the function $V \equiv 1 - Q_0$ in the form

$$V(s,t) = \int_0^{\infty} \frac{e^{-\frac{(s-\zeta)^2}{4\sigma^2 t}}}{\sigma\sqrt{4\pi t}} \phi(\zeta) d\zeta,\ \ \phi(\zeta) = 1 - q_0(\zeta)$$

and compute

$$V\left(-\frac{vt}{\sqrt{\varepsilon}}, t\right) = \int_0^{\infty} \frac{e^{-(-\frac{vt}{\sqrt{\varepsilon}} - \zeta)^2/(4\sigma^2 t)}}{\sigma\sqrt{4\pi t}} \phi(\zeta) d\zeta.$$

Substituting

$$\xi = \left(\frac{vt}{\sqrt{\varepsilon}} + \zeta\right) \frac{1}{\sqrt{t}}$$

we obtain

$$\left| V\left(-\frac{vt}{\sqrt{\varepsilon}}, t\right) \right| \le C \int_{v\sqrt{t/\varepsilon}} e^{-\frac{\xi^2}{4\sigma^2}} d\xi \le C e^{-\frac{\alpha t}{\varepsilon}} \quad (\text{for some } \alpha > 0).$$

Similarly we obtain

$$\left| \partial_s V\left(-\frac{vt}{\sqrt{\varepsilon}}, t\right) \right| \le (C/\sqrt{t}) e^{-\frac{\alpha t}{\varepsilon}}.$$

Consider the function $R = \tilde{Q}_\varepsilon - Q_0\varepsilon$. It satisfies the equation

$$\partial_t R - \sigma^2 \partial_s^2 R = 0 \text{ in } \Omega_T, \tag{2.43}$$

and, by the last two estimates,

$$|R|_{\Gamma_T} \le C e^{-\frac{\alpha t}{\varepsilon}}, \quad |\partial_s R|_{\Gamma_T} \le \frac{C}{\sqrt{t}} e^{-\frac{\alpha t}{\varepsilon}}. \tag{2.44}$$

If we multiply (2.43) by R and integrate over Ω_T, we obtain, after integration by parts,

$$\frac{1}{2}\int_{s_T}^{\infty} R^2(s,T)ds - \sigma^2 \iint_{\Omega_T} (\partial_s R)^2 = \frac{1}{2}\int_{\Gamma_T} R^2 ds - \sigma^2 \int_{\Gamma_T} R \cdot \partial_s R dt.$$

Using (2.44) we find that each of the two integrals on the right-hand side is bounded by $C\sqrt{\varepsilon}$, and thus we derive the estimate (2.42). ∎

Combining the estimates (2.32), (2.42) we obtain the following theorem.

THEOREM 2.6. *Consider the system* (2.1)–(2.4) *under the assumptions* (2.5) *and* (2.6). *Then we can write* q *in the form*

$$q(x,t) = Q_\varepsilon\left(\frac{x-vt}{\sqrt{\varepsilon}}, t\right), \tag{2.45}$$

where $Q_\varepsilon(s,t)$ *(extended by* 1 *for* $s < -vt/\sqrt{\varepsilon}$*) converges to the solution* $Q_0(s,t)$ *of* (2.40), (2.41) *as* $\varepsilon \to 0$ *in the following sense:*

$$\sup_{0\le t\le T}\int_{-\infty}^{\infty}(Q_\varepsilon - Q_0)^2(s,t)ds + \int_0^T\int_{-\infty}^{\infty}(\partial_s Q_\varepsilon - \partial_s Q_0)^2 dsdt \le C\sqrt{\varepsilon} \tag{2.46}$$

for any $0 < T < \infty$, *where* C *is a constant which may depend on* T.

Remark 2.1. The proof of Theorem 2.6 extends to the case where the first two conditions on $q_0(s)$ are replaced by the weaker condition that $\partial_s^j q_0(s)$ are continuous functions for $s \ge 0$ and they belong to $L^2(\mathbb{R})$ for $0 \le j \le 4$.

Remark 2.2. Theorem 2.6 extends, with essentially the same proof, to the case where $v_1 > 0$, provided $v_1 \ne v_2$ and we prescribe the boundary condition $p(x,t) \equiv \frac{k_2}{k_1}$ at $x = 0$.

Remark 2.3. Consider the case where $q_0 \equiv 0$, and take for simplicity $v_1 = 0$. Then the initial and boundary data form a function which is discontinuous at $(0,0)$, so that the proof of Theorem 2.6 cannot be extended to this case. If we introduce an approximating system by changing the initial data,

$$q(x,0) = q_{0\delta}\left(\frac{x}{\sqrt{\varepsilon}}\right), \quad q_{0\delta}(0) = 1,\ q'_{0\delta} \le 0,\ q_{0\delta}(s) = 0 \text{ if } s \ge \delta, \tag{2.47}$$

then for the corresponding solution (p_δ, q_δ) we have the following result.

THEOREM 2.7. *The following inequality holds:*

$$\sup_{T>0}\int_0^\infty [(p_\delta(x,T) - p(x,T))^2 + (q_\delta(x,T) - q(x,T))^2]dx \le C\delta, \tag{2.48}$$

where C *is a constant independent of the function* $q_{0\delta}$.

Proof. Set $\tilde{p} = p_\delta - p,\ \tilde{q} = q_\delta - q$. Then

$$\partial_t\tilde{p} = -k_1\tilde{p} + k_2\tilde{q},\ (\partial_t + v_1\partial_x)\tilde{q} = k_1\tilde{p} - k_2\tilde{q}.$$

Multiplying the first equation by $k_2\tilde{p}$ and the second equation by $k_1\tilde{q}$ and adding, we obtain the inequality

$$k_2\partial_t\tilde{p}^2 + k_1((\partial_t + v_1\partial_x)\tilde{q})^2 \le 0.$$

Integrating over $0 < x < \infty,\ 0 < t < T$, the inequality (2.48) easily follows. ∎

Theorem 2.7 combined with Theorem 2.6 suggests that, if $q_0(s) \equiv 0$, then $q(x,t) - Q_0(\frac{x-vt}{\sqrt{\varepsilon}}, t)$ converges to zero in some sense when Q_0 is the solution of (2.40), (2.41) with $q_0(s) \equiv 0$. This situation will be considered, for more general dynamical systems, in section 3.

3. The case $n > 2$. Let $K = (k_{ij})$ be an $n \times n$ matrix satisfying the following conditions:

$$k_{ij} \geq 0 \text{ if } i \neq j. \tag{3.1}$$

$$\sum_{i=1}^{n} k_{ij} = 0 \left(\text{so that } k_{jj} = -\sum_{\substack{i=1 \\ i\neq j}}^{n} k_{ij}\right). \tag{3.2}$$

$$\text{For any indices } i_0 \neq i_1 \text{ there are } j_1, j_2, \dots, j_m \text{ such that} \\ j_1 = i_0,\ j_m = i_1, \text{ and } k_{j_l j_{l+1}} > 0 \text{ for } l = 1, \dots, m-1. \tag{3.3}$$

As proved in [11], under conditions (3.1)–(3.3), the null space of the matrix (k_{ij}) is one-dimensional, and it is generated by a vector $(\lambda_1, \dots, \lambda_n)$ with positive components. For simplicity we take $\sum_{j=1}^{n} \lambda_j = 1$. For later reference we write

$$\sum_{j=1}^{n} k_{ij}\lambda_j = 0 \text{ for } 1 \leq i \leq n. \tag{3.4}$$

In this section we consider a collection of populations undergoing transitions

$$p_i \underset{k_{ji}}{\overset{k_{ij}}{\rightleftharpoons}} p_j \text{ for } i, j = 1, \dots, n$$

with the dynamics given by (1.2), in the special case (1.4), or, more generally, for the case when $v_j \geq 0$ for all j, and

$$p_i(x,0) = \lambda_i q_0\left(\frac{x}{\sqrt{\varepsilon}}\right),\ 1 \leq i \leq n, \\ p_j(0,t) = \lambda_j \text{ if } v_j > 0. \tag{3.5}$$

Here we have the following:

$$\text{either } q_0 \equiv 0, \text{ or } q_0(s) \text{ is of class } C^n, \text{ has compact} \\ \text{support, } q_0(0) = 1, \text{ and } q_0^{(k)}(0) = 0 \text{ for all } k = 1, \dots, n. \tag{3.6}$$

THEOREM 3.1. *Let the matrix (k_{ij}) satisfy conditions* (3.1)–(3.3)*, and consider the system* (1.2) *with $v_j \geq 0$ for all $1 \leq j \leq n$, $v_n > 0$, and with the initial and boundary conditions* (3.5)*, where q_0 is a function satisfying* (3.6)*. Then, for some constants $v > 0$ and $\sigma^2 > 0$, the following holds:*

$$p_j(x,t) = Q_{\varepsilon,j}\left(\frac{x - vt}{\sqrt{\varepsilon}}, t\right) \quad (1 \leq j \leq n), \tag{3.7}$$

where, as $\varepsilon \to 0$,

$$Q_{\varepsilon,j} \to \lambda_j Q_0 \text{ weakly in } L^r(\mathbb{R}^2_+) \tag{3.8}$$

for any $1 < r < \infty$, and $Q_0(s,t)$ is the bounded solution of (2.40), (2.41).

Proof. For clarity we first prove the theorem for $j = n$, $q_0(0) = 1, q_0 \in C^n$, and set $Q_{\varepsilon,j} = Q_\varepsilon$. As in section 2 one can prove that the functions $p_j(x,t)$ belong to

$C^n(\bar{D})$. Then, by algebraic elimination, as in [5, p. 14], it follows that each of the functions p_j satisfies the equation

$$\det\left(\lambda_{ij} - \delta_{ij}\varepsilon(\partial_t + v_j\partial_x)\right) w = 0. \tag{3.9}$$

We shall henceforth use this equation for the function $p_n(x,t)$. Introducing the function Q_ε as in (3.7), the calculations in [9], [11] show that

$$\partial_t Q_\varepsilon - \sigma^2\partial_s^2 Q_\varepsilon = P(\partial_s, \partial_t)Q_\varepsilon, \tag{3.10}$$

where $v = \sum_{j=1}^n \lambda_j v_j$, $-\sigma^2 = \frac{a_{02}}{a_{10}}$, where a_{kl} are defined by $\det(k_{ij} - \gamma\delta_{ij} - \lambda(v_i - v)\delta_{ij}) = \sum_{0\le k+l\le n} a_{kl}\gamma^k\lambda^l$, and

$$P(\partial_s, \partial_t) = \sum_{l+k\le n} \beta_{lk}\varepsilon^{l+\frac{k}{2}-1}\partial_t^l\partial_s^k, \tag{3.11}$$

where the β_{lk} are constants depending only on k_{ij} and v_j.

Set $p_i(x,t) = P_i(\frac{x-vt}{\sqrt{\varepsilon}}, t)$. Then

$$\varepsilon\left(\partial_t + \frac{v}{\sqrt{\varepsilon}}\partial_s\right)P_i + \frac{v_i}{\sqrt{\varepsilon}}\partial_s P_i = \sum_{j=1}^n k_{ij}P_j. \tag{3.12}$$

LEMMA 3.2. *There holds*

$$\partial_t^l\partial_x^k p_j(0,t) = 0 \text{ for all } 0 \le k+l \le n,\ t > 0,$$

or, equivalently,

$$\partial_t^l\partial_s^k P_{j,\varepsilon}\left(\frac{-vt}{\sqrt{\varepsilon}}, t\right) = 0 \text{ for all } 0 \le k+l \le n,\ t > 0.$$

Proof. Let $A = \{i : v_i = 0\},\ B = \{i : v_i > 0\}$. We break (1.2) at $x = 0$ into two subsystems:

$$\partial_t p_i(0,t) = \sum_{j\in A} k_{ij}p_j(0,t) + \sum_{j\in B} k_{ij}p_j(0,t) \text{ for } i \in A, \tag{3.13}$$

$$\partial_t p_i(0,t) + v_i\partial_x p_i(0,t) = \sum_{j=1}^n k_{ij}p_j(0,t) \text{ for } i \in B. \tag{3.14}$$

Since $p_j(0,t) \equiv \lambda_j$ if $j \in B$, and $p_i(0,0) = \lambda_i$ if $i \in A$, using (3.4) we deduce that the unique solution of the ODE system (3.13) is $p_i(0,t) \equiv \lambda_i$ for all $i \in A$. Then $p_j(0,t) \equiv \lambda_j$ for all $j = 1, \dots, n$ and (3.14) gives

$$\partial_x p_i(0,t) = 0 \text{ for } i \in B. \tag{3.15}$$

We now apply ∂_x to (1.2) and deduce analogously to (3.13), (3.14) that

$$\partial_t\partial_x p_i(0,t) = \sum_{j\in A} k_{ij}\partial_x p_j(0,t) + \sum_{j\in B} k_{ij}\partial_x p_j(0,t) \text{ for } i \in A, \tag{3.16}$$

$$\partial_t\partial_x p_i(0,t) + v_i\partial_x\partial_x p_i(0,t) = \sum_{j=1}^n k_{ij}\partial_x p_j(0,t) \text{ for } i \in B. \tag{3.17}$$

Note that, by (3.15), we have $\sum_{j\in B} k_{ij}\partial_x p_j(0,t)=0$; also, $\partial_x p_i(0,0)=0$ for all $i\in A$. Then the unique solution of the ODE system (3.16) is $\partial_x p_i(0,0)\equiv 0$ for all $i\in A$, so that, upon recalling (3.15), $\partial_x p_i(0,0)\equiv 0$ for all $i=1,\dots,n$. By differentiating (3.15) in t we obtain $\partial_t\partial_x p_i(0,t)\equiv 0$, and using (3.17) we conclude that $\partial_x^2 p_i(0,t)\equiv 0$ for all $i\in B$.

In the same way, if we differentiate (1.2) twice in x, we can conclude that $\partial_x^2 p_j(0,t)\equiv 0$ for all $1\le j\le n$, and similarly $\partial_x^k p_j(0,t)\equiv 0$ for all $1\le k\le n$, $1\le j\le n$. This implies the statement of the lemma. ∎

LEMMA 3.3. *There holds*

$$\partial_t^l\partial_s^k P_{j,\varepsilon}(s,0)=O(\varepsilon^{\frac{1}{2}-l}) \text{ for all } l\ge 1,\ k+l\le n,\ s>0.$$

Proof. By (3.12), at $t=0$,

$$\partial_t P_m(s,0)=\frac{v-v_m}{\sqrt{\varepsilon}}\partial_s P_m(s,0)+\frac{1}{\varepsilon}\sum_{j=1}^n k_{mj}P_j(s,0)=\frac{v-v_m}{\sqrt{\varepsilon}}\lambda_m q_0'(s),$$

i.e., $\partial_t P_m(s,0)=C_1^1\varepsilon^{-\frac{1}{2}}q_0'(s)$ for some constant C_1^1. Next, applying ∂_t to (3.12), we obtain

$$\begin{aligned}\partial_t^2 P_m(s,0)&=\partial_t\left(\frac{v-v_m}{\sqrt{\varepsilon}}\partial_s P_m(s,0)+\frac{1}{\varepsilon}\sum_{j=1}^n k_{mj}P_j\right)(s,0)\\&=C_1^2\varepsilon^{-\frac{3}{2}}q_0'(s)+C_2^2\varepsilon^{-1}q_0''(s)\end{aligned}$$

for some constants C_1^2 and C_2^2. Similarly, for any $l\le n$ we obtain

$$\partial_t^l P_m(s,0)=\sum_{j=1}^l C_j^l\varepsilon^{l-\frac{j}{2}}q_0^{(j)}(s)$$

for some constants C_j^l, which implies the statement of the lemma. ∎

We return to the proof of Theorem 3.1 for p_n, in the case $q_0(0)=1, q_0\in C^n$. As in the proof of the maximum principle (Lemma 2.1) one can prove that

$$0\le p_j(x,t)\le\lambda_j. \tag{3.18}$$

We extend the function $Q_\varepsilon(s,t)$ by 1 into $\{-\infty<s<-\frac{vt}{\sqrt{\varepsilon}},t>0\}$. By (3.18) with $j=n$, any sequence $\varepsilon'\to 0$ has a subsequence $\varepsilon''\to 0$ such that $Q_{\varepsilon''}\to\bar{Q}$ in $L^r(\mathbb{R}_2^+)$ for any $0<r<\infty$, where $\mathbb{R}_2^+=\{(s,t)\in\mathbb{R}_2: t>0\}$

Take any smooth function ϕ with compact support $K\subset\mathbb{R}_2^+$. If we multiply ϕ by the left-hand side of (3.10) and perform integration by parts, we obtain

$$\iint_K\phi(\partial_t Q_\varepsilon-\sigma^2\partial_s^2 Q_\varepsilon)=\iint_K Q_\varepsilon(-\partial_t-\sigma^2\partial_s^2)\phi, \tag{3.19}$$

provided ε is sufficiently small so that K stays to the right of Γ_∞. Similarly, from the right-hand side of (3.10) we get

$$\iint_K\phi P(\partial_s,\partial_t)Q_\varepsilon=\iint_K Q_\varepsilon P^*(\partial_s,\partial_t)\phi, \tag{3.20}$$

where P^* is the adjoint of the differential operator P defined in (3.11). As $\varepsilon = \varepsilon'' \to 0$ the right-hand side of (3.20) converges to zero. Hence, by (3.10), the same is true of each of the two sides of (3.19), so that

$$\iint_K \bar{Q}(-\partial_t - \sigma^2 \partial_s^2)\phi = 0.$$

It follows that $\bar{Q}$ is a weak solution of the heat equation

$$\partial_t \bar{Q} - \sigma^2 \partial_s^2 \bar{Q} = 0 \text{ in } \mathbb{R}_2^+. \tag{3.21}$$

By regularity of weak solutions we conclude that $\bar{Q}$ is a smooth solution of (3.21).

Next let ϕ be a smooth function with compact support K in $\{(s,t) : s > 0, -1 < t < \infty\}$. If we multiply the right-hand side of (3.10) by ϕ and integrate by parts, we obtain

$$\iint_K Q_\varepsilon P^*(\partial_s, \partial_t)\phi - \int_{K \cap \{t=0\}} \phi \left(\sum_{l+k \le n} \beta_{lk} \varepsilon^{l+\frac{k}{2}-1} \partial_t^{l-1} \partial_s^k \right) Q_\varepsilon,$$

and by Lemma 3.3 the last integral converges to zero as $\varepsilon \to 0$; the first integral also converges to zero, as in the previous case. We conclude from (3.10) that

$$\iint_K \phi(\partial_t Q_\varepsilon - \sigma^2 \partial_s^2 Q_\varepsilon) \to 0 \text{ as } \varepsilon \to 0.$$

By integration by parts, the left-hand side is equal to

$$\iint_K Q_\varepsilon(-\partial_t - \sigma^2 \partial_s^2)\phi - \int_{K \cap \{t=0\}} \lambda_n q_0 \phi.$$

Hence, as $\varepsilon = \varepsilon'' \to 0$, we get

$$\iint_K \bar{Q}(-\partial_t - \sigma^2 \partial_s^2)\phi - \int_{K \cap \{t=0\}} \lambda_n q_0 \phi = 0.$$

This means that $\bar{Q}$ takes the initial data $\lambda_n q_0(s)$ in a weak sense and, by regularity results, also in the classical sense.

Finally, take a smooth function ϕ with compact support K in $\{(s,t) : s < 0, -1 < t < \infty\}$. We proceed as in the previous case, but with the function $R_\varepsilon = Q_\varepsilon - \lambda_n$. By Lemma 3.3, when integrating by parts, we do not get any boundary integrals on Γ_∞. Hence, after going to the limit with $\varepsilon = \varepsilon'' \to 0$, we find that $\bar{Q} - \lambda_n$ takes the initial value 0 on $\{(s,t) : s < 0, t = 0\}$. We have thus proved that $\bar{Q} = Q_0$, and this completes the proof of the theorem for p_n in the case $q_0(0) = 1, q_0 \in C^n$.

Consider next the case $q_0 \equiv 0$. Since the solution is not continuous, the preceding proof cannot be applied directly. Instead, we approximate the problem by introducing initial data as in Theorem 1, but with

$$q_0'(s) \le 0, \ q_0(s) \equiv 0 \text{ if } s > \delta.$$

We denote the corresponding solutions by $p_{j,\delta}$ and set $q_{\delta,\varepsilon} = p_{j,\delta}$. We introduce a function $Q_{\delta,\varepsilon}(s,t)$ by

$$q_{\delta,\varepsilon}(x,t) = Q_{\delta,\varepsilon}(s,t), \ s = \frac{x - vt}{\sqrt{\varepsilon}}.$$

Then any sequence $(\delta', \varepsilon') \to 0$ has a subsequence $(\delta'', \varepsilon'') \to 0$ such that $Q_{\delta'', \varepsilon''} \to \bar{Q}$ weakly in $L^r(\mathbb{R}^+_2)$, and, as before, $\bar{Q}$ coincides with the solution of the heat equation (1.7).

The proof of Theorem 3.1 for any p_j is the same as for p_n, since Lemmas 3.2 and 3.3 hold for any $1 \le j \le n$. □

LINEAR PROBLEMS RELATED TO ASYMPTOTIC STABILITY OF SOLITONS OF THE GENERALIZED KdV EQUATIONS*

YVAN MARTEL†

Abstract. This paper is concerned with the classification of global and uniformly localized solutions of linear problems related to the dynamics of the generalized Korteweg–de Vries equations in a neighborhood of solitons. In this context, we give a simpler and more general proof of a classification result introduced by Martel and Merle [*J. Math. Pures Appl.*, 79 (2000), pp. 339–425], [*Arch. Ration. Mech. Anal.*, 157 (2001), pp. 219–254]. We also consider the case of a nonlinear equation similar to the Korteweg–de Vries equation which was introduced by Peregrine [*J. Fluid Mechanics*, 27 (1967), pp. 815–827] and Benjamin, Bona, and Mahony [*Philos. Trans. Roy. Soc. London Ser.*, 272 (1972), pp. 47–78].

Key words. generalized KdV equations, solitons, asymptotic stability

DOI. 10.1137/050637510

1. Introduction. This paper is concerned with the classification of global and uniformly localized solutions of linear problems related to the dynamics of the generalized Korteweg–de Vries equations (gKdV equations) in a neighborhood of solitons. We also consider the case of a nonlinear dispersive equation similar to the KdV equation which was introduced by Peregrine [22] and Benjamin, Bona, and Mahony [2]; see below in this section and section 4.

It is well known that the gKdV equations

$$\partial_t \psi + \partial_x(\partial_x^2 \psi + \psi^p) = 0, \quad t, x \in \mathbb{R}, \tag{1}$$

for $p \geq 2$ integer, have explicit traveling wave solutions. Let

$$Q(x) = \left(\frac{p+1}{2\cosh^2\left(\frac{p-1}{2}x\right)} \right)^{\frac{1}{p-1}} \tag{2}$$

be the unique H^1 positive solution (up to translations) of

$$Q'' + Q^p = Q \quad \text{on } \mathbb{R}.$$

Then, for any $c > 0$, $x_0 \in \mathbb{R}$, the functions

$$R_{c,x_0}(t,x) = Q_c(x - x_0 - ct), \quad \text{where} \quad Q_c(x) = c^{\frac{1}{p-1}} Q(\sqrt{c}x),$$

are solutions of the gKdV equations (1). We call these solutions *solitons*.

Let us recall some general results concerning the solutions of (1).

First, we recall that the local Cauchy problem for (1) is well-posed in H^1 for any $p \geq 2$ integer. More precisely, Kenig, Ponce, and Vega [10] proved that for any

*Received by the editors August 4, 2005; accepted for publication (in revised form) March 8, 2006; published electronically July 31, 2006.

$\psi_0 \in H^1(\mathbb{R})$ there exists a unique (in a suitable sense) maximal H^1 solution $\psi(t)$ of (1) satisfying $\psi(0) = \psi_0$. Moreover, the following quantities are invariant for such H^1 solutions:

$$\int_{\mathbb{R}} \psi^2(t) = \int_{\mathbb{R}} \psi^2(0), \tag{3}$$

$$\int_{\mathbb{R}} \left[\frac{1}{2}(\partial_x \psi(t))^2 - \frac{1}{p+1}\psi^{p+1}(t)\right] = \int_{\mathbb{R}} \left[\frac{1}{2}(\partial_x \psi(0))^2 - \frac{1}{p+1}\psi^{p+1}(0)\right]. \tag{4}$$

It follows that if $1 < p < 5$, then H^1 solutions are globally defined and uniformly bounded in H^1.

Second, we review results on the large time dynamics of (1) in a neighborhood of the solitons $R_{c,x_0}(t,x)$. We refer to Miura [19] and Schuur [23] for results on the KdV and modified KdV equations ($p = 2$, 3) which are specific to the integrability theory and the inverse scattering transform. We recall that the stability problem in the energy space H^1 is completely solved. Note that by the scaling and translation invariances of the equation, it is enough to study the stability of the solution $R(t,x) = Q(x-t)$. The following results are well known:

• For $1 < p < 5$, the solitons are stable in H^1, which means that the following result holds.

Stability of solitons (see [26]). *Let $p = 2$, 3, or 4. Let $\psi_0 \in H^1(\mathbb{R})$, and let $\psi(t)$ be the global H^1 solution of (1) satisfying $\psi(0) = \psi_0$. For all $\epsilon > 0$, there exists $\delta > 0$ such that if $\|\psi_0 - Q\|_{H^1} \le \delta$, then for all $t \in \mathbb{R}$, there exists $x(t) \in \mathbb{R}$ such that*

$$\|\psi(t, . + x(t)) - Q\|_{H^1} \le \epsilon.$$

See Benjamin [1], Bona [3], and Weinstein [26].

• For $p \ge 5$, the solitons are not stable in H^1. See Bona, Souganidis, and Strauss [4] for the case $p > 5$. For $p = 5$, the following stronger statement holds true: *there exist initial data ψ_0 arbitrarily close to Q in H^1 such that the corresponding solution of (1) blows up in the H^1 norm in finite time* (see Merle [17], Martel and Merle [14], and the references therein).

The next natural question concerns the asymptotic completeness of the family of solitons. First results related to this question are due to Pego and Weinstein [21], who have proved the asymptotic completeness of the family of solitons in some weighted spaces for (1) with $p = 2$ and 3.

Later, Martel and Merle [13] proved the asymptotic stability of solitons of the gKdV equations in the energy space for $p = 2$, 3, and 4. More precisely, they proved the following.

Asymptotic stability of solitons (see [13]). *Let $p = 2$, 3, or 4. Let $\psi_0 \in H^1(\mathbb{R})$, and let $\psi(t)$ be the global H^1 solution of (1) satisfying $\psi(0) = \psi_0$. There exists $\delta > 0$ such that if*

$$\|\psi_0 - Q\|_{H^1} < \delta, \tag{5}$$

then there exists c^+ close to 1, and for all $t \in \mathbb{R}^+$, there exist $x(t) \in \mathbb{R}$ such that

$$\|\psi(t) - Q_{c^+}(. - x(t))\|_{H^1(x>t/10)} \to 0 \quad \text{as } t \to +\infty, \tag{6}$$

$$\text{and} \quad x'(t) \to c^+ \quad \text{as } t \to +\infty. \tag{7}$$

See also Martel, Merle, and Tsai [16] for the case of multisoliton solutions.

Note that in (6) the convergence as $t \to +\infty$ holds for $x \geq t/10$, which is a large region around the soliton $Q_{c^+}(. - x(t))$ since $x'(t)$ is close to 1. We refer to [15] for the optimality of this result in H^1. Note that a similar result had been previously proved by the same techniques for $p = 5$; see Theorem 2 in [12] (the statement for $p = 5$ is weaker due to the instability of solitons and to a special degeneracy of the critical case).

The proofs of these results in [12] and [13] proceed into three independent steps:

1. First, the problem of asymptotic stability is reduced to a rigidity property of (1) close to the solitons. More precisely, we show that asymptotic stability is true if the following nonlinear Liouville-type theorem holds.

NONLINEAR LIOUVILLE PROPERTY (see [13]). *Let $p = 2$, 3, or 4. Let $\psi_0 \in H^1(\mathbb{R})$, and let $\psi(t)$ be the global H^1 solution of (1) satisfying $\psi(0) = \psi_0$. There exists $\delta > 0$ such that if*

$$\|\psi_0 - Q\|_{H^1} < \delta, \tag{8}$$

and if, for some function $t \in \mathbb{R} \mapsto x(t) \in \mathbb{R}$,

$$\forall \epsilon > 0,\ \exists A > 0,\ \forall t \in \mathbb{R}, \quad \int_{|x|>A} \psi^2(t, x + x(t))dx < \epsilon \tag{9}$$

is satisfied, then there exist c_1 close to 1 and $x_1 \in \mathbb{R}$ such that $\psi(t, x) \equiv R_{c_1,x_1}(t, x)$.

This result is an illustration of the rigidity of the gKdV equations around the solitons. See Theorem 1 in [12] and Theorem 2 in [13].

2. The second step is to prove the nonlinear Liouville property. This is done by reducing the proof to a similar property on a linear problem. Indeed, since we want to prove a result in a neighborhood of the function Q by passing to the limit ($\delta \to 0$) on renormalized problems, we show that it is sufficient to classify a related linearized problem. See a precise statement (linear Liouville property) in Theorem 1 below (see also Corollary 1 in section 3.4).

3. The last step is to prove the linear Liouville property. For $p = 2$, 3, 4, and 5, this property was proved in [12] and [13] by using the positivity of the quadratic form (15), under orthogonality conditions. The study of this quadratic form required at some point numerical calculations.

With respect to the first papers [12] and [13], some of the arguments, especially in the first step, have been simplified. Exponential decay properties of solutions that are uniformly localized in the L^2 norm can be proved more easily using monotonicity properties. See, for example, Laurent and Martel [11] for a simple approach of smoothness and decay for localized solutions.

In a third paper on the subject [15], the proof of asymptotic stability has been further simplified for $p = 2$, 3, and 4. Indeed the property of positivity of the quadratic form (15) could be used to determine a Liapunov functional for the original gKdV problem. This Liapunov functional implies directly the asymptotic stability result and the use of the linear or nonlinear Liouville property is not necessary. However, this approach does not seem to work in the critical case $p = 5$ and still relies on the study of the quadratic form (15) below. Moreover it was unclear whether such a problem could be solved by the same technique for $p > 5$, or even in general for $p \in (1, 5)$ not integer.

In this paper, we present a simpler approach to prove the linear Liouville property (i.e., step 3) which is successful for any real value of $p > 1$. Since there is no restriction

on p, it is now clear that this question is not related to the stability problem. Let

$$\mathcal{L}u = -\partial_x^2 u + u - pQ^{p-1}u = -\partial_x^2 u + u - \frac{p(p+1)}{2\cosh^2\left(\frac{p-1}{2}x\right)}u. \tag{10}$$

Our main result is the following theorem.

THEOREM 1 (linear Liouville property). *Let $p > 1$. Let $u \in C(\mathbb{R}, H^1(\mathbb{R})) \cap L^\infty(\mathbb{R}, H^1(\mathbb{R}))$ be a solution of*

$$\partial_t u = \partial_x (\mathcal{L}u) \quad \text{on } \mathbb{R}\times\mathbb{R}. \tag{11}$$

Assume that for two constants $C > 0$, $\sigma > 0$,

$$\forall t, x \in \mathbb{R}, \quad |u(t,x)| \le Ce^{-\sigma|x|}. \tag{12}$$

Then there exists a constant $b_0 \in \mathbb{R}$ such that for all $t \in \mathbb{R}$,

$$u(t) \equiv b_0 Q'. \tag{13}$$

Since $\mathcal{L}Q' = 0$ (see Lemma 1 below), it is clear that $u(t,x) = b_0 Q'(x)$ is a solution of (11). Theorem 1 claims that there is no other solution that is uniformly localized in the sense of (12).

Remark 1. Theorem 1 is not exactly the result required for the asymptotic stability result. See Corollary 1 in section 3.4 for a direct consequence of Theorem 1 that is the suitable form of the rigidity result to be used for the asymptotic stability.

Remark 2. Assumption (12) can be relaxed to the following condition:

$$\forall \epsilon > 0,\ \exists A > 0,\ \forall t \in \mathbb{R}, \quad \int_{|x|>A} u^2(t,x)dx < \epsilon. \tag{14}$$

Indeed, in this context (14) implies (12) and in fact a much stronger result: H^1 bounded solutions of (11) satisfying (14) are $C^\infty(\mathbb{R}\times\mathbb{R})$ and all their derivatives have exponential decay in x; see Lemma 4 in section 3.2. This is a consequence of smoothing properties of the gKdV equations observed by Kato [9] and of refined techniques introduced in [13] and [11].

Remark 3. Theorem 1 holds for all $p > 1$, and there is no difference in the proof for the various values of p. In particular, sub- or supercriticality of p (i.e., whether $1 < p < 5$ or $p \ge 5$) is not relevant in this problem.

As mentioned above, Theorem 1 (and Corollary 1) was already proved for $p = 5$ (see Theorem 3 in [12]) and for $p = 2$, 3, and 4 (see Proposition 5 in [13]). The proof presented here is simpler and does not require numerical computations. Moreover, it is a unified proof for all real values of $p > 1$.

Remark 4. From Theorem 1, we deduce that for $p \ge 6$ integer, asymptotic completeness of the family of solitons is true in the same sense as Theorem 2 in [12] for $p = 5$. The proof of this result requires some properties of stability of weak H^1 convergence through the flow of the gKdV equation (Lemma 17 in [12]). This property was checked in [12] for $p = 5$ and in [13] for $p = 2$, 3, and 4 using estimates of Kenig, Ponce, and Vega [10] used for proving the well-posedness of the Cauchy problem in H^s spaces. The same can be done for $p \ge 6$ integer.

Since $p > 1$ need not be an integer in Theorem 1, one can expect the asymptotic stability result to be true for all $p > 1$. This would require considering

$$\partial_t \psi + \partial_x(\partial_x^2\psi + |\psi|^{p-1}\psi) = 0$$

instead of (1) and adapting the methods of [10] to this situation.

We now sketch the proof of Theorem 1. Recall that the proof in [13] was based on the quantity $\int xu^2(t,x)dx$. A direct calculation gives for $u(t)$ a solution of (11):

$$-\frac{d}{dt}\int xu^2 = 3\int (\partial_x u)^2 + \int u^2 - p\int Q^{p-1}u^2 + p(p-1)\int xQ'Q^{p-2}u^2 = \overline{H}(u); \tag{15}$$

see Lemma 8 in [13]. When proving the positivity of the quadratic form $\overline{H}(u)$ under orthogonality conditions on $u(t)$, the term $\int Q^{p-1}u^2$ has the negative sign, but it is a classical potential, whose spectrum is explicit. The term $\int xQ'Q^{p-2}u^2$ also has a negative sign since $xQ'(x) \le 0$ for all $x \in \mathbb{R}$, and it is quite difficult to control.

In the present paper, the main idea is to consider the function $v(t,x) = \mathcal{L}u(t,x)$ instead of $u(t,x)$. It satisfies

$$\partial_t v = \mathcal{L}(\partial_x v).$$

Then, we have

$$-\frac{d}{dt}\int xv^2 = 3\int (\partial_x v)^2 + \int v^2 - p\int Q^{p-1}v^2 - p(p-1)\int xQ'Q^{p-2}v^2,$$

and thus the last term now has the good sign, which implies easily the positivity result for some values of p. In fact, we consider in this paper the quantity $\int v^2(t,x)g(x)dx$ for a suitable choice of function $g(x)$ (see Lemma 2) which allows us to prove at once the result for any $p > 1$.

Since we argue on $v(t,x)$ rather than on $u(t,x)$, we need to obtain some regularity on $v(t,x)$. In section 3.2, we prove that under the assumptions of Theorem 1, $u(t,x)$ is completely smooth. The main argument of Theorem 1 is presented in section 3.3.

We now turn to another nonlinear equation, introduced by Peregrine [22] and Benjamin, Bona, and Mahony [2]:

$$(1-\partial_y^2)\partial_s\psi + \partial_y(\psi + \psi^2) = 0, \quad s, y \in \mathbb{R}. \tag{16}$$

Equation (16) is not scaling invariant, but it still has a two-parameter family of traveling wave solutions: for any $c > 1$ and any $y_0 \in \mathbb{R}$,

$$S_{c,y_0}(s,y) = \varphi(y - cs - y_0) \tag{17}$$

is a solution of (16), where φ_c is an H^1 solution of

$$-c\partial_y^2\varphi_c + (c-1)\varphi_c - \varphi_c^2 = 0 \quad \text{on } \mathbb{R}. \tag{18}$$

Note that we have the following expression for φ_c:

$$\varphi_c(y) = (c-1)Q\left(\sqrt{\frac{c-1}{c}}y\right), \tag{19}$$

where Q is defined in (2).

Equation (16) has properties similar to the gKdV equation: it is globally well-posed in $H^1(\mathbb{R})$ (the proof is straightforward, unlike for the gKdV equation), and H^1

solutions have two invariant quantities: for all $s \in \mathbb{R}$,

$$\begin{aligned} &\int (\psi^2 + (\partial_y \psi)^2)(s) = \int (\psi^2 + (\partial_y \psi)^2)(0), \\ &\int \left(\frac{1}{2}\psi^2 + \frac{1}{3}\psi^3\right)(s) = \int \left(\frac{1}{2}\psi^2 + \frac{1}{3}\psi^3\right)(0). \end{aligned} \tag{20}$$

It was proved by Weinstein [27] that all traveling waves S_{c,y_0} are stable in H^1, by the same techniques as for the gKdV equation in [26], using only the invariant quantities (20).

The first result on asymptotic stability of traveling waves for (16) was given by Miller and Weinstein [18] in the spirit of the work of Pego and Weinstein [21] on gKdV. Next, Mizumachi [20] and El Dika [5], [6] gave independently the first result of asymptotic stability of S_{c,y_0} in the energy space. Their proof is in the spirit of [13], with several structural differences. It was first proved in [20] and [6] that asymptotic stability in H^1 is equivalent to a linear Liouville property. Then, their proof differs from the one of the KdV equation since Mizumachi and El Dika both apply a spectral result of Miller and Weinstein [18] to classify the linearized problem around φ_c. In fact, due to the use of Miller and Weinstein's result, the classification was obtained with the restriction $c \in (1, +\infty) \setminus E$, where E is an unknown set with no accumulation point (recall that (16) is not scaling invariant). Results for the case of several traveling waves were obtained by El Dika and Martel [8].

In the present paper, applying the strategy of the proof of Theorem 1, we are able to prove the linear Liouville property related to (16) for any $c > 1$. The linear equation related to the traveling waves S_{c,y_0} is

$$(1 - \partial_y^2)\partial_s \omega = \partial_y(-c\partial_y^2 \omega + (c-1)\omega - 2\varphi_c \omega). \tag{21}$$

We change the variable

$$x = \sqrt{\frac{c-1}{c}}\, y, \quad t = \frac{(c-1)^{3/2}}{c^{1/2}}\, s, \quad \text{and} \quad \omega(s,y) = u(t,x).$$

Then $u(t,x)$ satisfies

$$\left(1 - \frac{c-1}{c}\partial_x^2\right)\partial_t u = \partial_x(-\partial_x^2 u + u - 2Qu).$$

Let $\lambda = \frac{c-1}{c} \in (0,1)$. Note that $\lambda = 0$ corresponds to the limit case of the KdV equation, and $\lambda = 1$ corresponds to $c \to +\infty$. These limit cases, which make no sense for (16), are covered by our result. We claim the following theorem.

THEOREM 2 (linear Liouville property related to (16)). *Let $p = 2$. Let $\lambda \in [0,1]$. Let $u \in C(\mathbb{R}, H^1(\mathbb{R})) \cap L^\infty(\mathbb{R}, H^1(\mathbb{R}))$ be a solution of*

$$(1 - \lambda\partial_x^2)\partial_t u = \partial_x(\mathcal{L}u) \quad \text{on } \mathbb{R} \times \mathbb{R}. \tag{22}$$

Assume that for two constants $C > 0$, $\sigma > 0$,

$$\forall t, x \in \mathbb{R}, \quad \int (u^2 + (\partial_x u)^2)(t,x) e^{\sigma|x|} dx \le C. \tag{23}$$

Then there exists a constant $b_0 \in \mathbb{R}$ such that for all $t \in \mathbb{R}$,

$$u(t) \equiv b_0 Q'. \tag{24}$$

This result implies that the asymptotic stability results stated for (16) in [6] and [8] hold for all $c > 1$ (see [6, Theorem 1] for $p = 2$ and [8, Theorem 2] for $p = 2$ concerning the case of several traveling waves).

Remark 5. A condition of the type (14) on u and $\partial_x u$ is sufficient. See Remark 2 and El Dika [7].

Remark 6. Considering the generalized form of (16),

$$(1 - \partial_y^2)\partial_s \psi + \partial_y(\psi + \psi^p) = 0 \tag{25}$$

for $p > 1$ integer, the problem of asymptotic stability can be reduced to the classification of the following linear equation:

$$(1 - \lambda\partial_x^2)\partial_t u = \partial_x(\mathcal{L}u) \quad \text{on } \mathbb{R} \times \mathbb{R}, \tag{26}$$

where $\mathcal{L}u = -\partial_x^2 u + u - pQ^{p-1}u$. In the present paper, we consider only $p = 2$, and our proof does not seem to adapt immediately to the other cases. Note that $p = 3$ with the restriction $c \notin E$, for some set E without accumulation point, is treated by Miller and Weinstein [18] and thus also in [20] and [6].

The proof of Theorem 2 is given in section 4.

2. Preliminaries. We first gather in Lemma 1 some well-known properties of the operator $\mathcal{L}$. Recall that $\mathcal{L}$ is a classical operator (see Titchmarsh [24]). Then, in Lemma 2, we introduce the function $g(x)$ to be used in the proof of Theorem 1.

LEMMA 1 (properties of $\mathcal{L}$). *Let $p > 1$. The operator $\mathcal{L}$ defined in* (10) *satisfies the following properties:*

(i) *First eigenfunction:* $\mathcal{L}Q^{\frac{p+1}{2}} = -\frac{1}{4}(p-1)(p+3)Q^{\frac{p+1}{2}}$.
(ii) *Second eigenfunction:* $\mathcal{L}Q' = 0$, *and the kernel of* $\mathcal{L}$ *is* $\{\lambda Q', \lambda \in \mathbb{R}\}$.
(iii) *For any* L^2 *function* $h(x)$ *orthogonal to* Q' *for the* L^2 *scalar product, there exists a unique* $f(x) \in H^2(\mathbb{R})$ *orthogonal to* Q' *such that* $\mathcal{L}f = h$.
(iv) $\mathcal{L}(\frac{2}{p-1}Q + xQ') = -2Q$.
(v) *Positivity under orthogonality: for any function* $w \in H^1(\mathbb{R})$,

$$\int w(x)Q^{\frac{p+1}{2}}(x)dx = 0 \Rightarrow \int \left\{(\partial_x w)^2(x) + w^2(x) - pQ^{p-1}(x)w^2(x)\right\} dx \geq 0.$$

Proof. We recall that

$$Q'' = Q - Q^p \quad \text{and} \quad (Q')^2 = Q^2 - \frac{2}{p+1}Q^{p+1} \tag{27}$$

by integration. Thus,

$$\frac{d^2}{dx^2}Q^{\frac{p+1}{2}} = \frac{p+1}{2}\left[\frac{p-1}{2}Q'^2Q^{\frac{p-3}{2}} + Q''Q^{\frac{p-1}{2}}\right] = \left(\frac{p+1}{2}\right)^2 Q^{\frac{p+1}{2}} - pQ^{p-1}Q^{\frac{p+1}{2}},$$

and so $\mathcal{L}Q^{\frac{p+1}{2}} = -\left[\left(\frac{p+1}{2}\right)^2 - 1\right]Q^{\frac{p+1}{2}} = -\frac{1}{4}(p-1)(p+3)Q^{\frac{p+1}{2}}$.

The property $\mathcal{L}Q' = 0$ is easily checked. Moreover, the fact that the spectrum of $\mathcal{L}$ is restricted to $\{\lambda Q', \lambda \in \mathbb{R}\}$ was proved by ODE techniques (see Weinstein [25, Proposition 2.8(b)]). The third property is a direct consequence of the structure of $\mathcal{L}$ as well as the Lax–Milgram theorem. Property (iv) is obtained by direct calculations.

Finally, it follows from the fact that $Q'(x)$ has only one zero on $\mathbb{R}$ that 0 is the second eigenvalue of $\mathcal{L}$. Therefore, if $w \in H^1$ is orthogonal to $Q^{\frac{p+1}{2}}$, then

$$(\mathcal{L}w, w) = \int \left\{(\partial_x w)^2(x) + w^2(x) - pQ^{p-1}(x)w^2(x)\right\} dx \geq 0. \qquad \square$$

We introduce a suitable function $g(x)$ to be used in the proof of Theorem 1, and we list some of its properties.

LEMMA 2 (properties of the function $g(x)$). *Define*

$$g(x) = -\left(\frac{p+1}{p-1}\right)\frac{Q'(x)}{Q(x)}.$$

Then $g(x)$ satisfies the following properties for all $x \in \mathbb{R}$:

$$g'(x) = Q^{p-1}(x) = \frac{p+1}{2\cosh^2\left(\frac{p-1}{2}x\right)}, \quad \left(\frac{g''(x)}{g'(x)}\right)^2 = (p-1)^2\left(1-\frac{2}{p+1}Q^{p-1}(x)\right),$$
$$\frac{g'''(x)}{g'(x)} = (p-1)^2\left(1-\frac{3}{p+1}Q^{p-1}(x)\right), \quad g^2(x) = \left(\frac{p+1}{p-1}\right)^2\left(1-\frac{2}{p+1}Q^{p-1}(x)\right),$$

and

$$(Q^{p-1}g)' = -(p+1)Q^{p-1} + 3Q^{2p-2}, \quad |g(x)| \le \frac{p+1}{p-1}.$$

Proof. By (27) and direct calculations

$$g' = -\left(\frac{p+1}{p-1}\right)\frac{Q''Q-(Q')^2}{Q^2} = Q^{p-1},$$

$$\frac{g''}{g'} = (p-1)\frac{Q'}{Q}, \quad \left(\frac{g''}{g'}\right)^2 = (p-1)^2\left(\frac{Q'}{Q}\right)^2 = (p-1)^2\left(1-\frac{2}{p+1}Q^{p-1}\right).$$

Next,

$$g''' = (p-1)(p-2)(Q')^2Q^{p-3} + (p-1)Q''Q^{p-2} = (p-1)^2Q^{p-1}\left(1-\frac{3}{p+1}Q^{p-1}\right).$$

We also have

$$(Q^{p-1}g)' = -\frac{p+1}{p-1}(Q'Q^{p-2})' = -\frac{p+1}{(p-1)^2}g'''$$

and

$$g^2(x) = \left(\frac{p+1}{p-1}\right)^2\frac{(Q')^2}{Q^2} = \left(\frac{p+1}{p-1}\right)^2\left(1-\frac{2}{p+1}Q^{p-1}\right).$$

The last identity also implies $|g(x)| \le \frac{p+1}{p-1}$. □

3. Linear problem related to the gKdV equations. In this section, we prove Theorem 1. In sections 3.1 and 3.2, we recall some technical arguments for the proof. The main argument of the proof is presented in section 3.3.

3.1. The H^1 Cauchy problem. For the sake of completeness, we claim a well-posedness result for (11) in $H^1(\mathbb{R})$.

LEMMA 3 (H^1 well-posedness of the Cauchy problem for (11)). *Let $u_0 \in H^1(\mathbb{R})$. There exists one and only one function $u \in C(\mathbb{R}, H^1(\mathbb{R}))$ that satisfies (11) in the sense of distributions and such that $u(0) = u_0$. Moreover, if $u_0 \in H^s(\mathbb{R})$, for some*

$s > 1$, then $u \in C(\mathbb{R}, H^s(\mathbb{R}))$ and if (u_0^n) is a sequence of $H^s(\mathbb{R})$, $s \geq 2$, satisfying $u_0^n \to u_0$ in $H^1(\mathbb{R})$, then for all $T > 0$, the corresponding solutions u^n of (11) satisfy $u^n \to u$ in $C([-T, T], H^1(\mathbb{R}))$.

Proof. The existence proof is given in [12, Lemma 9], for $p = 5$. The same argument applies to any $p > 1$.

For uniqueness in the class of functions $C(\mathbb{R}, H^1(\mathbb{R}))$ satisfying (11) in the sense of distribution, since the equation is linear in $u(t)$, we only have to prove that a solution $u(t)$ in this class satisfying $u(0, x) \equiv 0$ is necessarily $u(t, x) \equiv 0$.

To do this, we apply an energy method not directly to $u(t)$ but to $v(t) \in C(\mathbb{R}, H^3(\mathbb{R}))$ defined for any $t \in \mathbb{R}$, by $v(t) = \left(1 - \partial_x^2\right)^{-1} u(t)$. Indeed, $v(t)$ satisfies

$$\partial_t v = -\partial_x^3 v + \partial_x v - p \left(1 - \partial_x^2\right)^{-1} [\partial_x (Q^{p-1} \left(1 - \partial_x^2\right) v)].$$

The second member is in L^2; thus we can take the L^2 scalar product by $v(t)$ and integrate by parts to obtain

$$\frac{d}{dt} \int v^2(t) = p \int Q^{p-1} [\left(1 - \partial_x^2\right) v] \left(1 - \partial_x^2\right)^{-1} \partial_x v.$$

By further integrations by parts, we obtain

$$\begin{aligned} \frac{d}{dt} \int v^2(t) = -\frac{p}{2} \int (Q^{p-1})' v^2 - p \int (Q^{p-1})'' v \left(1 - \partial_x^2\right)^{-1} \partial_x v \\ - 2p \int (Q^{p-1})' v \left(1 - \partial_x^2\right)^{-1} \partial_x^2 v. \end{aligned}$$

Since $\| \left(1 - \partial_x^2\right)^{-1} \partial_x v \|_{L^2} + \| \left(1 - \partial_x^2\right)^{-1} \partial_x^2 v \|_{L^2} \leq C \| v \|_{L^2}$, and by the properties of Q, we obtain by the Cauchy–Schwarz inequality $\left| \frac{d}{dt} \int v^2(t) \right| \leq C \int v^2(t)$. Thus, $v(0) = 0$ implies by the Gronwall inequality that $v(t) = 0$ and thus $u(t) = 0$. This proves the uniqueness statement. The persistence of regularity in H^s and continuous dependence results are easily checked. ∎

3.2. Smoothness and exponential decay. By applying arguments of [11] (see also [13]), we claim that a solution of (11) which is uniformly localized in the L^2 norm is necessarily completely smooth and exponentially decaying.

LEMMA 4 (smoothness and exponential decay). *Let $u(t)$ be an H^1 solution of (11), bounded in H^1 and satisfying*

$$\forall \epsilon > 0, \ \exists A > 0, \ \forall t \in \mathbb{R}, \quad \int_{|x| > A} u^2(t, x) dx < \epsilon. \tag{28}$$

Then $u \in C^\infty(\mathbb{R} \times \mathbb{R})$. Moreover, there exists $\sigma > 0$ and, for all $k \in \mathbb{N}$, there exists $C_k > 0$ such that

$$\forall t, x \in \mathbb{R}, \quad \left| \frac{\partial^k}{\partial x^k} u(t, x) \right| \leq C_k e^{-\sigma |x|}. \tag{29}$$

Remark 7. From the proof of Lemma 4, we can choose $\frac{1}{\sigma} = \max(2, \frac{1}{p-1})$. Note also that for the proof of Theorem 1, we only need to check $u \in H^3(\mathbb{R})$ and (29) for $k = 0$, 1, and 2.

Proof. The proof of Lemma 4 follows from arguments used in the proof of Theorem 1 in [11], but it is in fact simpler since the equation is linear and since the potential

Q^{p-1} has both smoothness and decay properties. Recall that Theorem 1 in [11] concerns similar properties for L^2 localized solutions of the nonlinear equation (1). We present in this proof formal calculations on $u(t)$ that can be justified rigorously by using Lemma 3 and some usual regularizing arguments.

Let $K = \max(2, \frac{1}{p-1})$. For $x \in \mathbb{R}$, let

$$\phi(x) = \frac{2}{\pi} \arctan(\exp(x/K)),$$

so that $\lim_{+\infty} \phi = 1$, $\lim_{-\infty} \phi = 0$, and, for all $x \in \mathbb{R}$, $\phi(-x) = 1 - \phi(x)$. Note also that by direct calculations

$$\phi'(x) = \frac{1}{K\pi \cosh(x/K)}, \quad \phi'''(x) \le \frac{1}{K^2}\phi'(x) \le \frac{1}{4}\phi'(x). \tag{30}$$

Let $x_0 > 0$, $t_0 \in \mathbb{R}$. We define, for all $t < t_0$,

$$I_{x_0,t_0}(t) = \int u^2(t,x)\, \phi\left(x - \frac{1}{2}(t_0 - t) - x_0\right) dx.$$

We first prove the following property of $I_{x_0,t_0}(t)$.

LEMMA 5. *There exists $\theta_0 > 0$ such that for all $x_0 > 0$, $t_0 \in \mathbb{R}$,*

$$\forall t \le t_0, \quad I_{x_0,t_0}(t_0) - I_{x_0,t_0}(t) \le \theta_0 \exp\left(-\frac{x_0}{K}\right).$$

Proof. Let $R_0 > 1$ to be chosen later, and let $x_0 > 2R_0$. Define $\tilde{x} = x - \frac{1}{2}(t_0 - t) - x_0$. Note that $\tilde{x} \le x$. By direct calculations, using the equation of $u(t)$, we have

$$\begin{aligned}
\frac{d}{dt} I_{x_0,t_0}(t) &= -3\int (\partial_x u)^2 \phi'(\tilde{x}) - \frac{1}{2}\int u^2 \phi'(\tilde{x}) + \int u^2 \phi'''(\tilde{x}) \\
&\quad + p\int \left[-(Q^{p-1})'\phi(\tilde{x}) + Q^{p-1}\phi'(\tilde{x})\right] u^2 \\
&\le -3\int (\partial_x u)^2 \phi'(\tilde{x}) - \frac{1}{4}\int u^2 \phi'(\tilde{x}) + p\int \left[-(Q^{p-1})'\phi(\tilde{x}) + Q^{p-1}\phi'(\tilde{x})\right] u^2
\end{aligned}$$

by using (30). By the properties of Q and ϕ, we have

$$\left|-(Q^{p-1})'\phi(\tilde{x}) + Q^{p-1}\phi'(\tilde{x})\right| \le Ce^{-(p-1)|x|}\phi(\tilde{x}).$$

We consider three cases depending on x:

- If $x < R_0$, then $\tilde{x} < -\frac{1}{2}(t_0 - t) - x_0 + R_0 < 0$ and so
$$e^{-(p-1)|x|}\phi(\tilde{x}) \le C\phi(\tilde{x}) \le Ce^{\frac{\tilde{x}}{K}} \le C\exp\left(-\frac{1}{2K}(t_0 - t) - \frac{x_0}{K} + \frac{R_0}{K}\right).$$
- If $R_0 < x < \frac{1}{2}(t_0 - t) + x_0$, then $\tilde{x} < 0$ and so
$$e^{-(p-1)|x|}\phi(\tilde{x}) \le e^{-(p-1)R_0}\phi(\tilde{x}) \le Ce^{-(p-1)R_0}\phi'(\tilde{x}),$$
since $\phi(y) \le C\phi'(y)$ for $y < 0$.
- If $x > \frac{1}{2}(t_0 - t) + x_0 > 0$, then
$$\begin{aligned}
e^{-(p-1)|x|}\phi(\tilde{x}) &\le Ce^{-(p-1)x} \le C\exp\left(-(p-1)\left[\frac{1}{2}(t_0 - t) + x_0\right]\right) \\
&\le C\exp\left(-\left[\frac{1}{2K}(t_0 - t) + \frac{x_0}{K}\right]\right),
\end{aligned}$$
since $K \ge 1/(p-1)$.

Therefore, we have, for all $x \in \mathbb{R}$,

$$\left|-(Q^{p-1})'\phi(\tilde{x}) + Q^{p-1}\phi'(\tilde{x})\right| \leq Ce^{\frac{R_0}{K}} \exp\left(-\frac{1}{2K}(t_0 - t) - \frac{x_0}{K}\right) + C'e^{-(p-1)R_0}\phi'(\tilde{x}).$$

We choose R_0 large enough so that

$$pC'e^{-(p-1)R_0} \int u^2\phi'(\tilde{x}) \leq \frac{1}{8} \int u^2\phi'(\tilde{x}).$$

The value of R_0 being fixed, since $\int u^2(t)$ is bounded, we obtain

$$\frac{d}{dt} I_{x_0,t_0}(t) \leq C \exp\left(-\frac{1}{2K}(t_0 - t) - \frac{x_0}{K}\right).$$

By integrating this estimate between t_0 and some $t < t_0$, we obtain the desired result for $x_0 > 2R_0$. The result for $0 < x_0 < 2R_0$ is clear by possibly taking a larger value of θ_0. □

We continue the proof of Lemma 4. By the proof of this result, proceeding exactly as in [11, pp. 162–164], and using (28), we first obtain

$$I_{x_0,t_0}(t_0) \leq \theta_0 \exp\left(-\frac{x_0}{K}\right).$$

Next, dividing by $\exp(-x_0/K)$, passing to the limit as $x_0 \to +\infty$, and using the properties of ϕ, we deduce that for some constant θ_0',

$$\forall t_0 \in \mathbb{R}, \quad \int u^2(t_0, x) \exp\left(\frac{x}{K}\right) dx + \int_{t_0-1}^{t_0} \int (\partial_x u)^2(s, x) \exp\left(\frac{x}{K}\right) dxds \leq \theta_0'.$$

Proceeding in the solution $u(t)$ of the linear problem (11) exactly as for the solution of (1) in [11, pp. 165–169], using the functionals

$$I^{(k)}_{x_0,t_0}(t) = \int (\partial_x^k u)^2(t, x)\, \phi\left(x - \frac{1}{2}(t_0 - t) - x_0\right) dx$$

for $k \geq 1$ integer, we find by iteration on k that for a constant $\theta_k > 0$, for any $t_0 \in \mathbb{R}$,

$$\int (\partial_x^k u)^2(t_0, x) \exp\left(\frac{x}{K}\right) dx + \int_{t_0-1}^{t_0} \int (\partial_x^{k+1} u)^2(s, x) \exp\left(\frac{x}{K}\right) dxds \leq \theta_k.$$

Since $u(-t, -x)$ is also a solution of (11) satisfying (28), we have as well

$$\int (\partial_x^k u)^2(t_0, x) \exp\left(\frac{|x|}{K}\right) dx + \int_{t_0-1}^{t_0} \int (\partial_x^{k+1} u)^2(s, x) \exp\left(\frac{|x|}{K}\right) dxds \leq \theta_k.$$

It follows that $u(t) \in \cap_{s \leq 0} H^s(\mathbb{R})$, and thus by the equation of $u(t)$ and the smoothness of $Q(x)$, we obtain $u \in C^\infty(\mathbb{R} \times \mathbb{R})$. Finally, by the Gagliardo–Nirenberg inequality

$$\|w\|^2_{L^\infty(x>R_0)} \leq 2\, \|w\|_{L^2(x>R_0)} \|\partial_x w\|_{L^2(x>R_0)},$$

we obtain pointwise estimates (29), as required. We refer to [11] for more details. The only difference in the proof is the method used to estimate the nonlinear terms, which we have detailed in the proof of Lemma 5 for I_{x_0,t_0}. The same estimates are applied to $\frac{d}{dt} I^{(k)}_{x_0,t_0}$. □

3.3. Main argument of the proof of Theorem 1. Let $u(t)$ be an H^1 bounded solution of

$$\partial_t u = \partial_x \left(\mathcal{L} u\right) \quad \text{on } \mathbb{R}\times\mathbb{R},$$

satisfying

$$\forall t, x \in \mathbb{R}, \quad |u(t,x)| \le C e^{-\sigma|x|}.$$

By Lemma 4 we have $u \in C^\infty(\mathbb{R}\times\mathbb{R})$ and

$$\forall k \in \mathbb{N},\ \forall t \in \mathbb{R},\ \forall x \in \mathbb{R}, \quad \left|\frac{\partial^k u}{\partial x^k}(t,x)\right| \le C_k e^{-\sigma|x|}. \tag{31}$$

Let $\tilde v(t,x) = \mathcal{L}u(t,x)$. The equation of $\tilde v(t)$ is

$$\partial_t \tilde v = \mathcal{L}(\partial_t u) = \mathcal{L}\left(\partial_x \tilde v\right). \tag{32}$$

Note also that $\int \tilde v Q' = \int u \mathcal{L} Q' = 0$. Now, we modify $\tilde v(t)$ to obtain a second orthogonality condition by setting

$$v(t,x) = \tilde v(t,x) - \left(\frac{\int \tilde v(t,x) Q^p(x) dx}{\int Q^{p+1}(x) dx}\right) Q(x),$$

so that

$$\int v(t,x) Q^p(x) dx = \int v(t,x) Q'(x) dx = 0.$$

Moreover, since $\mathcal{L}Q' = 0$, $v(t,x)$ satisfies the equation

$$\partial_t v = \mathcal{L}\left(\partial_x v\right) + \delta(t) Q, \tag{33}$$

where

$$\delta(t) = -\frac{1}{\int Q^{p+1}} \frac{d}{dt} \int \tilde v(t,x) Q^p(x) dx.$$

Note that $v \in C^\infty(\mathbb{R}\times\mathbb{R})$ and by (31) and the properties of $Q(x)$ there exist constants σ, $C > 0$ such that

$$\forall t \in \mathbb{R},\ \forall x \in \mathbb{R}, \quad |v(t,x)| \le C e^{-\sigma|x|}. \tag{34}$$

We multiply the equation of $v(t)$ by $2\, v(t,x) g(x)$, where $g(x)$ is defined in Lemma 2, and we integrate over $\mathbb{R}$; we obtain

$$\frac{d}{dt}\int v^2(t,x) g(x) dx = 2\int v \partial_t v g = 2\int \mathcal{L}\left(\partial_x v\right) v g + 2\,\delta(t) \int Q v g = 2\int \mathcal{L}\left(\partial_x v\right) v g.$$

The term in $\delta(t)$ disappears since $\int Q v(t) g = -\left(\frac{p+1}{p-1}\right)\int v(t) Q' = 0$, by the definition of the function $g(x)$ and orthogonality of $v(t)$. By integration by parts, we have

$$\begin{aligned} 2\int \mathcal{L}\left(\partial_x v\right) v g &= -2\int (\partial_x^3 v) v g + 2\int (\partial_x v) v g - 2p \int Q^{p-1} (\partial_x v) v g \\ &= 2\int (\partial_x^2 v)(\partial_x v) g + 2\int (\partial_x^2 v) v g' - \int v^2 g' + p\int (Q^{p-1} g)' v^2 \\ &= -3\int (\partial_x v)^2 g' - \int v^2 \left[-g''' + g' - p(Q^{p-1} g)'\right]. \end{aligned} \tag{35}$$

We now set $w(t,x) = v(t,x)\sqrt{g'(x)} = v(t,x)Q^{\frac{p-1}{2}}(x)$. We have

$$\partial_x w = \partial_x v\sqrt{g'} + \frac{1}{2}\frac{g''}{\sqrt{g'}}v,$$

and so by integration by parts,

$$\int (\partial_x w)^2 = \int (\partial_x v)^2 g' + \frac{1}{4}\int v^2\frac{(g'')^2}{g'} - \frac{1}{2}\int v^2 g''',$$

which also reads

$$\int (\partial_x v)^2 g' = \int (\partial_x w)^2 - \frac{1}{4}\int w^2\left(\frac{g''}{g'}\right)^2 + \frac{1}{2}\int w^2\left(\frac{g'''}{g'}\right).$$

Thus,

$$\frac{d}{dt}\int v^2(t,x)g(x)dx = -3\int (\partial_x w(t,x))^2 dx - \int w^2(t,x)A(x)dx,$$

where

$$A(x) = 1 + \frac{1}{2}\frac{g'''(x)}{g'(x)} - \frac{3}{4}\left(\frac{g''(x)}{g'(x)}\right)^2 - p\frac{(Q^{p-1}g)'(x)}{g'(x)}.$$

Using Lemma 2, we obtain the following expression for $A(x)$:

$$\begin{aligned} A(x) &= 1 + \frac{1}{2}(p-1)^2 - \frac{3(p-1)^2}{2(p+1)}Q^{p-1} - \frac{3}{4}(p-1)^2 + \frac{3(p-1)^2}{2(p+1)}Q^{p-1} \\ &\quad + p(p+1) - 3pQ^{p-1} \\ &= \frac{3}{4}(p+1)^2 - 3pQ^{p-1}. \end{aligned}$$

Therefore,

$$\begin{aligned} -\frac{1}{3}\frac{d}{dt}\int v^2(t,x)g(x)dx &= \int (\partial_x w)^2 + \left(\frac{p+1}{2}\right)^2\int w^2 - p\int Q^{p-1}w^2 \\ &= (\mathcal{L}w, w) + \frac{(p-1)(p+3)}{4}\int w^2 \end{aligned} \tag{36}$$

(where $(.,.)$ denotes the L^2 scalar product). In the right-hand member, we recognize a nonnegative quadratic form related to the operator $\mathcal{L}$. Note that

$$\int v(t,x)Q^p(x)dx = 0 \quad \text{is equivalent to} \quad \int w(t,x)Q^{\frac{p+1}{2}}(x)dx = 0.$$

By Lemma 1, we thus have $(\mathcal{L}w, w) \geq 0$,

$$-\frac{1}{3}\frac{d}{dt}\int v^2(t,x)g(x)dx \geq \frac{1}{4}(p-1)(p+3)\int w^2(t,x)dx. \tag{37}$$

Since $|g(x)| \leq \frac{p+1}{p-1}$, the function $\int v^2(t,x)g(x)dx$ is uniformly bounded in time, and so

$$\int_{-\infty}^{+\infty}\int w^2(t,x)dxdt < +\infty.$$

It follows that for some sequence $t_n \to +\infty$, we have

$$\int w^2(t_n, x)dx \to 0 \quad \text{as } n \to +\infty.$$

Thus, from (34), we obtain

$$\int v^2(t_n, x)dx \to 0 \quad \text{as } n \to +\infty.$$

Similarly, we have for a sequence $s_n \to +\infty$

$$\int v^2(-s_n, x)dx \to 0 \quad \text{as } n \to +\infty.$$

Using (37) integrated over $(-s_n, t_n)$ and the bound on $g(x)$, we obtain, for all $n \in \mathbb{N}$,

$$\int_{-s_n}^{t_n} \int w^2(t, x)dxdt \leq C \left(\int \left[v^2(t_n, x) + v^2(-s_n, x) \right] dx \right).$$

By passing to the limit as $n \to +\infty$, we obtain

$$\int_{-\infty}^{+\infty} \int w^2(t, x)dxdt = 0,$$

giving us $w(t, x) \equiv 0$, and thus $v(t, x) \equiv 0$. Therefore, $\mathcal{L}u(t, x) = \tilde{v}(t, x) = \gamma(t)Q(x)$, and so by Lemma 1,

$$u(t, x) = -\frac{1}{2}\gamma(t)\left(\frac{2}{p-1}Q + xQ' \right)(x) + b(t)Q'(x) = a(t)\left(\frac{2}{p-1}Q + xQ' \right)(x) + b(t)Q'(x).$$

But from the equation of $u(t, x)$, the functions $a(t)$, $b(t)$ satisfy the following relations:

$$a'(t) = 0, \quad b'(t) = -2a(t).$$

Since $u(t)$ is uniformly bounded, the only possible solutions $u(t)$ are for $b(t) \equiv b_0$ constant, and $a(t) \equiv 0$. Thus, $u(t) \equiv b_0 Q'$.

3.4. Classification for a more general problem. As a direct corollary of Theorem 1, we obtain the following classification result.

COROLLARY 1. *Let $p > 1$. Let $u \in C(\mathbb{R}, H^1(\mathbb{R})) \cap L^\infty(\mathbb{R}, H^1(\mathbb{R}))$ be a solution of*

$$\partial_t u = \partial_x (\mathcal{L}u) + \alpha(t) \left(\frac{2}{p-1}Q + xQ' \right) + \beta(t)Q' \quad \text{on } \mathbb{R} \times \mathbb{R}, \tag{38}$$

where $\alpha(t)$ and $\beta(t)$ are two continuous and bounded functions. Assume that for two constants $C > 0$, $\sigma > 0$,

$$\forall t, x \in \mathbb{R}, \quad |u(t, x)| \leq Ce^{-\sigma|x|}. \tag{39}$$

Then for all $t \in \mathbb{R}$,

$$u(t) \equiv a(t) \left(\frac{2}{p-1}Q + xQ' \right) + b(t)Q' \tag{40}$$

for some C^1 bounded functions $a(t)$ and $b(t)$ satisfying

$$a'(t) = \alpha(t), \quad b'(t) = -2\,a(t) + \beta(t). \tag{41}$$

Since by direct calculations

$$\mathcal{L}\left(\frac{2}{p-1}Q + xQ'\right) = -2Q \quad \text{and} \quad \mathcal{L}Q' = 0$$

(see Lemma 1), it is easily checked that (40)–(41) indeed define a solution of (38). Corollary 1 means that there is no other H^1 bounded solution of (38) satisfying (39).

Problem (38) is the one that really appears in the proof of asymptotic stability in [12], [13].

Proof. Let $u(t)$ be a solution of (38) as in the statement of Corollary 1, where $\alpha(t)$, $\beta(t)$ are bounded. We have to consider separately the cases $p \neq 5$ and $p = 5$, because of some structural differences.

Case $p \neq 5$. Since $p \neq 5$, we have, by integrating by parts,

$$\int \left(\frac{2}{p-1}Q + xQ'\right) Q = \frac{5-p}{2(p-1)} \int Q^2 \neq 0. \tag{42}$$

Multiplying the equation of $u(t)$ by Q and integrating on $\mathbb{R}$, using $\mathcal{L}Q' = 0$, we obtain by (42)

$$\frac{5-p}{2(p-1)} \left(\int Q^2\right) \alpha(t) = \frac{d}{dt} \int u(t)Q.$$

Let

$$\tilde{u}(t) = u(t) - \frac{2(p-1)}{5-p} \frac{1}{\int Q^2} \left(\int u(t)Q\right) \left(\frac{2}{p-1}Q + xQ'\right).$$

Then $\tilde{u}(t)$ satisfies, by $\mathcal{L}(\frac{2}{p-1}Q + xQ') = -2Q$,

$$\begin{aligned} \partial_t \tilde{u} - \partial_x(\mathcal{L}\tilde{u}) &= \partial_t u - \alpha(t) \left(\frac{2}{p-1}Q + xQ'\right) - \partial_x(\mathcal{L}u) - \frac{4(p-1)}{5-p} \frac{Q'}{\int Q^2} \left(\int u(t)Q\right) \\ &= \tilde{\beta}(t)Q', \end{aligned} \tag{43}$$

where $\tilde{\beta}(t) = \beta(t) - \frac{p-1}{5-p} \frac{4}{\int Q^2} \int u(t)Q$ is bounded. Moreover, for all $t \in \mathbb{R}$, $\int \tilde{u}(t)Q = 0$.

Now let

$$J(t) = \int_{\mathbb{R}} \tilde{u}(t,y) \left(\int_0^y \left(\frac{2}{p-1}Q + xQ'\right) dx\right) dy.$$

Then, since $\mathcal{L}(\frac{2}{p-1}Q + xQ') = -2Q$, we have

$$J'(t) = 2 \int \tilde{u}(t)Q - \tilde{\beta}(t) \int Q \left(\frac{2}{p-1}Q + xQ'\right), \text{ and so } \frac{5-p}{2(p-1)} \left(\int Q^2\right) \tilde{\beta}(t) = -J'(t).$$

Since $\mathcal{L}Q' = 0$, it follows that $w(t,x) = \tilde{u}(t) - \frac{2(p-1)}{5-p} \frac{1}{\int Q^2} J(t)Q'$ satisfies

$$\partial_t w - \partial_x(\mathcal{L}w) = 0,$$

and thus $w(t)$ satisfies the assumptions of Theorem 1. It follows that $w(t,x) = b_0 Q'(x)$, for some constant b_0, and

$$u(t,x) = \tilde{u}(t,x) + a(t)\left(\frac{2}{p-1}Q + xQ'\right) = a(t)\left(\frac{2}{p-1}Q + xQ'\right) + b(t)Q',$$

where $a(t)$ and $b(t)$ are bounded and satisfy

$$a'(t) = \alpha(t), \quad b'(t) = -2a(t) + \beta(t).$$

Case $p = 5$. Since $p = 5$, we have $\int (\frac{2}{p-1}Q + xQ')Q = 0$, and we need to modify the previous argument. In fact, the argument that we present now for $p = 5$ works also for any $p \neq 3$. Indeed, since $p \neq 3$, we have

$$\int \left(\frac{2}{p-1}Q + xQ'\right) = \frac{3-p}{p-1}\int Q \neq 0.$$

By integrating the equation of $u(t)$, we deduce

$$\frac{d}{dt}\int u(t) = \alpha(t)\frac{3-p}{p+1}\int Q.$$

Thus, we set

$$\tilde{u}(t) = u(t) - \frac{p+1}{3-p}\frac{1}{\int Q}\left(\int u(t)\right)\left(\frac{2}{p-1}Q + xQ'\right),$$

so that $\tilde{u}(t)$ satisfies (43) for some $\tilde{\beta}(t)$ and $\int \tilde{u}(t) = 0$.

Observe now that $\mathcal{L}(1) = 1 - pQ^{p-1}$. Let $j \in H^1(\mathbb{R})$ be such that $\int j(x)Q'(x)dx = 0$ and $\mathcal{L}j = pQ^{p-1}$ (the existence and uniqueness of $j(x)$ is a consequence of Lemma 1). Then $\mathcal{L}(1+j) = 1$. Multiplying the equation of $\tilde{u}(t)$ by $\int_0^x (1+j)(y)dy$ and integrating, we obtain the following:

$$\text{let} \quad J(t) = \int_{\mathbb{R}} \tilde{u}(t,x)\left(\int_0^x (1+j)(y)dy\right)dx; \quad \text{then} \quad J'(t) = -\tilde{\beta}(t)\int Q(1+j)(x).$$

But $\int Q(1+j) = -\frac{1}{2}\int \mathcal{L}(\frac{2}{p-1}Q + xQ')(1+j) = -\frac{1}{2}\int (\frac{2}{p-1}Q + xQ') = -\frac{1}{2}\frac{3-p}{p-1}\int Q$, so that by setting

$$w(t,x) = \tilde{u}(t,x) - \frac{2(p-1)}{3-p}\frac{Q'}{\int Q}J(t),$$

we obtain $\partial_t w - \partial_x(\mathcal{L}w) = 0$, and w satisfies the assumptions of Theorem 1. We finish as for the case $p \neq 5$. □

4. Linear problem related to (16). In this section, we prove Theorem 2. The proof follows closely that for the KdV case (i.e., Theorem 1 with $p = 2$). First, we observe that by the techniques developed by El Dika [7], if $u(t)$ is an H^1 solution of

$$(1 - \lambda\partial_x^2)\partial_t u = \partial_x(\mathcal{L}u) \quad \text{on } \mathbb{R}\times\mathbb{R},$$

satisfying

$$\forall t, x \in \mathbb{R}, \quad \int (u^2 + (\partial_x u)^2)(t,x)e^{\sigma_0|x|}dx \leq C,$$

then $u \in C^\infty(\mathbb{R}\times\mathbb{R})$ and satisfies

$$\forall t,x\in\mathbb{R},\quad \left|\frac{\partial^k}{\partial x^k}u(t,x)\right| \le C_k e^{-\sigma|x|}. \tag{44}$$

Using [7], the proof is similar to that of Lemma 4 and so we omit it.

We restrict ourselves to the case $p=2$ and consider any $\lambda\in[0,1]$ (which means that for the original nonlinear problem, we consider any speed $c>1$).

Let

$$v(t,x)=\mathcal{L}u(t,x)\quad\text{and}\quad \tilde{h}(t,x)=\left(1-\lambda\partial_x^2\right)^{-1}v(t,x), \tag{45}$$

i.e., for any $t\in\mathbb{R}$, $\tilde{h}(t)$ is solution of $\left(1-\lambda\partial_x^2\right)\tilde{h}(t)=v(t)$. Then $v(t,x)$ and $\tilde{h}(t,x)$ satisfy

$$\partial_t v=\mathcal{L}(\partial_x\tilde{h}),\quad \partial_t\tilde{h}=\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x\tilde{h}).$$

We set $R(x)=\left(1-\lambda\partial_x^2\right)Q(x)=(1-\lambda)Q(x)+\lambda Q^2(x)$, by the equation of $Q(x)$. We have

$$\int vQ'=\int u\mathcal{L}Q'=0\quad\text{and so}\quad \int\tilde{h}R'=0.$$

We modify $\tilde{h}$ in order to get another orthogonality condition. Indeed, setting

$$h(t,x)=\tilde{h}(t,x)-\frac{\int\tilde{h}(t,x)R(x)dx}{\int R(x)Q(x)dx}Q(x)$$

(note that $\int R(x)Q(x)dx=(1-\lambda)\int Q^2+\lambda\int Q^3\neq 0$), we have, for all $t\in\mathbb{R}$,

$$\int h(t,x)R(x)dx=\int h(t,x)R'(x)dx=0.$$

Moreover, since $\mathcal{L}Q'=0$, $h(t,x)$ satisfies the equation

$$\partial_t h=\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)+\delta(t)Q,$$

where

$$\delta(t)=-\frac{1}{\int RQ}\frac{d}{dt}\int\tilde{h}(t,x)R(x)dx.$$

In contrast to the KdV case, we will need an expression of $\delta(t)$ in terms of h. For this, we take the L^2 scalar product of the equation of h by $R(x)$. We obtain

$$0=\frac{d}{dt}\int h(t,x)R(x)dx=\int\left[\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)\right]R+\delta(t)\int QR.$$

Since $\left(1-\lambda\partial_x^2\right)^{-1}R=Q$ and $\mathcal{L}Q=-Q^2$, we obtain

$$\delta(t)=-\frac{1}{(1-\lambda)\int Q^2+\lambda\int Q^3}\int h(Q^2)'. \tag{46}$$

From (44) it follows that

$$\forall t \in \mathbb{R}, \quad \int v^2(t,x)\cosh(\sigma x)dx \le C, \tag{47}$$

where we choose $0 < \sigma < \frac{1}{2}$. Using $v(t) = \left(1 - \lambda\partial_x^2\right)\tilde{h}(t)$ and integrating by parts, we obtain

$$\forall t \in \mathbb{R}, \quad \int \left(\lambda^2(\partial_x^2\tilde{h}(t))^2 + 2\lambda(\partial_x\tilde{h}(t))^2 + (1-\lambda\sigma^2)\tilde{h}^2(t)\right)\cosh(\sigma x)dx \le C, \tag{48}$$

and so by the properties of Q,

$$\forall t \in \mathbb{R}, \quad \int \left[\lambda(\partial_x h(t))^2 + h^2(t)\right] e^{\sigma|x|}dx \le C. \tag{49}$$

We now choose the functional of $h(t,x)$ that will allow us to obtain $h = 0$. Set

$$K(t) = \lambda\int (\partial_x h)^2(t)g + \int h^2(t)g - \lambda\int h^2(t)g'',$$

where the function $g(x)$ is defined in Lemma 2. We claim the following lemma.

LEMMA 6. *For all $t \in \mathbb{R}$,*

$$K'(t) \le -H(t), \quad \textit{where } H(t) = -2\int \mathcal{L}(\partial_x h)hg - 2\int(\partial_x h)^2 g'. \tag{50}$$

Proof. We have by direct calculations using the equation of $h(t,x)$ and integration by parts,

$$\begin{aligned}\frac{d}{dt}\int(\partial_x h)^2 g &= 2\int \partial_x\left[\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)\right](\partial_x hg) + 2\delta(t)\int Q'(\partial_x hg)\\ &= -2\int\left[\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)\right](\partial_x^2 hg + \partial_x hg') - 2\delta(t)\int(Q'g)'h,\end{aligned}$$

$$\frac{d}{dt}\int h^2 g = 2\int\left[\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)\right]hg + 2\delta(t)\int Qhg,$$

and

$$\frac{d}{dt}\int h^2 g'' = 2\int\left[\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)\right]hg'' + 2\delta(t)\int Qhg''.$$

Thus,

$$\begin{aligned}K'(t) = 2\int&\left[\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)\right](-\lambda\partial_x^2 hg - \lambda\partial_x hg' - \lambda hg'' + hg)\\ &+ 2\delta(t)\int h\left(-\lambda(Q'g)' + Qg - \lambda Qg''\right).\end{aligned}$$

We set $V = -\lambda(Q'g)' + Qg - \lambda Qg''$. Moreover, we note that

$$-\lambda\partial_x^2 hg - 2\lambda\partial_x hg' - \lambda hg'' + hg = \left(1-\lambda\partial_x^2\right)(hg).$$

Thus, we obtain

$$
\begin{aligned}
K'(t) &= 2\int \left[\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)\right]\left(-\lambda\partial_x^2 hg - 2\lambda\partial_x hg' - \lambda hg'' + hg\right)\\
&\quad + 2\lambda\int \left[\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)\right]\partial_x hg' + 2\delta(t)\int hV \qquad (51)\\
&= 2\int \mathcal{L}(\partial_x h)hg + 2\lambda\int \left[\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)\right]\partial_x hg' + 2\delta(t)\int hV.
\end{aligned}
$$

The first term in (51), i.e., $2\int \mathcal{L}(\partial_x h)hg$, has already been developed for the KdV equation (see (35)). We consider the second term in (51). Since $\mathcal{L}h = -\partial_x^2 h + h - 2Qh = -\partial_x^2 h + h - 2g'h$, we have

$$
\begin{aligned}
&2\lambda\int \left[\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)\right]\partial_x hg'\\
&= 2\int (\partial_x h)^2 g' - 2(1-\lambda)\int \left[\left(1-\lambda\partial_x^2\right)^{-1}(\partial_x h)\right]\partial_x hg'\\
&\quad - 4\lambda\int \left[\left(1-\lambda\partial_x^2\right)^{-1}(\partial_x hg')\right]\partial_x hg'.
\end{aligned}
$$

For $t\in\mathbb{R}$, we denote by $a(t,x)$ and $b(t,x)$ the functions satisfying, respectively,

$$
\left(1-\lambda\partial_x^2\right)a(t,x) = h(t,x) \quad \text{and} \quad \left(1-\lambda\partial_x^2\right)b(t,x) = \partial_x h(t,x)g'(x).
$$

In other words, $a(t) = \left(1-\lambda\partial_x^2\right)^{-1}h(t)$ and $b(t) = \left(1-\lambda\partial_x^2\right)^{-1}(\partial_x h(t)g')$. Using these functions, we obtain

$$
\begin{aligned}
\int \left[\left(1-\lambda\partial_x^2\right)^{-1}(\partial_x h)\right]\partial_x hg' &= \int \partial_x a\left[\left(1-\lambda\partial_x^2\right)(\partial_x a)\right]g'\\
&= \int \left[(\partial_x a)^2 + \lambda(\partial_x^2 a)^2\right]g' - \frac{\lambda}{2}\int (\partial_x a)^2 g'''
\end{aligned}
$$

and

$$
\int \left(1-\lambda\partial_x^2\right)^{-1}(\partial_x hg')\partial_x hg' = \int b\left(1-\lambda\partial_x^2\right)b = \int \left[b^2 + \lambda(\partial_x b)^2\right].
$$

Thus, we have

$$
\begin{aligned}
&2\lambda\int \left[\left(1-\lambda\partial_x^2\right)^{-1}\mathcal{L}(\partial_x h)\right]\partial_x hg'\\
&= 2\int (\partial_x h)^2 g' - 2(1-\lambda)\int \left(\left[(\partial_x a)^2 + \lambda(\partial_x^2 a)^2\right]g' - \frac{\lambda}{2}(\partial_x a)^2 g'''\right)\\
&\quad - 4\lambda\int \left[b^2 + \lambda(\partial_x b)^2\right].
\end{aligned}
$$

By Lemma 2 for $p=2$, we have $g''' = g' - (g')^2 \le g'$, and thus by $\lambda \le 1$, we obtain

$$
\int \left(\left[(\partial_x a)^2 + \lambda(\partial_x^2 a)^2\right]g' - \frac{\lambda}{2}(\partial_x a)^2 g'''\right) \ge 0.
$$

It follows that

$$
K'(t) \le 2\int \mathcal{L}(\partial_x h)hg + 2\int (\partial_x h)^2 g' + 2\delta(t)\int hV.
$$

We now consider the term $2\delta(t)\int hV$, where $V = -\lambda(Q'g)' + Qg - \lambda Qg''$. We use Lemma 2 with $p = 2$ to compute V:

$$V = 3\lambda\left(\frac{(Q')^2}{Q}\right)' - 3Q' - \lambda QQ' = 3\lambda\left(Q - \frac{2}{3}Q^2\right)' - 3Q' - \frac{\lambda}{2}(Q^2)' = -3R' + \frac{\lambda}{2}(Q^2)'.$$

Thus, by (46) and $\int hR' = 0$, we obtain

$$2\delta(t)\int hV = -\frac{\lambda}{(1-\lambda)\int Q^2 + \lambda\int Q^3}\left(\int h(Q^2)'\right)^2 \le 0.$$

Therefore, we finally obtain

$$K'(t) \le 2\int \mathcal{L}(\partial_x h)hg + 2\int (\partial_x h)^2 g',$$

which finishes the proof of Lemma 6. □

We continue the proof of Theorem 2. By (35), we have

$$H(t) = \int (\partial_x h)^2 g' + \int h^2\left[-g''' + g' - 2(Qg)'\right].$$

We set $w(t,x) = h(t,x)\sqrt{g'(x)} = h(t,x)\sqrt{Q(x)}$. Note first that

$$\int hR = 0 \quad \Leftrightarrow \quad \int w\left[(1-\lambda)Q^{\frac{1}{2}} + \lambda Q^{\frac{3}{2}}\right] = 0.$$

Since

$$\int (\partial_x h)^2 g' = \int (\partial_x w)^2 - \frac{1}{4}\int w^2\left(\frac{g''}{g'}\right)^2 + \frac{1}{2}\int w^2\left(\frac{g'''}{g'}\right),$$

we obtain

$$H(t) = \int (\partial_x w)^2 + \int B(x)w^2,$$

where, by Lemma 2 applied to $p = 2$,

$$\begin{aligned} B(x) &= -\frac{1}{4}\left(\frac{g''}{g'}\right)^2 - \frac{1}{2}\left(\frac{g'''}{g'}\right) + 1 - 2\frac{(Qg)'}{g'} \\ &= -\frac{1}{4}\left(1 - \frac{2}{3}Q\right) - \frac{1}{2}(1-Q) + 1 + 2(3-3Q) = \frac{25}{4} - \frac{16}{3}Q. \end{aligned} \tag{52}$$

Now, we have to check the positivity of

$$H(t) = \int (\partial_x w)^2 + \frac{25}{4}\int w^2 - \frac{16}{3}\int Qw^2,$$

under the following orthogonality condition on w:

$$\int w\left[(1-\lambda)Q^{\frac{1}{2}} + \lambda Q^{\frac{3}{2}}\right] = 0.$$

The expression of H in w is related to the operator $-\partial_x^2+\frac{25}{4}-\frac{16}{3}Q$, which is a classical operator (see Titchmarsh [24]). Let us recall some computations related to Q^α for $\alpha>0$:

$$-(Q^\alpha)''=-\alpha^2Q^\alpha+\alpha\left(\frac{2\alpha+1}{3}\right)Q^{\alpha+1}. \tag{53}$$

Indeed, we have

$$\begin{aligned}-(Q^\alpha)''&=-\alpha\left(Q''Q^{\alpha-1}+(\alpha-1)(Q')^2Q^{\alpha-2}\right)\\&=-\alpha\left(\alpha Q^\alpha-\left(1+\frac{2(\alpha-1)}{3}\right)Q^{\alpha+1}\right)=-\alpha^2Q^\alpha+\alpha\left(\frac{2\alpha+1}{3}\right)Q^{\alpha+1}.\end{aligned}$$

This leads us to compare $H(t)$ to a quadratic form for which the first eigenfunction will be explicit and simple. Indeed, we decompose $H(t)$ as

$$H(t)=\int(\partial_xw)^2+\frac{25}{4}\int w^2-5\int Qw^2-\frac{1}{3}\int Qw^2,$$

and we observe that since $|Q(x)|\le\frac{3}{2}$, we have

$$H(t)\ge\int(\partial_xw)^2+\frac{23}{4}\int w^2-5\int Qw^2\equiv\tilde H(t).$$

The quadratic form $\tilde H(t)$ is related to the operator $\tilde{\mathcal{L}}=-\partial_x^2+\frac{23}{4}-5Q$, i.e., $\tilde H(t)=(\tilde{\mathcal{L}}w,w)$. By (53), we have $\tilde{\mathcal{L}}Q^{\frac{5}{2}}=-\frac{1}{2}Q^{\frac{5}{2}}$, which means that the first eigenvalue of $\tilde{\mathcal{L}}$ is $-\frac{1}{2}$. On the other hand, we check by elementary computation that $\tilde{\mathcal{L}}(Q^2)'=\frac{7}{4}(Q^2)'$, which means that the second eigenvalue of $\tilde{\mathcal{L}}$ is $\frac{7}{4}$. Moreover, $\tilde{\mathcal{L}}$ has a continuous spectrum, which is $[\frac{23}{4},+\infty)$. Thus, for odd functions, the operator is positive, and there is only one negative direction for even functions. We now want to check that there exists $\kappa>0$ such that, for any H^1 function w,

$$\int w\left[(1-\lambda)Q^{\frac{1}{2}}+\lambda Q^{\frac{3}{2}}\right]=0\quad\Rightarrow\quad(\tilde{\mathcal{L}}w,w)\ge\kappa\int w^2 \tag{54}$$

(where $(.,.)$ is the L^2 scalar product). Let $\tilde R=(1-\lambda)Q^{\frac{1}{2}}+\lambda Q^{\frac{3}{2}}$. Following Lemma E.1 of Weinstein [26], it suffices to check that $(\tilde R,Q^{\frac{5}{2}})>0$, which is clearly true, and $(\tilde{\mathcal{L}}^{-1}\tilde R,\tilde R)<0$. Using (53) it turns out that $\tilde{\mathcal{L}}^{-1}\tilde R$ can be computed explicitly.

Indeed, by (53) for $\alpha=\frac{3}{2}$, we have

$$\tilde{\mathcal{L}}Q^{\frac{3}{2}}=\frac{7}{2}Q^{\frac{3}{2}}-3Q^{\frac{5}{2}},$$

and since $\tilde{\mathcal{L}}Q^{\frac{5}{2}}=-\frac{1}{2}Q^{\frac{5}{2}}$, we deduce

$$Q^{\frac{3}{2}}=\tilde{\mathcal{L}}\left(\frac{2}{7}Q^{\frac{3}{2}}-\frac{12}{7}Q^{\frac{5}{2}}\right).$$

In a similar way, we have

$$\tilde{\mathcal{L}}Q^{\frac{1}{2}}=\frac{11}{2}Q^{\frac{1}{2}}-\frac{14}{3}Q^{\frac{3}{2}},$$

and so using $\tilde{\mathcal{L}}Q^{\frac{3}{2}}$ and $\tilde{\mathcal{L}}Q^{\frac{5}{2}}$, we obtain

$$Q^{\frac{1}{2}} = \tilde{\mathcal{L}}\left(\frac{2}{11}Q^{\frac{1}{2}} + \frac{8}{33}Q^{\frac{3}{2}} - \frac{16}{11}Q^{\frac{5}{2}}\right).$$

Thus, using

$$\int Q = \int Q^2, \quad \int Q^3 = \frac{6}{5}\int Q^2, \quad \int Q^4 = \frac{54}{35}\int Q^2 \tag{55}$$

(deduced from $Q'' = Q - Q^2$, $(Q')^2 = Q^2 - \frac{2}{3}Q^3$), we obtain

$$\begin{aligned}
(\tilde{\mathcal{L}}^{-1}Q^{\frac{3}{2}}, Q^{\frac{3}{2}}) &= \frac{2}{7}\int Q^3 - \frac{12}{7}\int Q^4 = -\frac{562}{245}\int Q^2 < 0,\\
(\tilde{\mathcal{L}}^{-1}Q^{\frac{1}{2}}, Q^{\frac{1}{2}}) &= \frac{2}{11}\int Q + \frac{8}{33}\int Q^2 - \frac{16}{11}\int Q^3 = -\frac{218}{165}\int Q^2 < 0,\\
(\tilde{\mathcal{L}}^{-1}Q^{\frac{3}{2}}, Q^{\frac{1}{2}}) &= (\tilde{\mathcal{L}}^{-1}Q^{\frac{1}{2}}, Q^{\frac{3}{2}}) = \frac{2}{7}\int Q^2 - \frac{12}{7}\int Q^3 = -\frac{62}{35}\int Q^2 < 0.
\end{aligned} \tag{56}$$

Since all the terms in (56) are negative, and $\tilde{R} = (1-\lambda)Q^{\frac{1}{2}} + \lambda Q^{\frac{3}{2}}$ with $\lambda \in [0,1]$, it is clear that $(\tilde{\mathcal{L}}^{-1}\tilde{R}, \tilde{R}) < 0$. Therefore, (54) is verified.

Using (54) and the previous calculations on $K'(t)$ (Lemma 6), we deduce

$$K'(t) \le -H(t) \le -\kappa \int w^2(t).$$

Integrating between $-\infty$ and $+\infty$, we deduce that $\int_{-\infty}^{+\infty}\int w^2(t,x)dxdt < +\infty$. Using this in the expression of $H(t)$, we also have $\int_{-\infty}^{+\infty}\int (\partial_x w)^2(t,x)dxdt < +\infty$. At this point, using (49), we obtain $w(t) \equiv 0$ on $\mathbb{R}\times\mathbb{R}$ exactly as in the proof of Theorem 1 in section 3.

By $w \equiv 0$ we obtain $h \equiv 0$, and thus $\tilde{h}(t,x) \equiv a(t)Q(x)$. Then $\partial_t \tilde{h} = 0$ implies $a'(t) = 0$, and so $\tilde{h}(t,x) = a_0 Q(x)$ for a constant $a_0 \in \mathbb{R}$. Finally, we obtain $\mathcal{L}u = a_0\left(1 - \lambda\partial_x^2\right)Q$, and so $u(t) = a_0\mathcal{L}^{-1}\left(\left(1-\lambda\partial_x^2\right)Q\right) + b(t)Q'$, and by the equation of $u(t)$, this implies $b'(t) = a_0$. But since $b(t)$ has to be bounded, this implies $a_0 = 0$ and $b(t) = b_0$ for some constant $b_0 \in \mathbb{R}$. Thus $u(t) \equiv b_0 Q'$, which is solution for any $b_0 \in \mathbb{R}$, and Theorem 2 is proved.

ON GLOBAL WELL-POSEDNESS OF THE LAGRANGIAN AVERAGED EULER EQUATIONS*

THOMAS Y. HOU† AND CONGMING LI‡

Abstract. We study the global well-posedness of the Lagrangian averaged Euler equations in three dimensions. We show that a necessary and sufficient condition for the global existence is that the bounded mean oscillation of the stream function is integrable in time. We also derive a sufficient condition in terms of the total variation of certain level set functions, which guarantees the global existence. Furthermore, we obtain the global existence of the averaged two-dimensional (2D) Boussinesq equations and the Lagrangian averaged 2D quasi-geostrophic equations in finite Sobolev space in the absence of viscosity or dissipation.

Key words. well-posedness, nonlinearity partial differential equations, Euler equations

1. Introduction.

The question of global existence for the three-dimensional (3D) incompressible Euler equations is a very challenging open question. The main difficulty is to understand the effect of vortex stretching, which is absent in the two-dimensional (2D) Euler equations. As part of the effort to understand the vortex stretching effect for 3D flows, various simplified model equations have been proposed in the literature. Amongst these models, the 2D Boussinesq system and the quasi-geostrophic equations are two of the most commonly used because they share a similar vortex stretching effect as that in the 3D incompressible flow. An interesting recent development is the Lagrangian averaged Euler equations [15, 16]. This work was originally motivated by the development of a one-dimensional (1D) shallow water theory [3]. The averaged Euler models have been used to study the average behavior of the 3D Euler and Navier–Stokes equations and used as a turbulent closure model (see, e.g., [5]). The theoretical and computational aspects of the Lagrangian averaged Euler and Navier–Stokes equations have been studied by several authors [4, 5, 16, 22, 21, 13]. However, the global existence of the 3D Lagrangian averaged Euler equations is still open, although the Lagrangian averaged Navier–Stokes equations have been shown to have global existence [21, 13].

In this paper, we consider the global existence of the 3D Lagrangian averaged Euler equations and the corresponding 2D Lagrangian averaged Boussinesq equations and the averaged 2D quasi-geostrophic equations in the absence of viscosity or dissipation. The 3D Lagrangian averaged Euler equations have been derived by Holm, Marsden, and Ratiu [15, 16] (see page 1458 of [21]) in the following form:

$$\partial_t u + (u_\alpha \cdot \nabla)u + (\nabla u_\alpha)^T \cdot u = -\nabla p; \tag{1}$$

here the notation is different from that in [21]. Our u_α corresponds to the original u and our u corresponds to $(1-\alpha^2\triangle)u$ in [21].

We will adopt the vorticity formulation [21]:

$$\partial_t\omega + (u_\alpha\cdot\nabla)\omega = \nabla u_\alpha\cdot\omega, \tag{2}$$

where u, ω, the α-averaged velocity u_α, and the divergence-free vector stream function ψ are related by

$$-\triangle\psi = \omega, \quad u = \nabla\times\psi, \tag{3}$$

$$u_\alpha = (1-\alpha^2\triangle)^{-1}u. \tag{4}$$

One of the important properties of the averaged Euler equations is the following identity (see (3.3) on page 1457 of [21]; recall that u_α is called u in [21]):

$$\frac{1}{2}\frac{d}{dt}\int_{R^3}\left(|u_\alpha|^2+\alpha^2|\nabla u_\alpha|^2\right)dx = 0.$$

This conservation property gives a priori bound on the H^1 norm of u_α:

$$\|u_\alpha\|_{H^1}\le C_\alpha. \tag{5}$$

The above reformulation gives a clear physical interpretation of the Lagrangian averaged Euler equations. The vorticity is convected by the α-averaged velocity field. If one discretizes the averaged Lagrangian Euler equations by the point vortex method, i.e., to approximate the initial vorticity by a collection of point vortices (Dirac delta functions), then the resulting numerical approximation is a vortex blob method with α being the vortex blob size [23, 14].

With the above interpretation of the averaged Lagrangian Euler equations, we can clearly apply the same averaging principle to other fluid dynamics equations. For example, if we apply the same Lagrangian averaging principle to the density equation, we would obtain the following Lagrangian averaged 2D Boussinesq equations:

$$\omega_t + u\cdot\nabla\omega = \rho_{x_1}, \tag{6}$$

$$\rho_t + u_\alpha\cdot\nabla\rho = 0\,, \tag{7}$$

where $u_\alpha = (1-\alpha^2\triangle)^{-1}u$ and u is related to the vorticity ω through the usual vorticity stream function formulation; see (3). We refer the reader to [25] for the derivation and discussions of the physical applications for the Boussinesq equations. Note that we replace the velocity by the averaged velocity only in the density equation but not in the vorticity equation. We remark that the global well-posedness of the viscous 2D Boussinesq equations has been obtained in [17].

Similarly, we can derive the Lagrangian averaged 2D quasi-geostrophic equations as follows:

$$\theta_t + u_\alpha\cdot\nabla\theta = 0, \tag{8}$$

$$u = \nabla^\perp\psi, \quad (-\triangle)^{1/2}\psi = \theta, \tag{9}$$

$$u_\alpha = (1-\alpha^2\triangle)^{-1/2}u\,, \tag{10}$$

where $\nabla^\perp \psi = (\partial_{x_2}\psi, -\partial_{x_1}\psi)$ and $(-\triangle)^{1/2}$ is defined as

$$(-\triangle)^{1/2}\psi \equiv \int e^{2\pi i x\cdot\xi}(2\pi|\xi|)\hat{\psi}(\xi)\, d\xi,$$

with $\hat{\psi}(\xi)$ being the Fourier transform of ψ. We refer the reader to [9] for derivation and discussions of the quasi-geostrophic equation. Note that we use a weaker averaged velocity field for the 2D quasi-geostrophic equation. The exponent 1/2 in the averaging operator corresponds to the critical case in the corresponding dissipative quasi-geostrophic equations [8].

In this paper, we prove that a necessary and sufficient condition for the global existence is that the bounded mean oscillation (BMO) norm (see [18]) of the stream function is integrable in time. This is an analogue of the well-known Beale–Kato–Majda condition [1] for the 3D Euler equations. For some recent results on the 3D Euler equations that explore the geometric properties of the Euler flow, we refer the reader to [10, 11]. Moreover, using a level formulation, we derive a sufficient condition for the global existence. The nonblow-up condition we obtain is expressed in terms of the total variation of a level set function; see (53) in section 3 for the precise definition. Assume that the initial vorticity can be expressed in the form $\omega(0,x) = \omega_0(\phi_0,\psi_0)\nabla\phi_0 \times \nabla\psi_0$ for some smooth and bounded level set functions ϕ_0 and ψ_0. Let ϕ and ψ be the level set functions satisfying

$$\begin{aligned} &\phi_t + (u_\alpha \cdot \nabla)\phi = 0, \quad \phi(0,x) = \phi_0(x),\\ &\psi_t + (u_\alpha \cdot \nabla)\psi = 0, \quad \psi(0,x) = \psi_0(x). \end{aligned}$$

Then vorticity can be expressed in terms of these two level set functions:

$$\omega = \omega_0(\phi,\psi)\nabla\phi \times \nabla\psi.$$

Moreover, if the total variation of either ϕ or ψ is integrable in time, then there is no finite time blow-up of the 3D averaged Euler equations. This result has a geometric interpretation. In particular, it excludes the possibility of a finite number of isolated singularities when vorticity is considered as a 1D function by fixing the other two variables. If there is a finite time singularity, the 1D restriction of vorticity must be highly oscillatory at the singularity time, and the singularities are dense in the singular region. We remark that global well-posedness of a family of Navier–Stokes alpha-like models has been recently studied by Olson and Titi [24].

Application of the same argument to the corresponding 2D models gives much sharper existence results. In particular, we prove the global existence of the Lagrangian averaged 2D Boussinesq equations and the averaged 2D quasi-geostrophic equations in finite Sobolev spaces without any assumption on the solution itself.

The rest of the paper is organized as follows. In section 2, we prove the necessary and sufficient condition for the 3D Lagrangian averaged Euler equations and prove the global existence for the averaged 2D Boussinesq equations and the averaged 2D quasi-geostrophic equations. In section 3 we present some results for the global existence of the 3D Lagrangian averaged Euler equations using a novel level set formulation.

2. Main results and proofs. In this section, we present three results. The first result is a necessary and sufficient condition for the global existence of the averaged Euler equations. The second result is the global existence of the averaged 2D Boussinesq equations. The third result is the global existence of the averaged 2D

quasi-geostrophic equations. We begin by stating our first result for the 3D averaged Euler equations. Our result uses the BMO norm. Before we state our existence result, we remind the reader of the definition of the BMO norm:

$$\|f\|_{BMO} = \sup_{x\in R^3}\sup_{r>0}\frac{1}{|B_r|}\int |f-\bar{f}|dx,$$

where $\bar{f} = \frac{1}{|B_r|}\int_{B_r} f(y)dy$, $B_r = \{y \in R^3, \quad |y-x| \le r\}$, and $|B_r|$ is the volume of B_r.

THEOREM 1. *Assume that $\omega_0 \in H^m(R^3)$, $m \ge 0$. Then for any $\alpha > 0$, the solution of the Lagrangian averaged 3D Euler equations (2)–(4) has a unique global solution in $H^m(R^3)$ satisfying*

$$\|\omega(t)\|_{H^m} \le C(T)\|\omega_0\|_{H^m} \quad \textit{for} \quad 0 \le t \le T$$

if we have

$$\int_0^T \|\psi\|_{BMO}dt < \infty \tag{11}$$

for any $T > 0$. Conversely, if the maximal time T of the existence of classical solutions is finite, then we necessarily have

$$\int_0^T \|\psi\|_{BMO}dt = \infty. \tag{12}$$

Proof. The proof relies on the following estimate obtained by Kozono and Taniuchi [19]:

$$\|f\|_\infty \le C\left(1 + \|f\|_{BMO}(1 + \log(\|f\|_{W^{s,p}} + e)\right) \tag{13}$$

for all $f \in W^{s,p}$ with $1 < p < \infty$ and $s > n/p$, where n is the space dimension. We remark that inequalities of similar type for various functional spaces have been obtained earlier; see, e.g., [28].

Another useful result is the following embedding estimate in the BMO norm:

$$\|Rf\|_{BMO} \le C\|f\|_{BMO} \tag{14}$$

for any Riesz-type operator R (see [26, 27]).

It follows from (2)–(4) that

$$u_\alpha = (1-\alpha^2\triangle)^{-1}\nabla \times \psi. \tag{15}$$

This implies that

$$\nabla u_\alpha = \tilde{R}\psi, \tag{16}$$

where $\tilde{R} = \nabla(1-\alpha^2\triangle)^{-1}\nabla\times$ is a Riesz-type operator.

Now applying the embedding estimate (14) to (16), we obtain

$$\|\nabla u_\alpha\|_{BMO} \le C\|\psi\|_{BMO}. \tag{17}$$

Using estimates (13) and (17), we get

$$\|\nabla u_\alpha\|_\infty \le C\,(1+\|\nabla u_\alpha\|_{BMO}\log(\|\nabla u_\alpha\|_{W^{1,4}}+e)) \tag{18}$$

$$\le C\,(1+\|\psi\|_{BMO}\log(\|\omega\|_{L^2}+e))\,,$$

where we have used $u=\nabla\times(-\triangle)^{-1}\omega$ and the Sobolev embedding estimate

$$\|\nabla u_\alpha\|_{W^{1,p}} \le C(\|u_\alpha\|_{H^3}) \le C(\|u_\alpha\|_{H^1}+\|\omega\|_{L^2})$$

for $p\in[2,6]$ and the fact that $\|u_\alpha\|_{H^1}$ is bounded from (5).

Next, we perform an energy estimate for the vorticity equation. Multiplying both sides of the vorticity equation (2) by ω and integrating over R^3, we get

$$\frac{1}{2}\frac{d}{dt}\int_{R^3}|\omega|^2dx+\int_{R^3}(u_\alpha\cdot\nabla\omega)\cdot\omega dx=\int_{R^3}(\nabla u_\alpha\omega)\cdot\omega dx. \tag{19}$$

Note that using integration by parts, we have

$$\int_{R^3}(u_\alpha\cdot\nabla\omega)\cdot\omega dx=\frac{1}{2}\int_{R^3}(u_\alpha\cdot\nabla)|\omega|^2dx=-\frac{1}{2}\int_{R^3}(\nabla\cdot u_\alpha)|\omega|^2dx=0, \tag{20}$$

since $\nabla\cdot u_\alpha=0$.

On the other hand, we obtain by using estimate (18)

$$\begin{aligned}\left|\int_{R^3}(\nabla u_\alpha\omega)\cdot\omega dx\right| &\le \|\nabla u_\alpha\|_\infty\int_{R^3}|\omega|^2dx\\ &\le C\,(1+\|\psi\|_{BMO}\log(\|\omega\|_{L^2}+e))\,\|\omega\|_{L^2}^2.\end{aligned} \tag{21}$$

Putting together estimates (19)–(21), we get

$$\frac{1}{2}\frac{d}{dt}\|\omega\|_{L^2}^2 \le C\,(1+\|\psi\|_{BMO}\log(\|\omega\|_{L^2}+e))\,\|\omega\|_{L^2}^2. \tag{22}$$

The Gronwall inequality then implies that

$$\|\omega(t)\|_{L^2}\le C(T)\quad\text{for}\quad 0\le t\le T, \tag{23}$$

since $\int_0^T\|\psi\|_{BMO}dt<\infty$ by our assumption (11). Moreover,

$$\|\nabla u_\alpha(t)\|_\infty \le C||u_\alpha||_{H^3}\le C(||u_\alpha||_{H^1}+||\omega||_{L^2})\le C(T). \tag{24}$$

Using (2) and (24), we can easily show that

$$\|\omega(t)\|_\infty\le\|\omega_0\|_\infty\exp\left(\int_0^T\|\nabla u_\alpha\|_\infty dt\right)\le C(T)\quad\text{for}\quad 0\le t\le T. \tag{25}$$

Now it is a standard exercise to obtain energy estimates in high-order Sobolev norms [20]

$$\frac{d}{dt}\|\omega\|_{H^m}\le C_m(\|\nabla u_\alpha\|_\infty+\|\omega\|_\infty)\|\omega\|_{H^m}. \tag{26}$$

Since $\|\nabla u_\alpha(t)\|_\infty$ and $\|\omega(t)\|_\infty$ are bounded for $0 \le t \le T$, we obtain the desired estimate for $\|\omega\|_{H^m}$ up to time T.

Now if the maximal time T of the existence of classical solutions is finite, then we must have

$$\int_0^T \|\psi\|_{BMO} dt = \infty,$$

since if $\int_0^T \|\psi\|_{BMO} dt < \infty$, the above argument would imply that $\|\omega(t)\|_{H^m} \le C(T)\|\omega_0\|_{H^m}$ for $t \le T$, which is a contradiction. This completes the proof.

Next, we prove the global existence of the averaged Boussinesq equations (6)–(7).

THEOREM 2. *Assume that $\omega_0 \in H^m(R^2)$ and $\rho_0 \in H^{m+1}(R^2)$ for $m \ge 0$. Then for any $\alpha > 0$, the Lagrangian averaged 2D Boussinesq equations* (6)–(7) *have a unique global solution in $H^m(R^2)$ satisfying*

$$\|\omega(t)\|_{H^m} + \|\rho(t)\|_{H^{m+1}} \le C(T)(\|\omega_0\|_{H^m} + \|\rho_0\|_{H^{m+1}}), \quad 0 \le t \le T,$$

for any $T > 0$.

Proof. First, a standard energy estimate shows that $\|u\|_{L^2}$ is bounded since $\|\rho\|_{L^2}$ is conserved in time and bounded.

Let $W = \nabla^\perp \rho$. Then W satisfies the following evolution equation:

$$W_t + (u_\alpha \cdot \nabla) W = \nabla u_\alpha \cdot W. \tag{27}$$

For any odd integer $p > 2$, we multiply (6) by ω^{p-1} and (27) by $|W|^{p-2}W$, respectively, and integrate over R^2. Upon using integration by parts for the convection terms and exploring the incompressibility of the velocity fields, u and u_α, we obtain

$$\begin{aligned} \frac{1}{p}\frac{d}{dt}\int_{R^2} (|\omega|^p + |W|^p)\, dx &\le (1 + \|\nabla u_\alpha\|_\infty) \int_{R^2} |W|^p dx + \int_{R^2} |\omega|^p dx \\ &\le (1 + \|\nabla u_\alpha\|_\infty) \left(\int_{R^2} |\omega|^p dx + \int_{R^2} |W|^p dx \right), \end{aligned} \tag{28}$$

where we have used Yang's inequality to obtain

$$\begin{aligned} \int_{R^2} \omega^{p-1} |\rho_{x_1}| dx &\le \frac{p-1}{p} \int_{R^2} |\omega|^p dx + \frac{1}{p} \int_{R^2} |\rho_{x_1}|^p dx \\ &\le \int_{R^2} |\omega|^p dx + \int_{R^2} |W|^p dx. \end{aligned}$$

Using estimates (13), we get

$$\begin{aligned} \|\nabla u_\alpha\|_\infty &\le C\,(1 + \|\nabla u_\alpha\|_{BMO} \log(\|\nabla u_\alpha\|_{W^{1,p}} + e)) \\ &\le C\,(1 + \|\nabla u_\alpha\|_{BMO} \log(\|\omega\|_{L^p} + e))\,, \end{aligned} \tag{29}$$

where we have used $u = \nabla^\perp(-\triangle)^{-1}\omega$ and the Sobolev embedding estimate

$$\|\nabla u_\alpha\|_{W^{1,p}} \le C(\|u_\alpha\|_{H^1} + \|\omega\|_{L^p})$$

for $p \ge 2$ and the fact that $\|u_\alpha\|_{H^1} \le C\|u\|_{L^2}$ is bounded.

On the other hand, we obtain by using the John–Nirenberg-type estimate (definition of BMO) in two dimensions

$$\|\nabla u_\alpha\|_{BMO} \le C\|\nabla u_\alpha\|_{H^1} \le C\|u\|_{L^2} \le C, \tag{30}$$

where we have used the fact that $\|u\|_{L^2}$ is bounded. Therefore, we obtain by combining (28), (29), and (30) that

$$\frac{d}{dt}\left(\|\omega\|_{L^p}^p + \|W\|_{L^p}^p\right) \le \left(\|\omega\|_{L^p}^p + \|W\|_{L^p}^p\right)\left(1 + \log(\|\omega\|_{L^p}^p + \|W\|_{L^p}^p + e)\right). \tag{31}$$

The Gronwall inequality then implies that

$$\|\omega(t)\|_{L^p} + \|W(t)\|_{L^p} \le C(T) \quad \text{for} \quad 0 \le t \le T. \tag{32}$$

Using (29), (30), and (32), we get

$$\|\nabla u_\alpha(t)\|_\infty \le C(T) \quad \text{for} \quad 0 \le t \le T. \tag{33}$$

It follows from (27) and (33) that

$$\|W(t)\|_\infty \le C(T) \quad \text{for} \quad 0 \le t \le T, \tag{34}$$

which in turns implies that

$$\|\omega(t)\|_\infty \le C(T) \quad \text{for} \quad 0 \le t \le T. \tag{35}$$

Now it is a standard exercise to show [20] that

$$\frac{d}{dt}\left(\|\omega\|_{H^m} + \|W\|_{H^m}\right) \le C(T)(\|\nabla u_\alpha\|_\infty + \|W\|_\infty)(\|\omega\|_{H^m} + \|W\|_{H^m}).$$

The theorem now follows from (34)–(35) and the Gronwall inequality. This completes the proof of the theorem.

Next, we prove the global existence of the averaged 2D quasi-geostrophic equations (8)–(10).

THEOREM 3. *Assume that $\theta_0 \in H^{m+1}(R^2)$ for $m \ge 0$. Then for any $\alpha > 0$, the solution of the Lagrangian averaged 2D quasi-geostrophic equations* (8)–(10) *has a unique global solution in $H^{m+1}(R^2)$ satisfying*

$$\|\theta(t)\|_{H^{m+1}} \le C(T)\|\theta_0\|_{H^{m+1}}), \quad 0 \le t \le T,$$

for any $T > 0$.

Proof. Again, we can perform a standard energy estimate to show that $\|\theta\|_{L^p}$ is bounded by $\|\theta_0\|_{L^p}$ (including $p = \infty$, which can be obtained via the so-called maximum principle).

Let $\omega = \nabla^\perp \theta$. Then ω satisfies the following evolution equation:

$$\omega_t + (u_\alpha \cdot \nabla)\omega = \nabla u_\alpha \cdot \omega. \tag{36}$$

Thus, ω shares the similar vortex stretching term as the 3D Euler equation. Now using an argument similar to our energy estimate for (27), we can obtain

$$\frac{1}{p}\frac{d}{dt}\int_{R^2} |\omega|^p dx \le \|\nabla u_\alpha\|_\infty \int_{R^2} |\omega|^p dx. \tag{37}$$

Note that

$$\nabla u_\alpha = \nabla(1-\alpha^2\triangle)^{-1/2}(-\triangle)^{-1/2}\nabla^\perp\theta \equiv R\theta$$

for some Riesz-type operator R. Using the embedding estimates

$$\|\nabla u_\alpha\|_{BMO} \le C\|\theta\|_{BMO}$$

and

$$\|\nabla u_\alpha\|_{W^{1,p}} \le C\|\theta\|_{W^{1,p}} \le C(\|\theta\|_{L^p} + \|\nabla\theta\|_{L^p}) \quad \text{for } 1 < p < \infty,$$

we obtain using (13) that

$$\begin{aligned}\|\nabla u_\alpha\|_\infty &\le C\left(1 + \|\nabla u_\alpha\|_{BMO}\log(\|\nabla u_\alpha\|_{W^{1,p}} + e)\right)\\ &\le C\left(1 + \|\theta\|_{BMO}\log(\|\theta\|_{L^p} + \|\omega\|_{L^p} + e)\right)\\ &\le C\left(1 + \|\theta\|_\infty \log(\|\omega\|_{L^p} + e)\right)\\ &\le C\left(1 + \log(\|\omega\|_{L^p} + e)\right). \qquad (38)\end{aligned}$$

Substituting (38) into (37) gives

$$\frac{d}{dt}\|\omega\|_{L^p}^p \le C\left(1 + \log(\|\omega\|_{L^p} + e)\right)\|\omega\|_{L^p}^p. \qquad (39)$$

The Gronwall inequality then implies that

$$\|\omega(t)\|_{L^p} \le C(T)\|\omega_0\|_{L^p}, \quad 0 \le t \le T, \qquad (40)$$

which, together with (38), gives

$$\|\nabla u_\alpha\|_\infty \le C(T), \quad 0 \le t \le T. \qquad (41)$$

Now it follows from (41) and (36) that

$$\|\omega\|_\infty \le C(T), \quad 0 \le t \le T. \qquad (42)$$

Now it is a standard exercise to show [20] that

$$\frac{d}{dt}\|\omega\|_{H^m} \le C(T)(\|\omega\|_\infty + \|\nabla u_\alpha\|_\infty)\|\omega\|_{H^m}.$$

The theorem now follows from (41)–(42) and the Gronwall inequality. This completes the proof of the theorem.

3. The level set formulation for the 3D Euler equations. In this section, we will present a level set formulation for the 3D Euler equations and show how they can be used to obtain a sufficient condition to guarantee the global existence of the averaged Euler equations.

We consider the 3D Euler equations in the vorticity form:

$$\partial_t\omega + (u\cdot\nabla)\omega = \nabla u\cdot\omega, \quad \omega(0,x) = \omega_0(x), \qquad (43)$$

where $\omega = \nabla\times u$ and u is divergence-free.

Let $X(t,\alpha)$ be the Lagrangian flow map satisfying

$$\frac{d}{dt}X(t,\alpha) = u(t,X(t,\alpha)), \quad X(0,\alpha) = \alpha. \tag{44}$$

Since u is divergence-free, we know that the determinant of the Jacobian matrix $\frac{\partial X}{\partial \alpha}$ is identically equal to one. It is well known that vorticity along the Lagrangian trajectory has the following analytical expression [6]:

$$\omega(t,X(t,\alpha)) = \frac{\partial X}{\partial \alpha}\omega_0(\alpha). \tag{45}$$

Let $\theta(t,x)$ be the inverse map of $X(t,\alpha)$, i.e., $X(t,\theta(t,x)) \equiv x$. Then it is easy to show that θ satisfies the following evolution equation:

$$\theta_t + (u\cdot\nabla)\theta = 0, \quad \theta(0,x) = x. \tag{46}$$

Let $\theta = (\theta_1,\theta_2,\theta_3)$ and $\omega_0 = (\omega_0^{(1)},\omega_0^{(2)},\omega_0^{(3)})$. Using (45) and the fact that $X_\alpha\theta_x = I$ and $|\theta_x| = 1$, we can show that

$$\omega(t,x) = \omega_0^{(1)}(\theta)\nabla\theta_2\times\nabla\theta_3 + \omega_0^{(2)}(\theta)\nabla\theta_3\times\nabla\theta_1 + \omega_0^{(3)}(\theta)\nabla\theta_1\times\nabla\theta_2. \tag{47}$$

Note that $\theta_j (j = 1,2,3)$ are level set functions convected by the flow velocity u. In general, one can show that if the initial vorticity $\omega(0,x) = \omega_0(\phi_0,\psi_0)\nabla\phi_0\times\nabla\psi_0$ and the level set functions ϕ and ψ satisfy

$$\phi_t + (u\cdot\nabla)\phi = 0, \quad \phi(0,x) = \phi_0(x), \tag{48}$$

$$\psi_t + (u\cdot\nabla)\psi = 0, \quad \psi(0,x) = \psi_0(x), \tag{49}$$

then the vorticity at a later time can be expressed in terms of these two level set functions and their gradients:

$$\omega(t,x) = \omega_0(\phi,\psi)\nabla\phi\times\nabla\psi. \tag{50}$$

This level set formulation has been considered by Deng, Hou, and Yu in their study of the 3D Euler equations [12]. The special case when $\omega_0 = 1$ is also known as the Clebsch representation [7]. In this case, the velocity field has the form

$$u = \nabla p + \phi\nabla\psi$$

for some potential function p.

It is easy to see that the above level set formulation of vorticity for the 3D Euler equations also applies to the 3D Lagrangian averaged Euler equations. The only change is that the level set functions now satisfy

$$\phi_t + (u_\alpha\cdot\nabla)\phi = 0, \quad \phi(0,x) = \phi_0(x), \tag{51}$$

$$\psi_t + (u_\alpha\cdot\nabla)\psi = 0, \quad \psi(0,x) = \psi_0(x). \tag{52}$$

Now we state a sufficient condition for the global existence of the Lagrangian averaged Euler equations in terms of the property of the level set functions defined by (51)–(52). Before we state our result, we first introduce a definition of the total variation of a level set function, ϕ, as follows:

$$\|\phi\|_{TVx_1} = \sup_{x_2,x_3}\int_{-\infty}^{\infty}\left|\frac{\partial}{\partial x_1}\phi(x_1,x_2,x_3)\right|dx_1. \tag{53}$$

We can define $\|\phi\|_{TVx_2}$ and $\|\phi\|_{TVx_3}$ similarly and let $\|\phi\|_{TV} = \sum_{i=1}^{3} \|\phi\|_{TVx_i}$.

THEOREM 4. *Assume that $\omega(0,x) = \omega_0(\phi_0,\psi_0)\nabla\phi_0 \times \nabla\psi_0$ is the form of the initial vorticity, with ω_0, ϕ_0, and ψ_0 being smooth and bounded. Moreover, we assume that ϕ and ψ satisfy* (51)–(52) *such that either $\int_0^T \|\phi\|_{TV}dt < \infty$ or $\int_0^T \|\psi\|_{TV}dt < \infty$ for any $T > 0$. Then the averaged 3D Euler equations have a unique smooth global solution satisfying*

$$\|\omega(t)\|_{H^m} \le C(T)\|\omega(0)\|_{H^m}), \quad 0 \le t \le T,$$

for any $T > 0$.

Remark. As we mentioned before, the above result has a clear geometric interpretation. It implies that if the 1D restriction of the level set function ϕ or ψ has a total variation which is integrable in time, then there is no finite time blow-up. This excludes the possibility of a finite number of isolated singularities when vorticity is considered as a 1D function by fixing the other two variables. In particular, if there is a finite time singularity, the 1D restriction of vorticity must be highly oscillatory at the singularity time, and the singularities are dense in the singular region.

Proof. Recall that

$$u_\alpha = (1-\alpha^2\triangle)^{-1}\nabla \times (-\triangle)^{-1}\omega.$$

Thus we have

$$\nabla u_\alpha = (1-\alpha^2\triangle)^{-1}R\omega,$$

where $R = \nabla\nabla\times(-\triangle)^{-1}$ is a Riesz operator.

First, we consider the special case when $\omega_0 \equiv 1$. In this case, we have $\omega = \nabla\phi\times\nabla\psi$ for all times. Without loss of generality, we may assume that $\int_0^T \|\psi\|_{TV}dt < \infty$. We can further rewrite $\omega = \nabla\times(\phi\nabla\psi)$.

Let $B(y)$ be the integral kernel of the operator $(1-\alpha^2\triangle)^{-1}R$ in R^3. We set $x = 0$ and omit the reference to time. Then we can express

$$\begin{aligned}|\nabla u_\alpha(0)| &= \left|\int_{R^3} B(y)\omega(y)dy\right| \\ &= \left|\int_{R^3} \nabla B(y) \times (\phi(y)\nabla\psi(y))dy\right|.\end{aligned}$$

One can show that

$$|\nabla B(y)| \le \frac{C_\alpha}{|y|^2(1+|y|^{\frac{1}{4}})}. \tag{54}$$

Let B_ϵ denote the ball centered at the origin with radius $\epsilon < 1$. Note that the level set functions ϕ and ψ are bounded for all times. Let $p > 3$, q be the conjugate of p satisfying $\frac{1}{p}+\frac{1}{q} = 1$. Further, we denote $r = \frac{3-2q}{q}$. If y_i is one of the three components of y in R^3, we denote by y' the remaining 2D vector excluding y_i. Then we have

$$\begin{aligned}|\nabla u_\alpha(0)| &= \left|\int_{B_\epsilon} + \int_{|y|\ge\epsilon} \nabla B(y) \times (\phi(y)\nabla\psi(y))dy\right| \\ &\le \|\phi\|_\infty \left(\epsilon^{\frac{3-2q}{q}}\|\nabla\psi\|_{L^p} + \sum_{i=1}^{3}\int_{|y'|^2+|y_i|^2\ge\epsilon^2} \frac{dy'}{(|y_i|^2+|y'|^2)(1+|y|^{\frac{1}{4}})} \int \left|\frac{\partial\psi}{\partial y_i}\right| dy_i\right)\end{aligned}$$

$$\leq \|\phi\|_\infty \left(\epsilon^r \|\nabla\psi\|_{L^p} + \|\psi\|_{TV} \int_{R^2} \frac{dy'}{(\epsilon^2 + |y'|^2)(1+|y|^{\frac{1}{4}})} \right.$$
$$\left. + \|\psi\|_{TV} \int_{|y'|\geq\epsilon} \frac{dy'}{|y'|^2(1+|y'|^{\frac{1}{4}})} \right)$$
$$\leq \|\phi\|_\infty \left(\epsilon^r \|\nabla\psi\|_{L^p} + \|\psi\|_{TV} \log\frac{1}{\epsilon} \right),$$

where we have used the Hölder inequality in the estimate for the inner part. Note that $\|\phi\|_\infty \leq \|\phi_0\|_\infty$. By setting $\epsilon^r(e + \|\nabla\psi\|_{L^p}) = 1$, we obtain

$$|\nabla u_\alpha(0)| \leq C\left(1 + \|\psi\|_{TV} \log(\|\nabla\psi\|_{L^p} + e)\right). \tag{55}$$

Differentiating (52) with respect to x, we obtain

$$(\nabla\psi)_t + (u_\alpha \cdot \nabla)(\nabla\psi) + \nabla u_\alpha \nabla\psi = 0. \tag{56}$$

Performing the energy estimate to (56), we get

$$\frac{\partial}{\partial t}\|\nabla\psi\|_{L^p} \leq \|\nabla u_\alpha\|_\infty \|\nabla\psi\|_{L^p}$$
$$\leq C\left(1 + \|\psi\|_{TV} \log(\|\nabla\psi\|_{L^p} + e)\right) \|\nabla\psi\|_{L^p}.$$

The Gronwall inequality then implies that

$$\|\nabla\psi\|_{L^p} \leq C(T), \tag{57}$$

provided that $\int_0^T \|\psi\|_{TV} dt < \infty$. Substituting (57) back into (55), we conclude that

$$\int_0^T \|\nabla u_\alpha\|_\infty dt \leq C \int_0^T \|\psi\|_{TV} dt \leq C(T). \tag{58}$$

The bound on $\int_0^T \|\nabla u_\alpha\|_\infty dt$ immediately gives the maximum bound on $\nabla\psi$ from (56). Similarly, we obtain the maximum bound for $\nabla\phi$. Combining the maximum estimates for $\nabla\psi$ and $\nabla\phi$, we obtain the maximum bound for vorticity ω. Then it is a standard argument to prove the energy estimate for ω in the H^m norm using

$$\frac{\partial}{\partial t}\|\omega\|_{H^m} \leq C(\|\nabla u_\alpha\|_\infty + \|\omega\|_\infty)\|\omega\|_{H^m}.$$

It remains to comment on the more general case when $\omega_0 \neq 1$. Note that

$$\omega_0(\phi,\psi)\nabla\phi\times\nabla\psi = \nabla(\omega_0\phi)\times\nabla\psi - \phi(\omega_0)_\phi \nabla\phi\times\nabla\psi$$
$$= \nabla\times(\omega_0\phi\nabla\psi) - \phi(\omega_0)_\phi\nabla\phi\times\nabla\psi.$$

Define

$$h(\phi,\psi) = \int_0^\phi s(\omega_0)_\phi(s,\psi)ds.$$

Then we have

$$\nabla h(\phi,\psi) = h_\phi\nabla\phi + h_\psi\nabla\psi$$
$$= \phi(\omega_0)_\phi\nabla\phi + h_\psi\nabla\psi.$$

This implies that

$$\begin{aligned}(\phi(\omega_0)_\phi \nabla\phi) \times \nabla\psi &= \nabla h \times \nabla\psi - h_\psi \nabla\psi \times \nabla\psi \\ &= \nabla \times (h\nabla\psi).\end{aligned}$$

Note that h is bounded since both ϕ and $(\omega_0)_\phi$ are bounded. Therefore, we can rewrite

$$\omega_0(\phi,\psi)\nabla\phi \times \nabla\psi = \nabla \times (\omega_0\phi\nabla\psi) - \nabla \times (h\nabla\psi),$$

with both $\omega_0\phi$ and h being bounded. Thus the previous argument for $\omega_0 = 1$ applies to the case when $\omega_0 \neq 1$. This completes the proof of the theorem.

A FULLY NONLINEAR VERSION OF THE INCOMPRESSIBLE EULER EQUATIONS: THE SEMIGEOSTROPHIC SYSTEM*

G. LOEPER†

Abstract. The semigeostrophic equations are used in meteorology. They appear as a variant of the two-dimensional Euler incompressible equations in vorticity form, where the Poisson equation that relates the stream function and the vorticity field is just replaced by the fully nonlinear elliptic Monge–Ampère equation. This work gathers new results concerning the semigeostrophic equations: existence and stability of measure-valued solutions, existence and uniqueness of solutions under certain continuity conditions for the density, and convergence to the incompressible Euler equations.

Key words. semigeostrophic equations, Monge–Ampère equations, optimal transportation

1. Introduction.

The semigeostrophic equations are an approximation of the Euler equations of fluid mechanics used in meteorology to describe atmospheric flows. They are believed (see [12]) to be an efficient model in describing frontogenesis. Different versions (incompressible [1], shallow water [10], compressible [11]) of this model have been studied, and we will focus here on the incompressible two-dimensional (2-d) and three-dimensional (3-d) versions. The 3-d model describes the behavior of an incompressible fluid in a domain $\Omega \subset \mathbb{R}^3$. To the evolution in Ω is associated a motion in a "dual" space, described by the following nonlinear transport equation:

$$\begin{aligned} &\partial_t \rho + \nabla \cdot (\rho \mathbf{v}) = 0, \\ &\mathbf{v} = (\nabla \Psi(x) - x)^{\perp}, \\ &\det D^2 \Psi = \rho, \\ &\rho(t=0) = \rho^0. \end{aligned}$$

Here ρ^0 is a probability measure on $\mathbb{R}^3$, and for every $\mathbf{v} = (v_1, v_2, v_3) \in \mathbb{R}^3$, $\mathbf{v}^{\perp}$ stands for $(-v_2, v_1, 0)$. The velocity field is recovered at each time step by solving a Monge–Ampère equation in the sense of the polar factorization of maps (see [3]), i.e., in the sense that Ψ is convex from $\mathbb{R}^3$ to $\mathbb{R}$ and satisfies $\nabla \Psi_{\#} \rho = \chi_\Omega \mathcal{L}^3$, where $\mathcal{L}^3$ is the Lebesgue measure of $\mathbb{R}^3$, and χ_Ω is the indicator function of Ω. It is imposed as a compatibility condition that Ω has Lebesgue-measure one. This model arises as an approximation of the primitive equations of meteorology, and we shall give a brief idea of the derivation of the model, although the reader interested in more details should refer to [12].

In this work we will deal with various questions related to the semigeostrophic (SG) system: existence and stability of measure-valued solutions, existence and uniqueness of smooth solutions, and finally convergence toward the incompressible Euler equations in 2-d. As stated in the title, we will exploit throughout the paper the

strong analogy with the 2-d incompressible Euler equations that we recall here:

$$\begin{aligned}
&\partial_t \omega + \nabla \cdot (\omega \mathbf{v}) = 0,\\
&\mathbf{v} = (\nabla \Phi)^{\perp},\\
&\Delta \Phi = \omega,\\
&\omega(t=0) = \omega^0.
\end{aligned}$$

We recognize clearly that the vorticity ω here plays the role of the density ρ in the SG system. One obtains the SG system just by replacing the Poisson equation $\Delta\Phi = \omega$ by the Monge–Ampère equation $\det(I + D^2\Phi) = \omega$. (However, note that the density ρ does not have a clear physical interpretation since it is a density in a dual space.) From this analogy, and inspired by the well-developed mathematical theory on the 2-d Euler equations (see [21] for instance), the goal of this paper is twofold:

The first goal is to the study of the initial value problem for the SG system. We will first establish a global existence result for weak measure-valued solutions, hence giving a framework for weak solutions that strictly contains the results obtained in previous works. We will also obtain local smooth solutions, trying to lower as much as possible the requirement on the initial data, and prove uniqueness in a certain class of smooth solutions. This well-posedness result for smooth initial data will be our main result.

The second goal is to give some rigorous mathematical justification of the derivation of the SG system from the 2-d Euler equations. In an attempt in this direction, we will show that in some asymptotic regime (namely, "small" solutions over a long time) the SG system and the 2-d Euler system are asymptotically close.

We will use a combination of various techniques: The SG system is a transport equation, and we will study it as such, using either the Eulerian or the Lagrangian point of view. Since the coupling between density and velocity field involves a Monge–Ampère equation, we will also rely on the regularity theory developed for this fully nonlinear elliptic equation, which is much more recent and far less known than the results on solutions to the Poisson equation. More originally we will use optimal transportation and the technique developed in [18] to show uniqueness of certain solutions. Note (though this is a coincidence) that optimal transportation will appear earlier in the present paper in the derivation of the SG system. Finally the proof of convergence toward the incompressible Euler equations will be made using modulated energy techniques, a general technique (also known as the "relative entropy method," documented in [13]) used for the asymptotic study of hyperbolic systems.

The paper is organized as follows: In the next paragraph we give a brief description of the derivation of the SG system from the Euler incompressible equations. To formulate rigorously the system, we then review the results concerning optimal transportation and polar factorization of maps, which are key concepts used throughout this paper (section 1.2). We are then able to formulate the SG system, both in its Lagrangian and Eulerian (or dual) forms (sections 1.3 and 1.4).

Section 1.5 is dedicated to a longer discussion on the results obtained and gives a sketch of some of the crucial arguments. This section closes the introduction. Each of the following sections is dedicated to the proof of one of the results.

Section 2 is devoted to the existence of a weak measure-valued solution, in section 3 we show existence of Dini continuous solutions, in section 4 we show uniqueness of solutions with Hölder continuous density, and in section 5 we show the convergence of solutions of SG equations toward solutions of the 2-d Euler incompressible equations.

All those results will be reviewed and discussed in greater detail in section 1.5, after we have derived the SG equations.

1.1. Derivation of the SG equations. We now give for the sake of completeness a brief and simplified idea of the derivation of the system, inspired by [1]; more complete arguments can be found in [12].

Lagrangian formulation. We start with the 3-d incompressible Euler equations with constant Coriolis parameter f in a domain Ω.

$$\begin{aligned}&\frac{D\mathbf{v}}{Dt} + f\mathbf{v}^\perp = \frac{1}{\rho}\nabla p - \nabla\varphi,\\ &\nabla\cdot\mathbf{v} = 0, \quad \frac{D\rho}{Dt} = 0,\\ &\mathbf{v}\cdot\partial\Omega = 0,\end{aligned}$$

where $\frac{D\cdot}{Dt}$ stands for $\partial_t + \mathbf{v}\cdot\nabla$, and we still use $\mathbf{v}^\perp = (-v_2, v_1, 0)$. The term $\nabla\varphi$ denotes the gravitational effects (here we will take $\varphi = gx_3$ with constant g), and the term $f\mathbf{v}^\perp$ is the Coriolis force due to rotation of the Earth. For large scale atmospheric flows, the Coriolis force $f\mathbf{v}^\perp$ dominates the advection term $\frac{D\mathbf{v}}{Dt}$ and renders the flow mostly 2-d. We use the hydrostatic approximation, $\partial_{x_3} p = -\rho g$, and restrict ourselves to the case $\rho \equiv 1$.

Keeping only the leading order terms leads to the geostrophic balance

$$\mathbf{v}_g = -f^{-1}\nabla^\perp p,$$

which defines $\mathbf{v}_g$, the geostrophic wind. Decomposing $\mathbf{v} = \mathbf{v}_g + \mathbf{v}_{ag}$, where the second component is the ageostrophic wind, a supposed small departure from the geostrophic balance, the SG system reads

$$\begin{aligned}\frac{D\mathbf{v}_g}{Dt} + f\mathbf{v}^\perp &= \nabla_H p,\\ \nabla\cdot\mathbf{v} &= 0,\end{aligned}$$

where $\nabla_H = (\partial_{x_1}, \partial_{x_2}, 0)$. Note, however, that the advection operator $\partial_t + \mathbf{v}\cdot\nabla$ still uses the full velocity $\mathbf{v}$. Introducing the potential

$$\Phi = \frac{1}{2}|x_H|^2 + f^{-2}p,$$

with $x_H = (x_1, x_2, 0)$, we obtain

$$\frac{D}{Dt}\nabla\Phi(t,x) = f(x - \nabla\Phi(t,x))^\perp.$$

We introduce the Lagrangian map $\mathbf{g} : \Omega\times\mathbb{R}^+ \mapsto \Omega$, giving the position at time t of the particle of fluid located at x_0 at time 0. The previous equation means that if for fixed $x \in \Omega$ we consider the trajectory in the "dual" space, defined by $X(t,x) = \nabla\Phi(t, \mathbf{g}(t,x))$, we have

$$\partial_t X(t,x) = f\left(\mathbf{g}(t,x) - X(t,x)\right)^\perp.$$

By rescaling the time, we can set $f = 1$. Under this form the system looks underdetermined: Indeed Φ is unknown; however, we have the condition $X(t,x) =$

$\nabla\Phi(t, \mathbf{g}(t,x))$. Moreover, the motion of the fluid being incompressible and contained in Ω, the map $\mathbf{g}(t,\cdot)$ must be measure preserving in Ω for each t, i.e.,

$$\mathcal{L}^3(\mathbf{g}(t)^{-1}(B)) = \mathcal{L}^3(B)$$

for each $B \subset \Omega$ measurable (where $\mathcal{L}^3$ denotes the Lebesgue measure of $\mathbb{R}^3$). We shall hereafter denote by $G(\Omega)$ the set of all such measure preserving maps. Then Cullen's stability criteria [12] asserts that the potential Φ should be convex for the system to be stable to small perturbations of a particle's positions in the x space. Indeed the convexity of Φ asserts that $\nabla\Phi$ minimizes some potential energy (the reader interested in a more detailed explanation of this variational principle should refer to [12]).

Hence, for each t, Φ must be a convex function such that

$$X(t,\cdot) = \nabla\Phi(t, \mathbf{g}(t,\cdot)),$$

with $\mathbf{g}(t,\cdot) \in G(\Omega)$.

In the next paragraph we shall see that, under very mild assumptions on X, this decomposition, called polar factorization, can only happen for a unique choice of $\mathbf{g}$ and $\nabla\Phi$. Now if Φ^* is the Legendre transform of Φ,

$$\Phi^*(y) = \sup_{x\in\Omega} x\cdot y - \Phi(x),$$

then $\nabla\Phi$ and $\nabla\Phi^*$ are inverse maps of each other, and the SG system then reads

$$\frac{DX}{Dt} = \left(\nabla\Phi^*(X(t)) - X(t)\right)^{\perp},$$

$$\nabla\Phi^*(t)\circ X(t) \in G(\Omega).$$

In this context, $X(t)$ is thus the dual trajectory to the physical trajectory $\mathbf{g}(t)$, and $(\nabla\Phi^*(X(t)) - X(t))^{\perp}$ is up to a multiplicative constant, the geostrophic wind at point $\mathbf{g}(t) = \nabla\Phi^*(X(t))$.

In the next paragraph, we review the results concerning the existence and uniqueness of the gradients $\nabla\Phi, \nabla\Phi^*$.

1.2. Polar factorization of vector valued maps. The polar factorization of maps has been discovered by Brenier in [3]. It was later extended to the case of general Riemannian manifolds by McCann in [23].

The Euclidean case. Let Ω be a fixed bounded domain of $\mathbb{R}^d$ of Lebesgue measure 1 and satisfying the condition $\mathcal{L}^d(\partial\Omega) = 0$. We consider a mapping $X \in L^2(\Omega;\mathbb{R}^d)$. We will also consider the push-forward of the Lebesgue measure of Ω by X, which we will denote by $X_{\#}\chi_\Omega\mathcal{L}^d = d\rho$ (or, in short, $X_{\#}dx$) and which is defined by

$$\forall f \in C_b^0(\mathbb{R}^d),\ \int_{\mathbb{R}^d} f(x)\ d\rho(x) = \int_\Omega f(X(x))\ dx.$$

Let $\mathcal{P}$ be the set of probability measures $\mathbb{R}^d$, and let $\mathcal{P}_a^2$ be the subset of $\mathcal{P}$ where the subscript a means absolutely continuous with respect to the Lebesgue measure (or equivalently that have a density in $L^1(\mathbb{R}^d)$), and the superscript 2 means with finite second moment, i.e., such that

$$\int_{\mathbb{R}^d} |x|^2 d\rho(x) < +\infty.$$

Note that for $X \in L^2(\Omega, \mathbb{R}^d)$, the measure $\rho = X_{\#}dx$ has necessarily a finite second moment, and thus belongs to $\mathcal{P}^2$.

THEOREM 1.1 (Brenier [3]). *Let Ω be as above, $X \in L^2(\Omega; \mathbb{R}^d)$, and $\rho = X_{\#}dx$.*

1. *There exists a unique up to a constant convex function, which will be denoted $\Phi[\rho]$, such that*

$$\forall f \in C_b^0(\mathbb{R}^d),\ \int_\Omega f(\nabla\Phi[\rho](x))\ dx = \int_{\mathbb{R}^d} f(x)d\rho(x).$$

2. *Let $\Psi[\rho]$ be the Legendre transform of $\Phi[\rho]$. If $\rho \in \mathcal{P}_a^2$, then $\Psi[\rho]$ is the unique up to a constant convex function satisfying*

$$\forall f \in C_b^0(\Omega),\ \int_{\mathbb{R}^d} f(\nabla\Psi[\rho](x))\ d\rho(x) = \int_\Omega f(x)dx.$$

3. *If $\rho \in \mathcal{P}_a^2$, X admits the following unique polar factorization:*

$$X = \nabla\Phi[\rho] \circ g,$$

with $\Phi[\rho]$ convex, g measure preserving in Ω.

Remark. $\Psi[\rho], \Phi[\rho]$ depend only on ρ, and are solutions (in some weak sense) in $\mathbb{R}^d$ and Ω, respectively, of the Monge–Ampère equations

$$\begin{aligned} \det D^2\Psi &= \rho, \\ \rho(\nabla\Phi)\ \det D^2\Phi &= 1. \end{aligned}$$

When Ψ and Φ are not in C_{loc}^2 these equations can be understood in the viscosity (or Alexandrov) sense or in the sense of Theorem 1.1, which is strictly weaker. For the consistency of the different weak formulations and regularity issues, the reader can refer to [8].

The periodic case. The polar factorization theorem has been extended to Riemannian manifolds in [23] (see also [9] for the case of the flat torus). In this case, we consider a mapping $X : \mathbb{R}^d \mapsto \mathbb{R}^d$ such that for all $\vec{p} \in \mathbb{Z}^d$, $X(\cdot + \vec{p}) = X + \vec{p}$. Then $\rho = X_{\#}dx$ is a probability measure on $\mathbb{T}^d$. We define $\Psi[\rho], \Phi[\rho]$ through the following.

THEOREM 1.2. *Let $X : \mathbb{R}^d \to \mathbb{R}^d$ be as above, with $\rho = X_{\#}dx$.*

1. *Up to an additive constant there exists a unique convex function $\Phi[\rho]$ such that $\Phi[\rho](x) - x^2/2$ is $\mathbb{Z}^d$-periodic (and thus $\nabla\Phi[\rho](x) - x$ is $\mathbb{Z}^d$-periodic), and*

$$\forall f \in C^0(\mathbb{T}^d),\ \int_{\mathbb{T}^d} f(\nabla\Phi[\rho](x))\ dx = \int_{\mathbb{T}^d} f(x)\ d\rho(x).$$

2. *Let $\Psi[\rho]$ be the Legendre transform of $\Phi[\rho]$. If ρ is Lebesgue integrable, then $\Psi[\rho]$ is the unique up to a constant convex function satisfying the statement that $\Psi[\rho](x) - x^2/2$ is $\mathbb{Z}^d$-periodic (and thus $\nabla\Psi[\rho](x) - x$ is $\mathbb{Z}^d$-periodic), and*

$$\forall f \in C^0(\mathbb{T}^d),\ \int_{\mathbb{T}^d} f(\nabla\Psi[\rho](x))\ d\rho(x) = \int_{\mathbb{T}^d} f(x)\ dx.$$

3. *If ρ is Lebesgue integrable, X admits the following unique polar factorization:*

$$X = \nabla\Phi[\rho] \circ g,$$

with g measure preserving from $\mathbb{T}^d$ into itself, and $\Phi[\rho]$ convex, $\Phi[\rho] - |x|^2/2$ periodic.

Remark 1. From the periodicity of $\nabla\Phi[\rho](x) - x, \nabla\Psi[\rho](x) - x$, for every f $\mathbb{Z}^d$-periodic, $f(\nabla\Psi[\rho]), f(\nabla\Phi[\rho])$ are well defined on $\mathbb{R}^d/\mathbb{Z}^d$.

Remark 2. Both in the periodic and nonperiodic cases, the definitions of $\Psi[\rho]$ and $\Phi[\rho]$ make sense if ρ is absolutely continuous with respect to the Lebesgue measure. If not, the definition and uniqueness of $\Phi[\rho]$ is still valid, as well as the property $\nabla\Phi[\rho]_{\#}\rho = \chi_\Omega \mathcal{L}^d$. The definition of $\Psi[\rho]$ as the Legendre transform of $\Phi[\rho]$ is still valid also, but then the expression $\int f(\nabla\Psi[\rho](x))\, d\rho(x)$ does not necessarily make sense since $\nabla\Psi[\rho]$ is not necessarily continuous, and hence not defined $d\rho$ almost everywhere. Moreover the polar factorization no longer holds.

Remark 3. We have (see [9]) the unconditional bound

$$\|\nabla\Psi[\rho](x) - x\|_{L^\infty(\mathbb{T}^d)} \leq \sqrt{d}/2,$$

which will be useful later on.

1.3. Lagrangian formulation of the SG system. From Theorems 1.1 and 1.2 the Lagrangian formulation of the SG equation then becomes

$$\frac{DX}{Dt} = [\nabla\Psi(X) - X]^\perp, \tag{1}$$

$$\Psi = \Psi[\rho], \quad \rho = X_{\#}dx. \tag{2}$$

1.4. Eulerian formulation in dual variables. In both cases (periodic and nonperiodic) we thus investigate the following system, which will be referred to as *SG in dual variables* (but we will only say SG hereafter): We look for a time-dependent probability measure $t \to \rho(t, \cdot)$ satisfying

$$\partial_t\rho + \nabla \cdot (\rho\mathbf{v}) = 0, \tag{3}$$

$$\mathbf{v}(t,x) = (\nabla\Psi[\rho(t)](x) - x)^\perp, \tag{4}$$

$$\rho(t=0) = \rho^0. \tag{5}$$

Global existence of weak solutions (which are defined below) of this system with L^p initial data for $p \geq 1$ has been shown in [1], [10], [20].

1.5. Results. In this work we deal with various mathematical problems related to this system: We first extend the notion of weak solutions that have been shown to exist for $\rho \in L^\infty(\mathbb{R}_+, L^q(\mathbb{R}^3))$, $q > 1$ (see [1], [10]), and then for $\rho \in L^\infty(\mathbb{R}_+, L^1(\mathbb{R}^3))$ (see [20]), to the more general case of bounded measures. The question of existence of measure-valued solutions was raised and left unanswered in those papers, and we show here existence of global solutions to the Cauchy problem with initial data a bounded compactly supported measure, and we show the weak stability/compactness of these *weak measure* solutions.

Then we show existence of continuous solutions; more precisely, we show local existence of solutions with Dini continuous (see (12)) density. For these solutions, the velocity field is then C^1 and the Lagrangian system (1)–(2) is defined everywhere.

This proof relies heavily on the available regularity results on solutions to the Monge–Ampère equation (Theorem 3.1). Note that the Dini condition is the lowest condition known on the right-hand side of the Poisson equation that enforces C^2 regularity for the solution. Our result is not totally satisfactory since it does not provide existence of a global smooth solution, which is the case for the 2-d incompressible Euler equation. The reason for this more powerful result is that for the Poisson equation

$$\Delta\Phi = \omega,$$

ω bounded implies that $\nabla\Phi$ is log-Lipschitz. This continuity is slightly weaker than the Lipschitz continuity, but allows one to define a Hölder continuous flow (see [21]). Moreover, the flow being incompressible, this implies (when $d = 2$) that the vorticity is just transported along the streamlines. The construction of global smooth solutions can then be achieved only by using those two arguments.

For the SG system, solutions to

$$\det D^2\Psi = \rho$$

are only $C^{1,\alpha}$ when ρ is merely bounded. This is not enough to build a continuous flow and prevents us from obtaining the same results as for Euler.

We also show uniqueness in the class of Hölder continuous solutions (a subclass of Dini continuous solutions). This proof uses in a crucial way the optimal transportation of measures by convex gradients and its regularity properties, and can be adapted to give a new proof of uniqueness for solutions of the 2-d Euler equation with bounded vorticity, but also for a broad class of nonlinearly coupled system. The typical application is a density evolving through a transport equation where the velocity field depends on the gradient of a potential. The potential is obtained by solving an elliptic equation, where the density appears in the right-hand side. Well-known examples of such cases are the Vlasov–Poisson and Euler–Poisson systems (see [18]). We point out that the results of existence and uniqueness obtained here are all obtained by working in a purely Lagrangian framework.

Finally, in the 2-d case, we study the convergence of the system to the Euler incompressible equations; this convergence is expected for ρ close to 1, since formally expanding $\Psi = x^2/2 + \epsilon\psi$, and linearizing the determinant around the identity matrix, we get

$$\rho = \det D^2\Psi = 1 + \epsilon\Delta\psi + O(\epsilon^2),$$

and the Monge–Ampère equation turns into the Poisson equation

$$\Delta\psi = \frac{\rho - 1}{\epsilon} =: \mu.$$

We then perform the change of time scale $t \to t/\epsilon$ and consider now $\mu^\epsilon(t) := \mu(\frac{t}{\epsilon})$. Then μ^ϵ solves

$$\begin{aligned} \partial_t\mu^\epsilon + \nabla\cdot(\mu^\epsilon\nabla^\perp\psi^\epsilon) &= O(\epsilon), \\ \Delta\psi^\epsilon &= \mu^\epsilon, \end{aligned}$$

which, when we set $O(\epsilon) = 0$, we recognize as the vorticity formulation of the 2-d Euler incompressible equation.

Let us comment on this scaling: We consider a small solution to SG, i.e., a solution where $\rho - 1$ is small. We then expand this solution by a factor of ϵ^{-1} and study it on a time scale of order ϵ^{-1}.

From a physical point of view, this asymptotic study may be seen as a justification of the consistency of the SG approximation when $d = 2$. Indeed, when $d = 2$, the Euler equations are not affected by the Coriolis force, i.e., the solutions to

$$\partial_t v + v \cdot \nabla v = -\nabla p, \tag{6}$$

$$\mathrm{div} v = 0 \tag{7}$$

and to

$$\partial_t v + v \cdot \nabla v + f v^\perp = -\nabla p, \tag{8}$$

$$\mathrm{div} v = 0 \tag{9}$$

are the same, since the term $v^\perp$ can be considered a pressure term (remember that $v = \nabla^\perp \Phi$). The term f is just a time scale, and the geostrophic regime is the one where $\frac{v}{L} \ll f$, where v denotes here the typical size of v and L the typical space scale of the system. Then, note that if $v(t,x)$ is a solution to (6), so is $v^\epsilon = \epsilon v(\epsilon t, x)$. But the ratio $\frac{v^\epsilon}{L}$ goes to 0 as ϵ goes to 0 (note that the space scales for v and v^ϵ are the same). Hence, in the limit $\epsilon \to 0$, i.e., for small solutions to Euler, the geostrophic approximation should be valid. It is precisely in this regime that we show that the SG system and the incompressible Euler system are asymptotically close to each other, since for SG, a small solution is one where ρ is close to 1. Hence what we show is the following: Let ρ^0 be a "small" initial data for SG. Consider μ^ϵ obtained from ρ as explained above; then μ^ϵ is close to some ω where ω solves the 2-d Euler incompressible equation in vorticity form

$$\partial_t \omega + \nabla \cdot (\omega \nabla^\perp \phi) = 0,$$
$$\Delta \phi = \omega.$$

In other words, when ρ goes to 1, ρ is equivalent to a solution of Euler, on a time that goes to infinity.

The study of this "quasi-neutral" limit is done in two different ways: One uses a modulated energy method similar to the one used in [4] and [5] and is valid for weak solutions. The other uses a more classical expansion of the solution, and regularity estimates, and is similar to the method used in [17]. The second method also yields almost global solutions: Indeed, it will be shown in this paper that smooth (say, with Lipschitz density) solutions exists in short time. The asymptotic study of the convergence to Euler shows that the Lipschitz bound on the solution remains valid on a time that goes to infinity when the solution is chosen with an initial condition that converges toward the uniform density.

2. Measure-valued solutions.

2.1. A new definition of weak solutions. We have first the following classical weak formulation of (3): $\rho \in C(\mathbb{R}+, L^1(\mathbb{R}^3) - w)$ is said to be a weak solution of SG if

$$\forall T > 0, \quad \forall \varphi \in C_c^\infty([0,T] \times \mathbb{R}^2),$$
$$\int \partial_t \varphi \, \rho + \nabla \varphi \cdot (\nabla \Psi[\rho] - x)^\perp \, \rho \, dt dx = \int \varphi(T,x) \rho(T,x) dx - \int \varphi(0,x) \rho(0,x) dx,$$

where, for all t, $\Psi[\rho]$ is as in Theorem 1.1. The problematic part in the case of measure-valued solutions is to give sense to the product $\rho\nabla\Psi[\rho]$ since at the point where ρ is singular $\nabla\Psi[\rho]$ is unlikely to be continuous. Therefore we use Theorem 1.1 to write, for any $\rho \in \mathcal{P}_a^2(\mathbb{R}^3)$,

$$\forall \varphi \in C_c^\infty(\mathbb{R}^3), \quad \int_{\mathbb{R}^3} \rho \nabla\Psi[\rho]^\perp \cdot \nabla\varphi = \int_\Omega x^\perp \cdot \nabla\varphi(\nabla\Phi[\rho])$$

(the integrals would be performed over $\mathbb{T}^3$ in the periodic case). The property $\nabla\Phi[\rho]_{\#}\chi_\Omega\mathcal{L}^3 = \rho$ is still valid when ρ is only a measure with finite second moment (see Remark 2 after Theorem 1.2). Therefore, the formulation on the right-hand side extends unambiguously to the case where $\rho \notin L^1(\mathbb{R}^2)$.

Geometric interpretation. This weak formulation has a natural geometric interpretation: At a point where $\Psi[\rho]$ is not differentiable, and thus where $\partial\Psi[\rho]$ is not reduced to a single point, $\nabla\Psi[\rho]$ should be replaced by $\bar\partial\Psi[\rho]$, the center of mass of the (convex) set $\partial\Psi[\rho]$. The function $\bar\partial\Psi[\rho]$ coincides Lebesgue almost everywhere with $\nabla\Psi$, and is defined as follows.

DEFINITION 2.1. *The map $\bar\partial\Psi[\rho]$ is defined at every point x by the center of mass with respect to the Lebesgue measure of the set $\partial\Psi[\rho](x)$. In other words, if $\partial\Psi[\rho](x)$ is a k-dimensional convex set, we have*

$$\bar\partial\Psi[\rho](x) = \int_{\partial\Psi[\rho](x)} y \, d\mathcal{L}^k(y).$$

This provides motivation for the following definition of weak measure solutions.

DEFINITION 2.2. *For all $t \in [0,T]$, let $\rho(t)$ be a probability measure of $\mathbb{R}^3$. It is said to be a* weak measure solution *to SG if*

1. *the time-dependent probability measure ρ belongs to $C([0,T], \mathcal{P} - w*)$;*
2. *there exists $t \to R(t)$ nondecreasing such that for all $t \in [0,T]$, $\rho(t,\cdot)$ is supported in $B(0,R(t))$;*
3. *for all $T > 0$ and for all $\varphi \in C_c^\infty([0,T]\times\mathbb{R}^3)$ we have*

$$\begin{aligned} &\int_{[0,T]\times\mathbb{R}^3} \partial_t\varphi(t,x)\ d\rho(dt,x) + \int_{[0,T]\times\Omega} \nabla\varphi(t,\nabla\Phi[\rho(t)](x))\cdot x^\perp\ dtdx \\ &\quad - \int_{[0,T]\times\mathbb{R}^3} \nabla\varphi(t,x)\cdot x^\perp\ d\rho(dt,x) \\ &\quad = \int \varphi(T,x) d\rho(T,x)\ dx - \int \varphi(0,x) d\rho(0,x)\ dx. \end{aligned} \tag{10}$$

This definition is consistent with the classical definition of weak solutions if, for all t, $\rho(t,\cdot)$ is absolutely continuous with respect to the Lebesgue measure.

2.2. Result. Here we prove the following.

THEOREM 2.3.

1. *Let ρ^0 be a probability measure compactly supported. There exists a global weak measure solution to the SG system in the sense of Definition 2.2.*
2. *For any $T > 0$, if $(\rho_n)_{n\in\mathbb{N}}$ is a sequence of weak measure solutions on $[0,T]$ to SG with initial data $(\rho_n^0)_{n\in\mathbb{N}}$, supported in B_R for some $R > 0$ independent of n, the sequence $(\rho_n)_{n\in\mathbb{N}}$ is precompact in $C([0,T],\mathcal{P} - w*)$ and every converging subsequence converges to a weak measure solution of SG.*

Proof of Theorem 2.3. We first show the weak stability of the formulation of Definition 2.2 and the compactness of weak measure solutions. We then use this result to obtain global existence of solutions to the Cauchy problem with initial data a bounded measure.

Weak stability of solutions. We consider a sequence $(\rho_n)_{n\in\mathbb{N}}$ of solutions of SG in the sense of Definition 2.2. The sequence is uniformly compactly supported at time 0. We first show that there exists a nondecreasing function $R(t)$ such that $\rho_n(t)$ is supported in $B(R(t))$ for all t, n.

LEMMA 2.4. *Let $\rho \in C([0,T], \mathcal{P}(\mathbb{R}^3) - w*)$ satisfy (10), and let $\rho^0 = \rho(t=0)$ be supported in $B(0,R^0)$. Then $\rho(t)$ is supported in $B(0, R^0 + C_\Omega t)$, $C_\Omega = \sup_{y\in\Omega}\{|y|\}$.*

Proof. Consider any function $\xi_\epsilon(t,r) \in C^\infty([0,T]\times\mathbb{R})$ such that

$$\begin{aligned}
&\xi_\epsilon(0,r) \equiv 1 \quad \text{if } -\infty < r \le R^0,\\
&\xi_\epsilon(0,r) \equiv 0 \quad \text{if } r \ge R^0 + \epsilon,\\
&\xi_\epsilon(t,r) = \xi_\epsilon(0, r - C_\Omega t),
\end{aligned}$$

with $\xi(0,\cdot)$ nonincreasing. Then applying (10) to the test function $\xi_\epsilon(t,|x|)$, we find

$$\begin{aligned}
\frac{d}{dt}\int \xi_\epsilon(t,|x|)\, d\rho(t,x) &= -\int \partial_r \xi_\epsilon(t,|x|) C_\Omega \, d\rho(t,x)\\
&\quad + \int_\Omega \partial_r \xi_\epsilon(t, |\nabla\Phi[\rho(t)]|) \frac{\nabla\Phi[\rho(t)]}{|\nabla\Phi[\rho(t)]|}\cdot x^\perp \, dx\\
&\ge \int_\Omega \partial_r \xi_\epsilon(t,|\nabla\Phi[\rho(t)]|)(-C_\Omega + |x|)\, dx\\
&\ge 0
\end{aligned}$$

since, by definition of C_Ω, for $x\in\Omega$, $|x| \le C_\Omega$ and ξ_ϵ is nonincreasing with respect to r. Note also that we have used $\int \nabla_x[\xi(t,|x|)]\cdot x^\perp d\rho(t,x)\, dx \equiv 0$. We know, on the other hand, that

$$\begin{aligned}
&\int_{\mathbb{R}^3} \xi_\epsilon(0,|x|) d\rho(0,x) = 1,\\
&\int_{\mathbb{R}^3} \xi_\epsilon(t,|x|) d\rho(t,x) \le 1.
\end{aligned}$$

Therefore we conclude that $\int_{\mathbb{R}^3} \xi_\epsilon(t,|x|) d\rho(t,x) \equiv 1$, which concludes the lemma by letting ϵ go to 0. ∎

From Lemma 2.4, we have

$$\begin{aligned}
&\left| -\int_{[0,T]\times\mathbb{R}^3} \nabla\varphi(t,x)\cdot x^\perp \, d\rho_n(dt,x) + \int_{[0,T]\times\Omega} \nabla\varphi(t, \nabla\Phi[\rho_n(t)](x))\cdot x^\perp \, dtdx \right|\\
&\quad \le C(T)\|\varphi\|_{L^1([0,T], C^1(B_{R(T)})}.
\end{aligned}$$

Thus from Definition 2.2, equation (10), we know that for any time $t \ge 0$, $\partial_t\rho_n(t,\cdot)$ is bounded in the dual of $L^1([0,T], C^1(\mathbb{R}^3))$ and thus in the dual of $L^1([0,T], W^{2,p}(\mathbb{R}^3))$ for $p > 3$ by Sobolev embeddings. Thus for some $p' > 1$ we have

$$\partial_t\rho_n \in L^\infty([0,T], W^{-2,p'}(\mathbb{R}^2)).$$

With the two above results, and using a classical compactness result (see [16, Chapter 1, Lemma 5.1]), we can obtain the following lemma.

LEMMA 2.5. *Let the sequence $(\rho_n)_{n\in\mathbb{N}}$ be as above. There exists $\rho \in C([0,T], \mathcal{P}-w*)$ and a subsequence $(\rho_{n_k})_{k\in\mathbb{N}}$, such that for all $t \in [0,T]$, $\rho_{n_k}(t)$ converges to $\rho(t)$ in the weak-$*$ topology of measures.*

With this lemma, we need to show that for all $\varphi \in C_c^\infty([0,T]\times\mathbb{R}^3)$ we have $\nabla\varphi(t, \nabla\Phi[\rho_n(t)])$ converging to $\nabla\varphi(t,\nabla\Phi[\rho(t)])$ whenever $\rho_n(t)$ converges weakly-$*$ to $\rho(t)$. This last step will be a consequence of the following stability theorem.

THEOREM 2.6 (Brenier [3]). *Let Ω be as above. Let $(\rho_n)_{n\in\mathbb{N}}$ be a sequence of probability measures on $\mathbb{R}^d$, such that for all n, $\int(1+|x|^2)d\rho_n \le C$, let $\Phi_n = \Phi[\rho_n]$, and let $\Psi_n = \Psi[\rho_n]$ be as in Theorem* 1.1. *If, for any $f \in C^0(\mathbb{R}^d)$ such that $|f(x)| \le C(1+|x|^2)$, $\int f\rho_n \to \int \rho f$, then the sequence Φ_n can be chosen in such a way that $\Phi_n \to \Phi[\rho]$ uniformly on each compact set of Ω and strongly in $W^{1,1}(\Omega;\mathbb{R}^d)$, and $\Psi_n \to \Psi[\rho]$ uniformly on each compact set of $\mathbb{R}^d$ and strongly in $W^{1,1}_{loc}(\mathbb{R}^d)$.*

From this result, we obtain that the sequence $\nabla\Phi[\rho_n]$ converges strongly in $L^1(\Omega)$ and almost everywhere (because of the convexity of $\Phi[\rho]$) to $\nabla\Phi[\rho]$. Thus $\nabla\varphi(t,\nabla\Phi[\rho_n])$ converges to $\nabla\varphi(t,\nabla\Phi[\rho])$ in $L^1(\Omega)$ and one can pass to the limit in the formulation of Definition 2.2. This ends the proof of point 2 of Theorem 2.3.

Existence of solutions. We show briefly the existence of a solution to the Cauchy problem in the sense of Definition 2.2. Indeed given ρ^0 the initial data for the problem that we want to solve, by smoothing ρ^0, we can take a sequence ρ_n^0 of initial data belonging to $L^1(\mathbb{R}^2)$, uniformly compactly supported and converging weakly-$*$ to ρ^0. We know already from [1], [10], [20] that for every ρ_n^0, one can build a global weak solution of (3)–(5) that will be uniformly compactly supported on $[0,T]$ for all $T \ge 0$. This sequence will also be a solution in the sense of Definition 2.2. We then use the stability Theorem 2.6 and conclude that, up to extraction of a subsequence, the sequence ρ_n converges in $C([0,T],\mathcal{P}-w*)$ to a weak measure solution of SG with initial data ρ^0. This achieves the proof of Theorem 2.3. □

Remark. One can prove in fact the more general result, valid for nonlinear functionals.

PROPOSITION 2.7. *Let $F \in C^0(\Omega\times\mathbb{R}^d)$, such that $|F(x,y)| \le C(1+|y|^2)$, and let $(\rho_n)_{n\in\mathbb{N}}$ be a bounded sequence of probability measures, Lebesgue integrable, with finite second moment. Let ρ be a probability measure with finite second moment, such that for all $f \in C^0(\mathbb{R}^d)$ such that $|f(x)| \le C(1+|x|^2)$, $\int f d\rho_n \to \int f d\rho$. Then, as n goes to ∞, we have*

$$\begin{aligned}\int_{\mathbb{R}^d} F(\nabla\Psi[\rho_n](x),x)\ d\rho_n(x) &= \int_\Omega F(y,\nabla\Phi[\rho_n](y))\ dy\\ \to_n \int_\Omega F(y,\nabla\Phi[\rho](y))\ dy &=: \int_{\mathbb{R}^d} F(\bar\partial\Psi[\rho](x),x)\ d\rho(x),\end{aligned}$$

where $\bar\partial\Psi[\rho]$ is given in Definition 2.1.

Remark. One checks easily that this definition of $\int_{\mathbb{R}^d} F(\bar\partial\Psi[\rho](x),x)\ d\rho(x)$ is consistent with the definition of $\int_{\mathbb{R}^d} F(\nabla\Psi[\rho](x),x)\ d\rho(x)$ whenever ρ is absolutely continuous with respect to the Lebesgue measure, or $\nabla\Psi[\rho]$ is continuous. Indeed, note that $\nabla\Psi$ and $\bar\partial\Psi$ always coincide Lebesgue almost everywhere, since as a convex and hence Lipschitz function Ψ is differentiable Lebesgue almost everywhere (Rademacher's theorem), and hence $\partial\Psi$ is single-valued Lebesgue almost everywhere.

3. Continuous solutions. What initial regularity is necessary in order to guarantee that the velocity fields remains Lipschitz, or that the flow remains continuous,

at least for a short time? The celebrated Youdovich's theorem for the Euler incompressible equation shows that when $d = 2$, if the initial vorticity data is bounded in L^∞, the flow is Hölder continuous, with Hölder index decreasing to 0 as time goes to infinity. This proof relies on the following regularity property of the Poisson equation: If $\Delta\phi$ is bounded in L^∞, then $\nabla\phi$ is log-Lipschitz. This continuity is enough to define a Hölder continuous flow for the vector field $\nabla\phi^\perp$. Such a result is not valid for the Monge–Ampère equation. As far as we know, the strongest regularity result for Monge–Ampère equations is the following.

3.1. Regularity of solutions to Monge–Ampère equation with Dini continuous right-hand side.

THEOREM 3.1 (Wang [25]). *Let u be a strictly convex Alexandrov solution of*

$$\det D^2 u = \rho \tag{11}$$

with ρ strictly positive. If $w(r)$, the modulus of continuity of ρ, satisfies

$$\int_0^1 \frac{w(r)}{r} dr < \infty, \tag{12}$$

then u is in C^2_{loc}.

We will work here in the periodic case. In this case, u the solution of (11) will be $\Psi[\rho]$ of Theorem 1.2. The arguments of [7], [8], adapted to the periodic case, show that $\Psi[\rho]$ is indeed a strictly convex Alexandrov solution of (11). Therefore we obtain the following corollary of Theorem 3.1.

COROLLARY 3.2. *Let $\rho \in \mathcal{P}(\mathbb{T}^d)$ be such that*

$$0 < m \le \rho \le M,$$
$$\int_0^1 \frac{w(r)}{r} dr = C < \infty,$$

where m, M, C are positive constants. Let $\Psi[\rho]$ be as in Theorem 1.2. We have, for some constant $\mathcal{H}$ depending only on m, M, C,

$$\|\Psi[\rho]\|_{C^2(\mathbb{T}^d)} \le \mathcal{H}.$$

3.2. Result. We will now prove the following.

THEOREM 3.3. *Let ρ^0 be a probability on $\mathbb{T}^3$, such that ρ is strictly positive and satisfies the continuity condition* (12). *Then there exist $T > 0$ and C_1, C_2 depending on ρ^0, such that on $[0, T]$ there exists a solution $\rho(t, x)$ of SG that satisfies the following for all $t \in [0, T]$:*

$$\int_0^1 \frac{w(t, r)}{r} dr \le C_1, \qquad \|\Psi(t, \cdot)\|_{C^2(\mathbb{T}^3)} \le C_2,$$

where $w(t, r)$ is the modulus of continuity (in space) of $\rho(t, .)$.

Proof of Theorem 3.3. Let us first sketch the proof: If $\Psi \in C^2$, then the flow $t \to X(t, x)$ generated by the velocity field $[\nabla\Psi(x) - x]^\perp$ is Lipschitz in space. Since the flow is incompressible, we have $\rho(t, x) = \rho^0(X^{-1}(t, x))$.

Now we use the following property: If two functions f, g have a modulus of continuity, respectively, w_f, w_g, then $g \circ f$ has modulus $w_g \circ w_f$.

Thus if $X^{-1}(t)$ is Lipschitz, we have $w_{\rho^0 \circ X^{-1}(t)} \leq w_{\rho^0}(L\,\cdot)$ with L the Lipschitz constant of $X^{-1}(t)$, and condition (12) remains satisfied.

Remark 4. Note that Hölder continuous functions satisfy condition (12).

Remark 5. Note also that we do not need any integrability on $\nabla\rho$ and the solution of the Eulerian system (3)–(5) still has to be understood in the distributional sense.

A fixed point argument. Let us introduce the seminorm

$$\|\mu\|_{\mathcal{C}} = \int_0^1 \frac{w_\mu(r)}{r} dr \tag{13}$$

defined on $\mathcal{P}(\mathbb{T}^3)$, where we recall that w_μ is the modulus of continuity of μ. We denote by $\mathcal{P}_C$ the set $\mathcal{P}$ equipped with this seminorm, i.e.,

$$\mathcal{P}_C = \{\mu \in \mathcal{P}(\mathbb{T}^3), \|\mu\|_{\mathcal{C}} < \infty\}.$$

From now on, we fix ρ^0 a probability density in $\mathcal{P}_C$, satisfying $m \leq \rho^0 \leq M$, where m and M are strictly positive constants. Let μ be a time-dependent probability density in $L^\infty([0,T];\mathcal{P}_C)$, such that $m \leq \mu(t) \leq M$ for all t. We consider the solution ρ of the initial value problem:

$$\partial_t \rho + (\nabla\Psi[\mu](x) - x)^\perp \cdot \nabla\rho = 0, \tag{14}$$

$$\rho(t=0) = \rho^0. \tag{15}$$

From Theorem 3.1 and its corollary, the vector field $\mathbf{v}[\mu] = (\nabla\Psi[\mu](x) - x)^\perp$ is C^1 uniformly in time; therefore there exists a unique solution to this equation, by the Cauchy–Lipschitz theorem. This solution can be built by the method of characteristics as follows: Consider the flow $X(t,x)$ of the vector field $\mathbf{v}[\mu]$. Then $\rho(t)$ is ρ^0 pushed forward by $X(t)$, i.e., $\rho(t) = \rho^0 \circ X^{-1}(t)$. From the incompressibility of $\mathbf{v}[\mu]$ the condition $m \leq \rho^0 \leq M$ implies that for all $t \in [0,T]$, $m \leq \rho(t) \leq M$.

The initial data ρ^0 being fixed, the map $\mu \mapsto \rho$ will be denoted by $\mathcal{F}$.

The spatial derivative of X, $D_x X$ satisfies

$$\partial_t D_x X(t) = D_x \mathbf{v}[\mu](X) D_x X(t); \tag{16}$$

therefore we have

$$|D_x X(t)| \leq \exp\left(t \sup_{s\in[0,t]} \|D_x \mathbf{v}[\mu](s)\|_{L^\infty}\right). \tag{17}$$

We have also, from (16),

$$\partial_t \left[D_x X^{-1}(t, X(t,x))\right] = D_x X^{-1}(t, X(t,x));$$

hence

$$|D_x X^{-1}(t)| \leq \exp\left(t \sup_{s\in[0,t]} \|D_x \mathbf{v}[\mu](s)\|_{L^\infty}\right). \tag{18}$$

Since $w_{f\circ g} \leq w_f \circ w_g$, and writing $C_t = \exp(t \sup_{s\in[0,t]} \|D_x \mathbf{v}[\mu]\|_{L^\infty})$, we obtain $w_{\rho(t)}(\cdot) \leq w_{\rho^0}(C_t \cdot)$, and

$$\begin{aligned}\int_0^1 \frac{w_{\rho(t)}(r)}{r} dr &\leq \int_0^{C_t} \frac{w_{\rho^0}(r)}{r} dr \\ &\leq \int_0^1 \frac{w_{\rho^0}(r)}{r} dr + (M-m)(C_t - 1)\end{aligned}$$

(using that, for all $r, w_\rho(r) \leq M - m$). Therefore,

$$\|\rho(t)\|_{\mathcal{C}} \leq \|\rho^0\|_{\mathcal{C}} + (M-m)(C_t - 1).$$

Now from Corollary 3.2, and m, M being fixed, there exists a nondecreasing function $\mathcal{H}$ such that

$$\|\mathbf{v}[\mu]\|_{C^1} \leq \mathcal{H}(\|\mu\|_{\mathcal{C}}),$$

and so $C_t \leq \exp(t\mathcal{H}(\|\mu\|_{L^\infty([0,t];\mathcal{P}_C)}))$. Hence we can choose $Q > 1$, and then T such that

$$\|\rho^0\|_{\mathcal{C}} + (M-m)(\exp(T\ \mathcal{H}(Q\|\rho^0\|_{\mathcal{C}})) - 1) = Q\|\rho^0\|_{\mathcal{C}}.$$

Note that for $Q > 1$, we necessarily have $T > 0$. Then the map $\mathcal{F} : \mu \mapsto \rho$ goes now from

$$\mathcal{A} = \big\{\mu,\ \|\mu\|_{L^\infty([0,T];\mathcal{P}_C)} \leq Q\|\rho^0\|_{\mathcal{C}},\ m \leq \mu \leq M\big\}$$

into

$$\mathcal{B} = \big\{\rho,\ \|\rho(t)\|_{\mathcal{C}} \leq \|\rho^0\|_{\mathcal{C}} + (M-m)(\exp(t\ \mathcal{H}(Q\|\rho^0\|_{\mathcal{C}})) - 1)\ \forall t \in [0,T]\big\},$$

and with our choice of $T = T(Q)$, we have $\mathcal{B} \subset \mathcal{A}$. Moreover from the unconditional bounds

$$\rho \leq M,$$
$$\|\mathbf{v}[\mu]\|_{L^\infty([0,T]\times\mathbb{T}^3)} \leq \sqrt{3}/2$$

(see the remark after Theorem 1.2 for the second bound), and using (14), we have also $\|\partial_t\rho\|_{L^\infty([0,T];W^{-1,\infty})} \leq K(M)$ whenever $\rho = \mathcal{F}(\mu)$.

Call $\tilde{\mathcal{A}}$ (resp., $\tilde{\mathcal{B}}$) the set $\mathcal{A} \cap \{\rho, \|\partial_t\rho\|_{L^\infty([0,T];W^{-1,\infty})} \leq K(M)\}$ (resp., $\mathcal{B} \cap \{\rho, \|\partial_t\rho\|_{L^\infty([0,T];W^{-1,\infty})} \leq K(M)\}$); we claim that

- $\mathcal{F}(\tilde{\mathcal{A}}) \subset \tilde{\mathcal{B}} \subset \tilde{\mathcal{A}}$;
- $\tilde{\mathcal{A}}$ is convex and compact for the $C^0([0,T]\times\mathbb{T}^3)$ topology;
- $\mathcal{F}$ is continuous for this topology,

so that we can apply the Schauder fixed point Theorem. We check only the last point, the second being a classical result of functional analysis. So let us consider a sequence $(\mu_n)_{n\in\mathbb{N}}$ converging to $\mu \in \mathcal{A}$ and the corresponding sequence $(\rho_n = \mathcal{F}(\mu_n))_{n\in\mathbb{N}}$. The sequence ρ_n is precompact in $C^0([0,T]\times\mathbb{T}^3)$, from the previous point, and we see (with the stability Theorem 2.6) that it converges to a solution ρ of

$$\partial_t\rho + \nabla\cdot(\rho\mathbf{v}[\mu]) = 0.$$

But, $\mathbf{v}[\mu]$ being Lipschitz, this solution is unique, and therefore $\mathcal{F}(\mu_n)$ converges to $\mathcal{F}(\mu)$, which proves the continuity of $\mathcal{F}$, and ends the proof of existence by the Schauder fixed point Theorem. □

We state here some consequences of the previous result.

COROLLARY 3.4. *Let $\rho^0 \in \mathcal{P}(\mathbb{T}^3)$, such that $0 < m \leq \rho \leq M$.*

1. *If $\rho^0 \in C^\alpha, \alpha \in]0,1]$, for $T^* > 0$ depending on ρ^0, a solution $\rho(t,x)$ to (3, 4, 5) exists in $L^\infty([0,T^*[, C^\alpha(\mathbb{T}^3))$.*
2. *If $\rho^0 \in W^{1,p}, p > 3$, for $T^* > 0$ depending on ρ^0, a solution $\rho(t,x)$ to (3, 4, 5) exists in $L^\infty([0,T[, W^{1,p}(\mathbb{T}^3))$.*

3. *If* $\rho^0 \in C^{k,\alpha}, \alpha \in]0,1], k \in \mathbb{N}$, *for* $T^* > 0$ *depending on* ρ^0, *a solution* $\rho(t,x)$ *to* (3)–(5) *exists in* $L^\infty([0,T^*[, C^{k,\alpha}(\mathbb{T}^3))$.

Moreover, for these solutions, the velocity field is, respectively, in $C^{1,\alpha}(\mathbb{T}^3)$, $W^{2,p}(\mathbb{T}^3)$, *and* $C^{k+1,\alpha}(\mathbb{T}^3)$ *on* $[0,T^*[$.

Proof. We prove only the first point. We use the representation formula $\rho(t) = \rho^0(X^{-1}(t))$. Since Hölder continuous functions satisfy condition (12), we can construct a solution such that $X^{-1}(t)$ remains Lipschitz with respect to the x variable. Then, composing a Hölder continuous function with a Lipschitz function, we obtain a Hölder continuous function, which yields the result.

4. Uniqueness of solutions to SG with Hölder continuous densities.

4.1. Result. Here we prove the following theorem.

THEOREM 4.1. *Suppose that* $\rho^0 \in \mathcal{P}(\mathbb{T}^3)$ *with* $0 < m \leq \rho^0 \leq M$ *and belongs to* $C^\alpha(\mathbb{T}^3)$ *for some* $\alpha > 0$. *From Theorem* 3.3, *for some* $T > 0$ *there exists a solution* $\bar{\rho}$ *to SG in* $L^\infty([0,T], C^\alpha(\mathbb{T}^3))$. *Then every solution of SG in* $L^\infty([0,T'], C^\beta(\mathbb{T}^3))$ *for* $T' > 0, \beta > 0$ *with the same initial data coincides with* $\bar{\rho}$ *on* $[0, \inf\{T, T'\}]$.

Remark 6. The uniqueness of weak solutions is still an open question.

Remark 7. Our proof of uniqueness is thus valid in a smaller class of solutions than the one found in the previous section, the reason for this being the following: During the course of the proof, we will need to solve a Monge–Ampère equation, whose right-hand side is a function of the second derivatives of the solution of another Monge–Ampère equation. In Theorem 3.1, if u is a solution to (11) with a right-hand side satisfying (12), although $u \in C^2$, it is not clear that the second derivatives of u satisfy (12). Actually, it is even known to be wrong in the case of the Laplacian (for a precise discussion on the subject, the reader may refer to [15]). However, from Theorem 4.3 below, if $\rho \in C^\alpha$, then $u \in C^{2,\alpha}$.

What we actually need is a continuity condition on the right-hand side of (11) such that the second derivative of the solution u satisfies (12). This may be a weaker condition than Hölder continuity; however, the proof would not be affected, and therefore it is enough to give it under the present form.

Proof of Theorem 4.1. Let ρ_1 and ρ_2 be two solutions of (3)–(5) in $L^\infty([0,T], C^\beta(\mathbb{T}^3))$ that coincide at time 0. Let X_1, X_2 be the two corresponding Lagrangian solutions, (i.e., solutions of (1,2)). The velocity field being C^1, for all $t \in [0,T]$, $X_1(t,\cdot)$ and $X_2(t,\cdot)$ are both C^1 diffeomorphisms of $\mathbb{T}^d$.

We call $\mathbf{v}_1$ (resp., $\mathbf{v}_2$) the velocity field associated to X_1 (resp., X_2), $\mathbf{v}_i(t,x) = [\nabla\Psi_i(t,x) - x]^\perp, i = 1,2$. We have

$$\begin{aligned}\partial_t(X_1 - X_2) &= \mathbf{v}_1(X_1) - \mathbf{v}_2(X_2)\\ &= (\mathbf{v}_1(X_1) - \mathbf{v}_1(X_2)) + (\mathbf{v}_1(X_2) - \mathbf{v}_2(X_2)).\end{aligned}$$

We want to obtain a Gronwall-type inequality for $\|X_1 - X_2\|_{L^2}$. Since $\mathbf{v}_1$ is uniformly Lipschitz in space (from Theorem 3.3), the first bracket is estimated in the L^2 norm by $C\|X_1 - X_2\|_{L^2}$.

We now need to estimate the second term. We first have that

$$\int |\mathbf{v}_1(X_2) - \mathbf{v}_2(X_2)|^2 = \int \rho_2 |\nabla\Psi_1 - \nabla\Psi_2|^2,$$

and since ρ_2 is bounded, we need to estimate $\|\nabla\Psi_1 - \nabla\Psi_2\|_{L^2}$. This will be done in the following proposition.

PROPOSITION 4.2. *Let X_1, X_2 be mappings from $\mathbb{T}^d$ into itself, such that the densities $\rho_i = X_{i\#}dx, i = 1, 2$, are in $C^\alpha(\mathbb{T}^d)$ for some $\alpha > 0$ and satisfy $0 < m \leq \rho_i \leq M$. Let $\Psi_i, i = 1, 2$, be convex such that*

$$\det D^2\Psi_i = \rho_i$$

in the sense of Theorem 1.1*, i.e., $\Psi_i = \Psi[\rho_i]$. Then*

$$\|\nabla\Psi_1 - \nabla\Psi_2\|_{L^2} \leq C\|X_1 - X_2\|_{L^2},$$

where C depends only on α (the Hölder index of ρ_i), $\|\rho_i\|_{C^\alpha(\mathbb{T}^d)}$, m, and M.

Before giving a proof of this result, we conclude the proof of Theorem 4.1. Proposition 4.2 implies immediately that

$$\|\partial_t(X_1 - X_2)\|_{L^2} \leq C\|X_1 - X_2\|_{L^2},$$

and we conclude the proof of the theorem by a standard Gronwall lemma. ∎

4.2. Energy estimates along Wasserstein geodesics.

Proof of Proposition 4.2. In the proof of this result we will need the following result on optimal transportation of measures by a gradient of convex functions.

THEOREM 4.3 (Brenier [3], McCann [23], Cordero-Erausquin [9], and Caffarelli [6]). *Let ρ_1, ρ_2 be two probability measures on $\mathbb{T}^d$, such that ρ_1 is absolutely continuous with respect to the Lebesgue measure.*

1. *There exists a convex function ϕ such that $\phi - |\cdot|^2/2$ is $\mathbb{Z}^d$-periodic, satisfying $\nabla\phi_\#\rho_1 = \rho_2$.*
2. *The map $\nabla\phi$ is the $d\rho_1$ a.e. unique solution of the minimization problem*

$$\inf_{T_\#\rho_1=\rho_2} \int_{\mathbb{T}^d} \rho_1(x)|T(x) - x|^2_{\mathbb{T}^d}\, dx, \tag{19}$$

   and for all $x \in \mathbb{R}^d$, $|\nabla\phi(x) - x|_{\mathbb{T}^d} = |\nabla\phi(x) - x|_{\mathbb{R}^d}$.
3. *If ρ_1, ρ_2 are strictly positive and belong to $C^\alpha(\mathbb{T}^d)$ for some $\alpha > 0$, then $\phi \in C^{2,\alpha}(\mathbb{T}^d)$ and satisfies pointwise*

$$\rho_2(\nabla\phi)\det D^2\phi = \rho_1.$$

For complete references on the optimal transportation problem (19) and its applications, the reader can refer to [24].

Remark 8. The expression $|\cdot|_{\mathbb{T}^d}$ denotes the Riemannian distance on the flat torus, whereas $|\cdot|_{\mathbb{R}^d}$ is the Euclidean distance on $\mathbb{R}^d$. The second assertion of point 2 means that, for all $x \in \mathbb{R}^d$, $|\nabla\phi(x) - x| \leq \mathrm{diam}(\mathbb{T}^d) = \sqrt{d}/2$.

Remark 9. Here again, note that since $\phi - |\cdot|^2/2$ is periodic, the map $x \mapsto \nabla\phi(x)$ is compatible with the equivalence classes of $\mathbb{R}^d/\mathbb{Z}^d$, and therefore is defined without ambiguity on $\mathbb{T}^d$.

Wasserstein geodesics between probability measures. In this part we use results from [2], [22]. Using Theorem 4.3, we consider the unique (up to a constant) convex potential ϕ such that

$$\nabla\phi_\#\rho_1 = \rho_2,$$
$$\phi - |\cdot|^2/2 \text{ is } \mathbb{Z}^d\text{-periodic.}$$

We consider, for $\theta \in [1,2]$, ϕ_θ defined by

$$\phi_\theta = (2-\theta)\frac{|x|^2}{2} + (\theta-1)\phi.$$

We also consider, for $\theta \in [1,2]$, ρ_θ defined by

$$\rho_\theta = \nabla\phi_\theta \,{}_\#\rho_1.$$

Then ρ_θ interpolates between ρ_1 and ρ_2. This interpolation was introduced in [2] and [22] as the time continuous formulation of the Monge–Kantorovich mass transfer. In this construction, a velocity field v_θ is defined $d\rho_\theta$ a.e. as follows:

$$\begin{aligned}\forall f \in C^0(\mathbb{T}^d;\mathbb{R}^d),\ \int \rho_\theta v_\theta \cdot f &= \int \rho_1 f(\nabla\phi_\theta)\cdot\partial_\theta\nabla\phi_\theta \\ &= \int \rho_1 f(\nabla\phi_\theta)\cdot(\nabla\phi(x)-x). \end{aligned} \tag{20}$$

It is easily checked that the pair ρ_θ, v_θ satisfies

$$\partial_\theta\rho_\theta + \nabla\cdot(\rho_\theta v_\theta) = 0,$$

and for any $\theta \in [1,2]$, we have (see [2])

$$\frac{1}{2}\int_{\mathbb{T}^d}\rho_\theta|v_\theta|^2 = \frac{1}{2}\int_{\mathbb{T}^d}\rho_1|\nabla\phi(x)-x|^2 = W_2^2(\rho_1,\rho_2),$$

where $W_2(\rho_1,\rho_2)$ is the Wasserstein distance between ρ_1 and ρ_2, defined by

$$W_2^2(\rho_1,\rho_2) = \inf_{T_\#\rho_1=\rho_2}\left\{\int\rho_1(x)|T(x)-x|^2_{\mathbb{T}^d}\right\}.$$

The Wasserstein distance can also be formulated as follows:

$$W_2^2(\rho_1,\rho_2) = \inf_{Y_1,Y_2}\left\{\int_{\mathbb{T}^d}|Y_1-Y_2|^2_{\mathbb{T}^d}\right\},$$

where the infimum is performed over all maps $Y_1, Y_2 : \mathbb{T}^d \mapsto \mathbb{T}^d$ such that $Y_{i\#}dx = \rho_i, i = 1,2$. From this definition we have easily

$$W_2^2(\rho_1,\rho_2) \le \int |X_2(t,a)-X_1(t,a)|^2\,da,$$

and it follows that, for every $\theta \in [1,2]$,

$$\int_{\mathbb{T}^d}\rho_\theta|v_\theta|^2 = W_2^2(\rho_1,\rho_2) \le \|X_2-X_1\|_{L^2}. \tag{21}$$

Regularity of the interpolant measure $\boldsymbol{\rho_\theta}$. From Theorem 4.3, for $\rho_1,\rho_2 \in C^\beta$ and pinched between the positive constants m and M, we know that $\phi \in C^{2,\beta}$ and satisfies

$$\det D^2\phi = \frac{\rho_1}{\rho_2(\nabla\phi)}.$$

We now estimate $\rho_\theta = \rho_1[\det D^2\phi_\theta]^{-1}$. From the concavity of $\log(\det(\cdot))$ on symmetric positive matrices, we have

$$\begin{aligned}\det D^2\phi_\theta &= \det((2-\theta)I + (\theta-1)D^2\phi)\\ &\geq [\det D^2\phi]^{\theta-1}\\ &\geq \frac{m}{M}.\end{aligned}$$

Moreover, since $\phi \in C^2$, $\det D^2\phi_\theta$ is bounded by above. Thus ρ_θ is uniformly bounded away from 0 and infinity, and is uniformly Hölder continuous.

Final energy estimate. If we consider, for every $\theta \in [1,2]$, Ψ_θ a solution of

$$\det D^2\Psi_\theta = \rho_\theta, \tag{22}$$

in the sense of Theorem 1.2, and we impose that

$$\int_{\mathbb{T}^d} \Phi_\theta = 0 \tag{23}$$

(see [19]), then Ψ_θ interpolates between Ψ_1 and Ψ_2, and $\Psi_\theta \in C^{2,\beta}$ uniformly, from the regularity of ρ_θ. We will estimate $\partial_\theta \nabla\Psi_\theta$ by differentiating (22) with respect to θ. The fact that Ψ_θ, Φ_θ is differentiable with respect to θ is a consequence of the results of [19]. We will have, following the a priori estimate of [19, Proposition 5.1, Theorem 2.3],

$$\begin{aligned}\partial_\theta\nabla\Phi_\theta, \partial_\theta\nabla\Psi_\theta \in L^\infty([1,2], L^2(\mathbb{T}^d)),\\ \partial_\theta\Phi_\theta, \partial_\theta\Psi_\theta \in L^\infty([1,2], C^\gamma(\mathbb{T}^d))\end{aligned}$$

for some $\gamma \in]0,1[$. (Note that we need the condition (23).)

Let us obtain a precise quantitative estimate in our present case. First we recall the following fact: For M, N two $d \times d$ matrices, $t \in \mathbb{R}$,

$$\det(M + tN) = \det M + t\ (\text{trace } M^t_{co}N) + o(t),$$

where M_{co} is the comatrix (or matrix of cofactors) of M. Moreover, for any $f \in C^2(\mathbb{R}^d;\mathbb{R})$, if M is the comatrix of $D^2 f$, it is a common fact that

$$\forall j \in \{1,\dots,d\},\ \sum_{i=1}^d \partial_i M_{ij} \equiv 0. \tag{24}$$

Hence, denoting by M_θ the comatrix of $D^2\Psi_\theta$, we obtain that $\partial_\theta\Psi_\theta$ satisfies

$$\begin{aligned}\nabla\cdot(M_\theta\nabla\partial_\theta\Psi_\theta) &= \partial_\theta\rho_\theta(t)\\ &= -\nabla\cdot(\rho_\theta v_\theta),\end{aligned} \tag{25}$$

where v_θ is given by (20). From the $C^{2,\beta}$ regularity of Ψ_θ, $D^2\Psi_\theta$ is a C^β smooth, positive definite matrix, and its comatrix M_θ is as well. Thus (25) is uniformly elliptic. If we multiply by $\partial_\theta\Psi_\theta$ and integrate by parts, we obtain

$$\int \nabla^t\partial_\theta\Psi_\theta\, M_\theta\, \nabla\partial_\theta\Psi_\theta = -\int \nabla\partial_\theta\Psi_\theta\cdot v_\theta\rho_\theta.$$

Using that $M_\theta \geq \lambda I$ for some $\lambda > 0$, and combining with the inequality (21) above, we obtain

$$\begin{aligned}\|\nabla \partial_\theta \Psi_\theta(t)\|_{L^2} &\leq \lambda^{-1} \|\rho_\theta v_\theta\|_{L^2} \\ &\leq \lambda^{-1} \|X_2 - X_1\|_{L^2} \left(\sup_\theta \|\rho_\theta\|_{L^\infty} \right)^{1/2}.\end{aligned}$$

The constant λ^{-1} depends only on $m, M, \beta, \{\|\rho_i\|_{C^\beta}, i = 1, 2\}$ and is thus bounded under our present assumptions. We have already seen that ρ_θ is uniformly bounded, and we finally obtain that

$$\|\nabla \Psi_1 - \nabla \Psi_2\|_{L^2} \leq C \|X_1 - X_2\|_{L^2}. \tag{26}$$

This ends the proof of Proposition 4.2. □

Remark 10. In [19], the author obtains also (weaker) estimates of the type of Proposition 4.2 for discontinuous densities ρ_1, ρ_2.

5. Uniqueness of solutions to the 2-d Euler equations with bounded vorticity: A new proof. As stated in the introduction, the method that we have presented here to show uniqueness of solutions to SG is in fact quite general. It has been shown in [18] to yield a uniqueness result for solutions to the Vlasov–Poisson system, the only condition being that the density in the physical space is bounded. In that paper it was also shown that the method could give a new proof of Youdovich's theorem for solutions in the whole space $\mathbb{R}^2$.

We give here a simplified version of this proof in the periodic case.

We start now from the following system:

$$\partial_t \rho + \nabla \cdot (\rho \nabla \psi^\perp) = 0, \tag{27}$$

$$\rho = \Delta \psi, \tag{28}$$

$$\rho(t = 0) = \rho^0. \tag{29}$$

We restrict ourselves to the periodic case, i.e., $x \in \mathbb{T}^2$, ρ, ψ periodic; this implies that ρ has total mass equal to 0. We reprove the following classical result.

THEOREM 5.1 (Youdovich [26]). *Given an initial data $\rho^0 \in L^\infty(\mathbb{T}^2)$ satisfying $\int_{\mathbb{T}^2} \rho^0 = 0$, there exists a unique solution to* (27)–(29) *such that ρ belongs to $L^\infty_{loc}(\mathbb{R}^+ \times \mathbb{T}^2)$.*

Proof of Theorem 5.1. We consider two solutions ρ_1, ψ_1 and ρ_2, ψ_2, such that $\rho_i, i = 1, 2$, are bounded in $L^\infty([0, T] \times \mathbb{T}^d)$. In this case the velocity fields $\mathbf{v}_i = \nabla \psi_i^\perp$ both satisfy (see [21, Chapter 8])

$$\forall (x, y) \in \mathbb{T}^2, \ |x - y| \leq \frac{1}{2}, \ |\mathbf{v}_i(x) - \mathbf{v}_i(y)| \leq C |x - y| \log \frac{1}{|x - y|}.$$

The flows $(t, x) \mapsto X_i(t, x)$ associated to the velocity fields $\mathbf{v}_i = \nabla \psi_i^\perp$ are then Hölder continuous, and one has, for all $t \in [0, T]$, $\rho_i(t) = X_i(t)_\# \rho^0$.

Applying the same technique as before, we need to estimate $\|\nabla \psi_1 - \nabla \psi_2\|_{L^2(\mathbb{T}^2)}$ in terms of $\|X_1 - X_2\|_{L^2(\mathbb{T}^2)}$. In the present case, the energy estimate of Proposition 4.2 will hold under the weaker assumptions that the two densities are bounded.

PROPOSITION 5.2. *Let X_1, X_2 be continuous injective mappings from $\mathbb{T}^d$ into itself, and let ρ^0 be a bounded measure, with $\int_{\mathbb{T}^d} \rho^0 = 0$. Let $\rho_i = X_{i\#} \rho^0, i = 1, 2$.*

Assume that ρ_1, ρ_2 have densities in L^∞ with respect to the Lebesgue measure. Let $\psi_i, i = 1, 2$, be periodic solutions of $\Delta\psi_i = \rho_i, i = 1, 2$. Then we have

$$\|\nabla\psi_1 - \nabla\psi_2\|_{L^2(\mathbb{T}^d)} \leq (2\max\{\|\rho_1\|_{L^\infty}, \|\rho_2\|_{L^\infty}\}\|\rho_0\|_{L^\infty})^{1/2} \|X_1 - X_2\|_{L^2(\mathbb{T}^d)}.$$

Remark 11. In other words, this proposition shows that for ρ_1, ρ_2 bounded, the H^{-1} norm of $\rho_1 - \rho_2$ is controlled by some "generalized" (since here we have unsigned measures) Wasserstein distance between ρ_1 and ρ_2.

Remark 12. We see that we obtain a result as in Proposition 4.2 under the weaker condition that the densities are bounded in L^∞ (and not in C^α). This is because the Laplacian is uniformly elliptic, independently of the regularity of the solution, while the Monge–Ampère operator is uniformly elliptic only for C^2 solutions.

To conclude the proof of Theorem 5.1, note first that for all $C > 0$, we can take T small enough so that $\|X_2 - X_1\|_{L^\infty([0,T]\times\mathbb{T}^2)} \leq C$. Now we have, for the difference $X_1 - X_2$, as long as $|X_1 - X_2| \leq 1/2$,

$$\begin{aligned}\|\partial_t(X_1 - X_2)\|_{L^2} &\leq \|\nabla\psi_1(X_1) - \nabla\psi_1(X_2)\|_{L^2} + \|\nabla\psi_1(X_2) - \nabla\psi_2(X_2)\|_{L^2} \\ &\leq C_1\||X_1 - X_2|\log(|X_1 - X_2|)\|_{L^2} + C_2\|X_1 - X_2\|_{L^2},\end{aligned}$$

where we have used Proposition 5.2 to evaluate the second term. We just need to evaluate $\||X_1 - X_2|\log(|X_1 - X_2|)\|_{L^2}$. We take T small enough so that $\|X_2 - X_1\|_{L^\infty([0,T]\times\mathbb{T}^2)} \leq 1/e$ and notice that $x \mapsto x\log^2 x$ is concave for $0 \leq x \leq 1/e$. Therefore by Jensen's inequality we have

$$\begin{aligned}\int_{\mathbb{T}^2} |X_2 - X_2|^2 \log^2(|X_1 - X_2|) &= \frac{1}{4}\int_{\mathbb{T}^2} |X_2 - X_2|^2 \log^2(|X_1 - X_2|^2) \\ &\leq \frac{1}{4}\int_{\mathbb{T}^2} |X_2 - X_1|^2 \log^2\left(\int_{\mathbb{T}^2} |X_2 - X_1|^2\right),\end{aligned}$$

and some elementary computations finally yield

$$\partial_t\|X_2 - X_1\|_{L^2} \leq C\|X_2 - X_1\|_{L^2}\log\frac{1}{\|X_2 - X_1\|_{L^2}}.$$

The conclusion $X_1 \equiv X_2$ then follows by standard arguments.

5.1. Energy estimates along Wasserstein geodesics.

Proof of Proposition 5.2. The proof of this proposition is very close to the proof of Proposition 4.2, and we will only sketch it, insisting on the specific points. Here the densities ρ_i cannot be of constant sign, since their mean value is zero; hence we introduce ρ_i^+ (resp., ρ_i^-) the positive (resp., negative) part of ρ_i, i.e., $\rho_i = \rho_i^+ - \rho_i^-$. The mappings X_i are supposed injective, and therefore we have $X_{i\#}\rho_0^\pm = \rho_i^\pm$. Now, $\rho_i^\pm$ are positive measures of total mass equal to, say, M, with $M < \infty$.

Wasserstein geodesic. We interpolate between the positive parts ρ_i^+, and the negative part is handled in the same way. As before, we introduce the density $\rho_\theta^+(t)$ that interpolates between $\rho_1^+(t)$ and $\rho_2^+(t)$. In this interpolation, we consider v_θ^+ such that

$$\partial_\theta\rho_\theta^+ + \nabla\cdot(\rho_\theta^+ v_\theta^+) = 0, \tag{30}$$

and we introduce $\rho_\theta^-, v_\theta^-$ as well. Then $\rho_\theta = \rho_\theta^+ - \rho_\theta^-$ has mean value zero. Let the potential ψ_θ be a solution to

$$\Delta\psi_\theta = \rho_\theta. \tag{31}$$

Note that ρ_θ has mean value zero, and therefore this equation is well posed on $\mathbb{T}^2$; moreover ψ_θ interpolates between ψ_1 and ψ_2.

Bound on the interpolant measure ρ_θ. Instead of interpolating between two smooth densities, we interpolate between bounded densities and use the following result from [22].

PROPOSITION 5.3 (McCann [22]). *Let ρ_θ^+ be the Wasserstein geodesic linking ρ_1^+ to ρ_2^+ defined above. Then, for all $\theta \in [1,2]$,*

$$\|\rho_\theta^+\|_{L^\infty} \le \max\left\{\|\rho_1^+\|_{L^\infty}, \|\rho_2^+\|_{L^\infty}\right\}.$$

The same holds for ρ_i^-, ρ_θ^-.

Remark. This property is often referred to as *displacement convexity*.

Energy estimates. Now we impose that $\int_{\mathbb{T}^d} \phi_\theta = 0$. Since $\rho_\theta^\pm, v_\theta^\pm$ are uniformly bounded in L^∞, we have, using (30), that $\partial_\theta \rho_\theta \in L^\infty([1,2]; W^{-1,\infty}(\mathbb{T}^d))$. We can thus differentiate (31) with respect to θ to obtain

$$\Delta \partial_\theta \psi_\theta = \partial_\theta \rho_\theta = -\nabla \cdot (\rho_\theta^+ v_\theta^+ - \rho_\theta^- v_\theta^-), \tag{32}$$

with $v_\theta^\pm$ the interpolating velocity defined as in (20) and satisfying, for all $\theta \in [1,2]$,

$$\int \rho_\theta^\pm(t) |v_\theta^\pm|^2(t) = W_2^2(\rho_1^\pm(t), \rho_2^\pm(t)).$$

Multiplying (32) by $\partial_\theta \psi_\theta$ and integrating over $\theta \in [1,2]$, we obtain

$$\begin{aligned}\|\nabla\psi_1 - \nabla\psi_2\|_{L^2(\mathbb{T}^d)} &\le \int_{\theta=1}^2 \|\rho_\theta^+ v_\theta^+\|_{L^2} + \|\rho_\theta^- v_\theta^-\|_{L^2} \\ &\le W_2(\rho_1^+, \rho_2^+)\Big(\sup_\theta \|\rho_\theta^+\|_{L^\infty}\Big)^{1/2} \\ &\quad + W_2(\rho_1^-, \rho_2^-)\Big(\sup_\theta \|\rho_\theta^-\|_{L^\infty}\Big)^{1/2}.\end{aligned}$$

Note that the energy estimate is easier here than in the Monge–Ampère case, since the problem is immediately uniformly elliptic.

The mappings X_i are injective and satisfy $X_{i\#}\rho_0 = \rho_i$; therefore we have $X_{i\#}(\rho_0^\pm) = \rho_i^\pm$. Hence,

$$\begin{aligned}W_2^2(\rho_1^\pm, \rho_2^\pm) &\le \int \rho_0^\pm |X_1 - X_2|^2 \\ &\le \|\rho_0\|_{L^\infty} \|X_1 - X_2\|_{L^2}.\end{aligned}$$

Using Proposition 5.3, we conclude:

$$\|\nabla\psi_1 - \nabla\psi_2\|_{L^2(\mathbb{T}^d)} \le 2\|\rho_0\|_{L^\infty}^{1/2} \|X_2 - X_1\|_{L^2} \left(\max\left\{\|\rho_1\|_{L^\infty}, \|\rho_2\|_{L^\infty}\right\}\right)^{1/2}.$$

This ends the proof of Proposition 5.2. Note that in our specific case, X_i are Lebesgue measure-preserving invertible mappings; therefore $\|\rho_i^\pm\|_{L^\infty} = \|\rho_0^\pm\|_{L^\infty}$, and the estimate can be simplified in

$$\|\nabla\psi_1 - \nabla\psi_2\|_{L^2(\mathbb{T}^d)} \le 2\|\rho_0\|_{L^\infty} \|X_2 - X_1\|_{L^2(\mathbb{T}^d)}. \qquad \square$$

6. Convergence to the Euler equation.

6.1. Scaling of the system. Here we present a rescaled version of the 2-d SG system and some formal arguments to motivate the next convergence results. Here $x \in \mathbb{T}^2, t \in \mathbb{R}^+$, and for $\mathbf{v} = (v_1, v_2) \in \mathbb{R}^2$, $\mathbf{v}^\perp$ now means $(-v_2, v_1)$. Introducing $\psi[\rho] = \Psi[\rho] - |x|^2/2$, where $\Psi[\rho]$ is given by Theorem 1.2, the periodic 2-d SG system now reads

$$\begin{aligned} \partial_t \rho + \nabla \cdot (\rho \nabla \psi^\perp) &= 0, \\ \det(I + D^2\psi) &= \rho. \end{aligned}$$

If ρ is close to one, then ψ should be small, and therefore one may consider the linearization $\det(I + D^2\psi) = 1 + \Delta\psi + O(|D^2\psi|^2)$, which yields $\Delta\psi \simeq \rho - 1$. Thus for small initial data, i.e., $\rho^0 - 1$ small, one expects $\psi, \mu = \rho - 1$ to stay close to a solution of the Euler incompressible equation EI,

$$\partial_t \bar{\rho} + \nabla \cdot (\bar{\rho} \nabla \bar{\phi}^\perp) = 0, \tag{33}$$

$$\Delta \bar{\phi} = \bar{\rho}. \tag{34}$$

We shall rescale the equation in order to consider quantities of order one. We introduce the new unknown

$$\begin{aligned} \rho^\epsilon(t,x) &= \frac{1}{\epsilon}\left(\rho\left(\frac{t}{\epsilon}, x\right) - 1\right), \\ \psi^\epsilon(t,x) &= \frac{1}{\epsilon}\psi\left(\frac{t}{\epsilon}, x\right). \end{aligned}$$

Then we have

$$\begin{aligned} \rho(t) &= 1 + \epsilon\rho^\epsilon(\epsilon t), \\ \Psi[\rho](t) &= |x|^2/2 + \epsilon\psi^\epsilon(\epsilon t), \end{aligned}$$

and we define ϕ^ϵ by

$$\epsilon\phi^\epsilon = |x|^2/2 - \Phi[\rho],$$

so that

$$\nabla\phi^\epsilon = \nabla\psi^\epsilon(\nabla\Phi[\rho]). \tag{35}$$

Hence, at a point $x \in \mathbb{T}^2$, $\nabla\phi^{\epsilon\perp}$ is the velocity of the associated dual point $\nabla\Phi[\rho](x)$. The evolution of these quantities is then governed by the system SG_ϵ,

$$\partial_t \rho^\epsilon + \nabla \cdot (\rho^\epsilon \nabla \psi^{\epsilon\perp}) = 0, \tag{36}$$

$$\det(I + \epsilon D^2\psi^\epsilon) = 1 + \epsilon\rho^\epsilon. \tag{37}$$

Remark. Note that this system admits global weak solutions with initial data any bounded measure $\rho^{\epsilon\,0}$, as long as

$$\int_{\mathbb{T}^2} \rho^{\epsilon\,0} = 0, \tag{38}$$

$$\rho^{\epsilon\,0} \geq -\frac{1}{\epsilon}. \tag{39}$$

Note also that if the pair $(\bar\rho, \bar\phi)$ is a solution to the EI system (33)–(34), so is the pair $(\frac{1}{\epsilon}\bar\rho(\frac{t}{\epsilon}, x),\ \frac{1}{\epsilon}\bar\phi(\frac{t}{\epsilon}, x))$.

We now present the convergence results. We show that solutions of SG_ϵ converge to solutions of EI in the following sense: If $\rho^{\epsilon\,0}$, the initial data of SG_ϵ, is close (in some sense depending on the type of convergence we wish to show) to a smooth initial data $\bar\rho^0$ for EI, then ρ^ϵ and $\bar\rho$ remain close for some time. This time goes to infinity when ϵ goes to 0.

We present two different versions of this result: The first one is for weak solutions of SG_ϵ, and the second one is for Lipschitz solutions.

6.2. Convergence of weak solutions.

THEOREM 6.1. *Let $(\rho^\epsilon, \psi^\epsilon)$ be a weak solution of the* SG_ϵ *system* (36)–(37). *Let $(\bar\rho, \bar\phi)$ be a smooth $C^3([0,T]\times\mathbb{T}^2)$ solution of the* EI *system* (33)–(34). *Let ϕ^ϵ be obtained from ψ^ϵ as in* (35), *and let $H_\epsilon(t)$ be defined by*

$$H_\epsilon(t) = \frac{1}{2}\int_{\mathbb{T}^2} \left|\nabla\phi^\epsilon - \nabla\bar\phi\right|^2.$$

Then

$$H_\epsilon(t) \le (H_\epsilon(0) + C\epsilon^{2/3}(1+t))\exp Ct,$$

where C depends only on $\sup_{0\le s\le t}\{\|D^3\bar\phi(s), D^2\partial_t\bar\phi(s)\ \|_{L^\infty(\mathbb{T}^2)}\}$.

In particular, if $H_\epsilon(0) \le C_0\epsilon^{2/3}$, we have, for all $T>0, t\in[0,T]$,

$$H_\epsilon(t) \le C_T\epsilon^{2/3},$$

where C_T depends on T, C, C_0 above.

Remark 13. Note that $\nabla\phi^{\epsilon\perp}(t,x)$ is the velocity at point $\nabla\Phi[\rho] = x - \epsilon\nabla\phi^\epsilon$. Thus we compare the SG_ϵ velocity at point $x - \epsilon\nabla\phi^\epsilon$ (the dual point of x) with the EI velocity at point x. Our result also allows comparison of the velocities at the same point by noticing that

$$\begin{aligned} G_\epsilon(t) &= \frac{1}{2}\int_{\mathbb{T}^2}\rho\left|\nabla\psi^\epsilon - \nabla\bar\phi\right|^2 \\ &= \frac{1}{2}\int_{\mathbb{T}^2}\left|\nabla\phi^\epsilon - \nabla\bar\phi(x-\epsilon\nabla\phi^\epsilon)\right|^2 \\ &\le C(H_\epsilon(t) + \epsilon^2), \end{aligned}$$

using the smoothness of $\bar\phi$, and if $\mathbf{v}_{sg_\epsilon}, \mathbf{v}_{ei}$ are the respective velocities of the SG_ϵ and EI systems, $G_\epsilon = \int_{\mathbb{T}^2}\rho^\epsilon|\mathbf{v}_{sg_\epsilon} - \mathbf{v}_{ei}|^2$.

Remark 14. The expansion $\det(I + D^2\psi) = 1 + \Delta\psi + O(|D^2\psi|^2)$, used in the heuristic argument above to justify the convergence, relies a priori on the control of $D^2\psi$ in the sup norm. But in Theorem 6.1, the initial data must satisfy $\nabla\psi^\epsilon$ close in the L^2 norm to $\nabla\bar\phi$; this condition means that $D^2\psi^\epsilon$ is close in the H^{-1} norm to $D^2\bar\phi$, which is smooth. This control does not allow us to justify the expansion $\det(I + D^2\psi) = 1 + \Delta\psi + O(|D^2\psi|^2)$, but we see that the result remains valid.

Proof of Theorem 6.1. In all the proof, we use C to denote any quantity that depends only on $\bar\phi$. We use the conservation of the energy of the SG_ϵ system, given by

$$E(t) = \int_{\mathbb{T}^2}|\nabla\phi^\epsilon|^2. \tag{40}$$

This fact, although formally easily justified, is actually not so straightforward for weak solutions, and has been proved by F. Otto in an unpublished work. The argument is explained in [5]. Therefore $E(t) = E_0$. The energy of the smooth solution of EI is given by

$$\bar{E}(t) = \int_{\mathbb{T}^2} |\nabla \bar{\phi}|^2 \tag{41}$$

and also conserved. For all smooth θ, we will use the notation

$$\langle D^2\theta\rangle(t,x) = \int_{s=0}^{1} (1-s) D^2\theta(t, x - s\epsilon\nabla\phi^\epsilon(t,x)).$$

Thus we have the identity

$$\int_{\mathbb{T}^2} \rho^\epsilon\theta = \int_{\mathbb{T}^2} \theta(x - \epsilon\nabla\phi^\epsilon) \tag{42}$$

$$= \int_{\mathbb{T}^2} \theta - \epsilon \int_{\mathbb{T}^2} \nabla\theta\cdot\nabla\phi^\epsilon + \epsilon^2 \int_{\mathbb{T}^2} \langle D^2\theta\rangle \nabla\phi^\epsilon\nabla\phi^\epsilon. \tag{43}$$

Using the energy bound, the last term is bounded by $\epsilon^2\|D^2\theta\|_{L^\infty(\mathbb{T}^2)}E_0$. Then, using the conservation of the energies E and $\bar{E}$ defined, respectively, in (40) and (41), we have

$$\frac{d}{dt}H_\epsilon(t) = -\frac{d}{dt}\int_{\mathbb{T}^2} \nabla\bar{\phi}\cdot\nabla\phi^\epsilon.$$

Using the identity (43), we have, for all smooth θ,

$$\epsilon\int_{\mathbb{T}^2} \nabla\theta\cdot\nabla\phi^\epsilon = -\int_{\mathbb{T}^2}\rho^\epsilon\theta + \int_{\mathbb{T}^2}\theta + \epsilon^2\int_{\mathbb{T}^2}\langle D^2\theta\rangle\nabla\phi^\epsilon\nabla\phi^\epsilon;$$

hence, replacing θ by $\bar{\phi}$ in this identity, we get

$$\frac{d}{dt}H_\epsilon(t) = \frac{1}{\epsilon}\frac{d}{dt}\int_{\mathbb{T}^2}[\rho^\epsilon\bar{\phi} - \bar{\phi} - \epsilon^2\langle D^2\bar{\phi}\rangle\nabla\phi^\epsilon\nabla\phi^\epsilon].$$

We can suppose without loss of generality that $\int_{\mathbb{T}^2}\bar{\phi}(t,x)\,dx \equiv 0$. Then if we define

$$Q_\epsilon(t) = \int_{\mathbb{T}^2} \epsilon\langle D^2\bar{\phi}\rangle\nabla\phi^\epsilon\nabla\phi^\epsilon$$

(note that $|Q_\epsilon(t)| \le C\epsilon$), we have

$$\frac{d}{dt}(H_\epsilon + Q_\epsilon) = \frac{1}{\epsilon}\frac{d}{dt}\int_{\mathbb{T}^2}\rho^\epsilon\bar{\phi}.$$

Hence we are left to compute

$$\begin{aligned}
\frac{1}{\epsilon}\frac{d}{dt}\int_{\mathbb{T}^2}\rho^\epsilon\bar{\phi} &= \frac{1}{\epsilon}\int_{\mathbb{T}^2}\partial_t\rho^\epsilon\bar{\phi} + \rho^\epsilon\partial_t\bar{\phi}\\
&= \frac{1}{\epsilon}\int_{\mathbb{T}^2}\rho^\epsilon\nabla\psi^{\epsilon\perp}\cdot\nabla\bar{\phi} - \epsilon\nabla\phi^\epsilon\cdot\nabla\partial_t\bar{\phi} + \epsilon^2\langle D^2\partial_t\bar{\phi}\rangle\nabla\bar{\phi}\nabla\bar{\phi}\\
&= \frac{1}{\epsilon}\int_{\mathbb{T}^2}\rho^\epsilon\nabla\psi^{\epsilon\perp}\cdot\nabla\bar{\phi} - \int_{\mathbb{T}^2}\nabla\phi^\epsilon\cdot\nabla\partial_t\bar{\phi} + O(\epsilon)\\
&= T_1 + T_2 + O(\epsilon),
\end{aligned}$$

where in the second line we have used (36) for the first term and (43) with $\theta = \partial_t \bar{\phi}$ for the second and third terms. (Remember also that we assume $\int \partial_t \bar{\phi} \equiv 0$.)

We will now use the other formulation of the Euler equation: $\mathbf{v} = \nabla \bar{\phi}^\perp$ satisfies

$$\partial_t \mathbf{v} + \mathbf{v} \cdot \nabla \mathbf{v} = -\nabla p.$$

After a rotation of $\pi/2$, this equation becomes

$$\partial_t \nabla \bar{\phi} + D^2 \bar{\phi} \nabla \bar{\phi}^\perp = \nabla p^\perp,$$

and thus for T_2 we have

$$\begin{aligned} T_2 &= -\int_{\mathbb{T}^2} \nabla \phi^\epsilon \cdot \nabla \partial_t \bar{\phi} \\ &= \int_{\mathbb{T}^2} \nabla \phi^\epsilon D^2 \bar{\phi} \nabla \bar{\phi}^\perp. \end{aligned}$$

For T_1, using (35) and (43), we have

$$\begin{aligned} \epsilon T_1 &= \int_{\mathbb{T}^2} \rho^\epsilon \nabla \psi^{\epsilon\perp} \cdot \nabla \bar{\phi} \\ &= \int_{\mathbb{T}^2} \nabla \psi^{\epsilon\perp}(x - \epsilon \nabla \phi^\epsilon) \cdot \nabla \bar{\phi}(x - \epsilon \nabla \phi^\epsilon) \\ &= \int_{\mathbb{T}^2} \nabla \phi^{\epsilon\perp} \cdot \nabla \bar{\phi} - \epsilon \nabla \phi^{\epsilon\perp} D^2 \bar{\phi} \nabla \phi^\epsilon + \epsilon \Xi, \end{aligned}$$

where Ξ is defined by

$$\Xi = \int_{\mathbb{T}^2} \nabla \phi^{\epsilon\perp} \left(D^2 \bar{\phi} - \int_{s=0}^1 D^2 \bar{\phi}(x - s\epsilon \nabla \phi^\epsilon)\, ds \right) \nabla \phi^\epsilon. \tag{44}$$

The term $\int_{\mathbb{T}^2} \nabla \phi^{\epsilon\perp} \cdot \nabla \bar{\phi}$ vanishes identically. Concerning Ξ, we claim the following estimate.

LEMMA 6.2. *Let Ξ be defined by* (44). *Then*

$$|\Xi| \leq C(\epsilon^{\frac{2}{3}} + H_\epsilon),$$

where C depends on $\|D^3 \bar{\phi}\|_{L^\infty}$.

We postpone the proof of this lemma until after the proof of Theorem 6.1. We now obtain

$$\frac{d}{dt}(H_\epsilon(t) + Q_\epsilon(t)) \leq \int_{\mathbb{T}^2} (\nabla \bar{\phi}^\perp - \nabla \phi^{\epsilon\perp}) D^2 \bar{\phi} \nabla \phi^\epsilon + C H_\epsilon + C \epsilon^{2/3}.$$

Noticing that for every $\theta : \mathbb{T}^2 \mapsto \mathbb{R}$ we have

$$\int_{\mathbb{T}^2} \nabla \theta^\perp D^2 \bar{\phi} \nabla \bar{\phi} = \int_{\mathbb{T}^2} \nabla \theta^\perp \cdot \nabla \left(\frac{1}{2} |\nabla \bar{\phi}|^2 \right) = 0,$$

we find that

$$\int_{\mathbb{T}^2} (\nabla \bar{\phi}^\perp - \nabla \phi^{\epsilon\perp}) D^2 \bar{\phi} \nabla \phi^\epsilon = \int_{\mathbb{T}^2} (\nabla \phi^\perp - \nabla \bar{\phi}^{\epsilon\perp}) D^2 \bar{\phi} (\nabla \phi^\epsilon - \nabla \bar{\phi}),$$

and hence

$$\frac{d}{dt}(H_\epsilon(t)+Q_\epsilon(t)) \le -\int_{\mathbb{T}^2}(\nabla\phi^{\epsilon\perp}-\nabla\bar\phi^\perp)D^2\bar\phi(\nabla\phi^\epsilon-\nabla\bar\phi)+CH_\epsilon+C\epsilon^{2/3}$$
$$\le C(H_\epsilon(t)+Q_\epsilon(t)+\epsilon^{2/3}),$$

using the fact that $Q_\epsilon(t)\le C\epsilon$. Therefore

$$H_\epsilon(t)+Q_\epsilon(t)\le (H_\epsilon(0)+Q_\epsilon(0)+C\epsilon^{2/3}t)\exp(Ct)$$

and finally

$$H_\epsilon(t)\le (H_\epsilon(0)+C\epsilon^{2/3}(1+t))\exp(Ct),$$

and the result follows. Check that the constant C depends only on $\sup_{0\le s\le t}\{\|D^3\bar\phi, D^2\partial_t\bar\phi\|_{L^\infty(\mathbb{T}^2)}\}$. This ends the proof of Theorem 6.1 □

Proof of Lemma 6.2. First we show that if $\Theta(R)=\int_{\{|\nabla\phi^\epsilon|\ge R\}}|\nabla\phi^\epsilon|^2$, then, for some $C>0$,

$$\Theta(R)\le C\int|\nabla\phi^\epsilon-\nabla\bar\phi|^2+\frac{C}{R^2}. \tag{45}$$

Indeed, $\int|\nabla\phi^\epsilon|^2\le C$ implies that $\text{meas}\{|\nabla\phi^\epsilon|\ge R\}\le C\frac{1}{R^2}$. Since $|\nabla\bar\phi(t,x)|\le C$ for $(t,x)\in[0,T']\times\mathbb{T}^d$, we have

$$\Theta(R)\le 2\int_{\{|\nabla\phi^\epsilon|\ge R\}}|\nabla\bar\phi|^2+2\int_{\{|\nabla\phi^\epsilon|\ge R\}}|\nabla\phi^\epsilon-\nabla\bar\phi|^2$$
$$\le\frac{2C}{R^2}+2\int|\nabla\phi^\epsilon-\nabla\bar\phi|^2.$$

Hence (45) is proved for C replaced by $\max\{2,2C\}$.

Then, letting

$$K(x)=D^2\bar\phi-\int_{s=0}^1 D^2\bar\phi(x-s\epsilon\nabla\phi^\epsilon)\,ds,$$

we have

$$\Xi\le C\Theta(R)+\int_{|\nabla\phi^\epsilon|\le R}|K(x)||\nabla\phi^\epsilon|^2$$

with $|K(x)|\le C\epsilon|\nabla\phi^\epsilon|$, and thus

$$\Xi\le C\epsilon\int_{|\nabla\phi^\epsilon|\le R}|\nabla\phi^\epsilon|^3+C\Theta(R)$$
$$\le C\left(\epsilon R\int|\nabla\phi^\epsilon|^2+\frac{1}{R^2}+\int|\nabla\phi^\epsilon-\nabla\bar\phi|^2\right)$$
$$\le C\left(\epsilon R+\frac{1}{R^2}+\int|\nabla\phi^\epsilon-\nabla\bar\phi|^2\right)$$

for all R, so for $R=\epsilon^{-1/3}$ we obtain

$$\Xi\le C\epsilon^{2/3}+C\int|\nabla\phi^\epsilon-\nabla\bar\phi|^2.$$

This proves Lemma 6.2 □

6.3. Convergence of strong solutions. We present here another proof of convergence, which holds for stronger norms. Let us consider as above the solution $(\bar\rho, \bar\phi)$ to Euler,

$$\begin{aligned}\partial_t\bar\rho + \nabla\cdot(\bar\rho\nabla\bar\phi^\perp) &= 0,\\ \Delta\bar\phi &= \bar\rho,\end{aligned}$$

and we recall the SG_ϵ system

$$\begin{aligned}\partial_t\rho^\epsilon + \nabla\cdot(\rho^\epsilon\nabla\psi^{\epsilon\perp}) &= 0,\\ \det(I+\epsilon D^2\psi^\epsilon) &= 1+\epsilon\rho^\epsilon.\end{aligned}$$

We then have the following theorem.

THEOREM 6.3. *Let $(\bar\rho,\bar\phi)$ be a solution of EI, such that $\bar\rho\in C^2_{loc}(\mathbb{R}^+\times\mathbb{T}^2)$. Let $\rho^{\epsilon\,0}$ be a sequence of initial data for SG_ϵ satisfying* (38)–(39)*, and such that $\frac{\rho^{\epsilon\,0}-\bar\rho^0}{\epsilon}$ is bounded in $W^{1,\infty}(\mathbb{T}^2)$. Then there exists a sequence $(\rho^\epsilon,\psi^\epsilon)$ of solutions to SG_ϵ that satisfies the following: For all $T>0$, there exists $\epsilon_T>0$, such that the sequence*

$$\frac{\rho^\epsilon-\bar\rho}{\epsilon}, \frac{\nabla\psi^\epsilon-\nabla\bar\phi}{\epsilon}$$

for $0<\epsilon<\epsilon_T$ is uniformly bounded in $L^\infty([0,T],W^{1,\infty}(\mathbb{T}^2))$.

Remark. In the previous theorem, we obtained estimates in the L^2 norm; here we obtain estimates in Lipschitz norm. Estimates of higher derivatives follow in the same way.

Proof of Theorem 6.3. We expand the solution of SG_ϵ as the solution of EI plus a small perturbation of order ϵ and show that this perturbation remains bounded in large norms (at least Lipschitz). We first remark that the assumption on $\bar\rho$ implies that for all $T>0$, $\bar\phi\in L^\infty([0,T];C^3(\mathbb{T}^2))$. Let us write

$$\begin{aligned}\rho^\epsilon &= \bar\rho+\epsilon\rho_1,\\ \psi^\epsilon &= \bar\phi+\epsilon\psi_1.\end{aligned}$$

Rewritten in terms of ρ_1,ψ_1, the SG_ϵ system reads

$$\begin{aligned}&\partial_t\rho_1 + (\nabla\bar\phi+\epsilon\nabla\psi_1)^\perp\cdot\nabla\rho_1 = -\nabla\psi_1^\perp\cdot\nabla\bar\rho,\\ &\Delta\psi_1+\epsilon\ \mathrm{trace}\,[D^2\psi_1 D^2\bar\phi]+\epsilon^2\det D^2\psi_1 = \rho_1-\det D^2\bar\phi.\end{aligned}$$

Differentiating the first equation with respect to space, we find the evolution equation for $\nabla\rho_1$:

(46)

$$\partial_t\nabla\rho_1 + ((\nabla\bar\phi+\epsilon\nabla\psi_1)^\perp\cdot\nabla)\nabla\rho_1 = -(D^2\bar\phi+\epsilon D^2\psi_1)\nabla\rho_1^\perp - D^2\psi_1\nabla\bar\rho^\perp - D^2\bar\rho\nabla\psi_1^\perp.$$

We claim that in order to conclude the proof it is enough to have an estimate of the form

$$\|\psi_1(t,\cdot)\|_{C^{1,1}(\mathbb{T}^2)} \le C(1+\|\rho_1(t,\cdot)\|_{C^{0,1}(\mathbb{T}^2)}), \tag{47}$$

where C depends on $\bar\phi$. Let us admit this bound temporarily, and finish the proof of the theorem: Using (47) and (46), we obtain

$$\frac{d}{dt}\|\nabla\rho_1\|_{L^\infty} \le C(t)(1+\|\nabla\rho_1\|_{L^\infty}+\epsilon\|\nabla\rho_1\|^2_{L^\infty}),$$

where the constant $C(t)$ depends on the $C^2(\mathbb{T}^2)$ norm of $(\bar\rho(t,\cdot),\bar\phi(t,\cdot))$. This quantity is bounded on every interval $[0,T]$.

Thus we conclude using Gronwall's lemma that $\|\nabla\rho_1(t,\cdot)\|_{L^\infty(\mathbb{T}^2)}$ remains bounded on $[0,T_\epsilon]$ with T_ϵ going to T as ϵ goes to 0. We then choose T as large as we want, since when $d=2$ the smooth solution to EI is global in time. From estimate (47) the $W^{1,\infty}$ bound on ρ_1 implies a $W^{2,\infty}$ bound on ψ_1. Then, we remember that

$$\rho_1=\frac{\rho^\epsilon-\bar\rho}{\epsilon},\quad \nabla\psi_1=\frac{\nabla\psi^\epsilon-\nabla\bar\phi}{\epsilon}$$

to conclude the proof of Theorem 6.3. □

Proof of the estimate (47). We write the equation followed by ψ_1 as follows:

$$\Delta\psi_1=-\text{trace }[\epsilon D^2\psi_1 D^2\bar\phi]-\epsilon^2\det D^2\psi_1+\rho_1-\det D^2\bar\phi.$$

We recall that

$$\|fg\|_{C^{2,\alpha}}\le\|f\|_{C^{2,\alpha}}\|g\|_{C^{2,\alpha}};$$

hence, using Schauder $C^{2,\alpha}$ estimates for solutions to the Laplace equation (see [14]), we have

$$\|\psi_1\|_{C^{2,\alpha}}\le C_1(1+\epsilon\|\psi_1\|_{C^{2,\alpha}}+\epsilon^2\|\psi_1\|^2_{C^{2,\alpha}}),\tag{48}$$

where C_1 depends on $\|\bar\phi\|_{C^{2,\alpha}},\|\rho_1\|_{C^\alpha}$. Inequality (48) will be satisfied in two cases: Either for $\|\psi_1\|_{C^{2,\alpha}}\le C_2$ or for $\|\psi_1\|_{C^{2,\alpha}}\ge C_3\epsilon^{-2}$, where C_2,C_3 are positive constants that depend on C_1.

Now we show that ψ^ϵ, the solution of (37), is bounded in $C^{2,\alpha}$ for ρ^ϵ bounded in the C^α norm. We consider for $t\in[0,1]$ ψ^ϵ_t the unique up to a constant periodic solution of

$$\det(I+\epsilon D^2\psi^\epsilon_t)=1+t\epsilon\rho^\epsilon.$$

Differentiating this equation with respect to t, we find

$$M_{ij}D_{ij}\partial_t\psi^\epsilon_t=\rho^\epsilon,$$

where M is the comatrix of $I+\epsilon D^2\psi^\epsilon_t$. From the regularity result of Theorem 4.3, M is C^α and strictly elliptic. From Schauder estimates, we then have $\|\partial_t\psi^\epsilon_t\|_{C^{2,\alpha}}\le C\|\rho^\epsilon\|_{C^{2,\alpha}}$, and integrated over $t\in[0,1]$, we get

$$\|\psi^\epsilon\|_{C^{2,\alpha}}\le C\|\rho^\epsilon\|_{C^{2,\alpha}}.$$

Hence, since $\psi^\epsilon=\bar\phi+\epsilon\psi_1$, we have ψ_1 bounded by C/ϵ in $C^{2,\alpha}$. Hence it cannot be bigger than C_3/ϵ^2, and to satisfy (48), we must have

$$\|\psi_1\|_{C^{2,\alpha}}\le C_2,$$

where C_2 as above depends on $\|\bar\phi\|_{C^{2,\alpha}},\|\rho_1\|_{C^\alpha}$. This proves estimate (47). □

ON THE CONTROL OF AN INTERACTING PARTICLE ESTIMATION OF SCHRÖDINGER GROUND STATES*

MATHIAS ROUSSET†

Abstract. We consider a general Schrödinger operator $L + V$ on a domain $E \subset \mathbb{R}^d$ and its associated positive ground state h solution to the maximal eigenvalue problem $L(h) + Vh = \lambda h$. In this work, an interacting particle model approximating the pair (h, λ) is studied. When $V \leq 0$, a basic version of this particle system consists of N walkers evolving independently according to the Markov generator L, each walker dying at a rate given by the value of the potential $|V|$ at the walker's current location; when a walker dies, any other one splits in two. The long time distribution of the particle system is then an estimator of h. Under some reasonable assumptions (with examples for $E = \mathbb{R}^d$), we get a nonasymptotic control of the $\mathbb{L}^p$ deviations (resp., the bias) of this estimator with the genuine rate of convergence in $1/\sqrt{N}$ (resp., $1/N$). We also compute explicitly the asymptotic standard deviation of the estimation of λ, which remains bounded in usual mild situations.

Key words. Schrödinger ground states, stochastic particle methods, long time behavior, quantum Monte Carlo

DOI. 10.1137/050640667

1. Introduction.

Our motivation can be split into two steps:

1. Control the long time behavior of an interacting particle approximation of Feynman–Kac formulas with genuine rate of convergence.
2. Use the long time distribution of the particle system as a Monte Carlo estimator of the ground state of Schrödinger operators.

The last question is of very high practical interest in quantum physics and chemistry, where one uses such diffusion Monte Carlo methods to compute observables of systems (see [3], [2] and the references therein). In the difficult yet crucial case of Fermi systems, the so-called fixed node approximation is used [3], [2], where one is resorting to the ground state of a general Schrödinger operator on a domain of $\mathbb{R}^d$.

We focus in this work on the interacting particle system (IPS) studied by Del Moral and Miclo in [7]. In its diffusive time-continuous version, it is particularly well suited to this context. Indeed, the fixed number of particles and the selection mechanism make it liable to be stable in the long run and to give rise to finite variance. Note that it has not yet inspired as such practitioners' heuristics. Several keys are given here to design it in practice, and some toy simulations will soon be available on the author's web page and in [12].

For the analysis we have used some semigroup and martingale techniques inherited from [6]. However, this paper is mostly self-contained. The good rate of convergence of the long time distribution of the IPS is a new result, technically demanding, and proved in a very reasonable setting which includes examples in $\mathbb{R}^d$. Intermediate results can be used to make some proofs of [7] precise (see Remark 5.5). For the stability questions, we have used a Foster–Lyapunov drift criterion to prove uniform

†Laboratoire J. A. Dieudonné, Université de Nice Sophia-Antipolis, 06108 Nice, France (mathias.rousset@polytechnique.org).

exponential convergence of Schrödinger semigroups (Proposition 2.2) under a quite general assumption, which seems to be a new point also.

If $K(x, dy)$ is an integral kernel, φ a test function, and μ a probability measure, we will use the notation $\mu K(\varphi) = \int \varphi(y) K(x, dy)\mu(dx)$. $(\quad)^+$ and $(\quad)^-$ denote, respectively, the positive and negative part.

Let us now give the main results of this paper. Suppose we are given an irreducible strong Feller diffusion X_t in an open connected domain $E \subset \mathbb{R}^d$ with generator L, reversible with respect to a probability measure $\mu(dx) = \frac{h_I^2(x)dx}{\int h_I^2(x)dx}$ for some $h_I \geq 0$. V denotes a potential function such that the Feynman–Kac semigroup

$$P_t^V(\varphi)(x) = \mathbb{E}\left(\varphi(X_t)e^{\int_0^t V(X_s)ds} | X_0 = x\right), \quad \varphi \in \mathbb{L}^2(\mu),$$

is strongly continuous in $\mathbb{L}^2(\mu)$ and Fellerian ($x \mapsto P_t^V(\varphi)(x)$ is continuous for φ bounded; see [8]). It gives rise to its associated self-adjoint Schrödinger operator

$$(L + V)(\varphi) = \lim_{t \to 0^+} \frac{P_t^V(\varphi) - \varphi}{t} \in \mathbb{L}^2(\mu)$$

defined on its domain $\mathcal{D}(L + V)$, where the latter limit exists (see [8]).

Our main example (detailed in section 2.1), which arises in many practical situations of interest (again in [3]), is some "importance sampling" transformation of the usual Schrödinger operator (with $h_I > 0$)

$$(L + V)(.) = h_I^{-1}\left(\frac{\Delta}{2} + V_0\right)(h_I .), \tag{1}$$

which leaves the spectrum of $\frac{\Delta}{2} + V_0$ invariant, and multiplies eigenfunctions by h_I^{-1}. X_t is then a Brownian motion with local drift $\nabla \ln h_I$.

We will work under the following usual assumption.

ASSUMPTION 1. *The spectrum of $L + V$ is bounded by a greatest eigenvalue λ and has a spectral gap $\lambda^* > 0$. λ is associated with a unique eigenfunction $h \in \mathbb{L}^2(\mu)$ (the ground state), which is continuous and strictly positive.*

Note that Assumption 1 is very general and idiomatic; see [8, Chapter 3], [4], [9], [11], and the example of section 2.1.

By spectral theory, we get that

$$P_t^{V-\lambda}(\varphi) \xrightarrow[t \to +\infty]{\exp} h\mu(h\varphi) \quad \text{in } \mathbb{L}^2(\mu)$$

with rate $\lambda^\star > 0$. If the initial probability law η_0 of X_0 has a density in $\mathbb{L}^2(\mu)$, the Cauchy–Schwarz inequality gives

$$\eta_0 P_t^{V-\lambda}(\varphi) \xrightarrow[t \to +\infty]{\exp} \eta_0(h)\mu(h\varphi).$$

This is not sufficient to compute h numerically, since of course λ is unknown. That's why we resort to the renormalized version of the semigroup

$$\eta_t = \frac{\eta_0 P_t^V(\varphi)}{\eta_0 P_t^V(1)} = \frac{\eta_0 P_t^{V-\lambda}(\varphi)}{\eta_0 P_t^{V-\lambda}(1)}.$$

This probability flow verifies from the discussion above that

$$\eta_t(\varphi) \xrightarrow[t \to +\infty]{\exp} \frac{\mu(h\varphi)}{\mu(h)} = \eta_\infty(\varphi),$$

the ground state eigenvalue λ can be recovered from η_∞ by the identity

$$\eta_\infty(V) = \frac{\mu(-L(h) + \lambda h)}{\mu(h)} = \lambda,$$

and the Feynman–Kac semigroup can be recovered from η_t by

$$\eta_0 P_t^V(\varphi) = \eta_t(\varphi) \exp\left(\int_0^t \eta_s(V) ds\right).$$

Thus a stochastic particle approximation of η_t enables the computation of P_t^V, of λ, and of h under a renormalized weak form.

Now we consider continuous and bounded potentials $V \in \mathcal{C}_b(E)$ and smooth test functions $\varphi \in \mathcal{C}_b^\infty(E)$, and we remark then that η_t is a weak solution to the "nonlinear" Fokker–Planck equation

$$\begin{aligned} \partial_t \eta_t(\varphi) &= \eta_t\left(L(\varphi) + (V - \eta_t(V))\varphi\right) \\ &= \eta_t(L_{\eta_t}(\varphi)). \end{aligned} \tag{2}$$

The "nonlinear" Markov generator L_η is a jump perturbation of L defined by (other choices are possible, as in the abstract; see subsection 3.1)

$$L_\eta(\varphi)(x) = L(\varphi)(x) + \int_E (\varphi(y) - \varphi(x)) \left((V(x) - \eta(V))^- + (V(y) - \eta(V))^+\right) \eta(dy).$$

To compute η_t, we construct a particle system associated to this mean-field interpretation. The latter is denoted $\xi_t = (\xi_t^1, \dots, \xi_t^N) \in E^N$ with initial law $\eta_0^{\otimes N}$, and its Markov generator is given by

$$\mathcal{L}(\psi)(\xi) = \sum_{i=1}^N L_{m(\xi)}^{(i)}(\psi)(\xi) \quad \text{with} \quad m(\xi) = \frac{1}{N}\sum_{j=1}^N \delta_{\xi^j} \tag{3}$$

for any $\xi = (\xi^1, \dots, \xi^N) \in E^N$. The exponent (i) means that the operator acts on the ith coordinate of the test function $\psi \in \mathcal{C}_b^\infty(E^N)$. The empirical measure of the particle system ξ_t denoted

$$\eta_t^N = m(\xi_t) = \frac{1}{N}\sum_{j=1}^N \delta_{\xi_t^j}$$

is then a stochastic approximation of η_t and converges to the ground state η_∞ in the long run.

ξ_t consists of N walkers evolving independently according to the Markov generator L, but constrained by the following birth and death mechanism:

1. With rate $(V(\xi_t^i) - \eta_t^N(V))^-$, each walker ξ_t^i jumps to the location of a uniformly randomly chosen walker.
2. With rate $(V(\xi_t^i) - \eta_t^N(V))^+$, a uniformly randomly chosen walker jumps to the location of each walker ξ_t^i.

Under some localization assumptions (Assumptions 1, 2, and 3, with examples in $\mathbb{R}^d$), we prove a strong control on the long time behavior of this IPS:

$$\sup_{T\geq 0}\mathbb{E}(|\eta_T^N(\varphi)-\eta_T(\varphi)|^p)^{1/p}\leq \frac{C_p\|\varphi\|_\infty}{\sqrt{N}},$$
$$\sup_{T\geq 0}|\mathbb{E}(\eta_T^N(\varphi))-\eta_T(\varphi)|\leq \frac{C\|\varphi\|_\infty}{N},$$
$$\sup_{T\geq 0}\|\mathrm{Law}(\xi_T^i)-\eta_T\|_{tv}\leq \frac{C}{N}.$$

To get a more quantitative result, we then consider the asymptotic standard deviation of the estimator of λ,

$$\mathrm{Ad}^2(V)=\lim_{N\to+\infty}\overline{\lim}_{T\to+\infty}N\mathbb{E}\left((\eta_T^N(V)-\lambda)^2\right), \tag{4}$$

and we give an explicit upper bound on the latter, which remains finite in the usual mild situations with general unbounded potentials V.

2. Assumptions and examples. We begin with our main example (see also [3]), which motivates the results of the paper.

2.1. Example. We say that a positive function h has exponential fall-off at infinity as soon as $-\ln h$ goes to infinity at least linearly.

Let E be an open domain of $\mathbb{R}^d$ with boundary ∂E. Classically, we consider the Schrödinger operator $\frac{\Delta}{2}+V_0$, with V_0 continuous on $\bar{E}$ and going to $-\infty$ at infinity $\lim_{+\infty}V_0=-\infty$.

$\frac{\Delta}{2}+V_0$ is then self-adjoint for the core $\mathcal{C}_c^\infty(E)$ of smooth test functions with compact support in E (Dirichlet conditions) and has compact resolvent (see [11, Chapter 13]). The operator thus has a discrete spectrum with maximal eigenvalue λ, a spectral gap λ^*, and a ground state $h_0>0$ on E. h_0 is continuous on $\bar{E}$ with $h_0|_{\partial E}=0$ and has exponential fall-off at infinity (see [1]).

Now we consider the importance sampling transformation (1) for $h_I\in\mathcal{C}^\infty\cap\mathbb{L}^2(\bar{E})$, with $h_I>0$ on E, $h_I|_{\partial E}=0$ and exponential fall-off. The resulting operator $L+V$ then reads

$$L=\frac{\Delta}{2}+\nabla\ln h_I\nabla,$$
$$V=V_0+h_I^{-1}\frac{\Delta}{2}h_I.$$

$L+V$ is self-adjoint for the core $\mathcal{C}_c^\infty(E)$ in $\mathbb{L}^2(\mu)$ with $\mu(dx)=\frac{h_I^2(x)dx}{\int h_I^2(x)dx}$; it has the same spectrum as $\frac{\Delta}{2}+V_0$, but with continuous ground state $h=h_0h_I^{-1}>0$. As a consequence, $L+V$ satisfies Assumption 1.

To stick to our probabilistic setting we additionally ask that the following hold:

1. $\nabla h_I\neq 0$ on ∂E.
2. For some constant a and b, $x.\nabla\ln h_I(x)\leq a|x|^2+b$ for all $x\in\bar{E}$.
3. V or $h_I^{-1}\frac{\Delta}{2}h_I$ is bounded above.

By Proposition 7 of [3], L then defines a nonexplosive strong Feller diffusion X_t in E, verifying the stochastic differential equations (for some Brownian motion $t\mapsto W_t$)

$$dX_t=dW_t+\nabla\ln h_I(X_t)dt,$$

and reversible with respect to μ. Here are two examples satisfying Assumptions 2 and 3.

Remark 2.1. Within the context of section 2.1, Assumptions 2 and 3 are satisfied as soon as V_0 is Hölder continuous, and that there is an $\epsilon > 0$ such that, outside some compact set,

$$\epsilon \leq h = h_I h_0^{-1} \leq \epsilon^{-1}, \tag{5}$$

$$-\epsilon^{-1} \leq h_I^{-1} \frac{\Delta}{2} h_I - h_0^{-1} \frac{\Delta}{2} h_0 \leq -\epsilon. \tag{6}$$

Heuristically, this means that h_I and h_0 must have a similar behavior outside compact sets, h_I being chosen slightly more concave than h_0.

First example for bounded domains. Suppose now that E is bounded and V_0 is Hölder. The Schrödinger operator is regularizing and h_0 is smooth. Note this classical fact:[1] $\nabla h_0 \neq 0$ on ∂E. It is now always possible to construct explicitly an h_I satisfying (5) and (6) and thus Assumptions 1, 2, and 3.

Proof. On the boundary ∂E, ∇h_0, and ∇h_I are nondegenerated and directed along the normal vector of ∂E. This ensures (5). Now adjust the concavity of h_I near the boundary so that (6) is satisfied. ∎

Second example for unbounded domains. This case is slightly more intricate, so we only give a particular explicit example:

Suppose that $E = \mathbb{R}^d$, V_0 is Hölder, and that h_0 has the following expression:

$$h_0(x) = \mathrm{e}^{-\frac{|x|^4}{4} + \epsilon_0(x)},$$

where ϵ_0 is smooth and bounded with bounded first derivatives.

Now if we choose h_I such that, outside some compact set,

$$h_I(x) = \mathrm{e}^{-\frac{|x|^4}{4} + \epsilon_0(x) - \frac{C}{|x|^2}}$$

for some $C > 0$, then (5) and (6), and thus Assumptions 1, 2, and 3, are satisfied.

Proof. Inequality (5) is obvious. A straightforward computation shows that at infinity $V(x) - \lambda = -4C + o(|x|^{-2})$, which gives (6). ∎

Third example for general situations. Here is our last example, which less restrictive (neither V nor h^{-1} shall be bounded). Assumptions 2 and 3 are not satisfied, but the expression of the asymptotic standard deviation of the eigenvalue estimation $\mathrm{Ad}(V)$ (defined by (4)) remains finite, which is a very favorable indication of practical efficiency.

Take $E = \mathbb{R}^d$ and suppose V_0 behaves polynomially at infinity. Choose h_I such that

1. $\ln h_I$ and its first two derivatives are of polynomial behavior;
2. $h = h_0 h_I^{-1}$ is bounded with exponential fall-off.

Then the expression of $\mathrm{Ad}(V)$ remains bounded. Note that it is practically easy to choose such an h_I, since the exponential fall-off of h_0 is known from V_0 (see [1]).

Proof. Recall that $V = V_0 + \frac{\Delta}{2} \ln(h_I) + \frac{1}{2}(\nabla \ln(h_I))^2$ is polynomially dominated, and that $\frac{d\eta_\infty}{d\mu}(x) \propto h(x) = h_0(x) h_I^{-1}(x)$, $\frac{d\eta_\infty}{dx}(x) \propto h_0(x) h_I(x)$, and $\frac{d\mu}{dx}(x) \propto h_I^2(x)$ are bounded with exponential fall-off. The result follows then from Proposition 4.5. ∎

This latter case could be generalized to noncontinuous potentials V_0 lying locally in the Kato class (see [5]).

[1] Consider Theorems 4.7 and 4.19 of [5], and an integration by parts between $\frac{\Delta}{2} h_0$ and positive solutions of the Dirichlet boundary value problem.

2.2. Convergence of semigroups in the uniform sense. We define the nonlinear propagator associated to η_t by

$$\Phi_{t,T}(\nu) = \frac{\nu P^V_{T-t}}{\nu P^V_{T-t}(1)} \in \mathcal{P}(E).$$

By the semigroup property, it verifies the propagation equation $\eta_T = \Phi_{t,T}(\eta_t)$.

In this subsection, we give an assumption for the uniform convergence of $P_t^{V-\lambda}$ and its consequence for the stability of $\Phi_{t,T}$. This will be crucial for the stability of the particle approximation. The only assumption we need is the following.

ASSUMPTION 2. *V is bounded above and there is an $\epsilon > 0$ such that the subset $K_\epsilon = \{x \in E \mid V(x) - \lambda \geq -\epsilon\}$ is relatively compact in E.*

This is a natural physical assumption, which ensures that h is a "strict bound" state in the sense that V is a strict potential barrier outside some compact set.

We then have the following.

PROPOSITION 2.2. *Under Assumptions 1 and 2, the Feynman–Kac semigroup is uniformly exponentially converging in the sense that there is some $C \geq 0$ and $0 < \rho < 1$ such that for any test function φ,*

$$\|P_t^{V-\lambda}(\varphi) - h\mu(h\varphi)\|_\infty \leq \|\varphi\|_\infty C\rho^t.$$

Proof. We use the results developed by Tweedie and collaborators, for instance, in [6]. We consider the strong Feller irreducible Markov diffusion semigroup

$$P_t^h(\varphi) = h^{-1}P_t^{V-\lambda}(h\varphi),$$

its associated diffusion process X_t^h, and its extended generator $L^h = h^{-1}(L + V - \lambda)(h.)$, reversible with respect to $h^2(x)\mu(dx)$. We show that h^{-1} is a strict Lyapunov function for L^h outside $\bar{K}_\epsilon$ (in the sense of condition $(\tilde{\mathcal{D}})$ of [7]). Indeed we have that

1. $\bar{K}_\epsilon$ is compact and thus is a petite set for X_t^h (see [13, Theorems 7.1 and 5.1]);
2. $L^h(h^{-1}) + \epsilon h^{-1} = (V - \lambda + \epsilon)h^{-1}$ is bounded on $\bar{K}_\epsilon$ and negative outside.

So by Theorem 5.2 of [7], X_t^h is h^{-1}-uniformly ergodic, which means that

$$\sup_{|g| \leq h^{-1}} |P_t^h(g)(x) - \mu(h^2 g)| \leq h^{-1}(x)C\rho^t,$$

and gives the result for $\varphi = gh$. □

We then harvest the uniform stability of $\Phi_{t,T}$.

COROLLARY 2.3. *Under Assumptions 1 and 2, we have for some $C \geq 0$, $0 < \rho < 1$, and any $\nu \in \mathcal{P}(E)$*

$$|\Phi_{t,T}(\varphi)(\nu) - \eta_\infty(\varphi)| \leq \|\varphi\|_\infty \frac{C}{\nu(h)}\rho^{T-t}.$$

Proof. We take $\|\varphi\|_\infty \leq 1$ and use the Landau symbol "O" uniformly with respect to t, T, ν, and φ. From Proposition 2.2 we get

$$\begin{aligned}\Phi_{t,T}(\varphi)(\nu) = \frac{\nu P^{V-\lambda}_{T-t}(\varphi)}{\nu P^{V-\lambda}_{T-t}(1)} &= \frac{\nu(h)\mu(h\varphi) + O(\rho^{T-t})}{\nu(h)\mu(h) + O(\rho^{T-t})} \\ &= \frac{\mu(h\varphi) + O(\frac{\rho^{T-t}}{\nu(h)})}{\mu(h) + O(\frac{\rho^{T-t}}{\nu(h)})},\end{aligned}$$

which gives the result. □

2.3. A last assumption. To construct the particle system and carry out the long time analysis, we will need some more boundedness and regularity hypotheses.

ASSUMPTION 3.

1. *V is continuous and bounded.*
2. *$\ln h$ is continuous and bounded.*
3. *For $\varphi \in \mathcal{C}_b^\infty(E)$, $(t,x) \mapsto P_t^V(\varphi)(x)$ is $\mathcal{C}_b^{1,2}(E \times \mathbb{R}^+)$.*

Remark 2.4. $\mathcal{C}_b^{1,2}(E \times \mathbb{R}^+)$ denotes bounded continuous functions of E with continuous time derivative and continuous second order space derivatives. The regularity assumption is probably necessary only for intermediate technical purpose.

The second assumption could be replaced by $\sup_{t,N} \mathbb{E}\big(\frac{1}{(\eta_t^N(h))^p}\big) < +\infty$.

The regularity of $P_t^V(\varphi)$ and V gives the backward Fokker–Planck equation in a pointwise sense.

LEMMA 2.5. *For all $\varphi \in \mathcal{C}_b^\infty(E)$, we have*

$$\begin{aligned}\partial_t P_{T-t}^V(\varphi) &= -P_{T-t}^V(L(\varphi) + V\varphi) \\ &= -L(P_{T-t}^V(\varphi)) + V P_{T-t}^V(\varphi).\end{aligned}$$

3. The IPS approximation.

3.1. The generator of the IPS. In this subsection, we design the interacting particle interpretation of the flow $(\eta_t)_{t\geq 0}$, with initial probability $\eta_0 \in \mathcal{P}(E)$. The bounded potential being given, we first consider two continuous bounded applications $(\mathcal{P}(E), \text{weak topology}) \to (\mathcal{C}_b(E), \| \ \|_\infty)$, whose images are nonnegative functions denoted

$$\eta \mapsto V_\eta^b \geq 0, \quad \eta \mapsto V_\eta^d \geq 0$$

and verifying

$$V_\eta^b(x) - V_\eta^d(x) = V(x) + C_\eta,$$

where C_η does not depend on x (as explained in section 3.2, "b" stands for "birth" and "d" for "death").

We define

$$V_\eta^* = V_\eta^b + V_\eta^d.$$

Example 3.1. Here are several possible choices of the above functions:

1. $V^b = 0, \quad V^d = \sup(V) - V$ (as in the abstract).
2. $V^b = V^+, \quad V^d = V^-$.
3. $V_\eta^b = (V - \eta(V))^+, \quad V_\eta^d = (V - \eta(V))^-$.

The last choice is of fundamental importance since it is invariant by the transformation $V \mapsto V + C$, which leaves η_t invariant.

Recall from (2) that η_t satisfies the fundamental nonlinear Markovian evolution equation

$$\partial_t \eta_t(\varphi) = \eta_t(L_{\eta_t}(\varphi)),$$

but here the nonlinear Markov generator is more generally defined by

$$L_\eta(\varphi)(x) = L(\varphi)(x) + \int (\varphi(y) - \varphi(x))(V_\eta^b(y) + V_\eta^d(x))\, \eta(dy).$$

Indeed we have that

$$\begin{aligned}\eta(L_\eta(\varphi)) &= \eta(L(\varphi)) + \eta(V_\eta^b\varphi) - \eta(V_\eta^d\varphi) + \eta(V_\eta^d)\eta(\varphi) - \eta(V_\eta^b)\eta(\varphi)\\ &= \eta(L(\varphi) + V\varphi) - \eta(\varphi)\eta(V).\end{aligned}$$

If A is a linear operator, the associated formal "carré-du-champs" Γ_A is a bilinear operator defined by

$$\Gamma_A(\varphi,\varphi) = A(\varphi^2) - 2\varphi A(\varphi).$$

Recall that when A is the generator of a Markov process X_t, $\Gamma_A(\varphi,\varphi) \geq 0$ and $\int_0^t \Gamma_A(\varphi,\varphi)(X_s)ds$ is the predictable quadratic variation of the martingale part of $\varphi(X_t)$.

We can then define

$$\Gamma_{L_\eta}(\varphi,\varphi)(x) = \Gamma_L(\varphi,\varphi)(x) + \int (\varphi(y)-\varphi(x))^2(V_\eta^b(y) + V_\eta^d(x))\eta(dy)$$

and remark that

$$\begin{aligned}\eta(\Gamma_{L_\eta}(\varphi,\varphi)) &= \eta(\Gamma_L(\varphi,\varphi)) + \eta(\varphi^2 V_\eta^*) + \eta(\varphi^2)\eta(V_\eta^*) - 2\eta(V_\eta^*\varphi)\eta(\varphi)\\ &= \eta(\Gamma_L(\varphi,\varphi)) + \eta\left((\varphi-\eta(\varphi))^2(V_\eta^* + \eta(V_\eta^*))\right).\end{aligned}$$

We now consider the interacting particle model $(\xi_t)_{t\in\mathbb{R}^+}$ associated to the nonlinear operator L_η as defined in the introduction by its initial law $\eta_0^{\otimes N}$ and its Markov generator $\mathcal{L}$ given in (3). The IPS is a Markov process resulting from a bounded jump perturbation of N independent copies of X_t, and thus is well defined.

When we use as a test function the empirical mean $m(.)(\varphi) \in \mathcal{C}_b^\infty(E^N)$ of a $\varphi \in \mathcal{C}_b^\infty(E)$, we have the following simple form of the generator and its associated carré-du-champs.

LEMMA 3.2.

$$\begin{aligned}\mathcal{L}(m(.)(\varphi)) &= m(.)(L_{m(.)}(\varphi)),\\ \Gamma_{\mathcal{L}}(m(.)(\varphi), m(.)(\varphi)) &= \frac{1}{N} m(.)(\Gamma_{L_{m(.)}}(\varphi,\varphi)).\end{aligned}$$

Proof. The first identity is by definition. The second one is a straightforward formal computation. We use the linearity of $A \mapsto \Gamma_A$ to get

$$\Gamma_{\mathcal{L}}(\psi,\psi) = \sum_{i=1}^N \Gamma^{(i)}_{L_{m(.)}}(\psi,\psi),$$

and since $L_\eta(\text{constant}) = 0$, for any $\xi \in E^N$, we have

$$\begin{aligned}\Gamma^{(i)}_{L_{m(\xi)}}(m(.)(\varphi), m(.)(\varphi))(\xi) &= \frac{1}{N^2} 2\sum_{j\neq i} \varphi(\xi^j) L_{m(\xi)}(\varphi)(\xi^i) + \frac{1}{N^2} L_{m(\xi)}(\varphi^2)(\xi^i)\\ &\quad - 2\left(\frac{1}{N}\sum_j \varphi(\xi^j)\right)\frac{1}{N} L_{m(\xi)}(\varphi)(\xi^i)\\ &= \frac{1}{N^2}\Gamma^{(i)}_{m(\xi)}(\varphi,\varphi)(\xi^i),\end{aligned}$$

and the result follows. □

Now we can state our key tool.

PROPOSITION 3.3. *For all $\varphi_. \in \mathcal{C}_b^{1,2}(E \times \mathbb{R}^+)$, the process*

$$\mathcal{M}_t(\varphi_.) = \eta_t^N(\varphi_t) - \eta_0^N(\varphi_0) - \int_0^t \eta_s^N \left(\partial_s \varphi_s + L_{\eta_s^N}(\varphi_s)\right) ds$$

is a local martingale, with predictable quadratic variation given by

$$\left\langle \mathcal{M}(\varphi_.)\right\rangle_0^t = \frac{1}{N} \int_0^t \eta_s^N \left(\Gamma_{L_{\eta_s^N}}(\varphi_s, \varphi_s)\right) ds,$$

and jumps estimated by

$$|\Delta \mathcal{M}_t(\varphi_.)| \leq \frac{2\|\varphi_t\|}{N}.$$

We recall that

$$\eta_s^N(L_{\eta_s^N}(\varphi)) = \eta_s^N \left(L(\varphi) + (V - \eta_s^N(V))\varphi\right)$$

and

$$\eta_s^N(\Gamma_{L_{\eta_s^N}}(\varphi,\varphi)) = \eta_s^N(\Gamma_L(\varphi,\varphi)) + \eta_s^N \left((\varphi - \eta_s^N(\varphi))^2 (V^*_{\eta_s^N} + \eta_s^N(V^*_{\eta_s^N}))\right).$$

Proof. This is a particular case of the usual martingale problem associated to the Markov process ξ_t. The statement can be proved with a standard application of the Itô formula, with Markov property arguments for the jump part.

The estimate on the jumps follows from the fact that each jump concerns only one particle (see the probabilistic construction in subsection 3.2). □

From the above proposition we immediately get the stochastic differential equation

$$d\eta_t^N(\varphi) = \eta_t^N(L_{\eta_t^N}(\varphi))dt + d\mathcal{M}_t(\varphi),$$

which is a perturbation of (2) of the dynamic of η_t by a martingale whose jumps and predictable quadratic variation are of order $\frac{1}{N}$. In this sense, we already see that η_t^N is a natural approximation of the flow η_t. Of course, this point of view is too elementary to enable an asymptotic analysis mainly because of the nonlinearity of (2).

3.2. Probabilistic construction and genetic interpretation. We start with a more explicit expression for the IPS generator.

PROPOSITION 3.4. *We have $\mathcal{L} = \mathcal{L}^{mut} + \mathcal{L}^{sel}$ with the pair mutation/selection generators defined by*

$$\begin{aligned}
\mathcal{L}^{mut}(\psi)(\xi) &= \sum_{i=1}^N L^{(i)}(\psi)(\xi), \\
\mathcal{L}^{sel}(\psi)(\xi) &= \sum_{i=1}^N V^d_{m(\xi)}(\xi^i) \frac{1}{N} \sum_{j=1}^N (\psi(\xi^{i\to j}) - \psi(\xi)) \\
&\quad + \sum_{i=1}^N V^b_{m(\xi)}(\xi^i) \frac{1}{N} \sum_{j=1}^N (\psi(\xi^{j\to i}) - \psi(\xi)),
\end{aligned}$$

where if $\xi' = \xi^{i\to j}$, then $\xi'^k = \xi^k$ except for $k = i$, where $\xi'^i = \xi^j$.

Proof. The jump part of $\mathcal{L}$ is by definition

$$\mathcal{L}^{\mathrm{sel}}(\psi)(\xi) = \sum_{i=1}^{N} V^d_{m(\xi)}(\xi^i)\left(\frac{1}{N}\sum_{j=1}^{N}\psi(\xi^{i\to j}) - \psi(\xi)\right) + \sum_{i=1}^{N}\frac{1}{N}\sum_{j=1}^{N} V^b_{m(\xi)}(\xi^j)(\psi(\xi^{i\to j}) - \psi(\xi)),$$

and the result follows by exchanging the indexes i and j in the second part of the right-hand side of the identity. ∎

Thus the N walkers evolve according to the following birth and death mechanism, for any $i \in [1, N]$ ($\tau^{d/b,i}_{n+1}$ designing independent exponential clocks of mean 1):

1. Between each jump time, the walkers evolve independently according to the mutation generator L.
2. At random times $T^{d,i}_n$ defined by $\int_{T^{d,i}_n}^{T^{d,i}_{n+1}} V^d_{\eta^N_s}(\xi^i_s)ds = \tau^{d,i}_{n+1}$, a walker is uniformly randomly chosen, and the ith walker then jumps to its location.
3. At random times $T^{b,i}_n$ defined by $\int_{T^{b,i}_n}^{T^{b,i}_{n+1}} V^b_{\eta^N_s}(\xi^i_s)ds = \tau^{b,i}_{n+1}$, a walker is uniformly randomly chosen, and then jumps to the location of the ith walker.

This explains how the selection generator tends to "get rid of" walkers with relatively high potential $V^d_{\eta^N_t}$, and tends to "reproduce" walkers with relatively high potential $V^b_{\eta^N_t}$. The effect of selection is then to favor walkers with relatively high potential $V = V^b_{\eta^N_t} - V^d_{\eta^N_t} - C_{\eta^N_t}$. In this sense, the IPS can be seen as a continuous time genetic algorithm with fitness function V and mutations of generator L.

Moreover this structure enables a nice parallelized implementation, where walkers are individually collecting information from V, but yet learns globally the structure of the ground state h.

In practice, one may use some Euler discretization scheme, and may approximate integrals with sums. This requires at least the continuity of the potential V.

4. Long time behavior of the IPS.

4.1. Nonasymptotic control.

We give directly the main theoretical results of this paper, the proof being postponed to section 5.

THEOREM 4.1 (time-uniform $\mathbb{L}^p$ estimate). *We suppose that Assumptions* 1, 2, *and* 3 *are verified.*

There are constants C_p such that, for all test function $\varphi \in \mathcal{C}_b(E)$ with $\|\varphi\|_\infty \le 1$,

$$\sup_{T\ge 0}\mathbb{E}\left(|\eta^N_T(\varphi) - \eta_T(\varphi)|^p\right)^{1/p} \le \frac{C_p}{\sqrt{N}}.$$

THEOREM 4.2 (bias estimate/time-uniform convergence of a particle). *We suppose that Assumptions* 1, 2, *and* 3 *are verified.*

There is a constant C such that, for all $\varphi \in \mathcal{C}_b(E)$ with $\|\varphi\|_\infty \le 1$,

$$\sup_{T\ge 0}\left|\mathbb{E}\left(\eta^N_T(\varphi)\right) - \eta_T(\varphi)\right| \le \frac{C}{N},$$

$$\sup_{T\ge 0}\|Law(\xi^i_T) - \eta_T\|_{tv} \le \frac{C}{N}.$$

Remark 4.3. One can easily show that the particle system ξ_t is recurrent and ergodic. If the invariant measure is finite, it converges in law to a random variable ξ_∞ (this always happens when E is compact). η_∞^N is then the natural estimator of η_∞ and we have the almost sure convergence

$$\eta_\infty^N \xrightarrow[N\to+\infty]{a.s.} \eta_\infty \quad \text{in the weak topology,}$$

which follows the $\mathbb{L}^p$ estimate for $p=4$ with a Borel–Cantelli argument.

This situation is probably true in general for N large enough, although the positivity seems difficult to prove. Anyway, one can take for η_∞^N any adherent limit (which is a positive measure) of η_t^N under the weak topology of evanescent functions.

We want to lay the emphasis on the difficulty of the proof of these results, which comes from the nonlinear propagation of the error made by the particle approximation.

We also propose an asymptotic study of the standard deviation.

4.2. Long time asymptotic standard deviation. The asymptotic standard deviation gives a quantitative information of the IPS approximation. We show in Proposition 4.5 that the latter is likely to remain bounded in many mild situations of interest.

THEOREM 4.4. *Under Assumptions* 1, 2, *and* 3, *we have for any* $\varphi \in \mathcal{C}_b(E)$ ($\bar\varphi = \varphi - \eta_\infty(\varphi)$)

$$\begin{aligned}&\lim_{N\to+\infty} \overline{\lim}_{T\to+\infty} N\mathbb{E}\left((\eta_T^N(\varphi)-\eta_\infty(\varphi))^2\right)\\ &= \mathrm{Ad}^2(\varphi) = \eta_\infty(\bar\varphi^2) + 2\int_0^{+\infty} \eta_\infty\left(P_s^{V-\lambda}(\bar\varphi)^2(V_{\eta_\infty}^b + \eta_\infty(V_{\eta_\infty}^d))\right) ds.\end{aligned}$$

Note that by Proposition 2.2, the local noise introduced by interactions

$$s \mapsto \eta_\infty\left(P_s^{V-\lambda}(\bar\varphi)^2(V_{\eta_\infty}^b + \eta_\infty(V_{\eta_\infty}^d))\right)$$

is exponentially decreasing with s.

We're interested in clarifying this quantity for the meaningful case $\varphi = V$, which corresponds to the eigenvalue estimation. We will take $V_\eta^b = (V-\eta(V))^+$ and $V_\eta^d = (V-\eta(V))^-$.

PROPOSITION 4.5. *Under Assumption* 1 *only, we have*

$$\mathrm{Ad}^2(V) \le \eta_\infty((V-\lambda)^2) + \frac{1}{\lambda^*}\left\|\frac{d\eta_\infty}{d\mu} \times \left((V-\lambda)^+ + \eta_\infty((V-\lambda)^-)\right)\right\|_\infty \mu((V-\lambda)^2).$$

Proof. Since $\bar\varphi = \varphi - \eta_\infty(\varphi)$ is orthogonal to h in $\mathbb{L}^2(\mu)$, we have by spectral theory $\mu(P_t^{V-\lambda}(\bar\varphi)^2) \le e^{-2\lambda^* t}\mu(\bar\varphi^2)$. The result follows from Theorem 4.4 for $\varphi = V$ with $\eta_\infty(V) = \lambda$. □

When $\frac{d\eta_\infty}{d\mu} = \frac{h}{\mu(h)}$ is bounded with exponential fall-off, this upper bound is expected to remain finite in almost any situation of interest (see the third example of section 2.1).

5. Proofs. Throughout this section we will use the following notation:

1. $T > 0$ will be a deterministic horizon time and we will take $t \in [0,T]$.
2. $n \ge 0$ $p \ge 1$ are integers.
3. $\|\ \|$ is the uniform norm.
4. $\varphi \in \mathcal{C}_b^\infty(E)$ is a test function such that $\|\varphi\| \le 1$, and $\bar\varphi = \varphi - \eta_T(\varphi)$.

5. $C > 0$ a constant independent of test functions, of the time parameters t, T and of the number of particles N. In the same spirit, we will use the Landau notation "O" uniformly with these variables. Note: The constant C and the "O" notation may depend on integers n and p.

We recall that $\|V\| \leq C$ and $\sup_\eta \|V_\eta^*\| \leq C$.

The proofs are based on the use of a "linearized" version of the propagator of η_t defined by

$$Q_{t,T}(\varphi) = \frac{P^V_{T-t}(\varphi)}{\eta_t P^V_{T-t}(1)},$$

which verifies the propagation equation

$$\eta_T(\varphi) = \eta_t Q_{t,T}(\varphi).$$

The main idea is to analyze the martingale part and the predictable part of the process $t \mapsto \eta_t^N Q_{t,T}(\bar{\varphi})$ for $\bar{\varphi} = \varphi - \eta_T(\varphi)$. Because we have $\eta_t(Q_{t,T}(\bar{\varphi})) = 0$, it can be interpreted as a stochastic perturbation of the identically null process. Note that $\eta_T^N(Q_{T,T}(\bar{\varphi})) = \eta_T^N(\varphi) - \eta_T(\varphi)$, which is the quantity we wish to control when $T \to +\infty$.

To lighten the computations, the test function φ will be omitted.

Throughout these proofs, we will use the following stability results.

LEMMA 5.1. *The propagator $Q_{t,T}$ verifies the following properties:*
n being given, there is a C such that for any test function φ

$$\|Q_{t,T}(\varphi)\| \leq C,$$
$$\int_t^T \|Q_{s,T}(\varphi)\|^{2^n} ds \leq C(T-t).$$

Moreover there is some $0 < \rho < 1$ such that for any $\bar{\varphi} = \varphi - \eta_T(\varphi)$

$$\|Q_{t,T}(\bar{\varphi})\| \leq C\rho^{T-t},$$
$$\int_t^T \|Q_{s,T}(\bar{\varphi})\|^{2^n} ds \leq C.$$

Proof. First we write

$$Q_{t,T}(\varphi) = \frac{P^{V-\lambda}_{T-t}(\varphi)(x)}{\eta_t P^{V-\lambda}_{T-t}(1)}.$$

We claim that

$$\frac{1}{\eta_t P^{V-\lambda}_{T-t}(1)} \leq C.$$

Indeed by definition and the semigroup property we have $\eta_t P^{V-\lambda}_{T-t}(1) = \frac{\eta_0 P^{V-\lambda}_T(1)}{\eta_0 P^{V-\lambda}_t(1)}$, and $t \mapsto \eta_0 P^{V-\lambda}_t(1)$ is continuous, positive, and goes from 1 to $\eta_0(h)\mu(h) > 0$.

By Proposition 2.2, we then get for any φ $\|Q_{t,T}(\varphi)\| \leq C$.

For $\bar{\varphi} = \varphi - \eta_T(\varphi)$ we use the decomposition

$$|Q_{t,T}(\bar{\varphi})| = \frac{1}{(\eta_t P^{V-\lambda}_{T-t}(1))^2} |\eta_t P^{V-\lambda}_{T-t}(1) P^{V-\lambda}_{T-t}(\varphi) - \eta_t P^{V-\lambda}_{T-t}(\varphi) P^{V-\lambda}_{T-t}(1)|,$$

and again Proposition 2.2 gives a $0 < \rho < 1$ such that for any $\bar{\varphi}$, $\|Q_{t,T}(\bar{\varphi})\| \leq C\rho^{T-t}$. □

Note the control on the initial error.

LEMMA 5.2. *We have for any* φ

$$\mathbb{E}((\eta_0^N(\varphi) - \eta_0(\varphi))^p) \leq \frac{C}{N^{p/2}}.$$

Proof. Since, at time $t = 0$, all particles are sampled independently with law η_0, $\eta_0^N(\varphi)$ is a sum of N zero-mean independently and identically distribute (i.i.d.) variables. The result is then the Burkholder–Davies–Gundy (BDG) inequality for i.i.d. variables. □

5.1. Precise L^p-estimate of the key martingales. We want to apply Proposition 3.3 to the collection $(Q_{t,T}(\varphi)^{2^n})_{n\geq 0} \equiv (Q_{t,T}^{2^n})_{n\geq 0}$. Recall that $\eta_t(P_{T-t}^V(1)) = \frac{\eta_0 P_T^V(1)}{\eta_0 P_t^V(1)}$ and so

$$\begin{aligned}\partial_t \eta_t\left(P_{T-t}^V(1)\right) &= -\frac{\eta_0 P_T^V(1)}{\eta_0 P_t^V(1)^2}\eta_0 P_t^V(V)\\ &= -\eta_t\left(P_{T-t}^V(1)\right)\eta_t(V)\ ;\end{aligned}$$

this yields, using Lemma 2.5,

$$\begin{aligned}\partial_t Q_{t,T} &= -L(Q_{t,T}) - VQ_{t,T} + \frac{1}{\eta_t(P_{T-t}^V(1))^2}\eta_t\left(P_{T-t}^V(1)\right)\eta_t(V)\\ &= -L(Q_{t,T}) - (V - \eta_t(V))Q_{t,T}\end{aligned}$$

and

$$\partial_t Q_{t,T}^{2^n} = -2^n Q_{t,T}^{2^n-1} L(Q_{t,T}) - 2^n Q_{t,T}^{2^n} \times (V - \eta_t(V))\,.$$

From Proposition 3.3, we obtain a collection of difference of martingales between t and T indexed by n:

$$\begin{aligned}\mathcal{M}_t^T(Q_{\cdot,T}^{2^n}) &= \mathcal{M}_T(Q_{\cdot,T}^{2^n}) - \mathcal{M}_t(Q_{\cdot,T}^{2^n})\\ &= \eta_T^N(Q_{T,T}^{2^n}) - \eta_t^N(Q_{t,T}^{2^n}) - \int_t^T \eta_s^N\left(L(Q_{s,T}^{2^n}) - 2^n Q_{s,T}^{2^n-1} L(Q_{s,T})\right) ds\\ &\quad - \int_t^T \eta_s^N\left(Q_{s,T}^{2^n} \times \left(V - \eta_s^N(V) - 2^n(V - \eta_s(V))\right)\right) ds, \qquad (7)\end{aligned}$$

with predictable quadratic variation given by

$$\begin{aligned}&N\left\langle \mathcal{M}(Q_{\cdot,T}^{2^n})\right\rangle_t^T\\ &= \int_t^T \eta_s^N\left(\Gamma_L\left(Q_{s,T}^{2^n}, Q_{s,T}^{2^n}\right)\right) + \eta_s^N\left(\left(Q_{s,T}^{2^n} - \eta_s^N(Q_{s,T}^{2^n})\right)^2\left(V^* + \eta_s^N(V^*)\right)\right) ds. \qquad (8)\end{aligned}$$

We can get rid of the carré-du-champs term and get the following bounds up to a martingale.

LEMMA 5.3. *For all* $n \geq 0$ *and any test function* φ *we have*

$$N\left\langle \mathcal{M}(Q_{\cdot,T}^{2^n}(\varphi))\right\rangle_t^T \leq C(T - t + 1) - \mathcal{M}_t^T(Q_{\cdot,T}^{2^{n+1}}(\varphi)),$$

and for any centered test function $\bar{\varphi} = \varphi - \eta_T(\varphi)$

$$N\big\langle \mathcal{M}(Q^{2^n}_{.,T}(\bar{\varphi}))\big\rangle^T_t \leq C - \mathcal{M}^T_t(Q^{2^{n+1}}_{.,T}(\bar{\varphi})).$$

Proof. The formal carré-du-champs upper bound (Lemma 6.1) gives

$$\int_t^T \eta^N_s\left(\Gamma_L(Q^{2^n}_{s,T}, Q^{2^n}_{s,T})\right) ds$$
$$\overset{(=\text{ for } n=0)}{\leq} \int_t^T \eta^N_s\left(L(Q^{2^{n+1}}_{s,T}) - 2^{n+1}Q^{2^{n+1}-1}_{s,T}L(Q_{s,T})\right) ds.$$

From (8), we use the above inequality and (7) at rank $n+1$ to find the upper bound

$$\begin{aligned} N\big\langle \mathcal{M}(Q^{2^n}_{.,T})\big\rangle^T_t &\overset{(=\text{ for } n=0)}{\leq} -\mathcal{M}^T_t(Q^{2^{n+1}}_{.,T}) + \eta^N_T(Q^{2^{n+1}}_{T,T}) - \eta^N_t(Q^{2^{n+1}}_{t,T}) \\ &\quad - \int_t^T \eta^N_s\left(Q^{2^{n+1}}_{s,T}\big(V - \eta^N_s(V) - 2^{n+1}(V - \eta_s(V))\big)\right) ds \\ &\quad + \int_t^T \eta^N_s\left(\big(Q^{2^n}_{s,T} - \eta^N_s(Q^{2^n}_{s,T})\big)^2\big(V^* + \eta^N_s(V^*)\big)\right) ds. \end{aligned} \tag{9}$$

The result follows then from Lemma 5.1. □

The case $n = 0$ is of crucial importance. From (7) or Proposition 3.3 we can get

$$d\eta^N_t(Q_{t,T}) = d\mathcal{M}_t(Q_{.,T}) + \big(\eta_t(V) - \eta^N_t(V)\big)\,\eta^N_t(Q_{t,T})dt, \tag{10}$$

which gives for centered test functions, by integrating on $[0,T]$,

$$\begin{aligned} \eta^N_T(\varphi) - \eta_T(\varphi) &= \eta^N_0(Q_{0,T}(\bar{\varphi})) + \mathcal{M}_T(Q_{.,T}(\bar{\varphi})) \\ &\quad + \int_0^T \big(\eta_s(V) - \eta^N_s(V)\big)\left(\eta^N_s(Q_{s,T}(\bar{\varphi})) - \eta_s(Q_{s,T}(\bar{\varphi}))\right) ds. \end{aligned} \tag{11}$$

The martingale part and the initial error $\eta^N_0(Q_{0,T}(\bar{\varphi}))$ is expected to be of order $\frac{1}{\sqrt{N}}$, and the predictable part of order $\frac{1}{N}$.

Note that by developing the right-hand side of (9) with the identity $V = V^b_{\eta^N_s} - V^d_{\eta^N_s} + C_{\eta^N_s}$, the predictable quadratic variation of the martingale gives

$$\begin{aligned} N\big\langle \mathcal{M}(Q_{.,T})\big\rangle^T_0 &= -\mathcal{M}_T(Q^2_{.,T}) + \eta^N_T(Q^2_{T,T}) - \eta^N_0(Q^2_{0,T}) \\ &\quad + 2\int_0^T \eta^N_s(Q^2_{s,T}V^b_{\eta^N_s}) + \eta^N_s(Q^2_{s,T})\eta_s(V^d_{\eta^N_s}) \\ &\quad - \eta^N_s(Q_{s,T})\eta^N_s(Q_{s,T}V^*_{\eta^N_s}) + \eta^N_s(Q^2_{s,T})\big(\eta^N_s(V^b_{\eta^N_s}) - \eta_s(V^b_{\eta^N_s})\big)ds. \end{aligned} \tag{12}$$

We can now state the first result of this section, which is the control of all moments of these martingales.

THEOREM 5.4. *For all* $p \geq 1$, *all* $n \geq 0$, *and all test functions* φ,

$$\mathbb{E}\left(\big(\big[\mathcal{M}(Q^{2^n}_{.,T}(\varphi)\big]^T_t\big)^p\right) \leq \frac{C(T-t+1)^p}{N^p},$$

and for centered test functions $\bar{\varphi}$,

$$\mathbb{E}\left(\big(\big[\mathcal{M}(Q^{2^n}_{.,T}(\bar{\varphi})\big]^T_t\big)^p\right) \leq \frac{C}{N^p}.$$

Proof. Note that by localization, we can suppose that we work with bounded martingales.

Thanks to the Jensen inequality, it is sufficient to prove the inequalities for all $p = 2^q$. We are going to use an induction on q to prove that

$$\begin{aligned}&\forall n \geq 0,\\ &\mathbb{E}\left(\left(\left\langle \mathcal{M}(Q^{2^n}_{\cdot,T})\right\rangle^T_t\right)^{2^q}\right) \leq \frac{C(T-t+1)^{2^q}}{N^{2^q}},\\ &\mathbb{E}\left(\left(\left[\mathcal{M}(Q^{2^n}_{\cdot,T})\right]^T_t\right)^{2^q}\right) \leq \frac{C(T-t+1)^{2^q}}{N^{2^q}}.\end{aligned}$$

For $q = 0$, these inequalities are a direct consequence of Lemma 5.3.

Suppose the inequality true at order q and lower. Again from Lemma 5.3, we get

$$\begin{aligned}&\mathbb{E}\left(N^{2^{q+1}}\left(\left\langle \mathcal{M}(Q^{2^n}_{\cdot,T})\right\rangle^T_t\right)^{2^{q+1}}\right)\\ &\quad\leq C(T-t+1)^{2^{q+1}} + C\mathbb{E}\left(\mathcal{M}^T_t(Q^{2^{n+1}}_{\cdot,T})^{2^{q+1}}\right)\\ &\quad\leq C(T-t+1)^{2^{q+1}} + C\mathbb{E}\left(\left(\left[\mathcal{M}(Q^{2^{n+1}}_{\cdot,T})\right]^T_t\right)^{2^q}\right) \quad \text{(by the BDG inequality).}\end{aligned}$$

By induction, this proves the first upper bound at rank $q+1$.

Now we use the alternate BDG inequality stated in Lemma 6.2 to the martingale $\mathcal{M}(Q^{2^n}_{\cdot,T})$, whose jumps, by Proposition 7, verify $a \leq \frac{2\|Q^{2^n}_{t,T}\|}{N} \leq \frac{C}{N}$. This gives

$$\mathbb{E}\left(\left(\left[\mathcal{M}(Q^{2^n}_{\cdot,T})\right]^T_t\right)^{2^{q+1}}\right) \leq C\sum_{k=0}^{q+1}\frac{1}{N^{2^{q+2}-2^{k+1}}}\mathbb{E}\Big(\left(\left\langle \mathcal{M}(Q^{2^n}_{\cdot,T})\right\rangle^T_t\right)^{2^k}\Big).$$

By induction,

$$\begin{aligned}\mathbb{E}\left(\left(\left[\mathcal{M}(Q^{2^n}_{\cdot,T})\right]^T_t\right)^{2^{q+1}}\right) &\leq C\sum_{k=0}^{q+1}\frac{(T-t)^{2^k}}{N^{2^{q+2}-2^{k+1}+2^k}}\\ &\leq \frac{C(T-t)^{2^{q+1}}}{N^{2^{q+1}}},\end{aligned}$$

which proves the second upper bound at rank $q+1$.

The case of centered test functions is identical. □

Remark 5.5. Some results of [6] use $\mathbb{L}^p$ estimates of a similar martingale (Lemma 3.23) whose proof uses the Itô formula but may be incorrect. Resorting to the Itô formula seems to be intractable, and the techniques used for Theorem 5.4 enables us to clarify these results.

5.2. Proof of Theorem 4.1. First of all let's define the following quantity:

$$I_p(N) = \sup_{T,\varphi}\mathbb{E}\left(\left(\eta^N_T(\varphi) - \eta_T(\varphi)\right)^p\right).$$

In this subsection, we will prove the time-uniform estimate $I_p(N) \leq \frac{C}{N^{p/2}}$. We start with our first key lemma.

LEMMA 5.6. *There is an $\epsilon > 0$ independent of p such that*

$$I_p(N) \leq \frac{C}{N^{\epsilon p/2}}.$$

Proof. Let's fix T and use the decomposition

$$\eta_T^N(\varphi) - \eta_T(\varphi) = \underbrace{\eta_T^N(\varphi) - \Phi_{t,T}(\eta_t^N)(\varphi)}_{a(t)} + \underbrace{\Phi_{t,T}(\eta_t^N)(\varphi) - \eta_T(\varphi)}_{b(t)}.$$

$a(t)$ can be controlled by the stochastic errors made by the particle approximation between t and T. $b(t)$ can be controlled by the stability property of the limiting propagator Φ between t and T. $b(0)$ can also be controlled by the error made by the initial condition. We then optimize the whole in t.

Control of $a(t)$. Let us define the continuous finite variation process

$$A_{t_1}^{t_2} = \exp\left(\int_{t_1}^{t_2} (\eta_s^N(V) - \eta_s(V))ds\right).$$

An elementary integration by parts for $s \in [t,T]$ gives

$$\begin{aligned} d\big(A_t^s\, \eta_s^N(Q_{s,T})\big) &= \eta_s^N(Q_{s,T})\, A_t^s\, (\eta_s^N(V) - \eta_s(V))\, ds \\ &\quad + A_t^s\, d\eta_s^N(Q_{s,T}) \\ &= A_t^s\, d\mathcal{M}_s(Q_{.,T}) \quad \text{(by (10))}. \end{aligned}$$

Integrating from t to T and simplifying by $(A_t^T)^{-1}$ gives

$$\eta_T^N(\varphi) - (A_t^T)^{-1}\eta_t^N(Q_{t,T}(\varphi)) = (A_t^T)^{-1}\int_t^T A_t^s\, d\mathcal{M}_s(Q_{.,T}(\varphi)). \tag{13}$$

Now, recalling that $\Phi_{t,T}(\eta_t^N)(\varphi) = \frac{(A_t^T)^{-1}\eta_t^N(Q_{t,T}(\varphi))}{(A_t^T)^{-1}\eta_t^N(Q_{t,T}(1))}$, we write $a(t)$ as

$$a(t) = \eta_T^N(\varphi) - (A_t^T)^{-1}\eta_t^N(Q_{t,T}(\varphi)) - \Phi_{T-t}(\eta_t^N)(\varphi)\big(1 - (A_t^T)^{-1}\eta_t^N(Q_{t,T}(1))\big),$$

which using (13) gives the upper bound

$$|a(t)| \le (A_t^T)^{-1}\left(\left|\int_t^T A_t^s\, d\mathcal{M}_s(Q_{.,T}(\varphi))\right| + \left|\int_t^T A_t^s\, d\mathcal{M}_s(Q_{.,T}(1))\right|\right),$$

and thus

$$\begin{aligned} \mathbb{E}\left(|a(t)|^p\right) &\le Ce^{2\|V\|p(T-t)}\mathbb{E}\left(\left|\int_t^T A_t^s\, d\mathcal{M}_s(Q_{.,T}(\varphi))\right|^p\right) \\ &\le Ce^{2\|V\|p(T-t)}\mathbb{E}\left(\left|\int_t^T (A_t^s)^2\, d\big[\mathcal{M}(Q_{.,T}(\varphi))\big]_s\right|^{p/2}\right) \text{ (by the BDG inequality)} \\ &\le Ce^{4\|V\|p(T-t)}\mathbb{E}\left(\left|\big[\mathcal{M}(Q_{.,T}(\varphi))\big]_t^T\right|^{p/2}\right) \\ &\le Ce^{4\|V\|p(T-t)}\frac{(T-t+1)^{p/2}}{N^{p/2}} \quad \text{(by Theorem 5.4)} \\ &\le C\frac{R^{p(T-t)}}{N^{p/2}} \quad (\text{for } R = \mathrm{e}^{4\|V\|+1} > 1). \end{aligned}$$

Control of $b(t)$. We have for some $0 < \rho < 1$, as a direct consequence of Corollary 2.3,

$$\begin{aligned} \mathbb{E}(|b(t)|^p) &= \mathbb{E}\big(\big|\Phi_{t,T}(\eta_t^N)(\varphi) - \Phi_{t,T}(\eta_t)(\varphi)\big|^p\big) \\ &\le \left(\mathbb{E}\left(\frac{1}{\eta_t^N(h)^p}\right) + 1\right)C\rho^{T-t} \\ &\le C\rho^{T-t} \quad \text{by Assumption 3.} \end{aligned}$$

Control of $b(0)$. We remark that $\eta_0(Q_{0,T}(1)) = 1$ and write $b(0)$ as

$$b(0) = \big(\eta_0^N(Q_{0,T}(\varphi)) - \eta_0(Q_{0,T}(\varphi))\big) + \Phi_{0,T}(\eta_0^N)(\varphi)\big(\eta_0(Q_{0,T}(1)) - \eta_0^N(Q_{0,T}(1))\big),$$

which gives by Lemma 5.2

$$\mathbb{E}(|b(0)|^p) \leq \frac{C}{N^{p/2}}.$$

Global control. We have

$$\mathbb{E}((a(0)+b(0))^p) \leq C\frac{R^{pT}+1}{N^{p/2}},$$
$$\mathbb{E}((a(t)+b(t))^p) \leq C\frac{R^{p(T-t)}}{N^{p/2}} + C\rho^{p(T-t)} \quad (\forall t \in [0,T]).$$

Now we take $\epsilon = \frac{-\ln\rho}{-\ln\rho + \ln R}$ and remark that

$$\frac{R^{\frac{1}{2}\frac{\ln N}{\ln R - \ln\rho}}}{N^{1/2}} = \frac{1}{N^{\epsilon/2}}$$

and

$$\rho^{\frac{1}{2}\frac{\ln N}{\ln R - \ln\rho}} = \frac{1}{N^{\epsilon/2}}.$$

We then get $\mathbb{E}((\eta_T^N(\varphi) - \eta_T(\varphi))^p) \leq \frac{C}{N^{\epsilon p/2}}$ from the first inequality when $T \leq \frac{1}{2}\frac{\ln N}{\ln R - \ln\rho}$, and from the second one otherwise for $T - t = \frac{1}{2}\frac{\ln N}{\ln R - \ln\rho}$. ∎

Now we go back to (11), which readily gives

$$\big(\eta_T^N(\varphi) - \eta_T(\varphi)\big)^p \leq C\big(\eta_0^N(Q_{0,T}(\bar\varphi))\big)^p + C\mathcal{M}_T^p(Q_{\cdot,T}) + C\bigg(\int_0^T |\eta_s^N(V) - \eta_s(V)||\eta_s^N(Q_{s,T}(\bar\varphi))|ds\bigg)^p.$$

From Lemma 5.2,

$$\mathbb{E}(\eta_0^N(Q_{0,T}(\bar\varphi))^p) \leq \frac{C}{N^{p/2}}.$$

From Theorem 5.4,

$$\mathbb{E}\big(\mathcal{M}_T^p(Q_{\cdot,T}(\bar\varphi))\big) \leq \frac{C}{N^{p/2}}.$$

On the other hand, using the Hölder inequality, we also have

$$\bigg(\int_0^T |\eta_s^N(V) - \eta_s(V)||\eta_s^N(Q_{s,T}(\bar\varphi))|ds\bigg)^p$$
$$\leq \int_0^T |\eta_s^N(V) - \eta_s(V)|^p \bigg|\eta_s^N\bigg(\frac{Q_{s,T}(\bar\varphi)}{\|Q_{s,T}(\bar\varphi)\|}\bigg)\bigg|^p \|Q_{s,T}(\bar\varphi)\|ds\bigg(\int_0^T \|Q_{s,T}(\bar\varphi)\|ds\bigg)^{p-1}$$
$$\leq C\int_0^T |\eta_s^N\bigg(\frac{V}{\|V\|}\bigg) - \eta_s\bigg(\frac{V}{\|V\|}\bigg)\bigg|^p \bigg|\eta_s^N\bigg(\frac{Q_{s,T}(\bar\varphi)}{\|Q_{s,T}(\bar\varphi)\|}\bigg) - \eta_s\bigg(\frac{Q_{s,T}(\bar\varphi)}{\|Q_{s,T}(\bar\varphi)\|}\bigg)\bigg|^p \|Q_{s,T}(\bar\varphi)\|ds.$$

Taking expectations, and then using the Cauchy–Schwarz inequality, we obtain

$$\begin{aligned}\mathbb{E}\left(\left(\int_0^T |\eta_s^N(V)-\eta_s(V)||\eta_s^N(Q_{s,T}(\bar\varphi))|ds\right)^p\right) &\le C\int_0^T I_{2p}(N)\|Q_{s,T}(\bar\varphi)\|ds\\ &\le CI_{2p}(N),\end{aligned} \tag{14}$$

which gives on the whole for all $p \le 1$

$$I_p(N) \le \frac{C}{N^{p/2}} + I_{2p}(N).$$

Applying this result to Lemma 5.6 gives

$$I_p(N) \le \frac{C}{N^{\inf(2\epsilon,1)p/2}},$$

and by induction we get

$$I_p(N) \le \frac{C}{N^{p/2}},$$

which ends the proof.

5.3. Proof of Theorem 4.2. We take expectation in (11) to find

$$\mathbb{E}(\eta_T^N(\varphi)) - \eta_T(\varphi) = \int_0^T \mathbb{E}\left(\left(\eta_s(V)-\eta_s^N(V)\right)\eta_s^N\left(\frac{Q_{s,T}(\bar\varphi)}{\|Q_{s,T}(\bar\varphi)\|}\right)\right)\|Q_{s,T}(\bar\varphi)\|ds.$$

As above, we use the Cauchy–Schwarz inequality and find that

$$\begin{aligned}|\mathbb{E}(\eta_T^N(\varphi)) - \eta_T(\varphi)| &\le C\int_0^T I_2(N)\|Q_{s,T}(\bar\varphi)\|ds\\ &\le CI_2(N) \le \frac{C}{N},\end{aligned} \tag{15}$$

which gives the estimate on the bias.

The second result is a direct consequence of exchangeability of particles.

5.4. Proof of Theorem 4.4. The study of the asymptotic standard deviation relies on the following asymptotic behavior.

LEMMA 5.7. *For all $T > 0$, and $\bar\varphi = \varphi - \eta_T(\varphi)$,*

$$\begin{aligned}\mathbb{E}\left((\eta_T^N(\varphi)-\eta_T(\varphi))^2\right) &= \frac{1}{N}\mathbb{E}(\eta_T^N(\bar\varphi)^2)\\ &\quad + \frac{2}{N}\mathbb{E}\left(\int_0^T \eta_s^N\left(Q_{s,T}^2(\bar\varphi)V_{\eta_s^N}^b\right) + \eta_s^N\left(Q_{s,T}^2(\bar\varphi)\right)\eta_s(V_{\eta_s^N}^d)ds\right) + O\left(\frac{1}{N^{3/2}}\right).\end{aligned}$$

Proof. Again we start from (11):

$$\begin{aligned}\eta_T^N(\varphi) - \eta_T(\varphi) &= \underbrace{\eta_0^N(Q_{0,T}(\bar\varphi)) + \mathcal{M}_T(Q_{\cdot,T}(\bar\varphi))}_{a}\\ &\quad + \underbrace{\int_0^T \left(\eta_s(V)-\eta_s^N(V)\right)\eta_s^N(Q_{s,T}(\bar\varphi))\,ds}_{b},\end{aligned}$$

which gives

$$\mathbb{E}((\eta_T^N(\varphi)-\eta_T(\varphi))^2)=\mathbb{E}(a^2)+\mathbb{E}(b^2)+2\mathbb{E}(ab).$$

Now we note by the results of the previous section—that is to say, by (14)—that

$$\mathbb{E}(b^2)=\mathbb{E}\bigg(\bigg|\int_0^T(\eta_s(V)-\eta_s^N(V))\eta_s^N\bigg(\frac{Q_{s,T}(\bar\varphi)}{\|Q_{s,T}(\bar\varphi)\|}\bigg)\|Q_{s,T}(\bar\varphi)\|ds\bigg|^2\bigg)=O\bigg(\frac{1}{N^2}\bigg),$$

and by Theorem 5.4 and Lemma 5.2

$$\mathbb{E}(a^2)=\mathbb{E}(\mathcal{M}_T(Q_{.,T}(\bar\varphi))^2)+\mathbb{E}(\eta_0^N(Q_{0,T}(\bar\varphi))^2)=O\bigg(\frac{1}{N}\bigg).$$

So we get

$$\mathbb{E}\left((\eta_T^N(\varphi)-\eta_T(\varphi))^2\right)=\mathbb{E}\left(\eta_0^N(Q_{0,T}(\bar\varphi))^2\right)+\mathbb{E}\big(\big\langle\mathcal{M}(Q_{.,T}(\bar\varphi))\big\rangle_0^T\big)+O\bigg(\frac{1}{N^{3/2}}\bigg).$$

Now we shall use the identity (12) to compute the asymptotic (with respect to N) value of $\mathbb{E}(\langle\mathcal{M}(Q_{.,T}(\bar\varphi))\rangle_0^T)$. For this purpose, we note that by Theorem 4.1

$$\begin{aligned}\bigg|\mathbb{E}\bigg(\eta_s^N\bigg(\frac{Q_{s,T}(\bar\varphi)}{\|Q_{s,T}(\bar\varphi)\|}\bigg)\eta_s^N\bigg(\frac{Q_{s,T}(\bar\varphi)}{\|Q_{s,T}(\bar\varphi)\|}V^*_{\eta_s^N}\bigg)\bigg)\bigg|&\le C\mathbb{E}\bigg(\bigg|\eta_s^N\bigg(\frac{Q_{s,T}(\bar\varphi)}{\|Q_{s,T}(\bar\varphi)\|}\bigg)\bigg|\bigg)\\&=O\bigg(\frac{1}{N^{1/2}}\bigg),\end{aligned}$$

and in the same way

$$\bigg|\mathbb{E}\bigg(\eta_s^N\bigg(\frac{Q^2_{s,T}(\bar\varphi)}{\|Q^2_{s,T}(\varphi)\|}\bigg)\big(\eta_s^N(V^b_{\eta_s^N})-\eta_s(V^b_{\eta_s^N})\big)\bigg)\bigg|=O\bigg(\frac{1}{N^{1/2}}\bigg).$$

Finally we remark that $\eta_0^N(Q_{0,T}(\bar\varphi))$ is a sum of centered i.i.d. random variables, and thus

$$\mathbb{E}\left(\eta_0^N(Q^2_{0,T}(\bar\varphi))\right)=\eta_0(Q^2_{0,T}(\bar\varphi))=\mathbb{E}\left(\eta_0^N(Q_{0,T}(\bar\varphi))^2\right),$$

which ends the proof. □

Now recall that Theorem 4.1 implies by a Borel–Cantelli argument:

$$\eta_s^N\xrightarrow{a.s.}\eta_s\quad\text{(in the weak sense)}$$

We take the limit first when $N\to+\infty$ in Lemma 5.7 uniformly with respect to T, and then when $T\to+\infty$. Of course, the two limits commute. This gives by the Lebesgue convergence theorem

$$\begin{aligned}\lim_{N\to+\infty}N\mathbb{E}\left((\eta_T^N(\varphi)-\eta_T(\varphi))^2\right)&=\eta_T\left((\varphi-\eta_T(\varphi))^2\right)\\&\quad+2\int_0^T\eta_s\big(Q^2_{s,T}(\bar\varphi)V^b_{\eta_s}\big)+\eta_s(Q^2_{s,T}(\bar\varphi))\eta_s(V^d_{\eta_s})ds.\end{aligned}$$

Now we do the change of variables $s\mapsto T-s$ in the above integrand and take the limit $T\to+\infty$. We have

$$\begin{aligned}\eta_{T-s}&\to\eta_\infty,\\\bar\varphi=\varphi-\eta_T(\varphi)&\to\bar\varphi=\varphi-\eta_\infty(\varphi),\\Q_{T-s,T}(\bar\varphi)&\to\frac{P_s^V(\bar\varphi)}{\eta_\infty P_s^V(1)}=P_s^{V-\lambda}(\bar\varphi),\end{aligned}$$

which gives the asymptotic standard deviation.

6. Two general lemmas.

LEMMA 6.1 (an upper bound for the "carré-du-champs" operator). *Let L be a Markov generator and Γ be its associated "carré-du-champs" operator defined by $\Gamma(\varphi,\varphi) = L(\varphi^2) - 2\varphi L(\varphi)$. Then we have the upper bound for all $n \geq 0$:*

$$\Gamma(\varphi^{2^n},\varphi^{2^n}) \leq L(\varphi^{2^{n+1}}) - 2^{n+1}\varphi^{2^{n+1}-1}L(\varphi).$$

Proof. Check out by induction the formal identity

$$\Gamma(\varphi^{2^n},\varphi^{2^n}) = L(\varphi^{2^{n+1}}) - 2^{n+1}\varphi^{2^{n+1}-1}L(\varphi) - \sum_{k=1}^{n} 2^{n+1-k}\varphi^{2^{n+1}-2^k}\Gamma(\varphi^{2^{k-1}},\varphi^{2^{k-1}}),$$

and use the positivity property $\Gamma(\varphi,\varphi) \geq 0$. □

LEMMA 6.2 (BDG inequalities). *Let M be a quasi-left-continuous (i.e., with continuous predictable increasing process) locally square-integrable martingale with $M_0 = 0$ and bounded jumps $\sup_t |\Delta M_t| \leq a < +\infty$. Then there is a constant C (dependant on q) such that*

$$\mathbb{E}\big(\sup_t M_t^{2^{q+1}}\big) \leq C\mathbb{E}\big(\big[M\big]_\infty^{2^q}\big) \leq C\sum_{k=0}^{q} a^{2^{q+1}-2^{k+1}}\mathbb{E}\big(\big\langle M\big\rangle_\infty^{2^k}\big).$$

Proof. The first inequality is the classical BDG inequality (p. 350 of [10]).

For the second, by localization, we can suppose that M is a square-integrable martingale. We are to use the martingale $N = \big[M\big] - \big\langle M\big\rangle$. Because $\big\langle M\big\rangle$ is continuous $\Delta N = \Delta\big[M\big] = (\Delta M)^2$. Moreover, N has finite variation, so

$$\begin{aligned}\big[N\big] &= \sum_{s\leq\cdot}(\Delta N_s)^2 = \sum_{s\leq\cdot}(\Delta M_s)^4 \\ &\leq a^2\sum_{s\leq\cdot}(\Delta M_s)^2 \leq a^2\big[M\big] \\ &\leq a^2(N + \big\langle M\big\rangle). \qquad (16)\end{aligned}$$

We will also us the general fact (C depends on q)

$$\forall x,y,\quad (x+y)^{2^q} \leq C(x^{2^q} + y^{2^q}). \qquad (17)$$

By definition of N and (17) we get

$$\mathbb{E}\big(\big[M\big]_\infty^{2^q}\big) \leq C\mathbb{E}\big(\sup_t N_t^{2^q}\big) + C\mathbb{E}\big(\big\langle M\big\rangle_\infty^{2^q}\big).$$

Now it remains to prove for any $q \geq 1$ that

$$\mathbb{E}\big(\sup_t N_t^{2^q}\big) \leq \sum_{k=0}^{q-1} Ca^{2^{q+1}-2^{k+1}}\mathbb{E}\big(\big\langle M\big\rangle_\infty^{2^k}\big), \qquad (18)$$

which we are going to do by induction on q. For $q = 1$, (18) follows from the BDG inequality applied to N_t, with (16). Suppose (18) is true for a given q. Applying again the BDG inequality to N_t, and using (16) and (17), we get

$$\mathbb{E}\big(\sup_t N_t^{2^{q+1}}\big) \leq Ca^{2^{q+1}}\mathbb{E}\big(\sup_t N_t^{2^q}\big) + Ca^{2^{q+1}}\mathbb{E}\big(\big\langle M\big\rangle_\infty^{2^q}\big).$$

Inequality (18) at rank $q+1$ then follows from the induction hypothesis. □

ANALYSIS OF AN INVERSE FIRST PASSAGE PROBLEM FROM RISK MANAGEMENT*

LAN CHENG†, XINFU CHEN†, JOHN CHADAM†, AND DAVID SAUNDERS‡

Abstract. We study the following "inverse first passage time" problem. Given a diffusion process X_t and a probability distribution q on $[0,\infty)$, does there exist a boundary $b(t)$ such that $q(t) = \mathbb{P}[\tau \le t]$, where τ is the first hitting time of X_t to the time-dependent level $b(t)$? A free boundary problem for a parabolic partial differential operator is associated with the inverse first passage time problem. We prove the existence and uniqueness of a viscosity solution to this problem. We also investigate the small time behavior of the boundary $b(t)$, presenting both upper and lower bounds. Finally, we derive some integral equations characterizing the boundary.

Key words. free boundary problem, mathematical finance, first passage problem, boundary crossing, inverse problem

1. Introduction.

In this paper we study the following free boundary problem: find a boundary $b(t)$ $(t > 0)$ and an unknown function $w = w(x,t)$ $(x \in \mathbb{R},\ t \ge 0)$ such that

$$
\begin{cases}
w_t(x,t) = \frac{1}{2}(\sigma^2 w_x)_x - \mu w_x & \text{for } x > b(t), \quad t > 0, \\
w(x,t) = p(t) & \text{for } x \le b(t), \quad t > 0, \\
w_x(x,t) = 0 & \text{for } x \le b(t), \quad t > 0, \\
0 \le w(x,t) < p(t) & \text{for } x > b(t), \quad t > 0, \\
w(x,0) = \mathbf{1}_{(-\infty,0)}(x) & \text{for } x \in \mathbb{R}, \quad t = 0,
\end{cases}
\tag{1.1}
$$

where $q(t) = 1 - p(t)$ is a given cumulative probability distribution function with the following properties:

$$
1 = p(0) = \lim_{t \searrow 0} p(t), \quad p(t_1) \ge p(t_2) \ge 0 \quad \forall\, t_1 < t_2. \tag{1.2}
$$

This problem arises from the consideration of the first passage times of diffusion processes to curved boundaries. More specifically, let X_t be the solution of the following stochastic differential equation:

$$
dX_t = \mu(X_t,t)dt + \sigma(X_t,t)dB_t, \qquad X_0 = 0, \tag{1.3}
$$

where B_t is a standard Brownian motion on a filtered probability space satisfying the usual conditions, $\mu : \mathbb{R} \times \mathbb{R}_+ \to \mathbb{R}$ and $\sigma : \mathbb{R} \times \mathbb{R}_+ \to \mathbb{R}$ are smooth bounded functions,

and $\sigma(x,t) > \varepsilon > 0$ for all $x \in \mathbb{R}, t \geq 0$. For a given function $b : \mathbb{R}_+ \to \mathbb{R}$ we define the first passage time of the diffusion process X_t to the curved boundary $b(t)$ to be

$$\tau = \inf\{t > 0 \mid X_t \leq b(t)\}. \tag{1.4}$$

Two important problems concerning the first passage time of a diffusion process to a curved boundary are the following:

1. *The first passage problem*: Given a barrier function $b(t)$, find the survival probability $p(t)$ that X does not cross b before or at t:

$$p(t) := \mathbb{P}\{\tau > t\}. \tag{1.5}$$

2. *The inverse first passage problem*: Given a survival probability function $p(t)$, find a barrier function $b(t)$, such that (1.5) holds.

The first passage problem is a classical problem in probability and is the subject of a rather large literature. It is also fundamental in many applications of diffusion processes to engineering, physics, biology, and economics. For a survey of techniques for approximating and computing first passage times to curved boundaries and a discussion of their applications in the biological sciences, we refer the reader to [18]. The financial applications motivating the current study are discussed below.

The work of Peskir [16, 17] on the first passage problem is of particular relevance for the inverse problem discussed in this paper. In [17], he derived a sequence of integral equations[1]

$$t^{n/2} H_n\left(\frac{b(t)}{\sqrt{t}}\right) + \int_0^t (t-s)^{n/2} H_n\left(\frac{b(t)-b(s)}{\sqrt{t-s}}\right) \dot{p}(s)ds = 0, \quad n = -1, 0, 1, \ldots, \tag{1.6}$$

where $H_{-1}(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$ and $H_n(x) = \int_x^\infty H_{n-1}(z)dz$ for $n \geq 0$. In [16], under the assumption that $b(t)$ is C^1 on $(0,\infty)$, decreasing, and concave, Peskir derived the equality

$$\dot{p}(0+) = -\lim_{t \searrow 0} \frac{1}{2\sqrt{2\pi}} \frac{b(t)}{t^{3/2}} e^{-\frac{b^2(t)}{2t}} = -\lim_{t \searrow 0} \frac{\dot{b}(t)}{\sqrt{2\pi t}} e^{-\frac{b^2(t)}{2t}},$$

provided that the second or third limit exists.

The inverse first passage problem is much harder than the direct problem, and there has been relatively little work on it. The studies on the problem to date are principally concerned with the numerical calculation of the boundary $b(t)$ for a given $p(t)$. There is no publication proving the well-posedness (existence and uniqueness) of the boundary given the survival probability.

Our interest in the inverse first passage problem originates[2] from structural models of credit risk in financial markets. Consider a company whose asset value and debt at time $t \geq 0$ are denoted by A_t and D_t, respectively, with D_t assumed to be deterministic. Assume the following:

1. $D_0 \leq A_0$ and the company is in *default* at a time $t > 0$ if $A_t < D_t$.

[1] In this reference, the derivations are carried out for the case $\sigma \equiv 1$ and $\mu \equiv 0$, i.e., when X_t is a Brownian motion. As mentioned in the reference, the techniques directly extend to other diffusion processes.

[2] We thank A. Kreinin and R. Stamicar for introducing us to this problem and for helpful discussions.

2. $A_t \geq 0$ follows a diffusion process (e.g., a geometric Brownian motion, as in [14]).

It is convenient to use the *default index* X_t and the *barrier function* $b(t)$ defined by

$$X_t := \log \frac{A_t}{A_0}, \qquad b(t) := \log \frac{D_t}{A_0}.$$

Then X_t is a diffusion process satisfying (1.3). In this context, the inverse first passage time problem is the problem of finding the default barrier $b(t)$ given the survival function $p(t)$.

The problem of finding the default barrier $b(t)$ given the survival function $p(t)$ is of critical importance in many problems in modern credit risk management. Hull and White [8, 9] show how the default barrier $b(t)$ can be used, once it is computed, in a model for pricing credit default swaps with counterparty default, and basket credit default swaps, and remark that it could be used to price other, exotic, credit derivatives.[3] They also show how the required input to our problem, the (risk-neutral) survival probability $p(t)$, can be derived from observed market prices. Iscoe, Kreinin, and Rosen [10] show how the inverse first passage problem is a key component in a multistep integrated market and credit risk portfolio model. They state that in their framework, the survival probability $p(t)$ may be derived from the internal model of a financial institution, from an external credit rating agency, or from published transition matrices for credit ratings, assuming a Markov process (see also [12]).

1.1. Mathematical formulation and existing results. Formulating the problems in a PDE setting, we introduce a new function $w(x,t)$ being the probability that the company does not default before or at t and its default index X_t is bigger than x, i.e.,

$$w(x,t) := \mathbb{P}\{X_t > x,\, \tau > t\}. \tag{1.7}$$

Then the density function of X_t when $\tau > t$ can be computed by

$$u(x,t) = \frac{d}{dx}\mathbb{P}\{X(t) \leq x, \tau > t\} = (p(t) - w(x,t))_x. \tag{1.8}$$

From (1.3) and the Kolmogorov forward equation, we see that (assuming sufficient regularity) $w(x,t)$ $(x \in \mathbb{R}, t \geq 0)$ satisfies (1.1). From this we see the following:

- The first passage problem is to solve (1.1) for p, with given b.
- The inverse first passage problem is to solve (1.1) for b, with given p.

The first passage problem can be solved as follows. From the Kolmogorov forward equation, we obtain the following closed system for $u(x,t)$:

$$\begin{cases} u_t(x,t) = \frac{1}{2}(\sigma^2 u)_{xx} - (\mu u)_x & \text{for } x > b(t), \quad t > 0, \\ u(x,t) = 0 & \text{for } x \leq b(t), \quad t > 0, \\ u(x,0) = \delta(x) & \text{for } x > 0, \quad t = 0, \end{cases} \tag{1.9}$$

[3] A standard credit default swap (CDS) is a credit derivative in which a buyer provides a series of payments to a seller in exchange for the seller's commitment to make a payment to the buyer in the event that a third party (the reference entity) defaults on one of its bonds. Pricing a CDS with counterparty default means taking into account the fact that the seller itself may default on its obligations before the reference entity defaults (in which case the buyer would not receive payment). In a basket CDS the seller provides a payment to the buyer when the first of a set of reference entities defaults.

where δ is a Dirac measure concentrated at 0. Given sufficiently regular b, this system has a unique solution. Then p and $\dot{p}$ can be computed from the formulas

$$p(t) = \int_{b(t)}^{\infty} u(x,t)dx \qquad \forall\, t \geq 0, \tag{1.10}$$

$$\dot{p}(t) = -\frac{1}{2}(\sigma^2 u)_x\big|_{x=b(t)} \qquad \forall\, t \geq 0. \tag{1.11}$$

It is possible to compute the solution in a closed form in only a few special cases. However, there is a large literature on numerical and analytic approximations of the solution.

Our system (1.1) is obtained directly from (1.9) and (1.8). Observe that since w is obtained by integrating u, the Dirichlet condition on u at the boundary $b(t)$ (corresponding to an absorbing barrier for the diffusion process) becomes a Neumann condition on w. The additional condition $w(x,t) = p(t), x \leq b(t)$, is obvious from the definition of w (1.7).

Avellaneda and Zhu [1] were the first to use (1.9) and (1.11) to study the inverse first passage problem. They performed a change of variables from X_t to $Y_t = X_t - b(t)$, whose financial meaning is the risk-neutral distance-to-default process for the company. Denote by $f(y,t) = u(y + b(t), t)$ the probability density function of Y_t when $\tau > t$. Equations (1.9) and (1.11) are equivalent to

$$\begin{cases} f_t = \dot{b}(t) f_y - (\mu f)_y + \frac{1}{2}(\sigma^2 f_y)_y & \text{for } y > 0, \quad t > 0, \\ f(0,t) = 0 & \text{for } y = 0, \quad t > 0, \\ f(y,0) = \delta_0(y - b(0)) & \text{for } y > 0, \quad t = 0, \\ \frac{1}{2}\sigma^2 f_y(0,t) + \dot{p}(t) = 0 & \text{for } y = 0, \quad t > 0. \end{cases} \tag{1.12}$$

In [11], Iscoe and Kreinin demonstrated that a Monte Carlo approach can be applied to solve the inverse first passage problem in discrete time, essentially by reducing it to the sequential estimation of conditional distributions. Hull and White [9] also consider a time discretization and compute the boundary by solving a system of nonlinear equations at each time point. Huang and Tian [7] apply a probabilistic method to construct piecewise linear solutions to the problem of constructing the default barriers. In [19], both a Monte Carlo algorithm based on a piecewise linear approximation of the boundary and a method based on the integral equation (1.6) with $n = 1$ are studied.

In this paper, we are particularly interested in the following fundamental questions: (1) Given a survival probability function $p(t)$ satisfying (1.2), is there a barrier function $b(t)$? (2) If there is a barrier function, how many are there? (3) What is the behavior of the barrier function for small times? Namely, we are concerned with the well-posedness (existence and uniqueness) of the free boundary problem (1.1) and the asymptotic properties of $b(t)$ near zero. The motivation for studying the well-posedness of the problem is evident. Aside from its intrinsic interest, knowledge of the behavior of the boundary near zero is essential for effective implementations of numerical solutions to the inverse first passage problem based on equations such as (1.6); see [2].

We point out that solutions to (1.1) are not smooth, so that a weaker concept of solutions has to be used. Instead of using the classical weak solution defined in the distributional sense (see Evans [4]), we use viscosity solutions, introduced by Crandall and Lions in 1981. In this paper, we shall prove the following theorem.

THEOREM 1. *Problem* (1.1) *is a well-posed problem; i.e., for any given* $p(t)$ *satisfying* (1.2), *there is a unique (viscosity) solution.*

The remainder of the paper is organized as follows. In section 2, we provide a definition of the viscosity solution to (1.1) and show there is at most one such solution. In section 3, we establish the existence of a viscosity solution. This is accomplished by first defining and studying a regularization of the problem obtained by penalizing the obstacle (a standard procedure for the obstacle problem; see Friedman [5]). The ε-regularization is carefully designed so that the solution is monotonic in ε, and therefore the existence of a limit as $\varepsilon \to 0$ is automatically guaranteed.[4] We show that the limit is a viscosity solution. In section 4, we study the asymptotic behavior of the boundary as $t \searrow 0$ by providing explicit upper and lower bounds. When $\limsup_{t\searrow 0} -\frac{1-p(t)}{t\dot{p}(t)} < \infty$, we prove that

$$\lim_{t\to 0} \frac{b(t)}{\sqrt{-2t\log(1-p(t))}} = -1.$$

In section 5, we derive integral equations for b when $\sigma \equiv 1$ and $\mu \equiv 0$ under the assumption that p is continuous and nonincreasing.

2. Viscosity solutions and uniqueness. By noticing that $w(x,t) < p(t)$ for all $x > b(t)$ when $\tau > t$, we can state the inverse first passage problem as follows. Find an unknown function $w = w(x,t)$ such that

$$\text{(2.1)} \qquad \begin{cases} \mathcal{L}w = 0 & \text{when } w(\cdot,t) < p(t), \\ 0 \le w(x,t) \le p(t) & \text{for any } (x,t) \in (\mathbb{R}\times(0,\infty)), \\ w(x,0) = \mathbf{1}_{(-\infty,0)}(x) & \text{for } x \in \mathbb{R}, \end{cases}$$

where $\mathcal{L}w := w_t - \frac{1}{2}(\sigma^2 w_x)_x + \mu w_x$. Define the free boundary as

$$b^w(t) := \inf\{x \,|\, w(x,t) < p(t)\}.$$

We can write (2.1) as a variational inequality:

$$\text{(2.2)} \qquad \begin{cases} \max\{\mathcal{L}w, w-p\} = 0 & \text{in } \mathbb{R}\times(0,\infty), \\ w(\cdot,0) = \mathbf{1}_{(-\infty,0)}(\cdot) & \text{on } \ \mathbb{R}\times\{0\}. \end{cases}$$

In this paper, we shall consider viscosity solutions to this variational inequality, as defined below (see also Crandall, Ishii, and Lions [3]). The principle motivation for doing so is to allow the maximum generality in specifying p. Of course, one could consider other notions of weak solution with corresponding assumptions on the problem data. The basic strategy of using penalization to construct approximations and analyze the properties of the solution would still be applicable (see, e.g., Friedman [5]).

For a given p, we define

$$p_*(t) = \liminf_{0\le s\to t} p(s), \quad p^*(t) = \limsup_{0\le s\to t} p(s) \quad \forall t \ge 0.$$

[4]For purely proving existence, such careful design of the sequence is unnecessary. We introduce the complication with a view towards applications in numerical simulations.

Since cumulative probability distribution functions (hence q) are increasing and right continuous, we see that for any b, $p(t) = \mathbb{P}\{\tau > t\} \geq 0$ is decreasing and right continuous, and in particular, $p = p_*$. Furthermore, Blumenthal's zero-one law (see, for example, [13]) implies that we must have either $p(0) = 0$ (in which case the problem is trivial) or $p(0) = 1$. Therefore, in the remainder of the paper, we shall consider only lower semicontinuous p for which $p(0) = 1$.

For a function w defined on $\mathbb{R} \times [0, \infty)$, we define w^* and w_* by

$$w^*(x,t) := \limsup_{y \to x, 0 \leq s \to t} w(y,s) \qquad \forall (x,t) \in \mathbb{R} \times [0,\infty),$$
$$w_*(x,t) := \liminf_{y \to x, 0 \leq s \to t} w(y,s) \qquad \forall (x,t) \in \mathbb{R} \times [0,\infty).$$

A function w is called *upper semicontinuous (USC)* if $w = w^*$ and *lower semicontinuous (LSC)* if $w = w_*$.

In what follows, the parabolic open ball $B_\delta(x,t)$ is defined as

$$B_\delta(x,t) := (x-\delta, x+\delta) \times (t-\delta^2, t) \qquad \forall \delta > 0, (x,t) \in \mathbb{R} \times [0,\infty).$$

For any cylindrical set of the form $D = (s,t) \times \Omega$, where $0 \leq s < t$ and $\Omega \subseteq \mathbb{R}$, the parabolic boundary is defined as

$$\partial_p D = \Big(\partial\Omega \times (s,t)\Big) \cup \Big(\bar{\Omega} \times \{s\}\Big).$$

Definition 1 (viscosity subsolution, supersolution, and solution).

1. *A function w defined on $\mathbb{R} \times (0,\infty)$ is called a* (viscosity) subsolution *if*

$$w = \min\{p, w^*\} \quad \text{in} \quad \mathbb{R} \times (0,\infty),$$

and $\mathcal{L}\varphi(x,t) \leq 0$ whenever φ is smooth and $w^* - \varphi$ attains at (x,t) a local maximum on $\bar{B}_\delta(x,t)$, where $x \in \mathbb{R}$ and $t > \delta^2 > 0$.

2. *A function w defined on $\mathbb{R} \times (0,\infty)$ is called a* (viscosity) supersolution *if*

$$0 \leq w = w_* \quad \text{in} \quad \mathbb{R} \times (0,\infty),$$

and $\max\{w(x,t) - p(t), \mathcal{L}\varphi(x,t)\} \geq 0$ whenever φ is smooth and $w - \varphi$ attains at (x,t) a local minimum on $\bar{B}_\delta(x,t)$, where $x \in \mathbb{R}$ and $t > \delta^2 > 0$.

3. *A function w defined on $\mathbb{R} \times [0,\infty)$ is called a* (viscosity) solution *if w is both a subsolution and a supersolution in $\mathbb{R} \times (0,\infty)$, and for all $x \in \mathbb{R}$,*

$$w(x,0) = \liminf_{y \to x, t \searrow 0} w(y,t) = \mathbf{1}_{(-\infty,0)}, \qquad \limsup_{y \to x, t \searrow 0} w(y,t) = \mathbf{1}_{(-\infty,0]}. \tag{2.3}$$

Remark 2.1. Here we use the default that a viscosity solution is LSC ($w = w_*$). Also, the (probabilistically obvious) condition $w \geq 0$ imposed for supersolutions is to ensure the boundedness of the supersolution, as is usually required. This condition could be relaxed to the assumption that $w \geq -e^{A(1+|x|^2)}$ for some $A > 0$.

To prove the uniqueness of the solution to (2.2), we first establish a few properties of viscosity solutions.

Lemma 2.1. *Let w be a viscosity solution and define*

$$Q := \{(x,t) \in \mathbb{R} \times [0,\infty) \mid w(x,t) < p(t)\}, \qquad \Pi := Q^c = \mathbb{R} \times [0,\infty) \setminus Q.$$

Then

1. *Q is open and w is a smooth solution to $\mathcal{L}w = 0$ in Q;*
2. *$\Pi = \{(x,t) \in \mathbb{R} \times [0,\infty) \mid w(x,t) = p(t)\} = \Pi_0 \cup \Pi_1 \cup \Pi_2$, where*

$$\Pi_0 := \{(x,t) \in \mathbb{R} \times [0,\infty) \mid w^*(x,t) = w_*(x,t) = p(t)\},$$
$$\Pi_1 := \{(x,t) \in \mathbb{R} \times [0,\infty) \mid p^*(t) > w^*(x,t) > w_*(x,t) = p(t)\},$$
$$\Pi_2 := \{(x,t) \in \mathbb{R} \times [0,\infty) \mid p^*(t) = w^*(x,t) > w_*(x,t) = p(t)\}.$$

In particular, if p is continuous, then w is continuous in $\mathbb{R} \times [0,\infty) \setminus \{(0,0)\}$.

Proof. 1. First, we show that Q is open and w is continuous in Q. For any $(x,t) \in Q$, $w(x,t) < p(t)$. As a supersolution, $w(x,t) = w_*(x,t)$, and as a subsolution, $w(x,t) = \min\{p(t), w^*(x,t)\} = w^*(x,t)$. Then $w_* = w = w^*$ at (x,t). Therefore w is continuous at (x,t) and $w < p$ in a neighborhood of (x,t). Consequently, Q is open and w is continuous in Q.

Next, we prove $\mathcal{L}w = 0$ in Q. Let $(x_0,t_0) \in Q$ with $t_0 > 0$. Then $w(x_0,t_0) < p(t_0)$ and w is continuous at (x_0,t_0). There exist positive constants η and δ such that $w < p - \eta$ in $\bar{D} \subset Q$, where $D = (x_0-\delta, x_0+\delta) \times (t_0-\delta^2, t_0+\delta^2)$. Denote by $\tilde{w}$ the solution to $\mathcal{L}\tilde{w} = 0$ in D with continuous initial data $\tilde{w}(\cdot, t_0-\delta^2) = w(\cdot, t_0-\delta^2)$ and boundary data $\tilde{w} = w$ on the parabolic boundary $\partial_p D$. Let $\varepsilon > 0$ and $\varphi^\varepsilon = \tilde{w} - \frac{\varepsilon}{t_0+\delta^2-t}$, $\psi^\varepsilon = \tilde{w} + \frac{\varepsilon}{t_0+\delta^2-t}$. We have that $w - \varphi^\varepsilon > 0$ on $\partial_p D$, and $w - \varphi^\varepsilon \to \infty$ as $t \nearrow t_0 + \delta^2$. Suppose there is a point $(x,t) \in D$ such that $w(x,t) - \varphi^\varepsilon(x,t) \le 0$; then $w - \varphi^\varepsilon$ will have a local minimum in D, say, at (x^*,t^*). Since w is a supersolution and $w(x^*,t^*) < p(t^*)$, we must have $-\frac{\varepsilon}{t_0+\delta^2-t^*} = \mathcal{L}\varphi^\varepsilon \ge 0$, which is a contradiction. Thus $w > \varphi^\varepsilon$. A similar argument gives that $w < \psi^\varepsilon$. Sending $\varepsilon \to 0$ we obtain $w = \tilde{w}$ in D, which implies that w is a smooth solution to $\mathcal{L}w = 0$ in Q.

2. Since $w \le p$, $\Pi := Q^c$. As a subsolution $w = \min\{p, w^*\} \le p$, and as a supersolution, $w = w_*$. It follows that $w_* = w = p \le w^*$ and $w^* \le p^*$ in Π. Hence $w_* = p \le w^* \le p^*$. There are only three possibilities for w^*: (i) $w^* = p$, (ii) $w^* \in (p, p^*)$, and (iii) $w^* = p^* > p$. Thus $\Pi = \Pi_0 \cup \Pi_1 \cup \Pi_2$. ∎

The following lemma characterizes the discontinuities of a solution.

LEMMA 2.2. *Suppose w is a viscosity solution. Then for each $t > 0$, the following hold:*

1. *$w(\cdot,t) = w_*(\cdot,t)$ is continuous in $\mathbb{R}$;*
2. *for each $x \in \mathbb{R}$,*

$$w_*(x,t) = \min\{p(t), w^*(x,t)\} = \lim_{y \to x, s \searrow t} w(y,s), \tag{2.4}$$
$$w^*(x,t) = \lim_{y \to x, s \nearrow t} w(y,s) \le p^*(t); \tag{2.5}$$

3. *if $w^*(x,t) < p^*(t)$, then for some $\delta > 0$, $w = w^*$ in $B_\delta(x,t)$ and w^* is a smooth solution to $\mathcal{L}w^* = 0$ in $\bar{B}_\delta(x,t)$.*

Proof. 1. If $w(x,t) < p(t)$, by Lemma 2.1 w is continuous near (x,t); otherwise $w(x,t) = p(t)$. Then using the subsolution property, $\liminf_{y \to x} w(y,t) \ge w_*(x,t) = w(x,t) = p(t) \ge \limsup_{y \to x} w(y,t)$. Thus $\liminf_{y \to x} w(y,t) = w(x,t) = \limsup_{y \to x} w(y,t)$, and the first assertion follows.

2. Next, we prove (2.4). The first equality is immediate since w is both a subsolution and a supersolution. The second follows by considering separately the cases $w(x,t) < p(t)$ and $w(x,t) = p(t)$ as in the previous step. If $w(x,t) < p(t)$, then w is continuous near (x,t). Therefore $w_*(x,t) = \min\{p(t), w^*(x,t)\} = \lim_{y \to x, s \searrow t} w(y,s)$. If $w(x,t) = p(t)$, then $w_*(x,t) = w(x,t) = p(t) \ge \lim_{y \to x, s \searrow t} w(y,s) \ge w_*(x,t)$. Thus (2.4) holds.

3. Now we prove (2.5) and the third assertion when $w^*(x,t) < p^*(t)$. By the upper semicontinuity of w^*, there exist some positive constants δ and η such that $w(\cdot,\cdot) < p^*(t) - \eta$ in $\bar{B}_\delta(x,t)$. For all $s < t$, $p(s) \geq p^*(t)$. Following the same proof as that for the previous lemma, we conclude that $w^* = w$ in $B_\delta(x,t)$ and w^* is a smooth solution to $\mathcal{L}w^* = 0$ in $\bar{B}_\delta(x,t)$. The third assertion and (2.5) for the case $w^*(x,t) < p^*(t)$ thus follow.

4. Finally, we verify (2.5) for the case $w^*(x,t) = p^*(t)$. For each small $\delta > 0$, we compare w in $B_\delta(x,t)$ with solutions $\bar{w}$ and $\underline{w}$ to

$$\begin{cases} \mathcal{L}\bar{w} = 0 & \text{in } B_\delta, \\ \bar{w} = w^* & \text{on } \partial_p B_\delta \end{cases} \quad \text{and} \quad \begin{cases} \mathcal{L}\underline{w} = 0 & \text{in } B_\delta, \\ \underline{w} = \min\{w^*, p^*(t)\} & \text{on } \partial_p B_\delta, \end{cases}$$

respectively. Note that $w \leq w^* = \bar{w}$ and $\underline{w} = \min\{w^*, p^*(t)\} \leq \min\{w^*, p\} = w$ on $\partial_p B_\delta$ since $\underline{w} \leq p^*(t) \leq p(s)$ for all $s < t$. By the maximum principle, $\underline{w} \leq w \leq \bar{w}$ in B_δ. Observing that $\max_{\bar{B}_\delta}\{\bar{w} - \underline{w}\} = \max_{\partial_p B_\delta}\{\bar{w} - \underline{w}\} \leq p^*(t - \delta^2) - p^*(t)$, we find that

$$\limsup_{y \to x, s \nearrow t} w(y,s) - \liminf_{y \to x, s \nearrow t} w(y,s) \leq \sup_{B_\delta(x,t)} \{\bar{w} - \underline{w}\} \leq p^*(t - \delta^2) - p^*(t).$$

Equation (2.5) then follows by sending $\delta \to 0$. ∎

THEOREM 2 (uniqueness). *There is at most one viscosity solution.*

Proof. Suppose w_1 and w_2 are two solutions. We claim that for any $\eta > 0$,

$$w_1(x,t) \leq w_2(x - \eta, t) \qquad \forall (x,t) \in \mathbb{R} \times [0,\infty). \tag{2.6}$$

Once this is proven, sending $\eta \to 0$ and using Lemma 2.2(1) allows one to conclude that $w_1 \leq w_2$ on $\mathbb{R} \times [0,\infty)$. Exchanging the roles of w_1 and w_2, we also have $w_2 \leq w_1$, so that $w_1 \equiv w_2$.

Suppose that (2.6) is not true; i.e., there exists at least one pair of $(\bar{x}, \bar{t}\,) \in \mathbb{R} \times [0,\infty)$ such that $w_1(\bar{x}, \bar{t}) > w_2(\bar{x} - \eta, \bar{t})$. Then for all sufficiently small positive ε,

$$M_\varepsilon := \sup_{x \in \mathbb{R}, t \geq 0} \{w_1(x,t) - w_2(x - \eta, t) - \varepsilon^4 x^2 - \varepsilon e^t\} > 0.$$

Hence fix such a positive ε such that $\varepsilon \leq 1/(1 + \|\sigma^2\|_\infty + 2\|\sigma\sigma_x - \mu\|_\infty)$. Let $\{(x_n, t_n)\}_{n=1}^\infty$ be a sequence in $\mathbb{R} \times [0,\infty)$ such that the supremum M_ε is attained along the sequence. This sequence is bounded since $0 \leq w_1, w_2 \leq 1$. By taking a subsequence if necessary, there exist the limits $(\hat{x}, \hat{t}\,) := \lim_{n\to\infty}(x_n, t_n)$, $\alpha := \lim_{n\to\infty} w_1(x_n, t_n)$, and $\beta := \lim_{n\to\infty} w_2(x_n - \eta, t_n)$. Note that

$$\begin{gathered} 0 \leq w_{1*}(\hat{x}, \hat{t}\,) \leq \alpha \leq w_1^*(\hat{x}, \hat{t}\,) \leq 1, \\ 0 \leq w_{2*}(\hat{x} - \eta, \hat{t}\,) \leq \beta \leq w_2^*(\hat{x} - \eta, \hat{t}\,) \leq 1, \\ \beta < \alpha. \end{gathered}$$

Consequently,

$$M_\varepsilon = \alpha - \beta - \varepsilon^4 \hat{x}^2 - \varepsilon e^{\hat{t}} > 0. \tag{2.7}$$

Additionally, $|\hat{x}| < \varepsilon^{-2}$. Otherwise $M_\varepsilon \leq \alpha - \beta - 1 - \varepsilon \leq -\varepsilon < 0$, which is a contradiction to (2.7).

Now we show that this is impossible by excluding the following three possibilities:

$$\text{(i)}\ \ \hat{t} = 0; \qquad \text{(ii)}\ \ \hat{t} > 0, \beta < p(\hat{t}); \qquad \text{(iii)}\ \ \hat{t} > 0, \beta \geq p(\hat{t}).$$

Case (i). Suppose $\hat{t} = 0$. If $\hat{x} \geq \eta$, then $0 \leq \beta < \alpha \leq w_1^*(\hat{x}, 0) = 0$; otherwise $1 \geq \alpha > \beta \geq w_{2*}(\hat{x} - \eta, 0) = 1$. Both are impossible.

Case (ii). Suppose $\hat{t} > 0$ and $\beta < p(\hat{t})$. Then $w_{2*}(\hat{x} - \eta, \hat{t}) \leq \beta < p(\hat{t})$. By Lemma 2.1, w_2 is a smooth solution to $\mathcal{L}w_2(\cdot - \eta, \cdot) = 0$ in $\bar{D}$, where $D = (\hat{x} - \delta, \hat{x} + \delta) \times (\hat{t} - \delta^2, \hat{t} + \delta^2)$ for some $\delta > 0$. Let

$$\varphi(x,t) = w_2(x - \eta, t) + \varepsilon^4 x^2 + \varepsilon e^t + (x - \hat{x})^4/\delta^4 + (t - \hat{t})^2/\delta^4.$$

Then φ is smooth in $\bar{D}$ and

$$\max_D \{w_1^* - \varphi\} = \sup_{\bar{D}} \{w_1 - \varphi\} \leq M_\varepsilon \leq w_1^*(\hat{x}, \hat{t}) - \varphi(\hat{x}, \hat{t}).$$

That is, $(\hat{x}, \hat{t})$ is a local maximum of $w_1^* - \varphi$ in D. As w_1 is a subsolution, $\mathcal{L}\varphi(\hat{x}, \hat{t}) \leq 0$. However, $\mathcal{L}\varphi(\hat{x}, \hat{t}) = \varepsilon e^{\hat{t}} - \varepsilon^4\sigma^2 - 2(\sigma\sigma_x - 2\mu)\varepsilon^4\hat{x} \geq \varepsilon - \varepsilon^2\|\sigma^2\|_\infty - 2\varepsilon^2\|\sigma\sigma_x - \mu\|_\infty > 0$ by the smallness of ε. This is a contradiction. Thus case (ii) is impossible.

Case (iii). Suppose $\hat{t} > 0$ and $\beta \geq p(\hat{t})$. Since $p^*(s) \leq p(t)$ for any $s > \hat{t}$, $w_1(x, s) \leq p(s) \leq p^*(t)$ for each x. Then $\sup_x w_1(x, s) \leq p(\hat{t}) \leq \beta < \alpha = \lim_{n\to\infty} w_1(x_n, t_n)$. We claim $t_n < \hat{t}$ for all sufficiently large n; i.e., there exists $N \in \mathbb{N}^+$ such that $t_n < \hat{t}$ for each $n \geq N$. To the contrary, suppose for each $N \in \mathbb{N}^+$ there exists $n > N$ such that $t_n > \hat{t}$. Then $\alpha > \beta \geq \sup_x w_1(x, t_n) > w_1(x_n, t_n)$. Hence there exists $\varepsilon > 0$, independent on n, such that $\alpha > w_1(x_n, t_n) + \varepsilon$. This is a contradiction to $\alpha = \lim_{n\to\infty} w_1(x_n, t_n)$. Consequently, from (2.5), we conclude that

$$\alpha = w_1^*(\hat{x}, \hat{t}) \leq p^*(\hat{t}), \qquad \beta = w_2^*(\hat{x} - \eta, \hat{t}) \leq \alpha < p^*(\hat{t}).$$

By Lemma 2.2(3), for some $\delta > 0$, $w_2^* = w_2$ in $B_\delta(\hat{x} + \eta, \hat{t})$ and w_2^* is a smooth solution to $\mathcal{L}w_2^* = 0$ in $\bar{B}_\delta(\hat{x} + \eta, \hat{t})$. Set

$$\phi(x,t) := w_2^*(x - \eta, t) + \varepsilon^4 x^2 + \varepsilon e^t + (x - \hat{x})^4/\delta^4 + (t - \hat{t})^2/\delta^4.$$

Then, by (2.5) and $w_2^* = w_2$ in $B_\delta(\hat{x} + \eta, \hat{t})$,

$$\max_{\bar{B}_\delta(\hat{x},\hat{t})} \{w_1^* - \phi\} = \sup_{B_\delta(\hat{x},\hat{t})} \{w_1 - \phi\} \leq M_\varepsilon = w_1^*(\hat{x}, \hat{t}) - \phi(\hat{x}, \hat{t}).$$

That is, $w_1^* - \phi$ obtains its local maximum at $(\hat{x}, \hat{t})$. As w_1 is a subsolution, $\mathcal{L}\phi(\hat{x}, \hat{t}) \leq 0$. However, $\mathcal{L}\phi(\hat{x}, \hat{t})\varepsilon e^{\hat{t}} - \varepsilon^4\sigma^2 - 2(\sigma\sigma_x - 2\mu)\varepsilon^4\hat{x} \geq \varepsilon - \varepsilon^2\|\sigma^2\|_\infty - 2\varepsilon^2\|\sigma\sigma_x - \mu\|_\infty > 0$ by the smallness of ε. This is a contradiction. Thus case (iii) is impossible.

The exclusion of cases (i), (ii), and (iii) implies that (2.6) holds for each $\eta > 0$. □

As a product, (2.6) and the uniqueness give the following.

COROLLARY 2.3. *The unique solution w, if it exists, is nonincreasing in x, i.e., $w(x,t) \leq w(x - \eta, t)$ for all $\eta > 0$ and $(x,t) \in \mathbb{R} \times [0, \infty)$.*

3. Existence of a viscosity solution. To establish a solution, we first define and study a regularization of the problem obtained by penalizing the obstacle. This ε-regularization is carefully designed so that the solution is monotonic in ε, and therefore the existence of a limit as $\varepsilon \to 0$ is automatically guaranteed. We prove some regularity properties of the solution to the penalized problem for the purpose of establishing compactness. Finally, we show that the limit is a viscosity solution.

3.1. The regularization. Following the classical penalization technique (see, for example, Friedman [5]) for variational inequalities, we consider a semilinear parabolic equation:

$$\begin{cases} \mathcal{L}w^\varepsilon = -\beta\Big(\varepsilon^{-1}(w^\varepsilon - p^\varepsilon)\Big) & \text{in } \mathbb{R}\times(0,\infty), \\ w^\varepsilon(\cdot,0) = W^\varepsilon(\cdot) & \text{on } \mathbb{R}\times\{0\}, \end{cases} \tag{3.1}$$

where p^ε and W^ε are the smooth approximations of p and $w(\cdot,0) = \mathbf{1}_{(-\infty,0)}$, respectively, and $\beta(\cdot)$ is a smooth function being identically zero in $(-\infty,0]$ and strictly increasing and convex in $[0,\infty)$. For definiteness, we take

$$\beta(s) := \max\{0, s^3\} \qquad \forall\, s\in\mathbb{R}.$$

The particular p^ε and W^ε are chosen so that the solution w^ε is strictly increasing in ε. Define

$$p^\varepsilon(t) := \frac{3}{4}\int_{-1}^{1}(1-z^2)p(t+\varepsilon+\varepsilon z)\,dz - 3\varepsilon^{2/3} \qquad \forall\varepsilon>0, t\ge 0.$$

Then $p^\varepsilon\in C^1([0,\infty))$, and

$$-\frac{1}{\varepsilon} \le \frac{d}{dt}p^\varepsilon(t) \le 0, \quad \frac{d}{d\varepsilon}p^\varepsilon(t) \le -\frac{2}{\varepsilon^{1/3}}, \quad \lim_{\varepsilon\searrow 0} p^\varepsilon(t) = p(t) \quad \forall\varepsilon>0, t\ge 0. \tag{3.2}$$

The first two inequalities follow directly from the definition of p^ε and monotonicity of p. Consequently, for any fixed $t>0$, the limit as $\varepsilon\searrow 0$ of $p^\varepsilon(t)$ exists and is $p(t)$.

When $t=0$, (3.2) yields $\lim_{\varepsilon\searrow 0} p^\varepsilon(0) = p(0) = 1$ and $p^\varepsilon(0)$ is a monotone function of ε. We denote by $\varepsilon^*>0$ the unique constant such that $p^{\varepsilon^*}(0) = 0$ and in what follows assume $\varepsilon\in(0,\varepsilon^*)$.

Fix a smooth function $W(\cdot)$ defined on $\mathbb{R}$ that satisfies

$$W(x) = 0\ \forall\, x\ge 0, \quad W(x) = 1\ \forall\, x\le -1, \quad \dot W \le 0\ \forall\ x\in(-1,0).$$

Set

$$W^\varepsilon(x) := p^\varepsilon(0)\ W(x/\varepsilon) \qquad \forall\, x\in\mathbb{R}.$$

Then W^ε is a smooth function satisfying

$$\frac{d}{d\varepsilon}W^\varepsilon(x)\le 0, \quad \frac{d}{dx}W^\varepsilon(x)\le 0, \quad W^\varepsilon(x) = 0\ \forall\, x\ge 0, \quad W^\varepsilon(x) = p^\varepsilon(0)\ \forall\, x\le -\varepsilon.$$

Before proving the existence of a solution to problem (3.1), we introduce the following functions.

1. Denote by $w_0^\varepsilon(x,t)$ the solution to

$$\begin{cases} \mathcal{L}w_0^\varepsilon = 0 & \text{in } \mathbb{R}\times(0,\infty), \\ w_0^\varepsilon(\cdot,0) = W^\varepsilon(\cdot) & \text{on } \mathbb{R}\times\{0\}. \end{cases} \tag{3.3}$$

Since the problem for w_0^ε is linear, the solution w_0^ε can be expressed as

$$w_0^\varepsilon(x,t) = \int_{\mathbb{R}} K(x,t;y,0)w_0^\varepsilon(y,0)\,dy = p^\varepsilon(0)\int_{-\infty}^{0} K(x,t;y,0)W(y/\varepsilon)\,dy,$$

where $K(x,t;y,s)$ is the fundamental solution associated with the linear operator $\mathcal{L}$. In particular, when $\mathcal{L} = \partial_t - \frac{1}{2}\partial_{xx}$, i.e., $\mu \equiv 0$ and $\sigma \equiv 1$,

$$K(x,t;y,s) = \Gamma(x-y, t-s), \qquad \Gamma(x,t) = \frac{1}{\sqrt{2\pi t}} e^{-x^2/2t}.$$

2. Denote by ρ^ε the solution to

$$\begin{cases} \frac{d}{dt}\rho^\varepsilon(t) = -\beta\left(\frac{\rho^\varepsilon(t) - p^\varepsilon(t)}{\varepsilon}\right) & \text{in } (0,\infty), \\ \rho^\varepsilon(0) = p^\varepsilon(0). \end{cases}$$

Comparing the solution ρ^ε with the functions of the form $p^\varepsilon + C$, where C is constant, one finds that

$$p^\varepsilon(t) \le \rho^\varepsilon(t) \le p^\varepsilon(t) + \varepsilon \|\dot{p}^\varepsilon\|_\infty^{1/3}, \quad \dot{\rho}^\varepsilon(t) \le 0 \quad \forall t \ge 0.$$

Now we are ready to begin studying the properties of (3.1).

THEOREM 3. *For each $\varepsilon > 0$, problem (3.1) admits a unique smooth $(C^{2,1})$ solution in $\mathbb{R} \times [0,\infty)$. The solution is continuously differentiable in ε and satisfies, for all $\varepsilon > 0$ and $(x,t) \in \mathbb{R} \times (0,\infty)$,*

$$w_0^\varepsilon(x,t) + \rho^\varepsilon(t) - \rho^\varepsilon(0) \le w^\varepsilon(x,t) \le \min\{\rho^\varepsilon(t), w_0^\varepsilon(x,t)\}, \tag{3.4}$$

$$w_x^\varepsilon(x,t) < 0, \qquad \frac{d}{d\varepsilon} w^\varepsilon(x,t) < 0. \tag{3.5}$$

Consequently, the following limit exists:

$$w(x,t) := \lim_{\varepsilon \searrow 0} w^\varepsilon(x,t) \qquad \forall\, (x,t) \in \mathbb{R} \times [0,\infty).$$

Proof. 1. Existence and uniqueness of a smooth solution w^ε to (3.1) in $\mathbb{R} \times [0,\infty)$ follows from standard results; see, for example, Friedman [6]. The fact that w^ε satisfies (3.4) follows from the comparison principle. In particular, since

$$\mathcal{L} w_0^\varepsilon + \beta\left(\frac{w_0^\varepsilon - p^\varepsilon}{\varepsilon}\right) = \beta\left(\frac{w_0^\varepsilon - p^\varepsilon}{\varepsilon}\right) \ge 0 = \mathcal{L} w^\varepsilon + \beta\left(\frac{w^\varepsilon - p^\varepsilon}{\varepsilon}\right)$$

and $w_0^\varepsilon(x,0) = w^\varepsilon(x,0)$ we have $w^\varepsilon(x,t) \le w_0^\varepsilon(x,t)$. Similarly, $\mathcal{L}\rho^\varepsilon + \beta(\frac{\rho^\varepsilon - p^\varepsilon}{\varepsilon}) = 0$ and $\rho^\varepsilon(0) = p^\varepsilon(0) \ge \max_{x\in\mathbb{R}} w^\varepsilon(x,0)$, so that $w^\varepsilon(x,t) \le \rho^\varepsilon(x,t)$. Combining the two upper bounds gives the right half of (3.4).

The proof of the lower bound is similar. Set $\underline{w}^\varepsilon := w_0^\varepsilon(x,t) + \rho^\varepsilon(t) - \rho^\varepsilon(0)$. We can compute

$$\begin{aligned} &\mathcal{L}\underline{w}^\varepsilon + \beta\Big(\frac{\underline{w}^\varepsilon - p^\varepsilon}{\varepsilon}\Big) \\ &= \mathcal{L} w_0^\varepsilon(x,t) + \mathcal{L}\rho^\varepsilon(t) + \beta\Big(\frac{\underline{w}^\varepsilon - p^\varepsilon}{\varepsilon}\Big) \\ &= -\left[\beta\Big(\frac{\rho^\varepsilon - p^\varepsilon}{\varepsilon}\Big) - \beta\Big(\frac{\rho^\varepsilon - p^\varepsilon + w_0^\varepsilon - \rho^\varepsilon(0)}{\varepsilon}\Big)\right] \le 0, \end{aligned}$$

since $\beta(\cdot)$ is nondecreasing. We also have

$$w^\varepsilon(x,0) = w_0^\varepsilon(x,0) = \underline{w}^\varepsilon(x,0), \tag{3.6}$$

so the comparison principle implies $w^\varepsilon(x,t) \ge \underline{w}^\varepsilon(x,t)$ for all x,t.

2. The estimates (3.5) can be proved by differentiating the system (3.1). More specifically, to prove the first inequality in (3.5) differentiate (3.1) with respect to x and let $u^\varepsilon := -w^\varepsilon_x$ to obtain

$$\mathcal{A}u^\varepsilon + \frac{1}{\varepsilon}\dot\beta\Big(\frac{w^\varepsilon - p^\varepsilon}{\varepsilon}\Big)u^\varepsilon = 0,$$
$$u^\varepsilon(x,0) = -\frac{d}{dx}w^\varepsilon(x,0) = -\frac{d}{dx}W^\varepsilon(x) \geq 0 \qquad \forall x \in \mathbb{R},$$

where $\mathcal{A}u = \mathcal{L}u - \sigma\sigma_x u_x + (\mu_x - \sigma\sigma_{xx} + (\sigma_x)^2)u$. Since $\frac{1}{\varepsilon}\dot\beta(\frac{w^\varepsilon - p^\varepsilon}{\varepsilon}) > 0$, the maximum principle implies that $-w^\varepsilon_x(x,t) = u^\varepsilon(x,t) > 0$ in $\mathbb{R}\times(0,\infty)$.

For the second half of (3.5), differentiating the system (3.1) with respect to ε we obtain

$$\frac{d}{d\varepsilon}w^\varepsilon(x,0) = \frac{d}{d\varepsilon}W^\varepsilon(x) \leq 0 \qquad \forall x \in \mathbb{R},$$
$$\mathcal{L}\frac{d}{d\varepsilon}w^\varepsilon + \frac{1}{\varepsilon}\dot\beta\Big(\frac{w^\varepsilon - p^\varepsilon}{\varepsilon}\Big)\frac{d}{d\varepsilon}w^\varepsilon = \frac{1}{\varepsilon^2}\dot\beta\Big(\frac{w^\varepsilon - p^\varepsilon}{\varepsilon}\Big)\left\{w^\varepsilon - p^\varepsilon + \varepsilon\frac{d}{d\varepsilon}p^\varepsilon\right\} \leq 0,$$

since $\dot\beta \geq 0$, $w^\varepsilon - p^\varepsilon \leq \rho^\varepsilon - p^\varepsilon \leq \varepsilon\|\dot p^\varepsilon\|_\infty^{1/3} \leq \varepsilon^{2/3}$, and $\frac{d}{d\varepsilon}p^\varepsilon \leq -2\varepsilon^{-1/3}$. Then, by the maximum principle, $\frac{d}{d\varepsilon}w^\varepsilon < 0$ in $\mathbb{R}\times(0,\infty)$. The monotonicity and boundedness of w^ε in ε imply that $w = \lim_{\varepsilon\searrow 0} w^\varepsilon$ exists. ∎

Also note that since w^ε_0 is monotonic in ε and bounded, the limit $w_0 := \lim_{\varepsilon\searrow 0} w^\varepsilon_0$ exists and is the solution to

$$\mathcal{L}w_0 = 0 \ \text{ in } \ \mathbb{R}\times(0,\infty), \qquad w_0(\cdot,0) = \mathbf{1}_{(-\infty,0)}.$$

By Theorem 3, $w^\varepsilon_x < 0$ and $w^\varepsilon(x,t) \geq \rho^\varepsilon(t) - \rho^\varepsilon(0)$ (since $w^\varepsilon_0 \geq 0$). We conclude that $\lim_{x\to\infty} w^\varepsilon$ exists. Similarly, the limit $\lim_{x\to\infty} w^\varepsilon_0$ exists and is nonnegative.

3.2. Continuity estimates and existence. In the previous section, we proved that the limit $w = \lim_{\varepsilon\searrow 0} w^\varepsilon$ of solutions to the system (3.1) exists. In this section, we will prove that this limit gives a viscosity solution to our variational inequality. In order to do so, we need to derive some supplementary estimates on the continuity of w. We first control the behavior of w in the space variable, keeping the time constant.

LEMMA 3.1. *For each $T > 0$, there exists a constant $C_1 = C_1(T)$ that depends only on σ and μ such that for all $\varepsilon \in (0,\varepsilon^*)$, $0 < t \leq T$, and $x, y \in \mathbb{R}$,*

$$-\frac{C_1 p^\varepsilon(0)}{\sqrt{t}} \leq w^\varepsilon_{0x}(x,t) \leq w^\varepsilon_x(x,t) \leq 0. \tag{3.7}$$

Consequently, the limit $w = \lim_{\varepsilon\searrow 0} w^\varepsilon$ satisfies

$$-\frac{C_1}{\sqrt{t}} \leq w_{0x}(x,t) \leq w_x(x,t) \leq 0, \tag{3.8}$$

and we have

$$|w^\varepsilon(x,t) - w^\varepsilon(y,t)| \leq \frac{C_1 p^\varepsilon(0)}{\sqrt{t}}|x-y|, \qquad |w(x,t) - w(y,t)| \leq \frac{C_1}{\sqrt{t}}|x-y|. \tag{3.9}$$

Proof. We will prove (3.7). It is clear that (3.8) then follows by letting $\varepsilon \searrow 0$, and (3.9) can be derived from (3.7) and (3.8) by integration. The upper bounds

in (3.7) can be obtained by differentiating the systems (3.1) and (3.3) with respect to x and applying the maximum principle. Using the notation from the previous theorem, we find that

$$\begin{aligned} \mathcal{A}w_x^\varepsilon = -\varepsilon^{-1}\dot\beta(\varepsilon^{-1}(w^\varepsilon - p^\varepsilon)w_x^\varepsilon \geq 0 = \mathcal{A}w_{0x}^\varepsilon \qquad &\text{in } \ \mathbb{R}\times(0,\infty), \\ w_x^\varepsilon(\cdot,0) = W_x^\varepsilon(\cdot) = w_{0x}^\varepsilon(\cdot,0) \qquad &\text{on } \ \mathbb{R}\times\{0\}, \end{aligned}$$

since $w_x^\varepsilon \leq 0$. Therefore by the maximum principle (the zeroth order term in $\mathcal{A}$ is bounded above) $w_{0x}^\varepsilon \leq w_x^\varepsilon \leq 0$.

Next, we estimate the lower bound of w_{0x}^ε. Differentiating the system (3.3) with respect to x, we obtain

$$\mathcal{A}w_{0x}^\varepsilon = 0 \ \text{ in } \ \mathbb{R}\times(0,\infty), \qquad w_{0x}^\varepsilon(\cdot,0) = W_x^\varepsilon(\cdot) \ \text{ on } \ \mathbb{R}\times\{0\}.$$

This is a linear problem, and the solution can be expressed as

$$w_{0x}^\varepsilon(x,t) = \int_{\mathbb{R}} \tilde K(x,t;y,0)W_y^\varepsilon(y)\,dy,$$

where $\tilde K$ is the fundamental solution associated with the linear operator $\mathcal{A}$, and we therefore have $\tilde K > 0$. Also $W_y^\varepsilon \leq 0$, so for any $0 < t \leq T$,

$$0 \leq -w_{0x}^\varepsilon(x,t) \leq \sup_{x,y\in\mathbb{R}}\{\tilde K(x,t;y,0)\}\int_{\mathbb{R}} -W_y^\varepsilon(y)\,dy \leq \frac{C_1}{\sqrt{t}}\int_{\mathbb{R}} -W_y^\varepsilon(y)\,dy = \frac{C_1 p^\varepsilon(0)}{\sqrt{t}},$$

where

$$C_1 = C_1(T) = \sup_{x,y\in\mathbb{R},0<t<T}\Big\{\sqrt{t}\ \tilde K(x,t;y,0)\Big\},$$

and the above quantity is finite by the standard Gaussian upper bound on the fundamental solution $\tilde K$ (see Friedman [6]). This gives the lower bound in (3.7). ∎

We now proceed to estimate the variation in the time variable, leaving the space variable fixed.

LEMMA 3.2. *For each $T > 0$, there exists a constant $C_2 = C_2(T)$ that depends only on σ and μ such that for all $\varepsilon \in (0,\varepsilon^*)$, $0 < s < t \leq T$, and $x \in \mathbb{R}$,*

$$|w^\varepsilon(x,t) - w^\varepsilon(x,s)| \leq \frac{2C_2 p^\varepsilon(0)\sqrt{t-s}}{\sqrt{s}} + \rho^\varepsilon(s) - \rho^\varepsilon(t), \tag{3.10}$$

$$w^\varepsilon(x,t) - w^\varepsilon(x,s) \leq \frac{2C_2\sqrt{t-s}}{\sqrt{s}}. \tag{3.11}$$

Consequently, the limit $w = \lim_{\varepsilon\searrow 0} w^\varepsilon$ satisfies

$$|w(x,t) - w(x,s)| \leq \frac{2C_2\sqrt{t-s}}{\sqrt{s}} + \rho^\varepsilon(s) - \rho^\varepsilon(t), \tag{3.12}$$

$$w^\varepsilon(x,t) - w^\varepsilon(x,s) \leq \frac{2C_2\sqrt{t-s}}{\sqrt{s}}. \tag{3.13}$$

We remark that when $\sigma \equiv 1$ and $\mu \equiv 0$, $C_1 = C_2 = (2\pi)^{-1/2}$ for all T.

Proof. Once again, we need only worry about the estimates (3.10) and (3.11) for w^ε as the corresponding results for w follow by letting $\varepsilon \searrow 0$. The estimates are derived by first controlling the difference between $w(x,t)$ and the average of w on a small space interval centered at (x,t) and then estimating the difference of the values of such averages with respect to time and space. More specifically, for $\delta > 0$, $s \in (0,T]$, we have, using (3.7),

$$\left| w^\varepsilon(x,s) - \frac{1}{2\delta}\int_{x-\delta}^{x+\delta} w^\varepsilon(y,s)\,dy \right| = \left| \frac{1}{2\delta}\int_{x-\delta}^{x+\delta} \left(w^\varepsilon(x,s) - w^\varepsilon(y,s)\right)\,dy \right|$$
$$\leq \frac{C_1 p^\varepsilon(0)}{2\delta\sqrt{s}}\int_{x-\delta}^{x+\delta} |y-x|\,dy \leq \frac{C_1\delta p^\varepsilon(0)}{\sqrt{s}}.$$

We now consider the variation in time of the integrals of w over intervals of size 2δ. Note that since $\beta(\cdot)$ is increasing and $w^\varepsilon \leq \rho^\varepsilon$,

$$0 \leq \beta(\varepsilon^{-1}(w^\varepsilon - p^\varepsilon)) \leq \beta(\varepsilon^{-1}(\rho^\varepsilon - p^\varepsilon)) = -\dot\rho^\varepsilon(t) \qquad \forall\, t \geq 0, x \in \mathbb{R}.$$

And therefore, for $0 < s < t \leq T$ and $x \in \mathbb{R}$,

$$\left| \int_{x-\delta}^{x+\delta} \{w^\varepsilon(y,t) - w^\varepsilon(y,s)\}\,dy \right| = \left| \int_{x-\delta}^{x+\delta}\int_s^t w^\varepsilon_v(y,v)\,dv\,dy \right|$$
$$= \left| \int_s^t \int_{x-\delta}^{x+\delta} \left(\frac{1}{2}(\sigma^2 w^\varepsilon_y)_y - \mu w^\varepsilon_y - \beta\left(\varepsilon^{-1}(w^\varepsilon - p^\varepsilon)\right)\right) dy\,dv \right|$$
$$\leq \left| \int_s^t \frac{1}{2}\sigma^2 w^\varepsilon_y \Big|_{x-\delta}^{x+\delta} dv \right| + \left| \int_s^t \int_{x-\delta}^{x+\delta} \mu\, w^\varepsilon_y dy\,dv \right| + \left| \int_s^t \int_{x-\delta}^{x+\delta} \beta\left(\varepsilon^{-1}(\rho^\varepsilon - p^\varepsilon)\right) dy\,dv \right|$$
$$\leq p^\varepsilon(0)(t-s)\left(\frac{C_1\|\sigma^2\|_\infty}{\sqrt{s}} + \|\mu\|_\infty \right) + \left| \int_s^t \int_{x-\delta}^{x+\delta} -\frac{d}{dv}\rho^\varepsilon(v) dy\,dv \right|$$
$$\leq p^\varepsilon(0)(t-s)\left(\frac{C_1\|\sigma^2\|_\infty}{\sqrt{s}} + \|\mu\|_\infty \right) + 2\delta(\rho^\varepsilon(s) - \rho^\varepsilon(t)).$$

We can now estimate the continuity in the time variable:

$$|w^\varepsilon(x,t) - w^\varepsilon(x,s)|$$
$$\leq \left| w^\varepsilon(x,t) - \frac{1}{2\delta}\int_{x-\delta}^{x+\delta} w^\varepsilon(y,t)\,dy \right| + \left| \frac{1}{2\delta}\int_{x-\delta}^{x+\delta} \left(w^\varepsilon(y,t) - w^\varepsilon(y,s)\right)\,dy \right|$$
$$+ \left| \frac{1}{2\delta}\int_{x-\delta}^{x+\delta} w^\varepsilon(y,s)\,dy - w^\varepsilon(x,s) \right|$$
$$\leq \frac{C_1 p^\varepsilon(0)}{\sqrt{s}}\left(2\delta + \frac{(t-s)\|\sigma^2\|_\infty}{2\delta} \right) + \frac{(t-s)2\|\mu\|_\infty p^\varepsilon(0)}{2\delta} + \rho^\varepsilon(s) - \rho^\varepsilon(t).$$

By taking $\delta = \frac{1}{2}\sqrt{\|\sigma^2\|_\infty(t-s)}$, we then obtain

$$|w^\varepsilon(x,t) - w^\varepsilon(x,s)| \leq \sqrt{\|\sigma^2\|_\infty(t-s)}\left(2\|w^\varepsilon_x\|^{s,t}_\infty + \frac{\|\mu\|_\infty p^\varepsilon(0)}{\|\sigma^2\|_\infty} \right) + \rho^\varepsilon(s) - \rho^\varepsilon(t)$$
$$\leq \frac{2C_2 p^\varepsilon(0)\sqrt{t-s}}{\sqrt{s}} + \rho^\varepsilon(s) - \rho^\varepsilon(t).$$

Observe that in estimating the upper bound of $w^\varepsilon(x,s) - w^\varepsilon(x,t)$, the term involving the integral of β can be dropped, so we have (3.11). ∎

It is now straightforward to derive the following estimates on the variation of w^ε and w.

LEMMA 3.3. *For each $T > 0$, there exists a constant $C = C(T)$ that depends only on σ and μ such that for all $\varepsilon \in (0, \varepsilon^*)$, $0 < t \le T$, and $x, y \in \mathbb{R}$,*

$$|w^\varepsilon(x,t) - w^\varepsilon(y,s)| \le \frac{Cp^\varepsilon(0)}{\sqrt{s}}\Big\{|x-y| + 2\sqrt{t-s}\Big\} + \rho^\varepsilon(s) - \rho^\varepsilon(t), \tag{3.14}$$

$$w^\varepsilon(x,t) - w^\varepsilon(y,s) \le \frac{Cp^\varepsilon(0)}{\sqrt{s}}\Big\{|x-y| + 2\sqrt{t-s}\Big\}. \tag{3.15}$$

Consequently, the limit $w = \lim_{\varepsilon \searrow 0} w^\varepsilon$ satisfies, for all $0 < s < t \le T$ and $x, y \in \mathbb{R}$,

$$|w(x,t) - w(y,s)| \le \frac{C}{\sqrt{s}}\Big\{|x-y| + 2\sqrt{t-s}\Big\} + p(s) - p(t), \tag{3.16}$$

$$w(x,t) - w(y,s) \le \frac{C}{\sqrt{s}}\Big\{|x-y| + 2\sqrt{t-s}\Big\}. \tag{3.17}$$

Proof. Using the previous two lemmas we have

$$\begin{aligned} &|w^\varepsilon(x,t) - w^\varepsilon(y,s)| \le |w^\varepsilon(x,t) - w^\varepsilon(x,s)| + |w^\varepsilon(x,s) - w^\varepsilon(y,s)| \\ &\le \frac{Cp^\varepsilon(0)}{\sqrt{s}}\left\{|x-y| + 2\sqrt{t-s}\right\} + \rho^\varepsilon(s) - \rho^\varepsilon(t). \end{aligned}$$

This proves (3.14). The proof of (3.15) is similar, and (3.16), (3.17) follow by sending $\varepsilon \searrow 0$. ∎

With the results from Lemma 3.3 we are now in a position to verify that w is indeed a viscosity solution to the variational inequality.

THEOREM 4. *Assume $p(\cdot)$ defined on $[0,\infty)$ is nonnegative, decreasing, and lower semicontinuous, with $p(0) = 1$. Then there is a unique viscosity solution, and it can be obtained as the limit $w := \lim_{\varepsilon \searrow 0} w^\varepsilon$.*

Proof. First, we verify that w satisfies the initial condition (2.3). For any $t > 0$, from (3.4) $|w^\varepsilon(\cdot,t) - w_0^\varepsilon(\cdot,t)| \le \rho^\varepsilon(0) - \rho^\varepsilon(t)$, so that

$$\|w(\cdot,t) - w_0(\cdot,t)\|_\infty \le \lim_{\varepsilon \searrow 0} \|w^\varepsilon(\cdot,t) - w_0^\varepsilon(\cdot,t)\|_\infty \ \le p(0) - p(t),$$

where

$$w_0(x,t) = \lim_{\varepsilon \to 0} w_0^\varepsilon(x,t) = \int_{-\infty}^0 K(x,t;y,0)\,dy,$$

$$\|w(\cdot,t) - w_0(\cdot,t)\|_\infty = \sup_{x \in \mathbb{R}} |w(\cdot,t) - w_0(\cdot,t)|.$$

Sending $t \searrow 0$, we see that w satisfies (2.3).

To verify that w is a viscosity solution in $\mathbb{R} \times (0,\infty)$ we consider two cases for each $(x,t) \in \mathbb{R} \times (0,\infty)$: (i) $p(t) - w(x,t) > 0$ and (ii) $p(t) - w(x,t) \le 0$.

Case (i). Suppose $p(t) - w(x,t) > 0$. Let $D_\delta = (x-\delta, x+\delta) \times (t-\delta^2, t+\delta^2)$ for all $\delta > 0$. Then, for each $(y,s) \in D_\delta$,

$$|\rho^\varepsilon(s) - \rho^\varepsilon(t)| \le |\rho^\varepsilon(s) - p^\varepsilon(s)| + |p^\varepsilon(s) - p^\varepsilon(t)| + |p^\varepsilon(t) - \rho^\varepsilon(t)| \le |p^\varepsilon(s) - p^\varepsilon(t)| + 2\varepsilon^{2/3},$$

since $0 \le \rho^\varepsilon - p^\varepsilon \le \varepsilon^{2/3}$. As $p^\varepsilon(\cdot)$ is decreasing, when $s > t$,

$$p^\varepsilon(t) - p^\varepsilon(s) + |p^\varepsilon(t) - p^\varepsilon(s)| = 2\left(p^\varepsilon(t) - p^\varepsilon(s)\right) \le 2\left(p^\varepsilon(t) - p^\varepsilon(t+\delta^2)\right);$$

and when $s \le t$,

$$p^\varepsilon(t) - p^\varepsilon(s) + |p^\varepsilon(t) - p^\varepsilon(s)| = 0 \le 2\left(p^\varepsilon(t) - p^\varepsilon(t+\delta^2)\right).$$

Using (3.14), we can compute

$$\begin{aligned} w^\varepsilon(y,s) - p^\varepsilon(s) &\le w^\varepsilon(x,t) + \tfrac{(2+2\sqrt{2})C\delta}{\sqrt{t-\delta^2}} + |\rho^\varepsilon(s) - \rho^\varepsilon(t)| - p^\varepsilon(s) \\ &\le \tfrac{(2+2\sqrt{2})C\delta}{\sqrt{t-\delta^2}} + w^\varepsilon(x,t) - p^\varepsilon(t) + p^\varepsilon(t) - p^\varepsilon(s) + |p^\varepsilon(t) - p^\varepsilon(s)| + 2\varepsilon^{2/3} \\ &\le \tfrac{(2+2\sqrt{2})C\delta}{\sqrt{t-\delta^2}} + w^\varepsilon(x,t) - p^\varepsilon(t) + 2(p^\varepsilon(t) - p^\varepsilon(t+\delta^2)) + 2\varepsilon^{2/3}. \end{aligned}$$

Then, if we take δ small enough,

$$\begin{aligned} \limsup_{\varepsilon\to 0} \max_{\bar{D}_\delta} \left\{w^\varepsilon - p^\varepsilon\right\} &\le \limsup_{\varepsilon\to 0} \tfrac{(2+2\sqrt{2})C\delta}{\sqrt{t-\delta^2}} \\ &\quad + w^\varepsilon(x,t) - p^\varepsilon(t) + 2(p^\varepsilon(t) - p^\varepsilon(t+\delta^2)) + 2\varepsilon^{2/3} \\ &\le \tfrac{(2+2\sqrt{2})C\delta}{\sqrt{t-\delta^2}} + w(x,t) - p(t) + 2(p(t) - p(t+\delta^2)) < 0. \end{aligned} \tag{3.18}$$

Thus, for all sufficiently small positive ε, $w^\varepsilon - p^\varepsilon < 0$ in $\bar{D}_\delta$. Consequently, $\mathcal{L}w^\varepsilon = -\beta(\frac{w^\varepsilon - p^\varepsilon}{\varepsilon}) = 0$ in $\bar{D}_\delta$. The limit w is then a smooth solution to $\mathcal{L}w = 0$ in D_δ.

Case (ii). Suppose $w(x,t) - p(t) \ge 0$. However, $w - p \le 0$ in $\mathbb{R}\times[0,\infty)$ since $w^\varepsilon \le \rho^\varepsilon$ and $\lim_{\varepsilon\searrow 0}\rho^\varepsilon(t) = p(t)$ in $\mathbb{R}\times[0,\infty)$. Hence, we must have $w(x,t) = p(t) = \min\{p(t), w^*(x,t)\}$. From (3.17)

$$w(x,t) - w_*(x,t) = \limsup_{y\to x, s\to t}(w(x,t) - w(y,s)) \le \limsup_{y\to x, s\to t}\left(\frac{C}{\sqrt{s}}\left\{|x-y| + 2\sqrt{t-s}\right\}\right) = 0.$$

Therefore $w_*(x,t) = w(x,t) = p(t)$. Thus the semicontinuity requirements for a viscosity solution hold.

In this case, we clearly have $\max\{w(x,t) - p(t), \mathcal{L}\varphi(x,t)\} \ge 0$ for *any* smooth φ. Therefore w is a supersolution. It remains to verify the differential inequality for subsolutions. To this end, let φ be a smooth function on $\bar{B}_\delta$, where $B_\delta = B_\delta(x,t)$ such that $w^*(y,s) - \varphi(y,s)$ attains at (x,t) a local maximum on $\bar{B}_\delta$. Set

$$\psi(y,s) = \varphi(y,s) + (y-x)^4/\delta^4 + (s-t)^2/\delta^4.$$

For each small positive ε, $w^\varepsilon - \psi$ attains a global maximum on $\bar{B}_\delta$. Denote any such point of maximum by $(y_\varepsilon, s_\varepsilon)$. Then $(w^\varepsilon - \psi)_s \ge 0$, $(w^\varepsilon - \psi)_{yy} \le 0$, $(w^\varepsilon - \psi)_y = 0$ at $(y_\varepsilon, s_\varepsilon)$. Thus, $\mathcal{L}\psi(y_\varepsilon, s_\varepsilon) \le \mathcal{L}w^\varepsilon(y_\varepsilon, s_\varepsilon) = -\beta(\varepsilon^{-1}(w^\varepsilon - p^\varepsilon)) \le 0$. If $(\bar{x},\bar{t})$ is a limit point of $\{(y_\varepsilon, s_\varepsilon)\}$ as $\varepsilon \to 0$, then $\mathcal{L}\psi(\bar{x},\bar{t}) \le 0$. Thus, it suffices to show that $(\bar{x},\bar{t}) = (x,t)$.

Since $w^\varepsilon \le w \le w^*$,

$$\begin{aligned} \limsup_{\varepsilon\searrow 0} \max_{\bar{B}_\delta}\left\{w^\varepsilon - \psi\right\} &\le \limsup_{\varepsilon\searrow 0}\left\{w^*(y_\varepsilon, s_\varepsilon) - \psi(y_\varepsilon, s_\varepsilon)\right\} \\ &\le w^*(\bar{x},\bar{t}) - \psi(\bar{x},\bar{t}) \le \max_{\bar{B}_\delta}(w^* - \varphi) - |\bar{x}-x|^4/\delta^4 - |\bar{t}-t|^2/\delta^4. \end{aligned}$$

On the other hand, from (3.16) and (3.17), we see that $w^*(\hat{x},t) = \lim_{s\nearrow t} w(\hat{x},s)$, so that

$$\begin{aligned}\limsup_{\varepsilon\searrow 0} \max_{\bar{B}_\delta}\Big\{w^\varepsilon - \psi\Big\} &\geq \lim_{s\nearrow t}\limsup_{\varepsilon\searrow 0}\{w^\varepsilon(x,s)-\psi(x,s)\}\\ &= \lim_{s\nearrow t}\{w(x,s)-\psi(x,s)\} = w^*(x,t)-\psi(x,t) = \max_{\bar{B}_\delta}(w^*-\varphi).\end{aligned}$$

Thus, we must have $(\bar{x},\bar{t}) = (x,t)$. This completes the proof. □

3.3. The differential equation and the free boundary problem. Since

$$0 \leq \beta(\varepsilon^{-1}(w^\varepsilon - p^\varepsilon)) \leq -\dot{\rho}^\varepsilon,$$

and $\rho^\varepsilon(\cdot)$ is decreasing, by weak compactness of measures, as $\varepsilon \to 0$,

$$\begin{aligned}\beta(\varepsilon^{-1}(w^\varepsilon - p^\varepsilon)) &\longrightarrow \gamma \qquad \text{as a measure in } \mathbb{R}\times[0,\infty),\\ \mathcal{L}w &= \gamma \qquad \text{on } \mathbb{R}\times(0,\infty),\end{aligned}$$

where γ is a Radon measure satisfying

$$0 \leq \gamma\, dx\, dt \leq -dx\, dp(t).$$

In addition, from Lemma 2.1(1), γ is supported on the set $w = p$.

Now suppose that p is continuous. Then $\gamma = \dot{p}$ on the contact set Π (noticing that Π_2 is empty). Hence, w is the solution to

$$\mathcal{L}w = \dot{p}(t)\mathbf{1}_{\{w=p\}} \text{ in } \mathbb{R}\times(0,\infty), \qquad w(\cdot,0) = \mathbf{1}_{(-\infty,0)} \text{ on } \mathbb{R}\times\{0\}. \tag{3.19}$$

Using a free boundary approach, this can be written as the solution to the free boundary problem for (b,w):

$$\begin{cases} \mathcal{L}w = \dot{p}(t)\mathbf{1}_{x<b(t)} & \text{in } \mathbb{R}\times(0,\infty),\\ b(t) := \inf\{x \mid w(x,t) < p(t)\} & \forall\ t \geq 0,\\ w(\cdot,0) = \mathbf{1}_{(-\infty,0)} & \text{on } \mathbb{R}\times\{0\}.\end{cases} \tag{3.20}$$

We emphasize that this formulation works only when p is continuous, since if p is not continuous at s, then

$$\mathcal{L}w = \min\{p(s) - w^*(x,\tau), 0\}\cdot\delta(t-s) \quad \text{on } \mathbb{R}\times\{s\},$$

where δ is the Dirac measure.

Remark 3.1. Suppose $\|\dot{p}\|_\infty := \sup_{t\geq 0}|\dot{p}(t)|$ is finite. Then $\|\dot{p}_\varepsilon\|_\infty \leq \|\dot{p}\|_\infty$ and $\rho^\varepsilon - p^\varepsilon \leq \varepsilon\|\dot{p}\|^{1/3}$. Consequently, $\dot{\rho}^\varepsilon = -\beta(\|\dot{p}\|^{1/3}) = -\|\dot{p}\|_\infty$. Hence

$$0 \leq \gamma^\varepsilon(x,t) \leq \|\dot{p}\|_\infty \qquad \forall (x,t)\in\mathbb{R}\times[0,\infty).$$

It is then easy to show that $w^\varepsilon(x,t) - w_0^\varepsilon \to w - w_0$ in $W_r^{2,1}([-R,R]\times[0,R^2])$ for any $r > 1$ and any $R > 0$.

4. Estimation of the free boundary. In this section, we provide both upper and lower bounds for the free boundary

$$b(t) := \inf\{x \in \mathbb{R} \mid w(x,t) < p(t)\} \in [-\infty, \infty] \qquad \forall\, t > 0$$

in the case of Brownian motion, i.e., when $\sigma \equiv 1$ and $\mu \equiv 0$.

Recall the notation $q(t) = 1 - p(t)$. Note that for any $s > 0$, $0 = q(0) = q^*(0) \leq q(s)$, and since p is LSC, q is USC. We define

$$\dot{q}(s) := \liminf_{t \nearrow s} \frac{q(s) - q(t)}{s - t} \in [0, \infty].$$

The following lemma is obvious from the probabilistic interpretation of our problem since it states that $\mathbb{P}[X_t \leq b(t)] \leq \mathbb{P}[\tau \leq t]$. Its analytic derivation is equally simple.

LEMMA 4.1. *For every $t > 0$,*

$$\frac{1}{\sqrt{\pi}} \int_{-\infty}^{b(t)/\sqrt{2t}} e^{-z^2}\, dz \leq q(t).$$

Proof. We need only consider the case $b(t) > -\infty$. Since $w(x,t) \leq w_0(x,t)$,

$$\begin{aligned} 1 - q(t) = p(t) = w(b(t),t) \leq w_0(b(t),t) &= \int_{-\infty}^{0} \Gamma(b(t) - y, t)\, dy \\ &= 1 - \frac{1}{\sqrt{2\pi t}} \int_0^{\infty} e^{-\frac{(b(t)-y)^2}{2t}}\, dy = 1 - \frac{1}{\sqrt{\pi}} \int_{-\infty}^{b(t)/\sqrt{2t}} e^{-z^2} dz. \qquad \square \end{aligned}$$

We observe that the above lemma immediately yields an upper bound on $b(t)$:

$$b(t) \leq \sqrt{t} \cdot \Phi^{-1}(q(t)),$$

where $\Phi(z)$ is the cumulative distribution function of a standard normal random variable, $\Phi(z) = \int_{-\infty}^{z} e^{-w^2/2} \frac{dw}{\sqrt{2\pi}}$. We now proceed to the more difficult task of deriving useful lower bounds on $b(t)$.

LEMMA 4.2 (method for lower bounds). *Assume that $\underline{w}$ defined on $\mathbb{R} \times [0,t]$ satisfies*

$$\text{(4.1)} \qquad \begin{cases} \mathcal{L}\underline{w} = 0 & \text{in } \ \mathbb{R} \times (0,t], \\ \underline{w}(\cdot,0) \leq w(\cdot,0) & \text{on } \ \mathbb{R} \times \{0\}, \\ \underline{w} \leq p & \text{on } \ \mathbb{R} \times (0,t), \\ \underline{w}(s,t) \geq p(t) & \text{at } \ (s,t). \end{cases}$$

Then

$$\underline{w} \leq w \ \ \text{in } \ \mathbb{R} \times [0,t), \qquad s \leq b(t).$$

Proof. First, consider the case where p is continuous at t, so $p(t) = p^*(t)$. For each $\varepsilon > 0$, let $\phi^\varepsilon = \underline{w} - \varepsilon e^r - \varepsilon x^2$. We claim that $\phi^\varepsilon \leq w$ on $\mathbb{R} \times [0,t]$. Suppose not; then $w - \phi^\varepsilon$ can attain a global negative minimum, say, at $(\hat{x}, \hat{r})$. Since $w(x,0) - \phi^\varepsilon(x,0) = w(x,0) - \underline{w}(x,0) + \varepsilon + \varepsilon x^2 \geq \varepsilon$, $\hat{r} > 0$. Therefore $\mathcal{L}\phi^\varepsilon(\hat{x},\hat{r}) = -\varepsilon e^{\hat{r}} + \varepsilon < 0$. As a

supersolution, $\max\{w(\hat{x},\hat{r})-p(\hat{r}), \mathcal{L}\phi^\varepsilon(\hat{x},\hat{r})\} \geq 0$; hence we must have $w(\hat{x},\hat{r})-p(\hat{r}) \geq 0$. The condition $\underline{w} \leq p$ on $\mathbb{R}\times(0,t)$, and $p^*(t) = p(t)$ implies that $\underline{w} \leq p$ on $\mathbb{R}\times(0,t]$. Then $w(\hat{x},\hat{r}) < \phi^\varepsilon(\hat{x},\hat{r}) < \underline{w}(\hat{x},\hat{r}) \leq p(\hat{r})$. This is a contradiction. Thus $\phi^\varepsilon \leq w$ in $\mathbb{R}\times(0,t]$ for each $\varepsilon > 0$. Sending $\varepsilon \searrow 0$, we conclude that $\underline{w} \leq w$ in $\mathbb{R}\times(0,t]$.

In general, let $\{t_n\}$ be a sequence of positive numbers such that $t_n \nearrow t$ as $n \to \infty$, and $p(\cdot)$ is continuous at t_n. Then $\underline{w} \leq w$ in $\mathbb{R}\times[0,t_n]$. Sending $n \to \infty$ we obtain $\underline{w} \leq w$ in $\mathbb{R}\times[0,t)$.

As a subsolution, $w = \min\{p, w^*\}$. From the above argument, $w^*(s,t) \geq \underline{w}(s,t) \geq p(t)$. Therefore $w(s,t) = w_*(s,t) = p(t)$. By the definition of $b(\cdot)$, we conclude that $b(t) \geq s$. ∎

LEMMA 4.3 (a criterion for lower bounds). *For each $s < 0 < t$, let*

$$Q(s,r) := q(r) - \frac{2}{\sqrt{\pi}} \int_{-\infty}^{s/\sqrt{2r}} e^{-z^2}\, dz.$$

Suppose (s,t) is such that

$$s < 0 < t, \quad Q(s,r) \leq Q(s,t) \quad \forall\, r \in (0,t). \tag{4.2}$$

Then $b(t) \geq s$.

Proof. Let $\underline{w}$ be the solution to

$$\begin{cases} \mathcal{L}\underline{w} = 0 & \text{in } \mathbb{R}\times(0,t], \\ \underline{w}(\cdot,0) = \theta\, \mathbf{1}_{(2s,0)} & \text{on } \mathbb{R}\times\{0\}. \end{cases}$$

where

$$\theta = p(t) \left(\frac{2}{\sqrt{\pi}} \int_{s/\sqrt{2t}}^{0} e^{-z^2} dz \right)^{-1}.$$

We claim $\underline{w}$ satisfies (4.1).

1. Since the problem for $\underline{w}$ is linear, it can be expressed as

$$\underline{w}(x,r) = \theta \int_{2s}^{0} \Gamma(x-y,r)dy = \frac{\theta}{\sqrt{\pi}} \int_{\frac{x}{\sqrt{2r}}}^{\frac{x-2s}{\sqrt{2r}}} e^{-z^2}\, dz \qquad \forall\, x \in \mathbb{R}, r > 0. \tag{4.3}$$

In particular, when $x = s$,

$$\underline{w}(s,t) = \frac{\theta}{\sqrt{\pi}} \int_{s/\sqrt{2t}}^{-s/\sqrt{2t}} e^{-z^2} dz = \frac{2\theta}{\sqrt{\pi}} \int_{s/\sqrt{2t}}^{0} e^{-z^2} dz = p(t).$$

2. By (4.3), we find that

$$\max_{x\in\mathbb{R}} \underline{w}(x,r) = \underline{w}(s,r) = \frac{p(t) \int_{s/\sqrt{2r}}^{0} e^{-z^2} dz}{\int_{s/\sqrt{2t}}^{0} e^{-z^2} dz} \qquad \forall r > 0. \tag{4.4}$$

For any $s < 0 < r$, we can compute

$$\frac{2}{\sqrt{\pi}} \int_{s/\sqrt{2r}}^{0} e^{-z^2}\, dz = 1 - \frac{2}{\sqrt{\pi}} \int_{-\infty}^{s/\sqrt{2r}} e^{-z^2} dz = 1 + Q(s,r) - q(r) = Q(s,r) + p(r). \tag{4.5}$$

From (4.4) and (4.5), for all $r \in (0,t)$,

$$\begin{aligned}\max_{x\in\mathbb{R}} \underline{w}(x,r) - p(r) &= \frac{p(t)[Q(s,r)+p(r)]}{Q(s,t)+p(t)} - p(r)\\ &= \frac{p(t)Q(s,r) - p(r)Q(s,t)}{Q(s,t)+p(t)}\\ &\le \frac{p(t)[Q(s,r)-Q(s,t)]}{Q(s,t)+p(t)} \le 0,\end{aligned}$$

i.e., $\underline{w} \le p$ on $\mathbb{R}\times(0,t)$.

3. Since $Q(s,\cdot)$ is increasing for any $s<0$, $Q(s,t) \ge \lim_{r\searrow 0} Q(s,r) = 0$. In particular, when $r=t$, (4.5) reads as

$$\frac{2}{\sqrt{\pi}} \int_{s/\sqrt{2t}}^{0} e^{-z^2}\,dz = Q(s,t) + p(t) \ge p(t).$$

Therefore $\theta \le 1$, and thus $\underline{w}(\cdot,0) \le w(\cdot,0)$ on $\mathbb{R}\times\{0\}$. Lemma 4.2 now gives $b(t) \ge s$. □

The above lemma has an interesting probabilistic interpretation. Recalling that we are assuming that X_t is a Brownian motion, define $\underline{X}_t = \min_{v\le t} X_v$. Then

$$\begin{aligned}Q(s,r) &= q(r) - \frac{2}{\sqrt{\pi}} \int_{-\infty}^{s/\sqrt{2r}} e^{-z^2}\,dz\\ &= \mathbb{P}[\tau \le r] - 2\mathbb{P}[X_r \le s]\\ &= \mathbb{P}[\tau \le r] - \mathbb{P}[\underline{X}_r \le s],\end{aligned}$$

where the last line follows from the reflection principle (see, for example, Karatzas and Shreve [13]). Rearranging (4.2) then yields that if $s<0<t$ are such that

$$\mathbb{P}[\underline{X}_r > s \text{ and } \underline{X}_t \le s] \le \mathbb{P}[r < \tau \le t]$$

for all $r \in (0,t)$, then $b(t) \ge s$. This result is clear in the case that $b(t)$ is monotone but requires a more careful argument, as above, in the general case.

Before we continue, we provide an interesting application of Lemmas 4.3 and 4.1.

COROLLARY 4.4. *For each $t>0$, let $\zeta(t) \in (-\infty,0)$ and $\nu(t) \in \mathbb{R}$ be defined by*

$$q(t) = \frac{2}{\sqrt{\pi}} \int_{-\infty}^{\zeta(t)/\sqrt{2t}} e^{-z^2}\,dz = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\nu(t)/\sqrt{2t}} e^{-z^2}\,dz.$$

1. *Suppose ζ is a constant function. Then the exact solution to* (1.1) *is given by*

$$\text{(4.6)} \qquad \begin{cases} w(x,t) = \frac{1}{\sqrt{\pi}} \int_{x/\sqrt{2t}}^{(x-2\zeta)/\sqrt{2t}} e^{-z^2}\,dz & \forall\, x \ge \zeta, t>0,\\ b(t) = \zeta & \forall\, t>0.\end{cases}$$

2. *Suppose $\zeta(r) \le \zeta(t)$ for all $r \in (0,t)$. Then $\zeta(t) \le b(t) \le \nu(t)$.*
3. *Suppose $\dot\zeta(t) \ge 0$ for all $t \in (0,T]$. Then*

$$\zeta(t) \le b(t) \le \nu(t) \quad \forall t \in (0,T], \quad \lim_{t\searrow 0} \frac{b(t)}{\zeta(t)} = 1.$$

Proof. 1. The first assertion may be verified by a direct computation. We note that it agrees with the formula for the first hitting time of Brownian motion to the level ζ (see, e.g., Karatzas and Shreve [13, pages 94–96]).

2. Suppose $\zeta(r) \le \zeta(t)$ for all $r \in (0,t)$. Set $s = \zeta(t)$. Then

$$Q(s,r) = q(r) - \frac{2}{\sqrt{\pi}} \int_{-\infty}^{\zeta(t)/\sqrt{2r}} e^{-z^2}\, dz = \frac{2}{\sqrt{\pi}} \int_{\zeta(t)/\sqrt{2r}}^{\zeta(r)/\sqrt{2r}} e^{-z^2} dz \le 0 = Q(s,t)$$

for each $r \in (0,t)$. Thus, by Lemma 4.3, $b(t) \ge s = \zeta(t)$. This is the lower bound for $b(t)$.

For $t > 0$, Lemma 4.1 reads as

$$\frac{1}{\sqrt{\pi}} \int_{-\infty}^{b(t)/\sqrt{2t}} e^{-z^2} dz \le q^*(t) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\nu^*(t)/\sqrt{2t}} e^{-z^2} dz,$$

which implies that $b(t) \le \nu^*(t)$.

3. Suppose $\dot{\zeta}(t) \ge 0$ in $(0,T]$. Then by Corollary 4.4(2) $\zeta(t) \le b(t) \le \nu(t)$ for all $t \in (0,T]$. To complete the proof, it remains to estimate the difference between $\alpha(t) := \nu^*(t)/\sqrt{2t}$ and $\gamma(t) := \zeta(t)/\sqrt{2t}$. Let $\delta(t) = \ln 2/(-2\gamma(t) - 1)$. Since $\lim_{t \searrow 0} \gamma(t) = -\infty$, we conclude that for all small positive $t > 0$, $\delta(t) \in (0,1)$. Note that

$$\begin{aligned}
\frac{1}{\sqrt{\pi}} \int_{-\infty}^{\alpha} e^{-z^2}\, dz = q(t) &= \frac{2}{\sqrt{\pi}} \int_{-\infty}^{\gamma} e^{-z^2}\, dz = \frac{2}{\sqrt{\pi}} \int_{-\infty}^{\gamma+\delta} e^{-z^2+2\delta z-\delta^2} dz \\
&\le \frac{2}{\sqrt{\pi}} \int_{-\infty}^{\gamma+\delta} e^{-z^2+2\delta(\gamma+\delta)-\delta^2} dz = \frac{2e^{\delta(2\gamma+\delta)}}{\sqrt{\pi}} \int_{-\infty}^{\gamma+\delta} e^{-z^2} dz \\
&= \frac{2e^{-\ln 2+\delta^2-\delta}}{\sqrt{\pi}} \int_{-\infty}^{\gamma+\delta} e^{-z^2}\, dz \le \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\gamma+\delta} e^{-z^2}\, dz.
\end{aligned}$$

Thus, $\alpha(t) \le \gamma(t) + \delta(t)$. Then

$$0 \le 1 - \frac{b(t)}{\zeta(t)} \le 1 - \frac{\nu(t)}{\zeta(t)} = 1 - \frac{\alpha(t)}{\gamma(t)} \le \frac{\delta(t)}{-\gamma(t)} = \frac{\ln 2}{2\gamma^2(t) + \gamma(t)}.$$

The third assertion of the lemma thus follows by sending $t \to 0$. □

Next, we present a sufficient condition for $Q(s,\cdot)$ to attain its maximum in $(0,t]$ at t. Note that for $0 < r < t$, $Q(s,r) \le Q(s,t)$ is equivalent to

$$\frac{q(t) - q(r)}{t - r} \ge \frac{2}{\sqrt{\pi}(t-r)} \left\{ \int_{-\infty}^{s/\sqrt{2t}} e^{-z^2} dz - \int_{-\infty}^{s/\sqrt{2r}} e^{-z^2} dz \right\} = \frac{-s\, e^{-s^2/(2\theta)}}{\theta^{3/2}\sqrt{2\pi}},$$

where $r < \theta \le t$. The second equality follows from the mean value theorem. To achieve the maximum in $(0,t]$ for $Q(s,\cdot)$, it is sufficient to have

$$\inf_{0<r<t} \frac{q(t) - q(r)}{t - r} \ge \sup_{r<\theta\le t} \frac{|s| e^{-s^2/(2\theta)}}{\theta^{3/2}\sqrt{2\pi}} = \frac{|s| e^{-s^2/(2t)}}{t^{3/2}\sqrt{2\pi}}, \tag{4.7}$$

provided that $s \le -\sqrt{3t}$. Taking the best possible $s \le -\sqrt{3t}$ for the inequality (4.7) to hold, we then obtain the following.

LEMMA 4.5. *Assume that $t > 0$ and*

$$k(t) := \inf_{0\le r\le t} \frac{q(t) - q(r)}{t - r} > 0.$$

Then

$$b(t) \geq \max\left\{ s \;\middle|\; s \leq -\sqrt{3t}\,;\, \frac{|s|}{\sqrt{2\pi}t^{3/2}} e^{-s^2/(2t)} \leq k(t) \right\}.$$

As an immediate consequence of the lemma, we have the following.

COROLLARY 4.6. *If $\dot{q}(t) > 0$, then $b(t) > -\infty$.*

We end this section with the following estimate on the asymptotic behavior of the boundary near 0. As mentioned above, this estimate is important when solving the inverse first passage problem numerically using integral equations such as (1.6); see [2].

THEOREM 5. *Assume that*

$$\limsup_{t \searrow 0} \frac{q(t)}{t\dot{q}(t)} < \infty. \tag{4.8}$$

Then

$$\lim_{t \searrow 0} \frac{b(t)}{\sqrt{-2t \log q(t)}} = -1. \tag{4.9}$$

Consequently, in special cases the following hold:

1. *when $q(t) = A\,t^m$, where A and m are positive constants,*

$$b(t) = -\sqrt{-2mt \log t}\;\; [1 + o(1)], \qquad \lim_{t \searrow 0} o(1) = 0;$$

2. *when $q(t) = A\,e^{-\gamma^2/(2t^m)}$, where A, m, γ are positive constants,*

$$b(t) = -\gamma\, t^{(1-m)/2}\;\; [1 + o(1)], \qquad \lim_{t \searrow 0} o(1) = 0.$$

In particular,

$$\lim_{t \searrow 0} b(t) = \begin{cases} -\infty & \text{if } m > 1, \\ \gamma & \text{if } m = 1, \\ 0 & \text{if } 0 < m < 1. \end{cases}$$

Proof. The idea is to estimate $k(r)$ via $q(r)/r$. Under the assumption (4.8), there exist positive constants C and T such that

$$0 < q(r) \leq C\, r\, \dot{q}(r) \qquad \forall\, r \in (0, T].$$

For any $0 < r < t \leq T$, we can compute

$$\begin{aligned} C\,(q(t) - q(r)) &\geq \int_r^t C\,\dot{q}(\theta)\,d\theta \geq \int_r^t \frac{q(\theta)}{\theta}\,d(\theta - r) \\ &= \frac{q(\theta)(\theta - r)}{\theta}\Big|_{\theta=r}^{\theta=t} - \int_r^t (\theta - r)\frac{\theta\dot{q}(\theta) - q(\theta)}{\theta^2}\,d\theta \\ &= \frac{(t-r)q(t)}{t} - \int_r^t \dot{q}(\theta)\,d\theta + \int_r^t \frac{r\theta\dot{q}(\theta) + (\theta - r)q(\theta)}{\theta^2}\,d\theta \\ &\geq (t-r)\frac{q(t)}{t} - [q(t) - q(r)]. \end{aligned}$$

That is, $(C+1)(q(t)-q(r)) \geq (t-r)\, q(t)/t$. It follows that

$$k(t) = \inf_{0<r<t} \frac{q(t)-q(r)}{t-r} \geq \frac{1}{C+1}\frac{q(t)}{t}.$$

Now fix $t \in (0,T]$, when $s \leq -\sqrt{3t}$, to be

$$\frac{|s|}{t^{3/2}\sqrt{2\pi}} \int_{-\infty}^{s/\sqrt{2t}} e^{-z^2} dz \leq \frac{|s|}{t^{3/2}\sqrt{2\pi}} e^{s^2/(2t)}.$$

Let $s < -\sqrt{3t}$ be the solution to

$$\frac{|s|}{\sqrt{2\pi}t^{3/2}} \int_{-\infty}^{s/\sqrt{2t}} e^{-z^2} dz = \frac{1}{C+1}\frac{q(t)}{t}. \tag{4.10}$$

For small t, $q(t)$ is small, so that $s/\sqrt{t} \ll -1$ and we can use the expansion, for $a < 0$,

$$\int_{-\infty}^{a} e^{-z^2} dz = \int_{a^2}^{\infty} \frac{e^{-x}dx}{2\sqrt{x}} = \frac{e^{-a^2}}{2|a|} - \int_{a^2}^{\infty} \frac{e^{-x}dx}{4x^{3/2}} = \frac{e^{-a^2}}{2|a|}\left\{1 - \frac{\theta}{2a^2}\right\},$$

where $\theta = \theta(a) \in (0,1)$. Hence, the equation for s reads as

$$e^{-s^2/(2t)}\left\{1 - \frac{\theta}{s^2/(2t)}\right\} = \frac{\sqrt{2\pi}}{C+1} q(t).$$

It then follows that

$$\begin{aligned} |s| &= \sqrt{2t}\left(-\log q(t) + \log(1-\theta t/s^2) + \log[(C+1)/\sqrt{2\pi}]\right)^{1/2} \\ &\leq \sqrt{-2t\log q(t)}\Big\{1 + (\log[(C+1)/\sqrt{4\pi}])/(-\log q(t))\Big\}^{1/2}. \end{aligned}$$

By Lemma 4.5, we then have

$$\begin{aligned} b(t) \geq s &\geq -\sqrt{-2t\log q(t)}\left\{1 + \frac{\log[(C+1)/\sqrt{2\pi}]}{|\log q(t)|}\right\}^{1/2} \\ &= -\sqrt{-2t\log q(t)}\{1+o(1)\}. \end{aligned}$$

This gives the lower bound for $b(t)$; now we estimate the upper bound. From Lemma 4.1,

$$q(t) \geq \frac{1}{\sqrt{\pi}} \int_{-\infty}^{b(t)/\sqrt{2t}} e^{-z^2}\, dz = \frac{\sqrt{t}}{\sqrt{2\pi}|b(t)|}\left\{1 - \frac{\theta\, t}{b^2(t)}\right\} e^{-b(t)^2/(2t)}.$$

This implies that

$$\begin{aligned} b(t) &\leq -\sqrt{-2t\log q(t)}\left\{1 + \frac{\log[1-\theta t/b^2(t)] - \log[\sqrt{2\pi}|b(t)|/\sqrt{t}]}{-\log q(t)}\right\}^{1/2} \\ &\leq -\sqrt{-2t\log q(t)}\left\{1 - \frac{O(1)\log|\log q(t)|}{|\log q(t) + o(1)|}\right\}^{1/2}. \end{aligned}$$

The assertion (4.9) thus follows. The remainder of the theorem is a direct application of (4.9). □

5. Integral equations. As in section 4, we assume $\sigma \equiv 1$ and $\mu \equiv 0$. Also we assume that p (and therefore q) is continuous. Then the solution to (3.19) can be expressed as

$$\begin{aligned} w(x,t) &= \int_{-\infty}^{0} \Gamma(x-y,t)dy + \int_0^t dp(s) \int_{-\infty}^{b(s)} \Gamma(x-y,t-s)\,dy \\ &= 1 - \int_0^{\infty} \Gamma(x-y,t)dy + \int_0^t dp(s) \left(1 - \int_{b(s)}^{\infty} \Gamma(x-y,t-s)\,dy\right) \\ &= p(t) - \int_{-\infty}^{x} \Gamma(z,t)\,dz + \int_0^t dq(s) \int_{-\infty}^{x-b(s)} \Gamma(z,t-s)\,dz, \end{aligned} \tag{5.1}$$

where the second equation is obtained by using $\int_{\mathbb{R}} \Gamma(x-y,s)dy = 1$ for all $s > 0$.

Now assume that b is smooth. Differentiating w, we can derive

$$u(x,t) = -w_x(x,t) = \Gamma(x,t) - \int_0^t \Gamma(x-b(s),t-s)\,dq(s). \tag{5.2}$$

Also, for $x \neq b(t)$, we can further differentiate to obtain

$$u_x(x,t) = \Gamma_x(x,t) - \int_0^t \Gamma_x(x-b(s),t-s)dq(s), \tag{5.3}$$

$$\begin{aligned} u_t(x,t) &= \Gamma_t(x,t) - \int_0^t \Gamma_t(x-b(s),t-s)dq(s) \\ &= \Gamma_t(x,t) + \int_0^t \left(\frac{d}{ds}\Gamma(x-b(s),t-s) + \dot{b}(s)\Gamma_x(x-b(s),t-s)\right) dq(s) \\ &= \Gamma_t(x,t) + \int_0^t \dot{b}(s)\Gamma_x(x-b(s),t-s)dq(s) + \int_0^t \dot{q}(s)d\Gamma(x-b(s),t-s) \\ &= \Gamma_t(x,t) + \int_0^t \dot{b}(s)\Gamma_x(x-b(s),t-s)dq(s) - \dot{q}(0)\Gamma(x,t) \\ &\quad - \int_0^t \Gamma(x-b(s),t-s)d\dot{q}(s), \end{aligned} \tag{5.4}$$

where the second equation is obtained by the equality

$$\Gamma_t(x-b(s),t-s) = -\frac{d}{ds}\Gamma(x-b(s),t-s) - \dot{b}(s)\Gamma_x(x-b(s),t-s)$$

and the third equation by using integration by parts to $\int_0^t \dot{q}(s)d\Gamma(x-b(s),t-s)$.

From potential theory, for any b and f with the certain regularity, we have

$$\lim_{x \to b(t) \pm 0} \int_0^t f(s)\Gamma_x(x-b(s),t-s)ds = \int_0^t f(s)\Gamma_x(b(t)-b(s),t-s)\,ds \mp f(t). \tag{5.5}$$

This can be derived as follows:

$$\begin{aligned}
&\lim_{x\to b(t)\pm 0}\int_0^t f(s)\Gamma_x(x-b(s),t-s)ds\\
&\quad=-\lim_{x\to b(t)\pm 0}\int_0^t f(s)\left[\frac{(b(t)-b(s))}{\sqrt{2\pi}(t-s)^{3/2}}e^{-\frac{(x-b(s))^2}{2(t-s)}}+\frac{(x-b(t))}{\sqrt{2\pi}(t-s)^{3/2}}e^{-\frac{(x-b(s))^2}{2(t-s)}}\right]ds\\
&\quad=\int_0^t f(s)\Gamma_x(b(t)-b(s),t-s)\,ds-\lim_{x\to b(t)\pm 0}\int_0^t f(s)\frac{x-b(t)}{\sqrt{2\pi}(t-s)^{3/2}}e^{-\frac{(x-b(s))^2}{2(t-s)}}ds\\
&\quad=\int_0^t f(s)\Gamma_x(b(t)-b(s),t-s)\,ds\\
&\qquad-\frac{2}{\sqrt{\pi}}\lim_{x\to b(t)\pm 0}\int_{\frac{x-b(t)}{\sqrt{2t}}}^{\pm\infty} f\left(t-\frac{(x-b(t))^2}{2\eta^2}\right)e^{-(\eta+\frac{b(t)-b(s)}{\sqrt{2(t-s)}})^2}d\eta\\
&\quad=\int_0^t f(s)\Gamma_x(b(t)-b(s),t-s)\,ds-\frac{2}{\sqrt{\pi}}\int_0^{\pm\infty} f(t)e^{-\eta^2}d\eta\\
&\quad=\int_0^t f(s)\Gamma_x(b(t)-b(s),t-s)\,ds\mp f(t).
\end{aligned}$$

Note that $w(x,t)=p$ and $0=u(x,t)=u_x(x,t)=u_t(x,t)$ for $x<b(t)$. Sending x to $b(t)$ from below in (5.1) and (5.2) we then obtain

$$\int_{-\infty}^{b(t)}\Gamma(z,t)dz=\int_0^t dq(s)\int_{-\infty}^{b(t)-b(s)}\Gamma(z,t-s)dz, \tag{5.6}$$

$$\Gamma(b(t),t)=\int_0^t\Gamma(b(t)-b(s),t-s)\,dq(s), \tag{5.7}$$

which reflect the free boundary condition $w(b(t),t)=p(t)$ and the condition $u(b(t),t)=0$, respectively. Sending x to $b(t)$ from below in (5.3) and (5.4) and using (5.5), we have

$$\dot q(t)=\Gamma_x(b(t),t)-\int_0^t\Gamma_x(b(t)-b(s),t-s)\,dq(s), \tag{5.8}$$

$$-\dot b(t)\dot q(t)=\Gamma_t(b(t),t)+\int_0^t\dot b(s)\Gamma_x(b(t)-b(s),t-s)dq(s),$$

$$-\dot q(0)\Gamma(b(t),t)-\int_0^t\Gamma(b(t)-b(s),t-s)d\dot q(s). \tag{5.9}$$

Equation (5.8) reflect the free boundary condition $u_x(b(t)^-,t)=0$ and $u_x(b(t)^+,t)=\dot q(t)$. Similarly, (5.9) reflects the free boundary condition that $u_t(b(t)^-,t)=0$ and $u_t(b(t)^+,t)=-\dot b(t)u_x(b(t)^+,t)=-\dot b(t)\dot q(t)$.

Clearly, these identities can provide numerical schemes much more flexible and economical than integrating the corresponding PDEs. For this purpose, it is necessary to study solutions to each of these identities.

One observes that if $b(\cdot)$ is a solution to (5.7), then $b_1(t):=-b(t)$ is also the solution. Hence, we need to be careful when considering solutions to the integral equation.

THEOREM 6. *Let $q:[0,\infty)\to[0,1)$ be continuous, increasing, and $q(0)=0$. Assume that $b:(0,T]\to\mathbb{R}$ is a continuous function. Then $x=b(t)$, $t\in(0,T]$, is the solution to the free boundary problem, provided that one of the following holds.*

1. *b satisfies* (5.6) *for all* $t \in (0,T]$*;*
2. *b satisfies* (5.7) *for all* $t \in (0,T]$*,* $b(t) < 0$ *for all sufficiently small positive* t*, and the function*

$$t \to q_{1/2}(t) := \int_0^t \frac{\dot{q}(t)}{\sqrt{2\pi(t-s)}} ds$$

is continuous in $(0,T]$ *with* $q_{1/2}(0+) = 0$*;*
3. *b satisfies* (5.8), $\lim_{t\searrow 0} \frac{b(t)}{\sqrt{t}} = -\infty$*,* $\dot{q}$ *is continuous in* $[0,T]$*, and the function*

$$t \to q^b_{3/2} := \int_0^t \frac{|b(t) - b(s)|}{\sqrt{2\pi}(t-s)^{3/2}} dq(s)$$

is continuous on $(0,T]$ *and is uniformly bounded.*

The analogous condition for (5.9) is too technical, and hence we omit it here.

Proof. With the given continuous function b, we define $w(x,t)$ as in (5.1). Note that

$$\begin{aligned} 0 \geq w(x,t) - w_0(x,t) &= \int_0^t dp(s) \int_{-\infty}^{b(s)} \Gamma(x-y, t-s) dy \\ &= \int_0^t dp(s) \left(1 - \int_{b(s)}^{\infty} \Gamma(x-y,t-s) dy \right) \\ &= -q(t) + \int_0^t dq(t) \int_{-\infty}^{x-b(s)} \Gamma(z, t-s) dz \geq -q(t). \end{aligned}$$

This implies that

$$|w(x,t) - w_0(x,t)| \leq q(t).$$

When $t = 0$, it reads as $|w(x,0) - w_0(x,0)| \leq q(0) = 0$, so that $w(x,0) = w_0(x,0) = \mathbf{1}_{(-\infty,0)}$.

In addition, upon differentiation, $\mathcal{L}w = \dot{p}\mathbf{1}_{\{x<b(t)\}} \leq 0$ as a measure in $\mathbb{R} \times (0,T]$. This can verified as follows. Direct calculation gives

$$\begin{aligned} w_{xx} &= -\Gamma_x(x,t) + \int_0^t \Gamma_x(x - b(s), t-\tau) dq(s), \\ w_t &= \dot{p}(t) - \int_{-\infty}^x \Gamma_t(z,t) dz + \int_0^t \int_{-\infty}^{x-b(s)} \Gamma_t(z, t-s) dz dq(s). \end{aligned}$$

Using the fact that $\Gamma_t = \frac{1}{2}\Gamma_{xx}$, we obtain

$$\int_{-\infty}^x \Gamma_t(z,t) dz = \int_{-\infty}^x \frac{1}{2}\Gamma_{xx}(z,t) dz = \frac{1}{2}\Gamma_x(z,t)\Big|_{z=-\infty}^{z=x} = \frac{1}{2}\Gamma_x(x,t).$$

When $x < b(s)$,

$$\begin{aligned} \int_0^t \int_{-\infty}^{x-b(s)} \Gamma_t(z, t-s) dz dq(s) &= \frac{1}{2} \int_0^t \Gamma_x(z, t-s)\Big|_{z=-\infty}^{z=x-b(s)} dq(s) \\ &= \frac{1}{2} \int_0^t \Gamma_x(x - b(s), t-\tau) dq(s). \end{aligned}$$

When $x > b(s)$,

$$\begin{aligned}
&\int_0^t \int_{-\infty}^{x-b(s)} \Gamma_t(z, t-s)dzdq(s) \\
&= \frac{1}{2}\int_0^t \Gamma_x(z, t-s)\Big|_{z=-\infty}^{z=(b(t)-b(s))^-} dq(s) + \frac{1}{2}\int_0^t \Gamma_x(z, t-s)\Big|_{z=(b(t)-b(s))^+}^{z=x-b(s)} dq(s) \\
&= \frac{1}{2}\int_0^t \Gamma_x(x-b(s), t-s)dq(s) + \lim_{z\nearrow(b(t)-b(s))} \frac{1}{2}\int_0^t \Gamma_x(z, t-s)dq(s) \\
&\quad - \lim_{z\searrow(b(t)-b(s))} \frac{1}{2}\int_0^t \Gamma_x(z, t-s)dq(s) \\
&= \dot{q}(t) + \frac{1}{2}\int_0^t \Gamma_x(x-b(s), t-s)dq(s) \\
&= -\dot{p}(t) + \frac{1}{2}\int_0^t \Gamma_x(x-b(s), t-s)dq(s).
\end{aligned}$$

Thus $\mathcal{L}w = \dot{p}\mathbf{1}_{\{x<b(t)\}} \le 0$ in $\mathbb{R}\times(0,T]$ holds.

It remains to show that $w(x,t) = p(t)$ for $x \le b(t)$ and $w < p(t)$ for $x > b(t)$.

(1) Assume the condition of the first assertion. We define

$$v(x,t) := w(x,t) - p(t) = -\int_{-\infty}^{x} \Gamma(z,t)\,dz + \int_0^t dq(s)\int_{-\infty}^{x-b(s)} \Gamma(z, t-s)\,dz.$$

Upon differentiation, $\mathcal{L}v = 0$ in $\{x < b(t)\}$. Note that v is bounded, continuous, and, by (5.6), $v(b(t),t) = 0$. It follows that $v(x,t) \equiv 0$ for all $x \le b(t)$, i.e., $w = p(t)$ for any $x \le b(t)$. Also by differentiation, we see that $\mathcal{L}v = -\dot{p} \le 0$ in $\{x > b(t)\}$. The strong maximum principle gives $v < 0$ in $\{x > b(t)\}$. That is, $w < p(t)$ in $\{x > b(t)\}$. Thus w is a variational solution.

(2) Assume the condition of the second assertion. We see that $u := -w_x$ given by (5.2) is continuous in $\mathbb{R}\times(0,\infty)$. For every small $\varepsilon > 0$, the function u satisfies $\mathcal{L}u = 0$ in

$$\Omega_\varepsilon := \{(x,t) \mid x < b(t), t \in (\varepsilon, T]\}.$$

Also, from (5.7), $u(b(t),t) = 0$ for all $t \in (0,T]$. Since $b(t) < 0$ for small positive t, we can assume that $b(\varepsilon) < 0$. It then follows from (5.2) that for all $x \le b(\varepsilon)$,

$$|u(x,\varepsilon)| \le \max\{\Gamma(x,\varepsilon), q_{1/2}(\varepsilon)\} \le \max\{\Gamma(b(\varepsilon),\varepsilon), q_{1/2}(\varepsilon)\} \le q_{1/2}(\varepsilon),$$

since for any $t \in (0,T]$

$$\int_0^t \Gamma(b(t)-b(s), t-s)dq(s) \le \int_0^t \frac{\dot{q}(s)}{\sqrt{2\pi(t-s)}}\,ds = q_{1/2}(t),$$

which holds for ε as well. It then follows from the maximum principle that

$$\max_{\Omega_\varepsilon} |u| \le q_{1/2}(\varepsilon).$$

Sending ε to 0 from above, we obtain $w_x = u \equiv 0$ in $\{(x,t) \mid x \le b(t), t > 0\}$. w is constant in $\{x \le b(t)\}$, and $w(-\infty,t) = p(t)$ imply that $w \equiv p(t)$ in $\{x \le b(t)\}$. From the first assertion, the second assertion of the theorem thus holds.

(3) Assume the conditions in the third assertion. Let $u := -w_x$ be given by (5.2) and $u_x := -w_{xx}$ by (5.3) when $x \neq b(t)$. Since b, $\dot{q}$, and $q^b_{3/2}$ are continuous, and (5.5) holds for $f = \dot{q}$, sending x to $b(t)$ from below in the equation for u_x and using (5.8) we derive that $u_x(b(t)^-, t) = 0$.

Next, we show that $u_x \equiv 0$ in $\{x < b(t)\}$. To do this, we first show that u_x given in (5.3) is uniformly bounded in $\{x < b(t)\}$. First, the boundedness of $q^b_{3/2}$ and (5.8) imply that $\Gamma_x(b(t), t)$ is uniformly bounded in $(0, T]$. Next, as $b(t) < -\sqrt{3t}$ for small positive t, we see that $0 < \Gamma_x(x, t) < \Gamma(b(t), t)$ for all $x < b(t)$. Thus $\Gamma_x(x, t)$ is bounded for all $x < b(t)$.

For $x < b(t)$, let $A_1 = \{s \in (0, t] \mid b(t) - x > 2|b(t) - b(s)|\}$ and $A_2 = [0, t] \setminus A_1$. Then

$$\int_0^t \Gamma_x(x - b(t), t - s)dq(s) = I_1 + I_2, \qquad I_i = \int_{A_i} \Gamma_x(x - b(t), t - s)dq(s).$$

Note that

$$|I_2| \leq \int_0^t \frac{|b(t) - b(s)|\dot{q}(s)}{2\sqrt{\pi}|t - s|^{3/2}} ds \leq 2q^b_{3/2}(t)$$

is uniformly bounded. To estimate I_i, notice that when $x - b(t) > 2|b(t) - b(s)|$, $(x - b(s))^2 = (x - b(t) - (b(t) - b(s)))^2 \geq \frac{1}{4}(x - b(t))^2$. Thus,

$$|I_1| \leq \int_0^t \frac{|x - b(t)|\dot{q}(s)e^{-|x-b(t)|^2/[16(t-s)]}ds}{\sqrt{2\pi}(t - s)^{3/2}} \leq \|\dot{q}\|_\infty,$$

and therefore u_x is uniformly bounded in $\{x < b(t)\}$.

Since $\mathcal{L}u_x = 0$ in $\{x < b(t), t > 0\}$, $u_x((b(t) - 0), t) = 0$, and $u_x(x, 0) = 0$ for all $x < 0$, a special maximum principle then implies that $u_x \equiv 0$ in $\{x < b(t)\}$. Using $u(-\infty, t) = 0$ we then conclude that $u \equiv 0$. Following (2), the third assertion of the theorem follows. □

VORTEX LATTICES IN ROTATING BOSE–EINSTEIN CONDENSATES*

AMANDINE AFTALION† AND XAVIER BLANC†

Abstract. The structure of the vortex lattice for a fast rotating condensate in a harmonic trap has been studied experimentally and numerically: it is an almost regular hexagonal lattice, with a distortion on the edges. In this paper, we provide rigorous proofs of results announced in [A. Aftalion, X. Blanc, and J. Dalibard, *Phys. Rev. A*, 71 (2005), p. 023611]. We analyze the vortex pattern in the framework of the Gross–Pitaevskii energy using wave functions in the lowest Landau level. We compute the energy of a regular triangular lattice and of a class of distorted lattices and find the optimal distortion which provides a decay of the wave function similar to an inverted parabola.

Key words. Bose–Einstein condensates, lattice, lowest Landau level, averaging process, Gross–Pitaevskii, vortices

1. Introduction.

One of the special features of Bose–Einstein condensates (BEC), related to superfluidity, is the existence of quantized vortices. These vortices can be observed in different types of experiments, one of them being the equivalent of what is known for helium as the rotating bucket experiment [17]. When a normal fluid is rotated, the velocity field inside the fluid is governed by solid body rotation. In contradistinction, a quantum fluid such as a BEC, described by a macroscopic wave function, nucleates vortices. This has been observed experimentally recently, in particular in the ENS group [13, 27] but also in [1, 28]. When the rotational velocity is small, there are only a few vortices in the system [12]. Their three dimensional shape is of interest, as has been described in [6, 7] using tools developed by [10] for Ginzburg–Landau vortices. At high velocity, the size of the condensate and the number of vortices increase: vortices arrange themselves in a lattice [1, 14, 18, 31, 33], referred to as an Abrikosov lattice due to the analogy with superconductors. Such a system can be related to homogeneous media since there are two scales emerging: the size of vortices (of order 1) and the size of the condensate (much larger). In this regime, vortices have approximately the same size as their mutual distance, which is very different from the lower rotation regime. Hence different mathematical tools need to be introduced relying on averaging effects (see [8]).

The description of the vortex lattice has been the focus of very recent papers in the condensed matter physics community, starting with the seminal paper of Ho [21] and very recently of Fischer and Baym [20], Baym and Pethick [9], Cooper, Komineas, and Read [15], Watanabe, Baym, and Pethick [37], and Sheehy and Radzihovsky [34]. Our aim is to provide mathematical insight to the lattice pattern. In particular, we show why a regular lattice has a higher energy than a distorted one and describe

the appropriate distortion and how the distortion towards the edges modifies the decay of the wave function. This is performed using the minimization of the Gross–Pitaevskii energy. This framework, known as the mean field Quantum Hall regime, is acceptable only if the number of vortices is much smaller than the number of atoms in the condensate, which is the case of the present experiments. Otherwise, one has to consider other models, as in [16, 35]. The reduction of the quantum many-body Hamiltonian to the Gross Pitaevskii energy is an open question for this fast rotating regime. It has been derived in the case of no rotation by Lieb, Seiringer, and Yngvason [25], and in the case of fixed rotation by Lieb and Seiringer [24].

The energy that we want to minimize is the following:

$$\int_{\mathbb{R}^2} \left(\frac{1}{2}|\nabla\phi(x)|^2 + \frac{1}{2}|x|^2|\phi(x)|^2 - \Omega\,(L\phi)\,(x)\overline{\phi}(x) + \frac{1}{2}G|\phi(x)|^4 \right) dx \tag{1.1}$$

under $\int_{\mathbb{R}^2} |\phi|^2 = 1$, where $x = (x_1, x_2) \in \mathbb{R}^2$, $L = i(x_2\partial_{x_1} - x_1\partial_{x_2})$ is the angular momentum, Ω is the rotational velocity. The contributions to the energy are the kinetic term $(1/2)|\nabla\phi|^2$, the term due to the potential trapping the atoms $(1/2)|x|^2|\phi|^2$ and the rotating term $-\Omega L$. The last term is due to atomic interactions, G being a positive constant equal to Na, where N is the number of atoms in the condensate and a the scattering length. In fact, we should have taken a three-dimensional version of this energy, but as we are interested in a rotational velocity Ω close to 1, the minima of the 2D and 3D energies are asymptotically the same (see [3]). Indeed, the effective perpendicular trapping frequency becomes $\sqrt{1-\Omega^2}$, and is thus much smaller than the trapping frequency in the x_3 direction, which is fixed: the condensate is strongly confined along the x_3 axis and it is expected that, as Ω tends to 1, the 3D wave function is well approximated by the product of a Gaussian in the x_3 direction times a 2D wave function minimizing (1.1). The kinetic and rotational terms in the energy (1.1) are the beginning of the expansion of a complete square. Adding and subtracting the missing term modifies the trapping potential, creating what is called the effective trapping potential, and the energy (1.1) can be rewritten as follows:

$$E(\phi) = \int_{\mathbb{R}^2} \frac{1}{2}|\nabla\phi - i\Omega x^{\perp}\phi|^2 + \frac{1}{2}(1-\Omega^2)|x|^2|\phi|^2 + \frac{1}{2}G|\phi|^4, \tag{1.2}$$

where $x^{\perp} = (-x_2, x_1)$. In order for the energy to be bounded below, we need to have $\Omega < 1$, which means that the trapping potential remains stronger than the rotating force. As $\Omega < 1$ approaches one, the extension of the condensate increases. The first term in the energy is identical to the energy of a particle placed in a uniform magnetic field 2Ω. It is also reminiscent of type II superconductors near the second critical field H_{c2}. The minimizers for

$$\int_{\mathbb{R}^2} \frac{1}{2}|\nabla\phi - i\Omega x^{\perp}\phi|^2 \text{ under } \int_{\mathbb{R}^2} |\phi|^2 = 1 \tag{1.3}$$

are well known [23, 26] through the study of the eigenvalues of the operator $-(\nabla - i\Omega x^{\perp})^2$. The minimum is Ω and it is achieved in a space of infinite dimension called the lowest Landau level (LLL). This space is spanned by

$$\phi(x_1, x_2) = P(z)e^{-\Omega|z|^2/2} \text{ with } z = x_1 + ix_2, \tag{1.4}$$

where P varies in the space of polynomials. The other eigenvalues are $(2k+1)\Omega$, $k \in \mathbb{N}$.

We will see that as Ω approaches 1, the second and third term in the energy (1.2) produce a contribution of order $\sqrt{1-\Omega}$, which is much smaller than the gap between two eigenvalues of $-(\nabla - i\Omega x^\perp)^2$, namely 2Ω. Thus, it is natural, as a first step, to restrict to the minimizers of (1.3) and minimize the energy (1.2) in this reduced infinite dimensional space. Since we want to keep the same space as Ω varies, we will use the rescaled wave function

$$\psi(x) = \frac{1}{\sqrt{\Omega}}\phi\left(\frac{x}{\sqrt{\Omega}}\right), \tag{1.5}$$

which satisfies the condition $\int |\psi|^2 = 1$. Therefore, the energy (1.2) provides $E(\phi) = \tilde{E}(\psi)$ with

$$\tilde{E}(\psi) = \int_{\mathbb{R}^2} \frac{\Omega}{2}|\nabla\psi - ix^\perp\psi|^2 + \frac{1-\Omega^2}{2\Omega}|x|^2|\psi|^2 + \frac{1}{2}G\Omega|\psi|^4, \tag{1.6}$$

and the condition (1.4) becomes

$$\psi(x) = P(z)e^{-|z|^2/2} \text{ with } P(z) = A\prod_{i=1}^{n}(z-z_i) \text{ and } z = x_1 + ix_2. \tag{1.7}$$

For such a ψ, the first term of the energy is equal to Ω. Hence, we find that the energy $\tilde{E}(\psi)$ is equal to

$$E_{LLL}(\psi) := \Omega + \int_{\mathbb{R}^2} \frac{1-\Omega^2}{2\Omega}|x|^2|\psi|^2 + \frac{G\Omega}{2}|\psi|^4. \tag{1.8}$$

The issue is to minimize the energy (1.8) on the space (1.7), and in particular understand the optimal location of the zeros or vortices z_i and the averaged behavior of ψ on large spheres.

The ansatz (1.7) is motivated by very recent physics papers: in a seminal paper, Ho [21] computed the energy (1.6) of a configuration of the type (1.7), where the z_i are located on a triangular lattice and found that the wave function averaged over vortex cells has a Gaussian decay. This was confirmed by [9]. Only recently did Cooper, Komineas, and Read [15] observe numerically the distortion of the lattice on the edges of the condensate and the decay of the wave function, which is closer to an inverted parabola than a Gaussian. The inverted parabola profile can be explained in two ways: either by taking contributions to the wave function in excited Landau levels or by distorting the lattice in the LLL—that is, moving the z_i in (1.7) away from a regular lattice. Watanabe, Baym, and Pethick [37] claimed (without rigorously proving it) that the minimizer is achieved by a distorted lattice inside the LLL. In this paper, we want to understand rigorously the distortion of the lattice and are going to provide a rigorous proof of the results announced in [2]: in [2], we have performed numerical computations, fixing an upper bound on the number of zeros and using a conjugate gradient on the z_i to find a minimizer of the energy. This provides the pattern for vortices illustrated in Figure 1. On the left, we have plotted the z_i and on the right $|\psi|$, where ψ is related to the z_i through (1.7): in a central region, vortices

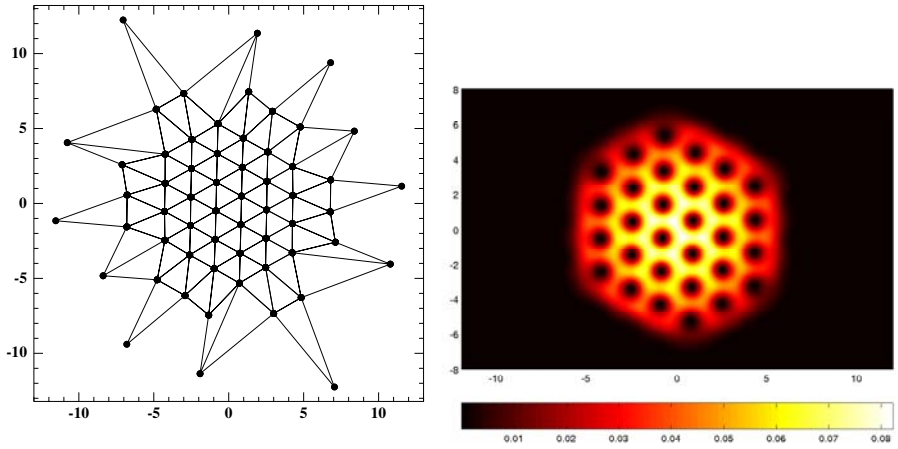

FIG. 1. *An example of (left) a configuration of z_i minimizing the energy for $\Omega = 0.999$, $G = 3$, and $n = 58$; (right) density plot of $|\psi|$.*

are located on a regular triangular lattice, while the lattice is distorted towards the edges. The density plot of $|\psi|$ shows that the only visible vortices are the central ones in the regular lattice part, the outer ones being in a region of very low density.

If we minimize the energy (1.8) without any ansatz, we find that the minimizer is

$$|\psi_{\min}(r)|^2 = \frac{2}{\pi R_0^2}\left(1 - \frac{r^2}{R_0^2}\right)_+, \quad R_0 = \left(\frac{4G\Omega^2}{\pi(1-\Omega^2)}\right)^{1/4}. \tag{1.9}$$

This is a first indication of the main scale of the problem: the extension of the condensate is of size R_0, which is large when Ω approaches 1. The value of the energy yields a lower bound for E_{LLL}:

$$\epsilon_{\min} := E_{LLL}(\psi_{\min}) - \Omega \underset{\Omega\to 1}{\sim} \frac{2\sqrt{2}}{3}\sqrt{\frac{G(1-\Omega)}{\pi}}\,. \tag{1.10}$$

Since $\psi_{\min}$ has compact support, it is not in the closure of the space spanned by (1.7). Thus, computing the energy of $\psi_{\min}$ requires going back to (1.6). This yields a contribution due to the kinetic energy of order R^2 and hence much larger than (1.10). Nevertheless, with an appropriate location of the zeros z_i, the aim is to build a test function whose energy can be of the same order as (1.10) and whose decay weakly approaches that of (1.9) as Ω tends to 1. Our main results, announced in [2], are the following: if the vortices are located on a regular lattice, the wave function decays like a Gaussian and we provide a rigorous proof of the energy estimate obtained by Ho [21]. On the other hand, we are able to build distortions of the lattice which improve the energy and hence modify the decay of the wave function. This decay is similar to that of an inverted parabola, as already observed by [15, 33, 37].

In what follows, ℓ will denote a regular hexagonal lattice, whose unit cell Q, centered at the origin has volume V. Moreover, we will identify complex numbers and vectors in $\mathbb{R}^2$ and in particular dz will denote the two dimensional Lebesgue measure $dx = dx_1\, dx_2$ when $z = x_1 + ix_2$ and $x = (x_1, x_2)$. The symbol $\fint$ is the average of an ℓ-periodic function: $\fint f = \frac{1}{V}\int_Q f$.

THEOREM 1.1. *Let ℓ be a regular hexagonal lattice and Q its unit cell. Let*

$$\psi_R(z) = A_R \prod_{j\in\ell\cap B_R} (z-j)e^{-|z|^2/2} \tag{1.11}$$

with A_R chosen such that $\|\psi_R\|_{L^2(\mathbb{R}^2)} = 1$. If $V = |Q| > \pi$, we define

$$\frac{1}{\sigma^2} = 1 - \frac{\pi}{V}, \tag{1.12}$$

then we have, as R tends to ∞,

$$|\psi_R(z)| \longrightarrow \psi(z) = \frac{1}{\sqrt{\pi}\sigma}\eta(z)e^{-|z|^2/(2\sigma^2)} \text{ in } L^p\left(\mathbb{R}^2, (1+|z|^2)dz\right) \forall p \geq 1, \tag{1.13}$$

where η is an ℓ-periodic function which vanishes at each point of ℓ. Moreover, η is the unique (up to multiplication by a constant) solution of

$$-\Delta(\ln\eta) = 2\pi\delta_0 - \frac{2\pi}{V} \quad \text{in } Q,$$

with periodic boundary conditions. In addition, $\lim_{R\to+\infty} E_{LLL}(\psi_R) = E_{LLL}(\psi)$. As σ tends to infinity,

$$E_{LLL}(\psi) - \Omega \sim \frac{1-\Omega^2}{2\Omega}\sigma^2 + \frac{1}{4}\frac{G\Omega b}{\pi\sigma^2} \quad \text{where } b = \frac{\fint |\eta|^4}{(\fint |\eta|^2)^2}, \tag{1.14}$$

uniformly with respect to Ω.

The main feature of the periodic lattice is to modify the decay of the Gaussian from $e^{-|z|^2/2}$ to $e^{-|z|^2/2\sigma^2}$, where σ depends on the volume through (1.12). The choice of the normalization by the L^2 norm implies convergence of ψ_R only if $V > \pi$.

We need to choose the optimal σ in (1.14), which yields

$$\sigma^4 = \frac{1}{2}\frac{Gb\Omega^2}{\pi(1-\Omega^2)}. \tag{1.15}$$

This value of σ indeed satisfies $\sigma \to +\infty$ as Ω tends to 1. The volume condition (1.12) matched with the value of σ (1.15) implies

$$V = \pi\left(1 + \sqrt{(1-\Omega)\frac{4\pi}{Gb}}\right) + O(1-\Omega). \tag{1.16}$$

This is close to the value predicted by solid body rotation arguments, π/Ω (see [21]), but different. The estimate of the energy is thus

$$E_{LLL}(\psi) - \Omega \underset{\Omega\to 1}{\sim} \sqrt{\frac{Gb}{\pi}(1-\Omega)}. \tag{1.17}$$

This is to be compared to (1.10), which is better by a factor $\sqrt{8/9b}$, but is of the same magnitude, as $1-\Omega$ is small. Let us emphasize the presence of the coefficient b: it takes into account the averaged vortex contribution in each cell. As in the case of superconductors near H_{c_2}, for the Abrikosov lattice, the optimal lattice minimizing the ratio b is the hexagonal one [22]. An approximate value of b is 1.16. Note that our proof holds with other lattices than the hexagonal one.

The aim of the paper is to improve the numerical factor in front of the square root in (1.17). The main observation is that modifying the location of the vortices from a regular lattice can change the decay of the wave function and hence improve the energy estimate.

THEOREM 1.2. *There exists a sequence of functions ψ_Ω of the form* (1.7), *such that as Ω tends to* 1,

$$E_{LLL}(\psi_\Omega) - \Omega \sim \frac{2\sqrt{2}}{3}\sqrt{\frac{Gb}{\pi}(1-\Omega)}. \tag{1.18}$$

This is closer to the lower bound (1.10) than the regular lattice: the numerical factor is the same as in (1.10), except for the coefficient b, coming from the averaged vortex contribution.

Let us now explain the main ideas of the proof, announced in [2]. For the regular lattice, we split $\ln|\psi_R(z)|$ into $v_R(z) + w_R(z)$ with

$$v_R(z) = \sum_{j\in\ell\cap B_R}\left(\ln|z-j| - \frac{1}{V}\int_Q \ln|z-y-j|\,dy\right), \tag{1.19}$$

$$w_R(z) = \ln A_R - \frac{|z|^2}{2} + \frac{1}{V}\sum_{j\in\ell\cap B_R}\int_Q \ln|z-y-j|\,dy. \tag{1.20}$$

At this stage, we have just added and subtracted the sum of the integrals. As R tends to ∞, we prove that v_R converges to a periodic series v and e^{w_R} to a Gaussian with modified decay $1/\sigma^2$. The computation of the energy uses the fact that for a periodic function η, $\eta(\sigma z)$ converges weakly to the average of η (see Lemma 2.5 and [8, 29]). This allows one to separate the integrals of the Gaussian and of v, which vary on two different scales; the v integral provides the term b.

Let us be more precise about Theorem 1.2. We define the radius R by

$$R = \left(\frac{2Gb}{\pi(1-\Omega)}\right)^{1/4}, \tag{1.21}$$

and we perform a general transformation of the lattice in the following way: for j in ℓ, a regular triangular lattice of unit cell with volume $V = \pi$, we define the transformed lattice ℓ'_R by

$$k \in \ell'_R \text{ if } k = \nu_R(|j|)\,j \text{ for } j \in \ell\cap B_R. \tag{1.22}$$

We assume that ν_R is close to 1 as Ω tends to 1, in the sense that

$$\nu_R^2(r) = 1 + \frac{f(r^2/R^2)}{R^2} + O\left(\frac{1}{R^4}\right), \tag{1.23}$$

where $f(t)$ is a continuous function, such that for some γ, $f(\gamma) = \infty$ and $\int_0^\gamma f(s)\,ds = \infty$. Actually, we will see in (1.28) that the one providing an energy minimizer is $f(s) = 1/(1-s)$.

We would like to apply the same proof as for the regular lattice, using v_R and w_R for this distorted lattice. Contrary to the proof for the regular lattice, we cannot study the two limits $R\to\infty$ in (1.13) and $\sigma\to\infty$ in (1.14) separately, since R is

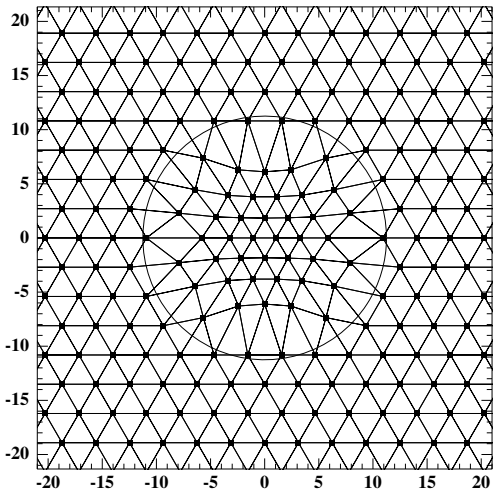

FIG. 2. *A plot of the distorted lattice defined by* (1.24).

now related to Ω through (1.21). Hence, the lattice has a finite extent at each R and we have to pass to the limit in the averaging process at the same time as the scale of the lattice. For technical reasons, we are unable to match w_R inside and outside the lattice and use the dominated convergence theorem.

In order to circumvent this problem, we introduce an outer regular lattice, whose characteristic size tends to infinity in a last step. Let $\alpha \in (0, \gamma)$, R be related to Ω by (1.21), and

$$\lambda_R(r) = \begin{cases} \nu_R(r) & \text{if} \quad r \leq \alpha R, \\ \nu_{\alpha,R} = \nu_R(\alpha R) & \text{if} \quad r > \alpha R, \end{cases} \tag{1.24}$$

and $\ell'_R = \{\lambda_R(|j|)j, \quad j \in \ell\}$. We have plotted such a transformation in Figure 2. For fixed α, we let R tend to ∞, and study the limit of the wave functions vanishing at each point of ℓ'_R:

$$\psi_R(z) = A_R \prod_{j \in \ell} (z - \lambda_R(|j|)j)\, e^{-|z|^2/2}. \tag{1.25}$$

Since α is fixed, $\nu_R(\alpha R)$ tends to 1. We use similar ideas as in the regular lattice case and identify two parts in the limit of $|\psi_R(Rz)|^2$ as R tends to ∞: a periodic part, which is rapidly oscillating and averaged in the limit, multiplied by a profile depending on the transformation f, which is equal to

$$|\psi(z)|^2 = e^{-F(|z|^2)} \mathbf{1}_{B_\alpha}(z) + e^{\alpha^2 f(\alpha^2) - F(\alpha^2) - f(\alpha^2)|z|^2} \mathbf{1}_{B_\alpha^c}(z), \tag{1.26}$$

where $F : \mathbb{R}^+ \to \mathbb{R}$ satisfies $F' = f$. The proof uses as a main tool that λ_R is close to one. As a final step only, once we have passed to the limit $\Omega \to 1$, we let α tend to γ, so that the exterior regular lattice has a unit volume cell which tends to infinity and the outer contribution disappears. We find an estimate for the energy:

$$E_{LLL}(\psi_\Omega) - \Omega \underset{\Omega \to 1}{\sim} \sqrt{\frac{2Gb(1-\Omega)}{\pi}} \int_0^\gamma \left(s e^{-F(s)} + \frac{1}{4} e^{-2F(s)} \right) ds, \tag{1.27}$$

where F is such that $F' = f$ and $\int_0^\gamma e^{-F(s)}\, ds = 1$.

We want to find which type of distortion f provides the optimal energy. The minimizer of (1.27) under $\int_0^\gamma e^{-F(s)}\,ds = 1$ is reached when

$$\gamma = 1 \text{ and } e^{-F(r^2)} = 2(1-r^2)_+. \tag{1.28}$$

Thus, the decay of the wave function is asymptotically an inverted parabola. The corresponding value of f is $f(s) = 1/(1-s)$. The limiting value of the energy is (1.18).

Let us point out that the proof uses two lattices: an initial regular lattice and an image lattice obtained by (1.22) and (1.23). The meaning of $\gamma = 1$ in (1.28) is that the initial lattice is truncated in the ball B_R: the points outside B_R are sent to infinity. There are two regions in the initial lattice: the points sufficiently far away from the circle of radius R, for which ν_R is almost one, and the points close to the circle, at distance less than $\sqrt{R}$ for instance. For the first category of points, the image lattice is an almost regular lattice and the image points are inside the disk B_R. These are the visible points on the density profile. On the contrary, the points close to the circle are strongly modified by (1.23) and sent far away. This allows one to better understand the distorted shape of Figure 1. It turns out that R is both the radius of the "horizon" for the initial lattice, but also the radius of the limiting inverted parabola (1.28). The points which are not visible in the density profile, and are in the distorted region, have nevertheless a contribution in creating the inverted parabola profile, since they provide the decay of the wave function: if they are removed, the decay is that of a Gaussian.

For each Ω, this analysis gives an estimate of the number N_v of points in the distorted lattice: it is given by the number of points in a regular lattice of unit volume π, included in a ball of radius R given by (1.21), namely

$$N_v \sim \sqrt{\frac{2Gb}{\pi(1-\Omega)}}.$$

This is probably a good estimate of the number of significant points to produce an energy of order (1.18). Nevertheless, adding more points in the low density region may lower the energy at the next order term in $(1-\Omega)$. In [2], we have studied numerically the dependence of E_n, the minimum of the energy over polynomials of degree less than or equal to n, which corresponds to at most n vortices. With the parameters $\Omega = 0.999$ and $G = 3$, we find that E_n becomes almost constant for $n \geq 52$ (with a precision of order 10^{-10}) which is comparable to the present estimate $N_v = 47$. Nevertheless, in [4, 5], we have now proved, using Bargmann spaces, that the minimizer has an infinite number of zereos. It means that additional zeroes appear in the low density region and contribute to decrease higher order terms in the energy. Consequently, the present upper bound only provides information for vortices entering in the first order expansion of the energy.

One of our technical tools in the proof is to use an outer regular lattice whose spacing tends to infinity in a last step. If one wanted to get rid of this trick, one would need to count the number of points in the lattice closest to the limiting circle of radius R and estimate the convergence of v_R and w_R due to the fact that these limiting points do not lie on a circle but on the edges of hexagons. We are not able to prove that the finite extension of the lattice (which becomes infinite with an outer regular lattice) does not create a boundary contribution in the energy. These boundary effects seem to be more important than we expected and are related to known problems about counting the number of points of a lattice in an annulus (see [11] and the references therein).

Our results deal with an upper bound for the energy. A natural question would be to also get the lower bound and prove Γ convergence–type results. The present gap between the lower bound (1.10) and the upper bound (1.18) lies in the coefficient b. We believe that an optimal lower bound should match the upper bound and that the limiting inverted parabola should have a radius given by (1.21) instead of (1.9); that is, the optimal inverted parabola should have the coefficient b. Let us give a few more explanations.

A first question is to understand the lower bound for the energy restricted to the LLL and prove that it matches our upper bound (1.18). For the moment, we are unable to prove it, though we expect that reproducing an inverted parabola profile in the space (1.7) requires a lot of vortices and thus creates a contribution in the energy through b. Our numerical computations agree with this. But proving that a minimizing sequence has zeros which are located on an almost regular lattice seems very difficult and is probably related to similar difficulties in crystalization and sphere packing problems.

Another issue is to check that the lower bound of the energy restricted to the LLL should provide the lower bound for the full energy (1.6). More precisely, if ψ is a minimizer of (1.6), we can project it on the LLL and its orthogonal through $\psi = \psi_{LLL} + \psi_\perp$. The upper bound and the properties of the operator (1.3) imply that $\|\psi_{LLL}\|_{L^2}$ is close to 1 and $\|\psi_\perp\|_{L^2}$ is small like $\sqrt{1-\Omega}$. If we had for E_{LLL} a lower bound in the LLL matching the upper bound (1.18), this would imply $\|\psi_\perp\|_{L^2} = o\left(\sqrt{1-\Omega}\right)$. Using the Poincaré inequality of Lu and Pan [26], one can improve the norm and get an L^∞ estimate for $\psi_\perp$. This should allow one to prove that the leading order term in the energy of ψ is $E_{LLL}(\psi_{LLL})$.

The authors of [37] provide a formal argument to exclude contributions of excited Landau levels. Let us give a gist on how to justify it. Let us call ρ the rescaled limiting density distribution given by (1.26), which can either be a Gaussian if the lattice is regular or approach an inverted parabola if the lattice is distorted. We have seen that the energy of this test function is computed through

$$\sqrt{\frac{2Gb(1-\Omega)}{\pi}} \int \left(r^2\rho^2 + \rho^4\right) \text{ under } \int \rho^2 = 1. \tag{1.29}$$

This is done by using a wave function ψ_Ω such that $|\psi_\Omega|^p \to (⨍ |\eta|^p)\rho^p$. In [37], the following ansatz is introduced: the authors replace ψ_Ω by $h_\Omega\psi_\Omega$, where ψ_Ω is the above wave function and h_Ω is a modulation due to the contribution of higher Landau levels. It is in addition assumed that h_Ω varies on a much larger scale than the vortex lattice. This assumption of slow variation allows them to compute the limit of $h_\Omega\psi_\Omega$ using averaging effects and find as a limiting energy of (1.6), when Ω tends to 1,

$$\sqrt{\frac{2Gb(1-\Omega)}{\pi}} \int \frac{1}{2}\rho^2|\nabla h|^2 + r^2\rho^2h^2 + \rho^4h^4 \text{ under } \int \rho^2h^2 = 1. \tag{1.30}$$

Note that $h = 1$ reproduces the previous computations. Minimizing (1.30) and using a convexity argument, we find that $\int \left(h^2\rho^2 - p^2\right)^2$ tend to 0, where p is the rescaled inverted parabola. If ρ itself is close to the inverted parabola, this implies that h is close to 1, and thus the contribution from higher Landau levels is negligible.

Let us point out that other trapping potentials than $|x|^2$ can be dealt with these techniques. In [2], we have addressed the case of $|x|^2 + k|x|^4$ with k small, following recent experiments [13, 36]. For certain values of Ω, a giant vortex can be obtained.

This paper is organized as follows: In section 2, we study the regular lattice case and prove Theorem 1.1. Then, in section 3, we prove Theorem 1.2. Finally, section 4 is devoted to remarks concerning other trapping potentials.

2. Regular lattice. In this section, we prove Theorem 1.1. We first need two technical lemmas:

LEMMA 2.1. *Let ℓ be a lattice, and denote by Q its unit cell centered at 0. Let $Q_R = \bigcup_{k\in\ell\cap B_R}(Q+k)$ and for x in $\mathbb{R}^2$, let*

$$h_R(x) = \int_{Q_R} (\ln|x-x'| - \ln|x'|)\,dx'.$$

Then there exists $C>0$ and $R_0>0$ such that

$$\forall R \geq R_0, \quad h_R(x) \leq \left(\frac{\pi}{2} + \frac{C}{R}\right)|x|^2.$$

Proof. If Q_R was a ball, then the integral could be computed explicitly. Thus, we use a ball close to Q_R and estimate the difference. We separate the integral defining h_R into two parts:

$$h_R(x) = \int_{B_{R-a}} (\ln|x-x'| - \ln|x'|)\,dx' + \int_{Q_R\setminus B_{R-a}} (\ln|x-x'| - \ln|x'|)\,dx',$$

where $a>0$ is independent of R and such that $B_{R-a}\subset Q_R$. The first term is the radial solution of $\Delta u = \mathbf{1}_{B_{R-a}}$ such that $u(0)=0$. One easily computes this solution:

$$u(x) = \frac{\pi}{2}|x|^2\mathbf{1}_{B_{R-a}} + \pi(R-a)^2\left(\frac{1}{2} + \ln\left(\frac{|x|}{R-a}\right)\right)\mathbf{1}_{B^c_{R-a}}.$$

Next, we consider the second term defining h_R and use the inequality $\ln(t)\leq\frac{1}{2}(t^2-1)$, valid for any $t>0$:

$$\begin{aligned}\int_{Q_R\setminus B_{R-a}} (\ln|x-x'| - \ln|x'|)\,dx' &\leq \int_{Q_R\setminus B_{R-a}} \frac{1}{2}\left(\frac{|x-x'|^2}{|x'|^2} - 1\right)dx' \\ &= |x|^2\int_{Q_R\setminus B_{R-a}} \frac{dx'}{2|x'|^2} \leq C\frac{|x|^2}{R},\end{aligned}$$

the constant C being independent of R and x. Collecting both results, we infer

$$\begin{aligned}h_R(x) &\leq \frac{\pi}{2}|x|^2\mathbf{1}_{B_{R-a}}(x) + \pi(R-a)^2\left(\frac{1}{2} + \ln\left(\frac{|x|}{R-a}\right)\right)\mathbf{1}_{B^c_{R-a}}(x) + \frac{C}{R}|x|^2 \\ &\leq \left(\frac{\pi}{2} + \frac{C}{R}\right)|x|^2,\end{aligned}$$

here using again $\ln(t)\leq\frac{1}{2}(t^2-1)$. This gives the result. ∎

LEMMA 2.2. *Let ℓ be the hexagonal lattice, and let Q be its elementary unit cell (i.e., the regular hexagon centered at 0). Let*

$$g(x) = \ln|x| - \frac{1}{|Q|}\int_Q \ln|x-y|\;dy. \tag{2.1}$$

Then we have, for some constant $C > 0$,

$$\forall x \in B_1^c, \quad |g(x)| \leq \frac{C}{|x|^3}. \tag{2.2}$$

Hence, the function

$$v(x) = \sum_{j \in \ell} g(x-j) \tag{2.3}$$

is such that $e^{v(x)}$ exists, is continuous on $\mathbb{R}^2$, and ℓ-periodic.

Proof. We first point out that g is continuous on $\mathbb{R}^2 \setminus \{0\}$. Hence, we need only to show (2.2) on B_a^c for some $a > 0$. We fix $a > 0$ such that $Q \subset B_{\frac{a}{2}}$. For any $x \in B_a^c$ and any $y \in Q$, we have $\frac{|x-y|}{|x|} \geq \frac{|x|-\frac{a}{2}}{|x|} \geq \frac{1}{2}$. Hence,

$$\frac{|x-y|^2}{|x|^2} - 1 \geq -\frac{3}{4}.$$

For any $t > -\frac{3}{4}$, we have

$$t - \frac{t^2}{2} - |t|^3 \leq \ln(1+t) \leq t - \frac{t^2}{2} + \frac{t^3}{3}.$$

Hence, writing $g(x) = -\frac{1}{|Q|}\int_Q \frac{1}{2} \ln\left(1 - \frac{2y\cdot x}{|x|^2} + \frac{|y|^2}{|x|^2}\right) dy$, we infer

$$\frac{1}{2|Q|}\int_Q \left(-\frac{2y\cdot x}{|x|^2} + \frac{|y|^2}{|x|^2} - \frac{1}{2}\left(-\frac{2y\cdot x}{|x|^2} + \frac{|y|^2}{|x|^2}\right)^2 - \left|-\frac{2y\cdot x}{|x|^2} + \frac{|y|^2}{|x|^2}\right|^3\right) dy \leq -g(x)$$
$$\leq \frac{1}{2|Q|}\int_Q \left(-\frac{2y\cdot x}{|x|^2} + \frac{|y|^2}{|x|^2} - \frac{1}{2}\left(-\frac{2y\cdot x}{|x|^2} + \frac{|y|^2}{|x|^2}\right)^2 + \frac{1}{3}\left(-\frac{2y\cdot x}{|x|^2} + \frac{|y|^2}{|x|^2}\right)^3\right) dy.$$

Since Q is symmetric with respect to the origin, $\int_Q y\cdot x\, dy = 0$. In addition, Q is invariant under the rotation of angle $\pi/3$, so one easily shows that $\int_Q \left(|y|^2 - 2(y\cdot x)^2\right) dy = 0$. We thus have

$$\frac{1}{2|Q|}\int_Q \left(\frac{2y\cdot x|y|^2}{|x|^4} - \frac{|y|^4}{|x|^4} - \left|-\frac{2y\cdot x}{|x|^2} + \frac{|y|^2}{|x|^2}\right|^3\right) dy \leq g(x)$$
$$\leq \frac{1}{2|Q|}\int_Q \left(\frac{2y\cdot x|y|^2}{|x|^4} - \frac{|y|^4}{|x|^4} + \frac{1}{3}\left(-\frac{2y\cdot x}{|x|^2} + \frac{|y|^2}{|x|^2}\right)^3\right) dy.$$

Using $|y| \leq \frac{a}{2}$, we end up with

$$|g(x)| \leq \frac{1}{|Q|}\int_Q \left(\frac{|y|^3}{|x|^3} + \frac{|y|^4}{2|x|^4} + \frac{1}{2}\left|\frac{2|y|}{|x|} + \frac{|y|^2}{|x|^2}\right|^3\right) dy \leq \frac{\frac{a^3}{8} + \frac{a^3}{16} + 2a^3}{|x|^3}.$$

This ensures that the series (2.3) converges normally on any set of the form $(\bigcup_{j\in\ell} B_\varepsilon(j))^c$, which implies that v exists, is ℓ-periodic, and continuous on $\mathbb{R}^2 \setminus \ell$. Near a point $k \in \ell$, we write

$$e^{v(x)} = |x-k| e^{-\frac{1}{|Q|}\int_Q \ln|x-y|\ dy} e^{\sum_{j\in\ell\setminus\{k\}} g(x-j)}$$

and the conclusion follows. ∎

Remark 2.3. It is in this lemma that we have used the symmetry properties of the lattice. However, the same proof applies to a general lattice (which does not necessarily have the above symmetries). In this case, one needs to use instead of $g = \ln|\cdot| * (\delta_0 - \frac{1}{|Q|}\mathbf{1}_Q)$ the convolution of $\ln|\cdot|$ with a distribution g_0 such that $\sum_{k\in\ell} g_0(x-k) = \sum_{k\in\ell}\delta_k - \frac{1}{|Q|}$ and such that the first harmonic moments of g_0 cancel. This is always possible (in such a case g_0 is not supported inside Q).

Remark 2.4. The estimate (2.2) is valid for a fixed hexagonal lattice ℓ_0. Now, $g = g_\ell$ depends on ℓ in the following way: if $\ell = \lambda\ell_0$, then $g_\ell(x) = g_{\ell_0}\left(\frac{x}{\lambda}\right)$. Hence, $|g_\ell(x)| \le \frac{C_0\lambda^3}{|x|^3}$ if $|x| \ge \lambda$ for some constant C_0 independent of ℓ.

We finally state the following lemma, which may be seen as the simplest case of two-scale convergence [8, 29]. The proof is standard and may be found, for example, in [8].

LEMMA 2.5. *Let $v \in L^1_{\mathrm{loc}}\left(\mathbb{R}^2\right)$, which is periodic, and set $v_\sigma(x) = v(\sigma x)$ for any $\sigma > 0$. Then*

$$v_\sigma \xrightarrow[\sigma\to\infty]{*} \fint v \text{ in } L^\infty(\mathbb{R}^2).$$

Proof of Theorem 1.1. Let $f_R(z) = \ln|\psi_R(z)|$. We split f_R into

$$f_R(z) = v_R(z) + w_R(z) \tag{2.4}$$

with

$$v_R(z) = \sum_{j\in l\cap B_R} \ln|z-j| - \frac{1}{V}\int_Q \ln|z-y-j|\,dy, \tag{2.5}$$

$$w_R(z) = \ln A_R - \frac{|z|^2}{2} + \frac{1}{V}\sum_{j\in\ell\cap B_R}\int_Q \ln|z-y-j|\,dy. \tag{2.6}$$

Let v be given by (2.3). We have

$$v_R(z) - v(z) = \sum_{j\in\ell\cap B_R^c} g(z-j).$$

Hence, if $z \in B_R$, we deduce from Lemma 2.2 that

$$|v_R(z) - v(z)| \le \sum_{j\in\ell\cap B_R^c} \frac{C}{|z-j|^3}$$

for some constant C independent of R and z. One can thus find a constant C independent of R such that

$$\forall A \in (0,R), \quad \|v_R - v\|_{L^\infty(B_{R-A})} \le \frac{C}{A}. \tag{2.7}$$

In addition, we have, for any $z \in \mathbb{R}^2$, denoting by j_z the unique point of ℓ such that $|j_z - z| < 1$,

$$v_R(z) \le \ln|z-j_z| + C + \sum_{j\in\ell\setminus\{j_z\}} \frac{C}{|z-j|^3} \le \ln|z-j_z| + C,$$

for various constants C independent of z and R. Hence, e^{v_R} is bounded in $L^\infty(\mathbb{R}^2)$ independently of R. Next, using the inequality $|e^a - e^b| \leq \frac{1}{2}(e^a + e^b)|a-b|$ and (2.7), we infer that e^{v_R} converges to e^v in $L^\infty_{\rm loc}(\mathbb{R}^2)$.

Let us call $\tilde{w}_R(z) = w_R(z) - w_R(0) - \ln(A_R) + \frac{1}{2\sigma^2}|z|^2$. Applying Lemma 2.1, we have

$$\tilde{w}_R(z) \leq -\frac{|z|^2}{2} + \left(\frac{\pi}{2V} + \frac{C}{R}\right)|z|^2 + \frac{1}{2\sigma^2}|z|^2 = \frac{C}{R}|z|^2. \tag{2.8}$$

In addition, $\tilde{w}_R$ is a harmonic function in $Q_R = \bigcup_{j\in\ell\cap B_R}(Q+j)$ and vanishes at 0. Hence, using Harnack inequality, $\tilde{w}_R$ is bounded and we may extract convergence of $\tilde{w}_R$ in $L^\infty_{\rm loc}(\mathbb{R}^2)$ to some $\tilde{w}$, which is harmonic nonpositive, and vanishes at 0. Applying Liouville theorem, we find that $\tilde{w} = 0$. Gathering all the previous results, we thus have

$$\frac{|\psi_R(z)|}{A_R e^{w_R(0)}} \longrightarrow e^{v(z)}e^{-|z|^2/(2\sigma^2)} \text{ almost everywhere in } \mathbb{R}^2. \tag{2.9}$$

For R large enough, (2.8) also implies

$$\frac{|\psi_R(z)|}{A_R e^{w_R(0)}} \leq Ce^{-\frac{|z|^2}{4\sigma^2}}. \tag{2.10}$$

From (2.9) and (2.10), we apply the dominated convergence theorem and find that, as R tends to infinity,

$$\frac{|\psi_R|}{A_R e^{w_R(0)}} \longrightarrow e^{v(z)}e^{-|z|^2/(2\sigma^2)} \text{ in } L^p(\mathbb{R}^2) \quad \forall p \geq 1.$$

Using the fact that $\|\psi_R\|_{L^2} = 1$, we deduce that $1/(A_R e^{w_R(0)})$ converges to the appropriate constant, so that (1.13) holds.

Then we write the limiting energy, z being identified with a vector in $\mathbb{R}^2$:

$$\begin{aligned} E_{LLL}(\psi) &= \Omega + \int_{\mathbb{R}^2}\left(\frac{1-\Omega^2}{2\Omega}|z|^2|\eta(z)|^2e^{-|z|^2/\sigma^2} + \frac{G\Omega}{2\sigma^2}|\eta(z)|^4e^{-2|z|^2/\sigma^2}\right)\frac{dz}{\pi\sigma^2} \\ &= \Omega + \int_{\mathbb{R}^2}\left(\frac{1-\Omega^2}{2\Omega}\sigma^2|\eta(\sigma\xi)|^2|\xi|^2e^{-|\xi|^2} + \frac{G\Omega}{2\sigma^2}|\eta(\sigma\xi)|^4e^{-2|\xi|^2}\right)\frac{d\xi}{\pi}. \end{aligned}$$

We want to find the limit as σ tends to infinity. Since the function η is periodic, Lemma 2.5 implies that $|\eta(\sigma\xi)|^2$ and $|\eta(\sigma\xi)|^4$, respectively, converge L^∞-weak-$*$ to $⨍|\eta|^2$ and $⨍|\eta|^4$, and (1.14) holds. □

3. Distorted lattice. In this section, we prove two theorems, which will imply Theorem 1.2. Theorem 3.1 consists of studying a distorted lattice analogous to Figure 2 and find the limit of the wave function with an infinite number of vortices. The proof is similar to the regular lattice case, since only the central vortices are displaced from their regular location. Theorem 3.2 identifies the limit of the modulus of the wave function as Ω tends to 1: a periodic, rapidly oscillating part which converges in L^∞-weak-$*$ and a slowly varying profile. The proof is more involved since this is precisely where the distortion of the lattice appears.

THEOREM 3.1. *Let ℓ be a hexagonal lattice, and let Q be the regular hexagon of area π centered at zero. Let $\gamma > 0$ and let f be a positive Lipschitz continuous function defined in $[0,\gamma)$ such that*

$$\lim_{t\to\gamma} f(t) = +\infty \quad \textit{and} \quad \lim_{t\to\gamma}\int_0^t f(s)ds = \infty. \tag{3.1}$$

Let us define

$$\nu_R(t) = 1 + \frac{1}{2R^2} f\left(\frac{t^2}{R^2}\right) + O\left(\frac{1}{R^4}\right), \tag{3.2}$$

where $O\left(\frac{1}{R^4}\right)$ *is uniform with respect to* $t \in \mathbb{R}^+$. *Let* $\alpha \in (0, \gamma)$

$$\lambda_R(t) = \begin{cases} \nu_R(t) & \text{if} \quad t \le \alpha R, \\ \nu_{\alpha,R} = \nu_R(\alpha R) & \text{if} \quad t > \alpha R. \end{cases} \tag{3.3}$$

For $R' > R$, *we define*

$$\psi_{R,R'}(x) = A_{R,R'} \prod_{j \in \ell \cap B_{R'}} (x - \lambda_R(|j|)j)\, e^{-|x|^2/2}, \tag{3.4}$$

where $A_{R,R'}$ *is such that* $\|\psi_{R,R'}\|_{L^2(\mathbb{R}^2)} = 1$. *Then, we have the following convergence in* $L^p(\mathbb{R}^2, (1+|x|^2)dx)$ *for any* $p < +\infty$*:*

$$|\psi_{R,R'}| \underset{R' \to +\infty}{\longrightarrow} A_R e^{v_R\left(\frac{x}{\nu_{\alpha,R}}\right) + w_R(x) + \left(\frac{1}{{\nu_{\alpha,R}}^2} - 1\right)\frac{|x|^2}{2}}, \tag{3.5}$$

where

$$w_R(x) = \sum_{j \in \ell \cap B_{\alpha R}} \frac{1}{\nu_{\alpha,R}^2 |Q|} \int_{\nu_{\alpha,R} Q} \ln\left(\frac{|x - y - \nu_R(|j|)j|}{|x - y - \nu_{\alpha,R} j|}\right) dy, \tag{3.6}$$

and

$$v_R(y) = \sum_{j \in \ell} g\left(y - \frac{\lambda_R(|j|)}{\nu_{\alpha,R}} j\right), \tag{3.7}$$

the function g *being defined by* (2.1).

Then, we let Ω tend to 1, or equivalently R to infinity.

THEOREM 3.2. *With the same definitions as in Theorem* 3.1, *we have*

$$\forall n \ge 1, \quad e^{n v_R(Rx)} \underset{R \to +\infty}{\overset{*}{\longrightarrow}} \fint e^{nv} \quad \text{in} \quad L^\infty(\mathbb{R}^2), \tag{3.8}$$

$$e^{2w_R(Rx) + \left(\frac{1}{\lambda_R(\alpha R)^2} - 1\right) R^2 |x|^2} \underset{R \to +\infty}{\longrightarrow} \rho(x) \tag{3.9}$$

in $L^p(\mathbb{R}^2, (1+|x|^2)dx)$ $\forall p \ge 1$, *where* v *is given by* (2.3),

$$\rho(x) = e^{-F(|x|^2)} \mathbf{1}_{B_\alpha}(x) + e^{\alpha^2 f(\alpha^2) - F(\alpha^2) - f(\alpha^2)|x|^2} \mathbf{1}_{B_\alpha^c}(x), \tag{3.10}$$

and F *is such that* $F' = f$ *and* $\fint e^{2v} \int \rho = 1$.

Proof of Theorem 1.2. We let Ω tend to 1, let R be given by (1.21), and take a diagonal sequence in R'. Theorems 3.1 and 3.2 provide the convergence of $\int |\psi_{R,R'}(Rz)|^2$ to $\fint e^{2v} \int \rho$, and similarly for the energy:

$$E_{LLL}(\psi_{R,R'}(Rz)) - \Omega \underset{\Omega \to 1}{\sim} \sqrt{\frac{2Gb(1-\Omega)}{\pi}} \left(\fint e^{2v} \int_0^\infty s\rho(\sqrt{s})\, ds + \frac{1}{4} \fint e^{4v} \int_0^\infty \rho^2(\sqrt{s})\, ds \right), \tag{3.11}$$

where ρ is defined by (3.10), F is such that $F' = f$ and $\int_0^\gamma e^{-F(s)}\, ds = 1$ and $\fint e^{2v} = 1$. If one lets α tend to γ: the contribution to ρ in the outer part B_γ^c vanishes and the energy is given by (1.27).

We want to find which type of distortion f provides the optimal energy. The minimizer of (1.27) under $\int_0^\gamma e^{-F(s)}\, ds = 1$ is reached when

$$\gamma = 1 \text{ and } e^{-F(r^2)} = 2(1 - r^2). \tag{3.12}$$

Thus, the decay of the wave function is asymptotically an inverted parabola. The corresponding value of f is $f(s) = 1/(1-s)$. The limiting value of the energy is (1.18).

Proof of Theorem 3.1. This proof is a mere adaptation of section 2. Indeed, up to normalization by a constant, the function $\ln|\psi_{R,R'}|^2$ is equal to

$$\ln|\psi_{R,R'}(x)|^2 = 2\sum_{j\in\ell\cap B_{R'}} \Bigg(\ln|x - \lambda_R(|j|)j| \tag{3.13}$$

$$-\frac{1}{{\nu_{\alpha,R}}^2|Q|}\int_{\nu_{\alpha,R}Q} \ln|x - y - \lambda_R(|j|)j|dy\Bigg) \tag{3.14}$$

$$+\sum_{j\in\ell\cap B_{R'}} \frac{2}{{\nu_{\alpha,R}}^2|Q|}\int_{\nu_{\alpha,R}Q} \ln|x - y - \lambda_R(|j|)j|dy \tag{3.15}$$

$$-|x|^2. \tag{3.16}$$

The sum (3.13)–(3.14) may be written

$$\sum_{j\in\ell\cap B_{R'}} g\left(\frac{x}{\nu_{\alpha,R}} - \frac{\lambda_R(|j|)}{\nu_{\alpha,R}}j\right), \tag{3.17}$$

where g is defined by (2.1). Now, R being fixed, Lemma 2.2 ensures that the above sum converges as R' goes to infinity to $v_R(\frac{x}{\nu(\alpha R)})$, where v_R is defined by (3.7). Moreover, the convergence of the exponential of (3.17) to $e^{v_R\left(\frac{x}{\nu(\alpha R)}\right)}$ is the same as in Theorem 1.1, that is, $L^\infty_{\mathrm{loc}}(\mathbb{R}^2)$. Next, the sum (3.15) is equal to

$$\begin{aligned}
&\sum_{j\in\ell\cap B_{R'}} \frac{2}{{\nu_{\alpha,R}}^2|Q|}\int_{\nu_{\alpha,R}Q} \ln|x - y - \lambda_R(|j|)j|dy \\
&= \sum_{j\in\ell\cap B_{\alpha R}} \frac{2}{{\nu_{\alpha,R}}^2|Q|}\int_{\nu_{\alpha,R}Q} \ln\frac{|x - y - \nu_R(|j|)j|}{|x - y - \nu_{\alpha,R}\, j|}dy \\
&+ \sum_{j\in\ell\cap B_{R'}} \frac{2}{{\nu_{\alpha,R}}^2|Q|}\int_{\nu_{\alpha,R}Q} \ln|x - y - \nu_{\alpha,R}\, j|dy.
\end{aligned} \tag{3.18}$$

The first sum in the left-hand side of (3.18) is $w_R(x)$, while the second sum is the one appearing in (2.6), with $\nu(\alpha R)\ell$ replacing ℓ. Since this lattice is also a hexagonal one (with a different volume for its unit cell), the proof of its convergence applies, using Lemma 2.1. ∎

Proof of Theorem 3.2. For simplicity, we will give the proof in the case where the $O(1/R^4)$ is zero. We start with the proof of (3.9). We define $\varepsilon > 0$ depending on R such that, as R tends to infinity,

$$\begin{cases} R\varepsilon \longrightarrow +\infty, \\ R\varepsilon^2 \longrightarrow 0. \end{cases} \tag{3.19}$$

For instance, $\varepsilon = R^{-3/4}$ is a suitable choice. Writing

$$w_R(Rx) = \sum_{k \in \frac{\ell}{R} \cap B_\alpha} \frac{R^2}{{\nu_{\alpha,R}}^2 |Q|} \int_{\frac{\nu_{\alpha,R}}{R} Q} \ln \left(\frac{|x - z - \nu_R(R|k|)k|}{|x - z - \nu_{\alpha,R} k|} \right) dz,$$

we split this sum into terms for which $|k - x| < \varepsilon$, and terms for which $|x - k| \geq \varepsilon$: in the first case, we use the inequality

$$\forall a, b > 0, \quad |\ln a - \ln b| \leq \frac{1}{2} \left(\frac{1}{a} + \frac{1}{b} \right) |b - a|,$$

and the fact that $|\nu_{\alpha,R} - \nu_R(|k|R)| \leq \frac{C}{R^2}$ for some constant C independent of R and x. Hence,

$$\begin{aligned}
&\left| \sum_{|k-x|<\varepsilon} \frac{R^2}{\nu_{\alpha,R}|Q|} \int_{\frac{\nu_{\alpha,R}}{R} Q} \ln \left(\frac{|x - z - \nu_R(R|k|)k|}{|x - z - \nu_{\alpha,R} k|} \right) dz \right| \\
&\leq \sum_{|k-x|<\varepsilon} \frac{R^2}{2\nu_{\alpha,R}|Q|} \int_{\frac{\nu_{\alpha,R}}{R} Q} \Bigg(\frac{1}{|x - z - \nu_R(R|k|)k|} \\
&+ \frac{1}{|x - z - \nu_{\alpha,R} k|} \Bigg) |k| |\nu_{\alpha,R} - \nu_R(|k|R)| dz \\
&\leq \frac{C}{R^2} \sum_{|k-x|<\varepsilon} \frac{R^2}{2\nu_{\alpha,R}|Q|} \int_{B_{\frac{3}{R}}} \frac{dy}{|y|} \leq C \# \left(\frac{\ell}{R} \cap B_\varepsilon(x) \right) \frac{1}{R} = CR\varepsilon^2,
\end{aligned}$$

which tends to zero as $R \to +\infty$. Next, we deal with $|k - x| \geq \varepsilon$, and denote the corresponding sum by $T_R(x)$:

$$T_R(x) = \sum_{|k-x|\geq\varepsilon} \frac{R^2}{{\nu_{\alpha,R}}^2 |Q|} \int_{\frac{\nu_{\alpha,R}}{R} Q} \ln \left(\frac{|x - z - \nu_R(R|k|)k|}{|x - z - \nu_{\alpha,R} k|} \right) dz.$$

Using the equality $\nu_R(R|k|) = 1 + \frac{f(|k|^2)}{2R^2}$, valid for any $|k| \leq \alpha$, we deduce

$$T_R(x) = \sum_{|k-x|\geq\varepsilon} \frac{R^2}{{\nu_{\alpha,R}}^2 |Q|} \int_{\frac{\nu_{\alpha,R}}{R} Q} \ln \left(\frac{|x - z - k - \frac{f(|k|^2)}{2R^2} k|}{|x - z - k - \frac{f(\alpha^2)}{2R^2} k|} \right) dz.$$

We have $|x - z - k| \geq |x - k| - |z| \geq \varepsilon - \frac{C}{R} = \varepsilon(1 - \frac{C}{\varepsilon R})$ for $z \in \frac{\nu_{\alpha,R}}{R} Q$, so that for R large enough, we get $|x - z - k| \geq \frac{\varepsilon}{2}$. Hence, developing the quotient in the logarithm, we get

$$T_R(x) = \sum_{|k-x|\geq\varepsilon} \frac{R^2}{2{\nu_{\alpha,R}}^2 |Q|} \int_{\frac{\nu_{\alpha,R}}{R} Q} \ln \left(\frac{1 - \frac{f(|k|^2)}{R^2 |x-z-k|^2} k \cdot (x - z - k) + O\left(\frac{1}{\varepsilon^2 R^4}\right)}{1 - \frac{f(\alpha^2)}{R^2 |x-z-k|^2} k \cdot (x - z - k) + O\left(\frac{1}{\varepsilon^2 R^4}\right)} \right) dz,$$

where the $O\left(\frac{1}{\varepsilon^2 R^4}\right)$ are uniform with respect to x and k. Developing the logarithm, we thus find

$$T_R(x) = \sum_{|k-x|\geq\varepsilon} \left(\frac{R^2}{{\nu_{\alpha,R}}^2 |Q|} \int_{\frac{\nu_{\alpha,R}}{R} Q} \frac{f(\alpha^2) - f(|k|^2)}{R^2} \frac{k \cdot (x - z - k)}{|x - z - k|^2} dz \right) + O\left(\frac{1}{\varepsilon^2 R^2} \right).$$

Using the fact that f is smooth in $[0,\alpha]$, and recalling that the sum is a sum over the set $\frac{\ell}{R}\cap B_\alpha\cap B_\varepsilon(x)^c$, we find that it converges to the corresponding integral, namely

$$\lim_{R\to+\infty} T_R(x)=\frac{1}{|Q|}\int_{B_\alpha}\left(f(\alpha^2)-f(|y|^2)\right)\frac{y\cdot(x-y)}{|x-y|^2}dy.$$

We then point out that $\frac{x-y}{|x-y|^2}=-\nabla_y \ln|x-y|$, so that, integrating by parts, we have

$$\lim_{R\to+\infty} w_R(Rx)=\frac{1}{|Q|}\int_{B_\alpha}\operatorname{div}\left(f(\alpha^2)-f(|y|^2)y\right)\ln|x-y|dy.$$

This limit is a radially symmetric function, which solves the partial differential equation $\Delta u=\frac{2\pi}{|Q|}\operatorname{div}\left(f(\alpha^2)-f(|y|^2)y\right)$ in B_α, $\Delta u=0$ elsewhere. For any F such that $F'=f$, the function $\frac12\left(f(\alpha^2)|y|^2-F(|y|^2)\right)\mathbf{1}_{B_\alpha}(y)+\frac12\left(\alpha^2 f(\alpha^2)-F(\alpha^2)\right)\mathbf{1}_{B_\alpha^c}(y)$ is such a solution, so we have (3.9) almost everywhere. In addition, the above proof allows one to bound $2w_R(Rx)+(\frac{1}{\nu_{\alpha,R}^2}-1)R^2|x|^2$ by $C-\frac{f(\alpha^2)}{4}|x|^2$ for some constant C independent of R and x, which allows one to apply the dominated convergence theorem.

We now prove (3.8). We fix $n=1$, the general proof following exactly the same pattern. It is sufficient to show that the following convergence holds for any measurable bounded set D:

$$\int_D e^{v_R(Rx)}\underset{R\to+\infty}{\longrightarrow}|D|\fint e^v. \tag{3.20}$$

Hence, we are going to prove that for any $a>0$,

$$\left|e^{v_R(x)}-e^{v(x)}\right|\le C\frac{1+\sqrt{|x|}}{R}\quad\text{for}\quad|x|\le aR. \tag{3.21}$$

Since, according to Lemma 2.5, $e^{v(Rx)}$ converges in L^∞ weak-$*$ to $\fint e^v$ (because e^v is continuous and periodic), (3.21) will give (3.20). Let j_x be the point of ℓ which is the closest to x. As R goes to infinity, $|(\lambda_R(|j_x|)-1)j_x|=O\left(\frac1R\right)$ uniformly with respect to x since $|x|\le aR$. Hence, for R large enough, $\lambda_R(|j_x|)j_x$ is the closest to x among all $\lambda_R(|j|)j$, $j\in\ell$. Hence, for $j\in\ell\setminus\{j_x\}$, we have, for some $\varepsilon>0$,

$$\forall y\in Q,\quad |x-j-y|\ge\varepsilon\quad\text{and}\quad|x-j-\lambda_R(|j|)(j+y)|\ge\varepsilon. \tag{3.22}$$

We then isolate j_x in the sum defining v_R and write

$$\left|e^{v_R(x)}-e^{v(x)}\right|\le\left|e^{g_R(x-\lambda_R(|j_x|)j_x)}-e^{g_R(x-j_x)}\right|e^{\sum_{j\neq j_x}g_R(x-\lambda_R(|j|)j)} \tag{3.23}$$

$$+e^{g_R(x-j_x)}\left|e^{\sum_{j\neq j_x}g_R(x-\lambda_R(|j|)j)}-e^{\sum_{j\neq j_x}g_R(x-j)}\right|, \tag{3.24}$$

where $g_R(z)=g(\frac{z}{\nu_{\alpha,R}})$. We first bound (3.23). For this purpose, we point out that, according to Lemma 2.2, one can find a constant C_ε such that

$$\forall z\in B_\varepsilon^c,\quad |g(z)|\le\frac{C_\varepsilon}{|z|^3}. \tag{3.25}$$

Hence, the sum appearing in (3.23) may be bounded as follows:

$$\sum_{j\neq j_x}|g_R(x-\lambda_R(|j|)j)|\le\sum_{j\neq j_x}\frac{C_\varepsilon{\nu_{\alpha,R}}^3}{|x-\lambda_R(|j|)j|^3},$$

which is bounded independently of R. Moreover, we have

$$\left|e^{g_R(x-\lambda_R(|j_x|)j_x)} - e^{g_R(x-j_x)}\right| \le C\,||x-\lambda_R(|j_x|)j_x| - |x-j_x||$$
$$+C\left|\int_Q \left(\ln\frac{|x-y-j_x|}{|x-y-\lambda_R(|j_x|)j_x|}\right)dy\right|;$$

thus

$$\left|e^{g_R(x-\lambda_R(|j_x|)j_x)} - e^{g_R(x-j_x)}\right| \le C\,|(1-\lambda_R(|j_x|)j_x|$$
$$+C\int_Q \left(\frac{1}{|x-y-j_x|}+\frac{1}{|x-y-\lambda_R(|j_x|)j_x|}\right)|1-\lambda_R(|j_x|)||j_x|dy.$$

This implies

$$\left|e^{g_R(x-\lambda_R(|j_x|)j_x)} - e^{g_R(x-j_x)}\right| \le C\frac{|x|}{R^2} + C\frac{|x|}{R^2}\int_{B_3}\frac{dy}{|y|} \le C\frac{|x|}{R^2}.$$

Hence, the left-hand side of (3.23) is bounded by $C\frac{|x|}{R^2}$. Next, we deal with (3.24). Since g is bounded from above, it is sufficient to show the following:

$$\left|\sum_{j\neq j_x} g_R(x-\lambda_R(|j|)j) - \sum_{j\neq j_x} g_R(x-j)\right| \le C\frac{1+\sqrt{|x|}}{R}. \tag{3.26}$$

In order to prove (3.26), we define $A>0$ depending on R and x, to be fixed later on, and distinguish in the above sum between terms for which $|j-j_x|\le A$ and those for which $|j-j_x|>A$. We have

$$\sum_{0<|j-j_x|\le A} |g_R(x-\lambda_R(|j|)j) - g_R(x-j)| \le \|\nabla g\|_{L^\infty(B_\varepsilon^c)} \sum_{0<|j-j_x|\le A} |j||\lambda_R(|j|)-1|$$
$$\le \frac{C}{R^2}\sum_{0<|j-j_x|\le A}|j| \le \frac{C}{R^2}A^2(|x|+A).$$

We have used here the fact that g is Lipschitz continuous in B_ε^c. Considering the case $|j-j_x|>A$, we have, using (3.25),

$$\sum_{A>|j-j_x|} |g_R(x-\lambda_R(|j|)j) - g_R(x-j)| \le \sum_{A>|j-j_x|}\frac{C}{|x-j|^3} \le \frac{C}{A}.$$

We thus may bound the left-hand side of (3.26) by $\frac{C}{A}+\frac{CA^2|x|}{R^2}+\frac{CA^3}{R^2}$. Choosing $A=\frac{\sqrt{R}}{1+|x|^{1/4}}$, we thus find (3.26), thereby concluding the proof of (3.21). ∎

4. Other trapping potentials. In the previous sections, we have studied a harmonic confinement, which is the case of most current experiments. As pointed out in [2], one could imagine a more general trapping potential, where in (1.2), $(1-\Omega^2)|x|^2/2$ is replaced by $(1-\Omega^2)|x|^2/2+W(x)$, and perform a similar analysis. Then, the limiting distribution replacing the inverted parabola should be

$$|\psi(x)|^2 = \left(\frac{\mu - \frac{1-\Omega^2}{2\Omega}|x|^2 - W\left(\frac{x}{\sqrt{\Omega}}\right)}{Gb\Omega}\right)_+, \tag{4.1}$$

where μ is such that $\int |\psi|^2 = 1$. There are two necessary conditions to apply our previous analysis: we need $E_{LLL}(\psi) - \Omega$ to be small and the extent of the condensate (where $|\psi|^2$ is nonzero) to be large. The first condition is required so that the lowest Landau level is indeed a good approximation. The second condition then allows one to write the wave function as the product of a rapidly oscillating function (which is averaged in the limit), multiplied by a slowly varying profile.

In recent experiments [13, 36], $W(x) = k|x|^4/4$. One can check that if $\Omega > \Omega_c = 1+\sqrt{\Delta}$, where $\Delta = (3k^2Gb/8\pi)^{2/3}$, then the limiting distribution (4.1) has its support in an annulus of inner and outer radii $R_\pm = 2(\Omega - 1 \pm \sqrt{\Delta})/k$. An interesting regime to study is when k is small and $\Omega - 1 = \alpha k^{2/3}$, with α such that $\Omega > \Omega_c$. Then the large scaling parameter replacing R is $k^{-1/6}$, which is the order of magnitude of $R_\pm$. The vortex lattice is located in the annulus (R_-, R_+) and is distorted towards the inner and outer edges, the inner disk corresponding to a giant vortex.

This approach does not allow one to study the case where Ω is large and the annulus gets thin [19]: vortices are arranged on concentric circles and there is only a few number of them in the condensate. The extent of the condensate is no longer much larger than a vortex cell so that we are no longer in the setting to use the averaging effect.

Acknowledgments. This work was motivated by many fruitful discussions with Jean Dalibard and the joint paper [2]. We would like to thank him warmly for all his comments and suggestions.

SPECTRAL CHARACTERIZATION OF THE TRACE SPACES $H^s(\partial\Omega)$*

GILES AUCHMUTY†

Abstract. This paper defines certain scales of trace spaces $H^s(\partial\Omega)$ using harmonic Steklov eigenfunction expansions. The approach is intrinsic and applies to bounded regions in $\mathbb{R}^n$ for which standard imbedding results hold. In particular it suffices that the boundary of the region be a finite disjoint union of Lipschitz surfaces. The definition generalizes the classical definitions that require the boundary to consist of smooth manifolds. The description depends on a special inner product on $H^1(\Omega)$, certain completeness theorems for Steklov eigenfunctions, and special properties of the harmonic Steklov eigenfunctions. The characterization provides explicit formulae for the inner products and norms of a function in $H^s(\partial\Omega)$ and allows the description of specific orthonormal bases for these spaces. For $s < 0$, the spaces are obtained by duality from the case for $s > 0$.

Key words. Hilbert trace spaces, Steklov eigenproblems, boundary trace operator, normal derivative operator

DOI. 10.1137/050626053

1. Introduction. This paper develops a spectral characterization of real Hilbert trace spaces associated with bounded regions in $\mathbb{R}^n$ whose boundary may consist of Lipschitz surfaces—or slightly more general surfaces of finite area. The description uses harmonic Steklov eigenfunction expansions and provides concrete formulae for the inner products, norms, and orthonormal bases.

The approach used here is based on the use of special inner products and related decompositions for $H^1(\Omega)$. A remarkable property of the harmonic Steklov eigenfunctions is that they provide an orthogonal set in $H^1(\Omega)$ with respect to a natural inner product as well as a maximal orthogonal set in $L^2(\partial\Omega, d\sigma)$. This property is used to develop a description of $H^s(\partial\Omega)$ for all real s. The resulting spaces form an interpolatory family of spaces, and explicit formulae for the inner products in $H^{1/2}(\partial\Omega)$ and $H^{-1/2}(\partial\Omega)$ are obtained. Moreover it enables the use of Hilbert space approximation results using these harmonic Steklov eigenfunctions.

The usual theory of trace spaces as described in Adams and Fournier [2], Dautray and Lions [8], Lions and Magenes [12], and McLean [14] requires the use of local diffeomorphisms of domains onto a half-space. Then the allowable functions in the trace spaces are described either via properties of their Fourier transforms, or else using double integrals over the boundary of certain potential theoretic expressions. These definitions required various regularity assumptions for the boundary; in [8] and [12] they are required to be C^∞-manifolds.

Here an intrinsic definition of these spaces is given which does not require any mappings of the underlying domain. This approach permits weaker regularity of the

†Division of Mathematical Sciences, National Science Foundation, Arlington, VA 22230 (gauchmut @nsf.gov), and Department of Mathematics, University of Houston, Houston, TX 77204-3008.

boundary than does the conventional theory. We require only that condition (B2) of section 2 hold. In particular this is satisfied when (B1) holds. The results here depend on the characterization, and completeness, of Steklov eigenfunctions proved in Auchmuty [4].

2. Definitions and notation. This paper will develop a spectral characterization of the trace spaces $H^s(\partial\Omega)$, where Ω is a bounded region in $\mathbb{R}^n$, and show that these spaces are Hilbert spaces with respect to a natural inner product. A region is a nonempty, connected, open subset of $\mathbb{R}^n$. Its closure is denoted $\overline{\Omega}$ and its boundary is $\partial\Omega := \overline{\Omega} \setminus \Omega$. A standard assumption on the region is the following.

(B1) *Ω is a bounded region in $\mathbb{R}^n$ and its boundary $\partial\Omega$ is the union of a finite number of disjoint closed Lipschitz surfaces, each surface having finite surface area.*

When this holds there is an outward unit normal ν defined at σ for a.e. point of $\partial\Omega$. The definitions and terminology of Evans and Gariepy [10] will be followed except that $\sigma, d\sigma$ will represent the Hausdorff $(n-1)$-dimensional measure and integration with respect to this measure, respectively. All functions in this paper will take values in $\overline{\mathbb{R}} := [-\infty, \infty]$ and derivatives should be taken in a weak sense.

The real Lebesgue spaces $L^p(\Omega)$ and $L^p(\partial\Omega, d\sigma)$, $1 \le p \le \infty$, are defined in the standard manner and have the usual p-norm denoted by $\|u\|_p$ and $\|u\|_{p,\partial\Omega}$, respectively. Their inner products are defined by

$$\langle u, v\rangle := \int_\Omega u(x)\, v(x)\, dx \qquad \text{and} \qquad \langle u, v\rangle_{\partial\Omega} := |\partial\Omega|^{-1} \int_{\partial\Omega} u\, v\, d\sigma.$$

Let $H^1(\Omega)$ be the usual real Sobolev space of functions on Ω. It is a real Hilbert space under the standard H^1-inner product

$$[u, v]_1 := \int_\Omega [u(x).v(x) \;+\; \nabla u(x) \cdot \nabla v(x)]\, dx. \tag{2.1}$$

Here ∇u is the gradient of the function u and the corresponding norm is denoted $\|u\|_{1,2}$.

When Ω satisfies (B1), then the *Gauss–Green* theorem holds in the form

$$\int_\Omega u(x) D_j\, v(x)\, dx \;=\; \int_{\partial\Omega} u\, v\nu_j\, d\sigma \;-\; \int_\Omega v(x) D_j\, u(x)\, dx \quad \text{for } 1 \le j \le n \tag{2.2}$$

and for all $u,\ v$ in $H^1(\Omega)$.

The region Ω is said to satisfy *Rellich's theorem* provided the imbedding of $H^1(\Omega)$ into $L^p(\Omega)$ is compact for $1 \le p < p_S$, where $p_S(n) := 2n/(n-2)$ when $n \ge 3$, or $p_S(2) = \infty$ when $n = 2$.

There are a number of different criteria on Ω and $\partial\Omega$ that imply this result. When (B1) holds it is Theorem 1 in section 4.6 of [10]; see also Amick [1]. DiBenedetto [9], in Theorem 14.1 of Chapter 9, shows that the result holds when Ω is bounded and satisfies a "cone property." Adams and Fournier give a thorough treatment of conditions for this result in Chapter 6 of [2] and show that it also holds for some classes of unbounded regions.

When (B1) holds and $u \in W^{1,1}(\Omega)$, then the trace of u on $\partial\Omega$ is well-defined and is a Lebesgue integrable function with respect to σ; see [10, section 4.2] for details. The region Ω is said to satisfy a *compact trace theorem*, provided the trace mapping $\Gamma : H^1(\Omega) \to L^2(\partial\Omega, d\sigma)$ is compact. The trace map is the linear extension of the

map restricting Lipschitz continuous functions on $\overline{\Omega}$ to $\partial\Omega$. Occasionally u will be used in place of Γu for the trace of a function on $\partial\Omega$.

Evans and Gariepy [10, section 4.3] show that Γ is continuous when $\partial\Omega$ satisfies (B1). Theorem 1.5.1.10 of Grisvard [11] proves an inequality that implies the compact trace theorem when $\partial\Omega$ satisfies (B1). This inequality is also proved in [9, Chapter 9, section 18], under stronger regularity conditions on the boundary.

The results in this paper require only that the region satisfy the following condition.

(B2) *Ω is a bounded region with a boundary $\partial\Omega$ such that the Gauss–Green, Rellich, and compact trace theorems hold.*

Condition (B2) holds when (B1) does. Discussion of general regions for which (B2) holds may be found in Maz'ya and Poborchi [13], especially section 6.3, and also section 3 of [7]. Our analysis uses the following (equivalent) inner product on $H^1(\Omega)$:

$$[u,v]_\partial := \int_\Omega \nabla u \cdot \nabla v \; dx \; + \; |\partial\Omega|^{-1} \int_{\partial\Omega} u \; v \; d\sigma. \tag{2.3}$$

The corresponding norm will be denoted by $\|u\|_\partial$. The proof that this norm is equivalent to the usual $(1,2)$-norm on $H^1(\Omega)$ when (B2) holds is Corollary 6.2 of [4] and also is part of Theorem 21A of [15].

A function $u \in H^1(\Omega)$ is said to be *harmonic on* Ω, provided it is a solution of Laplace's equation in the usual weak sense. Namely,

$$\int_\Omega \nabla u \cdot \nabla \varphi \; dx \; = \; 0 \qquad \text{for all } \varphi \in C_c^1(\Omega). \tag{2.4}$$

Here $C_c^1(\Omega)$ is the set of all C^1-functions on Ω with compact support in Ω.

Define $\mathcal{H}(\Omega)$ to be the space of all such harmonic functions on Ω. When (B1) holds, the closure of $C_c^1(\Omega)$ in the H^1-norm is the usual Sobolev space $H_0^1(\Omega)$. Then (2.4) is equivalent to saying that $\mathcal{H}(\Omega)$ is ∂-orthogonal to $H_0^1(\Omega)$. This may be expressed as

$$H^1(\Omega) \; = \; H_0^1(\Omega) \oplus_\partial \mathcal{H}(\Omega), \tag{2.5}$$

where $\oplus_\partial$ indicates that this is a ∂-orthogonal decomposition. This result is also discussed in section 22.4 of [15].

In this paper we shall use various standard results from the calculus of variations and convex analysis. Background material on such methods may be found in Blanchard and Brüning [6] or Zeidler [16], both of which have discussions of the variational principles for the Dirichlet eigenvalues and eigenfunctions of second order elliptic operators. The variational principles used here are variants of the principles described there and are analogous to those for the Laplacian described in section 5 of Auchmuty [3].

All the variational principles and functionals in this paper will be defined on (closed convex subsets of) $H^1(\Omega)$. When $\mathcal{F} : H^1(\Omega) \to (-\infty, \infty]$ is a functional, then $\mathcal{F}$ is said to be *G-differentiable* at a point $u \in H^1(\Omega)$ if there is an $\mathcal{F}'(u)$ such that

$$\lim_{t\to 0} \; t^{-1} \left[\mathcal{F}(u+tv) - \mathcal{F}(u)\right] \; = \; \mathcal{F}'(u)(v) \qquad \text{for all } v \in H^1(\Omega),$$

with $\mathcal{F}'(u)$ a continuous linear functional on $H^1(\Omega)$. In this case, $\mathcal{F}'(u)$ is called the G-derivative of $\mathcal{F}$ at u.

In this paper we will say that a real sequence $\{x_m : m \geq 1\}$ is said to be increasing if $x_{m+1} \geq x_m$ for all m; it is strictly increasing if strict inequality holds here for all m. Similarly a function u is said to be (strictly) positive on a set E, if $u(x) \geq (>)\ 0$ on E.

3. The harmonic Steklov eigenproblem. Assume Ω is a region in $\mathbb{R}^n$ which satisfies (B2). A nonzero function $s \in H^1(\Omega)$ is said to be a *harmonic Steklov eigenfunction* on Ω corresponding to the Steklov eigenvalue δ, provided s satisfies

$$\int_\Omega \nabla s \cdot \nabla v \, dx \;=\; \delta \, |\partial\Omega|^{-1} \int_{\partial\Omega} s \, v \, d\sigma \qquad \text{for all} \quad v \in H^1(\Omega). \tag{3.1}$$

This is the weak form of the boundary value problem

$$\Delta \, s \;=\; 0 \qquad \text{on } \Omega \quad \text{with } D_\nu \, s \;=\; \delta \, |\partial\Omega|^{-1} \, s \quad \text{on } \partial\Omega. \tag{3.2}$$

Here Δ is the Laplacian and $D_\nu \, s(x) := \nabla s(x) \cdot \nu(x)$ is the unit outward normal derivative of s at a point on the boundary.

$\delta_0 = 0$ is the least eigenvalue of this problem corresponding to the eigenfunction $s_0(x) \equiv 1$ on Ω. This eigenvalue is simple as Ω is connected. All other eigenvalues of (3.1) are strictly positive.

These eigenvalues and a corresponding family of ∂-orthonormal eigenfunctions may be found using variational principles as described in sections 6 and 7 of [4]. A different variational description is developed in Bandle [5, Chapter 3]. Let the first k Steklov eigenvalues be $0 = \delta_0 < \delta_1 \leq \delta_2 \leq \cdots \leq \delta_{k-1}$ and let $s_0, s_1, \ldots, s_{k-1}$ be a corresponding set of ∂-orthonormal eigenfunctions. The kth eigenfunction s_k will be a maximizer of the functional

$$\mathcal{B}(u) \;:=\; |\partial\Omega|^{-1} \int_{\partial\Omega} u^2 \, d\sigma \tag{3.3}$$

over the subset B_k of functions in $H^1(\Omega)$ which satisfy

$$\|s\|_\partial \;\leq\; 1 \qquad \text{and} \qquad [s, s_l]_\partial \;=\; 0 \quad \text{for} \quad 0 \leq l \leq k-1. \tag{3.4}$$

The existence and some properties of these eigenfunctions are described in sections 6 and 7 of [4]. In particular, that analysis shows that each δ_j is of finite multiplicity and $\delta_j \to \infty$ as $j \to \infty$; see Theorem 7.2 of [4]. Let $\mathcal{S} := \{s_j : j \geq 0\}$ be the maximal family of ∂-orthonormal eigenfunctions constructed inductively as above. For each $u \in H^1(\Omega)$, consider the series

$$P_H \, u(x) \;:=\; \sum_{j=0}^{\infty} [u, s_j]_\partial \; s_j(x). \tag{3.5}$$

THEOREM 3.1. *Assume $\Omega, \partial\Omega$ satisfy* (B2) *and P_H is defined by* (3.5)*; then P_H is the ∂-orthogonal projection of $H^1(\Omega)$ onto $\mathcal{H}(\Omega)$.*

Proof. This follows from standard results about orthogonal expansions and Theorem 7.3 of [4], which says that $\mathcal{S}$ is a maximal orthonormal subset of $\mathcal{H}(\Omega)$. □

An expression of the form

$$v(x) \;:=\; \sum_{j=0}^{\infty} c_j \, s_j(x) \qquad \text{with } c_j := [v, s_j]_\partial \tag{3.6}$$

will be called a harmonic Steklov expansion and, since $\mathcal{S}$ is a basis of $\mathcal{H}(\Omega)$, the Riesz–Fischer theorem implies that it represents an H^1-harmonic function on Ω if and only if

$$\sum_{j=0}^{\infty} |c_j|^2 \ < \ \infty. \tag{3.7}$$

As described in section 8 of [4], the Steklov eigenfunctions on the unit disc in $\mathbb{R}^2$ are the functions $r^k \cos k\theta$ and $r^k \sin k\theta$, so the above series are familiar from classical treatments of harmonic functions on a disc. Similarly when Ω is the unit ball in $\mathbb{R}^3$ the Steklov eigenfunctions are spherical harmonics and these series generalize some common expansions used in classical mathematical physics.

4. A spectral representation of the trace operator. The Steklov eigenfunctions s_j described in the preceding section have L^2 traces on the boundary $\partial\Omega$ whenever (B1) holds. Define

$$\hat{s_j}(x) \ := \ \sqrt{1+\delta_j}\ \Gamma\, s_j(x) \qquad \text{for } x \in \partial\Omega, \ \text{ and } \ j \geq 0. \tag{4.1}$$

Then (3.1) and (3.4) imply that the set $\hat{\mathcal{S}} := \{\hat{s_j} : j \geq 0\}$ will be an orthonormal set in $L^2(\partial\Omega, d\sigma)$ with respect to the inner product defined in section 2. The following result provides an explicit expression for the trace operator in terms of the harmonic Steklov expansion of a function $u \in H^1(\Omega)$.

THEOREM 4.1. *Assume $\Omega, \partial\Omega$ satisfy* (B2)*, with $\Gamma, \hat{\mathcal{S}}$ as above. Then $\hat{\mathcal{S}}$ is a maximal orthonormal set in $L^2(\partial\Omega, d\sigma)$ and*

$$\Gamma u \ = \ \sum_{j=0}^{\infty} (1+\delta_j)^{-1/2}\ [u, s_j]_\partial\ \hat{s_j} \quad \textit{for each } u \in H^1(\Omega). \tag{4.2}$$

Proof. The first claim is a special case of Theorem 9.4 in [4]. The null space of the operator Γ is $H_0^1(\Omega)$ from Theorem 3.40 of [14]. Hence, from (2.5) and Theorem 3.1, $\Gamma u = \Gamma P_H\, u$, where P_H is the projection onto the space $\mathcal{H}(\Omega)$. Equation (4.2) then follows from (4.1). □

Apply Parseval's identity to (4.2). Then

$$\|\Gamma\, u\|^2_{\partial\Omega} \ := \ |\partial\Omega|^{-1} \int_{\partial\Omega} |\Gamma\, u|^2\, d\sigma \ = \ \sum_{j=0}^{\infty} (1+\delta_j)^{-1}\ [u, s_j]_\partial{}^2 \tag{4.3}$$

for any $u \in H^1(\Omega)$, since $\hat{\mathcal{S}}$ is a basis of $L^2(\partial\Omega, d\sigma)$.

Suppose now that $g = \Gamma\, u$ for some $u \in H^1(\Omega)$. Then $g \in L^2(\partial\Omega, d\sigma)$ and

$$g(x) \ = \ \sum_{j=0}^{\infty} g_j\ \hat{s_j}(x) \qquad \text{with } g_j \ = \ \langle g, \hat{s_j}\rangle_{\partial\Omega}. \tag{4.4}$$

Equation (4.2) and the orthonormality of $\hat{\mathcal{S}}$ imply that

$$[u, s_j]_\partial \ = \ (1+\delta_j)^{1/2}\ g_j \qquad \text{for all } j \geq 0.$$

Let g_M be the Mth partial sum of the series (4.4) and consider the map $E_M : L^2(\partial\Omega, d\sigma) \to \mathcal{H}(\Omega)$ defined by

$$E_M\, g(x) \ := \ \sum_{j=0}^{M} (1+\delta_j)^{1/2}\ g_j\, s_j(x). \tag{4.5}$$

This is a harmonic function on Ω with boundary trace g_M. Define

$$E\,g(x) \;:=\; \lim_{M\to\infty} E_M\,g(x). \tag{4.6}$$

Then (3.7) shows that Eg is in $\mathcal{H}(\Omega)$ if and only if

$$\sum_{j=0}^{\infty} (1+\delta_j)\,|g_j|^2 \;<\; \infty. \tag{4.7}$$

Formally E defines a *harmonic extension* of the boundary data g to Ω.

5. A spectral definition of $H^s(\partial\Omega)$. The classical description of trace theorems for H^1-functions on a region requires the description of the boundary using local coordinates and mappings from canonical regions such as a half-space. See chapter 3 of McLean [14] for a detailed description under weak regularity conditions. A comparison of a number of methods for defining these spaces is given in the appendix to Chapter 4 of [8]. Here a very different definition will be described which should be much more useful for approximation theory and computational purposes. It is based on the use of a scale of spaces defined by weights that depend on the Steklov eigenvalues.

Specifically $H^s(\partial\Omega)$ is defined as that subspace of $L^2(\partial\Omega, d\sigma)$ of functions whose harmonic Steklov coefficients satisfy certain summability conditions. For $s \geq 0$, we define $H^s(\partial\Omega)$ to be the subspace of all functions $g \in L^2(\partial\Omega, d\sigma)$ with Steklov expansion (4.4) satisfying

$$\sum_{j=0}^{\infty} (1+\delta_j)^{2s}\,|g_j|^2 \;<\; \infty. \tag{5.1}$$

Define the *s-inner product* and *s-norm* on $H^s(\partial\Omega)$ by

$$[g,h]_{s,\partial\Omega} \;:=\; \sum_{j=0}^{\infty} (1+\delta_j)^{2s}\,g_j\,h_j \qquad \text{and} \qquad \|g\|^2_{s,\partial\Omega} \;:=\; \sum_{j=0}^{\infty} (1+\delta_j)^{2s}\,{g_j}^2. \tag{5.2}$$

When $s = 0$, one sees that $H^0(\partial\Omega) = L^2(\partial\Omega, d\sigma)$.

When $s = 1/2$, (4.7) shows that the space $H^{1/2}(\partial\Omega)$ will be precisely the class of all boundary values of H^1-functions on Ω—so this definition agrees with the classical definition based on Fourier methods when $\partial\Omega$ is a smooth manifold. Note that this definition of the spaces $H^s(\partial\Omega)$ requires only that $\partial\Omega$ be smooth enough for the Steklov eigenanalysis to hold.

For general $s > 0$, this definition corresponds to the spaces described via (complex) interpolation. The following results show that this definition satisfies the same intermediate space properties as the original definitions of Lions and Magenes [12, Chapter 1, section 7.3], which required that the boundary comprise C^∞-manifolds.

THEOREM 5.1. *Assume that $\Omega, \partial\Omega$ satisfy* (B2) *and $H^s(\partial\Omega)$ is defined as above. If $0 \leq s_1 < s_2$, then $H^{s_2}(\partial\Omega)$ is a dense subspace of $H^{s_1}(\partial\Omega)$ and the imbedding of $H^{s_2}(\partial\Omega)$ into $H^{s_1}(\partial\Omega)$ is compact.*

Proof. For $M \geq 1$, let $P_M : L^2(\partial\Omega, d\sigma) \to L^2(\partial\Omega, d\sigma)$ be the finite rank operator corresponding to the Mth partial sum of the Steklov expansion (4.4). That is,

$$P_M\,g(x) \;:=\; \sum_{j=0}^{M} \langle g, \hat{s_j}\rangle_{\partial\Omega}\;\hat{s_j}(x) \qquad \text{for } g \in L^2(\partial\Omega, d\sigma). \tag{5.3}$$

Obviously $P_M\, g \in H^s(\partial\Omega)$ for all $s \geq 0$ and the definition (5.2) yields that

$$\|g\|_{s_1,\partial\Omega} \;\leq\; \|g\|_{s_2,\partial\Omega} \qquad \text{whenever} \quad 0 \leq s_1 < s_2. \tag{5.4}$$

Given $g \in H^{s_1}(\partial\Omega)$, then the sequence $\{P_M\, g : M \geq 1\}$ is a subset of $H^{s_2}(\partial\Omega)$ which converges to g in $H^{s_1}(\partial\Omega)$. Thus $H^{s_2}(\partial\Omega)$ is a dense subspace of $H^{s_1}(\partial\Omega)$.

Consider the linear map $L_\theta : L^2(\partial\Omega, d\sigma) \to L^2(\partial\Omega, d\sigma)$ defined by

$$L_\theta\, g(x) \;:=\; \sum_{j=0}^{\infty} \,(1+\delta_j)^{-\theta}\; \langle g, \hat{s_j}\rangle_{\partial\Omega}\; \hat{s_j}(x). \tag{5.5}$$

For $\theta > 0$, using the fact that $\delta_j \to \infty$, L_θ is a compact linear operator, as it may be uniformly approximated by a finite rank operator. Moreover

$$\|L_\theta\, g\|^2_{s,\partial\Omega} \;=\; \sum_{j=0}^{\infty} \,(1+\delta_j)^{2(s-\theta)}\; \langle g, \hat{s_j}\rangle^2_{\partial\Omega}. \tag{5.6}$$

Thus L_θ is a linear isometry of $L^2(\partial\Omega, d\sigma)$ onto $H^\theta(\partial\Omega)$, so the imbedding of $H^s(\partial\Omega)$ into $L^2(\partial\Omega, d\sigma)$ is compact whenever $s > 0$. A translation in s then yields that the imbedding of $H^{s_2}(\partial\Omega)$ into $H^{s_1}(\partial\Omega)$ is compact whenever $s_1 < s_2$. □

The family of spaces $H^s(\partial\Omega)$ with $s \geq 0$ forms an interpolatory family (or scale) of real Hilbert spaces, as these s-norms satisfy the following log-convexity inequality.

THEOREM 5.2. *Assume that $\Omega, \partial\Omega$ satisfy* (B2) *and $H^s(\partial\Omega)$ is defined as above. If $0 \leq s_1 < s_2$ and $s = (1-\theta)s_1 + \theta s_2$ with $0 \leq \theta \leq 1$, then*

$$\|g\|_{s,\partial\Omega} \;\leq\; \|g\|^{1-\theta}_{s_1,\partial\Omega}\; \|g\|^{\theta}_{s_2,\partial\Omega} \qquad \textit{for all} \quad g \in H^{s_2}(\partial\Omega). \tag{5.7}$$

Proof. This is obviously true when $\theta = 0$ or 1. Assume $0 < \theta < 1$. Then from (5.2),

$$\|g\|^2_{s,\partial\Omega} \;:=\; \sum_{j=0}^{\infty} \,(1+\delta_j)^{2s}\, {g_j}^2. \tag{5.8}$$

Factor each term in the sum, so that $(1+\delta_j)^{2s}\, {g_j}^2 \;=\; c_j\, d_j$ with

$$c_j := (1+\delta_j)^{s_1(1-\theta)}\, {g_j}^{2(1-\theta)}, \qquad d_j := (1+\delta_j)^{s_2\theta}\, {g_j}^{2\theta}.$$

Apply Holder's inequality to (5.8) with $p := 1/(1-\theta), p^* := \theta^{-1}$. Then inequality (5.7) follows. □

Suppose F is a continuous linear functional on $H^s(\partial\Omega)$ with $s \;\geq\; 0$. F will be *represented by* a function $f \in L^2(\partial\Omega, d\sigma)$, provided

$$F(g) \;=\; |\partial\Omega|^{-1} \int_{\partial\Omega} f\, g\; d\sigma \;=\; \langle f, g\rangle_{\partial\Omega} \qquad \text{for all} \quad g \in H^s(\partial\Omega). \tag{5.9}$$

When f, g have Steklov expansions of the form (4.4) with Steklov coefficients f_j, g_j, then this becomes

$$F(g) \;=\; \sum_{j=0}^{\infty} \, f_j\, g_j. \tag{5.10}$$

Use of Schwarz's inequality here shows that each $f \in L^2(\partial\Omega, d\sigma)$ represents a continuous linear functional on such $H^s(\partial\Omega)$.

For $s < 0$, define the space $H^s(\partial\Omega)$ to be the completion of the space $L^2(\partial\Omega, d\sigma)$ with respect to the inner product and norm of (5.2). Elements of this space will be called *generalized functions* on $\partial\Omega$. Below we shall show that $H^{-s}(\partial\Omega)$ is precisely the dual space of $H^s(\partial\Omega)$ with respect to the pairing induced by the L^2-inner product on $\partial\Omega$. When $\partial\Omega$ is a C^∞-manifold, these will be spaces of distributions on $\partial\Omega$.

It is straightforward to verify that $H^s(\partial\Omega)$ with $s < 0$ is a real Hilbert space under the inner product of (5.2). The following theorem specifies the duality relationship.

THEOREM 5.3. *Assume that* $\Omega, \partial\Omega$ *satisfy* (B2), $H^s(\partial\Omega)$ *is defined as above with* $s > 0$, *and* F *is a continuous linear functional on* $H^s(\partial\Omega)$. *Then there is a unique generalized function* $f \in H^{-s}(\partial\Omega)$ *such that*

$$F(g) \;=\; \langle f, g\rangle_{\partial\Omega} \qquad \textit{for all} \quad g \in H^s(\partial\Omega). \tag{5.11}$$

Moreover the dual norm of F *is* $\|f\|_{-s,\partial\Omega}$.

Proof. Rewrite each term in the sum (5.10) as the product of

$$c_j := \mu_j^{-1}\, f_j \quad \text{and} \quad d_j := \mu_j\, g_j \qquad \text{with} \quad \mu_j := (1+\delta_j)^s.$$

Apply Schwarz's inequality to (5.10). Then the definitions of the norms yield

$$|F(g)| \;\le\; \|f\|_{-s,\partial\Omega}\, \|g\|_{s,\partial\Omega}. \tag{5.12}$$

Moreover equality holds here whenever $f_j = (1+\delta_j)^2\, g_j$ for all $j \ge 0$. Since F is continuous if and only if it is bounded, we see that each continuous linear functional on $H^s(\partial\Omega)$ will be represented by a generalized function in $H^{-s}(\partial\Omega)$. The dual norm is defined by

$$\|F\|_{*s} \;:=\; \sup_{\|g\|_{s,\partial\Omega}\,\le\,1} |F(g)|,$$

so (5.12) shows that it is given by the norm on $H^{-s}(\partial\Omega)$. ∎

6. Spectral representation of the normal derivative operator. When $\partial\Omega$ is locally a C^1-manifold, then the exterior unit normal ν is a continuous vector field. The exterior normal derivative of a C^1-function u on $\overline{\Omega}$ is then given by

$$D_\nu\, u(x) \;:=\; \nabla u(x) \cdot \nu(x) \qquad \text{for } x \in \partial\Omega. \tag{6.1}$$

When the Steklov eigenfunctions are sufficiently smooth, then (3.2) and (4.1) imply that

$$D_\nu\, s_j(x) \;=\; \frac{\delta_j}{|\partial\Omega|\,\sqrt{(1+\delta_j)}}\; \hat{s_j}(x) \qquad \text{for } x \in \partial\Omega \text{ and } j \ge 0. \tag{6.2}$$

Take this to hold for each Steklov eigenfunction. When $v \in \mathcal{H}(\Omega)$ has a Steklov expansion of the form (3.6), define the linear extension of D_ν to be

$$D_\nu\, v \;=\; |\partial\Omega|^{-1} \sum_{j=1}^{\infty} \frac{\delta_j}{\sqrt{(1+\delta_j)}}\; [v, s_j]_\partial\; \hat{s_j}. \tag{6.3}$$

The H^s-norm of this generalized function on $\partial\Omega$ is

$$\|D_\nu\, v\|^2_{s,\partial\Omega} \;=\; |\partial\Omega|^{-2}\; \sum_{j=1}^{\infty}\; (1+\delta_j)^{2s-1}{\delta_j}^2\; [v, s_j]^2_\partial. \tag{6.4}$$

In view of this calculation, this operator satisfies the following.

THEOREM 6.1. *Assume that $\Omega, \partial\Omega$ satisfy* (B2)*, and $H^s(\partial\Omega)$ is defined in section* 5*. Then the operator D_ν defined by* (6.3) *is a continuous map from $\mathcal{H}(\Omega)$ to $H^s(\partial\Omega)$ for $s \le -1/2$.*

Proof. From (6.4), the operator will be continuous if and only if there is a constant $C > 0$ such that

$$(1+\delta_j)^{2s-1}{\delta_j}^2 \;\le\; C \qquad \text{for all } j \ge 0.$$

Since $\delta_j \to \infty$, this holds if and only if $s \le -1/2$. □

7. Explicit inner product on $H^{1/2}(\partial\Omega)$. When $f, g \in H^{1/2}(\partial\Omega)$, the inner product on $H^{1/2}(\partial\Omega)$ was defined in section 5 in terms of a Steklov series expansion. Here it will be shown to have an expression in terms of the boundary trace and a normal derivative.

Given $g \in H^{1/2}(\partial\Omega)$, let Eg be its harmonic extension in $\mathcal{H}(\Omega)$ defined by (4.6). Then the outward normal derivative $D_\nu\, Eg$ will be in $H^{-1/2}(\partial\Omega)$ from Theorem 6.1.

THEOREM 7.1. *Assume that $\Omega, \partial\Omega$ satisfy* (B2) *and $H^{1/2}(\partial\Omega)$ is defined as above. Then E is a linear isometry from $H^{1/2}(\partial\Omega)$ to $\mathcal{H}(\Omega)$ and*

$$[f, g]_{1/2,\partial\Omega} \;=\; \langle f, g \,+\, |\partial\Omega|\, D_\nu\, Eg\rangle_{\partial\Omega} \qquad \textit{for all } f, g \in H^{1/2}(\partial\Omega). \tag{7.1}$$

Proof. From (4.6),

$$E\, g(x) \;=\; \sum_{j=0}^{\infty}\; (1+\delta_j)^{1/2}\;\; g_j\, s_j(x),$$

so

$$\|Eg\|^2_\partial \;=\; \sum_{j=0}^{\infty} (1+\delta_j)\, |g_j|^2 \;=\; \|g\|^2_{1/2,\partial\Omega} \qquad \text{for all } g \in H^{1/2}(\partial\Omega). \tag{7.2}$$

Hence E is an isometry as claimed. Substitute for Eg in (6.3). Then

$$D_\nu\, E\, g(x) \;=\; |\partial\Omega|^{-1}\; \sum_{j=0}^{\infty}\; \delta_j\; g_j\, \hat{s_j}(x).$$

This and the orthonormality of $\hat{\mathcal{S}}$ yield that

$$\langle f, g \,+\, |\partial\Omega|\, D_\nu\, Eg\rangle_{\partial\Omega} \;=\; \sum_{j=0}^{\infty}\; f_j\, (1+\delta_j)\, g_j, \tag{7.3}$$

which is (7.1). □

This result (7.1) may be written formally as

$$[f, g]_{1/2,\partial\Omega} \;=\; \int_{\partial\Omega}\; f\, (|\partial\Omega|^{-1}\, g \,+\, D_\nu g)\; d\sigma,$$

so the (1/2)-norm is defined by the quadratic form

$$\|g\|^2_{1/2,\partial\Omega} \;=\; \int_{\partial\Omega} \left[\, |\partial\Omega|^{-1}\, g^2 \;+\; g\, D_\nu g \,\right]\, d\sigma. \tag{7.4}$$

That is, $H^{1/2}(\partial\Omega)$ is the space of all functions in $L^2(\partial\Omega, d\sigma)$ for which this quadratic form is finite. Here $D_\nu g$ is actually the outward normal derivative of the harmonic extension of g to Ω.

8. The inner product on $H^{-1/2}(\partial\Omega)$. The space $H^{-1/2}(\partial\Omega)$ was defined as the completion of $L^2(\partial\Omega, d\sigma)$ with respect to the inner product defined by (5.2) with $s = -1/2$. In this section, this inner product will be characterized in terms of the solution of a Robin boundary value problem for Laplace's equation. More specifically, it will be described using a variational principle for such solutions.

Given $g \in H^{-1/2}(\partial\Omega)$, define the functional $\mathcal{D} : H^1(\Omega) \to \mathbb{R}$ by

$$\mathcal{D}(u) \;:=\; \int_\Omega |\nabla u|^2 \, dx \;+\; |\partial\Omega|^{-1} \int_{\partial\Omega} |\Gamma u|^2 \, d\sigma \;-\; 2\, \langle g, \Gamma u\rangle_{\partial\Omega}. \tag{8.1}$$

Consider the variational principle of minimizing $\mathcal{D}$ on $H^1(\Omega)$. The essential results about this problem can be stated as follows.

THEOREM 8.1. *Assume that $\Omega, \partial\Omega$ satisfy* (B2)*, $g \in H^{-1/2}(\partial\Omega)$, and $\mathcal{D}$ is defined by* (8.1)*. Then there is a unique minimizer $\hat{u}$ of $\mathcal{D}$ on $H^1(\Omega)$ and it satisfies*

$$\int_\Omega \nabla u \cdot \nabla v \; dx \;+\; \langle (\Gamma\, u \;-\; g), \Gamma\, v\rangle_{\partial\Omega} \;=\; 0 \qquad \textit{for all} \quad v \in H^1(\Omega). \tag{8.2}$$

Proof. The existence of a unique minimizer of $\mathcal{D}$ on $H^1(\Omega)$ is Theorem 9.2 of [4] with $\tau = 1/2$ and $g \in L^2(\partial\Omega, d\sigma)$. The extension to $g \in H^{-1/2}(\partial\Omega)$ is straightforward.

This functional $\mathcal{D}$ is convex and G-differentiable on $H^1(\Omega)$ and its derivative can be obtained from Theorems 3.1 and 6.1 of [4]. The left-hand side of (8.2) is the directional derivative of $\mathcal{D}$, so the extremality conditions imply that $\hat{u}$ will be a minimizer of $\mathcal{D}$ on $H^1(\Omega)$ if and only if it is a solution of (8.2). □

Note that (8.2) is the weak form of the Robin boundary value problem

$$\Delta\, u \;=\; 0 \qquad \text{on } \Omega \quad \text{ with } |\partial\Omega|\, D_\nu\, u \;+\; u \;=\; g \quad \text{on } \partial\Omega. \tag{8.3}$$

When $v \in H^1_0(\Omega)$, then $\Gamma v \equiv 0$, so (8.2) implies that (2.4) holds or the solution $\hat{u}$ is harmonic on Ω. Let $\hat{u}$ have a Steklov expansion of the form

$$\hat{u}(x) \;:=\; \sum_{j=0}^{\infty} \; u_j\, s_j(x) \qquad \text{on } \Omega. \tag{8.4}$$

Then, from (4.2), the boundary trace $\Gamma\, \hat{u}$ is given by

$$\Gamma\, \hat{u} \;:=\; \sum_{j=0}^{\infty} \; \frac{u_j}{\sqrt{(1+\delta_j)}}\, \hat{s_j}. \tag{8.5}$$

Assume that $g \in H^{-1/2}(\partial\Omega)$ has the Steklov representation

$$g \;:=\; \sum_{j=0}^{\infty} \; g_j\, \hat{s_j} \qquad \text{with } g_j \;:=\; \langle g, \hat{s_j}\rangle_{\partial\Omega}. \tag{8.6}$$

Substitute $v = s_0$ in (8.2) to find that $u_0 = g_0$.

For $k \geq 1$, put $v = s_k$ in (3.1). Then

$$\int_\Omega \nabla u \cdot \nabla s_k \, dx = \delta_k \, \langle s_k, \Gamma u \rangle_{\partial\Omega} \qquad \text{for all} \quad u \in H^1(\Omega). \tag{8.7}$$

Substitute this in (8.2) with $v = s_k$, to obtain

$$(1 + \delta_k) \, \langle \Gamma \hat{u}, \hat{s_k} \rangle_{\partial\Omega} = \langle g, \hat{s_k} \rangle_{\partial\Omega} \qquad \text{for all } k \geq 1. \tag{8.8}$$

The expression (8.5) for $\Gamma\hat{u}$ yields that the Steklov coefficients u_k of the solution of this variational problem are given by

$$u_k = (1 + \delta_k)^{-1/2} \, g_k \qquad \text{for each } k \geq 0. \tag{8.9}$$

Define $G_R : H^{-1/2}(\partial\Omega) \to \mathcal{H}(\Omega)$ to be the solution operator of this variational problem. Equations (8.4) and (8.9) show that G_R has the Steklov spectral representation

$$\hat{u}(x) := G_R \, g(x) = \sum_{k=0}^{\infty} (1 + \delta_k)^{-1/2} \, g_k \, s_k(x) \tag{8.10}$$

for any $g \in H^{-1/2}(\partial\Omega)$ as in (8.6). The boundary trace of this function will be

$$\Gamma G_R \, g = \sum_{k=0}^{\infty} (1 + \delta_k)^{-1} \, g_k \, \hat{s_k}. \tag{8.11}$$

Moreover a straightforward computation shows that

$$\|\Gamma G_R \, g\|_{1/2,\partial\Omega} = \|g\|_{-1/2,\partial\Omega}, \tag{8.12}$$

so this operator ΓG_R is an isometric linear mapping of $H^{-1/2}(\partial\Omega)$ onto $H^{1/2}(\partial\Omega)$. More generally ΓG_R will be an isometry from any space $H^s(\partial\Omega)$ onto $H^{s+1}(\partial\Omega)$.

This, together with the orthonormality of $\hat{\mathcal{S}}$, proves the following theorem.

THEOREM 8.2. *Assume that $\Omega, \partial\Omega$ satisfy* (B2) *and G_R is the operator defined by* (8.11). *Then the inner product on $H^{-1/2}(\partial\Omega)$ obeys*

$$[f, g]_{-1/2,\partial\Omega} = \langle f, \Gamma \, G_R \, g \rangle_{\partial\Omega} \qquad \textit{for all } f, g \in H^{-1/2}(\partial\Omega). \tag{8.13}$$

For other negative values of s, the inner products on $H^s(\partial\Omega)$ may be defined using fractional powers of the operator ΓG_R.

VARIATIONAL PRINCIPLES FOR WATER WAVES*

B. KOLEV† AND D. H. SATTINGER‡

Abstract. We describe the Hamiltonian structures, including the Poisson brackets and Hamiltonians, for free boundary problems for incompressible fluid flows with vorticity. The Hamiltonian structure is used to obtain variational principles for stationary gravity waves for both irrotational flows and flows with vorticity.

Key words. water waves, variational principles, Poisson structures

1. Introduction.

In 1933 Friedrichs [9] proposed the functional

$$J(\psi) = \iiint\limits_{0\le\psi\le 1} \left[(\nabla\psi)^2 + v^2(x,y)\right]\, d^2\mathbf{x},$$

where ψ is the stream function for an incompressible flow, as a variational method of obtaining solutions to free boundary value problems. Critical points of J are harmonic functions which satisfy the condition

$$(\nabla\psi)^2 = v^2$$

on the free boundary, given by $\psi = 1$. The free boundary condition relevant to theory of gravity waves, however, is the Bernoulli equation

$$\frac{(\nabla\varphi)^2}{2} + g\zeta = \text{constant},$$

where φ is either the velocity potential for irrotational flow or the stream function in the case of flows with vorticity. Thus some other variational principle is needed for the study of gravity waves.

Recently, a variational principle for gravity waves with vorticity was given by Constantin, Sattinger, and Strauss [7], using a direct, "hands-on" approach. More generally, a variational principle for a stationary wave may be obtained for systems possessing a Hamiltonian structure by minimizing the Hamiltonian computed in a Galilean frame moving with the wave. We illustrate that approach in this study.

We begin with a brief review of Euler's equations of incompressible flows and the associated free boundary value problems; in section 3 we describe the Hamiltonian structure of these problems, for irrotational flows and flows with vorticity, as given by Lewis et al. [15]. All the functions under consideration in this article, including the free boundaries, are assumed to be smooth.

2. Incompressible fluid flows. Let the velocity field of an incompressible fluid in a fixed region $\mathcal{D}$ be denoted by $\mathbf{v}$. The incompressibility of the fluid is expressed by the condition div $\mathbf{v} = 0$. We must have $\mathbf{v} \cdot \nu = 0$ on the boundary of $\mathcal{D}$, where ν is the outward unit normal at the boundary. Euler's equations of motion for the flow of an inviscid, incompressible fluid are

$$\frac{d\mathbf{x}}{dt} = \mathbf{v}, \qquad \rho \frac{d\mathbf{v}}{dt} = \rho(\mathbf{v}_t + (\mathbf{v} \cdot \nabla)\mathbf{v}) = -\nabla(p - \mathbf{g} \cdot \mathbf{x}), \tag{2.1}$$

$$\text{div } \mathbf{v} = 0,$$

where ρ is the density, p is the hydrodynamic pressure, and $\mathbf{g} \cdot \mathbf{x}$ is the gravitational potential. Henceforth we take $\rho = 1$.

Given a manifold $\mathcal{D} \in \mathbb{R}^3$ with smooth boundary, we denote by $\mathcal{L}^2(\mathcal{D})$ the Hilbert space of vector fields on $\mathcal{D}$ with the inner product

$$\langle \mathbf{v}, \mathbf{w} \rangle = \iiint_{\mathcal{D}} \mathbf{v} \cdot \mathbf{w} \, d^3\mathbf{x}.$$

We denote by $\mathcal{L}_\pi$ the closed subspace of $\mathcal{L}^2(\mathcal{D})$ generated by vector fields, of the form $\mathbf{w} = \nabla p$ for some function p with finite Dirichlet norm. The orthogonal complement $\mathcal{L}_\sigma = \mathcal{L}_\pi^\perp$ is the space of all vector fields $\mathbf{v}$ for which $\langle \mathbf{v}, \nabla p \rangle = 0$ for all $p \in W^{1,2}(\mathcal{D})$. By applying the Gauss divergence theorem, we see that if $\mathbf{v} \in \mathcal{L}^2(\mathcal{D})$ and is smooth, say C^1, then div $\mathbf{v} = 0$ and $\mathbf{v} \cdot \nu = 0$ on $\Sigma = \partial\mathcal{D}$, where ν denotes the outward unit normal on Σ. The Hilbert space $\mathcal{L}_\sigma$ is the space of weakly divergence-free vector fields. We denote the orthogonal projections onto $\mathcal{L}_\sigma$ and $\mathcal{L}_\pi$ by P_σ and P_π, respectively.

In many applications the fluid is not confined to a fixed region but instead carries the region with it. In such cases, the region $\mathcal{D}$ occupied by the fluid must also be determined. Such problems are called free boundary problems and occupy a substantial part of the literature on incompressible flows.

Given an irrotational flow (curl $\mathbf{v} = 0$) on a simply connected domain, there is velocity potential φ for which $\mathbf{v} = \nabla\varphi$. The velocity potential is defined only up to an arbitrary function of time; the transformation $\varphi \mapsto \varphi + k(t)$ is called a *gauge transformation* and will play a role in what follows.

The equation div $\mathbf{v} = 0$ implies that φ is harmonic. Substituting $\mathbf{v} = \nabla\varphi$ into the second equation in (2.1) we obtain

$$\nabla \left(\varphi_t + \frac{1}{2}(\nabla\varphi)^2 + gz + p \right) = 0;$$

hence

$$\varphi_t + \frac{1}{2}(\nabla\varphi)^2 + gz + p = k(t)$$

for some function of time, which can be eliminated by a gauge transformation of the velocity potential. We always choose the gauge to be such that

$$\varphi_t + \frac{1}{2}(\nabla\varphi)^2 + gz + p = 0$$

everywhere in the fluid.

An interface between the fluid and another medium—for example, air—is called a *free surface*. If the pressure is constant in the air, then it is also constant at the

surface of the fluid, and we may normalize the pressure to be zero at the free surface. Hence we obtain Bernoulli's equation

$$\varphi_t + \frac{1}{2}(\nabla\varphi)^2 + gz = 0,$$

where gz is the gravitational potential on the free surface.

The free surface is given in space-time by $\phi = 0$, where $\phi(x, y, z, t) = z - \zeta(x, y, t)$. The free surface moves with the fluid; hence the material derivative of ϕ vanishes, and

$$0 = \frac{d\phi}{dt} = \frac{d}{dt}(z - \zeta) = v^3 - \zeta_t - v^1\zeta_x - v^2\zeta_y.$$

Thus

$$\zeta_t + v^1\zeta_x + v^2\zeta_y - v^3 = 0.$$

This is called the *kinematic* condition on the free surface.

This collection of equations for gravity waves on a free surface is known as Euler's equations for waves on the surface of an inviscid, incompressible fluid with irrotational flow in the region $\mathcal{D} = \{(x, y, z) : 0 \le z \le h + \zeta(x, y, t)\}$. They are

$$\Delta\varphi = 0, \qquad 0 \le y \le h + \zeta,$$

$$\zeta_t + \varphi_x\zeta_x + \varphi_y\zeta_y = \varphi_z \qquad \text{on } S, \tag{2.2}$$

$$\varphi_t + \frac{1}{2}|\nabla\varphi|^2 + g\,z = 0 \qquad \text{on } S, \tag{2.3}$$

$$\varphi_z = 0 \qquad \text{on } z = 0.$$

Here, φ is the velocity potential of the flow, and $\zeta(x, y, t)$ the displacement of the fluid surface from equilibrium. We have neglected surface tension. The second equation is known as the *kinematic equation*; the third equation is Bernoulli's equation. At rest, the fluid lies in the region $0 \le z \le h$; g is the acceleration due to gravity. The free surface is denoted by $S = \{(x, y, z) : z = h + \zeta(x, y, t)\}$.

The two physical constants in the theory are g and h. Let c denote a characteristic velocity (e.g., the velocity of a gravity wave); then h/c is a characteristic time. We introduce dimensionless variables

$$(x, y, z) = h(x', y', z'), \qquad t = ht'/c, \qquad \varphi = ch\varphi'.$$

Equation (2.3) now becomes

$$\varphi'_{t'} + \frac{1}{2}(\nabla'\varphi')^2 + \lambda\,\zeta = 0, \qquad \lambda = \frac{gh}{c^2}, \tag{2.4}$$

where λ is the inverse square of the *Froude* number. The other equations in Euler's system are unchanged under the rescaling. From now on we drop the primes and understand that we are working in nondimensional variables.

The Euler equations are invariant under the one parameter subgroup of Galilean boosts along the x axis, given by

$$(x', y', t') = (x - ct, y, t), \qquad \mathbf{v}'(x', y', t') = \mathbf{v}(x, y, t) - (c, 0).$$

The velocity potential, however, is determined only up to a function of time. Thus the Galilean boosts on the velocity potential are given by

$$\varphi'(x', y', t') = \varphi(x, y, t) - cx + q(t).$$

Under these Galilean boosts,

$$\frac{\partial \varphi'}{\partial t'} + \frac{1}{2}(\nabla' \varphi')^2 = \frac{\partial \varphi}{\partial t} + \frac{1}{2}(\nabla \varphi)^2 + q'(t) - \frac{1}{2}c^2. \tag{2.5}$$

The result follows by direct calculation, noting that

$$\frac{\partial}{\partial t'} = \frac{\partial}{\partial t} + c\frac{\partial}{\partial x}, \qquad \frac{\partial}{\partial x'} = \frac{\partial}{\partial x}.$$

PROPOSITION 2.1. *Suppose the solutions of Euler's equations are stationary in a Galilean frame moving with speed c. Then* $\zeta_{t'} = \varphi'_{t'} = 0$, *and, choosing* $q(t) = c^2 t$, *the conditions on the free surface are* (*dropping the primes*)

$$\varphi_x \zeta_x = \varphi_y, \qquad \frac{\varphi_x^2 + \varphi_y^2}{2} + \lambda\, \zeta = \frac{c^2}{2}. \tag{2.6}$$

Proof. By (2.5) the Bernoulli equation in the moving frame is

$$\varphi'_{t'} + \frac{1}{2}(\nabla' \varphi')^2 + \lambda \zeta' = q'(t') - \frac{1}{2}c^2.$$

As $x \to \pm\infty$, $\zeta' \to 0$ while $(\nabla' \varphi')^2 \to c^2$. Moreover, $\varphi'_{t'} = 0$ by the assumption of stationarity. These conditions force the choice $q' = c^2$, and the result follows. The kinematic equation in the moving frame is immediate. ∎

PROPOSITION 2.2. *Let* $\mathbf{v}$ *be a divergence-free vector field in a domain* $\mathcal{D}$. *There is a unique orthogonal decomposition, known as the Weyl–Hodge decomposition,*

$$\mathbf{v} = \mathbf{w} + \nabla \varphi, \tag{2.7}$$

$$\Delta \varphi = 0, \quad \varphi_\nu = \mathbf{v} \cdot \nu; \qquad \operatorname{div} \mathbf{w} = 0, \quad \mathbf{w} \cdot \nu = 0. \tag{2.8}$$

The proof is left to the reader.

3. Poisson structures. Let M be a C^∞ manifold of dimension n, and let $F, G \in C^\infty(M)$. A bilinear form $\{F, G\}$ is said to be a *Poisson bracket* if

- $\{F, G\} = -\{G, F\}$;
- $\{F, GH\} = \{F, G\}H + G\{F, H\}$;
- $\{\{F, G\}, H\} + \{\{G, H\}, F\} + \{\{H, F\}, G\} = 0$.

The second property implies that the Poisson bracket is a derivation in each of its entries. Hence any $H \in C^\infty(M)$ generates a vector field X_H, called a *Hamiltonian* vector field on M, defined by $X_H F = \{H, F\}$. The Hamiltonian vector field X_H generates a flow on M; if x^i are a set of local coordinates on M, then the time evolution of the x^i on that chart is given by the ordinary differential equations

$$\dot{x}^i = \{H, x^i\}.$$

Due to the fact that the bracket acts as a derivation on each of its entries, we may represent a Poisson bracket in the form

$$\{F, G\} = \sum_{j,k=1}^{n} W^{jk} \frac{\partial F}{\partial x^j} \frac{\partial G}{\partial x^k},$$

where $W^{jk}(x)$ is a skew-symmetric matrix.

If $\det W \neq 0$, then it is easily seen that n must be even. A classical theorem of Darboux states that in this case it is always possible to find a set of local coordinates, called *canonical* coordinates q^i, p^i $(1 \leq i \leq n/2)$, in which the Poisson brackets take the form

$$\{F, G\} = \sum_{j=1}^{n} \frac{\partial F}{\partial p^j} \frac{\partial G}{\partial q^j} - \frac{\partial F}{\partial q^j} \frac{\partial G}{\partial p^j}.$$

A manifold with a Poisson bracket is called a *Poisson manifold*; if the brackets are nondegenerate, the manifold is called a *symplectic* manifold. On a symplectic manifold, the Hamiltonian flow takes the form

$$\dot{q}^i = \frac{\partial H}{\partial p^i}, \qquad \dot{p}^i = -\frac{\partial H}{\partial q^i}.$$

In this paper we shall restrict ourselves to the case in which M is a linear vector space with an inner product $\langle\ ,\ \rangle$, and we shall write the Poisson brackets in the form

$$\{F, G\} = \langle \nabla F, J_x \nabla G \rangle,$$

where J_x is a skew-symmetric linear transformation on M and ∇F is the gradient of the function F. The gradient is characterized as follows. Differentiating $F(x(t))$ along a curve $x(t)$ on M, we have

$$\frac{d}{dt} F = \langle \nabla F, \dot{x} \rangle.$$

If J_x is nonsingular, then the Poisson brackets are nondegenerate and have locally a canonical system of coordinates. In many problems of physical interest, however, the Poisson brackets are degenerate, i.e., $\det J_x = 0$. For example, in the study of rigid motions about a fixed point in $\mathbb{R}^3$, the Poisson bracket is

$$\{F, G\} = \langle \nabla F, \mathbf{x} \times \nabla G \rangle. \tag{3.1}$$

The operator $J_{\mathbf{x}}$ is defined by $J_{\mathbf{x}}\mathbf{v} = \mathbf{x} \times \mathbf{v}$; hence $\ker(J_{\mathbf{x}}) = \mathbb{R}\mathbf{x}$.

The bracket (3.1) vanishes for all regular functions G whenever F is spherically symmetric. Such a function F is called a *Casimir*. It is invariant under any Hamiltonian flow generated by these brackets.

Any Poisson bracket on an odd-dimensional manifold must be degenerate and therefore have Casimirs. The bracket (3.1) is an example of a noncanonical Poisson bracket.

The formalism of Poisson brackets and Hamiltonian flows can be extended to infinite dimensions—for example, in the study of continuum mechanics—although a number of technical difficulties arise. In particular, Poisson structures play a useful role in the theory of the Euler equations for an incompressible fluid. Two important such brackets are the Poisson bracket introduced by Arnold [3, 4, 5] in his study of incompressible fluids on fixed domains, and the Poisson bracket implicit in Zakharov's fundamental discovery [18] of the Hamiltonian structure of the Euler equations of gravity waves.

3.1. Arnold's Poisson brackets. Arnold observed that Euler's equations for an incompressible fluid in a fixed domain $\mathcal{D}$ are directly analogous to his equations for rigid body motion and that they have a Hamiltonian structure with the Hamiltonian and Poisson brackets given respectively by

$$H = \iiint_{\mathcal{D}} \frac{1}{2}\mathbf{v}\cdot\mathbf{v}\, d^3\mathbf{x} \tag{3.2}$$

and

$$\{F, G\} = \iiint_{\mathcal{D}} \frac{\delta F}{\delta \mathbf{v}} \cdot \left(\operatorname{curl} \mathbf{v} \times \frac{\delta G}{\delta \mathbf{v}}\right) d^3\mathbf{x}. \tag{3.3}$$

Here, F and G are functionals on $\mathcal{L}_\sigma$ with gradients in $\mathcal{L}_\sigma$. The gradient of F is $\delta F/\delta \mathbf{v}$, the Euler–Lagrange derivative of F with respect to $\mathbf{v}$. For example, $\frac{\delta H}{\delta \mathbf{v}} = \mathbf{v}$. The operator $J_{\mathbf{v}}$ in this case is

$$J_{\mathbf{v}}\mathbf{w} = P_\sigma(\operatorname{curl} \mathbf{v} \times \mathbf{w}).$$

Let us show that (2.1) are the Hamiltonian equations generated by (3.2) and (3.3). We have

$$\dot{F} = \iiint_{\mathcal{D}} \frac{\delta F}{\delta \mathbf{v}} \cdot \mathbf{v}_t\, d^3\mathbf{x},$$

$$\{H, F\} = \iiint_{\mathcal{D}} \frac{\delta H}{\delta \mathbf{v}} \cdot \left(\operatorname{curl} \mathbf{v} \times \frac{\delta F}{\delta \mathbf{v}}\right) d^3\,\mathbf{x} = \iiint_{\mathcal{D}} \frac{\delta F}{\delta \mathbf{v}} \cdot (\mathbf{v} \times \operatorname{curl} \mathbf{v})\, d^3\,\mathbf{x}.$$

The Hamiltonian flow $\dot{F} = \{H, F\}$ implies that

$$\iiint_{\mathcal{D}} \frac{\delta F}{\delta \mathbf{v}} \cdot (\mathbf{v}_t + (\operatorname{curl} \mathbf{v}) \times \mathbf{v})\, d^3\mathbf{x} = 0 \tag{3.4}$$

for all admissible F on $\mathcal{L}_\sigma$.

All linear functionals of the form $F_{\mathbf{w}}(\mathbf{v}) = \langle \mathbf{w}, \mathbf{v}\rangle$ are admissible, and the gradient of $F_{\mathbf{w}}$ is the vector $\mathbf{w}$. Therefore $\mathbf{v}_t + (\operatorname{curl} \mathbf{v}) \times \mathbf{v}$ belongs to $\mathcal{L}_\sigma^\perp = \mathcal{L}_\pi$. Hence it is a gradient, and

$$\mathbf{v}_t + (\operatorname{curl} \mathbf{v}) \times \mathbf{v} = \nabla f$$

for some function f. The Euler momentum equations (2.1) follow from this and the vector identity

$$(\operatorname{curl} \mathbf{v}) \times \mathbf{v} = (\mathbf{v}\cdot\nabla)\mathbf{v} - \frac{1}{2}\nabla|\mathbf{v}|^2 \tag{3.5}$$

if we let $f = -p + \frac{1}{2}\nabla|\mathbf{v}|^2$.

Just as in the case of rigid motion, the Arnold bracket is degenerate. This degeneracy is related to the action of the (formal) group of volume preserving diffeomorphisms acting on $\mathcal{D}$. Arnold's Poisson bracket is an example of a *Lie–Poisson* bracket.

3.2. Zakharov's Poisson brackets. In 1968, Zakharov made a striking observation: Euler's equations for *irrotational gravity waves* have a canonical Hamiltonian structure. The Hamiltonian (in nondimensional variables) is

$$H = \frac{1}{2}\iiint_{\mathcal{D}} (\nabla\varphi)^2\, d^3\mathbf{x} + \frac{1}{2}\lambda \iint_{\mathbb{R}^2} \zeta^2(x,y,t)\, d^2\mathbf{x}.$$

The Poisson brackets implicit in Zakharov's observation are the canonical brackets

$$\{F,G\} = \iint_{\mathbb{R}^2} \left(\frac{\delta F}{\delta\varphi}\frac{\delta G}{\delta\zeta} - \frac{\delta F}{\delta\zeta}\frac{\delta G}{\delta\varphi}\right) d^2\mathbf{x};$$

the Hamiltonian flow is then the canonical flow

$$\zeta_t = \frac{\delta H}{\delta\varphi}, \qquad \varphi_t = -\frac{\delta H}{\delta\zeta}.$$

The Hamiltonian H is regarded as a functional of $(\widetilde{\varphi},\, \zeta)$, where $\zeta = \zeta(x,y,t)$ is the height of the free surface and $\widetilde{\varphi} = \varphi|_S$ is the trace of the harmonic function φ on the free surface, with $\varphi_\nu = 0$ on the bottom. The evolution takes place in the space of harmonic functions on $\mathcal{D}$.

Zakharov's result is verified by calculating the gradients of H with respect to ζ and φ. Now

$$\frac{d}{d\varepsilon}H(\varphi,\zeta_\varepsilon)\Big|_{\varepsilon=0} = \iint_{\mathbb{R}^2}\left[\frac{1}{2}(\nabla\widetilde{\varphi})^2 + \lambda\zeta\right]\delta\zeta\, d^2\mathbf{x},$$

where $\nabla\widetilde{\varphi}$ denotes $\nabla\varphi\big|_{\mathbb{R}^2}$. By identification,

$$\frac{\delta H}{\delta\zeta} = \frac{1}{2}(\nabla\widetilde{\varphi})^2 + \lambda\zeta.$$

Similarly,

$$\begin{aligned}\frac{d}{d\varepsilon}H(\widetilde{\varphi}_\varepsilon,\zeta)\Big|_{\varepsilon=0} &= \iiint_{\mathcal{D}} \nabla\varphi\cdot\nabla\delta\varphi\, d^3\mathbf{x}\\ &= -\iiint_{\mathcal{D}} \delta\varphi\Delta\varphi\, d^3\mathbf{x} + \iint_{\Sigma}\delta\varphi\frac{\partial\varphi}{\partial\nu}dS = \iint_{\Sigma}\delta\varphi\frac{\partial\varphi}{\partial\nu}dS,\end{aligned}$$

since φ is harmonic in $\mathcal{D}$ and $\varphi_\nu = 0$ on the bottom.

On the free surface

$$\widetilde{\varphi}_\nu dS = \nabla\widetilde{\varphi}\cdot\frac{(-\zeta_x,-\zeta_y,1)}{\sqrt{1+\zeta_x^2+\zeta_y^2}}\sqrt{1+\zeta_x^2+\zeta_y^2}\,d^2\mathbf{x},$$

so

$$\frac{\delta H}{\delta\widetilde{\varphi}} = \widetilde{\varphi}_z - \widetilde{\varphi}_x\zeta_x - \widetilde{\varphi}_y\zeta_y.$$

The free boundary equations (2.2) and (2.3) are thus precisely the Hamiltonian equations for this system.

Remark. The effects of surface tension can be obtained by simply adding the boundary integral

$$\sigma \iint_{\Sigma} dS$$

to the Hamiltonian, where σ is the coefficient of surface tension and dS is the element of surface area on the free surface S. The inclusion of surface tension leads to an additional term in the Bernoulli equation; when the free surface is a graph $z = \zeta(x, y, t)$, it is

$$\varphi_t + \frac{1}{2}|\nabla\varphi|^2 + g\,z = \sigma\ \mathrm{div}\ \frac{\nabla\zeta}{\sqrt{1+(\nabla\zeta)^2}}, \qquad \nabla\zeta = (\zeta_x, \zeta_y).$$

The potential energy can also be written as the integral of the gravitational potential over the fluid domain, so that the Hamiltonian for gravity waves including the effects of surface tension is

$$H = \iiint_{\mathcal{D}} \left[\frac{(\nabla\varphi)^2}{2} + \lambda\, U_+(\mathbf{x})\right] d^3\mathbf{x} + \sigma \iint_{S} dS, \tag{3.6}$$

where $U_+(\mathbf{x})$ is the gravitational potential, truncated in such a way that the integral over the unbounded domain $\mathcal{D}$ converges. When the fluid is a horizontal layer and the gravity field is constant in the negative z direction, we take $U_+ = (z-1)_+$, where z_+ denotes the function given by z when $z > 0$ and by 0 when $z < 0$. The factor g has been absorbed into the pure parameter λ.

4. Free boundary flows with vorticity. Free boundary value flows with vorticity, with both gravitational forces and surface tension included, are generated by the Hamiltonian

$$H = \iiint_{\mathcal{D}} \mathcal{E}\, d^3\mathbf{x} + \sigma \iint_{\Sigma} dS, \qquad \mathcal{E} = \frac{\mathbf{v}\cdot\mathbf{v}}{2} + \lambda\, U_+(\mathbf{x}). \tag{4.1}$$

The corresponding Poisson brackets are [15]

$$\{F, G\} = \iiint_{\mathcal{D}} \frac{\delta F}{\delta \mathbf{v}} \cdot \left(\mathrm{curl}\ \mathbf{v} \times \frac{\delta G}{\delta \mathbf{v}}\right) d^3\mathbf{x} + \iint_{\Sigma} \left(\frac{\delta F}{\delta\varphi}\frac{\delta G}{\delta\Sigma} - \frac{\delta F}{\delta\Sigma}\frac{\delta G}{\delta\varphi}\right) dS, \tag{4.2}$$

where Σ is the free boundary and dS is the element of surface area on Σ.

Admissible functionals are regarded as functions of $\mathbf{v}$ and Σ, the free boundary of $\mathcal{D}$, and their gradients are defined implicitly by the relation

$$\frac{d}{d\varepsilon} F(\mathbf{v}_\varepsilon, \Sigma_\varepsilon)\Big|_{\varepsilon=0} = \iiint_{\mathcal{D}} \frac{\delta F}{\delta \mathbf{v}} \cdot \delta\mathbf{v}\, d^3\mathbf{x} + \iint_{\Sigma} \frac{\delta F}{\delta\Sigma}\delta\Sigma\, dS.$$

Variations with respect to the free surface are restricted to normal variations, in a sense explained below. Admissible functionals F are those for which $\delta F/\delta\mathbf{v}$ is a divergence free vector field. We require that $\iint_{\mathcal{D}} \delta\Sigma dS = 0$, reflecting the fact that only volume preserving variations are allowed. This means that the gradient of a functional with respect to Σ is determined only up to a constant.

Let $\mathcal{L}_d(\mathcal{D})$ be the space of divergence-free L^2 vector fields on $\mathcal{D}$. Let P_1 and P_2 be the orthogonal projections defined by $P_1\mathbf{v} = \mathbf{w}$ and $P_2\mathbf{v} = \nabla\varphi$ in the Weyl–Hodge decomposition.

LEMMA 4.1. *Let*

$$F(\mathbf{v}, \Sigma) = \iiint_{\mathcal{D}} \mathcal{F}(\mathbf{v}, \mathbf{x}) d^3\mathbf{x} + \sigma \iint_{\Sigma} dS$$

be an admissible functional. Then

$$\frac{\delta F}{\delta \mathbf{w}} = P_1 \frac{\delta F}{\delta \mathbf{v}} \in \mathcal{L}^2(\mathcal{D}, d^3\mathbf{x}).$$

The gradients with respect to φ and Σ lie in $\mathcal{L}^2(\Sigma, dS)$ and are given by

$$\frac{\delta F}{\delta \varphi} = \frac{\delta F}{\delta \mathbf{v}}\Big|_{\Sigma} \cdot \nu, \qquad \frac{\delta F}{\delta \Sigma} = \mathcal{F}(\mathbf{v}, \mathbf{x}) + \sigma\kappa\Big|_{\Sigma} \ \text{ mod constant},$$

where κ is the mean curvature function on Σ.

Proof. Applying the Weyl–Hodge decomposition to both $\delta\mathbf{v}$ and $\delta F/\delta\mathbf{v}$ we obtain

$$\left\langle \frac{\delta F}{\delta \mathbf{v}}, \delta\mathbf{v} \right\rangle = \iiint_{\mathcal{D}} \frac{\delta F}{\delta \mathbf{v}} \cdot \delta\mathbf{v}\, d^3\mathbf{x} = \iiint_{\mathcal{D}} P_1 \frac{\delta F}{\delta \mathbf{v}} \cdot \delta\mathbf{w} + P_2 \frac{\delta F}{\delta \mathbf{v}} \cdot \delta\nabla\varphi\, d^3\mathbf{x}.$$

By the uniqueness of the Weyl–Hodge decomposition, we may conclude

$$\frac{\delta F}{\delta \mathbf{w}} = P_1 \frac{\delta F}{\delta \mathbf{v}}, \qquad \frac{\delta F}{\delta \varphi} = P_2 \frac{\delta F}{\delta \mathbf{v}}.$$

Since $\delta F/\delta\mathbf{v}$ is divergence-free, we have, by the divergence theorem,

$$\iiint_{\mathcal{D}} P_2 \frac{\delta F}{\delta \mathbf{v}} \cdot \delta\nabla\varphi\, d^3\mathbf{x} = \iiint_{\mathcal{D}} \frac{\delta F}{\delta \mathbf{v}} \cdot \nabla\delta\varphi\, d^3\mathbf{x} = \iint_{\partial\mathcal{D}} \frac{\delta F}{\delta \mathbf{v}} \cdot \nu\, \delta\varphi\, dS,$$

and the second relation follows.

Let Σ_ε be a one parameter family of surfaces parameterized by a vector valued map

$$\mathbf{X}(u, v, \varepsilon) = \mathbf{X}_0(u, v) + \varepsilon\, \delta\Sigma\, \mathbf{N}(u, v),$$

where $\mathbf{N}$ is the normal vector field to Σ. For ε sufficiently small, the symmetric difference $\mathcal{D}_\varepsilon \Delta \mathcal{D}$ of the domains bounded respectively by Σ_ε and Σ is contained in a tubular neighborhood of Σ. In this neighborhood, the volume element of the 3-space can be written as $d^3\mathbf{x} = dr dS$, where dS is the area element on Σ and dr corresponds to the normal coordinate in the tubular neighborhood. We get

$$\delta \iiint_{\mathcal{D}} \mathcal{F}(\mathbf{v}, \mathbf{x})\, d^3\mathbf{x} = \lim_{\varepsilon\to 0} \frac{1}{\varepsilon} \iiint_{\mathcal{D}_\varepsilon \Delta \mathcal{D}} \mathcal{F}(\mathbf{v}, \mathbf{x})\, d^3\mathbf{x}$$

$$= \iint_{\Sigma} \left(\lim_{\varepsilon\to 0} \frac{1}{\varepsilon} \int_0^{\varepsilon\delta\Sigma} \mathcal{F}(\mathbf{v}, \mathbf{x})\, dr \right) dS = \iint_{\Sigma} \mathcal{F}(\mathbf{v}, \mathbf{x}) \delta\Sigma\, dS.$$

On the other hand, by classical differential geometry,

$$\delta \iint_\Sigma dS = \iint_\Sigma \kappa \delta\Sigma \, dS,$$

where κ is the mean curvature function on Σ, and this completes the proof of Lemma 4.1. □

Let us derive the equations of motion from the Hamiltonian structure. We have

$$\frac{\delta H}{\delta \mathbf{v}} = \mathbf{v}, \qquad \frac{\delta H}{\delta \varphi} = \mathbf{v} \cdot \nu, \qquad \frac{\delta H}{\delta \Sigma} = \mathcal{E}\Big|_\Sigma + \sigma\kappa.$$

From $\dot{F} = \{H, F\}$, we get

$$\iiint_\mathcal{D} \frac{\delta F}{\delta \mathbf{v}} \cdot \mathbf{v}_t \, d^3\mathbf{x} + \iint_\Sigma \frac{\delta F}{\delta \Sigma} \Sigma_t \, dS \tag{4.3}$$

$$= \iiint_\mathcal{D} (\mathbf{v} \times (\operatorname{curl} \mathbf{v})) \cdot \frac{\delta F}{\delta \mathbf{v}} \, d^3\mathbf{x} + \iint_\Sigma \left(\mathbf{v} \cdot \nu \frac{\delta F}{\delta \Sigma} - (\mathcal{E} + \sigma\kappa) \frac{\delta F}{\delta \varphi} \right) dS.$$

Since

$$\iint_\Sigma \mathcal{E} \frac{\delta F}{\delta \varphi} \, dS = \iint_\Sigma \mathcal{E} \frac{\delta F}{\delta \mathbf{v}} \cdot \nu \, dS = \iiint_\mathcal{D} \nabla \mathcal{E} \cdot \frac{\delta F}{\delta \mathbf{v}} \, d^3\mathbf{x}$$

and $\delta F / \delta \mathbf{v}$ is divergence-free, we get from (4.3), using functionals for which $\delta F / \delta \varphi = 0$,

$$\mathbf{v}_t + (\operatorname{curl} \mathbf{v}) \times \mathbf{v} = \nabla(-p + \mathcal{E}), \qquad \Sigma_t = \mathbf{v} \cdot \nu\Big|_\Sigma.$$

The boundary condition on the bottom is $\mathbf{v} \cdot \nu = 0$, where ν is the outward normal.

The first equation, together with (3.5), implies that $\Delta p = -\operatorname{div}(\mathbf{v} \cdot \nabla)\mathbf{v}$. Substituting the two equations above into (4.3), we obtain

$$\iiint_\mathcal{D} \nabla p \cdot \frac{\delta F}{\delta \mathbf{v}} \, d^3\mathbf{x} - \iint_\Sigma \sigma\kappa \frac{\delta F}{\delta \varphi} \, dS = 0$$

for all admissible functionals F. Applying the divergence theorem to the integral over $\mathcal{D}$ we obtain

$$\iint_\Sigma (p - \sigma\kappa) \frac{\delta F}{\delta \varphi} \, dS = 0$$

for all admissible functionals F. But

$$\iint_\Sigma \frac{\delta F}{\delta \varphi} \, dS = \iint_\Sigma \frac{\delta F}{\delta \mathbf{v}} \cdot \nu \, dS = \iiint_\mathcal{D} \operatorname{div} \frac{\delta F}{\delta \mathbf{v}} \, d^3\mathbf{x} = 0,$$

and therefore

$$p\Big|_\Sigma = \sigma\kappa + \text{constant}. \tag{4.4}$$

Thus the Hamiltonian approach yields the dynamic conditions on the free boundary in the case of surface tension [7, 15, 12].

Remark. In the general theory one considers normal variations of the free surface, whereas in the theory of gravity waves on a free surface over a horizontal bottom, it is customary to use the height of the free surface, ζ. More generally, if the surface Σ is a graph over a fixed manifold $\mathcal{M}$, we may represent Σ by a "height" function ζ defined on $\mathcal{M}$. In that case we refer to $\delta\zeta$ as the "vertical" variation and $\delta\Sigma$ as the "normal" variation.

PROPOSITION 4.2. *Let $\delta\Sigma$ and $\delta\zeta$ denote the normal and vertical variations of a surface Σ in the case when Σ is a graph over a fixed manifold. Let Σ be given in local coordinates by $\phi = 0$, where $\phi = z - \zeta$. Then $\delta\zeta = |\nabla\phi|\,\delta\Sigma$.*

Proof. Let $\mathbf{X} : U \mapsto \mathbb{R}^3$ be a local embedding of Σ in $\mathbb{R}^3$, and let $\mathbf{X}_\varepsilon$ be a one parameter family of embeddings, with $\mathbf{X}_0 = \mathbf{X}$. Then

$$\delta\Sigma = \frac{d}{d\varepsilon}\Big|_{\varepsilon=0} (\mathbf{X}_\varepsilon(u,v)) \cdot \nu.$$

Let Σ be defined by $\phi = 0$, $\phi = z - \zeta$. Then $\mathbf{X}_\varepsilon = (u, v, \zeta_\varepsilon(u,v)$, and

$$\delta\Sigma = \frac{d}{d\varepsilon}\Big|_{\varepsilon=0} \begin{pmatrix} u \\ v \\ \zeta_\varepsilon(u,v) \end{pmatrix} \cdot \nu = \begin{pmatrix} 0 \\ 0 \\ \delta\zeta \end{pmatrix} \cdot \frac{\nabla\phi}{|\nabla\phi|} = \frac{\delta\zeta}{|\nabla\phi|}. \qquad \square$$

5. Variational principles for traveling waves. The Hamiltonian structure of the equations for gravity waves can be used to obtain variational principles for traveling waves—waves of constant speed and shape. Such a wave is a stationary solution of the Hamiltonian system in a Galilean frame moving with the wave; thus the wave is a critical point for the Hamiltonian, computed in such a reference frame. We apply the method here to the general case of gravity waves on a horizontal surface. The variational principle for irrotational flows given below appears to be new.

A variational approach, if successful, would permit a global treatment of the existence of traveling waves by the direct methods of the calculus of variation, but so far, the existence of traveling waves for potential flows of low amplitude has been proved by perturbation methods. The first existence theorems were given independently for periodic wave trains by Levi-Civita [14] and Struik [17] in the case of finite depth. The existence of the solitary wave, which is a more difficult problem, was first proved by Friedrichs and Hyers [10], since the bifurcation problem in this case is a singular perturbation problem (see the discussion by Sattinger [16]). These authors used conformal mapping techniques. A dynamical systems approach to the existence of traveling waves has been developed by Kirchgässner [13]; Amick and Toland [2] have shown that periodic wave trains tend to a solitary wave in the limit as the period tends to infinity.

In the direct method, one first uses compactness properties of the functional to obtain a minimum from a minimizing sequence. In general, this guarantees only a weak solution of the associated Euler–Lagrange equations. In many cases, these are elliptic equations, and it is possible to prove sufficient regularity of the weak solution to show that in fact it is a classical solution to the problem. (See Alt and Caffarelli [1] for functionals of Friedrichs' type.) For the present, we simply indicate the method for the problems discussed here in the theorems below.

THEOREM 5.1. *Euler's equations for gravity waves are the Euler–Lagrange equations for the functional*

$$\mathcal{H}(\varphi,\zeta)=\iint\limits_{\mathcal{D}_\zeta}\left[\frac{1}{2}\left[(\nabla\varphi)^2-1\right]+\lambda(y-1)_+\right]d^2\mathbf{x}\,, \tag{5.1}$$

where

$$y_+=\begin{cases}0, & y\le 0,\\ y, & y\ge 0,\end{cases}$$

$$\mathcal{D}_\zeta=\{(x,y)\,:\,-\infty<x<\infty,\ 0\le y\le 1+\zeta(x)\},$$

and the minimum is taken over all functions φ for which

$$\iint\limits_{\mathcal{D}}\left[(\varphi_x-1)^2+\varphi_y^2\right]\,d^2\mathbf{x}<+\infty.$$

If (φ,ζ) is a local minimum of $\mathcal{H}$, then φ is harmonic on the interior of $\mathcal{D}_\zeta$; if ζ is C^1 and $\varphi\in H^2(\mathcal{D})$, then the kinematic and Bernoulli equations hold on the free surface.

Remark. The Hamiltonian (5.1) is the renormalization of the Hamiltonian in the moving frame. By carrying out the integration in y we obtain

$$\iint\limits_{\mathcal{D}}(y-1)_+\,d^2\mathbf{x}=\frac{1}{2}\int_{-\infty}^{\infty}\zeta^2\,dx;$$

thus $\mathcal{H}$ can also be written

$$\mathcal{H}(\varphi,\zeta)=\iint\limits_{\mathcal{D}}\frac{1}{2}\left[(\nabla\varphi)^2-1\right]\,d^2\mathbf{x}+\frac{\lambda}{2}\int_{-\infty}^{\infty}\zeta^2(x)\,dx.$$

If $\varphi\in H^2(\mathcal{D})$ and $\zeta\in C^1$, then $\nabla\varphi$ has an L^2 trace on the boundary $y=\zeta$, and Stokes' theorem applies.

Proof. Let (φ,ζ) be a minimizer of $\mathcal{H}$ and suppose that ζ is C^1 and $\varphi\in H^2(\mathcal{D})$. Let $(\varphi_\varepsilon,\zeta_\varepsilon)$ be a one parameter family of admissible functions and denote the corresponding domains by $\mathcal{D}_\varepsilon$. By the calculations in section 3.2 we have

$$\begin{aligned}\delta\mathcal{H}(\delta\varphi,\delta\zeta)&=\frac{\partial H(\varphi_\varepsilon,\zeta_\varepsilon)}{\partial\varepsilon}\Big|_{\varepsilon=0}\\ &=-\iint\limits_{\mathcal{D}}\Delta\varphi\delta\varphi\,d^2\mathbf{x}+\oint\limits_{\partial\mathcal{D}}\varphi_\nu\delta\varphi\,ds+\int_{-\infty}^{+\infty}\left[\frac{1}{2}(\nabla\varphi)^2-\frac{1}{2}+\lambda\zeta\right]\delta\zeta\,dx\\ &=0\end{aligned}$$

for all admissible $\delta\varphi$, $\delta\zeta$.

Since the bottom is fixed, $\varphi_\nu=0$ on $y=0$. We first restrict ourselves to variations for which $\delta\zeta=\delta\varphi\big|_S=0$. Then the double integral must vanish for a set of variations $\delta\varphi$ which are dense in $L^2(\mathcal{D})$; it follows that φ is harmonic in the interior of $\mathcal{D}$. As before, $\varphi_\nu ds=\nabla\varphi\cdot(-\zeta_x,1)dx=(\varphi_y-\zeta_x\varphi_x)dx$, and so

$$\delta\mathcal{H}=\int_{-\infty}^{+\infty}\left[\left(\frac{(\nabla\varphi)^2-1}{2}+\lambda\zeta\right)\delta\zeta+(\varphi_y-\varphi_x\zeta_x)\,\delta\varphi\right]dx.$$

Setting first $\delta\zeta=0$ and letting $\delta\varphi$ vary on Σ, we obtain the kinematic equation on the free surface. Therefore the second term always vanishes. Now allowing $\delta\zeta$ to vary, we see that Bernoulli's equation holds on Σ. ∎

6. A variational problem with constraint. Whereas Friedrich's paper shows that Bernoulli's equation is not obtained when the functional J is minimized with respect to the stream function, Constantin, Sattinger, and Strauss showed in [7] that traveling gravity waves in the rotational case are obtained as extremals of a variational problem for the stream function with constraints. The existence of traveling water waves with vorticity was established in [8] for the periodic case. In a recent Ph.D. thesis at Brown University, V. Hur [11] has constructed solitary waves with nonzero vorticity. Some of their qualitative properties were investigated in [6].

In the irrotational case we have the following theorem.

THEOREM 6.1. *Define the set of admissible functions $\mathcal{K} = \{\psi, \zeta\}$ with the following properties:*

$$\text{(i)} \qquad \int_{-\infty}^{+\infty} \zeta(x)dx = m, \quad \int_{-\infty}^{+\infty} \zeta^2\, dx < \infty,$$

$$\text{(ii)} \qquad \psi(x,0) = 0, \quad \psi(x, 1+\zeta(x)) = 1,$$

$$\text{(iii)} \qquad \iint\limits_{\mathcal{D}} \left[\psi_x^2 + (\psi_y - 1)^2\right] d^2\mathbf{x} < +\infty.$$

Consider the variational problem

$$\lambda = \inf_{\mathcal{K}} \frac{\iint_{\mathcal{D}} \left[(\nabla\psi)^2 - 1\right] d^2\mathbf{x}}{\int_{-\infty}^{+\infty} \zeta^2\, dx}.$$

Let (ψ, ζ) be a minimizer in $\mathcal{K}$ of the above variational principle. Then ψ is harmonic in the interior of $\mathcal{D}$. If ζ is C^1 and $\psi \in H^2(\mathcal{D})$, then the Bernoulli equation is satisfied on the free surface $\psi = 1$. Hence minima of the above variational problem provide an irrotational flow for the gravity wave problem.

Proof. Let (ψ, ζ) be a minimizer, and let $\psi_\varepsilon, \zeta_\varepsilon$ be a family of admissible functions with $\psi_0 = \psi$ and $\zeta_0 = \zeta$. Then $J(\varepsilon) \geq 0$ and $J(0) = 0$, where

$$J(\varepsilon) = \iint\limits_{\mathcal{D}_\varepsilon} \left[(\nabla\psi_\varepsilon)^2 - 1\right]\, d^2\mathbf{x} - \lambda \int_{-\infty}^{+\infty} \zeta_\varepsilon^2\, dx.$$

Then $\delta J(\delta\psi, \delta\zeta) = 0$ for all admissible variations, where

$$\begin{aligned}\delta J &= \iint\limits_{\mathcal{D}} 2\nabla\psi \cdot \nabla\, \delta\psi\, d^2\mathbf{x} + \int_{-\infty}^{+\infty} \left[(\nabla\psi)^2 - 1 - 2\lambda\zeta\right] \delta\zeta\, dx \\ &= -2 \iint\limits_{\mathcal{D}} \Delta\psi\, \delta\psi\, d^2\mathbf{x} + 2 \oint\limits_{\partial\mathcal{D}} \delta\psi\psi_\nu\, ds + \int_{-\infty}^{+\infty} \left[(\nabla\psi)^2 - 1 - 2\lambda\zeta\right] \delta\zeta\, dx.\end{aligned}$$

The integral over the bottom of the flow domain vanishes, since $\psi_\nu = 0$ there. On the free surface (see $\delta(2)$ [9, p. 65])

$$\delta\psi + \psi_y \delta\zeta = 0.$$

This follows immediately by differentiating the relation $\psi_\varepsilon(x, 1+\zeta_\varepsilon(x)) \equiv 1$ with respect to ε and setting ε equal to zero. Similarly, differentiating the expression $\psi(x, 1+\zeta(x)) \equiv 1$ with respect to x we find that $\psi_x/\psi_y = -\zeta_x$; hence

$$\psi_\nu = \nabla\psi \cdot \nu = \nabla\psi \cdot \frac{\nabla\psi}{||\nabla\psi||} = \frac{(\nabla\psi)^2}{\sqrt{\psi_x^2+\psi_y^2}} = \frac{(\nabla\psi)^2}{|\psi_y|\sqrt{1+\zeta_x^2}}.$$

Hence δJ reduces to

$$\delta J = -2\iint_{\mathcal{D}} \Delta\psi\,\delta\psi\,d^2\mathbf{x} - \int_{-\infty}^{+\infty} \left[(\nabla\psi)^2 + 1 + 2\lambda\zeta\right]\delta\zeta\,dx. \tag{6.1}$$

First restrict the variations to fixed domains, $\delta\zeta = 0$, and the first integral must vanish for all variations $\delta\psi$ which vanish on $\partial\mathcal{D}$. Hence ψ is harmonic in the interior of $\mathcal{D}$, and the double integral vanishes.

We next consider variations of the domain. Since $\int \zeta_\varepsilon\,dx = m$ for all variations, we have $\int \delta\zeta\,dx = 0$; then the condition

$$\int_{-\infty}^{+\infty} ((\nabla\psi)^2 + 1 + 2\lambda\zeta)\delta\zeta\,dx = 0$$

for all such $\delta\zeta$ implies that the integrand is a constant. We therefore have $(\nabla\psi)^2 + 2\lambda\zeta + 1 = C =$ constant on the line; letting $x \to \infty$ and noting that $\zeta \to 0$ while $(\nabla\psi)^2 \to 1$ we see that $C = 2$, and the Bernoulli equation is satisfied. □

Acknowledgment. The results in this paper were obtained during the authors' visit to the Mittag-Leffler Institute in October 2005 in conjunction with the Program on Wave Motion. The authors wish to extend their thanks to the institute for its generous sponsorship of the program, as well as to the organizers for their work.

STEADY PERIODIC CAPILLARY-GRAVITY WAVES WITH VORTICITY*

ERIK WAHLÉN†

Abstract. In this paper we prove the existence of steady periodic two-dimensional capillary-gravity waves on flows with an arbitrary vorticity distribution. The original free-surface problem is first transformed to a second-order quasi-linear elliptic equation with a second-order quasi-linear boundary condition in a fixed domain by a change of variables. We then use local bifurcation theory combined with the Schauder theory of elliptic equations with Venttsel boundary conditions and spectral theory in Pontryagin spaces to construct the solutions. We show that some bifurcation points are simple while others are double, a situation already known to occur in the case of irrotational capillary-gravity waves.

Key words. water waves, vorticity, capillarity, bifurcation theory

1. Introduction.

The mathematical studies of water waves have until recently been mainly restricted to irrotational flows (see, e.g., [8, 12, 16, 31, 38]). While the irrotational setting is regarded as appropriate for waves traveling into still water [19, 27], there are many situations in which it is necessary to take vorticity into account. For example, nonuniform currents generate water flows with vorticity [35, 36, 37] and the effect of a wind blowing in one direction results at first in the creation of capillary waves.

In the last few years there has been an increasing amount of research in the area of water waves with vorticity; see [4, 5] regarding the symmetry of rotational water waves, [14, 23, 24, 39] for questions of uniqueness, and [2, 3, 6, 7, 40] for existence results. However, in all of these recent investigations the surface tension is neglected. It is therefore an interesting task to study the effects of surface tension in the presence of vorticity. The recent paper [41] dealt with the existence of pure capillary waves with vorticity, that is, the force of gravity was neglected. In the present paper we take into account both gravity and capillarity. It is known that the irrotational capillary-gravity wave problem is a single problem in which many different bifurcation phenomena appear. One of the main differences from the theory of pure capillary and gravity waves is the presence of double bifurcation points. Closely connected with this is the existence of secondary bifurcation points. We refer the reader to [8, 20, 33, 34] (finite depth) and [8, 21, 22] (infinite depth) for a detailed presentation of the local bifurcation theory of irrotational capillary-gravity waves. As we shall see, double bifurcation points also occur when vorticity is present. However, we do not fully investigate the structure of the solution set at these points.

The main result of this paper is the proof of the existence of steady periodic capillary-gravity waves for an arbitrary vorticity distribution. The proof is inspired by the approach in [7], but there are several interesting differences. We will first formulate the water wave problem in terms of the stream function. After this we perform

a change of variables which transforms the free-boundary problem into a second-order quasi-linear elliptic equation in a fixed domain. As in [41], one difference to the pure gravity problem is that this elliptic equation has a second-order boundary condition. This means that we cannot use the standard Schauder theory for elliptic equations, but instead have to rely on similar estimates for so-called Venttsel boundary conditions (see [29]). A perhaps more dramatic difference is that the eigenvalue problem associated with bifurcation is not a standard Sturm–Liouville problem. The operator T involved is, however, self-adjoint with respect to an indefinite inner product (see [18]). Unlike the pure capillary case, the operator $T(\lambda)$ is not positive definite for all values of the bifurcation parameter λ. This is the key to why double bifurcation points occur when we also include gravity. After the proof of the main theorem, we investigate the distribution of the bifurcation points and present a necessary and sufficient condition for the existence of double bifurcation points. We also consider what happens as we vary the surface tension and gravity. Finally, at the end of the paper we take a closer look at the interesting special cases of irrotational flows ($\gamma \equiv 0$) and flows with nonzero, constant vorticity.

2. Preliminaries. In this section we present the governing equations for capillary-gravity waves [11, 19]. We consider two-dimensional waves propagating over water with a flat bed. In its undisturbed state the equation for the flat surface is $y = 0$ and the flat bottom is given by $y = -d$ for some $d > 0$. The x-variable represents the direction of propagation and the wavelength is $2\pi/k$, where $k \in \mathbb{R}^+$ is the wave number. The equations of motion are the equation of mass conservation

$$u_x + v_y = 0 \tag{2.1}$$

and Euler's equation

$$\begin{cases} u_t + uu_x + vu_y = -P_x, \\ v_t + uv_x + vv_y = -P_y - g, \end{cases} \tag{2.2}$$

where $P(t, x, y)$ denotes the pressure and g is the gravitational constant. The boundary conditions for capillary-gravity waves are the dynamic boundary condition

$$P = P_0 - \sigma \frac{\eta_{xx}}{(1 + \eta_x^2)^{\frac{3}{2}}} \quad \text{on} \quad y = \eta(t, x), \tag{2.3}$$

P_0 being the constant atmospheric pressure and $\sigma > 0$ being the coefficient of surface tension, as well as the kinematic boundary conditions

$$v = \eta_t + u\,\eta_x \quad \text{on} \quad y = \eta(t, x) \tag{2.4}$$

and

$$v = 0 \quad \text{on} \quad y = -d; \tag{2.5}$$

cf. [19].

We are looking for steady periodic waves traveling at speed $c > 0$, that is, the space-time dependence of the free surface, the pressure, and the velocity field is of the form $(x - ct)$. The map $x - ct \mapsto x$ transforms (2.2)–(2.5) into the stationary problem

$$\begin{cases} (u - c)u_x + vu_y = -P_x \\ (u - c)v_x + vv_y = -P_y - g \end{cases} \quad \text{on} \quad -d < y < \eta(x)$$

and

$$\begin{cases} v = (u-c)\eta_x \quad \text{at} \quad y = \eta(x), \\ P = P_0 - \sigma \frac{\eta_{xx}}{(1+\eta_x^2)^{\frac{3}{2}}} \quad \text{at} \quad y = \eta(x), \\ v = 0 \quad \text{at} \quad y = -d. \end{cases}$$

The equation of mass conservation (2.1) allows us to introduce the (relative) stream function ψ, satisfying $\psi_x = -v$, $\psi_y = u - c$. The kinematic boundary condition then shows that ψ is constant on the free surface, and we determine it uniquely by requiring that the constant value be zero. Field evidence indicates that for waves not near the spilling or breaking state, the propagation speed c of the surface wave is considerably larger than the horizontal velocity u of each individual water particle [28]. It follows that ψ is a strictly decreasing function of y for each fixed x. Let

$$p_0 = \int_{-d}^{\eta(x)} [u(x,y) - c] dy$$

be the relative mass flux—it follows by differentiation, using (2.1) and (2.4), that this expression is independent of $x \in \mathbb{R}$. Then by construction $\psi = -p_0$ on the flat bottom. We can now pose problem (2.1)–(2.5) in terms of ψ:

$$\begin{cases} \psi_y \psi_{xy} - \psi_x \psi_{yy} = -P_x \\ -\psi_y \psi_{xx} + \psi_x \psi_{xy} = -P_y - g \end{cases} \qquad \text{on} \quad -d < y < \eta(x)$$

and

$$\begin{cases} \psi = 0 \quad \text{at} \quad y = \eta(x), \\ P = P_0 - \sigma \frac{\eta_{xx}}{(1+\eta_x^2)^{\frac{3}{2}}} \quad \text{at} \quad y = \eta(x), \\ \psi = -p_0 \quad \text{at} \quad y = -d, \end{cases}$$

where P, ψ, and η are $2\pi/k$-periodic in the x-variable and $\psi_y < 0$.

The vorticity ω is defined by $\omega = v_x - u_y$. The assumption $u < c$ guarantees that ω is a function of ψ, that is, $\omega = \gamma(\psi)$ (see [7]). Thus $\Delta\psi = -\omega = -\gamma(\psi)$. Introduce the function

$$\Gamma(p) = \int_0^p \gamma(-s) ds, \qquad p_0 \le p \le 0,$$

and let $\Gamma_{\min} \le 0$ be its minimum value. Using the equations of motion and the properties of ψ we obtain Bernoulli's law, which states that

$$E = \frac{(c-u)^2 + v^2}{2} + gy + P - \Gamma(-\psi)$$

is constant throughout the fluid. On the free surface we have

$$E = \frac{(c-u)^2 + v^2}{2} + g\eta + P_0 - \sigma \frac{\eta_{xx}}{(1+\eta_x^2)^{\frac{3}{2}}},$$

so that letting $Q = 2(E - P_0 + gd)$ we obtain

$$(\psi_x^2 + \psi_y^2) + 2g(y+d) - 2\sigma \frac{\eta_{xx}}{(1+\eta_x^2)^{\frac{3}{2}}} = Q$$

on the free surface. This condition is equivalent to the dynamic boundary condition.

We have now obtained the following formulation of our problem:

$$\begin{cases} \Delta\psi = -\gamma(\psi) \quad \text{on} \quad -d < y < \eta(x), \\ |\nabla\psi|^2 + 2g(y+d) - 2\sigma\frac{\eta_{xx}}{(1+\eta_x^2)^{\frac{3}{2}}} = Q \quad \text{at} \quad y = \eta(x), \\ \psi = 0 \quad \text{at} \quad y = \eta(x), \\ \psi = -p_0 \quad \text{at} \quad y = -d. \end{cases}$$

The main difficulty with this formulation lies in the fact that η is not known a priori. For this purpose, we make a change of variables due to Dubreil-Jacotin [13]. Since ψ is constant on the free surface and on the bottom and strictly decreasing as a function of y, we choose the new variables $q = x$, $p = -\psi(x, y)$. A domain of one wavelength is then transformed to $R = \{(q, p) \in \mathbb{R}^2 : 0 < q < 2\pi/k,\ p_0 < p < 0\}$. Introducing the height function $h(q, p) = y + d$, we have

$$h_q = \frac{v}{u - c}, \quad h_p = \frac{1}{c - u}.$$

Thus

$$v = -\frac{h_q}{h_p}, \quad u = c - \frac{1}{h_p}, \quad \partial_x = \partial_q - \frac{h_q}{h_p}\partial_p, \quad \partial_y = \frac{1}{h_p}\partial_p.$$

Note also that $\omega = \gamma(-p)$ and that $\eta(x) = h(q, 0) - d$. We obtain the following formulation of the capillary-gravity problem:

$$\begin{cases} (1 + h_q^2)h_{pp} - 2h_p h_q h_{pq} + h_p^2 h_{qq} = -\gamma(-p)h_p^3 \quad \text{in} \quad p_0 < p < 0, \\ 1 + h_q^2 + (2gh - Q)h_p^2 - 2\sigma\frac{h_p^2 h_{qq}}{(1+h_q^2)^{\frac{3}{2}}} = 0 \quad \text{on} \quad p = 0, \\ h = 0 \quad \text{on} \quad p = p_0, \end{cases} \tag{2.6}$$

where h is $2\pi/k$-periodic in the q-variable and $h_p > 0$ throughout $\overline{R}$.

So far we have derived (2.6) from (2.1)–(2.5). We shall now see that it is also possible to derive (2.1)–(2.5) starting with (2.6). Denote the fluid domain

$$D_\eta = \{(x, y) \in \mathbb{R}^2 : -d < y < \eta(x)\}.$$

For the Hölder-parameter $\alpha \in (0, 1)$, let $C^{m+\alpha}_{\text{per}}(\overline{D}_\eta)$ be the space of functions $f : \overline{D}_\eta \to \mathbb{R}$ with Hölder-continuous derivatives of exponent α up to order m, and with period $2\pi/k$ in the x-variable. Similarly, $C^{m+\alpha}_{\text{per}}(\mathbb{R})$ denotes the space of $2\pi/k$-periodic real-valued functions on $\mathbb{R}$ of class $C^{m+\alpha}$. A small modification of the argument in [7] yields the following.

PROPOSITION 2.1. *Problem* (2.6) *is equivalent to* (2.1)–(2.5). *Furthermore, if* $h \in C^{2+\alpha}_{per}(\overline{R})$, *then* $(u, v, \eta) \in C^{1+\alpha}_{per}(\overline{D_\eta}) \times C^{1+\alpha}_{per}(\overline{D_\eta}) \times C^{2+\alpha}_{per}(\mathbb{R})$, *and if* h *is even in the* q*-variable, then* u *and* η *are even in* x *while* v *is odd.*

3. Main result.

THEOREM 3.1. *Let the wave speed* $c > 0$, *the relative mass flux* $p_0 < 0$, *the wave number* $k \in \mathbb{R}^+$, *and the vorticity function* $\gamma \in C^\alpha[0, |p_0|]$, $0 < \alpha < 1$, *be given. Then there exist infinitely many* C^1 *curves of small amplitude traveling wave solutions* (u, v, η) *of* (2.1)–(2.5) *in the space* $C^{1+\alpha}_{per}(\overline{D_\eta}) \times C^{1+\alpha}_{per}(\overline{D_\eta}) \times C^{2+\alpha}_{per}(\mathbb{R})$, *with period* $2\pi/k$, *speed* c, *and relative mass flux* p_0, *satisfying* $u < c$ *throughout the fluid. In*

particular, for sufficiently large numbers $n \in \mathbb{Z}^+$ there exist waves of minimal period $2\pi/(kn)$ with the property that (i) *the wave profile η has precisely one crest and one trough per period of length $2\pi/(kn)$;* (ii) *the wave profile is strictly monotone between crest and trough; and* (iii) *the functions u and η are even, while v is odd.*

Remark.

(i) We would like to point out that the depth varies along the solution continuum.

(ii) In Theorems 3.11 and 4.1, we will present more details about the set of small amplitude solutions.

LEMMA 3.2. *The trivial solutions (parallel shear flows with flat surfaces) $h(q,p) = H(p)$ of* (2.6) *are of the form*

$$H(p) = H(p;\lambda) = \int_0^p \frac{ds}{\sqrt{\lambda + 2\Gamma(s)}} + \frac{Q-\lambda}{2g} = \int_{p_0}^p \frac{ds}{\sqrt{\lambda + 2\Gamma(s)}},$$

where $0 \le -2\Gamma_{min} < \lambda$ and

$$Q(\lambda) = \lambda + 2g \int_{p_0}^0 \frac{dp}{\sqrt{\lambda + 2\Gamma(p)}}.$$

Proof. A solution of the form $H(p)$ satisfies the ordinary differential equation

$$H_{pp} = -\gamma(-p) H_p^3.$$

Integrating gives

$$H_p(p) = (\lambda + 2\Gamma(p))^{-\frac{1}{2}}$$

for $\lambda > -2\Gamma_{\min}$. The surface boundary condition $1 + (2gH(0) - Q)H_p^2(0) = 0$ yields $H(p) = \int_0^p \frac{ds}{\sqrt{\lambda+2\Gamma(s)}} + \frac{Q-\lambda}{2g}$ and the bottom boundary condition $H(p_0) = 0$ gives the expression for Q. ∎

Note that the function $Q(\lambda)$ is strictly convex for $\lambda > -2\Gamma_{\min}$ with $\lim_{\lambda\to\infty} Q'(\lambda) = 1$, respectively, $\lim_{\lambda\to -2\Gamma_{\min}} Q'(\lambda) = -\infty$. It follows that there is a unique $\lambda_0 > -2\Gamma_{\min}$ such that $Q'(\lambda_0) = 0$, that is,

$$\int_{p_0}^0 \frac{dp}{(\lambda_0 + 2\Gamma(p))^{3/2}} = \frac{1}{g}. \tag{3.1}$$

For every $Q > Q(\lambda_0)$ there is exactly one $\lambda > \lambda_0$ satisfying $Q(\lambda) = Q$, while for some Q there is a second solution in $(-2\Gamma_{\min}, \lambda_0)$.

Our goal is to show that the curve of trivial solutions parameterized by λ bifurcates at certain points. To identify these bifurcation points we will use the following tool.

THEOREM 3.3 (see [9]). *Let X and Y be Banach spaces, I an open interval in $\mathbb{R}$ containing λ^*, and $\mathcal{F}\colon I \times X \mapsto Y$ a continuous map with the following properties:*

(i) *$\mathcal{F}(\lambda, 0) = 0$ for all $\lambda \in I$;*

(ii) *$\mathcal{F}_\lambda$, $\mathcal{F}_w$, $\mathcal{F}_{\lambda w}$ exist and are continuous;*

(iii) *$\mathcal{N}(\mathcal{F}_w(\lambda^*, 0))$ and $Y/\mathcal{R}(\mathcal{F}_w(\lambda^*, 0))$ are one-dimensional, with the null space generated by w^*; and*

(iv) $\mathcal{F}_{\lambda w}(\lambda^*, 0)w^* \notin \mathcal{R}(\mathcal{F}_w(\lambda^*, 0))$.

Then there exists a continuous local bifurcation curve $\{(\lambda(s), w(s)) : |s| < \varepsilon\}$ *with* ε *sufficiently small such that* $(\lambda(0), w(0)) = (\lambda^*, 0)$ *and*

$$\{(\lambda, w) \in \mathcal{U} : w \neq 0,\ \mathcal{F}(\lambda, w) = 0\} = \{(\lambda(s), w(s)) : 0 < |s| < \varepsilon\}$$

for some neighborhood $\mathcal{U}$ *of* $(\lambda^*, 0) \in I \times X$. *Moreover, we have*

$$w(s) = sw^* + o(s) \quad \text{in } X,\ |s| < \varepsilon.$$

(v) *If* $\mathcal{F}_{ww}$ *is also continuous, then the curve is of class* C^1.

We will also need a slightly different bifurcation theorem based on the Morse lemma [17].

THEOREM 3.4 (see [30]). *Let* X, Y, *and* I *be as in Theorem* 3.3, *and let* $\mathcal{F}\colon I \times X \to Y$ *be a* C^m*-map with* $m > 2$. *Suppose that for some* $\lambda^* \in I$ *we have*

(i) $\mathcal{F}(\lambda^*, 0) = \mathcal{F}_\lambda(\lambda^*, 0) = 0$;

(ii) $\mathcal{N}(\mathcal{F}_w(\lambda^*, 0))$ *and* $Y/\mathcal{R}(\mathcal{F}_w(\lambda^*, 0))$ *are one-dimensional, with the null space spanned by* w^*;

(iii) $\mathcal{F}_{\lambda\lambda}(\lambda^*, 0) \in \mathcal{R}(\mathcal{F}_w(\lambda^*, 0))$ *and* $\mathcal{F}_{\lambda w}(\lambda^*, 0)w^* \notin \mathcal{R}(\mathcal{F}_w(\lambda^*, 0))$.

Then the set of solutions of $\mathcal{F}(\lambda, w) = 0$ *near* $(\lambda^*, 0)$ *consists of two* C^{m-2} *curves* $\mathcal{C}_1, \mathcal{C}_2$ *intersecting only at* $(\lambda^*, 0)$. *Furthermore,* $\mathcal{C}_1$ *is tangent to the* λ*-axis at* $(\lambda^*, 0)$ *and may be parameterized by* λ:

$$(\lambda, w(\lambda)), \qquad |\lambda - \lambda^*| < \varepsilon;$$

$\mathcal{C}_2$ *may be parameterized by a variable* s, $|s| < \varepsilon$, *as*

$$(\lambda(s), sw^* + w(s)),$$

with $w(0) = w'(0) = 0$, $\lambda(0) = \lambda^*$.

If $\mathcal{F}$ is regular enough, Theorem 3.3 follows as a special case of Theorem 3.4. In order to apply Theorems 3.3 and 3.4, we formulate our problem as an abstract operator equation. Let R be the rectangle $(0, 2\pi/k) \times (p_0, 0)$, let $T = \{p = 0\}$ be the top, and let $B = \{p = p_0\}$ be the bottom of its closure $\overline{R}$, and define the spaces

$$X = \{h \in C^{2+\alpha}_{\text{per}}(\overline{R}) : h = 0 \text{ on } B\},$$
$$Y = C^{\alpha}_{\text{per}}(\overline{R}) \times C^{\alpha}_{\text{per}}(T),$$

where the subscript "per" means periodicity and evenness in the variable q. We also define the subspaces $X_n \subseteq X$ and $Y_n \subseteq Y$ for $n \in \mathbb{N}$, consisting of functions that are $2\pi/(kn)$-periodic. For $n = 0$ we take this to mean that X_n and Y_n consist of functions that are independent of q.

We define the nonlinear operator $\mathcal{G}\colon \mathbb{R} \times X \to Y$ by $\mathcal{G}(Q, h) = (\mathcal{G}_1(Q, h), \mathcal{G}_2(Q, h))$, where

$$\mathcal{G}_1(Q, h) = (1 + h_q^2)h_{pp} - 2h_p h_q h_{pq} + h_p^2 h_{qq} + \gamma(-p)h_p^3$$

and

$$\mathcal{G}_2(Q, h) = 1 + h_q^2 + (2gh - Q)h_p^2 - 2\sigma \frac{h_p^2 h_{qq}}{(1 + h_q^2)^{\frac{3}{2}}}.$$

Then (Q, h) solves (2.6) if and only if $\mathcal{G}(Q, h) = 0$.

In order to apply Theorem 3.3 we introduce the operator $\mathcal{F}(\lambda, w) = \mathcal{G}(Q(\lambda), H(\lambda)+w)$ for $w \in X$ and $\lambda \in I = (-2\Gamma_{\min}, \infty)$. Thus $\mathcal{F}(\lambda, w) = (\mathcal{F}_1(\lambda, w), \mathcal{F}_2(\lambda, w))$, where

$$\begin{aligned}\mathcal{F}_1(\lambda, w) = (1 + w_q^2)(H_{pp} + w_{pp}) - 2(H_p + w_p)w_q w_{pq}\\ +(H_p + w_p)^2 w_{qq} + \gamma(-p)(H_p + w_p)^3\end{aligned}$$

and

$$\mathcal{F}_2(\lambda, w) = 1 + w_q^2 + (2g(H + w) - Q)(H_p + w_p)^2 - 2\sigma\frac{(H_p + w_p)^2 w_{qq}}{(1 + w_q^2)^{\frac{3}{2}}}.$$

We have $\mathcal{F}(\lambda, 0) \equiv 0$ by construction.

The Fréchet derivative of $\mathcal{F}$ with respect to w at $w = 0$ is the pair $\mathcal{F}_w(\lambda, 0) = (\mathcal{F}_{1w}(\lambda, 0), \mathcal{F}_{2w}(\lambda, 0))$, where

$$\begin{aligned}\mathcal{F}_{1w}(\lambda, 0) &= \partial_p^2 + H_p^2\partial_q^2 + 3\gamma(-p)H_p^2\partial_p \quad \text{in } R,\\ \mathcal{F}_{2w}(\lambda, 0) &= 2(g\lambda^{-1} - \lambda^{\frac{1}{2}}\partial_p - \lambda^{-1}\sigma\partial_q^2)\Big|_T,\end{aligned}$$

since $H_p(0) = \lambda^{-\frac{1}{2}}$, so that the linearization of the problem (2.6) at $w = 0$ is $\mathcal{F}_w(\lambda, 0)w = 0$, i.e.,

$$\begin{cases} w_{pp} + H_p^2 w_{qq} + 3\gamma(-p)H_p^2 w_p = 0 \quad \text{in} \quad p_0 < p < 0,\\ gw - \lambda^{\frac{3}{2}}w_p - \sigma w_{qq} = 0 \quad \text{on} \quad p = 0,\\ w = 0 \quad \text{on} \quad p = p_0. \end{cases} \tag{3.2}$$

Introducing $a_\lambda = \{\lambda + 2\Gamma(p)\}^{\frac{1}{2}}$, we can write this in the form

$$\begin{cases} \{a_\lambda^3 w_p\}_p + a_\lambda w_{qq} = 0 \quad \text{in} \quad p_0 < p < 0,\\ a_\lambda^3 w_p + \sigma w_{qq} - gw = 0 \quad \text{on} \quad p = 0,\\ w = 0 \quad \text{on} \quad p = p_0. \end{cases} \tag{3.3}$$

For each $n \in \mathbb{N}$ we let $\mathcal{F}^{(n)}$ be the restriction of $\mathcal{F}$ to $I \times X_n$. Note that $\mathcal{F}^{(n)}(I \times X_n) \subseteq Y_n$.

LEMMA 3.5. *For each fixed λ, the map $\mathcal{F}_w^{(n)}(\lambda, 0)\colon X_n \to Y_n$ is a Fredholm operator of index 0.*

Proof. For a fixed $\lambda \in I$ and $\mu \in \mathbb{R}$, define the operator $S(\mu)\colon X_n \to Y_n$ by

$$\begin{aligned}S_1(\mu) &= \partial_p^2 + H_p^2\partial_q^2 + 3\gamma(-p)H_p^2\partial_p - \mu,\\ S_2(\mu) &= 2(g\lambda^{-1} - \lambda^{\frac{1}{2}}\partial_p - \lambda^{-1}\sigma\partial_q^2 + \mu\partial_p)\Big|_T.\end{aligned}$$

Then the map $\mu \mapsto S(\mu) \in B(X_n, Y_n)$ is continuous and the following estimate holds for some $C = C(\mu) > 0$:

$$\|w\|_X \le C(\|w\|_{C^0(\overline{R})} + \|S(\mu)w\|_Y); \tag{3.4}$$

cf. [29]. It follows at once that for a fixed μ, $S(\mu)$ is semi-Fredholm, that is, it has finite-dimensional null space and closed range. For $\mu > \lambda^{1/2}$ the map $S(\mu)$ is an

isomorphism (see [29]) and therefore has index 0. By continuity of the index, we infer that this is also true for $\mu = 0$, whence the assertion follows. □

For each λ we introduce the inner product

$$\langle (\mathcal{A}_1, \mathcal{B}_1), (\mathcal{A}_2, \mathcal{B}_2) \rangle_Y = \iint_R a^3 \mathcal{A}_1 \mathcal{A}_2 \, dq \, dp + \frac{1}{2} \int_T a^2 \mathcal{B}_1 \mathcal{B}_2 \, dq,$$

where $a = a_\lambda$, on Y. Note that $\mathcal{N} = \mathcal{N}(\mathcal{F}_w^{(n)}(\lambda, 0))$ can be identified with the subspace $\widehat{\mathcal{N}} = \{(\mathcal{A}, \mathcal{B}) \in Y_n : \mathcal{A} \in \mathcal{N}, \, \mathcal{B} = \mathcal{A}|_T\}$ of Y_n. We have the following characterization of the range of $\mathcal{F}_w^{(n)}(\lambda, 0) \colon X_n \to Y_n$.

LEMMA 3.6. *The range of $\mathcal{F}_w^{(n)}(\lambda, 0)$ is given by the orthogonal complement $\widehat{\mathcal{N}}^\perp$ of $\widehat{\mathcal{N}}$ in Y_n with respect to the inner product $\langle \cdot, \cdot \rangle_Y$.*

Proof. Let $(\mathcal{A}, \mathcal{B}) \in Y_n$ belong to the range of $\mathcal{F}_w^{(n)}(\lambda, 0)$, and let $\varphi \in \mathcal{N} = \mathcal{N}(\mathcal{F}_w^{(n)}(\lambda, 0))$. Then

$$\iint_R \mathcal{A} \cdot a^3 \varphi \, dq \, dp + \frac{1}{2} \int_T \mathcal{B} \cdot a^2 \varphi \, dq = 0.$$

Indeed, $(\mathcal{A}, \mathcal{B})$ belongs to $\mathcal{R} = \mathcal{R}(\mathcal{F}_w^{(n)}(\lambda, 0))$ if and only if $\mathcal{A} = a^{-3}\{a^3 v_p\}_p + a^{-2} v_{qq}$ in R, $\mathcal{B} = 2(ga^{-2} v - a v_p - \sigma a^{-2} v_{qq})$ on T. We have

$$\begin{aligned} \iint_R \mathcal{A} \cdot a^3 \varphi \, dq \, dp &= \iint_R \{\{a^3 v_p\}_p + a v_{qq}\} \varphi \, dq \, dp \\ &= \iint_R \{\{a^3 \varphi_p\}_p + a \varphi_{qq}\} v \, dq \, dp + \int_T a^3 \{v_p \varphi - v \varphi_p\} dq \\ &= \int_T a^3 \{v_p \varphi - v \varphi_p\} dq, \end{aligned}$$

where the integral over R vanishes because of the equation satisfied by φ.

On the top we have $2(v_p \varphi - v \varphi_p) = 2 v_p \varphi - 2v(g a^{-3} \varphi - \sigma a^{-3} \varphi_{qq}) = -a^{-1} \mathcal{B} \varphi + 2\sigma a^{-3}(v \varphi_{qq} - v_{qq} \varphi)$. Thus the last integral equals

$$-\frac{1}{2} \int_T a^2 \mathcal{B} \varphi \, dq + \sigma \int_T (v \varphi_{qq} - v_{qq} \varphi) \, dq,$$

where the last term disappears after an integration by parts. Thus $\mathcal{R}(\mathcal{F}_w^{(n)}(\lambda, 0)) \subseteq \widehat{\mathcal{N}}^\perp$. Since $\operatorname{codim} \mathcal{R} = \dim \mathcal{N} = \dim \widehat{\mathcal{N}} = \operatorname{codim} \widehat{\mathcal{N}}^\perp < \infty$ (see [1]), we have $\mathcal{R} = \widehat{\mathcal{N}}^\perp$. □

Note that any function $\varphi \in X_n$ can be naturally identified with an element $\widehat{\varphi} = (\varphi, \varphi|_T) \in Y_n$.

LEMMA 3.7. *Let $0 \neq \varphi \in \mathcal{N}(\mathcal{F}_w^{(n)}(\lambda, 0))$ be of the form $\varphi = W(p) \cos(knq)$, $n \in \mathbb{N}$. Then $\langle \mathcal{F}_{w\lambda}(\lambda, 0) \varphi, \widehat{\varphi} \rangle_Y \neq 0$ and thus $\mathcal{F}_{w\lambda}^{(n)}(\lambda, 0) \varphi \notin \mathcal{R}(\mathcal{F}_w^{(n)}(\lambda, 0))$.*

Proof. Throughout the proof we let $a = a_\lambda$. Let us first calculate $\mathcal{F}_{w\lambda}$. We have

$$\mathcal{F}_{w\lambda}(\lambda, 0) = \left(-a^{-4} \partial_q^2 - 3\gamma a^{-4} \partial_p, 2 \left(a^{-4} \sigma \partial_q^2 - \frac{1}{2} a^{-1} \partial_p - a^{-4} g \right) \Big|_T \right).$$

This yields

$$\begin{aligned} \langle \mathcal{F}_{w\lambda}(\lambda, 0) \varphi, \widehat{\varphi} \rangle_Y = &\iint_R a^3 \varphi \cdot (-a^{-4} \varphi_{qq} - 3\gamma(-p) a^{-4} \varphi_p) \, dq \, dp \\ &+ \int_T a^2 \varphi \cdot (a^{-4} \sigma \varphi_{qq} - (2a)^{-1} \varphi_p - a^{-4} g \varphi) \, dq. \end{aligned}$$

The first term equals

$$(kn)^2 \iint_R a^{-1}\varphi^2 \, dq\, dp$$

due to the cosine. The second term equals

$$-\frac{3}{2}\iint_R a\varphi_p^2 \, dq\, dp - \frac{3(kn)^2}{2}\iint_R a^{-1}\varphi^2 \, dq\, dp + \frac{3}{2}\int_T a\varphi\varphi_p \, dq. \tag{3.5}$$

Indeed, using $a_p = \gamma(-p)a^{-1}$ (by definition) and $(a^3\varphi_p)_p = (kn)^2 a\varphi$ throughout R, we have that

$$\begin{aligned}
&\iint_R \gamma(-p)a^{-1}\varphi\varphi_p \, dq\, dp = \iint_R a_p\varphi\varphi_p \, dq\, dp \\
&= -\iint_R (a\varphi_p^2 + a\varphi\varphi_{pp}) \, dq\, dp + \int_T a\varphi\varphi_p \, dq - \int_B a\varphi\varphi_p \, dq \\
&= -\iint_R a\varphi_p^2 \, dq\, dp - (kn)^2 \iint_R a^{-1}\varphi^2 \, dq\, dp \\
&\quad + 3\iint_R \gamma(-p)a^{-1}\varphi\varphi_p \, dq\, dp + \int_T a\varphi\varphi_p \, dq
\end{aligned}$$

since $\varphi = 0$ on B. We now obtain

$$\iint_R \gamma(-p)a^{-1}\varphi\varphi_p \, dq\, dp = \frac{(kn)^2}{2}\iint_R a^{-1}\varphi^2 \, dq\, dp + \frac{1}{2}\iint_R a\varphi_p^2 \, dq\, dp - \frac{1}{2}\int_T a\varphi\varphi_p \, dq,$$

proving (3.5). The total contribution of the last three terms is

$$-\frac{3}{2}\int_T a\varphi\varphi_p \, dq,$$

due to the boundary condition satisfied by φ on T.

Adding up all terms we find that

$$\langle \mathcal{F}_{w\lambda}(\lambda,0)\varphi, \widehat{\varphi}\rangle_Y = -\frac{(kn)^2}{2}\iint_R a^{-1}\varphi^2 \, dq\, dp - \frac{3}{2}\iint_R a\varphi_p^2 \, dp < 0,$$

so that $\mathcal{F}_{w\lambda}^{(n)}(\lambda,0)\varphi \notin \mathcal{R}(\mathcal{F}_w^{(n)}(\lambda,0))$. □

In order to prove bifurcation, we must investigate the null space of $\mathcal{F}_w(\lambda,0)$. Note that any function w in X can be expanded in a cosine series,

$$w(q,p) = \sum_{n=0}^{\infty} w_n(p)\cos(knq).$$

We thus obtain $\mathcal{F}_w(\lambda,0)w = 0$ if and only if each component w_n satisfies

$$\begin{cases} (a^3 w_n')' = (kn)^2 a w_n, \quad p_0 < p < 0, \\ a^3(0)w_n'(0) = ((kn)^2\sigma + g)w_n(0), \\ w_n(p_0) = 0, \end{cases} \tag{3.6}$$

where $a = a_\lambda$.

To study this spectral problem we introduce the (complex) Pontryagin space (see [1, 18]) $\mathbb{H} = L^2[p_0, 0] \times \mathbb{C}$, with the indefinite inner product

$$[\tilde{u}_1, \tilde{u}_2] = \langle a u_1, u_2 \rangle_{L^2} - \sigma b_1 \overline{b_2},$$

where $\tilde{u}_i = (u_i, b_i) \in \mathbb{H}$, $i = 1, 2$. It is clear that $\mathbb{H}$ is a π_1-space, that is, any maximal negative definite (or negative semidefinite) subspace of $\mathbb{H}$ has dimension one. On $\mathbb{H}$ there is also an associated Hilbert space inner product, given by $\langle \tilde{u}, \tilde{v} \rangle_{\mathbb{H}} = [J\tilde{u}, \tilde{v}]$, where

$$J = \begin{pmatrix} I & 0 \\ 0 & -1 \end{pmatrix}.$$

Define the linear operator T by

$$T\tilde{u} = \big(-a^{-1}(a^3 u')', -a^3(0)\sigma^{-1}u'(0) + g\sigma^{-1}u(0)\big),$$

where we take as domain of definition $D(T) = \{\tilde{u} = (u, b) : u \in H^2[p_0, 0],\ u(p_0) = 0,\ b = u(0)\}$. Then (3.6) is equivalent with the eigenvalue problem $T\tilde{u} = \mu\tilde{u}$ for $\mu = -(kn)^2$. It is clear that $D(T)$ is dense in $\mathbb{H}$ and that T is closed. The identity

$$[T\tilde{u}, \tilde{u}] = \langle a^3 u', u' \rangle_{L^2} - g|u(0)|^2 \in \mathbb{R} \tag{3.7}$$

shows that T is symmetric.

LEMMA 3.8. *T is self-adjoint with discrete spectrum $\Sigma(T)$. Moreover, $0 \in \Sigma(T)$ if and only if $\lambda = \lambda_0$. For $\lambda > \lambda_0$ the operator T is positive with one negative eigenvalue.*

Proof. Note that $(T - \mu I)\tilde{u} = \tilde{f} := (f, b)$ is equivalent to the system of equations

$$\begin{cases} -(a^3 u')' - \mu a u = af, \\ B_1(u) := u(p_0) = 0, \\ B_2(u) := -a^3(0)u'(0) + gu(0) - \mu\sigma u(0) = \sigma b. \end{cases} \tag{3.8}$$

Let u_1 and u_2 be solutions of the equation $-(a^3 u')' - \mu a u = 0$ with initial data $u_1(p_0) = 0$, $u_1'(p_0) = 1$, respectively, $u_2(p_0) = 1$, $u_2'(p_0) = 0$. The characteristic determinant

$$\Delta(\mu) = \begin{vmatrix} B_1(u_1) & B_1(u_2) \\ B_2(u_1) & B_2(u_2) \end{vmatrix}$$

is an entire function of μ. If μ is not a zero of $\Delta(\mu)$, (3.8) is solvable by means of the formula

$$u(p) = c_1 u_1(p) + c_2 u_2(p) + \int_{p_0}^{0} G(p, r, \mu) f(r)\, dr,$$

where G is the Green's function for (3.8) and c_1, c_2 are chosen so that u satisfies the boundary conditions. Clearly, $(u, u(0)) \in D(T)$. On the other hand any zero of $\Delta(\mu)$ is an eigenvalue of T. Since $\mathcal{N}(\mathcal{F}_w(\lambda, 0))$ is finite-dimensional, there exist integers n such that $-(kn)^2$ is not an eigenvalue of T. Thus $\Delta(\mu) \not\equiv 0$ and $\Delta(\mu)$ has only isolated zeros of finite multiplicity. Since T is symmetric and closed, it is self-adjoint with discrete spectrum. The eigenvalues are geometrically simple as an elementary

consequence of the theory of ordinary differential equations. Moreover, since $\mathbb{H}$ is a π_1-space, T has a maximal invariant negative semidefinite subspace which is of dimension one; cf. [18]. Accordingly, it has at least one negative semidefinite eigenvalue. There are two possible cases: either there is a unique real negative semidefinite eigenvalue or there are two complex conjugate negative semidefinite eigenvalues. In the latter case the corresponding eigenspaces are neutral, that is, $[\cdot,\cdot]$ vanishes on each eigenspace. If μ is a nonneutral eigenvalue, we have a decomposition $\mathbb{H} = \mathcal{N} \,[\dot{+}]\, \mathcal{N}^{[\perp]}$, where $\mathcal{N} = \mathcal{N}(T - \mu_- I)$ and $\mathcal{N}^{[\perp]} = \{\tilde{u} \in \mathbb{H} : [\tilde{u}, \mathcal{N}] = 0\}$, as an orthogonal direct sum. Since $\mathcal{R}(T - \mu_- I) \subset \mathcal{N}^{[\perp]}$, it follows that μ is simple. Thus μ can be nonsimple only if it is neutral.

Note that $\Delta(\mu) = -B_2(u_1) = a^3(0)u_1'(0) - g u_1(0) + \mu\sigma u_1(0)$, so that $\Delta(0) = 0$ if and only if

$$\int_{p_0}^{0} \frac{dp}{a^3(p)} = \frac{1}{g}.$$

By (3.1) this is true if and only if $\lambda = \lambda_0$.

For $\lambda > \lambda_0$ we use the Cauchy–Schwarz inequality to conclude that if $0 \neq \tilde{u} \in D(T)$,

$$\begin{aligned} |u(0)|^2 &= \Big|\int_{p_0}^{0} u_p(p)\,dp\Big|^2 = \Big|\int_{p_0}^{0} \frac{a^{3/2}(p)}{a^{3/2}(p)} u_p(p)\,dp\Big|^2 \\ &\leq \int_{p_0}^{0} a^{-3}(p)\,dp \int_{p_0}^{0} a^3(p)|u_p(p)|^2\,dp < \frac{1}{g}\int_{p_0}^{0} a^3(p)|u_p(p)|^2\,dp. \end{aligned}$$

It follows that $[T\tilde{u}, \tilde{u}] > 0$ for nonzero $\tilde{u}$, i.e., T is positive definite. Thus the negative semidefinite eigenvalue is actually negative definite. For any eigenvector $\tilde{u}$ corresponding to the eigenvalue μ, we have

$$\mu[\tilde{u}, \tilde{u}] = [T\tilde{u}, \tilde{u}] > 0.$$

It follows therefore that $\mu < 0$ if and only if μ is of negative definite type. Hence the eigenvalue of negative definite type is the unique negative eigenvalue for $\lambda > \lambda_0$. ∎

Remark. From the above proof it follows that the eigenvalues are always geometrically simple. Moreover, they can only be algebraically nonsimple if they are neutral. As we shall see in section 6, for $\lambda \leq \lambda_0$ one cannot exclude the existence of neutral eigenvalues that are algebraically nonsimple. Nor can one exclude the existence of nonreal neutral eigenvalues.

An immediate corollary of Lemma 3.8 is that for $\lambda > \lambda_0$ the space $\mathcal{N}(\mathcal{F}_w(\lambda, 0))$ is at most one-dimensional. As we shall see in the following lemma it is in general at most two-dimensional.

LEMMA 3.9. *The null space of $\mathcal{F}_w(\lambda, 0)$ is at most two-dimensional.*

Proof. Let $Z = \{\tilde{u} = (u, b) \in H^1[p_0, 0] \times \mathbb{C} : u(p_0) = 0\}$ be endowed with the indefinite inner product $[\tilde{u}_1, \tilde{u}_2]_Z = \langle a^3 u_1', u_2'\rangle_{L^2} - g\, b_1 \overline{b_2}$. Clearly Z is a π_1-space and on the subspace $D(T)$ of Z we have $[\tilde{u}, \tilde{v}]_Z = [T\tilde{u}, \tilde{v}]$. We already know that T has at most one negative semidefinite eigenvalue in $(-\infty, 0]$. Suppose that there are two different positive definite eigenvalues $\mu_1, \mu_2 \leq 0$ and let $\tilde{u}_1$, respectively, $\tilde{u}_2$, be corresponding eigenvectors. Then $[\tilde{u}_i, \tilde{u}_i]_Z = \mu_i[\tilde{u}_i, \tilde{u}_i] \leq 0$ for $i = 1, 2$. Noting that $[\tilde{u}_1, \tilde{u}_2] = 0$, we obtain a two-dimensional negative semidefinite subspace of Z. This is a contradiction. Hence, there is at most one positive definite eigenvalue in $(-\infty, 0]$ and in total at most two nonpositive eigenvalues. ∎

We next present a lemma on the behavior of $\mu_-(\lambda)$ as $\lambda \to \infty$, where $\mu_-(\lambda)$ is the negative definite eigenvalue of $T(\lambda)$.

LEMMA 3.10. *We have $\mu_-(\lambda) \to -\infty$ as $\lambda \to \infty$.*

Proof. As in [41] it can be seen that for each $\lambda > \lambda_0$

$$\mu_- = \max_{[\tilde{u},\tilde{u}]<0} \frac{[T\tilde{u},\tilde{u}]}{[\tilde{u},\tilde{u}]}, \quad \tilde{u} \in D(T).$$

For $n > 0$ let $\lambda \geq n\sigma + n^{-1}g - 2\Gamma_{\min}$. Then $a_\lambda(p) = \sqrt{\lambda + 2\Gamma(p)} \geq \sqrt{n\sigma + n^{-1}g}$. This yields

$$\int_{p_0}^{0} (n^2 a_\lambda |u|^2 + a_\lambda^3 |u_p|^2)\, dp \geq \sqrt{n\sigma + n^{-1}g} \int_{p_0}^{0} (n^2|u|^2 + (n\sigma + n^{-1}g)|u_p|^2)\, dp$$
$$\geq n(n\sigma + n^{-1}g) \int_{p_0}^{0} 2\mathrm{Re}\, u\overline{u}_p\, dp = (n^2\sigma + g)|u(0)|^2$$

for $\tilde{u} \in D(T)$. It follows that if $[\tilde{u},\tilde{u}] < 0$, $\frac{[T\tilde{u},\tilde{u}]}{[\tilde{u},\tilde{u}]} \leq -n^2$. Hence $\mu_-(\lambda) \leq -n^2$. ∎

Before proving Theorem 3.1, we give a theorem which describes what happens at every point $\lambda^* \in I$ where $\mathcal{F}_w(\lambda^*, 0)\colon X \to Y$ has a nontrivial null space. At certain points (cases 1a, 1b, and 2c) we can find the full structure of the solution set of (2.6) close to $(Q(\lambda^*), H(\lambda^*))$, while at others (case 2a) we can only get a partial result. Theorem 3.1 will follow by showing that case 1a occurs for infinitely many points $\lambda^* \in I$. In the next section we will show that all the other cases occur for special values of k and σ (cf. Theorem 4.1 and the remark following the proof of Theorem 4.1).

THEOREM 3.11. *Let $\mathcal{N}$ be the null space of the operator $\mathcal{F}_w(\lambda^*, 0)\colon X \to Y$, and let $(Q^*, H^*) = (Q(\lambda^*), H(\lambda^*))$ be the corresponding point on the curve of trivial solutions in the (Q, h)-variables. By Lemma 3.9 we know that $\mathcal{N}$ is at most two-dimensional.*

1. *Suppose that* $\dim \mathcal{N} = 1$.
   (a) *If $\lambda^* \neq \lambda_0$, then $\mathcal{N}$ is spanned by a function of the form $W(p)\cos(knq)$ with $n \in \mathbb{Z}^+$ (this follows from Lemma 3.8) and there exists a neighborhood $\mathcal{U}$ of (Q^*, H^*) in $\mathbb{R} \times X$, such that the solution set of the equation (2.6) in $\mathcal{U}$ consists of the trivial solution curve, and a curve of nontrivial solutions of minimal period $2\pi/(kn)$, intersecting the trivial solution curve at (Q^*, H^*) transversally.*
   (b) *If $\lambda^* = \lambda_0$, there exists a neighborhood $\mathcal{U}$ of (Q^*, H^*) in $\mathbb{R} \times X$, such that the solution set of (2.6) in $\mathcal{U}$ consists only of the trivial solution curve.*
2. *Suppose that* $\dim \mathcal{N} = 2$.
   (a) *If $\lambda^* \neq \lambda_0$, it follows from Lemma 3.8 that $\mathcal{N}$ is spanned by two functions $\varphi_1(q,p) = W_1(q)\cos(kn_1 q)$ and $\varphi_2(q,p) = W_2(q)\cos(kn_2 q)$ with $0 < n_1 < n_2$.*
      - *If $n_1 \mid n_2$, then the solution set of (2.6) in a neighborhood of (Q^*, H^*) consists of the trivial solution curve, and at least two curves of nontrivial solutions having minimal period $2\pi/(kn_1)$, respectively, $2\pi/(kn_2)$, intersecting the trivial curve at (Q^*, H^*) transversally (and transversally to each other).*
      - *If $n_1 \nmid n_2$, then the solution set of (2.6) in a neighborhood of (Q^*, H^*) consists of the trivial solution curve, and at least one curve of nontrivial solutions having minimal period $2\pi/(kn_2)$, intersecting the trivial curve at (Q^*, H^*) transversally.*

(b) *If $\lambda^* = \lambda_0$, then $\mathcal{N}$ is spanned by the function $\varphi_1(q,p) = H_\lambda(p;\lambda_0)$ and a function $\varphi_2(q,p) = W(p)\cos(knq)$. The solution set of (2.6) in a neighborhood of (Q^*, H^*) consists of the trivial solution curve, and a curve of nontrivial solutions having minimal period $2\pi/(kn)$, intersecting the trivial curve at (Q^*, H^*) transversally.*

Proof.

Case 1a. If $\mathcal{N}$ is one-dimensional and $\lambda \neq \lambda^*$, then $\mathcal{N}$ is spanned by a function $\varphi(q,p) = W(p)\cos(knq)$ for some $n \in \mathbb{Z}^+$. We can then apply Theorem 3.3 to the equation $\mathcal{F}(\lambda, w) = 0$ directly. The regularity conditions (ii) and (v) are obvious, while (iii) and (iv) follow from Lemmas 3.5 and 3.7 with $n = 1$. This provides us with a C^1 curve $(\lambda(s), w(s))$, $|s| < \varepsilon$, of solutions to $\mathcal{F}(\lambda, w) = 0$, with $(\lambda(0), w(0)) = (\lambda^*, 0)$ and $w'(0) = W(p)\cos(knq)$. Since the bifurcation analysis can be carried out in X_n and Y_n (using Lemmas 3.5 and 3.7 with this n), by restricting the bifurcation curve we can assume that the solutions are $2\pi/(kn)$-periodic. These solutions correspond to solutions of (2.6) by the transformations $Q = Q(\lambda)$ and $h = H(\lambda) + w$. Note that since $H_p > 0$ throughout $\overline{R}$ we obtain $h_p > 0$ throughout $\overline{R}$ close to the bifurcation point.

Case 1b. Note that $\mathcal{N}$ is in this case generated by the function $H_\lambda(p;\lambda_0)$. Indeed, differentiating $\mathcal{F}(\lambda, 0) \equiv 0$ gives

$$\begin{aligned} 0 = \mathcal{F}_\lambda(\lambda_0, 0) &= \mathcal{G}_Q(Q(\lambda_0), H(\lambda_0))Q'(\lambda_0) + \mathcal{G}_h(Q(\lambda_0), H(\lambda_0))H_\lambda(\lambda_0) \\ &= \mathcal{G}_h(Q(\lambda_0), H(\lambda_0))H_\lambda(\lambda_0) = \mathcal{F}_w(\lambda_0, 0)H_\lambda(\lambda_0). \end{aligned}$$

Again one can apply Theorem 3.3 to the equation $\mathcal{F}(\lambda, w) = 0$ to obtain a locally unique curve of "nontrivial" solutions (in the sense that $w \neq 0$). However, we will now show that this curve is just a copy of the trivial solution curve. Since Q attains its minimum value at λ_0, there exists for every λ close to λ_0 a point $\tilde{\lambda} \neq \lambda$ with $Q(\tilde{\lambda}) = Q(\lambda)$. Letting $w(\lambda) = H(\tilde{\lambda}) - H(\lambda)$, we see that $(\lambda, w(\lambda))$ maps to $(Q(\lambda), H(\tilde{\lambda})) = (Q(\tilde{\lambda}), H(\tilde{\lambda}))$, so that $\mathcal{F}(\lambda, w(\lambda)) = 0$. By uniqueness, this is the solution curve found by the Crandall–Rabinowitz theorem. From the above, we see that in the original (Q,h)-variables, $(\lambda, w(\lambda))$ corresponds to a point on the trivial solution curve. The reason why we get this copy of the trivial solution curve in the (λ, w)-variables is that the trivial solution curve has a turning point in the (Q,h)-variables. We refer to [40] for a more detailed discussion.

Case 2a. Let $\mathcal{N}$ be generated by the functions φ_1, φ_2 of modes n_1, respectively, n_2, where $0 < n_1 < n_2$ and $n_1 \nmid n_2$. Denote by $\mathcal{F}^{(n_i)}$ the restriction of $\mathcal{F}$ to $I \times X_{n_i}$. By hypothesis $\mathcal{N}(\mathcal{F}_w^{(n_i)}(\lambda^*, 0))$ is spanned by φ_i. By Lemma 3.7 with $n = n_i$ it follows that $\mathcal{F}_{w\lambda}^{(n_i)}(\lambda^*, 0)\varphi_i \notin \mathcal{R}(\mathcal{F}_w^{(n_i)}(\lambda^*, 0))$. Thus we can apply Theorem 3.3 to infer the existence of two bifurcation curves $\mathcal{C}_{n_i,\lambda^*} \subset X_{n_i}$, $i = 1, 2$. These curves are clearly contained in X. Again, we can pass to solutions of (2.6) by letting $Q = Q(\lambda)$ and $h = H(\lambda) + w$.

Suppose that $n_1 \mid n_2$. Then we can apply the same considerations as above to n_2 but not to n_1. Thus we can only infer the existence of the curve $\mathcal{C}_{n_2,\lambda^*}$ containing solutions of mode n_2.

Case 2b. In this case we must have $\mu_+(\lambda_0) = 0$ while $\mu_-(\lambda_0) = -(kn)^2 < 0$. Here μ_+ denotes the smallest positive definite eigenvalue of T. The null space is then two-dimensional and generated by the functions $\varphi_1(q,p) = H_\lambda(p;\lambda_0)$ (see case 1b) and $\varphi_2(q,p) = W(p)\cos(knq)$. By identifying X with a subset of $C^{2+\alpha}(\overline{R}) \times C^{2+\alpha}(T)$ in the canonical way, we have the inner product $\langle \cdot, \cdot \rangle_Y$ on X. The null space $\mathcal{N} = \mathcal{N}(\mathcal{F}_w(\lambda_0, 0))$ can then be decomposed as the orthogonal sum $\mathcal{N} = \mathcal{N}_1 \oplus \mathcal{N}_2$, where

$\mathcal{N}_i$ is the span of φ_i for $i = 1, 2$. The eigenfunction φ_1 comes from the fact that $(Q(\lambda_0), H(\lambda_0))$ is a turning point for the trivial solution curve $(Q(\lambda), H(\lambda))$. In order to avoid the kind of problems that appeared in case 1b, we shall not use the (λ, w)-coordinates.

We define the function

$$g(r, Q, v) = \mathcal{G}(Q(\lambda_0) + Q, H(\lambda_0) + r\varphi_1 + v)$$

for $r, Q \in \mathbb{R}$ and $v \in \mathcal{N}_1^\perp$. Our aim is to apply Theorem 3.4 to the function g, regarding r as the bifurcation parameter. We have to verify properties (i)–(iii) of the theorem. For notational convenience we let $Q_0 = Q(\lambda_0)$ and $H_0 = H(\lambda_0)$. The regularity of g is obvious. We have $g(0,0,0) = 0$ and $g_r(0,0,0) = \mathcal{G}_h(Q_0, H_0)\varphi_1 = \mathcal{F}_w(\lambda_0, 0)\varphi_1 = 0$, so that (i) is satisfied. Furthermore,

$$g_{(Q,v)}(0,0,0)(Q, v) = \mathcal{G}_Q(Q_0, H_0)Q + \mathcal{G}_h(Q_0, H_0)v.$$

Note that $\mathcal{G}_Q(Q_0, H_0) = (0, -H_p^2(\lambda_0)) \in \widehat{\varphi}_2^\perp \backslash \mathcal{R}(\mathcal{F}_w(\lambda_0, 0))$ and thus $\mathcal{R}(g_{(Q,v)}(0,0,0))$ $= \widehat{\mathcal{N}}_1 \oplus \mathcal{R}(\mathcal{F}_w(\lambda_0, 0))$. It follows that $\mathcal{R}(g_{(Q,v)}(0,0,0))$ has codimension one. Moreover, $\mathcal{N}(g_{(Q,v)}(0,0,0)) = \{0\} \times \mathcal{N}_2$, since $\mathcal{G}_Q(Q_0, H_0) \notin \mathcal{R}(\mathcal{F}_w(\lambda_0, 0))$, so that the null space is one-dimensional. This proves (ii). As for (iii), we clearly have $g_{rr}(0,0,0) = \mathcal{G}_{hh}(Q_0, H_0)[\varphi_1, \varphi_1] \in \mathcal{R}(g_{(Q,v)}(0,0,0))$ since $\mathcal{G}_{hh}(Q_0, H_0)[\varphi_1, \varphi_1]$ is independent of q and thus orthogonal to $\widehat{\varphi}_2$. Finally, we have

$$g_{r(Q,v)}(0,0,0)(0, \varphi_2) = \mathcal{G}_{hh}(Q_0, H_0)[\varphi_1, \varphi_2].$$

On the other hand, using that $Q'(\lambda_0) = 0$ we obtain

$$\mathcal{F}_{w\lambda}(\lambda_0, 0)\varphi_2 = \mathcal{G}_{hh}(Q(\lambda_0), H(\lambda_0))[\varphi_1, \varphi_2].$$

By Lemma 3.7, $\langle \mathcal{F}_{w\lambda}(\lambda_0, 0)\varphi_2, \widehat{\varphi}_2 \rangle_Y \neq 0$, so that

$$g_{r(Q,v)}(0,0,0)(0, \varphi_2) \notin \mathcal{R}(g_{(Q,v)}(0,0,0)).$$

This takes care of (iii). We can now conclude that the zero set of g close to the origin consists of two curves $\mathcal{C}_1, \mathcal{C}_2$ intersecting only at the origin, such that $\mathcal{C}_1$ is of the form $(r, Q(r), v(r))$ and $\mathcal{C}_2$ is of the form $(r(s), Q(s), s\varphi_2 + v(s))$, $|s| < \varepsilon$, with $r(0) = Q(0) = Q'(0) = v(0) = v'(0) = 0$. Clearly the first curve is a simply a reparameterization of the trivial solution curve, while the second curve gives all nontrivial solutions near (Q_0, H_0). Thus, even if the null space of $\mathcal{F}_w(\lambda_0, 0)$ is two-dimensional, the point (Q_0, H_0) is in some sense only a simple bifurcation point. The first eigenfunction simply comes from the fact that the trivial solution curve turns at this point. □

We are now ready to prove Theorem 3.1.

Proof of Theorem 3.1. Note that $\mu_-(\lambda)$ is a real-analytic function for $\lambda > \lambda_0$. This is a simple consequence of the fact that, picking an appropriate branch of the square root, $T(\lambda)$ is an analytic family of unbounded operators on $L^2[p_0, 0] \times \mathbb{C}$ and that μ_- is the only eigenvalue in the lower half plane for each $\lambda > \lambda_0$ (cf. [25]). Using Lemma 3.10, we see that for any sufficiently large integer n there exists a $\lambda^* > \lambda_0$ such that $\mu_-(\lambda^*) = -(kn)^2$. Thus, we at least know that there are infinitely many points λ^* such that case 1a of Theorem 3.11 applies.

Proposition 2.1 allows us to pass from solutions of the problem (2.6) to solutions of the water wave problem (2.1)–(2.5). For any mode n-bifurcation curve (that is, with

solutions of minimal period $2\pi/(kn)$), we have $h(q,p) = H(p;\lambda(s)) + sW(p)\cos(knq) + o(s)$ in X along the bifurcation curve close to (Q^*, H^*). It follows that $h_q(q,0) = -knsW(0)\sin(knq) + o(s)$ in $C^{1+\alpha}_{\mathrm{per}}(T)$, while $h_{qq}(q,0) = -(kn)^2 sW(0)\cos(knq) + o(s)$ in $C^{\alpha}_{\mathrm{per}}(T)$. Choosing $q_0 \in (0, \pi/(2kn))$, we can find an ε such that for $0 < s < \varepsilon$, $h_q(q,0) < 0$ for $q \in (q_0, \pi/(kn) - q_0)$, $h_{qq}(q,0) < 0$ for $q \in [0, q_0)$, while $h_{qq}(q,0) > 0$ for $q \in (\pi/(kn) - q_0, \pi]$. Since $h(q,0)$ is even and $2\pi/(kn)$-periodic, it follows that $h_q(0,0) = h_q(\pi/(kn),0) = 0$ and thus by construction $h_q < 0$ in $(0, \pi/(kn))$ for $0 < s < \varepsilon$. Due to the antisymmetry of h_q with respect to $q = \pi/(kn)$, it follows for small positive s that $h_q > 0$ in $(\pi/(kn), 2\pi/(kn))$ and that $h|_T$ is strictly decreasing in $(0, \pi/(kn))$ and strictly increasing in $(\pi/(kn), 2\pi/(kn))$. For small $s < 0$ we have instead that $h|_T$ is strictly increasing in $(0, \pi/(kn))$ and strictly decreasing in $(\pi/(kn), 2\pi/(kn))$. The nodal properties now follow from $\eta = h|_T$. □

Remark. The above result is incomplete in the sense that it doesn't present the full structure of the solution set at the double bifurcation points. What makes a double bifurcation point different from a simple one is the presence of solutions of mixed modes, that is, solutions that do not rise and fall once per period. Such phenomena have been thoroughly studied in the irrotational case (see [20, 21, 22]), and the study of the full structure of the solution set for other vorticity distributions is an interesting problem, but is out of the scope of the present paper.

4. The distribution of the bifurcation points. We know from the previous section that there are only simple bifurcation points for $\lambda > \lambda_0$. In order to find double bifurcation points, we must look in $\lambda < \lambda_0$. The aim of this section is to prove the following theorem, which gives a necessary and sufficient condition for the existence of double bifurcation points.

THEOREM 4.1.

1. *If*

$$\int_{p_0}^{0} a_{\lambda_0}(p) \left(\int_{p_0}^{p} a_{\lambda_0}^{-3}(s)\, ds \right)^2 dp \le \frac{\sigma}{g^2}, \tag{4.1}$$

there are only simple bifurcation points which lie in $\lambda > \lambda_0$, one for each mode $n \in \mathbb{Z}^+$.

2. *If*

$$\int_{p_0}^{0} a_{\lambda_0}(p) \left(\int_{p_0}^{p} a_{\lambda_0}^{-3}(s)\, ds \right)^2 dp > \frac{\sigma}{g^2}, \tag{4.2}$$

there exists for every sufficiently large rational number n_2/n_1, $n_1, n_2 \in \mathbb{Z}^+$, a $k \in \mathbb{R}^+$ such that $\mathcal{F}$ has a double bifurcation point λ^* of mode (n_1, n_2) ($\mathcal{N}(\mathcal{F}_w(\lambda^*, 0))$ is spanned by two solutions of mode n_1, respectively, n_2). If (4.2) holds and $\gamma \le 0$, there exists for an arbitrary rational number $n_2/n_1 > 1$ (and some $k \in \mathbb{R}^+$ depending on n_1, n_2) a double bifurcation point of mode (n_1, n_2).

The proof of this theorem relies on three lemmas.

LEMMA 4.2. *The function μ_- is strictly decreasing for $\lambda > \lambda_0$.*

Proof. We denote $Lu = -(a^3 u_p)_p$, where $a = a_\lambda$, and let $W = W(p;\lambda)$ be defined as a real-analytic curve of solutions to the problem

$$LW = \mu_- aW, \quad W(p_0) = 0, \quad W_p(0) = (g - \mu_-\sigma)\lambda^{-\frac{3}{2}} W(0).$$

Denoting differentiation with respect to λ by a dot, $\dot{}$, we have $\dot{a} = 1/(2a)$. Furthermore,

$$L\dot{W} - \frac{3}{2}(aW_p)_p = \dot{\mu}_- aW + \frac{\mu_-}{2a} W + \mu_- a\dot{W},$$

$$\dot{W}(p_0) = 0,$$

and

$$\dot{W}_p(0) = -\dot{\mu}_-\lambda^{-\frac{3}{2}}\sigma W(0) - \frac{3}{2}(g-\mu_-\sigma)\lambda^{-\frac{5}{2}}W(0) + (g-\mu_-\sigma)\lambda^{-\frac{3}{2}}\dot{W}(0).$$

Multiplying the W equation by $\dot{W}$ and vice versa yields, after integrating,

$$\langle \dot{W}, LW\rangle_{L^2} = \mu_-\langle \dot{W}, aW\rangle_{L^2}$$

and

$$\begin{aligned}&\langle L\dot{W}, W\rangle_{L^2} + \frac{3}{2}\int_{p_0}^0 aW_p^2\,dp - \frac{3}{2}aW_pW\Big|^0\\ &= \dot{\mu}_-\int_{p_0}^0 aW^2\,dp + \int_{p_0}^0 \frac{\mu_-}{2a}W^2\,dp + \mu_-\langle a\dot{W}, W\rangle_{L^2},\end{aligned}$$

where $\langle\cdot,\cdot\rangle_{L^2}$ denotes the $L^2[p_0,0]$ inner product. On the other hand

$$\begin{aligned}\langle \dot{W}, LW\rangle_{L^2} - \langle L\dot{W}, W\rangle_{L^2} &= \int_{p_0}^0 \{-\dot{W}(a^3W_p)_p + (a^3\dot{W}_p)_pW\}dp\\ &= \{-a^3\dot{W}W_p + a^3\dot{W}_pW\}\big|^0.\end{aligned}$$

Combining the last three equations, we obtain

$$\begin{aligned}&\frac{3}{2}\int_{p_0}^0 aW_p^2\,dp - \frac{3}{2}aW_pW|^0\\ &= \dot{\mu}_-\int_{p_0}^0 aW^2\,dp + \int_{p_0}^0 \frac{\mu_-}{2a}W^2\,dp + a^3[\dot{W}_pW - \dot{W}W_p]\Big|^0.\end{aligned}$$

The boundary terms, evaluated at $p=0$, are

$$\begin{aligned}&a^3(\dot{W}_pW - \dot{W}W_p) + \frac{3}{2}aW_pW\\ &= \lambda^{\frac{3}{2}}\Big[-\dot{\mu}_-\lambda^{-\frac{3}{2}}\sigma W - \frac{3}{2}(g-\mu_-\sigma)\lambda^{-\frac{5}{2}}W + (g-\mu_-\sigma)\lambda^{-\frac{3}{2}}\dot{W} - (g-\mu_-\sigma)\lambda^{-\frac{3}{2}}\dot{W}\Big]W\\ &\quad + \frac{3}{2}(g-\mu_-\sigma)\lambda^{-1}W^2\\ &= -\dot{\mu}_-\sigma W^2.\end{aligned}$$

We thus have

$$\dot{\mu}_-[\tilde{W},\tilde{W}] = \dot{\mu}_-\Big(\int_{p_0}^0 aW^2\,dp - \sigma W^2(0)\Big) = -\mu_-\int_{p_0}^0 \frac{1}{2a}W^2\,dp + \frac{3}{2}\int_{p_0}^0 aW_p^2\,dp > 0,$$

so that μ_- is strictly decreasing in view of $[\tilde{W},\tilde{W}] < 0$. □

LEMMA 4.3. *Let $W = W(p;\lambda)$ be the solution of $-(a^3W')' = \mu aW$ with $W(p_0) = 0$ and $W'(p_0) = 1$ for a fixed $\mu \le 0$. Then*

$$B(\lambda) = a_\lambda^3(0)\frac{W'(0;\lambda)}{W(0;\lambda)}$$

is a strictly increasing function of $\lambda \in I$.

Proof. We proceed as in Lemma 4.2 to establish the formula

$$a^3(\dot{W}_p W - \dot{W} W_p) + \frac{3}{2} a W_p W \Big|^0 = \frac{3}{2} \int_{p_0}^0 a W_p^2 \, dp - \mu \int_{p_0}^0 \frac{1}{2a} W^2 \, dp,$$

where the dot denotes differentiation with respect to λ. Noting that the left-hand side is $W^2(0)B'(\lambda)$, the assertion follows. ∎

Note that by continuity, the negative semidefinite eigenvalue $\mu_-(\lambda_0)$ of $T(\lambda_0)$ must be nonpositive. Since $T(\lambda_0)$ has the eigenvalue 0, we either have $\mu_-(\lambda_0) = 0$, in which case $T(\lambda_0)$ has no negative eigenvalues, or $\mu_-(\lambda_0) < 0$, in which case $\mu_+(\lambda_0) = 0$, where $\mu_+(\lambda_0)$ is the first positive definite eigenvalue of $T(\lambda_0)$.

LEMMA 4.4. *If* $\mu_-(\lambda_0) = 0$, *there are no negative eigenvalues of* $T(\lambda)$ *for* $\lambda < \lambda_0$. *If* $\mu_-(\lambda_0) < 0$, *there is a minimal point* $\lambda_1 \in [-2\Gamma_{min}, \lambda_0)$ *such that for each* $\lambda \in I' = (\lambda_1, \lambda_0)$ *there is exactly two negative eigenvalues of* T. *These are the negative definite eigenvalue* μ_- *and the lowest positive definite eigenvalue* μ_+. *Moreover,* μ_- *is a strictly decreasing function of* $\lambda \in I'$, *while* μ_+ *is strictly increasing. If* $\lambda_1 > -2\Gamma_{min}$, *then* $\mu_-(\lambda_1) = \lim_{\lambda \to \lambda_1} \mu_{+/-}(\lambda)$ *and there are no negative eigenvalues for* $\lambda < \lambda_1$. *If* $\mu_-(\lambda_0) < 0$ *and* $\gamma \le 0$, *then* $\lambda_1 > -2\Gamma_{min}$.

Proof. We begin with the first case. Note that μ is an eigenvalue of $T(\lambda)$ if and only if $B(\lambda; \mu) = -\sigma\mu + g$, where B is the function in Lemma 4.3. By Lemma 3.10 and the assumption $\mu_-(\lambda_0) = 0$, every $\mu \le 0$ is an eigenvalue for some $\lambda \ge \lambda_0$. It follows from Lemma 4.3 that $B(\lambda; \mu) < -\sigma\mu + g$ for $\lambda < \lambda_0$. Hence, there are no negative eigenvalues in this region.

In the second case we note that at λ_0 the operator T has two simple nonpositive eigenvalues $\mu_-(\lambda_0) < 0$ and $\mu_+(\lambda_0) = 0$. The fact that $\mu_-(\lambda_0)$ is simple follows from the preservation of total algebraic multiplicity (see [25]) and from the simplicity of $\mu_-(\lambda)$ for $\lambda > \lambda_0$. By analytic perturbation theory it follows that the two eigenvalues can be represented as real-analytic functions μ_- and μ_+ of λ in a neighborhood of λ_0. Using the same argument as in Lemma 4.2, we see that

$$\dot{\mu}[\tilde{W}, \tilde{W}] = -\mu \int_{p_0}^0 \frac{1}{2a} W^2 \, dp + \frac{3}{2} \int_{p_0}^0 a W_p^2 \, dp > 0 \tag{4.3}$$

for $\mu = \mu_{+/-}$. We see from this that μ_- is negative definite and that it is a strictly decreasing function of λ close to λ_0. Similarly μ_+ is a strictly increasing function of λ close to λ_0. Thus $\mu_-(\lambda) < \mu_+(\lambda) < 0$ for $\lambda < \lambda_0$ close to λ_0.

We may now continue μ_- and μ_+ for $\lambda < \lambda_0$ until eventually either (i) we reach $-2\Gamma_{\min}$ or (ii) we reach a point $\lambda_1 > -2\Gamma_{\min}$ such that $\lim_{\lambda \to \lambda_1^+} \mu_-(\lambda) = \lim_{\lambda \to \lambda_1^+} \mu_+(\lambda)$. In the latter case $\mu_-(\lambda_1) = \lim_{\lambda \to \lambda_1^+} \mu_{+/-}(\lambda)$ is neutral and has algebraic multiplicity two. Note that it follows from (4.3) that $\dot{\mu}_{+/-}(\lambda)$ diverges at λ_1. Proceeding as for $\mu_-(\lambda_0) = 0$, we see that there are no negative eigenvalues for $\lambda < \lambda_1$.

If $\gamma \le 0$, it can be shown (see [40]) that $\lim_{\lambda \to \infty} B(\lambda; \mu) = \infty$, while $B(\lambda; \mu) \to 0$ as $\lambda \to -2\Gamma_{\min}$ for every $\mu < 0$. Consequently, every negative μ is an eigenvalue of $T(\lambda)$ for some $\lambda > -2\Gamma_{\min}$. It follows that $\lambda_1 > -2\Gamma_{\min}$, since otherwise there would exist a μ with $\lim_{\lambda \to -2\Gamma_{\min}} \mu_-(\lambda) \le \mu \le \lim_{\lambda \to -2\Gamma_{\min}} \mu_+(\lambda)$, which was never an eigenvalue of $T(\lambda)$. ∎

Remark. In section 6 we will see examples with $\mu_-(\lambda_0) = 0$ as well as $\mu_-(\lambda_0) < 0$. In the latter case we will show that both $\lambda_1 = -2\Gamma_{\min}$ and $\lambda_1 > -2\Gamma_{\min}$ can happen. Thus all the alternatives in Lemma 4.4 are possible.

Proof of Theorem 4.1. Since the eigenfunction corresponding to the eigenvalue 0 at λ_0 is

$$W(p) = \int_{p_0}^{p} a_{\lambda_0}^{-3}(s)\, ds,$$

with $W(0) = 1/g$ (cf. (3.6)), we see that the integral condition in the statement of the theorem corresponds to $[\tilde{W}, \tilde{W}] \leq 0$, respectively, $[\tilde{W}, \tilde{W}] > 0$. In the first case the eigenvalue 0 is of negative semidefinite type, that is, $\mu_-(\lambda_0) = 0$, while in the second case 0 is of positive definite type, that is, $\mu_-(\lambda_0) < 0$ and $\mu_+(\lambda_0) = 0$.

Suppose that the first case holds, that is, $\mu_-(\lambda_0) = 0$. The first statement in Theorem 4.1 is then a direct consequence of Lemma 4.2, Lemma 4.4, and the fact that the bifurcation points for $\lambda > \lambda_0$ are all simple.

Suppose instead that the second case holds, that is, $\mu_-(\lambda_0) < 0$. With μ_- and μ_+ as in Lemma 4.4, we then have $\mu_-(\lambda)/\mu_+(\lambda) \to \infty$ as $\lambda \to \lambda_0^-$. Hence there exists for every sufficiently large rational number n_2/n_1 a point $\lambda^* < \lambda_0$ with $\mu_-(\lambda^*) = (n_2/n_1)^2 \mu_+(\lambda^*)$. Letting $k = \sqrt{|\mu_+(\lambda^*)|}/n_1$, we obtain $\mu_+(\lambda^*) = -(kn_1)^2$ and $\mu_-(\lambda^*) = -(kn_2)^2$. Thus λ^* is a mode (n_1, n_2)-bifurcation point.

If in the second case $\lambda_1 > -2\Gamma_{\min}$, where λ_1 is as in Lemma 4.4, then $\mu_-(\lambda)/\mu_+(\lambda) \to 1$ as $\lambda \to \lambda_1^+$, so that $\mu_-(\lambda)/\mu_+(\lambda)$, $\lambda > \lambda_1$, ranges through all real numbers greater than 1. Hence, there are bifurcation points of all modes (n_1, n_2), $n_1, n_2 \in \mathbb{Z}^+$, with $n_2 > n_1$. In particular, if $\gamma \leq 0$, this is the case. □

Remark. Theorem 4.1 shows that case 2a of Theorem 3.11 can occur, both with $n_1 \mid n_2$ and $n_1 \nmid n_2$. Case 1b occurs, for example, when (4.1) holds, while case 2b occurs if (4.2) holds and we take $k = \sqrt{|\mu_-(\lambda_0)|}/n$ for an arbitrary $n \in \mathbb{Z}^+$. Thus all the cases in Theorem 3.11 are possible.

5. On the limiting cases $g \to 0$ and $\sigma \to 0$.

5.1. The case $g \to 0$. We now investigate what happens if we consider g and σ as parameters. First we consider for a fixed $\sigma > 0$ what happens as $g \to 0$. Note that λ_0 is defined by (3.1), and that by letting $g \to 0$ we obtain

$$\int_{p_0}^{0} \frac{dp}{(\lambda_0 + 2\Gamma(p))^{3/2}} \to \infty$$

and thus $\lambda_0 \to -2\Gamma_{\min}$. Furthermore, it is easy to see that $Q(\lambda) \to \lambda$. Thus, at a formal level we recover the results in [40] on bifurcation for pure capillary waves, where the bifurcation parameter is Q and T is positive definite for every $\lambda > -2\Gamma_{\min}$. In the case of pure capillary waves there are only simple bifurcation points.

5.2. The case $\sigma \to 0$. If we instead fix $g > 0$ and let $\sigma \to 0$, we see that the value of λ_0 doesn't change. Note that for each $\mu \leq 0$, the function $W = W(p; \mu, \lambda)$ satisfying

$$\begin{cases} -(a^3 W')' = \mu a W, \quad p_0 < p < 0, \\ W(p_0) = 0, \qquad W'(p_0) = 1 \end{cases} \tag{5.1}$$

has the property $W(0) > 0$. By continuous dependence on parameters, it follows that for each compact subset K of I and $R > 0$, there is an $\varepsilon > 0$ and a $\delta > 0$ such that $W(0; \mu, \lambda) \neq 0$ and $\langle aW, W \rangle_{L^2} / |W(0)|^2 \geq \delta$ for $\mu \in [-R, 0] + i[-\varepsilon, \varepsilon]$ and $\lambda \in K$. In $[\lambda_0, \infty)$ we already know that the negative definite eigenvalues are real and satisfy

$\mu_-(\lambda) \le \mu_-(\lambda_0)$. Hence, for each $\varepsilon > 0$ and $R > 0$ there is a neighborhood U of $-R \le \operatorname{Re}\mu \le 0$, $\operatorname{Im}\mu = 0$ such that for $\lambda \ge -2\Gamma_{\min} + \varepsilon$ and σ sufficiently small there are no negative semidefinite eigenvalues in U.

For sufficiently small σ we are clearly in the second situation described in Lemma 4.4. We now prove that $\lambda_1 \to -2\Gamma_{\min}$ as $\sigma \to 0$. Indeed, if $L = \limsup_{\sigma\to 0}\lambda_1 > -2\Gamma_{\min}$, we obtain for each $k > 0$ the existence of a sequence $\lambda_j \to \lambda^* > -2\Gamma_{\min}$ and $\sigma_j \to 0$ such that $-k^2$ is a positive definite eigenvalue of $T(\lambda_j)$. The corresponding eigenfunctions solve

$$\begin{cases} (a_{\lambda_j}^3 W_j')' = k^2 a_{\lambda_j} W_j, \quad p_0 < p < 0, \\ a_{\lambda_j}^3(0) W_j'(0) = (k^2\sigma_j + g) W_j(0), \\ W_j(p_0) = 0. \end{cases}$$

Letting $j \to \infty$ we obtain a solution of the eigenvalue problem

$$\begin{cases} -(a_{\lambda^*}^3 W')' = \mu a_{\lambda^*} W, \quad p_0 < p < 0, \\ a_{\lambda^*}^3(0) W'(0) = g W(0), \\ W(p_0) = 0, \end{cases} \tag{5.2}$$

with $\mu = -k^2$. This would mean that for each $k > 0$ there is a $\lambda^* \in [L, \lambda_0]$ such that $-k^2$ is an eigenvalue of the above problem. This is clearly not possible since it is known that (5.2) has a unique nonpositive eigenvalue μ for each $-2\Gamma_{\min} < \lambda \le \lambda_0$ and that $\mu(\lambda)$ is a continuous function of λ in this interval.

To summarize, as $\sigma \to 0$ there is a family of intervals $I_\sigma \subset I$ and real numbers R_σ such that $I_\sigma \to I$ and $R_\sigma \to -\infty$ as $\sigma \to 0$ and for $\lambda \in I_\sigma$ with $\lambda \le \lambda_0$ the nonpositive part of the spectrum of T consists of the eigenvalues μ_- and μ_+ with $\mu_- \le R_\sigma \le \mu_+$, while for $\lambda \ge \lambda_0$ the nonpositive part of the spectrum just consists of $\mu_- \le R_\sigma$. Thus at a formal level we recover the results [7], where the bifurcation points are given by the $\lambda^* \in I$ such that $\mu = -(kn)^2$ is an eigenvalue of (5.2). The eigenvalue problem (5.2) has one negative eigenvalue for each $\lambda \in (-2\Gamma_{\min}, \lambda_0)$ (and none in $\lambda > \lambda_0$) and the negative eigenvalue is an increasing function of λ in this interval. This curve of eigenvalues is simply the limit of the smallest positive definite eigenvalue of T for $\lambda < \lambda_0$ as $\sigma \to 0$.

6. Examples.

6.1. Irrotational flow. We will now take a closer look at irrotational flows, $\gamma \equiv 0$. In this case $\Gamma_{\min} = 0$ and the eigenvalue problem is, for $\lambda > 0$,

$$\begin{cases} \lambda W'' = (kn)^2 W \quad \text{in} \quad p_0 < p < 0, \\ \lambda^{3/2} W'(0) = ((kn)^2\sigma + g) W(0), \\ W(p_0) = 0. \end{cases}$$

Letting W satisfy the boundary condition at p_0 and $W_p(p_0) \ne 0$, we get $W(p) = C\sinh\left(\frac{kn(p-p_0)}{\sqrt{\lambda}}\right)$. Thus the condition for $-(kn)^2$ to be an eigenvalue is that

$$kn\lambda\cosh\Big(\frac{kn|p_0|}{\sqrt{\lambda}}\Big) = ((kn)^2\sigma + g)\sinh\Big(\frac{kn|p_0|}{\sqrt{\lambda}}\Big),$$

that is,

$$f(kn;\lambda) := \frac{(kn)^2\sigma + g}{kn\lambda}\tanh\Big(\frac{kn|p_0|}{\sqrt{\lambda}}\Big) = 1.$$

The depth corresponding to uniform flow is $d = |p_0|/\sqrt{\lambda}$ and $\lambda_0 = (g|p_0|)^{2/3}$. Using the integral condition in Theorem 4.1 with $a_{\lambda_0}(p) = \lambda_0^{1/2}$, it is easy to see that $\sigma_0 = 1/3(g|p_0|^4)^{1/3}$ is the unique value of σ for which 0 is a neutral eigenvalue of T at λ_0. For $\sigma > \sigma_0$ the eigenvalue 0 at λ_0 is negative definite, while it is positive definite for $\sigma < \sigma_0$. Note that $f(x;\lambda) \to \infty$ as $x \to \infty$ for each $\lambda > 0$, while $f(x;\lambda)$ is a strictly decreasing function of λ with $f(x;\lambda) \to \infty$ uniformly as $\lambda \to 0$. It follows that if $\sigma \geq \sigma_0$, the operator $T(\lambda)$ has no negative eigenvalues for $\lambda < \lambda_0$, while if $\sigma < \sigma_0$, we are in the second situation described in Lemma 4.4 with $\lambda_1 > 0$, and $T(\lambda)$ has no negative eigenvalues for $\lambda < \lambda_1$. This could also be seen directly from Lemma 4.4, since $\gamma \leq 0$.

The uniform flow corresponding to the bifurcation point λ^* has the velocity components $(c - u^*, v^*) = (\sqrt{\lambda^*}, 0)$, since

$$H(p;\lambda^*) = \frac{p - p_0}{\sqrt{\lambda^*}}.$$

We thus obtain the dispersion relation [19, 28] for linearized small amplitude waves traveling on a uniform current of velocity $(u^*, 0)$:

$$c - u^* = \sqrt{\frac{(kn)^2\sigma + g}{kn}\tanh(knd)}.$$

This relation was obtained for a fixed p_0. However, for any real $d > 0$ we can choose $c - u^*$ according to the above dispersion relation. Setting $|p_0| = d(c - u^*)$, this will in principle yield a curve of solutions having minimal period $2\pi/(kn)$ bifurcating at $\lambda^* = c - u^*$. The problem is that we may be in case 2a of Theorem 3.11. The bifurcation point is simple or double according to whether or not there exists an $m \in \mathbb{Z}^+$ such that m gives the same intrinsic wave speed $c - u^*$ as n. If furthermore $n \mid m$, we cannot tell if there are solutions of minimal period $2\pi/(kn)$.

Let us now try to relate our results in the irrotational case with the work of Jones [20]. In [20] the bifurcation parameter is the speed c and d is held fixed, while $|p_0|$ is allowed to vary. Furthermore, the horizontal speed u of the trivial flow is taken to be zero. For every $n \in \mathbb{Z}^+$ a bifurcation point is obtained at

$$c_n^2 = f(kn) := \frac{(kn)^2\sigma + g}{kn}\tanh(knd),$$

and c_n is double or simple depending upon whether there is an $m \in \mathbb{Z}^+$ as above with $c_n = c_m$. If $\sigma/gd^2 \geq 1/3$, the function $f(x)$, $x \geq 0$, is strictly increasing with the minimum value gd at 0. In this case all bifurcation points are simple. If $\sigma/gd^2 < 1/3$, the function f has a single minimum at some point $x_0 > 0$, is strictly decreasing between 0 and x_0, and is strictly increasing in $x > x_0$. It follows that there is some $x_1 > x_0$ with $f(x_1) = f(0) = gd$. For every $x \in (0, x_0)$ there is an $x' \in (x_0, x_1)$, depending continuously on x, with $f(x') = f(x)$. Moreover, as $x \to 0$ we have $x' \to x_1$. Thus we can always choose x' such that $x'/x \in \mathbb{Q}$. In this way it is always possible to find a double bifurcation point (for some wave number) if $\sigma/gd^2 < 1/3$.

The condition on σ/gd^2 is useful also in our setting, but it needs some explaining. Replacing c by $\lambda = c - u$, we obtain precisely the same bifurcation points. However, since we let the depth vary, while holding p_0 fixed, the conditions $\sigma/gd^2 < 1/3$ and $\mu_-(\lambda_0) < 0$ are related, but the correspondence is not one-to-one. What is true is that $\mu_-(\lambda_0) < 0$ if and only if $\sigma/gd_0^2 < 1/3$, where d_0 is the depth corresponding to

the trivial solution at λ_0. This follows from expressing $|p_0|$ in terms of d_0 and g and substituting this in the formula for σ_0. If we start with any bifurcation point λ^* such that $\sigma/gd^2 \geq 1/3$, it follows that $\lambda_0 = (g|p_0|)^{2/3} = (gd\sqrt{\lambda^*})^{2/3} < \lambda^*$. Hence, the bifurcation point λ^* is in this case simple. Note, however, that it does not follow that $\mu_-(\lambda_0) = 0$ for the point λ_0 on our corresponding trivial solution curve (it is easy to construct a counterexample). If $\sigma/gd^2 < 1/3$ and we choose kn with $\lambda^* = f(kn) < gd$, then $\lambda^* < \lambda_0$. Hence, $\mu_-(\lambda_0) < 0$ in this case.

6.2. Constant vorticity. In the case of constant vorticity $\gamma \neq 0$, the substitution

$$W(p) = \frac{2\gamma}{\sqrt{\lambda + 2\gamma p}} W_0\Big(\frac{\sqrt{\lambda + 2\gamma p}}{\gamma}\Big)$$

transforms the differential equation (3.6) into $W_0'' = (kn)^2 W_0$. We infer that

$$W(p) = \frac{1}{\sqrt{\lambda + 2\gamma p}} \sinh\Big(\frac{kn(\sqrt{\lambda + 2\gamma p} - \sqrt{\lambda + 2\gamma p_0})}{\gamma}\Big).$$

The boundary condition at $p = 0$ is then $f(kn; \lambda) = 1$, where

$$f(x;\lambda) := \frac{x^2\sigma + g + \gamma\sqrt{\lambda}}{x\lambda} \tanh\Big(\frac{2x|p_0|}{\sqrt{\lambda} + \sqrt{\lambda + 2\gamma p_0}}\Big), \quad x \geq 0.$$

Note that $\lim_{x\to\infty} f(x;\lambda) = \infty$ for each $\lambda > -2\Gamma_{\min}$. As in the irrotational case, there is a σ_0 such that 0 is a neutral eigenvalue at λ_0 exactly for $\sigma = \sigma_0$. We discern between the following two cases.

Case 1. Suppose that $\gamma < 0$. In this case $\Gamma_{\min} = 0$ and for $x^2\sigma + g + \gamma\sqrt{\lambda} > 0$ the function f is strictly decreasing in λ. Moreover, we have $f(x;\lambda) \to \infty$ uniformly as $\lambda \to 0$. It follows that the situation is as in the case of $\gamma \equiv 0$, that is, if $\sigma \geq \sigma_0$, there are no negative eigenvalues for $\lambda < \lambda_0$, while if $\sigma < \sigma_0$, we have $\lambda_1 > 0$ and there are no negative eigenvalues for $\lambda < \lambda_1$.

Case 2. Suppose instead that $\gamma > 0$. In this case we have $\Gamma_{\min} = \gamma p_0$ so that f is defined for $\lambda > 2\gamma|p_0|$. The function $f(x;\lambda)$ is now strictly decreasing in λ for all $x \geq 0$ and the limit as $\lambda \to 2\gamma|p_0|$ is

$$f(x;0) = \frac{\sigma x^2 + g + \gamma\sqrt{2\gamma|p_0|}}{2x\gamma|p_0|} \tanh\left(\sqrt{\frac{2|p_0|}{\gamma}}x\right).$$

If $\sigma \geq \sigma_0$, the situation is exactly as before. Suppose instead that $\sigma < \sigma_0$. If the minimum value of $f(x;0)$ is greater than one, then as earlier $\lambda_1 > -2\Gamma_{\min}$ and to the left of λ_1 the operator $T(\lambda)$ has no negative eigenvalues. However, if $\min f(x;0) \leq 1$, then $\lambda_1 = -2\Gamma_{\min}$ so that for each $\lambda \in (-2\Gamma_{\min}, \lambda_0)$ the operator $T(\lambda)$ has two negative eigenvalues. Both alternatives can be achieved by varying σ while keeping the other variables fixed.

The trivial flow corresponding to λ^* has the velocity components $(c - u^*, v^*) = (\sqrt{\lambda^*} + \gamma y, 0)$ because $u_y = -\gamma$. Note that

$$H(p;\lambda^*) = \frac{\sqrt{\lambda^* + 2\gamma p} - \sqrt{\lambda^* + 2\gamma p_0}}{\gamma}.$$

From the definition of p_0 we infer that $\sqrt{\lambda^*}d - \frac{\gamma}{2}d^2 = |p_0|$ and thus

$$d = \frac{2|p_0|}{\sqrt{\lambda^*} + \sqrt{\lambda^* + 2\gamma p_0}}.$$

For $y = 0$ we obtain the dispersion relation

$$c - u_0^* = \frac{\gamma}{2kn}\tanh(knd) + \sqrt{\frac{(kn)^2\sigma + g}{kn}\tanh(knd) + \frac{\gamma^2}{4(kn)^2}\tanh^2(knd)},$$

where u_0^* is the speed of the trivial flow at the surface. This is the dispersion relation for linearized small-amplitude waves traveling on a linearly sheared current of constant vorticity γ.

Acknowledgment. The author is grateful to the referees for suggestions which significantly improved the paper.

MULTISCALE ANALYSIS BY Γ-CONVERGENCE OF A ONE-DIMENSIONAL NONLOCAL FUNCTIONAL RELATED TO A SHELL-MEMBRANE TRANSITION*

NADIA ANSINI†, ANDREA BRAIDES‡, AND VANDA VALENTE§

Abstract. We study the asymptotic behavior of one-dimensional functionals associated with the energy of a thin nonlinear elastic spherical shell in the limit of vanishing thickness (proportional to a small parameter) ε and under the assumption of radial deformations. The functionals are characterized by the presence of a nonlocal potential term and defined on suitable weighted functional spaces. The shell-membrane transition is studied at three different relevant scales. For each we give a compactness result and compute the Γ-limit. In particular, we show that if the energies on a sequence of configurations scale as $\varepsilon^{3/2}$, then the limit configuration describes a (locally) finite number of transitions between the undeformed and the everted configurations of the shell. We also highlight a kind of "Gibbs phenomenon" by showing that nontrivial optimal sequences restricted between the undeformed and the everted configurations must have energy scaling of at least $\varepsilon^{4/3}$.

Key words. Γ-convergence, multiscale analysis, shell theory, membrane theory, relaxation, energy minimization, Gibbs phenomenon

1. Introduction.

It is well known that a spherical shell under zero loads can assume at least two configurations: the trivial reference configuration and the everted configuration, as they are both stable solutions of the equilibrium problem. The existence of everted shapes was first proved by Antman [1] for thick spherical shells. Later, the analysis concerning the eversion of thin shells was carried out from the theoretical and numerical points of view by Podio-Guidugli et al. [20] and Geymonat, Rosati, and Valente [15, 16].

The energy functional corresponding to the axially symmetric deformations of a spherical cap, without applied loads, may be written as

$$F_\varepsilon(u) = \varepsilon^2 \int_0^1 \theta^3 (u'(\theta))^2 \, d\theta + \int_0^1 \frac{1}{\theta^3} \left(\int_0^\theta \varphi^3 (u^2(\varphi) - 1) \, d\varphi \right)^2 d\theta \,.$$

The unknown u, which is a function of the normalized polar angle θ, is related to the slope of the deformed middle surface of the cap with respect to the initial spherical shape, and ε is the thinness parameter of the shell (for the derivation of the model

and physical interpretation of the variable, see the pioneering papers by Reiss [21], Bauer, Reiss, and Keller [2], and Podio-Guidugli et al. [20]; see also the functional approach introduced by Berger [4] for the mathematical study of the thin elastic plate buckling).

In [20, 15, 16], under suitable boundary conditions, it has been proved that, beside the trivial stable solution $u = 1$, for ε small enough there exists a second stable solution, namely, the everted stressed solution. The sequence of everted configurations tends toward an unstressed configuration ($u = -1$) that can be described as the reflection of the cap reference configuration. More recently, the problem has been further investigated. The existence of infinitely many stable solutions for the limit problem has been predicted, and several numerical experiments have been proposed by Geymonat and Leger [14].

Although the problem has been carefully studied in [20, 15, 16] for ε small, the asymptotic analysis of F_ε has remained an open problem, and it is the object of the present work, analyzed using the notation and techniques of variational calculus.

To describe the asymptotic behavior of F_ε we first focus on sequences (u_ε) such that $F_\varepsilon(u_\varepsilon) = O(1)$. In that case we prove that (u_ε) is locally weakly compact in $L^1(0,1)$, and sequences giving the optimal lower bound may oscillate between the values -1 and 1. This behavior is described by the Γ-limit F^0 (see the next section for the precise form of the limit) that not only captures these oscillations but also shows that the nonlocal character of the functional is maintained in the limit. Minimizing sequences are responsible for folding effects, which are also observed for flat membranes. The analytical reconstruction of the shell surface texture could allow us to both understand the material elastic properties and study the interactions between the two surfaces.

It must be noted that the Γ-limit F^0 coincides with the lower-semicontinuous envelope of the functional

$$G(u) = \int_0^1 \theta^{-3} \left(\int_0^\theta (u^2 - 1)\varphi^3 \, d\varphi \right)^2 d\theta,$$

with respect to the local weak L^1-convergence, and that minimizers of this functionals are all functions with $|u| = 1$ a.e. In terms of recovery sequences, we note that they may develop oscillations, but the occurrence of these is due to a nonlocal effect (see the example in Remark 3).

The minimum value for the Γ-limit F^0 is 0 and is achieved exactly on all functions u with $|u| \leq 1$. This large class of minimizers justifies the analysis at finer scales. We show that the next meaningful scale occurs when $F_\varepsilon(u_\varepsilon) = O(\varepsilon^{3/2})$. If this is the case, then we show that such a (u_ε) is strongly precompact in $L^1(0,1)$, its limits u are locally piecewise constant in $(0,1)$, and $|u(\theta)| = 1$ a.e. We describe this behavior by showing that the Γ-limit of the scaled energies $\varepsilon^{-3/2} F_\varepsilon$ on those functions takes the form

$$F^{3/2}(u) = c_0 \sum_{\theta \in S(u)} \theta^3,$$

where we denote by $S(u)$ the set of discontinuities of u (see Theorem 3.3).

The mechanical interpretation of this energetic asymptotic description is that minimal states of the energies F_ε subjected to boundary conditions will be approximately described for ε small by a mixture of undeformed and everted configurations,

the transitions between which are such as to minimize the energy $F^{3/2}$. A similar analysis can be performed for suitably scaled forcing terms (in which case the corresponding forcing term must be added to $F^{3/2}$).

The formal analogies with the corresponding functionals of the gradient theory of phase transitions

$$H_\varepsilon(u) = \varepsilon^2 \int_0^1 \theta^3 (u'(\theta))^2 \, d\theta + \int_0^1 \theta^3 (u^2(\theta) - 1)^2 \, d\theta$$

must be noted. Upon a normalization factor, the functionals $\varepsilon^{-1} H_\varepsilon$ also Γ-converge to $F^{3/2}$. Apart from the different scaling ε^{-1}, this analogy does not extend to the details of the proof. First, it must be noted that the compactness properties for functions with $F_\varepsilon(u_\varepsilon) = O(\varepsilon^{3/2})$ are much more difficult to prove by the cancellations that may occur in the integral $\int_0^\theta \varphi^3 (u_\varepsilon^2 - 1) \, d\varphi$ owing to the fact that $u_\varepsilon^2 - 1$ may change sign. Second, the way the constant c_0 is computed involves some optimal transitions that exhibit a sort of *Gibbs phenomenon*: even though their limit takes only the value ± 1, these transitions must take values external to the interval $[-1, 1]$.

In the final section, we show that this Gibbs phenomenon is substantial: if we impose the constraint $|u_\varepsilon| \le 1$ onto a sequence (u_ε) converging to u, then the values $\varepsilon^{-3/2} F_\varepsilon(u_\varepsilon)$ cannot converge to the value $F^{3/2}(u)$, and they must even diverge. We show that with this additional constraint the correct scaling is $\varepsilon^{-4/3}$. The scaled energies still converge to a phase-transition functional, but this time in a nonlocal form (see Theorem 4.2).

We believe that the techniques developed here can be adapted to other transition problems in nonlinear elasticity, leading to the study of functionals with similar nonlocal terms. Moreover, our analysis can be generalized to different weighted spaces. For these reasons we report our results with reference to a more general weighted functional (details follow in the next section).

Finally, we point out that functionals F_ε are derived from the scaled energy

$$\frac{1}{\varepsilon} \int_{\mathcal{C}_\varepsilon} \left(\mu |\mathbf{D}|^2 + \frac{\lambda}{2} (\operatorname{trace} \mathbf{D})^2 \right) dx,$$

where $\mathcal{C}_\varepsilon$ parameterizes a thin spherical shell of thickness ε, $\mathbf{D} = \frac{1}{2}(\nabla \mathbf{u} + \nabla \mathbf{u}^T) + \frac{1}{2}(\nabla \mathbf{u} \nabla \mathbf{u}^T)$ is the *nonlinear deformation tensor* related to the deformation $\mathbf{u}$ of the shell, and λ, μ are the Lamé constants (we refer, e.g., to [20] for the precise derivation). In this way, our paper may be partly related to recent works on dimension reduction for thin structures by the use of Γ-convergence (see, e.g., Le Dret and Raoult [17] for the limit analysis of thin shells, Friesecke, James, and Müller [13] and Conti and Maggi [10] for the analysis under various scaling, Ben Belgacem et al. [3] for complex patterns in recovery sequences, and Braides, Fonseca, and Francfort [9] for an example of application of the localization methods of Γ-convergence to thin structures).

1.1. Analytical description of the results. We conclude this introduction with a brief analytical description of the results in a more general setting, where we replace the weight θ^3 with a more general weight $\rho(\theta)$. We use the techniques of Γ-convergence for the asymptotic analysis of our functionals; for the definition, notation, and comprehensive study of Γ-convergence we refer to [6] and [11] (see also [7] and [8, Part 2]).

Let $\rho : [0, 1] \mapsto \mathbf{R}$ be a nondecreasing, continuous function, strictly positive on

$(0,1]$. For all $\varepsilon > 0$ and $\alpha \geq 0$ we define

$$F_\varepsilon^\alpha(u) = \varepsilon^{2-\alpha} \int_0^1 \rho\,(u')^2\,d\theta + \varepsilon^{-\alpha} \int_0^1 \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho\,(u^2-1)\,d\varphi \right)^2 d\theta$$

for $u \in H^1(0,1)$. When needed, the functionals are understood to take the value $+\infty$ when not otherwise defined. We will isolate particular values of α for which the Γ-limit is nontrivial.

We will consider separately the following cases.

Case 1 (section 2). $\alpha = 0$. In this case, minimizing sequences are weakly precompact in $L^2_{\mathrm{loc}}(0,1)$; hence, we compute the Γ-limit F^0 of F_ε^0 with respect to that convergence, and for every $u \in L^2_{\mathrm{loc}}(0,1)$ we get

$$F^0(u) = \min \left\{ \int_0^1 \frac{1}{\rho(\theta)} \Big(\mu([0,\theta)) - \int_0^\theta \rho\; d\varphi \Big)^2 d\theta \;:\; \mu \geq \rho\, u^2\, d\varphi \right\},$$

where the minimum is taken over all nonnegative measures μ. The set of the minimum points of F^0 is $\{|u| \leq 1\}$.

Case 2 (section 3). $\alpha = 3/2$. In this case, we scale F_ε^0 further and study the limit of $F_\varepsilon^{3/2} = \varepsilon^{-3/2} F_\varepsilon^0$. We prove that minimizing sequences are precompact with respect to the strong $L^1_{\mathrm{loc}}(0,1)$-convergence, and their limits u belong to $BV_{\mathrm{loc}}((0,1);\{-1,1\})$; i.e., u is locally piecewise constant on $(0,1)$ and takes only the values 1 and -1. We compute the Γ-limit $F^{3/2}$ of $F_\varepsilon^{3/2}$ with respect to that convergence and we get

$$F^{3/2}(u) = c_0 \sum_{\theta \in S(u)} \rho(\theta)$$

for every $u \in BV_{\mathrm{loc}}((0,1);\{-1,1\})$, where $S(u)$ is the set of points where u jumps between the points 1 and -1, and

$$c_0 = \inf_{T>0} \inf \left\{ \int_{-T}^T (v')^2\,ds + \int_{-T}^T \left(\int_{-T}^\sigma (v^2-1)\,ds \right)^2 d\sigma \;: \right.$$
$$\left. v \in H^1(-T,T), \quad v(\pm T) = \pm 1, \quad \int_{-T}^T (v^2-1)\,ds = 0 \right\}.$$

With this choice of the scaling we get a result of "Modica–Mortola" type with a different characterization of the constant c_0 (see [18, 19], or [5]).

Case 3 (section 4). In this case, we show that the characteristic scale changes if we impose the restriction that $u \in H^1((0,1);[-1,1])$, and there the correct scaling power is $\alpha = 4/3$. We treat only the case $\rho = 1$ for the sake of simplicity. By Case 1 above, we have that the Γ-limit of the restriction of F_ε^0 to $H^1((0,1);[-1,1])$, G_ε^0, is zero. We then rescale G_ε^0 to get a nontrivial limit problem, considering the family of functionals $G_\varepsilon^{4/3} = \varepsilon^{-4/3} G_\varepsilon^0$, and we prove that the minimizing sequences are compact

with respect to the strong L^1-convergence and its Γ-limit is nonlocal,

$$G^{4/3}(u) = \inf_{T>0} \inf \left\{ \sum_{i\in I} \left(\int_{-T}^{T} (v_i')^2 \, ds + (\theta_{i+1} - \theta_i) \left(\sum_{j=1}^{i} \int_{-T}^{T} (v_j^2 - 1) \, ds \right)^2 \right) : \right.$$

$$\left. v_i \in H^1((-T,T);[-1,1]), \quad v_i(\pm T) = \pm 1 \right\},$$

for every $u \in BV_{\rm loc}((0,1);\{-1,1\})$, where we have labeled the points in $S(u)$ by a set of indices $I \subset \mathbf{N}$ in such a way that $\theta_i < \theta_{i+1}$.

2. The case $\alpha = 0$: Oscillations. We consider the case $\alpha = 0$ first; i.e.,

$$F_\varepsilon^0(u) = \varepsilon^2 \int_0^1 \rho \, (u')^2 \, d\theta + \int_0^1 \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho \, (u^2 - 1) \, d\varphi \right)^2 d\theta$$

for $u \in H^1_{\rm loc}(0,1)$. In order to choose the topology in which to frame our limit problem we have to examine the compactness properties of sequences with bounded energy. Note that the presence of ε only in the first term of $F_\varepsilon^0(u)$ suggests the use of the weak L^2-convergence.

THEOREM 2.1 (compactness). *Let (u_ε) be a sequence such that $\sup_\varepsilon F_\varepsilon^0(u_\varepsilon) < +\infty$; then, up to subsequences, the measures $\rho u_\varepsilon^2 \, d\varphi$ converge weakly* in $(-\infty, 1)$ and, in particular, (u_ε) converges weakly in $L^2_{\rm loc}(0,1)$.*

Proof. By assumption, $\sup_\varepsilon \int_0^1 (1/\rho(\theta)) (\int_0^\theta \rho \, (u_\varepsilon^2 - 1) \, d\varphi)^2 \, d\theta < +\infty$, which implies that $\sup_\varepsilon \int_0^1 (\int_0^\theta \rho \, u_\varepsilon^2 \, d\varphi)^2 \, d\theta < +\infty$; hence, by Hölder's inequality, there exists a constant c independent of ε such that

$$\int_0^1 \left(\int_0^\theta \rho \, u_\varepsilon^2 \, d\varphi \right) d\theta \le c \tag{2.1}$$

for every $\varepsilon > 0$. By the monotonicity of $\theta \mapsto \int_0^\theta \rho \, u_\varepsilon^2 \, d\varphi$ we have that for a fixed $\theta_0 \in (0,1)$,

$$\int_0^{\theta_0} \rho \, u_\varepsilon^2 \, d\varphi \le \int_0^\theta \rho \, u_\varepsilon^2 \, d\varphi$$

for every $\theta \ge \theta_0$. Hence we get that

$$\int_{\theta_0}^1 \left(\int_0^{\theta_0} \rho \, u_\varepsilon^2 \, d\varphi \right) d\theta \le \int_{\theta_0}^1 \left(\int_0^\theta \rho \, u_\varepsilon^2 \, d\varphi \right) d\theta \le \int_0^1 \left(\int_0^\theta \rho \, u_\varepsilon^2 \, d\varphi \right) d\theta,$$

and by (2.1) we can conclude that for every $\theta_0 \in (0,1)$ there exists a constant $c(\theta_0)$ depending only on θ_0 such that $\int_0^{\theta_0} \rho \, u_\varepsilon^2 \, d\varphi \le c(\theta_0)$ for every $\varepsilon > 0$, which gives the desired compactness properties. ∎

Remark 1. The following example shows that we cannot expect weak compactness, but only local weak compactness, in $L^2(0,1)$ for a sequence (u_ε) with $\sup_\varepsilon F_\varepsilon^0(u_\varepsilon) < +\infty$. In fact, consider

$$u_\varepsilon(\theta) = \varepsilon^{-7/5} (\theta - \theta_\varepsilon)^+$$

with $\theta_\varepsilon = 1 - \varepsilon^{4/5}$; then $F^0_\varepsilon(u_\varepsilon) \le c$ for every $\varepsilon > 0$, but

$$\int_0^1 u_\varepsilon^2 \, d\theta = \frac{1}{3}\varepsilon^{-2/5} .$$

LEMMA 2.2. *Let*

$$G(u) = \int_0^1 \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho \, (u^2 - 1) \, d\varphi \right)^2 d\theta .$$

The lower-semicontinuous envelope of G with respect to the weak $L^2_{\rm loc}$ topology is

$$\overline{G}(u) := \min \left\{ \int_0^1 \frac{1}{\rho(\theta)} \left(\mu([0,\theta)) - \int_0^\theta \rho \, d\varphi \right)^2 d\theta \, : \, \mu \ge \rho u^2 \, d\varphi \right\} ,$$

where the minimum is taken in the space $\mathcal{M}^+([0,1))$ of locally finite positive measures on $[0,1)$.

Proof. Let (u_N) be a sequence weakly converging to u in $L^2_{\rm loc}$ such that

$$\lim_{N \to +\infty} G(u_N) < +\infty$$

and the sequence of positive measures $(\rho u_N^2 \, d\varphi)$ converges weakly* to μ in $\mathcal{M}^+([0,1))$. Then, by the lower semicontinuity of the L^2-norm and the convergence of the measures of almost all intervals, we have that

$$\frac{\mu(\theta - \delta, \theta + \delta)}{\delta} = \lim_{N \to +\infty} \fint_{\theta-\delta}^{\theta+\delta} \rho u_N^2 \, d\varphi \ge \fint_{\theta-\delta}^{\theta+\delta} \rho u^2 \, d\varphi$$

for almost all (a.a.) $\delta \in (0, \theta)$; by the Besicovitch derivation theorem, we conclude that for a.e. θ,

$$\frac{d\mu}{d\varphi}(\theta) \ge \rho(\theta) u^2(\theta) .$$

Since μ has at most countably many atoms, by the weak*-convergence in $\mathcal{M}^+([0,1))$, we have that

$$\lim_{N \to +\infty} \int_0^\theta \rho u_N^2 \, d\varphi = \mu([0,\theta)) \quad \text{for a.e. } \theta \in (0,1) . \tag{2.2}$$

It follows that

$$\frac{1}{\sqrt{\rho(\theta)}} \left(\int_0^\theta \rho \, (u_N^2 - 1) \, d\varphi \right) \quad \overset{L^2}{\rightharpoonup} \quad \frac{1}{\sqrt{\rho(\theta)}} \left(\mu([0,\theta)) - \int_0^\theta \rho \, d\varphi \right) ,$$

and by the weak lower semicontinuity of the L^2-norm, we get

$$\lim_{N \to +\infty} G(u_N) \ge \overline{G}(u) .$$

Note that the functional

$$\mu \mapsto \int_0^1 \frac{1}{\rho(\theta)} \left(\mu([0,\theta)) - \int_0^\theta \rho \, d\varphi \right)^2 d\theta$$

is weakly lower semicontinuous and coercive in $\mathcal{M}^+([0,1))$. Moreover, the set $\{\mu \geq \rho u^2\, d\varphi\}$ is convex; hence, the minimum is attained.

We now check the lim sup inequality for every $u \in L^2_{\rm loc}(0,1)$ such that $\overline{G}(u) < +\infty$. Let $\mu \in \mathcal{M}^+([0,1))$ be such that

$$\overline{G}(u) = \int_0^1 \frac{1}{\rho(\theta)} \left(\mu([0,\theta)) - \int_0^\theta \rho\, d\varphi \right)^2 d\theta\,.$$

For $0 < a < 1$ we define

$$u^a(\theta) = \begin{cases} u(\theta), & a \leq \theta \leq 1-a, \\ 0 & \text{otherwise} \end{cases}$$

and

$$\mu^a_N([0,\theta)) = \begin{cases} 0 & \text{if } \theta < a - 1/N, \\ \mu([0,a)) & \text{if } a - 1/N \leq \theta < a, \\ \mu([0,\theta)) & \text{if } a \leq \theta < 1-a, \\ \mu([0,1-a)) & \text{if } 1-a \leq \theta < 1 \end{cases}$$

for $N \in \mathbf{N}$ and $N > 1$. Then, $u^a \in L^2(0,1)$, $u^a \to u$, in $L^2_{\rm loc}(0,1)$ as $a \to 0^+$, μ^a_N converges to the measure μ^a defined by

$$\mu^a([0,\theta)) = \begin{cases} 0 & \text{if } \theta < a, \\ \mu([0,\theta)) & \text{if } a \leq \theta < 1-a, \\ \mu([0,1-a)) & \text{if } 1-a \leq \theta < 1 \end{cases}$$

(this can be checked, e.g., by using Theorem 1.16 in [12]), and

$$\overline{G}(u^a) \leq \int_a^1 \frac{1}{\rho(\theta)} \left(\mu^a([0,\theta)) - \int_0^\theta \rho\, d\varphi \right)^2 d\theta + o(1) \leq \overline{G}(u) + o(1) \tag{2.3}$$

as $a \to 0^+$. Indeed, since by assumption $\overline{G}(u) < +\infty$, then we have

$$\begin{aligned} &\int_a^1 \frac{1}{\rho(\theta)} \left(\mu^a([0,\theta)) - \int_0^\theta \rho\, d\varphi \right)^2 d\theta \\ &\quad = \int_a^{1-a} \frac{1}{\rho(\theta)} \left(\mu([0,\theta)) - \int_0^\theta \rho\, d\varphi \right)^2 d\theta \\ &\qquad + \int_{1-a}^1 \frac{1}{\rho(\theta)} \left(\mu([0,1-a)) - \int_0^\theta \rho\, d\varphi \right)^2 d\theta \\ &\quad \leq \overline{G}(u) + 2 \int_{1-a}^1 \frac{\mu([1-a,\theta))^2}{\rho(\theta)}\, d\theta \\ &\qquad + 2 \int_{1-a}^1 \frac{1}{\rho(\theta)} \left(\mu([0,\theta)) - \int_0^\theta \rho\, d\varphi \right)^2 d\theta \\ &\quad = \overline{G}(u) + o(1)\,, \end{aligned}$$

as $a \to 0^+$.

We denote $I_N = \{0, \dots, N-1\}$ and

$$\begin{cases} \overline{u}_N(\theta) = \fint_{i/N}^{(i+1)/N} u^a \, d\varphi \,, & i/N \le \theta \le (i+1)/N \,, \quad i \in I_N, \\ v_N(\theta) = N \, \mu_N^a([i/N, (i+1)/N)) \,, & i/N \le \theta \le (i+1)/N \,, \quad i \in I_N \,. \end{cases}$$

Note that, in particular,

$$\overline{u}_N(\theta) = 0 \,, \qquad 0 \le \theta \le [Na]/N,$$

and

$$v_N(\theta) = \begin{cases} 0, & 0 \le \theta \le ([Na]-1)/N, \\ N\mu([0,a)), & ([Na]-1)/N \le \theta \le [Na]/N \,. \end{cases}$$

Hence, we define

$$u_N(\theta) = \begin{cases} 0, & 0 \le \theta \le ([Na]-1)/N, \\ \sqrt{N\mu([0,a))/\rho(\theta)}, & ([Na]-1)/N \le \theta \le [Na]/N, \\ \overline{u}_N + \sqrt{(v_N/\rho_N^i) - (\overline{u}_N)^2}, & i/N \le \theta \le i/N + 1/2N, \\ & \quad i = [Na], \dots, N-1, \\ c_N\Big(\overline{u}_N - \sqrt{(v_N/\rho_N^i) - (\overline{u}_N)^2}\Big), & i/N + 1/2N \le \theta \le (i+1)/N, \\ & \quad i = [Na], \dots, N-1, \end{cases} \tag{2.4}$$

where

$$c_N(\theta) = \rho(\theta - 1/2N)/\rho(\theta) \,, \quad [Na]/N + 1/2N \le \theta \le 1$$

([t] denotes the *integer part* of t). Finally, it remains to fix ρ_N^i for $i = [Na], \dots, N-1$ such that

$$v_N(\theta) \ge \rho_N^i \, (\overline{u}_N(\theta))^2 \,, \quad i/N \le \theta \le (i+1)/N \,, \quad i = [Na], \dots, N-1 \,.$$

Since $\mu_N^a \ge \rho \, (u^a)^2 \, d\varphi$, for every $i = [Na], \dots, N-1$, there exists $\eta_N^i \in [i/N, (i+1)/N)$ such that

$$\begin{aligned} \mu_N^a[i/N, (i+1)/N) &\ge \int_{i/N}^{(i+1)/N} \rho \, (u^a)^2 \, d\varphi = \rho(\eta_N^i) \int_{i/N}^{(i+1)/N} (u^a)^2 \, d\varphi \\ &\ge \rho(\eta_N^i) N \left(\int_{i/N}^{(i+1)/N} u^a \, d\varphi \right)^2 = \rho(\eta_N^i) \frac{1}{N} (\overline{u}_N)^2 \,. \end{aligned}$$

Hence, we choose $\rho_N^i = \rho(\eta_N^i)$ in (2.4).

By definition, (u_N) is bounded in L^2; hence, up to subsequence, it converges weakly in L^2. To identify the weak limit function with u^a it is sufficient to check that $\lim_{N \to +\infty} \int_b^d u_N = \int_b^d u^a$ for every $(b, d) \subseteq (0, 1)$. In fact,

$$\int_0^{[Na]/N} u_N \, d\theta = \sqrt{N\mu([0,a))} \int_{([Na]-1)/N}^{[Na]/N} \frac{d\theta}{\sqrt{\rho(\theta)}} \le \frac{1}{\sqrt{N}} \sqrt{\frac{\mu([0,a))}{\rho(([Na]-1)/N)}} \,, \tag{2.5}$$

while, for $i = [Na], \dots, N-1$, we have that

$$\begin{aligned}
\int_{i/N}^{(i+1)/N} u_N \, d\theta &= \int_{i/N}^{i/N+1/2N} \overline{u}_N + \sqrt{(v_N/\rho_N^i) - (\overline{u}_N)^2}\, d\theta \\
&\quad + \int_{i/N+1/2N}^{(i+1)/N} \frac{\rho(\theta - \frac{1}{2N})}{\rho(\theta)} \left(\overline{u}_N - \sqrt{(v_N/\rho_N^i) - (\overline{u}_N)^2} \right) d\theta \\
&= \int_{i/N}^{(i+1)/N} \overline{u}_N \, d\theta + \int_{i/N+1/2N}^{(i+1)/N} \overline{u}_N \left(\frac{\rho(\theta - \frac{1}{2N})}{\rho(\theta)} - 1 \right) d\theta \\
&\quad + \int_{i/N+1/2N}^{(i+1)/N} \sqrt{(v_N/\rho_N^i) - (\overline{u}_N)^2} \left(1 - \frac{\rho(\theta - \frac{1}{2N})}{\rho(\theta)} \right) d\theta \\
&= \left(\int_{i/N}^{(i+1)/N} u^a \, d\theta \right) + \int_{i/N+1/2N}^{(i+1)/N} \overline{u}_N \left(\frac{\rho(\theta - \frac{1}{2N})}{\rho(\theta)} - 1 \right) d\theta \\
&\quad + \int_{i/N+1/2N}^{(i+1)/N} \sqrt{(v_N/\rho_N^i) - (\overline{u}_N)^2} \left(1 - \frac{\rho(\theta - \frac{1}{2N})}{\rho(\theta)} \right) d\theta \,. \qquad (2.6)
\end{aligned}$$

If we sum up on i, by the Hölder inequality, we get that

$$\begin{aligned}
&\left| \sum_{i \geq [Na]} \int_{i/N+1/2N}^{(i+1)/N} \overline{u}_N \left(\frac{\rho(\theta - \frac{1}{2N})}{\rho(\theta)} - 1 \right) d\theta \right| \qquad (2.7) \\
&\qquad \leq \left(\int_0^1 (\overline{u}_N)^2 \, d\theta \right)^{1/2} \left(\int_{a/2}^1 \left(1 - \frac{\rho(\theta - \frac{1}{2N})}{\rho(\theta)} \right)^2 d\theta \right)^{1/2}
\end{aligned}$$

and

$$\begin{aligned}
&\left| \sum_{i \geq [Na]} \int_{i/N+1/2N}^{(i+1)/N} \sqrt{(v_N/\rho_N^i) - (\overline{u}_N)^2} \left(1 - \frac{\rho(\theta - \frac{1}{2N})}{\rho(\theta)} \right) d\theta \right| \qquad (2.8) \\
&\quad \leq \left(\sum_{i \geq [Na]} \int_{i/N+1/2N}^{(i+1)/N} (v_N/\rho_N^i) + (\overline{u}_N)^2 \, d\theta \right)^{1/2} \left(\int_{a/2}^1 \left(1 - \frac{\rho(\theta - \frac{1}{2N})}{\rho(\theta)} \right)^2 d\theta \right)^{1/2} \\
&\quad \leq \left(\frac{\mu([0, 1-a))}{\rho(a/2)} + \int_0^1 (\overline{u}_N)^2 \, d\theta \right)^{1/2} \left(\int_{a/2}^1 \left(1 - \frac{\rho(\theta - \frac{1}{2N})}{\rho(\theta)} \right)^2 d\theta \right)^{1/2} .
\end{aligned}$$

Note that the sequence $(\overline{u}_N)$ is bounded in the L^2-norm since it converges to u^a strongly; moreover,

$$\lim_{N \to +\infty} \int_{a/2}^1 \left(1 - \frac{\rho(\theta - \frac{1}{2N})}{\rho(\theta)} \right)^2 d\theta = 0 \,.$$

Hence, by (2.5), (2.6), (2.7), and (2.8), we can easily conclude that $\lim_{N \to +\infty} \int_b^d u_N = \int_b^d u^a$ for every $(b, d) \subseteq (0, 1)$ and, therefore, we have the weak convergence of (u_N) to u^a in $L^2(0, 1)$.

We now examine

$$G(u_N) = \int_0^a \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho\, u_N^2 - \int_0^\theta \rho\ d\varphi \right)^2 d\theta + \int_a^1 \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho\, u_N^2 - \int_0^\theta \rho\ d\varphi \right)^2 d\theta\,; \tag{2.9}$$

in particular, we have that

$$\begin{aligned} &\int_0^{[Na]/N} \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho\, u_N^2\, d\varphi \right)^2 d\theta \\ &\quad = N^2 \mu([0,a))^2 \int_{([Na]-1)/N}^{[Na]/N} \frac{1}{\rho(\theta)} \left(\theta - \frac{[Na]-1}{N} \right)^2 d\theta \\ &\quad \le \frac{1}{3N} \frac{\mu([0,a))^2}{\rho(([Na]-1)/N)}\,. \end{aligned} \tag{2.10}$$

Then, passing to the limit as $N \to +\infty$ in (2.10), we get that

$$\limsup_{N\to+\infty} \int_0^a \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho\, u_N^2 - \int_0^\theta \rho\ d\varphi \right)^2 d\theta = o(1)\,, \tag{2.11}$$

as $a \to 0^+$. It remains to study the second term in (2.10). For $i = [Na], \dots, N-1$, we have that

$$\begin{aligned} &\int_{i/N}^{(i+1)/N} \rho\, u_N^2\, d\theta \\ &\quad = \int_{i/N}^{i/N+1/2N} \rho \left(\frac{v_N}{\rho_N^i} + 2\overline{u}_N \sqrt{(v_N/\rho_N^i) - (\overline{u}_N)^2} \right) d\theta \\ &\qquad + \int_{i/N+1/2N}^{(i+1)/N} \rho \left(\theta - \frac{1}{2N} \right) \left(\frac{v_N}{\rho_N^i} - 2\overline{u}_N \sqrt{(v_N/\rho_N^i) - (\overline{u}_N)^2} \right) d\theta \\ &\quad = 2 \int_{i/N}^{i/N+1/2N} \frac{\rho(\theta)}{\rho(\eta_N^i)}\, v_N(\theta)\, d\theta\,, \end{aligned} \tag{2.12}$$

where $\eta_N^i \in [i/N, (i+1)/N)$, $i = [Na], \dots, N-1$. We recall that $\rho u_N^2 = 0$ in $[0, ([Na]-1)/N) \cup [([N(1-a)]+1)/N, 1]$, while $\rho u_N^2 = N\mu([0,a))$ in $[([Na]-1)/N, [Na]/N)$; hence, by (2.12), we have that

$$\lim_{N\to+\infty} \int_0^\theta \rho\, u_N^2\, d\theta = \mu^a([0,\theta)), \quad \text{a.e. } \theta \in (a,1)\,.$$

Moreover, as already observed, (u_N) is bounded in L^2; hence,

$$\frac{1}{\rho(\theta)} \left(\int_0^\theta \rho\, u_N^2\, d\varphi - \int_0^\theta \rho\ d\varphi \right)^2 \le c$$

for every $\theta \in (a,1)$ and for every N. Therefore, we can apply Lebesgue's theorem in the second term of (2.10), and by (2.11), (2.3) we have

$$\limsup_{N\to+\infty} G(u_N) \le \int_a^1 \frac{1}{\rho(\theta)} \left(\mu^a([0,\theta)) - \int_0^\theta \rho \, d\varphi \right)^2 d\theta + o(1)$$

$$\le \overline{G}(u) + o(1) \quad \text{as} \quad a \to 0^+ . \tag{2.13}$$

Since $u^a \to u$ in $L^2_{\rm loc}(0,1)$ as $a \to 0^+$, we can conclude that, passing to a further subsequence, $u_N \rightharpoonup u$ in $L^2_{\rm loc}(0,1)$ as $N \to +\infty$, and

$$\limsup_{N\to+\infty} G(u_N) \le \overline{G}(u),$$

as desired. □

Remark 2. Note that the set of minimizers for $\overline{G}(u)$ is $\{|u| \le 1\}$.

Remark 3. The functional $\overline{G}$ can be estimated from above and from below as

$$G^-(u) \le \overline{G}(u) \le G^+(u), \tag{2.14}$$

where

$$G^+(u) = \int_0^1 \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho \, (u^2-1)^+ \, d\varphi \right)^2 d\theta$$

and

$$G^-(u) = \int_0^1 \frac{1}{\rho(\theta)} \left(\left(\int_0^\theta \rho \, (u^2-1) \, d\varphi \right)^+ \right)^2 d\theta \, .$$

The second inequality in (2.14) easily follows by testing the definition of $\overline{G}(u)$ with the measure $\mu = \rho(u^2 \vee 1)\, d\varphi$. To check the first inequality from below, we first note that $G(u) \ge G^-(u)$, and by Fatou's lemma and the weak $L^2_{\rm loc}$-lower semicontinuity of the functional $\int_0^\theta \rho \, u^2 \, d\varphi$ for every $\theta \in (0,1)$, we get that G^- is weakly $L^2_{\rm loc}$-lower semicontinuous. Hence, by Lemma 2.2 and the lower semicontinuity of G^-, we have that for every $u \in L^2_{\rm loc}(0,1)$ there exists a sequence u_N weakly $L^2_{\rm loc}$ converging to u such that

$$\overline{G}(u) = \lim_{N\to+\infty} G(u_N) \ge \liminf_{N\to+\infty} G^-(u_N) \ge G^-(u) \, .$$

We show now an example of function u such that $\overline{G}(u) = G^-(u)$. Let us consider for simplicity $\rho = 1$. Let

$$u(\varphi) = \begin{cases} \sqrt{2}, & \varphi \in (0,1/4), \\ 0, & \varphi \in (1/4,1) \, . \end{cases} \tag{2.15}$$

Note that

$$\int_0^\theta (u^2-1) \, d\varphi < 0 \quad \text{for all } \theta > 1/2 \, ,$$

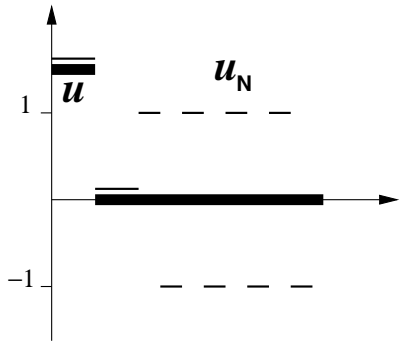

FIG. 1. *Nonlocal oscillations.*

so that

$$G^-(u) = \int_0^{1/4} \theta^2 \, d\theta + \int_{1/4}^{1/2} \left(\frac{1}{2} - \theta\right)^2 d\theta = \int_0^1 (\mu([0,\theta)) - \theta)^2 d\theta,$$

where the measure $\mu = v \, d\varphi$ is defined by

$$v(\varphi) = \begin{cases} 2, & \varphi \in (0, 1/4), \\ 0, & \varphi \in (1/4, 1/2), \\ 1, & (1/2, 1)\,. \end{cases}$$

Since $\mu \geq u^2 \, d\varphi$, we can test the definition of $\overline{G}(u)$ with μ getting $G^-(u) \geq \overline{G}(u)$, and then we have that $G^-(u) = \overline{G}(u)$ by (2.14). A recovery sequence (corresponding to (2.4) with $a = 0$ and $\rho = 1$) for $\overline{G}(u)$ is shown in Figure 1; it highlights the nonlocal nature of the oscillations that start at $\varphi = 1/2$, while the target function is 0 on the whole $(1/4, 1)$.

Note that u as in (2.15) is also an example of a function such that $\overline{G}(u) < G^+(u)$. Finally, we note that also the inequality $G^- \leq \overline{G}$ is sharp: if we consider

$$u(\varphi) = \begin{cases} 0, & \varphi \in (0, 1/2), \\ \sqrt{2}, & \varphi \in (1/2, 1), \end{cases}$$

we have that $G^-(u) = 0$ while $\overline{G}(u) > 0$ by Remark 2.

THEOREM 2.3 (Γ-convergence result). *We have*

$$\Gamma(\text{w-}L^2_{\text{loc}})\text{-}\lim_{\varepsilon \to 0} F^0_\varepsilon(u) = \overline{G}(u)$$

for every $u \in L^2_{\text{loc}}(0,1)$.

Proof. Let $u \in L^2_{\text{loc}}(0,1)$. By the definition of $\overline{G}$ for every sequence (u_ε) weakly L^2_{loc} converging to u, we have

$$F^0_\varepsilon(u_\varepsilon) \geq G(u_\varepsilon) \geq \overline{G}(u_\varepsilon)\,;$$

hence by the weak lower semicontinuity of $\overline{G}$ we get the lim inf inequality.

Conversely, let $u \in L^2_{\text{loc}}(0,1)$, and let

$$u^a(\theta) = \begin{cases} u(\theta) & \text{if } a \leq \theta \leq 1 - a, \\ 0 & \text{otherwise} \end{cases}$$

with $0 < a < 1$; hence, $u^a \in L^2(0,1)$ and $u^a \to u$ in $L^2_{\rm loc}(0,1)$ as $a \to 0^+$. By Lemma 2.2, there exists a sequence $(u_N) \in L^2(\mathbf{R})$ weakly converging to u^a in $L^2(0,1)$ such that

$$\overline{G}(u^a) = \lim_{N\to+\infty} G(u_N)\,.$$

Let $\eta : \mathbf{R} \mapsto [0,+\infty)$ be a mollifier; we define $\eta_\varepsilon(\theta) = \frac{1}{\sqrt{\varepsilon}}\,\eta(\frac{\theta}{\sqrt{\varepsilon}})$, then we have $u_\varepsilon^N = u_N * \eta_\varepsilon \in C_c^\infty(\mathbf{R})$ and $u_\varepsilon^N \to u_N$ in $L^2(0,1)$ as $\varepsilon \to 0$ for every N. Hence,

$$\begin{aligned}\lim_{\varepsilon\to0} F_\varepsilon^0(u_\varepsilon^N) &= \lim_{\varepsilon\to0}\Big(\varepsilon^2 \int_0^1 \rho\,(u_N * \eta_\varepsilon')^2\,d\theta + G(u_\varepsilon^N)\Big)\\ &= \lim_{\varepsilon\to0} G(u_\varepsilon^N) = G(u_N),\end{aligned}$$

and by the lower semicontinuity of the Γ-lim sup and (2.3), we have that

$$\begin{aligned}\Gamma\text{-}\limsup_{\varepsilon\to0} F_\varepsilon^0(u^a) &\le \liminf_{N\to+\infty}\Big(\Gamma\text{-}\limsup_{\varepsilon\to0} F_\varepsilon^0(u_N)\Big)\\ &\le \liminf_{N\to+\infty} G(u_N) = \overline{G}(u^a) \le \overline{G}(u) + o(1)\end{aligned}$$

as $a \to 0^+$. We again use the lower semicontinuity of the Γ-lim sup to get, as $a \to 0^+$, that

$$\Gamma\text{-}\limsup_{\varepsilon\to0} F_\varepsilon^0(u) \le \overline{G}(u),$$

which concludes the proof of the lim sup inequality (see [6, Remark 1.29]). ∎

3. The case $\alpha = 3/2$: Phase transitions. In section 2 we showed that the set of the minimum points of the Γ-limit F^0 is $\{|u| \le 1\}$ and showed that $\min F^0 = 0$. To reduce the choice in the minimizers of the limit problem we may further rescale F_ε^0; the next meaningful scaling is $\alpha = 3/2$. We then consider the family of functionals

$$F_\varepsilon^{3/2}(u) = \sqrt{\varepsilon}\int_0^1 \rho\,(u')^2\,d\theta + \varepsilon^{-3/2}\int_0^1 \frac{1}{\rho(\theta)}\left(\int_0^\theta \rho\,(u^2-1)\,d\varphi\right)^2 d\theta$$

for $u \in H^1(0,1)$.

THEOREM 3.1 (compactness). *Let (u_ε) be a sequence of equibounded energy, i.e., $\sup_\varepsilon F_\varepsilon^{3/2}(u_\varepsilon) < +\infty$; then (u_ε) is equibounded in $L^\infty_{\rm loc}(0,1)$ and, up to subsequences, (u_ε) converges to $u \in BV_{\rm loc}((0,1);\{-1,1\})$ strongly in $L^1_{\rm loc}$.*

Proof. Let $\eta_\varepsilon^\pm \neq \pm1$ such that $-1 < \eta_\varepsilon^+, \eta_\varepsilon^- < 1$ or $\eta_\varepsilon^+, \eta_\varepsilon^- > 1$ or $\eta_\varepsilon^+, \eta_\varepsilon^- < -1$. We denote by $(\delta_\varepsilon^-, \delta_\varepsilon^+)$ an interval such that $u_\varepsilon(\delta_\varepsilon^-) = \eta_\varepsilon^-$, $u_\varepsilon(\delta_\varepsilon^+) = \eta_\varepsilon^+$ and u_ε takes values between η_ε^- and η_ε^+. In what follows, we use $\eta^\pm = \eta_\varepsilon^\pm$, $\delta^\pm = \delta_\varepsilon^\pm$ so that we do not overburden notation. By assumption,

$$\sqrt{\varepsilon}\int_{\delta^-}^{\delta^+} \rho\,(u_\varepsilon')^2\,d\theta + \varepsilon^{-3/2}\int_{\delta^-}^{\delta^+} \frac{1}{\rho(\theta)}\left(\int_0^\theta \rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2 d\theta \le c\,. \tag{3.1}$$

For any fixed $0 < a < 1$, we assume $\delta^- \ge a$.

The crucial argument in the proof will be to estimate the length $\delta^+ - \delta^-$ of any such interval. We will show that

$$\sqrt{\varepsilon}\int_{\delta^-}^{\delta^+}\rho\,(u_\varepsilon')^2\,d\theta\;+\varepsilon^{-3/2}\int_{\delta^-}^{\delta^+}\frac{1}{\rho(\theta)}\left(\int_0^\theta\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2 d\theta$$
$$\geq \rho(a)|\eta^+-\eta^-|^2\left(\frac{\sqrt{\varepsilon}}{\delta}\right)+c(\lambda)\left(\frac{\delta}{\sqrt{\varepsilon}}\right)^3,$$

where λ is the minimum between $|\eta_-^2-1|$ and $|\eta_+^2-1|$, and $c(\lambda)$ is a suitable positive constant depending only on λ. From this estimate we will deduce that if $|\eta^+-\eta^-|\geq\zeta>0$, then $\delta^+-\delta^-$ is of the order $\sqrt{\varepsilon}$, and that

$$\sqrt{\varepsilon}\int_{\delta^-}^{\delta^+}\rho\,(u_\varepsilon')^2\,d\theta\;+\varepsilon^{-3/2}\int_{\delta^-}^{\delta^+}\frac{1}{\rho(\theta)}\left(\int_0^\theta\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2 d\theta\geq c\zeta^{3/2}.$$

From this, we will finally obtain that frequent large oscillations are forbidden, and in particular that the number of transitions from values close to 1 to values close to -1, and conversely, is equibounded, and then deduce the $L^1_{\rm loc}$-convergence in $(0,1)$.

Step 1. We define the set

$$A_\varepsilon=\left\{\theta\in(a,1]:\quad\frac{1}{\rho(\theta)}\left(\int_0^\theta\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2\leq\varepsilon\right\},$$

and we denote by A_ε^c its complementary set. Since $\sup_\varepsilon F_\varepsilon^{3/2}(u_\varepsilon)<+\infty$, we have that

$$|A_\varepsilon^c|\varepsilon<\int_{A_\varepsilon^c}\frac{1}{\rho(\theta)}\left(\int_0^\theta\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2\leq c\varepsilon^{3/2},$$

which implies that there exists $\overline{c}(\varepsilon)\leq c$ such that

$$|A_\varepsilon^c|=\overline{c}(\varepsilon)\,\sqrt{\varepsilon}\,. \tag{3.2}$$

Let $\theta_\varepsilon\in A_\varepsilon$ be such that $\theta_\varepsilon=\max\{\theta\in A_\varepsilon:\,\theta\leq\delta^-\}$; by definition,

$$\varepsilon\geq\frac{1}{\rho(\theta_\varepsilon)}\left(\int_0^{\theta_\varepsilon}\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2\geq\frac{1}{\rho(1)}\left(\int_0^{\theta_\varepsilon}\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2.$$

It follows that there exists $c_1(\varepsilon)$ such that $|c_1(\varepsilon)|\leq\sqrt{\rho(1)}$ and

$$\int_0^{\theta_\varepsilon}\rho\,(u_\varepsilon^2-1)\,d\varphi=c_1(\varepsilon)\,\sqrt{\varepsilon}\,. \tag{3.3}$$

Moreover, for every $\theta\in(\theta_\varepsilon,\delta^-)\subset A_\varepsilon^c$, we have that

$$|u_\varepsilon(\theta)-\eta^-|=|u_\varepsilon(\theta)-u_\varepsilon(\delta^-)|\leq\left(|A_\varepsilon^c|\int_{\theta_\varepsilon}^{\delta^-}(u_\varepsilon')^2\,d\theta\right)^{1/2}$$
$$\leq\left(\frac{|A_\varepsilon^c|}{\rho(a)}\int_{\theta_\varepsilon}^{\delta^-}\rho\,(u_\varepsilon')^2\,d\theta\right)^{1/2}.$$

Since $\sup_\varepsilon F_\varepsilon^{3/2}(u_\varepsilon) < +\infty$, by (3.2) we have that

$$|u_\varepsilon(\theta)| \le |\eta^-| + \tilde{c} \qquad \text{for all } \theta \in [\theta_\varepsilon, \delta^-], \tag{3.4}$$

which in turn implies

$$\left| \int_{\theta_\varepsilon}^{\delta^-} \rho\,(u_\varepsilon^2 - 1)\,d\theta \right| \le c(\eta^-)\,\sqrt{\varepsilon},$$

where $c(\eta^-) = c\,\rho(1)(1+(|\eta^-|+\tilde{c})^2)$. Hence, there exists $c_2(\varepsilon,\eta^-)$ such that $|c_2(\varepsilon,\eta^-)| \le c(\eta^-)$ and

$$\int_{\theta_\varepsilon}^{\delta^-} \rho\,(u_\varepsilon^2 - 1)\,d\theta = c_2(\varepsilon,\eta^-)\,\sqrt{\varepsilon}\,. \tag{3.5}$$

By (3.3) and (3.5) we get that

(3.6)

$$\begin{aligned}
&\int_{\delta^-}^{\delta^+} \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho\,(u_\varepsilon^2 - 1)\,d\varphi \right)^2 d\theta \\
&\quad = \int_{\delta^-}^{\delta^+} \frac{1}{\rho(\theta)} \left(\int_0^{\theta_\varepsilon} \rho\,(u_\varepsilon^2 - 1)\,d\varphi + \int_{\theta_\varepsilon}^{\delta^-} \rho\,(u_\varepsilon^2 - 1)\,d\varphi + \int_{\delta^-}^{\theta} \rho\,(u_\varepsilon^2 - 1)\,d\varphi \right)^2 d\theta \\
&\quad = c_5(c_1(\varepsilon) + c_2(\varepsilon,\eta^-))^2\,\varepsilon\,\delta + \int_{\delta^-}^{\delta^+} \frac{1}{\rho(\theta)} \left(\int_{\delta^-}^{\theta} \rho\,(u_\varepsilon^2 - 1)\,d\varphi \right)^2 d\theta \\
&\qquad + 2(c_1(\varepsilon) + c_2(\varepsilon,\eta^-))\,\sqrt{\varepsilon} \int_{\delta^-}^{\delta^+} \frac{1}{\rho(\theta)} \left(\int_{\delta^-}^{\theta} \rho\,(u_\varepsilon^2 - 1)\,d\varphi \right) d\theta\,,
\end{aligned}$$

where $c_5 = \int_{\delta^-}^{\delta^+} (1/\rho)\,d\theta$ and $\delta = \delta^+ - \delta^-$.

By assumption, u_ε takes values between η^- and η^+ for every $\theta \in [\delta^-, \delta^+]$ (note that either $(u_\varepsilon^2 - 1) > 0$ or $(u_\varepsilon^2 - 1) < 0$ for every $\theta \in [\delta^-, \delta^+]$); hence,

$$|u_\varepsilon^2 - 1| \ge \lambda := ||\eta^-|^2 - 1| \wedge ||\eta^+|^2 - 1|,$$

where we use the notation λ without an explicit dependence on $\eta^\pm$ since we want to emphasize that λ does not depend on the values of $\eta^\pm$ but on the minimum distance of $|\eta^\pm|^2$ from 1.

Moreover, on $[\delta^-, \delta^+]$,

$$|u_\varepsilon^2 - 1| \le c(\eta^\pm) := ||\eta^-|^2 - 1| \vee ||\eta^+|^2 - 1|;$$

then there exist $c_3(\varepsilon,\eta^\pm)$ and $c_4(\varepsilon,\lambda)$ such that

$$0 < |c_3(\varepsilon,\eta^\pm)| \le \frac{c(\eta^\pm)}{2}\,, \qquad c_4(\varepsilon,\lambda) \ge \frac{\lambda^2}{3}\,\frac{\rho(a)^2}{\rho(1)} \tag{3.7}$$

and

$$\int_{\delta^-}^{\delta^+} \frac{1}{\rho(\theta)} \left(\int_{\delta^-}^{\theta} \rho\,(u_\varepsilon^2 - 1)\,d\varphi \right) d\theta = c_3(\varepsilon,\eta^\pm)\,\delta^2\,, \tag{3.8}$$

$$\int_{\delta^-}^{\delta^+} \frac{1}{\rho(\theta)} \left(\int_{\delta^-}^{\theta} \rho\,(u_\varepsilon^2 - 1)\,d\varphi \right)^2 d\theta = c_4(\varepsilon,\lambda)\,\delta^3\,. \tag{3.9}$$

By (3.6), (3.8), and (3.9) we get that

$$\begin{aligned}
&\int_{\delta^-}^{\delta^+} \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho \,(u_\varepsilon^2 - 1)\, d\varphi \right)^2 d\theta \\
&\qquad = \delta^3 \Bigg\{ c_4(\varepsilon,\lambda) + c_5 (c_1(\varepsilon) + c_2(\varepsilon,\eta^-))^2 \left(\frac{\sqrt{\varepsilon}}{\delta} \right)^2 \\
&\qquad\qquad + \; 2c_3(\varepsilon,\eta^\pm)(c_1(\varepsilon) + c_2(\varepsilon,\eta^-)) \left(\frac{\sqrt{\varepsilon}}{\delta} \right) \Bigg\}. \qquad (3.10)
\end{aligned}$$

Note that c_4 and c_5 are always strictly positive while $c_3 \neq 0$ with $\operatorname{sign}(c_3) = \operatorname{sign}(u_\varepsilon^2 - 1)$. Moreover, we claim that

$$c_4 - (c_3^2/c_5) \geq c(\lambda), \qquad (3.11)$$

where $c(\lambda) := \lambda^2\, c(\delta^\pm)\rho(a)^2/\rho(1)$ with $1/12 \leq c(\delta^\pm) \leq 1/3$ for every $\delta^\pm$. Also in this case we prefer to use the notation $c(\lambda)$, omitting the dependence on $\delta^\pm$ because of the bound on $c(\delta^\pm)$. We check now (3.11). Let us denote

$$f(\theta) = \int_{\delta^-}^\theta \rho \,|u_\varepsilon^2 - 1|\, d\varphi\,;$$

hence, $f'(\theta) = \rho(\theta)|u_\varepsilon^2(\theta) - 1| \geq \lambda\rho(a)$. Then, there exists $\delta_0 \in (\delta^-, \delta^+)$ such that

$$|c_3| = \frac{1}{\delta^2} \int_{\delta^-}^{\delta^+} \frac{f(\theta)}{\rho(\theta)}\, d\theta = \frac{f(\delta_0)}{\delta^2} \int_{\delta^-}^{\delta^+} \frac{d\theta}{\rho(\theta)} = \frac{f(\delta_0)}{\delta} c_5 \qquad (3.12)$$

and

$$|f(\theta) - f(\delta_0)| \geq \lambda\rho(a)\,|\theta - \delta_0|\,.$$

It follows that

$$\begin{aligned}
\int_{\delta^-}^{\delta^+} \frac{(f(\theta) - f(\delta_0))^2}{\rho(\theta)}\, d\theta &\geq (\lambda\rho(a))^2 \int_{\delta^-}^{\delta^+} \frac{(\theta - \delta_0)^2}{\rho(\theta)}\, d\theta \\
&\geq (\lambda\rho(a))^2 \, \frac{(\delta^+ - \delta_0)^3 - (\delta^- - \delta_0)^3}{3\rho(1)} \\
&= \delta^3 \left(\lambda^2\, c(\delta^\pm)\, \frac{\rho(a)^2}{\rho(1)} \right), \qquad (3.13)
\end{aligned}$$

where $1/12 \leq c(\delta^\pm) \leq 1/3$ for every $\delta^\pm$. On the other hand, by (3.12) we have that

$$\begin{aligned}
&\int_{\delta^-}^{\delta^+} \frac{(f(\theta) - f(\delta_0))^2}{\rho(\theta)}\, d\theta \\
&\quad = \int_{\delta^-}^{\delta^+} \frac{f(\theta)^2}{\rho(\theta)}\, d\theta + f(\delta_0)^2 \int_{\delta^-}^{\delta^+} \frac{d\theta}{\rho(\theta)} - 2f(\delta_0) \int_{\delta^-}^{\delta^+} \frac{f(\theta)}{\rho(\theta)}\, d\theta \\
&\quad = \delta^3 \left(c_4 - c_5 \left(\frac{f(\delta_0)}{\delta} \right)^2 \right) \\
&\quad = \delta^3 \left(c_4 - \frac{c_3^2}{c_5} \right); \qquad (3.14)
\end{aligned}$$

hence, by (3.13) we get (3.11).

We now estimate the term with the derivative in (3.1); by Hölder's inequality we get that

$$\sqrt{\varepsilon}\int_{\delta^-}^{\delta^+}\rho\,(u_\varepsilon')^2\,d\theta \geq \rho(a)\,|\eta^+-\eta^-|^2\left(\frac{\sqrt{\varepsilon}}{\delta}\right). \tag{3.15}$$

By (3.10) and (3.15) we have then

$$\begin{aligned}&\sqrt{\varepsilon}\int_{\delta^-}^{\delta^+}\rho\,(u_\varepsilon')^2\,d\theta\;+\varepsilon^{-3/2}\int_{\delta^-}^{\delta^+}\frac{1}{\rho(\theta)}\left(\int_0^\theta\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2 d\theta\\ &\geq \rho(a)\,|\eta^+-\eta^-|^2\left(\frac{\sqrt{\varepsilon}}{\delta}\right)+\left(\frac{\delta}{\sqrt{\varepsilon}}\right)^3\left(\gamma\left(\frac{\sqrt{\varepsilon}}{\delta}\right)^2\pm\beta\left(\frac{\sqrt{\varepsilon}}{\delta}\right)+\alpha\right),\end{aligned} \tag{3.16}$$

where

$$\alpha=c_4\,,\quad \gamma=c_5(c_1+c_2)^2\,,\quad \beta=2|c_3(c_1+c_2)|\,.$$

Note that, as already observed, $\alpha>0$, $\gamma\geq 0$, and $c_3(c_1+c_2)$ may be ≥ 0 or ≤ 0 ($\gamma=0$ if and only if $\beta=0$). By (3.11), if we minimize $\gamma(\sqrt{\varepsilon}/\delta)^2\pm\beta(\sqrt{\varepsilon}/\delta)+\alpha$ in $(\sqrt{\varepsilon}/\delta)$, we have

$$\begin{aligned}&\rho(a)\,|\eta^+-\eta^-|^2\left(\frac{\sqrt{\varepsilon}}{\delta}\right)+\left(\gamma\left(\frac{\sqrt{\varepsilon}}{\delta}\right)^2\pm\beta\left(\frac{\sqrt{\varepsilon}}{\delta}\right)+\alpha\right)\left(\frac{\delta}{\sqrt{\varepsilon}}\right)^3\\ &\geq \rho(a)|\eta^+-\eta^-|^2\left(\frac{\sqrt{\varepsilon}}{\delta}\right)+\left(\alpha-\frac{\beta^2}{4\gamma}\right)\left(\frac{\delta}{\sqrt{\varepsilon}}\right)^3\\ &= \rho(a)|\eta^+-\eta^-|^2\left(\frac{\sqrt{\varepsilon}}{\delta}\right)+\left(c_4-\frac{c_3^2}{c_5}\right)\left(\frac{\delta}{\sqrt{\varepsilon}}\right)^3\\ &\geq \rho(a)|\eta^+-\eta^-|^2\left(\frac{\sqrt{\varepsilon}}{\delta}\right)+c(\lambda)\left(\frac{\delta}{\sqrt{\varepsilon}}\right)^3.\end{aligned} \tag{3.17}$$

Step 2. If

$$|\eta^+-\eta^-|\geq\zeta>0\,,$$

with ζ independent of ε, studying the function $x\mapsto\rho(a)|\eta^+-\eta^-|^2x+c(\lambda)/x^3$ for $x>0$, by (3.1), (3.16), and (3.17) we have that $\delta/\sqrt{\varepsilon}$ is bounded; i.e., there exist two positive constants α_1,α_2 such that $\alpha_1\sqrt{\varepsilon}\leq\delta\leq\alpha_2\sqrt{\varepsilon}$.

Step 3. The minimum point of $x\mapsto\rho(a)|\eta^+-\eta^-|^2x+c(\lambda)/x^3$ for $x>0$ is $x_m=c_m/|\eta^+-\eta^-|^{1/2}$; then by (3.16) and (3.17) we have that

$$\begin{aligned}&\sqrt{\varepsilon}\int_{\delta^-}^{\delta^+}\rho\,(u_\varepsilon')^2\,d\theta\;+\varepsilon^{-3/2}\int_{\delta^-}^{\delta^+}\frac{1}{\rho(\theta)}\left(\int_0^\theta\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2 d\theta\\ &\geq\tilde{c}(\lambda)\,|\eta^+-\eta^-|^{3/2}\geq\tilde{c}(\lambda)\,\zeta^{3/2}\,,\end{aligned} \tag{3.18}$$

where $\tilde{c}(\lambda)=(\rho(a)c_m+c(\lambda)/c_m^3)$. We recall that λ is the minimum distance of $|\eta^\pm|^2$ from 1. Since (u_ε) is a sequence with bounded energy, and estimate (3.18) depends on λ only, we deduce that the number of transitions of u_ε from η^- to η^+ is equibounded independently of ε.

Conclusions. By (3.1) and (3.18) we conclude that (u_ε) is equibounded in $L^\infty_{\rm loc}(0,1)$. Moreover, by Steps 2 and 3, we have that for every fixed $0<a<1$, (u_ε) converges in measure in $(a,1)$ to $u\in BV_{\rm loc}((0,1);\{-1,1\})$; hence, up to subsequences, $u_\varepsilon\to u$ a.e. $\theta\in(a,1)$. Since (u_ε) is equibounded in $L^\infty_{\rm loc}(0,1)$, we can conclude that, up to subsequences, (u_ε) converges strongly in $L^1_{\rm loc}(0,1)$ to $u\in BV_{\rm loc}((0,1);\{-1,1\})$. ∎

The following proposition gives an estimate of the measure of the set, where a sequence of bounded energy is not close to ±1.

PROPOSITION 3.2. *Let (u_ε) be a sequence converging to u in $L^1_{\rm loc}(0,1)$ such that $\sup_\varepsilon F_\varepsilon^{3/2}(u_\varepsilon)<+\infty$. Then for every fixed $0<a<1$ and $\eta>0$, there exists $\overline{c}=\overline{c}(\eta)$ such that*

$$|\{\theta\in[a,1-a]:\ |u_\varepsilon^2(\theta)-1|>\eta\}|\le\overline{c}\,\sqrt{\varepsilon}\,. \tag{3.19}$$

Proof. Let $0<a<1$ and $\eta>0$ be fixed. We define $\delta_i^\pm$ such that

$$\{\theta\in[a,1-a]:\ |u_\varepsilon^2(\theta)-1|>\eta\}\subseteq\bigcup_i[\delta_i^-,\delta_i^+]\,,$$

with $\delta_i^-<\delta_i^+$, $\delta_i^+\le\delta_j^-$ for every $i<j$ and

$$\begin{cases}|(u_\varepsilon(\delta_i^\pm))^2-1|=\eta/2 & \text{except if } \delta_i^+=1,\\ |u_\varepsilon^2(\theta)-1|>\eta/2 & \text{if } \theta\in(\delta_i^-,\delta_i^+),\\ \exists\delta_i\in(\delta_i^-,\delta_i^+) & \text{such that } |(u_\varepsilon(\delta_i))^2-1|=\eta\,.\end{cases}$$

Hence, we may have two cases:

$$u_\varepsilon(\delta_i^-)\ne u_\varepsilon(\delta_i^+),\quad\text{and hence}\quad u_\varepsilon(\delta_i^\pm)\in\left\{\pm\sqrt{1-\eta/2}\right\}, \tag{3.20}$$

or

$$u_\varepsilon(\delta_i^-)=u_\varepsilon(\delta_i^+)\in\left\{\pm\sqrt{1-\eta/2}\,,\,\pm\sqrt{1+\eta/2}\right\}. \tag{3.21}$$

In case (3.20) we may apply Steps 1–3 from the proof of Theorem 3.1 with $\eta^\pm\in\{\pm\sqrt{1-\eta/2}\}$, $\lambda=\eta/2$, and $\zeta=2\sqrt{1-\eta/2}$. If instead we are in case (3.21), we consider

$$\eta^-\in\left\{\pm\sqrt{1-\eta/2}\,,\,\pm\sqrt{1+\eta/2}\right\},\quad \eta^+\in\left\{\max_{[\delta_i^-,\delta_i^+]}u_\varepsilon\,,\ \min_{[\delta_i^-,\delta_i^+]}u_\varepsilon\right\},$$

or the converse. For example, if $u_\varepsilon(\delta_i^-)=u_\varepsilon(\delta_i^+)=\sqrt{1+\eta/2}$, then we apply Steps 1–3 two times: the first to

$$\eta^-=\sqrt{1+\eta/2}\,,\quad \eta^+=\max_{[\delta_i^-,\delta_i^+]}u_\varepsilon,$$

and then to

$$\eta^-=\max_{[\delta_i^-,\delta_i^+]}u_\varepsilon\,,\quad \eta^+=\sqrt{1+\eta/2}\,.$$

Hence, also in this case we may apply Steps 1–3 with $\zeta>0$.

We can then conclude that the number of intervals $[\delta_i^-, \delta_i^+]$ is finite (and independent of ε) and that there exist $\alpha_i^1, \alpha_i^2 > 0$ such that $\alpha_i^1\sqrt{\varepsilon} \le (\delta_i^+ - \delta_i^-) \le \alpha_i^2\sqrt{\varepsilon}$, which proves (3.19). □

THEOREM 3.3 (Γ-convergence result). *We have*

$$\Gamma(L^1_{\rm loc})\text{-}\lim_{\varepsilon\to 0} F_\varepsilon^{3/2}(u) = c_0 \sum_{\theta\in S(u)} \rho(\theta)$$

for every $u \in BV_{\rm loc}((0,1);\{-1,1\})$, *where*

$$c_0 = \inf_{T>0} \inf \left\{ \int_{-T}^{T} (v')^2\, ds + \int_{-T}^{T} \left(\int_{-T}^{\sigma} (v^2-1)\, ds \right)^2 d\sigma : \right.$$
$$\left. v \in H^1(-T,T), \quad v(\pm T) = \pm 1, \quad \int_{-T}^{T} (v^2-1)\, ds = 0 \right\}.$$

Proof (lim inf inequality). Let $u \in BV_{\rm loc}((0,1);\{-1,1\})$ and let (u_ε) be a sequence converging to u in $L^1_{\rm loc}(0,1)$ such that $\sup_\varepsilon F_\varepsilon^{3/2}(u_\varepsilon) < +\infty$.

Step 1. We fix $0 < a < 1$ and consider $\theta_i \in S(u)$ such that $a < \theta_i < 1-a$. Without loss of generality, we may assume that $u(\theta_i\pm) = \mp 1$. Let $\theta_\varepsilon \to \theta_i$, as $\varepsilon \to 0$, and let $M > 0$ be such that

$$u_\varepsilon > \frac{1}{2} \quad \text{on } I_\varepsilon^- := (\theta_\varepsilon - 2M\sqrt{\varepsilon}, \theta_\varepsilon - M\sqrt{\varepsilon})$$

and

$$u_\varepsilon < \frac{1}{2} \quad \text{on } I_\varepsilon^+ := (\theta_\varepsilon + M\sqrt{\varepsilon}, \theta_\varepsilon + 2M\sqrt{\varepsilon}).$$

We claim that for every fixed $\eta > 0$, there exist a constant $c > 0$ and $\theta_\varepsilon^\pm \in I_\varepsilon^\pm$ of the form $\theta_\varepsilon^\pm = \theta_\varepsilon \pm M_\varepsilon\sqrt{\varepsilon}$, with $M \le M_\varepsilon \le 2M$, such that

$$\left| \int_0^{\theta_\varepsilon^\pm} \rho\,(u_\varepsilon^2 - 1)\, d\varphi \right| \le \frac{c}{\sqrt{M}}\sqrt{\varepsilon} \tag{3.22}$$

and

$$|u_\varepsilon^2(\theta_\varepsilon^\pm) - 1| \le \eta\,. \tag{3.23}$$

In fact, reasoning by contradiction, assume that for every constant $c > 0$ we cannot find two points $\theta_\varepsilon^\pm \in I_\varepsilon^\pm$ such that (3.22) and (3.23) are satisfied at the same time. If we denote

$$B_c = \left\{ \theta : M\sqrt{\varepsilon} \le |\theta - \theta_\varepsilon| \le 2M\sqrt{\varepsilon},\ \left| \int_0^{\theta} \rho\,(u_\varepsilon^2 - 1)\, d\varphi \right| > \frac{c}{\sqrt{M}}\sqrt{\varepsilon} \right\},$$

then by (3.19) we have $|B_c| \ge \sqrt{\varepsilon}(2M - \overline{c})$, and hence

$$F_\varepsilon^{3/2}(u_\varepsilon) \ge \varepsilon^{-3/2} \int_{B_c} \frac{1}{\rho(\theta)} \left(\int_0^{\theta} \rho\,(u_\varepsilon^2 - 1)\, d\varphi \right)^2 d\theta$$
$$\ge \varepsilon^{-1/2} \frac{c^2}{\rho(1)} \frac{|B_c|}{M} \ge \frac{c^2}{\rho(1)} \left(2 - \frac{\overline{c}}{M} \right).$$

Note that we can choose M large enough such that $\overline{c} < 2M$. Since $\sup_\varepsilon F_\varepsilon^{3/2}(u_\varepsilon) < +\infty$, we get a contradiction by the arbitrariness of $c > 0$.

Step 2. We give an estimate on the contribution between θ_ε^- and θ_ε^+. By (3.22), there exists a sequence (c_-^ε), bounded independently of ε, such that

(3.24)

$$\begin{aligned}
&\sqrt{\varepsilon}\int_{\theta_\varepsilon^-}^{\theta_\varepsilon^+}\rho\,(u_\varepsilon')^2\,d\theta+\varepsilon^{-3/2}\int_{\theta_\varepsilon^-}^{\theta_\varepsilon^+}\frac{1}{\rho(\theta)}\left(\int_0^\theta\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2 d\theta\\
&\quad=\sqrt{\varepsilon}\int_{\theta_\varepsilon^-}^{\theta_\varepsilon^+}\rho\,(u_\varepsilon')^2\,d\theta+\varepsilon^{-3/2}\int_{\theta_\varepsilon^-}^{\theta_\varepsilon^+}\frac{1}{\rho(\theta)}\left(\frac{c_-^\varepsilon}{\sqrt{M}}\sqrt{\varepsilon}+\int_{\theta_\varepsilon^-}^\theta\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2 d\theta\\
&\quad=\int_{-M_\varepsilon}^{M_\varepsilon}\rho_\varepsilon\,(v')^2\,ds+\int_{-M_\varepsilon}^{M_\varepsilon}\frac{1}{\rho_\varepsilon(\sigma)}\left(\frac{c_-^\varepsilon}{\sqrt{M}}+\int_{-M_\varepsilon}^\sigma\rho_\varepsilon\,(v^2-1)\,ds\right)^2 d\sigma,
\end{aligned}$$

where $s=(\varphi-\theta_\varepsilon)/\sqrt{\varepsilon}$, $\sigma=(\theta-\theta_\varepsilon)/\sqrt{\varepsilon}$, $\rho_\varepsilon(t)=\rho(\theta_\varepsilon+t\sqrt{\varepsilon})$ and $v(s)=u_\varepsilon(\theta_\varepsilon+\sqrt{\varepsilon}s)$. By (3.22) there exists also a sequence (c_+^ε), bounded independently of ε, such that

$$\int_0^{\theta_\varepsilon^+}\rho\,(u_\varepsilon^2-1)\,d\varphi=\frac{c_+^\varepsilon}{\sqrt{M}}\sqrt{\varepsilon}\,;$$

hence,

$$\frac{1}{\sqrt{\varepsilon}}\int_{\theta_\varepsilon^-}^{\theta_\varepsilon^+}\rho\,(u_\varepsilon-1)^2\,d\varphi=\int_{-M_\varepsilon}^{M_\varepsilon}\rho_\varepsilon\,(v^2-1)\,ds=\frac{c_+^\varepsilon-c_-^\varepsilon}{\sqrt{M}}\,. \tag{3.25}$$

By (3.23) we get that $|v^2(\pm M_\varepsilon)-1|\le\eta$. We consider $v(s)=u_\varepsilon(\theta_\varepsilon+\sqrt{\varepsilon}s)$ for $s\in[-M_\varepsilon,M_\varepsilon]$ and we extend it to $[-3M,3M]$ in such a way that

$$v(\pm 3M)=\mp 1,\quad \int_{-3M}^{3M}\rho_\varepsilon\,(v^2-1)\,ds=0, \tag{3.26}$$

$$\int_{-3M}^{-M_\varepsilon}\rho_\varepsilon\,(v^2-1)\,ds=\frac{c_-^\varepsilon}{\sqrt{M}}\,.$$

Note that by (3.25) and (3.26) we have that

$$\int_{M_\varepsilon}^{3M}\rho_\varepsilon\,(v^2-1)\,ds=-\frac{c_+^\varepsilon}{\sqrt{M}}\,.$$

We explicitly construct v on $[-3M,-M_\varepsilon]$, the construction on $[M_\varepsilon,3M]$ being analogous. We also suppose that $c_-^\varepsilon\le 0$ and $v(-M_\varepsilon)\ge 1$ (the construction being the same or simpler in the other cases). We define v on $[-3M,-M_\varepsilon]$ as

$$v(s)=\begin{cases}1 & \text{if } s\in[-3M,-h_\varepsilon),\\ -s+\sqrt{1-\eta}-k_\varepsilon^- & \text{if } s\in[-h_\varepsilon,-k_\varepsilon^-),\\ \sqrt{1-\eta} & \text{if } s\in[-k_\varepsilon^-,-k_\varepsilon^+),\\ s+\sqrt{1-\eta}+k_\varepsilon^+ & \text{if } s\in[-k_\varepsilon^+,-M_\varepsilon],\end{cases} \tag{3.27}$$

where

$$-k_\varepsilon^- = -h_\varepsilon + 1 - \sqrt{1-\eta}, \qquad -k_\varepsilon^+ = -M_\varepsilon - v(-M_\varepsilon) + \sqrt{1-\eta}\,.$$

Note that k_ε^+ is fixed by Step 1 while k_ε^- is fixed by (3.26). In fact, since $|v^2-1| \le \eta$ on $[-h_\varepsilon, -k_\varepsilon^-)$ and $[-k_\varepsilon^+, -M_\varepsilon)$, we have that

$$\left| \int_{-h_\varepsilon}^{-k_\varepsilon^-} \rho_\varepsilon\,(v^2-1)\,ds + \int_{-k_\varepsilon^+}^{-M_\varepsilon} \rho_\varepsilon\,(v^2-1)\,ds \right| \le \eta\,\rho(1)\left(1+\sqrt{1+\eta}-2\sqrt{1-\eta}\right);$$

hence, there exists $r(\eta,\varepsilon)$ such that $|r(\eta,\varepsilon)| \le \rho(1)(1+\sqrt{1+\eta}-2\sqrt{1-\eta})$ uniformly in ε and

$$\int_{-3M}^{-M_\varepsilon} \rho_\varepsilon\,(v^2-1)\,ds = \eta\,(-k_\varepsilon + r(\eta,\varepsilon)) = \frac{c_-^\varepsilon}{\sqrt{M}}\,,$$

where $k_\varepsilon := -k_\varepsilon^+ + k_\varepsilon^-$. It follows that

$$k_\varepsilon = \frac{|c_-^\varepsilon|}{\eta\sqrt{M}} + r(\eta,\varepsilon)\,, \tag{3.28}$$

with $\lim_{\eta\to 0^+} |r(\eta,\varepsilon)| = 0$. Reasoning as above, by (3.28), we can also observe that

$$\begin{aligned}
&\int_{-3M}^{-M_\varepsilon} \frac{1}{\rho_\varepsilon(\sigma)} \left(\int_{-3M}^{\sigma} \rho_\varepsilon\,(v^2-1)\,ds \right)^2 d\sigma \\
&\quad = \int_{-h_\varepsilon}^{-M_\varepsilon} \frac{1}{\rho_\varepsilon(\sigma)} \left(\int_{-h_\varepsilon}^{\sigma} \rho_\varepsilon\,(v^2-1)\,ds \right)^2 d\sigma \\
&\quad \le \eta^2\,\frac{\rho(1)}{3}\Big(k_\varepsilon + 1 + \sqrt{1+\eta} - 2\sqrt{1-\eta}\Big)^3 \\
&\quad = \eta^2\,\frac{\rho(1)}{3}\left(\frac{|c_-^\varepsilon|}{\eta\sqrt{M}} + r(\eta,\varepsilon) + 1 + \sqrt{1+\eta} - 2\sqrt{1-\eta}\right)^3 .
\end{aligned}$$

We can prove a similar estimate also for the contribution corresponding to the interval $[M_\varepsilon, 3M]$; hence, we can conclude that there exists $R(M,\eta,\varepsilon) > 0$, bounded independently of ε, such that

$$\begin{aligned}
R(M,\eta,\varepsilon) = &\int_{-3M}^{-M_\varepsilon} \frac{1}{\rho_\varepsilon(\sigma)} \left(\int_{-3M}^{\sigma} \rho_\varepsilon\,(v^2-1)\,ds \right)^2 d\sigma \\
&+ \int_{M_\varepsilon}^{3M} \frac{1}{\rho_\varepsilon(\sigma)} \left(\frac{c_+^\varepsilon}{\sqrt{M}} + \int_{M_\varepsilon}^{\sigma} \rho_\varepsilon\,(v^2-1)\,ds \right)^2 d\sigma
\end{aligned} \tag{3.29}$$

and

$$\limsup_{\eta\to 0^+} \limsup_{M\to\infty} \limsup_{\varepsilon\to 0} R(M,\eta,\varepsilon) = 0\,. \tag{3.30}$$

By (3.29) we have that

$$\begin{aligned}
&\int_{-M_\varepsilon}^{M_\varepsilon} \frac{1}{\rho_\varepsilon(\sigma)} \left(\frac{c_-^\varepsilon}{\sqrt{M}} + \int_{-M_\varepsilon}^{\sigma} \rho_\varepsilon\,(v^2-1)\,ds \right)^2 d\sigma \\
&\quad = \int_{-3M}^{3M} \frac{1}{\rho_\varepsilon(\sigma)} \left(\int_{-3M}^{\sigma} \rho_\varepsilon\,(v^2-1)\,ds \right)^2 d\sigma - R(M,\eta,\varepsilon)\,.
\end{aligned} \tag{3.31}$$

The function v, constructed as in (3.27), gives the following contribution of the term with the derivative:

$$\int_{-3M}^{-M_\varepsilon} \rho_\varepsilon\,(v')^2\,ds \le \rho(1)\left(1+\sqrt{1+\eta}-2\sqrt{1-\eta}\right);$$

hence, reasoning similarly on $[M_\varepsilon, 3M]$, there exists $R_1(\eta,\varepsilon) > 0$, bounded independently of ε, such that

$$\int_{-M_\varepsilon}^{M_\varepsilon} \rho_\varepsilon\,(v')^2\,ds = \int_{-3M}^{3M} \rho_\varepsilon\,(v')^2\,ds - R_1(\eta,\varepsilon) \tag{3.32}$$

and

$$\limsup_{\eta\to 0^+}\limsup_{\varepsilon\to 0} R_1(\eta,\varepsilon) = 0\,. \tag{3.33}$$

By (3.24), (3.32), and (3.31) we get that

$$\begin{aligned}
&\sqrt{\varepsilon}\int_{\theta_\varepsilon^-}^{\theta_\varepsilon^+} \rho(\theta)(u_\varepsilon')^2\,d\theta + \varepsilon^{-3/2}\int_{\theta_\varepsilon^-}^{\theta_\varepsilon^+} \frac{1}{\rho(\theta)}\left(\int_0^\theta \rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2 d\theta\\
&\quad= \int_{-3M}^{3M} \rho_\varepsilon\,(v')^2\,ds + \int_{-3M}^{3M} \frac{1}{\rho_\varepsilon(\sigma)}\left(\int_{-3M}^{\sigma} \rho_\varepsilon\,(v^2-1)\,ds\right)^2 d\sigma\\
&\qquad - R_1(\eta,\varepsilon) - R(M,\eta,\varepsilon)\\
&\quad\ge \inf\left\{\int_{-T}^{T} \rho_\varepsilon\,(v')^2\,ds + \int_{-T}^{T} \frac{1}{\rho_\varepsilon(\sigma)}\left(\int_{-T}^{\sigma} \rho_\varepsilon\,(v^2-1)\,ds\right)^2 d\sigma\ :\right.\\
&\qquad\qquad \left. v\in H^1(-T,T),\quad v(\pm T)=\pm 1,\quad \int_{-T}^{T} \rho_\varepsilon\,(v^2-1)\,ds = 0\right\}\\
&\qquad + \delta(T,\eta,\varepsilon),
\end{aligned} \tag{3.34}$$

where $T = 3M$ and $\delta(T,\eta,\varepsilon) = -R_1(\eta,\varepsilon) - \tilde{R}(T,\eta,\varepsilon)$ with $\tilde{R}(T,\eta,\varepsilon) = R(M,\eta,\varepsilon)$. Note that in the last infimum problem we can take the boundary values indifferently as $v(\pm T) = \pm 1$ or $v(\pm T) = \mp 1$, by the symmetry of the problem, so that both types of transitions are taken into account.

By (3.30) and (3.33), we have that

$$\limsup_{\eta\to 0^+}\limsup_{T\to\infty}\limsup_{\varepsilon\to 0}|\delta(T,\eta,\varepsilon)|=0\,;$$

hence, it remains to study the behavior of the minimum problems as ε tends to 0. By the uniform convergence of ρ_ε to $\rho(\theta_i)$, as ε tends to 0, we have immediately the Γ-convergence of the functionals with respect to the strong L^2 convergence; i.e.,

$$\begin{aligned}\Gamma(L^2)\text{-}\lim_{\varepsilon\to 0}&\left(\int_{-T}^{T}\rho_\varepsilon\,(v')^2\,ds\,+\,\int_{-T}^{T}\frac{1}{\rho_\varepsilon(\sigma)}\left(\int_{-T}^{\sigma}\rho_\varepsilon\,(v^2-1)\,ds\right)^2\,d\sigma\right)\\&=\rho(\theta_i)\left(\int_{-T}^{T}(v')^2\,ds\,+\,\int_{-T}^{T}\left(\int_{-T}^{\sigma}(v^2-1)\,ds\right)^2\,d\sigma\right).\end{aligned}$$

This Γ-convergence result is stable by adding the constraint; indeed, since the constraint $\int_{-T}^{T}\rho_\varepsilon\,(v^2-1)\,ds=0$ is close for the strong L^2-convergence, the lim inf inequality is trivial. To check the lim sup inequality, let $v\in H^1(-T,T)$ such that $v(\pm T)=\pm 1$ and $\int_{-T}^{T}(v^2-1)\,ds=0$. To obtain a recovery sequence we consider

$$v_\varepsilon(s)=v(s)+t_\varepsilon\phi(s),\qquad s\in[-T,T],\tag{3.35}$$

where

$$\phi(s)=\begin{cases}(s+T)/T, & s\in[-T,0),\\[2mm](T-s)/T, & s\in[0,T]\end{cases}\tag{3.36}$$

(note that $v_\varepsilon\in H^1(-T,T)$ and $v_\varepsilon(\pm T)=\pm 1$) and $t_\varepsilon\in\mathbf{R}$ is chosen such that (v_ε) satisfies the constraint and converges to v in $L^2(-T,T)$; i.e.,

$$\int_{-T}^{T}\rho_\varepsilon\,((v+t_\varepsilon\phi)^2-1)\,ds=0\quad\text{and}\quad t_\varepsilon\to 0\quad\text{as}\quad\varepsilon\to 0\,.\tag{3.37}$$

More precisely, (v_ε) satisfies the constraint in (3.37) if $t_\varepsilon\in\mathbf{R}$ is a solution of the second order equation

$$\left(\int_{-T}^{T}\rho_\varepsilon\,\phi^2\,ds\right)t_\varepsilon^2+2\left(\int_{-T}^{T}\rho_\varepsilon\,v\phi\,ds\right)t_\varepsilon+\left(\int_{-T}^{T}\rho_\varepsilon\,(v^2-1)\,ds\right)=0\,.\tag{3.38}$$

Since $\lim_{\varepsilon\to 0}\int_{-T}^{T}\rho_\varepsilon(v^2-1)\,ds=0$, for ε small enough, (3.38) has two solutions, real and distinct, such that one of the two tends to 0 as ε tends to 0.

To conclude the proof of the lim sup inequality, we have to note that

$$\begin{aligned}\lim_{\varepsilon\to 0}&\left(\int_{-T}^{T}\rho_\varepsilon\,(v_\varepsilon')^2\,ds\,+\,\int_{-T}^{T}\frac{1}{\rho_\varepsilon(\sigma)}\left(\int_{-T}^{\sigma}\rho_\varepsilon\,(v_\varepsilon^2-1)\,ds\right)^2\,d\sigma\right)\\&=\rho(\theta_i)\left(\int_{-T}^{T}(v')^2\,ds\,+\,\int_{-T}^{T}\left(\int_{-T}^{\sigma}(v^2-1)\,ds\right)^2\,d\sigma\right).\end{aligned}\tag{3.39}$$

We go back now to (3.34); by the property of convergence of minima (see [6, Thm. 1.21]) we have that

$$\begin{aligned}
&\liminf_{\varepsilon\to 0}\left(\sqrt{\varepsilon}\int_{\theta_\varepsilon^-}^{\theta_\varepsilon^+}\rho\,(u_\varepsilon')^2\,d\theta+\varepsilon^{-3/2}\int_{\theta_\varepsilon^-}^{\theta_\varepsilon^+}\frac{1}{\rho(\theta)}\left(\int_0^\theta\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2 d\theta\right)\\
&\quad\geq\rho(\theta_i)\inf\left\{\int_{-T}^{T}(v')^2\,ds+\int_{-T}^{T}\left(\int_{-T}^{\sigma}(v^2-1)\,ds\right)^2 d\sigma\,:\,v\in H^1(-T,T),\right.\\
&\qquad\qquad\left.v(\pm T)=\pm1,\quad\int_{-T}^{T}(v^2-1)\,ds=0\right\}\\
&\qquad-\limsup_{\varepsilon\to 0}|\delta(T,\eta,\varepsilon)|\\
&\quad\geq\rho(\theta_i)\inf_{T>0}\inf\left\{\int_{-T}^{T}(v')^2\,ds+\int_{-T}^{T}\left(\int_{-T}^{\sigma}(v^2-1)\,ds\right)^2 d\sigma\,:\right.\\
&\qquad\qquad\left.v\in H^1(-T,T),\quad v(\pm T)=\pm1,\quad\int_{-T}^{T}(v^2-1)\,ds=0\right\}\\
&\qquad-\limsup_{T\to+\infty}\limsup_{\varepsilon\to 0}|\delta(T,\eta,\varepsilon)|\\
&\quad=\rho(\theta_i)\,c_0-\limsup_{T\to+\infty}\limsup_{\varepsilon\to 0}|\delta(T,\eta,\varepsilon)|\,,
\end{aligned}$$

where

$$\begin{aligned}
c_0:=\inf_{T>0}\inf\left\{\int_{-T}^{T}(v')^2\,ds+\int_{-T}^{T}\left(\int_{-T}^{\sigma}(v^2-1)\,ds\right)^2 d\sigma\,:\,v\in H^1(-T,T),\right.\\
\left.v(\pm T)=\pm1,\quad\text{and}\quad\int_{-T}^{T}(v^2-1)\,ds=0\right\}.
\end{aligned}$$

Passing to the limit as $\eta\to 0^+$, we get

$$\begin{aligned}
&\liminf_{\varepsilon\to 0}\left(\sqrt{\varepsilon}\int_{\theta_\varepsilon^-}^{\theta_\varepsilon^+}\rho\,(u_\varepsilon')^2\,d\theta+\varepsilon^{-3/2}\int_{\theta_\varepsilon^-}^{\theta_\varepsilon^+}\frac{1}{\rho(\theta)}\left(\int_0^\theta\rho\,(u_\varepsilon^2-1)\,d\varphi\right)^2 d\theta\right)\\
&\qquad\geq\rho(\theta_i)\,c_0\,.
\end{aligned}$$

Step 3. If we repeat Steps 1–2 for every $\theta\in S(u)\cap(a,1-a)$, we immediately get that

$$\liminf_{\varepsilon\to 0}F_\varepsilon^{3/2}(u_\varepsilon)\geq c_0\sum_{\theta\in S(u)\cap(a,1-a)}\rho(\theta)$$

and then the lim inf inequality taking the supremum in a.

Lim sup *inequality.* Let $u\in BV((0,1);\{-1,1\})$. We denote $S(u)=\{\theta_1,\cdots,\theta_N\}$ with $\theta_i<\theta_{i+1}$. With fixed $\eta>0$ there exist $T>0$ and $v\in H^1(-T,T)$ such that $v(\pm T)=\pm1$, $\int_{-T}^{T}(v^2-1)\,ds=0$, and

$$\int_{-T}^{T}(v')^2\,ds+\int_{-T}^{T}\left(\int_{-T}^{\sigma}(v^2-1)\,ds\right)^2 d\sigma\leq c_0+\eta\,. \tag{3.40}$$

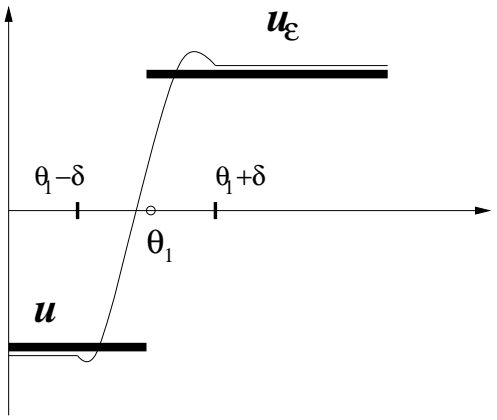

FIG. 2. *Recovery sequence with a Gibbs phenomenon.*

We denote $\delta = T\sqrt{\varepsilon}$, $K_i = [\theta_i + \delta, \theta_{i+1} - \delta]$ for $i = 1, \dots, N-1$, $K_N = [\theta_N + \delta, 1]$. We construct a sequence u_ε by setting

$$u_\varepsilon(\theta) = \begin{cases} v^i_\varepsilon(\pm\varepsilon^{-1/2}(\theta - \theta_i)) & \text{if } \theta \in [\theta_i - \delta, \theta_i + \delta], \quad i = 1, \dots, N, \\ u(\theta) & \text{if } \theta \in (0, \theta_1 - \delta) \cup_{i=1}^N K_i, \end{cases} \tag{3.41}$$

where $v^i_\varepsilon = v + t^i_\varepsilon \phi$ is defined as in Step 2 with ϕ given by (3.36) and $t^i_\varepsilon \in \mathbf{R}$ such that

$$\int_{-T}^{T} \rho^i_\varepsilon \left((v + t^i_\varepsilon \phi)^2 - 1\right) ds = 0 \quad \text{and} \quad t^i_\varepsilon \to 0 \quad \text{as} \quad \varepsilon \to 0 \tag{3.42}$$

for every $i = 1, \dots, N$, where $\rho^i_\varepsilon(s) = \rho(\theta_i + s\sqrt{\varepsilon})$. Note that the choice between the plus and minus sign, in (3.41), is made in such a way that the resulting function is continuous. The construction of u_ε is illustrated in Figure 2.

Note that, reasoning as in Step 2, we get

$$\begin{aligned} \lim_{\varepsilon \to 0} &\left(\int_{-T}^{T} \rho^i_\varepsilon \left(v^i_\varepsilon\right)'^2 ds + \int_{-T}^{T} \frac{1}{\rho^i_\varepsilon(\sigma)} \left(\int_{-T}^{\sigma} \rho^i_\varepsilon \left((v^i_\varepsilon)^2 - 1\right) ds \right)^2 d\sigma \right) \\ &= \rho(\theta_i) \left(\int_{-T}^{T} (v')^2 ds + \int_{-T}^{T} \left(\int_{-T}^{\sigma} (v^2 - 1) ds \right)^2 d\sigma \right). \end{aligned} \tag{3.43}$$

Hence,

$$\begin{aligned} F^{3/2}_\varepsilon(u_\varepsilon) = \sqrt{\varepsilon} \sum_{i=1}^{N} \int_{\theta_i - \delta}^{\theta_i + \delta} \rho \left(u'_\varepsilon\right)^2 d\theta \\ + \varepsilon^{-3/2} \sum_{i=1}^{N} \left(\int_{K_i} \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho \left(u^2_\varepsilon - 1\right) d\varphi \right)^2 d\theta \right. \\ \left. + \int_{\theta_i - \delta}^{\theta_i + \delta} \frac{1}{\rho(\theta)} \left(\int_0^\theta \rho \left(u^2_\varepsilon - 1\right) d\varphi \right)^2 d\theta \right). \end{aligned}$$

By the changes of variable $s = \varepsilon^{-1/2}(\varphi - \theta_i)$, $\sigma = \varepsilon^{-1/2}(\theta - \theta_i)$ and (3.42), we get that

$$\begin{aligned} F_\varepsilon^{3/2}(u_\varepsilon) &= \sum_{i=1}^N \int_{-T}^T \rho_\varepsilon^i \left(v_\varepsilon^i\right)'^2 ds \\ &\quad + \varepsilon^{-1/2} \sum_{i=1}^N \left(\int_{K_i} \frac{d\theta}{\rho(\theta)}\right) \left(\sum_{j=1}^i \int_{-T}^T \rho_\varepsilon^j \left((v_\varepsilon^j)^2 - 1\right) ds\right)^2 \\ &\quad + \varepsilon^{-1/2} \sum_{i=1}^N \int_{\theta_i-\delta}^{\theta_i+\delta} \frac{1}{\rho(\theta)} \left(\sum_{j=1}^{i-1} \int_{-T}^T \rho_\varepsilon^j \left((v_\varepsilon^j)^2 - 1\right) ds \right. \\ &\qquad \left. + \int_{-T}^{\varepsilon^{-1/2}(\theta-\theta_i)} \rho_\varepsilon^i \left((v_\varepsilon^i)^2 - 1\right) ds\right)^2 d\theta \\ &= \sum_{i=1}^N \int_{-T}^T \rho_\varepsilon^i \left(v_\varepsilon^i\right)'^2 ds + \int_{-T}^T \frac{1}{\rho_\varepsilon^i(\sigma)} \left(\int_{-T}^\sigma \rho_\varepsilon^i \left((v_\varepsilon^i)^2 - 1\right) ds\right)^2 d\sigma\,. \end{aligned}$$

By (3.40) and (3.43), we have

$$\begin{aligned} \limsup_{\varepsilon\to 0} F_\varepsilon^{3/2}(u_\varepsilon) &= \left(\sum_{i=1}^N \rho(\theta_i)\right) \left(\int_{-T}^T (v')^2 ds + \int_{-T}^T \left(\int_{-T}^\sigma (v^2 - 1) ds\right)^2 d\sigma\right) \\ &\le \left(\sum_{i=1}^N \rho(\theta_i)\right) (c_0 + \eta)\,. \end{aligned}$$

By the arbitrariness of η we get the lim sup inequality for every $u \in BV((0,1);\{-1,1\})$.

We now consider $u \in BV_{\rm loc}((0,1);\{-1,1\})$; let $u^a \in BV((0,1);\{-1,1\})$ be such that u^a converges to u strongly in $L^1(0,1)$ as $a \to 0^+$; e.g.,

$$u^a(\theta) = \begin{cases} u(a), & \theta \in [0,a), \\ u(\theta), & \theta \in [a, 1-a], \\ u(1-a), & \theta \in (1-a, 1], \end{cases}$$

with $0 < a < 1$ and $a, 1-a \notin S(u)$. By the lower semicontinuity of the Γ-lim sup, we have that

$$\begin{aligned} \Gamma\text{-}\limsup_{\varepsilon\to 0} F_\varepsilon^{3/2}(u) &\le \liminf_{a\to 0^+} \Big(\Gamma\text{-}\limsup_{\varepsilon\to 0} F_\varepsilon^{3/2}(u^a)\Big) \\ &\le c_0 \liminf_{a\to 0^+} \sum_{\theta\in S(u^a)} \rho(\theta) \le c_0 \sum_{\theta\in S(u)} \rho(\theta) \end{aligned}$$

for every $u \in BV_{\rm loc}((0,1);\{-1,1\})$ (see [6, Remark 1.29]). □

4. The case $\alpha = 4/3$ with constrained phase transitions. If we define G_ε^0 as the restriction of F_ε^0 to the space of functions $u : (0,1) \to [-1,1]$, then by Remark 2 the Γ-limit of G_ε^0 is identically 0. Still, one may find another scaling, $\alpha = 4/3$, such that the Γ-limit of $G_\varepsilon^{4/3} = \varepsilon^{-4/3} G_\varepsilon^0$ is not trivial. We consider for simplicity $\rho \equiv 1$ so that

$$G_\varepsilon^{4/3}(u) = \varepsilon^{2/3} \int_0^1 (u')^2 \, d\theta + \varepsilon^{-4/3} \int_0^1 \left(\int_0^\theta (u^2 - 1)\, d\varphi\right)^2 d\theta$$

for every $u \in H^1((0,1);[-1,1])$. Note that since $\varepsilon^{-4/3}F_\varepsilon^0 = \varepsilon^{1/6}F_\varepsilon^{3/2}$, by section 3 the Γ-limit of $\varepsilon^{-4/3}F_\varepsilon^0$ with respect to the strong L^1-convergence is zero. Hence, the constraint $|u| \le 1$ completely changes the characteristic scaling of the energy.

THEOREM 4.1 (compactness). *Let $(u_\varepsilon) \in H^1((0,1);[-1,1])$ be a sequence such that $\sup_\varepsilon G_\varepsilon^{4/3}(u_\varepsilon) < +\infty$; then up to subsequences, (u_ε) converges strongly in $L^1(0,1)$ to $u \in BV_{\rm loc}((0,1);\{-1,1\})$.*

Proof. Let $\eta_\varepsilon^\pm \neq \pm 1$ such that $-1 < \eta_\varepsilon^+, \eta_\varepsilon^- < 1$. We denote by $(\delta_\varepsilon^-, \delta_\varepsilon^+)$ an interval such that $u_\varepsilon(\delta_\varepsilon^-) = \eta_\varepsilon^-$, $u_\varepsilon(\delta_\varepsilon^+) = \eta_\varepsilon^+$ and u_ε takes values between η_ε^- and η_ε^+. In what follows, we use the notation $\eta^\pm = \eta_\varepsilon^\pm$, $\delta^\pm = \delta_\varepsilon^\pm$ to not overburden notation. By the constraint, $(u_\varepsilon^2 - 1)$ never changes sign; hence, we can select in the energy $G_\varepsilon^{4/3}(u_\varepsilon)$ the most significant contribution which permits us to easily estimate $(\delta^+ - \delta^-)$. More precisely, for every fixed $0 < a < 1$, we consider $\delta^+ \le 1 - a$; then,

$$\begin{aligned} G_\varepsilon^{4/3}(u_\varepsilon) &\ge \varepsilon^{2/3} \int_{\delta^-}^{\delta^+} (u')^2 \, d\theta + \varepsilon^{-4/3} \int_{\delta^+}^{1} \left(\int_{\delta^-}^{\delta^+} (u_\varepsilon^2 - 1) \, d\varphi \right)^2 d\theta \\ &\ge |\eta^+ - \eta^-|^2 \left(\frac{\varepsilon^{2/3}}{\delta} \right) + a\, \lambda^2 \left(\frac{\delta}{\varepsilon^{2/3}} \right)^2, \end{aligned}$$

where $\lambda := ||\eta^-|^2 - 1| \wedge ||\eta^+|^2 - 1|$, i.e., the minimum distance of $|\eta^\pm|^2$ from 1. Hence, if $|\eta^+ - \eta^-| \ge \zeta > 0$, with ζ independent of ε, we have that $\delta/\varepsilon^{2/3}$ is bounded; i.e., there exist two positive constants α_1, α_2 such that $\alpha_1 \varepsilon^{2/3} \le \delta \le \alpha_2 \varepsilon^{2/3}$. Moreover, the number of intervals (δ^-, δ^+) is finite in $[0, 1-a]$ for every $0 < a < 1$. Then (u_ε) converges in measure to $u \in BV_{\rm loc}((0,1);\{-1,1\})$, and since $|u_\varepsilon| \le 1$ we can conclude that, up to subsequences, (u_ε) converges strongly to u in L^1. ∎

Remark 4. Note that in general we cannot expect $u \in BV((0,1);\{-1,1\})$. To show this we construct a sequence (u_ε) with $\sup_\varepsilon G_\varepsilon^{4/3}(u_\varepsilon) < +\infty$ and strongly converging in L^1 to $u \in BV_{\rm loc}((0,1);\{-1,1\})$ with infinitely many jump points. To this end, consider a strictly increasing sequence $(\theta_i) \in (0,1)$ such that $\sup_{i \in \mathbf{N}} \theta_i = 1$, and let $v_i(s) = (s + T_i/T_i) - 1$ for $s \in [-T_i, T_i]$. With fixed $k \in \mathbf{N}$ and ε small enough, we define the sequence (u_ε^k) as

$$u_\varepsilon^k(\theta) = \begin{cases} v_i(\pm \varepsilon^{-2/3}(\theta - \theta_i)), & \theta \in [\theta_i - T_i\varepsilon^{2/3}, \theta_i + T_i\varepsilon^{2/3}], \quad i = 1, \dots, k, \\ \pm 1 & \text{otherwise in } [0,1], \end{cases}$$

where the choice between the plus and minus sign is made in such a way that the resulting function u_ε^k is continuous. For every $k \in \mathbf{N}$, we have that

$$\begin{aligned} G_\varepsilon^{4/3}(u_\varepsilon^k) &= \sum_{i=1}^{k} \left(\frac{2}{T_i} + (\theta_{i+1} - \theta_i) \left(c \sum_{j \le i} T_j \right)^2 \right) + O(\varepsilon^{2/3}) \\ &\le \sum_{i \in \mathbf{N}} \left(\frac{2}{T_i} + (\theta_{i+1} - \theta_i) \left(c \sum_{j \le i} T_j \right)^2 \right) + O(\varepsilon^{2/3}) \end{aligned}$$

(see a similar computation in Theorem 4.2 for the proof of the lim sup inequality). If we fix $T_i = i^\beta$, with $\beta > 1$, and (θ_i) such that $(\theta_{i+1} - \theta_i) = \gamma\, i^{(-3\beta-2)}$, with γ satisfying the condition $\gamma \sum_{i \in \mathbf{N}} i^{(-3\beta-2)} = (1 - \theta_1)$, then $\sup_\varepsilon G_\varepsilon^{4/3}(u_\varepsilon^k) \le c$, with c independent on k. Therefore, if $(\theta_i)_{i \in \mathbf{N}}$ is an increasing sequence of points distributed in $(0,1)$

as above, for every fixed $k \in \mathbf{N}$, we can construct a suitable sequence (u_ε^k) strongly converging in L^1 to $u^k \in BV((0,1);\{-1,1\})$, as $\varepsilon \to 0$, with $\sup_\varepsilon G_\varepsilon^{4/3}(u_\varepsilon^k) \le c$ and $S(u^k) = \{\theta_1, \dots, \theta_k\}$. We now consider $u \in BV_{\rm loc}((0,1);\{-1,1\})$ such that $S(u) = (\theta_i)_{i\in\mathbf{N}}$ and $u = u^k$ in $[0, \theta_{k+1})$; then u^k converges strongly in L^1 to u as k tends to $+\infty$. By a diagonal procedure we may extract from (u_ε^k) a subsequence with bounded energy and strongly converging to u in L^1.

THEOREM 4.2 (nonlocal Γ-limit). *We have*

$$\begin{aligned}\Gamma(L^1)\text{-}\lim_{\varepsilon\to 0} G_\varepsilon^{4/3}(u)\\ = \inf_{T>0} \inf\left\{ \sum_{i\in I}\left(\int_{-T}^{T} (v_i')^2\, ds + (\theta_{i+1}-\theta_i)\left(\sum_{j=1}^{i}\int_{-T}^{T}(v_j^2-1)\, ds\right)^2\right) :\right.\\ \left. v_i \in H^1((-T,T);[-1,1]),\quad v_i(\pm T) = \pm 1\right\}\end{aligned}$$

for every $u \in BV_{\rm loc}((0,1);\{-1,1\})$, where $I = \{i \in \mathbf{N} : \theta_i \in S(u)\,, \theta_i < \theta_{i+1}\}$.

Proof. Let $u \in BV_{\rm loc}((0,1);\{-1,1\})$, and let $(u_\varepsilon) \in H^1((0,1);[-1,1])$ be a sequence strongly converging to u in L^1 such that

$$\liminf_{\varepsilon\to 0} G_\varepsilon^{4/3}(u_\varepsilon) < +\infty\,.$$

For every fixed $0 < a < 1$, by Theorem 4.1 the limit function u has a finite number of discontinuity points in the interval $(0, 1-a]$; i.e., $S(u) \cap (0, 1-a] = \{\theta_1, \dots, \theta_{N(a)}\}$ with $\theta_i < \theta_{i+1}$. Up to subsequences, $u_\varepsilon \to u$ for a.e. $\theta \in (0,1)$, as ε tends to 0; hence, with fixed $\eta \in (0,1)$, we consider δ_i^1, δ_i^2 such that

$$u_\varepsilon(\theta_i - \delta_i^1) = -(1-\eta)\,, \qquad u_\varepsilon(\theta_i + \delta_i^2) = 1-\eta$$

or

$$u_\varepsilon(\theta_i - \delta_i^1) = 1-\eta\,, \qquad u_\varepsilon(\theta_i + \delta_i^2) = -(1-\eta)$$

for $i = 1, \dots, N(a)$. The following estimate is obtained by eliminating all the contributions of u_ε on the intervals where the sequence takes values "close" to $\{-1,1\}$; this choice is justified by the construction of the optimal sequence, in the lim sup inequality, that will be equal to $\{-1,1\}$ on such intervals (see (4.2)). We have then

$$\begin{aligned}G_\varepsilon^{4/3}(u_\varepsilon) \ge \varepsilon^{2/3}\sum_{i=1}^{N(a)}\int_{I_i}(u_\varepsilon')^2 d\theta + \varepsilon^{-4/3}\left(\sum_{i=1}^{N(a)}\int_{K_i}\left(\sum_{j=1}^{i}\int_{I_j}(u_\varepsilon^2-1)\, d\varphi\right)^2 d\theta\right.\\ \left. + \sum_{i=1}^{N(a)}\int_{I_i}\left(\sum_{j=1}^{i-1}\int_{I_j}(u_\varepsilon^2-1)\, d\varphi + \int_{\theta_i-\delta_i^1}^{\theta}(u_\varepsilon^2-1)\, d\varphi\right)^2 d\theta\right),\end{aligned}$$

where $I_i = [\theta_i - \delta_i^1, \theta_i + \delta_i^2]$ for $i = 1, \dots, N(a)$ and $K_i = (\theta_i + \delta_i^2, \theta_{i+1} - \delta_{i+1}^1)$ for $i = 1, \dots, N(a)-1$, $K_{N(a)} = (\theta_{N(a)} + \delta_{N(a)}^2, 1-a)$. We make the change of variable

$$w_j(s) = u_\varepsilon\left(\varepsilon^{2/3}s + \theta_j + \frac{\delta_j^2 - \delta_j^1}{2}\right);$$

hence, setting $T_j = \varepsilon^{-2/3}\delta_j$ with $\delta_j = \left(\frac{\delta_j^2+\delta_j^1}{2}\right)$ and

$$T_i(\theta) = \varepsilon^{-2/3}\left(\theta - \theta_i - \frac{(\delta_i^2 - \delta_i^1)}{2}\right),$$

we get

$$G_\varepsilon^{4/3}(u_\varepsilon) \geq \sum_{i=1}^{N(a)} \left(\int_{-T_i}^{T_i} (w_i')^2\, ds + \int_{K_i} \left(\sum_{j=1}^{i} \int_{-T_j}^{T_j} (w_j^2 - 1)\, ds \right)^2 d\theta \right.$$
$$\left. + \int_{I_i} \left(\sum_{j=1}^{i-1} \int_{-T_j}^{T_j} (w_j^2 - 1)\, ds + \int_{-T_i}^{T_i(\theta)} (w_i^2 - 1)\, ds \right)^2 d\theta \right).$$

We denote now

$$B_i = \int_{-T_i}^{T_i} (w_i')^2\, ds\,, \qquad A_j = \int_{-T_j}^{T_j} (w_j^2 - 1)\, ds\,;$$

by the change of variable $\sigma = T_i(\theta)$, we get

$$G_\varepsilon^{4/3}(u_\varepsilon) \geq \sum_{i=1}^{N(a)} B_i + \sum_{i=1}^{N(a)} \left((2\delta_i + \theta_{i+1} - \theta_i - \delta_{i+1}^1 - \delta_i^2) \left(\sum_{j=1}^{i} A_j \right)^2 \right)$$
$$+ \varepsilon^{2/3} \sum_{i=1}^{N(a)} \left(\int_{-T_i}^{T_i} \left(\int_\sigma^{T_i} (w_i^2 - 1)\, ds \right)^2 d\sigma \right.$$
$$\left. - 2 \left(\sum_{j=1}^{i} A_j \right) \int_{-T_i}^{T_i} \left(\int_\sigma^{T_i} (w_i^2 - 1)\, ds \right) d\sigma \right)$$
$$= \sum_{i=1}^{N(a)} \left(B_i + (\theta_{i+1} - \theta_i) \left(\sum_{j=1}^{i} A_j \right)^2 \right) + \sum_{i=1}^{N(a)} (\delta_i^1 - \delta_{i+1}^1) \left(\sum_{j=1}^{i} A_j \right)^2$$
$$+ \varepsilon^{2/3} \left(\sum_{i=1}^{N(a)} \int_{-T_i}^{T_i} \left(\int_\sigma^{T_i} (w_i^2 - 1)\, ds \right)^2 d\sigma \right.$$
$$\left. - 2 \left(\sum_{j=1}^{i} A_j \right) \int_{-T_i}^{T_i} \left(\int_\sigma^{T_i} (w_i^2 - 1)\, ds \right) d\sigma \right),$$

where $\theta_{N(a)+1} = 1 - a$ and $\delta_{N(a)+1}^1 = 0$. Hence,

$$G_\varepsilon^{4/3}(u_\varepsilon) \geq \sum_{i=1}^{N(a)} \left(\int_{-T_i}^{T_i} (w_i')^2\, ds + (\theta_{i+1} - \theta_i) \left(\sum_{j=1}^{i} \int_{-T_j}^{T_j} (w_j^2 - 1)\, ds \right)^2 \right) + O(\varepsilon^{2/3}),$$

where $w_i(\pm T_i)$ is equal to $\pm(1-\eta)$ or $\mp(1-\eta)$, and

$$\begin{aligned}&\liminf_{\varepsilon\to 0} G_\varepsilon^{4/3}(u_\varepsilon)\\ &\quad\geq \inf_{T>0}\ \inf\left\{\sum_{i=1}^{N(a)}\left(\int_{-T}^{T}(v_i')^2\,ds+(\theta_{i+1}-\theta_i)\left(\sum_{j=1}^{i}\int_{-T}^{T}(v_j^2-1)\,ds\right)^2\right):\right.\\ &\qquad\left. v_i\in H^1((-T,T);[-1,1]),\quad v_i(\pm T)=\pm(1-\eta)\right\},\end{aligned}$$

where, by symmetry, we may fix the boundary conditions as $v_i(\pm T)=\pm(1-\eta)$. We may now first pass to the limit as $\eta\to 0$ and then take the supremum on a; i.e.,

$$\begin{aligned}&\liminf_{\varepsilon\to 0} G_\varepsilon^{4/3}(u_\varepsilon)\\ &\geq \sup_{0<a<1}\inf_{T>0}\ \inf\left\{\sum_{i=1}^{N(a)}\left(\int_{-T}^{T}(v_i')^2\,ds+(\theta_{i+1}-\theta_i)\left(\sum_{j=1}^{i}\int_{-T}^{T}(v_j^2-1)\,ds\right)^2\right):\right.\\ &\qquad\left. v_i\in H^1((-T,T);[-1,1]),\quad v_i(\pm T)=\pm 1\right\}\\ &=\inf_{T>0}\ \inf\left\{\sum_{i\in I}\left(\int_{-T}^{T}(v_i')^2\,ds+(\theta_{i+1}-\theta_i)\left(\sum_{j=1}^{i}\int_{-T}^{T}(v_j^2-1)\,ds\right)^2\right):\right.\\ &\qquad\left. v_i\in H^1((-T,T);[-1,1]),\quad v_i(\pm T)=\pm 1\right\},\end{aligned}$$

where we have labeled the points in $S(u)$ by a set of indices $I\subset\mathbf{N}$ in such a way that $\theta_i<\theta_{i+1}$.

We now check the lim sup inequality. Let $u\in BV((0,1);\{-1,1\})$ with $S(u)=\{\theta_1,\dots,\theta_N\}$ and $\theta_i<\theta_{i+1}$. We denote

$$\begin{aligned}G^{4/3}(u)=\inf_{T>0}\ \inf\left\{\sum_{i=1}^{N}\left(\int_{-T}^{T}(v_i')^2\,ds+(\theta_{i+1}-\theta_i)\left(\sum_{j=1}^{i}\int_{-T}^{T}(v_j^2-1)\,ds\right)^2\right):\right.\\ \left. v_i\in H^1((-T,T);[-1,1]),\quad v_i(\pm T)=\pm 1\right\}.\end{aligned}$$

With fixed $\eta>0$, there exist $T>0$ and $(v_1,\dots,v_N)\in H^1((-T,T);[-1,1])$ such that $v_i(\pm T)=\pm 1$ and

$$\sum_{i=1}^{N}\left(\int_{-T}^{T}(v_i')^2\,ds+(\theta_{i+1}-\theta_i)\left(\sum_{j=1}^{i}\int_{-T}^{T}(v_j^2-1)\,ds\right)^2\right)\leq G^{4/3}(u)+\eta\,. \tag{4.1}$$

We denote $\delta = T\varepsilon^{2/3}$; $I_i = [\theta_i - \delta, \theta_i + \delta]$ for $i = 1, \dots, N$; $K_i = (\theta_i + \delta, \theta_{i+1} - \delta)$ for $i = 1, \dots, N-1$; and $K_N = (\theta_N + \delta, 1]$. We construct a sequence u_ε by setting

$$u_\varepsilon(\theta) = \begin{cases} v_i(\pm\varepsilon^{-2/3}(\theta - \theta_i)) & \text{if } \theta \in I_i, \quad i = 1, \dots, N, \\ u(\theta) & \text{if } \theta \in (0, \theta_1 - \delta) \cup \left(\cup_{i=1}^N K_i\right), \end{cases} \tag{4.2}$$

where the choice between the plus and minus sign is made in such a way that the resulting function is continuous. Hence, by the change of variables $s = \varepsilon^{-2/3}(\theta - \theta_i)$, we get

$$\begin{aligned} G_\varepsilon^{4/3}(u_\varepsilon) &= \varepsilon^{2/3} \sum_{i=1}^N \int_{I_i} (u_\varepsilon')^2 \, d\theta + \varepsilon^{-4/3} \sum_{i=1}^N \left(\int_{K_i} \left(\int_0^\theta (u_\varepsilon^2 - 1) \, d\varphi \right)^2 d\theta \right) \\ &\quad + \varepsilon^{-4/3} \sum_{i=1}^N \left(\int_{I_i} \left(\int_0^\theta (u_\varepsilon^2 - 1) \, d\varphi \right)^2 d\theta \right) \\ &= \sum_{i=1}^N \left(\int_{-T}^T (v_i')^2 \, ds + \int_{K_i} \left(\sum_{j=1}^i \int_{-T}^T (v_j^2 - 1) \, ds \right)^2 d\theta \right. \\ &\quad \left. + \int_{I_i} \left(\sum_{j=1}^{i-1} \int_{-T}^T (v_j^2 - 1) \, ds + \int_{-T}^{T_i(\theta)} (v_i^2 - 1) \, ds \right)^2 d\theta \right), \end{aligned}$$

where $T_i(\theta) = \varepsilon^{-2/3}(\theta - \theta_i)$. Setting

$$B_i = \int_{-T}^T (v_i')^2 \, ds \,, \qquad A_j = \int_{-T}^T (v_j^2 - 1) \, ds,$$

we then have

$$\begin{aligned} G_\varepsilon^{4/3}(u_\varepsilon) &= \sum_{i=1}^N \left(B_i + (\theta_{i+1} - \theta_i - 2\delta) \left(\sum_{j=1}^i A_j \right)^2 \right) \\ &\quad + \sum_{i=1}^N \int_{I_i} \left(\sum_{j=1}^i A_j - \int_{T_i(\theta)}^T (v_i^2 - 1) \, ds \right)^2 d\theta \\ &= \sum_{i=1}^N \left(B_i + (\theta_{i+1} - \theta_i) \left(\sum_{j=1}^i A_j \right)^2 \right) + \sum_{i=1}^N \int_{I_i} \left(\int_{T_i(\theta)}^T (v_i^2 - 1) \, ds \right)^2 d\theta \\ &\quad - 2 \sum_{i=1}^N \left(\sum_{j=1}^i A_j \right) \int_{I_i} \left(\int_{T_i(\theta)}^T (v_i^2 - 1) \, ds \right) d\theta \,. \end{aligned}$$

By (4.1) and the change of variable $\sigma = T_i(\theta)$, we get that

$$G_\varepsilon^{4/3}(u_\varepsilon) = \sum_{i=1}^{N} \left(B_i + (\theta_{i+1} - \theta_i) \left(\sum_{j=1}^{i} A_j \right)^2 \right) + O(\varepsilon^{2/3})$$

$$\leq G^{4/3}(u) + \eta + O(\varepsilon^{2/3})\,.$$

Passing to the limit as ε tends to 0, by the arbitrariness of η, we get the lim sup inequality for every $u \in BV((0,1);\{-1,1\})$.

We now consider $u \in BV_{\mathrm{loc}}((0,1);\{-1,1\})$. There exists $u^a \in BV((0,1);\{-1,1\})$ such that u^a converges to u strongly in $L^1(0,1)$ as $a \to 0^+$; i.e.,

$$u^a(\theta) = \begin{cases} u(a), & \theta \in [0,a), \\ u(\theta), & \theta \in [a, 1-a], \\ u(1-a), & \theta \in (1-a, 1], \end{cases}$$

with $0 < a < 1$ and $a, 1-a \notin S(u)$. Hence, by the lower semicontinuity of the Γ-lim sup, we have that

$$\begin{aligned}
&\Gamma\text{-}\limsup_{\varepsilon\to 0} G_\varepsilon^{4/3}(u) \\
&\quad \leq \liminf_{a\to 0^+} \left(\Gamma\text{-}\limsup_{\varepsilon\to 0} G_\varepsilon^{4/3}(u^a) \right) \\
&\quad \leq \liminf_{a\to 0^+} \inf_{T>0} \inf \left\{ \sum_{i\in I(a)} \left(\int_{-T}^{T} (v_i')^2\, ds + (\theta_{i+1} - \theta_i) \left(\sum_{j=1}^{i} \int_{-T}^{T} (v_j^2 - 1)\, ds \right)^2 \right) : \right. \\
&\qquad\qquad \left. v_i \in H^1((-T,T);[-1,1]), \quad v_i(\pm T) = \pm 1 \right\} \\
&\quad \leq \inf_{T>0} \inf \left\{ \sum_{i\in I} \left(\int_{-T}^{T} (v_i')^2\, ds + (\theta_{i+1} - \theta_i) \left(\sum_{j=1}^{i} \int_{-T}^{T} (v_j^2 - 1)\, ds \right)^2 \right) : \right. \\
&\qquad\qquad \left. v_i \in H^1((-T,T);[-1,1]), \quad v_i(\pm T) = \pm 1 \right\},
\end{aligned}$$

where $I(a) = \{i \in \mathbf{N} : \theta_i \in S(u^a)\,,\, \theta_i < \theta_{i+1}\}$ and $I = \{i \in \mathbf{N} : \theta_i \in S(u)\,,\, \theta_i < \theta_{i+1}\}$. □

POISSON KERNELS AS EXPANSIONS IN q-RACAH POLYNOMIALS*

CLAUDIO ALBANESE† AND STEPHAN LAWI‡

Abstract. This paper concerns stochastic processes on chains of arbitrary length whose Poisson kernel can be expressed in terms of the q-Racah polynomials, the most general q-deformed orthogonal polynomials in the discrete series of the Askey scheme. We give a new interpretation of this kernel as the probability transition density for a subordinated Markov process with only nearest neighbor hops. As an application, we give an elementary proof and extend a positivity result for a class of Poisson kernels which Gasper and Rahman established with direct methods.

Key words. orthogonal polynomials, basic hypergeometric polynomials, q-Racah polynomials, Markov chains, subordinators, positivity of Poisson kernels

1. Introduction.

In this paper, we give general conditions that allow one to construct Markov processes whose infinitesimal generator admits the q-Racah polynomials as eigenstates.

DEFINITION 1.1. *For $0 < q < 1$, the q-Racah polynomials*

$$R_n(\mu(x)) := R_n(\mu(x); \alpha, \beta, \gamma, \delta | q)$$

are defined using the q-deformed hypergeometric function ${}_4\phi_3$ as follows:

$$R_n(\mu(x)) = {}_4\phi_3 \left(\begin{matrix} q^{-n},\ \alpha\beta q^{n+1}, q^{-x}, \gamma\delta q^{x+1} \\ \alpha q, \beta\delta q, \gamma q \end{matrix} \middle| \, q; q \right) \tag{1.1}$$

for $n = 0, 1, \ldots, N$ and where $\mu(x) = q^{-x} + \gamma\delta q^{x+1}$. Moreover, they must belong to one of the three families defined by the additional condition that either $\alpha = q^{-N-1}$ or $\beta\delta = q^{-N-1}$ or $\gamma = q^{-N-1}$.

DEFINITION 1.2. *Let Λ_N denote the set $\{0, 1, \ldots, N\}$ and let $l^2(\Lambda_N)$ be the Hilbert space of the real valued functions on Λ_N.*

The objective of this paper is to construct a class of Markov processes supported on the set Λ_N whose transitional probability density can be expressed as a series in the q-Racah polynomials. Whether this can be done is a natural question, as the q-Racah polynomials satisfy an orthogonality relation with respect to a discrete weight supported on the set Λ_N (see [1], [10], [7], and the references therein for the properties of orthogonal polynomials in the Askey scheme). Namely,

$$\sum_{x \in \Lambda_N} R_m(\mu(x)) R_n(\mu(x)) w(x) = h_n \delta_{nm}, \tag{1.2}$$

where the weight is

$$w(x) = \frac{(\alpha q, \beta\delta q, \gamma q, \gamma\delta q; q)_x}{(q, \alpha^{-1}\gamma\delta q, \beta^{-1}\gamma q, \delta q; q)_x} \frac{1 - \gamma\delta q^{2x+1}}{(\alpha\beta q)^x (1 - \gamma\delta q)} \tag{1.3}$$

and the normalization factor is

$$h_n = \frac{(\alpha^{-1}\beta^{-1}\gamma, \alpha^{-1}\delta, \beta^{-1}, \gamma\delta q^2; q)_\infty}{(\alpha^{-1}\beta^{-1}q^{-1}, \alpha^{-1}\gamma\delta q, \beta^{-1}\gamma q, \delta q; q)_\infty} \frac{(1 - \alpha\beta q)(\gamma\delta q)^n}{1 - \alpha\beta q^{2n+1}} \frac{(q, \alpha\beta\gamma^{-1}q, \alpha\delta^{-1}q, \beta q; q)_n}{(\alpha q, \alpha\beta q, \beta\delta q, \gamma q; q)_n}. \tag{1.4}$$

Following [7], we denote $(a; q)_k$ for the q-analogue of the Pochhammer symbols:

$$(a; q)_0 = 1 \quad \text{and} \quad (a; q)_k = \prod_{i=0}^{k-1} (1 - a\ q^i) \tag{1.5}$$

for $k > 0$, with $(a_1, \dots, a_r; q)_k = (a_1; q)_k \cdots (a_r; q)_k$.

Recall now the following definitions of the Markov semigroup and the Bernstein function.

DEFINITION 1.3. *The one-parameter family of operators $(\mathcal{K}_t)_{t\geq 0}$ on $l^2(\Lambda_N)$ is said to be a Markov semigroup if its kernel $K_t(x, y)$ satisfies the following conditions for all $t, t' \geq 0$, $x, y \in \Lambda_N$:*

(i) *nonnegativity: $K_t(x, y) \geq 0$;*
(ii) *initial condition: $K_0(x, y) = \delta_{x,y}$;*
(iii) *contraction property: $\sum_{y\in\Lambda_N} K_t(x, y) \leq 1$;*
(iv) *semigroup property: $K_t(x, y)K_{t'}(x, y) = K_{t+t'}(x, y)$.*

DEFINITION 1.4. *Let $\Phi \in C^\infty([0, \infty))$ with $\Phi \geq 0$. Φ is a Bernstein function if $(-1)^n \Phi^{(n)} \leq 0$ for all integer $n > 0$.*

Our main result can be stated as follows.

THEOREM 1.5. *Assume that the parameters $q, \alpha, \beta, \gamma, \delta$ satisfy the restrictions of Definition 1.1 for the q-Racah polynomials. Assume also that the following two functions are negative or zero:*

$$B(x) = \frac{(1 - \alpha q^{x+1})(1 - \beta\delta q^{x+1})(1 - \gamma q^{x+1})(1 - \gamma\delta q^{x+1})}{(1 - \gamma\delta q^{2x+1})(1 - \gamma\delta q^{2x+2})},$$

$$D(x) = \frac{q(1 - q^x)(1 - \delta q^x)(\beta - \gamma q^x)(\alpha - \gamma\delta q^x)}{(1 - \gamma\delta q^{2x})(1 - \gamma\delta q^{2x+1})}.$$

Then for all Bernstein functions Φ the following series represents the kernel of a Markov semigroup:

$$K_t^\Phi(x, y) = \sum_{n=0}^{N} \frac{e^{-t\Phi(-\lambda_n)}}{h_n} R_n(\mu(x)) R_n(\mu(y))\ w(y), \tag{1.6}$$

where

$$\lambda_n = (1 - q^{-n})(1 - \alpha\beta q^{n+1}). \tag{1.7}$$

We also prove that there exists a Bernstein function such that $\Phi(-\lambda_n) = n$ for all integers $n = 1, 2, \dots, N$ so that we obtain the following corollary.

COROLLARY 1.6. *If in addition to the hypothesis of the theorem we also have that* $\alpha\beta \geq 0$, *then the function*

$$\Phi(z) = \frac{1}{|\ln q|} \ln \left(\frac{1+\alpha\beta q+z}{2} + \sqrt{\left(\frac{1+\alpha\beta q+z}{2}\right)^2 - \alpha\beta q} \right) \tag{1.8}$$

is a Bernstein function such that $\Phi(-\lambda_n) = n$ *for all integers* $n = 1, 2, \ldots, N$, *and the following series represents the kernel of a Markov semigroup on* Λ_N:

$$K_t^{\Phi}(x,y) = \sum_{n=0}^{N} \frac{e^{-nt}}{h_n} R_n(\mu(x)) R_n(\mu(y))\ w(y) - \max\left(1 - (\alpha\beta q)^{-\frac{t}{|\ln q|}}, 0\right)\ w(y). \tag{1.9}$$

This corollary extends the result by Gasper and Rahman in [6], where positivity of the Poisson kernel, defined as the series

$$\sum_{n=0}^{N} \frac{e^{-nt}}{h_n} R_n(\mu(x)) R_n(\mu(y)), \tag{1.10}$$

was established for the third family of q-Racah polynomials, i.e., $\gamma = q^{-N-1}$, and under the additional conditions that $0 < \alpha q < 1$, $0 \leq \beta q < 1$, and $0 < \delta < \alpha q^N$. The proof in [6] is based on a term by term analysis of the series expansion and resummation formulas of independent interest. Our argument is instead more elementary and based on probabilistic considerations.

2. Background and proofs. As a preparation to the proof of our results, we recall the basics of the theory of Markov processes and Bochner subordination. Let $(\Omega, \mathcal{F}, \mathrm{P})$ be a probability space equipped with the filtration $\{\mathcal{F}_t\}_{t\geq 0}$ satisfying the usual conditions; i.e., the filtration is right continuous and $\mathcal{F}_0$ contains all events of P-measure 0 in $\mathcal{F}$. Let $X = (X_t)_{t\geq 0}$ be an $\mathcal{F}_t$-adapted stochastic process on $D \subseteq \mathbb{R}$.

DEFINITION 2.1. *The stochastic process* X *is called a Markov process if*

$$\mathrm{E}\left[\ f(X_t) \mid \mathcal{F}_s\ \right] = \mathrm{E}\left[\ f(X_t) \mid X_s\ \right] \tag{2.1}$$

for all bounded measurable function $f : D \to \mathbb{R}$ *and all* $t \geq s \geq 0$.

The family of operators $(\mathcal{K}_t)_{t\geq 0}$ from Definition 1.3 defines the transitional probability density of a Markov process on $l^2(\Lambda_N)$ as follows:

$$\mathcal{K}_{t-s} f(x) = \mathrm{E}\left[\ f(X_t) \mid X_s = x\ \right] = \sum_{y\in\Lambda_N} f(y) K_{t-s}(x,y). \tag{2.2}$$

Subordinators are also Markov processes, but on $\mathbb{R}_+$, and can be thought of as stochastic time changes. They must therefore satisfy a few additional conditions, such as, if $T = (T_t)_{t\geq 0}$ is a subordinator, then $T_t \geq 0$ for each $t > 0$ almost surely (a.s.) and $T_s \leq T_t$ whenever $s \leq t$. Moreover, for the purpose of the present demonstration, only subordinators with an infinite lifetime will be considered, i.e., $\inf\{t \geq 0 : T_t = \infty\} = \infty$ a.s. The formal definition, as given by Bertoin in [3], follows.

DEFINITION 2.2. *Let* $T = (T_t)_{t\geq 0}$ *be a right-continuous increasing* $\mathcal{F}_t$*-adapted process started from* 0 *with values on* $[0, \infty]$, *where* ∞ *is an absorbing state.* T *is called a subordinator if it has independent and homogeneous increments on* $[0, \infty)$.

That is, the increment $T_{t+s} - T_t$ is independent of $\mathcal{F}_t$ and has the same distribution as T_s.

A remarkable probabilistic application of subordinators is due to Bochner [4], who proved the following.

THEOREM 2.3. *Let $X = (X_t)_{t\geq 0}$ be a Markov process and $T = (T_t)_{t\geq 0}$ be a subordinator. Then the stochastic process $Y = (Y_t)_{t\geq 0} = (X_{T_t})_{t\geq 0}$ is again a Markov process. Moreover, if X is stationary, then Y is stationary.*

A way to characterize subordinators is through their Laplace transform. A consequence of the independence and homogeneity of the increments is the following property:

$$\mathrm{E}\left[e^{\lambda T_{t+s}}\right] = \mathrm{E}\left[e^{\lambda T_t}\right]\mathrm{E}\left[e^{\lambda T_s}\right] \tag{2.3}$$

for every $s, t \geq 0$ and $\lambda \leq 0$. The Laplace transform can thus be expressed as

$$\mathrm{E}\left[e^{\lambda T_t}\right] = e^{-t\Psi(-\lambda)}, \tag{2.4}$$

where the function $\Psi : [0,\infty) \to [0,\infty)$ is called the Laplace exponent of the subordinator. A theorem due to de Finetti, Lévy, and Khintchine (see Bertoin [3]) gives a necessary and sufficient condition for a function to be the Laplace exponent of a subordinator. Moreover, one can establish a one-to-one correspondence between Laplace exponents and Bernstein functions [2]. We summarize these results in the following theorem.

THEOREM 2.4. *Let $\Phi \in C^\infty([0,\infty))$. Then, the following arguments are equivalent:*

1. *Φ is a Bernstein function.*
2. *Φ is the Laplace exponent of a subordinator.*
3. *There exists a semigroup $\{\rho_t\}_{t\geq 0}$ of positive measures on $[0,\infty)$ for which, for all $z \geq 0$,*

$$e^{-t\Phi(z)} = \int_0^\infty e^{-sz}\rho_t(ds). \tag{2.5}$$

The next theorem comes as a corollary of the previous two.

THEOREM 2.5. *Let $(\mathcal{K}_t)_{t\geq 0}$ be a Markov semigroup on $l^2(\Lambda_N)$ with kernel $K_t(x,y)$, and let Φ be a Bernstein function. Then, the semigroup of the subordinated process, denoted $(\mathcal{K}_t^\Phi)_{t\geq 0}$, is Markov and there exists a semigroup $\{\rho_t\}_{t\geq 0}$ of positive measures on $[0,\infty)$ such that for any $f \in l^2(\Lambda_N)$,*

$$\mathcal{K}_t^\Phi f(x) = \int_0^\infty \mathcal{K}_s f(x)\ \rho_t(ds). \tag{2.6}$$

This property extends to the transitional probability densities as follows:

$$K_t^\Phi(x,y) = \int_0^\infty K_s(x,y)\rho_t(ds). \tag{2.7}$$

The following definition leads to the explicit relation between q-Racah polynomials and Markov semigroups.

DEFINITION 2.6. *The operator $\mathcal{L}$ is the infinitesimal generator of a Markov semigroup on $l^2(\Lambda_N)$ if its kernel, $L(x,y)$ with $x, y \in \Lambda_N$, satisfies the following two conditions:*

(i) *nonnegativity:* $L(x,y) \geq 0$ *for all* $x \neq y \in \Lambda_N$;
(ii) *probability conservation:* $\sum_{y\in\Lambda_N} L(x,y) = 0$ *for all* $x \in \Lambda_N$.

Let us recall the elementary result from probability theory according to which a Markov semigroup $(\mathcal{K}_t)_{t\geq 0}$ on $l^2(\Lambda_N)$ can always be represented as follows in terms of the infinitesimal generator $\mathcal{L}$:

$$\mathcal{K}_t = \exp(t\mathcal{L}). \tag{2.8}$$

DEFINITION 2.7. *Let* Δ *and* ∇ *denote the difference operators on* $l^2(\Lambda_N)$ *defined as follows:*

$$\Delta f(x) = f(x+1) - f(x), \quad \nabla f(x) = f(x) - f(x-1), \tag{2.9}$$

with $f(N+1) = f(-1) = 0$.

The q-Racah polynomials introduced in Definition 1.1 satisfy the q-difference eigenvalue equation

$$\mathcal{L}R_n(\mu(x)) = \lambda_n R_n(\mu(x)), \tag{2.10}$$

where the operator $\mathcal{L}$ is given by

$$\mathcal{L} = -B(x)\Delta + D(x)\nabla, \tag{2.11}$$

with $B(x), D(x)$, and λ_n defined in Theorem 1.5 (see [7] and the references therein for a proof).

PROPOSITION 2.8. *If* $B(x) \leq 0$ *and* $D(x) \leq 0$, *then* $\mathcal{L}$ *is the infinitesimal generator of a Markov semigroup.*

Proof. Since the off-diagonal entries of the kernel $L(x,y)$ of $\mathcal{L}$ contain only $-B(x), -D(x)$, or 0, the nonnegativity condition in Definition 2.6 is satisfied by assumption. The second condition is also satisfied since

$$\sum_{y\in\Lambda_N} L(x,y) = -D(x) + (B(x) + D(x)) - B(x) = 0 \ \forall x = 1, \ldots, N-1,$$
$$\sum_{y\in\Lambda_N} L(0,y) = (B(0) + D(0)) - B(0) = D(0) = 0,$$
$$\sum_{y\in\Lambda_N} L(N,y) = -D(N) + (B(N) + D(N)) = B(N) = 0. \qquad \square$$

Note that one property of the infinitesimal generator of a Markov process is that it must satisfy the positive maximum principle [9],

$$\sup\{f(x) : x \in \Lambda_N\} = f(x_0) \geq 0 \Rightarrow (\mathcal{L}f)(x_0) \leq 0. \tag{2.12}$$

In particular, $\sup\{R_n(\mu(x)) : x \in \Lambda_N\} = R_n(\mu(x_0)) \geq 0$ for some $x_0 \in \Lambda_N$. Hence

$$\mathcal{L}R_n(\mu(x_0)) = \lambda_n R_n(\mu(x_0)) \leq 0, \tag{2.13}$$

which implies that the eigenvalues of the infinitesimal generator are negative or zero.

PROPOSITION 2.9. *The kernel of* $\mathcal{K}_t = \exp(t\mathcal{L})$ *has the following representation in terms of the q-Racah polynomials:*

$$K_t(x,y) = \sum_{n=0}^{N} \frac{e^{t\lambda_n}}{h_n} R_n(\mu(x)) R_n(\mu(y))\ w(y), \tag{2.14}$$

where $w(y) > 0$ is the invariant measure density.

Proof. The q-Racah polynomials form an orthogonal basis of the Hilbert space $l^2(\Lambda_N)$, with invariant measure density $w(y)$. From (2.10), $\mathcal{K}_t$ satisfies the eigenvalue equation

$$\mathcal{K}_t R_n(\mu(x)) = e^{t\lambda_n} R_n(\mu(x)). \tag{2.15}$$

The kernel can thus be written as an expansion in the q-Racah polynomials, and we recover (2.14) in the proposition. The invariant measure density $w(y)$ can be expressed recurrently as

$$w(0) = 1 \quad \text{and} \quad w(y+1) = \frac{B(y)}{D(y+1)}\, w(y) \quad \text{for } y = 0, 1, \ldots, N-1, \tag{2.16}$$

which proves its positivity since $B(y) < 0$ and $D(y+1) < 0$ for $y = 0, 1, \ldots, N-1$. ∎

We now proceed to the proof of our main result stated in the introduction. By Theorem 2.4, there exists a semigroup $\{\rho_t\}_{t\geq 0}$ of positive measures on $[0, \infty)$ associated with the Bernstein function Φ of Theorem 1.5. Theorem 2.5, together with Propositions 2.8 and 2.9, implies that the subordinated kernel takes the form

$$K_t^{\Phi}(x, y) = \sum_{n=0}^{N} \int_0^{\infty} e^{s\lambda_n} \rho_t(ds)\ \frac{1}{h_n} R_n(\mu(x)) R_n(\mu(y))\ w(y), \tag{2.17}$$

which gives (1.6) by definition of the measure $\rho_t(ds)$. Furthermore, the associated semigroup is again a Markov semigroup, so we proved Theorem 1.5.

Corollary 1.6 follows from the fact that the function

$$\Phi(z) = \frac{1}{|\ln q|} \ln \left[\frac{1 + \alpha\beta q + z}{2} + \sqrt{\left(\frac{1 + \alpha\beta q + z}{2} \right)^2 - \alpha\beta q} \right]$$

is a Bernstein function. One can indeed find an explicit expression for the semigroup $\{\rho_t\}_{t\geq 0}$ of positive measures that describes the subordinator. That is, for $\alpha\beta > 0$, there exists a one-parameter family of positive measures

$$\rho_t(ds) = \frac{t}{s|\ln q|}\ (\alpha\beta q)^{-\frac{t}{2|\ln q|}}\ e^{-(1+\alpha\beta q)s}\ I_{\frac{t}{|\ln q|}}\left(2\sqrt{\alpha\beta q}\ s \right) ds \tag{2.18}$$

that entirely characterizes Φ by Theorem 2.4 (see [5] or formula (8), page 314 in [8]). Notice that Φ is defined such that $\Phi(-\lambda_n) = n$ for $n = 1, 2, \ldots, N$ and is clearly non-negative for all $x \geq 0$. The eigenvalues λ_n being negative or zero implies in particular that $\alpha\beta q^2 \leq 1$. $\Phi(\lambda_0) = \Phi(0)$ thus depends on the value of $\alpha\beta q$ as follows:

$$\Phi(0) = \max\left(\frac{\ln(\alpha\beta q)}{|\ln q|}, 0 \right), \tag{2.19}$$

which leads to (1.9). Positivity of the Poisson kernel in (1.10) comes from (1.9) being Markovian and hence positive, $w(y) > 0$, and $\max(1 - (\alpha\beta q)^{-\frac{t}{|\ln q|}}, 0) \geq 0$.

In the limiting case $\alpha\beta = 0$, while the q-Racah polynomials converge either to the dual q-Hahn polynomials for $\alpha = 0$ or $\beta = 0$, or to the dual q-Krawtchouk polynomials

for $\alpha = \beta = 0$, the semigroup of positive measures consists of the well-known Gamma measures

$$\rho_t(ds) = \frac{s^{\frac{t}{|\ln q|}-1} e^{-s}}{\Gamma\left(\frac{t}{|\ln q|}\right)}\, ds. \tag{2.20}$$

Therefore, Φ is a Bernstein function for $\alpha\beta \geq 0$, which completes the proof of Corollary 1.6.

Remark 2.10. Corollary 1.6 unravels an interesting connection with free probability theory. Let $\tau = \frac{t}{|\ln q|}$ be the renormalized time of the process; then the semigroup of measure $\{\rho_\tau\}_{\tau \geq 0}$ reads

$$\rho_\tau(ds) = \frac{\tau}{s}\, (\alpha\beta q)^{-\frac{\tau}{2}}\, e^{-(1+\alpha\beta q)s}\, I_\tau\left(2\sqrt{\alpha\beta q}\, s\right) ds. \tag{2.21}$$

In the limit $q \to 0$, one recovers the Gamma measures

$$\rho_\tau(ds) = \frac{s^{\tau-1} e^{-s}}{\Gamma(\tau)}\, ds, \tag{2.22}$$

suggesting that the semigroup of Gamma measures defines a subordinator in the free case.

We conclude with the proof that Corollary 1.6 extends the result of positivity of the Poisson kernel given by Gasper and Rahman in [6].

PROPOSITION 2.11. *The set of conditions*

$$0 < q < 1, \quad \gamma = q^{-N-1}, \quad 0 < \alpha q < 1, \quad 0 \leq \beta q < 1, \quad 0 < \delta < \alpha q^N \tag{2.23}$$

is strictly stronger than

$$0 < q < 1, \quad 0 \leq \alpha\beta, \quad B(x) \leq 0, \quad D(x) \leq 0 \tag{2.24}$$

for all $x \in \Lambda_N$ and where $B(x)$ and $D(x)$ are defined as in Theorem 1.5.

Proof. Notice first that $0 < \alpha q < 1$ and $0 \leq \beta q < 1$ imply in particular $\alpha\beta \geq 0$. We show next that $B(x) \leq 0$ for all $x \in \Lambda_N$. With conditions (2.23), $B(x)$ becomes

$$\begin{aligned}
B(0) &= \frac{(1-\alpha q)(1-\beta\delta q)(1-q^{-N})}{1-\delta q^{1-N}},\\
B(x) &= \frac{(1-\alpha q^{x+1})(1-\beta\delta q^{x+1})(1-q^{x-N})(1-\delta q^{x-N})}{(1-\delta q^{2x-N})(1-\delta q^{2x+1-N})}, \quad x \in \{1,\ldots,N-1\},\\
B(N) &= 0.
\end{aligned}$$

For $x \in \{0,1,\ldots,N-1\}$ and since $q < 1$, we have

$$\begin{aligned}
&1 > 1-\alpha q^{x+1} > 1-q^x \geq 0,\\
&1 \geq 1-\beta\delta q^{x+1} > 1-\delta q^x > 1-q^{N+x-1} > 0,\\
&1 > 1-\delta q^{2x+1-N} > 1-\alpha q^{2x+1} > 1-q^{2x} \geq 0.
\end{aligned}$$

For $x \in \{1,\ldots,N-1\}$, we have

$$\begin{aligned}
&1 > 1-\delta q^{x-N} > 1-\alpha q^x > 1-q^{x-1} \geq 0,\\
&1 > 1-\delta q^{2x-N} > 1-\alpha q^{2x} > 1-q^{2x-1} \geq 0.
\end{aligned}$$

Since the only negative factor in $B(x)$ is $1 - q^{x-N}$ for all $x \in \{0, 1, \ldots, N-1\}$, $B(x) \leq 0$ for all $x \in \Lambda_N$. With conditions (2.23), $D(x)$ can be expressed as

$$\begin{aligned} D(0) &= 0, \\ D(x) &= \frac{q(1-q^x)(1-\delta q^x)(\beta - q^{x-N-1})(\alpha - \delta q^{x-N-1})}{(1-\delta q^{2x-N-1})(1-\delta q^{2x-N})}, \quad x \in \{1, \ldots, N-1\}, \\ D(N) &= \frac{q(1-q^N)(\beta - q^{-1})(\alpha - \delta q^{-1})}{1-\delta q^{N-1}}. \end{aligned}$$

For $x \in \{1, \ldots, N\}$, we have

$$\begin{aligned} &0 < \delta q^{-N} < \alpha \;\Rightarrow\; \delta q^{x-N-1} < \alpha \;\Rightarrow\; \alpha - \delta q^{x-N-1} > 0, \\ &0 \leq \beta < q^{-1} < q^{x-N-1} \;\Rightarrow\; \beta - q^{x-N-1} < 0 \end{aligned}$$

and, similarly as before,

$$\begin{aligned} &1 > 1 - \delta q^x > 1 - \alpha q^{x+N} > 1 - q^{x+N-1} > 0, \\ &1 > 1 - \delta q^{2x-N} > 1 - \alpha q^{2x} > 1 - q^{2x-1} > 0, \\ &1 > 1 - \delta q^{2x-N-1} > 1 - \alpha q^{2x-1} > 1 - q^{2x-2} \geq 0. \end{aligned}$$

Hence $D(x) \leq 0$ since the only negative factor is $\beta - q^{x-N-1}$. The condition $\alpha q < 1$ implies furthermore that the denominators of $B(x)$ and $D(x)$, respectively, are never zero. Finally, let

$$\alpha = \beta = -\delta = 1, \quad \gamma = q^{-N-1}.$$

The conditions in (2.24) are clearly satisfied, whereas $\delta > 0$ in (2.23) fails, so the inclusion is strict. □

STABILITY OF SOLITARY WAVES OF A GENERALIZED OSTROVSKY EQUATION*

STEVE LEVANDOSKY† AND YUE LIU‡

Abstract. Considered herein is the stability problem of solitary wave solutions of a generalized Ostrovsky equation, which is a modification of the Korteweg–de Vries equation widely used to describe the effect of rotation on surface and internal solitary waves or capillary waves.

Key words. solitary waves, stability, variational methods

1. Introduction.

The nonlinear dispersive equation

$$\left(u_t - \beta u_{xxx} + (u^2)_x\right)_x = \gamma u, \quad x \in \mathbf{R}, \tag{1.1}$$

was derived by Ostrovsky [20] in dimensionless space-time variables (x,t) as a model for the unidirectional propagation of weakly nonlinear long surface and internal waves of small amplitude in a rotating fluid. The liquid is assumed to be incompressible and inviscid. Here $u(t,x)$ represents the free surface of the liquid and the parameter $\gamma > 0$ measures the effect of rotation. The parameter β determines the type of dispersion, namely, $\beta < 0$ (negative dispersion) for surface and internal waves in the ocean or surface waves in a shallow channel with an uneven bottom and $\beta > 0$ (positive dispersion) for capillary waves on the surface of liquid or for oblique magneto-acoustic waves in plasma. See Benilov [2], Grimshaw [9], Galkin and Stepanyants [7], Gilman, Grimshaw, and Stepanyants [8], and Ostrovsky and Stepanyants [21].

Considered herein is the generalization of the Ostrovsky equation

$$(u_t - \beta u_{xxx} + f(u)_x)_x = \gamma u, \qquad x \in \mathbf{R}, \tag{1.2}$$

where f is a C^2 function which is homogeneous of degree $p \geq 2$, in the sense that it satisfies $sf'(s) = pf(s)$. This includes, for instance, nonlinearities of the form $f(u) = \pm|u|^p$ and $\pm|u|^{p-1}u$. Certain equations of this class have a direct relation to physical systems. In particular, when $p = 3$, (1.2) describes the propagation of internal waves of even modes, which possess a cubic nonlinearity, in the ocean. See Galkin and Stepanyants [7], Leonov [13], and Shrira [22, 23].

In this paper, we investigate the stability of solitary wave solutions of (1.2). Using variational methods, we prove the existence of solitary waves (Theorem 2.1). Solitary waves thus obtained are called *ground states*, and the set of all ground states is denoted by $G(\beta, c, \gamma)$. The variational characterization of the ground states permits us to consider the limiting behavior of the solitary waves as the rotation parameter γ

vanishes, and we show that the ground state solitary waves converge to solitary waves of the Korteweg–de Vries (KdV) equation (Theorem 2.5).

The stability analysis makes use of the conserved quantities

$$E(u) = \int_{\mathbf{R}} \frac{\beta}{2} u_x^2 + \frac{\gamma}{2} |D_x^{-1} u|^2 + F(u)\, dx$$

and

$$V(u) = \frac{1}{2} \int_{\mathbf{R}} u^2\, dx,$$

where $F' = f$ and $F(0) = 0$, and the operator D_x^{-1} is defined via the Fourier transform as

$$\widehat{D_x^{-1} f} = (-i\xi)^{-1} \hat{f}(\xi).$$

It was shown by Liu and Varlamov [18] that the classical Ostrovsky equation (1.1) is well-posed in the space

$$X_s = \{ f \in H^s(\mathbf{R}) \mid D_x^{-1} f \in H^s(\mathbf{R}) \}$$

with norm

$$\|f\|_{X_s} = \|f\|_s + \|D_x^{-1} f\|_s$$

for $s > 3/2$. The methods therein also imply the same result for the generalized Ostrovsky equation (1.2). We therefore make the following definition.

Definition 1.1. *A set $S \subset X$ is X-stable with respect to* (1.2) *if for any $\epsilon > 0$ there exists $\delta > 0$ such that for any $u_0 \in X \cap X_s$, $s > 3/2$, with*

$$\inf_{v \in S} \|u_0 - v\|_X < \delta, \tag{1.3}$$

the solution $u(t)$ of (1.2) *with initial value $u(0) = u_0$ can be extended to a solution in the space $C([0, \infty), X \cap X_s)$ and satisfies*

$$\inf_{v \in S} \|u(t) - v\|_X < \epsilon \tag{1.4}$$

for all $t \geq 0$. Otherwise we say that S is X-unstable.

Our main results apply to the set $G(\beta, c, \gamma)$, defined by (2.8). For each $y \in \mathbf{R}$, we define the translation operator by $\tau_y v = v(\cdot + y)$. Given a ground state φ in $G(\beta, c, \gamma)$, the *orbit* of φ is the set $\mathcal{O}_\varphi = \{\tau_y \varphi \mid y \in \mathbf{R}\}$. We show in Theorems 3.1 and 4.2 that the function d defined by (3.1) determines the stability or instability of the solitary waves in the sense that if $d''(c) > 0$, then $G(\beta, c, \gamma)$ is X_1-stable and if $d''(c) < 0$, then $\mathcal{O}_\varphi$ is X_1-unstable. Although these results are not quite complementary, the only difference is due to the possible nonuniqueness of ground states up to translation. That is, if ground states are unique up to translation, then $G(\beta, c, \gamma) = \mathcal{O}_\varphi$.

One difficulty in applying these results is the fact that an explicit formula for d is not available. It is also not known if $d(c)$ is twice differentiable. To remedy this, we also prove a second result, Theorem 4.3, which provides sufficient conditions for instability directly in terms of the parameters β, c, γ, and p. The result is based on the work of Gonçalves Ribeiro [10]. Another approach to dealing with the lack of information about $d(c)$ is to compute it numerically. We conclude the paper with some numerical calculations of d'' which approximately determine regions of stability and instability in terms of the parameters.

Notation. The norm in the classical Sobolev spaces $H^s(\mathbf{R})$ will be written $\|\cdot\|_s$. For $1 \leq q \leq \infty$, the norm in $L^q(\mathbf{R})$ will be written $|\cdot|_q$.

2. Solitary waves. Solitary-wave solutions of the form $u(x,t) = \varphi(x-ct)$ satisfy the stationary equation

$$\beta\varphi_{xx} + c\varphi + \gamma D_x^{-2}\varphi = f(\varphi). \tag{2.1}$$

We will prove existence of solitary waves in the space X_1 by considering the following variational problem. Define the functionals

$$I(u) = I(u;\beta,c,\gamma) = \int_{\mathbf{R}} \beta u_x^2 - cu^2 + \gamma(D_x^{-1}u)^2\,dx \tag{2.2}$$

and

$$K(u) = -(p+1)\int_{\mathbf{R}} F(u)\,dx, \tag{2.3}$$

where F satisfies $F' = f$ and $F(0) = 0$. Then if $\psi \in X_1$ achieves the minimum

$$M_\lambda = \inf\{I(u) \mid u \in X_1, K(u) = \lambda\} \tag{2.4}$$

for some $\lambda > 0$, then there exists a Lagrange multiplier μ such that

$$\beta\psi_{xx} + c\psi + \gamma D_x^{-2}\psi = \mu f(\psi). \tag{2.5}$$

Hence $\varphi = \mu^{\frac{1}{p-1}}\psi$ satisfies (2.1). We call such solutions *ground state* solutions and denote the set of all ground state solutions by $G(\beta,c,\gamma)$. By the homogeneity of I and K, ground states also achieve the minimum

$$m = m(\beta,c,\gamma) = \inf\left\{\frac{I(u)}{(K(u))^{\frac{2}{p+1}}} : u \in X_1, K(u) > 0\right\}, \tag{2.6}$$

and it follows that

$$M_\lambda = m\lambda^{\frac{2}{p+1}}. \tag{2.7}$$

We next note that the properties $sf'(s) = pf(s)$ and $F' = f$ imply that $sf(s) = (p+1)F(s)$, so that

$$K(u) = -\int_{\mathbf{R}} uf(u)\,dx,$$

and therefore multiplying (2.1) by φ and integrating yields $I(\varphi) = K(\varphi)$. Thus we may characterize the set of ground state solutions $G(\beta,c,\gamma)$ as

$$G(\beta,c,\gamma) = \left\{\varphi \in X_1 \mid K(\varphi) = I(\varphi;\beta,c,\gamma) = (m(\beta,c,\gamma))^{\frac{p+1}{p-1}}\right\}. \tag{2.8}$$

We now seek to prove that this set is nonempty. We say that a sequence ψ_k is a *minimizing sequence* if for some $\lambda > 0$,

$$\lim_{k\to\infty} K(\psi_k) = \lambda \quad \text{and} \quad \lim_{k\to\infty} I(\psi_k) = M_\lambda.$$

THEOREM 2.1. *Let $\beta > 0$, $\gamma > 0$, and $c < 2\sqrt{\beta\gamma}$. Let ψ_k be a minimizing sequence for some $\lambda > 0$. Then there exist a subsequence (renamed ψ_k) and scalars*

$y_k \in \mathbf{R}$ and $\psi \in X_1$ such that $\psi_k(\cdot + y_k) \to \psi$ in X_1. The function ψ achieves the minimum $I(\psi) = M_\lambda$ subject to the constraint $K(\psi) = \lambda$.

Proof. The result is an application of the concentration compactness lemma of Lions [16]. We outline the proof here. First, observe that by (2.7) the strict subadditivity condition

$$M_\alpha + M_{\lambda-\alpha} > M_\lambda \tag{2.9}$$

holds for any $\alpha \in (0, \lambda)$. Next, since $\beta > 0$, $\gamma > 0$, and $c < 2\sqrt{\beta\gamma}$, the functional I satisfies the coercivity condition

$$I(u) \geq A \int_{\mathbf{R}} u_x^2 + (D_x^{-1}u)^2 \, dx = A\|u\|_{X_1}^2,$$

where

$$A = \left\{ \begin{array}{ccc} \frac{4\beta\gamma - c^2}{2(\beta+\gamma+\sqrt{(\beta-\gamma)^2+c^2})} & \text{for} & 0 < c < 2\sqrt{\beta\gamma} \\ \min\{\beta, \gamma\} & \text{for} & c \leq 0 \end{array} \right\} > 0. \tag{2.10}$$

It is also clear that $I(u) \leq C\|u\|_{X_1}^2$ for some constant C, so $I(u)^{1/2}$ is equivalent to the norm on X_1. Now let ψ_k be a minimizing sequence. Then by coercivity of I, the sequence ψ_k is bounded in X_1, so if we define

$$\rho_k = |D_x\psi_k|^2 + |D_x^{-1}\psi_k|^2,$$

then after extracting a subsequence, we may assume

$$\lim_{k\to\infty} \int_{\mathbf{R}} \rho_k \, dx = L > 0.$$

We may assume further after normalizing that $\int_{\mathbf{R}} \rho_k \, dx = L$ for all k. By the concentration compactness lemma, a further subsequence ρ_k satisfies one of the following three conditions.

1. Vanishing: For every $R > 0$,

$$\lim_{k\to\infty} \sup_{y\in\mathbf{R}} \int_{B(y,R)} \rho_k \, dx = 0.$$

2. Dichotomy: There exists some $l \in (0, L)$ such that for any $\epsilon > 0$ there exist $R > 0$ and $R_k \to \infty$, $y_k \in \mathbf{R}$ and k_0 such that

$$\left| \int_{B(y_k,R)} \rho_k \, dx - l \right| < \epsilon \quad \text{and} \quad \left| \int_{R<|x-y_k|<R_k} \rho_k \, dx \right| < \epsilon$$

for $k \geq k_0$.

3. Compactness: There exists $y_k \in \mathbf{R}$ such that for any $\epsilon > 0$ there exists $R(\epsilon)$ such that

$$\int_{B(y_k,R(\epsilon))} \rho_k \, dx \geq \int_{\mathbf{R}} \rho_k \, dx - \epsilon$$

for all k.

In the same manner as in [14], it follows from the coercivity of I, the Sobolev inequality, and the subadditivity condition (2.9) that both vanishing and dichotomy may be ruled out, and therefore the sequence ρ_k is compact. Now set $\varphi_k(x) = \psi_k(x + y_k)$. Since φ_k is bounded in X_1, a subsequence φ_k converges weakly to some $\psi \in X_1$, and by the weak lower semicontinuity of I over X_1, we have

$$I(\psi) \le \lim_{k\to\infty} I(\varphi_k) = M_\lambda.$$

Furthermore, weak convergence in X_1, compactness of ρ_k, and the Sobolev inequality imply strong convergence of φ_k to ψ in L^{p+1}. Therefore

$$K(\psi) = \lim_{k\to\infty} K(\varphi_k) = \lambda,$$

so $I(\psi) \ge M_\lambda$. Together with the inequality above, this implies $I(\psi) = M_\lambda$, so ψ is a minimizer of I subject to the constraint $K(\varphi) = \lambda$. Finally, since I is equivalent to the norm on X_1, $\phi_k \rightharpoonup \psi$, and $I(\phi_k) \to I(\psi)$, it follows that ϕ_k converges strongly to ψ in X_1. □

At this time it is unknown whether or not the ground states are unique up to translation. Uniqueness would imply that if $\varphi \in G(\beta, c, \gamma)$ is any ground state, then $G(\beta, c, \gamma) = \mathcal{O}_\varphi$, in which case the stability and instability theorems (Theorems 3.1 and 4.2) are complementary. We suspect that the ground states are unique, at least in the case $c < -2\sqrt{\beta\gamma}$, when the ground states have nonoscillatory tails.

The function $m(\beta, c, \gamma)$ defined above plays an important role in our later results, so we now will investigate some of its properties. The first is a simple scaling identity.

LEMMA 2.2. *Let $\beta > 0$, $\gamma > 0$, and $c < 2\sqrt{\beta\gamma}$. For any $r > 0$ and $s > 0$ we have*

$$m(rs^2\beta, rc, rs^{-2}\gamma) = rs^{\frac{p-1}{p+1}} m(\beta, c, \gamma).$$

Proof. Let $u \in X_1$ with $K(u) \ne 0$. For any $r > 0$ we have

$$I(u; r\beta, rc, r\gamma) = rI(u; \beta, c, \gamma),$$

so $m(r\beta, rc, r\gamma) = rm(\beta, c, \gamma)$. Next let $v(x) = u(sx)$ for $s > 0$. Then

$$I(v; \beta, c, \gamma) = \frac{1}{s} I(u; s^2\beta, c, s^{-2}\gamma), \qquad K(v) = \frac{1}{s} K(u),$$

so

$$\frac{I(v; \beta, c, \gamma)}{K(v)^{\frac{2}{p+1}}} = s^{\frac{1-p}{p+1}} \frac{I(u; s^2\beta, c, s^{-2}\gamma)}{K(u)^{\frac{2}{p+1}}},$$

and consequently

$$m(s^2\beta, c, s^{-2}\gamma) = s^{\frac{p-1}{p+1}} m(\beta, c, \gamma). \qquad \square$$

Next, we show that m is continuous and monotone in each of its variables.

LEMMA 2.3. *The function m is continuous on the domain $\beta > 0$, $\gamma > 0$, $c < 2\sqrt{\gamma\beta}$. Furthermore, m is strictly increasing in γ and β and strictly decreasing in c.*

Proof. First, fix $\beta > 0$ and $\gamma > 0$ and consider $c_1 < c_2 < 2\sqrt{\beta\gamma}$. Let φ_{c_1} and φ_{c_2} be ground states with $c = c_1$ and $c = c_2$, respectively. Then

$$\begin{aligned} m(\beta, c_2, \gamma) &\leq \frac{I(\varphi_{c_1}; \beta, c_2, \gamma)}{K(\varphi_{c_1})^{\frac{2}{p+1}}} \\ &= \frac{I(\varphi_{c_1}; \beta, c_1, \gamma) + (c_1 - c_2)\int \varphi_{c_1}^2\, dx}{K(\varphi_{c_1})^{\frac{2}{p+1}}} \\ &= \frac{I(\varphi_{c_1}; \beta, c_1, \gamma)}{K(\varphi_{c_1})^{\frac{2}{p+1}}} + (c_1 - c_2)\frac{\int \varphi_{c_1}^2\, dx}{K(\varphi_{c_1})^{\frac{2}{p+1}}} \\ &= m(\beta, c_1, \gamma) + (c_1 - c_2)\frac{\int \varphi_{c_1}^2\, dx}{K(\varphi_{c_1})^{\frac{2}{p+1}}} \\ &< m(\beta, c_1, \gamma), \end{aligned}$$

so m is strictly decreasing in c. On the other hand,

$$\begin{aligned} m(\beta, c_1, \gamma) &\leq \frac{I(\varphi_{c_2}; \beta, c_1, \gamma)}{K(\varphi_{c_2})^{\frac{2}{p+1}}} \\ &= \frac{I(\varphi_{c_2}; \beta, c_2, \gamma) + (c_2 - c_1)\int \varphi_{c_2}^2\, dx}{K(\varphi_{c_2})^{\frac{2}{p+1}}} \\ &= m(\beta, c_2, \gamma) + (c_2 - c_1)\frac{\int \varphi_{c_2}^2\, dx}{K(\varphi_{c_2})^{\frac{2}{p+1}}}, \end{aligned}$$

so

$$0 \leq m(\beta, c_1, \gamma) - m(\beta, c_2, \gamma) \leq (c_2 - c_1)\frac{\int \varphi_{c_2}^2\, dx}{K(\varphi_{c_2})^{\frac{2}{p+1}}}.$$

Now since

$$I(\varphi_{c_2}; \beta, c_2, \gamma) \geq A\int \varphi_{c_2}^2\, dx,$$

where A is defined by (2.10), it follows that

$$|m(\beta, c_2, \gamma) - m(\beta, c_1, \gamma)| \leq A^{-1} m(\beta, c_2, \gamma)(c_2 - c_1),$$

so m is locally Lipschitz continuous in c. By similar reasoning it follows that m is increasing and locally Lipschitz in β and γ. ∎

We now consider the effect of letting the rotation parameter γ approach zero. Formally, this results in the generalized KdV equation

$$\beta\varphi_{xx} + c\varphi = f(\varphi). \tag{2.11}$$

For $c < 0$, ground state solutions of (2.11) achieve the minimum

$$m(\beta, c, 0) = \inf\left\{ \frac{I(u; \beta, c, 0)}{K(u)^{\frac{2}{p+1}}} : u \in H^1 K(u) > 0 \right\},$$

where

$$I(u; \beta, c, 0) = \int \beta u_x^2 - cu^2\, dx,$$

and K is defined as before by (2.3). Thus the set of ground states may be characterized as

$$G(\beta,c,\gamma)=\left\{\varphi\in H^1 \mid K(\varphi)=I(\varphi;\beta,c,0)=(m(\beta,c,0))^{\frac{p+1}{p-1}}\right\}.$$

Moreover, it is well known that the ground states are unique up to translation, so that $G(\beta,c,0)=\{\varphi_0(\cdot-y)\mid y\in\mathbf{R}\}$ for some φ_0. For example, in the case of the nonlinearity $f(u)=(-u)^p$, where $p\geq 2$ is an integer, we have the explicit formula

$$\varphi_0(x)=-\left(\frac{-c(p+1)}{2}\right)^{\frac{1}{p-1}}\operatorname{sech}^{\frac{2}{p-1}}\left(\frac{p-1}{2}\sqrt{\frac{-c}{\beta}}x\right).$$

Therefore the analogue of Theorem 2.1 takes the following form.

THEOREM 2.4. *Let $\beta>0$ and $c<0$. Let ψ_k be a sequence in H^1 such that*

$$\lim_{k\to\infty} I(\psi_k;\beta,c,0)=\lim_{k\to\infty} K(\psi_k)=(m(\beta,c,0))^{\frac{p+1}{p-1}}.$$

Then there exists a subsequence (renamed ψ_k), and there exist scalars $y_k\in\mathbf{R}$ such that $\psi_k(\cdot+y_k)\to\varphi_0$ in H^1.

THEOREM 2.5. *Fix $\beta>0$ and $c<0$ and consider any sequence $\gamma_k\to 0^+$. Denote by φ_k any element of $G(\beta,c,\gamma_k)$. Then there exists a subsequence (renamed γ_k) and translations y_k so that*

$$\varphi_k(\cdot+y_k)\to\varphi_0 \tag{2.12}$$

in H^1, as $\gamma_k\to 0^+$. That is, the generalized KdV solitary waves are the limits in H^1 of solitary waves of the generalized Ostrovsky equation.

To prove this theorem, we will show that the sequence of Ostrovsky solitary waves is a minimizing sequence for the KdV variational problem. The following lemma is proved in [15].

LEMMA 2.6. *The space X_1 is dense in H^1.*

Using the lemma, we next prove that the function m is continuous at $\gamma=0$.

LEMMA 2.7. *Fix $\beta>0$ and $c<0$. Then*

$$\lim_{\gamma\to 0^+} m(\beta,c,\gamma)=m(\beta,c,0). \tag{2.13}$$

Proof. Since m is strictly increasing in γ, it suffices to show that $m(\beta,c,\gamma_k)\to m(\beta,c,0)$ for some sequence $\gamma_k\to 0$. By the density of X_1 in H^1 we may choose ψ_k in X_1 such that $\|\psi_k-\varphi_0\|_{H^1}<\frac{1}{k}$ and define

$$\gamma_k=\min\left(\frac{1}{k},\frac{1}{k\int|D_x^{-1}\psi_k|^2\,dx}\right).$$

Then

$$\begin{aligned} m(\beta,c,\gamma_k)&\leq\frac{I(\psi_k;\beta,c,\gamma_k)}{K(\psi_k)^{\frac{2}{p+1}}}\\ &=\frac{I(\psi_k;\beta,c,0)+\gamma_k\int|D_x^{-1}\psi_k|^2\,dx}{K(\psi_k)^{\frac{2}{p+1}}}\\ &\leq\frac{I(\psi_k;\beta,c,0)+\frac{1}{k}}{K(\psi_k)^{\frac{2}{p+1}}}. \end{aligned}$$

Since $I(\cdot;\beta,c,0)$ and K are both continuous on H^1, we therefore have

$$\limsup_{k\to\infty} m(\beta,c,\gamma_k) \le \frac{I(\varphi_0;\beta,c,0)}{K(\varphi_0)^{\frac{2}{p+1}}} = m(\beta,c,0).$$

On the other hand, given $\varphi_k \in G(\beta,c,\gamma_k)$ we have $\varphi_k \in H^1$, so

$$\begin{aligned} m(\beta,c,0) &\le \frac{I(\varphi_k;\beta,c,0)}{K(\varphi_k)^{\frac{2}{p+1}}} \\ &= \frac{I(\varphi_k;\beta,c,\gamma_k) - \gamma_k \int |D_x^{-1}\varphi_k|^2\,dx}{K(\varphi_k)^{\frac{2}{p+1}}} \\ &< \frac{I(\varphi_k;\beta,c,\gamma_k)}{K(\varphi_k)^{\frac{2}{p+1}}} = m(\beta,c,\gamma_k). \end{aligned}$$

Thus

$$\liminf_{k\to\infty} m(\beta,c,\gamma_k) \ge m(\beta,c,0),$$

and the lemma follows. □

Proof of Theorem 2.5. By continuity of m at $\gamma = 0$, we have

$$\lim_{k\to\infty} K(\varphi_k) = \lim_{k\to\infty} m(\beta,c,\gamma_k)^{\frac{p+1}{p-1}} = m(\beta,c,0)^{\frac{p+1}{p-1}}$$

and

$$\begin{aligned} \limsup_{k\to\infty} I(\varphi_k;\beta,c,0) &= \limsup_{k\to\infty} I(\varphi_k;\beta,c,\gamma_k) - \gamma_k \int (D_x^{-1}\varphi_k)^2\,dx \\ &\le \lim_{k\to\infty} I(\varphi_k;\beta,c,\gamma_k) \\ &= \lim_{k\to\infty} m(\beta,c,\gamma_k)^{\frac{p+1}{p-1}} \\ &= m(\beta,c,0)^{\frac{p+1}{p-1}}. \end{aligned}$$

Thus φ_k is a minimizing sequence for the KdV variational problem, and the result follows from Theorem 2.4. □

3. Stability. The main result of this section is the following.

THEOREM 3.1. *Let $\beta > 0$, $\gamma > 0$, and $c < 2\sqrt{\beta\gamma}$. Let d be defined as in* (3.1). *If $d''(c) > 0$, then the set of ground states $G(\beta,c,\gamma)$ is X_1-stable.*

The proof is based on arguments in [14], which makes use of the method of [5]. We remark here that the condition $d''(c) > 0$ may be replaced with strict convexity of d in a neighborhood of c. See [24].

Given $\beta > 0$, $\gamma > 0$, and $c < 2\sqrt{\beta\gamma}$, we define

$$d(c) = d(\beta,c,\gamma) = E(\varphi) - cV(\varphi), \tag{3.1}$$

where φ is any element of $G(\beta,c,\gamma)$. Since

$$E(u) - cV(u) = \frac{1}{2}I(u) - \frac{1}{p+1}K(u), \tag{3.2}$$

it follows from (2.8) that

$$d(\beta,c,\gamma)=\frac{p-1}{2(p+1)}I(\varphi)=\frac{p-1}{2(p+1)}K(\varphi)=\frac{p-1}{2(p+1)}\left(m(\beta,c,\gamma)\right)^{\frac{p+1}{p-1}}. \tag{3.3}$$

Therefore d is well defined, and we may deduce its properties by examining the function $m(\beta,c,\gamma)$. The following two lemmas are immediate corollaries of Lemmas 2.2 and 2.3.

LEMMA 3.2. *Let $\beta>0$, $\gamma>0$, and $c<2\sqrt{\beta\gamma}$. For any $r>0$ and $s>0$, we have*

$$d(rs^2\beta,rc,rs^{-2}\gamma)=r^{\frac{p+1}{p-1}}sd(\beta,c,\gamma).$$

LEMMA 3.3. *The function d is continuous on the domain $\beta>0$, $\gamma>0$, $c<2\sqrt{\gamma\beta}$. Furthermore, d is strictly increasing in γ and β and strictly decreasing in c.*

LEMMA 3.4. *For each fixed $\beta>0$ and $\gamma>0$, the partial derivative $\partial d/\partial c(\beta,c,\gamma)$ exists for all but countably many $c<2\sqrt{\beta\gamma}$. Similarly, $\partial d/\partial\beta$ and $\partial d/\partial\gamma$ exist for all but countably many β and γ, respectively. At points where the partials exist,*

$$\begin{aligned}\frac{\partial d}{\partial\beta}&=\frac{1}{2}\int(\varphi_x)^2\,dx,\\ \frac{\partial d}{\partial c}&=-\frac{1}{2}\int\varphi^2\,dx,\\ \frac{\partial d}{\partial\gamma}&=\frac{1}{2}\int(D_x^{-1}\varphi)^2\,dx.\end{aligned}$$

Proof. Since d is continuous and monotone with respect to each variable, it follows that the partial derivatives exist at all but countably many points. To verify the formulas above, first fix $\beta>0$ and $\gamma>0$. Then by the inequalities in the proof of Lemma 2.3,

$$-\frac{\int\varphi_{c_2}^2\,dx}{K(\varphi_{c_2})^{\frac{2}{p+1}}}\le\frac{m(\beta,c_2,\gamma)-m(\beta,c_1,\gamma)}{c_2-c_1}\le-\frac{\int\varphi_{c_1}^2\,dx}{K(\varphi_{c_1})^{\frac{2}{p+1}}}$$

for $c_1<c_2<2\sqrt{\beta\gamma}$. Let

$$\begin{aligned}g_s(\beta,c,\gamma)&=\sup\left\{\int\varphi_c^2\,dx:\ \varphi_c\in G(\beta,c,\gamma)\right\},\\ g_i(\beta,c,\gamma)&=\inf\left\{\int\varphi_c^2\,dx:\ \varphi_c\in G(\beta,c,\gamma)\right\}.\end{aligned}$$

Then, for $c_1<c_2<2\sqrt{\beta\gamma}$,

$$-\frac{g_i(\beta,c_2,\gamma)}{m(\beta,c_2,\gamma)^{\frac{2}{p-1}}}\le\frac{m(\beta,c_2,\gamma)-m(\beta,c_1,\gamma)}{c_2-c_1}\le-\frac{g_s(\beta,c_1,\gamma)}{m(\beta,c_1,\gamma)^{\frac{2}{p-1}}}.$$

We now claim that

$$\lim_{c\to c_0}\sup g_i(\beta,c,\gamma)\le g_s(\beta,c_0,\gamma).$$

To see this, choose any $c_k\to c_0$ and $\varphi_k\in G(\beta,c_k,\gamma)$. The continuity of m, the characterization (2.8), and the relation (3.3) imply that $I(\varphi_k)\to\frac{2(p+1)}{p-1}d(\beta,c_0,\gamma)$

and $K(\varphi_k) \to \frac{2(p+1)}{p-1} d(\beta, c_0, \gamma)$. Therefore φ_k is a minimizing sequence, so by Theorem 2.1, there is a translated subsequence (renamed φ_k) which converges in X_1 to some function φ in $G(\beta, c_0, \gamma)$. Hence

$$\limsup_{k\to\infty} g_i(\beta, c_k, \gamma) \le \int \varphi^2 \, dx \le g_s(\beta, c_0, \gamma).$$

Consequently

$$\frac{\partial m}{\partial c}(\beta, c^+, \gamma) = -\frac{g_s(\beta, c, \gamma)}{m(\beta, c, \gamma)^{\frac{2}{p-1}}}.$$

Now, since $d = \frac{p-1}{2(p+1)} m^{\frac{p+1}{p-1}}$, this implies

$$\frac{\partial d}{\partial c}(\beta, c^+, \gamma) = -\frac{1}{2} g_s(\beta, c, \gamma).$$

Likewise,

$$\frac{\partial d}{\partial c}(\beta, c^-, \gamma) = -\frac{1}{2} g_i(\beta, c, \gamma).$$

So at points where the partial derivative exists, we must have $g_s(\beta, c, \gamma) = g_i(\beta, c, \gamma)$, and the first formula above follows. The proofs of the other formulas are similar. ∎

We note here that the preceding proof illustrates that uniqueness of ground states up to translation would imply differentiability of d. For if $G(\beta, c, \gamma)$ consists of translates of a single ground state, then $g_s(\beta, c, \gamma) = g_i(\beta, c, \gamma)$, from which the differentiability of d follows.

For the remainder of this section we will regard d only as a function of c for fixed β and γ. So notation such as d', d'', or d^{-1} should be interpreted with respect to the variable c. A key role in the stability analysis is played by the ϵ-neighborhood of the set of ground states defined by

$$U_{c,\epsilon} = \left\{ u \in X_1 \mid \inf_{\varphi \in G(\beta,c,\gamma)} \|u - \varphi\|_{X_1} < \epsilon \right\}.$$

Since d is strictly decreasing in c, we may define

$$c(u) = d^{-1}\left(\frac{p-1}{2(p+1)} K(u) \right).$$

This associates a speed $c(u)$ with any function $u \in X_1$. The following lemma provides the key estimate involving these speeds.

LEMMA 3.5. *If $d''(c) > 0$, then there is some $\epsilon > 0$ such that for any $u \in U_{c,\epsilon}$ and $\varphi \in G(\beta, c, \gamma)$, we have*

$$E(u) - E(\varphi) - c(u)(V(u) - V(\varphi)) \ge \frac{1}{4} d''(c) |c(u) - c|^2.$$

Proof. Since $d'(c) = -V(\varphi_c)$, it follows from Taylor's theorem that

$$d(c_1) = d(c) - V(\varphi_c)(c_1 - c) + \frac{1}{2} d''(c)(c_1 - c)^2 + o\left(|c_1 - c|^2\right)$$

for c_1 near c. By choosing ϵ sufficiently small, it then follows that

$$\begin{aligned} d(c(u)) &\geq d(c) - V(\varphi_c)(c(u)-c) + \frac{1}{4}d''(c)(c(u)-c)^2 \\ &= E(\varphi_c) - c(u)V(\varphi_c) + \frac{1}{4}d''(c)(c(u)-c)^2 \end{aligned}$$

for $u \in U_{c,\epsilon}$. Now if $\varphi_{c(u)} \in G(\beta, c(u), \gamma)$, then

$$K(\varphi_{c(u)}) = \frac{2(p+1)}{p-1}d(c(u)) = K(u),$$

and $\varphi_{c(u)}$ minimizes $I(\cdot;\beta,c(u),\gamma)$ subject to this constraint, so

$$\begin{aligned} E(u) - c(u)V(u) &= \frac{1}{2}I(u;\beta,c(u),\gamma) - \frac{1}{p+1}K(u) \\ &\geq \frac{1}{2}I(\varphi_{c(u)};\beta,c(u),\gamma) - \frac{1}{p+1}K(\varphi_{c(u)}) \\ &= d(c(u)). \end{aligned}$$

This completes the proof. □

Proof of Theorem 3.1. Suppose $G(\beta,c,\gamma)$ is X_1-unstable, and choose initial data u_0^k such that

$$\inf_{\varphi \in G(\beta,c,\gamma)} \|u_0^k - \varphi\|_{X_1} < \frac{1}{k},$$

and let $u^k(t)$ be the solution of (1.2) with $u^k(0) = u_0^k$. By continuity in t, there are some $\delta > 0$ and some times t_k such that

$$\inf_{\varphi \in G(\beta,c,\gamma)} \|u^k(t_k) - \varphi\|_{X_1} = \delta. \tag{3.4}$$

By the initial assumption, we can find $\varphi_k \in G(\beta,c,\gamma)$ such that

$$\lim_{k\to\infty} \|u_0^k - \varphi_k\|_{X_1} = 0.$$

Therefore, since E and V are continuous on X_1 and invariants of (1.2),

$$\lim_{k\to\infty} E(u^k(t_k)) - E(\varphi_k) = \lim_{k\to\infty} E(u_0^k) - E(\varphi_k) = 0 \tag{3.5}$$

and

$$\lim_{k\to\infty} V(u^k(t_k)) - V(\varphi_k) = \lim_{k\to\infty} V(u_0^k) - V(\varphi_k) = 0. \tag{3.6}$$

By Lemma 3.5, if δ is sufficiently small, we have

(3.7)

$$E(u^k(t_k)) - E(\varphi_k) - c(u^k(t_k))(V(u^k(t_k)) - V(\varphi_k)) \geq \frac{1}{4}d''(c)|c(u^k(t_k)) - c|^2.$$

By (3.4) there is some $\psi_k \in G(\beta,c,\gamma)$ such that $\|u^k(t_k) - \psi_k\|_{X_1} < 2\delta$, and by (2.10), we have

$$\|u^k(t_k)\|_{X_1} \leq \|\psi_k\|_{X_1} + 2\delta \leq 2\delta + A^{-1}I(\psi_k;\beta,c,\gamma) = 2\delta + \frac{2(p+1)}{A(p-1)}d(c) < \infty.$$

Thus since K is Lipschitz continuous on X_1 and d^{-1} is continuous, it follows that $c(u^k(t_k))$ is uniformly bounded in k. Thus by (3.5), (3.6), and (3.7) it follows that

$$\lim_{k\to\infty} c(u^k(t_k)) = c.$$

Continuity of K then implies

$$\lim_{k\to\infty} K(u^k(t_k)) = \lim_{k\to\infty} \frac{2(p+1)}{p-1} d(c(u^k(t_k))) = \frac{2(p+1)}{p-1} d(c). \tag{3.8}$$

By (3.2) and (3.1), we have

$$\begin{aligned} \frac{1}{2} I(u^k(t_k)) &= E(u^k(t_k)) - cV(u^k(t_k)) + \frac{1}{p+1} K(u^k(t_k)) \\ &= d(c) + E(u^k(t_k)) - E(\varphi_k) - c(V(u^k(t_k)) - V(\varphi_k)) + \frac{1}{p+1} K(u^k(t_k)), \end{aligned} \tag{3.9}$$

so it follows from (3.5), (3.6), and (3.8) that

$$\lim_{k\to\infty} I(u^k(t_k)) = \frac{2(p+1)}{p-1} d(c).$$

Thus $u^k(t_k)$ is a minimizing sequence and therefore has a subsequence which converges in X_1 to some $\varphi \in G(\beta, c, \gamma)$. This contradicts (3.4), so the proof of the theorem is complete. □

4. Instability. In this section we present two theorems which provide conditions for orbital instability of solitary waves. The first is complementary to the stability theorem, in that it guarantees instability when $d''(c) < 0$. The second does not involve the function d, but rather gives a set of sufficient conditions for instability directly in terms of the parameters β, γ, c, and p. While this result is not sharp, it does not rely on detailed knowledge of the function d. The proof is based on the work of Gonçalves Ribeiro [10], which is a modification of Shatah and Strauss' method [25].

The first theorem requires the following assumption.

Assumption 4.1. For each fixed $\beta > 0$ and $\gamma > 0$, there exists a C^1 map $c \mapsto \varphi_c$ from $(-\infty, 2\sqrt{\beta\gamma})$ to X_1 such that $\varphi_c \in G(\beta, c, \gamma)$.

THEOREM 4.2. *Suppose $\beta > 0$, $\gamma > 0$, $c < 2\sqrt{\beta\gamma}$ and Assumption* 4.1 *holds. If $d''(c) < 0$, then the orbit $\mathcal{O}_{\varphi_c}$ is X_1-unstable.*

THEOREM 4.3. *Let $\beta > 0$, $\gamma > 0$, $c < 2\sqrt{\beta\gamma}$, and $\varphi \in G(\beta, c, \gamma)$. Then the orbit $\mathcal{O}_\varphi$ is X_1-unstable if*

(i) *$c < 0$, $p > 5$, and $\gamma < \gamma_0$ for some small $\gamma_0 > 0$;*
(ii) *$c \le 0$, $p > 5 + 4\sqrt{2}$, and $\gamma > 0$; or*
(iii) *$c > 0$ and $p > \frac{10+k+\sqrt{(10+k)^2+4(7+k)}}{2}$, where $k = 8\left(\frac{2\sqrt{\beta\gamma}}{2\sqrt{\beta\gamma}-c} - 1\right)$.*

Theorems 4.2 and 4.3 are actually both direct corollaries of Theorem 4.4, with different choices of the "unstable direction" ϕ. The choices are given in Lemmas 4.10 and 4.11. As in the proof of the stability theorem, an important role will be played by the ϵ-neighborhoods of the orbits of solitary waves. Given $\varphi \in G(\beta, c, \gamma)$ and $\epsilon > 0$, we define

$$U_{\varphi,\epsilon} = \left\{ u \in X_1 \mid \inf_{v\in\mathcal{O}_\varphi} \|u - v\|_{X_1} < \epsilon \right\}.$$

THEOREM 4.4. *Assume $\beta > 0$, $\gamma > 0$, and $c < 2\sqrt{\beta\gamma}$. Let $\varphi \equiv \varphi_c \in G(\beta, c, \gamma)$ and define $\mathcal{M} = \{u \in X_1; V(u) = V(\varphi_c)\}$. If there exists $\phi \in L^2$ such that $\phi' \in X_s$, $s > 3/2$, $\phi'' \in X_1$, ϕ' is tangent to $\mathcal{M}$ at φ, and*

$$\langle L''(\varphi)\phi', \phi'\rangle < 0, \tag{4.1}$$

then there exist an $\epsilon > 0$ and a sequence $\{u_0^j\}$ in $U_{\varphi,\epsilon}$ such that

(i) *$u_0^j \to \varphi$ in X_1 as $j \to \infty$.*

(ii) *for all positive integers j, u^j is uniformly bounded, but escapes $U_{\varphi,\epsilon}$ in finite time, where u^j is the solution of (1.2) with $u^j(0) = u_0^j$.*

The proof of Theorem 4.4 is approached via a series of lemmas. Define

$$J(u) = \int \beta u_x^2 + \gamma(D_x^{-1}u)^2 - cu^2 + (p+1)F(u)\,dx \tag{4.2}$$

and

$$L(u) = E(u) - cV(u) = \frac{1}{2}J(u) + \frac{p-1}{2(p+1)}K(u).$$

LEMMA 4.5. *Assume $c < 2\sqrt{\beta\gamma}$. Then there exists a ground state $\varphi \in X_1$ satisfying $J(\varphi) = 0$ such that*

$$L(\varphi) = \inf\{L(u) \mid u \in X_1, u \neq 0, J(u) = 0\}. \tag{4.3}$$

Proof. The lemma follows by applying the arguments from the proof of Proposition 2.3 in [17]. □

LEMMA 4.6. *Fix $c < 2\sqrt{\gamma\beta}$ and let $\varphi \in G(\beta, c, \gamma)$. There are an $\epsilon_0 > 0$ and a unique C^2 map $\alpha : U_{\varphi,\epsilon_0} \to \mathbf{R}$ such that $\alpha(\varphi) = 0$ and for all $v \in U_{\varphi,\epsilon_0}$, and any $r \in \mathbf{R}$,*

(i) *$\langle \tau_{\alpha(v)}\varphi', v\rangle = 0$,*

(ii) *$\alpha(\tau_r v) = \alpha(v) + r$, and*

(iii) *$\alpha'(v) = -\frac{1}{\langle v, \varphi''(\cdot+\alpha(v))\rangle}\varphi'(\cdot + \alpha(v))$.*

In particular, for any $w \in \mathcal{O}_\varphi$, we have $\langle \alpha'(w), w\rangle = 0$, and $\alpha'(w) = \frac{1}{|\varphi'|_2^2}w'$.

Proof. The proof is standard. See Theorem 3.1 in [10], Lemma 3.5 in [1], or Lemma 3.5 in [3]. □

Consider a function $\phi \in L^2$ such that $\phi' \in X_1$. Define another vector field B_ϕ by

$$B_\phi(v) = \tau_{\alpha(v)}\phi' - \frac{\langle v, \tau_{\alpha(v)}\phi'\rangle}{\langle v, \tau_{\alpha(v)}\varphi''\rangle}\tau_{\alpha(v)}\varphi'' \tag{4.4}$$

for $v \in U_{\varphi,\epsilon}$.

The vector field B_ϕ is an extension of formula (4.2) in Bona, Souganidis, and Strauss [5], and a similar formula was also used in [1, 3, 10]. The important properties of B_ϕ are expressed in the following auxiliary result and will be used in the proof of Theorem 4.4.

LEMMA 4.7.

(i) *Assume that $\phi \in L^2$ such that $\phi', \phi'' \in X_1$. The mapping $B_\phi : U_{\varphi,\epsilon_0} \to X_1$ is C^1 with bounded derivative.*

(ii) *B_ϕ commutes with translations.*

(iii) *$\langle B_\phi(v), v\rangle = 0$ for all $v \in U_{\varphi,\epsilon_0}$.*

(iv) *If $\langle \varphi, \phi'\rangle = 0$, then $B_\phi(\varphi) = \phi'$.*

Proof. Since $\phi', \varphi'' \in X_1$, it is easy to see from the definition of B_ϕ that $B_\phi(v) \in X_1$ for all $v \in U_{\varphi,\epsilon}$. We now prove that B_ϕ is C^1 with bounded derivative. From part (iii) of Lemma 4.6 and (4.4), we have

$$B_\phi(v) = \tau_{\alpha(v)}\phi' + \left\langle v,\, \tau_{\alpha(v)}\phi' \right\rangle \frac{d}{dx}\alpha'(v).$$

A simple calculation shows

$$\begin{aligned} B'_\phi(v)w = {} & \langle \alpha'(v),\, w\rangle\, \tau_{\alpha(v)}\phi'' + \left\langle v,\, \tau_{\alpha(v)}\phi' \right\rangle \frac{d}{dx}\alpha''(v)w \\ & + \left(\left\langle w,\, \tau_{\alpha(v)}\phi' \right\rangle + \langle \alpha'(v),\, w\rangle \left\langle v,\, \tau_{\alpha(v)}\phi'' \right\rangle\right) \frac{d}{dx}\alpha'(v) \end{aligned} \tag{4.5}$$

for all $w \in X_1$. To show that B_ϕ is a C^1 function with bounded derivative, we need to show that all terms in the right side of (4.5) are bounded in $U_{\varphi,\epsilon}$. In fact, for $w \in X_1$ and $v \in U_{\varphi,\epsilon}$, we have

$$\begin{aligned} \left\langle v',\, \tau_{\alpha(v)}\varphi' \right\rangle \frac{d}{dx}\alpha''(v)w = {} & \langle \alpha'(v),\, w\rangle\, \tau_{\alpha(v)}\varphi''' + \left\langle \tau_{\alpha(v)}\varphi'',\, w \right\rangle \frac{d}{dx}\alpha'(v) \\ & - \langle \alpha'(v),\, w\rangle \left\langle v',\, \tau_{\alpha(v)}\varphi'' \right\rangle \frac{d}{dx}\alpha'(v). \end{aligned} \tag{4.6}$$

Setting $v = \varphi$ in (4.6) and using the relation $\alpha(\varphi) = 0$ yields

$$\frac{d}{dx}\alpha''(\varphi)w = \frac{\varphi'''}{|\varphi'|_2^4} \langle w,\, \varphi'\rangle + \frac{\varphi''}{|\varphi'|_2^4} \langle w,\, \varphi''\rangle . \tag{4.7}$$

Therefore,

$$\left\| \frac{d}{dx}\alpha''(\varphi) \right\|_{L(X_1,\, X_1)} \le C_0\left(\|\varphi\|_4\right)$$

and

$$\left\| \frac{d}{dx}\alpha'(\varphi) \right\|_{X_1} \le C_1(\|\varphi\|_3).$$

Since α is C^2 and $\frac{d}{dx}\alpha'$ and $\frac{d}{dx}\alpha''$ are continuous, by taking $\epsilon > 0$ small enough, if necessary, there exists a constant $C_2 > 0$ such that

$$\|\alpha'(v)\|_{X_1} \le C_2, \quad \left\| \frac{d}{dx}\alpha'(v) \right\|_{X_1} \le C_2, \quad \text{and} \quad \left\| \frac{d}{dx}\alpha''(v) \right\|_{L(X_1,\, X_1)} \le C_2$$

with $C_2 = C_2(\|\varphi\|_4)$ and for all $v \in U_{\varphi,\epsilon_0}$. It follows that B_ϕ is a C^1 function and the derivative of B_ϕ is bounded by

$$\left\| B'_\phi(v)w \right\|_{X_1} \le C_2\left(\|\phi''\|_{X_1} + (\epsilon + \|\varphi\|_{X_1})|\phi'|_2\right) \|w\|_{X_1},$$

which implies that

$$\|B'_\phi(v)\|_{L(X_1,\, X_1)} \le C \quad \forall v \in U_{\varphi,\epsilon},$$

where the constant C depends only on C_2, $\|\phi''\|_{X_1}$, $|\phi'|_2$, and $\|\varphi\|_{X_1}$. This proves (i). Statement (ii) can be obtained immediately from the relation $\alpha(\tau_y(v)) = \alpha(v) + y$ for

any $v \in X_1$ and $y \in \mathbf{R}$. Statement (iii) can obtained directly from the definition of B_ϕ. By $\alpha(\varphi) = 0$ and by the assumption in (iv), $\langle \varphi, \phi' \rangle = 0$, we have

$$B_\phi(\varphi) = \phi' + \frac{\langle \varphi, \phi' \rangle}{|\varphi'|_2^2} \varphi'' = \phi'.$$

This completes the proof of Lemma 4.7. □

LEMMA 4.8. *Let $\varphi \in G(\beta, c, \gamma)$. Assume that $\phi \in L^2$ is defined in Theorem* 4.4. *Then there exist $\epsilon_3 > 0$ and $\sigma_3 > 0$ such that for each $v_0 \in U_{\varphi,\epsilon_3}$,*

$$L(\varphi) \le L(v_0) + P(v_0)s \tag{4.8}$$

for some $s \in (-\sigma_3, \sigma_3)$, where $P(v) = \langle L'(v), B_\phi(v) \rangle$ and $L(v) = E(v) - cV(v)$.

Proof. Let $U_{\varphi,\epsilon}$ be as in Lemma 4.6. For each $v_0 \in U_{\varphi,\epsilon_0}$, consider the initial-value problem

$$\begin{aligned} \frac{dv}{ds} &= B_\phi(v), \\ v(0) &= v_0. \end{aligned} \tag{4.9}$$

By Lemma 4.7, it has a unique maximal solution $v(v_0, s) \in C^2(U_{\varphi,\epsilon_0}, (-\sigma, \sigma))$ with $\sigma = \sigma(v_0) > 0$. Moreover, for each $\epsilon_1 < \epsilon_0$, there exists $\sigma_1 > 0$ such that $\sigma(v_0) \ge \sigma_1$ for all $v_0 \in U_{\varphi,\epsilon_1}$. Hence, for fixed ϵ_1 and σ_1, we can define the C^2-mapping $s \in (-\sigma_1, \sigma_1) \mapsto L(v(v_0, s))$. Let $P(v) = \langle L'(v), B_\phi(v) \rangle$ and

$$R(v) = \langle L''(v) B_\phi(v), B_\phi(v) \rangle + \left\langle L'(v), B_\phi'(v)(B_\phi(v)) \right\rangle. \tag{4.10}$$

Applying Taylor's theorem yields

$$L(v(v_0, s)) = L(v_0) + P(v_0)s + \frac{1}{2} R(v(v_0, \xi s)) s^2 \tag{4.11}$$

for some $\xi \in (0, 1)$. Since $L'(\varphi) = 0$ and $R(\varphi) = \langle L''(\varphi)\phi', \phi' \rangle < 0$, it follows from the continuity of P and R that there exist $\epsilon_2 \in (0, \epsilon_1)$ and $\sigma_2 \in (0, \sigma_1)$ such that

$$L\left(v(v_0, s)\right) \le L(v_0) + P(v_0)s \tag{4.12}$$

for $v_0 \in B(\varphi, \epsilon_2)$ and $s \in (-\sigma_2, \sigma_2)$. On the other hand, a simple calculation shows that

$$J(v(v_0, s))\Big|_{(v_0,s)=(\varphi,0)} = 0$$

and

$$\frac{\partial}{\partial s} J(v(v_0, s))\Big|_{(v_0,s)=(\varphi,0)} = \langle J'(\varphi), \phi' \rangle. \tag{4.13}$$

We claim that $\langle J'(\varphi), \phi' \rangle \ne 0$. Otherwise, ϕ' would be tangent to $\mathcal{N}$ at φ, where

$$\mathcal{N} = \{ u \in X_1 \mid u \ne 0, J(u) = 0 \}.$$

Hence, $\langle L''(\varphi)\phi', \phi' \rangle \ge 0$ since φ minimizes L on $\mathcal{N}$ by Lemma 4.5. But this contradicts (4.1). Therefore, by the implicit function theorem, there exist $\epsilon_3 \in (0, \epsilon_2)$

and $\sigma_3 \in (0, \sigma_2)$ such that for every $v_0 \in B(\varphi, \epsilon_3)$, there exists a unique $s = s(v_0) \in (-\sigma_3, \sigma_3)$ such that

$$J\left(v(v_0, s(v_0))\right) = 0. \tag{4.14}$$

Applying (4.12) to $(v_0, s(v_0))$ given by (4.14) and taking into account that φ minimizes L on $\mathcal{N}$, we have

$$L(\varphi) \le L(v(v_0, s)) \le L(v_0) + P(v_0)s \tag{4.15}$$

for some $s \in (-\sigma_3, \sigma_3)$. The above inequality can be extended to U_{φ,ϵ_3} from the gauge invariance. □

Remark 4.9. From the relation

$$v(\varphi,\, s) = \varphi + \int_0^s \tau_{\alpha(v(\varphi,t))}\phi'\, dt - \int_0^s g(t)\tau_{\alpha(v(\varphi,\, t))}\varphi''\, dt,$$

where

$$g(t) = \frac{\left\langle v, \tau_{\alpha(v)}\phi' \right\rangle}{\left\langle v, \tau_{\alpha(v)}\varphi'' \right\rangle},$$

it is easy to see that $v(\varphi, s) \in X_l, l > \frac{3}{2}$, for all $s \in (-\sigma_3, \sigma_3)$.

Now we are in the position to prove Theorem 4.4.

Proof of Theorem 4.4. Since $v(v_0,\, s)$ commutes with τ_y, it follows by replacing v_0 with $v(\varphi, \delta)$ in (4.15) that

$$L(v(v(\varphi, \delta),\, s)) \le L(v(\varphi, \delta)) + P(v(\varphi,\, \delta))s \tag{4.16}$$

for any $s \in (-\sigma_2,\, \sigma_2)$ and $\delta \in (-\sigma_3, \sigma_3)$ with $0 < \sigma_3 < \sigma_2$. Taking $s = -\delta$, it thus transpires from (4.16) that

$$L(\varphi) \le L(v(\varphi,\, \delta)) - P(v(\varphi,\, \delta))\delta \tag{4.17}$$

for all $\delta \in (-\sigma_3,\, \sigma_3)$. Moreover, it follows from (4.11) and the fact that $P(\varphi) = 0$ that the mapping $\delta \mapsto L(v(\varphi,\, \delta))$ has a strict maximum locally at $\delta = 0$. Hence, we have

$$L(v(\varphi,\, \delta)) < L(\varphi) \tag{4.18}$$

for all $\delta \neq 0$ and $\delta \in (-\sigma_4,\, \sigma_4)$ with $0 < \sigma_4 \le \sigma_3$. This in turn implies from (4.17) that

$$P(v(\varphi,\, \delta)) < 0 \tag{4.19}$$

for all $\delta \in (0, \sigma_4)$. Let $\delta_j \in (0, \sigma_4)$ such that $\delta_j \to 0$ as $j \to \infty$. Consider the sequences of initial data $u_{0,j} = v(\varphi,\, \delta_j)$. Then by Remark 4.9, $u_{0,j} \in X_s$, $s > 3/2$ for all positive integers j and $u_{0,j} \to \varphi$ in X_1 as $j \to \infty$, which proves (i). For all integers j, we need only verify that the solution $u_j(t)$ of (1.2) with $u_j(0) = u_{0,j}$ escapes from U_{φ,ϵ_3} for some $\epsilon_3 > 0$ and for all positive integers j in finite time. To see this, let ϵ_3 be defined as in Lemma 4.8. Define

$$T_j = \sup\{\lambda > 0; \quad u_j(t) \in U_{\varphi,\epsilon_3}\ \forall t \in (0,\, \lambda)\}$$

and

$$P_- = \{v \in U_{\varphi,\epsilon_3}; \quad L(v) < L(\varphi), P(v) < 0\}.$$

Consider the case of the maximal existence time $T = +\infty$ by the definition of stability. It now follows from Lemma 4.8 that for all integers j and $t \in (0, T_j)$, there exists $s = s_j(t) \in (-\sigma_3, \sigma_3)$ satisfying

$$L(\varphi) \le L(u_j(t)) + P(u_j(t))s = L(u_{0,j}) + P(u_j(t))s. \tag{4.20}$$

By (4.18) and (4.19), $u_{0,j} \in P_-$. Then we deduce that $u_j(t) \in P_-$ for all $t \in [0, T_j]$. In fact, if $P(u_j(t_0)) > 0$ for some $t_0 \in [0, T_j]$, then the continuity of P implies that there exists some $t_1 \in [0, T_j]$ satisfying $P(u_j(t_1)) = 0$, and it thus follows from (4.20) that $L(\varphi) \le L(u_{0,j})$, which contradicts $u_{0,j} \in P_-$. Hence, by (4.20), P is bounded away from zero and

$$-P(u_j(t)) \ge \frac{L(\varphi) - L(u_{0,j})}{\sigma_3} = \eta_j > 0 \quad \forall t \in [0, T_j]. \tag{4.21}$$

We now define a Liapunov function

$$A(t) = \int_{\mathbf{R}} \phi(x + \alpha(u_j(t)))u_j(x,t)dx, \quad t \in [0, T_j]. \tag{4.22}$$

Then by the Cauchy–Schwarz inequality,

$$|A(t)| \le |\phi|_2 |u_j(t)|_2 = |\phi|_2 |u_{0,j}|_2 < +\infty, \quad t \in [0, T_j]. \tag{4.23}$$

On the other hand, using the Hamiltonian formulation

$$\frac{du_j}{dt} = -\partial_x E'(u_j)$$

of (1.2), we have

$$\begin{aligned}
\frac{dA}{dt} &= \alpha'(u_j(t)) \int_{\mathbf{R}} \phi'\left(x + \alpha(u_j(t))\right) u_j(t) + \int_{\mathbf{R}} \phi\left(x + \alpha(u_j(t))\right) \frac{du_j}{dt} \\
&= \left\langle \alpha'(u_j(t)), \frac{du_j}{dt} \right\rangle \left\langle \tau_{\alpha(u_j(t))}\phi', u_j \right\rangle + \left\langle \tau_{\alpha(u_j(t))}\phi, \frac{du_j}{dt} \right\rangle \\
&= \left\langle \left\langle \tau_{\alpha(u_j(t))}\phi', u_j(t) \right\rangle \frac{d\alpha'(u_j(t))}{dx} + \tau_{\alpha(u_j(t))}\phi', E'(u_j(t)) \right\rangle \\
&= \langle B_\phi(u_j(t)), E'(u_j(t)) \rangle \\
&= \langle B_\phi(u_j(t)), L'(u_j(t)) \rangle + c \langle B_\phi(u_j(t)), u_j(t) \rangle \\
&= P(u_j(t))
\end{aligned}$$

for $t \in [0, T_j]$, where $\langle B_\phi(u_j(t)), u_j(t) \rangle = 0$. Hence (4.21) yields the lower bound

$$-\frac{dA}{dt} \ge \eta_j > 0 \quad \forall t \in [0, T_j]. \tag{4.24}$$

Comparing (4.23) and (4.24), we conclude that $T_j < +\infty$ for all j. This completes the proof. □

In view of Theorem 4.4 we now look for functions ϕ that satisfy the inequality (4.1).

LEMMA 4.10. *Suppose $\beta > 0$, $\gamma > 0$, $c < 2\sqrt{\beta\gamma}$, and Assumption 4.1 holds. If $d''(c) < 0$, then there exists ϕ satisfying the conditions of Theorem 4.4.*

Proof. By Assumption 4.1, d is differentiable and by Lemma 3.4, $d'(c) = -V(\varphi_c)$. So if we define

$$g(h, \sigma) = V(\varphi_h + \sigma\varphi_c),$$

then $g(c, 0) = -d'(c)$ and

$$\frac{\partial g}{\partial h}(c, 0) = \left\langle V'(\varphi_c), \frac{\partial \varphi_c}{\partial c} \right\rangle = -d''(c) > 0.$$

Thus the implicit function theorem implies there is a C^2-mapping $h : (-\epsilon, \epsilon) \to (-\infty, 2\sqrt{\beta\gamma})$ such that $h(0) = c$ and

$$g(h(\sigma), \sigma) = V(\varphi_{h(\sigma)} + \sigma\varphi_c) = V(\varphi_c).$$

Therefore

$$0 = \frac{d}{d\sigma} g(h(\sigma), \sigma)\bigg|_{\sigma=0} = \left\langle V'(\varphi_c), h'(0)\frac{\partial \varphi_c}{\partial c} + \varphi_c \right\rangle, \tag{4.25}$$

so if we define

$$\phi(x) = \int_{-\infty}^{x} h'(0)\frac{\partial \varphi_c}{\partial c}(y) + \varphi_c(y)\, dy,$$

then ϕ' is tangent to $\mathcal{M}$ at φ_c and it follows from Assumption 4.1 that $\phi \in L^2$, $\phi' \in X_s$ for some $s > 3/2$ and $\phi'' \in X_1$. It remains to show that ϕ satisfies (4.1). First, observe that

$$L''(\varphi) = E''(\varphi_c) - cV''(\varphi_c) = -\beta\partial_x^2 - \gamma D_x^{-2} - c + f'(\varphi_c), \tag{4.26}$$

so

$$\begin{aligned} \langle L''(\varphi_c)\phi', \phi' \rangle = \langle L''(\varphi_c)\varphi_c, \varphi_c \rangle + 2h'(0)\left\langle L''(\varphi_c)\varphi_c, \frac{\partial \varphi_c}{\partial c} \right\rangle \\ + (h'(0))^2 \left\langle L''(\varphi_c)\frac{\partial \varphi_c}{\partial c}, \frac{\partial \varphi_c}{\partial c} \right\rangle. \end{aligned} \tag{4.27}$$

We claim that

$$\langle L''(\varphi_c)\varphi_c, \varphi_c \rangle = (1 - p)K(\varphi_c), \tag{4.28}$$

$$\left\langle L''(\varphi_c)\varphi_c, \frac{\partial \varphi_c}{\partial c} \right\rangle = -2d'(c), \tag{4.29}$$

and

$$\left\langle L''(\varphi_c)\frac{\partial \varphi_c}{\partial c}, \frac{\partial \varphi_c}{\partial c} \right\rangle = -d''(c). \tag{4.30}$$

To prove the first two identities, recall that $sf'(s) = pf(s)$ and $F' = f$. Thus

$$\begin{aligned}\langle L''(\varphi_c)\varphi_c, \varphi_c\rangle &= \int_{\mathbf{R}} (-\beta(\varphi_c)_{xx} - \gamma D_x^{-2}\varphi_c - c\varphi_c + pf(\varphi_c))\varphi_c\, dx \\ &= \int_{\mathbf{R}} (p-1)\varphi_c f(\varphi_c)\, dx \\ &= (1-p)K(\varphi_c)\end{aligned}$$

and

$$\begin{aligned}\left\langle L''(\varphi_c)\varphi_c, \frac{\partial\varphi_c}{\partial c}\right\rangle &= \int_{\mathbf{R}} (-\beta(\varphi_c)_{xx} - \gamma D_x^{-2}\varphi_c - c\varphi_c + pf(\varphi_c))\frac{\partial\varphi_c}{\partial c}\, dx \\ &= \int_{\mathbf{R}} (p-1)f(\varphi_c)\frac{\partial\varphi_c}{\partial c}\, dx \\ &= (p-1)\frac{d}{dc}\int_{\mathbf{R}} F(\varphi_c)\, dx \\ &= -2d'(c).\end{aligned}$$

For the third identity, differentiate the solitary wave equation with respect to c to find

$$\beta\left(\frac{\partial\varphi_c}{\partial c}\right)_{xx} + c\frac{\partial\varphi_c}{\partial c} + \varphi_c + \gamma D_x^{-2}\frac{\partial\varphi_c}{\partial c} = f'(\varphi)\frac{\partial\varphi_c}{\partial c},$$

so $L''(\varphi_c)\left(\frac{\partial\varphi_c}{\partial c}\right) = \varphi_c$, and therefore

$$\left\langle L''(\varphi_c)\frac{\partial\varphi_c}{\partial c}, \frac{\partial\varphi_c}{\partial c}\right\rangle = \left\langle \varphi_c, \frac{\partial\varphi_c}{\partial c}\right\rangle = \frac{1}{2}\frac{d}{dc}\int_{\mathbf{R}} \varphi_c^2\, dx = -d''(c)$$

by Lemma 3.4. We next compute $h'(0)$. Using (4.25) and Lemma 3.4, we have

$$0 = h'(0)\left\langle \varphi_c, \frac{\partial\varphi_c}{\partial c}\right\rangle + \langle\varphi_c, \varphi_c\rangle = \frac{1}{2}h'(0)\frac{d}{dc}\langle\varphi_c, \varphi_c\rangle + \langle\varphi_c, \varphi_c\rangle = -\frac{1}{2}h'(0)d''(c) - d'(c)$$

and therefore

$$h'(0) = -\frac{2d'(c)}{d''(c)}.$$

Finally, (4.27), (4.28), and (4.29) give

$$\langle L''(\varphi_c)\phi', \phi'\rangle = (1-p)K(\varphi_c) + 4\frac{(d'(c))^2}{d''(c)} < 0$$

under the assumption that $d''(c) < 0$. This proves the lemma. □

LEMMA 4.11. *Assume $c < 2\sqrt{\beta\gamma}$ and let $\varphi \in G(\beta, c, \gamma)$. Define*

$$\phi(x) = \int_{-\infty}^{x} (\varphi(y) + 2y\varphi'(y))\, dy.$$

Then

(i) *$\phi \in L^2$, $\phi' \in X_s, s > 3/2, \phi'' \in X_1$, and ϕ' is tangent to $\mathcal{M}$ at φ.*
(ii) *$\langle L''(\varphi)\phi', \phi'\rangle = \frac{(p-1)(5-p)}{p+1}K(\varphi) + 16\gamma\int_{\mathbf{R}}(D_x^{-1}\varphi)^2\, dx$.*

Proof. The first part of statement (i) is obvious because $\varphi \in X_s$ for $s > 3/2$ and φ is exponentially decaying at infinity. On the other hand, a simple calculation shows that

$$\langle \phi', \varphi \rangle = \int_{\mathbf{R}} (\varphi(x) + 2x\varphi'(x))\, \varphi(x)\, dx = \int_{\mathbf{R}} (x\varphi^2)'\, dx = 0.$$

This proves (i). Now we need to estimate the quantity $\langle L''(\varphi)\phi',\, \phi' \rangle$. Differentiating the solitary wave equation

$$\beta\varphi_{xx} + c\varphi + \gamma D_x^{-2}\varphi = f(\varphi) \tag{4.31}$$

gives

$$\beta\varphi_{xxx} + c\varphi_x + \gamma D_x^{-1}\varphi = f'(\varphi)\varphi_x. \tag{4.32}$$

We now claim that

$$\langle L''(\varphi)\varphi, x\varphi' \rangle = \frac{p-1}{p+1} K(\varphi) \tag{4.33}$$

and

$$\langle L''(\varphi)\,(x\varphi')\,, x\varphi' \rangle = \frac{p-1}{2(p+1)} K(\varphi) + 4\gamma \int_{\mathbf{R}} (D_x^{-1}\varphi)^2. \tag{4.34}$$

To prove these, again recall that $f'(\varphi)\varphi = pf(\varphi)$ and $F' = f$, so that

$$\begin{aligned}
\langle L''(\varphi)\varphi, x\varphi' \rangle &= \int_{\mathbf{R}} (-\beta\varphi_{xx} - \gamma D_x^{-2}\varphi - c\varphi + pf(\varphi)) x\varphi'\, dx \\
&= \int_{\mathbf{R}} (p-1) x\varphi' f(\varphi)\, dx \\
&= (1-p) \int_{\mathbf{R}} F(\varphi)\, dx \\
&= \frac{p-1}{p+1} K(\varphi).
\end{aligned}$$

Next, we note that the identities

$$\int_{\mathbf{R}} \beta\varphi_x^2 - c\varphi^2 + \gamma(D_x^{-1}\varphi)^2\, dx = K(\varphi) \tag{4.35}$$

and

$$\int_{\mathbf{R}} \frac{1}{2}\beta\varphi_x^2 + \frac{1}{2}c\varphi^2 - \frac{3}{2}\gamma(D_x^{-1}\varphi)^2\, dx = -\frac{1}{p+1} K(\varphi) \tag{4.36}$$

follow by multiplying (4.31) by φ and $x\varphi'$, respectively, and integrating. Combining these yields

$$\int_{\mathbf{R}} c\varphi^2\, dx - 2\gamma \int_{\mathbf{R}} (D_x^{-1}\varphi)^2\, dx + \frac{p+3}{2(p+1)} K(\varphi) = 0. \tag{4.37}$$

Next, we observe that

$$\begin{aligned}
L''(\varphi)(x\varphi') &= -\beta(x\varphi')'' - \gamma D_x^{-2}(x\varphi') - cx\varphi' + f'(\varphi)x\varphi' \\
&= -\beta(x\varphi''' + 2\varphi'') - \gamma x D_x^{-1}\varphi + 2\gamma D_x^{-2}\varphi - cx\varphi' + xf'(\varphi)\varphi' \\
&= -x(\beta\varphi''' + c\varphi' + \gamma D_x^{-1}\varphi - f'(\varphi)\varphi') - 2\beta\varphi'' + 2\gamma D_x^{-2}\varphi.
\end{aligned}$$

Using (4.31) and (4.32), this simplifies to

$$L''(\varphi)(x\varphi') = 2c\varphi + 4\gamma D_x^{-2}\varphi - 2f(\varphi),$$

so

$$\begin{aligned}\langle L''(\varphi)(x\varphi'), x\varphi'\rangle &= \int_{\mathbf{R}} (2c\varphi + 4\gamma D_x^{-2}\varphi - 2f(\varphi))x\varphi'\,dx \\ &= \int_{\mathbf{R}} -c\varphi^2 + 2F(\varphi) + 6\gamma(D_x^{-1}\varphi)^2\,dx.\end{aligned}$$

Together with (4.37), this implies

$$\begin{aligned}\langle L''(\varphi)(x\varphi'), x\varphi'\rangle &= 4\gamma\int_{\mathbf{R}} (D_x^{-1}\varphi)^2\,dx + \left(\frac{p+3}{2(p+1)} - \frac{2}{p+1}\right)K(\varphi) \\ &= 4\gamma\int_{\mathbf{R}} (D_x^{-1}\varphi)^2\,dx + \frac{p-1}{2(p+1)}K(\varphi),\end{aligned}$$

as claimed. Therefore we deduce from (4.28), (4.33), and (4.34) that

$$\begin{aligned}\langle L''(\varphi)\phi', \phi'\rangle &= \langle L''(\varphi)\varphi, \varphi\rangle + 4\langle L''(\varphi)\varphi, x\varphi'\rangle + 4\langle L''(\varphi)(x\varphi'), x\varphi'\rangle \\ &= (1-p)K(\varphi) + \frac{4(p-1)}{p+1}K(\varphi) + \frac{2(p-1)}{p+1}K(\varphi) + 16\gamma\int_{\mathbf{R}} \left(D_x^{-1}\varphi\right)^2\,dx \\ &= \frac{(p-1)(5-p)}{p+1}K(\varphi) + 16\gamma\int_{\mathbf{R}} \left(D_x^{-1}\varphi\right)^2\,dx.\end{aligned}$$

This completes the proof of the lemma. □

COROLLARY 4.12. *Let ϕ be defined as in Lemma 4.11. Then $\langle L''(\varphi)\phi', \phi'\rangle < 0$ if*

(i) *$c < 0$, $p > 5$, and $\gamma < \gamma_0$ for some small $\gamma_0 > 0$;*
(ii) *$c \le 0$, $p > 5 + 4\sqrt{2}$, and $\gamma > 0$; or*
(iii) *$0 < c < 2\sqrt{\gamma\beta}$ and $p > p_0$ with*

$$p_0 = \frac{10 + k + \sqrt{(10+k)^2 + 4(7+k)}}{2}$$

and

$$k = 8\left(\frac{2\sqrt{\beta\gamma}}{2\sqrt{\beta\gamma} - c} - 1\right) > 0.$$

Proof. To prove (i), we first claim that

$$\lim_{\gamma\to 0} \gamma\int_{\mathbf{R}} \left(D_x^{-1}\varphi\right)^2\,dx = 0.$$

In fact, in view of (4.35), we have

$$\begin{aligned}\gamma\int_{\mathbf{R}} \left(D_x^{-1}\varphi\right)^2\,dx &= \int_{\mathbf{R}} c\varphi^2 - \beta\varphi_x^2\,dx + K(\varphi) \\ &= \int_{\varphi} c\varphi^2 - \beta\varphi_x^2\,dx + (m(\beta, c, \gamma))^{\frac{p+1}{p-1}}.\end{aligned}$$

It is thereby inferred from Lemma 2.7 and Theorem 2.5 that

$$\lim_{\gamma\to 0}\gamma\int_{\mathbf{R}}\left(D_x^{-1}\varphi\right)^2\,dx=\int_{\mathbf{R}}c\varphi_0^2-\beta\left(\partial_x\varphi_0\right)^2\,dx+\left(m(\beta,c,0)\right)^{\frac{p+1}{p-1}}$$
$$=-I(\varphi_0;\beta,c,0)+\left(m(\beta,c,0)\right)^{\frac{p+1}{p-1}}=0,$$

where φ_0 is the ground state solution of the KdV equation with $c<0$. This in turn implies that

$$\lim_{\gamma\to 0}\langle L''(\varphi)\phi',\phi'\rangle=\frac{(p-1)(5-p)}{p+1}\left(m(\beta,c,0)\right)^{\frac{p+1}{p-1}}<0$$

for $c<0$ and $p>5$. This proves (i). To prove (ii) and (iii), we use (4.37) to write

$$2\gamma\int_{\mathbf{R}}\left(D_x^{-1}\varphi\right)^2\,dx=\frac{p+3}{2(p+1)}K(\varphi)+c\int_{\mathbf{R}}\varphi^2\,dx$$
$$=\frac{p+3}{2(p+1)}K(\varphi)-K(\varphi)+\int_{\mathbf{R}}\beta\varphi_x^2+\gamma\left(D_x^{-1}\varphi\right)^2\,dx$$
$$\leq\left(\frac{p+3}{2(p+1)}-1+\max\left\{1,\frac{2\sqrt{\beta\gamma}}{2\sqrt{\beta\gamma}-c}\right\}\right)K(\varphi).$$

Therefore it follows from formula (ii) in Lemma 4.11 that

$$\langle L''(\varphi)\phi',\phi'\rangle\leq\left(\frac{(p-1)(5-p)}{p+1}+\frac{4(p+3)}{p+1}-8(1-\rho)\right)K(\varphi),\tag{4.38}$$

where

$$\rho=\max\left\{1,\frac{2\sqrt{\beta\gamma}}{2\sqrt{\beta\gamma}-c}\right\}.$$

If $c\leq 0$, then $\rho=1$ and it follows that

$$\langle L''(\varphi)\phi',\phi'\rangle\leq\left(\frac{(p-1)(5-p)}{p+1}+\frac{4(p+3)}{p+1}\right)K(\varphi)$$
$$=-\frac{1}{p+1}\left(p-(5-4\sqrt{2})\right)\left(p-(5+4\sqrt{2})\right)K(\varphi)<0$$

under the assumption of p in (ii). If assumption (iii) is satisfied, then

$$p^2-(10+k)p-(7+k)>0,$$

where $k=8(\rho-1)>0$. It thus follows from (4.34) that

$$\langle L''(\varphi)\phi',\phi'\rangle=-\frac{1}{p+1}\left(p^2-(10+k)p-(7+k)\right)K(\varphi)<0.$$

The proof of the corollary is complete. □

5. Numerical results. We now present some numerical computations of $d(c)$ for the nonlinearity $f(u)=(-u)^p$, where $p\geq 3$ is an integer. The case $p=2$ is (1.1) and was considered in [15]. The strategy for computing d is to first compute numerically the solutions of the solitary wave equation (2.1) using a shooting method.

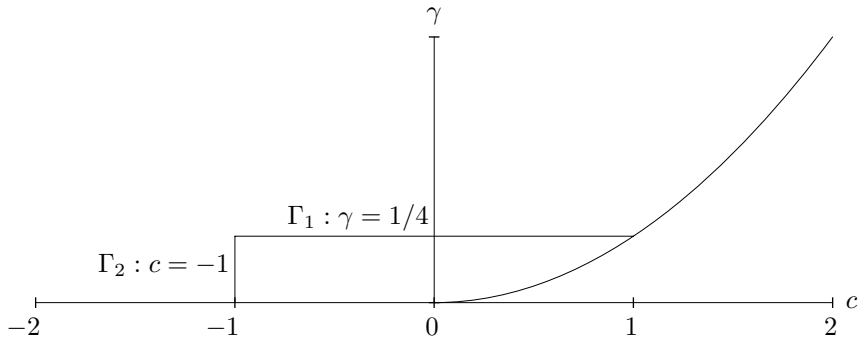
Then, using (3.3), we compute $d(c)$ and use a difference quotient to approximate $d''(c)$. The scaling property of d in Lemma 3.2 helps to reduce the calculations from the domain $c < 2\sqrt{\beta\gamma}$ to two finite line segments. To see this, substitute $r = 1/2\sqrt{\beta\gamma}$ and $s = (4\gamma/\beta)^{1/4}$ in the relation in Lemma 3.2 to get

$$d(\beta, c, \gamma) = \beta^{\frac{p+1}{2(p-1)}+\frac{1}{4}}(4\gamma)^{\frac{p+1}{2(p-1)}-\frac{1}{4}} d\left(1, \frac{c}{2\sqrt{\beta\gamma}}, \frac{1}{4}\right). \tag{5.1}$$

Thus the value of d along any surface of the form

$$S_\alpha = \{(\beta, c, \gamma) \mid c/2\sqrt{\beta\gamma} = \alpha\}$$

is determined by its value at any single point on that surface. We therefore need only compute d along some set of paths which crosses every such surface. We make the following choice. Let $\Gamma_1 = \{(1, c, 1/4) \mid -1 \le c < 1\}$ and $\Gamma_2 = \{(1, -1, \gamma) \mid 0 < \gamma \le 1/4\}$. Then Γ_1 crosses S_α for $-1 \le \alpha < 1$, and Γ_2 crosses S_α for $\alpha \le -1$. The paths Γ_1 and Γ_2 are shown below in the plane $\beta = 1$.



We now consider the sign of d_{cc} along these curves.

Along Γ_1. Differentiating (5.1) twice with respect to c gives

$$d_{cc}(\beta, c, \gamma) = \beta^{\frac{p+1}{2(p-1)}-\frac{3}{4}}(4\gamma)^{\frac{p+1}{2(p-1)}-\frac{5}{4}} d_{cc}\left(1, \frac{c}{2\sqrt{\beta\gamma}}, \frac{1}{4}\right).$$

Since $\beta > 0$ and $\gamma > 0$, it follows that the sign of d_{cc} within S_α is determined by the sign of $d_{cc}(1, \alpha, 1/4)$.

Along Γ_2. Using Lemma 3.2 again, we deduce that

$$d(1, c, \gamma) = (-c)^{\frac{p+3}{2(p-1)}} d\left(1, -1, \frac{\gamma}{c^2}\right)$$

for $c < 0$, so setting $q = \frac{p+3}{2(p-1)}$ and differentiating with respect to c gives

$$\begin{aligned} d_c(1, c, \gamma) &= -q(-c)^{q-1} d\left(1, -1, \frac{\gamma}{c^2}\right) - \frac{2\gamma}{c^3}(-c)^q d_\gamma\left(1, -1, \frac{\gamma}{c^2}\right) \\ &= -q(-c)^{q-1} d\left(1, -1, \frac{\gamma}{c^2}\right) + 2\gamma(-c)^{q-3} d_\gamma\left(1, -1, \frac{\gamma}{c^2}\right) \end{aligned}$$

and

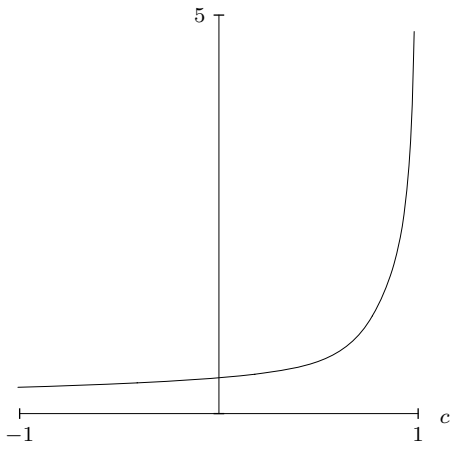
$$\begin{aligned} d_{cc}(1,c,\gamma) &= q(q-1)(-c)^{q-2}d\left(1,-1,\frac{\gamma}{c^2}\right) + \frac{2q\gamma}{c^3}(-c)^{q-1}d_\gamma\left(1,-1,\frac{\gamma}{c^2}\right) \\ &\quad - 2\gamma(q-3)(-c)^{q-4}d_\gamma\left(1,-1,\frac{\gamma}{c^2}\right) - \frac{4\gamma^2}{c^3}(-c)^{q-3}d_{\gamma\gamma}\left(1,-1,\frac{\gamma}{c^2}\right) \\ &= q(q-1)(-c)^{q-2}d\left(1,-1,\frac{\gamma}{c^2}\right) - 2\gamma(2q-3)(-c)^{q-4}d_\gamma\left(1,-1,\frac{\gamma}{c^2}\right) \\ &\quad + 4\gamma^2(-c)^{q-6}d_{\gamma\gamma}\left(1,-1,\frac{\gamma}{c^2}\right). \end{aligned}$$

Setting $r = \gamma/c^2$, this simplifies to $d_{cc}(1,c,\gamma) = (-c)^{q-2}g(r)$, where

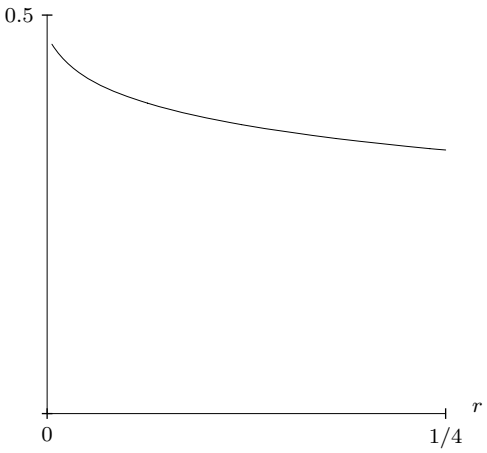
$$g(r) = 4r^2 d_{\gamma\gamma}(1,-1,r) - 2(2q-3)rd_\gamma(1,-1,r) + q(q-1)d(1,-1,r).$$

So it suffices to determine the sign of $g(r)$ for $0 < r \le \frac{1}{4}$. In the following 10 graphs, we consider the nonlinearity $f(u) = (-u)^p$ for several values of p. We remark that the case $p = 2$ is the classical Ostrovsky equation (1.1), for which it was shown by the authors in [15] using the same numerical method that $d''(c)$ is positive for all β, γ, and $c < 2\sqrt{\beta\gamma}$.

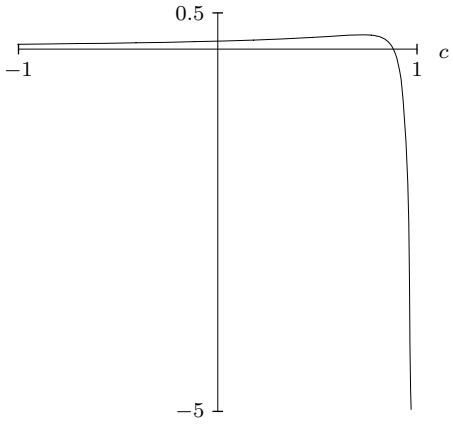
d_{cc}, $p = 3$, $\beta = 1$, $\gamma = 0.25$



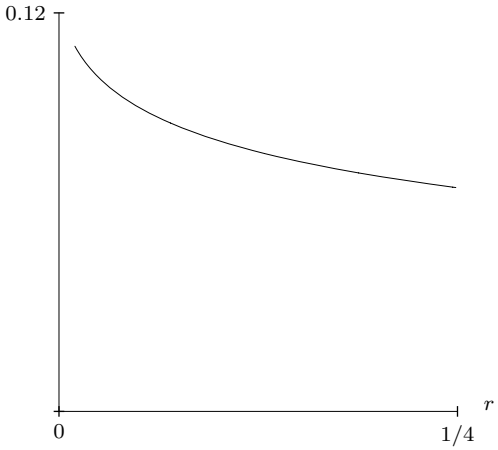
$g(r)$, $p = 3$, $\beta = 1$, $c = -1$

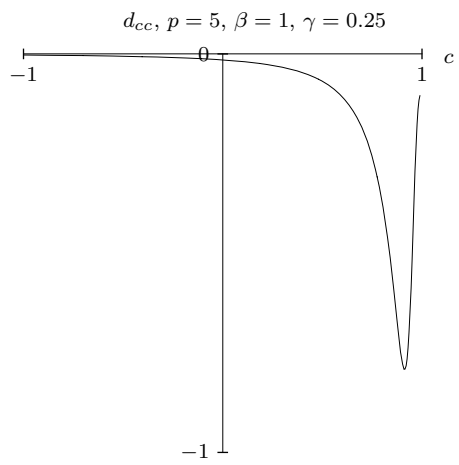


d_{cc}, $p = 4$, $\beta = 1$, $\gamma = 0.25$



$g(r)$, $p = 4$, $\beta = 1$, $c = -1$





d_{cc}, $p = 5$, $\beta = 1$, $\gamma = 0.25$

Using Theorems 3.1 and 4.3, we arrive at the following conclusions.

1. When $p = 3$, all solitary waves are stable for $c < 2\sqrt{\beta\gamma}$.
2. When $p = 4$, there exists α_0 (≈ 0.88) such that solitary waves are stable for $\frac{c}{2\sqrt{\beta\gamma}} < \alpha_0$ and solitary waves are unstable for $\alpha_0 < \frac{c}{2\sqrt{\beta\gamma}} < 1$.
3. When $p = 5$, 6, or 7, all solitary waves are unstable for $c < 2\sqrt{\beta\gamma}$.

The case $p = 4$ seems most interesting due to the change of stability. We conjecture that for all $p \geq 5$, solitary waves are unstable.

Acknowledgments. The authors are grateful for the constructive suggestions made by the referees.

THE DISCRETE PULSE TRANSFORM*

C. H. ROHWER† AND D. P. LAURIE†

Abstract. We investigate a recent algorithm, here called a discrete pulse transform (DPT), for the multiresolution analysis of a sequence. A DPT represents a sequence as a sum of pulses, where a pulse is a sequence which is zero everywhere except for a certain number of consecutive elements which have a constant nonzero value. Unlike the discrete Fourier and wavelet transforms, the DPT is not a discretization of an underlying continuous model, but is inherently discrete. The DPT is composed of nonlinear morphological filters based only on the order relations between elements of the sequence. It is comparable to, but computationally more efficient than, the median transform, and more amenable to theoretical analysis. In particular, we show that a DPT has remarkable shape preserving and consistency properties.

Key words. nonlinear smoothing, variation preservation, fully trend preserving, multiresolution decomposition

1. Introduction.

The *discrete Fourier transform* (DFT) has often been called the most important mathematical tool of modern technology. There are three main reasons for this high esteem:

Multiresolution. The DFT allows us to decompose a given finite sequence into a sum of component subsequences, each of which can be interpreted as a feature appearing at a particular frequency level.

Predictability. The theoretical properties of the DFT are well understood, making it possible to predict its behavior over a wide range of typical applications.

Efficiency. There exists a very efficient procedure (the fast fourier transform) for the computation of the DFT whenever the period of the sequence has no large prime factors.

However, the DFT is primarily intended for the analysis of smooth periodic phenomena and is ineffective when the data contains discontinuities (as attested by the well-known Gibbs phenomenon) or is mainly composed of local features. In an attempt to overcome these problems, wavelet decompositions were developed over the last twenty years (an excellent overview of the state of the art is [Chu97]) to the point where it would be fair to say that all three of the reasons for using the DFT are largely applicable to wavelet decompositions too.

In addition, wavelets have the following desirable property:

Locality. The component sequences are local in a precisely definable sense.

In particular, B-splines [Sch67] fit very well into the wavelet framework. Instead of frequency levels, as in the case of the FFT, we have *resolution levels*, so that a wavelet decomposition is a technique for *multiresolution analysis* (MRA). The aim of MRA is to decompose a signal as a sum of separate signals, each of which is meaningful at its own resolution level. Ideally, the signal at each resolution level is undisturbed

by those at the other resolution levels, allowing easy recognition of local features at each level.

In some crucial applications, such as image processing, the expectations raised by the more local nature of wavelet decompositions may have been too high. Wavelet transforms are conceptually based on orthogonality properties of continuous functions, and their application to discrete data can be thought of as a discretization of a process in which an underlying continuous function is decomposed into a sum of other continuous functions. Discontinuities can be handled, but only if their location can be pinpointed. The combination of an implied smooth model with a linear filter causes the well-known phenomenon of erosion of edges, which in image processing is a most undesirable side effect.

In these applications wavelet transforms are not fully satisfactory, and one must look elsewhere. Unavoidably, linearity of the transform must be sacrificed. The consensus among practitioners [BMS98] seems to be that the *median transform* works better than wavelet transforms.

Conceptually, the averaging filters of wavelet decomposition are replaced by median smoothers, and the analogy with wavelet decomposition is heuristically developed [BMS98]. The idea for the median transform stems from the theory of nonlinear smoothers, where running medians have for a long time [Vel77, Mal80] (longer, in fact, than wavelets) been the method of choice for the removal of impulsive noise.

A median filter has one very important property from the point of view of image processing:

Incisiveness. A sharp spike is recognized as impulsive noise that can be surgically removed without harming the signal; that same ability can be exploited to detect an edge as an important feature that should not be blurred.

In other words, a median filter does not exhibit the Gibbs phenomenon. Despite this obvious advantage, median transforms have some serious drawbacks. In particular, they fail in comparison to wavelets on two counts: they are computationally expensive and, perhaps more serious, there is almost no theory which can predict their behavior. In particular, they do not even have the property of idempotence, as can be seen from the well-known example where x is the square wave consisting of alternating trains of k zeros and k ones: if $n = 2k + 1$, the median-of-n operator produces $M_n x = 1 - x$.

In this paper we investigate a recent morphological transform which we call the *discrete pulse transform* (DPT). The DPT was proposed and motivated (although not under that name) in [Roh02b], and has among others the following notable properties:

Multiresolution. The DPT is a multiresolution decomposition in a precise sense. A sequence of nonlinear smoothing operators from the $LULU$ family [Roh89, Roh99, Roh02a, Roh02c, Roh03, Roh02b, RT91, RW02] are used to strip off the features of a sequence at different resolution levels.

Efficiency. There exists an efficient procedure for the computation of the DPT, much faster than the median transforms.

Locality. The component sequences are local in the following precisely definable sense: each can be seen as a pulse train, that is, a sum of (block-) pulses of the same sign and of equal width n, separated by at least n zeros. (A (block-) pulse of width n is a sequence that has a constant nonzero value at n contiguous elements and is zero elsewhere.)

Incisiveness. It behaves at least as well as the median transforms in the presence of discontinuities.

Predictability. The DPT is consistent in the following sense: if you analyze a sequence x by the DPT, form a new sequence z by a linear combination of those components *with all components multiplied by arbitrary nonnegative constants*, and analyze z by the DPT, you will recover the same components. Roughly speaking, one can say that this property is the analogue of the orthogonality property of the DFT.

In view of the nonlinearity of the smoothing operators used, the consistency of the DPT is perhaps the most surprising result of all. The main reason for it is that the underlying $LULU$ filters are stable in the sense that there is a clearly identifiable set of sequences (the n-monotone sequences, defined below) which pass unchanged through the first n filters. This property is shared by the median filters, but unlike the DPT, they do not necessarily generate such sequences.

Some of these properties were already given in earlier work [Roh89, Roh99, Roh02a, Roh02c, Roh03, Roh02b, RT91, RW02]. Others will be demonstrated in this article. The new results in this article deal with:

- some remarkable shape preserving properties of the smoothers involved in the decomposition,
- consistency of the decomposition: since it is not obvious in advance what is meant by a component, we work gradually towards a definition. Our main result, Theorem 8, shows that the DPT is consistent when a component is defined as a positive or negative pulse train filtered off at each resolution level.

We end with some remarks on the pulse structure of the decomposition, including the conjecture that in fact a component could be defined as an individual pulse without impairing the consistency of the decomposition.

2. A sneak preview. In this section, we show what the DPT can do, before going into details of what it is and how it does it, for the sake of those readers who believe that one example is worth a hundred theorems.

The research leading to the DPT was originally motivated by a particular application: that of recovering the time of arrival of an impulsive signal from a background of white noise. For example, any piece of equipment that relies on pulse length modulation (such as radio-controlled aircraft) leads to this problem.

In Figure 1 we show simulated data of this type: a time series with 100 points consisting of Gaussian white noise with mean 0 and variance 1 added to a positive pulse with amplitude 2 and length 11 in positions 63–73. Note that the amplitude of the noise occasionally exceeds that of the signal. The width of the pulse, and that it is positive, is in practice known, but not its position or amplitude.

Following the advice of Bijaoni, Murtagh, and Starck [BMS98], we dismiss all linear filters and try a median filter. In Figure 2 we show the results of the median-of-n filters with $n = 11$, with the original signal superimposed. This does not look very good, so we also try the idea of applying median-of-n filters with $n = 3, 5, 7, 9, 11$ successively. This looks better, and many people might be satisfied with the result, particularly those who have the advantage of knowing what the correct signal is. One could continue to $n = 13, 15, 17, 19, 21$, since all these filters should pass the signal through unharmed, and some of those look even better to the well-prepared human eye. However, there is no theory that tells us in advance where to stop. Moreover, the mere fact that all these smoothed values look good implies that little useful information can be had by scrutinizing the differences between them.

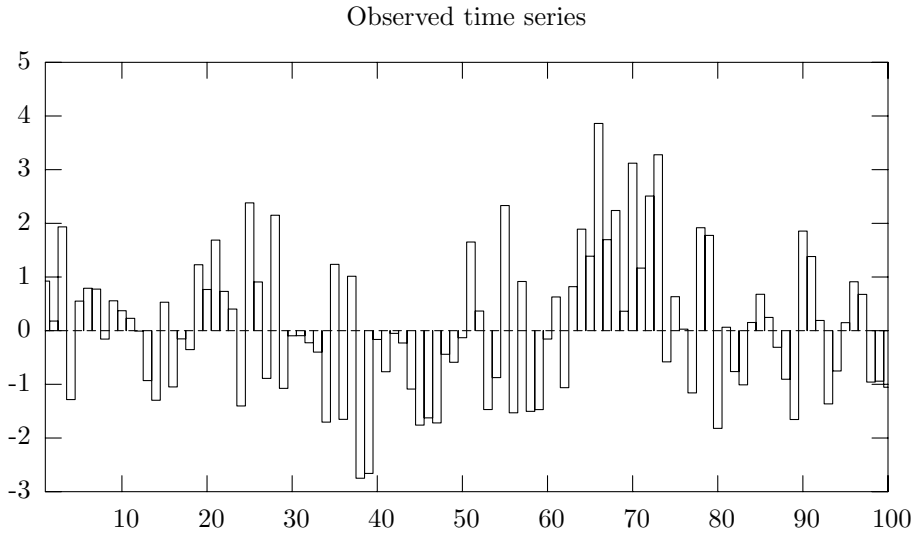

FIG. 1. *Observed time series of simulated data obtained by adding Gaussian random noise to a piecewise constant signal.*

There are two main flavors of the DPT:

$$\mathcal{C} = (C_1, C_2, C_3, \dots) \quad \text{and} \quad \mathcal{F} = (F_1, F_2, F_3, \dots),$$

each of which works like the iterated median in the sense that $F_n x$ is obtained by applying a certain nonlinear filter to $F_{n-1}x$, etc. In general, $F_n x \leqslant C_n x$; in an application, as in this example, one would apply both DPTs and base one's conclusion on what they agree on. In Figure 3 we show the result of the DPT filters C_9 and F_9, also with the original signal superimposed. The reason for stopping at this stage, before pulses of length 10 have been stripped off, will be given shortly, when we discuss conservation of variation. One could argue that both cases show a slightly sharper leading edge than the iterated median filter, but the argument would hardly be conclusive, as here, too, it would be based on knowledge of the actual signal.

However, the main point of the DPT is not the quality of the individual filters but the information given by the pulse decomposition, obtained from the differences $F_n x - F_{n-1}x$, $C_n x - C_{n-1}x$.

First, we look at the decomposition of total variation, shown in Table 1. This decomposition is analogous to the power spectrum of Fourier analysis. Note the property that the total variation of the various decomposition levels sums to the total variation of the data, in the same way that the squared norm of the components of a Fourier analysis sums to the squared norm of the data. The variation conservation property explains why the DPT is in practice found to be stable, even though it relies on order information.

Each component in the decomposition naturally splits into positive and negative pulses, analogous to the way that Fourier components split into odd and even parts. We expect a pulse of length 11 to show up at monotonicity level 11, with some spillover to levels 10 and 12. In fact, both DPT decompositions show no positive pulses at levels

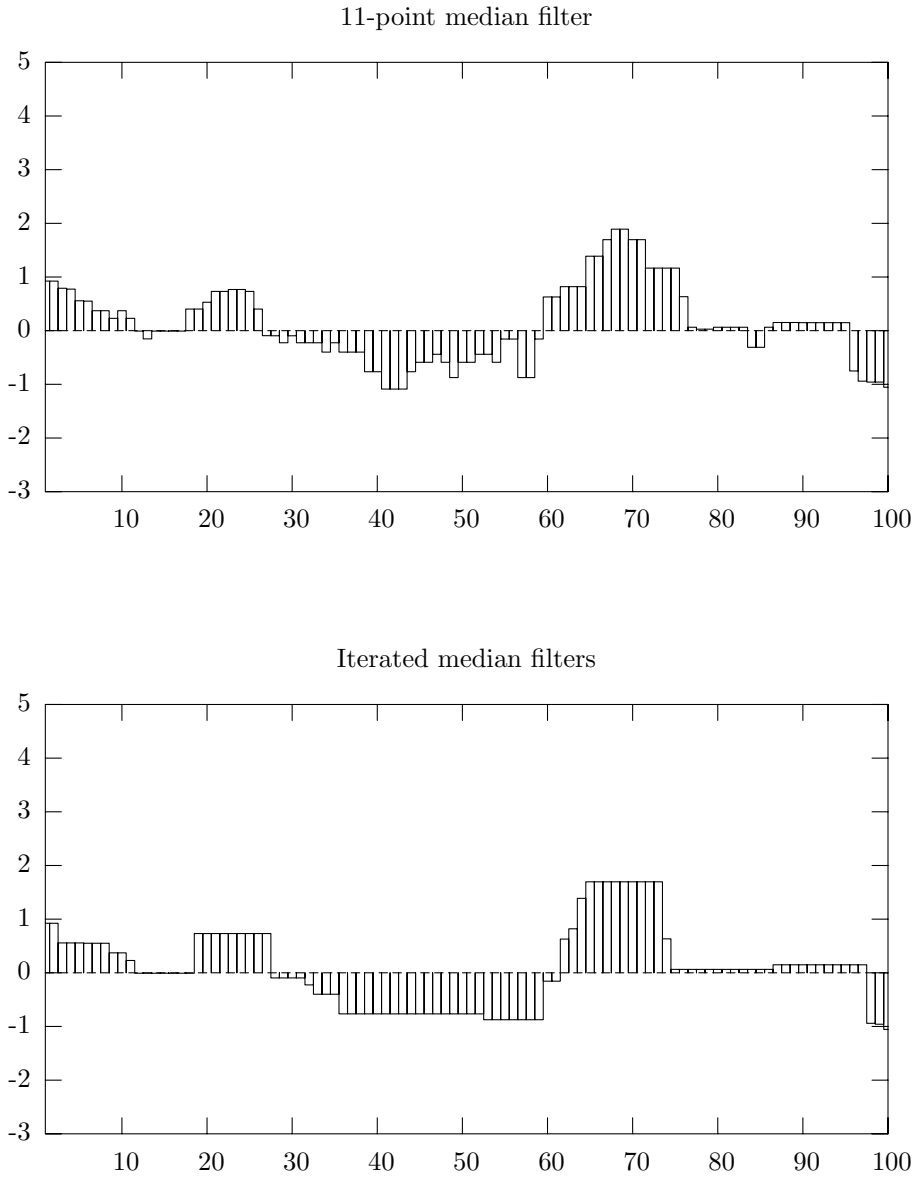

FIG. 2. *Median filters applied to the time series in Figure* 1. *In the first graph, the* 11*-point median filter was applied directly to the original time series; in the second graph, median filters of length* $3, 5, 7, 9,$ *and* 11 *were applied successively.*

9 and 12, so we form our reconstruction of the signal by combining the positive parts of levels 10 and 11. The result is shown in Figure 4.

It is not necessary to know in advance where to look to recognize a clear and unambiguous agreement between the two DPT transforms that a signal of the required kind is present. Although the DPT has not recovered the full amplitude of the signal,

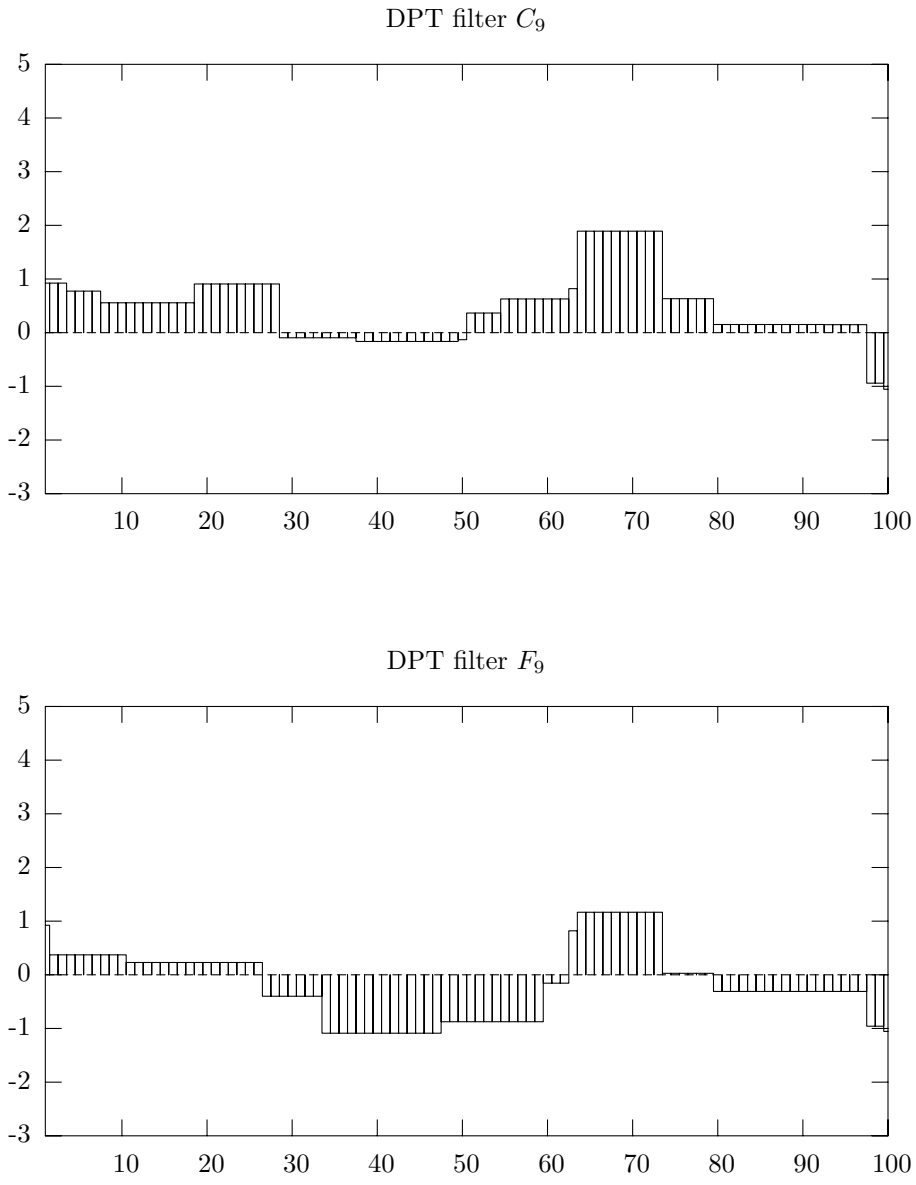

FIG. 3. *DPT filters applied to the time series in Figure* 1.

its position has been pinpointed. Also note that noise has been almost completely eliminated.

Now have another look at the figures arising from the median transform. Sure, there is a pulse somewhere in the midsixties. But can one say with confidence where it starts? Or how wide it is?

For this application, we are not aware of any other filter, linear or nonlinear, that can rival the DPT.

TABLE 1

Total variation v_m of the pulses, and p_m of the positive pulses, of width m identified by the DPT. Width ∞ refers to the final monotonic sequence. The omission of a width level means that no pulses were identified at that level. Note that in both cases $\sum v_m$ equals the total variation of the original observed sequence.

DPT using C_n			DPT using F_n

3. Analogy with the FFT. The easiest way to understand the DPT is by analogy with the well-known DFT. For the purpose at hand it is convenient to view the DFT in the following framework.

Conceptually, a finite sequence of length N,

$$x = \langle x_i,\ i = 1, 2, \ldots, N \rangle, \tag{1}$$

is extended to an infinite periodic sequence by the stipulation that $x_i = x_{i+N}$ holds for all i. The periodic extension is required for theoretical purposes: all computations involve only a sequence of length N. The practical implementation of the DFT is known as the FFT when all prime factors of N are small, but for our theoretical discussion we have no need for that hypothesis.

The DFT decomposes x into $M = \lfloor \frac{N}{2} + 1 \rfloor$ component sequences,

$$x = s^{(0)} + s^{(1)} + \cdots + s^{(M)},$$

where $s^{(0)}$ is a constant sequence and $s^{(n)}$ is a periodic sequence with frequency n times the fundamental frequency. As is well known, the mappings D_n that map x onto $s^{(n)}$ are projections onto a one-dimensional space when $n = 0$ (and for even N, also when $n = N/2$) and onto a two-dimensional space otherwise. The typical component sequence can thus be represented by one complex number, or by two real numbers, interpreted either as coefficients with respect to a chosen basis or an amplitude and phase pair. It is convenient to view the DFT as a vector of sequences

$$D(x) = DFT(x) = [D_0(x), D_1(x), \ldots, D_M(x)],$$

where $s^{(i)} = D_i(x)$.

Since the process is essentially a basis transformation it is obvious that the DFT is component consistent in the following sense:

$$\text{If } z = \sum_{i=0}^{M} \alpha_i D_i(x), \text{ then } D_n(z) = \alpha_n D_n(x) \quad \text{for each } n = 0, 1, \ldots, M.$$

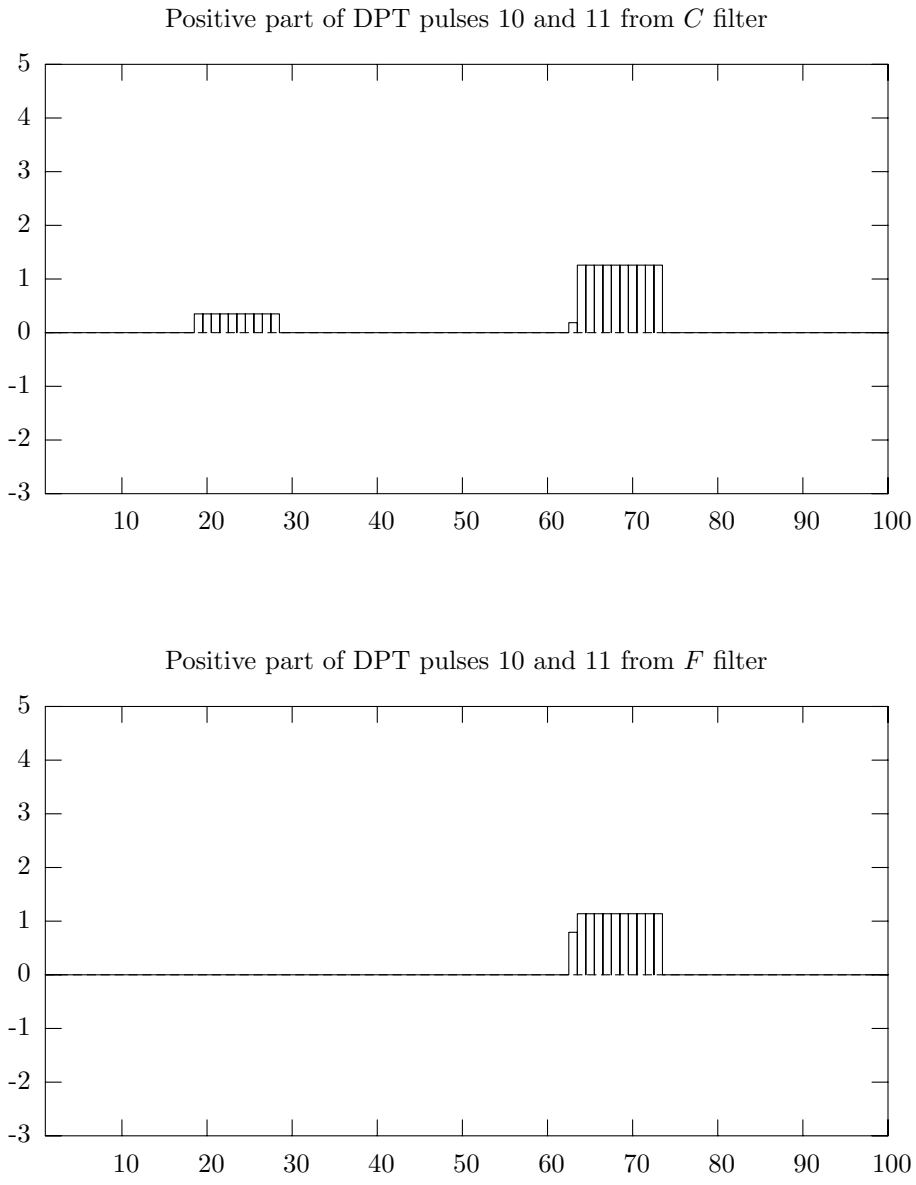

FIG. 4. *Positive pulses extracted from DPT filters applied to the time series in Figure* 1. *The pulses of length* 10 *and* 11 *have been added together.*

Furthermore, the orthonormal basis yields the so-called *energy preservation law*

$$\|x\|_2^2 = \sum_{i=0}^{M} \|D_i(x)\|_2^2,$$

so that it is possible to allocate a percentage of the energy in x to each frequency level.

In the same way, in deriving the DPT we aim to decompose a sequence into a sum of component sequences, but replacing periodic components with sequences consisting of pulses of length n at each resolution level n. From this point of view, the DPT proposed here can be seen as a mapping of a sequence x onto a vector of $M+1$ component sequences, $r^{(n)} = D_n(x)$, representing the different resolution levels, such that

$$x = D_1(x) + D_2(x) + \cdots + D_M(x) + D_\infty(x),$$

which we write as

$$D(x) = DPT(x) = [D_1(x), D_2(x), \ldots, D_M(x), D_\infty(x)]. \tag{2}$$

The final resolution level is numbered D_∞ rather than D_{M+1}, since the final sequence is constant and equal to zero if $x \in \ell_1$, which we shall assume.

There are two equivalent natural primary choices for such a decomposition procedure, which we call $\mathcal{C}$ and $\mathcal{F}$, starting respectively from one of the smoothers L_nU_n or U_nL_n that will be defined below. To avoid saying everything twice, we describe only the case where $DPT(x) = \mathcal{C}(x)$.

The decomposition proceeds recursively. In the first step, the operator L_1U_1 is applied to x to yield a sequence L_1U_1x smoother than x; the residual $(I - L_1U_1)x = D_1(x)$, where I is the identity operator, is the component of x at the finest resolution level. Thus L_1U_1 is not only a smoother, but also a separator (these terms will be defined precisely later). The smoothed part L_1U_1x is then separated by L_2U_2 to yield the second resolution component $r^{(2)} = D_2(x) = (I - L_2U_2)L_1U_1x$ and the smoothed part $L_2U_2L_1U_1x$, etc. The process is continued until only a constant sequence $D_0(x)$ remains.

Note that the DPT components are numbered in order of increasing smoothness, whereas the DFT components are numbered in order of decreasing smoothness.

The theory holds with certain changes if the periodicity condition is replaced by defining $x_i = x_1$ for $i < 1$ and $x_i = x_N$ for $i > N$: such sequences are *ultimately constant*. For example, the lowest resolution component $D_0(x)$ will then be monotone, but constant only when $x_1 = x_N$. For the sake of clarity of exposition, we will restrict ourselves in this paper to the periodic case.

In the course of the paper we shall refine this preliminary formulation of the DPT as more and more of its properties are discovered.

4. Properties of the *LULU* operators. Clearly the properties of the DPT depend crucially on those of the $LULU$ smoothers L_nU_n and U_nL_n. The properties listed in this section have been explored in previous papers [Roh89, Roh99, Roh02a, Roh02c, Roh03, Roh02b, RT91, RW02] and will not be rederived here. To start with, we need some definitions.

DEFINITION 1. *The L_n and U_n (mnemonic: lower and upper) operators are given by*

$$(U_nx)_i = \min\{\max\{x_{i-n}, \ldots, x_i\}, \ldots, \max\{x_i, \ldots, x_{i+n}\}\},$$
$$(L_nx)_i = \max\{\min\{x_{i-n}, \ldots, x_i\}, \ldots, \min\{x_i, \ldots, x_{i+n}\}\}.$$

DEFINITION 2. *The sequence x is* n-monotone *if either*

$$x_i \leqslant x_{i+1} \leqslant \cdots \leqslant x_{i+n} \leqslant x_{i+n+1}$$

or

$$x_i \geqslant x_{i+1} \geqslant \cdots \geqslant x_{i+n} \geqslant x_{i+n+1}$$

for all values of i such that x_i and x_{i+n+1} are both members of the sequence. The set of all n-monotone sequences is denoted by $\mathcal{M}_n$.

$\mathcal{M}_0$ is just the set of all sequences. Note that

$$\mathcal{M}_0 \supset \mathcal{M}_1 \supset \mathcal{M}_2 \supset \cdots, \tag{3}$$

and that the set $\mathcal{M}_n$ is not a vector space except when $n = 0$.

DEFINITION 3. *An operator A is* idempotent *if $A^2 = A$ and* coidempotent *if $I - A$ is idempotent.*

Note that the condition $A(I - A) = 0$ (we do not use a different notation than 0 for the zero operator) is equivalent to coidempotence, even when A is not a linear operator.

DEFINITION 4. *An operator A is a* smoother *if $AE = EA$, where $Ex_i = x_{i+1}$, $A(x + b) = Ax + b$ for all constant sequences b, and $A(cx) = c(Ax)$ for all scalars $c \geqslant 0$.*

In other words, a smoother is location invariant and scale invariant. Our definition differs from that of Mallows [Mal80] in disallowing negative scale factors.

DEFINITION 5. *A smoother A is a* separator *if it is both idempotent and coidempotent.*

DEFINITION 6. *When $x \in \mathcal{M}_0$ and $y \in \mathcal{M}_0$, $x \geqslant y$ means that $x_i \geqslant y_i$ for each i; when A and B are operators on a sequence, $A \geqslant B$ means that $Ax \geqslant Bx$ for all $x \in \mathcal{M}_0$.*

DEFINITION 7. *The nth* median smoother M_n *is given by*

$$(M_n x)_i = \text{median}\{x_{i-n}, \ldots, x_i, \ldots, x_{i+n}\}.$$

DEFINITION 8. *An operator A is* syntone *if $Ax \leqslant Ay$ whenever $x \leqslant y$. Serra* [Ser84] *uses the term "monotone" for this property.*

DEFINITION 9. *An operator A is* neighbor trend preserving *(NTP) if for each sequence x,*

$$x_i \geqslant x_{i+1} \implies (Ax)_i \geqslant (Ax)_{i+1},$$
$$x_i \leqslant x_{i+1} \implies (Ax)_i \leqslant (Ax)_{i+1}.$$

DEFINITION 10. *An operator A is* fully trend preserving *(FTP) if A is NTP and*

$$|(Ax)_i - (Ax)_{i+1}| \leqslant |x_i - x_{i+1}|.$$

DEFINITION 11. *An operator A is* total variation preserving *if $T(x) = T(Ax) + T(x - Ax)$ for each x, where*

$$T(x) = \sum |x_{i-1} - x_i|$$

is the total variation *of the sequence x. In the case of a periodic sequence, the sum is taken over one period.*

It can be shown [Roh03] that the property of total variation preservation is equivalent to that of being FTP.

DEFINITION 12. *The C_n and F_n operators (mnemonic: ceiling and floor) are given by*

$$C_0 = L_0 U_0 = I = U_0 L_0 = F_0,$$
$$C_{n+1} = L_{n+1} U_{n+1} C_n, \qquad F_{n+1} = U_{n+1} L_{n+1} F_n.$$

Here, then, is a list of properties of the $LULU$ operators, referred to below as property 1, etc.:

1. For each integer n, $U_n x = L_n x = x$ whenever $x \in \mathcal{M}_n$ [Roh89].
2. $L_n \leqslant U_n L_n \leqslant C_n \leqslant F_n \leqslant L_n U_n \leqslant U_n$.
3. For each integer n, the operators $L_n U_n$ (and $U_n L_n$) map onto $\mathcal{M}_n$ [Roh89].
4. $U_n U_k = U_m$ and $L_n L_k = L_m$, where $m = \max\{n, k\}$ [RW02].
5. $L_n U_n$ (and $U_n L_n$) are idempotent and coidempotent, and therefore are separators [Roh99].
6. $U_n L_n \leqslant M_n \leqslant L_n U_n$ [Roh89].
7. $L_n U_n$ (and $U_n L_n$) are syntone operators [Roh89].
8. $L_n U_n$ (and $U_n L_n$) are NTP operators [Roh02c].
9. $L_n U_n$ (and $U_n L_n$) are FTP operators [Roh02c].
10. U_n and L_n are variation preserving.
11. $(I - L_{n+1}U_{n+1})L_n U_n x \in \mathcal{M}_n$ (and $(I - U_{n+1}L_{n+1})L_n U_n x \in \mathcal{M}_n$) for each $x \in \mathcal{M}_0$.
12. The operators L_n and U_n are duals in that $U_n(-x) = -L_n(x)$ [Roh89].
13. $U_n(x + c) = U_n x + c$ (and $L_n(x + c) = L_n x + c$) for any constant sequence c [Roh89].
14. $U_n(\alpha x) = \alpha U_n(x)$ (and $L_n(\alpha x) = \alpha L_n x$) for any $\alpha \geqslant 0$ [Roh89].
15. F_n and C_n are separators.
16. If $x \in \mathcal{M}_{n-1}$ and A is FTP, then $U_n A U_n x = A U_n x$ and $L_n A L_n x = A L_n x$. Also $C_j C_k = C_{\max\{j,k\}}$ and $F_j F_k = F_{\max\{j,k\}}$.

5. How does one define consistency? For the DPT to be of practical (or theoretical) use, the heuristics that lead to its construction have to be supported by consistency in behavior and properties. But what do we mean by "consistency"?

In the case of a linear decomposition like the DFT, which is just a basis transformation, there is only one way to define consistency. The decomposition should recover the coordinates, given any linear transformation of basis vectors.

In the case of a nonlinear decomposition, it is not at all obvious what we should aim for. There is no vector space and therefore no basis. A level of consistency that is certainly out of our reach is that one of the two properties of linear operators might hold in general. If one checks whether $DPT(x + y) = DPT(x) + DPT(y)$ with some random sequences, a counterexample will be found quickly. Consistent scaling (i.e., $DPT(\alpha x) = \alpha DPT(x)$) is true (by property 14) when $\alpha \geqslant 0$ but not when $\alpha < 0$. Nevertheless, this rather weak property of consistent nonnegative scaling contains the germ of a strong consistency property.

The concept of consistency of a two-level decomposition can be made unambiguous. If an operator S is to separate a sequence into a "signal" Sx and (additive) "noise" $(I - S)x$, then consistency means that S and $(I - S)$ applied to the components separately should leave that component unchanged. For example, an idempotent linear operator (i.e., a projection) is a consistent separator: $S(Sx) = Sx$ and $(I - S)Sx = 0$. Similarly $(I - S)((I - S)x) = (I - S)x$ as a projection is linear and $S(I - S)x = 0$.

Nonlinear operators are much more intractable: the well-known median operators are not even idempotent. Idempotence by itself gives only consistent signal extraction (i.e., $S(Sx) = Sx$), not consistent noise extraction: $S(I - S)x$ does not necessarily equal $Sx - S^2x$. For consistent separation, both idempotence and coidempotence (the idempotence of $(I - S)$) are required; i.e., the operator must be a separator (Definition 5). A separator can be shown [Roh99] to have only two eigenvalues 1 and 0, with eigensequences corresponding respectively to signal and noise. Since $L_n U_n$ and $U_n L_n$ are separators (property 5), we hope to find some nontrivial consistency

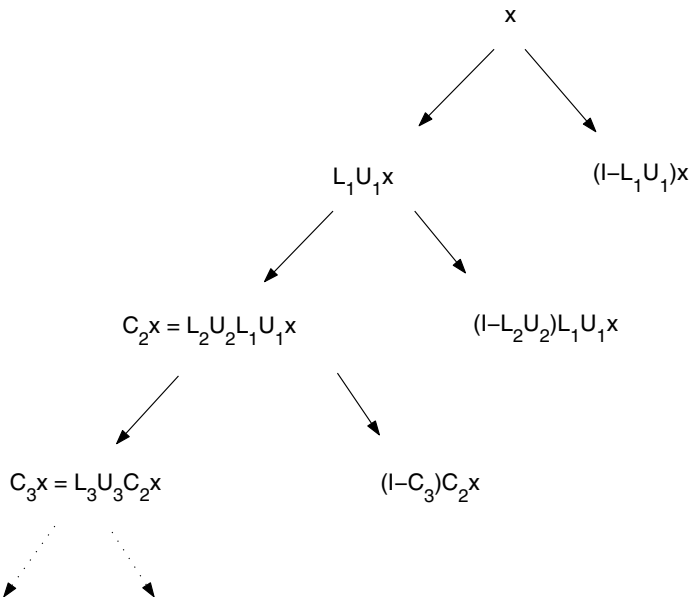

FIG. 5. *A schematic representation of the sequential separation in the DPT.*

properties of the DPT.

But first some words of caution.

Although $\mathcal{M}_n$ is exactly the set of eigensequences with respect to 1 of both L_nU_n and U_nL_n, it is not a subspace, since the sum of two sequences in $\mathcal{M}_n$ need not be in $\mathcal{M}_n$. Moreover (and this may come as a surprise), the operators $I - L_nU_n$ and $I - U_nL_n$ do not share their eigensequences w.r.t. the eigenvalue 0. In other words, L_nU_n and U_nL_n do not always agree on what is noise, although they agree on what is signal, since $L_nU_n(U_nL_n) = U_nL_n$ and $U_nL_n(L_nU_n) = L_nU_n$.

In general, $\mathcal{C}(x)$ and $\mathcal{F}(x)$ are not the same. This is true even when the input is only a single resolution component: if the nth resolution component $r^{(n)}$ of $\mathcal{C}(x)$ is fed to the $\mathcal{F}$ decomposition, then it will in general not be its own nth resolution component!

All of this makes the following innocent question highly problematic:

> When $\mathcal{C}(x)$ or $\mathcal{F}(x)$ is viewed as separating a given sequence x into a number of component sequences at different resolution levels, what should "consistency" mean?

Even so modest a demand as that when an individual resolution component $r^{(n)}$ of x is fed to the same DPT, its decomposition should yield $r^{(n)}$ at level n and zero at the other levels, is not obvious.

At this stage it is illuminating to consider the DPT in Figure 5, to illustrate the sequential separation by the separators L_nU_n.

In [Roh03] it is shown that the sequence $r^{(n)}$ at resolution level n consists of a sum of pulses of length n, far enough apart so that $L_nU_nr^{(n)} = 0$. In fact, [Roh03] gives a stricter characterization, but the latter property is all that is required here. An example of a randomly generated sequence x decomposed into the highest three resolution levels and the rest is depicted in Figure 6, to illustrate the concepts used.

The example demonstrates some essential features of what is achieved in prac-

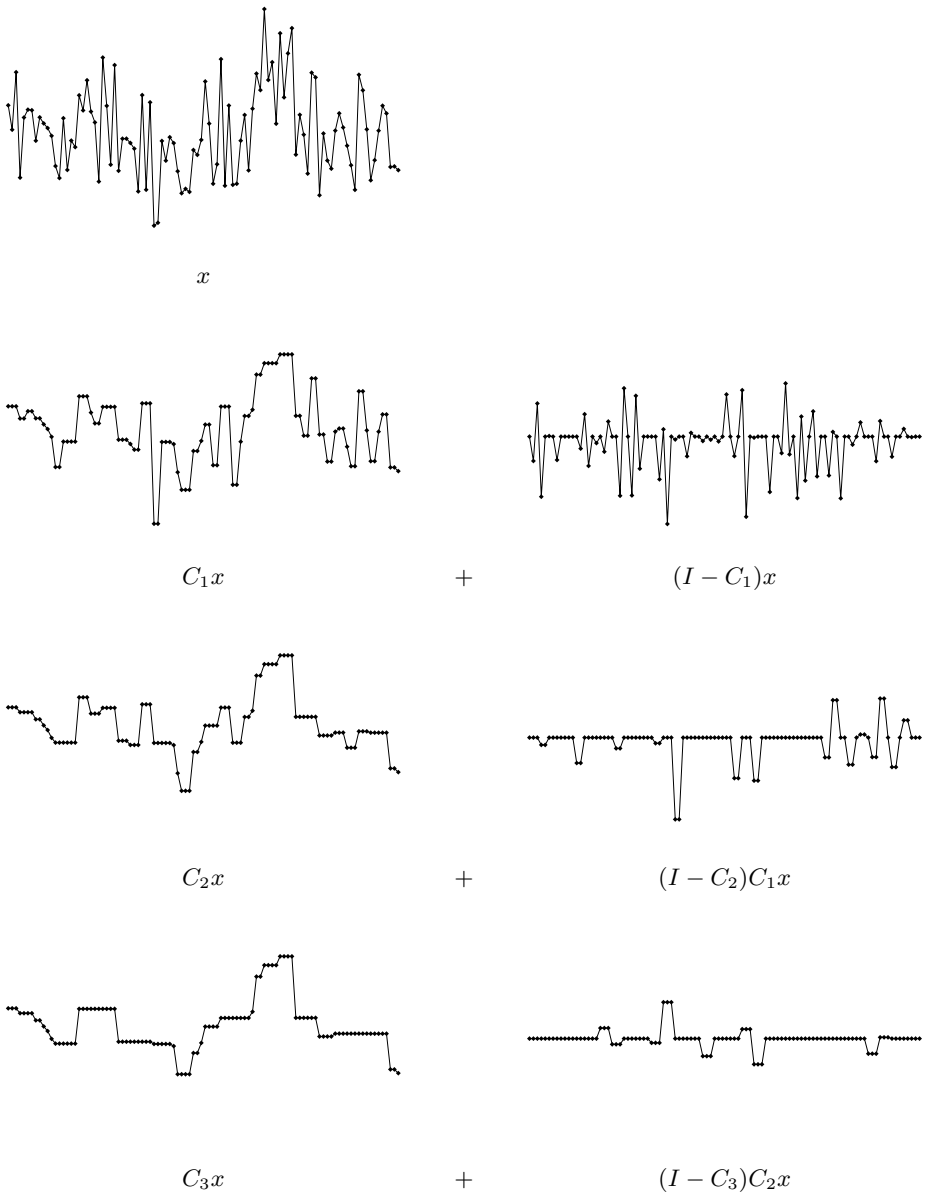

FIG. 6. *The sequence of Figure* 1 *decomposed into the three highest resolution components.*

tice. A sequence is decomposed into sequences of different resolution levels. $\mathcal{F}$ yields similar-looking decompositions that are usually very close to those obtained by $\mathcal{C}$. In Figure 3 we show both DPT transformations to illustrate the general observation that the differences are mainly due to, and proportional to, the random noise present.

It is necessary to proceed very carefully. Some of the theorems in the next sections may look very innocuous to an eye trained on linear operators, but each is an important step on the way to a remarkable consistency that to our knowledge is not shared generally by decomposition based on nonlinear morphological operators.

6. Basic consistency properties. We put

$$D_n x = (C_{n-1} - C_n)x = (I - L_n U_n)C_{n-1}x \tag{4}$$

in (2) to fix the definition of the DPT; in other words, we work with the $\mathcal{C}(x)$ form of the DPT. In view of the duality property (property 12), corresponding results and proofs hold also for $\mathcal{F}$.

Most of the rest of this article is devoted to answering the question of how to define consistency. We start with the most modest of aims, and each time that we achieve our aim the goalposts are shifted, until we reach a conjecture that as yet we cannot prove.

For a start, we demand that a signal consisting of only the output of a single resolution level should be reproduced by the DPT at that level, with zero components elsewhere. This is easy to show.

THEOREM 1. *Let the decomposition DPT be defined by*

$$DPT(x) = [D_1 x, D_2 x, \ldots, D_N x, D_0 x].$$

Then $D_j(D_i x) = \delta_{ij} D_i x$, where δ_{ij} is the Kronecker delta.

Proof. Let $n \geqslant 1$ and $z = D_n x$. Then $z \in \mathcal{M}_{n-1}$ by (4) and property 11, which by (3) and property 1 implies that $L_k U_k z = z$ for $k = 1, 2, \ldots, n-1$, and therefore that $C_k z = z$ for $k = 1, 2, \ldots, n-1$. It follows from (4) that $D_k z = (I - C_k)z$ for $k = 1, 2, \ldots, n$, giving $D_k z = 0$ for $k = 1, 2, \ldots, n-1$ and $D_n z = z - C_n z$. But since C_n is coidempotent, we have $C_n(I - C_n) = 0$, by property 15 and hence $C_n z = C_n(I - C_n)C_{n-1}x = 0$. Thus $D_n z = z$. Since $D_k z$ for $k > n$ is obtained by applying operators to $C_n z$, it follows that the higher resolution levels are all zero. ∎

Thus individual resolution components of a sequence are consistently decomposed. We now ask more: is the DPT consistent as a "low-pass" smoother? In other words, if z consists of all but the first n components of x, does the DPT applied to z yield the same later components as when applied to x? This is also easy.

THEOREM 2. *Let $r^{(m)} = D_m(x)$ and $z = x - \sum_{i=1}^{n} r^{(i)}$. Then*

$$D_m(z) = \begin{cases} 0 & \text{for } m < n, \\ r^{(m)} & \text{for } m \geqslant n. \end{cases}$$

Proof. The same argument as in the proof of Theorem 1 gives $D_k z = 0$ for $k = 1, 2, \ldots, n-1$. Thus, $C_{n-1} z = C_{n-1} x$, so that the n-stage of the DPT of z has the same input as the nth stage of the DPT of x. ∎

Emboldened by these quick successes, we now ask whether the DPT is also consistent as a high-pass smoother; i.e., if the input consists of the sum of only the first n resolution levels, are these levels reproduced unchanged?

Such a result cannot be derived in the same way as Theorem 2. It is true that when x has only two nonzero resolution levels, $r^{(1)} = D_1 x$ and $r^{(2)} = D_2 x$, since if we omit either of the resolution levels to form a sequence z, the decomposition would by Theorem 1 be consistent with that of x. But if there are more than two nonzero resolution levels, it is not so simple, as the following example shows.

Assume $z = r^{(1)} + r^{(2)} = x - r^{(3)}$. Then

$$D_1 z = (I - L_1 U_1)(I - L_1 U_1)x + (I - L_2 U_2)(C_1 x),$$

and since neither L_1U_1 nor $I - L_1U$ is linear, it is not clear that $D_1z = D_1x = r^{(1)}$. This seems to hinge on the fact that L_1U_1 acts linearly on the particular sum $r^{(1)} + r^{(2)} = x - C_2x = (I - C_2)x$. Omitting the resolution component $r^{(2)}$ yields similar problems in the proof of the consistent decomposition of the partial sum. Since experimentation suggests consistency of this type, there must exist some theory not yet explored. The observed consistency seems too good not to be true!

The clue to further development of the theory is suggested by a remarkable property, shared by any composition of different operators L_n and U_n [Roh02c]. The following lemma for **ftp** operators (which by property 9 includes all the $LULU$ operators) is as important as it may be surprising. The proof from [Roh02c] is repeated here to illustrate the concepts involved.

LEMMA 1. (a) *If A is FTP, then $I - A$ is FTP.*

(b) *If A and B are FTP, the composition, or any convex combination of A and B, is also FTP.*

Proof. For each sequence x, consider any index i. Suppose first that $x_i \geqslant x_{i+1}$. Since A is FTP, $Ax_i \geqslant Ax_{i+1}$ and $|Ax_i - Ax_{i+1}| \leqslant |x_i - x_{i+1}| = x_i - x_{i+1}$. Therefore $Ax_i - Ax_{i+1} \leqslant x_i - x_{i+1}$, giving $x_i - Ax_i \geqslant x_{i+1} - Ax_{i+1}$, so that $(I - A)x_i \geqslant (I - A)x_{i+1}$; in other words, $(I - A)$ is NTP. Then $|(I - A)x_i - (I - A)x_{i+1}| = (I - A)x_i - (I - A)x_{i+1} = x_i - x_{i+1} - (Ax_i - Ax_{i+1}) \leqslant x_i - x_{i+1} = |x_i - x_{i+1}|$, which shows that $(I - A)$ is FTP. The rest is easy.

A similar argument holds if $x_i \leqslant x_{i+1}$, completing the proof of (a). The proof of (b) is simple and is left as an exercise for the reader. ∎

COROLLARY 1. *A is FTP $\iff$ $I - A$ is FTP; a convex combination of any finite number of FTP operators is FTP; and αA is NTP if $0 \leqslant \alpha$.*

It is interesting to note that the only linear smoothers that have full trend preservation are the trivial ones I and O. This may explain the fact that the concept of FTP operators is unfamiliar.

In order to progress further, we need two results proved in [Roh03].

RESULT 1. *If $x \in M_{n-1}$ and A is FTP, then*

$$U_n(I - AU_n)x = U_nx - U_nAU_nx = U_nx - AU_nx,$$
$$L_n(I - AL_n)x = L_nx - L_nAL_nx = L_nx - AL_nx.$$

RESULT 2. *$C_j(I - C_n) = C_j - C_n$ and $F_j(I - F_n) = F_j - F_n$ for all $j \leqslant n$.*

Note that the expressions appearing in Result 2 are clearly equal to 0 if $j \geqslant n$, thus proving the coidempotence of F_n and C_n.

THEOREM 3. *Let $z = D_m(x) + D_{m+1}(x) + \cdots + D_n(x) = (C_{m-1} - C_n)x$. Then z decomposes consistently.*

Proof. The same argument as in the proof of Theorem 1 gives $D_jz = 0$ for $j = 1, 2, \ldots, m - 1$. For $m \leqslant j \leqslant n$, we have

$$C_j(z) = (I - C_n)C_jC_{m-1}x = (I - C_n)C_j(x)$$

and therefore, since $C_kC_l = C_{\max\{k,l\}}$,

$$\begin{aligned} D_j(z) &= (C_{j-1} - C_j)z \\ &= (I - C_n)C_{j-1}x - (I - C_n)C_jx \\ &= C_{j-1}x - C_jx - C_nC_{j-1}x + C_nC_jx \\ &= C_{j-1}x - C_jx \\ &= D_j(x). \end{aligned}$$

Finally $C_n(z) = C_n(I - C_n)C_{m-1}x = 0$, since $C_n(I - C_n) = 0$ by the coidempotence of C_n. Thus the components of z come out fully consistently. □

This theorem shows that the DPT is consistent as a "high-pass" smoother (the case where $m = 1$) and as a "band pass" smoother (general $m < n$).

7. Pseudolinearity. The difficulty in proving stronger consistency results comes as might be expected from the nonlinear nature of the filters used. We now establish some properties of the filter operators that resemble those of linear operators, but only in certain special circumstances.

The first of these theorems describes the interaction between U_n (or L_n) and NTP operators when applied to sequences known to be $(n-1)$-monotone.

THEOREM 4. *Let $x \in \mathcal{M}_{n-1}$, and A, B be NTP. Then for all $\alpha, \beta \geqslant 0$ the following hold:*

(a) $U_n(\alpha A + \beta B U_n)x \geqslant \alpha U_n A x + \beta B U_n x$;
$L_n(\alpha A + \beta B L_n)x \leqslant \alpha L_n A x + \beta B L_n x$.

(b) *If $AU_n x = U_n A x$, then $U_n(\alpha A + \beta B U_n)x = \alpha U_n A x + \beta B U_n x$.*

(c) *If $AL_n x = L_n A x$, then $L_n(\alpha A + \beta B L_n)x = \alpha L_n A x + \beta B L_n x$.*

Proof. (a) With the notation $U = U_n$, let $x \in \mathcal{M}_{n-1}$ and i be an index. Consider first the case when $Ux_i = x_i$. Then there is an index $j \in [i-n, i]$ such that $\max\{x_j, \dots, x_{j+n}\} \leqslant x_i$. However, the subsequences $\{x_j, \dots, x_i\}$ and $\{x_i, x_{j+n}\}$ are monotone. Thus

$$x_j \leqslant x_{j+1} \leqslant \cdots \leqslant x_{i-1} \leqslant x_i \geqslant x_{i+1} \cdots \geqslant x_{j+n}.$$

$A, BU, UA, UBU, \alpha A + \beta B$, and $U(\alpha A + \beta BU)$ all transfer these inequalities to their respective outputs, since they are NTP. Therefore

$$\begin{aligned} UAx_i &= Ax_i, \\ UBUx_i &= BUx_i, \\ U(\alpha A + \beta BU)x_i = \alpha Ax_i + \beta BUx_i &= \alpha UAx_i + \beta UBUx_i. \end{aligned}$$

This establishes the first part of (a) in the case where $Ux_i = x_i$.

The other possibility is that $Ux_i \neq x_i$ (and therefore $Ux_i > x_i$). Since each of the sets $\{x_j, x_{j+1}, \dots, x_{j+n}\}$ containing x_i has a maximum larger than x_i (from the definition of U_n) and the sequence x is $(n-1)$-monotone, there is a $j \in [i-n, i]$ such that

$$x_{j-1} > x_j = x_{j+1} = \cdots = x_i = \cdots = x_{j+n-1} < x_{j+n},$$

so that $Ux_j = \min\{x_{j-1}, x_{j+n}\}$. But since U is NTP,

$$Ux_{j-1} \geqslant Ux_j = Ux_{j+1} = \cdots = Ux_i = \cdots = Ux_{j+n-1} \leqslant Ux_{j+n},$$

and we obtain $Ux_i = \min\{x_{j-1}, x_{j+n}\}$.

All the operators in question are NTP so that again the inequalities are inherited by the outputs and

$$\begin{aligned} UAx_i &= \min\{Ax_{j-1}, Ax_{j+n}\}, \\ UBUx_i &= \min\{BUx_{j-1}, BUx_{j+n}\} = BUx_i \qquad \text{since } B \text{ is NTP.} \end{aligned}$$

Therefore

$$\begin{aligned} U(\alpha A + \beta BU)x_i &= \min\{(\alpha A + \beta BU)x_{j-1}, (\alpha A + \beta BU)x_{j+n}\} \\ &= \min\{\alpha Ax_{j-1} + \beta BUx_{j-1}, \alpha Ax_{j+n} + \beta BUx_{j+n}\}. \end{aligned}$$

Now $\alpha UAx_i + \beta BUx_i \leqslant \alpha Ax_{j-1} + \beta BUx_{j-1}$ and $\alpha UAx_i + \beta BUx_i \leqslant \alpha Ax_{j+n} + \beta BUx_{j+n}$. The inequality therefore also holds for the minimum of the two, proving that $\alpha UAx_i + \beta BUx_i \leqslant U(\alpha A + \beta B)x_i$. A similar argument proves the other part.

(b) Noting that $UAx_i = \min\{Ax_{j-1}, Ax_{j+1}\}$, assume that $Ax_{j-1} \leqslant Ax_{j+1}$ so that $UAx_i = Ax_{j-1}$ (a similar argument holds if the other is smaller). Then $Ux_{j-1} = Ux_j = \cdots = Ux_i = \cdots = Ux_{j+n-1} \leqslant Ux_{j+n}$. Since A and B are NTP the equalities are inherited by AUx and BUx, so that $AUx_i = AUx_{j-1} \leqslant AUx_{j+n}$ and $BUx_i = BUx_{j-1} \leqslant BUx_{j+n}$, so that

$$U(\alpha A + \beta BU)x_i \leqslant \alpha Ax_{j-1} + \beta BUx_{j-1} \leqslant \alpha UAx_{j-1} + \beta BUx_i.$$

If now $UAx_{j-1} = AUx_{j-1}$, then since $AUx_{j-1} = AUx_i$, we get

$$U(\alpha A + \beta BU)x_i \leqslant \alpha AUx_i + \beta BUx_i = \alpha UAx_i + \beta BUx_i.$$

This, together with the inequality of part (a) of the proof yields the result $U(\alpha B + \beta BU)x_i = \alpha UAx_i + \beta BUx_i$, which proves part (b) of the theorem.

(c) A similar proof to the above, or using a duality argument, yields the required equality. □

The next result says that U_n behaves like a linear operator when applied to a positive linear combination of the signal and noise obtained by separating an $(m-1)$-monotone sequence with L_nU_n. For completeness, we state the corresponding result with L_n and U_n interchanged.

THEOREM 5. *Let $x \in \mathcal{M}_{n-1}$ and $\alpha, \beta \geqslant 0$. Then*

$$U_n(\alpha(I - L_nU_n) + \beta L_nU_n)x = \alpha U_n(I - L_nU_n)x + \beta L_nU_nx,$$
$$L_n(\alpha(I - U_nL_n) + \beta U_nL_n)x = \alpha L_n(I - U_nL_n)x + \beta U_nL_nx.$$

Proof. L_n and $I - L_nU_n$ are FTP and thus NTP. By result 1, $I - L_nU_n$ commutes with U_n, and by Theorem 4(b) the first equality holds. A similar proof holds for the other equality. □

Now we prove that under the same conditions, L_nU_n also acts like a linear operator.

THEOREM 6. *Let $x \in \mathcal{M}_{n-1}$ on $\alpha, \beta \geqslant 0$. Then $L_nU_n(\alpha(I - L_nU_n) + \beta L_nU_n) = \beta L_nU_n$ and $U_nL_n(\alpha(I - U_nL_n) + \beta U_nL_n) = \beta U_nL_n$.*

Proof.

$$\begin{aligned}
&L_n(U_n(\alpha(I - L_nU_n) + \beta L_nU_n))x \\
&= L_n(\alpha U_n(I - L_nU_n) + \beta L_nU_n)x && \text{by Theorem 5} \\
&= L_n(\alpha(U_n - L_nU_n) + \beta L_nU_n)x && \text{by Theorem 4} \\
&= L_n(\alpha(I - L_n) + \beta L_n)U_nx \\
&= (\alpha L_n(I - L_n) + \beta L_n)U_nx && \text{by Theorem 4} \\
&= \beta L_nU_nx && \text{by the co-idempotence of } L_n.
\end{aligned}$$

A similar proof holds for the other equality. □

8. Strong consistency properties. We are now in a position to prove the following strong result: *the DPT acts like a basis transformation when the input is a linear combination of outputs from another application of the DPT, provided that the coefficients involved are nonnegative.*

THEOREM 7. *Let $x \in \mathcal{M}_0$ and $DPT(x) = [D_1x, D_2x, \ldots, D_Nx, D_0x]$, with $D_0x = C_Nx$. If $\alpha_i \geqslant 0$ and $\sum_{i=1}^{N} \alpha_i = 1$, then $z = \sum_{i=1}^{N} \alpha_i D_i x$ is decomposed consistently.*

Proof. Let $z = \sum_{i=1}^{n} \alpha_i D_i x$. Define $A_m = (\sum_{i=m}^{n} \alpha_i (I - C_i)C_{i-1})$. Since $D_i = (I - C_i)C_{i-1},\ i = 1, 2, \ldots, n$, are all FTP, it follows from Lemma 1 that A_m is FTP. Therefore

$$\begin{aligned}\sum_{i=m}^{n} \alpha_i D_i x &= \left(\sum_{i=m}^{n} \alpha_i (I - C_i)C_{i-1} \right) x \\ &= A_m C_{m-1} x \in \mathcal{M}_{m-1}\end{aligned}$$

since $C_{m-1}x \in \mathcal{M}_{m-1}$. Consider the induction hypothesis that $C_{j-1}z = (\sum_{i=j}^{n} \alpha_i D_i)$ $C_{j-1}x$ for $j < n$. (Clearly it is true for $j = 1$.) The operators $A_k = \sum_{i=k}^{n} \alpha_i D_i$ are all FTP, as they are convex combinations of FTP operators. Thus

$$\begin{aligned}C_j z &= L_j U_j \left(\alpha_j D_j + \left(\sum_{i=j+1}^{n} \alpha_i D_i \right) \right) C_{j-1} x \\ &= L_j U_j \left(\alpha_j (I - L_j U_j) + \left(\sum_{i=j+1}^{n} \alpha_i D_i \right) L_j U_j \right) C_{j-1} x \\ &= L_j (\alpha_j U_j D_j + (A_{j+1}) L_j U_j) C_{j-1} x \qquad \text{by Theorem 4} \\ &= L_j (\alpha_j U_j (I - L_j U_j) + (A_{j+1}) L_j U_j) C_{j-1} x \\ &= L_j (\alpha_j (I - L_j) U_j + (A_{j+1}) L_j U_j) C_{j-1} x \qquad \text{by result 1} \\ &= L_j (\alpha_j (I - L_j) + (A_{j+1}) L_j) U_j C_{j-1} x \\ &= (\alpha_j L_j (I - L_j) + (A_{j+1}) L_j) U_j C_{j-1} x \\ &= 0 + A_{j+1} C_j x.\end{aligned}$$

Thus $D_j z = (C_{j-1} - C_j)z = \alpha_j D_j x$ and $C_j z = (\sum_{i=j+1}^{n} \alpha_i D_i) C_j x$, which completes the induction. □

COROLLARY 2. *Any sequence $\sum_{i=0}^{N} \alpha_i D_i x$, with $\alpha_i \geqslant 0$, is decomposed consistently.*

The $\mathcal{F}$ form of the DPT has a similar consistency, and this can be proved in the same way as above or by using property 12. What is important to note is that the $\mathcal{F}$ and $\mathcal{C}$ forms generally give different resolution components, with a corresponding "interval of ambiguity." When the sequence is strongly correlated, the two decompositions yield essentially similar results, but the addition of additive random noise yields some separation, proportional to the amplitude of this noise. Practical experience and initial theoretical analysis demonstrates that this ambiguity will occur mainly in the first few (highest) resolution levels, becomes small in the middle resolutions, and may appear lower down again, especially if there is a strong specific frequency in the sequence.

An important side effect of the theorems proved here is that we can provide some theoretical support for the popular median decomposition, which hitherto has been motivated purely heuristically. The two DPT processes produce level 1 outputs that bracket the resolution 1 output that would appear out of an equivalent median decomposition, since the median operators involved are in the $LULU$ interval, i.e., $U_n L_n \leqslant M_n \leqslant L_n U_n$ [RT91].

However, at later resolution levels this strict inclusion need not hold. The most we can say is that some order holds on average, since the sequence that is passed on

from the mth separator to the $(m+1)$th separator lies between those of the other two. The median decomposition has in fact almost none of the strong consistency involved in the $LULU$ cases. Consensus is that it "works well" [BMS98]. Our analysis suggests that it can be expected to work well when both $LULU$ transforms work well, and give decompositions close to each other.

9. Consistent one-sided scaling. Although the result of the previous section appears to be what we sought, there is still further room for improvement.

We again turn to the DFT as a source for analogy. In the DFT, each "resolution level" (read: frequency level) is a two-dimensional space of sequences. Since the mapping from a sequence x onto the component sequence $s^{(n)}$,

$$s_i^{(n)} = \alpha_n^- \sin(ni\theta) + \alpha_n^+ \cos(ni\theta),$$

where $\theta = \pi/N$ for some natural number N, simply involves a particular choice of basis for the two-dimensional subspace, it is clear that a sequence consisting of arbitrary linear combinations of the sine and cosine components is decomposed consistently, so that each component comes out with its corresponding amplitude.

The pulse decomposition decomposes a sequence x onto different resolution levels. As noted before, the output at each resolution level is a union of nonoverlapping (in fact, progressively more well-separated) pulses. Here, too, it is possible to think of the output as two-dimensional, given the importance that the sign of the coefficients has in the theorems we have been able to prove.

Define the positive part B^+ and the negative part B^- of an operator B by

$$(B^+x)_i = \begin{cases} Bx_i & \text{if } Bx_i > 0, \\ 0 & \text{otherwise,} \end{cases}$$

$$(B^-x)_i = \begin{cases} Bx_i & \text{if } Bx_i < 0, \\ 0 & \text{otherwise.} \end{cases}$$

At each resolution level, $D_n(x)$ can uniquely be decomposed into a positive and a negative part:

$$D_n(x) = D_n^+(x) + D_n^-(x).$$

Thus D_n^+x contains all the positive pulses, and D_n^-x contains all the negative pulses.

We can thus refine the meaning of "component" so that D_n^+x and D_n^-x are regarded as separate components. This immediately raises the question of whether the DPT is consistent in terms of these components. That is, is it true that for all $\alpha_j^-, \alpha_j^+ \geqslant 0$ the input $z = \sum_{i=1}^n \alpha_i^- D_i^-(x) + \alpha_i^+ D_i^+(x)$ is decomposed consistently to yield $D_n^-(z) = \alpha_n^- D_n^-(x)$ and $D_n^+(z) = \alpha_n^+ D_n^+(x)$ for each $n > 0$?

Theorem 8, our main result, states precisely this. We shall need the following lemma.

LEMMA 2.

$$D_n^- = ((I - L_nU_n)C_{n-1})_- = (I - U_n)C_{n-1},$$
$$D_n^+ = ((I - L_nU_n)C_{n-1})_+ = (I - L_n)U_nC_{n-1}.$$

Proof. The first equation in each case follows from the definition of D_n. Let

$$\hat{D}_n^- = ((I - U_n)C_{n-1}) \quad \text{and} \quad \hat{D}_n^+ = (I - L_n)U_nC_{n-1}.$$

Clearly $\hat{D}_n^- + D_n^+ = D_n$, since

$$(I - U_n)C_{n-1} + (I - L_n)U_nC_{n-1} = (I - L_nU_n)C_{n-1}.$$

Now $(I - U_n)C_{n-1} \leqslant 0$, since $I - U_n \leqslant 0$; and $(I - L_n)U_nC_{n-1} \geqslant 0$, since $I - L_n \geqslant 0$. What is needed to complete the proof is to show that the set of indices i where $\hat{D}_n^- x_i < 0$ and the set of indexes where $\hat{D}_n^+ x_i > 0$ are disjoint.

Let x be a sequence. Then $C_{n-1}x = z$ is in M_{n-1}. Assume that $\hat{D}_n^- z_i < 0$ and $\hat{D}_n^- z_{i-1} = z_{i-1}$. Then

$$(U_n z)_i = \min\{\max\{z_{i-n}, \ldots, z_i\}, \ldots, \max\{z_i, \ldots, z_{i+n}\}\} > z_i.$$

To the left of z_i and to the right of z_i there are $z_\ell, z_r > z_i$ with $|r - \ell| < n + 1$. Since $z \in M_{n-1}$ we have a constant section $z_i = z_{i+1} = \cdots = z_{i+n-1}$, with $U_n z_i = \min\{z_{i-1}, z_{i+n}\} > z_i$. This is because $z_\ell > z_i$ are both in $\{z_{i-n}, \ldots z_i\}$, which is therefore monotone decreasing as $z \in M_{n-1}$. Similarly $\{z_i, \ldots, z_r, \ldots, z_{i+n}\}$ is monotone increasing, and the intersection must be constant. But if $j \in [i, i + n]$, then

$$(L_nU_nz)_j = \max\{\min\{U_nz_{i-n}, \ldots, U_nz_i\}, \ldots, \min\{U_nz_i, \ldots, U_nz_{i+n}\}\};$$

therefore $L_nU_nz_j = U_nz$ and $\hat{D}_n^+ z_j = 0$.

Thus $\hat{D}_n^+ z$ is zero where $\hat{D}_n^-$ is negative, and $\hat{D}_n^+ z$ can be positive only where $\hat{D}_n^- z$ is zero. Thus $\hat{D}_n^- = D_n^-$ and $\hat{D}_n^+ = D_n^+$.

The second part is proved by a generally similar argument, or by appealing to duality. □

Since $(I - U_n)C_{n-1}$ and $(I - L_n)U_nC_{n-1}$ are FTP, the following theorem is easy to prove in analogy with the previous one.

THEOREM 8. *Let $x \in \mathcal{M}_0$ and $DPT(x) = [D_1x, D_2x, \ldots, D_Nx, D_0x]$, with $D_0x = C_N(x)$. Then $z = \sum_{i=1}^N (\alpha_i^- D_n^-(x) + \alpha_i^+ D_n^+(x))$ is decomposed consistently.*

Proof. The proof proceeds as in Theorem 7, with $\alpha_i D_i x$ replaced by $\alpha_i^- D_i^- x + \alpha_i^+ D_i^+ x$, giving

$$C_j z = L_j U_j \left(\alpha_j^- D_j^- + \alpha_j^+ D_j^+ + \sum_{i=j+1}^{N} (\alpha_i^- D_i^- + \alpha_i^+ D_i^+) \right) C_{j-1}(x).$$

Applying U_j first, we get

$$\begin{aligned} U_j z &= U_j \left(\alpha_j^- D_j^- + \left(\alpha_j^+ D_j^+ + \sum_{i=j+1}^{N} \left(\alpha_i^- D_i^- + \alpha_i^+ D_i^+\right) \right) \right) C_{j-1}(x) \\ &= U_j(\alpha_j^-(I - U_j) + (A_{j+1}L_j)U_j)C_{j-1}(x) \end{aligned}$$

with A_{j+1} FTP. This implies by Theorem 4 (since $C_{j-1}(x) \in \mathcal{M}_{j-1}$) that

$$\begin{aligned} U_j z &= (\alpha_j^- U_j(I - U_j) + A_{j+1}L_jU_j)C_{j-1}(x) \\ &= A_{j+1}L_jU_jC_{j-1}(x) \end{aligned}$$

since $U_j(I - U_j) = 0$.

Applying L_j to $U_j z$ yields in a similar fashion that

$$C_j z = \sum_{i=j+1}^{n} (\alpha_i^- D_i^- + \alpha_i^+ D_i^+) C_{j-1}(x).$$

The resolution components that are removed at resolution layer j are therefore $\alpha_j^- D_j^- C_{j-1}(x) = \alpha_j^- D_j^-(x)$ and $\alpha_j^+ Dj^+(x)$, and the induction argument used in Theorem 6 completes the proof. □

10. The pulse structure of a DPT. Each individual component $D_n x$ decomposes into a number of nonoverlapping pulses of width exactly n. Moreover, we can show [Roh02c] that the pulses in $D_n^+ x$ and $D_n^- x$ are separated from each other by at least n zeros.

It is easy to obtain an upper bound on the total number of pulses in the decomposition. The difference sequence of x, i.e., $\{d_i = x_i - x_{i-1},\ i = 1, 2, \ldots, N\}$, obviously contains at most N distinct values. It is shown in [Roh02c] that for every pulse appearing in $D_n x$, the number of distinct values that the difference set of $C_n x$ can take is reduced by at least one. Thus, there can be at most N pulses in total in the entire decomposition.

Once the DPT of x has been computed, it is therefore possible to represent it by $K \leqslant N$ triples $(p_j, w_j, h_j),\ j = 1, \ldots, K$, representing position, width, and height of each pulse. That is,

$$x = \sum_{j=1}^{K} h_j P(p_j, w_j),$$

where

$$P_i(p, w) = \begin{cases} 1, & p \leqslant i < p + w, \\ 0 & \text{elsewhere.} \end{cases}$$

This economical representation in terms of at most $3N$ numbers is important from the point of view of storage and transmission of the data.

The temptation is strong to refine the notion of a component still further, provoking the audacious idea:

> *Can we define each individual pulse in a resolution level as a component and still obtain a consistent decomposition?*

This would give the DPT a consistency comparable to that of a wavelet decomposition, in which each individual wavelet is a member of a basis for a vector space. But that a similar property might hold for a transform as nonlinear as the DPT seems incredible.

Yet, if this idea is correct, the implications for image processing would be enormous. For example, if a square white slab were barely visible against a background that is nearly as white, a pulse decomposition on the rows (or columns) of a matrix of luminosity values obtained from a photo can locate the slab by its expected ratio of width to height. Amplifying this particular pulse would make the slab clearly visible, without distorting any of the surroundings.

To get a feeling for what is meant here, let us look at a simple example. A random sequence x is generated, and one level of the DPT is applied; the components $D_1^- x$ and $D_1^+ x$ are shown in Figure 7. Then each separate pulse is amplified by its own random positive factor. All the resolution levels are then added together again, and

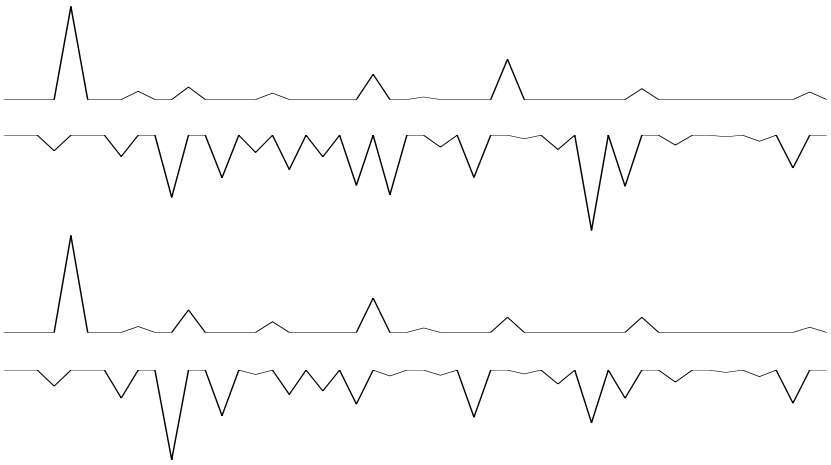

FIG. 7. *The sequences* $(I - U_1)x$ *and* $(I - L_1)U_1x$ *and their modified versions.*

the sum is decomposed. Comparing the first resolution levels demonstrates that the modified sequences have pulses in exactly the same positions.

We have overwhelming evidence from computer simulations that this behavior always occurs, but a general proof eluded us until this article was in revision. We think we now have a proof [LR06] based on a totally different approach to the problem, but the correctness of this proof is still to be checked. Therefore, we do not claim here that this idea is more than a formal conjecture, as follows.

> *Conjecture.* Let $(p_j, w_j, h_j),\ j = 1, \ldots, K$, be pulses in the DPT of x, and let $z = \sum_{j=1}^{K} h'_j P(p_j, w_j)$, where $h_j h'_j \geqslant 0$. Then the pulses in the DPT of z are $(p_j, w_j, h'_j),\ j = 1, \ldots, K$.

Of course, $h'_j = 0$ is understood to mean that the pulse is absent from the DPT of z.

11. Conclusion. We have shown that the discrete pulse transform has many of the properties of consistent component identification that are normally associated with linear transforms like the discrete Fourier transform. In particular, despite its essential nonlinearity, it acts like a basis transformation in a positive cone, with the basis comprising the positive and negative components extracted at each resolution level. This property already has significant potential in the field of image processing.

One area for future research is the characterization problem: what are the conditions under which some set of pulses forms a possible set of basis components? In the DFT and wavelet transforms, the basis is chosen in advance. In the DPT, the basis is constructed by the process itself. We know how to characterize the set of pulse trains that could appear as outputs at any particular resolution level n—pulses of the same sign must be at least n positions from each other—but we do not know how the various levels interact. In fact, the only way we know to find out whether a given set of pulse trains forms a "basis" is to combine them and to analyze that combination by the DPT to see whether they are recovered.

More work is required to establish the conjecture that the true basis components in the DPT are the individual pulses, in the sense that any nonnegative linear combination of them can be recovered by the DPT. Such a result would not only neatly round off the theory, but also provide compelling theoretical backing for the use of the DPT as a device for image enhancement. We are working on a promising idea that may also shed light on the characterization problem.

Acknowledgement. An anonymous referee found many small technical inaccuracies and prompted us to add section 2, which (we must admit) makes the final product more attractive.

REMARKS ON THE BLOWUP FOR THE L^2-CRITICAL NONLINEAR SCHRÖDINGER EQUATIONS*

TAOUFIK HMIDI† AND SAHBI KERAANI†

Abstract. This paper is dedicated to the formation of singularities of the solutions of L^2-critical nonlinear Schrödinger equations. We prove a refined compactness lemma adapted to the blowup analysis, and we use it to improve the recent result by Colliander et al. [*Math. Res. Lett.*, 12 (2005), pp. 357–375] on the concentration in the L^2-critical nonlinear Schrödinger equation below H^1.

Key words. time dependent Schrödinger equation, blowup, mass concentration

DOI. 10.1137/050624054

1. Introduction.

We consider the L^2-critical nonlinear Schrödinger equation:

$$\begin{cases} i\partial_t u + \Delta u + |u|^{\frac{4}{d}}u = 0, & x \in \mathbb{R}^d,\ t > 0, \\ u(0,x) = u_0(x). \end{cases} \tag{1.1}$$

Here, $\Delta = \sum_{i=1}^{d} \partial_{x_i}^2$ is the Laplace operator on $\mathbb{R}^d$ and $u_0 : \mathbb{R}^d \longrightarrow \mathbb{C}$. It is well known (see [5], for instance) that the Cauchy problem (1.1) is locally well-posed in H^s for every $s \geq 0$. The unique solution has the following conservation law:

$$\int_{\mathbb{R}^d} |u(t,x)|^2 dx = \int_{\mathbb{R}^d} |u_0(x)|^2 dx. \tag{1.2}$$

Also, if $s \geq 1$, the energy

$$E(t) = \frac{1}{2}\int_{\mathbb{R}^d} |\nabla u(t,x)|^2 dx - \frac{d}{4+2d}\int_{\mathbb{R}^d} |u(t,x)|^{\frac{4}{d}+2} dx$$

is conserved as t varies. For $s > 0$, (1.1) is subcritical: the lifespan of the solution depends only on the H^s norm of the data. This yields the following blowup alternative: either $T^* = \infty$ or $T^* < +\infty$ and

$$\lim_{t \uparrow T^*} \|u(t,\cdot)\|_{H^s} = +\infty.$$

The space L^2 and the equation have the same scaling. More precisely, if u solves (1.1), then for every $\lambda > 0$, so does $u_\lambda(x,t) = \lambda^{d/2}u(\lambda^2 t, \lambda x)$ with data $u_\lambda(0,x) = \lambda^{d/2}u_0(\lambda x)$. But $\|u_\lambda(0,\cdot)\|_{L^2} = \|u_0\|_{L^2}$, and from this point of view (1.1) is L^2-critical. In this case the situation is more subtle, and the time of existence depends on the shape of the data.

The local theory relies heavily on some integrability properties of the solution of the associated linear Schrödinger equation, called Strichartz estimates. In fact, by

†IRMAR, UMR 6625 du CNRS, Université de Rennes 1, Campus de Beaulieu, 35 042 Rennes cedex, France (thmidi@univ-renne1.fr, sahbi.keraani@univ-rennes1.fr).

using Fourier analysis in connection with the work by Tomas [23], as in [22], or an abstract operators theory as in [9], it was proved that

$$\|e^{it\Delta}u_0\|_{L^{\frac{4}{d}+2}(\mathbb{R}^{d+1})} \leq C\|u_0\|_{L^2(\mathbb{R}^d)}. \tag{1.3}$$

The local solution follows from solving the equivalent integral equation

$$u(t,x) = e^{it\Delta}u_0(x) + i\int_0^t e^{i(t-s)\Delta}|u|^{\frac{4}{d}}u(s,x)ds,$$

by a standard Picard iteration method. The small data theory asserts that there exists a $\delta > 0$ (related to the constant C in (1.3)) such that if

$$\|u_0\|_{L^2(\mathbb{R}^d)} < \delta,$$

the initial value problem (1.1) has a unique global solution. This follows by solving the Cauchy problem (1.1) directly in the whole space (the first step of the iteration method suffices to reach $T^* = \infty$). However, for large data, *blowup* may occur. The blowup or "wave collapse" corresponds to self-trapping of beams in laser propagation. A lot of theoretical and numerical works are dedicated to this subject when the initial data belongs to H^1. In fact, in this space energy arguments apply, and a blowup theory has been developed in the last two decades (see [5], [21], [16] and the references therein). This theory is connected to the notion of ground state: the unique positive radial solution of the elliptic problem

$$\Delta Q - Q + |Q|^{\frac{4}{d}}Q = 0.$$

In [25], Weinstein exhibited the following refined Gagliardo–Nirenberg inequality:

$$\|\psi\|^{\frac{4}{d}+2}_{L^{\frac{4}{d}+2}} \leq C_d\|\psi\|^{\frac{4}{d}}_{L^2}\|\nabla\psi\|^2_{L^2} \qquad \forall\psi \in H^1, \tag{1.4}$$

with $C_d = \frac{d+2}{d}\|Q\|^{-\frac{4}{d}}_{L^2}$. Combined with the conservation of energy, this implies that $\|Q\|_{L^2}$ is the critical mass for the formation of singularities: for every $u_0 \in H^1$ such that

$$\|u_0\|_{L^2} < \|Q\|_{L^2}$$

the solution of (1.1) with initial data u_0 is global. Also, this bound is optimal. By using the conformal invariance, one constructs

$$S(t,x) = (T^*-t)^{-d/2}e^{[(i/(T^*-t))+(-i|x|^2/T^*-t)]}Q\left(\frac{x}{T^*-t}\right),$$

a solution of (1.1) with $\|u\|_{L^2} = \|Q\|_{L^2}$ that blows up in a finite time T^*. In [14], Merle has proved that $S(t)$ is the unique minimal blowup solution in H^1 in the following sense: let $u_0 \in H^1$ with $\|u_0\|_{L^2} = \|Q\|_{L^2}$, and assume that $u(t)$ blows up at finite time; then $u(t) = S(t)$ up to symmetries of the equation in H^1. It is also proved (see [18] and [24]) that at the blowup there is a concentration phenomenon in the L^2 norm: there exist continuous functions $x(t)$ such that

$$\forall R > 0, \quad \liminf_{t\to T^*}\int_{|x-x(t)|\leq R}|u(t,x)|^2dx \geq \int Q^2. \tag{1.5}$$

For the case $u_0 \in H^s$, with $0 \le s < 1$, the classical energy arguments don't work. Nevertheless, the general consensus is that, in this case too, the same concentration phenomenon happens (the blowup solutions concentrate a minimal amount of mass which is equal to $\|Q\|_{L^2}$). The first result in this direction is due to Bourgain [3] in the case of two dimensions and $u_0 \in L^2$. In fact, by using a refined version of the Strichartz inequality (1.3) proved in [20] and harmonic analysis techniques, this author proved that if u is a blowup solution of (1.1) at finite time $T^* > 0$, then

$$\lim_{t\uparrow T^*} \left(\sup_{y\in\mathbb{R}^2} \int_{\{|x-y|<\sqrt{T^*-t}\}} |u(t,x)|^2 dx \right) > \alpha(\|u_0\|_{L^2}) > 0,$$

with $\alpha(\lambda) \to 0$ as $\lambda \to \infty$. Using the work by Bourgain [3], Merle and Vega [19] have proved, among other things, an asymptotic compactness property in $L^2(\mathbb{R}^2)$ up to the invariance of the equation.

In [11] the second author defined the minimal mass δ_0 as the L^2 norm necessary to ignite a wave collapse[1] and stressed its role in the blowup mechanism. This yields a better description of the blowup solutions of (1.1) in *one* and *two* space dimensions (see also [4]). It is worth noting that these results can be generalized to higher dimensions, thanks to recent work by Bégout and Vargas [2]. However, unlike the H^1-case, in this level of regularity there was no result connecting the blowup mechanism to the ground state Q, and an explicit quantification of the minimal amount of mass concentrated remains an open problem. Recently, very important progress in this direction has been made by Colliander et al. [6]. These authors have proved that blowup solutions, which are radially symmetric, concentrate at least the mass of the ground state, for an intermediate case $1 > s > s_Q$.[2] Their proof is based on the so-called I-method introduced by Colliander et al. (see [7] and the references therein).

In this paper we prove a compactness lemma adapted to the analysis of the blowup phenomenon of the nonlinear Schroödinger equation, and we use it to improve the results of [6]: we remove the assumption of radial symmetry of the initial data, and we prove that Q is a profile for the singular solutions with minimal mass. The main tools of the proof of this compactness lemma are an argument of profile decomposition, introduced by Gérard [8] to study the defect of compactness for Sobolev embedding, and the sharp Gagliardo–Nirenberg inequalities (1.4). We prove the following result.

THEOREM 1.1. *Let $\{v_n\}_{n=1}^\infty$ be a bounded family of $H^1(\mathbb{R}^d)$ such that*

$$\limsup_{n\to\infty} \|\nabla v_n\|_{L^2} \le M \qquad \text{and} \qquad \limsup_{n\to\infty} \|v_n\|_{L^{\frac{4}{d}+2}} \ge m. \tag{1.6}$$

Then there exists $\{x_n\}_{n=1}^\infty \subset \mathbb{R}^d$ such that, up to a subsequence,

$$v_n(\cdot + x_n) \rightharpoonup V \in H^1 \qquad \text{weakly}$$

with $\|V\|_{L^2} \ge (\frac{d}{d+2})^{d/4} \frac{m^{\frac{d}{2}+1}}{M^{d/2}} \|Q\|_{L^2}$.

Remark 1.2. The lower bound on the L^2 norm of V is optimal. In fact, if we take $v_n = Q$, then we get equality.

Remark 1.3. If $d = 2$, then we can interchange the roles of $\|\nabla v_n\|_{L^2}$ and $\|v_n\|_{L^2}$. More precisely, if we assume that $\limsup \|v_n\|_{L^2} \le M$ and that $\limsup \|v_n\|_{L^4} \ge m$,

[1] We have $\delta_0 \le \|Q\|_{L^2}$, and the equality is strongly conjectured.

[2] Some nonoptimal index $\le \frac{1+\sqrt{11}}{5}$.

then we get the same conclusion with $\|\nabla V\|_{L^2} \geq \frac{1}{\sqrt{2}} \frac{m^2}{M} \|Q\|_{L^2}$ instead of the lower bound on the L^2 norm.

Remark 1.4. In the H^1 context this theorem allows us to easily obtain the results on the concentration and uniqueness of the profile of concentration proved by Weinstein [26] using the concentration-compactness lemma of Lions [13]. To see this, take $u_0 \in H^1$ such that the corresponding solution u of (1.1) blows up in finite time $T^* > 0$ and $t_n \uparrow T^*$ as $n \to \infty$. We set

$$v_n(x) = \lambda_n^{d/2} u(t_n, \lambda_n x), \qquad \lambda_n = 1/\|\nabla u(t_n, .)\|_{L^2}.$$

Using conservation of energy, we get trivially that $\{v^n\}_{n=1}^{\infty}$ satisfies the assumptions of Theorem 1.1 with $M = 1$ and $m = (\frac{d+2}{d})^{\frac{d}{2d+4}}$, which implies that

$$\lambda_n^{d/2} u(t_n, \lambda_n(\cdot - x_n)) \rightharpoonup V,$$

with $\|V\|_{L^2} \geq \|Q\|_{L^2}$. This yields, in particular, the concentration estimate (1.5). If we assume, in addition, that $\|u_0\|_{L^2} = \|Q\|_{L^2}$, then the limit above becomes strong in H^1, and the variational characterization of the ground state Q implies the universality of the profile of the blowup solutions with minimal mass. It is worth noting that these arguments are indeed standard, and the novelty is just the use of Theorem 1.1 to avoid discussion of the concentration, vanishing, and dichotomy cases of the concentration-compactness lemma of Lions and then simplifying the proof.

As an application of Theorem 1.1 and the results of [6] we obtain the following result.

THEOREM 1.5. *Assume $d = 2$ and $s > s_Q$. Let $u_0 \in H^s(\mathbb{R}^2)$ be such that the corresponding solution u of (1.1) blows up in finite time $T^* > 0$. Then there exists a sequence $t_n \longrightarrow T^*$ such that the following holds true: there exists a function $V \in H^1$ with $\|V\|_{L^2} \geq \|Q\|_{L^2}$, and a sequence $\{\rho_n, x_n\}_{n=1}^{\infty} \subset \mathbb{R}_+^* \times \mathbb{R}^2$ satisfying*

$$\rho_n \leq A(T^* - t_n)^{s/2}$$

for some $A > 0$, such that

$$\rho_n u(t_n, \rho_n x + x_n) \rightharpoonup V \quad \textit{weakly}.$$

Remark 1.6. We do not know if ψ or $\|\psi\|_{L^2}$ depends on the time sequence $\{t_n\}_{n=1}^{\infty}$. Recently, Merle and Raphael [17] have proved that, in the H^1 context, Q is the universal blowup profile (for the strong $\dot{H}^1$ convergence) for the near-critical mass solutions.

Remark 1.7. Note that, despite the fact that $\{u(t_n, \cdot)\}_{n=1}^{\infty}$ belongs to H^s, the blowup profile V is in H^1. This fact corroborates the expectation that $V = Q$.

Theorem 1.5 and the variational characterization of the ground state allow us to prove the following theorem.

THEOREM 1.8. *Assume $d = 2$ and $s > s_Q$. Let $u_0 \in H^s(\mathbb{R}^2)$ with $\|u_0\|_{L^2} = \|Q\|_{L^2}$ such that the solution u of (1.1) blows up in finite time $T^* > 0$. Then there exists a sequence $t_n \longrightarrow T^*$ satisfying*

$$\rho_n \leq A(T^* - t_n)^{s/2}$$

for some $A > 0$, and a sequence $\{\rho_n, \theta_n, x_n\}_{n=1}^{\infty} \subset \mathbb{R}_+^* \times [0, 2\pi[\times\mathbb{R}^2$ such that

$$\rho_n e^{i\theta_n} u(t_n, \rho_n x + x_n) \longrightarrow Q$$

strongly in $H^{\tilde{s}-}$, *where* $\tilde{s} = \frac{s+1}{4-2s}$.

Remark 1.9. This result is the analogue of the one proved by Weinstein [26] in the H^1 case.[3] However, contrary to our case, the H^1 result of Weinstein holds for all t instead of along the sequence t_n, and the scaling parameter ρ_n is explicitly given by $\rho = \|\nabla Q\|_{L^2}/\|\nabla u(t,.)\|_{L^2}$.

As an application we obtain the next claim.

COROLLARY 1.10. *Under the assumptions of Theorem* 1.5, *let* $\lambda(t) > 0$ *such that* $\frac{(T^*-t)^{s/2}}{\lambda(t)} \longrightarrow 0$ *as* $t \to T^*$. *There exists* $x(t) \in \mathbb{R}^2$ *such that*

$$\limsup_{t\to T^*} \int_{|x-x(t)|\le\lambda(t)} |u(t,x)|^2 dx \ge \int Q^2.$$

Remark 1.11. As already remarked in [6], the fact that Theorems 1.5 and 1.8 hold for only a time sequence $\{t_n\}$ and the lim sup (instead of lim inf) in Corollary 1.10 is due to the lack of information on the monotonicity of the H^s norm of the blowup solutions near the collapse time.

The rest of this paper is structured as follows. In section 2 we prove Theorem 1.1. Section 3 is devoted to the proofs of blowup results.

2. Proof of Theorem 1.1. In what follows we set $2^* = \infty$ if $d = 1, 2$, and $2^* = \frac{2d}{d-2}$ if $d \ge 3$. Theorem 1.1 is a consequence of a profile decomposition of the bounded sequences in H^1 following the work by Gérard [8] (see also [1] and [10]). More precisely, we have the following result.

PROPOSITION 2.1. *Let* $\mathbf{v} = \{v_n\}_{n=1}^{\infty}$ *be a bounded sequence in* $H^1(\mathbb{R}^d)$. *Then there exist a subsequence of* $\{v_n\}_{n=1}^{\infty}$ (*still denoted* $\{v_n\}_{n=1}^{\infty}$), *a family* $\{\mathbf{x}^j\}_{j=1}^{\infty}$ *of sequences in* $\mathbb{R}^d$, *and a sequence* $\{V^j\}_{j=1}^{\infty}$ *of* H^1 *functions such that*

(i) *for every* $k \ne j$, $|x_n^k - x_n^j| \underset{n\to\infty}{\longrightarrow} +\infty$;

(ii) *for every* $\ell \ge 1$ *and every* $x \in \mathbb{R}^d$,

$$v_n(x) = \sum_{j=1}^{\ell} V^j(x - x_n^j) + v_n^\ell(x),$$

with

$$\limsup_{n\to\infty} \|v_n^\ell\|_{L^p(\mathbb{R}^d)} \underset{\ell\to\infty}{\longrightarrow} 0, \tag{2.1}$$

for every $p \in]2, 2^*[$.

Moreover, we have, as $n \to +\infty$,

$$\|v_n\|_{L^2}^2 = \sum_{j=1}^{\ell} \|V^j\|_{L^2}^2 + \|v_n^\ell\|_{L^2}^2 + o(1) \tag{2.2}$$

and

$$\|\nabla v_n\|_{L^2}^2 = \sum_{j=1}^{\ell} \|\nabla V^j\|_{L^2}^2 + \|\nabla v_n^\ell\|_{L^2}^2 + o(1). \tag{2.3}$$

[3] The asymptotic result by Weinstein was completed by the result of Kwong on the uniqueness of the ground state [12].

Proof. Let $\mathcal{V}(\mathbf{v})$ be the set of functions obtained as weak limits of subsequences of the translated $v_n(.+x_n)$ with $\{x_n\}_{n=1}^{\infty}\subset\mathbb{R}^d$. We denote

$$\eta(\mathbf{v})=\sup\{\|V\|_{H^1},\quad V\in\mathcal{V}(\mathbf{v})\}.$$

Clearly

$$\eta(\mathbf{v})\leq\limsup_{n\to\infty}\|v_n\|_{H^1}.$$

We will prove the existence of a sequence $\{V^j\}_{j=1}^{\infty}$ of $\mathcal{V}(\mathbf{v})$ and a family $\{\mathbf{x}^j\}_{j=1}^{\infty}$ of sequences of $\mathbb{R}^d$ such that

$$k\neq j\Longrightarrow|x_n^k-x_n^j|\underset{n\to\infty}{\longrightarrow}\infty,$$

and, up to extracting a subsequence, the sequence $\{v_n\}_{n=1}^{\infty}$ can be written as

$$v_n(x)=\sum_{j=1}^{\ell}V^j(x-x_n^j)+v_n^{\ell}(x),\quad \eta(\mathbf{v}^{\ell})\underset{\ell\to\infty}{\longrightarrow}0,$$

such that the identities (2.2)–(2.3) hold. Indeed, if $\eta(\mathbf{v})=0$, we can take $V^j\equiv0$ for all j; otherwise we choose $V^1\in\mathcal{V}(\mathbf{v})$ such that

$$\|V^1\|_{H^1}\geq\frac{1}{2}\eta(\mathbf{v})>0.$$

By definition, there exists some sequence $\mathbf{x}^1=\{x_n^1\}_{n=1}^{\infty}$ of $\mathbb{R}^d$ such that, up to extracting a subsequence, we have

$$v_n(\cdot+x_n^1)\rightharpoonup V^1\qquad\text{weakly.}$$

We set

$$v_n^1=v_n-V^1(\cdot-x_n^1).$$

Since $v_n^1(\cdot+x_n^1)\rightharpoonup0$, we get, as $n\to\infty$,

$$\begin{aligned}\|v_n\|_{L^2}^2&=\|V^1\|_{L^2}^2+\|v_n^1\|_{L^2}^2+o(1),\\ \|\nabla v_n\|_{L^2}^2&=\|\nabla V^1\|_{L^2}^2+\|\nabla v_n^1\|_{L^2}^2+o(1).\end{aligned}$$

Now, we replace $\mathbf{v}$ by $\mathbf{v}^1$ and repeat the same process. If $\eta(\mathbf{v}^1)>0$, we get V^2, $\mathbf{x}^2$, and $\mathbf{v}^2$. Moreover, we have

$$|x_n^1-x_n^2|\longrightarrow\infty\qquad\text{as}\quad n\to\infty.$$

Otherwise, up to extracting of a subsequence, we get

$$x_n^1-x_n^2\longrightarrow x_0$$

for some $x_0\in\mathbb{R}^d$. Since

$$v_n^1(\cdot+x_n^2)=v_n^1(\cdot+(x_n^2-x_n^1)+x_n^1)$$

and $v_n^1(\cdot+x_n^1)$ converge weakly to 0, then $V^2=0$. A contradiction. An argument of iteration and orthogonal extraction allows us to construct the families $\{\mathbf{x}^j\}_{j=1}^{\infty}$

and $\{V^j\}_{j=1}^{\infty}$ satisfying the claims above. Furthermore, the convergence of the series $\sum_{j=1}^{\infty}\|V^j\|_{H^1}^2$ implies that

$$\|V^j\|_{H^1} \underset{j\to\infty}{\longrightarrow} 0.$$

However, by construction, we have

$$\eta(\mathbf{v}^j) \le 2\|V^{j-1}\|_{H^1},$$

which proves that $\eta(\mathbf{v}^j) \to 0$k, as claimed. To complete the proof of Proposition 2.1, (2.1) remains to be proved. For that purpose let us introduce $\chi_R \in \mathcal{S}(\mathbb{R}^d)$ such that

$$\hat{\chi}_R(\xi) = 1 \quad \text{if } |\xi| \le R, \qquad \hat{\chi}_R(\xi) = 0 \quad \text{if } |\xi| \ge 2R.$$

Here $\hat{}$ denotes the Fourier transform. One has

$$v_n^\ell = \chi_R * v_n^\ell + (\delta - \chi_R) * v_n^\ell,$$

where $*$ stands for the convolution and δ for the Dirac distribution.

Let $p \in]2, 2^*[$ be fixed. On the one hand, using Sobolev embedding, we get

$$\|(\delta - \chi_R) * v_n^\ell\|_{L^p} \precsim \|(\delta - \chi_R) * v_n^\ell\|_{\dot{H}^\beta} \precsim R^{\beta-1}\|v_n^\ell\|_{H^1}$$

for $\beta = d(\frac{1}{2} - \frac{1}{p}) < 1$. On the other hand, one can estimate

$$\begin{aligned}\|\chi_R * v_n^\ell\|_{L^p} &\precsim \|\chi_R * v_n^\ell\|_{L^2}^{2/p}\|\chi_R * v_n^\ell\|_{L^\infty}^{1-2/p}\\ &\precsim \|v_n^\ell\|_{L^2}^{2/p}\|\chi_R * v_n^\ell\|_{L^\infty}^{1-2/p}.\end{aligned}$$

Now, observe that

$$\limsup_{n\to\infty}\|\chi_R * v_n^\ell\|_{L^\infty(\mathbb{R}^d)} = \sup_{\{x_n\}_{n=1}^\infty}\limsup_{n\to+\infty}|\chi_R * v_n^\ell(x_n)|.$$

Thus, in view of the definition of $\mathcal{V}(\mathbf{v}^\ell)$, we infer

$$\limsup_{n\to\infty}\|\chi_R * v_n^\ell\|_{L^\infty(\mathbb{R}^d)} \le \sup\left\{\left|\int_{\mathbb{R}^d}\chi_R(-x)V(x)dx\right|,\ V \in \mathcal{V}(\mathbf{v}^\ell)\right\}.$$

Therefore, by Hölder's inequality, it follows that

$$\limsup_{n\to\infty}\|\chi_R * v_n^\ell\|_{L^\infty(\mathbb{R}^d)} \le C(R)\sup\{\|V\|_{L^2(\mathbb{R}^d)},\ V \in \mathcal{V}(\mathbf{v}^\ell)\}.$$

Thus, we obtain

$$\limsup_{n\to\infty}\|\chi_R * v_n^\ell\|_{L^\infty(\mathbb{R}^d)} \le C(R)\eta(\mathbf{v}^\ell)$$

for every $\ell \ge 1$. Finally, we get

$$\|v_n^\ell\|_{L^p(\mathbb{R}^d)} \precsim R^{\beta-1}\|v_n^\ell\|_{H^1} + C(R)\|v_n^\ell\|_{L^2}^{2/p}\eta(\mathbf{v}^\ell)^{1-2/p}.$$

We successively let ℓ and R go to infinity, and since $\eta(\mathbf{v}^\ell) \underset{\ell\to\infty}{\longrightarrow} 0$ and the family of sequences $\{v_n^\ell\}$ are uniformly bounded in $H^1(\mathbb{R}^d)$, we infer

$$\limsup_{n\to\infty}\|v_n^\ell\|_{L^p} \underset{\ell\to\infty}{\longrightarrow} 0,$$

as claimed. This completes the proof of Proposition 2.1. □

Let us now prove Theorem 1.1. By extracting a subsequence, we may replace lim sup in the assumptions (1.6) by lim. According to Proposition 2.1, the sequence $\{v_n\}_{n=1}^{\infty}$ can be written, up to a subsequence, as

$$v_n(x) = \sum_{j=1}^{\ell} V^j(x - x_n^j) + v_n^{\ell}(x)$$

such that (2.1), (2.2), and (2.3) hold. This implies, in particular, that

$$m^{\frac{4}{d}+2} \leq \limsup_{n\to\infty} \|v_n\|_{L^{\frac{4}{d}+2}}^{\frac{4}{d}+2} = \limsup_{n\to\infty} \left\| \sum_{j=1}^{\infty} V^j(\cdot - x_n^j) \right\|_{L^{\frac{4}{d}+2}}^{\frac{4}{d}+2}.$$

The elementary inequality

$$\left| \left| \sum_{j=1}^{l} a_j \right|^{4/d+2} - \sum_{j=1}^{l} |a_j|^{4/d+2} \right| \leq C \sum_{j\neq k} |a_j||a_k|^{4/d+1},$$

and the pairwise orthogonality of the family $\{\mathbf{x}^j\}_{j=1}^{\infty}$ leads the mixed terms in the sum above to vanish, so that we get

$$m^{\frac{4}{d}+2} \leq \sum_{j=1}^{\infty} \|V^j\|_{L^{\frac{4}{d}+2}}^{\frac{4}{d}+2}.$$

However, in view of the precise version of the Gagliardo–Nirenberg inequality (1.4), we have

$$\sum_{j=1}^{\infty} \|V^j\|_{L^{\frac{4}{d}+2}}^{\frac{4}{d}+2} \leq C_d \sup\{\|V^j\|_{L^2}^{4/d}, j \geq 1\} \sum_{j=1}^{\infty} \|\nabla V^j\|_{L^2}^2.$$

Also, from (2.3), we infer

$$\sum_{j=1}^{\infty} \|\nabla V^j\|_{L^2}^2 \leq \limsup_{n\to\infty} \|\nabla v_n\|_{L^2}^2 \leq M^2.$$

Therefore,

$$\sup_{j\geq 1} \|V^j\|_{L^2}^{4/d} \geq \frac{m^{\frac{4}{d}+2}}{(M^2 C_d)^{d/4}}.$$

Since the series $\sum \|V^j\|_{L^2}^2$ converges, the supremum above is attained. In particular, there exists j_0 such that

$$\|V^{j_0}\|_{L^2} \geq \frac{m^{\frac{d}{2}+1}}{(C_d M^2)^{d/4}} = \left(\frac{d}{d+2}\right)^{d/4} \frac{m^{\frac{d}{2}+1}}{M^{d/2}} \|Q\|_{L^2}.$$

On the other hand, a change of variables gives

$$v_n(x + x_n^{j_0}) = V^{j_0}(x) + \sum_{\substack{1\leq j\leq \ell \\ j\neq j_0}} V^j(x + x_n^{j_0} - x_n^j) + \tilde{v}_n^{\ell}(x),$$

where $\tilde{v}_n^\ell(x) = v_n^\ell(x + x_n^{j_0})$. The pairwise orthogonality of the family $\{\mathbf{x}^j\}_{j=1}^\infty$ implies

$$V^j(\cdot + x_n^{j_0} - x_n^j) \rightharpoonup 0 \quad \text{weakly}$$

for every $j \neq j_0$. Hence, we get

$$v_n(\cdot + x_n^{j_0}) \rightharpoonup V^{j_0} + \tilde{v}^\ell,$$

where $\tilde{v}^\ell$ denote the weak limit of $\{\tilde{v}_n^\ell\}_{n=1}^\infty$. However, we have

$$\|\tilde{v}^\ell\|_{L^{\frac{4}{d}+2}} \leq \limsup_{n\to\infty} \|\tilde{v}_n^\ell\|_{L^{\frac{4}{d}+2}} = \limsup_{n\to\infty} \|v_n^\ell\|_{L^{\frac{4}{d}+2}} \underset{l\to\infty}{\longrightarrow} 0.$$

Thereby, by the uniqueness of the weak limit, we get

$$\tilde{v}^\ell = 0$$

for every $\ell \geq j_0$. Thus

$$v_n(\cdot + x_n^{j_0}) \rightharpoonup V^{j_0}.$$

The sequence $\{x_n^{j_0}\}_{n=1}^\infty$ and the function V^{j_0} now fulfill the conditions of Theorem 1.1. □

3. Proof of the main results.

3.1. The modified energy. Here we recall the result of almost conservation of the modified energy proved in [6].

I_N stands for the smoothing operators[4] $I_N : H^s \to H^1$:

$$\widehat{I_N u}(\xi) = m(\xi)\hat{u}(\xi),$$

where

$$m(\xi) = \begin{cases} 1, & |\xi| \leq N, \\ (\frac{|\xi|}{N})^{s-1}, & |\xi| > 3N, \end{cases}$$

with $m(\xi)$ smooth, radial, and monotone in $|\xi|$. The following properties of I_N are easily verified:

$$\begin{aligned} \|I_N u\|_{L^2} &\leq \|u\|_{L^2}, \\ \|u\|_{H^s} \leq &\|I_N u\|_{H^1} \leq N^{1-s}\|u\|_{H^s}. \end{aligned} \tag{3.1}$$

The *blowup parameter* associated with the H^s norm of the solution is

$$\Lambda(t) = \sup_{0\leq\tau\leq t} \|u(t)\|_{H^s}.$$

The following proposition is a restatement of the part of [6] which is relevant for us.

PROPOSITION 3.1 (see [6]). *There exists $s_Q \leq \frac{1}{5} + \frac{1}{5}\sqrt{11}$ such that for all $s > s_Q$ there exists $p(s) < 2$ with the following holding true: if $H^s \ni u_0 \longmapsto u(t)$ solves (1.1) on a maximal (forward) finite existence interval $[0, T^*)$, then for all $T < T^*$ there exists $N = N(T)$ such that*

$$|E[I_{N(T)}u(T)]| \leq C_0(\Lambda(T))^{p(s)} \tag{3.2}$$

[4] See [7] for more properties of this operator.

with $C_0 = C_0(s, T^*, \|u_0\|_{H^s})$. *Moreover,* $N(T) = C(\Lambda(T))^{\frac{p(s)}{2(1-s)}}$.

In [6], $p(s)$ is explicitly given by

$$p(s) = \frac{6^+}{2^- - 4^+(1-s)} 2(1-s), \tag{3.3}$$

where $\alpha^\pm = \alpha \pm \epsilon$ for some $\epsilon > 0$.

3.2. Proof of Theorem 1.5. As in [6], we choose $\{t_n\}_{n=1}^\infty$ to be a sequence such that $t_n \uparrow T^*$ and for each t_n

$$\|u(t_n)\|_{H^s} = \Lambda(t_n).$$

We set

$$\psi_n = \rho_n I_N u(t_n, \rho_n x),$$

where

$$\rho_n = \frac{\|\nabla Q\|_{L^2}}{\|\nabla I_N u(t_n, \cdot)\|_{L^2}}.$$

The estimate (3.1) yields

$$\rho_n \leq \frac{1}{\|u(t_n, \cdot)\|_{H^s}} = \frac{1}{\Lambda(t_n)}.$$

Also, from Corollary 3.6 in [6], it holds that

$$\rho_n \leq A(T^* - t_n)^{s/2}$$

for some constant $A > 0$. The sequence $\{\psi_n\}_{n=1}^\infty$ satisfies

$$\|\psi_n\|_{L^2} \leq \|u_0\|_{L^2}, \quad \|\nabla \psi_n\|_{L^2} = \|\nabla Q\|_{L^2}.$$

Furthermore, in view of Proposition 3.1,

$$E(\psi_n) = \rho_n^2 E[I_{N(t_n)} u(t_n)] \leq \rho_n^2 (\Lambda(t_n))^{p(s)} \leq (\Lambda(t_n))^{p(s)-2}.$$

Since $\|u(t_n)\|_{H^s} \longrightarrow +\infty$ and $p(s) < 2$, it holds that

$$E(\psi_n) \longrightarrow 0 \qquad \text{as} \quad n \to \infty,$$

which yields, in particular,

$$\|\psi_n\|_{L^4}^4 \longrightarrow 2\|\nabla Q\|_{L^2}^2 \qquad \text{as} \quad n \to \infty. \tag{3.4}$$

The family $\{\psi_n\}_{n=1}^\infty$ satisfies the conditions of Theorem 1.1 with

$$m = (2\|\nabla Q\|_{L^2}^2)^{1/4} \qquad \text{and} \qquad M = \|\nabla Q\|_{L^2}.$$

Thus, there exists $\{x_n\}_{n=1}^\infty \subset \mathbb{R}^2$ such that, up to a subsequence,

$$\psi_n(\cdot + x_n) \rightharpoonup V \in H^1, \tag{3.5}$$

with $\|V\|_{L^2} \geq \|Q\|_{L^2}$. Coming back to $\{\psi_n\}_{n=1}^{\infty}$, one obtains

$$\rho_n I_N u(t_n, \rho_n x + x_n) = V + \varepsilon_n,$$

where $\varepsilon_n \rightharpoonup 0$ in H^1.

However, for every $\bar{s} < s$, one has

$$\begin{aligned}\|\rho_n(I_N u(t_n) - u(t_n))(\rho_n \cdot + x_n)\|_{\dot{H}^{\bar{s}}(\mathbb{R}^2)} &\leq \rho_n^{\bar{s}} N^{\bar{s}-s} \|u(t_n, \cdot)\|_{H^s(\mathbb{R}^2)} \\ &\leq (\Lambda(t_n))^{\frac{p(s)(\bar{s}-s)}{2(1-s)}+1-\bar{s}}.\end{aligned}$$

Using the explicit formula of $p(s)$, an easy calculus yields that

$$\frac{p(s)(\bar{s}-s)}{2(1-s)} + 1 - \bar{s} < 0 \Longleftrightarrow \bar{s} < \tilde{s} := \frac{s+1}{4-2s}.$$

Under this choice, we get

$$\|\rho_n(I_N u(t_n) - u(t_n))(\rho_n \cdot + x_n)\|_{H^{\tilde{s}-}(\mathbb{R}^2)} \longrightarrow 0 \qquad \text{as} \quad n \to \infty.$$

Thus

$$\rho_n u(t_n, \rho_n x + x_n) = V + h_n, \tag{3.6}$$

where $h_n \rightharpoonup 0$ in $H^{\tilde{s}-}$. This concludes the proof of Theorem 1.5.

3.3. Proof of Theorem 1.8. If, in the context of the proof of Theorem 1.5, we assume also that $\|u_0\|_{L^2} = \|Q\|_{L^2}$, we get trivially (remember that we have already proved that $\|V\|_{L^2} \geq \|Q\|_{L^2}$)

$$\|V\|_{L^2} = \|Q\|_{L^2}.$$

Then the convergence (3.5) is strong in L^2 and, since $\{v_n\}$ is bounded in H^1, we have

$$v_n(\cdot + x_n) \longrightarrow V \qquad \text{in} \quad L^4.$$

Combined with (3.4) and the precise version of the Gagliardo–Nirenberg inequality (1.4), this leads to

$$\|\nabla V\|_{L^2} \geq \|\nabla Q\|_{L^2}.$$

However, one has

$$\|\nabla V\|_{L^2} \leq \limsup \|\nabla v_n\|_{L^2} = \|\nabla Q\|_{L^2},$$

which means that $\|\nabla V\|_{L^2} = \|\nabla Q\|_{L^2}$. As a result we get

$$v_n(\cdot + x_n) \longrightarrow V \qquad \text{in} \quad H^1$$

and $E(V) = 0$.

Let us summarize the properties of the profile V:

$$\|V\|_{L^2} = \|Q\|_{L^2}, \quad \|\nabla V\|_{L^2} = \|\nabla Q\|_{L^2}, \quad \text{and} \quad E(V) = 0.$$

The variational characterization of the ground state implies that

$$V(x) = e^{i\theta} Q(x + x_0)$$

for some $\theta \in [0, 2\pi[$ and $x_0 \in \mathbb{R}^2$.

Coming back to (3.6), one obtains

$$\rho_n u(t_n, \rho_n x + x_n) = \lambda e^{i\theta} Q(\lambda x + x_0) + \varepsilon_n,$$

where $h_n \to 0$ in $H^{\tilde{s}-}$. This ends the proof of Theorem 1.8.

3.4. Proof of Corollary 1.10. Let u be a blowup solution of (1.1) at finite time $T^* > 0$. According to Theorem 1.5, there exists a time sequence such that $t_n \longrightarrow T^*$, a profile $V \in H^1(\mathbb{R}^2)$ with $\|V\|_{L^2} \geq \|Q\|_{L^2}$, and a sequence $\{\rho_n, x_n\}_{n=1}^{\infty} \subset \mathbb{R}_+^* \times \mathbb{R}^2$ such that

$$\rho_n u(t_n, \rho_n x + x_n) \rightharpoonup V \tag{3.7}$$

and

$$\lim_{n\to\infty} \frac{\rho_n}{(T^* - t_n)^{s/2}} \leq A \tag{3.8}$$

for some $A \geq 0$. From (3.7), it follows that

$$\lim_{n\to\infty} \frac{1}{(\rho_n)^2} \int_{|x|\leq R} |u(t_n, \rho_n x + x_n)|^2 dx \geq \int_{|x|\leq R} |V|^2 dx$$

for every $R > 0$. Thus,

$$\lim_{n\to\infty} \sup_{y\in\mathbb{R}^2} \int_{|x-y|\leq R\rho_n} |u(t_n, x)|^2 dx \geq \int_{|x|\leq R} |V|^2 dx. \tag{3.9}$$

Since $\frac{(T^*-t)^{s/2}}{\lambda(t)} \to 0$ as $t \to T^*$, it follows from (3.8) that $\frac{\rho_n}{\lambda(t_n)} \to 0$, and then

$$\lim_{n\to\infty} \sup_{y\in\mathbb{R}^2} \int_{|x-y|\leq \lambda(t_n)} |u(t_n, x)|^2 dx \geq \int_{|x|\leq R} |V|^2 dx$$

for every R. We let R go to infinity to obtain

$$\lim_{n\to\infty} \sup_{y\in\mathbb{R}^2} \int_{\{|x-y|\leq \lambda(t_n)\}} |u(t_n, x)|^2 dx \geq \int_{\mathbb{R}^2} |V|^2 dx \geq \|Q\|_{L^2}^2.$$

This yields finally

$$\limsup_{t\uparrow T^*} \sup_{y\in\mathbb{R}^2} \int_{\{|x-y|\leq \lambda(t)\}} |u(t, x)|^2 dx \geq \|Q\|_{L^2}^2.$$

Since, for every t, the function $y \longmapsto \int_{\{|x-y|\leq\lambda(t)\}} |u(t,x)|^2 dx$ is continuous and goes to 0 at infinity, there exists a family $x(t)$ such that

$$\sup_{y\in\mathbb{R}^2} \int_{\{|x-y|\leq \lambda(t)\}} |u(t, x)|^2 dx = \int_{\{|x-x(t)|\leq \lambda(t)\}} |u(t, x)|^2 dx,$$

which concludes the proof of Corollary 1.10. ∎

Remark 3.2. While this manuscript was under review, we were informed that N. Tzirakis has written a paper following [6] in which he removed the radial symmetry assumption and established corresponding results for the focusing quintic nonlinear Schrödinger equation on $\mathbb{R}$.

Acknowledgments. The authors thank the anonymous referees for their very relevant and detailed comments, which helped to improve the manuscript.

HOMOGENIZATION AND FIELD CONCENTRATIONS IN HETEROGENEOUS MEDIA*

ROBERT LIPTON†

Abstract. A multiscale characterization of the field concentrations inside composite and polycrystalline media is developed. We focus on gradient fields associated with the intensive quantities given by the temperature and the electric potential. In the linear regime these quantities are modeled by the solution of a second order elliptic partial differential equation with oscillatory coefficients. The characteristic length scale of the heterogeneity relative to the sample size is denoted by ε and the intensive quantity is denoted by u^ε. Field concentrations are measured using the L^p norm of the gradient field $\|\nabla u^\varepsilon\|_{L^p(D)}$ for $2 \leq p < \infty$. The analysis focuses on the case when $0 < \varepsilon \ll 1$. Explicit lower bounds on $\liminf_{\varepsilon \to 0} \|\nabla u^\varepsilon\|_{L^p(D)}$ are developed. These bounds provide a way to rigorously assess field concentrations generated by the microgeometry without having to compute the actual field u^ε.

1. Introduction.

The initiation of failure inside heterogeneous media is a multiscale phenomenon. Loads applied at the structural scale are often amplified by the microstructure, creating local zones of high field concentration. The local amplification of the applied field creates conditions that are favorable for failure initiation [8]. This paper focuses on gradient fields associated with the intensive quantities given by the temperature and the electric potential inside heterogeneous media. The local integrability of the gradient directly correlates with singularity strength, which influences the onset of failure such as dielectric breakdown.

In this work it is shown how to assess the L^p integrability of the gradient fields in microstructured media by investigating the multiscale integrability of suitably defined quantities. The analysis is carried out with minimal regularity assumptions on the coefficients describing the local properties inside the heterogeneous media. The results are described in terms of the pth order moments of the solution of two-scale corrector problems. The quantities are sensitive to microscopic field concentrations and can become divergent for $p > 2$. This is in contrast to the well-known effective constitutive properties, which are based upon local averages and are bounded above independently of the microgeometry.

The results given here are presented in the context of two-scale homogenization [1], [18]. We consider a bounded domain Ω in $\mathbf{R}^n$, $n \geq 2$. A common microstructure

†Department of Mathematics, Louisiana State University, Baton Rouge, LA 70803 (lipton@math.lsu.edu).

that admits a two-scale description is a simple generalization of a uniformly periodic microstructure and is described as follows. Consider a partition of the domain Ω made up of measurable subsets Ω_ℓ, $\ell = 1, 2, \ldots, K$, such that $\Omega = \cup_{\ell=1}^{K} \Omega_\ell$. Inside each subdomain Ω_ℓ we place a different periodic microstructure made from N anisotropic heat conductors. This type of microstructure will be referred to as a piecewise periodic microstructure [4]. Well-known engineering composites that are modeled by piecewise periodic microstructures include fiber reinforced laminates [6], [19], [21].

The thermal conductivity tensor for the piecewise periodic microstructure is described as follows. The indicator function for each of the subdomains Ω_ℓ is denoted by $\chi_{\Omega_\ell}(\mathbf{x})$, taking the value 1 for points in Ω_ℓ and 0 outside. In order to describe the periodic microstructure inside the ℓth subdomain we introduce the unit period cell Q. The configuration of the N phases inside Q is described by the indicator functions $\chi_\ell^i(\mathbf{y})$, $i = 1, \ldots, N$, associated with each phase. Here $\chi_\ell^i(\mathbf{y}) = 1$ for points inside the ith phase and 0 outside. The length scale of the microstructure relative to the size of the domain Ω is given by $\varepsilon_k = 1/k$, $k = 1, 2 \ldots$. The microstructure is obtained by rescaling the configuration inside the unit period cell. The indicator function of the ith conductor in the microstructured composite is given by

$$\chi_i^{\varepsilon_k}(\mathbf{x}) = \chi_i(\mathbf{x}, \mathbf{x}/\varepsilon_k) = \sum_{\ell}^{K} \chi_{\Omega_\ell}(\mathbf{x}) \chi_\ell^i(\mathbf{x}/\varepsilon_k). \tag{1.1}$$

The local conductivity tensor A^{ε_k} has a two-scale structure and is given by

$$A^{\varepsilon_k}(\mathbf{x}) = A(\mathbf{x}, \mathbf{x}/\varepsilon_k) = \sum_{i}^{N} A^i \chi_i(\mathbf{x}, \mathbf{x}/\varepsilon_k). \tag{1.2}$$

Other heterogeneous media that are amenable to similar or more general two-scale descriptions include polycrystalline materials such as metals and ceramics. We state the general hypotheses under which the two-scale homogenization theory applies; see [1] and [2]. It is assumed that $A(\mathbf{x}, \mathbf{y})$ is a matrix defined on $\Omega \times Q$ and there exist positive numbers $\alpha < \beta$ such that for every vector η in $\mathbf{R}^n$,

$$\alpha|\eta|^2 \leq A(\mathbf{x}, \mathbf{y})\eta \cdot \eta \leq \beta|\eta|^2. \tag{1.3}$$

The conductivity $A_{ij}(\mathbf{x}, \mathbf{y})$ is Q-periodic in the second variable, $A_{ij}(\mathbf{x}, \mathbf{x}/\varepsilon_k)$ is measurable and satisfies

$$\lim_{\varepsilon_k \to 0} \int_\Omega \left| A_{ij}\left(\mathbf{x}, \frac{\mathbf{x}}{\varepsilon_k}\right) \right|^2 d\mathbf{x} = \int_{\Omega \times Q} |A_{ij}(\mathbf{x}, \mathbf{y})|^2 \, d\mathbf{x} d\mathbf{y}, \tag{1.4}$$

and for any suitable two-scale trial field $\psi(\mathbf{x}, \mathbf{y})$,

$$\lim_{\varepsilon_k \to 0} \int_\Omega A_{ij}\left(\mathbf{x}, \frac{\mathbf{x}}{\varepsilon_k}\right) \psi\left(x, \frac{\mathbf{x}}{\varepsilon_k}\right) d\mathbf{x} = \int_{\Omega \times Q} A_{ij}(\mathbf{x}, \mathbf{y}) \psi(\mathbf{x}, \mathbf{y}) \, d\mathbf{x} d\mathbf{y}. \tag{1.5}$$

The convergence given by (1.5) is a weak convergence and is known as two-scale convergence [1], [18]. The space of suitable two-scale trials is denoted by $L^2[D; C_{per}(Q)]$. Here $C_{per}(Q)$ denotes Q-periodic continuous functions defined on $\mathbf{R}^3$, and the space $L^2[D; C_{per}(Q)]$ is the space of functions $h : \Omega \to C_{per}(Q)$ which are measurable and satisfy $\int_\Omega \|h(\mathbf{x})\|^2_{C_{per}(Q)} d\mathbf{x} < \infty$. The norm $\|h(\mathbf{x})\|_{C_{per}(Q)}$ is defined by $\sup_{\mathbf{y} \in Q} |h(\mathbf{x}, \mathbf{y})|$.

In what follows, no other regularity hypothesis on the conductivity matrix $A(\mathbf{x},\mathbf{y})$ is made.

The temperature field u^{ε_k} associated with the conductivity tensor field $A^{\varepsilon_k}(\mathbf{x}) = A(\mathbf{x},\mathbf{x}/\varepsilon_k)$ is the solution of the equilibrium equation

$$-\text{div}\,(A^{\varepsilon_k}(\mathbf{x})\nabla u^{\varepsilon_k}) = f \ \text{ in } \ \Omega \tag{1.6}$$

with the boundary conditions given by $u^{\varepsilon_k} = 0$ on $\partial\Omega_D$ and $\mathbf{n}\cdot A^{\varepsilon_k}\nabla u^{\varepsilon_k} = g$ on $\partial\Omega_N$ with $\partial\Omega_D \cap \partial\Omega_N = \emptyset$ and $\partial\Omega = \overline{\partial\Omega}_D \cup \overline{\partial\Omega}_N$.

In what follows, we consider the limit as ε_k tends to zero. We fix a subdomain D of Ω and derive lower bounds on

$$\liminf_{\varepsilon_k\to 0} \|\nabla u^{\varepsilon_k}\|_{L^p(D)}. \tag{1.7}$$

The lower bound is expressed in terms of a two-scale integral that encodes the field amplification properties of the microstructure. It is formulated in terms of the solution of the homogenized problem together with a local corrector matrix that captures the interaction between the periodic microstructure and the gradients of the homogenized temperature field. The bounds introduced here provide a rigorous way to assess field concentrations generated by the microgeometry without having to compute the full solution u^{ε_k}.

We consider an orthonormal basis for $\mathbf{R}^n$ and denote the basis vectors by $\mathbf{e}^i$, $i = 1,\ldots,n$. The lower bound is given in terms of the solutions $w^i(\mathbf{x},\mathbf{y})$ to the local periodic problem. For each $\mathbf{x}$ in Ω, the function $w^i(\mathbf{x},\mathbf{y})$ is a Q-periodic function of the second variable $\mathbf{y}$ and is a solution of

$$\text{div}_{\mathbf{y}}\left(A(\mathbf{x},\mathbf{y})(\nabla_{\mathbf{y}} w^i(\mathbf{x},\mathbf{y}) + \mathbf{e}^i)\right) = 0, \tag{1.8}$$

with $\int_Q w^i(\mathbf{x},\mathbf{y})\,d\mathbf{y} = 0$. The corrector matrix $P(\mathbf{x},\mathbf{y})$ is defined by

$$P_{ij}(\mathbf{x},\mathbf{y}) = \partial_{y_j} w^i(\mathbf{x},\mathbf{y}) + \delta_{ij}, \tag{1.9}$$

where $\delta_{ij} = 1$ for $i = j$ and 0 otherwise. The associated effective conductivity tensor $A^E(\mathbf{x})$ is given by

$$A^E(\mathbf{x}) = \int_Q A(\mathbf{x},\mathbf{y})P(\mathbf{x},\mathbf{y})\,d\mathbf{y}. \tag{1.10}$$

The two-scale homogenization theory gives the following theorem [1].

THEOREM 1.1 (two-scale homogenization theorem). *The sequence of solutions* $\{u^{\varepsilon_k}\}_{\varepsilon_k>0}$ *of* (1.6) *converges weakly to* $u^H(\mathbf{x})$ *in* $H^1(\Omega)$*, where* u^H *is the solution of the homogenized problem*

$$\begin{aligned} -\text{div}\left(A^E(\mathbf{x})\nabla u^H(\mathbf{x})\right) &= f(\mathbf{x}) \ \textit{in}\ \Omega, \\ u^H(\mathbf{x}) &= 0 \ \textit{on}\ \partial\Omega_D, \ \textit{and} \\ \mathbf{n}\cdot A^E\nabla u^H &= g \ \textit{on}\ \partial\Omega_N. \end{aligned} \tag{1.11}$$

The field concentration functions of order p are defined by

$$f_p(\mathbf{x},\nabla u^H(\mathbf{x})) \equiv \left(\int_Q |P(\mathbf{x},\mathbf{y})\nabla u^H(\mathbf{x})|^p\,d\mathbf{y}\right)^{1/p}, \quad 2 \le p \le \infty, \tag{1.12}$$

and $f_p(\mathbf{x}, \nabla u^H(\mathbf{x})) \le f_q(\mathbf{x}, \nabla u^H(\mathbf{x}))$ for $p \le q$. It is clear that f_p corresponds to a pth order moment of the corrector matrix (1.9) and that

$$f_\infty(\mathbf{x}, \nabla u^H(\mathbf{x})) \equiv \lim_{p\to\infty} \left(\int_Q |P(\mathbf{x}, \mathbf{y}) \nabla u^H(\mathbf{x})|^p \, d\mathbf{y} \right)^{1/p}. \tag{1.13}$$

THEOREM 1.2 (lower bounds on field concentrations). *For* $2 \le p < \infty$,

$$\left(\int_D \left(f_p(\mathbf{x}, \nabla u^H(\mathbf{x})) \right)^p d\mathbf{x} \right)^{1/p} \le \liminf_{\varepsilon_k \to 0} \|\nabla u^{\varepsilon_k}\|_{L^p(D)}. \tag{1.14}$$

For multiphase conductivity problems with coefficients described by (1.2), the field concentration functions of order p are defined for each phase and are given by

$$f_p^i(\mathbf{x}, \nabla u^H(\mathbf{x})) \equiv \left(\int_Q \chi_i(\mathbf{x}, \mathbf{y}) |P(\mathbf{x}, \mathbf{y}) \nabla u^H(\mathbf{x})|^p \, d\mathbf{y} \right)^{1/p}, \ i = 1, \dots, N, \ 2 \le p \le \infty, \tag{1.15}$$

and $f_p^i(\mathbf{x}, \nabla u^H(\mathbf{x})) \le f_q^i(\mathbf{x}, \nabla u^H(\mathbf{x}))$ for $p \le q$. As before, one defines

$$f_\infty^i(\mathbf{x}, \nabla u^H(\mathbf{x})) \equiv \lim_{p\to\infty} \left(\int_Q \chi_i(\mathbf{x}, \mathbf{y}) |P(\mathbf{x}, \mathbf{y}) \nabla u^H(\mathbf{x})|^p \, d\mathbf{y} \right)^{1/p}. \tag{1.16}$$

For this case, lower bounds on

$$\liminf_{\varepsilon_k \to 0} \|\chi_i^{\varepsilon_k} \nabla u^{\varepsilon_k}\|_{L^p(D)} \tag{1.17}$$

are given by the following theorem.

THEOREM 1.3 (lower bounds for multiphase composites). *For* $2 \le p < \infty$,

$$\left(\int_D \left(f_p^i(\mathbf{x}, \nabla u^H(\mathbf{x})) \right)^p d\mathbf{x} \right)^{1/p} \le \liminf_{\varepsilon_k \to 0} \|\chi_i^{\varepsilon_k} \nabla u^{\varepsilon_k}\|_{L^p(D)}. \tag{1.18}$$

The bounds can be applied to develop a Chebyshev inequality for the distribution functions associated with the sequence $\{\chi_i^{\varepsilon_k} |\nabla u^{\varepsilon_k}|\}_{\varepsilon_k > 0}$. Here the distribution function $\lambda_i^{\varepsilon_k}(D, t)$ gives the measure of the set inside D, where $\chi_i^{\varepsilon_k} |\nabla u^{\varepsilon_k}| > t$.

Arguing as in Proposition 2.1 of [12] and combining with (1.18) gives the following.

THEOREM 1.4 (homogenized Chebyshev inequality).

$$\limsup_{\varepsilon_k \to 0} \lambda_i^{\varepsilon_k}(D, t) \le t^{-p} \left(\int_D \left(f_p^i(\mathbf{x}, \nabla u^H(\mathbf{x})) \right)^p d\mathbf{x} \right) \le t^{-p} \liminf_{\varepsilon_k \to 0} \|\chi_i^{\varepsilon_k} \nabla u^{\varepsilon_k}\|_{L^p(D)}^p. \tag{1.19}$$

We point out that Theorems 1.2 and 1.3 are obtained using the minimum regularity assumptions on the coefficients A^{ε_k}. Because of this, the hypotheses of Theorem 2.6 in [1] do not apply, and one cannot take advantage of the strong convergence given in that theorem. Instead, the theorems are proved using a perturbation approach introduced in [11] and [13]; see also our section 2.

The lower bounds are sensitive to the presence of singularities generated by the microstructure. To illustrate this we consider a microstructure made from a periodic

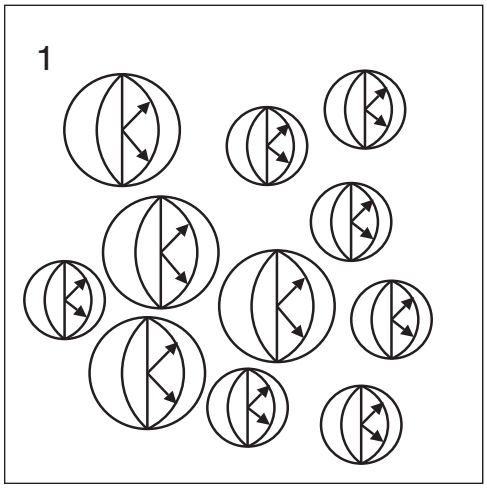

FIG. 1. *Unit period cell with Schulgasser crystallites embedded inside a material with unit thermal conductivity.*

distribution of uniaxial crystallites embedded in an isotropic matrix of unit conductivity. The period cell for the composite is illustrated in Figure 1. Each crystallite occupies a sphere and has conductivity λ_1 in the radial direction and λ_2 in the tangential direction. The dispersion of the N crystallites is specified by $\cup_\ell^N B(\mathbf{y}^\ell, r_\ell)$, where $B(\mathbf{y}^\ell, r_\ell)$ denotes the ℓth sphere centered at $\mathbf{y}^\ell$ with radius r_ℓ. Each crystallite has a conductivity tensor given by

$$A(\mathbf{y}) = \lambda_1 \mathbf{n} \otimes \mathbf{n} + \lambda_2 (I - \mathbf{n} \otimes \mathbf{n}), \tag{1.20}$$

where $\mathbf{n} = (\mathbf{y} - \mathbf{y}^\ell)/|\mathbf{y} - \mathbf{y}^\ell|$ for $\mathbf{y}$ in $B(\mathbf{y}^\ell, r_\ell)$ and I is the 3×3 identity. Outside the crystallites we set $A(\mathbf{y}) = I$. It is assumed that the aggregate of crystallites occupy a portion of the unit cell Q of volume $0 < \theta < 1$. It is noted that the conductivity inside each crystallite is precisely the one employed in the Schulgasser sphere assemblage [22].

When a constant gradient field is applied to a single isolated crystallite and when $\lambda_1 > \lambda_2$, the crystallite exhibits a gradient field singularity at its center. In what follows, we use the lower bound (1.14) to show how this local information affects the integrability of the sequence $\{\nabla u^{\varepsilon_k}\}_{\varepsilon_k > 0}$. We form $A^{\varepsilon_k} = A(\mathbf{x}/\varepsilon_k)$ and consider solutions u^{ε_k} of (1.6). To fix ideas we choose f to be in $L^r(\Omega)$ for $r > 3$ and g to be in $L^2(\partial\Omega_N)$. In what follows, λ_2 is restricted to lie in the interval $1/2 < \lambda_2 < 1$, and $\lambda_1 = 1/(2\lambda_2 - 1)$. For this choice it is shown in section 3 that the homogenized temperature field u^H is the solution of (1.11) with $A^E = I$.

For D compactly contained in Ω, it follows from the L^p theory [15] that $\|\nabla u^H\|_{L^p(D)} < \infty$ for every $1 \le p < \infty$. On the other hand, calculation and application of Theorem 1.2 show that

$$LB(p) \times \|\nabla u^H\|_{L^p(D)} \le \liminf_{\varepsilon_k \to 0} \|\nabla u^{\varepsilon_k}\|_{L^p(D)}, \tag{1.21}$$

where

$$LB(p) = \begin{cases} \frac{3p\theta(2\lambda_2 - 1)}{2(1-\lambda_2)(\frac{3}{2(1-\lambda_2)} - p)} + (1-\theta) & \text{for } p < \frac{3}{2(1-\lambda_2)}, \\ +\infty & \text{for } p \ge \frac{3}{2(1-\lambda_2)}. \end{cases} \tag{1.22}$$

For a fixed choice of λ_2, the value $p_c = \frac{3}{2(1-\lambda_2)}$ satisfies $3 < p_c < +\infty$, and we have

$$\liminf_{\varepsilon_k \to 0} \|\nabla u^{\varepsilon_k}\|_{L^p(D)} = +\infty \text{ for } p \geq p_c. \tag{1.23}$$

This is in stark contrast to the L^p integrability of the gradient of the homogenized solution, which holds for any $p < +\infty$. It is clear from this example that the information carried by the homogenized problem is not adequate and misses the singular behavior exhibited by the sequence $\{\nabla u^{\varepsilon_k}\}_{\varepsilon_k > 0}$. This example shows that failure initiation criteria based solely upon the solution of the homogenized equations will be optimistic. The inequalities given above are established in section 3.

The maximum integrability exponent for the gradient of the solution of the local problem (1.8) is referred to as the threshold exponent for the composite. The threshold exponent is introduced in the work of Milton [16] and measures the worst singularity of the gradient field. The threshold exponent is precisely p_c for the local problem considered here and corresponds to the divergence in the lower bound for $p \geq p_c$.

Next we consider an example for which the sequence $\{\nabla u^{\varepsilon_k}\}_{\varepsilon_k > 0}$ is uniformly bounded in L^p for some class of coefficients and right-hand sides f. For this case we show that the lower bound given in Theorem 1.2 is attained. In this example we make use of the a priori estimates for $\{\nabla u^{\varepsilon_k}\}_{\varepsilon_k > 0}$ developed in Theorem 4 of Avellaneda and Lin [3]. Let Ω be a $C^{1,\alpha}$ domain $(0 < \alpha \leq 1)$ and suppose for $0 < \gamma \leq 1$, $C > 0$, that $A(\mathbf{y}) \in C^\gamma(\mathbf{R}^n)$ and $\|A(\mathbf{y})\|_{C^\gamma(\mathbf{R}^n)} \leq C$. Then we choose $A^{\varepsilon_k} = A(\mathbf{x}/\varepsilon_k)$. For $\delta > 0$ suppose $2 \leq q \leq n + \delta$ and $f \in L^q$ and set $1/\hat{q} = 1/q - 1/(n+\delta)$. Given these choices, we consider the $W_0^{1,2}(\Omega)$ solutions u^{ε_k} of

$$-\text{div}\,(A^{\varepsilon_k}(\mathbf{x})\nabla u^{\varepsilon_k}) = f \quad \text{in} \quad \Omega. \tag{1.24}$$

It is shown in section 4 that (1.14) holds with equality for every p such that $p < \hat{q}$. In fact, it is seen more generally that, for $p < \hat{q}$ and any Carathéodory function $\psi : D \times \mathbf{R}^n \to \mathbf{R}$ satisfying

$$|\psi(\mathbf{x}, \eta)| \leq |\eta|^p \text{ for a.e. } \mathbf{x} \in D \text{ and } \eta \in \mathbf{R}^3, \tag{1.25}$$

we have

$$\lim_{\varepsilon_k \to 0} \int_D \psi(\mathbf{x}, \nabla u^{\varepsilon_k}(\mathbf{x}))\, d\mathbf{x} = \int_D \int_Q \psi(\mathbf{x}, P(\mathbf{y})\nabla u^H(\mathbf{x}))\, d\mathbf{y} d\mathbf{x}. \tag{1.26}$$

This is established in section 4.

It is anticipated that there are several classes of conductivity coefficients and right-hand sides f for which the lower bounds are attained. In this direction we point out the a priori estimates given in [7], [9], [10], and [23].

We conclude by noting that the analogues of the field concentration functions (1.12) and (1.15) have appeared earlier in the contexts of G-convergence and random media; see [11] and [12]. In those treatments they are shown to provide upper bounds for the distribution function of the local stress and electric field for G-convergent sequences of elasticity tensors and random dielectric tensors.

2. Derivation of the lower bounds. We recall the weak formulation of the $\varepsilon_k > 0$ problem given by (1.6). Let V denote the closure in $H^1(\Omega)$ of all smooth functions that vanish on $\partial\Omega_D$. We suppose that f is in $L^2(\Omega)$ and g belongs to

$L^2(\partial\Omega_N)$. The function u^{ε_k} belonging to V is the solution of the weak formulation of the boundary value problem given by

$$\int_\Omega A(\mathbf{x},\mathbf{x}/\varepsilon_k)\nabla u^{\varepsilon_k}\cdot\nabla\varphi\,d\mathbf{x}=\int_\Omega f\varphi\,d\mathbf{x}+\int_{\partial\Omega_N} g\varphi\,ds \tag{2.1}$$

for every φ in V. Here ds is an element of surface area.

In order to express the two-scale weak formulation of (1.11) we introduce the following function spaces. The space of square integrable Q-periodic mean zero functions with square integrable derivatives is denoted by $H^1_{per}(Q)/\mathbf{R}$. The norm of an element v in this space is denoted by $\|v\|_{H^1_{per}(Q)/\mathbf{R}}$. The space of measurable functions h from Ω to $H^1_{per}(Q)/\mathbf{R}$ for which $\int_\Omega \|h(\mathbf{x})\|^2_{H^1_{per}(Q)/\mathbf{R}}\,d\mathbf{x}<\infty$ is denoted by $L^2[\Omega;H^1_{per}(Q)/\mathbf{R}]$. This function space was introduced for the description of the two-scale homogenized problem in [18]. The weak formulation of the two-scale homogenized problem (1.11) is given by the unfolded variational principle [1], [5], [14].

THEOREM 2.1 (unfolded variational principle). *The pair (u^H,u_1) is the unique solution in $V\times L^2[\Omega;H^1_{per}(Q)/\mathbf{R}]$ of*

$$\begin{aligned}&\int_\Omega\int_Q A(\mathbf{x},\mathbf{y})(\nabla u^H(\mathbf{x})+\nabla_{\mathbf{y}}u_1(\mathbf{x},\mathbf{y}))\cdot(\nabla\varphi(\mathbf{x})+\nabla_{\mathbf{y}}\varphi_1(\mathbf{x},\mathbf{y}))\,d\mathbf{y}\,d\mathbf{x}\\&=\int_\Omega f\varphi\,d\mathbf{x}+\int_{\partial\Omega_N} g\varphi\,ds\end{aligned} \tag{2.2}$$

for every (φ,φ_1) in $V\times L^2[\Omega;H^1_{per}(Q)/\mathbf{R}]$. Moreover,

$$\nabla u^H+\nabla_{\mathbf{y}}u_1(\mathbf{x},\mathbf{y})=P(\mathbf{x},\mathbf{y})\nabla u^H(\mathbf{x}). \tag{2.3}$$

In order to establish Theorems 1.2 and 1.3 we recall the function spaces used in the description of two-scale convergence [14]. The space $C_{per}(Q)$ denotes Q-periodic continuous functions defined on $\mathbf{R}^3$. For $1\le r<\infty$, the space $L^r[D;C_{per}(Q)]$ is the space of functions $h:D\to C_{per}(Q)$, which are measurable and satisfy $\int_D\|h(\mathbf{x})\|^r_{C_{per}(Q)}d\mathbf{x}<\infty$. Here $\|h(\mathbf{x})\|_{C_{per}(Q)}=\sup_{\mathbf{y}\in Q}|h(\mathbf{x},\mathbf{y})|$. The intersection of the spaces $L^\infty(D\times Q)$ and $L^r[D;C_{per}(Q)]$ is denoted by V^r. For $1<r<\infty$ we introduce $1<r'<\infty$ such that $\frac{1}{r}+\frac{1}{r'}=1$. We establish Theorems 1.2 and 1.3 with the aid of the following lemmas.

LEMMA 2.1 (localization lemma). *Fix a domain of interest D inside Ω. Let $q(\mathbf{x},\mathbf{y})$ be any test function in V^r; then one can pass to the limit $\varepsilon_k\to 0$ in the sequence of solutions $\{u^{\varepsilon_k}\}_{\varepsilon_k>0}$ of (1.6) to obtain*

$$\lim_{\varepsilon_k\to 0}\int_D q(\mathbf{x},\mathbf{x}/\varepsilon_k)\,|\nabla u^{\varepsilon_k}|^2\,d\mathbf{x}=\int_D\int_Q q(\mathbf{x},\mathbf{y})\,|P(\mathbf{x},\mathbf{y})\nabla u^H(\mathbf{x})|^2\,d\mathbf{y}\,d\mathbf{x}. \tag{2.4}$$

For multiphase composites with coefficients described by (1.2) we restrict our attention to the inside of each phase and state the following lemma.

LEMMA 2.2 (localization lemma in multiphase composites). *Let $q(\mathbf{x},\mathbf{y})$ be any test function in V^r; then one can pass to the limit $\varepsilon_k\to 0$ in the sequence of solutions $\{u^{\varepsilon_k}\}_{\varepsilon_k>0}$ of (1.6) to obtain*

$$\begin{aligned}&\lim_{\varepsilon_k\to 0}\int_D q(\mathbf{x},\mathbf{x}/\varepsilon_k)\,\chi_i^{\varepsilon_k}(\mathbf{x})\,|\nabla u^{\varepsilon_k}|^2\,d\mathbf{x}\\&=\int_D\int_Q q(\mathbf{x},\mathbf{y})\,\chi_i(\mathbf{x},\mathbf{y})\,|P(\mathbf{x},\mathbf{y})\nabla u^H(\mathbf{x})|^2\,d\mathbf{y}\,d\mathbf{x}.\end{aligned} \tag{2.5}$$

The proofs of Lemmas 2.1 and 2.2 are given at the end of this section.

To illustrate the ideas, we use Lemma 2.2 to establish Theorem 1.3, noting that Theorem 1.2 follows from Lemma 2.1 in the same way.

Proof of Theorem 1.3. For each $\varepsilon_k > 0$, we apply Hölder's inequality to the left side of (2.5) to obtain

$$\begin{aligned}&\int_D \int_Q q(\mathbf{x},\mathbf{y})\,\chi_i(\mathbf{x},\mathbf{y})\,|P(\mathbf{x},\mathbf{y})\nabla u^H(\mathbf{x})|^2\,d\mathbf{y}\,d\mathbf{x}\\ &\le \lim_{\varepsilon_k\to 0}\left(\int_D |q(\mathbf{x},\mathbf{x}/\varepsilon_k)|^r\,dx\right)^{1/r} \liminf_{\varepsilon_k\to 0}\left(\int_D \chi_i^{\varepsilon_k}(\mathbf{x})\,|\nabla u^{\varepsilon_k}|^{2r'}\,d\mathbf{x}\right)^{1/r'}. \qquad (2.6)\end{aligned}$$

Noting [14] that

$$\lim_{\varepsilon_k\to 0}\left(\int_D |q(\mathbf{x},\mathbf{x}/\varepsilon_k)|^r\,dx\right)^{1/r} = \left(\int_D\int_Q |q(\mathbf{x},\mathbf{y})|^r\,d\mathbf{y}\,d\mathbf{x}\right)^{1/r} \equiv \|q(\mathbf{x},\mathbf{y})\|_{L^r(D\times Q)}, \qquad (2.7)$$

we obtain

$$\frac{\int_D\int_Q q(\mathbf{x},\mathbf{y})\,\chi_i(\mathbf{x},\mathbf{y})\,|P(\mathbf{x},\mathbf{y})\nabla u^H(\mathbf{x})|^2\,d\mathbf{y}\,d\mathbf{x}}{\|q(\mathbf{x},\mathbf{y})\|_{L^r(D\times Q)}} \le \liminf_{\varepsilon_k\to 0}\left(\int_D \chi_i^{\varepsilon_k}(\mathbf{x})|\nabla u^{\varepsilon_k}|^{2r'}d\mathbf{x}\right)^{1/r'}. \qquad (2.8)$$

Since V^r is dense in $L^r(D\times Q)$, we substitute an approximation of

$$\chi_i(\mathbf{x},\mathbf{y})\,|P(\mathbf{x},\mathbf{y})\nabla u^H(\mathbf{x})|^{2r'-2}$$

for q in (2.8) to find that

$$\left(\int_D\int_Q \chi_i(\mathbf{x},\mathbf{y})\,|P(\mathbf{x},\mathbf{y})\nabla u^H(\mathbf{x})|^{2r'}d\mathbf{y}\,d\mathbf{x}\right)^{1/r'} \le \liminf_{\varepsilon_k\to 0}\left(\int_D \chi_i^{\varepsilon_k}(\mathbf{x})|\nabla u^{\varepsilon_k}|^{2r'}d\mathbf{x}\right)^{1/r'}. \qquad (2.9)$$

Theorem 1.3 follows for $2 < p < \infty$ upon taking the square root on both sides of (2.9). The case $p = 2$ follows immediately upon choosing $q(\mathbf{x},\mathbf{y}) = 1$ in Lemma 2.2.

We conclude by providing the proof of Lemma 2.2; note that the proof of Lemma 2.1 is identical.

Proof of Lemma 2.2. The indicator function of the set of interest D is denoted by $\chi_D(\mathbf{x})$. We choose a test function $q(\mathbf{x},\mathbf{y})$ in V^r and set $p(\mathbf{x},\mathbf{y}) = \chi_D(\mathbf{x})\chi_i(\mathbf{x},\mathbf{y})q(\mathbf{x},\mathbf{y})$. For $\delta\beta > 0$ we form the perturbed conductivity tensor $\tilde{A}_{ij}(\mathbf{x},\mathbf{y}) = A_{ij}(\mathbf{x},\mathbf{y}) + \delta\beta p(\mathbf{x},\mathbf{y})\delta_{ij}$. We choose $\delta\beta$ sufficiently small so that $\tilde{A}(\mathbf{x},\mathbf{y})$ satisfies (1.3). By construction, $\tilde{A}(\mathbf{x},\mathbf{x}/\varepsilon_k)$ is measurable and satisfies (1.4) and (1.5). Consider the associated solution $\tilde{u}^{\varepsilon_k}$ in V of the weak formulation of the boundary value problem given by

$$\int_\Omega \tilde{A}(\mathbf{x},\mathbf{x}/\varepsilon_k)\nabla\tilde{u}^{\varepsilon_k}\cdot\nabla\varphi\,d\mathbf{x} = \int_\Omega f\varphi\,d\mathbf{x} + \int_{\partial\Omega_N} g\varphi\,ds \quad \text{for every } \varphi \text{ in } V. \qquad (2.10)$$

Set $\tilde{u}^{\varepsilon_k} = u^{\varepsilon_k} + \delta u^{\varepsilon_k}$; subtraction of (2.1) from (2.10) gives

$$\int_\Omega \tilde{A}(\mathbf{x},\mathbf{x}/\varepsilon_k)\nabla\delta u^{\varepsilon_k}\cdot\nabla\varphi\,d\mathbf{x} + \int_\Omega \delta\beta\,p(\mathbf{x},\mathbf{x}/\varepsilon_k)\nabla u^{\varepsilon_k}\cdot\nabla\varphi\,d\mathbf{x} = 0. \qquad (2.11)$$

Choosing $\varphi = u^{\varepsilon_k}$ in (2.11) and applying the identity

$$\int_\Omega A(\mathbf{x}, \mathbf{x}/\varepsilon_k)\nabla u^{\varepsilon_k} \cdot \nabla \delta u^{\varepsilon_k}\, d\mathbf{x} = \int_\Omega f \delta u^{\varepsilon_k}\, d\mathbf{x} + \int_{\partial\Omega_N} g\delta u^{\varepsilon_k}\, ds \tag{2.12}$$

gives

$$\delta\beta \times \int_\Omega p(\mathbf{x}, \mathbf{x}/\varepsilon_k)|\nabla u^{\varepsilon_k}|^2\, d\mathbf{x} + T^{\varepsilon_k} = -\int_\Omega f\delta u^{\varepsilon_k}\, d\mathbf{x} - \int_{\partial\Omega_N} g\delta u^{\varepsilon_k}\, ds, \tag{2.13}$$

where

$$T^{\varepsilon_k} = \delta\beta \times \int_\Omega p(\mathbf{x}, \mathbf{x}/\varepsilon_k)(\nabla \delta u^{\varepsilon_k}) \cdot \nabla u^{\varepsilon_k}\, d\mathbf{x}. \tag{2.14}$$

Next set $\varphi = \delta u^{\varepsilon_k}$ in (2.11); it then follows from Cauchy's inequality and (1.3) that

$$\|\nabla \delta u^{\varepsilon_k}\|_{L^2(\Omega)} \leq C\delta\beta, \tag{2.15}$$

where here and throughout C denotes a generic constant independent of ε_k. From this it is evident that

$$|T^{\varepsilon_k}| < C\delta\beta^2. \tag{2.16}$$

Next we pass to the $\varepsilon_k \to 0$ limit and apply Theorems 1.1 and 2.1 to find that the sequence $\{\tilde{u}^{\varepsilon_k}\}_{\varepsilon_k>0}$ converges weakly in $H^1(\Omega)$ to $\tilde{u}^H$, where $(\tilde{u}^H, \tilde{u}_1)$ is the solution in $V \times L^2[\Omega; H^1_{per}(Q)/\mathbf{R}]$ of

$$\begin{aligned} &\int_\Omega \int_Q \tilde{A}(\mathbf{x}, \mathbf{y})(\nabla \tilde{u}^H(\mathbf{x}) + \nabla_{\mathbf{y}}\tilde{u}_1(\mathbf{x}, \mathbf{y})) \cdot (\nabla\varphi(\mathbf{x}) + \nabla_{\mathbf{y}}\varphi_1(\mathbf{x}, \mathbf{y}))\, d\mathbf{y}\, d\mathbf{x} \\ &= \int_\Omega f\varphi\, d\mathbf{x} + \int_{\partial\Omega_N} g\varphi\, ds \end{aligned} \tag{2.17}$$

for every (φ, φ_1) in $V \times L^2[\Omega; H^1_{per}(Q)/\mathbf{R}]$. Set $\tilde{u}^H - u^H = \delta u^H$, $\tilde{u}_1 - u_1 = \delta u_1$; subtraction of (2.2) from (2.17) gives

$$\begin{aligned} &\int_\Omega \int_Q \tilde{A}(\mathbf{x}, \mathbf{y})(\nabla \delta u^H(\mathbf{x}) + \nabla_{\mathbf{y}}\delta u_1(\mathbf{x}, \mathbf{y})) \cdot (\nabla\varphi(\mathbf{x}) + \nabla_{\mathbf{y}}\varphi_1(\mathbf{x}, \mathbf{y}))\, d\mathbf{y}\, d\mathbf{x} \\ &+ \int_\Omega \int_Q \delta\beta p(\mathbf{x}, \mathbf{y})(\nabla u^H(\mathbf{x}) + \nabla_{\mathbf{y}}u_1(\mathbf{x}, \mathbf{y})) \cdot (\nabla\varphi(\mathbf{x}) + \nabla_{\mathbf{y}}\varphi_1(\mathbf{x}, \mathbf{y}))\, d\mathbf{y}\, d\mathbf{x} = 0. \end{aligned} \tag{2.18}$$

Choosing $(\varphi, \varphi_1) = (u^H, u_1)$ in (2.18) together with the identity

$$\begin{aligned} &\int_\Omega \int_Q A(\mathbf{x}, \mathbf{y})(\nabla u^H(\mathbf{x}) + \nabla_{\mathbf{y}}u_1(\mathbf{x}, \mathbf{y})) \cdot (\nabla \delta u^H(\mathbf{x}) + \nabla_{\mathbf{y}}\delta u_1(\mathbf{x}, \mathbf{y}))\, d\mathbf{y}\, d\mathbf{x} \\ &= \int_\Omega f\delta u^H\, d\mathbf{x} + \int_{\partial\Omega_N} g\delta u^H\, ds \end{aligned} \tag{2.19}$$

gives

$$\begin{aligned} &\delta\beta \times \int_\Omega \int_Q p(\mathbf{x}, \mathbf{y})|P(\mathbf{x}, \mathbf{y})\nabla u^H(\mathbf{x})|^2\, d\mathbf{y}\, d\mathbf{x} + \tilde{T} \\ &= -\int_\Omega f\delta u^H\, d\mathbf{x} - \int_{\partial\Omega_N} g\delta u^H\, ds, \end{aligned} \tag{2.20}$$

where

$$\tilde{T} = \delta\beta \times \int_\Omega \int_Q p(\mathbf{x},\mathbf{y})(\nabla \delta u^H + \nabla_{\mathbf{y}} \delta u_1(\mathbf{x},\mathbf{y})) \cdot (\nabla u^H + \nabla_{\mathbf{y}} u_1(\mathbf{x},\mathbf{y}))\, d\mathbf{x}. \tag{2.21}$$

Next set $(\varphi, \varphi_1) = (\delta u^H, \delta u_1)$ in (2.18); it then follows from Cauchy's inequality and (1.3) that

$$\|\nabla \delta u^H + \nabla_y \delta u_1\|_{L^2(\Omega \times Q)} \leq C\delta\beta, \tag{2.22}$$

and it follows easily that

$$|\tilde{T}| < C\delta\beta^2. \tag{2.23}$$

Taking the $\varepsilon_k \to 0$ limit in (2.13), noting that $\lim_{\varepsilon_k \to 0} \delta u^{\varepsilon_k} = \delta u^H$ (weakly in $H^1(\Omega)$), and recalling (2.16) gives

$$\delta\beta \times \lim_{\varepsilon_k \to 0} \int_\Omega p(\mathbf{x}, \mathbf{x}/\varepsilon_k) |\nabla u^{\varepsilon_k}|^2\, d\mathbf{x} + O(\delta\beta^2) = -\int_\Omega f \delta u^H\, d\mathbf{x} - \int_{\partial\Omega_N} g \delta u^H\, ds. \tag{2.24}$$

Lemma 2.2 now follows immediately from (2.20), (2.23), and (2.24) and from identifying like powers of $\delta\beta$.

3. Explicit lower bounds for aggregates of Schulgasser crystallites. In this section we derive the lower bound (1.22) for the microstructure consisting of Schulgasser crystallites embedded within a homogeneous matrix with unit thermal conductivity. The temperature field inside the unit period cell $\Phi^i(\mathbf{y}) = w^i(\mathbf{y}) + \mathbf{y}_i$ is the solution of the local problem

$$\operatorname{div}_{\mathbf{y}} \left(A(\mathbf{y})(\nabla_{\mathbf{y}} w^i(\mathbf{y}) + \mathbf{e}^i) \right) = 0, \tag{3.1}$$

with w^i Q-periodic and $\int_Q w^i(\mathbf{y})\, d\mathbf{y} = 0$. For this microstructure, $A(\mathbf{y})$ is given by (1.20) for $\mathbf{y}$ in $B(\mathbf{y}^\ell, r_\ell)$ and $A(\mathbf{y}) = I$ outside. Here we restrict λ_2 to the interval $(1/2, 1)$ and choose λ_1 so that $\lambda_1 = 1/(2\lambda_2 - 1)$. A calculation shows that the solution $\Phi^i(\mathbf{y})$ is given by

$$\Phi^i = \begin{cases} \mathbf{y}_i, & \mathbf{y} \in Q \setminus \cup_{\ell=1}^N B(\mathbf{y}^\ell, r_\ell), \\ r_\ell^{1-\alpha} |\mathbf{y} - \mathbf{y}^\ell|^{\alpha-1} (\mathbf{y}_i - \mathbf{y}_i^\ell) + \mathbf{y}_i^\ell, & \mathbf{y} \in B(\mathbf{y}^\ell, r_\ell), \end{cases} \tag{3.2}$$

where $\alpha = 2\lambda_2 - 1$. The corrector matrix $P(\mathbf{y})$ is given by

$$P(\mathbf{y}) = \begin{cases} I, & \mathbf{y} \in Q \setminus \cup_{\ell=1}^N B(\mathbf{y}^\ell, r_\ell), \\ r_\ell^{1-\alpha} |\mathbf{y} - \mathbf{y}^\ell|^{\alpha-1} (I + (\alpha - 1)\mathbf{n} \otimes \mathbf{n}), & \mathbf{y} \in B(\mathbf{y}^\ell, r_\ell), \end{cases} \tag{3.3}$$

where $\mathbf{n} = (\mathbf{y} - \mathbf{y}^\ell)/|\mathbf{y} - \mathbf{y}^\ell|$ for $\mathbf{y} \in B(\mathbf{y}^\ell, r_\ell)$. A direct calculation shows that

$$A^E = \int_Q A(\mathbf{y}) P(\mathbf{y})\, d\mathbf{y} = I. \tag{3.4}$$

Next we provide the lower bound for $\int_\Omega \int_Q |P(\mathbf{y}) \nabla u^H(\mathbf{x})|^p\, d\mathbf{y}\, d\mathbf{x}$. Note for any η in $\mathbf{R}^3$ that $P^T(\mathbf{y})P(\mathbf{y})\eta \cdot \eta = |P(\mathbf{y})\eta|^2$. The smallest eigenvalue $\lambda(\mathbf{y})$ of $P^T(\mathbf{y})P(\mathbf{y})$ delivers the lower bound $\lambda(\mathbf{y})|\eta|^2 \leq |P(\mathbf{y})\eta|^2$ and

$$\int_\Omega \int_Q \lambda(\mathbf{y})^{p/2} |\nabla u^H(\mathbf{x})|^p\, d\mathbf{y}\, d\mathbf{x} \leq \int_\Omega \int_Q |P(\mathbf{y}) \nabla u^H(\mathbf{x})|^p\, d\mathbf{y}\, d\mathbf{x}. \tag{3.5}$$

Calculation shows that

$$\lambda(\mathbf{y}) = \alpha^2 r_\ell^{2(1-\alpha)} |\mathbf{y} - \mathbf{y}^\ell|^{2(\alpha-1)} \tag{3.6}$$

for $\mathbf{y} \in B(\mathbf{y}^\ell, r_\ell)$ and $\lambda(\mathbf{y}) = 1$ for $\mathbf{y} \in Q \setminus \cup_\ell^N B(\mathbf{y}^\ell, r_\ell)$. The lower bound (1.22) follows upon substitution of (3.6) into (3.5).

4. Optimality of the lower bounds. Conditions are presented on f and $A(\mathbf{y})$ for which the lower bound (1.14) is attained for a range of exponents $2 < p < \hat{q}$. We suppose, as in Avellaneda and Lin [3], that Ω is a $C^{1,\alpha}$ domain ($0 < \alpha \leq 1$) and suppose for $0 < \gamma \leq 1$, $0 < C$, that $A(\mathbf{y}) \in C^\gamma(\mathbf{R}^n)$ and $\|A(\mathbf{y})\|_{C^\gamma(\mathbf{R}^n)} \leq C$. We set $A^{\varepsilon_k} = A(\mathbf{x}/\varepsilon_k)$. For $\delta > 0$ suppose $2 \leq q \leq n + \delta$ and $f \in L^q$ and set $1/\hat{q} = 1/q - 1/(n+\delta)$. Given these choices, we consider the $W_0^{1,2}(\Omega)$ solutions u^{ε_k} of

$$-\text{div}\,(A^{\varepsilon_k}(\mathbf{x})\nabla u^{\varepsilon_k}) = f \quad \text{in} \quad \Omega. \tag{4.1}$$

Theorem 4 of [3] shows that there exists a constant independent of ε_k for which

$$\|\nabla u^{\varepsilon_k}\|_{L^{\hat{q}}(\Omega)} \leq C \|f\|_{L^q(\Omega)} \tag{4.2}$$

holds for every $\varepsilon_k > 0$. Subject to these hypotheses it will be shown that the lower bound (1.14) is attained for $p < \hat{q}$.

Passing to a subsequence if necessary we start by considering the Young measure ν associated with the sequence $\{P(\mathbf{x}/\varepsilon_k)\nabla u^H(\mathbf{x})\}_{\varepsilon_k > 0}$. Here ν is represented by a family of probability measures $\nu = \{\nu_{\mathbf{x}}\}_{\mathbf{x}\in\Omega}$ depending measurably on $\mathbf{x}$. We denote by $C_0(\mathbf{R}^n)$ the set of continuous functions φ defined on $\mathbf{R}^n$ such that $\lim_{\eta\to\infty} \varphi(\eta) = 0$. Elementary arguments show that

$$\langle \nu_{\mathbf{x}}, \varphi \rangle = \int_{\mathbf{R}^n} \varphi(\eta) d\nu_{\mathbf{x}}(\eta) = \int_Q \varphi(P(\mathbf{z})\nabla u^H(\mathbf{x})) d\mathbf{z} \quad \text{a.e. } \mathbf{x} \in \Omega, \tag{4.3}$$

for every φ in $C_0(\mathbf{R}^n)$. From corrector theory [17] there exists an exponent $r \geq 1$ for which one has the strong convergence

$$\lim_{\varepsilon_k \to 0} \|\nabla u^{\varepsilon_k} - P(\mathbf{x}/\varepsilon_k)\nabla u^H\|_{L^r(\Omega)} = 0. \tag{4.4}$$

The strong convergence (4.4) shows that both sequences

$$\{\nabla u^{\varepsilon_k}\}_{\varepsilon_k > 0} \quad \text{and} \quad \{P(\mathbf{x}/\varepsilon_k)\nabla u^H(\mathbf{x})\}_{\varepsilon_k > 0}$$

share the same Young measure; see, for example, Lemma 6.3 of [20]. From (4.2) it follows, on passage to a subsequence if necessary, that $\{|\nabla u^{\varepsilon_k}|^p\}_{\varepsilon_k}$ is weakly convergent in $L^1(\Omega)$; thus,

$$\lim_{\varepsilon_k \to 0} \int_D |\nabla u^{\varepsilon_k}|^p \, d\mathbf{x} = \int_D \int_{\mathbf{R}^n} |\eta|^p \, d\nu_{\mathbf{x}}(\eta) \, d\mathbf{x} = \int_D \int_Q |P(\mathbf{z})\nabla u^H(\mathbf{x})|^p \, d\mathbf{z} \, d\mathbf{x}, \tag{4.5}$$

and optimality follows. Last, it follows immediately from Proposition 6.5 of [20] that for every Carathéodory function $\psi(\mathbf{x}, \eta)$ satisfying the growth condition (1.25) (on passage to a subsequence if necessary)

$$\lim_{\varepsilon_k \to 0} \int_D \psi(\mathbf{x}, \nabla u^{\varepsilon_k}) \, d\mathbf{x} = \int_D \int_{\mathbf{R}^n} \psi(\mathbf{x}, \eta) \, d\nu_{\mathbf{x}}(\eta) \, d\mathbf{x}, \tag{4.6}$$

and (1.26) follows since (4.3) implies that

$$\int_D \int_{\mathbf{R}^n} \psi(\mathbf{x}, \eta) \, d\nu_{\mathbf{x}}(\eta) \, d\mathbf{x} = \int_D \int_Q \psi(\mathbf{x}, P(\mathbf{z})\nabla u^H(\mathbf{x})) \, d\mathbf{z} \, d\mathbf{x}. \tag{4.7}$$

ON THE SEMIRELATIVISTIC HARTREE-TYPE EQUATION*

YONGGEUN CHO† AND TOHRU OZAWA†

Abstract. We study the global Cauchy problem and scattering problem for the semirelativistic Hartree-type equation in $\mathbb{R}^n$, $n \geq 1$, with nonlocal nonlinearity $F(u) = \lambda(|x|^{-\gamma} * |u|^2)u$, $0 < \gamma < n$. We prove the existence and uniqueness of global solutions for $0 < \gamma < \frac{2n}{n+1}$, $n \geq 2$ or $\gamma > 2$, $n \geq 3$, and the nonexistence of asymptotically-free solutions for $0 < \gamma \leq 1$, $n \geq 3$. We also specify asymptotic behavior of solutions as the mass tends to zero and infinity.

Key words. semirelativistic Hartree-type equation, global solution, scattering, nonexistence of asymptotically free solutions

1. Introduction.

In this paper we consider the following Cauchy problem:

$$\begin{cases} i\partial_t u = \sqrt{m^2 - \Delta}u + F(u) \ \text{ in } \ \mathbb{R}^n \times \mathbb{R}, \qquad n \geq 1, \\ u(x,0) = \varphi(x) \ \text{ in } \ \mathbb{R}^n, \end{cases} \tag{1.1}$$

where $m > 0$ denotes the mass of bosons in units $\hbar = c = 1$, $F(u)$ is a nonlinear functional of Hartree type such that $F(u) = (V_\gamma * |u|^2)u$, where $*$ denotes the convolution in $\mathbb{R}^n$, $V_\gamma(x) = \lambda|x|^{-\gamma}$ for some fixed constant $\lambda \in \mathbb{R}$, and $0 < \gamma < n$.

Equation (1.1) is called a semirelativistic Hartree equation which was used to describe Boson stars. See [8, 9, 20] and the references therein.

The purpose of this paper is to establish the local and global existence theory to (1.1) and the scattering theory of the global solutions. In this paper we study the Cauchy problem (1.1) in the form of the integral equation

$$u(t) = U(t)\varphi - i\int_0^t U(t-t')F(u)(t')dt', \tag{1.2}$$

where

$$U(t)\varphi(x) = (e^{-it\sqrt{m^2-\Delta}}\varphi)(x) = \frac{1}{(2\pi)^n}\int_{\mathbb{R}^n} e^{i(x\cdot\xi - t\sqrt{m^2+|\xi|^2})}\widehat{\varphi}(\xi)\,d\xi.$$

Here $\widehat{\varphi}$ denotes the Fourier transform of φ such that $\widehat{\varphi}(\xi) = \int_{\mathbb{R}^n} e^{-ix\cdot\xi}\varphi(x)\,dx$.

One of the key tools for the existence and scattering is the conservation law. If the solution u of (1.1) has sufficient decay at infinity and smoothness, it satisfies two conservation laws:

$$\begin{aligned} \|u(t)\|_{L^2} &= \|\varphi\|_{L^2}, \\ E(u) \equiv K_m(u) + V(u) &= E(\varphi), \end{aligned} \tag{1.3}$$

where $K_m(u) = \frac{1}{2}\langle\sqrt{m^2-\Delta}\,u, u\rangle$, $V(u) = \frac{1}{4}\langle F(u), u\rangle$, and $\langle,\rangle$ is the complex inner product in L^2. For actual proof of (1.3) a regularizing method is simply applicable, as in [21] in the case of $0 < \gamma \le 1$. For local solutions constructed by a contraction argument based on the Strichartz estimate stated below, the case of $1 < \gamma \le 2$ is treated by exactly the same method as in [29] without using approximate or a regularizing approach.

In section 2, local existence is shown for $0 < \gamma < n$ and $\varphi \in H^s$ with $s \ge \frac{\gamma}{2}$ by the Plancherel theorem and the standard contraction mapping theorem without resorting to a Strichartz estimate. Then we use the conservation laws to obtain the global existence for $s \ge \frac{1}{2}$, $0 < \gamma \le 1$, $n \ge 2$, and $0 < \gamma < 1$, $n = 1$. This result is an extension of the work of Lenzmann [21] in which global well-posedness is considered for a Coulomb-type potential in three space dimensions. From the energy conservation, we get a bound of a solution, which is uniform in the mass m on any finite time interval, if m is bounded from above, and then get a strong convergence of solutions of (1.1) to a solution of the equation without mass. However, if m is large, then the kinetic energy $K_m(u)$ is no longer bounded globally in time. Instead, we can get a uniform bound of local solutions in H^s, provided $s \ge \frac{\gamma}{2}$. Then after a phase modulation, we prove that the modulated solution is closely approximated by a solution of a Schrödinger equation of Hartree type if m is sufficiently large. This phenomenon can be interpreted as a kind of nonrelativistic limit and eventually as a semiclassical or vanishing dispersion limit. See Proposition 2.5 below.

The second tool is the Strichartz estimate. We consider the following Strichartz estimate for the unitary group $U(t)$ (see [22, 23]):

$$\begin{aligned} &\|U(t)\varphi\|_{L_T^{q_0}H_{r_0}^{s_0-\sigma_0}} \lesssim \|\varphi\|_{H^{s_0}}, \\ &\left\|\int_0^t U(t-t')f(t')\,dt'\right\|_{L_T^{q_1}H_{r_1}^{s_1-\sigma_1}} \lesssim \|f\|_{L_T^1 H^{s_1}}, \end{aligned} \tag{1.4}$$

where (q_i, r_i), $i = 0, 1$, satisfy that for any $\theta \in [0, 1]$

$$\begin{gathered} \frac{2}{q_i} = (n-1+\theta)\left(\frac{1}{2}-\frac{1}{r_i}\right), \quad 2\sigma_i = (n+1+\theta)\left(\frac{1}{2}-\frac{1}{r_i}\right), \\ 2 \le q_i, r_i \le \infty, \quad (q_i, r_i) \ne (2, \infty). \end{gathered} \tag{1.5}$$

We call the pair (q, r, σ) satisfying (1.5) the *admissible pair*. If $\theta = 0$, it is called wave admissible, and if $\theta = 1$, then it is called Schrödinger admissible. Here $H_r^s = (1-\Delta)^{-s/2}L^r$ is the usual Sobolev space, and $H^s = H_2^s$. Hereafter, we denote the space $L_T^q(B)$ by $L^q(0, T; B)$ and its norm by $\|\cdot\|_{L_T^q B}$ for some Banach space B, and also denote $L^q(B)$ with norm $\|\cdot\|_{L^q B}$ by $L^q(0, \infty; B)$, $1 \le q \le \infty$.

In section 3, we consider the global existence and scattering in the case when $0 < \gamma < n$. We first show the local existence for $0 < \gamma < n$, $n \ge 1$, and s slightly less than $\frac{\gamma}{2}$ by the Strichartz estimate of non–endpoint wave admissible pairs. Then we extend the local solution to the global one for $0 < \gamma < \frac{2n}{n+1}$ by the energy conservation and continuation procedure. The gain of upper bound $\frac{2n}{n+1}$ follows from the fact that the Sobolev exponent s can be made smaller than $\frac{\gamma}{2}$, which enables us to use the continuation procedure. Second, we get a small data global existence result and scattering for the case when $2 < \gamma < n$ and $n \ge 3$ by using the endpoint Strichartz estimate for the Schrödinger admissible pair.

In the last section, as the usual case of nonlinearity with long range potential, nonexistence of nontrivial asymptotically free solutions is shown for the cases

$0 < \gamma \le 1$, $n \ge 3$, and $0 < \gamma < \frac{n}{2}$, $n = 1, 2$, by a similar method applied to a large class of dispersive equations. See [2, 6, 14, 15, 24, 36].

Until now, it remains open to show the global existence for $\frac{2n}{n+1} \le \gamma \le 2$ as well as the scattering for $1 < \gamma \le 2$. For the blow-up result, we refer to [10] of Fröhlich and Lenzmann in which the finite time blow-up of radially symmetric solutions was shown in the case when $\gamma = 1$, $\lambda < 0$, $n = 3$, and $E(\varphi) < 0$.

There is a large literature on partial differential equations with Hartree-type nonlinearity. We refer the reader to [5, 11, 12, 16, 17, 18, 28, 26, 27] for Schrödinger-related equations and, to [1, 25, 31, 32, 35, 34, 37] for Klein–Gordon-related equations in both massive and massless cases.

If not specified, throughout this paper the notation $A \lesssim B$ and $A \gtrsim B$ denote $A \le CB$ and $A \ge C^{-1}B$, respectively. Different positive constants possibly depending on n, m, λ, and γ might be denoted by the same letter C. $A \sim B$ means that both $A \lesssim B$ and $A \gtrsim B$ hold.

2. Global existence I. In this section, we study the global existence and the limiting problem as $m \to 0$ or as $m \to \infty$ with $0 < \gamma \le 1$.

Let us first introduce the following local existence result.

PROPOSITION 2.1. *Let $0 < \gamma < n$ and $n \ge 1$. Suppose $\varphi \in H^s(\mathbb{R}^n)$ with $s \ge \frac{\gamma}{2}$. Then there exists a positive time T independent of m such that (1.2) has a unique solution $u \in C([0,T]; H^s)$ with $\|u\|_{L^\infty_T H^s} \le C\|\varphi\|_{H^s}$, where C does not depend on m.*

Proof. Let $(X^s_{T,\rho}, d)$ be a complete metric space with metric d defined by

$$X^s_{T,\rho} = \{u \in L^\infty_T(H^s(\mathbb{R}^n)) : \ \|u\|_{L^\infty_T H^s} \le \rho\}, \ \ d(u,v) = \|u - v\|_{L^\infty_T L^2}.$$

Now we define a mapping $N : u \mapsto N(u)$ on $X^s_{T,\rho}$ by

$$N(u)(t) = U(t)\varphi - i\int_0^t U(t-t')F(u)(t')\,dt'. \tag{2.1}$$

Our strategy is to use the standard contraction mapping argument. To do so, let us introduce a generalized Leibniz rule (see Lemmas A1–A4 in the appendix of [19]).

LEMMA 2.2. *For any $s \ge 0$ we have*

$$\|D^s(uv)\|_{L^r} \lesssim \|D^s u\|_{L^{r_1}}\|v\|_{L^{q_2}} + \|u\|_{L^{q_1}}\|D^s v\|_{L^{r_2}},$$

where $D^s = (-\Delta)^{s/2}$

and $\dfrac{1}{r} = \dfrac{1}{r_1} + \dfrac{1}{q_2} = \dfrac{1}{q_1} + \dfrac{1}{r_2}, \quad r_i \in (1,\infty),\ q_i \in (1,\infty], \quad i = 1,2.$

Then for all $u \in X(T,\rho)$ we have

$$\begin{aligned}
\|N(u)\|_{L^\infty_T H^s} &\le \|\varphi\|_{H^s} + T\|F(u)\|_{L^\infty_T H^s} \\
&\lesssim \|\varphi\|_{H^s} + T\Big(\|I_{n-\gamma}(|u|^2)\|_{L^\infty_T L^\infty}\|u\|_{L^\infty_T H^s} \\
&\qquad\qquad + \|I_{n-\gamma}(|u|^2)\|_{L^\infty_T H^s_{\frac{2n}{\gamma}}}\|u\|_{L^\infty_T L^{\frac{2n}{n-\gamma}}}\Big) \\
&\lesssim \|\varphi\|_{H^s} + T\left(\|u\|^2_{L^\infty_T H^{\frac{\gamma}{2}}}\|u\|_{L^\infty_T H^s} + \|u\|^2_{L^\infty_T L^{\frac{2n}{n-\gamma}}}\|u\|_{L^\infty_T H^s}\right) \\
&\lesssim \|\varphi\|_{H^s} + T\|u\|^2_{L^\infty_T H^{\frac{\gamma}{2}}}\|u\|_{L^\infty_T H^s} \lesssim \|\varphi\|_{H^s} + T\rho^3,
\end{aligned} \tag{2.2}$$

where I_α is the fractional integral operator given by $I_\alpha(v)(x) = \int_{\mathbb{R}^n} |x-y|^{\alpha-n} v(y)\,dy$. It is well known that I_α satisfies the inequality (see [33], for instance)

$$\|I_\alpha(\psi)\|_{L^q} \lesssim \|\psi\|_{L^p},\ \frac{1}{q} = \frac{1}{p} - \frac{\alpha}{n}, 1 < p < q < \infty.$$

For the third inequality we used the fractional integral inequality, generalized Leibniz rule (Lemma 2.2), and the fact that

$$\sup_{x\in\mathbb{R}^n} \left| \int_{\mathbb{R}^n} \frac{|u(x-y)|^2}{|y|^\gamma}\,dy \right| \lesssim \|u\|^2_{\dot{H}^{\frac{\gamma}{2}}}. \tag{2.3}$$

For the last one, we used the Sobolev embedding $H^{\frac{\gamma}{2}} \hookrightarrow L^{\frac{2n}{n-\gamma}}$.

If we choose ρ and T such that $\|\varphi\|_{H^s} \le \rho/2$ and $CT\rho^3 \le \rho/2$, then N maps $X^s_{T,\rho}$ to itself.

Now we have only to show that N is a Lipschitz map for sufficiently small T. Let $u, v \in X^s_{T,\rho}$. Then we have

$$\begin{aligned}
&d(N(u), N(v)) \\
&\quad\lesssim T \left\| I_{n-\gamma}(|u|^2)u - I_{n-\gamma}(|v|^2)v \right\|_{L^\infty_T L^2} \\
&\quad\lesssim T \left(\left\| I_{n-\gamma}(|u|^2)(u-v) \right\|_{L^\infty_T L^2} + \left\| I_{n-\gamma}(|u|^2 - |v|^2)v \right\|_{L^\infty_T L^2} \right) \\
&\quad\lesssim T \left(\|u\|^2_{L^\infty_T H^{\frac{\gamma}{2}}} d(u,v) + \|I_{n-\gamma}(|u|^2 - |v|^2)\|_{L^\infty_T L^{\frac{2n}{\gamma}}} \|v\|_{L^\infty_T L^{\frac{2n}{n-\gamma}}} \right) \\
&\quad\lesssim T \left(\rho^2 d(u,v) + \rho \| |u|^2 - |v|^2 \|_{L^\infty_T L^{\frac{2n}{2n-\gamma}}} \right) \\
&\quad\lesssim T \left(\rho^2 + \rho \left(\|u\|_{L^\infty_T L^{\frac{2n}{n-\gamma}}} + \|v\|_{L^\infty_T L^{\frac{2n}{n-\gamma}}} \right) \right) d(u,v) \\
&\quad\lesssim T\rho^2 d(u,v).
\end{aligned}$$

The above estimate implies that the mapping N is a contraction if T is sufficiently small.

The uniqueness and time continuity follows easily from (1.2) and the contraction argument. This completes the proof of the proposition. □

From the conservation laws (1.3), we get the following global well-posedness.

THEOREM 2.3. *Let $0 < \gamma \le 1$ for $n \ge 2$, $0 < \gamma < 1$ for $n = 1$, and $s \ge \frac{1}{2}$. Let T^* be the maximal existence time of the solution u as in Theorem 2.1. Then if $\lambda \ge 0$, or if $\lambda < 0$ and $\|\varphi\|_{L^2}$ is sufficiently small, then $T^* = \infty$. Moreover, $\|u(t)\|_{H^s} \le C\|\varphi\|_{H^s} e^{C(|E(\varphi)| + \|\varphi\|^2_{L^2})t}$, where C does not depend on m.*

Proof. From the estimate (2.3) and L^2 conservation, we have

$$|V(u)| \lesssim \|u\|^2_{\dot{H}^{\frac{\gamma}{2}}} \|u\|^2_{L^2} \lesssim \|u\|^{2\gamma}_{\dot{H}^{\frac{1}{2}}} \|\varphi\|^{4-2\gamma}_{L^2}. \tag{2.4}$$

Hence if $\lambda \ge 0$ or if $\lambda < 0$ and $\|\varphi\|_{L^2}$ is sufficiently small, then

$$\|u(t)\|^2_{\dot{H}^{\frac{\gamma}{2}}} \le C(|E(u)| + \|\varphi\|^2_{L^2}) = C(|E(\varphi)| + \|\varphi\|^2_{L^2}). \tag{2.5}$$

From (2.5) and a similar estimate to (2.2), we have

$$\begin{aligned}\|u(t)\|_{H^s} &\lesssim \|\varphi\|_{H^s} + \int_0^t \|u\|_{H^{\frac{\gamma}{2}}}^2 \|u\|_{H^s}\, dt' \\ &\lesssim \|\varphi\|_{H^s} + (|E(\varphi)| + \|\varphi\|_{L^2}^2) \int_0^t \|u\|_{H^s}\, dt'.\end{aligned}$$

Gronwall's inequality shows that

$$\|u(t)\|_{H^s} \le C\|\varphi\|_{H^s} \exp(C(|E(\varphi)| + \|\varphi\|_{L^2}^2)t).$$

This completes the proof. □

REMARK 1. *If $\lambda < 0$, $0 < \gamma < 2$, and $n \ge 2$, then*

$$\begin{aligned}|V(u)| &\lesssim \|V_\gamma * |u|^2\|_{L^n} \|u\|_{L^{\frac{2n}{n-1}}}^2 \lesssim \|u\|_{L^{\frac{2n}{n-\gamma+1}}}^2 \|u\|_{L^{\frac{2n}{n-1}}}^2 \\ &\lesssim \|u\|_{L^2}^\theta \|u\|_{L^{\frac{2n}{n-1}}}^{4-\theta} = \|\varphi\|_{L^2}^\theta \|u\|_{\dot H^{\frac12}}^{4-\theta}\end{aligned}$$

for some small positive number $\theta < 2$. Hence

$$E(u) \ge K_m(u) - |V(u)| \ge \frac{m}{2}\|\varphi\|_{L^2}^2 + \frac12 \|u\|_{\dot H^{\frac12}}^2 - C\|\varphi\|_{L^2}^\theta \|u\|_{\dot H^{\frac12}}^{4-\theta}.$$

Thus we can always make $E(u)$ strictly positive, provided $\|\varphi\|_{L^2}$ is sufficiently small, and with smaller $\|\varphi\|_{L^2}$ than in Theorem 2.3, *$|E(\varphi)|$ is changed by $E(\varphi)$. Using* (2.4), *the same argument holds for $n = 1$.*

If m is bounded above, then the energy $E(\varphi)$ is also bounded, and hence the H^s norm of solution u is bounded in a finite time interval uniformly on small m. This enables us to treat a limit problem as $m \to 0$. We have the following. See [1] for related second-order equations.

PROPOSITION 2.4. *If $u_m \in (C \cap L^\infty)(H^s)$ is the global solution of* (1.2) *satisfying the same condition as in Theorem* 2.3, *then for any finite time T, $u_m \to u_0$ in $L_T^\infty(H^s)$ with $s \ge \frac12$ as $m \to 0$, where u_0 is the global solution to the Cauchy problem*

$$i\partial_t u_0 = \sqrt{-\Delta} u_0 + F(u_0), \quad u_0(x,0) = \varphi(x) \in H^s. \tag{2.6}$$

Proof. One can easily show the global existence of (2.6) by the same argument as in the proof of Theorem 2.3. The solution u_0 can be written as

$$u_0(t) = U_0(t)\varphi - i\int_0^t U_0(t-t')F(u_0)(t')\, dt',$$

where $U_0(t) = e^{-it\sqrt{-\Delta}}$.

For any $T > 0$ there exists M such that $\sup_{0<m\le 1}(\|u_m\|_{L_T^\infty H^s} + \|u_0\|_{L_T^\infty H^s}) \le M$. Then observing that for any $t \in [0,T]$

$$\begin{aligned}\|(U(t) - U_0(t))\varphi\|_{H^s} &\le \||1 - e^{it(\sqrt{m^2+|\xi|^2}-|\xi|)}|(1+|\xi|^2)^{\frac{s}{2}}|\widehat{\varphi}|\|_{L^2} \\ &\le t\||\sqrt{m^2+|\xi|^2} - |\xi||(1+|\xi|^2)^{\frac{s}{2}}|\widehat{\varphi}|\|_{L^2} \\ &\le tm\|\varphi\|_{H^s},\end{aligned}$$

we have that

$$
\begin{aligned}
&\|u_m(t)-u_0(t)\|_{H^s}\\
&\le \|(U(t)-U_0(t))\varphi\|_{H^s}\\
&\qquad + \int_0^t \left(\|F(u_m)-F(u_0)\|_{H^s} + \|(U(t-t')-U_0(t-t'))F(u_0)\|_{H^s}\right)\,dt'\\
&\lesssim Tm\|\varphi\|_{H^s} + \int_0^t \|I_{n-\gamma}(|u_m|^2-|u_0|^2)u_m\|_{H^s}\,dt'\\
&\qquad + \int_0^t \|I_{n-\gamma}(|u_0|^2)(u_m-u_0)\|_{H^s})\,dt' + mT\int_0^t \|F(u_0)\|_{H^s}\,dt'.
\end{aligned}
\tag{2.7}
$$

From Lemma 2.2, fractional integration, and the estimate (2.3), it follows that

$$
\begin{aligned}
&\|I_{n-\gamma}(|u_m|^2-|u_0|^2)u_m\|_{H^s}\\
&\lesssim \|I_{n-\gamma}(|u_m|^2-|u_0|^2)\|_{L^\infty}\|u_m\|_{H^s} + \|I_{n-\gamma}(|u_m|^2-|u_0|^2)\|_{H^s_{\frac{2n}{\gamma}}}\|u_m\|_{L^{\frac{2n}{n-\gamma}}}\\
&\lesssim \|u_m-u_0\|_{H^{\frac{\gamma}{2}}}(\|u_m\|_{H^{\frac{\gamma}{2}}}+\|u_0\|_{H^{\frac{\gamma}{2}}})\|u_m\|_{H^s}\\
&\qquad + \||u_m|^2-|u_0|^2\|_{L^{\frac{2n}{2n-\gamma}}}\|u_m\|_{H^{\frac{\gamma}{2}}}\\
&\lesssim M^2\|u_m-u_0\|_{H^s}
\end{aligned}
$$

and similarly that

$$
\begin{aligned}
&\|I_{n-\gamma}(|u_0|^2)(u_m-u_0)\|_{H^s}\\
&\lesssim \|u_0\|^2_{H^{\frac{\gamma}{2}}}\|u_m-u_0\|_{H^s} + \|I_{n-\gamma}(|u_0|^2)\|_{H^s_{\frac{2n}{\gamma}}}\|u_m-u_0\|_{L^{\frac{2n}{n-\gamma}}}\\
&\lesssim M^2\|u_m-u_0\|_{H^s}.
\end{aligned}
$$

Substituting these into (2.7), we have for any $t\in[0,T]$ that

$$
\|u_m(t)-u_0(t)\|_{H^s} \lesssim MTm + M^3mT^2 + M^2\int_0^t \|u_m(t')-u_0(t')\|_{H^s}\,dt'.
$$

Then Gronwall's inequality implies the strong convergence $u_m\to u_0$ in $L^\infty_T(H^s)$. ∎

In the case of large mass, the situation is different. Since $E(u)=E(\varphi)=\frac{1}{2}\langle\sqrt{m^2-\Delta}\varphi,\varphi\rangle+V(\varphi)$ diverges as $m\to\infty$, it is difficult to obtain the uniform bound for $\|u\|_{H^{\frac{1}{2}}}$ from the energy conservation law. However, from Proposition 2.1 we see that the local existence time T and the constant C can be chosen independently of the mass m if $s\ge\frac{\gamma}{2}$. To be more specific, we have $\|u_m(t)\|_{H^s}\le C\|\varphi\|_{H^s}$, where u_m is the solution of the equation with mass m. Now using the phase modulation $v_m=e^{imt}u_m$, the function v_m satisfies the equation

$$
i\partial_t v_m = (\sqrt{m^2-\Delta}-m)v_m + F(v_m),\quad v_m(0)=\varphi,
$$

and equivalently

$$
v_m(t) = U_m(t)\varphi - i\int_0^t U_m(t-t')F(v_m)(t')\,dt',
\tag{2.8}
$$

where $U_m(t)=e^{-it(\sqrt{m^2-\Delta}-m)}$. Let $\widetilde{U}_m$ be the unitary group $e^{it\frac{1}{2m}\Delta}$. As was first observed by Segal [32] at a formal level, we expect that the linear solutions $U_m\varphi$

and $\widetilde{U}_m\varphi$ become very close in the $L^\infty_T(H^s)$ norm if T is finite and $\varphi \in H^s$. That observation is in fact justified by

$$\begin{aligned}
&\|(U_m(t) - \widetilde{U}_m(t))\varphi\|^2_{L^\infty_T H^s} \\
&\quad \le \sup_{0<t<T} \int_{|\xi|\le\sqrt{m}} \left|1 - e^{it(\sqrt{m^2+|\xi|^2}-m-\frac{|\xi|^2}{2m})}\right|^2 (1+|\xi|)^{2s}|\widehat{\varphi}|^2\,d\xi \\
&\qquad + 2\int_{|\xi|\ge\sqrt{m}} (1+|\xi|)^{2s}|\widehat{\varphi}|^2\,d\xi \\
&\quad \le T\int \left|2m/(\sqrt{m^2+|\xi|^2}+m) - 1\right|^2 (1+|\xi|)^{2s}|\widehat{\varphi}|^2\,d\xi \\
&\qquad + 2\int_{|\xi|\ge\sqrt{m}} (1+|\xi|)^{2s}|\widehat{\varphi}|^2\,d\xi \\
&\quad \to 0 \ \text{ as } \ m\to\infty.
\end{aligned}$$

Hence we can expect that v_m is very close to a function w_m in $L^\infty_T(H^s)$, where w_m is a solution of the nonlinear Schrödinger equation:

$$i\partial_t w_m = -\frac{1}{2m}\Delta w_m + F(w_m), \ \ w_m(0) = \varphi. \tag{2.9}$$

Of course, by the same argument as the proof of Proposition 2.1, we find T and C independently of m and a unique solution $w_m \in C([0,T];H^s)$ of (2.9) for $s \ge \frac{\gamma}{2}$ such that $\|w_m\|_{L^\infty_T H^s} \le C\|\varphi\|_{H^s}$.

Now let $T^*_{v_m}$ and $T^*_{w_m}$ be the maximal existence times of the solutions u_m and w_m, respectively. Then from the local existence result (Proposition 2.1) we deduce that $T^* \equiv \inf_{m>1}\min(T^*_{v_m}, T^*_{w_m})$ is strictly positive and has the following.

PROPOSITION 2.5. *If $s \ge \frac{\gamma}{2}$ and $T < T^*$, then $v_m - w_m \to 0$ in $L^\infty_T(H^s)$ as $m\to\infty$.*

Proof. First we consider the integral equation

$$u_\infty = \varphi - i\int_0^t F(u_\infty)\,dt',$$

which is equivalent to the ordinary differential equation $i\partial_t u_\infty = F(u_\infty)$, $u_\infty(x,0) = \varphi$. This equation has an exact solution $u_\infty(x,t) = \varphi(x)e^{-i\lambda t(|\cdot|^{-\gamma} * |\varphi|^2)(x)}$ for any $t \ge 0$. If $s \ge \frac{\gamma}{2}$, then the uniqueness of u_∞ is guaranteed.

To prove $v_m - w_m \to 0$ in $L^\infty_T(H^s)$, we have only to prove that $v_m - u_\infty \to 0$ in $L^\infty_T(H^s)$ and $w_m - u_\infty \to 0$ in $L^\infty_T(H^s)$. At first we have

$$\begin{aligned}
&\|v_m(t) - u_\infty(t)\|_{H^s} \\
&\le \|\,(U_m(t)-1)\,\varphi\|_{H^s} + \int_0^t \|(U_m(t-t')-1)F(u_\infty)\|_{H^s}\,dt' \\
&\qquad\qquad + \int_0^t \|F(v_m) - F(u_\infty)\|_{L^\infty}\,dt'
\end{aligned}$$

and

$$\begin{aligned}
&\|\,(U_m(t)-1)\,\varphi\|_{H^s}^2\\
&=\int\left|e^{-it(\sqrt{m^2+|\xi|^2}-m)}-1\right|^2|\widehat{\varphi}(\xi)|^2\,d\xi\\
&=\int_{|\xi|\le m^{\frac14}}+\int_{|\xi|>m^{\frac14}}\\
&\le\int_{|\xi|\le m^{\frac14}}\frac{t^2|\xi|^4}{(\sqrt{m^2+|\xi|^2}+m)^2}(1+|\xi|)^{2s}|\widehat{\varphi}(\xi)|^2\,d\xi+4\int_{|\xi|>m^{\frac14}}(1+|\xi|)^{2s}|\widehat{\varphi}(\xi)|^2\,d\xi\\
&=\frac{T^2}{4m}\|\varphi\|_{H^s}^2+4\int_{|\xi|>m^{\frac14}}(1+|\xi|)^{2s}|\widehat{\varphi}(\xi)|^2\,d\xi\\
&\to 0\ \text{ as }\ m\to\infty.
\end{aligned}$$

We take $M=M(T)$ such that $\sup_{m\ge1}(\|v_m\|_{L_T^\infty H^s}+\|w_m\|_{L_T^\infty H^s}+\|u_\infty\|_{L_T^\infty H^s})\le M$. Then since $F(u_\infty)\in L_T^\infty(H^s)$, we have

$$\int_0^T\|(U_m(t-t')-1)F(u_\infty)\|_{H^s}\,dt'\to0\ \text{ as }\ m\to\infty.$$

We also have

$$\|F(v_m)-F(u_\infty)\|_{H^s}\le CM^2\|v_m-u_\infty\|_{H^s}.$$

Thus

$$\|v_m(t)-u_\infty(t)\|_{H^s}\le o(1)+CM^2\int_0^t\|v_m-u_\infty\|_{H^s}\,dt',\tag{2.10}$$

and as for w_m, by the same argument as that of v_m

$$\|w_m(t)-u_\infty(t)\|_{H^s}\le o(1)+CM^2\int_0^t\|w_m-u_\infty\|_{H^s}\,dt'.\tag{2.11}$$

Therefore Gronwall's inequality yields the claim. □

3. Global existence II. In this section, we re-examine the existence result and get a slightly lower regularity by using the Strichartz estimate. The first result is the following local existence for $0<\gamma<n$.

PROPOSITION 3.1. *Let $0<\gamma<n$ and $n\ge2$. Then there is a number α with $0<\alpha<\min(\gamma,\frac{2n}{n+1})$ satisfying that given $s>\frac{\gamma}{2}-\frac{(n-1)\alpha}{4n}$ and $\varphi\in H^s$ there exists a positive time T such that (1.2) has a unique solution $u\in C([0,T];H^s)\cap L_T^q(H_r^{s-\sigma})$, where $q=\frac{4n}{(n-1)\alpha}$, $r=\frac{2n}{n-\alpha}$, and $\sigma=\frac{(n+1)\alpha}{4n}$.*

Proof. Given n and γ, choose a number α with $0<\alpha<\min(\gamma,\frac{2n}{n-1})$ and fix $s>\frac{\gamma}{2}-\frac{(n-1)\alpha}{4n}$. Then for some positive number T to be chosen later, let us define a complete metric space $(Y_{T,\rho}^s,d_T)$ with metric d_T by

$$\begin{aligned}
&Y_{T,\rho}^s=\left\{v\in L_T^\infty(H^s)\cap L_T^q(H_r^{s-\sigma}):\|v\|_{L_T^\infty H^s}+\|v\|_{L_T^qH_r^{s-\sigma}}\le\rho\right\},\\
&d_T(u,v)=\|u-v\|_{L_T^\infty H^s\cap L_T^qH_r^{s-\sigma}},
\end{aligned}$$

where q, r, σ are the same indices as in Proposition 3.1.

From now on, we will prove that the nonlinear mapping N defined as (2.1) is a contraction on $Y^s_{T,\rho}$, provided T is sufficiently small. We will use the following lemma instead of (2.3), which follows by estimating the (fractional) integral inside and outside the ball with radius $R > 0$ separately by Hölder's inequality and by minimizing the resulting estimates with respect to R.

LEMMA 3.2. *Let $0 < \gamma < n$. Then for any $0 < \varepsilon < n - \gamma$ we have*

$$\big\|I_{n-\gamma}(|u|^2)\big\|_{L^\infty} \lesssim \|u\|_{L^{\frac{2n}{n-\gamma-\varepsilon}}} \|u\|_{L^{\frac{2n}{n-\gamma+\varepsilon}}}.$$

If we take $\theta = 0$ in the Strichartz estimate (1.4), then the pair $(q, r, \sigma) = (\frac{4n}{(n-1)\alpha}, \frac{2n}{n-\alpha}, \frac{(n+1)\alpha}{4n})$ becomes an admissible one. Hence the Strichartz estimate together with the Plancherel theorem, Lemma 3.2, and generalized Leibniz rules (Lemma 2.2), enables us to deduce that for sufficiently small ε

$$\begin{aligned}
&\|N(u)\|_{L^\infty_T H^s \cap L^q_T H^{s-\sigma}_r} \\
&\quad\lesssim \|\varphi\|_{H^s} + \|F(u)\|_{L^1_T H^s} \\
&\quad\lesssim \|\varphi\|_{H^s} + \|I_{n-\gamma}(|u|^2)\|_{L^1_T L^\infty} \|u\|_{L^\infty_T H^s} \\
&\qquad\qquad + \int_0^T \|I_{n-\gamma}(|u|^2)\|_{H^s_{\frac{2n}{\gamma+\varepsilon}}} \|u\|_{L^{\frac{2n}{n-(\gamma+\varepsilon)}}} \, dt \\
&\quad\lesssim \|\varphi\|_{H^s} + \|u\|_{L^2_T L^{\frac{2n}{n-(\gamma+\varepsilon)}}} \|u\|_{L^2_T L^{\frac{2n}{n-(\gamma-\varepsilon)}}} \|u\|_{L^\infty_T H^s} \\
&\qquad\qquad + \int_0^T \||u|^2\|_{H^s_{\frac{2n}{2n-(\gamma-\varepsilon)}}} \|u\|_{L^{\frac{2n}{n-(\gamma+\varepsilon)}}} \, dt \\
&\quad\lesssim \|\varphi\|_{H^s} + \|u\|_{L^2_T L^{\frac{2n}{n-(\gamma+\varepsilon)}}} \|u\|_{L^2_T L^{\frac{2n}{n-(\gamma-\varepsilon)}}} \|u\|_{L^\infty_T H^s}.
\end{aligned} \tag{3.1}$$

Using Hölder's inequality for time integral, we have

$$\begin{aligned}
&\|N(u)\|_{L^\infty_T H^s \cap L^q_T H^{s-\sigma}_r} \\
&\quad\lesssim \|\varphi\|_{H^s} + T^{1-\frac{2}{q}} \|u\|_{L^q_T L^{\frac{2n}{n-(\gamma+\varepsilon)}}} \|u\|_{L^q_T L^{\frac{2n}{n-(\gamma-\varepsilon)}}} \|u\|_{L^\infty_T H^s}.
\end{aligned} \tag{3.2}$$

Now if we choose $\varepsilon > 0$ so small that $\varepsilon < \min(\gamma - \alpha, 2(s + \frac{(n-1)\alpha}{4n}) - \gamma)$, then since

$$\frac{2n}{n-\alpha} \le \frac{2n}{n-(\gamma-\varepsilon)} < \frac{2n}{n-(\gamma+\varepsilon)} \le \frac{2n}{n-\alpha-2(s-\sigma)},$$

we have from (3.2) and the Sobolev embedding $H^{s-\sigma}_r \hookrightarrow L^r \cap L^{\frac{2n}{n-\alpha-2(s-\sigma)}}$ that

$$\begin{aligned}
\|N(u)\|_{L^\infty_T H^s \cap L^q_T H^{s-\sigma}_r} &\le C(\|\varphi\|_{H^s} + T^{1-\frac{2}{q}} \|u\|_{L^\infty_T H^s} \|u\|^2_{L^q_T H^{s-\sigma}_r}) \\
&\le C(\|\varphi\|_{H^s} + T^{1-\frac{2}{q}} \rho^3)
\end{aligned}$$

for some constant C. Here we used the conventional embedding that if $2(s-\sigma) \ge n-\alpha$, then $H^{s-\sigma}_r \hookrightarrow L^{r_1}$ for any $r_1 \ge r$. Thus if we choose ρ and T so that $C\|\varphi\|_{H^s} \le \frac{\rho}{2}$ and $CT^{1-\frac{2}{q}}\rho^3 \le \frac{\rho}{2}$, then we conclude that N maps from $Y^s_{T,\rho}$ to itself.

For any $u, v \in Y^s_{T,\rho}$, we have

$$\begin{aligned}
d_T(N(u), N(v)) &\lesssim \|F(u) - F(v)\|_{L^1_T H^s} \\
&\lesssim \|I_{n-\gamma}(|u|^2 - |v|^2)u\|_{L^1_T H^s} + \|I_{n-\gamma}(|v|^2)(u-v)\|_{L^1_T H^s}.
\end{aligned} \tag{3.3}$$

By Lemma 3.2 and Hölder's inequality, we have for sufficiently small $\varepsilon > 0$

$$
\begin{aligned}
&\|I_{n-\gamma}(|u|^2-|v|^2)u\|_{L_T^1 H^s} \\
&\quad\lesssim \|I_{n-\gamma}(|u|^2-|v|^2)\|_{L_T^2 L^\infty}\|u\|_{L_T^\infty H^s} \\
&\qquad\quad + \|I_{n-\gamma}(|u|^2-|v|^2)\|_{L_T^2 H^s_{\frac{2n}{\gamma+\varepsilon}}}\|u\|_{L_T^2 L^{\frac{2n}{n-(\gamma+\varepsilon)}}} \\
&\quad\lesssim \rho\||u|^2-|v|^2\|^{\frac12}_{L_T^1 L^{\frac{n}{n-(\gamma+\varepsilon)}}}\||u|^2-|v|^2\|^{\frac12}_{L_T^1 L^{\frac{n}{n-(\gamma-\varepsilon)}}} \\
&\qquad + \rho\|u-v\|_{L_T^\infty H^s}\left(\|u\|_{L_T^2 L^{\frac{2n}{n-(\gamma-\varepsilon)}}}+\|v\|_{L_T^2 L^{\frac{2n}{n-(\gamma-\varepsilon)}}}\right) \\
&\qquad + \rho\|u-v\|_{L_T^2 L^{\frac{2n}{n-(\gamma-\varepsilon)}}}(\|u\|_{L_T^\infty H^s}+\|v\|_{L_T^\infty H^s}).
\end{aligned}
\tag{3.4}
$$

Now by another Hölder's inequality with respect to the time variable, we have

$$
\|I_{n-\gamma}(|u|^2-|v|^2)u\|_{L_T^1 H^s} \lesssim T^{1-\frac{2}{q}}\rho^2 d_T(u,v).
$$

Similarly,

$$
\begin{aligned}
&\|I_{n-\gamma}(|v|^2)(u-v)\|_{L_T^1 H^s} \\
&\lesssim \|I_{n-\gamma}(|v|^2)\|_{L_T^1 L^\infty}\|u-v\|_{L_T^\infty H^s} + \|I_{n-\gamma}(|v|^2)\|_{L_T^2 L^{\frac{2n}{\gamma+\varepsilon}}}\|u-v\|_{L_T^2 L^{\frac{2n}{n-(\gamma+\varepsilon)}}} \\
&\lesssim \|v\|_{L_T^2 L^{\frac{2n}{n-(\gamma-\varepsilon)}}}\|v\|_{L_T^2 L^{\frac{2n}{n-(\gamma+\varepsilon)}}} d_T(u,v) \\
&\quad + \|v\|_{L_T^\infty H^s}\|v\|_{L_T^2 L^{\frac{2n}{n-(\gamma-\varepsilon)}}}\|u-v\|_{L_T^2 L^{\frac{2n}{n-(\gamma+\varepsilon)}}}.
\end{aligned}
\tag{3.5}
$$

Hence we get

$$
\|I_{n-\gamma}(|v|^2)(u-v)\|_{L_T^1 H^s} \lesssim T^{1-\frac{2}{q}}\rho^2 d_T(u,v).
$$

Substituting these two estimates into (3.3) and then using the fact that $CT^{1-\frac{2}{q}}\rho^2 \le \frac12$ for small T, we conclude that N is a contraction mapping. ∎

REMARK 2. *If we follow the proof above with the Schrödinger admissible pairs, we conclude that Proposition* 3.1 *holds for* $n \ge 3$, $0 < \alpha < \gamma$, $\alpha \le 2$, $s > \frac{\gamma}{2} - \frac{n-2}{4n}\alpha$, $q = \frac{4}{\alpha}$, $r = \frac{2n}{n-\alpha}$, *and* $\sigma = \frac{(n+2)\alpha}{4n}$.

Now we show that the local solutions can be extended globally in time by using the energy conservation law.

THEOREM 3.3. *Let* $0 < \gamma < \frac{2n}{n+1}$, $n \ge 2$. *Then there exists an* α *with* $0 < \alpha < \gamma$ *such that if* $\varphi \in H^{\frac12}$ *and if* $\lambda > 0$, *or* $\lambda < 0$ *but* $\|\varphi\|_{L^2}$ *is sufficiently small, then* (1.2) *has a unique solution* $u \in C([0,\infty); H^{\frac12}) \cap L^q_{loc}(H_r^{\frac12-\sigma})$, *where* $q = \frac{4n}{(n-1)\alpha}$, $r = \frac{2n}{n-\alpha}$, *and* $\sigma = \frac{(n+1)\alpha}{4n}$.

Proof. Let T^* be the maximal existence time. We will prove that T^* is infinite by contradiction. Suppose that $T^* < \infty$. Then the local theory shows that $\|u\|_{L^q_{T^*} H_r^{\frac12-\sigma}} = \infty$. Since $\gamma < 2$, from the local existence proposition, Proposition 3.1, we see that the energy conservation law (1.3) holds. Thus at any $t < T^*$, the solution u satisfies that for $\lambda > 0$

$$
\frac12\|u(t)\|^2_{H^{\frac12}} \le \frac12\|u(t)\|^2_{L^2} + E(u) = \frac12\|\varphi\|^2_{L^2} + E(\varphi)
$$

and for $\lambda < 0$

$$\begin{aligned}\frac{1}{2}\|u(t)\|^2_{H^{\frac{1}{2}}} &\le \frac{1}{2}\|u(t)\|^2_{L^2} + |E(u)| + |V(u)| \\ &\le \frac{1}{2}\|\varphi\|^2_{L^2} + |E(\varphi)| + C\|u\|^2_{L^{\frac{2n}{n-\gamma+1}}}\|u\|^2_{H^{\frac{1}{2}}} \\ &\le \frac{1}{2}\|\varphi\|^2_{L^2} + |E(\varphi)| + C\|u\|^{2-\gamma}_{L^2}\|u\|^{1+\gamma}_{H^{\frac{1}{2}}} \\ &= \frac{1}{2}\|\varphi\|^2_{L^2} + |E(\varphi)| + C\|\varphi\|^{2-\gamma}_{L^2}\|u\|^{1+\gamma}_{H^{\frac{1}{2}}}.\end{aligned}$$

Hence by Young's inequality and the smallness of $\|\varphi\|_{L^2}$

$$\|u(t)\|^2_{H^{\frac{1}{2}}} \le C(\|\varphi\|^2_{L^2} + |E(\varphi)|). \tag{3.6}$$

From the estimates (3.6) and (3.2), which are used with $s = \frac{1}{2}$, we have

$$\|u\|_{L^q_T H^{\frac{1}{2}-\sigma}_r} \lesssim \|\varphi\|^2_{L^2} + |E(\varphi)| + T^{1-\frac{2}{q}}(\|\varphi\|^2_{L^2} + |E(\varphi)|)^{\frac{1}{2}}\|u\|^2_{L^q_T H^{\frac{1}{2}-\sigma}_r}.$$

Thus for sufficiently small T depending on $\|\varphi\|^2_{L^2} + |E(\varphi)|$,

$$\|u\|_{L^q(T_{j-1},T_j;H^{\frac{1}{2}-\sigma}_r)} \le C(\|\varphi\|^2_{L^2} + |E(\varphi)|),$$

where $T_j - T_{j-1} = T$ for $j \le k-1$ and $T_k = T^*$. This means that

$$\|u\|^q_{L^q(0,T^*;H^{\frac{1}{2}-\sigma}_r)} \le \sum_{1\le j\le k}\|u\|^q_{L^q(T_{j-1},T_j;H^{\frac{1}{2}-\sigma}_r)} \le (kC(\|\varphi\|^2_{L^2} + |E(\varphi)|))^q < \infty.$$

This is the contradiction to the hypothesis $T^* < \infty$.

The condition $\gamma < \frac{2n}{n+1}$ is necessary for the existence of α satisfying $s = \frac{1}{2} > \frac{\gamma}{2} - \frac{(n-1)\alpha}{4n}$, and $\alpha < \gamma$. This completes the proof. □

REMARK 3. *If we choose $\theta = 1$, then we deduce the same result as in Theorem* 3.3 *with $0 < \gamma < \frac{2n}{n+2}$, $q = \frac{4}{\alpha}$, $r = \frac{2n}{n-\alpha}$, and $\sigma = \frac{(n+2)\alpha}{4n}$.*

Now we consider the small data global existence and scattering for $2 < \gamma < n$.

THEOREM 3.4. *Let $2 < \gamma < n$, $n \ge 3$, and $s > \frac{\gamma}{2} - \frac{n-2}{2n}$. Then there exists $\rho > 0$ such that for any $\varphi \in H^s$ with $\|\varphi\|_{H^s} \le \rho$,* (1.2) *has a unique solution $u \in (C \cap L^\infty)(H^s) \cap L^2(H^{s-\frac{n+2}{2n}}_{\frac{2n}{n-2}})$. Moreover, there is $\varphi^+ \in H^s$ such that*

$$\|u(t) - U(t)\varphi^+\|_{H^s} \to 0 \ \text{ as } \ t \to \infty.$$

Proof. We will use the Strichartz estimate (1.4) with $\theta = 1$ and endpoint admissible pair $(q, r, \sigma) = (2, \frac{2n}{n-2}, \frac{n+2}{2n})$ (see Remark 2).

Let us define a complete metric space (Y^s_ρ, d) with metric d by

$$\begin{aligned}&Y^s_\rho = \left\{v \in L^\infty(H^s) \cap L^2(H^{s-\sigma}_r) : \|v\|_{L^\infty H^s \cap L^2 H^{s-\sigma}_r} \le \rho\right\}, \\ &d(u,v) = \|u - v\|_{L^\infty H^s \cap L^2 H^{s-\sigma}_r},\end{aligned}$$

Then from the estimate (3.2), we have

$$\|N(u)\|_{L^\infty H^s \cap L^2 H^{s-\sigma}_r} \le C\|\varphi\|_{H^s} + C\|u\|^2_{L^2 H^{s-\sigma}_r}\|u\|_{L^\infty H^s}.$$

If we choose sufficiently small ρ such that $C\|\varphi\|_{H^s} \le \frac{\rho}{2}$ and $C\rho^3 \le \frac{\rho}{2}$, then N maps Y^s_ρ to itself. Similarly, from (3.3)–(3.5), one can show that $d(N(u), N(v)) \le \frac{1}{2}d(u,v)$. This proves the existence part.

To prove the scattering, let us define a function φ^+ by

$$\varphi^+ = \varphi - i\int_0^\infty U(-t')F(u)(t')\,dt'.$$

Then since the solution u is in Y^s_ρ, $\varphi^+ \in H^s$, therefore it holds that

$$\begin{aligned}\|u(t) - u^+(t)\|_{H^s} &\lesssim \int_t^\infty \|F(u)\|_{H^s}\,dt' \\ &\lesssim \|u\|_{L^\infty H^s}\int_t^\infty \|u\|^2_{H^{s-\sigma}_r}\,dt' \to 0 \ \text{ as } \ t\to\infty. \qquad \square\end{aligned}$$

4. Nonexistence of scattering. We prove the nonexistence of nontrivial asymptotically free solution.

THEOREM 4.1. *Assume that $0 < \gamma \le 1$ for $n \ge 3$ and $0 < \gamma < \frac{n}{2}$ for $n = 1, 2$. Suppose that u is a smooth global solution in $C(0,\infty; H^{\frac12}) \cap C^1(0,\infty; H^{-\frac12})$ to (1.1) and there exists a smooth function $\varphi^+ \in H^{\frac12} \cap B^{\frac{n+2}{2}}_{1,1}$ such that*

$$\|u(t) - u^+(t)\|_{L^2} \to 0 \quad as \quad t\to\infty,$$

where $u^+(t) = U(t)\varphi^+$. Then $u = u^+ = 0$. Here $B^s_{1,1}$ is the standard inhomogeneous Besov space.

Proof. Let us define a function of $H(t)$ by

$$H(t) = sgn(\lambda)\mathrm{Re}\langle u(t), u^+(t)\rangle.$$

Then from the condition of u and u^+, $H(t)$ is uniformly bounded on t and

$$\frac{d}{dt}H(t) = |\lambda|\mathrm{Im}\langle I_{n-\gamma}(|u|^2)u, u^+\rangle. \tag{4.1}$$

Suppose $\varphi^+ \ne 0$. Then we derive a contradiction to the uniform boundedness of H on t.

The integration in (4.1) is rewritten as

$$\langle I_{n-\gamma}(|u|^2)u, u^+\rangle = J_1 + J_2 + J_3,$$

where

$$\begin{aligned}J_1 &= \langle I_{n-\gamma}(|u^+|^2)u^+, u^+\rangle, \\ J_2 &= \langle I_{n-\gamma}(|u|^2 - |u^+|^2)u^+, u^+\rangle, \\ J_3 &= \langle I_{n-\gamma}(|u|^2)(u-u^+), u^+\rangle.\end{aligned}$$

To estimate each J_i, we need the following time decay estimate; for its proof see [4, 13, 30].

LEMMA 4.2. *If $\varphi^+ \in B^{\frac{n+2}{2}}_{1,1}$, then*

$$\|U(t)\varphi^+\|_{L^\infty} \lesssim t^{-\frac{n}{2}}\|\varphi^+\|_{B^{\frac{n+2}{2}}_{1,1}}.$$

As for J_2, from Lemma 3.2, we have

$$\begin{aligned}
&|J_2(t)| \\
&\quad = |\langle (|u|^2 - |u^+|^2), I_{n-\gamma}(|u^+|^2)\rangle| \\
&\quad \le \|u-u^+\|_{L^2}(\|u\|_{L^2}+\|u^+\|_{L^2})\|I_{n-\gamma}(|u^+|^2)\|_{L^\infty} \\
&\quad \lesssim \|u-u^+\|_{L^2}(\|u\|_{L^2}+\|u^+\|_{L^2})\|u^+\|_{L^{\frac{2n}{n-\gamma-\varepsilon}}}\|u^+\|_{L^{\frac{2n}{n-\gamma+\varepsilon}}} \\
&\quad \lesssim \|u-u^+\|_{L^2}(\|u\|_{L^2}+\|u^+\|_{L^2})\|u^+\|_{L^2}^{\frac{n-\gamma-\varepsilon}{n}+\frac{n-\gamma+\varepsilon}{n}}\|u^+\|_{L^\infty}^{2-\frac{n-\gamma-\varepsilon}{n}+\frac{n-\gamma+\varepsilon}{n}} \\
&\quad \lesssim \|u-u^+\|_{L^2}(\|u\|_{L^2}+\|u^+\|_{L^2})\|u^+\|_{L^2}^{\frac{2(n-\gamma)}{n}}\|u^+\|_{L^\infty}^{\frac{2\gamma}{n}}.
\end{aligned} \tag{4.2}$$

For the fourth inequality we used Hölder's inequality

$$\|u\|_{L^r} \le \|u\|_{L^2}^{\frac{2}{r}}\|u\|_{L^\infty}^{1-\frac{2}{r}}. \tag{4.3}$$

Now from Lemma 4.2 we get

$$|J_2(t)| = o(t^{-\gamma}). \tag{4.4}$$

Since $\gamma \le 1$ for $n \ge 3$ and $\gamma < \frac{n}{2}$ for $n = 1, 2$, we can take $\varepsilon > 0$ such that $\gamma + \varepsilon < \frac{n}{2}$. Hence by the same argument for J_2 we have for J_3 that

$$\begin{aligned}
|J_3(t)| &= |\langle |u|^2, I_{n-\gamma}((\overline{u}-\overline{u^+})u^+)\rangle| \\
&\le \|u\|_{L^2}^2\|I_{n-\gamma}((\overline{u}-\overline{u^+})u^+)\|_{L^\infty} \\
&\lesssim \|u\|_{L^2}^2\left\||(\overline{u}-\overline{u^+})u^+|^{\frac12}\right\|_{L^{\frac{2n}{n-\gamma-\varepsilon}}}\left\||(\overline{u}-\overline{u^+})u^+|^{\frac12}\right\|_{L^{\frac{2n}{n-\gamma+\varepsilon}}} \\
&\lesssim \|u\|_{L^2}^2\left\|(\overline{u}-\overline{u^+})u^+\right\|_{L^{\frac{n}{n-\gamma-\varepsilon}}}^{\frac12}\left\|(\overline{u}-\overline{u^+})u^+\right\|_{L^{\frac{n}{n-\gamma+\varepsilon}}}^{\frac12} \\
&\lesssim \|u\|_{L^2}^2\|u-u^+\|_{L^2}\|u^+\|_{L^{\frac{2n}{n-2(\gamma+\varepsilon)}}}^{\frac12}\|u^+\|_{L^{\frac{2n}{n-2(\gamma-\varepsilon)}}}^{\frac12} \\
&\lesssim \|u\|_{L^2}^2\|u-u^+\|_{L^2}\|u^+\|_{L^2}^{\frac{n-2\gamma}{n}}\left\|u^+\right\|_{L^\infty}^{1-\frac{n-2\gamma}{n}} \\
&= o(t^{-\gamma}).
\end{aligned} \tag{4.5}$$

As for J_1, if $|x| \le At$ for some $A > 1$, then for any $t > 0$

$$\begin{aligned}
I_{n-\gamma}(|u^+|^2)(x) &\ge \int_{|y|\le At}|x-y|^{-\gamma}|u^+(y)|^2\,dy \\
&\ge \frac{1}{(2At)^\gamma}\int_{|y|\le At}|u^+(y)|^2\,dy.
\end{aligned}$$

Now we prove

$$\int_{|y|\le At}|u^+(y)|^2\,dy \gtrsim \|\varphi^+\|_{L^2}^2 \tag{4.6}$$

for large t, provided φ^+ is sufficiently smooth. Choose a large R such that $\|\eta_R\varphi^+\|_{L^2}^2 \ge \frac23\|\varphi^+\|_{L^2}^2$, where η_R is a smooth cut-off function supported in the ball of radius $2R$ with center at the origin. Then

$$\|u^+\|_{L^2(|x|\le At)}^2 \ge \left|\|U(t)(\eta_R\varphi^+)\|_{L^2(|x|\le At)}^2 - \|\varphi^+\|_{L^2(|x|>R)}^2\right|.$$

Since the linear solution u^+ has the finite propagation speed (actually speed 1), one can easily show that $|U(t)(\eta_R\varphi^+)(x)| \lesssim |x|^{-N}\|\varphi^+\|_{L^2}$ for any N, provided $|x| > 1+2R+t$. Hence we deduce that if $N > \frac{n}{2}$ and t is large enough so that $At > 1+3R+t$, then

$$\begin{aligned}\|U(t)(\eta_R\varphi^+)\|^2_{L^2(|x|\le At)} &= \|U(t)(\eta_R\varphi^+)\|^2_{L^2} - \int_{|x|>At} |U(t)\eta_R\varphi^+|^2\,dx \\ &\ge \|\eta_R\varphi^+\|_{L^2} - C\int_{|x|>At} |x|^{-2N}\,dx\|\varphi^+\|^2_{L^2} \\ &\ge \frac{2}{3}\|\varphi^+\|^2_{L^2} - C(At)^{n-2N}\|\varphi^+\|^2_{L^2}.\end{aligned}$$

Therefore for t large enough,

$$\|u^+\|^2_{L^2(|x|\le At)} \ge \frac{1}{3}\|\varphi^+\|^2_{L^2}$$

and hence

$$J_1(t) \gtrsim t^{-\gamma}. \tag{4.7}$$

Now combining (4.7) with (4.4) and (4.5), we deduce that for t sufficiently large

$$\frac{d}{dt}H(t) \gtrsim t^{-\gamma} \ge t^{-1}.$$

This is a contradiction to the uniform boundedness of $H(t)$ on t. ∎

Acknowledgments. The authors would like to thank Professor Kenji Nakanishi for enlightening discussions and the referees for their valuable comments which improved the presentation of this paper.

A SOLIDIFICATION PHENOMENON IN RANDOM PACKINGS*

L. BOWEN†, R. LYONS†, C. RADIN‡, AND P. WINKLER§

Abstract. We prove that uniformly random packings of copies of a certain simply connected figure in the plane exhibit global connectedness at all sufficiently high densities, but not at low densities.

Key words. sphere packing, solidification

1. Introduction.

The densest way to cover a large area with nonoverlapping unit disks is as in Figure 1, in which the disk centers form the vertices of a triangular lattice.

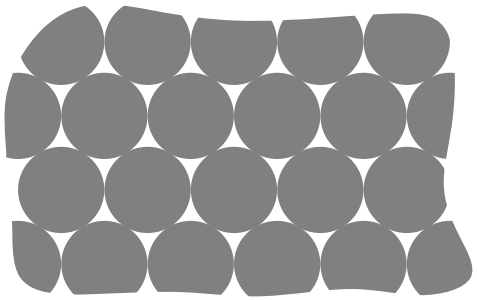

FIG. 1. *The densest packing of unit disks in the plane.*

A *packing* is a collection of congruent copies of a subset with pairwise disjoint interiors. See [5] for a proof that the above packing is indeed the densest possible for unit disks.

It is an old unsolved problem to understand whether densest packings of spheres, simplices, or other shapes, in a Euclidean or hyperbolic space of any dimension, exhibit crystallographic symmetry, such as that of Figure 1. This is the spirit, for instance, of Hilbert's eighteenth problem; see [5, 10] for background.

Using physics models of two- and three-dimensional matter as a guide, we are tempted to try to gain insight into densest packings by considering packings at densities below the maximum. (For an example concerning spheres in $\mathbb{R}^3$, see [9].) In

effect, we are emphasizing not so much that densest packings and low density packings differ by their *symmetry*, but rather that they differ in some fundamental geometric fashion. Indeed, it is commonly suggested in the physics literature (see, for instance, [1]) that two-dimensional models of matter do not exhibit crystallographic symmetry, and it is sometimes said by mathematicians that in high-dimensional Euclidean space, densest packings of spheres may not have crystallographic symmetry. So perhaps it is appropriate to re-examine the precise manner in which densest packings differ fundamentally from low density packings, and to use packings at less than optimum density as a guide.

In this work we replace round disks with deformed disks, which are copies of a "zipper" tile; see Figure 2. This tile can cover the plane completely, in which case the packing has density 1, and is completely connected in any sense. What we show is that even at somewhat lower densities, the uniform random packing still has rigid structure; in particular it has a form of connectedness associated with site percolation [7]. What this means for packing large but finite boxes (with torus boundary conditions) is that the necessary gross irregularities of most packings at such high densities disconnect the packings, if at all, along fault lines whose density tends to 0 as the size of the box tends to infinity. Although we define "uniform random packing" of the plane by limits of measures on packings of finite boxes, the key to our proof is to examine isometry-invariant probability measures on packings of the whole plane and to show that the ones that maximize "degrees of freedom per tile" are unique for high densities.

We show that at high density in our model there is a nonzero probability of an infinite linked component, and that this probability is zero at low density. Thus, there are different "phases" of the packings [2]. (This is closely related to continuum percolation, where one looks at overlapping disks with random independent centers, but our methods are quite different.)

Although we believe that such a result also holds for packings of disks or of spheres—pairs of which would be called "linked" if sufficiently close—we are able to prove the result only for our tiles, which are shaped to allow three well-defined levels of pairwise separation. (We discuss the appropriate notion of linking for collections of disks in the last section of the paper.) It is generally understood that true crystalline symmetry is not seen below optimal density in two dimensions—see [11]—so the form of connectedness we use may be useful in understanding the role of geometry in Hilbert's problem.

2. Description of the tile. We consider packings by a deformed disk denoted by t, referred to as "the tile" and depicted in Figure 2. In this section, we define it precisely.

Let H be a regular hexagon of area 1. Let r be the radius of the in-circle of H. Let D be a disk concentric with the in-circle and of radius $r + \rho$, where $0 < \rho \ll 1$ is a number we shall choose more precisely later. We shall construct the shape t by modifying H as follows; D will be called the *shadow disk* of t.

As shown in Figure 2, the tile t equals H with each side modified by a "fringe" and each corner modified by a hook and inlet, where a hook is about half an element of the fringe. As shown in Figure 3, the fringe height is 2ρ. The elements of the fringe have two different size "necks," one of size ρ^2 and one of size $2\rho^2$, allowing neighboring tiles to be linked in either of two well-defined modes, "tightly linked" and "loosely linked"; the former is illustrated in Figure 4 and the latter in Figure 5. We say that two tiles t are *linked* (tightly or loosely) if, when one is held fixed, the other can be moved continuously only by a bounded amount (without overlapping the first). A

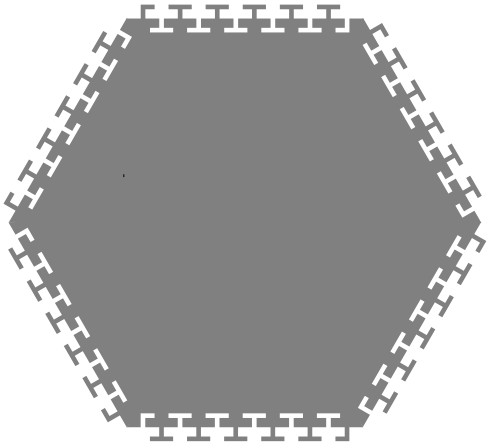

FIG. 2. *The zipper tile.*

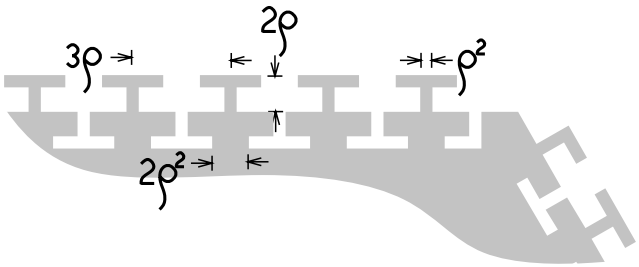

FIG. 3. *Close-up view of the fringe.*

tight link is one that permits no movement of one tile while fixing the other, while a link that is not tight is called *loose*. A key feature of our model is that when two tiles are tightly linked, any motion of one would necessitate a corresponding motion of the other. As we shall explain, the uniform probability distribution on packings of the plane at given density is a limit of such a distribution on packings of larger and larger tori. In our model, these distributions on packings of finite tori are concentrated on packings with the largest number of degrees of freedom, and therefore, roughly speaking, the fewest tiles bound by tight links. This gives us useful control on the packings in the support of our distributions.

A tile is called *fully linked on one side* if it is linked with another tile on that side in such a way that either they are tightly linked, and the line joining their centers goes through the midpoint of the sides of the corresponding hexagons, or they are not tightly linked but can be moved continuously so that their shadow disks touch each other. A tile is *fully linked* if it is fully linked on all sides. We note that the fully tightly linked packing (Figure 4) corresponds to a tiling by the original hexagon and has density 1, and that the tile has area 1 by construction.

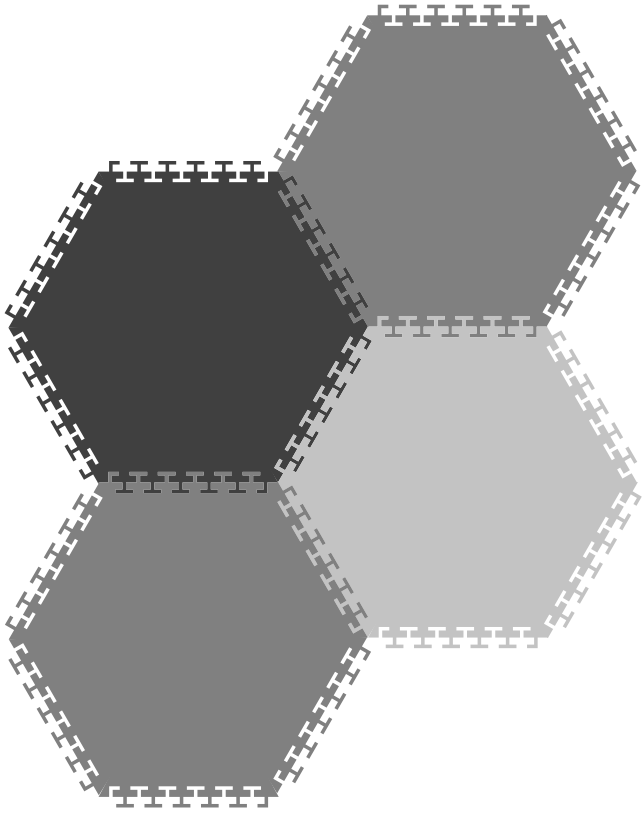

FIG. 4. *Tightly linked tiles.*

3. Statement of results. To state our results we need some notation. Let X be the space of all packings of the plane by the tile t. Given a compact subset K of the plane and two packings of the plane, we consider the distance between the two packings with respect to K to be the Hausdorff distance between the unions of the tiles in the respective packings intersected with K. Then X is endowed with the topology of Hausdorff convergence on compact subsets; X is compact. Intuitively, two packings are close in X if they are close in the Hausdorff sense in a large ball centered at the origin. We shall define a probability measure on X that is "uniform" on the set of all packings of a fixed density. For this, we shall need the space X_n of all packings by the tile of the $n \times n$ torus $\mathbb{R}^2/(n\mathbb{Z})^2$.

For any integer m, let $X_{n,m} \subset X_n$ consist of those packings which contain exactly m tiles ($X_{n,m}$ is empty if m is large enough). To each tile, we assign the set of six unit vectors based on its center and pointing toward the center of each of its edges. Through this assignment, we can view $X_{n,m}$ as a subset of T_n^m/Σ_m, where T_n is the unit tangent bundle of the $n \times n$ torus modulo a $2\pi/6$ rotation and the symmetric group Σ_m acts by permuting the factors.

When m/n^2 is small, $X_{n,m}$ is $(3m)$-dimensional. However, when m/n^2 is sufficiently large, the dimension of $X_{n,m}$ inside T_n^m/Σ_m is less than $3m$. This is because

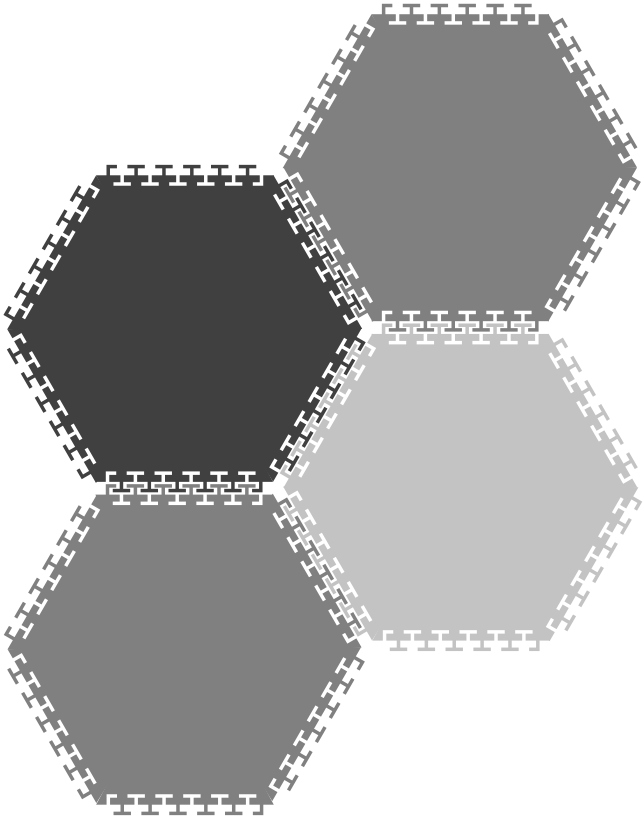

FIG. 5. *Loosely linked tiles.*

at least two tiles in any packing of $X_{n,m}$ will have to be tightly linked, so that it is impossible to move one continuously without moving the other. Thus, it is useful to decompose $X_{n,m}$ into a (finite) disjoint union of sets $X_{n,m,k}$ of packings containing exactly k tight links. Generically, the dimension of $X_{n,m,k}$ is $3(m-k)$. The dimension can be strictly less than this if the packings are jammed in the sense of [4], although this fact will not be important for us. The *top dimension* of $X_{n,m}$ means the maximum dimension of all $X_{n,m,k}$. Let $\mu_{n,m}$ be the probability measure on $X_{n,m}$ obtained by normalizing the Hausdorff measure on $X_{n,m}$ in the top dimension of $X_{n,m}$ with respect to the natural metric inherited from T_n^m/Σ_m. We interpret $\mu_{n,m}$ as being a uniform measure. The fact that $\mu_{n,m}$ is supported on those packings with the fewest tight links will be crucial in the analysis to follow.

Let $\widetilde{X}_n$ be the space of all $(n \times n)$-periodic packings of the plane. In other words, $\widetilde{X}_n$ consists of those packings that are preserved under translations by $n\mathbb{Z}\times n\mathbb{Z}$. Under the quotient map, this space is naturally identified with X_n. Therefore, we can view the measures $\mu_{n,m}$ as living on $\widetilde{X}_n \subset X$.

For a fixed density $d \in [0,1]$, let $\mu^{(d)}$ be any measure obtained as the weak* limit of measures of the form $\mu_{n,m}$ such that $n \to \infty$ and $m/n^2 \to d$. (Note that m/n^2 is the density of every packing in the support of $\mu_{n,m}$ and d is the average density

of a packing chosen with respect to $\mu^{(d)}$; see Lemma 5.1.) A priori, $\mu^{(d)}$ may not be unique, although we shall prove that it is for large enough d.

A *linked component* of a packing is a maximal subpacking in which for every two tiles t, t', there is a sequence $t = t_1, t_2, \ldots, t_n = t'$ such that t_i is linked to t_{i+1} $(i = 1, \ldots, n-1)$. A *tightly linked component* is defined similarly, except that we require t_i to be tightly linked to t_{i+1}.

We say that a measure on the space X of packings is invariant if it is preserved under the full isometry group of the plane. All the measures we consider are probability measures unless stated otherwise.

Let λ_0 be the unique invariant measure on tilings (packings that cover $\mathbb{R}^2$) by our tile. Let λ_1 be the unique invariant measure on packings by t such that all tiles are fully loosely linked, are as close as possible to each other, and the packing has hexagonal symmetry. Write $\lambda_s := s\lambda_1 + (1-s)\lambda_0$.

Our main results are the following.

THEOREM 3.1. *There exists $0 < d_1 < 1$ such that if $d \geq d_1$, $\mu^{(d)}$ is unique and equals λ_s, where $s := (1-d)/(1-d_1)$.*

COROLLARY 3.2. *The $\mu^{(d)}$-probability that the origin is inside a tile belonging to an infinite linked component is nonzero for $d \geq d_1$.*

PROPOSITION 3.3. *For some $d_2 > 0$, the probability (with respect to any $\mu^{(d)}$ for any $d < d_2$) that the origin is inside an infinite linked component is zero.*

4. Tile properties.

LEMMA 4.1. *For small ρ, if tiles t_1 and t_2 are not tightly linked and do not overlap, then the distance between their centers is at least $2r + 2\rho$.*

Proof. Consider the line segment from the center of t_1 to the center of t_2. If this segment traverses near a corner of t_1 or t_2, then it must be longer than $2r + 2\rho$ for small enough ρ. Suppose it crosses a fringe of t_1 and of t_2. If the tiles are not linked, then the claim is obvious. If they are linked, then to minimize the distance, it must be that their fringes match up (so they are fully linked on one side). Thus, they can come closest to each other when pushed flat up against each other so that their shadow disks touch. In this case, the distance between the centers is exactly $2r + \rho$. □

We shall say that two tiles are *densely loosely linked* if they are loosely linked and their shadow disks touch. There is a unique invariant measure on maximally dense packings by congruent disks [3]. Hence the probability measure λ_1 that we defined earlier is the unique invariant measure on packings by t such that all tiles are fully and densely loosely linked. Let d_1 be the density of such a packing.

Given a tile t in a packing P, we denote by $V(t)$ the Voronoi cell of the center of t with respect to the centers of the other tiles; that is, $V(t)$ is the open set of points closer to the center of t than to the center of any other tile. We denote the area of a region A of the plane by $|A|$.

LEMMA 4.2. *The following holds for small enough $\rho > 0$. For any packing P, if $t \in P$ is a tile that has no tight links, then the area of $V(t)$ is at least $1/d_1$. Moreover, equality holds iff the configuration of tiles determining $V(t)$ is congruent to a corresponding configuration of a packing in the support of λ_1.*

Proof. For a tile t, let $H(t)$ denote the hexagon from which t is created. For $x > 0$, let $H_x(t)$ denote the homothetic copy $\frac{r+x}{r} H(t)$ about the center of $H(t)$.

Suppose t is a tile of P without any tight links. Consider the rays $R_1, \ldots, R_6$ from the center of the hexagon $H(t)$ through each of its six vertices. These rays divide the plane into six sectors, $S_1, \ldots, S_6$.

By construction, if t and t_1 are loosely linked, then $|H_\rho(t) \cap H_\rho(t_1)| = \mathrm{O}(\rho^2)$: The hexagon interiors do not intersect if they are parallel, while if they are not parallel, they can intersect only very slightly at a corner. The openings at which a corner can enter have area $\mathrm{O}(\rho^2)$ as $\rho \to 0$.

Thus, we have proved that whenever t is loosely linked in the sector S_i, then $|V(t) \cap S_i| \geq |H_\rho(t)|/6 - \delta_1$, with $\delta_1 = \mathrm{O}(\rho^2)$ as $\rho \to 0$.

Similarly, if t and t_2 are not linked at all, then $|H_{2\rho}(t) \cap H_{2\rho}(t_2)| = \mathrm{O}(\rho^2)$: Again, their interiors do not intersect if they are parallel, while if they are not parallel, they can intersect only very slightly at a corner. So there exists $\delta_2 > 0$ such that whenever t is not linked in the sector S_i, we have $|V(t) \cap S_i| \geq |H_{2\rho}(t)|/6 - \delta_2$, with $\delta_2 = \mathrm{O}(\rho^2)$ as $\rho \to 0$.

Therefore, if t has no tight links but is not fully linked, then

$$|V(t)| \geq j\Big(\frac{|H_\rho(t)|}{6} - \delta_1\Big) + (6-j)\Big(\frac{|H_{2\rho}(t)|}{6} - \delta_2\Big)$$

for some j with $0 \leq j \leq 5$. Given that δ_1, δ_2 are of order ρ^2 while $|H_{2\rho}(t)| - |H_\rho(t)|$ is of order ρ, for ρ small enough we may conclude that $|V(t)| > |H_\rho(t)|$ in this case.

On the other hand, the geometry of a tile is such that for small ρ, if t_1 and t_2 are two tiles loosely linked to t, then t_1 cannot be tightly linked to t_2. Now suppose that t is fully loosely linked. Then the Voronoi cell of the center of t is determined by six tiles $t_1, \ldots, t_6$ all loosely linked to t and all with the property that their shadow disks $D, D_1, \ldots, D_6$ do not overlap (by the previous lemma). It follows [6] that $|V(t)| \geq |H_\rho(t)|$, with equality iff each of the disks $D_1, \ldots, D_6$ touches D. But there is only one way in which this can occur (up to isometry). So $V(t) = H_\rho(t)$ in this case. This implies that the configuration $t, t_1, \ldots, t_6$ is congruent to a corresponding configuration of a packing in the support of λ_1. □

It is easy to see that given $\rho > 0$, there exists $\varepsilon > 0$ such that for any finite component c of tightly linked tiles in any packing, the union V_c of the Voronoi cells of the centers of the tiles of c has area at least $j_c + \varepsilon \mathrm{Per}_c$. Here j_c is the number of tiles in c and Per_c is the perimeter of the union of hexagons corresponding to c. Let ε be the largest such constant. Let $\delta > 0$ be such that the area of the Voronoi cell in the fully densely loosely linked packing equals $1 + \varepsilon \mathrm{Per}_1 + \delta$, where Per_1 is the perimeter of the hexagon of a single tile. Since $\varepsilon = \rho + \mathrm{O}(\rho^2)$ and $\delta = \mathrm{O}(\rho^2)$, we have the following.

LEMMA 4.3. *For sufficiently small ρ, there are $\varepsilon, \delta > 0$ such that for any finite tightly linked component c,*

$$d_1 = \frac{1}{1 + \mathrm{Per}_1 \varepsilon + \delta},$$
$$|V_c| \geq j_c + \varepsilon \mathrm{Per}_c,$$

and

$$\delta \leq \varepsilon/100.$$

5. High density. Recall that X is the compact space of all packings of the plane by the tile (with the topology of Hausdorff-metric convergence on compact subsets). Let $\widetilde{M}$ be the space of isometry-invariant Borel probability measures on X. For any $\mu \in \widetilde{M}$, we denote by $|\mu| := \mu(A_0)$ the *density* of μ, where A_0 is the set of all packings $P \in X$, one of whose tiles contains the origin. Since a tile is the closure of its interior, A_0 is a closed set.

LEMMA 5.1. *If $\mu_i \in \widetilde{M}$ converges to μ in the weak* topology, then $|\mu_i|$ converges to $|\mu|$.*

Proof. Let $\widehat{P}$ denote the union of tiles in a packing, P. For any invariant probability measure ν and any $z \in \mathbb{R}^2$, we have

$$|\nu| = \int \mathbf{1}_{\{0 \in \widehat{P}\}} \, d\nu(P) = \int \mathbf{1}_{\{z \in \widehat{P}\}} \, d\nu(P).$$

Integrating over z in a unit-area disk, D, with respect to the Lebesgue measure and using Fubini's theorem gives the identity $|\nu| = \int |\widehat{P} \cap D| \, d\nu(P)$. Since the function $P \mapsto |\widehat{P} \cap D|$ is continuous on X, the lemma follows. □

Recall that λ_0 is the unique invariant measure on tilings by our tile, so that $|\lambda_0| = 1$. Recalling that d_1 is the density of a fully densely loosely linked tiling, fix a density d with $d_1 \le d \le 1$. Let μ_N be the uniform measure on configuration of tiles at density d_N in an $N \times N$ torus, where $d_N \to d$ as $N \to \infty$. To prove Theorem 3.1, we shall show that the weak* limit of μ_N exists and equals λ_s, where $s := (1-d)/(1-d_1)$.

We shall use several lemmas that depend on the following notation. Given a packing $P \in X$, let

- t_P be the tile of P such that the origin belongs to $V(t_P)$ (this exists as long as the origin is not on the boundary of a Voronoi cell),
- K_P be the tightly linked component containing t_P,
- j_P be the number of tiles in K_P, and
- $f(P) := 3/j_P$ if j_P is finite and t_P contains the origin, and 0 otherwise.

Thus $f(P)$, in a sense, measures the number of degrees of freedom per tile near the origin.

LEMMA 5.2. *If ν is any measure in $\widetilde{M}$, then $\int f \, d\nu(f) \le 3|\nu|$, with equality iff t_P has no tight links for ν-almost every packing P.*

The proof is immediate.

LEMMA 5.3. *If a sequence $\langle \nu_n \rangle \subset \widetilde{M}$ converges to ν in the weak* topology, then $\int f \, d\nu_n$ converges to $\int f \, d\nu$.*

Lemma 5.3 is proved in a manner similar to Lemma 5.1.

Given a finite tightly linked component c, let the congruence class of c be C and let $X_C \subset X$ be the space of all packings P for which t_P exists and K_P is in C. Let X'' be the space of all packings P with density 1, where "density" refers to the usual concept of the limit of the proportion of the area of P inside a large disk centered at the origin as the radius tends to infinity. Let $X' \subset X$ be the space of all packings P such that K_P is infinite and either the density of P is less than 1, the density is not defined, or t_P does not exist. Thus, X is the disjoint union of X', X'' and the collection of X_C for all C.

Let ν be any invariant probability measure with density d. Let ν_C be ν conditioned on X_C, ν' be ν conditioned on X', and ν'' be ν conditioned on X''. Since λ_0 is the only invariant probability measure with support in X'', we have $\nu'' = \lambda_0$. Thus,

$$\nu = \nu(X')\nu' + \nu(X'')\lambda_0 + \sum_C \nu(X_C)\nu_C.$$

Define the density $|\omega| := \omega(A_0)$ as before, but for any (invariant or noninvariant) probability measure ω on X. We have

$$d = |\nu| = \nu(X') \, |\nu'| + \nu(X'') + \sum_C \nu(X_C) \, |\nu_C|$$

and

$$\int f\,d\nu = \sum_C \nu(X_C) \int f\,d\nu_C = \sum_C \nu(X_C)\frac{3}{j_C}|\nu_C|,$$

where j_C is the number of tiles in C.

LEMMA 5.4. *Let $\nu \in \widetilde{M}$ and C be a finite-component class. Suppose that $0 \le s \le 1$ is such that $|\lambda_s| = |\nu_C|$. Then $\int f\,d\lambda_s \ge \int f\,d\nu_C$. Moreover, equality holds only if $j_C = 1$.*

Proof. As in the proof of Lemma 5.1, we have that $|\nu_C| = \int j_C/|V(t_P)|\,d\nu_C(P)$.

First suppose that $j_C = 1$. Then $|\nu_C| = \int 1/|V(t_P)|\,d\nu_C(P) \le d_1$ by Lemma 4.2. This means that $s = 1$ and $\int f\,d\nu_C = 3\,|\nu_C| = 3\,|\lambda_s| = \int f\,d\lambda_s$.

Now assume that $j = j_C > 1$ and put $p := \mathrm{Per}_C$. By definition,

$$\int f\,d\lambda_s = s\int f\,d\lambda_1 + (1-s)\int f\,d\lambda_0 = s\int f\,d\lambda_1 = 3sd_1.$$

Since $\nu_C(f) = 3|\nu_C|/j_C = 3|\lambda_s|/j_C = 3(sd_1 + 1 - s)/j$, it suffices to show that

$$sd_1 > \frac{sd_1 + (1-s)}{j},$$

which is equivalent to

$$s(jd_1 - d_1 + 1) > 1.$$

Now $sd_1 + (1-s) = |\nu_C| \le \frac{j}{j+\varepsilon p}$, where ε is from Lemma 4.3. Solving for s gives

$$s \ge \frac{1 - \frac{j}{j+\varepsilon p}}{1 - d_1},$$

whence it is enough to show that

$$(jd_1 - d_1 + 1)\frac{1 - \frac{j}{j+\varepsilon p}}{1 - d_1} > 1.$$

This boils down to

$$d_1(p\varepsilon + 1) > 1.$$

Now, $j > 1$ implies that $p \ge (7/6)\mathrm{Per}_1$, where Per_1 is the perimeter of a single tile. Since $\varepsilon/100 > \delta$ (by Lemma 4.3), this implies that $p\varepsilon + 1 > 1 + \varepsilon\mathrm{Per}_1 + \delta = 1/d_1$, proving the last inequality. □

LEMMA 5.5. *We have $\int f\,d\nu \le \int f\,d\lambda_s$ for all $\nu \in \widetilde{M}$ with $|\nu| = |\lambda_s|$. Equality holds only if*

- *$\nu(X_C) = 0$ for every component class C with $j_C > 1$, and*
- *whenever $\nu(X_C) > 0$ and $j_C = 1$, we have $|\nu_C| = d_1$.*

Proof. Recall that

$$\int f\,d\nu = \sum_C \nu(X_C) \int f\,d\nu_C.$$

For each component class C, let s_C be defined as follows:

- If there exists $s \in [0,1]$ such that $|\nu_C| = sd_1 + (1-s)$, then set $s_C := s$;
- otherwise, set $s_C := 1$.

Let $\omega_C := s_C\lambda_1 + (1-s_C)\lambda_0$ and

$$\sigma := \big(\nu(X') + \nu(X'')\big)\lambda_0 + \sum_C \nu(X_C)\omega_C.$$

From the previous lemma, if $|\nu_C| \geq d_1$, then $\int f\,d\nu_C \leq \int f\,d\omega_C$, with equality only if $j_C = 1$. If $|\nu_C| < d_1$, then $s_C = 1$ and

$$\int f\,d\nu_C = \frac{3\,|\nu_C|}{j_C} < 3d_1 = \int f\,d\omega_C.$$

Summing up, we obtain

$$\begin{aligned}\int f\,d\sigma &= \sum_C \nu(X_C)\int f\,d\omega_C \\ &\geq \sum_C \nu(X_C)\int f\,d\nu_C = \int f\,d\nu.\end{aligned}$$

Moreover, equality holds only if $\nu(X_C) = 0$ for every component C with $j_C > 1$ and $|\nu_C| = d_1$ whenever $j_C = 1$. Since $|\omega_C| \geq |\nu_C|$, we have

$$\begin{aligned}|\sigma| &= \nu(X') + \nu(X'') + \sum_C \nu(X_C)\,|\omega_C| \\ &\geq \nu(X')\,|\nu'| + \nu(X'') + \sum_C \nu(X_C)\,|\nu_C| \\ &= |\nu| \\ &= |\lambda_s|.\end{aligned}$$

Since σ and λ_s are both convex combinations of λ_0 and λ_1, this implies that $\int f\,d\sigma \leq \int f\,d\lambda_s$ with equality iff $\sigma = \lambda_s$. Thus, $\int f\,d\nu \leq \int f\,d\lambda_s$. In the equality case we must have $\int f\,d\nu = \int f\,d\sigma = \int f\,d\lambda_s$ and $\sigma = \lambda_s$. This implies that $\nu(X_C) = 0$ if $j_C > 1$ and $|\nu_C| = d_1$ if $j_C = 1$. □

LEMMA 5.6. *Let $\nu \in \widetilde{M}$. If $|\nu| = |\lambda_s|$, then $\int f\,d\nu \leq \int f\,d\lambda_s$. Equality holds iff $\nu = \lambda_s$.*

(Informally, λ_s uniquely maximizes the number of degrees of freedom per tile for invariant measures of a fixed density.)

Proof. The previous lemma implies $\int f\,d\nu \leq \int f\,d\lambda_s$. Assume $\int f\,d\nu = \int f\,d\lambda_s$; then

$$\nu = \nu(X')\nu' + \nu(X'')\lambda_0 + \nu(X_C)\nu_C,$$

where C is the component of size 1 and $|\nu_C| = d_1$. This gives $\int f\,d\nu = \nu(X_C)3d_1 = \int f\,d\lambda_s = 3sd_1$. Hence $\nu(X_C) = s$. Since ν' has density strictly less than $1 = |\lambda_0|$ but $|\nu| = |\lambda_s|$, we must have $\nu(X') = 0$. That is,

$$\nu = \nu(X'')\lambda_0 + \nu(X_C)\nu_C.$$

Since ν and λ_0 are isometry invariant, ν_C must also be isometry invariant. By Lemma 4.2, λ_1 is the unique isometry-invariant measure with support in X_C and with density d_1. Hence $\nu_C = \lambda_1$. This implies $\nu = \lambda_s$, and the proof is finished. □

Proof of Theorem 3.1. It is easy to see that one can pack the $N \times N$ torus in such a way that there is a large region of tightly linked tiles and a large region of densely loosely linked tiles, and in such a way that the interface between the two regions has a density which approaches zero as N tends to infinity, and the density d_N of the packing P_N tends to d. Let ω_N be the invariant measure supported on isometric copies of $\tilde{P}_N$ (a pull-back of P_N to the plane). Then ω_N tends to λ_s in the weak* topology. By Lemma 5.3, this implies that $\int f\, d\omega_N \to \int f\, d\lambda_s$.

Now μ_N, the uniform measure of density d_N on the $N \times N$ torus, satisfies $\int f\, d\mu_N \geq \int f\, d\omega_N$. This is because μ_N is by definition supported on packings with the maximal number of degrees of freedom for the given density d_N. Hence $\liminf_N \int f\, d\mu_N \geq \liminf_N \int f\, d\omega_N = \int f\, d\lambda_s$.

Therefore, if μ_∞ is any weak* subsequential limit of $\langle \mu_N \rangle_N$, then $\int f\, d\mu_\infty \geq \int f\, d\lambda_s$. But $d_N \to d$, so $|\mu_\infty| = |\lambda_s|$ by Lemma 5.1. The previous lemma now implies that $\mu_\infty = \lambda_s$. □

Returning to the discussion of the introduction, we note that from simulations of hard disks, one would expect the corollary to hold even for a range of densities below d_1, but we do not know how to prove this.

Remark on higher dimensions. The basic features of our argument can be generalized to dimension 3 or higher, except for our use in Lemma 4.2 of [6] on the minimal Voronoi region in disk packings in the plane. It would be of interest if this part of our proof could be replaced with an argument insensitive to dimension, since the Voronoi regions of, say, the spheres in a face-centered cubic lattice do not minimize volume per site [8].

6. Low density. In this final section, we confirm the intuition that at low densities there will be no infinite loosely linked component. It is obvious that there is no infinite *tightly* linked component at densities smaller than d_1.

We begin with a lemma that holds for any tile shape (in fact, for any *collection* of shapes and sizes, as long as each can be fit into a disk of some fixed radius s, and "density" is interpreted as the number of tiles per unit area).

LEMMA 6.1. *For small enough density d, if a packing P is drawn from $\mu^{(d)}$, then the probability that the disk B_R of radius R about the origin contains more than $9R^2d$ tile centers goes to zero as $R \to \infty$.*

Proof. Let s be the radius of the smallest disk containing the tile (in our case, s is about $2^{1/2} \cdot 3^{-3/4} \cdot (1+2\rho)$) and choose

$$0 < d < \frac{.05}{13\pi s^2} \ ;$$

for our zipper tiles with small enough ρ, $d \leq .003$ suffices. Let T be the set of tiles whose centers fall in B_R, $k := \lceil \pi R^2 d \rceil$, and $\ell > 9R^2 d$. Letting $\mu^{(d)}(\cdot)$ denote the probability of an event with respect to the measure $\mu^{(d)}$, we shall show that

$$\frac{\mu^{(d)}(|T| = \ell)}{\mu^{(d)}(|T| = k)} \leq \gamma^{\ell - k}$$

for some constant $\gamma < 1$. It then follows that

$$\mu^{(d)}(|T| > 9R^2 d) \leq \mu^{(d)}(|T| = k) \sum_{\ell = \lceil 9R^2 d \rceil}^{\infty} \gamma^{\ell - k} \leq \mu^{(d)}(|T| = k) \frac{\gamma^{\lfloor (9-\pi) R^2 d \rfloor}}{1 - \gamma} \to 0$$

as $R \to \infty$, as desired.

The measure $\mu^{(d)}$ is the limit of uniform distributions of configurations on the $N \times N$ torus $\mathbf{T}_N$, in turn obtainable by choosing a sequence of $n = \lfloor N^2 d \rfloor$ points from the Lebesgue distribution λ on $\mathbf{T}_N^n$ as the centers of the tiles, orienting each tile independently and uniformly at random, and finally conditioning on no overlap. We denote by $\lambda(|T|=j)$ the a priori probability that exactly j points fall inside B_R (which we take to be some fixed disk in the torus).

Let Φ be the event that there is no overlap among the tiles whose centers lie in B_R, and Ψ be the event that there is no overlap involving any tile whose center falls *outside* B_R. Then

$$\frac{\mu^{(d)}(|T|=\ell)}{\mu^{(d)}(|T|=k)} = \frac{\lambda(|T|=\ell)}{\lambda(|T|=k)} \cdot \frac{\lambda(\Phi \mid |T|=\ell)}{\lambda(\Phi \mid |T|=k)} \cdot \frac{\lambda(\Psi \mid |T|=\ell \wedge \Phi)}{\lambda(\Psi \mid |T|=k \wedge \Phi)},$$

and our job is to bound the three fractions on the right.

For the first, we note that $|T|$ is binomially distributed in the measure λ; hence

$$\frac{\lambda(|T|=\ell)}{\lambda(|T|=k)} = \frac{\binom{n}{\ell}\left(\frac{\pi R^2}{N^2}\right)^{\ell}\left(1-\frac{\pi R^2}{N^2}\right)^{n-\ell}}{\binom{n}{k}\left(\frac{\pi R^2}{N^2}\right)^{k}\left(1-\frac{\pi R^2}{N^2}\right)^{n-k}} \le \frac{(n-k)!/(n-\ell)!}{\ell!/k!}\left(\frac{\frac{k}{n}}{1-\frac{k}{n}}\right)^{\ell-k}$$
$$< \frac{(n-k)^{\ell-k}}{(\ell/e)^{\ell-k}} \cdot \frac{k^{\ell-k}}{(n-k)^{\ell-k}} = \left(\frac{ek}{\ell}\right)^{\ell-k} \le 0.95^{\ell-k}$$

for large R.

The next fraction is easy: Since we may throw the first k centers into B_R, then for the remaining $\ell-k$, we have that

$$\frac{\lambda(\Phi \mid |T|=\ell)}{\lambda(\Phi \mid |T|=k)}$$

is the probability that the additional $\ell-k$ centers do not cause a collision, which is at most 1.

For the (inverse of) the third fraction, we throw $n-\ell$ centers into the region outside B_R, then throw the remaining $\ell-k$. A new point, if it lands at a distance greater than $2s$ from any previous point or from the disk B_R, causes no new overlap, and at each stage there are fewer than $n-k$ points already placed. Hence

$$\frac{\lambda(\Psi \mid |T|=k \wedge \Phi)}{\lambda(\Psi \mid |T|=\ell \wedge \Phi)} > \left(\frac{N^2 - \pi(R+2s)^2 - (n-k)4\pi s^2}{N^2 - \pi R^2}\right)^{\ell-k}$$

$$\ge \left(1 - 4\pi s^2 d - \frac{4\pi sR + 4\pi s^2}{N^2 - \pi R^2}\right)^{\ell-k} > \left(1 - 13 s^2 d\right)^{\ell-k}$$

for $N \gg R$.

Putting the inequalities together, we have

$$\frac{\mu^{(d)}(|T|=\ell)}{\mu^{(d)}(|T|=k)} \le \left(\frac{.95}{1-13s^2 d}\right)^{\ell-k} = \gamma^{\ell-k},$$

where $\gamma := .95/(1-13s^2 d) < 1$ by choice of d. □

PROPOSITION 6.2. *For some $d_2 > 0$, the $\mu^{(d)}$-probability that the origin is inside an infinite connected component of loosely linked tiles is zero for $d < d_2$.*

Proof. Let $d \in (0, .003)$ be a density to be chosen later. Let P be a packing drawn from $\mu^{(d)}$; we aim to show that the probability that the origin is connected by a loosely linked chain of tiles of P to some point at distance R approaches zero as $R \to \infty$.

We again choose some large radius R and let T be the set of tiles of P whose centers fall inside the disk B_R.

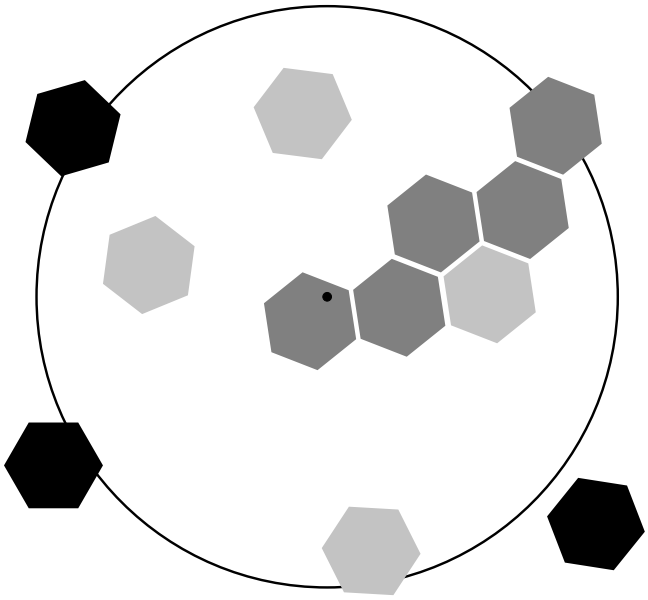

FIG. 6. *An unlikely configuration of tiles in and around B_R.*

Fix the positions of the tiles of $P \setminus T$ (the black tiles of Figure 6) and consider the space of packings having these tiles plus n tiles whose centers fall in B_R. We think of this space as being a subset of $T_1(B_R)^n/\Sigma_n$, where $T_1(B_R)$ is the unit tangent bundle of B_R (modulo a $2\pi/6$ rotation to take into account the symmetries of the tile) and the symmetric group acts by permuting the factors.

If α_n is the volume (in $T_1(B_R)^n/\Sigma_n$-space) of this space and $m < n$, then by packing $n-m$ tiles into B_R and then the remaining m in the leftover space, we have

$$\alpha_n \geq \frac{1}{\binom{n}{n-m}} \alpha_{n-m} \frac{1}{m!} \left[\pi(R-2s)^2 - n\pi(2s)^2\right]^m,$$

where s is, as before, the radius of the circle circumscribing a tile. This takes into account possible intrusion of tiles in $P - T$ into B_R, and the fact that a tile center at point x can exclude nearby centers, but only within distance $2s$ of x.

Let β denote the "wiggle room" of a tile t loosely linked to a stationary tile t', that is, the three-dimensional volume of the space of positions of t; then $\beta = \mathrm{O}(\rho^3)$ (but we use only that β is bounded by a constant). If a packing "percolates," that is, contains a chain of loosely linked tiles connecting the center to the boundary of

B_R, let $t_1, \ldots, t_m$ be a shortest such chain (the dark grey tiles of Figure 6). Note that $m \geq R/(2s)$. For each $i > 2$, the tile t_i is linked to one of the three sides of t_{i-1} farthest from the side of t_{i-1} linked to t_{i-2}, and has wiggle room at most β with respect to t_{i-1}. Accounting for the orientation of t_1 and allowing the remaining $n-m$ tile centers to fall anywhere in B_R, we have that the $3n$-dimensional volume of the set of percolating packings is bounded by $(\pi/3) \cdot 6 \cdot 3^{m-2} \cdot \beta^{m-1} \cdot \alpha_{n-m} < 3^m \beta^{m-1} \alpha_{n-m}$.

Comparing with the lower bound for α_n, we find that given $|T| = n \leq 9dR^2$, the probability of percolation is less than

$$\frac{3^m \beta^{m-1} \alpha_{n-m}}{\alpha_n} \leq \frac{3^m \beta^{m-1}\, n!/(n-m)!}{\left[\pi(R-2s)^2 - n\pi(2s)^2\right]^m} < \left(\frac{27\beta d R^2}{\pi\left[(R-2s)^2 - 36 d R^2 s^2\right]} \right)^m \Big/ \beta,$$

which goes to zero as R (thus also m) increases, for suitably chosen d. Since we know from Lemma 6.1 that $\mu^{(d)}(|T| \leq 9dR^2)$ approaches 1 as $R \to \infty$, the proposition follows. □

A more careful argument would prove Proposition 6.2 for any density below $1/\big(4\pi(2/3\sqrt{3})\big) = .2067^+$ for sufficiently small ρ, but clearly the probability of percolation will remain 0 for much higher densities than that.

7. A conjecture. We have shown that high-density random packings of zipper tiles in the plane contain an infinite loosely linked component with positive probability, while low-density random packings do not. What happens in the case of ordinary disks, where there is no apparent linking mechanism? We believe, but cannot prove, the following.

CONJECTURE. *Suppose $\mu^{(d)}$ is defined as above, but for geometric disks of radius 1. Join two centers by an edge if their distance is at most $2 + \varepsilon$ for some fixed $\varepsilon \ll 1$. Then for sufficiently high-density d below the maximum, the graph resulting from a configuration drawn from $\mu^{(d)}$ will contain an infinite connected component a.s.*

This connectedness property can in fact be proven by a standard Peierls-type argument for large ε. This may be known already, though we do not know a reference; it is a straightforward extension of the traditional percolation proof to a situation with a new length scale given by the size of the disks. In general, there is some parameter set of $(\varepsilon, d) \subset (0, \infty) \times (0, 1)$ for which there is an infinite component. For small d or for large ε, the problem is quite similar to continuum percolation, where one connects by an edge two points of a Poisson point process if their distance is at most r. Because of homotheties, one may fix the intensity of the point process to be 1. Then there is a phase transition in r. Our situation is quite different in that we really have two parameters, due to the size of the disks, but our conjecture is that there is a phase transition in d for every ε nevertheless.

There is a fundamental difference between the connectedness property for small ε and for large ε. An infinite set of disks connected or linked in the sense of small ε would resist shearing in a sense not true for a set linked only in the sense of large ε. We prove the connectedness property for the zipper model for small ε, using in an essential way special features of the nonconvex zipper tiles.

TIME PERIODIC SOLUTIONS FOR THE NONLINEAR WAVE EQUATION WITH LONG MINIMAL PERIOD*

LUCA BIASCO† AND LAURA DI GREGORIO†

Abstract. We prove existence and multiplicity of small amplitude periodic solutions for the wave equation with small "mass" and odd nonlinearity. Such solutions bifurcate from resonant finite dimensional invariant tori of the fourth order Birkhoff normal form of the associated Hamiltonian system. The number of geometrically distinct solutions and their minimal periods go to infinity when the "mass" goes to zero. This is the first result about long minimal period for the autonomous wave equation.

Key words. nonlinear wave equation, infinite dimensional Hamiltonian systems, periodic solutions, Birkhoff normal form

1. Introduction and main results.

Let us consider the nonlinear wave equation on the interval $[0,\pi]$ with Dirichlet boundary conditions

$$\begin{cases} u_{tt} - u_{xx} + \mu u + f(u) = 0, \\ u(t,0) = u(t,\pi) = 0, \end{cases} \tag{1}$$

where $\mu > 0$ and $f(0) = f'(0) = 0$.

Equation (1) can be studied as an infinite dimensional Hamiltonian system. Denoting $v = u_t$, the Hamiltonian is

$$H(v,u) = \int_0^\pi \left(\frac{v^2}{2} + \frac{u_x^2}{2} + \mu \frac{u^2}{2} + g(u) \right) dx,$$

where $g = \int_0^u f(s)ds$. The Hamiltonian equations are

$$u_t = \frac{\partial H}{\partial v} = v, \qquad v_t = -\frac{\partial H}{\partial u} = u_{xx} - \mu u - f(u).$$

Introducing coordinates $q = (q_1, q_2, \ldots)$, $p = (p_1, p_2, \ldots)$ through the relations

$$v(x) = \sum_{i\geq 1} \sqrt{\omega_i} p_i \chi_i(x), \qquad u(x) = \sum_{i\geq 1} \frac{q_i}{\sqrt{\omega_i}} \chi_i(x), \tag{2}$$

where $\chi_i(x) := \sqrt{2/\pi} \sin ix$ and $\omega_i := \sqrt{i^2 + \mu}$, the Hamiltonian takes the form

$$H = \frac{1}{2} \sum_{i\geq 1} \omega_i (q_i^2 + p_i^2) + \text{higher order terms}. \tag{3}$$

†Dipartimento di Matematica, Università "Roma Tre," Largo S. L. Murialdo 1, 00146 Roma, Italy (biasco@mat.uniroma3.it, digregorio@mat.uniroma3.it).

Since we are interested in small amplitude periodic solutions, the higher order terms in (3) may be neglected in first approximation, and we can consider only the Hamiltonian $\Lambda := \sum_{i\geq 1} \omega_i (q_i^2 + p_i^2)/2$. The origin is an elliptic equilibrium point for Λ, and the Λ-orbits are the superpositions of the harmonic oscillations $q_i(t) = A_i \cos(\omega_i t + \varphi_i)$ of the basic modes χ_i, where $A_i \geq 0$, $\varphi_i \in \mathbb{R}$, and ω_i are, respectively, the amplitude, the phase, and the frequency of the ith harmonic oscillator $\omega_i(q_i^2 + p_i^2)/2$, $i \geq 1$.

Analogously, by neglecting the term $f(u)$ in (1), we see that every solution of the linear equation $u_{tt} - u_{xx} + \mu u = 0$ is of the form

$$u(t,x) = \sum_{i\geq 1} a_i \cos(\omega_i t + \varphi_i) \sin ix, \tag{4}$$

with $a_i = A_i \sqrt{2/\pi\omega_i} \geq 0$. These solutions, in general, are periodic if only one basic mode is excited, namely, if $a_i = 0$ for any $i \neq i_0$, for a suitable $i_0 \geq 1$, while $a_{i_0} > 0$. If two basic modes are excited, the situation changes: Except a countable set of $\mu > 0$, for any $\mathcal{I} := \{i_1, \dots, i_N\} \subset \mathbb{N}^+$, $N \geq 2$, the vector $\omega := (\omega_{i_1}, \dots, \omega_{i_N})$ is rationally independent,[1] and, therefore, any solutions of the form $\sum_{i\in\mathcal{I}} a_i \cos(\omega_i t + \varphi_i) \sin ix$ is quasi periodic. Consequently, if at least two amplitudes in (4) are different from zero, the solution $u(t,x)$ cannot be periodic. One can conclude that, except a countable set of $\mu > 0$, the only periodic solutions of $u_{tt} - u_{xx} + \mu u = 0$ are of the form $u(t,x) = a_{i_0} \cos(\omega_{i_0} t + \varphi_{i_0}) \sin i_0 x$, for $i_0 \geq 1$.

In light of these considerations, a natural way to find periodic solutions of (1) (see, for example, [K87], [W90], [K93], [CW93], [Bou99], [B00]) is to extend the Lyapunov center theorem for finite dimensional Hamiltonian systems in a neighborhood of an elliptic equilibrium. Namely, for any fixed $i_0 \geq 1$, one constructs a family of small amplitude periodic orbits of the Hamiltonian H bifurcating from the i_0th basic mode. This can be done since, for μ far away from zero, the linear frequency ω_{i_0} is not resonant with the other ones. The frequencies $\tilde{\omega}$ of the solutions will be close to the linear frequency $\omega := \omega_{i_0}$, and the corresponding periods $2\pi/\tilde{\omega}$ will be close to the linear period $2\pi/\omega$.

Here we look for solutions having *large* minimal period. Such solutions are interesting as examples of the complexity of the dynamics and because they come up only as nonlinear phenomena.

A classical way to find long-period orbits, close to an elliptic equilibrium point[2] in finite dimensional systems, was carried out by Birkhoff and Lewis in [BL34] (see also [L34], [Mo77]). Their procedure consists of putting the system into fourth order Birkhoff normal form: the truncated Hamiltonian obtained by neglecting the five or higher order terms is integrable. If the so-called "twist" condition on the action-to-frequency map holds, there exist infinitely many resonant tori on which the motion of the truncated Hamiltonian is periodic. By the implicit function theorem and topological arguments, Birkhoff and Lewis showed the existence of a sequence of resonant tori accumulating at the origin with the property that at least two periodic orbits bifurcate from each of them.

In our paper we apply the Birkhoff–Lewis procedure to the nonlinear wave equation seen as an infinite dimensional Hamiltonian system. Such an extension to the Hamiltonian PDEs was recently carried out in [BaB] for the beam equation and the nonlinear Schrödinger (NLS) equation (see Remark 3.9 below for comparison).

[1] See Lemma A.1 in the appendix for a proof.

[2] Actually [BL34] considers a neighborhood of an elliptic, nonconstant, periodic orbit, but the scheme is essentially the same for elliptic equilibria.

We point out that, in the infinite dimensional case, one meets two difficulties that do not appear in the finite dimensional case: the generalization of the Birkhoff normal form, and a small divisors problem. Concerning the first difficulty, we consider only a "seminormal form" following [P96]. We suppose that f is a real analytic odd function $f = \sum_{m\geq 3} f_m u^m$ with $f_3 \neq 0$ and fix a *finite* subset $\mathcal{I} \subset \mathbb{N}$. Then we put the Hamiltonian $\bar{H}$ in (3) into the form

$$H = \Lambda + \bar{G} + \hat{G} + K,$$

where $\Lambda = \sum_{i\geq 1} \omega_i (p_i^2 + q_i^2)/2$, $\bar{G} + \hat{G}$ is the fourth order term, with $\bar{G}$ depending only on the "actions" $\mathcal{J}_i := (p_i^2 + q_i^2)/2$, $i \in \mathbb{N}^+$, and $\hat{G}$ depending only on p_i, q_i, $i \notin \mathcal{I}$, and K is the sixth order term. However, to put the Hamiltonian into normal form, the linear frequencies ω_i must satisfy a suitable nonresonance condition (see Lemma 2.6), which deteriorates for μ going to zero.

The truncated Hamiltonian $\Lambda + \bar{G} + \hat{G}$ possesses the $2N$-dimensional invariant manifold $\{p_i = q_i = 0,\ i \notin \mathcal{I}\}$, which is foliated by N-dimensional invariant tori. Due to the "twist" property of $\bar{G}$, which follows from $f_3 \neq 0$, the linear frequencies of such tori are an open set of $\mathbb{R}^N$. We focus on completely resonant frequencies $\tilde{\omega} := (\tilde{\omega}_{i_1}, \dots, \tilde{\omega}_{i_N})$, namely, $\tilde{\omega}$'s such that there exist T's with $\tilde{\omega} T/2\pi \in \mathbb{Z}^N$. Then the $(\Lambda + \bar{G} + \hat{G})$-flow on the associated N-dimensional tori is periodic with periods T. Such lower dimensional tori are highly degenerate. Hence, in order to show the persistence of periodic orbits for the whole Hamiltonian H, we have to impose some nondegeneracy conditions to avoid resonances between the torus frequencies and the frequencies of the normal oscillations. This is the point in which the small divisors problem appears.

The estimate on the small divisors is the crucial step. To overcome this problem, we have decided to impose a strong condition on the small divisors, avoiding KAM analysis (see Remark 3.12). For such a (technical) reason we can consider only periods T which are multiples of 2π (as in the classical variational approach of Rabinowitz, Brezis, Nirenberg, etc.), and we also need

$$\left| \mu \frac{T}{2\pi} - 2m \right| \geq \frac{1}{2} \qquad \forall\, m \in \mathbb{N}$$

and

$$\mu^2 T \ll 1.$$

We will denote by $\mathcal{T}$ the set of periods verifying the above properties.

Therefore we consider the "mass" $\mu > 0$ as a *small* parameter and we make our analysis perturbative with respect to it. On the other hand, for $\mu \to 0$ the frequencies ω_i tend to the *completely resonant* frequencies i, and the above described normal form *degenerates* in the sense that its domain of definition shrinks to zero while the remainder term K blows up.

We note that the set $\mathcal{T}$ of admissible periods is *finite*, but its cardinality goes to infinity, when μ goes to zero. μ^2-close to $\omega = (\omega_{i_1}, \dots, \omega_{i_N})$, we construct a set of completely resonant frequencies $\tilde{\omega} = \tilde{\omega}(T) \in \mathbb{R}^N$, parametrized by the periods $T \in \mathcal{T}$, with $\tilde{\omega} T/2\pi \in \mathbb{Z}^N$. At the same time, we construct a set of actions $\tilde{\mathcal{J}}_i = \tilde{\mathcal{J}}_i(T) \approx \mu^2$, $i \in \mathcal{I}$, parametrized by $T \in \mathcal{T}$, such that $\tilde{\omega}_i$ is the image of $\tilde{\mathcal{J}}_i$ through the action-to-frequency map $\partial_{\mathcal{J}_i} H$ on $\{p_i = q_i = 0,\ i \notin \mathcal{I}\}$. We will prove the existence

of T-periodic solutions of H, μ^2-close to the T-periodic solutions of the truncated Hamiltonian $\Lambda + \bar{G} + \hat{G}$ defined as

$$\begin{cases} p_i(t) = \sqrt{2\tilde{\mathcal{J}}_i}\sin(\tilde{\omega}_i t + \varphi_i), \quad q_i(t) = \sqrt{2\tilde{\mathcal{J}}_i}\cos(\tilde{\omega}_i t + \varphi_i) & \text{for } i \in \mathcal{I}, \\ p_i(t) = q_i(t) = 0 & \text{for } i \in \mathcal{I}^c, \end{cases} \tag{5}$$

where the angles φ_i, $i \in \mathcal{I}$, have to be determined.

We perform a Lyapunov–Schmidt reduction as in [BBiV], [BaB], splitting the problem into two equations: the kernel (or bifurcation) equation on the N-dimensional torus $\{\varphi_{i_1}, \dots, \varphi_{i_N}\}$ and the range equation on its orthogonal space. We first solve the infinite dimensional range equation by the contraction mapping theorem, using the above estimate on the small divisors and controlling the blow-up of the remainder term K for μ going to zero. Critical points of the action functional restricted to the solutions of the range equation satisfy the kernel equation. Since the restricted action functional is defined on an N-dimensional torus, existence of critical points and, therefore, of solutions of H, follows.

Before stating our main result, we return to the PDE formulation. Recalling (2) and (5), for every $T \in \mathcal{T}$, we find T-periodic solutions of (1), μ^2-close to the T-periodic "pseudosolution"

$$\tilde{u}(t,x) := \mu \sum_{i \in \mathcal{I}} a_i \cos(\tilde{\omega}_i t + \varphi_i) \sin ix,$$

where $\mu a_i := \sqrt{\tilde{\mathcal{J}}_i/\pi\omega_i}$, $a_i \approx 1$. We note that the minimal period of $\tilde{u}$ is $\tilde{T}^{\min} = T/\gcd(k_{i_1}, \dots, k_{i_N})$, where $k_i := \tilde{\omega}_i T/2\pi \in \mathbb{N}$, for $i \in \mathcal{I}$. Since $\tilde{\omega}$ is μ^2-close to the rationally independent[3] frequency ω, $\tilde{T}^{\min}$ will be large for μ small. Because $u - \tilde{u} \approx \mu^2$, we obtain an analogous estimate on the minimal period $T^{\min}$ of u. Not all the solutions of (1), corresponding to different T's belonging to $\mathcal{T}$, have to be geometrically distinct. However, by the very precise estimate $u - \tilde{u} \approx \mu^2$, we prove that the total number of geometrically distinct solutions found here is also large for μ small.

We now state our main result.

THEOREM 1.1. *Let f be a real analytic, odd function of the form $f(u) = \sum_{m \geq 3} f_m u^m$, $f_3 \neq 0$. Let $N \geq 2$ and $\mathcal{I} := \{i_1, \dots, i_N\} \subset \mathbb{N}^+$. Then there exists a constant $0 < c = c(\mathcal{I}) < 1$ such that, if $0 < \mu \leq c$, there exist at least c/μ geometrically distinct smooth periodic solutions $u(t,x)$ of (1), verifying*

$$\sup_{t \in \mathbb{R},\ x \in [0,\pi]} \left| u(t,x) - \mu \sum_{i \in \mathcal{I}} a_i \cos(\tilde{\omega}_i t + \varphi_i) \sin ix \right| \leq c^{-1}\mu^2, \tag{6}$$

for suitable $a_i \geq c$, $\varphi_i \in \mathbb{R}$, and $\tilde{\omega}_i \in \mathbb{R}$, verifying

$$|\tilde{\omega}_i - \omega_i| \leq c^{-1}\mu^2. \tag{7}$$

The minimal period $T^{\min}$ of any solution belongs to $\pi\mathbb{Q}$ and satisfies

$$\frac{c}{\mu} \leq T^{\min} \leq \frac{c}{\mu^2}. \tag{8}$$

Remark 1.1. The solutions $u(t,x)$ found in Theorem 1.1 are infinitely differentiable. Actually, they are analytic in the spatial variable. Estimate (6) can be improved and, in particular, one can obtain analogous estimates on the derivative of u

[3]Except a countable set of μ's.

of any order $k \geq 1$. However, in this case, the constant c will depend on k. See also Remark 3.19 for further details.

We stress that this is the first result about periodic solutions of *large minimal period* for the autonomous nonlinear wave equation (for a different type of results on large minimal period, in the forced case, see [T]).

We also mention the following substantial difference between the periodic solutions found by analogy of the Lyapunov center theorem and the theorems we construct. The "Lyapunov-type" orbits are obtained as the continuation of one linear mode to the nonlinear system; they involve only one of the linear harmonic oscillators, and the amplitudes on the other modes are much smaller (except in the resonant case $\mu = 0$, discussed in [BP01], [BBo03], [BBo04], [BBo06]). On the other hand, the periodic solutions constructed here involve $N \geq 2$ harmonic oscillators, oscillating with the same order of magnitude, and are a *truly nonlinear phenomenon*, as they do not have any analogue in the linear case, where all periodic orbits are the oscillation of only one basic mode and do not have long minimal period (see also [BBiV], [BaB]).

The results proved here have been announced in [BDG].

2. Hamiltonian setting and Birkhoff normal form. We study (1) as an infinite dimensional Hamiltonian system with coordinates u and $v = u_t$. Denoting $g = \int_0^u f(s)ds$, the Hamiltonian is

$$H(v,u) = \int_0^\pi \left(\frac{v^2}{2} + \frac{u_x^2}{2} + \mu \frac{u^2}{2} + g(u) \right) dx.$$

The equations of motion are

$$u_t = \frac{\partial H}{\partial v} = v, \qquad v_t = -\frac{\partial H}{\partial u} = u_{xx} - \mu u - f(u).$$

Let us rewrite the Hamiltonian in infinite coordinates $(p,q) \in \ell^{a,s} \times \ell^{a,s}$, where

$$\ell^{a,s} = \ell^{a,s}(\mathbb{R}) := \left\{ q = (q_1, \ldots),\ q_i \in \mathbb{R},\ i \geq 1 \ \text{ s.t. } \|q\|_{a,s}^2 = \sum_{i \geq 1} |q_i|^2 i^{2s} e^{2ai} < \infty \right\},$$

by the transformation

$$v = \mathcal{S}' p = \sum_{i \geq 1} \sqrt{\omega_i} p_i \chi_i, \quad u = \mathcal{S} q = \sum_{i \geq 1} \frac{q_i}{\sqrt{\omega_i}} \chi_i, \tag{9}$$

with $\omega_i = \sqrt{i^2 + \mu}$ and $\chi_i = \sqrt{2/\pi} \sin ix$. We get

$$H = \Lambda + G = \frac{1}{2} \sum_{i \geq 1} \omega_i (q_i^2 + p_i^2) + \int_0^\pi g(\mathcal{S} q)\, dx, \tag{10}$$

where we denote with Λ the integrable part and with G the nonintegrable part. The equations of motion are

$$\dot{p_i} = -\frac{\partial H}{\partial q_i} = -\omega_i q_i - \frac{\partial G}{\partial q_i}, \qquad \dot{q_i} = \frac{\partial H}{\partial p_i} = \omega_i p_i \tag{11}$$

with respect to the symplectic structure $\sum dp_i \wedge dq_i$ on $\ell^{a,s} \times \ell^{a,s}$. Here, " $\dot{}$ " denotes the time derivative.

For $k \in \mathbb{N}$, we consider the space $C^k(\mathbb{R}, \ell^{a,s})$ of all the functions $\mathbb{R} \ni t \mapsto q(t) \in \ell^{a,s}$ with finite norm

$$\|q\|_{C^k(\mathbb{R},\ell^{a,s})} := \sum_{h=0}^{k} \sup_{t\in\mathbb{R}} \|\partial_t^h q(t)\|_{a,s}. \tag{12}$$

Similarly, for a C^k function $\mathbb{R} \ni t \mapsto \big(p(t), q(t)\big) \in \ell^{a,s} \times \ell^{a,s}$ we consider the norm

$$\|(p,q)\|_{C^k(\mathbb{R},\ell^{a,s}\times\ell^{a,s})} := \|p\|_{C^k(\mathbb{R},\ell^{a,s})} + \|q\|_{C^k(\mathbb{R},\ell^{a,s})}.$$

LEMMA 2.1. *Let us assume that $a > 0$ and that s is arbitrary. Let be $\mathbb{R} \ni t \mapsto \big(p(t), q(t)\big) \in \ell^{a,s} \times \ell^{a,s}$ a solution of (11) of class C^k, $2 \le k \le \infty$; then*

$$u(t,x) := \sum_{i\ge 1} \frac{q_i(t)}{\sqrt{\omega_i}}\, \chi_i(x) \tag{13}$$

is a classical solution of (1) of class C^k.

Proof. See the appendix. □

Let us note that χ_i, for $i \ge 1$, is a complete orthonormal basis for the L^2 functions on $[0,\pi]$, but not for all analytic functions on $[0,\pi]$. Indeed, only the analytic functions on $[0,\pi]$, whose odd extension on $[-\pi,\pi]$ is still analytic, can be expanded in sine-series converging in the analytic norm $\|\cdot\|_{a,s}$.

We now discuss the regularity of the Hamiltonian vectorfield generated by G in (10). Let us consider ℓ^2_b and L^2, which are, respectively, the Hilbert spaces of all *bi*-infinite, square-integrable sequences with complex coefficients and all square-integrable complex valued functions on $[-\pi,\pi]$. To identify the two spaces we can consider the inverse discrete Fourier transform,

$$\mathcal{F} :\, \ell^2_b \to L^2, \qquad q \mapsto \big[\mathcal{F}q\big](x) := \frac{1}{\sqrt{2\pi}} \sum_{i\in\mathbb{Z}} q_i e^{\mathrm{i}ix},$$

which defines an isometry between the two spaces. Let $a \ge 0$ and $s \ge 0$. The subspaces $\ell^{a,s}_b \subset \ell^2_b$ contain all bi-infinite sequences, whose norm is defined by

$$\|q\|^2_{a,s} := |q_0|^2 + \sum_{i\in\mathbb{Z}} |q_i|^2 |i|^{2s} e^{2a|i|}.$$

In this way we obtain, through the Fourier transform $\mathcal{F}$, the subspaces $W^{a,s} \subset L^2$ endowed with the norm

$$\|\mathcal{F}q\|_{a,s} = \|q\|_{a,s}.$$

For $a > 0$, the subspaces $W^{a,s}$ consist of all 2π-periodic functions which are analytic and bounded in the complex strip $|\mathrm{Im} z| < a$ with trace functions on $|\mathrm{Im} z| = a$ belonging to the standard Sobolev space H^s. In this way, we obtain an orthonormal basis for all analytic functions on $[0,\pi]$.

The following two results were proved in [P96].

LEMMA 2.2. *For $a \ge 0$ and $s > 1/2$, the space $\ell^{a,s}_b$ is a Hilbert algebra with respect to convolution of the sequences*

$$\|q * p\,\|_{a,s} \le \mathrm{const}\, \|q\|_{a,s}\, \|p\,\|_{a,s}$$

with a constant depending only on s.

LEMMA 2.3. *For $a \geq 0$ and $s > 0$, the gradient $G_q := (\frac{\partial G}{\partial q_1}, \frac{\partial G}{\partial q_2}, \ldots)$ is a real analytic map from a neighborhood of the origin in $\ell^{a,s}$ into $\ell^{a,s+1}$. Moreover,*

$$\|G_q\|_{a,s+1} = O(\|q^3\|_{a,s}).$$

In light of these considerations, we have the real analytic Hamiltonian H in (10), defined in some neighborhood of the origin in the Hilbert space $\ell^{a,s} \times \ell^{a,s}$ with standard symplectic structure $\sum_{i\geq 1} dp_i \wedge dq_i$. The parameters a and s may be fixed arbitrarily; in particular we take $a > 0$ and $s > 1$. The term G is independent of p, so the associated Hamiltonian vectorfield,

$$X_G := \sum_{i\geq 1} \left(\frac{\partial G}{\partial p_i} \frac{\partial}{\partial q_i} - \frac{\partial G}{\partial q_i} \frac{\partial}{\partial p_i} \right),$$

is *smoothing* of order 1; that is, it defines a real analytic map from $\ell^{a,s} \times \ell^{a,s}$ into $\ell^{a,s+1} \times \ell^{a,s+1}$. In particular, for the nonlinearity u^3 one finds

$$G = \frac{1}{4} \int_0^\pi |u(x)|^4 \, dx = \frac{1}{4} \sum_{i,j,k,l} G_{ijkl} q_i q_j q_k q_l$$

with

$$G_{ijkl} = \frac{1}{\sqrt{\omega_i \omega_j \omega_k \omega_l}} \int_0^\pi \chi_i \chi_j \chi_k \chi_l \, dx.$$

In [P96] it is proved that $G_{ijkl} = 0$, unless $i \pm j \pm k \pm l = 0$, for some combination of plus and minus signs. In particular,

$$G_{iijj} = \frac{1}{2\pi} \frac{2 + \delta_{ij}}{\omega_i \omega_j}. \tag{14}$$

From now on, we focus our attention on the nonlinearity $f(u) = u^3$, since terms of order five or more do not make any difference.

2.1. Partial Birkhoff normal form. For the rest of this paper we introduce the complex coordinates

$$\mathrm{z}_i = \frac{1}{\sqrt{2}}(q_i + \mathrm{i}p_i), \quad \bar{\mathrm{z}}_i = \frac{1}{\sqrt{2}}(q_i - \mathrm{i}p_i) \tag{15}$$

that live in the now *complex* Hilbert space

$$\ell^{a,s} = \ell^{a,s}(\mathbb{C}) := \left\{ \mathrm{z} = (\mathrm{z}_1, \ldots),\ \mathrm{z}_i \in \mathbb{C},\ i \geq 1 \text{ s.t. } \|\mathrm{z}\|_{a,s}^2 = \sum_{i\geq 1} |\mathrm{z}_i|^2 i^{2s} e^{2ai} < \infty \right\},$$

with symplectic structure $-\mathrm{i}\sum_{i\geq 1} d\mathrm{z}_i \wedge d\bar{\mathrm{z}}_i = \sum_{i\geq 1} dp_i \wedge dq_i$. The Hamiltonian becomes

$$H = \Lambda + G = \sum_{i\geq 1} \omega_i |\mathrm{z}_i|^2 + G(\mathrm{z}, \bar{\mathrm{z}}), \tag{16}$$

where, with abuse of notation, we have still denoted by G the function $G(\mathrm{z}, \bar{\mathrm{z}}) = G(p, q)$. The Hamiltonian equations write $\dot{\mathrm{z}} = -\mathrm{i}\partial_{\bar{\mathrm{z}}} H$, $\dot{\bar{\mathrm{z}}} = \mathrm{i}\partial_{\mathrm{z}} H$. The Hamiltonian H

is real analytic. Real analytic means that H is a function of z and $\bar{\mathrm{z}}$, real analytic in the real and imaginary parts of z; we denote by $A(\ell^{a,s}, \ell^{a,s+1})$ the class of all real analytic maps from some neighborhood of the origin in $\ell^{a,s}$ into $\ell^{a,s+1}$.

Notation. Given a finite subset $\mathcal{I} = \{i_1, \dots, i_N\}$ of $\mathbb{N}^+$, we will denote by $\hat{\mathrm{z}}$ the infinite vector obtained by excising $\mathrm{z} = (\mathrm{z}_1, \mathrm{z}_2, \dots)$ of its $\mathcal{I}$-components, namely, $\hat{\mathrm{z}} := (\dots, \mathrm{z}_{i_1-1}, \mathrm{z}_{i_1+1}, \dots, \mathrm{z}_{i_j-1}, \mathrm{z}_{i_j+1}, \dots, \mathrm{z}_{i_N-1}, \mathrm{z}_{i_N+1}, \dots) = (\mathrm{z}_i)_{i\in\mathcal{I}^c}$, where $\mathcal{I}^c := \mathbb{N}^+ \setminus \mathcal{I}$. The symbol "$\vee$" will mean "or" in the sense of the Latin "vel"; for example, $i \vee j \in \mathcal{I}$ means that one of the following three cases holds: (1) $i \in \mathcal{I}$, $j \notin \mathcal{I}$; (2) $i \notin \mathcal{I}$, $j \in \mathcal{I}$; (3) $i, j \in \mathcal{I}$. Fix $a > 0$, $s > 1$. We will denote by const > 0 and $0 < c_i < 1$, $i = 1, 2, \dots$, suitable constants depending only on $\mathcal{I}, a, s$; moreover, $y = O(x)$ means that $|y| \le \text{const}\, x$. In the following, we will often omit the explicit expressions for $\bar{\mathrm{z}}$, since they can be derived by analogous expressions for z.

Next, following [P96], we transform the Hamiltonian H in (16) into some partial Birkhoff normal form of order four so that, in a small neighborhood of the origin, it appears as a perturbation of a nonlinear integrable system. However, as we have just said in the introduction, the normal form degenerates when μ is close to zero, in the sense that its domain shrinks to zero and the remainder blows up. Then, we need a quantitative version of the Birkhoff normal form, in which we explicitly investigate the dependence on μ, for μ small. Such an analysis is not available in literature.

PROPOSITION 2.4 (Birkhoff normal form). *Let be $0 < \mu < 1$, $\mathcal{I} \subset \mathbb{N}^+$. There exists a real analytic, close to the identity, symplectic change of coordinates $\mathrm{z} := \Gamma(\mathrm{z}_*)$ defined in $B_r \subset \ell^{a,s}$ into $B_{2r} \subset \ell^{a,s}$ with*

$$r := c_1\sqrt{\mu}, \tag{17}$$

verifying

$$\|\mathrm{z} - \mathrm{z}_*\|_{a,s+1} = O\left(\frac{\|\mathrm{z}_*\|^3_{a,s}}{\mu}\right), \tag{18}$$

transforming the Hamiltonian $H = \Lambda + G$ in (16) *into seminormal form up to order six. That is,*

$$H \circ \Gamma = \Lambda + \bar{G} + \hat{G} + K,$$

where

$$X_{\bar{G}}, X_{\hat{G}}, X_K \in A(\ell^{a,s}, \ell^{a,s+1}), \tag{19}$$

$$\bar{G} = \frac{1}{2} \sum_{i\vee j\,\in\mathcal{I}} \bar{G}_{ij} |\mathrm{z}_{*i}|^2 |\mathrm{z}_{*j}|^2,$$

with uniquely determined coefficients $\bar{G}_{ij} = (3/8\pi)\,(4 - \delta_{ij}/\omega_i\omega_j)$, and

$$|\hat{G}| = O(\|\hat{\mathrm{z}}_*\|^4_{a,s}), \qquad |K| = O\left(\frac{\|\mathrm{z}_*\|^6_{a,s}}{\mu}\right).$$

Remark 2.5. It is worth pointing out that the Hamiltonian $\Lambda + \bar{G}$ is integrable with integrals $|\mathrm{z}_{*i}|^2, i = 1, 2, \dots$. Moreover, although the fourth order term $\hat{G}$ is not

integrable, it depends only on $\hat{z}_* := (z_{*i})_{i\in\mathcal{I}^c}$; namely, it is independent of the $\mathcal{I}$-modes.

Proof. Let us introduce another set of coordinates $(\dots, w_{-2}, w_{-1}, w_1, w_2, \dots)$ in $\ell^{a,s}_b$ defined by $z_{*i} = w_i$ and $\bar{z}_{*i} = w_{-i}$. The Hamiltonian becomes

$$\begin{aligned} H &= \Lambda + G \\ &= \sum_{i\geq 1} \omega_i\, z_{*i}\bar{z}_{*i} + \frac{1}{16}\sum_{i,j,k,\ell} G_{ijk\ell}(z_{*i}+\bar{z}_{*i})\cdots(z_{*\ell}+\bar{z}_{*\ell}) \\ &= \sum_{i\geq 1} \omega_i\, w_i w_{-i} + \frac{1}{16}\sum_{i,j,k,\ell}{}' G_{ijk\ell}\, w_i w_j w_k w_\ell, \end{aligned}$$

where the prime means that the summation is over all nonzero integers. The coefficients are defined for arbitrary integers by setting $G_{ijk\ell} = G_{|i|,|j|,|k|,|\ell|}$. We notice that $G_{ijkl} = 0$, unless $i \pm j \pm k \pm l = 0$, for some combination of plus and minus signs. The transformation Γ is obtained as the time-1-map of the flow of the Hamiltonian vectorfield X_F given by a Hamiltonian

$$F = \sum_{i,j,k,\ell}{}' F_{ijk\ell}\, w_i w_j w_k w_\ell, \tag{20}$$

with coefficients

$$\mathrm{i}F_{ijk\ell} = \begin{cases} \dfrac{G_{ijk\ell}}{16(\omega'_i+\omega'_j+\omega'_k+\omega'_\ell)} & \text{for } \dfrac{(i,j,k,\ell)\ \in\ \mathcal{L}_\mathcal{I}}{\mathcal{N}_\mathcal{I}}, \\ 0 & \text{otherwise.} \end{cases} \tag{21}$$

Here $\omega'_i = \operatorname{sign} i \cdot \omega_{|i|}$,

$$\mathcal{L}_\mathcal{I} = \big\{\, (i,j,k,\ell)\in\mathbb{Z}^4 \quad \text{s.t.} \quad |i|\vee|j|\vee|k|\vee|\ell| \in \mathcal{I}\,\big\},$$

and $\mathcal{N}_\mathcal{I} \subset \mathcal{L}_\mathcal{I}$ is the subset of all $(i,j,k,\ell) = (p,-p,q,-q)$ or some permutation of it. For these indices the denominator $\omega'_i+\omega'_j+\omega'_k+\omega'_\ell$ vanishes identically in μ. In [P96] the following is proved.

LEMMA 2.6. *Let i,j,k,ℓ be nonzero integers such that $i\pm j\pm k\pm l = 0$, but $(i,j,k,\ell)\neq(p,-p,q,-q)$; then*

$$|\omega'_i+\omega'_j+\omega'_k+\omega'_\ell| \geq \frac{\operatorname{const}\mu}{(M^2+\mu)^{3/2}}, \quad M = \min(|i|,\dots,|\ell|),$$

with some absolute const > 0.

Moreover, we note that F is real. Indeed,

$$\begin{aligned} \bar{F} &= \sum_{i,j,k,\ell}{}' \overline{F}_{ijk\ell}\, \bar{w}_i\bar{w}_j\bar{w}_k\bar{w}_\ell \\ &= \sum_{i,j,k,\ell}{}' \mathrm{i}\frac{G_{ijk\ell}}{\omega'_i+\omega'_j+\omega'_k+\omega'_\ell}\, w_{-i}w_{-j}w_{-k}w_{-\ell} \\ &= -\sum_{i,j,k,\ell}{}' \mathrm{i}\frac{G_{ijk\ell}}{\omega'_i+\omega'_j+\omega'_k+\omega'_\ell}\, w_i w_j w_k w_\ell = F, \end{aligned}$$

where we used that $G_{ijk\ell} = G_{-i,-j,-k,-\ell} = G_{|i|,|j|,|k|,|\ell|}$ and $\omega'_{-i} = -\omega'_i$. Expanding at $t = 0$ with the Taylor's formula we obtain

$$\begin{aligned} H \circ \Gamma &= H \circ X_F^t\big|_{t=1} \\ &= H + \{H, F\} + \int_0^1 (1-t)\big\{\{H, F\}, F\big\} \circ X_F^t \, dt \\ &= \Lambda + G + \{\Lambda, F\} + \{G, F\} + \int_0^1 (1-t)\big\{\{H, F\}, F\big\} \circ X_F^t \, dt, \end{aligned}$$

where $\{\cdot, \cdot\}$ denote the Poisson brackets. We can compute

$$\{\Lambda, F\} = -\mathrm{i} \sum_{i,j,k,\ell}{}' (\omega'_i + \omega'_j + \omega'_k + \omega'_\ell) F_{ijk\ell} \, w_i w_j w_k w_\ell;$$

thus

$$G + \{\Lambda, F\} = \frac{1}{16} \left(\sum_{(i,j,k,\ell) \in \mathcal{N}_\mathcal{I}} + \sum_{(i,j,k,\ell) \notin \mathcal{L}_\mathcal{I}} G_{ijk\ell} \, w_i w_j w_k w_\ell \right) = \bar{G} + \hat{G},$$

where $\hat{G}$ is independent of the $\mathcal{I}$-coordinates.

In the variables z_*,$\bar{\mathrm{z}}_*$ we find, from (14) and counting the multiplicities, that

$$\bar{G} = \frac{1}{2} \sum_{i \vee j \in \mathcal{I}} \bar{G}_{ij} |\mathrm{z}_{*i}|^2 |\mathrm{z}_{*j}|^2,$$

with uniquely determined coefficients

$$\bar{G}_{ij} = \begin{cases} 24 G_{iijj} = \dfrac{3}{2\pi} \dfrac{1}{\omega_i \omega_j} & \text{for } i \neq j, \\ 12 G_{iiii} = \dfrac{9}{8\pi} \dfrac{1}{\omega_i \omega_j} & \text{for } i = j. \end{cases} \tag{22}$$

Hence, we have $H \circ \Gamma = \Lambda + \bar{G} + \hat{G} + K$, where

$$K = \{G, F\} + \int_0^1 (1-t)\big\{\{H, F\}, F\big\} \circ X_F^t \, dt \tag{23}$$

is composed by all the terms of order six or more.

Claim. The vectorfield of the Hamiltonian F is analytic, that is

$$X_F \in \mathcal{A}(\ell_b^{a,s}, \ell_b^{a,s+1}). \tag{24}$$

In fact, from Lemma 2.6, it results in

$$\begin{aligned} \left| \frac{\partial F}{\partial w_\ell} \right| &\leq \sum\nolimits'_{\pm i \pm j \pm k = l} |F_{ijk\ell}| \, |w_i w_j w_k| \\ &\leq \frac{\text{const}}{\mu \sqrt{\ell}} \sum\nolimits'_{\pm i \pm j \pm k = l} \frac{|w_i w_j w_k|}{\sqrt{|ijk|}} \\ &\leq \frac{\text{const}}{\mu \sqrt{\ell}} \sum\nolimits'_{i+j+k=l} \tilde{w}_i \tilde{w}_j \tilde{w}_k = \frac{\text{const}}{\mu \sqrt{\ell}} (\tilde{w} * \tilde{w} * \tilde{w})_\ell, \end{aligned}$$

where $\tilde{w}_i = \frac{|w_i|+|w_{-i}|}{\sqrt{|i|}}$. If $w \in \ell^{a,s}_b$, then $\tilde{w} \in \ell^{a,s+1/2}_b$, which is a Hilbert algebra for $s > 0$ by Lemma 2.2; thus $\tilde{w} * \tilde{w} * \tilde{w}$ also belongs to $\ell^{a,s+1/2}_b$. Therefore $F_w \in \ell^{a,s+1}_b$, with

$$\|F_w\|_{a,s+1} \leq \frac{\text{const}}{\mu}\|\tilde{w} * \tilde{w} * \tilde{w}\|_{a,s+1/2} \leq \frac{\text{const}}{\mu}\|\tilde{w}\|^3_{a,s+1/2} \leq \frac{\text{const}}{\mu}\|w\|^3_{a,s}. \tag{25}$$

The analyticity of F_w follows from the analyticity of each component function and its local boundedness, proving (24). From (24) and (25) it follows that the Hamiltonian flow X^t_F is well defined, in a sufficiently small neighborhood of the origin in $\ell^{a,s}$ for all $0 \leq t \leq 1$; in particular, by (25), for $\frac{\|w\|_{a,s}}{2} = \|\mathrm{z}_*\|_{a,s} \leq r$ the map $\Gamma := X^1_F$ verifies

$$\|\Gamma(\mathrm{z}_*) - \mathrm{z}_*\|_{a,s+1} \leq \frac{\text{const}}{\mu}\|\mathrm{z}_*\|^3_{a,s} \leq \text{const}\, c_1^3\sqrt{\mu} \leq c_1\sqrt{\mu} = r, \tag{26}$$

taking c_1 small enough in (17). In the same way (taking c_1 small enough),

$$\|D\Gamma - \mathbb{I}\|^{\text{op}}_{a,s+1,s} \leq \frac{\text{const}}{\mu}\, r^2 = \text{const}\, c_1^2 \leq \frac{1}{2},$$

where the operator norm $\|\cdot\|^{\text{op}}_{a,r,s}$, is defined by

$$\|\cdot\|^{\text{op}}_{a,r,s} = \sup_{w\neq 0}\frac{\|Aw\|_{a,r}}{\|w\|_{a,s}}.$$

Accordingly, $\Gamma : \ell^{a,s} \supset B_r \to B_{2r} \subset \ell^{a,s}$ is a real analytic, symplectic change of coordinates, and (18) follows from (26); moreover, since $\|D\Gamma - \mathbb{I}\|^{\text{op}}_{a,s+1,s+1} \leq \|D\Gamma - \mathbb{I}\|^{\text{op}}_{a,s+1,s}$, $D\Gamma$ defines an isomorphism of $B_r \subset \ell^{a,s+1}$. It follows that with $X_H \in \mathcal{A}(\ell^{a,s}, \ell^{a,s+1})$, we also have

$$D\Gamma^{-1} X_H \circ \Gamma = X_{H\circ\Gamma} \in \mathcal{A}(\ell^{a,s}, \ell^{a,s+1}).$$

The same holds for the Lie bracket: the boundedness of $\|DX_F\|^{\text{op}}_{a,s+1,s}$ implies that

$$[X_F, X_H] = X_{\{H,F\}} \in \mathcal{A}(\ell^{a,s}, \ell^{a,s+1}).$$

These two facts show that $X_K \in \mathcal{A}(\ell^{a,s}, \ell^{a,s+1})$. The analogue claims for $X_{\bar{G}}$ and $X_{\hat{G}}$ are obvious.

Finally, recalling (23), we can write

$$K = \{G, F\} + \int_0^1 (1-t)\big[\big\{\{\Lambda, F\}, F\big\} + \big\{\{G, F\}, F\big\}\big] \circ X^t_F\, dt. \tag{27}$$

It results in

$$\{G, F\} = O\left(\frac{\|w\|^6_{a,s}}{\mu}\right)$$

and

$$\big\{\{\Lambda, F\}, F\big\} = O\left(\frac{\|w\|^6_{a,s}}{\mu}\right), \tag{28}$$

since $\{\Lambda, F\} = \bar{G} + \hat{G} - G = O(\|w\|^4_{a,s})$. Moreover,

$$\big\{\{G, F\}, F\big\} = O\left(\frac{\|w\|^8_{a,s}}{\mu^2}\right); \tag{29}$$

hence, by (27)–(29),

$$|K| = O\left(\frac{\|w\|^6_{a,s}}{\mu}\right) \qquad \text{for} \quad \|w\|_{a,s} \le \text{const}\,\sqrt{\mu}.$$

Since we are looking for small amplitude solutions it is convenient to introduce the small parameter $0 < \eta < 1$ and perform the following rescaling:

$$\mathrm{z}_* =: \eta z, \quad \bar{\mathrm{z}}_* =: \eta \bar{z}, \qquad H \circ \Gamma \longrightarrow \eta^{-2}\big(H \circ \Gamma\big) =: \mathcal{H}, \tag{30}$$

by which the Hamiltonian is written

$$\mathcal{H}(z, \bar{z}; \eta) = \Lambda + \eta^2(\bar{G} + \hat{G}) + \eta^4 \widetilde{K}(z, \bar{z}; \eta), \qquad \|z\|_{a,s}, \|\bar{z}\|_{a,s} \le c_1 \frac{\sqrt{\mu}}{\eta}, \tag{31}$$

where

$$\widetilde{K}(z, \bar{z}; \eta) := \eta^{-2} K(\eta z, \eta \bar{z}), \qquad |\widetilde{K}| = O\left(\frac{\|z\|^6_{a,s}}{\mu}\right). \tag{32}$$

Remark 2.7. We note that the rescaling in (30) does not introduce a rescaling of time. In fact if $\big(z(t), \bar{z}(t)\big)$ is a solution of the Hamiltonian equations for $\mathcal{H}$,

$$\begin{cases} \dot{z}(t) = -\mathrm{i}\partial_{\bar{z}} \mathcal{H}\big(z(t), \bar{z}(t)\big) = -\mathrm{i}\eta^{-1} \partial_{\bar{\mathrm{z}}_*} H\big(\eta z(t), \eta \bar{z}(t)\big), \\ \dot{\bar{z}}(t) = \mathrm{i}\partial_z \mathcal{H}\big(z(t), \bar{z}(t)\big) = \mathrm{i}\eta^{-1} \partial_{\mathrm{z}_*} H\big(\eta z(t), \eta \bar{z}(t)\big), \end{cases}$$

then $(\mathrm{z}_*(t), \bar{\mathrm{z}}_*(t)) = (\eta z(t), \eta \bar{z}(t))$ is a solution of the Hamiltonian equations for H.

We now introduce action-angle variables $(I, \phi) \in \mathbb{R}^N_+ \times \mathbb{T}^N$ on the $\mathcal{I}$-modes by the following symplectic change of variables:

$$z_i := \sqrt{I_i}(\cos\phi_i - \mathrm{i}\sin\phi_i), \qquad \bar{z}_i := \sqrt{I_i}(\cos\phi_i + \mathrm{i}\sin\phi_i), \qquad i \in \mathcal{I}. \tag{33}$$

The action $I := (I_i)_{i \in \mathcal{I}}$, $I_i := z_i \bar{z}_i$, is defined for

$$|I| \le c_2 \frac{\mu}{\eta^2}. \tag{34}$$

We note that $\sum_{i \in \mathcal{I}} dI_i \wedge d\phi_i = -\mathrm{i} \sum_{i \in \mathcal{I}} dz_i \wedge d\bar{z}_i = \sum_{i \in \mathcal{I}} dp_i \wedge dq_i$, and the *phase space* is[4]

$$\mathcal{P}_{a,s} := \mathbb{R}^N_+ \times \mathbb{T}^N \times \ell^{a,s} \ni (I, \phi, \hat{z}). \tag{35}$$

In these variables the Hamiltonian becomes

$$\begin{aligned} \widetilde{\mathcal{H}}(I, \phi, \hat{z}, \bar{\hat{z}}; \eta) = \omega \cdot I + \Omega \cdot \hat{z}\bar{\hat{z}} + \eta^2 \left[\frac{1}{2}(AI, I) + (BI, \hat{z}\bar{\hat{z}}) + \hat{G}(\hat{z}, \bar{\hat{z}})\right] \\ + \eta^4 \widetilde{K}(I, \phi, \hat{z}, \bar{\hat{z}}; \eta), \end{aligned} \tag{36}$$

[4]Clearly here $\ell^{a,s} = \ell^{a,s}(\mathbb{C})$.

where

$$\omega := (\omega_{i_1}, \dots, \omega_{i_N}),$$
$$\Omega := (\dots, \omega_{i_1-1}, \omega_{i_1+1}, \dots, \omega_{i_j-1}, \omega_{i_j+1}, \dots, \omega_{i_N-1}, \omega_{i_N+1}, \dots);$$

$\Omega \cdot \hat{z}\bar{\hat{z}}$ is short for $\sum_{i\in\mathcal{I}^c} \omega_i \hat{z}_i \bar{\hat{z}}_i$, A is the $N \times N$ matrix

$$A = A_{\mathcal{I}} := \left(\bar{G}_{ij}\right)_{i,j\in\mathcal{I}},$$

and B is the $\infty \times N$ matrix

$$B = B_{\mathcal{I}} := \left(\bar{G}_{ij}\right)_{i\in\mathcal{I}^c,\, j\in\mathcal{I}} .$$

Moreover, $(\cdot,\cdot)$ denotes the standard scalar product, and we have denoted again by $\widetilde{K}$ the function $\widetilde{K}(I,\phi,\hat{z},\bar{\hat{z}};\eta) = \widetilde{K}(z,\bar{z};\eta)$. Recalling (22), we have

$$A = \frac{3}{8\pi}\begin{pmatrix} \frac{3}{\omega_{i_1}^2} & \frac{4}{\omega_{i_1}\omega_{i_2}} & \cdots & \frac{4}{\omega_{i_1}\omega_{i_N}} \\ \frac{4}{\omega_{i_2}\omega_{i_1}} & \frac{3}{\omega_{i_2}^2} & \cdots & \frac{4}{\omega_{i_2}\omega_{i_N}} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{4}{\omega_{i_N}\omega_{i_1}} & \frac{4}{\omega_{i_N}\omega_{i_2}} & \cdots & \frac{3}{\omega_{i_N}^2} \end{pmatrix},$$

$$B = \frac{3}{8\pi}\begin{pmatrix} \vdots & \vdots & \vdots \\ \frac{4}{\omega_{i_j-1}\omega_{i_1}} & \cdots & \frac{4}{\omega_{i_j-1}\omega_{i_N}} \\ \frac{4}{\omega_{i_j+1}\omega_{i_1}} & \cdots & \frac{4}{\omega_{i_j+1}\omega_{i_N}} \\ \vdots & \vdots & \vdots \end{pmatrix}.$$

Defining the matrices

$$D = D_{\mathcal{I}} := \operatorname{diag}[\omega] \in \mathrm{Mat}_{N\times N}, \qquad E = E_{\mathcal{I}} := \operatorname{diag}[\Omega] \in \mathrm{Mat}_{\infty\times\infty}, \tag{37}$$

we can rewrite A and B as

$$A = \frac{3}{8\pi} D^{-1}\tilde{A}D^{-1}, \qquad B = \frac{3}{2\pi} E^{-1}\tilde{B}D^{-1}, \tag{38}$$

where

$$\tilde{A} := \begin{pmatrix} 3 & 4 & \dots & 4 \\ 4 & 3 & \dots & 4 \\ \vdots & \vdots & \ddots & \vdots \\ 4 & 4 & \dots & 3 \end{pmatrix} \in \mathrm{Mat}_{N\times N}, \qquad \tilde{B} = \begin{pmatrix} 1 & \dots & 1 \\ 1 & \dots & 1 \\ \vdots & \vdots & \vdots \end{pmatrix} \in \mathrm{Mat}_{\infty\times\infty}. \tag{39}$$

We note that the matrix A is invertible, since

$$\det\tilde{A} =: d_N = 3d_{N-1} + (-1)^N(1-N)4^2 = (-1)^N(1-4N) \neq 0 \qquad (d_N \text{ is odd}). \tag{40}$$

Moreover,

$$\tilde{A}^{-1} = \frac{1}{4N-1}\begin{pmatrix} 5-4N & 4 & \dots & 4 \\ 4 & 5-4N & \dots & 4 \\ \vdots & \vdots & \ddots & \vdots \\ 4 & 4 & \dots & 5-4N \end{pmatrix}. \tag{41}$$

3. Long-period orbits. We will find periodic solutions of the Hamiltonian $\widetilde{\mathcal{H}}$ in (36) close to the ones of the integrable Hamiltonian

$$\widetilde{\mathcal{H}}_{int} = \omega \cdot I + \Omega \cdot \hat{z}\bar{\hat{z}} + \eta^2 \left[\frac{1}{2}(AI, I) + (BI, \hat{z}\bar{\hat{z}}) \right], \tag{42}$$

in which $\hat{G}$ and $\widetilde{K}$ have been neglected. The equations of motion for $\widetilde{\mathcal{H}}_{int}$,

$$\begin{cases} \dot{I} = 0, \\ \dot{\phi} = \omega + \eta^2 AI + \eta^2 B^t \hat{z}\bar{\hat{z}}, \\ \dot{\hat{z}}_i = -\mathrm{i}(\Omega + \eta^2 BI)_i \, \hat{z}_i, \qquad i \in \mathcal{I}^c, \end{cases} \tag{43}$$

can be easily integrated:

$$\begin{cases} I(t) = I_0 \\ \phi(t) = \phi_0 + \tilde{\omega} t + \eta^2 B^t \hat{z}_0 \bar{\hat{z}}_0 t \\ \hat{z}_i(t) = e^{-\mathrm{i}\tilde{\Omega}_i t} \, (\hat{z}_0)_i, \qquad i \in \mathcal{I}^c, \end{cases} \tag{44}$$

where

$$\tilde{\omega} := \tilde{\omega}(I_0, \eta) = \omega + \eta^2 A I_0 \tag{45}$$

is the vector of the *shifted linear frequencies*, and

$$\tilde{\Omega}_i := \tilde{\Omega}_i(I_0, \eta) = \Omega_i + \eta^2 (BI_0)_i = \omega_i + \eta^2 (BI_0)_i, \qquad i \in \mathcal{I}^c, \tag{46}$$

are the *shifted elliptic frequencies*. Consequently, for (42) $\{\hat{z} = 0\}$ is an invariant manifold which is completely foliated by the N-dimensional invariant tori

$$\mathcal{T}(I_0) := \big\{ I = I_0, \, \phi \in \mathbb{T}^N, \, \hat{z} = 0 \big\}.$$

On $\mathcal{T}(I_0)$ the flow

$$t \mapsto (I_0, \phi_0 + \tilde{\omega} t, 0)$$

is T-periodic, $T > 0$, if and only if

$$\tilde{\omega}(I_0, \eta)\tau =: k \in \mathbb{Z}^N, \tag{47}$$

where

$$\tau := \frac{T}{2\pi}$$

is the rescaled period. Hence, if (47) holds, the torus $\mathcal{T}(I_0)$ is completely resonant and supports the infinitely many T-periodic orbits of the family

$$\mathcal{F} := \big\{ I(t) = I_0, \quad \phi(t) = \phi_0 + \tilde{\omega} t, \quad \hat{z}(t) = 0 \big\}. \tag{48}$$

The family $\mathcal{F}$ will not persist in its entirety for the Hamiltonian $\widetilde{\mathcal{H}}$. However, we claim that if the period T is "sufficiently nonresonant" with the shifted elliptic frequencies, we can prove the persistence of at least N geometrically distinct T-periodic solutions of $\widetilde{\mathcal{H}}$ close to $\mathcal{F}$. More precisely, the required nonresonance condition is

$$\big| \ell - \tilde{\Omega}_i(I_0, \eta)\tau \big| \geq \frac{\text{const}}{i} \qquad \forall \, \ell \in \mathbb{Z}, \ \forall \, i \in \mathcal{I}^c. \tag{49}$$

We now consider the periodicity condition (47). As we have said in the introduction, we construct a set of actions and of completely resonant frequencies, parametrized by the (rescaled) periods τ. Such actions and frequencies are related by the action-to-frequency map $I \to (\partial_I \widetilde{\mathcal{H}}_{int})_{|\hat{z}=0} = \omega + \eta^2 AI$. Indeed, since A is invertible we can choose I_0 and k as functions of τ and η so that (47) is always satisfied:

$$I_0 := \frac{1}{\eta^2\tau} A^{-1}\left(\kappa - \{\omega\tau\}\right), \tag{50}$$

$$k := [\omega\tau] + \kappa, \tag{51}$$

where $[(x_1,\dots,x_N)] := ([x_1],\dots,[x_N])$, $\{(x_1,\dots,x_N)\} := (\{x_1\},\dots,\{x_N\})$, and

$$\kappa := (\kappa_i)_{i\in\mathcal{I}} \in \mathbb{Z}^N, \qquad \kappa_i := i^{-1}\tilde{\kappa}, \qquad \tilde{\kappa} := 10\prod_{j\in\mathcal{I}} j. \tag{52}$$

Here the functions $[\cdot] : \mathbb{R} \to \mathbb{Z}$ and $\{\cdot\} : \mathbb{R} \to [0,1)$ denote the integer part and the fractional part, respectively.

In order to have $I_0 \approx 1$ in (50), we choose the parameter η, which is related to the amplitude of the solution, as a function of the rescaled period τ such that

$$\eta^2\tau = 1, \qquad \text{namely,} \qquad \eta := 1/\sqrt{\tau}. \tag{53}$$

Consequently, we can express I_0, k, and $\tilde{\Omega}_i$ in (50), (51), (46) as functions of τ only:

$$I_0 := I_0(\tau) = A^{-1}\left(\kappa - \{\omega\tau\}\right), \tag{54}$$

$$k := k(\tau) = [\omega\tau] + \kappa, \tag{55}$$

$$\tilde{\Omega}_i := \tilde{\Omega}_i(\tau) = \omega_i + \eta^2\big(BI_0(\tau)\big)_i \qquad \text{for} \quad i \in \mathcal{I}^c. \tag{56}$$

We point out that the constant vector κ defined in (52) has been added to have $(I_0)_i > 0$ in view of (35). In particular the following lemma holds.

LEMMA 3.1. *If μ is small enough, then $(I_0)_i > \pi\omega_i$ for all $i \in \mathcal{I}$.*

Proof. By (38) and (54) we get

$$I_0 = \frac{8\pi}{3} D\tilde{A}^{-1} D\big(\kappa - \{\omega t\}\big).$$

Recalling (37) and (41) we have, for all $i \in \mathcal{I}$,

$$\begin{aligned}(I_0)_i &= \frac{8\pi\omega_i}{3(4N-1)}\left((1-4N)\big(\omega_i\kappa_i - \omega_i\{\omega_i t\}\big) + 4\sum_{j\in\mathcal{I}}\big(\omega_j\kappa_j - \omega_j\{\omega_j t\}\big)\right)\\ &= \frac{8\pi\omega_i}{3(4N-1)}\left((1-4N)\big(\tilde{\kappa} - i\{\omega_i t\}\big) + 4\sum_{j\in\mathcal{I}}\big(\tilde{\kappa} - j\{\omega_j t\}\big) + O(\mu)\right)\end{aligned}$$

since, recalling (52), $\omega_i\kappa_i = i^{-1}\omega_i\tilde{\kappa}$ and $1 < i^{-1}\omega_i = i^{-1}\sqrt{i^2+\mu} < 1+\mu$. Taking μ small enough we get

$$\begin{aligned}(I_0)_i &= \frac{8\pi\omega_i}{3(4N-1)}\left(\tilde{\kappa} + (4N-1)i\{\omega_i t\} - 4\sum_{j\in\mathcal{I}} j\{\omega_j t\} + O(\mu)\right)\\ &\geq \frac{8\pi\omega_i}{3(4N-1)}\left(\tilde{\kappa} - 4\sum_{j\in\mathcal{I}} j + O(\mu)\right) = \frac{8\pi\omega_i}{3(4N-1)}\left(10\prod_{j\in\mathcal{I}} j - 4\sum_{j\in\mathcal{I}} j + O(\mu)\right)\\ &\geq \frac{8\pi\omega_i}{3(4N-1)}\left(2\prod_{j\in\mathcal{I}} j + O(\mu)\right) \geq \frac{8\pi\omega_i}{3(4N-1)}\big(2N + O(\mu)\big) \geq \frac{8\pi\omega_i}{3(4N-1)}\frac{3N}{2}\\ &> \pi\omega_i,\end{aligned}$$

where we used that $2\prod_{j\in\mathcal{I}} j \geq \sum_{j\in\mathcal{I}} j$ and $\prod_{j\in\mathcal{I}} j \geq N$. □

We note that by the choice of η made in (53), it results that $|I_0| \leq$ const. Then I_0 belongs to the domain of definition of the Hamiltonian $\widetilde{\mathcal{H}}$, namely, it verifies (34), making the hypothesis

$$\mu\tau \geq c_3^{-1}. \tag{57}$$

We finally remark that, by (53) and (56), the quantities that we have to estimate in the crucial nonresonance condition (49) are

$$\ell - \tilde{\Omega}_i\tau = \ell - \tau\omega_i - \Big(BA^{-1}\big(\kappa - \{\omega\tau\}\big)\Big)_i, \qquad \ell \in \mathbb{Z}, i \in \mathcal{I}^c. \tag{58}$$

In this form, (49) clearly appears as a nonresonance condition between the frequency of the torus ω and the normal frequencies $\{\omega_i\}_{i\in\mathcal{I}^c}$.

3.1. Small divisors estimate. In order to estimate the quantities in (58) we will perform the expansion $\tau\omega_i = \tau\sqrt{i^2+\mu} = i\tau + \frac{\mu\tau}{2i} + O(\mu^2\tau)$, requiring that $\mu^2\tau$ is small, namely,

$$\mu^2\tau \leq c_4.$$

The other aspect of such a request is that, for any fixed μ, we have only a finite number of (rescaled) periods τ. Moreover, we note that the smallness of $\mu^2\tau$ implies that of μ since $\mu \leq c_3\mu^2\tau$ by (57). Hence, since for μ close to zero the Birkhoff normal form degenerates, it is not obvious that we can make $\mu^2\tau$ small for some fixed $\tau \geq 1$. Moreover, even if it is not necessary, for simplicity we limit our consideration to $\tau \sim \mu^{-2}$, namely, $c_4/2\mu^2 \leq \tau \leq c_4/\mu^2$. Again for technical reasons, we will need that τ is an *integer* and that $\mu\tau$ is far away from even integers. Let us define

$$\mathcal{T}_\mu := \left\{ \tau \in \mathbb{N}^+, \quad \frac{c_4}{2\mu^2} \leq \tau \leq \frac{c_4}{\mu^2} \quad \text{s.t.} \quad \mu\tau \in \mathcal{N} \right\}, \tag{59}$$

where

$$\mathcal{N} := \left\{ x > 0 \ \text{ s.t. } \ |x - 2m| \geq \frac{1}{2} \ \ \forall\, m \in \mathbb{Z} \right\} = \bigcup_{n>0 \text{ odd}} \left[n - \frac{1}{2}, n + \frac{1}{2} \right]. \tag{60}$$

The constant c_4 will be choose suitably small in the following.

PROPOSITION 3.2. *If μ is small enough and $\tau \in \mathcal{T}_\mu$, then the following estimate holds:*

$$\big|\ell - \tilde{\Omega}_i\tau\big| \geq \frac{c_5}{i} \qquad\qquad \forall\, \ell \in \mathbb{Z},\ i \in \mathcal{I}^c. \tag{61}$$

Proof. We will prove that

$$\big|\ell - \tau\sqrt{i^2+\mu} - \big(BI_0(\tau)\big)_i\big| \geq \frac{1}{6(4N-1)\, i} \qquad \forall\, \ell \in \mathbb{Z}, i \in \mathcal{I}^c. \tag{62}$$

Recalling (58), we see that the crucial estimate (61) follows from (62) taking $c_5 := \frac{1}{6(4N-1)}$. We first consider the term $BI_0(\tau)$. From (38) we have $BA^{-1} = 4(E^{-1}\tilde{B}\tilde{A}^{-1}D)$, while, by (41), $\tilde{B}\tilde{A}^{-1} = d^{-1}\tilde{B}$, where $d := 4N-1$. Recalling (54), we get

$$BI_0(\tau) = BA^{-1}\big(\kappa - \{\omega\tau\}\big) = 4d^{-1}\, E^{-1}\tilde{B}D\big(\kappa - \{\omega\tau\}\big)$$

and, in particular, for $i \in \mathcal{I}^c$,

$$(BI_0)_i = \frac{4}{d}\left(E^{-1}\tilde{B}D\big(\kappa - \{\omega\tau\}\big)\right)_i = \frac{4}{d\omega_i}\left(\tilde{B}D\big(\kappa - \{\omega\tau\}\big)\right)_i$$

$$= \frac{4}{d\omega_i}\left(\hat{\kappa} - \sum_{h\in\mathcal{I}} \omega_h\{\omega_h\tau\}\right), \tag{63}$$

where

$$\hat{\kappa} := \big(\tilde{B}D\kappa\big)_i = \left(\tilde{B}\begin{pmatrix} \vdots \\ \dfrac{\omega_h}{h}\,\tilde{\kappa} \\ \vdots \end{pmatrix}\right)_i = \sum_{h\in\mathcal{I}} \frac{\omega_h}{h}\,\tilde{\kappa} = \tilde{\kappa}N + O(\mu). \tag{64}$$

Now we need the following lemma.

LEMMA 3.3. *Let $0 < \mu < 1$. Then for all $h \in \mathbb{N}^+$ there exist $\delta_h^{(k)} > 0$, $k = 1, 2, 3$, such that*

$$\omega_h = h + \delta_h^{(1)}, \qquad \delta_h^{(1)} < \frac{\mu}{2h} \tag{65}$$

$$= h + \frac{\mu}{2h} - \delta_h^{(2)}, \quad \delta_h^{(2)} < \frac{\mu^2}{8h^3}. \tag{66}$$

Moreover, if $\tau \in \mathbb{N}^+$, there exists $n_h := n_h(\mu, \tau) \in \mathbb{Z}$ such that

$$\left|\omega_h\{\omega_h\tau\} - \frac{\mu\tau}{2} - n_h\right| \le \frac{\mu}{2h} + \frac{\mu^2\tau}{8h^2} \qquad \forall\, h \in \mathbb{N}^+. \tag{67}$$

By the elementary inequality $0 < 1 - (1+x)^{-1} < x$ for all $x > 0$, we get, using (65),

$$0 < \frac{1}{i} - \frac{1}{\omega_i} = \frac{1}{i}\left(1 - \frac{1}{1 + \delta_i^{(1)}/i}\right) < \frac{\delta_i^{(1)}}{i^2} < \frac{\mu}{2i^3},$$

namely,

$$\frac{1}{\omega_i} - \frac{1}{i} = O\left(\frac{\mu}{i^3}\right). \tag{68}$$

Since $|\{\omega_h\tau\}| \le 1$, by substituting (68) into (63) we get

$$(BI_0)_i = \frac{4}{di}\left(\hat{\kappa} - \sum_{h\in\mathcal{I}} \omega_h\{\omega_h\tau\}\right) + O\left(\frac{\mu}{i^3}\right);$$

hence, by (67) and (64),

$$(BI_0)_i = \frac{4}{di}\left(\tilde{\kappa}N - \sum_{h\in\mathcal{I}}\left(\frac{\mu\tau}{2} + n_h\right)\right) + O\left(\frac{\mu}{i} + \frac{\mu^2\tau}{i}\right). \tag{69}$$

Moreover, since by (66) we get

$$\tau\sqrt{i^2 + \mu} = \tau i + \frac{\mu\tau}{2i} + O\left(\frac{\mu^2\tau}{i^3}\right),$$

using (69) we have

$$\ell - \tau\sqrt{i^2+\mu} - \big(BI_0(\tau)\big)_i = \ell - \tau i - \frac{\mu\tau}{2i} + \frac{4}{di}\left(\sum_{h\in\mathcal{I}}\left(\frac{\mu\tau}{2}+n_h\right) - \tilde{\kappa}N\right) + O\left(\frac{\mu}{i}+\frac{\mu^2\tau}{i}\right). \tag{70}$$

From the hypothesis $\tau \in \mathcal{T}_\mu$ and for μ small enough, it follows that

$$\frac{\mu}{i} + \frac{\mu^2\tau}{i} < \frac{2c_4}{i}.$$

Hence, by (70) and choosing c_4 small enough, in order to prove (62) it is sufficient to show that

$$\left|\ell - \tau i - \frac{\mu\tau}{2i} + \frac{4}{di}\left(\sum_{h\in\mathcal{I}}\left(\frac{\mu\tau}{2}+n_h\right) - \tilde{\kappa}N\right)\right| \geq \frac{1}{4(4N-1)\,i}. \tag{71}$$

Now, since $d = 4N-1$ and $\sum_{h\in\mathcal{I}} 1 = N$, (71) is equivalent to

$$\left|\mu\tau + 2\left(id(\ell-\tau i) - 4\tilde{\kappa}N + 4\sum_{h\in\mathcal{I}} n_h\right)\right| \geq \frac{1}{2}. \tag{72}$$

Since

$$2\left(id(\ell-\tau i) - 4\tilde{\kappa}N + 4\sum_{h\in\mathcal{I}} n_h\right)$$

is an even integer, (72) follows by hypothesis $\tau \in \mathcal{T}_\mu$. □

Proof of Lemma 3.3. Since $\omega_h = h\sqrt{1+x}$ with $x := \mu/h^2$, $0 < x < 1$, (65) and (66) directly follow by the elementary inequalities

$$1 < \sqrt{1+x}, \qquad -\frac{x^2}{8} < \sqrt{1+x} - 1 - \frac{x}{2} < 0,$$

holding for any $0 < x < 1$. We now prove (67). Because $|\{\omega_h\tau\}| \leq 1$, we have

$$|\omega_h\{\omega_h\tau\} - h\{\omega_h\tau\}| = |(\omega_h - h)\{\omega_h\tau\}| \leq |\omega_h - h| \leq \frac{\mu}{2h}, \tag{73}$$

where in the last inequality we have used (65). Moreover, by (66)

$$\{\omega_h\tau\} = \omega_h\tau - [\omega_h\tau] = h\tau + \frac{\mu\tau}{2h} - \delta_h^{(2)}\tau - [\omega_h\tau],$$

from which we get

$$\left|h\{\omega_h\tau\} - \frac{\mu\tau}{2} - n_h\right| \leq \frac{\mu^2\tau}{8h^2}, \qquad \text{where} \quad n_h := h^2\tau - h[\omega_h\tau].$$

Then the proof follows by the previous inequality and (73). □

We now give a lower estimate on the cardinality of $\mathcal{T}_\mu$.

LEMMA 3.4. *For μ small enough,*

$$\sharp\, \mathcal{T}_\mu \geq \frac{c_4}{6\mu^2}.$$

Proof. We first claim that

$$\sharp\left\{\tau \in \mathbb{N} \quad \text{s.t.} \quad \mu\tau \in \left[n-\frac{1}{2}, n+\frac{1}{2}\right]\right\} \geq \left[\frac{1}{\mu}\right] \tag{74}$$

for any n odd. Indeed, if $\tau_0 := \min\{\tau \in \mathbb{N} \text{ s.t. } \mu\tau \geq n-1/2\}$, then $\mu\tau_0 < \mu + n - 1/2$, and therefore $\mu\tau_0 + \mu m \leq n + 1/2$ for any $0 \leq m \leq -1 + 1/\mu$, proving (74). Since

$$\sharp\left\{n \text{ odd} \quad \text{s.t.} \quad \frac{c_4}{2\mu} + \frac{1}{2} \leq n \leq \frac{c_4}{\mu} - \frac{1}{2}\right\} \geq \frac{c_4}{4\mu} - 2 \geq \frac{c_4}{5\mu},$$

then

$$\sharp\, \mathcal{T}_\mu \geq \frac{c_4}{5\mu}\left[\frac{1}{\mu}\right] \geq \frac{c_4}{6\mu^2},$$

for μ small enough. □

3.2. Functional setting. Since the problem is Hamiltonian, any T-periodic solution of the Hamiltonian equations for $\widetilde{\mathcal{H}}$ in (36), namely,

$$\begin{cases} \dot{I} = -\eta^4 \partial_\phi \widetilde{K}(I, \phi, \hat{z}, \bar{\hat{z}}), \\ \dot{\phi} = \omega + \eta^2 AI + \eta^2 B^t z\bar{z} + \eta^4 \partial_I \widetilde{K}(I, \phi, \hat{z}, \bar{\hat{z}}), \\ \dot{\hat{z}}_i = -\mathrm{i}(\Omega + \eta^2 BI)_i\, \hat{z}_i - \mathrm{i}\eta^2 \partial_{\bar{z}_i} \hat{G}(\hat{z}, \bar{\hat{z}}) - \mathrm{i}\eta^4 \partial_{\bar{z}_i} \widetilde{K}(I, \phi, \hat{z}, \bar{\hat{z}}), & i \in \mathcal{I}^c, \end{cases} \tag{75}$$

is a critical point of the Lagrangian action functional

$$S(I, \phi, \hat{z}) = \int_0^T \left(I \cdot \dot{\phi} - \mathrm{i} \sum_{i \in \mathcal{I}^c} z_i \dot{\bar{z}}_i - \widetilde{\mathcal{H}}(I, \phi, \hat{z}, \bar{\hat{z}}) \right) dt, \tag{76}$$

in the space of T-periodic, $\mathcal{P}_{a,s}$-valued curves $\big(I(t), \phi(t), \hat{z}(t)\big)$.

In particular we are looking for periodic orbits of the Hamiltonian $\widetilde{\mathcal{H}}$ near the family $\mathcal{F}$ defined in (48); namely, we seek solutions of the form

$$\begin{cases} I(t) = I_0 + J(t), \\ \phi(t) = \phi_0 + \tilde{\omega} t + \psi(t), \\ \hat{z}(t) = 0 + w(t), \end{cases} \tag{77}$$

where I_0 was defined in (54); $\phi_0 \in \mathbb{T}^N$ is a parameter to determine. Recalling (75), $\zeta(t) = (J(t), \psi(t), w(t))$ and $\phi_0 \in \mathbb{T}^N$ must satisfy

$$\begin{cases} \dot{\psi} - \eta^2 AJ = \eta^2 B^t w\bar{w} + \eta^4 \partial_I \widetilde{K}(I_0 + J, \phi_0 + \tilde{\omega} t + \psi, w, \bar{w}), \\ \dot{J} \qquad\qquad = -\eta^4 \partial_\phi \widetilde{K}(I_0 + J, \phi_0 + \tilde{\omega} t + \psi, w, \bar{w}), \\ \dot{w}_i + \mathrm{i}\tilde{\Omega}_i w_i = -\mathrm{i}\eta^2 \partial_{\bar{z}_i} \hat{G}(w, \bar{w}) - \mathrm{i}\eta^4 \partial_{\bar{z}_i} \widetilde{K}(I_0 + J, \phi_0 + \tilde{\omega} t + \psi, w, \bar{w}), \quad i \in \mathcal{I}^c. \end{cases} \tag{78}$$

We will look for $\zeta(t)$ as a T-periodic curve taking values in the covering space $\mathbb{R}^N \times \mathbb{R}^N \times \ell^{a,s}$ (that for simplicity we will still denote by $\mathcal{P}_{a,s}$) with $\int_0^T \psi(t) dt = 0$. For

$\zeta = (J, \psi, w) \in \mathbb{R}^N \times \mathbb{R}^N \times \ell^{a,s}$ we define the norm[5]

$$\|\zeta\|_{\mathcal{P}_{a,s}} = \|(J, \psi, w)\|_{\mathcal{P}_{a,s}} := |J| + |\psi| + \|w\|_{a,s}.$$

With this norm, $\mathcal{P}_{a,s}$ is a Banach algebra, recalling that $s > 1$ and Lemma 2.2.

In particular we will look for H^k-solutions $\zeta(t)$ in the Banach space

$$\overline{H}^k_{T,a,s} := \left\{ \zeta \in H^k_{T,a,s}, \quad \int_0^T \psi(t)dt = 0 \right\},$$

where $k \in \mathbb{N}$, $T > 0$,

$$H^k_{T,a,s} := \left\{ \zeta \in H^k(\mathbb{R}, \mathcal{P}_{a,s}), \quad \zeta(t+T) = \zeta(t) \right\},$$

and $H^k(\mathbb{R}, \mathcal{P}_{a,s})$ is the Sobolev space of the functions $\zeta : \mathbb{R} \to \mathcal{P}_{a,s}$ with k weak derivatives in $L^2(\mathbb{R}, \mathcal{P}_{a,s})$ (for $k = 0$, $H^0(\mathbb{R}, \mathcal{P}_{a,s}) = L^2(\mathbb{R}, \mathcal{P}_{a,s})$).

The space $H^k_{T,a,s}$ is endowed with the norm

$$\|\zeta\|_{H^k_{T,a,s}} := \sum_{h=0}^{k} T^h \|\partial_t^h \zeta\|_{T,a,s},$$

where

$$\begin{aligned}
\|\zeta\|_{T,a,s} &:= |J|_{L^2,T} + |\psi|_{L^2,T} + \|w\|_{L^2,T,a,s} + \|\bar{w}\|_{L^2,T,a,s}, \\
|J|^2_{L^2,T} &:= \frac{1}{T}\int_0^T |J(t)|^2 dt, \qquad |\psi|^2_{L^2,T} := \frac{1}{T}\int_0^T |\psi(t)|^2 dt, \\
\|w\|^2_{L^2,T,a,s} &:= \frac{1}{T}\int_0^T \|w(t)\|^2_{a,s} dt.
\end{aligned}$$

Note that $H^k_{T,a,s} = \overline{H}^k_{T,a,s} \oplus \mathbb{R}^N$.

Remark 3.5. With the above definitions the following result holds:

$$\|\zeta(t)\|_{\mathcal{P}_{a,s}} \leq \|\zeta\|_{H^1_{T,a,s}} \qquad \forall\, t \in \mathbb{R}. \tag{79}$$

Hence the spaces $H^k_{T,a,s}$, for $k \geq 1$, are Banach algebras, and the $H^k_{T,a,s}$-norm of the product of any component of a vector ζ with any component of a vector ζ' is bounded by $\|\zeta\|_{H^k_{T,a,s}} \|\zeta'\|_{H^k_{T,a,s}}$. We will consider system (78) as a functional equation in $H^k_{T,a,s}$.

To simplify notation we rewrite (78) in the form

$$L\zeta = N(\zeta; \phi_0), \tag{80}$$

where L is the linear operator

$$L\zeta = L(J, \psi, w) := (\dot{\psi} - \eta^2 AJ, \dot{J}, \dot{w}_i + \mathrm{i}\tilde{\Omega}_i w_i) \tag{81}$$

and N is the nonlinearity

$$N(\zeta; \phi_0) := \big(N_I(\zeta; \phi_0), N_\phi(\zeta; \phi_0), N_{\hat{z}}(\zeta; \phi_0)\big) \tag{82}$$

[5]Here $|\cdot|$ is the standard Euclidian norm on $\mathbb{R}^N$, $\|w\|^2_{a,s} = \sum_{i \in \mathcal{I}^c} |w_i|^2 i^{2s} e^{2ai}$.

defined by

$$
\begin{aligned}
(83)\quad N_I &:= \eta^2 B^t w\bar{w} + \eta^4 \partial_I \tilde{K}(I_0 + J, \phi_0 + \tilde{\omega}t + \psi, w),\\
N_\phi &:= -\eta^4 \partial_\phi \tilde{K}(I_0 + J, \phi_0 + \tilde{\omega}t + \psi, w),\\
(N_{z_i}) &:= -\mathrm{i}\eta^2 (BJ)_i w_i - \mathrm{i}\eta^2 \partial_{\bar{z}_i} \hat{G}(w) - \mathrm{i}\eta^4 \partial_{\bar{z}_i} \tilde{K}(I_0 + J, \phi_0 + \tilde{\omega}t + \psi, w), \quad i \in \mathcal{I}^c.
\end{aligned}
$$

We note that by (19) and Remark 3.5, we get that for all $\phi_0 \in \mathbb{T}^N$

$$
N(\cdot; \phi_0) \in C^\infty\big(H^k_{T,a,s}, H^k_{T,a,s+1}\big) \qquad \forall\, k \geq 1. \tag{84}
$$

Since A is invertible and the nonresonance condition (49) holds by Proposition 3.2, the kernel of the linear operator L is

$$
\mathcal{K} = \big\{\zeta(t) = (J(t), \psi(t), w(t)) \ \text{ s.t. } \ \psi(t) \equiv \text{const}, \ J(t) \equiv 0, w(t) \equiv 0\big\}.
$$

On the other hand, the range of L is composed by the curves $\tilde{\zeta}(t) := (\tilde{J}(t), \tilde{\psi}(t), \tilde{w}(t))$ with $\int_0^T \tilde{\psi} = 0$, as we will show in the next subsection concerning the inversion of L.

3.3. Inversion of the linear operator. Recall that $\tau = T/(2\pi) = \eta^{-2}$. By the theory of the symmetric operators, and since A is invertible, it possesses an orthonormal basis of eigenvectors $e^{(1)}, \dots, e^{(N)} \in \mathbb{R}^N$ with respective eigenvalues $\nu_1, \dots, \nu_N \in \mathbb{R} \setminus \{0\}$. In these coordinates we can write

$$
\begin{aligned}
\tilde{J}(t) &= \sum_{j=1}^N \tilde{J}^{(j)}(t) e^{(j)} = \sum_{j=1}^N e^{(j)} \sum_{\ell \in \mathbb{Z}} \tilde{J}^{(j)}_\ell \exp\left(\frac{\mathrm{i}\ell t}{\tau}\right),\\
\tilde{\psi}(t) &= \sum_{j=1}^N \tilde{\psi}^{(j)}(t) e^{(j)} = \sum_{j=1}^N e^{(j)} \sum_{\ell \in \mathbb{Z}} \tilde{\psi}^{(j)}_\ell \exp\left(\frac{\mathrm{i}\ell t}{\tau}\right),\\
\tilde{w}_i(t) &= \sum_{\ell \in \mathbb{Z}} \tilde{w}_{i\ell} \exp\left(\frac{\mathrm{i}\ell t}{\tau}\right), \qquad\qquad i \in \mathcal{I}^c.
\end{aligned}
$$

We define the linear operator

$$
\mathcal{L}\tilde{\zeta} = \mathcal{L}(\tilde{J}, \tilde{\psi}, \tilde{w}) := (J, \psi, w) = \zeta \tag{85}
$$

in the following way:

$$
J(t) := \tau \sum_{j=1}^N e^{(j)} \left(-\frac{1}{\nu_j} \tilde{J}^{(j)}_0 + \sum_{\ell \neq 0} \frac{1}{\mathrm{i}\ell} \tilde{\psi}^{(j)}_\ell \exp\left(\frac{\mathrm{i}\ell t}{\tau}\right)\right), \tag{86}
$$

$$
\psi(t) := \tau \sum_{j=1}^N e^{(j)} \sum_{\ell \neq 0} \frac{1}{\mathrm{i}\ell} \left(\frac{\nu_j}{\mathrm{i}\ell} \tilde{\psi}^{(j)}_\ell + \tilde{J}^{(j)}_\ell \right) \exp\left(\frac{\mathrm{i}\ell t}{\tau}\right), \tag{87}
$$

$$
w_i(t) := \tau \sum_{\ell \in \mathbb{Z}} \frac{1}{\mathrm{i}(\ell - \tilde{\Omega}_i \tau)} \tilde{w}_{i\ell} \exp\left(\frac{\mathrm{i}\ell t}{\tau}\right), \qquad i \in \mathcal{I}^c. \tag{88}
$$

The following proposition not only states that $\mathcal{L}$ is the inverse of L but also gives an upper bound of its norm. However, because of the small divisors $\ell - \tilde{\Omega}_i \tau$, appearing in (88), it turns out that $\mathcal{L}$ "loses one spatial derivative." On the other hand, $\mathcal{L}$ also

"gains one time derivative" if one gives up "two spatial derivatives." Estimate (61) will be crucial.

PROPOSITION 3.6. *Suppose $\tau \in \mathcal{T}_\mu$ and μ small enough. Take $k \in \mathbb{N}^+$. If $\tilde\zeta \in \overline{H}^k_{T,a,s+1}$, then $\zeta = \mathcal{L}\tilde\zeta \in \overline{H}^k_{T,a,s} \cap \overline{H}^{k+1}_{T,a,s-1}$ and*

$$\|\zeta\|_{H^k_{T,a,s}} + \|\zeta\|_{H^{k+1}_{T,a,s-1}} \le c_6^{-1}\,\tau\,\|\tilde\zeta\|_{H^k_{T,a,s+1}}. \tag{89}$$

Moreover,

$$L\mathcal{L}\tilde\zeta = L\zeta = \tilde\zeta. \tag{90}$$

Proof. First we note that the average of ψ is zero as it follows by (87). We now prove (89). Since

$$\frac{1}{T}\int_0^T \left|\sum_{\ell\in\mathbb{Z}} a_\ell \exp\left(\frac{\mathrm{i}\ell t}{\tau}\right)\right|^2 dt = \sum_{\ell\in\mathbb{Z}} |a_\ell|^2 \tag{91}$$

and ($\{e^{(j)}\}_{1\le j\le N}$ being an orthonormal basis) $\left|\sum_{j=1}^N b_j e^{(j)}\right|^2 = \sum_{j=1}^N |b_j|^2$, we have that

$$f(t) = \sum_{j=1}^N e^{(j)} \sum_{\ell\in\mathbb{Z}} f_\ell^{(j)} \exp\left(\frac{\mathrm{i}\ell t}{\tau}\right) \Longrightarrow |f|^2_{L^2,T} = \frac{1}{T}\int_0^T |f(t)|^2 dt = \sum_{j=1}^N \sum_{\ell\in\mathbb{Z}} |f_\ell^{(j)}|^2.$$

Hence, if $\tilde C := 2\max_{1\le j\le N}\{|\nu_j|^2, 1/|\nu_j|^2\}$, from (87) we get

$$|\psi|^2_{L^2,T} \le \tilde C\tau^2 \sum_{j=1}^N \sum_{\ell\ne 0} \ell^{-2}\left(|\tilde\psi_\ell^{(j)}|^2 + |\tilde J_\ell^{(j)}|^2\right) \le \tilde C\tau^2\left(|\tilde\psi|^2_{L^2,T} + |\tilde J|^2_{L^2,T}\right), \tag{92}$$

$$\begin{aligned} |\partial_t^h\psi|^2_{L^2,T} &\le \tilde C\tau^{2(1-h)} \sum_{j=1}^N \sum_{\ell\ne 0} \ell^{2(h-1)}\left(|\tilde\psi_\ell^{(j)}|^2 + |\tilde J_\ell^{(j)}|^2\right) \\ &\le \tilde C\tau^2\left(|\partial_t^{h-1}\tilde\psi|^2_{L^2,T} + |\partial_t^{h-1}\tilde J|^2_{L^2,T}\right) \quad \text{for} \quad h \ge 1. \end{aligned} \tag{93}$$

Similar estimates hold for J defined in (86), namely,

$$|J|^2_{L^2,T} \le \tilde C\tau^2\left(\sum_{j=1}^N |\tilde J_0^{(j)}|^2 + \sum_{j=1}^N \sum_{\ell\ne 0} \ell^{-2}|\tilde\psi_\ell^{(j)}|^2\right) \le \tilde C\tau^2\left(|\tilde J|^2_{L^2,T} + |\tilde\psi|^2_{L^2,T}\right), \tag{94}$$

$$|\partial_t^h J|^2_{L^2,T} = |\partial_t^{h-1}\tilde\psi|^2_{L^2,T} \qquad \text{for} \quad h \ge 1. \tag{95}$$

We now go on to estimate w defined in (88) in which the small divisors $\ell - \tilde\Omega_j\tau$ appear. By (91) we have that if $w(t) = (w_i(t))_{i\in\mathcal{I}^c}$ with $w_i(t) = \sum_{\ell\in\mathbb{Z}} w_{i\ell}\exp(\mathrm{i}\ell t/\tau)$, then

$$\begin{aligned} \|w\|^2_{L^2,T,a,s} &= \frac{1}{T}\int_0^T \|w(t)\|^2_{a,s} = \frac{1}{T}\int_0^T \sum_{i\in\mathcal{I}^c} i^{2s}e^{2ai}|w_i(t)|^2 dt \\ &= \sum_{i\in\mathcal{I}^c} i^{2s}e^{2ai}\frac{1}{T}\int_0^T |w_i(t)|^2 dt = \sum_{i\in\mathcal{I}^c} i^{2s}e^{2ai}\sum_{\ell\in\mathbb{Z}} |w_{i\ell}|^2. \end{aligned}$$

Hence, recalling (88), we get

$$\begin{aligned}\|\partial_t^h w\|^2_{L^2,T,a,s} &= \tau^2 \sum_{i\in\mathcal{I}^c} i^{2s} e^{2ai} \sum_{\ell\in\mathbb{Z}} \frac{|\ell|^{2h}}{\tau^{2h}} \frac{|\tilde{w}_{i\ell}|^2}{|\ell-\tilde{\Omega}_i\tau|^2} \\ &\le \frac{\tau^2}{c_5^2} \sum_{i\in\mathcal{I}^c} i^{2(s+1)} e^{2ai} \sum_{\ell\in\mathbb{Z}} \frac{|\ell|^{2h}}{\tau^{2h}} |\tilde{w}_{i\ell}|^2 = \frac{\tau^2}{c_5^2} \|\partial_t^h \tilde{w}\|^2_{L^2,T,a,s+1} \end{aligned} \tag{96}$$

by the crucial estimate (61). Moreover, we claim that by (61)

$$\frac{|\ell|}{|\ell-\tilde{\Omega}_i\tau|} \le \frac{4\tau i^2}{c_5}. \tag{97}$$

To prove (97) we distinguish two cases, $\ell \le 2\tilde{\Omega}_i\tau$ and $\ell > 2\tilde{\Omega}_i\tau$. In the first case we have by (61)

$$\frac{|\ell|}{|\ell-\tilde{\Omega}_i\tau|} \le \frac{|\ell| i}{c_5} \le \frac{2\tilde{\Omega}_i\tau i}{c_5} \le \frac{4\tau i^2}{c_5}$$

since $\tilde{\Omega}_i \le 2i$. On the other hand, if $\ell > 2\tilde{\Omega}_i\tau$, we have $|\ell-\tilde{\Omega}_i\tau| \ge |\ell|/2$, which implies

$$\frac{|\ell|}{|\ell-\tilde{\Omega}_i\tau|} \le 2 \le \frac{4\tau i^2}{c_5},$$

and (97) follows. Using (97) we get

$$\begin{aligned}\|\partial_t^h w\|^2_{L^2,T,a,s-1} &= \tau^2 \sum_{i\in\mathcal{I}^c} i^{2(s-1)} e^{2ai} \sum_{\ell\in\mathbb{Z}} \frac{|\ell|^{2h}}{\tau^{2h}} \frac{|\tilde{w}_{i\ell}|^2}{|\ell-\tilde{\Omega}_i\tau|^2} \\ &\le \frac{16\tau^2}{c_5^2} \sum_{i\in\mathcal{I}^c} i^{2(s+1)} e^{2ai} \sum_{\ell\in\mathbb{Z}} \frac{|\ell|^{2(h-1)}}{\tau^{2(h-1)}} |\tilde{w}_{i\ell}|^2 \\ &= \frac{16\tau^2}{c_5^2} \|\partial_t^{h-1} \tilde{w}\|^2_{L^2,T,a,s+1}. \end{aligned} \tag{98}$$

Therefore (89) follows from (92)–(96) and (98).

Finally we note that (90) directly follows from the definition of $\mathcal{L}$ given in (85)–(88).

We also remark that the constant c_6 does not depend on k, a, s. □

3.4. Lyapunov–Schmidt reduction. From the previous section it results that the kernel $\mathcal{K}$ and the range $\mathcal{R}$ of the linear operator L are $\{\tilde{\psi} \equiv \text{const}\}$ and $\{\int_0^T \tilde{\psi} = 0\}$, respectively. For $\tilde{\zeta} = (\tilde{J}, \tilde{\psi}, \tilde{w})$ let us define the projections

$$\Pi_{\mathcal{K}}\tilde{\zeta} := \big(0, \langle\tilde{\psi}\rangle, 0\big), \qquad \Pi_{\mathcal{R}}\tilde{\zeta} := \big(\tilde{J}, \tilde{\psi} - \langle\tilde{\psi}\rangle, \tilde{w}\big),$$

where $\langle\tilde{\psi}\rangle := \int_0^T \tilde{\psi}$. In such a way the equation $L\zeta = N(\zeta;\phi_0)$ decomposes into the equation on the kernel,

$$0 = \Pi_{\mathcal{K}} N(\zeta;\phi_0), \quad \text{namely,} \quad \big\langle N_\phi(\zeta,\phi_0)\big\rangle = 0, \tag{99}$$

and the one on the range,

$$L\zeta = \Pi_{\mathcal{R}} N(\zeta;\phi_0), \tag{100}$$

respectively. The idea is to solve first the range equation for any fixed ϕ_0, finding a solution $\zeta(t) = \zeta_{\phi_0}(t)$ by the contraction mapping theorem, and thereafter the kernel equation (99) for $\zeta = \zeta_{\phi_0}$, namely the *finite dimensional* equation

$$\big\langle N_\phi(\zeta_{\phi_0}; \phi_0)\big\rangle = 0, \tag{101}$$

determining ϕ_0 by a variational argument.

3.5. Range equation. We rewrite the range equation (100) in a fixed-point form:

$$\zeta = \Phi(\zeta; \phi_0)$$

with

$$\Phi(\zeta; \phi_0) := \mathcal{L}\Pi_{\mathcal{R}} N(\zeta; \phi_0).$$

By Proposition 3.6, the operator $\mathcal{L}$ "loses one derivative," but, by the smoothing property (84), the nonlinearity N gains exactly *one* derivative. In particular, we have that, for any $\phi_0 \in \mathbb{T}^N$ fixed,

$$\Phi(\cdot; \phi_0) \in C^\infty\big(\overline{H}^k_{T,a,s}, \overline{H}^k_{T,a,s}\big) \qquad \forall\, k \geq 1. \tag{102}$$

In the following lemma we prove that Φ is a contraction on a suitable closed ball of $\overline{H}^1_{T,a,s}$.

LEMMA 3.7. *Suppose $\tau \in \mathcal{T}_\mu$ and μ small enough. For any $\phi_0 \in \mathbb{T}^N$ the map $\Phi(\cdot; \phi_0)$ is a contraction on the closed ball of radius $\rho := c_7^{-1}\mu$ of $\overline{H}^1_{T,a,s}$.*

Proof. Let $\zeta, \zeta', h \in \overline{H}^1_{T,a,s}$ and $\|\zeta\|_{H^1_{T,a,s}}, \|\zeta'\|_{H^1_{T,a,s}} \leq \rho$. From (82), (83), (84), and (32), and recalling Proposition 2.4 and Remark 3.5, we get the following estimates on the nonlinearity:

$$\|N(\zeta)\|_{H^1_{T,a,s+1}} \leq c_8^{-1}\left(\eta^2\rho^2 + \frac{\eta^4}{\mu}\right), \tag{103}$$

$$\|DN(\zeta)[h]\|_{H^1_{T,a,s+1}} \leq c_8^{-1}\left(\eta^2\rho + \frac{\eta^4}{\mu}\right)\|h\|_{H^1_{T,a,s}}. \tag{104}$$

Using Proposition 3.6 and (103), we obtain

$$\|\Phi(\zeta)\|_{H^1_{T,a,s}} \leq (c_6c_8)^{-1}\left(\rho^2 + \frac{\eta^2}{\mu}\right) = (c_6c_8)^{-1}\rho^2 + \frac{\rho}{2} \leq \rho,$$

taking $c_7 := c_4c_6c_8/4$ and μ small enough. Hence Φ maps the ball in itself. Nothing remains but to show that Φ is a contraction. By (104) we get

$$\|N(\zeta) - N(\zeta')\|_{H^1_{T,a,s+1}} \leq c_8^{-1}\left(\eta^2\rho + \frac{\eta^4}{\mu}\right)\|\zeta - \zeta'\|_{H^1_{T,a,s}},$$

and by Proposition 3.6 we have

$$\|\Phi(\zeta) - \Phi(\zeta')\|_{H^1_{T,a,s}} \leq (c_6c_8)^{-1}\left(\rho + \frac{\eta^2}{\mu}\right)\|\zeta - \zeta'\|_{H^1_{T,a,s}}.$$

Since, for μ small enough,

$$(c_6c_8)^{-1}\left(\rho+\frac{\eta^2}{\mu}\right)\leq\left(\frac{1}{c_6c_8}+\frac{1}{2}\right)\frac{\mu}{c_7}<1,$$

Φ is a contraction. □

By the contraction mapping theorem and noting that the dependence of the nonlinearity N, and therefore of Φ, on the parameter ϕ_0 is smooth, we conclude that there exists a smooth function $\mathbb{T}^N\ni\phi_0\mapsto\zeta_{\phi_0}\in\overline{H}^1_{T,a,s}$ solving $\zeta_{\phi_0}=\Phi(\zeta_{\phi_0};\phi_0)$. By (90), ζ_{ϕ_0} also solves the range equation (100), as the following corollary states.

COROLLARY 3.8. *Suppose $\tau\in\mathcal{T}_\mu$ and μ small enough. Then there exists a smooth function $\mathbb{T}^N\ni\phi_0\mapsto\zeta_{\phi_0}\in\overline{H}^1_{T,a,s}$ solving* (100) *and satisfying*

$$\|\zeta_{\phi_0}\|_{H^1_{T,a,s}}\leq\frac{\mu}{c_7}.$$

Remark 3.9. In [BaB], instead of (49) the authors imposed the weaker "diophantine-type" condition $|\ell-\tilde{\Omega}_i\tau|\geq\operatorname{const}i^{-\sigma}$, $\sigma>1$, on the small divisors. Then the operator $\mathcal{L}$ "loses σ derivatives." If the nonlinearity N is smoothing of order $d>1$, namely it "gains d derivatives," taking $1<\sigma<d$, the contraction mapping theorem can still be used in solving the range equation for almost every rescaled period τ. In particular, $d=2$ for the beam equation and $d>1$ for the NLS. Since we have exactly $d=1$ for the wave equation, in order to have a positive measure set of rescaled periods, a KAM analysis is necessary (see Remark 3.12).

3.6. Kernel equation. Once we have solved the range equation (100) by finding the smooth function

$$\mathbb{T}^N\ni\phi_0\mapsto\zeta_{\phi_0}=:(J_{\phi_0},\psi_{\phi_0},w_{\phi_0})\in\overline{H}^1_{T,a,s},$$

we still have to solve the "reduced" kernel equation (101). As the solutions of the Hamiltonian equations (75) are critical points of the action functional S defined in (76), so the solutions of the "reduced" kernel equation (101) are critical points of the *reduced action functional*

$$\mathcal{S}(\phi_0):=S(I_{\phi_0},\phi_{\phi_0},\hat{z}_{\phi_0})=\int_0^T\left(I_{\phi_0}\dot{\phi}_{\phi_0}-\mathrm{i}\hat{z}_{\phi_0}\dot{\bar{\hat{z}}}_{\phi_0}-\widetilde{\mathcal{H}}(\phi_{\phi_0},I_{\phi_0},\hat{z}_{\phi_0},\bar{\hat{z}}_{\phi_0})\right)dt, \tag{105}$$

where

$$I_{\phi_0}(t):=I_0+J_{\phi_0}(t),\qquad\phi_{\phi_0}(t):=\phi_0+\tilde{\omega}t+\psi_{\phi_0}(t),\qquad\hat{z}_{\phi_0}(t):=w_{\phi_0}(t). \tag{106}$$

Actually we are claiming that

$$\langle N_\phi(\zeta_{\phi_0};\phi_0)\rangle=0$$

or equivalently

$$\partial_{\phi_0}\mathcal{S}(\phi_0)=0. \tag{107}$$

Indeed, (107) is a corollary of (36), (83), and the following.

LEMMA 3.10. *The reduced action functional satisfies*

$$\partial_{\phi_0}\mathcal{S}(\phi_0)=-T\langle\partial_\phi\widetilde{\mathcal{H}}(I_{\phi_0},\phi_{\phi_0},\hat{z}_{\phi_0},\bar{\hat{z}}_{\phi_0})\rangle.$$

Proof. We have

$$\begin{aligned}\partial_{\phi_0}\mathcal{S}(\phi_0) &= \int_0^T \Big[\big(\dot\phi_{\phi_0} - \partial_I\widetilde{\mathcal{H}}\big)\partial_{\phi_0} I_{\phi_0} + I_{\phi_0}\partial_{\phi_0}\dot\phi_{\phi_0} - \partial_\phi\widetilde{\mathcal{H}}\ \partial_{\phi_0}\phi_{\phi_0} \\ &\qquad -\big(\mathrm{i}\dot{\bar w}_{\phi_0} + \partial_{\bar z}\widetilde{\mathcal{H}}\big)\partial_{\phi_0} w_{\phi_0} - \mathrm{i} w_{\phi_0}\partial_{\phi_0}\dot{\bar w}_{\phi_0} - \partial_{\bar z}\widetilde{\mathcal{H}}\ \partial_{\phi_0}\bar w_{\phi_0}\Big]\,dt \\ &= I_{\phi_0}\partial_{\phi_0}\phi_{\phi_0}\Big|_0^T - \mathrm{i} w_{\phi_0}\partial_{\phi_0}\bar w_{\phi_0}\Big|_0^T - \int_0^T \big\langle\partial_\phi\widetilde{\mathcal{H}}\big\rangle\partial_{\phi_0}\phi_{\phi_0}\ dt\end{aligned}$$

by an integration by parts and since ζ_{ϕ_0} satisfies the range equation (100). Moreover, since ζ_{ϕ_0} is periodic and $\int_0^T \psi_{\phi_0} = 0$, we get

$$\begin{aligned} I_{\phi_0}\partial_{\phi_0}\phi_{\phi_0}\Big|_0^T &= I_{\phi_0}(0)\partial_{\phi_0}\big(\phi_{\phi_0}(T) - \phi_{\phi_0}(0)\big) = I_{\phi_0}\partial_{\phi_0}\tilde\omega T = 0, \\ w_{\phi_0}\partial_{\phi_0}\bar w_{\phi_0}\Big|_0^T &= w_{\phi_0}(0)\partial_{\phi_0}\big(\bar w_{\phi_0}(T) - \bar w_{\phi_0}(0)\big) = 0 \\ \int_0^T \phi_{\phi_0}(t)\,dt &= \int_0^T \big(\phi_0 + \tilde\omega t\big)\,dt + \int_0^T \psi_{\phi_0}(t)\,dt = \phi_0 T + \tilde\omega\frac{T^2}{2}.\end{aligned}$$

Finally

$$\partial_{\phi_0}\mathcal{S}(\phi_0) = -\int_0^T \big\langle\partial_\phi\widetilde{\mathcal{H}}\big\rangle\partial_{\phi_0}\phi_{\phi_0}\ dt = -\big\langle\partial_\phi\widetilde{\mathcal{H}}\big\rangle\partial_{\phi_0}\int_0^T \phi_{\phi_0}(t)\,dt = -\big\langle\partial_\phi\widetilde{\mathcal{H}}\big\rangle T. \qquad \square$$

3.7. Existence. By (107) every critical point $\phi_0 \in \mathbb{T}^N$ of the reduced action functional $\mathcal{S}$ defined in (105) solves the "reduced" kernel equation (101) and, therefore, the curve $\big(I_{\phi_0}(t), \phi_{\phi_0}(t), \hat z_{\phi_0}(t)\big)$ defined in (106) is a solution of the Hamiltonian equations (75). In particular we expect the existence of at least N geometrically distinct T-periodic solutions, namely solutions not obtained from each other simply by time translations.

Indeed, let us consider the restriction of $\mathcal{S}$ to the plane $E := [\tilde\omega]^\perp$. The set $\mathbb{Z}^N \cap E$ is a lattice of E; hence $\mathcal{S}$ can be defined on the quotient space $\Gamma := E/(\mathbb{Z}^N \cap E) \sim \mathbb{T}^{N-1}$. Due to the invariance of $\mathcal{S}$ with respect to the time shift, any critical point of $\mathcal{S}_{|\Gamma}\colon \Gamma \to \mathbb{R}$ is also a critical point of $\mathcal{S}\colon \mathbb{T}^N \to \mathbb{R}$. By the Lusternik–Schnirelman category theory (see, for example, [A]), since $\operatorname{cat}\Gamma = \operatorname{cat}\mathbb{T}^{N-1} = N$, we can define the N min-max critical values $\mathrm{c}_1 \le \mathrm{c}_2 \le \cdots \le \mathrm{c}_N$ for the reduced action functional $\mathcal{S}_{|\Gamma}$. If the critical levels c_i are all distinct, the corresponding T-periodic solutions are surely geometrically distinct, since their actions c_i are different. On the other hand, if some min-max critical levels coincide, then $\mathcal{S}_{|\Gamma}$ possesses infinitely many critical points. Although not all the corresponding T-periodic solutions are necessarily geometrically distinct, since a periodic solution can cross Γ at most a finite number of times, the existence of infinitely many geometrically distinct orbits follows (see [BBiV] for further details).

PROPOSITION 3.11. *Suppose $\tau \in \mathcal{T}_\mu$ and μ small enough. Then system* (75) *possesses (at least) N geometrically distinct T-periodic solutions*

(108)
$$\big(I_{\phi_0^{(j)}}(t), \phi_{\phi_0^{(j)}}(t), \hat z_{\phi_0^{(j)}}(t)\big) = \big(I_0(\tau), \phi_0^{(j)} + \tilde\omega t, 0\big) + \zeta_{\phi_0^{(j)}}(t), \qquad \zeta_{\phi_0^{(j)}} \in \overline{H}^1_{T,a,s},$$

parametrized by suitable $\phi_0^{(j)} \in \mathbb{T}^N$, $1 \le j \le N$. Moreover,

$$\|\zeta_{\phi_0^{(j)}}\|_{H^1_{T,a,s}} \le \frac{\mu}{c_7} \qquad \forall\, 1 \le j \le N. \tag{109}$$

Remark 3.12. In (49) we have imposed a strong condition on the small divisors in order to use the standard contraction mapping theorem in solving the range equation. The other side of such a condition is that we are able to consider only a finite number of periods. The natural way to deal with the small divisors problem (49), in order to obtain a positive measure set of periods, should be via a KAM analysis. The range equation should be solved by a Nash–Moser implicit function theorem. Thereafter, one should prove that, for any fixed value of the perturbative parameter η, the bifurcation equation $0 = \Pi_{\mathcal{K}} N(\zeta_{\phi_0}; \phi_0)$ has a solution for ϕ_0 belonging to a suitable η-dependent Cantor set $\mathcal{C}_\eta$ (see [BBo06] and [GMPr05], where the extension of Weinstein's theorem [We73] for completely resonant wave equation is considered). A standard way to proceed is to develop the reduced action functional in powers of the perturbative parameter and to prove that the first nontrivial term in the development has a nondegenerate critical point. Such nondegeneracy is used to show that, for any η in a suitable positive measure set, there exists a critical point $\phi_0 = \phi_0(\eta)$ of the whole reduced action functional, belonging to $\mathcal{C}_\eta$. However, in the present case, while the perturbative parameter η goes to zero, the period T goes to infinity. Then, in the computation of $\mathcal{S}$ in (105), one has to average over an *infinite* time. As a consequence, all the low order terms in the development of $\mathcal{S}$ vanish; the first nontrivial terms appear only at a very high order in η, and it is difficult to deal with them.

3.8. Regularity. The solutions $(I_0(\tau), \phi_0^{(j)} + \tilde{\omega} t, 0) + \zeta_{\phi_0^{(j)}}(t)$ of system (75) described in (108) belong to $H^1_{T,a,s}$ and verify estimate (109). With the same procedure, for any fixed $k \geq 1$, we can also find solutions in $H^k_{T,a,s}$ verifying

$$\|\zeta_{\phi_0^{(j)}}\|_{H^k_{T,a,s}} \leq \frac{\mu}{c_7}. \tag{110}$$

Indeed, we can solve the range equation (100) in $\overline{H}^k_{T,a,s}$, adapting Lemma 3.7. However, in this case, the constant c_7 *depends on* k.

On the other hand, giving up the $H^k_{T,a,s}$-estimate in (110), it is possible to prove, by a bootstrap argument, that the solutions (108) of Proposition 3.11 actually belong to $H^k_{T,a,s}$ for any $k \geq 1$. In particular we show that ζ_{ϕ_0} of Corollary 3.8 belongs to $\overline{H}^k_{T,a,s}$.

Indeed, $\zeta_{\phi_0} \in \overline{H}^1_{T,a,s}$ solves the fixed point equation $\zeta_{\phi_0} = \Phi(\zeta_{\phi_0}; \phi_0) = \mathcal{L}\Pi_{\mathcal{R}} N(\zeta_{\phi_0}; \phi_0)$. Since $N(\zeta_{\phi_0}; \phi_0) \in H^1_{T,a,s+1}$ by (84), then $\zeta_{\phi_0} \in \overline{H}^2_{T,a,s-1}$ by Proposition 3.6. Noting that $\overline{H}^k_{T,a,s-1} \subset \overline{H}^k_{T,\tilde{a},s}$ for any $k \geq 1$ and $0 < \tilde{a} < a$, we have $\zeta_{\phi_0} \in \overline{H}^2_{T,\tilde{a},s}$. Defining $a_k := a\left(\frac{1}{2} + \frac{1}{2^k}\right)$, we prove that $\zeta_{\phi_0} \in \overline{H}^k_{T,a_k,s}$ for any $k \geq 1$ and finally, $\zeta_{\phi_0} \in \overline{H}^k_{T,a/2,s}$ for any $k \geq 1$. However, in this fashion, the $H^k_{T,a,s}$-estimates deteriorate while k increases.

Summarizing, by the Sobolev immersions we have that $\zeta_{\phi_0} \in C^k(\mathbb{R}, \mathcal{P}_{a/2,s})$ for any $k \geq 1$. We have shown the following.

COROLLARY 3.13. *The solutions* (108) *of* (75) *belong to* $C^\infty(\mathbb{R}, \mathcal{P}_{a/2,s})$.

3.9. Minimal period.

LEMMA 3.14. *Let* $h, k \in \mathbb{N}^+$, $h < k$. *We have*

$$[\omega_k \tau - k\tau] \leq [\omega_h \tau - h\tau] < \frac{\mu\tau}{2h}. \tag{111}$$

Proof. We first proof that

$$\omega_k - k < \omega_h - h, \tag{112}$$

which implies $\omega_k\tau - k\tau < \omega_h\tau - h\tau$ and the first inequality in (111). Dividing by k, (112) is equivalent to

$$f(x) := \sqrt{x^2 + \mu/k^2} - x - \sqrt{1 + \mu/k^2} + 1 > 0 \qquad \text{for} \quad 0 < x < 1,$$

where $x := h/k$. Since $f(1) = 0$ and $f'(x) = x(x^2 + \mu/k^2)^{-1/2} - 1 < 0$ for $0 < x < 1$, we get $f(x) > 0$, and (112) follows. Then the second inequality in (111) directly follows from (65). ∎

LEMMA 3.15. *Let $T^{\min}$ be the minimal period of a T-periodic orbit* (108) *of Proposition* 3.11. *If $N \geq 2$, then*

$$T^{\min} \geq \frac{c_9}{\mu}. \tag{113}$$

Proof. Let $\big(I(t), \phi(t), \hat{z}(t)\big)$ be a T-periodic solution of Proposition 3.11. We know that $\phi(T) - \phi(0) = 2\pi k$ with $k \in \mathbb{Z}^N$ defined in (55). Denoting by $T_\phi^{\min} \leq T^{\min}$ the minimal period of $\phi(t)$, we have that there exist $n \in \mathbb{N}^+$ such that $nT_\phi^{\min} = T$ and $\tilde{k} \in \mathbb{Z}^N$ such that $\phi(T_\phi^{\min}) - \phi(0) = 2\pi\tilde{k}$, verifying $n\tilde{k} = k$. Hence we deduce that n divides $g := \gcd(k_{i_1}, \dots, k_{i_N})$, and we get that

$$T^{\min} \geq T_\phi^{\min} = \frac{T}{n} \geq \frac{T}{g}. \tag{114}$$

We claim that

$$\tilde{g} := \gcd(k_{i_1}, k_{i_2}) < \frac{\mu\tau i_2}{i_1}. \tag{115}$$

Then the lemma follows by (114) and (115), noting that $\tilde{g} \geq g$ and recalling that $T = 2\pi\tau$ (with $c_9 = 2\pi i_1/i_2$).

We now prove (115). Since $\tau \in \mathbb{N}$ we have $k_i = [\omega_i\tau] + \kappa_i = i\tau + [\omega_i\tau - i\tau] + \kappa_i$ for all $i \in \mathcal{I}$ and

$$\begin{aligned} i_2k_{i_1} - i_1k_{i_2} &= i_2[\omega_{i_1}\tau - i_1\tau] - i_1[\omega_{i_2}\tau - i_2\tau] + i_2\kappa_{i_1} - i_1\kappa_{i_2} \\ &\geq (i_2 - i_1)[\omega_{i_1}\tau - i_1\tau] + \left(\frac{i_2}{i_1} - \frac{i_1}{i_2}\right)\tilde{\kappa} > 0 \end{aligned} \tag{116}$$

by (111) and recalling (52). Moreover, since $\tilde{g} = \gcd(k_{i_1}, k_{i_2})$ there exist $h_1, h_2 \in \mathbb{N}$ such that $k_{i_1} = h_1\tilde{g}$ and $k_{i_2} = h_2\tilde{g}$. From (116) we have that $i_2k_{i_1} - i_1k_{i_2} > 0$, and therefore

$$i_2k_{i_1} - i_1k_{i_2} = \big(i_2h_1 - i_1h_2\big)\tilde{g} \geq \tilde{g}. \tag{117}$$

Finally, by (111)

$$\begin{aligned} i_2k_{i_1} - i_1k_{i_2} &= i_2[\omega_{i_1}\tau - i_1\tau] - i_1[\omega_{i_2}\tau - i_2\tau] + i_2\kappa_{i_1} - i_1\kappa_{i_2} \\ &< i_2[\omega_{i_1}\tau - i_1\tau] + \frac{i_2}{i_1}\tilde{\kappa} \leq \frac{i_2}{i_1}\left(\frac{\mu\tau}{2} + \tilde{\kappa}\right) \leq \frac{i_2\mu\tau}{i_1} \end{aligned} \tag{118}$$

for μ small enough. Then (115) follows from (117) and (118). ∎

3.10. Distinct orbits. Take $\tau, \tau' \in \mathcal{T}_\mu$. For μ small enough, τ, τ' satisfy the hypotheses of Proposition 3.11. Therefore, let

$$\big(I(t), \phi(t), \hat{z}(t)\big) := \big(I_0(\tau), \phi_0 + \tilde{\omega} t, 0\big) + \zeta(t), \qquad \phi_0 \in \mathbb{T}^N,\ \zeta \in \overline{H}^1_{T,a,s},\ T = 2\pi\tau,$$
$$\big(I'(t), \phi'(t), \hat{z}'(t)\big) := \big(I_0(\tau'), \phi'_0 + \tilde{\omega} t, 0\big) + \zeta'(t), \quad \phi'_0 \in \mathbb{T}^N,\ \zeta' \in \overline{H}^1_{T',a,s},\ T' = 2\pi\tau',$$

be two solutions of (75) found in Proposition 3.11; we recall that by (109),

$$\|\zeta\|_{H^1_{T,a,s}} \le \frac{\mu}{c_7}, \qquad \|\zeta'\|_{H^1_{T',a,s}} \le \frac{\mu}{c_7}. \tag{119}$$

Suppose that they are geometrically the same solution, namely, up to a time translation,

$$\big(I(t), \phi(t), \hat{z}(t)\big) = \big(I'(t), \phi'(t), \hat{z}'(t)\big) \qquad \forall\, t \in \mathbb{R}. \tag{120}$$

We claim that

$$|I_0(\tau) - I_0(\tau')| \le \frac{2\mu}{c_7}. \tag{121}$$

Indeed, using $I(t) = I'(t)$,

$$\begin{aligned} |I_0(\tau) - I_0(\tau')| &= |J(t) - J'(t)| \le |J(t)| + |J'(t)| \\ &\le \|\zeta(t)\|_{\mathcal{P}_{a,s}} + \|\zeta'(t)\|_{\mathcal{P}_{a,s}} \le \|\zeta\|_{H^1_{T,a,s}} + \|\zeta'\|_{H^1_{T',a,s}} \le \frac{2\mu}{c_7}, \end{aligned}$$

recalling (79) and (119).

Moreover, we claim that (120) implies also

$$\{\omega_{i_1}(\tau' - \tau)\} < \frac{\mu}{c_{10}} \qquad \text{or} \qquad \{\omega_{i_1}(\tau - \tau')\} < \frac{\mu}{c_{10}}, \tag{122}$$

with $c_{10} := c_7/2\|A\|$. Indeed, since $|A^{-1}v| \ge \|A\|^{-1}|v|$ for any $v \in \mathbb{R}^N$, recalling (54) and choosing $v := \{\omega\tau'\} - \{\omega\tau\}$, we have $I_0(\tau) - I_0(\tau') = A^{-1}v$, and therefore

$$|I_0(\tau) - I_0(\tau')| \ge \|A\|^{-1}|\{\omega\tau'\} - \{\omega\tau\}| \ge \|A\|^{-1}|\{\omega_{i_1}\tau'\} - \{\omega_{i_1}\tau\}|. \tag{123}$$

Noting that[6]

$$|\{\omega_{i_1}\tau'\} - \{\omega_{i_1}\tau\}| = \{\omega_{i_1}(\tau' - \tau)\} \qquad \text{or} \qquad |\{\omega_{i_1}\tau'\} - \{\omega_{i_1}\tau\}| = \{\omega_{i_1}(\tau - \tau')\},$$

(122) follows by (121) and (123).

LEMMA 3.16. *Let*

$$\mathcal{M} := \left\{ n \in \mathbb{Z}, \quad |n| \le \frac{c_4}{2\mu^2} \quad s.t. \quad \{\omega_{i_1} n\} \le \frac{\mu}{c_{10}} \right\}. \tag{124}$$

Then

$$\sharp\, \mathcal{M} \le \frac{10 c_4}{c_{10}\mu}.$$

[6]Indeed, if $\{x\} \ge \{y\}$, then

$$|\{x\} - \{y\}| = \{x\} - \{y\} = \big\{\{x\} - \{y\}\big\} = \{x - y - [x] + [y]\} = \{x - y\};$$

on the other hand, if $\{y\} \ge \{x\}$, then $|\{x\} - \{y\}| = \{y - x\}$.

Proof. We first note that, for μ small enough, we get

$$\left[\frac{2c_4}{i_1\mu}\right]\left[\frac{i_1}{\mu}\right] \geq \left(\frac{2c_4}{i_1\mu}-1\right)\left(\frac{i_1}{\mu}-1\right) \geq \frac{c_4}{\mu^2}+1,$$

and therefore,

$$\left[-\frac{c_4}{2\mu^2},\frac{c_4}{2\mu^2}\right] \subseteq \bigcup_{1\leq m\leq\left[\frac{2c_4}{i_1\mu}\right]} \left[\left[-\frac{c_4}{2\mu^2}\right]+(m-1)\left[\frac{i_1}{\mu}\right], \left[-\frac{c_4}{2\mu^2}\right]+m\left[\frac{i_1}{\mu}\right]\right). \tag{125}$$

Now we claim that

$$\sharp\left(\mathcal{M}\cap\left[\bar n,\bar n+\left[\frac{i_1}{\mu}\right]\right]\right) \leq \frac{4i_1}{c_{10}}+1 \qquad \forall\,\bar n\in\mathbb{Z}. \tag{126}$$

Then from (125) and (126) we have

$$\sharp\,\mathcal{M} \leq \left(\frac{4i_1}{c_{10}}+1\right)\left[\frac{2c_4}{i_1\mu}\right] \leq \frac{5i_1}{c_{10}}\frac{2c_4}{i_1\mu} \leq \frac{10c_4}{c_{10}\mu},$$

and the lemma follows.

Nothing remains but to prove (126). If $\mathcal{M}\cap\big[\bar n,\bar n+[i_1/\mu]\big)=\emptyset$, then (126) is trivially true. Otherwise let

$$n_0 := \min\big(\mathcal{M}\cap\big[\bar n,\bar n+[i_1/\mu]\big)\big).$$

By definition, $n\notin\mathcal{M}$ for any $\bar n\leq n<n_0$. Moreover, by (65), (66) we have

$$\{\omega_{i_1}n\}=\{\delta^{(1)}_{i_1}n\} \qquad \text{with} \quad \frac{\mu}{4i_1}<\delta^{(1)}_{i_1}<\frac{\mu}{2i_1}. \tag{127}$$

We now prove that

$$n\in\mathcal{M}\cap\big[\bar n,\bar n+[i_1/\mu]\big) \Longrightarrow n=n_0+n', \qquad 0\leq n'<4i_1/c_{10}, \tag{128}$$

from which (126) follows. By definition of n_0 it is obvious that $n'\geq 0$. Let us consider $n'\in\mathbb{N}$ such that

$$4i_1/c_{10}\leq n'<\bar n-n_0+[i_1/\mu].$$

For such n' we will show that $\{\omega_{i_1}(n_0+n')\}>\mu/c_{10}$. We have that

$$\{\omega_{i_1}(n_0+n')\}=\{\delta^{(1)}_{i_1}n_0+\delta^{(1)}_{i_1}n'\}=\{\{\delta^{(1)}_{i_1}n_0\}+\delta^{(1)}_{i_1}n'\}. \tag{129}$$

By (127)

$$\frac{\mu}{c_{10}}=\frac{\mu}{4i_1}\frac{4i_1}{c_{10}}<\{\delta^{(1)}_{i_1}n_0\}+\delta^{(1)}_{i_1}n'<\{\omega_{i_1}n_0\}+\frac{\mu}{2i_1}n'<\frac{\mu}{c_{10}}+\frac12\leq 1. \tag{130}$$

Therefore

$$\{\delta^{(1)}_{i_1}n_0\}+\delta^{(1)}_{i_1}n'=\big\{\{\delta^{(1)}_{i_1}n_0\}+\delta^{(1)}_{i_1}n'\big\}=\{\omega_{i_1}(n_0+n')\}$$

from (129). Finally, by (130),

$$\{\omega_{i_1}(n_0+n')\} > \frac{\mu}{c_{10}}.$$

Hence $n_0+n' \notin \mathcal{M}$, and (128) follows. □

LEMMA 3.17. *Fix $\tau \in \mathcal{T}_\mu$. For μ small enough*

$$\sharp\Big\{\tau' \in \mathcal{T}_\mu \quad s.t. \quad (120) \quad holds\Big\} \leq \frac{10c_4}{c_{10}\mu}.$$

Proof. If (120) holds, then τ and τ' verify (122). Hence $\tau - \tau' \in \mathcal{M}$, defined in (124). We conclude by Lemma 3.16. □

By Lemmas 3.4 and 3.17 we conclude that the number of geometrically distinct solutions found in Proposition 3.11 is greater than

$$\frac{c_4}{6\mu^2}\left(\frac{10c_4}{c_{10}\mu}\right)^{-1} = \frac{c_{10}}{60\mu}.$$

Actually, since in Proposition 3.11 N geometrically distinct orbits correspond to any τ, then the total number of geometrically distinct solutions is greater than c_{11}/μ with $c_{11} := c_{10}N/60$.

COROLLARY 3.18. *The total number of geometrically distinct solutions found in Proposition* 3.11 *is greater than c_{11}/μ.*

3.11. Proof of Theorem 1.1. Suppose that $\tau \in \mathcal{T}_\mu$, μ small enough, and consider a solution found in Proposition 3.11. Such a solution is of the form

$$(131)\quad \big(I(t),\phi(t),\hat{z}(t)\big) = \big(I_0(\tau),\tilde{\omega}t+\phi_0,0\big)+\zeta(t) = \big(I_0(\tau)+J(t),\tilde{\omega}t+\phi_0+\psi(t),w(t)\big)$$

with

$$(132)\qquad |J(t)| + |\psi(t)| + \|w(t)\|_{a,s} \leq \frac{\mu}{c_7} \quad \forall\, t \in \mathbb{R},$$

by (109) and (79). We now want to rewrite such a solution in the z variables defined in (30); by (33) and recalling that $\hat{z}_i = z_i$ for $i \in \mathcal{I}^c$ we get

$$\begin{cases} z_i(t) = \sqrt{I_i(t)}\big(\cos\phi_i(t) - \mathrm{i}\sin\phi_i(t)\big) & \text{for } i \in \mathcal{I}, \\ z_i(t) = w_i(t) & \text{for } i \in \mathcal{I}^c. \end{cases}$$

In the z_* variables of Proposition 2.4 we have

$$\begin{cases} \mathrm{z}_{*i}(t) = \eta\sqrt{I_i(t)}\big(\cos\phi_i(t) - \mathrm{i}\sin\phi_i(t)\big) & \text{for } i \in \mathcal{I}, \\ \mathrm{z}_{*i}(t) = \eta w_i(t) & \text{for } i \in \mathcal{I}^c \end{cases}$$

by (30) and

$$(133)\qquad \sup_{t\in\mathbb{R}} \|\mathrm{z}_*(t)\|_{a,s} = O(\eta).$$

We define $\check{z} := (\check{z}_i)_{i\geq 1}$ by

$$\check{z}_i(t) := \begin{cases} \sqrt{(I_0)_i}\big(\cos\big(\tilde{\omega}t + (\phi_0)_i\big) - \mathrm{i}\sin\big(\tilde{\omega}t + (\phi_0)_i\big)\big) & \text{for } i \in \mathcal{I}, \\ 0 & \text{for } i \in \mathcal{I}^c. \end{cases}$$

By (132) we get

$$\sup_{t\in\mathbb{R}} \|\mathrm{z}_*(t) - \eta\check{z}(t)\|_{a,s} = O\left(\eta\mu\right). \tag{134}$$

Concerning the z variables defined in (15) we have, recalling (18), (133), and (134),

$$\sup_{t\in\mathbb{R}} \|\mathrm{z}(t) - \eta\check{z}(t)\|_{a,s} = O\left(\eta\mu + \eta^3\right) = O\left(\eta\mu\right) = O\big(\mu^2\big), \tag{135}$$

since

$$\eta^2 = 1/\tau \le 2\mu^2/c_4, \tag{136}$$

recalling (53) and (59). Regarding the q variables defined in (9) we have, recalling (15) and (135),

$$\sup_{t\in\mathbb{R}} \|q(t) - \eta\check{q}(t)\|_{a,s} = O\big(\mu^2\big), \tag{137}$$

where $\check{q} := (\check{q}_i)_{i\ge1}$ and

$$\check{q}_i(t) := \begin{cases} \sqrt{2(I_0)_i}\cos\left(\tilde{\omega}t + (\phi_0)_i\right) & \text{for } i \in \mathcal{I}, \\ 0 & \text{for } i \in \mathcal{I}^c. \end{cases}$$

We note that, by Corollary 3.13, the solution in (131) belongs to $C^\infty(\mathbb{R}, \mathcal{P}_{a/2,s})$, and therefore, $q \in C^\infty(\mathbb{R}, \ell^{a/2,s})$. Finally, by Lemma 2.1, we have that

$$u(t,x) := \sum_{i\ge1} q_i(t)\sqrt{\frac{2}{\pi\omega_i}}\,\sin ix$$

belongs to $C^\infty(\mathbb{R}\times[0,\pi],\mathbb{R})$ and is a solution of (1). Defining

$$\tilde{u}(t,x) := \eta\sum_{i\in\mathcal{I}} 2\sqrt{\frac{(I_0)_i}{\pi\omega_i}}\cos\left(\tilde{\omega}t + (\phi_0)_i\right)\sin ix, \tag{138}$$

we have, for any $t\in\mathbb{R}$ and $x\in[0,\pi]$,

$$\begin{aligned} |u(t,x) - \tilde{u}(t,x)| &= \left|\sum_{i\ge1}\left(q_i(t) - \eta\check{q}_i(t)\right)\sqrt{\frac{2}{\pi\omega_i}}\,\sin ix\right| \\ &\le \sum_{i\ge1}\left|q_i(t) - \eta\check{q}_i(t)\right|\sqrt{\frac{2}{\pi\omega_i}} \\ &\le c_{12}\|q(t) - \eta\check{q}(t)\|_{a,s}, \end{aligned}$$

where, in the last line, we have used the Cauchy–Schwarz inequality. Therefore, by (137), we get

$$\sup_{t\in\mathbb{R},\, x\in[0,\pi]} |u(t,x) - \tilde{u}(t,x)| = O\big(\mu^2\big). \tag{139}$$

Define, for $i\in\mathcal{I}$,

$$a_i := 2\frac{\eta}{\mu}\sqrt{\frac{(I_0)_i}{\pi\omega_i}}. \tag{140}$$

Since $\eta = 1/\sqrt{\tau} \geq \mu/\sqrt{c_4}$ (recall (53) and (59)), by Lemma 3.1 we get

$$a_i \geq \frac{2}{\sqrt{c_4}}.$$

Defining $\varphi_i := (\phi_0)_i$ for $i \in \mathcal{I}$, (6) follows by (138), (139), and (140).

Estimate (8) follows from Lemma 3.15, while (7) follows from (45) and (136). Finally, the statement about the total number of geometrically distinct solutions follows from Corollary 3.18.

Remark 3.19. We can improve estimate (6) or, equivalently, (139). Indeed, for any fixed $k \geq 1$ and ζ in (131), by (110), we have $\|\zeta\|_{H^k_{T,a,s}} \leq \mathrm{const}(k)\,\mu$, where $\mathrm{const}(k)$ is a suitable large constant depending on $\mathcal{I}$, a, s, and k. Arguing as above and using the Sobolev immersion $H^k \subset C^{k-1}$, we get $\|q - \eta\check{q}\|_{C^{k-1}(\mathbb{R},\ell^{a,s})} \leq \mathrm{const}(k)\,\mu^2$. Therefore $\sup_{\mathbb{R}\times[0,\pi]} \left|\partial_t^h(u-\tilde{u})\right| \leq \mathrm{const}(k)\,\mu^2$ for any $h \leq k-1$. Since the estimates on the x-derivatives directly follows by the analyticity, we conclude that $\|u-\tilde{u}\|_{C^k(\mathbb{R}\times[0,\pi])} \leq \mathrm{const}(k)\,\mu^2$. We remark that, if one needs the previous C^k-estimate, the constant c in Theorem 1.1 must depend on k.

Appendix.

LEMMA A.1. *Except a countable set of $\mu > 0$ for any $\mathcal{I} = \{i_1 < \cdots < i_N\} \subset \mathbb{N}^+$, $N \geq 1$, the vector $\omega = (\omega_{i_1}, \ldots, \omega_{i_N})$, $\omega_i = \sqrt{i^2 + \mu}$, is rationally independent.*

Proof. For any $n \in \mathbb{Z}^N \setminus \{0\}$ let us define $E_n := \big\{\mu > 0 \quad \text{s.t.} \quad \omega \cdot n = 0\big\}$. We claim that E_n is at the most countable. Indeed, for $\mu > -1$, let us consider the analytic function

$$f_n(\mu) := \sum_{j=1}^{N} \sqrt{i_j^2 + \mu} \cdot n_j = \omega \cdot n.$$

It is enough to show that f_n is not identically zero, so that the set of its zeros is at the most countable. Suppose, by contradiction, that $f_n(\mu) \equiv 0$ for any $\mu > -1$, then $d^k f_n/d\mu^k(0) = 0$ for any $k \geq 1$, and therefore $\sum_{j=1}^N n_j\, i_j^{1-2k} = 0$ for any $k \geq 1$. Hence, multiplying for i_1^{2k-1}, we have

$$n_1 + \sum_{j=2}^{N} n_j \left(\frac{i_1}{i_j}\right)^{2k-1} = 0 \qquad \forall\, k \geq 1.$$

Noting that $i_j > i_1$ for any $j \geq 2$, and taking the limit for $k \to \infty$, we get $n_1 = 0$. In the same way one can prove that $n_2 = 0$ and, by induction, that $n_1 = \cdots = n_N = 0$. □

Proof of Lemma 2.1. We first prove that $u(t,x)$ is C^k. Moreover, for any fixed $t \in \mathbb{R}$, the function $x \mapsto \partial_t^h u(t,x)$, $h < k+1$, is real analytic with an analytic extension in the complex strip $|\mathrm{Im}\, x| < a$. Since $q \in C^k(\mathbb{R}, \ell^{a,s})$, we have that for all $t \in \mathbb{R}$,

$$\sum_{i\geq 1} |q_i(t)|^2 i^{2s} e^{2ai} = \|q(t)\|_{a,s}^2 \leq \|q\|^2_{C^k(\mathbb{R},\ell^{a,s})} < \infty. \tag{141}$$

For any fixed $\tilde{a} < a$ by (141), the Cauchy–Schwarz inequality, and

$$\sup_{|\mathrm{Im}\, x|\leq \tilde{a}} |\chi_i(x)| \leq \sup_{|\mathrm{Im}\, x|\leq \tilde{a}} |\sin ix| \leq e^{\tilde{a}i},$$

we get, for $i_0 \geq 1$,

$$\sup_{|\operatorname{Im} x|\leq \tilde{a}} \left| \sum_{i\geq i_0} \frac{q_i(t)}{\sqrt{\omega_i}}\, \chi_i(x) \right|^2 \leq \sum_{i\geq i_0} |q_i(t)|^2 i^{2s} e^{2ai} \sum_{i\geq i_0} \omega_i^{-1} i^{-2s} e^{-2(a-\tilde{a})i}$$
$$\leq \|q\|^2_{C^k(\mathbb{R},\ell^{a,s})} \sum_{i\geq i_0} \omega_i^{-1} i^{-2s} e^{-2(a-\tilde{a})i} \quad \stackrel{i_0\to\infty}{\longrightarrow} \quad 0,$$

from which we have that, for any $t \in \mathbb{R}$, the series in (13) uniformly converges to a 2π-periodic real analytic odd function with analytic extension on the complex strip $|\operatorname{Im} x| < a$. Moreover, again by the Cauchy–Schwarz inequality, we get

$$|\partial_x^h u(t,x)| \leq \|q(t)\|^2_{a,s} \sum_{i\geq 1} \omega_i^{-1} i^{2(h-s)} e^{-2ai} \qquad \forall\, (t,x) \in \mathbb{R}\times[0,\pi], \quad h \in \mathbb{N},$$

and, from (141), we have that

$$\forall\, h \in \mathbb{N} \;\; \exists\, c_{h,a,s} > 0 \;\; \text{s.t.} \qquad \sup_{(t,x)\in\mathbb{R}\times[0,\pi]} |\partial_x^h u(t,x)| \leq c_{h,a,s}. \tag{142}$$

By similar arguments one proves that for any $x \in [0,\pi]$, the function

$$\mathbb{R} \ni t \mapsto u(t,x) = \sum_{i\geq 1} \frac{q_i(t)}{\sqrt{\omega_i}}\, \chi_i(x)$$

is continuous since the series uniformly converges on $\mathbb{R}$ (and the functions $t \mapsto q_i(t)$ are continuous since $q \in C^0(\mathbb{R}, \ell^{a,s})$). The continuity in both variables follows by (142) and the continuity in t for x_0 fixed:

$$|u(t,x) - u(t_0,x_0)| \leq |u(t,x) - u(t,x_0)| + |u(t,x_0) - u(t_0,x_0)|$$
$$\leq c_{1,a,s}|x - x_0| + |u(t,x_0) - u(t_0,x_0)|.$$

Arguing as above one proves that, for any fixed $x \in [0,\pi]$, the series

$$\sum_{i\geq 1} \frac{1}{\sqrt{\omega_i}}\, \partial_t q_i(t) \chi_i(x)$$

uniformly converges for $t \in \mathbb{R}$; hence we can differentiate inside the summation in (13), obtaining

$$\partial_t u(t,x) = \sum_{i\geq 1} \frac{1}{\sqrt{\omega_i}}\, \partial_t q_i(t) \chi_i(x).$$

Carrying on the above arguments we finally have that $u \in C^k$ and that

$$\partial_t^h u(t,x) = \sum_{i\geq 1} \frac{1}{\sqrt{\omega_i}}\, \partial_t^h q_i(t) \chi_i(x), \qquad h < k+1, \tag{143}$$

is, for any fixed $t \in \mathbb{R}$, a 2π-periodic real analytic odd function with analytic extension on the complex strip $|\operatorname{Im} x| < a$.

We now prove that u, defined in (13), is a classical solution of (1). From (9) and (10),

$$\frac{\partial G}{\partial q_i} = \frac{1}{\sqrt{\omega_i}} \int_0^\pi f(u)\chi_i \, dx; \tag{144}$$

hence, we have, by (143) and (11),

$$\begin{aligned} u_{tt} &= \sum_{i\geq 1} \frac{\ddot{q}_i(t)}{\sqrt{\omega_i}} \chi_i(x) \\ &= \sum_{i\geq 1} \frac{1}{\sqrt{\omega_i}} \left(-\omega_i^2 q_i - \omega_i \frac{\partial G}{\partial q_i} \right) \chi_i \\ &= -\sum_{i\geq 1} \frac{q_i(t)}{\sqrt{\omega_i}} \, (\mu - \partial_{xx}) \, \chi_i(x) - \sum_{i\geq 1} \chi_i \int_0^\pi f(u)\chi_i \, dx, \end{aligned}$$

because ω_i^2 are the eigenvalues of the operator $\mu - \partial_{xx}$. Moreover, as χ_i for $i \geq 1$ is a complete orthonormal basis for the L^2 functions on $[0, \pi]$, we obtain

$$u_{tt} = -(\mu - \partial_{xx})u - \sum_{i\geq 1} \chi_i \int_0^\pi f(u)\chi_i \, dx = -(\mu - \partial_{xx})u - f(u). \qquad \square$$

ON THE GLOBAL EXISTENCE OF WEAK SOLUTIONS FOR THE NAVIER–STOKES EQUATIONS OF COMPRESSIBLE FLUID FLOWS*

MIKHAIL PEREPELITSA†

Abstract. We study the Cauchy problem for the two dimensional Navier–Stokes equations of compressible fluid flows with periodic initial data. We assume that the bulk viscosity coefficient depends on the density of the flow. The global existence of a weak solution with uniform lower and upper bounds on the density, as well as the decay of the solution to an equilibrium state, is proved when the initial datum, $(\rho_0, \mathbf{u}_0)$, does not contain vacuum and belongs to the space $L^\infty\left(\mathbb{T}^2\right) \times \left[W^{1,2}\left(\mathbb{T}^2\right)\right]^2$, where $\mathbb{T}^2 = \mathbb{R}^2/\mathbb{Z}^2$.

Key words. compressible Navier–Stokes equations, Orlicz spaces, commutator operators

1. Introduction.

In the mathematical model of the motion of a compressible, viscous, isentropic gas, the gas is described by its density (scalar), $\rho(t,x)$, and velocity (vector), $\mathbf{u}(t,x)$, both being functions of time t and position in physical space $x \in \mathbb{R}^3$. If there are no external forces acting on the gas, the flow of the gas is plane-parallel and does not depend on the displacement in the transversal direction. The model is described by the following system of the two dimensional compressible Navier–Stokes equations:

$$\rho_t + \operatorname{div} \rho\mathbf{u} = 0, \tag{1}$$

$$(\rho\mathbf{u})_t + \operatorname{div} \rho\mathbf{u} \otimes \mathbf{u} = \operatorname{div} \mathbb{S}, \tag{2}$$

$$(t,x) \in \mathbb{R}^+ \times \mathbb{R}^2,$$

where $\mathbf{u} = (u_1(t,x),\, u_2(t,x))$, $\mathbf{u} \otimes \mathbf{u}$ is a tensor with components $\{\mathbf{u} \otimes \mathbf{u}\}_{ij} = u_i u_j$, $i,j = 1,2$, and the stress tensor, $\mathbb{S}$, is given by the Stokes formula:

$$\mathbb{S} = (-P + \zeta \operatorname{div} \mathbf{u})\mathbb{I} + 2\mu\left(\mathbb{D} - \frac{1}{3}\operatorname{div} \mathbf{u}\, \mathbb{I}\right). \tag{3}$$

In the above formula, $\mu > 0$ and $\zeta \geq 0$ are the shear and the bulk viscosity coefficients, $P = a\rho^\gamma$, $\gamma > 1$, $a > 0$, is the pressure, $\mathbb{I}$ is the identity tensor, and $\mathbb{D}$ is the rate of strain tensor that has components $\mathbb{D}_{ij} = \frac{1}{2}\left(\partial_i u_j + \partial_j u_i\right)$, $i,j = 1,2$. We stress here that the condition on the flow to be isentropic holds only approximately, since the entropy is generated in the irreversible process set up in the flow by the friction; see [1, section 3.4]. Nevertheless, the full understanding of this model is essential in studying compressible flows and is not yet complete; see Feireisl [4], Hoff [7], Lions [11], [10], and Novotný and Straskraba [12] for detailed treatment of various models of motion of compressible flows.

The viscosity coefficients, in general, depend on the thermodynamic parameters. For example, for polyatomic gases it is expected that ζ, μ are proportional to θ^β,

$\beta > 0$, where θ is the temperature; see [1, section 1.7]. Since for isentropic flows $\theta \sim \rho^{\gamma-1}$, we are led to the following hypothesis:

$$\zeta = b\rho^{\beta}, \quad \mu = \text{const.} > 0, \quad b > 0,\ \beta > 0. \tag{4}$$

The assumption on the shear viscosity being a constant is the technical restriction that reflects the fact that at present we do not have tools to treat a nontrivial dependence $\mu = \mu(\rho)$.

We consider the Cauchy problem with the given initial data ρ_0 and u_0, which are periodic with period 1 in each space direction x_i, $i = 1, 2$, i.e., functions defined on $\mathbb{T}^2 = \mathbb{R}^2/\mathbb{Z}^2$. We require that

$$\mathbf{u}(0, x) = \mathbf{u}_0(x), \quad \rho(0, x) = \rho_0(x), \quad x \in \mathbb{T}^2. \tag{5}$$

There is a well-developed theory of weak solutions for the system of the multidimensional compressible Navier-Stokes equations with both viscosity coefficients, $\mu > 0$, $\zeta \geq 0$, being constants. In Lions [11], the global in time existence of weak solutions of the multidimensional isentropic Navier–Stokes equations is proved for the large values of γ. Later, Feireisl, Novotný, and Petzeltová [5] proved the existence of weak solutions for the physical range of γ, i.e., $\gamma > 1$ if $N = 2$ and $\gamma > \frac{5}{3}$ if $N = 3$. Weak solutions considered in those works have *a minimal amount of regularity*, and there are some important questions, such as formation of vacuum or blow up of uniform bounds on density, that are still unanswered.

A development in this direction was made in Desjardins [3], where the author proves that in dimensions $N = 2, 3$, with the assumption on the initial data, $\rho_0 \in L^{\infty}(\mathbb{T}^N)$, $\mathbf{u}_0 \in \left[W^{1,2}(\mathbb{T}^N)\right]^N$, there exists a weak solution such that the L^{∞} norm of the density does not blow up and no vacuum forms at *small times* $t \in [0, T_0[$. A related result of Hoff [7] establishes the global in time existence of weak solutions that are *small perturbations of an equilibrium state*, measured in weak norms. The weak solution constructed in the later work has a fair amount of regularity, and in particular, the density is a L^{∞} function and no vacuum occurs at positive times.

In contrast, under the assumptions (4), which have a certain physical background behind them, the problem (1)–(5) admits a *globally* defined solution with *no restrictions* on the size of initial data, and its regularity is controlled by the regularity of initial data. This result was proved in Kazhikhov and Waigant [8] and is stated below. Some extensions of these theorems that take into account the presence of external forces are possible; see [8].

The existence of the classical solution is established in the following theorem.

THEOREM A (see [8]). *Let $\beta > 3$ and $\gamma \geq 0$. Let $\rho_0(x)$, $\mathbf{u}_0(x)$ be such that*

$$0 < m < \rho_0(x) < M < +\infty, \quad x \in \mathbb{T}^2,$$
$$(\rho_0, \mathbf{u}_0) \in C^{1+\omega}\left(\mathbb{T}^2\right) \times \left[C^{2+\omega}\left(\mathbb{T}^2\right)\right]^2, \quad 0 < \omega < 1,$$

for some m, M. Then, there exists the unique, classical solution of the problem (1)–(5),

$$\rho \in C^{1+\omega/2, 1+\omega}\left([0, +\infty) \times \mathbb{T}^2\right),$$
$$\mathbf{u} \in \left[C^{1+\omega/2, 2+\omega}\left([0, +\infty) \times \mathbb{T}^2\right)\right]^2.$$

The solution exists for all times $t > 0$, and the density is bounded away from vacuum.

The existence of a weak solution is established in the next theorem.

THEOREM B (see [8]). *Let $\beta > 3$ and $\gamma \geq 0$. Let $\rho_0(x)$, $\mathbf{u}_0(x)$ be such that*

$$0 < m < \rho_0(x) < M < +\infty, \quad x \in \mathbb{T}^2,$$
$$(\rho_0, \mathbf{u}_0) \in W^{1,q}\left(\mathbb{T}^2\right) \times \left[W^{2,2}\left(\mathbb{T}^2\right)\right]^2, \quad q > 2,$$

for some m, M. Then, there exists a strong solution of the problem (1)–(5). The solution exists for all times $t > 0$, and the density is an L^∞ function and is bounded away from vacuum.

The existence of weak solutions for which the density is an element of L^p, $p > 1$, spaces is proved in the next theorem.

THEOREM C (see [8]). *Let $\beta > 3$ and $\gamma \geq 0$. Let $\rho_0(x)$, $\mathbf{u}_0(x)$ such that*

$$(\rho_0, \mathbf{u}_0) \in L^\infty\left(\mathbb{T}^2\right) \times \left[W^{1,2}\left(\mathbb{T}^2\right)\right]^2.$$

Then, there exists a weak solution of the problem (1)–(5). The solution exists for all times $t > 0$.

In Theorems A and B it is shown that the solution does not admit vacuum at positive times and the density of the flow is uniformly bounded. At the same time, the density at time $t = 0$ must be differentiable, in the classical or weak sense, ruling out the solutions with jump discontinuities.

On the other hand, in Theorem C, there is only one assumption on the density, $\rho_0 \in L^\infty$, but it is not known if the solution is bounded at positive times and/or there are vacuum zones appearing in the flow. This is the question we address in the present paper.

We derive *new a priori estimates* that provide the uniform bounds on the density form above and below.

We investigate, as well, the long time behavior and obtain a weak solution that converges in time to a constant state $(\int_{\mathbb{T}^2} \rho_0(\cdot), \mathbf{0})$ in the norm $\|\cdot\|_{L^\infty} \times \|\cdot\|_{L^p}$, $p > 1$, in the case that the bulk viscosity is comparable with the pressure ($\beta = \gamma$). We prove the following theorem.

THEOREM. *Let $\beta > 3$ and $\gamma > 1$. Let*

$$(\rho_0, \mathbf{u}_0) \in L^\infty\left(\mathbb{T}^2\right) \times \left[W^{1,2}\left(\mathbb{T}^2\right)\right]^2$$

and

$$0 < m < \operatorname{infess}_{\mathbb{T}^2} \rho_0(\cdot) \leq \operatorname{supess}_{\mathbb{T}^2} \rho(\cdot) < M \tag{6}$$

for some m, M. Then, there exists a global weak solution of the problem (1)–(5) with the following properties.

$$(\rho, \mathbf{u}) \in C\left([0, +\infty); L^2\left(\mathbb{T}^2\right)\right) \times \left[C\left([0, +\infty); L^2_w\left(\mathbb{T}^2\right)\right)\right]^2,$$

and for any $T > 0$ there are $\bar{M} = \bar{M}(T)$ and $\bar{m} = \bar{m}(T) > 0$ such that

$$\bar{m} < \rho(t, x) < \bar{M}, \quad t \in (0, T), \ x \text{ a.e. } \mathbb{T}^2.$$

If $\beta = \gamma$, then there exists a weak solution such that, for any $p > 1$,

$$\|\rho(t, \cdot) - \int_{\mathbb{T}^2} \rho_0(s)\, ds\|_{L^\infty(\mathbb{T}^2)} + \|\mathbf{u}(t, \cdot)\|_{L^p(\mathbb{T}^2)} \to 0, \quad t \to +\infty. \tag{7}$$

REMARK 1. *L^2_w is the space of L^2 functions with L^2 weak topology. The additional regularity for velocity* $\mathbf{u}$ *is available. The complete list of properties of* $\mathbf{u}$ *can be found in section* 6.

The central point of the proof is contained in the analysis of the rate of production of the density given by the quantity

$$-\rho \operatorname{div} \mathbf{u} = -\rho(4/3\mu+\zeta)^{-1}B - \rho(4/3\mu+\zeta)^{-1}P,$$

where $B = (4\mu/3+\zeta)\operatorname{div}\mathbf{u} - P$, the effective viscous flux, solves the following Poisson equation:

$$\Delta B = \partial_t(\operatorname{div}\rho\mathbf{u}) + \operatorname{div}\operatorname{div}\rho\mathbf{u}\otimes\mathbf{u}.$$

Accordingly, we can write

$$B + \frac{d}{dt}(-\Delta)^{-1}[\operatorname{div}\rho\mathbf{u}] = \mathbf{u}\cdot(-\Delta)^{-\frac{1}{2}}\nabla(-\Delta)^{-\frac{1}{2}}\operatorname{div}[\rho\mathbf{u}] - (-\Delta)^{-\frac{1}{2}}\operatorname{div}(-\Delta)^{-\frac{1}{2}}\operatorname{div}[\rho\mathbf{u}\otimes\mathbf{u}], \tag{8}$$

and the terms on the right-hand side can be written as a sum of commutators of Riesz transforms and the operators of multiplication by u_i. The framework of this analysis originates in the works of Hoff [7] and Lions [11]. Using the smoothing properties of the commutators we obtain an estimate on the L^∞ norm of the commutators in terms of L^∞ norm of ρ and $\|\nabla\mathbf{u}\|_{L^2}$. This is a delicate point of the analysis, as we have to use Poincaré–Sobolev type estimates stated in terms of Orlicz norms determined by the convex functions $r^2\log^p(2+r)$ to show that the right-hand side of (8) can be bounded by $\|\rho\|_{L^\infty}\log^\alpha(2+\|\nabla\mathbf{u}\|_{L^2})$, $\alpha > 2$.

On the other hand, using energy type estimates (at this point it is essential to work with function defined on $\mathbb{R}^2$) and dvi-curl lemma we show that $\log(2+\|\nabla\mathbf{u}\|_{L^2})$ does not exceed a linear function of $\|\rho\|_{L^\infty}$. Both estimates lead to the a priori estimate on $\|\rho\|_{L^\infty}$ when $\beta > 3$ and consequently on $\|\nabla\mathbf{u}\|_{L^2}$.

In the above argument $(\rho, \mathbf{u})$ is the classical solution which exists globally in time if initial data are smooth; see Theorem A. Naturally, the next step is the study of the compactness properties of the sequence of such solutions, $(\rho^n, \mathbf{u}^n)$, which correspond to the initial data approximating the given pair $(\rho_0, \mathbf{u}_0)$ from $L^\infty \times \left(W^{1,2}\right)^2$. Note that in the case when the viscosity coefficient depends on density, the argument of Lions [11] *cannot* be applied here since the effective viscous fluxes, B^n, incorporate the term $\zeta(\rho^n)\operatorname{div}\mathbf{u}^n$ that is not in general weakly continuous. This difficulty was resolved in Kazhikhov and Waigant [8] by utilizing a uniform boundedness of the norms $\|\nabla B^n\|_{L^2((0,T)\times\mathbb{T}^2)}$, $T > 0$, which provides the strong compactness of $\{B^n\}$. For the purpose of completeness of the work we present the proof of strong compactness of the sequence of smooth solutions in the last section.

The work is organized as follows. Section 2 contains notations, the necessary mathematical apparatus, and the derivation of the complimentary system of equations. In section 3 we obtain estimates based on the first energy inequality. Section 4 deals with additional energy type estimates. Section 5 is devoted to the derivation of uniform upper and lower bounds on the density. In section 6 we establish the existence of a weak solution as limit of smooth solutions for which bounds from the previous sections apply.

2. Notations and preliminary lemmas. We use the following notation:

$$\begin{cases} \partial_i = \frac{\partial}{\partial x_i},\ i=1,2, & \nabla = (\partial_1, \partial_2), \\ \nabla^\perp = (\partial_2, -\partial_1), & \frac{\mathrm{d}}{\mathrm{dt}} = \frac{\partial}{\partial t} + \mathbf{u}\cdot\nabla, \\ \operatorname{div}\mathbf{u} = \nabla\cdot\mathbf{u}, & \operatorname{rot}\mathbf{u} = \nabla^\perp\cdot\mathbf{u}, \\ \Pi = \left[-\frac{1}{2},\frac{1}{2}\right]\times\left[-\frac{1}{2},\frac{1}{2}\right]\subset\mathbb{R}^2, & f_\Pi = \frac{1}{|\Pi|}\int_{\mathbb{T}^2} f(x)\,dx. \end{cases}$$

Let $\mathbb{T}^2 = \mathbb{R}^2/\mathbb{Z}^2$ be a two dimensional torus. We identify functions defined on $\mathbb{T}^2$ with their periodic counterparts defined on $\mathbb{R}^2$. By $\|\cdot\|_p$, $1 \le p \le +\infty$, we denote Lebesgue $L^p(\mathbb{T}^2)$ norms of a function. We use standard notation $W^{k,q}\left(\mathbb{T}^2\right)$, $q \in [1,+\infty]$, k an integer, for Sobolev spaces of functions that possess weak derivative up to the kth order, which belong to $L^q(\mathbb{T}^2)$. $W^{-k,\frac{q}{q-1}}\left(\mathbb{T}^2\right)$, $q \in [1,+\infty)$ is the dual space of $W^{k,q}\left(\mathbb{T}^2\right)$. We use the same notation for norms of scalar and vector functions.

The material on Fourier series and integral operators presented below can be found, for example, in [14] and [15]. Let $f \in L^1\left(\mathbb{T}^2\right)$. The set of Fourier coefficients of f, $\{c_n\}_{n\in Z^2}$, where

$$c_n = \int_\Pi f(y) e^{-2\pi\mathbf{i}(n\cdot y)}\,dy,$$

is well defined, and we formally write $f \sim \sum_{n\in Z^2} c_n e^{2\pi\mathbf{i}(n\cdot x)}$. For $i = 1,2$, the ith Riesz transform of f is defined as a multiplier

$$R_i(f) \sim \sum_{n\in Z^2, n\neq 0} -\mathbf{i}\frac{n_i}{|n|} c_n e^{2\pi\mathbf{i}(n\cdot x)}.$$

It is well known that R_i is a linear continuous operator from any $L^p(\mathbb{T}^2)$ to itself, for $1 < p < +\infty$. We use this property in the following form.

LEMMA 1. *There is $C = C(p)$, $p \in]1,+\infty[$, such that for any $\mathbf{f} = (f_1, f_2)$, a vector function with components in $L^1(\mathbb{T}^2)$ such that $\mathbf{F} = (F_1, F_2) = (\operatorname{div}\mathbf{f}, \operatorname{rot}\mathbf{f})$ belongs to $\left(L^p(\mathbb{T}^2)\right)^2$, it holds that*

$$\|\nabla\mathbf{f}\|_p \le C\|\mathbf{F}\|_p. \tag{9}$$

Proof. Indeed, for $i = 1,2$ we can formally write

$$\begin{aligned} -\partial_i f_1 &= R_i \circ (R_1(F_1) + R_2(F_2)), \\ -\partial_i f_2 &= R_i \circ (R_2(F_1) - R_1(F_2)). \end{aligned}$$

Therefore, L^p estimates on singular integral operators apply, and using a suitable approximation argument we conclude. ∎

Let L^1_0 be the space of integrable functions with zero mean. Define normed spaces

$$\mathcal{H}^1 = \left\{ f \in L^1_0\left(\mathbb{T}^2\right) : ||f||_{\mathcal{H}^1} \triangleq ||f||_1 + ||R_1(f)||_1 + ||R_2(f)||_1 < +\infty \right\},$$

where R_i, $i = 1,2$, are Riesz transforms introduced above, and

$$\mathcal{BMO} = \left\{ f \in L^1_{loc}\left(\mathbb{T}^2\right) \,:\, ||f||_{\mathcal{BMO}} < +\infty \right\},$$

where $||f||_{\mathcal{BMO}} = \sup_{\{0<\epsilon<1,\, x\in\Pi\}} \frac{1}{|B_\epsilon(0)|}\int_{B_\epsilon(x)} |f(y) - f_{B_\epsilon(x)}|\,dy$. In the case of $\mathcal{BMO}$ space, functions are defined modulo additive constants.

We will use standard notation for operators $(\Delta)^{-1} : L_0^p\left(\mathbb{T}^2\right) \to W^{2,p}\left(\mathbb{T}^2\right)$, the inverse Laplace operator, and $(-\Delta)^{-1}\mathrm{div} : L^p\left(\mathbb{T}^2\right) \to W^{1,p}\left(\mathbb{T}^2\right)$, where $1 < p < +\infty$ and L_0^p is the space of L^p integrable functions with zero mean. In terms of Fourier series these operators are defined as follows:

$$\begin{cases} (-\Delta)^{-1}(f) & \sim & \sum_{n\in Z^2, n\neq 0} \frac{1}{4\pi^2|n|^2} c_n e^{2\pi \mathbf{i}(n\cdot x)}, \\ (-\Delta)^{-1}\mathrm{div}\,(f) & \sim & \sum_{n\in Z^2, n\neq 0} -\frac{\mathbf{i}}{2\pi} \frac{n_1+n_2}{|n|^2} c_n e^{2\pi \mathbf{i}(n\cdot x)}. \end{cases}$$

Consider the composition of two Riesz transforms, $R_i \circ R_j$, $i, j = 1, 2$. There is a representation of this operator as a singular integral

$$R_i \circ R_j(f)(x) = p.v. \int_{\mathbb{T}^2} K_{ij}(x-y) f(y)\, dy,$$

where the kernel $K_{ij}(x)$, $i, j = 1, 2$, has a singularity of the second order at 0 and

$$|K_{ij}(x)| \leq C|x|^{-2}, \quad x \in \mathbb{T}^2,$$

for some constant $C > 0$. Given function g, define the linear operator

$$[g, R_iR_j](f) \equiv gR_i \circ R_j(f) - R_i \circ R_j(gf), \quad i, j = 1, 2.$$

This operator can be written as a convolution with the singular kernel K_{ij},

$$[g, R_iR_j](f)(x) = p.v. \int_{\mathbb{T}^2} K_{ij}(x-y)(g(x) - g(y)) f(y)\, dy, \quad i, j = 1, 2.$$

The commutator possesses a number of remarkable properties. We will use the following result of Coifman et al. [2].

LEMMA 2. *Let g, $f \in C^\infty(\mathbb{T}^2)$, and $p > 1$. Then, there is $C = C(p)$ such that*

$$\|[g, R_iR_j](f)\|_p \leq C\|g\|_{\mathcal{BMO}}\|f\|_p, \quad i, j = 1, 2. \tag{10}$$

We will use Orlicz norms of functions as they arise naturally from the type of methods we use, i.e., energy estimates for gradients of functions defined on $\mathbb{T}^2$. The extensive study of these spaces is contained in [9].

DEFINITION 1. *Convex, even function $\Phi : \mathbb{R} \to \mathbb{R}^+$ is called a Young function if $\Phi(0) = 0$ and $\lim_{r\to\infty} \Phi(r) = +\infty$.*

Let Φ be a Young function.

DEFINITION 2. *The functional $N_\Phi : L^1(\mathbb{T}^2) \to \mathbb{R}^+$ defined by*

$$N_\Phi(f) = \inf\left\{\lambda > 0 : \int_{\mathbb{T}^2} \Phi\left(\frac{f}{\lambda}\right) dx \leq 1\right\} \tag{11}$$

is called an Orlicz norm of function f.

$N_\Phi(\cdot)$ is a norm. There is an analogue of Hölder inequalities for Orlicz norms. It is contained in the next lemma. The proof is an easy consequence of the definition of $N_\Phi(\cdot)$ and the convexity of the defining function Φ.

LEMMA 3. *Let Φ_i, $i = 1, 2, 3$, be left-continuous Young functions that satisfy the following inequality for all x, $y > 0$ and some positive constants C_1, C_2:*

$$\Phi_3(xy) \leq C_1\Phi_1(x) + C_2\Phi_2(y). \tag{12}$$

Then, for all f_1, f_2, $f_3 \in L^1(\mathbb{T}^2)$, and some constant $C > 0$,

$$N_{\Phi_3}(f_1 f_2) \le C N_{\Phi_1}(f_1) N_{\Phi_2}(f_2). \tag{13}$$

The use of Lemma 3 will be limited to the Young functions appearing in the next lemma, the proof of which is omitted.

LEMMA 4. *There are constants C_i, $i = 1, \dots, 3$, such that for all $x, y \ge 0$ the following inequalities hold:*

$$xy \le C_1(p) x^2 \left[\log(e^2 + x)\right]^p + C_1(p) y^2 \left[\log(e^2 + y)\right]^{-p}, \quad p > 0, \tag{14}$$

$$xy \le C_2(p) \left[\exp(x^p) - 1\right] + C_2(p) y \left[\log(e^2 + y)\right]^{\frac{1}{p}}, \quad p > 0, \tag{15}$$

$$(xy)^2 \left[\log(e^2 + xy)\right]^p \le C_3 \Psi_s(x) + C_3 y^2 \left[\log(e^2 + y)\right]^r \tag{16}$$

with $r > p > 1$, $s > 0$, and a Young function Ψ_s such that

$$\lim_{x \to +\infty} \frac{\exp\exp(2x^{\frac{1}{s}})}{\Psi_s(x)} = 1. \tag{17}$$

In what follows we use notation $\Phi_p(x) = x^2 \left[\log(e^2 + x)\right]^p$ and $\Upsilon_p(x) = e^{x^p} - 1$, $p > 1$, $x \ge 0$. We now derive Poincaré–Sobolev type inequalities.

LEMMA 5. *For any $p \in]1, +\infty[$ there are C and ϵ_0 such that for any $g \in C^\infty(\mathbb{T}^2)$ and $x \in \mathbb{T}^2$ it holds that*

$$|g(x + z) - g(x)| \le C \left[-\log \epsilon\right]^{-\frac{p-1}{2}} N_{\Phi_p}(\nabla g \,:\, B_{3\epsilon}(x)), \quad |z| < \epsilon < \epsilon_0.$$

Proof. Indeed, for all $y \in B_\epsilon(x)$, the integration by parts can be used to establish the inequality

$$|g(y) - g_{B_\epsilon(x)}| \le \frac{1}{|B_\epsilon(0)|} \int_{B_{3\epsilon}(0)} \frac{|\nabla g|(y + z)}{|z|}\, dz,$$

where $g_{B_\epsilon(x)}$ is the average of $g(x)$ over the ball $B_\epsilon(x) = \{|y - x| < \epsilon\}$. We now apply Lemma 3 together with Lemma 4, where we set $f_1(z) = |z|^{-1}$, $f_2(z) = |\nabla g|(y+z)$ with $\Phi_1(r) = \Phi_{-p}(r)$, $\Phi_2(r) = \Phi_p(r)$ and $\Phi_3(r) = r$. Let us compute $N_{\Phi_1}(|z|^{-1} \,:\, B_{3\epsilon}(0))$:

$$\begin{aligned} N_{\Phi_1}(|z|^{-1} \,:\, B_{3\epsilon}(0)) &= \inf\left\{\lambda > 0 \,:\, \int_{B_{3\epsilon}(0)} \frac{1}{|z|^2 \lambda^2 \log^p(e^2 + (|z|\lambda)^{-1})} < 1\right\} \\ &\le \inf\left\{0 < \lambda < (3\epsilon)^{-1} \,:\, 2\pi \int_0^{3\epsilon} \frac{1}{r\lambda^2 \log^p(r\lambda)^{-1}}\, dr < 1\right\}. \end{aligned}$$

Then, there is $C = C(p)$ such that

$$N_{\Phi_1}(|z|^{-1} : B_{3\epsilon}(0)) \le C \left[-\log \epsilon\right]^{-\frac{p-1}{2}},$$

when ϵ is sufficiently small (depending on p), and this concludes the proof. ∎

With the help of the last lemma we establish the L^∞ estimates on the commutators that have been introduced above.

LEMMA 6. *Let g, $f \in C^\infty(\mathbb{T}^2)$. Let $\Upsilon_\omega(r) = \exp(r^\omega) - 1$, $\omega > 0$. Then, if*

$$\frac{p-1}{2} - \frac{1}{\omega} > 1,$$

there is $C > 0$, independent of f and g, with the property

$$\sup_{\mathbb{T}^2} |[g, R_i R_j](f)(\cdot)| \le C N_{\Upsilon_\omega}(f) N_{\Phi_p}(\nabla g).$$

Proof. The proof is a simple application of the Hölder inequality given by Lemma 3. Let us use the letter C to denote the generic constant that is independent of functions f and g. In formula (2) we split the integral in two: one taken over the set $|y - x| > \epsilon$ and the singular part $|y - x| < \epsilon$, for some $\epsilon > 0$:

$$\begin{aligned}[g, R_i R_j](f)(x) = &\int_{\mathbb{T}^2 \cap \{|x-y| > \epsilon\}} K_{ij}(x-y)(g(x) - g(y)) f(y)\, dy \\ &+ p.v. \int_{\mathbb{T}^2 \cap \{|x-y| < \epsilon\}} K_{ij}(x-y)(g(x) - g(y)) f(y)\, dy.\end{aligned}$$

By the fact that $K_{ij}(x)$ has a singularity of the second order at 0, and using the estimate on $g(x) - g(y)$ from Lemma 5, we obtain

$$\begin{aligned}|[g, R_i R_j](f)(x)| \le{}& C(\epsilon) N_{\Phi_p}(|\nabla g|) \int_{\mathbb{T}^2} |f(y)| \\ &+ C N_{\Phi_p}(|\nabla g| : B_{3\epsilon}(x)) \int_{B_\epsilon(0)} |z|^{-2} [-\log |z|]^{-\frac{p-1}{2}} f(x+z).\end{aligned}$$

Young functions $\Upsilon_\omega(r)$ and $r \log^{\frac{1}{\omega}}(e^2 + r)$ satisfy conditions of Lemma 3 which we apply for the last integral. It is easy to see that there is $C > 0$ for which

$$N_{r \log^{\frac{1}{\omega}}(e^2+r)} \left(|z|^{-2} [-\log |z|]^{-\frac{p-1}{2}} \,:\, B_\epsilon(0) \right) < C.$$

This proves the lemma, since $\int_{\mathbb{T}^2} |f(x)|\, dx \le C N_{\Upsilon_\omega}(f)$, for suitable constant C. ∎

The next two lemmas are the well-known Poincaré–Sobolev inequalities. Proofs can be found, for example, in Ziemer [17].

LEMMA 7. *Let $2 < p < +\infty$, and $\mathcal{A} \subset \mathbb{T}^2$ of a nonzero Lebesgue measure. There is a constant $C = C(p, |\mathcal{A}|)$ for which*

$$\|f - f_{\mathcal{A}}\|_p \le C \|\nabla f\|_{\frac{2p}{2+p}}$$

holds for any $f \in C^\infty(\mathbb{T}^2)$. We use notation $f_{\mathcal{A}} = |\mathcal{A}|^{-1} \int_{\mathcal{A}} f(\cdot)$.

LEMMA 8. *For any $p > 2$ there is a $C = C(p) > 0$ such that*

$$\sup_{\mathbb{T}^2} |f| \le |f^2_{\mathbb{T}}| + C \|\nabla f\|_p$$

holds for any $f \in C^\infty(\mathbb{T}^2)$. Also, there are absolute constants c_1, $c_2 > 0$, such that for any cube C it holds that

$$\int_C \exp\left(\frac{|f(x) - f_C|^2}{c_1 \|\nabla f\|_2^2} \right) dx \le c_2 |C|$$

for any $f \in C^\infty(\mathbb{T}^2)$, *provided* $f \not\equiv \text{const}$.

REMARK 2. *The last inequality in the previous lemma can be used to show that*

$$N_{\Upsilon_2}(f) \le C\|\nabla f\|_2 + |\bar{f}|, \tag{18}$$

with $\bar{f} = \int_{\mathbb{T}^2} f(\cdot)$ *and some* $C > 0$ *independent of* f.

Lemma 1 can also be stated for Orlicz norms if the underlying Young functions are "comparable" with power functions. In particular, the next lemma holds.

LEMMA 9. *Let* $\mathbf{f} = (f_1, f_2) \in \left[C^\infty\left(\mathbb{T}^2\right)\right]^2$ *and* $\mathbf{F} = (F_1, F_2) = (\operatorname{div}\mathbf{f}, \operatorname{rot}\mathbf{f})$ *Then, for* $1 \le p < +\infty$, *there is a* $C = (p) > 0$ *such that*

$$N_{\Phi_p}(\nabla\mathbf{f}) \le C N_{\Phi_p}(\mathbf{F}).$$

Proof. We just have to notice that $\Phi_p(r)$ can be approximated by the linear combinations $\alpha r^2 + \beta r^3$, $r > 0$, and use Lemma 1 along with the definition of norm $N_{\Phi_p}(\cdot)$. □

Let us now assume that ρ_0 and $\mathbf{u}_0$ are $C^\infty\left(\mathbb{T}^2\right)$ functions. Let $\bar{\rho} = \int_{\mathbb{T}^2} \rho_0(\cdot)$ and $\bar{P} = P(\bar{\rho})$. By Theorem A, there exists the unique, global in time, *classical* solution $(\rho, \mathbf{u})$ of the problem (1)–(5). From (1) and (2) we derive equations needed for studying higher regularity of the solution. Note that in $\mathbb{R}^2$, $\operatorname{div}\mathbb{D} = \nabla\operatorname{div}\mathbf{u} + \frac{1}{2}\nabla^\perp \operatorname{rot}\mathbf{u}$ and system (2) can be written in the following form:

$$\frac{d\mathbf{u}}{dt} + \frac{1}{\rho}\nabla\left(P - \bar{P} - (4\mu/3 + \zeta)\operatorname{div}\mathbf{u}\right) - \frac{1}{\rho}\mu\nabla^\perp \operatorname{rot}\mathbf{u} = 0. \tag{19}$$

Introducing the shorthand notation

$$\left\{\begin{array}{lcl} A & = & \operatorname{rot}\mathbf{u}, \\ B & = & (4\mu/3 + \zeta)\operatorname{div}\mathbf{u} - P + \bar{P}, \end{array}\right. \tag{20}$$

and after applying differential operators rot and div to the above system, we obtain

$$\frac{dA}{dt} - (\partial_1\mathbf{u}\cdot\nabla)u_2 + (\partial_2\mathbf{u}\cdot\nabla)u_1 = \operatorname{rot}\frac{1}{\rho}\left(\nabla B + \mu\nabla^\perp A\right), \tag{21}$$

$$\frac{d}{dt}\operatorname{div}\mathbf{u} + (\partial_1\mathbf{u}\cdot\nabla)u_1 + (\partial_2\mathbf{u}\cdot\nabla)u_2 = \operatorname{div}\frac{1}{\rho}\left(\nabla B + \mu\nabla^\perp A\right). \tag{22}$$

Consequently, (22) can be written as

$$\begin{aligned} \frac{d}{dt}\left(\frac{B}{4\mu/3 + \zeta}\right) + (\partial_1\mathbf{u}\cdot\nabla)u_1 + (\partial_2\mathbf{u}\cdot\nabla)u_2 - \frac{d}{dt}\frac{P - \bar{P}}{4\mu/3 + \zeta} \\ = \operatorname{div}\frac{1}{\rho}\left(\nabla B + \mu\nabla^\perp A\right). \end{aligned} \tag{23}$$

The next equation is essential for the analysis of compressible, viscous flows and was studied in [7], [11], [13]. Let us apply operator $(-\Delta)^{-1}\operatorname{div}$ to system (2). With the notation

$$\psi = (-\Delta)^{-1}\operatorname{div}\rho\mathbf{u},\ \bar{B} = \int_{\mathbb{T}^2} B(t,\cdot), \tag{24}$$

we have

$$(4\mu/3 + \zeta)\operatorname{div}\mathbf{u} = \bar{B} + P - \bar{P} - \frac{d}{dt}\psi + \sum_{i,j=1,2}[u_i, R_iR_j](\rho u_j), \tag{25}$$

where we used the fact that $\mathbf{u}\cdot\nabla\psi-(-\Delta)^{-1}\operatorname{div}\operatorname{div}\rho\mathbf{u}\otimes\mathbf{u}$ can be written as a sum of commutators: $\sum_{i,j}[u_i,R_iR_j](\rho u_j)$. Using this in (1) we obtain

$$\frac{4\mu/3+\zeta}{\rho}\frac{d}{dt}\rho-\frac{d}{dt}\psi+P-\bar{P}=-\bar{B}+\sum_{i,j=1,2}[u_i,R_iR_j](\rho u_j). \tag{26}$$

Finally, by Calderón–Zygmund estimates of singular integral operators, for any $1<p<+\infty$, there is $C=C(p)>0$ such that

$$\|\nabla\psi(t,\cdot)\|_p\le C\|\rho(t,\cdot)\mathbf{u}(t,\cdot)\|_p, \tag{27}$$

and consequently, there is $C=C(p)$ such that

$$\|\nabla\psi(t,\cdot)\|_{\Phi_p}\le C\|\rho(t,\cdot)\mathbf{u}(t,\cdot)\|_{\Phi_p}. \tag{28}$$

In analyzing the system of equations, we encounter the problem of obtaining a "good" estimate for the term $\int_{\mathbb{T}^2}B\nabla u_1\cdot\nabla^\perp u_2\,dx$. One sees directly that it is bounded by $\|B\|_\infty\|\nabla\mathbf{u}\|_2^2$. Unfortunately, $\|B\|_\infty$ is not controlled by the $\|\nabla B\|_2$, the quantity naturally arising in energy estimates. This leads us to a more subtle estimate that takes into account the structure of the product term $\nabla u_1\cdot\nabla^\perp u_2$. The estimate is obtained by using the duality between Hardy $\mathcal{H}^1$ and $\mathcal{BMO}$ spaces. In [6], Fefferman proved that $\mathcal{BMO}$ is the dual space of $\mathcal{H}^1$. In particular, there is an absolute constant C such that

$$\left|\int_{\mathbb{T}^2}B\nabla u_1\cdot\nabla^\perp u_2\,dx\right|\le C||B||_{\mathcal{BMO}}||\nabla u_1\cdot\nabla^\perp u_2||_{\mathcal{H}^1}. \tag{29}$$

One readily notices that $\operatorname{rot}\nabla u_1=\operatorname{div}\nabla^\perp u_2=0$ and one can use the so-called "div-curl" lemma of compensated compactness; see [2, Theorem II.1]. It yields the following estimate with the suitable choice of an absolute constant C:

$$||\nabla u_1\cdot\nabla^\perp u_2||_{\mathcal{H}^1}\le C||\nabla u_1||_2||\nabla^\perp u_2||_2.$$

Finally, from Lemma 8 and definition of $||\cdot||_{\mathcal{BMO}}$ it follows that there is a constant $C>0$ such that

$$||B||_{\mathcal{BMO}}\le C||\nabla B||_2.$$

Combining the last two estimates in (29) we obtain

$$\left|\int_{\mathbb{T}^2}B\nabla u_1\cdot\nabla^\perp u_2\,dx\right|\le C||\nabla B||_2||\nabla\mathbf{u}||_2^2. \tag{30}$$

3. The first energy inequality. It follows from the equation of conservation of mass that $\rho(t,x)\ge0$ and $\int_{\mathbb{T}^2}\rho(t,\cdot)\,dx=\int_{\mathbb{T}^2}\rho_0(\cdot)\,dx=\bar{\rho}$. By multiplying (2) by $\mathbf{u}$, integrating over the domain Π, and using periodicity of the flow we obtain

$$\frac{d}{dt}\int_{\mathbb{T}^2}\rho\frac{|\mathbf{u}|^2}{2}\,dx+\int_{\mathbb{T}^2}(-P+(4\mu/3+\zeta)\operatorname{div}\mathbf{u})\operatorname{div}\mathbf{u}+\mu(\operatorname{rot}\mathbf{u})^2\,dx=0.$$

Since $P = a\rho^\gamma$, $\gamma > 1$ we deduce from (1) that $-(\gamma-1)P\operatorname{div}\mathbf{u} = (P)_t + \operatorname{div}(P\mathbf{u})$. Substituting this in the last equation we get

$$\sup_{t\in[0,+\infty)} \int_{\mathbb{T}^2} \rho(t,\cdot)\frac{|\mathbf{u}(t,\cdot)|^2}{2} + \frac{P(t,\cdot)}{\gamma-1}\,dx + \iint_{(0,+\infty)\times\mathbb{T}^2} (4\mu/3+\zeta)(\operatorname{div}\mathbf{u})^2 + \mu(\operatorname{rot}\mathbf{u})^2\,dxdt \le C\int_{\mathbb{T}^2} \rho_0(\cdot)\frac{|\mathbf{u}_0(\cdot)|^2}{2} + \frac{P(\rho_0(\cdot))}{\gamma-1}\,dx.$$

Let $E(t) = \int_{\mathbb{T}^2} \rho(t,\cdot)\frac{|\mathbf{u}(t,\cdot)|^2}{2} + \frac{P(t,\cdot)}{\gamma-1}\,dx$ denote the total energy of the gas and $E_0 = E(0)$. We will refer to the next inequality as the first energy inequality,

$$\sup_{t\in[0,+\infty)} E(t) + \iint_{(0,+\infty)\times\mathbb{T}^2} (4\mu/3+\zeta)(\operatorname{div}\mathbf{u})^2 + \mu(\operatorname{rot}\mathbf{u})^2\;\,dx\,dt \;\le\; E_0. \tag{31}$$

For the purpose of studying long time behavior of the solutions we will need a variant of the first energy inequality. Following [7] we introduce $G(\rho) = P(\rho) - P(\bar\rho) - P'(\bar\rho)(\rho-\bar\rho)$. Then, using the same arguments that lead to (31) we obtain

$$\frac{d}{dt}\int_{\mathbb{T}^2} \rho(t,x)\frac{|\mathbf{u}|(t,x)^2}{2} + G(\rho(t,x))\,dx + \int_{\mathbb{T}^2} (4\mu/3+\zeta(\rho(t,x)))|\operatorname{div}\mathbf{u}|^2(t,x) + \mu(\operatorname{rot}\mathbf{u})^2(t,x)\,dx = 0. \tag{32}$$

For the purpose of using imbedding theorems we will need bounds on averages of various functions. They are obtained in the following way. First,

$$\begin{aligned}\left|\int_{\mathbb{T}^2} (\mathbf{u}-\bar{\mathbf{u}})\,\rho\,dx\right| &\le \|\rho\|_\gamma \|\mathbf{u}-\bar{\mathbf{u}}\|_{\gamma/(\gamma-1)}\\ &\le C\|\nabla\mathbf{u}\|_2,\\ \left|\int_{\mathbb{T}^2} (\mathbf{u}-\bar{\mathbf{u}})\,\rho\,dx\right| &\ge |\bar{\mathbf{u}}|\int_{\mathbb{T}^2}\rho_0\,dx - \left|\int_{\mathbb{T}^2}\rho\mathbf{u}\,dx\right|\\ &= |\bar{\mathbf{u}}|\int_{\mathbb{T}^2}\rho_0\,dx - \left|\int_{\mathbb{T}^2}\rho_0\mathbf{u}_0\,dx\right|,\end{aligned}$$

where we used the fact that the momentum is conserved; $\frac{d}{dt}\int_{\mathbb{T}^2}\rho\mathbf{u}\,dx = 0$. Assume that $\int_{\mathbb{T}^2}\rho_0\mathbf{u}_0\,dx = 0$. This is a harmless assumption since system (1)–(2) is invariant under Galilean transformations, and it is satisfied in the reference frame (coordinate system) that moves with the constant velocity $\frac{\int_{\mathbb{T}^2}\rho_0\mathbf{u}_0\,dx}{\int_{\mathbb{T}^2}\rho_0\,dx}$ relative to the initially chosen frame. Then, since $\int_{\mathbb{T}^2}\rho(t)\,dx$ is positive and independent of time, we conclude that

$$|\bar{\mathbf{u}}| \le C\|\nabla\mathbf{u}\|_2. \tag{33}$$

By the definition of function A and periodicity of the flow,

$$\int_{\mathbb{T}^2} A(t,\cdot) = 0. \tag{34}$$

4. The second energy inequality.

REMARK 3. *We will prove the theorem only for the case $\beta \geq \gamma$. The case $\beta > 3$, $\gamma > 1$ is a straightforward adaptation of the proof if one takes into account the following estimate proved in* [8]*:*

$$\sup_{s\in(0,T)} \|\rho(s,\cdot)\|_p \leq C(T,p), \quad 1 \leq p < +\infty.$$

In this case all estimates become time dependent.

Let

$$\left.\begin{array}{rcl} Y^2(t) & = & \int_{\mathbb{T}^2} A^2(t,\cdot) + \frac{B^2(t,\cdot)}{\frac{4\mu}{3}+\zeta(t,\cdot)}, \\ X^2(t) & = & \int_{\mathbb{T}^2} \frac{(\nabla B(t,\cdot) + \mu\nabla^\perp A(t,\cdot))^2}{\rho(t,\cdot)}, \\ D^2(t) & = & \int_{\mathbb{T}^2} \left(\frac{4\mu}{3}+\zeta(t,\cdot)\right) |\operatorname{div}\mathbf{u}(t,\cdot)|^2 + \mu|\operatorname{rot}\mathbf{u}(t,\cdot)|^2 \end{array}\right\} \tag{35}$$

and $|\rho|(t) = 1 + \|\rho(t,\cdot)\|_\infty$.

LEMMA 10. *For any $\omega \in]0,1[$ there is $C = C(\omega,\mu,\beta,\gamma,b,E_0)$ such that*

$$\begin{aligned} \frac{d}{dt}Y^2(t) + X^2(t) \leq C_\omega \Big(& Y(t)D(t) + Y^2(t)D(t) \\ & + D(t)(Y(t)+D(t))X(t)|\rho|(t)^{\frac{1+\beta\omega}{2}} \Big). \end{aligned} \tag{36}$$

Proof. Multiplying (21) by $2A$ and using the fact that $-(\partial_1\mathbf{u}\cdot\nabla)u_2 + (\partial_2\mathbf{u}\cdot\nabla)u_1 = A\operatorname{div}\mathbf{u}$, we get

$$\frac{dA^2}{dt} + 2A^2\operatorname{div}\mathbf{u} = 2A\operatorname{rot}\frac{1}{\rho}(\nabla B + \mu\nabla^\perp A). \tag{37}$$

Multiplying (23) by $2B$, using the fact that

$$(\partial_1\mathbf{u}\cdot\nabla)u_1 + (\partial_2\mathbf{u}\cdot\nabla)u_2 = (\operatorname{div}\mathbf{u})^2 - 2\nabla u_1\cdot\nabla^\perp u_2,$$

and using the equation of mass conservation (1), we get

$$\begin{aligned} & \frac{d}{dt}\left(\frac{B^2}{4\mu/3+\zeta}\right) + \frac{B^2}{4\mu/3+\zeta}\operatorname{div}\mathbf{u} \\ & \quad - \frac{B^2}{4\mu/3+\zeta}\operatorname{div}\mathbf{u} + B^2\frac{d}{dt}\frac{1}{4\mu/3+\zeta} - 2B\frac{d}{dt}\frac{P-\bar{P}}{4\mu/3+\zeta} \\ & \quad + 2B(\operatorname{div}\mathbf{u})^2 - 4B\nabla u_1\cdot\nabla^\perp u_2 = 2B\operatorname{div}\frac{1}{\rho}(\nabla B + \mu\nabla^\perp A). \end{aligned} \tag{38}$$

Using identity (55) in (39) and adding (37) and (39), after the integration of the result

over $\mathbb{T}^2$, we get

$$\begin{aligned}(39)\quad &\frac{d}{dt}\left[\int_{\mathbb{T}^2} A^2+\frac{B^2}{4\mu/3+\zeta}\,dx\right]+2\int_{\mathbb{T}^2}\frac{(\nabla B+\mu\nabla^\perp A)^2}{\rho}\,dx\\ &\qquad=-\int_{\mathbb{T}^2} A^2\mathrm{div}\,\mathbf{u}\,dx+\int_{\mathbb{T}^2}-2B(\mathrm{div}\,\mathbf{u})^2+4B\nabla u_1\cdot\nabla^\perp u_2\\ &\quad-\int_{\mathbb{T}^2}\frac{(\beta-1)\zeta-4\mu/3}{(4\mu/3+\zeta)^2}B^2\mathrm{div}\,\mathbf{u}\,dx+\int_{\mathbb{T}^2}(P-\bar P)\frac{2\beta\zeta}{(4\mu/3+\zeta)^2}B\mathrm{div}\,\mathbf{u}\\ &\qquad-\frac{2\gamma P}{4\mu/3+\zeta}B\mathrm{div}\,\mathbf{u}\,dx+\int_{\mathbb{T}^2}(P-\bar P)\mathrm{div}\,\mathbf{u}\int_{\mathbb{T}^2}\frac{2(\gamma-1)B}{4\mu/3+\zeta}\,dx.\end{aligned}$$

By the Young inequality there is $C>0$ such that for all $t>0$

$$(40)\qquad Y^2(t)\le CD^2(t)+C\int_{\mathbb{T}^2}\frac{(P-\bar P)^2}{4\mu/3+\zeta}.$$

Also, from the energy inequality (31) and $\beta\ge\gamma$ it follows that there is $C>0$, independent of $t>0$, that verifies the inequality

$$(41)\qquad Y^2-C\le 2D^2(t)\le 4Y^2(t)+C.$$

Our goal will be to find the optimal estimate of the right-hand side of (39) in terms of Y, X, and $\|\rho\|_\infty$.

We will use the following result, based on Lemma 1, applied to the function $\mathbf{f}=(B,\mu A)$, and $\mathbf{F}=(\mathrm{div}\,\mathbf{f},\,\mathrm{rot}\,\mathbf{f})=\nabla B+\mu\nabla^\perp A$. The next estimate holds:

$$(42)\qquad \|\nabla A\|_2+\|\nabla B\|_2\le C\|\nabla B+\mu\nabla^\perp A\|_2.$$

Consider terms in (39). Using the estimate (31) and notation (20) we get

$$\begin{aligned}(43)\quad &\left|\int_{\mathbb{T}^2}\frac{B}{4\mu/3+\zeta}\,dx\right|\left|\int_{\mathbb{T}^2}P\mathrm{div}\,\mathbf{u}\,dx\right|\\ &\qquad\le C\left\|\frac{B}{\sqrt{4\mu/3+\zeta}}\right\|_2\|\sqrt{4\mu/3+\zeta}\mathrm{div}\,\mathbf{u}\|_2\le CY(t)D(t).\end{aligned}$$

The set of the following estimates is obtained by using the appropriate Young inequalities and the definition of B, (20):

$$\begin{aligned}(44)\qquad \int_{\mathbb{T}^2}|B|(\mathrm{div}\,\mathbf{u})^2\,dx&=\int_{\mathbb{T}^2}|B|\left|\frac{B+P-\bar P}{4\mu/3+\zeta}\right||\mathrm{div}\,\mathbf{u}|\,dx\\ &\le C\left\|\frac{B^2}{4\mu/3+\zeta}\right\|_2 D(t)+CY(t)D(t),\end{aligned}$$

$$(45)\qquad \int_{\mathbb{T}^2}\frac{B^2\zeta}{(4\mu/3+\zeta)^2}|\mathrm{div}\,\mathbf{u}|\,dx\le C\left\|\frac{B^2}{4\mu/3+\zeta}\right\|_2 D(t),$$

$$(46)\qquad \int_{\mathbb{T}^2}\frac{|B(P-\bar P)\mathrm{div}\,\mathbf{u}|\zeta}{(4\mu/3+\zeta)^2}\,dx\le CY(t)D(t),$$

$$(47)\qquad \int_{\mathbb{T}^2}\frac{|BP\mathrm{div}\,\mathbf{u}|}{4\mu/3+\zeta}\,dx\le CY(t)D(t).$$

Let us take $0 < \omega < 1$ and use the Hölder inequality to estimate the term

$$\left\| \frac{B^2}{4\mu/3+\zeta} \right\|_2 \le C \left\| \frac{B}{4\mu/3+\zeta} \right\|_2^{1-\omega} \| |B|^{1+\omega} \|_{\frac{2}{\omega}}. \tag{48}$$

Then, by Lemma 7, the Hölder inequality, and the estimate (42), we get with a number $K > 0$,

$$\begin{aligned} \| |B|^{1+\omega} \|_{\frac{2}{\omega}} &\le \left| \overline{|B|^{1+\omega} \chi_{\{\rho(t,\cdot)<K\}}} \right| + \| |B|^{1+\omega} - \overline{|B|^{1+\omega} \chi_{\{\rho(t,\cdot)<K\}}} \|_{\frac{2}{\omega}} \\ &\le \left| \overline{|B|^{1+\omega} \chi_{\{\rho(t,\cdot)<K\}}} \right| + C \| |B|^{\omega} \nabla B \|_{\frac{2}{1+\omega}} \\ &\le CY^{1+\omega} + C\|B\|_2^{\omega} \|\nabla B\|_2 \le CY^{1+\omega} + CY^{\omega} X |\rho|^{\frac{1+\beta\omega}{2}}, \end{aligned} \tag{49}$$

where we used the fact that $|\{\rho(t,\cdot) < K\}| > \frac{1}{2}$ when $K > 2 \int_{\mathbb{T}^2} \rho(t,\cdot) = 2 \int_{\mathbb{T}^2} \rho_0(\cdot)$. Substituting the last inequality in (48) we get

$$\left\| \frac{B^2}{4\mu/3+\zeta} \right\|_2 \le CY^2 + CYX |\rho|^{\frac{1+\beta\omega}{2}}, \tag{50}$$

where $C > 0$ depends upon $\omega \in (0,1)$ among other parameters.

Consider now the term $\int_{\mathbb{T}^2} |A|^2 \operatorname{div} \mathbf{u}$. By the same type of arguments that were used in derivation of the last estimates we obtain that

$$\begin{aligned} \left| \int_{\mathbb{T}^2} A^2 \operatorname{div} \mathbf{u} \right| &\le \|A^2\|_2 D(t) \\ &\le CY^2(t) D(t) + Y(t) D(t) X(t) |\rho|(t)^{\frac{1+\beta\omega}{2}}, \end{aligned} \tag{51}$$

with $\omega \in]0,1[$ and some $C > 0$. The term $\int_{\mathbb{T}^2} B \nabla u_1 \cdot \nabla^{\perp} u_2 \, dx$ is estimated by using the duality between $\mathcal{BMO}$ and Hardy $\mathcal{H}^1$ space, followed by "div-curl" lemma as it is explained in section 2,

$$\int_{\mathbb{T}^2} |B \nabla u_1 \cdot \nabla^{\perp} u_2| \, dx \le C \|\nabla B\|_2 \|\nabla u\|^2 \le C D^2(t) X(t) |\rho|^{\frac{1}{2}}(t). \tag{52}$$

Using estimate (43) in (45) and (45) and combining (43)–(47), (51), and (52) in (39) we get the inequality (36). □

We will use the estimate obtained in the following lemma.

LEMMA 11. *Let $\beta = \gamma$. There are $C = C(\mu, \beta, \gamma, b, E_0) > 0$ such that for all $t > 0$, it holds that (modulo a constant)*

$$\int_{\mathbb{T}^2} \frac{|P(t,\cdot) - \bar{P}|^2}{4\mu/3 + \zeta(t,\cdot)} \lesssim D^2(t) + \frac{d}{dt} \Psi(t), \tag{53}$$

where $|\Psi(t)| \le C$.

Proof. Equation (25) multiplied by $(P - \bar{P})(4\mu/3 + \zeta)^{-1}$ can be written as

$$\begin{aligned} \frac{(P-\bar{P})^2}{4\mu/3+\zeta} &= -\bar{B} \frac{P-\bar{P}}{4\mu/3+\zeta} - \psi \frac{d}{dt} \frac{P-\bar{P}}{4\mu/3+\zeta} \\ &\quad + \partial_t \frac{\psi(P-\bar{P})}{4\mu/3+\zeta} + \operatorname{div} \left(\frac{\psi(P-\bar{P})}{4\mu/3+\zeta} \mathbf{u} \right) \\ &\quad - \frac{\psi(P-\bar{P})}{4\mu/3+\zeta} \operatorname{div} \mathbf{u} + [\mathbf{u}, RR](\rho \mathbf{u}) \frac{P-\bar{P}}{4\mu/3+\zeta}, \end{aligned} \tag{54}$$

where we used the shorthand notation $[\mathbf{u}, RR](\rho\mathbf{u})$ to mean $\sum_{i,j}[u_i, R_iR_j](\rho u_j)$. Using the equation of mass conservation (1), we can write

$$\psi\frac{d}{dt}\frac{P-\bar{P}}{4\mu/3+\zeta} = \psi(P-\bar{P})\frac{\beta\zeta}{(4\mu/3+\zeta)^2}\operatorname{div}\mathbf{u} - \psi\frac{\gamma P}{4\mu/3+\zeta}\operatorname{div}\mathbf{u}.$$
$$+\psi\frac{(\gamma-1)}{4\mu/3+\zeta}\int_{\mathbb{T}^2}(P-\bar{P})\operatorname{div}\mathbf{u}\,dx. \tag{55}$$

Then, by the repeated use of Hölder inequalities, Lemma 7, the estimate (27), and (33) we derive the following inequalities:

$$\begin{aligned}\left|\int_{\mathbb{T}^2}\psi\frac{(P-\bar{P})\beta\zeta}{(4\mu/3+\zeta)^2}\operatorname{div}\mathbf{u}\,dx\right| &\le C\int_{\mathbb{T}^2}|\psi\operatorname{div}\mathbf{u}|\,dx \le C\|\psi\|_2\|\operatorname{div}\mathbf{u}\|_2\\ &\le C\|\nabla\psi\|_{1+\frac{\gamma-1}{2}}\|\operatorname{div}\mathbf{u}\|_2 \le C\|\rho\mathbf{u}\|_{1+\frac{\gamma-1}{2}}\|\operatorname{div}\mathbf{u}\|_2\\ &\le C\|\rho\|_\gamma\|\mathbf{u}\|_{\frac{\gamma(\gamma+1)}{\gamma-1}}\|\operatorname{div}\mathbf{u}\|_2 \le C\|\nabla\mathbf{u}\|_2^2.\end{aligned} \tag{56}$$

Similarly,

$$\left|\int_{\mathbb{T}^2}\psi\frac{\gamma P}{4\mu/3+\zeta}\operatorname{div}\mathbf{u}\,dx\right| \le C\|\nabla\mathbf{u}\|_2^2.$$

Collecting the above estimates in (55) we obtain

$$\left|\int_{\mathbb{T}^2}\psi\frac{d}{dt}\frac{P-\bar{P}}{4\mu/3+\zeta}\right| \le \frac{1}{8}\int_{\mathbb{T}^2}\frac{(P-\bar{P})^2}{4\mu/3+\zeta} + CD^2(t).$$

Since, by Hölder inequalities, Lemma 7, and the estimate (31),

$$\|\psi\|_1 \le C\|\nabla\psi\|_{\frac{2\gamma}{\gamma+1}} \le C\|\rho\mathbf{u}\|_{\frac{2\gamma}{\gamma+1}} \le C\|\sqrt{\rho}\mathbf{u}\|_2\|\rho\|_\gamma^{\frac{1}{2}} \le C(E_0),$$

we get that for $t \ge 0$,

$$\left|\int_{\mathbb{T}^2}\psi\frac{P(t,\cdot)-\bar{P}}{4\mu/3+\zeta(t,\cdot)}\,dx\right| \le C\|\psi(t,\cdot)\|_1 \le C \tag{57}$$

and

$$\left|\int_{\mathbb{T}^2}\psi\frac{P(t,\cdot)-\bar{P}}{4\mu/3+\zeta(t,\cdot)}\operatorname{div}\mathbf{u}\,dx\right| \le CD^2(t). \tag{58}$$

We denote $\Psi(t) = \int_{\mathbb{T}^2}\psi\frac{P(t,\cdot)-\bar{P}}{4\mu/3+\zeta(t,\cdot)}\,dx$.

By Lemmas 2 and 7 we obtain that

$$\begin{aligned}\|[\mathbf{u}, RR](\rho\mathbf{u})\|_1 &\le C\|[\mathbf{u}, RR](\rho\mathbf{u})\|_{\frac{2\gamma}{\gamma+1}} \le C\|\nabla\mathbf{u}\|_2\|\rho\mathbf{u}\|_{\frac{2\gamma}{\gamma+1}}\\ &\le C\|\nabla\mathbf{u}\|_2\|\mathbf{u}\|_{\frac{2\gamma}{\gamma-1}}\|\rho\|_\gamma \le C\|\nabla\mathbf{u}\|_2^2\|\rho\|_\gamma.\end{aligned}$$

In this way we obtain

$$\int_{\mathbb{T}^2}|[\mathbf{u}, RR](\rho\mathbf{u})|\frac{|P-\bar{P}|}{4\mu/3+\zeta} \le CD^2. \tag{59}$$

Finally, with Young's inequality we deduce that

$$\left|\int_{\mathbb{T}^2} -\bar{B}(t)\frac{P(t,\cdot)-\bar{P}}{4\mu/3+\zeta(t,\cdot)}\right| \le CD^2(t)+\frac{1}{8}\int_{\mathbb{T}^2}\frac{|P(t,\cdot)-\bar{P}|^2}{4/3\mu+\zeta(t,\cdot)}. \tag{60}$$

Collecting estimates (**??**)–(60) we conclude the proof. □

COROLLARY 1. *If $\rho(t,x)$ is uniformly bounded in space and time, using the fact that $G(\rho)\lesssim|P-\bar{P}|^2$, we obtain the following estimate:*

$$\int_0^{+\infty}\int_{\mathbb{T}^2} G(\rho(\cdot,\cdot)) \lesssim 1+\int_0^{+\infty} D^2(\cdot). \tag{61}$$

COROLLARY 2. *After dividing the inequality* (36) *by $e^2+Y^2(t)$ and integrating over time interval $]0,T[$, we deduce, using* (31), (40), (41), *and* (53), *that for $\omega\in]0,1[$ there is $C_\omega>0$ independent of T and such that*

$$\begin{aligned}\log(e^2+Y^2(T))+\int_0^T\frac{X^2(s)}{e^2+Y^2(s)} &\le \log(e^2+Y^2(0))\\ &+C_\omega\left(1+\sup_{[0,T]}|\rho|\int_0^T D^2(\cdot)+\int_0^T D^2(\cdot)|\rho|^{1+\omega\beta}(\cdot)\right).\end{aligned} \tag{62}$$

Note that from the first energy inequality (31) and (62) it follows that if $\rho(t,x)$ is bounded uniformly in space and time, then $Y(t)$ and consequently $D(t)$, the rate of energy dissipation, are bounded uniformly in time.

5. Uniform bounds on density. We use (26) to get pointwise bounds on $\rho(t,x)$. Let us fix time $t\in]0,+\infty[$ and estimate the $L^\infty(\mathbb{T}^2)$ norm of the terms on the right-hand side of this equation.

Consider the first term on the right-hand side of (26). We have

$$\begin{aligned}|\bar{B}(t)| &= \left|\overline{(4\mu/3+\zeta)\operatorname{div}\mathbf{u}}\right|\\ &\le \delta+C_\delta D(t)^2\end{aligned} \tag{63}$$

for any $\delta>0$ and some $C_\delta>0$. Lemma 6 and Remark 2 are used to get estimates on the commutator $[\mathbf{u},RR](\rho\mathbf{u})$. Specifically, in Lemma 6 we set $g(\cdot)=\mathbf{u}(t,\cdot)$, $f(\cdot)=\rho\mathbf{u}(t,\cdot)$, $p>4$, and $\omega=2$. Then, there is $C=C(p)$ such that

$$\begin{aligned}\|[\mathbf{u},RR](\rho\mathbf{u})\|_\infty &\le CN_{\Phi_p}(|\nabla\mathbf{u}|)N_{\Upsilon_2}(\rho\mathbf{u})\\ &\le C|\rho|_\infty N_{\Phi_p}(|\nabla\mathbf{u}|)N_{\Upsilon_2}(\mathbf{u}) \le C|\rho|_\infty N_{\Phi_p}(|\nabla\mathbf{u}|)D.\end{aligned} \tag{64}$$

Next, consider the term $N_{\Phi_p}(|\nabla\mathbf{u}|)$. By the estimate (28) we have

$$\begin{aligned}N_{\Phi_p}(|\nabla\mathbf{u}|) &\le CN_{\Phi_p}(|\operatorname{div}\mathbf{u}|)+CN_{\Phi_p}(|\operatorname{rot}\mathbf{u}|)\\ &= CN_{\Phi_p}(A)+CN_{\Phi_p}\left(\frac{B+P-\bar{P}}{4\mu/3+\zeta}\right) \le CN_{\Phi_p}(A)\\ &+CN_{\Phi_p}\left(\frac{B}{4\mu/3+\zeta}\right)+CN_{\Phi_p}\left(\frac{P-\bar{P}}{4\mu/3+\zeta}\right).\end{aligned} \tag{65}$$

From the first energy estimate (31) and condition $\beta\ge\gamma$ it follows that there is $C>0$ independent of time with the property

$$N_{\Phi_p}\left(\frac{P(t,\cdot)-\bar{P}}{4\mu/3+\zeta(t,\cdot)}\right)\le C. \tag{66}$$

The N_{Φ_p} norms of functions appearing in the above inequalities can be interpolated between the norms of L^2 and N_{Ψ_s}, where $\Psi_s(x)$ is defined in Lemma 4. Indeed, using Lemmas 3 and 4 with $r > p > 4$ and $2s > r$ we have

$$\begin{aligned} N_{\Phi_p}(A) &= N_{\Phi_p}\left(\frac{A}{\log^s(e^2+|A|)}\log^s(e^2+|A|)\right) \\ &\le N_{\Phi_r}\left(\frac{A}{\log^s(e^2+|A|)}\right) N_{\Psi_s}\left(\log^s(e^2+|A|)\right). \end{aligned} \tag{67}$$

Both norms appearing in the last inequality are estimated in the next lemma.

LEMMA 12. *Let p, r, s be chosen such that $4 < r < 2s < r+4$. There is $C = C(r,s,\mu)$ such that*

$$N_{\Phi_r}\left(\frac{A}{\log^s(e^2+|A|)}\right) \le C\left(1 + \frac{||A||_2}{[\log(e^2+||A||_2)]^{s-r/2}}\right),$$

$$N_{\Psi_s}\left(\log^s(e^2+|A|)\right) \le C\log^s(e^2+||\nabla A||_2).$$

Proof. By definition of N_{Φ_r},

$$N_{\Phi_r}\left(\tfrac{A}{\log^s(e^2+|A|)}\right) = \inf\left\{\lambda > 0 \,:\, \int_{\mathbb{T}^2} \tfrac{A^2}{\lambda^2\log^{2s}(e^2+|A|)}\log^r\left(e^2 + \tfrac{|A|}{\lambda\log^s(e^2+|A|)}\right) \le 1\right\}.$$

For any $\lambda > 1$,

$$\begin{aligned} &\int_{\mathbb{T}^2} \tfrac{A^2}{\lambda^2\log^{2s}(e^2+|A|)}\log^r\left(e^2 + \tfrac{|A|}{\lambda\log^s(e^2+|A|)}\right)dx \\ &\le \int_{\mathbb{T}^2} \tfrac{A^2}{\lambda^2\log^{2s-r}(e^2+|A|)}\,dx \le 2^{2s-r}\int_{\mathbb{T}^2} \tfrac{A^2}{\lambda^2\log^{2s-r}(e^2+|A|^2)}\,dx \\ &\le 2^{2s-r}\tfrac{1}{\lambda^2}\tfrac{y}{\log^{2s-r}(e^2+y)} \circ \int_{\mathbb{T}^2} A^2\,dx, \end{aligned}$$

where the last inequality is Jensen's inequality. Note that function

$$y\log^{-2s+r}(e^2+y)$$

for $y > 0$ and $2s < r+4$ is concave and $\mathrm{meas}(\mathbb{T}^2) = 1$. Thus, there is $C > 0$ such that

$$N_{\Phi_r}\left(\frac{A}{\log^s(e^2+|A|)}\right) \le 1 + C\frac{\left(\int_{\mathbb{T}^2} A^2\right)^{\frac{1}{2}}}{\log^{s-r/2}(e^2+\int_{\mathbb{T}^2} A^2)}.$$

Next, we have

$$N_{\Psi_s}\left(\log^s(e^2+|A|)\right) = \inf\left\{\lambda > 0 \,:\, \int_{\mathbb{T}^2}\left(\exp\exp\left(2\tfrac{\log(e^2+|A|)}{\lambda^{\frac{1}{s}}}\right) - e\right)dx \le 1\right\}.$$

Let c_1 be the constant from Lemma 8. Let

$$\lambda = 2^s N^s \log^s(e^2 + \sqrt{c_1}N\|\nabla A(t,\cdot)\|_2),$$

where $N > 1$ will be chosen later and

$$\mathcal{A} = \left\{x \in \mathbb{T}^2 \,:\, |A(t,x)| < \sqrt{c_1}N||\nabla A(t,\cdot)||_2\right\}.$$

Chebyshev's inequality and Lemma 8 are used to obtain the next bound,

$$|\mathbb{T}^2 \setminus \mathcal{A}| \leq \frac{||A||_1}{\sqrt{c_1}N||\nabla A||_2} \leq \frac{C}{N} \tag{68}$$

for some $C > 0$ independent of A. Then, for $x \in \mathbb{T}^2 \setminus \mathcal{A}$, it holds that

$$\frac{\log(e^2 + |A(t,x)|)}{\lambda^{\frac{1}{s}}} \leq \log\left(\frac{|A(t,x)|}{\sqrt{c_1}N\|\nabla A(t,\cdot)\|_2}\right). \tag{69}$$

Thus, we have

$$\int_{\mathbb{T}^2} \exp\exp\left(2\frac{\log(e^2+|A|)}{\lambda^{\frac{1}{s}}}\right) \;\leq\; \int_{\mathcal{A}} e^{e^{N^{-1}}} \;+\; \int_{\mathbb{T}^2\setminus\mathcal{A}} \exp\left(\frac{A^2}{c_1N^2\|\nabla A\|_2^2}\right). \tag{70}$$

Jensen's inequality and Lemma 7 can be used to show that (note that $\bar{A} = 0$, $|\mathbb{T}^2| = 1$)

$$\int_{\mathbb{T}^2\setminus\mathcal{A}} \exp\left(\frac{A^2}{c_1N^2\|\nabla A\|_2^2}\right) \leq |\mathbb{T}^2 \setminus \mathcal{A}|^{1-N^{-2}} \left(\int_{\mathbb{T}^2} \exp\left(\frac{A^2}{c_1\|\nabla A\|_2^2}\right)\right)^{N^{-2}}$$
$$\leq |\mathbb{T}^2 \setminus \mathcal{A}|^{1-N^{-2}} (c_2)^{N^{-2}}.$$

From this inequality, (70), and (68), it follows that

$$\int_{\mathbb{T}^2} \exp\exp\left(2\frac{\log(e^2+|A|)}{\lambda^{\frac{1}{s}}}\right) - e\,dx \leq e^{e^{N^{-1}}} + \left(\frac{C}{N}\right)^{1-N^{-2}} (c_2)^{N^{-2}} - e.$$

The right-hand side of the above inequality is smaller than 1 for N big enough (independently of A). With this choice of N we conclude that

$$N_{\Psi_s}\left(\log^s(e^2+|A|)\right) \leq \lambda(N).$$

This finishes the proof of the lemma. □

We apply this lemma to (67). For (p, r, s), such that $r + 4 > 2s > r > p > 4$, and a suitable $C = C(p, r, s, \mu) > 0$, it holds that

$$N_{\Phi_p}(A) \leq C\left(1 + \frac{\|A\|_2}{\log^{s-\frac{r}{2}}(e^2 + \|\nabla A\|_2)}\right)\log^s(e^2 + \|\nabla A\|_2^2). \tag{71}$$

The estimates for B are just slightly more involved because of the fact that B may not have a zero average over $\mathbb{T}^2$. With the same choice of (p, r, s) the following inequality holds:

$$N_{\Phi_p}\left(\frac{B}{4\mu/3+\zeta}\right) = N_{\Phi_p}\left(\frac{B}{(4\mu/3+\zeta)\log^s(e^2+|B|)}\log^s(e^2+|B|)\right)$$
$$\leq N_{\Phi_r}\left(\frac{B}{(4\mu/3+\zeta)\log^s(e^2+|B|)}\right)$$
$$\times \left(N_{\Psi_s}\left(\log^s(e^2+|B-\bar{B}|)\right) + C\log^s(e^2+|\bar{B}|)\right). \tag{72}$$

By arguments almost identical to those from the last lemma we get

$$N_{\Phi_p}\left(\frac{B}{4\mu/3+\zeta}\right) \leq C\left(1 + \frac{\|B/\sqrt{(4\mu/3+\zeta)}\|_2}{\log^{s-\frac{r}{2}}(e^2 + \|B/\sqrt{(4\mu/3+\zeta)}\|_2)}\right)$$
$$\times\, C\left(\log^s(e^2+\|\nabla B\|_2^2) + C\log^s(e^2+|\bar{B}|)\right). \tag{73}$$

By using notation (35) and estimates (42) we derive

$$\left.\begin{array}{lll} \|A\|_2 \le Y, & & \|B/\sqrt{(4\mu/3+\zeta)}\| \le Y, \\ \log^s(e^2+\|\nabla A\|_2^2) & \le & C\log^s\left(e^2+\frac{X^2}{(e^2+Y^4)(e^2+\|\rho\|_\infty)}\right) \\ & + & 12^s\log^s(e^2+Y^2) \\ & + & 6^s\log^s(e^2+|\rho|_\infty^{\frac{1}{2}}), \\ \log^s(e^2+\|\nabla B\|_2^2) & \le & C\log^s\left(e^2+\frac{X^2}{(e^2+Y^4)(e^2+\|\rho\|_\infty)}\right) \\ & + & 12^s\log^s(e^2+Y^2) \\ & + & 6^s\log^s(e^2+|\rho|_\infty^{\frac{1}{2}}). \end{array}\right\}$$

Systematic use of the set of the above inequalities and a Young inequality $xy \le Ce^{x^{s^{-1}}} + Cy\log^s(e^2+y)$, $x,y>0$, which is contained in Lemma 4, in (71) and (73) results in the following:

$$\begin{aligned} N_{\Phi_p}(A) + N_{\Phi_p}\left(\frac{B}{4\mu/3+\zeta}\right) \lesssim 1 + |\bar{B}| + |\rho|_\infty^{\frac{1}{2}} + Y\log^{\frac{r}{2}}(e^2+Y^2) \\ + \frac{X^2}{(e^2+Y^4)(e^2+|\rho|_\infty)}, \end{aligned} \tag{74}$$

where by $\lesssim$ we mean that the inequality holds modulo some positive, multiplicative constant C that depends on $(p,r,\mu,\gamma,b,\beta,E_0)$, but not time t (from now on we fix s in the interval $]r,r+4[$). Then, using the last inequality and (66) in (66), we get

$$\begin{aligned} N_{\Phi_p}(|\nabla\mathbf{u}|) \lesssim 1 + |\bar{B}| + |\rho|_\infty^{\frac{1}{2}} + Y\log^{\frac{r}{2}}(e^2+Y^2) \\ + \frac{X^2}{(e^2+Y^4)(e^2+|\rho|_\infty)}, \end{aligned}$$

with $r>p>4$. Now we can continue estimate (65) by making use of the last inequality, the inequality $xy \le \delta x^2 + y^2/(4\delta)$, $\delta>0$, and (**??**). We derive

$$\begin{aligned} \|[\mathbf{u},\,RR](\rho\mathbf{u})\|_\infty - \delta \lesssim D^2|\rho|_\infty + D^2|\rho|_\infty^2 + D^2|\rho|^{\frac{9}{4}} \\ + D^2|\rho|^{\frac{\beta-\gamma+2}{2}} + DY\log^{\frac{r}{2}}(e^2+Y^2)|\rho|_\infty + \frac{X^2}{e^2+Y^2}. \end{aligned} \tag{75}$$

The inequality holds modulo some positive multiplicative constant

$$C = C(\delta,p,r,\mu,\gamma,b,\beta,E_0).$$

(δ,p,r) will be set later. Upon using inequality (41) and the fact that $\beta>3$, we can write

$$\begin{aligned} \|[\mathbf{u},\,RR](\rho\mathbf{u})\|_\infty - \delta \lesssim D^2|\rho|^\beta + D^2\log^{\frac{r}{2}}(e^2+Y^2)|\rho| \\ + \frac{X^2}{e^2+Y^2}. \end{aligned} \tag{76}$$

Summarizing the result, we can write (26) and the estimates (63), (66), and (76) as

$$\left.\begin{aligned} &\tfrac{(4\mu/3+\zeta)}{\rho}\tfrac{d\rho}{dt} - \tfrac{d\psi}{dt} + P - \bar{P} = F, \\ &\sup_{\mathbb{T}^2} |F(t,\cdot)| \le \delta + C\left(D^2(t)|\rho|^\beta(t) + \tfrac{X^2(t)}{e^2+Y^2(t)}\right. \\ &\qquad \left. + D^2(t)\log^{\frac{r}{2}}(e^2+Y^2(t))|\rho|(t)\right), \\ &t>0,\ x\in\mathbb{T}^2, \quad C = C(\delta,p,r,\mu,\gamma,b,\beta,E_0). \end{aligned}\right\} \tag{77}$$

Consider the function $\psi(t,\cdot) = (-\Delta)^{-1}\mathrm{div}\,\rho(t,\cdot)\mathbf{u}(t,\cdot)$ that appears in (26). The elliptic estimate (28) that involves the Orlicz norm defined by the function $\Phi_k(x) = x^2\log^k(e^2+x)$, $k>1$, asserts that

$$N_{\Phi_k}\left(\nabla\psi(t,\cdot)\right) \le C N_{\Phi_k}\left(\rho(t,\cdot)\mathbf{u}(t,\cdot)\right). \tag{78}$$

Lemma 8 can be used to provide the following estimate on the $\sup|\psi|$ (note that $\overline{\psi(t,\cdot)} = 0$):

$$\sup_{\mathbb{T}^2}|\psi(t,\cdot)| \le C N_{\Phi_k}\left(\nabla\psi(t,\cdot)\right) \le C N_{\Phi_k}\left(\rho(t,\cdot)\mathbf{u}(t,\cdot)\right).$$

For some $2l > m > k$ we write

$$\begin{aligned} N_{\Phi_k}\left(\rho(t,\cdot)\mathbf{u}(t,\cdot)\right) &\le |\rho|^{\frac12} N_{\Phi_k}\left(\frac{\rho^{\frac12}|\mathbf{u}|}{\log^l(e^2+|\mathbf{u}|)}\log^l(e^2+|\mathbf{u}|)\right) \\ &\le |\rho|^{\frac12} N_{\Phi_m}\left(\frac{\rho^{\frac12}|\mathbf{u}|}{\log^l(e^2+|\mathbf{u}|)}\right) N_{\Psi_l}\left(\log^l(e^2+|\mathbf{u}|)\right), \end{aligned} \tag{79}$$

where Ψ_l was defined in Lemma 4. Proceeding with the same arguments as in the proof of Lemma 12 and using the first energy estimate (31) we obtain the following bounds for $2l > m > k$:

$$\begin{aligned} &N_{\Phi_m}\left(\tfrac{\rho^{\frac12}|\mathbf{u}|}{\log^l(e^2+|\mathbf{u}|)}\right) \\ &= \inf\left\{\lambda>0 \,:\, \textstyle\int_{\mathbb{T}^2} \tfrac{\rho|\mathbf{u}|^2}{\lambda^2\log^{2l}(e^2+|\mathbf{u}|)}\log^m\left(e^2+\tfrac{\rho^{\frac12}|\mathbf{u}|}{\lambda\log^l(e^2+|\mathbf{u}|)}\right)dx \le 1\right\}. \end{aligned}$$

For any $\lambda > 1$,

$$\begin{aligned} &\textstyle\int_{\mathbb{T}^2} \tfrac{\rho|\mathbf{u}|^2}{\lambda^2\log^{2l}(e^2+|\mathbf{u}|)}\log^m\left(e^2+\tfrac{\rho^{\frac12}|\mathbf{u}|}{\lambda\log^l(e^2+|\mathbf{u}|)}\right)dx \\ &\le \textstyle\int_{\mathbb{T}^2} \tfrac{\rho|\mathbf{u}|^2}{\lambda^2\log^{2l-m}(e^2+|\mathbf{u}|)}\,dx + \tfrac{\log^m(e^2+\|\rho\|_\infty^{\frac12})}{\lambda^2}\textstyle\int_{\mathbb{T}^2}\rho|\mathbf{u}|^2\,dx \\ &\le C\lambda^{-2}E_0|\rho|^{\frac12}. \end{aligned}$$

Thus, there is a constant $C(m,l,E_0)$ such that

$$N_{\Phi_m}\left(\frac{\rho^{\frac12}|\mathbf{u}|}{\log^l(e^2+|\mathbf{u}|)}\right) \le C|\rho|^{\frac14}. \tag{80}$$

Also, using the same arguments as in the proof of the second estimate of Lemma 12 and estimate (33) we obtain that

$$\begin{aligned} N_{\Psi_l}\left(\log^l(e^2+|\mathbf{u}-\mathbf{u}_{\mathbb{T}^2}|)\right) &\le N_{\Psi_l}\left(\log^l(e^2+|\mathbf{u}|)\right) + C\log^l(e^2+|\mathbf{u}_{\mathbb{T}^2}|) \\ &\le C\left(\log^l(e^2+|\mathbf{u}_{\mathbb{T}^2}|)+\log^l(e^2+\|\nabla\mathbf{u}\|_2)\right) \\ &\le C\log^l(e^2+\|\nabla\mathbf{u}\|_2). \end{aligned}$$

We now apply Lemma 1 with $\mathbf{f}=\mathbf{u}$ and use definition of A and B to get

$$\begin{aligned} \|\nabla\mathbf{u}\|_2 \;&\le\; C\left(\|\operatorname{div}\mathbf{u}\|_2+\|\operatorname{rot}\mathbf{u}\|_2\right) \le C\|\tfrac{B}{4\mu/3+\zeta}\|_2 + C\|A\|_2 \\ &+\; C\|\tfrac{P-\bar P}{4\mu/3+\zeta}\|_2 \le C\left(1+Y\right). \end{aligned}$$

And thus,

$$N_{\Psi_l}\left(\log^l(e^2+|\mathbf{u}|)\right) \le C\log^l(e^2+Y^2). \tag{81}$$

In the view of (80) and (81) the estimate (79) can be written as

$$\sup_{\mathbb{T}^2}|\psi(t,\cdot)| \le C|\rho|(t)\log^l(e^2+Y^2(t)),$$

and consequently, using the fact that $\beta>3$ we obtain

$$\sup_{\mathbb{T}^2}|\psi(t,\cdot)| \le \epsilon|\rho|^\beta(t)+C_\epsilon\log^{2l}(e^2+Y^2), \quad 2l>1, \tag{82}$$

where C_ϵ depends on l, ϵ, and other parameters, but not time.

Let us go back to (26). Let $\theta=\theta(\rho)$ be the solution of the Cauchy problem

$$\frac{d\theta}{d\rho} = \left(\frac{4\mu}{3}+\zeta(\rho)\right)\rho^{-1}, \quad \theta(1)=1.$$

$\theta(\rho)$ is uniquely defined and smooth for $\rho\in(0,+\infty)$. In fact,

$$\theta = 4\mu/3\log\rho + b\beta^{-1}\rho^\beta + 1 - b\beta^{-1}. \tag{83}$$

Let $\bar\theta=\theta\circ\left(a^{-2}\bar P\right)^{\frac{1}{\gamma}}$. Let $X_t(x_0)$ be a trajectory of the flow generated by $\mathbf{u}$, i.e.,

$$\frac{d}{dt}X_t(x_0) = \mathbf{u}\left(t,\, X_t(x_0)\right), \quad X_t(x_0)=x_0, \quad t=0,\, x_0\in\mathbb{T}^2,\, t>0,$$

and consider (26) at points $(t,\,x)=(t,\,X_t(x_0))$. Let $w(t)=\theta\circ\rho(t,X_t(x_0))-\bar\theta$. Then $P(\rho(t,x))-\bar P=\frac{a^2\gamma\rho_1^\gamma}{4\mu/3+\zeta(\rho_1)}w(t)$, where ρ_1 is a value in the interval with endpoints $(a^{-2}\bar P)^{\frac{1}{\gamma}}$ and $\rho(t,\,X_t(x_0))$. Let $S=\{t\,|\,w(t)>0\}$. Note that $\bar P=a^2\bar\rho^\gamma$, where $\bar\rho$ is the total mass of the gas, and so the inequality $w(t)>0$ implies $\rho(t,X_t(x_0))\ge\bar\rho$. For $t\in S$, factor $e^{-1}(t)\equiv\frac{4\mu/3+\zeta(\rho_1)}{a\gamma\rho_1^\gamma}$ is bounded by $c|\rho|^{\beta-\gamma}(t)$ with some constant c. Set S is open and consists of a countable disjoint union of intervals. Let $(\alpha,\,\alpha_1)$ be one

of those intervals. After multiplying the equation in (77) by $\exp\int_\alpha^t e(t)\,d\tau$ we get

$$\begin{aligned}\left(w(t)\exp\int_\alpha^t e(\tau)\,d\tau\right)' &\le \frac{d}{dt}\left[(\psi-\bar\theta)\exp\int_\alpha^t e(\tau)\,d\tau\right]\\ &\quad-(\psi-\bar\theta)\frac{d}{dt}\exp\int_\alpha^t e(\tau)\,d\tau\\ &\quad+\delta\exp\int_\alpha^t e(\tau)\,d\tau+\left(\sup_{\mathbb{T}^2}|F(t,\cdot)|-\delta\right)\exp\int_\alpha^t e(\tau)\,d\tau,\end{aligned}$$

where $\delta>0$ will be chosen later. Integrate above inequality over $(\alpha,\,t)$, $t<\alpha_1$ to get

$$\begin{aligned}w(t)\le C(\delta)|\rho|^{\beta-\gamma}(t)+4\sup_{(0,\,t)\times\mathbb{T}^2}|\psi(\cdot,\cdot)|+4|\bar\theta|\\ +\int_\alpha^t\max\{|F(\tau)|-\delta,0\}\,d\tau.\end{aligned}\tag{84}$$

Note that the right-hand side does not depend on x_0. Using the estimate (82) in (84) we can write for $t>0$

$$\begin{aligned}|\rho|^\beta(t)\le C\Bigg(1+\sup_{(0,\,t)}\log^{2l}(e^2+Y^2(\cdot))\\ +\int_0^t\max\{|F(\tau)|-\delta,0\}\,d\tau\Bigg),\ 2l>1.\end{aligned}\tag{85}$$

We use the estimates for $|F|$ obtained in (77) with $\delta=1$ and the bounds for $\log(e^2+Y^2)$ and $\int_0^t\frac{X^2}{e^2+Y^2}$ contained in the second energy inequality (62). Choose r and ω such that $4<r<2(\beta-1)$ and $0<r\beta\omega<2(\beta-1)-r$. This is possible only when $\beta>3$. Then, we can derive the following estimate for $t>0$, using the fact that $\int_0^{+\infty}D^2(\cdot)\le E_0$:

$$\begin{aligned}\int_0^t\max\{|F(t)|-1,0\}\,dt\le C\sup_{[0,t]}|\rho|^{1+\frac{r}{2}}\\ +C\int_0^t D^2(s)\sup_{[0,s]}|\rho|^\beta(s)\,ds.\end{aligned}\tag{86}$$

Returning to (85) we have

$$\begin{aligned}|\rho|^\beta(t)\le C\sup_{[0,t]}|\rho|^{1+\frac{r}{2}}+C\int_0^t D^2\sup_{[0,s]}|\rho|^\beta\\ +C\left[\int_0^t D^2\left(\sup_{[0,s]}|\rho|^{\frac{\beta-1}{2}}+\sup_{[0,s]}|\rho|^{\beta-\gamma}\right)\right]^{2l},\end{aligned}$$

where $\int_0^{+\infty}D^2\le E_0$. Finally, let us choose l that satisfies conditions $1<2l<\frac{\beta}{\beta-\gamma}$ and $l(\beta-\gamma)<\beta$. Then, using Gronwall type estimates we obtain the global in time upper bound for density,

$$\|\rho(t,\cdot)\|_\infty\le\bar M,\quad t>0.\tag{87}$$

Now we revisit the second energy estimate (62) to derive global in time bounds on $\int_{\mathbb{T}^2} |\nabla \mathbf{u}|^2(t,\cdot)$. It follows from (62) and (87) that

$$Y^2(t) + \int_0^t X^2(s)\, ds \le C, \quad t > 0, \tag{88}$$

with some $C > 0$ independent of time.

Let us now derive the lower bound on density. The equation of evolution of density (77) can be used to obtain the inequality

$$\frac{d}{dt}\theta \ge \frac{d}{dt}\psi + a^2(\bar{M})^\gamma - |F|, \tag{89}$$

where θ is defined by (83). Inequality (82) together with estimates (87) and (88) imply that

$$\sup_{]0,+\infty[\times\mathbb{T}^2} |\psi(\cdot,\cdot)| \le C. \tag{90}$$

The estimate for $|F|$ is contained in (77), where we set $\delta = a^2(\bar{M})^\gamma$. We integrate inequality (89) along a trajectory, and after using estimates (87) and (88) we obtain that

$$\theta(\rho(t, X_t(x_0)) \ge \theta(\rho_0(x_0)) - C, \quad t \in]0,+\infty[, \quad x_0 \in \mathbb{T}^2, \tag{91}$$

with $C > 0$ independent of (t, x_0). Since $\theta(\rho)$ behaves like a $\log \rho$ for small $\rho > 0$ and $\rho_0(x_0) > m > 0$ we conclude the existence of $\bar{m} > 0$ such that

$$\rho(t,x) \ge \bar{m}, \quad (t,x) \in]0,+\infty[\times\mathbb{T}^2. \tag{92}$$

Let us prove the decay estimate (7). First, we prove that the kinetic energy $\int_{\mathbb{T}^2} \rho(t,\cdot)|\mathbf{u}|^2(t,\cdot)$ decays to 0 with time. Indeed, by Lemma 7 and estimates (33) and (87) we can write

$$C\int_{\mathbb{T}^2} \rho(t,\cdot)|u|^2(t,\cdot) \le D^2(t), \quad t > 0,$$

for some $C > 0$ independent of time. We use the last inequality in (32) to get

$$\frac{d}{dt}\int_{\mathbb{T}^2} \rho(t,\cdot)\frac{|\mathbf{u}|^2(t,\cdot)}{2} + C\int_{\mathbb{T}^2} \rho\frac{|\mathbf{u}|^2(t,\cdot)}{2} \le -\frac{d}{dt}\int_{\mathbb{T}^2} G(\rho(t,\cdot)), \quad t > 0.$$

Integrating this inequality we get

$$\begin{aligned}\int_{\mathbb{T}^2} \rho(t_2,\cdot)\frac{|\mathbf{u}|^2(t_2,\cdot)}{2} &\le e^{-C(t_2-t_1)}E_0 \\ &\quad + C\int_{t_1}^{t_2}\int_{\mathbb{T}^2} G(\cdot,\cdot), t_2 > t_1 > 0.\end{aligned} \tag{93}$$

Consider the equation in (77). With notation $w = \theta(\rho) - \theta(\bar{\rho})$, we get some $\rho_1 \in (\bar{m}, \bar{M})$, such that

$$P(\rho) - \bar{P} = \frac{a^2\gamma(\rho_1)^\gamma}{4\mu/3 + \zeta(\rho_1)} w \triangleq m(t,x_0)w.$$

In view of uniform bounds (87) and (92) there exist $C, c > 0$ independent of time t and position x_0 such that

$$c \le m(t, x_0) \le C.$$

The equation in (77) can be integrated to yield

$$\begin{aligned} w(t_2, x_0) = {} & e^{-\int_{t_1}^{t_2} m(\cdot), x_0}(w(t_1, x_0) - \psi(t_1, x_0)) + \psi(t_2, X_{t_2}(x_0)) \\ & + \int_{t_1}^{t_2} \psi(s, X_s(x_0)) m(s, x_0) e^{-\int_s^{t_2} m(\cdot, x_0)}\, ds \\ & + \int_{t_1}^{t_2} F(s, X_s(x_0)) e^{-\int_s^{t_2} m(\cdot, x_0)}\, ds. \end{aligned} \tag{94}$$

In the view of uniform bounds on $m(t, x_0)$ stated above and bounds on ρ we derive

$$\begin{aligned} |w(t_2, x_0)| \le {} & e^{-c(t_2 - t_1)} w|(t_1, x_0)| + C\delta + C \sup_{s \in (t_1, t_2)} \|\psi(s, \cdot)\|_\infty \\ & + \int_{t_1}^{t_2} \max\{|F(s, X_s(x_0))| - \delta,\, 0\}|. \end{aligned} \tag{95}$$

The estimate for $\max\{|F| - \delta,\, 0\}|$ is given by (77). Employing bounds (87), (88) we derive

$$\int_{t_1}^{t_2} \max\{|F| - \delta,\, 0\}| \le C_\delta \int_{t_1}^{t_2} D^2(\cdot) + X^2(\cdot).$$

Using Lemma 7, estimate (27), the Hölder inequality, and uniform in time bounds (87), (88) we can write

$$\begin{aligned} \|\psi(t, \cdot)\|_\infty \le C \|\nabla \psi(t, \cdot)\|_4 \le C \|\rho(t, \cdot) \mathbf{u}(t, \cdot)\|_4 \\ \le C \|\sqrt{\rho(t, \cdot)} \mathbf{u}(t, \cdot)\|_2^{\frac{1}{3}} \|\mathbf{u}(t, \cdot)\|_4^{\frac{2}{3}} \le C \|\sqrt{\rho(t, \cdot)} \mathbf{u}(t, \cdot)\|_2^{\frac{1}{3}}, \end{aligned}$$

with C independent of t. Collecting the last two estimates in (95) we get

$$\begin{aligned} \|w(t_2, \cdot)\|_\infty \le {} & e^{-c(t_2 - t_1)} \|w(t_1, \cdot)\|_\infty + C\delta \\ & + C \sup_{s \in (t_1, t_2)} \|\sqrt{\rho}(s, \cdot) \mathbf{u}(s, \cdot)\|_2^{\frac{1}{3}} + C_\delta \int_{t_1}^{t_2} D^2(\cdot) + X^2(\cdot). \end{aligned} \tag{96}$$

The last inequality and (93) were derived for the approximate smooth solution $(\rho, \mathbf{u})$, but in the view of the convergence results that will be established in the next chapter these inequalities are also true for the weak solution itself. Moreover, for a weak solution, as it follows from (31), (61), and (62), it holds that

$$D^2,\, X^2,\, \int_{\mathbb{T}^2} G(\rho(\cdot, x))\, dx \in L^1\left(]0, +\infty[\right),$$

and consequently (93) and (96) imply that

$$\|\theta(\rho(t, \cdot)) - \theta(\bar{\rho})\|_\infty + \|\sqrt{\rho}(t, \cdot) \mathbf{u}(t, \cdot)\|_2 \to 0, \quad t \to +\infty,$$

which in turn implies (7) since ρ is bounded from below and above as well as $\|\nabla \mathbf{u}(t, \cdot)\|_2$.

6. Convergence of approximate solutions. In this section we consider the limit of classical solutions, for which bounds derived in the last section hold. These solutions solve the problem with smooth initial datum $(\rho_0^n,\, \mathbf{u}_0^n)$, $n > 0$, that converges strongly to $(\rho_0,\, \mathbf{u}_0)$.

Let $(\rho_0^n,\, \mathbf{u}_0^n) \in C^\infty\left(\mathbb{T}^2\right) \times \left[C^\infty\left(\mathbb{T}^2\right)\right]^2$ be such that

$$\begin{aligned} m < \rho_0^n(x) < M, \quad & x \in \mathbb{T}^2, \\ \rho_0^n \to \rho_0 \quad & \text{in } L^2(\mathbb{T}^2), \\ \mathbf{u}_0^n \to \mathbf{u} \quad & \text{in } \left[W^{1,2}\left(\mathbb{T}^2\right)\right]^2, \\ & n \to +\infty. \end{aligned}$$

Let $(\rho^n,\, \mathbf{u}^n)$ be the classical solution of the problem with $(\rho_0^n,\, \mathbf{u}_0^n)$ as the initial datum that exists by Theorem A. The bounds obtained in the previous section apply for these solutions so that

$$\begin{aligned} \mathbf{u}^n \text{ is bounded in } & L^\infty \cap L^2\left((0,T);\, \left[W^{1,2}\left(\mathbb{T}^2\right)\right]^2\right), \\ A^n,\, B^n \text{ is bounded in } & L^2\left((0,T);\, W^{1,2}\left(\mathbb{T}^2\right)\right), \\ \text{bounded in } & L^\infty\left((0,T);\, L^2(\mathbb{T}^2)\right), \\ \bar{m} < \rho^n(t,x) < \bar{M}, \quad & (t,x) \in (0,T) \times \mathbb{T}^2, \\ & T > 0, \end{aligned}$$

for some $\bar{m}$, $\bar{M}$ that are independent of T in the case $\beta \geq \gamma$. Here $A^n = \operatorname{rot} \mathbf{u}^n$, $B^n = (4\mu/3 + \zeta(\rho^n))\operatorname{div} \mathbf{u}^n$. Moreover, using the system of equations (19), (21), (23) and Lemma 8 we deduce

$$\begin{aligned} \partial_t \rho^n \text{ is bounded in } & L^2\left((0,T);\, W^{-1,2}\left(\mathbb{T}^2\right)\right), \\ \partial_t \mathbf{u}^n \text{ is bounded in } & L^2\left((0,T);\, \left[W^{-1,2}\left(\mathbb{T}^2\right)\right]^2\right), \\ \partial_t A^n,\, \partial_t B^n \text{ is bounded in } & L^2\left((0,T);\, W^{-1,\frac{4}{3}}\left(\mathbb{T}^2\right)\right), \\ & T > 0. \end{aligned}$$

The embedding $W^{1,2}\left(\mathbb{T}^2\right) \subset L^2\left(\mathbb{T}^2\right)$ is compact and $L^2\left(\mathbb{T}^2\right) \subset W^{-1,\frac{4}{3}}\left(\mathbb{T}^2\right)$ (or $W^{-1,2}\left(\mathbb{T}^2\right)$) is continuous. Aubin's lemma can be used; see [16, Theorem 2.1, Chapter III] to conclude that there are

$$\begin{aligned} \mathbf{u} \in L^\infty \cap L^2\left((0,T);\, \left[W^{1,2}\left(\mathbb{T}^2\right)\right]^2\right), \\ A,\, B \in L^2\left((0,T);\, W^{1,2}\left(\mathbb{T}^2\right)\right) \cap L^\infty\left((0,T);\, L^2(\mathbb{T}^2)\right), \end{aligned}$$

such that

$$\begin{cases} \mathbf{u}^n \to \mathbf{u} & \text{in } L^2\left((0,T);\, \left[L^2(\mathbb{T}^2)\right]^2\right), \\ A^n \to A & \text{in } L^2\left((0,T);\, L^2(\mathbb{T}^2)\right), \\ B^n \to B & \text{in } L^2\left((0,T);\, L^2(\mathbb{T}^2)\right). \end{cases} \tag{97}$$

From the uniform boundedness of ρ^n we conclude that there is $\rho(t,x)$ such that

$$\begin{aligned} \bar{m} \leq \rho(t,x) \leq \bar{M}, & (t,x) \in (0,T) \times \mathbb{T}^2, \\ \rho^n \to \rho, \text{ * - weakly in } & L^\infty\left((0,T) \times \mathbb{T}^2\right). \end{aligned} \tag{98}$$

This information is sufficient for passing to the limit in (1). We obtain

$$\begin{cases} \partial_t \rho + \operatorname{div} \rho \mathbf{u} = 0 & \text{in } \mathcal{D}'\left((0,+\infty)\times \mathbb{T}^2\right), \\ \rho(0,x) = \rho_0(x) & \text{a.e. } x \in \mathbb{T}^2. \end{cases} \tag{99}$$

Also, since $\rho \in L^\infty$, ρ is a renormalized solution of (2), i.e., for any $b = b(z) \in C^\infty(\mathbb{R})$ it holds that

$$\begin{cases} \partial_t b(\rho) + \operatorname{div} b(\rho)\mathbf{u} + (\rho b'(\rho) - b(\rho))\operatorname{div} \mathbf{u} = 0, & \mathcal{D}'\left((0,+\infty)\times \mathbb{T}^2\right), \\ b(\rho(0,x)) = b(\rho_0(x)) & \text{a.e. } x \in \mathbb{T}^2, \end{cases} \tag{100}$$

where $b'(z)$ is the derivative of b. Also,

$$\rho \in C\left([0,+\infty); L^p\left(\mathbb{T}^2\right)\right), \quad 1 < p < +\infty$$

(see the proof of Theorem 2.4 in [10]).

Due to the presence of nonlinear terms $\zeta(\rho)\operatorname{div} \mathbf{u}$ and $P(\rho)$, convergence results established in (97) and (98) are not enough to conclude that $(\rho, \mathbf{u})$ solves (2) in the weak sense. The missing ingredient is a.e. convergence of ρ_n. If we assume for a moment that, additionally to (97) and (98),

$$\rho^n \to \rho \text{ a.e. in } (0,+\infty)\times \mathbb{T}^2, \quad n \to +\infty, \tag{101}$$

holds, then it is easy to see that

$$\begin{aligned} \zeta(\rho^n)\operatorname{div} \mathbf{u}^n \to \zeta(\rho)\operatorname{div} \mathbf{u} \quad & \text{weakly in } L^2\left((0,T)\times \mathbb{T}^2\right), \\ P(\rho^n) \to P(\rho) \quad & \text{in } L^2\left((0,T)\times \mathbb{T}^2\right), \quad T > 0, \end{aligned}$$

and (ρ, u) is a weak solution of (1)–(5).

Let us prove (101). Let $b(z)$ be as above. The sequence $b(\rho^n)$ is uniformly bounded and so there is $\overline{b} \in L^\infty\left((0,T)\times \mathbb{T}^2\right)$, $T > 0$ such that $b(\rho^n) \to \overline{b}$ * - weakly in this space. Also we can write

$$\operatorname{div} \mathbf{u}^n = \frac{B^n + P(\rho^n)_{\mathbb{T}^2}}{4\mu/3 + \zeta(\rho^n)} - \frac{P(\rho^n)}{4\mu/3 + \zeta(\rho^n)},$$

and thus

$$\operatorname{div} \mathbf{u} = (B + \bar{P}_{\mathbb{T}^2})\overline{\left(\frac{1}{4\mu/3 + \zeta(\rho)}\right)} - \overline{\left(\frac{P(\rho)}{4\mu/3 + \zeta(\rho)}\right)}, \tag{102}$$

where $^-$ stays for the * - weak limit of the functions and the equality holds a.e. in space and time. Let $b(z) = z^2$ and $\nu = (4\mu/3 + \zeta(\rho))^{-1}$. The pair $(\rho^n, \mathbf{u}^n)$ satisfies (1) in the classical sense and so it holds that

$$\begin{cases} \partial_t(\rho^n)^2 + \operatorname{div}(\rho^n)^2\mathbf{u}^n \\ \qquad = -(\rho^n)^2 \operatorname{div} \mathbf{u}^n \\ \qquad = -\frac{(B^n + P(\rho^n)_{\mathbb{T}^2})(\rho^n)^2}{4\mu/3 + \zeta(\rho^n)} + \frac{(\rho^n)^2 P(\rho^n)}{4\mu/3 + \zeta(\rho^n)}, \\ \\ (\rho^n)^2(0,x) = (\rho_0^n)^2(x), \quad x \in \mathbb{T}^2. \end{cases} \tag{103}$$

Taking the limit in the above equation, in the view of (97) and (98), we obtain (note that initial datum converges strongly)

$$\begin{cases} \partial_t \overline{\rho^2} + \operatorname{div} \overline{\rho^2}\mathbf{u} &= -(B + \overline{P}_{\mathbb{T}^2})\overline{\rho^2\nu} + \overline{\rho^2 P(\rho)\nu} \\ & \quad \text{in } \mathcal{D}'\left((0,+\infty)\times\mathbb{T}^2\right), \\ \overline{\rho^2}(0,x) = \rho_0^2(x) & \quad \text{a.e. } x \in \mathbb{T}^2. \end{cases} \tag{104}$$

Also, from (100) and (102) it follows that

$$\begin{cases} \partial_t \rho^2 + \operatorname{div} \rho^2\mathbf{u} &= -(B + \overline{P}_{\mathbb{T}^2})\rho^2\overline{\nu} + \rho^2\overline{P(\rho)\nu} \\ & \quad \text{in } \mathcal{D}'\left((0,+\infty)\times\mathbb{T}^2\right), \\ \rho^2(0,x) = \rho_0^2(x) & \quad \text{a.e. } x \in \mathbb{T}^2. \end{cases} \tag{105}$$

Setting $\psi = \overline{\rho^2} - \rho^2 \geq 0$, and subtracting the last two equations we obtain

$$\begin{cases} \partial_t \psi + \operatorname{div} \psi\mathbf{u} &= (B + \overline{P}_{\mathbb{T}^2})\left(\rho^2\overline{\nu} - \overline{\rho^2\nu}\right) - \left(\rho^2\overline{P\nu} - \overline{\rho^2 P\nu}\right) \\ & \quad \text{in } \mathcal{D}'\left((0,+\infty)\times\mathbb{T}^2\right), \\ \psi(0,x) = 0 & \quad \text{a.e. } x \in \mathbb{T}^2. \end{cases} \tag{106}$$

By writing $(\rho^n)^2 - \rho^2 = 2\rho(\rho^n - \rho) + (\rho^n - \rho)^2$, we see that

$$\lim_{n\to\infty} \int_{\mathbb{T}^2} \phi(\cdot)(\rho^n(t,\cdot) - \rho(t,\cdot))^2\, dx = \int_{\mathbb{T}^2} \phi(\cdot)\psi(t,\cdot),$$

$t > 0$, for any test function ϕ. Also, for b—a smooth function—we have

$$\begin{aligned} (\rho^n)^2 b(\rho^n) - \rho^2 b(\rho^n) &= (\rho^n)^2 b(\rho^n) - \rho^2 b(\rho) - \rho^2(b(\rho^n) - b(\rho)) \\ &= (\rho^2 b(\rho))'\Big|_{\rho(t,x)}(\rho^n - \rho) + (\rho^2 b(\rho)/2)''\Big|_{\tilde{\rho}^n}(\rho^n - \rho)^2 \\ &\quad - \rho^2\left(b(\rho)'\Big|_{\rho(t,x)}(\rho^n - \rho) + (b(\rho)/2)''\Big|_{\hat{\rho}^n}(\rho^n - \rho)^2\right) \end{aligned}$$

for some $\tilde{\rho}^n$ and $\hat{\rho}^n$ in between ρ^n and ρ. Multiplying the above equality by $B + \overline{P}_{\mathbb{T}^2}$, integrating over domain $\mathbb{T}^2$, taking the limit $n \to +\infty$, and using the uniform boundedness of ρ^n we obtain

$$\begin{aligned} &\left|\int_{\mathbb{T}^2} (B(t,\cdot) + \overline{P}_{\mathbb{T}^2}(t))\left(\rho^2\overline{\nu}(t,\cdot) - \overline{\rho^2\nu}(t,\cdot)\right)\right| \\ &\qquad \leq C|\overline{P}_{\mathbb{T}^2}(t) + \bar{B}(t)| \int_{\mathbb{T}^2} \psi(t,\cdot) + C\int_{\mathbb{T}^2} |B - \bar{B}|(t,\cdot)\psi(t,\cdot) \end{aligned}$$

for some constant $C > 0$. By estimating the second term on the right-hand side in (106) in similar fashion and integrating the equation in (106) over $\mathbb{T}^2$ we derive the inequality

$$\begin{cases} \frac{d}{dt}\int_{\mathbb{T}^2} \psi(t,\cdot) \leq C\left(1 + |\bar{B}|(t)\int_{\mathbb{T}^2}\psi(t,\cdot) + \int_{\mathbb{T}^2}|B - \bar{B}|(t,\cdot)\psi(t,\cdot)\right) \\ \qquad\qquad \text{in } \mathcal{D}'\left((0,+\infty)\right), \\ \int_{\mathbb{T}^2}\psi(0,x) = 0. \end{cases}$$

We use the Hölder inequality for Orlicz spaces defined by functions $\exp(x^2)-1$ and $x\log^{\frac{1}{2}}(e^2+x)$ followed by Remark 2 to get the estimate

$$\begin{aligned}\int_{\mathbb{T}^2}|B-\bar{B}|\psi &\le N_{e^{x^2}-1}\left(B-\bar{B}\right)N_{x\log^{\frac{1}{2}}(e^2+x)}(\psi)\\ &\le C||\nabla B||_2\Gamma\left(\int_{\mathbb{T}^2}\psi\right),\end{aligned}$$

where $\Gamma(r)$, $r\ge 0$ is the inverse function of $\frac{r}{\log^{1/2}(e^2+c/r)}$, with some $c>0$ that bounds $\int_{\mathbb{T}^2}\psi(t,\cdot)$ for all $t>0$. Note that $||\nabla B(t,\cdot)||_2$, $|\bar{B}|(t)$ belong to $L^1((0,T))$ for any $T>0$. Also,

$$\int_{0+}\frac{1}{\Gamma(r)}\,dr=+\infty.$$

Thus, it follows that $\psi(t,x)=\overline{\rho^2}-\rho^2=0$ a.e. $(0,+\infty)\times\mathbb{T}^2$, and consequently (101). The proof of Theorem is now complete.

Acknowledgments. A part of this work was done as a Ph.D. thesis at Northwestern University (USA). I express much gratitude to Professor Gui-Qiang Chen for support and advice.

ON A HELE–SHAW TYPE DOMAIN EVOLUTION WITH CONVECTED SURFACE ENERGY DENSITY: THE THIRD-ORDER PROBLEM*

MATTHIAS GÜNTHER† AND GEORG PROKERT‡

Abstract. We investigate a moving boundary problem with a gradient flow structure which generalizes Hele–Shaw flow driven solely by surface tension to the case of nonconstant surface tension coefficient taken along with the liquid particles at boundary. The resulting evolution problem is first order in time, contains a third-order nonlinear pseudodifferential operator and is degenerate parabolic. Well-posedness of this problem in Sobolev scales is proved. The main tool is the construction of a variable symmetric bilinear form so that the third-order operator is semibounded with respect to it. Moreover, we show global existence and convergence to an equilibrium for solutions near trivial equilibria (balls with constant surface tension coefficient). Finally, numerical examples in 2D and 3D are given.

Key words. free boundary motion, degenerate nonlocal parabolic evolution

1. Introduction. It is the aim of the present paper to consider the generalization of the well-investigated Hele–Shaw flow problem to the case of nonconstant surface tension coefficient (or surface energy density). While experiments on such situations have been reported in the literature (e.g., [3, 12]), theoretical investigations of this seem to be lacking. A first step in this direction has been made in [10] where short-time solvability was proved for a Hele–Shaw problem with nonconstant surface tension coefficient and so-called kinetic undercooling. Here we discuss the problem without this regularization, using again the simple assumption that the surface energy density is convectively transported along the moving boundary.

This leads to the following moving boundary problem: For a given bounded domain $\Omega(0) \subset \mathbb{R}^m$ and a given nonnegative function γ_0 defined on $\partial\Omega(0)$ one looks for a family of C^2-domains $\Omega(t) \subseteq \mathbb{R}^m$, $t > 0$ and functions $\varphi(\cdot,t) \in C^2\big(\overline{\Omega(t)}\big)$, $\psi(\cdot,t) \in C^2\big(\overline{\Omega(t)}\big)$, $\gamma_t \in C^2\big(\Gamma(t)\big)$ such that

$$\left.\begin{aligned} \Delta\varphi(\cdot,t) &= 0 && \text{in } \Omega(t),\\ \Delta\psi(\cdot,t) &= 0 && \text{in } \Omega(t),\\ \partial_n\psi(\cdot,t) &= \Delta_{\Gamma(t)}\gamma_t && \text{on } \Gamma(t),\\ \varphi(\cdot,t) &= \gamma_t\kappa(t) - \psi(\cdot,t) && \text{on } \Gamma(t),\\ V_n &= \partial_n\varphi(\cdot,t) && \text{on } \Gamma(t). \end{aligned}\right\} \tag{1.1}$$

Here γ_t represents the variable surface tension coefficient (local surface energy density) on $\Gamma(t)$, $\varphi(\cdot,t)$ is the velocity potential inside the flow domain $\Omega(t)$, and ψ is an auxiliary function describing the nonlocal influence of the spatial variation of γ_t.

Furthermore, $\kappa(t)$ is the $(m-1)$-fold mean curvature of $\Gamma(t)$, with the sign taken such that κ is negative for convex domains, ∂_n is the outer normal derivative, and $V_n(t)$ is the (outer) normal velocity of $\Gamma(t)$, determining its time evolution. Note that by setting $\Phi = \varphi + \psi$, (1.1) simplifies to

$$\left.\begin{aligned} \Delta\Phi(\cdot,t) &= 0 && \text{in } \Omega(t),\\ \Phi(\cdot,t) &= \gamma_t\kappa(t) && \text{on } \Gamma(t),\\ V_n &= \partial_n\Phi(\cdot,t) - \Delta_{\Gamma(t)}\gamma_t && \text{on } \Gamma(t). \end{aligned}\right\} \tag{1.2}$$

This problem generalizes the well-known Hele–Shaw flow with surface tension regularization in the following way: Any solution represents a gradient flow with respect to the usual energy functional

$$E(\gamma,\Gamma) := \int_\Gamma \gamma \, d\Gamma,$$

where $\gamma > 0$ is now variable on Γ, and to the Riemannian metric g_Γ on the infinite-dimensional manifold $\mathcal{M}$ of surfaces Γ enclosing a fixed volume given by

$$g_\Gamma(v_1,v_2) := \int_\Omega \nabla\varphi_1 \nabla\varphi_2 \, dx, \tag{1.3}$$

where the φ_i, $i = 1,2$ are (weak) solutions of the Neumann problems

$$\Delta\varphi_i = 0 \text{ in } \Omega, \quad \partial_n\varphi_i = v_i \text{ on } \Gamma.$$

The functions v_i can be identified with tangent vectors of $\mathcal{M}$; note that the conservation of volume implies $\int_\Gamma v_i = 0 \, d\Gamma$. For more details and references, see [1, 7, 10]. Kinetic undercooling regularization corresponds to adding in (1.3) a boundary integral term $\beta \int_\Gamma v_1 v_2 \, d\Gamma$ with $\beta > 0$, this case is discussed in [10].

As mentioned already, we assume that the values of the function Γ are transported with the liquid particles: Introducing Lagrangian coordinates $x = x(\xi,t)$, $\xi \in \Gamma(0)$ corresponding to the velocity field via

$$\partial_t x(\xi,t) = \nabla\varphi\big(x(\xi,t),t\big) \text{ for } t \geq 0, \quad x(\xi,0) = \xi, \tag{1.4}$$

we obtain that $x = x(\cdot,t)$ is a diffeomorphism from $\Gamma(0)$ onto $\Gamma(t)$, and the transport law for γ_t takes the form

$$\gamma_t\big(x(\xi,t)\big) = \gamma_0(\xi), \quad \xi \in \Gamma(0), \ t \geq 0. \tag{1.5}$$

This assumption is reasonable, for example, when γ depends on temperature and heat diffusion is negligible compared to convection. While it certainly oversimplifies the physical situation in the case when, for example, surfactants play a role, it seems that the mathematical character of the problem is essentially the same there as in our case. Note, however, that the situation here is qualitatively different from other models like anisotropic Hele–Shaw flow (cf. [6]) because in our case the evolution is not determined solely by the shape of the evolving domain but there is a coupling with a transport problem in the moving boundary.

Our approach is based on reformulating (1.1) as a vector-valued evolution equation for a diffeomorphism mapping a fixed reference manifold to the moving boundary, i.e., we work with "Lagrangian cordinates" for the boundary. This approach which

might appear unnatural at first glance has two advantages: The transport problem for γ is simply solved by prescribing a fixed smooth positive function on this reference manifold and pushing it forward to the moving boundary. Moreover, the invariance of the problem with respect to reparametrizations of the boundary can be used to derive nonlocal analogues of Leibniz' rule of differentiation (3.10) which we will use in the course of our estimates. On the other hand, however, our approach implies that the resulting vector valued evolution equation (2.2), cannot be strictly parabolic, even for strictly positive γ. Instead, the (linearized) problem is degenerate in tangential directions, and although we have a third-order parabolic operator in normal direction, straightforward coercivity estimates for the vector valued problem are not available. Therefore we work with energy estimates with respect to a variable inner product (4.26) which is specifically constructed for this purpose. (This is similar to the usual treatment of symmetrizable hyperbolic systems.)

The paper is organized as follows.

After announcing our main results on short-time existence in section 2, we start the proofs in section 3 by investigating mapping properties of the occurring nonlocal operators in Sobolev scales. In particular, we derive flexible multilinear estimates for their Fréchet derivatives in low norms and extend them to higher norms by a generalized chain rule based on invariance properties. For related considerations concerning the analytic dependence of the Dirichlet–Neumann operator on the domain we refer to [5] and the references given there. Section 4 is devoted to the proof of the crucial estimate providing the semiboundedness of the evolution operator with respect to our variable inner product.

Technically, we use the natural decomposition of the right-hand side into a second-order operator mapping vectors to scalars and a first-order operator mapping scalars to vectors. Furthermore, we use the fact that the right-hand side is—in a sense to be made precise later—coercive with respect to the normal component. The semiboundedness enables us to invoke an abstract existence result based on Galerkin approximations and Rothe's method. This is done in section 5. In this way, we prove our main result (Theorems 2.1 and 2.2) on short-time wellposedness of the moving boundary problem (1.1), (1.4), (1.5). We will omit certain details as they are parallel to the discussion in [10]. However, the right-hand side of the evolution problem obtained there is of order two. As we are concerned here with an evolution equation whose right-hand side is of order three, we have to refine the construction of our variable inner product from [10] by including certain lower-order terms. Differing from the situation there, here we have to demand strict positivity of γ because its inverse γ^{-1} enters one of these terms.

Finally, in section 6 we investigate the evolution near the equilibrium solutions given by balls with constant γ. In this situation, Theorem 6.8 gives global existence in time and the evolving domain approaches a nontrivial equilibrium configuration depending on the given (nonconstant) γ and the initial domain. In contrast to the classical case of constant γ where the equilibria are given only by balls, any shape near a ball occurs as an equilibrium configuration for a certain function γ near the constant. Due to the degeneracy of our problem, the proof of long-time existence is more involved compared to the known proofs for the case of constant γ, cf. [4, 8, 13].

2. Statement of the local existence results. We begin by listing some notation. $C, C_1, \dots$ etc. denote generic constants; their dependencies on other quantities is only indicated if not obvious from the context. Let $E \subseteq \mathbb{R}^m$, $m \geq 2$ be a bounded domain with smooth boundary $S := \partial E$ and ν the outer unit normal on S. For

$M = S$ or $M = E$, we make constant use of the usual L^2-based Sobolev spaces $H^s(S)$, $H^s(S, \mathbb{R}^m)$ of order s with values in $\mathbb{R}$ and $\mathbb{R}^m$, respectively. The norms of these spaces will be denoted by $\|\cdot\|_s^M$; for $M = S$ the upper index M is dropped in most cases. When Fréchet derivatives of operator-valued mappings are considered, the additional arguments describing the variations are written in accolades ($\{\}$).

Now, as already mentioned in the introduction, we reformulate the moving boundary problem (1.1)—(1.5) by describing $\Gamma(t)$ as an embedding $u(\cdot, t) : S \to \mathbb{R}^m$ such that the curves $t \mapsto u(y, t)$ for fixed $y \in S$ are trajectories belonging to the velocity field and γ_t is constant along these curves. This approach enables us to consider γ_t as a known function during the evolution at the cost of describing the moving boundary by m functions. To do so, let

$$U := \big\{u : S \to \mathbb{R}^m \;\big|\; u = w|_S \text{ with } w \in \mathrm{Diff}(\bar{E}, \Omega_u \cup \Gamma_u)\big\}, \tag{2.1}$$

where

$$\Omega_u = w(E) \quad \text{and} \quad \Gamma_u = \partial\Omega_u = u(S).$$

Throughout this paper, we use the abbreviation

$$U_s := U \cap H^s(S, \mathbb{R}^m).$$

Now, (1.1)—(1.5) is reduced to the following Cauchy problem, which will be investigated afterwards. For a given $u_0 \in U_s$, s sufficiently large, we look for $T > 0$ and a mapping $[0, T] \ni t \mapsto u(t) \in U_s$, such that

$$u'(t) = \mathcal{F}\big(u(t)\big), \quad t \in [0, T], \tag{2.2}$$

$$u(0) = u_0. \tag{2.3}$$

Thereby, for $u \in U$, we have set

$$\mathcal{F}(u) := F(u)\mathcal{G}(u) \quad \text{with} \quad \mathcal{G}(u) := H(u) + G(u), \tag{2.4}$$

where, for any given function f on S,

$$F(u)f := \nabla\varphi(u, f) \circ u \tag{2.5}$$

and $\varphi = \varphi(u, f)$ denotes the solution of the Dirichlet problem

$$\Delta\varphi = 0 \text{ in } \Omega_u, \quad \varphi = f \circ u^{-1} \text{ on } \Gamma_u. \tag{2.6}$$

Further, $H(u)$, $G(u)$ are given by

$$H(u) := \gamma(\kappa_{\Gamma_u} \circ u), \quad G(u) := -A(u)\Delta(u)\gamma. \tag{2.7}$$

Here $\gamma \in C^\infty(S)$ is a fixed and given positive function, κ_{Γ_u} denotes the mean curvature of Γ_u with sign and scaling conventions as above, and

$$\Delta(u)w := \Delta_{\Gamma_u}(w \circ u^{-1}) \circ u \tag{2.8}$$

is the pullback to S of the Laplace–Beltrami operator Δ_{Γ_u} on Γ_u and

$$A(u)f := \varphi_N\big(u, f\big) \circ u \tag{2.9}$$

is the Neumann–Dirichlet operator, i.e., $\varphi_N = \varphi_N(u, f)$ solves the Neumann problem

$$\Delta\varphi_N = 0 \text{ in } \Omega_u, \quad \partial_n\varphi_N = c + f \circ u^{-1} \text{ on } \Gamma_u, \quad \int_{\Gamma_u} \varphi_N \, dx = 0. \tag{2.10}$$

The constant $c = c(u, f) \in \mathbb{R}$ in (2.10) is determined by the solvability condition

$$\int_{\Gamma_u} (f \circ u + c) \, d\Gamma_u = 0; \tag{2.11}$$

clearly $c(u, f) = 0$ for $f = \Delta(u)\gamma$. For fixed smooth γ on S, the mapping $u \mapsto H(u)$ constitutes a quasilinear second order differential operator on S. Moreover, the solutions of the boundary value problems (2.6), (2.10) depend smoothly on the domain Ω_u, i.e., on $u \in H^s$, $s > (m+1)/2$ and $f \mapsto F(u)f$, $f \mapsto A(u)f$ represent pseudodifferential operators of order one and minus one, respectively. In particular, G is a pseudodifferential operator of lower order than H and may be considered as a correction term to ensure the gradient flow structure of the evolution problem. We will show later that

$$[u \mapsto \mathcal{F}(u)] \in C^\infty\big(U_s, H^{s-3}(S, \mathbb{R}^m)\big) \tag{2.12}$$

for $s > (m+3)/2$, $s \geq 3$. Now we are in position to formulate our main results.

THEOREM 2.1 (short-time existence and uniqueness). *Fix an even integer $s_0 > (m+7)/2$, $s_0 \geq 6$ and assume $\gamma \in C^\infty(S)$ strictly positive on S. Let $s \geq s_0$ be an even integer and $u_0 \in U_s$. Then there exist $T > 0$ and a unique solution*

$$u \in C\big([0, T], U_s\big) \cap C^1\big([0, T], H^{s-3}(S, \mathbb{R}^m)\big) \tag{2.13}$$

of the initial value problem (2.2), (2.3). Additionally, any given $\bar{u}_0 \in U_{s_0}$ has a suitable H^{s_0}-neighborhood K, such that for initial values u_0 varying in $K \cap H^s$, there are $T > 0$ and C independent of u_0 such that

$$\|u(t)\|_s \leq C(1 + \|u(0)\|_s) \text{ for all } t \in [0, T]. \tag{2.14}$$

THEOREM 2.2 (regularity and continuous dependence on initial values). *Under the assumptions of Theorem 2.1 let u be a any solution to (2.2) in the class (2.13) with some $T > 0$. Then there holds the following:*

(i) *$u(0) \in H^{s+1}(S, \mathbb{R}^m)$ implies $u(t) \in H^{s+1}(S, \mathbb{R}^m)$ for all $t \in [0, T]$.*

(ii) *Assume $u_0^n \to u_0$ in $H^s(S, \mathbb{R}^m)$ for $n \to \infty$. Then, for n sufficiently large, there exist solutions u_n of (2.2) in the class (2.13) with initial values $u_n(0) = u_0^n$ and there holds $u_n \to u$ in $C\big([0, T], H^s(S, \mathbb{R}^m)\big)$.*

The proof of both theorems is given in section 5.

Remark 2.3. The restriction to even integers s is due purely to the construction of our bilinear form involving integer powers of a generalized Laplacian. This restriction can be lifted afterwards by using the nonlinear interpolation result given in [2, Proposition A.1 and Remark A.2]. The dimension independent restriction $s_0 \geq 6$ is needed as we use dual estimates for elliptic boundary value problems in norms with negative index.

3. Smooth domain dependence of the nonlocal operators. We start by gathering some properties of the nonlocal operators F, A, and $\mathcal{G}$ defined by (2.4)–(2.11). The multilinear estimates for the Fréchet derivatives can be seen as counterparts to the product estimate

$$\|u_1 \dots u_k\|_t \leq C\|u_1\|_{s_1} \dots \|u_k\|_{s_k}$$

holding if $0 \le t \le s_i \le \sigma$, $\sigma > (m-1)/2$, $\sum_{i=1}^k s_i \ge t + (k-1)\sigma$. Here, however, we have to deal with nonlocal operators of various orders involving differentiations and the solution of elliptic BVP.

The statements and their proofs are essentially parallel to Corollary 4.4 and Lemma 4.5 in [10], therefore proofs will be omitted. Note, however, that $f \mapsto F(u)f$ is an operator of order one here as (2.6) is a Dirichlet problem. In fact, the normal component of F is given by the Dirichlet–Neumann operator while the tangential component is given by the tangential gradient of f.

Due to the variability in the choice of the s_i, the estimates will be flexible enough to control various lower order terms that will occur in what follows.

LEMMA 3.1. (i) *Let $s > (m+1)/2$ and $t \in [1, s]$ be given. Then*

$$F \in C^\infty\big(U_s, \mathcal{L}(H^t(S), H^{t-1}(S, \mathbb{R}^m))\big),$$
$$A \in C^\infty\big(U_s, \mathcal{L}(H^{t-1}(S), H^t(S, \mathbb{R}^m))\big),$$

and for any $u \in U_s$ and any choice of $s_1, \dots s_{k+1} \in [t, s]$ with $s_1 + \dots + s_{k+1} \ge t + ks$ there exists a constant $C > 0$ such that for all $f \in H^s(S)$ and all $u_1, \dots, u_k \in H^s(S, \mathbb{R}^m)$ there holds

$$\big\|F^{(k)}(u)\{u_1, \dots, u_k\}f\big\|_{t-1} \le C\|u_1\|_{s_1} \cdots \|u_k\|_{s_k}\|f\|_{s_{k+1}}, \tag{3.1}$$

$$\big\|A^{(k)}(u)\{u_1, \dots, u_k\}f\big\|_{t} \le C\|u_1\|_{s_1} \cdots \|u_k\|_{s_k}\|f\|_{s_{k+1}-1}. \tag{3.2}$$

(ii) *Let $s > (m+3)/2$ and $t \in [2, s]$ be given. Then*

$$\mathcal{G} \in C^\infty\big(U_s, H^{s-2}(S)\big)$$

and for any $u \in U_s$ and any choice of $s_1, \dots s_k \in [t, s]$ with $s_1 + \dots + s_{k+1} \ge t + ks$ there exists a constant $C > 0$ such that for all $u_1, \dots, u_k \in H^s(S, \mathbb{R}^m)$ there holds

$$\big\|\mathcal{G}^{(k)}(u)\{u_1, \dots, u_k\}\big\|_{t-1} \le C\|u_1\|_{s_1} \cdots \|u_k\|_{s_k}. \tag{3.3}$$

The constants may be chosen independently of u as u varies in bounded and weakly closed subsets of U_s.

Remark 3.2. Note that a bounded subset of $H^s(S)$ is weakly closed if and only if it is closed in $H^t(S)$ for some $t < s$. Then it is compact in all $H^t(S)$ with $t < s$.

Remark 3.3. The estimate (3.3) is not optimal as we do not use the quasilinear character of $\mathcal{G}$. For our purposes, however, it will be sufficient.

Note that Lemma 3.1 implies the smoothness assertion (2.12).

Next, we prove some related estimates in norms with negative index. The use of such norms implies a loss of flexibility. Essentially, these estimates are parallel to product estimates of the type

$$\|u_1 \dots u_k\|_t \le C\|u_1\|_s \dots \|u_{k-1}\|_s\|u_k\|_t,$$

$t \in [-s, s]$, $s > (m-1)/2$, which can be proved by duality arguments if $t < 0$.

LEMMA 3.4. *Assume $s > (m+1)/2$, $s \ge 4$, $t \in [-3, s-1]$. Then*

$$F \in C^\infty\big(U_s, \mathcal{L}(H^{t+1}(S), H^t(S))\big),$$
$$A \in C^\infty\big(U_s, \mathcal{L}(H^{t-1}(S), H^t(S))\big),$$

and for $u \in U_s$

$$\|F'(u)u_1\|_t \le C\|u_1\|_s\|f\|_{t+1}, \tag{3.4}$$

$$\|A(u)f\|_t \le C\|f\|_{t-1}, \tag{3.5}$$

$$\|A^{(k)}(u)\{u_1,\dots,u_k\}f\|_t \le C\|u_1\|_s\dots\|u_k\|_s\|f\|_{t-1}, \tag{3.6}$$

$$\|A^{(k)}(u)\{u_1,\dots,u_k\}f\|_t \le C\|u_1\|_s\dots\|u_{k-1}\|_s\|u_k\|_t\|f\|_s, \tag{3.7}$$

$u_1,\dots,u_k \in H^s(S,\mathbb{R}^m)$, $k \in \mathbb{N}$. *The constants* C *can be chosen independently of* u *as* u *varies in bounded, weakly closed subsets of* U_s.

Proof. We will restrict ourselves to the assertions concerning A. Fix $s_0 \in ((m+1)/2, s)$ and an extension operator $\mathcal{E} \in \mathcal{L}(H^t(S), H^{t+1/2}(E))$, $t > 0$. Pick $v \in U_s$ and choose an H^{s_0}-neighborhood $V_{s_0} \subset U_s$ and $u_0 \in C^\infty(\overline{E},\mathbb{R}^m)$ such that

$$\widetilde{u} := u_0 + \mathcal{E}(u - u_0) \in \mathrm{Diff}(\overline{E}, \overline{\Omega}_u).$$

This is possible by Lemma 4.1 in [10].

For $u \in V_{s_0}$, let the transformed operators $L(u)$ and $\mathcal{B}(u)$ be defined by

$$L(u)\psi := \partial_i(\sqrt{g}g^{ij}\partial_j\psi), \quad \mathcal{B}(u)\psi := \nu_i\sqrt{g}g^{ij}\partial_j\psi,$$

where $\sqrt{g}$, g^{ij} are the volume element and the (inverse) coefficients of the metric on E induced by $\widetilde{u}$, respectively, and ν is the outer unit normal on S. We consider the transformed boundary value problem

$$L(u)\psi = \Phi_1, \quad \mathcal{B}(u)\psi = \omega(u)(\Phi_2 + c), \quad \int_s \omega(u)(\Phi_2 + c)\,dS = \int_E \sqrt{g}\Phi_1\,dx, \tag{3.8}$$

$c = c(u,\Phi_1,\Phi_2) \in \mathbb{R}$. Here $\omega(u) = d\Gamma_u/dS$ is the surface element belonging to the transformation induced by u which is given by a nonlinear first-order differential operator in $\widetilde{u}$.

For $\tau > 0$ and $v \in L^2(E)$ define

$$\|v\|_\tau := \sup_{z\in H^\tau(E),\|z\|_\tau=1} \left|\int vz\,dx\right|.$$

(This differs from the usual norm in $H^{-\tau}(E) := (H_0^\tau(E))'$.) The BVP (3.8) is uniquely solvable and ψ satisfies an estimate

$$\|\psi\|_t + \|\psi\|^E_{t+1/2} \le C\big(\|\Phi_1\|^E_{t-3/2} + \|\Phi_2\|_{t-1}\big) \tag{3.9}$$

(cf. [9, Lemma 3.1]).

As $A(u)f$ is the trace of the solution ψ of (3.8) with $\Phi_1 = 0$, $\Phi_2 = f$, we get (3.5) immediately from (3.9).

Note that $A'(u)\{u_1\}f$ is given as the solution ψ' of

$$\begin{aligned} &L(u)\psi' = -L'(u)\{u_1\}\psi,\\ &\mathcal{B}(u)\psi' = -\mathcal{B}'(u)\{u_1\}\psi + \omega'(u)\{u_1\}(f + c(u,0,f)) + \omega(u)\partial_u c(u,0,f)\{u_1\}. \end{aligned}$$

As $f \mapsto c(u,0,f)$ and $v \mapsto \partial_u c(u,0,f)\{v\}$ are given by smoothing operators, to obtain (3.6) and (3.7) it is sufficient to use (3.9) and estimate either

$$\|L'(u)\{u_1\}\psi\|^\Omega_{t-3/2} \le C\big(\|\mathcal{E}u_1\|^\Omega_{t+1/2} + \|u_1\|_t\big)\|\psi\|_{s+1} \le C\|u_1\|_t\|f\|_s$$

or

$$\|L'(u)\{u_1\}\psi\|^{\Omega}_{t-3/2} \le C\big(\|\psi\|^{\Omega}_{t+\frac12} + \|\psi\|_t\big)\|u_1\|_s \le C\|u_1\|_s\|f\|_{t-1},$$

together with analogous estimates for $\|\mathcal{B}'(u)\psi\|_{t-1}$ and $\|\omega'(u)\{u_1\}f\|_{t-1}$. The general case now follows by induction over k, cf. [10, Lemma 4.5].

The estimate (3.4) can be obtained in a similar fashion, discussing a Dirichlet problem instead of (3.8).

Finally, the uniformity of the estimates follows from the fact that bounded, weakly closed subsets of U_s are compact in $H^{s_0}(S)$. □

We choose m smooth vector fields $D_1, \dots, D_m$ on S such that

$$\mathrm{Span}\{D_1, \dots, D_m\} = T_x \ \text{ for all } \ x \in S$$

and use the multi-index notation $D^\alpha = D_1^{\alpha_1} \cdots D_m^{\alpha_m}$, $\alpha = (\alpha_1, \dots, \alpha_m)$ for higher order derivatives; for simplicity we assume that $(D_1, \dots, D_m)$ coincides with the tangential gradient on S. Note that, for any integer $s \ge 0$, we can use

$$(u, v)_s = \sum_{|\alpha| \le s} (D^\alpha u, D^\alpha v)_{L^2(S)}$$

as a scalar product generating the norm in $H^s(S)$. Moreover, as an immediate consequence of the invariance properties

$$\big(F(u)f\big) \circ \tau = F(u \circ \tau)(f \circ \tau)$$

for any diffeomorphism τ on S, we have a differentiation rule which resembles Leibniz' rule at an abstract level, cf. [10]: For any multi-index α and $u \in U_s$, $f \in H^s(S)$, $s > |\alpha| + (m+1)/2$ there holds

$$D^\alpha F(u)f = \sum c_{\beta_1,\dots,\beta_{k+1}} F^{(k)}(u)\{D^{\beta_1}u, \dots, D^{\beta_k}u\}D^{\beta_{k+1}}f, \tag{3.10}$$

where the sum has to be extended over all integers k and systems of nonnegative multi-indices $\beta_1, \dots, \beta_{k+1}$ with

$$0 \le k \le |\alpha|, \quad 1 \le |\beta_1|, \dots, |\beta_k|, \quad \beta_1 + \cdots + \beta_{k+1} = \alpha. \tag{3.11}$$

The coefficients are nonnegative integers, in particular $c_\alpha = c_{\alpha,0} = 1$.

Combining the differentiation rule for F with the estimate of the derivatives in lower norms we obtain the following proposition.

PROPOSITION 3.5. (i) *Let $s \ge s_0 > (m+1)/2$, s integer, $u \in U_s$. Then*

$$\|F(u)f\|_{s-1} \le C\big(\|u\|_s\|f\|_{s_0} + \|f\|_s\big) \tag{3.12}$$

with a uniform constant as long as u varies in H^{s_0}-bounded and weakly H^{s_0}-closed subsets of U_s.

(ii) *Assume additionally that $s \ge s_0 + 2$ and let α be any multi-index with $|\alpha| = s$. Writing $D^\alpha = D^{\alpha_1} \cdots D^{\alpha_s}$ with $|\alpha_1| = \cdots = |\alpha_s| = 1$, we have*

$$D^\alpha F(u)f = F(u)D^\alpha f + F'(u)\{D^\alpha u\}f + \sum_{i=1}^{s} F'(u)\{D^{\alpha_i}u\}D^{\beta_i}f + R_\alpha(u)f, \tag{3.13}$$

where $\alpha = \alpha_i + \beta_i$ and the remainder term allows the estimate

$$\|R_\alpha(u)f\|_0 \le C\big(\|u\|_s\|f\|_{s_0+1} + \|f\|_{s-1}\big).$$

The constant can be chosen uniformly as u varies in H^{s_0+2}-bounded, weakly H^{s_0+2}-closed subsets of U_s.

Proof. We consider the more complicated situation (ii) only. According to (3.10), the remainder term has a representation as a sum of terms

$$I_\beta = F^{(k)}(u)\{D^{\beta_1}u, \dots, D^{\beta_k}u\}D^{\beta_{k+1}}f,$$

where the multi-indices satisfy (3.11) and additionally

$$|\beta_1|, \dots, |\beta_k| \le s-1, \quad |\beta_{k+1}| \le s-2.$$

Hence $k \ge 1$. For each of the terms I_β, we will choose numbers $\theta_1, \dots, \theta_{k+1} \in [0,1]$ such that $\theta_1 + \cdots + \theta_{k+1} = 1$ and set

$$s_i := (1-\theta_i)s_0 + \theta_i.$$

If $k = 1$ we choose θ_1, θ_2 such that $\theta_1 + \theta_2 = 1$ and $|\beta_2| = \theta_1 + \theta_2(s-2)$. If $k = 2$ and $|\beta_3| = 0$ we choose $\theta_i := (|\beta_i| - 1)/(s-2)$ for $i = 1, 2$ and $\theta_3 := 0$. If $k = 2$ and $|\beta_3| \ge 1$ or $k \ge 3$ we choose

$$\theta_i := (|\beta_i| - 1)/(s-3) \text{ for } i = 1,2,3, \quad \theta_i := |\beta_i|/(s-3) \text{ for } i \ge 4.$$

In all cases, we have

$$\left.\begin{aligned} |\beta_i| + s_i &\le (1-\theta_i)(s_0+2) + \theta_i s, && i = 1, \dots, k, \\ |\beta_{k+1}| + s_{k+1} &\le (1-\theta_{k+1})(s_0+1) + \theta_{k+1}(s-1). \end{aligned}\right\} \tag{3.14}$$

Set $\lambda := \theta_1 + \cdots + \theta_k$. Using (3.1) with $t = 1$, $s = s_0$, (3.14), norm convexity, and Young's inequality we get

$$\begin{aligned} \|I_\beta\|_0 &\le C\|u\|_{|\beta_1|+s_1} \dots \|u\|_{|\beta_1|+s_k}\|f\|_{|\beta_{k+1}|+s_{k+1}} \\ &\le C\|u\|_{s_0+2}^{k-1}\big(\|u\|_{s_0+2}\|f\|_{s-1}\big)^{1-\lambda}\big(\|u\|_s\|f\|_{s_0+1}\big)^{\lambda} \\ &\le C\|u\|_{s_0+2}^{k-1}\big(\|u\|_{s_0+2}\|f\|_{s-1} + \|u\|_s\|f\|_{s_0+1}\big), \end{aligned}$$

and the result follows. ∎

The following lemma provides an explicit characterization for the linearization of F, namely up to terms of order zero in v,

$$F'(u)f \approx -F(u)(v \cdot F(u)f).$$

This structure will be important later. It can be verified in an informal way by performing the variation on Ω_u itself instead of transforming the problem to the reference domain.

LEMMA 3.6. *Let $s > (m+3)/2$. Then for $u \in U_s$, $v \in H^s(S, \mathbb{R}^m)$, and $f \in H^s(S)$ there holds*

$$\|F'(u)\{v\}f + F(u)(v \cdot F(u)f)\|_0 \le C\|f\|_s\|v\|_0.$$

Proof. From (2.5) we get

$$F_i'(u)\{v\}f = \partial_i\phi' \circ u + v_j\partial_i\partial_j\phi \circ u$$

with $\phi = \phi(u,f)$ from (2.6) and $\phi' = \phi'(u,f)\{v\}$ given by

$$\phi'(u,f)\{v\}(x) = \partial_\varepsilon(\phi(u+\varepsilon v, f)(x))|_{\varepsilon=0}, \quad x \in \Omega_u.$$

The function ϕ' satisfies

$$\Delta\phi' = 0 \text{ in } \Omega_u, \quad \phi' = -\nabla\phi \cdot v \text{ on } \Gamma_u, \tag{3.15}$$

therefore $\partial_i\phi' \circ u = -F_i(u)(v \cdot F(u)f)$.

Parallel to the proof of Lemma 5.1 in [10] one obtains

$$\|v_j\partial_i\partial_j\phi \circ u\|_0 \le C\|v\|_0\|\phi(u,f)\|_{C^2(\overline{\Omega}_u)} \le C\|f\|_s\|v\|_0.$$

This proves the assertion. □

4. The main estimate. In this section we prove a priori estimates in H^s for the nonlinear operator $\mathcal{F}$ w.r.t. variable bilinear forms which we define in what follows. As already mentioned in the introduction, these estimates are the main ingredient in the existence proof.

To begin with, for $u \in U_s$, $s > (m+1)/2$ we define

$$P(u)v := v \cdot \big(n(u) \circ u\big), \quad N(u)w := w\,\big(n(u) \circ u\big), \tag{4.1}$$

$$\Lambda(u)w := \nabla_{\Gamma_u}(w \circ u^{-1}) \circ u \tag{4.2}$$

as the Euclidean scalar product and multiplication with outer normal $n(u)$ of Γ_u and pullback of tangential gradient ∇_{Γ_u} along Γ_u, respectively. Considered as operators in v and w, the coefficients of $P(u)$, $N(u)$ and $\Lambda(u)$ are smooth functions of u and its first derivatives. Thus,

$$P(u) \in \mathcal{L}\big(H^t(S,\mathbb{R}^m), H^t(S)\big), \quad N(u) \in \mathcal{L}\big(H^t(S), H^t(S,\mathbb{R}^m)\big), \tag{4.3}$$

$$\Lambda(u) \in \mathcal{L}\big(H^t(S), H^{t-1}(S,\mathbb{R}^m)\big) \tag{4.4}$$

depend smoothly on $u \in U_s$ for $|t| \le s-1$ and $|t-1| \le s-1$, respectively. Clearly, the operators P, N, Λ satisfy invariance properties as stated for F in [10]. As a consequence, the differentiation rule (3.10) is also true for P, N, Λ; we make use of that without explicit mention. Further more, recall that the pullback $\Delta(u)w$ of the Laplace–Beltrami operator Δ_{Γ_u} on Γ_u according to (2.8) and the operator $H(u)$ according to (2.7) may be expressed as

$$\Delta(u)w = \Lambda_i(u)\big(\Lambda_i(u)w\big), \quad H(u) = -\gamma\Lambda_i(u)\big(n_i(u) \circ u\big), \tag{4.5}$$

respectively.

In the further considerations of this section we fix s_0 to be the smallest integer such that $s_0 \ge 6$ and $s_0 > (m+7)/2$ and set

$$\widetilde{U}_s := U_s \cap K \text{ for all } s \ge s_0$$

with a fixed H^{s_0}-bounded and weakly H^{s_0}-closed subset $K \subseteq U_{s_0}$. Note that

$$1 \le C\|u\|_{s_0} \le C'\|u\|_s, \quad \|u\|_{C^3(S)} \le C$$

for all $u \in \widetilde{U}_s$, $s \ge s_0$.

Furthermore, we have the estimates

$$\|\mathcal{G}(u)\|_{s-2}, \|\mathcal{F}(u)\|_{s-3} \le C\|u\|_s \ \text{ for all } \ u \in \widetilde{U}_s, s \ge s_0,$$

and the operators defined in (4.3), (4.4) are bounded uniformly with respect to $u \in \tilde{U}_s$.

Due to our choice of the differential operators D_i, the Laplace–Beltrami operator on the compact reference manifold S is given by $\Delta_0 := D_i D_i$. It has an approximate inverse, i.e., there is an operator $\Delta_0^+ \in \mathcal{L}\big(H^\tau(S), H^{\tau+2}(S)\big)$, $\tau \in \mathbb{R}$, such that

$$\Delta_0\Delta_0^+ = \Delta_0^+\Delta_0 = \mathrm{id} + Q_0,$$

with a smoothing operator Q_0 simply given by orthogonal projection in $L^2(S)$ onto the subspace of functions which are constant on each connectivity component of S; in particular, $Q_0 \in \mathcal{L}(H^\tau(S), H^\sigma(S))$ for any $\sigma, \tau \in \mathbb{R}$. In the same manner, we define the approximate inverse $\Delta^+(u)$ for $\Delta(u)$. In this case we have

$$[u \mapsto \Delta^+(u)] \in C^\infty\big(U_s, \mathcal{L}\big(H^t(S), H^{t+2}(S)\big)\big), \quad t \in [0, s-2]$$

and

$$\Delta(u)\Delta(u)^+ = \Delta(u)^+\Delta(u) = \mathrm{id} + Q(u), \tag{4.6}$$

where $Q(u) \in \mathcal{L}\big(H^\tau(S), H^\sigma(S)\big)$ for any $\sigma \in \mathbb{R}$, $\tau \ge 1 - s$, and the corresponding norms are bounded independently of $u \in \tilde{U}_s$.

LEMMA 4.1. *Let $s \ge s_0$ with $s = 2k$, $k \in \mathbb{N}$, and $u \in U_s$. Then we have*

$$\Delta_0^k \mathcal{F}(u) = \tilde{F}(u)\big(\tilde{G}(u)(\Delta_0^k u)\big) + F(u)\big(R_a(u)\big) + R_b(u), \tag{4.7}$$

where the abbreviations

$$\tilde{F}(u)f := F(u)f + F_0(u)f, \quad \tilde{G}(u)v := \gamma\Delta(u)(P(u)v) + G_1(u)v$$

have been used. Here $f \mapsto F_0(u)f$ and $v \mapsto G_1(u)v$ are operators of order zero and one, respectively,

$$F_0(u) \in \mathcal{L}\big(H^t(S), H^t(S, \mathbb{R}^m)\big), \quad G_1(u) \in \mathcal{L}\big(H^t(S, \mathbb{R}^m), H^{t-1}(S)\big), \tag{4.8}$$

$t \in [-1, s-1]$ and $t \in [-2, s-3]$, respectively, and the remainder terms R_a, R_b satisfy

$$\|R_a(u)\|_0 \le C\|u\|_{s-1}, \tag{4.9}$$

$$\|R_b(u)\|_0 \le C\big(\|\tilde{G}(u)(\Delta_0^k u)\|_{-1} + \|\mathcal{F}(u)\|_{s_0-3}\|u\|_s + \|u\|_{s-1}\big). \tag{4.10}$$

The constants are independent of u and the operator norms of $F_0(u)$ and $G_1(u)$ are bounded independently of u as long as u varies in a set $\tilde{U}_s$.

Proof. The operator $F(u)$ vanishes on constants and, by elliptic regularity,

$$\|f\|_{s_0-2} \le C\|F(u)f\|_{s_0-3}, \qquad u \in \tilde{U}_s \tag{4.11}$$

if f has zero mean value over S. We define

$$\tilde{\mathcal{G}}(u) := \mathcal{G}(u) - \frac{1}{|S|}\int_S \mathcal{G}(u)\, dS. \tag{4.12}$$

Using Proposition 3.5 (ii), we write $\Delta_0^k\mathcal{F}(u) = \Delta_0^k F(u)\tilde{\mathcal{G}}(u)$ in the form

$$\begin{aligned}&F(u)\big(\Delta_0^k\tilde{\mathcal{G}}(u)\big) + F'(u)\big\{\Delta_0^k u\big\}\tilde{\mathcal{G}}(u) + 2\sum_{j=0}^{k-1} F'(u)\big\{D_i u\big\}\Delta_0^j D_i\Delta_0^{k-1-j}\tilde{\mathcal{G}}(u) + R_1(u)\\ &= F(u)\big(\Delta_0^k\mathcal{G}(u)\big) + F'(u)\big\{\Delta_0^k u\big\}\tilde{\mathcal{G}}(u) + 2kF'(u)\big\{D_i u\big\}D_i\Delta_0^{k-1}\mathcal{G}(u)\\ &\quad + R_1(u) + R_2(u).\end{aligned}$$

According to this proposition and (4.11), $R_1(u)$ allows the estimate

$$\|R_1(u)\|_0 \le C\big(\|u\|_s\|\tilde{\mathcal{G}}(u)\|_{s_0-2} + \|\tilde{\mathcal{G}}(u)\|_{s-1}\big) \le C\big(\|u\|_s\|\mathcal{F}(u)\|_{s_0-3} + \|\mathcal{G}(u)\|_{s-1}\big).$$

For $R_2(u)$ we find from Lemma 3.1 (with $t = 1$) that

$$\begin{aligned}\|R_2(u)\|_0 &\le 2\sum_{j=0}^{k-1}\big\|F'(u)\big\{D_i u, [\Delta_0^j, D_i]\Delta_0^{k-1-j}\mathcal{G}(u)\big\}\big\|_0\\ &\le C\sum_{i,j}\big\|[\Delta_0^j, D_i]\Delta_0^{k-1-j}\mathcal{G}(u)\big\|_1 \le C\|\mathcal{G}(u)\|_{s-1}.\end{aligned}$$

Further, by Lemma 3.6 we have

$$F'(u)\big\{\Delta_0^k u\big\}\tilde{\mathcal{G}}(u) = -F(u)\big(\Delta_0^k u\cdot\mathcal{F}(u)\big) + R_3(u)$$

with

$$\|R_3(u)\|_0 \le C\|\Delta_0^k u\|_0\|\tilde{\mathcal{G}}(u)\|_{s_0-2} \le C\|u\|_s\|\mathcal{F}(u)\|_{s_0-3}.$$

Defining $F_0(u)$ by

$$F_0(u)v := 2kF'(u)\big\{D_i u\big\}D_i\Delta_0^+ v,$$

we get

$$\Delta_0^k\mathcal{F}(u) = \big(F(u) + F_0(u)\big)\big(\Delta_0^k\mathcal{G}(u) - \Delta_0^k u\cdot\mathcal{F}(u)\big) + R_4(u)$$

with a remainder term

$$R_4(u) = F_0(u)\big(\Delta_0^k u\cdot\mathcal{F}(u)\big) + R_1(u) + R_2(u) + R_3(u) - 2kF'(u)\{D_i u\}D_i Q_0\Delta_0^{k-1}\widetilde{\mathcal{G}}(u).$$

Hence, using

$$\big\|F_0(u)\big(\Delta_0^k u\cdot\mathcal{F}(u)\big)\big\|_0 \le C\|u\|_s\|\mathcal{F}(u)\|_{s_0-3}$$

and the above estimates for R_1, R_2, R_3, we obtain

$$\|R_4(u)\|_0 \le C\big(\|\mathcal{G}(u)\|_{s-1} + \|u\|_s\|\mathcal{F}(u)\|_{s_0-3}\big). \tag{4.13}$$

Recall that $\mathcal{G}(u)$ depends linearly on γ. Slightly abusing notation, we write $\mathcal{G}(u)\gamma$ etc. in the remaining part of this proof (see (6.6)). Note that in analogy to (3.10), we get, for sufficiently smooth u,

$$D^\alpha\mathcal{G}(u)\gamma = \sum c_{\beta_1,\dots,\beta_{k+1}}\mathcal{G}^{(k)}(u)\{D^{\beta_1}u,\dots,D^{\beta_k}u\}D^{\beta_{k+1}}\gamma$$

with (3.11) holding for k and the multi-indices $\beta_1, \dots, \beta_{k+1}$. Applying this differentiation rule, we get

$$\Delta_0^k \mathcal{G}(u)\gamma = \mathcal{G}'(u)\big\{\Delta_0^k u\big\}\gamma + \mathcal{G}_1(u)\gamma + R_5(u),$$

where $\mathcal{G}_1(u)$ contains all terms where derivatives of u of order $s-1$ and $s-2$ occur. Consequently, it is a sum of terms of the forms

$$\mathcal{G}'(u)\big\{\Delta_0^j D_i \Delta_0^{k-1-j} u\big\} D_i\gamma, \quad \mathcal{G}''(u)\big\{D_i u, \Delta_0^j D_i \Delta_0^{k-1-j} u\big\}\gamma,$$

with $j \in \{0, \dots, k-1\}$, and

$$\mathcal{G}'(u)\{z\}D_iD_l\gamma, \quad \mathcal{G}''(u)\{D_iu, z\}D_l\gamma, \quad \mathcal{G}''(u)\{D_iD_lu, z\}\gamma, \quad \mathcal{G}'''(u)\{D_iu, D_lu, z\}\gamma,$$

with $z := \Delta_0^j D_i \Delta_0^\mu D_l \Delta_0^{k-2-j-\mu} u$ and $j, \mu \in \{0, \dots, k-2\}$, $j + \mu \le k-2$. Using the estimates (3.3) and the assumption $s \ge s_0 > (m+7)/2$, one obtains from analogous arguments as in the proof of Proposition 3.5 (ii) that

$$\|R_5(u)\|_0 \le C\|u\|_{s-1}. \tag{4.14}$$

Writing in the above terms,

$$\Delta_0^{k-1-j} u \approx (\Delta_0^+)^{j+1} \Delta_0^k u, \quad \Delta_0^{k-2-j-\mu} u \approx (\Delta_0^+)^{j+\mu+2} \Delta_0^k u \tag{4.15}$$

up to smoothing remainder terms, we get

$$\Delta_0^k \mathcal{G}(u)\gamma = \mathcal{G}'(u)\big\{\Delta_0^k u\big\}\gamma + \mathcal{G}_2(u)\{\Delta_0^k u\}\gamma + R_6(u) \tag{4.16}$$

with a first-order operator $v \mapsto \mathcal{G}_2(u)\{v\}\gamma$ and a remainder term $R_6(u)$ satisfying the estimate (4.14) again. Hence, using that the linearization of the mean curvature $H(u)$ has $\Delta(u)(P(u)v)$ as its main part, i.e.,

$$\mathcal{G}'(u)\{v\}\gamma = \gamma\Delta(u)P(u)v + \mathcal{G}_3(u)\{v\}\gamma \tag{4.17}$$

with a first-order operator $v \mapsto \mathcal{G}_3(u)\{v\}\gamma$, we get the representation (4.7) with

$$G_1(u)v := \mathcal{G}_2(u)\{v\}\gamma + \mathcal{G}_3(u)\{v\}\gamma - v \cdot \mathcal{F}(u)$$

and with the remainder terms

$$R_a(u) := R_6(u), \quad R_b(u) := R_4(u) + F_0(u)\big(R_6(u)\big).$$

Now the estimate (4.9) of R_a coincides with (4.14), whereas the estimate (4.10) of R_b follows from

$$\begin{aligned}\|R_b(u)\|_0 &\le C\big(\|R_4(u)\|_0 + \|R_6(u)\|_0\big)\\ &\le C\big(\|\mathcal{G}(u)\|_{s-1} + \|u\|_s \|\mathcal{F}(u)\|_{s_0-3} + \|u\|_{s-1}\big)\end{aligned}$$

by (4.13), (4.14) and

$$\begin{aligned}\|\mathcal{G}(u)\|_{s-1} &\le C\big(\|\Delta_0^k \mathcal{G}(u)\|_{-1} + \|\mathcal{G}(u)\|_0\big)\\ &= C\big(\|\tilde{G}(u)(\Delta_0^k u) + R_6(u)\|_{-1} + \|\mathcal{G}(u)\|_0\big)\\ &\le C\big(\|\tilde{G}(u)(\Delta_0^k u)\|_{-1} + \|u\|_{s-1}\big).\end{aligned}$$

The statements (4.8) are consequences of Lemma 3.4 and (3.4). This becomes clear if G_1 is written out explicitly in terms of differential operators and Fréchet derivatives of A. □

Now fix $s \geq s_0$ with $s = 2k$, $k \in \mathbb{N}$. Taking F_0 and G_1 as in Lemma 4.1 we set for $u \in U_s$ that

$$\tilde{\mathcal{F}}(u)v := \big(F(u) + F_0(u)\big)\tilde{G}(u)v.$$

We are now ready to define the variable inner product for which we will prove the semiboundedness of $\mathcal{F}$. For $u \in U_s$ let $M(u)$ be the operator defined by

$$M(u)v := M_0(u)v + \tilde{M}_0(u)v, \quad \tilde{M}_0(u)v = M_1(u)P(u)v + N(u)M_2(u)v. \tag{4.18}$$

Here, the main part M_0 of M is given by

$$M_0(u)v := v - \Lambda(u)A(u)P(u)v \tag{4.19}$$

with A from (2.9) (cf. [10]), whereas the lower order terms are given by

$$M_1(u)w := -M_0(u)F_0(u)A(u)w, \tag{4.20}$$

$$M_2(u)v := \Delta(u)^+\big(\gamma^{-1}G_1(u)v\big). \tag{4.21}$$

From (3.5) and (4.8) we get

$$\begin{aligned} M_0(u) &\in \mathcal{L}\big(H^t(S,\mathbb{R}^m), H^t(S,\mathbb{R}^m)\big), \quad -4 \leq t \leq s-2,\\ M_1(u) &\in \mathcal{L}\big(H^t(S), H^{t+1}(S,\mathbb{R}^m)\big), \quad -2 \leq t \leq s-3,\\ M_2(u) &\in \mathcal{L}\big(H^t(S,\mathbb{R}^m), H^{t+1}(S)\big), \quad -2 \leq t \leq s-3. \end{aligned}$$

The operators depend smoothly on $u \in U_s$ and have uniformly bounded norms as u varies in $\widetilde{U}_s$.

Because of $P(u)\Lambda(u) = 0$, the operator $M_0(u)$ constitutes an isomorphism in $L^2(S,\mathbb{R}^m)$ with inverse

$$M_0(u)^{-1}v = v + \Lambda(u)A(u)P(u)v. \tag{4.22}$$

In particular, we have

$$c\|v\|_0 \leq \|M_0(u)v\|_0 \leq C\|v\|_0, \tag{4.23}$$

$$c\|v\|_0 - C\|v\|_{-1} \leq \|M(u)v\|_0 \leq C\|v\|_0 \tag{4.24}$$

with suitable positive constants c, C independent of $u \in \tilde{U}_s$ and $v \in L^2$.

The main motivation for our choice of M_0 is the easily checked identity

$$\big(M_0(u)F(u)f, M_0(u)v\big)_0 = \big(B(u)f, P(u)v\big)_0, \tag{4.25}$$

where $f \mapsto B(u)f := P(u)(F(u)f)$ is the Dirichlet–Neumann operator. Note that on the left we have an inner product for a vector-valued function while there is an inner product for scalar functions on the right; this will enable us to make use of the coercivity in the normal direction. The choice of M_1 and M_2 results from the need to control certain lower order terms that will appear in our estimates, in particular, (4.34).

For the sake of completeness, we gather some properties of B which we will need in what follows. We will use the commutator notation $[Q_1, Q_2] := Q_1Q_2 - Q_2Q_1$ for operators, in particular, if f is a function we will write $[f, Q]w := fQw - Q(fw)$. Note that property (b) is in fact the L^2-symmetry of $B(u)$ with respect to the measure induced from Γ_u.

LEMMA 4.2. *Assume $u \in \tilde{U}_s$, $f \in C^1(S)$, $w \in H^2(S)$, $v \in H^1(S)$. Then:*

(i) *If $f \geq \alpha > 0$, then*

$$\int_S fwB(u)w\,dS \geq c\|w\|_{1/2}^2 - C\|w\|_0^2$$

with $c = c(\alpha) > 0$, $C = C(\|f\|_{C^1})$. Moreover,

(ii)

$$\int_S w\,B(u)v\,dS = \int_S \omega(u)v\,B(u)(\omega(u)^{-1}w)\,dS,$$

(iii)

$$\|B(u)w\|_{-2} \leq C\|w\|_{-1},$$

(iv)

$$\|[f, B(u)]w\|_0 \leq C\|w\|_0$$

with $C = C(\|f\|_{C^1})$,

(v)

$$\|[\Lambda_i(u), B(u)]w\|_0 \leq C\|w\|_1.$$

All constants are independent of $u \in \tilde{U}_s$.

Proof. (i) As in the proof of Lemma 3.4 we extend u to a diffeomorphism from E to Ω_u and denote the coefficients of the corresponding induced metric by g^{ij} and the corresponding volume element by $\sqrt{g}$. Let ν denote the outer unit normal on S and let $\mathcal{E}$ denote the harmonic extension from S into E. Let ϕ be the solution of the Dirichlet problem

$$L(u)\phi := \partial_i(\sqrt{g}g^{ij}\partial_j\phi) = 0 \text{ in } E, \quad \phi|_S = w.$$

Then

$$B(u)w = \omega(u)^{-1}\nu_i\sqrt{g}g^{ij}\partial_j\phi,$$

and by integration by parts

$$\begin{aligned}
&\int_S fw\,B(u)w\,dS \\
&= \int_S f\phi\omega(u)^{-1}\nu_i\sqrt{g}g^{ij}\partial_j\phi\,dS = \int_E \partial_i(\mathcal{E}(f\omega(u)^{-1})\phi\sqrt{g}g^{ij}\partial_j\phi)\,dx \\
&= \int_E \mathcal{E}(f\omega(u)^{-1})\sqrt{g}g^{ij}\partial_i\phi\partial_j\phi\,dx + \int_E \partial_i(\mathcal{E}(f\omega(u)^{-1})\sqrt{g}g^{ij})\phi\partial_j\phi\,dx \\
&\geq c\|\phi\|_1^{E^2} - C\|\phi\|_1^E\|\phi\|_0^E \geq c\|\phi\|_1^{E^2} - C\|\phi\|_0^{E^2} \geq c\|w\|_{1/2}^2 - C\|w\|_0^2.
\end{aligned}$$

The uniformity of these estimates with respect to $u \in \tilde{U}_s$ follows by a compactness argument as in [10].

(ii) The assertion follows from transforming the integral to Γ_u, applying Green's formula and transforming back.

(iii) Using (ii), the assertion follows from a standard duality argument and the fact that $B(u) \in \mathcal{L}(H^2(S), H^1(S))$.

(iv) Maintaining the notation from the proof of (i), we have

$$[f, B(u)]w = \omega(u)^{-1}\nu_i\sqrt{g}g^{ij}(f\partial_j\phi - \partial_j\psi),$$

where ψ satisfies

$$L(u)\psi = 0 \text{ in } E, \quad \psi|_S = fw = f\phi|_S.$$

Therefore, by estimates parallel to Lemma 4.3 in [10],

$$\begin{aligned}\|[f, B(u)]w\|_{1/2} &\le \|\omega(u)^{-1}\nu_i\sqrt{g}g^{ij}\partial_j(\phi\mathcal{E}f - \psi)\|_{1/2} + C\|\phi\|_{1/2}\\ &\le C\left(\|L(u)(\phi\mathcal{E}f)\|_0^E + \|\phi\|_{1/2}\right) \le C\left(\|\phi\|_1^E + \|\phi\|_{1/2}\right) \le C\|w\|_{1/2}.\end{aligned}$$

As both multiplication by f and $B(u)$ are symmetric with respect to the L^2-inner product induced from Γ_u, we get by duality that

$$\|[f, B(u)]w\|_{-1/2} \le C\|w\|_{-1/2},$$

and the result follows by interpolation.

(v) We have, by the chain rule for the operators D_k,

$$\begin{aligned}[\Lambda_i(u), B(u)] &= [\alpha_k^i(u)D_k, B(u)] = [\alpha_k^i(u), B(u)]D_k + \alpha_k^i(u)[D_k, B(u)]\\ &= [\alpha_k^i(u), B(u)]D_k + \alpha_k^i(u)B'(u)\{D_ku\}.\end{aligned}$$

The result now follows from (ii) and the estimate

$$\|B'(u)\{D_ku\}w\|_0 \le C\|w\|_1,$$

which is a simple consequence of (3.1). □

The next lemma will be crucial in the proof of the main estimate as it will provide coercivity for the normal component.

LEMMA 4.3. *There are positive constants c, C such that*

$$(\Delta(u)^+(\gamma^{-1}w), B(u)w)_0 \le -c\|w\|_{-1/2}^2 + C\|w\|_{-2}^2$$

for all $u \in \tilde{U}_s$, $w \in H^1(S)$.

Proof. Set $z := \Delta(u)^+(\gamma^{-1}w)$. Then $w = \gamma\Delta(u)z + \gamma Q(u)(\gamma^{-1}z)$; see (4.6). By Lemma 4.2 (ii),

$$\begin{aligned}I &:= \left(\Delta(u)^+(\gamma^{-1}w), B(u)w\right)_0 \le \left(z, B(u)\gamma\Delta(u)z\right)_0 + \|z\|_1\|B(u)(\gamma Q(u)(\gamma^{-1}z))\|_{-1}\\ &\le \left(\omega(u)\gamma\Delta(u)z, B(u)(\omega(u)^{-1}z)\right)_0 + C\|w\|_{-1}^2.\end{aligned}$$

Setting $\tilde{z} := \omega(u)^{-1}z$, $\tilde{\gamma} := \omega(u)^2\gamma$ and using (4.5) we get

$$\begin{aligned}I &\le \left(\tilde{\gamma}\Delta(u)\tilde{z}, B(u)\tilde{z}\right)_0 + \left(\omega(u)\gamma[\omega(u), \Delta(u)]\tilde{z}, B(u)\tilde{z}\right)_0 + C\|w\|_{-1}^2\\ &\le \left(\tilde{\gamma}\Lambda_i(u)\Lambda_i(u)\tilde{z}, B(u)\tilde{z}\right)_0 + C\|z\|_1^2 + C\|w\|_{-1}^2.\end{aligned}$$

By integration by parts, one obtains an estimate

$$\left|\int_S \Lambda_i(u) f\, dS\right| \le C \int_S |f|\, dS,$$

cf. [10, (5.5)]. This yields

$$\begin{aligned} I &\le -(\Lambda_i(u)\tilde z, \Lambda_i(u)\tilde\gamma B(u)\tilde z)_0 + C\|z\|_1^2 + C\|w\|_{-1}^2 \\ &\le -(\Lambda_i(u)\tilde z, \tilde\gamma\Lambda_i(u) B(u)\tilde z)_0 + C\|z\|_1 \sum_i \|[\Lambda_i(u),\gamma]B(u)\tilde z\|_0 + C\|w\|_{-1}^2 \\ &\le -(\Lambda_i(u)\tilde z, \tilde\gamma B(u)\Lambda_i(u)\tilde z)_0 + C\|z\|_1 \sum_i \|[B(u),\Lambda_i(u)]\tilde z\|_0 + C\|w\|_{-1}^2 \\ &\le -c\|\Lambda_i(u)\tilde z\|_{1/2}^2 + C\|z\|_1^2 + C\|w\|_{-1}^2 \\ &\le -c\|\tilde z\|_{3/2}^2 + C\|w\|_{-1}^2 \le -c\|w\|_{-1/2}^2 + C\|w\|_{-2}^2, \end{aligned}$$

where parts (i) and (v) of Lemma 4.2 have been used together with interpolation in the scale $H^t(S)$. □

In view of (4.23), (4.24) for every fixed $u \in U_s$, $s \ge s_0$, $s = 2k$, $k \in \mathbb{N}$, and λ sufficiently large (independent of $u \in \widetilde{U}_s$),

$$(v,w)_{s,u} := \lambda\big(M_0(u)v, M_0(u)w\big)_0 + \big(M(u)\Delta_0^k v, M(u)\Delta_0^k w\big)_0 \tag{4.26}$$

defines a scalar product on $H^s(S,\mathbb{R}^m)$ which is equivalent to the usual one.

The next two lemmas provide properties of the inner product $(\cdot,\cdot)_{s,u}$, which will be used when we apply the abstract existence result of Theorem 5.2 to our situation. They are parallel to Lemmas 5.3 and 5.4 in [10], therefore the proofs are omitted here. Note the uniformity of all estimates with respect to $u \in \tilde U_s$.

LEMMA 4.4. *Assume $s \ge s_0$.*

(i) *There exists a $C > 0$ such that for all $v \in H^{s+3}(S,\mathbb{R}^m)$, $w \in H^s(S,\mathbb{R})$, $u \in \tilde U_s$*

$$(v,w)_{s,u} \le C\|v\|_{s+3}\|w\|_{s-3}.$$

(ii) *There exist λ_0, $c_0 > 0$ such that for all $v \in H^{s+6}(S,\mathbb{R}^m)$, $\lambda \ge \lambda_0$*

$$\big(v, (-\Delta_0^3 + \lambda)v\big)_{s,u} \ge c_0\|v\|_{s+3}^2.$$

As an immediate consequence of Lemma 4.4 (i) we get the existence of a continuous bilinear form $\langle\cdot,\cdot\rangle_{s,u}$ on $H^{s+3}(S,\mathbb{R}^m) \times H^{s-3}(S,\mathbb{R}^m)$ compatible with $(\cdot,\cdot)_{s,u}$, i.e., there holds $\langle v,w\rangle_{s,u} = (v,w)_{s,u}$ for all $v,w \in H^{s+3}(S,\mathbb{R}^m)$. Further, we put for $\varepsilon \in (0,1]$

$$\langle v,w\rangle_{s,u}^{\varepsilon} := \langle v,w\rangle_{s_0,u} + \varepsilon^2\langle v,w\rangle_{s,u}. \tag{4.27}$$

LEMMA 4.5. *We assume as above that $s \ge s_0$, $\varepsilon \in (0,1]$.*

(i) *For fixed $u \in U_s$, the mapping $\langle\cdot,\cdot\rangle_{s,u}^{\varepsilon} : H^{s+3}(S,\mathbb{R}^m) \times H^{s-3}(S,\mathbb{R}^m) \to \mathbb{R}$ constitutes a continuous, nondegenerate bilinear form whose restriction to $H^{s+3}(S,\mathbb{R}^m) \times H^{s+3}(S,\mathbb{R}^m)$ is symmetric.*

(ii) *With constants $C > 0$ independent of ε, u, v, w, one has for $u, w \in \tilde U_s$ and $v \in H^{s+3}(S,\mathbb{R}^m)$:*

$$C^{-1}\big(\|v\|_{s_0}^2 + \varepsilon^2\|v\|_s^2\big) \le \langle v,v\rangle_{s,u}^{\varepsilon} \le C\big(\|v\|_{s_0}^2 + \varepsilon^2\|v\|_s^2\big), \tag{4.28}$$

$$\langle v,v\rangle_{s,u}^{\varepsilon} \le \langle v,v\rangle_{s,w}^{\varepsilon}\big(1 + C\|u-w\|_{s_0-3}\big). \tag{4.29}$$

(iii) *Weak convergences* $u_n \rightharpoonup u$ *in* H^s, $w_n \rightharpoonup w$ *in* H^{s-3} *imply*

$$\langle v, w_n\rangle^{\varepsilon}_{s,u_n} \to \langle v, w\rangle^{\varepsilon}_{s,u}$$

for all $v \in H^{s+3}$.

Now we are prepared to formulate and prove the following a priori estimates for $\mathcal{F}$ w.r.t. the bilinear forms $(\cdot,\cdot)_{s,u}$.

PROPOSITION 4.6. *Let* $s \geq s_0$ *be an even integer. Then*

$$\big(u, \mathcal{F}(u)\big)_{s,u} \leq C\|u\|_s^2 \tag{4.30}$$

for all $u \in \widetilde{U}_s \cap C^\infty(S, \mathbb{R}^m)$ *with a constant* C *independent of* u.

Proof. For later use, we prove the estimate in the following stronger form: For every $\varepsilon > 0$ there exists a constant $C(\varepsilon)$ such that

$$\big(u, \mathcal{F}(u)\big)_{s,u} \leq C\|u\|_s\big((\varepsilon + \|\mathcal{F}(u)\|_{s_0-3})\|u\|_s + C(\varepsilon)\|u\|_{s-1}\big). \tag{4.31}$$

Setting $v := \Delta_0^k u$ and using the notations of Lemma 4.1 we have

$$\big(M(u)\Delta_0^k u, M(u)\Delta_0^k \mathcal{F}(u)\big)_0 = I(u)v^2 + J(u) + \big(M(u)v, M(u)R_b(u)\big)_0$$

with

$$I(u)v^2 := \big(M(u)v, M(u)\tilde{\mathcal{F}}(u)v\big)_0 \quad J(u) := \big(M(u)v, M(u)F(u)R_a(u)\big)_0.$$

From (4.10) we obtain

$$\big(M(u)v, M(u)R_b(u)\big)_0 \leq C\|u\|_s\big(\|\tilde{G}(u)v\|_{-1} + \|\mathcal{F}(u)\|_{s_0-3}\|u\|_s + \|u\|_{s-1}\big).$$

To estimate $J(u)$, we write this term as $J_1(u) + \cdots + J_4(u)$ with

$$J_1(u) = \big(M_0(u)v, M_0(u)F(u)R_a(u)\big)_0, \quad J_2(u) = \big(\tilde{M}_0(u)v, M_0(u)F(u)R_a(u)\big)_0,$$
$$J_3(u) = \big(M_0(u)v, \tilde{M}_0(u)F(u)R_a(u)\big)_0, \quad J_4(u) = \big(\tilde{M}_0(u)v, \tilde{M}_0(u)F(u)R_a(u)\big)_0.$$

Using (4.25) and (4.9), we obtain for J_1

$$J_1(u) = \big(B(u)R_a(u), P(u)v\big)_0 \leq C\|R_a(u)\|_0\|P(u)v\|_1 \leq C\|u\|_{s-1}\|P(u)v\|_1.$$

As

$$P(u)v = \Delta(u)^+\big(\gamma^{-1}(\tilde{G}(u)v - G_1(u)v)\big) - Q(u)(P(u)v) \tag{4.32}$$

we see from (4.8) that

$$\|P(u)v\|_1 \leq C\big(\|\tilde{G}(u)v\|_{-1} + \|v\|_0\big), \tag{4.33}$$

and consequently

$$J_1(u) \leq C\|u\|_{s-1}\big(\|\tilde{G}(u)v\|_{-1} + \|u\|_s\big).$$

For J_2 we have

$$J_2(u) \leq C\|\tilde{M}_0(u)v\|_1\|M_0(u)F(u)R_a(u)\|_{-1} \leq C\|v\|_0\|R_a(u)\|_0 \leq C\|u\|_s\|u\|_{s-1},$$

and the same estimates are valid for J_3, J_4, thus

$$J(u) \le C\|u\|_{s-1}\big(\|\tilde G(u)v\|_{-1} + \|u\|_s\big).$$

Further, we decompose I according to $I(u)v^2 = I_1(u)v^2 + \cdots + I_4(u)v^2$ in the same manner as J, i.e.,

$$\begin{aligned} I_1(u)v^2 &= \big(M_0(u)v, M_0(u)\tilde{\mathcal{F}}(u)v\big)_0, \quad I_2(u)v^2 = \big(\tilde M_0(u)v, M_0(u)\tilde{\mathcal{F}}(u)v\big)_0,\\ I_3(u)v^2 &= \big(M_0(u)v, \tilde M_0(u)\tilde{\mathcal{F}}(u)v\big)_0, \quad I_4(u)v^2 = \big(\tilde M_0(u)v, \tilde M_0(u)\tilde{\mathcal{F}}(u)v\big)_0 \end{aligned}$$

and each term is estimated separately. We start with the leading order term $I_1(u)v^2$. Using (4.25) again, it can be written as

$$\begin{aligned} I_1(u)v^2 &= \big(M_0(u)v, M_0(u)F(u)\tilde G(u)v\big)_0 + \big(M_0(u)v, M_0(u)F_0(u)\tilde G(u)v\big)_0\\ &= \big(P(u)v, B(u)\tilde G(u)v\big)_0 + \big(M_0(u)v, M_0(u)F_0(u)\tilde G(u)v\big)_0. \end{aligned}$$

In the first summand we insert (4.32) and use

$$\big|\big(Q(u)P(u)v, B(u)\tilde G(u)v\big)_0\big| \le C\|v\|_0\|\tilde G(u)v\|_{-1},$$

and by Lemma 4.3

$$\big(\Delta(u)^+(\gamma^{-1}\tilde G(u)v), B(u)\tilde G(u)v\big)_0 \le -c_0\|\tilde G(u)v\|^2_{-1/2} + C\|\tilde G(u)v\|^2_{-1}.$$

Remembering the definitions (4.20), (4.21) of M_1 and M_2, we have

$$\begin{aligned} \big(M_0(u)v, M_0(u)F_0(u)\tilde G(u)v\big)_0 &= -\big(M_0(u)v, M_1(u)B(u)\tilde G(u)v\big)_0,\\ \big(\Delta(u)^+(\gamma^{-1}G_1(u)v), B(u)\tilde G(u)v\big)_0 &= \big(M_2(u)v, B(u)\tilde G(u)v\big)_0, \end{aligned}$$

and consequently we arrive at

$$\begin{aligned} I_1(u)^2v \le &-\big(M_2(u)v, B(u)\tilde G(u)v\big)_0 - \big(M_0(u)v, M_1(u)B(u)\tilde G(u)v\big)_0\\ &- c_0\|\tilde G(u)v\|^2_{-1/2} + C\big(\|v\|_0 + \|\tilde G(u)v\|_{-1}\big)\|\tilde G(u)v\|_{-1}. \end{aligned} \tag{4.34}$$

This coercive estimate of $I_1(u)v^2$ with respect to $\tilde G(u)v$ is the crucial "leading order estimate" here and will be used below to control the lower order terms.

From Lemma 4.2 (iii) we get $F \in \mathcal{L}(H^{-1}(S), H^{-2}(S,\mathbb{R}^m))$ and therefore for I_4 we have the estimate

$$\begin{aligned} |I_4(u)v^2| &\le C\|\tilde M_0(u)v\|_1\|\tilde M_0(u)\tilde{\mathcal{F}}(u)v\|_{-1}\\ &\le C\|v\|_0\|(F(u)+F_0(u))\tilde G(u)v\|_{-2} \le C\|v\|_0\|\tilde G(u)v\|_{-1}, \end{aligned} \tag{4.35}$$

where (4.8) has been applied again. Further, concerning I_3 we have

$$I_3(u)v^2 = \big(M_0(u)v, \tilde M_0F(u)\tilde G(u)v\big)_0 + \big(M_0(u)v, \tilde M_0F_0(u)\tilde G(u)v\big)_0,$$

where the last summand allows the estimate

$$\big|\big(M_0(u)v, \tilde M_0(u)F_0(u)\tilde G(u)v\big)_0\big| \le C\|v\|_0\|\|\tilde G(u)v\|_{-1}.$$

Remembering $\tilde M_0(u) = M_1(u)P(u) + N(u)M_2(u)$, the first summand is written

$$\begin{aligned} &\big(M_0(u)v, \tilde M_0(u)F(u)\tilde G(u)v\big)_0\\ &\qquad = \big(M_0(u)v, M_1(u)B(u)\tilde G(u)v\big)_0 + \big(P(u)v, M_2(u)F(u)\tilde G(u)v\big)_0. \end{aligned}$$

Using (4.33) we get

$$\begin{aligned}\big|\big(P(u)v, M_2(u)F(u)\tilde G(u)v\big)_0\big| &\le C\|P(u)v\|_1\|\tilde G(u)v\|_{-1}\\ &\le C\big(\|v\|_0+\|\tilde G(u)v\|_{-1}\big)\|\tilde G(u)v\|_{-1},\end{aligned}$$

and consequently

$$I_3(u)v^2 \le \big(M_0(u)v, M_1(u)B(u)\tilde G(u)v\big)_0 + C\big(\|v\|_0+\|\tilde G(u)v\|_{-1}\big)\|\tilde G(u)v\|_{-1}. \tag{4.36}$$

Arguing along the same lines for I_2 we obtain

$$I_2(u)v^2 = \big(\tilde M_0(u)v, M_0(u)F(u)\tilde G(u)v\big)_0 + \big(\tilde M_0(u)v, M_0(u)F_0(u)\tilde G(u)v\big)_0,$$

where again

$$\big|\big(\tilde M_0(u)v, M_0F_0(u)\tilde G(u)v\big)_0\big| \le C\|v\|_0\|\tilde G(u)v\|_{-1}$$

and

$$\begin{aligned}&\big(\tilde M_0(u)v, M_0(u)F(u)\tilde G(u)v\big)_0\\ &\qquad = \big(M_2(u)v, B(u)\tilde G(u)v\big)_0 + \big(M_1(u)P(u)v, M_0(u)F(u)\tilde G(u)v\big)_0\end{aligned}$$

with

$$\begin{aligned}&\big|\big(M_1(u)P(u)v, M_0(u)F(u)\tilde G(u)v\big)_0\big|\\ &\qquad\le \|M_1(u)P(u)v\|_2\|M_0(u)F(u)\tilde G(u)v\|_{-2} \le C\|P(u)v\|_1\|\tilde G(u)v\|_{-1}\\ &\qquad\le C\big(\|v\|_0+\|\tilde G(u)v\|_{-1}\big)\|\tilde G(u)v\|_{-1}.\end{aligned}$$

Thus we have

$$I_2(u)v^2 \le \big(M_2(u)v, B(u)\tilde G(u)v\big)_0 + C\big(\|v\|_0+\|\tilde G(u)v\|_{-1}\big)\|\tilde G(u)v\|_{-1}. \tag{4.37}$$

Summarizing, we get

$$\begin{aligned}(u,\mathcal F(u))_{s,u} \le -c_1\|\tilde G(u)v\|^2_{-1/2} + C_1\big(&\|\tilde G(u)v\|^2_{-1} + \|u\|_s(\|\tilde G(u)v\|_{-1}\\ &+\|\mathcal F(u)\|_{s_0-3}\|u\|_s + \|u\|_{s-1})\big)\end{aligned}$$

and, estimating further,

$$\begin{aligned}\|u\|_s\|\tilde G(u)v\|_{-1} &\le \frac{\varepsilon}{C_1}\|u\|^2_s + C_2(\varepsilon)\|\tilde G(u)v\|^2_{-1},\\ \|\tilde G(u)v\|^2_{-1} &\le \frac{c_1}{C_1(1+C_2(\varepsilon))}\|\tilde G(u)v\|^2_{-1/2} + C(\varepsilon)\|\tilde G(u)v\|^2_{-3},\\ \|\tilde G(u)v\|^2_{-3} &\le C\|u\|^2_{s-1}\end{aligned}$$

we obtain (4.31). □

Remark 4.7. Reinspecting the estimates in the previous proofs it is straightforward to check that for fixed $s \ge s_0$ the occurring constants, in particular in (4.30), (4.31), are independent of γ as long as γ varies in some fixed set

$$\big\{\gamma \in C^\infty(S) \mid \gamma \ge \gamma^* > 0, \|\gamma\|_{s_1} \le M\big\} \tag{4.38}$$

with some sufficiently large $s_1 = s_1(s)$.

Using Lemma 3.6, we write for $u \in \tilde{U}_s$, $v \in H^s$, $s \geq s_0$

$$\mathcal{F}'(u)v = F(u)\big(\gamma\Delta(u)(P(u)v) + G_2(u)v\big) + R(u)v, \tag{4.39}$$

where $v \mapsto G_2(u)v := \mathcal{G}_3(u)v - \mathcal{F}(u) \cdot v$ and $v \mapsto R(u)v$ are operators of order one and zero, respectively. Note that $\mathcal{F}'(u)$ coincides with $\tilde{\mathcal{F}}(u)$ if G_1 is replaced by G_2 and F_0 is replaced by 0. Hence, by defining (cf. (4.18)–(4.21))

$$M_3(u) := \Delta(u)^+(\gamma^{-1}G_2(u)v), \quad \tilde{M}(u) := M_0(u) + M_3(u),$$

we find that $\tilde{M}$ has the same properties as M above, and we obtain, parallel to (4.31), the following estimate which will be used in the uniqueness proof.

LEMMA 4.8. *Let $s \geq s_0$. Then there exists a constant C such that for all $u \in \tilde{U}_s$, $v \in H^s$ we have*

$$\big(\tilde{M}(u)\mathcal{F}'(u)v, \tilde{M}(u)v\big)_0 \leq C\|v\|_0^2.$$

5. Proof of short time existence and uniqueness. We are now ready to prove our main results as announced in Theorems 2.1 and 2.2. As the existence proof is in some respects analogous to the corresponding considerations in [10], we restrict ourselves to an outline and refer to that paper for details.

Fix an even integer $s_0 > (m+7)/2$, $s_0 \geq 6$, and let $s \geq s_0$ be an even integer as well. Let $\tilde{U}_s$ be defined as above. The notations $C_w([0,T],X)$ and $C_w^1([0,T],X)$ will denote the spaces of weakly continuous and weakly continuously differentiable functions, respectively, with values in some subset X of a normed space.

At first an estimate which provides uniqueness and Lipschitz continuous dependence on the initial value in the L^2-norm is given.

PROPOSITION 5.1. *Let $u, v \in C_w([0,T],\tilde{U}_{s_0}) \cap C_w^1([0,T],H^{s_0-3}(S,\mathbb{R}^m))$ be two solutions of* (2.2). *Then*

$$\|v(t) - u(t)\|_0 \leq C\|v(0) - u(0)\|_0 \tag{5.1}$$

with C depending only on $\tilde{U}_{s_0}$ and on T.

Proof. Set $w(t) := v(t) - u(t)$ and note that

$$w(t) \in C([0,T],H^\sigma(S,\mathbb{R}^m)) \cap C^1([0,T],H^{\sigma-3}(S,\mathbb{R}^m))$$

for $\sigma < s_0$. In particular, the map

$$t \mapsto g(t) := \|\tilde{M}(u(t))w(t)\|_0^2$$

is differentiable and has the derivative

$$\begin{aligned} g'(t) = {} & 2\big(\tilde{M}'(u(t))\{u'(t)\}w(t), \tilde{M}(u(t))w(t)\big)_0 \\ & + 2\big(\tilde{M}(u(t))(\mathcal{F}(v(t)) - \mathcal{F}(u(t))), \tilde{M}(u(t))w(t)\big)_0. \end{aligned}$$

To estimate the first term we note that, parallel to the estimates in Lemma 3.1,

$$\begin{aligned} \|\tilde{M}'(u(t))\{u'(t)\}w(t)\|_0 &\leq C\|u'(t)\|_{s_0-3}\|w(t)\|_0 \\ &\leq C\|\mathcal{F}(u(t))\|_{s_0-3}\|w(t)\|_0 \leq C\|w(t)\|_0. \end{aligned}$$

The second term can be estimated by using

$$\mathcal{F}(v(t)) - \mathcal{F}(u(t)) = \mathcal{F}'(u(t))w(t) + R,$$

where

$$R := \int_0^1 \int_0^\tau \mathcal{F}''(\theta v(t) + (1-\theta)u(t))\{w(t), w(t)\}\, d\theta d\tau$$

allows an estimate

$$\|R\|_0 \le C\|w(t)\|_3 \|w(t)\|_{s_0-3} \le C\|w(t)\|_{s_0}\|w(t)\|_0 \le C\|w(t)\|_0,$$

where estimates on $\mathcal{F}''$ parallel to Lemma 3.1 and norm convexity have been used. Thus, by Lemma 4.8,

$$\begin{aligned} g'(t) &\le 2\big(\tilde{M}(u(t))\mathcal{F}'(u(t))w(t), \tilde{M}(u(t))w(t)\big)_0 + C\|w(t)\|_0^2 \\ &\le \|w(t)\|_0^2 \le Cg(t). \end{aligned}$$

Therefore, by Gronwall's inequality,

$$\|v(t) - u(t)\|_0^2 \le Cg(t) \le Cg(0) \le C\|v(0) - u(0)\|_0^2. \qquad \square$$

To prove existence, we will rely on an abstract existence theorem whose proof has been given in [10]. It generalizes an existence theorem concerning evolution equations with semibounded operators by Kato and Lai [11] to the case of variable bilinear forms. The setting is the following:

(H) Let $X \subseteq Y \subseteq Z$ be real and separable Banach spaces with dense and continuous embeddings and $\mathcal{U} \subseteq Y$ be open. For every $u \in \mathcal{U}$, let $\langle \cdot, \cdot \rangle_u : X \times Z \to \mathbb{R}$ be a continuous and nondegenerate bilinear form, such that with fixed constants $C \ge 1$, $M \ge 0$:

- (H1) $\langle v, w\rangle_u = \langle w, v\rangle_u$ for all $v, w \in X$;
- (H2) $C^{-1}\|v\|_Y^2 \le \langle v, v\rangle_u \le C\|v\|_Y^2$ for all $v \in X$, $u \in \mathcal{U}$;
- (H3) $\langle v, v\rangle_u \le \langle v, v\rangle_w\big(1 + M\|u - w\|_Z\big)$ for all $v \in X$, $u, w \in \mathcal{U}$;
- (H4) weak convergences $u_n \rightharpoonup u$ in Y, $u_n, u \in \mathcal{U}$, and $w_n \rightharpoonup w$ in Z imply $\langle v, w_n\rangle_{u_n} \to \langle v, w\rangle_u$ for all $v \in X$.

Assuming (H) holds, by the dense embedding $X \subseteq Y$ and

$$\big|\langle v, w\rangle_u\big|^2 \le \langle v, v\rangle_u \langle w, w\rangle_u \le C^2\|v\|_Y^2\|w\|_Y^2 \quad \text{for} \quad v, w \in X$$

there exists to each $u \in \mathcal{U}$ a scalar product $(\cdot, \cdot)_u$ on Y, which is compatible with $\langle \cdot, \cdot \rangle_u$, i.e., we have

$$(v, w)_u = \langle v, w\rangle_u \quad \text{for} \quad v \in X, w \in Y.$$

Moreover, for $u_n, u \in \mathcal{U}$, $u_n \rightharpoonup u$, $w_n \rightharpoonup w$ in Y implies

$$(v, w_n)_{u_n} \to (v, w)_u \quad \text{for all} \quad v \in X.$$

For the sake of brevity we put

$$\|v\|_u = (v, v)_u^{1/2}, \quad |||u||| = (u, u)_u^{1/2}\ .$$

THEOREM 5.2. *Assume* (H) *is satisfied with some ball*

$$\mathcal{U} = B := \big\{u \in Y \,\big|\, \|u\|_Y < R\big\}, \quad R > 0,$$

and $\mathcal{F} : B \to Z$ *is a weakly sequentially continuous mapping such that*

$$2\langle u, \mathcal{F}(u)\rangle_u + M\,\|\mathcal{F}(u)\,\|_Z |||u||| \le \beta\big(|||u|||^2\big) \ \text{ for all } \ u \in X \cap B \tag{5.2}$$

with a C^1*-function* $\beta : \mathbb{R}_+ \to \mathbb{R}_+ = [0,\infty)$. *Let* $u_0 \in B$,

$$|||u_0||| < r := R/(2C^3)^{1/2},$$

and $T > 0$ *such that the solution* ρ *of the scalar Cauchy problem*

$$d\rho/dt = \beta\big(\rho(t)\big), \quad \rho(0) = |||u_0|||^2 \tag{5.3}$$

exists on $[0,T]$ *and satisfies* $\rho(t) < r^2$ *there. Then the Cauchy problem*

$$u'(t) = \mathcal{F}(u(t)), \qquad u(0) = u_0 \tag{5.4}$$

possesses a solution $u \in C_w([0,T],\mathcal{U}) \cap C^1_w([0,T],Z)$ *for which additionally*

$$|||u(t)|||^2 \le \rho(t) \ \text{ for all } \ t \in [0,T],$$
$$u(t) \to u_0 \ \text{ in } \ Y \ \text{ for } \ t \to +0.$$

Proof of Theorems 2.1, 2.2 *(outline):* Instead of (2.2), (2.3) we consider the Cauchy problem

$$\left.\begin{array}{rcl} v'(t) &=& \hat{\mathcal{F}}(v) := \mathcal{F}(v + w_0), \\ v(0) &=& u_0 - w_0, \end{array}\right\} \tag{5.5}$$

where w_0 is smooth and near u_0.

To apply Theorem 5.2, we set for $\varepsilon \in (0,1]$

$$\begin{array}{ll} X := H^{s+3}(S,\mathbb{R}^m), & \|\cdot\|_X := \|\cdot\|_{s_0+3} + \varepsilon\|\cdot\|_{s+3}, \\ Y := H^{s}(S,\mathbb{R}^m), & \|\cdot\|_X := \|\cdot\|_{s_0} + \varepsilon\|\cdot\|_{s}, \\ Z := H^{s-3}(S,\mathbb{R}^m), & \|\cdot\|_X := \|\cdot\|_{s_0-3} + \varepsilon\|\cdot\|_{s-3}. \end{array}$$

For $u \in \tilde{U}_{s_0}$, let $\langle\cdot,\cdot\rangle^\varepsilon_u$ be the bilinear form compatible to the inner product on Y given by

$$(v,w)^\varepsilon_u := (v,w)_{s_0,u} + \varepsilon^2 (v,w)_{s,u}$$

with $(v,w)_{s_0,u}$, $(v,w)_{s,u}$ given by (4.26). Lemma 4.5 ensures that this bilinear form satisfies the assumptions (H), with constants independent of ε. Thus Theorem 5.2 yields existence of a solution

$$u \in C_w([0,T],\tilde{U}_s) \cap C^1_w([0,T],H^{s-3}(S,\mathbb{R}^m))$$

and an estimate

$$\|u(t)\|_s \le C(1 + \|u_0\|_s) \tag{5.6}$$

with C independent of u_0 and t.

The uniqueness result from Proposition 5.1 enables us to define an evolution operator T_t by setting $T_t u_0 := u(t)$. By a nonlinear interpolation result given in [2, Proposition A.1 and Remark A.2], the estimates (5.1) and (5.6) imply H^τ-continuity of T_t for $\tau \in [0, s)$, uniformly in $t \in [0, T]$. Approximation of the initial value u_0 by $u_0^n \in H^{s+1}$ and of the solution u by the corresponding solutions $u_0^n \in C([0,T], \tilde{U}_s) \cap C^1([0,T], H^{s-3}(S, \mathbb{R}^m))$ then yields

$$u \in C([0,T], \tilde{U}_s) \cap C^1([0,T], H^{s-3}(S, \mathbb{R}^m))$$

by uniform convergence. Finally, the existence time T can be shown to be independent of s by standard continuation arguments. For further details we refer to [10].

6. Nontrivial equilibria and long-time existence. In this section we will investigate the existence of equilibrium points and the long-time dynamic of the evolution problem (2.2). Our considerations are restricted to situations near trivial equilibria; i.e., we will assume that the domain is near a ball and γ is near a constant. Therefore in the following we specialize the reference domain to

$$E := \{x \in \mathbb{R}^m \mid |x| < 1\}, \quad S := \partial E = \{x \in \mathbb{R}^m \mid |x| = 1\}.$$

First we show that for any given domain Ω_u near a ball there exists a corresponding γ such that (u, γ) yields an equilibrium point for (2.2). Of course, the opposite question is more interesting for our evolution: Given a surface energy density, find a corresponding class of equilibrium shapes, and for given initial shape show global existence of the solution in time and convergence to some member of this class. Our proof of this is organized as follows. Using the refined semiboundedness estimate of Proposition 4.6 we obtain weak exponential growth of a solution in higher Sobolev norms provided the solution remains near the trivial equilibrium with respect to some lower norms. This enables us to show that the scalar function $f(t)$, which is defined by (6.11) below, controls the evolution. Then a simple discussion of the spectral properties of the evolution equation for f yields global existence.

We start by stating some simple integral identities needed later on; in particular, assertion (ii) of the following lemma together with volume conservation implies that the center of gravity remains fixed during evolutions under consideration.

LEMMA 6.1. (i) *We have*

$$\int_S \omega(u) N_i(u) u_j \, dS = \delta_{ij} |\Omega_u|, \tag{6.1}$$

where δ_{ij} denotes the Kronecker symbol, and

$$\int_S \omega(u) N(u) \big(\mathcal{G}(u)\gamma\big) \, dS = 0. \tag{6.2}$$

(ii) *For any solution $u = u(t)$ of (2.2) the vector of first moments*

$$M(t) := \int_{\Omega_{u(t)}} x \, dx \tag{6.3}$$

is independent of t.

Proof. (i) After retransformation onto Γ_u with outer normal n, (6.1) follows from

$$\int_{\Gamma_u} n_i x_j \, d\Gamma_u = \int_{\Omega_u} \partial_i x_j \, dx = \delta_{ij} |\Omega_u|,$$

whereas (6.2) reads

$$\int_{\Gamma_u} n(\gamma\kappa - \psi) \, d\Gamma_u = 0,$$

where ψ is harmonic in Ω_u with Neumann boundary condition $\partial_n \psi = \Delta_{\Gamma_u}\gamma$ on Γ_u. By Green's formula we get

$$\int_{\Gamma_u} n\psi \, d\Gamma_u = \int_{\Gamma_u} x \partial_n \psi \, d\Gamma_u;$$

hence, writing $n\kappa = \Delta_{\Gamma_u} x$ on Γ_u we obtain

$$\int_{\Gamma_u} n(\gamma\kappa - \psi) \, d\Gamma_u = \int_{\Gamma_u} \big(\gamma \Delta_{\Gamma_u} x - x \Delta_{\Gamma_u}\gamma\big) \, d\Gamma_u = 0 \tag{6.4}$$

by an integration by parts.
(ii) Consider the solution to (1.1) corresponding to u. We have, using Green's formula and (6.4),

$$\begin{aligned} \dot{M}(t) &= \int_{\Gamma(t)} x V_n \, d\Gamma(t) = \int_{\Gamma(t)} x \, \partial_n \phi \, d\Gamma(t) \\ &= \int_{\Gamma(t)} \partial_n x \, \phi \, d\Gamma(t) = \int_{\Gamma(t)} n(\gamma\kappa - \psi) \, d\Gamma(t) = 0, \end{aligned}$$

which is the assertion. ∎

Remark 6.2. Note that the presence of the correction term G is crucial not only for the generalized gradient flow property but also for the validity of Lemma 6.1.

In further considerations we assume $s \geq s_0$ with $s_0 \in \mathbb{N}$ fixed as in section 4, set

$$\tilde{U}_s := \big\{ u \in H^s(S, \mathbb{R}^m) \;\big|\; \|u - w_0\|_{s_0} \leq \delta_0 \big\}, \quad w_0(x) := x \;\text{ for }\; x \in S \tag{6.5}$$

and assume $\delta_0 > 0$ sufficiently small, whenever necessary. Moreover, to stress the dependency on γ, we consider now $\mathcal{F}(u)$ and $\mathcal{G}(u)$ as linear operators defined by

$$\mathcal{F}(u)v := F(u)\big(\mathcal{G}(u)v\big), \quad \mathcal{G}(u)v := -v\Lambda_i(u)\big(n_i(u) \circ u\big) - A(u)\Delta(u)v; \tag{6.6}$$

for $s \geq s_0$ und $2 \leq t \leq s$ the operators

$$\mathcal{G}(u) \in \mathcal{L}\big(H^t(S), H^{t-1}(S)\big), \quad \mathcal{F}(u) \in \mathcal{L}\big(H^t(S), H^{t-2}(S)\big) \tag{6.7}$$

depend smoothly on $u \in \tilde{U}_s$. For a given surface energy density $\gamma \in C^\infty(S)$ and $u_0 \in \tilde{U}_s$ the Cauchy problem (2.2), (2.3) reappears as

$$\dot{u} = \mathcal{F}(u)\gamma, \quad u(0) = u_0. \tag{6.8}$$

We call a function γ on S an *equilibrium surface energy density* for a given $u \in \tilde{U}_s$ if and only if

$$\mathcal{F}(u)\gamma = 0 \;\text{ on }\; S \quad \text{or equivalently} \quad \mathcal{G}(u)\gamma = \text{const. on } S. \tag{6.9}$$

The latter condition yields a nonlocal first-order elliptic equation for the determination of an equilibrium surface energy density γ. By straightforward perturbation arguments and expansion into spherical harmonics in case of $u = w_0$, the next lemma ensures the existence of a solution of this equation, uniquely determined up to a scaling factor and a linear combination of m functions.

LEMMA 6.3. *Assume $\delta_0 > 0$ sufficiently small. Then for any given $u \in \tilde{U}_s$, $s \geq s_0$ there exists a uniquely determined positive function $\gamma(u) \in H^{s-1}(S)$ such that*

$$\mathcal{G}(u)\gamma(u) = -1 \ \text{ on } \ S, \qquad \int_S N(u)\gamma(u)\,dS = 0.$$

Proof. By elliptic regularity it suffices to consider the case $s = s_0$. If $a \in \mathbb{R}^m$, $u \in \tilde{U}_s$, and $\gamma \in H^{s-1}(S)$ such that

$$\mathcal{G}(u)\gamma = -1 + a \cdot u \ \text{ on } \ S,$$

then (6.2) implies

$$\int_S \omega(u)N(u)(a \cdot u)\,dS = 0,$$

and further $a_1 = \cdots = a_m = 0$ by (6.1). Hence it suffices to show the invertibility of the operator

$$[(\gamma, a) \mapsto L(u)(\gamma, a)] \in \mathcal{L}\big(H^{s-1}(S) \times \mathbb{R}^m, H^{s-2}(S) \times \mathbb{R}^m\big)$$

given by

$$L(u)(\gamma, a) := \big(\mathcal{G}(u)\gamma - a \cdot u, c\big), \quad c := \int_S N(u)\gamma\,dS.$$

As $L(u)$ depends smoothly on $u \in \tilde{U}_s$ it remains to show the existence of

$$L(w_0)^{-1} \in \mathcal{L}\big(H^{s-2}(S) \times \mathbb{R}^m, H^{s-1}(S) \times \mathbb{R}^m\big). \tag{6.10}$$

In this case we have

$$\mathcal{G}(w_0)\gamma = -(m-1)\gamma - A_S\Delta_S\gamma,$$

where A_S and Δ_S denote the Neumann–Dirichlet operator and the Laplace–Beltrami operator on the unit sphere S, respectively. Hence, if we expand

$$\gamma = \sum_{l=0}^{\infty} \gamma_l, \quad \gamma_1 = b \cdot x,$$

where γ_l is a spherical harmonic of degree l and $b \in \mathbb{R}^m$, it follows from

$$\Delta_S\gamma_l = -l(l+m-2)\gamma_l, \qquad A_S\gamma_l = l^{-1}\gamma_l \quad (l > 0)$$

that

$$L(w_0)(\gamma, a) = \Big(-(m-1)\gamma_0 - a \cdot x + \sum_{l=2}^{\infty}(l-1)\gamma_l, \frac{|S|}{m}b\Big).$$

This immediately gives (6.10). Clearly, the equilibrium surface energy density belonging to w_0 is the constant function

$$\overline{\gamma} := \gamma(w_0) = L(w_0)^{-1}(-1,0) = -1/\kappa_0 \ \text{ on } \ S$$

with the curvature $\kappa_0 = -(m-1)$ on S. The proof is complete. ∎

In the following considerations, to derive a priori estimates independent of the existence interval $[0,T]$, let

$$u \in C^0\big([0,T],\tilde{U}_{s_0+4}\big) \cap C^1\big([0,T],H^{s_0+1}(S,\mathbb{R}^m)\big)$$

be any solution of (6.8). Thereby, without explicit mentioning, we always assume that

$$\|u_0\|_{s_0+4} = \|u(0)\|_{s_0+4} \le M$$

and γ is taken from some set of the form (4.38) with fixed positive constants γ^*, M and with a sufficiently large $s_1 \in \mathbb{N}$, such that, in view of Remark 4.7, the constants in the estimates of section 4 are independent of γ for $s \le s_0+4$. Further, we define (cf. (4.12))

$$f(t) := \tilde{\mathcal{G}}\big(u(t)\big)\gamma = \mathcal{G}\big(u(t)\big)\gamma - \frac{1}{|S|}\int_S \mathcal{G}\big(u(t)\big)\gamma\, dS. \tag{6.11}$$

Note that $F\big(u(t)\big)v \equiv 0$ for $v \equiv \text{const}$ implies

$$\dot{u}(t) = \mathcal{F}\big(u(t)\big)\gamma = F\big(u(t)\big)f(t). \tag{6.12}$$

Lemmas 6.4 and 6.5 show in which sense the evolution of u can be controlled by $f(t)$, $t \in [0,T]$ with constants independent of the existence time T. As the main step, we find from the improved semiboundedness estimate (4.31) that $\|u(t)\|$ has only slow exponential growth; more precisely, we have the following lemma.

LEMMA 6.4. *Let $\varepsilon > 0$, $a > 0$, $c > 0$ be given. There are constants $C = C(a,c,\varepsilon)$, $\delta = \delta(\varepsilon) > 0$ such that each of the assumptions*

(i) $\|f(t)\|_{s_0-2} \le \delta$, $t \in [0,T]$, *or*

(ii) $\|f(t)\|_{s_0-2} \le ce^{-at}$, $t \in [0,T]$,

implies

$$\|u(t)\|_{s_0+4} \le Ce^{\varepsilon t} \ \text{ for all } \ t \in [0,T]. \tag{6.13}$$

The constants C and δ may be chosen independently of u and T.

Proof. In view of Theorem 2.2 it is sufficient to prove (6.13) for any sufficiently regular solution $u = u(t)$ of (6.8). In particular, the mapping $t \mapsto g(t) := \big(u(t),u(t)\big)_{s,u(t)}$ with $s := s_0+4$ may be assumed to be differentiable. From Proposition 4.6, estimate (4.31) we get for any given $\varepsilon > 0$,

$$\big(u(t),\mathcal{F}(u(t))\gamma\big)_{s,u(t)} \le \Big(C\|\mathcal{F}(u(t))\gamma\|_{s_0-3} + \frac{\varepsilon}{2}\Big)\, g(t) + C(\varepsilon)$$

and, using $D(u)\{w\}v^2$ as abbreviation for the derivative of the mapping $u \mapsto (v,v)_{s,u}$,

$$\big|D(u(t))\{\mathcal{F}(u(t))\gamma\}u(t)^2\big| \le C\|\mathcal{F}(u(t))\gamma\|_{s_0-3}\|u(t)\|_s^2.$$

Consequently, by differentiating g, we have

$$\begin{aligned} g'(t) &= 2\big(u(t),\dot u(t)\big)_{s,u(t)} + D\big(u(t)\big)\big\{\dot u(t)\big\}u(t)^2 \\ &\le \Big(C\|\mathcal{F}(u(t))\gamma\|_{s_0-3} + \frac{\varepsilon}{2}\Big)\, g(t) + C(\varepsilon) \le \Big(C_1\|f(t)\|_{s_0-2} + \frac{\varepsilon}{2}\Big)\, g(t) + C(\varepsilon). \end{aligned}$$

Defining

$$\alpha(t) := \frac{\varepsilon}{2}t + C_1\int_0^t \|f(s)\|_{s_0-2}\,ds$$

and noting that under the assumptions (i) or (ii) we have

$$0 \le \alpha(t) \le \varepsilon t + C(a,c)$$

and we get from Gronwall's inequality that

$$\begin{aligned} \|u(t)\|_s^2 \le Cg(t) &\le Ce^{\alpha t}\left(g(0) + C(\varepsilon)\int_0^t e^{-\alpha(s)}\,ds\right) \\ &\le C(\varepsilon)e^{\varepsilon t}(g(0)+t) \le C(\varepsilon)e^{2\varepsilon t}(g(0)+1) \le C(\varepsilon)(M^2+1)e^{2\varepsilon t}. \end{aligned}$$

This implies the assertion. ∎

LEMMA 6.5. *Let $\varepsilon > 0$ and $a > 0$ be given. Then there exists $\delta > 0$ such that*

$$\|u(0) - w_0\|_{s_0} \le \delta, \quad \|f(t)\|_{s_0+1} \le \delta e^{-at} \ \text{ for all } \ t \in [0,T] \tag{6.14}$$

imply

$$\|u(t) - w_0\|_{s_0} \le \varepsilon \ \text{ for all } \ t \in [0,T].$$

The constant δ may be chosen independently of T and u.

Proof. We assume according to Lemma 6.4 that

$$\|u(t)\|_{s_0+1} \le Ce^{at/2} \ \text{ for } \ t \in [0,T].$$

Define $g(t) := \|u(t) - w_0\|_{s_0}^2$. Then

$$\begin{aligned} g'(t) = 2\big(\mathcal{F}(u(t))\gamma, u(t) - w_0\big)_{s_0} &\le C\|\mathcal{F}(u(t))\gamma\|_{s_0} \\ &= C\|F(u(t))f(t)\|_{s_0}, \end{aligned}$$

and, consequently,

$$g'(t) \le C\|u(t)\|_{s_0+1}\|f(t)\|_{s_0+1} \le C'\delta e^{at/2}e^{-at}.$$

Hence, for δ sufficiently small,

$$g'(t) \le \tfrac{1}{4}a\varepsilon^2 e^{-at/2} \quad \text{and} \quad g(0) \le \tfrac{1}{2}\varepsilon^2.$$

This implies

$$g(t) \le \tfrac{1}{2}\varepsilon^2(2 - e^{-at/2}) \le \varepsilon^2,$$

which is the assertion. ∎

Now, to obtain estimates of $f(t)$ we derive the evolution equation satisfied by f. Differentiation of (6.11) with respect to t gives

$$\dot f(t) = \mathcal{G}\big(u(t)\big)\big\{\dot u(t)\big\}\gamma - \frac{1}{|S|}\int_S \mathcal{G}\big(u(t)\big)\big\{\dot u(t)\big\}\gamma\,dS,$$

hence inserting (6.12) we obtain

$$\dot f(t) = \mathcal{H}\big(u(t),\gamma\big)f(t), \tag{6.15}$$

where the operator $\mathcal{H}$ is given by

$$\mathcal{H}(u,\gamma)w := \mathcal{G}'(u)\{F(u)w\}\gamma - \frac{1}{|S|}\int_S \mathcal{G}'(u)\{F(u)w\}\gamma\,dS. \tag{6.16}$$

The operator $\mathcal{H}$ is negative semibounded in L^2 in the following sense.

LEMMA 6.6. *For $\|u-w_0\|_{s_0}$ and $\|\gamma-\overline{\gamma}\|_{s_0}$ sufficiently small we have with a positive constant c independent of u and γ:*

$$\big(\mathcal{H}(u,\gamma)w,w\big)_0 \le -c\|w\|_{3/2}^2 \tag{6.17}$$

for all $w\in C^\infty(S)$ with

$$\int_S w\,dS = 0, \quad \int_S \omega(u)N_i(u)w\,dS = 0.$$

Proof. Instead of (6.17) we prove the estimate in the form

$$\big(\mathcal{H}(u,\gamma)w,w\big)_0 \le -c_1\|w\|_{3/2}^2 + c_2R(u,w) \tag{6.18}$$

for *all* $w\in C^\infty(S)$ with some constants $c_1,c_2>0$, where

$$R(u,w) := \left(\int_S w\,dS\right)^2 + \sum_{i=1}^m\left(\int_S \omega(u)N_i(u)w\,dS\right)^2.$$

Further, by perturbation arguments using

$$\|\mathcal{H}(u,\gamma)w - \mathcal{H}(w_0,\bar\gamma)w\|_{-3/2} \le C\|w\|_{3/2}\big(\|u-w_0\|_{s_0} + \|\gamma-\overline{\gamma}\|_{s_0}\big),$$

it suffices to show (6.18) for $u=w_0$, $\gamma=\bar\gamma$. For $\gamma=\bar\gamma$ we have

$$\mathcal{G}(u)\overline{\gamma} = \overline{\gamma}H(u),$$

therefore the linearization of the mean curvature at a sphere yields

$$\mathcal{G}'(w_0)\{v\}\overline{\gamma} = \overline{\gamma}\big((m-1)(x\cdot v) + \Delta_S(x\cdot v)\big).$$

As $[w\mapsto x\cdot F(w_0)w] = B_S$ is the Dirichlet–Neumann operator on the unit sphere S, this implies (6.18). ∎

LEMMA 6.7. *There exists $a>0$ with the property that for any $\varepsilon>0$ there exists $\delta>0$ such that $\|u(0)-w_0\|_{s_0}\le\delta$ and $\|\gamma-\bar\gamma\|_{s_0}\le\delta$ imply*

$$\|f(t)\|_{s_0+1} \le \varepsilon e^{-at} \quad \textit{for all } t\in[0,T].$$

δ may be chosen independently of u and $T>0$.

Proof. First, note that by definition of $f(t)$ and Lemma 6.1 (i) we have

$$\int_S f(t)\,dS = 0, \quad \int_S \omega\big(u(t)\big)N_i\big(u(t)\big)f(t)\,dS = 0.$$

Consequently (6.15) and Lemma 6.6 imply

$$\frac{d}{dt}\big(\|f(t)\|_0^2\big) = 2\big(\mathcal{H}(u(t),\gamma)f(t), f(t)\big)_0 \le -c\|f(t)\|_0^2,$$

with some $c > 0$, hence

$$\|f(t)\|_0 \le e^{-ct}\|f(0)\|_0.$$

Further, as

$$\|f(t)\|_{s_0-2} \le C\big(\|u(t) - w_0\|_{s_0} + \|\gamma - \bar\gamma\|_{s_0}\big) \le C(\delta_0 + \delta),$$

we get from Lemma 6.4 (i) by assuming δ and the constant δ_0 in the definition (6.5) of $\tilde U_s$ sufficiently small,

$$\|u(t)\|_{s_0+4} \le Ce^{\mu t}, \quad \mu := c/(2(s_0+1))$$

and, moreover, using the estimate (2.14),

$$\|f(t)\|_{s_0+2} = \|\mathcal{G}(u(t))\gamma\|_{s_0+2} \le C\|u(t)\|_{s_0+4} \le C'e^{\mu t}.$$

Now we have by interpolation

$$\|f(t)\|_{s_0+1} \le C\big(e^{\mu t}\big)^{\frac{s_0+1}{s_0+2}}\big(e^{-ct}\|f(0)\|_0\big)^{\frac{1}{s_0+2}} = C\|f(0)\|_0^{\frac{1}{s_0+2}}e^{-at}$$

with $a = c/(2(s_0+2))$. This implies the assertion. ∎

Now we are in position to formulate our main result about the long-time existence and convergence to an equilibrium configuration for $t \to \infty$.

THEOREM 6.8. *Let $M > 0$ be given. Then there exists an $\varepsilon > 0$ such that for $\gamma \in C^\infty(S)$ with $\|\gamma\|_{s_1} \le M$, $\|\gamma - \bar\gamma\|_{s_0} \le \varepsilon$ and for any initial value $u_0 \in H^{s_0+4}$ with $\|u_0\|_{s_0+4} \le M$, $\|u_0 - w_0\|_{s_0} \le \varepsilon$ the solution of the Cauchy problem (6.8) exists for all $t > 0$. Moreover, $u(t)$ converges exponentially to some $u^\star = u^\star(u_0,\gamma)$ in H^s, $s < s_0 + 4$ for $t \to \infty$, i.e.,*

$$\|u(t) - u^\star\|_s \le Ce^{-at} \tag{6.19}$$

with suitable $C, a > 0$ (depending on $s < s_0 + 4$). Finally, we have $\mathcal{G}(u^\star)\gamma = \text{const}$ on S, i.e., γ is an equilibrium surface energy density for $u^\star$.

Proof. First, choose $\delta \in (0, \delta_0)$ and $T > 0$ such that, by our local existence theorems, initial values $u_0 \in H^{s_0+4}$ with $\|u_0 - w_0\|_{s_0} \le \delta$ guarantees the (unique) solvability of (6.8) on the time interval $[0,T]$ with $u(t) \in \tilde U_{s_0+4}$, $t \in [0,T]$. Then, for $\varepsilon > 0$ sufficiently small, Lemmas 6.5 and 6.7 ensure $\|u(T) - w_0\|_{s_0} \le \delta$, hence the solution can be continued to the interval $[T, 2T]$ with $u(t) \in \tilde U_{s_0+4}$, $t \in [0, 2T]$. Applying now Lemma 6.5 and 6.7 to the time interval $[0, 2T]$ (note the independence of the constants in these lemmas of the time interval length), we obtain $\|u(2T) - w_0\|_{s_0} \le$

δ_0 again and the solution can be continued to the interval $[2T, 3T]$. Repeating these arguments yields global existence of the solution. Moreover, Lemma 6.7 implies

$$\|f(t)\|_{s_0+1} \le Ce^{-at} \text{ for all } t \ge 0$$

with $a > 0$. Consequently, for any $\varepsilon > 0$ there exists a constant $C(\varepsilon)$ such that

$$\|u(t)\|_{s_0+4} \le C(\varepsilon)e^{\varepsilon t} \text{ for all } t \ge 0 \tag{6.20}$$

by Lemma 6.4 (ii). Further, for $0 \le t \le \theta < \infty$,

$$\|u(t) - u(\theta)\|_0 \le \int_t^\theta \|F(u(\tau))f(\tau)\|_0 \, d\tau \le C \int_t^\theta \|f(\tau)\|_{s_0+1} \, d\tau \le Ce^{-at},$$

and by interpolation using (6.20) with ε sufficiently small,

$$\|u(t) - u(\theta)\|_s \le C_s e^{-a_s t} \text{ for } s < s_0 + 4$$

with suitable constants $C_s, a_s > 0$. This implies convergence of $u(t)$ to some $u^\star$ in $H^s(S)$, $s < s_0 + 4$ as $t \to \infty$ and the estimate (6.19). The final statement follows from letting $t \to \infty$ in (6.11). □

Remark 6.9. It is not hard to see the following regularity property of $u^\star$: if the initial value u_0 belongs additionally to H^s with some $s > s_0 + 4$, then $u^\star(u_0, \gamma) \in H^{s'}$ for $s' < s$ (recall that we have always assumed $\gamma \in C^\infty$). The question whether or not $u^\star$ belongs to H^s remains open and requires more sophisticated estimates.

To illustrate possible equilibrium shapes $\Gamma_{u^\star}$ according to Theorem 6.8 we have performed several numerical test calculations for $m = 2, 3$. In a 2D situation, starting from a circle $S = \Gamma_{w_0}$ and a surface energy density of form

$$\gamma(x) = 1 + 0.8\cos(6\varphi), \quad x = (\cos\varphi, \sin\varphi) \in S, \ 0 \le \varphi < 2\pi,$$

we obtain an equilibrium shape $\Gamma_{u^\star}$ as pictured by the solid line in Figure 1. In contrast, if the correction term $G(u)$, which ensures the gradient flow structure of the evolution problem, is dropped in the definition (2.4), then the resulting shape $\Gamma_{u^\star}$ is given by the dotted line in Figure 1. Clearly, in the latter situation the center of gravity remains fixed due to the symmetries of the chosen initial values and every equilibrium configuration (u, γ) is characterized by $\gamma\kappa = \text{const}$ on Γ_u, hence Γ_u must be convex. (This is similar to a Hele–Shaw evolution where the values of γ are transported only in normal direction to the moving boundary, as this also leads to a dropping of the term $G(u)$.) As Figure 1 shows, this convexity is not true for the full problem. The second example concerns an axisymmetric situation in 3D. Here the evolution starts from the unit sphere $S = \Gamma_{w_0}$ with the surface energy density

$$\gamma(x) = 1.0 + 0.8x_1(4.0x_1^2 - 3.0), \quad x = (x_1, x_2, x_3) \in S$$

and results in a equilibrium shape as shown in Figure 2. To indicate the length scale we have added grid lines with distance 0.25 in each direction.

LOW MACH NUMBER FLOWS AND COMBUSTION*

THOMAS ALAZARD†

Abstract. We prove uniform existence results for the full Navier–Stokes equations for time intervals which are independent of the Mach number, the Reynolds number, and the Péclet number. We consider general equations of state and give an application for the low Mach number limit combustion problem introduced by Majda in [*Compressible Fluid Flow and Systems of Conservation Laws in Several Space Variables*, Springer-Verlag, NewYork, 1984].

Key words. low Mach limit, uniform stability, combustion equation

1. Introduction.

For a fluid with density ϱ, velocity v, pressure P, temperature T, internal energy e, Lamé coefficients ζ, η, and coefficient of thermal conductivity k, the full Navier–Stokes equations, written in a nondimensional way, are

$$\begin{cases} \partial_t \rho + \operatorname{div}(\rho v) = 0, \\ \partial_t(\rho v) + \operatorname{div}(\rho v \otimes v) + \dfrac{\nabla P}{\varepsilon^2} = \mu\big(2\operatorname{div}(\zeta D v) + \nabla(\eta \operatorname{div} v)\big), \\ \partial_t(\rho e) + \operatorname{div}(\rho v e) + P \operatorname{div} v = \kappa \operatorname{div}(k \nabla T) + Q, \end{cases} \tag{1.1}$$

where $\varepsilon \in (0,1]$, $(\mu,\kappa) \in [0,1]^2$, and Q is a given source term (see [11, 16, 18]). In order to be closed, the system is supplemented with a thermodynamic closure law, so that ρ, P, e, T are completely determined by only two of these variables. Also, it is assumed that ζ, η, and k are smooth functions of the temperature.

This paper is devoted to the asymptotic limit where the Mach number ε tends to 0. We are interested in proving results independent of the Reynolds number $1/\mu$ and the Péclet number $1/\kappa$. Our main result asserts that the classical solutions of (1.1) exist and are uniformly bounded on a time interval independent of ε, μ, and κ.

This is a continuation of our previous work [1], where the study was restricted to perfect gases and small source terms Q of size $O(\varepsilon)$. We refer to the introduction of [1] for references and a short historical survey of the background of these problems (see also the survey papers of Danchin [9], Desjardins and Lin [10], Gallagher [13], Schochet [24], and Villani [26]).

The case of perfect gases is interesting in its own: first, perfect gases are widely studied in the physical literature; and second, it contains the important analysis of the singular terms. Yet, modeling real gases requires general equations of state (see [4, 19]). Moreover, we shall see that it is interesting to consider large source terms Q for it allows us to answer a question addressed by Majda in [18] concerning the combustion equations.

1.1. The equations. To be more precise, we begin by rewriting the equations under the form $L(u,\partial_t,\partial_x)u+\varepsilon^{-1}S(u,\partial_x)u=0$, which is the classical framework of a singular limit problem.

Before we proceed, three observations are in order. First, for the low Mach number limit problem, the point is not so much to use the conservative form of the equations, but instead to balance the acoustics components. This is one reason it is interesting to work with the unknowns P, v, T (see [18]). Second, the general case must allow for large density and temperature variations as well as very large acceleration of order of the inverse of the Mach number (see section 5 in [16]). Since $\partial_t v$ is of order $\varepsilon^{-2}\nabla P$, this suggests that we seek P under the form $P=\text{const}+O(\varepsilon)$. As in [20], since P and T are positive functions, it is pleasant to set

$$P=\underline{P}e^{\varepsilon p},\quad T=\underline{T}e^{\theta}, \tag{1.2}$$

where $\underline{P}$ and $\underline{T}$ are given positive constants, say the reference states at spatial infinity. Finally, the details of the following computations are given in the appendix.

From now on, the unknown is (p,v,θ) with values in $\mathbb{R}\times\mathbb{R}^d\times\mathbb{R}$. We are interested in the general case where p and θ are uniformly bounded in ε (so that $\nabla T=O(1)$ and $\partial_t v=O(\varepsilon^{-1})$).

By assuming that ρ and e are given smooth functions of (P,T), it is found that, for smooth solutions of (1.1), (P,v,T) satisfies a system of the form

$$\begin{cases}\alpha(\partial_t P+v\cdot\nabla P)+\operatorname{div}v=\kappa\beta\operatorname{div}(k\nabla T)+\beta Q,\\ \rho(\partial_t v+v\cdot\nabla v)+\dfrac{\nabla P}{\varepsilon^2}=\mu\big(2\operatorname{div}(\zeta Dv)+\nabla(\eta\operatorname{div}v)\big),\\ \gamma(\partial_t T+v\cdot\nabla T)+\operatorname{div}v=\kappa\delta\operatorname{div}(k\nabla T)+\delta Q,\end{cases} \tag{1.3}$$

where the coefficients α, β, γ, and δ are smooth functions of (P,T). Then, by writing $\partial_{t,x}P=\varepsilon P\partial_{t,x}p$, $\partial_{t,x}T=T\partial_{t,x}\theta$ and redefining the functions k, ζ, and η, it is found that (p,v,θ) satisfies a system of the form

$$\begin{cases}g_1(\phi)(\partial_t p+v\cdot\nabla p)+\dfrac{1}{\varepsilon}\operatorname{div}v=\dfrac{\kappa}{\varepsilon}\chi_1(\phi)\operatorname{div}(k(\theta)\nabla\theta)+\dfrac{1}{\varepsilon}\chi_1(\phi)Q,\\ g_2(\phi)(\partial_t v+v\cdot\nabla v)+\dfrac{1}{\varepsilon}\nabla p=\mu B_2(\phi,\partial_x)v,\\ g_3(\phi)(\partial_t\theta+v\cdot\nabla\theta)+\operatorname{div}v=\kappa\chi_3(\phi)\operatorname{div}(k(\theta)\nabla\theta)+\chi_3(\phi)Q,\end{cases} \tag{1.4}$$

where $\phi:=(\theta,\varepsilon p)$ and $B_2(\phi,\partial_x)=\chi_2(\phi)\operatorname{div}(\zeta(\theta)D\cdot)+\chi_2(\phi)\nabla(\eta(\theta)\operatorname{div}\cdot)$.

We are now in position to explain the main differences between ideal gases and general gases. First, we note that the source term Q introduces an arbitrary unsigned large term of order $1/\varepsilon$ in the equations. Second, to emphasize the role of the thermodynamics, we suppose now that $Q=0$ and mention that, for perfect gases, the coefficient $\chi_1(\phi)$ is a function of εp alone (see Proposition A.8). Hence, for perfect gases, the limit constraint is linear in the sense that it reads $\operatorname{div}v_e=0$ with $v_e=v-\kappa\chi_1(0)k(\theta)\nabla\theta$. By contrast, for general equations of state, the limit constraint is nonlinear.

1.2. Assumptions. To avoid confusion, we denote by $(\vartheta,\wp)\in\mathbb{R}^2$ the place holder of the unknown $(\theta,\varepsilon p)$. Hereafter, it is assumed that:

(H1) The functions ζ, η, and k are C^∞ functions of $\vartheta\in\mathbb{R}$, satisfying $k>0$, $\zeta>0$, and $\eta+2\zeta>0$.

(H2) The functions g_i and χ_i $(i=1,2,3)$ are C^∞ positive functions of $(\vartheta,\wp)\in\mathbb{R}^2$. Moreover,

$$\chi_1<\chi_3,$$

and there exist F, G such that $(\vartheta,\wp)\mapsto(F(\vartheta,\wp),\wp)$ and $(\vartheta,\wp)\mapsto(\vartheta,G(\vartheta,\wp))$ are C^∞ diffeomorphisms from $\mathbb{R}^2$ onto $\mathbb{R}^2$, $F(0,0)=G(0,0)=0$, and

$$g_1\frac{\partial F}{\partial\vartheta}=-g_3\frac{\partial F}{\partial\wp}>0,\qquad g_1\chi_3\frac{\partial G}{\partial\vartheta}=-g_3\chi_1\frac{\partial G}{\partial\wp}<0.$$

Remark 1.1. Assumption (H2) is used to prove various energy estimates. The main hypothesis is the inequality $\chi_1<\chi_3$. In the appendix, it is proved that the inequality $\chi_1<\chi_3$ holds whenever the density ρ and the energy e are C^∞ functions of $(P,T)\in(0,+\infty)^2$, such that $\rho>0$ and

$$P\frac{\partial\rho}{\partial P}+T\frac{\partial\rho}{\partial T}=\rho^2\frac{\partial e}{\partial P},\quad \frac{\partial\rho}{\partial P}>0,\quad \frac{\partial\rho}{\partial T}<0,\quad \frac{\partial e}{\partial T}\frac{\partial\rho}{\partial P}>\frac{\partial e}{\partial P}\frac{\partial\rho}{\partial T}. \tag{1.5}$$

1.3. Main result. We are interested in the case without smallness assumption and consider general initial data, general equations of state, and large source terms Q. To get around the above mentioned nonlinear features of the penalization operator, we establish a few new qualitative properties. These properties are enclosed in various uniform stability results, which assert that the classical solutions of (1.4) exist and are uniformly bounded for a time independent of ε, μ, and κ. We concentrate below on the whole space problem or the periodic case and work in the Sobolev spaces H^σ endowed with the norms $\|u\|_{H^\sigma}:=\|(I-\Delta)^{\sigma/2}u\|_{L^2}$.

The following result is the core of all our other uniform stability results. On the technical side, it contains the idea that one can prove uniform estimates without uniform control of the L^2_x norm of the velocity v.

THEOREM 1.2. *Let $d=1$ or $d\geqslant 3$ and $\mathbb{N}\ni s>1+d/2$. For all source term $Q=Q(t,x)\in C^\infty_0(\mathbb{R}\times\mathbb{R}^d)$ and all $M_0>0$, there exist $T>0$ and $M>0$ such that for all $(\varepsilon,\mu,\kappa)\in(0,1]\times[0,1]\times[0,1]$ and all initial data $(p_0,v_0,\theta_0)\in H^{s+1}(\mathbb{R}^d)$ satisfying*

$$\|(\nabla p_0,\nabla v_0)\|_{H^{s-1}}+\|(\theta_0,\varepsilon p_0,\varepsilon v_0)\|_{H^{s+1}}\leqslant M_0, \tag{1.6}$$

the Cauchy problem for (1.4) *has a unique solution (p,v,θ) in $C^0([0,T];H^{s+1}(\mathbb{R}^d))$ such that*

$$\sup_{t\in[0,T]}\|(\nabla p(t),\nabla v(t))\|_{H^{s-1}}+\|(\theta(t),\varepsilon p(t),\varepsilon v(t))\|_{H^s}\leqslant M. \tag{1.7}$$

A refined statement is proved in section 3.

A notable corollary of Theorem 1.2 is Theorem 4.1, which is the requested result for application to the low Mach number limit. Detailed discussions of the periodic case and the combustion equations are included in sections 5 and 6. The assumption $d\neq 2$ is explained in Remark 2.6.

2. Preliminaries. In order not to interrupt the proofs later on, we collect here some estimates. The main result of this section is Proposition 2.4, which complements the Friedrichs'-type estimate

$$\|\nabla v\|_{H^s}\leqslant\|\operatorname{div}v\|_{H^s}+\|\operatorname{curl}v\|_{H^s}, \tag{2.1}$$

which is immediate using Fourier transform. We prove a variant where div v is replaced by $\operatorname{div}(\rho v)$ where ρ is a positive weight.

Notation. The symbol $\lesssim$ stands for $\leqslant$ up to a positive, multiplicative constant, which depends only on parameters that are considered fixed.

2.1. Nonlinear estimates. Throughout the paper, we will make intensive and often implicit uses of the following estimates.

For all $\sigma \geqslant 0$, there exists K such that, for all $u, v \in L^\infty \cap H^\sigma(\mathbb{R}^d)$,

$$\|uv\|_{H^\sigma} \leqslant K \|u\|_{L^\infty} \|v\|_{H^\sigma} + K \|u\|_{H^\sigma} \|v\|_{L^\infty}. \tag{2.2}$$

For all $s > d/2$, $\sigma_1 \geqslant 0$, $\sigma_2 \geqslant 0$ such that $\sigma_1 + \sigma_2 \leqslant 2s$, there exists a constant K such that, for all $u \in H^{s-\sigma_1}(\mathbb{R}^d)$ and $v \in H^{s-\sigma_2}(\mathbb{R}^d)$,

$$\|uv\|_{H^{s-\sigma_1-\sigma_2}} \leqslant K \|u\|_{H^{s-\sigma_1}} \|v\|_{H^{s-\sigma_2}}. \tag{2.3}$$

For all $s > d/2$ and for all C^∞ function F vanishing at the origin, there exists a smooth function C_F such that, for all $u \in H^s(\mathbb{R}^d)$,

$$\|F(u)\|_{H^s} \leqslant C_F(\|u\|_{L^\infty}) \|u\|_{H^s}. \tag{2.4}$$

2.2. Estimates in $\mathbb{R}^3$. Consider the Fourier multiplier $\nabla\Delta^{-1}$ with symbol $-i\xi/|\xi|^2$. This operator is, at least formally, a right inverse for the divergence operator. The only thing we will use below is that $\nabla\Delta^{-1}u$ is well defined whenever $u = u_1 u_2$ with $u_1, u_2 \in L^\infty \cap H^\sigma(\mathbb{R}^d)$ for some $\sigma \geqslant 0$.

PROPOSITION 2.1. *Given $d \geqslant 3$ and $\sigma \in \mathbb{R}$, the Fourier multiplier $\nabla\Delta^{-1}$ is well defined on $L^1(\mathbb{R}^d) \cap H^\sigma(\mathbb{R}^d)$ with values in $H^{\sigma+1}(\mathbb{R}^d)$. Moreover, there exists a constant K such that, for all $u \in L^1(\mathbb{R}^d) \cap H^\sigma(\mathbb{R}^d)$,*

$$\left\|\nabla\Delta^{-1}u\right\|_{H^{\sigma+1}} \leqslant K \|u\|_{L^1} + K \|u\|_{H^\sigma}. \tag{2.5}$$

Proof. Set $\langle\xi\rangle := (1 + |\xi|^2)^{1/2}$. It is enough to check that the L^2-norm of $(\langle\xi\rangle^{\sigma+1}/|\xi|)\,|\widehat{u}(\xi)|$ is estimated by the right-hand side of (2.5). To do that we write

$$\int_{|\xi|\leqslant 1} \frac{\langle\xi\rangle^{2\sigma+2}}{|\xi|^2} |\widehat{u}(\xi)|^2 \, d\xi \lesssim \|u\|_{L^1}^2, \quad \int_{|\xi|\geqslant 1} \frac{\langle\xi\rangle^{2\sigma+2}}{|\xi|^2} |\widehat{u}(\xi)|^2 \, d\xi \lesssim \|u\|_{H^\sigma}^2,$$

where we used $1/|\xi|^2 \in L^1(\{|\xi| \leqslant 1\})$ for all $d \geqslant 3$. ∎

The next proposition is well known. Its corollary is a special case of a general estimate established in [5].

PROPOSITION 2.2. *Given $d \geqslant 3$ and $s > d/2$, there exists a constant K such that, for all $u \in H^s(\mathbb{R}^d)$,*

$$\|u\|_{L^\infty} \leqslant K \|\nabla u\|_{H^{s-1}}. \tag{2.6}$$

Proof. Since $H^s(\mathbb{R}^d) \hookrightarrow L^\infty(\mathbb{R}^d)$, it suffices to prove the result for u in the Schwartz class $\mathcal{S}(\mathbb{R}^d)$. Now, starting from the Fourier inversion theorem, the Cauchy–Schwarz inequality yields the desired estimate:

$$\|u\|_{L^\infty} \leqslant \left(\int \frac{d\xi}{|\xi|^2 \langle\xi\rangle^{2(s-1)}}\right)^{1/2} \left(\int \langle\xi\rangle^{2(s-1)} |\xi\widehat{u}(\xi)|^2 \, d\xi\right)^{1/2} \lesssim \|\nabla u\|_{H^{s-1}}. \qquad ∎$$

COROLLARY 2.3. *Given $d \geqslant 3$ and $\mathbb{N} \ni s > d/2$, there exists a constant K such that, for all $u_1, u_2 \in H^s(\mathbb{R}^d)$,*

$$\|u_1 u_2\|_{H^s} \leqslant K \|\nabla u_1\|_{H^{s-1}} \|u_2\|_{H^s}. \tag{2.7}$$

Proof. One has to estimate the L^2-norm of $\partial_x^\alpha(u_1 u_2)$, where $\alpha \in \mathbb{N}^d$ satisfies $|\alpha| \leqslant s$. Rewrite this term as $u_1 \partial_x^\alpha u_2 + [\partial_x^\alpha, u_1]u_2$. Since the commutator is a sum of terms of the form $\partial_x^\beta u_1 \partial_x^\gamma u_2$ with $\beta > 0$, the product rule (2.3) implies that

$$\|[\partial_x^\alpha, u_1]u_2\|_{L^2} \lesssim \|\nabla u_1\|_{H^{s-1}} \|u_2\|_{H^s}. \tag{2.8}$$

Moving to the estimate of the first term, we write

$$\|u_1 \partial_x^\alpha u_2\|_{L^2} \leqslant \|u_1\|_{L^\infty} \|u_2\|_{H^s} \lesssim \|\nabla u_1\|_{H^{s-1}} \|u_2\|_{H^s}. \qquad \square$$

2.3. Friedrichs' lemma. With these preliminaries established, we are prepared to prove the following.

PROPOSITION 2.4. *Let $d \geqslant 3$ and $\mathbb{N} \ni s > d/2$. There exists a function $\mathcal{C}$ such that, for all $\varphi \in H^{s+1}(\mathbb{R}^d)$ and all vector field $v \in H^{s+1}(\mathbb{R}^d)$,*

$$\|\nabla v\|_{H^s} \leqslant C \|\mathrm{div}(e^\varphi v)\|_{H^s} + C \|\mathrm{curl}\, v\|_{H^s}, \tag{2.9}$$

where $C := (1 + \|\varphi\|_{H^{s+1}})\mathcal{C}(\|\varphi\|_{H^s}, \|\nabla\varphi\|_{L^\infty})$.

Proof. For this proof, we use the notation

$$R = \|\mathrm{div}(e^\varphi v)\|_{H^s} + \|\mathrm{curl}\, v\|_{H^s},$$

and we denote by C_φ various constants depending only on $\|\varphi\|_{H^s} + \|\nabla\varphi\|_{L^\infty}$.

All the computations given below are meaningful since it is sufficient to prove (2.9) for C^∞ functions with compact supports. We begin by setting

$$\widetilde{v} = v + \nabla\Delta^{-1}\big(\nabla\varphi \cdot v\big).$$

The reason to introduce $\widetilde{v}$ is that

$$e^\varphi \,\mathrm{div}\,\widetilde{v} = \mathrm{div}(e^\varphi v), \quad \mathrm{curl}\,\widetilde{v} = \mathrm{curl}\, v.$$

Hence, by using (2.1), we have

$$\|\nabla\widetilde{v}\|_{H^s} \leqslant \big\|e^{-\varphi}\,\mathrm{div}(e^\varphi v)\big\|_{H^s} + \|\mathrm{curl}\, v\|_{H^s} \leqslant C_\varphi R. \tag{2.10}$$

The proof of (2.9) thus reduces to estimating $v_1 := v - \widetilde{v}$, which satisfies

$$\mathrm{div}(e^\varphi v_1) = -e^\varphi \nabla\varphi \cdot \widetilde{v}, \quad \mathrm{curl}\, v_1 = 0.$$

Again, to estimate v_1 we introduce $\widetilde{v}_1 := v_1 + \nabla\Delta^{-1}\big(\nabla\varphi \cdot v_1\big)$, which solves

$$\mathrm{div}\,\widetilde{v}_1 = -\nabla\varphi \cdot \widetilde{v}, \quad \mathrm{curl}\,\widetilde{v}_1 = 0.$$

The estimate (2.1) implies that $\|\nabla\widetilde{v}_1\|_{H^s} \leqslant \|\nabla\varphi \cdot \widetilde{v}\|_{H^s}$. By using (2.10) and the product rule (2.7), applied with $u_1 = \widetilde{v}$ and $u_2 = \nabla\varphi$, we find that

$$\|\nabla\widetilde{v}_1\|_{H^s} \leqslant \|\nabla\varphi \cdot \widetilde{v}\|_{H^s} \lesssim \|\varphi\|_{H^{s+1}} \|\nabla\widetilde{v}\|_{H^{s-1}} \leqslant \|\varphi\|_{H^{s+1}} C_\varphi R. \tag{2.11}$$

Hence, it remains only to estimate $v_2 = v_1 - \widetilde{v}_1$, which satisfies

$$\operatorname{div}(e^{\varphi} v_2) = -e^{\varphi} \nabla\varphi \cdot \widetilde{v_1} \quad \text{and} \quad \operatorname{curl} v_2 = 0.$$

To estimate v_2 the key point is the estimate

$$\|\nabla\varphi \cdot \widetilde{v}_1\|_{L^{d^\star}} \leqslant C_\varphi R \quad \text{with } d^\star = 2d/(d+2). \tag{2.12}$$

Let us assume (2.12) for a moment and continue the proof.

The constraint $\operatorname{curl} v_2 = 0$ implies that $v_2 = \nabla\Psi$, for some Ψ satisfying

$$\operatorname{div}(e^{\varphi}\nabla\Psi) = -e^{\varphi}\nabla\varphi \cdot \widetilde{v_1}.$$

This allows us to estimate $\nabla\Psi$ by a duality argument. We denote by $\langle\, \cdot, \cdot \,\rangle$ the scalar product in L^2 and write

$$\langle\, e^{\varphi}\nabla\Psi\,, \nabla\Psi \,\rangle = \langle\, e^{\varphi}\nabla\varphi \cdot \widetilde{v}_1\,, \Psi\,\rangle.$$

Denote by $\overline{d}$ the conjugate exponent of $d^\star$, $\overline{d} = d^\star/(d^\star - 1) = 2d/(d-2)$. The Hölder's inequality yields

$$\langle\, e^{\varphi}\nabla\Psi\,, \nabla\Psi\,\rangle \leqslant \|e^{\varphi}\nabla\varphi \cdot \widetilde{v}_1\|_{L^{d^\star}} \, \|\Psi\|_{L^{\overline{d}}}.$$

The first factor is estimated by means of the claim (2.12). In view of the Sobolev's inequality $\|\Psi\|_{L^{\overline{d}}} \lesssim \|\nabla\Psi\|_{L^2}$, we obtain

$$\langle\, e^{\varphi}\nabla\Psi\,, \nabla\Psi\,\rangle \leqslant C_\varphi R \, \|\nabla\Psi\|_{L^2}.$$

By using the elementary estimate $\|\nabla\Psi\|_{L^2}^2 \leqslant \|e^{-\varphi}\|_{L^\infty} \langle\, e^{\varphi}\nabla\Psi\,, \nabla\Psi\,\rangle$, we get

$$\|v_2\|_{L^2} = \|\nabla\Psi\|_{L^2} \leqslant C_\varphi R. \tag{2.13}$$

The end of the proof is straightforward. We write

$$\Delta\Psi = e^{-\varphi}\operatorname{div}(e^{\varphi}\nabla\Psi) - \nabla\varphi\cdot\nabla\Psi = -\nabla\varphi\cdot\widetilde{v}_1 - \nabla\varphi\cdot\nabla\Psi,$$

to obtain, for all $\sigma \in [0, s-1]$,

$$\|\nabla\Psi\|_{H^{\sigma+1}} \lesssim \|\nabla\Psi\|_{L^2} + \|\Delta\Psi\|_{H^\sigma} \lesssim \|\nabla\varphi\cdot\widetilde{v}_1\|_{H^\sigma} + (1 + \|\varphi\|_{H^s})\,\|\nabla\Psi\|_{H^\sigma}.$$

To estimate the first term on the right-hand side, we verify that the analysis establishing (2.7) also yields

$$\|\nabla\varphi\cdot\widetilde{v}_1\|_{H^{s-1}} \lesssim \|\varphi\|_{H^s}\,\|\nabla\widetilde{v}_1\|_{H^{s-1}} \leqslant C_\varphi R,$$

hence, by induction on σ,

$$\|\nabla\Psi\|_{H^s} \leqslant C_\varphi R + C_\varphi\,\|\nabla\Psi\|_{L^2}.$$

Exactly as above, one has

$$\begin{aligned}
&\|\nabla\Psi\|_{H^{s+1}} \lesssim \|\nabla\Psi\|_{L^2} + \|\Delta\Psi\|_{H^s} \lesssim \|\nabla\varphi\cdot\widetilde{v}_1\|_{H^s} + (1 + \|\varphi\|_{H^{s+1}})\,\|\nabla\Psi\|_{H^s}\\
&\|\nabla\varphi\cdot\widetilde{v}_1\|_{H^s} \lesssim \|\varphi\|_{H^{s+1}}\,\|\nabla\widetilde{v}_1\|_{H^{s-1}} \leqslant \|\varphi\|_{H^{s+1}}\,C_\varphi R.
\end{aligned}$$

As a consequence, we end up with

$$\|\nabla\Psi\|_{H^{s+1}} \leqslant \|\varphi\|_{H^{s+1}} (C_\varphi R + C_\varphi \|\nabla\Psi\|_{L^2}).$$

Therefore, the L^2 estimate (2.13) implies that

$$\|v_2\|_{H^{s+1}} = \|\nabla\Psi\|_{H^{s+1}} \leqslant \|\varphi\|_{H^{s+1}} C_\varphi R.$$

By combining this estimate with (2.11), we find that

$$\|\nabla v_1\|_{H^s} \leqslant \|\varphi\|_{H^{s+1}} C_\varphi R.$$

From the definition of v_1 and (2.10), we obtain the desired bound (2.9).

We now have to establish the claim (2.12).

With $\overline{d} = 2d/(d-2)$ as above, the Sobolev's inequality and (2.10) imply that

$$\|\widetilde{v}\|_{L^{\overline{d}}} \lesssim \|\nabla\widetilde{v}\|_{L^2} \leqslant C_\varphi R.$$

On the other hand, the Hölder's inequality yields

$$\|\nabla\varphi\cdot\widetilde{v}\|_{L^\delta} \lesssim \|\nabla\varphi\|_{L^2} \|\widetilde{v}\|_{L^{\overline{d}}} \quad \text{with } \delta = \frac{2\overline{d}}{2+\overline{d}} = \frac{d}{d-1}\cdot$$

By interpolating this estimate with $\|\nabla\varphi\cdot\widetilde{v}\|_{L^{\overline{d}}} \lesssim \|\nabla\varphi\|_{L^\infty} \|\widetilde{v}\|_{L^{\overline{d}}}$, we obtain

$$\forall p \in [\delta, \overline{d}], \quad \|\nabla\varphi\cdot\widetilde{v}\|_{L^p} \lesssim \|\nabla\varphi\|_{L^2\cap L^\infty} \|\widetilde{v}\|_{L^{\overline{d}}} \leqslant C_\varphi R.$$

Because $\operatorname{curl} v_1 = 0$, one can write $v_1 = \nabla\Psi_1$ for some function Ψ_1 satisfying $\Delta\Psi_1 = -\nabla\varphi\cdot\widetilde{v}$. Hence, the Calderon–Zygmund inequality and the previous estimate imply that

$$\|\nabla v_1\|_{L^\delta} = \big\|\nabla^2\Psi_1\big\|_{L^\delta} \lesssim \|\Delta\Psi_1\|_{L^\delta} \leqslant C_\varphi R.$$

Therefore, the Sobolev's inequality yields

$$\|v_1\|_{L^D} \leqslant C_\varphi R \quad \text{with } D = \frac{\delta d}{d-\delta} = \frac{d}{d-2},$$

hence, exactly as above, the Hölder's inequality gives

$$\forall p \in [\underline{d}, \overline{d}], \quad \|e^\varphi\nabla\varphi\cdot\widetilde{v}_1\|_{L^p} \leqslant C_\varphi R \quad \text{with } \underline{d} = \frac{2D}{2+D} = \frac{2d}{3d-4}\cdot \tag{2.14}$$

The key estimate (2.12) is now a consequence of the previous one. Indeed, the estimate (2.14) applies with $p = d^\star = 2d/(d+2)$ since

$$\forall d \geqslant 3, \qquad \underline{d} = \frac{2d}{3d-4} \leqslant \frac{2d}{d+2} \leqslant \frac{2d}{d-2} = \overline{d}.$$

This completes the proof of (2.9). □

For later references, we will need the following version of (2.9).

COROLLARY 2.5. *Let $d = 1$ or $d \geqslant 3$ and $\mathbb{N} \ni s > d/2$. There exists a function $\mathcal{C}$ such that, for all $\varphi \in H^{s+1}(\mathbb{R}^d)$ and all vector field $v \in H^{s+1}(\mathbb{R}^d)$,*

$$\|\nabla v\|_{H^s} \leqslant \mathcal{C}(\|\varphi\|_{H^{s+1}})\big(\|\operatorname{div} v\|_{H^s} + \|\operatorname{curl}(e^\varphi v)\|_{H^s}\big). \tag{2.15}$$

Proof. The case $d = 1$ is obvious. If $d \geqslant 3$, Proposition 2.4 (applied with (φ, v) replaced with $(-\varphi, e^{\varphi}v)$) yields

$$\|\nabla(e^{\varphi}v)\|_{H^s} \leqslant \mathcal{C}(\|\varphi\|_{H^{s+1}})\big(\|\operatorname{div} v\|_{H^s} + \|\operatorname{curl}(e^{\varphi}v)\|_{H^s}\big).$$

Hence, to prove (2.15) we need only prove that

$$\|\nabla v\|_{H^s} \leqslant \mathcal{C}(\|\varphi\|_{H^{s+1}})\,\|\nabla(e^{\varphi}v)\|_{H^s}\,. \tag{2.16}$$

To do that we write $\partial_i v = e^{-\varphi}\partial_i(e^{\varphi}v) - (e^{-\varphi}\partial_i\varphi)(e^{\varphi}v)$. The usual product rule (2.3) implies that the H^s norm of the first term is estimated by the right-hand side of (2.16). Moving to the second term, we use the product rule (2.7) to obtain $\|(e^{-\varphi}\partial_i\varphi)(e^{\varphi}v)\|_{H^s} \lesssim (1 + \|\varphi\|_{H^s})\,\|\partial_i\varphi\|_{H^s}\,\|\nabla(e^{\varphi}v)\|_{H^{s-1}}$. This proves the desired bound (2.16). ∎

Remark 2.6. The fact that Theorem 1.2 precludes the case $d = 2$ is a consequence of the fact that we do not know if (2.15) holds for $d = 2$.

3. Uniform stability. In this section, we prove Theorem 1.2. We follow closely the approach given in [1] and recall the scheme of the analysis and indicate the points at which the argument must be adapted.

Hereafter, we use the notations

$$a := (\varepsilon, \mu, \kappa) \in A := (0,1] \times [0,1] \times [0,1], \qquad \nu := \sqrt{\mu + \kappa},$$
$$\|u\|_{H^{\sigma+1}_{\alpha}} := \|u\|_{H^{\sigma}} + \alpha\,\|u\|_{H^{\sigma+1}} \qquad (\alpha \geqslant 0,\ \sigma \in \mathbb{R}).$$

Step 1: A refined statement. We first give our main result a refined form where the solutions satisfy the same estimates as the initial data. Also, to prove estimates independent of μ and κ, an important point is to seek the solutions in spaces which take into account an extra damping effect for the penalized terms.

Definition 3.1. *Let $T > 0$, $a = (\varepsilon, \mu, \kappa) \in [0,1]^3$ and set $\nu = \sqrt{\mu + \kappa}$. The space $\mathcal{X}^s_a(T)$ consists of these $(p, v, \theta) \in C^0([0,T]; H^s(\mathbb{R}^d))$ such that*

$$\nu(p, v, \theta) \in C^0([0,T]; H^{s+1}(\mathbb{R}^d)), \quad (\mu v, \kappa\theta) \in L^2(0,T; H^{s+2}(\mathbb{R}^d)).$$

The space $\mathcal{X}^s_a(T)$ is given the norm

$$\begin{aligned}\|(p, v, \theta)\|_{\mathcal{X}^s_a(T)} := {} & \|(\nabla p, \nabla v)\|_{L^\infty_T(H^{s-1})} + \|(\theta, \varepsilon p, \varepsilon v)\|_{L^\infty_T(H^{s+1}_\nu)} \\ & + \sqrt{\mu}\,\|\nabla v\|_{L^2_T(H^{s+1}_{\varepsilon\nu})} + \sqrt{\kappa}\,\|\nabla\theta\|_{L^2_T(H^{s+1}_\nu)} \\ & + \sqrt{\mu+\kappa}\,\|\nabla p\|_{L^2_T(H^s)} + \sqrt{\kappa}\,\|\operatorname{div} v\|_{L^2_T(H^s)}\,,\end{aligned}$$

with $\|\cdot\|_{L^p_T(X)}$ denoting the norm in $L^p(0,T;X)$.

For the study of nonlinear problems, it is important to relax the assumption that $Q \in C^\infty_0$. We will consider source terms Q in the following spaces.

Definition 3.2. *The space F^s consists of the function Q such that, for all $\mathbb{N} \ni m \leqslant s$, $\partial^m_t Q \in C^0_b(\mathbb{R}; H^{s+1-2m}(\mathbb{R}^d))$, where C^0_b stands for $C^0 \cap L^\infty$.*

Given a normed space X, we set $B(X; M) = \{x \in X : \|x\| \leqslant M\}$.

Theorem 3.3. *Assume that $d = 1$ or $d \geqslant 3$ and let $\mathbb{N} \ni s > 1 + d/2$. Given $M_0 > 0$ and $Q \in F^s$, there exist $T > 0$ and $M > 0$ such that, for all $a = (\varepsilon, \mu, \kappa) \in A$ and all initial data $(p_0, v_0, \theta_0) \in H^{s+1}(\mathbb{R}^d)$ satisfying*

$$\|(\nabla p_0, \nabla v_0)\|_{H^{s-1}} + \|(\theta_0, \varepsilon p_0, \varepsilon v_0)\|_{H^{s+1}} \leqslant M_0, \tag{3.1}$$

the Cauchy problem for (1.4) *has a unique solution* $(p,v,\theta)\in B(\mathcal{X}^s_a(T);M)$.

This theorem implies Theorem 1.2.

Remark 3.4. (i) The hybrid norm $\|\cdot\|_{H^{s+1}_{\varepsilon\nu}}$ was already used by Danchin in [8].

(ii) A close inspection of the proof indicates that Theorem 3.3 remains valid with (3.1) replaced by

$$\|(p_0,v_0,\theta_0)\|_{\mathcal{X}^s_a(0)}:=\|(\nabla p_0,\nabla v_0)\|_{H^{s-1}}+\|(\theta_0,\varepsilon p_0,\varepsilon v_0)\|_{H^{s+1}_\nu}\leqslant M_0.$$

Step 2: Local well posedness. We explain here how to reduce matters to proving uniform bounds. To do so, our first task is to establish the local well posedness of the Cauchy problem for fixed $a=(\varepsilon,\mu,\kappa)\in A$.

LEMMA 3.5. *Let* $d\geqslant 1$, $s>1+d/2$, *and* $a\in A$. *For all initial data* $U_0=(p_0,v_0,\theta_0)\in H^s(\mathbb{R}^d)$, *there exists a positive time* T *such that the Cauchy problem for* (1.4) *has a unique solution* $U=(p,v,\theta)\in C^0([0,T];H^s)$ *such that* $U(0)=U_0$. *Moreover, the interval* $[0,T^\star)$, *with* $T^\star<+\infty$, *is a maximal interval of* H^s *existence if and only if* $\limsup_{t\to T^\star}\|U(t)\|_{W^{1,\infty}(\mathbb{R}^d)}=+\infty$.

Lemma 3.5 is a special case of Proposition 4.5 established in section 4.

As in [1, 20], on account of the previous local existence result for fixed $a\in A$, Theorem 1.2 is a consequence of the following uniform estimates.

PROPOSITION 3.6. *Let* $d=1$ *or* $d\geqslant 3$, $\mathbb{N}\ni s>1+d/2$, *and* $M_0>0$. *Set* $H^\infty(\mathbb{R}^d):=\cap_{\sigma\geqslant 0}H^\sigma(\mathbb{R}^d)$. *There exist a constant* C_0 *and a nonnegative function* $C(\cdot)$ *such that, for all* $T\in(0,1]$ *and all* $a\in A$, *if* $(p,v,\theta)\in C^\infty([0,T];H^\infty(\mathbb{R}^d))$ *is a solution of* (1.4) *with initial data satisfying* (3.1), *then the norm* $\Omega_a(T):=\|U\|_{\mathcal{X}^s_a(T)}$ *satisfies*

$$\Omega_a(T)\leqslant C_0\exp\big((\sqrt{T}+\varepsilon)C(\Omega_a(T))\big). \tag{3.2}$$

To prove Proposition 3.6, as usual, a key step is to study the linearized system. This is the purpose of Theorem 3.10. With this result in hand, to establish the desired nonlinear estimates (3.2), the analysis is divided into four steps. This happens for two reasons. First, on the technical side, most of the work concerns the separation of the estimates into high and low frequency components, where the division occurs at frequencies of order of the inverse of ε (since the second-derivative terms with $O(1)$ coefficients and the first-derivative terms with $O(\varepsilon^{-1})$ coefficients balance there). Second, there is a division into terms whose evolution is estimated directly by eliminating large terms of size $O(\varepsilon^{-1})$ (see Lemmas 3.18 and 3.19), and terms whose size is estimated by means of Theorem 3.10 and the special structure of the equations (see Lemma 3.16).

This scheme of estimates has two useful properties. First, it avoids estimating the L^2 norm of p and v (to obtain a closed set of estimates, we will use the preliminary estimates from section 2). Second, it allows us to overcome the factor $1/\varepsilon$ in front of the source term Q. Indeed, the linear estimate in Theorem 3.10 is applied only to high-frequencies and weighted time derivatives $(\varepsilon\partial_t)^m$. Hence, the fact that the source term is assumed to be neither of high frequency nor have rapid time oscillations allows us to recover the lost factor of ε in the nonlinear estimates. Note that, in the combustion case, the assumptions on the source term Q may be verified directly from the equations. Also, we mention that the L^2 norm of (p,v) will later be estimated in section 4 under an additional hypothesis.

NOTATION 3.7. *From now on, we consider an integer* $s>1+d/2$, *a fixed time* $0<T\leqslant 1$, *a fixed triple of parameters* $a=(\varepsilon,\mu,\kappa)\in A$, *a bound* M_0, *a fixed smooth*

solution $U = (p, v, \theta) \in C^\infty([0,T]; H^\infty(\mathbb{R}^d))$ *of* (1.4) *with initial data satisfying* (3.1), *and we set*

$$\Omega := \|U\|_{\mathcal{X}^s_a(T)}\,.$$

With these notations, Proposition 3.6 *can be formulated concisely as follows: if* $d \neq 2$, *there exist constants* C_0 *depending only on* M_0 *and* C *depending only on* Ω *such that*

$$\Omega \leqslant C_0 e^{(\sqrt{T}+\varepsilon)C}.$$

Hereafter, we use the notations $\phi := (\theta, \varepsilon p)$ *and* $\nu := \sqrt{\mu+\kappa}$.

NOTATION 3.8. *For later application to the nonlinear case when* $Q = F(Y)$ *for some unknown function* Y, *we also give precise estimates in terms of norms of* Q. *For our purposes, the requested norm is the following:*

$$\Sigma := \sum_{0\leqslant m\leqslant s} \big\|(I-(\varepsilon\nu)^2\Delta)^{-m/2}\big(\varepsilon(\partial_t + v\cdot\nabla)\big)^m Q\big\|_{L^\infty(0,T;H^{s+1-m}_\nu)}. \tag{3.3}$$

Remark 3.9. To use nonlinear estimates, it is easier to work in Banach algebras. If $d \geqslant 3$, Proposition 2.2 shows that we can supplement the $\mathcal{X}^s_a$ estimates with L^∞ estimates for the velocity: it suffices to prove (3.2) with $C(\Omega_a(T))$ replaced by $C(\Omega^+_a(T))$, where $\Omega^+_a(T) := \Omega_a(T) + \|v\|_{L^\infty((0,T)\times\mathbb{R}^d)}$. Similarly, if $d \geqslant 3$, all the estimates involving the source term Q remain valid with Σ replaced by

$$\sum_{0\leqslant m\leqslant s} \big\|(I-(\varepsilon\nu)^2\Delta)^{-m/2}(\varepsilon\partial_t)^m Q\big\|_{L^\infty(0,T;H^{s+1-m}_\nu)}.$$

Step 3: An energy estimate for linearized equations. A key step in the analysis is to estimate the solution $(\widetilde{p},\widetilde{v},\widetilde{\theta})$ of linearized equations. As alluded to above, a notable fact is that we can see unsigned large terms $\varepsilon^{-1}f^\varepsilon(t,x)$ in the equations for p and v as source terms provided that: (1) they do not convey fast oscillations in time $\partial_t f^\varepsilon = O(1)$; (2) it does not imply a loss of derivatives. To be more precise, in the nonlinear estimates, we will see the term $\varepsilon^{-1}\chi_1(\phi)Q$ as a source term. Similarly, we can see terms of the form $\varepsilon^{-1}F(\varepsilon p, \theta, \sqrt{\kappa}\nabla\theta)$ as source terms. As a result, it is sufficient to consider the following linearized system:

$$\begin{cases} g_1(\phi)(\partial_t\widetilde{p} + v\cdot\nabla\widetilde{p}) + \dfrac{1}{\varepsilon}\operatorname{div}\widetilde{v} - \dfrac{\kappa}{\varepsilon}\operatorname{div}(k_1(\phi)\nabla\widetilde{\theta}) = F_1, \\ g_2(\phi)(\partial_t\widetilde{v} + v\cdot\nabla\widetilde{v}) + \dfrac{1}{\varepsilon}\nabla\widetilde{p} - \mu B_2(\phi,\partial_x)\widetilde{v} = F_2, \\ g_3(\phi)(\partial_t\widetilde{\theta} + v\cdot\nabla\widetilde{\theta}) + G(\phi,\nabla\phi)\cdot\widetilde{v} + \operatorname{div}\widetilde{v} - \kappa\chi_3(\phi)\operatorname{div}(k(\phi)\nabla\widetilde{\theta}) = F_3, \end{cases} \tag{3.4}$$

where the unknown $(\widetilde{p},\widetilde{v},\widetilde{\theta})$ is a smooth function of $(t,x) \in [0,T]\times\mathbb{R}^d$.

The following result establishes estimates on

$$\begin{aligned} \|(\widetilde{p},\widetilde{v},\widetilde{\theta})\|_{a,T} := {} & \|(\widetilde{p},\widetilde{v})\|_{L^\infty_T(H^1_{\varepsilon\nu})} + \|\widetilde{\theta}\|_{L^\infty_T(H^1_\nu)} \\ & + \sqrt{\kappa}\|\nabla\widetilde{\theta}\|_{L^2_T(H^1_\nu)} + \sqrt{\mu}\,\|\nabla\widetilde{v}\|_{L^2_T(H^1_{\varepsilon\nu})} \\ & + \sqrt{\mu+\kappa}\,\|\nabla\widetilde{p}\|_{L^2_T(L^2)} + \sqrt{\kappa}\,\|\operatorname{div}\widetilde{v}\|_{L^2_T(L^2)}\,, \end{aligned} \tag{3.5}$$

in terms of the norm $\|(\widetilde{p},\widetilde{v},\widetilde{\theta})\|_{a,0} := \|(\widetilde{p},\widetilde{v})(0)\|_{H^1_{\varepsilon\nu}} + \|\widetilde{\theta}(0)\|_{H^1_\nu}$ of the data.

THEOREM 3.10. *Let $d \geqslant 1$ and assume that G, k_1, and k_3 are C^∞ functions such that, for all $(\vartheta, \wp) \in \mathbb{R}^2$, $0 < k_1(\vartheta, \wp) < \chi_3(\vartheta, \wp)k(\vartheta)$. Set*

$$R_0 := \|\phi(0)\|_{H^{s-1}}, \quad R := \sup_{t\in[0,T]} \big\|(\phi, \partial_t\phi + v\cdot\nabla\phi, \nabla\phi, \nu\nabla^2\phi, \nabla v)(t)\big\|_{H^{s-1}}.$$

There exist constants C_0 depending only on R_0 and C depending only on R such that,

$$\|(\widetilde{p}, \widetilde{v}, \widetilde{\theta})\|_{a,T} \leqslant C_0 e^{TC} \|(\widetilde{p}_0, \widetilde{v}_0, \widetilde{\theta}_0)\|_{a,0} + C\int_0^T \|(F_1, F_2)\|_{H^1_{\varepsilon\nu}} + \|F_3\|_{H^1_\nu}\, dt.$$

In [1] we established the previous theorem with R_0 and R replaced by

$$R_0' = \|\phi(0)\|_{L^\infty}, \quad R' = \sup_{t\in[0,T]} \big\|(\phi, \partial_t\phi, v, \nabla\phi, \nu\nabla^2\phi, \nabla v)(t)\big\|_{L^\infty}.$$

To prove the above variant, we need only check two facts. First, in the proof of Theorem 4.3 in [1], the terms $\partial_t\phi$ and v always come together within terms involving the convective derivative $\partial_t\phi + v\cdot\nabla\phi$.

Second, we have to verify that the $L^\infty_{t,x}$ norms of the coefficients $(g_i(\phi), \dots)$ are estimated by constants of the form C_0e^{TC}. In [1] we used the estimate

$$\sup_{t\in[0,T]} \|F(\phi(t))\|_{L^\infty} \leqslant \|F(\phi(0))\|_{L^\infty} + T\sup_{t\in[0,T]} \|\partial_t F(\phi(t))\|_{L^\infty} \leqslant C_0' + TC',$$

for some constants depending only on R_0' and R'. Here, based on an usual estimate for hyperbolic equations, we can prove a similar bound.

LEMMA 3.11. *Let $F \in C^\infty(\mathbb{R}^2)$ be such that $F(0) = 0$. There exist constants C_0 depending only on R_0 and C depending only on R such that, for all $t \in [0,T]$, $\|F(\phi(t))\|_{H^{s-1}} \leqslant C_0e^{TC}$.*

Proof. Since $s - 1 > d/2$, the Moser's estimates (2.2) and (2.4) imply that there exists a function $\mathcal{C}$ depending only on the function F such that

$$\begin{aligned}\|(\partial_t + v\cdot\nabla)F(\phi)\|_{H^{s-1}} &\leqslant \big(1 + \|F'(\phi) - F'(0)\|_{H^{s-1}}\big)\, \|(\partial_t + v\cdot\nabla)\phi(t)\|_{H^{s-1}},\\ &\leqslant \mathcal{C}(\|(\phi, \partial_t\phi + v\cdot\nabla\phi)\|_{H^{s-1}}) \leqslant \mathcal{C}(R),\end{aligned}$$

and $\|F(\phi(0))\|_{H^{s-1}} \leqslant \mathcal{C}(\|\phi(0)\|_{H^{s-1}})$.

Hence, the desired estimate follows from the following estimate: there exists a constant V depending only on $\|\nabla v\|_{L^\infty_T H^{s-1}}$ such that

$$\sup_{t\in[0,T]} \|F(\phi(t))\|_{H^{s-1}} \leqslant \|F(\phi(0))\|_{H^{s-1}} + TV\sup_{t\in[0,T]} \|(\partial_t + v\cdot\nabla)F(\phi(t))\|_{H^{s-1}}.$$

To prove this result we set $\widetilde{u} := \partial_x^\alpha F(\phi)$, where $\alpha \in \mathbb{N}^d$ is such that $|\alpha| \leqslant s-1$. Then $\widetilde{u}$ solves

$$\partial_t u + v\cdot\nabla u = f := \partial_x^\alpha\big((\partial_t + v\cdot\nabla)F(\phi)\big) + [v, \partial_x^\alpha]\cdot\nabla F(\phi).$$

Since $s - 1 > d/2$, the product rule (2.3) implies that

$$\begin{aligned}\|[v, \partial_x^\alpha]\cdot\nabla F(\phi)\|_{L^2} &\lesssim \sum_{\beta+\gamma=\alpha,\ \beta>0} \|\partial_x^\beta v\partial_x^\gamma\nabla F(\phi)\|_{L^2}\\ &\lesssim \sum_{\beta+\gamma=\alpha,\ \beta>0} \|\partial_x^\beta v\|_{H^{s-1-(|\beta|-1)}}\, \|\partial_x^\gamma\nabla F\|_{H^{s-1-(|\gamma|+1)}},\end{aligned}$$

hence, $\|f\|_{L^2} \lesssim \|(\partial_t + v\cdot\nabla)F(\phi)\|_{H^{s-1}} + \|\nabla v\|_{H^{s-1}}\, \|F(\phi)\|_{H^{s-1}}$.

We next use an integration by parts argument yielding

$$\frac{d}{dt}\|\widetilde{u}\|_{L^2}^2 \leqslant (1+\|\operatorname{div} v\|_{L^\infty})\,\|\widetilde{u}\|_{L^2}^2 + \|f\|_{L^2}^2\,.$$

Gronwall's lemma concludes the proof. □

Step 4: High frequency estimates. We begin by estimating the high frequency component

$$\Omega^{\mathrm{HF}} := \|(I-J_{\varepsilon\nu})U\|_{\mathcal{X}_a^s(T)}\,,$$

where $\{J_h \,|\, h\in[0,1]\}$ is a Friedrichs' mollifier: $J_h = \jmath(hD_x)$ is the Fourier multiplier with symbol $\jmath(h\xi)$, where $\jmath$ is a C^∞ function of $\xi\in\mathbb{R}^d$ satisfying

$$0\leqslant \jmath\leqslant 1,\quad \jmath(\xi)=1 \text{ for } |\xi|\leqslant 1,\quad \jmath(\xi)=0 \text{ for } |\xi|\geqslant 2,\quad \jmath(\xi)=\jmath(-\xi)\,.$$

PROPOSITION 3.12. *Let $d\geqslant 1$. There exist constants C_0 depending only on M_0 and C depending only on Ω, such that*

$$\Omega^{\mathrm{HF}} \leqslant C_0 e^{\sqrt{T}C} + \sqrt{T}C\,\|Q\|_{L^\infty_T(H^{s+1}_\nu)}\,. \tag{3.6}$$

Proof. Introduce $P := (I-J_{\varepsilon\nu})\Lambda^s$ and $\widetilde{U} := (Pp, Pv, P\theta)$. Then, $\widetilde{U}$ satisfies system (3.4) with

$$k_1(\phi) := \chi_1(\phi)k(\theta),\quad G(\phi,\nabla\phi) := g_3(\phi)\nabla\theta,$$

and $F=(F_1,F_2,F_3)^T := f_{\mathrm{HF}}+f_Q+f_\chi$, where

$$f_Q := \begin{pmatrix} \varepsilon^{-1}P\big(\chi_1(\phi)Q\big)\\ 0\\ P\big(\chi_3(\phi)Q\big)\end{pmatrix},\quad f_\chi := \begin{pmatrix} -\kappa\varepsilon^{-1}\nabla\chi_1(\phi)\cdot\big(k(\theta)\nabla\widetilde{\theta}\big)\\ 0\\ 0\end{pmatrix},$$

and f_{HF} is given by

$$\begin{aligned}
f_{1,\mathrm{HF}} &= \big[g_1(\phi),P\big](\partial_t+v\cdot\nabla)p + g_1(\phi)\big[v,P\big]\cdot\nabla p \;-\frac{\kappa}{\varepsilon}\big[B_1(\phi,\partial_x),P\big]\theta,\\
f_{2,\mathrm{HF}} &= \big[g_2(\phi),P\big](\partial_t+v\cdot\nabla)v + g_2(\phi)\big[v,P\big]\cdot\nabla v \;-\mu\big[B_2(\phi,\partial_x),P\big]v,\\
f_{3,\mathrm{HF}} &= \big[g_3(\phi),P\big](\partial_t+v\cdot\nabla)\theta + g_3(\phi)\big\{v;P\big\}\cdot\nabla\theta - \kappa\big[B_3(\phi,\partial_x),P\big]\theta,
\end{aligned}$$

where $B_i(\phi,\partial_x)=\chi_i(\phi)\operatorname{div}(k(\theta)\nabla\cdot)$ $(i=1,3)$, $[A,B]=AB-BA$, and

$$\big\{v;P\big\}\cdot\nabla\theta := v\cdot\nabla P\theta + (Pv)\cdot\nabla\theta - P(v\cdot\nabla\theta).$$

Estimate for f_{HF}. We use the following analogue of Lemma 5.3 in [1]: there exists a constant $K=K(d,s)$ such that

$$\begin{aligned}
\big\|\big[f,P\big]u\big\|_{H^1_{\varepsilon\nu}} &\leqslant \varepsilon\nu K\,\|\nabla f\|_{L^\infty}\,\|u\|_{H^s} + \varepsilon\nu K\,\|\nabla f\|_{H^s}\,\|u\|_{L^\infty},\\
\big\|\big[f,P\big]u\big\|_{H^1_{\nu}} &\lesssim \nu K\,\|\nabla f\|_{L^\infty}\,\|u\|_{H^s} + \nu K\,\|\nabla f\|_{H^s}\,\|u\|_{L^\infty}.
\end{aligned}$$

The fact that the right-hand side only involves ∇f follows from the most simple of all the sharp commutator estimates established in [17]: for all $s>1+d/2$ and all Fourier

multiplier $A(D_x) \in \operatorname{Op} S^s_{1,0}$, there exists a constant K such that, for all $f \in H^s(\mathbb{R}^d)$ and all $u \in H^s(\mathbb{R}^d)$,

$$\|[f, A(D_x)]u\|_{L^2} \leqslant K \|\nabla f\|_{L^\infty} \|u\|_{H^{s-1}} + K \|\nabla f\|_{H^{s-1}} \|u\|_{L^\infty}. \tag{3.7}$$

As in [1], from this and the usual nonlinear estimates (2.2) and (2.4), it can be verified that there exists a generic function $\mathcal{C}$ (depending only on parameters that are considered fixed) such that,

$$\begin{aligned}
\|f_{1,\mathrm{HF}}\|_{H^1_{\varepsilon\nu}} &\leqslant \mathcal{C}\big(\|(\theta, \varepsilon p, \varepsilon v)\|_{H^{s+1}_\nu}\big)\{1 + \|\varepsilon(\partial_t + v\cdot\nabla)p\|_{H^s_\nu} + \kappa \|\theta\|_{H^{s+2}}\},\\
\|f_{2,\mathrm{HF}}\|_{H^1_{\varepsilon\nu}} &\leqslant \mathcal{C}\big(\|(\theta, \varepsilon p, \varepsilon v)\|_{H^{s+1}_\nu}\big)\{1 + \|\varepsilon(\partial_t + v\cdot\nabla)v\|_{H^s_\nu} + \mu \|\varepsilon v\|_{H^{s+2}}\},\\
\|f_{3,\mathrm{HF}}\|_{H^1_\nu} &\leqslant \mathcal{C}\big(\|(\theta, \varepsilon p, \varepsilon v)\|_{H^{s+1}_\nu}\big)\{1 + \|(\partial_t + v\cdot\nabla)\theta\|_{H^s_\nu} + \kappa \|\theta\|_{H^{s+2}}\}.
\end{aligned}$$

Set $\psi = (\theta, \varepsilon p, \varepsilon v)$. The key point is that

$$\begin{aligned}
&\|(\partial_t + v\cdot\nabla)\psi\|_{H^s_\nu}\\
&\quad\leqslant \mathcal{C}(\|\psi\|_{H^{s+1}_\nu})\big\{1 + \big\|(\nu\nabla p, \nu \operatorname{div} v, \varepsilon\mu\nabla^2 v, \kappa\nabla^2\theta)\big\|_{H^s} + \|Q\|_{H^s_\nu}\big\}.
\end{aligned} \tag{3.8}$$

This estimate differs from the one that appears in Lemma 5.14 in [1] in that the right-hand side does not involve v itself but only its derivatives. Yet, as the reader can verify, the same proof applies since we do not estimate $\partial_t\psi$, but instead $\partial_t\psi + v\cdot\nabla\psi$.

Estimate for f_Q and f_χ. By using the elementary estimate

$$\|(I - J_{\varepsilon\nu})u\|_{H^{\sigma+1}_{\varepsilon\nu}} \lesssim \varepsilon\nu \|u\|_{H^{\sigma+1}},$$

we find that

$$\frac{1}{\varepsilon}\|P(\chi_1(\phi)Q)\|_{H^1_{\varepsilon\nu}} + \|P(\chi_3(\phi)Q)\|_{H^1_\nu} \leqslant \|\chi_1(\phi)Q\|_{H^{s+1}_\nu} + \|\chi_3(\phi)Q\|_{H^{s+1}_\nu}.$$

The tame estimates (2.2) and (2.4) (see also Lemmas 5.5 and 5.6 in [1]) imply that

$$\|\chi_i(\phi)Q\|_{H^{s+1}_\nu} \lesssim (1 + \|\chi_i(\phi) - \chi_i(0)\|_{H^{s+1}_\nu})\,\|Q\|_{H^{s+1}_\nu} \lesssim \mathcal{C}(\|\phi\|_{H^{s+1}_\nu})\,\|Q\|_{H^{s+1}_\nu}$$

so that $\|f_{1,Q}\|_{L^\infty_T(H^1_{\varepsilon\nu})} + \|f_{3,Q}\|_{L^\infty_T(H^1_\nu)} \leqslant C\|Q\|_{L^\infty_T(H^{s+1}_\nu)}$. The technique for estimating f_χ is similar; we find that $\|f_{1,\chi}\|_{L^\infty_T(H^1_{\varepsilon\nu})} \leqslant C$.

By definition of $\|\cdot\|_{\mathcal{X}^s_a(T)}$, the previous estimates imply that there exists a constant C depending only on Ω such that

$$\begin{aligned}
\int_0^T \|(F_1, F_2)\|_{H^1_{\varepsilon\nu}} + \|F_3\|_{H^1_\nu}\,dt &\leqslant \sqrt{T}\bigg(\int_0^T \|(F_1, F_2)\|^2_{H^1_{\varepsilon\nu}} + \|F_3\|^2_{H^1_\nu}\,dt\bigg)^{1/2}\\
&\leqslant \sqrt{T}C + \sqrt{T}C\,\|Q\|_{L^\infty_T(H^{s+1}_\nu)}.
\end{aligned}$$

From here we can parallel the rest of the argument of section 5 in [1], to prove that $\|(Pp, Pv, P\theta)\|_{a,T} \leqslant C_0 \exp(\sqrt{T}C) + \sqrt{T}C\,\|Q\|_{L^\infty_T(H^{s+1}_\nu)}$, where the norm $\|\cdot\|_{a,T}$ is as defined in (3.5). Since $\Omega^{\mathrm{HF}} \lesssim \|(Pp, Pv, P\theta)\|_{a,T}$, this completes the proof. ∎

Step 5: Low frequency estimates. The following step is to estimate the low frequency part of the fast components:

$$\Omega^{\mathrm{LF}} := \|\operatorname{div} J_{\varepsilon\nu} v\|_{L^\infty_T(H^{s-1})} + \nu \|\operatorname{div} J_{\varepsilon\nu} v\|_{L^2_T(H^s)} + \|\nabla J_{\varepsilon\nu} p\|_{L^\infty_T(H^{s-1})} + \nu \|\nabla J_{\varepsilon\nu} p\|_{L^2_T(H^s)}.$$

PROPOSITION 3.13. *Let $d \geqslant 1$. There exist constants C_0 depending only on M_0, C depending only on Ω, and C' depending only on $\Omega + \Sigma$, such that*

$$\Omega^{\mathrm{LF}} \leqslant C_0 e^{(\sqrt{T}+\varepsilon)C} + \sqrt{T}C'. \tag{3.9}$$

By contrast with the high frequency regime, the estimate (3.9) cannot be obtained from the L^2 estimates by an elementary argument using differentiation of the equations (see [20, 24]). To overcome this problem, we first give estimates for the time derivatives, and next we use the special structure of the equations to estimate the spatial derivatives.

For the case of greatest physical interest ($d = 3$), the proof given in [1] applies with only minor changes. Indeed, as alluded to in Remark 3.9, it suffices to check that all the estimates involving $\|v\|_{H^s}$ remain valid with $\|v\|_{H^s}$ replaced by $\|v\|_{L^\infty} + \|\nabla v\|_{H^{s-1}}$. Yet, if $d \leqslant 2$, because of the lack of L^2 estimates for the velocity, we cannot use the time derivatives. For this problem, we use an idea introduced by Secchi in [25]. Namely, we replace ∂_t by the convective derivative

$$D_v := \partial_t + v \cdot \nabla.$$

For the reader's convenience, we indicate how to adapt the three main calculus inequalities in [1] when ∂_t is replaced by D_v.

First, to localize in the low frequency region we use the following commutator estimate. The thing of interest is the gain of an extra factor ε.

LEMMA 3.14. *Given $s > 1 + d/2$, there exists a constant K such that for all $\varepsilon \in [0,1]$, all $\nu \in [0,2]$, all $T > 0$, all $m \in \mathbb{N}$ such that $1 \leqslant m \leqslant s$, and all f, u, and v in $C^\infty([0,T]; H^\infty(\mathbb{D}))$,*

$$\big\| [f, J_{\varepsilon\nu}(\varepsilon D_v)^m] u \big\|_{H^{s-m+1}_{\varepsilon\nu}} \leqslant K\varepsilon \Big\{ \|f\|_{H^s} + \sum_{\ell=0}^{m-1} \|\Lambda^{-\ell}_{\varepsilon\nu} (\varepsilon D_v)^\ell D_v f\|_{H^{s-1-\ell}} \Big\} \times \Big\{ \|\Lambda^{-m}_{\varepsilon\nu} (\varepsilon D_v)^m u\|_{H^{s-m}_\nu} + \sum_{\ell=0}^{m-1} \|\Lambda^{-\ell}_{\varepsilon\nu} (\varepsilon D_v)^\ell u\|_{H^{s-1-\ell}} \Big\},$$

where $\Lambda^\sigma_{\varepsilon\nu} := (I - (\varepsilon\nu)^2 \Delta)^{\sigma/2}$.

To apply the previous lemma, we need estimates of the coefficients f and $D_v f$. Since, for system (1.4), the coefficients are functions of the slow variable $(\theta, \varepsilon p, \varepsilon v)$, the main estimates are the following.

LEMMA 3.15. *Let $s > 1 + d/2$ be an integer. There exists a function $\mathcal{C}(\cdot)$ such that, for all $a = (\varepsilon, \mu, \kappa) \in A$, all $T > 0$, and all smooth solution $(p, v, \theta) \in C^\infty([0,T]; H^\infty(\mathbb{D}))$ of (1.4), if $\nu \in [(\mu + \kappa)/2, 2]$, then the function Ψ defined by*

$$\Psi := \big(\psi, D_v\psi, \nabla\psi\big) \quad \text{where} \quad \psi := (\theta, \varepsilon p, \varepsilon v)$$

satisfies

$$\sum_{0\leqslant\ell\leqslant s}\|\Lambda_{\varepsilon\nu}^{-\ell}(\varepsilon D_v)^\ell\Psi\|_{H^{s-\ell-1}}\leqslant\mathcal{C}\big(\|\Psi\|_{H^{s-1}}+\Sigma\big),\tag{3.10}$$

$$\sum_{0\leqslant\ell\leqslant s}\|\Lambda_{\varepsilon\nu}^{-\ell}(\varepsilon D_v)^\ell\Psi\|_{H^{s-\ell}_\nu}\leqslant\mathcal{C}\big(\|\Psi\|_{H^{s-1}}+\Sigma\big)\,\|\Psi\|_{H^s_\nu},\tag{3.11}$$

where Σ *is as defined in* (3.3).

Once this is granted, we are in position to estimate the commutator of the equations (1.4) and $\mathcal{P}:=J_{\varepsilon\nu}(\varepsilon D_v)^s$:

$$\begin{aligned}
f_{1,\mathrm{LF}}&=\big[g_1(\phi),\mathcal{P}\big]D_vp+g_1(\phi)\big[v,\mathcal{P}\big]\cdot\nabla p-\frac{\kappa}{\varepsilon}\big[B_1(\phi,\partial_x),\mathcal{P}\big]\theta,\\
f_{2,\mathrm{LF}}&=\big[g_2(\phi),\mathcal{P}\big]D_vv+g_2(\phi)\big[v,\mathcal{P}\big]\cdot\nabla v-\mu\big[B_2(\phi,\partial_x),\mathcal{P}\big]v,\\
f_{3,\mathrm{LF}}&=\big[g_3(\phi),\mathcal{P}\big]D_v\theta+g_1(\phi)\big[v,\mathcal{P}\big]\cdot\nabla\theta-\kappa\big[B_3(\phi,\partial_x),\mathcal{P}\big]\theta.
\end{aligned}$$

It is found that

$$\|f_{1,\mathrm{LF}}\|_{H^1_{\varepsilon\nu}}+\|f_{2,\mathrm{LF}}\|_{H^1_{\varepsilon\nu}}+\|f_{3,\mathrm{LF}}\|_{H^1_\nu}\leqslant(1+\|\Psi\|_{H^s_\nu})\mathcal{C}(\|\Psi\|_{H^{s-1}}+\Sigma).$$

Note that Ψ is estimated by means of (3.8).

As in the high frequency regime, we have to estimate source terms of the form $\varepsilon^{-1}\mathcal{P}F(\Psi,Q)$. The fact that these large source terms cause no difficulty comes from the fact that $\varepsilon^{-1}J_{\varepsilon\nu}(\varepsilon D_v)^sF(\Psi,Q)=J_{\varepsilon\nu}(\varepsilon D_v)^{s-1}D_vF(\Psi,Q)$ together with $D_vF(\Psi,Q)=O(1)$ (the norm Σ introduced in (3.3) is the requested norm to give this statement a precise meaning).

With these results in hand, one can estimate $J_{\varepsilon\nu}(\varepsilon D_v)^s(p,v,\theta)$ by means of Theorem 3.10. Next, we estimate for $\operatorname{div}J_{\varepsilon\nu}v$ and $\nabla J_{\varepsilon\nu}p$ from the estimate of $J_{\varepsilon\nu}(\varepsilon D_v)^s(p,v,\theta)$ by means of the following induction argument.

LEMMA 3.16. *Set* $\|u\|_{\mathcal{K}^\sigma_\nu(T)}:=\|u\|_{L^\infty_T(H^{\sigma-1})}+\nu\,\|u\|_{L^2_T(H^\sigma)}$.

Let $\widetilde{U}:=(\widetilde{p},\widetilde{v},\widetilde{\theta})$ *solve*

$$\begin{cases}
g_1(\phi)(\partial_t\widetilde{p}+v\cdot\nabla\widetilde{p})+\varepsilon^{-1}\operatorname{div}\widetilde{v}-\kappa\varepsilon^{-1}\chi_1(\phi)\operatorname{div}(k(\theta)\nabla\widetilde{\theta})=f_1,\\
g_2(\phi)(\partial_t\widetilde{v}+v\cdot\nabla\widetilde{v})+\varepsilon^{-1}\nabla\widetilde{p}-\mu B_2(\phi,\partial_x)\widetilde{v}=f_2,\\
g_3(\phi)(\partial_t\widetilde{\theta}+v\cdot\nabla\widetilde{\theta})+\operatorname{div}\widetilde{v}-\kappa\chi_3(\phi)\operatorname{div}(k(\theta)\nabla\widetilde{\theta})=f_3.
\end{cases}\tag{3.12}$$

If support of the Fourier transform of $\widetilde{U}$ *is included in the ball* $\{|\xi|\leqslant 2/\varepsilon\nu\}$, *then there exist constant* C_0 *depending only on* M_0 *and* C *depending only on* Ω *such that, for all* $\sigma\in[1,s]$,

$$\begin{aligned}
&\|\nabla\widetilde{p}\|_{\mathcal{K}^\sigma_\nu(T)}+\|\operatorname{div}\widetilde{v}\|_{\mathcal{K}^\sigma_\nu(T)}\\
&\quad\leqslant\widetilde{C}\,\|(\varepsilon D_v)\widetilde{p}\,\|_{\mathcal{K}^\sigma_\nu(T)}+\widetilde{C}\,\|(\varepsilon D_v)\operatorname{div}\widetilde{v}\|_{\mathcal{K}^{\sigma-1}_\nu(T)}\\
&\qquad+\widetilde{C}\,\|\nabla\widetilde{p}\,\|_{L^\infty_T(L^2)}+\widetilde{C}\,\|\widetilde{\theta}(0)\|_{H^{\sigma+1}_\nu}+\varepsilon C\,\|\mu\widetilde{v}\|_{\mathcal{K}^{\sigma+1}_\nu(T)}\\
&\qquad+\varepsilon C\,\|(f_1,f_2)\|_{\mathcal{K}^\sigma_\nu(T)}+\nu\widetilde{C}\,\|f_3\|_{L^2_T(H^\sigma)},
\end{aligned}\tag{3.13}$$

where $\widetilde{C}:=C_0e^{(\sqrt{T}+\varepsilon)C}$.

Step 6: Estimates for the slow components. To complete the proof of (3.2), it remains to estimate $\operatorname{curl} v$ and θ. Yet, this is not straightforward. Following Métivier and Schochet [20], we begin by estimating $\operatorname{curl}(\gamma v)$ for some appropriate positive weight $\gamma = \Gamma(\theta, \varepsilon p)$.

LEMMA 3.17. *Let $d \geqslant 1$. There exist constants C_0 depending only on M_0 and C depending only on Ω, and there exists a function $\Gamma \in C^\infty(\mathbb{R}^2)$ such that, with $\gamma = \Gamma(\theta, \varepsilon p)$, there holds*

$$\|\operatorname{curl}(\gamma v)\|_{L^\infty_T(H^{s-1})} + \sqrt{\mu}\,\|\operatorname{curl}(\gamma v)\|_{L^2_T(H^s)} \leqslant C_0 e^{\sqrt{T}C} + \sqrt{T}C\,\|Q\|_{L^\infty_T(H^{s+1}_\nu)}.$$

LEMMA 3.18. *Let $d \geqslant 1$. There exist constants C_0 depending only on M_0 and C depending only on Ω, such that*

$$\|J_{\varepsilon\nu}\theta\|_{L^\infty_T(H^{s+1}_\nu)} + \sqrt{\kappa}\,\|J_{\varepsilon\nu}\theta\|_{L^2_T(H^{s+2}_\nu)} \leqslant C_0 e^{\sqrt{T}C} + \sqrt{T}C\,\|Q\|_{L^\infty_T(H^{s+1}_\nu)}.$$

The proofs of Lemmas 3.17 and 3.18 follow from a close inspection of the proofs of Lemmas 6.25 and 6.26 in [1]. We mention that this is where we use the function F of Assumption (H2) in section 1.2 (γ is related to the fluid entropy).

LEMMA 3.19. *Assume $d \geqslant 3$. There exist constants C_0 depending only on M_0 and C depending only on Ω such that, with $\gamma_0 = \Gamma(\theta_0, \varepsilon p_0)$, where Γ is as above, there holds*

$$\|\operatorname{curl}(\gamma_0 v)\|_{L^\infty_T(H^{s-1})} + \sqrt{\mu}\,\|\operatorname{curl}(\gamma_0 v)\|_{L^2_T(H^s)} \leqslant C_0 e^{\sqrt{T}C} + \sqrt{T}C\,\|Q\|_{L^\infty_T(H^{s+1}_\nu)}.$$

Proof. Set $\widetilde{\gamma} := \gamma - \gamma_0$. By Lemma 3.17, all we need to prove is that

$$\|\operatorname{curl}(\widetilde{\gamma} v)\|_{L^\infty_T(H^{s-1})} + \sqrt{\mu}\,\|\operatorname{curl}(\widetilde{\gamma} v)\|_{L^2_T(H^s)} \leqslant \sqrt{T}C + \sqrt{T}C\,\|Q\|_{L^\infty_T(H^{s+1}_\nu)}. \tag{3.14}$$

To do so, we claim that $\widetilde{\gamma}$ is small for small times:

$$\|\widetilde{\gamma}\|_{L^\infty_T(H^s)} + \nu\,\|\widetilde{\gamma}\|_{L^2_T(H^{s+1})} \leqslant \sqrt{T}C + \sqrt{T}C\,\|Q\|_{L^\infty_T(H^{s+1}_\nu)}. \tag{3.15}$$

Let us assume this and continue the proof.

We have to estimate $\operatorname{curl}(\widetilde{\gamma} v) = \widetilde{\gamma}\operatorname{curl} v + (\nabla\widetilde{\gamma}) \times v$. By combining the Cauchy–Schwarz estimate with the usual product rule (2.3) and the product rule (2.7), we find that

$$\begin{aligned}
\|\widetilde{\gamma}\operatorname{curl} v\|_{L^\infty_T(H^{s-1})} &\leqslant \|\widetilde{\gamma}\|_{L^\infty_T(H^{s-1})}\,\|\nabla v\|_{L^\infty_T(H^{s-1})},\\
\sqrt{\mu}\,\|\widetilde{\gamma}\operatorname{curl} v\|_{L^2_T(H^s)} &\leqslant \|\widetilde{\gamma}\|_{L^\infty_T(H^s)}\,\|\sqrt{\mu}\nabla v\|_{L^2_T(H^s)},\\
\|\nabla\widetilde{\gamma} \times v\|_{L^\infty_T(H^{s-1})} &\leqslant \|\widetilde{\gamma}\|_{L^\infty_T(H^s)}\,\|\nabla v\|_{L^\infty_T(H^{s-1})},\\
\sqrt{\mu}\,\|\nabla\widetilde{\gamma} \times v\|_{L^2_T(H^s)} &\leqslant \|\sqrt{\mu}\widetilde{\gamma}\|_{L^2_T(H^{s+1})}\,\|\nabla v\|_{L^\infty_T(H^{s-1})}.
\end{aligned}$$

The claim (3.15) then yields the desired bound (3.14).

We now have to prove the claim (3.15). We first note that

$$\begin{aligned}
\nu\,\|\widetilde{\gamma}\|_{L^2_T(H^{s+1})} &\leqslant \nu\sqrt{T}\,\|\widetilde{\gamma}\|_{L^\infty_T(H^{s+1})}\\
&\leqslant \nu\sqrt{T}\mathcal{C}(\|(\theta, \varepsilon p)\|_{L^\infty_T(L^\infty_x)})(1 + \|(\theta, \varepsilon p)\|_{L^\infty_T(H^{s+1})})\\
&\leqslant \sqrt{T}\mathcal{C}(\|(\theta, \varepsilon p)\|_{L^\infty_T(H^{s+1}_\nu)}) \leqslant \sqrt{T}C.
\end{aligned}$$

To prove the second half of (3.15), we verify that, directly from the definitions, $\widetilde{\gamma}$ satisfies an equation of the form $\partial_t\widetilde{\gamma}+v\cdot\nabla\widetilde{\gamma}=f$ with f bounded in $L^2(0,T;H^s(\mathbb{R}^d))$ by a constant depending only on $\Omega+\|Q\|_{L^\infty_T(H^{s+1}_\nu)}$. Then, we apply the above mentioned estimate for hyperbolic equations:

$$\|\widetilde{\gamma}\|_{L^\infty_T(H^s)}\lesssim e^{TV}\,\|\widetilde{\gamma}(0)\|_{H^s}+\int_0^T e^{(T-t)V}\,\|f\|_{H^s}\,dt, \tag{3.16}$$

where $V=K\int_0^T\|\nabla v\|_{H^{s-1}}\,dt$ with $K=K(s,d)$. Since $\widetilde{\gamma}(0)=0$, by applying the Cauchy–Schwarz inequality, it is found that the $L^\infty_T(H^s)$ norm of $\widetilde{\gamma}$ is estimated by $\sqrt{T}e^{TV}\,\|f\|_{L^2_T(H^s)}$, thereby obtaining the claim. □

Step 7: Closed set of estimates. To complete the proof of Proposition 3.6, it remains to check that we have proved a closed set of estimates.

The obvious estimate $\|u\|_{H^\sigma}\leqslant\|J_{\varepsilon\nu}u\|_{H^\sigma}+\|(I-J_{\varepsilon\nu})u\|_{H^\sigma}$ implies that

$$\|(\nabla p,\operatorname{div}v)\|_{L^\infty_T(H^{s-1})}+\sqrt{\mu+\kappa}\,\|(\nabla p,\operatorname{div}v)\|_{L^2_T(H^s)}\lesssim\Omega_{\mathrm{LF}}+\Omega_{\mathrm{HF}},$$

and, similarly, $\|\theta\|_{L^\infty_T(H^{s+1}_\nu)}+\sqrt{\kappa}\,\|\nabla\theta\|_{L^2_T(H^{s+1}_\nu)}$ is estimated by

$$\|J_{\varepsilon\nu}\theta\|_{L^\infty_T(H^{s+1}_\nu)}+\sqrt{\kappa}\,\|J_{\varepsilon\nu}\nabla\theta\|_{L^2_T(H^{s+1}_\nu)}+\Omega_{\mathrm{HF}}.$$

The estimate $\|\varepsilon u\|_{H^{\sigma+1}_\nu}\lesssim\|\varepsilon u\|_{L^2}+\|\nabla u\|_{H^{\sigma-1}}+\|(I-J_{\varepsilon\nu})u\|_{H^{\sigma+1}_\nu}$ yields

$$\begin{aligned}\|(\varepsilon p,\varepsilon v)\|_{L^\infty_T(H^{s+1}_\nu)}+\sqrt{\mu}\,\|\nabla v\|_{L^2_T(H^{s+1}_{\varepsilon\nu})}&\lesssim\|(\varepsilon p,\varepsilon v)\|_{L^\infty_T(L^2)}+\|(\nabla p,\nabla v)\|_{L^\infty_T(H^{s-1})}\\&\quad+\sqrt{\mu}\,\|\nabla v\|_{L^2_T(H^s)}+\Omega_{\mathrm{HF}}.\end{aligned} \tag{3.17}$$

On the other hand, Corollary 2.5 implies that, if $d\neq2$, there exists a constant C_0 depending only on M_0 such that

$$\begin{aligned}\|\nabla v\|_{L^\infty_T(H^{s-1})}+\sqrt{\mu}\,\|\nabla v\|_{L^2_T(H^s)}&\leqslant C_0\,\|(\operatorname{div}v,\operatorname{curl}(\gamma_0 v))\|_{L^\infty_T(H^{s-1})}\\&\quad+C_0\sqrt{\mu}\,\|(\operatorname{div}v,\operatorname{curl}(\gamma_0 v))\|_{L^2_T(H^s)}.\end{aligned}$$

By using the estimate (3.8), one can verify that the term $\|(\varepsilon p,\varepsilon v)\|_{L^\infty_T(L^2)}$ (in the left-hand side of (3.17)) can be estimated as in the proof of Lemma 3.11. Therefore, according to Propositions 3.12–3.13 and Lemmas 3.18–3.19, we have proved that, if $d\neq2$, then $\Omega\leqslant\widetilde{C}$ where $\widetilde{C}=C_0e^{(\sqrt{T}+\varepsilon)C}+\sqrt{T}C'$ for some constants C_0, C, and C' depending only on M_0, Ω and $\Omega+\Sigma$, respectively.

This concludes the proof of Proposition 3.6 and hence Theorem 3.3.

4. Uniform estimates in the Sobolev spaces. With regards to the low Mach number limit problem, we mention that the convergence results[1] proved in [1] apply to general systems (not only for perfect gases). To avoid repetition, we only mention that one can rigorously justify the low Mach number limit for general initial data provided that one can prove that the solutions are uniformly bounded in Sobolev spaces (see Proposition 8.2 in [1]). The problem presents itself: Theorem 1.2 only

[1] These results are strongly based on a theorem of Métivier and Schochet [20] about the decay to zero of the local energy for a class of wave operators with variable coefficients.

gives uniform estimates for the derivatives of p and v. In this section, we give uniform bounds in Sobolev norms.

THEOREM 4.1. *Let $d \geqslant 1$ and $\mathbb{N} \ni s > 1 + d/2$. Assume that $Q = 0$. Also, assume that either $\chi_1 = \chi_1(\vartheta, \wp)$ is independent of ϑ or that $d \geqslant 3$. Then, for all $M_0 > 0$, there exist $T > 0$ and $M > 0$ such that, for all $a = (\varepsilon, \mu, \kappa) \in A$ and all initial data $(p_0, v_0, \theta_0) \in H^{s+1}(\mathbb{R}^d)$ satisfying*

$$\|(p_0, v_0, \theta_0)\|_{H^{s+1}} \leqslant M_0,$$

the Cauchy problem for (1.4) has a unique solution (p, v, θ) in $C^0([0,T]; H^{s+1}(\mathbb{R}^d))$ such that

$$\sup_{t\in[0,T]} \|(p(t), v(t), \theta(t))\|_{H^s} \leqslant M.$$

The first half of this result is proved in [1]. Indeed, the assumption that $\chi_1(\vartheta, \wp)$ does not depend on ϑ is satisfied by perfect gases. Therefore, we concentrate on the second half ($d \geqslant 3$). In view of Theorem 3.3, it remains only to prove *a posteriori* uniform L^2 estimates. More precisely, the proof of Theorem 4.1 reduces to establishing the following result.

LEMMA 4.2. *Let $d \geqslant 3$. Consider a family of solutions (p^a, v^a, θ^a) of (1.4) (for some source terms Q^a) uniformly bounded in the sense of the conclusion of Theorem 3.3:*

$$\sup_{a\in A} \|(p^a, v^a, \theta^a)\|_{\mathcal{X}_a^s(T)} < +\infty, \tag{4.1}$$

for some $s > 1 + d/2$ and fixed $T > 0$. Assume further that the source terms Q^a are uniformly bounded in $C^1([0,T]; L^1 \cap L^2(\mathbb{R}^d))$ and that the initial data $(p^a(0), v^a(0))$ are uniformly bounded in $L^2(\mathbb{R}^d)$. Then the solutions (p^a, v^a, θ^a) are uniformly bounded in $C^0([0,T]; L^2(\mathbb{R}^d))$.

Remark 4.3. We allow $Q^a \neq 0$ for application to the combustion equations. To clarify matters, we note that one can replace (4.1) by

$$\sup_{a\in A} \sup_{t\in[0,T]} \|(\nabla p^a(t), \nabla v^a(t))\|_{H^s} + \|\theta^a(t)\|_{H^{s+1}} < +\infty,$$

for some $s > 2 + d/2$.

Proof. For this proof, we set

$$R := \sup_{a\in A} \Big\{ \|(p^a, v^a, \theta^a)\|_{\mathcal{X}_a^s(T)} + \|(p^a(0), v^a(0))\|_{L^2} + \|Q^a\|_{C^1([0,T];L^1\cap L^2)} \Big\},$$

and we denote by $C(R)$ various constants depending only on R.

The strategy of the proof consists of transforming the system (1.4) so as to obtain L^2 estimates uniform in ε by a simple integration by parts argument.

To do that we claim that there exist $U^a \in C^1([0,T]; L^2(\mathbb{R}^d))$ satisfying the following properties:

$$\sup_{a\in A} \|(p^a, v^a)\|_{L^\infty_T(L^2)} \leqslant \sup_{a\in A} \|U^a\|_{L^\infty_T(L^2)} + C(R), \tag{4.2}$$

$$\sup_{a\in A} \|U^a(0)\|_{L^2} \leqslant C(R), \tag{4.3}$$

and U^a solves a system having the form

$$E^a\partial_t U^a+\varepsilon^{-1}S(\partial_x)U^a=F^a, \tag{4.4}$$

where $S(\partial_x)$ is skew-symmetric, the symmetric matrices $E^a=E^a(t,x)$ are positive definite, and one has the uniform bounds

$$\sup_{a\in A}\|\partial_t E^a\|_{L^\infty([0,T]\times\mathbb{R}^d)}+\big\|(E^a)^{-1}\big\|^{-1}_{L^\infty([0,T]\times\mathbb{R}^d)}+\|F^a\|_{L^1_T(L^2)}\leqslant C(R). \tag{4.5}$$

Before we prove the claim, let us prove that it implies Lemma 4.2. To see this, we combine two basic ingredients:

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\langle\, E^aU^a\,,U^a\,\rangle&=-\varepsilon^{-1}\langle\, S(\partial_x)U^a\,,U^a\,\rangle+\langle\, F^a\,,U^a\,\rangle+\frac{1}{2}\langle(\partial_tE^a)U^a\,,U^a\,\rangle\\&\leqslant\|F^a\|_{L^2}^2+C(R)\,\|U^a\|_{L^2}^2\,,\end{aligned}$$

and $\big\|U^a\big\|_{L^2}^2\leqslant\big\|(E^a)^{-1}\big\|_{L^\infty}^{-1}\langle\, E^aU^a\,,U^a\,\rangle$. Hence, by (4.3) and (4.5), the Gronwall's lemma implies that $\big\|U^a\big\|_{L^\infty_T(L^2)}\leqslant C(R)$. The estimate (4.2) thus implies the desired result.

To prove the claim, we set $U^a:=(p^a,v^a-V^a)^T$, where

$$V^a:=\kappa\chi_1(\phi^a)k(\theta^a)\nabla\theta^a+\nabla\Delta^{-1}\big(-\kappa\nabla\chi_1(\phi^a)\cdot k(\theta^a)\nabla\theta^a+\chi_1(\phi^a)Q^a\big).$$

The fact that V^a is well defined follows from Proposition 2.1. We next verify that U^a satisfies (4.4) with

$$E^a=\begin{pmatrix}g_1(\phi^a)&0\\0&g_2(\phi^a)\end{pmatrix},\quad S(\partial_x)=\begin{pmatrix}0&\operatorname{div}\\\nabla&0\end{pmatrix},$$

$$F^a=\begin{pmatrix}-g_1(\phi^a)v^a\cdot\nabla p^a\\-g_1(\phi^a)v^a\cdot\nabla v^a+\mu B_2(\phi^a,\partial_x)v^a-g_2(\phi^a)\partial_tV^a\end{pmatrix}.$$

By (2.3), (2.4), and (2.6), to prove that the bounds (4.2) and (4.5) hold, it suffices to prove that $\|\partial_t\phi^a\|_{H^{s-1}}\leqslant C(R)$. Yet, this is nothing new. Indeed, we first observe that, directly from the equations,

$$\|\partial_t\phi^a+v^a\cdot\nabla\phi^a\|_{H^{s-1}}\leqslant C(R).$$

On the other hand, the product rule (2.7) implies that $\|v^a\cdot\nabla\phi^a\|_{H^{s-1}}$ is estimated by $\|\nabla v^a\|_{H^{s-1}}\,\|\phi^a\|_{H^s}\leqslant C(R)$. This completes the proof. □

Remark 4.4. For our purposes, one of the main differences between $\mathbb{R}^3$ and $\mathbb{R}$ is the following. For all $f\in C_0^\infty(\mathbb{R}^3)$, Proposition 2.5 implies that there exists a vector field $u\in H^\infty(\mathbb{R}^3)$ such that $\operatorname{div}u=f$. In sharp contrast, the mean value of the divergence of a smooth vector field $u\in H^\infty(\mathbb{R})$ is zero. This implies that Lemma 4.2 is false with $d=1$.

The following result contains an analysis of the easy case where initially $\theta_0=O(\varepsilon)$. This regime is interesting for the incompressible limit (see [3]).

PROPOSITION 4.5. *Let $d\geqslant1$ and $\mathbb{R}\ni s>1+d/2$. For all $M_0>0$, there exists $T>0$ and $M>0$ such that for all $a\in A$ and all initial data $(p_0,v_0,\theta_0)\in H^s(\mathbb{R}^d)$ satisfying*

$$\|(p_0,v_0)\|_{H^s}+\varepsilon^{-1}\,\|\theta_0\|_{H^s}\leqslant M_0, \tag{4.6}$$

the Cauchy problem for (1.4) *has a unique solution* (p, v, θ) *in* $C^0([0,T]; H^s(\mathbb{R}^d))$ *such that*

$$\sup_{t\in[0,T]} \|(p(t), v(t))\|_{H^s} + \varepsilon^{-1} \|\theta(t)\|_{H^s} \leqslant M. \tag{4.7}$$

Proof. The proof of this result is based on the change of unknown $(p, v, \theta) \mapsto (G(\theta, \varepsilon p), v, \theta)$, where G is as given by Assumption (H2) in section 1.2. By setting $\rho = G(\theta, \varepsilon p)$ it is found that (p, v, θ) satisfies (1.4) if and only if

$$\begin{cases} \chi_3(\partial_t \rho + v \cdot \nabla \rho) + (\chi_3 - \chi_1) \operatorname{div} v = 0, \\ g_2(\partial_t v + v \cdot \nabla v) + \varepsilon^{-2}\gamma_1 \nabla\theta + \varepsilon^{-2}\gamma_2 \nabla\rho - \mu B_2 v = 0, \\ g_3(\partial_t \theta + v \cdot \nabla\theta) + \operatorname{div} v - \kappa\chi_3 \operatorname{div}(k\nabla\theta) = 0, \end{cases} \tag{4.8}$$

where $\gamma_1 = (\chi_1 g_3)/(\chi_3 g_1)$ and $\gamma_2 = 1/g_1$. Notice that Assumption (H2) implies that the coefficients g_i, γ_i, χ_3 and $\chi_3 - \chi_1$ are positive.

The key point is that the assumption (4.6) allows us to symmetrize the equations by setting $u := (\tilde\rho, v, \tilde\theta)$, where

$$\tilde\rho := \varepsilon^{-1}\rho, \quad \tilde\theta := \varepsilon^{-1}\theta.$$

The fact that this change of unknowns is singular in ε causes no difficulty. Indeed, directly from the assumption (4.6), we have $\|\tilde\theta(0)\|_{H^s} \leqslant M_0$. On the other hand, the assumption $G(0,0) = 0$ implies that there is a function C_G such that $\|G(u)\|_{H^\sigma} \leqslant C_G(\|u\|_{L^\infty}) \|u\|_{H^\sigma}$ for all $u \in H^\sigma$ with $\sigma > d/2$. Therefore, we have

$$\begin{aligned} \|\tilde\rho\|_{H^s} = \varepsilon^{-1} \|G(\theta, \varepsilon p)\|_{H^s} &\leqslant \varepsilon^{-1} C_G(\|(\theta, \varepsilon p)\|_{L^\infty}) \|(\theta, \varepsilon p)\|_{H^s} \\ &\leqslant C_G(\|(\theta, \varepsilon p)\|_{L^\infty}) \|(\tilde\theta, p)\|_{H^s}, \end{aligned} \tag{4.9}$$

hence, $\|\tilde\rho(0)\|_{H^s} \leqslant C_0$ for some constant depending only on M_0.

Because $(\vartheta, \wp) \mapsto (\vartheta, G(\vartheta, \wp))$ is a C^∞ diffeomorphism with $G(0,0) = 0$, one can write $\varepsilon p = P\big(\theta, G(\theta, \varepsilon p)\big) = P(\theta, \rho)$, for some C^∞ function P vanishing at the origin. Therefore one can see the coefficients $(g_i, \chi_i, \gamma_i \dots)$ as functions of (θ, ρ). Hence, with $u = (\tilde\rho, v, \tilde\theta)$ as above, one can rewrite system (4.8) under the form

$$A_0(\varepsilon u)\partial_t u + \sum_{1\leqslant j\leqslant d} A_j(u, \varepsilon u)\partial_j u + \frac{1}{\varepsilon} \sum_{1\leqslant j\leqslant d} S_j(\varepsilon u)\partial_j u - B(\varepsilon u, \partial_x)u = 0, \tag{4.10}$$

where the matrices S_j, A_j are symmetric (with A_0 positive definite) and the viscous perturbation $B(\varepsilon u, \partial_x)$ is as in (4.8).

Note that one can always assume that the matrices S_j have constant coefficients. Furthermore, since the matrix A_0 multiplying the time derivative depends only on the unknown through εu, and since the initial data $u(0)$ are uniformly bounded in H^s, the proof of the uniform existence theorem of [15] applies. By that proof, we conclude that the solutions of (4.10) exist and are uniformly bounded for a time T independent of ε. Once this is granted, it remains to verify that the solutions (p, v, θ) of system (1.4) exist and are uniformly bounded in the sense of (4.7). To see this, as for $\tilde\rho$ in (4.9), we note that

$$\begin{aligned} \|p\|_{H^s} &= \|P(\theta, \rho)\|_{H^s} \\ &\leqslant \varepsilon^{-1} C_P(\|(\theta, \rho)\|_{L^\infty}) \|(\theta, \rho)\|_{H^s} = C_P(\|(\theta, \rho)\|_{L^\infty}) \|(\tilde\theta, \tilde\rho)\|_{H^s} \\ &\leqslant C(\|(\tilde\theta, \tilde\rho)\|_{H^s}), \end{aligned}$$

so that $\|(p, v)\|_{H^s} + \varepsilon^{-1} \|\theta\|_{H^s} \leqslant C(\|u\|_{H^s})$. This completes the proof. ∎

Remark 4.6. Consider the Euler equations ($\mu = 0 = \kappa$ and $\varepsilon = 1$). By a standard rescaling, Proposition 4.5 just says that the classical solutions with small initial data of size δ exist for a time of order of $1/\delta$. Following the approach initiated by Alinhac in [2], several much more precise results have been obtained. In particular, the interested reader is referred to the recent advance of Godin [14] (for the 3D non-isentropic Euler equations).

5. Spatially periodic solutions. In this section, we consider the case where x belongs to the torus $\mathbb{T}^d$.

THEOREM 5.1. *Let $d \geqslant 1$ and $\mathbb{N} \ni s > 1 + d/2$. For all source term $Q \in C^\infty(\mathbb{R} \times \mathbb{T}^d)$ and for all $M_0 > 0$, there exist $T > 0$ and $M > 0$ such that, for all $a \in A$ and all initial data $(p_0, v_0, \theta_0) \in H^{s+1}(\mathbb{T}^d)$ satisfying*

$$\|(p_0, v_0)\|_{H^s} + \|(\theta_0, \varepsilon p_0, \varepsilon v_0)\|_{H^{s+1}} \leqslant M_0,$$

the Cauchy problem for (1.4) *has a unique solution (p, v, θ) in $C^0([0,T]; H^{s+1}(\mathbb{T}^d))$ such that*

$$\sup_{t\in[0,T]} \|\nabla p(t)\|_{H^{s-1}} + \|v(t)\|_{H^s} + \|(\theta(t), \varepsilon p(t))\|_{H^s} \leqslant M.$$

The proof follows from two observations: first, the results proved in Steps 1–6 in section 3 apply *mutatis mutandis* in the periodic case; and second, as proved below, the periodic case is easier in that one can prove uniform L^2 estimates for the velocity. This in turn implies that (as in [1, 20]) one can directly prove a closed set of estimates by means of the estimate

$$\|v\|_{H^s(\mathbb{T}^d)} \leqslant C\,\|\operatorname{div} v\|_{H^{s-1}(\mathbb{T}^d)} + C\,\|\operatorname{curl}(\gamma v)\|_{H^{s-1}(\mathbb{T}^d)} + C\,\|v\|_{L^2(\mathbb{T}^d)},$$

for some constant C depending only on $\|\log\gamma\|_{H^s(\mathbb{T}^d)}$ (compare with (2.15)).

Let us concentrate on the main new qualitative property.

LEMMA 5.2. *Let $d \geqslant 1$. Consider a family of solutions (p^a, v^a, θ^a) of* (1.4) *(for some source terms Q^a) such that*

$$\sup_{a\in A} \|(p^a, v^a, \theta^a)\|_{\mathcal{X}^s_a(T)} < +\infty,$$

for some $s > 1+d/2$ and fixed $T > 0$. If Q^a is uniformly bounded in $C^1([0,T]; L^2(\mathbb{T}^d))$ and $(p^a(0), v^a(0))$ is uniformly bounded in $L^2(\mathbb{T}^d)$, then v^a is uniformly bounded in $C^0([0,T]; L^2(\mathbb{T}^d))$.

Proof. The main new technical ingredient is, as used by Schochet in [23], an appropriate ansatz for the pressure.

Again, the proof makes use of the Fourier multiplier $\nabla\Delta^{-1}$. Note that $\nabla\Delta^{-1}$ is bounded from $L^2_\sharp(\mathbb{T}^d)$ to $H^1(\mathbb{T}^d)$, where $L^2_\sharp(\mathbb{T}^d)$ consists of these functions $u \in L^2(\mathbb{T}^d)$ such that $\langle u\rangle := \int_{\mathbb{T}^d} u(x)\,dx = 0$.

Set

$$F^a := \kappa\chi_1(\phi^a)\operatorname{div}(k(\theta^a)\nabla\theta^a) + \chi_1(\phi^a)Q^a,$$

and introduce the functions $V^a = V^a(t,x)$ and $P^a = P^a(t)$ by

$$P^a := \frac{\langle F^a\rangle}{\langle g_1(\phi^a)\rangle} \quad \text{and} \quad V^a := \nabla\Delta^{-1}\big(F^a - g_1(\phi^a)P^a\big),$$

so that

$$F^a = g_1(\phi^a)P^a + \operatorname{div} V^a.$$

This allows us to rewrite the first equation in (1.4) as

$$g_1(\phi^a)(\partial_t p^a + v^a \cdot \nabla p^a) + \varepsilon^{-1} \operatorname{div}(v^a - V^a) = g_1(\phi^a)P^a.$$

Therefore, by introducing

$$U^a := (q^a, v^a - V^a)^T \quad \text{with} \quad q^a(t,x) = p^a(t,x) - P^a(t),$$

we are back in the situation of Lemma 4.2: U^a satisfies

$$E^a(\partial_t U^a + v^a \cdot \nabla U^a) + \varepsilon^{-1} S(\partial_x) U^a = F^a, \tag{5.1}$$

where $S(\partial_x)$ is skew-symmetric, the matrices E^a are positive definite, and

$$\|(E^a, \partial_t E^a + v^a \cdot \nabla E^a)\|_{L^\infty([0,T]\times\mathbb{R}^d)} + \big\|(E^a)^{-1}\big\|^{-1}_{L^\infty([0,T]\times\mathbb{R}^d)} + \|F^a\|_{L^1_T(L^2)}$$

is uniformly bounded.

As before, the proof proceeds by multiplying by U^a and integrating on $\mathbb{T}^d$. We find that $\partial_t \langle\, E^a U^a, U^a \,\rangle$ is given by

$$\langle ((\partial_t + v^a \cdot \nabla)E^a) U^a, U^a \rangle + \langle\, E^a (\operatorname{div} v^a) U^a, U^a \,\rangle + 2\langle\, F^a, U^a \,\rangle,$$

and hence conclude that U^a is uniformly bounded in $C^0([0,T]; L^2(\mathbb{T}^d))$. Since V^a is uniformly bounded in $C^0([0,T]; L^2(\mathbb{T}^d))$, this yields the desired result. □

Remark 5.3. In the periodic case, as shown by Métivier and Schochet [21, 22] as well as Bresch, Desjardins, Grenier, and Lin [6], the study of the behavior of the solutions when $\varepsilon \to 0$ involved many additional phenomena.

6. Low Mach number combustion. The system (1.1) is relevant whenever all nuclear or chemical reactions are frozen, which is the case in many treatments of fluid mechanics. By contrast, for the combustion, one has to replace the energy evolution equation by

$$\partial_t(\rho e) + \operatorname{div}(\rho v e) + P \operatorname{div} v = \kappa \operatorname{div}(k \nabla T) + F(Y),$$

with $Y := (Y_1, \dots, Y_L)$, where the Y_ℓ's denote the relative concentrations of nuclear or chemical species. The new unknown Y_ℓ satisfies

$$\partial_t(\rho Y_\ell) + \operatorname{div}(\rho v Y_\ell) = \lambda \operatorname{div}(D_\ell \nabla Y_\ell) + \rho \omega_\ell(t,x), \tag{6.1}$$

where ω_ℓ is a given source term, $D_\ell > 0$, and λ measures the importance of diffusion processes.

Many results have been obtained for the reactive gas equations (see [7] and the references therein). Yet, the previous studies do not include the dimensionless numbers. Here we consider the system

$$\begin{cases} \alpha(\partial_t P + v \cdot \nabla P) + \operatorname{div} v = \kappa\beta \operatorname{div}(k \nabla T) + F_1(Y,T,P), \\ \rho(\partial_t v + v \cdot \nabla v) + \dfrac{\nabla P}{\varepsilon^2} = \mu\big(2 \operatorname{div}(\zeta D v) + \nabla(\eta \operatorname{div} v)\big), \\ \gamma(\partial_t T + v \cdot \nabla T) + \operatorname{div} v = \kappa\delta \operatorname{div}(k \nabla T) + F_3(Y,T,P), \\ \rho(\partial_t Y + v \cdot \nabla Y) = \lambda \operatorname{div}(D \nabla Y), \end{cases} \tag{6.2}$$

where α, β, γ, and δ are given functions of (Y,T,P).

As explained in the introduction, it is convenient to introduce (p,θ,y) by $P=\underline{P}e^{\varepsilon p}$, $T=\underline{T}e^{\theta}$, $Y=\underline{Y}e^{y}$, where $(\underline{P},\underline{T},\underline{Y})\in[0,+\infty)^{2+L}$. For smooth solutions, (p,v,θ,y) satisfies a system of the form

$$\text{(6.3)}\qquad \begin{cases} g_1(\Phi)(\partial_t p+v\cdot\nabla p)+\dfrac{1}{\varepsilon}\operatorname{div}v=\dfrac{\kappa}{\varepsilon}\chi_1(\Phi)\operatorname{div}(k(\theta)\nabla\theta)+\dfrac{1}{\varepsilon}Q_1(\Phi),\\ g_2(\Phi)(\partial_t v+v\cdot\nabla v)+\dfrac{1}{\varepsilon}\nabla p=\mu\chi_2(\Phi)\big(\operatorname{div}(\zeta(\theta)Dv)+\nabla(\eta(\theta)\operatorname{div}v)\big),\\ g_3(\Phi)(\partial_t\theta+v\cdot\nabla\theta)+\operatorname{div}v=\kappa\chi_3(\Phi)\operatorname{div}(k(\theta)\nabla\theta)+Q_3(\Phi),\\ g_4(\Phi)(\partial_t y+v\cdot\nabla y)=\lambda\chi_4(\Phi)\operatorname{div}(D(\theta)\nabla y), \end{cases}$$

where $\Phi=(y,\theta,\varepsilon p)$.

ASSUMPTION 6.1. *Denote by $(\mathsf{y},\vartheta,\wp)\in\mathbb{R}^N$ the place holder of the unknown $(y,\theta,\varepsilon p)$. Parallel to Assumption $(H2)$ in section 1.2, we suppose that g_i and χ_i $(i=1,2,3)$ are C^∞ positive functions of $(\mathsf{y},\vartheta,\wp)\in\mathbb{R}^N$, $\chi_1<\chi_3$, and there exist two functions F and G such that $(\mathsf{y},\vartheta,\wp)\mapsto(\mathsf{y},F(\mathsf{y},\vartheta,\wp),\wp)$ and $(\mathsf{y},\vartheta,\wp)\mapsto(\mathsf{y},\vartheta,G(\vartheta,\wp))$ are C^∞ diffeomorphisms from $\mathbb{R}^N$ onto $\mathbb{R}^N$, F and G vanish at the origin, and*

$$g_1\frac{\partial F}{\partial\vartheta}=-g_3\frac{\partial F}{\partial\wp}>0,\quad g_1\chi_3\frac{\partial G}{\partial\vartheta}=-g_3\chi_1\frac{\partial G}{\partial\wp}<0.$$

Moreover, Q_1 and Q_3 are C^∞ functions of $(\mathsf{y},\vartheta,\wp)$ vanishing at the origin.

Introduce

$$B:=\big\{(\varepsilon,\mu,\kappa,\lambda)\in(0,1]\times[0,1]\times[0,1]\times[0,2]\,|\,\lambda\geqslant\sqrt{\mu+\kappa}\,\big\}.$$

DEFINITION 6.2. *Let $T>0$, $s\in\mathbb{R}$, $b=(\varepsilon,\mu,\kappa,\lambda)\in B$, and set $a:=(\varepsilon,\mu,\kappa)$. The space $\mathcal{Z}^s_b(T)$ consists of these $(p,v,\theta,y)\in C^0([0,T];H^s(\mathbb{R}^d))$ such that*

$$(p,v,\theta)\in\mathcal{X}^s_a(T),\quad \nu y\in C^0([0,T];H^{s+1}(\mathbb{R}^d)),\quad \lambda y\in L^2(0,T;H^{s+2}_\nu(\mathbb{R}^d)),$$

where $\nu:=\sqrt{\mu+\kappa}$ and $\mathcal{X}^s_a(T)$ is as defined in Definition 3.1. The space $\mathcal{Z}^s_b(T)$ is given the norm

$$\|(p,v,\theta,y)\|_{\mathcal{Z}^s_b(T)}:=\|(p,v,\theta)\|_{\mathcal{X}^s_a(T)}+\|y\|_{L^\infty_T(H^{s+1}_\nu)}+\sqrt{\lambda}\,\|y\|_{L^2_T(H^{s+2}_\nu)}.$$

Having proved estimates for the solutions of system (1.4) with precised estimates in terms of the norm Σ of the source term Q (see (3.3)), we are now in position to assert the following.

THEOREM 6.3. *Assume that $d\neq2$. Given $M_0>0$ and $\mathbb{N}\ni s>1+d/2$, there exist $T>0$ and $M>0$ such that, for all $b\in B$ and all initial data $(p_0,v_0,\theta_0,y_0)\in H^{s+1}(\mathbb{R}^d)$ satisfying*

$$\|(\nabla p_0,\nabla v_0)\|_{H^{s-1}}+\|(y_0,\theta_0,\varepsilon p_0,\varepsilon v_0)\|_{H^{s+1}}\leqslant M_0,$$

the Cauchy problem for (1.4) has a unique solution (p,v,θ,y) in the ball $B(\mathcal{Z}^s_b(T);M)$.

Remark 6.4 (low Mach number limit). For the case of greatest physical interest $(d=3)$, notice that Lemma 4.2 implies that, if, in addition, (p_0,v_0) belongs uniformly to $L^2(\mathbb{R}^3)$ and Q_1 satisfies $|Q_1(\mathsf{y},\vartheta,0)|\leqslant K(\mathsf{y},\vartheta)(|\mathsf{y}|^2+|\vartheta|^2)$ for some smooth function K, then the solutions (p,v,θ,y) are uniformly bounded in $C^0([0,T];H^s(\mathbb{R}^3))$. This result has two corollaries. As alluded to in section 4, it allows us to rigorously

justify, at least in the whole space case, the computations given by Majda in [18]. By the way, this proves the well posedness of the Cauchy problem for the zero Mach number combustion in the whole space (this was known only in the periodic case [11]). Moreover, note that the solutions given by Theorem 6.3 satisfy uniform estimates recovering in the limit $\varepsilon \to 0$ those obtained by Embid for the limit system. Finally, we mention that a close inspection of the high frequency regime indicates that the previous analysis applies with $Q_i(\Phi)$ $(i = 1, 3)$ replaced by $\chi_i(\Phi)Q(\Phi, \nabla y, \nabla^2 y)$ for some smooth function Q, yet we will not address this issue.

Appendix. General equations of state. Recall that in order to study the full Navier–Stokes equations (1.1), we chose to work with the unknown (P, v, T). In order to close this system, we must relate (ρ, e) to (P, T) by means of two equations of state: $\rho = \rho(P, T)$ and $e = e(P, T)$. The purpose of this section is to show that Assumption (H2) in section 1.2 is satisfied under general assumptions on the partial derivatives of ρ and e with respect to P and T.

A.1. Computation of the coefficients. We begin by expressing the coefficients g_i and χ_i, which appear in (1.4), in terms of the partial derivatives of ρ and e with respect to P and T. To do that it is convenient to introduce the entropy. Here is where the first identity in (1.5) enters.

ASSUMPTION A.1. *The functions ρ and e are C^∞ functions of $(P, T) \in (0, +\infty)^2$, satisfying*

$$P\frac{\partial \rho}{\partial P} + T\frac{\partial \rho}{\partial T} = \rho^2 \frac{\partial e}{\partial P}\cdot$$

Introduce the 1-form ω defined by $T\omega := \mathrm{d}\, e + P\, \mathrm{d}(1/\rho)$, where we started using the notation $\mathrm{d}\, f = (\partial f/\partial T)\, \mathrm{d}\, T + (\partial f/\partial P)\, \mathrm{d}\, P$. Assumption A.1 implies that $\mathrm{d}\, \omega = 0$. Hence, the Poincaré lemma implies that there exists a C^∞ function $S = S(P, T)$, defined on $(0, +\infty)^2$, satisfying the second principle of thermodynamics:

$$T\, \mathrm{d}\, S = \mathrm{d}\, e + P\, \mathrm{d}(1/\rho). \tag{A.1}$$

By combining the evolution equations for ρ and e with (A.1) written in the form $\rho T\, \mathrm{d}\, S = \rho\, \mathrm{d}\, e - (p/\rho)\, \mathrm{d}\, \rho$, we get an evolution equation for S, so that

$$(\partial_t + v \cdot \nabla) \begin{pmatrix} \rho \\ S \end{pmatrix} = \begin{pmatrix} -\rho & 0 \\ 0 & (\rho T)^{-1} \end{pmatrix} \begin{pmatrix} \operatorname{div} v \\ \kappa \operatorname{div}(k \nabla T) + Q \end{pmatrix}.$$

On the other hand, one has

$$(\partial_t + v \cdot \nabla) \begin{pmatrix} \rho \\ S \end{pmatrix} = J(\partial_t + v \cdot \nabla) \begin{pmatrix} P \\ T \end{pmatrix} \quad \text{with} \quad J = \begin{pmatrix} \partial\rho/\partial P & \partial\rho/\partial T \\ \partial S/\partial P & \partial S/\partial T \end{pmatrix}.$$

Equating both right-hand sides and inverting the matrix J, we obtain

$$\begin{cases} (\partial_t P + v \cdot \nabla P) + a \operatorname{div} v - \kappa b \operatorname{div}(k \nabla T) = bQ, \\ (\partial_t T + v \cdot \nabla T) + c \operatorname{div} v - \kappa d \operatorname{div}(k \nabla T) = dQ, \end{cases} \tag{A.2}$$

where

$$a = \frac{\rho(\partial S/\partial T)}{\det(J)},\ b = -\frac{\partial\rho/\partial T}{\rho T \det(J)},\ c = -\frac{\rho(\partial S/\partial P)}{\det(J)},\ d = \frac{\partial\rho/\partial P}{\rho T \det(J)}\cdot$$

To express the coefficients g_i and χ_i in terms of physically relevant quantities, we need some more notations. We introduce

$$\begin{aligned} &K_T := \frac{1}{\rho}\frac{\partial \rho}{\partial P}, \quad K_P := -\frac{1}{\rho}\frac{\partial \rho}{\partial T}, \quad \mathcal{R} := -\rho\frac{\partial S/\partial P}{\partial \rho/\partial P}, \\ &C_P := T\frac{\partial S}{\partial T}, \quad C_V := T\frac{(\partial S/\partial T)(\partial \rho/\partial P) - (\partial S/\partial P)(\partial S/\partial T)}{\partial \rho/\partial P}. \end{aligned} \tag{A.3}$$

The functions K_T, K_P, C_V, and C_P are known as the coefficient of isothermal compressibility, the coefficient of thermal expansion, and the specific heats at constant volume and pressure, respectively (see section 2 in [12]). The function $\mathcal{R}$ generalizes the usual gas constant: for perfect gases one can check that $\mathcal{R} = R$.

We now have to convert system (A.2) into equations for the fluctuations p and θ as defined by (1.2). Performing a little algebra we find that

$$\begin{cases} \dfrac{K_T C_V P}{C_P}(\partial_t p + v\cdot\nabla p) + \dfrac{1}{\varepsilon}\operatorname{div} v - \dfrac{\kappa}{\varepsilon}\dfrac{K_P}{\rho C_P}\operatorname{div}(kT\nabla\theta) = \dfrac{1}{\varepsilon}\dfrac{K_P}{\rho C_P}Q, \\ \rho(\partial_t v + v\cdot\nabla v) + \dfrac{1}{\varepsilon}P\nabla p = \mu\big(2\operatorname{div}(\zeta Dv) + \nabla(\eta\operatorname{div} v)\big), \\ \rho C_V T(\partial_t\theta + v\cdot\nabla\theta) + \mathcal{R}\rho T\operatorname{div} v - \kappa\operatorname{div}(kT\nabla\theta) = Q. \end{cases}$$

Hence, (p, v, θ) satisfies (1.4) with

$$g_1^* = \frac{K_T C_V P}{C_P},\ g_2^* = \frac{\rho}{P},\ g_3^* = \frac{C_V}{\mathcal{R}},\ \chi_1^* = \frac{K_P}{\rho C_P},\ \chi_2^* = \frac{1}{P},\ \chi_3^* = \frac{1}{\mathcal{R}\rho T}, \tag{A.4}$$

where we used the following notation: for all $f\colon (0,+\infty)^2 \to \mathbb{R}$,

$$f^*(\vartheta, \wp) := f(\underline{T}e^{\vartheta}, \underline{P}e^{\wp}). \tag{A.5}$$

A.2. Properties of the coefficients.

ASSUMPTION A.2. *The functions ρ and e are C^∞ functions of $(P,T) \in (0,+\infty)^2$ such that $\rho > 0$ and*

$$\frac{\partial \rho}{\partial P} > 0, \quad \frac{\partial \rho}{\partial T} < 0 \quad \textit{and} \quad \frac{\partial e}{\partial T}\frac{\partial \rho}{\partial P} > \frac{\partial e}{\partial P}\frac{\partial \rho}{\partial T}. \tag{A.6}$$

Remark A.3. This assumption is satisfied by general equations of state. Indeed, (A.6) just means that the coefficients K_T, K_P, and C_V are positive.

The following result proves that Assumptions A.1 and A.2 imply that our main structural assumption is satisfied.

PROPOSITION A.4. *If Assumptions* A.1 *and* A.2 *are satisfied, then $\chi_1 < \chi_3$ and g_i, χ_i $(i = 1, 2, 3)$ are C^∞ positive functions.*

Proof. In view of (A.4), the proof reduces to establishing that

$$0 < K_T, \quad 0 < K_P, \quad 0 < C_V < C_P \quad \text{and} \quad 0 < \mathcal{R} < \frac{C_P}{TK_P}.$$

The first two inequalities follow from the definitions of K_T and K_P. To prove the last two, we first establish the Maxwell identity $\partial S/\partial P = \rho^{-2}(\partial\rho/\partial T)$. To see this, by (A.1), we compute

$$\frac{\partial S}{\partial P}\,\mathrm{d}\,T \wedge \mathrm{d}\,P = \mathrm{d}\big(T\,\mathrm{d}\,S\big) = \mathrm{d}\left\{\mathrm{d}\,e + P\,\mathrm{d}\left(\frac{1}{\rho}\right)\right\} = -\frac{1}{\rho^2}\frac{\partial\rho}{\partial T}\,\mathrm{d}\,P \wedge \mathrm{d}\,T.$$

Since $\partial\rho/\partial T < 0$, the Maxwell identity implies that $\partial S/\partial P < 0$. By combining this inequality with $\partial\rho/\partial P > 0$, we find $\mathcal{R} > 0$. Also, the identity $\partial S/\partial P = \rho^{-2}(\partial\rho/\partial T)$ implies that

$$\frac{C_P}{C_V} = \frac{(\partial S/\partial T)(\partial\rho/\partial P)}{(\partial S/\partial T)(\partial\rho/\partial P) - \rho^{-2}\big(\partial\rho/\partial T\big)^2},$$

which proves $C_V < C_P$.

In view of (A.1), the assumption $\frac{\partial e}{\partial T}\frac{\partial\rho}{\partial P} > \frac{\partial e}{\partial P}\frac{\partial\rho}{\partial T}$ is equivalent to

$$\frac{\partial S}{\partial T}\frac{\partial\rho}{\partial P} > \frac{\partial S}{\partial P}\frac{\partial\rho}{\partial T}.$$

This inequality has two consequences. First, it implies that $C_V > 0$. Second, it yields

$$\frac{TK_P\mathcal{R}}{C_P} = \frac{(\partial S/\partial P)(\partial\rho/\partial T)}{(\partial S/\partial T)(\partial\rho/\partial P)} < 1.$$

This concludes the proof. ∎

We now discuss the physical meaning of the functions F and G introduced in section 1.2. These are compatibility conditions between the singular terms and the viscous terms. To see this, suppose (p, v, θ) is a smooth solution of (1.4) and let $\Psi = \Psi(\vartheta, \wp) \in C^\infty(\mathbb{R}^2)$. Then $\psi := \Psi(\theta, \varepsilon p)$ satisfies

$$\begin{aligned} &g_1 g_3\big(\partial_t\psi + v\cdot\nabla\psi\big) \\ &\quad + \underbrace{\left(g_1\frac{\partial\Psi}{\partial\vartheta} + g_3\frac{\partial\Psi}{\partial\wp}\right)}_{=:\Gamma_1(\Psi)}\operatorname{div} v = \kappa\underbrace{\left(g_1\chi_3\frac{\partial\Psi}{\partial\vartheta} + g_3\chi_1\frac{\partial\Psi}{\partial\wp}\right)}_{=:\Gamma_2(\Psi)}\big(\operatorname{div}(k(\theta)\nabla\theta) + Q\big), \end{aligned}$$

where the coefficients g_i, χ_i, $\partial\Psi/\partial\vartheta$ and $\partial\Psi/\partial\wp$ are evaluated at $(\theta, \varepsilon p)$. We next show that for appropriate function Ψ one can impose

$$[\Gamma_1(\Psi) = 0 \text{ and } \Gamma_2(\Psi) > 0] \quad \text{or} \quad [\Gamma_1(\Psi) > 0 \text{ and } \Gamma_2(\Psi) = 0]. \tag{A.7}$$

Proposition A.5. *Assume that Assumptions* A.1 *and* A.2 *are satisfied and use the notation* (A.5). *The functions S^* and ρ^* satisfy*

$$g_1\frac{\partial S^*}{\partial\vartheta} = -g_3\frac{\partial S^*}{\partial\wp} > 0, \qquad g_1\chi_3\frac{\partial\rho^*}{\partial\vartheta} = -g_3\chi_1\frac{\partial\rho^*}{\partial\wp} < 0. \tag{A.8}$$

Remark A.6. The fact that $\Psi = S^*$ (or $\Psi = \rho^*$) satisfies the first (respectively, second) set of conditions in (A.7) now follows from $\chi_1 < \chi_3$.

Proof. By (A.4) and the definitions given in (A.3), one has

$$\frac{g_1^*}{g_3^*} = -\frac{P(\partial S/\partial P)}{T(\partial S/\partial T)}. \tag{A.9}$$

By definition (A.5), $\partial f^*/\partial\vartheta = \big[T(\partial f/\partial T)\big]^*$ and $\partial f^*/\partial\wp = \big[P(\partial f/\partial P)\big]^*$. This proves that S^* satisfies the first identity in (A.8). Next, we compute

$$\frac{\chi_1^*}{\chi_3^*} = \frac{(\partial\rho/\partial T)(\partial S/\partial P)}{(\partial\rho/\partial P)(\partial S/\partial T)}.$$

By (A.9), this yields $\chi_1^* g_3^* P(\partial\rho/\partial P) = -\chi_3^* g_1^* T(\partial\rho/\partial T)$. Which proves that ρ^* satisfies the second identity in (A.8). □

Remark A.7. Assumption (H2) in section 1.2 requires, in addition, that $F = S^*$ and $G = \rho^*$ define bijections. This only means that the thermodynamic state is completely determined by (P, T), or (P, S) or (ρ, T).

The following result contains an example of an equation of state such that χ_1 depends on ϑ.

PROPOSITION A.8. *Assume that the gas obeys Mariotte's law: $P = R\rho T$, for some positive constant R, and $e = e(T)$ satisfies $C_V := \partial e/\partial T > 0$. Then, Assumptions* A.1 *and* A.2 *are satisfied. Moreover,*

$$\chi_1^* = R/((C_V(T) + R)P),$$

so that $\chi_1(\vartheta, \wp)$ is independent of ϑ if and only if C_V is constant.

Acknowledgments. I warmly thank Guy Métivier for helpful discussions. Thanks to Didier Bresch, Christophe Cheverry, Raphaël Danchin, and David Lannes for stimulating comments about this work. Thanks also to the referees who pointed to a number of ways in which the presentation of section 3 could be improved.

GRADIENT FLOWS AS A SELECTION PROCEDURE FOR EQUILIBRIA OF NONCONVEX ENERGIES*

CHRISTOPH ORTNER†

Abstract. For atomistic material models, global minimization gives the wrong qualitative behavior; a theory of equilibrium solutions needs to be defined in different terms. In this paper, a concept based on gradient flow evolutions, to describe local minimization for simple atomistic models based on the Lennard–Jones potential, is presented. As an application of this technique, it is shown that an atomistic gradient flow evolution converges to a gradient flow of a continuum energy as the spacing between the atoms tends to zero. In addition, the convergence of the resulting equilibria is investigated in the case of elastic deformation and a simple damaged state.

Key words. gradient flows, λ-convexity, atomistic models, continuum limit

1. Introduction.

This article is concerned with a possible concept for analyzing elastic energy functionals which do not satisfy the classical coercivity and weak lower semicontinuity conditions of the calculus of variations. The subject of study is the one-dimensional atomistic energy

$$E_{\text{atom}}\big((y_j)_{j=1}^n\big) = \sum_{j=1}^{n} \big[J(y_j - y_{j-1}) + f_j u_j\big], \tag{1.1}$$

where $n \in \mathbb{N}$, and y_j are the positions of the atoms with $y_0 = 0$. The family (f_j) represents a linear applied force. We assume that the Lennard–Jones type potential $J = J(z)$ satisfies

$$\begin{aligned} &J \in \mathrm{C}^2(0,\infty),\\ &J(z) = +\infty \text{ if } z \le 0 \text{ and } J(z) \to +\infty \text{ as } z \to 0,\\ &J'(1) = 0, J''(z) > 0 \text{ in } (0, z_1), \text{ and}\\ &J \text{ is concave, increasing and bounded above in } (z_1, \infty), \end{aligned} \tag{1.2}$$

with $1 < z_1 < +\infty$. The typical shape is shown in Figure 1.1. Note, that the nonconvexity of J is of a much more fundamental type than the geometric nonconvexity of classical elasticity.

It has been noted previously (see, for example, [24]) that, due to the sublinear growth of J, the energy in (1.1) should not be analyzed in terms of global minimization, as this would give unrealistic material behavior. The most popular example given is that a material described by (1.1) would break for arbitrarily small loads if it were to attain its global minimum. We shall describe this in more detail in section 1.1.

In general, for applications in mechanics, it is advantageous to consider metastable states. The difficulty here is that the number of critical points of E_{atom} tends to infinity as $n \to \infty$. Thus, we require a selection criterion to pick the "correct" equilibrium

points. Theoretically, we should consider the natural dynamics of the material and let time tend to infinity to find its equilibrium state. Here, we take a considerably easier route and use $|\cdot|_{\mathrm{H}^1}$-gradient flow dynamics. Our justification for the gradient flow is merely to accept it as a simple model for local minimization. Concerning the choice of the metric, there are also strong mathematical reasons for choosing an $|\cdot|_{\mathrm{H}^1}$-gradient flow evolution which are outlined in sections 2 and 3. Note that we do not try to analyze a physical evolution. Our aim is to simply demonstrate a concept which we believe gives better results than the traditional method of global minimization. The ideas in this paper have also important applications for the numerical analysis of coarse-graining techniques such as the QC method [17], as they give an indication how numerical optimization methods can be stabilized [20].

The main goal of the present work is to show that the $|\cdot|_{\mathrm{H}^1}$-gradient flow provides a selection criterion for critical points which results in good qualitative properties of the resulting equilibrium model. The simplicity of the one-dimensional model problem makes it possible to give complete results; however, many of the fundamental techniques applied here carry over to much more complicated settings. The additional challenges posed by higher dimensions will be discussed in section 5.

As an application of the idea to use gradient flows to analyze equilibrium points of nonconvex energies, we consider the continuum limit of a rescaled version of the atomistic functional E_{atom} as the number of atoms n tends to infinity. The novelty is that we primarily consider the convergence of the gradient flow evolutions (Theorem 3.1), and obtain the convergence of the equilibria almost as an afterthought (see Theorem 4.1 for elastic deformations and the discussion in section 4.2 for fracture). This procedure gives a different and, one might argue, more realistic continuum limit than previous work; see section 1.2 for a more extensive discussion. In addition, this shows that there is a strong relationship between the atomistic and continuum equilibria.

The local minimizers selected by the gradient flow are weak local minimizers, i.e., local minimizers with respect to the $\mathrm{W}^{1,\infty}$-norm. It is clear from the shape of the interaction potential (cf. Figure 1.1) and the comments at the end of section 4.1 that this is in fact the only possibility. In any weaker topology, even the elastic critical points are not local minimizers of the energy. The same is true for fractured states but the interpretation of $\mathrm{W}^{1,\infty}$ would be more subtle in this case.

If we replace the Lennard–Jones potential by a potential which is smooth at the origin and therefore J' Lipschitz-continuous, then the convergence analysis of the gradient flow requires only minor modifications of the classical convergence analysis of Galerkin discretizations. For the approach in this paper, however, convergence of

the energy is sufficient (cf. Theorem 2.4), which makes a result as general as Theorem 3.1 possible. To achieve this we use some generalizations of ideas in [1, Chapter 4].

For the analysis of equilibria, we use a lim inf condition for the slope of a family of functionals, whose proof is based on the notion of λ-convexity. This condition was also used in [23] to analyze the convergence of gradient flows. Using the techniques of this paper, which has a different aim than the present work, the convergence would have to be obtained by compactness principles (which are not available in our case) rather than λ-convexity.

1.1. The failure of global minimization. The Cauchy–Born hypothesis states that an atomistic body, subjected to a small affine boundary displacement, will follow this displacement in the bulk. Friesecke and Theil demonstrate in [15] a two-dimensional, mathematical version of this important foundation of continuum mechanics by considering global minima of an energy similar to (3.1) but with a quadratic interaction potential. When the potential has sublinear growth, global minimization will typically not reproduce this behavior.

Let us consider the atomistic energy $E_{\rm atom}$ in (1.1) with $f_i \equiv 0$, but apply a "Dirichlet" boundary condition at the right end of the domain as well. For each $\delta > 0$, we consider the minimization problem

$$\min_{y_n = n(1+\delta)} E_{\rm atom}\big((y_j)_{j=1}^n\big). \tag{1.3}$$

Concerning the formulation of the boundary displacement, note that the minimum of $J(z)$ is attained at $z = 1$. The choice of boundary displacement we have made here scales linearly with the number of atoms. An interesting different choice was made in [6] which we discuss briefly in section 1.2.

PROPOSITION 1.1. *There exist constants $\delta_0, C_0 > 0$, such that, for $\delta_0 > \delta > C_0 n^{-1/2}$, the affine state $y_j = (1+\delta)j$ is not the solution of* (1.3).

Proof. Consider the "fractured" deformation $y_j^f = j$ for $j = 0, 1, \ldots, n-1$ and $y_n^f = n(1+\delta)$. Then,

$$E_f(\delta) = E_{\rm atom}\big((y_j^f)_{j=1}^n\big) = (n-1)J(1) + J(1+n\delta) \le (n-1)J(1) + \sup_{z \ge 1} J(z).$$

The affine state $y_j^a = (1+\delta)j$ on the other hand has the energy

$$E_a(\delta) = E_{\rm atom}\big((y_j^a)_{j=1}^n\big) = nJ\big((1+\delta)\big).$$

The assumptions we have made in (1.2) allow us to estimate $J(z)$ from below by a quadratic

$$J(1) + c_0(z-1)^2 \le J(z) \text{ for } 1 \le z < \delta_0,$$

where $c_0 > 0$ and $\delta_0 > 0$ are appropriately chosen. Therefore, for $\delta < \delta_0$, we have $E_a(\delta) \ge n(J(1) + c_0\delta^2)$, and we obtain that $E_a(\delta) > E_f(\delta)$, if

$$\delta^2 \;>\; n^{-1}\Big(\frac{\sup_{z\ge 1} J(z) - J(1)}{c_0}\Big) =: C_0^2 n^{-1}. \qquad \square$$

The proof of Proposition 1.1, which is merely a review of well-known facts, actually suggests that not only is the Cauchy–Born hypothesis violated, but in fact any material with a sufficient number of atoms breaks for arbitrarily small boundary displacements or surface forces, if it were to attain its global energy minimum. This behavior is in clear contradiction to observations and, therefore, global minimization should be rejected for models of the type (1.1).

1.2. Continuum limits of atomistic energies. Continuum limits of atomistic models have been studied by many authors in the past. Because it is customary, we consider the case of Dirichlet boundary conditions in this section only. To be able to compute a continuum limit, we need to first rescale the energy (1.1) to a fixed, finite domain. The seemingly naive approach is to use a linear scaling of the energy as well as the boundary condition, which gives

$$E_n^{(1)}\big((y_j)_{j=0}^n\big) = \sum_{j=1}^n \frac{1}{n} J\big(n(y_j - y_{j-1})\big), \quad y_0 = 0, y_n = 1 + \delta. \tag{1.4}$$

If we assume that the body attains its global energy minimum, then for an arbitrarily small boundary displacement δ, the deformation will not be a continuum state (compare Proposition 1.1). This fact is reflected by the Γ-limit of $E_n^{(1)}$ as $n \to \infty$ (see, for example, [4, 5] and references therein) which gives the energy

$$E^{(1)}(y) = \int_0^1 J^{**}(y')\,\mathrm{d}x, y(0) = 0, y(1) = 1 + \delta,$$

where J^{**} is the convex envelope of J.

Motivated by an analysis quite similar to Proposition 1.1, it can be seen that if a different scaling is used, then the Γ-limit becomes more interesting [6]. If we define

$$E_n^{(2)}\big((u_j)_{j=0}^n\big) = \sum_{j=1}^n \Big[J\big(1 + \sqrt{n}(u_j - u_{j-1})\big) - J(1)\Big], \quad u_0 = 0, u_n = \delta,$$

then the Γ-limit turns out to be the Griffiths functional (compare [13])

$$G(u) = \alpha \int_0^1 |u'|^2\,\mathrm{d}x + \beta \sharp S_u, \quad u(0) = 0, u(1) = \delta,$$

where S_u is the set of jump-discontinuities of the displacement u, $\alpha = 1/2J''(1)$ and $\beta = \lim_{z\to\infty} J(z) - J(1)$. The boundary values of the possibly discontinuous functions u can be interpreted in a meaningful way. While it is interesting that the Griffiths functional can be obtained in this way, it should be noted that this model is typically used for crack propagation only, not crack initiation. In one dimension, however, only crack initiation can be analyzed.

The philosophy adopted in the present work is that the scaling of functional $E_n^{(1)}$ is actually the natural one; only the process of passing to the continuum limit is flawed. It will be shown that, if the continuum limit is analyzed in terms of an appropriate evolution, then the resulting model is in fact a very realistic candidate.

One of the problems addressed in this paper (see section 4) is to find the stable equilibrium that the material would "naturally" assume if we started in the reference configuration $y_i^n = x_i^n$, or a perturbation thereof, and then applied forces. In Theorem 4.1 we show that the resulting equilibria represent the correct elastic behavior. For this reason we prefer to work with surface forces rather than a prescribed displacement. This is, however, not a restriction. The entire convergence theory can also be repeated for Dirichlet conditions applied at both ends of the interval.

Closest in spirit to the approach advocated here is the work by Blanc, Le Bris, and Lions [3]. Except for the fact that they consider far more complicated atomistic interactions in three dimensions, their continuum limit is the same. In fact, the present

work may be seen as a small step towards a rigorous justification of the approach taken in [3].

From the point of view of numerical analysis, strong connections can be drawn to the local version of the quasicontinuum method [17]. In this respect, the results of E and Ming [11] have some similarities to our own.

For results on the continuum manifestation of some further interesting atomistic effects like finite-range interactions, the reader is referred to [25, 9].

1.3. Outline of the paper. We begin in section 2 by outlining the theoretical tools for the convergence analysis, a theory of gradient flows based on the notion of λ-convexity, and a corresponding approximation theory. We also review the notion of slope which is used to define the concept of critical points.

In section 3, we prove the convergence of an atomistic gradient flow evolution to the $|\cdot|_{\mathrm{H}^1}$-gradient flow of a nonconvex functional defined on H^1, giving a new type of continuum limit for atomistic functionals.

Finally, in section 4, we analyze the resulting equilibrium solutions which are obtained when $t \to \infty$ in the gradient flow. First, we consider the case of small loads and show that the equilibria obtained are the physically reasonable elastic deformations and not the "fractured" global energy minima. Then, we give a brief description of the behavior of the gradient flow evolution in the case when the loads are sufficiently large to create fracture. We demonstrate that the obtained equilibrium is reasonable given that we are always assuming perfect crystals and perfect equilibria. However, these critical points are highly unstable, as is demonstrated also in numerical computations. We may interpret this instability as the uncertainty of where fracture occurs in a material.

1.4. Connections to other models. In section 1.2, some connections to the works of Blanc, Le Bris, and Lions [3] and E and Ming [11] were briefly touched upon. In both of these works, the concept of global minimization of the energy is rejected and alternative means are sought to analyze equilibria of elastic energy functionals. A similar approach is taken by Rieger and Zimmer [22], who use a time-discrete gradient flow evolution of Young-measures to analyze material damage. In the slightly different setting of viscoelasticity [21, 2, 14], it is shown that dynamics can prevent the formation of finer and finer microstructure and therefore the attainment of a global energy minimum.

The model presented here is not to be confused, however, with quasistatic or rate independent evolutions (see, for example, [10, 13] for fracture, [8] for plasticity, or [16] for an abstract analysis). In their time-discrete form, at every timestep an equilibrium (typically a minimum) of a functional of the form

$$D(u_{j-1}, u) + E(u) \tag{1.5}$$

is sought, where D is a so-called dissipation metric. Rather, the gradient flow model we present here should be understood as a simple mechanism to find the equilibrium in the quasistatic evolution (1.5).

2. Approximation of gradient flows of nonconvex energies. Let $\mathscr{H}$ be a Hilbert space with inner product $(\cdot,\cdot)$ and norm $\|\cdot\|$, let $\mathscr{A}$ be a closed convex subset of $\mathscr{H}$, and let $\phi\colon \mathscr{H} \to (-\infty, \infty]$. If ϕ is Fréchet differentiable at a point u, we denote the representation of its derivative, i.e., its gradient, by $\phi'(u)$. Second order derivatives are denoted by $\phi''(u; v_1, v_2)$. We denote the domain of definition of ϕ by $D(\phi) = \{u \in \mathscr{H}\colon \phi(u) < \infty\}$. By using the convention $+\infty \leq +\infty$, we do in fact not

need to make much explicit use of the domain of definition. For example, a functional ϕ would then be convex if and only if $D(\phi)$ is convex and ϕ is convex in $D(\phi)$.

Naively, we may call a curve $u \in \mathrm{C}^1(a,b;\mathscr{H})$ a gradient flow of ϕ, if

$$\dot{u}(t) = -\phi'(u(t)) \quad \forall t \in (a,b). \tag{2.1}$$

Equation (2.1) in infinite-dimensional spaces is usually restated only for convex functionals ϕ. The natural condition on ϕ, under which a considerable part of the theory of gradient flows for convex functionals can be recovered, is the condition of λ-convexity [1]. We say that ϕ is λ-convex in $\mathscr{A}$ if there exists $\lambda \in \mathbb{R}$ such that

$$\phi\big((1-t)v_0 + tv_1\big) \le (1-t)\phi(v_0) + t\phi(v_1) - \frac{\lambda}{2}t(1-t)\|v_0 - v_1\|^2 \quad \forall v_0, v_1 \in \mathscr{A} \quad \forall t \in (0,1). \tag{2.2}$$

To obtain a better feel for the meaning of λ-convexity, consider the following simple proposition (for a proof, see [19]).

Proposition 2.1.

(a) *The functional ϕ is λ-convex in $\mathscr{A}$ if and only if $u \mapsto \phi(u) - \frac{\lambda}{2}\|u\|^2$ is convex in $\mathscr{A}$.*

(b) One-sided Lipschitz continuity of the gradient: *If ϕ is differentiable at every point of $\mathscr{A}$ and satisfies*

$$\big(\phi'(v_1) - \phi'(v_0), v_1 - v_0\big) \ge \lambda\|v_1 - v_0\|^2 \quad \forall\, v_1, v_0 \in \mathscr{A}, \tag{2.3}$$

then ϕ is λ-convex in $\mathscr{A}$.

(c) Boundedness below of the Hessian: *If ϕ is twice differentiable at every nonextremal point of $\mathscr{A}$ and*

$$\phi''(u; v-u, v-u) \ge \lambda\|v-u\|^2 \quad \forall u, v \in \mathscr{A}, \tag{2.4}$$

then ϕ is λ-convex in $\mathscr{A}$.

(d) *If $\phi = \phi_1 + \phi_2$, where $\phi_i \colon \mathscr{A} \to (-\infty, +\infty]$, ϕ_1 is λ_1-convex and ϕ_2 is λ_2-convex, then ϕ is $(\lambda_1 + \lambda_2)$-convex.*

If a functional is λ-convex, then its gradient flows have an alternative characterization. Suppose that a curve $u \in \mathrm{C}^1(a,b;\mathscr{H})$ satisfies (2.1), where ϕ is λ-convex. By a relatively straightforward energy argument, one can show that u also satisfies the evolutionary variational inequality

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|u(t) - v\|^2 + \frac{\lambda}{2}\|u(t) - v\|^2 + \phi(u(t)) \le \phi(v) \quad \forall\, v \in \mathscr{H}, \forall\, t \in (a,b).$$

This inequality is the basis for a powerful theory of gradient flows in metric spaces, then called curves of maximal slope, developed in Chapter 4 of [1]. Note, for example, that it makes sense to consider $u, v \in \mathscr{A}$ only, instead of all of $\mathscr{H}$. Theorem 2.2 is a collection of results in [1] translated to the Hilbert space setting which is sufficient for our purposes.

Theorem 2.2 (existence and uniqueness). *Let $\mathscr{A}$ be a closed, convex subset of a Hilbert space $\mathscr{H}$ and let $\phi \colon \mathscr{A} \to (-\infty, \infty]$ be (strongly) lower semicontinuous and λ-convex. For each $u_0 \in D(\phi)$, there exists a locally Lipschitz-continuous curve $u \colon [0,\infty) \to \mathscr{A}$ which is the unique solution of*

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|u(t) - v\|^2 + \frac{\lambda}{2}\|u(t) - v\|^2 + \phi(u(t)) \le \phi(v) \quad \forall\, v \in \mathscr{A} \text{ for a.e. } t > 0, \tag{2.5}$$

among all curves $v \in \mathrm{AC}_{\mathrm{loc}}(0,\infty;\mathscr{A})$*, satisfying* $v(0+) = u_0$*.*

For the remainder of the paper, we shall use the following definition for a gradient flow.

DEFINITION 2.3. *Let* $\mathscr{A}$ *be a closed, convex subset of a Hilbert space* $\mathscr{H}$ *and* $\phi\colon \mathscr{A} \to (-\infty,\infty]$ *a lower semicontinuous and* λ*-convex functional. We say that a locally Lipschitz-continuous curve* $u\colon [0,\infty) \to \mathscr{A}$ *is a gradient flow of* ϕ*, if it satisfies* (2.5)*.*

2.1. Approximation of gradient flows. Based on the evolutionary variational inequality stated above, an abstract convergence theory for gradient flows in a general metric setting for λ-convex functionals was developed in [19]. Theorem 2.4 below is one result therein which is relevant for the Hilbert space setting in the present work. For the sake of completeness, we give a sketch of the proof.

THEOREM 2.4. *Let* $\mathscr{A}$ *be a closed, convex subset of a Hilbert space* $\mathscr{H}$ *and, for* $n \in \mathbb{N}$*, let* $\phi, \phi_n\colon \mathscr{A} \to (-\infty,\infty]$ *be functionals defined on* $\mathscr{A}$*. Let* $u^0 \in D(\phi)$ *and* $u_n^0 \in D(\phi_n)$ *be given initial values, and assume that the following conditions are satisfied:*

(i) Lower semicontinuity: *The functionals* ϕ *and* ϕ_n *(*$n \in \mathbb{N}$*) are lower semicontinuous.*

(ii) Uniform λ-convexity: *There exists* $\lambda \in \mathbb{R}$*, such that the* ϕ_n *as well as* ϕ *are* λ*-convex.*

(iii) Equicoercivity: *There exists a point* $u^* \in \mathscr{A}$ *and* $\epsilon > 0$ *such that* $\inf_{n\in\mathbb{N}} \inf_{v\in\mathscr{A}, \|v-u^*\|\le\epsilon} \phi_n(v) > -\infty$*.*

(iv) Convergence of the initial data: $\sup_{n\in\mathbb{N}} \phi_n(u_n^0) < \infty$ *and* $\|u_n^0 - u^0\| \to 0$ *as* $n \to \infty$*.*

(v) Consistency: *If* $(w_n)_{n\in\mathbb{N}} \subset \mathscr{A}$ *is bounded in* $\mathscr{H}$*, then there exists a constant* $c_1 > 0$ *such that*

$$\limsup_{n\to\infty} \big(\phi(w_n) - \phi_n(w_n)\big) \le 0, \text{ and } \phi(w_n) \le c_1(1 + [\phi_n(w_n)]^+ + \|w_n\|^2).$$

(vi) Best approximation error: *For every* $n \in \mathbb{N}$*, there exists a Borel-measurable curve* $v_n\colon (0,\infty) \to \mathscr{A}$*, so that* $v_n \to u$ *in* $\mathrm{L}^2_{\mathrm{loc}}([0,\infty);\mathscr{H})$ *and*

$$\phi_n(v_n(t)) \to \phi(u(t)) \text{ and } \phi_n(v_n(t)) \le c_2(1 + [\phi(u(t))]^+ + \|u(t)\|^2),$$

where u *is the gradient flow of* ϕ *with initial data* u^0*.*

Then the gradient flows (in the sense of Definition 2.3*)* u_n *of* ϕ_n *with initial values* u_n^0 *converge in* $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathscr{H})$ *to the gradient flow* u *of* ϕ *with initial value* u^0*.*

Proof. Let u and u_n, respectively, satisfy

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|u(t)-v\|^2 + \frac{\lambda}{2}\|u(t)-v\|^2 + \phi(u(t)) \le \phi(v) \quad \forall\, v \in \mathscr{A}, \text{ and} \tag{2.6}$$

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|u_n(t)-v_n\|^2 + \frac{\lambda}{2}\|u_n(t)-v_n\|^2 + \phi(u_n(t)) \le \phi(v_n) \quad \forall\, v_n \in \mathscr{A}. \tag{2.7}$$

We test (2.6) with $v = u_n$ and choose a recovery sequence v_n satisfying (vi) to test (2.7). Adding (2.6) and (2.7) and some lengthy but relatively straightforward algebra gives the error estimate

$$\begin{aligned}\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|u-u_n\|^2 + \frac{\tilde\lambda}{2}\|u-u_n\|^2 \le \big(\phi_n(v_n) - \phi(u)\big) + \big(\phi(u_n) - \phi_n(u_n)\big) \\ + \frac{|\lambda|}{2}\|v_n-u\|^2 + \frac{1}{2}\|\dot u_n\|\|v_n-u\|,\end{aligned}$$

where $\tilde{\lambda} = \lambda - |\lambda|/2$. The λ-convexity can be used to derive an a priori estimate on the $\mathrm{L}^2(0,T)$-norm of $\|\dot{u}_n\|$ and $\phi(u_n)$. Using Gronwall's inequality, we obtain

$$\mathrm{e}^{2\tilde{\lambda}T}\|u(T) - u_n(T)\|^2 \leq \|u(0) - u_n(0)\|^2 + \int_0^T \mathrm{e}^{2\tilde{\lambda}t}(\text{error terms})\,\mathrm{d}t.$$

Using Fatou's lemma, the integral term on the right-hand side can be shown to tend to zero as $n \to \infty$, given the hypothesis of the theorem. □

Next, we state a result from [1], concerning the implicit Euler approximation of a gradient flow, which we will use frequently in section 4.

LEMMA 2.5. *Let $t_j = j\tau$, for $j = 0, 1, \ldots$, define a partition of $[0,\infty)$, with $0 < \tau < 1/\min(0, -\lambda)$. Let $u_0 \in \mathscr{H}$, and let the family $(u_i)_{i=1,2,\ldots}$ be defined by*

$$u_i = \operatorname{argmin}_{\mathscr{A}} \left[v \mapsto \frac{\|v - u_{i-1}\|^2}{2\tau} + \phi(v) \right].$$

Let $u(t)$ be the gradient flow of ϕ with $u(0) = u_0$ and let $\bar{u}_\tau(t)$ be the piecewise constant interpolant of (u_i), i.e.,

$$\bar{u}_\tau(0) = 0 \quad \text{and} \quad \bar{u}_\tau(t) = u_i \quad \text{if } t_{i-1} < t \leq t_i.$$

Then, $\bar{u}_\tau(t) \to u(t)$ in $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty), \mathscr{H})$, as $\tau \to 0$.

2.2. The slope. So far we have only described gradient flow evolutions. However, we are also interested in analyzing the resulting equilibria, which can often be obtained by letting time tend to infinity. A natural concept of equilibrium, or critical point, is given by the concept of local slope,

$$|\partial\phi|(u) = \limsup_{v \to u} \frac{(\phi(u) - \phi(v))^+}{\|u - v\|}. \tag{2.8}$$

We say that $u^* \in \mathscr{H}$ is a critical point of the functional ϕ, if $|\partial\phi|(u^*) = 0$. The following lemma can be used in certain situations to show that an accumulation point of critical points of approximate functionals ϕ_n must again be a critical point.

LEMMA 2.6. *Let $\mathscr{H}$ be a Hilbert space, let $\phi, \phi_n \colon \mathscr{H} \to (-\infty, \infty]$ be λ-convex, with a uniform λ, and suppose that ϕ_n Γ-converges to ϕ in the strong topology of $\mathscr{H}$, i.e.,*

$$v_n \to v \Rightarrow \phi(v) \leq \liminf_{n\to\infty} \phi_n(v_n) \tag{2.9}$$

$$\forall v \in \mathscr{H}\ \exists (v_n)_{n\in\mathbb{N}} \subset \mathscr{H} \text{ s.t. } v_n \to v \text{ and } \phi(v) = \lim_{n\to\infty} \phi(v_n). \tag{2.10}$$

Then, the slopes satisfy the lim inf condition

$$u_n \to u \Rightarrow |\partial\phi|(u) \leq \liminf_{n\to\infty} |\partial\phi_n|(u_n). \tag{2.11}$$

Proof. The crucial observation [1, Theorem 2.4.9] is that for λ-convex functionals, the slope can be rewritten as

$$|\partial\phi|(u) = \sup_{v \neq u} \left[\frac{\phi(u) - \phi(v)}{\|u - v\|} + \frac{\lambda}{2}\|u - v\|^2 \right]^+.$$

Let $u_n \to u$, and for some fixed $v \neq u$ let $(v_n)_{n\in\mathbb{N}}$ be a recovery sequence for v, satisfying (2.10). Then, we have

$$\begin{aligned}
&\left[\frac{\phi(u)-\phi(v)}{\|u-v\|} + \frac{\lambda}{2}\|u-v\|^2\right]^+ \\
&\leq \left[\frac{\liminf_{n\to\infty}\phi_n(u_n) - \lim_{n\to\infty}\phi_n(v_n)}{\lim_{n\to\infty}\|u_n-v_n\|} + \frac{\lambda}{2}\lim_{n\to\infty}\|u_n-v_n\|^2\right]^+ \\
&\leq \liminf_{n\to\infty}\left[\frac{\phi_n(u_n)-\phi_n(v_n)}{\|u_n-v_n\|} + \frac{\lambda}{2}\|u_n-v_n\|^2\right]^+ \\
&\leq \liminf_{n\to\infty} |\partial\phi_n|(u_n).
\end{aligned}$$

Taking the supremum over $v \neq u$, we obtain (2.11). ∎

3. Convergence of an atomistic evolution. In section 1.2, it was outlined that different scalings of the atomistic energy $E_{\rm atom}$ give rise to different continuum limits. We have adopted the point of view that a linear scaling of all terms considered is the most natural choice. For the forces we assume that $f_n = O(1)$ and $f_j = O(1/n)$ for $1 \leq j \leq n-1$, i.e., f_n represents a boundary force. It is then natural to consider the rescaled energy

$$E_n\big((y_j^n)_{j=1}^n\big) = \sum_{j=1}^n \epsilon_n \left[J\left(\frac{y_j^n - y_{j-1}^n}{\epsilon_n}\right) - f_j^n(y_j^n + y_{j-1}^n)/2\right] - g y_n^n, \tag{3.1}$$

where $\epsilon_n = 1/n$. The family $(f_i^n)_{i=1,\dots,n}$ defines a linear body force, which we assume is obtained by averaging an L^1 function, i.e.,

$$f_i^n = \fint_{x_{i-1}^n}^{x_i^n} f(x)\,\mathrm{d}x,$$

where $x_i^n = i/n$, for each $i \in \mathbb{Z}$. The scalar g describes a linear surface force. For technical reasons, we may wish to impose an L^∞ bound on the deformations, i.e., we shall assume that $y_i^n \leq M$, where $M \in (z_1, \infty]$.

To rewrite E_n as an integral functional it is customary to identify the atomistic deformation with a piecewise affine function. To this end, we define the set of "admissible" atomistic deformations to be

$$\mathscr{A}_n := \big\{v \in \mathrm{H}^1(0,1)\colon v(0) = 0, v \leq M, \text{ and } v \text{ is piecewise affine w.r.t. } (x_i^n)\big\}.$$

Letting

$$\begin{aligned}
y_n'(x) &= \frac{y_i^n - y_{i-1}^n}{\epsilon_n} \quad \text{if } x \in (x_{i-1}^n, x_i^n), \text{ and} \\
y_n(x) &= \int_0^x y_n'(x)\,\mathrm{d}x,
\end{aligned}$$

y_n is the piecewise-affine interpolant of (y_i^n) and y_n' is its weak derivative, and we have in particular that $y_n \in \mathscr{A}_n$. Thus, we can rewrite E_n as

$$E_n(y_n) = \int_0^1 \big[J(y_n') - f_n y_n\big]\,\mathrm{d}x - g y_n(1) \qquad \text{for } y_n \in \mathscr{A}_n, \tag{3.2}$$

where f_n is the piecewise constant interpolant of f with

$$f_n(x) = f_n^i \quad \text{for } x \in (x_{i-1}, x_i). \tag{3.3}$$

In the formulation (3.2) it becomes obvious that the nonconvexity is with respect to the deformation gradient. In order to balance it out with the evolution, we need to consider the gradient flow with respect to the $|\cdot|_{\mathrm{H}^1}$-seminorm, which is in fact a norm in the spaces $\mathscr{A}_n$. We shall show below, though it is already quite obvious at this point, that the functionals E_n are uniformly λ-convex in the $|\cdot|_{\mathrm{H}^1}$-seminorm. Therefore, from Theorem 2.4, we expect the correct limit energy with respect to the $|\cdot|_{\mathrm{H}^1}$-gradient flow evolution to be

$$E(y) = \int_0^1 \big[J(y') - fy\big]\,\mathrm{d}x - gy(1), \tag{3.4}$$

defined for $y \in \mathscr{A} := \{v \in \mathrm{H}^1(0,1)\colon v(0) = 0, v \le M\}$.

While it is possible to consider gradient flows with respect to the full H^1-norm as well, the analysis of equilibria becomes significantly more technical. In addition, the $|\cdot|_{\mathrm{H}^1}$-seminorm seems to be the more natural metric for the gradient flow. All results can, however, be translated to the H^1-norm case [18].

Theorem 3.1 states that the (atomistic) $|\cdot|_{\mathrm{H}^1}$-gradient flow of E_n in $\mathscr{A}_n$ converges to the (continuum) $|\cdot|_{\mathrm{H}^1}$-gradient flow of E in $\mathscr{A}$. We embed $\mathscr{A}_n$ in $\mathscr{A}$ by setting $E_n(y) = +\infty$ if $y \in \mathscr{A} \setminus \mathscr{A}_n$.

THEOREM 3.1. *Let $y^0 \in D(E)$, and let $y_n^0 \in \mathscr{A}_n$ be the piecewise affine interpolant of y^0 with respect to the mesh (x_i^n). Then, the $|\cdot|_{\mathrm{H}^1}$-gradient flow y_n of E_n with initial data y_n^0 converges in $\mathrm{L}^\infty_{\mathrm{loc}}([0,\infty);\mathscr{A})$ to the $|\cdot|_{\mathrm{H}^1}$-gradient flow y of E with initial data y^0.*

The convergence proof consists of three steps: first, establishing the λ-convexity of the functionals; second, estimating the perturbations caused by the discrete forcing term; and third, constructing a recovery sequence for the solution which satisfies condition (vi) of Theorem 2.4.

LEMMA 3.2. *With respect to the norm $|\cdot|_{\mathrm{H}^1}$, the functionals E and E_n ($n \in \mathbb{N}$) are λ-convex in $\mathscr{A}$, with $\lambda = \min_{z>0} J''(z)$, and lower semicontinuous.*

Proof. For the λ-convexity as well as the lower semicontinuity, note that the linear, continuous terms need not be considered and we assume without loss of generality that $f, g \equiv 0$. In the spirit of Proposition 2.1, we define $F(z) = J(z) - (\lambda/2)z^2$. By the definition of λ, $F''(y) \ge 0$ whenever $y > 0$, hence F is convex in $(0,\infty)$. Since $F(z) = +\infty$ for $z \le 0$, F is convex on $\mathbb{R}$. Therefore, the functional

$$G(y) = \int_0^1 \Big(J(y') - \frac{\lambda}{2}|y'|^2\Big)\,\mathrm{d}x \;=\; \int_0^1 F(y')\,\mathrm{d}x$$

is convex as well which implies, by Proposition 2.1, that E is λ-convex. Since $E(y) = G(y) - \lambda/2|y|^2_{\mathrm{H}^1}$, a sum of a convex and a continuous functional, E is lower semicontinuous. To see that E_n is lower semicontinuous, simply note that under the assumption that $f, g \equiv 0$, $E_n = E|_{\mathscr{A}_n}$, where $\mathscr{A}_n$ is convex and closed and hence the proof carries over to E_n as well. ∎

LEMMA 3.3. *If $f \in \mathrm{L}^1(0,1)$, then, for every $v \in \mathscr{A}$, we have*

$$\Big|\int_0^1 (f_n - f)v\,\mathrm{d}x\Big| \le |v|_{\mathrm{H}^1}\|f - f_n\|_{\mathrm{L}^1(0,1)}, \text{ and}$$
$$\|f - f_n\|_{\mathrm{L}^1} \to 0 \quad \text{as } n \to \infty,$$

where f_n is defined as in (3.3).

Proof. Hölder's inequality gives

$$\Big| \int_0^1 (f_n - f) v \,\mathrm{d}x \Big| \leq \|v\|_{\mathrm{L}^\infty} \|f - f_n\|_{\mathrm{L}^1(0,1)}.$$

Using $v(0) = 0$, we also have $\|v\|_{\mathrm{L}^\infty} \leq \|v'\|_{\mathrm{L}^1} \leq |v|_{\mathrm{H}^1}$, which gives the first result. The convergence $\|f_n - f\|_{\mathrm{L}^1} \to 0$ follows from the fact that f_n is the L^2-projection of f onto the piecewise constant functions with respect to the mesh (x_i^n), using also the density of $\mathrm{L}^2(0,1)$ in $\mathrm{L}^1(0,1)$. ∎

LEMMA 3.4. *Let E and E_n be, respectively, given by* (3.4) *and* (3.2)*, where $f \in \mathrm{L}^1(0,1)$ and f_n satisfies* (3.3)*. For every $y \in \mathscr{A}$ with $E(y) < +\infty$, the piecewise affine, continuous interpolants v_n of y with respect to the mesh (x_i^n) satisfy*

$$|v_n - y|_{\mathrm{H}^1} \to 0, E_n(v_n) \to E(y) \ \text{ as } n \to \infty,$$
$$|v_n|_{\mathrm{H}^1} \leq |y|_{\mathrm{H}^1}, \text{ and } \ E_n(v_n) \leq \left[2\|f\|_{\mathrm{L}^1}^2 + \sup_{z \geq 1} J(z) \right] + E(y) + 2|y|_{\mathrm{H}^1}^2.$$

Proof. Let $y \in \mathscr{A}$, and let v_n be the piecewise affine interpolant with respect to the mesh (x_i^n). Applying Jensen's inequality to

$$\int_{x_{i-1}^n}^{x_i^n} v_n' \,\mathrm{d}x = \int_{x_{i-1}^n}^{x_i^n} y' \,\mathrm{d}x,$$

and summing over i, we get $\|v_n'\|_{\mathrm{L}^2(0,1)} \leq \|y'\|_{\mathrm{L}^2(0,1)}$. It follows from standard interpolation error estimates and a simple density argument that $|y - v_n|_{\mathrm{H}^1} \to 0$ as $n \to \infty$.

To compute the bounds on the energy as well and to show its convergence, we start with the lower-order terms. Jensen's inequality gives $\|f_n\|_{\mathrm{L}^1} \leq \|f\|_{\mathrm{L}^1}$ and as in the proof of Lemma 3.3, $\|v_{(n)}\|_{\mathrm{L}^\infty} \leq |v_{(n)}|_{\mathrm{H}^1} \leq |v|_{\mathrm{H}^1}$. Thus, we have

$$\begin{aligned} -\int_0^1 f_n v_n \,\mathrm{d}x &= -\int_0^1 fy \,\mathrm{d}x + \int_0^1 \big[f(y - v_n) + (f - f_n) v_n \big] \,\mathrm{d}x \\ &\leq -\int_0^1 fy \,\mathrm{d}x + \|f\|_{\mathrm{L}^1} \|y - v_n\|_{\mathrm{L}^\infty} + \|f - f_n\|_{\mathrm{L}^1} \|v_n\|_{\mathrm{L}^\infty} \\ &\leq -\int_0^1 fy \,\mathrm{d}x + \|f\|_{\mathrm{L}^1} |y - v_n|_{\mathrm{H}^1} + \|f - f_n\|_{\mathrm{L}^1} |v|_{\mathrm{H}^1} \qquad (3.5) \\ &\leq -\int_0^1 fy \,\mathrm{d}x + 2\|f\|_{\mathrm{L}^1}^2 + 2|y|_{\mathrm{H}^1}^2. \qquad (3.6) \end{aligned}$$

Using Lemma 3.3 and the fact that $v_n(1) = y(1)$ for all $n \in \mathbb{N}$, we obtain from (3.5) and (3.6),

$$\begin{aligned} &-\int_0^1 f_n v_n \,\mathrm{d}x - g v_n(1) \to -\int_0^1 fy \,\mathrm{d}x - gy(1) \ \text{ as } n \to \infty, \text{ and} \qquad (3.7) \\ &-\int_0^1 f_n v_n \,\mathrm{d}x - g v_n(1) \leq -\int_0^1 fy \,\mathrm{d}x - gy(1) + 2\|f\|_{\mathrm{L}^2(0,1)}^2 + 2|y|_{\mathrm{H}^1}^2. \end{aligned}$$

To deal with the higher-order terms, let $J(z) = J_0(z) + J_1(z)$, where $J_0(z) = J(z)\chi_{(-\infty,1]}(z)$. In the interval (x_{i-1}^n, x_i^n), we have $v_n' = n \int_{x_{i-1}^n}^{x_i^n} y' \,\mathrm{d}x$ and, using

Jensen's inequality $J_0(v_n') \le n \int_{x_{i-1}^n}^{x_i^n} J_0(y')\,\mathrm{d}x$ (note that $1/n$ is the length of the interval). If we define

$$a_n(x) = n \int_{x_{i-1}^n}^{x_i^n} J_0(y')\,\mathrm{d}x + \sup_{z\ge 1} J(z) \quad \text{for } x \in (x_{i-1}^n, x_i^n),$$

then $J(v_n') \le a_n(x)$ a.e. in $(0,1)$ and

$$\int_0^1 a_n(x)\,\mathrm{d}x = \int_0^1 J_0(y')\,\mathrm{d}x + \sup_{z\ge 1} J(z) =: A.$$

In particular, we also have

$$\int_0^1 J(v_n')\,\mathrm{d}x \le \int_0^1 J(y')\,\mathrm{d}x + \sup_{z\ge 1} J(z),$$

which, together with (3.7) gives

$$E_n(v_n) \le \left[2\|f\|_{\mathrm{L}^1}^2 + \sup_{z\ge 1} J(z)\right] + E(y) + 2|y|_{\mathrm{H}^1}^2. \tag{3.8}$$

Since $x \mapsto J_0(y'(x)) \in \mathrm{L}^1(0,1)$, we have, by a slightly stronger version of Lebesgue's differentiation theorem ([12], section 1.7, Corollary 2),

$$\lim_{n\to\infty} a_n(x) = J_0(x) + \sup_{z\ge 1} J(z)$$

for a.e. $x \in (0,1)$, and similarly, $v_n' \to y'$ a.e. in $(0,1)$.

Using Fatou's lemma, and the fact that J is continuous in $(0,\infty)$, we have

$$\begin{aligned} 2A - \limsup_{n\to\infty} \int_0^1 \left|J(v_n') - J(y')\right| \mathrm{d}x &= \liminf_{n\to\infty} \int_0^1 \left[2a_n - |J(v_n') - J(y')|\right] \mathrm{d}x \\ &\ge \int_0^1 \liminf_{n\to\infty} \left[2a_n - |J(v_n') - J(y')|\right] \mathrm{d}x \\ &= 2\int_0^1 \left[J_0(y') + \sup_{z\ge 1} J(z)\right] \mathrm{d}x \\ &= 2A, \end{aligned}$$

and hence, using also (3.7), we have $E(v_n) \to E(y)$ as $n \to \infty$. ∎

We have now assembled all results required to prove Theorem 3.1.

Proof of Theorem 3.1. The result is a straightforward application of Theorem 2.4, using the preparations of this section.

Conditions (i) and (ii) were shown in Lemma 3.2. Condition (iii), the equi-coercivity, follows from the fact that J is bounded below and the forcing term is Lipschitz continuous. Condition (iv), the convergence of the initial data, is guaranteed by standard interpolation error results as well as Lemma 3.4. Condition (v) is controlled by Lemma 3.3, since E_n and $E|_{\mathscr{A}_n}$ differ only in the forcing term.

Let $v_n(t)$ be the piecewise affine interpolant of $y(t)$. Using Lemma 3.4 to obtain (vi) we only need to show that $t \mapsto v_n(t)$ is Borel measurable. In fact, it is fairly easy to see that it is even continuous. Since in one dimension, $\mathrm{H}^1(0,1)$ is embedded

in $\mathrm{C}[0,1]$, the mapping $t \mapsto y(t)$ lies in $\mathrm{C}(0,\infty;\mathrm{C}[0,1])$ and hence $t \mapsto y(t,x)$ is continuous as well. Since

$$v_n(t,x) = \sum_{j=1}^{n} y(t,x_j^n)\varphi_j^n(x),$$

where the φ_j^n are Lipschitz functions, this shows that $v \in \mathrm{C}(0,\infty;\mathrm{H}^1)$. ∎

4. Convergence of equilibria.

4.1. Elastic deformation. In this section we show that the gradient flows are a selection criterion which can be used to recover correct elastic behavior even when the energies are highly nonconvex.

The convergence result of Theorem 3.1 suggests the following procedure: for sufficiently small forces, there should be a critical point y_n^*, in fact a strict local minimum, of the atomistic functional E_n, such that $y_n^{*\prime} < z_1$, i.e., the deformation gradient lies in the region where J is convex. Hence, the gradient flow for sufficiently close starting points should converge to y_n^* as $t \to \infty$ and the deformation gradient should remain within the region where J is convex. Since the atomistic gradient flow converges to the continuum gradient flow, the continuum deformation gradient should remain in this region as well and therefore converge to a critical point in that set which should be the limit of the y_n^*. By y^* being a critical point of ϕ, we mean that $|\partial\phi|(y^*) = 0$, where $|\partial\phi|(y)$ is the $|\cdot|_{\mathrm{H}^1}$-slope of ϕ at y (see section 2.2).

The main difficulty is to show that the critical points y_n^* are "uniform local minimizers" in the sense that we do not require perturbations to tend to zero as $n \to \infty$.

Before we start with the suggested program, let us note that it would be quite easy to show all results for the continuum problem directly. However, we wish to show here that the elastic critical point of the continuum functional (3.4) arises as the limit of the elastic critical points of the atomistic functionals (3.2). Furthermore, it is an interesting feature of the analysis that all information about the continuum functional can be obtained from the knowledge about the atomistic evolution.

THEOREM 4.1. *Let $(E_n)_{n\in\mathbb{N}}, E$ be defined, respectively, by* (3.2) *and* (3.4)*, and assume that $|g| + \|f\|_{\mathrm{L}^1(0,1)} < J'(z_1)$ (compare* (1.2)*).*

(a) *There exist critical points y_n^* of E_n in $\mathscr{A}_n$, such that $y_n^{*\prime} < z_1$. These equilibria are stable in the sense that any $|\cdot|_{\mathrm{H}^1}$-gradient flow y_n of E_n with $y_n'(0,x) < z_1$ satisfies $\lim_{t\to\infty} y_n(t) = y_n^*$ in $\mathrm{H}^1(0,1)$.*

(b) *There exists a critical point $y^* \in \mathscr{A}$ of E such that $\lim_{n\to\infty} y_n^* = y^*$ and $\lim_{t\to\infty} y(t) = y^*$ in H^1, for every $|\cdot|_{\mathrm{H}^1}$-gradient flow y of E with $y'(0,x) \le z_1 - \epsilon$ for some $\epsilon > 0$.*

(c) *If, in addition, $f \equiv 0$, then $y_n^* = y^*$ are affine.*

On the one hand, Theorem 4.1 shows that the derived continuum model has the correct qualitative and quantitative behavior for small loads. On the other hand, it shows that in this situation, the atomistic model behaves essentially like a continuum. In particular, note that point (c) is the Cauchy–Born hypothesis for the model presented.

Note also that not all proofs in this section are "optimal." Particularly, the final proof of Theorem 4.1 is more technical than it needs to be. The purpose of this discussion is to show that most of the techniques used here can be applied to far more general problems and are, in particular, dimension independent.

The proof of Theorem 4.1 requires some preparation in the form of several lemmas which assemble information about the atomistic gradient flow. Let $\mathscr{B}$ be the set of all

deformations whose gradient remains in the region where J is convex, i.e., we define

$$\mathscr{B}_\epsilon = \{v \in \mathscr{A} \colon v'(x) \le z_1 - \epsilon \text{ for a.e. } x \in (0,1)\}, \tag{4.1}$$

and $\mathscr{B} = \mathscr{B}_0$.

LEMMA 4.2. *Suppose that $|g| + \|f\|_{\mathrm{L}^1(0,1)} \le J'(z_1 - \epsilon)$ for some $\epsilon > 0$; then there exists a unique critical point y_n^* of E_n in the set $\mathscr{B}_\epsilon$. The point y_n^* satisfies*

$$y_n^{*\prime}(x) = (J')^{-1}(F_j^n) \le z_1 - \epsilon \quad \text{for } x_{j-1}^n < x < x_j^n, \tag{4.2}$$

where F_j^n is defined by (4.3).

Proof. We compute the critical point by a change of variables. For $y_n \in \mathscr{A}_n$, let $r_j^n = (y_j^n - y_{j-1}^n)/\epsilon_n$. Then, setting

$$\tilde{f}_i^n = \begin{cases} \frac{1}{2} f_1^n & \text{if } i = 0, \\ \frac{1}{2}(f_i^n + f_{i+1}^n) & \text{if } 1 \le i \le n-1, \\ \frac{1}{2} f_n^n & \text{if } i = n, \end{cases}$$

we have, using $y_0^n = 0$,

$$\begin{aligned} E_n(y_n) &= \sum_{j=1}^n \epsilon_n J(r_j^n) - \sum_{j=0}^n \epsilon_n \tilde{f}_j^n y_j^n - g y_n^n \\ &= \sum_{j=1}^n \epsilon_n J(r_j^n) - \sum_{j=1}^n \epsilon_n \tilde{f}_j^n \sum_{i=1}^j \epsilon_n r_i^n - g \sum_{i=1}^n \epsilon_n r_i^n \\ &= \sum_{j=1}^n \epsilon_n J(r_j^n) - \sum_{i=1}^n \epsilon_n r_i^n \left[g + \sum_{j=i}^n \epsilon_n \tilde{f}_j^n \right] \\ &= \sum_{j=1}^n \epsilon_n \big[J(r_j^n) - F_j^n r_j^n \big], \end{aligned}$$

where

$$F_i^n \;=\; g + \sum_{j=i}^n \epsilon_n \tilde{f}_j^n \;=\; g + \frac{\epsilon_n}{2}(f_i^n + f_n^n) + \sum_{j=i+1}^{n-1} \epsilon_n f_j^n. \tag{4.3}$$

To compute r_j^n, we differentiate E_n with respect to r_j^n, which gives the equation

$$\frac{\partial E_n(y_n)}{\partial r_j^n} = \epsilon_n \big[J'(r_j^n) - F_j^n \big] = 0 \quad \text{for } j = 1, \dots, n,$$

or, equivalently, $J'(r_j^n) = F_j^n$. We estimate F_j^n, using the assumption that $\|f\|_{\mathrm{L}^1} + |g| \le J'(z_1 - \epsilon)$, by

$$\begin{aligned} |F_j^n| &= \left| g + \frac{1}{2} \int_{x_{j-1}^n}^{x_j^n} f(x)\,\mathrm{d}x + \int_{x_j^n}^{x_{n-1}^n} f(x)\,\mathrm{d}x + \frac{1}{2} \int_{x_{n-1}^n}^1 f(x)\,\mathrm{d}x \right| \\ &\le |g| + \int_{x_{j-1}^n}^1 |f(x)|\,\mathrm{d}x \\ &\le |g| + \|f\|_{\mathrm{L}^1(0,1)} \\ &\le J'(z_1 - \epsilon). \end{aligned} \tag{4.4}$$

In the region $\{z < z_1\}$, $J'(z)$ is strictly increasing and hence invertible. Therefore,

$$r_j^n = (J')^{-1}(F_j^n) \leq z_1 - \epsilon$$

describes the unique critical point of E_n in $\mathscr{B}_\epsilon$. ∎

LEMMA 4.3. *Under the conditions of Lemma* 4.2*, if* $y_n\colon [0,\infty) \to \mathscr{A}_n$ *is an* $|\cdot|_{\mathrm{H}^1}$*-gradient flow of* E_n *with* $y_n(0) \in \mathscr{B}_\epsilon$*, then* $y_n(t) \in \mathscr{B}_\epsilon$ *for all* $t > 0$.

Proof. Consider the time-discrete approximation $(U_n(t_j))_{j=0,1,\ldots}$, as described in Lemma 2.5, for some fixed, sufficiently small time-step τ. Let $R_n^i(t_j)$ be as in the proof of Lemma 4.2. Then, $R_n(t_j)$ minimizes

$$\frac{1}{2\tau}\|R_n(t_j) - R_n(t_{j-1})\|_{L^2}^2 + E_n(R_n(t_j)). \tag{4.5}$$

As in the proof of Lemma 4.2, we compute the Euler–Lagrange equation in terms of $R_n^i(t_j)$. At the minimum, the equation

$$\frac{1}{\tau}\Big(R_n^i(t_j) - R_n^i(t_{j-1})\Big) = F_j^n - J'(R_n^i(t_j))$$

has to be satisfied. For sufficiently small τ, there is a unique solution. Now assume inductively that $R_n^i(t_{j-1}) \leq z_1 - \epsilon$. To show that $R_n^i(t_j) \leq z_1 - \epsilon$, assume this is not true. Then $F_j^n - J'(R_n^i(t_j)) < 0$, which gives a contradiction. Hence, we have that for all $i = 1, \ldots, n$ and $j \in \mathbb{N}$, $R_n^i(t_j) \leq z_1 - \epsilon$. As $\tau \to 0$, the discrete solution converges to the gradient flow y_n and hence $y_n' \leq z_1 - \epsilon$ a.e. in $(0,1)$. ∎

COROLLARY 4.4. *Under the conditions of Lemma* 4.2*, every* $|\cdot|_{\mathrm{H}^1}$*-gradient flow* y_n *with* $y_n(0) \in \mathscr{B}_\epsilon$ *satisfies the evolutionary variational inequality*

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}|y_n - v|_{\mathrm{H}^1}^2 + \frac{\alpha}{2}|y_n - v|_{\mathrm{H}^1}^2 + E_n(y_n) \leq E_n(v) \quad \forall v \in \mathscr{B}_\epsilon, \tag{4.6}$$

where $\alpha = \min_{z \leq z_1 - \epsilon} J''(z) > 0$*. In particular, we have*

$$|y_n(t) - y_n^*|_{\mathrm{H}^1} \leq e^{-\alpha t}|y_n(0) - y_n^*|_{\mathrm{H}^1}.$$

Proof. We set $\tilde{E}_n = E_n|_{\mathscr{B}_\epsilon}$ and show that y_n is also a gradient flow for $\tilde{E}_n$ by considering the minimization problem (4.5) again. (Note that this procedure is equivalent to replacing E_n outside of $\mathscr{B}_\epsilon$ by a uniformly convex functional.) Since the minimizer remains in $\mathscr{B}_\epsilon$, it is also the minimizer of

$$\frac{1}{2\tau}\|R_n(t_j) - R_n(t_{j-1})\|_{\mathrm{L}^2}^2 + \tilde{E}_n(R_n(t_j)),$$

and hence the limit of the time-discretizations must also be the gradient flow of $\tilde{E}_n$. By arguing as in the proof of Lemma 3.2, we find that $\tilde{E}_n$ is α-convex (i.e., λ-convex with $\lambda = \alpha$), and hence y_n satisfies (4.6) if we replace E_n with $\tilde{E}_n$. For $v \in \mathscr{B}_\epsilon$, however, the functionals are the same.

On testing (4.6) with $v = y_n^*$, and multiplying the resulting inequality by $e^{2\alpha t}$, we obtain

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\Big(e^{\alpha t}|y_n(t) - y_n^*|_{\mathrm{H}^1}\Big)^2 \leq e^{\alpha t}\big(E_n(y_n^*) - E_n(y_n(t))\big) \leq 0.$$

Integrating from 0 to T gives the result. ∎

Proof of Theorem 4.1. Lemmas 4.2 and 4.3 and Corollary 4.4 immediately imply item (a) and we only need to establish the facts about the continuum limit. Note that almost all of the following analysis is independent of the specific structure of the problem. The only crucial condition which we require is that $y_n(t) \to y(t)$ as $n \to \infty$, for every $t \geq 0$, and $y_n(t) \to y_n^*$ as $t \to \infty$, uniformly in n.

For item (b), we first need to show that, given an initial condition $y(0)$ for the "continuum" $|\cdot|_{\mathrm{H}^1}$-gradient flow satisfying the assumptions of the theorem, there exist "atomistic" initial conditions $y_n(0)$ which satisfy the assumptions of Lemma 4.3. Let $y'(0,x) \leq z_1 - \epsilon$ for a.e. $x \in (0,1)$. Letting $y_n(0,x)$ be the piecewise affine interpolant of $y(0,x)$, we have

$$y_n'(0,x) = \frac{1}{\epsilon_n} \int_{x_{i-1}^n}^{x_i^n} y'(0,x)\,\mathrm{d}x \leq z_1 - \epsilon, \quad x \in (x_{i-1}^n, x_i^n).$$

Therefore, the atomistic $|\cdot|_{\mathrm{H}^1}$-gradient flows with starting point $y_n'(0,\cdot)$ converge uniformly in n (compare to Corollary 4.4) to the equilibria y_n^*, computed in item (a) or Lemma 4.2. We use this fact to estimate

$$\begin{aligned} |y_n^* - y_{n'}^*|_{\mathscr{H}} &\leq |y_n^* - y_n(t)|_{\mathscr{H}} + |y_n(t) - y_{n'}(t)|_{\mathscr{H}} + |y_n(t) - y_{n'}^*|_{\mathscr{H}} \\ &\leq 2\mathrm{const.} e^{-\alpha t} + |y_n(t) - y_{n'}(t)|_{\mathscr{H}}, \end{aligned}$$

thus showing that $(y_n^*)_{n\in\mathbb{N}}$ is a Cauchy-sequence. We denote its limit in $\mathscr{A}$ by y^*. To see that $y(t) \to y^*$ as $t \to \infty$, consider

$$|y(t) - y^*|_{\mathscr{H}} \leq \inf_{n\in\mathbb{N}} \left(|y(t) - y_n(t)|_{\mathscr{H}} + |y_n(t) - y_n^*|_{\mathscr{H}} + |y_n^* - y^*|\right) \leq \mathrm{const.} e^{-\alpha t}.$$

We have shown that the "discrete" equilibria y_n^* converge to a "continuum" deformation y^* and that $y(t) \to y^*$.

The fact that y^* is a critical point of E is easily verified by hand, but in fact this follows from the general theory as well, using the concepts introduced in section 2.2. It is straightforward to show that the functionals E_n $\Gamma(\mathrm{H}^1)$-converge to E in the strong H^1 topology. We merely note the limsup condition (2.10) is given by Lemma 3.4 while for the lim inf condition (2.9) E and E_n can be decomposed into a convex, lower semicontinous part and a continuous, uniformly convergent part (compare to the proof of λ-convexity in Lemma 3.2).

Since the functionals E and $(E_n)_{n\in\mathbb{N}}$ are also uniformly λ-convex, Lemma 2.6, shows that

$$|\partial E|(y^*) \leq \liminf_{n\to\infty} |\partial E_n|(y_n^*) = 0,$$

where $|\partial E_{(n)}|$ denotes the $|\cdot|_{\mathrm{H}^1}$-local slope of the functionals $E_{(n)}$. □

We conclude the discussion of elastic behavior with a remark on the structure of the elastic critical points. It may not be surprising that the continuum "elastic" critical point computed in section 4.1 are actually not local minimizers with respect to the H^1-topology. Indeed, let us assume that $f \equiv 0$ and $0 < g < J'(z_1)$ and define the curve $s \mapsto v(s)$ by

$$v'(s) = y^{*\prime} + \frac{1}{s}\chi_{(1/2,1/2+s^k)}.$$

It is straightforward to establish that for $k \geq 2p$, $v \in \mathrm{C}^{0,1/p}(0, s_0; \mathrm{W}^{1,p})$ and $E(v(s)) < E(y^*)$, where $s_0 > 0$ and $\mathrm{C}^{0,1/p}$ denotes the usual space of Hölder continuous functions. Thus, the critical point y^* is not an H^1-local minimum of the energy $E(y)$. This is also reflected by the fact that we only allow $\mathrm{W}^{1,\infty}$ perturbations in Theorem 4.1.

Why, we should ask ourselves, is this not in contradiction with Theorem 4.1? If there exists a curve along which the energy decreases, should the gradient flow not find this curve? The explanation is that the curve $v(s)$, which we have constructed, is not absolutely continuous in $\mathrm{H}^1(0,1)$ and hence is not a candidate for the gradient flow evolution. An interesting question is whether there actually can exist an absolutely continuous curve starting in y^* along which the energy decreases strictly. Unfortunately, we are unable to answer this question at this point. A negative answer would lead to an interesting selection criterion for equilibria. It would in particular imply that the choice of evolution is not so crucial after all, as such equilibria would be stable under any "sufficiently smooth" evolution.

4.2. Instability and fracture. If the forces f and g are sufficiently strong, then they will cause the material to break, i.e., the atoms debond. Mathematically, this means that the deformation gradient of the atomistic or continuum deformation enters the region where J is concave. In dimensions higher than one, though, the model is unable to describe fracture. There, effects other than debonding of atoms, most notably dislocations, become highly important and cannot be neglected. The discussion in this section can therefore not be generalized directly to higher dimensions.

If we do not restrict the motion of the material, i.e., if we let $M = \infty$ (compare to section 3), then the gradient flows $y_n(t)$ and $y(t)$ will not converge to a stationary point as $t \to \infty$, but diverge. Hence, we restrict the possible deformations by setting M to be a real number, $z_1 < M < \infty$. We assume throughout this section that $f \equiv 0$ and $g > J'(z_1)$.

PROPOSITION 4.5. *There exists $t_1 > 0$ and $\alpha \in \mathrm{W}^{1,\infty}(0,\infty)$ satisfying $\dot\alpha(t) > 0$ if $t < t_1$ and $\alpha(t) = M$ if $t \geq t_1$, such that the solution of the $|\cdot|_{\mathrm{H}^1}$-gradient flow in $\mathscr{A}$ with $y(0,x) = x$ is*

$$y(t,x) = \alpha(t)x.$$

Proof. We change coordinates to $r(t,x) = y'(t,x)$ to obtain, formally for the moment, the equation

$$r_t(t,x) = g - J'(r(t,x)),$$

which is the same ordinary differential equation for every point $x \in (0,1)$. Furthermore, $g - J'(r(t,x)) > 0$ for all x and t, hence $\alpha(t)$ is strictly increasing. Since the solution we have obtained is Lipschitz continuous in time, it is the required gradient flow.

When we reach a time t_1 for which $y(t_1, 1) = M$, the deformation y will be fixed at $y(1,t) = M$ for $t \geq t_1$. To see this, we consider again the time-discretization with initial value $r_0 = M$. The next timestep is the minimizer of

$$\int_0^1 \left[\frac{1}{2\tau}|r - M|^2 + J(r) - gr \right] \mathrm{d}x,$$

subject to $(r) := \int_0^1 r \,\mathrm{d}x \leq M$. If $(r) < M$, then r must satisfy

$$\frac{1}{\tau}(r - M) + J'(r) = g. \tag{4.7}$$

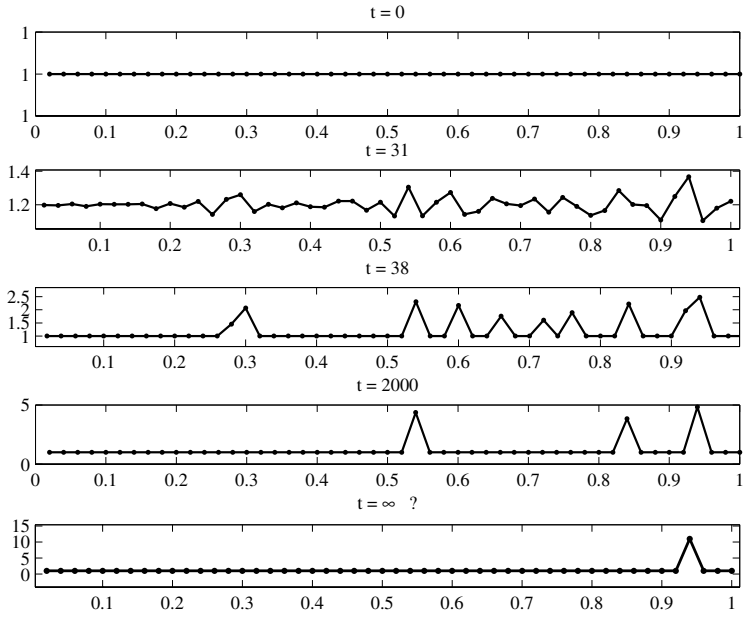

FIG. 4.1. *Snapshots of the deformation gradients of an* $|\cdot|_{\mathrm{H}^1}$*-gradient flow evolution, showing the instability of the final state, computed with* 51 *"atoms." The new final state* ($t = \infty$) *after instability sets in is not computed but guessed. This figure shows an* unstable *computation and should not be mistaken for the exact solution of the model! Note also the different scales in the respective plots.*

Since $(r) < m$, there must exist a set of positive measure where $r \leq M - \epsilon$ for some $\epsilon > 0$. However, since J' is bounded above, (4.7) cannot be satisfied in this set, if τ is sufficiently small.

By a uniqueness argument, we find that $y(t, x)$ satisfies the partial differential equation

$$-y_t'' = J'(y')' = J''(y')y'', \quad y(t,0) = 0, \quad y(t,1) = M, \quad y(t_1, x) = Mx,$$

which can be easily seen to be solved by $y(x,t) = Mx$. Therefore, the evolution remains in the affine state. □

Proposition 4.5 suggests that in our model fracture will never occur. However, the analytical solution obtained is highly unstable under perturbation as Figure 4.1, where a numerical computation is shown, demonstrates. In all computations, we chose $J(z)$ to be strictly increasing for $z > z_1$, i.e., there exists no threshold for the deformation gradient beyond which there are no internal forces.

In a second experiment we dominate the numerical round-off errors, and thus the instabilities in the $|\cdot|_{\mathrm{H}^1}$-gradient flow computation, by a controlled perturbation which could be interpreted, for example, as an impurity in the material. At time $t = 7.6$, we perturb the position of one node (or atom) by an amount of 10^{-8}. The effect of this is that the "fracture" occurs exactly at this position; see Figure 4.2 for the computational results. The instability of the evolution very much conforms with experimental observation that rupture in many types of materials is a highly unstable

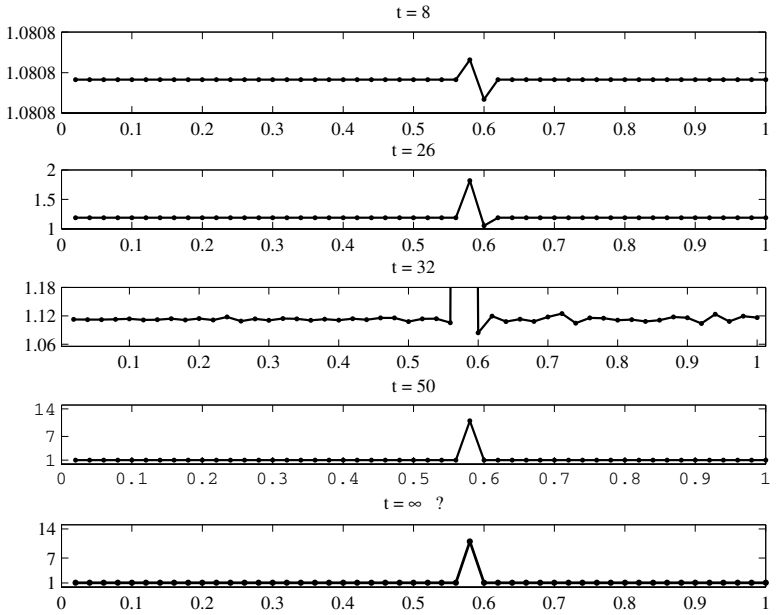

FIG. 4.2. *Snapshots of the deformation gradients of an* $|\cdot|_{\mathrm{H}^1}$*-gradient flow evolution, computed with* 51 *"atoms," with a controlled perturbation at time* $t = 7.6$ *by an amount of* 10^{-8}*. process. No fracture experiment can be reproduced exactly. Thus, the instability of the evolution could be thought of as representing the uncertainty of where damage occurs.

5. Remarks on extensions to two and three dimensions. The simple problem we have investigated here has a fair amount of one-dimensional structure. Although most of the techniques developed here can be readily generalized, the extension to two and three dimensions, which is of great importance to the modeling of material behavior, is not entirely trivial.

The first difficulty to notice is that the passage to higher dimensions in a simple nearest-neighbor system based on the Lennard–Jones potential suffers from a loss of λ-convexity, since the atomistic deformations do not necessarily have to remain orientation preserving. By cutting off the Lennard–Jones potential at the origin, a process which is intuitively reasonable but difficult to justify rigorously, the convergence of the gradient flow can be recovered completely. A more interesting, and mathematically much more challenging, alternative would be to consider a gradient flow with respect to a different metric, which may allow the blow-up behavior of the Lennard–Jones potential, but such a metric seems to be presently unavailable.

To analyze elastic equilibria, it is necessary to obtain L^∞ bounds on the deformation gradient. This step poses the biggest challenge in higher dimensions as these bounds cannot be computed explicitly anymore. One possible avenue to obtain them would be to use the implicit function theorem, for which uniform bounds can be constructed with a slightly refined analysis. It would be necessary, however, that the solution of the linearized system lies in $\mathrm{W}^{1,\infty}(\Omega)$, which can only be obtained in

some very restrictive cases, e.g., with smooth domains and Dirichlet boundary conditions. At re-entrant corners or interfaces between Dirichlet and Neumann boundaries (for example, a crack tip), the nearest neighbor model is too simple to describe the material behavior accurately.

While the convergence theory for gradient flows can still be analyzed if finite-range interactions are added to the energy functional, the analysis of the equilibria seems to be far more difficult if we consider damaged states, but remains essentially unchanged for elastic deformation. The case of infinity-range interactions is completely unclear. For examples of atomistic models with finite-range interactions and their relation to continuum theories, see [25, 9].

Finally, it should be noted that different evolutions can be analyzed as well. For example, it is straightforward to extend the convergence result from the gradient flow evolution to linear viscoelasticity following, for example, the theory developed in [7]. It is more difficult in this setting, however, to analyze the resulting stationary points in similar detail.

Acknowledgments. The initial idea for this work arose in a discussion with Bernd Kirchheim and Georg Dolzmann about generalizations of the work of Friesecke and Theil [15] to realistic interaction potentials during a visit to the Max Planck Institute in Mathematical Sciences, Leipzig. Johannes Zimmer helped with useful comments throughout the work on this paper. I have also benefited from useful discussions with Endre Süli and Benson Muite.

UNIQUE SOLVABILITY OF A SYSTEM OF NONLINEAR ELLIPTIC PDES ARISING IN SOLID STATE PHYSICS*

X. BLANC†

Abstract. This paper presents a uniqueness theorem for a system of nonlinear elliptic PDEs. This system is related to a quantum chemistry model, namely the Thomas–Fermi–von-Weizsäcker model. The present result is concerned with the solution of a system modeling a semicrystal, i.e., a periodic structure filling a half-space. This kind of uniqueness theorem has been studied in a previous work [I. Catto, C. Le Bris, and P.-L. Lions, *Mathematical Theory of Thermodynamic Limits: Thomas–Fermi Type Models*, Clarendon Press, Oxford University Press, New York, 1998] for the case of a whole crystal. We give here a simpler version of their proof, and then an adaptation to the case of a semicrystal. The methods we use are the maximum principle, supersolution methods, and elliptic estimates.

Key words. nonlinear elliptic PDEs, uniqueness, maximum principle, supersolution methods, thermodynamic limit, energy minimization

1. Introduction.

In this article we study the following system:

$$\begin{cases} -\Delta u + u^{7/3} - \phi u = 0, \\ -\Delta \phi = m - u^2, \\ u \geq 0, \end{cases} \tag{1.1}$$

where m is a nonnegative measure satisfying the following hypotheses:

(H0) $\mathrm{Supp}(m) \subset \{x = (x_1, x_2, x_3) \in \mathbb{R}^3, \quad x_3 \leq 0\} := H$;

(H1) $\sup_{x \in H} m(B_1(x)) < +\infty$;

(H2) $\exists R > 0$ such that $\inf_{x \in H} m(B_R(x)) > 0$.

System (1.1) is sometimes called the Thomas–Fermi–von Weizsäcker (TFW) system, in link with the corresponding model. In such a setting, m is the measure defining the nuclei, for example,

$$m = \sum_{i=1}^{N} \delta_{X_i}$$

is the measure of N point nuclei of positions $\{X_i\}_{1 \leq i \leq N}$. These nuclei are surrounded by N electrons of density $\rho \geq 0$, and the corresponding energy reads

$$\mathcal{E}^{\mathrm{TFW}}(\rho, \{X_i\}) = \int_{\mathbb{R}^3} |\nabla \sqrt{\rho}|^2 + \frac{3}{5}\rho^{\frac{5}{3}} - \sum_{i=1}^{N} \int_{\mathbb{R}^3} \frac{\rho(x)}{4\pi|x - X_i|} dx + \frac{1}{2} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \frac{\rho(x)\rho(y)}{4\pi|x-y|} dxdy + \frac{1}{2} \sum_{i \neq j} \frac{1}{4\pi|X_i - X_j|}.$$

†Laboratoire Jacques-Louis Lions UMR 7598, Université Pierre et Marie Curie, Boîte courrier 187, 75252 Paris Cedex 05, France (blanc@ann.jussieu.fr).

The electrons are assumed to be in their ground state, that is, ρ is the solution of the following minimization problem:

$$\mathcal{E}^{\mathrm{TFW}}(\{X_i\}) = \inf\left\{\mathcal{E}^{\mathrm{TFW}}(\rho,\{X_i\}),\ \rho\geq 0,\ \sqrt{\rho}\in H^1(\mathbb{R}^3),\ \int_{\mathbb{R}^3}\rho = N\right\}.$$

Setting $u=\sqrt{\rho}$, the corresponding Euler–Lagrange equation reads (see [2]):

$$-\Delta u + u^{7/3} + \left[\left(u^2 - \sum_{i=1}^N \delta_{X_i}\right) * \frac{1}{4\pi|x|}\right] u = \theta u,$$

where $\theta\in\mathbb{R}$ is the Lagrange multiplier associated to the mass constraint. Therefore, setting $m=\sum_{i=1}^N \delta_{X_i}$ and $\phi = (m-u^2)*\frac{1}{4\pi|x|}+\theta$, one finds (1.1). The above derivation may be made rigorous (see [2]) if N is finite (basically because the energy $\mathcal{E}^{\mathrm{TFW}}(\rho,\{X_i\})$ is convex with respect to ρ), but it is not clear when N is infinite, or equivalently when m satisfies hypotheses of the type (H0), (H1), and (H2). This problem is usually referred to as the "thermodynamic limit problem." As is explained in section 4, the main difficulty in such a problem is to prove uniqueness for the limit system (1.1) with hypotheses (H0), (H1), and (H2).

Of course, one may also expect some difficulties for the existence of solutions to (1.1) due to the absence of boundary conditions. The natural strategy to deal with this problem is precisely to use a thermodynamic limit as described in section 4. Another possibility is to define the solution (u_R,ϕ_R) of the system (1.1) set on the ball B_R with Dirichlet boundary conditions, prove that this solution is bounded in suitable spaces, and pass to the limit. Both strategies are equivalent. The first one is described in detail in [7].

In the following, we use the notation (here, Ω is a domain of $\mathbb{R}^3$)

$$L^p_{\mathrm{unif}}(\Omega) = \left\{f\in L^1_{\mathrm{loc}}(\Omega),\quad \sup_{x\in\Omega}\|f\|_{L^p(B_1(x)\cap\Omega)}<\infty\right\}.$$

In [7] it is proved that (1.1) has a unique solution $(u,\phi)\in L^\infty(\mathbb{R}^3)\times L^1_{\mathrm{unif}}(\mathbb{R}^3)$ assuming (H1) and (H2), where H is replaced by $\mathbb{R}^3$ (see Theorem 2.1).

After giving (in section 2) a proof of Theorem 2.1 simpler than that in the original [7], we prove the following result in section 3.

THEOREM 1.1. *Let m be a nonnegative measure satisfying* (H0), (H1), *and* (H2). *Then the system* (1.1) *has a unique solution (u,ϕ) in $L^\infty(\mathbb{R}^3)\times L^1_{\mathrm{unif}}(\mathbb{R}^3)$.*

As already pointed out above, we give in section 4 an application to the TFW theory.

Remark 1.2. The power $\frac{7}{3}$ in (1.1) may be replaced by any $p>1$. Indeed, the important point is that the corresponding TFW energy is strictly convex in ρ. The term u^p in (1.1) corresponds to the term $\int\rho^{\frac{p+1}{2}}$ in the energy, which is strictly convex as far as $p>1$. Note, however, that technically, the case $1<p\leq 3$ may be treated with exactly the same methods, whereas in the case $p>3$, Lemmas 3.2 and 3.3 need to be adapted.

2. The case when m is bounded from below. As announced above, this section is devoted to a proof of Theorem 2.1, which, regarding the uniqueness, is simpler than that given in [7].

THEOREM 2.1 (uniqueness for a TFW crystal, [7]). *Let m be a measure on $\mathbb{R}^3$, which satisfies the following assumptions:*

(H1') $\sup_{x\in\mathbb{R}^3} m(B_1(x)) < +\infty$;

(H2') $\exists R > 0$ *such that* $\inf_{x\in\mathbb{R}^3} m(B_R(x)) > 0$.

Then, problem (1.1) *has a unique solution* $(u,\phi) \in L^\infty(\mathbb{R}^3) \times L^1_{\text{unif}}(\mathbb{R}^3)$.

Proof. We leave aside the question of existence, which is dealt with in [7]. In addition, we only recall, again from [7], that any solution $(u,\phi) \in L^\infty(\mathbb{R}^3)\times L^1_{\text{unif}}(\mathbb{R}^3)$ of (1.1) satisfies the following:

$$u \in C^0(\mathbb{R}^3) \quad \text{and} \quad \nabla u \in L^2_{\text{unif}}(\mathbb{R}^3); \tag{2.1}$$

$$\forall p < 3, \quad \phi \in L^p_{\text{unif}}(\mathbb{R}^3); \tag{2.2}$$

$$\exists \alpha > 0 \quad \text{such that} \quad \forall x \in \mathbb{R}^3, \quad u(x) \geq \alpha. \tag{2.3}$$

For the sake of simplicity, we assume that m is smooth (say, continuous), so that standard elliptic regularity results [8] imply that u and ϕ are locally smooth, and in particular that $u, \phi \in W^{1,\infty}(\mathbb{R}^3)$. The following proof is easily adapted to the case of m being a measure. Details of this generalization can be found in [7]. See also Remark 2.2.

Consider now two solutions, (u,ϕ) and (v,ψ) of (1.1). Setting $w = u - v$ and $\eta = \phi - \psi$, we have

$$\begin{cases} -\Delta w + u^{7/3} - v^{7/3} - \frac{1}{2}(\phi+\psi)w - \frac{1}{2}(u+v)\eta = 0, \\ -\Delta\eta = -(u+v)w. \end{cases} \tag{2.4}$$

Then multiplying the above equations by $w\xi^2$ and $\eta\xi^2$, respectively, where $\xi \in \mathcal{D}(\mathbb{R}^3)$, and integrating over $\mathbb{R}^3$ we get

$$\int_{\mathbb{R}^3} |\nabla(w\xi)|^2 + \left(u^{7/3} - v^{7/3}\right) w\xi^2 - \frac{1}{2}(\phi+\psi)w^2\xi^2 = \int_{\mathbb{R}^3} \frac{1}{2}(u+v)\eta w\xi^2 + w^2|\nabla\xi|^2, \tag{2.5}$$

$$\int_{\mathbb{R}^3} |\nabla(\eta\xi)|^2 = \int_{\mathbb{R}^3} -(u+v)w\eta\xi^2 + \eta^2|\nabla\xi|^2. \tag{2.6}$$

Since the operator $L_u = -\Delta + u^{4/3} - \phi$ satisfies $L_u u = 0$, with $u \geq 0$, we necessarily have $L_u \geq 0$. Similarly, $L_v = -\Delta + v^{4/3} - \psi \geq 0$, so that $\frac{1}{2}(L_u + L_v) \geq 0$:

$$\left\langle \frac{1}{2}\left(L_u + L_v\right)(w\xi), w\xi \right\rangle \geq 0.$$

In addition, we have

$$\left(u^{7/3} - v^{7/3}\right) w \geq \left(u^{4/3} + v^{4/3}\right) w^2. \tag{2.7}$$

Using (2.3), this implies $\left(u^{7/3} - v^{7/3}\right) w \geq \frac{1}{2}\left(u^{7/3} - v^{7/3}\right) w + \nu w^2$, for some constant $\nu > 0$. Inserting this into (2.5), we have

$$\nu \int_{\mathbb{R}^3} w^2\xi^2 \leq \int_{\mathbb{R}^3} \frac{1}{2}(u+v)\eta w\xi^2 + w^2|\nabla\xi|^2.$$

Hence, by using (2.6) we obtain

$$\nu \int_{\mathbb{R}^3} w^2\xi^2 + \frac{1}{4}\int_{\mathbb{R}^3} |\nabla\eta|^2\xi^2 \leq \int_{\mathbb{R}^3} (w^2+\eta^2)|\nabla\xi|^2. \tag{2.8}$$

We then take for ξ a sequence of functions in $\mathcal{D}(\mathbb{R}^3)$ converging to the function

$$\xi(x) = \frac{1}{(1+|x|^2)^{\frac{k}{2}}}, \quad \text{with} \quad \frac{1}{2} < k < 1. \tag{2.9}$$

Note that $\nabla\xi \in L^2(\mathbb{R}^3)$, $\Delta\xi \in L^2(\mathbb{R}^3)$, but $\xi \notin L^2(\mathbb{R}^3)$. Inequality (2.8) implies that

$$\int_{\mathbb{R}^3} w^2\xi^2 < +\infty \quad \text{and} \quad \int_{\mathbb{R}^3} |\nabla\eta|^2\xi^2 < +\infty.$$

So far, our proof reproduces that of [7]. As in [7], we want now to prove that

$$\int \eta^2\xi^2 < +\infty, \tag{2.10}$$

but we will now argue somewhat differently. For this purpose, we multiply the first equation of (2.4) by $\eta\xi^2$, and integrate over $\mathbb{R}^3$

$$\frac{1}{2}\int_{\mathbb{R}^3} (u+v)\eta^2\xi^2 = \int_{\mathbb{R}^3} (-\Delta w)\eta\xi^2 + \left(u^{7/3}-v^{7/3}\right)\eta\xi^2 - \frac{1}{2}\int_{\mathbb{R}^3} (\phi+\psi)w\eta\xi^2. \tag{2.11}$$

Noticing that u, v, ϕ, and ψ are bounded, we have, for some constant C independent of ξ:

$$\int_{\mathbb{R}^3} \left|u^{7/3}-v^{7/3}\right| |\eta|\xi^2 \leq C\int_{\mathbb{R}^3} |w|\,|\eta|\xi^2 \leq C\left(\int_{\mathbb{R}^3} w^2\xi^2\right)^{\frac{1}{2}}\left(\int_{\mathbb{R}^3} \eta^2\xi^2\right)^{\frac{1}{2}},$$

along with

$$\int_{\mathbb{R}^3} |\phi+\psi|\,|w|\,|\eta|\xi^2 \leq C\int_{\mathbb{R}^3} |w|\,|\eta|\xi^2 \leq C\left(\int_{\mathbb{R}^3} w^2\xi^2\right)^{\frac{1}{2}}\left(\int_{\mathbb{R}^3} \eta^2\xi^2\right)^{\frac{1}{2}},$$

and

$$\begin{aligned}
\left|\int_{\mathbb{R}^3} (-\Delta w)\eta\xi^2\right| &= \left|\int_{\mathbb{R}^3} w\left(-\Delta\left(\eta\xi^2\right)\right)\right| \\
&\leq \left|\int_{\mathbb{R}^3} w(-\Delta\eta)\xi^2\right| + \left|\int_{\mathbb{R}^3} w\eta\left(-\Delta\xi^2\right)\right| + \left|4\int_{\mathbb{R}^3} w\xi\nabla\eta\nabla\xi\right| \\
&\leq \int_{\mathbb{R}^3} (u+v)w^2\xi^2 + C + 4\left(\int_{\mathbb{R}^3} w^2\xi^2\right)^{\frac{1}{2}}\left(\int_{\mathbb{R}^3} |\nabla\eta|^2|\nabla\xi|^2\right)^{\frac{1}{2}} \\
&< +\infty.
\end{aligned}$$

Using these three inequalities to bound the right-hand side of (2.11), we find that, since u and v are bounded away from zero,

$$\int_{\mathbb{R}^3} \eta^2\xi^2 \leq C + C\left(\int_{\mathbb{R}^3} \eta^2\xi^2\right)^{\frac{1}{2}} \quad \text{hence} \quad \int_{\mathbb{R}^3} \eta^2\xi^2 < +\infty.$$

The end of the argument then mimics again that of [7]: Defining the function $\xi_\varepsilon(x) = \xi(\varepsilon x)$, we have $|\nabla \xi_\varepsilon|^2 \le \varepsilon^{2-2k}\xi^2$, so

$$\frac{\nu}{(1+\varepsilon^2 R^2)^k}\int_{B_R} w^2 \le \int_{\mathbb{R}^3} w^2\xi_\varepsilon^2 \le \int_{\mathbb{R}^3}(w^2+\eta^2)|\nabla\xi_\varepsilon|^2 \le \varepsilon^{2-2k}\int_{\mathbb{R}^3}\left(w^2+\eta^2\right)\xi^2.$$

Letting ε go to zero, we find that w is zero on B_R. Since this is valid for any $R>0$, we have $w=0$. This in turn implies that $\eta = 0$. □

Remark 2.2. Let us point out here that we have made additional regularity assumptions on the measure m in order to simplify the proof, but the general case may be treated in the same way. Roughly speaking, one needs in this case to use interpolation spaces, noting that $\phi, \psi \in L^{3,\infty}_{\text{unif}}(\mathbb{R}^3)$ (see [3] or [7]) instead of $L^\infty(\mathbb{R}^3)$. This is sufficient to carry out the estimates of the preceeding proof. For instance, (2.8) and (2.9) still imply $\int w^2\xi^2 + \int |\nabla\eta|^2\xi^2 < +\infty$ because

$$\begin{aligned}\int_{\mathbb{R}^3}\eta^2|\nabla\xi|^2 &\le C\sum_{j\in\mathbb{Z}^3}\frac{1}{(1+|j|^2)^{k+1}}\|\eta\|_{L^2_{\text{unif}}(\mathbb{R}^3)}\\ &\le C\sum_{j\in\mathbb{Z}^3}\frac{1}{(1+|j|^2)^{k+1}}\|\eta\|_{L^{3,\infty}_{\text{unif}}(\mathbb{R}^3)} < +\infty.\end{aligned}$$

The same kind of remark holds for the proof of (2.10).

The above proof may be easily adapted to prove the following result, which asserts that the kernel of the linearized operator of system (1.1) is reduced to $\{0\}$.

COROLLARY 2.3. *Let m be a measure satisfying* (H1') *and* (H2'), *and let $(u,\phi) \in L^\infty(\mathbb{R}^3)\times L^1_{\text{unif}}(\mathbb{R}^3)$ be the unique solution of* (1.1). *If $(w,\eta)\in L^\infty(\mathbb{R}^3)\times L^1_{\text{unif}}(\mathbb{R}^3)$ satisfies*

$$\begin{cases} -\Delta w + \frac{7}{3}u^{4/3}w - \phi w - u\eta = 0,\\ -\Delta\eta = -2uw, \end{cases} \tag{2.12}$$

then $w=0$ and $\eta = 0$.

3. Uniqueness for (1.1) with (H0). We now turn to the proof of Theorem 1.1. The problem here is that u is no longer bounded from below. However we will see that $u(x) = u(x_1,x_2,x_3)$ converges to 0 as x_3 goes to infinity, uniformly with respect to x_1 and x_2. A careful analysis of this decay then allows us to circumvent the difficulty.

Here again, we assume that m is smooth, so that by elliptic regularity [8], u and ϕ are smooth. The following proof may be adapted with exactly the technique of [7].

3.1. A priori bounds. We first prove the following lemma.

LEMMA 3.1. *Let m be a smooth function satisfying* (H0), (H1), *and* (H2). *Consider $(u,\phi)\in L^\infty(\mathbb{R}^3)\times L^1_{\text{unif}}(\mathbb{R}^3)$ and $(v,\psi)\in L^\infty(\mathbb{R}^3)\times L^1_{\text{unif}}(\mathbb{R}^3)$ two solutions of* (1.1). *Then, setting $w = u-v$ and $\eta = \phi-\psi$, there exists two constants, $A>0$ and $\alpha>0$, such that*

$$\forall x\in H,\quad |w(x)| + |\eta(x)| \le Ae^{-\alpha|x_3|}. \tag{3.1}$$

Proof. We first prove that w and η go to zero as $x_3 \longrightarrow -\infty$. We argue by contradiction and assume that there exists a sequence x^n such that $x_3^n \longrightarrow -\infty$ as n goes to infinity, and $|w(x^n)| + |\eta(x^n)| \ge \varepsilon$ for some constant $\varepsilon > 0$. Then defining

$$\begin{aligned}\tilde{u}_n(x) = u(x+x^n),\quad \tilde{v}_n(x) &= v(x+x^n),\quad \tilde{\phi}_n(x) = \phi(x+x^n),\\ \tilde{\psi}_n(x) &= \psi(x+x^n),\quad m_n(x) = m(x+x_n),\end{aligned} \tag{3.2}$$

since all these functions are bounded, we can extract a converging subsequence in $\mathcal{D}'(\mathbb{R}^3)$. Elliptic regularity implies that $\tilde{u}_n$, $\tilde{v}_n$, $\tilde{\phi}_n$, and $\tilde{\psi}_n$ also converge in $L^\infty_{\rm loc}(\mathbb{R}^3)$ (at least) to some functions, which we, respectively, denote by $\tilde{u}$, $\tilde{v}$, $\tilde{\phi}$, and $\tilde{\psi}$. The limit of m_n is denoted by $\tilde{m}$, which satisfies (H1') and (H2'). Hence, $(\tilde{u}, \tilde{\phi})$ and $(\tilde{v}, \tilde{\psi})$ are two different bounded solutions of (1.1), with m satisfying the hypotheses of Theorem 2.1. This is a contradiction.

We next prove that the decay is indeed exponential. We set, for any $R > 0$,

$$M(R) = \sup_{x_3 \leq -R} |w(x)| + |\eta(x)|.$$

We want to prove that

$$\exists R > 0, \quad \exists \gamma \in (0,1) \quad \text{s.t.} \quad \forall T \geq 1, \quad M(R+T) \leq \gamma M(T). \tag{3.3}$$

Indeed, this implies that for any $S \geq R+1$, $M(S) \leq \gamma^{S-R-2} M(R+1)$, which implies (3.1).

Arguing again by contradiction, we assume that (3.3) is not satisfied, i.e., that there exist sequences R_n, γ_n, T_n satisfying the following:

$$\left\{ \begin{array}{l} R_n \longrightarrow +\infty, \\ \gamma_n \longrightarrow 1, \\ T_n \geq 1 \end{array} \right. \qquad \text{and} \quad M(R_n + T_n) > \gamma_n M(T_n).$$

Thus, one can find a sequence $x^n \in \mathbb{R}^3$ such that $x^n_3 \leq -R_n - T_n$, $\frac{|w(x^n)|+|\eta(x^n)|}{M(R_n+T_n)} \longrightarrow 1$ and $|w(x^n)|+|\eta(x^n)| \geq \gamma_n M(R_n)$ as n goes to infinity. Using here again the notation (3.2), we find that, extracting a subsequence if necessary, $(\tilde{u}_n, \tilde{\phi}_n)$ converges to a solution of (1.1). Moreover, defining $\tilde{w}_n(x) = \frac{w(x+x_n)}{M(R_n)}$ and $\tilde{\eta}_n(x) = \frac{\phi(x+x_n)}{M(R_n)}$, we also have convergence (possibly after extracting a subsequence) for $(\tilde{w}_n, \tilde{\eta}_n)$. We pass to the limit in the corresponding equation, finding that the limit (w, η) of $(\tilde{w}_n, \tilde{\eta}_n)$ satisfies (2.12). According to Corollary 2.3, we thus have $w = 0$ and $\eta = 0$, which is a contradiction. ∎

Next, we study the decay of u and ϕ in H^c.

LEMMA 3.2. *Let m be a smooth function satisfying* (H0), (H1), *and* (H2). *Consider a solution (u, ϕ) of* (1.1). *Then, there exists a constant $A > 0$ such that*

$$\forall x \in H^c, \quad u(x) \leq \frac{A}{(1+x_3)^{\frac{3}{2}}}, \tag{3.4}$$

$$\forall x \in H^c, \quad \phi(x) \leq \frac{A}{(1+x_3)^2}. \tag{3.5}$$

Proof. These decay estimates are simple applications of a method of Benguria and Lieb [1]. It was also used by Solovej [11]. A complete proof is also given in [4]. We only indicate here the main ideas: Let $\omega \in \mathcal{D}(\mathbb{R}^3)$ be such that ω is radially symmetric, $\omega \geq 0$ and $\int \omega = 1$, and define, for any $R > 0$,

$$g_R(x) = \frac{1}{R^3} \omega\left(\frac{x}{R}\right) \quad \text{and} \quad \overline{\phi}_R = \phi * g_R.$$

We then have, using the fact that the operator $-\Delta + u^{4/3} - \phi$ is nonnegative,

$$\overline{\phi}_R \leq g_R * u^{4/3} + \frac{B}{R^2}, \tag{3.6}$$

where $B > 0$ is a constant depending only on ω. We then point out that ϕ is subharmonic in H^c, and use the mean-value inequality to prove that:

$$\text{if} \quad x_3 \geq R, \quad \overline{\phi}_R(x) \geq \phi(x). \tag{3.7}$$

We then define $\tilde{\phi}_R(x) = \overline{\phi}_R(x) - \frac{B}{R^2}$, and get, using (3.6) and Jensen's inequality,

$$\tilde{\phi}_R \leq \left(g_R * u^2\right)^{2/3}.$$

Hence, convoluting the second equation of (1.1) by g_R,

$$-\Delta\tilde{\phi}_R + \left(\tilde{\phi}_R\right)_+^{3/2} \leq m * g_R.$$

In particular, if $x_3 \geq R$, we have $-\Delta\tilde{\phi}_R(x) + \left(\tilde{\phi}_R(x)\right)_+^{3/2} \leq 0$. Hence, using supersolution methods (note that $U(x) = \frac{C}{(1+x_3)^4}$ is a supersolution of $-\Delta U + U^{3/2} = 0$ in H^c if C is large enough), one easily gets that for any $R > 0$,

$$\tilde{\phi}_R(x) \leq \frac{B'R^2}{(x_3^2 - R^2)^2} \quad \text{if} \quad x_3 > R,$$

where B' is a universal constant. This estimate and (3.7) imply that

$$\text{if} \quad x_3 \geq R, \quad \phi(x) \leq \frac{B'R^2}{(x_3^2 - R^2)^2} + \frac{B}{R^2}.$$

Choosing $R = \frac{x_3}{2}$, we thus find (3.5).

Next, we use the first equation of (1.1) and have $-\Delta u + u^{\frac{7}{3}} = \phi u \leq \frac{3}{7}u^{7/3} + \frac{4}{7}\phi^{7/4}$, so that $-\Delta u + \frac{4}{7}u^{7/3} \leq \frac{4A^{7/4}}{7(1+x_3)^{7/2}}$. Using supersolution methods once again (here, a supersolution is given by $U(x) = \frac{C}{(1+x_3)^{3/2}}$, with $C > 0$ large enough) we find (3.4). □

Estimate (3.5) only provides an upper bound on ϕ. We now improve this estimate and show that $\phi(x)$ converges to some nonpositive constant l as x_3 goes to infinity

LEMMA 3.3. *Let m be a smooth function satisfying* (H0), (H1), *and* (H2). *If $(u, \phi) \in \left(L^\infty(\mathbb{R}^3)\right)^2$ is a solution of* (1.1), *then there exists two constants $C > 0$ and $l \leq 0$ such that*

$$\forall x \in H^c, \quad |\nabla\phi(x)| \leq \frac{C}{(1+x_3)^{7/4}} \tag{3.8}$$

$$\forall x \in H^c, \quad |\phi(x) - l| \leq \frac{C}{(1+x_3)^{3/4}}. \tag{3.9}$$

Proof. We first use standard regularity estimates [8], and get, since $\phi \in C^{2,\alpha}(\mathbb{R}^3)$ for some $\alpha > 0$,

$$\|\nabla\phi\|_{C^0(B_R)} \leq C\left(\frac{1}{R}\|\phi\|_{C^0(B_{2R})} + R\|\Delta\phi\|_{C^0(B_{2R})}\right), \tag{3.10}$$

for any $R > 0$, where C is a constant independent of R. Fixing $x \in H^c$, using $R = \frac{x_3}{4}$ and for B_R the ball centered at x, we have

$$\forall x \in H^c, \quad |\nabla \phi(x)| \leq \frac{C}{1+x_3}. \tag{3.11}$$

Next, we fix again a ball $B_R \subset H^c$, and define in this set two functions ϕ_1 and ϕ_2 by

$$\left\{ \begin{array}{l} -\Delta \phi_1 = -u^2, \\ \phi_{1|\partial B_R} = 0, \end{array} \right. \qquad \left\{ \begin{array}{l} -\Delta \phi_2 = 0, \\ \phi_{2|\partial B_R} = \phi. \end{array} \right.$$

Hence, $\phi = \phi_1 + \phi_2$ in B_R. The maximum principle and (3.4) imply that $-\frac{1}{2x_3} \leq \phi_1(x) \leq 0$ in B_R. We then use the Gagliardo–Nirenberg inequality [10], and get

$$\|\nabla \phi_1\|_{L^\infty(B_R)} \leq C \|\phi_1\|^{\frac{1}{2}}_{L^\infty(B_R)} \|\Delta \phi_1\|^{\frac{1}{2}}_{L^\infty(B_R)},$$

for some constant C independent of R. Hence, fixing $x \in H^c$ and using for B_R the ball $B_R(x)$ with $R = \frac{x_3}{2}$, we have

$$\forall z \in B_R, \quad |\nabla \phi_1(z)| \leq \frac{C}{(1+z_3)^2}. \tag{3.12}$$

We then point out that ϕ_2 is explicitly given by the following formula:

$$\phi_2(z) = -\int_{\partial B_R} \frac{(z-y)\cdot n}{|z-y|^3} \phi(y) d\sigma(y), \tag{3.13}$$

where σ is the Lebesgue measure on ∂B_R, and n denotes the normal vector of ∂B_R at the point y. We then slightly modify B_R, in a way which does not change estimate (3.12), by setting $B_R = B_R(x + Re_3)$, where e_3 is the third vector of the canonical basis. Letting R go to infinity, we get (3.13) with $J_x := \{x + y,\, y \in \partial H\} = \{y \in \mathbb{R}^3,\, y_3 = x_3\}$ instead of ∂B_R, namely

$$\phi_2(z) = (z_3 - x_3) \int_{J_x} \frac{\phi(y)}{|z-y|^3} d\sigma(y).$$

We then differentiate this expression with respect to z_1 and get

$$\begin{aligned} \partial_1 \phi_2(z) &= -3(z_3 - x_3) \int_{J_x} \frac{z_1 - y_1}{|z-y|^5} \phi(y) d\sigma(y) \\ &= -3(z_3 - x_3) \int_{J_x} \frac{z_1 - y_1}{|z-y|^5} \left(\phi(y) - \phi\left[(z_1, z_2, x_3)\right]\right) d\sigma(y). \end{aligned}$$

Hence, setting $R' > 0$ (which will be chosen later on), we get, using (3.11),

$$\begin{aligned} |\partial_1 \phi_2(z)| &\leq C|z_3 - x_3| \int_{y_1^2 + y_2^2 \leq R'^2} \frac{R' dy_1 dy_2}{|x_3| \left((z_3 - x_3)^2 + y_1^2 + y_2^2\right)^{\frac{5}{2}}} \\ &\quad + C|z_3 - x_3| \int_{y_1^2 + y_2^2 \geq R'^2} \frac{dy_1 dy_2}{\left((z_3 - x_3)^2 + y_1^2 + y_2^2\right)^{\frac{5}{2}}} \\ &\leq C \frac{R'}{|x_3|(z_3 - x_3)^2} + C \frac{|z_3 - x_3|}{R'^3}. \end{aligned}$$

Hence, setting $R' = z_3 - x_3$, we get $|\partial_1\phi_2(x)| \leq \frac{C}{x_3(z_3-x_3)} + \frac{C}{(z_3-x_3)^2}$. The same argument holds for $\partial_2\phi_2$ so that, using (3.12), we have, for any $x \in H^c$,

$$\forall z \in \mathbb{R}^3 \quad / \quad z_3 \geq x_3, \quad |\partial_1\phi(z)| + |\partial_2\phi(z)| \leq \frac{C}{x_3(z_3-x_3)} + \frac{C}{(z_3-x_3)^2}. \tag{3.14}$$

We then go back to (3.13), and carry out exactly the same computation as for $\partial_1\phi_2$, but for $\partial_3\phi_2$, finding

$$\forall z \in \mathbb{R}^3 \quad / \quad z_3 \geq x_3, \quad |\partial_3\phi_2(z)| \leq \frac{C}{x_3(z_3-x_3)^{1/2}} + \frac{C}{(z_3-x_3)^{3/2}}.$$

Setting $z_3 = 2x_3$, we thus have

$$\forall x \in H^c, \quad |\nabla\phi(x)| \leq \frac{C}{(1+x_3)^{3/2}}. \tag{3.15}$$

This estimate implies that ϕ converges to some limit l as x_3 goes to $+\infty$, uniformly with respect to (x_1, x_2). We then define $\tilde{\phi} = \phi - l$, which satisfies (3.15) and

$$\forall x \in H^c, \quad \left|\tilde{\phi}(x)\right| \leq \frac{C}{(1+x_3)^{1/2}}.$$

We then repeat exactly the same argument as above, but with $\tilde{\phi}$ instead of ϕ, and we finally have (3.8), which implies (3.9). The fact that $l \leq 0$ is a direct consequence of (3.5). □

LEMMA 3.4. *Let m be a smooth function satisfying* (H0), (H1), *and* (H2). *If $(u, \phi) \in \left(L^\infty(\mathbb{R}^3)\right)^2$ is a solution of* (1.1), *then there exist two constants $A > 0$ and $a > 0$ such that*

$$\forall x \in H^c, \quad u(x) \geq Ae^{-a|x_3|} \tag{3.16}$$

$$\forall x \in H, \quad u(x) \geq A. \tag{3.17}$$

Proof. The estimate (3.17) may be proved with exactly the same method as for (2.3). We refer to [7] for the proof. Turning to (3.16), we use the fact that $\phi \in L^\infty(\mathbb{R}^3)$, so that $-\Delta u + u^{\frac{7}{3}} = \phi u \geq -bu$, for some constant $b > 0$. Since u is also bounded, this implies that there exists some $c > 0$ such that

$$-\Delta u + cu \geq 0.$$

Hence, convoluting the above inequality with the Yukawa potential $\frac{e^{-\sqrt{c}|x|}}{|x|}$, we get that

$$4\pi u(x) \geq \frac{c}{2} u * \frac{e^{-\sqrt{c}|x|}}{|x|} \geq \frac{Ac}{2} \int_H \frac{e^{-\sqrt{c}|x-y|}}{|x-y|} dy \geq Be^{-\sqrt{c}x_3},$$

for some constant $B > 0$. □

3.2. Proof of Theorem 1.1. In this section, we conclude the proof of Theorem 1.1. We assume that (u,ϕ) and (v,ψ) are two solutions of (1.1), and use the same notation as in section 2, namely $w = u - v$ and $\eta = \phi - \psi$. We recall that, for simplicity, we have assumed that m is smooth, so that (2.1) and (2.2) hold in the present case. We now carry out the same calculation as in section 2, multiplying the first line of (2.4) by $w\xi^2$ and the second line by $\eta\xi^2$, where $\xi \in \mathcal{D}(\mathbb{R}^3)$, finding (2.5) and (2.6). Here again, the operators $L_u = -\Delta + u^{\frac{4}{3}} - \phi$ and $L_v = -\Delta + v^{\frac{4}{3}} - \psi$ are nonnegative, and (2.7) is still valid, so that (2.8) translates into

$$\frac{1}{2}\int_{\mathbb{R}^3}\left(u^{\frac{4}{3}} + v^{\frac{4}{3}}\right)w^2\xi^2 + \frac{1}{4}\int_{\mathbb{R}^3}|\nabla\eta|^2\xi^2 \leq \int_{\mathbb{R}^3}(w^2+\eta^2)|\nabla\xi|^2. \tag{3.18}$$

We then use for ξ a sequence of functions converging to $\xi(x) = \left(1 - \frac{|x-x_0|}{2R}\right)_+$, for any $R > 0$ and any $x_0 \in \mathbb{R}^3$, and find that there exists some constant $C > 0$ independent of R and x_0 such that

$$\int_{B_R(x_0)}\left(u^{\frac{4}{3}} + v^{\frac{4}{3}}\right)w^2 \leq CR, \quad \int_{B_R(x_0)}|\nabla\eta|^2 \leq CR. \tag{3.19}$$

Moreover, (2.11) is still valid, and allows to prove, using the same computations as in section 2, that for some constant C independent of x_0 and R,

$$\int_{B_R(x_0)}(u+v)\eta^2 \leq CR. \tag{3.20}$$

Next, we apply Lemma 3.3 to ϕ and ψ, and infer that η satisfies (3.9) for some $l \in \mathbb{R}$. Hence, for $t > 0$ large enough, we have $\eta^2(x_1,x_2,t) \geq \frac{l^2}{2}$, for any $(x_1,x_2) \in \mathbb{R}^2$. Applying (3.20) and (3.16), we have, for all $t > 0$ large enough,

$$CR \geq \int_{D_R(t)}(u+v)\eta^2 \geq 2Ae^{-at}R^2\frac{l^2}{2},$$

where $D_R(t) = \left\{(x_1,x_2,x_3) \in \mathbb{R}^3,\ \sqrt{x_1^2+x_2^2} \leq R,\ t \leq x_3 \leq t+1\right\}$. We then let R go to infinity and find that $l = 0$, and thus

$$\forall x \in H^c, \quad |\eta(x)| \leq \frac{C}{(1+x_3)^{3/4}}, \tag{3.21}$$

for some constant C. We then go back to (3.18), and using here again the same kind of function ξ, we have, using estimates (3.1), (3.4), and (3.21),

$$\int_{\mathbb{R}^3} w^2|\nabla\xi|^2 \leq \left(\int_{-\infty}^0 A^2e^{-2\alpha|x_3|}dx_3 + \int_0^{+\infty}\frac{dx_3}{(1+x_3)^3}\right)\frac{1}{R^2}\int_{x_1^2+x_2^2\leq R^2}dx_1dx_2 \leq C,$$

and

$$\int_{\mathbb{R}^3} \eta^2|\nabla\xi|^2 \leq \left(\int_{-\infty}^0 A^2e^{-2\alpha|x_3|}dx_3 + \int_0^{+\infty}\frac{dx_3}{(1+x_3)^{3/2}}\right)\frac{1}{R^2}\int_{x_1^2+x_2^2\leq R^2}dx_1dx_2 \leq C,$$

for some constant $C > 0$. Hence, using here again the same argument as the one leading to (3.19) and (3.20), we find that

$$\int_{\mathbb{R}^3}\left(u^{\frac{4}{3}} + v^{\frac{4}{3}}\right)w^2 < +\infty, \quad \int_{\mathbb{R}^3}|\nabla\eta|^2 < +\infty, \quad \int_{\mathbb{R}^3}(u+v)\eta^2 < +\infty. \tag{3.22}$$

We then use $\xi(x_1,x_2,x_3) = \left(1-\frac{x_1}{R}\right)_+ \left(1-\frac{x_2}{R}\right)_+$, and compute, setting

$$E_R = \left\{(x_1,x_2,x_3)\in\mathbb{R}^3, \quad |x_1|\le R \quad \text{and} \quad |x_2|\le R\right\},$$

and using (3.18) again,

$$\begin{aligned}
\frac{1}{8}\int_{E_{\frac{R}{2}}} \left(u^{\frac{4}{3}}+v^{\frac{4}{3}}\right) w^2 &\le \frac{1}{R^2}\int_{E_R} \eta^2 + w^2 \\
&\le \frac{1}{R^2}\int_{E_R\cap\{|x_3|\le A\}} \eta^2+w^2 + \int_{E_R\cap\{|x_3|\ge A\}} \eta^2+w^2 \\
&\le \frac{Ce^{\gamma A}}{R^2}\left[\int_{\mathbb{R}^3}\left(u^{\frac{4}{3}}+v^{\frac{4}{3}}\right)w^2 + (u+v)\eta^2\right] + \frac{CR^2}{R^2A^{\frac{1}{2}}} \\
&\le C\left(\frac{e^{\gamma A}}{R^2}+\frac{1}{A^{\frac{1}{2}}}\right),
\end{aligned}$$

where A is any positive number, and γ and C are positive constants independent of R and A. We first let R go to infinity, and then A, which proves that $w=0$. This clearly implies that $\eta = 0$. □

4. Application: Thermodynamic limit for a semicrystal in the Thomas–Fermi–von Weizsäcker model. In this section we give a few remarks on the notion of thermodynamic limit, and on the link between this problem and the present work.

4.1. The Thomas–Fermi–von Weizsäcker model for molecules. In the Thomas–Fermi–von Weizsäcker (TFW) model, a molecule consisting of N point nuclei, which have positions $\{X_i\}_{1\le i\le N}$ and charges $\{Z_i\}_{1\le i\le N}$, together with M electrons, has its energy modelled by the functional

$$\begin{aligned}
\mathcal{E}^{\mathrm{TFW}}(\rho,\{X_i\}) = \int_{\mathbb{R}^3} a|\nabla\sqrt{\rho}|^2 + b\rho^{\frac{5}{3}} - \sum_{i=1}^N \int_{\mathbb{R}^3} \frac{Z_i\rho(x)}{4\pi|x-X_i|}dx \\
+\frac{1}{2}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{\rho(x)\rho(y)}{4\pi|x-y|}dxdy + \frac{1}{2}\sum_{i\ne j}\frac{Z_iZ_j}{4\pi|X_i-X_j|},
\end{aligned} \tag{4.1}$$

where a and b are two positive constants. The function $\rho\in L^1(\mathbb{R}^3)$ denotes the electronic density and is constrained by $\int\rho = M$. The energy is defined only for densities ρ such that $\rho\ge 0$ and $\sqrt{\rho}\in H^1(\mathbb{R}^3)$, and the minimization problem corresponding to the determination of the ground state reads

$$\mathcal{E}^{\mathrm{TFW}}(\{X_i\}) = \inf\left\{\mathcal{E}^{\mathrm{TFW}}(\rho,\{X_i\}),\ \rho\ge 0,\ \sqrt{\rho}\in H^1(\mathbb{R}^3),\ \int_{\mathbb{R}^3}\rho = M\right\}. \tag{4.2}$$

In the special case of $a=1$ and $b=\frac{3}{5}$, and if we set

$$m = \sum_{i=1}^N Z_i\delta_{X_i},$$

$u=\sqrt{\rho}$, and $\phi = (\rho-m)*\frac{1}{|x|}-\theta$, then the Euler–Lagrange equation of (4.2) is (1.1). The constant θ in the definition of ϕ is the Lagrange multiplier associated to the mass constraint in (4.2).

In the special case $a=0$, the model reduces to the well-known Thomas–Fermi model [9].

4.2. Thermodynamic limit for a semicrystal. The thermodynamic limit is a way of deriving a solid-state model from a molecular one. Given an infinite number of atoms, one approximates it by a finite system, then lets the number of particles go to infinity in a suitable way and passes to the limit. We refer to [7] and [9] for a general presentation and the definition of the ground state energy of crystals (infinite periodic lattices) in the setting of Thomas–Fermi type theories.

The setting we consider for the finite size system is (4.1)–(4.2), and we will assume that $Z_i = 1$ for all $i \in \{1, 2, \dots, n\}$, although this can be generalized. The positions of the nuclei are assumed to be a subset of a periodic lattice intersected with H. For the sake of simplicity (this can be easily generalized to other periodic lattices, or to nonperiodic geometry, as in [5]) we assume that the set of nuclei is

$$\{X_i\}_{i\in\mathbb{N}} = \mathbb{Z}^3 \cap H,$$

and is approached by the truncated sets

$$\Lambda_R = \mathbb{Z}^3 \cap H \cap B_R,$$

for $R > 0$, where B_R is the ball of radius R centered at zero. Note that other types of truncation are also possible, as pointed out in [7]. We then define, according to (4.1)–(4.2), the number

$$I_R = \mathcal{E}^{\mathrm{TFW}}(\Lambda_R),$$

and denote by ρ_R the corresponding solution. We address the following questions:

(L1) *Does the energy per unit volume* $\frac{I_R}{|B_R|}$ *converge as* R *goes to infinity?*

(L2) *Does the minimizer* ρ_R *of* I_R *converge to a limit* ρ_∞ *as* R *goes to infinity?*

(L3) *Is the limit* ρ_∞ *the solution of some minimization problem of the form* (4.2)*?*

The method developed in [7] to deal with such a problem may be summarized as follows:

1. First, derive bounds on the density ρ_R,
2. next, using these bounds, pass to the limit in the Euler–Lagrange equation of I_R,
3. show a uniqueness theorem on the limit equation,
4. use this uniqueness property to prove a uniform convergence of the solution, which implies convergence of the energy.

Let us point out here that in the above strategy, step 3 is by far the most difficult.

Now, looking at the proofs given in [7] for the case of a full crystal, it is clear that the proofs of the first point carry through the present case. The next step is also clearly straightforward. Turning to step 3, we point out that the Euler–Lagrange equation of problem I_R can be rewritten as

$$\begin{cases} -\Delta u_R + u_R^{7/3} - \phi_R u_R = 0, \\ -\Delta \phi_R = m_R - u_R^2, \end{cases}$$

with $u_R = \sqrt{\rho}_R$ and $\phi_R = (\rho_R - m_R) * \frac{1}{|x|} - \theta_R$ (the number θ_R is the Lagrange multiplier), and

$$m_R = \sum_{k\in\Lambda_R} \delta_k.$$

Passing to the limit in this system, one gets (1.1) with

$$m = \sum_{k \in \mathbb{Z}^3 \cap H} \delta_k, \tag{4.3}$$

which clearly satisfies (H0), (H1), and (H2). Hence, one can apply Theorem 1.1, proving that the limit of the solution is unique. The thermodynamic limit problem can thus be dealt with in the present case.

Our final point is to write down a minimization problem for the limit density: since the solution of (1.1) with m defined by (4.3) is unique, it is periodic of period one in x_1 and x_2. Moreover, the exponential decay proved in Lemma 3.1 implies that $u - u_{\rm per}$ decays exponentially as x_3 goes to $-\infty$, where $u_{\rm per}$ is the solution of (1.1) with

$$m_{\rm per} = \sum_{k \in \mathbb{Z}^3} \delta_k.$$

The same decay is true for ∇u. In order to write down the limit minimization problem, we first define a periodic Coulomb potential (see [4, 6] for more details):

$$G(x) = -2\pi|x_3| + \sum_{k \in \mathbb{Z}^2 \times \{0\}} \left(\frac{1}{|x-k|} - \int_{K \times \{0\}} \frac{dy}{|x-y-k|} \right), \tag{4.4}$$

where K is the unit square of $\mathbb{R}^2$. We assume that χ is a cut-of function depending only on x_3 such that

$$\begin{aligned} &\chi(x) = 1 \quad \text{if} \quad x_3 < -1, \\ &\chi(x) = 0 \quad \text{if} \quad x_3 > 1, \\ &\int_Q \left[(\chi(x) - \mathbf{1}_{x_3<0}) u_{\rm per}^2(x) \right] dx = 0, \end{aligned}$$

where Q is the "unit cell"

$$Q = K \times \mathbb{R} = \left\{ (x_1, x_2, x_3) \in \mathbb{R}^3 \quad / \quad x_1 \in \left[-\frac{1}{2}, \frac{1}{2} \right), \quad x_1 \in \left[-\frac{1}{2}, \frac{1}{2} \right) \right\},$$

and we define the following energy, with $\rho_0 = \chi u_{\rm per}^2$,

$$\begin{aligned} \mathcal{E}(\tilde\rho) = &\int_Q (\tilde\rho + \rho_0)^{5/3} - \rho_0^{5/3} + \int_Q |\nabla \sqrt{\tilde\rho + \rho_0}|^2 - |\nabla \sqrt{\rho_0}|^2 - \int_Q \tilde\rho G \\ &+ \frac{1}{2} \int_Q \int_Q \tilde\rho(x) G(x-y) \tilde\rho(y) dx dy \\ &+ \int_Q \int_Q \tilde\rho(x) G(x-y) \rho_0(y) dx dy, \end{aligned} \tag{4.5}$$

where we have set formally $\tilde\rho = \rho - \rho_0$, and have subtracted the infinite energy of ρ_0 in order to get a finite value of the energy. This allows one to define the variational problem as follows:

$$\inf \left\{ \mathcal{E}(\tilde\rho), \quad \tilde\rho \in H^1_{\rm per}(Q), \quad \tilde\rho + \rho_0 \geq 0, \quad \sqrt{\tilde\rho + \rho_0} \in H^1_{\rm loc}(\mathbb{R}^3), \quad \int_Q \tilde\rho = 0 \right\}, \tag{4.6}$$

where $H^1_{\rm per}(Q)$ is the set of functions in $H^1(Q)$, which satisfy periodic boundary conditions in x_1 and x_2.

One can then check that the minimization problem (4.6) is well posed, that its solution does not depend on χ, and that its Euler–Lagrange equation is (1.1) with m defined by (4.3), where $u = \sqrt{\tilde{\rho} + \rho_0}$ and ϕ is the effective potential.

AN ASYMPTOTIC FORMULA FOR THE DISPLACEMENT FIELD IN THE PRESENCE OF THIN ELASTIC INHOMOGENEITIES*

ELENA BERETTA† AND ELISA FRANCINI‡

Abstract. We consider a plane isotropic homogeneous elastic body with thin elastic inhomogeneities in the form of small neighborhoods of simple smooth curves. We derive a rigorous asymptotic expansion of the boundary displacement field as the thickness of the neighborhoods goes to zero.

Key words. Lamé system, thin inhomogeneities, asymptotic formulas

1. Introduction.

Let $\Omega \subset \mathbb{R}^2$ be a bounded smooth domain representing the region occupied by an elastic material.

Let $\sigma_0 \subset \Omega$ be a simple smooth curve and define, for a positive small ϵ, the set

$$\omega_\epsilon = \{x \in \Omega \ : \ d(x, \sigma_0) < \epsilon\},$$

which represents an inclusion of small size made of a different elastic material.

Let $\mathbb{C}_0$ and $\mathbb{C}_1$ be the elastic tensor fields in $\Omega \setminus \overline{\omega}_\epsilon$ and ω_ϵ, respectively.

Given a traction field g on $\partial\Omega$, the displacement field u_ϵ, generated by this traction in the body containing the inclusion ω_ϵ, solves the following system of linearized elasticity:

$$\begin{cases} \operatorname{div}(\mathbb{C}_\epsilon \widehat{\nabla} u_\epsilon) &= 0 \quad \text{in} \quad \Omega, \\ (\mathbb{C}_\epsilon \widehat{\nabla} u_\epsilon) \cdot \nu &= g \quad \text{on} \quad \partial\Omega, \end{cases} \tag{1}$$

where $\mathbb{C}_\epsilon = \mathbb{C}_0 \chi_{\Omega \setminus \omega_\epsilon} + \mathbb{C}_1 \chi_{\omega_\epsilon}$, $\widehat{\nabla} u_\epsilon = \frac{1}{2}\left(\nabla u_\epsilon + (\nabla u_\epsilon)^T\right)$ is the symmetric deformation tensor and ν denotes the outward unit normal to $\partial\Omega$.

Let us also introduce the background displacement u_0, namely the solution of

$$\begin{cases} \operatorname{div}(\mathbb{C}_0 \widehat{\nabla} u_0) &= 0 \quad \text{in} \quad \Omega, \\ (\mathbb{C}_0 \widehat{\nabla} u_0) \cdot \nu &= g \quad \text{on} \quad \partial\Omega. \end{cases} \tag{2}$$

The goal of this paper is to find an asymptotic expansion for $(u_\epsilon - u_0)_{|\partial\Omega}$ as $\epsilon \to 0$. An analogous expansion has been derived in [BFV] for the case of thin conductivity inclusions. These expansions represent a powerful tool to solve the inverse problem of identifying the inclusions, given boundary measurements (see, [ABF] and [ABF2] for the case of thin conductivity inclusions and [AK] for further references).

‡Dipartimento di Matematica "U. Dini," Università degli Studi di Firenze, Viale Morgagni, 67A - 50134 Firenze, Italy (francini@math.unifi.it)

In [AKNT] the authors derive an asymptotic expansion for the boundary displacement field $(u_\epsilon - u_0)_{|\partial\Omega}$ in the case of diametrically small elastic inclusions, namely inclusions of the form $z + \epsilon B$, where z is a point in Ω and B is a bounded domain containing the origin. The approach they use, based on the method of layer potentials (see [AK]), allows them to find a very accurate expansion. Unfortunately, this method does not seem to work in the case of thin elastic inclusions. Hence, in order to derive the expansion in our context, we apply similar arguments as in [BFV] for conductivity inclusions; more precisely, we use a variational approach and fine regularity estimates for solutions of elliptic systems with discontinuous coefficients obtained by Li and Nirenberg in [LN]. The main difficulty arising in the framework of linear elasticity, compared to the conductivity case, consists of finding an explicit representation formula for the tensor appearing in the first order term of the asymptotic expansion.

The plan of the paper is as follows: in section 2 we introduce some notation and state the main result. Section 3 is devoted to the derivation of some estimates and properties of the displacement field, and in section 4 we prove our main result.

2. The main result. Let us introduce some notation and assumptions that will be useful in what follows.

(a) We will assume that σ_0 is of class C^3 and that there exists some $K > 0$ such that

$$\begin{aligned} d(\sigma_0, \partial\Omega) &\geq K^{-1}, \\ \|\sigma_0\|_{C^3} &\leq K, \\ K^{-1} \leq \text{length}(\sigma_0) &\leq K. \end{aligned} \tag{3}$$

Moreover, we assume that for every $x \in \sigma_0$ there are two discs, B_1 and B_2, of radius K^{-1} such that

$$\overline{B}_1 \cap \overline{B}_2 = \overline{B}_1 \cap \sigma_0 = \overline{B}_2 \cap \sigma_0 = \{x\}.$$

The latter assumption guarantees that different parts of σ_0 do not get too close, so that ω_ϵ does not self-intersect for small ϵ.

(b) Ω and ω_ϵ are both homogeneous and isotropic, i.e., the elastic tensor fields $\mathbb{C}_0$ and $\mathbb{C}_1$ are of the following form:

$$(\mathbb{C}_m)_{ijlk} = \lambda_m \delta_{ij}\delta_{kl} + \mu_m(\delta_{ki}\delta_{lj} + \delta_{kj}\delta_{li}), \text{ for } i,j,k,l = 1,2, \;\; m = 0,1, \tag{4}$$

where (λ_0, μ_0) and (λ_1, μ_1) are the Lamè coefficients corresponding to $\Omega \setminus \overline{\omega}_\epsilon$ and ω_ϵ, respectively, and $(\lambda_0 - \lambda_1)^2 + (\mu_0 - \mu_1)^2 \neq 0$.

(c) There are two positive constants α_0 and β_0 such that

$$\min(\mu_0, \mu_1) \geq \alpha_0, \quad \min(2\lambda_0 + 2\mu_0, 2\lambda_1 + 2\mu_1) \geq \beta_0. \tag{5}$$

We note that the last conditions ensure that $\mathbb{C}_\epsilon$ is strongly convex in Ω, i.e., if we set $\xi_0 = \min(2\alpha_0, \beta_0)$, then

$$\mathbb{C}_\epsilon A \cdot A \geq \xi_0 |A|^2,$$

for any symmetric 2×2 matrix A, where $A \cdot B = \sum_{ij} a_{ij} b_{ij}$ and $|A|^2 = A \cdot A$.

(d) We shall prescribe a traction field $g \in H^{-1/2}(\partial\Omega, \mathbb{R}^2)$ satisfying the compatibility condition

$$\int_{\partial\Omega} g \cdot R = 0, \tag{6}$$

for every infinitesimal rigid displacement R, that is $R(x) = c + Wx$, where c is any constant vector in $\mathbb{R}^2$ and W any constant 2×2 skew matrix.

Under our assumptions there exist weak solutions u_ϵ and $u_0 \in H^1(\Omega, \mathbb{R}^2)$ to the problems (1) and (2), respectively (see, for example, [V] or [F]). Concerning uniqueness we recall that solutions of the above problems are uniquely determined up to infinitesimal rigid displacements. Hence, in order to uniquely identify such solutions, we assume that u_ϵ and u_0 satisfy the normalization conditions

$$\int_{\partial\Omega} u = 0, \quad \int_\Omega \nabla u - (\nabla u)^T = 0. \tag{7}$$

It is easy to see that if u_ϵ is solution of (1), then it solves the Lamé system

$$\begin{cases} \mu_0 \Delta u_\epsilon + (\lambda_0 + \mu_0) \nabla(\operatorname{div} u_\epsilon) &= 0 \quad \text{in} \quad \Omega \setminus \overline{\omega}_\epsilon, \\ \mu_1 \Delta u_\epsilon + (\lambda_1 + \mu_1) \nabla(\operatorname{div} u_\epsilon) &= 0 \quad \text{in} \quad \omega_\epsilon, \\ u_\epsilon^i &= u_\epsilon^e \quad \text{on} \quad \partial\omega_\epsilon, \\ \left(\mathbb{C}_0 \widehat{\nabla} u_\epsilon^i\right) \nu &= \left(\mathbb{C}_1 \widehat{\nabla} u_\epsilon^e\right) \nu \quad \text{on} \quad \partial\omega_\epsilon, \end{cases} \tag{8}$$

where ν is the outward unit normal to $\partial\omega_\epsilon$, and, for $x \in \partial\omega_\epsilon$,

$$u_\epsilon^e(x) = \lim_{\substack{y \to x \\ y \in \Omega \setminus \overline{\omega}_\epsilon}} u_\epsilon(y), \quad u_\epsilon^i(x) = \lim_{\substack{y \to x \\ y \in \omega_\epsilon}} u_\epsilon(y),$$

and

$$\widehat{\nabla} u_\epsilon^e(x) = \lim_{\substack{y \to x \\ y \in \Omega \setminus \overline{\omega}_\epsilon}} \widehat{\nabla} u_\epsilon(y), \quad \widehat{\nabla} u_\epsilon^i(x) = \lim_{\substack{y \to x \\ y \in \omega_\epsilon}} \widehat{\nabla} u_\epsilon(y).$$

For $y \in \Omega$, we will denote by $N(\cdot, y)$ the Neumann function related to Ω, i.e., the weak solution to the problem

$$\begin{cases} \operatorname{div}\left(\mathbb{C}_0 \widehat{\nabla} N(\cdot, y)\right) &= -\delta_y \, \mathrm{I}_d \quad \text{in} \quad \Omega, \\ \left(\mathbb{C}_0 \widehat{\nabla} N(\cdot, y)\right) \cdot \nu &= -\frac{1}{|\partial\Omega|} \, \mathrm{I}_d \quad \text{on} \quad \partial\Omega, \end{cases} \tag{9}$$

with the normalization conditions (7) and where I_d is the identity matrix in $\mathbb{R}^2$.

Note that $N(x, y)$ is regular for $x \neq y$ and, at $x = y$, has the same singularities of $\Gamma(x - y)$, where $\Gamma = (\Gamma_{ij})_{i,j=1}^2$ is the fundamental solution in the free space of the system

$$\operatorname{div}\left(\mathbb{C}_0 \widehat{\nabla} \cdot\right) = 0 \quad \text{in} \quad \mathbb{R}^2,$$

and is given by

$$\Gamma_{ij}(x) = \frac{A}{2\pi} \, \delta_{ij} \ln |x| - \frac{B}{2\pi} \frac{x_i x_j}{|x|^2},$$

where $A = \frac{1}{2}\left(\frac{1}{\mu_0} + \frac{1}{\lambda_0 + 2\mu_0}\right)$ and $B = \frac{1}{2}\left(\frac{1}{\mu_0} - \frac{1}{\lambda_0 + 2\mu_0}\right)$.

Let us fix an orthonormal system (n, τ) on σ_0 such that n is a unit normal vector field to the curve and τ is a unit tangent vector field. If σ_0 is a closed curve, then we will take n to point in the outward direction of the domain it encloses. Let κ denote the curvature of σ_0 and, for $a, b \in \mathbb{R}^2$, let $a \otimes b$ denote the tensor product $a \otimes b = a_i b_j$.

We are now ready to state our main result.

THEOREM 2.1. *Let $\Omega \subset \mathbb{R}^2$ be a bounded smooth domain and let $\sigma_0 \subset\subset \Omega$ be a simple curve satisfying* (3). *Assume* (4), (5), *and* (6) *and let u_ϵ and u_0 be the solutions to* (1) *and* (2), *respectively, satisfying* (7). *For every $x \in \sigma_0$, there exists a fourth order symmetric tensor field $\mathcal{M}(x)$ such that, for $y \in \partial\Omega$ and $\epsilon \to 0$,*

$$(u_\epsilon - u_0)(y) = 2\epsilon \int_{\sigma_0} \mathcal{M}(x)\widehat{\nabla} u_0(x) \cdot \widehat{\nabla} N(x,y)\, d\sigma_0(x) + o(\epsilon). \tag{10}$$

The term $o(\epsilon)$ is bounded by $C\epsilon^{1+\theta}\|g\|_{H^{-1/2}(\partial\Omega)}$, with $0 < \theta < 1$ and C depending only on θ, Ω, α_0, β_0, and K.

Furthermore, on σ_0,

$$\begin{aligned}\mathcal{M}\widehat{\nabla} u_0 = {} & a \operatorname{div} u_0\, I_d + b\widehat{\nabla} u_0 \\ & + c\left(\frac{\partial(u_0 \cdot \tau)}{\partial \tau} + \kappa(u_0 \cdot n)\right)\tau \otimes \tau + d\frac{\partial(u_0 \cdot n)}{\partial n} n \otimes n,\end{aligned}$$

where

$$a = (\lambda_1 - \lambda_0)\frac{\lambda_0 + 2\mu_0}{\lambda_1 + 2\mu_1}, \quad b = 2(\mu_1 - \mu_0)\frac{\mu_0}{\mu_1}, \tag{11}$$

$$c = 2(\mu_1 - \mu_0)\left[\left(\frac{2\lambda_1 + 2\mu_1 - \lambda_0}{\lambda_1 + 2\mu_1} - \frac{\mu_0}{\mu_1}\right)\right], \tag{12}$$

and

$$d = 2(\mu_1 - \mu_0)\frac{\mu_1\lambda_0 - \mu_0\lambda_1}{\mu_1(\lambda_1 + 2\mu_1)}. \tag{13}$$

The proof of the theorem is contained in section 4.

3. Energy and a priori estimates. In this section we will show that, for $\epsilon \to 0$,

$$\|u_\epsilon - u_0\|_{H^1(\Omega)} = O(\epsilon^{1/2}). \tag{14}$$

In order to establish it we will need the following version of the Korn inequality.

LEMMA 3.1. *Let Ω be a Lipschitz connected open set in $\mathbb{R}^2$. Let $u \in H^1(\Omega, \mathbb{R}^2)$ and let $W_0 = \int_\Omega \frac{1}{2}\left(\nabla u - (\nabla u)^T\right)$.*

Then, there exists a constant C such that

$$\|\nabla u - W_0\|_{L^2(\Omega)} \le C\|\widehat{\nabla} u\|_{L^2(\Omega)}. \tag{15}$$

For the proof, see [T, section 3].

PROPOSITION 3.2. *Let u_ϵ and u_0 be solutions to* (1) *and* (2), *respectively. There exists a constant C depending on Ω, K, α_0, and β_0, such that*

$$\|u_\epsilon - u_0\|_{H^1(\Omega)} \le C\epsilon^{1/2}\|g\|_{H^{-1/2}(\partial\Omega)}. \tag{16}$$

Proof. Since $\int_{\partial\Omega}(u_\epsilon - u_0) = 0$, by the Poincaré inequality there exists a constant C, depending on Ω, such that

$$\int_\Omega |u_\epsilon - u_0|^2 \le C\int_\Omega |\nabla(u_\epsilon - u_0)|^2. \tag{17}$$

It thus suffices to estimate $\|\nabla(u_\epsilon - u_0)\|_{L^2(\Omega)}$.

By the strong convexity of $\mathbb{C}_\epsilon$ and the Korn inequality, in the form of Lemma 3.1, applied to $u_\epsilon - u_0$, and recalling that u_ϵ and u_0 satisfy (7), we get

$$\begin{aligned}\int_\Omega \mathbb{C}_\epsilon \widehat{\nabla}(u_\epsilon - u_0) \cdot \widehat{\nabla}(u_\epsilon - u_0) &\geq \xi_0 \int_\Omega |\widehat{\nabla}(u_\epsilon - u_0)|^2 \\ &\geq C \int_\Omega |\nabla(u_\epsilon - u_0)|^2, \end{aligned} \tag{18}$$

where C depends on α_0, β_0, and Ω.

Now, observe that

$$\int_\Omega \mathbb{C}_\epsilon \widehat{\nabla}(u_\epsilon - u_0) \cdot \widehat{\nabla}(u_\epsilon - u_0) = \int_{\omega_\epsilon} (\mathbb{C}_0 - \mathbb{C}_1)\widehat{\nabla} u_0 \cdot \widehat{\nabla}(u_\epsilon - u_0), \tag{19}$$

which follows by integration by parts and uses the fact that $(\mathbb{C}_\epsilon \widehat{\nabla} u_\epsilon)\cdot \nu = (\mathbb{C}_0 \widehat{\nabla} u_0)\cdot \nu$ on $\partial\Omega$. Indeed

$$\begin{aligned} &\int_\Omega \mathbb{C}_\epsilon \widehat{\nabla}(u_\epsilon - u_0) \cdot \widehat{\nabla}(u_\epsilon - u_0) - \int_{\omega_\epsilon} (\mathbb{C}_0 - \mathbb{C}_1)\widehat{\nabla} u_0 \cdot \widehat{\nabla}(u_\epsilon - u_0) \\ &= \int_{\Omega\setminus\omega_\epsilon} \mathbb{C}_0 \widehat{\nabla}(u_\epsilon - u_0) \cdot \widehat{\nabla}(u_\epsilon - u_0) + \int_{\omega_\epsilon} (\mathbb{C}_1 \widehat{\nabla} u_\epsilon - \mathbb{C}_0 \widehat{\nabla} u_0) \cdot \widehat{\nabla}(u_\epsilon - u_0) \\ &= \int_\Omega \mathbb{C}_\epsilon \widehat{\nabla} u_\epsilon \cdot \widehat{\nabla}(u_\epsilon - u_0) - \int_\Omega \mathbb{C}_0 \widehat{\nabla} u_0 \cdot \widehat{\nabla}(u_\epsilon - u_0) \\ &= \int_{\partial\Omega} \Big(\Big(\mathbb{C}_\epsilon \widehat{\nabla} u_\epsilon \Big) \cdot \nu - \Big(\mathbb{C}_0 \widehat{\nabla} u_0 \Big) \cdot \nu \Big) \cdot (u_\epsilon - u_0)\, d\sigma = 0, \end{aligned}$$

hence (19) holds.

On the other hand, by the Hölder inequality,

$$\begin{aligned} &\int_{\omega_\epsilon} (\mathbb{C}_0 - \mathbb{C}_1)\, \widehat{\nabla} u_0 \cdot \widehat{\nabla}(u_\epsilon - u_0)\, dx \\ &\leq \max\{2|\mu_0 - \mu_1|, |\lambda_0 - \lambda_1|\}\, \|\nabla u_0\|_{L^\infty(\omega_\epsilon)} |\omega_\epsilon|^{1/2} \|\nabla(u_\epsilon - u_0)\|_{L^2(\Omega)}. \end{aligned} \tag{20}$$

In order to bound $\|\nabla u_0\|_{L^\infty(\omega_\epsilon)}$ note that for small ϵ, say $\epsilon < K/2$, the distance between ω_ϵ and $\partial\Omega$ is bounded from below by $K/2$. Hence, by standard interior regularity estimates for elliptic systems (see [C]),

$$\|\nabla u_0\|_{L^\infty(\omega_\epsilon)} \leq C \|u_0\|_{H^1(\Omega)},$$

where C depends on α_0, β_0, and K.

By the divergence theorem, the trace theorem (see [LM]), and the Poincaré inequality,

$$\|u_0\|_{H^1(\Omega)} \leq C \|g\|_{H^{-1/2}(\partial\Omega)},$$

where C depends only on Ω. Finally,

$$\|\nabla u_0\|_{L^\infty(\omega_\epsilon)} \leq C \|g\|_{H^{-1/2}(\partial\Omega)}, \tag{21}$$

where C depends on Ω, α_0, β_0, and K.

So, by (18), (19), and (20) we obtain

$$\|\nabla(u_\epsilon - u_0)\|_{L^2(\Omega)} \leq C|\omega_\epsilon|^{1/2}\|g\|_{H^{-1/2}(\partial\Omega)},$$

where $C = C(\Omega, \alpha_0, \beta_0, K)$. By assumption (3), we can estimate

$$|\omega_\epsilon| \leq C\epsilon, \tag{22}$$

where C depends only on K. By putting together (21), (22), and the Poincarè inequality (17), we get (16). □

Besides the energy estimates (16), a key ingredient to establish the asymptotic expansion of Theorem 2.1 is a gradient estimate for elliptic systems modeling composite materials that has been established by Li and Nirenberg in [LN]. Here we state and use a simplified version of Proposition 5.1 in [LN].

Let D be the unit square $D = [-1, 1] \times [-1, 1]$, and let $f_0, \ldots, f_{l+1} \in C^2([-1, 1])$ such that

$$-1 = f_0(x_1) < f_1(x_1) < \cdots < f_{l+1}(x_1) = 1 \quad \text{for} \quad x_1 \in [-1, 1].$$

Let

$$D_m = \{x = (x_1, x_2) \in D : f_{m-1}(x_1) < x_2 < f_m(x_1)\} \quad \text{for} \quad 1 \leq m \leq l + 1.$$

We suppose that the origin does not belong to the graphs of the functions f_j, and we denote by m_0 the index for which

$$f_{m_0}(0) < 0 < f_{m_0+1}(0).$$

Let us also set $\frac{1}{2}D = [-\frac{1}{2}, \frac{1}{2}] \times [-\frac{1}{2}, \frac{1}{2}]$.

Let $\mathbb{C}$ be a bounded symmetric Lamé tensor defined in D and such that $\mathbb{C}$ is constant in each D_m with corresponding Lamé coefficients λ_m and μ_m. Then the following estimate holds.

PROPOSITION 3.3. *Let $u \in H^1(D, \mathbb{R}^2)$ be a weak solution to*

$$\operatorname{div}\left(\mathbb{C}\widehat{\nabla}u\right) = 0 \quad \text{in} \quad D.$$

Then, for any $x \in \overline{D}_{m_0} \cap \frac{1}{2}D$,

$$|\nabla u(x) - \nabla u(0)| \leq C\|u\|_{L^2(D)}|x|^\alpha, \tag{23}$$

where $\alpha \in (0, 1/4)$ and C depends on α, l, λ_m, μ_m, and $\|f_m\|_{C^2([-1,1])}$, for $m = 1, \ldots, l + 1$.

For the proof of this result, see [LN, section 5].

4. Proof of Theorem 2.1. We divide the proof into several steps: in the first step we write $(u_\epsilon - u_0)_{|\partial\Omega}$ in terms of an integral over ω_ϵ of the product of $\widehat{\nabla}u_\epsilon^i$ and $\widehat{\nabla}N$.

In the second step, by using the estimate of Proposition 3.3, we reduce this integral to an integral over some part of $\partial\omega_\epsilon$. In the third part, we use the transmission conditions and introduce the tensor $\mathcal{M}$. The fourth part contains the conclusion of the proof.

First step.

We are going to show that, for $y \in \partial\Omega$,

$$(u_\epsilon - u_0)(y) = \int_{\omega_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon \cdot \widehat{\nabla} N(\cdot, y). \tag{24}$$

In order to get (24) we recall that, for $y \in \Omega$, the function $N(\cdot, y)$ satisfies

$$\int_\Omega \mathbb{C}_0 \widehat{\nabla} N(\cdot, y) \cdot \widehat{\nabla} v = -v(y) + \frac{1}{|\partial\Omega|} \int_{\partial\Omega} v \quad \forall v \in H^1(\Omega).$$

By choosing $v = u_\epsilon - u_0$ and using the normalization (7) we get

$$\int_\Omega \mathbb{C}_0 \widehat{\nabla} N(\cdot, y) \cdot \widehat{\nabla}(u_\epsilon - u_0) = -(u_\epsilon - u_0)(y). \tag{25}$$

Observe now that

$$\begin{aligned} \int_\Omega \mathbb{C}_0 \widehat{\nabla} N(\cdot, y) \cdot \widehat{\nabla}(u_\epsilon - u_0) &= \int_{\omega_\epsilon} (\mathbb{C}_0 - \mathbb{C}_1)\, \widehat{\nabla} N(\cdot, y) \cdot \widehat{\nabla} u_\epsilon \\ &+ \int_\Omega \mathbb{C}_\epsilon \widehat{\nabla} N(\cdot, y) \cdot \widehat{\nabla} u_\epsilon - \int_\Omega \mathbb{C}_0 \widehat{\nabla} N(\cdot, y) \cdot \widehat{\nabla} u_0. \end{aligned} \tag{26}$$

Since u_ϵ and u_0 are solutions to (1) and (2), respectively, we have

$$\begin{aligned} \int_\Omega \mathbb{C}_0 \widehat{\nabla} N(\cdot, y) \cdot \widehat{\nabla} u_0 &= \int_{\partial\Omega} g \cdot N(\cdot, y) \\ &= \int_\Omega \mathbb{C}_\epsilon \widehat{\nabla} u_\epsilon \cdot \widehat{\nabla} N(\cdot, y), \end{aligned}$$

hence (26) becomes

$$\int_\Omega \mathbb{C}_0 \widehat{\nabla} N(\cdot, y) \cdot \widehat{\nabla}(u_\epsilon - u_0) = \int_{\omega_\epsilon} (\mathbb{C}_0 - \mathbb{C}_1)\, \widehat{\nabla} N(\cdot, y) \cdot \widehat{\nabla} u_\epsilon,$$

and, by inserting this last relation into (25,) we get (24) for $y \in \Omega$.

Finally, since $u_\epsilon - u_0$ is continuous up to $\partial\Omega$, we get (24) for any $y \in \partial\Omega$.

Second step.

Let β be a constant $0 < \beta < 1$, and set

$$\omega'_\epsilon = \left\{ x + \mu n(x) \,:\, x \in \sigma_0,\, d(x, \partial\sigma_0) > \epsilon^\beta,\, \mu \in (-\epsilon, \epsilon) \right\}.$$

Notice that if σ_0 is a closed simple curve, then $\omega'_\epsilon = \omega_\epsilon$.

Let us write

$$\begin{aligned} \int_{\omega_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon \cdot \widehat{\nabla} N(\cdot, y) &= \int_{\omega'_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon \cdot \widehat{\nabla} N(\cdot, y) \\ &+ \int_{\omega_\epsilon \setminus \omega'_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon \cdot \widehat{\nabla} N(\cdot, y). \end{aligned} \tag{27}$$

Concerning the last term in (27)

$$\begin{aligned} \left| \int_{\omega_\epsilon \setminus \omega'_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon \cdot \widehat{\nabla} N(\cdot, y) \right| &\le \left| \int_{\omega_\epsilon \setminus \omega'_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla}(u_\epsilon - u_0) \cdot \widehat{\nabla} N(\cdot, y) \right| \\ &+ \left| \int_{\omega_\epsilon \setminus \omega'_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_0 \cdot \widehat{\nabla} N(\cdot, y) \right|. \end{aligned} \tag{28}$$

In order to bound the first term on the right-hand side (RHS) of (28) we use the energy estimate (16) and the fact that, for $y \in \partial\Omega$, $\|\nabla N(\cdot, y)\|_{L^\infty(\omega_\epsilon)}$ is bounded uniformly in ϵ. Moreover, since

$$|\omega_\epsilon \setminus \omega'_\epsilon| \leq C\epsilon^{1+\beta},$$

we get

$$\left| \int_{\omega_\epsilon \setminus \omega'_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla}(u_\epsilon - u_0) \cdot \widehat{\nabla} N(\cdot, y) \right| \leq C\epsilon^{1+\beta/2} \|g\|_{H^{-1/2}(\partial\Omega)},$$

where $C = C(\Omega, K, \alpha_0, \beta_0)$.

In the last term on the RHS of (28) we use the regularity estimates for u_0 so that

$$\begin{aligned} \left| \int_{\omega_\epsilon \setminus \omega'_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_0 \cdot \widehat{\nabla} N(\cdot, y) \right| &\leq C \|\nabla u_0\|_{L^\infty(\omega_\epsilon)} \|\nabla N(\cdot, y)\|_{L^\infty(\omega_\epsilon)} \cdot |\omega_\epsilon \setminus \omega'_\epsilon| \\ &\leq C\epsilon^{1+\beta} \|g\|_{H^{-1/2}(\partial\Omega)}, \end{aligned}$$

where $C = C(K, \alpha_0, \beta_0)$ and so (27) becomes, for $\epsilon \to 0$,

$$\int_{\omega_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon \cdot \widehat{\nabla} N(\cdot, y) = \int_{\omega'_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon \cdot \widehat{\nabla} N(\cdot, y) + O(\epsilon^{1+\beta/2}). \tag{29}$$

Now let us denote by σ'_μ, for $\mu \in [-\epsilon, \epsilon]$, the curve

$$\sigma'_\mu = \left\{ x + \mu n(x) \,:\, x \in \sigma_0,\ d(x, \partial\sigma_0) > \epsilon^\beta \right\}.$$

For every point $x + \mu n(x) \in \omega'_\epsilon$ (for $\mu \in (-\epsilon, \epsilon)$), let us consider the point $x + \epsilon n(x) \in \sigma'_\epsilon$ and let us compare $\nabla u_\epsilon(x + \mu n(x))$ with $\nabla u^i_\epsilon(x + \epsilon n(x))$.

More precisely, we will establish that, for $\alpha \in (0, 1/4)$,

$$|\nabla u_\epsilon(x + \mu n(x)) - \nabla u^i_\epsilon(x + \epsilon n(x))| \leq C\epsilon^{-\beta(2+\alpha)} \epsilon^\alpha \|g\|_{H^{-1/2}(\partial\Omega)}, \tag{30}$$

where $C = C(K, \alpha_0, \beta_0, \alpha)$.

Let ϵ be small enough to have

$$2\epsilon < \frac{\epsilon^\beta}{2\sqrt{2}}. \tag{31}$$

We note that the distance between $x + \mu n(x)$ and $x + \epsilon n(x)$ is smaller than 2ϵ and that, in a neighborhood of $x + \mu n(x)$ of radius ϵ^β, the boundary $\partial\omega_\epsilon$ is represented by graphs of smooth functions. In particular, if we set the origin to $x + \mu n(x)$, up to a rotation of the coordinate system (z_1, z_2), we have that there exist two functions g_1 and g_2 such that, for $-\frac{\epsilon^\beta}{\sqrt{2}} < z_1 < \frac{\epsilon^\beta}{\sqrt{2}}$,

$$\mathbb{C}_\epsilon(z_1, z_2) = \begin{cases} \mathbb{C}_0 & \text{if} \quad -\frac{\epsilon^\beta}{\sqrt{2}} < z_2 < g_1(z_1), \\ \mathbb{C}_1 & \text{if} \quad g_1(z_1) < z_2 < g_2(z_1), \\ \mathbb{C}_0 & \text{if} \quad g_2(z_1) < z_2 < \frac{\epsilon^\beta}{\sqrt{2}}. \end{cases}$$

By the a priori assumptions on σ_0 we know that

$$\|g_1\|_{C^2}, \quad \|g_2\|_{C^2} \leq K.$$

Consider now the function

$$v(y) = u_\epsilon\left(\frac{\epsilon^\beta}{\sqrt{2}}y\right),$$

which is defined in $[-1,1]\times[-1,1]$. Notice that v solves

$$\operatorname{div}\left(\tilde{\mathbb{C}}\widehat{\nabla}v\right) = 0 \quad \text{in} \quad (-1,1)\times(-1,1),$$

where

$$\tilde{\mathbb{C}}(y_1,y_2) = \begin{cases} \mathbb{C}_0 & \text{if} \quad -1 < y_2 < f_1(y_1) = \sqrt{2}\epsilon^{-\beta} g_1(\frac{\epsilon^\beta}{\sqrt{2}}y_1), \\ \mathbb{C}_1 & \text{if} \quad f_1(y_1) < y_2 < f_2(y_1) = \sqrt{2}\epsilon^{-\beta} g_2(\frac{\epsilon^\beta}{\sqrt{2}}y_1), \\ \mathbb{C}_0 & \text{if} \quad f_2(y_1) < y_2 < 1. \end{cases}$$

Let us check that we can apply Proposition 3.3, with $l = 2$ and $m_0 = 1$. Since $|g_i(y_1)| < \frac{\epsilon^\beta}{\sqrt{2}}$ and the derivative of g_i is bounded by K for $i = 1,2$, then

$$\|g_i\|_{L^\infty} \le (K+1)\frac{\epsilon^\beta}{\sqrt{2}}, \quad i = 1,2.$$

From this last estimate, and from the C^2 bounds on g_1 and g_2, we get

$$\|f_i\|_{C^2([-1,1])} \le 2K+1 \quad \text{for} \quad i = 1,2.$$

Since we set the origin at the point $x + \mu n(x)$, we have that

$$|x+\epsilon n(x)| = |x+\mu n(x) + (\epsilon-\mu)n(x)| = |(\epsilon-\mu)n(x)| \le 2\epsilon.$$

Hence, if we set $\overline{y} = \sqrt{2}\epsilon^{-\beta}(x+\epsilon n(x))$ we have, by (31),

$$|\overline{y}| = \sqrt{2}\epsilon^{-\beta}|x+\epsilon n(x)| \le \sqrt{2}\epsilon^{-\beta}\cdot 2\epsilon \le \frac{1}{2},$$

and, $\overline{y} \in \overline{D}_{m_0} \cap \frac{1}{2}D$. By Proposition 3.3,

$$|\nabla v(\overline{y}) - \nabla v(0)| \le C\|v\|_{L^2(D)}|\overline{y}|^\alpha,$$

where C depends only on K, α_0, β_0, and $\alpha \in (0,1/4)$. If we read this estimate for the function u_ϵ we get

$$\begin{aligned} \left|\nabla u_\epsilon(x+\mu n(x)) - \nabla u_\epsilon^i(x+\epsilon n(x))\right| &\le C\|u_\epsilon\|_{L^2(\Omega)}\epsilon^{-\beta(2+\alpha)}|(\mu-\epsilon)n(x)|^\alpha \\ &\le C\|u_\epsilon\|_{L^2(\Omega)}\epsilon^{-\beta(2+\alpha)}\epsilon^\alpha. \end{aligned}$$

Since

$$\|u_\epsilon\|_{L^2(\Omega)} \le C\|\nabla u_\epsilon\|_{L^2(\Omega)} \le C\|g\|_{H^{-1/2}(\partial\Omega)}$$

we finally have (30).

Due to (30), we can approximate the values of ∇u_ϵ in ${\omega_\epsilon}'$ with the values on σ_ϵ'.

Let us denote by ${\sigma_0}' = \{x \in \sigma_0 : d(x,\partial\sigma_0) > \epsilon^\beta\}$. Due to the regularity assumption on σ_0,

$$d\sigma_x^\mu = (1+O(\epsilon))d\sigma_x^0,$$

where $d\sigma_x^\mu$ and $d\sigma_x^0$ denote the infinitesimal arclengths on σ'_μ and σ'_0, respectively.

Hence,

$$\begin{aligned}
&\int_{\omega'_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon(x) \cdot \widehat{\nabla} N(x,y)\, dx \\
&= \int_{-\epsilon}^{\epsilon} \int_{\sigma'_\mu} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon(x) \cdot \widehat{\nabla} N(x,y)\, d\sigma_x^\mu\, d\mu \\
&= \int_{-\epsilon}^{\epsilon} \int_{\sigma_0{}'} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon(x+\mu n(x)) \cdot \widehat{\nabla} N(x+\mu n(x), y)\, d\sigma_x^0\, d\mu + O(\epsilon^2) \\
&= \int_{-\epsilon}^{\epsilon} \int_{\sigma'_0} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon(x+\epsilon n(x)) \cdot \widehat{\nabla} N(x+\epsilon n(x), y)\, d\sigma_x^0\, d\mu \\
&\quad + O(\epsilon^{(1-\beta)(1+\alpha)}) \\
&= 2\epsilon \int_{\sigma'_\epsilon} (\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon^i \cdot \widehat{\nabla} N(\cdot, y) + O(\epsilon^{1+\alpha-\beta(2+\alpha)}), \qquad (32)
\end{aligned}$$

for $\beta < \alpha(2+\alpha)^{-1}$.

Third step.

Let us now extend the fields n and τ from σ_0 to ω'_ϵ. For $x \in \sigma'_0$ we set n and τ equal to $n(x)$ and $\tau(x)$ all along the line segment $x + \mu n(x)$, for $\mu \in [-\epsilon, \epsilon]$.

We will show, by using the transmission condition (8), that on σ'_ϵ,

$$(\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon^i = \mathcal{M}_\epsilon \widehat{\nabla} u_\epsilon^e, \qquad (33)$$

where

$$\begin{aligned}
\mathcal{M}_\epsilon \widehat{\nabla} u_\epsilon^e = a \operatorname{div} u_\epsilon^e\, \mathrm{I}_d + b \widehat{\nabla} u_\epsilon^e + c \left(\frac{\partial (u_\epsilon^e \cdot \tau)}{\partial \tau} + \kappa_\epsilon (u_\epsilon^e \cdot n) \right) \tau \otimes \tau \\
+ d \frac{\partial (u_\epsilon^e \cdot n)}{\partial n}\, n \otimes n,
\end{aligned}$$

with a, b, c, and d given by (11), (12), and (13), and κ_ϵ being the curvature of σ'_ϵ.

Let us express the transmission conditions (8) and $(\mathbb{C}_1 - \mathbb{C}_0)\, \widehat{\nabla} u_\epsilon^i$ in the n, τ coordinate system, namely

$$\begin{aligned}
&\frac{\partial (u_\epsilon^i \cdot \tau)}{\partial \tau} + \kappa_\epsilon (u_\epsilon^i \cdot n) = \frac{\partial (u_\epsilon^e \cdot \tau)}{\partial \tau} + \kappa_\epsilon (u_\epsilon^e \cdot n), \\
&\frac{\partial (u_\epsilon^i \cdot n)}{\partial \tau} - \kappa_\epsilon (u_\epsilon^i \cdot \tau) = \frac{\partial (u_\epsilon^e \cdot n)}{\partial \tau} - \kappa_\epsilon (u_\epsilon^e \cdot \tau), \qquad (34) \\
&\lambda_1 \left(\frac{\partial (u_\epsilon^i \cdot \tau)}{\partial \tau} + \kappa_\epsilon (u_\epsilon^i \cdot n) + \frac{\partial (u_\epsilon^i \cdot n)}{\partial n} \right) + 2\mu_1 \frac{\partial (u_\epsilon^i \cdot n)}{\partial n} \\
&\qquad = \lambda_0 \left(\frac{\partial (u_\epsilon^e \cdot \tau)}{\partial \tau} + \kappa_\epsilon (u_\epsilon^e \cdot n) + \frac{\partial (u_\epsilon^e \cdot n)}{\partial n} \right) + 2\mu_0 \frac{\partial (u_\epsilon^e \cdot n)}{\partial n}, \\
&\mu_1 \left(\frac{\partial (u_\epsilon^i \cdot \tau)}{\partial n} - \kappa_\epsilon (u_\epsilon^i \cdot \tau) + \frac{\partial (u_\epsilon^i \cdot n)}{\partial \tau} \right) = \mu_0 \left(\frac{\partial (u_\epsilon^e \cdot \tau)}{\partial n} - \kappa_\epsilon (u_\epsilon^e \cdot \tau) + \frac{\partial (u_\epsilon^e \cdot n)}{\partial \tau} \right),
\end{aligned}$$

and

$$
\begin{aligned}
(\mathbb{C}_1-\mathbb{C}_0)\,\widehat{\nabla}u_\epsilon^i &= (\lambda_1-\lambda_0)\left[\frac{\partial(u_\epsilon^i\cdot\tau)}{\partial\tau}+\frac{\partial(u_\epsilon^i\cdot n)}{\partial n}+\kappa_\epsilon(u_\epsilon^i\cdot n)\right](n\otimes n+\tau\otimes\tau)\\
&\quad+2(\mu_1-\mu_0)\left[\left(\frac{\partial(u_\epsilon^i\cdot\tau)}{\partial\tau}+\kappa_\epsilon(u_\epsilon^i\cdot n)\right)\tau\otimes\tau+\frac{\partial(u_\epsilon^i\cdot n)}{\partial n}\,n\otimes n\right.\\
&\quad\left.+\frac{1}{2}\left(\frac{\partial(u_\epsilon^i\cdot\tau)}{\partial n}+\frac{\partial(u_\epsilon^i\cdot n)}{\partial\tau}-\kappa_\epsilon(u_\epsilon^i\cdot\tau)\right)(\tau\otimes n+n\otimes\tau)\right]. \qquad (35)
\end{aligned}
$$

By solving the system (34) with respect to the derivatives of the components of u_ϵ^i, and inserting the result into (35), we derive (33).

Now, by inserting (33) into (32), we get

$$
\int_{\sigma_\epsilon'}(\mathbb{C}_1-\mathbb{C}_0)\,\widehat{\nabla}u_\epsilon^i\cdot\widehat{\nabla}N(\cdot,y)=2\epsilon\int_{\sigma_\epsilon'}\mathcal{M}_\epsilon\widehat{\nabla}u_\epsilon^e\cdot\widehat{\nabla}N(\cdot,y)+O(\epsilon^{1+\alpha-\beta(2+\alpha)}). \qquad (36)
$$

Fourth step.
We will show that

$$
\|\nabla u_\epsilon^e-\nabla u_0\|_{L^\infty(\sigma_\epsilon')}\le C\epsilon^\gamma\|g\|_{H^{-1/2}(\partial\Omega)} \qquad (37)
$$

for some positive γ.

In order to prove the above inequality, we need the following theorem.

THEOREM 4.1 (mean value property). *Let Ψ be a biharmonic scalar, vector, or tensor field in a open bounded domain D. Then, for any ball $B_\rho(y)\subset\subset D$,*

$$
\Psi(y)=\frac{1}{2\pi}\left[\frac{4}{\rho^2}\int_{B_\rho(y)}\Psi(x)\,dx-\frac{1}{\rho}\int_{\partial B_\rho(y)}\Psi(x)\,d\sigma_x\right]. \qquad (38)
$$

For the proof of Theorem 4.1, see [N].

Since $\nabla u_\epsilon-\nabla u_0$ is biharmonic in $\Omega\setminus\overline{\omega}_\epsilon$ we might use the mean value property (38) for points in the set $\Omega_K\setminus\overline{\omega}_d$, where $\Omega_K=\left\{x\in\Omega\,:\,d(x,\partial\Omega)>\frac{1}{2K}\right\}$ and d is such that $2\epsilon<d$.

Observe that, by (38), for every $y\in\Omega_K\setminus\overline{\omega}_d$ and for $0<\lambda\le\frac{d}{2}$,

$$
\nabla(u_\epsilon-u_0)(y)=\frac{1}{2\pi}\left[\frac{4}{\lambda^2}\int_{B_\lambda(y)}\nabla(u_\epsilon-u_0)-\frac{1}{\lambda}\int_{\partial B_\lambda}\nabla(u_\epsilon-u_0)\right]. \qquad (39)
$$

By using the divergence theorem we can rewrite (39) as follows:

$$
\nabla(u_\epsilon-u_0)(y)=\frac{1}{2\pi}\left[\frac{4}{\lambda^2}\int_{\partial B_\lambda(y)}(u_\epsilon-u_0)\otimes\tilde{\nu}\,d\sigma-\frac{1}{\lambda}\int_{\partial B_\lambda}\nabla(u_\epsilon-u_0)\right],
$$

where $\tilde{\nu}$ is the outward normal vector to ∂B_λ. If we multiply the last relation by λ^3 and integrate from 0 to $\rho=\frac{d}{2}$ we get

$$
\nabla(u_\epsilon-u_0)(y)=\frac{12}{\pi}\left[\frac{4}{d^4}\int_{B_{\frac{d}{2}}(y)}(u_\epsilon-u_0)\otimes\underline{r}\,dx-\frac{1}{d^4}\int_{B_{\frac{d}{2}}(y)}r^2\nabla(u_\epsilon-u_0)\,dx\right], \qquad (40)
$$

where $\underline{r}(x) = x - y$, $r = |\underline{r}|$.

From (40) and (16) we have that

$$\|\nabla(u_\epsilon - u_0)\|_{L^\infty(\Omega_K \setminus \omega_d)} \leq C d^{-2} \epsilon^{\frac{1}{2}}, \tag{41}$$

where $C = C(\Omega, K, \alpha_0, \beta_0)$. Let $x = z + \epsilon n(z)$ be any point on σ'_ϵ and let x_d be the point $x_d = z + dn(z)$. Since the entire line segment from x to x_d lies in $\Omega \setminus \overline{\omega}_\epsilon$ and has distance greater than $\frac{\epsilon^\beta}{2}$ from $\partial\sigma_0$, by Proposition 3.3 and arguing similarly as we did to prove (30), we have

$$|\nabla u^e_\epsilon(x) - \nabla u_\epsilon(x_d)| \leq C \epsilon^{-(2+\alpha)\beta} d^\alpha \|g\|_{H^{-1/2}(\partial\Omega)}, \tag{42}$$

where $C = C(K, \alpha_0, \beta_0)$.

By combining (41) and (42) we have that for any $x \in \sigma'_\epsilon$

$$\begin{aligned} |\nabla u^e_\epsilon(x) - \nabla u_0(x)| &\leq |\nabla u^e_\epsilon(x) - \nabla u_\epsilon(x_d)| \\ &\quad + |\nabla u_\epsilon(x_d) - \nabla u_0(x_d)| + |\nabla u_0(x_d) - \nabla u_0(x)| \\ &\leq C \left(d^\alpha \epsilon^{-(2+\alpha)\beta} + d^{-2} \epsilon^{\frac{1}{2}} + d \right) \|g\|_{H^{-1/2(\partial\Omega)}}. \end{aligned}$$

By choosing

$$d = \epsilon^{\frac{1}{2(\alpha+2)} + \beta}$$

we have (37) with $\gamma = \frac{\alpha}{2(\alpha+2)} - 2\beta$. Notice that $\gamma > 0$ if we choose $\beta < \frac{\alpha}{4(\alpha+2)}$.

By using (37), we have

$$2\epsilon \int_{\sigma'_\epsilon} \mathcal{M}_\epsilon \widehat{\nabla} u^e_\epsilon \cdot \widehat{\nabla} N(\cdot, y) = 2\epsilon \int_{\sigma'_\epsilon} \mathcal{M}_\epsilon \widehat{\nabla} u_0 \cdot \widehat{\nabla} N(\cdot, y) + O(\epsilon^{1+\gamma}).$$

Now, we recall that $d\sigma^\epsilon_x = (1 + O(\epsilon)) d\sigma_0$ and observe that, by assumption (3), $\mathcal{M}_\epsilon = (1 + O(\epsilon))\mathcal{M}$. Hence

$$2\epsilon \int_{\sigma'_\epsilon} \mathcal{M}_\epsilon \widehat{\nabla} u^e_\epsilon \cdot \widehat{\nabla} N(\cdot, y) = 2\epsilon \int_{\sigma_0} \mathcal{M} \widehat{\nabla} u_0 \cdot \widehat{\nabla} N(\cdot, y) + O(\epsilon^{1+\gamma}). \tag{43}$$

Finally, if we compare the remainders in the expansion in formulas (29), (32), (36), and (43), we have that (10) holds, if we choose $\alpha \in (0, 1/4)$ and $\beta \in (0, 1)$ such that $\beta < \frac{\alpha}{4(\alpha+2)}$. ∎

Remark 4.2. The asymptotic expansion also holds in the case where $\sigma_0 = \cup_{i=1}^M \sigma_i$ and $\sigma_1, \ldots, \sigma_M$ are disjoint and far from each other. In that case

$$(u_\epsilon - u_0)(y) = 2\epsilon \sum_{i=1}^M \int_{\sigma_i} \mathcal{M}_i \widehat{\nabla} u_0 \cdot \widehat{\nabla} N(\cdot, y)\, d\sigma_i + o(\epsilon),$$

where $\mathcal{M}_i$ is the restriction to σ_i of the tensor $\mathcal{M}$.

RIGOROUS UPSCALING OF THE REACTIVE FLOW THROUGH A PORE, UNDER DOMINANT PECLET AND DAMKOHLER NUMBERS*

ANDRO MIKELIĆ†, VINCENT DEVIGNE‡, AND C. J. VAN DUIJN§

Abstract. In this paper we present a rigorous derivation of the effective model for enhanced diffusion through a narrow and long 2D pore. The analysis uses a singular perturbation technique. The starting point is a local pore scale model describing the transport by convection and diffusion of a reactive solute. The solute particles undergo a first-order reaction at the pore surface. The transport and reaction parameters are such that we have large, dominant Peclet and Damkohler numbers with respect to the ratio of characteristic transversal and longitudinal lengths (the small parameter ε). We give a rigorous mathematical justification of the effective behavior for small ε. Error estimates are presented in the energy norm as well as in L^∞ and L^1 norms of the space variable. They guarantee the validity of the upscaled model. As a special case, we recover the well-known Taylor dispersion formula.

Key words. Taylor's dispersion, large Peclet number, singular perturbation, surface chemical reaction, large Damkohler number

1. Introduction.

We consider the transport of a reactive solute by diffusion and Poiseuille's convection in a semi-infinite 2D channel. The solute particles do not react among themselves. Instead they undergo a first-order chemical reaction at the wall of the channel. Following [12], we consider the following model for the solute concentration c^*:

(a) transport through channel $\Omega^* = \{(x^*, y^*) : 0 < x^* < +\infty, |y^*| < H\}$:

$$\frac{\partial c^*}{\partial t^*} + q(y^*)\frac{\partial c^*}{\partial x^*} - D^*\frac{\partial^2 c^*}{\partial (x^*)^2} - D^*\frac{\partial^2 c^*}{\partial (y^*)^2} = 0 \quad \text{in } \Omega^*, \tag{1}$$

where $q(z) = Q^*(1 - (z/H)^2)$ and where Q^* (velocity) and D^* (molecular diffusion) are positive constants.

(b) reaction at channel wall $\Gamma^* = \{(x^*, y^*) : 0 < x^* < +\infty, |y^*| = H\}$:

$$D^*\frac{\partial c^*}{\partial y^*} + k^* c^* = 0 \quad \text{on } \Gamma^*, \tag{2}$$

where k^* is the surface reaction coefficient.

§Department of Mathematics and Computer Science, Technische Universiteit Eindhoven, P. O. Box 513, 5600 MB Eindhoven, The Netherlands (c.j.v.duijn@tue.nl).

The natural way of analyzing this problem is to introduce appropriate scales. This requires characteristic or reference values for the parameters and variables involved. The obvious transversal length scale is H. For all other quantities we use reference values denoted by the subscript R. Setting

$$c = \frac{c^*}{\hat{c}_R},\ x = \frac{x^*}{L_R},\ y = \frac{y^*}{H},\ t = \frac{t^*}{T_R},\ Q = \frac{Q^*}{Q_R},\ D = \frac{D^*}{D_R},\ k = \frac{k^*}{k_R}, \tag{3}$$

where L_R is the "observation distance," we obtain the dimensionless equations

$$\frac{\partial c}{\partial t} + \frac{Q_R T_R}{L_R} Q(1-y^2)\frac{\partial c}{\partial x} - \frac{D_R T_R}{L_R^2} D\frac{\partial^2 c}{\partial x^2} - \frac{D_R T_R}{H^2} D\frac{\partial^2 c}{\partial y^2} = 0 \quad \text{in } \Omega \tag{4}$$

and

$$-\frac{D D_R}{H k_R}\frac{\partial c}{\partial y} = kc \quad \text{on } \Gamma, \tag{5}$$

where

$$\Omega = (0,+\infty)\times(-1,1) \quad \text{and} \quad \Gamma = (0,+\infty)\times\{-1,1\}. \tag{6}$$

The equations involve the following time scales:

$$T_L = \text{characteristic longitudinal time scale} = \frac{L_R}{Q_R},$$
$$T_T = \text{characteristic transversal time scale} = \frac{H^2}{D_R},$$
$$T_C = \text{superficial chemical reaction time scale} = \frac{H}{k_R},$$

and the nondimensional numbers

$$\mathbf{Pe} = \frac{L_R Q_R}{D_R} \quad \text{(Peclet number)},$$
$$\mathbf{Da} = \frac{L_R^2 k_R}{H D_R} \quad \text{(Damkohler number)}.$$

In this paper we fix the reference time by setting $T_R = T_L$. We are going to investigate the behavior of (4)–(5) with respect to the small parameter $\varepsilon = \frac{H}{L_R}$. Specifically, we will derive expressions for the effective values of the dispersion coefficient and velocity, and an effective 1D transport equation for small values of ε. To carry out the analysis, we need to compare the dimensionless numbers with respect to ε. For this purpose we set

$$\mathbf{Pe} = \varepsilon^{-\alpha} \quad \text{and} \quad \mathbf{Da} = \varepsilon^{\beta} \quad (\alpha, \beta \text{ to be chosen later}).$$

In the absence of chemical reactions, Taylor obtained in his well-known paper [19] an explicit expression for the enhanced diffusion originating from (1). It is known as Taylor's dispersion formula. We will recover this formula as a special case in our approach by setting $\alpha = 1$, $k = 0$ and by assuming $Q = \mathcal{O}(1)$. Note that

$$\frac{T_T}{T_L} = \frac{H Q_R}{D_R}\varepsilon = \varepsilon^2\ \mathbf{Pe} = \varepsilon \text{ (whenever } \alpha = 1).$$

Introducing the dimensionless numbers in (4)–(5) and considering constant initial/boundary conditions yields the problem

$$\frac{\partial c^\varepsilon}{\partial t} + Q(1-y^2)\frac{\partial c^\varepsilon}{\partial x} = D\varepsilon^\alpha \frac{\partial^2 c^\varepsilon}{\partial x^2} + D\varepsilon^{\alpha-2}\frac{\partial^2 c^\varepsilon}{\partial y^2} \quad \text{in } \Omega^+ \times (0,T), \tag{7}$$

$$-D\varepsilon^{\alpha-2}\frac{\partial c^\varepsilon}{\partial y} = -D\frac{1}{\varepsilon^2 \mathbf{Pe}}\frac{\partial c^\varepsilon}{\partial y} = k\frac{\mathbf{Da}}{\mathbf{Pe}}c^\varepsilon = k\varepsilon^{\alpha+\beta}c^\varepsilon \quad \text{on } \Gamma^+ \times (0,T), \tag{8}$$

$$c^\varepsilon(x,y,0) = 1 \quad \text{for } (x,y) \in \Omega^+, \tag{9}$$

$$c^\varepsilon(0,y,t) = 0 \quad \text{for } (y,t) \in (0,1)\times(0,T), \tag{10}$$

$$\frac{\partial c^\varepsilon}{\partial y}(x,0,t) = 0 \quad \text{for } (x,t) \in (0,+\infty)\times(0,T). \tag{11}$$

The latest condition results from the y-symmetry of the solution. Further

$$\Omega^+ = (0,+\infty)\times(0,1), \quad \Gamma^+ = (0,+\infty)\times\{1\},$$

and T is an arbitrarily chosen positive number.

We study the behavior of this problem as $\varepsilon \searrow 0$, while keeping the coefficients Q, D, and k all $\mathcal{O}(1)$. The most interesting case results when $\alpha+\beta=0$ and $0 \le \alpha < 2$, because then chemistry balances with flow in the limit as $\varepsilon \searrow 0$. Consequently, we shall restrict our attention to this situation.

In this paper we prove that the correct upscaling of (7)–(11) gives the 1D parabolic problem

$$\text{(EFF)} \qquad \begin{cases} \partial_t c + Q\left(\dfrac{2}{3} + \dfrac{4k}{45D}\varepsilon^{2-\alpha}\right)\partial_x c + k\left(1 - \dfrac{k}{3D}\varepsilon^{2-\alpha}\right)c \\ \\ = \left(D\varepsilon^\alpha + \dfrac{8}{945}\dfrac{Q^2}{D}\varepsilon^{2-\alpha}\right)\partial_{xx} c \ \text{ in } \ (0,+\infty)\times(0,T), \\ \\ c|_{x=0} = 0, \ c|_{t=0} = 1, \ \partial_x c \in L^2((0,+\infty)\times(0,T)). \end{cases}$$

We note that for $k=0$ and $\alpha=1$ this is exactly the effective model of Taylor [19].

What is known concerning the derivation of the effective problem (EFF), with or without chemical reactions? Below we give a short overview.

• In the absence of chemical reactions, Aris [1] presented a formal derivation using the method of moments.

• For the probabilistic justification of the Taylor dispersion, in the absence of chemical reactions, we refer to the lecture notes by Caflisch and Rubinstein [4]. This approach does not give an error estimate for the approximation.

• There have been numerous attempts to give a rigorous justification for the approximation in the absence of chemical reactions. The most convincing is the *near rigorous* derivation using the center manifold theory by Mercer and Roberts [13]. In this paper the initial value problem is studied and the Fourier transform with respect to x is applied. The center manifold theory is applied to obtain effective equations at various orders, however, without addressing the fact that one is dealing with an infinite dimensional case.

• Flow with chemistry, as described by (2), is considered by Paine, Carbonell, and Whitaker [15], who use the "single-point" closure schemes of turbulence modeling by Launder to obtain a closed model for the averaged concentration.

These studies do not provide a rigorous mathematical derivation of the Taylor dispersion formula, and in the presence of the chemical reactions it is even not clear how to average the problem.

It should be noted that the real interest is in deriving *dispersion equations* for reactive flows through porous media. If we consider a porous medium comprising a bundle of capillary tubes, then we arrive at our problem. The disadvantage is that a bundle of capillary tubes represents a geometrically oversimplified model of a porous medium. Nevertheless, there is considerable insight to be gained from the analysis of our model problem.

Our technique is strongly motivated by the paper by Rubinstein and Mauri [18], where effective dispersion and convection in porous media is studied using the homogenization approach. Their analysis is based on a hierarchy of time scales. In setting up the dimensionless equations, we followed their approach. To our knowledge, the only rigorous result concerning effective dispersion in porous media in the presence of high Peclet numbers (no chemistry) and with the characteristic transport time scale is given in the recent paper by Bourgeat, Jurak, and Piatnitski [3]. Their approach uses regular solutions with compatible data for the underlying linear transport equation. They assume a high order compatibility between the initial and boundary data, involving derivatives up to order five. They construct a smooth solution of the linear transport equation, add the appropriate boundary layer and initial layer, and add the correction due to the perturbation of the mean flow. The effective solution obtained in this way is an H^1-approximation of order ε and an L^2-approximation of order ε^2. However, in problems involving chemistry, one often encounters a jump between the initial value of the concentration and its value imposed at the injection boundary $x = 0$. This is also the case in the experiment described by Taylor [19].

Averaging the concentration in a tube with dissolution/precipitation occurring on the wall and with $\mathbf{Pe} = \mathcal{O}(1)$ is considered in [5].

For bounds on convection enhanced diffusion in porous media we refer to the work of Fannjiang, Papanicolaou, Zhikov, Kozlov, and Piatnitski. We do not give specific references because there is such an enormous number of papers on the subject. A detailed review of known results on the derivation of the effective equations of motion for the mean concentration, in the case of general heterogeneous media and transport velocities, is given in [11]. There one finds the rigorous homogenization theory for the spatio-temporal periodic velocity fields. However, in [11], the reference time is set to be the characteristic diffusion time, contrary to the choice made in [3] and the choice we have made. The case with chemical reactions, but in the absence of the transport, is considered in [2].

We note that our results also cover the case when the physical parameters result in large Peclet and small Damkohler numbers. This follows by setting $k = 0$, yielding Taylor's effective equation. In fact the effective equation (20) remains valid; only the effective terms representing the surface reaction are smaller and less important.

The plan of the paper is the following. In section 2 we study the homogenized problem. It turns out that it has an explicit solution having the form of a moving Gaussian, just as the 1D boundary layers of parabolic equations, when viscosity goes to zero (see [9]). Its behavior with respect to ε and t is singular.

In section 3 we give a justification of a lower order approximation, using a simple energy argument. In fact this approximation does not use Taylor's dispersion formula and gives an error of the same order in $L^\infty(L^2)$ as the solution to the linear transport equation.

In section 4 we give a formal derivation of the upscaled problem (EFF), using the approach proposed in [18].

The construction of the spatial boundary layer that takes care of the injection boundary is carried out in section 5.

Then in sections 6 and 7 we prove that the effective concentration satisfying the corresponding 1D parabolic problem, with Taylor's diffusion coefficient and the reactive correction, is an approximation in $L^\infty(L^2)$ and in $L^\infty(L^\infty)$ to the actual physical concentration.

To satisfy the curiosity of the reader not familiar with singular perturbation techniques, we give here the simplified version of the results stated in Theorems 5–7 from section 7. For simplicity, we compare only the physical concentration c^ε with c. Keeping the correction terms is necessary to have the same precision as stated in the theorems. Throughout the paper $H(x)$ denotes Heaviside's function

$$H(x) = 1,\ x > 0, \quad H(x) = 0,\ x \le 0. \tag{12}$$

Furthermore, using elementary parabolic theory one concludes that problem (7)–(11) has a unique bounded variational solution c^ε, with square integrable derivatives in x and y. Furthermore, c^ε belongs to C^∞ for $x > 0$ and stabilizes to 1 exponentially fast when $x \to \infty$.

THEOREM 1. *Let c be the unique solution of (EFF) and let $\Omega_K = (0, K) \times (0, 1)$, $K > 0$. Then we have*

$$\|t^3(c^\varepsilon - c)\|_{L^\infty(0,T;L^1(\Omega_K))} \le C\varepsilon^{2-\alpha}, \tag{13}$$

$$\|t^3(c^\varepsilon - c)\|_{L^\infty(0,T;L^2(\Omega_K))} \le C\big(\varepsilon^{2-5\alpha/4}H(1-\alpha) + \varepsilon^{3/2-3\alpha/4}H(\alpha-1)\big), \tag{14}$$

$$\|t^3\partial_y c^\varepsilon\|_{L^2(\Omega_K\times(0,T))} \le C\big(\varepsilon^{2-5\alpha/4}H(1-\alpha) + \varepsilon^{3/2-3\alpha/4}H(\alpha-1)\big), \tag{15}$$

$$\|t^3\partial_x(c^\varepsilon - c)\|_{L^2(\Omega_K\times(0,T))} \le C\big(\varepsilon^{2-7\alpha/4}H(1-\alpha) + \varepsilon^{3/2-5\alpha/4}H(\alpha-1)\big). \tag{16}$$

Note that c has disappeared in estimate (15) since it is only x and t dependent. This estimate is superior to estimate (16) because of the large $\mathcal{O}(\varepsilon^{\alpha-2})$ transversal diffusivity.

THEOREM 2. *Let c be the unique solution of (EFF). Then there exists a linear combination $\mathcal{C}_{cor}(x, y, t, \varepsilon)$ of products between polynomials in y and derivatives of c up to order 3, such that*

$$\|t^3(c^\varepsilon - c - \mathcal{C}_{cor})\|_{L^\infty((0,T)\times\Omega^+)} \le \begin{cases} C\varepsilon^{4-7\alpha/2-\delta} & \forall\delta > 0 \quad \text{if } \alpha < 1, \\ C\varepsilon^{3/2-\alpha-\delta} & \text{if } \alpha \ge 1. \end{cases} \tag{17}$$

COROLLARY 1. *Let $\alpha = 1$ and $k = 0$, as in Taylor's case. Then we have*

$$\|t^3(c^\varepsilon - c - \mathcal{C}_{cor})\|_{L^\infty((0,T)\times\Omega^+)} \le C\varepsilon^{1/2-\delta} \quad \forall\delta > 0, \tag{18}$$

$$\|t^3(c^\varepsilon - c)\|_{L^\infty(0,T;L^1(\Omega_K))} \le C\varepsilon. \tag{19}$$

The expression $\mathcal{C}_{cor}(x, y, t, \varepsilon)$ is given explicitly in Theorem 7 of section 7.

Our result could be stated in dimensional form as follows.

THEOREM 3. *Let us suppose that* $L_R > \max\{D_R/Q_R, Q_R H^2/D_R, H\}$. *Then the upscaled dimensional approximation to* (1), (2) *reads*

$$\frac{\partial c^{*,eff}}{\partial t^*} + \left(\frac{2}{3} + \frac{4}{45}\mathbf{Da}_T\right) Q^* \frac{\partial c^{*,eff}}{\partial x^*} + \frac{k^*}{H}\left(1 - \frac{1}{3}\mathbf{Da}_T\right) c^{*,eff} = D^*\left(1 + \frac{8}{945}\mathbf{Pe}_T^2\right)\frac{\partial^2 c^{*,eff}}{\partial (x^*)^2}, \tag{20}$$

where $\mathbf{Pe}_T = \frac{Q^* H}{D^*}$ *is the transversal Peclet number and* $\mathbf{Da}_T = \frac{k^* H}{D^*}$ *is the transversal Damkohler number.*

We conclude this section by noting that in the known literature on boundary layers for parabolic regularization, the transport velocity is assumed to be zero at the injection boundary (see [7]). Hence our result extends the existing framework.

One could try to get even higher order approximations. Unfortunately, our procedure then leads to higher order differential operators and it is not clear if they are easy to handle. In the absence of the boundaries, higher order terms were determined in [13] using the program REDUCE.

2. Study of the upscaled diffusion-convection equation on the half-line. For $\bar{Q}, \bar{D}, \varepsilon > 0$ and $\bar{k} \geq 0$, we consider the problem

$$\begin{cases} \partial_t u + \bar{Q}\partial_x u + \bar{k}u = \gamma \bar{D}\partial_{xx} u \ \text{ in } \ (0,+\infty)\times(0,T), \\ \partial_x u \in L^2((0,+\infty)\times(0,T)), \\ u(x,0) = 1 \ \text{ in } \ (0,+\infty), \quad u(0,t) = 0 \ \text{ at } \ x = 0. \end{cases} \tag{21}$$

The unique solution is given by the explicit formula

$$u(x,t) = e^{-\bar{k}t}\left(1 - \frac{1}{\sqrt{\pi}}\left[e^{\frac{\bar{Q}x}{\gamma \bar{D}}}\int_{\frac{x+t\bar{Q}}{2\sqrt{\gamma \bar{D}t}}}^{+\infty} e^{-\eta^2}\, d\eta + \int_{\frac{x-t\bar{Q}}{2\sqrt{\gamma \bar{D}t}}}^{+\infty} e^{-\eta^2}\, d\eta\right]\right). \tag{22}$$

This expression allows us to find the exact behavior of u with respect to γ. Note that for $\alpha \in [0,1]$, we will set $\gamma = \varepsilon^\alpha$; for $\alpha \in [1,2)$, we choose $\gamma = \varepsilon^{2-\alpha}$. The derivatives of u are found using Maple, and then their norms are estimated. Since the procedure is standard, we do not give the details. In more general situations, there are no explicit solutions and these estimates could be obtained using the technique and results from [9].

By the maximum principle we have

$$0 \leq u(x,t) \leq 1. \tag{23}$$

We first estimate the difference between $\chi_{\{x>\bar{Q}t\}}$ and u.

LEMMA 1. *Function* u *satisfies the estimates*

$$\int_0^\infty |e^{-\bar{k}t}\chi_{\{x>\bar{Q}t\}} - u(t,x)|\, dx = 3\sqrt{\gamma \bar{D}t}e^{-\bar{k}t} + C\gamma, \tag{24}$$

$$\|e^{-\bar{k}t}\chi_{\{x>\bar{Q}t\}} - u\|_{L^\infty(0,T;L^p((0,+\infty)))} \leq C\gamma^{1/(2p)} \quad \forall p \in (1,+\infty). \tag{25}$$

For the derivatives of u we have the following.

LEMMA 2. *Let ζ be defined by*

$$\zeta(t) = \begin{cases} \left(\dfrac{t}{\bar{D}\gamma}\right)^r & \text{for } 0 \le t \le \bar{D}\gamma, \\ 1 & \text{otherwise}, \end{cases} \tag{26}$$

with $r \ge q \ge 1$. Then

$$\|\zeta(t)(|\partial_t u| + |\partial_x u|)\|_{L^q((0,T)\times(0,+\infty))} \le C(\gamma\bar{D})^{\min\{1/(2q)-1/2,2/q-1\}},\ q \ne 3, \tag{27}$$

$$\|\zeta(t)(|\partial_t u| + |\partial_x u|)\|_{L^3((0,T)\times(0,+\infty))} \le C\left((\gamma\bar{D})^{-1}\log\left(\frac{1}{\gamma\bar{D}}\right)\right)^{1/3}. \tag{28}$$

Next we estimate the second-order derivatives.

LEMMA 3. *Let ζ be defined by* (26). *Then*

$$\begin{aligned} &\|\zeta(t)u_{tt}\|_{L^q((0,T)\times(0,+\infty))} + \|\zeta(t)u_{tx}\|_{L^q((0,T)\times(0,+\infty))} + \|\zeta(t)u_{xx}\|_{L^q((0,T)\times(0,+\infty))} \\ &\qquad \le C_q(\gamma\bar{D})^{\min\{1/(2q)-1,2/q-2\}},\ q \ne 3/2, \end{aligned} \tag{29}$$

$$\begin{aligned} &\|\zeta(t)u_{tt}\|_{L^{3/2}((0,T)\times(0,+\infty))} + \|\zeta(t)u_{tx}\|_{L^{3/2}((0,T)\times(0,+\infty))} + \|\zeta(t)u_{xx}\|_{L^{3/2}((0,T)\times(0,+\infty))} \\ &\qquad \le C\left((\gamma\bar{D})^{-1}\log\left(\frac{1}{\gamma\bar{D}}\right)\right)^{2/3}. \end{aligned} \tag{30}$$

For the third-order derivatives we have the following.

LEMMA 4. *Let ζ be defined by* (26). *Then*

$$\begin{aligned} &\|\partial_{xxx}(\zeta(t)u)\|_{L^q((0,T)\times(0,+\infty))} + \|\zeta(t)\partial_{xxt}u\|_{L^q((0,T)\times(0,+\infty))} \\ &\quad + \|\zeta(t)\partial_{xtt}u\|_{L^q((0,T)\times(0,+\infty))} \le C_q(\gamma\bar{D})^{2/q-3},\ q > 1, \end{aligned} \tag{31}$$

$$\begin{aligned} &\|\partial_{xxx}(\zeta(t)u)\|_{L^1((0,T)\times(0,+\infty))} + \|\zeta(t)\partial_{xxt}u\|_{L^1((0,T)\times(0,+\infty))} \\ &\quad + \|\zeta(t)\partial_{xtt}u\|_{L^1((0,T)\times(0,+\infty))} \le C_1(\gamma\bar{D})^{-1}\log\frac{1}{\gamma\bar{D}}. \end{aligned} \tag{32}$$

3. A simple L^2 error estimate. The simplest way to average problem (7)–(11) is to take the mean value with respect to y. Assuming that the mean of the product is the product of the means, which is in general wrong, we get the following problem for the "averaged" concentration $c_0^{eff}(x,t)$:

$$\begin{cases} \dfrac{\partial c_0^{eff}}{\partial t} + \dfrac{2Q}{3}\dfrac{\partial c_0^{eff}}{\partial x} + kc_0^{eff} = \varepsilon^\alpha D\dfrac{\partial c_0^{eff}}{\partial x^2} \ \text{ in } \ (0,+\infty)\times(0,T), \\ \partial_x c_0^{eff} \in L^2((0,+\infty)\times(0,T)), \quad c_0^{eff}|_{t=0} = 1, \quad c_0^{eff}|_{x=0} = 0. \end{cases} \tag{33}$$

This is problem (21) with $\tilde{Q} = \frac{2}{3}Q$, $\bar{k} = k$, and $\bar{D} = D$. The small parameter γ is equal to ε^α. For convenience we introduce the operator

$$\mathcal{L}^\varepsilon(w) := \frac{\partial w}{\partial t} + Q(1-y^2)\frac{\partial w}{\partial x} - D\varepsilon^\alpha\left(\frac{\partial^2 w}{\partial x^2} + \varepsilon^{-2}\frac{\partial^2 w}{\partial y^2}\right). \tag{34}$$

(7)–(11) are written as

$$\mathcal{L}^\varepsilon(c^\varepsilon) = 0 \quad \text{in } \Omega^+ \times (0,T), \tag{35}$$

$$c^\varepsilon(0,y,t) = 0 \quad \text{on } (0,1)\times(0,T), \tag{36}$$

$$\partial_y c^\varepsilon(x,0,t) = 0 \quad \text{on } (0,+\infty)\times(0,T), \tag{37}$$

$$-D\varepsilon^{\alpha-2}\partial_y c^\varepsilon(x,1,t) = kc^\varepsilon(x,1,t) \quad \text{on } (0,+\infty)\times(0,T), \tag{38}$$

$$c^\varepsilon(x,y,0) = 1 \quad \text{on } (0,+\infty)\times(0,1). \tag{39}$$

We want to approximate c^ε by c_0^{eff}. For this purpose we write

$$\mathcal{L}^\varepsilon(c_0^{eff}) = -kc_0^{eff} + Q\partial_x c_0^{eff}(1/3 - y^2) = R^\varepsilon,$$

$$\mathcal{L}^\varepsilon(c^\varepsilon - c_0^{eff}) = -R^\varepsilon \text{ in } \Omega^+\times(0,T), \quad \text{and} \tag{40}$$

$$-D\varepsilon^{\alpha-2}\partial_y(c^\varepsilon(x,1,t) - c_0^{eff}) = kc^\varepsilon(x,1,t) \quad \text{on } (0,+\infty)\times(0,T), \tag{41}$$

and we have the following useful estimate.

PROPOSITION 1. *Let $\Psi(x) = 1/(x+1)$ and let g^ε, ξ_0^ε, and R^ε be measurable functions satisfying*

$$\Psi g^\varepsilon \in H^1(\Omega^+\times(0,T)),\ \Psi\xi_0^\varepsilon \in L^2(\Omega^+),\ \text{and}\ \Psi R^\varepsilon \in L^2(\Omega^+\times(0,T)). \tag{42}$$

Furthermore, let $\xi \in L^\infty(\Omega^+\times(0,T))$, $\Psi\xi \in C([0,T];L^2(\Omega^+))$, $\Psi\nabla_{x,y}\xi \in L^2(\Omega^+\times(0,T))^2$ be a solution of the initial/boundary problem

$$\mathcal{L}^\varepsilon(\xi) = -R^\varepsilon \ \text{in}\ \Omega^+\times(0,T);\quad \partial_y\xi|_{y=0} = 0 \ \text{on}\ (0,+\infty)\times(0,T), \tag{43}$$

$$-D\varepsilon^{\alpha-2}\partial_y\xi|_{y=1} = k\xi|_{y=1} + g^\varepsilon|_{y=1} \quad \text{on}\ (0,+\infty)\times(0,T), \tag{44}$$

$$\xi|_{t=0} = \xi_0^\varepsilon \ \text{on}\ \Omega^+ \quad \text{and} \quad \xi|_{x=0} = 0 \ \text{on}\ (0,1)\times(0,T). \tag{45}$$

Then we have the energy estimate

$$\begin{aligned}\mathcal{E}(\xi,t) &= \frac{1}{2}\int_{\Omega^+}\Psi(x)^2\xi^2(t)\,dxdy + \frac{D}{2}\varepsilon^\alpha\int_0^t\int_{\Omega^+}\Psi(x)^2\\ &\times\left\{\varepsilon^{-2}|\partial_y\xi|^2 + |\partial_x\xi|^2\right\}dxdyd\tau + k\int_0^t\int_0^{+\infty}\xi^2|_{y=1}\Psi^2(x)\,dxd\tau\\ &\le -\int_0^t\int_{\Omega^+}\Psi(x)^2R^\varepsilon\xi\,dxdyd\tau - \int_0^t\int_0^{+\infty}g^\varepsilon|_{y=1}\xi|_{y=1}\Psi^2(x)\,dxd\tau\\ &+ 2D\varepsilon^\alpha\int_0^t\int_{\Omega^+}\Psi(x)^2\xi^2\,dxdyd\tau + \frac{1}{2}\int_{\Omega^+}\Psi(x)^2(\xi_0^\varepsilon)^2\,dxdy.\end{aligned} \tag{46}$$

Proof. We test (43)–(45) by $\Psi^2(x)\xi$ to obtain

$$\begin{aligned}&\frac{1}{2}\int_{\Omega^+}\xi^2(t)\Psi^2(x)\,dxdy + D\varepsilon^\alpha\int_0^t\int_{\Omega^+}\Psi^2(x)\left\{\varepsilon^{-2}|\partial_y\xi|^2 + |\partial_x\xi|^2\right\}dxdyd\tau\\ &\qquad + k\int_0^t\int_0^{+\infty}\xi^2|_{y=1}\Psi^2\,dxd\tau \le \frac{1}{2}\int_{\Omega^+}(\xi_0^\varepsilon)^2\Psi^2(x)\,dxdy\\ &\qquad - k\int_0^t\int_0^{+\infty}(g^\varepsilon\xi)|_{y=1}\Psi^2\,dxd\tau - D\varepsilon^\alpha\int_0^t\int_{\Omega^+}\partial_x\xi\xi\partial_x\Psi^2(x)\,dxdyd\tau.\end{aligned} \tag{47}$$

Next we use

$$D\varepsilon^\alpha \int_0^t \int_{\Omega^+} \partial_x \xi \xi \partial_x \Psi^2(x)\, dxd\tau \le \frac{D}{2}\varepsilon^\alpha \int_0^t \int_{\Omega^+} \Psi^2(x)|\partial_x \xi|^2\, dxdyd\tau$$
$$+ 2D\varepsilon^\alpha \int_0^t \int_{\Omega^+} \Psi^2(x)|\xi|^2\, dxdyd\tau, \tag{48}$$

giving directly (46). □

This simple result allows us to prove the following.

PROPOSITION 2. *There exist positive constants C_i^F, $i = 1, 2, 3$, such that*

$$\|\Psi(x)(c^\varepsilon - c_0^{eff})\|_{L^\infty(0,T;L^2(\Omega^+))} \le \varepsilon^{1-\alpha/2}\frac{F^0}{\sqrt{D}}, \tag{49}$$

$$\|\Psi(x)\partial_x(c^\varepsilon - c_0^{eff})\|_{L^2(0,T;L^2(\Omega^+))} \le \varepsilon^{1-\alpha}\frac{F^0}{D}, \tag{50}$$

$$\|\Psi(x)\partial_y(c^\varepsilon - c_0^{eff})\|_{L^2(0,T;L^2(\Omega^+))} \le \varepsilon^{2-\alpha}\frac{F^0}{D}, \tag{51}$$

where

$$F^0 = C_1^F \|\partial_x c_0^{eff}\|_{L^2((0,+\infty)\times(0,T))} + C_2^F k \le C_3^F \varepsilon^{-\alpha/4}. \tag{52}$$

Proof. We are in the situation of Proposition 1 with $\xi_0^\varepsilon = 0$ and $g^\varepsilon = kc_0^{eff}$. Consequently, for $\xi = c^\varepsilon - c_0^{eff}$ we have

$$\mathcal{E}(\xi, t) \le k\int_0^t \int_0^{+\infty} c_0^{eff}\left(\int_0^1 c^\varepsilon\, dy - c^\varepsilon|_{y=1}\right)\Psi^2\, dxd\tau + 2D\varepsilon^\alpha$$
$$\cdot \int_0^t \int_{\Omega^+} |\xi|^2\Psi^2(x)\, dxdyd\tau - \int_0^t \int_{\Omega^+} Q\left(\frac{1}{3} - y^2\right)\xi\partial_x c_0^{eff}\Psi^2\, dxdyd\tau. \tag{53}$$

It remains to estimate the first and third terms on the right. We have

$$\left|\int_0^t \int_{\Omega^+} Q\partial_x c_0^{eff}\left(\frac{1}{3} - y^2\right)\xi\Psi^2(x)\, dxdyd\tau\right|$$
$$= \left|\int_0^t \int_{\Omega^+} Q\partial_x c_0^{eff}\left(\frac{y}{3} - \frac{y^3}{3}\right)\partial_y\xi\Psi^2(x)\, dxdyd\tau\right| \tag{54}$$

and

$$k\left|\int_0^t \int_0^{+\infty} c_0^{eff}\left(\int_0^1 \xi\, dy - \xi|_{y=1}\right)\Psi^2\, dxd\tau\right|$$
$$\le \frac{D}{8}\varepsilon^\alpha \int_0^t \int_{\Omega^+} \Psi^2(x)|\partial_y\xi|^2\, dxdyd\tau + \frac{k^2}{D}\varepsilon^{2-\alpha}\int_0^t \int_0^{+\infty} (c_0^{eff})^2\Psi^2\, dxd\tau. \tag{55}$$

Inserting (54)–(55) into (53) gives

$$\mathcal{E}(c^\varepsilon - c_0^{eff}, t) \le \varepsilon^{2-\alpha}\int_0^t \int_0^{+\infty}\left\{\frac{2k^2}{D}(c_0^{eff})^2 + \frac{32}{315}\frac{Q^2}{D}(\partial_x c_0^{eff})^2\right\}\Psi^2\, dxd\tau$$
$$+ \int_0^t \int_0^1 \int_0^{+\infty} 2D\varepsilon^\alpha\Psi^2(x)(c^\varepsilon - c_0^{eff})^2\, dxdyd\tau, \tag{56}$$

and applying Gronwall's inequality results in (49)–(51). ∎

COROLLARY 2. *Let* $\Omega_K = (0,K)\times(0,1)$, $K>0$. *Then we have*

$$\|c^\varepsilon - c_0^{eff}\|_{L^\infty(0,T;L^2(\Omega_K))} \le C\varepsilon^{1-3\alpha/4}. \tag{57}$$

Remark 1. It is reasonable to expect L^1 estimates with better powers for ε. Unfortunately, testing (40) by the regularized sign $(c^\varepsilon - c_0^{eff})$ does not lead to a useful result. Hence at this stage claiming a $\sqrt{\varepsilon}$ estimate in L^1 is not justified.

Remark 2. There are results by Grenier [7] and Grenier and Guès [8] on singular perturbation problems. In [7] Grenier supposes that q is smooth and zero at $x=0$, together with its derivatives. Such hypotheses allow better estimates.

Remark 3. For $\alpha = 1$, the estimates (24) and (57) imply that the functions $\exp\{-kt\}\chi_{\{x>Qt\}}$ and c_0^{eff} approximate c^ε in $L^\infty(L^2)$ with the same order given by $C\varepsilon^{1/4}$.

Remark 4. Estimate (57) is not useful when $\alpha > 4/3$.

4. The formal 2-scale expansion leading to Taylor's dispersion. The estimate obtained in the previous section is not satisfactory. However, it is known that the Taylor dispersion model gives a very good 1D approximation. This motivates us to derive higher precision approximations. We give a formal 2-scale asymptotic expansion to obtain Taylor's (including the chemistry) dispersion formula.

We start with the problem (35)–(39) and search for c^ε in the form

$$c^\varepsilon = c^0(x,t;\varepsilon) + \varepsilon c^1(x,y,t) + \varepsilon^2 c^2(x,y,t) + \cdots. \tag{58}$$

After introducing (58) into (35) we get

$$\begin{aligned} &\varepsilon^0\Big\{\partial_t c^0 + Q(1-y^2)\partial_x c^0 - D\varepsilon^{\alpha-1}\partial_{yy}c^1\Big\} \\ &+\varepsilon\Big\{\partial_t c^1 + Q(1-y^2)\partial_x c^1 - D\varepsilon^{\alpha-1}\partial_{xx}c^0 - D\varepsilon^{\alpha-1}\partial_{yy}c^2\Big\} = \mathcal{O}(\varepsilon^2). \end{aligned} \tag{59}$$

To satisfy (59) for every $\varepsilon\in(0,\varepsilon_0)$, all coefficients in front of the powers of ε should be zero.

The problem corresponding to the ε^0 is

$$\begin{cases} -D\partial_{yy}c^1 = -\varepsilon^{1-\alpha}Q\left(\frac{1}{3}-y^2\right)\partial_x c^0 - \varepsilon^{1-\alpha}\left(\partial_t c^0 + 2Q\partial_x c^0/3\right) \ \text{ on } \ (0,1), \\ \partial_y c^1 = 0 \ \text{ on } \ y=0 \ \text{ and } \ -D\partial_y c^1 = k\varepsilon^{1-\alpha}c^0 \ \text{ on } \ y=1 \end{cases} \tag{60}$$

for every $(x,t)\in(0,+\infty)\times(0,T)$. By Fredholm's alternative, this problem has a solution if and only if

$$\partial_t c^0 + \frac{2Q\partial_x c^0}{3} + kc^0 = 0 \quad \text{in } \ (0,L)\times(0,T). \tag{61}$$

Unfortunately our initial and boundary data are incompatible, and therefore the solution to this hyperbolic equation is discontinuous. Since the asymptotic expansion for c^ε involves derivatives of c^0, (61) does not suit our needs. In [3] this difficulty was overcome by assuming compatible initial and boundary data. We proceed by following an idea from [18] and suppose that

$$\partial_t c^0 + \frac{2Q\partial_x c^0}{3} + kc^0 = \mathcal{O}(\varepsilon) \quad \text{in } \ (0,+\infty)\times(0,T). \tag{62}$$

This hypothesis will be justified a posteriori, after getting an equation for c^0.

Combining (60) and (61) and using hypothesis (62) leads us to consider

$$\left\{\begin{array}{l} -D\partial_{yy}c^1 = -\varepsilon^{1-\alpha}Q\left(\frac{1}{3}-y^2\right)\partial_x c^0 + \varepsilon^{1-\alpha}kc^0 \ \text{ on } \ (0,1), \\ \partial_y c^1 = 0 \ \text{ on } \ y=0 \ \text{ and } \ -D\partial_y c^1 = k\varepsilon^{1-\alpha}c^0 \ \text{ on } \ y=1 \end{array}\right. \tag{63}$$

for every $(x,t)\in(0,+\infty)\times(0,T)$. Consequently

$$c^1(x,y,t) = \varepsilon^{1-\alpha}\left(\frac{Q}{D}\left(\frac{y^2}{6}-\frac{y^4}{12}\right)\partial_x c^0 + \frac{k}{D}\left(\frac{1}{6}-\frac{y^2}{2}\right)c^0 + C_0(x,t)\right), \tag{64}$$

where C_0 is an arbitrary function.

The problem corresponding to ε^1 is

$$\left\{\begin{array}{l} -D\partial_{yy}c^2 = D\varepsilon\partial_{xx}c^1 - \varepsilon^{1-\alpha}Q(1-y^2)\partial_x c^1 + D\partial_{xx}c^0 - \varepsilon^{1-\alpha}\partial_t c^1 \\ -\varepsilon^{-\alpha}\left(\partial_t c^0 + \frac{2Q\partial_x c^0}{3} + kc^0\right) \quad \text{on } \ (0,1), \\ \partial_y c^2 = 0 \ \text{ on } \ y=0 \ \text{ and } \ -D\partial_y c^2 = k\varepsilon^{1-\alpha}c^1 \ \text{ on } \ y=1 \end{array}\right. \tag{65}$$

for every $(x,t)\in(0,+\infty)\times(0,T)$. This problem has a solution if and only if

$$\begin{aligned} &\partial_t c^0 + \frac{2Q\partial_x c^0}{3} + k(c^0+\varepsilon c^1|_{y=1}) + \varepsilon\partial_t\left(\int_0^1 c^1\ dy\right) - \varepsilon^\alpha D\partial_{xx}c^0 \\ &+ Q\varepsilon\partial_x\left(\int_0^1(1-y^2)c^1\ dy\right) - D\varepsilon^{1+\alpha}\partial_{xx}\left(\int_0^1 c^1 dy\right) = 0 \quad \text{in } \ (0,+\infty)\times(0,T). \end{aligned} \tag{66}$$

Note that this is the equation for c^0. In order to get the simplest possible equation we choose C_0 such that $\int_0^1 c^1\ dy = 0$. This implies

$$c^1(x,y,t) = \varepsilon^{1-\alpha}\left(\frac{Q}{D}\left(\frac{y^2}{6}-\frac{y^4}{12}-\frac{7}{180}\right)\partial_x c^0 + \frac{k}{D}\left(\frac{1}{6}-\frac{y^2}{2}\right)c^0\right), \tag{67}$$

and (66) becomes

$$\partial_t c^0 + Q\left(\frac{2}{3}+\frac{4k}{45D}\varepsilon^{2-\alpha}\right)\partial_x c^0 + k\left(1-\frac{k}{3D}\varepsilon^{2-\alpha}\right)c^0 = \varepsilon^\alpha\tilde{D}\partial_{xx}c^0 \quad \text{in } \ (0,+\infty)\times(0,T), \tag{68}$$

with

$$\tilde{D} = D + \frac{8}{945}\frac{Q^2}{D}\varepsilon^{2(1-\alpha)}. \tag{69}$$

As a result, problem (65) transforms into

$$\left\{\begin{array}{l} -D\partial_{yy}c^2 = \varepsilon^{2-2\alpha}\left\{-\frac{Q^2}{D}\partial_{xx}c^0\left\{\frac{8}{945}+(1-y^2)\left(\frac{y^2}{6}-\frac{y^4}{12}-\frac{7}{180}\right)\right\}\right. \\ +\partial_x c^0\frac{Qk}{D}\left\{\frac{2}{45}-(1-y^2)\left(\frac{1}{6}-\frac{y^2}{2}\right)\right\} + \frac{2kQ}{45D}\partial_x c^0 \\ -\frac{k^2}{3D}c^0 - \left(\frac{y^2}{6}-\frac{y^4}{12}-\frac{7}{180}\right)\left(\partial_{xt}c^0\frac{Q}{D} - \varepsilon^\alpha Q\partial_{xxx}c^0\right) \\ \left.-\left(\frac{1}{6}-\frac{y^2}{2}\right)\left(\partial_t c^0\frac{k}{D} - \varepsilon^\alpha k\partial_{xx}c^0\right)\right\} \ \text{ on } \ (0,1), \quad \partial_y c^2 = 0 \ \text{ on } \ y=0, \\ \text{and } \ -D\partial_y c^2 = \frac{Qk}{D}\varepsilon^{2-2\alpha}\partial_x c^0\frac{2}{45} - \frac{k^2}{3D}\varepsilon^{2-2\alpha}c^0 \ \text{ on } \ y=1. \end{array}\right. \tag{70}$$

If we choose c^2 such that $\int_0^1 c^2\ dy = 0$, then

$$
\begin{aligned}
c^2(x,y,t) = \varepsilon^{2-2\alpha}\Bigg\{ & -\frac{Q^2}{D^2}\partial_{xx}c^0\left(\frac{281}{453600} + \frac{23}{1512}y^2 - \frac{37}{2160}y^4 + \frac{1}{120}y^6 - \frac{1}{672}y^8\right) \\
& + \left(\frac{Q}{D^2}\partial_{xt}c^0 - \varepsilon^\alpha\frac{Q}{D}\partial_{xxx}c^0\right)\left(\frac{31}{7560} - \frac{7}{360}y^2 + \frac{y^4}{72} - \frac{y^6}{360}\right) \\
& + \frac{Qk}{D^2}\partial_x c^0\left(\frac{y^6}{60} - \frac{y^4}{18} + \frac{11y^2}{180} - \frac{11}{810}\right) \\
& + \left(\frac{k}{2D^2}\partial_t c^0 - \frac{k}{2D}\varepsilon^\alpha\partial_{xx}c^0\right)\left(-\frac{y^4}{12} + \frac{y^2}{6} - \frac{7}{180}\right) + \left(\frac{Qk}{45D^2}\partial_x c^0 - \frac{k^2}{6D^2}c^0\right)\left(\frac{1}{3} - y^2\right)\Bigg\}.
\end{aligned}
\tag{71}
$$

5. Boundary layer. The higher order approximations in the asymptotic expansion for c^ε do not satisfy the boundary conditions. Such incompatibility suggests that we should correct them using an appropriate boundary layer:

$$
\begin{cases}
-\Delta_{y,z}\beta = 0 \quad \text{for } (z,y) \in \Omega^+, \\
-\partial_y\beta = 0 \ \text{ for } y = 1, \quad \text{and for } y = 0, \\
\beta = \dfrac{y^2}{6} - \dfrac{y^4}{12} - \dfrac{7}{180} \ \text{ for } z = 0.
\end{cases}
\tag{72}
$$

Using the elementary variational theory for PDEs, we obtain the existence of a unique solution $\beta \in L^2_{loc}(\Omega^+)$ such that $\nabla\beta \in L^2_{loc}(\Omega^+)^2$. Since the average of the boundary value at $z = 0$ is zero, it follows that $\int_0^1 \beta(z,y)\ dy = 0$ for every $z \in (0,+\infty)$. This allows us to apply Poincaré's inequality in H^1:

$$
\int_0^1 \varphi^2\ dy \le \frac{1}{\pi^2}\int_0^1 |\partial_y\varphi|^2\ dy\ \ \forall\varphi \in H^1(0,1),\ \ \int_0^1 \varphi\ dy = 0,
\tag{73}
$$

and conclude that in fact $\beta \in H^1(\Omega^+)$. In order to prove that β represents a boundary layer, one should prove the exponential decay. We apply the theory from [14] and get the following result describing the decay of β as $z \to +\infty$.

PROPOSITION 3. *There exists a constant $\gamma_0 > 0$ such that the solution β of* (72) *satisfies the estimates*

$$
\int_z^{+\infty}\int_0^1 |\nabla_{y,z}\beta|^2\ dydz \le c_0 e^{-\gamma_0 z}, \quad z > 0,
\tag{74}
$$

$$
|\beta(y,z)| \le c_0 e^{-\gamma_0 z} \quad \forall (y,z) \in \Omega^+.
\tag{75}
$$

6. First correction. As explained, estimate (57) is not satisfactory. To get a better approximation we consider the correction, which was constructed using the formal 2-scale expansion in section 4.

Let $0 \leq \alpha < 2$. We start with the $\mathcal{O}(\varepsilon^{4-2\alpha})$ approximation and consider the function

(76)
$$c_1^{eff}(x,y,t;\varepsilon) = c(x,t;\varepsilon) + \varepsilon^{2-\alpha}\zeta(t)\left(\frac{Q}{D}\left(\frac{y^2}{6} - \frac{y^4}{12} - \frac{7}{180}\right)\frac{\partial c}{\partial x} + \frac{k}{D}\left(\frac{1}{6} - \frac{y^2}{2}\right)c\right),$$

where c is the solution to the effective problem with Taylor's dispersion coefficient including the reaction terms:

(77)
$$\begin{cases} \partial_t c + Q\left(\frac{2}{3} + \frac{4k}{45D}\varepsilon^{2-\alpha}\right)\partial_x c + k\left(1 - \frac{k}{3D}\varepsilon^{2-\alpha}\right)c \\ = \left(D\varepsilon^{\alpha} + \frac{8}{945}\frac{Q^2}{D}\varepsilon^{2-\alpha}\right)\partial_{xx} c \ \text{ in } \ (0,+\infty)\times(0,T), \\ c|_{x=0} = 0,\ c|_{t=0} = 1,\ \partial_x c \in L^2((0,+\infty)\times(0,T)). \end{cases}$$

The cut-off in time ζ is given by (26) and we use it to eliminate the time-like boundary layer appearing at $t = 0$. These effects are not visible in the formal expansion.

Let $\mathcal{L}^\varepsilon$ be the differential operator given by (34). Following the formal expansion from section 4, we find that $\mathcal{L}^\varepsilon$ applied to the correction without boundary layer functions and cut-offs would give $F_1^\varepsilon + F_2^\varepsilon + F_3^\varepsilon + F_4^\varepsilon + F_5^\varepsilon$, where

(78)
$$\begin{cases} F_1^\varepsilon = \partial_{xx} c\frac{Q^2}{D}\varepsilon^{2-\alpha}\left\{\frac{8}{945} + (1-y^2)\left(\frac{y^2}{6} - \frac{y^4}{12} - \frac{7}{180}\right)\right\}, \\ F_2^\varepsilon = \partial_x c\frac{Qk}{D}\varepsilon^{2-\alpha}\left\{-\frac{2}{45} + (1-y^2)\left(\frac{1}{6} - \frac{y^2}{2}\right)\right\}, \\ F_3^\varepsilon = \varepsilon^{2-\alpha}\left(\frac{y^2}{6} - \frac{y^4}{12} - \frac{7}{180}\right)\left\{\partial_{xt} c\frac{Q}{D} - \varepsilon^{\alpha}\partial_{xxx} cQ\right\}, \\ F_4^\varepsilon = \varepsilon^{2-\alpha}\left(\frac{1}{6} - \frac{y^2}{2}\right)\left\{\partial_t c\frac{k}{D} - \varepsilon^{\alpha}\partial_{xx} ck\right\}, \\ F_5^\varepsilon = \varepsilon^{2-\alpha}\left\{-\frac{2}{45}\partial_x c\frac{Qk}{D} + \frac{k^2}{3D}c\right\}. \end{cases}$$

These functions are not integrable up to $t = 0$, and for handling them we introduce the cut-off ζ.

Applying $\mathcal{L}^\varepsilon$ to c_1^{eff} gives

$$\begin{aligned} \mathcal{L}^\varepsilon(c_1^{eff}) &= \zeta(t)\sum_{j=1}^{5} F_j^\varepsilon + \left(\varepsilon^{2-\alpha}\partial_{xx} c\frac{Q^2}{D}\frac{8}{945} + Q\left(\frac{1}{3} - y^2\right)\partial_x c - kc\right) \\ &\times (1-\zeta(t)) + \zeta'(t)\varepsilon^{2-\alpha}\left(\partial_x c\frac{Q}{D}\left\{\frac{y^2}{6} - \frac{y^4}{12} - \frac{7}{180}\right\} + \frac{k}{2D}\left(\frac{1}{3} - y^2\right)c\right) \\ &=: \Phi_1^\varepsilon \ \text{ and } \ -\mathcal{L}^\varepsilon(c_1^{eff}) = \mathcal{L}^\varepsilon(c^\varepsilon - c_1^{eff}) = -\Phi_1^\varepsilon. \end{aligned} \tag{79}$$

At the lateral boundary $y = 1$ we have

$$-D\varepsilon^{\alpha-2}\partial_y c_1^{eff}|_{y=1} = \zeta(t)kc, \tag{80}$$

$$kc_1^{eff}|_{y=1} = k\left(c + \varepsilon^{2-\alpha}\frac{Q}{D}\zeta(t)\frac{2}{45}\partial_x c - \varepsilon^{2-\alpha}\frac{k}{3D}c\zeta(t)\right). \tag{81}$$

Now $c^\varepsilon - c_1^{eff}$ satisfies the system

$$\mathcal{L}^\varepsilon(c^\varepsilon - c_1^{eff}) = -\Phi_1^\varepsilon \text{ in } \Omega^+ \times (0,T), \tag{82}$$

$$\partial_y(c^\varepsilon - c_1^{eff})|_{y=0} = 0 \text{ on } (0,+\infty)\times(0,T), \tag{83}$$

$$-D\varepsilon^{\alpha-2}\partial_y(c^\varepsilon - c_1^{eff})|_{y=1} = k(c^\varepsilon - c_1^{eff})|_{y=1} + g^\varepsilon|_{y=1} \text{ on } (0,+\infty)\times(0,T), \tag{84}$$

$$(c^\varepsilon - c_1^{eff})|_{t=0} = 0 \text{ on } \Omega^+ \text{ and } (c^\varepsilon - c_1^{eff})|_{x=0} = \eta_0^\varepsilon \text{ on } (0,1)\times(0,T), \tag{85}$$

$$\text{with } g^\varepsilon = k\zeta(t)\varepsilon^{2-\alpha}\left(\partial_x c\frac{2Q}{45D} - c\frac{k}{3D}\right) + (1-\zeta)kc \tag{86}$$

$$\text{and } \eta_0^\varepsilon = -\varepsilon^{2-\alpha}\zeta(t)\partial_x c|_{x=0}\left(\frac{y^2}{6} - \frac{y^4}{12} - \frac{7}{180}\right)\frac{Q}{D}. \tag{87}$$

As a next step we estimate Φ_1^ε to find out if the right-hand side is smaller than in section 3.

PROPOSITION 4. *Let $O_t = \Omega^+ \times (0,t)$ and let $\varphi \in H^1(O_T)$ satisfy $\varphi = 0$ at $x = 0$. Then we have*

$$\left|\int_0^t\int_{\Omega^+} \zeta F_1^\varepsilon\varphi \, dxdyd\tau\right| \le C\varepsilon^{3(2-\alpha)/2}\|\zeta(\tau)\partial_{xx}c\|_{L^2(O_t)}\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}$$
$$\le C\big(\varepsilon^{3-5\alpha/2}H(1-\alpha) + \varepsilon^{1-\alpha/2}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}; \tag{88}$$

$$\left|\int_0^t\int_{\Omega^+} \zeta(\tau) F_3^\varepsilon\varphi \, dxdyd\tau\right| \le C\varepsilon^{3(2-\alpha)/2}$$
$$\cdot\left(\|\zeta(\tau)\partial_{xt}c\|_{L^2(O_t)} + \|\zeta(\tau)\partial_{xx}c\|_{L^2(O_t)}\right)\cdot\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}$$
$$\le C\big(\varepsilon^{3-5\alpha/2}H(1-\alpha) + \varepsilon^{1-\alpha/2}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}; \tag{89}$$

$$\left|\int_0^t\int_{\Omega^+} (1-\zeta)\partial_{xx}c\varepsilon^{2-\alpha}\frac{Q^2}{D}\varphi \, dxdyd\tau\right| \le C\varepsilon^{2-3\alpha/2}\|\varepsilon^{\alpha/2}\partial_x\varphi\|_{L^2(O_t)}$$
$$\cdot\|(1-\zeta)\partial_x c\|_{L^2(O_t)} \le C\varepsilon^{2-3\alpha/2}\|\varepsilon^{\alpha/2}\partial_x\varphi\|_{L^2(O_t)}; \tag{90}$$

$$\left|\int_0^t\int_{\Omega^+} (1-\zeta)Q\left(\frac{1}{3} - y^2\right)\partial_x c\varphi \, dxdyd\tau\right| \le C\varepsilon^{1-\alpha/2}\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}$$
$$\cdot\|(1-\zeta)\partial_x c\|_{L^2(O_t)} \le C\varepsilon^{1-\alpha/2}\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}; \tag{91}$$

$$\left|\int_0^t\int_{\Omega^+} \zeta'\left(\frac{t}{D\varepsilon}\right)\varepsilon^{2-\alpha}\left\{\partial_x c\frac{Q}{D}\left\{\frac{y^2}{6} - \frac{y^4}{12} - \frac{7}{180}\right\} - \frac{k}{2D}\left(\frac{1}{3} - y^2\right)c\right\}\cdot\varphi \, dxdyd\tau\right|$$
$$\le C\varepsilon^{3-3\alpha/2}\|\zeta'\partial_x c\|_{L^2(O_t)}\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}$$
$$\le C\big(\varepsilon^{3-5\alpha/2}H(1-\alpha) + \varepsilon^{1-\alpha/2}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}. \tag{92}$$

Proof. First note that in (88)–(89) and (91)–(92) the averages of the polynomials in y are zero. We write them in the form $P(y) = \partial_y P_1(y)$, where P_1 has zero traces at $y = 0, 1$. After partial integration with respect to y and applying the results from section 2, we obtain the estimates (88)–(89) and (91)–(92). Since $(1-\zeta)\partial_{xx}c$ is not square integrable, we cannot use the same approach to obtain (90). It is obtained by partial integration with respect to x. ∎

PROPOSITION 5. *With φ as in Proposition 4 we have*

$$\begin{aligned}\left|\int_0^t\int_{\Omega^+}\zeta F_2^\varepsilon\varphi\ dxdyd\tau\right| &\le C\varepsilon^{3(1-\alpha/2)}\|\zeta\partial_x c\|_{L^2(O_t)}\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}\\ &\le C\big(\varepsilon^{3-7\alpha/4}H(1-\alpha)+\varepsilon^{5/2-5\alpha/4}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)};\end{aligned}\tag{93}$$

$$\begin{aligned}\left|\int_0^t\int_{\Omega^+}\zeta F_4^\varepsilon\varphi\ dxdyd\tau\right| &\le C\varepsilon^{3-3\alpha/2}\Big(\|\zeta\partial_t c\|_{L^2(O_t)}+\varepsilon^\alpha\|\zeta\partial_{xx}c\|_{L^2(O_t)}\Big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}\\ &\le C\big(\varepsilon^{3-7\alpha/4)}H(1-\alpha)+\varepsilon^{5(2-\alpha)/4}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)};\end{aligned}\tag{94}$$

$$\begin{aligned}&\left|\int_0^t\int_0^{+\infty}\zeta\partial_x c\varepsilon^{2-\alpha}\Big(\int_0^1\varphi\ dy-\varphi|_{y=1}\Big)\ dxd\tau\right|\\ &\le C\varepsilon^{2-\alpha}\|\partial_x c\|_{L^2(0,t;L^2((0,+\infty)))}\left\|\int_0^1\varphi\ dy-\varphi|_{y=1}\right\|_{L^2(O_t)}\\ &\le C\big(\varepsilon^{3-7\alpha/4}H(1-\alpha)+\varepsilon^{5(2-\alpha)/4}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)};\end{aligned}\tag{95}$$

$$\left|\int_0^t\int_0^{+\infty}\zeta(t)c\varepsilon^{2-\alpha}\Big(\int_0^1\varphi\ dy-\varphi|_{y=1}\Big)\ dxd\tau\right|\le C\varepsilon^{3(1-\alpha/2)}\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)};\tag{96}$$

$$\begin{aligned}&\left|\int_0^t\int_0^{+\infty}(1-\zeta(t))c\Big(\int_0^1\varphi\ dy-\varphi|_{y=1}\Big)\ dxd\tau\right|\\ &\le C\big(\varepsilon H(1-\alpha)+\varepsilon^{2-\alpha}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}.\end{aligned}\tag{97}$$

COROLLARY 3. *With Φ_1^ε given by (79), g^ε by (86), and with φ as in Proposition 4 we have*

$$\begin{aligned}&\left|\int_0^t\int_{\Omega^+}\Phi_1^\varepsilon\varphi\ dxdyd\tau+\int_0^t\int_0^{+\infty}g^\varepsilon|_{y=1}\varphi|_{y=1}\ dxd\tau\right|\\ &\le C\big(\varepsilon^{1-\alpha/2}H(1-\alpha)+\varepsilon^{2-3\alpha/2}H(\alpha-1)\big)\Big\{\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}+\|\varepsilon^{\alpha/2}\partial_x\varphi\|_{L^2(O_t)}\Big\}.\end{aligned}\tag{98}$$

A natural next step would be to correct c_1^{eff} at $x=0$ and then apply Proposition 1. Due to the presence of the term containing the first-order derivative in x, the boundary layer corresponding to our problem does not enter into the theory from [14]. Consequently, one should generalize it to the second-order elliptic equations with first-order terms. The generalization in the case of periodic boundary conditions at the lateral boundary is done in [16]. To our knowledge, the generalization in the case of Neumann's boundary conditions at the lateral boundary was never published. It seems that the results from [16] apply also to this case (see [17]). In order to avoid developing a new boundary layer theory of second-order elliptic operators with important first-order terms, we simply use the boundary layer function corresponding to the Neumann problem for the Laplace operator (72). Then the transport term is ignored and a large error in the forcing term is created. The error is concentrated at small times, and by eliminating it we would obtain an appropriate estimate.

In order to use this particular point, we prove the following proposition.

PROPOSITION 6. *Let $\Psi(x) = 1/(x+1)$ and let g^ε and Φ^ε be measurable bounded functions satisfying the conditions*

$$\Psi g^\varepsilon \in H^1(\Omega^+ \times (0,T)) \ \text{ and } \ \Psi\Phi^\varepsilon \in L^2(\Omega^+ \times (0,T)). \tag{99}$$

Furthermore, let $\xi \in L^\infty(\Omega^+ \times (0,T))$, $\Psi\xi \in C^{0,\alpha_0}([0,T]; L^2(\Omega^+))$, $\Psi\nabla_{x,y}\xi \in L^2(\Omega^+ \times (0,T))^2$ be a solution of the initial/boundary problem

$$\mathcal{L}^\varepsilon(\xi) = -\Phi^\varepsilon \ \text{ in } \ \Omega^+ \times (0,T); \quad \partial_y\xi|_{y=0} = 0 \ \text{ on } \ (0,+\infty) \times (0,T), \tag{100}$$

$$-D\varepsilon^{\alpha-2}\partial_y\xi|_{y=1} = k\xi|_{y=1} + g^\varepsilon|_{y=1} \quad \text{on } \ (0,+\infty) \times (0,T), \tag{101}$$

$$\xi|_{t=0} = 0 \ \text{ on } \ \Omega^+ \quad \text{and} \quad \xi|_{x=0} = 0 \ \text{ on } \ (0,1) \times (0,T). \tag{102}$$

Then we have

$$\begin{aligned}
&\mathcal{E}(t^m\xi,t) = t^{2m}\int_{\Omega^+}\Psi(x)^2\xi^2(t)\,dxdy + D\varepsilon^\alpha\int_0^t\int_{\Omega^+}\Psi(x)^2\tau^{2m} \\
&\times\left\{\varepsilon^{-2}|\partial_y\xi|^2 + |\partial_x\xi|^2\right\}dxdyd\tau + k\int_0^t\int_0^{+\infty}\tau^{2m}\xi^2|_{y=1}\Psi^2(x)\,dxd\tau \\
&\le \left|\int_{\Omega^+}\tau^{2m}\Psi(x)^2\Phi^\varepsilon\xi\,dxdyd\tau\right| + \left|\int_0^t\int_0^{+\infty}\tau^{2m}g^\varepsilon\right|_{y=3D1}\xi|_{y=3D1}\Psi^2(x)\,dxd\tau| \\
&+ C_2D\varepsilon^\alpha\int_0^t\int_{\Omega^+}\tau^{2m}\Psi(x)^2\xi^2\,dxdyd\tau \quad \forall m \ge 1.
\end{aligned} \tag{103}$$

Remark 5. Clearly, we want to apply this abstract result to $\xi = c^\varepsilon - c_1^{eff}$. Then $\zeta(t)\partial_x c$ has the required regularity, since the cut-off eliminates the singularity. With c the analysis is more complicated. By direct calculation we have $\partial_t c \in L^q(0,T; L^2((0,+\infty)))$ for all $q \in [1,4/3)$ and we obtain the required Hölder regularity by the Sobolev imbedding. $\int_0^A\int_0^1 |\xi(x,y,t)|^2\,dxdy$ is Hölder-continuous with some exponent $\alpha_0 > 0$ for all $A < +\infty$, *independent of* ε. In complete analogy, c_0^{eff} defined by (33) also has the required regularity. Finally, the difference $c^\varepsilon - c_0^{eff}$ satisfies (40) and (41) and it is zero at $x = 0$ and $t = 0$. Then the classical parabolic regularity theory (see, e.g., [10]) implies the Hölder regularity in the time of the L^2 norm with respect to x, y. After combining all these results, we obtain the required regularity of ξ.

Proof. By the supposed Hölder continuity, there exists $t_M \in [0,T]$, $t_M > 0$, such that

$$\frac{1}{t_M^{\alpha_0}}\int_0^{+\infty}\int_0^1 |\xi(x,y,t_M)|^2\Psi^2(x)\,dxdy = \max_{t\in[0,T]}\frac{1}{t^{\alpha_0}}\int_0^{+\infty}\int_0^1 |\xi(x,y,t)|^2\Psi^2(x)\,dx. \tag{104}$$

Then we have

$$\begin{aligned}
\int_0^{t_M} m\tau^{2m-1}\int_{\Omega^+}|\xi|^2\Psi^2(x)\,dxdyd\tau &\le \int_{\Omega^+}\frac{|\xi|^2(t_M)}{t_M^{\alpha_0}}\Psi^2(x)\int_0^{t_M} m\tau^{2m-1+\alpha_0}\,d\tau \\
&= \frac{m}{2m+\alpha_0}t_M^{2m}\int_{\Omega^+}|\xi|^2(t_M)\Psi^2(x)\,dxdy
\end{aligned} \tag{105}$$

and

$$\begin{aligned}
&\frac{1}{2}t_M^{2m}\int_{\Omega^+}|\xi|^2(t_M)\Psi^2(x)\,dxdy + k\int_0^{t_M}\int_0^{+\infty}\tau^{2m}\xi^2|_{y=1}\Psi^2(x)\,dxd\tau\\
&+\int_0^{t_M} D\left(\varepsilon^\alpha\int_{\Omega^+}\tau^{2m}|\partial_x\xi|^2(\tau)\Psi^2(x)\,dxdy+\varepsilon^{\alpha-2}\int_{\Omega^+}\tau^{2m}|\partial_y\xi|^2(\tau)\Psi^2(x)\,dxdy\right)d\tau\\
&\qquad\le -\int_0^{t_M}\int_{\Omega^+}\tau^{2m}\Phi^\varepsilon\xi\,dxdyd\tau - k\int_0^t\int_0^{+\infty}\tau^{2m}\xi|_{y=1}g^\varepsilon|_{y=1}\Psi^2(x)\,dxd\tau\\
&\qquad + D\varepsilon^\alpha\int_0^{t_M}\int_{\Omega^+}\tau^{2m}\Psi^2(x)\xi^2\,dxdyd\tau + m\int_0^{t_M}\int_{\Omega^+}\tau^{2m-1}|\xi|^2\Psi^2\,dxdyd\tau. \qquad (106)
\end{aligned}$$

Using (105) we find (103) for $t = t_M$ and with $C_2 = 0$. Getting the estimate (103) for general $t \in (0,T)$ is now straightforward. ∎

To use this estimate we should refine the estimates in Propositions 4 and 5. First, we note that estimate (29) changes to

$$\begin{aligned}
&\|t^m\partial_{tt}c\|_{L^q((0,T)\times(0,+\infty))} + \|t^m\partial_{tx}c\|_{L^q((0,T)\times(0,+\infty))} + \|t^m\partial_{xx}c\|_{L^q((0,T)\times(0,+\infty))}\\
&\qquad\le C_q(m)(\gamma\bar{D})^{1/(2q)-1}. \qquad (107)
\end{aligned}$$

Hence one gains $\varepsilon^{\alpha/4}$ (respectively, $\varepsilon^{1/2-\alpha/4}$) for the L^2 norm. In analogy with Propositions 4 and 5 we have Proposition 7.

PROPOSITION 7. *Let φ be as in Proposition 4 and let $m > 1$. Then we have*

$$\begin{aligned}
&\left|\int_0^t\int_0^\infty\int_0^1\tau^m\zeta F_1^\varepsilon\varphi\,dxdyd\tau\right| \le C\varepsilon^{3(2-\alpha)/2}\|\tau^m\partial_{xx}c\|_{L^2(O_t)}\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}\\
&\qquad\le C\big(\varepsilon^{3-9\alpha/4}H(1-\alpha)+\varepsilon^{3/2-3\alpha/4}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}; \qquad (108)
\end{aligned}$$

$$\begin{aligned}
&\left|\int_0^t\int_0^\infty\int_0^1\tau^m\zeta F_3^\varepsilon\varphi\,dxdyd\tau\right| \le C\varepsilon^{3(2-\alpha)/2}\\
&\quad\cdot\left(\|\tau^m\partial_{xt}c\|_{L^2(O_t)}+\|\tau^m\partial_{xx}c\|_{L^2(O_t)}\right)\cdot\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}\\
&\qquad\le C\big(\varepsilon^{3-9\alpha/4}H(1-\alpha)+\varepsilon^{3/2-3\alpha/4}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}; \qquad (109)
\end{aligned}$$

$$\begin{aligned}
&\left|\int_0^t\int_{\Omega^+}\zeta\tau^m F_2^\varepsilon\varphi\,dxdyd\tau\right| \le C\varepsilon^{3(1-\alpha/2)}\|\tau^m\zeta\partial_x c\|_{L^2(O_t)}\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}\\
&\qquad\le C\big(\varepsilon^{3-7\alpha/4}H(1-\alpha)+\varepsilon^{5/2-5\alpha/4}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}; \qquad (110)
\end{aligned}$$

$$\begin{aligned}
&\left|\int_0^t\int_{\Omega^+}\zeta\tau^m F_4^\varepsilon\varphi\,dxdyd\tau\right| \le C\varepsilon^{3-3\alpha/2}\\
&\quad\cdot\left(\|\zeta\tau^m\partial_t c\|_{L^2(O_t)}+\varepsilon^\alpha\|\zeta\tau^m\partial_{xx}c\|_{L^2(O_t)}\right)\cdot\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}\\
&\qquad\le C\big(\varepsilon^{3-7\alpha/4)}H(1-\alpha)+\varepsilon^{5(2-\alpha)/4}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}; \qquad (111)
\end{aligned}$$

$$\begin{aligned}&\left|\int_0^t\int_0^{+\infty}\zeta\tau^m\partial_x c\varepsilon^{2-\alpha}\left(\int_0^1\varphi\ dy-\varphi|_{y=1}\right)\ dxd\tau\right|\\&\le C\varepsilon^{2-\alpha}\|\tau^m\partial_x c\|_{L^2(O_t)}\left\|\int_0^1\varphi\ dy-\varphi|_{y=1}\right\|_{L^2(O_t)}\\&\le C\big(\varepsilon^{3-7\alpha/4}H(1-\alpha)+\varepsilon^{5(2-\alpha)/4}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)};\end{aligned}\tag{112}$$

$$\begin{aligned}&\left|\int_0^t\int_0^{+\infty}\zeta(t)\tau^m c\varepsilon^{2-\alpha}\left(\int_0^1\varphi\ dy-\varphi|_{y=1}\right)\ dxd\tau\right|\\&\le C\varepsilon^{3(1-\alpha/2)}\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}.\end{aligned}\tag{113}$$

Proof. These estimates are straightforward consequences of Propositions 4 and 5. □

We improve these results with respect to the other terms.

Without proof we state the following.

PROPOSITION 8. *Let φ be as in Proposition 4 and let $m>1$. Then we have*

$$\begin{aligned}&\left|\int_0^t\int_0^{\infty}\int_0^1(1-\zeta)\tau^m\partial_{xx}c\frac{Q^2}{D}\varepsilon^{2-\alpha}\varphi\ dxdyd\tau\right|\\&\le C\varepsilon^{2-3\alpha/2}\|(1-\zeta)\tau^m\partial_x c\|_{L^2(O_t)}\|\varepsilon^{\alpha/2}\partial_x\varphi\|_{L^2(O_t)}\\&\le C\big(\varepsilon^{m\alpha+2-3\alpha/2}H(1-\alpha)+\varepsilon^{m(2-\alpha)+2-3\alpha/2}H(\alpha-1)\big)\|\varepsilon^{\alpha/2}\partial_x\varphi\|_{L^2(O_t)};\end{aligned}\tag{114}$$

$$\begin{aligned}&\left|\int_0^t\int_0^{\infty}\int_0^1(1-\zeta)\tau^m Q\left(\frac13-y^2\right)\partial_x c\varphi\ dxdyd\tau\right|\\&\le C\varepsilon^{1-\alpha/2}\|(1-\zeta)\tau^m\partial_x c\|_{L^2(O_t)}\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}\\&\le C\big(\varepsilon^{m\alpha+1-\alpha/2}H(1-\alpha)+\varepsilon^{m(2-\alpha)+1-\alpha/2}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)};\end{aligned}\tag{115}$$

$$\begin{aligned}&\left|\int_0^t\int_{\Omega^+}\zeta'\left(\frac{t}{D\varepsilon}\right)\tau^m\varepsilon^{2-\alpha}\left\{\partial_x c\frac{Q}{D}\left\{\frac{y^2}{6}-\frac{y^4}{12}-\frac{7}{180}\right\}-\frac{k}{2D}\left(\frac13-y^2\right)c\right\}\cdot\varphi\ dxdyd\tau\right|\\&\le C\varepsilon^{3-3\alpha/2}\|\zeta'\tau^m\partial_x c\|_{L^2(O_t)}\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}\\&\le C\big(\varepsilon^{3-3\alpha/2+\alpha(m-1)}H(1-\alpha)+\varepsilon^{3-3\alpha/2+(2-\alpha)(m-1)}H(\alpha-1)\big)\|\varepsilon^{\alpha/2-1}\partial_y\varphi\|_{L^2(O_t)}.\end{aligned}\tag{116}$$

Before applying Proposition 6 and getting the final estimate, we should correct the trace at $x=0$. This is done by adding

$$\bar c_1^{eff}=-\varepsilon^{2-\alpha}\zeta(t)\beta^\varepsilon\partial_x c\frac{Q}{D},\tag{117}$$

where $\beta^\varepsilon(x,y)=\beta(x/\varepsilon,y)$ is the boundary layer function given by (72). Let $g_1^\varepsilon=g^\varepsilon-\varepsilon^{2-\alpha}\frac{kQ\zeta\partial_x c\beta^\varepsilon}{D}$. Then for $\xi^\varepsilon=c^\varepsilon-c_1^{eff}-\bar c_1^{eff}$ we have the problem

$$\mathcal{L}^\varepsilon(\xi^\varepsilon) = -\Phi^\varepsilon = -\Phi_1^\varepsilon + \partial_t\zeta\varepsilon^{2-\alpha}\partial_x c\frac{Q}{D}\beta^\varepsilon + \varepsilon^{2-\alpha}\beta^\varepsilon\zeta(t)$$
$$\times\left\{\partial_{xt}c\frac{Q}{D} - \varepsilon^\alpha\partial_{xxx}cQ\right\} + \partial_x\beta^\varepsilon\frac{Q^2}{D}(1-y^2)\zeta\varepsilon^{2-\alpha}\partial_x c - \varepsilon^{2-\alpha}Q\partial_{xx}c\zeta(t)$$
$$\times\left(2\varepsilon^\alpha\partial_x\beta^\varepsilon - \beta^\varepsilon(1-y^2)\frac{Q}{D}\right) \text{ in } \Omega^+\times(0,T), \tag{118}$$

$$-D\varepsilon^{\alpha-2}\partial_y\xi^\varepsilon = k\xi^\varepsilon + g_1^\varepsilon \text{ on } (0,+\infty)\times\{1\}\times(0,T), \tag{119}$$

$$\partial_y\xi^\varepsilon|_{y=0} = 0 \text{ on } (0,+\infty)\times(0,T), \tag{120}$$

$$\xi^\varepsilon|_{t=0} = 0 \text{ on } \Omega^+ \quad\text{and}\quad \xi^\varepsilon|_{x=0} = 0 \text{ on } (0,1)\times(0,T). \tag{121}$$

We need an estimate for the new terms. It will be obtained from the following auxiliary result.

LEMMA 5. *With β and c defined by* (72) *and* (77)*, respectively, and with $m \geq 1$, we have*

$$\|\tau^m\zeta'\beta^\varepsilon\partial_x c\|_{L^2(O_t)} \leq C\varepsilon^{m-(\alpha+3)/4}\big\{H(1-\alpha) + \varepsilon^{(\alpha-1)/2}H(\alpha-1)\big\} \leq C\varepsilon^{m-1}; \tag{122}$$

$$\|\tau^m\zeta\beta^\varepsilon|_{y=1}\partial_x c\|_{L^2(O_t)} \leq C\varepsilon^{m+1/4}\big\{\varepsilon^{-\alpha/4}H(1-\alpha) + \varepsilon^{\alpha/4-1/2}H(\alpha-1)\big\} \leq C\varepsilon^m; \tag{123}$$

$$\|\tau^m\zeta\partial_x\beta^\varepsilon\partial_x c\|_{L^2(O_t)} \leq C\varepsilon^{m-3/4}\big\{\varepsilon^{-\alpha/4}H(1-\alpha) + \varepsilon^{\alpha/4-1/2}H(\alpha-1)\big\} \leq C\varepsilon^{m-1}; \tag{124}$$

$$\|\tau^m\zeta\partial_x\beta^\varepsilon\partial_t c\|_{L^2(O_t)} \leq C\varepsilon^{m-5/4}\big\{\varepsilon^{\alpha/2}H(1-\alpha) + \varepsilon^{1-\alpha/2}H(\alpha-1)\big\} \leq C\varepsilon^{m-5/4}; \tag{125}$$

$$\begin{aligned}&\|\tau^m\zeta\beta^\varepsilon\partial_{xx}c\|_{L^2(O_t)}\\ &\leq C\varepsilon^m\big\{(\varepsilon^{-1/4-\alpha/2} + \varepsilon^{1/4-3\alpha/4})H(1-\alpha) + (\varepsilon^{\alpha/2-5/4} + \varepsilon^{-5/2+3\alpha/4})H(\alpha-1)\big\}\\ &\leq C\varepsilon^{m-7/4};\end{aligned} \tag{126}$$

$$\begin{aligned}&\|\tau^m\zeta\partial_x\beta^\varepsilon\partial_{xx}c\|_{L^2(O_t)}\\ &\leq C\varepsilon^{m-1}\big\{(\varepsilon^{-1/4-\alpha/2} + \varepsilon^{1/4-3\alpha/4})H(1-\alpha) + (\varepsilon^{\alpha/2-5/4} + \varepsilon^{-5/2+3\alpha/4})H(\alpha-1)\big\}\\ &\leq C\varepsilon^{m-7/4}.\end{aligned} \tag{127}$$

Proof. Since

$$\begin{aligned}\int_0^{+\infty}|\partial_x c\beta^\varepsilon|^2\,dx &\leq C\int_0^{+\infty}\exp\left\{-\frac{2\gamma_0 x}{\varepsilon}\right\}\exp\left\{-\frac{(x-\tau\bar{Q})^2}{2\gamma\bar{D}\tau}\right\}\frac{dx}{\gamma\tau\bar{D}}\\ &\leq C(\varepsilon D\tau)^{-1/2}\exp\{-C_0\tau/\varepsilon\}\,dxd\tau,\end{aligned} \tag{128}$$

inequalities (122), (123), and (124) follow by integration with respect to τ. Furthermore, since

$$\begin{aligned}\int_0^{+\infty}|\partial_t c\beta^\varepsilon|^2\,dx &\leq C\int_0^{+\infty}x^2\exp\left\{-\frac{2\gamma_0 x}{\varepsilon}\right\}\exp\left\{-\frac{(x-\tau\bar{Q})^2}{2\gamma\bar{D}\tau^3}\right\}\frac{dx}{\gamma\tau\bar{D}}\\ &\leq C(\varepsilon D\tau^3)^{-1/2}\exp\{-C_0\tau/\varepsilon\}\,dxd\tau,\end{aligned} \tag{129}$$

inequality (125) follows. Finally, since

$$\begin{aligned}&\|\tau^m\zeta\beta^\varepsilon\partial_{xx}c\|_{L^2(O_t)}\\ &\le C(\|\tau^m\zeta\beta^\varepsilon\partial_x c\|_{L^2(O_t)}+\|\tau^m\zeta\beta^\varepsilon\partial_t c\|_{L^2(O_t)})(\varepsilon^{-\alpha}H(1-\alpha)+\varepsilon^{\alpha-2}H(\alpha-1)),\end{aligned}\tag{130}$$

we obtain (126) and (127). □

PROPOSITION 9. *With φ as in Proposition 4, we have*

$$\begin{aligned}&\left|\int_0^t\int_{\Omega^+}\varepsilon^{2-\alpha}\tau^m\zeta(\tau)\beta^\varepsilon\left\{\partial_{xt}c\frac{Q}{D}-\varepsilon^\alpha\partial_{xxx}cQ\right\}\varphi\ dxdyd\tau\right|\\ &\le C\varepsilon^{2-\alpha}\Big(\big\{\|\zeta\tau^m\partial_t c\partial_x\beta^\varepsilon\|_{L^2(O_t)}+\varepsilon^\alpha\|\tau^m\zeta\partial_x\beta^\varepsilon\partial_{xx}c\|_{L^2(O_t)}\big\}\|\varphi\|_{L^2(O_t)}\\ &\quad+\varepsilon^{-\alpha/2}\big\{\|\zeta\tau^m\partial_t c\beta^\varepsilon\|_{L^2(O_t)}+\varepsilon^\alpha\|\tau^m\zeta\partial_{xx}c\|_{L^2(O_t)}\big\}\|\varepsilon^{\alpha/2}\partial_x\varphi\|_{L^2(O_t)}\Big)\\ &\le C\varepsilon^{m+1/4-\alpha}\big(\|\varphi\|_{L^2(O_t)}+\|\varepsilon^{\alpha/2}\partial_x\varphi\|_{L^2(O_t)}\big);\end{aligned}\tag{131}$$

$$\begin{aligned}&\left|\int_0^t\int_{\Omega^+}\varepsilon^{2-\alpha}\zeta\tau^m\partial_{xx}c\varphi\left(-\beta^\varepsilon\frac{Q}{D}(1-y^2)+2\varepsilon^\alpha\partial_x\beta^\varepsilon\right)\ dxdyd\tau\right|\\ &\le C\varepsilon^{2-\alpha}\big(\|\tau^m\zeta\partial_x\beta^\varepsilon\partial_{xx}c\|_{L^2(O_t)}+\|\tau^m\zeta\partial_x\beta^\varepsilon\partial_{xx}c\|_{L^2(O_t)}\big)\|\varphi\|_{L^2(O_t)}\\ &\le C\varepsilon^{m-\alpha+1/4}\|\varphi\|_{L^2(O_t)};\end{aligned}\tag{132}$$

$$\begin{aligned}&\left|\int_0^t\int_{\Omega^+}\varepsilon^{2-\alpha}\zeta\tau^m\partial_x c\partial_x\beta^\varepsilon(1-y^2)\varphi\ dxdyd\tau\right|\\ &\le C\varepsilon^{2-\alpha}\|\tau^m\zeta\partial_x\beta^\varepsilon\partial_x c\|_{L^2(O_t)}\|\varphi\|_{L^2(O_t)}\le C\varepsilon^{m-\alpha+1}\|\varphi\|_{L^2(O_t)};\end{aligned}\tag{133}$$

$$\begin{aligned}&\left|\int_0^t\int_0^{+\infty}\varepsilon^{2-\alpha}\zeta\tau^m\partial_x c\varphi|_{y=1}\beta^\varepsilon|_{y=1}\ dxd\tau\right|\\ &\le C\varepsilon^{2-\alpha}\|\tau^m\zeta\partial_x\beta^\varepsilon\partial_x c\|_{L^2(O_t)}\|\varphi\|_{L^2((0,t)\times\Gamma^+)}\le C\varepsilon^{m-\alpha+1}\|\varphi\|_{L^2((0,t)\times\Gamma^+)};\end{aligned}\tag{134}$$

$$\begin{aligned}&\left|\int_0^t\int_{\Omega^+}\varepsilon^{2-\alpha}\zeta'(\tau)\tau^m\partial_x c\varphi\beta^\varepsilon\ dxdyd\tau\right|\\ &\le C\varepsilon^{2-\alpha}\|\tau^m\zeta'\beta^\varepsilon\partial_x c\|_{L^2(O_t)}\|\varphi\|_{L^2(O_t)}\le C\varepsilon^{m-\alpha+3/4}\|\varphi\|_{L^2(O_t)}.\end{aligned}\tag{135}$$

At this point the application of Proposition 6 is straightforward. As a result we get the following.

THEOREM 4. *Let c be the solution of (77) and let c_1^{eff} and $\bar{c}_1^{eff}$ be given by (76) and (117), respectively. With $\Omega_K=(0,K)\times(0,1)$, $K>0$, we have*

$$\begin{aligned}&\|t^3(c^\varepsilon-c_1^{eff}(x,t;\varepsilon)-\bar{c}_1^{eff})\|_{L^\infty(0,T;L^2(\Omega_K))}\\ &\le C\big(\varepsilon^{3-9\alpha/4}H(1-\alpha)+\varepsilon^{3(1-\alpha/2)/2}H(\alpha-1)\big);\end{aligned}\tag{136}$$

$$\begin{aligned}&\|t^3\partial_y(c^\varepsilon-c_1^{eff}(x,t;\varepsilon)-\bar{c}_1^{eff})\|_{L^2(\Omega_K\times(0,T))}\\ &\le C\varepsilon^{1-\alpha/2}\big(\varepsilon^{3-9\alpha/4}H(1-\alpha)+\varepsilon^{3(1-\alpha/2)/2}H(\alpha-1)\big);\end{aligned}\tag{137}$$

$$\begin{aligned}&\|t^2\partial_x(c^\varepsilon-c_1^{eff}(x,t;\varepsilon)-\bar{c}_1^{eff})\|_{L^2(\Omega_K\times(0,T))}\\ &\le C\varepsilon^{-\alpha/2}\big(\varepsilon^{3-9\alpha/4}H(1-\alpha)+\varepsilon^{3(1-\alpha/2)/2}H(\alpha-1)\big).\end{aligned}\tag{138}$$

7. Error estimate involving the second order in expansion. The most important power in the Peclet number α is $\alpha = 1$ because it describes Taylor's scaling. In this case our approximation is of order $\varepsilon^{3/4}$ in L^2. It is of interest to reach the order ε at least in this case. Also, it is of interest to get the higher order estimates because ε is *frequently* not very small.

After the results of section 6, the leading order terms in the estimates are ζF_1^ε and ζF_3^ε, where F_j^ε, $j = 1, \dots, 3$, are defined in (78). When deriving formally the effective equation, we have seen that they could be eliminated by introducing the next order correction. Following the formal expansion, we find that c_1^{eff} should be replaced with $c_1^{eff} + c_2^{eff}$, where

$$
\begin{aligned}
c_2^{eff} = -\varepsilon^{4-2\alpha}\frac{Q}{D^2}\zeta(t)\Big\{ & Q\partial_{xx}c\Big(\frac{281}{453600} + \frac{23}{1512}y^2 - \frac{37}{2160}y^4 + \frac{1}{120}y^6 - \frac{1}{672}y^8 - \tilde\beta_1\Big) \\
& -(\partial_{xt}c - D\varepsilon^\alpha\partial_{xxx}c)\Big(-\frac{1}{360}y^6 + \frac{1}{72}y^4 - \frac{7}{360}y^2 - \frac{31}{7560} - \tilde\beta_2\Big)\Big\} \\
+\varepsilon^{4-2\alpha}\frac{k}{D^2}\zeta(t)\Big\{ & Q\partial_x c\Big(\frac{1}{60}y^6 - \frac{1}{18}y^4 + \frac{11}{180}y^2 - \frac{11}{810} - \tilde\beta_3\Big) \\
& + \frac{1}{2}(\partial_t c - D\varepsilon^\alpha\partial_{xx}c)\Big(-\frac{1}{12}y^4 + \frac{1}{6}y^2 - \frac{7}{180} - \tilde\beta_5\Big) \\
& + \frac{Q}{45}\partial_x c\Big(\frac{1}{3} - y^2 - \tilde\beta_4\Big) - \frac{k}{6}c\Big(\frac{1}{3} - y^2\Big)\Big\},
\end{aligned} \tag{139}
$$

where $\tilde\beta_j$, $j = 1, \dots, 5$, are boundary layers analogous to (72).

The application of this additional correction term gives the following.

THEOREM 5. *With the notation of Theorem* 4*, we have*

$$
\begin{aligned}
&\|t^5(c^\varepsilon - c_1^{eff}(x,t;\varepsilon) - \bar c_1^{eff})\|_{L^\infty(0,T;L^2(\Omega_K))} \\
&\le C\big(\varepsilon^{4-13\alpha/4}H(1-\alpha) + \varepsilon^{3(1-\alpha/2)/2}H(\alpha-1)\big);
\end{aligned} \tag{140}
$$

$$
\begin{aligned}
&\|t^5\partial_y(c^\varepsilon - c_1^{eff}(x,t;\varepsilon) - \bar c_1^{eff})\|_{L^2(0,T;L^2(\Omega_K))} \\
&\le C\varepsilon^{1-\alpha/2}\big(\varepsilon^{4-13\alpha/4}H(1-\alpha) + \varepsilon^{3(1-\alpha/2)/2}H(\alpha-1)\big);
\end{aligned} \tag{141}
$$

$$
\begin{aligned}
&\|t^5\partial_x(c^\varepsilon - c_1^{eff}(x,t;\varepsilon) - \bar c_1^{eff})\|_{L^2(0,T;L^2(\Omega_K))} \\
&\le C\varepsilon^{-\alpha/2}\big(\varepsilon^{4-13\alpha/4}H(1-\alpha) + \varepsilon^{3(1-\alpha/2)/2}H(\alpha-1)\big).
\end{aligned} \tag{142}
$$

Proof. Applying the operator $\mathcal{L}^\varepsilon$, given by (34), to $c^\varepsilon - c_1^{eff} - \bar c_1^{eff} - c_2^{eff}$ we obtain a forcing term Φ_2^ε, analogous to Φ^ε, given by (118). To control its behavior we are going to study the expression $\zeta\sum_{j=1}^5 F_j$. As we have seen in Proposition 8, Lemma 5, and Proposition 9, other terms are small. We have the following:

- F_1^ε and F_3^ε are replaced with $\tilde F_1^\varepsilon$ and $\tilde F_3^\varepsilon$, given by

$$
\begin{cases}
\tilde F_1^\varepsilon = (1-y^2)\dfrac{Q^2\varepsilon^{4-2\alpha}}{D^2}\Big\{-\partial_{xxx}cP_8(y)Q \\
\qquad\qquad + (\partial_{xxt}c - D\varepsilon^\alpha\partial_{xxxx}c)P_6(y)\Big\}, \\
\tilde F_3^\varepsilon = -\varepsilon^{4-2\alpha}P_8(y)\dfrac{Q^2}{D^2}\Big\{\partial_{xxt}c - \varepsilon^\alpha\partial_{xxxx}cD\Big\} \\
+\varepsilon^{4-2\alpha}P_6(y)\dfrac{Q}{D^2}\Big\{\partial_{xtt}c - 2D\varepsilon^\alpha\partial_{xxxt}c + \varepsilon^{2\alpha}\partial_{xxxxx}cD^2\Big\},
\end{cases} \tag{143}
$$

where

$$\begin{cases} P_8(y) = \dfrac{281}{453600} + \dfrac{23}{1512}y^2 - \dfrac{37}{2160}y^4 + \dfrac{1}{120}y^6 - \dfrac{1}{672}y^8, \\ P_4(y) = \dfrac{y^2}{6} - \dfrac{y^4}{12} - \dfrac{7}{180};\ P_6(y) = \dfrac{y^3}{18} - \dfrac{y^5}{60} - \dfrac{7y}{180} - \dfrac{31}{7560}. \end{cases}$$

Using (32) we find, analogous to (108)–(109), that

$$\begin{aligned} &\int_0^t \int_0^\infty \int_0^1 \tau^m \zeta(|\tilde{F}_1^\varepsilon| + |\tilde{F}_3^\varepsilon|)|\varphi|\ dxdyd\tau \\ &\le C\big(\varepsilon^{4-13\alpha/4} H(1-\alpha) + \varepsilon^{3/2-3\alpha/4} H(\alpha-1)\big)\|\varphi\|_{L^2(O_t)} \end{aligned} \tag{144}$$

for all $\varphi \in H^1(O_T)$, $\varphi = 0$ at $x = 0$ and $m > 2$.

- F_2^ε and F_4^ε are replaced with

$$\begin{cases} \tilde{F}_2^\varepsilon = (1-y^2)\dfrac{Qk\varepsilon^{4-2\alpha}}{D}\Big\{\partial_{xx}c\dfrac{Q}{D}\tilde{P}_6(y) \\ \quad + \Big(\partial_{xt}c\dfrac{1}{2D} - \varepsilon^\alpha\partial_{xxx}c\dfrac{1}{2}\Big)P_4(y) + \Big(\dfrac{Q}{45D}\partial_x c - \dfrac{k}{6D}c\Big)P_2(y)\Big\}, \\ \tilde{F}_4^\varepsilon = -\varepsilon^{4-2\alpha}\tilde{P}_6(y)\dfrac{Qk}{D^2}\Big\{\partial_{xt}c - \varepsilon^\alpha\partial_{xxx}cD\Big\} \\ \quad + \varepsilon^{4-2\alpha}P_4(y)\dfrac{k}{2D^2}\Big\{\partial_{tt}c - 2D\varepsilon^\alpha\partial_{xxt}c + D^2\varepsilon^{2\alpha}\partial_{xxxx}c\Big\} \\ \quad + \varepsilon^{4-2\alpha}P_2(y)\dfrac{k}{3D^2}\Big\{\dfrac{Q}{15}\partial_{xt}c - \dfrac{k}{2}\partial_t c \\ \qquad\qquad - \dfrac{DQ\varepsilon^\alpha}{15}\partial_{xxx}c + \dfrac{Dk\varepsilon^\alpha}{2}\partial_{xx}c\Big\}, \end{cases} \tag{145}$$

where $P_2(y) = \frac{1}{3} - y^2$ and $\tilde{P}_6 = \frac{y^6}{60} - \frac{y^4}{18} + \frac{11y^2}{180} - \frac{11}{810}$. Using (32) we find, analogous to (110)–(111), that

$$\begin{aligned} &\int_0^t \int_0^\infty \int_0^1 \tau^m \zeta(|\tilde{F}_2^\varepsilon| + |\tilde{F}_4^\varepsilon|)|\varphi|\ dxdyd\tau \\ &\le C\big(\varepsilon^{4-11\alpha/4} H(1-\alpha) + \varepsilon^{5/2-5\alpha/4} H(\alpha-1)\big)\|\varphi\|_{L^2(O_t)} \end{aligned} \tag{146}$$

for all $\varphi \in H^1(O_T)$, $\varphi = 0$ at $x = 0$ and $m > 2$.

- It should be noted that the means of the polynomials in y, contained in $\tilde{F}_1$ and $\tilde{F}_3$, are no longer zero. Hence we cannot gain powers of ε using the derivative with respect to y of the test function.
- F_5 and the boundary term $k\zeta(t)\varepsilon^{2-\alpha}\big(\partial_x c\frac{2Q}{45D} - c\frac{k}{3D}\big)$ are canceled. At the boundary $y = 1$ we have a new nonhomogeneous term

$$\hat{g}^\varepsilon = (1-\zeta)kc - \zeta\varepsilon^{4-2\alpha}\Big(\frac{2Qk^2}{45D^2}\partial_x c\tilde{P}_6|_{y=1} + \Big(\frac{k}{2D^2}\partial_t c - \varepsilon^\alpha\frac{k}{2D}\partial_{xx}c\Big)P_4|_{y=1}\Big), \tag{147}$$

and the principal boundary contribution is given by

$$\begin{aligned}&\left|\int_0^t\int_0^\infty\int_0^1 \tau^m\zeta\varepsilon^{4-2\alpha}\left(\frac{2Qk^2}{45D^2}\partial_x c\tilde{P}_6|_{y=1}\right.\right.\\&\left.\left.+\left(\frac{k}{2D^2}\partial_t c-\varepsilon^\alpha\frac{k}{2D}\partial_{xx}c\right)P_4|_{y=1}\right)\varphi|_{y=1}\;dxdyd\tau\right|\\&\le C\big(\varepsilon^{4-9\alpha/4}H(1-\alpha)+\varepsilon^{7/2-7\alpha/4}H(\alpha-1)\big)\|\varphi|_{y=1}\|_{L^2((0,t)\times(0,+\infty))}.\end{aligned}\tag{148}$$

- Other terms are much smaller and do not have to be discussed.

After collecting the powers of ε and applying Proposition 6 we obtain the estimates (140)–(142). ∎

THEOREM 6. *Let c_2^{eff} be given by* (139). *Then, with the notation of Theorem* 4, *we have*

$$\begin{aligned}&\|t^5(c^\varepsilon-c_1^{eff}(x,t;\varepsilon)-\bar{c}_1^{eff}-c_2^{eff})\|_{L^\infty(0,T;L^1(\Omega_K))}\\&\le C\big(\varepsilon^{4-3\alpha}H(1-\alpha)+\varepsilon^{2-\alpha}H(\alpha-1)\big),\end{aligned}\tag{149}$$

$$\begin{aligned}&\|t^5(c^\varepsilon-c_1^{eff}(x,t;\varepsilon)-\bar{c}_1^{eff}-c_2^{eff})\|_{L^2(0,T;L^2(\Omega_K))}\\&\le C\big(\varepsilon^{4-3\alpha}H(1-\alpha)+\varepsilon^{2-\alpha}H(\alpha-1)\big).\end{aligned}\tag{150}$$

Proof. First we prove the $L^\infty(L^1)$ estimate (149). We test the equation for $\xi=c^\varepsilon-c_1^{eff}(x,t;\varepsilon)-\bar{c}_1^{eff}-c_2^{eff}$ by a regularized sign of ξ, multiplied by Ψ^2, and get

$$\begin{aligned}&t^m\int_{\Omega^+}\Psi(x)^2|\xi|(t)\;dxdy+k\int_0^t\int_0^{+\infty}\tau^m|\xi|_{y=1}|\Psi^2(x)\;dxd\tau\\&\le C_1\int_0^t\int_{\Omega^+}\tau^m\Psi(x)^2|\Phi_2^\varepsilon|\;dxdyd\tau+\int_0^t\int_0^{+\infty}\tau^m|\hat{g}^\varepsilon|_{y=1}|\Psi^2(x)\;dxd\tau|\\&+C_2\varepsilon^\alpha\int_0^t\int_{\Omega^+}\tau^m\Psi(x)^2|\xi|\;dxdyd\tau+m\int_0^t\int_{\Omega^+}\tau^{m-1}|\xi|\Psi^2\;dxdyd\tau\end{aligned}\tag{151}$$

for all $m\ge 3$. As before, the L^1 norm of $\Psi^2\xi$ is Hölder-continuous in time with some exponent $\alpha_0>0$. Arguing as in the proof of Proposition 6, we obtain

$$\sup_{0\le t\le T}\|t^m\Psi^2\xi(t)\|_{L^1(\Omega^+)}\le C(\|\Psi^2\Phi_2^\varepsilon\|_{L^1(\Omega^+\times(0,T))}+\|\Psi^2\hat{g}^\varepsilon|_{y=1}\|_{L^1((0,+\infty)\times(0,T))}),\tag{152}$$

and the estimate (149) is proved.

The improved $L^2(L^2)$ estimate (150) follows from (149), (141), and Poincaré's inequality in H^1 (see, e.g., [6]). ∎

At this point we use Moser's iterations to obtain an $L^\infty(L^\infty)$ error estimate.

THEOREM 7. *Let $O_T=\Omega^+\times(0,T)$. Then, with the notation of Theorem* 6, *we have*

$$\begin{aligned}&\|t^5(c^\varepsilon-c_1^{eff}(x,t;\varepsilon)-\bar{c}_1^{eff}-c_2^{eff})\|_{L^\infty(O_T)}\\&\le C(\delta)\big(\varepsilon^{4-7\alpha/2-\delta}H(1-\alpha)+\varepsilon^{3/2-\alpha-\delta}H(\alpha-1)\big)\quad\forall\delta>0.\end{aligned}\tag{153}$$

Remark 6. From the proof we see that $C(\delta)$ has an exponential growth when $\delta\to 0$.

Proof. Let $M > 0$, $\xi = c^\varepsilon - c_1^{eff}(x,t;\varepsilon) - \bar{c}_1^{eff} - c_2^{eff}$, and $\xi_M = \sup\{t^m\xi - M, 0\}$. We test the equation for ξ by $\Psi^2\xi_M$ and get

$$\begin{aligned}
&\frac{1}{2}\int_{\Omega^+}\Psi(x)^2\xi_M^2(t)\ dxdy + D\varepsilon^\alpha\int_0^t\int_{\Omega^+}\Psi(x)^2|\partial_x\xi_M(\tau)|^2\ dxdyd\tau\\
&+ D\varepsilon^{\alpha-2}\int_0^t\int_{\Omega^+}\Psi(x)^2|\partial_y\xi_M(\tau)|^2\ dxdyd\tau + k\int_0^t\int_0^{+\infty}(\xi_M|_{y=1}\\
&+ M\tau^m)\xi_M|_{y=1}\Psi^2(x)\ dxd\tau \le C_1\left|\int_0^t\int_{\Omega^+}\tau^m\Psi(x)^2|\Phi_3^\varepsilon|\xi_M\ dxdyd\tau\right.\\
&\left.+\int_0^t\int_0^{+\infty}\tau^m|\hat{g}^\varepsilon|_{y=1}\xi_M|_{y=1}\Psi^2(x)\ dxd\tau\right| + C_2\varepsilon^\alpha\int_0^t\int_{\Omega^+}\tau^{2m}\Psi(x)^2\xi_M^2\ dxdyd\tau
\end{aligned} \tag{154}$$

for all $m \ge 3$, where $\tau^m\Phi_3^\varepsilon = -\tau^m\Phi_2^\varepsilon + m\tau^{m-1}\xi$. We suppose that

$$kM \ge \sup_{0\le\tau\le T}\tau^m\|\Psi\hat{g}^\varepsilon(\tau)|_{y=1}\|_{L^\infty(0,+\infty)} = c_0\big(\varepsilon^{4-5\alpha/2}H(1-\alpha) + \varepsilon^{3(1-\alpha/2)}H(\alpha-1)\big). \tag{155}$$

As in the classical derivation of the Nash–Moser estimate (see [10, pp. 181–186]) we introduce

$$\mu(M) = \int_0^T\int_{\Omega^+\cap\{t^m\xi - M > 0\}}\Psi^2\ dxdydt. \tag{156}$$

Now in exactly the same way as in [10, pp. 181–186], on a time interval which could be smaller than $[0,T]$, but assumed equal to it without losing the generality, we get

$$\begin{aligned}
&\|\xi_M\|_{V_2}^2 = \sup_{0\le t\le T}\int_{\Omega^+}\Psi(x)^2\xi_M^2(t)\ dxdy + D\varepsilon^\alpha\int_0^T\int_{\Omega^+}\Psi(x)^2|\partial_x\xi_M(\tau)|^2\ dxdyd\tau\\
&+ D\varepsilon^{\alpha-2}\int_0^T\int_{\Omega^+}\Psi(x)^2|\partial_y\xi_M(\tau)|^2\ dxdyd\tau \le \beta_0^2\|\tau^m\Phi_3^\varepsilon\Psi\|_{L^q(O_T)}^2\mu(M)^{1-2/q},\\
&q > 2.
\end{aligned} \tag{157}$$

Next, the estimate (157) is iterated in order to conclude that $\xi_M = 0$. Here we modify the classical argument from [10, pp. 102–103] and adapt it to our situation.

We note that, after making appropriate extensions, one finds

$$\|\Psi\varphi\|_{L^4(O_T)} \le c_0\|\Psi\varphi\|_{L^2(O_T)}^{1/2}\|\Psi\varphi\|_{H^1(O_T)}^{1/2} \le c_0\varepsilon^{-\alpha/4}\|\varphi\|_{V_2} \tag{158}$$

for all $\varphi \in V_2$, such that $\varphi|_{x=0} = 0$. As in [10, p. 102], at this point we take the sequence of levels $k_h = M(2-2^{-h})$, $h = 0,1,\dots$. Then

$$(k_{h+1} - k_h)\mu^{1/4}(k_{h+1}) \le \|\Psi\xi_{k_h}\|_{L^4(O_T)} \le \frac{\bar{\beta}\varepsilon^{-\alpha/4}}{k_{h+1}-k_h}\|\xi_{k_h}\|_{V_2} \tag{159}$$

and, with $\kappa = 1 - 2/q > 0$,

$$\mu^{1/4}(k_{h+1}) \le 2^h\frac{2\bar{\beta}\beta_0\|\tau^m\Phi_3^\varepsilon\Psi\|_{L^q(O_T)}\varepsilon^{-\alpha/4}}{M}\mu^{(1+\kappa)/4}(k_h). \tag{160}$$

$\mu^{1/4}(k_{h+1})$ will tend to zero for $h \to \infty$ if $\mu^{1/4}(M)$ satisfies

$$\mu^{1/4}(M) \le \left(\frac{2\bar{\beta}\beta_0 \|\tau^m \Phi_3^\varepsilon \Psi\|_{L^q(\Omega^+ \times (0,T))} \varepsilon^{-\alpha/4}}{M} \right)^{-1/\kappa} 2^{-1/\kappa^2}. \tag{161}$$

Equation (161) is satisfied if M equals the right-hand side of estimate (153). ∎

Our next result concerns higher order norms. It it not very satisfactory for large α and we state it without giving the proof, which follows from the demonstrations given above.

THEOREM 8. *With the notation of Theorem* 4, *we have*

$$\begin{aligned} &\|t^5 \partial_x (c^\varepsilon - c_1^{eff}(x,t;\varepsilon) - \bar{c}_1^{eff})\|_{L^\infty(0,T;L^2(\Omega_K))} \\ &\le C\big(\varepsilon^{4-15\alpha/4} H(1-\alpha) + \varepsilon^{(1-\alpha/2)/2} H(\alpha-1)\big), \end{aligned} \tag{162}$$

$$\begin{aligned} &\|t^5 \partial_t (c^\varepsilon - c_1^{eff}(x,t;\varepsilon) - \bar{c}_1^{eff})\|_{L^2(0,T;L^2(\Omega_K))} \\ &\le C\big(\varepsilon^{4-15\alpha/4} H(1-\alpha) + \varepsilon^{(1-\alpha/2)/2} H(\alpha-1)\big). \end{aligned} \tag{163}$$

Our final improvement concerns the error estimate in the $L^\infty(L^2)$ norm for small values of α. As mentioned in the proof of Theorem 5, $\tilde{F}_1^\varepsilon$ and $\tilde{F}_3^\varepsilon$ do not have zero means with respect to y, and consequently, the proof does not give the expected precision for the second-order correction. Nevertheless, when computing the term c^2 in the asymptotic expansion, there is a liberty of adding an arbitrary function C_2 of x and t. This function can be chosen such that the appropriate means are zero and the left-hand sides of the estimates (140)–(142) are multiplied by $\varepsilon^{1-\alpha/2}$. Unfortunately, there is a simultaneous new contribution of the form $QP_2(y)\partial_x C_2$. Its norm deteriorates the estimate for $\alpha \ge 4/5$. Consequently, this amelioration is not of real importance and we just give the result. The proof is completely analogous to the preceding ones.

COROLLARY 4. *Let the polynomials $P_j(y)$ be defined by* (143)–(145) *and let C_2 be given by the initial/boundary value problem*

(164)

$$\begin{aligned} &\frac{\partial C_2}{\partial t} + \frac{2Q}{3}\frac{\partial C_2}{\partial x} - \varepsilon^\alpha D \frac{\partial^2 C_2}{\partial x^2} \\ &= -\frac{Qk}{D}\zeta(t)\bigg\{ \partial_{xx} c \frac{Q}{D} \int_0^1 (1-y^2)\tilde{P}_6(y)\, dy + \left(\partial_{xt} c \frac{1}{2D} - \varepsilon^\alpha \partial_{xxx} c \frac{1}{2} \right) \int_0^1 (1-y^2) P_4(y)\, dy \\ &\qquad + \left(\frac{Q}{45D} \partial_x c - \frac{k}{6D} c \right) \int_0^1 (1-y^2) P_2(y)\, dy \bigg\} \\ &\quad - \frac{Q^2}{D^2}\zeta(t)\bigg\{ -\partial_{xxx} c Q \int_0^1 (1-y^2) P_8(y)\, dy \\ &\qquad + (\partial_{xxt} c - D\varepsilon^\alpha \partial_{xxxx} c) \int_0^1 (1-y^2) P_6(y)\, dy \bigg\} \quad in \quad (0,+\infty) \times (0,T), \end{aligned}$$

$$\partial_x C_2 \in L^2((0,+\infty)\times(0,T)), \quad C_2|_{t=0} = 0, \quad C_2|_{x=0} = 0. \tag{165}$$

Then, with the notation of Theorem 6 *and for $\alpha \in [0, 4/5]$ we have*

$$\|t^5 (c^\varepsilon - c_1^{eff} - \bar{c}_1^{eff} - c_2^{eff} - C_2)\|_{L^\infty(0,T;L^2(\Omega_K))} \le C\varepsilon^{5-17\alpha/4}, \tag{166}$$

$$\|t^5 \partial_y (c^\varepsilon - -c_1^{eff} - \bar{c}_1^{eff} - c_2^{eff})\|_{L^2(0,T;L^2(\Omega_K))} \le C\varepsilon^{6-19\alpha/4}, \tag{167}$$

$$\|t^5 \partial_x (c^\varepsilon - c_1^{eff} - \bar{c}_1^{eff} - c_2^{eff} - C_2)\|_{L^2(0,T;L^2(\Omega_K))} \le \varepsilon^{5-19\alpha/4}. \tag{168}$$

Acknowledgments. The authors are grateful to I. S. Pop for his assistance and they acknowledge the referees for their valuable comments.

THE KELLER–SEGEL MODEL FOR CHEMOTAXIS WITH PREVENTION OF OVERCROWDING: LINEAR VS. NONLINEAR DIFFUSION*

MARTIN BURGER†, MARCO DI FRANCESCO‡, AND YASMIN DOLAK-STRUSS§

Abstract. The aim of this paper is to discuss the effects of linear and nonlinear diffusion in the large time asymptotic behavior of the Keller–Segel model of chemotaxis with volume filling effect. In the linear diffusion case we provide several sufficient conditions for the diffusion part to dominate and yield decay to zero solutions. We also provide an explicit decay rate towards self–similarity. Moreover, we prove that no stationary solutions with positive mass exist. In the nonlinear diffusion case we prove that the asymptotic behavior is fully determined by whether the diffusivity constant in the model is larger or smaller than the threshold value $\varepsilon = 1$. Below this value we have existence of nondecaying solutions and their convergence (along subsequences) to stationary solutions. For $\varepsilon > 1$ all compactly supported solutions are proved to decay asymptotically to zero, unlike in the classical models with linear diffusion, where the asymptotic behavior depends on the initial mass.

Key words. chemotaxis, nonlinear diffusion, asymptotic behavior, Keller–Segal model, overcrowding

1. Introduction.

This paper focuses on the mathematical analysis of a chemotaxis model in the cases of linear and nonlinear diffusion. The general structure of the model we consider is

$$\begin{cases} \dfrac{\partial \rho}{\partial t} = \nabla \cdot (M(\rho) \nabla \mu(\rho, S)) \\ -\Delta S + S = \rho, \end{cases} \tag{1.1}$$

posed on $\mathbb{R}^d \times \mathbb{R}^+$ subject to the initial condition

$$\rho(x,0) = \rho_0(x), \quad \rho_0 \in L^1(\mathbb{R}^d), \quad 0 \le \rho_0(x) \le 1, \quad x \in \mathbb{R}^d. \tag{1.2}$$

The mobility term M is given by $M(\rho) = \rho(1-\rho)$. Such a choice takes into account the prevention of the overcrowding effect, sometimes also referred to as "volume filling" effect (see the motivations and references below). The potential μ reads

$$\mu(\rho, S) = \frac{\delta E}{\delta \rho}(\rho, S), \tag{1.3}$$

where $\frac{\delta E}{\delta \rho}$ denotes the functional derivative of some energy functional with respect to ρ. If we model the energy as a combination of a logarithmic entropy and an aggregation part, i.e.,

$$\begin{aligned} E(\rho, S) = \varepsilon \int_{\mathbb{R}^d} (\rho \log \rho + (1-\rho)\log(1-\rho))\ dx \\ - \int_{\mathbb{R}^d} \rho S\ dx + \frac{1}{2} \int_{\mathbb{R}^d} \left(|\nabla S|^2 + S^2\right)\ dx, \end{aligned} \tag{1.4}$$

with $\varepsilon > 0$, then system (1.1) becomes

$$\begin{cases} \dfrac{\partial \rho}{\partial t} = \nabla \cdot (\varepsilon \nabla \rho - \rho(1-\rho)\nabla S) \\ -\Delta S + S = \rho, \end{cases} \tag{1.5}$$

which is a special case of the Keller–Segel model for chemotaxis, describing the behavior of a cell population ρ under the influence of the chemical S produced by the cells themselves. Introduced in 1970 [KS70] to describe aggregation of slime mold amoebae, this model has become one of the most widely studied models in mathematical biology. The cell flux on the right-hand side of (1.5) comprises two counteracting phenomena: random motion of cells described by Fick's law and cell movement in the direction of the gradient of the chemical S. In contrast to the equations presented here, the gradient of S is multiplied by a linear instead of a nonlinear function of ρ in the classical version of the model. An interesting feature of this choice is the fact that solutions can become unbounded in finite time, thus giving rise to concentration phenomena. Whether this blow-up of solutions occurs or not depends typically on the initial data and the space dimension d, and conditions for the blow-up of solutions have been derived by many authors (see [Hor03, Hor04] and the references therein). Most studies focus on models where the evolution of the chemical S is governed by a parabolic equation (as in the original Keller–Segel model). Typical alternative formulations for the evolution of S are given either by an elliptic equation of a more general form than in (1.1) or by the Poisson equation. In the majority of the cases, the model is considered on bounded domains, typically with Neumann boundary conditions. Concerning the case of an unbounded domain, an extensive analysis of the model on $\mathbb{R}^d$, $d \geq 2$, has been performed recently in [CPZ04], where the authors prove that solutions exist globally when the $L^{d/2}$-norm of the initial data does not exceed a critical value. In the recent contribution [DP04] it is proved that the critical value 8π of the initial mass produces an optimal threshold between blow-up and global existence when $d = 2$.

Although of great mathematical interest, models allowing for the infinite growth of solutions have often been criticized because their biological interpretation is not fully understood. Several generalizations of the Keller–Segel model, where the formation of singularities is prevented *a priori*, have been studied recently (see, e.g., [HP01]). These models superimpose a maximal value for the cell density, which yields the global existence of solutions. Such an assumption is reasonable in certain physical situations where cells stop aggregating after a certain size of the aggregate has been reached. The model presented in [HP01] is of type (1.5) but with a parabolic equation for S. Note that the main difference from a standard derivation of the model without prevention of overcrowding is the additional factor $(1-\rho)$ in the mobility term $M(\rho)$ in (1.1) and the additional entropy term depending on $(1-\rho)$ in the energy. Intuitively, this change of mobility seems obvious, since the possibility of cells to move freely

is limited by the cells around them. Therefore, in the case of overcrowding (which happens in our scaling for $\rho \geq 1$) their motion would be stopped. It is less obvious how to interpret the additional entropy term depending on $(1-\rho)$—it somehow forces cells to diffuse even in the case of overcrowding. On the other hand if the volume-filling mechanism is thought of as a finite size effect really blocking the cells, then also no diffusion would be allowed and the volume-filling effect would have consequences only upon mobility but not on the energy. Such a possibility is supported by results in [BO04], where the authors observe that many chemicals appear both to stimulate directed motion up the chemotactic gradient and to alter the random mobility (i.e., the nonlinear diffusion coefficient). As a consequence of that, they establish a direct relationship between the chemotaxis and random motion coefficients. In particular, they both may vanish at the threshold value of the density.

This argument is the main reason why we shall also discuss a different choice for the energy in this paper. More precisely, we shall use a quadratic energy of the form

$$E(\rho, S) = \frac{\varepsilon}{2} \int_{\mathbb{R}^d} \rho^2 \, dx - \int_{\mathbb{R}^d} \rho S \, dx + \frac{1}{2} \int_{\mathbb{R}^d} \left(|\nabla S|^2 + S^2 \right) \, dx, \tag{1.6}$$

yielding the degenerate parabolic-elliptic problem

$$\begin{cases} \dfrac{\partial \rho}{\partial t} = \nabla \cdot (\rho(1-\rho)\nabla(\varepsilon\rho - S)) \\ -\Delta S + S = \rho. \end{cases} \tag{1.7}$$

Several reformulations of the Keller–Segel model have been studied recently, with a nonlinear diffusion term in the evolution of the cell density replacing the linear one (see [Hor03, Chapter 6]). An interesting issue is whether it is possible to avoid blow-up of solutions by introducing nonlinear diffusion effects without the help of the volume-filling term in the mobility (see also [CC05]). We stress that the main feature in our nonlinear model (1.7) is that the random mobility vanishes at the threshold value $\rho = 1$. Such a property is not usually covered in the literature concerning chemotaxis models with nonlinear diffusion.

A further reason to study (1.7) relates to the asymptotic behavior of its solutions, in particular to the possibility of achieving either existence of nontrivial stationary solutions or a large time decay to zero in L^∞. Whether the former or the latter phenomenon takes place depends upon the size of the diffusivity ε. We recall that the long-time asymptotics of the linear case (1.5) in bounded intervals (under Neumann boundary conditions) have been recently studied in [DS05] and, with a parabolic equation for S, in [PH05]. The observed behavior is a coarsening process reminiscent of phase change models, where plateau-like peaks of the cell density form after a short transition period and then merge exponentially slowly. Numerical studies indicate that in most situations the only stable stationary states are single plateaus located at the boundary of the domain. It is therefore not surprising that the behavior of solutions on the whole space is different. Roughly speaking, the cells are not stopped by any boundaries and therefore the linear model would allow them to spread out rather than aggregate. We shall make this statement more rigorous by several results on the decay of the cell density ρ for large time. For now we emphasize that, to our knowledge, system (1.7) is the only one known to admit stationary profiles on the whole space.

In order to make the comparison between the linear and nonlinear diffusion case more concrete, we provide a guideline through the paper for readers who are interested

in the results rather than on the detailed proofs. The first step towards the large time behavior of solutions is an investigation of possible stationary solutions. Here we find a first difference between the two cases. More precisely, no finite mass stationary solutions different from zero exist for linear diffusion (subsection 2.2.1), while finite mass nontrivial stationary solutions do exist for nonlinear diffusion in the case $\varepsilon < 1$ (subsection 3.4.2). A partly numerical construction of stationary solutions even indicates their existence for arbitrary mass if $\varepsilon < 1$ (section 3.5). The detailed large-time behavior is described by:

- Decay to zero of solutions in the linear diffusion case in the following two cases:
  - with arbitrary initial mass for $\varepsilon > \frac{1}{4}$ in 1–d (section 2.2),
  - with small initial mass for arbitrary $\varepsilon > 0$ (section 2.2).

  In both cases, solutions converge in L^1 towards the self-similar Gaussian solution of the heat equation with variance ε (section 2.3).
- Existence of nondecaying solutions for $\varepsilon < 1$ in the nonlinear case (subsection 3.4.1). These solutions converge (along subsequences) to stationary solutions (subsection 3.4.2). For $\varepsilon > 1$ all compactly supported solutions decay and their support must become unbounded as $t \to \infty$ (subsection 3.4.3).

2. Linear diffusion. In this section, we first cover the existence and uniqueness theory for weak solutions of model (1.5). We then turn our attention to the asymptotic behavior for large time.

2.1. Existence theory and preliminaries. We study the Cauchy problem for the following parabolic-elliptic system

$$\begin{cases} \frac{\partial \rho}{\partial t} = \varepsilon \Delta \rho - \nabla \cdot (\rho(1-\rho)\nabla S) \\ -\Delta S + S = \rho, \\ \rho(x,0) = \rho_0(x), \end{cases} \tag{2.1}$$

where $x \in \mathbb{R}^d$, $d \geq 1$, $t \geq 0$, $\varepsilon > 0$, ρ, and S are scalar functions, and ρ_0 belongs in $L^1(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d)$. We recall that the above system can be decoupled in order to get a nonlocal parabolic equation for ρ by means of the convolution representation formula

$$S(x,t) = \int_{\mathbb{R}^d} \mathcal{B}(x-y)\rho(y,t)dy, \tag{2.2}$$

where $\mathcal{B}$ is the *Bessel potential*

$$\mathcal{B}(x) = \frac{1}{(4\pi)^{d/2}} \int_0^{+\infty} \frac{e^{-t-\frac{|x|^2}{4t}}}{t^{d/2}} dt. \tag{2.3}$$

For further reference we recall the formula for the heat convolution kernel

$$\mathcal{G}(x,t) = \frac{1}{(4\pi\varepsilon t)^{d/2}} e^{-\frac{|x|^2}{4\varepsilon t}}, \quad x \in \mathbb{R}^d,\ t > 0. \tag{2.4}$$

The proof of the following lemma follows by straightforward computations.

LEMMA 2.1. *The following estimates are satisfied:*

$$\|\mathcal{B}\|_{L^1(\mathbb{R}^d)} = 1, \tag{2.5}$$

$$\|\nabla \mathcal{B}\|_{L^1(\mathbb{R}^d)} < +\infty, \tag{2.6}$$

$$\|\mathcal{G}(\cdot,t)\|_{L^p(\mathbb{R}^d)} \leq Ct^{-\frac{d(p-1)}{2p}}, \quad p \geq 1, \tag{2.7}$$

$$\|\nabla \mathcal{G}(\cdot,t)\|_{L^p(\mathbb{R}^d)} \leq Ct^{-\frac{d(p-1)}{2p}-\frac{1}{2}}, \quad p \geq 1, \tag{2.8}$$

The estimates provided by the previous lemma enable us to prove local existence of $L^1 \cap L^\infty$ solutions of (2.1) by means of the implicit representation formula

$$\rho(x,t) = (\mathcal{G} * \rho_0)(x,t) + \int_0^t \int_{\mathbb{R}^d} \nabla \mathcal{G}(x-y, t-s)\, (\rho(1-\rho)\nabla(\mathcal{B} * \rho))(y,s) dsdy \tag{2.9}$$

and by a standard fixed point argument. This leads to the following theorem, whose proof is rather standard and will be omitted (see also [Hor03] and the references therein for the local existence theory of other models closely related to (2.1)).

THEOREM 2.2 (local existence). *Let $\rho_0 \in L^1(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d)$ (resp., $\rho_0 \in L^\infty(\mathbb{R}^d)$). Then, there exists a unique solution $\rho(x,t)$ to* (2.1) *such that*

$$\rho \in L^\infty\left([0,T], L^1(\mathbb{R}^d) \cap L^\infty(\mathbb{R}^d)\right)$$

(resp., $\rho \in L^\infty\left([0,T], L^\infty(\mathbb{R}^d)\right)$) for a small enough positive time T.

Again by standard fixed point technique, the local-in-time solution $\rho(x,t)$ provided by Theorem 2.2 can be endowed with the same regularity (with respect to x) as the initial datum. Some regularity for ρ without the help of any further requirements on the initial datum can be obtained at least in 1–d.

PROPOSITION 2.3 (regularizing effect). *Let the initial datum $\rho_0 \in L^1(\mathbb{R}) \cap L^\infty(\mathbb{R})$. Then, at any positive time t, the solution $\rho(t)$ of* (2.1) *is continuous with respect to x.*

Proof. Since $\mathcal{G} * \rho_0$ is a C^∞ function, we only need to prove that $\rho - \mathcal{G} * \rho_0$ is continuous. By formula (2.9), we have for small $h > 0$

$$\begin{aligned}&(\rho - \mathcal{G} * \rho_0)(x+h,t) - (\rho - \mathcal{G} * \rho_0)(x,t)\\ &= \int_0^t \int_{-\infty}^{+\infty} \left[\mathcal{G}_x(x+h-y, t-s) - \mathcal{G}_x(x-y,t-s)\right] (\rho(1-\rho)\nabla(\mathcal{B} * \rho))(y,s) dsdy.\end{aligned}$$

We recall that the term $(\rho(1-\rho)\nabla(\mathcal{B} * \rho))$ is (locally) bounded. Moreover, thanks to (2.8) we can find nonnegative functions $H(x,y,t,s)$ and $K \in L^1$ such that

$$|\mathcal{G}_x(x+h-y,t-s) - \mathcal{G}_x(x-y,t-s)| \le H(x,y,t,s) \le (t-s)^{-1} K\left(\frac{|x-y|^2}{t-s}\right).$$

Therefore, the limit as $h \to 0$ in the above integral is zero due to Lebesgue's dominated convergence theorem. ∎

The representation formula (2.9) is also the basis of the result in the following proposition, the proof of which is again omitted.

PROPOSITION 2.4 (continuity with respect to the initial data). *Let ρ and $\overline{\rho}$ be two local-in-time solutions to* (2.1)*, with initial data $\rho_0, \overline{\rho}_0 \in L^1 \cap L^\infty$, respectively. Then, for a small T we have*

$$\|\rho(t) - \overline{\rho}(t)\|_{L^1} \le C(T) \|\rho_0 - \overline{\rho}_0\|_{L^1} \tag{2.10}$$

for all $t \in [0,T]$.

As suggested by the divergence form, L^1 solutions of (2.1) preserve the total mass, i.e.,

$$\int_{\mathbb{R}^d} \rho(x,t) dx = \int_{\mathbb{R}^d} \rho_0(x) dx. \tag{2.11}$$

The proof of the above identity is standard (see, for instance, [Váz92, Chapter III–section 2]).

In order to achieve global existence of solutions, from now on in this section we shall restrict our analysis to the case of initial data ρ_0 in (2.1) satisfying the assumption

$$0 \le \rho_0(x) \le 1, \quad x \in \mathbb{R}^d. \tag{2.12}$$

Our next aim is to prove that condition (2.12) is invariant under the flow induced by the model (2.1). Such a property together with the conservation of the total mass will imply the global existence of the solution of (2.1). Similar properties are proved in [HP01] for the fully parabolic model and in [DS05] in a bounded domain.

THEOREM 2.5 (global existence). *Assume the initial datum $\rho_0 \in L^1(\mathbb{R}^d)$ satisfies* (2.12)*. Then there exists a unique global solution to the Cauchy problem* (2.1)*, satisfying*

$$0 \le \rho(x,t) \le 1 \quad \textit{for any} \quad (x,t) \in \mathbb{R}^d \times [0,\infty). \tag{2.13}$$

In particular,

$$0 < \rho(x,t) < 1 \quad \textit{if} \quad 0 < \rho_0(x) < 1. \tag{2.14}$$

Proof. Writing (2.1) as $\rho_t + \nabla\rho \cdot \nabla S(1-2\rho) + \rho(1-\rho)(S-\rho) = \varepsilon\Delta\rho$, it can be seen immediately that $\underline{\rho} \equiv 0$ and $\overline{\rho} \equiv 1$ are lower and upper solutions, respectively. By the mean value theorem of multidimensional calculus, the function $\underline{w}(x,t) = \rho - \underline{\rho}$ satisfies the inequality

$$\underline{w}_t + A(x,t)\nabla\underline{w} + B(x,t)\underline{w} - \varepsilon\Delta\underline{w} \ge 0,$$

with bounded coefficients $A(x,t)$ and $B(x,t)$. For $\overline{w}(x,t) = \rho - \overline{\rho}$, the same equations with a reversed inequality sign holds, and the boundedness of ρ follows from the Phragmèn–Lindelöf principle for parabolic equations [PW84]. Therefore the proof is complete in view of the conservation of the total mass. ∎

2.2. Decay of solutions as $t \to +\infty$. In this subsection we determine sufficient conditions on the diffusivity constant ε in (2.1) and on the initial datum ρ_0 such that the $L^\infty(\mathbb{R}^d)$ norm of the corresponding solution $\rho(x,t)$ tends to zero as $t \to +\infty$. We prove here that this is the case either when the total mass is smaller than a threshold value depending on ε or without any condition on the total mass in case $\varepsilon > 1/4$ and $d = 1$. It is already known in case of models without prevention of overcrowding that, when the mass of the initial datum is much smaller than some constant depending on ε, the diffusion term becomes dominant and produces a long time decay of the solution (see [CPZ04, DP04]). For the sake of completeness we shall reproduce the same result for our model in the following proposition, the proof of which is partly the same as in [CPZ04].

PROPOSITION 2.6. *Let $\varepsilon > 0$ and let $\rho_0 \in L^1(\mathbb{R}^d)$ satisfy* (2.12)*. Then, there exists a constant $C(d)$ depending only on the dimension d such that, for total mass satisfying*

$$\int_{\mathbb{R}^d} \rho_0 dx < \left(\frac{4\varepsilon}{C(d)}\right)^{1/\beta} \qquad \beta = \min\{1, 2/d\}. \tag{2.15}$$

The solution $\rho(x,t)$ to (2.1) satisfies the decay estimates

$$\|\rho(t)\|_{L^p(\mathbb{R}^d)} \le C(t+1)^{-\frac{d(p-1)}{2p}} \quad \text{if } 2 \le p < +\infty, \tag{2.16}$$

$$\|\rho(t)\|_{L^\infty(\mathbb{R}^d)} \le C(t+1)^{-\frac{d}{2}}. \tag{2.17}$$

Proof. Let us start with the L_p estimates for finite p. By multiplying the equation in (2.1) by $p\rho^{p-1}$ and after integration by parts we obtain

$$\begin{aligned}
&\frac{d}{dt}\int_{\mathbb{R}^d} \rho^p(x,t)dx = \varepsilon p \int_{\mathbb{R}^d} \rho^{p-1}\Delta\rho dx + p(p-1)\int_{\mathbb{R}^d}(\rho^{p-1}-\rho^p)\nabla S\cdot\nabla\rho dx\\
&\le -\varepsilon\frac{4(p-1)}{p}\int_{\mathbb{R}^d}|\nabla\rho^{p/2}|^2dx + (p-1)\int_{\mathbb{R}^d}\nabla\rho^p\cdot\nabla S dx\\
&\le -\varepsilon\frac{4(p-1)}{p}\int_{\mathbb{R}^d}|\nabla\rho^{p/2}|^2dx + (p-1)\int_{\mathbb{R}^d}\rho^{p+1}dx,
\end{aligned}$$

where we have used the a priori estimate $0 \le \rho \le 1$ and $S \ge 0$. By means of the Gagliardo–Nirenberg inequality (see also [CPZ04])

$$\int_{\mathbb{R}^d}\rho^{p+1}dx \le C(d)\|\rho\|_{L^\alpha(\mathbb{R}^d)}\int_{\mathbb{R}^d}|\nabla\rho^{p/2}|^2dx,$$

where $\alpha = 1$ for $d = 1, 2$, $\alpha = d/2$ for $d > 2$, we easily get

$$\frac{d}{dt}\int_{\mathbb{R}^d}\rho^p(x,t)dx \le -(p-1)\left(\frac{4\varepsilon}{p} - C(d)\left(\int_{\mathbb{R}^d}\rho_0 dx\right)^\beta\right)\int_{\mathbb{R}^d}|\nabla\rho^{p/2}|^2dx,$$

where $\beta = \min\{1, 2/d\}$. Hence, for

$$\int_{\mathbb{R}^d}\rho_0 dx < \left(\frac{4\varepsilon}{pC(d)}\right)^{1/\beta}, \tag{2.18}$$

we can write, for some $C > 0$,

$$\frac{d}{dt}\int_{\mathbb{R}^d}\rho^p(x,t)dx + C\int_{\mathbb{R}^d}|\nabla\rho^{p/2}|^2dx \le 0.$$

Thanks to the following interpolation inequality (see, e.g., [EZ91]):

$$\|\rho\|_{L^p(\mathbb{R}^d)}^{\frac{(d(p-1)+2)p}{d(p-1)}} \le \overline{C}(p,d)\|\nabla\rho^{p/2}\|_{L^2(\mathbb{R}^d)}^2\|\rho\|_{L^1(\mathbb{R}^d)}^{\frac{2p}{d(p-1)}},$$

we have

$$\frac{d}{dt}\int_{\mathbb{R}^d}\rho^p(x,t)dx + Cm\left(\int_{\mathbb{R}^d}\rho^p dx\right)^{\frac{d(p-1)+2}{d(p-1)}} \le 0,$$

which implies the desired polynomial time-decay in L^p

$$\|\rho(t)\|_{L^p(\mathbb{R}^d)} \le C(p,d)(t+1)^{-d(p-1)/2p}, \tag{2.19}$$

where the term $(t+1)$ instead of t is justified by the global-in-time control of all the L^p norms proved in the previous subsection. We remark that the previous L^p decay

has been obtained for solutions with initial data satisfying (2.18) where the constant on the right-hand side depends on p, unlike in the statement of Theorem 2.5. We shall recover the threshold condition (2.15) later on in this proof. In order to obtain the L^∞ estimate (2.17), we employ the implicit representation of the solution ρ provided by the Duhamel principle

$$\begin{aligned}\rho(x,2t) &= \mathcal{G}(t) * \rho(t) + \int_t^{2t} \nabla\mathcal{G}(2t-\sigma) * (\rho(1-\rho)\nabla\mathcal{B} * \rho)(\sigma)d\sigma \\ &= \mathcal{G}(2t) * \rho(t) + \int_0^t \nabla\mathcal{G}(t-s) * (\rho(1-\rho)\nabla\mathcal{B} * \rho)(t+s)ds. \qquad (2.20)\end{aligned}$$

By taking the L^∞ norm in (2.20), we obtain

$$\begin{aligned}&\|\rho(2t)\|_{L^\infty(\mathbb{R}^d)} \le \|\mathcal{G}(t)\|_{L^\infty(\mathbb{R}^d)}\|\rho(t)\|_{L^1(\mathbb{R}^d)} \\ &+ \int_0^t \|\nabla\mathcal{G}(t-s)\|_{L^r(\mathbb{R}^d)}\|\rho(1-\rho)\nabla\mathcal{B} * \rho(t+s)\|_{L^{r'}(\mathbb{R}^d)}ds \\ &\le Ct^{-\frac{d}{2}} + C\int_0^t (t-s)^{-\frac{d(r-1)}{2r}-\frac{1}{2}}\|\rho(t+s)\|^2_{L^{2r'}(\mathbb{R}^d)}ds, \qquad r' = \frac{r}{r-1}.\end{aligned}$$

Here $r > 1$ can be chosen arbitrarily with the only restriction $r < \frac{d}{d-2}$ in case $d > 2$. Once r and r' are fixed, we require that ρ_0 satisfies (2.18) with $p = 2r'$. Hence, (2.19) implies

$$\|\rho(2t)\|_{L^\infty(\mathbb{R}^d)} \le Ct^{-\frac{d}{2}} + \int_0^t (t-s)^{-\frac{d(r-1)}{2r}-\frac{1}{2}}(t+s)^{-\frac{d(2r'-1)}{2r'}}ds = Ct^{-\frac{d}{2}} + Ct^{\frac{1}{2}-d}.$$

Since $\|\rho(t)\|_{L^\infty(\mathbb{R}^d)}$ is uniformly bounded and since $d \ge 1$, we obtain the estimate

$$\|\rho(t)\|_{L^\infty(\mathbb{R}^d)} \le C(t+1)^{-\frac{d}{2}}$$

and the L^p decay rates (2.16) can be easily obtained by interpolation. □

In the next proposition we prove that solutions to (2.1) enjoy a time decay rate as in (2.16) no matter how large the mass is, provided $\varepsilon > 1/4$ and $d = 1$. This result constitutes an essential difference of the present model with respect to the classical Keller–Segel type models.

PROPOSITION 2.7. *Let $\varepsilon > 1/4$ and $d = 1$. Let $\rho_0 \in L^1(\mathbb{R})$ satisfying (2.12). Then, the solution $\rho(x,t)$ to (2.1) satisfies the decay estimates*

$$\|\rho(t)\|_{L^p(\mathbb{R})} \le C(t+1)^{-\frac{(p-1)}{2p}}, \quad 2 \le p \le \infty. \qquad (2.21)$$

Proof. We start with the L^2 estimate

$$\begin{aligned}\frac{d}{dt}\int_{\mathbb{R}} \rho^2(x,t)dx &= 2\varepsilon\int_{\mathbb{R}} \rho\rho_{xx}dx + 2\int_{\mathbb{R}} \rho(1-\rho)S_x\rho_x dx \\ &\le -2\varepsilon\int_{\mathbb{R}} \rho_x^2 dx + \frac{1}{2}\int_{\mathbb{R}} |\rho_x S_x|dx.\end{aligned}$$

As a consequence of the Young inequality for convolutions we have (recalling (2.2))

$$\frac{d}{dt}\int_{\mathbb{R}} \rho^2(x,t)dx \le -2\left(\varepsilon - \frac{1}{4}\right)\int_{\mathbb{R}} \rho_x^2 dx.$$

Then, by means of the Gagliardo–Nirenberg inequality, as in the previous proposition, we obtain the decay in L^2

$$\|\rho(t)\|_{L^2(\mathbb{R})} \leq C(t+1)^{-1/4}.$$

By taking the L^4 norm in the representation (2.20), in a similar fashion as in the previous proposition, we obtain

$$\begin{aligned}\|\rho(2t)\|_{L^4(\mathbb{R})} &\leq C(t+1)^{-3/8} + \int_0^t \|\nabla \mathcal{G}(t-s)\|_{L^4} \|\rho \nabla \mathcal{B} * \rho(t+s)\|_{L^1} ds \\ &\leq C(t+1)^{-3/8} + \int_0^t (t-s)^{-7/8}(t+s)^{-1/2} ds \leq C(t+1)^{-3/8} + Ct^{-3/8}.\end{aligned}$$

Finally,

$$\begin{aligned}\|\rho(2t)\|_{L^\infty(\mathbb{R})} &\leq C(t+1)^{-1/2} + \int_0^t \|\nabla \mathcal{G}(t-s)\|_{L^2} \|\rho \nabla \mathcal{B} * \rho(t+s)\|_{L^2} ds \\ &\leq C(t+1)^{-1/2} + \int_0^t (t-s)^{-3/4}(t+s)^{-3/4} ds \leq C(t+1)^{-1/2}.\end{aligned}$$

The remaining L^p estimates are easily obtained by interpolation. ∎

2.2.1. Some remarks and the nonexistence of stationary solutions. Clearly, an open question is whether solutions to (2.1) decay for any ε and for arbitrarily large masses. In bounded domains, for $d = 1$ and Neumann boundary conditions, solutions of the system (2.1) has been shown to decay to the constant solution if $\varepsilon > \frac{1}{4}$, but if ε is small enough, stationary, periodic solutions in $L^1((0, L))$ exist (see [DS05] and [PH05]). However, one can easily prove that there exist no nonzero stationary solutions to (2.1) in $L^1(\mathbb{R}^d)$ in the case of unbounded domains: We define the energy functional $E(\rho, S)$ of system (2.1) by

$$E = \frac{1}{2}\int (|\nabla S|^2 + S^2) dx - \int \rho S dx + \varepsilon \int [\rho \log \rho + (1-\rho)\log(1-\rho)] dx, \tag{2.22}$$

with

$$\frac{\partial E}{\partial \rho} = -S + \varepsilon \log \frac{\rho}{(1-\rho)} \quad \text{and} \quad \frac{\partial E}{\partial S} = -\Delta S + S - \rho. \tag{2.23}$$

Rewriting the first equation of (2.1) as

$$\frac{\partial \rho}{\partial t} = \nabla \cdot \left(\rho(1-\rho) \nabla \frac{\partial E}{\partial \rho} \right), \tag{2.24}$$

and differentiating the energy with respect to time, we obtain

$$\begin{aligned}\frac{dE}{dt} =& \frac{\partial E}{\partial S}\frac{\partial S}{\partial t} + \frac{\partial E}{\partial \rho}\frac{\partial \rho}{\partial t} = \int \nabla \cdot \left(\rho(1-\rho) \nabla \frac{\partial E}{\partial \rho} \right) \frac{\partial E}{\partial \rho} dx \\ =& -\int \rho(1-\rho) \left| \nabla \frac{\partial E}{\partial \rho} \right|^2 dx \leq 0.\end{aligned}$$

Hence, the energy is decreasing in time, and the stationary state $\frac{dE}{dt} = 0$ is only reached if $\rho = 0$, $\rho = 1$ or $\frac{\partial E}{\partial \rho} =$const., the latter implying that the stationary solution (ρ, S) should satisfy, for some positive constant C,

$$\frac{\rho}{1-\rho} = e^{\frac{S+C}{\varepsilon}},$$

in some open set $\Omega \subset \mathbb{R}^d$, with $\rho = 0$ at some point of $\partial\Omega$. However, this is incompatible with S being bounded, because of the continuity of ρ stated in Proposition 2.3.

2.3. Self-similar long time behavior. The aim of this subsection is to prove that, under suitable assumptions on the initial datum ρ_0, the solution of (2.1) decays towards the fundamental solution of the heat equation with a polynomial rate. To perform this task we employ the entropy dissipation method (see [AMTU01]). The long time decay properties of the solution $\rho(x,t)$ are a crucial ingredient in the arguments below. We shall prove our result by assuming *a priori* that the solution $\rho(x,t)$ satisfies the decay estimate

$$\|\rho(t)\|_{L^\infty(\mathbb{R}^d)} \le C(t+1)^{-\frac{d}{2}} \tag{2.25}$$

which we proved to be fulfilled under the assumptions in Propositions 2.6 and 2.7. Our first step is the following standard time dependent rescaling:

$$\begin{cases} \rho(x,t) = R(t)^{-\frac{d}{2}} v(y,s), \\ y = R(t)^{-\frac{1}{2}} x, \\ s = \frac{1}{2}\log R(t), \\ R(t) = 2t+1. \end{cases} \tag{2.26}$$

Then, it is easy to see that $v(y,s)$ solves the Cauchy problem

$$\begin{cases} \frac{\partial v}{\partial s} = \nabla\cdot(\varepsilon\nabla v + yv) - e^{-ds}\nabla\cdot(v(1-e^{-s}v)\mathcal{B}_s * \nabla v) \\ v(y,0) = \rho_0(y), \end{cases} \tag{2.27}$$

where $\mathcal{B}_s(y) = e^s\mathcal{B}(e^s y)$. For future reference we write (2.27) as follows:

$$\frac{\partial v}{\partial s} = \varepsilon\nabla\cdot\left(v\nabla\left(\log v + \frac{|y|^2}{2\varepsilon}\right)\right) - e^{-ds}\nabla\cdot(v(1-e^{-s}v)\mathcal{B}_s * \nabla v). \tag{2.28}$$

We remark that the fundamental solution $\mathcal{G}(x,t)$ of the heat equation in rescaled variables depends only on y; more precisely, it is given by $\mathcal{U}_m(y) = Ce^{-\frac{|y|^2}{2\varepsilon}}$, where C depends on the mass m of ρ_0. Moreover, we recall that $\mathcal{U}_m$ satisfies the elliptic equation $\nabla\cdot(\varepsilon\nabla\mathcal{U}_m + y\mathcal{U}_m) = 0$. We shall make use of the classical entropy functional

$$\mathrm{E}(v) = \int_{\mathbb{R}^d} v(y)\log v(y)dy + \frac{1}{2\varepsilon}\int_{\mathbb{R}^d}|y|^2 v(y)dy, \tag{2.29}$$

and of the *relative entropy* $\mathrm{RE}(v|\mathcal{U}_m) = \mathrm{E}(v) - \mathrm{E}(\mathcal{U}_m)$. Once the mass m is fixed, the relative entropy functional attains zero as minimum value at the ground state $\mathcal{U}_m$. The following inequality (see [AMTU00] for the proof) establishes a connection between the convergence in relative entropy and the convergence in L^1.

THEOREM 2.8 (Csiszár–Kullback inequality). *Let $v \in L^1(\mathbb{R}^d)$ having mass m. Then, there exists a fixed constant C (depending on m) such that*

$$\|v - \mathcal{U}_m\|^2 \le C\mathrm{RE}(v|\mathcal{U}_m). \tag{2.30}$$

For future reference, we recall the following logarithmic Sobolev inequality (see, e.g., [AMTU01]).

THEOREM 2.9 (logarithmic Sobolev inequality). *Let $v \in L^1(\mathbb{R}^d)$ having mass m and such that $\mathrm{E}(v) < +\infty$. Then, the following inequality is satisfied:*

$$\mathrm{RE}(v|\mathcal{U}_m) \leq \frac{\varepsilon}{2}\mathrm{I}(v|\mathcal{U}_m), \tag{2.31}$$

where

$$\mathrm{I}(v|\mathcal{U}_m) = \int_{\mathbb{R}^d} v \left|\nabla\left(\log\frac{v}{\mathcal{U}_m}\right)\right|^2 dy = \int_{\mathbb{R}^d} v \left|\nabla\left(\log v + \frac{|y|^2}{2\varepsilon}\right)\right|^2 dy$$

is called (relative) Fisher information.

Finally, we remark that assumption (2.25) for ρ in the new variables $v(y,s)$ reads

$$\|v(s)\|_{L^\infty(\mathbb{R}^d)} \leq C \tag{2.32}$$

for some fixed $C > 0$ depending only on the initial datum. We are ready to state the main theorem of this subsection.

THEOREM 2.10. *Let $\rho \in L^1(\mathbb{R}^d)$ satisfy* (2.12) *and $\mathrm{E}(\rho_0) < \infty$, where* E *is defined in* (2.29). *Suppose that the corresponding solution $\rho(x,t)$ to* (2.1) *satisfies the time decay condition* (2.25). *Then,*

$$\|\rho(t) - \mathcal{G}(t)\|_{L^1(\mathbb{R}^d)} = \begin{cases} o(t^{-\frac{1}{2}+\delta}) & \text{for arbitrary } 0 < \delta \ll 1 \quad \text{if } d = 1 \\ O(t^{-\frac{1}{2}}) & \text{if } d > 1, \end{cases} \tag{2.33}$$

where $\mathcal{G}$ is the Gaussian solution (2.4) *of the heat equation with same mass as ρ_0.*

Proof. In what follows, we shall denote a generic positive constant independent on s by C. Let us multiply (2.27) by $\log v(y) + \frac{|y|^2}{2\varepsilon}$ and integrate over $\mathbb{R}^d$. Then, integration by parts and conservation of the total mass yield

$$\begin{aligned}
&\frac{d}{ds}\mathrm{E}(v(s)|\mathcal{U}_m) = -\varepsilon\int_{\mathbb{R}^d} v\left|\nabla\left(\log\frac{v}{\mathcal{U}_m}\right)\right|^2 dy + Ce^{-ds}\int_{\mathbb{R}^d} v\nabla\mathcal{B}_s * v\cdot\nabla\left(\log v + \frac{|y|^2}{2\varepsilon}\right)dy \\
&\leq -\varepsilon\mathrm{I}(v|\mathcal{U}_m) + Ce^{-ds}\left(\int_{\mathbb{R}^d} v\left|\nabla\mathcal{B}_s * v\right|^2 dy\right)^{1/2}\left(\int_{\mathbb{R}^d} v\left|\nabla\left(\log v + \frac{|y|^2}{2\varepsilon}\right)\right|^2 dy\right)^{1/2} \\
&=: -\varepsilon\mathrm{I}(v|\mathcal{U}_m) + J.
\end{aligned} \tag{2.34}$$

We now estimate the term J by using (2.32) and Young's inequality,

$$\begin{aligned}
J &\leq Ce^{-ds}\left(\int_{\mathbb{R}^d}\frac{1}{v}\left|\nabla v\right|^2 dy\right)^{1/2} I(v|\mathcal{U}_m)^{1/2} \\
&= Ce^{-ds}\left(I(v|\mathcal{U}_m) + 2d\int_{\mathbb{R}^d} v - \frac{1}{\varepsilon}\int_{\mathbb{R}^d} v|y|^2 dy\right)^{1/2} I(v|\mathcal{U}_m)^{1/2} \\
&\leq Ce^{-ds}\left(I(v|\mathcal{U}_m) + I(v|\mathcal{U}_m)^{1/2}\right).
\end{aligned}$$

Therefore, inequality (2.34) implies

$$\frac{d}{ds}\mathrm{E}(v(s)|\mathcal{U}_m) \leq -(\varepsilon - Ce^{-ds} - Ce^{-2\delta s})I(v|\mathcal{U}_m) + Ce^{-2ds+2\delta s},$$

for an arbitrarily small $\delta > 0$ and for a fixed $C > 0$. For $s \geq s_0(\varepsilon)$ we have $\varepsilon - Ce^{-ds} - Ce^{-2\delta s} > 0$ and we can use inequality (2.31) to obtain

$$\frac{d}{ds}\mathrm{E}(v(s)|\mathcal{U}_m) \leq -\frac{2(\varepsilon - Ce^{-ds} - Ce^{-2\delta s})}{\varepsilon}\mathrm{E}(v(s)|\mathcal{U}_m) + Ce^{-2ds+2\delta s}.$$

Hence, due to the variation of constants formula we obtain the following decay rates as $s \to +\infty$ (here $\delta > 0$ is arbitrarily small):

$$\mathrm{E}(v(s)|\mathcal{U}_m) = \begin{cases} O(e^{-2(1-\delta)s}) & \text{if } d = 1 \\ O(e^{-2s}) & \text{if } d > 1. \end{cases} \tag{2.35}$$

Finally, by means of the Csiszár–Kullback inequality (2.30) and by using the original variables $\rho(x,t)$ according to (2.26), we obtain the desired estimate (2.33). ∎

3. Nonlinear diffusion. In this section we focus our attention on the nonlinear model

$$\begin{cases} \dfrac{\partial \rho}{\partial t} = \nabla \cdot (\rho(1-\rho)\nabla(\varepsilon\rho - S)) \\ -\Delta S + S = \rho, \end{cases} \tag{3.1}$$

subject to the initial condition

$$\rho(x,0) = \rho_0(x), \quad \rho_0 \in L^1(\mathbb{R}^d), \quad 0 \leq \rho_0(x) \leq 1, \quad x \in \mathbb{R}^d. \tag{3.2}$$

3.1. Existence of weak solutions. We start by providing a suitable definition of weak solutions. In order to simplify the notation, we fix $\varepsilon = 1$. We denote

$$A(\rho) = \int_0^\rho \xi(1-\xi)d\xi = \frac{\rho^2}{2} - \frac{\rho^3}{3}, \qquad \mathcal{A}(\rho) = \int_0^\rho A(\xi)d\xi = \frac{\rho^3}{6} - \frac{\rho^4}{12}.$$

Definition 3.1. *A function $\rho \in L^2([0,+\infty) \times \mathbb{R}^d)$ is called a* weak solution *of the Cauchy problem* (3.1)–(3.2) *on $\mathbb{R}^d \times [0,T]$ (T eventually $+\infty$) if the following conditions are satisfied:*

(i) $\mathcal{A}(\rho) \in L^\infty([0,T]; L^1(\mathbb{R}^d))$
(ii) $\nabla A(\rho) \in L^2([0,T] \times \mathbb{R}^d)$
(iii) $0 \leq \rho(x,t) \leq 1$ *almost everywhere in* $[0,T] \times \mathbb{R}^d$.
(iv) *For all $\varphi \in C_c^\infty([0,T) \times \mathbb{R}^d)$, the following relation holds:*

$$\int_0^T \int_{\mathbb{R}^d} \rho\varphi_t dxdt - \int_0^T \int_{\mathbb{R}^d} \nabla A(\rho) \cdot \nabla\varphi dxdt + \int_0^T \int_{\mathbb{R}^d} \rho(1-\rho)\nabla S \cdot \nabla\varphi dxdt + \int_{\mathbb{R}^d} \rho(x,0)\varphi(x,0)dx = 0,$$

where $S = S[\rho]$ is the unique H^1 solution to $-\Delta S + S = \rho$.

The existence of weak solutions in the sense of the above definition is stated in the following theorem.

Theorem 3.2 (global existence of solutions). *There exists at least a global weak solution $\rho(x,t)$ to the Cauchy problem* (3.1)–(3.2) *in the sense of Definition* 3.1.

The proof of the previous theorem can be performed by a standard approximation procedure. We refer in particular to [Car99, CP03] for existence theory of degenerate convection diffusion equations and to [BCM03, CMV03] for problems including

nonlocal terms. The main technical problem in our case is related to the degeneracy of the nonlinear diffusion coefficient at the threshold value $\rho = 1$. We can overcome this difficulty by including the invariant domain property $0 \leq \rho \leq 1$ in Definition 3.1. This property prevents the mobility coefficient $\rho(1-\rho)$ from turning into the backward diffusion range. For the sake of completeness, let us give an outline of the proof. As a first step we consider a nondegenerate approximation of our problem on a smooth bounded domain with Dirichlet boundary conditions. If S is given, the solution ρ is provided by the classical theory of parabolic equations. Hence, the existence of the solution to the coupled problem can be provided by compactness of the solution operator $S = S(\rho)$ and by Schauder's fixed point theorem. The nondegenerate mobility coefficients can be carefully chosen in order to preserve the conditions in (3.2) in time. This property can be proved in the same way as in Theorem 2.5 due to the nondegeneracy of the parabolic equation. The second step consists in taking the limit in the mobility coefficients in order to prove existence for the degenerate problem in a closed ball. Finally one can send the radius of the ball to infinity and complete the proof. In the last two steps one can use the classical energy estimate technique from [Váz92] in order to achieve sufficient compactness.

Remark 3.3. The conservation of the total mass can be proved in the same way as in the case of linear diffusion.

3.2. entropy solutions. In the following we turn our attention to the problem of uniqueness of suitable solutions. For equations with an interaction of nonlocal fluxes and degenerate diffusions there is no straightforward way to prove the uniqueness of weak solutions (cf. also [BCM03, Car99]) and one might even expect nonuniqueness, as for nonlocal transport equations (cf. [DGT00]). We therefore turn our attention to a rather natural restriction of weak solutions, the so-called *entropy solutions*. Apart from uniqueness, the main motivation for considering entropy solutions is to obtain the correct dissipation of entropy functionals, which will be discussed in the subsections below. Due to the fact that the convolution $\mathcal{B} * \rho$ is smooth anyway, the behavior of dissipation functionals on this part seems unimportant and we shall therefore adapt the definition of entropy solutions for fixed flux $\nabla S(x,t)$ (cf. [BCM03] for a more detailed discussion).

Definition 3.4 (entropy solutions). *We shall say that a nonnegative function* $\rho \in L^1([0,T] \times \mathbb{R}^d) \cap C(0,T;L^1(\mathbb{R}^d))$ *is an* entropy solution *of the Cauchy problem* (3.1)–(3.2) *on* $\mathbb{R}^d \times [0,T]$ *if the following conditions are satisfied:*

(i) *For all* $c \in \mathbb{R}$ *and all nonnegative test functions* $\varphi \in C_c^\infty([0,T) \times \mathbb{R}^d)$*, the following entropy inequality holds:*

$$\int_0^T \int_{\mathbb{R}^d} \Big[|\rho - c| \varphi_t + \text{sign } (\rho - c) \left(\rho(1-\rho) - c(1-c)\right) \nabla S \cdot \nabla \varphi + \varepsilon |A(\rho) - A(c)| \Delta \varphi - \text{sign } (\rho - c) c(1-c) \Delta S \varphi \Big] \, dx \, dt \geq 0, \tag{3.3}$$

where $S = S[\rho]$ *is the unique* H^1 *solution to* $-\Delta S + S = \rho$.

(ii) $A(\rho) \in L^2(0,T;H^1(\mathbb{R}^d))$

(iii) $0 \leq \rho(x,t) \leq 1$ *almost everywhere in* $[0,T] \times \mathbb{R}^d$.

(iv) *Essentially, as* $t \downarrow 0$,

$$\int_{\mathbb{R}^d} |\rho(x,t) - \rho_0(x)| \, dx \to 0.$$

In order to prove the existence of entropy solutions, one can follow the same nondegenerate approximation procedure briefly discussed in the previous subsection and even obtain a unique classical solution. The classical solution clearly satisfies the corresponding entropy condition (with smoothed nonlinearities on the bounded domain). Due to *a priori* bounds on ρ, $A(\rho)$, and $S = \mathcal{B} * \rho$ (see once again the aforementioned reference [Váz92]) we always extract suitably convergent subsequences when passing from the nondegenerate approximation to (3.1), so that the entropy inequality (3.3) carries over to the limit. Hence, we obtain the following result.

THEOREM 3.5. *Let $\rho_0 \in L^1(\mathbb{R}^d)$ satisfy $0 \le \rho_0 \le 1$. Then there exists an entropy solution of* (3.1), (3.2) *according to Definition* (3.4).

In order to prove uniqueness of the entropy solution, we shall use the continuous dependence of entropy solutions on the flux in the L^1-norm.

LEMMA 3.6. *Let $S^1, S^2 \in C(0,T;H^1(\mathbb{R}^d)) \cap L^\infty([0,T]\times\mathbb{R}^d)$, with*

$$\nabla S^j \in C(0,T;W^{1,1}_{loc}(\mathbb{R}^d)) \cap C([0,T]\times\mathbb{R}^d), \qquad \Delta S^j \in L^\infty([0,T]\times\mathbb{R}^d)$$

be given and let $u^j \in L^\infty(0,T;BV(\mathbb{R}^d))$ be entropy solutions of

$$u^j_t = \nabla\cdot\big(u^j(1-u^j)\nabla(\varepsilon u^j - S^j)\big)$$

with initial values $u^j_0 \in BV(\mathbb{R}^d)$ for $j = 1, 2$.

$$\begin{aligned}\|u^1(t)-u^2(t)\|_{L^1(\mathbb{R}^d)} \le \|u^1_0 - u^2_0\|_{L^1(\mathbb{R}^d)} + \frac{t}{4}\|\nabla S^1 - \nabla S^2\|_{L^\infty(0,t;BV(\mathbb{R}^d))}\\ + t\max\{V_1,V_2\}\|\nabla S^1 - \nabla S^2\|_{L^\infty([0,t]\times\mathbb{R}^d)},\end{aligned} \tag{3.4}$$

where $V_j = \|\nabla S^j\|_{L^\infty(0,t;BV(\mathbb{R}^d))}$.

Proof. The proof can be carried out as the proof of Theorem 1.3 in [KR03] by appropriately using the time-dependence of the flux in the estimates and the fact that the function $p \mapsto p(1-p)$ has Lipschitz constant 1 and supremum $\frac{1}{4}$ on the interval $[0,1]$. □

Below we shall prove a uniqueness result in the smaller class of entropy solutions of bounded variation in the case of spatial dimension one. Before proving their uniqueness, we verify the existence of such entropy solutions.

PROPOSITION 3.7 (regularity of entropy solutions). *Let $\rho_0 \in BV(\mathbb{R}^1;[0,1])$, then an entropy solution of* (3.1), (3.2) *satisfies*

$$\rho \in L^\infty(0,T;BV(\mathbb{R}^1)).$$

Proof. We construct the BV-solution by smooth approximation. Let ρ be an L^1 viscosity solution of (3.1), (3.2) and let $\rho^\delta \in C(0,T;C^1(\mathbb{R}^1))$ such that $0 \le \rho^\delta \le 1$ almost everywhere and $\rho^\delta \to \rho$ in $C(0,T;BV(\mathbb{R}^1))$. Then we also have

$$S^\delta = \mathcal{B} * \rho \in C(0,T;BV(\mathbb{R}^1))$$

and consequently

$$S^\delta_{xx} = S^\delta - \rho^\delta \in C(0,T;BV(\mathbb{R}^d)).$$

The results of [KR01] imply the existence of an entropy solution u^δ of

$$u_t - \big(u(1-u)(\delta u - S^\delta)_x\big) = 0$$

with initial value $u(0) = \rho_0$, u^δ belonging in the space $\in L^\infty(0,T;BV(\mathbb{R}^1)$. Moreover, since $u_h^\delta(x,t) = u^\delta(x+h,t)$ is an entropy solution of the same equation with $S^\delta(x.t)$ replaced by $S_h^\delta(x,t) := S^\delta(x+h,t)$ and initial value $\rho_0(.+h)$, we may apply the continuous dependence estimate to deduce

$$\begin{aligned}\|u_h^\delta(t) - u^\delta(t)\|_{L^1(\mathbb{R}^1)} \le \|\rho_0(.+h) - \rho^0\|_{L^1(\mathbb{R}^1)} + \frac{t}{4}\|S_x^\delta - (S_h^\delta)_x\|_{L^\infty(0,t;BV(\mathbb{R}^1))} \\ + tV^\delta \|S_x^\delta - (S_h^\delta)_x\|_{L^\infty([0,t]\times\mathbb{R}^1)},\end{aligned}$$

with $V^\delta = \|S_x^\delta\|_{L^\infty(0,t;BV(\mathbb{R}^1))}$. After division by h we obtain in the limit $h \to 0$,

$$\|u^\delta(t)\|_{BV(\mathbb{R}^1)} \le \|\rho^0\|_{BV(\mathbb{R}^1)} + \frac{t}{4}\|S_{xx}^\delta\|_{L^\infty(0,t;BV(\mathbb{R}^1))} + tV^\delta\|S_{xx}^\delta\|_{L^\infty([0,t]\times\mathbb{R}^1)}.$$

From the uniform bounds for ρ^δ in $L^\infty(\mathbb{R}^1) \cap L^1(\mathbb{R}^1)$ one can easily deduce uniform estimates for V^δ and $\|S_{xx}^\delta\|_{L^\infty([0,t]\times\mathbb{R}^1)}$. Moreover, there exists a constant $c > 0$ (independent of δ and t) such that

$$\|S_{xx}^\delta\|_{L^\infty(0,t;BV(\mathbb{R}^1))} \le c\|\rho^\delta\|_{L^\infty(0,t;BV(\mathbb{R}^1))}.$$

Hence, we deduce

$$\|u^\delta\|_{L^\infty(0,t;BV(\mathbb{R}^1))} \le \|\rho^0\|_{BV(\mathbb{R}^1)} + \frac{ct}{4}\|\rho^\delta\|_{L^\infty(0,t;BV(\mathbb{R}^1))} + Ct.$$

As $\delta \to 0$, one can prove in a standard way that $u^\delta \to \rho$. Now let t be such that $2ct < 1$, then by lower semicontinuity

$$\begin{aligned}\frac{1}{2}\|\rho\|_{L^\infty(0,t;BV(\mathbb{R}^1))} &\le \limsup\left(\|u^\delta\|_{L^\infty(0,t;BV(\mathbb{R}^1))} - \frac{1}{2}\|\rho^\delta\|_{L^\infty(0,t;BV(\mathbb{R}^1))}\right) \\ &\le \|\rho^0\|_{BV(\mathbb{R}^1)} + Ct,\end{aligned}$$

and hence, $\rho \in L^\infty(0,t;BV(\mathbb{R}^1))$.

By applying the same argument consecutively to time intervals of length smaller than $\frac{1}{2c}$ we finally obtain that $\rho \in L^\infty(0,T;BV(\mathbb{R}^1))$. ∎

Finally, from the continuous dependence it is a small step to prove the main uniqueness result.

THEOREM 3.8 (uniqueness). *The entropy solution ρ of* (3.1), (3.2) *is unique in the space $L^\infty(0,T;BV(\mathbb{R}^1))$.*

Proof. Let ρ^1 and ρ^2 be two different entropy solutions belonging in the space $L^\infty(0,T;BV(\mathbb{R}^1))$. Then we can assume without restriction of generality that $\|\rho^1(t) - \rho^2(t)\| \neq 0$ for $t > 0$ is arbitrarily small (otherwise we can take τ as the maximal time before which the solutions are equal and rescale time to $t - \tau$).

One can verify in a straightforward way that S^1 and S^2 satisfy the assumptions of Lemma 3.6 and that there exists a constant $C > 0$ such that

$$\|S_x^1 - S_x^2\|_{L^\infty(0,t;BV(\mathbb{R}^1))} \le C\|\rho^1 - \rho^2\|_{L^\infty(0,t;L^1(\mathbb{R}^1))}$$

and

$$\|S_x^1 - S_x^2\|_{L^\infty([0,t]\times\mathbb{R}^1)} \le C\|\rho^1 - \rho^2\|_{L^\infty(0,t;L^1(\mathbb{R}^1))}.$$

Hence, by Lemma 3.6 the estimate

$$\|\rho^1(t) - \rho^2(t)\|_{L^1(\mathbb{R}^1)} \le \tilde{C}t\|\rho^1(t) - \rho^2(t)\|_{L^1(\mathbb{R}^1)}$$

holds for some constant $\tilde{C}$. Since we can choose t small enough such that $Ct < 1$, this yields a contradiction. ∎

3.3. Finite speed of propagation in one space dimension. In this subsection we focus our attention on the Cauchy problem in one space dimension

$$\begin{cases} \partial_t \rho = \partial_x \left(\rho(1-\rho) \partial_x \left(\varepsilon \rho - S \right) \right), \\ \rho(x,0) = \rho_0(x), \end{cases} \tag{3.5}$$

where ρ_0 is compactly supported and satisfies the usual condition $0 \leq \rho_0 \leq 1$. Our aim is to prove that the solution $\rho(t)$ at any time $t > 0$ is still compactly supported. This feature is usually referred to as the *the finite rate of propagation property*, and it is typically satisfied by nonlinear diffusion equations of the form

$$\rho_t = A(\rho)_{xx},$$

when $A : \mathbb{R}_+ \to \mathbb{R}_+$ is a smooth nondecreasing function such that $A'(0) = 0$. Our approach in proving such a property is closely related with the estimates of the Wasserstein distances between any two solutions to a nonlinear diffusion equation developed in [CGT04]. For a positive integer n, we define the $2n$th moment of a nonnegative, integrable function ρ as

$$M_{2n}(\rho) := \int_{-\infty}^{+\infty} x^{2n} \rho(x) dx.$$

The distribution function of ρ is given by

$$F(x) = \int_{-\infty}^{x} \rho(y) dy.$$

The *pseudoinverse* function of F, defined on the interval $[0, m]$, $m = \int_{-\infty}^{+\infty} \rho(x) dx$, is given by

$$F^{-1}(\xi) = \inf \left\{ x \in \mathbb{R} \,\middle|\, F(x) > \xi \right\}.$$

If $\rho(x) > 0$ almost everywhere, then F^{-1} is a real inverse, and the change of variables

$$x \in \operatorname{supp}(\rho) \mapsto \xi = F(x) \in [0, m]$$

is a bijection. Therefore, one can change variables in the definition of the moments above and get

$$M_{2n}(\rho) = \int_{-\infty}^{+\infty} x^{2n} \rho(x) dx = \int_0^m F^{-1}(\xi)^{2n} d\xi.$$

Obviously we have

$$\left[\frac{1}{m} \int_0^m F^{-1}(\xi)^{2n} d\xi \right]^{1/2n} \to \| F^{-1} \|_{L^\infty([0,m])},$$

as $n \to +\infty$. Moreover, it is clear that

$$\operatorname{meas}(\operatorname{supp}(\rho)) \leq 2 \| F^{-1} \|_{L^\infty([0,m])}. \tag{3.6}$$

Thus, a uniform estimate with respect to n of $M_{2n}^{1/2n}(\rho(t))$, where $\rho(t)$ is the solution to (3.5), at time t automatically ensures the finiteness of the size of the support of

$\rho(t)$. We shall prove that such an estimate is true. For future reference we briefly recall the following result in [Kne77] for a nonlinear friction equation.

THEOREM 3.9. *Let* $A(\rho) = \frac{\rho^2}{2} - \frac{\rho^3}{3}$. *Let* $\overline{\rho}(t)$ *be a nonnegative solution to the equation*

$$\overline{\rho}_t = A(\overline{\rho})_{xx} \tag{3.7}$$

with initial datum having compact support. Let $\overline{F}^{-1}(t)$ *be the pseudoinverse of the distribution function of* $\overline{\rho}(t)$. *Then, there exists a continuous (increasing) function of time* $t \mapsto C(t)$ *such that*

$$\|\overline{F}^{-1}(t)\|_{L^{2n}} \leq C(t), \tag{3.8}$$

where $C(t)$ *does not depend on* n.

We now state our result for (3.5).

THEOREM 3.10 (finite speed of propagation). *Let* $\rho(x,t)$ *be the unique entropy solution to* (3.5) *with compactly supported initial datum* ρ_0. *Then, the profile* $\rho(t)$ *has compact support at any positive time* t.

Proof. As pointed out before, to pursue our aim we only need to control $M_{2n}^{1/2n}$ uniformly in n in any finite time interval $[0,T]$. We shall perform this task by a formal computation of the L^{2n} norm of the pseudoinverse of the distribution function of ρ. This formal computation can be easily made rigorous by an approximation procedure that allows us both to cancel out the boundary terms due to integration by parts and to treat the pseudoinverse of the distribution function of ρ as a real inverse. This procedure is well explained in [CGT04] and we shall omit the details about it. We only observe that classical energy estimates on (3.5) in the spirit of [Váz92] provide the necessary compactness needed to extend such approximation argument to our case.

We denote by ρ the solution of (3.5) with an initial datum ρ_0 having mass $m = \int \rho_0$. Let $u(t) : [0,m] \to \mathbb{R}$ be the pseudoinverse of the distribution function of ρ. Let us also consider the solution $\overline{\rho}(t)$ of the nonlinear diffusion equation (3.7) having ρ_0 as initial datum. Let $\overline{u}(t)$ be the pseudoinverse of the distribution function of $\overline{\rho}(t)$. A standard computation with pseudoinverses (see, e.g., [CGT04]) shows that u and $\overline{u}$ satisfy the following equations:

$$\begin{aligned}
\partial_t u &= -\partial_\xi A\left((\partial_\xi u)^{-1}\right) + \left(1 - (\partial_\xi u)^{-1}\right) \int_0^m B'(u(\xi) - u(\eta))d\eta, \\
\partial_t \overline{u} &= -\partial_\xi A\left((\partial_\xi \overline{u})^{-1}\right).
\end{aligned}$$

For fixed n we have, after integration by parts,

$$\begin{aligned}
&\frac{d}{dt}\int_0^m [u(t) - \overline{u}(t)]^{2n} d\xi \\
&= +2n(2n-1)\int_0^m (u-\overline{u})^{2n-2}\left[\partial_\xi u - \partial_\xi \overline{u}\right]\left[A((\partial_\xi u)^{-1}) - A((\partial_\xi \overline{u})^{-1})\right] d\xi \\
&\quad + 2n\int_0^m (u-\overline{u})^{2n-1}\left(1 - (\partial_\xi u)^{-1}\right)\int_0^m B'(u(\xi) - u(\eta))d\eta d\xi.
\end{aligned}$$

Hence, since the function $t \to A(t^{-1})$ is nonincreasing we can get rid of the first addend on the right-hand side above. Therefore, due to the uniform bound of ρ in

L^∞ and to the definition of $\mathcal{B}$, there exists a fixed constant $C > 0$ such that

$$\frac{d}{dt}\int_0^m [u(t) - \overline{u}(t)]^{2n} d\xi \le Cn\left[\int_0^m [u(t) - \overline{u}(t)]^{2n} d\xi + 1\right],$$

and, in view of (3.8) and of the Gronwall inequality,

$$\|u(t)\|_{L^{2n}[0,m]} \le e^{Ct}$$

for some positive constant C independent of n. We can now send $n \to \infty$ to get a uniform estimate for $\|u(t)\|_{L^\infty[0,m]}$ and the proof is complete in view of (3.6). ∎

3.4. Asymptotic behavior. In the following we investigate the asymptotic behavior of weak solutions to (3.1), (3.2) for large time. The main idea in this case is the analysis of the behavior of the associated energy functional

$$\tilde{E}(\rho) := \int_{\mathbb{R}^d} \rho(\varepsilon\rho - S(\rho))\ dx, \tag{3.9}$$

where $S(\rho)$ is the unique solution to $-\Delta S + S = \rho$ decaying at infinity. This energy functional is to be considered on the admissible set

$$\mathcal{K} := \{\rho \in L^2(\mathbb{R}^d) \cap L^1(\mathbb{R}^d) \mid 0 \le \rho \le 1 \text{ a.e. }\}. \tag{3.10}$$

For the nonlinear diffusion case, the change from $\varepsilon > 1$ to $\varepsilon < 1$ is of particular interest, since $\tilde{E}(\rho)$ changes from a strictly convex (for $\varepsilon > 1$) to a nonconvex functional, which we verify in the following lemma.

LEMMA 3.11. *The functional $\tilde{E} : \mathcal{K} \to \mathbb{R}$ is bounded below by $-\int_{\mathbb{R}^d} \rho\ dx$ for $\varepsilon > 0$. Moreover, $\tilde{E}$ is positive and strictly convex for $\varepsilon > 1$.*

Proof. First of all, since $\rho \le 1$ and $S(\rho) \ge 0$, we have

$$\tilde{E}(\rho) := \int_{\mathbb{R}^d} \rho(\varepsilon\rho - S(\rho))\ dx \ge -\int_{\mathbb{R}^d} S(\rho)\ dx.$$

The property $\int_{\mathbb{R}^d} S(\rho)\ dx = \int_{\mathbb{R}^d} \rho\ dx$ can be deduced immediately from the elliptic equation satisfied by $S(\rho)$ and hence,

$$\tilde{E}(\rho) \ge -\int_{\mathbb{R}^d} \rho\ dx.$$

Since $\tilde{E}$ is a quadratic functional, convexity is equivalent to strict positivity. From the Cauchy–Schwarz inequality we have

$$\tilde{E}(\rho) = \int_{\mathbb{R}^d} \rho(\varepsilon\rho - S(\rho))\ dx \ge (\varepsilon - 1)\int_{\mathbb{R}^d} \rho^2\ dx + \frac{1}{2}\int_{\mathbb{R}^d} \left(\rho^2 - S(\rho)^2\right)\ dx.$$

Finally, a standard energy estimate for the elliptic equation satisfied by $S(\rho)$ shows that the second term is nonnegative, and hence,

$$\tilde{E}(\rho) \ge (\varepsilon - 1)\int_{\mathbb{R}^d} \rho^2\ dx > 0$$

for $\rho \ne 0$ and $\varepsilon > 1$. ∎

A fundamental property of the model is the dissipation of the energy $\tilde{E}$. Formally, if we compute the time derivative of $\tilde{E}(\rho(t))$, insert the equations and apply Gauss' theorem, then we obtain

$$\begin{aligned}\frac{d}{dt}\tilde{E}(\rho(t)) &= \int_{\mathbb{R}^d} \rho_t(2\varepsilon\rho - \mathcal{B}*\rho)\ dx - \int_{\mathbb{R}^d} \rho\mathcal{B}*\rho_t\ dx \\ &= 2\int_{\mathbb{R}^d} \rho_t(\varepsilon\rho - \mathcal{B}*\rho)\ dx \\ &= 2\int_{\mathbb{R}^d} \nabla\cdot[\rho(1-\rho)\nabla(\varepsilon\rho - \mathcal{B}*\rho)]\,(\varepsilon\rho - \mathcal{B}*\rho)\ dx \\ &= -2\int_{\mathbb{R}^d} \rho(1-\rho)\left|\nabla(\varepsilon\rho - \mathcal{B}*\rho)\right|^2\ dx := -2I(\rho,S) < 0. \end{aligned} \tag{3.11}$$

This estimate can be made rigorous by standard smooth approximation techniques, and thus, we have derived the following result.

PROPOSITION 3.12 (energy dissipation). *Let ρ be a weak solution of* (3.1), (3.2). *Then the functional*

$$e : \mathbb{R}^+ \to \mathbb{R}, t \mapsto e(t) := \tilde{E}(\rho(t))$$

is nonincreasing. Moreover, $e(s) = e(t)$ for $s > t$ if and only if ρ is stationary in the interval $[s,t]$ and

$$\rho(1-\rho)\nabla(\varepsilon\rho - S(\rho)) = 0 \qquad \text{a.e. in } \mathbb{R}^d \times [s,t].$$

3.4.1. Nondecaying solutions in 1-*d* for moderate diffusivity. It is an important consequence of the previous proposition that for an initial value ρ_0 for (3.1) with $\tilde{E}(\rho_0) < 0$, the existence of nondecaying solutions follows: in this case, we have $\tilde{E}(\rho(t)) \le \tilde{E}(\rho_0) < 0$ due to the energy dissipation. Hence, such solutions cannot decay for $t \to \infty$, since otherwise one would have $\liminf \tilde{E}(\rho(t)) \ge \tilde{E}(0) = 0$.

In one space dimension and for every $\varepsilon < 1$, we can verify that the functional $\tilde{E}$ is not positive—and hence nondecaying solutions do exist—by an explicit construction of appropriate densities.

PROPOSITION 3.13. *Let $d = 1$ and $\varepsilon < 1$, then for each $m > 0$ there exists $\rho \in \mathcal{K}$ satisfying*

$$\tilde{E}(\rho) < 0, \qquad \text{and} \qquad \int_{\mathbb{R}^d} \rho\ dx = m. \tag{3.12}$$

Proof. Let $0 < \alpha^2 < \frac{1}{\varepsilon} - 1$ and let ψ^α be a continuous function satisfying

$$\begin{aligned} -\tfrac{d^2\psi^\alpha}{dx^2} + \psi^\alpha &= \tfrac{1}{c}, && 0 \le x < a, \\ -\tfrac{d^2\psi^\alpha}{dx^2} - \alpha^2\psi^\alpha &= 0, && a \le x \le b, \\ -\tfrac{d^2\psi^\alpha}{dx^2} + \psi^\alpha &= 0, && x > b, \end{aligned}$$

with boundary conditions $\psi^\alpha(0) = 1$, $\frac{d\psi^\alpha}{dx}(0) = 0$ and $\psi^\alpha(x) \to 0$ as $x \to \infty$, and some constant c satisfying

$$0 < \varepsilon < c < \frac{1}{\alpha^2 + 1} < 1. \tag{3.13}$$

We find that if $a < \ln \frac{c}{1-c}$, a continuously differentiable, nonnegative solution exists and is given by

$$\psi^\alpha(x) = \begin{cases} \frac{1}{c}(1-(c-1)\cosh x), & 0 \le x < a, \\ c_1 \sin(\alpha(x-a)) + c_2 \cos(\alpha(x-a)), & a \le x \le b, \\ c_3 e^{b-x}, & b < x, \end{cases}$$

where the constants satisfy

$$\begin{aligned} c_1 &= \tfrac{c-1}{\alpha c} \sinh a < 0, \\ c_2 &= (1+(c-1)\cosh a)/c, \\ c_3 &= c_1 \sin(\alpha(b-a)) + c_2 \cos(\alpha(b-a)), \end{aligned}$$

and the length of the second interval is fixed by the relation

$$b = a + \frac{1}{\alpha} \arctan\Big(-\frac{c_2 + \alpha c_1}{c_1 - \alpha c_2}\Big).$$

If we choose S as the symmetric extension of $c\psi^\alpha$ to $\mathbb{R}$ and

$$\rho(x) = \begin{cases} 1, & -a < x < a, \\ c(\alpha^2+1)\psi^\alpha(x), & a \le x \le b, \\ c(\alpha^2+1)\psi^\alpha(-x), & -b \ge x \ge -a, \\ 0, & |x| > b, \end{cases}$$

then S satisfies $-\frac{d^2S}{dx^2} + S = \rho$ and $\rho \in \mathcal{K}$. Moreover, we have

$$\tilde{E}(\rho) = \int_{\mathbb{R}^d} \rho(\varepsilon\rho - S)\, dx = 2\Big[\int_0^a (\varepsilon - S)\, dx + (\varepsilon(\alpha^2+1)-1)(\alpha^2+1)\int_a^b S^2\, dx\Big].$$

This expression is negative if $a < \operatorname{arccosh}\Big(\frac{1-\varepsilon}{1-c}\Big)$. The mass m is given by

$$\frac{1}{2}m = a + (\alpha^2+1)\int_a^b S\, dx = a + c(\alpha^2+1)\int_a^b c_1 \sin(\alpha(x-a)) + c_2\cos(\alpha(x-a))\, dx.$$

Because of (3.13), we have that $\frac{1}{2}m < a + \int_a^b c_1 \sin(\alpha(x-a)) + c_2\cos(\alpha(x-a))\, dx$. If α is chosen small enough, we can choose the constant c to be so close to 1 that the constraints on a, and hence on m, become arbitrarily large. Thus, for any given mass m, we can always construct a solution $\rho \in \mathcal{K}$ such that (3.12) holds. ∎

3.4.2. Attractors of the semigroup in 1-*d*. As another interesting consequence of the energy estimate (3.11), for any positive ε we can characterize the set of attractors of the semigroup (3.1), (3.2) as the set of its stationary entropy solutions, i.e., the set of all $\rho \in L^1$, $0 \le \rho \le 1$ such that

$$\rho(1-\rho)\nabla(\varepsilon\rho - S(\rho)) = 0 \qquad \text{a.e. in } \mathbb{R}\times[0,+\infty), \tag{3.14}$$

where $S(\rho)$ is the unique solution to $-\Delta S + S = \rho$ decaying at infinity.

THEOREM 3.14 (attractors of the semigroup). *Let $\rho(t)$ be the solution to* (3.1), (3.2) *in one space dimension. Then, any sequence of times admits a subsequence t_k such that $\rho(t_k) \to \rho^\infty$ almost everywhere. Moreover, ρ^∞ is a solution to* (3.14).

Proof. We set

$$B(\rho) = \int_0^\rho \sqrt{r(1-r)}dr$$

and we observe that (3.11) implies that the quantity

$$\int_0^{+\infty} I(\rho(t), S(t))dt = \int_0^{+\infty} \int_{-\infty}^{+\infty} \left[\varepsilon^2 B(\rho)_x^2 - 2\varepsilon A(\rho)_x S_x + \rho(1-\rho)S_x^2\right] dxdt$$

is uniformly bounded. Therefore, any sequence of times tending to infinity has a subsequence $t_k \to +\infty$ such that $I(\rho(t_k), S(t_k)) \to 0$ as $k \to \infty$. Since

$$\int_{-\infty}^{+\infty} \rho(1-\rho)S_x^2 dx \le \frac{1}{4}\int_{\mathbb{R}^d} \rho^2 dx,$$

and $\rho(t)$ is uniformly bounded in $L^1 \cap L^\infty$, and because of

$$-2\varepsilon \int_{\mathbb{R}^d} A(\rho)_x S_x dx = 2\varepsilon \int_{\mathbb{R}^d} A(\rho)(\rho - S)dx,$$

we easily get a uniform (with respect to time) bound for

$$\int_{-\infty}^{+\infty} B(\rho(t_k))_x^2 dx.$$

Thanks to the uniform bound in $L^1 \cap L^\infty$ for the solution $\rho(t)$, by Sobolev embedding we can extract a new subsequence of times (still denoted by t_k for simplicity) such that

$$\begin{cases} \rho(t_k) \to \rho^\infty \ \text{ a.e. in } \mathbb{R} \times [0+\infty) \\ \rho(t_k) \to \rho^\infty \ \text{ in } \ L^2_{loc}(\mathbb{R}) \\ B(\rho(t_k))_x \to v^\infty \ \text{ weakly in } L^2(\mathbb{R}) \\ I(\rho(t_k), S(t_k)) \to 0, \end{cases}$$

as $k \to \infty$. Now, for any test function $\phi \in C_0^\infty(\mathbb{R})$ we have

$$\begin{aligned} \int_{-\infty}^{+\infty} v^\infty \phi \ dx &= \lim_{k\to\infty} \int_{-\infty}^{+\infty} B(\rho(t_k))_x \phi \ dx \\ &= -\lim_{k\to\infty} \int_{-\infty}^{+\infty} B(\rho(t_k))\phi_x dx = -\int_{-\infty}^{+\infty} B(\rho^\infty)\phi_x dx \end{aligned}$$

and therefore $v^\infty = B(\rho^\infty)_x$ almost everywhere. We denote by S^∞ the solution to $-S_{xx} + S = \rho^\infty$. By weak lower semicontinuity of the L^2 norm and by the strong compactness of $S_x = \mathcal{B}' * \rho$ in L^2 we can extract another subsequence such that

$$\begin{aligned} I(\rho^\infty, S^\infty) &= \varepsilon^2 \int_{-\infty}^{+\infty} \varepsilon B(\rho^\infty)_x^2 dx - 2\varepsilon \int_{-\infty}^{+\infty} A(\rho^\infty)_x S_x^\infty dx \\ &+ \int_{-\infty}^{+\infty} \rho^\infty(1-\rho^\infty)(S_x^\infty)^2 dx \le \liminf_{k\to\infty} \left\{ \int_{-\infty}^{+\infty} B(\rho(t_k))_x dx \right. \\ &\left. -2\varepsilon \int_{-\infty}^{+\infty} A(\rho(t_k))_x S(t_k)_x dx + \int_{-\infty}^{+\infty} \rho(t_k)(1-\rho(t_k))S(t_k)_x^2 dx \right\} \\ &= \lim_{k\to\infty} I(\rho(t_k), S(t_k)) = 0. \end{aligned}$$

Recalling that $I(\rho,S)=\int_{-\infty}^{+\infty}\rho(1-\rho)(\varepsilon\rho-S)_x^2dx$, the assertion follows. ∎

Remark 3.15. In the arguments above we have implicitly supposed existence of stationary solutions. The convergence of subsequences in the above theorem is strong enough to prove existence of stationary, weak, entropy solutions of (3.1), (3.2) in one space dimension. Due to the nondecay result in subsection 3.4.1, we deduce existence of stationary solutions which are not identically zero in case of $\varepsilon<1$.

3.4.3. Characterization of the attractors for large diffusivity in 1-*d*. In this subsection we prove that the only attractor of the semigroup, and hence the only solution to the stationary problem (3.14) is the constant solution $\rho^\infty\equiv 0$ in the case of large diffusivity $\varepsilon>1$. To perform this task, we need an additional energy estimate, i.e., we compute the evolution of the logarithmic functional

$$L(\rho)=\int_{-\infty}^{+\infty}[\rho\log\rho+(1-\rho)\log(1-\rho)]dx.$$

As for the energy estimate in the previous subsections, we compute the evolution of $L(\rho)$ by means of a formal computation which can be made rigorous by approximation. Integration by parts and conservation of the total mass yield

$$\begin{aligned}L(\rho(t))-L(\rho(0))&=\int_0^t\int(\log\rho-\log(1-\rho))\rho_t dxd\tau\\&=-\int_0^t\int\left(\frac{\rho_x}{\rho}+\frac{\rho_x}{1-\rho}\right)(\varepsilon\rho(1-\rho)\rho_x-\rho(1-\rho)S_x)\,dxd\tau\\&=-\varepsilon\int_0^t\int\rho_x^2dxd\tau+\int_0^t\int\rho_xS_xdxd\tau\le-(\varepsilon-1)\int_0^t\int\rho_x^2dxd\tau.\end{aligned}\tag{3.15}$$

The logarithmic functional L cannot be used directly to discern the asymptotic behavior of the solution ρ. However, the estimate performed above can be used to characterize the stationary solutions for $\varepsilon>1$. We have the following theorem.

THEOREM 3.16 (attractors for large diffusivity in 1–*d*). *Let ρ,S be a solution to* (3.1) *with $\varepsilon>1$ such that ρ has finite support at any time. Then, the support of ρ is not uniformly bounded with respect to t. Consequently, there exist no compactly supported stationary solutions ρ,S to* (3.1) *if $\varepsilon>1$ is different from zero.*

Proof. Suppose that $\rho(t)$ is a solution with uniformly bounded support. Since the function

$$[0,1]\ni\rho\mapsto\rho\log\rho+(1-\rho)\log(1-\rho)$$

is bounded, $L(\rho(t))$ is uniformly bounded in time. Therefore, as in the proof of Theorem 3.14, we can handle the right-hand side of estimate (3.15) in a clever way in order to derive strong compactness. More precisely, there exists a divergent sequence of times t_k such that $\rho(t_k)$ converges to some ρ^∞ almost everywhere and strongly in L^2_{loc}, and such that $\rho(t_k)_x$ converges to zero strongly in L^2. As in Theorem 3.14, we can easily prove that $\rho_x^\infty=0$ and, by Fatou's lemma, we conclude that $\rho^\infty=0$. By the Sobolev interpolation lemma we get $\rho(t_k)\to 0$ uniformly, and this contradicts $\rho(t)$ having uniformly bounded support because of the conservation of the mass. This proves the first assertion of the theorem. In particular, we have also proven that any compactly supported stationary solution must equal zero. ∎

As a consequence of the previous theorem, we have the following asymptotic decay result in the case of large diffusivity.

COROLLARY 3.17 (decay of solutions in 1-d for large diffusivity). *Let ρ be the solution to* (3.1) *with compactly supported initial datum ρ_0 satisfying* (3.2). *Then,*

$$\lim_{t\to\infty} \|\rho(t)\|_{L^\infty(\mathbb{R})} = 0.$$

Proof. From Theorem 3.14, any divergent sequence of times admits a subsequence t_k such that $\rho(t_k)$ converges almost everywhere to a stationary solutions satisfying (3.14). Thanks to the results in Theorems 3.10 and 3.16, such a solution must be the constant solution $\rho \equiv 0$. Moreover, the convergence to zero holds in L^∞ in view of $B(\rho(t_k)) \to 0$ in L^2 and by the Sobolev interpolation lemma. ∎

3.5. Stationary solutions. As stated in Proposition 3.12, stationary solutions of (3.1), (3.2) have to satisfy $\rho = 0$, $\rho = 1$ or $\varepsilon\nabla\rho = \nabla S$. In one space dimension, this means that we can construct nontrivial stationary solutions by arranging subintervals on $\mathbb{R}$ such that ρ is in the admissible set $\mathcal{K}$ and satisfies one of these conditions in every interval.

PROPOSITION 3.18. *Let $d = 1$ and $\varepsilon < 1$, then for each $m > 0$ small enough there exists a stationary solution of* (3.1) *satisfying $\rho \in \mathcal{K}$.*

Proof. Let ρ and S be the symmetric extension to $\mathbb{R}$ of

$$\bar{S}(x) = \begin{cases} \frac{\varepsilon}{\varepsilon-1}c_1 + c_2\cos\left(\sqrt{\frac{1-\varepsilon}{e}}x\right), & 0 \le x \le a, \\ c_3 e^{a-x}, & a \le x, \end{cases} \qquad \bar{\rho}(x) = \begin{cases} \frac{1}{\varepsilon}S + c_1, & 0 \le x \le a, \\ 0, & a \le x, \end{cases}$$

and let the constants satisfy

$$c_1 = c\frac{\sqrt{\varepsilon}-1}{\sqrt{\varepsilon}} < 0, \quad c_2 = \frac{c(\varepsilon\sqrt{\varepsilon}-\varepsilon)}{\varepsilon-1} > 0, \quad c_3 = -\varepsilon c_1,$$

where c is the maximal value of ρ and a is given by

$$a = \sqrt{\frac{\varepsilon}{1-\varepsilon}}\arccos(-\sqrt{\varepsilon}).$$

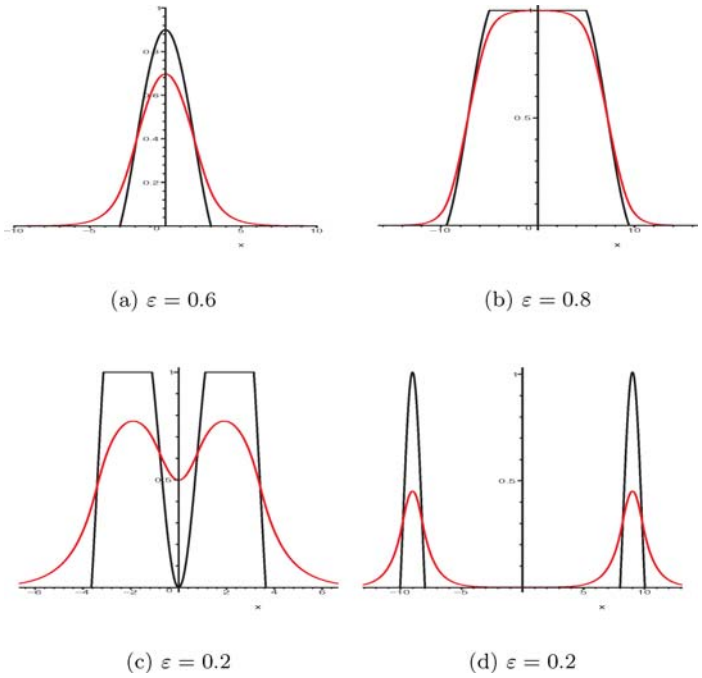
Then, a simple calculation shows that for any given values of $\varepsilon < 1$ and $0 \le c \le 1$, a nonnegative solution $\rho \in C(\mathbb{R})$ and $S \in C^1(\mathbb{R})$ exists. Moreover, S and ρ are decreasing functions on $[0, a]$, implying the assertion. ∎

An example of this type of solution is shown in Figure 1(a), where we set $c = 0.9$ and $\varepsilon = 0.6$.

In general, more complicated stationary solutions can also be constructed, for instance, solutions with

$$\bar{\rho}(x) = \begin{cases} 1, & 0 \le x \le a, \\ \frac{1}{\varepsilon}S + c_1, & a \le x \le b, \\ 0, & b \le x, \end{cases} \tag{3.16}$$

or solutions with several peaks (see Figure 1(b)–1(d)). It is no longer straightforward to show that these solutions exist for any choice of $\varepsilon < 1$, but there is strong numerical evidence. As an example, we chose a stationary solution of type (3.16): it seems that for any mass m large enough and $\varepsilon < 1$, a solution can be uniquely determined. Figure 2 shows the interval a as a function of the mass for different values of ε. Depending on ε, there exists a minimal value for m, which is due to the fact that the slope of ρ, and hence also the minimal distance between intervals where $\rho = 1$ and $\rho = 0$, is proportional to ε.



(a) $\varepsilon = 0.6$ (b) $\varepsilon = 0.8$

(c) $\varepsilon = 0.2$ (d) $\varepsilon = 0.2$

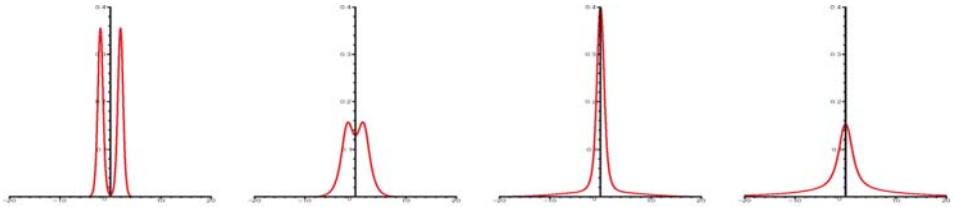
4. Numerical simulation. In the following we discuss the numerical simulation of the linear and nonlinear model in one and two space dimensions. We discretize (2.1) and (3.1) numerically by applying a straightforward finite difference method: for each time step, S is computed using an implicit discretization of the elliptic equation, then the cell density ρ is calculated using the updated value for S. This is done by standard operator splitting of the equation for ρ. First, the advection term is calculated with an upwind scheme (cf. [LeV90]). The solution obtained from this step is subsequently used as an initial value for a time step in the diffusion problem $\rho_t = \varepsilon\Delta\rho$ and $\rho_t = \varepsilon\Delta A(\rho)$ for the linear and the nonlinear case, respectively. If ε is relatively large and the parabolic CFL condition $\Delta t \leq C\frac{\Delta x^2}{\varepsilon}$ becomes too expensive compared to the hyperbolic CFL condition for the advection term, we use a Crank–Nicholson scheme (an implicit, weighted average method, cf. [Qua03]) for the time



(a) $t = 4$ (b) $t = 40$ (c) $t = 400$ (d) $t = 2000$

FIG. 3. *Linear problem,* $\varepsilon = 0.05$.

integration of the linear diffusion term.

This numerical approach requires the approximation of the solution on an unbounded domain by (artificial) boundary conditions on a bounded domain. For the numerical simulations presented below, we take Dirichlet boundary conditions for S and ρ and perform the computations on large domains.

As a test whether this method is reliable, we compared our results for the nonlinear model to the numerical solution obtained by a so-called Lagrangian approach, where the equation for the pseudoinverse of the distribution function is discretized (see, for instance, [GT05]). Since this method is posed on the interval $(0, 1)$, it does not require any artificial cut of the computational domain. Our comparisons showed that the maximal value of the error is approximately Δx (data not shown) and thus of the same order as the as the error caused by the discretization itself. Hence, the cutting of the domain in our numerical method seems to introduce only a negligible error.

Since the distribution function and its pseudoinverse do not exist in multiple dimensions, we could not compare our numerical solutions to those obtained by the Lagrangian approach for the two-dimensional case. However, we checked our results by successively doubling the size of the domain and comparing the corresponding numerical solutions, which also produced negligible variations for reasonably large domain size.

4.1. One-dimensional simulations. The evolution of the cell density in (1.1) is illustrated in Figures 3 and 4 for the linear and nonlinear case, respectively: starting with a symmetrical initial condition for ρ consisting of two peaks both with mass $\frac{1}{2}$, we compute the solutions with the numerical scheme described above, using $\Delta x = 10^{-2}$, $\Delta t = 5 \times 10^{-3}$ in the linear case and $\Delta x = 10^{-2}$, $\Delta t = 5 \times 10^{-4}$ in the nonlinear case. In order to reduce the computation time, we consider symmetric initial data with compact support on $0 \le x \le a$ and prescribe Neumann boundary conditions at $x = 0$, so that we only have to compute on half of the domain.

In Figure 3 one observes that in the linear case the two initial peaks merge into a single peak that eventually decays with time. In Figure 4 the time evolution of the nonlinear diffusion problem (3.1) is illustrated. In order to have a more fair comparison with the linear case we set $\varepsilon = 0.5$, i.e., ten times the value we took for the linear case (but simulations with smaller ε showed a very similar behavior). Starting with the same initial conditions, the solution first behaves as in the linear case: there is attraction between the two peaks and they merge to a single one. In contrast to the linear problem, however, this peak does not decay, but approaches a nontrivial stationary solution as characterized in Proposition 3.18.

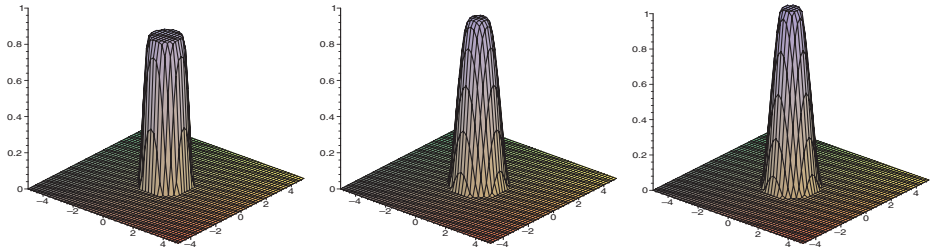
FIG. 5. *Linear problem,* $\varepsilon = 0.04$.



(a) $t = 0.25$ (b) $t = 2$ (c) $t = 35$

FIG. 6. *Nonlinear problem,* $\varepsilon = 0.2$.

4.2. Two-dimensional simulations. In two space dimensions, we perform numerical experiments on a rectangular grid with $\Delta x = \Delta t = 5 \times 10^{-2}$ for the linear model and $\Delta x = 5 \times 10^{-2}$, $\Delta t = 4 \times 10^{-4}$ for the nonlinear model. The diffusivities are $\varepsilon = 0.04$ for the linear and $\varepsilon = 0.2$ for the nonlinear model. Figure 5 illustrates the temporal evolution of the solution ρ of the linear problem, starting from the initial condition shown in the first picture. We see that the maximal value of the density remains close to 1 for a long time interval, but for even larger time diffusion dominates aggregation and the density starts to decay. In Figure 6 the behavior of the nonlinear model with the same initial conditions is shown. One observes that the solution is not decaying, and eventually a stationary state with finite support is approached.

UNIQUENESS, RENORMALIZATION, AND SMOOTH APPROXIMATIONS FOR LINEAR TRANSPORT EQUATIONS*

FRANÇOIS BOUCHUT† AND GIANLUCA CRIPPA‡

Abstract. Transport equations arise in various areas of fluid mechanics, but the precise conditions on the vector field for them to be well-posed are still not fully understood. The renormalized theory of DiPerna and Lions for linear transport equations with an unsmooth coefficient uses the tools of approximation of an arbitrary weak solution by smooth functions, and also uses the renormalization property; that is, the possibility of writing an equation on a nonlinear function of the solution. Under some $W^{1,1}$ regularity assumption on the coefficient, well-posedness holds. In this paper, we establish that these properties are indeed equivalent to the uniqueness of weak solutions to the Cauchy problem, without any regularity assumption on the coefficient. Coefficients with unbounded divergence but with bounded compression are also considered.

Key words. linear transport equations with an unsmooth coefficient, renormalized solutions, approximation by smooth functions, coefficients of bounded compression

1. Introduction.

In this paper we consider linear transport equations

$$\partial_t u + \operatorname{div}(bu) = 0 \qquad \text{in } (0,T)\times\mathbb{R}^d, \tag{1}$$

where $b(t,x)\in\mathbb{R}^d$ is the coefficient and u is scalar. Such equations arise in many areas of fluid mechanics, and a precise analysis of them is a key issue for the understanding of the particle flows in applications. In the present work, we give sharp results characterizing the well-posedness of transport equations. The question of well-posedness for the associated Cauchy problem for (1) has a well-known answer when b is continuous and Lipschitz continuous with respect to x, because of the Cauchy–Lipschitz theorem and the relation between (1) and the ordinary differential equation $dX/ds = b(s,X(s))$. When b is not smooth, the well-posedness is much more delicate. A general theory has been developed in [13] in the case when $b\in L^1((0,T),W^{1,1}_{loc}(\mathbb{R}^d))$, $\operatorname{div} b\in L^\infty$, and under some growth conditions on b. After some intermediate results (see in particular [5], [9], and [10]), the theory has been generalized in [2] to the case of only BV regularity for b instead of $W^{1,1}$. However, some recent counterexamples (as in [11] and [12], both inspired by [1]) show that there is not much room in which to weaken the regularity assumptions. Nevertheless, some questions remain open, such as the case of BD regularity for b (the symmetric part of $\nabla_x b$ is a measure, instead of the full matrix as in the BV case); see [8] and [4] for some partial results in this direction. For a detailed exposition and for a wider bibliography, the reader is referred to [3].

In this paper, we intend to give results of a different type that do not give directly the answer to the well-posedness problem, but rather give equivalent conditions for it to hold, without regularity assumptions on b. For simplicity we shall always assume

that $b \in L^\infty((0,T)\times\mathbb{R}^d)$, and consider an L^2 framework. The approach of [13] and [2] relies on an approximation by convolution of a given weak solution to (1) and on the renormalized property; that is, if u solves (1) and if $\mathrm{div} b = 0$ (to simplify), then $\beta(u)$ also solves (1) for any suitable nonlinearity β. Theorem 2.1 states that such properties are indeed equivalent to the well-posedness of both forward and backward Cauchy problems, up to the fact that the smooth approximate solution (in the sense of the norm of the graph of the transport operator) is not necessarily given by convolution. Then, one can consider separately the two different issues of forward and backward uniqueness. Theorem 3.1 states that a characterization of backward uniqueness is the existence of a solution to the forward Cauchy problem that is approximable by smooth functions in the sense of the norm of the graph of the transport operator. Finally, we also consider the case of a coefficient b with unbounded divergence, but with *bounded compression*. We show that the previous results extend naturally to this case.

2. Forward-backward formulation.

THEOREM 2.1. *Let $b \in L^\infty((0,T)\times\mathbb{R}^d;\mathbb{R}^d)$ such that $\mathrm{div} b = 0$. Then the following statements are equivalent:*

(i) *b has the uniqueness property for weak solutions in $C([0,T];L^2(\mathbb{R}^d)-w)$ for both the forward and the backward Cauchy problems starting, respectively, from 0 and T; i.e., the only solutions in $C([0,T];L^2(\mathbb{R}^d)-w)$ to the problems*

$$\begin{cases} \partial_t u_F + \mathrm{div}(bu_F) = 0, \\ u_F(0,\cdot) = 0, \end{cases} \qquad \begin{cases} \partial_t u_B + \mathrm{div}(bu_B) = 0, \\ u_B(T,\cdot) = 0 \end{cases}$$

are $u_F \equiv 0$ and $u_B \equiv 0$.

(ii) *The Banach space*

$$\mathcal{F} := \left\{ \begin{array}{c} u \in C([0,T];L^2(\mathbb{R}^d)-w) \text{ such that} \\ \partial_t u + \mathrm{div}(bu) \in L^2((0,T)\times\mathbb{R}^d) \end{array} \right\} \tag{2}$$

with norm

$$\|u\|_{\mathcal{F}} := \|u\|_{B([0,T];L^2(\mathbb{R}^d))} + \|\partial_t u + \mathrm{div}(bu)\|_{L^2((0,T)\times\mathbb{R}^d)} \tag{3}$$

has the property that the space of functions in $C^\infty([0,T]\times\mathbb{R}^d)$ with compact support in x is dense in $\mathcal{F}$.

(iii) *Every weak solution in $C([0,T];L^2(\mathbb{R}^d)-w)$ of $\partial_t u + \mathrm{div}(bu) = 0$ lies in $C([0,T];L^2(\mathbb{R}^d)-s)$ and is a renormalized solution, i.e., for every function $\beta \in C^1(\mathbb{R};\mathbb{R})$ such that $|\beta'(s)| \le C(1+|s|)$ for some constant $C \ge 0$, one has $\partial_t\big(\beta(u)\big) + \mathrm{div}\big(b\beta(u)\big) = 0$ in $(0,T)\times\mathbb{R}^d$.*

In the statement of the theorem we used the notation $C([0,T];L^2(\mathbb{R}^d)-w)$ and $C([0,T];L^2(\mathbb{R}^d)-s)$ for the spaces of maps which are continuous from $[0,T]$ into $L^2(\mathbb{R}^d)$, endowed with the weak or the strong topology, respectively. We recall the classical fact that, up to a redefinition in a negligible set of times, every solution to (1) belongs to $C([0,T];L^2(\mathbb{R}^d)-w)$ (see, for example, Remark 3 in [3]).

Proof of Theorem 2.1.

(i) $\Rightarrow$ (ii).

Step 1. *Cauchy problem in $\mathcal{F}$.* It is easy to check that $\mathcal{F}$ is a Banach space, since L^2 and $B([0,T];L^2(\mathbb{R}^d))$ are Banach spaces (the latter denotes the space of bounded functions, with the supremum norm). We preliminarily show that for any $f \in L^2((0,T)\times\mathbb{R}^d)$ and $u^0 \in L^2(\mathbb{R}^d)$, the Cauchy problem

$$\begin{cases} \partial_t u + \mathrm{div}(bu) = f, \\ u(0,\cdot) = u^0 \end{cases} \tag{4}$$

has a unique solution in $\mathcal{F}$. We proceed by regularization. Consider a sequence of smooth vector fields $\{b_n\}_n$, with $b_n \to b$ a.e., b_n uniformly bounded in L^∞, and $\mathrm{div} b_n = 0$ for every n. Let u_n be the solution to the problem

$$\begin{cases} \partial_t u_n + \mathrm{div}(b_n u_n) = f, \\ u_n(0,\cdot) = u^0. \end{cases}$$

Then, by standard results on the smooth theory of transport equations (see, for example, [6]), we know that the solution u_n is unique in $C([0,T];L^2(\mathbb{R}^d))$ and is given by

$$u_n(t,x) = u^0(X_n(0,t,x)) + \int_0^t f(\tau, X_n(\tau,t,x))\,d\tau,$$

where $X_n(s,t,x)$ is the flow of b_n at time s, starting at the point x at time t, i.e., the solution to the ordinary differential equation

$$\begin{cases} \dfrac{dX_n}{ds}(s,t,x) = b_n(s, X_n(s,t,x)), \\ X_n(t,t,x) = x. \end{cases}$$

Recalling that $\mathrm{div} b_n = 0$, so that $X_n(s,t,\cdot)_\# \mathcal{L}^d = \mathcal{L}^d$ for every s and t (we denote by $\mathcal{L}^d$ the d-dimensional Lebesgue measure on $\mathbb{R}^d$), we can estimate the L^2 norm of $u_n(t,\cdot)$ as follows:

$$\begin{aligned} \|u_n(t,\cdot)\|_{L^2} &\le \|u^0(X_n(0,t,\cdot))\|_{L^2} + \int_0^t \|f(\tau, X_n(\tau,t,\cdot))\|_{L^2}\,d\tau \\ &\le \|u^0\|_{L^2} + \int_0^t \|f(\tau,\cdot)\|_{L^2}\,d\tau \\ &\le \|u^0\|_{L^2} + \sqrt{T}\|f\|_{L^2}. \end{aligned}$$

This implies that the sequence $\{u_n\}_n$ is equibounded in $C([0,T];L^2(\mathbb{R}^d))$. From the equation on u_n, we have also that for any $\varphi \in C_c^\infty(\mathbb{R}^d)$, $d/dt(\int u_n \varphi dx)$ is bounded in $L^2(0,T)$. We deduce that for any $\varphi \in L^2(\mathbb{R}^d)$, $\int u_n \varphi dx$ is uniformly in n equicontinuous in $[0,T]$. Thus, up to the passage to a subsequence (which does not depend on t), we can suppose that $u_n(t,\cdot) \rightharpoonup u(t,\cdot)$ in $L^2(\mathbb{R}^d) - w$, with $u \in C([0,T];L^2(\mathbb{R}^d) - w)$. By the semicontinuity of the norm with respect to weak convergence we also obtain that

$$\|u(t,\cdot)\|_{L^2} \le \|u^0\|_{L^2} + \sqrt{T}\|f\|_{L^2}. \tag{5}$$

Passing to the limit in the transport equation, we obtain that u solves the Cauchy problem

$$\begin{cases} \partial_t u + \mathrm{div}(bu) = f, \\ u(0,\cdot) = u^0. \end{cases}$$

Noticing that $\partial_t u + \mathrm{div}(bu) = f \in L^2$, we conclude that $u \in \mathcal{F}$. Uniqueness is clear: every solution to the Cauchy problem (4) is by definition a weak solution in $C([0,T];L^2(\mathbb{R}^d) - w)$ of the forward Cauchy problem with right-hand side, and thus by linearity, uniqueness is guaranteed by the forward part of assumption (i).

Step 2. *Density of smooth functions.* Define a linear operator

$$A: \begin{array}{ccc} \mathcal{F} & \to & L^2(\mathbb{R}^d)\times L^2((0,T)\times\mathbb{R}^d), \\ u & \mapsto & \big(u(0,\cdot),\ \partial_t u+\operatorname{div}(bu)\big). \end{array}$$

This operator in clearly bounded by the definition of the norm we have taken on $\mathcal{F}$. It is also a bijection because of Step 1, with continuous inverse because of (5). This means that A is an isomorphism, and thus we can identify $\mathcal{F}$ with the space $L^2(\mathbb{R}^d)\times L^2((0,T)\times\mathbb{R}^d)$, and its dual $\mathcal{F}^*$ with $L^2(\mathbb{R}^d)\times L^2((0,T)\times\mathbb{R}^d)$. Therefore, for every functional $L\in\mathcal{F}^*$, we can uniquely define $v_0\in L^2(\mathbb{R}^d)$ and $v\in L^2((0,T)\times\mathbb{R}^d)$ in such a way that

$$Lu=\int_{(0,T)\times\mathbb{R}^d}\big(\partial_t u+\operatorname{div}(bu)\big)v\,dtdx+\int_{\mathbb{R}^d}u(0,\cdot)v_0\,dx\qquad\text{for every } u\in\mathcal{F}.$$

We recall the classical fact that a subspace of a Banach space is dense if and only if every functional which is zero on the subspace is in fact identically zero. Then the density of smooth functions is equivalent to the following implication:

$$\begin{array}{c} \int_{(0,T)\times\mathbb{R}^d}\big(\partial_t u+\operatorname{div}(bu)\big)v\,dtdx+\int_{\mathbb{R}^d}u(0,\cdot)v_0\,dx=0 \\ \text{for every } u\in C^\infty([0,T]\times\mathbb{R}^d) \text{ with compact support in } x \\ \Longrightarrow v_0=0 \text{ and } v=0. \end{array} \tag{6}$$

If we first take u arbitrary but with compact support also in time, we obtain that

$$\int_{(0,T)\times\mathbb{R}^d}\big(\partial_t u+\operatorname{div}(bu)\big)v\,dtdx=0,$$

and since $\operatorname{div}b=0$, this is precisely the weak form of

$$\partial_t v+\operatorname{div}(bv)=0.$$

This implies that $v\in C([0,T];L^2(\mathbb{R}^d)-w)$. Now let χ be a cut-off function on $\mathbb{R}$, i.e., $\chi\in C_c^\infty(\mathbb{R})$, $\chi(z)=1$ for $|z|\le 1$, and $\chi(z)=0$ for $|z|\ge 2$. For every function $\varphi\in C_c^\infty(\mathbb{R}^d)$, take a function $\tilde u\in C^\infty([0,T]\times\mathbb{R}^d)$ with compact support in x such that $\tilde u(T,\cdot)=\varphi$. Then, testing in (6) with $u(t,x)=\tilde u(t,x)\chi\big((T-t)/\varepsilon\big)$, we obtain for $0<\varepsilon<T/2$

$$\begin{aligned} 0&=\int_{(0,T)\times\mathbb{R}^d}\left[\partial_t\left(\tilde u(t,x)\chi\left(\frac{T-t}{\varepsilon}\right)\right)+\operatorname{div}\left(b(t,x)\tilde u(t,x)\chi\left(\frac{T-t}{\varepsilon}\right)\right)\right]v(t,x)\,dtdx \\ &=\int_{(0,T)\times\mathbb{R}^d}\left[\partial_t\tilde u(t,x)+\operatorname{div}(b(t,x)\tilde u(t,x))\right]v(t,x)\chi\left(\frac{T-t}{\varepsilon}\right)dtdx \\ &\quad-\int_{(0,T)\times\mathbb{R}^d}\frac{1}{\varepsilon}\chi'\left(\frac{T-t}{\varepsilon}\right)\tilde u(t,x)v(t,x)\,dtdx. \end{aligned} \tag{7}$$

Letting $\varepsilon\to 0$, we observe that the first integral clearly converges to 0 since the support of $\chi\big((T-t)/\varepsilon\big)$ is contained in $[T-2\varepsilon,\,T+2\varepsilon]$. The second integral can be rewritten as

$$-\int_0^T\frac{1}{\varepsilon}\chi'\left(\frac{T-t}{\varepsilon}\right)\left[\int_{\mathbb{R}^d}\tilde u(t,x)v(t,x)\,dx\right]dt.$$

Now, since $\tilde{u}$ is smooth and $v \in C([0,T];L^2(\mathbb{R}^d)-w)$, the integral over $\mathbb{R}^d$ is a continuous function of t. Moreover, it is easy to check that

$$-\int_0^T \frac{1}{\varepsilon}\chi'\left(\frac{T-t}{\varepsilon}\right)dt = 1.$$

Therefore, coming back to (7) and letting $\varepsilon \to 0$ we get

$$0 = \int_{\mathbb{R}^d} \tilde{u}(T,x)v(T,x)\,dx = \int_{\mathbb{R}^d} \varphi(x)v(T,x)\,dx.$$

Since $\varphi \in C_c^\infty(\mathbb{R}^d)$ is arbitrary, we obtain $v(T,\cdot) = 0$. We conclude that $v \in C([0,T];L^2(\mathbb{R}^d)-w)$ solves the Cauchy problem

$$\begin{cases} \partial_t v + \operatorname{div}(bv) = 0, \\ v(T,\cdot) = 0. \end{cases}$$

Thus, by the backward part of the uniqueness assumption (i), we get that $v = 0$. Substituting in (6), we get that $\int_{\mathbb{R}^d} u(0,\cdot)v_0\,dx = 0$ for every $u \in C^\infty([0,T]\times\mathbb{R}^d)$ with compact support in space, and this implies that $v_0 = 0$. This concludes the proof of the implication (6), which ensures that (ii) holds.

(ii) $\Rightarrow$ (iii). Let $u \in C([0,T],L^2(\mathbb{R}^d)-w)$ satisfy $\partial_t u + \operatorname{div}(bu) = 0$. Then by (ii), there exists a sequence $\{u_n\}$ of functions in $C^\infty([0,T]\times\mathbb{R}^d)$ with compact support in space such that $\|u_n - u\|_{\mathcal{F}} \to 0$. In particular this gives that $u_n \to u$ in $B([0,T];L^2(\mathbb{R}^d))$; thus $u \in C([0,T],L^2(\mathbb{R}^d)-s)$. Then, define $f_n = \partial_t u_n + \operatorname{div}(bu_n) \in L^2((0,T)\times\mathbb{R}^d)$. By the definition of convergence in $\mathcal{F}$ we have that $f_n \to 0$ strongly in $L^2((0,T)\times\mathbb{R}^d)$. For every function β with the regularity stated we can apply the classical chain-rule, giving

$$\partial_t(\beta(u_n)) + \operatorname{div}(b\beta(u_n)) = \beta'(u_n)f_n.$$

The left-hand side clearly converges to $\partial_t(\beta(u)) + \operatorname{div}(b\beta(u))$ in the sense of distributions. According to the assumed bound on β', we have that the sequence $\beta'(u_n)$ is equibounded in $L^2_{loc}((0,T)\times\mathbb{R}^d)$; hence with the strong convergence of f_n we deduce that the right-hand side converges strongly in $L^1_{loc}((0,T)\times\mathbb{R}^d)$ to zero. This implies that $\partial_t\big(\beta(u)\big) + \operatorname{div}\big(b\beta(u)\big) = 0$.

(iii) $\Rightarrow$ (i). This step is classical. Let $u \in C([0,T],L^2(\mathbb{R}^d)-w)$ satisfy $\partial_t u + \operatorname{div}(bu) = 0$. According to (iii), u lies in $C([0,T],L^2(\mathbb{R}^d)-s)$, and applying the renormalization property with $\beta(u) = u^2$, we get

$$\partial_t(u^2) + \operatorname{div}(bu^2) = 0,$$

with $u^2 \in C([0,T],L^1(\mathbb{R}^d)-s)$. Testing this equation against smooth functions of the form $\psi(t)\varphi_R(x)$, where $\psi \in C_c^\infty((0,T))$ and $\varphi_R(x) = \varphi(x/R)$ with $\varphi \in C_c^\infty(\mathbb{R}^d)$ is a cut-off function equal to 1 on the ball of radius 1 and equal to 0 outside the ball of radius 2, we get

$$\int_0^T \left[\int_{\mathbb{R}^d} u^2\varphi\left(\frac{x}{R}\right)dx\right]\psi'(t)\,dt + \int_0^T \left[\int_{\mathbb{R}^d} bu^2\frac{1}{R}\nabla\varphi\left(\frac{x}{R}\right)dx\right]\psi(t)\,dt = 0.$$

Thus, we get in the sense of distributions in $(0,T)$

$$\frac{d}{dt}\int_{\mathbb{R}^d} u^2\varphi\left(\frac{x}{R}\right)dx = \int_{\mathbb{R}^d} bu^2\frac{1}{R}\nabla\varphi\left(\frac{x}{R}\right)dx.$$

Since the right-hand side is in $L^\infty(0,T)$ and since for every t it is bounded by $\frac{1}{R}\|b\|_{L^\infty_{t,x}}\|\nabla\varphi\|_{L^\infty_x}\|u(t,\cdot)\|^2_{L^2_x}$, letting $R\to+\infty$ we obtain

$$\frac{d}{dt}\int_{\mathbb{R}^d} u(t,x)^2\,dx = 0 \quad \text{in } (0,T).$$

Recalling that $u^2\in C([0,T],L^1(\mathbb{R}^d)-s)$, this yields $\int u(t,x)^2dx = cst$ on $[0,T]$, which implies uniqueness for both forward and backward Cauchy problems, proving (i). ∎

Remark 2.2 (well-posedness). The space $\mathcal{F}$ defined in (2) is a natural space for the study of the Cauchy problem (4). Whenever one of the statements of Theorem 2.1 is true, we have existence and uniqueness in $\mathcal{F}$ with the estimate (5), as shown in the proof. Moreover, every solution is renormalized and strongly continuous with respect to time, i.e., $u\in C([0,T];L^2(\mathbb{R}^d)-s)$. Overall, the following weak stability holds: If $\{f_n\}_n$ is a bounded sequence in $L^2((0,T)\times\mathbb{R}^d)$ which converges weakly to f, $\{u_n^0\}_n$ is a bounded sequence in $L^2(\mathbb{R}^d)$ which converges weakly to u^0, and $\{b_n\}_n$ is a bounded sequence in $L^\infty((0,T)\times\mathbb{R}^d)$ which converges strongly in L^1_{loc} to b and such that $\mathrm{div}b_n = 0$ for every n, then the solutions $\{u_n\}_n$ to

$$\partial_t u_n + \mathrm{div}(b_n u_n) = f_n, \qquad u_n(0,\cdot) = u_n^0$$

converge in $C([0,T];L^2(\mathbb{R}^d)-w)$ to the solution u to the Cauchy problem (4).

Remark 2.3 (L^p case). We can modify the summability exponent in the definition of the space $\mathcal{F}$. For every $p\in\,]1,\infty[$, define $\mathcal{F}_p$ as the space containing those functions $u\in C([0,T];L^p(\mathbb{R}^d)-w)$ that satisfy $\partial_t u+\mathrm{div}(bu)\in L^p((0,T)\times\mathbb{R}^d)$ and define the norm $\|\cdot\|_{\mathcal{F}_p}$ in the obvious way, which makes $\mathcal{F}_p$ a Banach space. Denoting by p' the conjugate exponent of p, i.e., $\frac{1}{p}+\frac{1}{p'}=1$, the following statements are equivalent:

(i) Smooth functions with compact support in x are dense in $\mathcal{F}_p$ and in $\mathcal{F}_{p'}$.

(ii) The vector field b has the forward uniqueness property for weak solutions in $C([0,T];L^p(\mathbb{R}^d)-w)$ and the backward uniqueness property for weak solutions in $C([0,T];L^{p'}(\mathbb{R}^d)-w)$.

Remark 2.4 (equivalent norms). According to the proof of Theorem 2.1, if one of the properties (i), (ii), and (iii) holds, then the norm of $\mathcal{F}$ is equivalent to the norm

$$\|u\|_{\mathcal{F},0} = \|u(0,\cdot)\|_{L^2(\mathbb{R}^d)} + \|\partial_t u+\mathrm{div}(bu)\|_{L^2((0,T)\times\mathbb{R}^d)}$$

(see the estimate (5)). In the same spirit, it is easy to prove that $\|\cdot\|_{\mathcal{F}}$ is in fact equivalent to every norm of the form

$$\|u\|_{\mathcal{F},s} = \|u(s,\cdot)\|_{L^2(\mathbb{R}^d)} + \|\partial_t u+\mathrm{div}(bu)\|_{L^2((0,T)\times\mathbb{R}^d)}$$

for $s\in[0,T]$.

Remark 2.5 (Depauw's counterexample). A simple modification (translation in time) of the counterexample constructed in [12] shows that the renormalization property is really linked to the uniqueness in *both* the forward and the backward Cauchy problems. In fact, we can construct a divergence-free vector field $b\in L^\infty((0,1)\times\mathbb{R}^2;\mathbb{R}^2)$ and a function $\bar u\in L^\infty(\mathbb{R}^2)$ such that

1. the backward Cauchy problem with datum $\bar u$ at time $t=1$ has a unique solution, which is, however, *not* renormalized and *not* strongly continuous with respect to time;

2. the forward Cauchy problem with datum 0 at time $t=0$ has more than one solution;

3. the unique solution $u(t,x)$ to the backward Cauchy problem with datum $\bar{u}$ at time $t=1$ satisfies

$$\begin{cases} |u(t,x)| = 0 & \text{for } 0 \le t \le 1/2, \\ |u(t,x)| = 1 & \text{for } 1/2 < t \le 1; \end{cases}$$

hence the equivalence of the norms in Remark 2.4 does *not* hold.

Remark 2.6 (the Sobolev and the BV cases). In the case of a vector field with Sobolev regularity with respect to the space variable, $b \in L^1((0,T); W^{1,p'}_{loc}(\mathbb{R}^d))$ with $1 < p < \infty$, it is almost possible to prove that the natural regularization by convolution with respect to the space variable of $u \in \mathcal{F}_p$ (see Remark 2.3) converges to u with respect to $\|\cdot\|_{\mathcal{F}_p}$. Indeed, let η_ε be a standard convolution kernel in $\mathbb{R}^d$ and set $u_\varepsilon = u * \eta_\varepsilon$. We can compute

$$\begin{aligned} &\partial_t u + \operatorname{div}(bu) - \partial_t u_\varepsilon - \operatorname{div}(bu_\varepsilon) \\ &\quad = \big[\partial_t u + \operatorname{div}(bu)\big] - \big[\partial_t u + \operatorname{div}(bu)\big] * \eta_\varepsilon + \big[\operatorname{div}(bu) * \eta_\varepsilon - \operatorname{div}(bu_\varepsilon)\big]. \end{aligned}$$

Then the convergence of u_ε to u with respect to $\|\cdot\|_{\mathcal{F}_p}$ is equivalent to the strong convergence in $L^p((0,T)\times\mathbb{R}^d)$ to zero of the *commutator*

$$r_\varepsilon = \operatorname{div}(bu) * \eta_\varepsilon - \operatorname{div}(bu_\varepsilon).$$

The results of [13] ensure this strong convergence for every convolution kernel η_ε, except that it holds in L^1_{loc} instead of L^p. We need also a regularization with respect to time and a cut-off in order to get the density property in Theorem 2.1(ii), but this means that our strategy is more or less "equivalent" to the one of [13], in the framework of Sobolev vector fields. However, the situation is different in the BV case studied in [2]. In general, the commutator r_ε is not expected to converge strongly to zero; our result shows that, even in this case, there exists some smooth approximation of the solution, but it is less clear how to construct it in an explicit way.

Remark 2.7 (strong continuity condition). The condition of continuity with values in strong L^2 in Theorem 2.1(iii) cannot be removed; otherwise the equivalence with (i) fails. This can be seen again with Depauw's counterexample with singularity at time $t=0$. In this case all weak solutions are renormalized in $(0,T)\times\mathbb{R}^d$ since b is locally BV in x, but uniqueness of weak solutions does not hold. Another remark is that, in general, a renormalized solution does not need to be continuous with values in strong L^2, even inside the interval, as the following counterexample shows. On the interval $(-1,1)$, take for b the one of Depauw's counterexample in $(0,1)$ (with singularity at 0), and define on $(-1,0)$ the vector field as $b(t,x) = -b(-t,x)$. Consider then the weak solution u with value 0 at $t=0$, which we extend on $(-1,0)$ by $u(t,x) = u(-t,x)$. Then u is a renormalized solution on $(-1,1)$ but is not strongly continuous at $t=0$.

3. One-way formulation.

THEOREM 3.1. *Let $b \in L^\infty((0,T)\times\mathbb{R}^d;\mathbb{R}^d)$ such that* $\operatorname{div} b \in L^\infty((0,T)\times\mathbb{R}^d)$, *and let $c \in L^\infty((0,T)\times\mathbb{R}^d)$. Define the Banach space $\mathcal{F}$ and its norm $\|\cdot\|_{\mathcal{F}}$ as in* (2)–(3). *Moreover, define $\mathcal{F}^0 \subset \mathcal{F}$ as the closure (with respect to $\|\cdot\|_{\mathcal{F}}$) of the subspace of functions in $C^\infty([0,T]\times\mathbb{R}^d)$ with compact support in x. Then the following statements are equivalent:*

(i) *For every $u^0 \in L^2(\mathbb{R}^d)$ and every $f \in L^2((0,T)\times\mathbb{R}^d)$ there exists a solution $u \in \mathcal{F}^0$ to the Cauchy problem*

$$\begin{cases} \partial_t u + \operatorname{div}(bu) + cu = f, \\ u(0,\cdot) = u^0, \end{cases} \qquad u \in \mathcal{F}^0.$$

(ii) *There is uniqueness for weak solutions in* $C([0,T];L^2(\mathbb{R}^d)-w)$ *for the backward dual Cauchy problem starting from* T*; i.e., the only function* v *belonging to* $C([0,T];L^2(\mathbb{R}^d)-w)$ *which solves*

$$\begin{cases} \partial_t v + b\cdot\nabla v - cv = 0, \\ v(T,\cdot) = 0 \end{cases}$$

is $v \equiv 0$.

Here and further on, the advection term $b\cdot\nabla v$ is defined according to $b\cdot\nabla v \equiv \mathrm{div}(bv) - v\,\mathrm{div}b$, which makes sense since $\mathrm{div}b \in L^\infty$.

Remark 3.2. The two statements in Theorem 3.1 are really the "nontrivial" properties relative to the vector field b. In general, there is always uniqueness in $\mathcal{F}^0$ (see Step 1 in the proof) and there is always existence of weak solutions in $\mathcal{F}$ (this can be easily proved by regularization, as in the first step of the proof of Theorem 2.1).

Before proving the theorem, we recall the following standard result of functional analysis (see, for example, Theorems II.19 and II.20 of [7]).

LEMMA 3.3. *Let* E *and* F *be Banach spaces and let* $L : E \to F$ *be a bounded linear operator. Denote by* $L^* : F^* \to E^*$ *the adjoint operator, defined by*

$$\langle v, Lu\rangle_{F^*,F} = \langle L^*v, u\rangle_{E^*,E} \qquad \text{for every } u\in E \text{ and } v\in F^*.$$

Then

(i) L *is surjective if and only if* L^* *is injective and with closed image;*

(ii) L^* *is surjective if and only if* L *is injective and with closed image.*

Proof of Theorem 3.1.

Step 1. *An energy estimate in* $\mathcal{F}^0$. In this first step we prove that for every $u\in\mathcal{F}^0$ the following energy estimate holds:

(8)
$$\|u(t,\cdot)\|_{L^2_x} \le \left(\|u(0,\cdot)\|_{L^2_x} + \sqrt{T}\|\partial_t u + \mathrm{div}(bu) + cu\|_{L^2_{t,x}}\right)\exp\left(T\left\|c+\frac{1}{2}\mathrm{div}b\right\|_{L^\infty_{t,x}}\right).$$

Let us first prove the estimate for u smooth with compact support in x. We define

$$f = \partial_t u + \mathrm{div}(bu) + cu,$$

and we multiply this relation by u, giving

$$\partial_t\frac{u^2}{2} + \mathrm{div}\left(b\frac{u^2}{2}\right) + \left(c+\frac{1}{2}\mathrm{div}b\right)u^2 = fu.$$

For justifying the previous identity, we used the Leibnitz rule

$$\partial_i(H\psi) = \psi\partial_i H + H\partial_i\psi, \tag{9}$$

valid for $\psi\in C^\infty$ and H any distribution. Then, integrating over $x\in\mathbb{R}^d$ we get in the sense of distributions in $(0,T)$

$$\frac{d}{dt}\int_{\mathbb{R}^d} u(t,x)^2dx = 2\int_{\mathbb{R}^d} fu\,dx - 2\int_{\mathbb{R}^d}\left(c+\frac{1}{2}\mathrm{div}b\right)u^2dx.$$

Therefore, we get for a.e. $t\in(0,T)$

$$\left|\frac{d}{dt}\int_{\mathbb{R}^d} u(t,x)^2dx\right| \le 2\|f(t,\cdot)\|_{L^2_x}\|u(t,\cdot)\|_{L^2_x} + 2\left\|\left(c+\frac{1}{2}\mathrm{div}b\right)(t,\cdot)\right\|_{L^\infty_x}\|u(t,\cdot)\|^2_{L^2_x}.$$

This differential inequality can be easily integrated, obtaining

$$\|u(t,\cdot)\|_{L^2_x} \le \|u(0,\cdot)\|_{L^2_x} \exp\left(\int_0^t \left\|\left(c+\frac{1}{2}\mathrm{div}b\right)(s,\cdot)\right\|_{L^\infty_x} ds\right) + \int_0^t \|f(s,\cdot)\|_{L^2_x} \exp\left(\int_s^t \left\|\left(c+\frac{1}{2}\mathrm{div}b\right)(\tau,\cdot)\right\|_{L^\infty_x} d\tau\right) ds,$$

which clearly implies (8). In the general case of $u \in \mathcal{F}^0$, we can find approximations u_n smooth with compact support such that $\|u_n - u\|_{\mathcal{F}} \to 0$, and we obtain the estimate (8) at the limit.

Step 2. *The operator* A^0. As in the proof of Theorem 2.1, we consider the linear operator

$$A^0 : \begin{array}{ccc} \mathcal{F}^0 & \to & L^2(\mathbb{R}^d) \times L^2((0,T)\times\mathbb{R}^d), \\ u & \mapsto & \big(u(0,\cdot),\ \partial_t u + \mathrm{div}(bu) + cu\big). \end{array}$$

Since we can estimate

$$\begin{aligned} \|A^0 u\|_{L^2_x \times L^2_{t,x}} &= \|u(0,\cdot)\|_{L^2_x} + \|\partial_t u + \mathrm{div}(bu) + cu\|_{L^2_{t,x}} \\ &\le \|u\|_{B_t(L^2_x)} + \|\partial_t u + \mathrm{div}(bu)\|_{L^2_{t,x}} + \|c\|_{L^\infty_{t,x}}\sqrt{T}\|u\|_{B_t(L^2_x)} \\ &\le \big(1 + \|c\|_{L^\infty_{t,x}}\sqrt{T}\big)\|u\|_{\mathcal{F}}, \end{aligned}$$

we deduce that A^0 is a bounded operator. Next, the energy estimate established in the first step gives that for any $u \in \mathcal{F}^0$,

$$\|u\|_{B_t(L^2_x)} \le \exp\left(T\left\|c+\frac{1}{2}\mathrm{div}b\right\|_{L^\infty_{t,x}}\right)\max(1,\sqrt{T})\|A^0 u\|_{L^2_x\times L^2_{t,x}}.$$

But we have

$$\|\partial_t u + \mathrm{div}(bu)\|_{L^2_{t,x}} \le \|\partial_t u + \mathrm{div}(bu) + cu\|_{L^2_{t,x}} + \|c\|_{L^\infty_{t,x}}\sqrt{T}\|u\|_{B_t(L^2_x)},$$

and we conclude that

$$\|u\|_{\mathcal{F}} \le C\,\|A^0 u\|_{L^2_x\times L^2_{t,x}}, \qquad u \in \mathcal{F}^0. \tag{10}$$

This means that A^0 is injective and with closed image. Notice that the injectivity of A^0 is equivalent to the fact that the only solution $u \in \mathcal{F}^0$ to

$$\begin{cases} \partial_t u + \mathrm{div}(bu) + cu = 0, \\ u(0,\cdot) = 0 \end{cases}$$

is $u \equiv 0$.

Step 3. *Proof of the equivalence of the two statements.* Since by Step 2, A^0 is injective with closed image, we can apply Lemma 3.3(ii) to get the surjectivity of the adjoint operator $(A^0)^* : L^2(\mathbb{R}^d)\times L^2((0,T)\times\mathbb{R}^d) \to (\mathcal{F}^0)^*$. We recall that the adjoint operator is characterized by the condition

$$\begin{aligned} \langle (A^0)^*(v_0,v), u\rangle &= \langle (v_0,v), A^0 u\rangle \\ &= \int_{\mathbb{R}^d} v_0 u(0,\cdot)\,dx + \int_{(0,T)\times\mathbb{R}^d} v\big(\partial_t u + \mathrm{div}(bu) + cu\big)\,dtdx, \end{aligned} \tag{11}$$

for $(v_0, v) \in L^2(\mathbb{R}^d) \times L^2((0,T) \times \mathbb{R}^d)$ and $u \in \mathcal{F}^0$. Since $(A^0)^*$ is surjective, in particular it has closed image. Therefore, applying Lemma 3.3(i) we get the equivalence between surjectivity of A^0 and injectivity of $(A^0)^*$.

It is clear that the surjectivity of the operator A^0 is equivalent to the existence of solutions in $\mathcal{F}^0$ (statement (i)). Therefore, it remains only to characterize the injectivity of $(A^0)^*$. Recalling the definition of $\mathcal{F}^0$ as the closure of the set of smooth functions with compact support in x, and recalling the characterization of the adjoint operator given in (11), we obtain that the injectivity of $(A^0)^*$ is equivalent to the following implication:

$$\begin{aligned} &\textstyle\int_{(0,T)\times\mathbb{R}^d} \big(\partial_t u + \operatorname{div}(bu) + cu\big) v \, dtdx + \int_{\mathbb{R}^d} u(0,\cdot) v_0 \, dx = 0 \\ &\text{for every } u \in C^\infty([0,T] \times \mathbb{R}^d) \text{ with compact support in } x \\ &\qquad\qquad \Longrightarrow v_0 = 0 \text{ and } v = 0. \end{aligned} \tag{12}$$

Arguing as in Step 2 of the proof of Theorem 2.1, and eventually testing the integral condition with smooth functions of the form $u(t,x) = \chi(t/\varepsilon)\tilde{u}(t,x)$ (using the same notation as in the proof of Theorem 2.1), we obtain that the following two properties are equivalent for given $v_0 \in L^2(\mathbb{R}^d)$ and $v \in L^2((0,T) \times \mathbb{R}^d)$:

1. For every $u \in C^\infty([0,T] \times \mathbb{R}^d)$ with compact support in x we have

$$\int_{(0,T)\times\mathbb{R}^d} \big(\partial_t u + \operatorname{div}(bu) + cu\big) v \, dtdx + \int_{\mathbb{R}^d} u(0,\cdot) v_0 \, dx = 0.$$

2. $v \in C([0,T]; L^2(\mathbb{R}^d) - w)$, $v_0 = v(0,\cdot)$, and v is a weak solution of the backward dual Cauchy problem

$$\begin{cases} \partial_t v + b \cdot \nabla v - cv = 0, \\ v(T,\cdot) = 0. \end{cases}$$

Therefore we deduce that the implication (12) is equivalent to the uniqueness of weak solutions in $C([0,T]; L^2(\mathbb{R}^d) - w)$ of the backward dual Cauchy problem, i.e., statement (ii). □

Remark 3.4 (time inversion). By reversing the direction of time, we see that there is existence for the backward Cauchy problem in $\mathcal{F}^0$ if and only if there is uniqueness for weak solutions to the forward dual Cauchy problem.

Remark 3.5 (approximation by smooth functions and renormalization). Solutions in $\mathcal{F}^0$ lie in $C([0,T], L^2(\mathbb{R}^d) - s)$ and are renormalized: this can be seen as in the proof of the implication (ii) $\Rightarrow$ (iii) of Theorem 2.1, using the density of smooth functions in $\mathcal{F}^0$. Conversely, it is possible that some renormalized solutions do not belong to $\mathcal{F}^0$. This can be seen by noticing that one can have several renormalized solutions to the same Cauchy problem (see an example in [13]), while there is always uniqueness in $\mathcal{F}^0$. Another difference between the criterion of approximation by smooth functions and the renormalization property is that $\mathcal{F}^0$ is a vector space, while in general, renormalized solutions are not a vector space.

Remark 3.6 (Depauw's example again). We notice that forward uniqueness and backward uniqueness of weak solutions are really distinct properties: the example described in Remark 2.5 shows how to construct bounded divergence-free vector fields with backward uniqueness, but not forward uniqueness, and vice versa.

4. Vector fields of bounded compression. We shall say that a vector field $b \in L^\infty((0,T) \times \mathbb{R}^d; \mathbb{R}^d)$ has *bounded compression* if there exists a function

$\rho \in C([0,T];L^\infty(\mathbb{R}^d)-w^*)$, with $0<C^{-1}\le\rho\le C<\infty$ for some constant $C>0$, such that the identity

$$\partial_t\rho+\mathrm{div}(b\rho)=0 \tag{13}$$

holds in the sense of distributions in $(0,T)\times\mathbb{R}^d$. We remark that every vector field b with bounded divergence has bounded compression (if b is smooth, take for ρ the Jacobian determinant of the flow generated by b, $\rho(t,x)=\det\nabla_x X(0,t,x)$, which is bounded since $\rho(t,x)=\exp\big[-\int_0^t(\mathrm{div}b)(\sigma,X(\sigma,t,x))d\sigma\big]$, where $X(s,t,x)$ satisfies $dX(s,t,x)/ds=b(s,X(s,t,x))$, $X(t,t,x)=x$), but in general a vector field of bounded compression does not need to have absolutely continuous divergence.

THEOREM 4.1. *Let $b\in L^\infty((0,T)\times\mathbb{R}^d;\mathbb{R}^d)$ be a vector field of bounded compression, and fix an associated function $\rho\in C([0,T];L^\infty(\mathbb{R}^d)-w^*)$. We define the Banach space $\mathcal{F}$ and its norm $\|\cdot\|_{\mathcal{F}}$ as in* (2)–(3). *Let $\mathcal{F}^1\subset\mathcal{F}$ be the closure of*

$$\big\{\rho\varphi\ :\ \ \varphi\in C^\infty([0,T]\times\mathbb{R}^d)\ \textit{with compact support in } x\big\}$$

with respect to $\|\cdot\|_{\mathcal{F}}$. Then the following statements are equivalent:

(i) *For every $u^0\in L^2$ and every $f\in L^2$ there exists a solution $u\in\mathcal{F}^1$ to the Cauchy problem*

$$\begin{cases}\partial_t u+\mathrm{div}(bu)=f,\\ u(0,\cdot)=u^0,\end{cases}\qquad u\in\mathcal{F}^1.$$

(ii) *There is uniqueness for weak solutions in $C([0,T];L^2(\mathbb{R}^d)-w)$ for the backward dual Cauchy problem starting from T; i.e., the only function ρ belonging to $C([0,T];L^2(\mathbb{R}^d)-w)$ which solves*

$$\begin{cases}\partial_t(\rho v)+\mathrm{div}(b\rho v)=0,\\ \rho(T,\cdot)v(T,\cdot)=0\end{cases}$$

is $\rho v\equiv 0$.

Remark 4.2. In this context, the equation $\partial_t(\rho v)+\mathrm{div}(b\rho v)=0$ is dual to the equation $\partial_t u+\mathrm{div}(bu)=0$, since we can write (formally, since it is not possible to give a meaning to the product $b\cdot\nabla v$ without a condition of absolute continuity of $\mathrm{div}b$)

$$\partial_t(\rho v)+\mathrm{div}(b\rho v)=\rho\big(\partial_t v+b\cdot\nabla v\big).$$

Proof of Theorem 4.1. The proof is very close to that of Theorem 3.1; thus we shall sometimes omit the technical details.

Step 1. *An energy estimate in $\mathcal{F}^1$.* We preliminarily prove that for every $u\in\mathcal{F}^1$ the following estimate holds (C is the constant related to the function ρ):

$$\|u\|_{B_t(L^2_x)}\le C\|u(0,\cdot)\|_{L^2_x}+C\sqrt{T}\|\partial_t u+\mathrm{div}(bu)\|_{L^2_{t,x}}. \tag{14}$$

Fix a smooth function φ with compact support in $\mathbb{R}^d$, and define $f=\partial_t(\rho\varphi)+\mathrm{div}(b\rho\varphi)=\rho(\partial_t\varphi+b\cdot\nabla\varphi)$ (use the Leibniz rule (9) and formula (13)). We deduce with the same argument that $2\varphi f=\rho(\partial_t\varphi^2+b\cdot\nabla\varphi^2)=\partial_t(\rho\varphi^2)+\mathrm{div}(b\rho\varphi^2)$. Thus, we get the following estimate in the sense of distributions in $(0,T)$:

$$\begin{aligned}\frac{d}{dt}\int_{\mathbb{R}^d}\rho(t,x)\varphi(t,x)^2\,dx &= 2\int_{\mathbb{R}^d}\varphi(t,x)f(t,x)\,dx\\ &\le 2\|f(t,\cdot)\|_{L^2_x}\|\varphi(t,\cdot)\|_{L^2_x}\\ &\le 2\sqrt{C}\|f(t,\cdot)\|_{L^2_x}\left[\int_{\mathbb{R}^d}\rho(t,x)\varphi(t,x)^2\,dx\right]^{1/2}.\end{aligned}$$

By integration with respect to time this implies

$$\left[\int_{\mathbb{R}^d}\rho(t,x)\varphi(t,x)^2\,dx\right]^{1/2}\le\left[\int_{\mathbb{R}^d}\rho(0,x)\varphi(0,x)^2\,dx\right]^{1/2}+\sqrt{C}\int_0^t\|f(s,\cdot)\|_{L^2_x}\,ds.$$

Using the fact that $C^{-1}\le\rho\le C$ we deduce

$$\frac{1}{\sqrt{C}}\|\rho(t,\cdot)\varphi(t,\cdot)\|_{L^2_x}\le\sqrt{C}\|\rho(0,\cdot)\varphi(0,\cdot)\|_{L^2_x}+\sqrt{C}\int_0^t\|f(s,\cdot)\|_{L^2_x}\,ds,$$

and thus

$$\|\rho(t,\cdot)\varphi(t,\cdot)\|_{L^2_x}\le C\|\rho(0,\cdot)\varphi(0,\cdot)\|_{L^2_x}+C\sqrt{T}\|\partial_t(\rho\varphi)+\operatorname{div}(b\rho\varphi)\|_{L^2_{t,x}}. \tag{15}$$

But by definition of $\mathcal{F}^1$, the validity of (15) for every smooth function φ with compact support in x implies the validity of (14) for every function $u\in\mathcal{F}^1$.

Step 2. *The operator* A^1. We define the linear operator

$$A^1:\begin{array}{ccc}\mathcal{F}^1 & \to & L^2(\mathbb{R}^d)\times L^2((0,T)\times\mathbb{R}^d),\\ u & \mapsto & \big(u(0,\cdot),\ \partial_t u+\operatorname{div}(bu)\big).\end{array}$$

It is immediate to see that the operator A^1 is bounded. Using the energy estimate (14) it is also immediate to check that $\|u\|_{\mathcal{F}}\le\tilde{C}\|A^1u\|$, and therefore that A^1 is injective with closed image. Applying Lemma 3.3(ii) we obtain that the adjoint operator

$$(A^1)^*:L^2(\mathbb{R}^d)\times L^2((0,T)\times\mathbb{R}^d)\to(\mathcal{F}^1)^*$$

is surjective. The adjoint operator is characterized by the identity

$$\begin{aligned}\langle(A^1)^*(v_0,v),u\rangle &= \langle(v_0,v),A^1u\rangle\\ &= \int_{\mathbb{R}^d}v_0u(0,\cdot)\,dx+\int_{(0,T)\times\mathbb{R}^d}v\big(\partial_tu+\operatorname{div}(bu)\big)\,dtdx\end{aligned} \tag{16}$$

for $(v_0,v)\in L^2(\mathbb{R}^d)\times L^2((0,T)\times\mathbb{R}^d)$ and $u\in\mathcal{F}^1$.

Step 3. *Proof of the equivalence of the two statements.* Statement (i) (existence of solutions in $\mathcal{F}^1$) is the surjectivity of the operator A^1, which is equivalent (applying Lemma 3.3(i) and using the surjectivity of $(A^1)^*$ proved in Step 2) to the injectivity of $(A^1)^*$. But recalling the characterization (16) and the definition of the space $\mathcal{F}^1$, we see that the injectivity of $(A^1)^*$ is equivalent to the following implication for $v_0\in L^2(\mathbb{R}^d)$ and $v\in L^2((0,T)\times\mathbb{R}^d)$:

$$\begin{aligned}&\textstyle\int_{(0,T)\times\mathbb{R}^d}\big(\partial_t(\rho\varphi)+\operatorname{div}(b\rho\varphi)\big)v\,dtdx+\int_{\mathbb{R}^d}\rho(0,\cdot)\varphi(0,\cdot)v_0\,dx=0\\ &\quad\text{for every }\varphi\in C^\infty([0,T]\times\mathbb{R}^d)\text{ with compact support in }x\\ &\qquad\Longrightarrow v_0=0\text{ and }v=0.\end{aligned} \tag{17}$$

Arguing as in Step 3 of the proof of Theorem 3.1 we obtain that the following two properties are equivalent:

1. For every $\varphi \in C^\infty([0,T]\times\mathbb{R}^d)$ with compact support in x we have

$$\int_{(0,T)\times\mathbb{R}^d} \big(\partial_t(\rho\varphi) + \operatorname{div}(b\rho\varphi)\big)v\,dtdx + \int_{\mathbb{R}^d} \rho(0,\cdot)\varphi(0,\cdot)v_0\,dx = 0.$$

2. $\rho v \in C([0,T];L^2(\mathbb{R}^d)-w)$, $\rho(0,\cdot)v_0 = \rho(0,\cdot)v(0,\cdot)$, and ρv is a weak solution of the backward dual Cauchy problem

$$\begin{cases} \partial_t(\rho v) + \operatorname{div}(b\rho v) = 0, \\ \rho(T,\cdot)v(T,\cdot) = 0. \end{cases}$$

Then we deduce that implication (17) is equivalent to statement (ii), and this concludes the proof of the theorem. □

SCATTERING OF ELECTROMAGNETIC WAVES BY THIN DIELECTRIC PLANAR STRUCTURES*

HABIB AMMARI†, HYEONBAE KANG‡, AND FADIL SANTOSA§

Abstract. The problem of scattering of electromagnetic waves by a thin dielectric planar structure is considered. If the squared index of refraction of the scatterer scales as $1/h$, where h is the thickness of the structure, we show that an approximate solution to the scattering problem can be obtained by a perturbation method. The approximate solution consists of two terms, the zeroth order term and the first order corrector, both of which can be found by solving 2-D integral equations for 3-D problems. We provide error estimates for the approximation. Therefore, the method described in this work can be viewed as a computational approach which can potentially greatly simplify scattering calculations for problems involving thin scatterers.

Key words. electromagnetic scattering, Maxwell's equations, approximate solution, asymptotics, error estimates

1. Introduction.

To understand how light behaves in a thin-film structure with a high-refractive-index contrast, we need to solve the time-harmonic Maxwell's equation. The structure is usually surrounded by air. Thus, the domain in which Maxwell's equation must be solved will be all of $\mathbb{R}^3$. The thin-film structure is modeled by prescribing the index of refraction to a subdomain of $\mathbb{R}^3$.

The standard approach for performing the required simulation of wave propagation in such a structure is the finite-difference time-domain (FDTD) method [2], with absorbing boundary conditions. While the computation proceeds in a straightforward manner, it can be very time consuming.

In this paper, we consider a scattering problem in which an incident wave strikes a thin-film structure. Our goal is to derive an asymptotic expansion for the solution of Maxwell's equation. The approach is to exploit the fact that the scattering structure is thin, and the index of refraction is large. In this work, we assume that the squared index of refraction is $O(1/h)$, where h is the scatterer thickness. Under a regularity assumption on the index of refraction, we show that an approximate solution, consisting of a leading term and first order (in h) corrector, can be obtained by solving a 2-D integral equation for a 3-D problem. Thus, the expansion described here can be thought of as a computational approach.

This work is an extension of [5] which considered the scattering problem in the context of the scalar Helmholtz equation. In that work, a perturbation approach

based on the thickness h is developed to reduce the complexity of the computation by one dimension. The present paper addresses the case of Maxwell's equations, which is the correct model for the propagation phenomena. We start with the Lippmann–Schwinger formulation of the electromagnetic scattering problem which involves a 3-D (volume) integral equation. Based on delicate estimates on the kernels involved in this integral formulation, we carefully derive the asymptotic expansion of the electric field in h and provide rigorous error estimates. Using our asymptotic expansion in h, we then simplify the scattering calculations to solving a 2-D (surface) integral equation.

The paper is organized as follows. We give a description of the problem we wish to solve in the next section. The perturbation approach and its rigorous justification are presented in section 3. Our justification uses a nontrivial bound on the $\mathcal{C}^{1,\alpha}$-norm of the electric field proved in Appendix A.

The results in this paper are expected to lead to a very effective computational algorithm for solving the electromagnetic scattering problem for thin-film devices in the parameter regime, where the approximation is accurate.

2. Problem statement. Let E and H denote the electric and magnetic fields. The governing Maxwell's equations are given by

$$\begin{cases} \nabla \times E = ikH, \\ \nabla \times H = -ikn(x,z)E, \end{cases}$$

where $k > 0$ is the normalized frequency. The total field consists of the incident field and the scattered field. We write $E = E^i + E^s$, where E^i is a given incident wave. The scattered electric field E^s satisfies the Sommerfeld radiation condition. We call the function $n(x,z)$ the *squared index of refraction*.

Here $x = (x_1, x_2)$ and z is the third direction. The squared index of refraction $n(x,z)$ is defined by

$$n(x,z) := \begin{cases} 1 \quad \text{for } |z| > \dfrac{h}{2}, \\ \dfrac{n_0(x)}{h} \quad \text{for } |z| < \dfrac{h}{2}. \end{cases}$$

Therefore, the thin scattering structure has been incorporated into the definition of $n(x,z)$. Let Ω be a bounded domain in $\mathbb{R}^2$. We denote $\Omega_h := \Omega \times (-h/2, h/2)$.

We assume that n_0 is a $\mathcal{C}^2$ function, and that $(1 - n_0/h)$ is supported in Ω_d for some $d > 0$, where $\Omega_d := \{x \in \Omega : \operatorname{dist}(x, \partial\Omega) > d\}$, $\Re n_0(x) \geq C > 0$, and $\Im n_0(x) \geq 0$.

The problem we wish to solve is to determine the total field E given the incident wave E^i and a scatterer $n(x,z)$. We will seek an approximate solution for this problem by exploiting the fact that h will be small. The approach we take is to write the field E as a perturbation series in h.

3. Derivation of the asymptotic expansion. For $x, x' \in \mathbb{R}^2$ and $z, z' \in \mathbb{R}$, let the fundamental solution Φ be defined by

$$\Phi(x,z,x',z') := \frac{1}{4\pi} \frac{e^{ik|(x,z)-(x',z')|}}{|(x,z)-(x',z')|}.$$

According to [3], we can rewrite the problem as the following Lippmann–Schwinger equation:

(3.1)
$$\begin{aligned} E(x,z) &= E^i(x,z) - k^2 \int_\Omega \int_{-h/2}^{h/2} \Phi(x,z,x',z') \left(1 - \frac{n_0(x')}{h}\right) E(x',z') dx' dz' \\ &\quad - \nabla_{x,z} \int_\Omega \int_{-h/2}^{h/2} \Phi(x,z,x',z') \frac{\nabla n_0(x')}{n_0(x')} \cdot E(x',z') dx' dz'. \end{aligned}$$

Consequently, it suffices to construct an approximation of the electric field E inside Ω_h and insert it into the right-hand side of (3.1) to obtain an expansion of E for all points outside the thin structure Ω_h.

After scaling $z = h\zeta$ and $z' = h\zeta'$, (3.1) can be written as

(3.2)
$$\begin{aligned} E(x,h\zeta) &= E^i(x,h\zeta) - k^2 \int_\Omega \int_{-1/2}^{1/2} \Phi(x,h\zeta,x',h\zeta')(h - n_0(x')) E(x',h\zeta') dx' d\zeta' \\ &\quad - \begin{pmatrix} h\nabla_x \\ \nabla_\zeta \end{pmatrix} \int_\Omega \int_{-1/2}^{1/2} \Phi(x,h\zeta,x',h\zeta') \frac{\nabla n_0(x')}{n_0(x')} \cdot E(x',h\zeta') dx' d\zeta'. \end{aligned}$$

For a scalar function f defined in Ω_h, define the integral operators K_1 and K_2 by

$$\begin{aligned} K_1(f)(x,\zeta) &:= \int_\Omega \int_{-1/2}^{1/2} \Phi(x,h\zeta,x',h\zeta') f(x',h\zeta') dx' d\zeta', \\ K_2(f)(x,\zeta) &:= \begin{pmatrix} h\nabla_x \\ \nabla_\zeta \end{pmatrix} \int_\Omega \int_{-1/2}^{1/2} \Phi(x,h\zeta,x',h\zeta') f(x',h\zeta') dx' d\zeta'. \end{aligned}$$

Then the integral representation (3.2) can be rewritten as

(3.3)
$$E(x,h\zeta) = E^i(x,h\zeta) + k^2 K_1(n_0 E)(x,\zeta) - hk^2 K_1(E)(x,\zeta) - K_2(n_0^{-1} \nabla n_0 \cdot E)(x,\zeta).$$

We now investigate the behavior of the integral operators K_1 and K_2 as $h \to 0$. We begin by proving the following lemma.

LEMMA 3.1. *Let $0 < \alpha < 1$. Suppose that f is $\mathcal{C}^{1,\alpha}$ in Ω_h; then*

$$\begin{aligned} K_1(n_0 f)(x,\zeta) &= \int_\Omega \Phi(x,0,x',0) n_0(x') f(x',0) dx' - \frac{h}{2}\left(\zeta^2 + \frac{1}{4}\right) n_0(x) f(x,0) \\ &\quad + O\left(h^{1+\alpha} \|f\|_{\mathcal{C}^{1,\alpha}(\Omega_h)}\right). \end{aligned} \tag{3.4}$$

Suppose that $g \in L^\infty(\Omega_h)$; then

$$K_1(g)(x,\zeta) = \int_\Omega \Phi(x,0,x',0) g(x',0) dx' + O(h \|g\|_{L^\infty(\Omega_h)}). \tag{3.5}$$

Proof. Observe that

$$\begin{aligned} &\Phi(x,h\zeta,x',h\zeta') f(x',h\zeta') - \Phi(x,0,x',0) f(x',0) \\ &= \Phi(x,h\zeta,x',h\zeta') \left(f(x',0) + h\zeta' \frac{\partial f}{\partial z}(x',0) + O(h^{1+\alpha}) \right) - \Phi(x,0,x',0) f(x',0) \\ &= \left[\Phi(x,h\zeta,x',h\zeta') - \Phi(x,0,x',0) \right] f(x',0) + \Phi(x,h\zeta,x',h\zeta') \left(h\zeta' \frac{\partial f}{\partial z}(x',0) + O(h^{1+\alpha}) \right). \end{aligned}$$

Let $S := \Omega \times (-1/2, 1/2)$. We then have

$$\begin{aligned}
&\int_S \Big[\Phi(x,h\zeta,x',h\zeta')n_0(x')f(x',h\zeta') - \Phi(x,0,x',0)n_0(x')f(x',0)\Big]dx'd\zeta' \\
&= \int_S \Big[\Phi(x,h\zeta,x',h\zeta') - \Phi(x,0,x',0)\Big]n_0(x')f(x',0)dx'd\zeta' \\
&\quad + \int_S \Phi(x,h\zeta,x',h\zeta')n_0(x')h\zeta'\frac{\partial f}{\partial z}(x',0)dx'd\zeta' + O(h^{1+\alpha})\int_S \Phi(x,h\zeta,x',h\zeta')n_0(x')dx'd\zeta' \\
&:= I_1 + I_2 + I_3.
\end{aligned}$$

Since

$$\left|\int_S \Phi(x,h\zeta,x',h\zeta')n_0(x')dx'd\zeta'\right| \le C$$

regardless of h, one can see that $I_3 = O(h^{1+\alpha})$.

To estimate I_2, we first observe that

$$\int_{-1/2}^{1/2} \zeta'\frac{\partial f}{\partial z}(x',0)d\zeta' = 0,$$

and hence

$$I_2 = h\int_S \Big[\Phi(x,h\zeta,x',h\zeta') - \Phi(x,0,x',0)\Big]n_0(x')\zeta'\frac{\partial f}{\partial z}(x',0)dx'd\zeta'.$$

Therefore, we get

$$|I_2| \le \|f\|_{C^1(\Omega_h)}h\int_S \Big|\Phi(x,h\zeta,x',h\zeta') - \Phi(x,0,x',0)\Big|dx'd\zeta'.$$

For a given $(x,\zeta) \in S$ and $h > 0$, let $S_h := \{(x',\zeta') \mid |x-x'| > 2h|\zeta-\zeta'|\}$. If $(x',\zeta') \in S_h$, then

$$(|x-x'|^2 + h^2|\zeta-\zeta'|^2)^{1/2} = |x-x'|\left(1 + O\left(\frac{h^2|\zeta-\zeta'|^2}{|x-x'|^2}\right)\right),$$

and hence

$$\begin{aligned}
\Phi(x,h\zeta,x',h\zeta') &= \frac{1}{4\pi}\frac{e^{ik(|x-x'|^2+h^2|\zeta-\zeta'|^2)^{1/2}}}{(|x-x'|^2+h^2|\zeta-\zeta'|^2)^{1/2}} \\
&= \frac{1}{4\pi}e^{ik|x-x'|}\left(1 + O\left(\frac{h^2|\zeta-\zeta'|^2}{|x-x'|}\right)\right)\left(\frac{1}{|x-x'|} + O\left(\frac{h^2|\zeta-\zeta'|^2}{|x-x'|^3}\right)\right).
\end{aligned}$$

Thus we get

(3.6)
$$\Big|\Phi(x,h\zeta,x',h\zeta') - \Phi(x,0,x',0)\Big| \le C\frac{h^2|\zeta-\zeta'|^2}{|x-x'|^2} + C\frac{h^2|\zeta-\zeta'|^2}{|x-x'|^3} + C\frac{h^4|\zeta-\zeta'|^4}{|x-x'|^4}.$$

One can easily show that

$$\int_{-1/2}^{1/2}\int_{|x-x'|>2h|\zeta-\zeta'|} \frac{h^2|\zeta-\zeta'|^2}{|x-x'|^2}dx'dz' \le Ch^2,$$

$$\int_{-1/2}^{1/2}\int_{|x-x'|>2h|\zeta-\zeta'|}\frac{h^2|\zeta-\zeta'|^2}{|x-x'|^3}dx'dz' \le Ch,$$

and

$$\int_{-1/2}^{1/2}\int_{|x-x'|>2h|\zeta-\zeta'|}\frac{h^4|\zeta-\zeta'|^4}{|x-x'|^4}dx'dz' \le Ch^2.$$

Thus we get

$$\int_{S_h}\Big|\Phi(x,h\zeta,x',h\zeta')-\Phi(x,0,x',0)\Big|dx'd\zeta' \le Ch.$$

On the other hand, one can also easily see that

$$\begin{aligned}&\int_{S\setminus S_h}\Big|\Phi(x,h\zeta,x',h\zeta')-\Phi(x,0,x',0)\Big|dx'd\zeta'\\ &\le\int_{-1/2}^{1/2}\int_{|x-x'|\le 2h|\zeta-\zeta'|}\frac{1}{|x-x'|+h|\zeta-\zeta'|}+\frac{1}{|x-x'|}dx'd\zeta' \le Ch,\end{aligned}$$

and hence we obtain

$$|I_2| \le Ch^2.$$

We now estimate I_1. Since $n_0(x')-h$ is compactly supported in Ω, we can write

$$\begin{aligned}I_1 =& \int_{-1/2}^{1/2}\int_{B_R(x)}\Big[\Phi(x,h\zeta,x',h\zeta')-\Phi(x,0,x',0)\Big](n_0(x')-h)f(x',0)dx'd\zeta'\\ &+h\int_S\Big[\Phi(x,h\zeta,x',h\zeta')-\Phi(x,0,x',0)\Big]f(x',0)dx'd\zeta',\end{aligned}$$

where $B_R(x)$ is a disk of radius R centered at x containing Ω. One can prove that the second term in the right-hand side of above identity is $O(h^2)$ as before, while the first term equals

$$\begin{aligned}&\int_{B_R(x)}\big[\Phi(x,h\zeta,x',h\zeta')-\Phi(x,0,x',0)\big]\big[(n_0(x')-h)f(x',0)-(n_0(x)-h)f(x,0)\big]dx'd\zeta'\\ &+(n_0(x)-h)f(x,0)\int_{B_R(x)}\big[\Phi(x,h\zeta,x',h\zeta')-\Phi(x,0,x',0)\big]dx'd\zeta'.\end{aligned}$$

Since $|(n(x')-h)f(x',0)-(n(x)-h)f(x,0)| \le C|x-x'|$, one can show that the first term of the above is $O(h^2)$ in a similar way to the estimate of I_2. On the other hand, it is proved in [5] that

$$\int_{B_R(x)}\big[\Phi(x,h\zeta,x',h\zeta')-\Phi(x,0,x',0)\big]dx'd\zeta' = -\frac{h}{2}\left(\zeta^2+\frac{1}{4}\right)+O(h^2) \quad \text{as } h\to 0.$$

Thus we have

$$I_1 = -\frac{h}{2}\left(\zeta^2+\frac{1}{4}\right)n_0(x)f(x,0)+O(h^2).$$

Combining all these estimates we obtain (3.4).

Estimate (3.5) can be proved in a similar but simpler way, so we omit the proof. □

We now derive the leading-order term in the asymptotic expansion of the integral operator K_2.

LEMMA 3.2. *Let $0 < \alpha < 1$. Define $\widetilde{K}_2^1(f)(x)$ by*

(3.7)
$$\widetilde{K}_2^1(f)(x) := \int_\Omega \nabla_x \Phi(x,0,x',0)[f(x',0) - f(x,0)]dx' + f(x,0)\int_\Omega \nabla_x \Phi(x,0,x',0)dx',$$

and $\widetilde{K}_2(f)(x,\zeta)$ by

$$\widetilde{K}_2(f)(x,\zeta) := \begin{pmatrix} \widetilde{K}_2^1(f)(x) \\ (\frac{\zeta}{2} - 1)f(x,0) \end{pmatrix}. \tag{3.8}$$

Then, for any $\mathcal{C}^{1,\alpha}$-function f such that $f(\cdot,z)$ is supported in Ω_d for each z,

$$K_2(f)(x,\zeta) = h\widetilde{K}_2(f)(x,\zeta) + O(h^{1+\alpha}), \tag{3.9}$$

where $O(h^{1+\alpha})$ is bounded by $Ch^{1+\alpha}\|f\|_{\mathcal{C}^{1,\alpha}(\Omega_h)}$.

Proof. Note that

$$\begin{aligned}
&\nabla_x \int_S \Phi(x,h\zeta,x',h\zeta')f(x',h\zeta')dx'd\zeta' \\
&= \int_S \nabla_x \Phi(x,h\zeta,x',h\zeta')\Big[f(x',h\zeta') - f(x,h\zeta')\Big]dx'd\zeta' \\
&\qquad + \int_S \nabla_x \Phi(x,h\zeta,x',h\zeta')f(x,h\zeta')dx'd\zeta'.
\end{aligned}$$

Thus,

$$\begin{aligned}
&\nabla_x \int_S \Phi(x,h\zeta,x',h\zeta')f(x',h\zeta')dx'd\zeta' - \widetilde{K}_2^1(f(\cdot,0))(x) \\
&= \int_S \Big[\nabla_x \Phi(x,h\zeta,x',h\zeta') - \nabla_x \Phi(x,0,x',0)\Big]\Big[f(x',h\zeta') - f(x,h\zeta')\Big]dx'd\zeta' \\
&\quad + \int_S \nabla_x \Phi(x,0,x',0)\Big[f(x',h\zeta') - f(x,h\zeta') - f(x',0) + f(x,0)\Big]dx'd\zeta' \\
&\quad + \int_S \Big[\nabla_x \Phi(x,h\zeta,x',h\zeta') - \nabla_x \Phi(x,0,x',0)\Big]f(x,h\zeta')dx'd\zeta' \\
&\quad + \int_S \nabla_x \Phi(x,0,x',0)\Big[f(x,h\zeta') - f(x,0)\Big]dx'd\zeta' \\
&:= I_1 + I_2 + I_3 + I_4.
\end{aligned}$$

Since

$$\begin{aligned}
&\nabla_x \Phi(x,h\zeta,x',h\zeta') \\
&= \frac{1}{4\pi} e^{ik(|x-x'|^2 + h^2|\zeta-\zeta'|^2)^{1/2}}\left[ik\frac{x-x'}{|x-x'|^2 + h^2|\zeta-\zeta'|^2} - \frac{x-x'}{(|x-x'|^2 + h^2|\zeta-\zeta'|^2)^{3/2}}\right],
\end{aligned}$$

we get for $|x-x'| \geq 2h|\zeta-\zeta'|$

$$\begin{aligned}
&\nabla_x \Phi(x, h\zeta, x', h\zeta') \\
&= \frac{ik}{4\pi} e^{ik|x-x'|}\left[1 + O\left(\frac{h^2|\zeta-\zeta'|^2}{|x-x'|}\right)\right]\left[ik\frac{x-x'}{|x-x'|^2} - \frac{x-x'}{|x-x'|^3} + O\left(\frac{h^2|\zeta-\zeta'|^2}{|x-x'|^4}\right)\right] \\
&= \nabla_x \Phi(x, 0, x', 0) + O\left(\frac{h^2|\zeta-\zeta'|^2}{|x-x'|^4}\right).
\end{aligned}$$

It then follows that

$$\begin{aligned}
&\int_{S_h}\left[\nabla_x \Phi(x, h\zeta, x', h\zeta') - \nabla_x \Phi(x, 0, x', 0)\right]\Big[f(x', h\zeta') - f(x, h\zeta')\Big]dx'd\zeta' \\
&\leq C\|f\|_{\mathcal{C}^1(\Omega_h)} \int_{-1/2}^{1/2}\int_{|x-x'|\geq 2h|\zeta-\zeta'|} \frac{h^2|\zeta-\zeta'|^2}{|x-x'|^4}|x-x'|dx'd\zeta' \\
&\leq Ch.
\end{aligned}$$

On the other hand, we get

$$\begin{aligned}
&\int_{S\setminus S_h}\left[\nabla_x \Phi(x, h\zeta, x', h\zeta') - \nabla_x \Phi(x, 0, x', 0)\right]\Big[f(x', h\zeta') - f(x, h\zeta')\Big]dx'd\zeta' \\
&\leq C\|f\|_{\mathcal{C}^1(\Omega_h)} \int_{-1/2}^{1/2}\int_{|x-x'|\geq 2h|\zeta-\zeta'|} \frac{1}{|x-x'|^2}|x-x'|dx'd\zeta' \\
&\leq Ch.
\end{aligned}$$

Therefore, we obtain

$$|I_1| \leq Ch.$$

Observe that

$$\begin{aligned}
\Big|f(x', h\zeta') - f(x, h\zeta') - f(x', 0) + f(x, 0)\Big| &= \left|\int_0^{h\zeta'}\left[\frac{\partial}{\partial z}f(x', z) - \frac{\partial}{\partial z}f(x, z)\right]\right| \\
&\leq C\|f\|_{\mathcal{C}^{1,\alpha}(\Omega_h)} h|x-x'|^\alpha.
\end{aligned}$$

It then follows that

$$|I_2| \leq C\|f\|_{\mathcal{C}^{1,\alpha}(\Omega_h)} h\int_{-1/2}^{1/2}\int_\Omega \frac{1}{|x-x'|^2}|x-x'|^\alpha dx'd\zeta' \leq C\|f\|_{\mathcal{C}^{1,\alpha}(\Omega_h)} h.$$

If $x \in \operatorname{supp}(f)$, then $B_d(x) \subset \Omega$. Moreover,

$$\int_{B_d(x)} \nabla_x \Phi(x, h\zeta, x', h\zeta')dx' = \int_{B_d(x)} \nabla_x \Phi(x, 0, x', 0)dx' = 0 \quad \text{for all } \zeta \text{ and } \zeta'.$$

Therefore we get

$$\begin{aligned}
|I_3| &= \int_{-1/2}^{1/2}\int_{\Omega\setminus B_d(x)}\Big[\nabla_x \Phi(x, h\zeta, x', h\zeta') - \nabla_x \Phi(x, 0, x', 0)\Big]f(x, h\zeta')dx'd\zeta' \\
&\leq C\|f\|_{L^\infty(\Omega_h)} h^2 \int_{-1/2}^{1/2}|\zeta-\zeta'|^2 d\zeta' \leq C\|f\|_{L^\infty(\Omega_h)} h^2.
\end{aligned}$$

Finally, we arrive at

$$|I_4| = C\|f\|_{\mathcal{C}^1(\Omega_h)} h \int_{\Omega\setminus B_d(x)} \frac{1}{|x-x'|^2} dx' \le C\|f\|_{\mathcal{C}^1(\Omega_h)} h.$$

So far we proved that

$$\nabla_x \int_S \Phi(x, h\zeta, x', h\zeta') f(x', h\zeta') dx' d\zeta' = \widetilde{K}_2^1(f(\cdot,0))(x) + O(h^\alpha \|f\|_{\mathcal{C}^{1,\alpha}(\Omega_h)}) \quad \text{as } h \to 0.$$

We now investigate the behavior of

$$\frac{\partial}{\partial z} \int_S \Phi(x, h\zeta, x', h\zeta') f(x', h\zeta') dx' d\zeta'$$

as $h \to 0$.

Elementary computations show that

$$\begin{aligned}
&\frac{\partial}{\partial z}\Phi(x, h\zeta, x', h\zeta') \\
&= \frac{1}{4\pi} e^{ik(|x-x'|^2+h^2|\zeta-\zeta'|^2)^{1/2}} \left[ik \frac{h^2(\zeta-\zeta')}{|x-x'|^2+h^2|\zeta-\zeta'|^2} - \frac{h^2(\zeta-\zeta')}{(|x-x'|^2+h^2|\zeta-\zeta'|^2)^{3/2}} \right] \\
&= -\frac{1}{4\pi} \frac{h^2(\zeta-\zeta')}{(|x-x'|^2+h^2|\zeta-\zeta'|^2)^{3/2}} + O\left(\frac{h^2|\zeta-\zeta'|}{|x-x'|^2+h^2|\zeta-\zeta'|^2} \right).
\end{aligned}$$

Since $-\frac{1}{4\pi}\frac{t}{(|x-x'|^2+t^2)^{3/2}}$ is the Poisson kernel for the half space and $f(\cdot, h\zeta')$ has a compact support in Ω, we get

$$-\frac{1}{4\pi} \int_\Omega \frac{h^2(\zeta-\zeta')}{(|x-x'|^2+h^2|\zeta-\zeta'|^2)^{3/2}} f(x', h\zeta') dx' = -\frac{h}{2} f(x,0) \frac{\zeta-\zeta'}{|\zeta-\zeta'|} + O(h^2),$$

where the $O(h^2)$-term is bounded by $h^2\|f\|_{\mathcal{C}^1(\Omega_h)}$. On the other hand,

$$\int_\Omega \frac{h^2|\zeta-\zeta'|}{|x-x'|^2+h^2|\zeta-\zeta'|^2} |f(x', h\zeta')| dx' \le C\|f\|_{L^\infty(\Omega_h)} h^2|\zeta-\zeta'|\,|\ln(h|\zeta-\zeta'|)|.$$

It then follows that

$$\begin{aligned}
&\frac{\partial}{\partial z} \int_S \Phi(x, h\zeta, x', h\zeta') f(x', h\zeta') dx' d\zeta' \\
&= -\frac{h}{2} f(x,0) \int_{-1/2}^{1/2} \frac{\zeta-\zeta'}{|\zeta-\zeta'|} d\zeta' + O(h^2|\ln h|) \\
&= h\left(\frac{\zeta}{2} - 1\right) f(x,0) + O(h^2|\ln h|).
\end{aligned}$$

This completes the proof. □

REMARK 3.3. *It is worth noticing that the above lemma applies if f is $\mathcal{C}^{1,\alpha}$ in the z variable and only $\mathcal{C}^1$ in the x variable.*

The following lemma is also of use to us.

LEMMA 3.4. *The operator*

$$T : f \in \mathcal{C}^0(\overline{\Omega}) \mapsto f(x) - k^2 \int_\Omega \Phi(x, 0, x', 0) n_0(x') f(x')\, dx' \in \mathcal{C}^0(\overline{\Omega})$$

is invertible.

Proof. As proved in [5], the operator

$$f \in L^2(\Omega) \mapsto \int_\Omega \Phi(x,0,x',0) n_0(x') f(x')\, dx' \in L^2(\Omega)$$

is compact. Since $n_0(x)$ is compactly supported in Ω, we can actually prove that

$$f \in \mathcal{C}^0(\overline{\Omega}) \mapsto \int_\Omega \Phi(x,0,x',0) n_0(x') f(x')\, dx' \in \mathcal{C}^0(\overline{\Omega})$$

is compact. Thus, by the Fredholm alternative, it suffices to show that T is injective on $\mathcal{C}^0(\overline{\Omega})$. Let $f \in \mathcal{C}^0(\overline{\Omega})$ be a solution to

$$f(x) - k^2 \int_\Omega \Phi(x,0,x',0) n_0(x') f(x')\, dx' = 0.$$

Define the function $u(x,z)$ in $\mathbb{R}^3 \setminus \overline{\Omega}$ by

$$u(x,z) = \int_\Omega \Phi(x,z,x',0) n_0(x') f(x')\, dx'.$$

It follows that

$$\begin{cases} (\Delta + k^2) u(x) = 0 \quad \text{in } \mathbb{R}^3 \setminus \overline{\Omega}, \\ u|_+ - u|_- = 0 \quad \text{on } \Omega, \\ \dfrac{\partial u}{\partial z}\Big|_+ (x) - \dfrac{\partial u}{\partial z}\Big|_- (x) = n_0(x) f(x) \quad \text{on } \Omega, \\ u \text{ satisfies the Sommerfeld radiation condition.} \end{cases}$$

Let B_R be a sphere of center the origin and of radius R which is such that $\Omega \subset B_R$. Integrating by parts we obtain that

$$\int_{B_R \setminus \overline{\Omega}} |\nabla u|^2 - k^2 \int_{B_R} |u|^2 - \int_{\partial B_R} \frac{\partial u}{\partial \nu} \overline{u} - \int_\Omega \left[\frac{\partial u}{\partial z}\right] \overline{u} = 0,$$

where $[\partial u/\partial z] = \partial u/\partial z|_+ - \partial u/\partial z|_-$ denotes the jump of $\partial u/\partial z$ across Ω. Since $u = (1/k^2) f$ and $[\partial u/\partial z] = n_0 f$ on Ω we get

$$\int_\Omega \left[\frac{\partial u}{\partial z}\right] \overline{u} = \frac{1}{k^2} \int_\Omega n_0(x) |f(x)|^2\, dx.$$

Thus,

$$\Im \int_{\partial B_R} \frac{\partial u}{\partial \nu} \overline{u} = -\Im \frac{1}{k^2} \int_\Omega n_0(x) |f(x)|^2\, dx \le 0,$$

since $\Im n_0(x) \ge 0$. By the Rellich lemma (see [3]), the above inequality implies that $u \equiv 0$ in $\mathbb{R}^3 \setminus \overline{\Omega}$, and hence $n_0 f = [\partial u/\partial z] = 0$ which gives $f = 0$ on Ω since $\Re n_0(x) \ge C > 0$. ∎

We finally establish the following bound on the $\mathcal{C}^{1,\alpha}$-norm of E.

PROPOSITION 3.5. *Let E be the solution of the Lippmann–Schwinger equation (3.1). Then for any $0 < \alpha < 1$, there exists a constant C independent of h such that*

$$\|E\|_{\mathcal{C}^{1,\alpha}(\overline{\Omega_h})} \leq C|\log h|^2. \tag{3.10}$$

We will give a proof of Proposition 3.5 in Appendix A.

At this point we have all the necessary ingredients to state and prove our main result in this paper. Let

$$\widetilde{K}_1(f)(x) = \int_\Omega \Phi(x,0,x',0)f(x')\,dx', \quad x \in \Omega, \tag{3.11}$$

and $\widetilde{K}_2(f)$ be as in (3.8). Equation (3.3), together with Lemmas 3.1 and 3.2, yields the pointwise approximation

(3.12)

$$\begin{aligned} E(x,h\zeta) &= E^i(x,h\zeta) + k^2\widetilde{K}_1(n_0E_0)(x,0) \\ &\quad - h\left[k^2\widetilde{K}_1(E_0)(x) + \frac{k^2}{2}\left(\zeta^2+\frac{1}{4}\right)n_0(x)E_0(x) + \widetilde{K}_2(n_0^{-1}\nabla n_0\cdot E_0)(x,\zeta)\right] \\ &\quad + O(h^{1+\alpha}), \end{aligned}$$

where $E_0(x) = E(x,0)$ and $O(h^{1+\alpha}) \leq Ch^{1+\alpha}||E||_{\mathcal{C}^{1,\alpha}(\Omega_h)}$ for some positive constant C. Using Lemma 3.4, we define $E^{(0)}$ and $E^{(1)}$ as the unique solutions to the integral equations posed on Ω:

$$T(E^{(0)}) := E^{(0)} - k^2\widetilde{K}_1(n_0E^{(0)})(x) = E^i(x,0)$$

and

$$\begin{aligned} T(E^{(1)}) &= -\left[k^2\widetilde{K}_1(E^{(0)})(x) + \frac{k^2}{2}\left(\zeta^2+\frac{1}{4}\right)n_0(x)E^{(0)}(x) + \widetilde{K}_2(n_0^{-1}\nabla n_0\cdot E^{(0)})(x,\zeta)\right] \\ &\quad + \zeta\partial_z E^i(x,0). \end{aligned}$$

REMARK 3.6. *Note that $E^{(0)}$ is independent of ζ while $E^{(1)}(x,\zeta)$ is a second order polynomial in the stretched variable ζ.*

Let

(3.13)

$$\begin{aligned} \widetilde{E}(x,h\zeta) &= E^i(x,h\zeta) + k^2\widetilde{K}_1(n_0(E^{(0)}+hE^{(1)})(x,0) \\ &\quad - h\left[k^2\widetilde{K}_1(E^{(0)})(x) + \frac{k^2}{2}\left(\zeta^2+\frac{1}{4}\right)n_0(x)E^{(0)}(x) + \widetilde{K}_2(n_0^{-1}\nabla n_0\cdot E^{(0)})(x,\zeta)\right], \end{aligned}$$

for $x \in \Omega$ and $\zeta \in (-1/2, 1/2)$. The following error estimate is our main result in this paper.

THEOREM 3.7. *Let $\widetilde{E}$ be defined by (3.13) in $\Omega\times(-1/2,1/2)$. For any $0 < \nu < 1$ we have*

$$||E(x,h\zeta) - \widetilde{E}(x,h\zeta)||_{\mathcal{C}^0(\overline{\Omega}\times[-1/2,1/2])} \leq Ch^{1+\nu},$$

for some positive constant C independent of h and E.

Proof. Let $0 < \nu < 1$. From (3.12) we immediately obtain that

$$T\Big(E_0 - (E^{(0)} + hE^{(1)})\Big) = O(h^{1+\alpha}),$$

where $\alpha = (1+\nu)/2$, which shows that

$$||E_0 - (E^{(0)} + hE^{(1)})||_{\mathcal{C}^0(\overline{\Omega})} \leq Ch^{1+\alpha}||E||_{\mathcal{C}^{1,\alpha}(\Omega_h)}.$$

Inserting this approximation of E_0 into the right-hand side of (3.12) and using the fact from Lemma 3.4 that T has a bounded inverse together with the definition (3.13) of $\widetilde{E}$, we arrive at the desired estimate since, by Proposition 3.5, the quantity $h^{\frac{1-\alpha}{2}}\,||E||_{\mathcal{C}^{1,\alpha}(\Omega_h)}$ is uniformly bounded in h. ∎

To conclude the paper we make the following remarks.

REMARK 3.8. *To obtain an approximate solution to the scattering problem, we find $E^{(0)}$ and $E^{(1)}$ by solving integral equations in $\Omega \subset\subset \mathbb{R}^2$. The electric field within the thin structure is easily obtained using* (3.13). *Should we wish to evaluate the field outside the scatterer, we can use the Lippman–Schwinger equation. Thus, the analysis described in this work can be viewed as a computational method. The method is efficient since only* 2*-D integral equations need to be solved to obtain the desired approximate solution. We note that in* [5] *numerical calculations were carried out to assess the accuracy of the method for the scalar problem in two dimensions. See also* [6].

REMARK 3.9. *If n_0 is constant, then the leading-order term $E^{(0)}$ satisfies the integral equation*

$$E^{(0)}(x,0) - k^2 n_0 \int_\Omega \Phi(x,0,x',0)E^{(0)}(x',0)\,dx' = E^i(x,0), \quad x \in \Omega,$$

and therefore, the tangential component of $E^{(0)}$ on $\Omega \times \{0\}$ is continuous while $e_z \times (\nabla \times E^{(0)})$ on $\Omega \times \{0\}$ has a jump given by $-k^2 n_0 e_z \times (e_z \times E^{(0)})$, where e_z is the basis vector in the z-direction. These jump conditions are exactly those derived by Bouchitté in [1].

REMARK 3.10. *We should emphasize the fact that the asymptotic expansion derived in this paper is not valid in the case of piecewise constant media such as holes in the slab. The regularity assumption on n_0 is essential to first write the Lippmann–Schwinger equation on the electric field E and then to establish the asymptotic expansion* (3.12) *using Lemmas* 3.1 *and* 3.2. *In fact, the estimate of the remainder in* (3.12) *may not be valid if the regularity assumption on n_0 does not hold. This important case in practice requires further delicate analysis and will be the subject of a forthcoming work.*

REMARK 3.11. *We believe that the approach presented in this paper can be easily generalized to deal with a dielectric layer having a curved mean surface.*

Appendix A. Proof of Proposition 3.5. Here we prove Proposition 3.5. Define

$$Tf(x,z) := \int_\Omega \int_{-h/2}^{h/2} \Phi(x,z,x',z')f(x',z')dx'dz', \quad (x,z) \in \Omega_h.$$

We show the following regularity properties of the operator T.

LEMMA A.1. *Let $m(x)$ be a $\mathcal{C}^1$-function compactly supported in Ω. For any $\alpha \in (0,1)$, there exists a constant C independent of h and f such that*

(i) $\|T(mf)\|_{\mathcal{C}^{2,\alpha}(\overline{\Omega_h})} \le C\|m\|_{\mathcal{C}^1(\Omega)}\|f\|_{\mathcal{C}^\alpha(\overline{\Omega_h})}$,
(ii) $\|T(mf)\|_{\mathcal{C}^1(\overline{\Omega_h})} \le Ch|\log h|\,\|m\|_{L^\infty(\Omega)}\|f\|_{L^\infty(\Omega_h)}$,
(iii) $\|T(mf)\|_{\mathcal{C}^2(\overline{\Omega_h})} \le Ch|\log h|\,\|m\|_{\mathcal{C}^1(\Omega)}\|f\|_{\mathcal{C}^1(\overline{\Omega_h})}$.

Before proving Lemma A.1, let us first show that Proposition 3.5 follows from Lemma A.1. Equation (3.1) can be written as

$$E = E^i - k^2 T\left(\left(1 - \frac{n_0}{h}\right)E\right) - \nabla_{x,z} T\left(\frac{\nabla n_0}{n_0}\cdot E\right). \tag{A.1}$$

Since the solution E to (A.1) is uniformly bounded in $L^\infty(\Omega_h)$, it follows from Lemma A.1(ii) that $\|E\|_{\mathcal{C}^1(\overline{\Omega_h})} \le C|\log h|$, and hence from (A.1)(i), (iii) we obtain that $\|E\|_{\mathcal{C}^{1,\alpha}(\overline{\Omega_h})} \le C|\log h|^2$ for some constant C independent of h.

Proof of Lemma A.1. We first note that

$$|D^s\Phi(x,z,x',z')| \le \frac{C}{|(x,z)-(x',z')|^{1+s}}, \tag{A.2}$$

for $s = 0, 1, \ldots$, where D^s denotes any sth order derivative.

Let $(x,z) = y$, $(x',z') = y'$, and D_{ij} denote the second order partial derivative with respect to y_i and y_j. Then it is known that for $i,j = 1,2,3$,

$$\begin{aligned} D_{ij}T(mf)(y) &= \int_{\Omega_h} D_{ij}\Phi(y-y')m(x')(f(y')-f(y))dy \\ &\quad - f(y)\int_{\partial\Omega_h} D_i\Phi(y-y')m(x')\nu_j(y')d\sigma(y') \\ &:= I_1(y) - f(y)I_2(y), \end{aligned} \tag{A.3}$$

where $\nu = (\nu_1,\nu_2,\nu_3)$ is the outward unit normal to $\partial\Omega_h$. See Lemma 4.2 in [4, p. 55]. By a standard Hölder estimate (see, for example, the proof of Lemma 4.4 in [4, p. 57]), we can show that

$$|I_1(y) - I_1(\bar y)| \le C\|m\|_{L^\infty(\Omega)}\|f\|_{\mathcal{C}^\alpha(\overline{\Omega_h})}|y-\bar y|^\alpha, \quad y,\bar y \in \Omega_h.$$

Observe that $\partial\Omega_h$ consists of two parts: $\Omega\times\{h/2,-h/2\}$ and $\partial\Omega\times[-h/2,h/2]$. Since m has a compact support in Ω, we have

$$I_2(y) = \int_{\Omega\times\{h/2,-h/2\}} D_i\Phi(y-y')m(x')\nu_j(y')dx'.$$

Moreover, $\nu_j = 0$ on $\partial\Omega\times\{h/2,-h/2\}$ if $j \ne 3$, and then we have only to consider the quantity I_2 when $j = 3$. If $j = 3$, then

$$I_2(y) = \int_\Omega D_i\Phi(x,z,x',h/2)m(x')dx' - \int_\Omega D_i\Phi(x,z,x',-h/2)m(x')dx'.$$

Suppose that $i = 1$ or 2. Then, since m has a compact support in Ω and $D_i\Phi(x,z,x',z') = -D_i'\Phi(x,z,x',z')$ where D' denotes the derivative with respect to y' variables, we have

$$I_2(y) = \int_\Omega \Phi(x,z,x',h/2)D_i m(x')dx' - \int_\Omega \Phi(x,z,x',-h/2)D_i m(x')dx'. \tag{A.4}$$

Thus, we have

$$|I_2(y) - I_2(\bar{y})| \le C\|m\|_{\mathcal{C}^1(\Omega)}|y - \bar{y}|^\alpha, \quad y, \bar{y} \in \Omega_h,$$

for any $0 < \alpha < 1$.

Suppose now that $i = 3$. In this case

$$I_2(y) = -\int_{\partial\Omega} \frac{\partial}{\partial z'}\Phi\left(x, z, x', \frac{h}{2}\right) m(x')dx' + \int_{\partial\Omega} \frac{\partial}{\partial z'}\Phi\left(x, z, x', -\frac{h}{2}\right) m(x')dx'.$$

Using once again the fact that m has a compact support and $\Omega_h = \Omega \times (-h/2, h/2)$, we can write $I_2(y)$ as

$$I_2(y) = -\int_{\partial\Omega_h} \nabla_{y'}\Phi(y - y') \cdot \nu(y) m(x')d\sigma(y').$$

Since $(\Delta + k^2)\Phi(y - y') = \delta(y - y')$, we obtain from the divergence theorem that

$$I_2(y) = -m(x) + k^2 \int_{\Omega_h} \Phi(y - y')m(x')dy' - \int_{\Omega_h} \nabla_{y'}\Phi(y - y') \cdot \nabla m(x')dy'. \tag{A.5}$$

Thus it follows from (A.2) and standard arguments that

$$|I_2(y) - I_2(\bar{y})| \le C\|m\|_{\mathcal{C}^1(\Omega)}|y - \bar{y}|^\alpha,$$

and hence

$$|f(y)I_2(y) - f(\bar{y})I_2(\bar{y})| \le C\|m\|_{\mathcal{C}^1(\Omega)}\|f\|_{\mathcal{C}^\alpha(\overline{\Omega_h})}|y - \bar{y}|^\alpha.$$

This completes the proof of (i).

To prove (ii), we first compute

$$\begin{aligned}
\int_{\Omega_h} |D_j\Phi(x, z, x', z')|dx'dz' &\le C \int_{-h/2}^{h/2} \int_\Omega \frac{1}{|x - x'|^2 + |z - z'|^2} dx'dz' \\
&\le C \int_{-h/2}^{h/2} (1 + |\log|z - z'||)dz' \\
&\le Ch|\log h|,
\end{aligned}$$

for h small enough. Therefore, we get

$$|D_j T(mf)(x, z)| \le Ch|\log h|\|mf\|_{L^\infty(\Omega_h)}.$$

To prove (iii) we use (A.3), (A.4), and (A.5). Then the same estimates lead us to (iii). For example, from (A.4) we get

$$\begin{aligned}
|I_2(y)| &\le C \int_{-h/2}^{h/2} \int_\Omega \left|\frac{\partial}{\partial z'}\Phi(x, z, x', z')\right| |\nabla m(x')|dx'dz' \\
&\le Ch|\log h|\|\nabla m\|_{L^\infty(\Omega)}.
\end{aligned}$$

This completes the proof. ∎

ON TRANSONIC SHOCKS IN TWO-DIMENSIONAL VARIABLE-AREA DUCTS FOR STEADY EULER SYSTEM*

HAIRONG YUAN†

Abstract. This paper concerns transonic shocks in compressible inviscid flow passing a two-dimensional variable-area duct for the complete steady Euler system. The flow is supersonic at the entrance of the duct, whose boundaries are slightly curved. The condition of impenetrability is posed on the boundaries. After crossing a nearly flat shock front, which passes through a fixed point on the boundary of the duct, the flow becomes subsonic. We show that to ensure the stability of such shocks, pressure should not be completely given at the exit: it only should be given with freedom one, that is, containing an unknown constant to be determined by the upstream flow and the profile of the duct. Careful analysis shows that this is due to the requirement of conservation of mass in the duct. We used Lagrangian transformation and characteristic decomposition to write the Euler system as a 2×2 system, which is valid for general smooth flows. Due to such a simplification, we can employ the theory of boundary value problems for elliptic equations to discuss well-posedness or ill-posedness of transonic shock problems in variable-area duct for various conditions given at the exit.

Key words. Euler system, transonic shocks, free boundary problem, hyperbolic-elliptic composite system, ill-posed problem

1. Introduction.

Using nozzles and pipes to transport and control fluid flows has numerous applications. For instance, one of the important phenomena in gas dynamics is that by appropriate design of a nozzle there may generate one or several shock waves to adjust the supersonic gas flow at the entrance of the nozzle to a certain subsonic state at the exit, which is required, for example, for the jet engines of some types of supersonic airplanes to work. (See, for instance, [31, section 7.13] for detailed discussions.) Other examples are various wind tunnels [25]. Since compressible flows in nozzles exhibit abundant phenomena; such as choking, local supersonic bubble, formation of shock waves and their interactions with the boundaries of nozzles, etc. (see [12, Chapter 5] and [24, section 6.2.3]), rigorous and thorough mathematical analysis of flows in nozzles is a formidable task.

Nevertheless, progress has been made for several model problems. For unsteady quasi–one-dimensional gas flow in a duct of variable area (see [27, section 8.1]), Liu showed in a series of papers [22], [23], [17] that supersonic and subsonic flows are stable, and for transonic flows, the shock waves tend to decelerate along an expanding duct and accelerate along a contracting duct. See also [18]. For inviscid isentropic irrotational gas flows, using the full velocity potential equation, Chen and Feldman studied the existence and stability of multidimensional transonic shocks through an infinite nozzle and determined the state of the flows at infinity by the data of the coming flows and the geometry of the nozzle [4], [5], [6]. In [28] Xin and Yin considered a similar problem for finite nozzle with a class of conditions involving potential giving

at the exit. It is also remarkable that Kuz'min [19] studied subsonic-supersonic smooth flows in nozzles by using the Chaplygin equation (which is equivalent to the full velocity potential equation) and the simplified von Kármán equation. See also, for example, [9], [10], [13] for other interesting and important works concerning systems of conservation laws, multidimensional shock waves, and flow patterns in nature.
